SOME MATHEMATICAL ASPECTS ON A PROBLEM OF THE OPTIMAL DESIGN OF A VIBRATING BEAM*

KJELL HOLMÅKER†

Abstract. An optimal design problem for a vibrating beam is considered. The problem is to maximize (with respect to a design function α) the smallest eigenvalue of a certain eigenvalue problem involving a fourth order differential equation. There is no positive lower bound prescribed for α. Instead it is found that the proper condition on α is that a certain integral should be convergent. It is shown that without this condition the eigenvalue problem need not have any solution. On the other hand it is shown that for functions α satisfying the condition there are eigenvalues and, furthermore, that there is an α_0 such that the smallest eigenvalue is as large as possible. Finally, some necessary conditions satisfied by α_0 are derived in a rigorous way.

Key words. optimal design, eigenvalue optimization, vibrating beam

AMS(MOS) subject classifications. 34B25, 49A40, 49B40, 73K12, 73K40

1. Introduction. Problems of optimal design of beams or plates have been much studied in the engineering literature during the last decades, see e.g. [9], [7], [10] and [11] ([11] is a review paper with many references). In a mathematical formulation it is often the question of maximizing (with respect to a "design variable") the least eigenvalue of a certain eigenvalue problem involving a differential equation of the second or fourth order. Some of the mathematical problems appearing are the questions of existence of an optimal solution and of a rigorous derivation of the necessary conditions (justifying the formal calculations in many papers). Existence proofs when the design variable is bounded away from zero can be found in some papers, e.g. [8] and [3]. In this paper, however, we will have no such restriction. Necessary conditions for optimality for certain problems are derived in [1] and [2]. For eigenvalue problems the question of differentiability of the least eigenvalue with respect to the design variable is important; this is discussed in [6].

In this paper we will take up the problem from [9] and discuss the questions of existence and necessary conditions. The problem in [9] is to find the optimal shape of a simply supported vibrating beam. The equation of motion gives, after separation of variables, the eigenvalue problem

$$\frac{d^2}{dx^2}\left(EI(x)\frac{d^2y}{dx^2}\right)=\omega^2\rho A(x)y, \qquad 0<x<L,$$

$$y(0)=y(L)=0, \qquad EI(x)y''(x)|_{x=0}=EI(x)y''(x)|_{x=L}=0$$

where y is the deflection, L is the length of the beam, E is Young's modulus, ρ is the density, $I(x)$ is the cross sectional moment of inertia, $A(x)$ is the cross sectional area and ω is a natural frequency of the beam. We consider the volume of the beam to be given

$$\int_0^L A(x)\,dx=V,$$

and we want to choose the cross section in such a way that the least natural frequency becomes as large as possible. We will assume a relation between $I(x)$ and $A(x)$ of the form

$$I(x)=c[A(x)]^p$$

where $p=1,2,3$ are of particular interest (see [7]). Introduce the dimensionless variable $\xi=x/L$ and replace then ξ by x. The equations are then simplified to the following:

$$\frac{d^2}{dx^2}\left(\alpha^p(x)\frac{d^2y}{dx^2}\right)=\lambda\alpha(x)y,\qquad 0<x<1, \tag{1.1a}$$

$$y(0)=y(1)=0, \tag{1.1b}$$

$$\alpha^p(x)y''(x)|_{x=0}=\alpha^p(x)y''(x)|_{x=1}=0, \tag{1.1c}$$

$$\int_0^1 \alpha(x)\,dx=1 \tag{1.2}$$

where

$$\alpha(x)=\frac{A(xL)L}{V},\qquad \lambda=\frac{\omega^2\rho L^{p+3}}{cEV^{p-1}}.$$

The function α is $\geqq 0$, and we allow that $\alpha(x)=0$ at some points, so that (1.1a) might be singular. We shall first (in §§ 2 and 3) consider the eigenvalue problem (1.1) for a fixed α. It turns out that there exist eigenvalues if and only if

$$\int_0^1 x^2(1-x)^2\alpha^{-p}(x)\,dx<\infty, \tag{1.3}$$

provided that α satisfies (1.2) and α^{-p} is locally integrable in (0, 1).

In § 4 we prove that, in the class of α's satisfying (1.2) and (1.3), there exists an α_0 such that the corresponding smallest eigenvalue λ_1 is maximal. Finally, in § 5, we derive some necessary conditions for optimality.

2. The eigenvalue problem. Let $\alpha:[0,1]\to\mathbb{R}$ be a measurable function satisfying

$$\alpha(x)\geqq 0 \text{ a.e.},\qquad \int_0^1 \alpha(x)\,dx<\infty, \tag{2.1}$$

$$\int_0^1 x^2(1-x)^2\alpha^{-p}(x)\,dx<\infty, \tag{2.2}$$

and consider the eigenvalue problem (1.1).

In discussing this problem it is convenient to introduce some classes of functions.

DEFINITION 2.1. (i) Let D be the class of all functions $f:[0,1]\to\mathbb{R}$ such that f' exists on all [0, 1] and is absolutely continuous on [0, 1]. If $f\in D$, it follows that f is absolutely continuous on [0, 1], and f'' exists a.e. and belongs to $L_1(0,1)$.

(ii) Let D_{loc} be the class of all functions $f:[0,1]\to\mathbb{R}$ such that f is absolutely continuous on [0, 1], f' exists on (0, 1) and is absolutely continuous on closed subintervals of (0, 1). If $f\in D_{\text{loc}}$, it follows that $f'\in L_1(0,1)$ and $f''\in L_{1,\text{loc}}(0,1)$.

(iii) Let D_α be the class of all functions $f:[0,1]\to\mathbb{R}$ such that $f\in D_{\text{loc}}$, $f(0)=f(1)=0$, and $\alpha^{p/2}f''\in L_2(0,1)$.

The eigenvalue problem consists of finding λ and $y \neq 0$ such that $y \in D_{\mathrm{loc}}$, $\alpha^p y'' \in D$, and such that (1.1) is satisfied; this means that there exists a $g \in D$ such that

$$\begin{aligned} &\alpha^p(x)y''(x) = g(x) \quad \text{a.e.,} \\ (2.3) \qquad &g''(x) = \lambda\alpha(x)y(x) \quad \text{a.e.,} \\ &y(0) = y(1) = 0, \qquad g(0) = g(1) = 0. \end{aligned}$$

If (in a formal calculation) (1.1) is multiplied by y and integrated, then after partial integrations, taking (1.1b), (1.1c) into account, we find that λ satisfies

$$\lambda = \frac{\int_0^1 \alpha^p(x)[y''(x)]^2\,dx}{\int_0^1 \alpha(x)[y(x)]^2\,dx}.$$

(If y satisfies the conditions above, this can be justified.)

In most treatments (see e.g. [9], [7], [11]) the eigenvalue problem is replaced by the problem of minimizing this Rayleigh quotient. It is therefore of interest to show that the minimum is attained for some y. The exact problem is to find the minimum of

$$(2.4) \qquad R(y) = \frac{\int_0^1 \alpha^p(x)[y''(x)]^2\,dx}{\int_0^1 \alpha(x)[y(x)]^2\,dx}$$

as y varies over $D_\alpha \backslash \{0\}$. One can show by direct methods that this problem has a solution y. Then, as a consequence of the necessary conditions for minimum, one can show that $\alpha^p y'' \in D$ and that (1.1) is satisfied (note in particular that (1.1c) results from the necessary conditions). We shall however proceed differently and transform (1.1) to an eigenvalue problem for an integral operator. The following lemma will then be useful.

LEMMA 2.1. *The differential equation*

$$\begin{cases} y'' = f & \text{in } (0,1), \\ y(0) = y(1) = 0 \end{cases}$$

has the unique solution

$$(2.5) \qquad y(x) = \int_0^1 h(x,t)f(t)\,dt, \qquad x \in [0,1],$$

where

$$(2.6) \qquad h(x,t) = \begin{cases} -(1-x)t & \text{for } 0 \leqq t \leqq x, \\ -x(1-t) & \text{for } x \leqq t \leqq 1, \end{cases}$$

if

(a) $f \in L_1(0,1)$, *in which case* $y \in D$ *and* $\alpha^{-p/2}y \in L_2(0,1)$, *or*

(b) $f = \alpha^{-p/2}v$, *where* $v \in L_2(0,1)$, *in which case* $y \in D_\alpha$.

The proof consists of an easy verification, so we omit the details. Let us only remark that we use that

$$(2.7) \qquad |h(x,t)| \leqq \min(x(1-x), t(1-t)),$$

and that the function $t \mapsto t(1-t)\alpha^{-p/2}(t)$ belongs to $L_2(0,1)$.

THEOREM 2.1. *Let* α *satisfy* (2.1) *and* (2.2). *Then the eigenvalue problem* (1.1) (*or* (2.3)) *has infinitely many eigenvalues,* $0 < \lambda_1 \leqq \lambda_2 \leqq \cdots$. *The Rayleigh quotient* (2.4) *attains its minimum* λ_1 *if and only if* y *is an eigenfunction corresponding to* λ_1. *The least eigenvalue* λ_1 *is simple and the corresponding eigenfunction can be chosen to be positive in* $(0,1)$.

Proof. By a double application of Lemma 2.1 we see that a function $y \neq 0$ such that $y \in D_{\text{loc}}$ and $\alpha^p y'' \in D$ satisfies (1.1) if and only if

$$y(x) = \lambda \int_0^1 h(x,t)\alpha^{-p}(t)\left[\int_0^1 h(t,\tau)\alpha(\tau)y(\tau)\,d\tau\right]dt. \tag{2.8}$$

We have then used that $t \mapsto \alpha^{-p/2}(t)\int_0^1 h(t,\tau)\alpha(\tau)y(\tau)\,d\tau$ belongs to $L_2(0,1)$. This fact also implies that $y \in D_\alpha$.

Let us introduce the integral operator K_α defined by

$$(K_\alpha v)(x) = \int_0^1 h(x,t)\alpha^{1/2}(x)\alpha^{-p/2}(t)v(t)\,dt. \tag{2.9}$$

For the kernel

$$k_\alpha(x,t) = h(x,t)\alpha^{1/2}(x)\alpha^{-p/2}(t)$$

we have

$$\int_0^1\int_0^1 k_\alpha^2(x,t)\,dx\,dt \leqq \int_0^1 \alpha(x)\,dx \cdot \int_0^1 t^2(1-t)^2\alpha^{-p}(t)\,dt < \infty,$$

and therefore K_α is a Hilbert–Schmidt operator from $L_2(0,1)$ to $L_2(0,1)$. This means in particular that K_α is compact. Its adjoint K_α^* is defined by

$$(K_\alpha^* v)(x) = \int_0^1 h(x,t)\alpha^{1/2}(t)\alpha^{-p/2}(x)v(t)\,dt, \qquad v \in L_2(0,1).$$

We see then that (2.8) can be written

$$z = \lambda(K_\alpha K_\alpha^*)z \tag{2.10}$$

where

$$z(x) = \alpha^{1/2}(x)y(x).$$

Thus the eigenvalue problem (1.1) is equivalent to the eigenvalue problem (2.10) for the compact selfadjoint operator $K_\alpha K_\alpha^*$. From the general theory for such operators we know that there are infinitely many eigenvalues $0 < \lambda_1 \leqq \lambda_2 \leqq \cdots$, each with finite multiplicity.

By Lemma 2.1(b) there is a one-to-one correspondence between $L_2(0,1)$ and D_α given by

$$v = \alpha^{p/2}y'', \quad y = \alpha^{-1/2}K_\alpha v, \quad v \in L_2(0,1), \quad y \in D_\alpha. \tag{2.11}$$

Since the eigenvalues of $K_\alpha K_\alpha^*$ are also the eigenvalues of $K_\alpha^* K_\alpha$, we see from (2.4) and (2.11) that

$$\lambda_1 = \min_{\substack{v \in L_2(0,1)\\ v \neq 0}} \frac{\|v\|^2}{\|K_\alpha v\|^2} = \min_{\substack{y \in D_\alpha\\ y \neq 0}} R(y) \tag{2.12}$$

where $\|\cdot\|$ is the norm in $L_2(0,1)$. Thus the Rayleigh quotient $R(y)$ attains its minimum for some $y_0 \in D_\alpha \backslash \{0\}$ and it is also easy to see that this happens if and only if y_0 is an eigenfunction corresponding to λ_1.

It follows from general properties for compact operators with positive kernels that λ_1 is simple and that the corresponding eigenfunction y can be chosen such that $y(x) > 0$ a.e.; see e.g. [4, pp. 287-288]. But then (2.3) shows that $y(x) > 0$ for all $x \in (0,1)$. □

3. A nonexistence result. If condition (2.2) is not satisfied, then the analysis in § 2 breaks down. Let us in this section assume that $\alpha(x) \geqq 0$, $\alpha \in L_1(0,1)$, $\alpha^{-p} \in L_1(a,b)$ for each $[a,b] \subset (0,1)$, and $\int_0^1 x^2(1-x)^2\alpha^{-p}(x)\,dx = \infty$. The problem of minimizing $R(y)$ over $D_\alpha \backslash \{0\}$ still makes sense, but we shall show that it has no solution in this case.

Let, for $0 < \delta < \frac{1}{2}$, χ_δ be the characteristic function of the interval $[\delta, 1-\delta]$. Define

$$v_\delta(x) = -x(1-x)\alpha^{-p/2}(x)\chi_\delta(x),$$

$$y_\delta(x) = \int_0^1 h(x,t)\alpha^{-p/2}(t)v_\delta(t)\,dt,$$

$$A_\delta = \int_\delta^{1-\delta} x^2(1-x)^2\alpha^{-p}(x)\,dx = \int_0^1 v_\delta^2(x)\,dx.$$

It follows from Lemma 2.1(b) that $y_\delta'' = \alpha^{-p/2}v_\delta$ and $y_\delta \in D_\alpha \backslash \{0\}$. Let $x_0 \in (0,1)$ be such that $y_\delta(x_0) = \max_{x\in[0,1]} y_\delta(x)$. By using (2.6) and the fact that $y_\delta'(x_0) = 0$, we easily find that $y_\delta(x_0) \geqq \frac{1}{2}A_\delta$. Since $y_\delta'' \leqq 0$, y_δ is concave and

$$y_\delta(x) \geqq y_\delta(x_0)\frac{x}{x_0} \quad \text{for } 0 \leqq x \leqq x_0,$$

$$y_\delta(x) \geqq y_\delta(x_0)\frac{1-x}{1-x_0} \quad \text{for } x_0 \leqq x \leqq 1.$$

From this we find that $\int_0^1 \alpha(x)y_\delta^2(x)\,dx \geqq ky_\delta^2(x_0)$ for a certain constant $k > 0$ (independent of x_0). Therefore

$$R(y_\delta) = \frac{\int_0^1 \alpha^p(x)y_\delta''^2(x)\,dx}{\int_0^1 \alpha(x)y_\delta^2(x)\,dx} = \frac{A_\delta}{\int_0^1 \alpha(x)y_\delta^2(x)\,dx} \leqq \frac{4}{kA_\delta}.$$

But $A_\delta \to \infty$ as $\delta \to 0^+$. Thus

$$\inf_{y \in D_\alpha \backslash \{0\}} R(y) = 0.$$

But $R(y)$ can obviously not attain the value 0.

4. Maximizing the least eigenvalue. Now we want to let α vary in the class of functions satisfying (2.1), (2.2) and (1.2), and we want to maximize the least eigenvalue λ_1 of (1.1). We consider however also a slightly larger class.

Let, for $p \geqq 1$, $\mathscr{A}_p$ be the class of all measurable functions $\alpha : [0,1] \to \mathbb{R}$ such that

$$\alpha(x) \geqq 0 \text{ a.e.}, \qquad 0 < \int_0^1 \alpha(x)\,dx \leqq 1, \tag{4.1}$$

$$A_p(\alpha) = \int_0^1 x^2(1-x)^2\alpha^{-p}(x)\,dx < \infty. \tag{4.2}$$

Let $\mathscr{A}_p'$ be the class of those α in $\mathscr{A}_p$ for which $\int_0^1 \alpha(x)\,dx = 1$.

For each $\alpha \in \mathscr{A}_p$ there are eigenvalues of the eigenvalue problem (1.1) (see § 2), and in particular there is a smallest one given by (2.12); let us denote it by $\lambda(\alpha)$.

The main result of this section is the following theorem. We prove it now for $p > 1$, whereas the result for $p = 1$ will be obtained in § 5.

THEOREM 4.1. *There is an* $\alpha_0 \in \mathscr{A}_p'$ *such that*

$$\lambda(\alpha_0) = \sup_{\alpha \in \mathscr{A}_p} \lambda(\alpha).$$

In the proof the following lemma will be used.

LEMMA 4.1. *Let $(x, u)\mapsto h(x, u)$ be a function defined for $x\in[0, 1]$ and $u\in I$, where $I\subseteq\mathbb{R}$ is a closed interval, with values in $[0,\infty]$. Assume that $h(\cdot, u)$ is measurable for each $u\in I$, and that $h(x, \cdot)$ is continuous and convex for each $x\in[0, 1]$. If $u_n:[0, 1]\to I$, $n=1, 2, \cdots$, is a sequence of functions in $L_r(0, 1)$ such that $u_n\to u$ weakly in $L_r(0, 1)$ as $n\to\infty$ for some r, $1\leqq r<\infty$, then $u(x)\in I$ a.e., and*

$$\int_0^1 h(x, u(x))\,dx\leqq\liminf_{n\to\infty}\int_0^1 h(x, u_n(x))\,dx. \tag{4.3}$$

A similar result can be found in [5, p. 7], so we only remark that the proof of Lemma 4.1 is based on Mazur's Theorem and Fatou's Lemma.

In the proof of Theorem 4.1 we need an estimate of $\lambda(\alpha)$ in terms of $A_p(\alpha)$. This estimate is first proved in a separate lemma.

LEMMA 4.2. *There is a constant $C>0$ such that*

$$\frac{1}{A_p(\alpha)}\leqq\lambda(\alpha)\leqq\frac{C}{[A_p(\alpha)]^{1-1/p}}$$

for all $\alpha\in\mathcal{A}_p$.

Proof. If $v_0\in L_2(0, 1)\backslash\{0\}$ achieves minimum in (2.12), we get from the Cauchy-Schwarz inequality, using (2.12), (2.9), (4.2) and (4.1), the following:

$$\lambda(\alpha)=\frac{\|v_0\|^2}{\|K_\alpha v_0\|^2}\geqq\frac{\|v_0\|^2}{\int_0^1\alpha(x)A_p(\alpha)\|v_0\|^2\,dx}\geqq\frac{1}{A_p(\alpha)}.$$

To get an estimate of $\lambda(\alpha)$ from above, choose

$$v(x)=-x(1-x)\alpha^{-p/2}(x)$$

and define

$$y(x)=\int_0^1 h(x, t)\alpha^{-p/2}(t)v(t)\,dt.$$

Since $v\in L_2(0, 1)$, Lemma 2.1(b) shows that $y\in D_\alpha$ and $y''=\alpha^{-p/2}v\leqq 0$. By the same arguments as in § 3 we obtain

$$y(x_0)=\max_{x\in[0,1]}y(x)\geqq\tfrac{1}{2}A_p(\alpha), \tag{4.4}$$

and

$$\begin{aligned}\|K_\alpha v\|^2&=\int_0^1\alpha(x)y^2(x)\,dx\\ &\geqq y^2(x_0)\left[x_0^{-2}\int_0^{x_0}x^2\alpha(x)\,dx+(1-x_0)^{-2}\int_{x_0}^1(1-x)^2\alpha(x)\,dx\right].\end{aligned} \tag{4.5}$$

Now, by Hölder's inequality

$$\begin{aligned}\int_0^{x_0}x^{1+1/p}(1-x)^{1/p}\,dx&=\int_0^{x_0}[x(1-x)\alpha^{-p/2}(x)]^{1/p}x\alpha^{1/2}(x)\,dx\\ &\leqq x_0^{(p-1)/(2p)}\left[\int_0^{x_0}x^2(1-x)^2\alpha^{-p}(x)\,dx\right]^{1/(2p)}\\ &\quad\cdot\left[\int_0^{x_0}x^2\alpha(x)\,dx\right]^{1/2},\end{aligned}$$

so that

$$x_0^{-2}\int_0^{x_0}x^2\alpha(x)\,dx\geqq x_0^{-(3-1/p)}A_p^{-1/p}(\alpha)\left[\int_0^{x_0}x^{1+1/p}(1-x)^{1/p}\,dx\right]^2,$$

and in the same way

$$(1-x_0)^{-2}\int_{x_0}^{1}(1-x)^2\alpha(x)\,dx \geqq (1-x_0)^{-(3-1/p)}A_p^{-1/p}(\alpha)\left[\int_{x_0}^{1}x^{1/p}(1-x)^{1+1/p}\,dx\right]^2.$$

From (4.4) and (4.5) we then obtain

$$\|K_\alpha v\|^2 \geqq kA_p^{2-1/p}(\alpha)$$

for some constant $k>0$ (which is independent of x_0). For our choice of v, $\|v\|^2=A_p(\alpha)$, so that

$$\lambda(\alpha)\leqq\frac{\|v\|^2}{\|K_\alpha v\|^2}\leqq\frac{1}{kA_p^{1-1/p}(\alpha)}. \qquad \square$$

Proof of Theorem 4.1 *for* $p>1$. Let $p>1$ and

$$\lambda_0=\sup_{\alpha\in\mathscr{A}_p}\lambda(\alpha).$$

From Lemma 4.2 we deduce that $A_p^{-1/p}(\alpha)\leqq C$ and $\lambda(\alpha)\leqq C^p$ for all $\alpha\in\mathscr{A}_p$, and therefore $0<\lambda_0<\infty$. Let $\alpha_n\in\mathscr{A}_p$ be a maximizing sequence, i.e., $\lambda(\alpha_n)\to\lambda_0$ as $n\to\infty$. We may assume that $\lambda(\alpha_n)\geqq\lambda_0/2$ for all n. Then Lemma 4.2 gives

$$A_p(\alpha_n)\leqq\left[\frac{C}{\lambda(\alpha_n)}\right]^{p/(p-1)}\leqq\left(\frac{2C}{\lambda_0}\right)^{p/(p-1)}=C_1\quad\text{for all } n. \tag{4.6}$$

Let $\beta_n=\alpha_n^{1/2}$ and $g_n(x)=x(1-x)\beta_n^{-p}(x)$. Then (4.1), (4.2) and (4.6) show that β_n and g_n are uniformly bounded in $L_2(0,1)$. Therefore we can find a subsequence (we may assume that it is the original sequence) such that $\beta_n\to\bar\beta$ and $g_n\to g$ weakly in $L_2(0,1)$ as $n\to\infty$ for some $\bar\beta\geqq0$ and $g\geqq0$ in $L_2(0,1)$. Define

$$\beta(x)=\left[\frac{x(1-x)}{g(x)}\right]^{1/p}.$$

By Lemma 4.1

$$\int_0^1\beta(x)\phi(x)\,dx\leqq\liminf_{n\to\infty}\int_0^1[x(1-x)]^{1/p}g_n^{-1/p}(x)\phi(x)\,dx=\int_0^1\bar\beta(x)\phi(x)\,dx$$

for all $\phi\in L_2(0,1)$ such that $\phi\geqq0$. Thus

$$0\leqq\beta(x)\leqq\bar\beta(x)\text{ a.e.} \tag{4.7}$$

Lemma 4.1 also gives

$$\int_0^1\bar\beta^2(x)\,dx\leqq\liminf_{n\to\infty}\int_0^1\beta_n^2(x)\,dx\leqq1. \tag{4.8}$$

If we put $\alpha_0=\beta^2$, (4.7), (4.8) and the fact that $A_p(\alpha_0)=\int_0^1g^2(x)\,dx<\infty$ show that $\alpha_0\in\mathscr{A}_p$.

Let $v_0\in L_2(0,1)\backslash\{0\}$ be such that

$$\lambda(\alpha_0)=\frac{\|v_0\|^2}{\|K_{\alpha_0}v_0\|^2}. \tag{4.9}$$

We want to show that $\lambda(\alpha_n)\to\lambda(\alpha_0)$ as $n\to\infty$. We have that

$$\lambda(\alpha_n)\leqq\frac{\|v_0\|^2}{\|K_{\alpha_n}v_0\|^2}, \tag{4.10}$$

and

$$(4.11)\qquad \begin{aligned}(K_{\alpha_n}v_0)(x)&=\alpha_n^{1/2}(x)\int_0^1 h(x,t)\alpha_n^{-p/2}(t)v_0(t)\,dt\\&=\beta_n(x)\int_0^1\frac{h(x,t)}{t(1-t)}g_n(t)v_0(t)\,dt=\beta_n(x)y_n(x)\end{aligned}$$

where $y_n(x)$ is defined as the integral. If we also define

$$y(x)=\int_0^1\frac{h(x,t)}{t(1-t)}g(t)v_0(t)\,dt=\int_0^1 h(x,t)\alpha_0^{-p/2}(t)v_0(t)\,dt,$$

then, since $g_n\to g$ weakly, $y_n(x)\to y(x)$ as $n\to\infty$ for each $x\in[0,1]$.

Let ε, $0<\varepsilon<1$, be arbitrary, and choose $\delta>0$ such that

$$(4.12)\qquad \int_\delta^{1-\delta}\alpha_0(x)y^2(x)\,dx>(1-\varepsilon)\int_0^1\alpha_0(x)y^2(x)\,dx=(1-\varepsilon)\|K_{\alpha_0}v_0\|^2.$$

Now we have

$$|y_n(x)|\leqq\int_0^1 g_n(t)|v_0(t)|\,dt\leqq C_1^{1/2}\|v_0\|\quad\text{for all } x\in[0,1],$$

and (using (2.6))

$$|y_n'(x)|\leqq\frac{1}{\delta}\int_0^1 t(1-t)\alpha_n^{-p/2}(t)|v_0(t)|\,dt\leqq\frac{1}{\delta}C_1^{1/2}\|v_0\|\quad\text{for all } x\in[\delta,1-\delta],$$

so that the sequence $\{y_n\}_1^\infty$ is uniformly bounded and equicontinuous on $[\delta,1-\delta]$. The Ascoli-Arzelà Theorem and the fact that $y_n(x)\to y(x)$ pointwise show that $y_n\to y$ uniformly on $[\delta,1-\delta]$ as $n\to\infty$. Using (4.11), Lemma 4.1, (4.7) and (4.12), we then get

$$\begin{aligned}\liminf_{n\to\infty}\|K_{\alpha_n}v_0\|^2&\geqq\liminf_{n\to\infty}\int_\delta^{1-\delta}\beta_n^2(x)y_n^2(x)\,dx\\&=\liminf_{n\to\infty}\int_\delta^{1-\delta}\beta_n^2(x)y^2(x)\,dx\\&\geqq\int_\delta^{1-\delta}\bar\beta^2(x)y^2(x)\,dx\geqq\int_\delta^{1-\delta}\beta^2(x)y^2(x)\,dx\\&=\int_\delta^{1-\delta}\alpha_0(x)y^2(x)\,dx>(1-\varepsilon)\|K_{\alpha_0}v_0\|^2.\end{aligned}$$

From (4.10) and (4.9) we then get

$$\lambda_0=\lim_{n\to\infty}\lambda(\alpha_n)\leqq\limsup_{n\to\infty}\frac{\|v_0\|^2}{\|K_{\alpha_n}v_0\|^2}\leqq\frac{1}{1-\varepsilon}\frac{\|v_0\|^2}{\|K_{\alpha_0}v_0\|^2}=\frac{1}{1-\varepsilon}\lambda(\alpha_0).$$

But $\varepsilon>0$ is arbitrary, so therefore $\lambda(\alpha_0)=\lambda_0=\sup_{\alpha\in\mathscr{A}_p}\lambda(\alpha)$.

From the fact that $\lambda(\mu\alpha_0)=\mu^{p-1}\lambda(\alpha_0)$ for $\mu>1$, we find that $\int_0^1\alpha_0(x)\,dx=1$, so that $\alpha_0\in\mathscr{A}_p'$.

Let us also remark that in fact $\bar\beta=\beta$ and $\beta_n\to\beta$ strongly in $L_2(0,1)$. We have

$$\begin{aligned}1=\int_0^1\alpha_0(x)\,dx&=\int_0^1\beta^2(x)\,dx\leqq\int_0^1\bar\beta^2(x)\,dx\\&\leqq\liminf_{n\to\infty}\int_0^1\beta_n^2(x)\,dx\leqq\limsup_{n\to\infty}\int_0^1\beta_n^2(x)\,dx\leqq1,\end{aligned}$$

so that $\bar\beta(x)=\beta(x)$ a.e. and $\|\beta_n\|\to\|\beta\|$ as $n\to\infty$. This together with the weak convergence of β_n towards β implies strong convergence. □

5. Necessary conditions. Assume that $\alpha_0 \in \mathscr{A}'_p$, $p \geqq 1$ and $v_0 \in L_2(0, 1) \backslash \{0\}$ are such that

$$\lambda_0 = \lambda(\alpha_0) = \max_{\alpha \in \mathscr{A}_p} \lambda(\alpha) = \frac{\|v_0\|^2}{\|K_{\alpha_0} v_0\|^2} = \min_{\substack{v \in L_2(0,1) \\ v \neq 0}} \frac{\|v\|^2}{\|K_{\alpha_0} v\|^2}.$$

Let $\delta > 0$ be arbitrary. Put

$$I_\delta = \{x \in [0, 1]\colon \alpha_0(x) \geqq \delta\}$$

and let $\phi : [0, 1] \to \mathbb{R}$ be an arbitrary measurable function such that $|\phi(x)| \leqq 1$ for all x, $\phi(x) = 0$ for $x \in [0, 1] \backslash I_\delta$, $\int_0^1 \phi(x)\, dx = 0$, and define

$$\alpha_\varepsilon(x) = \alpha_0(x) + \varepsilon \phi(x) \quad \text{for } |\varepsilon| \leqq \frac{\delta}{2}.$$

It follows that $\alpha_\varepsilon \in \mathscr{A}'_p$. We consider the perturbed operator $H_\varepsilon = K^*_{\alpha_\varepsilon} K_{\alpha_\varepsilon}$ and find that its kernel $h_\varepsilon(x, t)$ can be expanded in a convergent power series

$$h_\varepsilon(x, t) = h_0(x, t) + \varepsilon h^{(1)}(x, t) + \cdots + \varepsilon^n h^{(n)}(x, t) + \cdots \text{ for } |\varepsilon| \leqq \frac{\delta}{2}$$

where

$$|h^{(n)}(x, t)| \leqq x(1-x)\alpha_0^{-p/2}(x) \cdot t(1-t)\alpha_0^{-p/2}(t) \cdot K^n$$

for some constant $K > 0$. For $h^{(1)}$ we get

$$(5.1)\qquad \begin{aligned} h^{(1)}(x, t) &= \alpha_0^{-p/2}(x)\alpha_0^{-p/2}(t) \\ &\cdot \left\{ \int_0^1 h(x, s)h(t, s)\phi(s)\, ds - \frac{p}{2}\left[\frac{\phi(x)}{\alpha_0(x)} + \frac{\phi(t)}{\alpha_0(t)}\right] \int_0^1 \alpha_0(s) h(x, s) h(t, s)\, ds \right\}. \end{aligned}$$

Let $h^{(n)}(x, t)$ be the kernel of a selfadjoint Hilbert-Schmidt operator $H^{(n)}$ from $L_2(0, 1)$ to $L_2(0, 1)$. We can now apply a theorem of Rellich (see [13, § 2] or [4, pp. 171-172]) which says that the eigenvalue $\mu_\varepsilon = \lambda^{-1}(\alpha_\varepsilon)$ of H_ε and a suitable corresponding eigenfunction v_ε depend analytically on ε (note that $\mu_0 = \lambda_0^{-1}$ is a simple eigenvalue according to Theorem 2.1). Write

$$H_\varepsilon = H_0 + \varepsilon H^{(1)} + \cdots, \quad v_\varepsilon = v_0 + \varepsilon v^{(1)} + \cdots \quad \text{and} \quad \mu_\varepsilon = \mu_0 + \varepsilon \mu^{(1)} + \cdots$$

where we assume that $\|v_0\| = 1$. By identifying the coefficients of ε in the equation $H_\varepsilon v_\varepsilon = \mu_\varepsilon v_\varepsilon$ we get, after scalar multiplication by v_0

$$\mu^{(1)} = (H^{(1)} v_0, v_0).$$

From the extremal property of λ_0 we get $0 = (d/d\varepsilon)\mu_\varepsilon|_{\varepsilon=0} = \mu^{(1)}$, so that $(H^{(1)} v_0, v_0) = 0$. From (5.1) we obtain after some computations

$$(5.2)\qquad 0 = (H^{(1)} v_0, v_0) = \int_0^1 \frac{\phi(x)}{\alpha_0(x)} [(K_{\alpha_0} v_0)^2(x) - p\mu_0 v_0^2(x)]\, dx.$$

Now $y_0 = \alpha_0^{-1/2} K_{\alpha_0} v_0$ is an eigenfunction of (1.1) with $\alpha = \alpha_0$ corresponding to the eigenvalue $\lambda_0 = \mu_0^{-1}$. Since (5.2) holds for all ϕ of the form described above, we get

$$(5.3)\qquad y_0^2(x) - p\mu_0 \alpha_0^{-1}(x) v_0^2(x) = -a$$

a.e. on I_δ, where a is a constant. Since $\alpha_0(x) > 0$ a.e. on $[0, 1]$, and $\delta > 0$ is arbitrary, (5.3) holds a.e. on $[0, 1]$. If (5.3) is multiplied by α_0 and integrated, we get

$$a = (p-1)\|K_{\alpha_0} v_0\|^2 \geqq 0.$$

Since $y_0'' = \alpha_0^{-p/2} v_0$, we find that y_0 must satisfy

$$p\alpha_0^{p-1}(x) y_0''^2(x) - \lambda_0 y_0^2(x) = k \quad \text{a.e.,} \tag{5.4}$$

where

$$k = (p-1)\lambda_0 \int_0^1 \alpha_0(x) y_0^2(x)\, dx. \tag{5.5}$$

Equations (5.4) and (5.5) constitute the necessary conditions for optimality for our problem. They can be utilized to devise a numerical algorithm as in [7] and [9]. From them we can also obtain more information on the behavior of α_0 and y_0. We consider now the case $p > 1$, where we know that an optimal α_0 exists. From (2.3) we get

$$\alpha_0^p(x) y_0''(x) = g(x) \quad \text{a.e.,} \tag{5.6}$$

$$g''(x) = \lambda_0 \alpha_0(x) y_0(x) \quad \text{a.e.,} \tag{5.7}$$

$$g(0) = g(1) = 0, \tag{5.8}$$

for some $g \in D$. From Theorem 2.1 we know that we may assume that $y_0(x) > 0$ in $(0, 1)$. Then (5.7) and (5.8) imply that $g(x) < 0$ in $(0, 1)$. From (5.4)-(5.6) we get

$$\alpha_0(x) = \left[\frac{pg^2(x)}{k + \lambda_0 y_0^2(x)}\right]^{1/(p+1)} \quad \text{where } k > 0. \tag{5.9}$$

We can redefine α_0 on a set of measure zero so that (5.9) holds for all x. Then we see that α_0 is continuous on $[0, 1]$ and positive in $(0, 1)$. Combining (5.7) and (5.9) we find that g satisfies the equation

$$g''(x) = \psi(x)[g^2(x)]^{1/(p+1)} \tag{5.10}$$

for some function ψ continuous on $[0, 1]$. We want to prove that $g'(0) \neq 0$. Assume $g'(0) = 0$. Then (5.10) implies that $|g(x)| \leqq C \cdot x^{2(p+1)/(p-1)}$ for some constant $C > 0$. From (5.6) and (5.9) we then get $y_0''(x) \leqq -C_1 x^{-2}$, and hence $y_0(x) \leqq C_1 \ln x + C_2$ in a neighborhood of 0, for certain constants $C_1 > 0$ and C_2, and that is impossible. Thus $g'(0) \neq 0$. Then $g(x) = O(x)$ as $x \to 0$, and from (5.9) and (5.6) we get

$$\alpha_0(x) = O(x^{2/(p+1)}) \quad \text{as } x \to 0,$$

and $y_0''(x) = O(x^{-(p-1)/(p+1)})$, so that $y_0'' \in L_1(0, \frac{1}{2})$ and

$$y_0(x) = y_0'(0)x + O(x^{(p+3)/(p+1)}) \quad \text{as } x \to 0.$$

The behavior at $x = 1$ is similar.

We can now settle the question of existence in the case $p = 1$, which was left open in the proof of Theorem 4.1. If there is a solution for $p = 1$, then λ_0, α_0 and y_0 must satisfy (5.6)-(5.8) and

$$y_0''^2(x) = \lambda_0 y_0^2(x).$$

As we noted above, (5.6) implies that y_0 and y_0'' are of opposite sign, so that

$$y_0''(x) = -\sqrt{\lambda_0}\, y_0(x), \qquad y_0(0) = y_0(1) = 0, \tag{5.11}$$

which has the solution $\lambda_0 = \pi^4$, $y_0(x) = c_1 \sin \pi x$, $c_1 \neq 0$. For g we obtain the same equation, so that $g(x) = c_2 \sin \pi x$, $c_2 \neq 0$, and $\alpha_0(x) = g(x)/y_0''(x) = -c_2/(\pi^2 c_1) = c_3$. The condition $\int_0^1 \alpha_0(x)\, dx = 1$ gives $c_3 = 1$.

By an argument partly inspired by [12] we can show that the necessary conditions, which λ_0, α_0 and y_0 satisfy, also are sufficient, i.e., that $\alpha_0(x) \equiv 1$ really is optimal. To that end, consider the Rayleigh quotient

$$R(\alpha, y)=\frac{\int_0^1 \alpha(x)[y''(x)]^2\,dx}{\int_0^1 \alpha(x)[y(x)]^2\,dx}$$

where $\alpha \in \mathscr{A}_1'$, $y \in D_\alpha \backslash\{0\}$. Let $y_\alpha \in D_\alpha \backslash\{0\}$ be such that

$$\lambda(\alpha)=R(\alpha, y_\alpha)=\min_{y \in D_\alpha \backslash\{0\}} R(\alpha, y).$$

Since y_0'' is bounded, $y_0 \in D_\alpha$ for all α (see Definition 2.1), so that

$$R(\alpha, y_\alpha) \leqq R(\alpha, y_0)=\lambda_0;$$

in the last step we used (5.11). Since $\lambda_0=\lambda(\alpha_0)$ by construction, we see that $\lambda(\alpha) \leqq \lambda(\alpha_0)$ for all $\alpha \in \mathscr{A}_1'$, which means that α_0 is optimal.

A NOTE ON THE IDENTIFIABILITY OF DISTRIBUTED PARAMETERS IN ELLIPTIC EQUATIONS*

CARMEN CHICONE† AND JÜRGEN GERLACH†

Abstract. For u and f given smooth functions on a bounded domain Ω we consider solutions of the PDE $-\text{div}\,(a\nabla u)=f$ for the parameter a. This problem arises in the identification of the flow of groundwater. We say a is identifiable if, for given u and f, a is unique. Our main result shows that a is identifiable on the points in Ω which are the closure of the interior of the set of points which stay in Ω for all positive time (or negative time) under the flow of the gradient field ∇u. We also show a is identifiable on Ω if the set of critical points of u has nonempty interior and the co-normal derivative of u is specified on $\partial\Omega$.

Key words. parameter identification, uniqueness, inverse problems

AMS(MOS) subject classifications. 35R30, 76S05

1. Introduction. In this paper we investigate the following situation: A bounded region $\Omega\subset R^n$ with smooth boundary $\partial\Omega$ and a function $u\in C^2(\bar\Omega)$ are given. We consider solutions $a(x)$ of the equation

$$\text{div}\,(a\nabla u)=0, \tag{1}$$

where $a\in C^1(\bar\Omega)$. Obviously, $a(x)\equiv 0$ solves (1). The main question which we are going to address in this note is the following: What are the conditions on the function $u(x)$ so that $a(x)\equiv 0$ is the only solution of (1)?

Background. This problem arises in the identification of the flow of groundwater. If we denote the pressure head of an aquifer by $u(x)$, its transmissivity by $a(x)$, and if we denote external sources such as wells by $f(x)$, we obtain the equation

$$-\text{div}\,(a\nabla u)=f \tag{2}$$

in the case of a steady flow. The actual flow rates q are then calculated from $q=a\nabla u$. Suppose that f and u are known everywhere, and suppose that (2) is satisfied for two transmissivity functions $a_1(x)$ and $a_2(x)$; then their difference $a(x):=a_1(x)-a_2(x)$ satisfies (1). If $a(x)\equiv 0$ is the only possible solution of (1), then the data u and f can be explained by exactly one transmissivity function. In this case we call the parameter $a(x)$ identifiable from the data u. In § 4 we will consider test conditions under which $a(x)$ is identifiable.

A related question can be asked from the point of view of dynamical systems: Suppose we are given a gradient flow ∇u; when is it possible to multiply the gradient field by a nonzero function $a(x)$ so that the resulting vector field $v=a\nabla u$ is divergence free?

Uniqueness of $a(x)$ plays an important role in numerical schemes for parameter identifications, e.g., this assumption is needed for the methods suggested by Kravaris and Seinfeld [7], and Gerlach and Guenther [4]. Kitamura and Nakagiri [6] study the identifiability for a one-dimensional time dependent problem, and Kunisch and White [9] investigate the identifiability of a discretized version of (2) for several finite element approximations for one space dimension. In higher dimensions Falk [3] considers the case where the flow satisfies $\nabla u\cdot\nu\geqq\sigma>0$ for some fixed vector $\nu\in R^n$, and some constant σ, and uses inflow data for stability estimates. Similarly, Richter [11] considers

* Received by the editors May 7, 1986; accepted for publication (in revised form) October 29, 1986.

† Department of Mathematics, University of Missouri, Columbia, Missouri 65211.

the special cases where $|\nabla u|>0$, $\Delta u>0$, and $\max\{|\nabla u|, \Delta u\}>0$, and uses inflow data on the boundary for estimates. Alessandrini considers the uniqueness problem in two spatial variables with $u\equiv 0$ on $\partial\Omega$ for $f=0$ [2], and $f=\delta(x-x_0)$ [1]. In this paper we obtain uniqueness of the parameter on subregions of Ω which are solely determined by the observation u. In particular, uniqueness is not linked to flow data on the boundary.

2. Notation and preliminaries. We first note two special cases of the identification problem:

(1) If u is constant in a subregion of Ω, the gradient will vanish identically there, and $a(x)$ can be chosen arbitrarily.

(2) If u is harmonic on Ω, (1) will be satisfied for any constant function $a(x)$.

In addition we observe that (1) can be viewed as a first-order partial differential equation for $a(x)$, and we can rewrite it in the form

$$\nabla a\cdot\nabla u+a\Delta u=0. \tag{3}$$

The gradient field of u defines the characteristic curves for this equation, and $a(x)$ could be found by integration along the characteristics, provided Cauchy data for a are known along a noncharacteristic manifold. The linear character of (3) implies that $a(x)$ does not change sign along characteristic curves, and in particular, if $a(P)=0$ at some point P, it vanishes identically along the characteristic through that point. We also recall that the function u itself is strictly increasing along flow lines of the gradient field.

In what follows Ω is an open, bounded and connected subset of R^n with smooth boundary $\partial\Omega$. The function $u(x)$ belongs to $C^2(\bar\Omega)$, i.e., there exists an open set D such that $\bar\Omega\subset D$ and $u\in C^2(D)$. The set of all critical points of u is denoted by C.

Next we consider the gradient field of u. Its trajectories are denoted by $\phi_t(P)$, i.e., if $x(t)$ is a solution of

$$\frac{dx}{dt}=\nabla u,\qquad x(0)=P, \tag{4}$$

we write $\phi_t(P):=x(t)$. It is understood that we take the maximal t-intervals so that $\phi_t(P)\in D$.

Now we define subsets of $\bar\Omega$ by

$$\Omega_+:=\{P\in\bar\Omega\colon \phi_t(P)\in D-\bar\Omega \text{ for some } t>0\},$$

$$\Omega_-:=\{P\in\bar\Omega\colon \phi_t(P)\in D-\bar\Omega \text{ for some } t<0\},$$

$$\Omega_0:=\Omega_+\cap\Omega_-.$$

Any one of these sets may be empty, or may be equal to $\bar\Omega$, and none of them contains critical points of u. The complements of Ω_+ and Ω_- are denoted in the following way:

$$\Omega_f:=\bar\Omega-\Omega_+\quad\text{and}\quad\Omega_b:=\bar\Omega-\Omega_-.$$

The set Ω_f contains all points P of $\bar\Omega$ for which the trajectories $\phi_t(P)$ remain in $\bar\Omega$ for all $t>0$. In particular, the singular points of u are contained in the intersection of Ω_f and Ω_b.

The structure of the sets just defined is important to our considerations. We need the following easy proposition, which we state without proof.

PROPOSITION 1. *Ω_+, Ω_-, and Ω_0 are relatively open in $\bar\Omega$. Thus, also Ω_f, Ω_b, and Ω_1 are closed subsets of R^n.*

DEFINITION. The parameter $a(x) \in C^1(\bar{\Omega})$ is called identifiable at a point $P \in \bar{\Omega}$ from the data $u(x)$, if for any solution $a(x)$ of the equation $\operatorname{div}(a\nabla u) = 0$ on $\bar{\Omega}$ necessarily $a(P) = 0$. We call the parameter identifiable on $S \subset \bar{\Omega}$, if it is identifiable for all $P \in S$.

PROPOSITION 2. *$a(x)$ is not identifiable in Ω_0.*

Proof. Let $P \in \Omega_0$. By Proposition 1 and the fact that P is a nonsingular point of u, there is an open $(n-1)$-dimensional disk $S \subset \Omega_0$ of radius $r > 0$ contained in the level set M of u through P.

Let $f\colon S \to R$ be a smooth bump function with $0 \leqq f(s) \leqq 1$, and $f \equiv 0$ on $S - S_0$, where S_0 is the disk in M of radius $r/2$. We define a function $a(x)$ in $\bar{\Omega}$ as follows: If for some t we have $Q = \phi_t(P_0)$, where $P_0 \in S$, we define $a(Q)$ as $a(t)$, where $a(\tau)$ is the solution of (3) with initial value $a(0) = f(P_0)$. Else we set $a(Q) = 0$. It follows that in $\bar{\Omega}$, a satisfies $\operatorname{div}(a\nabla u) = 0$, and $a(P) = 1$. Thus, a is not identifiable at P, and P was arbitrary in Ω_0. □

3. The main result. In the previous part we have seen that $a(x)$ is not identifiable on Ω_0, and in the introduction it was pointed out that $a(x)$ is not identifiable in regions where $u(x)$ is identically constant. Our goal now is to show that $a(x)$ is identifiable in all other parts of $\bar{\Omega}$. To this end we set

$$\Omega_1 := \bar{\Omega} - \Omega_0 \quad \text{and} \quad \Omega_2 := \Omega_1 - C.$$

LEMMA 1. *Let $V_0 \subset \Omega$ be any volume, and denote by $V(t)$ the volume which is obtained from V_0 by following the gradient flow for time t, i.e.*

$$V(t) := \{P\colon \exists Q \in V_0 \text{ with } P = \phi_t(Q)\}.$$

Then

$$\int_{V_0} a(x)\,dx = \int_{V(t)} a(x)\,dx$$

for all t for which $V(t) \subset \Omega$.

Proof. We apply the Reynolds transport theorem (cf. [10, p. 443]) and the divergence theorem to obtain the following:

$$\begin{aligned}\frac{d}{dt}\left(\int_{V(t)} a(x)\,dx\right) &= \int_{V(t)} \partial_t a(x)\,dx + \int_{\partial V(t)} a\nabla u \cdot n\,dx \\ &= \int_{V(t)} \operatorname{div}(a\nabla u)\,dx = 0.\end{aligned}$$

Therefore the integral of $a(x)$ over any volume which follows the flow remains constant. □

LEMMA 2. *Suppose there exists an open set $U \subset \Omega_2$, such that either $U \subset \Omega_b$ or $U \subset \Omega_f$. Then $a \equiv 0$ on U.*

Proof. We assume $P \in U \subset \Omega_f$, and $a(P) > 0$, the other cases being similar.

Since a is continuous, there is an open set $W \subset \Omega_2$ on which a is everywhere positive. Moreover, since P is not a critical point of u, the level set of u through P is a smooth section for the flow ϕ_t. Let S denote an open disk in this level set containing P and contained in W. Also define $R_s := [s, \infty)$ and $I_s := [0, s)$. The map $\phi\colon R_s \times S \to \Omega$ given by $\phi(t, Q) = \phi_t(Q)$ is a diffeomorphism onto its image which we denote by V_s. Moreover, by the remarks following (3), a is positive on V_s. If we set $W_s := \phi(I_s \times S)$, we find that $V_s \cup W_s = V_0$.

Now since V_s is an open subset of the bounded region Ω, $a(x)$ is integrable over V_s and, in fact, its integral over V_s is a finite positive number. But clearly

$$\int_{V_s} a(x)\,dx + \int_{W_s} a(x)\,dx = \int_{V_0} a(x)\,dx,$$

so

$$\int_{V_s} a(x)\,dx < \int_{V_0} a(x)\,dx,$$

which contradicts Lemma 1. (See Fig. 1).

THEOREM 1. *$a(x)$ is identifiable on the closure of* int (Ω_2).

Proof. Suppose int (Ω_2) is not empty, and let P belong to this set. If there exists a neighborhood U of P which belongs entirely to either Ω_f or Ω_b, then $a(P)=0$ by virtue of Lemma 2. Otherwise, every open neighborhood U of P contains points of Ω_f and Ω_b.

Let us consider the remaining case, and assume WLOG that $P \in \Omega_f \cap \Omega$. Let U be an open neighborhood of P and set $V := U \cap \Omega_+$ (recall that Ω_+ is the complement of Ω_f, and relatively open by Proposition 1). Then V is not empty, open, and $P \in \partial V$. Therefore $a(x)$ vanishes on V due to Lemma 2, $a(x)$ being continuous, and $P \in \partial V$ implies $a(P)=0$. □

To illustrate Proposition 2 and Theorem 1, consider the following simple example. Let Ω denote the interior of the unit disk in R^2 and let $u = x^3/3 - y^2/2$. The phase portrait of ∇u, shown in Fig. 2, is easily described since the origin is the only stationary point and it is a saddle node.

Now, in our notation, the portion of the region $\bar{\Omega}$ in the closed left half-plane together with the positive x-axis is Ω_2, and the portion of the region $\bar{\Omega}$ in the open first and fourth quadrants is Ω_0. Thus, by our theorems, the parameter a in div $(a\nabla u)=0$ is identifiable in the closed left half-plane, and not identifiable on the open first and fourth quadrants. However, in this example, we can make explicit calculations to illustrate our results. Moreover, we can see that a is not identifiable at points in Ω_2 along the positive x-axis. Hence we cannot replace the closure of int (Ω_2) by Ω_2 in Theorem 1.

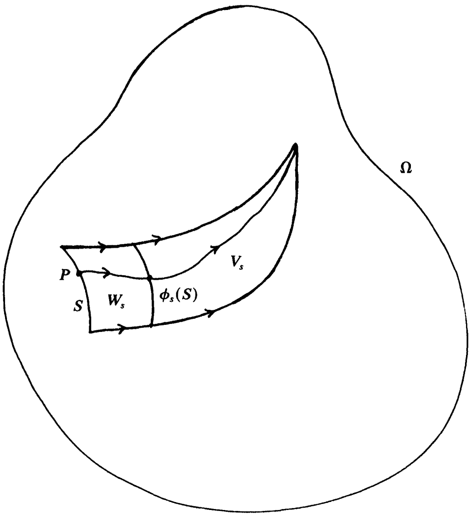

FIG. 1. *Section S and "vortex" tube given by the gradient flow of u.*

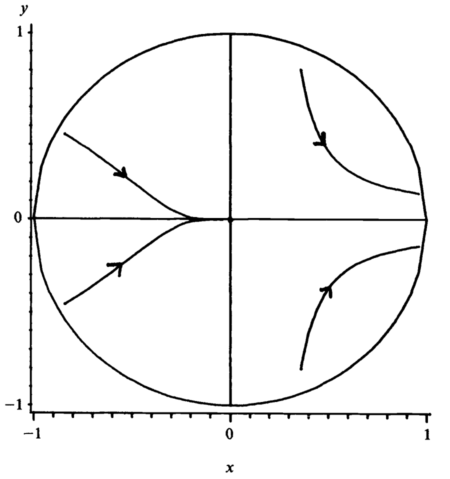

FIG. 2. *Phase portrait for the gradient of* $u = x^3/3 - y^2/2$.

For the calculations just consider the PDE for $a(x, y)$ given by $\operatorname{div}(a\nabla u) = 0$ as the first order PDE

$$x^2 a_x - y a_y + (2x-1)a = 0,$$

which has the general solution

$$a(x, y) = f_i(y/e^{1/x})/(x^2\, e^{1/x})$$

for any smooth functions f_i, where f_1 is defined for points in the left half-plane, and f_2 for points in the right half-plane subject only to the constraint that $a(x, y)$ be smooth on the y-axis.

However, for any choice of f_1 nonvanishing, $a(x, y)$ will fail to be continuous at the origin. To see this, observe that the characteristic curves of the PDE are given by $y = ce^{1/x}$. Thus, to have $a(x, y)$ defined continuously at the origin, the limit of $f_1(c)/(x^2 e^{1/x})$ must be finite as $x \to 0^-$. But the only way to insure this is to take $f_1 \equiv 0$. Therefore, any solution $a(x, y)$ must vanish in the closed left half-plane, and $a(x, y)$ is identifiable there as predicted by Theorem 1.

To see that points in the right half-plane are not identifiable we may choose $f_1 \equiv 0$, and $f_2 \equiv 1$, so

$$a(x, y) = \begin{cases} 1/x^2 e^{1/x}, & x > 0, \\ 0, & x \leqq 0. \end{cases}$$

We obtain $a(x, y)$ as a smooth parameter which is nonzero in the open right half-plane (including the positive x-axis) as predicted by Proposition 2.

4. Test conditions. In practice the function u is not arbitrary. It is obtained from the (unknown) parameter $a(x)$ and the function $f(x)$ as a solution of (2)

$$-\operatorname{div}(a\nabla u) = f$$

on Ω with appropriate boundary conditions. While for the well-posedness of this problem it is necessary that $a(x) \geqq a_0 > 0$, we may drop this last requirement in our approach. We assume that the functions a, u and f are given so that (2) is satisfied, and ask for conditions which imply that a is unique.

In this section we will use the term "identifiable" in a slightly modified way. For fixed f and u the parameter a is called identifiable at a point $P \in \bar{\Omega}$ if any parameter which satisfies (2), with possibly prescribed Cauchy data, agrees with a at the point

P. Identifiability on subsets of $\bar{\Omega}$ is defined similarly. The connection to our original definition becomes obvious when we consider the difference of two solutions for a.

PROPOSITION 3. *Suppose a is a solution of* (2), *satisfying* $a(x) \geqq a_0 > 0$, *and no Cauchy data for a are prescribed. Then if f vanishes on Ω, a is not identifiable on $\bar{\Omega}$.*

The proof of this result is trivial. However, Proposition 3 clearly shows that no information about the flow rates $q = a\nabla u$ can be obtained if the rates at which water is added to or taken from the aquifer are identically zero throughout the region Ω. If f vanishes on a subregion U of Ω, the argument in the proof cannot be repeated directly without introducing discontinuities if U is adjacent to a region on which a is identifiable.

PROPOSITION 4. *Let u be a solution of* (2) *with $u \equiv u_0$ on $\partial\Omega$, where u_0 is a constant, and suppose that* int $(C) = \emptyset$. *Then a is identifiable on $\bar{\Omega}$.*

Proof. Let $P \in \bar{\Omega}$, and assume that P is not a critical point of u. Then the trajectory $\phi_t(P)$ contains at most one point of $\partial\Omega$, since u increases along any trajectory, and u is constant on the boundary. Therefore $\Omega_0 = \emptyset$, $\bar{\Omega} = \Omega_1$ and $\Omega_2 = \bar{\Omega} - C$. Thus int $(\Omega_2) = \Omega - C$, and the closure of int (Ω_2) is all of $\bar{\Omega}$, since int $(C) = \emptyset$. The identifiability of a on $\bar{\Omega}$ now follows from Theorem 1. □

PROPOSITION 5. *Let u be a solution of* (2) *with $a\partial u/\partial n = g$ on $\partial\Omega$, and assume that* int $(C) = \emptyset$. *Then a is identifiable on $\bar{\Omega}$.*

Proof. Suppose we have two functions $a_1(x)$, and $a_2(x)$ which meet the conditions stated in the hypotheses; then their difference $a(x) := a_1(x) - a_2(x)$ satisfies div $(a\nabla u) = 0$ on Ω. Also $a\partial u/\partial n = 0$ on $\partial\Omega$.

Suppose $P \in \Omega_+ \cup \Omega_-$, and assume $P \in \Omega_+$, the case $P \in \Omega_-$ being similar. Then there is a point $Q \in \partial\Omega$ such that $Q = \phi_t(P)$ and $\phi_s(Q) \in (D - \bar{\Omega})$ for small $s > 0$.

There are two cases. First suppose $a(Q) = 0$. Since a satisfies the linear equation (3) along $\phi_t(Q)$ it follows that $a(P) = 0$. If $a(Q) \neq 0$, we find a neighborhood U of Q on $\partial\Omega$ on which a is nonzero. Hence $\partial u/\partial n \equiv 0$ on U. But in this case $\phi_t(t)$ will remain in $U \cap \partial\Omega$, which contradicts the choice of Q. Hence we have shown that $a(P) = 0$ on $\Omega_+ \cup \Omega_-$, and since $\Omega_0 \subset \Omega_+ \cup \Omega_-$, it follows that $a \equiv 0$ on Ω_0.

To complete the proof, we recall that Theorem 1 implies $a \equiv 0$ on the closure of int (Ω_2). Since $\bar{\Omega} = \Omega_0 \cup \Omega_2 \cup C$, and int $(C) = \emptyset$, the continuity of $a(x)$ implies $a(x) \equiv 0$ on $\bar{\Omega}$. □

Proposition 5 agrees with a result of Falk's [3] without using the assumption that $\nabla u \cdot \nu \geqq \sigma > 0$ on Ω for some fixed vector ν and a constant σ.

EXISTENCE OF GENERALIZED SOLUTIONS OF A NONLINEAR DIFFUSION CAUCHY PROBLEM*

CARMEN CORTAZAR† AND MANUEL ELGUETA†

Abstract. In this paper we prove the existence of a generalized solution of the initial value problem $\partial u/\partial t = \partial/\partial x\, \Phi(u, \partial\Sigma(u)/\partial x)$; $u(x, 0) = u_0(x)$ and the uniqueness of such a solution under certain conditions.

Key words. existence, parabolic, nonlinear, Cauchy problem

AMS(MOS) subject classifications. 35K65, 35D05

1. Introduction. In this note we prove the existence of at least one generalized solution of the initial value problem

$$\frac{\partial u}{\partial t}=\frac{\partial}{\partial x}\Phi\left(u,\frac{\partial\Sigma(u)}{\partial x}\right), \tag{1.1}$$

$$u(x,0)=f(x). \tag{1.2}$$

This is a generalization of the equation $\partial u/\partial t = \partial^2\Sigma(u)/\partial x^2$ that includes $\partial u/\partial t = \partial/\partial x(|\partial u/\partial x|^{N-1}\partial u/\partial x)$ and $\partial u/\partial t = \partial/\partial x(|\partial u^{\lambda}/\partial x|^{N-1}\,\partial u/\partial x)$.

By a *generalized solution* to the above problem we understand a function $u(x, t)$ defined on $S = \mathbb{R}\times[0,\infty)$ so that

(i) $u(x, t)$ is continuous in $S=\mathbb{R}\times[0,\infty)$;

(ii) $\partial\Sigma(u)/\partial x$, which exists in the sense of distributions, belongs to L^{∞};

(iii) $$\iint\left[u\phi_t-\Phi\left(u,\frac{\partial\Sigma(u)}{\partial x}\right)\phi_x\right]dx\,dt + \int_{-\infty}^{+\infty} f(x)\phi(x,0)\,dx=0 \quad \forall\phi\in C_0^{\infty}(S).$$

Throughout this paper the functions $\Phi:[0,\infty)\times\mathbb{R}\to\mathbb{R}$ and $\Sigma:[0,\infty)\to[0,\infty)$ will satisfy

$$\Phi\in C^1([0,\infty)\times\mathbb{R}), \Sigma\in C^1([0,\infty)), \Sigma\in C^2([0,\infty)), \tag{1.3}$$

$$\begin{gathered} y_1<y_2\Rightarrow\Phi(z,y_1)<\Phi(z,y_2) \quad \forall z\in[0,\infty), \\ \Phi(z,-y)=-\Phi(z,y) \quad \forall(z,y)\in[0,\infty)\times\mathbb{R}, \end{gathered} \tag{1.4}$$

(1.5) there exist constants $\alpha_1>0$, $\alpha_2>0$, $\beta>0$, $C>0$ and a function $\psi\in C^{\infty}([0,\infty))$, $\psi(s)>0$ for all $s>0$ and $\int_0^z \psi^{1/\alpha_1}(s)\Sigma'(s)s\,ds<\infty$ so that $|\Phi(z,y)|\leqq\psi(z)|y|^{\alpha_1}$ if $|y|\leqq\beta$ and $|\Phi(z,y)|\geqq C|y|^{\alpha_2}$ if $|y|\geqq\beta$,

(1.6) $\Sigma'(s)\geqq 0$ and $\Sigma'(s)>0$ if $s>0$.

We will produce a generalized solution to problem (1.1), (1.2) as the limit of classical solutions of strictly parabolic problems that converge in a suitable way to

problem (1.1), (1.2). Namely, for $n=0,1,2,\cdots$, let $\Phi_n:[0,\infty)\times\mathbb{R}\to\mathbb{R}$ and $\Sigma_n:[0,\infty)\to[0,\infty)$ be functions that satisfy hypotheses (1.3)-(1.6) with the constants α_1, α_2, β, C and the function ψ independent of n, and such that $\Sigma_n\in C^2([0,\infty))$. Assume moreover that

$$\frac{\partial\Phi_n}{\partial y}(z,y)\geqq a_n\gneqq 0 \quad \forall n, \tag{1.7}$$

$$\Sigma_n'(s)\geqq a_n\gneqq 0 \quad \forall n, \tag{1.8}$$

$$\Phi_0(z,y)\geqq\Phi_n(z,y) \quad \forall z,\quad \forall y\geqq 0,\quad n=0,1,2,\cdots, \tag{1.9}$$

$$\Sigma_0'(s)\geqq\Sigma_n'(s) \quad \forall s\geqq 0,\quad n=0,1,2,\cdots, \tag{1.10}$$

and

(1.11) $\Phi_n(z,y)\to\Phi(z,y)$ as $n\to+\infty$ uniformly on compact subsets,

(1.12) $\Sigma_n'(s)\to\Sigma'(s)$ as $n\to+\infty$ uniformly on compact subsets and $\Sigma_n(0)\to\Sigma(0)$ as $n\to+\infty$,

(1.13) Let $f_n:\mathbb{R}\to\mathbb{R}$ so that $f_n\to f$ on $L^1(\mathbb{R})$ as $n\to+\infty$ and $\|f_n(x)\|_\infty\leqq M<\infty$ with M independent of n. Let $u_n(x,t)$ be the solution in S of the strictly parabolic problem,

$$\frac{\partial u}{\partial t}=\frac{\partial}{\partial x}\Phi_n\left(u,\frac{\partial\Sigma_n(u)}{\partial x}\right), \tag*{(1.1)$_n$}$$

$$u(x,0)=f_n(x). \tag*{(1.2)$_n$}$$

(For the existence of such a solution see [13].) We will refer to $(1.1)_n$, $(1.2)_n$ as an approximating sequence to problem (1.1), (1.2).

More precisely we will prove the following.

THEOREM 1. *Let $u_n(x,t)$ be a solution of problem* $(1.1)_n$, $(1.2)_n$ *with Φ_n, Σ_n and f_n as in the preceding paragraph and such that*

$$\left\|\frac{\partial}{\partial x}\Phi_n\left(f_n,\frac{\partial\Sigma_n(f_n)}{\partial x}\right)\right\|_1\leqq P \tag{1.14}$$

with P independent of n. Then there exists a subsequence of $\{u_n(x,t)\}_{n=1}^\infty$ which converges uniformly on compact subsets of S to a generalized solution $u(x,t)$ of problem (1.1), (1.2). *Moreover, for a fixed $t\geqq 0$ the functions $u_n(\cdot,t)$ converge to $u(\cdot,t)$ in $L^1(\mathbb{R})$.*

As a corollary we obtain the following existence result.

COROLLARY 1. *If Φ and Σ satisfy hypotheses* (1.3)-(1.7) *and f, $\partial f/\partial x$, $\partial^2 f/\partial x^2$ and $\partial^2\Sigma(f)/\partial x^2$ belong to $L^1(\mathbb{R})$ then the initial value problem* (1.1), (1.2) *has at least a generalized solution in S.*

Related existence results appear in [4], [6], [7], and [13]-[15].

The next theorem shows that no matter which sequence of approximating problems is taken, the solution we obtain is the same. In particular this proves that the sequence $\{u_n(x,t)\}_{n=1}^\infty$ of Theorem 1 itself converges to a generalized solution of problem (1.1), (1.2).

THEOREM 2. *Let $\Phi_n^{(i)}$, $\Sigma_n^{(i)}$, $f_n^{(i)} i=1,2$; $n=0,\cdots$, be sequences of functions that satisfy hypotheses* (1.3)-(1.14).

Let $u^{(i)}(x,t) i=1,2$ be defined by

$$u^{(i)}(x,t)=\lim_{n\to+\infty}u_n^{(i)}(x,t)$$

where $u_n^{(i)}(x, t)$ *is the solution of problem*

$$\frac{\partial u}{\partial t}=\frac{\partial}{\partial x}\Phi_n^{(i)}\left(u, \frac{\partial \Sigma_n^{(i)}(u)}{\partial x}\right), \qquad u(x,0)=f_n^{(i)}(x).$$

Then $u^{(1)}(x, t)=u^{(2)}(x, t)$ *for all* $(x, t)\in S$.

Although we have not been able to prove uniqueness of the generalized solution of problem (1.1), (1.2) we have the following uniqueness theorem.

THEOREM 3. *Let* $u(x, t)$ *and* $v(x, t)$ *be two generalized solutions of problem* (1.1), (1.2). *In addition to hypotheses* (1.3)-(1.7) *assume that* $\Phi\in C^\infty([0,\infty)\times\mathbb{R})$, $\Sigma\in C^\infty[0,\infty))$ *and* $\partial\Phi/\partial y(z, y)\geqq a>0$, *for all* $(z, y)\in[0,\infty)\times\mathbb{R}$. *Then* $u\equiv v$.

For some uniqueness results see [3], [5] and [15].

We would like to note that several properties of the solutions of strictly parabolic problems are inherited by the limit solution given by Theorem 1, among them the comparison theorems as they appear in [8]. This permits us, using the same techniques as in [9] and [12], to study asymptotic behaviour of the solutions so obtained. The details will appear somewhere else.

2. Proof of Theorem 1. Let $u_n(x, t)$ be the solution of problem $(1.1)_n$, $(1.2)_n$; it is known that these are classical solutions. Since $\|u_n(\cdot,\cdot)\|_\infty\leqq\|f_n\|_\infty\leqq M$ we obtain, by (1.10), $\|\Sigma_n(u_n(\cdot,\cdot))\|_\infty\leqq\Sigma_0(M)$. We will prove now that the sequence $\Sigma_n(u_n)$ is equicontinuous in S.

By Theorem 1 of [8] and (1.14) we get

$$\left\|\frac{\partial}{\partial x}\Phi_n\left(u_n, \frac{\partial\Sigma_n(u_n)}{\partial x}\right)\right\|_1\leqq\left\|\frac{\partial}{\partial x}\Phi_n\left(f_n, \frac{\partial\Sigma_n(f_n)}{\partial x}\right)\right\|_1\leqq P \quad \forall n.$$

Therefore

$$\left\|\Phi_n\left(u_n, \frac{\partial\Sigma_n(u_n)}{\partial x}\right)\right\|_\infty\leqq P$$

and, by (1.5), recalling that the constants do not depend on n, we obtain

$$\left\|\frac{\partial\Sigma_n}{\partial x}(u_n)\right\|_\infty\leqq C \quad \forall n\geqq 0.$$

Hence, for a fixed t, $\Sigma_n(u_n(\cdot, t))$ is Lipschitz continuous in x, with Lipschitz constant C independent of t and n.

On the other hand, since the solution $u_n(x, t)$ is given by a contraction semigroup,

$$\|u_n(\cdot, t_1)-u_n(\cdot, t_2)\|_1\leqq P\quad|t_1-t_2|$$

(see [8], [13]).

Therefore, by (1.10),

$$\|\Sigma_n(u_n(\cdot, t_1))-\Sigma_n(u_n(\cdot, t_2))\|_1\leqq C\cdot P\quad|t_1-t_2|.$$

This, and the uniform Lipschitz continuity in x, imply by a standard argument that $\{\Sigma_n(u_n)\}_{n=0}^\infty$ is equicontinuous in S.

Now the Ascoli-Arzela Theorem gives a subsequence $\{\Sigma_{n_k}(u_{n_k})\}_{k=0}^\infty$ and hence a subsequence $\{u_{n_k}\}_{k=0}^\infty$ that converges uniformly on compact subsets of S to a continuous function u. An immediate consequence of this is that $\partial\Sigma_{n_k}(u_{n_k})/\partial x$ converges weakly to $\partial\Sigma(u)/\partial x$. Since $\|\partial\Sigma_{n_k}(u_{n_k})/\partial x\|_\infty$ are uniformly bounded we get $\partial\Sigma(u)/\partial x\in L^\infty$.

We will now prove that $u(x, t)$ satisfies (iii) of the definition of a generalized solution.

We define

$$H_n(z, \eta)=y \Leftrightarrow \Phi_n(z, y)=\eta \quad \text{and} \quad H(z, \eta)=y \Leftrightarrow \Phi(z, y)=\eta.$$

Now, since for a fixed t,

$$\left\| \frac{\partial}{\partial x} \Phi_{n_k}\left(u_{n_k}, \frac{\partial \Sigma_{n_k}(u_{n_k})}{\partial x}\right)(\cdot, t)\right\|_1 \leqq P$$

by the inbedding [11, Thm. 11.2, p. 31], we have that for a fixed interval $[-A, A]$ there exists a subsequence $\{n_{k'}\}_{k'=0}^{\infty}$ of $\{n_k\}$ so that

$$\Phi_{n_{k'}}\left(u_{n_{k'}}, \frac{\partial \Sigma_{n_{k'}}(u_{n_{k'}})}{\partial x}\right)(\cdot, t) \rightarrow \eta(\cdot, t)$$

as $k' \rightarrow +\infty$ in $L^1[-A, A]$ and so we can extract another subsequence $\{n_{k''}\}$ so that

$$\eta_{n_{k''}}(\cdot, t)=\Phi_{n_{k''}}\left(u_{n_{k''}}, \frac{\partial \Sigma_{n_{k''}}(u_{n_{k''}})}{\partial x}\right)(\cdot, t) \rightarrow \eta(\cdot, t)$$

as $k'' \rightarrow +\infty$ a.e. in $[-A, A]$. But

$$\frac{\partial \Sigma_{n_{k''}}(u_{n_{k''}})}{\partial x}(x, t)=H_{n_{k''}}(u_{n_{k''}}, \eta_{n_{k''}})$$

and if we let $k'' \rightarrow +\infty$, since

$$\frac{\partial \Sigma_{n_{k''}}(u_{n_{k''}})}{\partial x} \rightarrow \frac{\partial \Sigma(u)}{\partial x}$$

weakly as $k'' \rightarrow +\infty$, we get

$$\frac{\partial \Sigma(u)}{\partial x}(x, t)=H(u, \eta)(x, t) \quad \text{a.e. in } [-A, A].$$

So

$$\eta(x, t)=\Phi\left(u(x, t), \frac{\partial \Sigma(u)}{\partial u}(x, t)\right) \quad \text{a.e. in } [-A, A]$$

and

$$\Phi_{n_{k''}}\left(u_{n_{k''}}(\cdot, t), \frac{\partial \Sigma_{n_{k''}}(u_{n_{k''}})}{\partial x}(\cdot, t)\right) \rightarrow \Phi\left(u(\cdot, t), \frac{\partial \Sigma(u)}{\partial x}(\cdot, t)\right)$$

as $k'' \rightarrow +\infty$ in $L^1([-A, A])$.

Therefore the same is true for the whole subsequence $\{u_{n_k}\}_{k=1}^{\infty}$. Since

$$\left\| \Phi_{n_k}\left(u_{n_k}, \frac{\partial \Sigma_{n_k}(u_{n_k})}{\partial x}\right)(\cdot, \cdot)\right\|_{\infty} \leqq P$$

the dominated convergence theorem implies that $\Phi_{n_k}(u_{n_k}, \partial \Sigma_{n_k}(u_{n_k})/\partial x)$ converges to $\Phi(u, \partial \Sigma(u)/\partial x)$ in $L^1([-A, A] \times [0, T])$ for our rectangle $[-A, A] \times [0, T]$.

Finally, letting $k \rightarrow +\infty$ in

$$\iint_S \left[u_{n_k} \phi_t-\Phi_{n_k}\left(u_{n_k}, \frac{\partial \Sigma_{n_k}(u_{n_k})}{\partial x}\right) \phi_x\right] dx\, dt+\int_{-\infty}^{+\infty} f_{n_k}(x) \phi(x, 0)\, dx=0,$$

we obtain that $u(x, t)$ is a generalized solution of (1.1), (1.2).

We have proved that the subsequence $\{u_{n_k}(x, t)\}_{k=1}^{\infty}$ converges uniformly on compact subsets to a generalized solution of problem (1.1), (1.2). It remains to prove that $\{u_{n_k}(\cdot, t)\}_{k=1}^{\infty}$ converges in $L^1(\mathbb{R})$ to $u(\cdot, t)$. Now we need the following lemma.

LEMMA 1. *Let $u_n(x, t)$ be a solution of problem $(1.1)_n$, $(1.2)_n$. Then given $\varepsilon > 0$ and $T > 0$ there exists $A > 0$ so that*

$$\int_{|y| \geqq A} u_n(y, t)\, dy \leqq \varepsilon \quad \forall n, \quad \forall t \in [0, T].$$

Proof. The main tool in the proof is the comparison theorem [8, Thm. 3] (see also [16]).

We prove first the case $f_n = f \in C_0^{\infty}$. In this case let $g \in C_0^{\infty}$ symmetric with respect to $x = 0$, increasing for $x \leqq 0$ and $f(x) \leqq g(x)$ for all x.

Let $v_n(x, t) n = 0, 1, 2, \cdots$, be the solution of

$$\frac{\partial v}{\partial t} = \frac{\partial}{\partial x} \Phi_n\left(v, \frac{\partial \Sigma_n(v)}{\partial x}\right), \qquad v(x, 0) = g(x).$$

According to the above-mentioned comparison theorem, we have

$$\int_{|y| \geqq A} u_n(y, t)\, dy \leqq \int_{|y| \geqq A} v_n(y, t)\, dy \leqq \int_{|y| \geqq A} v_0(y, t) \leqq \int_{|y| \geqq A} v_0(y, T)\, dy.$$

As $v_0(\cdot, T) \in L^1(\mathbb{R})$ the lemma is proved in the case $f_n = f \in C_0^{\infty}$. The general case follows now from the well-known fact that

$$\|u_n(\cdot, t) - \tilde{u}_n(\cdot, t)\|_1 \leqq \|u_n(\cdot, 0) - \tilde{u}_n(\cdot, 0)\|_1$$

where u_n and $\tilde{u}_n$ are solutions of $(1.1)_n$. This ends the proof of Lemma 1.

Lemma 1 and the fact that $u_{n_k} \to u$ uniformly on compact subsets of S imply that $u_{n_k}(\cdot, t) \to u(\cdot, t)$ in $L^1(\mathbb{R})$. This proves Theorem 1.

Remark. We would like to observe that an alternative proof to Theorem 1 could be obtained by using nonlinear semigroup theory, in particular P. Benilan's result that states that if A_n, $n = 1, 2, \cdots, \infty$ is an m-accretive operator in a Banach space and $A_n \to A_\infty$ as $n \to +\infty$ in a suitable way; then for the corresponding semigroups $S_n(t)$ one has $S_n(t) \to S_\infty(t)$ as $n \to +\infty$. For a precise statement of this result see [1], [2] or [10].

Proof of Corollary 1. From the hypothesis it is easy to construct sequences Φ_n, Σ_n that satisfy the requirements of Theorem 1 with $f_n = f$, for all n.

3. Proof of Theorem 2. First we need the following lemma.

LEMMA 2. *Let $u_n(x, t)$ be a solution of problem $(1.1)_n$, $(1.2)_n$ and assume that $0 < a \leqq f_n(x)$, for all $x \in [-A, A]$ for all n. Then given $T > 0$ there exists $b > 0$ independent of n so that $u_n(x, t) > b$ for all $(x, t) \in [-A, A] \times [0, T]$.*

Proof. Let g be C_0^{∞}, symmetric with respect to $-A$ increasing for $x \leqq -A$, $g(-A) \neq 0$, $g(x) \leqq f_n(x)$ for all $x \in \mathbb{R}$.

Let $v_n(x, t)$ be a solution of $(1.1)_n$ with initial condition g. The comparison theorem ([8], [16]) implies

$$\int_{-\infty}^{x} v_n(y, t) \leqq \int_{-\infty}^{x} v_0(y, T) \qquad \forall x \leqq -A, \quad \forall t \in [0, T].$$

Therefore, since $\int_{-\infty}^{-A} v_n = \int_{-\infty}^{-A} v_0 = \int_{-\infty}^{-A} g$,

$$\int_{x}^{-A} v_n(y, t)\, dy \geqq \int_{x}^{0} v_0(y, T)\, dy \quad \forall x \leqq -A.$$

Hence

$$v_n(-A, t) \geqq v_0(-A, T).$$

Pointwise comparison (see [8], [13]) gives

$$u_n(-A, t) \geqq v_0(-A, T) > 0.$$

Similarly,

$$u_n(A, t) \geqq v_0^+(A, T) > 0$$

where $v_0^+(A, T)$ is a solution to $(1.1)_0$ with initial condition $g^+ \in C_0^\infty$, symmetric with respect to A, increasing for $x \leqq A$, $g^+(A) \neq 0$, $g^+(x) \leqq f_n(x)$ for all $x \in \mathbb{R}$.

Since, by hypothesis, $u_n(x, 0) = f_n(x) \geqq a > 0$ for $x \in [-A, A]$, the minimum principle for parabolic equations implies that

$$u_n(x, t) > \min(a, v_0(-A, T), v_0^+(A, T)) = b > 0$$

for all $(x, t) \in [-A, A] \times [0, T]$ and the lemma is proved.

Proof of Theorem 2. Let $\varepsilon > 0$ be given. There exists $\tilde{f}$: $\mathbb{R} \to \mathbb{R}$ and $N > 0$ so that $\tilde{f}$, $\partial \tilde{f}/\partial x$, $\partial^2 \tilde{f}^2/\partial x^2 \in L^1(\mathbb{R})$ and $\|f_n - \tilde{f}\| \leqq \varepsilon$ for all $n \geqq N$.

Let $\tilde{u}_n^{(i)}(x, t)$ be the solution of $(1.1)_n$ with initial condition $\tilde{u}_n^{(i)}(x, 0) = \tilde{f}(x)$.

It is well known that

$$\|\tilde{u}_n^{(i)}(\cdot, t) - u_n^{(i)}(\cdot, t)\|_1 \leqq \|\tilde{f} - f_n\|_1. \tag{3.1}$$

Since

$$\begin{aligned} e^{-t} \int_{-\infty}^{x} [u_n^{(1)}(y, t) - u_n^{(2)}(y, t)]\, dy = {} & e^{-t} \int_{-\infty}^{x} [u_n^{(1)}(y, t) - \tilde{u}_n^{(1)}(y, t)]\, dy \\ & + e^{-t} \int_{-\infty}^{x} [\tilde{u}_n^{(1)}(y, t) - \tilde{u}_n^{(2)}(y, t)]\, dy \\ & + e^{-t} \int_{-\infty}^{x} [\tilde{u}_n^{(2)}(y, t) - u_n^{(2)}(y, t)]\, dy, \end{aligned}$$

and ε is arbitrary, by (3.1) in order to show that $u^{(1)} \equiv u^{(2)}$ it suffices to show that for

$$J_n(x, t) = e^{-t} \int_{-\infty}^{x} [\tilde{u}_n^{(1)}(y, t) - \tilde{u}_n^{(2)}(y, t)]\, dy$$

we have

$$\max_{(x,t) \in S} |J_n(x, t)| \to 0 \quad \text{as } n \to +\infty. \tag{3.2}$$

In order to prove (3.2) assume that

$$\overline{\lim_{n \to +\infty}} \max_{(x,\, t) \in S} J_n(x, t) = d > 0;$$

then there exists $n > 0$ and $T > 0$ such that

$$\max_{(x,t) \in S} J_n(x, t) = \max_{(x,\, t) \in \mathbb{R} \times [0,\, T]} J_n(x, t) \geqq \frac{d}{2} > 0. \tag{3.3}$$

By Lemma 1 we can find $A>0$ so that

$$\max_{(x,t)\in S} J_n(x,t)=J_n(x_n,t_n)$$

and $(x_n, t_n)\in[-A, A]\times[0, T]$.

Since the maximum of $J_n(x, t)$ is attained at (x_n, t_n), the relations $(\partial/\partial x)J_n(x_n, t_n)=0$, $(\partial^2/\partial x^2)J_n(x_n, t_n)\leqq 0$ and $(\partial J_n/\partial x)(x_n, t_n)=0$ imply

$$\tilde{u}_n^{(1)}(x_n,t_n)=\tilde{u}_n^{(2)}(x_n,t_n), \tag{3.4}$$

$$\frac{\partial\tilde{u}_n^{(1)}}{\partial x}(x_n,t_n)\leqq\frac{\partial\tilde{u}_n^{(2)}}{\partial x}(x_n,t_n), \tag{3.5}$$

$$\begin{aligned} J_n(x_n,t_n)=\Phi_n^{(1)}&\left(\tilde{u}_n^{(1)}(x_n,t_n),\frac{\partial\Sigma_n^{(1)}(\tilde{u}_n^{(1)})}{\partial x}(x_n,t_n)\right)\\ &-\Phi_n^{(2)}\left(\tilde{u}_n^{(2)}(x_n,t_n),\frac{\partial\Sigma_n^{(2)}(\tilde{u}_n^{(2)})}{\partial x}(x_n,t_n)\right). \end{aligned} \tag{3.6}$$

So from (3.3) and (3.6) we obtain

$$0<\frac{d}{2}\leqq I_n^{(1)}+I_n^{(2)}+I_n^{(3)}$$

where

$$I_n^{(1)}=\Phi_n^{(1)}\left(\tilde{u}_n^{(1)},\frac{\partial\Sigma_n^{(1)}(\tilde{u}_n^{(1)})}{\partial x}\right)-\Phi\left(\tilde{u}_n^{(1)},\frac{\partial\Sigma^{(1)}(\tilde{u}_n^{(2)})}{\partial x}\right),$$

$$I_n^{(2)}=\Phi\left(\tilde{u}_n^{(2)},\frac{\partial\Sigma_n^{(2)}(\tilde{u}_n^{(2)})}{\partial x}\right)-\Phi_n^{(2)}\left(\tilde{u}_n^{(2)},\frac{\partial\Sigma_n^{(2)}(\tilde{u}_n^{(2)})}{\partial x}\right),$$

$$I_n^{(3)}=\Phi\left(\tilde{u}_n^{(1)},\frac{\partial\Sigma_n^{(1)}(u_n^{(1)})}{\partial x}\right)-\Phi\left(\tilde{u}_n^{(2)},\frac{\partial\Sigma_n^{(2)}(u_n^{(2)})}{\partial x}\right),$$

evaluated at the point (x_n, t_n).

From the fact that $\Phi_n^{(i)}\to\Phi$ uniformly on compact subsets as $n\to+\infty$ we have that $I_n^{(1)}$, $I_n^{(2)}\to 0$ as $n\to+\infty$. Therefore in order to obtain the contradiction we are looking for it suffices to prove that $\overline{\lim}\, I_n^{(3)}\leqq 0$ as $n\to+\infty$.

Using (3.4) and (3.5) and the monotonicity of the function Φ on the second variable we get

$$\begin{aligned} I_n^{(3)}&\leqq\left|\Phi\left(\tilde{u}_n^{(2)},\frac{\partial\Sigma_n^{(1)}(\tilde{u}_n^{(2)})}{\partial x}\right)-\Phi\left(\tilde{u}_n^{(2)},\frac{\partial\Sigma_n^{(2)}(\tilde{u}_n^{(2)})}{\partial x}\right)\right|\\ &\leqq K\left|\frac{\partial\Sigma_n^{(1)}(\tilde{u}_n^{(2)})}{\partial x}-\frac{\partial\Sigma_n^{(2)}(\tilde{u}_n^{(2)})}{\partial x}\right| \end{aligned}$$

where K is a Lipschitz constant for the C^1 function $\Phi(\cdot,\cdot)$ in a suitable compact set and does not depend on n.

Or, setting $\sigma_n^{(i)}(s)=(\Sigma_n^{(i)})'(s)$, we get

$$I_n^{(3)}\leqq K\left\|\frac{\partial\Sigma_n^{(2)}(\tilde{u}_n^{(2)})}{\partial x}\right\|_\infty\cdot\left|\frac{\sigma_n^{(1)}(\tilde{u}_n^{(2)})-\sigma_n^{(2)}(\tilde{u}_n^{(2)})}{\sigma_n^{(2)}(\tilde{u}_n^{(2)})}\right|.$$

But we know that

$$\left\|\frac{\partial\Sigma_n^{(2)}(\tilde{u}_n^{(2)})}{\partial x}\right\|_\infty\leqq K,$$

independently of n and, by Lemma 5 and the hypothesis $\sigma_n^{(2)} \to \sigma$ uniformly on compact subsets as $n \to +\infty$, we have $|\sigma_n^{(2)}(u_n(x_n, t_n))| \geqq c > 0$ for all n large enough where c is independent of n.

Therefore

$$I_n^{(3)} \leqq C|\sigma_n^{(1)}(\tilde{u}_n^{(2)}(x_n, t_n)) - \sigma_n^{(2)}(\tilde{u}_n^{(2)}(x_n, t_n))|$$

for a suitable constant C and letting $n \to +\infty$ we get $\overline{\lim}\, I_n^{(3)} \leqq 0$.

Analogously we can prove that

$$\underline{\lim}_{n \to +\infty} \max_{(x,t) \in S} J_n(x, t) \geqq 0$$

and consequently (3.2) is proved.

4. Proof of Theorem 3. The proof of Theorem 3 is based on the following lemma whose proof is exactly the same as the proof of Theorem 7 in [8], and we will not give it here.

LEMMA 3. *Let the hypothesis of Theorem* 3 *hold. If $u(x, t)$ is a generalized solution of problem* (1.1), (1.2), *then $u(x, t)$ is a classical solution of* (1.1) *in a neighborhood of any point (x_0, y_0) so that $u(x_0, t_0) > 0$.*

Now we can prove Theorem 3. We note that we can assume that $u(x, t)$ is the solution given by Theorem 1 to problem (1.1), (1.2). From this it follows that

$$u(x, t) = \lim_{n \to +\infty} u_n(x, t) \quad \text{in } L^1$$

where $u_n(x, t)$ is a solution of $(1.1)_n$ with initial condition

$$u_n(x, 0) = f_n(x)$$

where $f_n(x) > 0$ for all $x \in \mathbb{R}$ and $f_n \to f$ in L^1.

Now we essentially repeat the argument of the proof of Theorem 2.

Set

$$J_n(x, t) = e^{-t} \int_{-\infty}^{x} (u_n(y, t) - v(y, t))\, dy.$$

Assume that

$$\max_{(x,t) \in S} \int_{-\infty}^{x} (u(y, t) - v(y, t))\, dy = d > 0.$$

Then for n large enough we have

$$\max_{(x,t) \in S} J_n(x, t) = J_n(x_n, t_n) \geqq \frac{d}{2} > 0.$$

At the point (x_n, t_n) where this maximum is attained we have

$$v(x_n, t_n) = u_n(x_n, t_n) > 0.$$

So by Lemma 3, $v(x, t)$ is a classical solution in a neighborhood of (x_n, t_n); this lets us take higher order derivatives at this point to obtain, as in the proof of Theorem 2,

$$\frac{\partial u_n}{\partial x}(x_n, t_n) \leqq \frac{\partial v}{\partial x}(x_n, t_n)$$

and

$$0<\frac{d}{2}<J_n(x_n,t_n)=\Phi\left(u_n(x_n,t_n),\frac{\partial\Sigma(u_n)}{\partial x}\right)-\Phi\left(v(x_n,t_n),\frac{\partial\Sigma(v)}{\partial x}\right)\leqq 0,$$

which is a contradiction. Consequently

$$\int_{-\infty}^{x} u(y,t)\,dy \leqq \int_{-\infty}^{x} u(y,t)\,dy \quad \forall x,\quad \forall t.$$

Analogously we obtain the reverse inequality to get $\int_{-\infty}^{x} u(y,t)\,dy=\int_{-\infty}^{x} v(y,t)\,dy$ and hence $u\equiv v$.

THREE-DIMENSIONAL TEMPERATURE RESPONSE TO IMPULSIVE INPUT OUTSIDE A SPHERICAL RESERVOIR*

JAMES A. COCHRAN†

Abstract. The classical expression for the Green's function associated with heat conduction external to a spherical reservoir involves an infinite series in which the radial/time contributions are given by Laplace-type integrals containing cross products of spherical Bessel functions. This expression is most useful, numerically, for large distances and/or long times. In this paper, using a combination of transform and integral equations techniques, alternative expressions are derived for the radial/time components predominantly in terms of *polynomials* in the time variable. These new representations are thus valuable for short-time heat conduction calculations. Moreover, when re-expressed in a quantum-mechanical setting, they provide particularly useful closed-form expressions in terms of familiar functions for all the higher-order partial waves of the two-particle density matrix under the assumption of hard-core interaction.

Key words. Green's functions, heat conduction, quantum mechanical scattering, spherical Bessel functions

1. Introduction.

The three-dimensional temperature distribution $u(\vec{r}, \vec{r}'; t)$ in an unbounded homogeneous medium exterior to a spherical fixed-temperature reservoir, which results from an impulsive input at time $t=0$, satisfies the combined boundary/initial value problem

$$\begin{aligned} &\nabla^2 u = k\frac{\partial u}{\partial t} \quad |\vec{r}|, |\vec{r}'| > 1, \quad t>0; \\ &u \equiv 0 \quad \text{for } |\vec{r}| \leqq 1, \\ &\lim_{t\to 0} u = \delta(\vec{r}-\vec{r}'). \end{aligned} \tag{1}$$

Here k is a positive constant, $\vec{r}'$ is the impulsive source point and the reservoir has been both localized to the unit ball about the origin and given the normalized temperature zero. If separation of variables in spherical coordinates is then applied, the desired solution should have the following form, owing to symmetry and boundedness considerations:

$$u(\vec{r}, \vec{r}'; t) = \sum_{n=0}^{\infty} \left(\frac{2n+1}{4\pi}\right) u_n(r, r'; t) P_n(\cos\theta). \tag{2}$$

In this expression θ is the angle between the position vectors $\vec{r}$ and $\vec{r}'$, $r \equiv |\vec{r}|$, $r' \equiv |\vec{r}'|$, P_n is the Legendre polynomial of nonnegative order n and $u_n(r, r'; t)$ is the bounded solution of

$$\begin{aligned} &\frac{\partial}{\partial r}\left(r^2\frac{\partial u_n}{\partial r}\right) - n(n+1)u_n = kr^2\frac{\partial u_n}{\partial t}, \qquad r, r' > 1, \quad t>0, \\ &u_n(1, r'; t) = 0, \\ &\lim_{t\to 0} u_n(r, r'; t) = \frac{\delta(r-r')}{rr'}. \end{aligned} \tag{3}$$

The classical representation [2, p. 382] for the solution of (3) can be expressed as the Laplace-type integral

$$-\frac{1}{2\pi}\int_0^\infty \frac{D_n(vr)D_n(vr')}{h_n^{(1)}(v)h_n^{(2)}(v)} e^{-v^2 t/k} v^2\, dv \qquad (n=0,1,2,\cdots)$$

where $D_n(z)\equiv h_n^{(1)}(z)h_n^{(2)}(v)-h_n^{(2)}(z)h_n^{(1)}(v)$ and the $h_n^{(1,2)}$ are the spherical Hankel functions of the first and second kinds, respectively, of nonnegative integer order n. When this integral representation is employed in (2), an expression for the Dirichlet heat conduction Green's function is obtained which is most useful, computationally, when r (or r') and t are large.

The problem (1) arises in other contexts as well, e.g., the quantum mechanical interaction of two particles under the assumption of hard cores. Recently, alternative representations have been derived in this setting for the lower-order solutions to (3) ([8], $n=1$, 2; see also [9], $n=0$) which show them to be polynomials in t modified by familiar functions such as exponentials, error functions and, of course, spherical Hankel functions. In this paper, we continue in this same spirit and, using a combination of transform and integral equations techniques, derive an analogous representation for the general solution of (3) in the case of arbitrary n. This expression proves to be of a form particularly advantageous in short-time heat conduction calculations.

The next section of this paper contains this new general solution of (3) along with remarks concerning the nature of the solution and its behavior in various limiting regimes. A word or two about computation of the solution components is included also. The major details of the solution derivation are presented in § 3.

2. General form of the solution $u_n(r, r'; t)$. As we shall show in the next section, the solution of (3) may be expressed as the three-term summation

$$u_n(r, r'; t)\equiv I_n(r, r'; t)+J_n(r, r'; t)+K_n(r, r'; t) \tag{4}$$

with each term in this representation having particular characteristics.

Singular term. The initial term in (4) is given by the formula

$$\begin{aligned} I_n(r, r'; t) &\equiv e^{-k(r^2+r'^2)/4t}(-i)^n\left(\frac{\pi}{4}\right)\left(\frac{k}{\pi t}\right)^{3/2} h_n^{(2)}\left(\frac{ikrr'}{2t}\right) \\ &= \frac{e^{-k(r-r')^2/4t}}{rr'}\sqrt{\frac{k}{4\pi t}}\sum_{m=0}^{n}(-1)^m\left(n+\tfrac{1}{2}, m\right)\left(\frac{t}{krr'}\right)^m \end{aligned} \tag{5}$$

where $h_n^{(2)}$ is again the spherical Hankel function of the second kind of nonnegative integer order n, $i\equiv\sqrt{-1}$ and $(n+\frac{1}{2}, m)\equiv(n+m)!/\{m!(n-m)!\}$. This component of u_n is a "singular" solution of the equation in (3) and gives rise to the prescribed delta function behavior as $t\to 0$.

Balancing term. The second term in the representation (4) is also a polynomial in t modified by $\sqrt{t}$ and multiplied by an exponential. One expression for J_n takes the form

$$\begin{aligned} J_n(r, r'; t) \equiv &-\frac{e^{-k(r+r'-2)^2/4t}}{rr'}\sqrt{\frac{k}{4\pi t}} \\ &\cdot\left\{1+\sum_{m=0}^{n}\sum_{l=0}^{n}\sum_{p=m+l}^{m+l+n}(-1)^{m+l}\frac{(n+\frac{1}{2}, m)(n+\frac{1}{2}, l)(n+\frac{1}{2}, p-m-l)}{r^m(r')^l 2^p}\right. \\ &\left.\cdot\sum_{j=n}^{p-2}A_{p-j}(\alpha; t)S_{j+1}(n)\right\}. \end{aligned} \tag{6}$$

Here, for $m \geqq 0$,

$$A_{m+2}(\alpha;\,t) \equiv \sum_{j=0}^{[m/2]} \sum_{l=0}^{j} \frac{(\alpha)^{m+2l-2j}(4t/k)^{j+1-l}}{(2j+2)!\,(m-2j)!} \left\{ \frac{(j+1)!}{l!} - \frac{(m-2j)\Gamma(j+3/2)}{2\Gamma(l+3/2)} \right\}, \tag{7}$$

with $\alpha \equiv r + r' - 2$, while the S_j are constants, depending upon n, which are generated recursively from

$$\begin{aligned} S_{n+1}(n) &= \frac{(-2)^n}{(n+\frac{1}{2},\, n)}, \\ S_{n+p}(n) &= -\sum_{l=n+1}^{n+p-1} \frac{(n+\frac{1}{2},\, l-p)}{(n+\frac{1}{2},\, n)} (-2)^{n+p-l} S_l(n) \end{aligned} \tag{8}$$

($p \geqq 2$). In (7) and elsewhere, $[x]$ designates the greatest integer $\leqq x$. Moreover, throughout this paper we adopt the usual convention of ignoring summations in which the upper index is strictly less than the lower index.

Alternatively, J_n can be expressed in a manner which more clearly exhibits its dependence upon t, namely

$$J_n(r, r';\, t) \equiv \frac{e^{-k(r+r'-2)^2/4t}}{rr'} \sqrt{\frac{k}{4\pi t}} \sum_{m=0}^{n} f_m(n;\, r, r') \left(\frac{t}{k}\right)^m \tag{9}$$

where

$$f_0(n;\, r, r') = -1$$

and

$$f_n(n; r, r') = (-1)^{n+1} \frac{(n+\frac{1}{2},\, n)}{(rr')^n}.$$

In this representation the intermediate f_m $(1 \leqq m \leqq n-1)$ are given recursively by

$$\begin{aligned} &\sum_{m=[(p-n+1)/2]}^{n} f_m(n;\, r, r') \sum_{l=a}^{b} (n+\tfrac{1}{2}, p-l-m)(m+\tfrac{1}{2}, l)(r+r'-2)^{m-l} \\ &\qquad = -\sum_{m=c}^{n} \sum_{l=d}^{e} (-1)^{l+m+p} \frac{(n+\frac{1}{2},\, m)(n+\frac{1}{2},\, l)(n+\frac{1}{2}, p-l-m)}{r^m (r')^l} \end{aligned} \tag{10}$$

with p an integral parameter and a, b, c, d, e integral limits which satisfy

$$\left.\begin{aligned} a &= p-m-n \\ b &= m \\ c &= p-2n \\ d &= p-m-n \\ e &= n \end{aligned}\right\} \text{for } 2n+1 \leqq p \leqq 3n,$$

$$\left.\begin{aligned} a&=0\\ b&=p-m\\ c&=0\\ d&=0\\ e&=p-m \end{aligned}\right\}\quad \text{for } n+1\leqq p\leqq 2n.$$

The term $J_n(r, r'; t)$, like $I_n(r, r'; t)$, is symmetric in r, r' and "balances out" the contribution of I_n when $r=1$, i.e.,

$$J_n(1, r'; t) = -I_n(1, r'; t).$$

Last term. The remaining term in (4) is only present if $n \geqq 1$ in which case the appropriate formula is

$$\begin{aligned} K_n(r, r'; t) &\equiv \tfrac{1}{2}(-i)^n\, e^{-k(r+r'-2)^2/4t}\\ &\cdot \sum_{j=1}^{n} \lambda_j^3 C_j h_n^{(1)}(i\lambda_j) h_n^{(2)}(i\lambda_j r) h_n^{(2)}(i\lambda_j r')\, e^{-\lambda_j(r+r'-1)}\\ &\cdot w\left\{i\left(\lambda_j\sqrt{\frac{t}{k}}+\frac{r+r'-2}{2\sqrt{t/k}}\right)\right\}. \end{aligned} \tag{11}$$

Here $h_n^{(1)}$ and $h_n^{(2)}$ are the spherical Hankel functions of the first and second kinds, respectively, of order n, the λ_j $(j=1, 2, \cdots, n)$ are the n roots of

$$h_n^{(2)}(i\lambda)=0,$$

the C_j $(j=1, 2, \cdots, n)$ are the (unique) solutions of the simultaneous equations

$$\sum_{j=1}^{n} C_j/\lambda_j^m = -\delta_{1m} \qquad (m=1, 2, \cdots, n), \tag{12}$$

formed with these roots and w is the complementary error function as given by

$$w(iz) \equiv e^{z^2}\operatorname{erfc}(z) \equiv \frac{2}{\sqrt{\pi}} e^{z^2}\int_z^\infty e^{-x^2}\,dx \tag{13}$$

(see [1, p. 297]).

In view of the nature of the λ_j, $K_n(1, r'; t)$ vanishes. The three-term summation (4) therefore has the appropriate behavior both for $r=1$ and as $r\to r'$. Hence the presence of K_n may be viewed as ensuring that u_n satisfies the differential equation given in (3).

Component computation. Numerical evaluation of $u_n(r, r'; t)$ for fixed n, k and varying r, r', and t is straightforward for small to moderate values of n. With appropriate organization, the bulk of the computation of I_n and J_n can be performed with integer arithmetic. Evaluation of K_n, however, is more demanding.

The spherical Hankel functions are given by

$$h_n^{(1,2)}(iz) = \frac{i^{\mp(n+1)}}{iz}\, e^{\mp z} \sum_{m=0}^{n} \frac{(n+\frac{1}{2}, m)}{(\pm 2z)^m}, \tag{14}$$

and the zeros λ_j $(j=1, 2, \cdots, n)$ of $h_n^{(2)}(i\lambda)$ therefore lie in the right half of the complex λ-plane (see [1, p. 373]). (The λ_j occur in complex conjugate pairs, except of course, when n is odd, then one of the λ_j is real.) If λ_j is real, the corresponding C_j is real as well. Otherwise the associated C_j also occur in complex conjugate pairs. This behavior, coupled with the nature of the complementary error function, implies the expected reality of K_n.

3. Derivation of the solution $u_n\ (r, r'; t)$. The boundary/initial value problem (3) is ideally suited to application of the Laplace transform. If we define

$$U_n(r, r'; s) \equiv \mathscr{L}(u_n) \equiv \int_0^\infty u_n(r, r'; t)\, e^{-st}\, dt,$$

then U_n is the bounded (in r) solution of the ordinary boundary-value problem

$$(15)\qquad (r^2 U_n')' - (r^2 ks + n(n+1))U_n = -k\delta(r-r'), \qquad U_n(1, r'; s) = 0.$$

The solutions underlying the homogeneous equation in (15) are the spherical Hankel functions of order n and argument $i\sqrt{ks}\,r$, and in view of (14), only $h_n^{(1)}(iz)$ is bounded for large z. The desired solution of (15), therefore, is essentially nothing more than the ordinary Green's function associated with this problem (see [4, p. 239], for example). We thus deduce for $r \leqq r'$

$$(16)\quad U_n(r, r'; s) \equiv \frac{k}{2}\sqrt{ks}\{h_n^{(1)}(i\sqrt{ks}\,r)h_n^{(2)}(i\sqrt{ks}) - h_n^{(2)}(i\sqrt{ks}\,r)h_n^{(1)}(i\sqrt{ks})\}\frac{h_n^{(1)}(i\sqrt{ks}\,r')}{h_n^{(1)}(i\sqrt{ks})},$$

with a symmetric expression valid in the regime $r \geqq r'$. To determine u_n we shall invert U_n. Indeed, the classical representation for u_n given in the Introduction is equivalent to the *formal* inverse Laplace transform of U_n.

The easier inversion. The "singular" component I_n in the representation (4) arises as a result of the following.

THEOREM 1.

$$\mathscr{L}^{-1}\left\{-\frac{k}{2}\sqrt{ks}\,h_n^{(2)}(i\sqrt{ks}\,r)h_n^{(1)}(i\sqrt{ks}\,r')\right\} = I_n(r, r'; t).$$

Proof. We establish the result in the forward direction assuming $r \leqq r'$. From (5)

$$\begin{aligned}\mathscr{L}(I_n(r, r'; t)) &= \mathscr{L}\left\{e^{-k(r^2+r'^2)/4t}(-i)^n\left(\frac{\pi}{4}\right)\left(\frac{k}{\pi t}\right)^{3/2} h_n^{(2)}\left(\frac{ikrr'}{2t}\right)\right\}\\ &= \sqrt{\frac{k}{4\pi}}\sum_{m=0}^{n}(-1)^m\left(n+\frac{1}{2}, m\right)\left(\frac{1}{krr'}\right)^{m+1} k\int_0^\infty t^{m-1/2}e^{-st}\, e^{-k(r-r')^2/4t}\, dt\\ &= -k\sqrt{ks}\sum_{m=0}^{n}(-1)^m\left(n+\frac{1}{2}, m\right)\left(\frac{r'-r}{2rr'\sqrt{ks}}\right)^{m+1} i^m h_m^{(1)}(i(r'-r)\sqrt{ks})\end{aligned}$$

by virtue of [7, 3.471(9), p. 340], and the relationship of the modified Bessel function $K_{m+1/2}(z)$ to $h_m^{(1)}(iz)$. Hence, using (14) and expanding the resulting powers of $r'-r$,

$$\begin{aligned}\mathscr{L}(I_n) &= k\, e^{(r-r')\sqrt{ks}}\sum_{m=0}^{n}\sum_{l=0}^{m}(-1)^m\frac{(n+\frac{1}{2}, m)(m+\frac{1}{2}, l)(r'-r)^{m-l}}{(rr')^{m+1}(2\sqrt{ks})^{m+l+1}}\\ &= k\, e^{(r-r')\sqrt{ks}}\sum_{m=0}^{n}\sum_{l=0}^{m}(-1)^m\frac{(n+\frac{1}{2}, m)(m+\frac{1}{2}, l)}{(2\sqrt{ks})^{m+l+1}}\\ &\quad\cdot\sum_{j=0}^{m-l}\binom{m-l}{j}(-1)^j r^{j-m-1}(r')^{-l-j-1}.\end{aligned}$$

Changing the index j into $m-j$, and then interchanging the last summation with the first two, results in

$$\mathscr{L}(I_n) = ke^{(r-r')\sqrt{ks}} \sum_{j=0}^{n} \sum_{m=j}^{n} \sum_{l=0}^{j} (-1)^j \frac{(n+\frac{1}{2}, m)(m+\frac{1}{2}, l)}{(2\sqrt{ks})^{m+l+1}}$$

$$\cdot \binom{m-l}{m-j} r^{-j-1}(r')^{j-l-m-1},$$

and replacing l with $l-m+j$ this can be rewritten as

$$\mathscr{L}(I_n) = k\, e^{(r-r')\sqrt{ks}} \sum_{j=0}^{n} \sum_{m=j}^{n} \sum_{l=m-j}^{m} (-1)^j \frac{(n+\frac{1}{2}, m)(m+\frac{1}{2}, l-m+j)}{(2\sqrt{ks})^{j+l+1}}$$

$$\cdot \binom{2m-l-j}{m-j} r^{-j-1}(r')^{-l-1}$$

$$= k\, e^{(r-r')\sqrt{ks}} \sum_{j=0}^{n} \sum_{m=0}^{n} \sum_{l=0}^{n} \frac{(-1)^j r^{-j-1}(r')^{-l-1}}{(2\sqrt{ks})^{j+l+1}}$$

$$\cdot \frac{(n+m)!\,(l+j)!}{m!\,(n-m)!\,(l+j-m)!\,(m-j)!\,(m-l)!}.$$

In the last expression we have written out explicitly the various factorials and taken advantage of the fact that the summand vanishes for $0 \leqq m < j$, $0 \leqq l < m-j$ and $m < l \leqq n$. The summation over m only involves factorials and fortuitously can be carried out using a variant of Saalschutz's formula (see [5, p. 66]) to give, using (14),

$$\mathscr{L}(I_n) = k\, e^{(r-r')\sqrt{ks}} \sum_{j=0}^{n} \sum_{l=0}^{n} \frac{(-1)^j r^{-j-1}(r')^{-l-1}}{(2\sqrt{ks})^{j+l+1}}$$

$$\cdot \frac{(n+j)!\,(n+l)!}{j!\,(n-j)!\,l!\,(n-l)!}$$

$$= -\frac{k\sqrt{ks}}{2} \left\{ \frac{e^{\sqrt{ks}\,r}}{i\sqrt{ks}\,r} \sum_{j=0}^{n} \frac{(n+\frac{1}{2}, j)}{(-2\sqrt{ks}\,r)^j} \right\}$$

$$\cdot \left\{ \frac{e^{-\sqrt{ks}\,r'}}{i\sqrt{ks}\,r'} \sum_{l=0}^{n} \frac{(n+\frac{1}{2}, l)}{(2\sqrt{ks}\,r')^l} \right\}$$

$$= -\frac{k\sqrt{ks}}{2} h_n^{(2)}(i\sqrt{ks}\,r)\, h_n^{(1)}(i\sqrt{ks}\,r'). \qquad \square$$

The remaining components. Inversion of the rest of $U_n(r, r'; s)$ as given by (16) is detailed in the lemmas and theorems which follow. The general method is believed to be of wide applicability. Our approach recognizes the transform at hand as a quotient and begins with an inversion of the numerator. The inverse transform of the quotient itself is then shown to satisfy an inhomogeneous integral equation of Volterra type. Solution of this integral equation yields *three* terms, two of which can be recognized as the J_n and K_n of (4). The third term is a multi-summation which, surprisingly, sums to zero for arbitrary n.

LEMMA 1.

$$\frac{k}{2}\sqrt{ks}\, h_n^{(1)}(i\sqrt{ks}\,r)\, h_n^{(1)}(i\sqrt{ks}\,r')\, h_n^{(2)}(i\sqrt{ks}) / h_n^{(1)}(i\sqrt{ks}) = \frac{P}{Q}$$

where

$$P \equiv -k\,e^{-\sqrt{ks}\,(r+r'-2)} \sum_{m=0}^{n} \sum_{l=0}^{n} \sum_{j=0}^{n} (-1)^j \frac{(n+\frac{1}{2}, m)(n+\frac{1}{2}, l)(n+\frac{1}{2}, j)}{r^{m+1}(r')^{l+1}} \cdot \left(\frac{1}{2\sqrt{ks}}\right)^{j+l+m+1}$$

and

$$Q \equiv \sum_{m=0}^{n} (n+\tfrac{1}{2}, m)\left(\frac{1}{2\sqrt{ks}}\right)^{m}.$$

Proof. We prove by substitution using (14). □

Lemma 2.

$$\mathscr{L}^{-1}\left(\frac{k\,e^{-\alpha\sqrt{ks}}}{\sqrt{ks}}\right) \equiv I^{(0)}(\alpha;\, t) \equiv \frac{e^{-k\alpha^2/4t}}{\sqrt{\pi t/k}}$$

and for integer $n \geqq 1$

$$\mathscr{L}^{-1}\left(\frac{k\,e^{-\alpha\sqrt{ks}}}{(\sqrt{ks})^{n+1}}\right) \equiv (-1)^n I^{(-n)}(\alpha;\, t)$$

$$\equiv \frac{1}{(n-1)!} \int_{\alpha}^{\infty} \frac{(\beta-\alpha)^{n-1}\, e^{-k\beta^2/4t}}{\sqrt{\pi t/k}}\, d\beta.$$

Proof. Apply iterated integration to [6, 5.6(6), p. 246]. □

Lemma 3. *For integer* $n \geqq 2$, $I^{(-n)}(\alpha;\, t)$ *can be expressed as a sum of polynomials in* α *and* t *multiplied by* $I^{(0)}(\alpha;\, t)$ *and* $I^{(-1)}(\alpha;\, t)$, *respectively. The precise relationship is*

$$I^{(-n)}(\alpha;\, t) = A_n(\alpha;\, t) I^{(0)}(\alpha;\, t) + B_n(\alpha;\, t) I^{(-1)}(\alpha;\, t)$$

where $A_n(\alpha;\, t)$ *is as defined by* (7) *and*

$$B_{n+1}(\alpha;\, t) \equiv \sum_{j=0}^{[n/2]} \frac{\alpha^{n-2j}(t/k)^j}{(n-2j)!\,j!}. \tag{17}$$

Proof. One way to establish this result is to show that A_n, B_n are the solutions of the appropriate initial-value problems. Unfortunately, while it is trivial to verify $dB_n/d\alpha = B_{n-1}$ and the necessary initial values, the demonstration of $dA_n/d\alpha = (k\alpha/2t)A_n + A_{n-1} - B_n$ requires substantial series manipulations and sophisticated knowledge regarding the sums of multi-binomial expressions. It is probably far easier, therefore, to rederive the representation from the definition of $I^{(-n)}$ given in the preceding lemma, by expanding the $(\beta-\alpha)^{n-1}$ factor and integrating by parts. Note that odd powers of β contribute to A_n and even powers to B_n. We leave the details to the interested reader. □

Lemma 4.

$$\mathscr{L}^{-1}(P) = -\sum_{m=0}^{n} \sum_{l=0}^{n} \sum_{j=0}^{n} (-1)^{m+l} \frac{(n+\frac{1}{2}, m)(n+\frac{1}{2}, l)(n+\frac{1}{2}, j)}{r^{m+1}(r')^{l+1} 2^{j+l+m+1}} \cdot I^{(-j-l-m)}(\alpha;\, t)$$

where $\alpha \equiv r + r' - 2$.

Proof. The proof is a consequence of Lemmas 1 and 2. □

Lemma 5. *For* $n \geqq 1$, $\phi(\alpha;\, t) \equiv \mathscr{L}^{-1}(P/Q)$ *satisfies the Volterra integral equation*

$$\phi(\alpha;\, t) = \mathscr{L}^{-1}(P) - \int_{\alpha}^{\infty} \sum_{m=1}^{n} \frac{(n+\frac{1}{2}, m)}{2^m} \frac{(\beta-\alpha)^{m-1}}{(m-1)!} \phi(\beta;\, t)\, d\beta. \tag{18}$$

If $n = 0$, $\phi(\alpha;\, t) = \mathscr{L}^{-1}(P)$ *since* $Q \equiv 1$ *in this case.*

Proof. The integral equation (18) is equivalent to the initial-value problem

$$\sum_{j=0}^{n} (-1)^j \frac{(n+\frac{1}{2}, j)}{2^j} \phi^{(n-j)}(\alpha; t) = \frac{d^n}{d\alpha^n}\{\mathscr{L}^{-1}(P)\},$$

$$\lim_{\alpha\to\infty} \phi^{(j)}(\alpha; t) = 0, \qquad j = 0, 1, 2, \cdots, n-1.$$

Since differentiation with respect to the parameter α can be interchanged with transform inversion, the left-hand side of this differential equation becomes for $\phi(\alpha; t) = \mathscr{L}^{-1}(P/Q)$, from Lemmas 1, 2 and 4.

$$\mathscr{L}^{-1}\left\{\frac{1}{Q}\sum_{j=0}^{n} (-1)^j \frac{(n+\frac{1}{2}, j)}{2^j} \frac{d^{n-j}P}{d\alpha^{n-j}}\right\} = \mathscr{L}^{-1}\left\{\frac{P}{Q}\sum_{j=0}^{n} \frac{(n+\frac{1}{2}, j)}{2^j}(-1)^n(\sqrt{ks})^{n-j}\right\}$$

$$= \mathscr{L}^{-1}\{(-1)^n(\sqrt{ks})^n P\}$$

$$= \frac{d^n}{d\alpha^n}\{\mathscr{L}^{-1}(P)\}.$$

The "initial" conditions are likewise a ready consequence of the form of P, Q as given in Lemma 1. □

LEMMA 6. *The resolvent kernel associated with the Volterra integral equation* (18) *when* $n \geqq 1$ *has the representation*

$$R(\alpha, \beta) = \sum_{j=1}^{n} C_j e^{\lambda_j(\alpha-\beta)}$$

where the λ_j $(j = 1, 2, \cdots, n)$ *are the n roots of*

$$h_n^{(2)}(i\lambda) = 0$$

and the C_j $(j = 1, 2, \cdots, n)$ *are the* (*unique*) *solutions of the simultaneous equations*

$$\sum_{j=1}^{n} C_j/\lambda_j^m = -\delta_{1m} \qquad (m = 1, 2, \cdots, n). \tag{12'}$$

Proof. If $L(\alpha, \beta)$ designates the kernel of (18), we merely need to verify the validity of one of the classic Fredholm identities, say,

$$R(\alpha, \beta) = L(\alpha, \beta) + \int_\alpha^\beta L(\alpha, \gamma)R(\gamma, \beta)\, d\gamma$$

(see [3, p. 58], for example). Substituting, we obtain

$$\sum_{j=1}^{n} C_j e^{\lambda_j(\alpha-\beta)}$$

$$= -\sum_{m=1}^{n} \frac{(n+\frac{1}{2}, m)}{2^m} \frac{(\beta-\alpha)^{m-1}}{(m-1)!} - \int_\alpha^\beta \sum_{m=1}^{n} \frac{(n+\frac{1}{2}, m)(\gamma-\alpha)^{m-1}}{2^m(m-1)!} \sum_{j=1}^{n} C_j e^{\lambda_j(\gamma-\beta)}\, d\gamma$$

$$= -\sum_{m=1}^{n} \frac{(n+\frac{1}{2}, m)}{2^m} \frac{(\beta-\alpha)^{m-1}}{(m-1)!}$$

$$+ \sum_{m=1}^{n} \frac{(n+\frac{1}{2}, m)}{2^m} \sum_{j=1}^{n} C_j\left\{\sum_{l=1}^{m} \frac{(\alpha-\beta)^{m-l}}{(m-l)!\,\lambda_j^l} - \frac{e^{\lambda_j(\alpha-\beta)}}{\lambda_j^m}(-1)^m\right\}$$

or, rearranging we find

$$\sum_{j=1}^{n} C_j\, e^{\lambda_j(\alpha-\beta)} \sum_{m=0}^{n} \frac{(n+\frac{1}{2}, m)}{(-2\lambda_j)^m}$$

$$= \sum_{m=1}^{n} \frac{(\beta-\alpha)^{m-1}}{(m-1)!}\left\{\frac{-(n+\frac{1}{2}, m)}{2^m} - \sum_{j=1}^{n} C_j \sum_{p=m}^{n} \frac{(n+\frac{1}{2}, p)(-1)^{(p+m)}}{2^p \lambda_j^{p-m+1}}\right\}.$$

Observe, however, that both sides of this equation vanish owing to (12′), the definition of λ_j and (14). □

LEMMA 7. *If $n \geqq 1$, let $S_l(n) \equiv \sum_{j=1}^{n} C_j/\lambda_j^l$ where the λ_j and the C_j are as defined in Lemma 6. Then for $l > n$ we have*

$$S_{n+1}(n) = \frac{(-2)^n}{(n+\frac{1}{2}, n)}$$

and

$$S_{n+p}(n) = -\sum_{l=n+1}^{n+p-1} \frac{(n+\frac{1}{2}, l-p)}{(n+\frac{1}{2}, n)}(-2)^{n+p-l} S_l(n) \qquad (p \geqq 2). \tag{8′}$$

Proof. By virtue of the definition of λ_j, using (14) we obtain

$$\begin{aligned} 0 &= \sum_{j=1}^{n} \frac{C_j}{(-2\lambda_j)^p}\left[\sum_{m=0}^{n} \frac{(n+\frac{1}{2}, n)}{(-2\lambda_j)^m}\right] \\ &= \sum_{l=p}^{n+p} \left(n+\frac{1}{2}, l-p\right)(-2)^{-l} S_l(n). \end{aligned} \tag{19}$$

Setting $p=1$ we easily determine S_{n+1} since $S_l = -\delta_{1l}$ $(l = 1, 2, \cdots, n)$ by (12′). The recursive expression given above for S_{n+p} with $p \geqq 2$ is likewise a ready consequence of this identity. (Note that if $p > n+1$, the lower summation index can be decreased to $n+1$ since $(n+\frac{1}{2}, l-p) = 0$ for $n+1 \leqq l < p$.) □

LEMMA 8.

$$\int_{\alpha}^{\beta} e^{\lambda(\alpha-\beta)} I^{(-n)}(\beta;\, t)\, d\beta = \sum_{m=1}^{n} I^{(-m)}(\alpha;\, t)\lambda^{m-1-n} + \lambda^{-n}\, e^{(\alpha\lambda+\lambda^2 t/k)} I^{(-1)}(\alpha + 2\lambda t/k;\, t).$$

Proof. We prove by substitution, using the definition of $I^{(-n)}$ from Lemma 2, and integration by parts. The summation term does not appear if $n=0$. □

We come now to the principal results of this subsection.

THEOREM 2. *$\phi(\alpha;\, t) \equiv \mathscr{L}^{-1}(P/Q)$ is given uniquely by*

$$\phi(\alpha;\, t) = J_n(r, r';\, t) + K_n(r, r';\, t) + L_n(r, r';\, t)$$

where $\alpha \equiv r + r' - 2$, J_n and K_n have the representations (6)–(10) *and* (11)–(13), *respectively, and*

$$\begin{aligned} L_n(r, r';\, t) \equiv I^{(-1)}(\alpha;\, t) &\sum_{m=0}^{n} \sum_{l=0}^{n} \sum_{p=m+l}^{m+l+n} (-1)^{m+l+1} \frac{(n+\frac{1}{2}, m)(n+\frac{1}{2}, l)(n+\frac{1}{2}, p-m-l)}{r^{m+1}(r')^{l+1} 2^{p+1}} \\ &\cdot \sum_{j=n}^{p-1} B_{p-j}(\alpha;\, t) S_{j+1}(n). \end{aligned} \tag{20}$$

In this last expression the $B_n(\alpha;\, t)$ are given by (17) *for $n \geqq 2$ $(B_1 = 1)$ and the S_j are defined recursively by* (8′).

Proof. Applying fundamental integral equations theory (see [3, pp. 36, 37, 58], for example), Lemmas 5 and 6 imply that $\phi(\alpha; t)$ is given uniquely by

$$\begin{aligned}\phi(\alpha; t) &= \mathscr{L}^{-1}(P(\alpha)) + \int_\alpha^\infty R(\alpha, \beta)\mathscr{L}^{-1}(P(\beta))\, d\beta \\ &= \mathscr{L}^{-1}(P(\alpha)) + \int_\alpha^\infty \sum_{j=1}^n C_j e^{\lambda_j(\alpha-\beta)}\mathscr{L}^{-1}(P(\beta))\, d\beta \\ &= \mathscr{L}^{-1}(P(\alpha)) + \sum_{j=1}^n C_j \int_\alpha^\infty e^{\lambda_j(\alpha-\beta)}\mathscr{L}^{-1}(P(\beta))\, d\beta.\end{aligned}$$

(The interchange of integration and summation here is justified by the exponential decay of the integrand for large β.) Substituting for $\mathscr{L}^{-1}(P)$ from Lemma 4, using the results of Lemmas 8 and 3, and introducing the definition of $S_l(n)$ from Lemma 7, we easily derive the above expression (20) for L_n (if $n \geqq 1$) and the representation (6)-(8) for J_n. Neither L_n nor K_n are present unless $n \geqq 1$, in which case the relation (11) for K_n is a consequence of back-substitution using (14) and replacement of $I^{(-1)}(2z\sqrt{t/k}; t)$ by $-e^{-z^2}w(iz)$ using (13).

The alternative representation (9), (10) for J_n is of a different character. It follows from matching powers of $\sqrt{ks}$ in the Laplace transforms of $\phi(\alpha; t)$ and of $J_n(r, r'; t) + K_n(r, r'; t)$, anticipating the result of Theorem 3. Here it is helpful to recall

$$\mathscr{L}(t^{m-1/2}\, e^{-k\alpha^2/4t}) = -\sqrt{\frac{\pi}{k}}\frac{(k\alpha)^{m+1}}{(-2i\sqrt{ks})^m} h_m^{(1)}(i\alpha\sqrt{ks})$$

(see the proof of Theorem 1) and, in particular,

$$\mathscr{L}(t^{-1/2}\, e^{-k\alpha^2/4t}) = \sqrt{\pi/s}\, e^{-\alpha\sqrt{ks}},$$
$$\mathscr{L}(t^{-3/2}\, e^{-k\alpha^2/4t}) = 2\sqrt{\pi/(k\alpha^2)}\, e^{-\alpha\sqrt{ks}},$$

which together imply

$$\mathscr{L}\left(e^{-k\alpha^2/4t} w\left\{i\left(\lambda\sqrt{\frac{t}{k}} + \frac{\alpha}{2\sqrt{t/k}}\right)\right\}\right) = \frac{\sqrt{k/s}}{\lambda + \sqrt{ks}}\, e^{-\alpha\sqrt{ks}}.$$

The tedious details, which involve several summation interchanges and repeated recognition that $(l+\frac{1}{2}, m)$ vanishes unless $0 \leqq m \leqq l$, are left to the interested reader. □

THEOREM 3. *For* $n \geqq 1$, $L_n(r, r'; t) \equiv 0$.

Proof. The result may be established by showing from (20) that for arbitrary integer q $(q = 0, 1, 2, \cdots)$

$$0 = k^q \frac{d^q\{L_n(r, r'; t)/I^{(-1)}(\alpha; t)\}}{dt^q}\bigg|_{t=0}$$

$$(21) \qquad = \sum_{m=0}^{n}\sum_{l=0}^{n}\sum_{p=m+l}^{m+l+n}\sum_{j=n}^{p-1}(-1)^{m+l+1}\frac{(n+\frac{1}{2}, m)(n+\frac{1}{2}, l)(n+\frac{1}{2}, p-m-l)}{r^{m+1}(r')^{l+1}2^{p+1}} \cdot S_{j+1}(n)\frac{\alpha^{p-j-1-2q}}{(p-j-1-2q)!}$$

where $\alpha = r + r' - 2$. The demonstration involves expanding $\alpha^{p-j-1-2q}$ in powers of r and r', collecting all the like powers together, and then verifying that the resulting coefficient vanishes in each instance. Since a considerable number of special cases needs to be examined, the remainder of the proof is relegated to the Appendix. □

Appendix. In order to complete the proof of Theorem 3 we need to show that

$$M_n \equiv \sum_{m=0}^{n} \sum_{l=0}^{n} \sum_{p=m+l}^{m+l+n} \sum_{j=n}^{p-1} \sum_{s=0}^{p-j-1-2q} \sum_{t=0}^{p-j-1-2q-s} I \tag{21'}$$

vanishes for $n \geqq 1$ and arbitrary nonnegative integer q, where

$$I \equiv (-1)^{m+l+1} \frac{(n+\frac{1}{2}, m)(n+\frac{1}{2}, l)(n+\frac{1}{2}, p-m-l)}{r^{m+1}(r')^{l+1} 2^{p+1}}$$

$$\cdot\, S_{j+1} \binom{p-j-1-2q}{s} \binom{p-j-1-2q-s}{t} \frac{r^s (r')^t (-2)^{p-j-1-2q-s-t}}{(p-j-1-2q)!}.$$

Toward this end, we replace the indices s and t with $\alpha \equiv m+1-s$ and $\beta \equiv l+1-t$ and then interchange summations until the α and β summations appear first. The demonstration now devolves to several cases.

CASE 1: $2q+1 \geqq n$.

$a < 2+2q-n$: No terms with such indices appear in M_n.

$2+2q-n \leqq \alpha \leqq n+1$: No terms with such indices appear in M_n unless $3+2q-\alpha \leqq \beta \leqq n+1$ also, in which case the resulting coefficient is

$$C(n, q; \alpha, \beta) = \sum_{m=\alpha-1}^{n} \sum_{l=\beta-1}^{n} \sum_{p=m+l+n-a}^{m+l+n} \sum_{j=n}^{p-m-l+a} I$$

where $a \equiv \alpha+\beta-3-2q$, or, rearranging and shifting indices,

$$C = \frac{2^{a-1}}{r^\alpha (r')^\beta} D(n; \alpha) D(n; \beta) E(n, q; \alpha, \beta)$$

with

$$D(n; \alpha) \equiv \sum_{m=\alpha-1}^{n} \frac{(n+\frac{1}{2}, m)}{(m+1-\alpha)!} \frac{(-1)^m}{2^m}$$

and

$$E(n, q; \alpha, \beta) \equiv \sum_{j=n}^{n+\alpha} \frac{S_{j+1}}{2^j} \left[\sum_{p=0}^{n-j+a} (-1)^{p+1} \frac{(n+\frac{1}{2}, p+j-a)}{p!} \right]$$

$$= \sum_{j=n}^{n+a} \frac{S_{j+1}}{2^j} [(-1)^{n+j} (n+\tfrac{1}{2}, j-a)].$$

If $a > 0$, this last summation is zero by virtue of the identity (19).

For the case $a = 0$ we reason as follows. $D(n; \alpha)$ can be alternatively expressed in terms of the derivative of a product as

$$D(n; \alpha) = \frac{(-2)^{1-\alpha}}{n!} (x^n (1+x)^n)^{(\alpha+n-1)} \Big|_{x=-1/2} \tag{A.1}$$

and this is readily seen to vanish whenever $\alpha+n$ is even, by symmetry. But if $a \equiv \alpha+\beta-3-2q = 0$, α and β must be of opposite parity, one of $\alpha+n$ or $\beta+n$ must be even and the product $D(n; \alpha)D(n; \beta)$ must therefore be zero.

$n+1 < \alpha$: No terms with such indices appear in M_n.

CASE 2: $2q+1 < n$.

$\alpha < 2+2q-n$: No terms with such indices appear in M_n.

$\alpha=2+2q-n$: We find $l=n$, $p=2n+m$, $j=n$, $\beta=n+1$, and hence the relevant coefficient is

$$C(n, q; 2+2q-n, n+1)=\frac{(-1)^{n+1}(n+\frac{1}{2}, n)^2}{r^{2+2q-n}(r')^{n+1}2^{2n+1}}S_{n+1}D(n; 2+2q-n)$$

which vanishes since $\alpha+n=2+2q$ is even (see (A.1) above).

$2+2q-n<\alpha\leqq 2q+2$: Precisely the same situation occurs as in Case 1.

$2q+2<\alpha\leqq n+1$: No terms with such indices appear in M_n unless $3+2q-\alpha\leqq\beta\leqq n+1$. For $\beta\leqq 3+2q-\alpha+n$, the analysis again duplicates that of Case 1. Since $(n+\frac{1}{2}, p-m-l)=0$ for $p<m+l$, rearrangements are possible when $3+2q-\alpha+n<\beta\leqq n+1$ which also make this situation equivalent to Case 1.

$n+1<\alpha$: No terms with such indices appear in M_n.

Acknowledgment. Special thanks are due to Dr. Anthony Klemm for proposing the investigation of which this research is a part.

EXISTENCE OF A SOLUTION TO A CERTAIN PLANE PREMIXED FLAME PROBLEM WITH TWO-STEP KINETICS*

C. M. BRAUNER† AND CL. SCHMIDT-LAINÉ†

Abstract. We consider a nonlinear differential system modelling a two-step reaction in a plane premixed flame. The unknowns are two functions u and v (temperature and mass fraction) and a parameter δ associated with the burning rate. We introduce a normalized problem which is first studied on a bounded interval. Upper and lower solutions induce a priori estimates which enable us to pass to the limit of a doubly infinite interval. We obtain the existence of a solution and we provide an explicit value for δ which is related to the L^2-norm of $w=u-v$.

Key words. nonlinear system, unbounded domain, upper/lower solutions, combustion, premixed flame, 2-step kinetics

1. Physical framework. In a recent paper [6], G. Joulin, A. Liñan, G. S. S. Ludford, N. Peters and one of the authors introduced a two-step irreversible reaction for a steady plane flame, with chain-branching/chain-breaking kinetics:

$$A+X\rightarrow 2X, \qquad 2X+M\rightarrow 2P+M. \tag{1.1}$$

Radical X is obtained in the production step, which has a very large activation energy θ and provides product P in the recombination step for which the activation energy is taken to be zero; A is the reactant and M a third body.

This two-step scheme is presented as an alternative to classical single-step kinetics [3] and allows the description of a wider range of phenomena.

The equations are derived in the stretched flame zone, described by the one-dimensional space variable η, $-\infty<\eta<+\infty$, by assuming a fast recombination, i.e., that both production and recombination of radicals take place in the same thin zone. The system reads (see [6, p. 423])

$$u''=q_1 r\delta(u-v)v\,e^{-u}+\delta(u-v)^2, \qquad v''=r\delta(u-v)v\,e^{-u}, \tag{1.2}$$

and the associated boundary conditions are

$$\begin{aligned} &u=-\eta+o(1), \quad v=-\eta+o(1) \quad \text{as } \eta\rightarrow-\infty,\\ &u=o(1), \quad v=o(1) \quad \text{as } \eta\rightarrow+\infty. \end{aligned} \tag{1.3}$$

The unknowns are positive functions u and v, representing temperature and mass fraction of the reactant and a positive constant δ, representing the burning rate. The parameters q_1 and q_2 are the proportions of the total heat released in the first and second steps of the reaction, so that $q_1+q_2=1$. Physical considerations require the recombination step to be exothermic, so that $q_2>0$. Finally r is a positive parameter, corresponding to the ratio of the two reaction rates. The boundary conditions (1.3) are obtained by matching with expansions on either side of the flame sheet [6, p. 422].

† Ecole Centrale de Lyon, Département de Mathématiques, Informatique et Systèmes, BP 163, 69131 Ecully Cedex, France.

The mathematical problem is the following: q_1, q_2 and $r>0$ being given, find two functions $u>0$, $v>0$ and the constant $\delta>0$ satisfying (1.2), (1.3). We refer again to [6] for a numerical treatment of this problem, leading to curves in the (r, δ)-plane.

It is particularly convenient for our study to deal with an equivalent formulation of the system involving the radical mass fraction $w=u-v>0$. It consists of the equations

$$v''=r\delta vw\,e^{-v}\,e^{-w}, \qquad w''=-q_2r\delta vw\,e^{-v}\,e^{-w}+\delta w^2, \tag{1.4}$$

together with the boundary conditions

$$\begin{aligned} &v=-\eta+o(1), \quad w=o(1) \quad \text{as } \eta\to-\infty,\\ &v=o(1), \quad w=o(1) \quad \text{as } \eta\to+\infty. \end{aligned} \tag{1.5}$$

We remark that q_1 is no longer involved. In the sequel the only hypothesis is $q_2>0$, which has a physical basis.

2. Main results. Let us introduce the following problem in the x-variable, which is obtained from (1.4) by taking δ equal to 1:

$$\frac{d^2v}{dx^2}=rvw\,e^{-v}\,e^{-w}, \qquad \frac{d^2w}{dx^2}=-q_2rvw\,e^{-v}\,e^{-w}+w^2. \tag{2.1}$$

We consider this nonlinear system subject to the following boundary conditions:

$$v'\to0 \quad \text{as } x\to+\infty, \qquad w\to0 \quad \text{as } x\to\pm\infty, \tag{2.2}$$

together with the normalization condition

$$v(0)=1. \tag{2.3}$$

In this paper, we will prove the following theorem.

THEOREM 2.1. *For any $r>0$ fixed, there exists a solution $(v, w)\in(C^\infty(\mathbb{R}))^2$ to problem* (2.1)-(2.3) *such that*

$$0<w<M_0=q_2\frac{r}{e}, \tag{2.4}$$

$$\begin{aligned} &v>0, \quad v'<0, \quad v\to+\infty \quad \textit{as } x\to-\infty,\\ &v\to0 \quad \textit{as } x\to+\infty. \end{aligned} \tag{2.5}$$

Moreover, $w\in H^2(\mathbb{R})$ and, as $x\to-\infty$, $v(x)=-l(x-x_0)+$ E.S.T., where $x_0\in\mathbb{R}$ and

$$l=\frac{1}{q_2}\int_{-\infty}^{+\infty} w^2(x)\,dx=\frac{1}{q_2}\,\|w\|^2_{L^2(\mathbb{R})}. \tag{2.6}$$

To return to the initial problem (1.4), (1.5), we make the transformation

$$\eta=l(x-x_0). \tag{2.7}$$

Then (2.1) becomes

$$\begin{aligned} &\frac{d^2v}{d\eta^2}=\frac{1}{l^2}\,rvw\,e^{-v}\,e^{-w},\\ &\frac{d^2w}{d\eta^2}=-\frac{1}{l^2}\,q_2rvw\,e^{-v}\,e^{-w}+\frac{1}{l^2}\,w^2 \end{aligned} \tag{2.8}$$

and, as $\eta \to -\infty$, $v(\eta) = -\eta + \text{E.S.T.}$ Thus it is clear that (1.4), (1.5) is solved by the pair $(v(\eta), w(\eta))$ with

$$\delta = \frac{1}{l^2}. \tag{2.9}$$

Therefore, we have determined

$$\delta = \frac{q_2}{\int_{-\infty}^{+\infty} w^2(\eta)\, d\eta}. \tag{2.10}$$

In the sequel, we give a detailed demonstration of Theorem 2.1. A sketch of the proof is the following: First, we exhibit positive upper and lower solutions of the problem in a formal way. Next, we consider the system (2.1) on a bounded interval $[-a, b]$ with suitable boundary conditions and we prove the existence of a solution (v, w) in a closed convex set K, by a fixed point argument (the convex K involves the upper and lower solutions). We derive a priori estimates in the $\mathscr{C}^1$-norm as well as in the H^1-norm. Finally, we let a and b tend to $+\infty$ and prove the existence of a limit which solves (2.1)–(2.3). Properties (2.5), (2.6) appear as a "spinoff" of the existence proof.

Problem (2.1) is "nearly homogeneous" at $\eta = \pm\infty$, i.e., the exponential terms are effectively constant there. In the reference [8] the stability of the homogeneous problem

$$v'' = r\delta v w, \qquad w'' = -q_2 r \delta v w + \delta w^2$$

is investigated near the equilibrium point $0 \in \mathbb{R}^4$ corresponding to $\eta \to +\infty$. The authors exhibit a critical value $r = 1$, corresponding to a bifurcation point. This value of r has also been pointed out in [6] by means of formal asymptotic expansions.

As an extension to the problem, it is possible to consider, instead of the exponential e^{-v}, some function $\theta(v)$ with algebraic decay as $v \to +\infty$. Then the asymptotic expansion of $v(\eta)$ as $\eta \to -\infty$ will be governed by the behavior of θ. See e.g. [1].

Finally, let us mention that a summary of this work has been presented as a Note aux Comptes Rendus [2]. An alternative proof by a topological shooting method has been announced by S. P. Hastings, C. Lu and Y. H. Wan [5]. The idea of considering the problem in a bounded domain and taking an infinite domain limit is already used in [4] in the case of one-step kinetics (see also [10]).

3. Upper and lower solutions in a formal setting. In this section, we perform a formal analysis of the system (2.1)–(2.3), which is a nonlinear eigenvalue problem: it admits the trivial solution $w = 0$, $v = 1$. In order to prove the existence of a nontrivial solution, a positive lower solution $\underline{w}$ is needed. The main trick is a logarithmic transformation, but it turns out that a large part of the analysis lies on elementary properties of the mapping $t \to t e^{-t}$.

Let us state first the main comparison principles used, which go back to Nagumo. Consider a nonlinear BVP on some interval (α, β), namely: $(*)$ $-z'' + F(x, z) = 0$, $z(\alpha) = z(\beta) = 0$, where F is continuous (say). An upper solution $\bar{z}$ to $(*)$ is a C^2 function satisfying: $-\bar{z}'' + F(x, \bar{z}) \geqq 0$, $\bar{z}(\alpha) \geqq 0$, $\bar{z}(\beta) \geqq 0$. A lower solution $\underline{z}$ satisfies the opposite inequalities. If $\underline{z} \leqq \bar{z}$, then the problem $(*)$ has a solution z such that $\underline{z} \leqq z \leqq \bar{z}$ on $[\alpha, \beta]$. For more general statements, see e.g. [9].

Part 1. Assume that (2.1)–(2.3) has a smooth positive solution (v, w). We remark that $v e^{-v} e^{-w}$ is bounded by $1/e$ so on $(0, +\infty)$ a lower solution to (2.1a) is

$$\underline{v}'' = \frac{r}{e} \underline{v}, \quad \underline{v}(0) = 1, \quad \underline{v}' \to 0 \quad \text{as } x \to +\infty. \tag{3.1}$$

Since $v''>0$, $v'<0$, and $v<1$ for $x>0$, $v>1$ for $x<0$. So we define

$$\underline{v}(x)=e^{-cx},\quad c=\sqrt{r/e}\quad \text{for } x>0,$$
$$\underline{v}(x)=1\quad \text{for } x\leqq 0.^1 \tag{3.2}$$

Integrating (2.1a) backwards from $+\infty$ yields

$$v'^2(x)=2r\int_{+\infty}^{x} w\,e^{-w}v\,e^{-v}v'\,ds\leqq\frac{2r}{e}\int_{x}^{+\infty}-vv'\,e^{-v}\,ds$$
$$=\frac{2r}{e}[(v+1)\,e^{-v}]_0^\infty<\frac{2r}{e},$$

so

$$0<-v'(x)<M_1=\sqrt{2r/e}. \tag{3.3}$$

We define

$$\bar{v}(x)=-M_1x+1\quad \text{for } x<0,$$
$$\bar{v}(x)=1\quad \text{for } x\geqq 0.^1 \tag{3.4}$$

Part 2. We look for an upper solution $\bar{w}$ of the form

$$\bar{w}=M_0=Cst>0. \tag{3.5}$$

Replacing w by M_0 and using (2.1b), we obtain

$$M_0^2-q_2rv\,e^{-v}M_0\,e^{-M_0}>M_0^2-\frac{q_2r}{e}M_0,$$

so we may choose

$$M_0=\frac{q_2r}{e}. \tag{3.6}$$

Remark 3.1. The choice of $\bar{w}$ may be improved by taking the root of

$$M_0\,e^{-y}=y. \tag{3.7}$$

Part 3. Finally, we look for a lower solution of (2.1b), i.e., a C^2 function satisfying

$$\underline{w}<\bar{w},$$
$$-\underline{w}''+w^2-q_2rv\,e^{-v}\underline{w}\,e^{-\underline{w}}\leqq 0, \tag{3.8}$$
$$\underline{w}\to 0\quad \text{as } x\to\pm\infty.$$

Minorizing $v\,e^{-v}$ by $\underline{v}\,e^{-\bar{v}}$, we obtain

$$v\,e^{-v}\geqq\frac{1}{e}e^{-cx}\quad \text{if } x>0,\qquad v\,e^{-v}\geqq\frac{1}{e}e^{M_1x}\quad \text{if } x<0. \tag{3.9}$$

When we set $\rho=\max(c,M_1)=M_1$, (3.9) yields

$$v\,e^{-v}\geqq\frac{1}{e}e^{-\rho|x|},\qquad -\infty<x<+\infty. \tag{3.10}$$

So we may replace (3.8) by

$$\underline{w}<\bar{w},$$
$$-\underline{w}''+\underline{w}^2-M_0\,e^{-M_0}\,e^{-\rho|x|}\underline{w}\leqq 0, \tag{3.11}$$
$$\underline{w}\to 0\quad \text{as } x\to\pm\infty.$$

To avoid the trivial lower solution $\underline{w}=0$, we introduce the logarithmic transformation

$$f=-\ln \underline{w}. \tag{3.12}$$

[1] Note that $\underline{v}$ and $\bar{v}$ are genuine lower and upper solutions to (2.1) only on $(0,+\infty)$, i.e., they verify: $\underline{v}''\geqq r\underline{v}w\,e^{-v}\,e^{-w}$ and $\bar{v}''\leqq r\bar{v}w\,e^{-\bar{v}}\,e^{-w}$. On $(-\infty,0)$ it holds that $\underline{v}\leqq v\leqq\bar{v}$. Therefore we do not need $\underline{v}$ and $\bar{v}$ to be smooth at the origin.

Therefore the equivalent is to find $f>0$ such that

$$e^{-f}<\min(1, M_0),$$

$$f''-f'^2+e^{-f}\leqq M_0\, e^{-M_0}\, e^{-\rho|x|}, \tag{3.13}$$

$$f\to+\infty \quad \text{as } x\to\pm\infty.$$

LEMMA 3.1. *A convenient choice of f is*

$$f=\frac{1}{2\rho}M_0\,e^{-M_0}\left(\frac{1}{\rho}e^{-\rho|x|}+|x|+\gamma\right),\qquad \gamma=Cst. \tag{3.14}$$

Proof. Remark that f is even and C^2. Since

$$f''-f'^2-M_0\,e^{-M_0}\,e^{-\rho|x|}=-f'^2-\tfrac{1}{2}M_0\,e^{-M_0}\,e^{-\rho|x|}<0$$

and does not vanish at $\pm\infty$, it is obviously possible to choose the constant γ such that the maximum of e^{-f} is small enough to satisfy simultaneously (3.13a and b). □

4. The problem on a bounded interval. Let a and b be two positive real numbers. We consider the system (2.1) on the interval $(-a, b)$, viz.,

$$-v''+rv\,e^{-v}w\,e^{-w}=0,\qquad -w''+w^2=q_2rv\,e^{-v}w\,e^{-w}, \tag{4.1}$$

with the following conditions:

$$\begin{aligned} &v(0)=1, && v'(b)=0,\\ &w(-a)=\underline{w}(-a), && w(b)=\underline{w}(b). \end{aligned} \tag{4.2}$$

We formulate it as a fixed point problem:

$$(v, w)=T[(v, w)] \tag{4.3}$$

in the following way: consider the space $E=\{\mathscr{C}^1([-a, b])\}^2$ and the closed convex set $K\subset E$:

$$K=\{(v, w)\in E,\ \underline{w}\leqq w\leqq \bar{w},\ \underline{v}\leqq v\leqq \bar{v},\ 0\leqq -v'\leqq M_1,\ |w'|\leqq m\} \tag{4.4}$$

where the functions $\bar{v}$, $\bar{w}$ and $\underline{v}$, $\underline{w}$, as well as the constant M_1, have been defined in the preceding section; they do not depend on a and b. Here only the constant m depend on a and b.

For $(v, w)\in K$, we define the operator T by

$$(V, W)=T[(v, w)]. \tag{4.5}$$

First V is solution of the nonlinear problem

$$\begin{aligned} &-V''+rw\,e^{-w}V\,e^{-V}=0,\\ &V(0)=1,\qquad V'(b)=0. \end{aligned} \tag{4.6}$$

LEMMA 4.1. *V is the unique solution of the* BVP (4.6) *on* $[0, b]$. *Moreover,* $\underline{v}\leqq V\leqq 1$.

Proof. $\underline{v}$ defined by (3.1) is clearly a lower solution to (4.6), while 1 is an upper solution. So (4.6) admits a solution such that $\underline{v}\leqq V\leqq 1$. The uniqueness of V is guaranteed by the monotonicity of the mapping $t\to t\,e^{-t}$ for $0\leqq t\leqq 1$. □

LEMMA 4.2. *On* $[-a, 0]$, *V is the unique solution of the nonlinear* IVP (4.6a) *with*

$$V(0)=1,\qquad V'(0^-)=V'(0^+). \tag{4.7}$$

Proof. The IVP (4.6a), (4.7) has a local solution V in some interval $\xi \leqq x \leqq 0$ which can be extended to $[-a, 0]$, for $1 \leqq V \leqq e^{-cx}$. □

Next W is given by the nonlinear BVP

$$\begin{aligned} &-W''+W^2=q_2rv\,e^{-v}w\,e^{-w},\\ &W(-a)=\underline{w}(-a), \qquad W(b)=\underline{w}(b). \end{aligned} \tag{4.8}$$

LEMMA 4.3. *W is the unique solution of* (4.8) *on* $[-a, b]$. *Moreover* $\underline{w} \leqq W \leqq \bar{w} = M_0$.

Proof. (i) Let us check that M_0 is an upper solution

$$M_0^2-q_2rv\,e^{-v}w\,e^{-w} \geqq M_0^2-\frac{q_2r}{e}w \geqq 0 \quad \text{for } w \leqq M_0.$$

(ii) Now we verify that $\underline{w}$ is a lower solution:

$$-\underline{w}''+\underline{w}^2-q_2rv\,e^{-v}w\,e^{-w} \leqq -\underline{w}''+\underline{w}^2-\frac{q_2r}{e}\,e^{-\rho|x|}\underline{w}\,e^{-M_0} \leqq 0$$

after (3.10), (3.11) and $w \geqq \underline{w}$.

(iii) So (4.8) admits a solution such that $\underline{w} \leqq W \leqq \bar{w}$. The uniqueness follows from the monotonicity of the mapping $t \to t^2$ for $t \geqq 0$. □

LEMMA 4.4. *T is a continuous compact mapping from K into itself.*

Proof. (i) T maps K into itself. We already know $V \geqq \underline{v}$, $\underline{w} \leqq W \leqq \bar{w}$. Since $V''>0$, $V' \leqq 0$. From (4.6) we find for $-a \leqq x < b$:

$$\begin{aligned} V'^2(x) &= 2r\int_b^x w\,e^{-w}\,V e^{-V}\,V'\,ds \\ &\leqq \frac{2r}{e}\int_x^b -VV'\,e^{-V}\,ds \\ &\leqq \frac{2r}{e} = M_1^2, \end{aligned}$$

and clearly $V(x) \leqq \bar{v}(x) = -M_1x+1$ on $[-a, 0]$.

Finally, let us consider W'. Let x_0 be a point where $W'(x_0)=0$. Writing $W'(x) = \int_{x_0}^x W''(s)\,ds$, we find $m=2(a+b)M_0^2$.

(ii) T is a continuous and compact mapping. Whenever $(v, w) \in K$, V'' and W'' are clearly bounded on $[-a, b]$, which induces the boundedness of Range (T) in $(C^2[-a, b])^2$. Therefore Range (T) is relatively compact in E.

To show that T is continuous, take a sequence $(v_n, w_n) \in K$, converging to (v, w) in E; let $(V_n, W_n) = T[v_n, w_n]$. Since Range (T) is relatively compact in K, there exists a subsequence (V_{n_p}, W_{n_p}) converging to $(V, W) \in K$, in E. We shall show that $(V, W) = T[(V, W)]$: let ϕ be a smooth function with compact support in $(-a, b)$; then (4.6)-(4.8) yield

$$\begin{aligned} &\int_{-a}^b V'_{n_p}\phi'\,dx + r\int_{-a}^b w_{n_p}\,e^{-V_{n_p}}\,e^{-w_{n_p}}v_{n_p}\phi\,dx = 0,\\ &\int_{-a}^b W'_{n_p}\phi'\,dx + \int_{-a}^b W_{n_p}^2\phi\,dx = q_2r\int_{-a}^b v_{n_p}w_{n_p}\,e^{-v_{n_p}}\,e^{-w_{n_p}}\phi\,dx, \end{aligned} \tag{4.9}$$

and the convergence of the above integrals is straightforward. Finally $T[(v_n, w_n)] \to T[(v, w)]$ by contradiction. □

THEOREM 4.1. *Problem* (4.1), (4.2) *has a solution* (v, w) *belonging to* $K \cap (C^\infty[-a, b])^2$.

Proof. From Lemma 4.4, T is a continuous and compact mapping from K into K and Schauder's Fixed-Point Theorem implies the existence of a fixed point of T in K. The smoothness of v and w is straightforward. □

We may establish further estimates independently of a and b.

THEOREM 4.2. *There exist positive constants* M_2, M_3 *and* M_4, *independent of a and b, such that*

$$(4.10)\qquad \begin{aligned} &|w'| \leqq M_2,\\ &\int_{-a}^{b} w^2\,dx \leqq M_3, \qquad \int_{-a}^{b} w'^2\,dx \leqq M_4. \end{aligned}$$

Proof. (i) Let us estimate w'; let x_0 be a point where $w'(x_0)=0$; an integration of (4.1b) leads to

$$\begin{aligned} \frac{w'^2(x)}{2} &= q_2 r[v\,e^{-v}\,e^{-w}(w+1)]_{x_0}^{x} - q_2 r\int_{x_0}^{x} e^{-w}(w+1)v'\,e^{-v}\,ds \\ &\quad + q_2 r\int_{x_0}^{x} e^{-w}(w+1)v'v\,e^{-v}\,ds + \left[\frac{w^3}{3}\right]_{x_0}^{x} \\ &\leqq 2q_2 r \sup\{v\,e^{-v}\,e^{-w}(w+1)\} + q_2 r\sup\{e^{-w}(w+1)\}\int_{-a}^{b} -v'\,e^{-v}\,ds \\ &\quad + q_2 r\sup\{e^{-w}(w+1)\}\int_{-a}^{b} -vv'\,e^{-v}\,ds + \frac{2}{3}M_0^3. \end{aligned}$$

Hence

$$(4.11)\qquad M_2 = 2\left[q_2 r\left(1+\frac{1}{e}\right) + \frac{M_0^3}{3}\right]^{1/2}.$$

(ii) We are now going to estimate $\int_{-a}^{b} w^2\,dx$. First, we combine (4.1) to get

$$(4.12)\qquad w'' + q_2 v'' = w^2.$$

By integrating (4.12) and making use of the previous estimates, we obtain

$$(4.13)\qquad M_3 = 2M_2 + 2q_2 M_1.$$

(iii) Finally, we multiply (4.1b) by w and integrate on $(-a, b)$ to obtain

$$\begin{aligned} \int_{-a}^{b} w'^2\,dx &= q_2 r\int_{-a}^{b} v\,e^{-v}\,e^{-w}w^2\,dx - \int_{-a}^{b} w^3\,dx + [ww']_{-a}^{b} \\ &\leqq q_2 r\frac{1}{e}\int_{-a}^{b} w^2\,dx + M_0\int_{-a}^{b} w^2\,dx + 2M_0M_2. \end{aligned}$$

Therefore

$$(4.14)\qquad M_4 = 2M_0(M_2 + M_3).$$

5. Passage to the limit. In this section, we will let a and b tend to infinity. Inasmuch as our proof may have some numerical meaning and since the behavior of v near ±∞ is substantially different, it is interesting to let a and b tend independently to infinity, although it is obviously possible to take $a = b$.

Let a_n and b_n be two sequences tending to infinity, as $n \to +\infty$. We consider a sequence of solution to (4.1), (4.2) on the interval $[-a_n, b_n]$, denoted by (v_n, w_n), satisfying

$$v_n'' = r v_n w_n e^{-v_n} e^{-w_n}, \qquad w_n'' = -q_2 r v_n w_n e^{-v_n} e^{-w_n} + w_n^2, \tag{5.1}$$

with

$$\begin{aligned} &v_n(0) = 1, \qquad v_n'(b_n) = 0, \\ &w_n(-a_n) = \underline{w}(a_n), \qquad w_n(b_n) = \underline{w}(b_n). \end{aligned} \tag{5.2}$$

Next we extend (v_n, w_n) to $\mathbb{R}$ by

$$\begin{aligned} \tilde{v}_n(x) &= v_n(x) \quad \text{if } x \in [-a_n, b_n] \\ &= v_n(-a_n) \quad \text{if } x < -a_n \\ &= v_n(b_n) \quad \text{if } x > b_n, \\ \tilde{w}_n(x) &= w_n(x) \quad \text{if } x \in [-a_n, b_n] \\ &= \underline{w}(x) \quad \text{if not.} \end{aligned} \tag{5.3}$$

Note that $\underline{w}$ given by (3.12), (3.14) is obviously in $H^1(\mathbb{R})$. With Theorems 4.1 and 4.2, we have the following estimates on sequences $\tilde{v}_n$ and $\tilde{w}_n$:

$$\begin{aligned} &\underline{w} \leqq \tilde{w}_n \leqq \bar{w} = M_0, \qquad |\tilde{w}_n'| \leqq M_2 + \|\underline{w}'\|_{L^\infty(\mathbb{R})}, \\ &\|\tilde{w}_n\|^2_{H^1(\mathbb{R})} \leqq M_3 + M_4 + \|\underline{w}\|^2_{H^1(\mathbb{R})}, \\ &0 \leqq -\tilde{v}_n' \leqq M_1, \\ &\underline{v}(x) \leqq \tilde{v}_n(x) \leqq \bar{v}(X), \qquad -\infty < -X \leqq x < +\infty, \\ &\int_{-X}^{+\infty} |v_n'(x)|\, dx \leqq 1 + \bar{v}(X). \end{aligned} \tag{5.4}$$

As a consequence of these estimates, we have the following.

LEMMA 5.1. *There exists a subsequence (v_{n_k}, w_{n_k}) and a pair (v, w) such that, as $n_k \to +\infty$,*

$$\tilde{v}_{n_k} \to v, \ \tilde{w}_{n_k} \to w \quad \textit{uniformly on compact subsets of } \mathbb{R}. \tag{5.5}$$

Moreover, $\tilde{w}_{n_k} \to w$ in $H^1(\mathbb{R})$ weakly, $\tilde{v}_{n_k}' \to v'$ in $L^p(-X, +\infty)$ weakly for all $X > 0$, $p > 1$.

Proof. Let $X_0 > 0$ be fixed. The sequences $\tilde{v}_n$ and $\tilde{w}_n$ are bounded in $W^{1,\infty}([-X_0, X_0])$ by (5.4), so one can extract two subsequences $\tilde{v}_n^{X_0}$ and $\tilde{w}_n^{X_0}$ converging uniformly on $[-X_0, X_0]$. By means of a diagonal process one obtains two subsequences which converge uniformly on $[-X, X]$, for all $X > 0$.

On the other hand, (5.4) yields that $\tilde{w}_n$ is bounded in $H^1(\mathbb{R})$ and the sequence $\tilde{v}_n'$ is bounded in $L^p(-X, +\infty)$, $\forall X > 0, p \geqq 1$, hence the lemma. □

Now, let ϕ be a smooth test function, supp $\phi \subset (-X, X)$, $X > 0$ fixed, and let n_k be large enough so that $a_{n_k} > X$, $b_{n_k} > X$. It follows that

$$\int_{-X}^{X} v_{n_k}' \phi' \, dx = -r \int_{-X}^{X} v_{n_k} w_{n_k} e^{-v_{n_k}} e^{-w_{n_k}} \phi \, dx$$

and

$$\int_{-X}^{X} w_{n_k}' \phi' \, dx = +q_2 r \int_{-X}^{X} v_{n_k} w_{n_k} e^{-v_{n_k}} e^{-w_{n_k}} \phi \, dx - \int_{-X}^{X} w_{n_k}^2 \phi \, dx.$$

In the limit $n_k \to +\infty$, at least in the sense of distributions on $\mathbb{R}$, we find that (v, w) is a solution of[2]

$$(5.6) \qquad v'' = rvw\, e^{-v}\, e^{-w}, \qquad w'' = -q_2 rvw\, e^{-v}\, e^{-w} + w^2.$$

By bootstrapping the solution (v, w) is in fact in $(C^\infty(\mathbb{R}))^2$. We have $v(0) = 1$ and since, $w \in H^1(\mathbb{R})$,

$$(5.7) \qquad w(x) \to 0 \quad \text{as } x \to \pm\infty.$$

Also the upper and lower solutions are preserved at the limit, in fact

$$(5.8) \qquad \underline{v} \leqq v \leqq \bar{v}, \qquad \underline{w} \leqq w \leqq \bar{w}.$$

In particular, it follows that $v > 0$, $w > 0$.

6. Asymptotic properties. We have already proved the existence of a positive solution (v, w) to (5.6), i.e., (2.1). Some of the boundary conditions have been satisfied. We now complete the proof of Theorem 2.1 by a couple of lemmas.

LEMMA 6.1. *$v' < 0$; $v(x)$ and $v'(x) \to 0$ as $x \to +\infty$.*

Proof. Through the limit process, we know $v' \leqq 0$, $v' \in L^p(-X, +\infty)$, for all $X > 0$, $1 < p \leqq +\infty$. Since $vw > 0$, we have $v'' > 0$, hence $v' < 0$ and $v'(x)$ has a limit as $x \to +\infty$, which is necessarily 0. Next, $v(x)$ has a limit v_l as $x \to +\infty$ (in particular it yields $v' \in L^1(-X, +\infty)$). Assume that $v_l > 0$. Locally the behavior of w is given by the dynamical system

$$(6.1) \qquad \dot{y}_1 = y_2, \qquad \dot{y}_2 = y_1(y_1 - q_2 r\, e^{-y_1} v_l\, e^{-v_l}),$$

whose equilibrium point $(0, 0)$ is a center. Therefore w cannot tend to 0 without oscillations, a contradiction. Hence $v_l = 0$ and the degenerate equilibrium point $(0, 0)$ has a one-dimensional stable manifold in the range $y_1 > 0$, $y_2 < 0$. For a more complete stability analysis, we refer to [7], [8]. □

LEMMA 6.2. *$w \in H^2(\mathbb{R})$.*

Proof. We already know that $w \in H^1(\mathbb{R})$. From (5.6b), $|w''| \leqq 2M_0 w$; hence $w'' \in L^2(\mathbb{R})$. □

Remark 6.1. Further results on regularity can be easily obtained in higher-order Sobolev spaces. We conjecture that $w \in W^{2,1}(\mathbb{R})$ from the formal asymptotic developments of [6].

LEMMA 6.3. *As $x \to -\infty$,*

$$(6.2) \qquad v'(x) \to -l$$

with

$$(6.3) \qquad l = \frac{1}{q^2} \int_{-\infty}^{+\infty} w^2(x)\, dx$$

and there exists $x_0 \in \mathbb{R}$, such that

$$(6.4) \qquad v(x) = -l(x - x_0) + \text{E.S.T.}$$

Proof. Since $v' < 0$ and bounded from below, we may define $l = \lim_{x \to -\infty} (-v'(x))$. Let us combine the system again as in (4.12)

$$(6.5) \qquad w'' + q_2 v'' = w^2.$$

[2] As an alternative proof, it is easy to build subsequences such that the first and second derivatives converge uniformly on compact subsets of $\mathbb{R}$.

Integration of (6.5) on $\mathbb{R}$ yields, with Lemmas 6.2 and 6.3,

$$q_2 l = \int_{\mathbb{R}} w^2(x)\, dx.$$

Therefore, $v \to +\infty$ as $x \to -\infty$ and

$$v'' = rvw\, e^{-v}\, e^{-w} \xrightarrow[x \to -\infty]{} 0 \quad \text{exponentially.} \tag{6.6}$$

Relation (6.6) may clearly be integrated twice to get (6.4). x_0 is an integration constant. So Theorem 2.1 is proved. □

Acknowledgments. We are indebted to F. Conrad, G. Bayada and M. Chambat for their comments on the preliminary draft. We thank G. S. S. Ludford for his careful reading of the manuscript.

SHAPE SENSITIVITY ANALYSIS OF UNILATERAL PROBLEMS*

JAN SOKOŁOWSKI† AND JEAN-PAUL ZOLESIO‡

Abstract. After a short introduction we turn to the sensitivity analysis of an abstract variational inequality and we apply this result to the sensitivity analysis of an obstacle problem: Ω_t is a domain built by a speed vector field V, $K(\Omega_t)$ a closed convex subset of the Sobolev space $H^1(\Omega_t)$, z_t is the element of $K(\Omega_t)$ solution of an elliptic variational inequality. We characterize the shape derivative $z' = \dot{z} - \nabla z . V(0)$ (where $\dot{z}$ is the material derivative, $\dot{z} = ((d/dt)z_t \circ T_t)_{t=0}$) as the solution of another variational inequality well posed on a new convex subset $S_V(\Omega)$ of $H^1(\Omega)$ depending on the speed vector field V only by boundary expression (see Theorem 2). Finally we characterize the material derivative $\dot{\mathbf{u}}$ of the solution of the Signorini variational inequality associated with planar linear elasticity. For this purpose the material derivative has been generalized to vectors situation by $\dot{\mathbf{u}} = d/dt\ (DT_t^{-1}.\mathbf{u}_t \circ T_t)_{t=0}$. This material derivative is the solution of a variational inequality posed on a convex subset $S(\Omega)$ of $H^1(\Omega_t)^2$.

1. Introduction. This paper is devoted to sensitivity analysis of unilateral boundary value problems with respect to the perturbations of the domain of integration.

Let us consider an example. Given a domain $\Omega \subset R^2$, let us consider a family of continuously differentiable, one-to-one mappings

$$T_t : R^2 \to R^2.$$

Ω_t is then the transformed domain; see Fig. 1. For the details we refer the reader to § 3. Here $t \in [0, \delta)$ is a real parameter. Let us consider the following obstacle problem defined in $\Omega_t = T_t(\Omega)$ for a fixed parameter $t \in [0, \delta)$. Find $Y_t \in H_0^1(\Omega_t)$ such that:

$$(1)\quad \begin{aligned} &-\Delta Y_t(x) - f(x) \leqq 0 \text{ in } \Omega_t, \\ &Y_t(x) - 1 \leqq 0 \quad \text{in } \Omega_t, \\ &(Y_t(x) - 1)(\Delta Y_t(x) + f(x)) = 0 \quad \text{in } \Omega_t \end{aligned}$$

where $f(\cdot) \in L^2(R^2)$ is a given element. It is well known [1] that there exists a unique solution to the obstacle problem.

We denote here by $E(Y_t)$ the coincidence set, by γ_t the free boundary, i.e. (see Fig. 2),

$$E(Y_t) = \{x \in \Omega_t \mid Y_t(x) = 1\}.$$

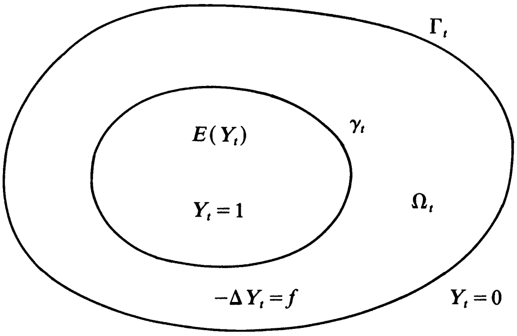

FIG. 2

Let us denote $\mu_t=-f|_{E(Y_t)}$. Since $Y_t(\cdot)$ is sufficiently smooth [1], it folllows that the element $Y_t(\cdot)\in H_0^1(\Omega_t)$ satisfies the equation

$$-\Delta Y_t(x)=f(x)+\mu_t(x) \quad \text{in } \Omega_t.$$

The obstacle problem (1) can be transported to the domain $\Omega_0\equiv\Omega$ using transformation T_t, i.e. the function $Y^t(X)\overset{\text{def}}{=}(Y_t\circ T_t)(X)$ is given by the following obstacle problem defined in the fixed domain Ω. Find $Y^t\in H_0^1(\Omega)$ such that:

$$\begin{aligned}
&-\operatorname{div}(A(t,X)\operatorname{grad} Y^t(X))-f^t(X)\leqq 0 \quad \text{in } \Omega,\\
(2)\qquad &Y^t(X)-1\leqq 0 \quad \text{in } \Omega,\\
&(Y^t(X)-1)(-\operatorname{div}(A(t,X)\operatorname{grad} Y^t(X))-f^t(X))=0 \quad \text{in } \Omega.
\end{aligned}$$

Here we denote

$$\begin{aligned}
f^t(X)&=\det(DT_t(X))(f\circ T_t)(X),\\
A(t,X)&=\det(DT_t(X))(DT_t(X))^{-1}\cdot{}^*(DT_t(X))^{-1},
\end{aligned}$$

where $DT_t(X)$ is the Jacobian matrix of transformation $T_t: R^2\to R^2$ evaluated at $X\in\Omega$.

We prove that there exists the limit

$$\overset{\circ}{Y}=\lim_{t\downarrow 0}(Y^t-Y^0)/t$$

in $H_0^1(\Omega)$. The element $\overset{\circ}{Y}\in H_0^1(\Omega)$ is given by the following variational problem (see Fig. 3). Find $\overset{\circ}{Y}\in H^1(\Omega)$ that minimizes:

$$\begin{aligned}
&I(\eta)=\frac{1}{2}\int_\Omega(\nabla\eta)^2\,dx+\int_\Omega\langle A'\cdot\nabla Y^0,\nabla\eta\rangle_{R^2}\,dx-\int_\Omega f'\eta\,dx\\
(3)\qquad &\text{subject to constraints}\\
&\eta(X)=0 \quad \text{for q.e. } X\in\operatorname{supp}\mu_0,\\
&\eta(X)\leqq 0 \quad \text{for q.e. } X\in E(Y_0)\backslash\operatorname{supp}\mu_0.
\end{aligned}$$

Here

$$\begin{aligned}
A'(X)&=\lim_{t\downarrow 0}(A(t,X)-A(0,X))/t,\\
f'(X)&=\lim_{t\downarrow 0}(f^t(X)-f^0(X))/t.
\end{aligned}$$

The element $\overset{\circ}{Y}$ is the so-called material derivative of the solution to the obstacle problem (1) in the direction of a transformations $\{T_t\}$. Using this result we prove that

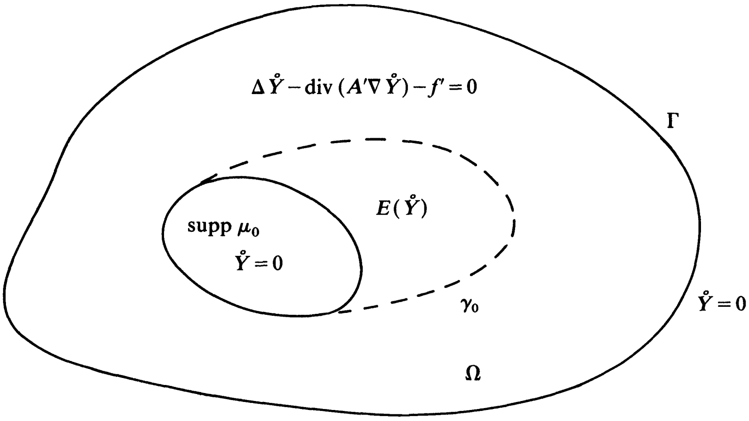

FIG. 3

for an extension $\tilde{Y}_t$ to R^2 of elements $Y_t \in H_0^1(\Omega_t)$

$$\tilde{Y}_t(X) = \begin{cases} Y_t(X), & X \in \Omega_t, \\ 0, & X \in R^2 \backslash \Omega_t, \end{cases}$$

we have the following expansion with respect to the parameter t, for $t > 0$, t small enough,

$$\tilde{Y}_t|_\Omega = Y_0 + tY' + O(t) \quad \text{in } H^1(\Omega)$$

where $\| O(t) \|_{H^1(\Omega)}/t \to 0$ with $t \downarrow 0$ and $Y' \in H^1(\Omega)$ is given by the following variational problem:

find $Y' \in H^1(\Omega)$ that minimizes

$$J(\eta) = \frac{1}{2} \int_\Omega (\nabla\eta)^2 \, dx$$

subject to constraints

$$\eta = -v \frac{\partial Y_0}{\partial n} \quad \text{on } \Gamma,$$

$$\eta = 0 \quad \text{q.e. on supp } \mu_0,$$

$$\eta \leqq 0 \quad \text{q.e. on } E(Y_0) \backslash \text{supp } \mu_0.$$

Here $v(X)$, $X \in \Gamma$ is a function uniquely determined by the family $\{T_t\}$, $t \in [0, \delta)$; for the details we refer the reader to § 3.

In this paper the continuous evolution of a given domain $\Omega \subset R^n$, $n \geqq 2$ that depends on a vector field $\mathbf{V}$ is introduced [2], [15]. The so-called material derivative [16] of the solution of the boundary value problem in a direction of the field $\mathbf{V}$ is defined. Existence of the material derivative is proved for an obstacle problem and for the Signorini variational inequality of the plane elasticity. In the case of the obstacle problem the so-called domain derivative in the direction of a field $\mathbf{V}$ is characterized as a unique solution to an auxiliary variational inequality. Such characterization of the domain derivative can be obtained under the assumption that the solution of the unilateral boundary value problem is sufficiently smooth. Shape sensitivity analysis of linear boundary value problems was investigated by many authors, in particular by J. Cea [2], [3], J.-P. Zolesio [15], [16]; see also [9], [10] and references given in [3].

Related results concerning sensitivity analysis of unilateral problems were presented in [4], [8], [11]-[14]. For a detailed description of the material derivative method we refer to the paper [16].

The plan of the paper is as follows. Notation is introduced in the next section. In § 2, differentiability properties of the solution to an abstract variational inequality with respect to a parameter are investigated. Section 3 describes the results obtained for the obstacle problem. Section 4 contains the results for the Signorini variational inequality.

1.1. Notation. Let H be a Hilbert space. Denote by H' the dual space and by $\langle\cdot,\cdot\rangle$ the duality pairing between H' and H. Let $a(\cdot,\cdot): H\times H\to R$ be a bilinear form and assume that there exist constants α and M, $0<\alpha\leqq M$, such that

$$a(\phi,\phi)\geqq\alpha\|\phi\|_H^2\quad\forall\phi\in H, \tag{1.1}$$

$$|a(\phi,\zeta)|\leqq M\|\phi\|_H\|\zeta\|_H\quad\forall\phi,\zeta\in H. \tag{1.2}$$

Consider the nonlinear mapping:

$$P: H'\to H, \tag{1.3}$$

which is defined in the following way:

for each $f\in H'$ the corresponding element $P(f)\in H$ satisfies the variational inequality

$$\begin{aligned}&P(f)\in K,\\&a(P(f),\zeta-P(f))\geqq\langle f,\zeta-P(f)\rangle\quad\forall\zeta\in K,\end{aligned} \tag{1.4}$$

where K is a convex and closed subset of H.

It is well known [5], [6] that under assumptions (1.1) and (1.2) for any $f\in H'$ there exists a unique solution to (1.4).

DEFINITION 1. Mapping (1.3) is Gateaux differentiable at $f^0\in H'$ if there exists a continuous mapping

$$Q: H'\to H \tag{1.5}$$

such that

$$\forall h\in H': \lim_{\tau\downarrow 0}\|(P(f^0+\tau h)-P(f^0))/\tau-Q(h)\|_H=0. \tag{1.6}$$

Remark. Mapping $Q(\cdot)$ is positively homogeneous,

$$Q(\tau h)=\tau Q(h)\quad\forall\tau>0,\quad\forall h\in H'. \tag{1.7}$$

However, in general, $Q(-h)\neq -Q(h)$.

2. Sensitivity analysis of an abstract variational inequality. Consider the following family of variational inequalities depending on a parameter $t\in[0,\delta)$, $\delta>0$:

$$\begin{aligned}&p^t\in K,\\&a^t(p^t,\zeta-p^t)\geqq\langle f^t,\zeta-p^t\rangle\quad\forall\zeta\in K\end{aligned} \tag{2.1}$$

where for each $t\in[0,\delta]$, $a^t(\cdot,\cdot): H\times H\to R$ is a bilinear form and $f^t\in H'$ is given. For fixed $t\in[0,\delta)$ denote $p^t=P^t(f^t)$, $f^t\in H'$.

THEOREM 1. *Assume that*

(i) *Bilinear forms* $a^t(\cdot,\cdot)$ *satisfy* (1.1), (1.2) *uniformly for* $t\in[0,\delta)$ *and there exists a linear operator* $A'\in L(H;H')$ *such that*

$$\lim_{t\downarrow 0}\sup_{\substack{\|\phi\|_H\leqq 1\\ \|w\|_H\leqq 1}}|(a^t(w,\phi)-a^0(w,\phi))/t-\langle A'w,\phi\rangle|=0; \tag{2.2}$$

(ii) *There exists an element* $f' \in H'$ *such that*

$$\lim_{t\downarrow 0} \sup_{\|\phi\|_H \leqq 1} |\langle f^t - f^0, \phi\rangle / t - \langle f', \phi\rangle| = 0; \tag{2.3}$$

(iii) $P^0(f), f \in H'$ *denotes a unique solution of the variation inequality*

$$\begin{aligned} &P^0(f) \in K, \\ &a^0(P^0(f), \xi - P^0(f)) \geqq \langle f, \xi - P^0(f)\rangle \quad \forall \xi \in K. \end{aligned} \tag{2.4}$$

Assume that the mapping $P^0(\cdot): H' \to H$ *is Gateaux differentiatiable, i.e. for* $t > 0$, t *small enough,*

$$\forall h \in H'\colon P^0(f^0 + th) = P^0(f^0) + tQ(h) + o(t) \tag{2.5}$$

where $\|o(t)\|_H/t \to 0$ *with* $t \downarrow 0$.

Then the solution $p^t \in H$ *to variational inequality* (2.1) *is right-differentiable at* $t = 0$ *in the norm of space* H:

$$p^t = p^0 + tQ(f' - A'p^0) + o(t) \tag{2.6}$$

where $\|o(t)\|_H/t \to 0$ *with* $t \downarrow 0$.

Proof. By standard argument it follows that

$$a^0(p^0 - p^t, p^0 - p^t) \leqq \langle f^t - f^0, p^0 - p^t\rangle + a^0(p^t, p^t - p^0) - a^t(p^t, p^t - p^0). \tag{2.7}$$

Using (1.1) we obtain

$$\alpha \| p^0 - p^t \|_H^2 \leqq \| f^t - f^0 \|_{H'} \| p^0 - p^t \|_H + |a^0(p^t, p^t - p^0) - a^t(p^t, p^t - p^0)|. \tag{2.8}$$

By assumption (i) there exists a constant $C < \infty$ such that for $t > 0$, t small enough,

$$|a^0(p^t, p^t - p^0) - a^t(p^t, p^t - p^0)| \leqq Ct \| p^t \|_H \| p^t - p^0 \|_H. \tag{2.9}$$

Therefore, in view of (2.9), it follows from (2.8) that

$$\| p^t - p^0 \|_H \leqq C_1 t, \qquad t \in [0, \delta). \tag{2.10}$$

Simple calculations show that the element $p^t \in H$ satisfies the following variational inequality:

$$\begin{aligned} &p^t \in K, \\ &a^0(p^t, \xi - p^t) \geqq \langle f^0 + t(f' - A'p^0), \xi - p^t\rangle + \langle r(t), \xi - p^t\rangle \quad \forall \xi \in K \end{aligned} \tag{2.11}$$

where

$$\langle r(t), \xi\rangle = \sum_{i=1}^{3} \langle r_i(t), \xi\rangle \quad \forall \xi \in H,$$

$$r_1(t) = f^t - f^0 - tf', \tag{2.12}$$

$$\langle r_2(t), \xi\rangle \overset{\text{def}}{=} a^0(p^0, \xi) - a^t(p^0, \xi) + t\langle A'p^0, \xi\rangle \quad \forall \xi \in H, \tag{2.13}$$

$$\langle r_3(t), \xi\rangle \overset{\text{def}}{=} a^0(p^t - p^0, \xi) - a^t(p^t - p^0, \xi) \quad \forall \xi \in H. \tag{2.14}$$

By assumptions (i) and (ii) it follows that $\| r_i(t) \|_{H'}/t \to 0$ with $t \downarrow 0$, $i = 1, 2$. Furthermore, in view of (2.2), for $t > 0$, t small enough,

$$|\langle r_3(t), \xi\rangle| \leqq \gamma(t) \| p^t - p^0 \|_H \| \xi \|_{H'} \quad \forall \xi \in H \tag{2.15}$$

where $\gamma(t) \downarrow 0$ with $t \downarrow 0$. Therefore, taking into account (2.10), we obtain

$$\| r_3(t) \|_{H'}/t \to 0 \quad \text{with } t \downarrow 0. \tag{2.16}$$

Thus

$$\|r(t)\|_{H'}/t \to 0 \quad \text{with } t \downarrow 0. \tag{2.17}$$

Hence

$$\begin{aligned} p^t &= P^0(f^0 + t(f' - A'p^0) + r(t)) = P^0(f^0 + t(f' - A'p^0)) + o(t) \\ &= P^0(f^0) + tQ(f' - A'p^0) + o(t) \end{aligned} \tag{2.18}$$

where

$$\|o(t)\|_H/t \to 0 \quad \text{with } t \downarrow 0.$$

3. Sensitivity analysis of an obstacle problem. This section is devoted to sensitivity analysis with respect to the parameter $t \in [0, \delta)$ of an obstacle problem posed in a domain $\Omega_t \subset R^n$.

First we introduce notation. The following notation is used for the scalar product in R^n:

$$\mathbf{a} \cdot \operatorname{grad} \zeta = \langle \mathbf{a}, \operatorname{grad} \zeta \rangle_{R^n} = \sum_{i=1}^n a_i \frac{\partial \zeta}{\partial x_i}$$

where $\mathbf{a} = \operatorname{col}(a_1, \cdots, a_n)$ is a vector and $\operatorname{grad} \zeta = \operatorname{col}(\partial\zeta/\partial x_i, \cdots, \partial\zeta/\partial x_n)$ denotes the gradient of a given function $\zeta = \zeta(x)$, $x = (x_1, \cdots, x_n) \in R^n$. Given $n \times n$ matrix $A = [a_{ij}]$, we denote by $*A$ its transpose matrix, i.e., $*A = [a_{ji}]$. As in [3], [16], we introduce a family of regular domains $\{\Omega_t\} \subset R^n$, $t \in [0, \delta)$ corresponding to a given vector field:

$$\mathbf{V}(\cdot, \cdot): [0, \delta) \times R^n \to R^n. \tag{3.1}$$

Domains Ω_t are constructed as follows. Denote by $T_t = T_t(\mathbf{V})$, $t \in [0, \delta)$ the family of mappings of the form

$$T_t \colon R^n \ni X \to x(t) \in R^n \tag{3.2}$$

where the vector function $x(\cdot)$ satisfies the following ordinary differential equation:

$$\begin{aligned} &\frac{dx}{dt}(s) = \mathbf{V}(s, x(s)), \qquad s \in [0, \delta), \\ &x(0) = X, \end{aligned} \tag{3.3}$$

and denote

$$\Omega_t = T_t(\mathbf{V})(\Omega) = \{x \in R^n \mid \exists X \in \Omega \text{ such that } x = x(t),\ x(0) = X\}. \tag{3.4}$$

Vector field $\mathbf{V}(\cdot, \cdot)$ is assumed to be regular, i.e.,

$$\mathbf{V}(t, \cdot) \in C^1(R^n, R^n) \quad \forall t \in [0, \delta), \tag{3.5}$$

$$\mathbf{V}(\cdot, x) \in C([0, \delta)) \quad \forall x \in R^n. \tag{3.6}$$

Note that from (3.3) and (3.4) it follows that $\Omega_0 \equiv \Omega$.

Denote by $DT_t(X)$ the Jacobian matrix of mapping (3.2) evaluated at $X \in R^n$. Given the family of domains $\{\Omega_t\} \subset R^n$, consider the following variational inequality, parametrized by $t \in [0, \delta)$:

$$\begin{aligned} &z_t \in K_t(\Omega_t) = \{\zeta_t \in H^1(\Omega_t) \mid \zeta = \phi \text{ on } \partial\Omega_t,\ \zeta_t(x) \geqq \psi_0(x) \text{ a.e. in } \Omega_t\}, \\ &a_t(z_t, \zeta_t - z_t) \geqq \langle f_t, \zeta_t - z_t \rangle_t \quad \forall \zeta_t \in K_t(\Omega_t) \end{aligned} \tag{3.7}$$

where $\phi(\cdot)$ and $\psi_0(\cdot)$ are given elements of $C^1(R^n)$, $\langle \cdot, \cdot \rangle_t$ is the duality pairing between $(H^1(\Omega_t))'$ and $H^1(\Omega_t)$. Bilinear forms $a_t(\cdot, \cdot)$ and element $f_t \in (H^1(\Omega_t))'$ are defined respectively by

$$\begin{aligned} a_t(y_t, \zeta_t) = \int_{\Omega_t} &\{\langle A(x) \cdot \operatorname{grad} y_t(x), \operatorname{grad} \zeta_t(x)\rangle_{R^n} \\ &+\zeta_t(x)\langle \mathbf{a}(x), \operatorname{grad} y_t(x)\rangle_{R^n} + a_0(x) y_t(x) \zeta_t(x)\}\, dx, \\ &\qquad t \in [0, \delta) \quad \forall \zeta_t, y_t \in H^1(\Omega_t), \end{aligned} \tag{3.8}$$

$$\langle f_t, \zeta_t\rangle_t = \int_{\Omega_t} \{F_0(x)\zeta_t(x) + \langle \mathbf{F}(x) + \operatorname{grad} \zeta_t(x)\rangle_{R^n}\}\, dx, \qquad t \in [0, \delta) \quad \forall \zeta_t \in H^1(\Omega_t) \tag{3.9}$$

where $A(x) = [a_{ij}(x)]_{n\times n}$, $\mathbf{a}(x) = \operatorname{col}(a_1(x), \cdots, a_n(x))$, $\mathbf{F}(x) = \operatorname{col}(F_1(x), \cdots, F_n(x))$, $a_0(x)$, $F_0(x)$ are given elements and $x \in R^n$.

We shall characterize the so-called domain derivative [16] $z' \in H^1(\Omega)$ for a solution to problem (3.7). Recall that in the case of variational inequality (3.7) the domain derivative can be defined as follows:

$$z'(x) \overset{\text{def}}{=} \frac{\partial \tilde{z}}{\partial t}(0^+, x), \qquad x \in \Omega \tag{3.10}$$

where

$$\tilde{z}(t, x) = \begin{cases} z_t(x), & x \in \Omega_t, \quad t \in [0, \delta), \\ \phi(x), & x \in R^n \backslash \Omega_t, \quad t \in [0, \delta). \end{cases} \tag{3.11}$$

THEOREM 2. *Assume that*

(i) $K_t(\Omega_t)$ *is a nonempty, closed and convex subset of space* $H^1(\Omega_t)$ *for* $t \in [0, \delta)$.

(ii) $a_{ij}(\cdot), a_i(\cdot), a_0(\cdot), F_i(\cdot), F_0(\cdot) \in C^1(R^n), \quad i, j = 1, \cdots, n,$

(iii) *There exists a constant* $\alpha > 0$ *such that*

$$a_t(\zeta_t, \zeta_t) \geqq \alpha \|\zeta_t\|^2_{H^1(\Omega_t)} \quad \forall \zeta_t \in H^1(\Omega_t), \quad \forall t \in [0, \delta); \tag{3.12}$$

(iv) $-\beta(x) \overset{\text{def}}{=} \phi(x) - \psi_0(x) > 0 \quad \forall x \in R^n$,

$\beta(\cdot), \quad 1/\beta(\cdot) \in C^1(R^n), \quad \phi \in C^2(R^n)$;

then the domain derivative $z' \in H^1(\Omega)$ *for the problem* (1) *exists and is given by the following variational inequality*:

$$\begin{aligned} &z' \in S_v(\Omega), \\ &a_0(z', \zeta - z') \geqq 0 \quad \forall \zeta \in S_v(\Omega), \end{aligned} \tag{3.13}$$

where the cone $S_v(\Omega) \subset H^1(\Omega)$ *is defined by*

$$\begin{aligned} S_v(\Omega) = \Big\{ \xi \in H^1(\Omega) \,|\, \xi = -v\frac{\partial}{\partial n}(z_0 - \phi) \textit{ on } \Gamma \xi(X) \geqq 0 \quad \textit{q.e. on } Z = Z(z_0 - \psi_0), \\ \int_Z (F_0(X) - \operatorname{div} \mathbf{F}(X) - \mathbf{a}(X) \cdot \nabla \psi_0(X) - a_0(X)\psi_0(X) \\ + \operatorname{div}(A(X) \cdot \nabla \psi_0(X)))\xi(X)\, dX = 0 \Big\}. \end{aligned}$$

For the proof of Theorem 2 we need some lemmas. Lemma 1 describes the results obtained in the case of an obstacle problem defined in the fixed domain Ω. We introduce the necessary notation. Let there be given $n\times n$ matrix function $C(t,x)=[c_{ij}(t,x)]$, vector functions $\mathbf{c}(t,x)=\mathrm{col}\,(c_1(t,x),\cdots,c_n(t,x))$, $\mathbf{H}(t,x)=\mathrm{col}\,(H_1(t,x),\cdots,H_n(t,x))$ and elements $c_0(t,x)$, $H_0(t,x)$, $t\in[0,\delta)$, $x\in\bar{\Omega}$, which are supposed to be continuous on $[0,\delta)x\bar{\Omega}$ and continuously differentiable with respect to t at $t=0^+$. Define the following:

1) bilinear form $c^t(\cdot,\cdot)$ on $H_0^1(\Omega)$

$$\begin{aligned} c^t(y,\zeta)=\int_\Omega \{&\langle C(t,x)\cdot\operatorname{grad} y(x),\operatorname{grad}\zeta(x)\rangle_{R^n}\\ &+\zeta(x)\langle \mathbf{c}(t,x),\operatorname{grad} y(x)\rangle_{R^n}+c_0(t,x)y(x)\zeta(x)\}\,dx \end{aligned}\tag{3.14}$$

$$\forall y,\zeta\in H_0^1(\Omega),\quad \forall t\in[0,\delta);$$

2) elements $\dot{h}^t\in H^{-1}(\Omega)$

$$\langle h^t,\zeta\rangle=\int_\Omega\{H_0(t,x)\zeta(x)+\langle\mathbf{H}(t,x),\operatorname{grad}\zeta(x)\rangle_{R^n}\}\,dx\tag{3.15}$$

$$\forall\zeta\in H_0^1(\Omega),\quad\forall t\in[0,\delta);$$

3) linear operator $C'\in L(H_0^1(\Omega);H^{-1}(\Omega))$

$$\begin{aligned}\langle C'y,\zeta\rangle=\int_\Omega\bigg\{&\left\langle\frac{\partial C}{\partial t}(0^+,x)\cdot\operatorname{grad} y(x),\operatorname{grad}\zeta(x)\right\rangle_{R^n}\\ &+\zeta(x)\left\langle\frac{\partial \mathbf{c}}{\partial t}(0^+,x),\operatorname{grad} y(x)\right\rangle_{R^n}+\frac{\partial c_0}{\partial t}(0^+,x)y(x)\zeta(x)\bigg\}\,dx\end{aligned}\tag{3.16}$$

$$\forall y,\zeta\in H_0^1(\Omega);$$

4) element $h'\in H^{-1}(\Omega)$

$$\langle h',\zeta\rangle=\int_\Omega\left\{\frac{\partial H_0}{\partial t}(0^+,x)\zeta(x)+\left\langle\frac{\partial\mathbf{H}}{\partial t}(0^+,x),\operatorname{grad}\zeta(x)\right\rangle_{R^n}\right\}dx\qquad\forall\zeta\in H_0^1(\Omega).\tag{3.17}$$

Consider the variational inequality

$$\begin{aligned}&w^t\in K(\Omega)=\{\zeta\in H_0^1(\Omega)\,|\,\zeta(x)\leqq\gamma\text{ a.e. in }\Omega\},\\ &c^t(w^t,\zeta-w^t)\geqq\langle h^t,\zeta-w^t\rangle\quad\forall\zeta\in K(\Omega)\end{aligned}\tag{3.18}$$

where $\gamma\in R$ is given constant. In the sequel, without loss of generality we assume that $\gamma=1$.

LEMMA 1. *Assume that there exists $\alpha>0$ such that*

$$\forall t\in[0,\delta):\quad c^t(\zeta,\zeta)\geqq\alpha\|\zeta\|^2_{H_0^1(\Omega)}\quad\forall\zeta\in H_0^1(\Omega).$$

Then

$$w^t=w^0+tq+o(t)\tag{3.19}$$

where $\|o(t)\|_{H_0^1(\Omega)}/t\to0$ with $t\downarrow0$ and $q\in H_0^1(\Omega)$. Sensitivity coefficient $q\in H_0^1(\Omega)$ satisfies the variational inequality

$$\begin{aligned}&q\in S_0(\Omega),\\ &c^0(q,\zeta-q)\geqq\langle h'-C'w^0,\zeta-q\rangle\quad\forall\zeta\in S_0(\Omega)\end{aligned}\tag{3.20}$$

where

$$S_0(\Omega)=\{\zeta\in H_0^1(\Omega)\,|\,\zeta(x)\leqq0\ q.e.\ on\ \Omega_0(w^0),\ c^0(w^0,\zeta)=\langle h^0,\zeta\rangle\}\tag{3.21}$$

and

$$\Omega_0(w^0)=\{x\in\Omega \mid w^0(x)=1\}. \tag{3.22}$$

Proof. We apply Theorem 1 to variational inequality (3.18). Assumptions (i) and (ii) of Theorem 1 are obviously satisfied by operator C' and element h'.

We verify assumption (iii) of Theorem 1. Denote by $w^0=\pi(f^0)$ the unique solution to (3.18) for $t=0$.

By a result of Mignot [8] we have

$$\forall h\in H^{-1}(\Omega)\colon \pi(f^0+\tau h)=\pi(f^0)+\tau\pi'(h)+o(\tau) \tag{3.23}$$

where element $\pi'(h)\in S_0(\Omega)$ satisfies the variational inequality

$$c^0(\pi'(h),\zeta-\pi'(h))\geqq\langle h,\zeta-\pi'(h)\rangle \quad \forall\zeta\in S_0(\Omega). \tag{3.24}$$

Hence in this case $Q(h)\overset{\text{def}}{=}\pi'(h)$, $\forall h\in H^{-1}(\Omega)$.

Next Lemma 2 below applies to an obstacle problem posed in variable domain Ω_t

$$\begin{aligned}&w_t\in K(\Omega_t),\\&b_t(w_t,\zeta_t-w_t)\geqq\langle g_t,\zeta_t-w_t\rangle \quad \forall\zeta_t\in K(\Omega_t),\end{aligned} \tag{3.25}$$

where

$$K(\Omega_t)=\{\zeta_t\in H_0^1(\Omega_t)\mid \zeta_t(x)\leqq 1 \text{ a.e. in } \Omega_t\}, \tag{3.26}$$

$$\begin{aligned}b_t(y_t,\zeta_t)=\int_{\Omega_t}&\{\langle B(x)\cdot\operatorname{grad} y_t(x),\operatorname{grad}\zeta_t(x)\rangle_{R^n}\\&+\zeta_t(x)\langle \mathbf{b}(x),\operatorname{grad} y_t(x)\rangle_{R^n}+b_0(x)y_t(x)\zeta_t(x)\}\,dx\\&\qquad\forall y_t,\zeta_t\in H_0^1(\Omega_t),\quad t\in[0,\delta),\end{aligned} \tag{3.27}$$

$$\langle g_t,\zeta_t\rangle_t=\int_\Omega\{G_0(x)\zeta_t(x)+\langle \mathbf{G}(x),\operatorname{grad}\zeta_t(x)\rangle_{R^n}\}\,dx \qquad \forall\zeta_t\in H_0^1(\Omega_t). \tag{3.28}$$

Henceforth we assume that there exists a unique solution $w_t\in H_0^1(\Omega_t)$ to (3.25) for $t\in[0,\delta)$ and denote

$$\dot w(\Omega)=\lim_{t\downarrow 0}(w_t\circ T_t-w_0)/t. \tag{3.29}$$

LEMMA 2. *Assume that*

(i) $G_0(\cdot)\in C^1(R^n)$, $\quad \mathbf{G}(\cdot)\in[C^1(R^n)]^n$,

$B(\cdot)\in[C^1(R^n)]^{n^2}$, $\quad \mathbf{b}(\cdot)\in[C^1(R^n)]^n$,

$b_0(\cdot)\in C^1(R^n)$;

(ii) *There exists a constant* $\alpha>0$ *such that*

$$b_t(\zeta_t,\zeta_t)\geqq\alpha\|\zeta_t\|^2_{H_0^1(\Omega_t)} \quad \forall\zeta_t\in H_0^1(\Omega_t),\quad \forall t\in[0,\delta); \tag{3.30}$$

then mapping

$$[0,\delta)\ni t\to w_t\circ T_t\in H_0^1(\Omega) \tag{3.31}$$

is strongly differentiable at $t=0^+$ and the element $\dot{w}(\Omega)\in H_0^1(\Omega)$ satisfies the variational inequality

$$\begin{aligned}&\dot{w}(\Omega)\in S_1(\Omega),\\ &b_0(\dot{w}(\Omega),\zeta-\dot{w}(\Omega))\geqq\langle g'-B'w_0,\zeta-\dot{w}(\Omega)\rangle\quad\forall\zeta\in S_1(\Omega)\end{aligned}\tag{3.32}$$

where

$$\begin{aligned}&S_1(\Omega)=\{\zeta\in H_0^1(\Omega)\,|\,\zeta(x)\leqq 0 \text{ q.e. on } \Omega_1(w_0),\ b_0(w_0,\zeta)=\langle g_0,\zeta\rangle\},\\ &\Omega_1(w_0)=\{x\in\Omega\,|\,w_0(x)=1\}.\end{aligned}\tag{3.33}$$

Element $g'\in H^{-1}(\Omega)$ and operator $B'\in L(H_0^1(\Omega);\ H^{-1}(\Omega))$ are defined by (3.52) *and* (3.51), *respectively.*

Proof. Using mapping T_t we transport variational inequality (3.25) defined in Ω_t to the domain $\Omega=T_t^{-1}(\Omega_t)$. Then we can apply Lemma 1 to the resulting variational inequality defined in Ω. To this end we need the following notation:

$$B^t(x)=\gamma(t,x)(^*DT_t^{-1})(x)\cdot(B\circ T_t)(x)\cdot(DT_t^{-1})(x),\tag{3.34}$$

$$\mathbf{b}^t(x)=\gamma(t,x)(DT_t^{-1})(x)\cdot(\mathbf{b}\circ T_t)(x),\tag{3.35}$$

$$b_0^t(x)=\gamma(t,x)(b_0\circ T_t)(x),\tag{3.36}$$

$$\mathbf{G}^t(x)=\gamma(t,x)(^*DT_t^{-1})(x)\cdot(\mathbf{G}\circ T_t)(x),\tag{3.37}$$

$$G_0^t(x)=\gamma(t,x)(G_0\circ T_t)(x)\tag{3.38}$$

where $\gamma(t,x)=\det(DT_t(x))$,

$$\begin{aligned}b^t(y,\zeta)=\int_\Omega&\{\langle B^t(x)\operatorname{grad}y(x),\operatorname{grad}\zeta(x)\rangle_{R^n}\\ &+\zeta(x)\langle\mathbf{b}^t(x),\operatorname{grad}y(x)\rangle_{R^n}+b_0^t(x)y(x)\zeta(x)\}\,dx\qquad\forall y,\zeta\in H_0^1(\Omega),\end{aligned}\tag{3.39}$$

$$\langle g^t,\zeta\rangle=\int_\Omega\{G_0^t(x)\zeta(x)+\langle\mathbf{G}^t(x),\operatorname{grad}\zeta(x)\rangle_{R^n}\}\,dx\quad\forall\zeta\in H_0^1(\Omega).\tag{3.40}$$

It can be verified that

$$b^t(y_t\circ T_t,\zeta_t\circ T_t)=b_t(y_t,\zeta_t)\quad\forall y_t,\zeta_t\in H_0^1(\Omega_t),\tag{3.41}$$

$$\langle g^t,\zeta_t\circ T_t\rangle=\langle g_t,\zeta_t\rangle\quad\forall\zeta_t\in H_0^1(\Omega_t).\tag{3.42}$$

Furthermore

$$y_t\circ T_t\in K(\Omega)\quad\text{iff } y_t\in K(\Omega_t).\tag{3.43}$$

Hence it follows that element $w_t\circ T_t\in H_0^1(\Omega)$ satisfies the variational inequality

$$\begin{aligned}&w_t\circ T_t\in K(\Omega),\\ &b^t(w_t\circ T_t,\zeta-w_t\circ T_t)\geqq\langle g^t,\zeta-w_t\circ T_t\rangle\quad\forall\zeta\in K(\Omega).\end{aligned}\tag{3.44}$$

By assumption (iii) (see [14]), there exists a constant $\alpha=\alpha(\delta)>0$, for $\delta>0$, sufficiently small, such that

$$b^t(\zeta,\zeta)\geqq\alpha\|\zeta\|^2_{H_0^1(\Omega)}\quad\forall\zeta\in H_0^1(\Omega),\quad\forall t\in[0,\delta).\tag{3.45}$$

Hence there exists a unique solution to (3.44). In order to apply Lemma 1 to variational inequality (3.44), we calculate derivatives with respect to t at $t=0^+$ of the coefficients of bilinear form $b^t(\cdot,\cdot)$ and linear forms $g^t\in H^{-1}(\Omega)$. We obtain

$$\frac{\partial B^t}{\partial t}(x)=(\operatorname{div}\mathbf{V})(x)B(x)-((^*D\mathbf{V})(x)\cdot B(x)+B(x)\cdot(D\mathbf{V})(x))+\hat{B}(x) \tag{3.46}$$

where

$$\hat{B}=[\hat{b}_{ij}]_{n\times n},$$

$$\hat{b}_{ij}(\mathbf{x})=\sum_{k=1}^{n}\frac{\partial}{\partial x_k}b_{ij}(x)V_k(x),\qquad i,j=1,\cdots,n,$$

$$\frac{\partial \mathbf{b}^t}{\partial t}(x)=(\operatorname{div}\mathbf{V})(x)\mathbf{b}(x)-(D\mathbf{V})(x)\cdot\mathbf{b}(x)+\hat{\mathbf{b}}(x), \tag{3.47}$$

$$\hat{\mathbf{b}}=\operatorname{col}(\hat{b}_1,\cdots,\hat{b}_n),$$

$$\hat{b}_i(x)=\sum_{k=1}^{n}\frac{\partial}{\partial x_k}b_i(x)V_k(x),\qquad i=1,\cdots,n,$$

$$\frac{\partial b_0^t}{\partial t}(x)=\operatorname{div}(b_0\mathbf{V})(x), \tag{3.48}$$

$$\frac{\partial \mathbf{G}^t}{\partial t}(x)=(\operatorname{div}\mathbf{V})(x)\mathbf{G}(x)-(^*D\mathbf{V})(x)\cdot\mathbf{G}(x)+\hat{\mathbf{G}}(x), \tag{3.49}$$

$$\frac{\partial G_0^t}{\partial t}x=\operatorname{div}(G_0\mathbf{V})(x) \tag{3.50}$$

where $\mathbf{V}(x)=\mathbf{V}(0,x)$ and $\hat{\mathbf{G}}(x)$ is defined in exactly the same way as $\hat{\mathbf{b}}(x)$.

Denote by $B'\in L(H_0^1(\Omega);H^{-1}(\Omega))$, $g'\in H^{-1}(\Omega)$

$$\begin{aligned}\langle B'y,\zeta\rangle=\int_\Omega\Big\{&\Big\langle\frac{\partial B^t}{\partial t}(x)\operatorname{grad}y(x),\operatorname{grad}\zeta(x)\Big\rangle_{R^n}\\&+y(x)\Big\langle\frac{\partial \mathbf{b}^t}{\partial t}(x),\operatorname{grad}\zeta(x)\Big\rangle_{R^n}+\frac{\partial b_0^t}{\partial t}(x)y(x)\zeta(x)\Big\}\,dx\end{aligned} \tag{3.51}$$

$$\forall y,\zeta\in H_0^1(\Omega),$$

$$\langle g',\zeta\rangle=\int_\Omega\Big\{\frac{\partial G_0^t}{\partial t}(x)\zeta(x)+\Big\langle\frac{\partial \mathbf{G}^t}{\partial t}(x),\operatorname{grad}\zeta(x)\Big\rangle_{R^n}\Big\}\,dx\quad\forall\zeta\in H_0^1(\Omega). \tag{3.52}$$

Since, in the case of variational inequality (3.44), all assumptions of Lemma 1 are satisfied it follows that

$$w_t\circ T_t=w_0+t\dot{w}(\Omega)+o(t)$$

where $\|o(t)\|_{H_0^1(\Omega)}/t\to 0$ with $t\downarrow 0$ and element $\dot{w}(\Omega)\in H_0^1(\Omega)$ is a unique solution to (3.32).

We now characterize the domain derivative

$$w'=\dot{w}-\langle\operatorname{grad}w_0,\mathbf{V}\rangle_{R^n} \tag{3.53}$$

in the case of variational inequality (3.25).

We prove that w' depends actually on $v=\langle\mathbf{V}(0),\mathbf{n}\rangle_{R^n}$, v is the normal component of the vector field $\mathbf{V}(0)$ on Γ.

LEMMA 3. *If assumptions* (i) *and* (ii) *of Lemma* 2 *are satisfied, then the domain derivative* $w' \in H^1(\Omega)$ *satisfies the variational inequality*

$$\begin{aligned} &w' \in S_v^0(\Omega), \\ &b_0(w', \zeta - w') \geqq 0 \quad \forall \zeta \in S_v^0(\Omega) \end{aligned} \tag{3.54}$$

where

$$\begin{aligned} S_v^0(\Omega) = \Bigg\{ \zeta \in H^1(\Omega) \,|\, \zeta|_\Gamma = -\mathbf{v}\frac{\partial w_0}{\partial n},\ \zeta(x) \leqq 0 \text{ } q.e. \text{ } on\, Z(w_0-1), \\ \cdot \int_{Z(w_0-1)} (G_0(x) - b_0(x) - \operatorname{div} \mathbf{G}(x))\zeta(x)\,dx = 0 \Bigg\}, \end{aligned} \tag{3.55}$$

$$Z(w_0-1) = \{x \in \Omega \,|\, w_0(x) = 1\}.$$

Proof. If the assumptions of Lemma 2 are satisfied then (see [1])

$$w_0 \in H^2(\Omega) \cap C^{1,\alpha}(\bar{\Omega}) \quad \forall \alpha < 1. \tag{3.56}$$

Hence $\langle \operatorname{grad} w_0, \mathbf{V} \rangle_{R^n} \in H^1(\Omega)$ for an arbitrary regular vector field $\mathbf{V} = \mathbf{V}(0, \cdot)$.

Denote

$$S_v^0(\Omega) = \{\phi \in H^1(\Omega) \,|\, \phi = \zeta - \langle \operatorname{grad} w_0, \mathbf{V} \rangle_{R^n},\ \zeta \in S_2(\Omega)\}. \tag{3.57}$$

Simple calculations show, by taking into account (3.56), that cone (3.57) has the form (3.55).

Note that

$$S_v^0(\Omega) - S_v^0(\Omega) = S_2(\Omega) - S_2(\Omega). \tag{3.58}$$

On the other hand, it follows from (3.53) that

$$\begin{aligned} &w' \in S_v^0(\Omega), \\ &b_0(w', \zeta - w') \geqq G(w_0, \mathbf{V}, \zeta - w') \quad \forall \zeta \in S_v^0(\Omega) \end{aligned} \tag{3.59}$$

where

$$G(w_0, \mathbf{V}, \zeta) = \langle g' - B'w_0, \zeta \rangle - b_0(\langle \operatorname{grad} w_0, \mathbf{V} \rangle_{R^n}, \zeta). \tag{3.60}$$

Element $g' \in H^{-1}(\Omega)$ and operator $B' \in L(H_0^1(\Omega);\ H^{-1}(\Omega))$ are defined by (3.52) and (3.51), respectively.

Observe that for a vector field $\mathbf{V}$ such that $\langle \mathbf{V}, \mathbf{n} \rangle_{R^n} = 0$ on Γ, the mapping $[0, \delta) \ni t \to \Omega_t \subset R^n$ is constant, i.e. $\Omega_t = \Omega$, $t \in [0, \delta)$, hence $w' = 0$ and $\dot{w} = \langle \operatorname{grad} w_0, \mathbf{V} \rangle_{R^n}$, whence

$$0 \geqq G(w_0, \mathbf{V}, \zeta) \quad \forall \zeta \in \{S_2(\Omega) - S_2(\Omega)\}. \tag{3.61}$$

If we put $\pm\mathbf{V}$ in (3.61) then we obtain

$$G(w_0, \mathbf{V}, \zeta) = 0 \quad \forall \zeta \in \{S_2(\Omega) - S_2(\Omega)\} \tag{3.62}$$

for an arbitrary vector field $\mathbf{V}$ such that $\mathbf{V}|_\Gamma \cdot \mathbf{n} = 0$, where we denote $\mathbf{V}|_\Gamma \cdot \mathbf{n} = \langle \mathbf{V}|_\Gamma, \mathbf{n} \rangle_{R^n}$.

From a general result of J. P. Zolesio [15] it follows that there exists a distribution $g_n \in D_1'(\Gamma)$ such that

$$G(w_0, \mathbf{V}, \zeta) = \langle g_n(w_0, \zeta), \mathbf{V} \cdot \mathbf{n} \rangle_{D_1'(\Gamma) \times D_1(\Gamma)} \quad \forall \zeta \in \{S_2(\Omega) - \mathrm{S}_2^0(\Omega)\} \tag{3.63}$$

and domain derivative $w' \in H^1(\Omega)$ satisfies the variational inequality

$$\begin{aligned} &w' \in S_v(\Omega), \\ &b_0(w', \zeta - w') \geqq \langle g_n(w_0, \zeta - w'), \mathbf{V} \cdot \mathbf{n} \rangle_{D_1'(\Gamma) \times D_1(\Gamma)} \quad \forall \zeta \in S_v^0(\Omega). \end{aligned} \tag{3.64}$$

Taking into account (3.56) and by integrating by parts we obtain

$$G(w_0, \mathbf{V}, \zeta) = \int_\Omega K(w_0, \zeta) \cdot \mathbf{V}\, dx + \int_\Gamma g_n(w_0, \zeta)\mathbf{V} \cdot \mathbf{n}\, d\Gamma \qquad \forall \zeta \in H^2(\Omega) \cap \{S_v^0(\Omega) - S_v^0(\Omega)\}, \tag{3.65}$$

and from (3.63) it follows that

$$\mathbf{K}(w_0, \zeta) = \mathbf{0} \quad \forall \zeta \in H^2(\Omega) \cap \{S_v^0(\Omega) - S_v^0(\Omega)\}. \tag{3.66}$$

Simple calculations show (see [14]) that

$$\int_\Gamma g_n(w_0, \zeta)\mathbf{V} \cdot \mathbf{n}\, d\Gamma = 0 \quad \forall \zeta \in H^2(\Omega) \cap H_0^1(\Omega). \tag{3.67}$$

Hence

$$G(w_0, \mathbf{V}, \zeta) = 0 \quad \forall \zeta \in H^2(\Omega) \cap \{S_v^0(\Omega) - S_v^0(\Omega)\}. \tag{3.68}$$

In order to prove that (3.68) is satisfied for an arbitrary element $\zeta \in \{S_v^0(\Omega) - S_v^0(\Omega)\}$, consider vector field $\mathbf{V}$ with compact support in some open neighbourhood of the boundary $\Gamma = \partial\Omega$. Let U, $U_1 \subset \Omega$ be open sets such that $\bar{U} \subset U_1$, $\overline{Z(w_0 - 1)} \subset U$ and let $\eta(\cdot)$ be a smooth function such that

$$\begin{aligned} &0 \leqq \eta(x) \leqq 1, \quad x \in \bar{\Omega}, \\ &\eta(x) = 1, \quad x \in U, \\ &\eta(x) = 0, \quad x \in \bar{\Omega} \backslash U_1. \end{aligned} \tag{3.69}$$

Given an element $\phi \in \{S_v^0(\Omega) - S_v^0(\Omega)\}$, let $\{\phi_n\} \subset H_0^1(\Omega) \cap H^2(\Omega)$ be a sequence such that

$$\phi_n \to \phi \quad \text{strongly in } H_0^1(\Omega). \tag{3.70}$$

Note that the sequence

$$\zeta_n = (1 - \eta)\phi_n \in \{S_v^0(\Omega) - S_v^0(\Omega)\} \cap H^2(\Omega) \tag{3.71}$$

for every vector field $\mathbf{V} \equiv 0$ on U_1.

Since

$$G(w_0, \mathbf{V}, \phi_n) = \int_\Gamma g_n(w_0, (1 - \eta)\phi_n)\mathbf{V} \cdot \mathbf{n}\, d\Gamma = 0, \qquad n = 1, 2, \cdots,$$

it follows that

$$G(w_0, \mathbf{V}, \phi) = \lim_{n \to \infty} G(w_0, \mathbf{V}, \phi_n) = 0 \qquad \forall \phi \in \{S_v^0(\Omega) - S_v^0(\Omega)\}.$$

Proof of Theorem 2. In order to use Lemma 3 we make a particular choice of coefficients of bilinear form $b_t(\cdot, \cdot)$ and linear form $\langle g_t, \cdot \rangle$ in order to obtain the solution $z_t \in H^1(\Omega_t)$ to the problem (3.7) in the form

$$z_t = \beta w_t + \phi, \qquad t \in [0, \delta) \tag{3.72}$$

where $w_t \in H_0^1(\Omega_t)$ is a unique solution to the problem (3.25), $\beta(x) = \psi_0(x) - \phi(x)$, $x \in R^n$. We select the coefficients $B(\cdot)$, $\mathbf{b}(\cdot)$, $b_0(\cdot)$ of bilinear form (3.27) and the coefficients $G_0(\cdot)$, $\mathbf{G}(\cdot)$ of linear form (3.28) in the following way:

$$B(x) = \beta^2(x)A(x), \tag{3.73}$$

$$\mathbf{b}(x) = \beta(x)({}^*A(x) - A(x)) \cdot \nabla\beta(x) + \beta^2(x)\mathbf{a}(x), \tag{3.74}$$

$$b_0(x) = \beta(x)(\beta(x)a_0(x) + \mathbf{a}(x) \cdot \nabla\beta - \operatorname{div}(A(x) \cdot \nabla\beta(x))), \tag{3.75}$$

$$\begin{aligned} G_0(x) &= \beta(x)(F_0(x) - \mathbf{a}(x) \cdot \nabla\phi(x) - a_0(x)\phi(x)) + \mathbf{F}(x) \cdot \nabla\beta(x) \\ &\quad - \langle A(x) \cdot \nabla\phi(x), \nabla\beta(x)\rangle_{R^n}, \end{aligned} \tag{3.76}$$

$$\mathbf{G}(x) = \beta(x)(\mathbf{F}(x) - A(x) \cdot \nabla\phi(x)) \tag{3.77}$$

where $A(\cdot)$, $\mathbf{a}(\cdot)$, $a_0(\cdot)$ and $F_0(\cdot)$, $\mathbf{F}(\cdot)$ are the coefficients of bilinear form (3.8) and linear form (3.9), respectively.

Using (3.73)-(3.77) we obtain

$$b_t(w_t, \xi_t) = a_t(\beta w_t, \beta\xi_t) \quad \forall w_t, \xi_t \in H_0^1(\Omega_t), \tag{3.78}$$

$$\langle g_t, \xi_t\rangle_t = \langle f_t, \beta\xi_t\rangle_t - a_t(\phi, \beta\xi_t) \quad \forall \xi_t \in H_0^1(\Omega_t), \tag{3.79}$$

therefore simple calculations show that (3.72) holds.

The domain derivative $w' \in H^1(\Omega)$ for the problem (3.25) is given by (3.54), henceforth, in view of (3.72), it follows that there exists the domain derivative $z' \in H^1(\Omega)$ for the problem (3.7) of the form

$$z' = \beta w'. \tag{3.80}$$

Furthermore, $z'/\beta \in S_v^0(\Omega)$.

Let us denote by $S_v(\Omega) \subset H^1(\Omega)$ a closed and convex cone such that $z' \in S_v(\Omega)$. Furthermore,

$$\beta\xi \in S_v(\Omega) \quad \text{iff } \xi \in S_v^0(\Omega).$$

Let $\eta \in S_v(\Omega)$ be a given element; then $\xi = \eta/\beta \in S_v^0(\Omega)$ and using (3.55) we obtain

(i) $\eta = -v(\partial/\partial n)(z_0 - \phi)$ on Γ, since $\xi = \eta/\beta = -v(\partial w_0/\partial n)$ on Γ and $w_0 = (z_0 - \phi)/(\psi_0 - \phi)$;

(ii) $\eta \geqq 0$ q.e. on $Z(z_0 - \psi_0)$ since $\eta/\beta \leqq 0$ q.e. on $Z(w_0 - 1)$ and $\beta(x) < 0$ for all $x \in R^n$;

(iii) It can be shown, in view of (3.75)-(3.77), that using the integral condition on $Z(w_0 - 1)$ we obtain

$$\begin{aligned} \int_{Z(z_0 - \psi_0)} &(F_0(x) - \operatorname{div} \mathbf{F}(x) - \mathbf{a}(x) \cdot \nabla\psi_0(x) - a_0(x)\psi_0(x) \\ &+ \operatorname{div}(A(x) \cdot \nabla\psi_0(x)))\eta(x)\, dx = 0. \end{aligned}$$

4. Sensitivity analysis of the Signorini variational inequality. Let $\Omega \in R^2$ be a domain with smooth boundary $\Gamma = \partial\Omega$. Given a vector field $\mathbf{V}(t, x)$, $t \in [0, \delta)$, $x \in R^2$, let $\{\Omega_t\} \subset R^2$ be the corresponding family of domains (3.4). We assume that $\Omega_t \subset R^2$, for each $t \in [0, \delta)$ is a bounded connected region with smooth boundary $\partial\Omega_t$ and may be expressed as

$$\partial\Omega_t = \Gamma_t^0 \cup \Gamma_t^1 \cup \Gamma_t^c \tag{4.1}$$

where $\Gamma_t^0, \Gamma_t^1, \Gamma_t^c$ are smooth, disjoint and open one-dimensional manifolds.

We assume that Ω_t lies on one side of $\partial\Omega_t$ and that the one-dimensional measures of Γ_t^0, Γ_t^c are strictly positive for $t \in [0, \delta)$.

We denote $\partial\Omega=\Gamma^0\cup\Gamma^1\cup\Gamma^c$. Furthermore, $\mathbf{n}=(n_t^1, n_t^2)$ and $\mathbf{n}=(n_1, n_2)$ denote the unit outward normals to $\partial\Omega_t$ and $\partial\Omega$, respectively. A vector function $\mathbf{V}_t$ and a tensor function $\boldsymbol{\tau}_t$ defined on Ω_t have components v_t^i, τ_t^{ij}, respectively, for $i, j=1,2$. A vector function $\mathbf{v}$ and tensor functions $\boldsymbol{\tau}$, $\mathbf{c}$ defined on R^2 or on Ω have components v_i, τ_{ij}, c_{ijkl} respectively, and $i, j, k, l=1,2$.

We use the summation convention of summing on all repeated indices. The following notation is used for the scalar product of vectors:

$$\boldsymbol{\zeta}\cdot\mathbf{n}=\zeta_i n_i \tag{4.2}$$

and for the convolution of tensors:

$$\begin{gathered}\mathbf{e}\,..\,\mathbf{c}\,..\,\boldsymbol{\tau}=c_{ijkl}e_{ij}\tau_{kl},\\ \boldsymbol{\zeta}\,.\,\boldsymbol{\tau}\,.\,\mathbf{v}=\tau_{ij}\zeta_i v_j,\\ (\boldsymbol{\tau}\cdot\mathbf{v})_i=\tau_{ij}v_j.\end{gathered} \tag{4.3}$$

Denote

$$\mathbf{H}(\Omega_t)=\{\boldsymbol{\zeta}_t\in[H^1(\Omega_t)]^2\,|\,\boldsymbol{\zeta}_t(x)=\mathbf{0}, x\in\Gamma_t^0\} \tag{4.4}$$

and let $\mathbf{K}(\Omega_t)$ be a convex and closed set of the form

$$\mathbf{K}(\Omega_t)=\{\boldsymbol{\zeta}_t\in\mathbf{H}(\Omega_t)\,|\,\boldsymbol{\zeta}_t\cdot\mathbf{n}_t\leqq 0 \text{ a.e. on } \Gamma_t^c\}. \tag{4.5}$$

Given a tensor function $\mathbf{c}$ with components $c_{ijkl}\in L^\infty_{\text{loc}}(R^2)$, $i, j, k, l=1,2$, assume that the following conditions are satisfied:

$$c_{ijkl}(x)=c_{jikl}(x)=c_{klij}(x),\quad x\in R^2,\quad i, j, k, l=1,2, \tag{4.6}$$

$\exists\nu_0>0$ such that

$$c_{ijkl}(x)e_{ij}e_{kl}\geqq\nu_0 e_{ij}e_{ij},\qquad x\in R^2 \tag{4.7}$$

for every symmetric tensor $\mathbf{e}$.

Denote $\mathbf{a}_t(\cdot,\cdot)$, $t\in[0,\delta)$, the bilinear form

$$\mathbf{a}_t(\mathbf{v}_t,\zeta_t)=\int_{\Omega_t}\boldsymbol{\varepsilon}(\mathbf{v}_t)\,..\,\mathbf{c}\,..\,\boldsymbol{\varepsilon}(\boldsymbol{\zeta}_t)\,dx \tag{4.8}$$

where the symmetric tensor $\boldsymbol{\varepsilon}(\mathbf{v})$ have components

$$\varepsilon_{ij}(\mathbf{v})(x)=\frac{1}{2}\left(\frac{\partial v_j}{\partial x_i}(x)+\frac{\partial v_i}{\partial x_j}(x)\right). \tag{4.9}$$

Given elements $\mathbf{f}=(f_1, f_2)\in[L^2(R^2)]^2$, $\mathbf{P}=(P_1, P_2)\in[H^1(R^2)]^2$, denote $\mathbf{F}_t\in(\mathbf{H}(\Omega_t))'$

$$\langle\mathbf{F}_t,\boldsymbol{\zeta}_t\rangle_t\overset{\text{def}}{=}\int_{\Omega_t}f_i(x)\zeta_t^i(x)\,dx+\int_{\Gamma_t^1}P_i(x)\zeta_t^i(x)\,d\Gamma\quad\forall\boldsymbol{\zeta}_t\in\mathbf{H}(\Omega_t). \tag{4.10}$$

Consider, for $t\in[0,\delta)$, the Signorini variational inequality

$$\begin{gathered}\mathbf{u}_t\in\mathbf{K}(\Omega_t),\\ \mathbf{a}_t(\mathbf{u}_t,\boldsymbol{\zeta}_t-\mathbf{u}_t)\geqq\langle\mathbf{F}_t,\boldsymbol{\zeta}_t-\mathbf{u}_t\rangle\quad\forall\boldsymbol{\zeta}_t\in\mathbf{K}(\Omega_t).\end{gathered} \tag{4.11}$$

THEOREM 3. *Mapping*

$$[0,\delta)\ni t\to u_t\circ T_t\in\mathbf{H}(\Omega) \tag{4.12}$$

is differentiable at $t=0^+$, *i.e.*,

$$\mathbf{u}_t \circ T_t = \mathbf{u}_0 + t\dot{\mathbf{u}} + o(t) \tag{4.13}$$

where $\|o(t)\|_{\mathbf{H}(\Omega)}/t \to 0$ *with* $t \downarrow 0$.

The element $\dot{\mathbf{u}} \in \mathbf{H}(\Omega)$ is a unique solution to the variational inequality

$$\begin{aligned} &\dot{\mathbf{u}} \in \mathbf{S}(\Omega), \\ &\mathbf{a}_0(\dot{\mathbf{u}}, \boldsymbol{\zeta}-\dot{\mathbf{u}}) \geqq \langle \mathbf{F}' - B\mathbf{u}_0, \boldsymbol{\zeta}-\dot{\mathbf{u}}\rangle + \mathbf{a}_0(D\mathbf{V}\cdot\mathbf{u}_0, \boldsymbol{\zeta}-\dot{\mathbf{u}}) \quad \forall \boldsymbol{\zeta} \in \mathbf{S}(\Omega) \end{aligned} \tag{4.14}$$

where

$$\begin{aligned} \mathbf{S}(\Omega) = \{\boldsymbol{\zeta} \in \mathbf{H}(\Omega) \,|\, \mathbf{n}\cdot\boldsymbol{\zeta} \leqq \mathbf{n}\cdot D\mathbf{V}\cdot\mathbf{u}_0 \text{ a.e. on } Z(\mathbf{u}_0) \subset \Gamma^c, \\ \mathbf{a}_0(\mathbf{u}_0, \zeta) - \langle \mathbf{F}_0, \boldsymbol{\zeta}\rangle = \mathbf{a}_0(D\mathbf{V}\cdot\mathbf{u}_0, \mathbf{u}_0)\}, \end{aligned} \tag{4.15}$$

$$Z(\mathbf{u}_0) = \{x \in \Gamma^c \,|\, \mathbf{u}_0(x)\cdot\mathbf{n}(x) = 0\}. \tag{4.16}$$

Element $\mathbf{F}' \in (\mathbf{H}(\Omega))'$ and operator $B \in L(\mathbf{H}(\Omega); (\mathbf{H}(\Omega))')$ are defined by (4.55) and (4.56) respectively.

For the proof of Theorem 3 we need some lemmas. First consider sensitivity analysis of the Signorini variational inequality defined in Ω:

$$\begin{aligned} &\mathbf{w}^t \in \mathbf{K}(\Omega), \\ &\mathbf{b}^t(\mathbf{w}^t, \boldsymbol{\zeta}-\mathbf{w}^t) \geqq \langle \mathbf{G}^t, \boldsymbol{\zeta}-\mathbf{w}^t\rangle \quad \forall \boldsymbol{\zeta} \in \mathbf{K}(\Omega) \end{aligned} \tag{4.17}$$

where

$$\mathbf{b}^t(\mathbf{w}, \boldsymbol{\zeta}) = \int_\Omega \boldsymbol{\varepsilon}(\mathbf{w}) \,..\, \mathbf{b}(t) \,..\, \boldsymbol{\varepsilon}(\boldsymbol{\zeta})\, dx, \tag{4.18}$$

$$\langle \mathbf{G}^t, \boldsymbol{\zeta}\rangle = \int_\Omega g_i(t,x)\zeta_i(x)\,dx + \int_{\Gamma^1} G_i(t,x)\zeta_i(x)\,dx, \tag{4.19}$$

$\mathbf{b}(t)$, $t \in [0, \delta)$, is a tensor function with components $b_{ijkl}(t,x)$—we assume that conditions (4.6) and (4.7) are satisfied by $b_{ijkl}(\cdot,\cdot)$ on $[0,\delta)\times\Omega$, $i, j, k, l = 1, 2$. Furthermore

$$b_{ijkl}(\cdot,\cdot) \in C([0,\delta); L^\infty(\Omega)),$$

$$\frac{\partial b_{ijkl}}{\partial t}(0,\cdot) \in L^\infty(\Omega), \qquad i, j, k, l = 1, 2.$$

Elements $g_i \in C([0,\delta); L^2(\Omega))$, $G_i \in C([0,\delta); L^2(\Gamma^1))$ are assumed to be differentiable with respect to t, at point $t = 0^+$ with

$$\frac{\partial g_i}{\partial t}(0,\cdot) \in \mathrm{L}^2(\Omega),$$

$$\frac{\partial G_i}{\partial t}(0,\cdot) \in L^2(\Gamma^1), \qquad i = 1, 2.$$

We also need the following notation. Let $E \in L(\mathbf{H}(\Omega); (\mathbf{H}(\Omega))')$, $\mathbf{G}' \in (\mathbf{H}(\Omega))'$ be defined as follows

$$\langle E\mathbf{w}, \boldsymbol{\zeta}\rangle = \int_\Omega \frac{\partial b_{ijkl}}{\partial t}(0,x)\varepsilon_{ij}(\mathbf{w})(x)\varepsilon_{kl}(\boldsymbol{\zeta})(x)\,dx \quad \forall \mathbf{w}, \boldsymbol{\zeta} \in \mathbf{H}(\Omega), \tag{4.20}$$

$$\langle \mathbf{G}', \boldsymbol{\zeta}\rangle = \int_\Omega \frac{\partial g_i}{\partial t}(0,x)\zeta_i(x)\,dx + \int_{\Gamma^1} \frac{\partial G_i}{\partial t}(0,x)\zeta_i(x)\,d\Gamma \quad \forall \boldsymbol{\zeta} \in \mathbf{H}(\Omega). \tag{4.21}$$

LEMMA 4. *Mapping*

$$[0,\delta)\ni t\to w^t\in \mathbf{H}(\Omega) \tag{4.22}$$

is differentiable at $t=0^+$, *i.e.*,

$$\mathbf{w}^t=\mathbf{w}^0+t\mathbf{r}+o(t), \tag{4.23}$$

where $\|o(t)\|_{\mathbf{H}(\Omega)}/t\to 0$ *with* $t\downarrow 0$ *and the element* $\mathbf{r}\in\mathbf{H}(\Omega)$ *is a unique solution to the variational inequality*

$$\begin{aligned}&\mathbf{r}\in \mathbf{S}_1(\Omega),\\ &\mathbf{b}^0(\mathbf{r},\boldsymbol{\zeta}-\mathbf{r})\geqq\langle \mathbf{G}'-E\mathbf{w}^0,\boldsymbol{\zeta}-\mathbf{r}\rangle\quad \forall\boldsymbol{\zeta}\in\mathbf{S}_1(\Omega)\end{aligned} \tag{4.24}$$

where

$$\mathbf{S}_1(\Omega)=\{\boldsymbol{\zeta}\in\mathbf{H}(\Omega)\,|\,\boldsymbol{\zeta}\cdot\mathbf{n}\leqq 0 \textit{ a.e. on } Z(\mathbf{w}^0)\subset\Gamma^c,\ \mathbf{b}^0(\mathbf{w}^0,\boldsymbol{\zeta})=\langle\mathbf{G}^0,\boldsymbol{\zeta}\rangle\}. \tag{4.25}$$

Proof. We shall apply Theorem 1. Assumptions (i) and (ii) of Theorem 1 are verified by linear operator $E\in L(\mathbf{H}(\Omega);\ (\mathbf{H}(\Omega))')$ and element $\mathbf{G}'\in(\mathbf{H}(\Omega))'$. We have to verify assumption (iii) of Theorem 1.

Assume that the outward unit normal vector on Γ^c has the form

$$\mathbf{n}(x)=(1,0),\qquad x\in\Gamma^c, \tag{4.26}$$

and denote by $R\in L(\mathbf{H}(\Omega);\ L^2(\Gamma^c))$ the linear mapping

$$(R\boldsymbol{\zeta})(x)=\zeta_1(x)=\mathbf{n}(x)\cdot\boldsymbol{\zeta}(x),\qquad x\in\Gamma^c\quad\forall\boldsymbol{\zeta}\in\mathbf{H}(\Omega). \tag{4.27}$$

Denote by $H(\Gamma^c)\subset L^2(\Gamma^c)$ the linear subspace

$$H(\Gamma^c)=\{\eta\in L^2(\Gamma^c)\,|\,\exists\boldsymbol{\zeta}\in\mathbf{H}(\Omega)\text{ such that }R\boldsymbol{\zeta}=\eta\}. \tag{4.28}$$

Define scalar product $((\cdot,\cdot))$ in space $H(\Gamma^c)$

$$((\eta_1,\eta_2))\overset{\text{def}}{=}\mathbf{b}^0(R^{-1}\eta_1,R^{-1}\eta_2)\quad\forall\eta_1,\eta_2\in H(\Gamma^c). \tag{4.29}$$

It can be verified that space $H(\Gamma^c)$ with scalar product (4.29) is a Hilbert space. Consider the following variational inequality posed on Γ^c, given element $\mathbf{h}\in(\mathbf{H}(\Omega))'$, determine $\Phi(\mathbf{h})$:

$$\begin{aligned}&\Phi(\mathbf{h})\in K(\Gamma^c)=\{\eta\in H(\Gamma^c)\,|\,\eta(x)\geqq 0\text{ a.e. on }\Gamma^c\},\\ &((\Phi(\mathbf{h}),\eta-\Phi(\mathbf{h})))\geqq\langle\mathbf{h},R^{-1}(\eta-\Phi(\mathbf{h}))\rangle\quad\forall\eta\in K(\Gamma^c).\end{aligned} \tag{4.30}$$

Denote by $\mathbf{w}^0=P(\mathbf{G}^0)$ the solution of (4.17) for $t=0$. It follows that

$$P(\mathbf{G}^0)=R^{-1}\Phi(\mathbf{G}^0)+Y(\mathbf{G}^0) \tag{4.31}$$

where the element $Y(\mathbf{G}^0)$ solves the variational equation

$$\begin{aligned}&Y(\mathbf{G}^0)\in\mathbf{H}_1(\Omega)=\ker R,\\ &b^0(Y(\mathbf{G}^0),\boldsymbol{\zeta})=\langle\mathbf{G}^0,\boldsymbol{\zeta}\rangle\quad\forall\boldsymbol{\zeta}\in\mathbf{H}_1(\Omega).\end{aligned} \tag{4.32}$$

Assume for the moment that the following conditions are satisfied:

$$\eta^+,\eta^-\in H(\Gamma^c)\quad\forall\eta\in H(\Gamma^c) \tag{A1}$$

where $\eta^+=\max\{0,\eta\}$,

$$((\eta^+,\eta^-))\leqq 0\quad\forall\eta\in H(\Gamma^c), \tag{A2}$$

$$H(\Gamma^c)\cap C_{\text{comp}}(\Gamma^c)\text{ is dense in }C_{\text{comp}}(\Gamma^c). \tag{A3}$$

Then from a result of Mignot [8] it follows that the solution to (4.30) is conically differentiable with respect to $\mathbf{h} \in (\mathbf{H}(\Omega))'$, i.e., $\forall \mathbf{z} \in (\mathbf{H}(\Omega))'$,

$$\Phi(\mathbf{h}+\tau\mathbf{z}) = \Phi(\mathbf{h}) + \tau w(\mathbf{z}) + o(\tau) \tag{4.33}$$

where $\| o(\tau) \|_{\mathbf{H}(\Gamma^c)}/\tau \to 0$ with $\tau \downarrow 0$ and the element $w(\mathbf{z}) \in H(\Gamma^c)$ is a unique solution of the variational inequality

$$\begin{aligned} & w(\mathbf{z}) \in S(\Gamma^c), \\ & ((w(\mathbf{z}), \eta - w(\mathbf{z}))) \geqq \langle \mathbf{z}, R^{-1}(\eta - w(\mathbf{z}))\rangle \quad \forall \eta \in S(\Gamma^c), \end{aligned} \tag{4.34}$$

where

$$S(\Gamma^c) = \{\eta \in H(\Gamma^c) \mid \eta(x) \leqq 0 \text{ a.e. on } Z(\Phi(\mathbf{h})) \subset \Gamma^c, ((\Phi(\mathbf{h}), \eta)) = \langle \mathbf{h}, R^{-1}\eta\rangle\}, \tag{4.35}$$

$$Z(\Phi(\mathbf{h})) = \{x \in \Gamma^c \mid \Phi(\mathbf{h})(x) = 0\}. \tag{4.36}$$

Hence, taking into account (4.31) we obtain $\forall \mathbf{z} \in (\mathbf{H}(\Omega))'$,

$$P(\mathbf{G}^0 + \tau\mathbf{z}) = P(\mathbf{G}^0) + \tau Q(\mathbf{z}) + o(\tau) \tag{4.37}$$

where

$$Q(\mathbf{z}) \overset{\text{def}}{=} R^{-1}w(\mathbf{z}) + Y(\mathbf{z}), \tag{4.38}$$

which implies that assumption (iii) of Theorem 1 is verified. From (1.11) follows (4.23) with

$$\mathbf{r} = Q(\mathbf{G}' - E\mathbf{w}^0).$$

The form (4.25) of cone $S_1(\Omega)$ can be obtained by simple calculations, taking into account (4.34), (4.35) and (4.36). Assumption (4.26) is not restrictive, since for $\Gamma^c \subset C^{1,1}$ the following linear transformation of displacement field $\boldsymbol{\zeta}$ can be defined

$$\begin{gathered} [H^1(\Omega)]^2 \ni \boldsymbol{\psi} \to \boldsymbol{\zeta} \in [H^1(\Omega)]^2, \\ \psi_1 = N_1\zeta_1 + N_2\zeta_2, \\ \psi_2 = -N_2\zeta_1 + N_1\zeta_2 \end{gathered}$$

where $N(\cdot) \in [W^{1,\infty}(\Omega)]^2$ is an extension of normal field $\mathbf{n}(x)$, $x \in \Gamma$. Since

$$\mathbf{n}(x) \cdot \boldsymbol{\zeta}(x) = \psi_1(x), \qquad x \in \Gamma^c,$$

it follows that for displacement field $\boldsymbol{\psi}$ condition (4.26) is satisfied.

For the proof of (A1)–(A3) see the following Lemma 5.

LEMMA 5. *Assumptions* (A1)–(A3) *are satisfied.*

Proof. Assumption (A1) is obviously verified since space $H(\Gamma^c)$ is a closed, linear subspace of Sobolev space $H^{1/2}(\Gamma^c)$. It follows from a general property of Sobolev spaces $H^{1/2}$ [7] that assumption (A3) is satisfied. We prove that (A2) holds.

Recall that

$$(R\boldsymbol{\zeta})(\cdot) = \zeta_1(\cdot) \in H(\Gamma^c) \quad \forall \boldsymbol{\zeta} = (\zeta_1, \zeta_2) \in \mathbf{H}(\Omega).$$

Let $\eta \in H(\Gamma^c)$ be a given element, and denote

$$\boldsymbol{\zeta}^* = R^{-1}\eta, \qquad \zeta^* = (\zeta_1^*, \zeta_2^*). \tag{4.39}$$

We denote $b(\cdot, \cdot) = \mathbf{b}^0(\cdot, \cdot)$.

Note that

$$((\eta, \eta)) = \inf\{b(\boldsymbol{\zeta}, \boldsymbol{\zeta}) : \boldsymbol{\zeta} \in \mathbf{H}(\Omega), R\boldsymbol{\zeta} = \eta\} = b(\boldsymbol{\zeta}^*, \boldsymbol{\zeta}^*). \tag{4.40}$$

Since we have

$$b(\boldsymbol{\zeta},\boldsymbol{\zeta})=b_1(\zeta_1,\zeta_1)+b_2(\zeta_1,\zeta_2)+b_3(\zeta_2,\zeta_1)+b_4(\zeta_2,\zeta_2) \tag{4.41}$$

with appropriate bilinear forms $b_i(\cdot,\cdot)$, $i=1,\cdots,4$, by taking into account the necessary and sufficient optimality conditions for (4.40), we obtain that

$$b(\boldsymbol{\zeta}^*,\boldsymbol{\zeta}^*)=b_1(\zeta_1^*,\zeta_1^*)-b_4(\zeta_2^*,\zeta_2^*). \tag{4.42}$$

Denote

$$\boldsymbol{\psi}^*=R^{-1}|\eta| \tag{4.43}$$

where

$$|\eta|=\eta^++\eta^- \quad \text{for} \quad \eta\in H(\Gamma^c).$$

Furthermore, since $\zeta_i^*\in H^1(\Omega)$, $i=1,2$ it follows that $|\zeta_i^*|\in H^1(\Omega)$, $i=1,2$, where we denote

$$|\boldsymbol{\zeta}^*|\overset{\text{def}}{=}(|\zeta_1^*|,|\zeta_2^*|)\in\mathbf{H}(\Omega). \tag{4.44}$$

Note that

$$|\boldsymbol{\zeta}^*|-\boldsymbol{\psi}^*\in\mathbf{H}_1(\Omega)=\ker R, \tag{4.45}$$

$$\boldsymbol{\psi}^*\in\mathbf{H}_2(\Omega)=(\ker R)^\perp, \tag{4.46}$$

hence

$$b(\boldsymbol{\psi}^*,|\boldsymbol{\zeta}^*|-\boldsymbol{\psi}^*)=0 \tag{4.47}$$

whence

$$\begin{aligned} b(\boldsymbol{\psi}^*,\boldsymbol{\psi}^*)-b(|\boldsymbol{\zeta}^*|,|\boldsymbol{\zeta}^*|)&=2b(\boldsymbol{\psi}^*,\boldsymbol{\psi}^*-|\boldsymbol{\zeta}^*|)-b(\boldsymbol{\psi}^*-|\boldsymbol{\zeta}^*|,\boldsymbol{\psi}^*-|\boldsymbol{\zeta}^*|)\\ &=-b(\boldsymbol{\psi}^*-|\boldsymbol{\zeta}^*|,\boldsymbol{\psi}^*-|\boldsymbol{\zeta}^*|)\leqq 0. \end{aligned} \tag{4.48}$$

By (4.48) it follows that

$$\begin{aligned} ((|\eta|,|\eta|))=b(\boldsymbol{\psi}^*,\boldsymbol{\psi}^*)&\leqq b(|\boldsymbol{\zeta}^*|,|\boldsymbol{\zeta}^*|)\\ &=b_1(|\zeta_1^*|,|\zeta_1^*|)-b_4(|\zeta_2^*|,|\zeta_2^*|)\\ &=b_1(\zeta_1^*,\zeta_1^*)-b_4(\zeta_2^*,\zeta_2^*)\\ &=((\eta,\eta)). \end{aligned} \tag{4.49}$$

The condition $((\eta^+,\eta^-))\leqq 0$, $\forall\eta\in H(\Gamma^c)$ follows from (4.49).

Proof of Theorem 3. Denote

$$\mathbf{z}^t=DT_t^{-1}\cdot\mathbf{u}_t\circ T_t. \tag{4.50}$$

Since we have

$$\boldsymbol{\zeta}_t\in\mathbf{K}(\Omega_t) \quad \text{iff } \boldsymbol{\zeta}=DT_t^{-1}\cdot\zeta_t\circ T_t\in\mathbf{K}(\Omega) \tag{4.51}$$

it follows that the element $\mathbf{z}^t\in\mathbf{H}(\Omega)$ solves the variational inequality

$$\begin{aligned} &\mathbf{z}^t\in\mathbf{K}(\Omega),\\ &\mathbf{a}^t(\mathbf{z}^t,\boldsymbol{\zeta}-\mathbf{z}^t)\geqq\langle\mathbf{F}(t),\boldsymbol{\zeta}-\mathbf{z}^t\rangle \quad \forall\boldsymbol{\zeta}\in\mathbf{K}(\Omega) \end{aligned} \tag{4.52}$$

with appropriate bilinear forms $\mathbf{a}^t(\cdot,\cdot)$ and linear forms $\mathbf{F}(t)\in(\mathbf{H}(\Omega))'$, $t\in[0,\delta)$. It can be verified that a proper choice of bilinear forms $\mathbf{a}^t(\cdot,\cdot)$ and elements $\mathbf{F}(t)$ is the following:

$$\mathbf{a}^t(\mathbf{u},\boldsymbol{\zeta})=\int_\Omega \varepsilon^t(\mathbf{u})\,..\,\mathbf{c}^t\,..\,\boldsymbol{\varepsilon}^t(\boldsymbol{\zeta})\,dx \quad \forall\mathbf{u},\boldsymbol{\zeta}\in\mathbf{H}(\Omega) \tag{4.53}$$

where

$$\boldsymbol{\varepsilon}^t(\boldsymbol{\zeta})=\tfrac{1}{2}\{D(DT_t\cdot\boldsymbol{\zeta})\cdot DT_t^{-1}+{}^*DT_t^{-1}\cdot{}^*(D(DT_t\cdot\boldsymbol{\zeta}))\}$$

and tensor $\mathbf{c}^t$ has components

$$c^t_{ijkl}=\det(DT_t)c_{ijkl}\circ T_t,\qquad i,j,k,l=1,2,\tag{4.54}$$

$$\langle\mathbf{F}(t),\boldsymbol{\zeta}\rangle=\int_\Omega \mathbf{f}^t\cdot\boldsymbol{\zeta}\,dx+\int_\Gamma \mathbf{P}^t\cdot\boldsymbol{\zeta}\,d\Gamma$$

where

$$\mathbf{f}^t=\det(DT_t)^*DT_t\cdot(\mathbf{f}\circ T_t),$$

$$\mathbf{P}^t=\|M(DT_t)\cdot\mathbf{n}\|_{R^2}{}^*DT_t\cdot\mathbf{P}\circ T_t,$$

$$M(DT_t)=\det(DT_t)^*DT_t^{-1}.$$

We need the following notation:

$$\begin{aligned}\langle\mathbf{F}',\boldsymbol{\zeta}\rangle=&\int_\Omega\left\{\sum_{i=1}^{2}(\operatorname{div}(f_i\mathbf{V}(0))\xi_i)+\mathbf{f}\cdot D\mathbf{V}(0)\cdot\boldsymbol{\xi}\right\}dx\\&+\int_{\Gamma_1}\left\{\sum_{i=1}^{2}(\operatorname{div}(P_i\mathbf{V}(0))\xi_i)-(\mathbf{n}\cdot D\mathbf{V}(0)\cdot\mathbf{n})\mathbf{P}\cdot\boldsymbol{\xi}+\mathbf{P}\cdot D\mathbf{V}(0)\cdot\boldsymbol{\xi}\right\}d\Gamma,\end{aligned}\tag{4.55}$$

$$\begin{aligned}\langle B\mathbf{u},\boldsymbol{\zeta}\rangle=&\int_\Omega\boldsymbol{\varepsilon}(\mathbf{u})\,..\,\mathbf{c}'\,..\,\boldsymbol{\varepsilon}(\boldsymbol{\zeta})\,dx+\int_\Omega\boldsymbol{\varepsilon}'(\mathbf{u})\,..\,\mathbf{c}\,..\,\boldsymbol{\varepsilon}(\boldsymbol{\zeta})\,dx\\&+\int_\Omega\boldsymbol{\varepsilon}(\mathbf{u})\,..\,\mathbf{c}\,..\,\boldsymbol{\varepsilon}'(\boldsymbol{\zeta})\,dx\quad\forall\mathbf{u},\boldsymbol{\zeta}\in\mathbf{H}(\Omega)\end{aligned}\tag{4.56}$$

where

$$\boldsymbol{\varepsilon}'(\boldsymbol{\zeta})=\frac{\partial}{\partial t}\varepsilon^t(\boldsymbol{\zeta})\bigg|_{t=0}=\frac{1}{2}\{D(D\mathbf{V}\cdot\boldsymbol{\zeta})+{}^*(D(D\mathbf{V}\cdot\boldsymbol{\zeta}))-D\boldsymbol{\zeta}\cdot D\mathbf{V}-{}^*D\mathbf{V}\cdot{}^*D\boldsymbol{\zeta}\}.$$

Tensor field $c'=(\partial/\partial t)c^t|_{t=0}$ has components

$$c'_{ijkl}=\frac{\partial}{\partial t}c^t_{ijkl}\bigg|_{t=0}=\operatorname{div}\mathbf{V}c_{ijkl}+\operatorname{grad}c_{ijkl}\cdot\mathbf{V}.$$

It can be verified that element $F'\in(\mathbf{H}(\Omega))'$ and operator $B\in L(\mathbf{H}(\Omega);(\mathbf{H}(\Omega))')$ satisfy

$$\langle\mathbf{F}',\boldsymbol{\zeta}\rangle=\frac{d}{dt}\langle\mathbf{F}(t),\boldsymbol{\zeta}\rangle\bigg|_{t=0^+}\quad\forall\boldsymbol{\zeta}\in\mathbf{H}(\Omega),$$

$$\langle B\mathbf{u},\boldsymbol{\zeta}\rangle=\frac{d}{dt}\mathbf{a}^t(\mathbf{u},\boldsymbol{\zeta})\bigg|_{t=0^+}\quad\forall\mathbf{u},\boldsymbol{\zeta}\in\mathbf{H}(\Omega).$$

Furthermore conditions corresponding to (2.3) and (2.2) are verified. We can apply Lemma 4 to (4.52), hence the mapping

$$[0,\delta)t\to\mathbf{z}^t\in\mathbf{H}(\Omega)\tag{4.57}$$

is differentiable at $t=0^+$, i.e.

$$\mathbf{z}^t=\mathbf{z}^0+t\partial\mathbf{z}+o(t) \tag{4.58}$$

where $\|o(t)\|_{H(\Omega)}/t\to 0$ with $t\downarrow 0$,

$$\begin{gathered}\partial\mathbf{z}\in\mathbf{S}_2(\Omega),\\ a^0(\partial\mathbf{z},\boldsymbol{\zeta}-\partial\mathbf{z})\geqq\langle\mathbf{F}'-B\mathbf{z}^0,\boldsymbol{\zeta}-\partial\mathbf{z}\rangle\quad\forall\boldsymbol{\zeta}\in\mathbf{S}_2(\Omega),\end{gathered} \tag{4.59}$$

$$\mathbf{S}_2(\Omega)=\{\boldsymbol{\zeta}\in\mathbf{H}(\Omega)\,|\,\boldsymbol{\zeta}\cdot\mathbf{n}\leqq 0 \text{ a.e. on } Z(\mathbf{z}^0),\, a^0(\mathbf{z}^0,\boldsymbol{\zeta})=\langle\mathbf{F}(0),\mathbf{z}\rangle\},$$

$$Z(\mathbf{z}^0)=\{x\in\Gamma^c\,|\,\mathbf{z}^0(x)\cdot\mathbf{n}(x)=0\}.$$

On the other hand, since

$$\mathbf{u}_t\circ T_t=DT_t\cdot\mathbf{z}^t \quad\text{and}\quad DT_t|_{t=0}=I, \tag{4.60}$$

it follows that

$$\begin{aligned}\dot{\mathbf{u}}&=\partial\mathbf{z}-DV\cdot\mathbf{z}^0\\ &=\partial\mathbf{z}-DV\cdot\mathbf{u}_0\end{aligned} \tag{4.61}$$

and simple calculations show that $\dot{\mathbf{u}}$ is determined by (4.14).

We use the material derivative $\dot{\mathbf{u}}'$ in order to derive the form of the so-called Eulerian semiderivative $dJ(\Omega;\mathbf{V})$ of a functional $J(\Omega)$ in the direction of a vector field $\mathbf{V}(\cdot,\cdot)$.

Let us consider a functional

$$J(\Omega)=\int_\Omega F(\mathbf{u}(x))\,dx$$

where $F(\cdot)\in C^1(R^2)$ and $\mathbf{u}(\cdot)$ is given by (4.11) for $t=0$.

We denote

$$dJ(\Omega;\mathbf{V})\overset{\text{def}}{=}\lim_{t\downarrow 0}(J(\Omega_t)-J(\Omega))/t.$$

It can be verified that

$$dJ(\Omega;\mathbf{V})=\int_\Omega (DF(\mathbf{u}(x))\cdot\dot{\mathbf{u}}(x)+F(\mathbf{u}(x))\operatorname{div}\mathbf{V}(0,x))\,dx.$$

Let us assume now, that the following regularity condition is verified

$$D\mathbf{u}\cdot\mathbf{V}(0)\in(H^1(\Omega))^2;$$

then there exists [17] the so-called domain derivative for problem (4.11) given by

$$\mathbf{u}'=\dot{\mathbf{u}}-D\mathbf{u}\cdot V(0).$$

Furthermore,

$$dJ(\Omega;\mathbf{V})=\int_\Omega DF(\mathbf{u}(x))\cdot\mathbf{u}'(x)\,dx+\int_{\partial\Omega}F(\mathbf{u}(x))\langle\mathbf{V}(0,x),\mathbf{n}(x)\rangle\,d\Gamma.$$

The form of the domain derivative $\mathbf{u}'$ is given in [14], [17] and [19].

THE INITIAL VELOCITY OF THE EMERGING FREE BOUNDARY IN A TWO-PHASE STEFAN PROBLEM WITH IMPOSED FLUX*

A. SOLOMON†, V. ALEXIADES†‡ AND D. G. WILSON†

Abstract. Consider the one-dimensional, two-phase Stefan problem with an imposed flux, in which the phase change front originates at the material boundary. We prove that, subject to suitable assumptions on the initial temperature and imposed flux, the initial speed of the phase change front is equal to the jump between the surface and initial fluxes at the boundary. Similarly, we prove that the front $X(t)$ is continuously differentiable in the closed interval $[0, t^*]$ for some $t^* > 0$.

Key words. two-phase Stefan problem, initial interface speed, onset of melting, L^2-estimates, smoothness of free boundary, maximum principle

AMS(MOS) subject classifications. 35R35, 35K05, 35B65

Introduction. Consider a slab of material occupying the interval $0 \leqq x \leqq L$ which is initially totally solid, with a known temperature distribution (below the critical temperature T_{cr} of the material). Heat is input at $x = 0$ via a known heat flux $q(t) > 0$, while the face $x = L$ is kept insulated. Then at some time t_0 a melt front $x = X(t)$ will emerge from $x = 0$ and move into the material, separating liquid $(x < X(t))$ from solid $(x > X(t))$. The location $X(t)$ of the front as well as the temperature $T(x, t)$ are to be determined.

The mathematical problem here is a one-dimensional two-phase Stefan problem which, however, involves the appearance of a new phase. The onset of melting is a major source of difficulties for both the physical understanding of the phenomenon as well as the mathematical analysis of the problem.

One of the key problems associated with the onset of melting is determining the initial velocity of the melt front, which is the objective of this study. The possibilities range from no melting at all (Solomon, Alexiades and Wilson [14]) to initially infinite propagation speed (when a temperature jump is imposed at $x = 0$ (Carslaw and Jaeger [2])). Hence, finding conditions on the data that guarantee melting is also useful.

The problem we described in the beginning is typical of problems arising in diverse areas of applications ranging from latent heat thermal energy storage (Solomon [10]) to crystal growth (Rubinstein [9]). The need to know the initial interface speed also appears in the study of phase-change problems by either approximation methods (Solomon [11]) or numerical methods (Solomon [12]). In particular, front tracking numerical schemes for an emerging front require the initial front speed to be known (Landau [7]).

Returning to the problem at hand, we note that it consists of two distinct parts: a pure heat conduction problem until melting begins, and afterwards a Stefan problem which is the one of interest. Taking as initial time $(t = 0)$ the instant at which the front emerges, we are interested in finding $X'(0)$ when we know the input flux $q(t) > 0$ and the initial temperature $T(x, 0) = f(x) \leqq T_{cr}$. This temperature $f(x)$ is the result of the premelting heat conduction problem and as such it has certain natural properties like

$f(0)=T_{cr}, f'(x)\leqq 0, f''(x)\geqq 0$, which we take as assumptions for the data of the melting problem (see § 1).

At first glance, it appears reasonable that the initial speed should be determined by the jump in the flux at the surface $x=0$ at $t=0$, namely

$$\rho HX'(0)=q(0)-[-k_s f'(0)] \tag{0.1}$$

(see § 1 for notation). In fact, (0.1) is merely the limiting value, as $t\downarrow 0$, of the Stefan condition along the interface. Also, (0.1) is obeyed by a number of asymptotic results for the first and third boundary conditions in Rubinstein [9] and for a problem with internal heating and $q(0)=-k_s f'(0)=0$ in Lacey and Shillor [6]. Thus, the question of whether or not (0.1) is valid amounts to whether or not the fluxes in the liquid and in the solid are continuous down to $t=0$. Unfortunately, the existing literature on the two-phase problem with imposed flux, for an initially one-phase state, does not answer this smoothness question. Indeed, despite the very extensive literature on Stefan-type problems (Wilson, Solomon and Trent [15], Niezgodka [8]), very few papers actually allow a new phase to appear and we are not aware of any works establishing the well-posedness of the classical formulation of our problem. Nevertheless, the methods of Cannon and Primicerio [1] and of Ishii [5], dealing with Dirichlet data on $x=0$, can also be applied to the case of imposed flux and thus answer the well-posedness question. Furthermore, under certain restrictions on the flux $q(t)$, the work of Fasano and Primicerio [3] also applies.

In this paper we prove the continuity of the fluxes down to $t=0$ under realistic assumptions on the data $f(x)$ and $q(t)$. It then follows that $X(t)$ is differentiable down to $t=0$ and (0.1) holds. These results and the notations are stated in § 1. The steps necessary to complete the proof are divided into four parts. Crucial bounds on the interface location are derived in § 2, and needed L^2-estimates of T_x and T_{xx} are derived in § 3. In § 4 we generalize a version of the maximum principle (Solomon, Alexiades and Wilson [13]) to the two-phase problem and establish the global boundedness of T_x. The proof of the main results is finally completed in § 5.

1. Notation and main results. Consider the following one-dimensional two-phase Stefan problem with imposed flux:

For a given $t_\infty>0$, find a function $X(\cdot)\in C[0,t_\infty]\cap C^1(0,t_\infty)$, $X(0)=0$, and a function $T(\cdot,\cdot)\in C(\bar{D}_l\cup\bar{D}_s)$, where

$$D_l=\{(x,t)\colon 0<x<X(t), 0<t<t_\infty\}\quad \text{(liquid)},$$

$$D_s=\{(x,t)\colon X(t)<x<L, 0<t<t_\infty\}\quad \text{(solid)}$$

such that: for each $t\in(0,t_\infty)$, $T_x(\cdot,t)$ is continuous on $[0,X(t))$ and $(X(t),L]$ and on each of the closed intervals can be extended to a continuous function with a possible jump discontinuity at $X(t)$; T_t, T_{xx} are continuous in D_l and D_s;

$$T_t=\alpha_i T_{xx}\quad \text{in } D_i,\quad i=l,s, \tag{1.1}$$

$$T(x,0)=f(x),\qquad 0\leqq x\leqq L, \tag{1.2}$$

$$-k_l T_x(0,t)=q(t),\qquad 0<t<t_\infty, \tag{1.3}$$

$$T_x(L,t)=0,\qquad 0<t<t_\infty, \tag{1.4}$$

$$T(X(t),t)=T_{cr},\qquad 0\leqq t\leqq t_\infty, \tag{1.5}$$

$$\rho HX'(t)=-k_l T_x^-[t]+k_s T_x^+[t],\qquad 0<t<t_\infty. \tag{1.6}$$

Here, $T_x^{\pm}[t] := \lim_{x\to X(t)\pm} T_x(x,t)$; $k=k_l$ or k_s is the conductivity; $\alpha=\alpha_l$ or α_s is the diffusivity, $\alpha_i = k_i/\rho c_i$, $i=l,\ s$, ρ being the density and c_l, c_s the specific heats; H is the latent heat, T_{cr} the critical temperature and L the slab thickness. All these thermophysical parameters are positive constants.

On the data $q(t)$ and $f(x)$ we assume

$$q\in C^1[0,t_\infty),\quad q(t)\geqq 0,\quad 0\leqq t\leqq t_\infty, \tag{1.7}$$

$$f\in C^2[0,L]\cap H^3(0,L), \tag{1.8}$$

$$f(x)\leqq T_{cr},\quad f'(x)\leqq 0,\quad f''(x)\geqq 0\quad \text{for } 0\leqq x\leqq L, \tag{1.9}$$

$$f(0)=T_{cr},\qquad f'(L)=0. \tag{1.10}$$

As mentioned in the Introduction, the assumptions on $f(x)$ are natural for the temperature of an initially cold solid, insulated at $x=L$, and heated by a smooth flux at $x=0$. In fact, in that case f will also satisfy

$$-k_s f'(0)=q(0). \tag{1.11}$$

The well-posedness of this Stefan problem we take as known (see the Introduction). Precisely, we assume there exists a solution $X(t)$, $T(x,t)$ with

$$X\in C^{\mu}[0,t_\infty]\cap C^\infty(0,t_\infty)\quad \text{for some } 0<\mu<1, \tag{1.12}$$

$$T\in C(\overline{D_l\cup D_s})\cap C^\infty(D_l\cup D_s). \tag{1.13}$$

The paper is devoted to proving the following.

MAIN THEOREM 1.1. *Under the assumptions* (1.7)-(1.10), *the solution of* (1.1)-(1.6) *has the following properties*:

T_x *is continuous on each of* D_l *and* D_s *and has a continuous extension to each of* $\bar{D}_l$ *and* $\bar{D}_s$; *these continuous extensions differ along the line* $\{(t,x)\,|\,x=X(t)\}$ *by a finite jump*;

$$X\in C^1[0,t_\infty),$$

$$\rho H X'(0)=q(0)+k_s f'(0). \tag{1.14}$$

COROLLARY 1.2. *At the onset of melting of an initially solid slab* $[0,L]$, *insulated at* $x=L$ *and heated by a flux* $q(t)\geqq 0$, *the initial velocity of the phase-change front is zero.*

2. Bounds on the interface. We begin with the derivation of bounds on the interface location.

By the maximum principle (Friedman [4]), the assumptions $q(t)\geqq 0$, $f(x)\leqq T_{cr}$, and $f''(x)\leqq 0$ imply the following.

LEMMA 2.1. $f(x)\leqq T(x,t)\leqq T_{cr}$ *in the solid* D_s *and* $T(x,t)\geqq T_{cr}$ *in the liquid* D_l. *Hence*

$$T_x^-[t]\equiv T_x(X(t)-,t)\leqq 0$$

and

$$T_x^+[t]\equiv T_x(X(t)+,t)\leqq 0,\qquad 0<t\leqq t_\infty.$$

Proof. Let $z(x,t)=T(x,t)-f(x)$ in $\bar{D}_s$. Then $z\in C(\bar{D}_s)$ satisfies $z_t-\alpha_l z_{xx}=\alpha_l f''(x)\leqq 0$ in D_s; $z(X(t),t)=T_{cr}-f(X(t))\geqq 0$, $z_x(L,t)=0$, $0\leqq t\leqq t_\infty$; $z(x,0)=0$, $0\leqq x\leqq L$. Hence its minimum value must be $\geqq 0$. The remaining inequalities are proved similarly.

Next we obtain a crucial upper bound for the front location.

THEOREM 2.2. *There exists a constant* $M_0>0$ *such that*

$$X(t)\leqq M_0 t,\qquad 0<t\leqq t_\infty. \tag{2.1}$$

Proof. For any $0<t\leqq t_\infty$, using (1.1)-(1.6) we have

$$\begin{aligned}\frac{d}{dt}\int_0^L \rho c[T(x,t)-T_{cr}]\,dx&=\frac{d}{dt}\int_0^{X(t)}\rho c_l[T-T_{cr}]\,dx+\frac{d}{dt}\int_{X(t)}^L \rho c_s[T-T_{cr}]\,dx\\&=k_lT_x^-[t]-k_lT_x(0,t)+k_sT_x(L,t)-k_sT_x^+[t]\\&=-\rho HX'(t)+q(t).\end{aligned}$$

Integrating over (τ, t) with $0\leqq\tau<t\leqq t_\infty$, we obtain

$$\int_0^L \rho c[T(x,t)-T_{cr}]\,dx-\int_0^L \rho c[T(x,\tau)-T_{cr}]\,dx+\rho H[X(t)-X(\tau)]=\int_\tau^t q(s)\,ds.$$

Taking $\tau\to 0$, using $X(0)=0$ and (1.2), and splitting $\int_0^L$ into $\int_0^{X(t)}+\int_{X(t)}^L$, we obtain the following heat balance:

$$\begin{aligned}(2.2)\qquad &\int_0^{X(t)}\rho c_l[T-T_{cr}]\,dx+\int_{X(t)}^L \rho c_s[T-f(x)]\,dx+\rho HX(t)\\&=\int_0^t q(s)\,ds+\int_0^{X(t)}\rho c_l[f(x)-T_{cr}]\,dx.\end{aligned}$$

By Lemma 2.1, the first two terms on the left are nonnegative and the last term on the right is nonpositive. We conclude that

$$\rho HX(t)\leqq\int_0^t q(s)\,ds\leqq q_{\max}\cdot t,$$

where $q_{\max}:=\max q(t)$ over $0\leqq t\leqq t_\infty$. This establishes (2.1) with $M_0:=q_{\max}/\rho H$.

To obtain a lower bound on $X(t)$, we compare T with the solution of the following heat conduction problem without phase change:

$$\begin{aligned}&w_t=\alpha_l w_{xx}, && x>0,\quad t>0,\\&w(x,0)\equiv T_{cr}, && x>0,\\&-k_lw_x(0,t)=q(t)\geqq 0, && t>0,\end{aligned}$$

the solution of which is given explicitly (Carslaw and Jaeger [2, p. 76]) by

$$(2.3)\qquad w(x,t)=T_{cr}+k_l^{-l}\left(\frac{\alpha_l}{\pi}\right)^{1/2}\int_0^t q(t-s)\exp\{-x^2/4\alpha_l(t-s)\}s^{-1/2}\,ds.$$

It is easy to see that $T(x,t)\leqq w(x,t)$ in $D_l\cup D_s$ and that $w(x,t)\geqq T_{cr}\geqq f(x)$, $0\leqq x\leqq L$, $t>0$. Hence, (2.2) implies the following.

PROPOSITION 2.3.

$$\rho HX(t)\geqq\int_0^t q(s)\,ds-\rho c_{\max}\int_0^L [w(x,t)-f(x)]\,dx,\qquad 0<t<t_\infty,$$

where $c_{\max}:=\max\{c_l, c_s\}$ *and* $w(x,t)$ *is given by* (2.3).

This says that melting may not necessarily begin immediately, but since the right-hand side will eventually become positive, the liquid will have to expand with increasing time.

Another useful relation obtainable from the heat balance (2.2) is

$$\rho c_{\min} \int_0^t [T(x,t)-f(x)]\,dx \leqq \int_0^t q(s)\,ds, \qquad 0<t\leqq t_\infty,$$

where $c_{\min} := \min\{c_l, c_s\}$.

3. Estimates on T_x and T_{xx}.

Lemma 3.1. *For any* $0<t\leqq t_\infty$,

$$0 \leqq \int_0^t -k_l T_x^-[s]\,ds \leqq \int_0^t q(s)\,ds. \tag{3.1}$$

Proof. This is obtained from the heat balance in the liquid as follows:

$$\frac{d}{dt}\int_0^{X(t)} \rho c_l [T(x,t)-T_{cr}]\,dx = k_l T_x^-[t] + q(t).$$

Integrating over $(0, t)$ and since $T \geqq T_{cr}$ (see Lemma 2.1), we have

$$\int_0^t q(s)\,ds + \int_0^t k_l T_x^-[s]\,ds = \int_0^{X(t)} \rho c_l[T-T_{cr}]\,dx \geqq 0.$$

Theorem 3.2. *There exists a constant* $M_1>0$, *independent of time, such that*

$$\int_0^t \int_0^L |T_x(x,s)-f'(x)|^2\,dx\,ds \leqq M_1 \cdot t^2, \qquad 0<t\leqq t_\infty. \tag{3.2}$$

Proof. For $t>0$,

$$\begin{aligned} \frac{d}{dt}\int_0^L \frac{1}{2}\rho c[T(x,t)-f(x)]^2\,dx &= \frac{1}{2}\rho(c_l-c_s)[T_{cr}-f(X)]^2 X'(t) \\ &\quad + \int_0^L k[T-f(x)][T-f(x)]_{xx}\,dx \\ &\quad + \int_0^L k[T-f(x)]f''(x)\,dx. \end{aligned} \tag{3.3}$$

By integration by parts, the first integral in the right-hand side becomes

$$\begin{aligned} \int_0^L k[T-f][T_x-f']_x\,dx = \int_0^L k([T-f][T_x-f'])_x - k[T_x-f']^2 \\ = k_l[T_{cr}-f(X)][T_x^-[t]-f'(X)] \\ - k_l[T(0,t)-f(0)][T_x(0,t)-f'(0)] \\ + k_s[T(L,t)-f(L)][T_x(L,t)-f'(L)] \\ - k_s[T_{cr}-f(X)][T_{cr}-f(X)][T_x^+[t]-f'(X)] \\ - \int_0^L k[T_x-f')]^2\,dx \end{aligned}$$

and using (1.6), (1.10), (1.3) and $f'(x)\leqq 0$,

$$=[f(0)-f(X)]\{-\rho HX'(t)-(k_l-k_s)f'(X)\}$$
$$+[T(0,t)-T_{cr}][q(t)+k_lf'(0)]-\int_0^L k[T_x-f']^2\,dx.$$

Substituting this into (3.3) and integrating over (τ, t), $0<\tau<t\leqq t_\infty$, we find

$$\int_0^L \frac{\rho c}{2}[T(x,t)-f(x)]^2\,dx-\int_0^L \frac{\rho c}{2}[T(x,\tau)-f(x)]^2\,dx+\int_\tau^t\int_0^L k[T_x-f']^2\,dx$$

$$\begin{aligned} &=\int_\tau^t \frac{\rho(c_l-c_s)}{2}X'(s)[f(0)-f(X(s))]^2\,ds \\ &\quad-\int_\tau^t \{\rho HX'(s)+(k_l-k_s)f'(X(s))\}[f(0)-f(X(s))]\,ds \\ &\quad+\int_\tau^t [T(0,s)-T_{cr}][q(s)+k_lf'(0)]\,ds \\ &\quad+\int_\tau^t\int_0^L k[T-f(x)]f''(x)\,dx\,ds. \end{aligned} \tag{3.4}$$

Now, applying (2.1) and (1.7)-(1.10), we estimate each term separately as follows.

$$\left|\int_\tau^t \frac{\rho(c_l-c_s)}{2}X'(s)[f(0)-f(X(s))]^2\,ds\right|=\left|\int_{X(\tau)}^{X(t)}\frac{\rho(c_l-c_s)}{2}[f(0)-f(\xi)]^2\,d\xi\right|$$
$$\leqq \rho c_{\max}|f'_{\max}|^2\frac{X(t)^3-X(\tau)^3}{3}\leqq M_{12}\cdot t^3,$$

$$\left|\int_\tau^t \rho HX'(s)[f(X(s))-f(0)]\,ds\right|=\left|\int_{X(\tau)}^{X(s)}\rho H[f(\xi)-f(0)]\,d\xi\right|$$
$$\leqq \rho H|f'_{\max}|\frac{X(t)^2}{2}\leqq M_{13}\cdot t^2,$$

$$\begin{aligned} &\left|\int_\tau^t (k_l-k_s)f'(X(s))[f(0)-f(X(s))]\,ds\right| \\ &\leqq k_{\max}|f'_{\max}|^2\int_\tau^t X(s)\,ds \\ &\leqq M_{14}\cdot t^2, \end{aligned}$$

$$\begin{aligned} &\left|\int_\tau^t [T(0,s)-T_{cr}][q(s)+k_lf'(0)]\,ds\right| \\ &=\left|\int_\tau^t\left\{\int_0^{X(s)}[T_x(x,s)-f'(x)]\,dx+[f(0)-f(X(s))]\right\}[q(s)+k_lf'(0)]\,ds\right| \\ &\leqq[q_{\max}+k_l|f'(0)|]\left\{\int_\tau^t X(s)^{1/2}\int_0^{X(s)}X(s)^{-1/2}|T_x(x,s)-f'(x)|\,dx\,ds\right. \\ &\qquad\left.+\int_\tau^t|f(0)-f(X(s))|\,ds\right\} \end{aligned}$$

$$\leqq M_{15}\left\{\int_\tau^t\left[\frac{X(s)}{2\varepsilon}+\frac{\varepsilon}{2X(s)}\left(\int_0^{X(s)}1\cdot|T_x(x,s)-f'(x)|\,dx\right)^2\right]ds+|f'_{\max}|\int_\tau^t X(s)\,ds\right\},\qquad \varepsilon>0, \tag{3.5}$$

$$\leqq \frac{M_{16}}{\varepsilon} t^2 + \frac{\varepsilon M_{15}}{2} \int_\tau^t \int_0^L |T_x - f'|^2 \, dx \, ds,$$

$$0 \leqq \int_\tau^t \int_0^L k[T(x,s) - f(x)] f''(x) \, dx \, ds \leqq f''_{\max} \int_\tau^t \int_0^L k[T(x,s) - T(x,0)] \, dx \, ds$$

$$\leqq k_{\max} f''_{\max} \int_\tau^t \int_0^L \left\{ \int_0^s T_t(x,\sigma) \, d\sigma \right\} dx \, ds = M_{17} \int_\tau^t \int_0^s \int_0^L T_t(x,\sigma) \, dx \, d\sigma \, ds$$

$$= M_{17} \int_\tau^t \int_0^s \left\{ \frac{1}{\rho c_l} \int_0^{X(\sigma)} k_l T_{xx}(x,\sigma) \, dx + \frac{1}{\rho c_s} \int_{X(\sigma)}^L k_s T_{xx}(x,\sigma) \, dx \right\} d\sigma \, ds$$

$$= M_{18} \int_\tau^t \int_0^s \{-\rho H X'(\sigma) + q(\sigma)\} \, d\sigma \, ds \leqq 0 + M_{18} q_{\max} \frac{t^2}{2} = M_{19} \cdot t^2.$$

We incorporate these estimates into the right-hand side of (3.4), take $\tau \downarrow 0$ (which makes the negative term on the left-hand side vanish) and discard the first (positive) term. We thus obtain

$$\left[k_{\min} - \frac{\varepsilon M_{15}}{2} \right] \int_0^t \int_0^L [T_x - f']^2 \, dx \leqq M_{12} t^3 + M_{13} t^2 + M_{14} t^2 + \frac{M_{16}}{\varepsilon} t^2 + M_{19} t^2.$$

Choosing $\varepsilon M_{15}/2 = \frac{1}{2} k_{\min}$, we finally establish (3.2). Note that the constant M_1 is essentially known explicitly.

By the Mean Value Theorem we immediately obtain the following.

COROLLARY 3.3. *For each $t \in (0, t_\infty)$, there exists $t^* \in (t/2, t)$ such that*

$$\int_0^L |T_x(x, t^*) - f'(x)|^2 \, dx \leqq M_2 t. \tag{3.6}$$

Next we estimate the second derivative.

THEOREM 3.4. *There exists a constant $M_3 > 0$, independent of time, such that*

$$\int_0^t \int_0^L |T_{xx}(x,s) - f''(x)|^2 \, dx \, ds \leqq M_3 \cdot t, \qquad 0 < t < t_\infty. \tag{3.7}$$

Proof. We begin with

$$\begin{aligned} \frac{d}{dt} \int_0^L \frac{k^2}{2} [T_x(x,t) - f'(x)]^2 \, dx &= \frac{X'(t)}{2} \{ k_l^2 [T_x^-[t] - f'(X(t))]^2 - k_s^2 [T_x^+[t] - f'(X(t))]^2 \} \\ &\quad + \int_0^L k^2 [T_x(x,t) - f'(x)] \alpha T_{xxx}(x,t) \, dx. \end{aligned} \tag{3.8}$$

The last integral can be rewritten as

$$\int_0^L \alpha k^2 [T_x - f'][T_{xxx} - f'''] \, dx + \int_0^L \alpha k^2 [T_x - f'] f''' \, dx$$

$$= \int_0^L \alpha k^2 \{ [(T_x - f')(T_{xx} - f'')]_x - [T_{xx} - f'']^2 + f'''[T_x - f'] \} \, dx$$

$$= \alpha_l k_l^2 [T_x^-[t] - f'(X)][T_{xx}^-[t] - f''(X)] - \alpha_l k_l^2 [T_x(0,t) - f'(0)][T_{xx}(0,t) - f''(0)]$$

$$+0-\alpha_s k_s^2[T_x^+[t]-f'(X)][T_{xx}^+[t]-f'(X)]$$
$$-\int_0^L \alpha k^2\{[T_{xx}-f'']^2-f'''[T_x-f']\}\,dx.$$

By (1.12), (1.13) the front is C^∞ for $t>0$ and the heat equation is valid along it from each side. Moreover, $T(X(t),t)=T_{cr}$ implies $T_t^\pm+X'(t)T_x^\pm=0$, so we have

$$\alpha T_{xx}^\pm[t]=T_t^\pm=-X'(t)T_x^\pm[t], \qquad t>0.$$

Then (3.8) becomes

$$\begin{aligned}
&\frac{d}{dt}\int_0^L \frac{k^2}{2}[T_x-f']^2\,dx\\
&\quad=\frac{X'(t)}{2}\{k_l^2[T_x^-[t]-f'(X)]^2-k_s^2[T_x^+[t]-f'(X)]^2\}\\
&\qquad+k_l^2[T_x^--f'(X)][-X'T_x^--\alpha_l f''(X)]\\
&\qquad-k_l^2[T_x(0,t)-f'(0)][T_t(0,t)-\alpha_l f''(0)]\\
&\qquad-k_s^2[T_x^+-f'(X)][-X'T_x^+-\alpha_s f''(X)]\\
&\qquad-\int_0^L \alpha k^2[T_{xx}-f'']^2\,dx+\int_0^L \alpha k^2 f'''[T_x-f']\,dx\\
&\quad=\frac{X'}{2}(k_s^2T_x^{+2}-k_l^2T_x^{-2})+\frac{1}{2}(k_l^2-k_s^2)X'f'(X)^2+(k_s^2\alpha_sT_x^+-k_l^2\alpha_lT_x^-)f''(X)\\
&\qquad+(k_l^2\alpha_l-k_s^2\alpha_s)f'(X)f''(X)+k_l[q(t)+k_lf'(0)][T_t(0,t)-\alpha_lf''(0)]\\
&\qquad-\int_0^L \alpha k^2[T_{xx}-f'']^2\,dx+\int_0^L \alpha k^2 f'''[T_x-f']\,dx.
\end{aligned}$$

Integrating over (τ,t), $0<\tau<t<t_\infty$, we obtain

$$\begin{aligned}
&\int_0^L \frac{k^2}{2}|T_x(x,t)-f'(x)|^2\,dx-\int_0^L \frac{k^2}{2}|T_x(x,\tau)-f'(x)|^2\,dx\\
&\qquad+\int_\tau^t\int_0^L \alpha k^2|T_{xx}-f''|^2\,dx\,ds\\
&\quad=\frac{1}{2}\int_\tau^t X'(s)(k_s^2T_x^+[s]^2-k_l^2T_x^-[s]^2)\,ds+\frac{1}{2}(k_l^2-k_s^2)\int_\tau^t X'(s)f'(X(s))^2\,ds\\
&\qquad+\int_\tau^t (k_s^2\alpha_sT_x^+[s]-k_l^2\alpha_lT_x^-[s])f''(X(s))\,ds\\
&\qquad+(k_l^2\alpha_l-k_s^2\alpha_s)\int_\tau^t f'(X(s))f''(X(s))\,ds\\
&\qquad+k_l\int_\tau^t [q(s)+k_lf'(0)][T_t(0,s)-\alpha_lf''(0)]\,ds\\
&\qquad+\int_\tau^t\int_0^L \alpha k^2f'''(x)[T_x(x,s)-f'(x)]\,dx\,ds.
\end{aligned} \tag{3.9}$$

We now estimate each term separately as follows:

$$\frac{1}{2}\int_\tau^t X'(s)(k_sT_x^+-k_lT_x^-)(k_sT_x^++k_lT_x^-)\,ds=\frac{1}{2}\int_\tau^t \rho HX'(s)^2(k_sT_x^++k_lT_x^-)\,ds\leqq 0,$$

because of Lemma 2.1;

$$\int_\tau^t f'(X(s))^2 X'(s)\,ds=\int_{X(\tau)}^{X(t)} f'(\xi)^2\,d\xi \leqq |f'_{\max}|^2 X(t)\leqq M_{31}\cdot t,$$

$$\int_\tau^t (k_s^2\alpha_s T_x^+ - k_l^2\alpha_l T_x^-) f''(X)\,ds \leqq 0+k_l^2\alpha_l \int_\tau^t -k_l T_x^-[s] f''(X(s))\,ds$$

$$\leqq M_{32}\int_\tau^t -k_l T_x^-[s]\,ds \leqq M_{32}\int_\tau^t q(s)\,ds \leqq M_{33}\cdot t,$$

where we have used Lemmas 2.1 and 3.1;

$$\int_\tau^t f'(X(s)) f''(X(s))\,ds \leqq M_{34}\cdot t,$$

$$\int_\tau^t [q(s)+k_l f'(0)][T_t(0,s)-\alpha_l f''(0)]\,ds$$

$$(3.10)\qquad = [q(s)+k_l f'(0)][T(0,s)-T_{cr}]\Big|_\tau^t$$

$$-\int_\tau^t q'(s)[T(0,s)-T_{cr}]\,ds - \int_\tau^t [q(s)+k_l f'(0)]\alpha_l f''(0)\,ds$$

$$\leqq M_{35}|T(0,t)-T_{cr}|+|q'_{\max}|\int_\tau^t |T(0,s)-T_{cr}|\,ds + M_{36}\cdot t,$$

where now the second term can be made $<M_{35}\cdot t$ by choosing τ small enough. The other terms are estimated as follows:

$$|T(0,t)-T_{cr}|\leqq \int_0^{X(t)} |T_x(x,t)-f'(x)|\,dx + |f(0)-f(X(t))|$$

$$\leqq \int_0^{X(t)} \left\{\frac{1}{2\varepsilon}+\frac{\varepsilon}{2}|T_x-f'|^2\right\} dx + |f'_{\max}|\cdot X(t)\quad (\varepsilon>0)$$

$$\leqq M_{37}\cdot t+\frac{\varepsilon}{2}\int_0^L |T_x-f'|^2\,dx,$$

$$\int_\tau^t |T(0,s)-T_{cr}|\,ds \leqq M_{38}t^2+\frac{1}{2}\int_\tau^t\int_0^L |T_x-f'|^2\,dx\,ds \quad \text{(as in (3.5))}$$

$$\leqq M_{38}t^2+\frac{M_1}{2}t^2,\quad \text{by (3.2).}$$

Hence the right-hand side of (3.10) is bounded by

$$M_{39}\cdot t+M_{40}\cdot\varepsilon\int_0^L |T_x-f'|^2\,dx + M_{35}\cdot t + M_{41}t^2 + M_{36}\cdot t$$

$$=M_{42}\cdot t + M_{40}\cdot\varepsilon\int_0^L |T_x-f'|^2\,ds.$$

Finally, for the last term in (3.9) we have

$$\int_\tau^t \int_0^L \alpha k^2 f'''(x)[T_x(x,s)-f'(x)]\,dx\,ds \leqq \int_\tau^t \int_0^L \alpha k^2\left\{\frac{1}{2}|f'''|^2+\frac{1}{2}|T_x-f'|^2\right\}dx\,ds$$
$$\leqq M_{43}\cdot t+M_{44}\cdot t^2.$$

Incorporating all these bounds into (3.9) we obtain

$$\int_\tau^t \int_0^L \alpha k^2|T_{xx}-f''|^2\,dx\,ds \leqq M_{45}\cdot t+\int_0^L\left(\varepsilon M_{40}-\frac{k^2}{2}\right)|T_x-f'|^2\,dx$$
$$+\int_0^L \frac{k^2}{2}|T_x(x,\tau)-f'(x)|^2\,dx.$$

By Corollary 3.3 there exists $\tau<t$ such that the last term is $\leqq M_2 t$. Thus, choosing $\varepsilon M_{40}>k^2_{\max}/2$, we finally obtain (3.7).

COROLLARY 3.5. *There exists a constant $M_4>0$, independent of x and t, such that*

$$(3.11)\qquad \int_0^t |T_x(x,s)|^2\,ds \leqq M_4\cdot t \quad \textit{for } 0\leqq x\leqq L,\quad 0<t<t_\infty.$$

Proof. Fix (x_0,t), $0<x_0\leqq L$, $0<t<t_\infty$. We have

$$|T_x(x_0,t)-f'(x_0)|^2 \leqq 2\left|\int_0^{x_0}[T_{xx}(x,t)-f''(x)]\,dx\right|^2+2|T_x(0,t)-f'(0)|^2$$
$$\leqq 2x_0\int_0^{x_0}|T_{xx}-f''|^2\,dx+2\left|-\frac{q(t)}{k_l}-f'(0)\right|^2$$
$$\leqq 2L\int_0^L |T_{xx}-f''|^2\,dx+M_{46}.$$

Integrating and using (3.7) we obtain

$$|T_x(x_0,\cdot)|_{L^2(0,t)}\leqq\left(\int_0^t |f'(x_0)|^2\,ds\right)^{1/2}+(M_{47}t)^{1/2}\leqq(M_{48}t)^{1/2};$$

hence

$$\int_0^t |T_x(x_0,s)|^2\,ds\leqq M_{48}\cdot t,\qquad 0<x_0\leqq L,\quad 0<t<t_\infty.$$

For $x_0=0$, $|T_x(0,t)|=|-q(t)/k_l|\leqq M_{49}$ and (3.11) still holds.

COROLLARY 3.6. *There exists a constant $M_5>0$ and a sequence of times $\{t_n\}\to 0$ such that*

$$(3.12)\qquad \int_0^L |T_{xx}(x,t_n)|^2\,dx\leqq M_5.$$

Proof. By the Mean Value Theorem applied to (3.7), for any $\tau_n>0$ there exists $0<t_n<\tau_n$ such that

$$\tau_n\int_0^L |T_{xx}(x,t_n)-f''(x)|^2\,dx\leqq M_3\tau_n,$$

i.e.,

$$|T_{xx}(\cdot, t_n) - f''(\cdot)|^2_{L^2(0,L)} \leqq M_3;$$

hence

$$|T_{xx}(\cdot, t_n)|_{L^2(0,L)} \leqq \sqrt{M_3} + |f''|_{L^2(0,L)} =: \sqrt{M_5}.$$

4. Maximum principle and boundedness of the fluxes. Boundedness of the fluxes, $-k_l T_x$ and $-k_s T_x$, can be deduced from Corollary 3.5 once we make certain that unboundedness could only occur at the origin. This is shown in Theorem 4.2, the proof of which requires the following form of the Corner Point Maximum Principle, proved in Solomon, Alexiades and Wilson [13, p. 205].

LEMMA 4.1. *Let D be a simply connected domain in the x, t plane and $P_0 = (x_0, t_0)$ a point of its boundary. Let N be a disk of radius $\delta > 0$ centered at P_0, and set $G^0 = D \cap N \cap \{t < t_0\}$, $\hat{G}^0 = \bar{G}^0 - \partial D$. If* (a) *$u \in C(\bar{D})$, u_x, u_t, $u_{xx} \in C(D)$, and $u_t - \alpha u_{xx} \leqq 0$ in D, and* (b) *$u(P) < u(P_0)$ for $P \in \hat{G}^0$, $u(P) \leqq u(P_0)$ for $P \in \partial D \cap N$ and $\partial D \cap N$ is a C^2-curve representable as $x = X(t)$, then*

$$\limsup_{\substack{P \to P_0 \\ P \in \hat{G}^0}} \frac{u(P) - u(P_0)}{|P - P_0|} < 0,$$

where P tends to P_0 in any nontangential direction.

THEOREM 4.2. *The maximum and minimum values of the flux over any strip $\sum_{t_2}^{t_1} = \{(x, t) \colon 0 \leqq x \leqq L,\ t_1 \leqq t \leqq t_2\}$, $0 < t_1 < t_2 < t_\infty$, are attained either on the line $x = 0$, $t_1 \leqq t \leqq t_2$ or on the bottom $0 \leqq x \leqq L$, $t = t_1$.*

Proof. Let $u(x, t) := -kT_x(x, t)$ where, as before $k = k_l$ in liquid and $k = k_s$ in the solid. Since u satisfies the heat equation in $D_l \cap \sum_{t_2}^{t_1}$ and in $D_s \cap \sum_{t_2}^{t_1}$, its extrema over $\sum_{t_2}^{t_1}$ must be attained on the parabolic boundaries of these domains. By Lemma 4.1, they cannot be assumed on $x = L$, $t_1 \leqq t \leqq t_2$ due to the boundary condition $u(L, t) = -k_s T_x(L, t) \equiv 0$ there. Thus the result will be proved once we show that the extrema cannot be attained on the interface $x = X(t)$, $t_1 < t \leqq t_2$.

Let $u^{\pm}[t] := -kT_x^{\pm}[t]$ be the values of the flux on $x = X(t)$ from the solid (+) and the liquid (−) respectively. Suppose $u(x, t)$ attains its maximum over $\sum_{t_2}^{t_1}$ at a point $(X(t^*), t^*)$, $t_1 < t^* \leqq t_2$. Note that, by Lemma 2.1, $u^{\pm}[t^*] \geqq 0$.

If $X'(t^*) \geqq 0$ then $\rho H X'(t^*) = u^-[t^*] - u^+[t^*] \geqq 0$ implies the maximum of u must be $u^-[t^*]$. But $T(X(t), t) = T_{cr} \Rightarrow T_t^- + T_x^- X'(t) = 0 \Rightarrow k_l T_{xx}^-[t] = \rho c_l T_t^-[t] = -\rho c_l T_x^-[t] X'(t) \Rightarrow u_x^-[t^*] = \rho c_l T_x^-[t^*] X'(t^*) = -(\rho c_l / k_l) u^-[t^*] X'(t^*) \leqq 0$. This contradicts Lemma 4.1 and we conclude that the maximum cannot occur at time t^* but at an earlier time, down to $t = t_1$.

If $X'(t^*) < 0$ then, similarly to the previous case we obtain $u_x^+[t^*] = -(\rho c_s / k_s) u^+[t^*] X'(t^*) \geqq 0$, whereas Lemma 4.1 requires <0. Again, the maximum must be at an earlier time, down to $t = t_1$.

At a minimum, all the inequalities reverse and we draw the same conclusion.

THEOREM 4.3. *The flux is bounded uniformly in $\overline{D_l \cup D_s}$.*

Proof. Suppose $u(x, t) = -kT_x(x, t)$ is unbounded in $\overline{D_l \cup D_s}$. By Theorem 4.2, it can only become unbounded at (0, 0) because on $x = 0$, $u = q$ is bounded and at $t = 0$, $0 < x \leqq L$, $u = -k_s f'(x)$ is also bounded. Therefore, near (0, 0), $T_x(x, t)$ is either uniformly large or experiences unbounded oscillations. But the former possibility contradicts (3.11) while the latter one contradicts (3.12). We conclude that there exists a constant $M_6 > 0$ such that

$$|T_x(x, t)| \leqq M_6 \quad \text{in } \overline{D_l \cup D_s}, \tag{4.1}$$

in the sense that

$$-M_6 \leqq \liminf T_x \leqq \limsup T_x \leqq M_6 \quad \text{as } (x, t) \to (0, 0)$$

in case $T_x(0, 0)$ does not exist.

COROLLARY 4.4. *The interface speed is uniformly bounded for* $0 \leqq t \leqq t_\infty$, *i.e., there exists a constant* $M_7 > 0$ *such that*

$$|X'(t)| \leqq M_7, \qquad 0 \leqq t \leqq t_\infty, \tag{4.2}$$

in the sense

$$-M_7 \leqq \liminf_{t \to 0} X'(t) \leqq \limsup_{t \to 0} X'(t) \leqq M_7.$$

(*Note that we have not yet shown the existence of* $X'(0)$.)

5. Continuity of the fluxes. The uniform boundedness of the fluxes established in the previous section allows us to estimate the third space derivation of T and improve (3.12) at the same time, leading to our goal.

THEOREM 5.1. *There exists a constant* $M_8 > 0$, *independent of time, such that*

$$\int_0^L |T_{xx}(x, t)|^2 \, dx \leqq M_8 \quad \textit{for any } 0 < t < t_\infty. \tag{5.1}$$

Proof. We begin with

$$\begin{aligned} \frac{d}{dt} \int_0^L \frac{1}{2} T_{xx}(x, t)^2 \, dx &= \frac{1}{2} X'(t) \{ T_{xx}^-[t]^2 - T_{xx}^+[t]^2 \} + \int_0^L T_{xx} T_{xxt} \, dx \\ &= \frac{1}{2} X'(t) \{ T_{xx}^-[t]^2 - T_{xx}^+[t]^2 \} + T_{xx} T_{xt}|_{x=L} - T_{xx} T_{xt}|_{x=0} \\ &\quad + \{ T_{xx}^-[t] T_{xt}^-[t] - T_{xx}^+[t] T_{xt}^+[t] \} - \int_0^L \alpha T_{xxx}(x, t)^2 \, dx. \end{aligned} \tag{5.2}$$

On $x = L$, $T_x(L, t) = 0$ implies $T_{xt} \equiv 0$. On $x = 0$, by parabolic regularity theory, the heat equation is valid up to the boundary so $-T_{xx} T_{xt}|_{x=0} = (1/\alpha_l) T_t(0, t)(q'(t)/k_l)$, $t > 0$. Similarly along the front, but separately from each side

$$\begin{aligned} T_{xx}^\pm[t] T_{xt}^\pm[t] &= \frac{1}{\alpha} T_t^\pm[t] T_{xt}^\pm[t] = -\frac{1}{\alpha} X'(t) T_x^\pm[t] T_{xt}^\pm[t] \\ &= -\frac{X'(t)}{\alpha} \left\{ \frac{d}{dt} \left[\frac{1}{2} (T_x^\pm)^2 \right] - X'(t) T_{xx}^\pm[t] \right\} \\ &= -\frac{X'(t)}{2a} \frac{d}{dt} (T_x^\pm[t]^2) + \frac{X'(t)^2}{\alpha} T_{xx}^\pm[t] \\ &= -\frac{1}{2\alpha} \frac{d}{dt} [X'(T_x^\pm)^2] + \frac{1}{2\alpha} X''(t) T_x^\pm[t]^2 + \frac{X'(t)^2}{\alpha} T_{xx}^\pm[t], \qquad t > 0. \end{aligned}$$

With these modifications, we integrate (5.2) over (t_n, t), where $t_n \to 0$ is the sequence in (3.12) and $t > 0$ is arbitrary, to obtain

$$\begin{aligned}
&\int_{t_n}^{t}\int_0^L \alpha T_{xxx}(x, s)^2\,dx\,ds + \frac{1}{2}\int_0^L T_{xx}(x, t)^2\,dx \\
&\quad = \frac{1}{2}\int_0^L T_{xx}(x, t_n)^2\,dx + \frac{1}{2}\int_{t_n}^{t} X'(s)\{T_{xx}^-[s]^2 - T_{xx}^+[s]^2\}\,ds + \frac{1}{\alpha_l k_l}\int_{t_n}^{t} T_t(0, s)q'(s)\,ds \\
&\qquad + \int_{t_n}^{t}\left\{-\frac{1}{2\alpha_l}\frac{d}{ds}(X'(s)T_x^-[s]^2) + \frac{1}{2\alpha_l}X''(s)T_x^-[s]^2 + \frac{1}{\alpha_l}X'(s)^2T_{xx}^-[s]\right\}ds \\
&\qquad - \int_{t_n}^{t}\left\{-\frac{1}{2\alpha_s}\frac{d}{ds}(X'(s)T_x^+[s]^2) + \frac{1}{2\alpha_s}X''(s)T_x^+[s]^2 + \frac{1}{\alpha_s}X'(s)^2T_{xx}^+[s]\right\}ds.
\end{aligned} \tag{5.3}$$

Each term on the right can be bounded as follows.

By the choice of t_n as in (3.12), the first integral is bounded by M_5. Along the front, thanks to (4.1) and (4.2),

$$T_{xx}^{\pm}[t] = \frac{1}{\alpha}T_t^{\pm}[t] = \frac{1}{\alpha}(-X'(t)T_x^{\pm}[t]) \leqq \frac{1}{\alpha}M_7M_6; \tag{5.4}$$

hence the second integral is bounded by (constant) · t. If we apply the second Mean Value Theorem, there exists $\tilde{t}_n \in (t_n, t)$ such that

$$\left|\int_{t_n}^{t} T_t(0, s)q'(s)\,ds\right| = |q'(\tilde{t}_n)[T(0, t) - T(0, t_n)] \leqq M_{51},$$

and there exists $\tilde{t}_n \in (t_n, t)$ such that

$$\int_{t_n}^{t} X''(s)T_x^-[s]^2\,ds = T_x^-[\tilde{t}_n]^2(X'(t) - X'(t_n)) \leqq 2M_6^2M_7.$$

Also,

$$\left|\int_{t_n}^{t} \frac{d}{ds}(X'(s)T_x^-[s]^2)\,ds\right| \leqq 2M_6M_7,$$

$$\left|\int_{t_n}^{t} X'(s)^2T_{xx}^-[s]\,ds\right| \leqq \frac{1}{\alpha_l}M_7^3M_6 \quad \text{as in (5.4).}$$

It is similar for the last three terms (from the solid side).

With its right-hand side thus bounded, (5.3) yields

$$\int_{t_n}^{t}\int_0^L \alpha T_{xxx}(x, s)^2\,dx\,ds + \frac{1}{2}\int_0^L T_{xx}(x, t)^2\,dx \leqq M_{52}, \qquad 0 < t_n < t \leqq t_\infty.$$

Taking $t_n \to 0$, we obtain

$$\int_0^t\int_0^L |T_{xxx}(x, s)|^2\,dx\,ds \leqq M_{53} \quad \text{for } 0 < t < t_\infty, \tag{5.5}$$

as well as estimate (5.1).

COROLLARY 5.2. *For any points (x_1, t), (x_2, t) in $\bar{D}_s$, $t>0$,*

$$|T_x(x_2, t)-T_x(x_1, t)| \leqq M_8^{1/2}|x_2-x_1|^{1/2}, \tag{5.6}$$

uniformly in $0<t<t_\infty$. Hence the family $\{T_x(\cdot, t)\colon 0<t<t_\infty\}$ is equicontinuous.

Proof. $|T_x(x_2, t)-T_x(x_1, t)|^2=|\int_{x_1}^{x_2} T_{xx}(x, t)\,dx|^2 \leqq |x_2-x_1| \int_0^L |T_{xx}|^2\,dx \leqq M_8|x_2-x_1|$, independently of $t \in (0, t_\infty)$.

THEOREM 5.3. *The solid flux $-k_sT_x(x, t)$ is continuous on $\bar{D}_s$. Hence,*

$$T_x(x, t) \to f'(0) \quad \textit{as } (x, t) \to (0, 0) \quad \textit{inside } \bar{D}_s,$$

and in particular,

$$T_x^+[t] \to f'(0) \quad \textit{as } t \downarrow 0.$$

Proof. The family of functions $\{T_x(\cdot, t)\colon 0<t<t_\infty\}$ is equicontinuous on $[0, L]$ by (5.6) and equibounded by (4.1). The Ascoli-Arzela lemma implies that there exists a sequence of times $\{t_n^*\} \to 0$ such that $T_x(x, t_n^*)$ converges to its limit $f'(x)$ uniformly in $x \in [0, L]$.

Suppose now that $T_x(x, t)$ is not continuous at $(0, 0)$, i.e., that there exists $M>0$ and a sequence of points $(x_n, t_n) \to (0, 0)$ such that

$$|T_x(x_n, t_n)-f'(0)| \geqq M.$$

Then, by Ascoli-Arzela, there exists a subsequence $\{t_n^*\} \to 0$ such that

$$M<|T_x(x_n, t_n^*)-f'(0)| \leqq |T_x(x_n, t_n^*)-T_x(x_n, 0)|+|f'(x_n)-f'(0)|,$$

the right-hand side of which can be made arbitrarily small by choosing x_n sufficiently close to $x=0$, a contradiction.

THEOREM 5.4. *The liquid flux $-k_lT_x(x, t)$ is continuous on $\bar{D}_l$. Hence,*

$$-k_lT_x(x, t) \to q(0) \quad \textit{as } (x, t) \to (0, 0) \textit{ inside } \bar{D}_l,$$

and in particular,

$$-k_lT_x^-[t] \to q(0) \quad \textit{as } t \downarrow 0.$$

Proof. For $(x, t) \in \bar{D}_l$, $t>0$, we have

$$\begin{aligned}
|-k_lT_x(x, t)-q(0)| &\leqq k_l|T_x(x, t)-T_x(0, t)|+|q(t)-q(0)| \\
&= k_l\left|\int_0^x T_{xx}(\xi, t)\,d\xi\right|+|q(t)-q(0)| \\
&\leqq k_lx^{1/2}\left(\int_0^L |T_{xx}(\xi, t)|^2\,d\xi\right)^{1/2}+|q(t)-q(0)| \\
&\leqq k_lM_8^{1/2}\sqrt{x}+|q(t)-q(0)|,
\end{aligned}$$

which $\to 0$ as $(x, t) \to (0, 0)$.

COROLLARY 5.5. *The speed $X'(t)$ of the phase change front is continuous for $0 \leqq t \leqq t_\infty$, and*

$$\begin{aligned}
\rho HX'(t) &= -k_lT_x^-[t]+k_sT_x^+[t] \\
&\to q(0)+k_sf'(0) \quad \textit{as } t \downarrow 0.
\end{aligned}$$

ON THE SINGULAR LIMIT FOR A CLASS OF PROBLEMS MODELLING PHASE TRANSITIONS*

NICHOLAS D. ALIKAKOS† AND K. C. SHAING‡

Abstract. The total variation is a measure of the complexity of a given solution to $(\varepsilon)/\varepsilon^2 u_\varepsilon'' - f(x, u_\varepsilon) = 0$. For stable solutions, under appropriate conditions on f, the total variation can be bounded uniformly in ε. This estimate provides sufficient compactness for relating the stable solutions of (ε) to those of the limiting equation $(\varepsilon = 0)$.

Key words. singular perturbations, phase transitions, complexity of stable equilibria, total variation

AMS(MOS) subject classifications. 34C35, 34D15, 35B45

1. Introduction. Consider

$$\varepsilon^2 u_\varepsilon'' - f(x, u_\varepsilon) = 0, \quad u_\varepsilon'(0) = u_\varepsilon'(1) = 0, \quad 0 \leqq x \leqq 1. \tag{1}$$

Let

$$F(x, u) = \int^u f(x, z)\, dz, \qquad \text{an antiderivative of } f,$$

and assume that for $x_1 < x_0 < x_2$ we have (see Fig. A): The energy functional associated to (1) is

$$J_\varepsilon(u) = \frac{\varepsilon^2}{2} \int (u')^2 + \int F(x, u). \tag{2}$$

For $\varepsilon = 0$ the global minimizer is given by

$$\bar{u}(x) = \begin{cases} \beta, & 0 \leqq x < x_0, \\ \alpha, & x_0 < x \leqq 1. \end{cases} \tag{3}$$

‡ Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831.

The question we investigate concerns the convergence of any sequence $\{u_\varepsilon\}$ of global minimizers of (2) to $\bar{u}$ as $\varepsilon \to 0$. Since $\bar{u}$ is discontinuous, one expects a sharp transition for u_ε near $x = x_0$ and so a penalty in the energy in terms of a substantial contribution from $\int (u'_\varepsilon)^2$, a fact that makes the problem from the mathematical point of view not entirely clear (note that α, β are local minimizers of J_ε for all ε). Setting $\varepsilon = 0$ and so obtaining a profile by locally minimizing the energy is the natural approach in applications. As a rule the equation is coupled to a system and the limiting case has the advantage of simplicity and therefore it is of interest to have rigorous justification of the approximation. A typical physical setting where the question of the relation between local and nonlocal models is raised can be found in Shaing [S].

Fife [F] constructs solutions to (1) that converge as $\varepsilon \to 0$ to a given solution of the limiting equation by developing singular perturbation techniques based ultimately on a suitable implicit function theorem. No evaluation of the energy of the approximating family is considered in that work.

Recently Carr, Gurtin and Slemrod [CGS1][1] studied phase transitions on a finite interval. They minimize the functional

$$J_\varepsilon(u) = \frac{\varepsilon^2}{2}\int (u'(x))^2 + \int W(u(x)) \tag{4}$$

with the constraint

$$\int u = M \tag{5}$$

where $W(u)$ has a sigmoid shape. Utilizing that the Euler–Lagrange equation to (4), (5) is autonomous, they employ elaborate phase plane analysis arguments and establish under appropriate conditions that the minimizers converge as $\varepsilon \to 0$ to a two-phase solution of the $\varepsilon = 0$ problem.

Our approach is different from any of the above. It is based on the observation that if $\{u_\varepsilon\}$ is a family of *stable* equilibria of (1), bounded uniformly in ε,

$$|u_\varepsilon|_{L^\infty} \leqq C,$$

then the total variations, $V(u_\varepsilon)$, are uniformly bounded,

$$V(u_\varepsilon) \leqq C, \qquad C \text{ independent of } \varepsilon. \tag{6}$$

The obvious counterexample, $u_\varepsilon(x) = \cos(x/\varepsilon)$, for $\varepsilon^2 u''_\varepsilon + u_\varepsilon = 0$, $u'_\varepsilon(0) = u'_\varepsilon(1) = 0$, shows that the hypothesis of stability is essential. By employing Helly's compactness theorem we can pass to the limit in the weak formulation of the ε-problem along a subsequence of minimizers and conclude its convergence to a solution of the $\varepsilon = 0$ problem. The rest of the argument turns out not to be difficult. This method, being a compactness argument, has the advantage of not distinguishing between autonomous and nonautonomous equations and it is potentially applicable to systems relevant, for example, to the study of phase transitions of fluids which differ in more than one scalar parameter (Cahn and Hilliard [CH, p. 260]), and to equations in more than one space dimension. Estimates of the variation under general circumstances will be pursued elsewhere. Here we describe the main idea in the simplest of circumstances. In § 2 under appropriate hypotheses on f the pointwise convergence of the global minimizers to $\bar{u}$ is established. Finally in an appendix we give a quick self-contained proof of the main result in [CGS1].

[1] See also Novick-Cohen and Segel [NS].

2. We will assume for simplicity that α, β, γ are independent of x and that $F(\cdot, u)$ changes in a monotone way from A-I to A-III, i.e. the left branch goes down while the right goes up and that otherwise F is as in Fig. A. More precisely we introduce the hypotheses:

(H1) F is C^1 in both arguments.

(H2) $f(x, \alpha) = f(x, \beta) = f(x, \gamma) = 0$, $0 \leqq x \leqq 1$, $u \to f(x, u)$ changes sign as u crosses the roots, $f(x, u) < 0$ for $u < \alpha$, $[F(0, \alpha) - F(0, \beta)][F(1, \alpha) - F(1, \beta)] < 0$.

(H3) $f_x(x, u) > 0$ for $u \notin \{\alpha, \beta, \gamma\}$, $0 \leqq x \leqq 1$.

We take

$$F(x, u) = \int_\gamma^u f(x, z)\, dz + \text{const} \geqq 0.$$

Note that $F_x(x, u) \leqq 0$ $(\geqq 0)$ for $u \leqq \gamma$ $(u \geqq \gamma)$. A concrete example would be

$$f(x, u) = u(u^2 - 1) \int_{-\infty}^{(x-1/2)u(u^2-1)} g(t)\, dt$$

where $g(t) > 0$ with $\int_{-\infty}^{\sigma} g(t)\, dt < +\infty$, $\forall \sigma \in \mathbb{R}$, $\alpha = -1$, $\beta = 1$, $\gamma = 0$, $x_0 = \frac{1}{2}$.

LEMMA 1. *There is a global minimizer u_ε of $J_\varepsilon(u)$ over $W^{1,2}$ that is a classical solution to* (1) *and satisfying*

$$\alpha \leqq u_\varepsilon \leqq \beta \tag{7}$$

with the inequalities being strict if u_ε is not identically constant.

Proof. This is standard. We sketch the argument for the convenience of the reader.

Take $\varepsilon = 1$ for definiteness. First note that for a given u in $W^{1,2}$ the truncated $v = \min\{u, \beta\}$ has energy less or equal to u. Clearly

$$\int v_x^2 \leqq \int u_x^2.$$

Also,

$$\int F(x, u) = \int_{u \leqq \beta} F(x, u) + \int_{u \geqq \beta} F(x, u)$$
$$\geqq \int_{u \leqq \beta} F(x, u) + \int_{u \geqq \beta} F(x, \beta)$$

since $\partial F(x, u)/\partial u = f(x, u) \geqq 0$ for $u \geqq \beta$ by (H2). Therefore

$$J_1(v) \leqq J_1(u).$$

Applying an analogous argument to v, we conclude that $\max\{\alpha, \min\{u, \beta\}\}$ has energy less than or equal to u. Consider J_1 on

$$X = \{u \in W^{1,2} \mid \alpha \leqq u \leqq \beta\}. \tag{8}$$

Clearly J_1 is coercive on X (with the obvious norm) since $F(x, u) \geqq 0$ and weakly lower semicontinuous. Therefore J_1 attains its infimum over X. By the observation above this minimizer u_1 minimizes J_1 over $W^{1,2}$ as well. From

$$\left.\frac{d}{d\lambda}\right|_{\lambda=0} J_1(u_1 + \lambda h) = 0 \tag{9}$$

we obtain that u_1 is a weak solution to (1). A standard regularity argument shows that u_1 is a classical solution. By applying a familiar variant of the strong maximum principle we obtain strict inequalities when the minimizer is not identically equal to a constant. Q.E.D.

LEMMA 2. *Let u_ε be a global minimizer. Then we have the estimate*[2]

$$\int |u'_\varepsilon|^2 \leqq \frac{C}{\varepsilon^2}. \tag{10}$$

Proof. It follows from (1) by multiplying with u_ε, integrating, and using the Schwarz inequality and the uniform bound in (7). Q.E.D.

LEMMA 3. *Stable equilibria of* (1) *are necessarily monotone decreasing in x.*

Proof. We will show that if u_ε is not monotone then the second variation of J_ε

$$J''_\varepsilon(u_\varepsilon)(h, h) = \varepsilon^2 \int (h')^2 + \int f_u(x, u_\varepsilon)h^2$$

is strictly negative for some $h \in W^{1,2}$. We drop the ε for convenience. Differentiating (1) we obtain for $u' = w$

$$\varepsilon^2 w'' - f_u(x, u)w = f_x(x, u), \qquad w(0) = w(1) = 0. \tag{11}$$

Since w is in $W^{1,2}$ (cf. Lemma 1), so is $w^+ = \max\{w, 0\}$. Multiplying (11) by w^+ and integrating, we obtain

$$-\varepsilon^2 \int |(w^+)|^2 - \int f_u(x, u)(w^+)^2 = \int f_x(x, u)w^+. \tag{12}$$

By (H3) the right-hand side is positive. Hence stability implies $(u_x)^+ = 0$. Q.E.D.

LEMMA 4. *Let $\{u_{\varepsilon_n}\}$ be a sequence of global minimizers of J_{ε_n} over $W^{1,2}$. Then there is a subsequence, denoted again by $\{u_{\varepsilon_n}\}$ such that*

$$u_{\varepsilon_n} \underset{\varepsilon_n \to 0}{\longrightarrow} u \quad \textit{pointwise on } [0, 1] \tag{13}$$

where u is monotone decreasing

$$\alpha \leqq u \leqq \beta \tag{14}$$

and

$$f(x, u(x)) = 0 \quad \textit{on } [0, 1] \tag{15}$$

and thus $u(x) \in \{\alpha, \gamma, \beta\}$.

Proof. By Lemma 3 the elements of the sequence $\{u_{\varepsilon_n}\}$ are monotone decreasing functions of x. We write u_ε in the place of u_{ε_n} for convenience. Since

$$\alpha \leqq u_\varepsilon \leqq \beta$$

$V(u_\varepsilon) \leqq \beta - \alpha$ and so by Helly's theorem [N, p. 220] there is a subsequence, denoted again by $\{u_\varepsilon\}$ such that

$$u_\varepsilon(x) \to u(x), \qquad x \in [0, 1] \tag{16}$$

where $u(x)$ necessarily is monotone decreasing and satisfies (14). Multiplying (1) by

[2] The stronger estimate $\int |u'_\varepsilon|^2 \leqq C/\varepsilon$ holds. See [AS].

ϕ, a smooth function and integrating by parts,

$$\varepsilon^2 \int u'_\varepsilon \phi' + \int f(x, u_\varepsilon)\phi = 0. \tag{17}$$

The first term in (17) goes to zero as $\varepsilon \to 0$ by the estimate (10). By (14) and the dominated convergence theorem we obtain from (16), (17)

$$\int f(x, u)\phi = 0 \tag{18}$$

and therefore (15) follows. Q.E.D.

Remark 1. Since $u(x)$ is monotone decreasing, the only left continuous possibilities are:

(i) $$u(x) \equiv \text{constant},$$

(ii) $$u(x) = \begin{cases} \beta, & 0 \leqq x \leqq \bar{x}, \\ \alpha, & \bar{x} < x \leqq 1, \end{cases}$$

(iii) $$u(x) = \begin{cases} \beta, & 0 \leqq x \leqq \bar{x}, \\ \gamma, & \bar{x} < x < 1, \end{cases}$$

(iv) $$u(x) = \begin{cases} \gamma, & 0 \leqq x \leqq \bar{x}, \\ \alpha, & \bar{x} < x \leqq 1, \end{cases}$$

(v) $$u(x) = \begin{cases} \beta, & 0 \leqq x \leqq \bar{x}, \\ \gamma, & \bar{x} \leqq x \leqq \bar{x}, \\ \alpha, & \bar{x} < x \leqq 1. \end{cases}$$

LEMMA 5. *Let $\{u_{\varepsilon_n}\}$ be a sequence of global minimizers. Then*

$$J_{\varepsilon_n}(u_{\varepsilon_n}) \to J_0(\bar{u}) = \int F(x, \bar{u}(x))$$

as $\varepsilon_n \to 0$.

Proof. Replace ε_n by ε for simplicity. Consider the functions

$$\tilde{u}_\varepsilon(x) = \begin{cases} \beta, & 0 \leqq x \leqq x_0 - \varepsilon, \\ \alpha, & x_0 + \varepsilon \leqq x \leqq 1, \\ \text{linear}, & x_0 - \varepsilon \leqq x \leqq x_0 + \varepsilon, \end{cases}$$

$\tilde{u}_\varepsilon \in W^{1,2}$ and

$$J_\varepsilon(\tilde{u}_\varepsilon) = \frac{\varepsilon^2}{2} \int_{x_0-\varepsilon}^{x_0+\varepsilon} \left(\frac{\beta - \alpha}{2\varepsilon}\right)^2 + \int_0^{x_0-\varepsilon} F(x, \beta) + \int_{x_0+\varepsilon}^1 F(x, \alpha) + \int_{x_0-\varepsilon}^{x_0+\varepsilon} F(x, \tilde{u}_\varepsilon(x)).$$

Clearly $J_\varepsilon(\tilde{u}_\varepsilon) \to J_0(\bar{u})$, and since $J_0(\bar{u}) \leqq J_\varepsilon(u_\varepsilon) \leqq J_\varepsilon(\tilde{u}_\varepsilon)$, we are done. Q.E.D.

Remark 2. The weaker statement $\overline{\lim}_{\varepsilon \to 0} J_\varepsilon(u_\varepsilon) \leqq J_0(\bar{u})$ would suffice.

THEOREM 6. *Let $\{u_{\varepsilon_n}\}$ be a sequence of global minimizers corresponding to J_{ε_n} over $W^{1,2}$. Then*

$$u_{\varepsilon_n} \to \bar{u} \quad \textit{pointwise on } [0, 1]$$

as $\varepsilon_n \to 0$.

Proof. Assume that the limit u of some subsequence, denoted again by $\{u_{\varepsilon_n}\}$, is different from $\bar{u}$. By Remark 1 it has to be one of the remaining four possibilities. Since the global minimizer for J_0 is unique, we can choose δ such that

$$\int F(x, \bar{u}) = J_0(\bar{u}) < J_0(u) - \delta = \int F(x, u) - \delta. \tag{19}$$

On the other hand by Lemma 5 above for ε sufficiently small

$$J_\varepsilon(u_\varepsilon) = \frac{\varepsilon^2}{2}\int (u'_\varepsilon)^2 + \int F(x, u_\varepsilon) \leqq J_0(\bar{u}) + \frac{\delta}{2} = \int F(x, \bar{u}) + \frac{\delta}{2}.$$

Therefore,

$$\frac{\varepsilon^2}{2}\int (u'_\varepsilon)^2 \leqq \int F(x, \bar{u}) - \int F(x, u_\varepsilon) + \frac{\delta}{2}. \tag{20}$$

Taking now the limit and using that $u_\varepsilon \to u$ pointwise, we obtain via (19) that the right-hand side of (20) becomes negative for ε sufficiently small, a contradiction. Q.E.D.

Remark 3. The degree of complexity of stable equilibria for the case in which F does not depend explicitly on x has been investigated in one space dimension by Chafee [C] and in higher space dimensions by Casten and Holland [CH2] and independently by Matano [M]. That the extent of complexity of stable equilibria in the general case ($\mathscr{F} = F(x, u)$) can be estimated uniformly with respect to the diffusion coefficient is a point that apparently has not been exploited in settings similar to ours.

Remark 4. How small ε has to be taken so that u_ε is a qualitatively good approximation to $\bar{u}$ is determined by the difference between the energy levels. It can be shown via the implicit function theorem that if ε is outside this range then u_ε in general will not exhibit a sharp transition and so it will be a poor (qualitatively) approximation. For example, $u_\varepsilon \equiv$ constant for ε large enough is a possibility for appropriate $\mathscr{F}$. This question seems to be intimately related to uniqueness for the minimizer of J_ε [AS].

Appendix. We refer the reader to [CGS1] and to the references therein for the physical background of the problem.

Consider the functional

$$J_\varepsilon(u) = \int_{-1}^{1} [W(u(x)) + \varepsilon^2(u'(x))^2] \tag{21}$$

with the constraint

$$\int_{-1}^{1} u = M. \tag{22}$$

(P_ε): Minimize J_ε under the constraint (22) for $u > 0$, $u \in W^{1,2}$.

(P_0): Minimize J_0 under the constraint (22) for $u > 0$ such that $W(u) \in L^1$. We take

(i) $W \in C^2(0, \infty)$,

(ii) $W'' > 0$ on $(0, \bar{\alpha}) \cup (\bar{\beta}, \infty)$, $W'' < 0$ on $(\bar{\alpha}, \bar{\beta})$,

(iii) $W'(0) < W'(\bar{\beta})$, $W'(\infty) > W'(\bar{\alpha})$,

(iv) $\alpha_0 < r < \beta_0$, $r = M/2$.

(See Fig. B.)

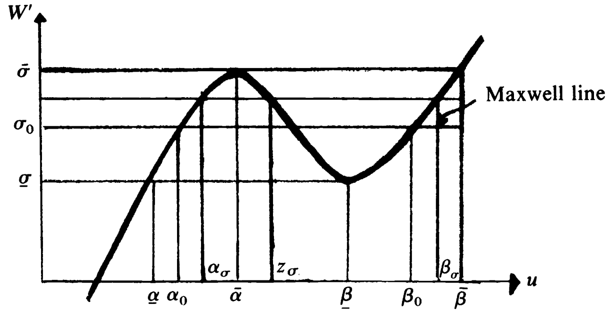

FIG. B

The problem (P_0) is solved with the auxiliary functional

$$\int_{-1}^{1} [W(u(x)) - \sigma u(x)],$$

σ = constant, a Lagrange multiplier. At a minimum the Weierstrass-Erdmann corner conditions have to be satisfied:

$$W'(u) = \sigma \text{ at points of continuity of } u,$$

$$W(u) = \sigma u \text{ continuous across jumps of } u.$$

These last conditions force the solution to be either constant or piecewise constant:

$$\bar{u}(x) = \begin{cases} \alpha_0, & x \in S_1, \\ \beta_0, & x \in S_2. \end{cases} \tag{23}$$

S_1, S_2 are disjoint measurable sets whose union is $[-1, 1]$ and

$$W(\beta_0) - W(\alpha_0) = \sigma_0(\beta_0 - \alpha_0),$$

$$\sigma_0 = W'(\alpha_0) = W'(\beta_0),$$

$$l_i = |S_i|, \quad l_1 = \frac{2(\beta_0 - r)}{\beta_0 - \alpha_0}, \quad l_2 = \frac{2(r - \beta_0)}{\beta_0 - \alpha_0}.$$

The condition $\alpha_0 < r < \beta_0$ forces the two-phase solution as the only possibility. Since only the measures l_i are determined but not the sets themselves there are infinitely many global minimizers for (P_0). The following theorem shows that from these infinitely many two-phase solutions the single-interface solution

$$\bar{u}(x) = \begin{cases} a_0, & -1 \leqq x \leqq -1 + l_1, \\ \beta_0, & -1 + l_1 < x \leqq 1 \end{cases}$$

or its reversal, $\bar{u}(-x)$, are preferred. In fact we have the following.

THEOREM A1 [CGS1]. *Let $\{u_{\varepsilon_n}\}$ be a sequence of global minimizers of* (21), (22). *Then u_{ε_n} or its reversal converges as $\varepsilon_n \to 0$, pointwise, to $\bar{u}(x)$.*

Remark A1. In [CGS1] additional information about the asymptotic shape (in ε) of the global minimizers is obtained as well as uniqueness of the global minimizer for ε small enough.

Fix ε and consider the Euler-Lagrange equation corresponding to (21), (22):

$$2\varepsilon^2 u_\varepsilon'' = W'(u_\varepsilon) - \sigma_\varepsilon, \qquad u_\varepsilon'(-1) = u_\varepsilon'(1) = 0. \tag{24}$$

LEMMA A2. *There is a smooth minimizer to* (21), (22) *that satisfies classically* (24) *and moreover*

$$\underset{\sim}{\sigma} \leqq \sigma_\varepsilon \leqq \bar{\sigma}, \qquad \underset{\sim}{\alpha} \leqq u_\varepsilon \leqq \bar{\beta} \tag{25}$$

with strict inequalities for nonconstant solutions.

Proof. The existence of a smooth minimizer is classical and is omitted. To establish (25), note that it follows from (24) if u_ε attains its minimum and its maximum in the interior. Indeed, in this case $W'(\max u_\varepsilon) \leqq \sigma_\varepsilon \leqq W'(\min u_\varepsilon)$ and the conclusion follows from Fig. B. In general by reflecting we can extend u_ε periodically on $\mathbb{R}$ so that the extension satisfies (24) everywhere and thus we reduce the situation to that previously considered. Q.E.D.

LEMMA A3. *Let u_ε be a global minimizer. Then we have the estimate*

$$\int |u_\varepsilon'|^2 \leqq \frac{C}{\varepsilon^2}. \tag{26}$$

Proof. The argument is identical to that in Lemma 2, § 2.

LEMMA A4. *Nonmonotonic solutions of* (24) *are not stable.*

Proof. The argument is similar to the proof of Lemma 3. See also [CGS1, p. 348].

LEMMA A5. *Let $\{u_{\varepsilon_n}\}$ be a sequence of* (*monotone increasing*) *global minimizers. Then there is a subsequence, denoted again by $\{u_{\varepsilon_n}\}$ that converges pointwise to a monotone function u which satisfies at points of continuity*

$$W'(u) = \sigma \quad \textit{for some } \sigma \textit{ in } [\underset{\sim}{\sigma}, \bar{\sigma}].$$

Proof. Multiplying (24) by ϕ, a smooth function, and integrating by parts, we obtain ($\varepsilon_n \equiv \varepsilon$)

$$-2\varepsilon^2 \int u_\varepsilon' \phi' = \int W'(u_\varepsilon)\phi - \int \sigma_\varepsilon \phi. \tag{27}$$

By Lemma A3 and the Schwarz inequality we obtain that the left-hand side of (27) converges to zero as $\varepsilon \to 0$. By (24A) we may assume that

$$\sigma_\varepsilon \to \sigma, \qquad \underset{\sim}{\sigma} \leqq \sigma \leqq \bar{\sigma}.$$

By Helly's theorem and the dominated convergence theorem we conclude from (26)

$$\int W'(u)\phi - \int \sigma\phi = 0 \tag{28}$$

and by (22),

$$\int_{-1}^{1} u = M = 2r. \tag{29}$$

The lemma follows from (28). Q.E.D.

Since u is monotone increasing, the only continuous possibilities left in the light of $a_0 < r < \beta_0$ are (see Fig. B):

$$\text{(i)} \qquad u(x) = \begin{cases} \alpha_\sigma & \text{on } [-1, x_1]. \\ z_\sigma & \text{on } (x_1, x_2], \\ \beta_\sigma & \text{on } (x_2, 1], \end{cases}$$

$$\text{(ii)} \qquad u(x) = \begin{cases} \alpha_\sigma & \text{on } [-1, x_1], \\ z_\sigma & \text{on } (x_1, 1], \end{cases}$$

$$\text{(iii)} \qquad u(x) = \begin{cases} \alpha_\sigma & \text{on } [-1, x_1], \\ \beta_\sigma & \text{on } (x_1, 1], \end{cases}$$

$$\text{(iv)} \qquad u(x) = \begin{cases} z_\sigma & \text{on } [-1, x_1], \\ \beta_\sigma & \text{on } (x_1, 1]. \end{cases}$$

By the Weierstrass-Erdmann criterion from these the only one that is a global minimizer for J_0 under the constraint (22) is given in (23).

LEMMA A6. *Let u_ε be as in Lemma* A5. *Then*

$$\overline{\lim_{\varepsilon \to 0}}\, J_\varepsilon(u_\varepsilon) \leqq J_0(\bar{u}). \tag{30}$$

Proof. Consider the function

$$\tilde{u}_\varepsilon(x) = \begin{cases} \alpha_0 & \text{on } [-1, -1 + l_1 - \varepsilon], \\ \beta_0 & \text{on } (1 - l_2 + \varepsilon, 1], \\ \text{linear} & \text{on } (-1 + l_1 - \varepsilon,\ 1 - l_2 + \varepsilon]. \end{cases}$$

Note that $\int_{-1}^{1} \tilde{u}_\varepsilon = M$. A simple computation reveals that $J_\varepsilon(\tilde{u}_\varepsilon) \to \int_{-1}^{1} W(\bar{u}) = J_0(\bar{u})$. Since $J_\varepsilon(u_\varepsilon) \leqq J_\varepsilon(\tilde{u}_\varepsilon)$ we are done. Q.E.D.

Proof of Theorem A1 (*conclusion*). Assume that for some subsequence the limiting state u given by Lemma A5 is different from $\bar{u}$. In the light of the remark following that lemma we may assume that

$$J_0(\bar{u}) < J_0(u) - \delta, \qquad \delta > 0 \quad \text{fixed.} \tag{31}$$

On the other hand by (30) for ε sufficiently small we have

$$J_\varepsilon(u_\varepsilon) \leqq J_0(\bar{u}) + \frac{\delta}{2}. \tag{32}$$

Therefore

$$\varepsilon^2 \int_{-1}^{1} (u_\varepsilon'(x))^2 \leqq \int W(\bar{u}) - \int W(u_\varepsilon) + \frac{\delta}{2}. \tag{33}$$

Since $\int W(u_\varepsilon) \to \int W(u) = J_0(u)$ we conclude via (31) that the right-hand side of (33) becomes negative in the limit, a contradiction. Q.E.D.

Remark A2. In a similar way one can establish the analogue of Theorem A1 for

$$J_\varepsilon(u) = \int_{-1}^{1} [W(u'(x)) + \varepsilon^2 (u''(x))^2]$$

subject to

$$u(-1) = u(1) = 0$$

that models exchanges of phase of a one-dimensional elastic material, originally studied with phase plane techniques by Carr, Gurtin and Slemrod [CGS2].

Acknowledgments. We are indebted to P. Fife for a valuable communication; also we would like to acknowledge a conversation with B. Nicolaenko in the course of which [CGS1] was brought to our attention. Finally we wish to thank H. Simpson for useful discussions on the contents of this paper.

FILIPPOV SOLUTIONS TO SINGULAR DIFFERENTIAL EQUATIONS*

SHIVA SHANKAR†

Abstract. This paper considers solutions to singular differential equations in the sense of Filippov. Such singular systems occur in the order reduced models of singularly perturbed systems as well as in the semistate description of nonlinear circuits.

Key words. singular differential equations, Filippov solutions

AMS(MOS) subject classifications. 34E15, 34A08, 34A34

Introduction. A problem often encountered in control and system theory is the modelling of dynamical systems exhibiting a multi-time-scale behaviour. A model that is often employed is the singular perturbation model, where the derivatives of some of the state vectors are multiplied by a small parameter ε, namely

$$(1_\varepsilon)\qquad \begin{aligned} &\dot{x}-f(t,x,y)=0,\\ &\varepsilon\dot{y}-g(t,x,y)=0,\\ &x(t_0)=x_\varepsilon, \qquad y(t_0)=y_\varepsilon \end{aligned}$$

where x is in $\mathbb{R}^n$, y in $\mathbb{R}^p$, and f and g are functions defined on some open subset of $\mathbb{R}\times\mathbb{R}^n\times\mathbb{R}^p$ with values in $\mathbb{R}^n$ and $\mathbb{R}^p$, respectively. A first step in the analysis and design of controllers for such systems consists of "order reduction" where ε is formally equated to 0. This reduced model

$$(2)\qquad \begin{aligned} &\dot{x}-f(t,x,y)=0,\\ &g(t,x,y)=0,\\ &x(t_0)=x_0, \qquad y(t_0)=y_0, \end{aligned}$$

represents the slow response or the "quasi-steady-state." Note that while the initial conditions in (1_ε) can be arbitrary, in (2) they must satisfy $g(t_0,x_0,y_0)=0$. For more details see Kokotovic, O'Malley and Sannuti [6]. Systems such as (2) also occur in the semistate description of nonlinear circuits [7].

The analysis of the reduced model (2) usually begins with the assumption that at the initial point (t_0,x_0,y_0) satisfying $g(t_0,x_0,y_0)=0$, the partial derivative $(\partial g/\partial y)$ is nonsingular. The implicit function theorem is then employed to determine the (locally) unique manifold $y=y(t,x)$ on which the system (2) is constrained to evolve. Of late there have been attempts to develop a theory when the above assumption of nonsingularity of $(\partial g/\partial y)$ is not satisfied (Rabier and Shankar [8]), or even when g fails to be of class C^1 (Dolezal and Shankar [2]). This note presents another approach to this problem and is motivated by the following considerations.

An important difference between systems (1_ε) and (2), apart from the discrepancy noted above in the assignment of initial values, is that while solutions to (1_ε) are guaranteed for an arbitrary continuous function g, this is not the case as regards system (2). Given that $g(t_0,x_0,y_0)=0$, it may not be that g vanishes on a set whose projection

* Received by the editors November 27, 1983; accepted for publication (in revised form) September 17, 1986.

† Tata Institute of Fundamental Research, Bangalore 560012, India.

to the $\mathbb{R}\times\mathbb{R}^n$ space contains a neighbourhood, say V, of (t_0, x_0). And even if so, the zero set of g may not admit appropriate sections (that is a function $y=y(t,x)$ for (t,x) in V with $g(t,x,y(t,x))=0$) whose substitution in (2) allows the existence of a solution to the resulting system, namely to

$$\dot{x}-f(t,x,y(t,x))=0, \qquad x(t_0)=x_0.$$

This is certainly undesirable, for we would like to consider system (2) as a limit of system (1_ε) as ε tends to 0, and hence would not like to impose any greater regularity on g than is strictly necessary. However minimising regularity requirements on g usually results in a loss of regularity of the solution. In this note we consider solutions to system (2) in the sense of Filippov.

Definition. For D an open set in $\mathbb{R}\times\mathbb{R}^n$, let $h:D\to\mathbb{R}^n$ map (t,x) in D to $h(t,x)$ in $\mathbb{R}^n$. The function $x(t)$ defined on an interval I is called a solution in the sense of Filippov (or a Filippov solution) of the differential equation $\dot{x}-h(t,x)=0$ if $x(t)$ is absolutely continuous and if for almost all t in I and for arbitrary $\delta>0$, the vector $\dot{x}(t)$ belongs to the smallest closed convex set (of $\mathbb{R}^n$) containing all the values of the function $h(t,x)$ where x ranges over almost all of the δ-neighbourhood of the point $x(t)$ (with t fixed). Denoting by konv(E) the convex closure of E, $x(t)$ is then a Filippov solution if for almost all t

$$\dot{x}(t)\in\bigcap_{\delta>0}\ \bigcap_{\mu M=0}\operatorname{konv} f(t, N_\delta(x(t))-M)$$

where $N_\delta(x(t))$ is the δ-ball about $x(t)$ in $\mathbb{R}^n$ and μ is Lebesgue measure.

Filippov solutions to $\dot{x}(t)-h(t,x)=0$ are guaranteed by the following.

THEOREM 1 (Filippov [3]). *Let D be an open set in $\mathbb{R}\times\mathbb{R}^n$ and $h:D\to\mathbb{R}^n$ a locally integrable measurable function. Then for any (t_0,x_0) in D, there exists a Filippov solution to $\dot{x}-h(t,x)=0$ satisfying $x(t_0)=x_0$.*

PROPOSITION. *For X a Polish space and V an open subset of $\mathbb{R}^p$, let $g:X\times V\to\mathbb{R}^p$ be a continuous function such that for some x_0 in X, the partial map $g_{x_0}=g(x_0,\cdot):V\to\mathbb{R}^p$ is injective and whose image contains the origin. Then there exists a neighbourhood N_{x_0} of x_0 in X and a Borel function $h:N_{x_0}\to V$ such that $g(x,h(x))=0$ for all x in N_{x_0}.*

Proof. By the invariance of domain theorem $g(x_0,V)$ is open in $\mathbb{R}^p$ and g_{x_0} is a homeomorphism from V onto $g(x_0,V)$. Choose a closed ball B centered at the origin and contained in $g(x_0,V)$. Let δ be small enough such that for all points v in $B_\delta(v_1)$ for any v_1 in $Bd(B)$—where $B_\delta(v_1)$ is the ball of radius δ with centre v_1 and $Bd(B)$ is the boundary of B—the straight line from 0 through v intersects $Bd(B)$ at a point w with $\|w-v_1\|<$ diameter (B).

Let y_0 and F be the pre-images in V of 0 and B respectively. F is compact and contains y_0. Choose any y in F. Since g is continuous at (x_0,y) there exist neighbourhoods M_y of y and $N_y\subset X$ of x_0 such that

$$\|g(x,y')-g(x_0,y)\|<\frac{\delta}{2} \tag{3}$$

for all x in N_y and y' in M_y. The collection $\{M_y: y\in F\}$ is then an open cover of F, and consequently there exists a finite subcollection $\{M_{y_i}: y_i\in F,\ 1\leqq i\leqq n\}$ which also covers F. Let $N_{x_0}=\bigcap_{i=1}^n N_{y_i}$. Then N_{x_0} is a neighbourhood of x_0 in X.

Given any x in N_{x_0} and y in F, there is an i, $1\leqq i\leqq n$ such that y belongs to M_{y_i}. As x belongs to $N_{x_0}\subset N_{y_i}$, (3) yields

$$\|g(x,y)-g(x_0,y_i)\|<\frac{\delta}{2}.$$

Further as x_0 belongs to N_{y_i},

$$\|g(x_0, y) - g(x_0, y_i)\| < \frac{\delta}{2}.$$

Hence by the triangle inequality

$$\|g(x, y) - g(x_0, y)\| < \delta.$$

Now suppose that 0 is not contained in $g(x, V)$ for some x in N_{x_0}. Let $G: B \to Bd(B)$ be the function which maps u in B to the intersection of $Bd(B)$ with the straight line from 0 through $g(x, g_{x_0}^{-1}(u))$. As 0 is not in $g(x, V)$, G is well defined. Clearly G is continuous. Moreover the choice of δ ensures that $\|G(u) - u\|$ is strictly less than the diameter of B.

G restricted to the boundary of B is homotopic to the identity where the homotopy H moves $G(u)$ to u along the shorter great circle path. Consider $H \circ G: B \to Bd(B)$. This map is a retraction of the ball B onto its boundary, which is absurd (Brouwer's fixed point theorem). Thus for all x in N_{x_0}, $g(x, V)$ contains the origin.

Let $Z_x = \{y \in V: g(x, y) = 0\}$. By the above Z_x is nonempty for each x in N_{x_0}. By the continuity of g_x, each Z_x is closed. The union of the Z_x for x in N_{x_0} is then clearly a Polish subspace of $X \times V$. A standard result now guarantees the existence of a Borel section (Arveson, [1, p. 75, Thm. 3.4.1]) that is a Borel function $h: N_{x_0} \to V$ such that $h(x)$ is in Z_x. But then $g(x, h(x)) = 0$ for all x in N_{x_0}. □

THEOREM 2. *Let $f: D \to \mathbb{R}^n$, $g: D \to \mathbb{R}^p$ be functions defined on an open set $D \subset \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^p$ such that*

(i) *f is a locally integrable Borel map,*

(ii) *g is continuous and for some (t_0, x_0, y_0) in D the partial map $g(t_0, x_0, \cdot)$ is injective with y_0 the (unique) point such that $g(t_0, x_0, y_0) = 0$.*

Then there exists an open interval containing t_0, an absolutely continuous function $x: I \to \mathbb{R}^n$ and a Borel measurable function $y: I \to \mathbb{R}^p$ such that for all t in I $(t, x(t), y(t))$ is in D with

$$\begin{aligned} &\dot{x}(t) - f(t, x(t), y(t)) = 0 \qquad \textit{(in the sense of Filippov)},\\ &g(t, x(t), y(t)) = 0,\\ &x(t_0) = x_0, \qquad y(t_0) = y_0. \end{aligned}$$

Proof. By the above proposition, the projection of the zero set of g onto a subset of $\mathbb{R} \times \mathbb{R}^n$ contains an open neighbourhood N of (t_0, x_0). Further there exists a Borel function $h: N \to \mathbb{R}^p$ such that $g(t, x, h(t, x)) = 0$ for every (t, x) in N. Clearly $h(t_0, x_0) = y_0$.

Define the function $\underset{\sim}{f}: N \to \mathbb{R}^n$ which maps (t, x) in N to $f(t, x, h(t, x))$. Obviously $\underset{\sim}{f}$ is Borel. By replacing D by its intersection with a sufficiently large closed ball, it can be assumed that $h(N)$ is bounded. Hence $\underset{\sim}{f}$ is locally integrable. By Filippov's Theorem, there is an absolutely continuous $x: I \to \mathbb{R}^n$ that is a Filippov solution to

$$\dot{x} - \underset{\sim}{f}(t, x) = 0, \qquad x(t_0) = x_0.$$

Let $y(t) = h(t, x(t))$. Then $y(t)$ is Borel and

$$\begin{aligned} &\dot{x}(t) - f(t, x(t), y(t)) = 0 \quad \text{(in the sense of Filippov)},\\ &g(t, x(t), y(t)) = 0,\\ &x(t_0) = x_0, y(t_0) = y_0. \end{aligned}$$

□

Remark. Although Filippov's Theorem requires only Lebesgue measurability it is necessary to assume that f be Borel measurable in the above theorem. This is because Lebesgue measurability of f and even continuity of h does not imply measurability of $f(t, x, h(t, x))$ (Halmos [4, p. 83]).

The above result can be somewhat sharpened for scalar constrained systems, namely when p is equal to 1, that is, when g is a real valued function.

THEOREM 3. *Let $f: D \to \mathbb{R}^n$, $g: D \to \mathbb{R}$ be functions defined on an open set $D \subset \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}$* such that

(i) *f is a locally integrable Borel map*;

(ii) *g is continuous in the (t, x) and y variables separately. For some (t_0, x_0), the image of the partial map $g(t_0, x_0, \cdot)$ contains a neighbourhood of the origin.*

Then given y_0 in $\mathbb{R}$ such that $g(t_0, x_0, y_0) = 0$, there exists an open interval containing t_0, an absolutely continuous function $x: I \to \mathbb{R}^n$ and a Lebesgue measurable function $y: I \to \mathbb{R}$ such that for all t in I $(t, x(t), y(t))$ is in D with

$$\dot{x}(t) - f(t, x(t), y(t)) = 0 \qquad (\textit{in the sense of Filippov}),$$

$$g(t, x(t), y(t)) = 0,$$

$$x(t_0) = x_0, \qquad y(t_0) = y_0.$$

Proof. Choose compact sets T and X in $\mathbb{R}$ and $\mathbb{R}^n$ with nonempty interior that contain the points t_0 and x_0 respectively. Let Y be a compact interval in $\mathbb{R}$ such that $g(t_0, x_0, Y)$ contains a neighbourhood of the origin. Consider g restricted to $T \times X \times Y$. By a result of B. E. Johnson (namely Proposition 2.1 in [5]), $Z = g^{-1}(0)$ is a Borel subset of $T \times X \times Y$. It can be easily verified that the projection of Z onto a subset of $T \times X$ contains a neighbourhood N of (t_0, x_0). By Theorem 3.4.3 in Arveson [1] there exists a Lebesgue measurable function $h: N \to \mathbb{R}$ such that $g(t, x, h(t, x)) = 0$. Also $h(t_0, x_0)$ can be chosen to equal y_0 (as the value at a point can be changed without effecting the measurability of h).

The remainder of the proof now follows in a manner identical to that of the second half of the proof of Theorem 2. □

Acknowledgments. These results appeared in [9]. I am grateful to Professor V. Dolezal for many discussions as well as to Professor A. H. Zemanian for his careful reading of that manuscript.

ASYMPTOTIC ANALYSIS OF A SINGULAR PERTURBATION PROBLEM*

SHAGI-DI SHIH† AND R. BRUCE KELLOGG‡

Abstract. We study, in a rectangle $0 < x < a$ and $0 < y < b$, the Dirichlet problem for an elliptic differential equation of the form

$$-\epsilon\Delta u_\epsilon + p\frac{\partial u_\epsilon}{\partial x} + qu_\epsilon = f(x,y)$$

where ϵ is a small parameter $0 < \epsilon \ll 1$, Δ is the Laplacian operator, p is a positive number, q is a nonnegative number and all of the input data are smooth. We establish a constructive procedure for obtaining an asymptotic approximation of arbitrary order with respect to ϵ of this singular perturbation problem, and also give a proof of its uniform validity in the closed rectangle by the use of the maximum principle and exponential estimates of all boundary or corner layer functions. The corner singularities of parabolic boundary layer functions are removed by introducing elliptic boundary layer functions along the characteristic boundaries $y = 0$ and $y = b$. Both ordinary corner layer functions and elliptic corner layer functions are employed at the outflow corners $(a, 0)$ and (a, b).

An application is made to settle a long-standing problem in the magnetohydrodynamic flow in a rectangular duct.

Key words. singular perturbation, outer approximation, ordinary boundary layer, elliptic boundary layer, parabolic boundary layer, ordinary corner layer, elliptic corner layer, maximum principle, magnetohydrodynamics

where ϵ is a small parameter $0 < \epsilon \ll 1$, Δ is the Laplacian operator, p is a positive number, q is a nonnegative number, the remaining input data $f(x,y)$, $g_1(y)$, $g_2(y)$, $g_3(x)$, and $g_4(x)$ are assumed to be smooth. We also suppose that the assigned boundary functions are continuous at the corners. That is,

$$g_1(0) = g_3(0), \qquad g_1(b) = g_4(0), \tag{1.3a,b}$$

$$g_2(0) = g_3(a), \qquad g_2(b) = g_4(a). \tag{1.3c,d}$$

The distinguishing feature of a singular perturbation problem is that a small parameter multiplies some terms in the differential equation which, if absent, would change the character of the equation. Often these contain the highest derivatives in the equation and the approximation as this parameter tends to zero is therefore governed by a lower order equation which cannot satisfy all the boundary conditions prescribed. Hence the solution converges nonuniformly in the domain as the parameter tends to zero. Problems of this type frequently arise in fluid dynamics [14], [29], [34], [44], heat transfer [1], [3], theory of plates and shells [30], oil reservoir simulation [38], and magnetohydrodynamic flow [41]. The specific character of the problem (1.1), (1.2a,b,c,d) is brought about by the presence of the four corners of right angle for the domain and by the fact that the parts of the boundary, $y = 0$ and $y = b$, coincide with the characteristic curves of the reduced equation

$$p\frac{\partial u_0}{\partial x} + qu_0 = f(x,y), \tag{1.4}$$

which is obtained from (1.1) by putting $\epsilon = 0$. The boundary $x = 0$ is called the inflow boundary while the boundary $x = a$ is called the outflow boundary.

The purpose of this paper is to establish a constructive procedure for obtaining the asymptotic approximation of arbitrary order with respect to ϵ of this singular perturbation problem, and to give a proof of its uniform validity in the closed rectangle by use of the maximum principle and exponential estimates of all boundary or corner layer functions, which will be defined in Section 3. It is well known [13] that ordinary boundary layer functions appear along the outflow boundary $x = a$ while parabolic boundary layer functions occur along the characteristic boundaries $y = 0$ and $y = b$. In 1966, W. Eckhaus and E. M. De Jager [11] discovered the singularities of parabolic boundary layer functions near the inflow corners $(0,0)$ and $(0,b)$. These corner singularities of parabolic boundary layer functions are removed by introducing elliptic boundary layer functions along the characteristic boundaries. Both ordinary corner layer functions and elliptic corner layer functions are employed at the outflow corners $(a,0)$ and (a,b).

An application is made to settle a long-standing problem in the magnetohydrodynamic flow in a rectangular duct.

We give a brief historical survey of studies on the elliptic singular perturbation problems of the type considered in this work. In providing references we have tried to give those that might be of interest for further reading, rather than presenting a comprehensive bibliography of the subject. We apologize to those who feel neglected.

2. Historical survey. In 1944, W. Wasow [46] studied the problem of the following type

$$-\epsilon\Delta u + \frac{\partial u}{\partial x} = f(x,y) \tag{2.1}$$

over a finite plane domain B with the smooth boundary C under the prescribed boundary condition

$$u = g(x,y) \tag{2.2}$$

on C. Both f and g are smooth functions. It is shown that, as $\epsilon \to 0+$, the solution of the problem (2.1), (2.2) converges to the solution of the reduced equation

$$\frac{\partial u}{\partial x} = f(x,y),$$

assuming the prescribed boundary values along the inflow boundary of C, not the whole boundary.

In 1950, N. Levinson [32] considered the Dirichlet boundary value problem for the equation of the following type:

$$-\epsilon\Delta u + A(x,y)u_x + B(x,y)u_y + C(x,y)u = D(x,y) \tag{2.3}$$

over an open simply or multiply connected region R whose boundary S consists of a finite number of simple closed curves. Let $R \cup S$ be contained in an open connected region R' and suppose all of the data of the problem are smooth in R'. Furthermore, we require that $A^2(x,y) + B^2(x,y) > 0$ in R' and that either R' is simply connected or $C(x,y) > 0$ in R'. Either hypothesis suffices to establish a maximum principle in $R \cup S$. Under these conditions, the Dirichlet boundary value problem for (2.3) has a unique solution in $R \cup S$ for each $\epsilon > 0$.

Let S_1 be a segment of one of curves of S such that $(A,B)\cdot \boldsymbol{n} < 0$, where $\boldsymbol{n}$ is an outward normal vector of S at point (x,y). Let the characteristic curves of the reduced equation corresponding to (2.3) emanating from S_1 pass out of R on the segment S_2 of a curve of S. The closed simply connected region in $R \cup S$ bounded by S_1 and S_2 and by the two characteristics of the reduced equation of (2.3) joining the endpoints of S_1 and S_2 is called a "regular quadrilateral". Then Levinson proved the following result.

THEOREM 2.1. *In a regular quadrilateral Q in $R \cup S$ we have*

$$u(x,y) = u_0(x,y) + w(x,y;\epsilon) + O(\sqrt{\epsilon})$$

uniformly in the quadrilateral. The function $u_0(x,y)$ is the solution of the reduced equation of (2.3) *which takes on the given boundary value of u on S_1. The ordinary boundary layer term $w(x,y;\epsilon)$ is defined as follows:*

$$w(x,y;\epsilon) = \begin{cases} h(x,y)\exp\left[\dfrac{-g(x,y)}{\epsilon}\right], & \textit{near } S_2, \\ \exp\left(-\dfrac{\delta}{\epsilon}\right) & \textit{for some } \delta > 0 \textit{ elsewhere in } Q, \end{cases}$$

where $h = u - u_0$ and $g = 0$ on S_2 and g is positive away from S_2. The function g satisfies the nonlinear equation

$$g_x^2 + g_y^2 + Ag_x + Bg_y = 0$$

(g exists and is uniquely determined in a neighborhood of S_2).

In terminology that we will establish below, Levinson treated the "ordinary boundary layer" part of the solution.

In 1957, M. I. Vishik and L. A. Lyusternik [45] studied the equation of the following type

$$-\epsilon\Delta u + \frac{\partial u}{\partial x} + u = f(x,y) \tag{2.4}$$

in the rectangle Ω, $0 < x < a$ and $0 < y < b$, under the homogeneous boundary condition

$$u = 0$$

on the boundary of Ω. They gave an expansion of the solution of the form for some $\delta > 0$

$$u(x,y) = u_0(x,y) + z_0(x,Y)\,\psi\Big(\frac{y}{\delta}\Big) + z_0^T(x,Y^T)\,\psi\Big(\frac{b-y}{\delta}\Big) + w_0(X_1,y)\,\psi\Big(\frac{a-x}{\delta}\Big) + R_0(x,y;\epsilon)$$

where $Y = y/\sqrt{\epsilon}$, $Y^T = (b-y)/\sqrt{\epsilon}$, $X_1 = (a-x)/\epsilon$ and the infinitely differentiable smoothing function $\psi(x)$ is identically equal to 1 for $x \le \frac{1}{3}$ and equal to zero for $x \ge \frac{2}{3}$. The function u_0 satisfies the reduced equation under the condition $u_0(0,y) = 0$. The function $z_0(x,Y)$ is a boundary layer near the boundary $y = 0$, which satisfies the parabolic equation

$$-\frac{\partial^2 z_0}{\partial Y^2} + \frac{\partial z_0}{\partial x} + z_0 = 0$$

over the semi-infinite region $0 < x < a$, $0 < Y < \infty$ under the conditions

$$z_0(0,Y) = 0, \quad z_0(x,0) = -u_0(x,0).$$

The function z_0^T is a boundary layer near the part of the boundary given by $y = b$, $0 \le x \le a$, which has the same structure as z_0. The function $w_0(X_1,y)$ is a boundary layer along the boundary $x = a$, $0 \le y \le b$, which satisfies the ordinary differential equation

$$\frac{\partial^2 w_0}{\partial {X_1}^2} + \frac{\partial w_0}{\partial X_1} + \epsilon w_0 = 0$$

on the unbounded interval $0 < X_1 < \infty$ under the boundary condition

$$w_0(0,y) = -u_0(a,y) - z_0\Big(a, \frac{y}{\sqrt{\epsilon}}\Big)\,\psi\Big(\frac{y}{\delta}\Big) - z_0^T\Big(a, \frac{b-y}{\sqrt{\epsilon}}\Big)\,\psi\Big(\frac{b-y}{\delta}\Big).$$

From this Vishik and Lyusternik deduced on the basis of the maximum principle [39] that

$$R_0 = O(\epsilon)$$

everywhere except in the neighborhood of the points $(a,0)$ and (a,b), under the assumption that the smooth function $f(x,y)$ vanishes at the points $(0,0)$ and $(0,b)$. They also asserted that on applying an iteration process, one can obtain, as above, an asymptotic formula of arbitrary order if the parameters of the problem are sufficiently smooth. In 1966, W. Eckhaus and E. M. De Jager [11] made the remark that the extension of the theory involving parabolic boundary layers to higher order approximation should not be considered a trivial matter.

In our terminology, Vishik and Lyusternik treated the "parabolic boundary layers" along the characteristic boundaries of the region.

In 1964, J. K. Knowles and R. E. Messick [30] discussed a class of singular perturbation problems arising in the theory of thin elastic plates and shells. An important feature of these problems is that the boundary of the domain coincides either partially or entirely with portions of characteristic curves of the reduced equations. In order to understand this exceptional character of a characteristic boundary, Knowles and Messick considered the equation of the following type

$$-\epsilon\Delta u + \frac{\partial u}{\partial x} = 0 \tag{2.5}$$

in the semi-infinite strip $R: 0 < x < a$ and $0 < y < \infty$, under the boundary conditions

$$u(0,y) = 0, \quad u(a,y) = 0, \quad 0 < y < \infty, \tag{2.6a, b}$$

$$u(x,0) = g(x), \quad 0 \leq x \leq a, \tag{2.6c}$$

where the function u and its partial derivatives are required to be bounded as $y \to \infty$. They obtained as an approximation to the solution the function

$$z_0(x,Y) + W_0(X_1,Y) + V_0(X_1,Y_1)$$

where $Y = y/\sqrt{\epsilon}$, $X_1 = (a-x)/\epsilon$, and $Y_1 = y/\epsilon$. Note that for this problem, the solution of the reduced equation under the condition $u_0(0,y) = 0$ is $u_0(x,y) = 0$, which also satisfies the boundary condition (2.6b). Therefore the ordinary boundary layer along the boundary $x = a$ is identical to zero. The function $z_0(x,Y)$ is the parabolic boundary layer function along the boundary $y = 0$, defined by the equation

$$-\frac{\partial^2 z_0}{\partial Y^2} + \frac{\partial z_0}{\partial x} = 0$$

over the domain $0 < x < a$, $0 < Y < \infty$ under the conditions

$$z_0(x,0) = g(x), \quad z_0(0,Y) = 0,$$

and the condition that $z_0(x,Y)$ decays exponentially in Y. The function $W_0(X_1,Y)$ is a "corner layer" at the outflow corner $(a,0)$, defined by the ordinary differential equation

$$\frac{\partial^2 W_0}{\partial {X_1}^2} + \frac{\partial W_0}{\partial X_1} = 0$$

on the unbounded interval $0 < X_1 < \infty$ under the conditions

$$W_0(0,Y) = -z_0(a,Y)$$

and

$W_0(X_1,Y)$ has the exponential decay property in both X_1 and Y.

Then it follows that

$$W_0(X_1,Y) = -z_0(a,Y)\exp(-X_1).$$

The function $V_0(X_1,Y_1)$ is a "corner layer" at the outflow corner $(a,0)$, defined by the elliptic equation

$$-\Big(\frac{\partial^2 V_0}{\partial {X_1}^2} + \frac{\partial^2 V_0}{\partial {Y_1}^2}\Big) + \frac{\partial V_0}{\partial X_1} = 0$$

over the quarter-plane $0 < X_1 < \infty$ and $0 < Y_1 < \infty$ under the conditions

$$\begin{aligned} &V_0(X_1,0) = -W_0(X_1,0) = g(a)\exp(-X_1),\\ &V_0(0,Y_1) = 0, \end{aligned}$$

and

$V_0(X_1,Y_1)$ decays exponentially in X_1 and Y_1.

Knowles and Messick mentioned that using a representation of the solution to the original boundary value problem (2.5), (2.6a,b,c), which involves the expansion of the Green's function in a series of modified Bessel functions, it is possible to prove the statements listed below. First let us define some notation: Let S be the boundary of R. δ denotes an arbitrary small positive number. The symbols ${}_\delta D$ and D_δ represent quarter-discs at $(0,0)$ and $(a,0)$, respectively, and are defined as follows:

$$\begin{aligned} {}_\delta D &= \{(x,y) : x \geq 0,\ y \geq 0,\ x^2 + y^2 < \delta^2\},\\ D_\delta &= \{(x,y) : x \geq 0,\ y \leq a,\ x^2 + (y-a)^2 < \delta^2\}. \end{aligned}$$

It can be shown that

i) There exist positive constants $M(\delta)$, $c(\delta)$ such that

$$|u(x,y)| \leq M(\delta)\exp\Big(-\frac{c(\delta)}{\epsilon}\Big)$$

for all $y \geq \delta$, $0 \leq x \leq a$.

ii) There exists a positive constant $M(\delta)$ such that

$$\Big|u(x,y) - z_0\Big(x, \frac{y}{\sqrt{\epsilon}}\Big)\Big| < M(\delta)\epsilon \tag{2.7}$$

for all $(x,y) \in R \cup S - {}_\delta D - D_\delta$.

iii) If $g(x) = O(x)$ as $x \to 0+$, then there exists a constant $M(\delta) > 0$ such that (2.7) holds for $(x,y) \in R \cup S - D_\delta$.

iv) If $g(x) = O(x)$ as $x \to 0+$ and $g(x) = O(a-x)$ as $x \to a-$, then there exists a positive constant M such that

$$\left|u(x,y) - z_0\left(x, \frac{y}{\sqrt{\epsilon}}\right) - W_0\left(\frac{a-x}{\epsilon}, \frac{y}{\sqrt{\epsilon}}\right)\right| \leq M\epsilon$$

for all $(x,y) \in R \cup S$.

In our terminology, Knowles and Messick have thus treated the "ordinary corner layer" and the "elliptic corner layer" at the outflow corner of the region.

In 1966, W. Eckhaus and E. M. De Jager [11] investigated the problem of the following type

$$L_\epsilon u \equiv -\epsilon\Delta u + \frac{\partial u}{\partial x} = 0 \tag{2.8}$$

in the domain Ω, $0 < x < a$ and $0 < y < b$, with the boundary conditions

$$\begin{array}{llll} \text{(2.9a,b)} & u(0,y) = g_1(y), & u(a,y) = g_2(y), & 0 < y < b, \\ \text{(2.9c,d)} & u(x,0) = g_3(x), & u(x,b) = g_4(x), & 0 < x < a. \end{array}$$

The boundary data are assumed to be smooth and to be continuous at the corner points. The solution of the reduced problem is $g_1(y)$, which does not satisfy the given boundary conditions (2.9b,c,d) generally. The local variable $Y = y/\sqrt{\epsilon}$ along the characteristic boundary $y = 0$ transforms (2.8) into

$$-\frac{\partial^2 u}{\partial Y^2} + \frac{\partial u}{\partial x} = \epsilon\frac{\partial^2 u}{\partial x^2}.$$

Define the function $z_0(x,Y)$ as the solution of the reduced equation in local coordinates, that is, we have

$$-\frac{\partial^2 z_0}{\partial Y^2} + \frac{\partial z_0}{\partial x} = 0$$

in the domain $0 < x < a$ and $0 < Y < \infty$. Let z_0 satisfy boundary conditions

$$\begin{aligned} &z_0(0,Y) = 0, \\ &z_0(x,0) = g_3(x) - g_1(0) \equiv \gamma(x). \end{aligned}$$

An explicit form of this function is easily obtained as follows:

$$z_0(x,Y) = \sqrt{\frac{2}{\pi}}\int_{Y/\sqrt{2x}}^{\infty} \exp\left(-\frac{t^2}{2}\right)\gamma\left(x - \frac{Y^2}{2t^2}\right)dt.$$

Furthermore, we have

$$L_\epsilon z_0 = -\epsilon\frac{\partial^2 z_0}{\partial x^2}. \tag{2.10}$$

Due to the assumed continuity of the boundary data, i.e., $\gamma(0) = 0$, we obtain

$$\frac{\partial^2 z_0(x,Y)}{\partial x^2} = \sqrt{\frac{2}{\pi}}\Big[\int_{Y/\sqrt{2x}}^{\infty} \exp\Big(-\frac{t^2}{2}\Big)\,\gamma''\Big(x - \frac{Y^2}{2t^2}\Big)\,dt$$
$$+ \gamma'(0)\,Y\,(2x)^{-3/2}\exp\Big(-\frac{Y^2}{4x}\Big)\Big],$$

where the primes indicate derivatives with respect to the argument. We see that $\partial^2 z_0/\partial x^2$ is uniformly bounded in the closure of Ω if and only if $\gamma'(0) = 0$, which was assumed to be true in the analysis of Vishik and Lyusternik [45]. In the case of general boundary conditions, where $\gamma'(0) \neq 0$, the right-hand side of (2.10) has a singularity at the origin $x = 0$, $y = 0$. The nature of the singularity is most clearly revealed if in (2.10) the origin is approached along any curve $Y = mx^n$, where m and n are constants. The presence of this "corner singularity" indicates that in attempting a proof of the asymptotic properties of the parabolic boundary layer, difficulties should be expected. Also this corner singularity gives more singular functions in the course of the construction of a high order approximation to the parabolic boundary layer.

Eckhaus and De Jager constructed a regularized parabolic boundary layer function $\bar{z}_0$ by replacing $\gamma(x)$ in z_0 by

$$\bar{\gamma}(x) = \gamma(x) - \gamma'(0)\,x\exp\Big(-\frac{x}{\sqrt{\epsilon}}\Big).$$

In other words,

$$\bar{z}_0(x,Y) = \sqrt{\frac{2}{\pi}}\int_{Y/\sqrt{2x}}^{\infty} \exp\Big(-\frac{t^2}{2}\Big)\,\bar{\gamma}\Big(x - \frac{Y^2}{2t^2}\Big)\,dt.$$

The important properties of this function $\bar{\gamma}(x)$ are

i) $\bar{\gamma}(0) = \bar{\gamma}'(0) = 0$, which implies that $\partial^2 \bar{z}_0/\partial x^2$ is bounded uniformly in the closure of Ω, and moreover,

$$\frac{\partial^2 \bar{z}_0}{\partial x^2} = O(1) + O\Big(\epsilon^{-1/2}\Big)$$

in the closure of Ω.

ii) $\bar{\gamma}(x) = \gamma(x) + O(\sqrt{\epsilon})$, which implies that

$$\bar{z}_0(x,Y) = z_0(x,Y) + O\big(\sqrt{\epsilon}\big)$$

uniformly in the closure of Ω.

Define another regularized parabolic boundary layer function $\bar{z}_0^T$ along the boundary $y = b$ similarly. Introduce the local coordinate $X_1 = (a - x)/\epsilon$ along the boundary $x = a$ and define the boundary layer function $\tilde{w}_0(X_1, y)$ as the solution of the ordinary differential equation

$$\frac{\partial^2 \tilde{w}_0}{\partial {X_1}^2} + \frac{\partial \tilde{w}_0}{\partial X_1} = 0$$

over the unbounded interval $0 < X_1 < \infty$ under the conditions

$$\begin{aligned}\tilde{w}_0(0,y) &= g_2(y) - g_1(y) - \bar{z}_0\Big(a, \frac{y}{\sqrt{\epsilon}}\Big) - \bar{z}_0^T\Big(a, \frac{b-y}{\sqrt{\epsilon}}\Big)\\ &\equiv \psi(y),\end{aligned}$$

and

$$\lim_{X_1\to\infty} \tilde{w}_0(X_1, y) = 0.$$

Then it follows that

$$\tilde{w}_0(X_1, y) = \psi(y)\exp(-X_1).$$

Eckhaus and De Jager first showed by using the maximum principle [39] that the solution u of the boundary value problem (2.8) with the boundary conditions (2.9a,b,c,d) has the asymptotic expansion

$$u(x,y) = g_1(y) + \bar{z}_0\Big(x, \frac{y}{\sqrt{\epsilon}}\Big) + \bar{z}_0^T\Big(x, \frac{b-y}{\sqrt{\epsilon}}\Big) + \tilde{w}_0\Big(\frac{a-x}{\epsilon}, y\Big) + R_0(x, y; \epsilon),$$

where the remainder R_0 satisfies

$$R_0 = O(\sqrt{\epsilon})$$

uniformly in the closure of Ω with the exception of a neighborhood of the two corner points $(a, 0)$ and (a, b). Note that at $y = 0$ and $y = b$, $\psi''(y)$ is bounded but of order of $1/\epsilon$. To get a better estimate for the remainder term, they introduced the expansion

$$u(x,y) = g_1(y) + \bar{z}_0\Big(x, \frac{y}{\sqrt{\epsilon}}\Big) + \bar{z}_0^T\Big(x, \frac{b-y}{\sqrt{\epsilon}}\Big) + \bar{w}_0\Big(\frac{a-x}{\epsilon}, y\Big) + \bar{R}_0(x, y; \epsilon),$$

with

$$\bar{w}_0\Big(\frac{a-x}{\epsilon}, y\Big) = [\psi(y) + \epsilon(a-x)\,\psi''(y)]\exp\Big(-\frac{a-x}{\epsilon}\Big)$$

and arrived at the conclusion that

$$\bar{R}_0 = O(\sqrt{\epsilon})$$

uniformly in the closure of Ω on the basis of the maximum principle. Furthermore they showed that

$$\bar{w}_0\Big(\frac{a-x}{\epsilon}, y\Big) = \tilde{w}_0\Big(\frac{a-x}{\epsilon}, y\Big) + O(\epsilon)$$

uniformly in the closure of Ω. Summarizing these results, Eckhaus and De Jager have established the following theorem.

THEOREM 2.2. *The asymptotic approximation for* $u(x,y)$

$$u(x,y) = g_1(y) + z_0\Big(x, \frac{y}{\sqrt{\epsilon}}\Big) + z_0^T\Big(x, \frac{b-y}{\sqrt{\epsilon}}\Big) + \tilde{w}_0\Big(\frac{a-x}{\epsilon}, y\Big) + O(\sqrt{\epsilon})$$

holds uniformly in the closure of Ω*, including the four corner points.*

We remark that the order of the asymptotic error in the above theorem is determined by the presence of corner singularities. If one studies the exceptional case $g_3'(0) = 0$, $g_4'(0) = 0$ in which the corner singularities are absent, one finds along the lines of the preceding analysis that the asymptotic error is no longer $O(\sqrt{\epsilon})$ but $O(\epsilon)$. J. Mauss [35], [36] claimed to improve the estimate of the above theorem and to obtain an $O(\epsilon)$ remainder by using a rather special inequality for the maximum principle when the right-hand side of the differential operator L_ϵ has the singular behavior. The result asserted by Mauss is inconsistent with higher order expansions obtained in this paper.

All of the ideas discussed here need to be modified in order to develop higher order asymptotic expansions. The difficulties involved are

i) Corner singularities appear at the inflow corners of the region in the construction of the parabolic boundary layers along the characteristic boundaries $y = 0$ and $y = b$.

ii) The parabolic boundary layer and ordinary boundary layer overlap in the vicinities of the outflow corners of the region.

The proper way to treat the item ii) is to follow the construction of the ordinary corner layer and the elliptic corner layer done by Knowles and Messick [30] after the modification of the ordinary boundary layer. More precisely, the function $\bar{w}_0(X_1, y)$ in the construction due to Eckhaus and De Jager may be decomposed as

$$\begin{aligned}\bar{w}_0(X_1, y) &= w_0(X_1, y) + W_0(X_1, Y) + W_0^T(X_1, Y^T) \\ &\quad + \epsilon[W_1(X_1, Y) + W_1^T(X_1, Y^T)] + \epsilon^2 w_2(X_1, y),\end{aligned}$$

where the ordinary boundary layer functions $w_0(X_1, y)$ and $w_2(X_1, y)$ satisfy the equations

$$\frac{\partial^2 w_i}{\partial X_1{}^2} + \frac{\partial w_i}{\partial X_1} = \begin{cases} 0, & i = 0, \\ -\dfrac{\partial^2 w_{i-2}}{\partial y^2}, & i = 2, \end{cases}$$

over the unbounded interval $0 < X_1 < \infty$ under the conditions

$$w_i(0, y) = \begin{cases} g_2(y) - g_1(y), & i = 0, \\ 0, & i = 2, \end{cases}$$

and

$$w_i(X_1, y) \text{ decays exponentially as } X_1 \to \infty;$$

the ordinary corner layer functions $W_0(X_1, Y)$ and $W_1(X_1, Y)$ satisfy the equations

$$\frac{\partial^2 W_i}{\partial X_1{}^2} + \frac{\partial W_i}{\partial X_1} = \begin{cases} 0, & i = 0, \\ -\dfrac{\partial^2 W_{i-1}}{\partial Y^2}, & i = 1, \end{cases}$$

over the unbounded interval $0 < X_1 < \infty$ under the conditions

$$W_i(0, Y) = \begin{cases} -\bar{z}_0(a, Y), & i = 0, \\ 0, & i = 1, \end{cases}$$

and

$$W_i(X_1, Y) \text{ decays exponentially as } X_1 \to \infty.$$

The functions W_0^T and W_1^T are defined similarly. It is clear that the term w_2 plays no role in this improvement of estimate.

Eckhaus and De Jager investigated the singularities of parabolic boundary layers near the inflow corners, obtained a formal approximation, and proved the uniform validity of the asymptotic approximation to the solution with the estimate of $O(\sqrt{\epsilon})$. Since then, the problem of dealing with these singularities has attracted much attention from mathematicians, e.g., J. Grasman [15] – [18]; L. P. Cook, G. S. S. Ludford and J. S. Walker [9]; L. P. Cook and G. S. S. Ludford [10]; A. M. Il'in and E. F. Lelikova [24]; V. F. Butuzov [4]; and D. J. Temperley [43]. This type of difficulty also takes place in the problems of the interior layers due to the nonsmooth boundary conditions [8], [20], [36], the domains with corners and noncharacteristic boundary [20], and the nonconvex domains [20], [36].

A similar phenomenon occurs in the problem

$$-(\epsilon u_{yy} + u_{xx}) + u_y = f(x, y), \quad 0 < \epsilon \ll 1,$$

defined on the unit square T, $0 < x < 1$ and $0 < y < 1$, with the prescribed Dirichlet boundary conditions. In the event that the solution of this problem converges to the solution of the reduced problem, we can anticipate the ordinary boundary layer behavior in the vicinity of the upper edge of T, since the solution $u_0(x, y)$ of the reduced equation is uniquely determined throughout T by the boundary values assumed on the other three edges. Note that the reduced equation is a partial differential equation of parabolic type. Thus when one attempts to determine an asymptotic solution, one has to treat the corner singularities of the derivative $\partial^2 u_0/\partial y^2$ first. Such singularities always exist no matter how smooth the prescribed boundary conditions may be unless certain compatibility conditions hold. Furthermore, the construction of the ordinary boundary layer requires the smoothness of the derivative $\partial^2 u_0/\partial x^2$ at point $(x, 1)$. This type of problem had been studied to obtain an asymptotic approximation of arbitrary order with respect to ϵ by G. E. Latta [31], R. E. O'Malley, Jr. [37], and Peng-Cheng Lin and Fa-Wang Liu [33]. None of these authors have treated the difficulties mentioned above.

J. Grasman [15] studied the problem of the following type

$$L_\epsilon u \equiv -\epsilon \Delta u + \frac{\partial u}{\partial x} = 0 \tag{2.11}$$

over the quarter-plane $0 < x < \infty$ and $0 < y < \infty$ under the boundary conditions

$$u(x, 0) = g(x), \qquad g(0) = 0, \tag{2.12a}$$

$$u(0, y) = 0, \tag{2.12b}$$

by means of the Green's theorem, which yields the exact solution. The asymptotic expansion of the integral representation of the solution is shown to be

$$\begin{aligned}u(x,y) &= \sqrt{\frac{2}{\pi}}\int_{y/\sqrt{2\epsilon x}}^{\infty}\exp\Big(-\frac{t^2}{2}\Big)\, g\Big(x-\frac{y^2}{2\epsilon t^2}\Big)\,dt\\ &\quad+\epsilon\Big\{\tilde v_0\Big(\frac{x}{\epsilon},\frac{y}{\epsilon}\Big)-g'(0)\,\epsilon^{-1}\sqrt{\frac{2}{\pi}}\int_{y/\sqrt{2\epsilon x}}^{\infty}\exp\Big(-\frac{t^2}{2}\Big)\cdot\Big(x-\frac{y^2}{2\epsilon t^2}\Big)\,dt\\ &\quad+\sqrt{\frac{2}{\pi}}\int_{y/\sqrt{2\epsilon x}}^{\infty}\exp\Big(-\frac{t^2}{2}\Big)\frac{t^2-1}{2}\Big[g'\Big(x-\frac{y^2}{2\epsilon t^2}\Big)-g'(0)\Big]\,dt\Big\}\\ &\quad+O(\epsilon^2)\end{aligned}$$

uniformly for $x \geq 0$, $y \geq 0$, where the term $\epsilon\tilde v_0(x/\epsilon, y/\epsilon)$ represents the solution of boundary value problem (2.11), (2.12a,b) in the case that $g(x) = xg'(0)$. In order to understand this uniformly valid expansion from another viewpoint, let us define the functions $v_0(x/\epsilon, y/\epsilon;\epsilon)$, $z_0(x, y/\sqrt{\epsilon})$, and $z_1(x, y/\sqrt{\epsilon})$ by

$$v_0\Big(\frac{x}{\epsilon},\frac{y}{\epsilon};\epsilon\Big)=\epsilon\tilde v_0\Big(\frac{x}{\epsilon},\frac{y}{\epsilon}\Big),$$

$$z_0\Big(x,\frac{y}{\sqrt{\epsilon}}\Big)=\sqrt{\frac{2}{\pi}}\int_{y/\sqrt{2\epsilon x}}^{\infty}\exp\Big(-\frac{t^2}{2}\Big)\Big[g\Big(x-\frac{y^2}{2\epsilon t^2}\Big)-g'(0)\cdot\Big(x-\frac{y^2}{2\epsilon t^2}\Big)\Big]\,dt,$$

and

$$z_1\Big(x,\frac{y}{\sqrt{\epsilon}}\Big)=\sqrt{\frac{2}{\pi}}\int_{y/\sqrt{2\epsilon x}}^{\infty}\exp\Big(-\frac{t^2}{2}\Big)\frac{t^2-1}{2}\Big[g'\Big(x-\frac{y^2}{2\epsilon t^2}\Big)-g'(0)\Big]\,dt,$$

respectively. In other words, it follows that

$$u(x,y)=z_0\Big(x,\frac{y}{\sqrt{\epsilon}}\Big)+\epsilon\, z_1\Big(x,\frac{y}{\sqrt{\epsilon}}\Big)+v_0\Big(\frac{x}{\epsilon},\frac{y}{\epsilon};\epsilon\Big)+O(\epsilon^2)\,.$$

From a direct computation, one finds that

i) The functions $z_0(x,Y)$ and $z_1(x,Y)$ are the solutions of the equations

$$-\frac{\partial^2 z_k}{\partial Y^2}+\frac{\partial z_k}{\partial x}=\begin{cases}0, & k=0,\\ \dfrac{\partial^2 z_{k-1}}{\partial x^2}, & k=1,\end{cases}$$

over the quarter plane $0 < x < \infty$ and $0 < Y < \infty$ under the conditions

$$z_k(0,Y)=0,$$

$$z_k(x,0)=\begin{cases}g(x)-g'(0)\,x, & k=0,\\ 0, & k=1,\end{cases}$$

and

$$z_k(x,Y)\to 0 \qquad \text{as } x^2+Y^2\to\infty \text{ (and } x>0 \text{ when } k=0).$$

ii) The function $v_0(X, Y_1; \epsilon)$ is the solution of the elliptic partial differential equation

$$-\left(\frac{\partial^2 v_0}{\partial X^2} + \frac{\partial^2 v_0}{\partial {Y_1}^2}\right) + \frac{\partial v_0}{\partial X} = 0$$

over the quarter-plane $0 < X < \infty$ and $0 < Y_1 < \infty$ under the conditions

$$v_0(0, Y_1; \epsilon) = 0, \quad v_0(X, 0; \epsilon) = g'(0)X\epsilon,$$

and

$$v_0(X, Y_1; \epsilon) \to 0 \qquad \text{as } X^2 + Y_1^2 \to \infty \text{ and } X > 0.$$

This means that a uniformly valid approximation with an accuracy $O(\epsilon^2)$ can be constructed by the usual perturbation method even though Grasman claimed that this cannot be done [15]. The detailed construction of such functions v_k, which will be called as the "elliptic boundary layer" functions, is in Section 3.3. It will be clear later that $v_k(x/\epsilon, y/\epsilon; \epsilon) \equiv 0$, for $k \geq 1$ in the problem (2.11), (2.12a,b). For the sake of convenience, let us write the function z_0 as

$$z_0 = z_0^1 - z_0^2$$

where z_0^1 denotes the integral which contains the function $g(\cdot)$ as part of integrand and z_0^2 is the remaining part of z_0. Grasman [15], [16] asserted that

i) the function z_0^1 is a uniformly valid approximation of the solution of problem (2.11), (2.12a,b) with a remainder term $O(\epsilon)$ for $x \geq 0$, $y \geq 0$, and

ii) the estimate $v_0 - z_0^2 = O(\epsilon)$ holds uniformly for $x \geq 0$, $y \geq 0$.

We cannot draw these conclusions because of the singularity of z_0^2 at the origin $x = 0$, $y = 0$. For it is clear that $v_0 - z_0^2$ vanishes when $x = 0$ or $y = 0$, but

$$L_\epsilon(v_0 - z_0^2) = \epsilon\frac{\partial^2 z_0}{\partial x^2} = g'(0)\sqrt{\frac{\epsilon}{4\pi}}\, y\, x^{-3/2}\exp\left(-\frac{y^2}{4\epsilon x}\right)$$

is singular in the neighborhood of the origin.

Cook and Ludford [10] studied the problem on a semi-infinite strip and analyzed the asymptotic approximation from an exact representation of the solution obtained by means of the Fourier sine transforms. Il'in and Lelikova [24] used the asymptotic behavior of the solution at the inflow corners to obtain the uniqueness of the parabolic boundary layer functions by matching two different asymptotic expansions. Butuzov [4] imposed certain compatibility conditions on the input data so that the corner singularities of the parabolic boundary layers disappear, and employed the corner layers at the outflow corners to obtain the asymptotic approximations of arbitrary order with respect to ϵ, which is proved to be valid uniformly in the closure of the rectangular region.

3. Main results.

The main tool used in this paper for estimating solutions of elliptic boundary value problems is furnished by the so-called maximum principle and the concept of barrier function. For the proof of the maximum principle see Eckhaus and De Jager [11]. We now repeat the formulation of the boundary layer problem:

$$L_\epsilon u_\epsilon \equiv -\epsilon \Delta u_\epsilon + p\frac{\partial u_\epsilon}{\partial x} + qu_\epsilon = f(x,y) \quad \text{in } \Omega, \tag{1.1}$$

with boundary conditions

$$u_\epsilon(0,y) = g_1(y), \quad u_\epsilon(a,y) = g_2(y), \quad 0 < y < b, \tag{1.2a, b}$$

$$u_\epsilon(x,0) = g_3(x), \quad u_\epsilon(x,b) = g_4(x), \quad 0 < x < a, \tag{1.2c, d}$$

where ϵ is a small parameter $0 < \epsilon \ll 1$, Δ is the Laplacian operator, p is a positive number, q is a nonnegative number, Ω is the rectangular region $0 < x < a$ and $0 < y < b$, and the remaining input data $f(x,y)$, $g_1(y)$, $g_2(y)$, $g_3(x)$, and $g_4(x)$ are assumed to be smooth. We also suppose that the assigned boundary functions are continuous at the corners. We are ready to state the maximum principle.

MAXIMUM PRINCIPLE. *Let Φ and Ψ be twice continuously differentiable functions in Ω such that*

$$|L_\epsilon[\Phi]| \le L_\epsilon[\Psi] \quad \text{in } \Omega,$$

$$|\Phi| \le \Psi \quad \text{on } \partial\Omega.$$

Then

$$|\Phi| \le \Psi \quad \text{in } \bar{\Omega}.$$

Remark 3.1. For an elliptic differential operator of second order in an unbounded domain a maximum principle holds if the solution satisfies a certain growth condition at infinity. We will discuss this in Section 3.3.

In this work we investigate an asymptotic approximation of the solution of the elliptic boundary value problem given by (1.1), (1.2a,b,c,d). From the assumption that q is nonnegative in Ω, it follows that the solution is unique. Under the conditions assumed, it is well known that for a fixed value of ϵ, $u_\epsilon(x,y)$ is continuous in $\bar{\Omega}$ and is smooth in Ω_1 where Ω_1 is any compact subregion of $\bar{\Omega}$ with positive distance from the corners. In 1979, A. Azzam [2] improved this result to obtain the following:

THEOREM 3.1. *For any fixed value of ϵ, there exists a number $\nu \in (1,2)$ such that the solution u_ϵ of the Dirichlet boundary value problem* (1.1), (1.2a,b,c,d) *with the assumptions stated at the beginning of this section satisfies $u_\epsilon(x,y) \in C_\nu(\bar{\Omega})$. Moreover, in a sufficiently small neighborhood of the corner, $r^\tau D^2 u_\epsilon \in C_\mu$ for some τ, $\mu \in (0,1)$, where r is the distance from the corner point to (x,y) and $D^2 u_\epsilon$ is any second partial derivative of u_ϵ.*

Remark 3.2. The maximum principle implies that the solution $u_\epsilon(x,y)$ is bounded uniformly with respect to ϵ in $\bar{\Omega}$.

3.1. Outer approximation.

In order to obtain the first rough approximation of the solution $u_\epsilon(x,y)$ for small values of the parameter ϵ, we consider a function $u_0(x,y)$ which satisfies the reduced equation

$$p\frac{\partial u_0}{\partial x} + qu_0 = f(x,y). \tag{1.4}$$

The function $u_0(x,y)$ can satisfy only one of the prescribed boundary conditions

$$u_0(0,y) = g_1(y), \tag{1.2a}$$

and

$$u_0(a,y) = g_2(y). \tag{1.2b}$$

THEOREM 3.2. *There exists a positive constant C independent of ϵ such that the inequality*

$$\left|u_\epsilon(x,y) - g_1(y)\right| \le Cx \tag{3.1}$$

holds uniformly in the closure of Ω for all values of ϵ.

Proof. The function $\Phi_\epsilon(x,y)$, defined by

$$\Phi_\epsilon(x,y) \equiv u_\epsilon(x,y) - g_1(y),$$

satisfies in Ω the differential equation

$$L_\epsilon[\Phi_\epsilon] = f(x,y) + \epsilon g_1''(y) - qg_1(y)$$

with the boundary conditions

$$\begin{aligned}
&\Phi_\epsilon(0,y) = 0,\\
&\Phi_\epsilon(a,y) = g_2(y) - g_1(y),\\
&\Phi_\epsilon(x,0) = g_3(x) - g_1(0) = g_3(x) - g_3(0),\\
&\Phi_\epsilon(x,b) = g_4(x) - g_1(b) = g_4(x) - g_4(0).
\end{aligned}$$

We now introduce the barrier function $\Psi(x) = Cx$, where C is some positive constant independent of ϵ. By taking C sufficiently large it follows that the inequalities

$$\left|\Phi_\epsilon(x,y)\right| \le \Psi(x)$$

on the boundary of Ω and

$$\left|L_\epsilon[\Phi_\epsilon]\right| \le L_\epsilon[\Psi]$$

in Ω can be satisfied for all values of ϵ. Applying the maximum principle, we get the desired inequality (3.1) uniformly valid in the closure of Ω for all values of ϵ. This completes the proof.

According to Theorem 3.2, as ϵ tends to zero, we are led to the inequality

$$\left|u_0(x,y) - g_1(y)\right| \le Cx.$$

Therefore (1.2a) is the proper condition for the solution $u_0(x,y)$. Now the function u_0 is easily determined, and the result is

$$u_0(x,y) = g_1(y)\exp\Bigl(-\frac{qx}{p}\Bigr) + p^{-1}\int_0^x f(s,y)\exp\Bigl[-\frac{(x-s)q}{p}\Bigr]\,ds.$$

Since the remaining boundary conditions (1.2b,c,d) are not satisfied by the function $u_0(x,y)$ and the difference $u_\epsilon - u_0$ satisfies in Ω the differential equation

$$L_\epsilon[u_\epsilon - u_0] = \epsilon \Delta u_0,$$

it is quite evident that this approximation for $u_\epsilon(x,y)$ is not valid in a neighborhood of three parts of the boundary of Ω, $x = a$, $y = 0$, and $y = b$, and is valid in the remaining subregion of Ω including the neighborhood of the inflow boundary $x = 0$ up to the order $O(\epsilon)$.

First of all, a better approximation of the solution $u_\epsilon(x,y)$ in this subregion is to be obtained by adding to $u_0(x,y)$ a sum $\sum_{k=1}^{n} \epsilon^k u_k(x,y)$ which equals zero along the inflow boundary $x = 0$ and has the property that $\sum_{k=0}^{n} \epsilon^k u_k(x,y)$ satisfies (1.1) up to the order $O(\epsilon^{n+1})$ for some positive integer n. The functions $u_k(x,y)$ are determined by iteration from the differential equations

$$p\frac{\partial u_k}{\partial x} + q u_k = \Delta u_{k-1}, \tag{3.2}$$

with the boundary conditions

$$u_k(0,y) = 0, \tag{3.3}$$

for $k = 1, 2, \ldots, n$. Therefore it follows that the functions $u_k(x,y)$ are given by the expressions

$$u_k(x,y) = p^{-1} \int_0^x \Delta u_{k-1}(s,y) \exp\left[-\frac{(x-s)q}{p}\right] ds$$

for $k = 1, 2, \ldots, n$.

We will call the series

$$u(x,y;\epsilon) = \sum_{k=0}^{n} \epsilon^k u_k(x,y) \tag{3.4}$$

the outer asymptotic approximation (OA). (Other names that are given are the asymptotic approximation or the interior asymptotic approximation of $u_\epsilon(x,y)$ in Ω.) Applying the differential operator L_ϵ to the function $u^*(x,y;\epsilon)$, defined by

$$u^* = u_\epsilon - u, \tag{3.5}$$

yields the differential equation in Ω

$$L_\epsilon[u^*] = \epsilon^{n+1} \Delta u_n \tag{3.6}$$

with the boundary conditions

$$u^*(0,y;\epsilon) = 0, \tag{3.7a}$$

$$u^*(a,y;\epsilon) = g_2(y) - u_0(a,y) - \sum_{k=1}^{n} \epsilon^k u_k(a,y), \tag{3.7b}$$

$$u^*(x,0;\epsilon) = g_3(x) - u_0(x,0) - \sum_{k=1}^{n} \epsilon^k u_k(x,0), \tag{3.7c}$$

$$u^*(x,b;\epsilon) = g_4(x) - u_0(x,b) - \sum_{k=1}^{n} \epsilon^k u_k(x,b). \tag{3.7d}$$

Now the outer approximation $u(x, y; \epsilon)$ satisfies the boundary conditions (1.2a) and introduces discrepancies in the boundary conditions (1.2b,c,d) on the remaining parts of the boundary of Ω. To obtain a "uniform" approximation of the solution u_ϵ in Ω, we eliminate these discrepancies along the boundaries $x = a$, $y = 0$, and $y = b$ by introducing other functions, called boundary layer functions and corner layer functions, along the three boundaries and the two outflow corners $(a, 0)$ and (a, b). These functions will have the property that when acted on by L_ϵ, the result will be of order $O(\epsilon^{n+1})$ uniformly in the closure of Ω. Also the boundary layer functions have the property of being asymptotically equal to zero everywhere in Ω except for a small neighborhood of one of these three boundaries while the corner layer functions have the property of being asymptotically equal to zero everywhere in Ω except for a small neighborhood of one of the outflow corners of Ω. The boundary layer functions along the outflow boundary $x = a$ satisfy ordinary differential equations and define the ordinary boundary layer (OBL). The boundary layer functions along the characteristic boundaries $y = 0$ and $y = b$ are of two types. One type of function satisfies a parabolic differential equation and is the parabolic boundary layer (PBL) function. The other type of boundary layer functions along the characteristic boundaries $y = 0$ and $y = b$ satisfies an elliptic differential equation and is designed to remove the corner singularities of PBL; it is called the elliptic boundary layer (EBL). There are two types of corner layers at each of the outflow corners. One type of the corner layer function satisfies an ordinary differential equation and is employed to remove the discrepancy in the vicinity of the corner due to the PBL. This function is called an ordinary corner layer (OCL) function. The other type of corner layer function satisfies an elliptic differential equation and is used to remove the discrepancy in the vicinity of the corner due to the EBL, OBL and OCL; this function is called an elliptic corner layer (ECL) function. The detailed construction of these functions will be investigated in the subsequent sections. The location of all functions is indicated in Figure 3.1 and the order of construction is shown in Figure 3.2.

$v_k(x/\epsilon, y/\epsilon; \epsilon)$
5. Ordinary Corner Layer at Outflow Corner $(a,0)$
$W_k((a-x)/\epsilon, y/\sqrt{\epsilon})$
4. Parabolic Boundary Layer along Characteristic Boundary $y = 0$
$z_k(x, y/\sqrt{\epsilon})$

FIG. 3.2. *Order of constructions.*

The uniform asymptotic approximation of the solution $u_\epsilon(x,y)$ in the closure of Ω is expressed as follows:

$$\begin{aligned} u_\epsilon(x,y) = \mathrm{OA} + \mathrm{OBL} + \mathrm{BEBL} + \mathrm{BPBL} + \mathrm{BOCL} + \mathrm{BECL} \\ + \mathrm{TEBL} + \mathrm{TPBL} + \mathrm{TOCL} + \mathrm{TECL} \\ + \mathrm{REMAINDER}, \end{aligned} \tag{3.8}$$

where BEBL and TEBL stand for the EBL along the characteristic boundaries $y = 0$ and $y = b$, respectively, etc.

In order to estimate the term REMAINDER in (3.8), we need the following result, which is a consequence of the maximum principle.

THEOREM 3.3. *If* $\Phi_\epsilon(x,y)$ *is the solution of the boundary value problem*

$$L_\epsilon[\Phi_\epsilon] = h_\epsilon(x,y),$$

valid in Ω *with*

$$\Phi_\epsilon(x,y)\big|_\Gamma = \Psi_\epsilon(x,y)\big|_\Gamma$$

along the boundary Γ *of* Ω, *and if*

$$h_\epsilon(x,y) = O(\epsilon^\mu) \ \ \textit{in } \bar{\Omega}, \quad \mu \geq 0,$$

and

$$\Psi_\epsilon(x,y) = O(\epsilon^\nu) \ \ \textit{along } \Gamma, \quad \nu \geq 0,$$

then at most

$$\Phi_\epsilon(x,y) = O\left(\epsilon^{\min(\mu,\nu)}\right) \ \ \textit{in } \bar{\Omega}.$$

From this theorem, we conclude that if it is possible to have L_ϵ[REMAINDER] being of order $O(\epsilon^{n+1})$ in the closure of Ω and the term REMAINDER being of order $O(\epsilon^{n+1})$ on the boundary of Ω, then it follows that the estimate

$$\text{REMAINDER} = O(\epsilon^{n+1})$$

holds uniformly in the closure of Ω.

3.2. Ordinary boundary layer along the outflow boundary $x = a$. Let the stretched variable X_1 along the outflow boundary $x = a$ be defined by $x = a - \epsilon X_1$. The ordinary boundary layer along the outflow boundary $x = a$ is defined by the series

$$w(X_1, y; \epsilon) = \sum_{k=0}^{n+1} \epsilon^k \, w_k(X_1, y) \tag{3.9}$$

where the functions $w_k(X_1, y)$ are defined iteratively by the ordinary differential equations

$$\frac{\partial^2 w_k}{\partial {X_1}^2} + p \frac{\partial w_k}{\partial X_1} = \pi_k(X_1, y) \tag{3.10}$$

over the unbounded interval $0 < X_1 < \infty$, where y is a parameter $0 \leq y \leq b$, and the functions $\pi_k(X_1, y)$ have the expressions

$$\pi_0(X_1, y) = 0,$$
$$\pi_1(X_1, y) = q w_0,$$

and for $2 \leq k \leq n+1$,

$$\pi_k(X_1, y) = -\frac{\partial^2 w_{k-2}}{\partial y^2} + q w_{k-1}.$$

The boundary conditions imposed on the functions $w_k(X_1, y)$ are such that the discrepancy, due to the introduction of the outer approximation $u(x, y; \epsilon)$ in the boundary condition (1.2b) at the outflow boundary $x = a$, disappears and such that the functions $w_k(X_1, y)$ approach zero as $x \neq a$ and ϵ tends to zero. That is, we impose the boundary conditions

$$\begin{aligned} &w_0(0, y) = g_2(y) - u_0(a, y) \\ &w_k(0, y) = -u_k(a, y) \qquad \text{for } 1 \leq k \leq n, \\ &w_{n+1}(0, y) = 0 \end{aligned} \tag{3.11a}$$

and for $0 \leq k \leq n+1$,

$$w_k(X_1, y) \to 0 \qquad \text{as } X_1 \to \infty. \tag{3.11b}$$

It is easy to see that when $k = 0$ and $k = 1$ we obtain the solutions in the form

$$\begin{aligned} w_0(X_1, y) &= \left[g_2(y) - u_0(a, y)\right] \exp(-pX_1), \\ w_1(X_1, y) &= \left[-u_1(a, y) - \left(g_2(y) - u_0(a, y)\right)p^{-1}qX_1\right] \exp(-pX_1). \end{aligned}$$

In general, for $k \geq 2$, each of the functions $\pi_k(X_1, y)$ is the product of $\exp(-pX_1)$, the function of boundary layer type along the boundary $x = a$, and a polynomial of degree $k-1$ in X_1 with the coefficients depending on y. Hence the solutions w_k can be expressed as

$$w_k(X_1, y) = \ell_k(X_1, y) \exp(-pX_1),$$

where $\ell_k(X_1, y)$ is a polynomial of degree k in X_1 with the coefficients depending on y.

Remark 3.3. From ODE theory, if p is a positive number, the integral

$$\int_0^\infty f(s) \exp(-ps)\, ds$$

converges and

$$\exp(-px) \int_0^x f(s)\, ds$$

converges to 0 as x tends to ∞, then the solution of the ordinary differential equation

$$u''(x) + pu'(x) = f(x) \exp(-px)$$

defined over the unbounded interval $0 < x < \infty$ under the boundary conditions

$$u(0) = A \qquad \text{and} \qquad u(x) \to 0 \quad \text{as } x \to \infty,$$

has the form

$$\begin{aligned} u(x) = A \exp(-px) &- p^{-1} \exp(-px) \int_0^x f(s)\, ds \\ &- p^{-1} \int_x^\infty f(s) \exp(-ps)\, ds + p^{-1} \exp(-px) \int_0^\infty f(s) \exp(-ps)\, ds. \end{aligned} \tag{3.12}$$

THEOREM 3.4. *There exist two positive constants C and c independent of ϵ such that the inequalities*

$$\left| \frac{\partial^\ell}{\partial y^\ell} w_k(X_1, y) \right| \leq C \exp(-cX_1) \tag{3.13}$$

hold for $0 \leq k \leq n+1$ and $\ell = 0$ and 2.

Proof. The above inequalities are quite clear because the functions w_k, and $\partial^2 w_k/\partial y^2$ are products of $\exp(-pX_1)$ and a polynomial in X_1 with the coefficients depending on y.

Applying the differential operator L_ϵ to the series w gives

$$(3.14)\qquad \begin{aligned} L_\epsilon w &= \sum_{k=0}^{n+1} \epsilon^k L_\epsilon w_k \\ &= \sum_{k=0}^{n+1} \epsilon^k \Big(-\epsilon \frac{\partial^2 w_k}{\partial x^2} - \epsilon \frac{\partial^2 w_k}{\partial y^2} + p \frac{\partial w_k}{\partial x} + q w_k\Big). \end{aligned}$$

The equation (3.10) may be written as

$$(3.15)\qquad -\epsilon \frac{\partial^2 w_k}{\partial x^2} + p \frac{\partial w_k}{\partial x} = -\epsilon^{-1} \pi_k\Big(\frac{a-x}{\epsilon}, y\Big).$$

Substitution of (3.15) into (3.14) yields

$$(3.16)\qquad \begin{aligned} L_\epsilon w &= -\sum_{k=0}^{n+1} \epsilon^{k+1} \frac{\partial^2 w_k}{\partial y^2} + \sum_{k=0}^{n+1} \epsilon^k q w_k + \sum_{k=0}^{n+1} \epsilon^{k-1} \pi_k\Big(\frac{a-x}{\epsilon}, y\Big) \\ &= \epsilon^{n+1}\Big(-\epsilon \frac{\partial^2 w_{n+1}}{\partial y^2} - \frac{\partial^2 w_n}{\partial y^2} + q w_{n+1}\Big). \end{aligned}$$

It follows from (3.13) that the estimate

$$L_\epsilon w = O(\epsilon^{n+1})$$

is valid uniformly in the closure of Ω. Furthermore, let us examine this series on the boundary of Ω.

i) At $x = a$, the series

$$(3.17a)\qquad w = \sum_{k=0}^{n+1} \epsilon^k w_k(0, y) = g_2(y) - \sum_{k=0}^{n} \epsilon^k u_k(a, y)$$

is equal to $u^*(a, y; \epsilon)$.

ii) At $x = 0$, the series

$$(3.17b)\qquad w = \sum_{k=0}^{n+1} \epsilon^k w_k\Big(\frac{a}{\epsilon}, y\Big)$$

is asymptotically exponentially small with respect to ϵ in the interval $0 \le y \le b$.

iii) At $y = 0$ and $y = b$, the series

$$(3.17c)\qquad w = \sum_{k=0}^{n+1} \epsilon^k w_k\Big(\frac{a-x}{\epsilon}, y\Big)$$

is asymptotically exponentially small with respect to ϵ for each x in the interval $0 \le x < a$, but not in the closed interval $0 \le x \le a$. To circumvent this difficulty, we define two series, called the elliptic corner layers, at the outflow corners $(a, 0)$ and (a, b). The construction of these elliptic corner layers is given in Section 3.6.

3.3. Elliptic boundary layer along the characteristic boundary $y = 0$. Usually the given problem (1.1), (1.2a,b,c,d) may not have the necessary compatibility conditions for the solution $u_\epsilon(x, y)$ at the inflow corner $(0, 0)$ to insure the smoothness of the parabolic boundary layer function $z_0(x, Y)$, which satisfies the parabolic differential equation (3.26) in a semi-strip $0 < x < a$ and $0 < Y < \infty$. The second partial derivative of z_0 with respect to the time-like variable x is singular near the origin, and consequently the right-hand side of the differential equation for z_1 is singular in the vicinity of the origin. To remedy the presence of this "corner singularity," we introduce some functions $v_k(X, Y_1)$ with the stretched variables $X = x/\epsilon$ and $Y_1 = y/\epsilon$, which are defined by elliptic differential equations over the quarter plane $0 < X < \infty$ and $0 < Y_1 < \infty$ with the values zero as the boundary conditions along $X = 0$ and a suitable boundary condition along $Y_1 = 0$ such that the desired compatibility conditions for parabolic differential equations can be obtained to guarantee the boundedness of the second partial derivative of all functions $z_k(x, Y)$ with respect to x in the semi-strip domain. This enables us to carry out an iteration process related to the parabolic boundary layer.

The elliptic boundary layer along the characteristic boundary $y = 0$ is defined by the series

$$v(X, Y_1; \epsilon) = \sum_{k=0}^{n+1} \epsilon^k \, v_k(X, Y_1; \epsilon), \tag{3.18}$$

where the functions $v_k(X, Y_1; \epsilon)$ are defined iteratively by the elliptic differential equations

$$-\Big(\frac{\partial^2 v_k}{\partial X^2} + \frac{\partial^2 v_k}{\partial {Y_1}^2}\Big) + p\,\frac{\partial v_k}{\partial X} + \epsilon q v_k = 0 \tag{3.19}$$

over the quarter plane $0 < X < \infty$ and $0 < Y_1 < \infty$. We impose the boundary conditions for v_k in the following way:

$$v_k(0, Y_1; \epsilon) = 0, \quad 0 \le k \le n+1, \tag{3.20a}$$

and

$$v_k(X, 0; \epsilon) = \omega_k(X; \epsilon), \quad 0 \le k \le n+1, \tag{3.20b}$$

where the functions $\omega_k(X; \epsilon)$ have the expressions

$$\omega_0(X; \epsilon) = \sum_{i=1}^{N} \frac{X^i}{i!}\Big(g_3^{(i)}(0) - \frac{\partial^i}{\partial x^i}\, u_0(0, 0)\Big)\epsilon^i,$$

and for $1 \le k \le n$,

$$\omega_k(X;\epsilon) = -\sum_{i=1}^{N-2k} \frac{X^i}{i!}\frac{\partial^i}{\partial x^i} u_k(0,0)\,\epsilon^i,$$

and

$$\omega_{n+1}(X;\epsilon) = 0.$$

Note that $\omega_k(0;\epsilon) = 0$. In addition to the Dirichlet boundary conditions (3.20a,b), we impose the following conditions at infinity:

$$v_k(X,Y_1;\epsilon) \to 0 \qquad \text{as } X^2 + Y_1^2 \to \infty \text{ and } Y_1 > 0,\ 0 \le k \le n+1. \tag{3.20c}$$

We remark that an equivalent condition is

$$v_k(X,Y_1;\epsilon) \text{ does not grow exponentially as } X^2 + Y_1^2 \to \infty.$$

The elliptic equation (3.19) with the conditions (3.20a,b,c) has a unique solution, and the maximum principle is valid for this problem [12], [39]. The parameter ϵ appears in this problem as a regular perturbation parameter. Therefore, $v_k(X,Y_1;\epsilon)$ could itself be written as a finite series in ϵ plus a remainder term that is $O(\epsilon^{n+1})$. The particular form of the function $v_k(X,Y_1;\epsilon)$ was chosen to make subsequent computations more tractable.

THEOREM 3.5. *The solutions $v_k(X,Y_1;\epsilon)$ have the integral representations*

$$v_k(X,Y_1;\epsilon) = \frac{\tau Y_1}{\pi}\int_0^\infty \left[r_5^{-1}K_1(\tau r_5) - r_6^{-1}K_1(\tau r_6)\right]\omega_k(s;\epsilon)\exp\left[-\frac{p(s-X)}{2}\right]ds,$$

where

$$\tau = \left(\frac{p^2}{4} + \epsilon q\right)^{1/2},$$
$$r_5 = \left[(X-s)^2 + Y_1^2\right]^{1/2},$$
$$r_6 = \left[(X+s)^2 + Y_1^2\right]^{1/2},$$

and K_1 is the modified Bessel function of the second kind of the first order.

Proof. The transformation

$$v_k(X,Y_1;\epsilon) = v_k^*(X,Y_1;\epsilon)\exp\left(\frac{pX}{2}\right)$$

yields the differential equations for v_k^*

$$-\left(\frac{\partial^2 v_k^*}{\partial X^2} + \frac{\partial^2 v_k^*}{\partial {Y_1}^2}\right) + \left(\frac{p^2}{4} + \epsilon q\right)v_k^* = 0 \tag{3.21}$$

over the quarter plane $0 < X < \infty$ and $0 < Y_1 < \infty$ under the boundary conditions

$$v_k^*(X,0;\epsilon) = \omega_k(X;\epsilon)\exp\Big(-\frac{pX}{2}\Big),$$
$$v_k^*(0,Y_1;\epsilon) = 0,$$

and

$$v_k^*(X,Y_1;\epsilon) \to 0 \quad \text{as } X^2+Y_1^2 \to \infty.$$

Since the fundamental solution for this differential operator (3.21) is

$$\frac{1}{2\pi}K_0\Big(\tau\sqrt{X^2+Y_1^2}\Big),$$

the Green's function for this differential operator over the quarter plane is given by

$$G(X,Y_1;s,t) = \frac{1}{2\pi}\big[K_0(\tau r_1) - K_0(\tau r_2) + K_0(\tau r_3) - K_0(\tau r_4)\big]$$

where K_0 is the modified Bessel function of the second kind of the zeroth order, and

$$r_1 = \big[(X-s)^2+(Y_1-t)^2\big]^{1/2}, \qquad r_2 = \big[(X+s)^2+(Y_1-t)^2\big]^{1/2},$$
$$r_3 = \big[(X+s)^2+(Y_1+t)^2\big]^{1/2}, \qquad r_4 = \big[(X-s)^2+(Y_1+t)^2\big]^{1/2}.$$

It follows that the functions v_k^* have the expressions

$$v_k^*(X,Y_1;\epsilon) = \int_0^\infty \omega_k(s;\epsilon)\exp\Big(-\frac{ps}{2}\Big)\frac{\partial G}{\partial t}(X,Y_1;s,0)\,ds.$$

A computation gives, by using $K_0'(x) = -K_1(x)$,

$$\frac{\partial G}{\partial t}(X,Y_1;s,0) = \frac{\tau Y_1}{\pi}\big[r_5^{-1}K_1(\tau r_5) - r_6^{-1}K_1(\tau r_6)\big].$$

Therefore we have the desired integral representations for $v_k^*(X,Y_1;\epsilon)$. This completes the proof.

The value of the positive integer N should be at least $2n+1$ in order to guarantee the smoothness of the parabolic boundary layer function $(\partial^2/\partial x^2)z_n(x,Y)$ and the ordinary corner layer function $(\partial^2/\partial Y^2)W_{n+1}(X_1,Y)$, which will be discussed shortly.

In order to estimate the elliptic boundary layer, the following exponential estimates for $v_k(X, Y_1; \epsilon)$ are needed.

THEOREM 3.6. *There exist two positive constants C and c independent of ϵ such that the inequalities*

$$|v_k(X, Y_1; \epsilon)| \leq C \exp\left[-c\left(\sqrt{X^2 + Y_1^2} - X\right)\right] \tag{3.22}$$

hold for $0 \leq k \leq n + 1$.

Proof. The condition at infinity (3.20c) enables us to have the maximum principle for the boundary value problem over the unbounded domain. By the linearity, it suffices to prove that the solutions $v_k(X, Y_1; \epsilon)$ for the differential equation (3.19) over the quarter plane $0 < X < \infty$ and $0 < Y_1 < \infty$ under the boundary conditions (3.20a) and

$$v_k(X, 0; \epsilon) = X^i \epsilon^i,$$

and (3.20c) satisfy the estimate (3.22). Let the barrier function $U(X, Y_1; \epsilon)$ be defined by

$$U(X, Y_1; \epsilon) = \epsilon^i \sum_{j=0}^{i} c_j \, (X^2 + Y_1^2)^{j/2} \exp\left[-\tfrac{p}{2}\left(\sqrt{X^2 + Y_1^2} - X\right)\right],$$

where the values of positive constants c_j will be determined in the course of this proof. Note that the function U satisfies the restricted growth condition at infinity (3.20c). It is clear that

$$U(X, 0; \epsilon) = \epsilon^i \sum_{j=0}^{i} c_j \, X^j \geq v_k(X, 0; \epsilon)$$

for all k if $c_j = 1$ and $c_j \geq 0$ for $0 \leq j \leq i - 1$, and

$$U(0, Y_1; \epsilon) = \epsilon^i \sum_{j=0}^{i} c_j \, Y_1^j \exp\left(-\tfrac{p}{2} Y_1\right) > v_k(0, Y_1; \epsilon)$$

for all k. A computation yields

$$
\begin{aligned}
&-\left(\frac{\partial^2 U}{\partial X^2}+\frac{\partial^2 U}{\partial Y_1{}^2}\right)+p\frac{\partial U}{\partial X}+\epsilon q U\\
&=\epsilon^i\exp\left[-\frac{p}{2}\left(\sqrt{X^2+Y_1^2}-X\right)\right]\left(\sum_{j=0}^{i}c_j p(j+\tfrac12)(X^2+Y_1^2)^{(j-1)/2}\right.\\
&\qquad\left.-\sum_{j=0}^{i}c_j j^2(X^2+Y_1^2)^{(j-2)/2}+\sum_{j=0}^{i}\epsilon q c_j(X^2+Y_1^2)^{j/2}\right)\\
&=\epsilon^i\exp\left[-\frac{p}{2}\left(\sqrt{X^2+Y_1^2}-X\right)\right]\\
&\quad\cdot\left(\epsilon q c_i(X^2+Y_1^2)^{i/2}+\left[\epsilon q c_{i-1}+c_i p(i+\tfrac12)\right](X^2+Y_1^2)^{(i-1)/2}\right.\\
&\qquad+\sum_{j=1}^{i-1}\left[\epsilon q c_{j-1}+c_j p(j+\tfrac12)-c_{j+1}(j+1)^2\right]\\
&\qquad\quad\left.\cdot(X^2+Y_1^2)^{(j-1)/2}\left(c_0\frac{p}{2}-c_1\right)(X^2+Y_1^2)^{-1/2}\right)\\
&\ge\epsilon^i\exp\left[-\frac{p}{2}\left(\sqrt{X^2+Y_1^2}-X\right)\right]\left(c_i p(i+\tfrac12)(X^2+Y_1^2)^{(i-1)/2}\right.\\
&\qquad\left.+\sum_{j=0}^{i-1}\left[c_j p(j+\tfrac12)-c_{j+1}(j+1)^2\right](X^2+Y_1^2)^{(j-1)/2}\right),
\end{aligned}
$$

which is greater than or equal to zero if the numbers c_j are chosen so that the inequalities

$$c_j p(j+\tfrac12)\ge c_{j+1}(j+1)^2$$

hold for $j=i-1, i-2, \ldots, 2, 1, 0$, then it follows from the maximum principle that the inequalities

$$\left|v_k(X,Y_1;\epsilon)\right|\le\epsilon^i\sum_{j=0}^{i}c_j(X^2+Y_1^2)^{j/2}\exp\left[-\frac{p}{2}\left(\sqrt{X^2+Y_1^2}-X\right)\right]$$

hold for $0\le x<\infty$ and $0\le Y_1<\infty$. By the definition of the stretched variables X and Y_1, we obtain

$$\left|v_k\left(\frac{x}{\epsilon},\frac{y}{\epsilon};\epsilon\right)\right|\le\sum_{j=0}^{i}c_j(a^2+b^2)^{j/2}\exp\left[-\frac{p}{2\epsilon}\left(\sqrt{x^2+y^2}-x\right)\right].$$

Hence over the closure of Ω, we are led to the estimate

$$\left|v_k\left(\frac{x}{\epsilon},\frac{y}{\epsilon};\epsilon\right)\right|\le C\exp\left[-\frac{p}{2\epsilon}\left(\sqrt{x^2+y^2}-x\right)\right],$$

where C is some constant independent of ϵ. This completes the proof.

Now applying the differential operator L_ϵ to the series v yields

$$\begin{aligned} L_\epsilon v &= \sum_{k=0}^{n+1} \epsilon^k L_\epsilon v_k \\ &= \sum_{k=0}^{n+1} \epsilon^k \Big[-\epsilon \Big(\frac{\partial^2 v_k}{\partial x^2} + \frac{\partial^2 v_k}{\partial y^2} \Big) + p \frac{\partial v_k}{\partial x} + q v_k \Big]. \end{aligned}$$

Equation (3.19) can be written as

$$-\epsilon \Big(\frac{\partial^2 v_k}{\partial x^2} + \frac{\partial^2 v_k}{\partial y^2} \Big) + p \frac{\partial v_k}{\partial x} + q v_k = 0.$$

Hence it follows that

$$L_\epsilon v = 0 \tag{3.23}$$

is valid uniformly in the closure of Ω. Moreover, let us examine this series on the boundary of Ω.

i) At $y = 0$, the series becomes

$$v = \sum_{i=1}^{N} \frac{x^i}{i!} \Big[g_3^{(i)}(0) - \frac{\partial^i}{\partial x^i} u_0(0,0) \Big] - \sum_{k=1}^{n} \epsilon^k \Bigg[\sum_{i=1}^{N-2k} \frac{x^i}{i!} \frac{\partial^i}{\partial x^i} u_k(0,0) \Bigg]. \tag{3.24a}$$

ii) At $x = 0$,

$$v = 0. \tag{3.24b}$$

iii) At $y = b$, the series

$$v = \sum_{k=0}^{n} \epsilon^k v_k \Big(\frac{x}{\epsilon}, \frac{b}{\epsilon}; \epsilon \Big) \tag{3.24c}$$

is asymptotically exponentially small with respect to ϵ in the closed interval $0 \le x \le a$.

iv) At $x = a$, the series

$$v = \sum_{k=0}^{n} \epsilon^k v_k \Big(\frac{a}{\epsilon}, \frac{y}{\epsilon}; \epsilon \Big) \tag{3.24d}$$

is asymptotically exponentially small with respect to ϵ in the interval $0 < y \le b$, but not in the closed interval $0 \le y \le b$. To overcome this difficulty, we will define a series, called an elliptic corner layer (ECL), at the outflow corner $(a, 0)$. The ECL is constructed in Section 3.6.

3.4. Parabolic boundary layer along the characteristic boundary $y = 0$. The stretched variable Y along the characteristic boundary $y = 0$ is defined by $y = \sqrt{\epsilon}\,Y$. The parabolic boundary layer along the characteristic boundary $y = 0$ is defined by the series

$$z(x, Y; \epsilon) = \sum_{k=0}^{n} \epsilon^k z_k(x, Y), \tag{3.25}$$

where the functions $z_k(x, Y)$ are defined iteratively by the parabolic differential equations

$$-\frac{\partial^2 z_k}{\partial Y^2} + p\frac{\partial z_k}{\partial x} + q z_k = \mu_k(x, Y) \tag{3.26}$$

over the semi-strip $0 < x < a$ and $0 < Y < \infty$. The functions μ_k are given by

$$\mu_0(x, Y) = 0$$

and for $1 \leq k \leq n$,

$$\mu_k(x, Y) = \frac{\partial^2 z_{k-1}}{\partial x^2}.$$

We impose boundary conditions on the functions z_k to eliminate the discrepancy along the boundary $y = 0$ introduced by both the outer approximation $u(x, y; \epsilon)$ and the elliptic boundary layer $v(X, Y_1; \epsilon)$, and to arrange that the functions $z_k(x, Y)$ approach zero for $Y \neq 0$ and as $\epsilon \to 0$. For this, we impose the following initial-boundary conditions

$$z_k(0, Y) = 0, \tag{3.27a}$$

$$z_k(x, 0) = \gamma_k(x), \tag{3.27b}$$

and

$$z_k(x, Y) \to 0 \quad \text{as } Y \to \infty. \tag{3.27c}$$

The functions $\gamma_k(x)$ are defined by

$$\gamma_0(x) = g_3(x) - u_0(x, 0) - \sum_{i=1}^{N} \frac{x^i}{i!}\left[g_3^{(i)}(0) - \frac{\partial^i}{\partial x^i} u_0(0, 0)\right],$$

and for $1 \leq k \leq n$,

$$\gamma_k(x) = -\left[u_k(x, 0) - \sum_{i=1}^{N-2k} \frac{x^i}{i!}\frac{\partial^i}{\partial x^i} u_k(0, 0)\right].$$

Note that $\gamma_k(0) = 0$ for each k.

THEOREM 3.7. *The solutions $z_k(x,Y)$ for the initial-boundary value problems* (3.26), (3.27a,b,c) *have the integral representations*

$$z_0(x,Y) = \sqrt{\frac{2}{\pi}} \int_{Y/\sqrt{2x/p}}^{\infty} \exp\Big(-\frac{t^2}{2}\Big)\,\gamma_0\Big(x-\frac{pY^2}{2t^2}\Big) \exp\Big(-\frac{qY^2}{2t^2}\Big)\,dt, \tag{3.28}$$

and for $1 \le k \le n$,

$$\begin{aligned} z_k(x,Y) = {} & \sqrt{\frac{2}{\pi}} \int_{Y/\sqrt{2x/p}}^{\infty} \exp\Big(-\frac{t^2}{2}\Big)\,\gamma_k\Big(x-\frac{pY^2}{2t^2}\Big) \exp\Big(-\frac{qY^2}{2t^2}\Big)\,dt \\ & + \frac{1}{2\sqrt{\pi}} \int_0^{x/p}\int_0^{\infty} \frac{1}{\sqrt{s}}\Big\{\exp\Big[-\frac{(Y-t)^2}{4s}\Big] - \exp\Big[-\frac{(Y+t)^2}{4s}\Big]\Big\} \\ & \cdot \frac{\partial^2}{\partial x^2} z_{k-1}(x-ps,t)\exp(-qs)\,dt\,ds. \end{aligned} \tag{3.29}$$

Proof. The transformation

$$z_k(x,Y) = z_k^*\Big(\frac{x}{p},Y\Big)\exp\Big(-\frac{qx}{p}\Big)$$

yields the heat equation for $z_k^*(x,Y)$

$$-\frac{\partial^2 z_k^*}{\partial Y^2} + \frac{\partial z_k^*}{\partial x} = \mu_k(px,Y)\exp(qx) \tag{3.30}$$

over the semi-strip $0 < x < a/p$ and $0 < Y < \infty$ under the initial-boundary conditions

$$z_k^*(0,Y) = 0, \quad z_k^*(x,0) = \gamma_k(px)\exp(qx),$$

and

$$z_k^*(x,Y) \to 0 \quad \text{as } Y \to \infty.$$

The fundamental solution for the differential operator of (3.30) is

$$K(x,Y) = \frac{1}{\sqrt{4\pi x}}\exp\Big(-\frac{Y^2}{4x}\Big),$$

and hence Green's function for the differential operator over the semi-strip $0 < x < a/p$ and $0 < Y < \infty$ is given by

$$G(x,Y;s,t) = K(x-s,Y-t) - K(x-s,Y+t).$$

Therefore the solutions $z_k^*(x,Y)$ can be expressed as [5]

$$\begin{aligned} z_k^*(x,Y) = {} & \int_0^x \frac{\partial G}{\partial t}(x,Y;s,0)\,\gamma_k(ps)\exp(qs)\,ds \\ & + \int_0^x\int_0^{\infty} G(x,Y;s,t)\,\mu_k(ps,t)\exp(qs)\,dt\,ds. \end{aligned}$$

A computation shows that

$$\begin{aligned}\frac{\partial G}{\partial t}(x,Y;s,0) &= -2\frac{\partial}{\partial Y}K(x-s,Y)\\ &= \frac{Y}{2\sqrt{\pi}\,(x-s)^{3/2}}\exp\Big[-\frac{Y^2}{4(x-s)}\Big],\end{aligned}$$

and then we obtain

$$\begin{aligned}z_k^*(x,Y) &= \frac{Y}{2\sqrt{\pi}}\int_0^x \frac{1}{(x-s)^{3/2}}\exp\Big[-\frac{Y^2}{4(x-s)}\Big]\gamma_k(ps)\exp(qs)\,ds\\ &\quad+\int_0^x\int_0^\infty G(x,Y;s,t)\,\mu_k(ps,t)\exp(qs)\,dt\,ds.\end{aligned}$$

Making the changes of integrators as follows: let $Y/\sqrt{2(x-t)}=t$ in the first integral, and let $x-s=s'$ and then replace s' by s in the second integral of z_k^*, we get

$$\begin{aligned}z_k^*(x,Y) &= \sqrt{\frac{2}{\pi}}\int_{Y/\sqrt{2x}}^\infty \exp\Big(-\frac{t^2}{2}\Big)\gamma_k\Big(px-\frac{pY^2}{2t^2}\Big)\exp\Big(qx-\frac{qY^2}{2t^2}\Big)\,dt\\ &\quad+\frac{1}{2\sqrt{\pi}}\int_0^x\int_0^\infty \frac{1}{\sqrt{s}}\Big\{\exp\Big[-\frac{(Y-t)^2}{4s}\Big]-\exp\Big[-\frac{(Y+t)^2}{4s}\Big]\Big\}\\ &\qquad\cdot\mu_k(px-ps,t)\exp[q(x-s)]\,dt\,ds,\end{aligned}$$

which gives the desired expressions for $z_k(x,Y)$. This completes the proof.

THEOREM 3.8. *There exist two positive constants C and c independent of ϵ such that the inequalities*

$$\Big|\frac{\partial^i}{\partial x^i}z_k(x,Y)\Big| \le C\exp(-cY), \tag{3.31}$$

and

$$\Big|\frac{\partial^{2i}}{\partial Y^{2i}}z_k(x,Y)\Big| \le C\exp(-cY), \tag{3.32}$$

hold for $0\le i\le 2n+2-2k$. The inequalities (3.32) will be used in Section 3.5 to obtain estimates for the ordinary corner layer functions $W_k(X_1,Y)$.

Proof. First of all, let us prove the inequality (3.31) when $k=0$. Thanks to the construction of $\gamma_0(x)$, it is easy to see that

$$\gamma_0^{(i)}(0)=0,$$

for $i=0,1,2,\ldots,2n+1$ (the value of N should be at least $2n+1$), and hence we have

$$\frac{\partial^i}{\partial x^i}z_0(x,Y)=\sqrt{\frac{2}{\pi}}\int_{Y/\sqrt{2x/p}}^\infty \exp\Big(-\frac{t^2}{2}\Big)\gamma_0^{(i)}\Big(x-\frac{pY^2}{2t^2}\Big)\,dt,$$

for $0 \le i \le 2n+2$. Since

$$\left|\gamma_0^{(i)}\Big(x - \frac{pY^2}{2t^2}\Big)\right| \le C$$

and for arbitrary constant $c > 0$,

$$\exp\Big(-\frac{t^2}{2}\Big) \le \exp\Big(\frac{c^2}{2} - ct\Big) = \exp\Big(\frac{c^2}{2}\Big)\cdot\exp(-ct)$$
$$= C\exp(-ct),$$

we have

$$\left|\frac{\partial^i}{\partial x^i} z_0(x,Y)\right| \le C\int_{Y/\sqrt{2x/p}}^{\infty}\exp(-ct)\,dt = C\exp\Big(-c\frac{Y}{\sqrt{2x/p}}\Big)$$
$$\le C\exp\Big(-c\frac{Y}{\sqrt{2a/p}}\Big) = C\exp(-cY),$$

for $0 \le Y < \infty$. It follows from (3.26) that $\partial^{2i}z_0/\partial Y^{2i}$ is a linear combination of $\partial^j z_0/\partial x^j$ for $0 \le j \le i$. Consequently, the inequality (3.32) is obtained for $k = 0$. Next consider the case $k = 1$, we have from (3.29)

$$\frac{\partial^i}{\partial x^i} z_1(x,Y) = \sqrt{\frac{2}{\pi}}\int_{Y/\sqrt{2x/p}}^{\infty}\exp\Big(-\frac{t^2}{2}\Big)\gamma_1^{(i)}\Big(x - \frac{pY^2}{2t^2}\Big)\exp\Big(-\frac{qY^2}{2t^2}\Big)\,dt$$
$$+ \frac{1}{2\sqrt{\pi}}\int_0^{x/p}\int_0^{\infty}\frac{1}{\sqrt{s}}\Big[\exp\Big(-\frac{(Y-t)^2}{4s}\Big) - \exp\Big(-\frac{(Y+t)^2}{4s}\Big)\Big]$$
$$\cdot\frac{\partial^{2+i}}{\partial x^{2+i}} z_0(x-ps,t)\,dt\,ds$$

for $0 \le i \le 2n$, because of

$$\gamma_1^{(i)}(0) = 0$$

for $0 \le i \le 2n-1$ and

$$\frac{\partial^j}{\partial x^j} z_0(0,y) = 0$$

for $2 \le j \le 2n{+}1$. (Note that $(\partial^j/\partial x^j)z_0(0,Y)$ is a linear combination of $(\partial^{2i}/\partial Y^{2i})z_0$ $(0,Y)$ for $0 \le i \le j$.) As in the case $k = 0$, the first integral of $(\partial^i/\partial x^i)z_1(x,Y)$ has the desired estimate, and therefore we consider the second integral only. Now the estimates

$$\left|\frac{\partial^{2+i}}{\partial x^{2+i}} z_0(x-ps,t)\right| \le C\exp(-ct)$$

and

$$\left|\exp\Big(-\frac{(Y-t)^2}{4s}\Big) - \exp\Big(-\frac{(Y+t)^2}{4s}\Big)\right|$$
$$\le \exp\Big(-\frac{(Y-t)^2}{4s}\Big) \le C\exp\Big(-c\frac{|Y-t|}{2\sqrt{s}}\Big)$$
$$\le C\exp\Big(-c\frac{|Y-t|}{2\sqrt{x/p}}\Big) \le C\exp(-c|Y-t|)$$

imply

$$\begin{aligned}&\left|\text{second integral of } \frac{\partial^i}{\partial x^i} z_1(x,Y)\right|\\ &\quad\le C\int_0^{x/p}\int_0^\infty \frac{1}{\sqrt{s}}\left[\exp(-c|Y-t|)\exp(-ct)\right]dt\,ds\\ &\quad= C\int_0^{x/p}\frac{1}{\sqrt{s}}\,ds\int_0^\infty \exp\left[-c(|Y-t|+t)\right]dt\\ &\quad= C\exp(-cY).\end{aligned}$$

This completes the case $k = 1$ for inequality (3.31). From (3.26), one can see that $\partial^{2i}z_1/\partial Y^{2i}$ depends linearly on $\partial^j z_1/\partial x^j$ and $\partial^{\ell+1}z_0/\partial x^{\ell+1}$ for $0 \le i \le 2n$, $0 \le j \le i$ and $1 \le \ell \le i$.

Continuing in this manner, one can show the inequalities (3.31) and (3.32) for $k = 2, 3, \ldots, n$. This completes the proof.

Now applying the differential operator L_ϵ to the series z yields

$$\begin{aligned}L_\epsilon z &= \sum_{k=0}^{n} \epsilon^k L_\epsilon z_k\\ &= \sum_{k=0}^{n}\epsilon^k\left(-\epsilon\frac{\partial^2 z_k}{\partial x^2} - \epsilon\frac{\partial^2 z_k}{\partial y^2} + p\frac{\partial z_k}{\partial x} + qz_k\right).\end{aligned}\tag{3.33}$$

Equation (3.26) can be written as

$$-\epsilon\frac{\partial^2 z_k}{\partial y^2} + p\frac{\partial z_k}{\partial x} + qz_k = \mu_k\left(x, \frac{y}{\sqrt{\epsilon}}\right).\tag{3.34}$$

Substitution of (3.34) into (3.33) gives

$$\begin{aligned}L_\epsilon z &= -\sum_{k=0}^{n}\epsilon^{k+1}\frac{\partial^2 z_k}{\partial x^2} + \sum_{k=0}^{n}\epsilon^k\mu_k\left(x,\frac{y}{\sqrt{\epsilon}}\right)\\ &= -\epsilon\frac{\partial^2 z_n}{\partial x^2}.\end{aligned}\tag{3.35}$$

It follows from (3.31) that the estimate

$$L_\epsilon z = O\left(\epsilon^{n+1}\right)$$

is valid uniformly in the closure of Ω. Moreover, let us examine the parabolic boundary layer z along the boundary of Ω.

i) At $x = 0$,

$$z = 0.\tag{3.36a}$$

ii) At $y = 0$,

$$z = u^*(x,0;\epsilon) - v\left(\frac{x}{\epsilon},0;\epsilon\right).\tag{3.36b}$$

iii) At $y = b$, the series

$$z = \sum_{k=0}^{n} \epsilon^k z_k\Big(x, \frac{b}{\sqrt{\epsilon}}\Big) \tag{3.36c}$$

is asymptotically exponentially small with respect to ϵ in the closed interval $0 \leq x \leq a$.

iv) At $x = a$, the series

$$z = \sum_{k=0}^{n} \epsilon^k z_k\Big(a, \frac{y}{\sqrt{\epsilon}}\Big) \tag{3.36d}$$

is asymptotically exponentially small with respect to ϵ in the interval $0 < y \leq b$, but not $0 \leq y \leq b$. In the next section we define a series, called ordinary corner layer, at the outflow corner $(a, 0)$ to overcome this difficulty.

3.5. Ordinary corner layer at the outflow corner $(a, 0)$. As defined above, the stretched variables X_1 and Y are expressed by $x = a - \epsilon X_1$ and $y = \sqrt{\epsilon}Y$. The ordinary corner layer at the outflow corner $(a, 0)$ is defined by the series

$$W(X_1, Y; \epsilon) = \sum_{k=0}^{n+1} \epsilon^k W_k(X_1, Y), \tag{3.37}$$

where the functions $W_k(X_1, Y)$ are defined iteratively by the ordinary differential equations

$$\frac{\partial^2 W_k}{\partial {X_1}^2} + p\frac{\partial W_k}{\partial X_1} = \tau_k(X_1, Y) \tag{3.38}$$

over the unbounded interval $0 < X_1 < \infty$. In these equations, Y may be regarded as a parameter $0 \leq Y < \infty$ and the functions τ_k are defined as

$$\tau_0(X_1, Y) = 0,$$

and for $1 \leq k \leq n + 1$,

$$\tau_k(X_1, Y) = -\frac{\partial^2 W_{k-1}}{\partial Y^2} + qW_{k-1}.$$

The boundary conditions imposed on the functions W_k remove the discrepancy along the outflow boundary $x = a$ introduced by the parabolic boundary layer z and are such that the functions $W_k(X_1, Y)$ become boundary layer functions with respect to X_1. That is, we define

$$\begin{aligned} &W_k(0, Y) = -z_k(a, Y) \quad \text{for } 0 \leq k \leq n, \\ &W_{n+1}(0, Y) = 0, \end{aligned} \tag{3.39a}$$

and for $0 \le k \le n+1$,

$$W_k(X_1, Y) \to 0 \quad \text{as } X_1 \to \infty. \tag{3.39b}$$

It is easy to see that the function $W_0(X_1, Y)$ has the following representation:

$$W_0(X_1, Y) = -z_0(a, Y) \exp(-pX_1).$$

In general, for $k \ge 1$, the functions $\tau_k(X_1, Y)$ are the products of a boundary layer function $\exp(-pX_1)$ and a polynomial of degree $k-1$ in X_1 with the coefficients depending on the parabolic boundary layer functions $z_i(a, Y)$, $0 \le i \le k-1$, and their even-order partial derivatives with respect to Y. Therefore, it follows from (3.12) that the solutions $W_k(X_1, Y)$ can be expressed as

$$W_k(X_1, Y) = m_k(X_1, Y) \exp(-pX_1),$$

where the function m_k is a polynomial of degree k in X_1 with the coefficients depending on the functions $z_i(a, Y)$, $0 \le i \le k$ ($0 \le i \le n$ when $k = n+1$), and their even-order partial derivatives with respect to Y, $(\partial^{2j}/\partial Y^{2j}) z_i(a, Y)$, for $0 \le i \le k-1$, and $1 \le j \le k-i$.

Note that the functions $W_k(X_1, Y)$ and their second partial derivatives with respect to Y (the latter is required for the estimate of $L_\epsilon W$) determine how smooth the parabolic boundary layer functions $z_k(x, Y)$ should be in the domain $0 \le x \le a$ and $0 \le Y < \infty$.

THEOREM 3.9. *There exist two positive constants C and c independent of ϵ such that the inequalities*

$$\left| \frac{\partial^i}{\partial Y^i} W_k(X_1, Y) \right| \le C \exp\left[-c(X_1 + Y)\right] \tag{3.40}$$

hold for $i = 0$ and $i = 2$.

Proof. The functions W_k and $\partial^2 W_k / \partial Y^2$ are products of $\exp(-pX_1)$ and a polynomial in X_1 with the coefficients depending on the functions z_i and $\partial^{2j} z_i / \partial Y^{2j}$. It follows from (3.32) that we have the desired inequalities.

Now applying the differential operator L_ϵ to the ordinary corner layer W yields

$$\begin{aligned} L_\epsilon W &= \sum_{k=0}^{n+1} \epsilon^k L_\epsilon W_k \\ &= \sum_{k=0}^{N+1} \epsilon^k \left(-\epsilon \frac{\partial^2 W_k}{\partial x^2} - \epsilon \frac{\partial^2 W_k}{\partial y^2} + p \frac{\partial W_k}{\partial x} + q W_k \right). \end{aligned} \tag{3.41}$$

Equation (3.38) can be written as

$$-\epsilon \frac{\partial^2 W}{\partial x^2} + p \frac{\partial W_k}{\partial x} = -\epsilon^{-1} \tau_k \left(\frac{a-x}{\epsilon}, \frac{y}{\sqrt{\epsilon}} \right). \tag{3.42}$$

Substitution of (3.42) into (3.41) gives

$$L_\epsilon W = \epsilon^{n+1}\Big(-\frac{\partial^2 W_{n+1}}{\partial Y^2} + qW_{n+1}\Big). \tag{3.43}$$

It follows from (3.40) that the estimate

$$L_\epsilon W = O\big(\epsilon^{n+1}\big)$$

holds uniformly in the closure of Ω. Moreover, let us examine the ordinary corner layer W along the boundary of Ω.

i) At $x = a$,

$$W = -z(a, Y; \epsilon). \tag{3.44a}$$

ii) At $x = 0$, the series

$$W = \sum_{k=0}^{n+1} \epsilon^k W_k\Big(\frac{a}{\epsilon}, \frac{y}{\sqrt{\epsilon}}\Big) \tag{3.44b}$$

is asymptotically exponentially small with respect to ϵ in the closed interval $0 \leq y \leq b$.

iii) At $y = b$, the series

$$W = \sum_{k=0}^{n+1} \epsilon^k W_k\Big(\frac{a-x}{\epsilon}, \frac{b}{\sqrt{\epsilon}}\Big) \tag{3.44c}$$

is asymptotically exponentially small with respect to ϵ in the closed interval $0 \leq x \leq a$.

iv) At $y = 0$, the series

$$W = \sum_{k=0}^{n+1} \epsilon^k W_k\Big(\frac{a-x}{\epsilon}, 0\Big) \tag{3.44d}$$

is asymptotically exponentially small with respect to ϵ in the interval $0 \leq x < a$, but not the closed interval $0 \leq x \leq a$. We shall define a series, called the elliptic corner layer, at the outflow corner $(a, 0)$ to overcome this difficulty.

3.6. Elliptic corner layer at the outflow corner $(a,0)$. As defined above, the stretched variables X_1 and Y_1 are expressed by $x = a - \epsilon X_1$ and $y = \epsilon Y_1$. The elliptic corner layer at the outflow corner $(a, 0)$ is defined by the series

$$V(X_1, Y_1; \epsilon) = \sum_{k=0}^{n+1} \epsilon^k V_k(X_1, Y_1; \epsilon), \tag{3.45}$$

where the functions $V_k(X_1, Y_1; \epsilon)$ are defined by the elliptic differential equations

$$-\Big(\frac{\partial^2 V_k}{\partial {X_1}^2} + \frac{\partial^2 V_k}{\partial {Y_1}^2}\Big) - p\frac{\partial V_k}{\partial X_1} + \epsilon q V_k = 0 \tag{3.46}$$

over the quarter plane $0 < X_1 < \infty$ and $0 < Y_1 < \infty$. The boundary conditions for $V_k(X_1, Y_1; \epsilon)$ are specified so that

i) the discrepancy introduced by both the ordinary boundary layer $w(X_1, y; \epsilon)$ and the ordinary corner layer $W(X_1, Y; \epsilon)$ in the boundary condition along $y = 0$ is eliminated;

ii) the discrepancy introduced by the elliptic boundary layer $v(X, Y_1; \epsilon)$ in the boundary condition along $x = a$ is eliminated; and

iii) the functions $V_k(X_1, Y_1; \epsilon)$ are corner layer functions with respect to X_1 and Y_1.

Thus, we impose the following conditions

$$\text{(3.47a)} \qquad \begin{aligned} V_k(X_1, 0; \epsilon) &= \xi_k(X_1) \qquad\qquad 0 \le k \le n+1, \\ &\equiv -w_k(X_1, 0) - W_k(X_1, 0), \end{aligned}$$

$$\text{(3.47b)} \qquad \begin{aligned} V_k(0, Y_1; \epsilon) &= \varsigma_k(Y_1; \epsilon) \\ &\equiv \begin{cases} -v_k\Big(\dfrac{a}{\epsilon}, Y_1; \epsilon\Big), & 0 \le k \le n, \\ 0, & k = n+1, \end{cases} \end{aligned}$$

and

$$\text{(3.47c)} \qquad V_k(X_1, Y_1; \epsilon) \to 0 \qquad \text{as } X_1^2 + Y_1^2 \to \infty,\ 0 \le k \le n+1.$$

Note that $\xi_k(0) = \varsigma_k(0; \epsilon)$ for $0 \le k \le n+1$. The elliptic problem (3.46), (3.47a,b,c) has a unique solution, and the maximum principle is valid for this problem. Note that the parameter ϵ appears in the equation (3.46) as a regular perturbation problem. The particular form of the functions $V_k(X_1, Y_1; \epsilon)$ was chosen to make the computations more tractable.

THEOREM 3.10. *The solutions* $V_k(X_1, Y_1; \epsilon)$ *of the boundary value problem* (3.46), (3.47a,b,c) *have the integral representations*

$$\begin{aligned} V_k(X_1, Y_1; \epsilon) = {} & \frac{\tau Y_1}{\pi} \int_0^\infty \Big(\frac{K_1(\tau\rho_5)}{\rho_5} - \frac{K_1(\tau\rho_6)}{\rho_6} \Big) \xi_k(s) \exp\Big(\frac{p(s - X_1)}{2}\Big)\, ds \\ & + \frac{\tau X_1}{\pi} \int_0^\infty \Big(\frac{K_1(\tau\rho_7)}{\rho_7} - \frac{K_1(\tau\rho_8)}{\rho_8} \Big) \varsigma_k(t; \epsilon) \exp\Big(-\frac{pX_1}{2}\Big)\, dt, \end{aligned}$$

where

$$\rho_5 = \big[(X_1 - s)^2 + Y_1^2\big]^{1/2}, \qquad \rho_6 = \big[(X_1 + s)^2 + Y_1^2\big]^{1/2},$$
$$\rho_7 = \big[X_1^2 + (Y_1 - t)^2\big]^{1/2}, \qquad \rho_8 = \big[X_1^2 + (Y_1 + t)^2\big]^{1/2},$$

and

$$\tau = \Big[\frac{p^2}{4} + \epsilon q\Big]^{1/2}.$$

Proof. The transformation

$$V_k(X_1, Y_1; \epsilon) = V_k^*(X_1, Y_1; \epsilon) \exp\Big(-\frac{pX_1}{2}\Big)$$

yields the differential equation for V_k^*

$$-\Big(\frac{\partial^2 V_k^*}{\partial X_1{}^2} + \frac{\partial^2 V_k^*}{\partial Y_1{}^2}\Big) + \Big(\frac{p^2}{4} + \epsilon q\Big) V_k^* = 0$$

over the quarter plane $0 < X_1 < \infty$ and $0 < Y_1 < \infty$ under the boundary conditions

$$V_k^*(X_1, 0; \epsilon) = \xi_k(X_1) \exp\Big(\frac{pX_1}{2}\Big),$$

$$V_k^*(0, Y_1; \epsilon) = \varsigma_k(Y_1; \epsilon)$$

and

$$V_k^*(X_1, Y_1; \epsilon) \to 0 \qquad \text{as } X_1^2 + Y_1^2 \to \infty,\ Y_1 > 0.$$

As in the case of the elliptic boundary layer, the solution V_k^* has the expression of the form

$$V_k^*(X_1, Y_1; \epsilon) = \int_0^\infty \xi_k(s) \exp\Big(\frac{ps}{2}\Big) \frac{\partial G}{\partial t}(X_1, Y_1; s, 0)\, ds + \int_0^\infty \varsigma_k(t; \epsilon) \frac{\partial G}{\partial s}(X_1, Y_1; 0, t)\, dt,$$

where the Green's function for this problem is given by

$$G(X_1, Y_1; s, t) = \frac{1}{2\pi}\big[K_0(\tau\rho_1) - K_0(\tau\rho_2) + K_0(\tau\rho_3) - K_0(\tau\rho_4)\big],$$

with

$$\rho_1 = \big[(X_1 - s)^2 + (Y_1 - t)^2\big]^{1/2}, \qquad \rho_2 = \big[(X_1 + s)^2 + (Y_1 - t)^2\big]^{1/2},$$
$$\rho_3 = \big[(X_1 + s)^2 + (Y_1 + t)^2\big]^{1/2}, \qquad \rho_4 = \big[(X_1 - s)^2 + (Y_1 + t)^2\big]^{1/2}.$$

Computations give

$$\frac{\partial G}{\partial t}(X_1, Y_1; s, 0) = \frac{\tau Y_1}{\pi}\Big[\frac{K_1(\tau\rho_5)}{\rho_5} - \frac{K_1(\tau\rho_6)}{\rho_6}\Big],$$

and

$$\frac{\partial G}{\partial s}(X_1, Y_1; 0, t) = \frac{\tau X_1}{\pi}\Big[\frac{K_1(\tau\rho_7)}{\rho_7} - \frac{K_1(\tau\rho_8)}{\rho_8}\Big],$$

and hence we obtain the desired integral representations. This completes the proof.

THEOREM 3.11. *There exist two positive constants C and c independent of ϵ such that the inequalities*

$$|V_k(X_1, Y_1; \epsilon)| \le C \exp\Big[-c\Big(X_1 + \sqrt{\Big(\frac{a}{\epsilon}\Big)^2 + Y_1^2} - \frac{a}{\epsilon}\Big)\Big] \tag{3.48}$$

hold.

Proof. From (3.22), we have

$$|V_k(0, Y_1; \epsilon)| \le C \exp\Big[-\frac{p}{2}\Big(\sqrt{\Big(\frac{a}{\epsilon}\Big)^2 + Y_1^2} - \frac{a}{\epsilon}\Big)\Big].$$

The estimates (3.13) and (3.40) give

$$|V_k(X_1, 0; \epsilon)| \le C \exp(-cX_1)$$

for some constant c between $p/2$ and p. Let the barrier function $V^*(X_1, Y_1; \epsilon)$ be defined by

$$V^*(X_1, Y_1; \epsilon) = C \exp\Big[-\frac{p}{2}\Big(X_1 + \sqrt{\Big(\frac{a}{\epsilon}\Big)^2 + Y_1^2} - \frac{a}{\epsilon}\Big)\Big].$$

Then a computation yields

$$\begin{aligned} &-\Big(\frac{\partial^2 V^*}{\partial {X_1}^2} + \frac{\partial^2 V^*}{\partial {Y_1}^2}\Big) - p\frac{\partial V^*}{\partial X_1} + \epsilon q V^* \\ &= V^*\Big(\frac{p^2}{4}\frac{(a/\epsilon)^2}{(a/\epsilon)^2 + Y_1^2} + \frac{p}{2}\frac{(a/\epsilon)^2}{[(a/\epsilon)^2 + Y_1^2]^{3/2}} + \epsilon q\Big) > 0. \end{aligned}$$

Furthermore, we have

$$\begin{aligned} \big|V_k(0, Y_1; \epsilon)\big| &\le V^*(0, Y_1; \epsilon), \\ \big|V_k(X_1, 0; \epsilon)\big| &\le V^*(X_1, 0; \epsilon), \end{aligned}$$

for sufficiently large values of C in the definition of V^*. By the maximum principle, we are led to have the desired inequalities for $0 \le k \le n+1$, $0 \le X_1 < \infty$, and $0 \le Y_1 < \infty$. This completes the proof.

Now applying the differential operator L_ϵ to the elliptic corner layer V yields

$$L_\epsilon V = \sum_{k=0}^{n+1} \epsilon^k \Big(-\epsilon\frac{\partial^2 V_k}{\partial x^2} - \epsilon\frac{\partial^2 V_k}{\partial y^2} + p\frac{\partial V_k}{\partial x} + qV_k\Big). \tag{3.49}$$

Equation (3.46) can be written as

$$-\epsilon\Big(\frac{\partial^2 V_k}{\partial x^2} + \frac{\partial^2 V_k}{\partial y^2}\Big) + p\frac{\partial V_k}{\partial x} + qV_k = 0, \tag{3.50}$$

for each k. Therefore substitution of (3.50) into (3.49) gives

$$L_\epsilon V = 0, \tag{3.51}$$

uniformly in the closure of Ω. Moreover, let us examine this function V along the boundary of Ω.

i) At $y = 0$,

$$V = -w\Big(\frac{a-x}{\epsilon}, 0; \epsilon\Big) - W\Big(\frac{a-x}{\epsilon}, 0; \epsilon\Big). \tag{3.52a}$$

ii) At $x = a$,

$$V = -v\Big(\frac{a}{\epsilon}, \frac{y}{\epsilon}; \epsilon\Big). \tag{3.52b}$$

iii) At $y = b$, the series

$$V = \sum_{k=0}^{n+1} \epsilon^k V_k\Big(\frac{a-x}{\epsilon}, \frac{b}{\epsilon}; \epsilon\Big) \tag{3.52c}$$

is asymptotically exponentially small with respect to ϵ in the closed interval $0 \leq x \leq a$.

iv) At $x = 0$, the series

$$V = \sum_{k=0}^{n+1} \epsilon^k V_k\Big(\frac{a}{\epsilon}, \frac{y}{\epsilon}; \epsilon\Big) \tag{3.52d}$$

is asymptotically exponentially small with respect to ϵ in the closed interval $0 \leq y \leq b$.

By symmetry, the remaining functions v_k^T, z_k^T, W_k^T, and V_k^T can be constructed similarly along the upper characteristic boundary $y = b$ for the terms TEBL, TPBL, TOCL, and TECL, respectively.

3.7. Asymptotic representation of the solution. Consider the remainder term $R_{n+1}(x, y; \epsilon)$, which is defined by

$$\begin{aligned} R_{n+1} &= u_\epsilon(x,y) - u(x,y;\epsilon) - w(X_1, y;\epsilon) \\ &\quad - v(X, Y_1;\epsilon) - z(x, Y;\epsilon) - W(X_1, Y;\epsilon) - V(X_1, Y_1;\epsilon) \\ &\quad - v^T(X, Y_1^T;\epsilon) - z^T(x, Y^T;\epsilon) - W^T(X_1, Y^T;\epsilon) - V^T(X_1, Y_1^T;\epsilon), \end{aligned}$$

where u_ϵ is the solution of the boundary value problem (1.1), (1.2a,b,c,d); the functions u, w, v, z, W, V are defined in (3.4), (3.9), (3.18), (3.25), (3.37), (3.45), respectively; and analogously for the other terms. Here we have used the stretched variables: $X_1 = (a-x)/\epsilon$, $X = x/\epsilon$, $Y_1 = y/\epsilon$, $Y = y/\sqrt{\epsilon}$, $Y_1^T = (b-y)/\epsilon$, $Y^T = (b-y)/\sqrt{\epsilon}$. Then it follows from the analysis of the preceding sections that the function R_{n+1} satisfies the elliptic differential equation

$$\begin{aligned} L_\epsilon R_{n+1} = \epsilon^{n+1}\Big(&\Delta u_n + \epsilon \frac{\partial^2 w_{n+1}}{\partial y^2} + \frac{\partial^2 w_n}{\partial y^2} - q w_{n+1} \\ &+ \frac{\partial^2 z_n}{\partial x^2} + \frac{\partial^2 W_{n+1}}{\partial Y^2} - q W_{n+1} + \frac{\partial^2 z_n^T}{\partial x^2} + \frac{\partial^2 W_{n+1}^T}{\partial {Y^T}^2} - q W_{n+1}^T\Big), \end{aligned}$$

which is of order $O(\epsilon^{n+1})$ in the closure of Ω, and we have the following conditions for R_{n+1} along the boundary of Ω.

i) At $x = 0$, the remainder

$$\begin{aligned} R_{n+1} = &-w\Big(\frac{a}{\epsilon}, y;\epsilon\Big) - W\Big(\frac{a}{\epsilon}, \frac{y}{\sqrt{\epsilon}};\epsilon\Big) - V\Big(\frac{a}{\epsilon}, \frac{y}{\epsilon};\epsilon\Big) \\ &- W^T\Big(\frac{a}{\epsilon}, \frac{b-y}{\sqrt{\epsilon}};\epsilon\Big) - V^T\Big(\frac{a}{\epsilon}, \frac{b-y}{\epsilon};\epsilon\Big) \end{aligned}$$

is asymptotically exponentially small for $0 \leq y \leq b$.

ii) At $x = a$,

$$R_{n+1} = 0 \quad \text{for } 0 \leq y \leq b.$$

iii) At $y = 0$, the remainder

$$R_{n+1} = -v^T\Big(\frac{x}{\epsilon}, \frac{b}{\epsilon}; \epsilon\Big) - z^T\Big(x, \frac{b}{\sqrt{\epsilon}}; \epsilon\Big) - W^T\Big(\frac{a-x}{\epsilon}, \frac{b}{\sqrt{\epsilon}}; \epsilon\Big) - V^T\Big(\frac{a-x}{\epsilon}, \frac{b}{\epsilon}; \epsilon\Big)$$

is asymptotically exponentially small for $0 \leq x \leq a$.

iv) At $y = b$, the remainder

$$R_{n+1} = -v\Big(\frac{x}{\epsilon}, \frac{b}{\epsilon}; \epsilon\Big) - z\Big(x, \frac{b}{\sqrt{\epsilon}}; \epsilon\Big) - W\Big(\frac{a-x}{\epsilon}, \frac{b}{\sqrt{\epsilon}}; \epsilon\Big) - V\Big(\frac{a-x}{\epsilon}, \frac{b}{\epsilon}; \epsilon\Big)$$

is asymptotically exponentially small for $0 \leq x \leq a$.

By using Theorem 3.3., we have the following estimate:

$$R_{n+1} = O\big(\epsilon^{n+1}\big),$$

which holds uniformly in the closure of Ω. Furthermore, the functions w_{n+1}, v_{n+1}, W_{n+1}, and V_{n+1} are uniformly bounded in the closure of Ω. Consequently, we obtain finally the following:

THEOREM 3.12. *The solution $u_\epsilon(x, y)$ of the boundary value problem* (1.1), (1.2a,b,c,d) *has a uniform approximation $U(x, y; \epsilon)$ in the closure of the rectangular region Ω with error $O\big(\epsilon^{n+1}\big)$, where U is defined by the series.*

$$\begin{aligned} U(x, y; \epsilon) = \sum_{k=0}^{n} \epsilon^k \big[&u_k(x, y) + w_k(X_1, y) + v_k(X, Y_1) + z_k(x, Y) \\ &+ W_k(X_1, Y) + V_k(X_1, Y_1) + v_k^T(X, Y_1^T) + z_k^T(x, Y^T) \\ &+ W_k^T(X_1, Y^T) + V_k^T(X_1, Y_1^T)\big]. \end{aligned}$$

4. Magnetohydrodynamic flow in a rectangular duct with nonconducting walls. The design of magnetohydrodynamic generators, flow-meters, pumps and accelerators requires an understanding of the flows of conducting fluids in rectangular ducts under transverse magnetic fields. These flows have received much attention from theoreticians because the governing equations are linear but the phenomena are neither trivially simple nor physically attainable in the laboratory.

In 1937, Jul. Hartmann [19] solved the one-dimensional problem where the flow was between two parallel walls, the fluid being virtually infinite in directions perpendicular to the imposed transverse magnetic field. Coordinates are then dependent on the transverse coordinate only.

We are concerned with the flow of a steady, incompressible, electrically conducting fluid through a rectangular duct with a uniform, external magnetic field applied transverse to the flow and parallel to two of the walls. Various forms of this problem with different combinations of conducting and nonconducting bounding walls have been considered, see J. A. Shercliff [41], C. C. Chang and T. S. Lundgren [6], W. E. Williams [47], J. C. R. Hunt [21], J. C. R. Hunt and K. Stewartson [22], D. Chiang and T. Lundgren [7], J. C. R. Hunt and J. A. Shercliff [23], D. J. Temperley and L. Todd [42], and L. A. Kalyakin [25] - [28].

As is known from the work of Shercliff [41] and Chang and Lundgren [6], the problem of magnetohydrodynamic flow in a rectangular duct with an applied magnetic field transverse to the axis of the duct is described by two second-order elliptic partial differential equations for the fluid velocity V and the axial component of the magnetic field B, namely, the z-component of the momentum equation

$$\rho\nu\Delta V + \frac{B_0}{\mu_0}\frac{\partial B}{\partial x} = \frac{\partial p}{\partial z},$$

and the z-component of the curl of Ohm's law

$$\Delta B + \sigma\mu_0 B_0 \frac{\partial V}{\partial x} = 0,$$

where ρ is the mass density; ν is the kinematic viscosity; B_0 is the magnitude of the transverse magnetic field which is applied in the x-direction; μ_0 is the permeability in a vacuum; $\partial p/\partial z$ is the pressure gradient, which is a constant; and σ is the electrical conductivity of the incompressible fluid medium. Let the origin be the centerline of the duct and let $2a$ and $2b$ be the lengths of the sides of the duct (see Figure 4.1).

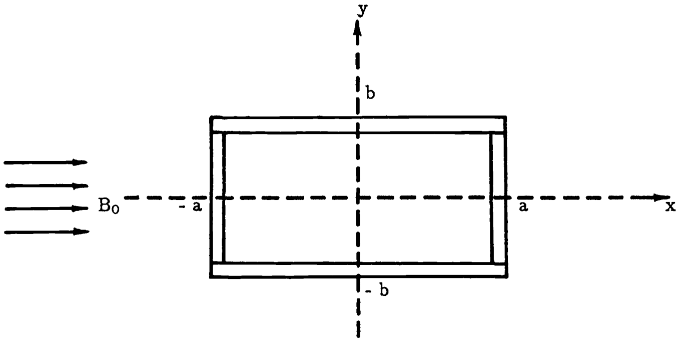

FIG. 4.1. *Rectangular duct.*

In the case of nonconducting walls, the boundary conditions are

$$V = B = 0 \quad \text{at } x = \pm a,$$
$$V = B = 0 \quad \text{at } y = \pm b.$$

We shall examine the flow for large Hartmann number M, which is defined by

$$M = B_0 a\sqrt{\frac{\sigma}{\rho\nu}},$$

or the small value of $\epsilon = 1/M$. With these dimensionless variables

$$\xi = \frac{x}{a}, \qquad \nu = \frac{y}{a}, \qquad V^* = 2\mu_0\sqrt{\rho\nu\sigma}\, B_0^{-1} V,$$
$$B^* = 2B_0^{-1}B, \qquad P = -2\mu_0 a B_0^{-2}\,\frac{\partial p}{\partial z},$$

the problem is to solve

$$\epsilon\Big(\frac{\partial^2 V^*}{\partial \xi^2} + \frac{\partial^2 V^*}{\partial \eta^2}\Big) + \frac{\partial B^*}{\partial \xi} = -P,$$
$$\epsilon\Big(\frac{\partial^2 B^*}{\partial \xi^2} + \frac{\partial^2 B^*}{\partial \eta^2}\Big) + \frac{\partial V^*}{\partial \xi} = 0,$$

with the boundary conditions

$$V^* = B^* = 0 \quad \text{at } \xi = \pm 1,$$
$$V^* = B^* = 0 \quad \text{at } \eta = \pm \ell, \ \ell = b/a.$$

The equations can be decoupled by the change of variables

$$u = P^{-1}(V^* - B^*),$$

and

$$v = P^{-1}(V^* - B^*).$$

The equations for u and v are

$$-\epsilon \Delta u + \frac{\partial u}{\partial \xi} = 1,$$

and

$$-\epsilon \Delta v - \frac{\partial v}{\partial \xi} = 1,$$

with the boundary conditions

$$u = v = 0 \quad \text{at } \xi = \pm 1,$$
$$u = v = 0 \quad \text{at } \eta = \pm \ell.$$

It is obvious that having determined the functions u, we can find v by the relationship

$$v(\xi, \eta) = u(-\xi, \eta).$$

Hence the function u alone needs to be investigated. The asymptotic approximation to u, being uniformly valid in the closure of the rectangular duct for large Hartmann number M, is still an open question in the literature, see Shercliff [41], Roberts [40, pp. 186–190], Cook, Ludford and Walker [9], and Temperley [43].

With an application of the preceding analysis, we conclude that the solution u can be written as

$$u(\xi, \eta) = (1 + \xi) - 2\exp(-\xi_2) + v_1(\xi_1, \eta_1; \epsilon) + V_1(\xi_2, \eta_1; \epsilon)$$
$$+ v_2(\xi_2, \eta_1; \epsilon) + V_2(\xi_2, \eta_2; \epsilon) + \text{AES},$$

where the stretched variables are

$$\xi_1 = \frac{\xi+1}{\epsilon}, \qquad \xi_2 = \frac{1-\xi}{\epsilon}, \qquad \eta_1 = \frac{\ell-\eta}{\epsilon} \quad \text{and} \quad \eta_2 = \frac{\eta+\ell}{\epsilon};$$

the function $1+\xi$ is known as a "core flow"; the function $-2\exp(-\xi_2)$ is called a "Hartmann boundary layer"; the functions $v_1(\xi_1,\eta_1;\epsilon)$ and $v_2(\xi_1,\eta_2;\epsilon)$ satisfy the elliptic partial differential equation of the form

$$-\left(\frac{\partial^2 v_i}{\partial {\xi_1}^2} + \frac{\partial^2 v_i}{\partial {\eta_i}^2}\right) + \frac{\partial v_i}{\partial \xi_1} = 0 \quad \text{for } i = 1,2,$$

over the quarter plane $0 < \xi_1 < \infty$ and $0 < \eta_i < \infty$ under the boundary conditions

$$v_i(\xi_1, 0; \epsilon) = -\epsilon\xi_1, \quad v_i(0,\eta_1;\epsilon) = 0,$$

and

$$v_i(\xi_1,\eta_i;\epsilon) \to 0 \quad \text{as } \xi_1^2 + \eta_i^2 \to \infty \text{ and } \eta_i > 0;$$

and the functions $V_1(\xi_2,\eta_1;\epsilon)$ and $V_2(\xi_2,\eta_2;\epsilon)$ satisfy the elliptic partial differential equation of the form

$$\left(\frac{\partial^2 V_i}{\partial {\xi_2}^2} + \frac{\partial^2 V_i}{\partial {\eta_i}^2}\right) + \frac{\partial V_i}{\partial \xi_2} = 0 \quad \text{for } i = 1,2,$$

over the quarter plane $0 < \xi_2 < \infty$ and $0 < \eta_i < \infty$ under the boundary conditions

$$V_i(\xi_2, 0; \epsilon) = 2\exp(-\xi_2),$$
$$V_i(0,\eta_i;\epsilon) = -v_i\left(\frac{2}{\epsilon},\eta_i;\epsilon\right),$$

and

$$V_i(\xi_2,\eta_i;\epsilon) \to 0 \quad \text{as } \xi_2^2 + \eta_i^2 \to \infty;$$

and AES denotes asymptotically exponentially small terms with respect to ϵ in the closure of the rectangular duct.

A TRIPLE PRODUCT THEOREM FOR HYPERGEOMETRIC SERIES*

PETER HENRICI†

Abstract. The product of three hypergeometric series of type ${}_0F_1$ with arguments x, ωx, $\omega^2 x$ (ω = third root of unity) is expressed as a single hypergeometric series of type ${}_2F_7$. The proof uses differential equations; the basic idea (elimination of irreducible terms by means of the Cayley-Hamilton theorem) is more generally applicable.

Key words. hypergeometric series, product theorems for special functions

AMS(MOS) subject classifications. 33A30, 33A35, 34B30

1. THEOREM. *Let c be complex, $6c \neq 0, -1, -2, \cdots$, and let $\omega := \exp(2\pi i/3)$. In the usual notation for generalized hypergeometric series (see Bailey [1936]) there holds*

$$(1)\qquad \begin{aligned}&{}_0F_1[6c;\, x]\,{}_0F_1[6c;\, \omega x]\,{}_0F_1[6c;\, \omega^2 x]\\ &\quad = {}_2F_7\left[\begin{matrix}3c-\frac14,\, 3c+\frac14;\\ 6c,\, 2c,\, 2c+\frac13,\, 2c+\frac23,\, 4c-\frac13,\, 4c,\, 4c+\frac13;\end{matrix}\ (\tfrac49)^3x^3\right].\end{aligned}$$

The proof is given in §§ 2-4 below. The idea is to regard (1) as an identity between formal power series and to show that the series on the left and on the right formally satisfy the same hypergeometric differential equation. Section 5 features corollaries and remarks.

2. Derivatives. If

$$P = \sum_{n=0}^{\infty} a_n x^n$$

is any formal power series (over $\mathbb{C}$, or over any field of characteristic 0), we call

$$\theta P := \sum_{n=0}^{\infty} n a_n x^n$$

the *derivate* of P. (The relation to the ordinary derivative P' is obvious.) Derivatives satisfy many of the usual rules of calculus, such as the product rule,

$$\theta(PQ) = P\theta Q + Q\theta P,$$

and the further rules (such as the Leibniz rule for the higher derivatives of a product) that follow from it.

In terms of derivates, the (formal) generalized hypergeometric series

$$P = {}_pF_q\left[\begin{matrix}\alpha_1, \alpha_2, \cdots, \alpha_p;\\ \beta_1, \beta_2, \cdots, \beta_q;\end{matrix}\ x\right],$$

where p and q are arbitrary nonnegative integers, satisfies the differential equation

$$(2)\qquad \{\theta(\theta+\beta_1-1)\cdots(\theta+\beta_q-1) - x(\theta+\alpha_1)\cdots(\theta+\alpha_p)\}P = 0;$$

see Bailey [1936]. Similarly if $a \in \mathbb{C}$ and s is a positive integer,

$$Q = {}_pF_q\left[\begin{matrix}\alpha_1, \alpha_2, \cdots, \alpha_p;\\ \beta_1, \beta_2, \cdots, \beta_q;\end{matrix}\ ax^s\right]$$

* Received by the editors December 16, 1985; accepted for publication December 1, 1986.

† Department of Mathematics, University of North Carolina, Chapel Hill, North Carolina 27514. It is with great regret that SIAM learned of the untimely death of Peter Henrici in March 1987. The editorial staff of the SIAM Journal on Mathematical Analysis feel especially his absence, as Peter was an active member of the Editorial Board for many years.—J.B.

satisfies

$$\{\theta(\theta+s\beta_1-s)\cdots(\theta+s\beta_q-s)-as^{n+1-m}x^s(\theta+s\alpha_1)\cdots(\theta+s\alpha_p)\}Q=0. \tag{3}$$

Conversely, if the β_i are such that none of the numbers $s\beta_i-s$ is zero or a negative integer, the series Q is a formal solution of (3), and it is the only such solution that has zeroth coefficient 1.

3. The triple product $\Pi_0F_1[6c,\omega^k x]$ and its derivatives. To prove (1), let

$$U:={}_0F_1[6c;x],\quad V:={}_0F_1[6c;\omega x],\quad W:={}_0F_1[6c;\omega^2x].$$

If $a:=6c-1$, the differential equation satisfied by U is

$$\theta(\theta+a)-xU=0.$$

We thus have

$$\theta^2U=-a\theta U+xU \tag{4a}$$

and similarly

$$\theta^2V=-a\theta V+\omega xV, \tag{4b}$$

$$\theta^2W=-a\theta W+\omega^2xW. \tag{4c}$$

To discover a differential equation satisfied by

$$Z:=UVW,$$

we form the derivatives θZ, $\theta^2Z,\cdots$ and eliminate derivates of U, V, W of order $\geqq2$ by means of (4). Some of the remaining terms $\sum\theta^iU\theta^jV\theta^kW$ may be expressed in terms of Z or

$$\theta Z=UV\theta W+VW\theta U+WU\theta V,$$

and thus are "reducible," but many terms cannot be so expressed. It is convenient to define a basis for the space of irreducible terms as follows:

$$\begin{aligned}
F&:=U\theta V\theta W+V\theta W\theta U+W\theta U\theta V,\\
P&:=\theta U\theta V\theta W,\\
A&:=VW\theta U+\omega WU\theta V+\omega^2UV\theta W,\\
B&:=U\theta V\theta W+\omega V\theta W\theta U+\omega^2W\theta U\theta V,\\
C&:=VW\theta U+\omega^2WU\theta V+\omega^4UV\theta W,\\
D&:=U\theta V\theta W+\omega^2V\theta W\theta U+\omega^4W\theta U\theta V.
\end{aligned} \tag{5}$$

We require the derivates of these irreducible forms. We have, for instance,

$$\theta F=3\theta U\theta V\theta W+U\theta^2V\theta W+U\theta V\theta^2W+V\theta^2W\theta U+V\theta W\theta^2U+W\theta^2U\theta V+W\theta U\theta^2V$$

and thus, using (4),

$$\begin{aligned}
\theta F&=3P+U(\omega xV-a\theta V)\theta W+U\theta V(\omega^2xW-a\theta W)+V(\omega^2xW-a\theta W)\theta U\\
&\quad+V\theta W(xU-a\theta U)+W(xU-a\theta U)\theta V+W\theta U(\omega xV-a\theta V)\\
&=3P+x[(1+\omega)UV\theta W+(\omega+\omega^2)VW\theta U+(\omega^2+1)WU\theta V]\\
&\quad-2a[U\theta V\theta W+V\theta W\theta U+W\theta U\theta V]
\end{aligned}$$

or, using $1+\omega+\omega^2=0$,

$$\theta F=-2aF+3P-xA. \tag{6a}$$

In a similar manner we obtain

$$\begin{aligned} \theta P &= -3aP+xB, \\ \theta A &= -aA-B, \\ \theta B &= -2aB+2xC, \\ \theta C &= -aC-D-3xZ, \\ \theta D &= -2aD-x\theta Z. \end{aligned} \tag{6b}$$

Defining the vector of irreducible terms

$$\mathbf{v}=\begin{pmatrix} F \\ P \\ xA \\ xB \\ x^2C \\ x^2D \end{pmatrix},$$

the matrix

$$\mathbf{M}=\begin{pmatrix} -2a & 3 & -1 & 0 & 0 & 0 \\ 0 & -3a & 0 & 1 & 0 & 0 \\ 0 & 0 & 1-a & -1 & 0 & 0 \\ 0 & 0 & 0 & 1-2a & 2 & 0 \\ 0 & 0 & 0 & 0 & 2-a & -1 \\ 0 & 0 & 0 & 0 & 0 & 2-2a \end{pmatrix},$$

and the vector of operators

$$\mathbf{s}(\theta)=\begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 3 \\ -\theta \end{pmatrix},$$

the relations (6) are expressed as

$$\theta\mathbf{v}=\mathbf{M}\mathbf{v}+x^3\mathbf{s}(\theta)Z. \tag{7}$$

(Here we have used, for instance, that $\theta(x^2C)=2xC+x^2\theta C$.)

4. Elimination of the irreducible terms. Using (4), we have

$$\begin{aligned} \theta^2 Z &= UV\theta^2 W+VW\theta^2 U+WU\theta^2 V+2(U\theta V\theta W+V\theta W\theta U+W\theta U\theta V) \\ &= UV(\omega^2 xW-a\theta W)+VW(xU-a\theta U)+WU(\omega xV-a\theta V)+2(\cdots) \\ &= -a\theta Z+2F. \end{aligned}$$

Introducing $\mathbf{c}:=(2,0,0,0,0,0)^T$, this is written:

$$\theta(\theta+a)Z=\mathbf{c}^T\mathbf{v}. \tag{8}$$

By successive applications of θ, always using (7), there results

$$\theta^2(\theta+a)Z=\mathbf{c}^T(\mathbf{M}\mathbf{v}+x^3\mathbf{s}(\theta)Z),$$
$$\theta^3(\theta+a)Z=\mathbf{c}^T\{\mathbf{M}^2\mathbf{v}+x^3[\mathbf{M}+(\theta+3)\mathbf{I}]\mathbf{s}(\theta)Z\},$$

and generally, as may be verified by induction,

(9) $$\theta^{k+1}(\theta+a)Z=\mathbf{c}^T\{\mathbf{M}^k\mathbf{v}+x^3[\mathbf{M}^{k-1}+(\theta+3)\mathbf{M}^{k-2}+\cdots+(\theta+3)^{k-1}\mathbf{I}]\mathbf{s}(\theta)Z\},$$

$k=0,1,\cdots$. A hypergeometric differential equation for Z (of the type (3) where $s=3$) will result if $\mathbf{v}$ can be eliminated by forming a suitable linear combination of sufficiently many of the relations (9). To effect the elimination, the Cayley-Hamilton theorem offers itself. The characteristic polynomial of the matrix $\mathbf{M}$ is

$$p(\lambda)=(\lambda+2a)(\lambda+3a)\cdots$$
$$=\sum_{k=0}^{6}\gamma_k\lambda^k,$$

say. For later reference we note that

(10) $$\gamma_6=1,\quad \gamma_5=11a-6,\quad \gamma_4=49a^2-57a+13.$$

We multiply the kth relation (9) by γ_k ($k=0,1,\cdots,6$) and add. On the left we obtain

$$\sum_{k=0}^{6}\gamma_k\theta^{k+1}(\theta+a)Z=\theta(\theta+a)p(\theta)Z.$$

On the right, the factor of $\mathbf{v}$ is

$$\mathbf{c}^T\sum_{k=0}^{6}\gamma_k\mathbf{M}^k=\mathbf{c}^Tp(\mathbf{M}),$$

which vanishes by the Cayley-Hamilton theorem. The vector $\mathbf{v}$ thus is eliminated. There remains

$$x^3\mathbf{c}^T\left\{\sum_{k=1}^{6}\gamma_k[\mathbf{M}^{k-1}+(\theta+3)\mathbf{M}^{k-2}+\cdots+(\theta+3)^{k-1}\mathbf{I}]\mathbf{s}(\theta)Z\right\}$$
$$=x^3\mathbf{c}^T\left\{\sum_{k=1}^{6}\gamma_k(\theta+3)^{k-1}\mathbf{I}+\sum_{k=2}^{6}\gamma_k(\theta+3)^{k-2}\mathbf{M}\right.$$
$$\left.+\sum_{k=3}^{6}\gamma_k(\theta+3)^{k-3}\mathbf{M}^2+\cdots+\gamma_6\mathbf{M}^5\right\}\mathbf{s}(\theta)Z.$$

We evaluate this expression by first forming the iterates $\mathbf{c}^T\mathbf{M}^j$, $j=0,1,2,\cdots,5$. Since only the last two components of $\mathbf{s}(\theta)$ are $\neq 0$, only the last two components of these iterates are relevant for the result. These components are different from zero only for $j\geqq 3$, and they have the following values (see Table 1). With the values of the γ_k given

TABLE 1

k	5	6
$(\mathbf{c}^T\mathbf{M}^3)_k$	16	0
$(\mathbf{c}^T\mathbf{M}^4)_k$	$-120a+52$	-16
$(\mathbf{c}^T\mathbf{M}^5)_k$	$584a^2-452a+128$	$152a-84$

in (10), we thus find

$$\begin{aligned}\mathbf{c}^T&\left\{\sum_{j=0}^{5}\sum_{k=j+1}^{6}\gamma_k(\theta+3)^{k-1}\mathbf{M}^j\right\}\mathbf{s}(\theta)\\ &=\mathbf{c}^T\{[\gamma_4+\gamma_5(\theta+3)+\gamma_6(\theta+3)^2]\mathbf{M}^3\mathbf{s}(\theta)\\ &\qquad+[\gamma_5+\gamma_6(\theta+3)]\mathbf{M}^4\mathbf{s}(\theta)+\gamma_6\mathbf{M}^5\mathbf{s}(\theta)\}\\ &=64\theta^2+(192a+192)\theta+114a^2+288a+108\\ &=64\left(\theta+\frac{3a}{2}+\frac{3}{4}\right)\left(\theta+\frac{3a}{2}+\frac{9}{4}\right).\end{aligned}$$

It follows that $Z=UVW$ is a solution of the generalized hypergeometic differential equation

$$\left\{\theta(\theta+a)p(\theta)-64x^3\left(\theta+\frac{3a}{2}+\frac{3}{4}\right)\left(\theta+\frac{3a}{2}+\frac{9}{4}\right)\right\}Z=0.$$

By (3), if expressed in terms of $c=a/6+1/6$, this solution must be identical with the series on the right of (1).

5. Remarks and corollaries. (i) By using obvious identities for Pochhammer symbols, the series on the right of (1) may also be expressed as

$$(11)\qquad {}_2F_7=\sum_{k=0}^{\infty}\frac{(12c-1+3k)_k}{k!(6c)_k(6c)_{2k}(6c)_{3k}}x^{3k}.$$

(ii) Any product theorem for hypergeometric series, i.e., any theorem expressing a product of hypergeometric series as a single such series, on comparing coefficients furnishes a formula expressing a sum of products of Pochhammer symbols (or of binomial coefficients) by a single such product. In this manner we obtain from (1), using the representation (11) and letting $b:=6c$,

$$(12)\qquad \sum_{k+l+m=n}\frac{\omega^{l-m}}{k!l!m!(b)_k(b)_l(b)_m}=\begin{cases}0, & n\not\equiv 0 \bmod 3,\\ \dfrac{(2b+3q-1)_q}{q!(b)_q(b)_{2q}(b)_{3q}}, & n=3q.\end{cases}$$

For instance, for $b=1$ this yields

$$(13)\qquad \sum_{0\leqq k\leqq m\leqq n}\binom{n}{m}^2\binom{m}{k}^2\omega^{k+m}=\begin{cases}0, & n\not\equiv 0 \bmod 3,\\ \dbinom{4q}{2q}\dbinom{2q}{q}, & n=3q.\end{cases}$$

Formula (12) is of a similar type as the formulas

$$(14)\qquad \sum_{k+l+m=n}\frac{\omega^{l-m}}{k!l!m!}=\begin{cases}1, & n=0,\\ 0, & n>0,\end{cases}$$

and

$$(15)\qquad \sum_{k+l+m=n}\frac{(a)_k(a)_l(a)_m}{k!l!m!}\omega^{l-m}=\begin{cases}0, & n\not\equiv 0 \bmod 3,\\ (a)_q/q!, & n=3q,\end{cases}$$

which follows from the trivial product theorems[1]

$$ {}_0F_0[x]\,{}_0F_0[\omega x]\,{}_0F_0[\omega^2 x] = 1 $$

(i.e., $\exp((1+\omega+\omega^2)x)=1$) and

$$ {}_1F_0[a;\, x]\,{}_1F_0[a;\, \omega x]\,{}_1F_0[a;\, \omega^2 x] = {}_1F_0[a;\, x^3] $$

(i.e., $(1-x)^{-a}(1-\omega x)^{-a}(1-\omega^2 x)^{-a} = (1-x^3)^{-a}$).

(iii) The method used in this work has the advantage of not requiring the result to be known in advance. Although the algebraic manipulations, if done by hand, soon become unmanageable, the method can be used in principle whenever the irreducible terms in the derivatives of a product satisfy a recurrence relation of the general form (7).

CANONICAL EQUATIONS AND SYMMETRY TECHNIQUES FOR q-SERIES*

A. K. AGARWAL†, E. G. KALNINS‡ AND WILLARD MILLER, JR.§

Abstract. The authors introduce symmetry techniques for the classification and derivation of generating functions for families of basic hypergeometric functions, in analogy with the Lie theory techniques for ordinary hypergeometric functions. To each family of basic hypergeometric functions there is associated a canonical system of partial q-difference equations and the symmetries of these equations are used to derive q-series identities and orthogonality relations for the special functions.

Key words. q-series, q-difference equations, basic hypergeometric functions

1. Introduction. In [11], [13], [14] a Lie algebraic method was developed which associated with each family of multivariable hypergeometric functions a canonical system of partial differential equations constructed from the differential recurrence relations obeyed by the family. (The basic idea behind this method followed from the work of Weisner [16].) The hypergeometric functions arise by partial separation of variables in the canonical systems and any analytic solution of these equations can be considered as a generating function for this family. Furthermore the generating functions can be characterized in terms of symmetry operators for the canonical systems.

In this paper we present the foundations of an analogous theory for families of many-variable basic hypergeometric functions. To each family we associate a canonical system of partial q-difference equations constructed from the q-difference recurrence relations obeyed by the family. The basic hypergeometric functions arise by partial separation of variables in the canonical systems and any analytic solution of these equations is a generating function for the family. Symmetry operators for the canonical system can be used to characterize the generating functions. Thus a direct link is established between symmetries of the canonical system and identities obeyed by q-series.

In § 2 we show how to derive the canonical system of q-difference equations associated with a given family of q-series, using as examples the one-variable hypergeometric functions ${}_r\varphi_s$ and the two-variable function f_2, a q-analogue of the Appell function F_2. In § 3 we describe how to relate two different families of basic hypergeometric functions, that is, the procedures of *embedding* and *augmentation*. In the procedure of embedding the canonical system for one basic hypergeometric family restricts through a specialization of variables to the canonical system for a second hypergeometric family, so that the restricted family can be considered as a generating function for the second family. Augmentation is a process inverse to this. By augmentation we can write the defining equations for a generating function as the restriction of a canonical system of higher dimension.

In § 4 we apply our techniques to derive and characterize in terms of symmetries, a variety of generating functions for the families ${}_r\varphi_s$. In § 5 we treat the family ${}_2\varphi_1$ in somewhat more detail. (This family needs special treatment because its canonical

system admits symmetries not shared by the systems for general ${}_r\varphi_s$.) Furthermore we show how orthogonality relations for q-series follow from symmetry ideas.

Our theory provides a simple uniform procedure for derivation and symmetry classification of a wide variety of q-identities, in analogy with the Lie theoretic procedures for ordinary hypergeometric series. The full power of the theory becomes evident in the study of many-variable q-series and in the study of Askey-Wilson polynomials, as we will show in future papers. However, in distinction to the case of differential equations we do not have the tools of local Lie transformation group theory or the relationship between Lie symmetries and separation of variables to help us obtain the generating functions in the most compact form. Our procedures enable us to classify and characterize generating functions in terms of symmetry operators; unaided, they do not enable us to write the generating functions in simplest form, i.e., factorized or in terms of a new choice of variables. It will be very interesting to see if (as is the case for differential equations) factorization and coordinates have symmetry operator interpretations.

The symmetry techniques presented here apply to formal power series and are essentially independent of convergence criteria. Hence, we shall ordinarily not specify the domains of validity for the identities derived in this paper. In most cases they can be determined easily for one-variable hypergeometric functions by the ratio test. For multivariable hypergeometric functions the full domain of convergence may be very difficult to determine (or even unknown). In those cases one can specialize some of the parameters in the functions (so that infinite series truncate to finite series for example) to guarantee convergence.

Finally we note that the symbolic method of Burchnall and Chaundy for ordinary hypergeometric series [4], [5], and some works of Hahn on q-series [7], [8] contain points of similarity with our method, although these authors did not use symmetry techniques.

2. The "basic" idea.

We begin our study of canonical equations for q-series by deriving the canonical form associated with the q-hypergeometric functions ${}_r\varphi_s$:

$$(2.1)\qquad {}_r\varphi_s\left(\begin{matrix}a_1,\cdots,a_r\\ b_1,\cdots,b_s\end{matrix};x\right)=\sum_{n=0}^{\infty}\frac{(a_1;q)_n\cdots(a_r;q)_n x^n}{(b_1;q)_n\cdots(b_s;q)_n(q;q)_n}$$

where $a_i=q^{\alpha_i}$, $b_j=q^{\beta_j}$ and

$$(2.2)\qquad (a;q)_n=\frac{(a;q)_\infty}{(aq^n;q)_\infty},\qquad (a;q)_\infty=\prod_{m=0}^{\infty}(1-q^m a).$$

Here α_i, β_j, x are complex variables, $(\beta_j\neq 0,-1,-2,\cdots)$ and we normally require that $0<q<1$. Note that for n a nonnegative integer we have

$$(2.3)\qquad (a;q)_n=(1-a)(1-qa)\cdots(1-q^{n-1}a).$$

As is well known [3], [5] ${}_r\varphi_s$ is a q-analogue of the hypergeometric series

$$(2.4)\qquad {}_rF_s\left(\begin{matrix}\alpha_1,\cdots,\alpha_r\\ \beta_1,\cdots,\beta_s\end{matrix};x\right)=\sum_{n=0}^{\infty}\frac{(\alpha_1)_n\cdots(\alpha_r)_n}{(\beta_1)_n\cdots(\beta_s)_n}\frac{x^n}{n!}$$

where

$$(2.5)\qquad (\alpha)_n=\frac{\Gamma(\alpha+n)}{\Gamma(\alpha)}$$

and $\Gamma(\,\cdot\,)$ is the gamma function. For n a nonnegative integer

$$(2.6)\qquad (\alpha)_n=\alpha(\alpha+1)\cdots(\alpha+n-1).$$

Here ${}_r\varphi_s$ and ${}_rF_s$ are related by

$$(2.7)\qquad {}_rF_s\left(\begin{matrix}\alpha_i\\ \beta_j\end{matrix};\,x\right)=\lim_{q\to 1}{}_r\varphi_s\left(\begin{matrix}a^i\\ b_j\end{matrix};\,\frac{x}{(1-q)^{r-s-1}}\right).$$

Let T_u be the q-dilation operator corresponding to the variable u, i.e., T_u maps a function f of the variables $u, v, w, \cdots$ to the function

$$(2.8)\qquad T_uf(u,v,w,\cdots)=f(qu,v,w,\cdots).$$

From the q-series (2.1) one can easily verify the recurrence relations

$$(1-a_kT_x)\,{}_r\varphi_s\left(\begin{matrix}a_i\\ b_j\end{matrix};\,x\right)=(1-a_k)\,{}_r\varphi_s\left(\begin{matrix}e^ka_i\\ b_j\end{matrix};\,x\right),\qquad 1\leqq k\leqq r,$$

$$(2.9)\qquad (1-b_lq^{-1}T_x)\,{}_r\varphi_s\left(\begin{matrix}a_i\\ b_j\end{matrix};\,x\right)=(1-b_lq^{-1})\,{}_r\varphi_s\left(\begin{matrix}a_i\\ e_lb_j\end{matrix};\,x\right),\qquad 1\leqq l\leqq s,$$

$$x^{-1}(1-T_x)\,{}_r\varphi_s\left(\begin{matrix}a_i\\ b_j\end{matrix};\,x\right)=\frac{(1-a_1)\cdots(1-a_r)}{(1-b_1)\cdots(1-b_s)}\,{}_r\varphi_s\left(\begin{matrix}qa_i\\ qb_j\end{matrix};\,x\right)$$

where

$$(2.10)\qquad \begin{aligned} e^ka_i&=\begin{cases}a_i & \text{if } i\neq k,\\ qa_k & \text{if } i=k,\end{cases}\\ e_lb_j&=\begin{cases}b_j & \text{if } j\neq l,\\ q^{-1}b_l & \text{if } j=l.\end{cases}\end{aligned}$$

Note that relations (2.9) imply the fundamental q-difference equation satisfied by the ${}_r\varphi_s$:

(2.11)

$$\{x(1-a_1T_x)\cdots(1-a_rT_x)-(1-T_x)(1-b_1q^{-1}T_x)\cdots(1-b_sq^{-1}T_x)\}\,{}_r\varphi_s\left(\begin{matrix}a_i\\ b_j\end{matrix};\,x\right)=0.$$

Indeed, for $\beta_j\neq 0, -1, -2, \cdots$ the only solution of this equation which is analytic in x at $x=0$ is ${}_r\varphi_s(\begin{smallmatrix}a_i\\ b_j\end{smallmatrix};\,x)$.

Now we define the function ${}_r\Phi_s$ of $2(r+s)+1$ variables by

$$(2.12)\qquad {}_r\Phi_s(a_i,b_j;u_p)={}_r\varphi_s\left(\begin{matrix}a_i\\ b_j\end{matrix};\,\frac{u_{r+1}\cdots u_{r+s+1}}{u_1\cdots u_r}\right)u_1^{-\alpha_1}\cdots u_r^{-\alpha_r}u_{r+1}^{\beta_1-1}\cdots u_{r+s}^{\beta_s-1}.$$

Let $\Delta_p^{\pm}$ be the q-difference operators

$$(2.13)\qquad \begin{aligned}\Delta_p^{+}&=u_p^{-1}(1-T_{u_p}),\\ \Delta_p^{-}&=u_p^{-1}(1-T_{u_p}^{-1}),\qquad 1\leqq p\leqq r+s+1.\end{aligned}$$

In terms of these operators, relations (2.9) take the simple form

$$
\begin{aligned}
&\Delta_k^-\,{}_r\Phi_s=(1-a_k)\,{}_r\Phi_s\begin{pmatrix}e^k a_i\\ b_j\end{pmatrix}, && 1\leqq k\leqq r,\\
(2.14)\qquad &\Delta_{r+l}^+\,{}_r\Phi_s=(1-b_lq^{-1})\,{}_r\Phi_s\begin{pmatrix}a_i\\ e_lb_j\end{pmatrix}, && 1\leqq l\leqq s,\\
&\Delta_{r+s+1}^+\,{}_r\Phi_s=\frac{(1-a_1)\cdots(1-a_r)}{(1-b_1)\cdots(1-b_s)}\,{}_r\Phi_s\begin{pmatrix}qa_i\\ qb_j\end{pmatrix}
\end{aligned}
$$

and (2.11) becomes the (canonical) partial q-difference equation

$$
(2.15)\qquad \left(\prod_{k=1}^{r}\Delta_p^- - \prod_{p=r+1}^{r+s+1}\Delta_p^+\right){}_r\Phi_s=0.
$$

Furthermore ${}_r\Phi_s$ satisfies the eigenvalue equations

$$
(2.16)\qquad
\begin{aligned}
&T_{r+s+1}^{-1}T_k^{-1}\,{}_r\Phi_s=q^{\alpha_k}\,{}_r\Phi_s, && 1\leqq k\leqq r,\\
&T_{r+s+1}^{-1}T_{r+l}\,{}_r\Phi_s=q^{\beta_l-1}\,{}_r\Phi_s, && 1\leqq l\leqq s.
\end{aligned}
$$

Indeed, ${}_r\Phi_s$ is characterized by (2.15), (2.16): It is (to within a constant multiple) the only solution of these equations analytic in the u_p at $u_{r+s+1}=0$.

We can regard an analytic solution $\Psi(u_p)$ of the canonical equation

$$
(2.17)\qquad (\Delta_1^-\cdots\Delta_r^- - \Delta_{r+1}^+\cdots\Delta_{r+s+1}^+)\Psi=0
$$

as a generating function for basic hypergeometric functions. Indeed, expanding Ψ as a power series

$$
(2.18)\qquad \Psi(u_p)=\sum_{\alpha_i,\beta_j} f_{\alpha_i\beta_j}(x)u_1^{-\alpha_1}\cdots u_r^{-\alpha_r}u_{r+1}^{\beta_1-1}\cdots u_{r+s}^{\beta_s-1}
$$

where $x=u_{r+1}\cdots u_{r+s+1}/u_1\cdots u_r$, we see that if Ψ is analytic at $x=0$ and if no nonzero term occurs with some $\beta_j=0,-1,-2,\cdots$ then always

$$
(2.19)\qquad f_{\alpha_i\beta_j}(x)=c_{\alpha_i\beta_j}\,{}_r\varphi_s\left(\begin{matrix}a_i\\ b_j\end{matrix};\,x\right)
$$

for some constants $c_{\alpha_i\beta_j}$. We shall typically compute such a generating function Ψ by characterizing it as a simultaneous eigenfunction of a set of $r+s$ commuting symmetry operators for (2.17). By a symmetry operator for the canonical equation we mean a linear operator L which maps any local analytic solution Ψ for (2.17) into another local analytic solution $L\Psi$. Clearly the dilation operators $T_{r+s+1}^{-1}T_k^{-1}$ $(1\leqq k\leqq r)$, $T_{r+s+1}^{-1}T_{r+l}$ $(1\leqq l\leqq s)$ are commuting symmetries, and the eigenvalue equations (2.16) characterize the basis solutions ${}_r\Phi_s$ in terms of these symmetries. Furthermore the q-difference operators Δ_i^- $(1\leqq i\leqq r)$ and Δ_{r+h}^+ $(1\leqq h\leqq s+1)$ are commuting symmetries. Note also that any permutation of the variables $\{u_i\colon 1\leqq i\leqq r\}$ is a symmetry of (2.17) as is any permutation of the variables $\{u_{r+h}\colon 1\leqq h\leqq s+1\}$. (For example, the transposition symmetry (u_{r+1}, u_{r+s+1}) implies that

$$
{}_r\varphi_s\left(\begin{matrix}a_ib_1^{-1}q\\ q^2b_1^{-1},\ b_jb_1^{-1}q\end{matrix};\,x\right)x^{1-\beta_1}
$$

is another solution of (2.11).)

The canonical equation (2.17) for q-hypergeometric functions is a clear analogue of the canonical equation for the hypergeometric functions ${}_rF_s$ [13]. Indeed the basis functions

$$(2.20)\qquad {}_r\mathscr{F}_a\left(\begin{matrix}\alpha_i\\ \beta_j\end{matrix}; u_p\right) = {}_rF_s\left(\begin{matrix}\alpha_i\\ \beta_j\end{matrix}; \frac{u_{r+1}\cdots u_{r+s+1}}{u_1\cdots u_r}\right) u_1^{-\alpha_1}\cdots u_r^{-\alpha_r} u_{r+1}^{\beta_1-1}\cdots u_{r+s}^{\beta_s-1}$$

satisfy the canonical equation

$$(2.21)\qquad (\partial_{u_1}\cdots\partial_{u_r} - (-1)^r\partial_{u_{r+1}}\cdots\partial_{u_{r+s+1}})\,{}_r\mathscr{F}_s = 0$$

and the eigenvalue equations

$$(2.22)\qquad \begin{aligned} &(-D_{r+s+1}-D_k)\,{}_r\mathscr{F}_s = \alpha_k\,{}_r\mathscr{F}_s, && 1\leqq k\leqq r,\\ &(-D_{r+s+1}+D_{r+l})\,{}_r\mathscr{F}_s = (\beta_l-1)\,{}_r\mathscr{F}_s, && 1\leqq l\leqq s,\end{aligned}$$

where $D_p = u_p\partial_{u_p}$. Furthermore ${}_r\mathscr{F}_s$ is the only solution of (2.21), (2.22) that is analytic in the u_p at $u_{r+s+1}=0$.

Our procedure applies to a family of q-analogues for the ${}_rF_s$. Let δ be a function with domain $\{1, 2, \cdots, r+s+1\}$ and range contained in the set $\{+, -\}$. The canonical equation

$$(2.23)\qquad (\Delta_1^{\delta(1)}\cdots\Delta_r^{\delta(r)} - \Delta_{r+1}^{\delta(r+1)}\cdots\Delta_{r+s+1}^{\delta(r+s+1)})\Psi = 0$$

and eigenvalue equations

$$(2.24)\qquad \begin{aligned} &T_{r+s+1}^{-1}T_k^{-1}\Psi = q^{\alpha_k}\Psi, && 1\leqq k\leqq r,\\ &T_{r+s+1}^{-1}T_{r+l}\Psi = q^{\beta_l-1}\Psi, && 1\leqq l\leqq s,\end{aligned}$$

have the unique (to within a constant multiple) solution

$$(2.25)\qquad {}_r\Phi_s^{\delta}\left(\begin{matrix}a_i\\ b_i\end{matrix}; u_p\right) = {}_r\varphi_s^{\delta}\left(\begin{matrix}a_i\\ b_j\end{matrix}; \frac{u_{r+1}\cdots u_{r+s+1}}{u_1\cdots u_r}\right) u_1^{-\alpha_1}\cdots u_r^{-\alpha_r} u_{r+1}^{\beta_1-1}\cdots u_{r+s}^{\beta_s-1}$$

where

$$(2.26)\qquad \begin{aligned} {}_r\varphi_s^{\delta}\left(\begin{matrix}a_i\\ b_j\end{matrix}; x\right) = \sum_{n=0}^{\infty} &\frac{(q^{\delta'(1)\alpha_1}; q^{\delta'(1)1})_n}{(q^{\delta(r+1)\beta_1}; q^{\delta(r+1)1})_n}\cdots\frac{(q^{\delta'(r)\alpha_r}; q^{\delta'(r)1})_n}{(q^{\delta(r+s)\beta_s}; q^{\delta(r+s)1})_n}\\ &\cdot\frac{x^n}{(q^{\delta(r+s+1)}; q^{\delta(r+s+1)1})_n}\end{aligned}$$

and

$$(2.27)\qquad \delta'(p) = \begin{cases} + & \text{if } \delta(p) = -,\\ - & \text{if } \delta(p) = +.\end{cases}$$

Each of these q-analogues of ${}_rF_s$ can be further treated by the methods presented in this paper.

Canonical equations for many-variable hypergeometric q-series can be derived almost as easily as for the one-variable case. Consider for example the Appell function F_2:

$$(2.28)\qquad F_2\left(\begin{matrix}\alpha, \beta, \beta'\\ \gamma, \gamma'\end{matrix}; x, y\right) = \sum_{n,m=0}^{\infty}\frac{(\alpha)_{m+n}(\beta)_m(\beta')_n x^m y^n}{(\gamma)_m(\gamma')_n m!n!}.$$

As shown in [11] the canonical differential equations are

$$(2.29)\qquad (\partial_{u_1}\partial_{u_2} - \partial_{u_3}\partial_{u_4})\mathscr{F}_2 = 0, \qquad (\partial_{u_1}\partial_{u_5} - \partial_{u_6}\partial_{u_7})\mathscr{F}_2 = 0$$

with eigenvalue equations

$$\begin{gathered} D_1+D_3+D_6\sim -\alpha, \qquad D_2+D_3\sim -\beta, \\ D_4-D_3\sim \gamma-1, \quad D_5+D_6\sim -\beta', \quad D_7-D_6\sim \gamma'-1. \end{gathered} \tag{2.30}$$

Here $A\sim\alpha$ stands for $A\mathscr{F}_2=\alpha\mathscr{F}_2$, and $D_i=u_i\partial_{u_i}$. Furthermore,

$$\mathscr{F}_2=F_2\begin{pmatrix} \alpha,\beta,\beta' & ; & \dfrac{u_3u_4}{u_1u_2}, \dfrac{u_6u_7}{u_1u_5} \\ \gamma,\gamma' & & \end{pmatrix} u_1^{-\alpha}u_2^{-\beta}u_5^{-\beta'}u_4^{\gamma-1}u_7^{\gamma'-1}.$$

Now consider the q-analogue

$$f_2\begin{pmatrix} a,b,b' & ;x,y \\ c,c' & \end{pmatrix}=\sum_{n,m=0}^{\infty}\frac{(a;q)_{m+n}(b;q)_m(b';q)_nx^my^n}{(c;q)_m(c';q)_n(q;q)_m(q;q)_n}$$

where $a=q^\alpha$, $b=q^\beta$, etc. The function

$$f_2=f_2\begin{pmatrix} a,b,b' & ; & \dfrac{u_3u_4}{u_1u_2}, \dfrac{u_6u_7}{u_1u_5} \\ c,c' & & \end{pmatrix} u_1^{-\alpha}u_2^{-\beta}u_5^{-\beta'}u_4^{\gamma-1}u_7^{\gamma'-1} \tag{2.31}$$

satisfies the recurrence relations

$$\begin{gathered} \Delta_1^-f_2=(1-a)f_2(aq), \qquad \Delta_2^-f_2=(1-b)f_2(bq), \\ \Delta_3^+f_2=\frac{(1-a)(1-b)}{(1-c)}f_2\begin{pmatrix} aq,bq \\ cq \end{pmatrix}, \\ \Delta_4^+f_2=(1-cq^{-1})f_2(cq^{-1}), \qquad \Delta_5^-f_2=(1-b')f_2(b'q), \\ \Delta_6^+f_2=\frac{(1-a)(1-b')}{(1-c')}f_2\begin{pmatrix} aq,b'q \\ c'q \end{pmatrix}, \\ \Delta_7^+f_2=(1-c'q^{-1})f_2(c'q^{-1}), \end{gathered} \tag{2.32}$$

hence the canonical equations

$$\Delta_1^-\Delta_2^--\Delta_3^+\Delta_4^+\sim 0, \qquad \Delta_1^-\Delta_5^--\Delta_6^+\Delta_7^+\sim 0. \tag{2.33}$$

(Here again $A\sim\chi$ signifies that f_2 is an eigenfunction of the operator A with eigenvalue χ.) Furthermore f_2 satisfies the dilation eigenvalue equations

$$\begin{gathered} T_1T_3T_6\sim a^{-1}, \quad T_2T_3\sim b^{-1}, \quad T_4T_3^{-1}\sim cq^{-1}, \\ T_5T_6\sim b'^{-1}, \quad T_7T_6^{-1}\sim c'q^{-1}, \end{gathered} \tag{2.34}$$

and for $\gamma, \gamma'\neq 0, -1, -2, \cdots$ the only solution of equations (2.33), (2.34) analytic in the u_i at $u_3=u_6=0$ is (2.31). The standard pair of q-difference equations for the function f_2

$$\begin{gathered} [(1-aT_xT_y)(1-bT_x)-x^{-1}(1-T_x)(1-cq^{-1}T_x)]f_2=0, \\ [(1-aT_xT_y)(1-b'T_y)-y^{-1}(1-T_y)(1-c'q^{-1}T_y)]f_2=0, \end{gathered}$$

is obtained directly from the canonical equations by setting $x=u_3u_4/u_1u_2$, $y=u_6u_7/u_1u_5$ and factoring out the remaining "ignorable" variables. Note the perfect correspondence between the differential equations (2.29), (2.30) for the Appell function and the q-difference equations (2.33), (2.34) for the q-analogue.

Just as in the single-variable case we can study a family of q-analogues for F_2, one for each function δ with domain $\{1, 2, \cdots, 7\}$ and range contained in $\{+, -\}$. The canonical equations are

$$\begin{aligned}&\Delta_1^{\delta(1)}\Delta_2^{\delta(2)} - \Delta_3^{\delta(3)}\Delta_4^{\delta(4)} \sim 0,\\ &\Delta_1^{\delta(1)}\Delta_5^{\delta(5)} - \Delta_6^{\delta(6)}\Delta_7^{\delta(7)} \sim 0\end{aligned} \tag{2.35}$$

and the corresponding q-series is

$$\begin{aligned}f_2^\delta\begin{pmatrix} a, b, b' \\ c, c' \end{pmatrix}; x, y\Big) &= \sum_{m,n=0}^{\infty} \frac{(q^{\delta'(1)\alpha}; q^{\delta'(1)1})_{m+n}(q^{\delta'(2)\beta}; q^{\delta'(2)1})_m}{(q^{\delta(r)\gamma}; q^{\delta(r)1})_m(q^{\delta(7)\gamma'}; q^{\delta(7)1})_n}\\ &\quad\cdot \frac{(q^{\delta'(5)\beta'}; q^{\delta'(5)1})_n x^m y^n}{(q^{\delta(3)}; q^{\delta(3)1})_m(q^{\delta(6)}; {}^{\delta(6)1})_n}.\end{aligned} \tag{2.36}$$

Similar computations can be performed for any two-variable (or many-variable) q-hypergeometric series g. Corresponding to each parameter $a = q^\alpha$ such that the symbol $(a; q)_{Am+Bn}$ appears in the numerator of the expansion

$$g = \sum_{m,n} \frac{(a; q)_{Am+Bn} \cdots}{(c; q)_{Cm+Dn} \cdots} \frac{x^m y^m}{(q; q)_m(q; q)_n}$$

there is a "raising operator" $E^\alpha = \Delta^-$ associated with the recurrence relation

$$(1 - aT_x^A T_y^B)g = (1 - a)g(aq).$$

Similarly, for each denominator parameter c we can construct a "lowering operator" $E_\gamma = \Delta^+$ associated with

$$(1 - cq^{-1}T_x^C T_y^D)g = (1 - cq^{-1})g(cq^{-1}).$$

Application of $x^{-1}(1 - T_x)$, corresponding to Δ^+, takes each numerator parameter a to aq^A and each denominator parameter c to cq^C, whereas application of $y^{-1}(1 - T_y)$, corresponding to Δ^+, takes each numerator parameter a to aq^B and each denominator parameter c to cq^D.

Hrabowski [9] has discussed the general procedures for associating a system of canonical differential equations and eigenvalue equations with a given hypergeometric series and, conversely, for associating one or more hypergeometric series with a given system of canonical differential equations and eigenvalue equations. His analysis applies, with minor modifications, to q-hypergeometric series as we will discuss in a subsequent paper. The principal distinction is that there are two types of q-difference operators $\Delta_u^\pm$ and only one type of differential operator ∂_u.

3. Embeddings and augmentations. If the canonical equations of a q-hypergeometric series can be identified with a subset of the canonical equations of a second q-hypergeometric series, then by a suitable restriction of coordinates we can regard the second series to be a generating function for the first series. As an illustrative example we consider the canonical equation

$$\Delta_1^-\Delta_2^- - \Delta_3^+\Delta_4^+ \sim 0 \tag{3.1}$$

for the basic hypergeometric function

$$\begin{aligned}&{}_2\Phi_1 = {}_2\varphi_1\begin{pmatrix} a, b \\ c \end{pmatrix}; \frac{u_3u_4}{u_1u_2}\Big)u_1^{-\alpha}u_2^{-\beta}u_3^{\gamma-1},\\ &T_4^{-1}T_1^{-1} \sim q^\alpha, \qquad T_4^{-1}T_2^{-1} \sim q^\beta, \qquad T_4^{-1}T_3 \sim q^{\gamma-1},\end{aligned} \tag{3.2}$$

and the canonical equations (2.33) and eigenvalue equations (2.34) for the q-Appell function f_2. Identifying the variables $u_1, \cdots, u_4$ for ${}_2\Phi_1$ with the variables $u_1, \cdots, u_4$ for f_2 we see from (2.33) and (3.1) that for any choice of u_5, u_6, u_7 the function $f_2(u_p)$ can be regarded as a solution of the canonical equation (3.1) for ${}_2\Phi_1$. For uniqueness we require $u_5 = u_6 = u_7 = 1$ and obtain the solution

$$f_2 = f_2\begin{pmatrix} a, b, b' \\ c, c' \end{pmatrix}; \frac{u_3u_4}{u_1u_2}, \frac{1}{u_1}\Big) u_1^{-\alpha}u_2^{-\beta}u_4^{\gamma-1} \tag{3.3}$$

of (3.1). Our approach is to characterize the generating function (3.3) in terms of symmetry operators for (3.1). However the remaining canonical equation for f_2 and the eigenvalue equations (2.34) involve the variables u_5, u_6, u_7. We need to evaluate the operators $\Delta_5^-, \Delta_6^+, \Delta_7^+$ applied to f_2 for $u_5 = u_6 = u_7 = 1$, in terms of operators acting only on functions of the variables $u_1, \cdots, u_4$. From (2.34) we find

$$T_6 \sim a^{-1}T_1^{-1}T_3^{-1}, \qquad T_5^{-1} \sim b'a^{-1}T_1^{-1}T_3^{-1}, \qquad T_7 \sim c'q^{-1}a^{-1}T_1^{-1}T_3^{-1}.$$

Thus the solution (3.3) is characterized by the equations

$$\begin{gathered} T_2T_3 \sim b^{-1}, \qquad T_4T_3^{-1} \sim cq^{-1}, \\ \Delta_1^-\left(1 - \frac{b'}{a}T_1^{-1}T_3^{-1}\right) - \left(1 - \frac{1}{a}T_1^{-1}T_3^{-1}\right)\left(1 - \frac{c'}{qa}T_1^{-1}T_3^{-1}\right) \sim 0. \end{gathered} \tag{3.4}$$

Note that the operators T_2T_3, $T_4T_3^{-1}$, Δ_1^- and $T_1^{-1}T_3^{-1}$ are all symmetries of $\Delta_1^-\Delta_2^- - \Delta_3^+\Delta_4^+$, so that we have characterized the solution (3.3) of (3.1) in terms of a set of (mixed) eigenvalue equations for symmetries of (3.1). (It is not always the case that the generating function of the restricted canonical system obtained through this process is characterized in terms of symmetries of the restricted system. An example is the restriction of the canonical system for the Appell function F_1 to the wave equation [11]. However, in this case and in all other such examples known to the authors appropriate functional linear combinations of the mixed eigenvalue equations can be expressed in terms of symmetry operators and the resulting system still uniquely characterizes the generating function.) This is the process of *embedding.*

The process inverse to embedding is augmentation. Here we are given a canonical system of q-difference equations and a characterization of a generating function for this system by a set of mixed eigenvalue equations expressed in terms of symmetry operators for the canonical system. Our aim is to establish simple rules for determination of the generating function as an explicit q-hypergeometric series by recasting the defining equations as a canonical system with dilation eigenvalue equations in a greater number of variables than the original problem.

To see how this procedure works, consider the generating function, characterized as the function analytic in $u_1, \cdots, u_4$ at $u_3 = 0$ and satisfying the canonical equation (3.1) and the mixed eigenvalue equations (3.4). Since the last equation in (3.4) is neither a canonical equation or a dilation eigenvalue equation for (3.1), we cannot determine the power series expression for the generating function by inspection. However, we can replace the expressions

$$1 - b'a^{-1}T_1^{-1}T_3^{-1}, \qquad 1 - a^{-1}T_1^{-1}T_3^{-1}, \qquad 1 - c'q^{-1}a^{-1}T_1^{-1}T_3^{-1}$$

by Δ_5^-, Δ_6^+, Δ_7^+, respectively, for $u_5 = u_6 = u_7 = 1$ where $T_5^{-1} \sim b'a^{-1}T_1^{-1}T_3^{-1}$, $T_6 \sim a^{-1}T_1^{-1}T_3^{-1}$ and $T_7 = c'q^{-1}a^{-1}T_1^{-1}T_3^{-1}$. Then for general u_p the defining equations of the generating function take the canonical form (2.33), (2.34) with the unique solution (2.31), analytic at $u_3 = u_6 = 0$. Setting $u_5 = u_6 = u_7 = 1$ we obtain the generating function.

(Note that the choice Δ_5^-, Δ_6^+, Δ_7^+ is unique. If we had taken Δ_5^+ for example, we would have obtained the condition $T_5T_1T_3 \sim b'a^{-1}$, but $T_5T_1T_3$ is *not* a symmetry of the canonical equations (2.33).) We also note that q-analogues of the Appell function F_3 and the Horn function $\mathcal{H}_2$ correspond to these same canonical equations but have different analyticity properties [11].

The following sections contain several more examples of augmentation.

4. Generating functions for ${}_r\varphi_s$. Here we will present several examples showing how generating functions for the ${}_r\varphi_s$, (2.1) are associated with the canonical equation

$$(4.1) \qquad (\Delta_1^- \cdots \Delta_r^- - \Delta_{r+1}^+ \cdots \Delta_{r+s+1}^+)\Psi = 0.$$

Recall that

$${}_r\Phi_s = {}_r\varphi_s\left(\begin{matrix} a_i \\ b_j \end{matrix}; \frac{u_{r+1}\cdots u_{r+s+1}}{u_1\cdots u_r}\right) u_1^{-\alpha_1}\cdots u_r^{-\alpha_r} u_{r+1}^{\beta_1-1}\cdots u_{r+s}^{\beta_s-1}$$

is a solution of (4.1) and that Δ_i^-, $(1 \leqq i \leqq r)$, Δ_{r+k}^+, $(1 \leqq k \leqq s)$, $T_{r+s+1}T_i$ and $T_{r+s+1}^{-1}T_k$ are symmetries of this equation.

There appears to be no convenient general q-analogue of the local Lie theory which permits us to compute Lie group symmetries of differential equations from Lie algebra symmetries through the process of exponentiation. However, in particular cases the analogy is successful. Consider the q-exponential

$$(4.2) \qquad e_q(x) = \sum_{n=0}^{\infty} \frac{x^n}{(q;q)_n} = \frac{1}{(x;q)_\infty}, \qquad |x| < 1$$

satisfying $\Delta_x^+ e_q = e_q$ [15, p. 92]. In a formal sense at least, the operator $e_q(\lambda\Delta_1^-)$, $\lambda \in \mathbb{C}$, is a symmetry of (4.1). Applying this operator to a basis solution ${}_r\Phi_s$ and making use of (2.14), (4.2) we obtain

$$(4.3) \qquad e_q(\lambda\Delta_1^-)\,{}_r\Phi_s(a_1) = \sum_{n=0}^{\infty} \frac{\lambda^n (a_1;q)_n}{(q;q)_n}\,{}_r\varphi_s(a_1q^n).$$

To compute the left-hand side of (4.3) we utilize Heines's (q-binomial) theorem [15, p. 92], [2],

$$\sum_{m=0}^{\infty} \frac{(a;q)_m}{(q;q)_m} t^m = \frac{(at;q)_\infty}{(t;q)_\infty}$$

to derive

$$(4.4) \qquad e_q(\lambda\Delta_x^-)x^n = x^n \frac{(\lambda q^{-n}/x;q)_\infty}{(\lambda/x;q)_\infty} = \frac{x^n}{(\lambda/x,q)_{-n}}.$$

From (4.4), (2.1) and (2.12) we find

$$(4.5) \qquad \begin{aligned} e_q(\lambda\Delta_1^-)\,{}_r\Phi_s(a_1) &= \frac{(\lambda/a_1u_1;q)_\infty}{(\lambda/u_1;q)_\infty}\,{}_r\varphi_{s+1}\left(\begin{matrix} a_i \\ b_j \end{matrix}; \lambda/a_1u_1; \frac{u_{r+1}\cdots u_{r+s+1}}{u_1\cdots u_r}\right) \\ &\quad \cdot u_1^{-\alpha_1}\cdots u_r^{-\alpha_r} u_{r+1}^{\beta_1-1}\cdots u_{r+s}^{\beta_s-1} \end{aligned}$$

so that

$$(4.6) \qquad \frac{(x/a_1;q)_\infty}{(x;q)_\infty}\,{}_r\varphi_{s+1}\left(\begin{matrix} a_i \\ b_j \end{matrix}; x/a_1; y\right) = \sum_{n=0}^{\infty} \frac{(a_1^{-1};q)_n}{(q;q)_n} x^n\,{}_r\varphi_s\left(\begin{matrix} a_1q^n, a_2, \cdots, a_r \\ b_j \end{matrix}; y\right).$$

Another way to understand this result is to note that the right-hand side of (4.3) is an eigenfunction of the operator $T_{r+s+1}T_1-\lambda q^{-1}\Delta_1^- T_{r+s+1}T_1$ with eigenvalue a_1^{-1}. The method of augmentation can then be employed to derive (4.5). Still another point of view is that since ${}_r\Phi_s(a_1)$ is an eigenfunction of the symmetry operator $T_{r+s+1}T_1$ with eigenvalue a_1^{-1} then $e_q(\lambda\Delta_1^-){}_r\Phi_s(a_1)$ must be an eigenfunction of the formal symmetry operator

$$e_q(\lambda\Delta_1^-)T_{r+s+1}T_1E_q(-\lambda\Delta_1^-) \tag{4.7}$$

with the same eigenvalue. Here [15, p. 93]

$$\begin{aligned} E_q(x)&=\sum_{n=0}^{\infty}\frac{q^{n(n-1)/2}}{(q;q)_n}x^n=(-x;q)_\infty,\\ \Delta_x^-E_q&=-q^{-1}E_q,\qquad e_q(x)E_q(-x)=1.\end{aligned} \tag{4.8}$$

Let X, Y be linear operators.

LEMMA.

$$f(\lambda)\equiv e_q(\lambda X)YE_q(-\lambda X)=\sum_{n=0}^{\infty}\frac{\lambda^n}{(q;q)_n}[X,Y]_n \tag{4.9}$$

where

$$\begin{aligned} &[X,Y]_0=Y,\qquad [X,Y]_1=XY-YX,\\ &[X,Y]_{n+1}=X[X,Y]_n-q^n[X,Y]_nX,\qquad n=1,2,\cdots.\end{aligned} \tag{4.10}$$

Proof. This result is equivalent to the identity $\Delta_\lambda^+ f(\lambda)=Xf(\lambda)-T_\lambda f(\lambda)X$ and the identity can be verified by formal power series expansion in the variable λ. (The authors learned of this result from Mourad Ismail and Dennis Stanton.)

For $X=\Delta_1^-$, $Y=T_{r+s+1}T_1$ it is easily verified that $[X,Y]_1=(1-q^{-1})\Delta_1^-T_{r+s+1}T_1$, $[X,Y]_2=0$ so, by the lemma:

$$e_q(\lambda\Delta_1^-)T_{r+s+1}T_1E_q(-\lambda\Delta_1^-)=T_{r+s+1}T_1-q^{-1}\lambda\Delta_1^-T_{r+s+1}T_1.$$

Using the q-binomial theorem we can verify that

$$E_q(-\lambda\Delta_x^+)x^n=x^n\frac{(\lambda/x;q)_\infty}{(\lambda q^n/x;q)_\infty}. \tag{4.11}$$

From (2.14) we have

$$E_q(-\lambda\Delta_{r+1}^+){}_r\Phi_s(b_1)=\sum_{n=0}^{\infty}\frac{(b\lambda/q)^n(b^{-1}q;q)_n}{(q;q)_n}{}_r\Phi_s(b_1q^{-n}),$$

$$\begin{aligned} E_q(-\lambda\Delta_{r+s+1}^+){}_r\Phi_s\begin{pmatrix}a_i\\ b_j\end{pmatrix}=\sum_{n=0}^{\infty}&\frac{(-\lambda)^nq^{n(n-1)/2}}{(q;q)_n}\\ &\cdot\frac{(a_1;q)_n\cdots(a_r;q)_n}{(b_1;q)_n\cdots(b_s;q)_n}{}_r\Phi_s\begin{pmatrix}a_iq^n\\ b_jq^n\end{pmatrix}.\end{aligned}$$

Applying (4.11) we obtain the generating functions

$$\begin{aligned} \frac{(qx/b;q)_\infty}{(x;q)_\infty}{}_{r+1}\varphi_s\begin{pmatrix}a_i,x\\ b_j\end{pmatrix};y\Bigg)&=\sum_{n=0}^{\infty}\frac{(q/b_1;q)_n}{(q;q)_n}{}_r\varphi_s\begin{pmatrix}a_i\\ b_1q^{-n},b_2\cdots b_s\end{pmatrix};y\Bigg)x^n,\\ {}_{r+1}\varphi_s\begin{pmatrix}a_i,x\\ b_j\end{pmatrix};y\Bigg)&=\sum_{n=0}^{\infty}\frac{q^{n(n-1)/2}}{(q;q)_n}\frac{(a_1;q)_n\cdots(a_r;q)_n}{(b_1;q)_n\cdots(b_s;q)_n}{}_r\varphi_s\begin{pmatrix}a_iq^n\\ b_jq^n\end{pmatrix};y\Bigg)(-xy)^n.\end{aligned} \tag{4.12}$$

Now we consider some examples where the generating functions are directly characterized in terms of symmetry operators for the canonical equation (4.1). Let A, B, C be nonnegative integers with $B \geqq 1$, $A+B=r$, $C+B=s$. We look for an eigenfunction of (4.1) characterized by the following conditions:

$$\begin{array}{ll}
\multicolumn{2}{l}{\Delta_1^- \Delta_2^- \cdots \Delta_A^- - \Delta_{r+1}^+ \Delta_{r+2}^+ \cdots \Delta_{r+C}^+ \Delta_{r+s+1}^+ \sim 0,} \\
\multicolumn{2}{l}{\Delta_{A+1}^- \Delta_{A+2}^- \cdots \Delta_r^- - \Delta_{r+C+1}^+ \Delta_{r+C+2}^+ \cdots \Delta_{r+s}^+ \sim 0,} \\
T_1^{-1} T_{r+s+1}^{-1} \sim a_1, & T_{r+1} T_{r+s+1}^{-1} \sim c_1 q^{-1}, \\
\vdots & \vdots \\
T_A^{-1} T_{r+s+1}^{-1} \sim a_A, & T_{r+C} T_{r+s+1}^{-1} \sim c_C q^{-1}, \\
T_{A+1} T_r^{-1} \sim b_1 q^{-1}, & T_{r+C+1}^{-1} T_r^{-1} \sim d_1, \\
\vdots & \vdots \\
T_{A+B-1} T_r^{-1} \sim b_{B-1} q^{-1}, & T_{r+C+B}^{-1} T_r^{-1} \sim d_B.
\end{array} \tag{4.13}$$

Choosing u_r and u_{r+s+1} as the distinguished variables such that the generating function is analytic at $u_r = u_{r+s+1} = 0$, we see that equations (4.13) are in canonical form with solution

$$\begin{aligned}
&{}_A\varphi_C\left(\begin{matrix} a_1, \cdots, a_A \\ c_1, \cdots, c_C \end{matrix}; \frac{u_{r+1} \cdots u_{r+C}}{u_1 \cdots u_A} u_{r+s+1}\right) u_1^{-\alpha_1} \cdots u_A^{-\alpha_A} u_{r+1}^{\gamma_1 - 1} \cdots u_{r+C}^{\gamma_C - 1} \\
&\quad \cdot {}_B\varphi_{B-1}\left(\begin{matrix} d_1, \cdots, d_B \\ b_1, \cdots, b_{B-1} \end{matrix}; \frac{q b_1 \cdots b_{B-1} u_{A+1} \cdots u_{A+B-1}}{d_1 \cdots d_B u_{r+C+1} \cdots u_{r+s}} u_r\right) \\
&\quad \cdot u_{A+1}^{\beta_1 - 1} \cdots u_{A+B-1}^{\beta_{B-1}} u_{r+C+1}^{-\delta_1} \cdots u_{r+s}^{-\delta_B} \\
&= \sum_{n=0}^{\infty} X_n \, {}_{A+B}\varphi_{C+B}\left(\begin{matrix} a_1, \cdots, a_A; q^{-n}, q^{1-n}/b_1, \cdots, q^{1-n}/b_{B-1} \\ c_1, \cdots, c_C; q^{1-n}/d_1, \cdots, q^{1-n}/d_B \end{matrix}; \frac{u_{r+1} \cdots u_{r+s+1}}{u_1 \cdots u_r}\right) \\
&\quad \cdot u_1^{-\alpha_1} \cdots u_A^{-\alpha_A} u_{A+1}^{\beta_1 + n - 1} \cdots u_{A+B-1}^{\beta_{B-1} + n - 1} u_r^n u_{r+1}^{\gamma_1 - 1} \cdots u_{r+C}^{\gamma_C - 1} u_{r+C+1}^{-\delta_1 - n} \cdots u_{r+s}^{-\delta_B - n}.
\end{aligned}$$

Setting $u_{r+s+1} = 0$, we find that

$$X_n = \left(\frac{q b_1 \cdots b_{B-1}}{d_1 \cdots d_B}\right)^n \frac{(d_1; q)_n \cdots (d_B; q)_n}{(b_1; q)_n \cdots (b_{B-1}; q)_n (q; q)_n}$$

and the generating function simplifies to

$$\begin{aligned}
&{}_A\varphi_C\left(\begin{matrix} a_1, \cdots, a_A \\ c_1, \cdots, c_C \end{matrix}; \frac{d_1 \cdots d_B}{b_1 \cdots b_{B-1}}; tz\right) {}_B\varphi_{B-1}\left(\begin{matrix} d_1, \cdots, d_B \\ b_1, \cdots, b_{B-1} \end{matrix}; t\right) \\
&= \sum_{n=0}^{\infty} \frac{(d_1; q)_n \cdots (d_B; q)_n}{(b_1; q)_n \cdots (b_{B-1}; q)_n} \\
&\quad \cdot {}_{A+B}\varphi_{C+B}\left(\begin{matrix} a_1, \cdots, a_A; q^{-n}, q^{1-n}/b_1, \cdots, q^{1-n}/b_{B-1} \\ c_1, \cdots, c_C; q^{1-n}/d_1, \cdots, q^{1-n}/d_B \end{matrix}; qz\right) \frac{t^n}{(q; q)_n}.
\end{aligned} \tag{4.14}$$

Finally we derive a generating function for the q-series

$$
\begin{aligned}
&{}_{p+1}\hat{\varphi}_{p+r}\left(\begin{matrix} a_1, \cdots, a_{p+1} \\ b_1, \cdots, b_{p+r} \end{matrix}; q^{-1}, x\right) \\
&= \sum_{n=0}^{\infty} \frac{(a_1; q^{-1})_n \cdots (a_{p+1}; q^{-1})_n}{(b_1; q^{-1})_n \cdots (b_{p+r}; q^{-1})_n} \frac{x^n}{(q^{-1}; q^{-1})_n} \\
&= \sum_{n=0}^{\infty} \frac{(a_1^{-1}; q)_n \cdots (a_{p+1}^{-1}; q)_n (-1)^{rn} q^{rn(n-1)/2}}{(b_1^{-1}; q)_n \cdots (b_{p+r}^{-1}; q)_n (q; q)_n} \left(\frac{x a_1 \cdots a_{p+1}}{b_1 \cdots b_{p+r} q}\right)^n.
\end{aligned}
\tag{4.15}
$$

Consider the equations

$$\Delta_1^+ \cdots \Delta_{p+1}^+ - \Delta_{p+2}^- \cdots \Delta_{2p+r+2}^- \sim 0, \tag{4.16}$$

$$
\begin{aligned}
&T_1^{-1} T_{2p+r+2}^{-1} \sim q^{\alpha_i} = a_i^{-1}, \qquad 1 \leqq i \leqq p+1, \\
&T_j T_{2p+r+2}^{-1} \sim q^{\beta_j - 1} = b_j^{-1} q^{-1}, \qquad p+2 \leqq j \leqq 2p+r+1,
\end{aligned}
\tag{4.17}
$$

in canonical form. The solution of these equations, analytic at $u_{2p+r+2} = 0$ is:

$$
\begin{aligned}
&{}_{p+1}\hat{\varphi}_{p+r}\left(\begin{matrix} a_1, \cdots, a_{p+1} \\ b_1, \cdots, b_{p+r} \end{matrix}; q^{-1}, \frac{u_{p+2} \cdots u_{2p+r+2}}{u_1 \cdots u_{p+1}}\right) \\
&\cdot u_1^{-\alpha_1} \cdots u_{p+1}^{-\alpha_{p+1}} u_{p+2}^{\beta_1 - 1} \cdots u_{2p+r+1}^{\beta_{p+r} - 1}.
\end{aligned}
\tag{4.18}
$$

We search for a generating function satisfying (4.16) and the following conditions:

$$
\begin{aligned}
&\text{(a)} \quad \Delta_1^+ + c T_1 T_{2p+r+2} \sim 1, \\
&\text{(b)} \quad T_1^{-1} T_{2p+r+2}^{-1} \sim a_i^{-1}, \qquad 2 \leqq i \leqq p+1, \\
&\qquad\quad T_j T_{2p+r+2}^{-1} \sim b_j^{-1} q^{-1}, \qquad p+2 \leqq j \leqq 2p+r+1.
\end{aligned}
\tag{4.19}
$$

Introducing a new variable u_{2p+r+3} and conditions

$$T_1 T_{2p+r+2} T_{2p+r+3} \sim c^{-1}, \qquad \Delta_1^+ - \Delta_{2p+r+3}^- \sim 0 \tag{4.20}$$

we see that (4.20) reduces to (4.19) (a) when $u_{2p+r+3} = 1$ and conditions (4.16), (4.19) (b), (4.20) are in canonical form. It is straightforward to write down the generating function analytic at $u_1 = u_{2p+r+3} = 0$ and, with simplification, to obtain the identity

$$
\begin{aligned}
&\frac{(ct; q)_\infty}{(t; q)_\infty} {}_{p+1}\Phi_{p+r+1}\left[\begin{matrix} c, a_2^{-1}, \cdots, a_{p+1}^{-1} \\ ct, b_1^{-1}, \cdots, b_{p+r}^{-1} \end{matrix}; q, xt\right] \\
&= \sum_{k=0}^{\infty} \frac{(c; q)_k}{(q; q)_k} {}_{p+1}\Phi_{p+r}\left[\begin{matrix} q^{-n}, a_2^{-1}, \cdots, a_{p+1}^{-1} \\ b_1^{-1}, \cdots, b_{p+r}^{-1} \end{matrix}; q, xq^n\right] t^k
\end{aligned}
\tag{4.21}
$$

where

$$
\begin{aligned}
&{}_{p+1}\Phi_{p+r}\left[\begin{matrix} a_1, \cdots, a_{p+1} \\ b_1, \cdots, b_{p+r} \end{matrix}; q, x\right] \\
&= \sum_{n=0}^{\infty} \frac{(a_1; q)_n \cdots (a_{p+1}; q)_n (-1)^r q^{rn(n-1)/2}}{(b_1; q)_n \cdots (b_{p+r}; q)_n} \frac{x^n}{(q; q)_n}.
\end{aligned}
\tag{4.22}
$$

The generating functions derived above are not "deep." Indeed each can be proven by equating coefficients of powers of appropriate variables and using the q-binomial theorem. Furthermore, more general generating functions hold when some of the q-shifted factorials are replaced by arbitrary sequences; see [6]. Our point is that generating functions in their totality can be classified and derived using symmetry methods. In the following section we consider cases where the q-series have a richer symmetry structure and the generating functions are more interesting.

5. Generating functions for ${}_2\varphi_1$. The canonical equations for the q-hypergeometric functions ${}_2\varphi_1$ and ${}_1\varphi_1$ admit certain simple symmetry operators which do not extend to symmetries of the equations for general ${}_r\varphi_s$. This is closely related to the fact that ${}_2\varphi_1$ and ${}_1\varphi_1$ obey q-difference recurrence relations not shared by general ${}_r\varphi_s$. We shall examine the case ${}_2\varphi_1$ in some detail. Here the canonical equation is

$$Q \equiv \Delta_1^- \Delta_2^- - \Delta_3^+ \Delta_4^+ \sim 0 \tag{5.1}$$

and the eigenvalue equations for the basis

$${}_2\Phi_1 = {}_2\varphi_1\begin{pmatrix} a, b & ; & \dfrac{u_3 u_4}{u_1 u_2} \\ c & & \end{pmatrix} u_1^{-\alpha} u_2^{-\beta} u_3^{\gamma-1}$$

are

$$T_4^{-1} T_1^{-1} \sim a, \qquad T_4^{-1} T_2^{-1} \sim b, \qquad T_4^{-1} T_3 \sim cq^{-1}. \tag{5.2}$$

In addition to the dilation operators $T_4 T_1$, $T_4 T_2$, $T_4 T_3^{-1}$, their products and inverses, we have as symmetries of (5.1) the operators

$$\begin{gathered}
E^\alpha = \Delta_1^-, \quad E^\beta = \Delta_2^-, \quad E_\gamma = \Delta_3^+, \quad E^{\alpha\beta\gamma} = \Delta_4^+, \\
E_\alpha = -q^{-1} u_3 u_4 T_1^{-2} T_4^{-2} \Delta_2^- + u_1 u_3 T_1^{-1} T_4^{-1} \Delta_3^+ - q u_1 T_3 T_4^{-1} + u_1 T_1^{-1} T_3 T_4^{-2}, \\
E_\beta = -u_3 u_4 q^{-1} T_2^{-2} T_4^{-2} \Delta_1^- + u_2 u_3 T_2^{-1} T_4^{-1} \Delta_3^+ - q u_2 T_3 T_4^{-1} + u_2 T_2^{-1} T_3 T_4^{-2}, \\
E^\gamma = u_3\left[q T_3 T_4^{-2} - T_1^{-1} T_2^{-1} T_4^{-2} + q^2 \frac{u_1 u_2}{u_3} T_3 \Delta_4^- T_4^{-1} \right], \\
E_{\alpha\beta\gamma} = -u_1 u_2 T_4^{-1} \Delta_3^+ + q^{-1} u_4 T_4^{-1} - q^{-2} u_4 T_1^{-1} T_2^{-1} T_4^{-2}, \\
E^{\alpha\gamma} = u_3 T_4^{-1} \Delta_1^- + q u_2 \Delta_4^-, \qquad E^{\beta\gamma} = u_3 T_4^{-1} \Delta_2^- + q u_1 \Delta_4^-, \\
E_{\alpha\gamma} = -u_1 \Delta_3^+ + q^{-1} u_4 T_1^{-1} T_4^{-1} \Delta_2^-, \qquad E_{\beta\gamma} = -u_2 \Delta_3^+ + q^{-1} u_4 T_2^{-1} T_4^{-1} \Delta_1^-.
\end{gathered} \tag{5.3}$$

These symmetry operators correspond to recurrence relations for the ${}_2\varphi_1$ since, when applied to the standard basis ${}_2\Phi_1\binom{a,b}{c}$, they yield

$$\begin{gathered}
E^\alpha\, {}_2\Phi_1 = (1-a)\,{}_2\Phi_1(aq), \qquad E_\alpha\, {}_2\Phi_1 = (a-c)\,{}_2\Phi_1(aq^{-1}), \\
E^\beta\, {}_2\Phi_1 = (1-b)\,{}_2\Phi_1(bq), \qquad E_\beta\, {}_2\Phi_1 = (b-c)\,{}_2\Phi_1(bq^{-1}), \\
E^\gamma\, {}_2\Phi_1 = \frac{(c-a)(c-b)}{c-1}\,{}_2\Phi_1(cq), \qquad E_\gamma\, {}_2\Phi_1 = \left(1-\frac{c}{q}\right){}_2\Phi_1(cq^{-1}), \\
E^{\alpha\beta\gamma}\, {}_2\Phi_1 = \frac{(1-a)(1-b)}{1-c}\,{}_2\Phi_1\begin{pmatrix} aq, bq \\ cq \end{pmatrix}, \qquad E_{\alpha\beta\gamma}\, {}_2\Phi_1 = \left(\frac{c}{q}-1\right){}_2\Phi_1\begin{pmatrix} aq^{-1}, bq^{-1} \\ cq^{-1} \end{pmatrix}, \\
E^{\alpha\gamma}\, {}_2\Phi_1 = \frac{(b-c)(1-a)}{1-c}\,{}_2\Phi_1\begin{pmatrix} aq \\ cq \end{pmatrix}, \qquad E_{\alpha\gamma}\, {}_2\Phi_1 = \left(1-\frac{c}{q}\right){}_2\Phi_1\begin{pmatrix} aq^{-1} \\ cq^{-1} \end{pmatrix}, \\
E^{\beta\gamma}\, {}_2\Phi_1 = \frac{(a-c)(1-b)}{1-c}\,{}_2\Phi_1\begin{pmatrix} bq \\ cq \end{pmatrix}, \qquad E_{\beta\gamma}\, {}_2\Phi_1 = \left(1-\frac{c}{q}\right){}_2\Phi_1\begin{pmatrix} bq^{-1} \\ cq^{-1} \end{pmatrix}.
\end{gathered} \tag{5.4}$$

There appear to be no simple standardized expressions for these symmetries as q-difference operators applied to the null space of Q. Indeed one can always multiply each such symmetry by a dilation symmetry and obtain a recurrence relation (5.4) equivalent to the original relation. Second, given any q-difference operator D we can add DQ to any symmetry operator, since DQ acts as the zero operator on the null space of Q. One can use the above modifications to simplify considerably some of the expressions for the operators (5.3), but at the expense of complicating relations (5.4).

From the raising and lowering operators E we can form the following equations, each equivalent to the canonical equation (5.1):

$$\begin{gathered}
E^{\alpha}E_{\alpha}+T_4^{-1}(qT_3-T_1^{-1})(1-q^{-1}T_4^{-1}T_1^{-1})\sim 0,\\
E^{\beta}E_{\beta}+T_4^{-1}(qT_3-T_2^{-1})(1-q^{-1}T_4^{-1}T_2^{-1})\sim 0,\\
E^{\gamma}E_{\gamma}+T_4^{-2}(T_3-T_1^{-1})(T_3-T_2^{-1})\sim 0,\\
E^{\alpha\beta\gamma}E_{\alpha\beta\gamma}+(1-q^{-1}T_4^{-1}T_1^{-1})(1-q^{-1}T_4^{-1}T_2^{-1})\sim 0,\\
E^{\alpha\gamma}E_{\alpha\gamma}-T_4^{-1}(T_2^{-1}-T_3^{-1})(1-q^{-1}T_4^{-1}T_1^{-1})\sim 0,\\
E^{\beta\gamma}E_{\beta\gamma}-T_4^{-1}(T_1^{-1}-T_3^{-1})(1-q^{-1}T_4^{-1}T_2^{-1})\sim 0.
\end{gathered} \tag{5.5}$$

The operators E and the dilation symmetries T_4T_1, T_4T_2, $T_4T_3^{-1}$ form a q-analogue of the 15-dimensional conformal symmetry algebra of the wave equation in four-dimensional space-time. Although these q-symmetry operators do not generate a finite-dimensional Lie algebra under operator commutation they still permit us to construct the invariants (5.5).

The method of augmentation can be used to obtain explicit expressions for many generating functions characterized by E symmetry operators. For example, while the conditions

$$E_{\alpha}\sim -c,\quad T_2T_4\sim b^{-1},\quad T_3T_4^{-1}\sim cq^{-1} \tag{5.6}$$

would be difficult to solve directly, due to the complicated expression for E_{α}, we note that the first of these conditions implies $E^{\alpha}E_{\alpha}\sim -cE^{\alpha}$ so from the first expression (5.5) for $E^{\alpha}E_{\alpha}$

$$\Delta_1^- -(1-c^{-1}T_4^{-1}T_1^{-1})(1-q^{-1}T_4^{-1}T_1^{-1})\sim 0.$$

Setting $T_5\sim c^{-1}T_4^{-1}T_1^{-1}$, $T_6\sim q^{-1}T_4^{-1}T_1^{-1}$, we see that the desired generating functions are the restrictions to $u_5=u_6=1$ of certain solutions of the canonical system

$$\begin{gathered}
\Delta_1^-\Delta_2^- -\Delta_3^+\Delta_4^+\sim 0,\qquad \Delta_1^- -\Delta_5^+\Delta_6^+\sim 0,\\
T_2T_4\sim b^{-1},\qquad T_3T_4^{-1}\sim cq^{-1},\\
T_1T_4T_5\sim c^{-1},\qquad T_1T_4T_6\sim q^{-1}.
\end{gathered} \tag{5.7}$$

We can immediately write down a series solution:

$$\Psi=f_2\left(\begin{matrix}c,b,0\\ c,c\end{matrix};\frac{u_3u_4}{u_1u_2},\frac{u_5u_6}{u_1}\right)u_1^{-\gamma}u_2^{-\beta}u_3^{\gamma-1}u_6^{\gamma-1} \tag{5.8}$$

where f_2 is defined by (2.31). Setting $u_5=u_6=1$ we find the (not very interesting) generating function

$$f_2\left(\begin{matrix}c,b,0\\ c,c\end{matrix};z,t\right)=\sum_{n=0}^{\infty}\frac{1}{(q;q)_n}\,{}_2\varphi_1\left(\begin{matrix}cq^n,b\\ c\end{matrix};z\right)t^n. \tag{5.9}$$

We shall return to this example after introducing the q-Kummer transformation symmetry.

The q-Kummer transformation

$$(5.10)\qquad {}_2\varphi_1\left(\begin{matrix}a,b\\ c\end{matrix};x\right)=\frac{(ax;q)_\infty}{(x;q)_\infty}\sum_{n=0}^{\infty}\frac{(a;q)_n(c/b;q)_n q^{n(n-1)/2}}{(c;q)_n(q;q)_n}\frac{(-bn)^n}{(ax;q)_n}$$

[1] and the q-Euler transform

$$(5.11)\qquad {}_2\varphi_1\left(\begin{matrix}a,b\\ c\end{matrix};x\right)=\frac{(abx/c;q)_\infty}{(x;q)_\infty}\,{}_2\varphi_1\left(\begin{matrix}c/a,c/b\\ c\end{matrix};\frac{abx}{c}\right)$$

[15, p. 97], [2] can be related to symmetries of (5.1). For this we consider the restriction of the operator Q, (5.1), to the space of convergent Laurent series in the monomials

$$(5.12)\qquad f_{k,\alpha,\beta,\gamma}=\left(\frac{u_3u_4}{u_1u_2}\right)^k u_1^{-\alpha}u_2^{-\beta}u_3^{\gamma-1}$$

where k is a nonnegative integer and α, β, γ are complex numbers such that $\gamma\neq 0, -1, -2, \cdots$. (That is, we do not consider the complication of logarithmic solutions.) We define the operator R_1 on this space as the unique linear operator such that

$$(5.13)\qquad \begin{aligned}R_1(f_{k,\alpha,\beta,\gamma})&=\frac{(azq^k;q)_\infty}{(z;q)_\infty}q^{k(k-1)/2}\left(\frac{-cz}{b}\right)^k u_1^{-\alpha}u_2^{\beta-\gamma}u_3^{\gamma-1}\\ &=\left(\frac{-c}{b}\right)^k q^{k(k-1)/2}\sum_{n=0}^{\infty}\frac{(aq^k;q)_n}{(q;q)_n}z^{n+k}u_1^{-\alpha}u_2^{\beta-\gamma}u_3^{\gamma-1},\end{aligned}$$

$$z=\frac{u_3u_4}{u_1u_2},\quad a=q^\alpha,\quad b=q^\beta,\quad c=q^\gamma.$$

(This is a q-analogy of the inversion in a cone conformal symmetry of $\partial_{12}-\partial_{34}\sim 0$.) Similarly we define R_2 by

$$(5.14)\qquad R_2(f_{k,\alpha,\beta,\gamma})=\left(\frac{-cz}{a}\right)^k q^{k(k-1)/2}\frac{(bzq^k;q)_\infty}{(z;q)_\infty}u_1^{\alpha-\gamma}u_2^{-\beta}u_3^{\gamma-1}$$

and linearity, and S by linearity and

$$(5.15)\qquad S(f_{k,\alpha,\beta,\gamma})=\frac{(cz/ab;q)_\infty}{(z;q)_\infty}\left(\frac{cz}{ab}\right)^k u_1^{\beta-\gamma}u_2^{\alpha-\gamma}u_3^{\gamma-1}.$$

It is not difficult to show that (5.10), (5.11) are equivalent to the assertion that R_1, R_2 and S are symmetries of (5.1). (The direct proofs of (5.10), (5.11) involve nothing more complicated than the q-Vandermonde theorem [3].)

Note that a basis for the solution space of $Q\sim 0$ and the eigenvalue equations $T_1^{-1}T_4^{-1}\sim a$, $T_2^{-1}T_4^{-1}\sim b$, $T_3T_4^{-1}\sim cq^{-1}$ consists of the functions

$${}_2\Phi_1\left(\begin{matrix}a,b\\ c\end{matrix}\right)={}_2\varphi_1\left(\begin{matrix}a,b\\ c\end{matrix};z\right)u_1^{-\alpha}u_2^{-\beta}u_3^{\gamma-1}\quad\text{and}$$

$${}_2\Phi_1'\left(\begin{matrix}a,b\\ c\end{matrix}\right)={}_2\varphi_1\left(\begin{matrix}qa/c,qb/c\\ q^2/c\end{matrix};z\right)z^{1-\gamma}u_1^{-\alpha}u_2^{-\beta}u_3^{\gamma-1}.$$

Furthermore the operators R_1, R_2, S satisfy

$$
\begin{aligned}
&R_1\,{}_2\Phi_1\begin{pmatrix} a,\, b \\ c \end{pmatrix} = {}_2\Phi_1\begin{pmatrix} a,\, c/b \\ c \end{pmatrix},\\
&R_1\,{}_2\Phi_1'\begin{pmatrix} a,\, b \\ c \end{pmatrix} = (-c^{1/2}/b)^{1-\gamma}{}_2\Phi_1'\begin{pmatrix} a,\, c/b \\ c \end{pmatrix},\\
&R_2\,{}_2\Phi_1\begin{pmatrix} a,\, b \\ c \end{pmatrix} = {}_2\Phi_1\begin{pmatrix} c/a,\, b \\ c \end{pmatrix},\\
&R_2\,{}_2\Phi_1'\begin{pmatrix} a,\, b \\ c \end{pmatrix} = (-c^{1/2}/a)^{1-\gamma}{}_2\Phi_1'\begin{pmatrix} c/a,\, b \\ c \end{pmatrix},\\
&R_1^2 = R_2^2 = S^2 = I, \qquad R_1R_2 = R_2R_1 = S,
\end{aligned}
\tag{5.16}
$$

where I is the identity operator. Other easily derived properties of R_1 are as follows:

$$
\begin{aligned}
&R_1E^\alpha R_1^{-1} = E^\alpha, \qquad R_1E^\beta R_1^{-1} = E_\beta T_2T_4,\\
&R_1E_\alpha R_1^{-1} = E_\alpha, \qquad R_1E_{\alpha\gamma}R_1^{-1} = -E_{\alpha\beta\gamma},\\
&R_1E_\beta R_1^{-1} = qE^\beta T_3T_2, \qquad R_1E^\gamma R_1^{-1} = -qE^{\beta\gamma}T_3T_2,\\
&R_1E_\gamma R_1^{-1} = E_{\beta\gamma}, \qquad R_1E^{\alpha\beta\gamma}R_1^{-1} = E^{\alpha\gamma}T_2T_4,\\
&R_1T_1^{-1}T_4^{-1}R_1^{-1} = T_1^{-1}T_4^{-1}, \qquad R_1T_2^{-1}T_4^{-1}R_1^{-1} = qT_2T_3,\\
&R_1T_3T_4^{-1}R_1^{-1} = T_3T_4^{-1}.
\end{aligned}
\tag{5.17}
$$

Similar results for R_2 follow from (5.17) and the interchanges $1 \leftrightarrow 2$, $\alpha \leftrightarrow \beta$, and the corresponding results for S follow from $S = R_1R_2 = R_2R_1$.

As an example of the use of these symmetries we consider a generating function Ψ characterized by

$$
E^\alpha E_\beta \sim \lambda, \qquad T_4^{-1}T_3 \sim \lambda, \qquad T_4^2T_1T_2 \sim 1/\lambda\mu q. \tag{5.18}
$$

Due to the occurrence of the operator E_β, it is not easy to find a simple form for the generating function by direct computation from Ψ. However, we can transform this problem into a simpler one. Indeed, $\Psi' = R_1\psi$ satisfies

$$
qE^\alpha E^\beta T_3T_2 \sim \lambda, \qquad T_4^{-1}T_3 \sim \lambda, \qquad T_1^{-1}T_2 \sim \mu. \tag{5.19}
$$

Although these equations are not in canonical form they are easy to solve by substituting a formal power series for Ψ'. The solution analytic at $u_1 = u_4 = 0$ is

$$
\Psi' = \sum_{k=0}^{\infty} \frac{q^{k(k-1)/2 - lk - l(l+1)/2}u_1^k u_2^{k+\mu}u_3^{l+\lambda}(q^{\mu+1}u_4)^l}{(q^{\mu+1};q)_k(q^{\lambda+1};q)_l(q;q)_k(q;q)_l}.
$$

From (5.13) we then find easily that

$$
\Psi = R_1\Psi' = \sum_{k=0}^{\infty}\frac{(z^{-1};q)_k(-zt/q)^k}{(q^{\mu+1};q)_k(q;q)_k}\sum_{l=0}^{\infty}\frac{(-q^{\lambda-1}zt)^l q^{l^2}}{(q^{\lambda+1};q)_l(q;q)_l}u_2^{-\mu-\lambda-1}u_3^\lambda \tag{5.20}
$$

where $z = u_3u_4/u_1u_2$, $t = u_1/u_2$. (The factorization in this expression is not surprising, based on variable separation for the corresponding differential equation problem and the fact that the operators E^α, E_β commute.) The generating relation is

$$
\Psi = \sum_{n=0}^{\infty}\frac{q^{n(n-1)/2}}{(q;q)_n(q^{\mu+1};q)_n}\,{}_2\varphi_1\begin{pmatrix} q^{-n},\, q^{\mu+\lambda+n+1} \\ q^{\lambda+1} \end{pmatrix};\, z\Big)t^n u_2^{-\mu-\lambda-1}u_3^\lambda \tag{5.21}
$$

where the coefficient of ${}_2\varphi_1$ has been determined by setting $z=0$ in (5.20). This is the generating function for little q-Jacobi polynomials [10]; set $z=qx$.

For our final example we return to (5.6) and note that the function $\Psi' = R_2\Psi$ satisfies the conditions

$$E^{\alpha}T_1T_4 \sim -1, \quad T_2T_4 \sim b^{-1}, \quad T_3T_4^{-1} \sim cq^{-1}$$

which are easily solved by power series substitution to yield

$$\Psi' = \sum_{k,l=0}^{\infty} \frac{q^{-k(k+1)/2-lk}(q^{\beta}; q)_k(-z)^k u_1^{l+k} u_2^{-\beta} u_3^{\gamma-1}}{(q^{\gamma}; q)_k(q; q)_k(q; q)_l}.$$

Then from (5.14) we find

$$\Psi = R_2\Psi' = \frac{(q^{\beta}z; q)_{\infty}}{(z; q)_{\infty}(t; q)_{\infty}} \sum_{k=0}^{\infty} \frac{q^{k^2}(q^{\gamma}zt)^k t^{\gamma} u_2^{-\beta} u_3^{\gamma-1}}{(q^{\beta}z; q)_k(q^{\gamma}; q)_k(q; q)_k}$$

$$= \sum_{n=0}^{\infty} \frac{1}{(q; q)_n} {}_2\varphi_1\left(\begin{matrix} cq^n, b \\ c \end{matrix}; z\right) t^{n+\gamma} u_2^{-\beta} u_3^{\gamma-1}$$

where $z = u_3u_4/u_1u_2$, $t = u_1^{-1}$.

Our symmetry approach has profound relationships with the theory of orthogonal polynomials. We shall illustrate these relationships by presenting a new derivation of the orthogonality for little q-Jacobi polynomials which we normalize in the form

$$(5.22) \qquad \Phi_n^{(a,b)}(x) = {}_2\varphi_1\left(\begin{matrix} q^{-n}, q^{n+1}ab \\ aq \end{matrix}; qx\right), \qquad n = 0, 1, 2, \cdots$$

with $-1 < q < 1$, $0 < aq < 1$, $bq < 1$ [10]. The symmetries $E^{\alpha\beta\gamma}$ and $E_{\alpha\beta\gamma}$, (5.3), induce recurrences for these polynomials:

$$(5.23) \qquad \begin{aligned} \tau^{(a,b)}\Phi_n^{(a,b)}(x) &= \frac{q(1-q^{-n})(1-q^{n+1}ab)}{(1-aq)} \Phi_{n-1}^{(aq,bq)}(x), \\ \tau^{*(aq,bq)}\Phi_{n-1}^{(aq,bq)}(x) &= -(1-q)\Phi_n^{(a,b)}(x) \end{aligned}$$

where

$$\tau^{(a,b)} = \Delta_x^+, \qquad \tau^{*(aq,bq)} = (x-1)T_x^{-1} + (aq - abq^2x).$$

The existence of this pair of "raising" and "lowering" operators suggests that there might exist a Hilbert space structure with respect to which τ^* and τ are mutually adjoint, so that $\tau^*\tau$ would be selfadjoint.

To be more explicit, let $w_{a,b}(x)$ be a (complex-valued) weight function and $S_{a,b}$ the indefinite inner-product space of polynomials $f(x)$ with respect to the inner product

$$(5.24) \qquad (f_1, f_2)_{a,b} = \frac{1}{2\pi i} \int_C f_1(x) f_2(x) w_{a,b}(x) \frac{dx}{x}$$

where the contour C is a deformation of the circle $|x| = 1 + \varepsilon$, $\varepsilon > 0$ in the complex x-plane. Consider $\tau^{(a,b)}$ and $\tau^{*(aq,bq)}$ as mappings:

$$\tau^{(a,b)}: S_{a,b} \to S_{aq,bq}, \qquad \tau^{*(aq,bq)}: S_{aq,bq} \to S_{a,b}$$

and determine $w_{a,b}(x)$ so that

$$(5.25) \qquad (\tau f, g)_{aq,bq} = (f, \tau^* g)_{a,b}$$

for all $f \in S_{a,b}$, $g \in S_{aq,bq}$. A straightforward "integration by parts" yields the following conditions:

$$\frac{-q}{x}\frac{w_{aq,bq}(x/q)}{w_{a,b}(x)} = x-1, \qquad \frac{1}{x}\frac{w_{aq,bq}(x)}{w_{a,b}(x)} = aq(1-bqx)$$

with the solution

$$(5.26) \qquad \begin{aligned} w_{a,b}(x) &= \frac{(x/a;\,q)_\infty(qa/x;\,q)_\infty}{(xbq;\,q)_\infty(1/x;\,q)_\infty s(a,\,q)}, \\ s(a,\,q) &= (aq;\,q)_\infty(1/a;\,q)_\infty(-aq;\,q)_\infty(-1/a;\,q)_\infty. \end{aligned}$$

It follows immediately that $\tau^*\tau$ is selfadjoint on $S_{a,b}$ and from the recurrence relations (5.23) we have

$$(5.27) \qquad \tau^*\tau\Phi_n^{(a,b)} = \lambda_n\Phi_n^{(a,b)}, \qquad \lambda_n = -q(1-q^{-n})(1-q^{n+1}ab).$$

Clearly $\lambda_n \neq \lambda_m$ if $n \neq m$ and since eigenfunctions corresponding to distinct eigenvalues are orthogonal we have

$$(5.28) \qquad (\Phi_n^{(a,b)}, \Phi_m^{(a,b)})_{a,b} = 0 \quad \text{for } n \neq m.$$

From (5.23) and (5.25) with $f = \Phi_n^{(a,b)}$, $g = \Phi_{n-1}^{(aq,bq)}$ we obtain the following recurrence:

$$(5.29) \qquad \|\Phi_n^{(a,b)}\|_{a,b}^2 = \frac{-q(1-q^{-n})(1-q^{n+1}ab)}{(1-aq)^2}\|\Phi_{n-1}^{(aq,bq)}\|_{aq,bq}^2.$$

From (5.29) we can compute $\|\Phi_n^{(a,b)}\|_{a,b}^2$ once we know $\|1\|_{a,b}^2 = (\Phi_0^{(a,b)}, \Phi_0^{(a,b)})_{a,b}$ for all admissible a, b.

We now turn to the task of computing $\|1\|_{a,b}^2$. We know that $(\Phi_1^{(a,b)}, \Phi_0^{(a,b)})_{a,b} = 0$ and, substituting the explicit expression (5.22) for the orthogonal polynomial $\Phi_1^{(a,b)}(x)$, we can write this relation in the form

$$(5.30) \qquad \|1\|_{a,bq}^2 = \frac{(1-bq)}{(1-abq^2)}\|1\|_{a,b}^2.$$

(Here we have used the evident fact that $(1-xbq, 1)_{a,b} = \|1\|_{a,bq}^2$.) To obtain an additional condition on the norm we consider the symmetries E^γ, E_γ in the form:

$$(5.31) \qquad \begin{aligned} \mu^{(a,b)}\Phi_n^{(a,b)} &= (1-a)\Phi_n^{(aq^{-1},bq)}, \\ \mu^{*(aq^{-1},bq)}\Phi_n^{(aq^{-1},bq)} &= \frac{q^{-n}(1-aq^n)(1-bq^{n+1})}{a(1-a)}\Phi_n^{(a,b)} \end{aligned}$$

where

$$\mu^{(a,b)} = 1 - aT_x^1, \qquad \mu^{(a,b)}: S_{a,b} \to S_{aq^{-1},bq},$$

$$\mu^{*(aq^{-1},bq)} = \frac{x-1}{ax}T_x^{-1} + \frac{1-bqx}{ax}, \qquad \mu^{*(aq^{-1},bq)}: S_{aq^{-1},bq} \to S_{a,b}.$$

It is easily verified that

$$(5.32) \qquad (\mu f, g)_{aq^{-1},bq} = (f, \mu^* g)_{a,b}$$

for all $f \in S_{a,b}$, $g \in S_{aq^{-1},bq}$ so that μ and μ^* are mutually adjoint. Setting $f = \Phi_0^{(a,b)}$, $g = \Phi_0^{(aq^{-1},bq)}$ in this relation, we see immediately that

$$(5.33) \qquad \|1\|_{aq^{-1},bq}^2 = \frac{(1-bq)}{a(1-a)}\|1\|_{a,b}^2.$$

The recurrences (5.30), (5.33) have the solution

$$\|1\|^2_{a,b}=\frac{(abq^2;\,q)_\infty K(q)}{(bq;\,q)_\infty(aq;\,q)_\infty(-1/a;\,q)_\infty(-aq;\,q)_\infty}.$$

Thus

$$\frac{1}{2\pi i}\int_C \frac{(x/a;\,q)_\infty(qa/x;\,q)_\infty dx}{(1/a;\,q)_\infty(1/x;\,q)_\infty(xbq;\,q)_\infty x}=\frac{(abq^2;\,q)_\infty K(q)}{(bq;\,q)_\infty(aq;\,q)_\infty}. \tag{5.34}$$

(Here we are assuming $a>1+\varepsilon>1>qa$.) With the choice $bq=1/a$ the integral becomes trivial to evaluate and we find that $K(q)=1/(q;\,q)_\infty$. The complex orthogonality relations just determined can be recast as real discrete orthogonality through evaluation of the contour integral by residues at the poles $x=q^k$, $k=0,1,2,\cdots$. The final result is

$$\begin{aligned}&\sum_{k=0}^{\infty}\frac{(aq)^k(q^{k+1};\,q)_\infty}{(bq^{k+1};\,q)_\infty}\Phi_n^{(a,b)}(q^k)\Phi_m^{(a,b)}(q^k)\\ &\qquad=\frac{(aq)^n(abq^{n+1};\,q)_\infty(q;\,q)_n\delta_{m,n}}{(bq^{n+1};\,q)_\infty(aq;\,q)_\infty(aq;\,q)_n(1-abq^{2n+1})}.\end{aligned} \tag{5.35}$$

Note that the proof of this result follows entirely from the symmetries; no special function identities are needed.

The ideas behind this derivation of orthogonality relations can be generalized substantially. In particular in [12] it is shown how to derive the orthogonality relations for the Askey-Wilson polynomials (the most general extension of the classical orthogonal polynomials known) using this symmetry method. A simple corollary of the derivation is an identity for ${}_4\varphi_3$ polynomials (Sears' transformation) that includes the q-Kummer and q-Euler transforms as special cases.

The fundamental symmetry concepts introduced in this paper extend to the very important q-series of the form

$${}_{r+1}\varphi_r\begin{pmatrix}a_i,x\\ b_j\end{pmatrix};q\Big) \quad\text{and}\quad {}_{r+1}\varphi_r\begin{pmatrix}a_i,ax,a/x\\ b_j\end{pmatrix};q\Big).$$

They will be the subject of future papers by the authors.

A PROBABILISTIC PROOF OF RAMANUJAN'S ${}_1\psi_1$ SUM*

KEVIN W. J. KADELL†

Abstract. The q-binomial theorem and Ramanujan's ${}_1\psi_1$ sum provide q-analogues of the beta and F distributions, respectively. We obtain these discrete distributions using order statistics, thus deriving the summation formulas probabilistically. We obtain a q-analogue of the χ^2 distribution and interpret it probabilistically. We show that an appropriate ratio follows our q-analogue of the F distribution.

Key words. Ramanujan's ${}_1\psi_1$ sum, q-binomial theorem, q-gamma function, Gaussian polynomial, order statistics, beta distribution, F distribution, and χ^2 distribution

AMS(MOS) subject classifications. Primary 33A15; secondary 05A15, 60C05, 62E15

1. Introduction and summary. Fix q with $|q|<1$ and set

$$(1.1)\qquad \begin{aligned} &(\alpha)_0=1,\\ &(\alpha)_n=\prod_{i=0}^{n-1}(1-\alpha q^i), \qquad n\geqq 1,\\ &(\alpha)_\infty=\lim_{n\to\infty}(\alpha)_n=\prod_{i=0}^{\infty}(1-\alpha q^i). \end{aligned}$$

The q-binomial theorem is (see [3, (2.2.1)])

$$(1.2)\qquad \sum_{n=0}^{\infty}\frac{(a)_n}{(q)_n}t^n=\frac{(at)_\infty}{(t)_\infty}, \qquad |t|<1.$$

We can interpret $(\alpha)_n$ for all integers n by

$$(1.3)\qquad (\alpha)_n=\frac{(\alpha)_\infty}{(\alpha q^n)_\infty}.$$

Ramanujan's ${}_1\psi_1$ sum is

$$(1.4)\qquad \sum_{n=-\infty}^{\infty}\frac{(a)_n}{(b)_n}t^n=\frac{(at)_\infty(qa^{-1}t^{-1})_\infty(q)_\infty(ba^{-1})_\infty}{(t)_\infty(ba^{-1}t^{-1})_\infty(b)_\infty(qa^{-1})_\infty}, \qquad |ba^{-1}|<|t|<1.$$

The sum on the left side of (1.4) is usually denoted ${}_1\psi_1\left[{a;q,t \atop b}\right]$. By (1.3), we have

$$(1.5)\qquad \frac{1}{(q)_n}=0, \qquad n<0.$$

Thus Ramanujan's sum (1.4) reduces to the q-binomial theorem (1.2) when $b=q$. Ismail [12] gave an elegant proof of (1.4) by observing that (1.4) reduces to (1.2) when $b=q^n$ for all integers n and that both sides of (1.4) are analytic at $b=0$. Ramanujan's sum (1.4) then follows using the following well-known theorem.

THEOREM 1. *If f and g are analytic at z_0 and agree at infinitely many points which include z_0 as an accumulation point, then $f=g$.*

The work of this author was supported in part by a faculty grant-in-aid from Arizona State University, Tempe, Arizona 85287.

See Andrews [1], [2], Andrews and Askey [4], Askey [6], Hahn [11] and M. Jackson [14] for some other proofs of (1.4).

There are a number of other opportunites to use Ismail's argument to prove summation formulas for basic hypergeometric series. Askey and Ismail [7] used it to prove the summation formula for a very well poised ${}_6\psi_6$ using the limiting form of Jackson's theorem. Gauss [10] introduced the q-binomial coefficient

$$\begin{bmatrix} m \\ k \end{bmatrix} = \frac{(1-q^m)(1-q^{m-1})\cdots(1-q^{m-k+1})}{(1-q)(1-q^2)\cdots(1-q^k)}, \qquad 0 \leqq k \leqq m, \tag{1.6}$$

which clearly tends to $\binom{m}{k}$ as q tends to 1. Setting $a=q^{-m}$, $t=xq^{N+m}$, where $m \geqq 0$ in (1.2), we obtain

$$\sum_{k=0}^{m} q^{Nk+\binom{k}{2}} \begin{bmatrix} m \\ k \end{bmatrix} (-x)^k = (xq^N)_m. \tag{1.7}$$

Equating coefficients in (1.7), we have the representation

$$\sum_{N \leqq n_1 < n_2 < \cdots < n_k \leqq N+m-1} q^{[\sum_{i=1}^{k} n_i]} = q^{Nk+\binom{k}{2}} \begin{bmatrix} m \\ k \end{bmatrix}, \qquad 0 \leqq k \leqq m, \tag{1.8}$$

from which it immediately follows that $\left[\begin{smallmatrix} m \\ k \end{smallmatrix}\right]$ is a polynomial. Equivalent formulations of (1.8) occur in a number of related topics. Kendall and Stuart [15, pp. 496-512] evaluate the characteristic function of the Wilcoxon rank sum (Mann-Whitney U) statistic. Polya [16] gives the probability generating function of an equivalent statistic on lattice paths. Andrews [3, Chaps. 3 and 13] gives an extensive account of the role of $\left[\begin{smallmatrix} m \\ k \end{smallmatrix}\right]$ in the theory of partitions and finite vector spaces.

The basic result (1.8) implies (1.7) directly. Thus (1.2) holds for $a=q^{-m}$, $t=xq^{N+m}$. Set $z=at$. Equation (1.2) now follows using Theorem 1 twice since both sides are analytic at $z=0$ and at $t=0$.

Askey [5] has observed that (1.2) and (1.4) provide q-analogues of the beta integral

$$\frac{\Gamma(x)\Gamma(y)}{\Gamma(x+y)} = \int_0^1 t^{(x-1)}(1-t)^{(y-1)}\,dt \tag{1.9}$$

$$= c^x \int_0^\infty s^{(x-1)} \frac{ds}{(1+cs)^{(x+y)}}, \tag{1.10}$$

where $c>0$, Re $(x)>0$, and Re $(y)>0$, on the intervals $(0,1)$ and $(0,\infty)$, respectively. When these are normalized to integrate to 1, the resulting probability mass functions provide q-analogues of the beta and F distributions, respectively.

In § 2, we use (1.8) to show that the order statistics of a certain discrete random sample follow our q-beta distribution. This proves the q-binomial theorem (1.2) using Theorem 1. In § 3, we use a simple transformation to show that the F distribution also arises from order statistics. We give the q-F distribution with both degrees of freedom equal to 2. In § 4, we give an extension of (1.8). We use the order statistics of a discrete random sample to obtain the q-F distribution. This establishes Ramanujan's sum (1.4) using Theorem 1. In § 5, we set the denominator degrees of freedom in our q-F distribution equal to ∞. This gives a q-analogue of the χ^2 distribution with $2x$ degrees of freedom, which we interpret probabilistically. We obtain a different q-analogue of the χ^2 distribution from our q-beta distribution. We show that an appropriate ratio follows our q-F distribution.

2. The q-beta distribution. Let x and y be positive integers and let u_i, $1 \leqq i \leqq x+y-1$, be i.i.d. uniform random variables on $(0, 1)$. We denote the order statistics by

$$u_{(1)} < u_{(2)} < \cdots < u_{(x+y-1)}. \tag{2.1}$$

The xth order statistic $u_{(x)}$ has a beta distribution with parameters x and y. The density is

$$be_{x,y}(t) = \frac{\Gamma(x+y)}{\Gamma(x)\Gamma(y)} t^{(x-1)}(1-t)^{(y-1)}, \qquad 0 < t < 1, \tag{2.2}$$

which integrates to 1 by (1.9). Feller [8, pp. 21-24] establishes this fact by a direct combinatorial argument. We require the case $q = 1$ of (1.8). It is

$$\sum_{N \leqq n_1 < n_2 < \cdots < n_k \leqq N+m-1} 1 = \binom{m}{k} = \frac{m!}{k!(m-k)!}. \tag{2.3}$$

Let $u_{(x)} = u_n$ and set

$$S = \{s_1, \cdots, s_{x-1}\} = \{s \mid u_s < u_{(x)}\}, \qquad L = \{l_1, \cdots, l_{y-1}\} = \{l \mid u_l > u_{(x)}\}. \tag{2.4}$$

There are

$$(x+y-1)\binom{x+y-2}{x-1} = \frac{\Gamma(x+y)}{\Gamma(x)\Gamma(y)}$$

ways of choosing n, S and L. We have

$$\begin{aligned} &\frac{1}{\Delta t} \text{Prob}\left[t - \frac{\Delta t}{2} \leqq u_{(x)} < t + \frac{\Delta t}{2}\right] \\ &= \sum_{n,S,L} \frac{1}{\Delta t} \int_{t-\Delta t/2}^{t+\Delta t/2} \text{Prob}\,[u_s < u_n \text{ for all } s \in S \text{ and } u_l > u_n \text{ for all } l \in L]\,du_n \\ &= \frac{\Gamma(x+y)}{\Gamma(x)\Gamma(y)} \frac{1}{\Delta t} \int_{t-\Delta t/2}^{t+\Delta t/2} u^{(x-1)}(1-u)^{(y-1)}\,du. \end{aligned} \tag{2.5}$$

The density $be_{x,y}(t)$ of $u_{(x)}$ follows by letting Δt tend to 0.

Fix q with $0 < q < 1$. F. H. Jackson [13] introduced the q-gamma function

$$\Gamma_q(a) = \frac{(q)_\infty}{(q^a)_\infty}(1-q)^{(1-a)}, \tag{2.6}$$

which clearly tends to $\Gamma(a)$ when a is a positive integer. Askey [5] treats the general case. F. H. Jackson [13] also gave the q-integral

$$\int_0^1 f(t)\,d_qt = (1-q) \sum_{n=0}^{\infty} q^n f(q^n). \tag{2.7}$$

This is the approximation which results when the unit interval is partitioned by the powers of q. The measure du of a uniform random variable u is replaced by

$$d_q(q^n) = q^n(1-q) = \text{Prob}\,[q^{n+1} \leqq u < q^n], \qquad n \geqq 0, \tag{2.8}$$

which is the probability mass function of a geometric distribution with parameter $\theta = 1 - q$. While n follows a generalization of the exponential distribution, q^n follows a natural discrete version of the uniform.

A random sample from a continuous distribution will be distinct with probability 1. Choose $x+y-1$ distinct observations from the distribution (2.8). Our sample contains

$$q^{n_{(x+y-1)}} < \cdots < q^{n_{(2)}} < q^{n_{(1)}} \leqq 1, \tag{2.9}$$

where the exponents are

$$0 \leqq n_{(1)} < n_{(2)} < \cdots < n_{(x+y-1)}. \tag{2.10}$$

We require the limiting case of (1.8) as m tends to ∞. It is

$$\sum_{N \leqq n_1 < n_2 < \cdots < n_k} q^{[\sum_{i=1}^{k} n_i]} = \frac{q^{Nk+\binom{k}{2}}}{(q)_k}. \tag{2.11}$$

The joint probability mass function of the order statistics is given by

$$q^{-\binom{x+y-1}{2}} (q)_{(x+y-1)} q^{[\sum_{i=1}^{x+y-1} n_{(i)}]}, \tag{2.12}$$

where (2.10) holds and 0 otherwise. This is clearly correct up to a constant which is supplied by setting $N=0$, $k=x+y-1$, in (2.11). The xth order statistic from our sample (2.9) is $q^{n_{(y)}}$. We have the probability mass function

$$\begin{aligned} {}_q be_{x,y}(q^t) &= \operatorname{Prob}[n_{(y)} = y-1+t] \\ &= q^{-\binom{x+y-1}{2}} (q)_{(x+y-1)} \left(\sum_{0 \leqq n_{(1)} < \cdots < n_{(y-1)} \leqq y-2+t} q^{[\sum_{i=1}^{y-1} n_{(i)}]} \right) \\ &\quad \cdot q^{(y-1+t)} \left(\sum_{y+t \leqq n_{(y+1)} < \cdots < n_{(x+y-1)}} q^{[\sum_{i=y+1}^{x+y-1} n_{(i)}]} \right), \end{aligned} \tag{2.13}$$

where $t \geqq 0$. We may evaluate the two sums on the right side of (2.13) by setting $N=0$, $m=y-1+t$ and $k=y-1$ in (1.8) and $N=y+t$, $k=x-1$ in (2.11). This yields

$$\begin{aligned} {}_q be_{x,y}(q^t) &= q^{-\binom{x+y-1}{2}} (q)_{(x+y-1)} q^{\binom{y-1}{2}} \begin{bmatrix} y-1+t \\ y-1 \end{bmatrix} \frac{q^{(y+t)(x-1)+\binom{x-1}{2}}}{(q)_{(x-1)}} \\ &= q^{tx} \frac{(q)_{(x+y-1)}}{(q)_{(x-1)}(q)_{(y-1)}} \frac{(q)_{(y-1+t)}}{(q)_t} \\ &= \frac{\Gamma_q(x+y)}{\Gamma_q(x)\Gamma_q(y)} (q^t)^{(x-1)} (q^{t+1})_{(y-1)} [q^t(1-q)]. \end{aligned} \tag{2.14}$$

Since ${}_q be_{x,y}(q^t)$ is a probability, we have

$$\begin{aligned} 1 &= \sum_{t=0}^{\infty} {}_q be_{x,y}(q^t) \\ &= \sum_{t=0}^{\infty} q^{tx} \frac{(q)_{(x+y-1)}}{(q)_{(x-1)}(q)_{(y-1)}} \frac{(q)_{(y-1+t)}}{(q)_t} \\ &= \frac{(q^x)_\infty}{(q^{x+y})_\infty} \sum_{t=0}^{\infty} \frac{(q^y)_t}{(q)_t} (q^x)^t. \end{aligned} \tag{2.15}$$

Solving for the sum on the right side of (2.15), we find that (1.2) holds for $a=q^y$, $t=q^x$, where x and y are positive integers. Since both sides are analytic at $a=0$ and at $t=0$, the result (1.2) follows from two applications of Theorem 1.

We may also rewrite (2.15) as the q-analogue

$$\int_0^1 t^{(x-1)} \frac{(qt)_\infty}{(q^y t)_\infty} d_q t = \frac{\Gamma_q(x)\Gamma_q(y)}{\Gamma_q(x+y)} \tag{2.16}$$

of the beta integral (1.9). Two applications of Theorem 1 establish (2.16) for Re $(x)>0$, Re $(y)>0$. See Askey [5].

3. A transformation. Let $c>0$ be a fixed scale parameter. Then

$$v_i=c^{-1}\frac{u_i}{(1-u_i)},\qquad 1\leqq i\leqq x+y-1, \tag{3.1}$$

are i.i.d. random variables with the density function

$$\frac{c}{(1+ct)^2},\qquad t>0. \tag{3.2}$$

Since our transformation is monotonic, it preserves order. Thus the xth order statistic

$$v_{(x)}=c^{-1}\frac{u_{(x)}}{(1-u_{(x)})} \tag{3.3}$$

has the density function

$$c^x\frac{\Gamma(x+y)}{\Gamma(x)\Gamma(y)}\frac{s^{(x-1)}}{(1+cs)^{x+y}},\qquad s>0. \tag{3.4}$$

This integrates to 1 by (1.10). For $c=xy^{-1}$, we observe that $v_{(x)}$ has an F distribution with numerator and denominator degrees of freedom $2x$ and $2y$, respectively. This also follows from Fisher's principle [9]. Let e_i, $1\leqq i\leqq x+y$, be i.i.d. exponential random variables (with any scale parameter) and set $s=e_1+e_2+\cdots+e_{x+y}$. Then the random variables

$$\left(\frac{e_1}{s},\frac{e_1+e_2}{s},\cdots,\frac{e_1+e_2+\cdots+e_{x+y-1}}{s}\right) \tag{3.5}$$

have the same joint distribution as the order statistics

$$(u_{(1)},u_{(2)},\cdots,u_{(x+y-1)}). \tag{3.6}$$

For a given value of the sum s, the joint density of the random variables (3.5) is constant. Integrating over s, the joint density of (3.5) is constant, as is that of the order statistics (3.6). Since they have the same support, they both have the joint density

$$f(t_1,t_2,\cdots,t_{x+y-1})=\begin{cases}(x+y-1)! & \text{if } 0<t_1<\cdots<t_{x+y-1}<1,\\ 0 & \text{otherwise.}\end{cases} \tag{3.7}$$

The density of $u_{(x)}$ may be obtained by integrating over all of the variables except t_x. This is, of course, what was done in § 2 with the q-analogue (2.12) of (3.7).

Choosing the common scale parameter $E(e_1)=2$, we have

$$e_i\sim\chi^2(2),\qquad 1\leqq i\leqq x+y. \tag{3.8}$$

We have the independent random variables

$$\omega_x=e_1+e_2+\cdots+e_x\sim\chi^2(2x),\qquad \omega_y=e_{x+1}+\cdots+e_{x+y}\sim\chi^2(2y). \tag{3.9}$$

Observe for a Poisson process with parameter 1, that ω_x is the waiting time for the xth event and ω_y is the waiting time between the xth and the $(x+y)$th events. Clearly $s=\omega_x+\omega_y\sim\chi^2(2x+2y)$. We have

$$u_{(x)}\sim\frac{e_1+e_2+\cdots+e_x}{s}=\frac{\omega_x}{\omega_x+\omega_y} \tag{3.10}$$

and

$$v_{(x)}=c^{-1}\frac{u_{(x)}}{(1-u_{(x)})}\sim c^{-1}\frac{\omega_x}{\omega_y}\sim c^{-1}\frac{\chi^2(2x)}{\chi^2(2y)}, \tag{3.11}$$

which has an F distribution when $c=xy^{-1}$.

We require a q-analogue of the density function (3.2). Let u be uniformly distributed on $(0,1)$ and set $s=q^n$, where n is the unique integer satisfying

$$q^{n+1}\leqq c^{-1}\frac{u}{(1-u)}<q^n. \tag{3.12}$$

We have the probability mass function

$$\begin{aligned}\text{Prob}\left[q^{n+1}\leqq c^{-1}\frac{u}{(1-u)}<q^n\right]&=\text{Prob}\left[\frac{cq^{n+1}}{(1+cq^{n+1})}\leqq u<\frac{cq^n}{(1+cq^n)}\right]\\&=\frac{c(1-q)q^n}{(1+cq^n)(1+cq^{n+1})}=\frac{c(1-q)q^n}{(-cq^n)_2}.\end{aligned} \tag{3.13}$$

This provides a q-analogue of the F distribution with both degrees of freedom equal to 2.

4. The *q-F* distribution. We want to find the distribution of the order statistics of an appropriate random sample from the distribution (3.13). This requires a new representation of the Gaussian polynomial $[{m \atop k}]$. Replace each n_i on the right side of (2.3) by n_i+i-1. Then (2.3) becomes

$$\sum_{\substack{N\leqq n_1,n_k\leqq N+m+k-2\\ n_i+2\leqq n_{i+1},1\leqq i\leqq k-1,}} 1=\binom{m}{k}. \tag{4.1}$$

We have the following theorem.

THEOREM 2.

$$\sum_{\substack{N\leqq n_1,n_k\leqq N+m+k-2\\ n_i+2\leqq n_{i+1},1\leqq i\leqq k-1,}}\prod_{i=1}^{k}\frac{q^{n_i}}{(-cq^{n_i})_2}=\frac{q^{Nk+2\binom{k}{2}}}{(-cq^N)_k(-cq^{N+m})_k}\begin{bmatrix}m\\k\end{bmatrix},\qquad 0\leqq k\leqq m. \tag{4.2}$$

Proof. We proceed by induction on k. For $k=1$, we have

$$\begin{aligned}\sum_{N\leqq n_1\leqq N+m-1}\frac{q^{n_1}}{(-cq^{n_1})_2}&=\frac{1}{c(1-q)}\sum_{n=N}^{N+m-1}\text{Prob}\left[\frac{cq^{n+1}}{(1+cq^{n+1})}\leqq u<\frac{cq^n}{(1+cq^n)}\right]\\&=\frac{1}{c(1-q)}\text{Prob}\left[\frac{cq^{N+m}}{(1+cq^{N+m})}\leqq u<\frac{cq^N}{(1+cq^N)}\right]\\&=\frac{q^N}{(1+cq^N)(1+cq^{N+m})}\frac{(1-q^m)}{(1-q)},\end{aligned} \tag{4.3}$$

as required. For each $k\geqq 1$, we proceed by induction on m. For $m=k$, the sum on the left side of (4.2) contains only the term with

$$n_i=N+2i-2,\qquad 1\leqq i\leqq k, \tag{4.4}$$

and we easily verify (4.2). Let $F(N,m,k)$ denote the sum on the left side of (4.2). Classifying the terms of the sum according to whether $n_1>N$ or $n_1=N$, we have

$$F(N,m,k)=F(N+1,m-1,k)+\frac{q^N}{(-cq^N)_2}F(N+2,m-1,k-1). \tag{4.5}$$

Substitute the right side of (4.2) into (4.5) and divide by

$$\frac{q^{Nk+2\binom{k}{2}}}{(-cq^N)_k(-cq^{N+m})_k}\begin{bmatrix} m-1 \\ k-1 \end{bmatrix}.$$

This gives

$$\frac{(1-q^m)}{(1-q^k)}=q^k\frac{(1-q^{m-k})}{(1-q^k)}\frac{(1+cq^N)}{(1+cq^{N+k})}+\frac{(1+cq^{N+m})}{(1+cq^{N+k})}, \tag{4.6}$$

which is easily verified. Equation (4.5) completes our induction on k and m. □

Observe that the condition of minimal difference 2 is precisely what is required for each term of the sum on the left side of (4.2) to have only simple poles as a function of c. We have the limiting cases $m=\infty$

$$\sum_{\substack{N\leqq n_1 \\ n_i+2\leqq n_{i+1}, 1\leqq i\leqq k-1,}} \prod_{i=1}^{k}\frac{q^{n_i}}{(-cq^{n_i})_2}=\frac{q^{Nk+2\binom{k}{2}}}{(-cq^N)_k}\frac{1}{(q)_k} \tag{4.7}$$

and $N=-\infty$, $N+m=M$,

$$\sum_{\substack{n_k\leqq M+k-2 \\ n_i+2\leqq n_{i+1}, 1\leqq i\leqq k-1,}} \prod_{i=1}^{k}\frac{q^{n_i}}{(-cq^{n_i})_2}=\frac{c^{-k}q^{\binom{k}{2}}}{(-cq^M)_k}\frac{1}{(q)_k}. \tag{4.8}$$

We also require the case $N=-\infty$ of (4.7) (or $M=\infty$ of (4.8)). It is

$$\sum_{n_i+2\leqq n_{i+1}, 1\leqq i\leqq k-1,} \prod_{i=1}^{k}\frac{q^{n_i}}{(-cq^{n_i})_2}=\frac{c^{-k}q^{\binom{k}{2}}}{(q)_k}. \tag{4.9}$$

Choose a sample q^{n_i}, $1\leqq i\leqq x+y-1$, of $x+y-1$ random variables from the distribution (3.13) subject to the condition

$$n_{(i)}+2\leqq n_{(i+1)}, \qquad 1\leqq i\leqq x+y-2. \tag{4.10}$$

The joint probability mass function of the order statistics is given by

$$q^{-\binom{x+y-1}{2}}(q)_{(x+y-1)}\prod_{i=1}^{x+y-1}\frac{cq^{n_{(i)}}}{(-cq^{n_{(i)}})_2}, \tag{4.11}$$

where (4.10) holds and 0 otherwise. The constant is obtained by setting $k=x+y-1$ in (4.9). The xth order statistic is $q^{n_{(y)}}$. It has probability mass function

$$\begin{aligned} {}_q^cF_{2x,2y}(q^s) &= \text{Prob}\,[n_{(y)}=y-1+s] \\ &= q^{-\binom{x+y-1}{2}}(q)_{(x+y-1)}\Bigg(\sum_{\substack{n_{(y-1)}\leqq y-3+s \\ n_{(i)}+2\leqq n_{(i+1)}, 1\leqq i\leqq y-2,}}\prod_{i=1}^{y-1}\frac{cq^{n_{(i)}}}{(-cq^{n_{(i)}})_2}\Bigg) \\ &\quad\cdot\frac{cq^{y-1+s}}{(-cq^{y-1+s})_2}\Bigg(\sum_{\substack{y+1+s\leqq n_{(y+1)} \\ n_{(i)}+2\leqq n_{(i+1)}, y+1\leqq i\leqq x+y-2,}}\prod_{i=y+1}^{x+y-1}\frac{cq^{n_{(i)}}}{(-cq^{n_{(i)}})_2}\Bigg). \end{aligned} \tag{4.12}$$

We may evaluate the two sums on the right side of (4.12) by setting $N=y+1+s$, $k=x-1$ in (4.7) and $M=s$, $k=y-1$ in (4.8). This yields

$$\begin{aligned} {}_q^cF_{2x,2y}(q^s) &= q^{-\binom{x+y-1}{2}}(q)_{(x+y-1)}\frac{q^{\binom{y-1}{2}}}{(-cq^5)_{(y-1)}}\frac{1}{(q)_{(y-1)}} \\ &\quad\cdot\frac{cq^{y-1+s}}{(-cq^{y-1+s})_2}c^{(x-1)}\frac{q^{(y+1+s)(x-1)+2\binom{x-1}{2}}}{(-cq^{y+1+s})_{(x-1)}}\frac{1}{(q)_{(x-1)}} \end{aligned}$$

(4.13)
$$= \frac{c^x q^{\binom{x}{2}+sx}}{(-cq^s)_{(x+y)}} \frac{(q)_{(x+y-1)}}{(q)_{(x-1)}(q)_{(y-1)}}$$
$$= c^x q^{\binom{x}{2}} \frac{\Gamma_q(x+y)}{\Gamma_q(x)\Gamma_q(y)} \frac{(q^s)^{(x-1)}}{(-cq^s)_{(x+y)}} [q^s(1-q)].$$

Since ${}_q^cF_{2x,2y}(q^s)$ is a probability, we have

(4.14)
$$1 = c^x q^{\binom{x}{2}} \frac{(q)_{(x+y-1)}}{(q)_{(x-1)}(q)_{(y-1)}} \sum_{s=-\infty}^{\infty} \frac{(q^x)^s}{(-cq^s)_{(x+y)}}.$$

Observe that

(4.15)
$$c^x q^{\binom{x}{2}} = \frac{(-c)_\infty(-c^{-1}q)_\infty}{(-cq^x)_\infty(-c^{-1}q^{1-x})_\infty}$$

holds, but only when x is an integer. Solving for the sum on the right side of (4.14), we obtain

(4.16)
$$\sum_{s=-\infty}^{\infty} \frac{(-c)_s}{(-cq^{x+y})_s}(q^x)^s = \frac{(-cq^x)_\infty(-c^{-1}q^{1-x})_\infty(q)_\infty(q^{x+y})_\infty}{(-cq^{x+y})_\infty(-c^{-1}q)_\infty(q^x)_\infty(q^y)_\infty}.$$

Thus Ramanujan's sum (1.4) holds for $a=-c$, $b=-cq^{x+y}$, $t=q^x$. Since

(4.17)
$$(a)_{-n} = \frac{(a)_\infty}{(aq^{-n})_\infty} = \frac{1}{(1-aq^{-n})\cdots(1-aq^{-1})} = \frac{q^{\binom{n+1}{2}}}{(-a)^n}\frac{1}{(qa^{-1})_n},$$

we have

(4.18)
$$\sum_{n=-\infty}^{\infty} \frac{(a)_n}{(b)_n} t^n = \sum_{n=-\infty}^{\infty} \frac{(a)_{-n}}{(b)_{-n}} t^{-n} = \sum_{n=-\infty}^{\infty} \frac{(qb^{-1})_n}{(qa^{-1})_n}(ba^{-1}t^{-1})^n.$$

This shows the analyticity at $b=0$ used by Ismail [12]. Both sides of (1.4) are analytic at any value of a which does not give a pole. Fix $t=q^x$, where x is a positive integer. Two applications of Theorem 1 establish Ramanujan's sum (1.4) in this case. Now fix a and t. By (4.18), (1.4) holds for $ba^{-1}t^{-1}=q^x$, which is $b=atq^x$. The full result (1.4) now follows by a third application of Theorem 1.

Using

(4.19)
$$\int_0^\infty f(s)\,d_qs = (1-q)\sum_{n=-\infty}^{\infty} q^n f(q^n),$$

we may write (4.14) as the q-analogue

(4.20)
$$\int_0^\infty s^{(x-1)}\frac{(-csq^{x+y})_\infty}{(-cs)_\infty}\,d_qs = \frac{(-cq^x)_\infty(-c^{-1}q^{1-x})_\infty}{(-c)_\infty(-c^{-1}q)_\infty}\frac{\Gamma_q(x)\Gamma_q(y)}{\Gamma_q(x+y)}$$

of the beta integral (1.10). Three applications of Theorem 1 establish (4.20) for $\operatorname{Re}(x)>0$, $\operatorname{Re}(y)>0$, and all c for which the integrand has no poles. See Askey [5].

5. The $q-\chi^2$ distribution. The F distribution normally occurs as the ratio of two χ^2 distributions, each of which is divided by its degrees of freedom. It is well known (we may use the Central Limit Theorem) that $\chi^2(n)/n$ converges in distribution to 1 as n tends to ∞. Hence we may recover the χ^2 distribution from the F distribution by letting either the numerator or denominator degrees of freedom tend to ∞. Setting $y=\infty$ in (4.13), we have the probability mass function

$$(5.1)\qquad {}^{c}_{q}\chi^2_{2x}(q^s)=\frac{c^x q^{\binom{x}{2}+sx}}{(-cq^s)_\infty}\frac{1}{(q)_{(x-1)}},$$

which provides a q-analogue of the χ^2 distribution with $2x$ degrees of freedom. Since

$$(5.2)\qquad {}^{c}_{q}F_{2x,2y}(q^s)={}^{c^{-1}q^{-(x+y)}}_{\qquad\quad q}F_{2y,2x}(q^{1-s}),$$

we obtain essentially the same q-analogue of the χ^2 distribution by taking $x=\infty$.

To obtain a q-analogue of a Poisson process with c events per unit time, we let the events occur independently at integer powers of q with

$$(5.3)\qquad \text{Prob}\,[\text{event at } q^t]=\frac{cq^t}{(1+cq^t)}.$$

The following theorem interprets our $q-\chi^2$ distribution probabilistically.

THEOREM 3.

$$(5.4)\qquad {}^{c}_{q}\chi^2_{2x}(q^t)=\text{Prob}\,[x\textit{th event at } q^t].$$

Proof. We may, of course, use (1.8) to sum over all of the possible occurrences of the first $x-1$ events. We proceed by induction on x. For $x=1$, we have

$$(5.5)\qquad \begin{aligned}\text{Prob}\,[\text{first event at } q^t]&=\text{Prob}\,[\text{event at } q^t]\prod_{n=t+1}^{\infty}\text{Prob}\,[\text{no event at } q^n]\\ &=\frac{cq^t}{(1+cq^t)}\prod_{n=t+1}^{\infty}\frac{1}{(1+cq^n)}=\frac{cq^t}{(-cq^t)_\infty},\end{aligned}$$

as required. We have

$$(5.6)\qquad \begin{aligned}&\text{Prob}\,[x\text{th event at } q^t]\\ &\quad=\text{Prob}\,[\text{event at } q^t]\sum_{n=t+1}^{\infty}\text{Prob}\,[(x-1)\text{st event at } q^n]\\ &\qquad\cdot\prod_{j=t+1}^{n-1}\text{Prob}\,[\text{no event at } q^j]\\ &\quad=\frac{cq^t}{(1+cq^t)}\sum_{n=t+1}^{\infty}\frac{c^{(x-1)}q^{\binom{x-1}{2}+n(x-1)}}{(-cq^n)_\infty}\frac{1}{(q)_{(x-2)}}\prod_{j=t+1}^{n-1}\frac{1}{(1+cq^j)}\\ &\quad=\frac{c^x q^{\binom{x-1}{2}+t}}{(-cq^t)_\infty}\frac{1}{(q)_{(x-2)}}\sum_{n=t+1}^{\infty}q^{n(x-1)}.\end{aligned}$$

The result (5.4) follows using the well-known sum (put $a=q$ in the q-binomial theorem (1.2)) of a geometric series. □

The limiting case $b=0$ of Ramanujan's sum (1.4) is

$$(5.7)\qquad \sum_{n=-\infty}^{\infty}(a)_n t^n=\frac{(at)_\infty(qa^{-1}t^{-1})_\infty(q)_\infty}{(t)_\infty(qa^{-1})_\infty},\qquad |t|<1.$$

Since ${}^{c}_{q}\chi^2_{2x}(q^t)$ sums to 1, (5.7) holds for $a=-c$, $t=q^x$. By Theorem 1, it holds for $t=q^x$, where x is a positive integer. Observe that we have only used the sum of a geometric series to obtain this result.

The χ^2 distribution may be obtained by rescaling the beta distribution on $(0, y)$ and letting y tend to ∞. We find that

$$(5.8)\qquad {}_qbe_{2y,\infty}(q^n)=(q^y)_\infty\frac{q^{yn}}{(q)_n},\qquad n\geqq 0,$$

is also a q-analogue of the χ^2 distribution. We close by showing that our q-F distribution also arises as a ratio of (5.1) and (5.8).

THEOREM 4. *If q^t has the $q-\chi^2$ distribution* (5.1) *and q^n has the distribution* (5.8), *then the ratio q^{t-n} has the q-F distribution* (4.13).

Proof. A simple application of the q-binomial theorem (1.2) gives

$$(5.9)\qquad \begin{aligned}\operatorname{Prob}[q^{t-n}=q^s]&=\sum_{n=0}^{\infty}{}_q^c\chi^2_{2x}(q^{s+n})\,{}_qf_{2y}(q^n)\\&=\sum_{n=0}^{\infty}\frac{c^xq^{\binom{x}{2}+(s+n)x}}{(-cq^{s+n})_\infty}\frac{1}{(q)_{(x-1)}}(q^y)_\infty\frac{q^{yn}}{(q)_n}\\&=\frac{c^xq^{\binom{x}{2}+sx}}{(-cq^s)_\infty}\frac{(q^y)_\infty}{(q)_{(x-1)}}\sum_{n=0}^{\infty}\frac{(-cq^s)_n}{(q)_n}q^{n(x+y)}\\&=\frac{c^xq^{\binom{x}{2}+sx}}{(-cq^s)_{(x+y)}}\frac{(q)_{(x+y-1)}}{(q)_{(x-1)}(q)_{(y-1)}},\end{aligned}$$

as required. □

NEW INEQUALITIES FOR THE ZEROS OF JACOBI POLYNOMIALS*

LUIGI GATTESCHI†

Abstract. It is shown that certain asymptotic approximations are upper or lower bounds for the zeros $\theta_{n,k}(\alpha,\beta)$ of Jacobi polynomials $P_n^{(\alpha,\beta)}(\cos\theta)$. The procedure for deriving these bounds is based on the Sturm comparison theorem. Numerical examples are given to illustrate the sharpness of the new inequalities.

Key words. Jacobi polynomials, zeros, inequalities, Sturm comparison theorem

AMS(MOS) subject classifications. Primary 33A65; secondary 34C10, 64D20

1. Introduction. The purpose of this paper is to show that certain asymptotic approximations for the zeros of Jacobi polynomials are in fact inequalities.

The main tool that we need is the well-known Sturm comparison theorem in the following form given by Szegö [9, p. 19].

THEOREM 1.1 (Sturm's comparison theorem). *Let $f(x)$ and $F(x)$ be functions continuous in $x_0<x<X_0$ with $f(x)\leqq F(x)$. Let the functions $y(x)$ and $Y(x)$, both not identically zero, satisfy the differential equations*

$$y''+f(x)y=0, \qquad Y''+F(x)Y=0, \tag{1.1}$$

respectively. Let x' and x'', $x'<x''$, be two consecutive zeros of $y(x)$. Then the function $Y(x)$ has at least one zero in the interval $x'<x<x''$ provided $f(x)\not\equiv F(x)$ in $[x',x'']$.

The statement also holds for $x'=x_0[y(x_0+0)=0]$ if the additional condition

$$\lim_{x\to x_0+0}[y'(x)Y(x)-y(x)Y'(x)]=0 \tag{1.2}$$

is satisfied (similarly for $x''=X_0$).

Throughout this paper we denote by $x_{n,k}\equiv x_{n,k}(\alpha,\beta)$ the zeros, in decreasing order, of the Jacobi polynomial $P_n^{(\alpha,\beta)}(x)$:

$$1>x_{n,1}>x_{n,2}>\cdots>x_{n,n}>-1,$$

and by $\theta_{n,k}\equiv\theta_{n,k}(\alpha,\beta)$,

$$0<\theta_{n,1}<\theta_{n,2}<\cdots<\theta_{n,n}<\pi,$$

the corresponding zeros of $P_n^{(\alpha,\beta)}(\cos\theta)$.

Let us recall the following asymptotic results and inequalities.

THEOREM 1.2 (Frenzen and Wong [3], [4]). *Let $\alpha>-\frac{1}{2}$, $\alpha+\beta\geqq-1$. Then as $n\to\infty$*

$$\theta_{n,k}=\frac{j_{\alpha,k}}{N}-\frac{1}{4N^2}\left[\left(\frac{1}{4}-\alpha^2\right)\left(\frac{2}{t}-\cot\frac{t}{2}\right)+\left(\frac{1}{4}-\beta^2\right)\tan\frac{t}{2}\right]+t^2O(n^{-3}) \tag{1.3}$$

where

$$N=n+\frac{\alpha+\beta+1}{2}, \tag{1.4}$$

$j_{\alpha,k}$ is the kth positive zero of the Bessel function $J_\alpha(x)$ and $t=j_{\alpha,k}/N$. The O-term is uniformly bounded for all values of $k=1,2,\cdots,[\gamma n]$, where $\gamma\in(0,1)$.

* Received by the editors April 2, 1986; accepted for publication (in revised form) September 17, 1986. This work was supported by the Consiglio Nazionale delle Ricerche of Italy and by the Ministero della Pubblica Istruzione of Italy.

† Dipartimento di Matematica dell'Università, Torino, Italy.

THEOREM 1.3 (Gatteschi and Pittaluga [6], [7]). *Let $-\frac{1}{2}\leqq\alpha\leqq\frac{1}{2}$, $-\frac{1}{2}\leqq\beta\leqq\frac{1}{2}$. Then for all the zeros $\theta_{n,k}$ belonging to the interval $a<\theta<b$, with $0<a<b<\pi$, the following asymptotic expansion holds as $n\to\infty$:*

$$\theta_{n,k}=\phi_{n,k}+\frac{1}{4N^2}\left[\left(\frac{1}{4}-\alpha^2\right)\cot\frac{\phi_{n,k}}{2}-\left(\frac{1}{4}-\beta^2\right)\tan\frac{\phi_{n,k}}{2}\right]+O(n^{-4}) \tag{1.5}$$

where

$$\phi_{n,k}=\frac{2k+\alpha-1/2}{N}\frac{\pi}{2},$$

and N has the same meaning as in the previous theorem.

THEOREM 1.4 (Buell's inequalities; see Szegö [9, p. 125]). *Under the conditions $-\frac{1}{2}\leqq\alpha\leqq\frac{1}{2}$, $-\frac{1}{2}\leqq\beta\leqq\frac{1}{2}$ and excluding the case $\alpha^2=\beta^2=\frac{1}{4}$, we have*

$$\frac{k+(\alpha+\beta-1)/2}{N}\pi<\theta_{n,k}<\frac{k}{N}\pi, \qquad k=1,2,\cdots,n, \tag{1.6}$$

whereas in the ultraspherical case $\alpha=\beta$

$$\theta_{n,k}>\frac{k+\alpha/2-1/4}{N}\pi, \qquad k=1,2,\cdots,\left[\frac{n}{2}\right]. \tag{1.7}$$

When $\alpha=\beta=-\frac{1}{2}$, $\alpha=\beta=\frac{1}{2}$, $\alpha=-\beta=-\frac{1}{2}$, $\alpha=-\beta=\frac{1}{2}$, we notice that

$$\theta_{n,k}=\frac{k-1/2}{n}\pi,\quad \frac{k}{n+1}\pi,\quad \frac{k-1/2}{n+1/2}\pi,\quad \frac{k}{n+1/2}\pi,$$

respectively.

THEOREM 1.5 (Gatteschi [5], [6]). *Let $-\frac{1}{2}\leqq\alpha\leqq\frac{1}{2}$, $-\frac{1}{2}\leqq\beta\leqq\frac{1}{2}$. Then*

$$\frac{j_{\alpha,k}}{\nu^*}\leqq\theta_{n,k}\leqq\frac{j_{\alpha,k}}{\nu}, \qquad k=1,2,\cdots,\left[\frac{n}{2}\right] \tag{1.8}$$

where $j_{\alpha,k}$, as in Theorem 1.2, is the kth positive zero of $J_\alpha(x)$ and

$$\begin{aligned}\nu&=\left[N^2+\frac{1-\alpha^2-3\beta^2}{12}\right]^{1/2},\\ \nu^*&=\left[N^2+\frac{1}{4}-\frac{\alpha^2+\beta^2}{2}-\frac{1-4\alpha^2}{\pi^2}\right]^{1/2}.\end{aligned} \tag{1.9}$$

We remark (see Gatteschi [6, Thm. 3.1]) that the inequality

$$\theta_{n,k}\leqq\frac{j_{\alpha,k}}{\nu}, \tag{1.10}$$

under the same conditions for the parameters α and β, holds for all the zeros $\theta_{n,k}$ located in the interval $0<\theta<\pi$.

For the ultraspherical case $\alpha=\beta$, using Sturm's theorem, Ahmed, Muldoon and Spigler [2] have recently obtained the following interesting inequalities involving only elementary functions.

THEOREM 1.6. *Let $\alpha=\beta$ and let $x_{n,k}(\alpha)$, $k=1,2,\cdots,[n/2]$, be the zeros of the ultraspherical polynomial $P_n^{(\alpha,\alpha)}(x)$. Then, for $-\frac{1}{2}<\alpha<\frac{1}{2}$ and $k=1,2,\cdots,[n/2]$, we have*

$$x_{n,k}(\alpha)<\left[\frac{2n^2+4n+3}{2n^2+1+(2\alpha+1)(2n+1)}\right]^{1/2}\cos\frac{k\pi}{n+1}, \tag{1.11}$$

and

$$x_{n,k}(\alpha) > \left[\frac{2n^2+1}{2n^2+1+(2\alpha+1)(2n+1)}\right]^{1/2} \cos\frac{2k-1}{2n}\pi. \tag{1.12}$$

Ahmed, Muldoon and Spigler [2] have considered also values of α outside the range $-\frac{1}{2} < \alpha < \frac{1}{2}$, but the method used cannot be applied to obtain similar results for the general Jacobi case [8].

2. A lower bound for the zeros of $P_n^{(\alpha,\beta)}(\cos\theta)$. We shall assume throughout this paper that the parameters α and β satisfy the inequalities

$$-\tfrac{1}{2} \leqq \alpha \leqq \tfrac{1}{2}, \qquad -\tfrac{1}{2} \leqq \beta \leqq \tfrac{1}{2}. \tag{2.1.}$$

Moreover, we shall refer to the differential equation

$$\frac{d^2u}{d\theta^2} + \left[N^2 + \frac{1/4-\alpha^2}{4\sin^2\theta/2} + \frac{1/4-\beta^2}{4\cos^2\theta/2}\right]u = 0, \qquad N = n + \frac{\alpha+\beta+1}{2} \tag{2.2}$$

which is satisfied by

$$u(\theta) = \left(\sin\frac{\theta}{2}\right)^{\alpha+1/2}\left(\cos\frac{\theta}{2}\right)^{\beta+1/2} P_n^{(\alpha,\beta)}(\cos\theta). \tag{2.3}$$

Now we observe that the function

$$z(\theta) = \left(\frac{f}{f'}\right)^{1/2} J_\alpha[f(\theta)] \tag{2.4}$$

satisfies the differential equation

$$\frac{d^2z}{d\theta^2} + F(\theta)z = 0 \tag{2.5}$$

where

$$F(\theta) = \frac{1}{2}\frac{f'''}{f'} - \frac{3}{4}\left(\frac{f''}{f'}\right)^2 + \left(\frac{1}{4}-\alpha^2\right)\left(\frac{f'}{f}\right)^2 + f'^2. \tag{2.6}$$

In this section we assume that

$$f(\theta) = N\theta + \frac{1}{4N}\left[\left(\frac{1}{4}-\alpha^2\right)\left(\frac{2}{\theta} - \cot\frac{\theta}{2}\right) + \left(\frac{1}{4}-\beta^2\right)\tan\frac{\theta}{2}\right] \tag{2.7}$$

and make use of (2.5) as a comparison equation to derive, by means of Sturm's method, inequalities for the zeros $\theta_{n,k}(\alpha,\beta)$, $k = 1, 2, \cdots, n$, of $P_n^{(\alpha,\beta)}(\cos\theta)$.

LEMMA 2.1. *Let α and β satisfy* (2.1). *The function $F(\theta)$ defined by* (2.6) *and* (2.7) *is such that*

$$F(\theta) \geqq N^2 + \frac{1/4-\alpha^2}{4\sin^2\theta/2} + \frac{1/4-\beta^2}{4\cos^2\theta/2} \tag{2.8}$$

for $0 < \theta < \pi$. Here the equality sign holds if and only if $\alpha^2 = \beta^2 = \frac{1}{4}$.

For the proof we put

$$A = \tfrac{1}{4} - \alpha^2, \qquad B = \tfrac{1}{4} - \beta^2,$$

$$a(\theta) = \frac{2}{\theta} - \cot\frac{\theta}{2}, \qquad b(\theta) = \tan\frac{\theta}{2},$$

and we observe that

$$f'^2(\theta)=N^2+\frac{A}{4\sin^2\theta/2}-\frac{A}{\theta^2}+\frac{B}{4\cos^2\theta/2}+\frac{1}{16N^2}(Aa'+Bb')^2.$$

Hence

$$F(\theta)-N^2-\frac{A}{4\sin^2\theta/2}-\frac{B}{4\cos^2\theta/2}$$
$$=\frac{1}{2f'}F_1(\theta)+\frac{A(f'\theta+f)}{f^2\theta^2}F_2(\theta)+\frac{1}{16N^2}(Aa'+Bb')^2$$

where

$$F_1(\theta)=f'''-\frac{3}{2}\frac{f''^2}{f'},\qquad F_2(\theta)=f'\theta-f,$$

and it suffices to show that $F_1(\theta)\geqq 0$ and $F_2(\theta)\geqq 0$.

To this end we note that $a(\theta)$ and $b(\theta)$ are positive increasing functions for $0<\theta<\pi$ as are all their derivatives. Moreover, the following expansions hold [1, p. 75]:

$$a(\theta)=\frac{\theta}{6}+\frac{\theta^3}{360}+\cdots+\frac{(-1)^{n-1}2B_{2n}}{(2n)!}\theta^{2n-1}+\cdots\qquad(|\theta|<2\pi),$$

$$b(\theta)=\frac{\theta}{2}+\frac{\theta^3}{24}+\cdots+\frac{(-1)^{n-1}2(2^{2n}-1)B_{2n}}{(2n)!}\theta^{2n-1}+\cdots\qquad(|\theta|<\pi)$$

where B_{2n} is the $2n$th Bernoulli number.

It is readily seen that $F_2(\theta)\geqq 0$ for $0<\theta<\pi$. Indeed, we have

$$F_2(\theta)=\frac{A}{4N}(a'\theta-a)+\frac{B}{4N}(b'\theta-b)\geqq 0.$$

To study $F_1(\theta)$ we first consider the interval $0<\theta\leqq\pi/2$ where we have

$$Aa'''+Bb'''\geqq\frac{A}{60}+\frac{B}{4},\qquad Aa''+Bb''\leqq A\left(\frac{32}{\pi^3}-1\right)+B\leqq\frac{8}{\pi^3};$$

thus

$$F_1(\theta)=\frac{1}{4N}\left[Aa'''+Bb'''-\frac{3}{2}\frac{(Aa''+Bb'')^2}{4N^2+Aa'+Bb'}\right]$$
$$\geqq\frac{1}{4N}\left\{\frac{A}{60}+\frac{B}{4}-\frac{3}{N^2}\left[A\left(\frac{32}{\pi^3}-1\right)+B\right]\frac{1}{\pi^3}\right\}\geqq 0.$$

Similar considerations may be applied to

$$4N(4N^2+Aa'+Bb')F_1(\theta)$$

for the interval $\pi/2<\theta<\pi$. More precisely, it is straightforward to prove that

$$4N^2Aa'''-\frac{3}{2}A^2a''^2\geqq A\left[4N^2a'''\left(\frac{\pi}{2}\right)-\frac{3}{8}a''^2(\pi)\right]\geqq 0,$$

$$b'''b'-\frac{3}{2}b''^2=\frac{1}{8}\frac{1}{\cos^4\theta/2}>0,$$

and

$$a'b''' - 3a''b'' > \frac{1}{2\cos^2\theta/2}\left[\frac{1}{2}\left(1-\frac{8}{\pi^2}\right)\left(1+3\tan^2\frac{\theta}{2}\right)-\frac{12}{\pi^3}\tan\frac{\theta}{2}\right] > 0.$$

Having established both $F_1(\theta)$ and $F_2(\theta) \geqq 0$, Lemma 2.1 is proved and we can state the following main result of this section.

THEOREM 2.1. *Let* $-\frac{1}{2} \leqq \alpha \leqq \frac{1}{2}$, $-\frac{1}{2} \leqq \beta \leqq \frac{1}{2}$. *Then the Frenzen-Wong approximation for* $\theta_{n,k}(\alpha, \beta)$, *obtained by omitting the* $O(n^{-3})$ *term in* (1.3), *is in fact a lower bound*; *that is*

$$\theta_{n,k}(\alpha,\beta) \geqq \frac{j_{\alpha,k}}{N} - \frac{1}{4N^2}\left[\left(\frac{1}{4}-\alpha^2\right)\left(\frac{2}{t}-\cot\frac{t}{2}\right)+\left(\frac{1}{4}-\beta^2\right)\tan\frac{t}{2}\right] \tag{2.9}$$

where

$$N = n + \frac{\alpha+\beta+1}{2}, \qquad t = \frac{j_{\alpha,k}}{N}$$

and $k = 1, 2, \cdots, n$. *The equality sign in* (2.9) *holds when* $\alpha^2 = \beta^2 = \frac{1}{4}$.

Indeed, the validity of (2.8) enables us to apply Theorem 1.1 to the differential equations (2.2) and (2.5) and to compare the positive zeros of the function $z(\theta)$ defined by (2.4), i.e., the positive zeros $\tau_{n,k}$, $k = 1, 2, \cdots$,

$$\tau_{n,1} < \tau_{n,2} < \cdots < \tau_{n,n}$$

of the function $J_\alpha[f(\theta)]$, with the zeros

$$0, \theta_{n,1}, \theta_{n,2}, \cdots, \theta_{n,n}$$

of the function $u(\theta)$ defined by (2.3).

The condition (1.2), which is required when we apply Theorem 1.1 to the interval $[0, \theta_{n,1}]$, is satisfied. Hence, we conclude that

$$\tau_{n,k} \leqq \theta_{n,k}, \qquad k = 1, 2, \cdots, \tag{2.10}$$

where, since $f(\theta)$ is a continuous increasing function in $0 < \theta < \pi$,

$$N\tau_{n,k} + \frac{1}{4N}\left[\left(\frac{1}{4}-\alpha^2\right)\left(\frac{2}{\tau_{n,k}}-\cot\frac{\tau_{n,k}}{2}\right)+\left(\frac{1}{4}-\beta^2\right)\tan\frac{\tau_{n,k}}{2}\right] = j_{\alpha,k}. \tag{2.11}$$

We also have

$$j_{\alpha,k} \leqq f(\theta_{n,k}), \qquad k = 1, 2, \cdots, n.$$

Now, when we set

$$h(\theta) = \frac{j_{\alpha,k}}{N} - \frac{1}{4N^2}\left[\left(\frac{1}{4}-\alpha^2\right)\left(\frac{2}{\theta}-\cot\frac{\theta}{2}\right)+\left(\frac{1}{4}-\beta^2\right)\tan\frac{\theta}{2}\right],$$

it follows that the equation $\theta = h(\theta)$ has the solution $\theta = \tau_{n,k}$. Since the function $h(\theta)$ decreases and, from (1.10),

$$\theta_{n,k} \leqq \frac{j_{\alpha,k}}{\nu} \leqq \frac{j_{\alpha,k}}{N},$$

we obtain the following from (2.10):

$$\theta_{n,k} \geqq \tau_{n,k} = h(\tau_{n,k}) \geqq h(\theta_{n,k}) \geqq h\left(\frac{j_{\alpha,k}}{\nu}\right) \geqq h\left(\frac{j_{\alpha,k}}{N}\right),$$

which proves the theorem.

This theorem can be improved by using (1.10) and by observing that $\theta_{n,k} \geqq h(j_{\alpha,k}/\nu)$, $k = 1, 2, \cdots, n$.

THEOREM 2.2. *Let* $-\frac12 \leqq \alpha \leqq \frac12$, $-\frac12 \leqq \beta \leqq \frac12$. *Then for the zeros* $\theta_{n,k}(\alpha,\beta)$ *of* $P_n^{(\alpha,\beta)}(\cos\theta)$ *the following inequalities hold*:

$$\theta_{n,k}(\alpha,\beta) \geqq \frac{j_{\alpha,k}}{N} - \frac{1}{4N^2}\left[\left(\frac14-\alpha^2\right)\left(\frac{2}{\tau}-\cot\frac{\tau}{2}\right)+\left(\frac14-\beta^2\right)\tan\frac{\tau}{2}\right], \quad k=1,2,\cdots,n \tag{2.12}$$

where

$$N = n+\frac{\alpha+\beta+1}{2}, \quad \nu=\left(N^2+\frac{1-\alpha^2-3\beta^2}{12}\right)^{1/2}, \quad \tau=\frac{j_{\alpha,k}}{\nu}.$$

As before, the equality sign in (2.12) *holds when* $\alpha^2=\beta^2=\frac14$.

Using this result and the property

$$P_n^{(\alpha,\beta)}(\cos\theta) = (-1)^n P_n^{(\beta,\alpha)}[\cos(\pi-\theta)], \tag{2.13}$$

we can obtain upper bounds for $\theta_{n,k}(\alpha,\beta)$, $k=1,2,\cdots,n$.

COROLLARY 2.1. *Let* $-\frac12 \leqq \alpha \leqq \frac12$, $-\frac12 \leqq \beta \leqq \frac12$. *Then*

$$\begin{aligned}\theta_{n,k}(\alpha,\beta) &= \pi - \theta_{n,n-k+1}(\beta,\alpha)\\ &\leqq \pi - \frac{j_{\beta,n-k+1}}{N} + \frac{1}{4N^2}\left[\left(\frac14-\beta^2\right)\left(\frac{2}{\bar\tau}-\cot\frac{\bar\tau}{2}\right)+\left(\frac14-\alpha^2\right)\tan\frac{\bar\tau}{2}\right],\end{aligned} \tag{2.14}$$

$$k=1,2,\cdots,n$$

where

$$N = n+\frac{\alpha+\beta+1}{2}, \quad \bar\nu=\left(N^2+\frac{1-\beta^2-3\alpha^2}{12}\right)^{1/2}, \quad \bar\tau=\frac{j_{\beta,n-k+1}}{\bar\nu},$$

the equality sign holding when $\alpha^2=\beta^2=\frac14$.

Inequalities (2.12) and (2.14) give very sharp results for the zeros which are close to π, when we apply (2.12), or close to zero, when we apply (2.14). Table 1 provides lower and upper bounds, obtained using (2.12) and (2.14), in the case $n=10$, $\alpha=\frac13$ and $\beta=0$.

TABLE 1
Zeros of $P_{10}^{(1/3,0)}(\cos\theta)$.

k	Lower bound	Exact value	Upper bound
1	0.2720 2843	0.2720 2854	0.2721 5052
2	0.5653 8156	0.5653 8183	0.5653 9792
3	0.8594 3899	0.8594 3944	0.8594 4435
4	1.1536 6321	1.1536 6395	1.1536 6610
5	1.4479 3628	1.4479 3750	1.4479 3864
6	1.7422 0569	1.7422 0784	1.7422 0853
7	2.0364 2307	2.0364 2737	2.0364 2780
8	2.3305 0083	2.3305 1150	2.3305 1177
9	2.6241 7391	1.6242 1351	2.6242 1367
10	2.9157 9656	2.9161 9539	2.9161 9545

Should we be interested in obtaining sharper numerical results, it is convenient to use the inequalities (2.12) and (2.14) jointly with the following simpler ones

$$\begin{aligned}&\theta_{n,k}(\alpha,\beta) \leqq j_{\alpha,k}\left(N^2+\frac{1-\alpha^2-3\beta^2}{12}\right)^{-1/2},\\ &\theta_{n,k}(\alpha,\beta) \geqq \pi - j_{\beta,n-k+1}\left(N^2+\frac{1-\beta^2-3\alpha^2}{12}\right)^{-1/2} \quad (k=1,2,\cdots,n)\end{aligned} \tag{2.15}$$

obtained by means of the inequality (1.10) and the property (2.13). Indeed, the first of (2.15) may be better than (2.14) for the first few values of k, while the second of (2.15) may be better than (2.12) for the last few values of k. Thus, for example, by using (2.15) we obtain

$$\theta_{10,1}(\tfrac{1}{3},0)<0.2720\,2892, \qquad \theta_{10,2}(\tfrac{1}{3},0)<0.5653\,8602,$$

$$\theta_{10,8}(\tfrac{1}{3},0)>2.3305\,0366, \qquad \theta_{10,9}(\tfrac{1}{3},0)>2.6242\,1163,$$

$$\theta_{10,10}(\tfrac{1}{3},0)>2.9161\,9528,$$

which are better than those given in Table 1.

The sharpness of the results furnished by applying inequalities (2.12) and (2.14) together with (2.15) is shown in Fig. 1 for $n=16$, $\alpha=-\frac{1}{3}$, $\beta=\frac{1}{3}$ and $\alpha=0$, $\beta=\frac{1}{4}$. More precisely, in the Fig. 1 we can see the digits of accuracy

$$\rho_n(\alpha,\beta;k)=-\log_{10}\frac{U_k-L_k}{U_k},$$

obtained by means of the upper bound U_k and the lower bound L_k of the kth zero $\theta_{n,k}(\alpha,\beta)$.

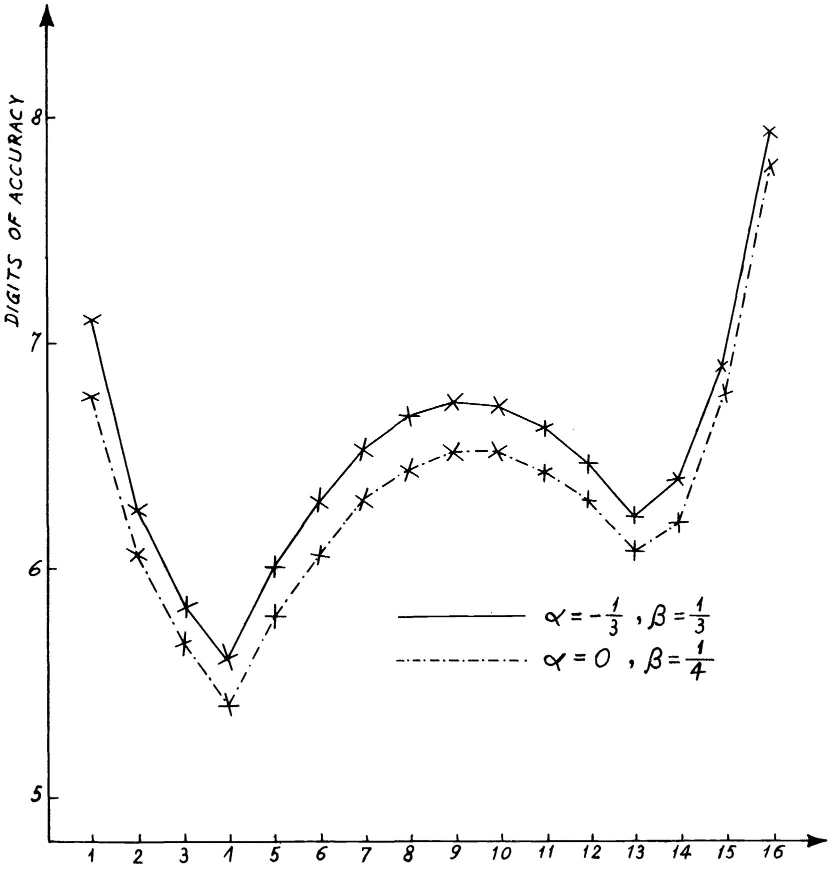

FIG. 1. $\rho_{16}(\alpha,\beta;k)$ *versus* $k=1(1)16$.

In the ultraspherical case $\alpha=\beta$ Theorem 2.2 and the first of inequalities (2.15) yield the following corollary.

COROLLARY 2.2. *Let $-\frac{1}{2}\leqq\alpha\leqq\frac{1}{2}$ and let $\theta_{n,k}(\alpha)$ be the zeros of the ultraspherical polynomial $P_n^{(\alpha,\alpha)}(\cos\theta)$. Then*

$$\frac{j_{\alpha,k}}{N}-\frac{1-4\alpha^2}{8N^2}\left(\frac{\nu}{j_{\alpha,k}}-\cot\frac{j_{\alpha,k}}{\nu}\right)\leqq\theta_{n,k}(\alpha)\leqq\frac{j_{\alpha,k}}{\nu}\tag{2.16}$$

where

$$N=n+\alpha+\frac{1}{2},\quad \nu=\left(N^2+\frac{1-4\alpha^2}{12}\right)^{1/2},\quad k=1,2,\cdots,n.$$

The equality signs in (2.16) *hold when* $|\alpha|=\frac{1}{2}$.

3. Other separation results for the zeros of $P_n^{(\alpha,\beta)}(\cos\theta)$ and upper bounds in the ultraspherical case. We now use the differential equation

$$\frac{d^2z}{d\theta^2}+G(\theta)z=0,\tag{3.1}$$

with

$$G(\theta)=\frac{1}{2}\frac{g'''}{g'}-\frac{3}{4}\left(\frac{g''}{g'}\right)^2+g'^2,$$

satisfied by

$$z=(g')^{-1/2}\cos g(\theta).$$

Further, we assume that

$$g(\theta)=N\theta-\left(\alpha+\frac{1}{2}\right)\frac{\pi}{2}-\frac{1}{4N}\left[\left(\frac{1}{4}-\alpha^2\right)\cot\frac{\theta}{2}-\left(\frac{1}{4}-\beta^2\right)\tan\frac{\theta}{2}\right],\tag{3.2}$$

suggested by (1.5), and we show that

$$G(\theta)\geqq N^2+\frac{1/4-\alpha^2}{4\sin^2\theta/2}+\frac{1/4-\beta^2}{4\cos^2\theta/2},\qquad -\frac{1}{2}\leqq\alpha,\quad\beta\leqq\frac{1}{2},\tag{3.3}$$

with equality sign when $\alpha^2=\beta^2=\frac{1}{4}$.

For the proof we set

$$A=\tfrac{1}{4}-\alpha^2,\qquad B=\tfrac{1}{4}-\beta^2$$

and we study the sign of

$$\frac{1}{2}\frac{g'''}{g'}-\frac{3}{4}\left(\frac{g''}{g'}\right)^2+g'^2-N^2-\frac{A}{4\sin^2\theta/2}-\frac{B}{4\cos^2\theta/2},$$

when $A\geqq0$, $B\geqq0$, $g(\theta)$ is defined by (3.2) and $0<\theta<\pi$.

We find that

$$g'^2-N^2-\frac{A}{4\sin^2\theta/2}-\frac{B}{4\cos^2\theta/2}=\frac{1}{64N^2}\left(\frac{A}{\sin^2\theta/2}+\frac{B}{\cos^2\theta/2}\right)^2\geqq0$$

and

$$\frac{1}{2}\frac{g'''}{g'}-\frac{3}{4}\left(\frac{g''}{g'}\right)^2=\frac{1}{2g'}\left(g'''-\frac{3}{2}\frac{g''^2}{g'}\right)$$

$$=\frac{1}{32Ng'}\left[\frac{A}{\sin^4\theta/2}r(\theta)+\frac{B}{\cos^4\theta/2}s(\theta)+6ABt(\theta)\right]$$

where

$$t(\theta)=(8N^2\sin^2\theta/2\cos^2\theta/2+A\cos^2\theta/2+B\sin^2\theta/2)^{-1},$$
$$r(\theta)=3-2\sin^2\theta/2-3At(\theta)\cos^4\theta/2,$$
$$s(\theta)=3-2\cos^2\theta/2-3Bt(\theta)\sin^4\theta/2.$$

When we observe that $t(\theta)>0$ and that

$$r(\theta)>3-2\sin^2\theta/2-3\cos^2\theta/2=\sin^2\theta/2,$$
$$s(\theta)>3-2\cos^2\theta/2-3\sin^2\theta/2=\cos^2\theta/2,$$

the proof of (3.3) immediately follows.

The application of Sturm's method to the differential equations (3.1) and (2.2) requires an accurate study of the distribution of the zeros $\psi_{n,k}\equiv\psi_{n,k}(\alpha,\beta)$ of the function

$$z_n^{(\alpha,\beta)}(\theta)=[g'(\theta)]^{-1/2}\cos g(\theta). \tag{3.4}$$

If we exclude not only the case $\alpha^2=\beta^2=\frac{1}{4}$, but also the cases in which only one of the two parameters α and β is $\pm\frac{1}{2}$, it is easy to see that $z_n^{(\alpha,\beta)}(\theta)$ has infinitely many zeros

$$\cdots<\psi_{n,-2}<\psi_{n,-1}<\psi_{n,0}<\psi_{n,1}<\psi_{n,2}<\cdots, \tag{3.5}$$

lying in the interval $0<\theta<\pi$. These zeros can be obtained by solving the equations

$$\begin{gathered}N\theta-\left(\alpha+\frac{1}{2}\right)\frac{\pi}{2}-\frac{1}{4N}\left(A\cot\frac{\theta}{2}-B\tan\frac{\theta}{2}\right)=(2k-1)\frac{\pi}{2},\\ A=\tfrac{1}{4}-\alpha^2,\quad B=\tfrac{1}{4}-\beta^2,\quad k=0,\pm1,\pm2,\cdots,\end{gathered} \tag{3.6}$$

with respect to θ; that is they are (see Fig. 2) the abscissae of the intersections of the

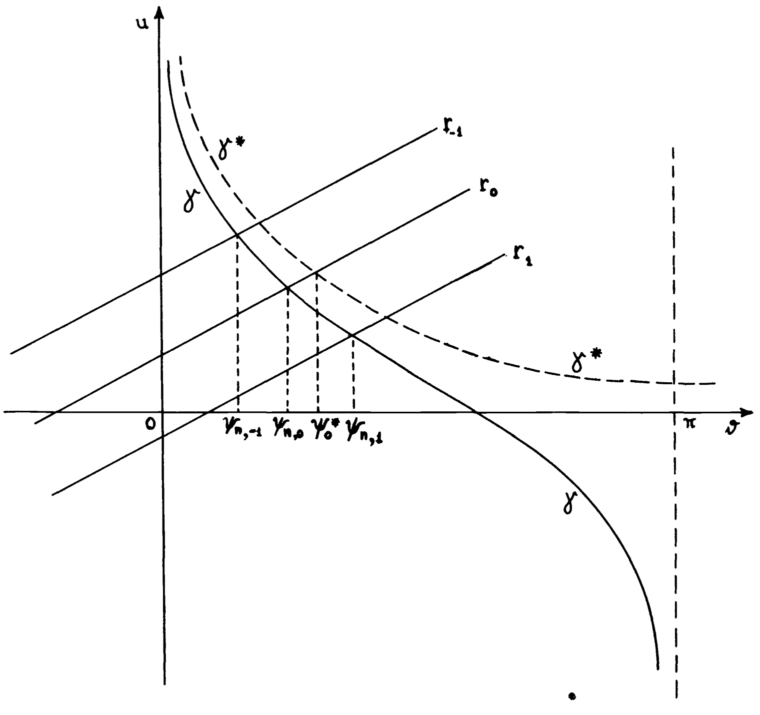

FIG. 2

straight lines r_k

$$u = N\theta - \left(2k + \alpha - \frac{1}{2}\right)\frac{\pi}{2}, \qquad k = 0, \pm 1, \pm 2, \cdots,$$

with the curve γ

$$u = \frac{1}{4N}\left(A \cot\frac{\theta}{2} - B \tan\frac{\theta}{2}\right), \qquad 0 < \theta < \pi.$$

LEMMA 3.1. *The function $z_n^{(\alpha,\beta)}(\theta)$ satisfies the identity*

$$z_n^{(\alpha,\beta)}(\pi - \theta) = (-1)^n z_n^{(\beta,\alpha)}(\theta). \tag{3.7}$$

Consequently, for the zeros $\psi_{n,k}(\alpha, \beta)$ we have

$$\psi_{n,k}(\alpha, \beta) = \pi - \psi_{n,n-k+1}(\beta, \alpha), \qquad k = 0, \pm 1, \pm 2, \cdots. \tag{3.8}$$

The proof is readily obtained by means of (3.4).

LEMMA 3.2. *The zeros $\psi_{n,1}, \psi_{n,2}, \cdots, \psi_{n,n}$* of *$z_n^{(\alpha,\beta)}(\theta)$ belong to the same interval*

$$\frac{1 + (\alpha + \beta - 1)/2}{N}\pi < \theta < \frac{n}{N}\pi, \tag{3.9}$$

as do (*in view of the inequalities of Buell* (1.6)) *the zeros $\theta_{n,k}$ of $P_n^{(\alpha,\beta)}(\cos\theta)$, while the other zeros of $z_n^{(\alpha,\beta)}(\theta)$, i.e., $\cdots < \psi_{n,-2} < \psi_{n,-1} < \psi_{n,0}$ and $\psi_{n,n+1} < \psi_{n,n+2} < \cdots$, lie outside this interval* (3.9).

For the proof we first observe that

$$A \cot\frac{\theta}{2} - B \tan\frac{\theta}{2} < A\frac{2}{\theta}.$$

Then, if ψ_0^* denotes the abscissa (see Fig. 2) of the intersection of the straight line r_0 with the curve γ^*

$$u = \frac{A}{2N\theta}, \qquad \theta > 0,$$

i.e.,

$$\psi_0^* = \frac{1}{2N}\left[\left(\alpha - \frac{1}{2}\right)\frac{\pi}{2} + \sqrt{\left(\alpha - \frac{1}{2}\right)^2\frac{\pi^2}{4} + 2A}\right],$$

it is easy to see that, for $-\frac{1}{2} < \alpha < \frac{1}{2}$ and $-\frac{1}{2} < \beta < \frac{1}{2}$,

$$\psi_{n,0} < \psi_0^* < \frac{\alpha + \beta + 1}{2N}\pi < \psi_{n,1}.$$

By applying Lemma 3.1 we have analogously

$$\psi_{n,n} < \frac{n}{N}\pi < \psi_{n,n+1}.$$

The above results can be extended to the cases $\alpha = \pm\frac{1}{2}$ or $\beta = \pm\frac{1}{2}$ taking into account that, instead of the sequence (3.5), we have one of the two sequences

$$\psi_{n,1} < \psi_{n,2} < \cdots < \psi_{n,n} < \psi_{n,n+1} < \cdots, \text{ or}$$

$$\cdots < \psi_{n,-2} < \psi_{n,-1} < \psi_{n,0} < \psi_{n,1} < \cdots < \psi_{n,n}.$$

We now apply Theorem 1.1 to the differential equations (2.2) and (3.1) relatively to the interval (3.9). Inequality (3.3) readily furnishes the following separation result.

THEOREM 3.1. *Let $-\frac{1}{2}\leqq\alpha\leqq\frac{1}{2}$, $-\frac{1}{2}\leqq\beta\leqq\frac{1}{2}$. Then, between any two consecutive zeros $\theta_{n,h}(\alpha,\beta)$, $h=1,2,\cdots,n$, of the Jacobi polynomial $P_n^{(\alpha,\beta)}(\cos\theta)$ there is at least one zero $\psi_{n,k}(\alpha,\beta)$, $k=1,2,\cdots,n$, of the function $z_n^{(\alpha,\beta)}(\theta)$ defined by* (3.4).

We notice that this theorem does not allow us to derive inequalities satisfied by the zeros $\theta_{n,k}$ for general α and β, $-\frac{1}{2}\leqq\alpha\leqq\frac{1}{2}$ and $-\frac{1}{2}\leqq\beta\leqq\frac{1}{2}$. Indeed, it assures us only that if $\psi_{n,1}\leqq\theta_{n,1}$ or $\psi_{n,n}\geqq\theta_{n,n}$ then, for each $k=1,2,\cdots,n-1$, either $\theta_{n,k}<\psi_{n,k+1}<\theta_{n,k+1}$ or $\theta_{n,k}<\psi_{n,k}<\theta_{n,k+1}$; otherwise there is one of the intervals $[\theta_{n,h},\theta_{n,h+1}]$, $h=1,2,\cdots,n-1$, which contains two ψ-zeros and all the others contain exactly one ψ-zero in their interior. A more precise result can be obtained for the ultraspherical case $\alpha=\beta$.

THEOREM 3.2. *Let $-\frac{1}{2}\leqq\alpha\leqq\frac{1}{2}$ and let $\theta_{n,k}(\alpha)\equiv\theta_{n,k}(\alpha,\alpha)$, $k=1,2,\cdots,n$, be the zeros of the ultraspherical polynomial $P_n^{(\alpha,\alpha)}(\cos\theta)$. Then*

$$\theta_{n,k}(\alpha)\leqq\psi_{n,k}(\alpha),\qquad k=1,2,\cdots,\left[\frac{n}{2}\right]\tag{3.10}$$

where $\psi_{n,k}(\alpha)$ is the root lying in $0<\theta<\pi/2$ of the equation

$$N\theta-\frac{1}{2N}\left(\frac{1}{4}-\alpha^2\right)\cot\theta=\left(2k+\alpha-\frac{1}{2}\right)\frac{\pi}{2},\tag{3.11}$$

with $N=n+\alpha+\frac{1}{2}$. The equality sign in (3.10) *holds only when $\alpha^2=\frac{1}{4}$.*

For the proof we exclude the trivial case $\alpha^2=\frac{1}{4}$ and observe that, according to Lemma 3.1, the zeros $\psi_{n,k}(\alpha)$ are symmetric with respect to $\pi/2$ and that the same property holds for the zeros $\theta_{n,k}(\alpha)$. Hence for n even, the "central" interval

$$\theta_{n,n/2}(\alpha)<\theta<\theta_{n,n/2+1}(\alpha),$$

must contain, by virtue of Theorem 3.1, exactly the two zeros $\psi_{n,n/2}(\alpha)$ and $\psi_{n,n/2+1}(\alpha)$, and consequently each of the other $n-2$ intervals

$$\theta_{n,k}(\alpha)<\theta<\theta_{n,k+1}(\alpha),\qquad k=1,2,\cdots,n-1,\quad k\neq\frac{n}{2},$$

contains exactly one zero $\psi_{n,k}(\alpha)$. For n odd, we have $\psi_{n,(n+1)/2}(\alpha)=\theta_{n,(n+1)/2}(\alpha)=\pi/2$ and each interval

$$\theta_{n,k}(\alpha)<\theta<\theta_{n,k+1}(\alpha),\qquad k=1,2,\cdots,n-1,$$

contains exactly one zero $\psi_{n,k}(\alpha)$, $k\neq(n+1)/2$.

As a consequence of Theorem 3.2 we can obtain an exact statement concerning the location of the zeros of Jacobi polynomials with α or $\beta=\pm\frac{1}{2}$. Indeed, it is well known that the following formulas hold [9, p. 59]:

$$P_{2n}^{(\alpha,\alpha)}(\cos\theta)=\frac{\Gamma(2n+\alpha+1)\Gamma(n+1)}{\Gamma(n+\alpha+1)\Gamma(2n+1)}P_n^{(\alpha,-1/2)}(\cos 2\theta),$$

$$P_{2n+1}^{(\alpha,\alpha)}(\cos\theta)=\frac{\Gamma(2n+\alpha+2)\Gamma(n+1)}{\Gamma(n+\alpha+1)\Gamma(2n+2)}\cos\theta P_n^{(\alpha,1/2)}(\cos 2\theta).$$

Now, observe that similar relationships are valid for the function $z_n^{(\alpha,\beta)}(\theta)$ defined by (3.4). Specifically we have

$$z_{2n}^{(\alpha,\alpha)}(\theta)=2^{-1/2}z_n^{(\alpha,-1/2)}(2\theta),\qquad z_{2n+1}^{(\alpha,\alpha)}(\theta)=2^{-1/2}z_n^{(\alpha,1/2)}(2\theta)$$

where $0<\theta<\pi/2$. Hence, applying Theorem 3.2 and recalling Lemma 3.1, we obtain the following result.

COROLLARY 3.1. *Let* $-\frac{1}{2}\leqq\alpha\leqq\frac{1}{2}$, $-\frac{1}{2}\leqq\beta\leqq\frac{1}{2}$. *Then*

$$\begin{aligned}\theta_{n,k}(\alpha, \pm\tfrac{1}{2})&\leqq\psi_{n,k}(\alpha, \pm\tfrac{1}{2}),\\ \theta_{n,k}(\pm\tfrac{1}{2}, \beta)&\geqq\psi_{n,k}(\pm\tfrac{1}{2}, \beta),\end{aligned}\qquad k=1,2,\cdots n, \tag{3.12}$$

where $\psi_{n,k}(\alpha, \pm\frac{1}{2})$ *and* $\psi_{n,k}(\pm\frac{1}{2}, \beta)$ *are the roots, in* $0<\theta<\pi$, *of the equations*

$$\left[n+(\alpha+1)/2\pm\frac{1}{4}\right]\theta-\frac{1/4-\alpha^2}{4[n+(\alpha+1)/2\pm1/4]}\cot\frac{\theta}{2}=\left(2k+\alpha-\frac{1}{2}\right)\frac{\pi}{2},$$

$$\left[n+(\beta+1)/2\pm\frac{1}{4}\right]\theta+\frac{1/4-\beta^2}{4[n+(\beta+1)/2\pm1/4]}\tan\frac{\theta}{2}=\left(2k\pm\frac{1}{2}-\frac{1}{2}\right)\frac{\pi}{2},$$

respectively. The equality signs in (3.12) *hold when* $\alpha=\pm\frac{1}{2}$ *or* $\beta=\pm\frac{1}{2}$.

Another interesting consequence of Theorem 3.2 can be obtained by observing that $\psi_{n,k}(\alpha)$ is the solution of the equation $\theta=h(\theta)$ in the interval $0<\theta<\pi/2$, where

$$h(\theta)=\frac{2k+\alpha-1/2}{N}\frac{\pi}{2}+\frac{1}{2N^2}\left(\frac{1}{4}-\alpha^2\right)\cot\theta,$$

and that, from (3.10) and (1.7),

$$\psi_{n,k}(\alpha)\geqq\theta_{n,k}(\alpha)\geqq\phi_{n,k}(\alpha)=\frac{2k+\alpha-1/2}{N}\frac{\pi}{2}.$$

Since $h(\theta)$ is monotonic decreasing, we have

$$\theta_{n,k}(\alpha)\leqq\psi_{n,k}(\alpha)=h(\psi_{n,k}(\alpha))\leqq h(\phi_{n,k}(\alpha));$$

that is, the following final result holds.

COROLLARY 3.2. *Let* $-\frac{1}{2}\leqq\alpha\leqq\frac{1}{2}$ *and let* $\theta_{n,k}(\alpha)$, $k=1,2,\cdots,[n/2]$, *be the zeros of* $P_n^{(\alpha,\alpha)}(\cos\theta)$. *Then*

$$\phi_{n,k}(\alpha)\leqq\theta_{n,k}(\alpha)\leqq\phi_{n,k}(\alpha)+\frac{1}{2N^2}\left(\frac{1}{4}-\alpha^2\right)\cot\phi_{n,k}(\alpha) \tag{3.13}$$

where

$$N=n+\alpha+\frac{1}{2},\qquad \phi_{n,k}(\alpha)=\frac{2k+\alpha-1/2}{N}\frac{\pi}{2}.$$

The equality signs in (3.13) *hold only when* $|\alpha|=\frac{1}{2}$.

This corollary establishes that the approximations obtained by omitting the O-term in the Gatteschi-Pittaluga formula (1.5) are upper bounds for $\theta_{n,k}(\alpha)$, $k=1,2,\cdots,[n/2]$, in the ultraspherical case.

These bounds are very sharp, except for the early values of k, and numerical comparisons have shown that they are better than those derived from the Ahmed, Muldoon and Spigler inequality (1.12).

Corollary 2.1 provides lower bounds of a nonelementary type, that is in terms of the zeros of the Bessel function $J_\alpha(x)$. For elementary lower bounds we can use (3.13), that is the Buell inequality (1.7). Moreover, we can use also, as soon as it is convenient, the inequality

$$\theta_{n,k}(\alpha) \geqq \arccos x^*_{n,k}(\alpha) \tag{3.14}$$

where $x^*_{n,k}(\alpha)$ is defined by

$$x^*_{n,k}(\alpha) = \left[\frac{2n^2+4n+3}{2n^2+1+(2\alpha+1)(2n+1)}\right]^{1/2} \cos\frac{k\pi}{n+1}$$

for the values of k and α such that the right-hand side of (1.11) is $\leqq 1$. Ahmed, Muldoon and Spigler [2] have observed that (3.14) is sometimes sharper than (1.7).

In Table 2 the exact values of the zeros $\theta_{16,k}(0)$, $k = 1, 2, \cdots, 8$, of the Legendre polynomial $P_{16}(\cos\theta)$ are compared with the upper bounds given by (3.13), the lower bounds given by the nonelementary inequality (2.16) and the lower bounds obtained from the larger of (3.13) or (3.14). The asterisk indicates the case where the lower bound in (3.14) is better than the one in (3.13).

TABLE 2

Bounds for the zeros $\theta_{16,k}(0)$.

k	Lower bound (3.13) or (3.14)	Lower bound (2.16)	Exact value	Upper bound (3.13)

NEW PROPERTIES OF THE ZEROS OF A JACOBI POLYNOMIAL IN RELATION TO THEIR CENTROID*

ÁRPÁD ELBERT† AND ANDREA LAFORGIA‡

Abstract. In this paper we investigate the sign of $(d/dx)^i P_n^{(\alpha,\beta)}(x)$, $(i=0,1,\cdots,n)$ at the point $x=s_n=(\beta-\alpha)/(2n+\alpha+\beta)$, where $P_n^{(\alpha,\beta)}(x)$ is the Jacobi polynomial of degree n. As an application we establish new inequalities for the zeros $x_{nk}^{(\alpha,\beta)}$ of $P_n^{(\alpha,\beta)}(x)$. The asymptotic property $x_{nk}^{(\alpha,\beta)}\to s_n$, as the parameters α, β tend to ∞ in a particular way, is shown.

Key words. Jacobi polynomials, zeros of Jacobi polynomials, asymptotics

AMS(MOS) subject classification. Primary 33A65

1. Introduction and preliminaries. The ultraspherical polynomials $P_n^{(\lambda)}(x)$ satisfy the symmetry relation [3, p. 80]

$$(1.1)\qquad P_n^{(\lambda)}(-x)=(-1)^n P_n^{(\lambda)}(x),\qquad n=1,2,\cdots,\quad \lambda>-\tfrac{1}{2}$$

which implies

$$(1.2)\qquad P_{2k-1}^{(\lambda)}(0)=0,\quad \frac{d}{dx}P_{2k}^{(\lambda)}(x)\bigg|_{x=0}=0,\quad k=1,2,\cdots,\quad \lambda>-\tfrac{1}{2}.$$

Thus the value $x=0$ plays a particular role in studying the properties of the ultraspherical polynomials. The usefulness of properties (1.2) can be seen for example in applications of Sturmian comparison theorems where the value $x=0$ is used as the initial point. Unfortunately the properties (1.1) and (1.2) cannot be extended to the more general case of Jacobi polynomials $P_n^{(\alpha,\beta)}(x)$, $\alpha,\beta>-1$. (In the common notation we have $P_n^{(\lambda)}(x)=P_n^{(\lambda-1/2,\lambda-1/2)}(x)$.) Thus in Jacobi's case the question arises naturally to find a value s_n which would play a similar role as $x=0$ in (1.2).

For $\alpha,\beta>-1$ and $n=1,2,\cdots$ let s_n be defined by

$$(1.3)\qquad s_n=s_n^{(\alpha,\beta)}=\frac{\beta-\alpha}{2n+\alpha+\beta}.$$

We know that $P_n^{(\alpha,\beta)}(x)$ has single zeros $x_{nk}=x_{nk}^{(\alpha,\beta)}(k=1,2,\cdots,n)$ in $(-1,1)$ denoted in decreasing order, i.e., $1>x_{n1}>x_{n2}>\cdots>x_{nn}>-1$.

We observe that the zeros x_{nk} and the value s_n in (1.3) are connected by

$$(1.4)\qquad s_n=\frac{1}{n}\sum_{k=1}^{n}x_{nk}.$$

The meaning of (1.4) is that s_n is the *centroid* of the zeros of $P_n^{(\alpha,\beta)}(x)$. In fact the polynomial $P_n^{(\alpha,\beta)}(x)$ can be written as

$$\begin{aligned}P_n^{(\alpha,\beta)}(x)&=k_n^{(\alpha,\beta)}(x-x_{n1})(x-x_{n2})\cdots(x-x_{nn})\\&=k_n^{(\alpha,\beta)}[x^n-(x_{n1}+x_{n2}+\cdots+x_{nn})x^{n-1}+\cdots]\\&=k_n^{(\alpha,\beta)}(x^n+r_n^{(\alpha,\beta)}x^{n-1}+\cdots).\end{aligned}$$

Therefore [1, p. 169]

$$x_{n1}+x_{n2}+\cdots+x_{nn}=-r_n^{(\alpha,\beta)}=n\frac{\beta-\alpha}{2n+\alpha+\beta}$$

which proves (1.4).

Actually we have by [1, 10.8 (16), (17)]

$$2P_1^{(\alpha,\beta)}(x)=(2+\alpha+\beta)x-\beta+\alpha,$$

$$\frac{d}{dx}P_2^{(\alpha,\beta)}(x)=\frac{1}{2}(\alpha+\beta+3)P_1^{(\alpha+1,\beta+1)}(x)=\frac{1}{2}(\alpha+\beta+3)[(4+\alpha+\beta)x+\alpha-\beta],$$

and it is not difficult to see that

$$P_1^{(\alpha,\beta)}(s_1)=0,\qquad \frac{d}{dx}P_2^{(\alpha,\beta)}(s_2)=0$$

which resembles (1.2) for $n=1$ and $n=2$.

Now we can formulate the main results, which shows that the situation changes completely for $n\geqq 3$.

THEOREM 1.1. *Let $n=1,2,\cdots$, $\alpha,\beta>1$, $\alpha\neq\beta$. Let s_n be defined by* (1.4) *and put $k=[(n-1)/2]$, $\gamma_k=8k^2/(k-1)(2k-1)$. Then the Jacobi polynomial $P_n^{(\alpha,\beta)}(x)$ satisfied the relations*

$$\left(\frac{d}{dx}\right)^n P_n^{(\alpha,\beta)}(x)\bigg|_{x=s_n}>0,\quad \left(\frac{d}{dx}\right)^{n-1} P_n^{(\alpha,\beta)}(x)\bigg|_{x=s_n}=0,$$

$$(-1)^i\left(\frac{d}{dx}\right)^{n-2i} P_n^{(\alpha,\beta)}(x)\bigg|_{x=s_n}>0,\quad (-1)^{i+1}(\beta-\alpha)\left(\frac{d}{dx}\right)^{n-2i-1} P_n^{(\alpha,\beta)}(x)\bigg|_{x=s_n}>0, \tag{1.5}$$

for $i=1$ and for $i=2,3,\cdots,k$, $|\alpha-\beta|<\sqrt{\gamma_k}$. Moreover if n is even then also the inequality

$$(-1)^{n/2}P_n^{(\alpha,\beta)}(s_n)>0$$

holds for $\alpha,\beta>0$ and $|\alpha-\beta|\leqq\sqrt{\gamma_{k+1}}$.

Theorem 1.1 will be proved in § 2. In § 3 some applications and consequences of our theorem will be given.

2. The proof of Theorem 1.1. For the proof of the theorem we shall need the following result.

LEMMA 2.1. *For real variables a,b let the functions δ_i, $\varepsilon_i (i=1,2,\cdots)$ be defined by the recurrence relations*

$$\varepsilon_1=0,\qquad \delta_1=ab(a+b),$$

$$\varepsilon_{i+1}=\delta_i+ab\left(\frac{a+b}{2i-1}-1\right)\varepsilon_i, \tag{2.1}$$

$$\delta_{i+1}=\left[ab\left(\frac{a+b}{2i}-1\right)-(a-b)^2\right]\delta_i-(a-b)^2ab\left(\frac{a+b}{2i-1}-1\right)\varepsilon_i.$$

Let $j=1,2,3,\cdots$; suppose $a,b\geqq 2j$, for $j=2,3,\cdots$ also $|a-b|\leqq\sqrt{\gamma_j}$, where γ_j has the same meaning as in Theorem 1.1. *Then*

$$\delta_i>\frac{2j-1}{2i-1}(j-i)(a-b)^2\varepsilon_i,\quad \varepsilon_{i+1}>0,\quad \textit{for } i=1,2,\cdots,j. \tag{2.2}$$

Proof. It is clear that the function $\varepsilon_i=\varepsilon_i(a, b)$ and $\delta_i=\delta_i(a, b)$ are polynomials in the variables a, b.

The proof of (2.2) will be carried out by complete induction.

By (2.1) we obtain

$$\delta_1=ab(a+b)>(2j-1)(j-1)(a-b)^2\varepsilon_1=0,$$

$$\varepsilon_2=\delta_1+ab(a+b-1)\varepsilon_1=\delta_1>0,$$

which proves also the validity of (2.2) at $j=1$.

From now on we may assume $j\geqq 2$. Suppose the validity of (2.2) for a fixed $i\in\{1,2,\cdots,j-1\}$. Then we have to prove that

$$\delta_{i+1}>\frac{2j-1}{2i+1}(j-i-1)(a-b)^2\varepsilon_{i+1}$$

which can be written in the form

$$\delta_{i+1}>\sigma_{i+1}\Delta^2\varepsilon_{i+1} \tag{2.3}$$

where the notation

$$\sigma_i=\frac{2j-1}{2i-1}(j-i), \qquad \Delta=|a-b|$$

have been used. By (2.1) the inequality (2.3) is equivalent to

$$\left[ab\left(\frac{a+b}{2i}-1\right)-\Delta^2-\sigma_{i+1}\Delta^2\right]\delta_i>\Delta^2ab\left(\frac{a+b}{2i-1}-1\right)(1+\sigma_{i+1})\varepsilon_i. \tag{2.4}$$

First we prove that the quantity in the brackets is positive. Since $a, b\geqq 2j$, we have

$$ab\left(\frac{a+b}{2i}-1\right)\geqq 4j^2\left(\frac{2j}{i}-1\right)$$

and $\Delta^2\leqq\gamma_j$, hence it is sufficient to show that

$$(2i+1)\left(\frac{2j}{i}-1\right)-\frac{2}{(j-1)(2j-1)}[(2j-1)(j-i-1)+2i+1]>0.$$

Since

$$\frac{(2j-i)(2i+1)}{i}>4j-2i+1$$

then we need only to prove that

$$4j-2i+1-\frac{2}{(j-1)(2j-1)}[(2j-1)(j-i-1)+2i+1]>0, \qquad i=1,2,\cdots,j-1.$$

The expression on the left-hand side is linear in i, thus we have to check this inequality only at $i=1$ and $i=j-1$. Actually at $i=0$ we have

$$4j-1-\frac{2}{(j-1)(2j-1)}>0$$

and at $i=j-1$

$$2j+3-\frac{2}{j-1}>0,$$

respectively. Therefore the coefficient of δ_i in (2.4) is positive. By induction we know that $\delta_i > \sigma_i\Delta^2\varepsilon_i \geqq 0$; thus instead of (2.4) it is sufficient to prove the inequality

$$\sigma_i\left(\frac{a+b}{2i}-1\right)-(1+\sigma_{i+1})\left(\frac{a+b}{2i-1}-1\right)\geqq\sigma_i(1+\sigma_{i+1})\frac{\Delta^2}{ab},\qquad i=1,2,\cdots,j-1,$$

or equivalently

$$\begin{aligned}(a+b-4j+4)[(2j-1)(j+i)-2i(2i+1)]+(j-i-1)[4j(2j-1)+8(j-1)i-8i^2]&\\ \geqq 2i(2j-1)(j-i)[(2j-1)(j-i-1)+2i+1]\frac{\Delta^2}{ab},\qquad i=1,2,\cdots,j-1.&\end{aligned}\tag{2.5}$$

Since the coefficient of $(a+b-4j+4)$ is positive and $a, b\geqq 2j, \Delta^2\leqq\gamma_j=8j^2/(2j-1)(j-1)$, we have only to show that

$$\begin{aligned}Q(i)=4[(2j-1)(j+i)-2i(2i+1)]+(j-i-1)[4j(2j-1)+8(j-1)i-8i^2]&\\ -4i\frac{j-i}{j-1}[(2j-1)(j-i-1)+2i+1]\geqq 0.&\end{aligned}$$

By straightforward calculations $Q(i)$ can be written as

$$Q(i)=4\frac{j-i-1}{j-1}[i(j-i-1)+j(4j^2-j-2)]$$

which is clearly positive for $i=1,2,\cdots,j-2$, while for $i=j-1$, $Q(j-1)=0$. Thus we have proved the inequality $\delta_{i+1}>\sigma_{i+1}\Delta^2\varepsilon_{i+1}$. Since by induction step we know that $\varepsilon_{i+1}>0$, hence $\delta_{i+1}>0$.

To complete the proof of Lemma 2.1 we have still to show that $\varepsilon_{i+2}>0$. But this is true by the recurrence relation (2.1). This completes the proof of Lemma 2.1.

Now we can pass over to the proof of Theorem 1.1.

From [3, p. 68] we know that

$$P_n^{(\alpha,\beta)}(x)=2^{-n}\sum_{m=0}^{n}\binom{n+\alpha}{m}\binom{n+\beta}{n-m}(x-1)^{n-m}(x+1)^m.\tag{2.6}$$

Let us consider the positive variables a, b as

$$a=n+\alpha,\qquad b=n+\beta;\tag{2.7}$$

then by using (1.3) and (2.6) we get

$$s_n=\frac{b-a}{a+b},\qquad P_n^{(\alpha,\beta)}(x)=2^{-n}\sum_{m=0}^{n}\binom{a}{m}\binom{b}{n-m}(x-1)^{n-m}(x+1)^m.\tag{2.8}$$

From [3, p. 63]

$$\begin{aligned}\frac{d}{dx}P_n^{(\alpha,\beta)}(x)&=\frac{1}{2}(n+\alpha+\beta+1)P_{n-1}^{(\alpha,\beta)}(x)\\ &=2^{-n}(n+\alpha+\beta+1)\cdot\sum_{m=0}^{n-1}\binom{a}{m}\binom{b}{n-m-1}(x-1)^{n-m-1}(x+1)^m,\end{aligned}$$

it follows

$$\left(\frac{d}{dx}\right)^l P_n^{(\alpha,\beta)}(x)=2^{-n}(n+\alpha+\beta+1)\cdots(n+\alpha+\beta+l) \tag{2.9}$$
$$\cdot\sum_{m=0}^{n-l}\binom{a}{m}\binom{b}{n-m-l}(x-1)^{n-m-l}(x+1)^m,\quad l=0,1,\cdots,n.$$

For our purposes it is convenient to use the notation

$$c_h=c_h(a,b)=2^{-h}(a+b)^h\sum_{m=0}^{h}\binom{a}{m}\binom{b}{h-m}(s-1)^{h-m}(s+1)^m,\quad h=0,1,\cdots. \tag{2.10}$$

By (2.8) we have $s-1=-2a/(a+b)$, $s+1=2b/(a+b)$; hence

$$c_h=\sum_{m=0}^{h}\binom{a}{m}\binom{b}{h-m}(-a)^{h-m}b^m,\qquad h=0,1,\cdots.$$

It is clear that the function $c_h(a,b)$ is a polynomial in the variables a, b and moreover

$$c_0=1,\quad c_1=0,\quad c_2=\frac{-1}{2}ab(a+b). \tag{2.11}$$

The functions c_h satisfy a recurrence relation which we are going to find. To this end we consider the generating function

$$\phi(x)=\sum_{h=0}^{\infty}c_hx^h. \tag{2.12}$$

We claim that

$$\phi(x)=(1-ax)^b(1+bx)^a, \tag{2.13}$$

so the power series in (2.12) is convergent for $|x|<\min\{1/a, 1/b\}$. Indeed

$$(1-ax)^b=\sum_{k=0}^{\infty}\binom{b}{k}(-ax)^k,\qquad (1+bx)^a=\sum_{m=0}^{\infty}\binom{a}{m}(bx)^m;$$

therefore

$$(1-ax)^b(1+bx)^a=\sum_{k=0}^{\infty}\sum_{m=0}^{\infty}\binom{a}{m}\binom{b}{k}(-a)^kb^mx^{k+m}$$
$$=\sum_{h=0}^{\infty}x^h\sum_{m=0}^{h}\binom{a}{m}\binom{b}{h-m}(-a)^{h-m}b^m=\sum_{h=0}^{\infty}c_hx^h=\phi(x).$$

Taking the logarithmic derivative of $\phi(x)$ in (2.13) we get

$$\frac{\phi'}{\phi}=\frac{-ab(a+b)x}{(1-ax)(1+bx)},$$

or equivalently,

$$[1+(b-a)x-abx^2]\phi'=-ab(a+b)x\phi.$$

Equating the coefficients of the terms x^m in both sides we obtain

$$(m+1)c_{m+1}=-(b-a)mc_m+ab(m-1-a-b)c_{m-1},\qquad m=1,2,\cdots. \tag{2.14}$$

This follows directly from [1, 10.8 (14), (17)]. Now because of (2.11) the values of c_0 and c_1 are known, hence the sequence $\{c_n\}_{n=0}^{\infty}$ is well defined.

Replacing in (2.14) c_m by

$$\begin{aligned}(2i-1)c_{2i-1}&=(-1)^i(b-a)\varepsilon_i, \qquad i=1,2,\cdots,\\ 2ic_{2i}&=(-1)^i\delta_i,\end{aligned}\tag{2.15}$$

we obtain for ε_i and δ_i the recurrence relations (2.1) given in Lemma 2.1. By (2.9), (2.10), (2.15) the connection between the derivatives of $P_n^{(\alpha,\beta)}(x)$ at $x=s_n$ and the functions ε_i and δ_i is the following:

$$(-1)^i\left(\frac{d}{dx}\right)^{n-2i}P_n^{(\alpha,\beta)}(x)\Bigg|_{x=s_n}=\frac{2^{2i-n-1}}{i}(a+b)^{-2i}\delta_i\prod_{j=1}^{n-2i}(n+\alpha+\beta+j),$$

$$(-1)^{i+1}(\beta-\alpha)\left(\frac{d}{dx}\right)^{n-2i-1}P_n^{(\alpha,\beta)}(x)\Bigg|_{x=s_n}$$

$$=\frac{2^{2i-n+1}}{2i+1}(\beta-\alpha)^2(a+b)^{-2i-1}\varepsilon_{i+1}\prod_{j=1}^{n-2i-1}(n+\alpha+\beta+j),$$

where, in view of (2.7), the relation $b-a=\beta-\alpha$ was used. In order to prove Theorem 1.1 we need to show that $\varepsilon_2, \varepsilon_3, \cdots, \varepsilon_{k+1}, \delta_1, \delta_2, \cdots, \delta_k$ are positive.

When n is odd, i.e., $n=2k+1$, applying Lemma 2.1 with $j=k$ we have that $\varepsilon_2, \cdots, \varepsilon_{k+1}$ and $\delta_1, \cdots, \delta_k$ are positive. Finally when n is even, i.e., $n=2k+2$ we have as before the desired sign of the derivatives in (1.5) as in the previous case.

It remains only to investigate the inequality $(-1)^{n/2}P_n^{(\alpha,\beta)}(s_n)>0$, which is equivalent to the relation $\delta_{k+1}>0$. But for $\alpha, \beta \geqq 0$ we can apply the lemma with $j=k+1$ leading to $\delta_{k+1}>0$.

The proof of Theorem 1.1 is complete.

3. Further results. We are concerned in this section with some consequences of Theorem 1.1 and related problems. The first result is the following.

THEOREM 3.1. *Let $x_{ni}^{(\alpha,\beta)}$ denote the ith zero of $P_n^{(\alpha,\beta)}(x)$ in decreasing order and suppose $|\alpha-\beta|<\sqrt{\gamma_k}$, where γ_k has been defined in Theorem 1.1. Then*

(i) *for* $\beta>\alpha>-1$ $\quad x_{2k+1,k+2}^{(\alpha,\beta)}<s_{2k+1}^{(\alpha,\beta)}<x_{2k+1,k+1}^{(\alpha,\beta)}$,

(ii) *for* $\alpha>\beta>-1$ $\quad x_{2k+1,k+1}^{(\alpha,\beta)}<s_{2k+1}^{(\alpha,\beta)}<x_{2k+1,k}^{(\alpha,\beta)}$,

(iii) *for* $\alpha, \beta>0$ $\quad x_{2k,k+1}^{(\alpha,\beta)}<s_{2k}^{(\alpha,\beta)}<x_{2k,k}^{(\alpha,\beta)}$.

Proof. In the interval $(x_{n,i+1}^{(\alpha,\beta)}, x_{ni}^{(\alpha,\beta)})\equiv(x_{i+1}, x_i)$ the polynomial $P_n^{(\alpha,\beta)}(x)$ has the same sign as $(-1)^i$. Moreover applying Theorem 1.1 with $\beta>\alpha$ we get that $(-1)^{k+1}P_{2k+1}^{(\alpha,\beta)}(s_{2k+1})$ is positive. Hence s_{2k+1} belongs to one of the intervals

$$\cdots, (x_{k+4}, x_{k+3}), (x_{k+2}, x_{k+1}), (x_k, x_{k-1}), \cdots.$$

Letting $\beta\to\alpha$ we get $x_{k+1}\to x_{2k+1,k+1}^{(\alpha,\alpha)}=0=s_{2k+1}^{(\alpha,\alpha)}$, thus by continuity argumentation we obtain the only possibility $s_{2k+1}^{(\alpha,\beta)}\in(x_{k+2}^{(\alpha,\beta)}, x_{k+1}^{(\alpha,\beta)})$ which proves the first part of Theorem 3.1. The second part can be proved similarly.

For $\alpha>\beta>-1$ we have $(-1)^kP_{2k+1}^{(\alpha,\beta)}(s_{2k+1}^{(\alpha,\beta)})>0$, thus s_{2k+1} belongs to one of the intervals $\cdots(x_{k+3}, x_{k+2}), (x_{k+1}, x_k), (x_{k-1}, x_{k-2}), \cdots$ and again by continuity argumentation we have the conclusion of part (ii) of Theorem 3.1.

Finally when n is even we have from Theorem 1.1 $(-1)^k P_{2k}^{(\alpha,\beta)}(s_{2k})>0$ and s_{2k} belongs to one of the intervals

$$\cdots, (x_{2k,k+3}, x_{2k,k+2}), (x_{2k,k+1}, x_{2k,k}), (x_{2k,k-1}, x_{2k,k-2}), \cdots.$$

Now, letting $\beta \to \alpha$ we get $s_{2k}^{(\alpha,\beta)} \to 0$.

Moreover by symmetry properties of the ultraspherical polynomials we know that $x_{2k,k}^{(\alpha,\alpha)}>0$ and $x_{2k,k+1}^{(\alpha,\alpha)}<0$. Therefore as before by continuity argumentation we obtain $s_{2k}^{(\alpha,\beta)} \in (x_{2k,k+1}^{(\alpha,\beta)}, x_{2k,k}^{(\alpha,\beta)})$. The proof of Theorem 3.1 is complete.

As an immediate consequence of Theorem 3.1 we have the following result.

COROLLARY 3.1. *For* $|\alpha-\beta|<\sqrt{\gamma_k}$ *the following inequalities*

$$\begin{aligned}
&x_{2k+1,k+1}^{(\alpha,\beta)} > \frac{\beta-\alpha}{4k+\alpha+\beta+2}, \qquad \beta>\alpha>-1,\\
&x_{2k+1,k+1}^{(\alpha,\beta)} < \frac{\beta-\alpha}{4k+\alpha+\beta+2}, \qquad \alpha>\beta>-1,\\
&x_{2k,k}^{(\alpha,\beta)} > \frac{\beta-\alpha}{4k+\alpha+\beta}, \qquad \beta>\alpha>0,\\
&x_{2k,k+1}^{(\alpha,\beta)} < \frac{\beta-\alpha}{4k+\alpha+\beta}, \qquad \alpha>\beta>0
\end{aligned} \tag{3.1}$$

hold.

Remark 3.1. The bounds given in Corollary 3.1 are more stringent than the ones which we could obtain by applying the results of Stieltjes [3, p. 121]

$$\frac{\partial}{\partial\beta} x_{ni}^{(\alpha,\beta)}>0, \qquad \frac{\partial}{\partial\alpha} x_{ni}^{(\alpha,\beta)}<0.$$

Remark 3.2. We do not believe that the inequalities (3.1) are the best ones. Indeed in the particular case $\alpha=-\frac{1}{2}, \beta=\frac{1}{2}$ the Jacobi polynomial $P_n^{(-1/2,1/2)}(x)$ has the form [3, p. 60]

$$P_n^{(-1/2,1/2)}(\cos\theta)=\frac{1\cdot 3\cdot \cdots \cdot(2n-1)}{2\cdot 4\cdot \cdots \cdot 2n}\,\frac{\cos((2n+1)/2)\,\theta}{\cos\theta/2}.$$

Thus for $n=2k+1$ we get

$$x_{2k+1,k+1}^{(-1/2,1/2)}=\cos\frac{2k+1}{4k+3}\pi=\sin\frac{\pi}{2(4k+3)},$$

while $s_{2k+1}=1/(4k+2)$. So we lead to the following question: Let $-1<\alpha<\beta$. For which values of $\mu_1, \mu_2>0$ do the inequalities

$$\mu_1\frac{\beta-\alpha}{4k+\alpha+\beta+2}<x_{2k+1,k+1}^{(\alpha,\beta)}<\mu_2\frac{\beta-\alpha}{4k+\alpha+\beta+2}$$

hold? By Theorem 3.1 this is true with $\mu_1=1$. We suspect that $\mu_2=\pi/2$. It is clear that a similar question can be considered for even n.

Concerning the zeros of Jacobi polynomials $P_n^{(\alpha,\beta)}(x)$ under the condition $-\frac{1}{2}\leqq\alpha\leqq\frac{1}{2}$, $-\frac{1}{2}\leqq\beta\leqq\frac{1}{2}$ we have the inequalities [3, p. 125]

$$\frac{2i+\alpha+\beta-1}{2n+\alpha+\beta+1}\pi<\theta_{ni}^{(\alpha,\beta)}<\frac{2i}{2n+\alpha+\beta+1}\pi, \qquad i=1,2,\cdots,n, \tag{3.2}$$

where, as usual

$$x_{ni}^{(\alpha,\beta)}=\cos\,\theta_{ni}^{(\alpha,\beta)}=\cos\,\theta_{ni}.$$

The results of Theorem 3.1 enable us to improve several bounds in (3.2). The results are given in what follows.

THEOREM 3.2. *For* $-\frac{1}{2}\leqq\alpha<\beta\leqq\frac{1}{2}$ *the function* $P_{2k+1}^{(\alpha,\beta)}(\cos\,\theta)$ *has exactly k zeros such that*

$$\frac{\pi}{2}<\theta_{2k+1,k+2}<\theta_{2k+1,k+3}<\cdots\theta_{2k+1,2k+1}<\pi.$$

Moreover the inequalities

$$\theta_{2k+1,i}<\frac{\pi}{2}-\tau+\frac{2(i-k-1)}{4k+\alpha+\beta+3}\pi,\qquad i=k+1,\cdots,2k+1,$$

hold, where

$$\tau=\arcsin\,((\beta-\alpha)/(4+\alpha+\beta+2)).$$

Proof. By the lower bound in (3.2) we obtain for $n=2k+1$, $i=k+2$

$$\theta_{2k+1,k+2}>\frac{2k+\alpha+\beta+3}{4k+\alpha+\beta+3}\pi$$

and the right-hand side is larger than $\pi/2$, because $\alpha+\beta+3>0$. Therefore the values $\theta_{2k+1,i}(i=k+2,k+3,\cdots,2k+1)$ lie in $(\pi/2,\pi)$.

On the other hand by [3, p. 125, (6.3.3)] we have also the inequality

$$\theta_{2k+1,i+1}-\theta_{2k+1,i}\leqq\frac{2\pi}{4k+\alpha+\beta+3},\qquad i=1,2,\cdots,2k,\tag{3.3}$$

where equality occurs only for $|\alpha|=\frac{1}{2}$, $|\beta|=\frac{1}{2}$.

For $\beta-\alpha\leqq1<\sqrt{\gamma_k}$ we can apply Theorem 3.1 leading to the inequality

$$x_{2k+1,k+1}=\cos\,\theta_{2k+1,k+1}>\frac{\beta-\alpha}{4k+\alpha+\beta+2}=\cos\left(\frac{\pi}{2}-\tau\right),$$

hence

$$\theta_{2k+1,k+1}^{(\alpha,\beta)}<\frac{\pi}{2}-\tau.$$

We conclude that there are exactly k zeros in $(\pi/2,\pi)$.

By repeated applications of inequality (3.3) for $i=k+1,k+2,\cdots,2k$ we obtain the desired inequality for $\theta_{2k+1,i+1}$ which completes the proof of Theorem 3.2.

In the case $|\alpha|\geqq\frac{1}{2}$, $|\beta|\geqq\frac{1}{2}$ similar results are established in the following theorem.

THEOREM 3.3. *For* $|\alpha|\geqq\frac{1}{2}$, $|\beta|\geqq\frac{1}{2}$ *and* $-1<\alpha<\beta<\alpha+\sqrt{\gamma_k}$ *the function* $P_{2k+1}^{(\alpha,\beta)}(\cos\,\theta)$ *has at least* $k+1$ *zeros in* $(0,\pi/2)$ *such that the inequalities*

$$\theta_{2k+1,i}<\frac{\pi}{2}-\tau-\frac{2(k+1-i)}{4k+\alpha+\beta+3}\pi,\qquad i=1,2,\cdots,k+1$$

hold, where τ *is the same as in Theorem* 3.2.

Proof. The proof runs on the same lines as the proof of Theorem 3.2. We observe that following the same arguments given in [3, p. 125] for the proof of inequality (3.3) we obtain

$$\theta_{2k+1,i+1}-\theta_{2k+1,i}\geqq\frac{2\pi}{4k+\alpha+\beta+3},\qquad i=1,2,\cdots,2k,|\alpha|\geqq\tfrac{1}{2},\qquad|\beta|\geqq\tfrac{1}{2}$$

(where equality occurs if and only if $|\alpha|=|\beta|=\frac{1}{2}$) and the conclusion of Theorem 3.3 follows from these inequalities using Theorem 3.1.

Remark 3.3. For $|\alpha|, |\beta| \geqq \frac{1}{2}$, $\alpha>\beta$ a similar argumentation gives that the function $P^{(\alpha,\beta)}_{2k+1}(\cos\theta)$ has exactly k zeros $\theta_{2k+1,i}(i=k+2, \cdots 2k+1)$ in $(\pi/2, \pi)$ which satisfy

$$\theta_{2k+1,i}>\frac{\pi}{2}+\tau+\frac{2(i-k-1)}{4k+\alpha+\beta+3}\pi, \quad i=k+2, \cdots 2k+1, \quad \alpha-\beta<\sqrt{\gamma_k}.$$

In the case $n=2k$ the following result can be established.

THEOREM 3.4. *For $0<\alpha<\beta\leqq\frac{1}{2}$ the last $k+1$ zeros of the function $P^{(\alpha,\beta)}_{2k}(\cos\theta)$ satisfy the inequalities*

$$\theta_{2k,k}<\frac{\pi}{2}<\theta_{2k,k+1}<\cdots<\theta_{2k,2k}<\pi,$$

$$\theta_{2k,i}<\frac{\pi}{2}-\nu+\frac{2(i-k)}{4k+\alpha+\beta+1}\pi, \qquad i=k+1, \cdots, 2k$$

where

$$\nu=\arcsin((\beta-\alpha)(4k+\alpha+\beta)).$$

Proof. From (3.2) we obtain

$$\theta_{2k,k+1}>\frac{2k+\alpha+\beta+1}{4k+\alpha+\beta+1}\pi>\frac{\pi}{2}.$$

Therefore the values $\theta_{2k,i}(i=k+1, k+2, \cdots 2k)$ lie in $(\pi/2, \pi)$.

On the other hand

$$\theta_{2k,k}<\frac{2k}{4k+\alpha+\beta+1}\pi<\frac{\pi}{2}$$

and we conclude that in $(\pi/2, \pi)$ there are *exactly* k zeros of $P^{(\alpha,\beta)}_{2k}(\cos\theta)$. Now by Corollary 3.1 with $\beta>\alpha$ we obtain

$$x_{2k,k}=\cos\theta_{2k,k}>\frac{\beta-\alpha}{4k+\alpha+\beta}=\cos\left(\frac{\pi}{2}-\nu\right), \qquad \beta>\alpha>0,$$

hence

$$\theta_{2k,k}<\frac{\pi}{2}-\nu.$$

Using this inequality in [3, (6.3.3)], by repeated applications, we get

$$\theta_{2k,i}<\frac{\pi}{2}-\nu+\frac{2(i-k)}{4k+\alpha+\beta+1}\pi, \qquad i=k+1, \cdots, 2k$$

which is the conclusion of the theorem.

Now we turn our attention to another interesting property of Jacobi polynomial $P^{(\alpha,\beta)}_n(x)$ which is also related to the *centroid* s_n of its zeros.

THEOREM 3.5. *Suppose $\alpha, \beta>-1$ and $\mu\geqq1$. Denote by $x_1(\mu), x_2(\mu)\cdots x_n(\mu)$ the zeros of the Jacobi polynomial $P^{((\mu-1)n+\mu\alpha, (\mu-1)n+\mu\beta)}_n(x)$ in decreasing order. Then the asymptotic relations*

$$\lim_{\mu\to\infty} x_i(\mu)=s_n=-\frac{\beta-\alpha}{2n+\alpha+\beta}, \qquad i=1,2, \cdots, n \tag{3.4}$$

hold.

Proof. Using (2.7) and (2.8) we have to consider the polynomial

$$Q_n(x;\mu)=2^nP_n^{((\mu-1)n+\mu\alpha,\,(\mu-1)n+\mu\beta)}(x)$$
$$=\sum_{m=0}^{n}\binom{\mu a}{m}\binom{\mu b}{n-m}(x-1)^{n-m}(x+1)^m.$$

It is clear that $Q_n(x;\mu)$ is also a polynomial with respect to μ which can be written in the form

$$Q_n(x;\mu)=\mu^nR_{nn}(a,b;x)+\mu^{n-1}R_{n,n-1}(a,b;x)+\cdots+R_{n0}(a,b;x),$$

where

$$R_{nn}(a,b;x)=\sum_{m=0}^{n}\frac{a^mb^{n-m}}{m!(n-m)!}(x-1)^{n-m}(x+1)^m$$
$$=\frac{1}{n!}[a(x+1)+b(x-1)]^n=\frac{(a+b)^n}{n!}(x-s)^n.$$

Substituting $x=x_i(\mu)$ in $Q_n(x;\mu)$ and letting $\mu\to\infty$, we find the desired result.

Remark 3.4. We observe that for $\alpha=\beta$, Theorem 3.4 gives the known result [1, p. 203, (6)] that the zeros of ultraspherical polynomial $P_n^{(\lambda)}(x)$ tend to zero if $\lambda\to\infty$. This result together with the classical Stieltjes' theorem [3, p. 121]

$$\frac{\partial}{\partial\lambda}x_{ni}^{(\lambda)}<0,\qquad i=1,2,\cdots,\left[\frac{n}{2}\right]$$

gives that $x_{ni}^{(\lambda)}$ tends to zero monotonically.

This property suggests the following question: Do the zeros $x_i(\mu)(i=1,2,\cdots n)$ of the polynomial $P_n^{((\mu-1)n+\alpha n,\,(\mu-1)n+\beta n)}(x)$ tend monotonically to zero if $\mu\to\infty$?

We conjecture that this property is true.

Remark 3.5. Finally we observe that (3.4) can be thought of as complementing the result of Moak, Saff and Varga proved in [2] where for $n\to\infty$ the behavior of the smallest and largest zeros of the Jacobi polynomials was studied.

EXPLICIT FORMULA RELATING THE JACOBI, HAHN AND BERNSTEIN POLYNOMIALS*

Z. CIESIELSKI†

Abstract. A new connection between Jacobi and Hahn polynomials is given.

Key words. orthogonal polynomials, Jacobi polynomials, Hahn polynomials, Bernstein polynomials

AMS(MOS) subject classification. 33A65

The real linear space of all algebraic polynomials of degree not exceeding n is denoted by Π_n. Clearly, $\dim \Pi_n = n+1$.

The Bernstein polynomials

$$N_{i,n}(x)=\binom{n}{i}\left(\frac{1+x}{2}\right)^i\left(\frac{1-x}{2}\right)^{n-i}, \qquad i=0,\cdots,n$$

form a basis in Π_n.

For $\alpha, \beta > -1$ the Jacobi polynomials are defined by the Rodrigues formula

$$P_n^{(\alpha,\beta)}(x)=\frac{(-1)^n}{2^n n!(1-x)^\alpha(1+x)^\beta}D^n[(1-x^2)^n(1-x)^\alpha(1+x)^\beta], \qquad n=0,1,\cdots$$

where $D=d/dx$. The set $(P_n^{(\alpha,\beta)})_0^\infty$ is orthogonal with respect to the scalar product

$$\int_{-1}^1 f(x)g(x)(1-x)^\alpha 1+x)^\beta\,dx.$$

Since

$$\Pi_n=\operatorname{span}[P_0^{(\alpha,\beta)},\cdots,P_n^{(\alpha,\beta)}]$$

it follows that for each $j=0,\cdots,n$ there is a unique vector $(h_{j,n}(0),\cdots,h_{j,n}(n))$ such that

$$P_j^{(\alpha,\beta)}=\sum_{i=0}^n h_{j,n}(i)N_{i,n}.$$

We denote by $h_{j,n}$ the polynomial $h_{j,n}(\cdot)\in\Pi_n$ interpolating the points $(0,h_{j,n}(0)),\cdots,(n,h_{j,n}(n))$.

Our aim is to show that $(h_{j,n})_{j=0}^n$ are proportional to the Hahn polynomials.

For given $\alpha,\beta>-1$ and integer $n\geqq 0$ the jth Hahn polynomial $h_{j,n}^{(\alpha,\beta)}$ is defined by the Rodriques formula [3]

$$h_{j,n}^{(\alpha,\beta)}(x)=\frac{(-1)^j}{j!}\frac{1}{\rho(x)}\nabla^j_{\rho_j}(x),$$

where $\nabla f(x)=f(x)-f(x-1)$ and

$$\rho(x)=\frac{\Gamma(\alpha+1+n-x)\Gamma(\beta+1+x)}{\Gamma(1+n-x)\Gamma(1+x)},$$

$$\rho_j(x)=\frac{\Gamma(\alpha+1+n-x)\Gamma(\beta+1+x+j)}{\Gamma(1+n-(x+j))\Gamma(1+x)}.$$

* Received by the editors April 15, 1986; accepted for publication July 2, 1986.

† Instytut Matematyczny PAN, 81-825, Sopot, Poland.

For $j=0,\cdots,n$, we have $h_{j,n}^{(\alpha,\beta)}\in\Pi_j$ and these polynomials are orthogonal with respect to the scalar product

$$\sum_{i=0}^{n} f(i)g(i)\rho(i)$$

with the weight ρ.

THEOREM. *Let $\alpha,\beta>-1$ and the integer $n\geqq 0$ be given. Then*

$$(n)_jP_j^{(\alpha,\beta)}=\sum_{i=0}^{n} h_{j,n}^{(\alpha,\beta)}(i)N_{i,n},\qquad j=0,\cdots,n$$

where $(n)_j=n(n-1)\cdots(n-j+1)$.

For the proof we introduce the following singular operators:

$$(Lf)(x)=(1-x^2)(D^2f)(x)+[\beta-\alpha-(\alpha+\beta+2)x](Df)(x),$$
$$(l_nf)(i)=i(n+\alpha+1-i)(\nabla\Delta f)(i)+[(\beta+1)n-(\alpha+\beta+2)i](\Delta f)(i),$$

where $(\Delta f)(i)=f(i+1)-f(i)$.

LEMMA. *Let $H\in\Pi_n$ and let*

$$H=\sum_{i=0}^{n} h(i)N_{i,n}.$$

Then

$$LH=\sum_{i=0}^{n}(l_nh)(i)N_{i,n}.$$

Proof. One checks directly the identity $(i=0,\cdots,n)$

$$DN_{i,n}=\frac{n}{2}[N_{i-1,n-1}-N_{i,n-1}],$$

where $N_{-1,n-1}=N_{n,n-1}=0$. It gives the formulas

$$DH=\frac{n}{2}\sum_{i=0}^{n-1}\Delta h(i)N_{i,n-1},$$

$$D^2H=\frac{n(n-1)}{4}\sum_{i=0}^{n-2}\Delta^2h(i)N_{i,n-2}.$$

This and the definition of $N_{i,n}$ imply that

$$x(DH)(x)=\left[\frac{1+x}{2}-\frac{1-x}{2}\right](DH)(x)$$
$$=\frac{1}{2}\sum_{i=0}^{n}[i(\nabla h)(i)-(n-i)(\Delta h)(i)]N_{i,n}(x)$$

and

$$(1-x^2)(D^2H)(x)=\sum_{i=0}^{n} i(n-i)(\nabla\Delta)h(i)N_{i,n}(x).$$

Moreover, since

$$N_{i,n-1}=\frac{i+1}{n}N_{i+1,n}+\frac{n-i}{n}N_{i,n}$$

we have

$$DH=\frac{1}{2}\sum_{i=0}^{n}[i(\nabla h)(i)+(n-i)(\Delta h)(i)]N_{i,n}.$$

Now, $\nabla\Delta=\Delta-\nabla$ and therefore

$$\begin{aligned}i(n-i)\nabla\Delta+\frac{\beta-\alpha}{2}i\nabla+\frac{\beta-\alpha}{2}(n-i)\Delta-\frac{\alpha+\beta+2}{2}i\nabla+\frac{\alpha+\beta+2}{2}(n-i)\Delta\\ =i(n-i)\nabla\Delta+(\alpha+1)i(\nabla\Delta-\Delta)+(\beta+1)(n-i)\Delta\\ =i(n-i+\alpha+1)\nabla\Delta+[(\beta+1)n-(\alpha+\beta+2)i]\Delta,\end{aligned}$$

whence we infer the thesis of the lemma.

Proof of the theorem. It is known [3] that $j(j+\alpha+\beta+1), j=0,\cdots,n$, are simple eigenvalues for both operators $L:\Pi_n\to\Pi_n$ and $l_n:\Pi_n\to\Pi_n$.

Their corresponding eigenvectors are $P_j^{(\alpha,\beta)}, j=0,\cdots,n$, and $h_{j,n}^{(\alpha,\beta)}, j=0,\cdots,n$, respectively. Applying the lemma to $H=P_j^{(\alpha,\beta)}$we find

$$0=LH-j(j+\alpha+\beta+1)H=\sum_{i=0}^{n}(l_nh-j(j+\alpha+\beta+1)h)(i)N_{i,n},$$

whence

$$l_nh=j(j+\alpha+\beta+1)h,$$

and therefore $h=Ch_j^{(\alpha,\beta)}$ i.e.

$$P_j^{(\alpha,\beta)}=C\sum_{i=0}^{n}h_{j,n}^{(\alpha,\beta)}(i)N_{i,n}.$$

Using the Rodriques formulas defining $P_j^{(\alpha,\beta)}$ and $h_{j,n}^{(\alpha,\beta)}$ we find that $C\cdot(n)_j=1$, and this completes the proof.

The theorem in case of $\alpha=\beta=0$ was established earlier in [1] by a different method not extendable to the general case of $\alpha,\beta>-1$.

Consequences and applications of the theorem will be discussed elsewhere.

Remark. After this note was submitted to this Journal, Richard Askey and George Gasper kindly communicated to the author that the theorem can also be obtained with the help of the hypergeometric representations of the Jacobi and Hahn polynomials.

MULTILATERAL SUMMATION THEOREMS FOR ORDINARY AND BASIC HYPERGEOMETRIC SERIES IN $U(n)$*

R. A. GUSTAFSON†

Abstract. In this paper we prove generalizations of ${}_2H_2$, ${}_5H_5$, ${}_1\Psi_1$, and ${}_6\Psi_6$ summation theorems for hypergeometric series in $U(n)$. This includes a further generalization of Milne's ${}_1\Psi_1$ summation theorem for basic hypergeometric series in $U(n)$. These results are mostly obtained by use of contour integration together with Milne's $U(n)$ generalizations of the Gauss, ${}_5F_4$ and ${}_6\varphi_5$ summation theorems.

Key words. hypergeometric series in $U(n)$, summation theorems, contour integrals, basic hypergeometric series, bilateral series

AMS(MOS) subject classifications. 33A75, 33A30, 33A35

1. Introduction and statement of results. In 1976 Holman, Biedenharn and Louck [12] and later Holman [11] defined interesting multivariable generalizations of the classical hypergeometric series and well-poised hypergeometric series, which they called hypergeometric series in $U(n)$. These definitions arose out of a problem in mathematical physics of finding analogues of the Wigner $(3-j)$ and Racah $(6-j)$ coefficients of angular momentum theory for the higher dimensional unitary groups. It was realized that many of the fundamental identities for the $3-j$ and $6-j$ coefficients were consequences of classical transformation and summation theorems for hypergeometric series. Holman [11] showed that, conversely, the corresponding identities for higher dimensional multiplicity-free Wigner and Racah coefficients implied generalizations of classical summation theorems to the setting of hypergeometric series in $U(n)$.

There were several important summation and transformation theorems for classical hypergeometric series for which Holman did not provide generalizations for hypergeometric series in $U(n)$. For example, he did not prove generalizations of the nonterminating Gauss summation theorem, nor a $U(n)$ generalization of Whipple's well-poised ${}_7F_6$ transformation. Furthermore, there remained the question of defining a q-analogue of the hypergeometric series in $U(n)$ whose properties would generalize those of the classical basic hypergeometric series. The importance of doing so was discussed by Andrews in [2].

Recently, Milne has proved a nonterminating $U(n)$ Gauss summation theorem [20] (see Theorem 2.7 below) and the present author gave a generalization of Whipple's transformation for hypergeometric series in $U(n)$ [10]. Milne has also defined a basic analogue of the hypergeometric series in $U(n)$ and proved a number of important properties for them [15]-[20]. Using a $U(n)$ generalization of the q-binomial theorem [15] that he found and an analytic continuation argument similar to that in Ismail [13], Milne [18] proved a $U(n)$ generalization of Ramanujan's ${}_1\Psi_1$, summation theorem for bilateral basic hypergeometric series. A specialization of Milne's ${}_1\Psi_1$ theorem gives the Macdonald identities for affine root systems of type $A_l^{(1)}$ [14], [15] in the same way as a specialization of the classical ${}_1\Psi_1$ theorem gives the Jacobi triple product identity. Milne also proved a $U(n)$ generalization of a terminating version of the well-poised ${}_6\varphi_5$ summation theorem [17] and used analytic continuation to obtain a nonterminating $U(n)$ ${}_6\varphi_5$ summation theorem [19]. This theorem is also important in that it clarifies the concept of "well-poised" hypergeometric series in the setting of hypergeometric series in $U(n)$.

* Received by the editors July 23, 1986; accepted for publication February 9, 1987.

† Department of Mathematics, Texas A&M University, College Station, Texas 77843.

In this paper we prove $U(n)$ generalizations of some of the classical summation theorems for bilateral hypergeometric series and also for basic bilateral hypergeometric series. The method of proof is to begin with a summation theorem for one-sided (basic) hypergeometric series in $U(n)$ and use contour integration to inductively prove their multilateral generalizations. We also obtain a further generalization of Milne's ${}_1\Psi_1$ summation theorem as a consequence of a $U(n)$ generalization of the well-poised ${}_6\Psi_6$ summation theorem.

In order to define hypergeometric series we must first define the rising factorial (or Pochhammer symbol):

$$(c)_n=\frac{\Gamma(c+n)}{\Gamma(c)} \tag{1.1}$$

for $n\in\mathbb{Z}$, $c\in\mathbb{C}$.

If $n>0$, then

$$(c)_n=(c)(c+1)\cdots(c+n-1), \tag{1.2a}$$

$$(c)_{-n}=\frac{(-1)^n}{(1-c)(2-c)\cdots(n-c)} \tag{1.2b}$$

and

$$(c)_0=1. \tag{1.2c}$$

For the q-analogue, let q be a complex number with $|q|<1$ and for $a\in\mathbb{C}$, $n>0$, define

$$[a]_n=(a;\,q)_n=(1-a)(1-aq)\cdots(1-aq^{n-1}) \tag{1.3a}$$

and

$$[a]_\infty=\prod_{k=0}^{\infty}(1-aq^k). \tag{1.3b}$$

For $n\in\mathbb{Z}$, define

$$[a]_n=\frac{[a]_\infty}{[aq^n]_\infty}. \tag{1.3c}$$

The definition (1.3c) agrees with (1.3a) for $n>0$. It follows from (1.3c) that, for $n>0$, we have

$$[a]_{-n}=(a;\,q)_{-n}=\frac{1}{(1-a/q)(1-a/q^2)\cdots(1-a/q^n)}$$

$$=\frac{(-1)^n q^{n(n+1)/2}}{[q/a]_n a^n} \tag{1.4a}$$

and

$$[a]_0=1. \tag{1.4b}$$

An ordinary bilateral hypergeometric series with A numerator parameters, B denominator parameters, and variable z is defined by

$${}_AH_B\begin{bmatrix} a_1, a_2, \cdots, a_A; & \\ b_1, b_2, \cdots, b_B; & z\end{bmatrix}=\sum_{n=-\infty}^{\infty}\frac{(a_1)_n(a_2)_n\cdots(a_A)_n}{(b_1)_n(b_2)_n\cdots(b_B)_n}z^n \tag{1.5}$$

where $a_1,\cdots,a_A,b_1,\cdots,b_B,z\in\mathbb{C}$. Similarly, the basic bilateral hypergeometric series is defined by

$${}_A\Psi_B\begin{bmatrix} a_1, a_2, \cdots, a_A; & \\ b_1, b_2, \cdots, b_B; & q, z\end{bmatrix}=\sum_{n=-\infty}^{\infty}\frac{[a_1]_n[a_2]_n\cdots[a_A]_n}{[b_1]_n[b_2]_n\cdots[b_B]_n}z^n \tag{1.6}$$

where $|q|<1$ and $a_1,\cdots,a_A,\ b_1,\cdots,b_B,\ z\in\mathbb{C}$.

If one of the denominator parameters, e.g., b_1, equals one, then the terms in the bilateral series (1.5) vanish for $n<0$ and the series (1.5) reduces to the ordinary hypergeometric series

$$ {}_AF_{B-1}\left[\begin{matrix} a_1,\cdots,a_A; \\ b_2,\cdots,b_B; \end{matrix}\; z\right]. $$

Similarly, if b_1 equals q in (1.6), then the basic bilateral series (1.6) reduces to the one-sided basic hypergeometric series

$$ {}_A\varphi_{B-1}\left[\begin{matrix} a_1,\cdots,a_A; \\ b_2,\cdots,b_B; \end{matrix}\; z\right]. $$

Summation theorems for bilateral hypergeometric series date back to 1907, when Dougall [9] discovered the following pair of identities. He proved

$$ (1.7)\qquad {}_2H_2\left[\begin{matrix} a,b; \\ c,d; \end{matrix}\; 1\right]=\Gamma\left[\begin{matrix} c,d,1-a,1-b,c+d-a-b-1 \\ c-a,d-a,c-b,d-b \end{matrix}\right] $$

where $\operatorname{Re}(c+d-a-b-1)>0$ and

$$ \Gamma\left[\begin{matrix} a_1,\cdots,a_l \\ b_1,\cdots,b_k \end{matrix}\right]\equiv\frac{\Gamma(a_1)\Gamma(a_2)\cdots\Gamma(a_l)}{\Gamma(b_1)\Gamma(b_2)\cdots\Gamma(b_k)} $$

for $a_1,\cdots,a_l,b_1,\cdots,b_k\in\mathbb{C}$. He also proved

$$ \begin{aligned} &{}_5H_5\left[\begin{matrix} 1+\tfrac12 a,b,c,d,e; \\ \tfrac12 a,1+a-b,1+a-c,1+a-d,1+a-e; \end{matrix}\; 1\right] \\ (1.8)\qquad &=\Gamma\left[\begin{matrix} 1-b,1-c,1-d,1-e,1+a-b,1+a-c,1+a-d, \\ 1+a,1-a,1+a-b-c,1+a-b-d,1+a-b-e, \end{matrix}\right. \\ &\qquad\qquad\left.\begin{matrix} 1+a-e,1+2a-b-c-d-e \\ 1+a-c-d,1+a-c-e,1+a-d-e \end{matrix}\right], \end{aligned} $$

where, for convergence, we assume $\operatorname{Re}(3+4a-2b-2c-2d-2e)>0$. The ${}_2H_2$ identity (1.7) generalizes the classical Gauss summation theorem and the ${}_5H_5$ identity generalizes the well-poised ${}_5F_4$ summation theorem.

For basic bilateral series there are two summation theorems which are particularly important. They are Ramanujan's ${}_1\Psi_1$ summation theorem and W. N. Bailey's well-poised ${}_6\Psi_6$ summation theorem [8]. We have

$$ (1.9)\qquad {}_1\Psi_1\left[\begin{matrix} a; \\ b; \end{matrix}\; q,z\right]=\Pi\left[\begin{matrix} b/a,az,q/az,q; \\ q/a,b/az,b,z; \end{matrix}\; q\right] $$

where $|b/a|<|z|<1$ and

$$ \Pi\left[\begin{matrix} a_1,\cdots,a_l; \\ b_1,\cdots,b_k; \end{matrix}\; q\right]=\frac{[a_1]_\infty[a_2]_\infty\cdots[a_l]_\infty}{[b_1]_\infty[b_2]_\infty\cdots[b_k]_\infty} $$

for $a_1,\cdots,a_l,b_1,\cdots,b_k\in\mathbb{C}$ and $|q|<1$. Similarly

$$ \begin{aligned} &{}_6\Psi_6\left[\begin{matrix} q\sqrt{a},-q\sqrt{a},b,c,d,e; \\ \sqrt{a},-\sqrt{a},aq/b,aq/c,aq/d,aq/e; \end{matrix}\; q,a^2q/bcde\right] \\ (1.10)\qquad &=\Pi\left[\begin{matrix} aq,aq/bc,aq/bd,aq/be,aq/cd,aq/ce,aq/de,q,q/a; \\ q/b,q/c,q/d,q/e,aq/b,aq/c,aq/d,aq/e,a^2q/bcde; \end{matrix}\; q\right] \end{aligned} $$

where $|a^2q/bcde|<1$.

These basic bilateral summation theorems have many important applications. Both the q-binomial theorem and Jacobi's triple product formula can be obtained from (1.9) by appropriate specializations and limits. Also the ${}_1\Psi_1$ theorem can be used to prove some interesting integral identities (see Askey [4], [5]) which have applications to orthogonal polynomials (e.g., the Rogers q-ultra spherical polynomials [6]). Some of the applications of the ${}_6\Psi_6$ identity to number theory and the theory of partitions are discussed in Andrews' article [1]. These include a proof of Ramanujan's partition function congruence $p(5n+4)\equiv 0 \bmod 5$ and also formulas for the number of representations of an integer as a sum of 2, 4 or 8 squares. Both of the identities (1.9) and (1.10) also play an important role in the analytic theory of partitions [3].

Generalizations of the ${}_2H_2$, ${}_5H_5$, ${}_1\Psi_1$, and ${}_6\Psi_6$ identities for bilateral hypergeometric series in $U(n)$ will be stated below. It is hoped that these $U(n)$ generalizations might prove useful in higher dimensional analogues of the problems just mentioned.

In § 2 the following generalization of the ${}_2H_2$ summation theorem is proved.

THEOREM 1.11. *Let $n \geqq 1$ be an integer and* $\operatorname{Re}\left(\sum_{i=1}^{n+1}(\beta_i-\alpha_i)\right) > n$. *Then*

$$\sum_{y_1,\cdots,y_n=-\infty}^{\infty} \prod_{1\leqq i<j\leqq n}\left(\frac{(z_i+y_i)-(z_j+y_j)}{z_i-z_j}\right)\prod_{i=1}^{n+1}\prod_{k=1}^{n}\frac{(\alpha_i+z_k)_{y_k}}{(\beta_i+z_k)_{y_k}} = \frac{\Gamma\left(-n+\sum_{i=1}^{n+1}(\beta_i-\alpha_i)\right)\prod_{i=1}^{n+1}\prod_{k=1}^{n}\Gamma(1-\alpha_i-z_k)\Gamma(\beta_i+z_k)}{\prod_{i,j=1}^{n+1}\Gamma(\beta_i-\alpha_j)\prod_{1\leqq i<j\leqq n}\Gamma(1-z_i+z_j)\Gamma(1+z_i-z_j)} \tag{1.12}$$

where $z_i\neq z_j$ for $1\leqq i<j\leqq n$, and α_i+z_k and $1-\beta_i-z_k$ are not positive integers for $1\leqq i\leqq n+1$ and $1\leqq k\leqq n$.

In § 3 we prove a $U(n)$ generalization of the ${}_5H_5$ summation theorem for each $n\geqq 2$. The case $n=2$ is equivalent to the ${}_5H_5$ identity (1.8).

THEOREM 1.13. *With* $\operatorname{Re}\left(\sum_{i=1}^{n}(b_i-a_i)\right)>n-1$ *we have*

$$\sum_{\substack{y_1,\cdots,y_n=-\infty\\ y_1+\cdots+y_n=0}}^{\infty} \prod_{1\leqq i<j\leqq n}\left(\frac{(z_i+y_i)-(z_j+y_j)}{z_i-z_j}\right)\prod_{i,k=1}^{n}\frac{(a_i-z_i+z_k)_{y_k}}{(b_i-z_i+z_k)_{y_k}} = \frac{\Gamma\left(1-n+\sum_{i=1}^{n}(b_i-a_i)\right)\prod_{i,k=1}^{n}\Gamma(1-a_i+z_i-z_k)\Gamma(b_i-z_i+z_k)}{\prod_{i,k=1}^{n}\Gamma(b_i-a_k-z_i+z_k)\prod_{1\leqq i<j\leqq n}\Gamma(1+z_i-z_j)\Gamma(1-z_i+z_j)} \cdot\frac{1}{\Gamma\left(1-\sum_{i=1}^{n}a_i\right)\Gamma\left(1-n+\sum_{i=1}^{n}b_i\right)} \tag{1.14}$$

where $z_i\neq z_j$ for $1\leqq i<j\leqq n$, and $a_i-z_i+z_j$ and $1-b_i+z_i-z_j$ are not positive integers for $1\leqq i,j\leqq n$.

In § 4 we prove a $U(n)$ generalization of the ${}_6\Psi_6$ summation theorem for each $n\geqq 2$. Again the case $n=2$ is equivalent to identity (1.10).

THEOREM 1.15. *With $|q|<1$ and $|q^{1-n}\prod_{i=1}^{n}(b_i/a_i)|<1$, we have*

$$\sum_{\substack{y_1,\cdots,y_n=-\infty\\ y_1+\cdots+y_n=0}}^{\infty}\ \prod_{1\leqq i<j\leqq n}\left(\frac{z_iq^{y_i}-z_jq^{y_j}}{z_i-z_j}\right)\prod_{i,k=1}^{n}\frac{[a_iz_k/z_i]_{y_k}}{[b_iz_k/z_i]_{y_k}}$$

$$(1.16)\qquad =\frac{[q]_\infty^{n-1}\prod_{i,k=1}^{n}[(b_iz_k)/(a_kz_i)]_\infty\prod_{1\leqq i<j\leqq n}[qz_i/z_j]_\infty[qz_j/z_i]_\infty}{\left[q^{1-n}\prod_{i=1}^{n}(b_i/a_i)\right]_\infty\prod_{i,k=1}^{\infty}[(qz_i)/(a_iz_k)]_\infty[b_iz_k/z_i]_\infty}$$

$$\cdot\left[q\Big/\prod_{i=1}^{n}a_i\right]_\infty\left[q^{1-n}\prod_{i=1}^{n}b_i\right]_\infty,$$

where $z_i\neq z_j$ for $1\leqq i<j\leqq n$, and $a_iz_j/z_i\neq q^l$ and $q^{-1}b_iz_j/z_i\neq q^{-l}$ for a positive integer l and $1\leqq i,j\leqq n$.

In § 5 we prove a $U(n)$ generalization of the ${}_1\Psi_1$ summation theorem for $n\geqq 2$. The classical ${}_1\Psi_1$ identity (1.9) corresponds to the case $n=1$ and is used, along with Theorem 1.15, to prove the general result for $n\geqq 2$. The argument here is similar to that in [18].

THEOREM 1.17. *Let $|q|<1$ and $|q^{1-n}\prod_{i=1}^{n}(b_i/a_i)|<|t|<1$. Then*

$$\sum_{y_1,\cdots,y_n=-\infty}^{\infty}\ \prod_{1\leqq i<j\leqq n}\left(\frac{z_iq^{y_i}-z_jq^{y_j}}{z_i-z_j}\right)\prod_{i,k=1}^{n}\frac{[a_iz_k/z_i]_{y_k}}{[b_iz_k/z_i]_{y_k}}\,t^{(y_1+\cdots+y_n)}$$

$$(1.18)\qquad =\frac{\left[t\prod_{i=1}^{n}a_i\right]_\infty\left[q\left(t\prod_{i=1}^{n}a_i\right)^{-1}\right]_\infty}{[t]_\infty\left[q^{1-n}t^{-1}\prod_{i=1}^{n}(b_i/a_i)\right]_\infty}\prod_{i,k=1}^{n}\frac{[(b_iz_k)/(a_kz_i)]_\infty[qz_i/z_k]_\infty}{[(qz_i)/(a_iz_k)]_\infty[b_iz_k/z_i]_\infty}$$

where $z_i\neq z_j$ and $1\leqq i<j\leqq n$, and $a_iz_j/z_i\neq q^l$ and $q^{-1}b_iz_j/z_i\neq q^{-l}$ for a positive integer l and $1\leqq i,j\leqq n$.

The special cases of Theorems 1.15 and 1.17 when $b_1=\cdots=b_n=b$ have previously been obtained by Milne as Theorems 1.24 and 1.15 of [18].

We finally remark that the method of contour integration used to prove the identities in the present paper has a long history, which is discussed in Slater [22]. Slater and Lakin [23] give a contour integration proof of the ${}_6\Psi_6$ identity (1.10). The major difficulty in extending their method is to find the correct integrand which will permit an inductive proof of a $U(n)$ multilateral summation theorem, with induction on the number of summation indices allowed to take on negative integral values. The starting points for the induction are Milne's generalizations of the Gauss, the ${}_5F_4$ and the ${}_6\varphi_5$ summation theorems [20], [19]. There are also certain trigonometric function and theta function identities, Lemmas 2.14, 3.14 and 4.14, which are used in the proofs of Theorems 1.13, 1.15 and 1.17 here.

2. A generalization of the ${}_2H_2$ summation theorem.

For $1\leqq l\leqq n$, let

$$f_l(s)=(-1)^{n-l}\frac{\sin\pi s}{\sin\pi(z_l-s)}\prod_{i=1}^{n+1}\frac{\Gamma(1-\beta_i-s)}{\Gamma(1-\alpha_i-s)}$$

$$(2.1)\qquad\cdot\sum_{y_1,\cdots,y_{l-1}=0}^{\infty}\ \sum_{y_{l+1},\cdots,y_n=-\infty}^{\infty}\ \prod_{\substack{i=1\\ i\neq l}}^{n}(z_i+y_i-s)$$

$$\cdot\prod_{\substack{1\leqq i<j\leqq n\\ i,j\neq l}}((z_i+y_i)-(z_j+y_j))\prod_{i=1}^{n+1}\prod_{\substack{k=1\\ k\neq l}}^{n}\frac{(\alpha_i+z_k)_{y_k}}{(\beta_i+z_k)_{y_k}}$$

where $\beta_i = 1 - z_i$ for $i = 1, \cdots, l-1$, and $s \in \mathbb{C}$, and we assume that the series converges absolutely. We also assume that $(\beta_i + z_k)$ is not a negative integer or zero for $1 \leqq k \leqq n$, $1 \leqq i \leqq n+1$, and $(\alpha_i + z_k)$ is not a positive integer for $l \leqq k \leqq n$, $1 \leqq i \leqq n+1$.

$f_l(s)$ can also be written as

$$f_l(s) = \frac{\sin \pi s}{\sin \pi(z_l - s)} \prod_{i=1}^{n+1} \frac{\Gamma(1-\beta_i - s)}{\Gamma(1-\alpha_i - s)} \sum_{\sigma \in S_n} \varepsilon(\sigma) \sum_{y_1, \cdots, y_{l-1}=0}^{\infty} \sum_{y_{l+1}, \cdots, y_n = -\infty}^{\infty} \cdot \prod_{i=1}^{n} (c_i)^{n-\sigma(i)} \prod_{i=1}^{n+1} \prod_{\substack{k=1 \\ k \neq l}}^{n} \frac{(\alpha_i + z_k)_{y_k}}{(\beta_i + z_k)_{y_k}}, \tag{2.2}$$

where $c_i = z_i + y_i$ for $1 \leqq i \leqq n$, $i \neq l$, and $c_l = -s$ and $\varepsilon(\sigma)$ equals the sign of the permutation $\sigma \in S_n$. S_n is the symmetric group on $\{1, \cdots, n\}$.

We then obtain

$$\begin{aligned} f_l(s) = & \frac{\sin(\pi s)}{\sin(\pi(\alpha_l - s))} \prod_{i=1}^{n+1} \frac{\Gamma(1-\beta_i - s)}{\Gamma(1-\alpha_i - s)} \\ & \cdot \sum_{\sigma \in S_n} \varepsilon(\sigma)(-s)^{n-\sigma(l)} \prod_{k=1}^{l-1} \left[\sum_{y_k=0}^{\infty} \prod_{i=1}^{n+1} \frac{(\alpha_i + z_k)_{y_k}}{(\beta_i + z_k)_{y_k}} (z_k + y_k)^{n-\sigma(k)} \right] \\ & \cdot \prod_{k=l+1}^{n} \left[\sum_{y_k=-\infty}^{\infty} \prod_{i=1}^{n+1} \frac{(\alpha_i + z_k)_{y_k}}{(\beta_i + z_k)_{y_k}} (z_k + y_k)^{n-\sigma(k)} \right] \end{aligned} \tag{2.3}$$

with assumptions as above (cf. Lemma 2.1 of [18]).

The series

$$\sum_{y_k=-\infty}^{\infty} \prod_{i=1}^{n+1} \frac{(\alpha_i + z_k)_{y_k}}{(\beta_i + z_k)_{y_k}} (z_k + y_k)^{n-\sigma(k)}$$

for $l < k \leqq n$ and the similar series for $1 \leqq k < l$ converges absolutely whenever $\operatorname{Re}(\sigma(k) - n + \sum_{i=1}^{n+1} (\beta_i - \alpha_i)) > 1$. The proof of this fact is standard and is given for the ordinary ${}_2F_1$ hypergeometric series on p. 46 of [21].

It follows that the original series expression (2.1) for $f_l(s)$ converges absolutely whenever

$$\operatorname{Re}\left(\sum_{i=1}^{n+1} (\beta_i - \alpha_i) \right) > n. \tag{2.4}$$

For $1 < l < n$, we consider the contour integral $(-1/2\pi i) \int_C f_l(s)\, ds$, where $C = C(w)$, $w \in \mathbb{R}$, $w > 0$, is the sum of the directed line segments going from $-iw - w$ to $-iw + w$, from $-iw + w$ to $iw + w$, from $iw + w$ to $iw - w$, and from $iw - w$ to $-iw - w$. We will let $w \to \infty$ through the values w_0, $w_0 + 1$, $w_0 + 2, \cdots$, where w_0 is chosen so that the contours $C(w)$ avoid the poles of $f_l(s)$.

We will need asymptotic estimates for the integrand $f_l(s)$ when $\operatorname{Re}(s) \geqq 0$ and when $\operatorname{Re}(s) \leqq 0$. We use the reflection formula $[\Gamma(z)\Gamma(1-z)]^{-1} = \pi^{-1} \sin(\pi z)$, as well as Sterling's formula

$$\Gamma(a+s) = \sqrt{2\pi} s^{a+s-1/2} e^{-s} \left(1 + O\left(\frac{1}{s} \right) \right)$$

as $s \to \infty$ in $S_\theta = \{s\colon |\arg s| < \theta\}$, $0 < \theta < \pi$, and the estimates

$$|\sin \pi s| = O(e^{\pi |\operatorname{Im} s|})$$

in the entire plane, and

$$|\sin \pi(a-s)|^{-1} = O(e^{-\pi|\mathrm{Im}\, s|})$$

in the whole plane excluding ε-neighborhoods of the poles.

These formulas together with (2.3) imply that

$$|f_l(s)| = O(s^{n-1+\mathrm{Re}\,(\sum_{i=1}^{n+1}(\alpha_i-\beta_i))}) \tag{2.5}$$

as $s \to \infty$ with $\mathrm{Re}\,(s) \geqq 0$ (or $\mathrm{Re}\,(s) \leqq 0$) excluding an ε-neighborhood of the poles. If $\mathrm{Re}\,(\sum_{i=1}^{n+1}(\beta_i-\alpha_i)) > n$, it follows that

$$\lim_{w\to\infty} -\frac{1}{2\pi i}\int_C f_l(s)\,ds = 0. \tag{2.6}$$

Before going further we shall state Milne's $U(n)$ generalization of the Gauss summation theorem [20], which is used to start the inductive proof of Theorem 1.11.

THEOREM 2.7. *Let* $\mathrm{Re}\,(\gamma_{n+1}-b+\sum_{i=1}^{n}(\gamma_i-z_i)) > 0$. *Then*

$$\begin{aligned} &\sum_{y_1,\cdots,y_n=0}^{\infty} \prod_{1\leqq i<j\leqq n}\left(\frac{(z_i+y_i)-(z_j+y_j)}{z_i-z_j}\right)\prod_{l=1}^{n}\left[\frac{(z_l-\gamma_{n+1})_{y_l}}{(z_l-b)_{y_l}}\prod_{k=1}^{n}\frac{(z_l-\gamma_k)_{y_l}}{(1+z_l-z_k)_{y_l}}\right] \\ &\qquad = \frac{\Gamma\left(\gamma_{n+1}-b+\sum_{i=1}^{n}(\gamma_i-z_i)\right)}{\Gamma(\gamma_{n+1}-b)}\prod_{i=1}^{n}\frac{\Gamma(z_l-b)}{\Gamma(\gamma_l-b)}, \end{aligned} \tag{2.8}$$

where we assume that z_i-z_j *and* z_i-b *are not negative integers or zero for* $1\leqq i\neq j\leqq n$.

Remark 2.9. Theorem 2.7 can also be obtained from a limit (by sending $z_n\to\infty$) of a $U(n)$ Dougall theorem ([10, Cor. 3.1]).

Proof of Theorem 1.11. We prove identity (1.12) by induction on l, $1\leqq l\leqq n$. Suppose (1.12) is true for all l satisfying $n\geqq l>t$, where t is an integer, $1\leqq t\leqq n$. We shall then prove (1.12) for $l=t$.

Setting $l=t$ and $\mathrm{Re}\,(\sum_{i=1}^{n+1}(\beta_i-\alpha_i))>n$ and assumptions as in (1.12), we compute the residues of the integral

$$\frac{-1}{2\pi i}\int_C f_l(s)\,ds. \tag{2.10}$$

First consider the residues at $s=1-\beta_m+y_l$, where $1\leqq m\leqq n+1$ and y_l is a nonnegative integer. We then sum over $y_l\geqq 0$:

$$\begin{aligned} &\frac{\sin(\pi\beta_m)}{\sin(\pi(z_l+\beta_m-1))}\prod_{\substack{i=1\\ i\neq m}}^{n+1}\frac{\Gamma(1-\beta_i-(1-\beta_m))}{\Gamma(1-\alpha_i-(1-\beta_m))} \\ &\quad\cdot\frac{1}{\Gamma(1-\alpha_m-(1-\beta_m))}\sum_{y_1,\cdots,y_l=0}^{\infty}\ \sum_{y_{l+1},\cdots,y_n=-\infty}^{\infty} \\ &\quad\cdot\prod_{\substack{1\leqq i<j\leqq n\\ i,j\neq l}}((z_i+y_i)-(z_j+y_j))\prod_{\substack{i=1\\ i\neq l}}^{n}((z_i+y_i)-(1-\beta_m+y_l)) \\ &\quad\cdot\prod_{i=1}^{n+1}\left[\frac{(\alpha_i+\beta_m+1)_{y_l}}{(\beta_i-\beta_m+1)_{y_l}}\prod_{k=1}^{l-1}\frac{(\alpha_i+z_k)_{y_k}}{(1-z_i+z_k)_{y_k}}\prod_{k=l+1}^{n}\frac{(\alpha_i+z_k)_{y_k}}{(\beta_i+z_k)_{y_k}}\right], \end{aligned} \tag{2.11}$$

recalling that $\beta_i=1-z_i$ for $1\leqq i<l$ and assuming temporarily that $\beta_i-\beta_m$ is not an integer for all $1\leqq i$, $m\leqq n+1$.

If $l = n$, then we can sum the series (2.11) by the $U(n)$ Gauss summation Theorem 2.7. If $l < n$, then we can sum the series (2.11) by the induction hypothesis for (1.12). Expression (2.11) now becomes

$$\begin{aligned}
&= \frac{\Gamma\left(-n+\sum_{i=1}^{n+1}(\beta_i-\alpha_i)\right)\prod_{i=1}^{n+1}\prod_{k=1,k\neq l}^{n}[\Gamma(\beta_i+z_k)\Gamma(1-z_k-\alpha_i)]}{\prod_{i,j=1}^{n+1}\Gamma(\beta_i-\alpha_j)\prod_{1\leqq i<j\leqq n, i,j\neq l}[\Gamma(1-z_i+z_j)\Gamma(z_i-z_j)]} \\
(2.12)\qquad &\cdot \frac{\prod_{i=1}^{n+1}\Gamma(\beta_i+1-\beta_m)\prod_{i=1,i\neq m}^{n+1}\Gamma(\beta_m-\beta_i)}{\prod_{j=1}^{l-1}[\Gamma(2-z_j-\beta_m)\Gamma(z_j+\beta_m-1)]\prod_{j=l+1}^{n}[\Gamma(\beta_m+z_j)\Gamma(1-\beta_m-z_j)]} \\
&\cdot \frac{\sin\pi(\beta_m)}{\sin\pi(z_l+\beta_m-1)}.
\end{aligned}$$

When $1 \leqq m < l$, then expression (2.11) vanishes. This is because then $z_m = 1-\beta_m$ and (2.11) becomes both symmetric and skew-symmetric under the transposition $y_m \leftrightarrow y_l$.

If we sum expression (2.12) over m, $l \leqq m \leqq n+1$, we obtain

$$\begin{aligned}
(2.13)\qquad &\frac{\Gamma\left(-n+\sum_{i=1}^{n+1}(\beta_i-\alpha_i)\right)\prod_{i=1}^{n+1}\prod_{k=1,k\neq l}^{n}[\Gamma(\beta_i+z_k)\Gamma(1-z_k-\alpha_i)]}{\prod_{i,j=1}^{n+1}\Gamma(\beta_i-\alpha_j)\prod_{1\leqq i<j\leqq n, i,j\neq l}[\Gamma(1-z_i+z_j)\Gamma(z_i-z_j)]} \\
&\cdot(-\pi)\sum_{m=l}^{n+1}\frac{\sin\pi(\beta_m)\prod_{j=l+1}^{n}\sin\pi(\beta_m+z_j)}{\sin\pi(\beta_m+z_l)\prod_{i=l,i\neq m}^{n+1}\sin\pi(\beta_m-\beta_i)}.
\end{aligned}$$

To finish the proof of (1.12) we will need the following

LEMMA 2.14. *With assumptions as above we have*

$$(2.15)\qquad \sum_{m=l}^{n+1}\frac{\sin\pi(\beta_m)\prod_{j=l+1}^{n}\sin\pi(\beta_m+z_j)}{\sin\pi(\beta_m+z_l)\prod_{i=l,i\neq m}^{n+1}\sin\pi(\beta_m-\beta_i)} = \frac{\sin\pi(z_l)\prod_{j=l+1}^{n}\sin\pi(z_l-z_j)}{\prod_{i=l}^{n+1}\sin\pi(\beta_i+z_l)}.$$

Proof. Using the identity $\sin\theta = (e^{i\theta}-e^{-i\theta})/2i$ and setting $e^{\pi i\beta_k} = g_k$ and $e^{\pi i z_j} = a_j$ for $l \leqq k \leqq n+1$ and $l \leqq j \leqq n$, then we are reduced to verifying

$$(2.16)\qquad \sum_{m=l}^{n+1}\frac{(g_m-g_m^{-1})\prod_{j=l+1}^{n}(g_m a_j-g_m^{-1}a_j^{-1})}{(g_m a_l-g_m^{-1}a_l^{-1})\prod_{i=l,i\neq m}^{n+1}(g_m g_i^{-1}-g_m^{-1}g_i)} = \frac{(a_l-a_l^{-1})\prod_{j=l+1}^{n}(a_l a_j^{-1}-a_l^{-1}a_j)}{\prod_{i=l}^{n+1}(g_i a_l-g_i^{-1}a_l^{-1})}.$$

Identity (2.16) can be proved directly using the Louck and Biedenharn lemma (see

[16, Thm. 1.20]). It can also be obtained by considering the residues of the contour integral

$$(2.17)\qquad \frac{1}{2\pi i}\int_D \frac{(z-1)\prod_{j=l+1}^{n}(za_j-a_j^{-1})}{(za_l-a_l^{-1})\prod_{i=l}^{n+1}(zg_i^{-1}-g_i)}\,dz,$$

where D is a sufficiently large circle containing the poles of the integrand and traversed in the counterclockwise direction. Q.E.D.

Returning to the contour integral (2.10), we consider its residues at $s=z_l+y_l$ where y_l is an integer. Summing these residues over y_l, $-\infty<y_l<\infty$, we obtain

$$(2.18)\qquad \begin{aligned} &\sin \pi(z_l)\prod_{i=1}^{n+1}\left[\frac{\Gamma(1-\beta_i-z_l)}{\Gamma(1-\alpha_i-z_l)}\right]\sum_{y_1,\cdots,y_{l-1}=0}^{\infty}\ \sum_{y_l,\cdots,y_n=-\infty}^{\infty}\\ &\cdot\prod_{1\leqq i<j\leqq n}((z_i+y_i)-(z_j+y_j))\prod_{i=1}^{n+1}\prod_{k=1}^{n}\frac{(\alpha_i+z_k)_{y_k}}{(\beta_i+z_k)_{y_k}}, \end{aligned}$$

where $\beta_i=1-z_i$ for $1\leqq i<l$. By an argument similar to that for expressions (2.2) and (2.3), the series (2.18) converges absolutely whenever $\operatorname{Re}\left(\sum_{i=1}^{n+1}(\beta_i-\alpha_i)\right)>n$.

The limit (2.6) implies that the limit of the sum of the residues of (2.10), i.e., the sum of (2.13) and (2.18), is zero; after substituting (2.15) into (2.13) and simplifying, we prove the inductive step $l=t$ for (1.12). The assumption made in (2.11) that $\beta_i-\beta_m$ is not an integer for $1\leqq i$, $m\leqq n+1$ can be dropped by continuity. This completes the proof of (1.12) by induction.

3. A generalization of the ${}_5H_5$ summation theorem. For $1\leqq l\leqq n-1$, let

$$(3.1)\qquad \begin{aligned} &h_l(s;y_1,\cdots,y_{l-1},y_{l+1},\cdots,y_{n-1})\\ &\quad=h_l(s;y)\\ &\quad=(-1)^{n-l-1}\frac{\sin\pi(z_n+z_l-s)}{\sin\pi(z_l-s)}(s-u)\prod_{\substack{i=1\\ i\neq l}}^{n-1}[(z_i+y_i-s)(z_i+y_i-u)]\\ &\qquad\cdot\prod_{i=1}^{n}\left[\frac{\Gamma(1-b_i+z_i-s)\,\Gamma(1-b_i+z_i-u)}{\Gamma(1-a_i+z_i-s)\,\Gamma(1-a_i+z_i-u)}\right]\\ &\qquad\cdot\prod_{\substack{1\leqq i,j\leqq n-1\\ i,j\neq l}}((z_i+y_i)-(z_j+y_j))\prod_{i=1}^{n}\prod_{\substack{j=1\\ j\neq l}}^{n-1}\frac{(a_i-z_i+z_j)_{y_j}}{(b_i-z_i+z_j)_{y_j}}, \end{aligned}$$

where we assume that $a_i-z_i+z_j$ for $1\leqq i\leqq n$, $l\leqq j\leqq n$, is not a positive integer and $b_i-z_i+z_j$ is not a negative integer or zero for $1\leqq i, j\leqq n$. We also assume $y_1,\cdots,y_{l-1}$ are nonnegative integers and $y_{l+1},\cdots,y_{n-1}$ integers and

$$(3.2)\qquad s+u+\sum_{\substack{i=1\\ i\neq l}}^{n-1} y_i=z_n+z_l.$$

For $1\leqq l\leqq n-1$, we consider the contour integral

$$\frac{-1}{2\pi i}\int_C h_l(s;y)\,ds,$$

where $C=C(w)$ is defined as in § 2. As in § 2 we will let $w\to\infty$ through values w_0, w_0+1, $w_0+2,\cdots$, where w_0 is chosen so that the contours $C(w)$ avoid the poles of $h_l(s;y)$ for all y.

By an argument similar to § 2 one shows that

$$|h_l(s;y)| = O(s^{2n-3+2\,\mathrm{Re}\,(\sum_{i=1}^{n}(a_i-b_i))}) \tag{3.3}$$

as $s\to\infty$ with $\mathrm{Re}\,(s)\geqq 0$ (or $\mathrm{Re}\,(s)\leqq 0$) excluding an ε-neighborhood of the poles.

It follows that if $\mathrm{Re}\,(\sum_{i=1}^{n}(b_i-a_i))>n-1$, then

$$\lim_{w\to\infty}\frac{-1}{2\pi i}\int_C h_l(s;y)\,ds=0. \tag{3.4}$$

Proof of Theorem 1.13. We shall prove the absolute convergence of the series in (1.14) for $\mathrm{Re}\,(\sum_{i=1}^{n}(b_i-a_i))>n-1$ in Lemma 3.19.

To prove (1.14) we make the induction hypothesis that $b_i=1$ for $1\leqq i\leqq l-1$. This will reduce the summation in (1.14) to $y_1,\cdots,y_{l-1}\geqq 0$ and $y_l,\cdots,y_n\in\mathbb{Z}$. The other terms will vanish.

For $l=n$ identity (1.14) is an immediate consequence of Theorem 7.30 of [19]. (Note that the proof of Theorem 7.30 is incomplete. However, the proof is correct in the case of a terminating series. The general result follows by an application of Carlson's theorem [7, p. 39].) Now suppose (1.14) is true for all l satisfying $n\geqq l>t$, where t is an integer, $1\leqq t\leqq n$. We shall then prove (1.14) for $l=t$.

Consider the residue of the integral $(-1/2\pi i)\int_C h_l(s;y)\,ds$ at $s=1-b_m+z_m+y_l$ for $1\leqq m\leqq n$ and $y_l\geqq 0$, and sum over $y_1,\cdots,y_l\geqq 0$ and $y_{l+1},\cdots,y_n\in\mathbb{Z}$, where $y_1+\cdots+y_n=0$. Abbreviating $(1-b_i+z_i)=c_i$ and $b_i-1-z_i+z_l+z_n=d_i$ for $1\leqq i\leqq n$, we obtain

$$\begin{aligned}
&(-1)^{n-l-1}\frac{\sin\pi(z_n+z_l-c_m)}{\sin\pi(z_l-c_m)}\prod_{\substack{i=1\\ i\neq m}}^{n}\Gamma(c_i-c_m)\\
&\cdot\prod_{i=1}^{n}\frac{\Gamma(c_i-d_m)}{\Gamma(1-a_i+z_i-c_m)\Gamma(1-a_i+z_i-d_m)}\\
&\cdot\sum_{y_1,\cdots,y_l=0}^{\infty}\ \sum_{\substack{y_{l+1},\cdots,y_n=-\infty\\ y_1+\cdots+y_n=0}}^{\infty}\ \prod_{\substack{1\leqq i<j\leqq n-1\\ i,j\neq l}}((z_i+y_i)-(z_j+y_j))\\
&\cdot\prod_{\substack{i=1\\ i\neq l}}^{n-1}[((z_i+y_i)-(c_m+y_l))((z_i+y_i)-(d_m+y_n))]((c_m+y_l)-(d_m+y_n))\\
&\cdot\prod_{i=1}^{n}\left[\frac{(a_i+z_i+c_m)_{y_l}}{(b_i-z_i+c_m)_{y_l}}\frac{(a_i-z_i+d_m)_{y_n}}{(b_i-z_i+d_m)_{y_n}}\prod_{\substack{j=1\\ j\neq l}}^{n-1}\frac{(a_i-z_i+z_j)_{y_j}}{(b_i-z_i+z_j)_{y_j}}\right].
\end{aligned} \tag{3.5}$$

We denote expression (3.5) by

$$\frac{\sin\pi(z_n-z_l-z_m+b_m-1)}{\sin\pi(z_l-z_m+b_m-1)}R_m. \tag{3.6}$$

Under the condition $\mathrm{Re}\,(\sum_{i=1}^{n}(b_i-a_i))>n-1$, it follows from Lemma 3.19 below that R_m is absolutely convergent.

If we consider the residue of $(-1/2\pi i)\int_C h_l(s;y)\,ds$ at $u=1-b_m+z_m+y_l$ where u satisfies (3.2) and sum over $y_1,\cdots,y_l\geqq 0$ and $y_{l+1},\cdots,y_n\in\mathbb{Z}$ with $y_1+\cdots+y_n=0$ as above, we obtain

$$\frac{\sin\pi(1-b_m+z_m)}{\sin\pi(1-b_m+z_m-z_n)}R_m. \tag{3.7}$$

Finally, observe that since $b_i = 1$ for $1 \leqq i \leqq l-1$, then R_m is both symmetric and skew-symmetric upon interchange of y_m and y_l for $1 \leqq m \leqq l-1$. Hence

$$R_m = 0 \quad \text{for } 1 \leqq m \leqq l-1. \tag{3.8}$$

Now consider the residue of $(-1/2\pi i) \int_C h_l(s; y)\, ds$ at $s = z_l + y_l$, where $y_l \in Z$, and sum over $y_1, \cdots, y_{l-1} \geqq 0$ and $y_l, \cdots, y_n \in \mathbb{Z}$ with $y_1 + \cdots + y_n = 0$. We obtain

$$\begin{aligned}&\frac{\sin(\pi z_n)}{\pi} \prod_{i=1}^{n} \left[\frac{\Gamma(1-b_i+z_i-z_l)}{\Gamma(1-a_i+z_i-z_l)} \frac{\Gamma(1-b_i+z_i-z_n)}{\Gamma(1-a_i+z_i-z_n)} \right] \\ &\cdot \sum_{y_1,\cdots,y_{l-1}=0}^{\infty} \sum_{\substack{y_l,\cdots,y_n=-\infty \\ y_1+\cdots+y_n=0}}^{\infty} \prod_{1 \leqq i<j \leqq n} ((z_i+y_i)-(z_j+y_j)) \\ &\cdot \prod_{i,j=1}^{n} \frac{(a_i-z_i+z_j)_{y_j}}{(b_i-z_i+z_j)_{y_j}}.\end{aligned} \tag{3.9}$$

We denote expression (3.9) by

$$\frac{\sin(\pi z_n)}{\pi} \prod_{i=1}^{n} \left[\frac{\Gamma(1-b_i+z_i-z_l)}{\Gamma(1-a_i+z_i-z_l)} \frac{\Gamma(1-b_i+z_i-z_n)}{\Gamma(1-a_i+z_i-z_n)} \right] B_l. \tag{3.10}$$

Again, it follows from Lemma 3.19 that B_l is absolutely convergent under the condition $\operatorname{Re}(\sum_{i=1}^{n}(b_i-a_i)) > n-1$.

Now the fact the series B_l and R_m for $1 \leqq m \leqq n$ are absolutely convergent and that $\lim_{w \to 0} -1/2\pi i \int_C h_l(s; y)\, ds = 0$ imply that

$$\begin{aligned}&\sum_{y_1,\cdots,y_{l-1} \geqq 0} \sum_{y_{l+1},\cdots,y_{n-1}=-\infty}^{\infty} \lim_{w \to \infty} \frac{-1}{2\pi i} \int_C h_l(s; y)\, ds \\ &= \sum_{m=1}^{n} \left[\frac{\sin \pi(z_n+z_l-z_m+b_m-1)}{\sin \pi(z_l-z_m+b_m-1)} + \frac{\sin \pi(1-b_m+z_m)}{\sin \pi(1-b_m+z_m-z_n)} \right] R_m \\ &+ \frac{\sin \pi(z_n)}{\pi} \prod_{i=1}^{n} \left[\frac{\Gamma(1-b_i+z_i-z_l)}{\Gamma(1-a_i+z_i-z_l)} \frac{\Gamma(1-b_i+z_i-z_n)}{\Gamma(1-a_i+z_i-z_n)} \right] B_l = 0\end{aligned} \tag{3.11}$$

where $R_m = 0$ for $1 \leqq m < l$.

We abbreviate $1-b_i+z_i = c_i$ and $b_i-1-z_i+z_l+z_n = d_i$ for $1 \leqq i \leqq n$ as above. By the induction hypothesis and writing $b_m - z_m$ as $1-c_m$, then R_m for $l \leqq m \leqq n$ can be summed. Using that $[\Gamma(u)\Gamma(1-u)]^{-1} = \pi^{-1} \sin \pi u$, we obtain for $l \leqq m \leqq n$

$$\begin{aligned}R_m = &\prod_{\substack{i=1 \\ i \neq m}}^{n} \Gamma(c_i-c_m) \prod_{i=1}^{n} \Bigg[\Gamma(c_i-d_m)\Gamma(b_i-z_i+c_m)\Gamma(b_i-z_i+d_m) \\ &\cdot \prod_{\substack{k=1 \\ k \neq l}}^{n-1} \Gamma(1-a_i+z_i-z_k)\Gamma(b_i-z_i+z_k) \Bigg] \\ &\cdot \prod_{\substack{1 \leqq i<j \leqq n-1 \\ i,j \neq l}} \pi^{-1} \sin \pi(z_i-z_j) \prod_{i=1}^{l} \pi^{-1} \sin \pi(z_i-c_m) \\ &\cdot \prod_{j=l+1}^{n-1} \pi^{-1} \sin \pi(c_m-z_j) \prod_{\substack{i=1 \\ i \neq l}}^{n-1} \pi^{-1} \sin \pi(z_i-d_m) \\ &\cdot \frac{\pi^{-1} \sin \pi(c_m-d_m)}{\prod_{i,k=1}^{n} \Gamma(b_i-a_k-z_i+z_k)} \frac{\Gamma\left(1-n+\sum_{i=1}^{n}(b_i-a_i)\right)}{\Gamma\left(1-\sum_{i=1}^{n} a_i\right)\Gamma\left(1-n+\sum_{i=1}^{n} b_i\right)}\end{aligned} \tag{3.12}$$

where we have used that $c_m+d_m=z_m+z_l$ to show that

$$\Gamma\left(1-\sum_{i=1}^{n}a_i-c_m-d_m+z_n+z_l\right)=\Gamma\left(1-\sum_{i=1}^{n}a_i\right)$$

and similarly for

$$\Gamma\left(1-n+\sum_{i=1}^{n}b_i\right).$$

From (3.12) it follows that

$$\begin{aligned}
&\sum_{m=1}^{n}\left[\frac{\sin\pi(z_n+z_l-z_m+b_m-1)}{\sin\pi(z_l-z_m+b_m-1)}+\frac{\sin\pi(1-b_m+z_m)}{\sin\pi(1-b_m+z_m-z_n)}\right]R_m\\
&\quad=\sum_{m=l}^{n}\left\{\left[\frac{\sin\pi(z_n+z_l-c_m)}{\sin\pi(z_l-c_m)}+\frac{\sin\pi(z_n+z_l-d_m)}{\sin\pi(z_l-d_m)}\right]\right.\\
&\qquad\left.\cdot\frac{\prod_{i=l+1}^{n-1}\sin\pi(z_i-c_m)\sin\pi(z_i-d_m)}{\prod_{i=l,i\neq m}^{n}\sin\pi(b_i-z_i+c_m)\sin\pi(b_i-z_i+d_m)}\right\}\\
&\qquad\cdot\frac{(-1)^{n-l-1}\pi^2\prod_{i=1}^{n}\prod_{k=1,k\neq l}^{n-1}\Gamma(1-a_i+z_i-z_k)\Gamma(b_i-z_i+z_k)}{\Gamma\left(1-\sum_{i=1}^{n}a_i\right)\Gamma\left(1-n+\sum_{i=1}^{n}b_i\right)\prod_{i,k=1}^{n}\Gamma(b_i-a_k-z_i+z_k)}\\
&\qquad\cdot\Gamma\left(1-n+\sum_{i=1}^{n}(b_i-a_i)\right)\prod_{\substack{1\leqq i<j\leqq n-1\\ i,j\neq l}}\pi^{-1}\sin\pi(z_i-z_j),
\end{aligned}\tag{3.13}$$

where we have used the induction hypothesis that $b_i=1$ for $1\leqq i\leqq l-1$.

To finish the proof of (1.14) we need the following:

LEMMA 3.14. *With assumptions as above we have*

$$\begin{aligned}
&\sum_{m=l}^{n}\left[\frac{\sin\pi(z_n+z_l-c_m)}{\sin\pi(z_l-c_m)}+\frac{\sin\pi(z_n+z_l-d_m)}{\sin\pi(z_l-d_m)}\right]\\
&\qquad\cdot\frac{\prod_{i=l+1}^{n-1}\sin\pi(z_i-c_m)\sin\pi(z_i-d_m)}{\prod_{\substack{i=l\\ i\neq m}}^{n}\sin\pi(b_i-z_i+c_m)\sin\pi(b_i-z_i+d_m)}\\
&\quad=\frac{\prod_{i=l+1}^{n-1}\sin\pi(z_i-z_l)\sin\pi(z_i-z_n)}{\prod_{i=l}^{n}\sin\pi(z_l-c_i)\sin\pi(d_i-z_l)}\cdot\sin\pi(z_n-z_l)\sin\pi(z_n).
\end{aligned}\tag{3.15}$$

Proof. The proof is very similar to that of Lemma 2.14. Setting $e^{\pi i a_j} = \alpha_j$, $e^{\pi i b_j} = \beta_j$, $e^{\pi i z_j} = \gamma_j$, $e^{\pi i c_j} = \tau_j$, and $e^{\pi i d_j} = \delta_j$ for $1 \leqq j \leqq n$, then we are reduced to verifying

$$\tag{3.16} \begin{aligned} &\sum_{m=l}^{n} \left[\frac{(\gamma_n \gamma_l \tau_m^{-1} - \gamma_n^{-1} \gamma_l^{-1} \tau_m)}{(\gamma_l \tau_m^{-1} - \gamma_l^{-1} \tau_m)} + \frac{(\gamma_n \gamma_l \delta_m^{-1} - \gamma_n^{-1} \gamma_l^{-1} \delta_m)}{(\gamma_l \delta_m^{-1} - \gamma_l^{-1} \delta_m)} \right] \\ &\qquad \cdot \frac{\prod_{i=l+1}^{n-1} (\gamma_i \tau_m^{-1} - \gamma_i^{-1} \tau_m)(\gamma_i \delta_m^{-1} - \gamma_i^{-1} \delta_m)}{\prod_{i \neq l, i = m}^{n} (\beta_i \tau_m \gamma_i^{-1} - \beta_i^{-1} \tau_m^{-1} \gamma_i)(\beta_i \delta_m \gamma_i^{-1} - \beta_i^{-1} \delta_m^{-1} \gamma_i)} \\ &= \frac{\prod_{i=l+1}^{n-1} (\gamma_i \gamma_l^{-1} - \gamma_i^{-1} \gamma_l)(\gamma_i \gamma_n^{-1} - \gamma_i^{-1} \gamma_n)}{\prod_{i=l}^{n} (\gamma_l \tau_i^{-1} - \gamma_l^{-1} \tau_i)(\delta_i \gamma_l^{-1} - \delta_i^{-1} \gamma_l)} (\gamma_n \gamma_l^{-1} - \gamma_n^{-1} \gamma_l)(\gamma_n - \gamma_n^{-1}). \end{aligned}$$

Identity (3.16) can be obtained by considering the residues of the contour integral

$$\tag{3.17} \begin{aligned} &\frac{1}{2\pi i} \int_D \frac{\prod_{i=l+1}^{n-1} [(\gamma_i - \gamma_i^{-1} s)(\gamma_i \gamma_n^{-1} \gamma_l^{-1} s - \gamma_i^{-1} \gamma_n \gamma_l)]}{\prod_{i=l}^{n} [(s \tau_i^{-1} - \tau_i)(\delta_i - \delta_i^{-1} s)]} \\ &\qquad \cdot \frac{(\gamma_n \gamma_l - \gamma_n^{-1} \gamma_l^{-1} s^2)(\gamma_n \gamma_l - \gamma_n^{-1} \gamma_l^{-1} s)}{(\gamma_l - \gamma_l^{-1} s)} \, ds, \end{aligned}$$

where D is a sufficiently large circle containing the poles of the integrand and traversed in the counterclockwise direction. Q.E.D.

Substituting identity (3.15) into (3.13) we obtain

$$\tag{3.18} \begin{aligned} &\sum_{m=l}^{n} \left[\frac{\sin \pi(z_n + z_l - z_m + b_m - 1)}{\sin \pi(z_l - z_m + b_m - 1)} + \frac{\sin \pi(1 - b_m + z_m)}{\sin \pi(1 - b_m + z_m - z_n)} \right] R_m \\ &= \frac{-\pi^{-1} \sin \pi(z_n) \prod_{i=1}^{n} \prod_{k=1, k \neq l}^{n-1} \Gamma(1 - a_i + z_i - z_k) \Gamma(b_i - z_i + k)}{\prod_{i,k=1}^{n} \Gamma(b_i - a_k - z_i + z_k) \prod_{1 \leqq i < j \leqq n-1, i, j \neq l} \Gamma(z_i - z_j) \Gamma(1 - z_i + z_j)} \\ &\quad \cdot \frac{\prod_{i=1}^{n} \Gamma(z_l - c_i) \Gamma(1 - z_l + c_i) \Gamma(d_i - z_l) \Gamma(1 - d_i + z_l)}{\Gamma\left(1 - \sum_{i=1}^{n} a_i\right) \Gamma\left(1 - n + \sum_{k=1}^{n} b_i\right) \Gamma(z_l - z_n) \Gamma(1 - z_l + z_n)} \\ &\quad \cdot \frac{\Gamma\left(1 - n + \sum_{i=1}^{n} (b_i - a_i)\right)}{\prod_{i=l+1}^{n-1} \Gamma(z_l - z_i) \Gamma(1 - z_l + z_i) \Gamma(z_i - z_n) \Gamma(1 - z_i + z_n)}. \end{aligned}$$

Now substituting identity (3.18) into (3.11) and using that $b_i = 1$, $1 \leqq i \leqq l - 1$, we obtain identity (1.14). Q.E.D.

LEMMA 3.19. *With assumptions as in Theorem* 1.13 *the series*

$$\sum_{\substack{y_1,\cdots,y_n=-\infty\\ y_1+\cdots+y_n=0}}^{\infty} \prod_{1\leqq i<j\leqq n} ((z_i+y_i)-(z_j+y_j)) \prod_{i,k=1}^{n} \frac{(a_i-z_i+z_k)_{y_k}}{(b_i-z_i+z_k)_{y_k}} \tag{3.20}$$

converges absolutely whenever $\operatorname{Re}(\sum_{i=1}^n (b_i-a_i))>n-1$.

Proof. (cf. [18, Lemma 2.6].) The proof is similar to that for the convergence of the series (2.1). With notation as above and as in (2.3), we write

$$\begin{aligned}&\prod_{1\leqq i<j\leqq n} ((z_i+y_i)-(z_j+y_j)) \prod_{i,k=1}^{n} \frac{(a_i-z_i+z_k)_{y_k}}{(b_i-z_i+z_k)_{y_k}}\\ &\quad=\sum_{\sigma\in S_n} \varepsilon(\sigma) \prod_{k=1}^{n}\left[(z_{\sigma(k)}+y_{\sigma(k)})^{n-k}\prod_{i=1}^{n}\frac{(a_i-z_i+z_{\sigma(k)})_{y_{\sigma(k)}}}{(b_i-z_i+z_{\sigma(k)})_{y_{\sigma(k)}}}\right].\end{aligned} \tag{3.21}$$

Using the well-known identity

$$\Gamma(z)=\lim_{n\to\infty}\frac{(n-1)!\,n^z}{(z)_n} \tag{3.22}$$

[21, p. 11], one shows that

$$\lim_{|y_{\sigma(1)}|\to\infty} (z_{\sigma(1)}+y_{\sigma(1)})^{n-1} \prod_{i=1}^{n}\frac{(a_i-z_i+z_{\sigma(1)})_{y_{\sigma(1)}}}{(b_i-z_i+z_{\sigma(1)})_{y_{\sigma(1)}}}=0 \tag{3.23}$$

since $\operatorname{Re}(\sum_{i=1}^n (b_i-a_i))>n-1$. Hence

$$\left|(z_{\sigma(1)}+y_{\sigma(1)})^{n-1} \prod_{i=1}^{n}\frac{(a_i-z_i+z_{\sigma(1)})_{y_{\sigma(1)}}}{(b_i-z_i+z_{\sigma(1)})_{y_{\sigma(1)}}}\right|\leqq M \tag{3.24}$$

for some constant $M>0$ independent of $y_{\sigma(1)}$. It now follows that the series (3.20) converges absolutely whenever the following series converges:

$$\sum_{\sigma\in S_n} M \prod_{k=2}^{n}\left[\sum_{y_{\sigma(k)}=-\infty}^{\infty}\left|(z_{\sigma(k)}+y_{\sigma(k)})^{n-k}\prod_{i=1}^{n}\frac{(a_i-z_i+z_{\sigma(k)})_{y_{\sigma(k)}}}{(b_i-z_i+z_{\sigma(k)})_{y_{\sigma(k)}}}\right|\right]. \tag{3.25}$$

Since $\operatorname{Re}(\sum_{i=1}^n (b_i-a_i))>n-1$, then each interior series of (3.25) for $k=2,\cdots,n$ converges absolutely by a standard argument (see [21, p. 46]). Q.E.D.

4. A generalization of the ${}_6\Psi_6$ summation theorem.

In this section we consider basic hypergeometric series in $U(n)$, with base q such that $|q|<1$. Similar to § 3, let

$$\begin{aligned}&k_l(s;y_1,\cdots,y_{l-1},y_{l+1},\cdots,y_{n-1})=k_l(s;y)\\ &\qquad=(-1)^{n-l-1}\frac{[z_nz_l/s]_\infty[qs/(z_nz_l)]_\infty[z_nz_l/u]_\infty[qu/(z_nz_l)]_\infty}{[z_l/s]_\infty[qs/z_l]_\infty[z_l/u]_\infty[qu/z]_\infty}\\ &\qquad\cdot\left(z_n\prod_{i=1}^{n}(b_i/a_i)\right)^{\sum_{i=1,i\neq l}^{n-1}y_i}\prod_{\substack{i=1\\ i\neq l}}^{n-1}(z_iq^{y_i}-s)(z_iq^{y_i}-u)\\ &\qquad\cdot\prod_{i=1}^{n}\frac{[qa_i^{-1}z_is^{-1}]_\infty[qa_i^{-1}z_iu^{-1}]_\infty}{[qb_i^{-1}z_is^{-1}]_\infty[qb_i^{-1}z_iu^{-1}]_\infty}\prod_{\substack{1\leqq i<j\leqq n-1\\ i,j\neq l}}(z_iq^{y_i}-z_jq^{y_j})\prod_{i=1}^{n}\prod_{\substack{j=1\\ j\neq l}}^{n-1}\frac{[a_iz_j/z_i]_{y_j}}{[b_iz_j/z_i]_{y_j}},\end{aligned} \tag{4.1}$$

where we assume that $a_iz_j/z_i \neq q^k$ for $1 \leqq i \leqq n$, $l \leqq j \leqq n$, and $q^{-1}b_iz_j/z_i \neq q^{-k}$ for $1 \leqq i, j \leqq n$, where k is a positive integer. We also assume that $y_1, \cdots, y_{l-1}$ are nonnegative integers and $y_{l+1}, \cdots, y_{n-1}$ are integers and

$$\text{(4.2)} \qquad suq^{\sum_{i=1, i\neq l}^{n-1} y_i} = z_n z_l.$$

As in § 3 we consider the contour integral, for $1 \leqq l \leqq n-1$, $(-1/2\pi i) \int_C k_l(s; y)\, ds$, where $C = C_1(w) + C_2(w)$, for $w > 0$, and $C_1(w)$ is the circle of radius w^{-1} traversed in the clockwise direction and $C_2(w)$ is the circle of radius w traversed in the counterclockwise direction. We will let $w \to \infty$ through values w_0, $w_0|q|^{-1}$, $w_0|q|^{-2}, \cdots$, where w_0 is chosen so that the contours $C_1(w) + C_2(w)$ avoid the poles of $k_l(s; y)$ for all $y_1, \cdots, y_{l-1} \geqq 0$; and $y_{l+1}, \cdots, y_n \in \mathbb{Z}$. If for $a, z \in \mathbb{C}$ we define $\sigma(a, z) = [a/z]_\infty [qz/a]_\infty$, then

$$\text{(4.3)} \qquad \sigma(a, qz) = -(a/qz)\sigma(a, z).$$

From identity (4.3) one shows that for fixed $y_1, \cdots, y_{l-1}, y_{l+1}, \cdots, y_{n-1}$, we have

$$\text{(4.4)} \qquad |k_l(s; y)| = O\left(\left|q^{(2-n)|k|} \prod_{i=1}^n (b_i/a_i)\right|\right)$$

for $|q|^k \geqq |s| > |q|^{k+1}$ as $k \to \infty$ or $k \to -\infty$. It follows that if $|q^{1-n} \prod_{i=1}^n (b_i/a_i)| < 1$, then

$$\text{(4.5)} \qquad \lim_{w\to\infty} -\frac{1}{2\pi i} \int_C k_l(s; y)\, ds = 0.$$

Proof of Theorem 1.15. The proof of the absolute convergence for $|q^{1-n} \prod_{i=1}^n (b_i/a_i)| < 1$ of the series (1.16) is similar to the proof of Lemma 3.19 and will be given in Lemma 4.22.

As in the proof of Theorem 1.13, we make the induction hypothesis that $b_i = q$ for $1 \leqq i \leqq l-1$. This reduces the summation in (1.16) to $y_1, \cdots, y_{l-1} \geqq 0$ and $y_l, \cdots, y_n \in \mathbb{Z}$. The other terms vanish. Also, we shall multiply both sides of identity (1.16) by $\prod_{1 \leqq i<j \leqq n} (z_i - z_j)$. We are reduced to proving

$$\sum_{y_1, \cdots, y_{l-1}=0}^{\infty} \sum_{\substack{y_l, \cdots, y_n=-\infty \\ y_1+\cdots+y_n=0}}^{\infty} \prod_{1\leqq i<j\leqq n} (z_iq^{y_i} - z_jq^{y_j}) \prod_{i,k=1}^{n} \frac{[a_iz_j/z_i]_{y_j}}{[b_iz_j/z_i]_{y_j}}$$

$$\text{(4.6)} \qquad = \frac{[q]_\infty^{n-1} \prod_{i=1}^n z_i^{n-1} \prod_{i,k=1}^n [(b_iz_k)/(a_kz_i)]_\infty}{\prod_{i,k=1}^n [(qz_i)/(a_iz_k)]_\infty [b_iz_k/z_i]_\infty}$$

$$\cdot \prod_{1\leqq i<j\leqq n} [qz_i/z_j]_\infty [z_j/z_i]_\infty \frac{\left[q\Big/\prod_{i=1}^n a_i\right]_\infty \left[q^{1-n} \prod_{i=1}^n b_i\right]_\infty}{\left[q^{1-n} \prod_{i=1}^n (b_i/a_i)\right]_\infty}.$$

For $l = n$, identity (4.6) is an immediate consequence of Theorem 1.44 of [19]. Now suppose (4.6) is true for all l satisfying $n \geqq l > t$, where t is an integer, $1 \leqq t \leqq n$. We shall then prove (4.6) for $l = t$.

As in § 3 we consider the residue of the integral

$$\frac{-1}{2\pi i} \int_C k_l(s; y)\, ds \text{ at } s = z_m q^{y_l+1} b_m^{-1},$$

for $1 \leqq m \leqq n$ and $y_l \geqq 0$, and sum over $y_1, \cdots, y_l \geqq 0$ and $y_{l+1}, \cdots, y_n \in \mathbb{Z}$, where

$y_1+\cdots+y_n=0$. Abbreviating $qb_i^{-1}z_i=c_i$ and $b_iq^{-1}z_i^{-1}z_lz_n=d_i$, for $1\leqq i\leqq n$, we obtain

$$
\begin{aligned}
R_m={}&\frac{(-1)^{n-l-1}[z_nz_l/c_m]_\infty[qc_m/(z_nz_l)]_\infty[z_nz_l/d_m]_\infty[qd_m/(z_nz_l)]_\infty}{[q]_\infty[z_l/c_m]_\infty[qc_m/z_l]_\infty[z_l/d_m]_\infty[qd_m/z_l]_\infty}\\
&\cdot\prod_{i=1}^{n}\frac{[qz_i/(a_ic_m)]_\infty[qz_i/(a_id_m)]_\infty}{[c_i/d_m]_\infty}\prod_{\substack{i=1\\ i\neq m}}^{n}\frac{1}{[c_i/c_m]_\infty}\\
&\cdot\sum_{\substack{y_1,\cdots,y_l=0\\ y_1+\cdots+y_n=0}}^{\infty}\;\sum_{y_{l+1},\cdots,y_n=-\infty}^{\infty}c_mq^{y_l}\prod_{\substack{1\leqq i<j\leqq n-1\\ i,j\neq l}}(z_iq^{y_i}-z_jq^{y_j})\\
&\cdot\prod_{\substack{i=1\\ i\neq l}}^{n-1}[(z_iq^{y_i}-c_mq^{y_l})(z_iq^{y_i}-d_mq^{y_n})]\\
&\cdot\prod_{i=1}^{n}\prod_{\substack{j=1\\ j\neq l}}^{n-1}\frac{[a_iz_j/z_i]_{y_j}}{[b_iz_j/z_i]_{y_j}}\prod_{i=1}^{n}\frac{[a_ic_m/z_i]_{y_l}[a_id_m/z_i]_{y_n}}{[b_ic_m/z_i]_{y_l}[b_id_m/z_i]_{y_n}}.
\end{aligned}
\tag{4.7}
$$

Under the condition $|q^{1-n}\prod_{i=1}^{n}(b_i/a_i)|<1$, it follows as in Lemma 4.22 below that R_m is absolutely convergent.

If we consider the residue of $(-1/2\pi i)\int_C k_l(s;y)\,ds$ at $u=z_mq^{y_l+1}\cdot b_m^{-1}$, where u satisfies (4.2), and sum over $y_1,\cdots,y_l\geqq 0$ and $y_{l+1},\cdots,y_n\in\mathbb{Z}$ with $y_1+\cdots+y_n=0$, we obtain a similar series R'_m. The series R'_m is also absolutely convergent under the condition $|q^{1-n}\prod_{i=1}^{n}(b_i/a_i)|<1$. We have

$$
\begin{aligned}
R_m+R'_m={}&\frac{(-1)^{n-l-1}[z_nz_l/c_m]_\infty[qc_m/(z_nz_l)]_\infty[z_nz_l/d_m]_\infty[qd_m/(z_nz_l)]_\infty}{[q]_\infty[z_l/c_m]_\infty[qc_m/z_l]_\infty[z_l/d_m]_\infty[qd_m/z_l]_\infty}\\
&\cdot\prod_{i=1}^{n}\frac{[qz_i/(a_ic_m)]_\infty[qz_i/(a_id_m)]_\infty}{[c_i/d_m]_\infty}\prod_{\substack{i=1\\ i\neq m}}^{n}\frac{1}{[c_i/c_m]_\infty}\\
&\cdot\sum_{\substack{y_1,\cdots,y_l=0\\ y_1+\cdots+y_n=0}}^{\infty}\;\sum_{y_{l+1},\cdots,y_n=-\infty}^{\infty}(c_nq^{y_l}-d_mq^{y_n})\prod_{\substack{1\leqq i<j\leqq n-1\\ i,j\neq l}}(z_iq^{y_i}-z_jq^{y_j})\\
&\cdot\prod_{\substack{i=1\\ i\neq l}}^{n-1}[(z_iq^{y_i}-c_mq^{y_l})(z_iq^{y_i}-d_mq^{y_n})]\\
&\cdot\prod_{i=1}^{n}\prod_{\substack{j=1\\ j\neq l}}^{n-1}\frac{[a_iz_j/z_i]_{y_j}}{[b_iz_j/z_i]_{y_j}}\prod_{i=1}^{n}\frac{[a_ic_m/z_i]_{y_l}[a_id_m/z_i]_{y_n}}{[b_ic_m/z_i]_{y_l}[b_id_m/z_i]_{y_n}}.
\end{aligned}
\tag{4.8}
$$

By a symmetry argument similar to that for identity (3.8) of § 3, one shows that

$$R_m+R'_m=0\quad\text{for } 1\leqq m\leqq l-1. \tag{4.9}$$

Now considering the residues of $(-1/2\pi i)\int_C k_l(s;y)\,ds$ at $s=z_lq^{y_l}$ and $u=z_lq^{y_l}$ for $y_l\in\mathbb{Z}$ and summing over $y_1,\cdots,y_{l-1}\geqq 0$ and $y_l,\cdots,y_n\in\mathbb{Z}$ with $z_1+\cdots+y_n=0$, we obtain

$$
\begin{aligned}
B_l={}&\frac{[z_n]_\infty[q/z_n]_\infty[z_l]_\infty[q/z_l]_\infty}{[q]_\infty^2[z_l/z_n]_\infty[qz_n/z_l]_\infty}\prod_{i=1}^{n}\frac{[qa_i^{-1}z_iz_l^{-1}]_\infty[qa_i^{-1}z_iz_n^{-1}]_\infty}{[c_iz_l^{-1}]_\infty[c_iz_n^{-1}]_\infty}\\
&\cdot\sum_{\substack{y_1,\cdots,y_{l-1}=0\\ y_1+\cdots+y_n=0}}^{\infty}\;\sum_{y_l,\cdots,y_n=-\infty}^{\infty}\prod_{1\leqq i<j\leqq n}(z_iq^{y_i}-z_jq^{y_j})\prod_{i,j=1}^{n}\frac{[a_iz_j/z_i]_{y_j}}{[b_iz_j/z_i]_{y_j}}.
\end{aligned}
\tag{4.10}
$$

B_l is absolutely convergent under the condition $|q^{1-n}\prod_{i=1}^{n}(b_i/a_i)|<1$.

As in § 3, the fact that the series B_l and R_m, R'_m for $1 \leqq m \leqq n$ are absolutely convergent and that $\lim_{w\to\infty}(-1/2\pi i)\int_C k_l(s; y)\,ds = 0$ imply that

$$\sum_{y_1,\cdots,y_{l-1}\geqq 0}^{\infty}\ \sum_{y_{l+1},\cdots,y_{n-1}=-\infty}^{\infty} \lim_{w\to\infty}\frac{-1}{2\pi i}\int_C k_l(s; y)\,ds = B_l + \sum_{m=1}^{n}(R_m + R'_m) = 0. \tag{4.11}$$

By the induction hypothesis $R_m + R'_m$ for $l \leqq m \leqq n$ can be summed by (4.6):

$$\begin{aligned}
R_m + R'_m = {}& \frac{[q]_\infty^{n-2}[z_n z_l/c_m]_\infty[qc_m/z_n z_l]_\infty}{[z_l/c_m]_\infty[qc_m/z_l]_\infty}(c_m)^{n-l} \\
& \cdot \frac{[z_n z_l/d_m]_\infty[qd_m/z_n z_l]_\infty}{[z_l/d_m]_\infty[qd_m/z_l]_\infty}\prod_{i=1}^{n}\frac{[qz_i/a_i c_m]_\infty[qz_i/a_i d_m]_\infty}{[c_i/d_m]_\infty} \\
& \cdot \prod_{\substack{i=1\\ i\neq m}}^{n}\frac{1}{[c_i/c_m]_\infty}\prod_{i=1}^{n-1} z_i^{n-1}\prod_{i,k=1}^{n}[(b_i z_k)/(a_k z_i)]_\infty \\
& \cdot \frac{\displaystyle\prod_{1\leqq i<j\leqq n-1,i,j\neq l}[qz_i/z_j]_\infty[z_j/z_i]_\infty}{\displaystyle\prod_{i,k=1,k\neq l,n}^{n}[(qz_i)/(a_i z_k)]_\infty[b_i z_k/z_i]_\infty} \\
& \cdot \frac{\displaystyle\prod_{i=1}^{l-1}[qz_i/c_m]_\infty[c_m/z_i]_\infty\prod_{j=l+1}^{n-1}[qc_m/z_j]_\infty[z_j/c_m]_\infty}{\displaystyle\prod_{i=1}^{n}[qz_i/(a_i c_m)]_\infty[qz_i/(a_i d_m)]_\infty[b_i c_m/z_i]_\infty[b_i d_m/z_i]_\infty} \\
& \cdot \frac{\displaystyle\prod_{i=1,i\neq l}^{n-1}[qz_i/d_m]_\infty[d_m/z_i]_\infty\cdot\left[q\Big/\prod_{i=1} a_i\right]_\infty\left[q^{1-n}\prod_{i=1} b_i\right]_\infty}{\left[q^{1-n}\displaystyle\prod_{i=1}^{n}(b_i/a_i)\right]_\infty} \\
& \cdot [qc_m/d_m]_\infty[d_m/c_m]_\infty
\end{aligned} \tag{4.12}$$

$$\begin{aligned}
= {}& c_m^{n-l}(-d_m/c_m)(z_n z_l)^{l-1}\prod_{i=1}^{l-1} z_i^{-2}\prod_{i=1}^{n-1} z_i^{n-i} \\
& \cdot \frac{\displaystyle\prod_{j=l+1}^{n-1}[qc_m/z_j]_\infty[z_j/c_m]_\infty[qz_j/d_m]_\infty[d_m/z_j]_\infty}{\displaystyle\prod_{i=l,i\neq m}^{n}[c_i/c_m]_\infty[qc_m/c_i]_\infty[c_i/d_m]_\infty[qd_m/c_i]_\infty} \\
& \cdot \frac{[z_n z_l/c_m]_\infty[qc_m/(z_n z_l)]_\infty[z_n z_l/d_m]_\infty[qd_m/(z_n z_l)]_\infty}{[z_l/c_m]_\infty[qc_m/z_l]_\infty[z_l/d_m]_\infty[qd_m/z_l]_\infty} \\
& \cdot \frac{\displaystyle\prod_{i,k=1}^{n}[(b_i z_k)/(a_k z_i)]_\infty\prod_{1\leqq i<j\leqq n-1,i,j\neq l}[qz_i/z_j]_\infty[z_j/z_i]_\infty}{\left[q^{1-n}\displaystyle\prod_{i=1}^{n}(b_i/a_i)\right]_\infty\displaystyle\prod_{i=1}^{n}\prod_{k=1,k\neq l}^{n-1}[(qz_i)/(a_i z_k)]_\infty[b_i z_k/z_i]_\infty} \\
& \cdot \left[q\Big/\prod_{i=1} a_i\right]_\infty\left[q^{1-n}\prod_{i=1}^{n} b_i\right]_\infty[q]_\infty^{n-3}.
\end{aligned} \tag{4.13}$$

The following lemma will be used to compute the sum $\sum_{m=l}^{n}(R_m + R'_m)$.

LEMMA 4.14. *Assume that c_i, d_i, $z_i \in \mathbb{C}$, $l \leqq i \leqq n$, are defined as above and define*

$$E_m = c_m^{n-l}\left(\frac{-d_m}{c_m}\right)\frac{\prod\limits_{j=l+1}^{n-1}[qc_m/z_j]_\infty[z_j/c_m]_\infty[qz_j/d_m]_\infty[d_m/z_j]_\infty}{\prod\limits_{i=l,i\neq m}^{n}[c_i/c_m]_\infty[qc_m/c_i]_\infty[c_i/d_m]_\infty[qd_m/c_i]_\infty} \tag{4.15a}$$
$$\cdot\frac{[z_nz_l/c_m]_\infty[qc_m/(z_nz_l)]_\infty[z_nz_l/d_m]_\infty[qd_m/(z_nz_l)]_\infty}{[z_l/c_m]_\infty[qc_m/z_l]_\infty[z_l/d_m]_\infty[qd_m/z_l]_\infty},$$

for $l \leqq m \leqq n$, and

$$E_{n+1} = (z_l)^{n-l}\left(\frac{-z_n}{z_l}\right)\frac{\prod\limits_{j=l+1}^{n-1}[qz_l/z_j]_\infty[z_j/z_l]_\infty[qz_j/z_n]_\infty[z_n/z_j]_\infty}{\prod\limits_{i=1}^{n}[c_i/z_l]_\infty[qz_l/c_i]_\infty[c_i/z_n]_\infty[qz_n/c_i]_\infty} \tag{4.15b}$$
$$\cdot [z_n]_\infty[q/z_n]_\infty[z_l]_\infty[q/z_l]_\infty.$$

Then

$$E = \sum_{m=l}^{n+1} E_m = 0, \tag{4.16}$$

where it is assumed that the denominators of the E_m, $l \leqq m \leqq n+1$, do not vanish.

Proof. Consider E and E_m, $l \leqq m \leqq n+1$, as functions of the variables $c_l, \cdots, c_n$, $z_l, \cdots, z_n \in \mathbb{C}^*$ (where $\mathbb{C}^* = \mathbb{C} - \{0\}$). Observe that for $l \leqq s \leqq n$ and $l \leqq m \leqq n+1$, we have

$$\begin{aligned} &E_m(c_l, \cdots, c_{s-1}, qc_s, c_{s+1}, \cdots, c_n, z_l, \cdots, z_n) \\ &\quad = \left(\frac{c_s}{d_s}\right) E_m(c_l, \cdots, c_{s-1}, c_s, c_{s+1}, \cdots, z_n). \end{aligned} \tag{4.17}$$

We first show that $E(c_l, \cdots, c_n, z_l, \cdots, z_n)$ is holomorphic in the region $(\mathbb{C}^*)^{2(n-l+1)}$. The possible poles of E occur when $c_s = q^k c_t$, $c_s = q^k d_t$, $c_s = q^k z_l$ or $c_s = q^k z_n$ for $l \leqq s$, $t \leqq n$, $s \neq t$, and k an integer. It follows from (4.17) that if suffices to show that E has no poles for $k = 0$.

One now verifies that for $l \leqq s, t \leqq n$ and $s \neq t$, we have $\lim_{c_s \to c_t}(E_s + E_t)$ and $\lim_{c_s \to d_t}(E_s + E_t)$ exist and are finite. Since E_m for $l \leqq m \leqq n+1$ and $m \neq s, t$ is continuous as $c_s \to c_t$ and $c_s \to d_t$, it follows that E has no pole at $c_s = c_t$ or at $c_s = d_t$. Similarly for $l \leqq s \leqq n$ we verify that $\lim_{c_s \to z_l}(E_s + E_{n+1})$ exist and are finite, while E_m is continuous as $c_s \to z_l$ and $c_s \to z_n$ for $l \leqq m \leqq n$ and $m \neq s$. Hence E has no pole at $c_s = z_l$ or at $c_s = z_n$ and $E(c_l, \cdots, z_n)$ is holomorphic in the region $(\mathbb{C}^*)^{2(n-l+1)}$.

Now choose an integer s, $l \leqq s \leqq n$, and fix the variables $c_l, \cdots, c_{s-1}, c_{s+1}, \cdots, c_n$, $z_l, \cdots, z_n \in \mathbb{C}^*$. Let

$$M = \max_{|q| \leqq |c_s| \leqq 1} |E(c_l, \cdots, c_n, z_l, \cdots, z_n)|. \tag{4.18}$$

An application of identity (4.17) yields

$$\begin{aligned} &E(c_l, \cdots, c_{s-1}q^k c_s, c_{s+1}, \cdots, c_n, z_l, \cdots, z_n) \\ &\quad = q^{k(k-1)}\left(\frac{c_s}{d_s}\right)^k E(c_l, \cdots, c_{s-1}, c_s, c_{s+1}, \cdots, z_n) \end{aligned} \tag{4.19}$$

where k is an integer. By the maximum principle for holomorphic functions (in the variable c_s), we find

$$\max_{|q|^{h+1}\leqq|c_s|\leqq|q|^{-j}} |E(c_l, \cdots, z_n)| \leqq M \max\left(|q|^{h(h-1)}|z_n z_l|^{-h}, |q|^{j(j+1)}|z_n z_l|^{j}\right), \tag{4.20}$$

where j and h are nonnegative integers. It follows that for fixed $(c_l, \cdots, c_{s-1}, c_{s+1}, \cdots, c_n, z_l, \cdots, z_n)$ we have $\lim_{c_s\to 0} E=0$ and $\lim_{c_s\to\infty} E=0$. Hence by the maximum principle E must be identically 0. This completes the proof of Lemma 4.14.

Putting together expressions (4.11), (4.13), and (4.16), we obtain

$$\begin{aligned}
-\sum_{m=l}^{n}(R_m+R'_m) = B_l &= \frac{-z_n}{z_l}\prod_{i=1}^{n-1} z_i^{n-1}\prod_{i=1}^{l-1}\left(\frac{z_n z_l}{z_i^2}\right)[q]_\infty^{n-3} \\
&\cdot\frac{\prod_{j=l+1}^{n-1}[qz_l/z_j]_\infty[z_j/z_l]_\infty[qz_j/z_n]_\infty[z_n/z_j]_\infty}{\prod_{i=l}^{n}[c_i/z_l]_\infty[qz_l/c_i]_\infty[c_i/z_n]_\infty[qz_n/c_i]_\infty} \\
&\cdot\frac{\prod_{i,k=1}^{n}[(b_i z_k)/(a_k z_i)]_\infty \prod_{1\leqq i<j\leqq n-1, i,j\neq l}[qz_i/z_j]_\infty[z_j/z_i]_\infty}{\left[q^{1-n}\prod_{i=1}^{n}(b_i/a_i)\right]_\infty \prod_{i=1}^{n}\prod_{k=1,k\neq l}^{n-1}[(qz_i)/(a_i z_k)]_\infty[b_i z_k/z_i]_\infty} \\
&\cdot [z_n]_\infty[q/z_n]_\infty[z_l]_\infty[q/z_l]_\infty\left[q\Big/\prod_{i=1}^{n}a_i\right]_\infty\left[q^{1-n}\prod_{i=1}^{n}b_i\right]_\infty.
\end{aligned} \tag{4.21}$$

Equating expressions (4.10) and (4.21) for B_l, we obtain after a little algebra identity (4.6). Theorem 1.15 now follows by induction once we prove the previously promised Lemma 4.22 for the absolute convergence of the series (4.6).

LEMMA 4.22. *With assumptions as in Theorem* 1.15, *the series*

$$\sum_{\substack{y_1,\cdots,y_n=-\infty \\ y_1+\cdots+y_n=0}}^{\infty}\prod_{1\leqq i<j\leqq n}(z_i q^{y_i}-z_j q^{y_j})\prod_{i,k=1}^{n}\frac{[a_i z_k/z_i]_{y_k}}{[b_i z_k/z_i]_{y_k}} \tag{4.23}$$

converges absolutely whenever $|q^{1-n}\prod_{i=1}^{n}(b_i/a_i)|<1$.

Proof. The proof is similar to that of Lemma 3.19 with some modification. We write

$$\begin{aligned}
&\prod_{1\leqq i<j\leqq n}(z_i q^{y_i}-z_j q^{y_j})\prod_{i,k=1}^{n}\frac{[a_i z_k/z_i]_{y_k}}{[b_i z_k/z_i]_{y_k}} \\
&\quad=\sum_{\sigma\in S_n}\varepsilon(\sigma)\prod_{k=1}^{n}(z_{\sigma(k)}q^{y_{\sigma(k)}})^{n-k}\prod_{i=1}^{n}\frac{[a_i z_{\sigma(k)}/z_i]_{y_{\sigma(k)}}}{[b_i z_{\sigma(k)}/z_i]_{y_{\sigma(k)}}}.
\end{aligned} \tag{4.24}$$

We have

$$\lim_{y_{\sigma(n)}\to\infty}\left|\prod_{i=1}^{n}\frac{[a_i z_{\sigma(n)}/z_i]_{y_{\sigma(n)}}}{[b_i z_{\sigma(n)}/z_i]_{y_{\sigma(n)}}}\right| = \prod_{i=1}^{n}\left|\frac{[a_i z_{\sigma(n)}/z_i]_\infty}{[b_i z_{\sigma(n)}/z_i]_\infty}\right| \tag{4.25a}$$

and

$$\lim_{y_{\sigma(n)}\to-\infty}\left|\prod_{i=1}^{n}\frac{[a_i z_{\sigma(n)}/z_i]_{y_{\sigma(n)}}}{[b_i z_{\sigma(n)}/z_i]_{y_{\sigma(n)}}}\right| = \lim_{y_{\sigma(n)_n}\to-\infty}\prod_{i=1}^{n}\left|\frac{b_i}{a_i}\right|^{-y_{\sigma(n)}}\left|\frac{[qz_i/(b_i z_{\sigma(n)})]_{-y_{\sigma(n)}}}{[qz_i/(a_i z_{\sigma(n)})]_{-y_{\sigma(n)}}}\right| = 0, \tag{4.25b}$$

since $|\prod_{i=1}(b_i/a_i)|<|q|^{n-1}$. Hence

$$\left|\prod_{i=1}^{n}\frac{[a_iz_{\sigma(n)}/z_i]_{y_{\sigma(n)}}}{[b_iz_{\sigma(n)}/z_i]_{y_{\sigma(n)}}}\right|\leqq M \tag{4.26}$$

for some constant $M>0$ independent of $y_{\sigma(n)}$. It follows that the series (4.24) converges absolutely whenever the following series converges:

$$\sum_{\sigma\in S_n} M\prod_{i=1}^{n-1}\left[\sum_{y_{\sigma(n)}=-\infty}^{\infty}\left|[(z_{\sigma(k)}q^{y_{\sigma(k)}})^{n-k}\prod_{i=1}^{n}\frac{[a_iz_{\sigma(k)}/z_i]_{y_{\sigma(k)}}}{[b_iz_{\sigma(k)}/z_i]_{y_{\sigma(k)}}}\right|\right]. \tag{4.27}$$

Since $|\prod_{i=1}^{n}(b_i/a_i)|<|q|^{n-1}$, then each interior series for $k=1,\cdots,n-1$ converges absolutely by an application of the ratio test to the sums for $y_{\sigma(k)}\geqq 0$ and $y_{\sigma(k)}<0$. Q.E.D.

5. A generalization of the ${}_1\Psi_1$ summation theorem.

Proof of Theorem 1.17. The notation and assumptions below are as in the statement of Theorem 1.17.

First, by an argument virtually identical to that of Lemma 2.5 of [18], it follows that the series (1.18) converges for

$$\left|q^{1-n}\prod_{i=1}^{n}(b_i/a_i)\right|<|t|<1.$$

We rewrite the series in (1.18) as

$$\prod_{1\leqq i<j\leqq n}(z_i-z_j)^{-1}\sum_{M=-\infty}^{\infty}t^M\sum_{\substack{y_1,\cdots,y_n=-\infty\\ y_1,\cdots,y_n=M}}^{\infty}\prod_{1\leqq i<j\leqq n}(z_iq^{y_i}-z_jq^{y_j})\prod_{i,k=1}^{n}\frac{[a_iz_k/z_i]_{y_k}}{[b_iz_k/z_i]_{y_k}}. \tag{5.1}$$

Set $y_1'=y_1-M$, $z_1'=z_1q^M$, $a_1'=a_1q^M$, $b_1'=b_1q^M$, and $y_l'=y_l$, $z_l'=z_l$, $a_l'=a_l$, $b_l'=b_l$ for $2\leqq l\leqq n$. Then expression (5.1) becomes

$$\begin{aligned}&=\prod_{1\leqq i<j\leqq n}(z_i-z_j)^{-1}\\ &\quad\cdot\sum_{M=-\infty}^{\infty}\left\{t^M\prod_{i=1}^{n}\frac{[a_iz_1/z_i]_M}{[b_iz_1/z_i]_M}\right.\\ &\qquad\cdot\left.\sum_{\substack{y_1',\cdots y_n'=-\infty\\ y_1'+\cdots+y_n'=0}}^{\infty}\prod_{1<i<j\leqq n}(z_i'q^{y_1'}-z_j'q^{y_1'})\prod_{i,k=1}^{n}\frac{[a_i'z_k'/z_i']_{y_k'}}{[b_i'z_k'/z_i']_{y_k'}}\right\}.\end{aligned} \tag{5.2}$$

Applying Theorem 1.15 and some algebra we obtain

$$\begin{aligned}&=\frac{[q]_\infty^{n-1}\prod_{i,k=1}^{n}[(b_iz_k)/(a_kz_i)]_\infty\prod_{1<i<j\leqq n}[qz_i/z_j]_\infty[qz_j/z_i]_\infty}{\left[q^{1-n}\prod_{i=1}^{n}(b_i/a_i)\right]_\infty\prod_{i,k=1}^{\infty}[(qz_i)/(a_iz_k)]_\infty[b_iz_k/z_i]_\infty}\\ &\quad\cdot\left[q\Big/\prod_{i=1}^{n}a_i\right]_\infty\left[q^{1-n}\prod_{i=1}^{n}b_i\right]_\infty\sum_{M=-\infty}^{\infty}\frac{\left[\prod_{i=1}^{n}a_i\right]_M}{\left[q^{1-n}\prod_{i=1}^{n}b_i\right]_M}t^M.\end{aligned} \tag{5.3}$$

Identity (1.18) and Theorem 1.17 now follow by an application of the classical ${}_1\Psi_1$ summation theorem (1.9). Q.E.D.

ASYMPTOTIC BEHAVIOUR OF THE COEFFICIENTS OF SOME SEQUENCES OF POLYNOMIALS*

W. VAN ASSCHE†, G. FANO‡ AND F. ORTOLANI§

Abstract. The asymptotic behaviour of the Taylor coefficients of a sequence of polynomials $\{p_n(x); n=1,2,3,\cdots\}$ is given under the conditions that all the zeros are negative and that the limit $p_n(x)^{1/n} (n\to\infty)$ exists for $x>0$. The result is then applied to orthogonal polynomials and to the iterations of a polynomial.

Key words. coefficients of polynomials, zeros of polynomials, orthogonal polynomials

AMS(MOS) subject classifications. Primary 26C05; secondary 33A65, 42C05

1. Introduction. Suppose we are given a sequence of monic polynomials $\{p_n(x)= x^n+\cdots; n=1,2,3,\cdots\}$. Let us denote its Taylor series around $x=0$ by

$$(1)\qquad p_n(x)=\sum_{j=0}^{n} a_{j,n}x^{n-j} \qquad (a_{0,n}=1)$$

and its zeros by $\{x_{j,n}, j=1,2,\cdots,n\}$. The Taylor coefficients and the zeros are related by the elementary symmetric relations of Viète

$$a_{j,n}=\frac{(-1)^j}{j!}\sum_{\alpha_1\neq\alpha_2\neq\cdots\neq\alpha_j} x_{\alpha_1,n}x_{\alpha_2,n}\cdots x_{\alpha_j,n},$$

and if we suppose that all the zeros of p_n are negative then

$$(2)\qquad \begin{aligned} a_{j,n} &=\frac{1}{j!}\sum_{\alpha_1\neq\alpha_2\neq\cdots\neq\alpha_j} |x_{\alpha_1,n}x_{\alpha_2,n}\cdots x_{\alpha_j,n}| \\ &= \sum_{\alpha_1<\alpha_2<\cdots<\alpha_j} |x_{\alpha_1,n}x_{\alpha_2,n}\cdots x_{\alpha_j,n}| \end{aligned}$$

from which we easily deduce the positivity of the coefficients $\{a_{j,n}, j=0,1,2,\cdots,n\}$.

If one knows the asymptotic behaviour of the polynomials p_n when n increases to infinity, then a natural question is to ask for the asymptotic behaviour of its Taylor coefficients $a_{j,n}$ for increasing n. To cover as many limits as possible we let j tend to infinity together with n in such a way that $j/n\to d\in(0,1)$. This question is analogous to a problem in physics when one wants to obtain the free energy per unit volume of an infinite system from the grand partition function [7]. In particular the analysis of the thermodynamic limit of the famous Bardeen-Cooper-Schrieffer superconductivity state was studied in [5], [6] using standard techniques in statistical mechanics. The general mathematical problem of "dense sums" (like $a_{j,n}$ when j and n tend to infinity) was investigated in [5]. Let us define the distribution of the zeros by the following:

$$(3)\qquad F_n(t)=\frac{1}{n}\{\text{number of zeros of } p_n \text{ in } (-\infty,t]\}$$

then F_n makes a jump of size k/n at a zero $x_{j,n}$ of multiplicity k. From now on we suppose that all the zeros are in $(-A, -B]$ $(0<B<A)$ so that F_n is an increasing function with $F_n(-A)=0$ and $F_n(-B)=1$ (later on we will allow B to go to zero). We will devote all our attention to those sequences of polynomials for which the sequence $\{F_n, n=1,2,\cdots\}$ converges weakly to a distribution function F, i.e.,

$$\int_{-A}^{-B} f(t)\,dF_n(t) \to \int_{-A}^{-B} f(t)\,dF(t) \qquad (n\to\infty)$$

for every (bounded and) continuous function f on $[-A, -B]$. Since

$$\frac{1}{n}\log p_n(x) = \frac{1}{n}\sum_{j=1}^{n} \log(x-x_{j,n}), \qquad x>0$$

it follows that

$$\frac{1}{n}\log p_n(x) \to \int_{-A}^{-B} \log(x-y)\,dF(y), \qquad x>0 \tag{4}$$

and in fact (4) also implies the weak convergence of F_n to F, so that this weak convergence is equivalent to the asymptotic behaviour

$$\lim_{n\to\infty} \{p_n(x)\}^{1/n} = \exp\left\{\int_{-A}^{-B} \log(x-y)\,dF(y)\right\}, \qquad x>0. \tag{5}$$

2. The main result. This paper is devoted to the proof of the following theorem.

THEOREM 1. *Let $\{p_n(x), n=1,2,3,\cdots\}$ be a sequence of polynomials for which all the zeros are in $[-A, 0]$, $(0<A)$ and for which the distribution functions F_n given in* (3) *converge weakly to a distribution function F having no jump at zero. Then there exists a concave and differentiable function g on* $(0,1)$ *such that*

$$\frac{1}{n}\log a_{j,n} \to g(d), \tag{6}$$

$$\frac{a_{j,n}}{a_{j-1,n}} \to e^{g'(d)} = f(d) \tag{7}$$

when $n\to\infty$ and $j/n\to d\in(0,1)$. The inverse function of f is given by

$$f^{-1}(x) = -\int_{-A}^{0} \frac{y}{x-y}\,dF(y), \qquad x>0 \tag{8}$$

and

$$g(d) = -(1-d)\log f(d) + \int_{-A}^{0} \log[f(d)-y]\,dF(y), \qquad 0<d<1. \tag{9}$$

We will prove this theorem using the techniques of [5], [6], [7]. The result is not true if one only assumes weak convergence. The condition that the zeros are negative is needed to make all the $a_{j,n}$ positive. If $p_n(x)$ is an even polynomial then the coefficients of x^{2j+1} are zero and the left-hand side in (6) and (7) is not defined for many j's. Roughly speaking, the proof consists of two steps. In a first step we will show that the theorem holds for a special sequence of polynomials $\{q_n(x), n=1,2,\cdots\}$ satisfying the conditions. The second step consists in proving, by a perturbation argument, that the theorem remains to be true for any sequence of polynomials satisfying the conditions. We start by assuming that all the zeros lie in $[-A, -B]$ $(0<B<A)$. The inverse F^{-1} of the distribution function F is defined as

$$F^{-1}(y)=\inf\{x\in\mathbb{R}\,|\,F(x)\geqq y\}$$

making F^{-1} a left-continuous increasing function on $(0, 1]$. Define

$$y_{j,n}=F^{-1}\left(\frac{j}{n}\right),\qquad j=1,2,\cdots,n, \tag{10}$$

then every $y_{j,n}$ is negative and belongs to $(-A, -B]$. We will consider the sequence of polynomials $\{q_n(x),\ n=1,2,3,\cdots\}$ given by

$$q_n(x)=\prod_{j=1}^{n}(x-y_{j,n})=\sum_{j=0}^{n}b_{j,n}x^{n-j}\qquad(b_{0,n}=1). \tag{11}$$

By construction we find that these polynomials satisfy the conditions of Theorem 1.

LEMMA 2. *Let* $\{b_{j,n},\ 0\leqq j\leqq n,\ n=1,2,3,\cdots\}$ *be given by* (11), *then*

$$b_{k,n+m}\geqq\sum_{i+j=k}b_{i,n}b_{j,m}. \tag{12}$$

Proof. By (2) we have

$$b_{k,n+m}=\frac{1}{k!}\sum_{\alpha_1\neq\alpha_2\neq\cdots\neq\alpha_k}\left|F^{-1}\left(\frac{\alpha_1}{n+m}\right)F^{-1}\left(\frac{\alpha_2}{n+m}\right)\cdots F^{-1}\left(\frac{\alpha_k}{n+m}\right)\right|.$$

For every integer α there exist integers α' and β' such that

$$\frac{\alpha'-1}{n}\leqq\frac{\alpha}{n+m}<\frac{\alpha'}{n},\qquad\frac{\beta'-1}{m}\leqq\frac{\alpha}{n+m}<\frac{\beta'}{m}.$$

Replace systematically every number $\alpha/(n+m)$ by α'/n (when $\beta'/m\geqq\alpha'/n$) or by β'/m (when $\alpha'/n>\beta'/m$). This gives a one-to-one mapping from $(1/(n+m), 2/(n+m),\cdots,(n+m)/(n+m))$ to $(1/n, 2/n,\cdots,n/n, 1/m, 2/m,\cdots,m/m)$ and since F^{-1} is an increasing and negative function we find that $|F^{-1}|$ is a decreasing function so that by grouping together all the terms that have i members from $\{1/n, 2/n,\cdots,n/n\}$ and $k-i$ from $\{1/m, 2/m,\cdots,m/m\}$ we find that

$$\begin{aligned}b_{k,n+m}&\geqq\frac{1}{k!}\sum_{i=0}^{k}\binom{k}{i}\sum_{\alpha_1'\neq\alpha_2'\neq\cdots\neq\alpha_i'}\left|F^{-1}\left(\frac{\alpha_1'}{n}\right)\cdots F^{-1}\left(\frac{\alpha_i'}{n}\right)\right|\\&\quad\cdot\sum_{\beta_1'\neq\cdots\neq\beta_{k-i}'}\left|F^{-1}\left(\frac{\beta_1'}{m}\right)\cdots F^{-1}\left(\frac{\beta_{k-i}'}{m}\right)\right|\\&=\sum_{i+j=k}\frac{1}{i!}\sum_{\alpha_1'\neq\cdots\neq\alpha_i'}|y_{\alpha_1',n}\cdots y_{\alpha_i',n}|\frac{1}{j!}\sum_{\beta_1'\neq\cdots\neq\beta_j'}|y_{\beta_1',m}\cdots y_{\beta_j',m}|\end{aligned}$$

from which we obtain (12). □

Let us now introduce a sequence of continuous functions

$$g(d,n)=\begin{cases}\dfrac{1}{n}\log b_{j,n}\quad\text{if } d=\dfrac{j}{n}\quad(0\leqq j\leqq n),\\[2ex]\dfrac{1}{n}\log b_{j,n}+(nd-j)\left(\dfrac{1}{n}\log b_{j+1,n}-\dfrac{1}{n}\log b_{j,n}\right)\\[2ex]\qquad\qquad\qquad\text{if}\ \dfrac{j}{n}<d<\dfrac{j}{n+1}\qquad(0\leqq j<n).\end{cases} \tag{13}$$

These functions are bounded from below since every $|y_{j,n}| \geqq B$ so that

$$\begin{aligned}\inf_{0\leqq d\leqq 1} g(d,n) &= \min_{0\leqq j\leqq n} \frac{1}{n}\log b_{j,n}\\ &\geqq \min_{0\leqq j\leqq n} \frac{1}{n}\log \binom{n}{j} B^j\\ &\geqq \frac{1}{n}\min_{0\leqq j\leqq n}\left(\log\binom{n}{j}+j\log B\right)\\ &\geqq \frac{1}{n}\min_{0\leqq j\leqq n}\log\binom{n}{j}+\frac{1}{n}\min_{0\leqq j\leqq n} j\log B\end{aligned}$$

and because $\binom{n}{j}\geqq 1$, we then have

$$\inf_{0\leqq d\leqq 1} g(d,n) \geqq \min(\log B, 0). \tag{14}$$

LEMMA 3. *The sequence of functions* $\{g(d,n);\ n=1,2,3,\cdots,\ d\in[0,1]\}$ *converges uniformly on every compact set of* $(0,1)$ *to a concave continuous function* g.

Proof. First consider $d\in D_\infty=\{j/2^n;\ 0\leqq j\leqq 2^n,\ n\in\mathbb{N}\}$, then there exists an $N\in\mathbb{N}$ so that $d\in D_N=\{j/2^N,\ 0\leqq j\leqq 2^N\}$, say $d=K2^{-N}$. By Lemma 2 ($m=n=2^{M+N}$; $k=K2^{M+1}$) we have

$$b_{K2^{M+1},2^{M+N+1}} \geqq b^2_{K2^M,2^{M+N}}$$

so that by taking logarithms, we obtain

$$g(d, 2^{M+N+1}) \geqq g(d, 2^{M+N}).$$

The sequence $\{g(d,2^n),\ n=N, N+1,\cdots\}$ with $d\in D_N$ is therefore increasing. We always have $|y_{j,n}|\leqq A$ so that

$$\begin{aligned}\sup_{0\leqq d\leqq 1} g(d,n) &= \max_{0\leqq j\leqq n}\frac{1}{n}\log b_{j,n}\\ &\leqq \max_{0\leqq j\leqq n}\frac{1}{n}\log\binom{n}{j}A^j\\ &\leqq \frac{1}{n}\max_{0\leqq j\leqq n}\log\binom{n}{j}+\frac{1}{n}\max_{0\leqq j\leqq n} j\log A.\end{aligned}$$

Now $\binom{n}{j}\leqq 2^n$ from which

$$\sup_{0\leqq d\leqq 1} g(d,n)\leqq \log 2+\max(0,\log A)$$

so that the sequence $\{g(d,n);\ n=1,2,3,\cdots,\ d\in[0,1]\}$ is bounded from above. Together with (14) we may then conclude that there exists a function $g(d)$ on D_∞ such that

$$\lim_{n\to\infty} g(d,2^n)=g(d),\qquad d\in D_\infty.$$

Take d_1 and d_2 in D_∞, say $d_1=K_12^{-N}$ and $d_2=K_22^{-N}$, then by Lemma 2 ($n=m=2^{M+N}$, $k=(K_1+K_2)2^M$)

$$b_{(K_1+K_2)2^M,2^{M+N+1}}\geqq b_{K_12^M,2^{M+N}}b_{K_22^M,2^{M+N}}$$

and by taking logarithms

$$g\left(\frac{d_1+d_2}{2}, 2^{M+N+1}\right) \geqq \frac{1}{2}g(d_1, 2^{M+N}) + \frac{1}{2}g(d_2, 2^{M+N}).$$

Let M go to infinity to obtain the important inequality

$$(15) \qquad g\left(\frac{d_1+d_2}{2}\right) \geqq \frac{1}{2}g(d_1) + \frac{1}{2}g(d_2), \qquad d_1, d_2 \in D_\infty.$$

Now D_∞ is dense in $[0, 1]$, and by means of (15) and the boundedness of g we therefore can extend g to be a continuous concave function on $(0, 1)$ (see for example [8] or [13]), and since the functions $g(d, n)$ are all continuous we have

$$(16) \qquad \lim_{n\to\infty} g(d, 2^n) = g(d), \qquad 0 < d < 1$$

and this will hold uniformly on every compact subset of $(0, 1)$ because the convergence is monotonic ([14, Thm. 7.13]).

In order to show that the whole sequence $\{g(d, n), n = 1, 2, \cdots\}$ converges to g uniformly on every compact interval in $(0, 1)$ we need some extra results. Denote by d_n a number in $\{j/n; j = 0, 1, \cdots, n\}$ such that $|d - d_n| \leqq 1/n$. Since $g(d, n)$ is linear between any two numbers $1/n \log b_{j,n}$ and $1/n \log b_{j-1,n}$

$$|g(d_n, n) - g(d, n)| \leqq \frac{1}{n} \max_{0<j\leqq n} |\log b_{j,n} - \log b_{j-1,n}|$$

$$= \frac{1}{n} \max_{0<j\leqq n} \left|\log \frac{b_{j,n}}{b_{j-1,n}}\right|.$$

We will see later (Lemma 5) that the sequence $\{b_{j,n}/b_{j-1,n}; j = 1, 2, \cdots, n\}$ is decreasing, hence

$$\left|\log \frac{b_{j,n}}{b_{j-1,n}}\right| \leqq \max\left(\left|\log \frac{b_{n,n}}{b_{n-1,n}}\right|, |\log b_{1,n}|\right)$$

where

$$b_{1,n} = \sum_{j=1}^{n} |y_{j,n}| \sim n \int_{-A}^{-B} |x| \, dF(x),$$

$$\frac{b_{n-1,n}}{b_{n,n}} = \frac{\sum_{j=1}^{n} |y_{1,n} \cdots y_{j-1,n} y_{j+1,n} \cdots y_{n,n}|}{|y_{1,n} \cdots y_{n,n}|}$$

$$= \sum_{j=1}^{n} \frac{1}{|y_{j,n}|} \sim n \int_{-A}^{-B} \frac{1}{|x|} \, dF(x).$$

This means that

$$\sup_{0<d<1} |g(d_n, n) - g(d, n)| = O\left(\frac{\log n}{n}\right).$$

If K is a closed interval in $(0, 1)$ and $\varepsilon > 0$, then we can choose $N \in \mathbb{N}$ such that

$$\sup_{d\in K} |g(d, 2^k) - g(d)| < \varepsilon, \qquad k > N$$

(which is possible because of the uniform convergence on K) and

$$\sup_{d\in K} |g(d_{2^k})-g(d)|<\varepsilon, \qquad k>N$$

(which can be done since y is uniformly continuous on K). Then for $k>N$

$$|g(d_{2^k}, 2^k)-g(d)|\leqq |g(d_{2^k}, 2^k)-g(d_{2^k})|+|g(d_{2^k})-g(d)|$$

and if every $d_k\in K$, then

$$\begin{aligned}\sup_{d\in K} |g(d_{2^k}, 2^k)-g(d)| &\leqq \sup_{d\in K} |g(d, 2^k)-g(d)|+\sup_{d\in K} |g(d_{2^k})-g(d)|\\ &<2\varepsilon.\end{aligned}$$

If we decompose n into its binary decomposition

$$n=\sum_{k\in n^*} 2^k$$

where the definition of n^* is obvious, then

$$\begin{aligned}\sup_{d\in K} \frac{1}{n}\sum_{k\in n^*} 2^k|g(d_{2^k}, 2^k)-g(d)| &\leqq \frac{1}{n}\sup_{d\in K}\sum_{\substack{k\in n^*\\ k\leqq N}} 2^k|g(d_{2^k}, 2^k)-g(d)|\\ &\quad+\frac{1}{n}\sup_{d\in K}\sum_{\substack{k\in n^*\\ k>N}} 2^k|g(d_{2^k}, 2^k)-g(d)|\\ &\leqq \frac{2^{N+1}}{n}\max_{k\leqq N} 2^k|g(d_{2^k}, 2^k)-g(d)|+2\varepsilon\end{aligned}$$

which means that

$$\sup_{d\in K}\frac{1}{n}\sum_{k\in n^*} 2^k|g(d_{2^k}, 2^k)-g(d)|\to 0 \qquad (n\to\infty).$$

Now use Lemma 2 to find that

$$\begin{aligned}g(d, n)-g(d) &= g(d, n)-g(d_n, n)+g(d_n, n)-g(d)\\ &\geqq g(d, n)-g(d_n, n)+\frac{1}{n}\sum_{k\in n^*} 2^k\{g(d_{2^k}, 2^k)-g(d)\}\end{aligned}$$

and with the results above

$$\liminf_{n\to\infty}\inf_{d\in K}\{g(d, n)-g(d)\}\geqq 0.$$

In a similar way we may put $k=[\log_2 n]+1$ and decompose 2^k-n into its binary decomposition

$$2^k-n=\sum_{l\in n^{**}} 2^l;$$

then from Lemma 2

$$g(d_{2^k}, 2^k)\geqq\frac{n}{2^k}g(d_n, n)+\frac{2^k-n}{2^k}g(d_{2^k-n}, 2^k-n).$$

As in the previous estimation we find that

$$\begin{aligned} g(d,n)-g(d)&=g(d,n)-g(d_n,n)+g(d_n,n)-g(d)\\ &\leqq g(d,n)-g(d_n,n)+\frac{2^k}{n}\{g(d_{2^k},2^k)-g(d)\}\\ &\quad-\frac{2^k-n}{n}\{g(d_{2^k-n},2^k-n)-g(d)\}\\ &\leqq g(d,n)-g(d_n,n)+\frac{2^k}{n}\{g(d_{2^k},2^k)-g(d)\}\\ &\quad-\frac{1}{n}\sum_{l\in n^{**}}2^l\{g(d_{2^l},2^l)-g(d)\} \end{aligned}$$

from which

$$\limsup_{n\to\infty}\sup_{d\in K}\{g(d,n)-g(d)\}\leqq 0.$$

Hence $g(d,n)$ converges uniformly to $g(d)$ on every compact subset of $(0,1)$. □

Let us now relate the function g to the weak limit F.

LEMMA 4. *The limit g of Lemma 3 is differentiable on* $(0,1)$ *and if*

(17) $$h(x)=-\int_{-A}^{-B}\frac{y}{x-y}\,dF(y),\qquad x>0,$$

then

(18) $$g(h(x))+(1-h(x))\log x=\int_{-A}^{-B}\log(x-y)\,dF(y)$$

and

(19) $$g'(h(x))=\log x.$$

Proof. Since g is a concave function, it will be differentiable except for possibly a denumerable set at points $\Lambda\subset(0,1)$. The derivative of g will be a decreasing function and the left-hand and right-hand derivatives at points in Λ exist, call then $g'_-(d)$ and $g'_+(d)$, and satisfy $g'_-(d)>g'_+(d)$. Define

$$f(d)=e^{g'(d)},\qquad d\in(0,1)\backslash\Lambda$$

then f is a decreasing function with jumps at Λ. The inverse function f^{-1} then exists, and we call this function h. The function h is increasing and therefore differentiable except for a denumerable set of points Λ^*. If $y\notin\Lambda^*$ then $h(y)\in(0,1)\backslash\Lambda$, so that g is differentiable at $h(y)$. The function $g'(d)-\log x$ (with x fixed) clearly vanishes for $d=h(x)$ (by the definition of h and f), hence

(20) $$\sup_{0<d<1}\{g(d)+(1-d)\log x\}=g(h(x))+(1-h(x))\log x$$

whenever $x\notin\Lambda^*$ (this follows since $g(d)+(1-d)\log x$ can have at most one maximum).

On the other hand, it is clear that for every $j\leqq n$

$$b_{j,n}x^{n-j}\leqq q_n(x)$$

so that

$$\frac{1}{n}\log b_{j,n}+\frac{n-j}{n}\log x\leqq\frac{1}{n}\log q_n(x).$$

Now let $n\to\infty$ and $j/n\to d$, then from the uniform convergence of $g(d,n)$ to $g(d)$ we obtain

$$\sup_{0<d<1}\{g(d)+(1-d)\log x\}\leqq\int_{-A}^{-B}\log(x-y)\,dF(y).$$

We also find that

$$q_n(x)\leqq n\max_{0\leqq j\leqq n} b_{j,n}x^{n-j}$$

so that

$$\frac{1}{n}\log q_n(x)\leqq\frac{1}{n}\log n+\max_{0\leqq j\leqq n}\left\{\frac{1}{n}\log b_{j,n}+\frac{n-j}{n}\log x\right\}.$$

Let $n\to\infty$ and $j/n\to d$, then

$$\int_{-A}^{-B}\log(x-y)\,dF(y)\leqq\sup_{0<d<1}\{g(d)+(1-d)\log x\}.$$

Combination of these inequalities and (20) obviously leads to (18). Differentiate (18) with respect to x, then (remember that (19) holds)

$$1-h(x)=\int_{-A}^{-B}\frac{x}{x-y}\,dF(y)$$

so that h is differentiable for every $x>-B$ and (17) holds. The relations (18) and (19) then hold for all $x>-B$. □

Up until now we have proved Theorem 1(6) for the special sequence $\{q_n(x), n=1,2,3,\cdots\}$. For (7) of the theorem for this sequence we need the following lemma.

LEMMA 5 ([3, Thm. 2.82]). *Let $p_n(x)=\sum_{j=0}^{n}a_{j,n}x^j$ be a polynomial of degree n with only real zeros $(a_{-1,n}=a_{n+1,n}=0)$, then*

$$(j+1)a_{j+1,n}a_{j-1,n}\leqq ja_{j,n}^2,\qquad j=1,2,\cdots,n.$$

Applied to our case, we have $b_{j,n}=a_{n-j,n}$, so that

$$\frac{b_{j+1,n}}{b_{j,n}}\leqq\frac{n-j}{n-j+1}\frac{b_{j,n}}{b_{j-1,n}}\leqq\frac{b_{j,n}}{b_{j-1,n}}\qquad(j=1,\cdots,n).$$

From this inequality one easily finds that

$$\frac{b_{j+k,n}}{b_{j,n}}\leqq\left(\frac{b_{j,n}}{b_{j-1,n}}\right)^k,\qquad j=1,\cdots,n-k+1.$$

Hence

$$\frac{b_{j,n}}{b_{j-1,n}}\geqq\left(\frac{b_{j+k,n}}{b_{j,n}}\right)^{1/k}$$
$$=\exp\left\{\frac{n}{k}\left[\frac{1}{n}\log b_{j+k,n}-\frac{1}{n}\log b_{j,n}\right]\right\}.$$

Take $k=[\varepsilon n]$ $(\varepsilon>0)$ and let $n\to\infty$ $(j/n\to d)$, then

$$\liminf\frac{b_{j,n}}{b_{j-1,n}}\geqq\exp\left\{\frac{1}{\varepsilon}[g(d+\varepsilon)-g(d)]\right\}.$$

In a similar way, using $b_{j,n}/b_{j-k,n} \geqq (b_{j,n}/b_{j-1,n})^k$, $(j = k, \cdots, n)$ we obtain

$$\limsup \frac{b_{j,n}}{b_{j-1,n}} \leqq \exp\left\{\frac{1}{\varepsilon}[g(d) - g(d-\varepsilon)]\right\}.$$

Taking $\varepsilon \to 0$ we obtain (7). This proves Theorem 1 for the sequence of polynomials $\{q_n(x),\ n = 1, 2, \cdots\}$.

In a second step we will prove that the same limits (6) and (7) hold for any sequence of polynomials $\{p_n(x),\ n = 1, 2, \cdots\}$ that satisfy the conditions of the theorem. Set

$$p_n(x) = \sum_{j=0}^{n} a_{j,n} x^{n-j} = \prod_{j=1}^{n} (x - x_{j,n})$$

then we want to compare the coefficients $a_{j,n}$ with the coefficients $b_{j,m}$, with m close to n. Let $N(n;\ \alpha, \beta)$ be the number of zeros of p_n in the interval $(\alpha, \beta]$ and $N^0(n;\ \alpha, \beta)$ the number of zeros of q_n in $(\alpha, \beta]$, then

$$\begin{aligned} N(n;\ \alpha, \beta) &= n\{F(\beta) - F(\alpha)\} + c_n(\alpha, \beta), \\ N^0(n;\ \alpha, \beta) &= n\{F(\beta) - F(\alpha)\} + c_n^0(\alpha, \beta) \end{aligned} \tag{21}$$

where $(1/n)c_n(\alpha, \beta) \to 0$ and by construction $|c_n^0(\alpha, \beta)| \leqq 1$. Hence

$$\lim_{n\to\infty} \frac{N(n;\ \alpha, \beta)}{N^0(n;\ \alpha, \beta)} = 1. \tag{22}$$

Now let $\delta_k = -B\,e^{k\varepsilon}$ $(\varepsilon > 0$ arbitrary), then $\{(\delta_i, \delta_{i-1}],\ i = 1, \cdots, N = [(1/\varepsilon)\log(A/B)] + 1\}$ covers the interval $[-A, -B]$. From this sequence we delete all the intervals for which $F(\delta_{i-1}) - F(\delta_i) = 0$, so that we have a finite number of intervals $\{(\delta_i^*, \delta_{i-1}^*],\ i = 1, \cdots, M\}$. Define

$$m = \left[n\left\{1 - \max_{1\leqq i\leqq M} \left\{ \frac{|c_n(\delta_i^*, \delta_{i-1}^*)| + 1}{n\{F(\delta_{i-1}^*) - F(\delta_i^*)\}} \right\}\right\}\right]$$

where as usual $[\alpha]$ denotes the integer part of α. Clearly we find that

$$\max_{1\leqq i\leqq M} \frac{|c_n(\delta_i^*, \delta_{i-1}^*) + 1|}{n\{F(\delta_{i-1}^*) - F(\delta_i^*)\}} \to 0 \qquad (n \to \infty)$$

so that as $n \to \infty$ the ratio m/n tends to 1. Also, by (21),

$$\begin{aligned} N(n;\ &\delta_i^*, \delta_{i-1}^*) - N^0(m;\ \delta_i^*, \delta_{i-1}^*) \\ &= (n-m)\{F(\delta_{i-1}^*) - F(\delta_i^*)\} + c_n(\delta_i^*, \delta_{i-1}^*) - c_m^0(\delta_i^*, \delta_{i-1}^*) \\ &\geqq \left\{ \max_{1\leqq j\leqq M} \frac{|c_n(\delta_j^*, \delta_{j-1}^*)| + 1}{F(\delta_{j-1}^*) - F(\delta_j^*)} \right\} \{F(\delta_{i-1}^*) - F(\delta_i^*)\} + c_n(\delta_i^*, \delta_{i-1}^*) - 1 \\ &\geqq |c_n(\delta_i^*, \delta_{i-1}^*)| + c_n(\delta_i^*, \delta_{i-1}^*) \geqq 0 \end{aligned}$$

and if $(\delta_i, \delta_{i-1}]$ is such that $F(\delta_{i-1}) - F(\delta_i) = 0$ then obviously $N^0(m;\ \delta_i, \delta_{i-1}) = 0$ so that the number of zeros of p_n in each interval $(\delta_i, \delta_{i-1}]$ $(i = 1, \cdots, N)$ is greater than or equal to the number of zeros of q_m in that interval.

Define $\{t_{j,n},\ 1 \leqq j \leqq n\} = \{y_{j,m},\ 1 \leqq j \leqq m\} \cup \{t'_{j,n},\ 1 \leqq j \leqq n-m\}$ where $t'_{j,n}$ are points such that the number of points of $\{t_{j,n}\}$ in every interval $(\delta_i, \delta_{i-1}]$ is equal to the number of zeros of p_n in that interval. If we order the zeros $x_{1,n} \leqq x_{2,n} \leqq \cdots \leqq x_{n,n}$ and $t_{1,n} \leqq t_{2,n} \leqq \cdots \leqq t_{n,n}$ then $x_{j,n}$ and $t_{j,n}$ will belong to the same interval $(\delta_i, \delta_{i-1}]$ and

$$e^{-\varepsilon} = \frac{|\delta_{i-1}|}{|\delta_i|} \leqq \frac{|t_{j,n}|}{|x_{j,n}|} \leqq \frac{|\delta_i|}{|\delta_{i-1}|} = e^{\varepsilon}.$$

Let $\{c_{j,n},\ 0 \leqq j \leqq n\}$ be the coefficients of the polynomial with $\{t_{j,n},\ 1 \leqq j \leqq n\}$ as zeros,

$$\sum_{j=0}^{n} c_{j,n} x^{n-j} = \prod_{j=1}^{n} (x - t_{j,n})$$

then

$$\frac{c_{j,n}}{a_{j,n}} = \frac{\sum_{\alpha_1 \neq \cdots \neq \alpha_j} |t_{\alpha_1,n} \cdots t_{\alpha_j,n}|}{\sum_{\alpha_1 \neq \cdots \neq \alpha_j} |x_{\alpha_1,n} \cdots x_{\alpha_j,n}|} \leqq \max_{\alpha_1 \neq \cdots \neq \alpha_j} \frac{|t_{\alpha_1,n}| \cdots |t_{\alpha_j,n}|}{|x_{\alpha_1,n}| \cdots |x_{\alpha_j,n}|}$$
$$\leqq e^{j}$$

and similarly $c_{j,n}/a_{j,n} \geqq e^{-j\varepsilon}$, hence

$$\begin{aligned} -d\varepsilon &\leqq \liminf \left\{ \frac{1}{n} \log c_{j,n} - \frac{1}{n} \log a_{j,n} \right\} \\ &\leqq \limsup \left\{ \frac{1}{n} \log c_{j,n} - \frac{1}{n} \log a_{j,n} \right\} \leqq d\varepsilon \end{aligned} \tag{23}$$

where $n \to \infty$ and $j/n \to d$. Denote the polynomial with zeros $\{t'_{j,n}\}$ by

$$\sum_{j=0}^{n-m} c'_{j,n} x^{n-m-j} = \prod_{j=1}^{n-m} (x - t'_{j,n})$$

then, since $\sum_{j=0}^{n} c_{j,n} x^{n-j}$ is the product of the polynomials q_m and $\sum_{j=0}^{n-m} c'_{j,n} x^{n-m-j}$ their coefficients are related by

$$c_{j,n} = \sum_{i=0}^{n} c'_{i,n} b_{j-i,m}. \tag{24}$$

For the coefficients $\{c'_{j,n}, 0 \leqq j \leqq n-m\}$ we have the obvious inequality

$$\begin{aligned} c'_{j,n} &= \frac{1}{j!} \sum_{\alpha_1 \neq \cdots \neq \alpha_j} |t'_{\alpha_1,n} \cdots t'_{\alpha_j,n}| \\ &\leqq \frac{1}{j!} \left(\sum_{i=1}^{n-m} |t'_{i,n}| \right)^{j} \\ &\leqq \frac{\{(n-m)A\}^{j}}{j!} \end{aligned}$$

so that from (24) we have on one hand (for $j \leqq m$)

$$\frac{c_{j,n}}{b_{j,m}} \geqq c'_{0,n} = 1$$

and on the other hand

$$\begin{aligned} \frac{c_{j,n}}{b_{j,m}} &\leqq \sum_{i=0}^{n} \frac{b_{j-i,m}}{b_{j,m}} \frac{\{(n-m)A\}^{i}}{i!} \\ &\leqq \sum_{i=0}^{\infty} \left(\frac{b_{j-1,m}}{b_{j,m}} \right)^{i} \frac{\{(n-m)A\}^{i}}{i!} \\ &= \exp\left\{ \frac{b_{j-1,m}}{b_{j,m}} (n-m)A \right\} \end{aligned}$$

so that when $n \to \infty$ and $j/n \to d$

$$0 \leqq \limsup \left\{ \frac{1}{n} \log c_{j,n} - \frac{m}{n} \frac{1}{m} \log b_{j,m} \right\} \leqq \lim \left\{ \frac{n-m}{n} A \frac{b_{j-1,m}}{b_{j,m}} \right\}$$

from which

$$\lim \frac{1}{n} \log c_{j,n} = \lim \frac{1}{m} \log b_{j,m} = g(d).$$

This means that the limit of $(1/n) \log c_{j,n}$ is independent of ε and since (23) is valid for every $\varepsilon > 0$ we then obtain

$$\lim \frac{1}{n} \log a_{j,n} = g(d), \qquad 0 < d < 1$$

which proves (6) of Theorem 1. (7) now follows from Lemma 5 in exactly the same way as for the polynomials $\{q_n(x), n = 1, 2, \cdots\}$.

We now only have to remove the condition that $B > 0$. Define the functions f_ε, f_ε^{-1} and g_ε by (8) and (9), where the integration is over $[-A, -\varepsilon]$ $(\varepsilon > 0)$. It is clear (since F has no jump at 0) that $f_\varepsilon^{-1}(x)$ converges to $f^{-1}(x)$ for $x > 0$ and $f^{-1}(x)$ is a positive, continuous and decreasing function that maps $(0, \infty)$ into $(0, 1)$. Its inverse mapping f is then a positive, continuous and increasing function that maps $(0, 1)$ into $(0, \infty)$, and by (9) we conclude that g_ε converges to g, being a continuous function on $(0, 1)$. Define the polynomials

$$p_n^+(x) = \prod_{|x_{j,n}| \geqq \varepsilon} (x - x_{j,n}) = \sum_{j=0}^{n_1} a_{j,n}^+ x^{n_1 - j},$$

$$p_n^-(x) = \prod_{|x_{j,n}| < \varepsilon} (x - x_{j,n}) = \sum_{j=0}^{n-n_1} a_{j,n}^- x^{n - n_1 - j}.$$

The degree n_1 of $p_n^+(x)$ is $N(n; -A, -\varepsilon) = nF(-\varepsilon) + c_n(\varepsilon)$ where $c_n(\varepsilon)/n \to 0$ for every $\varepsilon > 0$. Since $p_n(x)$ is the product of p_n^+ and p_n^- we have the relation

$$a_{j,n} = \sum_{k=0}^{n} a_{j-k,n}^+ a_{k,n}^-$$

so that $(j \leqq n_1)$

$$\begin{aligned} 1 \leqq \frac{a_{j,n}}{a_{j,n}^+} &\leqq \sum_{k=0}^{n} \frac{a_{j-k,n}^+}{a_{j,n}^+} a_{k,n}^- \\ &\leqq \sum_{k=0}^{\infty} \left(\frac{a_{j-1,n}^+}{a_{j,n}^+} \right)^k \frac{1}{k!} \{(n - n_1)\}^k \\ &= \exp \left\{ \frac{a_{j-1,n}^+}{a_{j,n}^+} (n - n_1) \varepsilon \right\} \end{aligned}$$

where we have used Lemma 5 and a straightforward inequality for $a_{k,n}^-$. When we take logarithms and let $n \to \infty$, $j/n \to d \in (0, 1)$ this leads to

$$0 \leqq \limsup \left\{ \frac{1}{n} \log a_{j,n} - \frac{1}{n} \log a_{j,n}^+ \right\} \leqq \varepsilon \{1 - F(-\varepsilon)\} / f_\varepsilon(d).$$

Now if $n\to\infty$ and $j/n\to d\in(0,1)$

$$\begin{aligned}\frac{1}{n}\log a_{j,n}^{+}&=\frac{n_1}{n}\frac{1}{n_1}\log a_{j,n}^{+}\\&\to F(-\varepsilon)g_\varepsilon(d)\end{aligned}$$

so that

$$0\leqq \limsup \frac{1}{n}\log a_{j,n}-F(-\varepsilon)g_\varepsilon(d)\leqq \varepsilon\{1-F(-\varepsilon)\}\frac{1}{f_\varepsilon(d)}.$$

Letting ε tend to zero we obtain the result for the general case.

3. Applications. Let us apply Theorem 1 to some relevant cases.

Example 1 (Degenerate case). Consider the sequence of polynomials given by

$$p_n(x)=(x+a)^n \qquad (a>0).$$

Clearly we have

$$\{p_n(x)\}^{1/n}\to x+a=\exp\left\{\int_{-A}^{0}\log(x-y)\,dF(y)\right\},\qquad x>0 \tag{25}$$

so that the weak limit F is given by

$$\begin{aligned}F(t)&=1,\qquad t\geqq -a,\\&=0,\qquad t<-a.\end{aligned}$$

By (8) we easily find that

$$f^{-1}(x)=\frac{a}{x+a},\qquad x>0$$

from which, by inversion, we obtain

$$f(d)=a\frac{1-d}{d},\qquad 0<d<1. \tag{26}$$

Formula (9) becomes, using (25) and (26),

$$g(d)=d\log a-d\log d-(1-d)\log(1-d).$$

Applying Theorem 1 to this case we obtain

$$\begin{aligned}&\frac{1}{n}\log a_{j,n}\to d\log a-d\log d-(1-d)\log(1-d),\\&\frac{a_{j,n}}{a_{j-1,n}}\to a\frac{1-d}{d}\end{aligned} \tag{27}$$

where $n\to\infty$ and $j/n\to d\in(0,1)$. This result could also be obtained by a direct calculation. We have

$$p_n(x)=\sum_{j=0}^{n}\binom{n}{j}a^jx^{n-j}$$

from which $a_{j,n}=\binom{n}{j}a^j$ follows. Stirling's formula then leads to the result in (27).

Example 2 (Orthogonal polynomials on a compact set). Consider the sequence of monic polynomials $\{p_n(x),\ n=0,1,2,\cdots\}$ that satisfies

$$\int_E p_n(x)p_m(x)\,d\mu(x)=0,\qquad n\neq m \tag{28}$$

where E is a compact set on the negative real axis with positive capacity $C(E)>0$ [16], and μ is a positive measure on E. Let μ_E be the equilibrium measure on E (Frostman measure) [16]. This is the probability measure that minimizes the logarithmic energy

$$\int_E\int_E \log\frac{1}{|x-y|}\,d\mu_E(x)\,d\mu_E(y)=\inf_{\mu\in\Omega_E}\int_E\int_E \log\frac{1}{|x-y|}\,d\mu(x)\,d\mu(y)$$

where Ω_E is the set of all probability measures on E. Then from a result of Widom [19, Thm. 1] (see also Van Assche [18]) we can obtain the following lemma.

LEMMA 6. *Suppose $\mu=\mu_1+\mu_2$, where μ_1 is absolutely continuous with respect to $\mu_E(\mu_1\ll\mu_E)$ and μ_2 is singular with respect to $\mu_E(\mu\perp\mu_E)$. Denote the Radon-Nikodym derivative $d\mu_1/d\mu_E$ by w, then $\mu_E(\{w(x)>0\})=1$ implies the weak convergence of $F_n(t)$ to $F(t)=\mu_E((-\infty,t])$.*

(This follows because μ is an "admissible" measure, in Widom's terminology.)

If E is a compact set on the negative real axis, we then have

$$\frac{1}{n}\log p_n(x)\to\int_E \log(x-y)\,d\mu_E(y)\qquad(x>0)$$

so that Theorem 1 holds with

$$\begin{aligned}&f^{-1}(x)=-\int_E\frac{y}{x-y}\,d\mu_E(y),\qquad x>0,\\ (29)\qquad&\\ &g(d)=-(1-d)\log f(d)+\int_E \log[f(d)-y]\,d\mu_E(y),\qquad 0<d<1.\end{aligned}$$

Let us, for example, take $E=[-1,0]$, then

$$\mu_E(A)=\frac{1}{\pi}\int_A\frac{dt}{\sqrt{t(1+t)}},\qquad A\subset(0,1)$$

and

$$(30)\qquad \int_E \log(x-y)\,d\mu_E(y)=-2\log 2+\log\{2x+1+2\sqrt{x^2+x}\},\qquad x>0.$$

Simple calculations then yield

$$f^{-1}(x)=1-x\int_E\frac{1}{x-y}\,d\mu_E(y)=1-\frac{x}{\sqrt{x^2+x}},\qquad x>0$$

from which

$$(31)\qquad f(d)=\frac{(1-d)^2}{1-(1-d)^2},\qquad 0<d<1.$$

By means of (30) and (31) one then computes

$$g(d)=-2\log 2-d\log d+(2-d)\log(2-d)-2(1-d)\log(1-d),\qquad 0<d<1.$$

We therefore obtain the limits

$$\begin{aligned}&\frac{1}{n}\log a_{j,n}\to-2\log 2-d\log d+(2-d)\log(2-d)-2(1-d)\log(1-d),\\ (32)\qquad&\\ &\frac{a_{j,n}}{a_{j-1,n}}\to\frac{(1-d)^2}{1-(1-d)^2}\end{aligned}$$

when $n \to \infty$ and $j/n \to d \in (0, 1)$. These results could again have been obtained from a direct computation. We may, for example, take the sequence of polynomials $\{P_n^{(\alpha,\beta)}(1+2x),\ n = 0, 1, 2, \cdots\}$, where $P_n^{(\alpha,\beta)}$ is a Jacobi polynomial [15]. This sequence contains orthogonal polynomials with weight function

$$w(x;\,\alpha,\beta) = (-x)^\alpha(1+x)^\beta \qquad (\alpha > -1;\ \beta > -1)$$

and the monic polynomials are given by

$$\hat{P}_n^{(\alpha,\beta)}(1+2x) = \frac{\Gamma(\alpha+n+1)}{n!\,\Gamma(\alpha+\beta+2n+1)} \sum_{j=0}^{n} \binom{n}{j} \frac{\Gamma(\alpha+\beta+n+j+1)}{\Gamma(\alpha+j+1)} x^j$$

so that

$$a_{j,n} = \frac{\Gamma(\alpha+n+1)}{\Gamma(\alpha+\beta+2n+1)} \binom{n}{n-j} \frac{\Gamma(\alpha+\beta+2n-j+1)}{\Gamma(\alpha+\beta+n-j+1)}$$

and applying Stirling's formula leads to (32). In Figs. 1 and 2 we have plotted the functions g and f of (32).

Example 3 (Orthogonal polynomials with exponential weights). Let us take a sequence of monic polynomials $\{p_n(x),\ n = 0, 1, 2, \cdots\}$ for which

$$\int_{-\infty}^{0} p_n(x) p_m(x) w(x)\, dx = 0, \qquad n \neq m$$

where $w(x) > 0$ almost everywhere on $(-\infty, 0)$ and

$$\lim_{x \to -\infty} \frac{\log w(x)}{|x|^\gamma} = -1, \qquad \gamma > 0. \tag{33}$$

Rakhmanov [12] showed that for $\gamma > \frac{1}{2}$

$$\frac{1}{n} \log |k_n^{-n} p_n(k_n x)| \to \int_{-1}^{0} \log |x-y|\, dF^{(\gamma)}(y), \tag{34}$$

uniformly on compact subsets of $\mathbb{C}\backslash(-\infty, 0]$, where

$$k_n = \left(\frac{2n}{A(\gamma)}\right)^{1/\gamma}, \qquad A(\gamma) = \frac{\Gamma(2\gamma)}{2^{2\gamma-1}\{\Gamma(\gamma)\}^2} \tag{35}$$

and the distribution function $F^{(\gamma)}$ is given by

$$\begin{aligned} F^{(\gamma)}(t) &= \int_{-1}^{t} b_\gamma(s)\, ds, \qquad 0 \leqq t \leqq 1, \\ b_\gamma(s) &= \frac{\gamma}{\pi} |s|^{\gamma-1} \int_{|s|}^{1} u^{-\gamma-1/2} \frac{du}{\sqrt{1-u}}, \qquad -1 \leqq s \leqq 0. \end{aligned} \tag{36}$$

Mhaskar and Saff [10] have analysed the weight functions $w(x) = e^{-|x|^\gamma}$ and they obtained the same result for these functions, however, also for $0 < \gamma \leqq \frac{1}{2}$. The function $b_\gamma(s)$ can be written in terms of hypergeometric functions [10], [12], [17] and is sometimes called an Ullman weight (on $[-1, 0]$). Applying the theorem to this sequence yields the following: If

$$p_n(x) = \sum_{j=0}^{n} a_{j,n} x^{n-j},$$

then

$$k_n^{-n} p_n(k_n x) = \sum_{j=0}^{n} a_{j,n} k_n^{-j} x^{n-j}$$

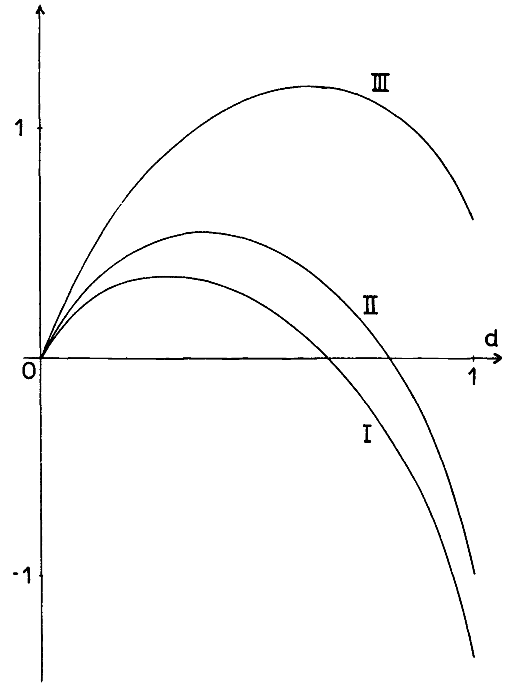

FIG. 1. *The function g for:* I—*Orthogonal polynomials on* $[-1, 0]$; II—*Laguerre polynomials on* $(-\infty, 0]$; III—*Iterations of* z^2+6z+1.

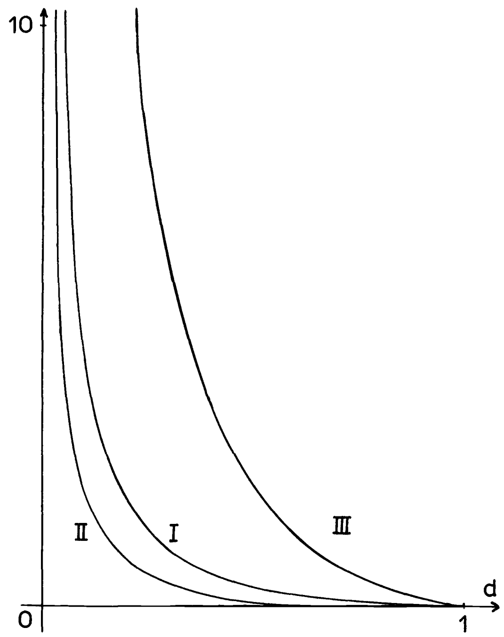

FIG. 2. *The function f for:* I—*Orthogonal polynomials on* $[-1, 0]$; II—*Laguerre polynomials on* $(-\infty, 0]$; III—*Iterations of* z^2+6z+1.

so that

$$
\tag{37}
\begin{aligned}
&\frac{1}{n}\log a_{j,n} - d\log k_n \to g(d),\\
&\frac{1}{k_n}\frac{a_{j,n}}{a_{j-1,n}} \to f(d),
\end{aligned}
\qquad n\to\infty, \qquad \frac{j}{n}\to d\in(0,1)
$$

where k_n is given by (35) and

$$
\tag{38}
\begin{aligned}
&f^{-1}(x) = -\int_{-1}^{0}\frac{y}{x-y}b_\gamma(y)\,dy, \qquad x>0,\\
&g(d) = -(1-d)\log f(d) + \int_{-1}^{0}\log\,[f(d)-y]b_\gamma(y)\,dy, \qquad 0<d<1.
\end{aligned}
$$

Let us take $\gamma=1$, then

$$b_1(s) = \frac{2}{\pi}\sqrt{\frac{1+s}{-s}}, \qquad -1\leqq s\leqq 0$$

and

$$
\begin{aligned}
\int_{-1}^{0} b_1(y)\log\,(x-y)\,dy = 2\log\,[x+\sqrt{x^2+x}] - \log x&\\
+2[-x+\sqrt{x^2+x}] - 2\log 2 - 1,& \qquad x>0.
\end{aligned}
$$

Straightforward calculus leads to

$$f^{-1}(x) = 1 - x\frac{2}{x+\sqrt{x^2+x}} = 2x+1-2\sqrt{x^2+x}$$

and by inversion

$$f(d) = \frac{(1-d)^2}{4d}.$$

The concave function g is then given by

$$g(d) = -2(1-d)\log\,(1-d) - d\log d - 2d\log 2 - d.$$

Moreover (35) becomes $k_n = 4n$, so that we find

$$
\tag{39}
\begin{aligned}
&\frac{1}{n}\log a_{j,n} - d\log n \to -2(1-d)\log\,(1-d) - d\log d - d,\\
&\frac{1}{4n}\frac{a_{j,n}}{a_{j-1,n}} \to \frac{(1-d)^2}{4d}
\end{aligned}
$$

where $n\to\infty$ and $j/n\to d\in(0,1)$. These results for $\gamma=1$ could also have been obtained by analyzing the sequence of polynomials $\{L_n^{(\alpha)}(-x),\ n=0,1,2,\cdots\}$, where $L_n^{(\alpha)}$ is a Laguerre polynomial [15] for which (33) is valid with $\gamma=1$. The Laguerre polynomial is given by

$$L_n^{(\alpha)}(x) = \sum_{j=0}^{n}\binom{n+\alpha}{n-j}\frac{(-x)^j}{j!}$$

and its asymptotic properties are given in [15], [9].

The coefficients of the monic polynomial are given by

$$a_{j,n} = n!\binom{n+\alpha}{j}\frac{1}{(n-j)!},$$

and by means of Stirling's formula one can then easily obtain (39). The limit functions of (39) are plotted in Figs. 1 and 2.

Example 4 (Iterations of polynomials). As a last example we consider a polynomial T of degree $k \geqq 2$:

$$T(z) = z^k + a_{k-1}z^{k-1} + \cdots + a_0$$

and its iterations $\{T^{(n)}(z),\ n = 0, 1, 2, \cdots\}$, where $T^{(0)}(z) = z$ and $T^{(n)}(z) = T^{(n-1)}(T(z))$. The Julia set J for this polynomial T is the set of complex numbers for which the sequence $\{T^{(n)}(z),\ n = 0, 1, 2, \cdots\}$ is not normal (in Montel's sense) [1], [2], [4]. It is known [4] that the set J is compact and has capacity one. We suppose that the set J is real and on the negative real axis. The orthogonal polynomials with respect to the equilibrium measure μ_J on the Julia set are denoted by $\{p_n(x; J),\ n = 0, 1, 2, \cdots\}$ and are related to the iterated polynomial sequence $\{T^{(n)}(z),\ n = 0, 1, 2, \cdots\}$ by ([1], [11])

$$\begin{aligned} p_1(x; J) &= x + \frac{1}{k}a_{k-1}, \\ p_{nk}(x; J) &= p_n(T(x); J), \qquad n = 0, 1, 2, \cdots. \\ p_{k^n}(x; J) &= T^{(n)}(x) + \frac{1}{k}a_{k-1}, \end{aligned}$$

If we write

$$T^{(n)}(x) = \sum_{j=0}^{k^n} t_{j,n}x^{k^n-j}$$

then we may apply (29) to obtain

$$\frac{1}{k^n}\log t_{j,n} \to g(d), \qquad \frac{t_{j,n}}{t_{j-1,n}} \to f(d)$$

where $n \to \infty$ and $j/k^n \to d \in (0, 1)$ and f and g are given by

$$f^{-1}(x) = -\int_J \frac{y}{x-y}\,d\mu_J(y), \qquad x > 0,$$

$$g(d) = -(1-d)\log f(d) + \int_J \log\,[f(d) - y]\,d\mu_J(y), \qquad 0 < d < 1.$$

As an example one may consider the polynomial

$$T(z) = z^2 + 2bz + c. \tag{40}$$

By the Möbius transformation $L(z) = z - b$, we find that

$$\tilde{T}(z) = L^{-1} \circ T \circ L(z) = z^2 - p \qquad (p = b^2 - b - c).$$

It is well known that for $p \geqq 2$ the Julia set $\tilde{J}$ for $\tilde{T}$ is real and contained in $[-q, q]$, $(q = \frac{1}{2} + \sqrt{\frac{1}{4} + p})$ ([4, Thm. 12.1]) and for $p > 2$ the Julia set is a Cantor set. The Julia set for the polynomial T is given by $L(J)$, so that J is contained in $[-q - b, q - b]$ whenever $b^2 - b - c \geqq 2$. If we choose the parameters b and c in (40) such that

$$b \geqq -\tfrac{1}{2}, \quad c \geqq 0, \quad b^2 - b - c \geqq 2$$

then J will be a Cantor set on the negative real axis, contained in $[-b-\frac{1}{2}-\sqrt{\frac{1}{4}+b^2-b-c}, -b+\frac{1}{2}+\sqrt{\frac{1}{4}+b^2-b-c}]$. In Figs. 1 and 2 we have plotted the functions f and g for $T(z)=z^2+6z+1$.

Theorem 1 is not valid for the iterations of the polynomial $T(z)=z^2-p$ $(p\geqq 2)$ since every function $T^{(n)}(x)$ is an even function and the coefficients of odd powers of x vanish. If $\{p_n(x; J),\ n=0,1,2,\cdots\}$ are the monic orthogonal polynomials with respect to the equilibrium measure on the Julia set J of z^2-p $(p\geqq 2)$, then $\{p_n^-(x);\ n=0,1,\cdots\}$ with

$$p_n^-(-x)=(-1)^n p_{2n}(\sqrt{x}; J)$$

will be orthogonal on a set J^+ in $[-q^2, 0]$ $(q=\frac{1}{2}+\sqrt{\frac{1}{4}+p})$. If we put

$$T^{(n)}(x)=\sum_{j=0}^{2^{n-1}}(-1)^j t_{j,n}x^{2^n-2j}$$

then

$$p_{2^{n-1}}^-(x)=T^{(n)}(i\sqrt{x})=\sum_{j=0}^{2^{n-1}} t_{j,n}x^{2^{n-1}-j}$$

and since Theorem 1 is valid for $\{p_n^-(x);\ n=1,2,\cdots\}$ we have

$$\frac{1}{2^{n-1}}\log t_{j,n}\to g(d),\qquad \frac{t_{j,n}}{t_{j-1,n}}\to f(d)$$

whenever $n\to\infty$ and $j2^{-n+1}\to d\in(0,1)$, with

$$f^{-1}(x)=-\int_{J^+}\frac{y}{x-y}\,d\mu_{J^+}(y),\qquad x>0,$$

$$g(d)=-(1-d)\log f(d)+\int_{J^+}\log[f(d)-y]\,d\mu_{J^+}(y),\qquad 0<d<1.$$

The case where $p=2$ gives essentially the Chebyshev polynomials of the first kind on $[-2,2]$ and, up to some constant, the formula (32) holds.

Acknowledgments. G. Fano is indebted to Dr. M. F. Barnsley for stimulating discussions and to Dr. S. Turrini for his help in the use of the algebraic SCHOONSCHIP language, which allowed numerical computations on the iterated maps.

ON A SIMPLIFIED ASYMPTOTIC FORMULA FOR THE MATHIEU FUNCTION OF THE THIRD KIND*

D. NAYLOR†

Abstract. This paper considers the asymptotic form of solutions of the equation $y_{xx}=(u^2-2h^2\cosh 2x)y$ for fixed real values of x and h and large complex values of u. Attention is focused on that solution known as the Mathieu function of the third kind, $M_\nu^{(3)}(x)$, and for values of u in the half plane Re $(u)\geqq 0$. The basic asymptotic formulas require the determination of an elliptic integral but, when u is large, it is shown how this integral can be approximated by elementary functions.

Key words. Mathieu functions, asymptotic formulas

AMS(MOS) subject classifications. Primary 33A55, 41A60

1. Introduction. The solution of wave propagation problems involving infinite domains bounded internally by cylinders of elliptic cross section requires the consideration of the functions $M_\nu^{(j)}(x)\, j=1,2,3,4$, which satisfy the modified form of Mathieu's differential equation:

$$w_{xx}=(u^2-2h^2\cosh 2x)w, \qquad a\leqq x<\infty. \tag{1.1}$$

The constants h, a are supposed real and positive but the parameter u may take both real and complex values. The quantity ν (the characteristic exponent) used in the standard notation of the Mathieu functions is connected with the parameter u by a complicated relation which for large values of u can be approximated by the following equation [2, p. 125]:

$$u^2=\nu^2+O\left(\frac{h^2}{\nu^2}\right). \tag{1.2}$$

In this paper attention is focussed on the solution of (1) that is associated with outgoing waves. This solution is the function $M_\nu^{(3)}(x)$ which behaves [2, p. 170] for fixed ν and large x according to the formula

$$M_\nu^{(3)}(x)=H_\nu^{(1)}(2h\cosh x)[1+O(\operatorname{sech} x)] \tag{1.3}$$

as $x\to+\infty$, where $H_\nu^{(1)}$ denotes the Hankel function of the first kind. The object is to obtain an asymptotic formula describing the behaviour of $M_\nu^{(3)}(x)$ for large values of u in the half plane Re $(u)\geqq 0$. It is clear that, if x is confined to some bounded interval of values, solutions $w^{(1)}$ and $w^{(2)}$ of (1.1) exist possessing the asymptotic forms

$$w^{(1)}\sim e^{ux}, \qquad w^{(2)}\sim e^{-ux}$$

as $u\to\infty$. Since any solution of (1.1) is expressible as a linear combination of $w^{(1)}$ and $w^{(2)}$ it follows that

$$M_\nu^{(3)}(x)\sim c_1\,e^{ux}+c_2\,e^{-ux} \tag{1.4}$$

where the coefficients c_1, c_2 may depend on u but not on x. The precise form of the relation (1.4), which will be determined by following a procedure developed by Olver [4], is given by the following equation:

$$M_\nu^{(3)}(x)=\sqrt{\frac{2}{\pi u}}\,e^{i(u-\nu)(\pi/2)}[e^{ux-u\log(2u/he)}-ie^{-ux+u\log(2u/he)}]\left[1+O\left(\frac{1}{u}\right)\right]. \tag{1.5}$$

* Received by the editors June 23, 1986; accepted for publication (in revised form) December 11, 1986.

† Department of Applied Mathematics, University of Western Ontario, London, Ontario, Canada N6A 5B9.

Olver's method requires the consideration of basic solutions of (1.1) for complex values of the independent variable and matching combinations of these solutions in different domains. We therefore replace x by the complex variable z and consider the differential equation

$$w_{zz}=(u^2-2h^2\cosh 2z)w. \tag{1.6}$$

A standard discussion of the asymptotic form of solutions of this equation when both z and u are large may be affected by means of a Liouville transformation. The asymptotic expressions for the solutions of (1.6) obtained by this method involve a variable $\xi(z, u)$ defined by an integral of the form

$$\xi(z, u)=\int_c^z (u^2-2h^2\cosh 2t)^{1/2}\,dt \tag{1.7}$$

in which c is independent of z. Since (1.7) is an elliptic integral it is desirable to obtain an asymptotic expression for it in terms of simpler functions. This problem was considered, for real values of z, in [3] where it was shown how to approximate the value of such an integral for large values of u by means of elementary functions. In the next section of this paper it is shown how similar asymptotic expressions may be obtained for the value of the relevant elliptic integral when the variable z is complex. The actual construction of the formula (1.5) is carried out in § 3.

2. Asymptotic formulas for $\zeta(z, u)$. In this section asymptotic formulas are constructed for the function $\zeta(z, u)$ defined by the elliptic integral

$$\zeta(z, u)=\int_{z_0}^z (u^2-2h^2\cosh 2t)^{1/2}\,dt \tag{2.1}$$

where $z_0=x_0+iy_0$ is that solution of the equation $2h^2\cosh 2z_0=u^2$ that is given for large values of u by the approximate formula $z_0\sim\log(u/h)$ the principal value of the logarithm being taken. Because attention is confined to values of u such that $|\arg u|\leqq\pi/2$, the point z_0 is located in the strip $|\operatorname{Im} z_0|\leqq\pi/2$. Since the modified Mathieu functions are periodic in z we could consider the effect of the mapping (2.1) on the strip $0\leqq\operatorname{Im} z\leqq\pi$ but in applying Olver's technique it is helpful to consider the larger strip $|\operatorname{Im} z|\leqq\pi$. Branch cuts parallel to the real axis are introduced from z_0 to $z_0+\infty$ and from $-z_0$ to $-z_0-\infty$ and the branch of the radical chosen is that which is asymptotically equal to ihe^z as $z\to\infty$ on the lower side of the first such cut. With this choice the function ζ is also asymptotically equal to ihe^z as $z\to\infty$ in the stated manner.

In order to obtain approximate formulas for ζ in terms of elementary functions it will be necessary to consider separately three different parts of the strip $|\operatorname{Im} z|\leqq\pi$, as defined by the inequalities:

(i) $\operatorname{Re}(z)\geqq\frac{1}{2}x_0$,

(ii) $|\operatorname{Re}(z)|\leqq\frac{1}{2}x_0$, and

(iii) $\operatorname{Re}(z)\leqq-\frac{1}{2}x_0$.

Case (i). To extract the dominant contribution to the integral in (2.1) when u is large, the integrand is decomposed as the sum of four parts as specified by the following equation:

$$\begin{aligned}(u^2-2h^2\cosh 2t)^{1/2}=&-\frac{2h^2\sinh 2t}{(u^2-2h^2\cosh 2t)^{1/2}}+\frac{u^2\tanh 2t}{(u^2-2h^2\cosh 2t)^{1/2}}\\&-\frac{2h^2e^{-2t}}{(u^2-2h^2\cosh 2t)^{1/2}}+\frac{u^2e^{-2t}}{\cosh 2t(u^2-2h^2\cosh 2t)^{1/2}}.\end{aligned}$$

Upon integrating the terms on the right-hand side of the preceding equation along a path in the complex t-plane connecting the points z_0 and z we find that

$$\begin{aligned}\zeta(z, u) = -2h^2 &\int_{z_0}^{z} \frac{\sinh 2t\,dt}{(u^2-2h^2\cosh 2t)^{1/2}} \\ &+ u^2 \int_{z_0}^{z} \frac{\sinh 2t\,dt}{\cosh 2t(u^2-2h^2\cosh 2t)^{1/2}} - 2h^2 I_1 + u^2 I_2\end{aligned} \tag{2.2}$$

where

$$I_1 = \int_{z_0}^{z} \frac{e^{-2t}\,dt}{(u^2-2h^2\cosh 2t)^{1/2}}, \qquad I_2 = \int_{z_0}^{z} \frac{e^{-2t}\,dt}{\cosh 2t(u^2-2h^2\cosh 2t)^{1/2}}. \tag{2.3}$$

It will be shown shortly that $I_1 = O(u^{-2})$ and $I_2 = O(u^{-3})$. Since the first two integrals present on the right-hand side of (2.2) may be evaluated explicitly, we find the equation

$$\begin{aligned}\zeta(z, u) = (u^2-2h^2\cosh 2z)^{1/2} &- u \log[u + (u^2-2h^2\cosh 2z)^{1/2}] \\ &+ \frac{u}{2}\log(2h^2\cosh 2z) + O(u^{-1})\end{aligned} \tag{2.4}$$

which applies for sufficiently large u and $\operatorname{Re}(z) \geqq \frac{1}{2}\log|u/h|$.

To obtain the stated bounds on I_1 and I_2 the path of integration connecting z_0 and z is taken to consist of the straight line from $z_0 = x_0 + iy_0$ to $x_0 + iy$ together with the straight line from $x_0 + iy$ to $z = x + iy$. On writing $t = \tau + i\eta$ we find, since $u^2 = 2h^2\cosh 2z_0$, that

$$\begin{aligned}|u^2 - 2h^2\cosh 2t| &= 2h^2|\cosh 2z_0 - \cosh 2t| \\ &= 4h^2|\sinh(z_0+t)\sinh(z_0-t)| \\ &= 4h^2[\sinh^2(x_0+\tau) + \sin^2(y_0+\eta)]^{1/2} \\ &\quad\cdot[\sinh^2(x_0-\tau)+\sin^2(y_0-\eta)]^{1/2} \\ &\geqq 2\sqrt{2}\,h^2\sinh(x_0+\tau)[\sinh|x_0-\tau| + |\sin(y_0-\eta)|]\end{aligned} \tag{2.5}$$

after using the inequality $(a^2+b^2)^{1/2} \geqq (a+b)/\sqrt{2}$ which holds for any two positive numbers a and b. On the line joining z_0 and x_0+iy we have $t = x_0 + i\eta$ so that, by (2.5), the contribution of this part of the path of integration to the value of I_1 does not exceed the quantity

$$\frac{Ce^{-2x_0}}{(\sinh 2x_0)^{1/2}}\left|\int_{y_0}^{y}\frac{d\eta}{|\sin(y_0-\eta)|^{1/2}}\right| \tag{2.6}$$

where C is a constant. This expression is $O(e^{-3x_0}) = O(u^{-3})$, since $x_0 \sim \log|u/h|$, the integral in (2.6) being bounded independently of u because $|y| < \pi$ and $0 < y_0 < \pi/2$. On the part of the path of integration that connects z with (x_0+iy) we use the following simplified form of the inequality (2.5):

$$|u^2-2h^2\cosh 2t| \geqq 2\sqrt{2}\,h^2\sinh(x_0+\tau)\sinh|x_0-\tau|.$$

The contribution to I_1 of this part of the path is bounded by the quantity

$$C\left|\int_{x}^{x_0}\frac{e^{-2\tau}\,d\tau}{[\sinh(x_0+\tau)\sinh|x_0-\tau|]^{1/2}}\right|. \tag{2.7}$$

If $x_0 \leqq x < \infty$ this expression is less than the integral

$$\frac{C e^{-2x_0}}{(\sinh 2x_0)^{1/2}} \int_{x_0}^{\infty} \frac{d\tau}{[\sinh(\tau - x_0)]^{1/2}}.$$

This expression is $O(e^{-3x_0})$ which is again $O(u^{-3})$. If $x_0/2 \leqq x \leqq x_0$ we note that $\sinh(x_0 + \tau) \geqq \sinh(3x_0/2)$ so that the expression (2.7) does not exceed the quantity

$$(2.8)\quad \begin{aligned} &\frac{C}{[\sinh(3x_0/2)]^{1/2}} \int_x^{x_0} \frac{e^{-2\tau}\, d\tau}{[\sinh(x_0 - \tau)]^{1/2}} = \frac{C e^{-2x_0}}{[\sinh(3x_0/2)]^{1/2}} \int_0^{x_0 - x} \frac{e^{2\xi}\, d\xi}{(\sinh \xi)^{1/2}} \\ &\leqq \frac{2Ce^{-x_0-x}}{[\sinh(3x_0/2)]^{1/2}} \int_0^{x_0-x} \frac{\cosh \xi\, d\xi}{(\sinh \xi)^{1/2}} = \frac{4C e^{-x_0-x}[\sinh(x_0 - x)]^{1/2}}{[\sinh(3x_0/2)]^{1/2}} \end{aligned}$$

after setting $\xi = x_0 - \tau$ and using the fact that $e^{2\xi} \leqq 2e^{\xi} \cosh \xi \leqq 2e^{x_0 - x} \cosh \xi$. Since $x \geqq x_0/2$ the final expression in (2.8) is $O(e^{-2x_0})$ which is $O(u^{-2})$. On combining the above bounds we can see that $I_1 = O(u^{-2})$, as stated.

The treatment of I_2 is similar, except that since $|\cosh 2(\tau + i\eta)| \geqq \sinh 2\tau \geqq \sinh x_0$ on the entire path of integration, the extra factor $\cosh 2t$ present in the integrand of I_2 gives rise to an additional factor of $\operatorname{cosech} x_0 = O(e^{-x_0}) = O(u^{-1})$ in the final result so that $I_2 = O(u^{-3})$. This establishes the validity of (2.4).

If e^z is large compared with u^2, the formula (2.4) can be simplified by expanding the terms on the right-hand side of this equation in powers of $u^2 \operatorname{sech}^2 z$ and this leads to the formula

$$(2.9)\quad \zeta(z, u) = ihe^z - \frac{iu\pi}{2} + O(u^2 e^{-z}) + O(u^{-1}).$$

Case (ii). The bounds on I_1 and I_2 stated in the preceding section do not apply when $\operatorname{Re}(z)$ is large and negative or when $|\operatorname{Re}(z)| < \frac{1}{2}x_0$. To obtain an approximate formula for $\zeta(z, u)$ in the latter case we introduce the quantity $z_1 = \frac{1}{2}\log(u/h)$, whose real part is intermediate between 0 and x_0, and write

$$\zeta(z, u) = \int_{z_0}^{z_1} (u^2 - 2h^2 \cosh 2t)^{1/2}\, dt + \int_{z_1}^{z} (u^2 - 2h^2 \cosh 2t)^{1/2}\, dt.$$

The first integral appearing on the right-hand side of the preceding equation equals $\zeta(z_1, u)$ and can be estimated for large values of u by applying the formula (2.4) just proved. On setting $z = z_1$ in (2.4) and simplifying the resulting expression, we find that

$$(2.10)\quad \zeta(z, u) = u - \frac{h}{4} - \frac{u}{2} \log\left(\frac{4u}{h}\right) + \int_{z_1}^{z} (u^2 - 2h^2 \cosh 2t)^{1/2}\, dt + O(u^{-1}).$$

The integral remaining in this equation may be estimated by expanding the integrand in powers of $u^{-2} \cosh 2t$ and integrating term by term, since $|u^{-2} \cosh 2t| \leqq |u^{-2} \cosh 2\tau| \leqq |u^{-2} \cosh 2x_1| = O(u^{-1})$ therein. This leads to the formula

$$(2.11)\quad \int_{z_1}^{z} (u^2 - 2h^2 \cosh 2t)^{1/2}\, dt = uz - \frac{h^2}{2u} \sinh 2z - \frac{u}{2} \log\left(\frac{u}{h}\right) + \frac{h}{4} + O(u^{-1})$$

which holds whenever u is large and $|\operatorname{Re}(z)| \leqq \operatorname{Re}(z_1)$, where $z_1 = \frac{1}{2}\log(u/h)$. Upon inserting the result (2.11) into (2.10), we obtain the formula

$$(2.12)\quad \zeta(z, u) = uz - \frac{h^2}{2u} \sinh 2z - u \log(2u/he) + O(u^{-1})$$

for $|\mathrm{Re}(z)| \leqq \mathrm{Re}(z_1)$. This formula applies in particular for $z = a$ when it reduces to the following formula, which we record for future use,

$$\zeta(a, u) = -u \log\left(\frac{2u}{he^{a+1}}\right) + O(u^{-1}). \tag{2.13}$$

Case (iii). The formula (2.4) ceases to apply in the domain $\mathrm{Re}(z) < -\frac{1}{2}x_0$ where however $\zeta(z, u)$ may be calculated from the equation:

$$\zeta(z, u) = -g_0(u) - \zeta(-z, u) \tag{2.14}$$

where

$$g_0(u) = 2u \log\left(\frac{2u}{he}\right) + O(u^{-1}). \tag{2.15}$$

If $\mathrm{Re}(z) < -\frac{1}{2}x_0$ then $\mathrm{Re}\,(-z) > \frac{1}{2}x_0$ and the second term on the right-hand side of (2.14) may be estimated from the formula (2.4) already established. Therefore, for such values of z, equation (2.14) can be employed to determine $\zeta(z, u)$. To verify (2.14) we note from the definition (2.1) that

$$\zeta(z, u) + \zeta(-z, u) = \int_{z_0}^{z} (u^2 - 2h^2 \cosh 2t)^{1/2}\, dt + \int_{z_0}^{-z} (u^2 - 2h^2 \cosh 2t)^{1/2}\, dt.$$

On reversing the sign of the integration variable in the second integral it becomes one along a path connecting z to $-z_0$ and on combining the two integrals we find the formula

$$\begin{aligned}\zeta(z, u) + \zeta(-z, u) &= \int_{z_0}^{-z_0} (u^2 - 2h^2 \cosh 2t)^{1/2}\, dt \\ &= -2\int_{0}^{z_0} (u^2 - 2h^2 \cosh 2t)^{1/2}\, dt = 2\zeta(0, u).\end{aligned}$$

On calculating $\zeta(0, u)$ from (2.12) by inserting the value $z = 0$ therein we deduce the relation (2.14) stated above.

3. Determination of the asymptotic form of $M_\nu^{(3)}(x)$. The determination of the coefficients c_1, c_2 in the relation (1.4) is regarded as a connection formula problem which will be solved by applying the method used by Olver [4]. This method requires a consideration of the mapping of the z-plane onto the ζ-plane defined by the equation (2.1). Properties of this mapping have been investigated by Sharples [6]. For real values of u, Sharples reduces (2.1) to a Schwarz-Christoffel transformation by means of a change of the variable of integration, but this approach is not effective if u is complex. Alternatively, when u is large, a discussion of the mapping may be carried out with the aid of equations (2.4) and (2.12) and the intermediate variable $\tau = u^{-1}w^{1/2}$ where $w = 2h^2 \cosh 2z$. In terms of this variable, equation (2.4) reduces to

$$u^{-1}\zeta = (1 - \tau^2)^{1/2} - \log\left[\frac{1 + (1 - \tau^2)^{1/2}}{\tau}\right] + O(u^{-2}). \tag{3.1}$$

This decomposition of the mapping is applicable to large values of u, both real and complex, but like Sharples, it is helpful to consider real values of u first. Properties of the mapping of the τ-plane onto the plane of the function of τ appearing on the right-hand side of (3.1) are considered on p. 420 of [5]. Cuts are placed in the z-plane along the segments (x_0, ∞) and $(-\infty, -x_0)$ of the real axis, where x_0 denotes the positive root of the equation $2h^2 \cosh 2x_0 = u^2$. In Figs. 1 and 2 corresponding points are

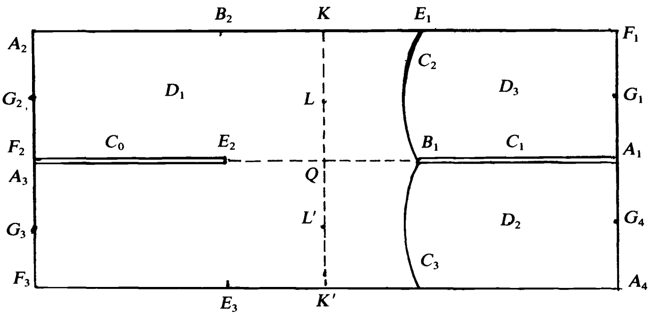

FIG. 1. *z-plane*, $\theta = 0$.

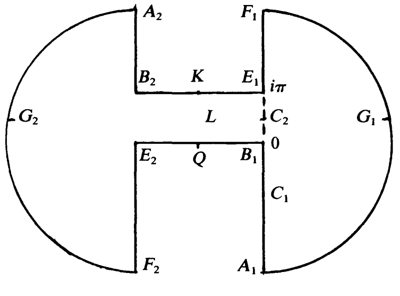

FIG. 2(a). $u^{-1}\zeta$-*plane*, $\theta = 0$.

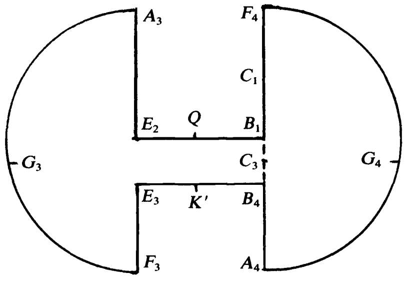

FIG. 2(b). $u^{-1}\zeta$-*plane*, $\theta = 0$.

indicated by the same letters. The distant points G_1, F_1 of the z-plane have ordinates $\pi/2$, π, respectively. The right-hand side of Fig. 2(a) illustrates the $u^{-1}\zeta$-map of the strip $\operatorname{Re}(z) > 0$, $0 < \operatorname{Im}(z) < \pi$. The point B_1 denotes $\zeta = 0$ and the point E_1 is situated at $\zeta = iu\pi$. The left-hand side of Fig. 2(a) is constructed from the right-hand side of the same figure by appealing to formula (2.14) together with the reflection principle, which, since $u^{-1}\zeta$ is real when z is real and between the points $\pm x_0$, implies that $u^{-1}\zeta(x - iy)$ is the conjugate of $u^{-1}\zeta(x + iy)$. On setting $z = -x + iy$ in (2.14) we find, for positive values of u, the necessary formula

$$\begin{aligned} u^{-1}\zeta(-x+iy) &= -u^{-1}\zeta(x-iy) - u^{-1}g_0(u) \\ &= -u^{-1}\overline{\zeta(x+iy)} - u^{-1}g_0(u). \end{aligned}$$

This equation relates the value of ζ at the point $x + iy$ with its value at the image point $-x + iy$ so that, for instance, $\zeta(A_2) = -\bar{\zeta}(F_1) - g_0(u)$, and similarly for the values of ζ at other points on the left-hand side of Fig. 1. In this way the left-hand side of Fig. 2(a) is obtained. The points K, L, Q, L', K' lie outside the domain of validity of (2.4) and their ζ-values are given instead by (2.12) which after division by u reduces to the formula

$$u^{-1}\zeta = z - \log\left(\frac{2u}{he}\right) + O(u^{-1}). \tag{3.2}$$

The strip $-\pi < y < \pi$ is divided into domains D_1, D_2, D_3 by the curves C_1, C_2, C_3 which emanate from the point B_1 and along each of which $\operatorname{Re}\zeta = 0$. The curve C_1 coincides with the segment (x_0, ∞) of the real axis and corresponds to the part B_1A_1 of the imaginary axis of the $u^{-1}\zeta$-plane, whilst C_2 corresponds to the segment B_1E_1 of that axis. Figure 2(a) gives the $u^{-1}\zeta$-map of the strip $0 < \operatorname{Im}(z) < \pi$, for real values of u. For such values of u the ζ-map of the adjoining strip $-\pi < \operatorname{Im}(z) < 0$, Fig. 2(b), is readily constructed from Fig. 2(a) by means of the reflection principle.

If u is complex we set $u = Re^{i\theta}$ where $0 \leqq \theta \leqq \pi/2$ and regard the points A_i, G_i, F_i, for $i = 1, 4$ as being fixed in the $u^{-1}\zeta$-plane, that is they correspond to values of τ independent of u as shown in Figs. 3(a) and 3(b).

Since $u^2\tau^2 = 2h^2 \cosh 2z \sim h^2e^{2z}$ the corresponding (distant) points A_1, G_1, F_1 of the z-plane will now have ordinates θ, $\theta + \pi/2$, $\theta + \pi$, respectively. The remote points A_2, G_2, F_2 on the left-hand side of the z-plane will be displaced a distance θ in the downwards direction. The points Q, L, L', K, K' are taken to be fixed in the z-plane, and their associated ζ-values are given by (3.2), which for complex values of u, can be written in the form

$$u^{-1}\zeta = z - \log\left(\frac{2R}{he}\right) - i\theta + O(R^{-1}).$$

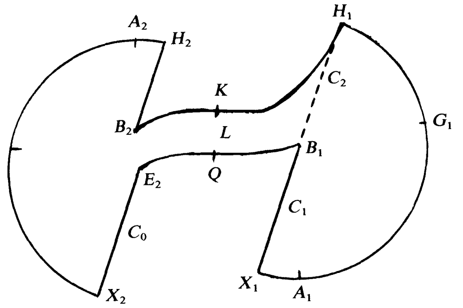

FIG. 3(a). $u^{-1}\zeta$-plane, $0 < \theta < \pi/2$.

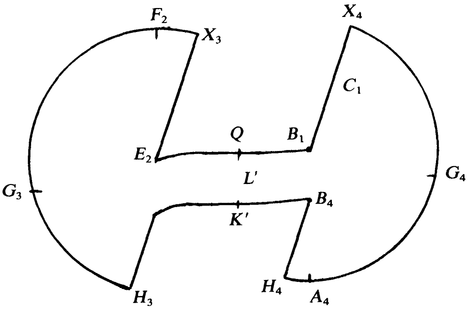

FIG. 3(b). $u^{-1}\zeta$-plane, $0 < \theta < \pi/2$.

This equation shows that the points Q, L, L', K, K' of the $u^{-1}\zeta$-plane move downwards through a distance equal to θ. The turning point B_1 is given for large values of u by the equation $z_0 \sim \log(u/h)$ and the curves C_1, C_2, C_3 through B_1 correspond to rays for which $\arg(u^{-1}\zeta) = \pm\pi/2 - \theta$ in the $u^{-1}\zeta$-plane. The images of these curves in the z-plane are depicted in Fig. 4. For complex values of u the cut emanating from B_1 is taken to coincide with the curve C_1 and that emanating from E_1 is taken to be the curve C_0 congruent to C_1 and orientated as shown in Fig. 4. In constructing the curves C_1, C_2, C_3 appearing in Figs. 1, 4 and 5 it is helpful to set $\tau = \operatorname{sech}\sigma$, $\sigma = \alpha + i\beta$, $u = \mathrm{R}e^{i\theta}$ in the formula (3.1) which then yields the equation

$$(3.3) \quad R^{-1}\operatorname{Re}\zeta = \left(\frac{\sinh 2\alpha}{\cosh 2\alpha + \cos 2\beta} - \alpha\right)\cos\theta - \left(\frac{\sin 2\beta}{\cosh 2\alpha + \cos 2\beta} - \beta\right)\sin\theta.$$

Since $2h^2\cosh 2z = u^2\tau^2 = u^2\operatorname{sech}^2\sigma$ we also find, for large positive values of x, the relations

$$(3.4) \qquad 1 + \cosh 2\alpha\cos 2\beta = e^{2(x_0 - x)}\cos 2(\theta - y),$$

$$(3.5) \qquad \sinh 2\alpha \sin 2\beta = e^{2(x_0 - x)}\sin 2(\theta - y),$$

$$(3.6) \qquad \cosh 2\alpha\cos 2\beta = e^{2(x_0 - x)}$$

where $x_0 \sim \log(R/h)$. The curves C_1, C_2, C_3 leave z_0 in directions making angles equal to $-\frac{2}{3}\theta$, $\frac{2}{3}(\pi - \theta)$ and $\frac{2}{3}(2\pi - \theta)$ with the positive real axis, respectively. When $\theta = 0$ the equation (3.3) shows that the curves along which $\operatorname{Re}\zeta$ vanishes are given by either $\alpha = 0$ or $\cosh 2\alpha + \cos 2\beta = \alpha^{-1}\sinh 2\alpha$. The equation $\alpha = 0$ gives the curve C_1 which coincides with the part of the x-axis to the right of the branch point B_1(Fig. 1). The other condition, when used in conjunction with (3.4) and (3.5) to eliminate the variable β, leads to the following equations:

$$\cos 2y = \cosh 2\alpha - \alpha\sinh 2\alpha, \qquad e^{2(x_0 - x)} = \alpha^{-1}\sinh 2\alpha.$$

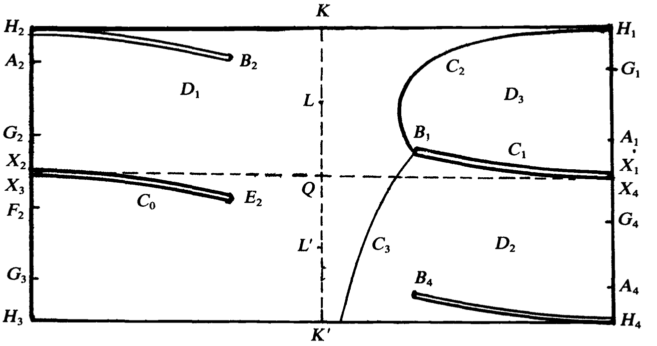

FIG. 4. *z-plane*, $0 < \theta < \pi/2$.

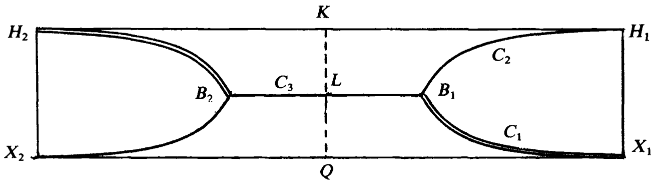

FIG. 5. *z-plane*, $\theta = \pi/2$.

These are the parametric equations of the two remaining curves C_2 and C_3 (for the value $\theta=0$), which are shown along with C_1 in Fig. 1. The corresponding curves associated with the value $\theta=\pi/2$ are shown in Fig. 5. In this case it follows from (3.3) that $\operatorname{Re}\zeta$ vanishes when either $\beta=0$ or $\cosh 2\alpha+\cos 2\beta=\beta^{-1}\sin 2\beta$. The curve C_3 now comprises the line joining the points $\pm x_0+i\pi/2$ and the condition $\beta=0$ gives the part of this line for which (3.3) holds, viz: $x\geqq\frac{1}{2}x_0$. The alternative condition $\cosh 2\alpha+\cos 2\beta=\beta^{-1}\sin 2\beta$, when combined with (3.4) and (3.6) to eliminate the variable α, yields the parametric equations of the curves C_2 and C_1 in the following form:

$$\cos 2y=-\cos 2\beta-\beta\sin 2\beta,\qquad e^{2(x_0-x)}=\beta^{-1}\sin 2\beta.$$

It should be noted that, for large values of R, the curves C_1, C_2, C_3 originating at z_0 can only extend into the left-hand side of the fundamental strip of the z-plane if the angle θ is sufficiently close to $\pm\pi/2$, so that $\cos\theta=O[(\log R)^{-1}]$. To verify this result we note that to reach the left-hand region such a curve must traverse the domain (ii) of § 2 in which the formula (2.12) applies. Upon setting $z=x+iy$, $u=Re^{i\theta}$ in this formula we find that

$$(3.7)\qquad R^{-1}\operatorname{Re}\zeta=\left[x-\log\left(\frac{2R}{he}\right)\right]\cos\theta-(y-\theta)\sin\theta+O(R^{-1}).$$

This formula applies for $|x|\leqq\frac{1}{2}\log(R/h)$. Since y, θ are bounded it follows that a $\operatorname{Re}\zeta=0$ curve cannot enter or traverse this domain unless $\cos\theta=O[(\log R)^{-1}]$ as stipulated.

If $\theta\neq 0$, $\pi/2$ explicit parametric equations for C_1, C_2, C_3 in terms of one or other of the variables α, β are not obtainable, for then the condition $\operatorname{Re}\zeta=0$ retains the more intricate form

$$(\alpha\cos\theta-\beta\sin\theta)(\cosh 2\alpha+\cos 2\beta)=\sinh 2\alpha\cos\theta-\sin 2\beta\sin\theta.$$

In this case the curves may best be sketched by following the variation of the slope dy/dx as the point z, starting at z_0, moves along such a curve. For this purpose appeal is made to the differential equation of the curves. If we write $\tan\phi=dy/dx$ and use the equation (2.1), it can be shown that this differential equation can be written in the following form:

$$\cot 2(\theta+\phi)=[\cos 2(\theta-y)-e^{2(x_0-x)}]\operatorname{cosec} 2(\theta-y).$$

The connection formula, in the form stated by Olver, will now be outlined. This formula relates three solutions w_1, w_2, w_3 of the differential equation (1.5). Let D be the domain $-\pi<\operatorname{Im} z<\pi$, then the solution w_j is defined in D cut along the corresponding curve C_j and along the branch line C_0 through $-z_0$ and possesses the property such that

$$(3.8)\qquad w_j(z)=\phi_j(z)e^{-\zeta_j(z)}[1+\varepsilon_j(z)]$$

where $\zeta_j(z)$ denotes the branch of $\zeta(z)$ that is continuous in D cut along C_0 and C_j and is such that $\operatorname{Re}\zeta_j>0$ in D_j whilst $\operatorname{Re}\zeta_j\leqq 0$ elsewhere. The function $\phi_3(z)$ may be defined to be that branch of $(u^2-2h^2\cosh 2z)^{-1/4}$ that is continuous in D cut along C_1 and C_0, except at $\pm z_0$, and which is asymptotically equal to $h^{-1/2}\exp(-x/2+i\pi/4)$

as $x \to +\infty$. The remaining functions ϕ_1 and ϕ_2 are defined by the equations $\phi_j = e^{i\pi/6}\phi_{j-1}$ for $z \in D_j \cup D_{j-1}$. The quantity $\varepsilon_j(z)$ appearing in (3.8) is subject to the bound

$$(3.9) \qquad |e_j(z)| \leqq \exp\left\{\left|\int_{a_j}^{z} |R(z)| \cdot |dz|\right|\right\} - 1$$

where

$$(3.10) \quad R(z) = 2h^2 \cosh 2z(u^2 - 2h^2 \cosh 2z)^{-3/2} + 5h^4 \sinh^2 2z(u^2 - 2h^2 \cosh 2z)^{-5/2}.$$

The integral appearing in (3.9) is taken along a path connecting z and an arbitrary reference point a_j, the path being one along which Re $\zeta_j(z)$ is nondecreasing and tends to $+\infty$ as $z \to a_j$. It follows that

$$(3.11) \qquad |\varepsilon_j(a_i)| \leqq \exp\left|\int_{a_i}^{a_j} |R(z)| \cdot |dz|\right| - 1$$

where the integral is taken along a path connecting a_i and a_j along which Re ζ_j is monotone. It is assumed that such a path exists for each pair of reference points. The connection formula is then

$$(3.12) \qquad -[1+\varepsilon_2(a_3)]w_1 + [1+\varepsilon_1(a_3)]e^{i\pi/3}w_2 + [1+\varepsilon_1(a_2)]e^{-i\pi/3}w_3 = 0.$$

To fix the solutions w_1, w_2, w_3 we let $a_1 = -\infty + i\pi/2$, $a_2 = \infty - i\pi/2$ and $a_3 = \infty + i\pi/2$. The resulting domains of definitions of w_1, w_2, w_3 are adequate for the intended applications. The function $\zeta_1(z)$ is the branch of $\zeta(z)$ that has positive real part in D_1 and Re $\zeta_1 \to \infty$ as Re $(z) \to -\infty$ in D_1 whilst Re $\zeta_1 \to -\infty$ as Re $(z) \to +\infty$ in D_2 and D_3. On referring to (2.9) we see that, for large z in D_2 and D_3,

$$\zeta_1 = \pm\left[ihe^x(\cos y + i \sin y) - \frac{iu\pi}{2} + O(u^2e^{-x}) + O(u^{-1})\right].$$

The stipulated asymptotic behaviour of ζ_1 requires that the positive sign be chosen for $z \in D_3$ and the negative sign chosen for $z \in D_2$. This leads to the relations

$$(3.13) \qquad \zeta_1 = ihe^z - \frac{iu\pi}{2} + O(u^2e^{-x}) + O(u^{-1})$$

for Re $(z) \to +\infty$ in D_3, and

$$(3.14) \qquad \zeta_1 = -\left[ihe^z - \frac{iu\pi}{2} + O(u^2e^{-x}) + O(u^{-1})\right]$$

for Re $(z) \to +\infty$ in D_2. The corresponding equations giving the behaviour of ζ_1 as Re $(z) \to -\infty$ (in D_1) are obtained by applying the relation (2.14) to (3.12) or (3.13), as the case may be. Thus we obtain the equations

$$(3.15) \qquad \zeta_1 = -2u \log\left(\frac{2u}{he}\right) + ihe^{-z} - \frac{iu\pi}{2} + O(u^2e^x) + O(u^{-1})$$

for Re $(z) \to -\infty$ in the part of D_1 above the cut C_0, and

$$(3.16) \qquad \zeta_1 = -2u \log\left(\frac{2u}{he}\right) - ihe^{-z} + \frac{iu\pi}{2} + O(u^2e^x) + O(u^{-1})$$

as Re $(z) \to -\infty$ in the part of D_1 below C_0. The asymptotic forms of the functions ζ_2 and ζ_3 can be obtained from the appropriate formulae (3.13)-(3.16) by using the relations (i) $\zeta_2 = \zeta_3 = -\zeta_1$ for $z \in D_1$ (ii) $\zeta_2 = -\zeta_3 = -\zeta_1$ for $z \in D_2$, and (iii) $\zeta_2 = -\zeta_3 = \zeta_1$

for $z \in D_3$. It will be shown that the quantities $\varepsilon_i(a_j)$ appearing in the formula (3.12) are such that $\varepsilon_2(a_3)=0$ whilst $\varepsilon_2(a_1)$ and $\varepsilon_3(a_1)$ are each $O(u^{-1})$. We consider $\varepsilon_3(a_1)$ first and apply the inequality (3.11) in which the path of integration connecting a_1 and a_3 is the straight line $\operatorname{Im} z=\pi/2$. On this line we set $z=x+i\pi/2$ and obtain

$$(3.17)\qquad \begin{aligned}(u^2-2h^2\cosh 2z)^{1/2}&=(R^2e^{2i\theta}+2h^2\cosh 2x)^{1/2}\\ &=(R^2\cos 2\theta+2h^2\cosh 2x+iR^2\sin 2\theta)^{1/2}.\end{aligned}$$

Since $\operatorname{Re}\zeta_3\to+\infty$ as $x\to+\infty$ it is necessary to select the branch of (3.17) whose real part is positive as $x\to+\infty$. It is then readily verified that $\operatorname{Re}(u^2-2h^2\cosh 2z)^{1/2}>0$ for all real values of x.

Since $d\zeta_3=(u^2-2h^2\cosh 2z)^{1/2}\,dx$, along the chosen path, it also follows that $(d/dx)(\operatorname{Re}\zeta_3)>0$ so that $\operatorname{Re}\zeta_3$ is nondecreasing along this path. Furthermore it is proved in the Appendix that

$$(3.18)\qquad |(u^2+2h^2\cosh 2x)^{1/2}|\geqq(R^2+2h^2\cosh 2x)^{1/2}\sin\delta\geqq(R^2+h^2e^{|2x|})^{1/2}\sin\delta$$

for u in the sector $0\leqq\theta\leqq\pi/2-\delta$. On using this inequality in the definition (3.10) of the function $R(x)$ it is seen that this function is $O[e^{|2x|}(R^2+h^2e^{|2x|})^{-3/2}]$ on the line joining a_1 and a_3 and that the integral present in (3.11) is $O(u^{-1})$ so that ε_{13} is itself $O(u^{-1})$.

To prove that $\varepsilon_2(a_3)=0$ we connect a_2 and a_3 by means of the three straight lines from a_2 to $\sigma-i\pi/2$, then to $\sigma+i\pi/2$ and finally to a_3, where σ is an arbitrarily large positive number. It follows from (2.9) that, on all three parts of the chosen path, $\zeta_3\sim-ihe^z+iu\pi/2$, the signs of (2.9) being reversed since $\operatorname{Re}\zeta_3\to+\infty$ as $x\to+\infty$ in D_3. Therefore $\operatorname{Re}\zeta_3\sim he^x\sin y+\text{constant}$, which verifies that $\operatorname{Re}\zeta_3$ increases steadily from $-\infty$ at a_2 to $+\infty$ at a_3. In addition since $|(u^2-2h^2\cosh 2z)^{1/2}|\sim he^x$ we see that $R(x)=O(e^{-x})$ and that

$$\int_{a_2}^{a_3}|R|\cdot|dz|\leqq 2C\int_\sigma^\infty e^{-x}\,dx+Ce^{-\sigma}\int_{-\pi/2}^{\pi/2}dy=2Ce^{-\sigma}+\pi Ce^{-\sigma}.$$

It follows that $|\varepsilon_3(a_2)|\leqq\exp[(\pi+2)Ce^{-\sigma}]-1$ where σ is arbitrarily large, so that, on letting $\sigma\to+\infty$ we see that $\varepsilon_3(a_2)$ is actually zero.

To show that $\varepsilon_2(a_1)=O(u^{-1})$ we again apply the inequality (3.11) in which the path of integration connecting a_1 and a_2 consists of the three straight lines from a_1 to $i\pi/2$, then to $-i\pi/2$ and finally to $a_2=\infty-i\pi/2$. On the line joining the points $\pm i\pi/2$ the formula (2.12) applies, with all signs on the right-hand side reversed, since the dominant term is the logarithmic one and we require $\operatorname{Re}\zeta_1>0$ in D_1. Therefore, on this segment

$$\begin{aligned}\zeta_1&=-uz+u\log\left(\frac{2u}{he}\right)+O(1)\\ &=-iuy+u\log\left(\frac{2u}{he}\right)+O(1)\end{aligned}$$

so that $\operatorname{Re}\zeta_1=yR\sin\theta+\operatorname{Re}[u\log(2u/he)]$ which decreases when the segment is described in the stated direction, and on this segment,

$$(u^2-2h^2\cosh 2z)^{1/2}=(R^2e^{2i\theta}-2h^2\cos 2y)^{1/2}=-\mathrm{R}e^{i\theta}+O(R^{-1})$$

uniformly for $|y|\leqq\pi/2$. On the infinite parts of the path the formula (3.17) applies, except that it is now necessary to choose the value whose real part is negative as $x\to+\infty$, since then we require that $\operatorname{Re}\zeta_1\to-\infty$. It follows that $\operatorname{Re}(u^2-2h^2\cosh 2z)^{1/2}<0$, and that Re ζ_1 is decreasing, on the whole path. In addition the inequality (3.18) applies on the infinite parts so that $R(x)=O[e^{|2x|}(R^2+h^2e^{|2x|})^{-3/2}]$ on the entire path and therefore

$$\int_{a_1}^{a_2}|R|\cdot|dz|=O(u^{-1}).$$

Finally we see that $|\varepsilon_2(a_1)|\leqq \exp[0(u^{-1})]-1$ and this implies that $\varepsilon_2(a_1)$ is itself $O(u^{-1})$ as claimed. Since $\varepsilon_2(a_3)=0$ and $\varepsilon_1(a_3)$ and $\varepsilon_1(a_2)$ are $O(u^{-1})$, (3.12) reduces to

$$w_1(z)=[e^{i\pi/3}w_2(z)+e^{-i\pi/3}w_3(z)][1+O(u^{-1})]. \tag{3.19}$$

To relate $M_\nu^{(3)}(x)$ to the solutions w_1, w_2, w_3 we appeal to the property (1.3) and the Hankel asymptotic formula [1]

$$H_\nu^{(1)}(2h\cosh x)=\frac{1}{\sqrt{\pi h\cosh x}}\exp\left[2ih\cosh x-i\left(\nu+\frac{1}{2}\right)\frac{\pi}{2}\right][1+O(e^{-x})] \tag{3.20}$$

as $x\to+\infty$. It follows on combining (1.3) and (3.20) that

$$M_\nu^{(3)}(x)=\frac{1}{\sqrt{\pi h\cosh x}}\exp\left[2ih\cosh x-i\left(\nu+\frac{1}{2}\right)\frac{\pi}{2}\right][1+O(e^{-x})] \tag{3.21}$$

as $x\to+\infty$.

Since $\zeta_3\sim -ihe^z+iu\pi/2$ as Re $(z)\to+\infty$ in D_2 and D_3 the formula (3.8) applied to w_3 shows that

$$w_3(z)=\phi_3(z)e^{ihe^z-iu\pi/2}[1+\varepsilon_3(z)]. \tag{3.22}$$

The above formula for w_3 applies for all points z that can be connected to a_3 by a path along which Re ζ_3 is nondecreasing. If $z=\sigma$ is positive, and large compared with u^2, a suitable path can be composed of the straight line from σ to $(\sigma+i\pi/2)$ together with the straight line from $\sigma+i\pi/2$ to a_3. This path is the upper half of that introduced in the preceding proof that $\varepsilon_2(a_3)=0$ and on it $R=O(e^{-x})$ and Re ζ_3 is nondecreasing so that

$$\int_{\sigma}^{a_3}|R|\cdot|dz|=O(e^{-\sigma}).$$

Therefore $\varepsilon_3(\sigma)\to 0$ as $\sigma\to-\infty$. Hence, since $\phi_3\sim h^{-1/2}e^{-x/2+i\pi/4}$ as $x\to\infty$, it follows from (3.21) that

$$w_3(x)=h^{-1/2}e^{-x/2+ihe^x-iu\pi/2+i\pi/4}[1+\varepsilon_3(x)] \tag{3.23}$$

where $\varepsilon_3(x)\to 0$ as $x\to+\infty$.

Upon comparing (3.21) with (3.23) we see that

$$M_\nu^{(3)}(x)=\sqrt{\frac{2}{\pi}}\,e^{i(u-\nu)(\pi/2)-i\pi/2}w_3(x) \tag{3.24}$$

$$=\sqrt{\frac{2}{\pi}}\,e^{i(u-\nu)(\pi/2)}[e^{-i\pi/6}w_1(x)-e^{i\pi/6}w_2(x)][1+O(u^{-1})] \tag{3.25}$$

by (3.19).

We now obtain the desired formula for $M_\nu^{(3)}(x)$. Since this is to be applicable to sufficiently large values of u but bounded values of x, the latter variable will be located in the domain D_1. In this domain Re $(\zeta_1)>0$ so that ζ_1 is given by (2.12) with the signs of the terms on the right-hand side of this equation reversed. For the values of

x in question, the second term on the right-hand side of the same equation is $O(u^{-1})$ and can be absorbed into the last term so that $\zeta_1(x, u) = -ux + \frac{1}{2}g_0(u)$ and

$$w_1(x) = \phi_1(x)e^{ux-(1/2)g_0(u)}[1+\varepsilon_1(x)]$$

where $g_0(u)$ is defined by equation (2.15). Since $\zeta_2 = -\zeta_1$ in D_1 we also have the equation

$$w_2(x) = \phi_2(x)e^{-ux+(1/2)g_0(u)}[1+\varepsilon_2(x)].$$

It is clear from the reasoning followed in discussing $\varepsilon_1(a_2)$ that $\varepsilon_1(x)$ and $\varepsilon_2(x)$ are $O(u^{-1})$. On inserting the above expressions for w_1 and w_2 into (3.25) and using the facts that $\phi_1 e^{-i\pi/6} = \phi_2 e^{-i\pi/3} = \phi_3 \sim u^{-1/2}$ in D_1, we find the formula (1.5) already stated.

If $-\pi/2 < \theta < 0$ the desired formula for $M_\nu^{(3)}(x)$ is obtainable at once from (3.24) where $w_3(z)$ is given by (3.22), the connection formula (3.19) being now unnecessary. The formula (3.22) itself now applies for fixed real values of z and, for such values, $\varepsilon_3(z) = O(u^{-1})$. To establish this result it is first verified that points representing fixed real values of z can be connected to a_3 by a path satisfying the monotonic property. If x is positive and small compared with $\log(2u/he)$, a suitable path consists of the straight line from x to $x + i\pi/2$ followed by the line from $x + i\pi/2$ to a_3. In the domain D_1, Re ζ_3 is negative and equal to the expression on the right-hand side of (3.7) which, since $\sin\theta$ is negative, confirms that Re ζ_3 increases along the first part of the stated path. The remainder of the path is positioned on the line Im $z = \pi/2$ on which (3.17) holds. Since Re $\zeta_3 \to +\infty$ as $z \to a_3$ along this line it follows as before that Re ζ_3 is nondecreasing on this section of the path as well. Since $R(z) = O(u^{-1})$ on the first part of the path and $R(z) = O[e^{2x}(|u|^2 + h^2e^{2x})^{-3/2}]$ on the second part it follows, as in the earlier discussion of $\varepsilon_2(a_1)$, that $\varepsilon_3(x) = O(u^{-1})$ for positive values of x small compared with $\log(2u/he)$. On combining (3.24) and (3.22) we find since $\phi_3 \sim u^{-1/2}$ in D_1 that

$$M_\nu^{(3)}(x) = \sqrt{\frac{2}{\pi u}}\, e^{i(u-\nu)\pi/2 - i\pi/2 - \zeta_3}[1 + O(u^{-1})]$$

$$= -i\sqrt{\frac{2}{\pi u}}\, e^{i(u-\nu)\pi/2 - ux + u\log(2u/he)}[1 + O(u^{-1})]$$

for $-\pi/2 < \theta < 0$.

Appendix. It remains to establish the inequality (3.18). We write

$$(u^2 + 2h^2\cosh 2x)^{1/2} = A + iB. \tag{A.1}$$

On setting $u = t + is$, squaring both sides and equating real and imaginary parts, we find the equations

$$t^2 - s^2 + 2h^2\cosh 2x = A^2 - B^2, \qquad st = AB. \tag{A.2}$$

Upon eliminating s from the last two equations and rearranging the result we find that

$$A^2 = t^2\left[1 + \frac{2h^2\cosh 2x}{B^2 + t^2}\right]. \tag{A.3}$$

It follows from this equation that $|A| \geqq |t|$, and therefore from (A.2) that $|B| \leqq |s|$. On using the latter inequality in (A.3), we find that

$$A^2 \geqq t^2\left[1 + \frac{2h^2\cosh 2x}{s^2 + t^2}\right]$$

so that, since $u = t + is = \mathrm{Re}^{i\theta}$,

$$|A| \geqq (R^2 + 2h^2\cosh 2x)^{1/2}|\cos\theta|.$$

Since

$$|u^2+2h^2\cosh 2x|^{1/2}=(A^2+B^2)^{1/2}\geqq|A|\geqq(R^2+2h^2\cosh 2x)^{1/2}|\cos\theta|$$

the result (3.18) follows for all values of u in the sector

$$0\leqq\theta\leqq\frac{\pi}{2}-\delta.$$

ASYMPTOTIC EXPANSION OF A MULTIPLE INTEGRAL*

J. P. McCLURE† AND R. WONG†

Abstract. An alternative derivation is given for the asymptotic expansion, as $s \to 0^+$, of the multiple integral

$$J(s) = \int_{[0,1]^n} g(x^\alpha / s) x^\beta f(x)\, dx,$$

where $g \in \mathscr{S}(\mathbb{R})$ and $f \in C^\infty(\mathbb{R}^n)$. The integral $J(s)$ is first expressed as a contour integral, in which the integrand is a meromorphic function in the complex plane. The asymptotic expansion is then obtained by moving the contour to the left, the terms of the expansion being the residues of the integrand.

Key words. asymptotic expansion, multiple integral, Mellin transform

AMS (MOS) subject classification. Primary 41A60

1. Let $g \in \mathscr{S}(\mathbb{R})$, the Schwarz space, $f \in C^\infty(\mathbb{R}^n)$ and $K_n = [0, 1]^n$. Recently, Brüning [4] has derived an asymptotic expansion, as $s \to 0^+$, for the multi-dimensional integral

$$(1) \qquad J(s) = \int_{K_n} g\left(\frac{x^\alpha}{s}\right) x^\beta \log^\gamma x f(x)\, dx,$$

where $x \in \mathbb{R}^n$, α and $\beta \in \mathbb{R}^n_+$, $\gamma \in \mathbb{Z}^n_+$, $x^\alpha = x_1^{\alpha_1} \cdots x_n^{\alpha_n}$ and

$$\log^\gamma x = \log^{\gamma_1} x_1 \cdots \log^{\gamma_n} x_n.$$

Here, $\mathbb{R}_+ = [0, \infty)$. To avoid triviality, we assume that the components $\alpha_1, \cdots, \alpha_n$ of α are all positive. According to Brüning, integrals of this type play an important role in the asymptotic expansion of the trace of the equivariant heat kernel [3]. A related integral has been treated by Barlet [1] in the analysis of complex spaces. The main result of Brüning is the following.

THEOREM. *As $s \to 0^+$, we have that*

$$(2) \qquad J(s) \sim \sum I_{jkl}(f) s^{(\beta_l + j + 1)/\alpha_l} \log^k s,$$

where the summation is over all $j \geqq 0$, $0 \leqq k \leqq |\gamma| + n - 1$ and $1 \leqq l \leqq n$. The I_{jkl} are distributions with support in the set $\{x \in K_n : x^\alpha = 0\}$.

Brüning uses an inductive argument, and bases his analysis on real-variable techniques. However, his proof is difficult to follow; in particular, we believe that the argument of §§ 5, 6 and 7, which involves passing back and forth between one- and two-variable expansions, is more subtle than is indicated. Moreover, the combination of the inductive method and the reduction to various special cases makes the calculation of the coefficients of the expansion (2) impossible in any practical sense.

In the present note, we give a quite different and more straightforward method for deriving the expansion (2). A discussion of this method, but in the case of one-dimensional integrals, is given in [2]. This method involves some elementary complex-variable techniques and has two major advantages over Brüning's argument. First, the method remains the same, whatever the number of dimensions, so that no induction is necessary on the dimension of the integral. Second, our method leads to explicit formulas for the coefficients in (2).

2. For simplicity of presentation, we shall consider only the case $n=2$, and assume that $\gamma=0$ in (1). The logarithmic factors can always be introduced subsequently by differentiating both sides of the resulting expansion for $J(s)$ with respect to the exponents of x; see the last statement in § 4. The formulas, of course, become more complicated as the dimension increases. However, the method itself remains unchanged. Thus we are concerned with only the integral

$$J(s)=\int_0^1\int_0^1 g(x^a y^b/s)x^\alpha y^\beta f(x,y)\,dx\,dy, \tag{3}$$

where a and b are positive, α and β are nonnegative, $g\in\mathcal{S}(\mathbb{R})$ and $f\in C^\infty(\mathbb{R}^2)$.

Our approach is based on some properties of Mellin transforms. We recall that the Mellin transform of a locally integrable function h on $(0,\infty)$ is defined by the integral

$$M[h;z]=\int_0^\infty t^{z-1}h(t)\,dt \tag{4}$$

when it exists. If (4) holds, then the inverse Mellin transform is given by

$$h(t)=\frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty} t^{-z}M[h;z]\,dz, \tag{5}$$

where the path of integration is a suitably chosen vertical line in the domain of analyticity of $M[h;z]$. For conditions and proofs of (4) and (5), see [5, p. 46, § 1.29].

Since $g\in\mathcal{S}$, it is straightforward to show that the Mellin transform $M[J;z]$ exists and is analytic in the strip $-d_{11}<\operatorname{Re} z<0$, where

$$d_{11}=\min\left\{\frac{1+\alpha}{a},\frac{1+\beta}{b}\right\}. \tag{6}$$

Furthermore, in this strip,

$$\begin{aligned} M[J;z]&=\int_0^\infty s^{z-1}J(s)\,ds\\ &=\int_0^1\int_0^1 x^\alpha y^\beta f(x,y)\left[\int_0^\infty s^{z-1}g(x^a y^b/s)\,ds\right]dx\,dy \qquad (7)\\ &=M[g;-z]\int_0^1\int_0^1 x^{\alpha+az}y^{\beta+bz}f(x,y)\,dx\,dy. \end{aligned}$$

Put

$$F(z)=\int_0^1\int_0^1 x^{\alpha+az}y^{\beta+bz}f(x,y)\,dx\,dy. \tag{8}$$

Then, by the inversion formula, we have

$$J(s)=\frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty} s^{-z}F(z)M[g;-z]\,dz, \tag{9}$$

where $-d_{11}<c<0$; cf. [5, Thm. 28]. Note that the Mellin transform $M[g;-z]$ is analytic in the half-plane $\operatorname{Re} z<0$ and is bounded in $\operatorname{Re} z\leqq c$ for any $c<0$. Also, the double integral $F(z)$ is analytic in the half-plane $-d_{11}<\operatorname{Re} z$. In the following section, we shall show that $F(z)$ can be analytically continued to a meromorphic function in the entire z-plane.

3. For $-d_{11}<\operatorname{Re} z<0$, integration by parts gives

$$\begin{aligned} F(z)&=\frac{1}{\alpha+az+1}\left[\int_0^1 y^{\beta+bz}f(1,y)\,dy-\int_0^1\int_0^1 x^{\alpha+az+1}y^{\beta+bz}f_{1,0}(x,y)\,dx\,dy\right]\\ &=\frac{1}{(\alpha+az+1)(\beta+bz+1)}\left[f(1,1)-\int_0^1 y^{\beta+bz+1}f_{0,1}(1,y)\,dy\right.\\ &\qquad -\int_0^1 x^{\alpha+az+1}f_{1,0}(x,1)\,dx\\ &\qquad \left.+\int_0^1\int_0^1 x^{\alpha+az+1}y^{\beta+bz+1}f_{1,1}(x,y)\,dx\,dy\right]. \end{aligned} \tag{10}$$

The double integral on the extreme right is analytic for $\operatorname{Re} z>-d_{22}$, where

$$d_{22}=\min\left\{\frac{\alpha+2}{a},\frac{\beta+2}{b}\right\}.$$

Thus, through (10), $F(z)$ is extended to a meromorphic function in the half-plane $\operatorname{Re} z>-d_{22}$ with at least one pole at $z=-d_{11}$ and possibly two poles, one at $z=-(\alpha+1)/a$ and one at $z=-(\beta+1)/b$, depending on whether $d_{22}>\max\{(\alpha+1)/a,(\beta+1)/b\}$. Equation (10) also shows that $F(z)=O((\operatorname{Im} z)^{-2})$ as $z\to\infty$ along vertical lines in $\operatorname{Re} z>-d_{22}$. Now observe that the last double integral in (10) is in exactly the same form as $F(z)$. Hence, the procedure in (10) can be repeated, and n-applications of this give

$$\begin{aligned} F(z)=\sum_{k=1}^{n}&\left[\prod_{j=1}^{k}(\alpha+az+j)(\beta+bz+j)\right]^{-1}\\ &\cdot\left\{f_{k-1,k-1}(1,1)-\int_0^1 y^{\beta+bz+k}f_{k-1,k}(1,y)\,dy-\int_0^1 x^{\alpha+az+k}f_{k,k-1}(x,1)\,dx\right\}\\ &+\left[\prod_{j=1}^{n}(\alpha+az+j)(\beta+bz+j)\right]^{-1}\int_0^1\int_0^1 x^{\alpha+az+n}y^{\beta+bz+n}f_{n,n}(x,y)\,dx\,dy. \end{aligned}$$

Further integration by parts shows that for any positive integer n,

$$\begin{aligned} F(z)= &\sum_{k,l=1}^{n} (-1)^{k+l} f_{k-1,l-1}(1,1)\left[\prod_{j=1}^{k} (\alpha+az+j) \prod_{i=1}^{l} (\beta+bz+i)\right]^{-1} \\ &+\sum_{k=1}^{n} (-1)^{k+n-1}\left[\prod_{j=1}^{k} (\alpha+az+j) \prod_{i=1}^{n} (\beta+bz+i)\right]^{-1} \\ &\cdot \int_0^1 y^{\beta+bz+n} f_{k-1,n}(1,y)\,dy \\ &+\sum_{l=1}^{n} (-1)^{l+n-1}\left[\prod_{j=1}^{n} (\alpha+az+j) \prod_{i=1}^{l} (\beta+bz+i)\right]^{-1} \\ &\cdot \int_0^1 x^{\alpha+az+n} f_{n,l-1}(x,1)\,dx + \left[\prod_{j=1}^{n} (\alpha+az+j) \prod_{i=1}^{n} (\beta+bz+i)\right]^{-1} \\ &\cdot \int_0^1 \int_0^1 x^{\alpha+az+n} y^{\beta+bz+n} f_{n,n}(x,y)\,dx\,dy. \end{aligned} \tag{11}$$

From (11) it is evident that $F(z)$ is meromorphic for $\operatorname{Re} z > -d_{n+1,n+1}$, where

$$d_{nn}=\min\left\{\frac{\alpha+n}{a}, \frac{\beta+n}{b}\right\}.$$

Since $d_{nn}\to\infty$ as $n\to\infty$, we have proved the following result.

LEMMA. *The function $F(z)$, defined by* (8), *can be analytically continued to a meromorphic function in the entire z-plane, with poles at $-(\alpha+n)/a$, $-(\beta+n)/b$ ($n=1,2,\cdots$). Furthermore, $F(z)=O((\operatorname{Im} z)^{-2})$, as $|z|\to\infty$, uniformly in any strip $-\infty<d\leqq \operatorname{Re} z\leqq c<0$.*

To facilitate the calculation of the residues of $F(z)$, we state the following variant of (11), which is obtained by varying the number of integrations by parts. For any positive integers n and m, we have

$$\begin{aligned} F(z)= &\sum_{k=1}^{n}\sum_{l=1}^{m} (-1)^{k+l} f_{k-1,l-1}(1,1)\left[\prod_{j=1}^{k} (az+\alpha+j) \prod_{i=1}^{l} (bz+\beta+i)\right]^{-1} \\ &+\sum_{k=1}^{n} (-1)^{k+m-1}\left[\prod_{j=1}^{k} (az+\alpha+j) \prod_{i=1}^{m} (bz+\beta+i)\right]^{-1} \\ &\cdot \int_0^1 y^{\beta+bz+m} f_{k-1,m}(1,y)\,dy \\ &+\sum_{l=1}^{m} (-1)^{l+n-1}\left[\prod_{j=1}^{n} (az+\alpha+j) \prod_{i=1}^{l} (bz+\beta+i)\right]^{-1} \\ &\cdot \int_0^1 x^{\alpha+az+n} f_{n,l-1}(x,1)\,dx \\ &+(-1)^{n+m}\left[\prod_{j=1}^{n} (az+\alpha+j) \prod_{i=1}^{m} (bz+\beta+i)\right]^{-1} \\ &\cdot \int_0^1 \int_0^1 x^{\alpha+az+n} y^{\beta+bz+m} f_{n,m}(x,y)\,dx\,dy. \end{aligned} \tag{12}$$

Note that each integral on the right-hand side of (12) is analytic in $\operatorname{Re} z > -d_{n+1\,m+1}$, where

$$d_{nm} = \min\left\{\frac{\alpha+n}{a}, \frac{\beta+m}{b}\right\},$$

and that the sequence d_{nm} is monotonically increasing with respect to each of n and m. Moreover, $d_{nm} \to \infty$ as $n, m \to \infty$.

Now let w be a pole of $F(z)$, and let n and m be the smallest positive integers such that $w > -d_{n+1\,m+1}$. To be more specific, we suppose that $w = -(\alpha+n)/a$, and that $-(\alpha+n)/a \neq -(\beta+m)/b$ for all positive integers m. Thus w is a simple pole. From (12) we have

$$\begin{aligned}\operatorname{Res}\left[F; -\frac{\alpha+n}{a}\right] = \frac{1}{a(n-1)!} & \\ \cdot\Bigg\{ & \sum_{l=1}^{m} (-1)^{l-1} f_{n-1,l-1}(1,1) \prod_{i=1}^{l}\left(\beta+i-b\frac{\alpha+n}{a}\right)^{-1} \\ & + (-1)^m \prod_{i=1}^{m}\left(\beta+i-b\frac{\alpha+n}{a}\right)^{-1} \\ & \qquad \cdot \int_0^1 y^{\beta+m-b(n+\alpha)/a} f_{n-1,m}(1,y)\,dy \\ & + \sum_{l=1}^{m} (-1)^{l} \prod_{i=1}^{l}\left(\beta+i-b\frac{\alpha+n}{a}\right)^{-1} \\ & \qquad \cdot \int_0^1 f_{n,l-1}(x,1)\,dx + (-1)^{m-1} \prod_{i=1}^{m}\left(\beta+i-b\frac{\alpha+n}{a}\right)^{-1} \\ & \qquad \cdot \int_0^1\int_0^1 y^{\beta+m-b(n+\alpha)/a} f_{n,m}(x,y)\,dx\,dy \Bigg\}.\end{aligned} \tag{13}$$

Performing the obvious integration with respect to x in the second sum and the last term on the right simplifies (13) to

$$\begin{aligned}\operatorname{Res}\left[F; -\frac{\alpha+n}{a}\right] = \frac{1}{a(n-1)!}\Bigg\{ & \sum_{l=1}^{m} (-1)^{l+1} \prod_{i=1}^{l}\left(\beta+i-b\frac{\alpha+n}{a}\right)^{-1} f_{n-1,l-1}(0,1) \\ & + (-1)^m \prod_{i=1}^{m}\left(\beta+i-b\frac{n+\alpha}{a}\right)^{-1} \\ & \qquad \cdot \int_0^1 y^{\beta+m-b(n+\alpha)/a} f_{n-1,m}(0,y)\,dy \Bigg\}.\end{aligned} \tag{14}$$

Similarly, if $w = -(\beta+m)/b$ is a simple pole, and if n, m are chosen as before, then we have

$$\begin{aligned}\operatorname{Res}\left[F; -\frac{\beta+m}{b}\right] = \frac{1}{b(m-1)!}\Bigg\{ & \sum_{k=1}^{n} (-1)^{k+1} \prod_{j=1}^{k}\left(\alpha+j-a\frac{\beta+m}{b}\right)^{-1} f_{k-1,m-1}(1,0) \\ & + (-1)^n \prod_{j=1}^{n}\left(\alpha+j-a\frac{\beta+m}{b}\right)^{-1} \\ & \qquad \cdot \int_0^1 x^{\alpha+n-a(\beta+m)/b} f_{n,m-1}(x,0)\,dx \Bigg\}.\end{aligned} \tag{15}$$

Finally, suppose that for some integers n and m, we have $(\alpha+n)/a=(\beta+m)/b$. Then $F(z)$ has a double pole at $-(\alpha+n)/a$. The principal part of $F(z)$ can be calculated from (12), and is given by

$$\begin{aligned}
&\frac{1}{ab(n-1)!(m-1)!}\biggl\{f_{n-1,m-1}(1,1)-\int_0^1 f_{n-1,m}(1,y)\,dy\\
&\qquad -\int_0^1 f_{n,m-1}(x,1)\,dx+\int_0^1\int_0^1 f_{n,m}(x,y)\,dx\,dy\biggr\}\left(z+\frac{\alpha+n}{a}\right)^{-2}\\
&+\frac{1}{ab(n-1)!(m-1)!}\biggl\{\biggl[f_{n-1,m-1}(1,1)-\int_0^1 f_{n-1,m}(1,y)\,dy\\
&\qquad -\int_0^1 f_{n,m-1}(x,1)\,dx+\int_0^1\int_0^1 f_{n,m}(x,y)\,dx\,dy\biggr](aH_{n-1}+bH_{m-1})\\
&\qquad -b\int_0^1 \log y f_{n-1,m}(1,y)\,dy\\
&\qquad -a\int_0^1 \log x f_{n,m-1}(x,1)\,dx\\
&\qquad +\int_0^1\int_0^1 (a\log x+b\log y)f_{n,m}(x,y)\,dx\,dy\\
&\qquad -a\sum_{k=1}^{n-1}(n-k-1)!f_{k-1,m-1}(1,1)\\
&\qquad -b\sum_{l=1}^{m-1}(m-l-1)!f_{n-1,l-1}(1,1)\\
&\qquad +a\sum_{k=1}^{n-1}(n-k-1)!\int_0^1 f_{k-1,m}(1,y)\,dy\\
&\qquad\qquad +b\sum_{l=1}^{m-1}(m-l-1)!\int_0^1 f_{n,l-1}(x,1)\,dx\biggr\}\left(z+\frac{\alpha+n}{a}\right)^{-1},
\end{aligned}$$

where $H_n=\sum_{k=1}^n(1/k)$. Upon simplification, the above expression reduces to

$$\begin{aligned}
\operatorname{Prin}\left[F;-\frac{\alpha+n}{a}\right]&=\frac{1}{ab(n-1)!(m-1)!}f_{n-1,m-1}(0,0)\left(z+\frac{\alpha+n}{a}\right)^{-2}\\
&\quad+\frac{1}{ab(n-1)!(m-1)!}\\
&\quad\cdot\biggl\{f_{n-1,m-1}(0,0)(aH_{n-1}+bH_{m-1})\\
&\qquad -b\int_0^1 \log y f_{n-1,m}(0,y)\,dy-a\int_0^1 \log x f_{n,m-1}(x,0)\,dx\\
&\qquad -a\sum_{k=1}^{n-1}(n-k-1)!f_{k-1,m-1}(1,0)\\
&\qquad\qquad -b\sum_{l=1}^{m-1}(m-l-1)!f_{n-1,l-1}(0,1)\biggr\}\left(z+\frac{\alpha+n}{a}\right)^{-1}.
\end{aligned}\tag{16}$$

Observe that the right-hand side of (14) can be regarded as the result of a distribution acting on the C^∞-function $f(x, y)$ and supported on the coordinate axes. The same remark applies to (15) and (16).

4. We are now ready to derive the asymptotic expansion of $J(s)$. First we return to the contour integral representation in (9). For any positive number $d > -c$ we can choose an arbitrarily small ε such that $F(z)$ has no pole in the strip $-d < \operatorname{Re} z \leqq -d+\varepsilon$. Since $M[g; -z]$ is analytic and bounded for $\operatorname{Re} z \leqq c < 0$, by the lemma above we can shift the contour in (9) to the left and obtain

$$\begin{aligned} J(s) = &\sum_{-d+\varepsilon<\operatorname{Re} z<c} \operatorname{Res}\{s^{-z}F(z)M[g; -z]\} \\ &+\frac{1}{2\pi i}\int_{-d+\varepsilon-i\infty}^{-d+\varepsilon+i\infty} s^{-z}F(z)M[g; -z]\,dz. \end{aligned} \tag{17}$$

The last integral is clearly bounded by a constant multiple of $s^{d-\varepsilon}$. Thus we have

$$J(s) = \sum_{-d<\operatorname{Re} z<c} \operatorname{Res}\{s^{-z}F(z)M[g; -z]\} + O(s^{d-\varepsilon}), \tag{18}$$

as $s \to 0^+$. Each simple pole $w = -(\alpha+n)/a$ of $F(z)$ contributes a term of the form

$$s^{(\alpha+n)/a} M\left[g; \frac{\alpha+n}{a}\right] \operatorname{Res}\left[F; -\frac{\alpha+n}{a}\right] \tag{19}$$

to the asymptotic expansion of $J(s)$. Similarly, each simple pole $w = -(\beta+m)/b$ contributes a term of the form

$$s^{(\beta+m)/b} M\left[g; \frac{\beta+m}{b}\right] \operatorname{Res}\left[F; -\frac{\beta+m}{b}\right]. \tag{20}$$

If $w = -(\alpha+n)/a = -(\beta+m)/b$ is a double pole of $F(z)$, then the residue of

$$s^{-z}F(z)M[g; -z] = \exp(-z \log s)F(z)M[g; -z]$$

at w can be calculated from (16), and to the expansion of $J(s)$ the point contributes the term

$$a_n(f)s^{(\alpha+n)/a}\log s + b_n(f)s^{(\alpha+n)/a}, \tag{21}$$

where

$$a_n(f) = -\frac{f_{n-1,m-1}(0, 0)}{ab(n-1)!(m-1)!} M\left[g; \frac{\alpha+n}{a}\right] \tag{22}$$

and

$$\begin{aligned} b_n(f) = &-\frac{f_{n-1,m-1}(0, 0)}{ab(n-1)!(m-1)!} M'\left[g; \frac{\alpha+n}{a}\right] + \frac{1}{ab(n-1)!(m-1)!} \\ &\cdot\left\{ f_{n-1,m-1}(0, 0)(aH_{n-1}+bH_{m-1}) \right. \\ &-b\int_0^1 \log y f_{n-1,m}(0, y)\,dy - a\int_0^1 \log x f_{n,m-1}(x, 0)\,dx \\ &-a\sum_{k=1}^{n-1}(n-k-1)!f_{k-1,m-1}(1, 0) \\ &\left. -b\sum_{l=1}^{m-1}(m-l-1)!f_{n-1,l-1}(0, 1)\right\} M\left[g; \frac{\alpha+n}{a}\right]. \end{aligned} \tag{23}$$

Inserting (19), (20) and (21) into (18), we obtain an asymptotic expansion for $J(s)$ in terms of powers and logarithms of s. In view of the statement following (16), the theorem in § 1 is proved for the case $n=2$ and $\gamma=0$.

As remarked before, the above method can easily be extended to integrals of higher dimensions. The formulas for the coefficients in the expansion, however, will become overwhelmingly complicated, and hence will not be given. The case $\gamma\neq 0$ in (1) can be included by employing a frequently used device in asymptotics, namely, we first replace each term in the sum in (17) by its corresponding value given in (19), (20) or (21), and then differentiate both sides of (17) with respect to α and β an appropriate number of times.

INCOMPLETE LAPLACE INTEGRALS: UNIFORM ASYMPTOTIC EXPANSION WITH APPLICATION TO THE INCOMPLETE BETA FUNCTION*

N. M. TEMME†

Abstract. The incomplete Laplace integral

$$\frac{1}{\Gamma(\lambda)}\int_\alpha^\infty t^{\lambda-1}\,e^{-zt}f(t)\,dt$$

is considered for large values of z. Both λ and α are uniformity parameters in $[0,\infty)$. The basic approximant is an incomplete gamma function, that is, the above integral with $f=1$. Also, a loop integral in the complex plane is considered with the same asymptotic features. The asymptotic expansions are furnished with error bounds for the remainders in the expansions. The results of the paper combine four kinds of asymptotic problems considered earlier. An application is given for the incomplete beta function. The present investigations are a continuation of earlier works of the author for the above integral with $\alpha=0$. The new results are significantly based on the previous case.

Key words. uniform asymptotic expansion of integrals, incomplete gamma function, incomplete beta function, incomplete Laplace integral, construction of error bounds

AMS(MOS) subject classification. 41 A60, 30 F15, 33 A15, 44 A10

1. Introduction. This paper is the third in a set dealing with uniform asymptotic expansions of Laplace type integrals. The previous papers are [11] and [12]. In the present paper, we consider the integral

$$F_\lambda(z,\alpha)=\frac{1}{\Gamma(\lambda)}\int_\alpha^\infty t^{\lambda-1}\,e^{-zt}f(t)\,dt, \tag{1.1}$$

where z is a large parameter and f is holomorphic in a domain Ω that contains the nonnegative reals; λ, α and z are real variables for which the integral is properly defined. Say, $\alpha\geqq 0$, $\lambda\geqq 0$ and $z>0$. An interpretation of $F_0(z,0)$ follows from

$$\lim_{\lambda\to 0}F_\lambda(z,\alpha)=\begin{cases}0 & \text{if } \alpha>0,\\ f(0) & \text{if } \alpha=0.\end{cases}$$

The second case follows from integration by parts.

We are interested in the asymptotic expansion of (1.1) for $z\to\infty$ which is uniformly valid with respect to both λ and α in $[0,\infty)$. The parameters λ and α may be coupled with the large parameter z, or they may range independently through the uniformity interval. For a description of the various asymptotic features, four different cases with their own asymptotic phenomena can be distinguished.

(i) α fixed, λ fixed. For this classical case Watson's lemma gives an expansion. When $\alpha=0$, $f(t)$ is expanded in powers of t, when $\alpha>0$, $t^{\lambda-1}f(t)$ is expanded in powers of $t-\alpha$. See [6, p. 113].

(ii) $\alpha\geqq 0$, λ fixed. An incomplete gamma function (i.e., (1.1) with $f=1$) is needed to describe the uniform transition of $\alpha=0$ to $\alpha>0$; [4], [8], [9] and [14] are appropriate references. The asymptotic feature is the possible coalescence of two critical points: $t=0$ (an algebraic singularity) and $t=\alpha$ (end-point of integration).

* Received by the editors November 11, 1985; accepted for publication (in revised form) May 13, 1986.

† Centre for Mathematics and Computer Science, P.O. Box 4079, 1009 AB Amsterdam, The Netherlands.

(iii) $\alpha = 0$, $\lambda \geqq 0$. The saddle point of $t^{\lambda} e^{-zt}$, which occurs at $t = \mu := \lambda / z$, may coalesce with $t = 0$, the end-point of integration. In that event (i.e., when $\mu \to 0$) the saddle point disappears, since e^{-zt} does not have a saddle point. No extra special function is needed to describe this feature; in fact the (complete) gamma function, which is incorporated in (1.1) for normalization, can handle this case. See [11] and [12].

(iv) $\alpha > 0$ (fixed), $\lambda \geqq 0$. When $\mu := \lambda / z$ is larger than α, the saddle point is inside the interval of integration; otherwise it is outside. This transition can be described by using an error function. A transformation gives an integral of the form

$$\int_{\eta}^{\infty} e^{-zu^2} g(u)\, du,$$

and here the transition occurs at $\eta = 0$. See [10]; similar cases are considered in [2] and [13].

These four cases are combined in our approach, where $\alpha \geqq 0$, $\lambda \geqq 0$. As in case (ii), the basic approximant is the incomplete gamma function. However, in case (ii) the full ranges of both parameters of this approximant are not completely exploited. As discussed in [7], it is expected that a two-variable approximant is needed to handle a three-variable case as in (1.1).

Apart from combining four existing methods, our results are interesting in view of applications. We consider the well-known incomplete beta function $I_x(p, q)$, and we give an expansion for large values of p, valid uniformly with respect to both x and q; $x \in [0, 1]$, $q \geqq 0$. Since $I_x(p, q) = 1 - I_{1-x}(q, p)$, the parameters p and q are interchangeable. So we solve an open problem mentioned in [10], where the incomplete beta function is considered as belonging to case (ii), as well as to case (iv). A transition from one case to another was not available at that moment.

The plan of the paper is as follows. In § 2 we give the formal expansion of (1.1). It appears that an essential part of the expansion is that of the complete integral (1.1) with $\alpha = 0$. Subsequent sections give representations of the remainders, conditions on f, the asymptotic nature of the expansions and the construction of error bounds. In § 8 we consider analogous results for loop integrals in the complex plane. A loop integral with essentially the same asymptotic features as (1.1) has the form

$$\int t^{-\lambda} e^{zt} \frac{f(t)}{t - \alpha}\, dt.$$

For $\alpha = 0$ it reduces, just as (1.1), to a form that we considered earlier. Section 9 gives two new expansions for the incomplete beta function

Terminology. We call a variable *fixed* when it is independent of z, λ and α. A sequence of functions $\{\psi_s\}$ is called an *asymptotic scale* when, for $s = 0, 1, \cdots$, $\psi_{s+1} = o(\psi_s)$ as $z \to \infty$. The formal series $\sum_{s=0}^{\infty} f_s(z)$ is said to be an *asymptotic expansion* of $F(z)$ *with respect to the scale* $\{\psi_s\}$, if for $n = 0, 1, 2, \cdots$

$$F(z) - \sum_{s=0}^{n} f_n(z) = o(\psi_n) \quad \text{as } z \to \infty. \tag{1.2}$$

In this case we write

$$F(z) \sim \sum_{s=0}^{\infty} f_s(z), \qquad \{\psi_s\} \quad \text{as } z \to \infty. \tag{1.3}$$

In uniform expansions it is required that the "o" symbols in (1.2) and in the definition of the scale hold uniformly (with respect to α, λ or $\mu = \lambda / z$ in certain domains, say). See [3].

2. Uniform expansions: construction of the formal series.

Before considering the general case (1.1), we repeat the procedure for $F_\lambda(z, 0)$, which will be denoted by

$$F_\lambda(z)=\frac{1}{\Gamma(\lambda)}\int_0^\infty t^{\lambda-1}\,e^{-zt}f(t)\,dt. \tag{2.1}$$

This function and its expansion play an essential role in the expansion of (1.1). The following integration by parts procedure takes into account the role of the *critical point*: the saddle point of $t^\lambda\,e^{-zt}$, i.e., the point $t=\mu$, where

$$\mu=\lambda/z. \tag{2.2}$$

We write

$$f(t)=f(\mu)+(t-\mu)g(t), \tag{2.3}$$

and we obtain

$$\begin{aligned}F_\lambda(z)&=f(\mu)z^{-\lambda}+\frac{1}{\Gamma(\lambda)}\int_0^\infty t^{\lambda-1}\,e^{-zt}(t-\mu)g(t)\,dt\\ &=f(\mu)z^{-\lambda}-\frac{1}{z\Gamma(\lambda)}\int_0^\infty g(t)\,d(t^\lambda\,e^{-zt})\\ &=f(\mu)z^{-\lambda}+\frac{1}{z\Gamma(\lambda)}\int_0^\infty t^{\lambda-1}\,e^{-zt}f_1(t)\,dt,\end{aligned}$$

where we assume that integrated terms at $t=0$, $t=\infty$ vanish, and

$$f_1(t)=t\frac{d}{dt}g(t)=t\frac{d}{dt}\frac{f(t)-f(\mu)}{t-\mu}.$$

Repeating this process, we obtain the formal expansion

$$F_\lambda(z)\sim z^{-\lambda}\sum_{s=0}^\infty f_s(\mu)z^{-s},\qquad z\to\infty, \tag{2.4}$$

where $f_0(t)=f(t)$ and

$$f_{s+1}(t)=t\frac{d}{dt}\frac{f_s(t)-f_s(\mu)}{t-\mu},\qquad s=0,1,\cdots. \tag{2.5}$$

For the general case (1.1) we again take (2.3) as the first step. Now we have an integrated term at $t=\alpha$. It is not difficult to see that we obtain the formal expansion

$$F_\lambda(z,\alpha)\sim z^{-\lambda}Q(\lambda,\alpha z)\sum_{s=0}^\infty f_s(\mu)z^{-s}+\frac{\alpha^\lambda\,e^{-\alpha z}}{z\Gamma(\lambda)}\sum_{s=0}^\infty B_s(\alpha)z^{-s},\qquad z\to\infty, \tag{2.6}$$

where $f_s(\mu)$ are the same as in (2.4), $B_s(\alpha)$ are defined by

$$B_s(\alpha)=\frac{f_s(\alpha)-f_s(\mu)}{\alpha-\mu},\qquad s=0,1,\cdots, \tag{2.7}$$

and $Q(a,x)$ is the incomplete gamma function ratio

$$Q(a,x)=\frac{1}{\Gamma(a)}\int_x^\infty t^{a-1}\,e^{-t}\,dt. \tag{2.8}$$

We observe that the first series in (2.6) does not depend on α; in fact we recognize the expansion given in (2.4). Furthermore, the integrated terms at $t=\alpha$, which generate the second series, all vanish when $\alpha\to0$.

These observations lead us to the representation, including the definition of a new function B_λ,

$$F_\lambda(z,\alpha)=Q(\lambda,\alpha z)F_\lambda(z)+\frac{\alpha^\lambda e^{-\alpha z}}{z\Gamma(\lambda)}B_\lambda(z,\alpha), \tag{2.9}$$

which should not be interpreted as an asymptotic relation, but as an exact identity. We consider the incomplete gamma ratio as a known function, of which the asymptotic features are well known (see [10]). For numerical aspects concerning this function see [5]. As mentioned above, the asymptotic expansion of $F_\lambda(z)$, i.e., (2.4), is also settled earlier. More details on this point will be given below. So we are left with the function $B_\lambda(z,\alpha)$, of which the asymptotic expansion formally follows from the second series in (2.6).

A somewhat different method used to obtain the expansion for $B_\lambda(z,\alpha)$ is based on a differential equation for this function. By differentiating (2.9) with respect to α, we easily obtain

$$\frac{\alpha}{z}B'_\lambda(z,\alpha)+(\mu-\alpha)B_\lambda(z,\alpha)=z^\lambda F_\lambda(z)-f(\alpha). \tag{2.10}$$

Substitution of (2.4) and of the formal series

$$B_\lambda(z,\alpha)\sim\sum_{s=0}^{\infty}\frac{B_s(\alpha)}{z^s} \tag{2.11}$$

into (2.10) shows that this equation is formally satisfied if

$$\begin{aligned}(\mu-\alpha)B_s(\alpha)&=f_s(\mu)-\alpha B'_{s-1}(\alpha), \qquad s=1,2,\cdots,\\ B_0(\alpha)&=[f(\alpha)-f(\mu)]/(\alpha-\mu).\end{aligned} \tag{2.12}$$

Here, and in (2.10), the prime denotes differentiation with respect to α. It easily follows that (2.12) generates the same coefficients $B_s(\alpha)$ as those defined in (2.7). Therefore, by using (2.9), we again arrive at (2.6).

The following integral

$$E_\lambda(z,\alpha)=\frac{1}{\Gamma(\lambda)}\int_0^\alpha t^{\lambda-1}e^{-zt}f(t)\,dt \tag{2.13}$$

is strongly related to (1.1). It has a similar representation as (2.9). When we use the following complementary relations

$$E_\lambda(z,\alpha)+F_\lambda(z,\alpha)=F_\lambda(z), \qquad Q(\lambda,\alpha z)+P(\lambda,\alpha z)=1, \tag{2.14}$$

we obtain

$$E_\lambda(z,\alpha)=P(\lambda,\alpha z)F_\lambda(z)-\frac{\alpha^\lambda e^{-\alpha z}}{z\Gamma(\lambda)}B_\lambda(z,\alpha). \tag{2.15}$$

Consequently, when we give expansions for $F_\lambda(a)$ and $B_\lambda(z,\alpha)$, the results can be used for both integrals (1.1) and (2.13). The function $P(a,x)$ again is an incomplete gamma function, with representation

$$P(a,x)=\frac{1}{\Gamma(a)}\int_0^x t^{a-1}e^{-t}\,dt. \tag{2.16}$$

3. Representations for the remainders. We introduce remainders for (2.4) and (2.11) by writing

$$z^\lambda F_\lambda(z)=\sum_{s=0}^{n-1} f_s(\mu)z^{-s}+z^{-n}\bar{f}_n, \tag{3.1}$$

$$B_\lambda(z,\alpha)=\sum_{s=0}^{n-1} B_s(\alpha)z^{-s}+z^{-n}\bar{B}_n, \tag{3.2}$$

where $n=0,1,2,\cdots$. When $n=0$ the sums are empty and they have to be replaced by 0.

The procedure leading to (2.4) yields for $\bar{f}_n$ the representation

$$\bar{f}_n=\frac{z^\lambda}{\Gamma(\lambda)}\int_0^\infty t^{\lambda-1}\,e^{-zt}f_n(t)\,dt. \tag{3.3}$$

To obtain a representation for $\bar{B}_n$, we write (2.9) in the form

$$B_\lambda(z,\alpha)=z\,e^{\alpha z}\alpha^{-\lambda}\int_\alpha^\infty t^{\lambda-1}\,e^{-zt}[f(t)-z^\lambda F_\lambda(z)]\,dt. \tag{3.4}$$

Writing

$$B_\lambda(z,\alpha)=B_0(\alpha)+z^{-1}\bar{B}_1,\qquad z^\lambda F_\lambda(z)=f(\mu)+z^{-1}\bar{f}_1,$$

and using integration by parts in the form

$$t^{\lambda-1}\,e^{-zt}\,dt=\frac{-1}{z(t-\mu)}\,d(t^\lambda\,e^{-zt}),$$

we obtain

$$\bar{B}_1=z\alpha^{-\lambda}\,e^{\alpha z}\int_\alpha^\infty t^{\lambda-1}\,e^{-zt}[f_1(t)-\bar{f}_1]\,dt.$$

Repeating this, and using the recursions

$$\bar{B}_n=B_n(\alpha)+z^{-1}\bar{B}_{n+1},\qquad \bar{f}_n=f_n(\mu)+z^{-1}\bar{f}_{n+1},$$

we finally have

$$\bar{B}_n=z\alpha^{-\lambda}\,e^{\alpha z}\int_\alpha^\infty t^{\lambda-1}\,e^{-zt}[f_n(t)-\bar{f}_n]\,dt, \tag{3.5}$$

where $n=0,1,2,\cdots$. For $n=0$ this equals the starting point (3.4). An equivalent representation is

$$\bar{B}_n=-z\alpha^{-\lambda}\,e^{\alpha z}\int_0^\alpha t^{\lambda-1}\,e^{-zt}[f_n(t)-\bar{f}_n]\,dt, \tag{3.6}$$

which easily follows by writing $\int_\alpha^\infty=\int_0^\infty-\int_0^\alpha$ and using (3.3).

The availability of both forms (3.5) and (3.6) is important in the analysis to be given below. Namely, for bounding $\bar{B}_n$ we always have an integral in which the saddle point μ is not an interior point of the interval of integration.

The above representations for $\bar{f}_n$ and $\bar{B}_n$ are formally obtained. In the next section we give the conditions on f to justify the above results, and to discuss the asymptotic nature of the expansions.

4. Assumptions on f. We consider real values of α, λ and z, with $\alpha, \lambda \geqq 0$, $z > 0$. We accept that f depends on the uniformity parameter μ defined in (2.2). The reason is that in applications usually a transformation to the standard form is needed, which yields a function f depending on μ. In [12] a detailed discussion of such a transformation is given. By means of several examples, it is shown that the assumption f depends on μ may be relevant and quite acceptable. The parameter α plays a completely different role, and we do not suppose that f depends on it. The example in § 9 on the incomplete beta function shows more details on the transformation to the standard form (1.1), and on the role of α and μ.

The analysis is based on the assumption that f is holomorphic in a domain of the complex plane. Again, for applications in the theory of special functions, this condition is quite natural. Another point is that part of the analysis runs rather elegantly when using complex function theory. However, the construction of the expansions, the representations of the remainders in (3.3), (3.5), and the construction of error bounds can also be given for functions f belonging to continuity classes $C^k([0, \infty))$. When $k < \infty$ we cannot, of course, define the complete expansions (2.4), (2.11).

We assume that f is holomorphic in a simply connected domain Ω of the complex plane; Ω may depend on μ and Ω should contain $\mathbb{R}^+$. We suppose that the distance $d(t)$ from $t \in \mathbb{R}^+$ to the boundary $\partial\Omega$ of Ω is increasing according to the following requirement:

$$d(t) \geqq d_0(\delta + t)^\kappa, \qquad t \geqq 0. \tag{4.1}$$

where δ, d_0 and κ are fixed, $\delta, d_0 > 0$, and $\frac{1}{2} \leqq \kappa \leqq 1$.

It follows that, for large μ, the singularities of f are rather far from the saddle point $t = \mu$, this distance being $\mathcal{O}(\mu^\kappa)$. This condition is important for investigating the asymptotic nature of the expansion (2.4). The requirement that (4.1) holds for any positive t, and not only for $t = \mu$, is important for expansion (2.11).

A geometrical interpretation of (4.1) is as follows. Let D_t be the disc around $t \in \mathbb{R}^+$ with radius $d_0(\delta + t)^\kappa$. Then the above condition implies that Ω contains the subset

$$\Omega_0 = \bigcup_{t \geqq 0} D_t. \tag{4.2}$$

When $\kappa = \frac{1}{2}$ the boundary $\partial\Omega_0$ of Ω_0 is a parabola; that is,

$$\partial\Omega_0 = \{t = u + iv \mid v^2 = d_0^2(u + \delta + \tfrac{1}{4}d_0^2)\}. \tag{4.3}$$

When $\kappa = 1$ we have two possibilities depending on d_0:

(i) $0 < d_0 \leqq 1$, Ω_0 is a sector with vertex at $t = -\delta$ such that $|\arg(t + \delta)| \leqq \arcsin(d_0)$; when $d_0 = 1$ this sector is the half-plane $\operatorname{Re} t \geqq -\delta$.

(ii) $d_0 > 1$, $\Omega_0 = \mathbb{C}$.

It is clear that for $\frac{1}{2} < \kappa < 1$ the set Ω_0 is something "between" a parabola-shaped domain and a sector. Geometrically, values of κ larger than unity make no sense, although the analysis will accept such values.

We also need a growth condition on f in Ω_0. We assume that, when μ is fixed, f is of algebraic growth at infinity. That is,

$$M(\mu) = \sup_{t \in \Omega} (1 + |t|^{-p})|f(t)| \tag{4.4}$$

should exist for all finite values of μ in $[0, \infty)$. Condition (4.4) will not exclude functions in (1.1) that can be written as

$$f(t) = e^{\sigma t}\tilde{f}(t), \qquad \sigma \text{ fixed in } \mathbb{C}.$$

When in such a decomposition $\tilde{f}$ meets the above conditions, we absorb the exponential part of this splitting into $\exp(-zt)$ of (1.1), just by a shift in the large parameter z. Afterwards, we proceed with $\tilde{f}$.

5. Estimates for $f_s(t)$, $f_s(\mu)$ and $B_s(\alpha)$. The conditions on f yield estimates for the functions $f_s(t)$ defined in (2.5) and for the coefficients $f_s(\mu)$. With the help of these estimates, the asymptotic scales for the expansions (3.1), (3.2) are chosen.

Let Ω_r be the subset of Ω_0 defined by

$$\Omega_r = \bigcup_{t \geqq 0} \tilde{D}_t, \tag{5.1}$$

where $\tilde{D}_t$ is a disc around t with radius $r(\tilde{\delta}+t)^\kappa$, with $0<\tilde{\delta}<\delta, 0<r<d_0$, $\tilde{\delta}$ and r fixed. Then the derivatives of f at t can be written as

$$f^{(s)}(t) = \frac{s!}{2\pi i}\int_{C_r} \frac{f(\tau)}{(\tau-t)^{s+1}}\,d\tau, \tag{5.2}$$

where C_r is the boundary of $\tilde{D}_t$.

It follows that we can assign numbers K_s, not depending on t and μ, such that

$$|f^{(s)}(t)| \leqq K_s M(\mu)(1+|t|)^{p-s\kappa}, \qquad s=0,1,2,\cdots,$$

for all $t \in \Omega_r$, and all $\mu \in [0,\infty)$. That is,

$$f^{(s)}(t) = M(\mu)(1+|t|)^{p-s\kappa}\mathcal{O}(1), \qquad s=0,1,2,\cdots, \tag{5.3}$$

with $t \in \Omega_r$, uniformly with respect to μ in $[0,\infty)$.

The functions $f_s(t)$ defined in (2.5) are analytic in Ω. They can be expressed in terms of the derivatives of f, as follows from their definition. For t-values near μ, the functions cannot be estimated by repeated application of (2.5), owing to the factors $1/(t-\mu)$ and powers of it. Another approach is using the mean value theorem on

$$\begin{aligned} f_s(t) &= t\frac{d}{dt}\int_0^1 f'_{s-1}[\mu+\tau(t-\mu)]\,d\tau \\ &= t\int_0^1 \tau f''_{s-1}[\mu+\tau(t-\mu)]\,d\tau, \end{aligned}$$

which gives $f_s(t) = \frac{1}{2}tf''_{s-1}(\tau_s)$, where τ_s is a value between t and μ. By repeating this, we obtain

$$f_s(t) = t\sum_{j=0}^{s-1} p_j f^{(s+j+1)}(\tau_j), \qquad s \geqq 1, \tag{5.4}$$

where τ_j are between t and μ, and p_j is a homogeneous polynomial of degree j of j variables, all between t and μ. The coefficients of p_j do not depend on μ and t. Therefore, we have

$$\begin{aligned} p_j &= (1+\mu+t)^j\mathcal{O}(1), \\ f^{(s+j+1)}(\tau_j) &= M(\mu)(1+\mu+t)^{p-(s+j+1)\kappa}\mathcal{O}(1), \end{aligned}$$

with $\mu \geqq 0$, $t \geqq 0$. It follows that (5.4) can be written as

$$f_s(t) = tM(\mu)(1+\mu+t)^{p-1-s\bar{\kappa}}\mathcal{O}(1), \qquad \bar{\kappa} = 2\kappa-1, \quad s=1,2,\cdots, \tag{5.5}$$

for all $t \in \Omega_r$, uniformly with respect to $\mu \in [0,\infty)$.

The values $f_s(\mu)$, which are the coefficients of the expansion (2.4), can be written as

$$f_s(\mu)=\mu\sum_{j=0}^{s-1} q_j\mu^j f^{(s+j+1)}(\mu), \qquad s=1,2,\cdots,$$

where q_j are fixed numbers. An estimate as in (5.5) reads

$$(5.6)\quad f_s(\mu)=\mu M(\mu)(1+\mu)^{p-1-s\bar{\kappa}}\mathcal{O}(1), \qquad \bar{\kappa}=2\kappa-1, \quad s=1,2,\cdots, \quad \mu\geqq 0.$$

The coefficients $B_s(\alpha)$ defined in (2.7) can be estimated by means of

$$B_s(\alpha)=\int_0^1 f_s'[\mu+\tau(\alpha-\mu)]\,d\tau=f_s'(\tau_s),$$

where τ_s is between μ and α. Therefore,

$$B_s(\alpha)=\frac{1}{2\pi_i}\int_{C_r}\frac{f_s'(\tau)}{(\tau-\tau_s)^2}\,d\tau,$$

where C_r is a circle in Ω_r around τ_s with radius $\mathcal{O}(1+\tau_s)^\kappa=\mathcal{O}(1+\mu+\alpha)^\kappa$. By using (5.5), it follows that

$$(5.7)\qquad B_s(\alpha)=M(\mu)(1+\mu+\alpha)^{p-s\bar{\kappa}-\kappa}\mathcal{O}(1), \qquad s=0,1,\cdots,$$

with α, $\mu\geqq 0$.

Example 5.1. When $f(t)=1/(1+t)$, we have $p=\kappa=1$, and M slightly larger than 1. The first coefficients B_0, B_1 are

$$B_0(\alpha)=-1/[(\alpha+1)(\mu+1)], \qquad B_1(\alpha)=(1-\alpha\mu)/[(\alpha+1)^2(\mu+1)^3],$$

which confirms (5.7).

To conclude this section we consider limiting values of $\bar{B}_n$ at $\alpha=0$ and $\alpha=\infty$. For $\alpha\to 0$ we write $t=\alpha\tau$ in (3.6). We obtain

$$(5.8)\qquad \bar{B}_n=\frac{\bar{f}_n-f_n(0)}{\mu} \quad \text{at } \alpha=0.$$

This expression is regular at $\mu=0$. To see this, replace (5.8) by

$$\bar{B}_n=\frac{f_n(\mu)-f_n(0)}{\mu}+\frac{1}{\lambda}\bar{f}_{n+1}.$$

From (2.5) we see that $f_n(t)/t$ is regular at $t=0$, when $n\geqq 1$. Hence, using (3.3), we obtain

$$(5.9)\qquad \bar{B}_n=f_n'(0)+\int_0^\infty e^{-zt}f_{n+1}(t)t^{-1}\,dt \quad \text{at } \alpha=0, \mu=0, \text{and } n=0,1,\cdots.$$

For the limiting value of $\bar{B}_n$ at $\alpha=\infty$, consider (3.5) in the following form:

$$(5.10)\qquad \bar{B}_n=z\int_0^\infty (1+t)^{\lambda-1}\,e^{-\alpha zt}[f_n(\alpha(1+t))-\bar{f}_n]\,dt.$$

Using (5.5), and considering $\alpha\gg\mu$, we can easily estimate $\bar{B}_n$ as $\alpha\to\infty$. For instance, when $p-n\bar{\kappa}=1$ and $\lim_{t\to\infty}f_n(t)/t$ exists (and is L), we have

$$(5.11)\qquad \bar{B}_n=L \quad \text{at } \alpha=\infty, \quad \mu \text{ finite}.$$

6. The asymptotic nature of the expansions.

6. The asymptotic nature of the expansions. First we discuss the expansions (2.4), (3.1), although the complete integral (2.1) is considered in the previous paper [12]. However, there we mainly investigated an expansion somewhat different from (2.4) and, therefore, it is appropriate to consider (2.4), (3.1) in the present set-up once again.

6.1. The asymptotic nature of (3.1). We introduce the asymptotic scale $\{\psi_s z^{-s}\}$ by writing

$$\begin{aligned}\psi_0 &= M(\mu)(1+\mu)^p,\\ \psi_s &= \mu M(\mu)(1+\mu)^{p-1-s\bar{\kappa}}, \qquad s=1,2,\cdots,\end{aligned} \tag{6.1}$$

which is suggested by (5.6). Since we allow f to depend on μ, we have to use a scale that reflects the possible growth of f when μ ranges in the domain $[0,\infty)$. With the above scale we are able to control the behaviour of the remainder $\bar{f}_n$ defined in (3.3).

It is easily verified that $\{\psi_s z^{-s}\}$ is a uniform asymptotic scale with z as large parameter and μ as uniformity parameter in $[0,\infty)$. Moreover, when $\kappa>\frac{1}{2}$ (i.e., $\bar{\kappa}>0$) it also is an asymptotic scale for $\mu\to\infty$, uniformity with respect to $z\in[z_0,\infty)$, z_0 being a fixed positive number. Observe that for $\kappa<\frac{1}{2}$ the scale fails to be uniform with respect to μ on $[0,\infty)$, but it still is on compact subsets of $[0,\infty)$.

THEOREM 6.1. *For the expansions* (2.4), (3.1) *we can write*

$$z^\lambda F_\lambda(z) \sim \sum_{s=0}^{\infty} f_s(\mu) z^{-s}, \qquad \{\psi_s z^{-s}\} \quad \textit{as } z\to\infty, \tag{6.2}$$

uniformly with respect to $\mu=\lambda/z$ *in* $[0,\infty)$.

Proof. It is sufficient to show that $\bar{f}_n=\mathcal{O}(\psi_n)$, where $\bar{f}_n$ is defined in (3.3). The interval of integration in (3.3) is split up as follows:

$$[0,\infty)=\Delta_-\cup[t_-,t_+]\cup\Delta_+, \tag{6.3}$$

where

$$\Delta_-=[0,t_-],\quad \Delta_+=[t_+,\infty),\quad t_\pm=\mu\pm\varepsilon(\mu+1)^\kappa,$$

with ε fixed, and small enough such that $[t_-,t_+]$ lies inside Ω_r of (5.1). When t_- happens to be negative, we replace it by 0. For $t\in[t_-,t_+]$ we have $t=\mathcal{O}(\mu)$. Therefore, (5.5) yields

$$f_s(t)=\mu M(\mu)(1+\mu)^{p-1-s\bar{\kappa}}\mathcal{O}(1), \qquad s=1,2,\cdots.$$

Hence, (3.3) can be written as

$$\bar{f}_n=I_-+I_++\mathcal{O}(\psi_n) \quad \text{as } z\to\infty, \tag{6.4}$$

where $I_\pm$ are the contributions to (3.3) from $\Delta_\pm$. They are of order $\mathcal{O}(\psi_n)$, also. It is possible to show more: they are asymptotically equal to 0 with respect to the scale $\{\psi_s\}$. That is, $I_\pm=\mathcal{O}(\psi_m)$ for any m as $z\to\infty$, uniformly with respect to $\mu\in[0,\infty)$.

Again, the proof can be based on the estimates given in (5.5). In [12, § 3.4] a detailed analysis is given for proving that contributions from $\Delta_\pm$ for similar integrals are asymptotically negligible. This analysis will not be repeated here. □

6.2. Two lemmas for (3.2). The next step is to consider (3.2), and to estimate the remainder defined in (3.5), (3.6). The analysis boils down to the following two lemmas, the results of which are formulated in terms of strict inequalities. So we are able to use them once again in § 7 for deriving strict error bounds.

LEMMA 6.1. *Consider the function*

$$g(\alpha, \lambda, z) = \alpha^{-\lambda} e^{\alpha z} \int_0^\alpha t^\lambda e^{-zt}\, dt, \tag{6.5}$$

where $0 \leqq \alpha \leqq \mu$, $\mu = \lambda/z$. *Let* ζ *be defined by* $\frac{1}{2}\zeta^2 = \alpha - \mu + \mu \log(\mu/\alpha)$, $\zeta \geqq 0$. *Then for* $z > 0$

$$g(\alpha, \lambda, z) \leqq \min\left\{\frac{\alpha}{(\mu-\alpha)z}, \frac{\alpha\zeta}{\mu-\alpha}\sqrt{\frac{\pi}{2\zeta}}\right\}. \tag{6.6}$$

Proof. Write g in the form

$$g(\alpha, \lambda, z) = \int_0^\alpha e^{-z\phi(t)}\, dt, \qquad \phi(t) = t - \mu \log t - \alpha + \mu \log \alpha.$$

Integrating with respect to ϕ, we have for $0 \leqq \alpha < \mu$

$$g(\alpha, \lambda, z) = \int_0^\infty e^{-z\phi} \frac{t}{\mu - t}\, d\phi \leqq \frac{\alpha}{(\mu-\alpha)z},$$

which gives the first possibility in (6.6). To obtain the second one we write

$$\phi(t) = \tfrac{1}{2}w^2 + \zeta w, \qquad w \geqq -\zeta,$$

with the corresponding relations

$$t = 0 \leftrightarrow w = +\infty, \qquad t = \alpha \leftrightarrow w = 0, \qquad t = \mu \leftrightarrow w = -\zeta,$$

where ζ is defined above. Now we obtain

$$g(\alpha, \lambda, z) = \int_0^\infty e^{-z[w^2/2+\zeta w]} f(w)\, dw, \qquad f(w) = \frac{t(w+\zeta)}{\mu - t}.$$

We have $0 \leqq f(w) \leqq f(0)$, $w \geqq 0$. To verify the upper bound, we write

$$f^2(w) = 2t \frac{1 - x + x \log x}{(x-1)^2}, \qquad x = \frac{\mu}{t}.$$

The x-part of this is monotonically decreasing on the x-interval $[1, \infty)$; $x = \mu/\alpha$ corresponds to $w = 0$. Hence we obtain $f(w) \leqq \alpha\zeta/(\mu - \alpha)$. It follows that

$$g(\alpha, \lambda, z) \leqq \frac{\alpha\zeta}{\mu - \alpha} \int_0^\infty e^{-zw^2/2}\, dw,$$

which gives the second possibility in (6.6). This proves the lemma. □

LEMMA 6.2. *Consider the function*

$$G_q(\alpha, \lambda, z) = \alpha^{-\lambda} e^{\alpha z}(1+\alpha)^{-q} \int_\alpha^\infty t^{\lambda-1} e^{-zt}(1+t)^q\, dt, \tag{6.7}$$

where $\alpha \geqq 0$, $\mu \leqq \alpha$, $\mu = \lambda/z$, q *fixed*, $q \in \mathbb{R}$. *Let* ζ *be defined by*

$$\zeta = \begin{cases} +\infty, & \mu < 0, \\ +\left[2\left(\alpha - \mu + \mu \log \dfrac{\mu}{\alpha}\right)\right]^{1/2}, & 0 \leqq \mu \leqq \alpha. \end{cases}$$

Then for $z > 0$

$$G_0(\alpha, \lambda, z) \leqq \min\left\{\frac{1}{(\alpha-\mu)z}, \frac{\zeta}{\alpha-\mu}\sqrt{\frac{\pi}{2z}}\right\}. \tag{6.8}$$

Furthermore, when $0 \leqq \mu \leqq \alpha$,

$$G_q(\alpha, \lambda, z) = \mathcal{O}[G_0(\alpha, \lambda, z)] \quad \text{as } z \to \infty, \tag{6.9}$$

uniformly with respect to α, μ.

Proof. We first consider G_0, for which we obtain

$$G_0(\alpha, \lambda, z) = \int_\alpha^\infty e^{-z\phi(t)} \frac{dt}{t} = \int_0^\infty e^{-z\phi} \frac{d\phi}{t-\mu} \leqq \frac{1}{(\alpha-\mu)z},$$

where $\phi(t)$ is the same as in Lemma 6.1. Observe that this result also holds for negative values of μ. For the second possibility in (6.8), we proceed with $\mu \geqq 0$. We again write $\frac{1}{2}w^2 + \zeta w = \phi(t)$, $w \geqq -\zeta$, now with the correspondences

$$t = \infty \leftrightarrow w = \infty, \qquad t = \alpha \leftrightarrow w = 0, \qquad t = \mu \leftrightarrow w = -\zeta.$$

It follows that

$$G_0(\alpha, \lambda, z) = \int_0^\infty e^{-z[w^2/2+\zeta w]} f(w)\, dw,$$

with $f(w) = (w+\zeta)/(t-\mu)$. Using

$$f^2(w) = \frac{2}{\mu} \frac{x - \log x - 1}{(x-1)^2} \leqq f^2(0), \qquad x = \frac{t}{\mu} \geqq 1,$$

we obtain the second choice in (6.8).

When $q \leqq 0$ the proposition (6.9) is trivial. Writing

$$G_{q+1} = \frac{1+\mu}{1+\alpha} G_q + \frac{\alpha^{-\lambda}}{} \frac{e^{\alpha z}(1+\alpha)^{-q-1}}{-z} \int_\alpha^\infty (1+t)^q d(e^{-zt}t^\lambda),$$

we obtain by performing integration by parts

$$G_{q+1} = \frac{1+\mu}{1+\alpha} G_q + \frac{1}{z(1+\alpha)} - \frac{q}{z(1+\alpha)^2} G_{q-1} + \frac{q}{z(1+\alpha)} G_q.$$

Since q is fixed and $0 \leqq \mu \leqq \alpha$, the result (6.9) follows by recursion, say from negative q-values. □

Remark 6.1. The first alternatives in both (6.6) and (6.8) grow indefinitely when $\alpha \to \mu$, whereas the other ones remain finite. We have

$$\zeta/(\mu - \alpha) \to 1, \qquad \zeta/(\alpha - \mu) \to 1,$$

for (6.6), (6.8), respectively. Therefore, the second alternatives give a bound for g and G_0 valid for the whole range of parameters given in the lemmas. The first bound is given since it is sharp when z is large and α and μ are bounded away from each other. A more uniform description, which includes both alternatives in (6.6), (6.8), is possible, by using a bound in terms of an error function. That is, in fact, g and G_0 can be estimated by

$$f(0) \int_0^\infty e^{-z[w^2/2+\zeta w]}\, dw = f(0) \sqrt{\frac{\pi}{2z}}\, e^{z\zeta^2/2} \operatorname{erf} c(\zeta\sqrt{z/2}).$$

We take $\zeta = 0$ because it gives a very simple and manageable result.

6.3. The asymptotic nature of (3.2). We proceed with (3.2), and we estimate the remainder $\bar{B}_n$ defined in (3.5), (3.6). We use the asymptotic scale $\{\chi_s z^{-s}\}$ defined by

$$\chi_s = M(\mu)(1+\mu+\alpha)^{p-s\bar{\kappa}-\kappa}, \qquad s = 0, 1, 2, \cdots, \tag{6.10}$$

z is the large parameter, α and μ are uniformity parameters. The choice of scale is suggested by (5.7).

THEOREM 6.2. *For the expansions* (2.11) *and* (3.2) *we can write*

$$B_\lambda(z,\alpha)\sim\sum_{s=0}^{\infty}B_s(\alpha)z^{-s},\qquad \{\chi_s z^{-s}\}\quad \textit{as } z\to\infty, \tag{6.11}$$

uniformly with respect to μ, α *in* $[0,\infty)$.

Proof. All $\mathcal{O}$-symbols in the proof hold uniformly with respect to μ and α in $[0,\infty)$; the large parameter is not needed in some results.

It is sufficient to show that $\bar{B}_n$ of (3.5) or (3.6) is $\mathcal{O}(\chi_n)$. Write

$$\bar{B}_n=B_n(\alpha)+z^{-1}\bar{B}_{n+1},\qquad n=0,1,2,\cdots. \tag{6.12}$$

Since $B_n(\alpha)=\mathcal{O}(\chi_n)$, we proceed with $\bar{B}_{n+1}$. That is, we consider (3.5), (3.6) for $n\geqq 1$. We have two cases.

(i) $0\leqq\alpha\leqq\mu$. In (3.6) we use

$$\bar{f}_n=\mathcal{O}(\psi_n)=\mu M(\mu)(1+\mu+\alpha)^{p-1-n\bar{\kappa}}\mathcal{O}(1),$$
$$f_n(t)=tM(\mu)(1+\mu+\alpha)^{p-1-n\bar{\kappa}}\mathcal{O}(1),$$

where the first line follows from Theorem 6.1 and the second one from (5.5). The estimate for $f_n(t)$ gives in (3.6) a contribution

$$zM(\mu)(1+\mu+\alpha)^{p-1-n\bar{\kappa}}g(\alpha,\lambda,z)\mathcal{O}(1), \tag{6.13}$$

where g is defined in (6.5). The above estimate for $\bar{f}_n$ gives in (3.6) a contribution

$$\begin{aligned}
&z\mu M(\mu)(1+\mu+\alpha)^{p-1-n\bar{\kappa}}\alpha^{-\lambda}\,e^{\alpha z}\mathcal{O}(1)\int_0^\alpha t^{\lambda-1}\,e^{-zt}\,dt\\
&\quad=M(\mu)(1+\mu+\alpha)^{p-1-n\bar{\kappa}}\alpha^{-\lambda}\,e^{\alpha z}\mathcal{O}(1)\int_0^\alpha e^{-zt}\,dt^\lambda\\
&\quad=zM(\mu)(1+\mu+\alpha)^{p-1-n\bar{\kappa}}[g(\alpha,\lambda,z)\mathcal{O}(1)+\mathcal{O}(z^{-1})].
\end{aligned}\tag{6.14}$$

From Lemma 6.1 it follows that

$$g(\alpha,\lambda,z)=\mathcal{O}(\sqrt{\alpha/z})=\mathcal{O}[(1+\mu+\alpha)^\kappa/\sqrt{z}].$$

Neglecting the term $\mathcal{O}(z^{-1})$ in the last line of (6.14), we conclude that both (6.13) and (6.14) are estimated by

$$\sqrt{z}M(\mu)(1+\mu+\alpha)^{p-1-n\bar{\kappa}+\kappa}\mathcal{O}(1).$$

Taking into account that in (6.12) $z^{-1}\bar{B}_{n+1}$ has to be considered, we obtain

$$\bar{B}_n=\mathcal{O}(\chi_n)+M(\mu)(1+\mu+\alpha)^{p-1-(n+1)\bar{\kappa}+\kappa}\mathcal{O}(z^{-1/2})=\mathcal{O}(\chi_n).$$

This finishes the first part of the proof.

(ii) $0\leqq\mu\leqq\alpha$. In this case the starting point for $\bar{B}_n$ is (3.5). For $\bar{f}_n$ we take the representation as in the previous case, for $f_n(t)$ we consider (5.5). We integrate by parts in the contribution from $\bar{f}_n$. Starting with (6.12) and using Lemma 6.2 twice, with $q=0$ and with $q=p-1-(n+1)\bar{\kappa}$, we obtain the required estimate $\bar{B}_n=\mathcal{O}(\chi_n)$. □

As remarked after the introduction of the scale functions ψ_s in (6.1), the large parameter z and the uniformity parameter μ are interchangeable, only if $\kappa>\frac{1}{2}$. It is important enough to formulate this property as a theorem.

THEOREM 6.3. *Let $\frac{1}{2}<\kappa\leqq 1$. Then in* (6.2) *$\mu$ may act as the large parameter and z as the uniformity parameter. In* (6.9), *α (or μ) may act as large parameter, μ (or α) and z as uniformity parameters. The uniformity domain for μ and α is $[0,\infty)$, for z it is $[z_0,\infty)$, z_0 being a fixed positive number.*

Proof. The proof follows easily from the properties of the asymptotic scales used in (6.2) and (6.11), and from the proofs of the earlier theorems. □

Remark 6.2. The above theorems are formulated and proved for real values of the parameters. By slight adaptation of the scales they hold for complex values of α and μ, as long as these values are restricted to Ω_r introduced in (5.1). Some care in the interpretation of (1.1) is needed when α assumes complex values around the origin, since t^λ is not single valued. However, the many-valuedness of $F_\lambda(z,\alpha)$ is completely described in (2.9) by the known functions $Q(\lambda, \alpha z)$ and α^λ. From (3.6) it easily follows that $B_\lambda(z,\alpha)=\bar{B}_0$ is regular at $\alpha=0$, and in fact in Ω_r. See also (5.8). Another problem is: How do we handle complex values of z? The holomorphic function f in (1.1) allows the contour of integration to be deformed. When doing so, we can extend the domains for the parameters z, α and μ considerably. We will not go into further details here for this complicated technical problem.

Remark 6.3. It is tempting to take $\{f_s(\mu)z^{-s}\}$ and $\{B_s(\alpha)z^{-s}\}$ as asymptotic scales in (6.2) and (6.1.1). However, the conditions on f do not imply that they have this property. When they do not the theorems may still be applicable; however, rather useless expansions may arise. It is instructive to consider what is happening in the case $f(t)=1+\exp(-t)$.

7. Error bounds for the remainders. The theorems of the previous section are based on the concept of generalized asymptotic expansions. The estimates for proving the asymptotic properties are given in terms of $\mathcal{O}$-symbols. So far, no information is available on the sharpness of these estimates, say in terms of exact error bounds. That is, it would be interesting to have available an estimate in the form

$$(7.1)\qquad |\bar{f}_n|\leqq K_n|f_n(\mu)|,\qquad \mu\geqq 0,\quad z\geqq z_0>0,$$

instead of $\bar{f}_n=\mathcal{O}(\psi_n)$, used in Theorem 6.1. When $f_n(\mu)$ happens to vanish, (7.1) can be modified. K_n in (7.1) may depend on z and μ.

The required form of the bound (7.1) reflects the expectation that $\bar{f}_n$ will not deviate too much from $f_n(\mu)$. For slowly varying functions f, say for $f(t)=1/(1+t)$, this surely will be true, especially when z is large. However, the scale functions ψ_n, χ_n are constructed in terms of the global estimate $M(\mu)$, introduced in (4.4). Consequently, the asymptotic scales used in the theorems may be too rough to describe what is really happening in the asymptotic expansions.

To show this by way of a simple example, we consider $f(t)=\exp[\mu/(1+t)]$. It is easily verified that is satisfies the conditions of § 4; $\Omega=\mathbb{C}\backslash\{-1\}$, Ω_0 is the half-plane $\operatorname{Re} t\geqq-\delta$, where $0<\delta<1$. In (4.4), $p=0$ and $M(\mu)=\exp[\mu/(1-\delta)]$, which is exponentially large, when μ is large. However, we expect that the remainder $\bar{f}_n$ in the expansion (3.1) is comparable with $f_n(\mu)$, which is only algebraic in μ. Therefore, the theorems of the previous section are applicable, but the chosen asymptotic scales are not able to control the remainders of the expansion in a realistic way. This is especially true for expansion (6.2); for (6.9), which is more global in character due to the second uniformity parameter, the chosen scale may be more suitable. We want to emphasize that in this example only the scales default, whereas the expansions themselves are appropriate and may be of interest. The above noticed imperfections (see also Remark 6.3) are inherent in the definition of generalized asymptotic expansions. We have chosen this framework in order to be able to describe precisely the propositions and what we want to prove. We consider this important in asymptotics, especially when one or more uniformity parameters are involved. On the other hand, we have the need of constructing sharp error bounds for the remainders in the expansions, so that we can interpret the expansions in a realistic way. An ideal procedure would be a combination of both approaches, but in this stage, for lack of a unified approach, we prefer to discuss them separately.

7.1. Error bounds for (3.1). As remarked earlier, the quantities $f_s(\mu)$ and $B_s(\alpha)$ may be grossly overestimated by the global upper bound $M(\mu)$ introduced in (4.4). A better approach, say for arriving at (7.1), seems to be to give a sharp estimate for $f_n(t)$ near $t=\mu$, whereas the estimate "far away" of this saddle point may be rather crude. To be more explicit, we need a *comparison function* $w(t,\mu)$, $w:\mathbb{R}^+\times\mathbb{R}^+\to[1,\infty)$, that satisfies the condition $w(\mu,\mu)=1$, and that may be large outside an interval around $t=\mu$. We suppose that we can assign quantities M_n, which may depend on μ and which are strictly larger than unity:

$$M_n \geqq 1+\varepsilon_n, \quad \varepsilon_n \text{ fixed and positive,} \tag{7.2}$$

such that for all $t\geqq 0$ we have

$$|f_n(t)|\leqq M_n|f_n(\mu)|w(t,\mu). \tag{7.3}$$

Furthermore, we suppose that it is easy to calculate or estimate the integral

$$|\bar{f}_n|\leqq\frac{M_n|f_n(\mu)|z^\lambda}{\Gamma(\lambda)}\int_0^\infty t^{\lambda-1}\,e^{-zt}w(t,\mu)\,dt, \tag{7.4}$$

obtained from (3.3) by bounding $f_n(t)$ in this way. When $f_n(\mu)$ happens to have zeros on $(0,\infty)$, (7.3) and (7.4) have to be modified, say by replacing $|f_n(\mu)|$ by $\delta_n+|f_n(\mu)|$, $\delta_n>0$.

Since f, and hence all f_n, have algebraic growth on $[0,\infty)$ (see (4.4)), it will be sufficient that $w(t,\mu)=\mathcal{O}[\exp(\sigma t)]$ for some positive σ. This suggests as a possible choice $w(t,\mu)=\cosh[\sigma(t-\mu)]$, which meets all requirements formulated thus far. Substituting this into (7.4), we obtain

$$\begin{aligned}\frac{z^\lambda}{\Gamma(\lambda)}\int_0^\infty t^{\lambda-1}\,e^{-zt}\cosh[\sigma(t-\mu)]\,dt&=\tfrac{1}{2}[(1-\sigma/z)^\lambda\,e^{-\sigma\mu}+(1+\sigma/z)^\lambda\,e^{\sigma\mu}]\\ &=\mathcal{O}[\cosh(\tfrac{1}{2}\lambda\sigma^2/z^2)],\end{aligned} \tag{7.5}$$

as $z\to\infty$. When $\sigma=\mathcal{O}(1)$ $(\mu\geqq 0)$, this contribution to the right-hand side of (7.4) is quite acceptable, so long as $\lambda=o(z^2)$. But for a uniformity domain $[0,\infty)$ it is unacceptable.

This brings us to a further requirement that

$$\frac{z^\lambda}{\Gamma(\lambda)}\int_0^\infty t^{\lambda-1}\,e^{-zt}w(t,\mu)\,dt=\mathcal{O}(1), \tag{7.6}$$

as $z\to\infty$, uniformly with respect to $\mu\in[0,\infty)$.

For several reasons the following comparison function is very convenient:

$$w_\sigma(t,\mu)=[(t/\mu)^{-\mu}\,e^{t-\mu}]^\sigma, \qquad \sigma\geqq 0, \tag{7.7}$$

where σ may depend on μ, but not on t. For $\mu=0$ we define $w_\sigma(t,0)=\exp(\sigma t)$. This choice fits better in the dominant part $t^\lambda\,e^{-zt}$ of (7.4) than the cosh-function tried before.

For (7.3) we write

$$|f_n(t)|\leqq M_n|f_n(\mu)|w_{\sigma_n}(t,\mu), \tag{7.8}$$

and (7.4) becomes

$$(7.9)\qquad |\bar{f}_n| \leqq M_n Q_n |f_n(\mu)|, \qquad Q_n = (1-\sigma_n/z)^{-1/2}\Gamma^*(\lambda - \mu\sigma_n)/\Gamma^*(\lambda),$$

where

$$(7.10)\qquad \Gamma^*(z) = [z/(2\pi)]^{1/2}\, e^z z^{-z}\Gamma(z) = 1 + \mathcal{O}(z^{-1}),$$

as $z \to \infty$. Compared with (7.5), this result is much more acceptable, since now we have

$$(7.11)\qquad Q_n = 1 + \mathcal{O}(z^{-1}) \quad \text{as } z \to \infty,$$

uniformly with respect to λ or μ in $[0, \infty)$. Especially, large values of λ are in favor in (7.11). The only condition is that σ_n in (7.8) is fixed or a bounded function of μ on $[0, \infty)$. In this event $z - \sigma_n$ can be viewed as large parameter in Q_n, although $z > \sigma_n$ is enough.

For the construction of error bounds it is sufficient that $f_n(t)$ is continuous on $[0, \infty)$, i.e., that f belongs to the continuity class $C^{2n}([0, \infty))$ (see (5.4)). A different point is that, as remarked earlier, a slight modification is needed when $f_n(\mu) = 0$. A special case is $\mu = 0$, where $f_n, \bar{f}_n$ vanish for $n \geqq 1$. In that case we can define $\sigma_n = 0$. When we construct error bounds, the assumption (4.4) on the algebraic growth is only needed for $t \geqq 0$. Another assumption on f may be that σ_n of (7.8) is a bounded function of μ. A proper choice of M_n, for instance by making M_n a function of μ, will yield a wide class of admissible functions f. The construction of error bounds is not enough to investigate the nature of the asymptotic expansion. However, when $\sigma_n, M_n, f_n(\mu)/f(\mu)$ $(f(\mu) \neq 0)$ are bounded functions of μ on $[0, \infty)$ for each $n \geqq 0$, then we can use the Poincaré-type scale $\{z^{-s}\}$, and the uniformity with respect to μ in $[0, \infty)$ easily follows.

A possible approach to compute M_n and σ_n of (7.8) is to start with trial values of M_n satisfying (7.2). Then we compute

$$(7.12)\qquad \sigma_n = \sup_{t \geqq 0} \tilde{f}_n(t), \quad \mu \text{ fixed in } [0, \infty),$$

where

$$(7.13)\qquad \tilde{f}_n(t) = \frac{\log |f_n(t)/[M_n f_n(\mu)]|}{t - \mu - \mu \log(t/\mu)}, \qquad t \neq \mu, \quad f_n(\mu) \neq 0.$$

For two examples we have computed σ-values. A third example is considered in § 9 for the incomplete beta function.

Example 7.1. $f(t) = 1/(1+t)$. We have

$$f_2(\mu) = \frac{\mu(\mu-2)}{(1+\mu)^5}, \qquad f_2(t) = \frac{t(\mu t - \mu - 2)}{(1+\mu)^3(1+t)^3}.$$

Since $f_2(\mu)$ vanishes at $\mu = 2$, we replace it by

$$f_2^*(\mu) = \frac{\mu(1 + |\mu - 2|)}{(1+\mu)^5}.$$

We consider three choices of M_2 and we obtain σ_2 via (7.12) for several values of μ. We also show corresponding values of Q_2 of (7.9) for $z = 5$. For larger values of z, Q_2 is closer to unity. The results are shown in Table 7.1. It follows that the remainder $z^{-2}\bar{f}_2$ of (3.3) is rather close to the first neglected term $z^{-2}f_2(\mu)$ for the values of μ and z used in the table. Larger values of μ and z confirm this tendency even better.

TABLE 7.1

μ	$M_2=1.1$		$M_2=1.5$		$M_2=2.0$	
	σ_2	Q_2	σ_2	Q_2	σ_2	Q_2

100	0.05	1.0047	0.01	1.0014	0.00	1.0001

Example 7.2. $f(t)=\exp[\mu/(1+t)]$. We use (7.3), (7.7) with $n=0$, which gives a bound (7.8) for $\bar{f}_0$ of (3.3), i.e., for $z^\lambda F_\lambda(z)$ of (2.1). The results are shown in Table 7.2, again with $z=5$.

TABLE 7.2

μ	$M_0=1.1$		$M_0=1.5$		$M_0=2.0$	
	σ_0	Q_0	σ_0	Q_0	σ_0	Q_0

7.2. Error bounds for (3.2). For the construction of error bounds for the remainder of expansion (3.2), we use as comparison function $w_\sigma(t,\alpha)$, with w_σ defined in (7.7). The comparison function $w_\sigma(t,\mu)$ may yield unrealistic bounds, when α and μ are not of the same size. In Theorem 6.2 we used (6.10) in order to get rid of the factor z in (3.5), (3.6). However, this factor is neutralized by the expression $f_n(t)-\bar{f}_n$ in the integral (the minus-sign is important here). In the following error analysis this expression will not be replaced by $|f_n(t)|+|\bar{f}_n|$.

We write

$$g_n(t)=f_n(t)-\bar{f}_n,\qquad n=0,1,\cdots. \tag{7.14}$$

When $g_n(\alpha)\neq 0$, we estimate g_n as follows:

$$|g_n(t)|\leqq M_n|g_n(\alpha)|w_{\tau_n}(t,\alpha), \tag{7.15}$$

where M_n satisfies (7.2) and w is defined in (7.7). We consider two cases.

(i) $0\leqq\alpha\leqq\mu$. Starting point is (3.6); (7.15) has to be considered for $t\in[0,\alpha]$. We obtain

$$|\bar{B}_n|\leqq zM_n\alpha^{\alpha\tau_n-\lambda}\,e^{\alpha(z-\tau_n)}|g_n(\alpha)|\int_0^\alpha t^{\lambda-\alpha\tau_n-1}\,e^{-(z-\tau_n)t}\,dt.$$

Integration by parts gives

$$|\bar{B}_n|\leqq\frac{zM_n}{\lambda-\alpha\tau_n}|g_n(\alpha)|[1+(z-\tau_n)g(\alpha,\lambda-\alpha\tau_n,z-\tau_n)],$$

where g is defined in (6.5). In Lemma 6.1 it is supposed that in $g(\alpha, \lambda, z)$ the parameters satisfy $0 \leqq \alpha \leqq \lambda/z$. In the present g-function this relation holds as well. The only condition is $z > \tau_n$. For a better representation of the above bound for $\bar{B}_n$ we write

$$\frac{z}{\lambda - \alpha\tau_n}|g_n(\alpha)| = \frac{\lambda}{\lambda - \alpha\tau_n}\frac{|g_n(\alpha)|}{\mu}.$$

The first factor at the right equals $1/(1-\alpha\tau_n/\mu z)$ which is $1+\mathcal{O}(z^{-1})$ as $z \to \infty$, uniformly with respect to α and μ, $0 \leqq \alpha \leqq \mu$. The second factor $|g_n(\alpha)|/\mu$ is properly defined in the limit $\mu \to 0$, as follows from a similar argument as used for (5.8). By using Lemma 6.1 we obtain for $z > \tau_n$

$$|\bar{B}_n| \leqq \frac{\lambda M_n}{\lambda - \alpha\tau_n}\frac{|g_n(\alpha)|}{\mu}\left[1 + \frac{\alpha}{\bar{\mu} - \alpha}\min\{1, \bar{\zeta}\sqrt{\tfrac{1}{2}\pi(z-\tau_n)}\}\right], \tag{7.16}$$

where $\bar{\mu}$ and $\bar{\zeta}$ are defined by

$$\tfrac{1}{2}\bar{\zeta}^2 = \alpha - \bar{\mu} + \bar{\mu}\log(\bar{\mu}/\alpha), \quad \bar{\zeta} \geqq 0, \quad \bar{\mu} = (\lambda - \alpha\tau_n)/(z-\tau_n). \tag{7.17}$$

The conditions $0 \leqq \alpha \leqq \mu$ and $z > \tau_n$ imply $0 \leqq \alpha \leqq \bar{\mu}$.

(ii) $0 \leqq \mu \leqq \alpha$. We consider (7.15) for $t \geqq \alpha$. Representation (3.5) gives for $z > \tau_n$

$$|\bar{B}_n| \leqq zM_n|g_n(\alpha)|G_0(\alpha, \lambda - \alpha\tau_n, z - \tau_n).$$

Using Lemma 6.2, we obtain

$$|\bar{B}_n| \leqq \frac{M_n|g_n(\alpha)|}{(\alpha - \bar{\mu})(1-\tau_n/z)}\min\{1, \bar{\zeta}\sqrt{\tfrac{1}{2}\pi(z-\tau_n)}\}. \tag{7.18}$$

When $\lambda - \alpha\tau_n < 0$ we define $\bar{\zeta} = +\infty$, otherwise it is defined by (7.17), with $0 \leqq \bar{\mu} \leqq \alpha$.

Remark 7.1. The numbers $\bar{\zeta}$, M_n and τ_n in (7.16) and (7.18) need not be the same. When $\alpha \to \bar{\mu}$, $\bar{\zeta}$ has to be combined with the factor $1/(\bar{\mu} - \alpha)$, as explained in Remark 6.1.

Remark 7.2. We can write $g_n(t)$ of (7.14) in the form

$$g_n(t) = \tilde{g}_n(t) - \frac{1}{z}\bar{f}_{n+1}, \qquad \tilde{g}_n(t) = f_n(t) - f_n(\mu). \tag{7.19}$$

Bounds for $\bar{f}_{n+1}$ follow from (7.8). Contributions owing to $\tilde{g}_n(t)$ are as in (7.16), (7.18) with $g_n(\alpha)$ replaced by $\tilde{g}_n(\alpha)$. Observe that (see (2.7))

$$\tilde{g}_n(\alpha)/(\alpha - \mu) = B_n(\alpha),$$

which shows up in (7.18) when we use (7.19). There is something to recommend about the approach based on (7.19). The point is that g_n of (7.14) may be difficult to evaluate without the splitting in (7.19). Furthermore, M_n and τ_n of (7.15) may depend on z. However, this dependence will be very weak when z is large.

8. A loop integral with analogue asymptotic features. In previous papers [11], [12] we stated the analogy between the following integrals:

$$F_\lambda(z) = \frac{1}{\Gamma(\lambda)}\int_0^\infty t^{\lambda-1}e^{-zt}f(t)\,dt, \tag{8.1}$$

$$G_\lambda(z) = \frac{\Gamma(\lambda+1)}{2\pi i}\int_{-\infty}^{(0+)} t^{-\lambda-1}e^{zt}f(t)\,dt, \tag{8.2}$$

where (8.1) is the complete integral given in (2.1). The contour in (8.2) starts and ends at $t=-\infty$ (respectively, with $\arg t=-\pi$, $\arg t=\pi$), and encircles the origin in positive direction. The analogy, from an asymptotic point of view, is that of their asymptotic expansions:

$$z^{\lambda}F_{\lambda}(z)\sim\sum_{s=0}^{\infty}f_s(\mu)z^{-s}, \tag{8.3}$$

$$z^{-\lambda}G_{\lambda}(z)\sim\sum_{s=0}^{\infty}(-1)^s f_s(\mu)z^{-s}, \tag{8.4}$$

as $z\to\infty$; (8.3) is considered in the present paper, for instance in (2.4). The construction of (8.4) is based on the same integration by parts procedure, by using Hankel's integral for the reciprocal gamma function. That is, (8.2) reduces to z^{λ}, when f is the identity. Conditions on f, especially the domain of holomorphy, have to be modified, before we can state that (8.2) has (8.4) as a uniform expansion with z as the large parameter and $\mu=\lambda/z$ as uniformity parameter.

It seems that the following integral

$$G_{\lambda}(z,\alpha)=\frac{\Gamma(\lambda+1)}{2\pi i}\int_{-\infty}^{(0^+)}t^{-\lambda}e^{zt}g(t)\frac{dt}{t-\alpha} \tag{8.5}$$

is the relative of $F_{\lambda}(z,\alpha)$ defined in (1.1). That is, (8.5) has four asymptotic phenomena that are in some sense equivalent to the four discussed in § 1 for (1.1). However, the asymptotic expansions show an interesting difference, although the characteristics of both are exactly the same.

8.1. Uniform approximation for loop integrals. We suppose that the contour in (8.5) cuts the positive real axis at the point t_0. We first give (8.5) for $g=1$. Multiplying by $\exp(-\alpha z)$ and differentiating with respect to z, we obtain (8.2) with $f=1$. Integrating with respect to z, and taking into account some limiting values, we obtain two forms for (8.5) with $g=1$:

$$G_{\lambda}(z,\alpha)=\lambda\alpha^{-\lambda}e^{\alpha z}\begin{cases}\gamma(\lambda,\alpha z), & t_0>\alpha,\\ (-1)\Gamma(\lambda,\alpha z), & 0<t_0<\alpha,\end{cases} \tag{8.6}$$

where $\gamma(a,x)$, $\Gamma(a,x)$ are incomplete gamma functions. The transition from one form to the other in (8.6) also follows from (8.5), by shifting the contour across the pole at $t=\alpha$, and using $\gamma(a,x)+\Gamma(a,x)=\Gamma(a)$.

Suppose now that $0<t_0<\alpha$. Writing $g(t)=g(\alpha)+[g(t)-g(\alpha)]$, we obtain for (8.5)

$$G_{\lambda}(z,\alpha)=G_{\lambda}(z)-\lambda g(\alpha)\alpha^{-\lambda}e^{\alpha z}\Gamma(\lambda,\alpha z) \tag{8.7}$$

where

$$G_{\lambda}(z)=\frac{\Gamma(\lambda+1)}{2\pi i}\int_{-\infty}^{(0^+)}t^{-\lambda-1}e^{zt}h(t)\,dt,\qquad h(t)=t\frac{g(t)-g(\alpha)}{t-\alpha}. \tag{8.8}$$

Therefore, assuming appropriate conditions on g, and hence on h, the asymptotic expansion of $G_{\lambda}(z)$ is given in (8.4) with $f_s(\mu)$ replaced by $h_s(\mu)$. The latter are generated as $f_s(\mu)$ in (2.5), with f_0 replaced by h and f_s by h_s.

We conclude that, apart from normalization, (8.7) has with (8.4) a similar expansion as $F_\lambda(z,\alpha)$ in (2.6). An interesting difference is that now the incomplete gamma function does not multiply a full asymptotic expansion but just one term involving $g(\alpha)$. This gives a simpler asymptotic problem. For instance, the construction of error bounds only applies to $G_\lambda(z)$, i.e., for the complete integral (8.2), where f is replaced by h of (8.8).

A representation for the remainders in the expansion of $G_\lambda(z)$ in (8.7) follows by writing

$$z^{-\lambda}G_\lambda(z)=\sum_{s=0}^{n-1}(-1)^s h_s(\mu)z^{-s}+(-1)^n z^{-n}\bar{h}_n, \tag{8.9}$$

$$\bar{h}_n=\frac{z^{-\lambda}\Gamma(\lambda+1)}{2\pi i}\int_{-\infty}^{(0^+)} t^{-\lambda-1}\,e^{zt}h_n(t)\,dt, \tag{8.10}$$

where $h_n(t)$ is generated by the recursion (2.5), with starting function $h_0=h$ defined in (8.8).

8.2. Error bounds for loop integrals. For the construction of error bounds, we select a special contour in (8.10). Writing

$$t^{-\lambda}\,e^{zt}=e^{z[\rho e^{i\theta}-\mu\log\rho-i\mu\theta]},\qquad t=\rho\,e^{i\theta},$$

we see that the imaginary part of the phase function will vanish, when we take

$$\rho=\rho(\theta)=\mu\theta/\sin\theta,\qquad -\pi<\theta<\pi.$$

This defines the path of steepest descent through the saddle point $t=\mu$. Integrating (8.10) with respect to the parameter θ along this contour, we use

$$\frac{1}{t}\frac{dt}{d\theta}=\frac{1}{\rho}\frac{d\rho}{d\theta}+i,$$

giving

$$\bar{h}_n=\frac{\Gamma(\lambda+1)\lambda^{-\lambda}\,e^{\lambda}}{2\pi}\int_{-\pi}^{\pi} e^{-\lambda\phi(\theta)}\tilde{h}_n(t)\,d\theta, \tag{8.11}$$

where

$$t=\rho\,e^{i\theta}=\mu[\theta\operatorname{cotg}\theta+i\theta],$$

$$\tilde{h}_n(t)=\frac{1}{it}\frac{dt}{d\theta}h_n(t), \tag{8.12}$$

$$\phi(\theta)=-\theta\operatorname{cotg}\theta+\log\frac{\theta}{\sin\theta}+1.$$

A bound for $\tilde{h}_n$ is obtained by writing as in (7.8)

$$|\tilde{h}_n(t)|\leqq M_n|h_n(\mu)|\,e^{\mu\delta_n\phi(\theta)}, \tag{8.13}$$

where M_n satisfies (7.2), $\delta_n<z$, and where it is assumed that $h_n(\mu)\neq 0$. We obtain as in (7.9)

$$|\bar{h}_n|\leqq M_n\tilde{Q}_n|h_n(\mu)|, \tag{8.14}$$

where $\tilde{Q}_n=1/[(1-\delta_n/z)Q_n]$. We have used that (8.10) reduces to unity when h_n equals unity.

Observe that to compute error bounds for the expansion (8.9), exactly the same comparison function is used as in (7.8); the forms are different owing to the mapping $t \to \theta$.

Remark 8.1. Representation (8.7) is obtained under the condition $0 < t_0 < \alpha$, where t_0 is the point where the contour of (8.5) cuts the real positive axis. When (8.5) is presented with $t_0 > \alpha$, $G_\lambda(z, \alpha)$ has representation (8.7), with $\Gamma(\lambda, \alpha z)$ replaced by $-\gamma(\lambda, \alpha z)$. This complementary relation is of the same kind as for the real integrals described in (2.14), (2.15).

9. The incomplete beta function. We use the incomplete beta function in the notation

$$I_x(p, q) = \frac{1}{B(p, q)} \int_0^x \tau^{p-1}(1-\tau)^{q-1}\, d\tau, \tag{9.1}$$

where $B(p, q) = \Gamma(p)\Gamma(q)/\Gamma(p+q)$ is the complete beta function. The asymptotic problem is to give an expansion of $I_x(p, q)$ with p as large parameter and $x \in [0, 1]$ and $\mu = q/p \in [0, \infty)$ as uniformity parameters. We can use

$$I_x(p, q) = 1 - I_{1-x}(q, p) \tag{9.2}$$

to interchange the role of p and q. For information on $I_x(p, q)$ we refer to [1, p. 944]. In [10] we considered the asymptotic problem for $I_x(p, q)$ for more restricted ranges of the parameters. We believe that the expansions of this section are new in the sense that the uniformity domain of μ or q is the complete interval $[0, \infty)$. Earlier results prescribed q to belong to a compact subset of $(0, \infty)$ (case (ii) of § 1), or p/q to a compact subset of $(0, \infty)$ (case (iv)). Extension to complex values of the parameters is possible, but will not be considered here.

To describe the asymptotic features of (9.1) in more detail, we compute the saddle point of $\tau^p(1-\tau)^q$. It occurs at

$$\tau_0 = \frac{p}{p+q}. \tag{9.3}$$

When $p+q$ is large, the value $I_x(p, q)$ is very small when $x < \tau_0$, and it is close to unity when $x > \tau_0$. When τ_0 is restricted to a compact subset of $(0, 1)$, this transition can properly be described by an error function (normal distribution function); when $\tau_0 \to 1$ the basic approximant is an incomplete gamma function. We will show that this function can handle the complete uniformity domain for q, i.e., $[0, \infty)$. It is essential to transform (9.1) to the standard form (1.1), by means of a rather complicated transformation.

9.1. Transformation to standard form. A first transformation $\tau \to e^{-\tau}$ gives

$$I_x(p, q) = \frac{1}{B(p, q)} \int_{-\log x}^{\infty} (1-e^{-\tau})^{q-1} e^{-p\tau}\, d\tau. \tag{9.4}$$

Comparing this with (1.1), we observe that it has the standard form when $\lambda = q$, $z = p$ and $f(t) = [(1-e^{-\tau})/\tau]^{q-1}$. However, for several reasons this choice of f will not give a uniform expansion for the q-interval $[0, \infty)$. One reason is that large values of q will have much influence on coefficients $f_s(\mu)$, $B_s(\alpha)$. Observe that for f dependence only on μ is assumed in § 4, and not on λ.

A better way for transforming (9.4) in (1.1) is to use the mapping $\tau \to t(\tau)$ defined by

$$\tau - \mu \log(1-e^{-\tau}) = t - \mu \log t + A(\mu), \tag{9.5}$$

where $\mu = q/p$. The left-hand side has a saddle point at

$$\tau_1 = \log(\mu+1) = -\log \tau_0, \tag{9.6}$$

the right-hand side at $t=\mu$. To make the mapping properly defined we require the correspondences

$$\tau = 0 \leftrightarrow t = 0, \qquad \tau = \tau_1 \leftrightarrow t = \mu, \qquad \tau = +\infty \leftrightarrow t = +\infty. \tag{9.7}$$

The middle one gives

$$A(\mu) = (1+\mu)\log(1+\mu) - \mu. \tag{9.8}$$

The point $\tau = -\log x$, the lower end point of integration in (9.4), is mapped to $t = \alpha$, which is defined by the implicit relation

$$-\log x - \mu \log(1-x) = \alpha - \mu \log \alpha + A(\mu), \tag{9.9}$$

with corresponding points

$$x = 0 \leftrightarrow \alpha = +\infty, \qquad x = \tau_0 \leftrightarrow \alpha = \mu, \qquad x = 1 \leftrightarrow \alpha = 0. \tag{9.10}$$

Observe that the middle one satisfies (9.9) due to the choice (9.8). In fact, the mappings (9.5) and (9.9) are the same, up to parametrization.

The transformed version of (9.4) is

$$I_x(p,q) = \frac{e^{-pA(\mu)}}{B(p,q)} \int_\alpha^\infty t^{q-1} e^{-pt} f(t)\, dt, \tag{9.11}$$

where

$$f(t) = \frac{t}{1-e^{-\tau}} \frac{d\tau}{dt} = \frac{t-\mu}{1-(1+\mu)\, e^{-\tau}}. \tag{9.12}$$

The regularity of the transformation (9.5), and that of f, is extensively discussed in [12, § 4]. From that analysis it follows that f satisfies the conditions of § 4. In (4.1) we have to take $\kappa = \frac{1}{2}$, and d_0 and δ both somewhat less than $\sqrt{2\pi}$. Ω_0 is a parabola-shaped domain, and for the number p in (4.4) we take $p = 1$ (which follows easily from (9.12)). The function f is positive on $[0, \infty)$; $f(0) = 1$, $f(\mu) = \sqrt{1+\mu}$. We verified numerically that

$$\sup_{\substack{t \geqq 0 \\ \mu \geqq 0}} \frac{f(t)}{1+t} = 1.$$

Therefore, $M(\mu)$ of (4.4) will not deviate very much from unity, especially when δ and d_0 are small.

9.2. Uniform expansion of incomplete beta function. In the notation of (1.1), (2.1), (2.9), we can write

$$\begin{aligned} I_x(p,q) &= \frac{e^{-pA(\mu)}\Gamma(p+q)}{\Gamma(p)} F_q(p,\alpha), \\ F_q(p,\alpha) &= Q(q,\alpha p) F_q(p) + \frac{\alpha^q\, e^{-\alpha p}}{p\Gamma(q)} B_q(p,\alpha). \end{aligned} \tag{9.13}$$

However, the "complete" integral $F_q(p)$ can be written in this case in terms of known functions. Since $I_1(p,q) = 1$, we have

$$F_q(p) = e^{pA(\mu)}\Gamma(p)/\Gamma(p+q) = \left(\frac{p+q}{p}\right)^{p+q} e^{-q}\Gamma(p)/\Gamma(p+q). \tag{9.14}$$

Although it is possible to give for $F_q(p)$ an expansion as in (2.4) (see [12, § 4] for a related expansion), it is more attractive now to write (9.13) in the form

$$I_x(p,q)=Q(q,\alpha p)+\frac{\alpha^q\,e^{-\alpha p+q}}{pB(p,q)}\left(\frac{p}{p+q}\right)^{p+q}B_q(p,\alpha). \tag{9.15}$$

By using (9.9), and (2.11) we can write

$$I_x(p,q)=Q(q,\alpha p)+\frac{x^p(1-x)^q}{pB(p,q)}B_q(p,\alpha),\qquad B_q(p,\alpha)\sim\sum_{s=0}^{\infty}\frac{B_s(\alpha)}{p^s}\quad \text{as } p\to\infty. \tag{9.16}$$

It follows that we have only to consider the asymptotic expansion for $B_q(p,\alpha)$, which, however, is not the simpler one of (2.4), (2.11). The first coefficient is

$$B_0(\alpha)=\frac{f(\alpha)-f(\mu)}{\alpha-\mu}, \tag{9.17}$$

with

$$f(\alpha)=\frac{\alpha-\mu}{1-(1+\mu)x},\qquad f(\mu)=\sqrt{1+\mu}.$$

Special values are

$$B_0(0)=\frac{\sqrt{1+\mu}-1}{\mu},\qquad B_0(\mu)=\lim_{\alpha\to\mu}f'(\alpha)=\frac{\mu-1+\sqrt{1+\mu}}{3\mu},\qquad B_0(\infty)=1, \tag{9.18}$$

and they satisfy $0\leqq B_0(0)\leqq B_0(\mu)\leqq B_0(\infty)$, for $\mu\geqq 0$.

In fact, all $B_s(\alpha)$ can be expressed in terms of α, x and μ, and those three are related by (9.9). When $\alpha\neq\mu$, an explicit representation of $B_s(\alpha)$ in terms of say x and $\mu=q/p$ is not possible, since (9.9) cannot be solved explicitly for α. When $\mu=0$, (9.5) reduces to the identity mapping and f of (9.12) becomes $t/[1-\exp(-t)]$. The latter has singularities at $t=\pm 2\pi i, \pm 4\pi i,\cdots$. When $\mu>0$, singular points of f originate from these points, of which $\pm 2\pi i$ are most important. The singular points of f starting from $\pm 2\pi i$ $(\mu=0)$ are located in the half-plane $\operatorname{Re} t>0$. For large values of μ they are approximately near $\mu+2\sqrt{\pi\mu}\exp(\pm i\pi/4)$. The value $\kappa=\frac{1}{2}$ in (4.1) comes from $\sqrt{\mu}$ in this asymptotic value. The coefficients $B_s(\alpha)$ have the same domain of regularity as $f(\alpha)$. Since $M(\mu)=\mathcal{O}(1)$, $p=1$, $\kappa=\frac{1}{2}$, $\bar\kappa=0$, we have for (5.7)

$$B_s(\alpha)=\mathcal{O}(1+\mu+\alpha)^{1/2},\quad s=0,1,2,\cdots,\quad \mu\geqq 0,\quad \alpha\geqq 0. \tag{9.19}$$

This estimate gives a good impression of the asymptotic nature of the expansion in (9.16), although the estimate for $s=0$ seems to be too large (cf. (9.18)).

9.3. Uniform expansion based on a loop integral. An interesting variant of (9.16) is obtained by using a contour integral for $I_x(p,q)$ in the complex plane, and by applying the method of § 8. Consider the integral

$$I=\frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty}t^{-p}(1-t)^{-q}\frac{dt}{t-x},\qquad 0<c<1,$$

with $p+q>0$ and $0<x<c$. When $t\in(0,1)$ the phases of t, $(1-t)$ and of the multi-valued functions are zero. By deforming the contour around the negative axis, we obtain for $p<1$

$$\begin{aligned}I&=x^{-p}(1-x)^{-q}-\frac{\sin\pi p}{\pi}\int_0^\infty\tau^{-p}(1+\tau)^{-q}\frac{d\tau}{\tau+x}\\&=x^{-p}(1-x)^{-q}I_x(p,q),\end{aligned}$$

where we used formulas 6.1.17, 15.3.1, 15.3.3, 15.3.4, 26.5.23 and 26.5.2 of [1]. It follows that

$$(9.20)\qquad I_x(p,q)=\frac{x^p(1-x)^q}{2\pi i}\int_{c-i\infty}^{c+i\infty}\tau^{-p}(1-\tau)^{-q}\frac{d\tau}{\tau-x},\qquad 0<c<1,$$

with $0<x<c$. The restriction $p<1$, which is needed to evaluate the contour integral for I, can be dropped by using the principle of analytic continuation. We still need the condition $p+q>0$ for convergence at infinity.

Representation (9.20) is the analogue of (9.1). To obtain standard form (8.5), we use the transformation $\tau\to\exp(-\tau)$. This gives

$$(9.21)\qquad I_x(p,q)=\frac{x^p(1-x)^q}{2\pi i}\int_{-\infty}^{(0^+)}e^{pt}(1-e^{-\tau})^q\frac{d\tau}{1-xe^{\tau}},$$

which is the analogue of (9.4). The contour cuts the positive real τ-axis at a point τ_0 such that $\tau_0<-\log x$. A final transformation

$$(9.22)\qquad \tau-\mu\log(1-e^{-\tau})=t-\mu\log t+A(\mu),$$

where $\mu=q/p$ and $A(\mu)$ is given in (9.8), gives

$$(9.23)\qquad I_x(p,q)=x^p(1-x)^q e^{-q}(1+q/p)^{p+q}\frac{1}{2\pi i}\int_{-\infty}^{(0^+)}e^{pt}t^{-q}\frac{g(t)}{t-\alpha}\,dt,$$

where α is defined in (9.9), and

$$(9.24)\qquad g(t)=\frac{t-\alpha}{1-xe^{\tau}}\frac{d\tau}{dt}.$$

A relation for $d\tau/dt$ is given in (9.12). The contour in (9.23) cuts the positive t-axis at a point t_0 satisfying $t_0<\alpha$. Splitting off the pole, we obtain for (9.23)

$$(9.25)\qquad I_x(p,q)=Q(q,\alpha p)+x^p(1-x)^q e^{-q}(1+q/p)^{p+q}G_q(p)/\Gamma(q+1),$$

with $G_q(p)$ as in (8.8). Here we used $g(\alpha)=-1$, which follows from (9.24) by l'Hôpital's rule (observe that $t=\alpha$ corresponds with $\tau=-\log x$ in (9.22)).

Observe that the transformations (9.5) and (9.22) are exactly the same. The real corresponding points in (9.7) determine the mapping in the complex plane. Therefore, no new correspondences have to be defined for (9.22). In fact, the mapping has a very global character. As remarked earlier, we have investigated the mapping (9.5) in [12], with emphasis on what is happening in a neighbourhood of $\mathbb{R}^+$. However, the domain of regularity extends to the full half-plane Re $t\leqq 0$. To understand the mapping in the complex plane, it is instructive to see that the contours of steepest descent in (9.21), (9.23) are mapped onto each other. On these contours the imaginary parts in the left- and right-hand side of (9.22) vanish.

Comparing (9.15) and (9.25), we conclude that the function $B_q(p,\alpha)$ has (in the special case of this section) an asymptotic expansion which corresponds to that of a "complete" integral (8.2). We have

$$(9.26)\qquad B_q(p,\alpha)=\frac{\Gamma(p+1)\,e^{-q}(1+q/p)^{p+q}}{q\Gamma(p+q)}G_q(p),$$

where $G_q(p)$ is given in (8.8), with expansion as in (8.9); g is defined in (9.24).

By using (7.10) and (8.9) we can write (9.26) in the form

$$(9.27)\quad B_q(p,\alpha)=\frac{\sqrt{\mu+1}}{\mu}\frac{\Gamma^*(p)}{\Gamma^*(p+q)}p^{-q}G_q(p),\qquad p^{-q}G_q(p)\sim\sum_{s=0}^{\infty}(-1)^s h_s(\mu)p^{-s}.$$

Therefore, the approach based on a complex contour gives for $I_x(p, q)$ a simpler asymptotic expansion and simpler error bounds than the approach based on, say, (9.11). The computation of the coefficients $h_s(\mu)$ is not a simple problem. Also, the bound for $|h_n(t)|$ in (8.13) has to be computed on a contour in the complex plane. But the form of the error bound (8.14) is much simpler than those obtained in § 7.

To show some of the steps needed to evaluate the coefficients $h_s(\mu)$ in (9.27), we compute $h_0(\mu)$ and its limiting form for $\alpha \to \mu$. We have, using h of (8.8) and g of (9.24),

$$g(\mu)=\frac{\mu-\alpha}{1-(1+\mu)x}\frac{d\tau}{dt}, \tag{9.28}$$

where the derivative is evaluated at $t=\mu$. From (9.12), we have

$$\lim_{t\to\mu}\frac{d\tau}{dt}=\frac{1}{\mu+1}\lim_{t\to\mu}\frac{t-\mu}{1-(1+\mu)\,e^{-\tau}}=\frac{1}{\mu+1}\frac{dt}{d\tau},$$

by using l'Hôpital's rule. Hence

$$\frac{d\tau}{dt}=\frac{1}{\sqrt{\mu+1}}\quad \text{at } t=\mu.$$

The square root has a + sign, since τ is an increasing function of t on $[0,\infty)$. Earlier we computed $g(\alpha)=-1$. So we have

$$h_0(\mu)=\frac{\mu}{\mu-\alpha}\left[\frac{(\mu-\alpha)/\sqrt{\mu+1}}{1-(\mu+1)x}+1\right],\qquad \mu\neq\alpha. \tag{9.29}$$

To evaluate this at $\alpha=\mu$, we have to investigate the relation between x and α in more detail. From (9.9) it follows that

$$\alpha[(\mu+1)x-1]\frac{dx}{d\alpha}=x(1-x)(\alpha-\mu).$$

Substituting the expansion

$$x=\frac{1}{\mu+1}+c_1(\alpha-\mu)+c_2(\alpha-\mu)^2+\cdots,$$

we obtain

$$c_1=-(1+\mu)^{-3/2},\qquad c_1c_2=\frac{1}{3\mu(1+\mu)^3}\left[\frac{1-\mu}{\sqrt{1+\mu}}-1\right].$$

When $\alpha\to\mu$, $h_0(\mu)$ of (9.28) has the expansion

$$h_0(\mu)=-\mu c_2/c_1+\mathcal{O}(\mu-\alpha).$$

Hence

$$\lim_{\alpha\to\mu}h_0(\mu)=\frac{1}{3}\left[1-\frac{1-\mu}{\sqrt{\mu+1}}\right].$$

It follows that $B_0(\alpha)$ of (9.17) and $h_0(\mu)$ of (9.29) are related by

$$B_0(\alpha)=\frac{\sqrt{\mu+1}}{\mu}h_0(\mu).$$

A relation between the higher coefficients is obtained as follows. Comparing (9.16) with (9.27), we arrive at the formal identity

$$\sum_{s=0}^{\infty} B_s(\alpha)p^{-s} = \frac{\sqrt{\mu+1}}{\mu}\frac{\Gamma^*(p)}{\Gamma^*(p+q)}\sum_{s=0}^{\infty}(-1)^s h_s(\mu)p^{-s}.$$

We can expand

$$\frac{\Gamma^*(p)}{\Gamma^*(p+q)} \sim \sum_{s=0}^{\infty} d_s(\mu)p^{-s}, \qquad d_0(\mu)=1,$$

by dividing the two expansions for $\Gamma^*(p)$ and $\Gamma^*(p(1+\mu))$ (see also [12, § 4]). Thus we obtain

$$B_s(\alpha) = \frac{\sqrt{\mu+1}}{\mu}\sum_{r=0}^{s}(-1)^r h_r(\mu)d_{s-r}(\mu),$$

which is (9.30) for $s=0$.

9.4. Some numerical results. We used the method of § 7.2 to compute an upper bound for $B_q(p, \alpha)$. That is, we computed M_0 and τ_0 for (7.16), (7.18), and we evaluated the expression at the right-hand sides of these inequalities. For $z = p = 10\ (10)\ 100$ these expressions were evaluated at the x, μ-grid with $x = 0.05\ (0.05)\ 0.95$, $\mu = 1\ (1)\ 10$. For each z the maximal value occurred at $x = 0.05$, $\mu = 1$. The corresponding α-value for this x, μ-pair is $4.06254 \cdots$. The upper bounds show an interesting feature. For $z = 10$ it is 0.97111 and it steadily increases to 0.97371 for $z = 100$. The ratio of this last upper bound and $B_0(\alpha)$ of (9.17) $(=0.64933\cdots)$ equals $1.500\cdots$, which is the number M_0 that we used in (7.15), (7.16) and (7.18). We observe that the computed upper bounds are slightly less than $M_0B_0(\alpha)$, and tend to this value when z increases. The choice $M_0 = 1.1$ showed the same features: the upper bound of $B_q(p, \alpha)$ is slightly less than $M_0B_0(\alpha)$.

The numerical experiments yield the following conclusion:

$$\sup B_q(p, \alpha) = 1, \quad p \text{ fixed},$$

where the supremum is taken over $x \in [0, 1]$ (or $\alpha \geqq 0$) and $\mu = q/p \in [0, \infty)$. The maximum is assumed at $x = 0$ $(\alpha = \infty)$ and $\mu = 0$. See also (5.11); for $n = 0$ this limit L equals 1. Incidentally, (5.9) gives for $n = 0$

$$B_q(p, \alpha) = p[\log p - \psi(p)] \tag{9.30}$$

at $\alpha = 0$, $\mu = 0$, where $\psi(p)$ is the logarithmic derivative of the gamma function. This follows from well-known representations of this function, and from the fact that f of (9.12) equals $t/(1-\exp(-t))$ at $\mu = 0$. From (9.13) and the asymptotic expansion of the ψ-function, it follows that

$$B_0(p, 0) = \tfrac{1}{2} + \mathcal{O}(p^{-1}) \quad \text{as } p \to \infty.$$

We conjecture that $\frac{1}{2} \leqq B_q(p, \alpha) \leqq 1$ for $\alpha \in [0, \infty)$ (or $x \in [0, 1]$), and $\mu = q/p \in [0, \infty)$, and for all p sufficiently large (say $p \geqq 10$).

SOME PROPERTIES OF THE ZEROS OF POLYNOMIAL SOLUTIONS OF STURM-LIOUVILLE EQUATIONS*

R. G. CAMPOS†

Abstract. In this paper certain equalities holding for the zeros of a polynomial satisfying a linear differential equation of the second order are obtained in terms of the coefficients of this equation using an elementary approach. They are applied to the polynomial solutions of a Sturm-Liouville equation. As an example, a new expression for the zeros of the classical polynomials is presented.

Key words. differential equations, polynomials, zeros

AMS(MOS) subject classifications. 65(01)H05, 30(01)A08

1. Introduction. In the past few years, a number of remarkable properties of the zeros of the classical polynomials have been obtained mainly as byproducts of the study of certain integrable many-body problems (Ahmed et al. [2] and Calogero [3]). The purpose of this paper is to present certain results of this kind obtained also as a spin-off, but in this case of the developing of a technique to compute the eigenvalues of the Schrödinger Equation (Campos [5]).

The algebraic relations between the zeros of a polynomial that satisfies an ordinary differential equation (ODE) of the second order and the coefficients of this equation are obtained through an elementary method in § 2. These results are applied to a Sturm-Liouville (SL) equation to illustrate some interesting features of its polynomial solutions. An example is given in § 3 and some final remarks are made in § 4.

2. Properties of the zeros. There are various methods for studying the zeros of polynomials. The method that will be followed in this section is based on an approach due to Laguerre (see Szëgo [9, p. 117]).

We begin by defining

$$\sum_{k=1}^{N}{}' (x_i - x_k)^{-l} \equiv S_N^l(x_i), \qquad l=1,2,\cdots$$

where the prime appended to the sum indicates the omission of the singular term and the points x_k, $k=1,2,\cdots,N$, are the N (complex) zeros of a polynomial $f(x)$ of degree N that satisfies the ODE

$$f''(x)+p(x)f'(x)+q(x)f(x)=0. \tag{1}$$

Then we have the following proposition.

PROPOSITION 1. *If $p(x)$ and $q(x)$ are analytic at x_k, $k=1,2,\cdots,N$, then*

$$S_N^1(x_i) = -\tfrac{1}{2}p(x_i), \tag{2}$$

$$S_N^2(x_i) = \tfrac{1}{3}p'(x_i)+\tfrac{1}{3}q(x_i)-\tfrac{1}{12}[p(x_i)]^2, \tag{3}$$

$$\begin{aligned} S_N^3(x_i) &= \tfrac{1}{8}p(x_i)p'(x_i)-\tfrac{1}{8}p''(x_i)-\tfrac{1}{4}q'(x_i) \\ &= \tfrac{1}{8}\{\tfrac{1}{2}[p(x_i)]^2-p'(x_i)-2q(x_i)\}', \end{aligned} \tag{4}$$

$$\begin{aligned} S_N^4(x_i) = {} & \tfrac{1}{720}[p(x_i)]^4+\tfrac{1}{180}p'(x_i)[p(x_i)]^2-\tfrac{1}{90}q(x_i)[p(x_i)]^2 \\ & -\tfrac{2}{45}[p'(x_i)]^2+\tfrac{1}{45}[q(x_i)]^2-\tfrac{1}{45}p'(x_i)q(x_i) \\ & -\tfrac{1}{20}p''(x_i)p(x_i)+\tfrac{1}{30}p'''(x_i)+\tfrac{1}{10}q''(x_i). \end{aligned} \tag{5}$$

Proof. The idea that we will follow is very simple and it requires only some algebra. A derivative in this proof will be denoted by primes or numbers enclosed by parentheses

* Received by the editors June 18, 1986; accepted for publication (in revised form) December 15, 1986.

† Escuela de Física y Matemáticas, Universidad Michoacana, 58000 Morelia, Michoacán, México.

appended to the function. For the sake of simplicity we will prove only (3). Equations (2), (4) and (5) can be proved along these lines.

Let $f(x)=\prod_{k=1}^N (x-x_k)$ be a solution of (1). Let us define

$$g(x)=(x-x_1)(x-x_2)\cdots(x-x_{i-1})(x-x_{i+1})\cdots(x-x_N).$$

Thus,

$$\sum_{\substack{k=1\\k\neq i}}^{N}(x-x_k)^{-2}=\left[\frac{g'(x)}{g(x)}\right]^2-\frac{g''(x)}{g(x)}. \tag{6}$$

Since $p(x)$ and $q(x)$ are analytic at x_i for all x_i, these points are all distinct and $g^{(l)}(x_i)=(l+1)^{-1}f^{(l+1)}(x_i)$ for $l=0,1,\cdots$. Therefore, (6) becomes

$$S_N^2(x_i)=\frac{1}{4}\left[\frac{f''(x_i)}{f'(x_i)}\right]^2-\frac{1}{3}\frac{f'''(x_i)}{f'(x_i)}.$$

Now, using (1), we get (3).

It should be noted that (4) can be interpreted as an extremal property of these zeros: the function of the N continuous variables $z_1, z_2, \cdots, z_N$,

$$H(z_1,z_2,\cdots,z_N)\equiv H(z)=\sum_{\substack{i,j=1\\i\neq j}}^{N}\frac{1}{(z_i-z_j)^2}+\sum_{j=1}^{N}u(z_j)$$

where

$$u(z)=\tfrac{1}{4}[p(z)]^2-\tfrac{1}{2}p'(z)-q(z)+\lambda',$$

and λ' is an arbitrary constant, takes a stationary value at $z_i=x_i$, $i=1,2,\cdots,N$, whenever z_i is in the domain in which the polynomial $f(x)$ satisfies (1). Furthermore, it is not difficult to see that if $u''(x_i)>0$ for all x_i, the function $H(z)$ has an absolute minimum. On the other hand, if $u(x)$ is a symmetric function, the zeros are symmetrically located about the origin.

If an SL equation, like Schrödinger's, is considered, the function $H(x)$ can be interpreted in some cases as the trace of certain finite representation of the Hamiltonian operator with potential $u(x)$ (Campos [5]).

Some interesting features of relations (2)-(5) can be made apparent if we consider zeros of polynomial solutions of an SL equation. The following corollary is an immediate application of Proposition 1.

COROLLARY 1. *Consider the normal* SL *equation*[1]

$$\psi''(x)+[\lambda-V(x)]\psi(x)=0$$

with a solution in the form $\psi(x)=F(x)f(x)$, where $f(x)$ is a polynomial of degree N with zeros x_i, $i=1,2,\cdots,N$, and $F(x_i)\neq 0$ for all x_i. Then, the relation

$$S_N^1(x_i)=-\frac{F'(x_i)}{F(x_i)}$$

holds for all x_i and the eigenvalues are related with the zeros through

$$\lambda=3S_N^2(x_i)-3\frac{F''(x_i)}{F(x_i)}+3\left[\frac{F'(x_i)}{F(x_i)}\right]^2+V(x_i),\qquad i=1,2,\cdots,N. \tag{7}$$

[1] The general SL differential equation can be considered along the same lines.

Moreover, the function

$$(8)\qquad H(z)=\sum_{\substack{i,j\\ i\neq j}}^{N}\frac{1}{(z_i-z_j)^2}+\sum_{i=1}^{N}u(z_i)$$

with

$$u(x)=V(x)-2\frac{F''(x)}{F(x)}+2\left[\frac{F'(x)}{F(x)}\right]^2+(\lambda'-\lambda),$$

where λ' is an arbitrary constant, takes a stationary value in $z_i=x_i$, $i=1,2,\cdots,N$. This value is an absolute minimum if $u''(x_i)>0$ for all x_i. If $u(x)$ is a symmetric function, the zeros are symmetrically located about the origin. Furthermore, they satisfy

$$S_N^4(x_i)=\frac{1}{15}\frac{F^{(IV)}(x_i)}{F(x_i)}-\frac{7}{15}\frac{F'''(x_i)F'(x_i)}{[F(x_i)]^2}+\frac{9}{5}\frac{F''(x_i)[F'(x_i)]^2}{[F(x_i)]^3}$$
$$-\frac{2}{5}\left[\frac{F''(x_i)}{F(x_i)}\right]^2-\frac{7}{9}\left[\frac{F'(x_i)}{F(x_i)}\right]^4-\frac{4}{45}[\lambda-V(x_i)]\left[\frac{F'(x_i)}{F(x_i)}\right]^2+[\lambda-V(x_i)]^2.$$

3. Examples. In this section we consider the zeros of the Hermite, Laguerre and Jacobi polynomials; we use the definitions of these functions given in [7]. The relations obtained through (2)-(4) ((2)-(5)) for Laguerre and Jacobi (Hermite) zeros are already known (see [1] and [2]). Of these equations, only (3) and (4) will be rewritten in this section using the expressions of Corollary 1 for the three cases. The relations corresponding to (5) is given only for Laguerre and Jacobi zeros.

A. Hermite zeros. The differential equation for the Hermite functions $\psi(x)=\exp(-x^2/2)H_N(x)$, is the Schrödinger equation for the harmonic potential $V(x)=(1/2)x^2$:

$$\psi''(x)+(\lambda-x^2)\psi(x)=0,\qquad \lambda=2N+1.$$

If x_k, $k=1,2,\cdots,N$, are the N zeros of $H_N(x)$, then (7) becomes

$$2(N-1)=3S_N^2(x_i)+x_i^2,\qquad i=1,2,\cdots,N,$$

and the function given by (8), with $u(z)=(1/2)z^2$, and $-\infty<z_i<\infty$ for all z_i, has an absolute minimum $H(x)=N(N-1)/2$ at these points (Campos [6]) and, additionally, they are symmetrically located about the origin, as is well known.

B. Laguerre zeros. The differential equation for the Laguerre functions

$$\psi(x)=\exp(-x/2)x^{(\alpha+1)/2}L_N^\alpha(x),$$

where $\alpha>-1$, $x>0$ and $L_N^\alpha(x)$ is the associated Laguerre polynomial, is the Schrödinger-type equation for the potential $V(\alpha,x)=-(2N+\alpha+1)/2x+(\alpha^2-1)/4x^2$:

$$\psi''(x)+\left(\frac{2N+\alpha+1}{2x}+\frac{1-\alpha^2}{4x^2}+\lambda\right)\psi(x)=0,\qquad \lambda=-\frac{1}{4}.$$

Let x_k, $k=1,2,\cdots,N$, be the N zeros of $L_N^\alpha(x)$. Then (7) becomes

$$-\frac{1}{4}=3S_N^2(x_i)+\frac{(\alpha+5)(\alpha+1)}{4x_i^2}-\frac{2N+\alpha+1}{2x_i},\qquad i=1,2,\cdots,N.$$

The function $H(z)$ given by (8) with $z_i > 0$ for all z_i has a stationary value at these points if $u(z) = V(\alpha+2, z) + (1/z) + \lambda'$, where λ' is an arbitrary constant. There also holds

$$S_N^4(x_i) = \left[\frac{\alpha^4 - 110\alpha^2 - 360\alpha - 251}{720}\right]x_i^{-4} - \left[\frac{\alpha^3 + (2N+1)\alpha^2 - 19\alpha - (38N+19)}{180}\right]x_i^{-3} \tag{9}$$

$$+\left[\frac{3\alpha^2 + 4(2N+1)\alpha + (8N^2+8N+1)}{360}\right]x_i^{-2} - \left[\frac{\alpha+2N+1}{180}\right]x_i^{-1} + \frac{1}{720}.$$

C. Jacobi zeros. The SL form of the differential equation for the Jacobi polynomials $f(x) = P_N^{(\alpha,\beta)}(x)$, $\alpha > -1$, $\beta > -1$, is

$$[(1-x)^{\alpha+1}(1+x)^{\beta+1}f'(x)]' + \lambda(1-x)^{\alpha}(1+x)^{\beta}f(x) = 0, \qquad \lambda = N(N+\alpha+\beta+1).$$

Let x_k, $k = 1, 2, \cdots, N$ be the zeros of $P_N^{(\alpha,\beta)}(x)$. The corresponding form of (7) is:

$$N(N+\alpha+\beta+1) = 3(1-x_i^2)S_N^2(x_i) + \frac{(\alpha+5)(\alpha+1)}{4}\frac{(1+x_i)}{(1-x_i)}$$

$$+\frac{(\beta+5)(\beta+1)}{4}\frac{(1-x_i)}{(1+x_i)} - \frac{(\alpha+1)(\beta+1)}{2}, \qquad i = 1, 2, \cdots, N.$$

The function $H(z)$ defined by (8) where $-1 < z_i < 1$ for all z_i has a stationary value at these points if

$$u(z) = \frac{(\alpha+1)(\alpha+3)}{4(1-z)^2} + \frac{(\beta+1)(\beta+3)}{4(1+z)^2} - \frac{2\lambda + (\alpha+1)(\beta+1)}{2(1-z^2)} + \lambda',$$

where λ' is an arbitrary constant. Defining $a = \alpha - \beta$ and $b = \alpha + \beta + 2$, there also holds

$$S_N^4(x_i) = \frac{c_4(x_i)}{(1-x_i^2)^4} + \frac{c_3(x_i)}{(1-x_i^2)^3} + \frac{c_2(x_i)}{(1-x_i^2)^2} + \frac{c_1(x_i)}{(1-x_i^2)} \tag{10}$$

where

$$c_4(x) = \left(\frac{b^4}{720} - \frac{b^3}{90} - \frac{8b^2}{45} - \frac{48b}{30}\right)x^4 - \left(\frac{ab^3}{180} - \frac{ab^2}{30} - \frac{34ab}{45} - \frac{2b^2}{5} - \frac{8a}{5}\right)x^3$$

$$+\left(\frac{a^2b^2}{120} + \frac{7ab}{18} - \frac{a^2b}{45} - \frac{26a^2}{45}\right)x^2 - \frac{a^3(b-2)}{180}x + \frac{a^4}{720},$$

$$c_3(x) = -\left(\frac{b^3}{180} + \frac{8b^2}{45} + \frac{48b}{30} - \frac{2\lambda b}{45} - \frac{4\lambda}{5}\right)x^2$$

$$+\left(\frac{ab^2}{90} + \frac{43ab}{90} - \frac{3b^2}{10} + \frac{12a}{15} - \frac{2\lambda a}{45}\right)x - \left(\frac{a^2b}{180} + \frac{a^2 - ab}{10}\right),$$

$$c_2(x) = -\frac{\lambda}{90}x^2 + \frac{\lambda ab}{45}x + \left[\frac{\lambda^2}{45} - (a^2 + 2b - 18)\frac{\lambda}{90} - \frac{b}{5}\right],$$

$$c_1(x) = -\frac{2b^2}{45}.$$

4. Final remarks. The method used in this paper to obtain the sums $S_N^l(x_i)$ for zeros of polynomials satisfying a second order linear ODE is quite elementary. However, it is applicable to any polynomial (belonging to certain family or not, with complex or real zeros) whenever the coefficients of the ODE are analytic functions at its zeros.

It makes it possible to relate the sums $S_N^l(x_i)$ to the coefficients evaluated at x_i. An interesting feature of these relations is that $S_N^3(x_i)$ turns out to be the value of the derivative of a certain function evaluated at x_i. This can be interpreted as an extremal property of the zeros.

In the case of a polynomial solution of an SL equation, these expressions give a direct relation between the zeros and the eigenvalue of the equation and it is interesting to note that in the Hermite and Laguerre cases, the function whose derivative is related to $S_N^3(x_i)$ is the "potential function" appearing when the differential equation is written in its normal form.

The sums $S_N^l(x_i)$ can be related to the coefficients of the ODE just through (6), the expression that follows for $g^{(l)}(x_i)$ in terms of $f^{(l+1)}(x_i)$, and the differential equation for $f(x)$. An alternative technique to obtain these relationships has been used by S. Ahmed (see [1]); however, some interesting aspects of these relations, like the minimal property of the zeros, are not shown in that work.

The extremal property of the zeros of the classical polynomials can also be interpreted as the equilibrium condition for certain classical one-dimensional many-body problems (Calogero [4]) and, closely related to this, it is found their electrostatic interpretation (Szëgo [9, § 6.7]; Forrester and Rogers [8]).

All of the equations reported in this paper in § 3 concerning the sums $S_N^l(x_i)$ are already known (Ahmed et al. [2]), with the exception of (9) and (10), which are presumably new.

ON AN EXPANSION THEOREM OF F. V. ATKINSON AND P. BINDING*

HANS VOLKMER†

Abstract. We study an expansion theorem of F. V. Atkinson and P. Binding for the right definite multiparameter eigenvalue problem

$$x_m = T_m x_m + \sum_{n=1}^{k} \lambda_n V_{mn} x_m, \qquad m = 1, \cdots, k$$

where $\lambda_1, \cdots, \lambda_k$ are real, x_m is a nonzero element of some separable Hilbert space and T_m, V_{mn} are compact symmetric. We present a new version of the theorem which is easier to use in order to prove completeness of eigenvectors under some additional assumptions. In particular, we prove completeness of eigenvectors (i) under Minkowski's definiteness condition and (ii) for arbitrary two parameter problems.

Key words. multiparameter problem, completeness of eigenfunctions, Minkowski matrices, integral equations

AMOS(MOS) subject classifications. 47A70, 45C05

1. Introduction. This paper is devoted to an open question in the theory of right definite multiparameter eigenvalue problems that is the fundamental question of the completeness of eigenvectors. We know the expansion theorem of Atkinson [1, Thms. 11.8.1, 11.10.1] which has been generalized and improved by several authors. Binding, Källström and Sleeman [5, Thm. 4.2] derived an expansion theorem under a definiteness condition weaker than that used by Atkinson. Binding [3, Thm. 4.1] gave another version of the expansion theorem for right definite problems on the basis of his oscillation theorem. However, it turns out that it is often difficult to decide on the completeness of eigenvectors by means of these expansion theorems (see [14]).

In this paper we modify known proofs of the theorem in order to obtain simpler sufficient conditions for the completeness of eigenvectors. There are two main results. In § 2 we prove the completeness of eigenvectors under Minkowski's definiteness condition. In § 3 we demonstrate the completeness of eigenvectors for the general two parameter right definite problem. Thus some progress is achieved in the question of completeness but, for instance, the question remains open for the general three parameter problem.

We now formulate the multiparameter eigenvalue problem under consideration and give a short survey on its theory. The notation and the results are mainly taken from Binding [3].

Let T_m, V_{mn} be compact symmetric operators on separable Hilbert spaces H_m for $m, n = 1, \cdots, k$. Then define the compact symmetric operators

$$W_m(\lambda) = T_m + \sum_{n=1}^{k} \lambda_n V_{mn}$$

for $m = 1, \cdots, k$, $\lambda = (\lambda_1, \cdots, \lambda_k) \in \mathbb{R}^k$ and consider the k-parameter eigenvalue problem

$$x_m = W_m(\lambda) x_m, \qquad 0 \neq x_m \in H_m, \quad m = 1, \cdots, k. \tag{1.1}$$

λ is called an eigenvalue of (1.1) if there exist nonzero vectors x_m in H_m such that $x_m = W_m(\lambda) x_m$ for all $m = 1, \cdots, k$. The tensor $x_1 \otimes \cdots \otimes x_k$ in the Hilbert space tensor

* Received by the editors July 15, 1985; accepted for publication (in revised form) December 1, 1986.

† Fachbereich 6, Mathematik, Universität, GHS Essen, Universitätsstr. 3, D-4300 Essen 1, West Germany.

product $H=H_1\otimes\cdots\otimes H_k$ is called an eigenvector of (1.1) corresponding to the eigenvalue λ. The tensor product setting is necessary in order to give any sense to the question of the completeness of the eigenvectors. The eigenvalue problem (1.1) has been studied mostly under the "right definiteness" condition

$$\text{(1.2)}\qquad \det_{1\leqq m,n\leqq k}(V_{mn}x_m, x_m)>0 \quad \text{for all } 0\neq x_m\in H_m.$$

We shall assume (1.2) throughout this paper.

In § 4, the theory of (1.1) will be applied to eigenvalue problems for integral operators

$$\text{(1.3)}\quad x_m(\xi_m)=\int_{a_m}^{b_m} t_m(\xi_m,\eta_m)x_m(\eta_m)\,d\eta_m+\sum_{n=1}^{k}\lambda_n\int_{a_m}^{b_m} v_{mn}(\xi_m,\eta_m)x_m(\eta_m)\,d\eta_m$$

where t_m and v_{mn} are real symmetric functions continuous on $[a_m, b_m]\times[a_m, b_m]$. The corresponding Hilbert spaces are

$$H_m=L^2(a_m,b_m)\quad\text{and}\quad H=H_1\otimes\cdots\otimes H_k=L^2\left(\prod_{m=1}^{k}(a_m,b_m)\right).$$

The eigenvalue problems (1.1) and (1.3) have also been discussed by Anna Pell [11] in the special case of two parameters. Pell assumes that $H_1=H_2=l^2$ and $T_1=T_2=0$. The operators V_{mn} are defined by real symmetric Hilbert-Schmidt matrices. The eigenvalue problem is assumed to be left-definite, i.e., V_{12} and $-V_{22}$ are positive definite. I intend to generalize the results of Pell in the left-definite case to more than two parameters in another paper.

The theory of (1.1) can also be applied to multiparameter problems involving unbounded operators. Let T'_m and V'_{mn} be selfadjoint operators on H_m, with V'_{mn} bounded and T'_m bounded above with compact resolvent.

Then the multiparameter eigenvalue problem

$$\text{(1.4)}\qquad T'_m x_m+\sum_{n=1}^{k}\lambda_n V'_{mn}x_m=0,\quad 0\neq x_m\in D(T'_m),\quad m=1,\cdots,k,$$

can be transformed into a problem of the form (1.1) (see [3, § 1]).

A special case of (1.4) is the k-parameter Sturm-Liouville eigenvalue problem

$$\text{(1.5)}\qquad \frac{d^2x_m}{d\xi_m^2}+q_m x_m+\sum_{n=1}^{k}\lambda_n v_{mn}x_m=0,\qquad m=1,\cdots,k,$$

with the boundary conditions

$$\alpha_{m1}x_m(a_m)+\alpha_{m2}\frac{dx_m}{d\xi_m}(a_m)=0,\qquad (0,0)\neq(\alpha_{m1},\alpha_{m2})\in\mathbb{R}^2,$$

$$\beta_{m1}x_m(b_m)+\beta_{m2}\frac{dx_m}{d\xi_m}(b_m)=0,\qquad (0,0)\neq(\beta_{m1},\beta_{m2})\in\mathbb{R}^2.$$

This problem appears when we solve boundary value problems for partial differential equations by the method of separation of variables. For example, if we consider the vibration problem of an elliptic membrane with clamped boundary then we obtain a two-parameter eigenvalue problem of the form (1.5) where the ordinary differential equations are Mathieu equations (see [10, § 4.3]).

The eigenvalue problems (1.4) and (1.5) have been investigated by many authors. Cordes [7] proved the completeness of eigenfunctions in the two-parameter case if V'_{11}, V'_{12}, $-V'_{21}$, V'_{22} are positive definite and $V'_{11}+V'_{12}=Id_1$, $-V'_{21}+V'_{22}=Id_2$ where Id_m denotes the identity operator on H_m. This result has been generalized by Volkmer [14] to more than two parameters.

Faierman [8] proved the completeness of eigenfunctions of problem (1.5) under the assumption of continuous v_{mn} satisfying

$$\det_{1\leqq m,n\leqq k} v_{mn}(\xi_m)>0 \quad \text{for all } \xi_m\in[a_m, b_m].$$

More generally, the combined results of Browne [6], Källström and Sleeman [9] and Volkmer [15] establish the completeness of eigenvectors if the eigenvalue problem (1.4) is strongly definite. By a result of Binding [2] this means that

$$(1.6) \qquad \det_{1\leqq m,n\leqq k} (V'_{mn}x_m, x_m)\geqq \varepsilon \prod_{m=1}^{k} (x_m, x_m) \quad \text{for all } x_m\in H_m.$$

It should be noted that the eigenvalue problem (1.1) cannot be strongly definite (i.e., (1.6) holds with V_{mn} in place of V'_{mn}) unless H has finite dimensions because the operators V_{mn} are compact.

The following oscillation theorem of Binding [3, Cor. 3.3] proves the existence of eigenvalues of (1.1).

THEOREM 1.1. *Let $i=(i_1,\cdots,i_k)$ be a multi-index where $1\leqq i_m\leqq \dim H_m$ for each m. Then there exists a unique eigenvalue of* (1.1), *denoted by λ^i, such that the i_mth greatest eigenvalue of $W_m(\lambda)$ is equal to* 1 *for each m. Of course, the eigenvalues of $W_m(\lambda)$ are counted according to multiplicity.*

In order to formulate the expansion theorem we need some further notation. The operator determinant Δ_0 is defined by

$$(1.7) \qquad \Delta_0=\otimes\begin{vmatrix} V_{11}\cdots V_{1k}\\ \vdots \qquad \vdots\\ V_{k1}\cdots V_{kk}\end{vmatrix}$$

where $\otimes$ indicates that the tensor product of operators is used in the expansion of the determinant. For $n=1,\cdots,k$, the operator determinant Δ_n is defined as in (1.7) with the nth column of the determinant replaced by Id_m-T_m, $m=1,\cdots,k$. Then $\Delta_0,\cdots,\Delta_k$ are bounded symmetric operators on the tensor product H. We write

$$(1.8) \qquad [z_1, z_2]=(\Delta_0 z_1, z_2)$$

for $z_1, z_2\in H$. It follows from (1.2) that the form [,] is positive semi-definite (see [1, p. 194]).

We can choose eigenvectors e^i of (1.1) corresponding to the eigenvalues λ^i such that the e^i form an orthonormal system in $(H, [\ ,\ ])$. If all the spaces H_m have finite dimensions then the completeness of the e^i follows easily from the oscillation theorem by counting the number of the indices i. This completeness result was shown earlier by Atkinson [1, Thm. 7.9.1]. If at least one of the spaces H_m has infinite dimensions then the e^i form an infinite orthonormal system in $(H, [\ ,\ ])$. The expansion theorem of Binding [3, Thm. 4.1] which is closely related to a theorem of Atkinson [1, Thm. 1.10.1] now reads as follows.

THEOREM 1.2. *Let $y=y_1\otimes\cdots\otimes y_k$ be a decomposable tensor in H and assume that*

$$(1.9) \qquad \Delta_n y\in\Delta_0(H)$$

for all $n=1,\cdots,k$. Then there holds the Parseval's equality

$$[y,y]=\sum_i |[y,e^i]|^2.$$

In general, it is difficult to check condition (1.9) which guarantees that y can be expanded in a series of eigenvectors. In the next section we shall reprove Theorem 1.2 in order to point out the modifications we need to obtain conditions which are simpler to check than (1.9).

2. Expansion theorems for k-parameter eigenvalue problems. Consider the eigenvalue problem (1.1) under the definiteness condition (1.2) and let $y=y_1\otimes\cdots\otimes y_k$ be a decomposable tensor in H. We shall discuss the question of whether y can be expanded in a series of eigenvectors of (1.1). As for the expansion theorems of Atkinson and Binding our results will be based on sequences of orthoprojectors P_m^j on H_m strongly convergent to Id_m as $j\to\infty$ for all $m=1,\cdots,k$. We choose these projectors so that the range spaces

$$H_m^j:=P_m^j(H_m)$$

have finite dimensions, contain y_m and are montone increasing

$$y_m\in H_m^1\subseteq H_m^2\subseteq H_m^3\subseteq\cdots.$$

Then we consider the approximating eigenvalue problems

$$x_m=P_m^jW_m(\lambda)x_m,\quad 0\neq x_m\in H_m^j,\quad m=1,\cdots,k. \tag{2.1}$$

We denote the eigenvalues of (2.1) by λ^{ij} according to Theorem 1.1 where

$$i\in I_j:=\{(i_1,\cdots,i_k)\colon 1\leqq i_m\leqq \dim H_m^j\}.$$

Choose corresponding unit vectors u_m^{ij} so that

$$u_m^{ij}=P_m^jW_m(\lambda^{ij})u_m^{ij}$$

and the tensors $u^{ij}=u_1^{ij}\otimes\cdots\otimes u_k^{ij}$, $i\in I_j$, form an [,]-orthogonal system of eigenvectors of (2.1).

Binding [3, Cor. 3.3] has shown that the sequences λ^{ij} converge to the unique eigenvalue λ^i of Theorem 1.1 as $j\to\infty$ and that the weak limit points of the sequences u_m^{ij} are also strong limit points and furnish corresponding eigenvectors. Therefore, by taking subsequences, we may assume that

$$\lambda^{ij}\to\lambda^i,\qquad u_m^{ij}\to u_m^i\quad\text{as } j\to\infty\quad\text{for } i\in I:=\bigcup_j I_j.$$

Condition (1.2) allows us to renormalize the eigenvectors

$$e^{ij}=u^{ij}/[u^{ij},u^{ij}]^{1/2},$$
$$e^i=u^i/[u^i,u^i]^{1/2}\quad\text{where } u^i=u_1^i\otimes\cdots\otimes u_k^i$$

so that the e^{ij} form an orthonormal basis in the finite dimensional space $(H_1^j\otimes\cdots\otimes H_k^j$, [,]) and the e^i form a possibly incomplete orthonormal system in (H, [,]). Hence there holds the expansion

$$y=\sum_{i\in I_j}\alpha^{ij}e^{ij},\qquad \alpha^{ij}=[y,e^{ij}] \tag{2.2}$$

and Parseval's equality

$$[y,y]=\sum_{i\in I_j}|\alpha^{ij}|^2 \tag{2.3}$$

for every j. We see that $\alpha^{ij} \to [y, e^i]$ as $j \to \infty$. Hence (2.3) will give the desired Parseval's equality

$$[y, y] = \sum_{i \in I} |[y, e^i]|^2 \tag{2.4}$$

provided that (empty sum $= 0$)

$$\sum_{i \in I_j \setminus I_{j_0}} |\alpha^{ij}|^2 \to 0 \quad \text{as } j_0 \to \infty \text{ uniformly in } j. \tag{2.5}$$

The next lemma yields a convenient method in order to verify this condition. We denote by Q the set of all $\lambda \in \mathbb{R}^k$ such that

$$1 = (W_m(\lambda)u_m, u_m), \qquad m = 1, \cdots, k \tag{2.6}$$

for some unit vectors u_m in H_m. Obviously, all eigenvalues λ^{ij} and λ^i belong to Q.

LEMMA 2.1. *Assume that there exists a functional $f: Q \to \mathbb{R}$ bounded from below so that*

(i) *the set*

$$\{\lambda \in Q \,|\, f(\lambda) \leqq c\}$$

is bounded for all real c and

(ii) *the sequence*

$$\sum_{i \in I_j} |\alpha^{ij}|^2 f(\lambda^{ij}), \qquad j = 1, 2, \cdots$$

is bounded.

Then (2.5) *is satisfied and hence Parseval's equality* (2.4) *holds.*

Proof. Conditions (i) and (ii) remain valid if we replace $f(\lambda)$ by $f(\lambda) + c_0$ where c_0 is a constant. Hence we may assume that $f(\lambda) \geqq 0$ on Q. It follows from (ii) that there is a real number c_1 independent of j and j_0 so that

$$0 \leqq \sum_{i \in I_j \setminus I_{j_0}} |\alpha^{ij}|^2 f(\lambda^{ij}) \leqq \sum_{i \in I_j} |\alpha^{ij}|^2 f(\lambda^{ij}) \leqq c_1.$$

We know from [3, Thm. 2.5] that the sequence $\lambda^{i(j)j}$, $j = 1, 2, 3, \cdots$, is unbounded whenever the sequence of indices $i(j)$ is unbounded. Hence (i) implies that, for any given $c > 0$, there is a j_0 such that

$$f(\lambda^{ij}) \geqq c \quad \text{if } j \geqq j_0, \qquad i \in I_j \setminus I_{j_0}.$$

It follows that

$$0 \leqq c \cdot \sum_{i \in I_j \setminus I_{j_0}} |\alpha^{ij}|^2 \leqq \sum_{i \in I_j \setminus I_{j_0}} |\alpha^{ij}|^2 f(\lambda^{ij}) \leqq c_1$$

which proves (2.5). □

If we choose

$$f(\lambda) = \lambda_1^2 + \cdots + \lambda_k^2 \tag{2.7}$$

then we obtain the following expansion theorem which slightly improves Theorem 1.2.

THEOREM 2.2. (i) *If*

$$\Delta_n y \in \Delta_0^{1/2}(H) \tag{2.8}$$

for some n, then the sequence

$$\sum_{i \in I_j} |\alpha^{ij}|^2 |\lambda_n^{ij}|^2, \qquad j = 1, 2, 3, \cdots$$

is bounded.

(ii) *Assume that* (2.8) *holds for all $1 \leqq n \leqq k$. Then Parseval's equality* (2.4) *is satisfied hence y can be expanded in a series of eigenvectors of* (1.1).

Proof. Condition (ii) is a consequence of (i) and Lemma 2.1 applied to the functional (2.7). Hence it suffices to prove (i).

Since the e^{ij}'s are eigenvectors of (2.1) we know from [1, Thm. 6.8.1] that

$$(P_1^j \otimes \cdots \otimes P_k^j)\Delta_n e^{ij} = \lambda_n^{ij}(P_1^j \otimes \cdots \otimes P_k^j)\Delta_0 e^{ij}. \tag{2.9}$$

We multiply (2.9) from the left by y and obtain

$$(\Delta_n y, e^{ij}) = \lambda_n^{ij}\alpha^{ij}$$

from (2.2) and $(P_1^j \otimes \cdots \otimes P_k^j)y = y$. Hence

$$\sum_{i \in I_j} |\alpha^{ij}|^2 |\lambda_n^{ij}|^2 = \sum_{i \in I_j} |(\Delta_n y, e^{ij})|^2. \tag{2.10}$$

By assumption, we can write $\Delta_n y = \Delta_0^{1/2} x$.

Without loss of generality, we may assume that x is orthogonal to the kernel of $\Delta_0^{1/2}$. Then there exists a sequence x^q in H such that $\Delta_0^{1/2} x^q \to x$ as $q \to \infty$. Consequently, $\Delta_0 x^q \to \Delta_0^{1/2} x = \Delta_n y$. It follows from Bessel's inequality that

$$\sum_{i \in I_j} |[x^q, e^{ij}]|^2 \leqq [x^q, x^q].$$

This inequality gives

$$\sum_{i \in I_j} |(\Delta_n y, e^{ij})|^2 \leqq (x, x) \tag{2.11}$$

as $q \to \infty$. Now (2.10) and (2.11) imply (i). □

The condition (2.8) of Theorem 2.2 is weaker than the corresponding condition (1.9) of Theorem 1.2 because the range of Δ_0 is contained in the range of $\Delta_0^{1/2}$. This weakening will be important in the next section in connection with Lemma 3.4.

However, the main idea of this paper is to replace the functional (2.7) by some other functionals.

THEOREM 2.3. *Let f be a linear functional on $\mathbb{R}^k$.*

(i) *Then condition* (ii) *of Lemma* 2.1 *is automatically satisfied.*

(ii) *If f satisfies condition* (i) *of that lemma then there exists an orthonormal basis of eigenvectors of* (1.1) *in* $(H, [\ ,\ ])$.

Proof. (i) Multiply (2.9) from the right by $e^{i_0 j}$. It follows that

$$(\Delta_n e^{ij}, e^{i_0 j}) = \lambda_n^{ij}(\Delta_0 e^{ij}, e^{i_0 j}) = \begin{cases} 0 & \text{if } i \neq i_0, \\ \lambda_n^{ij} & \text{if } i = i_0. \end{cases}$$

Now (2.2) gives

$$(\Delta_n y, y) = \sum_{i \in I_j} |\alpha^{ij}|^2 \lambda_n^{ij}.$$

Therefore, the numbers $\sum_{i \in I_j} |\alpha^{ij}|^2 f(\lambda^{ij})$ are independent of j and hence bounded.

(ii) Since f is linear and satisfies (i) of Lemma 2.1, it follows that f is bounded from below on Q. Therefore, we can use Lemma 2.1 to prove Parseval's equality (2.4) for the given decomposable tensor y. Now the decomposable tensors form a total subset of H, i.e., their linear hull is dense in H. Since y can be chosen arbitrarily in this total subset of H we see that (2.4) holds for all y in H and every choice of the $[\ ,\ ]$-orthonormal system e^i $(i \in I)$ of eigenvectors of (1.1). This proves the theorem. □

Let us apply this theorem to an eigenvalue problem (1.1) which satisfies Minkowski's definiteness condition, i.e.,

(i) V_{mn} is negative definite for all $m \neq n$, and

(ii) $\sum_{n=1}^{k} V_{mn}$ is positive definite for all m.

This condition has been introduced in multiparameter theory by Binding and Browne [4]. They showed that, under Minkowski's condition, the operator determinant Δ_0 and all the cofactors Δ_{omn} of V_{mn} in the expansion of Δ_0 are positive definite. These results and Theorem 2.3 lead to the following theorem.

THEOREM 2.4. *If the eigenvalue problem* (1.1) *satisfies Minkowski's definiteness condition then there exists an orthonormal basis of eigenvectors of* (1.1) *in* $(H, [\ ,\ ])$.

Proof. Let $\lambda \in Q$. Then Cramer's rule applied to the linear system (2.6) yields

$$\lambda_n = \frac{(\Delta_n u, u)}{(\Delta_0 u, u)}, \qquad n = 1, \cdots, k \tag{2.12}$$

where $u = u_1 \otimes \cdots \otimes u_k$. In addition to the hypothesis of the theorem let us assume that $Id_m - T_m$ is positive semi-definite for all m. Then

$$\Delta_n = \sum_{m=1}^{k} (Id_m - T_m) \otimes \Delta_{omn}$$

shows that $(\Delta_n u, u)$ is nonnegative for all n. Hence, by (2.12), $Q \subseteq [0, \infty[^k$ and, therefore, condition (i) of Lemma 2.1 is satisfied if we choose $f(\lambda) = \sum_{n=1}^{k} \lambda_n$. By Theorem 2.3(ii), this completes the proof under our additional assumption. If the operator T_m has eigenvalues greater than 1 for some m then we apply the following simple lemma to transform the eigenvalue problem in such a way that our additional assumption is satisfied. □

LEMMA 2.5. *There exists a translation* $\lambda = \hat{\lambda} + \mu$ *in the parameter space* $\mathbb{R}^k$ *which transforms* (1.1) *into*

$$x_m = \hat{T}_m x_m + \sum_{n=1}^{k} \hat{\lambda}_n V_{mn} x_m, \qquad m = 1, \cdots, k$$

such that all eigenvalues of $\hat{T}_m$ *are smaller than* 1.

Proof. Let μ be the eigenvalue of the problem

$$x_m = 2 W_m(\lambda) x_m, \quad 0 \neq x_m \in H_m, \quad m = 1, \cdots, k$$

corresponding to the multiindex $i = (1, \cdots, 1)$. Then the greatest eigenvalue of $2 W_m(\mu)$ is equal to one. Hence the greatest eigenvalue of $W_m(\mu) = \hat{T}_m$ is equal to $\frac{1}{2}$. □

3. Two-parameter eigenvalue problems. In this section we want to prove the completeness of eigenvectors for the eigenvalue problem (1.1) in the special case of two parameters

$$\begin{aligned} x_1 &= T_1 x_1 + \lambda_1 V_{11} x_1 + \lambda_2 V_{12} x_1, \qquad 0 \neq x_1 \in H_1, \\ x_2 &= T_2 x_2 + \lambda_1 V_{21} x_1 + \lambda_2 V_{22} x_2, \qquad 0 \neq x_2 \in H_2, \end{aligned} \tag{3.1}$$

under the definiteness condition

$$\begin{vmatrix} (V_{11} x_1, x_1) & (V_{12} x_1, x_1) \\ (V_{21} x_2, x_2) & (V_{22} x_2, x_2) \end{vmatrix} > 0 \quad \text{for all } 0 \neq x_1 \in H_1, 0 \neq x_2 \in H_2. \tag{3.2}$$

As a first step we reduce (3.1) to an appropriate canonical form by an affine transformation of the eigenvalues

$$\lambda_1 = \gamma_{10} + \gamma_{11} \hat{\lambda}_1 + \gamma_{12} \hat{\lambda}_2, \qquad \lambda_2 = \gamma_{20} + \gamma_{21} \hat{\lambda}_1 + \gamma_{22} \hat{\lambda}_2 \tag{3.3}$$

where

$$\gamma_{11}\gamma_{22}-\gamma_{12}\gamma_{21}=1. \tag{3.4}$$

Such a transformation takes (3.1) into

$$x_1=\hat{T}_1x_1+\hat{\lambda}\hat{V}_{11}x_1+\hat{\lambda}_2\hat{V}_{12}x_1, \qquad x_2=\hat{T}_2x_2+\hat{\lambda}_1\hat{V}_{21}x_2+\hat{\lambda}_2\hat{V}_{22}x_2, \tag{3.5}$$

where

$$\hat{T}_m:=T_m+\gamma_{10}V_{m1}+\gamma_{20}V_{m2} \qquad \hat{V}_{mn}:=\gamma_{1n}V_{m1}+\gamma_{2n}V_{m2}.$$

It follows from (3.4) that the operator determinant $\hat{\Delta}_0$ for (3.5) is equal to Δ_0:

$$\begin{aligned}\hat{\Delta}_0&=\hat{V}_{11}\otimes\hat{V}_{22}-\hat{V}_{12}\otimes\hat{V}_{21}\\&=(\gamma_{11}V_{11}+\gamma_{21}V_{12})\otimes(\gamma_{12}V_{21}+\gamma_{22}V_{22})\\&\qquad-(\gamma_{12}V_{11}+\gamma_{22}V_{12})\otimes(\gamma_{11}V_{21}+\gamma_{21}V_{22})\\&=(\gamma_{11}\gamma_{22}-\gamma_{12}\gamma_{21})(V_{11}\otimes V_{22}-V_{12}\otimes V_{21})\\&=\Delta_0.\end{aligned}$$

Moreover, (3.1) and (3.5) have the same eigenvectors. Hence it will be sufficient to prove the completeness of eigenvectors for (3.5). The reduction to canonical form will be achieved by the next lemma.

LEMMA 3.1. *There exists an affine transformation* (3.3), (3.4) *such that the transformed eigenvalue problem* (3.5) *satisfies* (i) *and* (ii).

(i) *There holds one of the following six sets of sign conditions*:

(1) $\hat{V}_{11}>0,\quad \hat{V}_{21}=0,\quad \hat{V}_{22}>0$;

(2) $\hat{V}_{11}=0,\quad \hat{V}_{21}<0,\quad \hat{V}_{12}>0$;

(3) $\hat{V}_{11}>0,\quad \hat{V}_{21}\leqq 0,\quad \hat{V}_{12}\geqq 0,\quad \hat{V}_{22}>0$;

(4) $\hat{V}_{11}\geqq 0,\quad \hat{V}_{21}<0,\quad \hat{V}_{12}>0,\quad \hat{V}_{22}\geqq 0$;

(5) $\hat{V}_{11}>0,\quad \hat{V}_{21}\leqq 0,\quad \hat{V}_{12}>0,\quad \hat{V}_{22}\geqq 0,\quad -\hat{V}_{21}+\hat{V}_{22}>0$;

(6) $\hat{V}_{11}\geqq 0,\quad \hat{V}_{21}<0,\quad \hat{V}_{12}\geqq 0,\quad \hat{V}_{22}>0,\quad \hat{V}_{11}+\hat{V}_{12}>0$.

(ii) $\hat{\Delta}_2=\hat{V}_{11}\otimes(Id_2-\hat{T}_2)-(Id_1-\hat{T}_1)\otimes\hat{V}_{21}$ *is positive definite.*

Proof. First we construct $\gamma_{11},\gamma_{21},\gamma_{12},\gamma_{22}$ such that (i) holds. By [1, Thm. 9.2.2] there exist nonzero $\alpha=(\alpha_1,\alpha_2)$, $\beta=(\beta_1,\beta_2)\in\mathbb{R}^2$ such that

$$\begin{aligned}\alpha_1V_{11}+\alpha_2V_{12}&\geqq 0, \qquad &\beta_1V_{11}+\beta_2V_{12}&\geqq 0,\\ \alpha_1V_{21}+\alpha_2V_{22}&\leqq 0, \qquad &\beta_1V_{21}+\beta_2V_{22}&\geqq 0.\end{aligned}$$

Suppose that $\alpha=\mu\beta$ for some real μ. Then

$$\begin{aligned}\alpha_1V_{11}+\alpha_2V_{12}&=\beta_1V_{11}+\beta_2V_{12}=0\quad\text{if } \mu<0,\\ \alpha_1V_{21}+\alpha_2V_{22}&=\beta_1V_{21}+\beta_2V_{22}=0\quad\text{if } \mu>0.\end{aligned}$$

Set $\gamma_{11}=\alpha_1$, $\gamma_{21}=\alpha_2$ and choose γ_{21}, γ_{22} such that (3.4) holds. If $\mu>0$ then it follows that $\hat{V}_{11}\geqq 0$ and $\hat{V}_{21}=0$. Hence $\Delta_0=\hat{\Delta}_0=\hat{V}_{11}\otimes\hat{V}_{22}$ and (3.2) yield $\hat{V}_{11}>0$ and $\hat{V}_{22}>0$. Therefore, (i) (1) is satisfied. Similarly, if $\mu<0$ then (i) (2) holds.

Now suppose that α,β are linearly independent. Then we set $\gamma_{11}=\alpha_1$, $\gamma_{21}=\alpha_2$, $\gamma_{12}=\beta_1$, $\gamma_{22}=\beta_2$ where we may assume (3.4). We obtain

$$\hat{V}_{11}\geqq 0,\quad \hat{V}_{21}\leqq 0,\quad \hat{V}_{12}\geqq 0,\quad \hat{V}_{22}\geqq 0.$$

Since $(\hat{V}_{11}x_1, x_1)(\hat{V}_{22}x_2, x_2) - (\hat{V}_{12}x_1, x_1)(\hat{V}_{21}x_2, x_2) > 0$ for every $0 \neq x_1 \in H_1$, $0 \neq x_2 \in H_2$, we conclude that

$$\hat{V}_{11} > 0 \quad \text{or} \quad \hat{V}_{21} < 0$$

and

$$\hat{V}_{12} > 0 \quad \text{or} \quad \hat{V}_{22} > 0.$$

Further, we see that

$$\hat{V}_{11} + \hat{V}_{12} > 0 \quad \text{and} \quad -\hat{V}_{21} + \hat{V}_{22} > 0.$$

Hence, there holds one of the last four sets of sign conditions.

Now we construct γ_{10}, γ_{20} such that (ii) holds. By Lemma 2.5, we can choose γ_{10} and γ_{20} such that $Id_1 - \hat{T}_1 > 0$ and $Id_2 - \hat{T}_2 > 0$. By (i), we know that $\hat{V}_{11} \geqq 0$ and $\hat{V}_{21} \leqq 0$ where at least one of these two operators is definite.

Now we use the easily established facts that

$$A_1 \geqq 0, \quad A_2 \geqq 0 \quad \text{imply } A_1 \otimes A_2 \geqq 0$$

and

$$A_1 > 0, \quad A_2 > 0 \quad \text{imply } A_1 \otimes A_2 > 0$$

whenever A_m are bounded symmetric operators on H_m. Hence $\hat{V}_{11} \otimes (Id_2 - \hat{T}_2) \geqq 0$, $-(Id_1 - \hat{T}_1) \otimes \hat{V}_{21} \geqq 0$ and one of these operators is positive definite. Therefore, (ii) is true. □

The following definiteness result shows that, for $k = 2$, the form (1.5) is not only positive semi-definite but positive definite on H. Hence $(H, [\ ,\ ])$ is a pre-Hilbert space under the assumptions of this section. A similar result for general k greater than two is not known.

THEOREM 3.2. *Condition* (3.2) *implies that* Δ_0 *is positive definite on* H.

Proof. We may assume that (3.1) is already reduced to one of the six canonical forms of Lemma 3.1. In case (1) we have $\Delta_0 = V_{11} \otimes V_{22}$ and V_{11} and V_{22} are positive definite. Hence Δ_0 is positive definite. Case (2) is similar. If (3) holds then $\Delta_0 \geqq V_{11} \otimes V_{22} > 0$. Case (4) is similar. Suppose that (5) holds. Since $\Delta_0 \geqq 0$ it suffices to show that $(\Delta_0 z, z) = 0$ implies $z = 0$. Hence assume that $(\Delta_0 z, z) = 0$ for some $z \in H$. Then

$$(V_{11} \otimes V_{22} z, z) = (V_{12} \otimes V_{21} z, z) = 0,$$

consequently $V_{11} \otimes V_{22} z = V_{12} \otimes V_{21} z = 0$.

Since $(V_{11} \otimes Id_2)(Id_1 \otimes V_{22}) z = V_{11} \otimes V_{22} z$ and $V_{11} > 0$ it follows that $Id_1 \otimes V_{22} z = 0$. Similarly, $Id_1 \otimes V_{21} z = 0$. By assumption, $-V_{21} + V_{22} > 0$, hence $Id_1 \otimes (-V_{21} + V_{22}) z = 0$ implies $z = 0$. Finally, case (6) is similar to case (5). □

We need some further lemmas.

LEMMA 3.3. *Let T and V be compact symmetric operators on a separable Hilbert space H. Let V be positive definite. Then there is a sequence of eigenpairs (λ^p, x^p) of the eigenvalue problem*

$$x = Tx + \lambda Vx, \qquad 0 \neq x \in H \tag{3.6}$$

such that x^p is total in H.

Proof. By Lemma 2.5, we may assume, without loss of generality, that $Id - T$ is boundedly invertible. By Theorem 2.4 with $k = 1$, there exists a sequence of eigenpairs (λ^p, x^p) of (3.6) such that x^p forms an orthonormal basis in the pre-Hilbert space $(H, [\ ,\ ])$ where $[x, y] = (Vx, y)$ and $(\ ,\ )$ denotes the original inner product in H. The sequence x^p is total in $(H, [\ ,\ ])$ and it remains to show that x^p is total in H, also. Since x^p is total in $(H, [\ ,\ ])$ and $V^{1/2}$ is an isometry from $(H, [\ ,\ ])$ onto $(V^{1/2}(H), (\ ,\ ))$ the sequence $V^{1/2}x^p$ is total in $(V^{1/2}(H), (\ ,\ ))$. Now, $V^{1/2}$ is continuous on H and hence $Vx^p = V^{1/2}(V^{1/2}x^p)$ is total in $(V(H), (\ ,\ ))$. It follows that Vx^p is total in H because the range $V(H)$ of the positive definite operator V is dense in H. By assumption, the operator $Id - T$ is boundedly invertible, in particular, the eigenvalues λ^p are different from zero. It follows that $x^p = \lambda^p(Id - T)^{-1}Vx^p$ is total in H. □

LEMMA 3.4. *Let A and B be bounded symmetric operators on a Hilbert space H such that $0 \leqq A \leqq B$. Then the range of A is contained in the range of the square root $B^{1/2}$ of B.*

For the proof see [12, Hilfssatz 8].

LEMMA 3.5. *Assume that the eigenvalue problem* (3.1) *has the canonical form described in Lemma* 3.1.

Then there is a total subset of decomposable tensors $y_1 \otimes y_2$ in H which satisfy

$$\Delta_1(y_1 \otimes y_2) \in \Delta_0^{1/2}(H). \tag{3.7}$$

Proof. We give the proof in the cases (1), (3) and (5). In the other three cases the proof is similar and will be omitted. Under our assumptions, the operator $-V_{21} + V_{22}$ is positive definite. Hence, by Lemma 3.3, there are sequences λ_2^p and x_2^p such that

$$x_2^p = T_2x_2^p + \lambda_2^p(-V_{21} + V_{22})x_2^p \tag{3.8}$$

and the x_2^p are total in H_2. Now consider the one-parameter eigenvalue problem

$$x_1 = (T_1 + \lambda_2^p V_{12})x_1 + \lambda_1 V_{11}x_1$$

where p is fixed. Since V_{11} is positive definite we can apply Lemma 3.3 to this problem. We obtain sequences λ_1^{pq} and x_1^{pq} such that

$$x_1^{pq} = (T_1 + \lambda_2^p V_{12})x_1^{pq} + \lambda_1^{pq} V_{11}x_1^{pq} \tag{3.9}$$

and the vectors x_1^{pq}, $q = 1, 2, \cdots$, are total in H_1 for every p. Now (3.8), (3.9) and

$$\Delta_1 = (Id_1 - T_1) \otimes V_{22} - V_{12} \otimes (Id_2 - T_2)$$

give

$$\begin{aligned}\Delta_1(x_1^{pq} \otimes x_2^p) &= \lambda_1^{pq} V_{11}x_1^{pq} \otimes V_{22}x_2^p + \lambda_2^p V_{12}x_1^{pq} \otimes V_{21}x_2^p \\ &\in (V_{11} \otimes V_{22})(H) + (V_{12} \otimes V_{21})(H).\end{aligned}$$

Since $0 \leqq V_{11} \otimes V_{22} \leqq \Delta_0$ and $0 \leqq -V_{12} \otimes V_{21} \leqq \Delta_0$ it follows from Lemma 3.4 that

$$(V_{11} \otimes V_{22})(H) \subseteq \Delta_0^{1/2}(H), \qquad (V_{12} \otimes V_{21})(H) \subseteq \Delta_0^{1/2}(H).$$

This proves that $\Delta_1(x_1^{pq} \otimes x_2^p)$ is in the range of $\Delta_0^{1/2}$ for all p and q. Since x_2^p, $p = 1, 2, \cdots$, is total in H_2 and x_1^{pq}, $q = 1, 2, \cdots$, is total in H_1 for every p the set of tensors $x_1^{pq} \otimes x_2^p$, $p, q = 1, 2, \cdots$, is total in $H = H_1 \otimes H_2$. The proof of the last statement is easy and similar to the proof of [13, Thm. 2.3]. This completes the proof. □

Now we are in a position to prove the main result of this section.

THEOREM 3.6. *There exists an orthonormal basis in the pre-Hilbert-space $(H_1 \otimes H_2, [\ ,\ ])$ consisting of eigenvectors of the two-parameter problem* (3.1) *provided the definiteness condition* (3.2) *holds.*

Proof. Without loss of generality, we shall assume that (3.1) is reduced to one of the six canonical forms of Lemma 3.1. Let $y_1 \otimes y_2$ be a tensor in H which satisfies

(3.7). Now we choose sequences of orthoprojectors P_m^j as at the beginning of the second section. Then we apply Lemma 2.1 to the functional

$$f(\lambda)=\lambda_1^2+\lambda_2. \tag{3.10}$$

Since $\Delta_2>0$ it follows from (2.12) that $\lambda_2>0$ whenever $(\lambda_1,\lambda_2)\in Q$. Hence the functional (3.10) satisfies (i) of Lemma 2.1. Now Theorem 2.3 (i) shows that the sequence

$$\sum_{i\in I_j}|\alpha^{ij}|^2\lambda_2^{ij},\qquad j=1,2,3,\cdots$$

is bounded. Theorem 2.2 (i) and (3.7) show that

$$\sum_{i\in I_j}|\alpha^{ij}|^2|\lambda_1^{ij}|^2,\qquad j=1,2,3,\cdots$$

is bounded. Hence the hypothesis of Lemma 2.1 is satisfied and, therefore, Parseval's equality (2.4) holds for the given $y_1\otimes y_2$. This completes the proof because the set of these $y_1\otimes y_2$ is total in H by Lemma 3.5. □

4. An expansion theorem for k-parameter integral equations. In this section we consider the eigenvalue problem (1.3) under the assumption of right definiteness (1.2). The operator determinant Δ_0 is now an integral operator

$$(\Delta_0x)(\xi)=\int_\pi d_0(\xi,\eta)x(\eta)\,d\eta \tag{4.1}$$

where $\xi=(\xi_1,\cdots,\xi_k)$, $\eta=(\eta_1,\cdots,\eta_k)\in\pi=\prod_{m=1}^k[a_m,b_m]$ and

$$d_0(\xi,\eta)=\det_{1\leqq m,n\leqq k}v_{mn}(\xi_m,\eta_m).$$

The sesquilinear form

$$[x,y]=\int_\pi\int_\pi d_0(\xi,\eta)x(\eta)\overline{y(\xi)}\,d\xi\,d\eta \tag{4.2}$$

is positive semidefinite on $L^2(\pi)$. Therefore, there holds Bessel's inequality

$$\sum_p|[x^p,y]|^2\leqq[y,y] \tag{4.3}$$

for every $y\in L^2(\pi)$ and every finite system x^p which is orthonormal with respect to [,].

Now we fix a point $\tilde{\xi}$ in π and choose a sequence $y^1,y^2,\cdots$ of continuous nonnegative functions on π such that

$$\int_\pi y^q(\eta)\,d\eta=1\quad\text{and}\quad y^q(\xi)=0\quad\text{if }\|\xi-\tilde{\xi}\|\geqq\frac{1}{q}$$

where $\|\ \|$ denotes Euclidean norm. Then the representations (4.1) and (4.2) and some elementary analysis show that

$$[x,y^q]\to(\Delta_0x)(\tilde{\xi})\quad\text{for }x\in L^2(\pi),$$
$$[y^q,y^q]\to d_0(\tilde{\xi},\tilde{\xi}),$$

as $q\to\infty$. We substitute y^q for y in (4.3) and let $q\to\infty$. Then we obtain

$$\sum_p|(\Delta_0x^p)(\tilde{\xi})|^2\leqq d_0(\tilde{\xi},\tilde{\xi}). \tag{4.4}$$

This inequality can be used to prove the following expansion theorem.

THEOREM 4.1. *Let e^i, $i \in I$, be a system of eigenfunctions of* (1.3) *corresponding to the eigenvalues λ^i such that e^i is orthonormal with respect to $[\ ,\ ]$. Assume that the function y in $L^2(\pi)$ can be expanded in a Fourier series*

$$y = \sum_{i \in I} [y, e^i] e^i. \tag{4.5}$$

Then the expansion

$$\Delta_0 y = \sum_{i \in I} [y, e^i] \Delta_0 e^i \tag{4.6}$$

holds where the series converges absolutely and uniformly on π.

Proof. The Cauchy-Schwarz inequality and (4.4) show that

$$\left(\sum_{i \in J} |[y, e^i](\Delta_0 e^i)(\xi)| \right)^2 \leqq d_0(\xi, \xi) \sum_{i \in J} |[y, e^i]|^2 \tag{4.7}$$

for every finite subset J of I and every ξ in π. Now d_0 is bounded on π and $\sum_{i \in I} |[y, e^i]|^2 < \infty$ by Bessel's inequality. Hence it follows from (4.7) that, for every positive ε, there is a finite subset K of I such that

$$\sum_{i \in J} |[y, e^i](\Delta_0 e^i)(\xi)| \leqq \varepsilon$$

for every ξ in π and every finite subset J of I disjoint from K. This means that the series in (4.6) is absolutely and uniformly convergent. It is clear from (4.5) that the uniform limit of this series is $\Delta_0 y$. □

By Theorem 2.4 and Theorem 3.6 the condition (4.5) is satisfied for all y in $L^2(\pi)$ provided that Minkowski's definiteness condition holds or that $k = 2$.

We remark that Pell [11, Thm. 4] proved a theorem similar to Theorem 4.1 for a left-definite two-parameter integral equation.

A PERIODIC WAVE AND ITS STABILITY TO A CIRCULAR CHAIN OF WEAKLY COUPLED OSCILLATORS*

YOSHIHISA MORITA†

Abstract. A circular chain of weakly coupled oscillators with nearest neighbor and isotropic coupling is considered. The identical oscillator is represented by an ordinary differential equation which has a stable limit cycle bifurcating from a steady state. This equation of coupled oscillators has two parameter and a high degenerate singularity for a parameter value. Studying a bifurcation problem around the singularity shows that periodic traveling wave solutions, together with a homogeneous periodic one, bifurcate from the steady state for suitable parameter values. Furthermore, in a certain parameter region, a classification of stability for those solutions is presented. These results can also be extended to a class of retarded functional differential equations.

Key words. periodic wave, weakly coupled oscillators, bifurcation, center manifold, linearized stability

AMS(MOS) subject classifications. 34C15, 34C25, 34D05, 34K15

1. Introduction. We are able to observe a variety of oscillatory phenomena in models of coupled oscillators arising in the fields of biology, biochemical, electric circuits, etc. For instance, synchronization (or entrainment), phase-locking, periodic wave, chaos and so forth are found in many works including [3], [10], [11], [15]-[19].

In this paper, as a model of coupled oscillators, we shall study a circular chain of n weakly coupled equation which is represented by

$$(1.1)\qquad \begin{aligned}&\frac{d}{dt}u_k(t)=F(\mu,u_k)+\nu\{N(u_{k-1}-u_k)+N(u_{k+1}-u_k)\},\qquad k=0,1,\cdots,n-1,\\ &u_{-1}=u_{n-1},\qquad u_n=u_0\end{aligned}$$

where $u_k\in\mathbf{R}^m(m\geqq 2)$, ν is nonnegative parameter. We assume that $F:I_0\times\mathbf{R}^m\to\mathbf{R}^m$($I_0$: an interval containing the origin) and $N:\mathbf{R}^m\to\mathbf{R}^m$ are sufficiently smooth mappings satisfying $F(\mu,0)=0$ and $N(0)=0$, respectively. The coupling of (1.1) is nearest neighbor and isotropic. Moreover it is assumed that in the absence of the coupling each component of (1.1), that is,

$$(1.2)\qquad \frac{d}{dt}u(t)=F(\mu,u(t)),$$

represents an oscillator; more precisely we assume that there exists a family of periodic solutions for small $\mu>0$, such that they bifurcate from the steady state, $u=0$, at $\mu=0$. This bifurcation (called Hopf bifurcation) occurs under the condition that the linearized equation of (1.2) around $u=0$ has a pair of simple conjugate eigenvalues, $\lambda_0(\mu)$ and $\overline{\lambda_0(\mu)}$, satisfying $\lambda_0(0)=i\omega_0$ and $\operatorname{Re}(d\lambda_0/d\mu)(0)>0$.

Here we shall approach (1.1) along the lines of studying a bifurcation problem associated with (1.1) under the above conditions. We first see that at $(\mu,\nu)=(0,0)$ the equation (1.1) has high degenerate singularity, that is, the linearized equation around $u_k=0$, $k=0,\cdots,n-1$, has a pair of conjugate pure imaginary eigenvalues, $\pm i\omega_0$, with multiplicity n. A structure of bifurcation around such a singularity may be complicated and it is not easy to make clear the complete bifurcation picture. Therefore, in this

† Research Institute for Mathematical Sciences, Kyoto University, Kitashirakawa, Sakyo-Ku, Kyoto 606, Japan.

article, as the first step of the investigation, we shall study the primary bifurcation from the steady state and the stability of the bifurcating solution in a neighborhood of $(\mu, \nu) = (0, 0)$.

It is clear that for any ν and small $\mu > 0$ (1.1) has a homogeneous (or synchronized) periodic solution whose components are given by the periodic solution of (1.2). Moreover we will show the existence of open $n-1$ periodic solutions bifurcating from the steady state. Those $n-1$ periodic solutions, $\mathbf{u}^l = (u_0^l, \cdots, u_{n-1}^l)$, $l = 1, \cdots, n-1$, can be expressed as follows:

$$(1.3) \qquad u_k^l(t) = \phi^l\left(t + lT^l \cdot \frac{k}{n}\right), \qquad k = 0, \cdots, n-1$$

where $\phi^l(t)$ is a periodic function with period T^l, and satisfies $\phi^{n-l}(t) = \phi^l(t)$. This expression is due to symmetry associated with (1.1), that is, covariance of the vector field of (1.1) with respect to the transformations $u_k \to u_{k+1} (k = 0, \cdots, n-1)$ and $u_k \to u_{n-k} (k = 0, \cdots, n-1)$; for the details see §§ 3 and 4. By (1.3) we have

$$(1.4) \qquad u_{k+1}^l(t) = u_k^l\left(t + \frac{lT^l}{n}\right), \quad u_{k+1}^{n-l}(t) = u_k^{n-l}\left(t - \frac{lT^l}{n}\right), \quad k = 0, \cdots, n-1,$$

so these solutions are called periodic (traveling) wave solutions to (1.1). Note that the homogeneous periodic solution satisfies (1.3) (or (1.4)) for $l = 0$; we may call it a solution of (1.3) for $l = 0$.

Next we shall state the stability of the above solutions. Let us consider the situation that all the periodic wave solutions are unstable sufficiently near the corresponding bifurcation points except for the homogeneous one. This implies that for fixed $\nu > 0$, in μ increasing, the first bifurcation from the steady state occurs for the homogeneous solution (at $\mu = 0$). Then there are two typical cases classifying the stability of the solution in a domain of (μ, ν) satisfying $\nu/\mu \ll 1$. One case is that the solutions of (1.3) for l and $n-l, 0 \leqq l \leqq n/4$ (resp. $n/4 < l \leqq n/2$) are unstable (resp. stable) in the domain. The other is that those for l and $n-l, 0 \leqq l < n/4$ (resp. $n/4 \leqq l \leqq n/2$) are stable (resp. unstable) (see Theorem 5.2 in § 5). Hence we can see the stability change of periodic waves. In fact, as we vary μ or ν, we might observe several (or a few) times of secondary bifurcation along each branch of the periodic solution. In spite of the complex feature of bifurcation, as mentioned above, we can classify the stability of the primary bifurcating periodic solutions in the domain satisfying $\nu/\mu \ll 1$.

Our program to obtain these results is along the following lines. In § 2 we reduce the equation (1.1) on a center manifold constructed around the singularity of $(\mu, \nu, \mathbf{u}) = (0, 0, \mathbf{0})$, and then we transform this equation into a simpler one (called the reduced equation) by a nonlinear transformation. Considering the symmetry of this equation, we can obtain the periodic solutions satisfying (1.3) by the standard Lyapunov-Schmidt method (see § 4). In § 5 we shall discuss the linearized stability of (1.3). By virtue of the reduced equation, it is possible to do this. The reader will see an application to a specific equation in § 6. As a further application, we can extend our results to some class of retarded functional differential equations, which is described in § 7.

We remark that several kinds of coupled oscillators involve abundant phenomena as first described, while there are many unsolved mathematical problems. For the equation (1.1) a further step in its study is expected in the future.

We also find in [3], [15], [17], [18] that another approach to a class of the equation (1.1) is possible by investigating an equation on an invariant n-dimensional torus associated with the original one. This method has an advantage in that we can apply a large amplitude periodic solution of (1.2) to (1.1), while difficulty for an analytic expression of the periodic solution restricts its application to specific examples. Moreover it is difficult to apply it to the retarded functional differential equation as in § 7. (We also refer to [4] as a related work.)

This study was motivated by the book [11]. The reduced equation (4.19) in § 4 is proposed as a discrete space version of the Ginzburg–Landau equation which is obtained by a formal perturbation method in the book.

2. The reduced equation on a center manifold. Let $A(\mu)\equiv(\partial F/\partial u)(\mu,0)$ and $D\equiv(dN/du)(0)$. As described in § 1, we assume that $A(\mu)$ has a pair of simple eigenvalues, $\lambda_0(\mu)$ and $\overline{\lambda_0(\mu)}$, satisfying $\lambda_0(0)=i\omega_0$ and that all the remaining eigenvalues have negative real parts for $\mu=0$. We denote an eigenvector of $A(\mu)$ (resp. ${}^tA(\mu)$) corresponding to $\lambda_0(\mu)$ (resp. $\overline{\lambda_0(\mu)}$) by $\zeta_0(\mu)$ (resp. $\zeta_0^*(\mu)$), where ${}^tA(\mu)$ is the transpose of $A(\mu)$. Let $(\cdot,\cdot)$ be the hermite product in $\mathbf{C}^m$. We simply write $\zeta_0\equiv\zeta_0(0)$ and $\zeta_0^*\equiv\zeta_0^*(0)$; moreover we may assume that $(\zeta_0,\zeta_0^*)=1$ by normalizing it.

The equation (1.1) can be written as follows:

$$\begin{aligned}&\dot u_k=A(0)u_k+G(\mu,u_k)+\nu\tilde N_k(\mathbf{u}),\qquad k=0,1,\cdots,n-1,\\ &\dot\mu=0,\\ &\dot\nu=0\end{aligned}\tag{2.1}$$

where $\cdot$ denotes d/dt, and

$$\begin{aligned}&G(\mu,u)\equiv F(\mu,u)-A(0)u,\\ &\tilde N_k(\mathbf{u})\equiv N(u_{k-1}-u_k)+N(u_{k+1}-u_k),\qquad k=0,\cdots,n-1.\end{aligned}\tag{2.2}$$

Note that $(\partial/\partial u)G(0,0)=0$ and $(\partial^j/\partial\mu^j)G(\mu,0)=0, j=1,2,\cdots$. It is always understood that $u_{-1}=u_{n-1}$ and $u_n=u_0$, even if they are not written explicitly.

Using the projections, P and Q, defined by

$$u_k^P=Pu_k\equiv(u_k,\zeta_0^*)\zeta_0+(u_k,\bar\zeta_0^*)\bar\zeta_0,\qquad u_k^Q=Qu_k\equiv u-u_k^P,$$

we have the decomposition of (2.1) as follows:

$$\begin{aligned}&\dot u_k^P=A(0)u_k^P+PG(\mu,u_k^P+u_k^Q)+\nu P\tilde N_k(\mathbf{u}^P+\mathbf{u}^Q),\\ &\dot\mu=0,\\ &\dot\nu=0,\end{aligned}\tag{2.3a}$$

$$\dot u_k^Q=A(0)u_k^Q+QG(\mu,u_k^P+u_k^Q)+\nu Q\tilde N_k(\mathbf{u}^P+\mathbf{u}^Q)\tag{2.3b}$$

where

$$\mathbf{u}^P\equiv\begin{pmatrix}u_0^P\\ \vdots\\ u_{n-1}^P\end{pmatrix},\qquad \mathbf{u}^Q\equiv\mathbf{u}-\mathbf{u}^P.$$

All the eigenvalues of the linear part of (2.3a) (resp. (2.3b)) have zero real parts (resp. negative real parts) by the above assumption. Therefore we easily see that the center manifold theorem can apply to (2.3) (refer to [1]). This theorem implies that there exists a local invariant manifold in a neighborhood of $(\mu,\nu,\mathbf{u})=(0,0,\mathbf{0})$, and it is tangent to the space of $(\mu,\nu,\mathbf{u}^P)=(0,0,\mathbf{0})$. Moreover we see from the attractivity of the center manifold that asymptotic behaviors of all solutions of (2.3) with small amplitudes are determined by an equation which is reduced on this manifold.

Now we adopt complex variables, $z_k=(u_k, \zeta_0^*)$, $k=0, 1, \cdots, n-1$ (or $\mathbf{z}={}^t(z_0, \cdots, z_{n-1})$). Then the center manifold is represented by a sufficiently smooth mapping, $u_k^Q=h_k(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}})$, $k=0, \cdots, n-1$, defined in a neighborhood of $(\mu, \nu, \mathbf{z})=(0, 0, \mathbf{0})$, and the equation on the manifold is given by

$$\begin{aligned}\dot z_k &= i\omega_0 z_k+(G(\mu, z_k\zeta_0+\overline{z_k\zeta_0}+h_k(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}})), \zeta_0^*)\\ &\quad+\nu(\tilde N_k(\mathbf{z}\zeta_0+\overline{\mathbf{z}\zeta_0}+\mathbf{h}(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}})), \zeta_0^*),\\ z_{-1}&=z_{n-1}, \qquad z_n=z_0\end{aligned} \tag{2.4}$$

where $\mathbf{h}(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}})={}^t(h_0(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}}), \cdots, h_{n-1}(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}}))$ and $\mathbf{z}\zeta_0$ denotes ${}^t(z_0\zeta_0, \cdots, z_{n-1}\zeta_0)$. We note that $\overline{h_k(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}})}=h_k(\mu, \nu, \bar{\mathbf{z}}, \mathbf{z})$, $h_{-1}(\cdot)=h_{n-1}(\cdot)$, $h_n(\cdot)=h_0(\cdot)$ and $h_k(0, 0, \mathbf{0}, \mathbf{0})=0$; moreover the first derivatives, together with $(\partial^j/\partial^{j_1}\mu\partial^{j_2}\nu)h_k, j=j_1+j_2\geqq 1$, vanish for $(\mu, \nu, \mathbf{z})=(0, 0, \mathbf{0})$.

We let

$$C_1\equiv(D\zeta_0, \zeta_0^*), \qquad C_2\equiv(D\bar\zeta_0, \zeta_0^*), \tag{2.5}$$

and we can define

$$h(\mu, z_k, \bar z_k)\equiv h_k(\mu, 0, \mathbf{z}, \bar{\mathbf{z}}) \tag{2.6}$$

for any $k, 0\leqq k\leqq n-1$; virtually, $h(\mu, \cdot, \cdot)$ represents a center manifold of (1.2) constructed around $(\mu, u)=(0, 0)$. Then (2.4) is written as

$$\begin{aligned}\dot z_k &= i\omega_0 z_k+(G(\mu, z_k\zeta_0+\overline{z_k\zeta_0}+h(\mu, z_k, \bar z_k)), \zeta_0^*)\\ &\quad+\nu C_1(z_{k-1}-2z_k+z_{k+1})+\nu C_2(\bar z_{k-1}-2\bar z_k+\bar z_{k+1})+R_k^1(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}}),\\ R_k^1&=O(\nu\{|(\mathbf{z}, \bar{\mathbf{z}})|^2+|\mu(\mathbf{z}, \bar{\mathbf{z}})|\}).\end{aligned} \tag{2.7}$$

The Taylor expansion of (2.7) is as follows:

$$\begin{aligned}\dot z_k &= i\omega_0 z_k+g(\mu, z_k, \bar z_k)+\nu C_1(z_{k-1}-2z_k+z_{k+1})\\ &\quad+\nu C_2(\bar z_{k-1}-2\bar z_k+\bar z_{k+1})+R_k^2(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}}),\end{aligned} \tag{2.8}$$

$$\begin{aligned}g(\mu, z_k, \bar z_k) &= \mu(a_{10}z_k+a_{01}\bar z_k)+a_{20}z_k^2+a_{11}|z_k|^2+a_{02}\bar z_k^2\\ &\quad+a_{30}z_k^3+a_{21}|z_k|^2z_k+a_{12}|z_k|^2\bar z_k+a_{03}\bar z_k^3,\end{aligned} \tag{2.9}$$

$$R_k^2(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}})=R_k^1+O(|(z_k, \bar z_k)|\{|(z_k, \bar z_k)|^3+|\mu(\mu, z_k, \bar z_k)|\}) \tag{2.10}$$

where the coefficients, $a_{ij}(i, j=0, 1, 2, 3)$ are given by $(\alpha 4)$ in Appendix A.

Now we shall transform equation (2.8) into a simpler one. Since the coefficients of g depend only on $F(\cdot, \cdot)$ (independent of ν and $N(\cdot)$), we can use the nonlinear transformation found in [8], that is,

$$z_k=w_k+\mu b_{01}\bar w_k+b_{20}w_k^2+b_{11}|w_k|^2+b_{02}\bar w_k^2+b_{03}w_k^3+b_{12}|w_k|^2\bar w_k+b_{30}\bar w_k^3, \tag{2.11}$$

whose coefficients are determined by a_{ij}, $i, j=0, 1, 2, 3$, in an appropriate manner. By (2.11), the equation (2.8) is transformed into

$$\begin{aligned}\dot w_k &= i\omega_0 w_k+\mu A_1 w_k+B_1|w_k|^2w_k+\nu C_1(w_{k-1}-2w_k+w_{k+1})\\ &\quad+\nu C_2(\bar w_{k-1}-2\bar w_k+\bar w_{k+1})+R_k^3(\mu, \nu, \mathbf{w}, \bar{\mathbf{w}})\end{aligned} \tag{2.12}$$

where

$$A_1\equiv a_{10}=\frac{d\lambda_0}{d\mu}(0) \qquad \text{(by } (\alpha 1) \text{ and } (\alpha 4) \text{ in Appendix A),} \tag{2.13}$$

$$B_1 \equiv a_{21} + \frac{i}{\omega_0} a_{20} a_{11} - \frac{i}{\omega_0} |a_{11}|^2 - \frac{2i}{3\omega_0} |a_{02}|^2, \tag{2.14}$$

and R_k^3 is of the same order as R_k^2 in (2.10).

Further calculation in Appendix A shows a formula about the coefficient, B_1, i.e.,

$$B_1 = (F_{uu}(0)(\zeta_0, \hat{\zeta}_2), \zeta_0^*) + (F_{uu}(0)(\bar{\zeta}_0, \zeta_2), \zeta_0^*) + \tfrac{1}{2}(F_{uuu}(0)(\zeta_0, \zeta_0, \bar{\zeta}_0), \zeta_0^*) \tag{2.15}$$

where ζ_2 and $\hat{\zeta}_2$ are defined by

$$\zeta_2 = (2i\omega_0 - A(0))^{-1} \tfrac{1}{2} F_{uu}(0)(\zeta_0, \zeta_0), \qquad \hat{\zeta}_2 = -A(0)^{-1} F_{uu}(0)(\zeta_0, \bar{\zeta}_0) \tag{2.16}$$

(note that $F_{uu}(0) \equiv \partial^2/\partial u^2 F(0,0)$ and $F_{uuu}(0) \equiv \partial^3/\partial u^3 F(0,0)$).

Applying the following transformation to (2.12):

$$w_k = z_k - \frac{\nu C_2}{2i\omega_0} (\bar{z}_{k-1} - 2\bar{z}_k + \bar{z}_{k+1}), \tag{2.17}$$

we obtain the equation with a simpler form:

$$\begin{aligned} \dot{z}_k &= i\omega_0 z_k + \mu A_1 z_k + B_1 |z_k|^2 z_k + \nu C_1 (z_{k-1} - 2z_k + z_{k+1}) + R_k^4(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}}), \\ z_{-1} &= z_{n-1}, \qquad z_n = z_0 \end{aligned} \tag{2.18}$$

where R_k^4 also has the same order as R_k^2. (Note that $\overline{R_k^4(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}})} = R_k^4(\mu, \nu, \bar{\mathbf{z}}, \mathbf{z})$.) The equation (2.18) is expressed in vector form as

$$\begin{aligned} \dot{\mathbf{z}} &= i\omega_0 \mathbf{z} + \mu A_1 \mathbf{z} + B_1 \mathbf{V}(\mathbf{z}, \bar{\mathbf{z}}) \mathbf{z} + \nu C_1 \Delta_d \mathbf{z} + \mathbf{R}(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}}) \\ &\equiv \mathbf{f}(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}}), \end{aligned} \tag{2.19}$$

$$\mathbf{V}(\mathbf{z}, \bar{\mathbf{z}}) \equiv \begin{pmatrix} |z_0|^2 & & \\ & \ddots & \\ & & |z_{n-1}|^2 \end{pmatrix},$$

$$\Delta_d \equiv \begin{pmatrix} -2 & 1 & 0 & \cdot & 0 & 1 \\ 1 & -2 & 1 & 0 & \cdot & 0 \\ 0 & 1 & \cdot & \cdot & \cdot & \cdot \\ \cdot & 0 & \cdot & \cdot & \cdot & 0 \\ 0 & \cdot & \cdot & \cdot & \cdot & 1 \\ 1 & 0 & \cdot & 0 & 1 & -2 \end{pmatrix}, \qquad \mathbf{R}(\cdot) \equiv \begin{pmatrix} R_0^4(\cdot) \\ \vdots \\ R_{n-1}^4(\cdot) \end{pmatrix}. \tag{2.20}$$

Hence we obtain the next lemma.

Lemma 2.1. *Consider the equation* (1.1). *The asymptotic behavior of any solution to* (1.1) *having small amplitude in a neighborhood of* $(\mu, \nu, \mathbf{u}) = (0, 0, \mathbf{0})$ *is determined by the* $2n$*-dimensional system of* (2.18) (*or* (2.19)). *This reduced equation has the symmetry such that*

$$S_j \mathbf{f}(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}}) = \mathbf{f}(\mu, \nu, S_j \mathbf{z}, \overline{S_j \mathbf{z}}), \qquad j = 1, 2 \tag{2.21}$$

where

$$S_1 \equiv \begin{pmatrix} 0 & 1 & 0 & \cdot & 0 \\ \cdot & 0 & 1 & 0 & \cdot \\ \cdot & & \cdot & \cdot & 0 \\ 0 & 0 & & \cdot & 1 \\ 1 & 0 & \cdot & \cdot & 0 \end{pmatrix}, \qquad S_2 \equiv \begin{pmatrix} 1 & 0 & \cdots & 0 \\ 0 & 0 & & 1 \\ \vdots & & \iddots & \\ & & & \\ 0 & 1 & & 0 \end{pmatrix}. \tag{2.22}$$

The latter part of the lemma about the symmetry will be shown in the next section.

Remark 2.1. In the case of $m=2$, it is clear that the center manifold is not necessary to get the above reduced equation (2.19). For the case of $m \geqq 3$, we also see from (2.13) and (2.15) that the leading terms of (2.19) can be obtained by no explicit computation about the center manifold.

Remark 2.2. In § 7 the above argument will be extended to a case of coupled oscillators represented by a functional differential equation. Then an equation quite similar to (2.18) will be obtained together with a formula for its coefficients corresponding to A_1, B_1 and C_1 in (2.18) (see (7.10)).

3. Symmetry of the reduced equation. We show (2.21) in Lemma 2.1. Let

$$\mathbf{F}(\mu, \nu, \mathbf{u}) \equiv \begin{pmatrix} F(\mu, u_0) + \nu \tilde{N}_0(\mathbf{u}) \\ \vdots \\ F(\mu, u_{n-1}) + \nu \tilde{N}_{n-1}(\mathbf{u}) \end{pmatrix}$$

where $\tilde{N}_k$ is defined in (2.2). By this definition of $\mathbf{F}$,

$$\Sigma_j \mathbf{F}(\mu, \nu, \mathbf{u}) = \mathbf{F}(\mu, \nu, \Sigma_j \mathbf{u}), \qquad j=1,2 \tag{3.1}$$

where

$$\Sigma_1 \mathbf{u} = \Sigma_1 \begin{pmatrix} u_0 \\ \vdots \\ u_{n-1} \end{pmatrix} \equiv \begin{pmatrix} u_1 \\ u_2 \\ \vdots \\ u_{n-1} \\ u_0 \end{pmatrix}, \qquad \Sigma_2 \mathbf{u} = \Sigma_2 \begin{pmatrix} u_0 \\ \vdots \\ u_{n-1} \end{pmatrix} \equiv \begin{pmatrix} u_0 \\ u_{n-1} \\ u_{n-2} \\ \vdots \\ u_2 \\ u_1 \end{pmatrix}.$$

Uniqueness of the solution to (1.1) and (3.1) imply that the center manifold constructed in § 2 satisfies

$$\Sigma_j \mathbf{h}(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}}) = \mathbf{h}(\mu, \nu, S_j \mathbf{z}, \overline{S_j \mathbf{z}}), \qquad j=1,2.$$

Hence it is easily seen that the right-hand side of (2.8), say $\tilde{\mathbf{g}}(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}})$, is covariant for $S_j, j=1,2$, that is,

$$S_j \tilde{\mathbf{g}}(\mu, \nu, \mathbf{z}, \bar{\mathbf{z}}) = \tilde{\mathbf{g}}(\mu, \nu, S_j \mathbf{z}, \overline{S_j \mathbf{z}}), \qquad j=1,2.$$

This property is invariant under the transformation of (2.11). Moreover since S_j commutes with Δ_d defined in (2.20), it is also invariant under the transformation of (2.17) which is expressed in vector form as $\mathbf{w} = \mathbf{z} + \alpha \Delta_d \bar{\mathbf{z}}$, $\alpha = -\nu C_2 / 2i\omega_0$. This implies the completion of the proof of Lemma 2.1.

Next we shall define some matrices and observe how they change by a certain transformation. This observation will be useful for the later argument in § 5.

Let

$$\mathbf{P} \equiv (p_{k,m})_{k,m=0,\cdots,n-1}, \qquad p_{k,m} \equiv e^{ik \cdot 2m\pi/n} / \sqrt{n} \tag{3.2}$$

be a matrix whose kth row and mth column is $p_{k,m}$, and let

$$\mathbf{P}_l \equiv \begin{pmatrix} p_{0,l} & & 0 \\ & \ddots & \\ 0 & & p_{n-1,l} \end{pmatrix}. \tag{3.3}$$

It is easily seen that

$$\mathbf{P}^{-1}\Delta_d\mathbf{P}=-\Lambda\equiv-\begin{pmatrix}\sigma_0 & & & 0\\ & \sigma_1 & & \\ & & \ddots & \\ 0 & & & \sigma_{n-1}\end{pmatrix} \tag{3.4}$$

where

$$\sigma_k\equiv 4\sin^2\frac{k\pi}{n},\qquad k=0,\cdots,n-1. \tag{3.5}$$

Moreover since $\mathbf{P}^{-1}=\mathbf{P}^*\equiv{}^t\mathbf{P}$ and $\mathbf{P}_l\mathbf{P}=(1/\sqrt{n})(p_{k,l+m})_{k,m=0,\cdots,n-1}$, we have

$$(\mathbf{P}_l\mathbf{P})^{-1}\Delta_d(\mathbf{P}_l\mathbf{P})=-\Lambda_l\equiv-\begin{pmatrix}\sigma_l & & & 0\\ & \sigma_{l+1} & & \\ & & \ddots & \\ 0 & & & \sigma_{l+n-1}\end{pmatrix}, \tag{3.6}$$

$$(\mathbf{P}_l\mathbf{P})^{-1}\mathbf{P}_l^2\overline{\mathbf{P}_l\mathbf{P}}=\frac{1}{n}\mathbf{P}^{-1}\bar{\mathbf{P}}=\frac{1}{n}S_2 \tag{3.7}$$

(S_2 is as in (2.22)). Note that $p_{k+n,m}=p_{k,n+m}=p_{k,m}$ and $\sigma_k=\sigma_{n+k}$, so we understand that $p_{k,m}=p_{k-n,m}$, $\sigma_{k-n}=\sigma_k$ (resp. $p_{k,m}=p_{k,m-n}$) for $k\geqq n$ (resp. $m\geqq n$).

4. Existence of the periodic wave solutions. We shall consider (2.19). If we truncate R_k^4, and if Re $A_1\neq 0$, Re $B_1\neq 0$, then there exists a solution for $\mu=\mu_2^l$ such as

$$z_k^l=\varepsilon e^{i\omega_2^l t}e^{ik\cdot 2l\pi/n}\qquad (k=0,\cdots,n-1) \tag{4.1}$$

where μ_2^l and ω_2^l are defined as

$$\begin{aligned}\mu_2^l&\equiv-\frac{b_1}{a_1}\varepsilon^2+\frac{D_1\sigma_l}{a_1}\nu,\\ \omega_2^l&\equiv\omega_0+\mu_2^l a_2+b_2\varepsilon^2-\nu\sigma_l D_2,\end{aligned} \tag{4.2}$$

and

$$\begin{aligned}&a_1\equiv\operatorname{Re}A_1,\quad a_2\equiv\operatorname{Im}A_2,\quad b_1\equiv\operatorname{Re}B_1,\quad b_2\equiv\operatorname{Im}B_2,\\ &D_1\equiv\operatorname{Re}C_1,\qquad D_2\equiv\operatorname{Im}C_2\end{aligned} \tag{4.3}$$

(σ_l is as in (3.5)). We, however, have to discuss more precisely the existence of periodic solutions whose leading terms are given by (4.1), because we may never neglect the terms included in R_k^4.

To seek a periodic solution of (2.19), we shall consider

$$\omega\frac{d}{ds}\mathbf{y}(s)=\mathbf{f}(\mu,\nu,\mathbf{y}(s),\overline{\mathbf{y}(s)}),\qquad \mathbf{y}(s)\equiv\mathbf{z}\left(\frac{s}{\omega}\right), \tag{4.4}$$

on the space,

$$\mathbf{P}_{2\pi,l}\equiv\{\mathbf{y}={}^t(y_0,\cdots,y_{n-1});\ y_0(s)\text{ is a }2\pi\text{-periodic continuous function with values in }\mathbf{C}^m\text{ and }y_k(s)=y_0(s+k\cdot 2l\pi/n)\}.$$

A solution of (4.4) in $\mathbf{P}_{2\pi,l}(l\geqq 1)$ gives a traveling periodic wave solution to (1.1) mentioned in the Introduction. By virtue of the symmetry of $\mathbf{f}$ in (2.21), the equation (4.4) is well defined on the space, $\mathbf{P}_{2\pi,l}$; this yields that (4.4) can be reduced to the following 2-dimensional equation with respect to $y_0(s)$ on a space of 2π-periodic functions:

$$\omega \frac{d}{ds} y_0(s) = f_0\left(\mu, \nu, y_0(s), \cdots, y_0\left(s+(n-1)\cdot \frac{2l\pi}{n}\right), \overline{y_0(s)}, \cdots\right). \tag{4.5}$$

Applying the standard Lyapunov-Schmidt method to (4.5), we obtain the following theorem.

THEOREM 4.1. *Consider* (2.19) *under the assumption,*

$$\text{Re}\, \frac{d\lambda_0}{d\mu}(0) = \text{Re}\, A_1 > 0. \tag{A1}$$

Then for sufficiently small positive numbers, $\bar{\varepsilon}$ and $\bar{\nu}$, there exist smooth functions, $\mu = \mu^l(\varepsilon, \nu)$ and $\omega = \omega^l(\varepsilon, \nu)$ $(l = 0, \cdots, n-1)$, defined in $I_{\varepsilon,\nu} \equiv (0, \bar{\varepsilon}) \times (-\bar{\nu}, \bar{\nu})$, such that

$$\mu^l(\varepsilon, \nu) = \mu_2^l(\varepsilon, \nu) + \hat{\mu}^l(\varepsilon, \nu), \qquad \omega^l(\varepsilon, \nu) = \omega_0 + \omega_2^l(\varepsilon, \nu) + \hat{\omega}^l(\varepsilon, \nu), \tag{4.6}$$

where $\mu_2^l(\varepsilon, \nu)$ and $\omega_2^l(\varepsilon, \nu)$ satisfy (4.2), *and $\hat{\mu}^l(\varepsilon, \nu) = O(|(\varepsilon, \nu)||(\varepsilon^2, \nu)|) = \hat{\omega}^l(\varepsilon, \nu)$. For each $\mu = \mu^l(\varepsilon, \nu)$ and $(\varepsilon, \nu) \in I_{\varepsilon,\nu}$, there exists a periodic solution of* (2.19) *bifurcating from the origin with period, $T^l(\varepsilon, \nu) \equiv 2\pi/\omega^l(\varepsilon, \nu)$.*

This bifurcating periodic solution is expressed as follows:

$$\mathbf{z}^l(t) = \begin{pmatrix} z_0^l(t) \\ \vdots \\ z_{n-1}^l(t) \end{pmatrix} = \varepsilon\, e^{i\omega^l(\varepsilon,\nu)t} \begin{pmatrix} 1 \\ e^{i(2l\pi/n)} \\ \vdots \\ e^{i(n-1)\cdot 2l\pi/n} \end{pmatrix} + \mathbf{w}^l(t), \tag{4.7}$$

$$\mathbf{w}^l(\cdot) = O(|(\varepsilon, \nu)|^2),$$

and satisfies, $z_k^l(t) = z_0^l(\omega^l(\varepsilon, \nu)t + k\cdot 2l\pi/n)$, $k = 1, \cdots, n-1$. Furthermore $\mu^{n-l}(\varepsilon, \nu) = \mu^l(\varepsilon, \nu)$, $\omega^{n-l}(\varepsilon, \nu) = \omega^l(\varepsilon, \nu)$ and $z_k^{n-l}(t) = z_{n-k}^l(t)$, $k = 0, \cdots, n-1$ (by a suitable phase shift) hold for l, $1 \leqq l \leqq n/2$.

We shall omit the proof of the theorem, since it will be easily shown by the standard Hopf bifurcation theory. For example, we refer to the works [5], [8], [9]. We only note that $z_k^{n-l}(t) = z_{n-k}^l(t)$, $k = 0, \cdots, n-1$, is shown by the symmetry of $\mathbf{f}$ with respect to S_2.

The next corollary follows immediately from the above theorem.

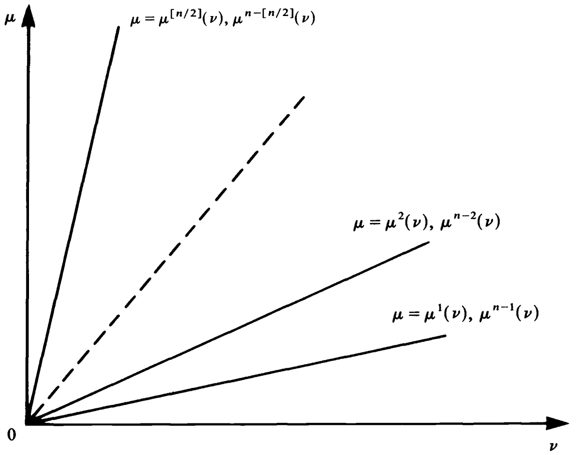
COROLLARY 4.2. *Consider* (1.1) *under the same condition of Theorem* 4.1. *Then, for $\mu = \mu^l(\varepsilon, \nu)$, $(\varepsilon, \nu) \in I_{\varepsilon,\nu}$ and $1 \leqq l \leqq n/2$, there exist traveling periodic wave solutions, $\mathbf{u}^l = (u_0^l, \cdots, u_{n-1}^l)$ and $\mathbf{u}^{n-l} = (u_0^{n-l}, \cdots, u_{n-1}^{n-l})$ satisfying* (1.4), *where $\mu^l(\varepsilon, \nu)$ and $T^l(\varepsilon, \nu)$ are as in Theorem* 4.1. *Moreover for each $l = 1, \cdots, n/2$, $u_0^l(t) = u_0^{n-l}(t + \rho)$, where ρ is a suitable shift in phase.*

Hereafter we will assume that

$$\text{Re}\, B_1 = b_1 < 0, \tag{A2}$$

in addition to (A1). The assumption (A2) implies that bifurcation occurs supercritically with respect to μ, that is, each periodic solution exists for $\mu > \mu^l(0, \nu)$. In Figs. 1-3, we find bifurcation diagrams of this case with an additional condition $\text{Re}\, C_1 = D_1 > 0$.

5. Stability of the periodic wave solutions. We shall discuss the stability of the periodic solutions to (1.1) obtained in the previous section. By virtue of the attractivity of the center manifold, it is enough to investigate the solution of (4.7) to (2.19). The reduced form of (2.19) will play a central role in the argument below.



μ
$\mu=\mu^{[n/2]}(\nu),\ \mu^{n-[n/2]}(\nu)$
$\mu=\mu^{2}(\nu),\ \mu^{n-2}(\nu)$
$\mu=\mu^{1}(\nu),\ \mu^{n-1}(\nu)$
0
ν

FIG. 1. *Bifurcation lines,* $\mu^l(\nu)=\mu^l(0,\nu)$, *are figured for the case,* $D_1=\text{Re }C_1>0$. *The periodic wave solutions,* $\mathbf{u}^l$ and $\mathbf{u}^{n-l}$, *in Corollary* 4.2 *bifurcate at* $\mu=\mu^l(\nu)$.

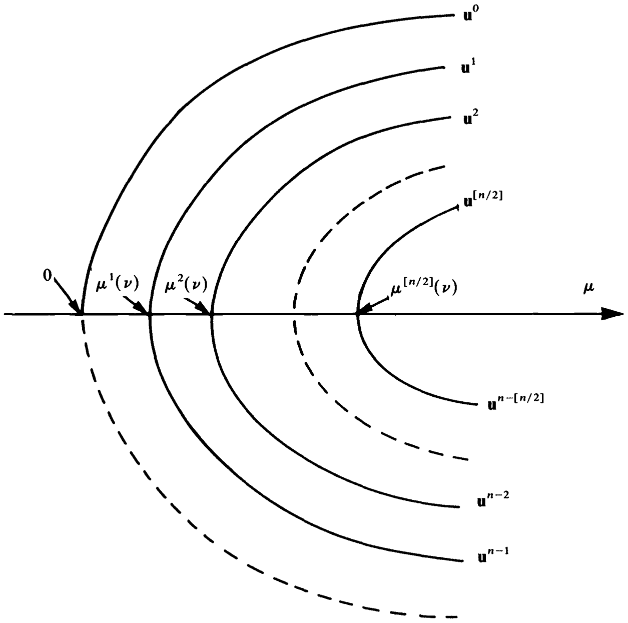


FIG. 2. *A bifurcation diagram for fixed* $\nu>0$, *under the same condition as in Fig.* 1. *Vertical direction indicates a function space schematically. The branches of* $\mathbf{u}^l$ *and* $\mathbf{u}^{n-l}$ *are drawn symmetric with respect to the horizontal axis, which symbolizes that* $\mathbf{u}^l$ *and* $\mathbf{u}^{n-l}$ *are symmetric each other in the sense of Corollary* 4.2.

The linearized equation around the solution (4.7) is given by:

$$\begin{aligned}\dot{y}_k&=(i\omega_0+\mu^lA_1+2B_1|z_k^l(t)|^2)y_k+B_1\{z_k^l(t)\}^2\bar{y}_k\\ &\quad+\nu C_1(y_{k-1}-2y_k+y_{k+1})+\frac{\partial}{\partial\mathbf{z}}R_k^4(\mu^l,\nu,\mathbf{z}^l(t),\bar{\mathbf{z}}^l(t))\mathbf{y}\qquad(5.1)\\ &\quad+\frac{\partial}{\partial\bar{\mathbf{z}}}R_k^4(\mu^l,\nu,\mathbf{z}^l(t),\bar{\mathbf{z}}^l(t))\bar{\mathbf{y}}\end{aligned}$$

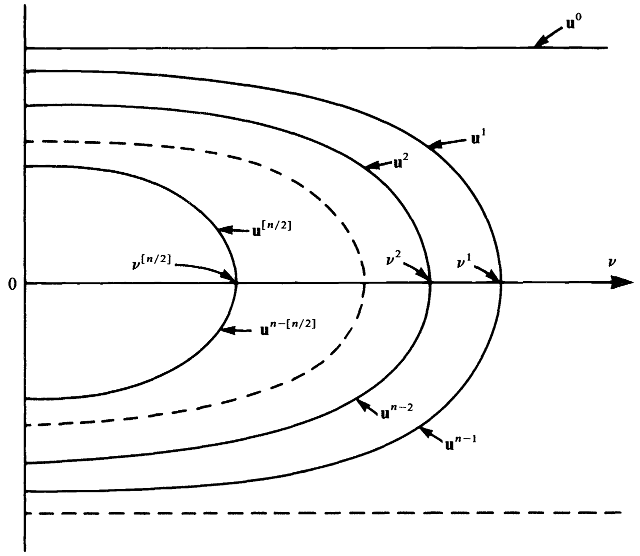

FIG. 3. *A bifurcation diagram for fixed $\mu > 0$, say $\tilde{\mu}$. The value, ν^l, is determined by $\mu^l(\nu^l) = \tilde{\mu}$. This picture is illustrated in the similar manner as in Fig. 2.*

where, $y_{-1} = y_{n-1}$, $y_n = y_0$ and $\mu^l = \mu^l(\varepsilon, \nu)$. Let

$$\alpha_1 \equiv i\omega^l(\varepsilon, \nu) + \varepsilon^2 B_1 + \nu\sigma^l C_1, \qquad \alpha_2(t) \equiv \varepsilon^2 B_1\, e^{2i\omega^l(\varepsilon,\,\nu)t}. \tag{5.2}$$

Then, considering the expression of (4.7), we can rewrite (5.1) in the following vector form:

$$\dot{\mathbf{y}} = \alpha_1\mathbf{y} + n\alpha_2(t)(\mathbf{P}_l)^2\bar{\mathbf{y}} + \nu C_1\Delta_d\mathbf{y} + \mathbf{w}^1(\varepsilon, \nu, t)\mathbf{y} + \mathbf{W}^2(\varepsilon, \nu, t)\bar{\mathbf{y}} \tag{5.3}$$

where $\mathbf{P}_l$ is defined by (3.3) and $\mathbf{W}^j, j = 1, 2$, are matrices whose elements are periodic with period, $T^l(\varepsilon, \nu) = 2\pi/\omega^l(\varepsilon, \nu)$, and are $O(\varepsilon|(\varepsilon, \nu)|^2 + |\nu(\varepsilon, \nu)|)$. Using (3.6), (3.7) and

$$\mathbf{y} = \mathbf{P}_l\mathbf{P}\mathbf{v}, \tag{5.4}$$

we transform (5.3) into

$$\begin{aligned} &\dot{\mathbf{v}} = \alpha_1\mathbf{v} + \alpha_2(t)S_2\bar{\mathbf{v}} - \nu C_1\mathbf{\Lambda}_l\mathbf{v} + \tilde{\mathbf{W}}^1(\varepsilon, \nu, t)\mathbf{v} + \tilde{\mathbf{W}}^2(\varepsilon, \nu, t)\bar{\mathbf{v}}, \\ &\tilde{\mathbf{W}}^j \equiv (\mathbf{P}_l\mathbf{P})^{-1}\mathbf{W}^j(\mathbf{P}_l\mathbf{P}), \qquad j = 1, 2 \end{aligned} \tag{5.5}$$

where S_2 and Λ_l are as in (2.22) and (3.6), respectively.

In general, let $\Phi(t)$ be a fundamental matrix solution (with $\Phi(0) = I$, the identity matrix) of a linear periodic system such as (5.5). Then Floquet theory (for example, see [6]) implies that $\Phi(t)$ can be expressed as $\Phi(t) = X(t)\, e^{\mathbf{M}t}$, where $X(t)$ is periodic with the same period as the original system, and $\mathbf{M}$ is a certain matrix. By virtue of this expression, the real part of an eigenvalue of $\mathbf{M}$ gives a criteria for stability of the zero solution. The eigenvalue of $\mathbf{M}$ is called a Floquet exponent.

In the case of (5.5), after the change of variables, $v_k = w_k\, e^{i\omega^l(\varepsilon,\,\nu)t}$, $k = 0, \cdots, n-1$, (5.5) is written in the form,

$$\begin{pmatrix}\mathbf{w}\\ \dot{\bar{\mathbf{w}}}\end{pmatrix} = (\mathbf{M}_0 + \mathbf{M}_1(\varepsilon, \nu, t))\begin{pmatrix}\mathbf{w}\\ \bar{\mathbf{w}}\end{pmatrix} \tag{5.6}$$

where $\mathbf{M}_0$ is a constant matrix with $O(\varepsilon^2 + \nu)$ and $\mathbf{M}_1 = O(\nu|(\varepsilon, \nu)| + \varepsilon|(\varepsilon, \nu)|^2)$. This fundamental matrix solution, $\Phi(t)$, satisfies

$$\Phi(t)=e^{\mathbf{M}_0 t}\left(I+\int_0^t e^{-\mathbf{M}_0 s}\mathbf{M}_1(\varepsilon,\nu,s)\Phi(s)\,ds\right),$$

from which we see that

$$e^{\mathbf{M}\cdot T^l(\varepsilon,\nu)}=e^{\mathbf{M}_0\cdot T^l(\varepsilon,\nu)}\{I+O(\nu|(\varepsilon,\nu)|+\varepsilon|(\varepsilon,\nu)|^2)\}.$$

This implies that an eigenvalue of $\mathbf{M}_0$ gives the principal part of the one corresponding to $\mathbf{M}$, if ε and ν are sufficiently small. Since in the absence of $\mathbf{M}_1$ the components of the equation (5.6) are given by:

$$\begin{aligned}\dot{w}_k&=\{\varepsilon^2B_1+\nu C_1(\sigma_l-\sigma_{l+k})\}w_k+\varepsilon^2B_1\bar{w}_{n-k},\\ \dot{\bar{w}}_{n-k}&=\{\varepsilon^2\bar{B}_1+\nu\bar{C}_1(\sigma_l-\sigma_{l-k})\}\bar{w}_{n-k}+\varepsilon^2\bar{B}_1w_k,\end{aligned}\qquad k=0,\cdots,n-1 \tag{5.7}$$

(note $\sigma_{l+n-k}=\sigma_{l-k}$), the next lemma immediately follows.

LEMMA 5.1. *The linearized equation of* (2.19) *around the periodic solution,* $\mathbf{z}^l(t)$, *given by* (4.7) *has the Floquet exponent such that*

$$\gamma=\gamma_2(\varepsilon,\nu)+\hat{\gamma}(\varepsilon,\nu)$$

where $\hat{\gamma}(\varepsilon,\nu)=O(\varepsilon|(\varepsilon,\nu)|^2+\nu|(\varepsilon,\nu)|)$ *and* $\gamma_2(\varepsilon,\nu)$ *is a root of the equation,*

$$\gamma_2^2-\xi_k^l\gamma_2+\eta_k^l=0,\qquad k=0,\cdots,n-1, \tag{5.8}$$

whose coefficients are defined by

$$\begin{aligned}\xi_k^l&\equiv 2\varepsilon^2b_1-\nu D_1(\sigma_{l-k}-2\sigma_l+\sigma_{l+k})+i\nu D_2(\sigma_{l-k}-\sigma_{l+k}),\\ \eta_k^l&\equiv\nu^2(D_1^2+D_2^2)(\sigma_l-\sigma_{l+k})(\sigma_l-\sigma_{l-k})\\ &\qquad-\nu\varepsilon^2(D_1b_1+D_2b_2)(\sigma_{l-k}-2\sigma_l+\sigma_{l+k})\\ &\qquad-i\nu\varepsilon^2(D_1b_2-D_2b_1)(\sigma_{l-k}-\sigma_{l+k})\end{aligned} \tag{5.9}$$

($b_j, D_j, j=1,2$ *are defined in* (4.3)). *Furthermore,*

$$\xi_{n-k}^l=\bar{\xi}_k^l,\quad \eta_{n-k}^l=\bar{\eta}_k^l,\quad \xi_k^{n-l}=\bar{\xi}_k^l\quad\text{and}\quad \eta_k^{n-l}=\bar{\eta}_k^l, \tag{5.10}$$

hold.

Now consider the equation (5.8). For $k=0$, (5.8) is $\gamma_2^2-2\varepsilon^2b_1\gamma_2=0$, which has roots $0, 2\varepsilon^2b_1(<0$ by (A2)). A zero Floquet exponent always exists for the linearized equation around a periodic solution. The above zero corresponds to this.

Next consider the case $k\geqq 1$. In the specific cases $l=0$ and $n/2$ (for n: even), the coefficients of (5.7) are real valued such as:

$$\begin{aligned}\xi_k^0&=2(\varepsilon^2b_1-\nu D_1\sigma_k),\\ \eta_k^0&=\nu\sigma_k(D_1^2+D_2^2)\left\{\nu\sigma_k-\frac{2\varepsilon^2E_1}{D_1^2+D_2^2}\right\},\\ \xi_k^{n/2}&=2\{\varepsilon^2b_1+\nu D_1(\sigma_{n/2}-\sigma_{n/2-k})\},\\ \eta_k^{n/2}&=\nu(\sigma_{n/2}-\sigma_{n/2-k})(D_1^2+D_2^2)\left\{\nu(\sigma_{n/2}-\sigma_{n/2-k})+\frac{2\varepsilon^2E_1}{D_1^2+D_2^2}\right\},\end{aligned}$$

where, $E_1=D_1b_1+D_2b_2$. Note that $\sigma_{n/2}-\sigma_{n/2-k}=\sigma_{n/2}-\sigma_{n/2+k}>0$, $k\geqq 1$. We let $D_1>0$, $E_1>0$. Then both roots for $l=0$ exist in the left half of the complex plane for ε near the zero, and one of them crosses the origin from left to right as ε increases, while for $l=n/2$, the pair of roots in the right for small ε cross the imaginary axis from right to left as ε increases. If $D_1>0$ and $E_1<0$, then for $l=0$, both roots remain in the left half plane, while for $l=n/2$, there are two cases. For $D_1E_1+D_2E_2<0$ ($E_2=D_1b_2-D_2b_1$), one of them always has positive real part. In the case of $D_1E_1+D_2E_2>0$, the roots in the right half for ε small cross the imaginary axis from right to left, moreover thereafter one of them crosses the origin from left to right.

We can also check the change of roots in a similar manner for the case $D_1<0$. For general l, the movement of the root of (5.8) in the complex plane is more complicated when ε increases (or ν decreases). In a specific region of the parameter space (μ, ν), however, we can see from Appendix B the stability of all the periodic solutions in (4.7) as follows.

THEOREM 5.2. *Consider the periodic solutions of* (1.1) *which bifurcate from the origin, under the assumptions,* (A1), (A2) *and*

$$\text{(A3)} \qquad D_1=\operatorname{Re}(D\zeta_0, \zeta_0^*)>0.$$

If $\operatorname{Re}((D\zeta_0, \zeta_0^*)\bar{B}_1)=D_1b_1+D_2b_2$ *is positive* (*i.e.,* $D_2b_2>-D_1b_1>0$) *and fixed, there exists a sufficiently small* $\theta_1>0$ *such that for* $(\mu, \nu), 0<\nu<\theta_1\mu$, *the periodic solution in* (1.3) *with indices, l and $n-l$, $0\leqq l\leqq n/4$* (*resp. $n/4<l\leqq n/2$*) *are unstable* (*resp. stable*); *if $D_1b_1+D_2b_2<0$, then in a region satisfying, $0<\nu<\theta_2\mu$ and $0<\theta_2\ll 1$, those solutions with l and $n-l$, $0\leqq l<n/4$* (*resp. $n/4\leqq l\leqq n/2$*) *are stable* (*resp. unstable*). *The numbers, $\theta_j, j=1, 2$, depend on l, $0\leqq l\leqq n/2$ and the values of $D_1b_1+D_2b_2$.*

Remark 5.1. The assumptions (A1) and (A3) imply that the steady state is stable (resp. unstable) for $\mu<0$ (resp. $\mu>0$). The above discussion for the Floquet exponents of (5.1) (or (5.5)) with $l=0$ yields that the homogeneous periodic solution is always stable for $E_1<0$ and that for $E_1>0$ it becomes unstable in a region, if (A1)-(A3) hold. On the other hand, under (A1)-(A3) the bifurcation of all the periodic wave solutions occurs in the unstable region of the steady state (see Fig. 1), which implies that these solutions are unstable fairly near the bifurcation points. Theorem 5.2 says that recovery of stability occurs for several of the periodic solutions and that they have the stable region as described in the statement.

Remark 5.2. For the case $D_1=\operatorname{Re}(D\zeta_0, \zeta_0^*)<0$, we can also discuss the stability. To avoid repeating a similar statement, we omit the case in the above theorem. The condition $D_1<0$ is supposed to be a more specific case than $D_1>0$ (see the examples in §§ 6 and 7), which is another reason to omit it here. We also note that $D_1>0$ implies $\operatorname{Re}(\partial\lambda_l/\partial\nu)(0, 0)<0, l=1, \cdots, n-1$, by ($\alpha$3) in Appendix A.

Remark 5.3. When the eigenvalue of (5.1) crosses the imaginary axis, a secondary bifurcation occurs and an invariant torus or a new periodic solution might appear. For the specific case $n=2$ (i.e., two coupled oscillators) the structure of a secondary bifurcation of a periodic solution to a class of equation (1.1) has already been studied in [14].

To recover the stability, some kinds of secondary bifurcation occur along the branch of the periodic solution. Therefore the complicated structure of (1.1) for a large system (having many oscillators) is imagined. In spite of this, Theorem 5.2 states that the stability of the primary bifurcating solution is clearly classified in a parameter region.

6. An example. The following equation which is called the Brusselator is known as a simple biochemical reaction model:

$$(6.1) \qquad \dot{x}(t)=A-(B+1)x+x^2y, \qquad \dot{y}(t)=Bx-x^2y$$

where A and B are positive parameters. The equation (6.1) has a steady state, $(x, y)=(A, B/A)$, and at $B=A^2+1$ a Hopf bifurcation occurs; a family of stable limit cycles bifurcate from the steady state (see [19]). Hence $F(\mu, \cdot)$ in (1.1) (or (1.2)) is given by

$$F(\mu, u, v)=\begin{pmatrix} A^2+\mu & A^2 \\ -(A^2+1+\mu) & -A^2 \end{pmatrix}\begin{pmatrix} u \\ v \end{pmatrix}+\left(\frac{A^2+1+\mu}{A}u^2+2Auv+u^2v\right)\begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

where $B=A^2+1+\mu$, $x=A+u$ and $y=B/A+v$.

After a calculation (referring to [11, Appendix]), we have

$$\zeta_0=\begin{pmatrix} 1 \\ \dfrac{i-A}{A} \end{pmatrix}, \qquad \zeta_0^*=\frac{1+Ai}{2}\begin{pmatrix} 1 \\ \dfrac{A}{A-i} \end{pmatrix},$$

$$B_1=-\frac{1}{2}\left(\frac{A^2+2}{A^2}+i\frac{4A^4-7A^2+4}{3A^2}\right),$$

and if

$$D=\begin{pmatrix} d_1 & 0 \\ 0 & d_2 \end{pmatrix}, \quad d_1, d_2 \geqq 0, \quad d_1+d_2>0,$$

then

$$(D\zeta_0, \zeta_0^*)=\frac{1}{2}\{(d_1+d_2)+iA(d_2-d_1)\},$$

$$\operatorname{Re}(\bar{B}_1(D\zeta_0, \zeta_0^*))=-\frac{1}{12A^2}\{3(d_1+d_2)(A^2+2)+(d_2-d_1)(4A^4-7A^2+4)\}.$$

Since $\operatorname{Re}(D\zeta_0, \zeta_0^*)>0$, we can apply Theorem 5.2 to this case. According to the choice of d_1, d_2 and A, $\operatorname{Re}(\bar{B}_1(D\zeta_0, \zeta_0^*))$ takes negative or positive value.

7. Application to a retarded functional differential equation. One may encounter a model of an oscillator represented by a differential equation with time delay. As a specific example, we shall take the following equation:

$$\dot{u}(t)=-\left(\frac{\pi}{2}+\mu\right)(1+u(t))u(t-1). \tag{7.1}$$

This equation has a periodic solution which bifurcates from the origin at $\mu=0$ (for example, see [8]). Using this equation, we get to a chain of weakly coupled equations such as

$$\begin{gathered} \dot{u}_k(t)=-\left(\frac{\pi}{2}+\mu\right)(1+u_k(t))u_k(t-1)+\nu(u_{k-1}(t)-2u_k(t)+u_{k+1}(t)), \\ k=0, \cdots, n-1, \\ u_{-1}=u_{n-1}, \qquad u_n=u_0. \end{gathered} \tag{7.2}$$

The equations (7.1) and (7.2) are included in a class of retarded functional differential equations. In this section, first we shall state the formulation for a functional differential equation of general form (by following [6]), and then we shall show that the results obtained in the preceding sections can be extended to this case. Finally we shall give the values corresponding to A_1, B_1 and C_1 in (2.19) for the above equation (7.2). (We refer to [8] about the formulation below.)

Let $C=C([-r, 0]; \mathbf{R}^m)$ be a set of all continuous functions defined on $[-r, 0]$ with the values in $\mathbf{R}^m$; C is a Banach space equipped with supremum norm. We define $u_t \in C$, $t \in [a, b]$ by $u_t(\theta)=u(t+\theta)$, $-r \leqq \theta \leqq 0$, for a continuous function $u(t) \in$

$C([a-r, b]; \mathbf{R}^m)$. Let $F(\cdot, \cdot): I_0 \times C \to \mathbf{R}^m$ be a sufficiently smooth operator satisfying $F(\mu, 0) = 0$, $\mu \in I_0$. Using this operator, we consider the equation,

$$\dot{u}(t) = F(\mu, u_t) = L(\mu)u_t + M(\mu, u_t) \tag{7.3}$$

where $L(\mu)$ and $M(\mu, \cdot)$ are the linear and nonlinear parts of $F(\mu, \cdot)$, respectively.

Riesz's representation theorem implies that there is an $m \times m$ matrix function $\eta(\theta; \mu)$ whose elements have bounded variation in θ such that

$$L(\mu)\phi = \int_{-r}^{0} [d\eta(\theta; \mu)]\phi(\theta), \qquad \phi \in C.$$

The generator $A(\mu)$ of a semigroup $\{T(t)\}_{t \geqq 0}$, associated with the equation

$$\dot{u}(t) = L(\mu)u_t$$

is defined by

$$A(\mu)\phi = \begin{cases} \dfrac{d\phi}{d\theta}, & -r \leqq \theta < 0 \\ L(\mu)\phi, & \theta = 0 \end{cases} \quad \text{for } \phi \in \mathscr{D}(A(\mu)). \tag{7.4}$$

Then the eigenvalue is given by a root of the characteristic equation

$$\det\left(\lambda I - \int_{-r}^{0} e^{\lambda\theta}[d\eta(\theta; \mu)]\right) = 0. \tag{7.5}$$

We assume that $A(\mu)$ has a pair of simple eigenvalues, $\lambda_0(\mu)$ and $\overline{\lambda_0(\mu)}$, satisfying $\lambda_0(0) = i\omega_0$, $\operatorname{Re}(d\lambda_0/d\mu)(0) > 0$. The function, $\zeta_1(\theta)$, $-r \leqq \theta \leqq 0$, denotes an eigenfunction corresponding to $i\omega_0$. Define $\tilde{G}(\mu, \cdot)$ by:

$$\tilde{G}(\mu, \phi)(\theta) \equiv \begin{cases} 0, & -r \leqq \theta < 0, \\ G(\mu, \phi) \equiv F(\mu, \phi) - L(0)\phi, & \theta = 0. \end{cases}$$

By this and (7.4) the equation (7.3) can be written as

$$\begin{aligned} \frac{d}{dt} u_t &= A(0)u_t + \tilde{G}(\mu, u_t) \\ &= \begin{cases} \dfrac{du(t+\theta)}{d\theta}, & -r \leqq \theta < 0, \\ L(0)u_t + G(\mu, u_t), & \theta = 0. \end{cases} \end{aligned} \tag{7.6}$$

We shall introduce a bilinear form:

$$\begin{aligned} \langle \phi, \psi \rangle = (\phi(0), \psi(0)) - \int_{-r}^{0} \int_{0}^{\theta} {}^t\overline{\psi(\xi - \theta)}[d\eta(\theta; 0)]\phi(\xi)\, d\xi \\ \text{for } \phi \in C([-r, 0]; \mathbf{C}^m) \text{ and } \psi \in C^* = C([0, r]; \mathbf{C}^m). \end{aligned} \tag{7.7}$$

The adjoint operator A^* of $A(0)$ is defined by

$$[A^*\psi](s) \equiv \begin{cases} -\dfrac{d\psi}{ds}(s), & 0 < s \leqq r, \\ \displaystyle\int_{-r}^{0} {}^t[d\eta(\theta; 0)]\psi(-\theta), & s = 0, \end{cases} \qquad \psi \in C^*,$$

that is, A^* satisfies $\langle A(0)\phi, \psi \rangle = \langle \phi, A^*\psi \rangle$. We let $\zeta_1^*(s)$, $0 \leqq s \leqq r$, be an eigenfunction of A^* corresponding to $-i\omega_0$, and let $\langle \zeta_1, \zeta_1^* \rangle = 1$ (note $\langle \bar{\zeta}_1, \zeta_1^* \rangle = 0$). We can decompose (7.6) as

$$
\begin{aligned}
\dot z &= i\omega_0 z + \langle \tilde G(\mu, z\zeta_1 + \overline{z\zeta_1} + u_t^Q), \zeta_1^* \rangle \\
&= i\omega_0 z + (G(\mu, z\zeta_1 + \overline{z\zeta_1} + u_t^Q), \zeta_0^*) \qquad (\zeta_0^* = \zeta_1^*(0)), \\
\frac{d}{dt} u_t^Q &= A(0)u_t^Q + Q\tilde G(\mu, z\zeta_1 + \overline{z\zeta_1} + u_t^Q)
\end{aligned} \tag{7.8}
$$

where $z(t) \equiv \langle u_t, \zeta_1^* \rangle$, $u^Q \equiv u - u^P = u - (z\zeta_1 + \overline{z\zeta_1})$. The existence of a center manifold of (7.8) was shown in [2], by which we are able to reduce (7.8) to an equation on the manifold. This calculation is similar to the case of an ordinary differential equation (see [8]).

We shall consider the following coupled equations of (7.3):

$$
\begin{aligned}
&\dot u^k = F(\mu, u_t^k) + \nu\{N(u_t^{k-1} - u_t^k) + N(u_t^{k+1} - u_t^k)\}, \\
&u^{-1} = u^{n-1}, \qquad u^n = u^0
\end{aligned} \tag{7.9}
$$

where $N(\cdot)$ is a smooth operator of C into $\mathbf{R}^m$ with $N(0) = 0$ and $D = (dN/du)(0)$. By (7.8) the equation (7.9) can be decomposed as seen in (2.3), and the center manifold theorem yields an equation on the manifold. After computations quite similar to those described in § 2 and Appendix A, we have a slightly modified formula of the reduced equation; that is, in this case, A_1, B_1 and C_1 in (2.19) are given by:

$$
\begin{aligned}
A_1 &= \left(\frac{d}{d\mu} L(0)\zeta_1, \zeta_0^*\right) = \frac{d\lambda_0}{d\mu}(0), \\
B_1 &= (F_{uu}(0)(\zeta_1, \hat\zeta_2), \zeta_0^*) + (F_{uu}(0)(\bar\zeta_1, \zeta_2), \zeta_0^*) + \tfrac{1}{2}(F_{uuu}(0)(\zeta_1, \zeta_1, \overline{\zeta_1}), \zeta_0^*), \\
C_1 &= (D\zeta_1, \zeta_0^*)
\end{aligned} \tag{7.10}
$$

where

$$
\begin{aligned}
&\zeta_2 \equiv (2i\omega_0 - A(0))^{-1}\tfrac{1}{2}\tilde F_{uu}(0)(\zeta_1, \zeta_1), \\
&\hat\zeta_2 \equiv -A(0)^{-1}\tilde F_{uu}(0)(\zeta_1, \bar\zeta_1), \\
&[\tilde F_{uu}(0)(\cdot,\cdot)](\theta) \equiv \begin{cases} 0, & -r \leqq \theta < 0, \\ F_{uu}(0)(\cdot,\cdot), & \theta = 0. \end{cases}
\end{aligned}
$$

Now consider (7.2). Then we have

$$
F(\mu, \phi) = -\left(\frac{\pi}{2} + \mu\right)(1 + \phi(-1))\phi(0), \quad D\phi = \phi(0), \quad \phi \in C[-1, 0].
$$

In this case, A_1, B_1 and C_1 in (7.10) are easily calculated as follows:

$$
A_1 = \left(\frac{\pi}{2} + i\right) \Big/ \left(1 + \frac{\pi^2}{4}\right), \qquad B_1 = \frac{\pi}{10}(1 - 3i)\left(1 - \frac{\pi}{2}i\right) \Big/ \left(1 + \frac{\pi^2}{4}\right),
$$

$$
C_1 = \left(1 - \frac{\pi}{2}i\right) \Big/ \left(1 + \frac{\pi^2}{4}\right)
$$

(refer to [12]). Hence we obtain $\operatorname{Re}(\bar B_1 C_1) = \pi/10/(1 + \pi^2/4) > 0$.

Appendix A. Calculation of coefficients for equations (2.8)–(2.10). First we note that

$$
\frac{d\lambda_0}{d\mu}(0) = (A(0)\zeta_0, \zeta_0^*), \tag{α1}
$$

which is derived from $A(\mu)\zeta_0(\mu) = \lambda_0(\mu)\zeta_0(\mu)$. The linearized equation of (1.1) around

$u_k = 0$, $k = 0, \cdots, n-1$, is given by

$$(\alpha 2) \qquad \begin{aligned} &\dot{u}_k = A(\mu)u_k + \nu D(u_{k-1} - 2u_k + u_{k+1}), \qquad k = 0, \cdots, n-1,\\ &u_{-1} = u_{n-1}, \qquad u_n = u_0. \end{aligned}$$

It is easily checked that (α2) has the eigenvalues $\lambda_l(\mu, \nu)$, $l = 1, \cdots, n-1$ satisfying $\lambda_l(\mu, 0) = \lambda_0(\mu)$ in a neighborhood of $(\mu, \nu) = (0, 0)$. Furthermore a corresponding eigenvector to $\lambda_l(\mu, \nu)$ is given by

$$\xi_k = e^{ik \cdot 2l\pi/n} \zeta_l(\mu, \nu), \qquad k = 0, \cdots, n-1$$

where $\zeta_l(\mu, \nu)$ satisfies

$$(A(\mu) - \nu\sigma_l D)\zeta_l(\mu, \nu) = \lambda_l(\mu, \nu)\zeta_l(\mu, \nu)$$

(σ_l is as in (3.5)). Hence, in addition to (α1), we obtain the relation

$$(\alpha 3) \qquad \frac{\partial \lambda_l}{\partial \nu}(0, 0) = -\sigma_l(D\zeta_0, \zeta_0^*),$$

by differentiating it with respect to ν.

The coefficients of (2.9) which are necessary for the later calculation are as follows:

$$(\alpha 4) \qquad \begin{aligned} &a_{10} = (F_{\mu u}(0)\zeta_0, \zeta_0^*), \qquad a_{20} = \tfrac{1}{2}(F_{uu}(0)(\zeta_0, \zeta_0), \zeta_0^*),\\ &a_{11} = (F_{uu}(0)(\zeta_0, \bar{\zeta}_0), \zeta_0^*), \qquad a_{02} = (F_{uu}(0)(\bar{\zeta}_0, \bar{\zeta}_0), \zeta_0^*),\\ &a_{21} = (F_{uu}(0)(\zeta_0, h_{z\bar{z}}(0)), \zeta_0^*) + \tfrac{1}{2}(F_{uu}(0)(\bar{\zeta}_0, h_{zz}(0)), \zeta_0^*)\\ &\qquad + \tfrac{1}{2}(F_{uuu}(0)(\zeta_0, \zeta_0, \bar{\zeta}_0), \zeta_0^*) \end{aligned}$$

where $F_{\mu u}(0) \equiv (\partial^2/\partial\mu\, \partial u)F(0, 0)$, $F_{uu}(0) \equiv (\partial^2/\partial u^2)F(0, 0)$, $h_{zz}(0) \equiv (\partial^2/\partial z^2)h(0, 0, 0)$ and so forth. We can also check that

$$(\alpha 5) \qquad \begin{aligned} &h_{zz}(0) = (2i\omega_0 - A(0))^{-1}QF_{uu}(0)(\zeta_0, \zeta_0),\\ &h_{z\bar{z}}(0) = -A(0)^{-1}QF_{uu}(0)(\zeta_0, \bar{\zeta}_0),\\ &h_{\bar{z}\bar{z}}(0) = \overline{h_{zz}(0)}. \end{aligned}$$

We shall consider (2.14). By the relations (α4),

$$(\alpha 6) \qquad \begin{aligned} B_1 &= a_{21} + \frac{i}{\omega_0}(2a_{20}a_{11} - a_{20}a_{11}) - \frac{i}{\omega_0}\overline{a_{11}}a_{11} - \frac{2i}{3\omega_0}\overline{a_{02}}a_{02}\\ &= a_{21} + \frac{i}{\omega_0}a_{11}(F_{uu}(0)(\zeta_0, \zeta_0), \zeta_0^*) - \frac{i}{\omega_0}\overline{a_{11}}(F_{uu}(0)(\zeta_0, \bar{\zeta}_0), \zeta_0^*)\\ &\quad - \frac{i}{\omega_0}a_{20}(F_{uu}(0)(\zeta_0, \overline{\zeta_0}), \zeta_0^*) - \frac{i}{3\omega_0}\overline{a_{02}}(F_{uu}(0)(\overline{\zeta_0}, \overline{\zeta_0}), \zeta_0^*)\\ &= \left(F_{uu}(0)\left(\zeta_0, h_{z\bar{z}}(0) + \frac{i}{\omega_0}a_{11}\zeta_0 - \frac{i}{\omega_0}\overline{a_{11}\zeta_0}\right), \zeta_0^*\right)\\ &\quad + \left(F_{uu}(0)\left(\bar{\zeta}_0, h_{zz}(0) - \frac{i}{\omega_0}a_{20}\zeta_0 - \frac{i}{3\omega_0}\overline{a_{02}\zeta_0}\right), \zeta_0^*\right)\\ &\quad + \tfrac{1}{2}(F_{uuu}(0)(\zeta_0, \zeta_0, \overline{\zeta_0}), \zeta_0^*). \end{aligned}$$

On the other hand, by (α5), ζ_2 defined in (2.16) is written as:

$$(\alpha 7) \qquad \begin{aligned} \zeta_2 &= \tfrac{1}{2}h_{zz}(0) + \tfrac{1}{2}(2i\omega_0 - A(0))^{-1}PF_{uu}(0)(\zeta_0, \zeta_0)\\ &= \tfrac{1}{2}h_{zz}(0) + (2i\omega_0 - A(0))^{-1}(a_{20}\zeta_0 + \overline{a_{02}\zeta_0}). \end{aligned}$$

Similarly,

$$(\alpha 8)\qquad \begin{aligned}\hat{\zeta}_2 &= h_{z\bar{z}}(0) - A(0)^{-1}PF_{uu}(0)(\zeta_0, \overline{\zeta_0})\\ &= h_{z\bar{z}}(0) - A(0)^{-1}(a_{11}\zeta_0 + \overline{a_{11}\zeta_0}).\end{aligned}$$

We easily check that

$$(\alpha 9)\qquad \begin{aligned}&(2i\omega_0 - A(0))^{-1}\zeta_0 = -\frac{i}{\omega_0}\zeta_0, \qquad (2i\omega_0 - A(0))^{-1}\overline{\zeta_0} = -\frac{i}{3\omega_0}\overline{\zeta_0},\\ &-A(0)^{-1}\zeta_0 = \frac{i}{\omega_0}\zeta_0, \qquad -A(0)^{-1}\overline{\zeta_0} = -\frac{i}{\omega_0}\overline{\zeta_0}.\end{aligned}$$

Combining (α6), (α7), (α8) and (α9), we obtain (2.15).

Appendix B. Proof of Theorem 5.2: Stability of periodic solutions. Let $\gamma_\alpha = \gamma_1 + i\gamma_2$ and $\gamma_\beta = \gamma_3 + i\gamma_4$ be the roots of (5.8). Then,

$$(\beta 1)\qquad \begin{aligned}&\gamma_1 + \gamma_3 = 2\varepsilon^2 b_1 - \nu D_1 \Delta_k^l \sigma,\\ &\gamma_2 + \gamma_4 = \nu D_2(\sigma_{l-k} - \sigma_{l+k}),\\ &\gamma_1\gamma_3 - \gamma_2\gamma_4 = \nu^2(D_1^2 + D_2^2) S_k^l\sigma - \nu\varepsilon^2 E_1 \Delta_k^l\sigma,\\ &\gamma_1\gamma_4 + \gamma_2\gamma_3 = -\nu\varepsilon^2 E_2(\sigma_{l-k} - \sigma_{l+k})\end{aligned}$$

where $E_1 \equiv D_1 b_1 + D_2 b_2$, $E_2 \equiv D_1 b_2 - D_2 b_1$ and

$$\Delta_k^l\sigma \equiv \sigma_{l-k} - 2\sigma_l + \sigma_{l+k} = 8\sin^2\frac{k\pi}{n}\cos\frac{2l\pi}{n},$$

$$S_k^l\sigma \equiv (\sigma_l - \sigma_{l+k})(\sigma_l - \sigma_{l-k}) = 16\sin^2\frac{k\pi}{n}\sin\frac{k+2l}{n}\pi\sin\frac{k-2l}{n}\pi.$$

We are only interested in the signs of γ_1 and γ_3, so by (5.10) it is enough to consider the cases $1 \leqq l < n/2$, $1 \leqq k \leqq n/2$.

First we note that

$$(\beta 2)\qquad \Delta_k^l\sigma = \begin{cases} >0, & 1 \leqq l < \frac{n}{4},\\ =0, & l = \frac{n}{4},\\ <0, & \frac{n}{4} < l < \frac{n}{2},\end{cases}$$

$$(\beta 3)\qquad S_k^l\sigma = \begin{cases} <0, & 1 \leqq k < 2l,\\ =0, & k = 2l, \qquad \text{for } l,\ 1 \leqq l < \frac{n}{4},\\ >0, & 2l < k \leqq \frac{n}{2},\end{cases}$$

$$S_k^l\sigma = \begin{cases} <0, & 1 \leqq k < n-2l,\\ =0, & k = n-2l, \qquad \text{for } l,\ \frac{n}{4} < l < \frac{n}{2},\\ >0, & n-2l < k \leqq \frac{n}{2},\end{cases}$$

and

$$(\beta 4)\qquad S_k^{n/4}\sigma = -(\sigma_{n/4}-\sigma_{n/4\pm k})^2 = \begin{cases} =0, & k=\dfrac{n}{2}, \\ <0, & k\neq\dfrac{n}{2}. \end{cases}$$

(1) Assume that $\Delta_k^l\sigma \neq 0$: Let ε vanish in $(\beta 1)$. A little consideration reveals that $\gamma_1\gamma_3>0$ (resp. <0) holds for $\gamma_1\gamma_3-\gamma_2\gamma_4>0$ (resp. <0), and that $\gamma_1\gamma_3=0$ for $\gamma_1\gamma_3-\gamma_2\gamma_4=0$ (i.e., $S_k^l\sigma=0$). Next let $\nu/\varepsilon^2 \ll 1$ in $(\beta 1)$. Putting $\nu=0$ in $(\beta 1)$, we have $\gamma_2=\gamma_4=0$. Therefore, $\gamma_2=O(\nu)=\gamma_4$, which implies that

$$(\beta 5)\qquad \begin{aligned} &\operatorname{sign}(\gamma_1+\gamma_3)=\operatorname{sign}(2b_1\varepsilon^2), \\ &\operatorname{sign}(\gamma_1\gamma_3-\gamma_2\gamma_4)=\operatorname{sign}\{-\nu\varepsilon^2E_1\Delta_k^l\sigma\}=\operatorname{sign}(\gamma_1\gamma_3). \end{aligned}$$

Hence $(\beta 2)$ and $(\beta 5)$ show the stability result in Theorem 5.2 for $l\neq n/4$.

(2) Assume that $\Delta_k^l\sigma=0$ (i.e., $l=n/4$): We see from $(\beta 4)$ that $\gamma_2=\gamma_4=0$, $\gamma_1\gamma_3=0$ and $\gamma_1+\gamma_3<0$ for $k=n/2$. Next let $k\neq n/2$. If $\gamma_1=0$, then

$$\begin{aligned} &\gamma_2+\gamma_4=\nu D_2(\sigma_{l-k}-\sigma_{l+k})=2\nu D_2(\sigma_{l-k}-\sigma_l), \\ &\gamma_2\gamma_4=-\nu^2(D_1^2+D_2^2)S_k^l\sigma, \end{aligned}$$

which yields a contradiction: $(\gamma_2-\gamma_4)^2=(\gamma_2+\gamma_4)^2-4\gamma_2\gamma_4<0$. Thus the roots γ_α and γ_β never cross the imaginary axis in this case. This concludes the proof of Theorem 5.2.

Acknowledgment. The author expresses thanks to Professor Masaya Yamaguti for his suggestion which proved to be fruitful.

MELNIKOV'S METHOD AT A SADDLE-NODE AND THE DYNAMICS OF THE FORCED JOSEPHSON JUNCTION*

STEPHEN SCHECTER†

Abstract. A version of Melnikov's method is developed for time-periodic perturbations of a planar vector field having a separatrix loop at a saddle-node. The method is applied to the forced pendulum, or Josephson junction, equation $\beta\ddot{\phi}+\dot{\phi}+\sin\phi=\rho+\varepsilon\sin\omega t$.

Key words. Melnikov's method, saddle-node separatrix-loop bifurcation, pendulum, Josephson junction

AMS(MOS) subject classification. 58F14

1. Introduction. Melnikov's method [6], [3] is an analytic technique for showing the existence of transverse homoclinic orbits, which imply the complicated dynamics associated with horseshoes. The method applies to time-periodic perturbations of an autonomous planar vector field having a separatrix loop at a saddle point. In this work we shall extend Melnikov's method to the case in which the unperturbed vector field has a separatrix loop at a saddle-node.

Planar vector fields having a saddle-node separatrix loop occur generically in two-parameter families. It therefore seems natural to study three-parameter problems:

$$\begin{aligned}&\dot{x}=\tilde{f}(x,\nu_1,\nu_2)+\tilde{g}(x,\nu_1,\nu_2,\nu_3,t),\\&x\in\mathbb{R}^2,\qquad \nu_1,\nu_2,\nu_3\in\mathbb{R},\end{aligned}\tag{1}$$

with $\tilde{g}(x,\nu_1,\nu_2,0,t)\equiv 0$ and $\tilde{g}$ T-periodic in t. Here $\dot{x}=\tilde{f}(x,0,0)$ has a saddle-node separatrix loop, and $\dot{x}=\tilde{f}(x,\nu_1,\nu_2)$ is a generic unfolding. The analytic condition for such a generic unfolding was derived in [9]. There we studied the analogue of Melnikov's method for autonomous perturbations of a saddle-node separatrix loop.

(Similarly, saddle separatrix loops occur generically in one-parameter families of autonomous planar vector fields. Therefore, in the study of the usual Melnikov method it is natural to consider two-parameter problems in which the second parameter corresponds to a small time-periodic perturbation. This point of view is taken, for example, in [2] and [7].)

The motivating problem for this work is the pendulum equation with linear damping, a constant applied torque, and a small sinusoidal applied torque:

$$\beta\ddot{\phi}+\dot{\phi}+\sin\phi=\rho+\varepsilon\sin\omega t.$$

The same differential equation describes the AC–DC current-driven point Josephson junction. Setting $y=\dot{\phi}$, we have the system

$$\begin{aligned}&\dot{\phi}=y,\\&\dot{y}=\frac{1}{\beta}(-y-\sin\phi+\rho+\varepsilon\sin\omega t).\end{aligned}\tag{2}$$

There is a number $\beta_0>0$ such that the system (2) with $\rho=1$, $\beta=\beta_0$, $\varepsilon=0$ has a saddle-node separatrix loop. It is shown in [9] that the two-parameter autonomous unfolding obtained from (2) by setting $\varepsilon=0$ is generic. Thus (2) has the form (1) with $\nu_1=\rho-1$, $\nu_2=\beta-\beta_0$, $\nu_3=\varepsilon$. It follows from [5] and the calculations of [9] that there is a curve $\beta=\beta(\rho)$, $0<\rho\leqq 1$, having a quadratic tangency with the line $\rho=1$ at $(1,\beta_0)$,

such that (2) with $\beta=\beta(\rho)$, $0<\rho<1$, $\varepsilon=0$, has a saddle separatrix loop. In [8] Salam and Sastry applied Melnikov's method to (2) at these saddle separatrix loops. For fixed ρ, $0<\rho<1$, they found that for most ω (all but a discrete set), there is an $\mathcal{O}(\varepsilon)$-sized β-interval containing $\beta(\rho)$ such that for β in this interval, (2) has a transverse homoclinic orbit. A consequence of the present work is that, roughly speaking, the size of this interval remains uniformly $\mathcal{O}(\varepsilon)$ as $\rho\to 1$. This conclusion is consistent with Fig. 12 of [8]. Salam and Sastry speculate [8, p. 794] that for fixed ε, the size of the interval decreases as $\rho\to 1$. Whether or not this is so can presumably be decided by computing a second-order Melnikov function, but we do not pursue this point in the present paper.

The usual Melnikov method requires the evaluation of an integral around the separatrix loop; the integral involves the first-order approximation of the time-periodic perturbation. The present case is basically the same, except that one perturbation parameter must be rescaled as in [9], and certain boundary terms that go to zero in the saddle case must be retained.

In most applications of Melnikov's method the separatrix loop is known explicitly, and the required integral is explicitly calculated. The saddle separatrix loops of (2), however, are not known explicitly. Nevertheless Salam and Sastry succeed in [8] in determining enough about the integral to derive their results. Here also the saddle-node separatrix loop of (2) with $\rho=1$, $\beta=\beta_0$, $\varepsilon=0$ is not known explicitly, but enough can be calculated to derive the results.

This paper is organized as follows. In § 2 the results about equation (1) are described. The functions in terms of which the results are stated are specified more precisely in § 3. Proofs are given in § 4 through § 7. In § 8 the results are applied to (2).

2. Melnikov's method at a saddle-node. We shall consider the three-parameter problem (1) with $\tilde{g}(x,\nu_1,\nu_2,0,t)\equiv 0$, $\tilde{g}$ T-periodic in t. We assume:

(i) $\tilde{f}$ and $\tilde{g}$ are C^{k+1}, $k\geqq 5$,

(ii) $\tilde{f}(p,0,0)=0$,

(iii) $D_x\tilde{f}(p,0,0)$ has eigenvalues 0 and $-\lambda$, where $\lambda>0$.

Let u be a right eigenvector and w a left eigenvector of the eigenvalue 0, with w chosen so that $wu>0$.

(iv) $wD_x^2\tilde{f}(p,0,0)(u,u)>0$,

(v) $\dot{x}=\tilde{f}(x,0,0)$ has a separatrix loop Γ at p,

(vi) $wD_{\nu_1}\tilde{f}(p,0,0)>0$.

As in [9], these assumptions imply that $\dot{x}=\tilde{f}(x,0,0)$ has a saddle-node at p with one negative eigenvalue. The vector u is one tangent vector to Γ at p. As in [9] we let v denote a right eigenvector of $D_x\tilde{f}(p,0,0)$ for the eigenvalue $-\lambda$, chosen so that v is also tangent to Γ at p. See [9, Fig. 1]. Perturbation in the positive ν_1-direction eliminates the equilibrium p, while perturbation in the negative ν_1-direction splits the equilibrium in two.

For fixed $\nu=(\nu_1,\nu_2,\nu_3)$, let $\tilde{P}_\nu:\mathbb{R}^2\to\mathbb{R}^2$ be the time $(0,T)$ advance map of (2). Then $\tilde{P}_0$ has a fixed point of saddle-node type at p. In fact, assumptions (i) to (iv) and (vi) imply that there is a C^k function $\alpha(\nu_2,\nu_3)$, with $\alpha(0,0)=0$, such that $\tilde{P}_\nu$ has a fixed point of saddle-node type near p if and only if $\nu_1=\alpha(\nu_2,\nu_3)$. A fixed point of $\tilde{P}_\nu$ corresponds to a T-periodic solution of (1).

Let $f(x,\mu_1,\mu_2)=\tilde{f}(x,\nu_1,\nu_2)$, where $\mu_1=\nu_1-\alpha(\nu_2,0)$ and $\mu_2=\nu_2$. Let $g(x,\mu_1,\mu_2,\mu_3,t)=\tilde{g}(x,\nu_1,\nu_2,\nu_3,t)$, where $\mu_1=\nu_1-\alpha(\nu_2,\nu_3)$, $\mu_2=\nu_2$, $\mu_3=\nu_3$. We consider

$$\dot{x}=f(x,\mu_1,\mu_2)+g(x,\mu_1,\mu_2,\mu_3,t). \tag{3}$$

Notice f and g are C^k. For fixed $\mu=(\mu_1, \mu_2, \mu_3)$, let $P_\mu:\mathbb{R}^2\to\mathbb{R}^2$ be the time $(0, T)$ advance map of (3). Then P_μ has a fixed point of saddle-node type near p if and only if $\mu_1=0$. If $\mu_1<0$, then P_μ has two fixed points, one a saddle and one a sink, near p. If $\mu_1>0$ there are no fixed points of P_μ near p.

We shall show in § 3 that the fixed points of the maps P_μ can be parameterized as follows. There is a C^{k-2} mapping $p(\delta, \mu_2, \mu_3)$, from a neighborhood of $(0, 0, 0)$ in $\mathbb{R}^3$ to $\mathbb{R}^2$, such that $p(0, 0, 0)=p$; $p(0, \mu_2, \mu_3)$ is the fixed point of saddle-node type of $P_{(0,\mu_2,\mu_3)}$ near p; $p(\delta, \mu_2, \mu_3)$ is the fixed point of saddle-type of $P_{(-\delta^2,\mu_2,\mu_3)}$ near p if $\delta>0$, and is the sink of $P_{(-\delta^2,\mu_2,\mu_3)}$ near p if $\delta<0$.

We define $p(\delta, \mu_2, \mu_3, t)$ to be the T-periodic solution of

$$\dot{x}=f(x, -\delta^2, \mu_2)+g(x, -\delta^2, \mu_2, \mu_3, t) \tag{4}$$

that passes through $p(\delta, \mu_2, \mu_3)$ at $t=0$. Thus for $\delta\geqq 0$ there might exist solutions of (4) homoclinic to $p(\delta, \mu_2, \mu_3, t)$. For $\delta>0$, a homoclinic orbit is of course an orbit in the intersection of the stable and unstable manifolds of $p(\delta, \mu_2, \mu_3, t)$; for $\delta=0$, we consider only homoclinic orbits in the intersection of the stable and center manifolds of $p(0, \mu_2, \mu_3, t)$. We shall define in § 3 a C^{k-2} function $d(\delta, \mu_2, \mu_3, t_0)$, T-periodic in t_0, such that (4) has such a homoclinic orbit if and only if for $\delta\geqq 0$ and for some t_0, $d(\delta, \mu_2, \mu_3, t_0)=0$. Moreover, $d(\delta, \mu_2, 0, t_0)$ is independent of t_0, and $d(0, 0, 0, t_0)\equiv 0$. The homoclinic orbit is transverse if, in addition, $(\partial d/\partial t_0)(\delta, \mu_2, \mu_3, t_0)\neq 0$.

If $w=(w_1, w_2)$ and $z=(z_1, z_2)$, we define $w\wedge z=w_1z_2-w_2z_1$. The following theorem gives formulas for the partial derivatives of d at $(0, 0, 0, t_0)$.

THEOREM 1.

$$\frac{\partial d}{\partial\delta}(0, 0, 0, t_0)=\frac{\partial p}{\partial\delta}(0, 0, 0)\wedge\lim_{t_1\to\infty} f(q(t_1), 0, 0)\exp\left[-\int_0^{t_1}\operatorname{div} f(q(s), 0, 0)\,ds\right],$$

a negative multiple of $u\wedge v$ *that is independent of* t_0.

$$\begin{aligned}\frac{\partial d}{\partial\mu_2}(0, 0, 0, t_0)=&\frac{\partial p}{\partial\mu_2}(0, 0, 0)\wedge\lim_{t_1\to\infty} f(q(t_1), 0, 0)\exp\left[-\int_0^{t_1}\operatorname{div} f(q(s), 0, 0)\,ds\right]\\&+\int_{-\infty}^{\infty}\exp\left[-\int_0^{t}\operatorname{div} f(q(s), 0, 0)\,ds\right]f(q(t), 0, 0)\\&\wedge\frac{\partial f}{\partial\mu_2}(q(t), 0, 0)\,dt\end{aligned}$$

independent of t_0, *where the limit is a negative multiple of* v *and the integral converges.*

$$\begin{aligned}\frac{\partial d}{\partial\mu_3}(0, 0, 0, t_0)=\lim_{t_1\to\infty}\Bigg\{&\frac{\partial p}{\partial\mu_3}(0, 0, 0, t_1)\wedge f(q(t_1-t_0), 0, 0)\\&\cdot\exp\left[-\int_{t_0}^{t_1}\operatorname{div} f(q(s-t_0), 0, 0)\,ds\right]\\&+\int_{t_0}^{t_1}\exp\left[-\int_{t_0}^{t}\operatorname{div} f(q(s-t_0), 0, 0)\,ds\right]f(q(t-t_0), 0, 0)\\&\wedge\frac{\partial g}{\partial\mu_3}(q(t-t_0), 0, 0, t)\,dt\Bigg\}.\end{aligned}$$

The limit is finite. Each summand is asymptotically periodic of period T in t_1 as $t_1 \to \infty$. In particular, $(\partial p/\partial \mu_3)$ $(0, 0, 0, t_1)$ *has period T in t_1, and*

$$f(q(t_1 - t_0), 0, 0) \exp\left[-\int_{t_0}^{t_1} \operatorname{div} f(q(s - t_0), 0, 0)\, ds \right]$$

approaches a finite negative multiple of v as $t_1 \to \infty$, independent of t_0.

If the constant $(\partial d/\partial \mu_2)$ $(0, 0, 0, t_0) \neq 0$, then there is a C^{k-2} function $\mu_2(\delta)$ such that for δ and μ_2 small, $d(\delta, \mu_2, 0, t_0) = 0$ if and only if $\mu_2 = \mu_2(\delta)$. If $(\partial d/\partial \mu_2)(0, 0, 0, t_0) \neq 0$, we define the Melnikov function

$$M(t_0) = -\frac{\partial d}{\partial \mu_3}(0, 0, 0, t_0) / \frac{\partial d}{\partial \mu_2}(0, 0, 0, t_0).$$

THEOREM 2. *Assume* (1) $(\partial d/\partial \mu_2)(0, 0, 0, t_0)$, *a constant independent of t_0 by Theorem* 1, *is not zero*; (2) $M(t_0)$ *attains its maximum* (*resp. minimum*) *value on* $0 \leqq t_0 < T$ *at a unique* $t_0^{\max}$ (*resp.* $t_0^{\min}$), *and* $M(t_0)$ *has a nondegenerate extremum at* $t_0^{\max}$ (*resp.* $t_0^{\min}$); (3) *if* $0 \leqq t_0 < T$, $t_0 \neq t_0^{\min}$, $t_0^{\max}$, *then* $M'(t_0) \neq 0$. *Then there are functions* $\gamma_*(\delta, \mu_3)$ *and* $\gamma^*(\delta, \mu_3)$, *with* $\gamma_*(\delta, 0) \equiv \gamma^*(\delta, 0) \equiv 0$ *and* $(\partial \gamma_*/\partial \mu_3)(0, 0) = M(t_0^{\min})$, $(\partial \gamma^*/\partial \mu_3)(0, 0) = M(t_0^{\max})$, *such that, for* (δ, μ_2, μ_3) *small, the equation* $d(\delta, \mu_2, \mu_3, t_0) = 0$ *has a solution if and only if either*

(a) $\mu_3 \geqq 0$ *and* $\gamma_*(\delta, \mu_3) \leqq \mu_2 - \mu_2(\delta) \leqq \gamma^*(\delta, \mu_3)$, *or*

(b) $\mu_3 \leqq 0$ *and* $\gamma^*(\delta, \mu_3) \leqq \mu_2 - \mu_2(\delta) \leqq \gamma_*(\delta, \mu_3)$.

Therefore, there is a homoclinic orbit of (3) *asymptotic to the periodic solution* $p(\sqrt{-\mu_1}, \mu_2, \mu_3, t)$ *if and only if either*

(a) $\mu_3 \geqq 0$ *and* $\gamma_*(\sqrt{-\mu_1}, \mu_3) \leqq \mu_2 - \mu_2(\sqrt{-\mu_1}) \leqq \gamma^*(\sqrt{-\mu_1}, \mu_3)$, *or*

(b) $\mu_3 \leqq 0$ *and* $\gamma^*(\sqrt{-\mu_1}, \mu_3) \leqq \mu_2 - \mu_2(\sqrt{-\mu_1}) \leqq \gamma_*(\sqrt{-\mu_1}, \mu_3)$.

There is a transverse homoclinic orbit of (3) *asymptotic to this periodic solution if and only if* (a) *or* (b) *holds with all inequalities replaced by strict inequalities.*

See Fig. 1. The upper and lower curves in Fig. 1 meet the μ_2-axis at $\mu_2 = \gamma^*(0, \mu_3) \approx \mu_3 M(t_0^{\max})$ and $\mu_2 = \gamma_*(0, \mu_3) \approx \mu_3 M(t_0^{\min})$. In drawing Fig. 1 we have assumed $\mu_3 > 0$ and $M(t_0^{\min}) < 0 < M(t_0^{\max})$.

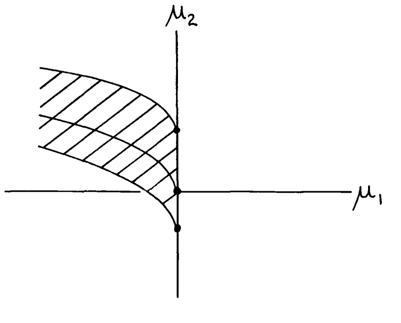

FIG. 1

Theorem 2 remains true if (2) and (3) are replaced by the assumption that $M(t_0)$ is a Morse function (all critical points nondegenerate, no two have the same value of M). Slightly weaker assumptions also suffice. A similar approach to the usual saddle case is in [2] and [7].

3. Functions used in the statements of Theorems 1 and 2. In this section we describe more precisely the functions $p(\delta, \mu_2, \mu_3)$, $p(\delta, \mu_2, \mu_3, t)$, and $d(\delta, \mu_2, \mu_3, t_0)$ used in the statements of Theorems 1 and 2.

We first note that the system

$$\begin{aligned} &\dot{x} = f(x, \mu_1, \mu_2) + g(x, \mu_1, \mu_2, \mu_3, t), \\ &\dot{\mu}_i = 0 \qquad (i = 1, 2, 3) \end{aligned} \tag{5}$$

has the constant solution

$$(x(t), \mu_1(t), \mu_2(t), \mu_3(t)) \equiv (p, 0, 0, 0). \tag{6}$$

This T-periodic solution of (5) has a five-dimensional C^k local center manifold $N_{\text{loc}} \subset \mathbb{R}^2 \times \mathbb{R}^3 \times \mathbb{R}$; the last variable is time t. (Note that a solution of (5) is a curve in $x\mu$-space, but an invariant manifold of (5) is a submanifold of $x\mu t$-space.) N_{loc} meets each space $\mathbb{R}^2 \times \{(\mu_1, \mu_2, \mu_3)\} \times \mathbb{R}$, (μ_1, μ_2, μ_3) small, in a two-dimensional surface. For $(\mu_1, \mu_2, \mu_3) = (0, 0, 0)$, this surface contains

$$(\text{a portion of } \Gamma \text{ tangent at } p \text{ to } u \times \{(0, 0, 0)\}) \times \mathbb{R}.$$

N_{loc} is T-periodic in t [1, § 9.4].

We shall now give a useful parameterization of the center manifold. Let $q(t)$ be a solution of $\dot{x} = f(x, 0, 0)$ with $q(0) \in \Gamma$. Let N denote the "global" center manifold that contains N_{loc}, i.e., the invariant manifold of (5) obtained from N_{loc} by completing solution curves. N meets each space $\mathbb{R}^2 \times \{(\mu_1, \mu_2, \mu_3)\} \times \mathbb{R}$, (μ_1, μ_2, μ_3) small, in a two-dimensional surface, which we identify with a surface $N(\mu_1, \mu_2, \mu_3)$ in $\mathbb{R}^2 \times \mathbb{R}$ (xt-space). Let L be a line segment in $\mathbb{R}^2$ perpendicular to Γ at $q(0)$. Then the surface $N(0, 0, 0)$ meets $L \times \mathbb{R}$ transversally in $\mathbb{R}^2 \times \mathbb{R}$ along the line $\{q(0)\} \times \mathbb{R}$. Therefore for (μ_1, μ_2, μ_3) small there is a C^k function $x(\mu_1, \mu_2, \mu_3, t_0)$, T-periodic in t_0, such that $x(0, 0, 0, t_0) \equiv q(0)$, and $x(\mu_1, \mu_2, \mu_3, t_0) \in N(\mu_1, \mu_2, \mu_3) \cap L \times \{t_0\}$. Since a C^k vector field has a C^k flow, there is a C^k family of solutions of (3):

$$q^c(\mu_1, \mu_2, \mu_3, t_0, t), \qquad (\mu_1, \mu_2, \mu_3) \text{ small},$$

such that $q^c(\mu_1, \mu_2, \mu_3, t_0, t_0) = x(\mu_1, \mu_2, \mu_3, t_0)$. Thus

$$q^c(\mu_1, \mu_2, \mu_3, t_0 + T, t + T) = q^c(\mu_1, \mu_2, \mu_3, t_0, t).$$

Notice $q^c(0, 0, 0, t_0, t) = q(t - t_0)$, and the curve

$$\{(q^c(\mu_1, \mu_2, \mu_3, t_0, t), t) \colon t \in \mathbb{R}\} \tag{7}$$

lies in $N(\mu_1, \mu_2, \mu_3)$. For $\mu_1 < 0$, the curve (7) lies in the unstable manifold of a T-periodic solution of saddle-type of (3); for $\mu_1 = 0$, it lies in the center manifold of a T-periodic solution of saddle-node type of (3). (Similar terminology is used in [9], except that the problem studied there is autonomous. See Fig. 3 of [9].)

We next describe coordinates that simplify the differential equation. According to [1, § 9.4] there is a C^k change of coordinates

$$y(x, \mu_1, \mu_2, \mu_3, t) = (y_1(x, \mu_1, \mu_2, \mu_3, t), y_2(x, \mu_1, \mu_2, \mu_3, t)), \tag{8}$$

T-periodic in t, defined for $\|x - p\|$, μ_1, μ_2, μ_3 small, such that (1) $y(p, 0, 0, 0, t) \equiv 0$; (2) $N_{\text{loc}} \cap \mathbb{R}^2 \times \{(\mu_1, \mu_2, \mu_3, t)\}$ is transformed into the line $y_2 = 0$; (3) the lines $y_1 =$ constant in $\mathbb{R}^2 \times \{(\mu_1, \mu_2, \mu_3)\}$ are mapped into each other by the (t_1, t_2)-advance maps. In other words, in the new coordinates (3) becomes the C^k differential equation

$$\begin{aligned} \dot{y}_1 &= a(y_1, \mu_1, \mu_2) + \mu_3 b(y_1, \mu_1, \mu_2, \mu_3, t), \\ \dot{y}_2 &= y_2[c(y_1, y_2, \mu_1, \mu_2) + \mu_3\, e(y_1, y_2, \mu_1, \mu_2, \mu_3, t)]. \end{aligned}$$

Since the stable manifold of the constant solution (6) necessarily is transformed into the plane $y_1=0$ in $\mathbb{R}^2\times\{(0,0,0)\}\times\mathbb{R}$, it is easy to arrange that

$$D_x y(p,0,0,0,t)u\equiv(1,0),\qquad D_x y(p,0,0,0,t)v\equiv(0,1).$$

We may also assume the coordinates are chosen so that for each (μ_2,μ_3), the fixed point of $P_{(0,\mu_2,\mu_3)}$ near p corresponds to $y_1=y_2=0$.

Consider the system

$$\begin{aligned}\dot y_1&=a(y_1,\mu_1,\mu_2)+\mu_3 b(y_1,\mu_1,\mu_2,\mu_3,t),\\ \dot y_2&=y_2[c(y_1,y_2,\mu_1,\mu_2)+\mu_3\, e(y_1,y_2,\mu_1,\mu_2,\mu_3,t)],\\ \dot\mu_i&=0,\qquad i=1,2,3.\end{aligned}\tag{9}$$

As in [9] it can be shown that the fixed points of the time $(0,T)$ advance map of (9) near $((0,0),0,0,0)$ comprise a set of the form

$$\{((\hat p_1(\delta,\mu_2,\mu_3),0),-\delta^2,\mu_2,\mu_3):(\delta,\mu_2,\mu_3)\text{ small}\},$$

with $\hat p_1$ of class C^{k-2},

$$\hat p_1(0,\mu_2,\mu_3)\equiv0\quad\text{and}\quad\frac{\partial p_1}{\partial\delta}(0,\mu_2,\mu_3)>0.$$

Let $(\hat p_1(\delta,\mu_2,\mu_3,t),0)$ denote the T-periodic solution of

$$\begin{aligned}\dot y_1&=a(y_1,-\delta^2,\mu_2)+\mu_3 b(y_1,-\delta^2,\mu_2,\mu_3,t),\\ \dot y_2&=y_2[c(y_1,y_2,-\delta^2,\mu_2)+\mu_3\, e(y_1,y_2,-\delta^2,\mu_2,\mu_3,t)]\end{aligned}\tag{10}$$

that has $\hat p_1(\delta,\mu_2,\mu_3,0)=\hat p_1(\delta,\mu_2,\mu_3)$.

Let $x=x(y,\mu_1,\mu_2,\mu_3,t)$ be the change of coordinates inverse to (8). Define

$$p(\delta,\mu_2,\mu_3)=x((\hat p_1(\delta,\mu_2,\mu_3),0),-\delta^2,\mu_2,\mu_3,0).$$

Then $p(\delta,\mu_2,\mu_3)$ is C^{k-2}, $p(0,0,0)=p$, and $p(\delta,\mu_2,\mu_3)$ is a fixed point of saddle-node type of $P_{(0,\mu_2,\mu_3)}$ if $\delta=0$; a fixed point of saddle type of $P_{(-\delta^2,\mu_2,\mu_3)}$ if $\delta>0$; a sink of $P_{(-\delta^2,\mu_2,\mu_3)}$ if $\delta<0$. Let $p(\delta,\mu_2,\mu_3,t)=x((\hat p_1(\delta,\mu_2,\mu_3,t),0),-\delta^2,\mu_2,\mu_3,t)$, the T-periodic solution of (4) with $p(\delta,\mu_2,\mu_3,0)=p(\delta,\mu_2,\mu_3)$.

System (10) has at the T-periodic solution $(\hat p_1(\delta,\mu_2,\mu_3,t),0)$ the invariant manifold $\{(y_1,y_2,t):y_1=\hat p_1(\delta,\mu_2,\mu_3,t)\}$. For $\delta=0$, this surface is the stable manifold of the saddle-node T-periodic solution $(\hat p_1(0,\mu_2,\mu_3,t),0)$ of (10); for $\delta>0$ it is the stable manifold of the saddle T-periodic solution $(\hat p_1(\delta,\mu_2,\mu_3,t),0)$ of (10); and for $\delta<0$, it is the strong stable manifold of the attracting T-periodic solution $(\hat p_1(\delta,\mu_2,\mu_3,t),0)$ of (10). Returning to x-coordinates, we find that (4) has at the T-periodic solution $p(\delta,\mu_2,\mu_3,t)$ the local invariant manifold $\{(x((y_1,y_2),-\delta^2,\mu_2,\mu_3,t),t):y_1=\hat p_1(\delta,\mu_2,\mu_3,t)\}$.

For each (δ,μ_2,μ_3) the local invariant manifold of (4) constructed above extends to a "global" invariant manifold $Q(\delta,\mu_2,\mu_3)$ by completing solution curves. $Q(\delta,\mu_2,\mu_3)$ is a two-dimensional submanifold of $\mathbb{R}^2\times\mathbb{R}$ that depends C^{k-2} on (δ,μ_2,μ_3). Notice that $Q(0,0,0)$ contains $\Gamma\times\mathbb{R}$. Now a construction similar to that of $q^c(\mu_1,\mu_2,\mu_3,t)$ yields a C^{k-2} family

$$q^s(\delta,\mu_2,\mu_3,t_0,t),\qquad(\delta,\mu_2,\mu_3)\text{ small},$$

each a solution of (4), such that $q^s(\delta,\mu_2,\mu_3,t_0,t_0)\in L$, $(q^s(\delta,\mu_2,\mu_3,t_0,t),t)\in Q(\delta,\mu_2,\mu_3)$, $q^s(0,0,0,t_0,t)=q(t-t_0)$, and $q^s(\delta,\mu_2,\mu_3,t_0+T,t+T)=q^s(\delta,\mu_2,\mu_3,t_0,t)$.

We can now discuss homoclinic solution of (1). For any vector $w=(w_1, w_2)\in R^2$, recall that $w^\perp=(-w_2, w_1)$. If $z=(z_1, z_2)$, let $w\wedge z=w_1z_2-w_2z_1=w^\perp\cdot z$. Define $d^c(\mu_1, \mu_2, \mu_3, t_0)$ and $d^s(\delta, \mu_2, \mu_3, t_0)$ by

$$q^c(\mu_1, \mu_2, \mu_3, t_0, t_0)=q(0)+[d^c(\mu_1, \mu_2, \mu_3, t_0)/\|f(q(0), 0, 0)\|^2]f^\perp(q(0), 0, 0),$$

$$q^s(\delta, \mu_2, \mu_3, t_0, t_0)=q(0)+[d^s(\delta, \mu_2, \mu_3, t_0)/\|f(q(0), 0, 0)\|^2]f^\perp(q(0), 0, 0).$$

Then d^c is C^k and d^s is C^{k-2}. We have

$$\begin{aligned}d^c(\mu_1, \mu_2, \mu_3, t_0)&=f^\perp(q(0), 0, 0)\cdot[q^c(\mu_1, \mu_2, \mu_3, t_0, t_0)-q(0)]\\&=f(q(0), 0, 0)\wedge[q^c(\mu_1, \mu_2, \mu_3, t_0, t_0)-q(0)].\end{aligned}$$

Similarly,

$$d^s(\delta, \mu_2, \mu_3, t_0)=f(q(0), 0, 0)\wedge[q^s(\delta, \mu_2, \mu_3, t_0, t_0)-q(0)].$$

There is a homoclinic orbit of (4) asymptotic to the T-periodic solution $p(\delta, \mu_2, \mu_3, t)$ if and only if $\delta\geqq 0$ and for some t_0,

$$d(\delta, \mu_2, \mu_3, t_0)\underset{\text{def}}{=}d^c(-\delta^2, \mu_2, \mu_3, t_0)-d^s(\delta, \mu_2, \mu_3, t_0)=0.$$

Here $d(\delta, \mu_2, \mu_3, t_0)$ is C^{k-2}. The homoclinic orbit is transverse if, in addition, $(\partial d/\partial t_0)(\delta, \mu_2, \mu_3, t_0)\neq 0$.

4. Proof of Theorem 1. Since for $\mu_3=0$ the perturbation is autonomous, the formulas for $\partial d/\partial\delta$ and $\partial d/\partial\mu_2$ follow immediately from [9]. We shall derive the formula for $\partial d/\partial\mu_3$. To simplify the notation, we set

$$\begin{aligned}&f(x, \mu_3)=f(x, 0, 0, \mu_3),\\&g(x, \mu_3, t)=g(x, 0, 0, \mu_3, t),\\&p(\mu_3)=p(0, 0, \mu_3),\\&p(\mu_3, t)=p(0, 0, \mu_3, t),\\&q^{c,s}(\mu_3, t_0, t)=q^{c,s}(0, 0, \mu_3, t_0, t),\\&d^{c,s}(\mu_3, t_0)=d^{c,s}(0, 0, \mu_3, t_0).\end{aligned}$$

For $q^{c,s}(\mu_3, t_0, t)$, we have the variational equations

$$\frac{d}{dt}\frac{\partial q^{c,s}}{\partial\mu_3}(0, t_0, t)=D_xf(q(t-t_0), 0)\frac{\partial q^{c,s}}{\partial\mu_3}(0, t_0, t)+\frac{\partial g}{\partial\mu_3}(q(t-t_0), 0, t).$$

Define

$$(11^{c,s})\qquad \Delta_{\mu_3}^{c,s}(t_0, t)=f(q(t-t_0), 0)\wedge\frac{\partial q^{c,s}}{\partial\mu_3}(0, t_0, t).$$

For $d^{c,s}(\mu_3, t_0)$ we have the derivative formulas

$$\frac{\partial d^{c,s}}{\partial\mu_3}(0, t_0)=\Delta_{\mu_3}^{c,s}(t_0, t_0).$$

Using the variational equations for q^c and q^s, we compute as in [3]:

$$\frac{d}{dt}\Delta_{\mu_3}^{c,s}(t_0, t)=\operatorname{div}f(q(t-t_0), 0)\,\Delta_{\mu_3}^{c,s}(t_0, t)+f(q(t-t_0), 0)\wedge\frac{\partial g}{\partial\mu_3}(q(t-t_0), 0, t).$$

Solving these linear differential equations, we obtain, for any t_1

$$\begin{aligned}\Delta^{c,s}_{\mu_3}(t_0, t_0) = \Delta^{c,s}_{\mu_3}(t_0, t_1) \exp\left[-\int_{t_0}^{t_1} \operatorname{div} f(q(t-t_0), 0)\, dt \right] \\ -\int_{t_0}^{t_1} \exp\left[-\int_{t_0}^{t} \operatorname{div} f(q(s-t_0), 0)\, ds \right] \\ \cdot f(q(t-t_0), 0) \wedge \frac{\partial g}{\partial \mu_3}(q(t-t_0), 0, t)\, dt.\end{aligned} \tag{$12^{c,s}$}$$

We define new C^k coordinates $y(x, \mu_3, t)$, T-periodic in t, on $\mathbb{R}^2$ near p, such that

$$y(p(\mu_3, t), \mu_3, t) \equiv 0, \tag{13}$$

the local stable manifold of the T-periodic solution $p(\mu_3, t)$ becomes the plane $y_1 = 0$ in yt-space, and the local center manifold of $p(\mu_3, t)$ becomes the plane $y_2 = 0$ in yt-space. (This coordinate change is a little different from that used in § 2.)

We shall first study (12^s) in the limit $t_1 \to \infty$. Define

$$\begin{aligned}\tilde{q}^s(\mu_3, t_0, t) &= y(q^s(\mu_3, t_0, t), \mu_3, t) \\ &= (0, y_2(\mu_3, t_0, t)).\end{aligned} \tag{14}$$

Since $q^s(\mu_3, t_0, t) \to p(\mu_3, t)$ as $t \to \infty$, for each μ_3 near 0, $\tilde{q}^s(\mu_3, t_0, t)$ and hence $y_2(\mu_3, t_0, t)$ are defined for sufficiently large t.

LEMMA 1. $(\partial y_2/\partial \mu_3)(0, t_0, t) \to 0$ *as* $t \to \infty$.

We shall postpone the proof of Lemma 1 to § 5. From Lemma 1 and (14) it follows immediately that

$$\frac{\partial q^s}{\partial \mu_3}(0, t_0, t) \to 0 \quad \text{as } t \to \infty. \tag{15}$$

By (14),

$$\frac{\partial q^s}{\partial \mu_3}(0, t_0, t) = D_x y(q(t-t_0), 0, t) \frac{\partial q^s}{\partial \mu_3}(0, t_0, t) + \frac{\partial y}{\partial \mu_3}(q(t-t_0), 0, t). \tag{16}$$

By (13),

$$D_x y(p, 0, t) \frac{\partial p}{\partial \mu_3}(0, t) + \frac{\partial y}{\partial \mu_3}(p, 0, t) = 0. \tag{17}$$

Let $t \to \infty$ in (16). Then $q(t-t_0) \to p$, so (15), (16), (17), and the invertibility of $D_x y$ imply

$$\lim_{t \to \infty} \left[\frac{\partial q^s}{\partial \mu_3}(0, t_0, t) - \frac{\partial p}{\partial \mu_3}(0, t) \right] = 0. \tag{18}$$

Since $(\partial p/\partial \mu_3)(0, t)$ is T-periodic in t, $(\partial q^s/\partial \mu_3)(0, t_0, t)$ is asymptotically T-periodic in t as $t \to \infty$.

Using (11^s) we rewrite (12^s) as

$$\begin{aligned}-\Delta^s_{\mu_3}(t_0, t) = \frac{\partial q^s}{\partial \mu_3}(0, t_0, t_1) \wedge f(q(t_1-t_0), 0) \exp\left[-\int_{t_0}^{t_1} \operatorname{div} f(q(t-t_0), 0)\, dt \right] \\ +\int_{t_0}^{t_1} \exp\left[-\int_{t_0}^{t} \operatorname{div} f(q(s-t_0), 0)\, ds \right] \\ \cdot f(q(t-t_0), 0) \wedge \frac{\partial g}{\partial \mu_3}(q(t-t_0), 0, t)\, dt.\end{aligned} \tag{19}$$

Now,

$$\lim_{t_1\to\infty} f(q(t_1-t_0),0)\exp\left[-\int_{t_0}^{t_1}\operatorname{div} f(q(t-t_0),0)\,dt\right]$$
$$=\lim_{t_1\to\infty} f(q(t_1-t_0),0)\exp\left[-\int_{0}^{t_1-t_0}\operatorname{div} f(q(s),0)\,ds\right]$$

is a negative multiple of v by [9]. Therefore (18) implies that the first summand of (19) is asymptotically periodic in t_1 as $t_1\to\infty$ with period T. Therefore the second summand of (19), the integral, is asymptotically periodic in t_1 as $t_1\to\infty$ with period T.

Next we shall study (12^c) in the limit $t_1\to-\infty$. Define

(20) $$\begin{aligned}\tilde{q}^c(\mu_3,t_0,t)&=y(q^c(\mu_3,t_0,t),\mu_3,t)\\&=(y_1(\mu_3,t_0,t),0).\end{aligned}$$

Since $q^c(\mu_3,t_0,t)\to p(\mu_3,t)$ as $t\to-\infty$, for each μ_3 near 0, $\tilde{q}^c(\mu_3,t_0,t)$ and hence $y_1(\mu_3,t_0,t)$ are defined for sufficiently negative t.

LEMMA 2. *$(\partial y_1/\partial\mu_3)(0,t_0,t)\to 0$ as $t\to-\infty$.*

We postpone the proof of Lemma 2 to § 6. Given Lemma 2, we prove as in [9] that the first summand of (12^c) approaches zero as $t_1\to-\infty$, so that the second summand of (12^c), the integral, approaches a limit as $t_1\to-\infty$. Therefore,

(21) $$\begin{aligned}\Delta^c_{\mu_3}(t_0,t_0)=\int_{-\infty}^{t_0}&\exp\left[-\int_{t_0}^{t}\operatorname{div} f(q(s-t_0),0)\,ds\right]f(q(t-t_0),0)\\&\wedge\frac{\partial g}{\partial\mu_3}(t-t_0,0,t)\,dt.\end{aligned}$$

The formula for $\partial d/\partial\mu_3$ in Theorem 1 now follows by adding (21) to (19) and using (18).

5. Proof of Lemma 1. To simplify notation, we fix t_0 and let $z(\mu_3,t)=y_2(\mu_3,t_0,t)$. Then $z(\mu_3,t)$ satisfies a differential equation of the form

(22) $$\dot z=-\lambda(\mu_3,t)z(1+zG(z,\mu_3,t)),$$

where $\lambda(0,t)\equiv\lambda>0$, $G(z,0,t)$ is independent of t, $\lambda(\mu_3,t)$ and $G(z,\mu_3,t)$ are T-periodic in t. When $\mu_3=0$ we can solve (22) by separation of variables as in [9] to obtain

(23) $$z(0,t)=\mathcal{O}(e^{-\lambda t})\quad\text{as } t\to\infty.$$

Using (23), we find that the variational equation for (22) along $z(0,t)$ is

$$\frac{d}{dt}\frac{\partial z}{\partial\mu_3}(0,t)=A(t)\frac{\partial z}{\partial\mu_3}(0,t)+B(t),$$

where $A(t)=-\lambda+\mathcal{O}(e^{-\lambda t})$ as $t\to\infty$, $B(t)=\mathcal{O}(e^{-\lambda t})$ as $t\to\infty$. Therefore

$$\begin{aligned}\frac{\partial z}{\partial\mu_3}(0,t)&=\int_0^t B(s)\exp\left(\int_s^t A(r)\,dr\right)ds\\&=\int_0^t\mathcal{O}(e^{-\lambda s})\exp\left(\int_s^t-\lambda+\mathcal{O}(e^{-\lambda r})\,dr\right)ds\\&=\int_0^t\mathcal{O}(e^{-\lambda s})e^{-\lambda(t-s)}\exp\left(\int_s^t\mathcal{O}(e^{-\lambda r})\,dr\right)ds\\&\leqq Kte^{-\lambda t}\to 0\quad\text{as } t\to\infty.\end{aligned}$$

6. Proof of Lemma 2. The function $y_1(\mu_3, t_0, t)$ satisfies a differential equation of the form

$$\dot{z} = h(z, \mu_3, t), \tag{24}$$

with h T-periodic in t and $h(0, \mu_3, t) \equiv 0$. We have

$$h(z, 0, t) = \eta z^2(1 + zH(z))$$

with $\eta > 0$. Moreover, for μ_3 small the time $(t_0, t_0 + T)$ advance map of (24) has the form

$$z \to z + A(\mu_3, t_0)z^2(1 + B(z, \mu_3, t_0)), \tag{25}$$

with $A(\mu_3, t_0) = A_1 + \mu_3 A_2(\mu_3, t_0)$, $B(z, \mu_3, t_0) = z[B_1(z) + \mu_3 B_2(z, \mu_3, t_0)]$, A_2 and B_2 T-periodic in t_0.

Let $\zeta(z, \mu_3, t_0, t)$ be the solution of (24) that has the value z at $t = t_0$. Then

$$\zeta(z, 0, t_0, t_0 + t) = \zeta(z, 0, 0, t) = z + \eta t z^2(1 + zC(z, t)). \tag{26}$$

Comparing (25) and (26), we see that

$$A_1 = \eta T \quad \text{and} \quad B_1(z) = C(z, t). \tag{27}$$

Choose numbers m and n such that $mT < A_2(\mu_3, t_0) < nT$ for μ_3 small and all t_0. Let $\eta_*(\mu_3) = \eta + m\mu_3$, $\eta^*(\mu_3) = \eta + n\mu_3$. Then for $\mu_3 > 0$ small and any t_0,

$$\eta_*(\mu_3)T < A(\mu_3, t_0) < \eta^*(\mu_3)T. \tag{28}$$

Consider, in addition to (25), the autonomous differential equations

$$\dot{z} = \eta_*(\mu_3)z^2(1 + zH(z)), \tag{29}$$

$$\dot{z} = \eta^*(\mu_3)z^2(1 + zH(z)). \tag{30}$$

The flows are

$$\zeta_*(z, \mu_3, t) = z + \eta_*(\mu_3)tz^2(1 + z[C(z, t) + \mu_3 C_*(z, \mu_3, t)]), \tag{31}$$

$$\zeta^*(z, \mu_3, t) = z + \eta^*(\mu_3)tz^2(1 + z[C(z, t) + \mu_3 C^*(z, \mu_3, t)]). \tag{32}$$

Therefore

$$\zeta^*(z, 0, t) = \zeta(z, 0, t_0, t_0 + t) = \zeta_*(z, 0, t) \tag{33}$$

for z small and any t_0, t. From (25), (27), (28), (31), (32), and $\eta > 0$, it follows that for $z > 0$ and $\mu_3 > 0$ small, any t_0, and any integer $N < 0$,

$$\zeta^*(z, \mu_3, NT) < \zeta(z, \mu_3, t_0, t_0 + NT) < \zeta_*(z, \mu_3, NT). \tag{34}$$

Now fix t_0 and consider $s \in [t_0 - T, t_0]$. Let $z(\mu_3, s) = y_1(\mu_3, t_0, s)$, so that

$$y_1(\mu_3, t_0, s + NT) = \zeta(z(\mu_3, s), \mu_3, s, s + NT). \tag{35}$$

Then (34) and (35) imply for $\mu_3 > 0$ small and any integer $N < 0$,

$$\zeta^*(z(\mu_3, s), \mu_3, NT) < y_1(\mu_3, t_0, s + NT) < \zeta_*(z(\mu_3, s), \mu_3, NT). \tag{36}$$

Also, (33) and (35) imply, for any integer N,

$$\zeta^*(z(0, s), 0, NT) = y_1(0, t_0, s + NT) = \zeta_*(z(0, s), 0, NT). \tag{37}$$

Let $\theta^*(\mu_3, s, t) = \zeta^*(z(\mu_3, s), \mu_3, t)$, $\theta_*(\mu_3, s, t) = \zeta_*(z(\mu_3, s), \mu_3, t)$. For each fixed (μ_3, s), $\theta^*(\mu_3, s, t)$ (resp. $\theta_*(\mu_3, s, t)$) is a solution of (30) (resp. (29)). Then (36) and (37) imply, for any integer $N < 0$,

$$(38)\qquad \frac{\partial \theta^*}{\partial \mu_3}(0, s, NT) \leqq \frac{\partial y_1}{\partial \mu_3}(0, t_0, s+NT) \leqq \frac{\partial \theta_*}{\partial \mu_3}(0, s, NT).$$

The proof of Lemma 3 in [9] can easily be adapted to show that

$$(39)\qquad \lim_{t\to-\infty} \frac{\partial \theta^*}{\partial \mu_3}(0, s, t) = \lim_{t\to-\infty} \frac{\partial \theta_*}{\partial \mu_3}(0, s, t) = 0,$$

and the limit is uniform in $s \in [t_0 - T, t_0]$. On the other hand, every $t < t_0$ can be expressed as $t = s + NT$, $s \in [t_0 - T, t_0]$, N a negative integer. Lemma 2 therefore follows from (38) and (39).

7. Proof of Theorem 2. Since $d(\delta, \mu_2(\delta), 0, t_0) \equiv 0$, we have

$$(40)\qquad \begin{aligned} d(\delta, \mu_2, \mu_3, t_0) = {} & \frac{\partial d}{\partial \mu_2}(\delta, \mu_2(\delta), 0, t_0)(\mu_2 - \mu_2(\delta)) \\ & + \frac{\partial d}{\partial \mu_3}(\delta, \mu_2(\delta), 0, t_0)\mu_3 \\ & + o(|\mu_2 - \mu_2(\delta)| + |\mu_3|). \end{aligned}$$

Since $(\partial d/\partial \mu_2)(0, 0, 0, t_0)$ is a nonzero constant, by the implicit function theorem there is a C^{k-2} function $\gamma(\delta, \mu_3, t_0)$, T-periodic in t_0, such that for δ, $\mu_2 - \mu_2(\delta)$, and μ_3 small, $d(\delta, \mu_2, \mu_3, t_0) = 0$ if and only if

$$(41)\qquad \mu_2 - \mu_2(\delta) = \gamma(\delta, \mu_3, t_0) = \gamma_1(\delta, t_0)\mu_3 + o(\mu_3).$$

For fixed (δ, μ_2, μ_3) there is a solution t_o of (41) if and only if

$$\min_{t_0} \gamma(\delta, \mu_3, t_0) \leqq \mu_2 - \mu_2(\delta) \leqq \max_{t_0} \gamma(\delta, \mu_2, t_0).$$

If $\mu_3 \neq 0$, an extremum with respect to t_0 of $\gamma(\delta, \mu_3, t_0)$ is also an extremum with respect to t_0 of

$$(42)\qquad \xi(\delta, \mu_3, t_0) = \frac{1}{\mu_3}\gamma(\delta, \mu_3, t_0) = \gamma_1(\delta, t_0) + \mathcal{O}(\mu_3),$$

ξ is T-periodic in t_0. At an extremum with respect to t_0 of ξ we have

$$\frac{\partial \xi}{\partial t_0}(\delta, \mu_3, t_0) = \frac{\partial \gamma_1}{\partial t_0}(\delta, t_0) + \mathcal{O}(\mu_3) = 0.$$

If we substitute (41) into (40), set $d = 0$, and solve to order μ_3, we obtain

$$(43)\qquad \gamma_1(\delta, t_0) = -\frac{\partial d}{\partial \mu_3}(\delta, \mu_2(\delta), 0, t_0) \Big/ \frac{\partial d}{\partial \mu_2}(\delta, \mu_2(\delta), 0, t_0).$$

(Of course this formula is also a consequence of the implicit function theorem.) Thus $\gamma_1(0, t_0) = M(t_0)$. By assumption, at $t_0 = t_0^{\min}$ we have $M'(t_0) = 0$ and $M''(t_0) > 0$. By the implicit function theorem there is a function $t_*(\delta, \mu_3)$, defined for (δ, μ_3) near $(0, 0)$, with $t_*(0, 0) = t_0^{\min}$, such that $(\partial \xi/\partial t_0)(\delta, \mu_3, t_*(\delta, \mu_3)) = 0$. Since $M(t_0)$ attains its minimum on $0 \leqq t < T$ uniquely at $t_0 = t_0^{\min}$, it follows easily from (42) that for (δ, μ_3) small, $\xi(\delta, \mu_3, t_0)$ attains its minimum on $0 \leqq t_0 < T$ uniquely at $t_*(\delta, \mu_3)$. Let $\gamma_*(\delta, \mu_3) = \gamma(\delta, \mu_3, t_*(\delta, \mu_3))$. A similar argument at $t = t_0^{\max}$ allows us to define $\gamma^*(\delta, \mu_3)$.

For a transverse homoclinic orbit we need $d(\delta, \mu_2, \mu_3, t_0) = 0$ and $(\partial d/\partial t_0)(\delta, \mu_2, \mu_3, t_0) \neq 0$. We shall now show that for δ, $\mu_2 - \mu_2(\delta)$, and $\mu_3 \neq 0$ all small, the only simultaneous solutions of $d = 0$ and $(\partial d/\partial t_0) = 0$ occur when $\mu_2 - \mu_2(\delta) = \gamma_*(\delta, \mu_3)$ or $\mu_2 - \mu_2(\delta) = \gamma^*(\delta, \mu_3)$. By (41) it suffices to consider

$$\begin{aligned} &\frac{\partial d}{\partial t_0}(\delta, \mu_2(\delta) + \gamma(\delta, \mu_3, t_0), \mu_3, t_0) \\ (44) \qquad &= \left[\frac{\partial^2 d}{\partial \mu_2 \partial t_0}(\delta, \mu_2(\delta), 0, t_0)\frac{\partial \gamma}{\partial \mu_3}(\delta, 0, t_0) + \frac{\partial^2 d}{\partial \mu_3 \partial t_0}(\delta, \mu_2(\delta), 0, t_0)\right]\mu_3 + o(\mu_3). \end{aligned}$$

But $(\partial\gamma/\partial\mu_3)(\delta, 0, t_0) = \gamma_1(\delta, t_0)$. We substitute (43) into (44) and rearrange to obtain

(45)

$$\begin{aligned} &\frac{\partial d}{\partial t_0}(\delta, \mu_2(\delta) + \gamma(\delta, \mu_3, t_0), \mu_3, t_0) \\ &\quad = \frac{\partial d}{\partial \mu_2}(\delta, \mu_2(\delta), 0, t_0) \cdot \frac{\partial}{\partial t_0}\left[\frac{\partial d}{\partial \mu_3}(\delta, \mu_2(\delta), 0, t_0) \Big/ \frac{\partial d}{\partial \mu_2}(\delta, \mu_2(\delta), 0, t_0)\right]\mu_3 + o(\mu_3) \\ &\quad = \left[\frac{\partial d}{\partial \mu_2}(0, 0, 0, t_0) + \mathcal{O}(\delta)\right] \cdot [M'(t_0) + \mathcal{O}(\delta)]\mu_3 + o(\mu_3). \end{aligned}$$

For $\mu_3 \neq 0$, (45) is zero if and only if $1/\mu_3 \cdot$ (45) is zero. Since $M'(t_0) = 0$ if and only if $t_0 = t_0^{\min}$ or $t_0 = t_0^{\max}$, and $M'' \neq 0$ at these points, we may use the implicit function theorem to show that for δ, $\mu_2 - \mu_2(\delta)$, and $\mu_3 \neq 0$ small, (45) is zero if and only if $t_0 = t_*(\delta, \mu_3)$ or $t_0 = t^*(\delta, \mu_3)$. This implies the result.

8. Dynamics of the Josephson junction. We shall study the family of differential equations (2) using Theorems 1 and 2. The variable ϕ is taken mod 2π, so that (2) is a family of differential equations on the cylinder. We first set $\varepsilon = 0$ in (2), yielding a family of autonomous equations. If $\rho = 1$, there is a saddle-node at $(\pi/2, 0)$. According to [5], there is a unique $\beta_0 > 0$ such that there is a saddle-node separatrix loop Γ at $\rho = 1$, $\beta = \beta_0$. We let $u = (1, 0)$, $v = (-\beta_0, 1)$; these are eigenvectors at $(\pi/2, 0)$ for the eigenvalues 0, $-1/\beta_0$, and they are tangent to Γ at $(\pi/2, 0)$. If we put $x = (\phi, y)$, $\nu_1 = \rho - 1$, $\nu_2 = \beta - \beta_0$, $\nu_3 = \varepsilon$, then assumptions (i)-(vi) are satisfied at $p = (\pi/2, 0)$ [9].

There is a C^∞ function $\rho = R(\beta, \varepsilon)$, defined near $(\beta_0, 0)$, with $R(\beta, 0) \equiv 1$, such that for $(\rho, \beta, \varepsilon)$ near $(1, \beta_0, 0)$, (2) has a period $2\pi/\omega$ solution of saddle-node type near the constant solution $(\phi, y) \equiv (\pi/2, 0)$ if and only if $\rho = R(\beta, \varepsilon)$. In order to use Theorem 1, we must calculate R to first order at $(\beta_0, 0)$.

LEMMA 3. $(\partial R/\partial\varepsilon)(\beta_0, 0) = 0$.

Let $\rho(\varepsilon) = R(\beta_0, \varepsilon)$. Then

$$(46) \qquad \beta_0\ddot{\phi} + \dot{\phi} + \sin\phi = \rho(\varepsilon) + \varepsilon\sin\omega t$$

has a smooth family of $2\pi/\omega$ periodic solutions $\phi(\varepsilon, t)$, one of whose Floquet multipliers is one. Of course, $\phi(0, t) \equiv \pi/2$. We shall need to calculate ϕ to order ε at $\varepsilon = 0$.

LEMMA 4. $\phi(\varepsilon, t) = \pi/2 - \varepsilon(\cos\omega t + \beta_0\omega\sin\omega t)/\omega(1 + \beta_0^2\omega^2) + \mathcal{O}(\varepsilon^2)$.

Proof of Lemmas 3 *and* 4. Write

$$\rho(\varepsilon) = 1 + \rho_1\varepsilon + \mathcal{O}(\varepsilon^2),$$

$$\phi(\varepsilon, t) = \frac{\pi}{2} + \left(a_0 + \sum_{n=1}^{\infty} a_n\cos n\omega t + \sum_{n=1}^{\infty} b_n\sin n\omega t\right)\varepsilon + \mathcal{O}(\varepsilon^2).$$

Then

$$\sin \phi(\varepsilon, t) = \cos\left[\left(a_0 + \sum_{n=1}^{\infty} a_n \cos n\omega t + \sum_{n=1}^{\infty} b_n \sin n\omega t\right)\varepsilon + \mathcal{O}(\varepsilon^2)\right]$$
$$= 1 + \mathcal{O}(\varepsilon^2).$$

Substituting into (46) and collecting terms of order ε, we find that

$$-\beta_0\left(\sum_{n=1}^{\infty} n^2\omega^2 a_n \cos n\omega t + \sum_{n=1}^{\infty} n^2\omega^2 b_n \sin n\omega t\right)$$
$$-\sum_{n=1}^{\infty} n\omega a_n \sin n\omega t + \sum_{n=1}^{\infty} n\omega b_n \cos n\omega t = \rho_1 + \sin \omega t.$$

Therefore, $\rho_1 = 0$, which proves Lemma 3. Also,

$$(47) \qquad a_1 = \frac{-1}{\omega(1+\beta_0^2\omega^2)}, \qquad b_1 = \frac{-\beta_0}{(1+\beta_0^2\omega^2)},$$

and, for $n > 1$, $a_n = b_n = 0$. Thus

$$(48) \qquad \phi(\varepsilon, t) = \frac{\pi}{2} + (a_0 + a_1 \cos \omega t + b_1 \sin \omega t)\varepsilon + \mathcal{O}(\varepsilon^2)$$

where a_1 and b_1 are given by (47) and a_0 is yet to be determined. To complete the proof of Lemma 4, we must show that $a_0 = 0$.

Let $y(\varepsilon, t) = (\partial\phi/\partial t)(\varepsilon, t)$. We linearize (2) about $(\phi(\varepsilon, t), y(\varepsilon, t))$ to obtain the variational equation

$$(49) \qquad \frac{\partial}{\partial t}\begin{bmatrix} \psi(\varepsilon, t) \\ z(\varepsilon, t)\end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -(1/\beta_0)\cos\phi(\varepsilon, t) & -1/\beta_0\end{bmatrix}\begin{bmatrix} \psi(\varepsilon, t) \\ z(\varepsilon, t)\end{bmatrix}.$$

Since $(\phi(\varepsilon, t), y(\varepsilon, t))$ has exactly one Floquet multiplier that is one, there is a smooth family of solutions $(\psi(\varepsilon, t), z(\varepsilon, t))$ of (49) such that $(\psi(\varepsilon, t), z(\varepsilon, t))$ has period $2\pi/\omega$ in t. We may choose

$$(50) \qquad (\psi(0, t), z(0, t)) \equiv (1, 0),$$

since $u = (1, 0)$.

Differentiating (49) with respect to ε we obtain

$$\frac{\partial}{\partial t}\begin{bmatrix} \dfrac{\partial\psi}{\partial\varepsilon} \\[2mm] \dfrac{\partial z}{\partial\varepsilon}\end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -\dfrac{1}{\beta_0}\cos\phi(\varepsilon, t) & -\dfrac{1}{\beta_0}\end{bmatrix}\begin{bmatrix} \dfrac{\partial\psi}{\partial\varepsilon} \\[2mm] \dfrac{\partial z}{\partial\varepsilon}\end{bmatrix} + \begin{bmatrix} 0 & 0 \\ \dfrac{1}{\beta_0}\sin\phi(\varepsilon, t)\dfrac{\partial\phi}{\partial\varepsilon} & 0\end{bmatrix}\begin{bmatrix} \psi \\ z\end{bmatrix}.$$

We set $\varepsilon = 0$ and use $\phi(0, t) \equiv \pi/2$ and (50) to obtain

$$\frac{\partial}{\partial t}\begin{bmatrix} \dfrac{\partial\psi}{\partial\varepsilon}(0, t) \\[2mm] \dfrac{\partial z}{\partial\varepsilon}(0, t)\end{bmatrix} = \begin{bmatrix} \dfrac{\partial z}{\partial\varepsilon}(0, t) \\[2mm] -\dfrac{1}{\beta_0}\dfrac{\partial\psi}{\partial\varepsilon}(0, t)\end{bmatrix} + \begin{bmatrix} 0 \\[2mm] \dfrac{1}{\beta_0}\dfrac{\partial\phi}{\partial\varepsilon}(0, t)\end{bmatrix}.$$

This constant coefficient nonhomogeneous linear differential equation has the solution

$$(51) \qquad \frac{\partial\psi}{\partial\varepsilon}(0, t) = \frac{\partial\psi}{\partial\varepsilon}(0, 0) + \int_0^t \frac{\partial z}{\partial\varepsilon}(0, s)\, ds,$$

$$(52) \qquad \frac{\partial z}{\partial\varepsilon}(0, t) = e^{-t/\beta_0}\left[\frac{\partial z}{\partial\varepsilon}(0, 0) + \frac{1}{\beta_0}\int_0^t \frac{\partial\phi}{\partial\varepsilon}(0, s)\, e^{s/\beta_0}\, ds\right].$$

We substitute (48) into (52) and integrate to obtain

$$\begin{aligned}\frac{\partial z}{\partial \varepsilon}(0, t) &= e^{-t/\beta_0}\left[\frac{\partial z}{\partial \varepsilon}(0,0) - a_0 - (a_1 - \omega\beta_0 b_1)/(1+\omega^2\beta_0^2)\right] \\ &\quad + a_0 + [(a_1 - \omega\beta_0 b_1)\cos \omega t + (b_1 + \omega\beta_0 a_1)\sin \omega t]/(1+\omega^2\beta_0^2).\end{aligned} \tag{53}$$

Now we set $t = 2\pi/\omega$ in (53) and require $(\partial z/\partial\varepsilon)(0, 2\pi/\omega) = (\partial z/\partial \varepsilon)(0,0)$. This yields

$$\frac{\partial z}{\partial \varepsilon}(0,0) = a_0 + (a_1 - \omega\beta_0 b_1)/(1+\omega^2\beta_0^2).$$

Therefore,

$$\frac{\partial z}{\partial \varepsilon}(0, t) = a_0 + [(a_1 - \omega\beta_0 b_1)\cos \omega t + (b_1 + \omega\beta_0 a_1)\sin \omega t]/(1+\omega^2\beta_0^2). \tag{54}$$

We substitute (54) into (51) and integrate to obtain

(55)

$$\frac{\partial \psi}{\partial \varepsilon}(0, t) = \frac{\partial \psi}{\partial \varepsilon}(0,0) + a_0 t + [(a_1 - \omega\beta_0 b_1)\sin \omega t - (b_1 + \omega\beta_0 a_1)\cos \omega t]/\omega(1+\omega^2\beta_0^2).$$

Now we set $t = 2\pi/\omega$ in (55) and require $(\partial\varphi/\partial\varepsilon)\ (0, 2\pi/\omega) = (\partial\varphi/\partial\varepsilon)(0,0)$. We find that $a_0 = 0$. This completes the proof of Lemma 4. □

In order to use Theorem 1, we must change to the new parameters

$$\mu_1 = \rho - R(\beta, \varepsilon), \quad \mu_2 = \beta - \beta_{0'} \quad \mu_3 = \varepsilon.$$

Since $R(\beta, 0) \equiv 1$, and $(\partial R/\partial \varepsilon)(\beta_0, 0) = 0$ by Lemma 3, we have

$$\frac{\partial(\mu_1, \mu_2, \mu_3)}{\partial(\rho, \beta, \varepsilon)}(1, \beta_0, 0) = \text{Identity}.$$

Thus instead of calculating derivatives with respect to μ_1, μ_2, μ_3 at $(0,0,0)$, we may calculate derivatives with respect to ρ, β, ε, at $(1, \beta_0, 0)$.

Let

$$f(\phi, y, \rho, \beta) = \left(y, \frac{1}{\beta}(-y - \sin \phi + \rho)\right),$$

$$g(\phi, y, \rho, \beta, \varepsilon, t) = (0, \varepsilon \sin \omega t),$$

$q(t) = (\phi(t), y(t)) =$ a solution of $(\dot\phi, \dot y) = f(\phi, y, 1, \beta_0)$ that lies in Γ,

$$p(\varepsilon, t) = \begin{bmatrix}\phi(\varepsilon, t)\\ y(\varepsilon, t)\end{bmatrix} = \begin{bmatrix}\pi/2 - \varepsilon(\cos \omega t + \beta_0\omega \sin \omega t)/\omega(1+\beta_0^2\omega^2) + \mathcal{O}(\varepsilon^2)\\ \varepsilon(\omega \sin \omega t - \beta_0\omega^2 \cos \omega t)/\omega(1+\beta_0^2\omega^2) + \mathcal{O}(\varepsilon^2)\end{bmatrix}.$$

From [9], we know that $(\partial d/\partial \beta)(1, \beta_0, 0, t_0) > 0$. We now turn to $(\partial d/\partial\varepsilon)$ $(1, \beta_0, 0, t_0)$.

LEMMA 5. $(\partial d/\partial \varepsilon)(1, \beta_0, 0, t) = A(\omega)\cos \omega t + B(\omega) \sin \omega t$, *where*

$$A(\omega) = \lim_{s_1\to\infty}\left[\frac{k}{\omega}\cos \omega s_1 + \int_{-\infty}^{s_1} e^{s/\beta_0}\frac{y(s)}{\beta_0}\sin \omega s\, ds\right],$$

$$B(\omega) = \lim_{s_1\to\infty}\left[-\frac{k}{\omega}\sin \omega s_1 + \int_{-\infty}^{s_1} e^{s/\beta_0}\frac{y(s)}{\beta_0}\cos \omega s\, ds\right].$$

Proof. We have

$$\frac{\partial p}{\partial \varepsilon}(0,t) = -\left(\cos \omega t \begin{bmatrix} 1 \\ \omega^2 \beta_0 \end{bmatrix} + \sin \omega t \begin{bmatrix} \omega\beta_0 \\ -\omega \end{bmatrix}\right) \Big/ \omega(1+\beta_0^2\omega).$$

According to Theorem 1,

$$\lim_{t\to\infty} f(q(t-t_0),1,\beta_0)\exp\left[-\int_{t_0}^{t} \operatorname{div} f(q(s-t_0),1,\beta_0)\,ds\right] = -kv = -k\begin{bmatrix}\beta_0 \\ 1\end{bmatrix}, \tag{56}$$

where k is a positive constant. Therefore, as $t_1 \to \infty$,

$$\frac{\partial p}{\partial \varepsilon}(0,t_1)\wedge f(q(t_1-t_0),1,\beta_0)\exp\left[-\int_{t_0}^{t_1} \operatorname{div} f(q(s-t_0),1,\beta_0)\,ds\right] \to \frac{k}{\omega}\cos \omega t_1 \tag{57}$$

independent of t_0.

To study the second summand of the expression for $(\partial d/\partial\varepsilon)(1,\beta_0,0,t_0)$ given by Theorem 1, the integral, we note that

$$\operatorname{div} f(\phi, y, 1, \beta_0) = -\frac{1}{\beta_0},$$

$$\frac{\partial g}{\partial \varepsilon}(\phi, y, 1, \beta_0, 0, t_0) = \begin{bmatrix} 0 \\ 1/\beta_0 \sin \omega t \end{bmatrix},$$

$$f(q(t-t_0),1,\beta_0)\wedge \frac{\partial g}{\partial\varepsilon}(q(t-t_0),1,\beta_0,0,t) = \begin{bmatrix} \dot\phi(t-t_0) \\ \dot y(t-t_0)\end{bmatrix}$$

$$\wedge \begin{bmatrix} 0 \\ 1/\beta_0 \sin\omega t\end{bmatrix} = \frac{1}{\beta_0}\dot\phi(t-t_0)\sin\omega t = \frac{1}{\beta_0} y(t-t_0)\sin\omega t.$$

Therefore the integral becomes

$$\int_{-\infty}^{t_1} e^{(t-t_0)/\beta_0}\frac{1}{\beta_0} y(t-t_0)\sin\omega t\,dt. \tag{58}$$

Let $s = t - t_0$, $s_1 = t_1 - t_0$ in (58). We obtain

$$\left[\int_{-\infty}^{s_1} e^{s/\beta_0}\frac{y(s)}{\beta_0}\sin\omega s\,ds\right]\cos\omega t_0 + \left[\int_{-\infty}^{s_1} e^{s/\beta_0}\frac{y(s)}{\beta_0}\cos\omega s\,ds\right]\sin\omega t_0. \tag{54}$$

We now combine (57) and (59) and rewrite $\cos\ \omega t_1 = \cos \omega s_1\ \cos\omega t_0 - \sin\omega s_1 \sin\omega t_0$:

$$\frac{\partial d}{\partial\varepsilon}(1,\beta_0,0,t_0) = \lim_{s_1\to\infty}\left\{\left[\frac{k}{\omega}\cos\omega s_1 + \int_{-\infty}^{s_1} e^{s/\beta_0}\frac{y(s)}{\beta_0}\sin\omega s\,ds\right]\cos\omega t_0\right.$$
$$\left.+\left[-\frac{k}{\omega}\sin\omega s_1 + \int_{-\infty}^{s_1} e^{s/\beta_0}\frac{y(s)}{\beta_0}\cos\omega s\,ds\right]\sin\omega t_0\right\},$$

where the limit exists by Theorem 1. Setting $t_0 = 0$ and $t_0 = \pi/2\omega$ we show that each term in square brackets approaches a limit as $s_1 \to \infty$. Let $A(\omega)$ and $B(\omega)$ equal these limits. □

LEMMA 6. *$A(\omega) \neq 0$ for all but a discrete set of ω's.*

Proof. Let

$$h(s) = \begin{cases} 0, & -\infty \leqq s < 0, \\ -k, & 0 \leqq s < \infty. \end{cases}$$

Then

$$\int_{-\infty}^{s_1}\left[e^{s/\beta_0}\frac{y(s)}{\beta_0}+h(s)\right]\cos\omega s\,ds\to B(\omega)\quad\text{as } s_1\to\infty,$$

$$\int_{-\infty}^{s_1}\left[e^{s/\beta_0}\frac{y(s)}{\beta_0}+h(s)\right]\sin\omega s\,ds\to A(\omega)-\frac{k}{\omega}\quad\text{as } s_1\to\infty.$$

We claim that

$$\left[e^{s/\beta_0}\frac{y(s)}{\beta_0}+h(s)\right]e^{s/\beta_0}\to 0\quad\text{as } s\to\infty.$$

From formula (29) in [9], for example, we have that

$$\begin{bmatrix}\phi(t)\\ y(t)\end{bmatrix}=c\begin{bmatrix}-\beta\\ 1\end{bmatrix}e^{-t/\beta_0}+\mathcal{O}(e^{-t/\beta_0})^2$$

for a positive constant c. Therefore,

$$e^{t/\beta_0}\frac{y(t)}{\beta_0}=\frac{c}{\beta_0}+\mathcal{O}(e^{-t/\beta_0}).\tag{60}$$

But (56) can be rewritten as

$$\lim_{t\to\infty}\begin{bmatrix}\dot\phi(t)\\ \dot y(t)\end{bmatrix}e^{t/\beta_0}=-k\begin{bmatrix}-\beta_0\\ 1\end{bmatrix}.\tag{61}$$

Since $\dot\phi(t)=y(t)$, (60) and (61) imply that $c/\beta_0=k$. Therefore (60) implies that as $t\to\infty$,

$$e^{t/\beta_0}\frac{y(t)}{\beta_0}+h(t)=\mathcal{O}(e^{-t/\beta_0}).$$

Therefore,

$$e^{t/\beta_0}\frac{y(t)}{\beta_0}+h(t)\in L^2(-\infty,\infty).$$

On the other hand, the Fourier transform of $e^{t/\beta_0}(y(t)/\beta_0)+h(t)$ is

$$F(\omega)=\int_{-\infty}^{\infty}\left[e^{s/\beta_0}\frac{y(s)}{\beta_0}+h(s)\right]e^{i\omega s}\,ds$$

$$=B(\omega)+i\left(A(\omega)-\frac{k}{\omega}\right).$$

If $A(\omega)\equiv 0$, then $F(\omega)\notin L^2\ (-\infty,\infty)$, which contradicts a well-known fact about the Fourier transform. Since $A(\omega)$ is analytic (because $e^{t/\beta_0}(y(t)/\beta_0)+h(t)$ is also absolutely integrable on $(-\infty,\infty)$), $A(\omega)\neq 0$ except on a discrete set of ω's. □

The idea of relating Melnikov functions to Fourier transforms comes from [4].

From Lemmas 5 and 6 and § 5 of [9] we have immediately the following theorem.

THEOREM 3. *If ω does not belong to the discrete set of Lemma* 6, *then the family* (2) *satisfies the hypotheses of Theorem* 2 *at* $(\phi,y,\rho,\beta,\varepsilon)=(\pi/2,0,1,\beta_0,0)$.

In fact, it only remains to remark that since $M(t_0)$ is a constant multiple of $A(\omega)\cos\omega t_0+B(\omega)\sin\omega t_0$, we have $M(t_0^{\max})>0$ and $M(t_0^{\min})<0$. It follows that for fixed small $\varepsilon\neq 0$, the set of (ρ,β), near $(1,\beta_0)$ for which (2) has a homoclinic orbit is given by Fig. 1. In interpreting Fig. 1, the reader should recall that $\mu_1=\rho-R(\beta,\varepsilon)$ and $\mu_2=\beta-\beta_0$. This result is consistent with [8], where it is shown that at every positive parameter pair (ρ,β) at which the autonomous equation $(\dot\phi,\dot y)=f(\phi,y,\rho,\beta)$ has a saddle separatrix loop, homoclinic orbits occur when one perturbs in the ε-direction.

ON STOCHASTIC FUNCTIONAL-DIFFERENTIAL EQUATIONS WITH UNBOUNDED DELAY*

CONSTANTIN TUDOR†

Abstract. In this paper we examine the existence and the pathwise uniqueness of solutions to infinite delay stochastic differential equations with general initial conditions and the Lipschitz conditions replaced by some less restrictive ones. Similar questions have been considered by Hale and Kato [3], Kappel and Schappacher [7], Schumacher [13] for deterministic equations and by Rodkina [11] for stochastic equations.

Key words. stochastic equations, strong and weak solutions

AMS(MOS) subject classification. 60H20

1. Introduction. Suppose we are given $(\Omega, \mathcal{F}, P, (\mathcal{F}_t)_{t\geqq 0})$ a filtered probability space satisfying the usual assumptions, $Z=\{Z(t)\}_{t\geqq 0}$ a continuous R^m-valued semimartingale with $Z(0)=0$ and $Q=\{Q(t)\}_{t\geqq 0}$ a continuous control process for Z, i.e.,

$$E\left(\sup_{t\leqq\sigma}\left|\int_0^t f(u)\,dZ(u)\right|^2\right)\leqq E\left(Q_\sigma\int_0^\sigma |f(u)|^2\,dQ(u)\right)$$

for every stopping time σ and bounded predictable process f. $\tilde{Y}$ is the linear space of all R^d-valued processes $\{\phi(s)\}_{s\leqq 0}$ with $\mathcal{B}(\phi(s);\ s\leqq 0)\subset\mathcal{F}_0$ (*initial histories*). If $f: R\to R^d$ and $t\geqq 0$ *the history up to* t is the map $f_t: R_-\mapsto R^d$ defined by $f_t(s)=f(t+s)$.

We shall denote by R_∞ the set of all $(x_0, x_1, \cdots)$, $x_i\in R^d$, and by $\mathcal{B}_\infty$ the product Borel field on R_∞. We shall denote by C the set of all continuous functions defined on R_+ and with values in R^d (C is endowed with the compact convergence), by $\mathcal{C}$ the Borel field on C and by $(\mathcal{C}_t)_{t\geqq 0}$ the canonical filtration on C. Also, we shall denote $\bar{\Omega}=\Omega\times C$, $\bar{\mathcal{F}}=\mathcal{F}\otimes\mathcal{C}$, $\bar{\mathcal{F}}_t=\bigcap_{s>t}(\mathcal{F}_s\otimes\mathcal{C}_s)$ and by $\{\bar{x}(t)\}_{t\geqq 0}$ the canonical process defined by $\bar{x}(t,\omega,f)=f(t)$.

The topic of our study is the Cauchy problem (I) for the stochastic functional equation of Doleans-Dade-Protter type

$$\text{(I)}\qquad dx(t)=a(t,x_t)\,dZ(t),\qquad x_0=\phi\in\hat{Y}$$

where $a:\hat{Y}\subset\tilde{Y}\mapsto R^d\otimes R^m$.

Following Jacod and Memin [6] we consider two possible definitions of "a solution" to equation (I).

DEFINITION 1. Let $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{P}, (\tilde{\mathcal{F}}_t))$ be an extension of $(\Omega, \mathcal{F}, P, (\mathcal{F}_t))$, i.e.:

(1) $\tilde{\Omega}=\Omega\times\Omega'$, Ω' an auxiliary space;

(2) $\mathcal{F}\subset\tilde{\mathcal{F}}$, $\mathcal{F}_t\subset\tilde{\mathcal{F}}_t$ for every t;

(3) $\tilde{P}/\mathcal{F}=P$.

A process $\tilde{x}=\{\tilde{x}(t)\}_{t\geqq 0}$ is a solution process (or strong solution) of (I) if:

(i_1) Z is a semimartingale on $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{P}, (\tilde{\mathcal{F}}_t))$;

(i_2) $\tilde{x}$ is continuous and $\tilde{\mathcal{F}}_t$-adapted;

(i_3) $a(t,\tilde{x}_t)$ is $\tilde{\mathcal{F}}_t$-predictable and Z-integrable (here $\tilde{x}$ is extended onto R_- by $\tilde{x}(s)=\phi(s)$);

(i_4) $\tilde{P}$-a.s. and for all $t\geqq 0$

$$\tilde{x}(t)=\phi(0)+\int_0^t a(s,\tilde{x}_s)\,dZ(s).$$

DEFINITION 2. A probability measure $\bar{P}$ on $\bar{\mathscr{F}}$ is a solution measure (or weak solution) of (I) if $(\bar{\Omega}, \bar{\mathscr{F}}, \bar{P}, (\bar{\mathscr{F}}_t))$ is an extension of $(\Omega, \mathscr{F}, P, (\mathscr{F}_t))$ on which the canonical process $\bar{x}$ is a solution process of (I).

DEFINITION 3. A solution process on $(\tilde{\Omega}, \tilde{\mathscr{F}}, \tilde{P}, (\tilde{\mathscr{F}}_t))$ (resp. a solution measure $\bar{P}$) is very good (or regular) if every martingale on $(\Omega, \mathscr{F}, P, (\mathscr{F}_t))$ is also a martingale on $(\tilde{\Omega}, \tilde{\mathscr{F}}, \tilde{P}, (\tilde{\mathscr{F}}_t))$ (resp. $(\bar{\Omega}, \bar{\mathscr{F}}, \bar{P}, (\bar{\mathscr{F}}_t))$).

We introduce the following two families of functions:

$$LS = \left\{ \alpha : R_+ \mapsto R_+;\ \alpha \text{ concave, nondecreasing and } \int_{0+}^{1} dt/\alpha(t) = \infty \right\},$$

and for a measurable function $h: R_+ \mapsto R_+$ and $a < b$,

$K(a, b, h) = \{Z(t, x): [a, b] \times R_+ \mapsto R_+;$ Z is measurable in (t, x), $Z(t, \cdot)$ is continuous, concave and nondecreasing such that for each $a < c \leqq b$ $u = 0$ is the unique nonnegative nondecreasing solution of $u(t) \leqq C \int_a^t Z(s, u(h(s)))\, ds$, $a \leqq t \leqq c$, for a constant C large enough$\}$.

In § 2, problem (I) is considered for initial histories which have paths in a general space of functions. The existence of weak (resp. strong) solutions of (I) is established for bounded (this assumption can be relaxed) coefficients $a(t, f)$ that are continuous in f (resp. a is $x|\log x|^{1-\varepsilon}$-Hölder-continuous in f). Also the convergence of successive approximations to the solution is obtained.

In § 3 we consider the equation (I) with $Z(t) = (t, w(t))'$ (w is a standard Wiener process) and with general histories. Existence and uniqueness of strong solutions are proved under less restrictive conditions (the Lipschitz functions are replaced by those of Osgood or Hölder).

Finally a stochastic version of the dangling spider equation is considered.

2. Stochastic functional-differential equations of Doleans–Dade and Protter type with unbounded delay. In this section the initial histories are taken with paths in a semi-normed linear space. More precisely, let X denote a linear real vector space of functions mapping R_- into R^d endowed with a semi-norm $|\cdot|_X$. We require that X satisfies the following general qualitative properties: If $f: R \mapsto R^d$ is continuous on $[\sigma, \infty)$ and $f_\sigma \in X$ then:

(j_1) $f_t \in X$ for every $t \geqq \sigma$;

(j_2) (*The fundamental inequality*): there exist K_1, K_2 locally bounded such that

$$|f_t|_X \leqq K_1(t-\sigma) \max_{\sigma \leqq s \leqq t} |f(s)| + K_2(t-\sigma)|f_\sigma|_X;$$

(j_3) The map $t \mapsto f_t$ is continuous.

Remark 2.1. Such a space X has been considered as phase space in the theory of retarded functional equations (see [1], [3], [7], [12]).

THEOREM 2.1. *Let $\phi \in \tilde{Y}$ be an initial history with the paths in X and $a(t, \omega, f): R_+ \times \Omega \times X \mapsto R^d \otimes R^m$ be a functional such that*

(1) *$a(t, \omega, \cdot)$ is continuous for every t, ω and a is bounded*;

(2) *The process $\{a(t, f_t)\}_t$ is $\mathscr{F}_t$-predictable for every process $\{f(t)\}_{t \in R}$ with $f_0 = \phi$ and $\{f(t)\}_{t \geqq 0}$ continuous and $\mathscr{F}_t$-adapted. Then there exists a regular weak solution of* (I).

THEOREM 2.2. *Assume the hypotheses of Theorem* 2.1 *are satisfied. Moreover suppose that there is $\alpha \in LS$ such that*

$$|a(t, \omega, f) - a(t, \omega, g)|^2 \leqq \gamma(t, \omega)\alpha(|f-g|_X^2)$$

for every $t \in R_+$, $\omega \in \Omega$, $f, g \in X$ and for a Q-integrable and predictable process γ. Then there exists a pathwise unique strong solution of (I).

Proof of Theorems 2.1 *and* 2.2. It follows from the following two lemmas and the corresponding results for the Doleans-Dade and Protter equation (see [6], [8], [10]) for weak solutions and [15] for strong solutions.

LEMMA 1. *Let a be as in Theorem* 2.1. *Define the functional* $a': R_+ \times \Omega \times C \mapsto R^d \otimes R^m$ *by* $a'(t, \omega, f) = a(t, \omega, \bar{f}_t)$, *where*

$$\bar{f}(t) = f(0)\lambda_{(-\infty,0)}(t) + f(t)\lambda_{R_+}(t).$$

Then

(k_1) $a'(t, \omega, \cdot)$ *is continuous with respect to the compact convergence and* a' *is bounded*,

(k_2) a' *is* $\mathscr{F}_t \otimes \mathscr{C}_t$*-predictable.*

Proof. (k_1). It is a consequence of the fundamental inequality and of hypothesis (1) of Theorem 2.1.

(k_2). By the monotone class theorem it is sufficient to consider the case $a'(t, \omega, f) = a_1(t, \omega)a_2(\bar{f}_t)$ with a_1 $\mathscr{F}_t$-predictable and a_2 X-continuous. Since $t \mapsto a_2(\bar{f}_t)$ is continuous it remains to prove that $a_2(\bar{f}_t)$ is $\mathscr{C}_t$-adapted. If $f, g \in C$ are such that $f(s) = g(s)$ for $s \leqq t$ then $\bar{f}_t = \bar{g}_t$, where from $a_2(\bar{f}_t) = a_2(\bar{g}_t)$.

LEMMA 2. *Assume the hypotheses of Theorem* 2.1 *are satisfied. Then, for every coefficient a, the following three assertions are equivalent*:

(k) *For every initial process* ϕ *there exists a strong* (*resp. a regular weak*) *solution of* (I).

(k') *There exists a strong* (*resp. a regular weak*) *solution of* (I) *with* $\phi = 0$.

(k'') *There exists a strong* (*resp. a regular weak*) *solution for the Doleans-Dade and Protter equation*

$$\text{(II)} \qquad dy(t) = a'(t, y)\, dZ(t), \qquad y(0) = 0$$

(*here* a' *is defined as in Lemma* 1).

Proof. The implications $(k) \Rightarrow (k') \Rightarrow (k'')$ are immediate. $(k'') \Rightarrow (k)$. Let y be a strong solution of (II) associated with the functional $a(t, \omega, f + (\bar{\phi})_0)$, where $\bar{\phi}(t) = \phi(t)\lambda_{(-\infty,0)}(t) + \phi(0)\lambda_{R_+}(t)$. It is easy to check that $x(t) = y(t) + \phi(0)$, $t \geqq 0$, is a strong solution of (I) with ϕ as the initial process.

We now consider the case of regular weak solutions. Define the mapping $\Psi: \bar{\Omega} \mapsto \bar{\Omega}$ by $\Psi(\omega, f) = (\omega, f - \phi(0))$. Ψ is bijective, bimeasurable and $\Psi(\bar{\mathscr{F}}_t) = \Psi^{-1}(\bar{\mathscr{F}}_t) = \bar{\mathscr{F}}_t$.

Denote $\hat{a} = a \circ \Psi^{-1}$ and let $\hat{P}$ be a regular solution of

$$y(t) = \int_0^t \hat{a}'(s, y)\, dZ(s)$$

or equivalently of

$$z(t) = \int_0^t \hat{a}(s, z_s)\, dZ(s), \qquad z_0 = 0.$$

Then the probability measure $\bar{P} = \hat{P} \circ \Psi$ is a regular weak solution of (I).

COROLLARY. *Let* $F(s, \omega, x): R_+ \times \Omega \times R_\infty \mapsto R^d \otimes R^m$ *be such that*

(1) *F is* $\mathscr{P} \otimes \mathscr{R}_\infty$*-measurable and bounded* ($\mathscr{P}$ *is the Borel field of predictable sets on* $R_+ \times \Omega$).

(2) *There exists* $\alpha \in LS$ *such that*

$$|F(t, \omega, x) - F(t, \omega, y)|^2 \leqq \gamma(t, \omega)\alpha\left(\sum_{i \geqq 0} c_i|x_i - y_i|^2\right)$$

for every $t \in R_+$, $\omega \in \Omega$, $x, y \in R$ *and for some Q-integrable and predictable process* γ, *where* $c_i \geqq 0$, $\sum_{i \geqq 0} c_i = 1$. *Then the stochastic equation*

$$dx(t) = F(t, \tilde{x}_t)\, dZ(t), \qquad x_0 = \phi$$

has a pathwise unique strong solution for every initial process ϕ *with paths in* X, *where* $\tilde{x}_t = (x(t), x(t-s_1), \cdots)$, $s_i \geqq 0$.

THEOREM 2.3. *Suppose the hypotheses of Theorem* 2.2 *are satisfied and let* x *be the strong solution of* (I). *Define the successive approximations*

$$\begin{aligned} x^0(t) &= \phi(t), \qquad t<0, \\ &= \phi(0), \qquad t \geqq 0, \\ x^{n+1}(t) &= \phi(t), \qquad t<0, \\ &= \phi(0) + \int_0^t a(s, x_s^n)\, dZ(s), \qquad t \geqq 0. \end{aligned}$$

Then x^n *converges to* x *with respect to the compact convergence in probability.*

Proof. It is sufficient to prove the assertion for the Doleans-Dade and Protter equation (II) associated by Lemma 2.

Denote y^n the successive approximations associated to (II). Choose a stopping time θ such that $Q(\theta)+(\gamma \cdot Q)(\theta) \leqq c$. All we need to show is that

$$E\left(\sup_{t \leqq \theta} |y^n(t)-y(t)|^2\right) \mapsto 0.$$

By standard arguments we see that there exists a constant K such as

$$\sup_n E\left(\sup_{t \leqq \theta} |y^n(t)|^2\right) + E\left(\sup_{t \leqq \theta} |y(t)|^2\right) \leqq K.$$

By using the time change theorem with $\theta_s = \inf(t \leqq \theta; (\gamma \cdot Q)(t) > s)$ and the Jensen inequality we get

$$\overline{\lim_{n\to\infty}}\, E\left(\sup_{t \leqq \theta_s} |y^n(t)-y(t)|^2\right) \leqq \int_0^s \alpha\left(\overline{\lim_{n\to\infty}}\, E\left[\sup_{u \leqq \theta_t} |y^n(u)-y(u)|^2\right]\right) dt$$

where from

$$\lim_{n\to\infty} E\left(\sup_{t \leqq \theta_s} |y^n(t)-y(t)|^2\right) = 0 \quad \text{for every } s \leqq c.$$

Taking $s = c$, we obtain the conclusion.

Remark 2.2. The result of Theorem 2.3 for Ito equations and for non-Lipschitz conditions has been proved in [16].

Remark 2.3. If the semi-norm $|\cdot|_X$ satisfies $|f(0)| \leqq c|f|_X$ for all f and for some constant c and the initial process ϕ is such that $E(|\phi|_X^2) < \infty$, then the boundedness hypothesis on a can be replaced by the following: There is a Q-integrable and predictable process γ such that

$$|a(t, \omega, f)|^2 \leqq \gamma(t, \omega)(1+|f|_X^2)$$

for every $t \geqq 0$, $\omega \in \Omega$, $f \in X$.

3. Stochastic functional-differential equations of Ito type with unbounded delay. For every $t>0$ let $(\tilde{C}_t, |\cdot|_t)$ be a Banach space of continuous adapted R^d-valued processes $\{\eta(s)\}_{0 \leqq s \leqq t}$ with $\eta(0)=0$ such that if $\eta \in \tilde{C}_t$ and $s<t$ then $\eta \in \tilde{C}_s$ and $|\eta|_s \leqq |\eta|_t$.

Let w be an R^m-valued Wiener process. For $\psi \in \tilde{Y}$ and a process $\{\eta(t)\}_{t \geqq 0}$ we define the process $\psi \vee \eta$ by

$$(\psi \vee \eta)(s) = \psi(s)\lambda_{(-\infty,0)}(s) + [\psi(0)+\eta(s)]\lambda_{R_+}(s).$$

We consider the operators $I_i(t): \tilde{C}_t \mapsto L^2([0, t] \times \Omega, ds \times dP)$, $i = 1, 2$, defined by

$$(I_1(t)\eta)(s) = \int_0^s \eta(u)\, dw(u); \qquad (I_2(t)\eta)(s) = \int_0^s \eta(u)\, du.$$

We introduce the following assumptions.

ASSUMPTION 1. A subset $\hat{Y}$ of $\tilde{Y}$ is given such that for $\psi \in \hat{Y}$, $\eta \in \tilde{C}_t$ we have $(\psi \vee \eta)_t \in \hat{Y}$.

ASSUMPTION 2. There exist $B_1(t)$, $B_2(t)$ locally bounded such that for every $\eta \in \tilde{C}_t$ and $0 < s < t$ we have

$$|\eta|_t^2 \leqq B_1(t-s)|\eta|_s^2 + B_2(t-s)E\left(\max_{s \leqq u \leqq t} |\eta(u)|^2\right).$$

ASSUMPTION 3. There exist $C_1(t)$, $C_2(t)$ locally bounded such that

$$|I_i(t)\eta|_t^2 \leqq C_i(t) \| |\eta|.\|_{L^2([0,t]\times\Omega)} \qquad i = 1, 2.$$

Remark 3.1. Concrete Banach spaces $\tilde{C}_t$ can be found in [11] and typical examples of spaces $\hat{Y}$ are given by $L^2(\Omega, \mathscr{F}, P, X)$, where X is as shown in the beginning of § 2.

Consider the stochastic functional-differential equation of neutral type:

$$\text{(III)} \qquad d[x(t) - f(t, x_t)] = F(t, x_t)\, dt + G(t, x_t)\, dw(t), \qquad x_0 = \phi \in \hat{Y}$$

where

$$F(t, \psi), f(t, \psi): R_+ x \hat{Y} \mapsto L^2(\Omega, \mathscr{F}, P, R^d),\ G(t, \psi): R_+ \times \hat{Y} \mapsto L^2(\Omega, \mathscr{F}, P, R^d \otimes R^m).$$

THEOREM 3.1. *Suppose Assumptions* 1 *and* 2 *are satisfied. Moreover assume that*

(i) *There exists* $H \in L^1_{\text{loc}}(R_+)$ *such that* $|F(t, \psi)|^2 + |G(t, \psi)|^2 \leqq H(t)$ *for all* $\psi \in \hat{Y}$.

(ii) *For every* $\psi \in \hat{Y}$ *and process* $\eta = \{\eta(t)\}_{t \geqq 0}$ *such that* $\eta \in \tilde{C}_t$ *for every* t, *the processes* $s \to F(s, (\psi \vee \eta)_s)$, $s \to G(s, (\psi \vee \eta)_s)$ *are measurable and adapted.*

(iii) *For every* $\psi \in \hat{Y}$ *and* $t > 0$ *the operators*

$$\eta \to \int_0^t F(s, (\psi \vee \eta)_s)\, ds, \qquad \eta \to \int_0^t G(s, (\psi \vee \eta)_s)\, dw(s): \tilde{C}_t \mapsto L^2(\Omega, \mathscr{F}_t, P, R^d),$$

$$\eta \to \int_0^{\cdot} F(s, (\psi \vee \eta)_s)\, ds, \qquad \eta \to \int_0^{\cdot} G(s, (\psi \vee \eta)_s)\, dw(s): \tilde{C}_t \mapsto \tilde{C}_t$$

are continuous.

(iv) *There exists a measurable function* $h: R_+ \to R_+$ *with* $h(s) \leqq s$ *for all* s *and for every* $t_0 \geqq 0$ *there exist* $J = [t_0, t_0 + \varepsilon]$ *and* $Z \in K(J, h)$ *such that for all* $t \in J$, $\psi \in \hat{Y}$, η, $\eta' \in \tilde{C}_t$

$$\text{(3.1)} \qquad \int_{t_0}^t E[|F(s, (\psi \vee \eta)_s) - F(s, (\psi \vee \eta')_s)|^2]\, ds \leqq \int_{t_0}^t Z(s, |\eta - \eta'|_{h(s)}^2)\, ds,$$

$$\text{(3.2)} \qquad \int_{t_0}^t E[|G(s, (\psi \vee \eta)_s) - G(s, (\psi \vee \eta')_s)|^2]\, ds \leqq \int_{t_0}^t Z(s, |\eta - \eta'|_{h(s)}^2)\, ds.$$

(v) *For every* $\psi \in \hat{Y}$ *and* $t > 0$ *the operator* $\hat{F}: \tilde{C}_t \mapsto \tilde{C}_t$ *defined by*

$$(\hat{F}\eta)(s) = f(s, (\psi \vee \eta)_s) - f(0, \psi)$$

satisfies

$$|\hat{F}\eta - \hat{F}\eta'|_t \leqq k|\eta - \eta'|_t, \qquad k < 1.$$

For $\phi \in \hat{Y}$ define the successive approximations by

$$(y^{n+1})_0 = \phi,$$

$$y^{n+1}(t) = (\hat{F}y^{n+1})(t) + \int_0^t F(s, (\phi \vee y^n)_s)\, ds + \int_0^t G(s, (\phi \vee y^n)_s)\, dw(s),$$

for $t \geqq 0$, where the initial approximation is $y^0 = \phi \vee \tilde{y}$, $\tilde{y} \in \tilde{C}_T$ for all T. Then there exists a continuous process $\{y(t)\}_{t \geqq 0}$ such that

$$|y^n - y|_T \mapsto 0 \quad \textit{for every } T \geqq 0.$$

In particular the process $x_0 = \phi$, $x(t) = y(t) + \phi(0)$, $t \geqq 0$, is a solution of (III), *i.e., x is continuous for $t \geqq 0$ and satisfies*

$$x(t) = f(t, x_t) - f(0, \phi) + \phi(0) + \int_0^t F(s, x_s)\, ds + \int_0^t G(s, x_s)\, dw(s).$$

Proof. Step 1. Assume that $\lim_{m,n\to\infty} |y^m - y^n|_t = 0$ and choose $y = \{y(s)\}_{s \leqq t} \in \tilde{C}_t$ such that $|y^n - y|_t \mapsto 0$.

Denote

$$I_n(t) = \int_0^t [F(s, (\phi \vee y^n)_s) - F(s, (\phi \vee y)_s)]\, ds,$$

$$J_n(t) = \int_0^t [G(s, (\phi \vee y^n)_s) - G(s, (\phi \vee y)_s)]\, dw(s),$$

$$\theta_n(t) = \|I_n(t)\|^2_{L^2(\Omega, \mathcal{F}, P)} + \|J_n(t)\|^2_{L^2(\Omega, \mathcal{F}, P)} + |I_n|^2_t + |J_n|^2_t.$$

By hypothesis (iii) we have $\lim_{m\to\infty} \theta_m(t) = 0$. By Assumption 1, (3.1), (3.2), and Doob and Schwartz's inequalities we get for $T - t$ small enough and for a constant $C(T)$:

$$|y^{m+1} - y^{n+1}|^2_T \leqq C(T)\left[\theta_m(t) + \theta_n(t) + \int_t^T H(s)\, ds\right] \bigg/ (1-k)^2, \tag{3.3}$$

$$|y^{m+1} - y^{n+1}|^2_T \leqq C(T)\left[\theta_m(t) + \theta_n(t) + \int_t^T Z(s, |y^m - y^n|^2_s)\, ds\right] \bigg/ (1-k)^2. \tag{3.4}$$

Step 2. Define $T = \sup\,(t \geqq 0;\ \lim_{m,n\to\infty} |y^m - y^n|_t = 0)$. We have $T \geqq 0$ and we want to prove that $T = \infty$. Assume $T < \infty$. From (3.3) we have that

$$\lim_{m,n\to\infty} |y^m - y^n|_T = 0. \tag{3.5}$$

It is easily seen that

$$\sup_n \sup_{s \leqq t} |y^n|^2_s \leqq C(t) < \infty.$$

Denote $\delta_p(t) = \sup_{m,n \geqq p} |y^m - y^n|^2_t$; $\delta(t) = \lim_{p\to\infty} \delta_p(t)$ and let $J = [T, T + \varepsilon]$ and $Z \in K(J, H)$ be given by hypothesis (iv).

From (3.4) and for $t \in J$ we deduce

$$\delta_{p-1}(t) \leqq C(T+\varepsilon)\left[\sup_{m \geqq p} \theta_m(T) + \sup_{n \geqq p} \theta_n(T) + \int_T^t Z(s, \delta_p(s))\, ds\right] \bigg/ (1-k)^2;$$

hence

$$\delta(t) \leqq C \int_T^t Z(s, \delta(s))\, ds$$

where from $\delta(t)=0$. In particular we obtain $\lim_{m,n\to\infty}|y^m-y^n|_{T+\varepsilon}=0$ which contradicts the definition of T.

THEOREM 3.2. *Suppose Assumptions* 1 *and* 3 *and hypothesis* (v) *of Theorem* 3.1 *are satisfied. Moreover assume that*

(1) *For every* $\psi\in\hat{Y}$ *and* $t>0$ *the operators*

$$F(\cdot,(\psi\vee\cdot).),\ G_i(\cdot,(\psi\vee\cdot).):\tilde{C}_t\mapsto\tilde{C}_t,\ i=1,\cdots,d$$

are continuous.

(2) *There is a measurable function* $h:R_+\mapsto R_+$ *with* $h(s)\leqq s$ *for each* s *and for every* $t_0\geqq 0$ *there exists* $J=[t_0,t_0+\varepsilon]$ *and* $Z\in K(J,h)$ *such that for each* $t\in J$, $\psi\in\hat{Y}$, η, $\eta'\in\tilde{C}_t$

$$|F(\cdot,(\psi\vee\eta).)-F(\cdot,(\psi\vee\eta')).)|_t^2+|G(\cdot,(\psi\vee\eta).)-G(\cdot,(\psi\vee\eta')).)|_t^2\leqq Z(t,|\eta-\eta'|_{h(t)}^2).$$

Then we have the same conclusion as in Theorem 3.1.

Proof. It is easily seen that

$$|y^{n+1}|_s^2\leqq C(t,k,\phi)\left(1+\int_0^s|y^n|_u^2\,du\right)$$

where from by induction we obtain

$$\sup_n\sup_{s\leqq t}|y_s^n|^2\leqq C(t)<\infty. \tag{3.6}$$

Now we fix a positive constant T and assume that $\lim_{m,n\to\infty}|y^m-y^n|_t=0$ for every $t<T$.

Let $\{y(t)\}_{0\leqq t<T}$ be a continuous adapted process such that $|y^n-y|_t\mapsto 0$ for every $t<T$. Then we have

$$\int_0^T|F(\cdot,(\phi\vee y^m).)-F(\cdot,(\phi\vee y^n).)|_t^2\,dt\leqq 2\int_0^T|F(\cdot,(\phi\vee y^m).)$$
$$-F(\cdot,(\phi\vee y).)|_t^2\,dt+2\int_0^T|F(\cdot,(\phi\vee y^n).)-F(\cdot,(\phi\vee y).)|_t^2\,dt\to 0$$

as $m,n\to\infty$ by the continuity of F, (3.6) and the dominated convergence theorem.

An analogue computation holds for G. Therefore if we put

$$\delta_{m,n}(T)=\int_0^T[|F(\cdot,(\phi\vee y^m).)-F(\cdot,(\phi\vee y^n).)|_t^2$$
$$+|G(\cdot,(\phi\vee y^m).)-G(\cdot,(\phi\vee y^n).)|_t^2]\,dt$$

then we have

$$\lim_{m,n\to\infty}\delta_{m,n}(T)=0. \tag{3.7}$$

Let T be as in step 2 of Theorem 2.1. If we assume $T<\infty$ then a little computation yields

$$|y^{m+1}-y^{n+1}|_t^2\leqq C(k,T,\phi)\left[\delta_{m,n}(T)+\int_T^t Z(s,|y^m-y^n|_{h(s)}^2)\,ds\right]$$

Now the proof continues as in Theorem 2.1.

COROLLARY. *Suppose Assumptions* 1 *and* 2 *and hypotheses* (i), (ii) *and* (v) *of Theorem* 3.1 *are satisfied. Moreover assume there exist a measurable function* $h:R_+\mapsto R_+$ *with* $h(s)\leqq s$ *for each* s *and* $Z\in K(R_+,h)$ *such that* (3.1) *and* (3.2) *hold for every* $t\geqq 0$, $\psi\in\hat{Y}$, η, $\eta'\in\tilde{C}_t$. *Then the equation* (III) *has a pathwise unique strong solution.*

Remark 3.2. The results of Theorems 3.1 and 3.2 and of the corollary cover those from [5], [11], [14].

Remark 3.3. An abstract deterministic case closely related to our setting has been considered in [13].

Remark 3.4. Another general approach for Ito integrodifferential equations can be found in [9].

THEOREM 3.3. *For* $j=1,2,\cdots$ *let* $A_j : R_+ \times R^d \mapsto R^d$, $B_j : R_+ \times R^d \mapsto R^d \otimes R^m$, $a_j, b_j : R_+ \mapsto R_+$ *be measurable functions and let* $Z : R_+^2 \mapsto R_+$ *be such that* Z *is measurable,* $Z(t,\cdot)$ *is continuous, concave and nondecreasing. Assume the following*:

(i) *There exists a sequence* $\theta_{-1} = -\theta < 0 = \theta_0 < \theta_1 < \cdots$, $\theta_n \nearrow \infty$ *such as*:

(i_1) *For each* j, $k \geqq 1$, a_j, b_j map $[\theta_{k-1}, \theta_k]$ *into* $[\theta_{r-1}, \theta_r]$ *with* $r \leqq k$;

(i_2) *If* a_j, b_j map $[\theta_{k-1}, \theta_k]$ *into* $[\theta_{k-1}, \theta_k]$, *then* $a_j(t) \leqq t$, $b_j(t) \leqq t$ *for* $\theta_{k-1} \leqq t \leqq \theta_k$,

(i_3) *If we define for* $k \geqq 0$

$$J_1(k) = \{j;\ a_j([\theta_{k-1}, \theta_k]) \subset [\theta_{k-1}, \theta_k]\},$$

$$J_2(k) = \{j;\ b_j([\theta_{k-1}, \theta_k]) \subset [\theta_{k-1}, \theta_k]\},$$

then $u=0$ *is the unique nondecreasing solution of*

$$\begin{aligned} u &= 0, \qquad t \leqq \theta_{k-1}, \\ &\leqq C \int_{\theta_{k-1}}^{t} \left[\sum_{j \in J_1(k)} Z(s, u(a_j(s))) + \sum_{j \in J_2(k)} Z(s, u(b_j(s))) \right] ds, \qquad t \geqq \theta_{k-1}, \end{aligned}$$

for a constant C *large enough.*

(ii) *There is a locally integrable function* γ such that

$$\sum_{j \geqq 1} |A_j(t,x)|^2 + \sum_{j \geqq 1} |B_j(t,x)|^2 \leqq \gamma(t) \quad \textit{for all } t \geqq 0, \quad x \in R^d.$$

(iii) *For every* $j \geqq 1$, $t \geqq 0$, $x, y \in R^d$

$$|A_j(t,x) - A_j(t,y)|^2 + |B_j(t,x) - B_j(t,y)|^2 \leqq Z(t, |x-y|^2).$$

Let $(w_j)_{j \geqq 1}$ *be an infinite number of independent d-dimensional Wiener processes.*

Then the stochastic equation

$$x_0 = \phi \in \hat{Y},$$

$$\text{(IV)} \qquad \begin{aligned} x(t) &= \phi(0) + \sum_{j \geqq 1} \int_0^t A_j(s, x(a_j(s)))\, ds \\ &\quad + \sum_{j \geqq 1} \int_0^t B_j(s, x(b_j(s)))\, dw_j(s), \qquad t \geqq 0 \end{aligned}$$

has a pathwise unique strong solution (*for definition and properties of stochastic integral* $\sum_{j \geqq 1} \int_0^t B_j(\cdot)\, dw_j(\cdot)$; *see* [4]).

Proof. We proceed by induction on the intervals $[\theta_{k-1}, \theta_k]$. Assume that a unique solution exists on $[0, \theta_k]$. We shall prove the existence of a unique solution on $[\theta_k, \theta_{k+1}]$. On the interval $[\theta_k, \theta_{k+1}]$ the equation (IV) becomes

$$x(t) = z(t) + Sx(t)$$

where

$$z(t) = x(\theta_k) + \sum_{j \notin J_1(k)} \int_{\theta_k}^{t} A_j(s, x(a_j(s)))\, ds + \sum_{j \notin J_2(k)} \int_{\theta_k}^{t} B_j(s, x(b_j(s)))\, dw_j(s),$$

$$Sx(t) = \sum_{j \in J_1(k)} \int_{\theta_k}^{t} A_j(s, x(a_j(s)))\, ds + \sum_{j \in J_2(k)} \int_{\theta_k}^{t} B_j(s, x(b_j(s)))\, dw_j(s).$$

Remark that $z(t)$ depends only on the known values of x on $[-\theta, \theta_k]$. Now the conclusion of the theorem is a consequence of Theorem 3.1 (the fact that Sx is an infinite sum of integrals does not change the proof and the validity of Theorem 3.1).

Remark 3.5. Theorem 3.3 represents a stochastic version of a result of Datko [2, Thm. 2.6].

4. An example. We conclude by briefly outlining a stochastic version of the dangling spider equation (see [11], [12] for the deterministic case). The initial histories have the paths in $X = \{f = (f_1, f_2): R_- \mapsto R^2;\ f \text{ continuous}\}$. The semi-norm in X is given by

$$|f|_X = |f_1(0)| + |f_2(0)| + \left[\int_{-\infty}^{0} k(s)|f_1(s)|^p\, ds \right]^{1/p}$$

where $p \geqq 1$, $k \in L_{\text{loc}}(R_-, R_+)$ and $\bar{k}(t) = \operatorname{ess\,sup} k(s+t)/k(s) < \infty$. The stochastic functional equation which we consider is

$$\text{(V)} \qquad \begin{aligned} dv(t) &= [F(t, x(t), v(t)) - \tau(t, x_t)]\, dt + \sigma(t, x(t), v(t))\, dM(t), \\ dx(t) &= v(t)\, dt \end{aligned}$$

where $F: R_+^2 \times R \mapsto R_+$, $\tau: R_+^2 \times X \mapsto R_+$, $\sigma: R_+^2 \times R \mapsto R$ and $\{M(t)\}_{t \geqq 0}$ is a continuous square integrable martingale.

The equation (V) can describe the evolution in time of the length of an extensible, massless, viscoelastic filament which has one end fixed while the other supports a ball (or spider) of unit mass. It is assumed that the ball moves "up and down" with velocity $v(t)$ and $x(t)$ denotes the length of the filament at t. The number $F(t, x(t), v(t))$ is an applied force pulling the ball downward, $\tau(t, x_t)$ is the tension in the filament and $\sigma(t, x(t), v(t))\, dM(t)$ is a random perturbation.

The equation (V) can be written in the form (I) with

$$a(t,f) = \begin{pmatrix} F(t, f_1(0), f_2(0)) - \tau(t, f_1) & \sigma(t, f_1(0), f_2(0)) \\ f_2(0) & 0 \end{pmatrix},$$

$$Z(t) = (t, M(t))'.$$

By using Theorem 2.2 we can state Theorem 4.1:

THEOREM 4.1. *Suppose the following*:

(1) $a(t, 0)$ *is locally bounded.*

(2) *There exist* $\alpha \in LS$ *and* $\gamma(t)$ *locally bounded such that*

$$|F(t, x, y) - F(t, x', y')|^2 + |\sigma(t, x, y) - \sigma(t, x', y')|^2 \leqq \gamma(t)\alpha(|x - x'|^2 + |y - y'|^2),$$

$$|\tau(t, f) - \tau(t, g)|^2 \leqq \gamma(t)\alpha(|f - g|_X^2)$$

for every $t \geqq 0, f, g \in X, x, x', y, y' \in R$. *Then* (V) *has a pathwise unique strong solution for all initial history* ϕ *which is continuous and* $E(|\phi|_X^2) < \infty$.

STABILITY OF SINGULARLY PERTURBED SOLUTIONS TO SYSTEMS OF REACTION-DIFFUSION EQUATIONS*

YASUMASA NISHIURA† AND HIROSHI FUJII†

Abstract. Stability theorem is presented for large amplitude singularly perturbed solutions (SPS) of reaction-diffusion systems on a finite interval. Spectral analysis shows that there exists a unique real critical eigenvalue $\lambda_c(\varepsilon)$ which behaves like $\lambda_c(\varepsilon) \simeq \tau\varepsilon$ as $\varepsilon \downarrow 0$, where ε is a small parameter contained in the system. All the other noncritical eigenvalues have strictly negative real parts independent of ε. The singular limit eigenvalue problem in § 2 plays a key role to judge the sign of τ, which determines the stability of SPS for small ε. Under a natural framework of nonlinearities, τ becomes negative, namely, SPS is asymptotically stable. Instability result is also shown in § 4.

Key words. stability, singularly perturbed solutions, reaction-diffusion equations, asymptotic behaviors

AMS(MOS) subject classifications. 35B25, 35B40, 35K57

Introduction. In this paper, we present a stability theorem of singularly perturbed (and *large amplitude*) stationary solutions with an interior transition layer (SPS1) to systems of reaction-diffusion equations of the form:

$$\text{(P)} \qquad \begin{aligned} &u_t = \varepsilon^2 u_{xx} + f(u, v), \\ &v_t = D v_{xx} + g(u, v), \end{aligned} \qquad (t, x) \in (0, \infty) \times I, \quad I = (0, 1),$$

$$u_x = 0 = v_x, \qquad (t, x) \in (0, \infty) \times \partial I, \quad \partial I = \{0, 1\},$$

where ε is a small parameter and $D > 0$.

The system (P) appears in a number of fields such as eco-systems, morphogenesis in developing biology, chemical reactions, and so on. For some classes of f and g, (P) exhibits as its stationary solutions large amplitude patterns with interior transition layers when one of the diffusion coefficients ε is small. Singular perturbation approaches have been one of the most established methods to construct such spatially inhomogeneous large amplitude patterns. See Fife [4] and the survey by Conway [3]. There have been many works concerning the construction of such singularly perturbed solutions (SPS), e.g., Fife [4], Mimura, Tabata and Hosono [15], Ito [11], Mimura, Nishiura, Tesei and Tsujikawa [13], Fujii and Hosono [5] and so on, in which not only solutions of interior transition layer type but also boundary layer type and mixture of both types are treated. On the other hand, concerning the stability properties of SPS, very few works have been known at least to the authors' best knowledge. (See the survey [3].) The difficulty may lie in the largeness of amplitude of SPS and subtle behaviors of the spectra of the linearized operators as ε tends to zero. The work for the degenerate case $\varepsilon = 0$ of a simple density-dependent diffusion system, by Aronson, Tesei and Weinberger [1], appears to be an exception. However, there is a gap between the degenerate and nondegenerate cases, as will become clear in § 2. Recent works of the authors [17], [19] show the stability of SPS1, i.e., SPS of mode 1, for the nondegenerate case ($\varepsilon > 0$) with large $D > 0$. The basic method there is a perturbation from the limit of $D \uparrow +\infty$. Nevertheless, for a general D, the stability problem of SPS has remained open up to the present time.

The goal of this paper is to give a stability theorem to SPS1 for a general D, which provides a framework of global assumptions to be imposed on the nonlinearities to obtain a *stable* SPS1. A violation of our stability assumptions may cause instability. In fact, we shall show an instability theorem at the final section.

A key role in our theory will be played by the *singular limit eigenvalue problem* introduced in § 2, which preserves information on the interior transition layer in the form of *Dirac's δ-function*, even though it is a limit equation of $\varepsilon \downarrow 0$.

In order to treat the limiting case as $D \uparrow \infty$ equally, we set $D = 1/\sigma$. The stationary problem of (P) becomes

$$\text{(SP)} \qquad \varepsilon^2 u_{xx} + f(u, v) = 0, \quad \frac{1}{\sigma} v_{xx} + g(u, v) = 0, \quad u_x = 0 = v_x \quad \text{on } \partial I.$$

When $\sigma \downarrow 0$, (P) is replaced by

$$\text{(P)}_0 \qquad u_t = \varepsilon^2 u_{xx} + f(u, \xi), \quad \xi_t = \int_I g(u, \xi)\, dx, \quad u_x = 0,$$

where $v = \xi$ is a constant function of x and the associated stationary problem is given by the following:

$$\text{(SP)}_0 \qquad \begin{aligned} &\varepsilon^2 u_{xx} + f(u, \xi) = 0, \quad \int_I g(u, \xi)\, dx = 0 \quad \text{in } I, \\ &u_x = 0 \quad \text{on } \partial I. \end{aligned}$$

(SP)$_0$ is called the *shadow system* (see Nishiura [16] for details).

Since (P) is a system of semilinear parabolic equations with diagonal diffusion matrix, the stability of SPS1 is determined by the spectra of the linearized eigenvalue problem:

$$\text{(LP)} \qquad \begin{gathered} \mathcal{L}^{\varepsilon,\sigma}\begin{pmatrix} w \\ z \end{pmatrix} \overset{\text{def}}{=} \begin{bmatrix} \varepsilon^2 \dfrac{d^2}{dx^2} + f_u^{\varepsilon,\sigma} & f_v^{\varepsilon,\sigma} \\ g_u^{\varepsilon,\sigma} & \dfrac{1}{\sigma}\dfrac{d^2}{dx^2} + g_v^{\varepsilon,\sigma} \end{bmatrix} \begin{pmatrix} w \\ z \end{pmatrix} = \lambda \begin{pmatrix} w \\ z \end{pmatrix}, \\ w_x = 0 = z_x \quad \text{on } \partial I, \end{gathered}$$

where all partial derivatives are evaluated at SPS1, $U^{\varepsilon,\sigma}$ (see Theorem 1.1 in § 1), namely, $f_u^{\varepsilon,\sigma} = f_u(u(x; \varepsilon, \sigma), v(x; \varepsilon, \sigma))$ and so on. For the limiting case as $\sigma \downarrow 0$, (LP) is replaced by

$$\text{(LP)}_0 \qquad \begin{gathered} \mathcal{L}^{\varepsilon,0}\begin{pmatrix} w \\ \eta \end{pmatrix} \overset{\text{def}}{=} \begin{bmatrix} \varepsilon^2 \dfrac{d^2}{dx^2} + f_u^{\varepsilon,0} & f_v^{\varepsilon,0} \\ \displaystyle\int_I g_u^{\varepsilon,0} & \displaystyle\int_I g_v^{\varepsilon,0} \end{bmatrix} \begin{pmatrix} w \\ \eta \end{pmatrix} = \lambda \begin{pmatrix} w \\ \eta \end{pmatrix}, \\ w_x = 0 \quad \text{on } \partial I, \end{gathered}$$

where $z = \eta$ is a constant function. Hereafter, (LP) automatically means (LP)$_0$ when $\sigma = 0$. If $\operatorname{Re} \lambda < 0$ for all eigenvalues of (LP), then, $U^{\varepsilon,\sigma}$ is an asymptotically stable solution of (P). It will be convenient to divide the spectra into two classes: one is the class of *critical eigenvalues* which tend to zero as $\varepsilon \downarrow 0$, and the other *noncritical* ones which are bounded away from zero for small ε. We will see in § 2 that noncritical eigenvalues are not dangerous to the stability of SPS1 (Proposition 2.1). Therefore, the stability wholely depends on the asymptotic behavior of critical eigenvalues as $\varepsilon \downarrow 0$. Our conclusion is the following.

MAIN THEOREM. *Under* (A.5), *and* (A.0)-(A.4) *as well, there exists only one critical eigenvalue* $\lambda = \lambda_c(\varepsilon, \sigma)$ *for* $(\varepsilon, \sigma) \in \Omega_{\varepsilon_0, \sigma_0}$ (*see Theorem* 1.1), *and which is real and simple. Furthermore, the principal part of* $\lambda_c(\varepsilon, \sigma)$ *as* $\varepsilon \downarrow 0$ *is given by*

$$\lambda_c(\varepsilon, \sigma) \simeq \tau_N^{*,\sigma} \varepsilon (\tau_N^{*,\sigma} < 0), \tag{0.1}$$

namely, λ_c *approaches to zero from the negative side with* $O(\varepsilon)$ *when* $\varepsilon \downarrow 0$.

Apparently, this theorem implies the asymptotic stability of SPS1 for any small ε. The Main Theorem has been announced in Nishiura and Fujii [18].

Now we state the assumptions for f and g (see Fig. 1).

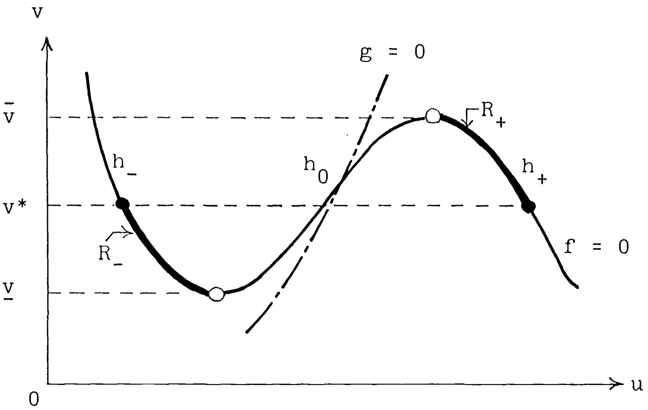

FIG. 1. *Functional forms of f and g.*

Existence Assumptions.

(A.0) f and g are smooth functions of u and v defined on some open set $\mathcal{O}$ in $\mathbb{R}^2$.

(A.1) The nullcline of f is sigmoidal and consists of three continuous curves $u = h_-(v)$, $h_0(v)$ and $h_+(v)$ defined on the intervals I_-, I_0 and I_+, respectively. Let $\min I_- = \underline{v}$ and $\max I_+ = \bar{v}$, then the inequality $h_-(v) < h_0(v) < h_+(v)$ holds for $v \in I^* \overset{\text{def}}{=} (\underline{v}, \bar{v})$, and $h_+(v)(h_-(v))$ coincides with $h_0(v)$ at only one point $v = \bar{v}(\underline{v})$, respectively.

(A.2) $J(v)$ has an isolated zero at $v = v^* \in I^*$ such that $dJ/dv < 0$ at $v = v^*$, where $J(v) = \int_{h_-(v)}^{h_+(v)} f(s, v)\, ds$.

(A.3) $f_u < 0$ on $R_+ \cup R_-$, where $R_+(R_-)$ denotes the part of the curve $u = h_+(v)$ $(h_-(v))$ defined by $R_+(R_-) = \{(u, v) \mid u = h_+(v)\ (h_-(v)) \text{ for } v^* \leqq v < \bar{v}(\underline{v} < v \leqq v^*)\}$ (solid parts of $f = 0$ in Fig. 1), respectively.

(A.4) (a) $g|_{R_-} < 0 < g|_{R_+}$.

(b) $\det(\partial(f, g)/\partial(u, v))|_{R_+ \cup R_-} > 0$.

Stability Assumption.

(A.5) $g_v|_{R_+ \cup R_-} \leqq 0$.

Remark 0.1. Let $G_\pm(v) \overset{\text{def}}{=} g(h_\pm(v), v)$ for $v \in I_\pm$. Then, the assumption (A.4b) is equivalent to

$$\frac{d}{dv} G_\pm(v)|_{R_\pm} < 0, \quad \text{respectively,} \tag{0.2}$$

since it follows from $f(h_\pm(v), v) = 0$ and (A.3) that

$$\frac{d}{dv}G_\pm(v)\bigg|_{R_\pm} = \frac{f_u g_v - f_v g_u}{f_u}\bigg|_{R_\pm}.$$

Note that in [15] the condition (0.2) is assumed in place of (A.4b).

Remark 0.2. It holds that $f_u = 0$ at $(h_+(\bar{v}), \bar{v})$ and $(h_-(\underline{v}), \underline{v})$. Moreover, in general, g and $\det(\partial(f, g)/\partial(u, v))$ in (A.4) may become zero at these end points.

The outline of this paper is the following. In § 1, first, the existence theorem of SPS1 and the asymptotic form of the stretched SPS1 are presented. Second, the spectral behavior of the Sturm-Liouville operator $L^{\varepsilon,\sigma}$ with respect to the parameters (ε, σ) is studied in detail, which is a basic result for later spectral analysis. In § 2, we introduce the singular limit eigenvalue problem (SLEP), which characterizes the asymptotic behavior of the critical eigenvalues of (LP) as $\varepsilon \downarrow 0$. A geometric consideration of the solution of SLEP implies that the critical eigenvalue really behaves as in Main Theorem. It is also proved that all the other noncritical eigenvalues have strictly negative real parts independent of ε. A justification of SLEP is given in § 3, namely, it is shown that the critical eigenvalue is real, unique and simple, and the asymptotic behavior of it as $\varepsilon \downarrow 0$ is just the same as is given by SLEP in § 2. Finally, in § 4, the instability of SPS1 is discussed when some of the assumptions for nonlinearities are violated.

We show several examples which fall into our framework.

Example 1 (*Diffusive prey-predator model* [14]. See Fig. 2).

$$u_t = \varepsilon^2 u_{xx} + f_0(u)u - kuv, \qquad v_t = Dv_{xx} + g_0(v)v + kuv,$$

where k is a positive constant; $f_0(u)$ is a smooth function such that

$$f_0(0) \geqq 0, \quad \frac{d}{du}f_0(u)\begin{cases} >0, & 0 \leqq u < c, \\ =0, & u = c, \\ <0, & u > c, \end{cases}$$

for some positive constant c, and $g_0(v) = c_0 + c_1 v^m$ $(c_0, c_1, m > 0)$. We assume that

$$g_0(v^*) + \left(\frac{d}{dv}g_0(v^*)\right)v^* > kh_+(v^*),$$

which guarantees the stability assumption (A.5), where $u = h_+(v)$ is the right branch of the nullcline $f(u, v) = 0$.

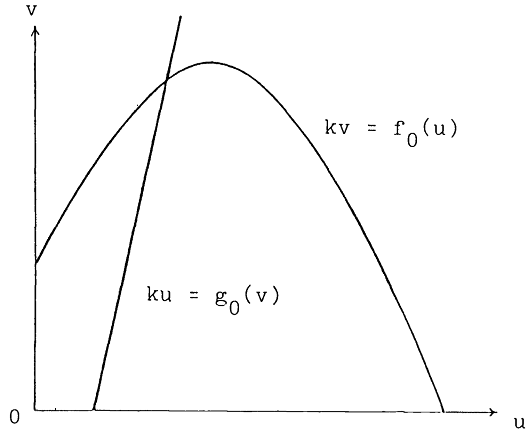

FIG. 2. *Functional forms of prey-predator model.*

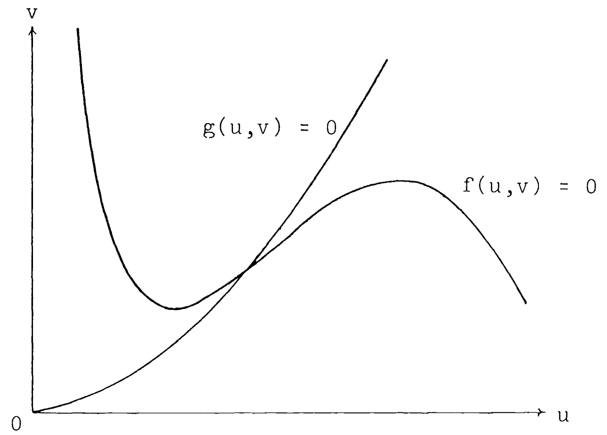

FIG. 3. *Functional forms of Gierer-Meinhardt model with saturation.*

Example 2 (*Gierer-Meinhardt model with saturation* [9]. See Fig. 3).

$$u_t = \varepsilon^2 u_{xx} + \rho\rho_0 + \frac{c\rho u^2}{v(1+\kappa u^2)} - \mu u,$$

$$v_t = Dv_{xx} + c'\rho' u^2 - \nu v,$$

where ρ, ρ', ρ_0, c, c', κ, μ and ν are all positive constants.

Example 3 (*Seelig's model with diffusion* [12]. See Fig. 4).

$$u_t = \varepsilon^2 u_{xx} + j_1 - u - \beta r(u, v), \qquad v_t = Dv_{xx} + j_2 - \gamma r(u, v),$$

where $r(u, v) = uv/(1+u+v+Ku^2)$ and j_1, j_2, β, γ and K are all positive constants.

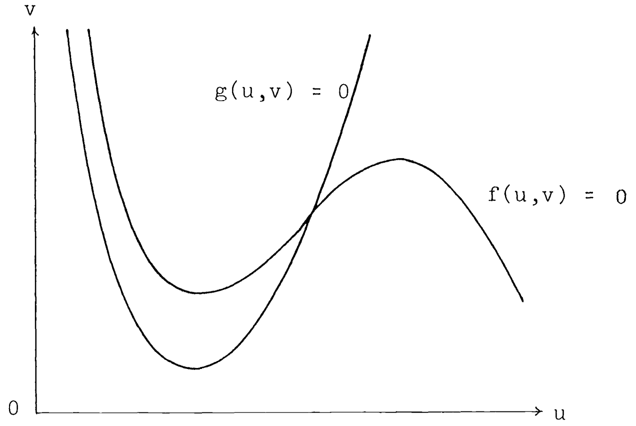

FIG. 4. *Functional forms of Seelig's model.*

We use the following notation and acronym (with page reference) throughout the paper:

$C^p(\bar{I})$ = the space of p-times continuous differentiable functions on $\bar{I}$ with usual norm,

$C^p_\varepsilon(\bar{I})$ = the space of p-times continuous differentiable functions on $\bar{I}$ with the norm

$$\|u\|_{C^p_\varepsilon} = \sum_{k=0}^{p} \max \left| \left(\varepsilon \frac{d}{dx} \right)^k u(x) \right|,$$

$H^p(I)=$ the usual Sobolev space,

$H^p_N(I)=$ the space of closure of $\{\cos(n\pi x)\}_{n=0}^{\infty}$ in $H^p(I)$.

$\langle\cdot,\cdot\rangle=$ the inner product in $L^2(I)$-space.

$C^k_{\text{c.u.}}(\Omega)=$ the compact uniform convergence in C^k-sense in Ω, namely, the uniform convergence on any compact subset of Ω in C^k-sense.

1. Existence theorem and preliminaries. In this section, we show the existence theorem of SPS1 and prepare several lemmas which will be used in subsequent sections.

First, let us begin with the study of reduced solutions and their σ-dependency to understand the form of SPS1. *The reduced problem* is given by putting $\varepsilon=0$ in (SP),

$$\text{(RP.1)} \qquad f(u,v)=0,$$

$$\text{(RP.2)} \qquad \frac{1}{\sigma}v_{xx}+g(u,v)=0,$$

subject to zero flux boundary conditions and $(u,v)\in L^2(I)\times\{H^2(I)\cap H^1_N(I)\}$. The amount of solutions expand to a great extent, when we switch the problem from (SP) to (RP). However, we are interested in the solutions of (RP) which are the limits of those of (SP) as $\varepsilon\downarrow 0$. One of the important such classes is the following. We take

$$\text{(1.1)} \qquad u=h^*(v)=\begin{cases} h_-(v) & \text{for } v\leqq v^*,\ v\in I_-, \\ h_+(v) & \text{for } v\geqq v^*,\ v\in I_+, \end{cases}$$

as a special solution of (RP.1). Substituting this into (RP.2), we have a scalar equation for v, i.e., the *reduced equation,*

$$\text{(RSP)} \qquad \frac{1}{\sigma} v_{xx} + G^*(v) = 0, \qquad v \in H^2(I) \cap H^1_N(I),$$

where $G^*(v) = g(h^*(v), v)$. It follows from (0.2) that $G^*(v)$ is strictly decreasing in each of the subintervals $\underline{v} \leqq v \leqq v^*$ and $v^* \leqq v \leqq \bar{v}$ and that it has a discontinuity of the first kind at $v = v^*$ as in Fig. 5. We only consider monotone increasing C^1-matching solutions of (RSP) at $v = v^*$. Let Num $(v(x))$ denotes the numerical range of a monotone increasing solution $v(x)$ of (RSP), i.e.,

$$\text{Num}\,(v(x)) = [\min_{x \in I} v(x), \max_{x \in I} v(x)].$$

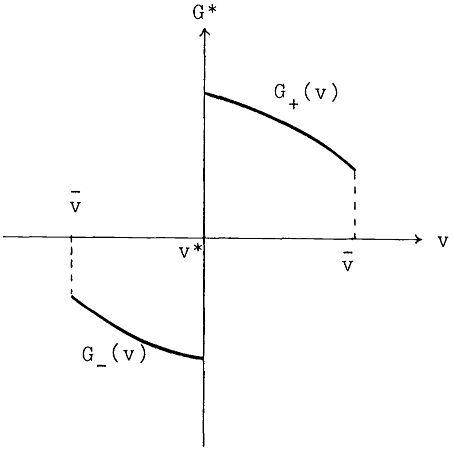

FIG. 5. *Functional form of* $G^*(v)$.

PROPOSITION 1.1. *There exists a uniquely determined positive constant* σ_1^* *such that*

(a) *Monotone increasing* C^1*-matching solutions* $V^{*,\sigma}(x)$ *of* (RSP) *exist for* $0 < \sigma \leqq \sigma_1^*$,

(b) Num $(V^{*,\sigma}(x))$ *is a monotone increasing sequence of intervals of* σ *with respect to inclusion relation and satisfies* $\lim_{\sigma \downarrow 0} \text{Num}\,(V^{*,\sigma}(x)) = \{v^*\}$. *Moreover,* $\lim_{\sigma \downarrow 0} V^{*,\sigma}(x) = v^*$ *in* $C^1(\bar{I})$*-sense*;

(c) Num $(V^{*,\sigma_1^*}(x))$ *contains at least one of the end points* $\underline{v}$ *and* $\bar{v}$, *namely, the reduced solution* (*see* (1.2)) *covers completely at least one of the curves* R_+ *and* R_- *defined in* (A.3).

Proof. See Appendix 1 and Proposition 3.2 in [6] (see also § 3 in [15]).

Using (1.1), we obtain the σ-family of reduced solutions (see Fig. 6),

$$(1.2) \qquad (U^{*,\sigma}(x), V^{*,\sigma}(x)), \qquad 0 \leqq \sigma \leqq \sigma_1^*,$$

where $U^{*,\sigma}(x) = h^*(V^{*,\sigma}(x))$.

Remark 1.1. The value $\sigma = \sigma_1^*$ is an interesting point from a global bifurcation point of view. In fact, it is a taking off point of the D_1 (i.e., one-mode solution)-sheet from the singular wall. Namely, SPS1 constructed by our method ceases to exist for $\sigma > \sigma_1^*$. See [6] and [7] for more detailed discussions.

PROPOSITION 1.2. *The matching point* $x_1^*(\sigma)$ *is well defined by*

$$(1.3) \qquad V^{*,\sigma}(x_1^*(\sigma)) = v^*$$

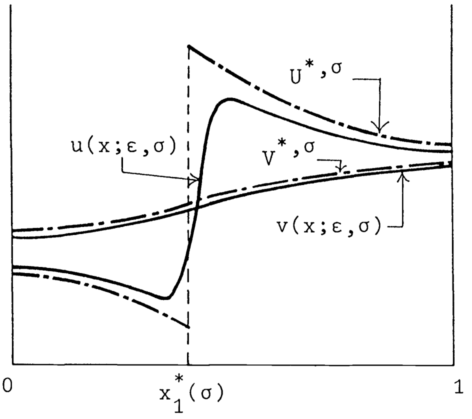

FIG. 6. *Reduced solution and* SPS.

due to the monotonicity of $V^{*,\sigma}(x)$. Then, $x_1^*(\sigma)$ is a continuous function of σ for $0<\sigma\leqq\sigma_1^*$ and uniquely extendable to $\sigma=0$. Here $x_1^*(0)=\lim_{\sigma\downarrow 0}x_1^*(\sigma)$ is determined by

$$\int_I g(U^{*,0}(x),v^*)\,dx=0,$$

where

$$U^{*,0}(x)=\begin{cases}h_-(v^*) & \mathit{for}\, x\in[0,x_1^*(0)),\\ h_+(v^*) & \mathit{for}\, x\in(x_1^*(0),1].\end{cases}\tag{1.4}$$

Proof. See Appendix 1, [15] and [16].

THEOREM 1.1 (*Existence Theorem of* SPS1). *For any σ_0 with $0<\sigma_0<\sigma_1^*$, there is an $\varepsilon_0>0$ such that* (SP) *has an (ε,σ)-family of solutions $U^{\varepsilon,\sigma}=(u(x;\varepsilon,\sigma),v(x;\varepsilon,\sigma))\in C_\varepsilon^2(\bar I)\times C^2(\bar I)$ for $(\varepsilon,\sigma)\in\Omega_{\varepsilon_0,\sigma_0}=\{(\varepsilon,\sigma)\,|\,0<\varepsilon<\varepsilon_0,\ 0\leqq\sigma<\sigma_0\}$. $U^{\varepsilon,\sigma}$ are uniformly bounded in $C_\varepsilon^2(\bar I)\times C^2(\bar I)$, and satisfy*

$$\lim_{\varepsilon\downarrow 0}u(x;\varepsilon,\sigma)=U^{*,\sigma}(x)\quad \mathit{uniformly\ on}\ I\backslash I_\kappa\ \mathit{for\ any}\ \kappa>0\tag{1.5}$$

and

$$\lim_{\varepsilon\downarrow 0}v(x;\varepsilon,\sigma)=V^{*,\sigma}(x)\quad \mathit{uniformly\ on}\ I,\tag{1.6}$$

where $I_\kappa=(x_1^*(\sigma)-\kappa,\ x_1^*(\sigma)+\kappa)$, and σ_1^*, $U^{*,\sigma}(x)$ and *$V^{*,\sigma}(x)$ are defined in Proposition* 1.2 *and* (1.2). *See Fig.* 6.

Moreover, when $\sigma\downarrow 0$, $U^{\varepsilon,\sigma}$ converges to the shadow SPS1 *$U^{\varepsilon,0}=(u(x;\varepsilon,0),\ \xi(\varepsilon))$ of* $(\mathrm{SP})_0$ *satisfying*

$$\lim_{\varepsilon\downarrow 0}(x;\varepsilon,0)=U^{*,0}(x),\tag{1.7}$$

$$\lim_{\varepsilon\downarrow 0}\xi(\varepsilon)=v^*,\tag{1.8}$$

where $U^{*,0}(x)$ is defined in Proposition 1.2, *and the convergent manner is the same as in* (1.5) *and* (1.6) *replacing $x_1^*(\sigma)$ by $x_1^*(0)$.*

Finally, $U^{\varepsilon,\sigma}$ depends continuously on $(\varepsilon,\sigma)\in\Omega_{\varepsilon_0,\sigma_0}$ in $C_\varepsilon^2\times C^2$-topology, and continuously on $(\varepsilon,\sigma)\in\bar\Omega_{\varepsilon_0,\sigma_0}$ in $L^2\times C^1$-topology, where $\bar\Omega_{\varepsilon_0,\sigma_0}=\{(\varepsilon,\sigma)\,|\,0\leqq\varepsilon<\varepsilon_0,\ 0\leqq\sigma<\sigma_0\}$.

Proof. See Appendix 1. Also, see Mimura, Tabata and Hosono [15], Hosono and Mimura [10] and Ito [11].

In the following, we use the same notation ε_0 for the bound of ε, though we may replace it by a smaller one at need.

The following lemmas concern the asymptotic form of the stretched solution and the spectral behavior of the Sturm-Liouville operator. Here the *stretching* means the change of variables from x to $y=(x-x_1(\varepsilon,\sigma))/\varepsilon$, where $x_1(\varepsilon,\sigma)$ is the C^1-matching point of SPS1 with $\lim_{\varepsilon\downarrow 0} x_1(\varepsilon,\sigma)=x_1^*(\sigma)$ and $u(x_1(\varepsilon,\sigma);\varepsilon,\sigma)=h_0(v^*)$ (see (17) in Appendix 1). For a given function $w(x)$ on I, we denote the *stretched function* by $\tilde{w}(y)$, i.e.,

$$\tilde{w}(y)=w(x_1(\varepsilon,\sigma)+\varepsilon y). \tag{1.9}$$

We also use the following notation for the stretched intervals:

$$\tilde{I}=(-l/\varepsilon, r/\varepsilon),\quad \tilde{I}_-=(-l/\varepsilon,0)\quad\text{and}\quad \tilde{I}_+=(0,r/\varepsilon), \tag{1.10}$$

where $l=x_1(\varepsilon,\sigma)$ and $r=1-x_1(\varepsilon,\sigma)$.

The first lemma is on the convergence of the stretched SPS1 to the static front solution as $\varepsilon\downarrow 0$.

LEMMA 1.1. *Let $\tilde{U}^{\varepsilon,\sigma}=(\tilde{u}(y;\varepsilon,\sigma),\tilde{v}(y;\varepsilon,\sigma))$ be the stretched solution of* SPS1 $U^{\varepsilon,\sigma}$, *and let $\tilde{u}^*$ be a unique monotone increasing solution on $\mathbb{R}$ of the following problem*

$$\frac{d^2}{dy^2}u+f(u,v^*)=0, \tag{1.11a}$$

$$u(\pm\infty)=h_\pm(v^*), \tag{1.11b}$$

$$u(0)=h_0(v^*). \tag{1.11c}$$

Then we have

$$\lim_{\varepsilon\downarrow 0}\tilde{U}^{\varepsilon,\sigma}=\tilde{U}^*\quad in\ C^2_{\text{c.u.}}(\mathbb{R})\text{-}sense, \tag{1.12}$$

where $\tilde{U}^*$ is defined by $\tilde{U}^*=(\tilde{u}^*,v^*)$.

Recall that $C^2_{\text{c.u.}}(\mathbb{R})$ is the abbreviation of *compact uniform convergence in C^2-sense on* $\mathbb{R}$. Here, we note that the limiting function $\tilde{U}^*$ is independent of σ. The convergence (1.12) is uniform with respect to σ for $0\leqq\sigma<\sigma_0$.

Remark 1.2. Though $\tilde{U}^{\varepsilon,\sigma}$ is not defined for all $x\in\mathbb{R}$, (1.12) makes sense, because for any fixed compact interval K, there exists an ε_K such that $\tilde{U}^{\varepsilon,\sigma}$ is defined on K for $0<\varepsilon<\varepsilon_K$.

Proof of Lemma 1.1. We can assume without loss of generality that $u(x;\varepsilon,\sigma)$ takes the value $h_0(v^*)$ at the matching point $x=x_1(\varepsilon,\sigma)$. We prove this lemma according to the construction of SPS1 in Appendix 1.

We divide the solution $U^{\varepsilon,\sigma}$ into two parts at $x=x_1(\varepsilon,\sigma)$, i.e.,

$$U^{\varepsilon,\sigma}=\begin{cases}U_-^{\varepsilon,\sigma} & \text{for } x\in\bar{I}_-=[0,x_1(\varepsilon,\sigma)],\\ U_+^{\varepsilon,\sigma} & \text{for } x\in\bar{I}_+=[x_1(\varepsilon,\sigma),1].\end{cases}$$

We shall show that $\tilde{U}_+^{\varepsilon,\sigma}(\tilde{U}_-^{\varepsilon,\sigma})$ converges to the right(left)-half of $\tilde{U}^*$ in $C^2_{\text{c.u.}}$-sense on $\mathbb{R}^+(\mathbb{R}^-)$ as $\varepsilon\downarrow 0$, where $\mathbb{R}^+=[0,+\infty)$ ($\mathbb{R}^-=(-\infty,0]$). First, note the following two remarks: For any interval $I_\#\subseteqq I$; (i) Let $w(x;\varepsilon)$ be uniformly bounded in $C^2_\varepsilon(I_\#)$-sense for small $\varepsilon(I_\#\subseteqq I)$, then after stretching, $\tilde{w}(y;\varepsilon)$ is uniformly bounded in $C^2(\tilde{I}_\#)$; (ii) Let $w(x;\varepsilon)$ be uniformly bounded in $C^2(I_\#)$-sense for small ε, and $w(x_1(\varepsilon,\sigma);\varepsilon)$ converges to w^* as $\varepsilon\downarrow 0$, then $\tilde{w}(y;\varepsilon)$ converges to w^* in $C^2_{\text{c.u.}}(\tilde{I}_\#)$-sense as $\varepsilon\downarrow 0$.

In view of (8) and (10) in Appendix 1, $U_{\pm}^{\varepsilon,\sigma} = (u_{\pm}(x;\, \varepsilon, \sigma), v_{\pm}(x;\, \varepsilon, \sigma))$ has the form

$$\begin{aligned} u_{\pm}(x;\, \varepsilon, \sigma) &= h_{\pm}(\hat{V}_{\pm}(x;\, \delta, \omega, \sigma)) + z_{\pm}(x;\, \delta, \omega, \varepsilon, \sigma) + r_{\pm}(\varepsilon, \sigma) \\ &\quad + \sigma \frac{d}{dv} h_{\pm}(\hat{V}_{\pm}(x;\, \delta, \omega, \sigma)) \cdot s_{\pm}(\varepsilon, \sigma), \end{aligned} \tag{1.13}$$

$$v_{\pm}(x;\, \varepsilon, \sigma) = v^* + \omega + \sigma\{W_{\pm}(x;\, \delta, \omega, \sigma) + \varepsilon^2 Y_{\pm} + s_{\pm}(\varepsilon, \sigma)\}. \tag{1.14}$$

Since $v_{\pm}(x;\, \varepsilon, \sigma)$ remains uniformly bounded in $C^2(I_{\pm})$ for small ε, it follows from the above remark, Lemma A.2, Remark A.2, Theorem A.1, and (16) in Appendix 1 that

$$\lim_{\varepsilon \downarrow 0} \tilde{v}_{\pm}(y;\, \varepsilon, \sigma) = v^* \quad \text{in } C^2_{\text{c.u.}}(\mathbb{R}^{\pm})\text{-sense.} \tag{1.15}$$

For the u-component, first note that $\lim_{\varepsilon \downarrow 0} \hat{V}_{\pm} = v^*$ in $C^2_{\text{c.u.}}(\mathbb{R}^{\pm})$-sense (see (7) in Appendix 1). Therefore, we have

$$\lim_{\varepsilon \downarrow 0} h_{\pm}(\hat{V}_{\pm}) = h_{\pm}(v^*) \quad \text{in } C^2_{\text{c.u.}}(\mathbb{R}^{\pm})\text{-sense.} \tag{1.16}$$

On the other hand, it follows from the definition of $z_{\pm}$ (see § A.2 in Appendix 1) and the continuous dependence of solutions on initial data and parameters on any fixed compact interval that

$$\lim_{\varepsilon \downarrow 0} \tilde{z}_{\pm} = \tilde{z}_{\pm}^* \quad \text{in } C^2_{\text{c.u.}}\ (\mathbb{R}^{\pm})\text{-sense,} \tag{1.17}$$

where $\tilde{z}_{\pm}^*$ is the unique solution of

$$\begin{gathered} \frac{d^2}{dy^2} \tilde{z}_{\pm}^* + f(h_{\pm}(v^*) + \tilde{z}_{\pm}^*, v^*) = 0, \\ \tilde{z}_{\pm}^*(0) = h_0(v^*) - h_{\pm}(v^*), \\ \tilde{z}_{+}^*(+\infty) = 0 \quad \text{or} \quad \tilde{z}_{-}^*(-\infty) = 0. \end{gathered} \tag{1.18}$$

Using the above results and Theorem A.1 in Appendix 1 and recalling that $\tilde{u}_{-}(y;\, \varepsilon, \sigma)$ and $\tilde{u}_{+}(y;\, \varepsilon, \sigma)$ are matched in C^2-sense at $y = 0$, we can see that

$$\lim_{\varepsilon \downarrow 0} \tilde{u}(y;\, \varepsilon, \sigma) = \tilde{u}^*(y) \quad \text{in } C^2_{\text{c.u.}}(\mathbb{R})\text{-sense.} \tag{1.19}$$

Since all the above convergence results have a uniformity with respect to σ, the convergence (1.12) is uniform for $0 \leqq \sigma < \sigma_0$, which completes the proof of Lemma 1.1.

Remark 1.3. Differentiating (1.11a) with respect to y, we see that $(d/dy)\tilde{u}^*(y)$ is a constant multiple of the positive normalized principal eigenfunction ϕ_0^* of the Sturm–Liouville operator $(d^2/dy^2) + f_u(\tilde{u}^*(y), v^*)$ on $\mathbb{R}$. Therefore, it follows from Lemma 1.1 that

$$\frac{d}{dy} \tilde{u}(y;\, \varepsilon, \sigma) \xrightarrow[\varepsilon \downarrow 0]{} \kappa^{*^{-1}} \hat{\phi}_0^* \left(= \frac{d}{dy} \tilde{u}^*(y) \right) \tag{1.20}$$

compact uniformly in C^2-sense, where $\kappa^{*^{-1}} = \|(d/dy)\tilde{u}^*(y)\|_{L^2(\mathbb{R})}$.

COROLLARY 1.1. *Let $F(u, v)$ be a smooth function of u and v. Then, the composite function $F(\tilde{u}(y;\, \varepsilon, \sigma), \tilde{v}(y;\, \varepsilon, \sigma))$ converges to $F(\tilde{u}^*, v^*)$ compact uniformly in C^2-sense.*

In view of the construction of $U^{\varepsilon,\sigma}$ and the properties of $z_{\pm}$, we have the following.

COROLLARY 1.2. *For any $\gamma > 0$, there exists $M > 0$ such that*

$$|\tilde{U}^{\varepsilon,\sigma}(y;\, \varepsilon, \sigma) - \tilde{U}^{*,\sigma}| < \gamma \quad \textit{for } |y| > M \textit{ and all small } \varepsilon,$$

where $\tilde{U}^{*,\sigma}$ is the stretched function of the reduced solution, i.e., $\tilde{U}^{*,\sigma} = U^{*,\sigma}(x_1(\varepsilon, \sigma) + \varepsilon y)$.

Let us introduce the following Sturm-Liouville problem at $U^{\varepsilon,\sigma}$,

$$\text{(SL)}\qquad \begin{aligned} &L^{\varepsilon,\sigma}\phi \overset{\text{def}}{=} \left(\varepsilon^2\frac{d^2}{dx^2}+f_u^{\varepsilon,\sigma}\right)\phi=\zeta\phi \quad \text{in } I,\\ &\phi_x=0 \quad \text{on } \partial I,\end{aligned}$$

where $f_u^{\varepsilon,\sigma}=f_u(u(x;\,\varepsilon,\sigma),\ v(x;\,\varepsilon,\sigma))$ (see Fig. 7(a)). Let $\{\phi_n^{\varepsilon,\sigma}\}_{n\geqq 0}$ be the complete orthonormal set (CONS), and $\{\zeta_n^{\varepsilon,\sigma}\}_{n\geqq 0}$ the associated eigenvalues of (SL), which are all real and simple. It is convenient to define the stretched Sturm-Liouville problem for (SL):

$$(\widetilde{\text{SL}})\qquad \begin{aligned} &\tilde{L}^{\varepsilon,\sigma}\hat{\phi} \overset{\text{def}}{=} \left(\frac{d^2}{dy^2}+\tilde{f}_u^{\varepsilon,\sigma}\right)\hat{\phi}=\zeta\hat{\phi} \quad \text{in } \tilde{I},\\ &\hat{\phi}_y=0 \quad \text{on } \partial\tilde{I},\end{aligned}$$

where $\tilde{f}_u^{\varepsilon,\sigma}$ is the stretched potential of $f_u^{\varepsilon,\sigma}$ (see Fig. 7(b)). Similarly as above, let $\{\hat{\phi}_n^{\varepsilon,\sigma}\}_{n\geqq 0}$ be the CONS and $\{\zeta_n^{\varepsilon,\sigma}\}_{n\geqq 0}$ the associated real simple eigenvalues of $(\widetilde{\text{SL}})$. Note that the set of eigenvalues $\{\zeta_n^{\varepsilon,\sigma}\}_{n\geqq 0}$ remain the same after stretching. On the other hand, we need $\sqrt{\varepsilon}$-factor for the eigenfunctions

$$(1.21)\qquad \hat{\phi}_n^{\varepsilon,\sigma}=\sqrt{\varepsilon}\,\tilde{\phi}_n^{\varepsilon,\sigma},$$

where $\tilde{\phi}_n^{\varepsilon,\sigma}$ is the stretched function of $\phi_n^{\varepsilon,\sigma}$, i.e.,

$$\tilde{\phi}_n^{\varepsilon,\sigma}(y)=\phi_n^{\varepsilon,\sigma}(x_1(\varepsilon,\sigma)+\varepsilon y).$$

The relation (1.21) comes from the normalization

$$\int_I(\phi_n^{\varepsilon,\sigma})^2\,dx=1=\int_{\tilde{I}}(\sqrt{\varepsilon}\,\tilde{\phi}_n^{\varepsilon,\sigma})^2\,dy.$$

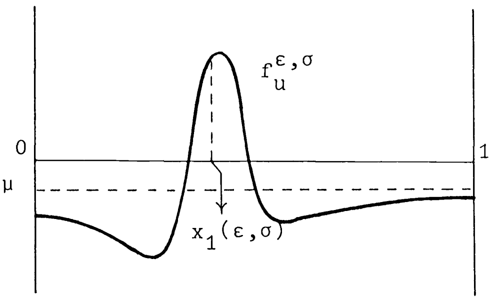

FIG. 7(a). *Functional form of the potential* $f_u^{\varepsilon,\sigma}$.

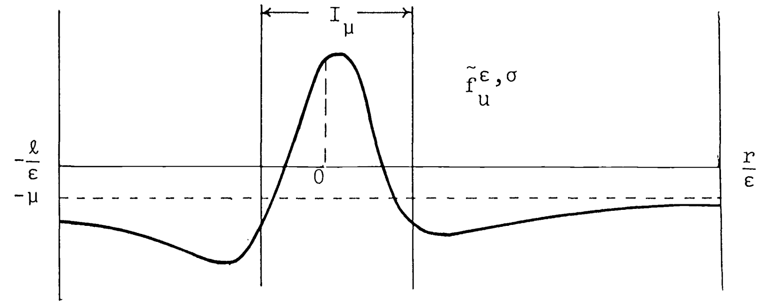

FIG. 7(b). *The stretched potential* $\tilde{f}_u^{\varepsilon,\sigma}$.

Motivated by

$$\tilde{f}_u^{\varepsilon,\sigma} \underset{\varepsilon\downarrow 0}{\longrightarrow} \tilde{f}_u^* \quad \text{in } C^2_{\text{c.u.}}\text{-sense,}$$

which follows from Corollary 1.1, where $\tilde{f}_u^* = f_u(\tilde{u}^*, v^*)$, we introduce a Sturm-Liouville problem on $\mathbb{R}$:

$$\text{(SL)}^* \qquad \tilde{L}^*\hat{\phi} = \left(\frac{d^2}{dy^2} + \tilde{f}_u^*\right)\hat{\phi} = \zeta\hat{\phi} \quad \text{in } \mathbb{R},$$

which is a natural limiting problem of $(\widetilde{\text{SL}})$ as $\varepsilon \downarrow 0$. In view of (A.3) and Lemma A.3 in Appendix 1, we see that the potential $\tilde{f}_u^*$ approaches to negative constants $f_u(h_\pm(v^*), v^*)$ as $y \to \pm\infty$ in the following way (see Fig. 7(c));

$$(1.22) \qquad |f_u(\tilde{u}^*(y), v^*) - f_u(h_\pm(v^*), v^*)| \leqq C \exp(-\gamma|y|), \qquad y \to \pm\infty,$$

where C and γ are positive constants.

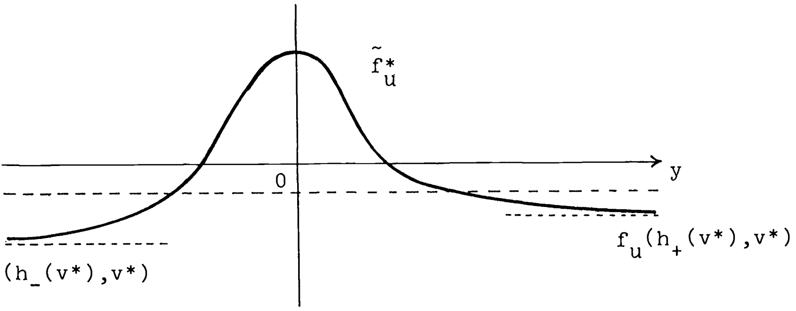

FIG. 7(c). *Limiting form $\tilde{f}_u^*$ of the stretched potential.*

The following observation for $(\text{SL})^*$ is useful.

LEMMA 1.2. *The value 0 is the principal eigenvalue of* $(\text{SL})^*$, *which is simple in* $L^2(\mathbb{R})$, *and the associated normalized positive eigenfunction $\hat{\phi}_0^*$ is given by*

$$\hat{\phi}_0^* = \kappa^* \frac{d}{dy}\tilde{u}^*$$

with

$$\kappa^* = \left\| \frac{d}{dy}\tilde{u}^* \right\|^{-1}_{L^2(\mathbb{R})}.$$

Proof. Noting that the potential $\tilde{f}_u^*$ of $(\text{SL})^*$ is of well-type, which satisfies (1.22), this lemma is a direct consequence of Remark 1.3 and the fact that $(\text{SL})^*$ is of limit point type (see Coddington and Levinson [2, Chap. 9]).

The principal eigenfunction $\hat{\phi}_0^{\varepsilon,\sigma}$ of $(\widetilde{\text{SL}})$ converges to that of $(\text{SL})^*$ in the following sense.

LEMMA 1.3. *It follows that*

$$\hat{\phi}_0^{\varepsilon,\sigma}(=\sqrt{\varepsilon}\tilde{\phi}_0^{\varepsilon,\sigma}) \underset{\varepsilon\downarrow 0}{\longrightarrow} \hat{\phi}_0^* \quad \textit{in } C^2_{\text{c.u.}}(\mathbb{R})\textit{-sense,}$$

$\hat{\phi}_0^{\varepsilon,\sigma}(\hat{\phi}_0^*)$ *is the normalized positive principal eigenfunction of* $(\widetilde{\text{SL}})$ $((\text{SL})^*)$, *respectively. This convergence is uniform for* $0 \leqq \sigma < \sigma_0$.

Proof. First, since $\tilde{u}^*$ approaches to $h_+(v^*)$ (or, $h_-(v^*)$) with an exponential order as $y \to +\infty$ (or, $-\infty$) (Lemma A.3 in Appendix 1), $\tilde{f}_u^{\varepsilon,\sigma}$ converges to $\tilde{f}_u^* = f_u(\tilde{u}^*, v^*)$ in $C^2_{\text{c.u.}}$-sense from Corollary 1.1. Second, from Corollary 1.2 and (A.3),

$$(1.23) \qquad \tilde{f}_u^{\varepsilon,\sigma} < -\mu < 0$$

holds uniformly for $(\varepsilon, \sigma) \in \Omega_{\varepsilon_0,\sigma_0}$ outside of an appropriate fixed finite interval I_μ, μ being independent of ε and σ. Therefore, it is easy to verify that $\{\hat{\phi}_0^{\varepsilon,\sigma}\}_{0<\varepsilon<\varepsilon_0}(\|\hat{\phi}_0^{\varepsilon,\sigma}\|_{L^2(\tilde{I})} = 1)$ is uniformly bounded, with the decaying estimate

$$\hat{\phi}_0^{\varepsilon,\sigma}(y) \leqq \hat{C} \exp(-\hat{\gamma}|y|) \quad \text{for } y \in \tilde{I} \backslash I_\mu, \tag{1.24}$$

where $\hat{C}$ and $\hat{\gamma}$ are positive constants which do not depend on (ε, σ). Let K be an arbitrary compact interval. Then, using the above fact, and that $\hat{\phi}_0^{\varepsilon,\sigma}$ is a solution of $(\widetilde{\mathrm{SL}})$, we can see that $\{\hat{\phi}_0^{\varepsilon,\sigma}\}_{0<\varepsilon<\varepsilon_0}$ forms an Ascoli-Arzela set on K in C^2-sense (i.e., precompact set in C^2-topology on K). Let us choose a subsequence $\{\hat{\phi}_0^{\varepsilon_n,\sigma}\}_{n\geqq 1}$ which constitutes a Cauchy sequence on K in C^2-sense. Using a diagonal argument on an expanding sequence of compact intervals which eventually covers the whole line $\mathbb{R}$, we can select a subsequence $\{\hat{\phi}_0^{\varepsilon_n,\sigma}\}_{n\geqq 1}$ (we use the same symbol as before) which converges uniformly on any compact interval. Namely, it forms a convergent sequence on $\mathbb{R}$ in $C^2_{\text{c.u.}}$-topology. Let us denote this limit by Φ^*. Let $\{\zeta_0^{\varepsilon_n,\sigma}\}$ be the set of corresponding eigenvalues. We can then assume without loss of generality that $\zeta_0^{\varepsilon_n,\sigma} \to \zeta^*$ as $n \to +\infty$, since it must be in the bounded interval

$$\left[\min_{y\in\bar{I},(\varepsilon,\sigma)\in\Omega_{\varepsilon_0,\sigma_0}} f_u^{\varepsilon,\sigma}, \max_{\text{the same region}} f_u^{\varepsilon,\sigma}\right].$$

Consequently, Φ^* satisfies

$$\begin{gathered} \frac{d^2}{dy^2}\Phi^* + \tilde{f}_u^*\Phi^* = \zeta^*\Phi^*, \\ \Phi^* > 0, \qquad \|\Phi^*\|_{L^2(\mathbb{R})} = 1. \end{gathered} \tag{1.25}$$

The strict positivity comes from $\hat{\phi}_0^{\varepsilon,\sigma} > 0$ and that Φ^* satisfies the above equation. On the other hand, 0 is the principal eigenvalue of (SL)* from Lemma 1.2, and the associated normalized positive eigenfunction is given by $\hat{\phi}_0^*(= \kappa^*(d/dy)\tilde{u}^*)$. By virtue of the uniqueness of the normalized positive principal eigenfunction and the orthogonal property of eigenfunctions, we can conclude that $\Phi^* = \hat{\phi}_0^*$ and $\zeta^* = 0$. Thus, the limit Φ^* does not depend on the choice of subsequences. Hence, $\hat{\phi}_0^{\varepsilon,\sigma}$ itself converges to $\hat{\phi}_0^*$ in $C^2_{\text{c.u.}}$-sense. The uniformity with respect to σ is easily shown by contradiction with the aid of the uniqueness of $\hat{\phi}_0^*$.

COROLLARY 1.3.

$$\int_I \phi_0^{\varepsilon,\sigma}\, dx = L(\varepsilon, \sigma)\sqrt{\varepsilon},$$

where $L(\varepsilon, \sigma)$ *is a positive continuous function of* $(\varepsilon, \sigma) \in \bar{\Omega}_{\varepsilon_0\sigma_0}$. *Moreover,*

$$L^* \overset{\text{def}}{=} L(0, \sigma) = \kappa^*(h_+(v^*) - h_-(v^*)) > 0. \tag{1.26}$$

Note that the limit L^* *is independent of* σ.

Proof. Using a stretched variable $y = (x - x_1(\varepsilon, \sigma))/\varepsilon$, the integral is rewritten as

$$\int_I \phi_0^{\varepsilon,\sigma}\, dx = \sqrt{\varepsilon} \int_{\tilde{I}} \sqrt{\varepsilon}\tilde{\phi}_0^{\varepsilon,\sigma}\, dy.$$

Define $L(\varepsilon, \sigma)$ by

$$L(\varepsilon, \sigma) = \int_{\tilde{I}} \sqrt{\varepsilon}\tilde{\phi}_0^{\varepsilon,\sigma}\, dy. \tag{1.27}$$

It is clear from the smooth parametric dependency of SPS1 $U^{\varepsilon,\sigma}$ in $\Omega_{\varepsilon_0,\sigma_0}$ that $L(\varepsilon,\sigma)$ is a continuous function in $\Omega_{\varepsilon_0,\sigma_0}$. It follows from Lemmas 1.2 and 1.3 and (1.24) that

$$\begin{aligned}\lim_{\varepsilon\downarrow 0} L(\varepsilon,\sigma) &= \int_{\mathbb{R}} \hat{\phi}_0^* \, dy \\ &= \kappa^* \int_{\mathbb{R}} \frac{d}{dy}\tilde{u}^* \, dy \\ &= \kappa^*(h_+(v^*) - h_-(v^*)) \quad \text{uniformly for } 0 \leqq \sigma < \sigma_0.\end{aligned}$$

Note that the right-hand side does not depend on σ. Consequently, we see that $L(\varepsilon,\sigma)$ is uniquely extended to be a continuous function on $\bar{\Omega}_{\varepsilon_0,\sigma_0}$ with the limit condition (1.26).

Remark 1.4. Let $\phi_{0,\alpha}^{\varepsilon,\sigma}$ be the normalized positive principal eigenfunction of

$$(\mathrm{SL})_\alpha \qquad \begin{aligned} &L^{\varepsilon,\sigma} = \left(\varepsilon^2 \frac{d^2}{dx^2} + f_u^{\varepsilon,\sigma}\right)\phi = \zeta\phi \quad \text{in } I, \\ &\alpha_i \frac{\partial u}{\partial n} + (1-\alpha_i)u = 0 \quad \text{at } x = i \ (i=0,1), \end{aligned}$$

where $0 \leqq \alpha_i \leqq 1$ $(i=0,1)$ and $\partial/\partial n$ denotes the outer normal derivative at the boundary point. Then, Lemma 1.3 and Corollary 1.3 also hold for $\phi_{0,\alpha}^{\varepsilon,\sigma}$ without any change. In particular, one can take Dirichlet boundary conditions at both ends or Dirichlet boundary condition at one end and Neumann boundary condition on the other end.

LEMMA 1.4. *Let* $\{\zeta_n^{\varepsilon,\sigma}\}_{n\geqq 0}$ *be the complete set of real simple eigenvalues of* (SL). *Then, it holds that for* $(\varepsilon,\sigma) \in \Omega_{\varepsilon_0,\sigma_0}$ *(see Fig.* 8),

$$(1.28) \qquad \begin{aligned} &\zeta_0^{\varepsilon,\sigma} > 0 > \zeta_1^{\varepsilon,\sigma} > \cdots > \zeta_n^{\varepsilon,\sigma} > \cdots, \\ &\zeta_0^{\varepsilon,\sigma} = \hat{\zeta}_0(\varepsilon,\sigma)\varepsilon\sigma + \mathrm{Exp}(\varepsilon,\sigma), \end{aligned}$$

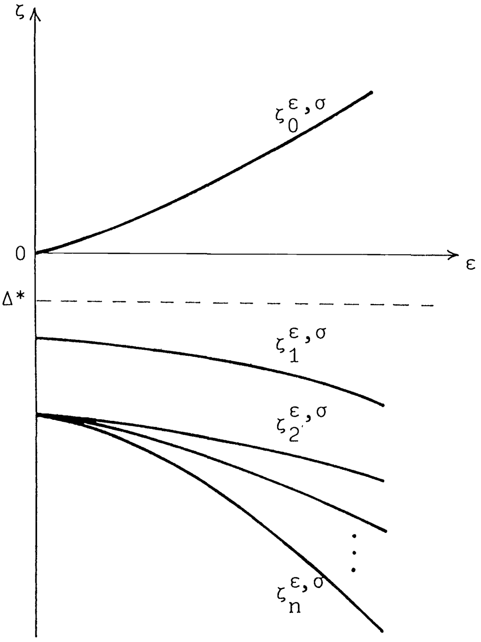

FIG. 8. *Asymptotic behaviors of the eigenvalues of* (SL).

and

$$\zeta_1^{\varepsilon,\sigma} < -\Delta^* < 0, \tag{1.29}$$

where $\hat{\zeta}_0(\varepsilon, \sigma)$ *is a positive continuous function in* $\Omega_{\varepsilon_0,\sigma_0}$ *uniquely extendable to* $\varepsilon = 0$ *as*

$$\hat{\zeta}_0^{*,0} \overset{\text{def}}{=} \lim_{\varepsilon \downarrow 0} \hat{\zeta}_0(\varepsilon, \sigma) = (\kappa^*)^2 \frac{dJ}{dv}(v^*) \int_0^{x_1^*(\sigma)} g(U^{*,\sigma}, V^{*,\sigma})\, dx, \tag{1.30}$$

and Exp *is a continuous function of* $(\varepsilon, \sigma) \in \Omega_{\varepsilon_0,\sigma_0}$ *satisfying*

$$|\text{Exp}\,(\varepsilon, \sigma)| \leqq C \exp(-\gamma/\varepsilon). \tag{1.31}$$

Here, Δ^*, C, *and* γ *are positive constants independent of* $(\varepsilon, \sigma) \in \Omega_{\varepsilon_0,\sigma_0}$.

Proof. For simplicity, we use the symbols $u^{\varepsilon,\sigma}$, $\tilde{u}^{\varepsilon,\sigma}$ and $\tilde{u}_y^{\varepsilon,\sigma}$ instead of $u(x; \varepsilon, \sigma)$, $\tilde{u}(y; \varepsilon, \sigma)$, and $(d/dy)\tilde{u}(y; \varepsilon, \sigma)$ in the following proof.

First we show the asymptotic formula (1.28). The principal eigenfunction $\hat{\phi}_0^{\varepsilon,\sigma}$ of $(\widetilde{\text{SL}})$ satisfies

$$\frac{d^2}{dy^2}\hat{\phi}_0^{\varepsilon,\sigma} + \tilde{f}_u^{\varepsilon,\sigma}\hat{\phi}_0^{\varepsilon,\sigma} = \zeta_0^{\varepsilon,\sigma}\hat{\phi}_0^{\varepsilon,\sigma}. \tag{1.32}$$

The stretched equations for (SP) becomes

$$(\widetilde{\text{SP}}) \qquad \frac{d^2}{dy^2}\tilde{u}^{\varepsilon,\sigma} + f(\tilde{u}^{\varepsilon,\sigma}, \tilde{v}^{\varepsilon,\sigma}) = 0, \qquad \frac{1}{\sigma}\frac{d^2}{dy^2}\tilde{v}^{\varepsilon,\sigma} + \varepsilon^2 g(\tilde{u}^{\varepsilon,\sigma}, \tilde{v}^{\varepsilon,\sigma}) = 0.$$

Differentiating the first equation of $(\widetilde{\text{SP}})$ with respect to y, we obtain

$$\frac{d^2}{dy^2}\tilde{u}_y^{\varepsilon,\sigma} = \tilde{f}_u^{\varepsilon,\sigma}\tilde{u}_y^{\varepsilon,\sigma} = -\tilde{f}_v^{\varepsilon,\sigma}\tilde{v}_y^{\varepsilon,\sigma}. \tag{1.33}$$

Multiplying $\tilde{u}_y^{\varepsilon,\sigma}$ to (1.32), we have

$$\left\langle \frac{d^2}{dy^2}\hat{\phi}_0^{\varepsilon,\sigma}, \tilde{u}_y^{\varepsilon,\sigma} \right\rangle + \langle \tilde{f}_u^{\varepsilon,\sigma}\hat{\phi}_0^{\varepsilon,\sigma}, \tilde{u}_y^{\varepsilon,\sigma} \rangle = \zeta_0^{\varepsilon,\sigma}\langle \hat{\phi}_0^{\varepsilon,\sigma}, \tilde{u}_y^{\varepsilon,\sigma} \rangle.$$

Applying the integration by parts twice, and using $(\widetilde{\text{SP}})$ and (1.33), we have

$$\hat{\phi}_0^{\varepsilon,\sigma} f(\tilde{u}^{\varepsilon,\sigma}, \tilde{v}^{\varepsilon,\sigma})|_{-l/\varepsilon}^{r/\varepsilon} + \langle \hat{\phi}_0^{\varepsilon,\sigma}, -\tilde{f}_v^{\varepsilon,\sigma}\tilde{v}_y^{\varepsilon,\sigma} \rangle = \zeta_0^{\varepsilon,\sigma}\langle \hat{\phi}_0^{\varepsilon,\sigma}, \tilde{u}_y^{\varepsilon,\sigma} \rangle. \tag{1.34}$$

Owing to Remark 1.3, Lemma 1.3, and (1.24), we see that

$$\langle \hat{\phi}_0^{\varepsilon,\sigma}, \tilde{u}_y^{\varepsilon,\sigma} \rangle \xrightarrow[\varepsilon \downarrow 0]{} \kappa^{*^{-1}}\langle \hat{\phi}_0^*, \hat{\phi}_0^* \rangle = \kappa^{*^{-1}} \tag{1.35}$$

holds uniformly for $0 \leqq \sigma < \sigma_0$. This implies $\langle \hat{\phi}_0^{\varepsilon,\sigma}, \tilde{u}_y^{\varepsilon,\sigma} \rangle$ is positive and uniformly bounded away from zero for $(\varepsilon, \sigma) \in \Omega_{\varepsilon_0,\sigma_0}$. Integrating the second equation of $(\widetilde{\text{SP}})$, we have

$$\tilde{v}_y^{\varepsilon,\sigma}(y) = \left(-\varepsilon \int_{-l/\varepsilon}^{y} g(\tilde{u}^{\varepsilon,\sigma}, \tilde{v}^{\varepsilon,\sigma})\, dy\right)\varepsilon\sigma \overset{\text{def}}{=} \tilde{\Theta}(y; \varepsilon, \sigma)\varepsilon\sigma. \tag{1.36}$$

Substituting (1.36) into (1.34), we obtain the following

$$\zeta_0^{\varepsilon,\sigma} = \hat{\zeta}_0(\varepsilon, \sigma)\varepsilon\sigma + \text{Exp}\,(\varepsilon, \sigma),$$

where

$$\hat{\zeta}_0(\varepsilon, \sigma) \overset{\text{def}}{=} \left\langle \hat{\phi}_0^{\varepsilon,\sigma}, -\tilde{f}_v^{\varepsilon,\sigma}\left(-\varepsilon \int_{-l/\varepsilon}^{y} g(\tilde{u}^{\varepsilon,\sigma}, \tilde{v}^{\varepsilon,\sigma})\, dy\right)\right\rangle \Big/ P(\varepsilon, \sigma), \tag{1.37}$$

$$\text{Exp}\,(\varepsilon, \sigma) \overset{\text{def}}{=} [\hat{\phi}_0^{\varepsilon,\sigma} f(\tilde{u}^{\varepsilon,\sigma}, \tilde{v}^{\varepsilon,\sigma})]|_{l/\varepsilon}^{r/\varepsilon} / P(\varepsilon, \sigma) \tag{1.38}$$

and

$$P(\varepsilon, \sigma) = \langle \hat{\phi}_0^{\varepsilon,\sigma}, \tilde{u}_y^{\varepsilon,\sigma} \rangle. \tag{1.39}$$

It is easily seen from Theorem 1.1, (A.0) and the continuous dependence of solutions on coefficients that $\hat{\zeta}_0(\varepsilon, \sigma)$ and Exp (ε, σ) are continuous functions of $(\varepsilon, \sigma) \in \Omega_{\varepsilon_0, \sigma_0}$. In view of the definition (1.38), the estimate (1.31) easily follows from (1.24) and (1.35). In order to study the behavior of $\hat{\zeta}_0(\varepsilon, \sigma)$, we first consider the term $\tilde{\Theta}(y; \varepsilon, \sigma)$. It is apparent from the definition (1.36) that $\tilde{\Theta}(y; \varepsilon, \sigma)$ is the stretched function of

$$\Theta(x; \varepsilon, \sigma) \overset{\text{def}}{=} -\int_0^x g(u^{\varepsilon,\sigma}, v^{\varepsilon,\sigma})\, dx$$

by using $y = (x - x_1(\varepsilon, \sigma))/\varepsilon$. $\Theta(x; \varepsilon, \sigma)$ is uniformly bounded in $C^1(I)$-sense for $(\varepsilon, \sigma) \in \Omega_{\varepsilon_0, \sigma_0}$, and converges to the following value as $\varepsilon \downarrow 0$ at $x = x_1(\varepsilon, \sigma)$,

$$\Theta(x_1(\varepsilon, \sigma); \varepsilon, \sigma) \xrightarrow[\varepsilon \downarrow 0]{} -\int_0^{x_1^*(\sigma)} g(U^{*,\sigma}, V^{*,\sigma})\, dx.$$

Consequently, we can see that the stretched function $\tilde{\Theta}(y; \varepsilon, \sigma)$ satisfies

$$\tilde{\Theta}(y; \varepsilon, \sigma) \xrightarrow[\varepsilon \downarrow 0]{} -\int_0^{x_1^*(\sigma)} g(U^{*,\sigma}, V^{*,\sigma})\, dx, \tag{1.40}$$

compact uniformly in C^1-sense. On the other hand, it follows from Corollary 1.1, Lemma 1.3 and (1.24) that

$$\begin{aligned} \lim_{\varepsilon \downarrow 0} \langle \hat{\phi}_0^{\varepsilon,\sigma}, -\tilde{f}_v^{\varepsilon,\sigma} \rangle &= -\kappa^* \int_{-\infty}^{\infty} \tilde{f}_v^* \tilde{u}_y^*\, dy \\ &= -\kappa^* \int_{h_-(v^*)}^{h_+(v^*)} \tilde{f}_v^*\, d\tilde{u}^* \\ &= -\kappa^* \frac{dJ}{dv}(v^*) > 0 \quad (\text{see (A.2)}). \end{aligned} \tag{1.41}$$

Thus, combining the above results (1.35), (1.40), (1.41), and recalling (1.24) again, we can see that

$$\hat{\zeta}_0^{*,\sigma} \overset{\text{def}}{=} \lim_{\varepsilon \downarrow 0} \hat{\zeta}_0(\varepsilon, \sigma) = (\kappa^*)^2 \frac{dJ}{dv}(v^*) \int_0^{x_1^*(\sigma)} g(U^{*,\sigma}, V^{*,\sigma})\, dx. \tag{1.30}$$

Since $x_1^*(\sigma)$ is a continuous function of σ (see Proposition 1.2), so is $\hat{\zeta}_0^{*,\sigma}$. Here, it holds from (A.2) and (A.3) that

$$\hat{\zeta}_0^{*,\sigma} > 0 \quad \text{for } 0 \leqq \sigma < \sigma_0. \tag{1.42}$$

Since the convergence (1.30) is uniform for $0 \leqq \sigma < \sigma_0$, we can conclude from (1.42) that $\hat{\zeta}_0(\varepsilon, \sigma)$ is uniquely extendable to be a strictly positive continuous function on $\bar{\Omega}_{\varepsilon_0, \sigma_0}$.

Finally, we shall show (1.29), namely, $\zeta_1^{\varepsilon,\sigma}$ is bounded away from zero and strictly negative for small ε. As we have seen in (1.23),

$$\tilde{f}_u^{\varepsilon,\sigma} < -\mu < 0, \tag{1.43}$$

holds outside of a fixed finite interval I_μ, where μ and I_μ do not depend on $(\varepsilon, \sigma) \in \Omega_{\varepsilon_0, \sigma_0}$. Therefore, we can assume without loss of generality that

$$\tilde{f}_u^{\varepsilon,\sigma} - \zeta_1^{\varepsilon,\sigma} < -\hat{\mu} < 0 \tag{1.44}$$

holds outside of a fixed finite interval $I_{\hat{\mu}}$, where $\hat{\mu}$ and $I_{\hat{\mu}}$ do not depend on

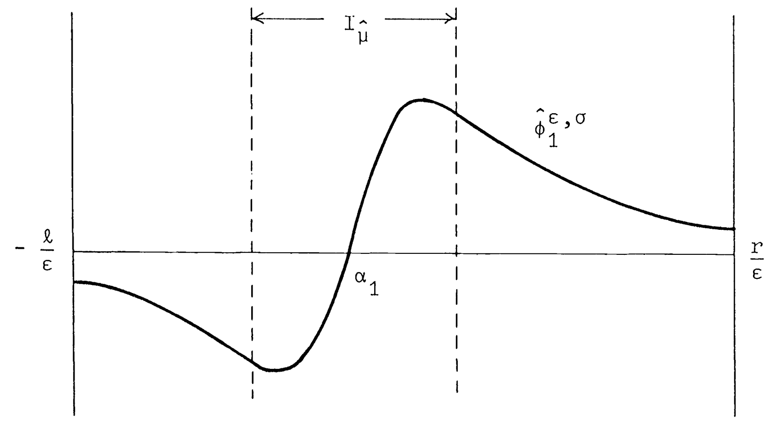

FIG. 9. *Functional form of* $\hat\phi_1^{\varepsilon,\sigma}$.

$(\varepsilon,\sigma)\in\Omega_{\varepsilon_0,\sigma_0}$; otherwise $\zeta_1^{\varepsilon,\sigma}$ already satisfies (1.29). From the nodal property, the associated eigenfunction $\hat\phi_1^{\varepsilon,\sigma}$ has only one zero. This zero, denoted by α_1, is located inside of $I_{\hat\mu}$, since $\hat\phi_1^{\varepsilon,\sigma}$and its y-derivative behave, without changing signs, monotonically in the region where $\hat f_u^{\varepsilon,\sigma}-\zeta_1^{\varepsilon,\sigma}<-\hat\mu<0$. See Fig. 9.

Then, we may assume that in $(\alpha_1, r/\varepsilon]$, $\hat\phi_1^{\varepsilon,\sigma}>0$. $\hat\phi_1^{\varepsilon,\sigma}$ satisfies the equation

$$\frac{d^2}{dy^2}\hat\phi_1^{\varepsilon,\sigma}+\tilde f_u^{\varepsilon,\sigma}\hat\phi_1^{\varepsilon,\sigma}=\zeta_1^{\varepsilon,\sigma}\hat\phi_1^{\varepsilon,\sigma}. \tag{1.45}$$

By using (1.44) and (1.45), we see that $\hat\phi_1^{\varepsilon,\sigma}$ satisfies the same type of estimate as (1.24). Making $(1.32)\times\hat\phi_1^{\varepsilon,\sigma}-(1.46)\times\hat\phi_0^{\varepsilon,\sigma}$ and integrating over $(\alpha_1, r/\varepsilon)$, we have

$$\left(\frac{d}{dy}\hat\phi_0^{\varepsilon,\sigma}\right)\hat\phi_1^{\varepsilon,\sigma}\Big|_{\alpha_1}^{r/\varepsilon}-\left(\frac{d}{dy}\hat\phi_1^{\varepsilon,\sigma}\right)\hat\phi_0^{\varepsilon,\sigma}\Big|_{\alpha_1}^{r/\varepsilon}=(\zeta_0^{\varepsilon,\sigma}-\zeta_1^{\varepsilon,\sigma})\int_{\alpha_1}^{r/\varepsilon}\hat\phi_0^{\varepsilon,\sigma}\hat\phi_1^{\varepsilon,\sigma}\,dy. \tag{1.46}$$

Noting that $\hat\phi_1^{\varepsilon,\sigma}(\alpha_1)=0$ and the exponentially decaying property of eigenfunction in the outer region, (1.46) becomes

$$\left(\frac{d}{dy}\hat\phi_1^{\varepsilon,\sigma}\right)(\alpha_1)\cdot\hat\phi_0^{\varepsilon,\sigma}(\alpha_1)+O\{\exp(-\bar\gamma/\varepsilon)\}=(\zeta_0^{\varepsilon,\sigma}-\zeta_1^{\varepsilon,\sigma})\int_{\alpha_1}^{r/\varepsilon}\hat\phi_0^{\varepsilon,\sigma}\hat\phi_1^{\varepsilon,\sigma}\,dy, \tag{1.47}$$

where $\bar\gamma$ is a positive constant which does not depend on (ε,σ). Since both $\hat\phi_0^{\varepsilon,\sigma}$ and $\hat\phi_1^{\varepsilon,\sigma}$ are L^2-normalized eigenfunctions on $\tilde I$ and decay monotonically with exponential order outside of $I_{\hat\mu}$, it is easy to verify by contradiction that

$$\left(\frac{d}{dy}\hat\phi_1^{\varepsilon,\sigma}\right)(\alpha_1)\cdot\hat\phi_0^{\varepsilon,\sigma}(\alpha_1)\quad\text{and}\quad\int_{\alpha_1}^{r/\varepsilon}\hat\phi_0^{\varepsilon,\sigma}\hat\phi_1^{\varepsilon,\sigma}\,dy \tag{1.48}$$

are positive and uniformly bounded away from zero for $(\varepsilon,\sigma)\in\Omega_{\varepsilon_0,\sigma_0}$. Consequently, using (1.47) and (1.28), we can conclude (1.29).

Remark 1.5. Lemma 1.4 also holds for $(\mathrm{SL})_\alpha$ without an essential change, since the asymptotic limit $\lim_{\varepsilon\downarrow 0}\hat\phi_{0,\alpha}^{\varepsilon,\sigma}(=\hat\phi_0^*)$ does not depend on α (see Remark 1.4), and the exponentially decaying estimate (1.24) also holds for the L^2-normalized eigenfunctions of the stretched problem $(\widetilde{\mathrm{SL}})_\alpha$. Especially, using the similar identify as (1.46), we can show that the difference of principal eigenvalues $|\zeta_{0,\alpha}^{\varepsilon,\sigma}-\zeta_{0,\alpha'}^{\varepsilon,\sigma}|$ $(0\leqq\alpha,\alpha'\leqq 1)$ is at most of exponentially decaying order. Therefore, the asymptotic limit of the coefficient $\hat\zeta_{0,\alpha}(\varepsilon,\sigma)$ of $\varepsilon\sigma$ (see (1.28)) does not depend on α, namely,

$$\lim_{\varepsilon\downarrow 0}\hat\zeta_{0,\alpha}(\varepsilon,\sigma)=\hat\zeta_0^*(\sigma). \tag{1.49}$$

2. Singular limit eigenvalue problem and the behavior of critical eigenvalues. In order to obtain the stability of SPS1, we have to show the following:

(P2)$_a$ All noncritical eigenvalue of (LP) have strictly negative real parts.

(P2)$_b$ If there is a critical eigenvalues of (LP), it has to approach to zero from the left-half plane ($\mathrm{Re}\,\lambda < 0$) as $\varepsilon \downarrow 0$.

Note that when $\varepsilon \downarrow 0$, (LP) becomes singular in two ways, namely, the degeneracy of the second-order term due to ε, and the discontinuity of coefficients $f_u^{\varepsilon,\sigma}$, $f_v^{\varepsilon,\sigma}$, $g_u^{\varepsilon,\sigma}$ and $g_v^{\varepsilon,\sigma}$ at the layer position.

A natural and standard approach to deal with the above problems may be to look for an appropriate limit problem of (LP) as $\varepsilon \downarrow 0$, and then extract from it information on the spectral behavior for $\varepsilon > 0$. In fact, the most optimistic way may be to put $\varepsilon = 0$ in (LP) to have

$$\text{(REP)} \qquad f_u^{*,\sigma} w + f_v^{*,\sigma} z = \lambda w, \qquad \frac{1}{\sigma} z_{xx} + g_u^{*,\sigma} w + g_v^{*,\sigma} z = \lambda z,$$

subject to zero flux boundary conditions for z, where all the partial derivatives are evaluated at the reduced solution (1.2), i.e., $f_u^{*,\sigma} = f_u(U^{*,\sigma}(x), V^{*,\sigma}(x))$ and so on. This is called the *reduced eigenvalue problem* (REP) of (LP), since it is formally obtained by linearizing (RP) in § 1. Since $f_u^{*,\sigma} < 0$ (see (A.3)), we can solve the first equation of (REP) as $w = -f_v^{*,\sigma} z/(f_u^{*,\sigma} - \lambda)$, assuming that $\mathrm{Re}\,\lambda > -\mu$ (see (1.23)). Substituting this into the second equation of (REP), we obtain after some computation

$$\text{(2.1)} \qquad \frac{1}{\sigma} z_{xx} + \frac{\det^{*,\sigma}}{f_u^{*,\sigma} - \lambda} z = \lambda \left(1 + \frac{g_v^{*,\sigma}}{f_u^{*,\sigma} - \lambda} \right) z,$$

where $\det^{*,\sigma} = f_u^{*,\sigma} g_v^{*,\sigma} - f_v^{*,\sigma} g_u^{*,\sigma}$. Recalling (A.4) and (A.5), we can show as in Proposition 2.1 that there are no spectra of (2.1) in the region $\mathrm{Re}\,\lambda > -\mu^*$ for an appropriate positive number μ^*. Thus, one may think that the stability of SPS1 is obtained in a straightforward way from (REP). However, if we look at (REP) carefully, we realize that it includes no terms which come from the interior transition layer. The reason for this is clear. (REP) is the formal L^2-limit of (LP). Therefore, the contribution from the layer part, the width of which is of $O(\varepsilon)$, becomes negligible as $\varepsilon \downarrow 0$. Recalling that not all solutions of (RP) are extended to be solutions of (SP) for $\varepsilon > 0$, (REP) may be inadequate for our purpose in the sense that it is too rough to solve our whole problem. In fact, it loses information on the behavior of critical eigenvalues. Nevertheless, (REP) is useful to solve the first problem (P2)$_a$ (see Proposition 2.1), and Lemma 2.2 plays an important role to justify this step.

Now the problem is that "What is the exact limit of (LP) of $\varepsilon \downarrow 0$?", which inherits necessary information from the layer part, governing the asymptotic behavior of critical eigenvalues. Lemma 2.3 becomes a keystone to answer this question. It shows that when $\varepsilon \downarrow 0$, the information on layer is condensed into *the Dirac's δ-function* at $x = x_1^*(\sigma)$, and its magnitude determines the asymptotic behavior of the critical eigenvalue. Using Lemma 2.3 as well as Lemma 2.2, we obtain a new limiting problem of (LP) in H^{-1}-sense as $\varepsilon \downarrow 0$ called the *singular limit eigenvalue problem* (SLEP), which essentially enables us to solve both problems (PS)$_a$ and (P2)$_b$.SLEP is simple and much more tractable than the original linearized problem (LP). The justification of SLEP as well as the uniqueness and simplicity of the critical eigenvalue will be given in the next section.

First we note the following lemma.

LEMMA 2.1. *It holds that $\zeta_0^{\varepsilon,\sigma} \notin \sigma(\mathrm{LP})$ for small $\varepsilon > 0$, i.e., the principal eigenvalue of $L^{\varepsilon,\sigma}$ in Lemma* 1.4 *never becomes an eigenvalue of* (LP) *for small positive ε, where $\sigma(\mathrm{LP})$ denotes the set of spectra of* (LP).

Proof. See Appendix 2.

Remark 2.1. Though $\zeta_0^{\varepsilon,\sigma} \notin \sigma(\mathrm{LP})$ for small $\varepsilon > 0$, $\lim_{\varepsilon\downarrow 0} \zeta_0^{\varepsilon,\sigma}(=0)$ is contained in the limit set of $\sigma(\mathrm{LP})$ as $\varepsilon \downarrow 0$ (see Lemma 1.4 and Main Theorem).

Now we start to solve (LP). Hereafter, we only consider the spectra of (LP) which lie in the region Λ_1 defined by

$$\text{(2.2)} \qquad \Lambda_1 = \{\lambda \mid \operatorname{Re}\lambda > -\mu_1 > \max\{-\Delta^*, -\mu\}\} \quad \text{for some fixed } \mu_1 > 0,$$

where $-\Delta^*$ and $-\mu$ are the constants which appeared in (1.29) and (1.23), respectively. Apparently, this restriction does not lose any generality. Noting Lemmas 2.1, 1.4 and (2.2), the first equation of (LP) can be solved with respect to w as

$$\text{(2.3)} \qquad w = (L^{\varepsilon,\sigma} - \lambda)^{-1}(-f_v^{\varepsilon,\sigma} z).$$

Applying the eigenfunction expansion to (2.3), we have

$$\text{(2.4)} \qquad w = \frac{\langle -f_v^{\varepsilon,\sigma} z, \phi_0^{\varepsilon,\sigma}\rangle}{\zeta_0^{\varepsilon,\sigma} - \lambda}\phi_0^{\varepsilon,\sigma} + \sum_{n\geqq 1} \frac{\langle -f_v^{\varepsilon,\sigma} z, \phi_n^{\varepsilon,\sigma}\rangle}{\zeta_n^{\varepsilon,\sigma} - \lambda}\phi_n^{\varepsilon,\sigma}.$$

Substituting (2.4) into the second equation of (LP), we obtain the scalar eigenvalue problem for z:

$$\text{(2.5)} \qquad \frac{1}{\sigma} z_{xx} + \frac{\langle -f_v^{\varepsilon,\sigma} z, \phi_0^{\varepsilon,\sigma}\rangle}{\zeta_0^{\varepsilon,\sigma} - \lambda} g_u^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma} + g_u^{\varepsilon,\sigma}(L^{\varepsilon,\sigma} - \lambda)^{\dagger}(-f_v^{\varepsilon,\sigma} z) + g_v^{\varepsilon,\sigma} z = \lambda z,$$

$$z \in H^2(I) \cap H_N^1(I),$$

where $(L^{\varepsilon,\sigma} - \lambda)^{\dagger}$ is defined by

$$\text{(2.6)} \qquad (L^{\varepsilon,\sigma} - \lambda)^{\dagger}(\cdot) = \sum_{n\geqq 1} \frac{\langle \cdot, \phi_n^{\varepsilon,\sigma}\rangle}{\zeta_n^{\varepsilon,\sigma} - \lambda}\phi_n^{\varepsilon,\sigma}, \qquad L^2(I) \to L^2(I) \cap \{\phi_0^{\varepsilon,\sigma}\}^{\perp}.$$

It follows from (1.29) and (2.2) that $\zeta_n^{\varepsilon,\sigma} - \lambda$ $(n \geqq 1)$ is uniformly bounded away from zero. Therefore, in view of the definition (2.6), $(L^{\varepsilon,\sigma} - \lambda)^{\dagger}$ is a uniformly L^2-bounded operator for $(\varepsilon, \sigma) \in \Omega_{\varepsilon_0,\sigma_0}$ and $\lambda \in \Lambda_1$. More precisely, we have the estimate,

$$\text{(2.7)} \qquad \|(L^{\varepsilon,\sigma} - \lambda)^{\dagger}\| \leqq \frac{1}{|\zeta_1^{\varepsilon,\sigma} - \lambda|}.$$

Remark 2.2. It follows from the definition (2.6) that the generalized inverse $(L^{\varepsilon,\sigma} - \lambda)^{\dagger}$ depends analytically on λ for $\lambda \in \Lambda_1$ as an L^2-bounded operator-valued function, and satisfies the resolvent formula

$$(L^{\varepsilon,\sigma} - \lambda_1)^{\dagger} - (L^{\varepsilon,\sigma} - \lambda_2)^{\dagger} = (\lambda_1 - \lambda_2)(L^{\varepsilon,\sigma} - \lambda_1)^{\dagger}(L^{\varepsilon,\sigma} - \lambda_2)^{\dagger}.$$

In order to study the asymptotic behavior of the spectra of (LP), we need explicit characterizations of the asymptotic form of the second and the third terms of (2.5) as $\varepsilon \downarrow 0$.

The first key lemma is about the behavior of the operator $(L^{\varepsilon,\sigma} - \lambda)^{\dagger}$ as $\varepsilon \downarrow 0$.

LEMMA 2.2. (*The first key lemma.*) *Let $F(u, v)$ be a smooth function of u and v. Then,*

$$\text{(2.8)} \qquad (L^{\varepsilon,\sigma} - \lambda)^{\dagger}(F^{\varepsilon,\sigma} h) \xrightarrow[\varepsilon\downarrow 0]{} \frac{F^{*,\sigma} h}{f_u^{*,\sigma} - \lambda} \quad \textit{strongly in } L^2\textit{-sense},$$

for any function $h \in L^2(I) \cap L^\infty(I)$ *and* $\lambda \in \Lambda_1$, *where* $F^{\varepsilon,\sigma} = F(u(x;\varepsilon,\sigma),\ v(x;\varepsilon,\sigma))$ *and* $F^{*,\sigma} = F(U^{*,\sigma}(x),\ V^{*,\sigma}(x))$ (*see* (1.2)). *The convergence* (2.8) *is uniform for* $0 \leqq \sigma < \sigma_0$ *and* $\lambda \in \Lambda_1$. *Furthermore, if h belongs to* $H^1(I)$, *the above convergence is also uniform on a bounded set in* $H^1(I)$.

Proof. Let $s_k^*(x)$ be a smooth cut-off function at $x = x_1^*(\sigma)$ satisfying

$$s_k^*(x) = \begin{cases} 1 & \text{if } |x - x_1^*(\sigma)| \geqq k/2, \\ 0 & \text{if } |x - x_1^*(\sigma)| \leqq k/4 \end{cases}$$

with

$$(2.9) \qquad 0 \leqq s_k^*(x) \leqq 1, \quad \sup_{x \in I} \left| \frac{d}{dx} s_k^*(x) \right| \leqq M_k, \quad \sup_{x \in I} \left| \frac{d^2}{dx^2} s_k^*(x) \right| \leqq M_k.$$

Here, the positive constant M_k tends to $+\infty$ as $k \downarrow 0$. Define $F_k^{\varepsilon,\sigma}$ by $F_k^{\varepsilon,\sigma} = s_k^* F^{\varepsilon,\sigma}$. Then, it holds that

$$(2.10) \qquad \lim_{k \downarrow 0} \| F_k^{\varepsilon,\sigma} - F^{\varepsilon,\sigma} \|_{L^2} = 0 \quad \text{uniformly for } (\varepsilon, \sigma) \in \Omega_{\varepsilon_0 \cdot \sigma_0}$$

because of the uniform boundedness of $F^{\varepsilon,\sigma}$ with respect to ε and σ. Let $H^{\varepsilon,\sigma}$ and $H_k^{\varepsilon,\sigma}$ be defined by

$$H^{\varepsilon,\sigma} = (L^{\varepsilon,\sigma} - \lambda)^\dagger F^{\varepsilon,\sigma} h \quad \text{and} \quad H_k^{\varepsilon,\sigma} = (L^{\varepsilon,\sigma} - \lambda)^\dagger F_k^{\varepsilon,\sigma} h,$$

respectively.

It suffices to prove Lemma 2.2 where $F^{\varepsilon,\sigma}$ and $F^{*,\sigma}$ are replaced by $F_k^{\varepsilon,\sigma}$ and $F_k^{*,\sigma}$, respectively, for any $k > 0$. In fact, for an arbitrary $\rho > 0$, there exists a $k_0 > 0$ such that

$$\| H^{\varepsilon,\sigma} - H_k^{\varepsilon,\sigma} \|_{L^2} \leqq \| (L^{\varepsilon,\sigma} - \lambda)^\dagger \| \, \| F^{\varepsilon,\sigma} - F_k^{\varepsilon,\sigma} \|_{L^2} \| h \|_{L^\infty} < \frac{\rho}{3},$$

and

$$\left\| \frac{F^{*,\sigma} h}{f_u^{*,\sigma} - \lambda} - \frac{F_k^{*,\sigma} h}{f_u^{*,\sigma} - \lambda} \right\|_{L^2} < \frac{\rho}{3},$$

hold for $0 < k < k_0$ uniformly with respect to ε and σ. On the other hand, if this lemma is true for the cut-off case, then, for any fixed k_1 with $0 < k_1 < k_0$, we can find an ε_1 such that

$$\left\| H_{k_1}^{\varepsilon,\sigma} - \frac{F_{k_1}^{*,\sigma} h}{f_u^{*,\sigma} - \lambda} \right\|_{L_2} < \rho/3 \quad \text{for } 0 < \varepsilon < \varepsilon_1$$

holds. Combining these three inequalities, we have

$$(2.11) \qquad \begin{aligned} \left\| H^{\varepsilon,\sigma} - \frac{F^{*,\sigma} h}{f_u^{*,\sigma} - \lambda} \right\|_{L_2} &< \| H^{\varepsilon,\sigma} - H_{k_1}^{\varepsilon,\sigma} \|_{L^2} + \left\| H_{k_1}^{\varepsilon,\sigma} - \frac{F_{k_1}^{*,\sigma} h}{f_u^{*,\sigma} - \lambda} \right\|_{L_2} \\ &\quad + \left\| \frac{F_{k_1}^{*,\sigma} h}{f_u^{*,\sigma} - \lambda} - \frac{F^{*,\sigma} h}{f_u^{*,\sigma} - \lambda} \right\|_{L^2} < \rho \end{aligned}$$

for $0 < \varepsilon < \varepsilon_1$. Since ρ is arbitrary, (2.11) implies (2.8). The uniformity of convergence for $\lambda \in \Lambda_1$ follows from that of the above three inequalities.

Now, let us prove Lemma 2.2 for the cut-off case,

$$(2.12) \qquad (L^{\varepsilon,\sigma} - \lambda)^\dagger (F_k^{\varepsilon,\sigma} h) \xrightarrow[\varepsilon \downarrow 0]{} \frac{F_k^{*,\sigma} h}{f_u^{*,\sigma} - \lambda} \quad \text{in } L^2\text{-strong sense.}$$

Here, we can assume without loss of generality that h is smooth and $h_x = 0$ on ∂I, since any bounded L^2-function can be approximated arbitrarily close by such a function in L^2-sense. We divide $H_k^{\varepsilon,\sigma}$ into two parts,

$$(2.13)\qquad H_k^{\varepsilon,\sigma} = H_{1,k}^{\varepsilon,\sigma} + H_{2,k}^{\varepsilon,\sigma}, \quad \text{where } H_{1,k}^{\varepsilon,\sigma} = F_k^{*,\sigma} h/(f_u^{*,\sigma} - \lambda).$$

We have to show that $H_{2,k}^{\varepsilon,\sigma}$ goes to zero in L^2-sense uniformly for $\lambda \in \Lambda_1$, when $\varepsilon \downarrow 0$. First note that $H_{1,k}^{\varepsilon,\sigma}$ becomes a smooth function due to $F_k^{*,\sigma}$, though $f_u^{*,\sigma}$ has a discontinuity at $x = x_1^*(\sigma)$. The equation $H_k^{\varepsilon,\sigma} = (L^{\varepsilon,\sigma} - \lambda)^\dagger (F_k^{\varepsilon,\sigma} h)$ is equivalent to

$$(2.14)\qquad (L^{\varepsilon,\sigma} - \lambda) H_k^{\varepsilon,\sigma} = F_k^{\varepsilon,\sigma} h - P(F_k^{\varepsilon,\sigma} h),\ H_k^{\varepsilon,\sigma} \in \{\phi_0^{\varepsilon,\sigma}\}^\perp,$$

where P is an orthogonal projection onto $\phi_0^{\varepsilon,\sigma}$, i.e., $P(\cdot) = \langle \cdot, \phi_0^{\varepsilon,\sigma}\rangle \phi_0^{\varepsilon,\sigma}$. Substituting $H_{1,k}^{\varepsilon,\sigma}$ of (2.13) into (2.14), we have the following equation for $H_{2,k}^{\varepsilon,\sigma}$,

$$(2.15)\quad (L^{\varepsilon,\sigma} - \lambda) H_{2,k}^{\varepsilon,\sigma} = F_k^{\varepsilon,\sigma} h - P(F_k^{\varepsilon,\sigma} h) - \frac{f_u^{\varepsilon,\sigma} - \lambda}{f_u^{*,\sigma} - \lambda} F_k^{*,\sigma} h - \varepsilon^2 \frac{d^2}{dx^2}\left(\frac{F_k^{*,\sigma} h}{f_u^{*,\sigma} - \lambda}\right).$$

We denote the right-hand side of (2.15) by $R_k^{\varepsilon,\sigma}$. Since both $F_k^{*,\sigma}/(f_u^{*,\sigma} - \lambda)$ and h are smooth and satisfy Neumann boundary conditions, we have the following by using integration by parts;

$$\begin{aligned}
\langle R_k^{\varepsilon,\sigma}, \phi_0^{\varepsilon,\sigma}\rangle &= -\left\langle \frac{f_u^{\varepsilon,\sigma} - \lambda}{f_u^{*,\sigma} - \lambda} F_k^{*,\sigma} h, \phi_0^{\varepsilon,\sigma}\right\rangle - \left\langle \varepsilon^2 \frac{d^2}{dx^2}\left(\frac{F_k^{*,\sigma} h}{f_u^{*,\sigma} - \lambda}\right), \phi_0^{\varepsilon,\sigma}\right\rangle \\
&= -\left\langle \frac{f_u^{\varepsilon,\sigma} - \lambda}{f_u^{*,\sigma} - \lambda} F_k^{*,\sigma} h, \phi_0^{\varepsilon,\sigma}\right\rangle - \left\langle \frac{F_k^{*,\sigma} h}{f_u^{*,\sigma} - \lambda}, \varepsilon^2 \frac{d^2}{dx^2}\phi_0^{\varepsilon,\sigma}\right\rangle \\
&= -\left\langle \frac{f_u^{\varepsilon,\sigma} - \lambda}{f_u^{*,\sigma} - \lambda} F_k^{*,\sigma} h, \phi_0^{\varepsilon,\sigma}\right\rangle - \left\langle \frac{F_k^{*,\sigma} h}{f_u^{*,\sigma} - \lambda}, (-f_u^{\varepsilon,\sigma} + \zeta_0^{\varepsilon,\sigma})\phi_0^{\varepsilon,\sigma}\right\rangle \\
&= (\lambda - \zeta_0^{\varepsilon,\sigma})\left\langle \frac{F_k^{*,\sigma} h}{f_u^{*,\sigma} - \lambda}, \phi_0^{\varepsilon,\sigma}\right\rangle.
\end{aligned}$$

Thus, we have

$$(2.16)\qquad P(R_k^{\varepsilon,\sigma}) = (\lambda - \zeta_0^{\varepsilon,\sigma})\left\langle \frac{F_k^{*,\sigma} h}{f_u^{*,\sigma} - \lambda}, \phi_0^{\varepsilon,\sigma}\right\rangle \phi_0^{\varepsilon,\sigma}.$$

In view of (2.15) and (2.16), we can see that $H_{2,k}^{\varepsilon,\sigma}$ is given by

$$(2.17)\qquad H_{2,k}^{\varepsilon,\sigma} = (L^{\varepsilon,\sigma} - \lambda)^\dagger (R_k^{\varepsilon,\sigma}) - \left\langle \frac{F_k^{*,\sigma} h}{f_u^{*,\sigma} - \lambda}, \phi_0^{\varepsilon,\sigma}\right\rangle \phi_0^{\varepsilon,\sigma}.$$

It is apparent from (2.13) and (2.17) that

$$P(H_k^{\varepsilon,\sigma}) = P(H_{1,k}^{\varepsilon,\sigma} + H_{2,k}^{\varepsilon,\sigma}) = 0.$$

Using the expression (2.17) for $H_{2,k}^{\varepsilon,\sigma}$, we shall show that $H_{2,k}^{\varepsilon,\sigma} \to 0$ in L^2-sense as $\varepsilon \downarrow 0$. Since $F_k^{*,\sigma} h/(f_u^{*,\sigma} - \lambda)$ is uniformly bounded for $\lambda \in \Lambda_1$, we can see from Corollary 1.3 that when $\varepsilon \downarrow 0$, the second term of (2.17) converges to zero with $O(\sqrt{\varepsilon})$ in L^2-sense uniformly for $\lambda \in \Lambda_1$. For the first term of (2.17), it suffices to prove $\|R_k^{\varepsilon,\sigma}\|_{L^2} \downarrow 0$ as $\varepsilon \downarrow 0$, because of the uniform L^2-boundedness of $(L^{\varepsilon,\sigma} - \lambda)^\dagger$ for $\lambda \in \Lambda_1$ (see (2.7)). Recalling that the C^2-norm of the outer part of the reduced solution is uniformly bounded for $(\varepsilon, \sigma) \in \Omega_{\varepsilon_0, \sigma_0}$, and that (2.9), we can see that

$$(2.18)\qquad \lim_{\varepsilon \downarrow 0} \left\| \varepsilon^2 \frac{d^2}{dx^2}\left(\frac{F_k^{*,\sigma} h}{f_u^{*,\sigma} - \lambda}\right)\right\|_{L^2} = 0 \quad \text{uniformly for } \lambda \in \Lambda_1.$$

It is easily seen that

$$\lim_{\varepsilon\downarrow 0}\left\|F_k^{\varepsilon,\sigma}h-\frac{f_u^{\varepsilon,\sigma}-\lambda}{f_u^{*,\sigma}-\lambda}F_k^{*,\sigma}h\right\|_{L^2}=0 \quad \text{uniformly for } \lambda\in\Lambda_1, \tag{2.19}$$

$$\lim_{\varepsilon\downarrow 0}\|P(F_k^{\varepsilon,\sigma}h)\|_{L^2}=0. \tag{2.20}$$

Using (2.18)-(2.20), we obtain

$$\lim_{\varepsilon\downarrow 0}\|R_k^{\varepsilon,\sigma}\|_{L^2}=0 \quad \text{uniformly for } \lambda\in\Lambda_1,$$

which leads to the conclusion

$$H_{2,k}^{\varepsilon,\sigma}\xrightarrow[\varepsilon\downarrow 0]{} 0 \quad \text{in } L^2\text{-sense uniformly for } \lambda\in\Lambda_1. \tag{2.21}$$

In view of (2.13), we can see that (2.12) and therefore (2.8) are proved. It also follows from the above arguments that the convergence (2.8) is uniform for $0\leqq\sigma<\sigma_0$.

Finally, we show, by contradiction, the last part of Lemma 2.2. Suppose that the convergence (2.8) is not uniform on $H_M^1 \overset{\text{def}}{=} \{h\in H^1(I)|\ \|h\|_{H^1}\leqq M\}$, then we can find a positive constant δ and a sequence $\{h_{\varepsilon_n}\}(\varepsilon_n\downarrow 0$, as $n\uparrow\infty)$ in H_M^1 such that

$$\left\|(L^{\varepsilon_n,\sigma}-\lambda)^{\dagger}(F^{\varepsilon_n,\sigma}h_{\varepsilon_n})-\frac{F^{*,\sigma}h_{\varepsilon_n}}{f_u^{*,\sigma}-\lambda}\right\|_{L^2}\geqq\delta>0 \quad \text{for } n\geqq 1, \tag{2.22}$$

where δ does not depend on n. Since H_M^1 is compact in $L^2(I)$, we can choose a subsequence $\{h_{\varepsilon_n}\}$ (we use the same notation as before), which converges to $\hat{h}$ strongly in L^2-sense. Then, we have the inequality,

$$\begin{aligned}\left\|(L^{\varepsilon_n,\sigma}-\lambda)^{\dagger}(F^{\varepsilon_n,\sigma}h_{\varepsilon_n})-\frac{F^{*,\sigma}h_{\varepsilon_n}}{f_u^{*,\sigma}-\lambda}\right\|_{L^2}&\leqq\|(L^{\varepsilon_n,\sigma}-\lambda)^{\dagger}\{F^{\varepsilon_n,\sigma}(h_{\varepsilon_n}-\hat{h})\}\|_{L^2}\\&\quad+\left\|(L^{\varepsilon_n,\sigma}-\lambda)^{\dagger}(F^{\varepsilon_n,\sigma}\hat{h})-\frac{F^{*,\sigma}\hat{h}}{f_u^{*,\sigma}-\lambda}\right\|_{L^2}\\&\quad+\left\|\frac{F^{*,\sigma}}{f_u^{*,\sigma}-\lambda}(\hat{h}-h_{\varepsilon_n})\right\|_{L^2}.\end{aligned} \tag{2.23}$$

The right-hand side of (2.23) converges to zero as $n\uparrow\infty$, which contradicts (2.22). Thus, we have finished the proof of Lemma 2.2.

Remark 2.3. Lemma 2.2 also holds for the general boundary conditions $(\mathrm{SL})_\alpha$ in Remark 1.4.

Making use of Lemma 2.2, the next proposition shows that noncritical eigenvalues are not dangerous to the stability of SPS1.

PROPOSITION 2.1 (*a priori bound for noncritical eigenvalues*). *Let B_δ be a closed ball with center at the origin and radius δ in the complex plane $\mathbb{C}$. Suppose that λ is an arbitrary noncritical eigenvalue of* (LP) *which stays outside of B_δ for small ε.*

Then, there exist positive constants μ^* and ε_δ such that

$$\operatorname{Re}\lambda<-\mu^*<0 \quad \textit{for } 0<\varepsilon<\varepsilon_\delta, \tag{2.24}$$

where μ^* does not depend on δ and $(\varepsilon,\sigma)\in\Omega_{\varepsilon_\delta,\sigma_0}$.

Proof. Let $\Lambda_{1,\delta}(\subset\Lambda_1)$ be defined by

$$\Lambda_{1,\delta}=\{\lambda\in\mathbb{C}|\lambda\in\Lambda_1 \text{ and } \lambda\in C\backslash B_\delta\}. \tag{2.25}$$

We can assume without loss of generality that $\lambda \in \Lambda_{1,\delta}$ in the following. Let us start from the eigenvalue problem (2.5) for $\sigma > 0$.

$$\frac{1}{\sigma} z_{xx} + \frac{\langle -f_v^{\varepsilon,\sigma} z, \phi_0^{\varepsilon,\sigma} \rangle}{\zeta_0^{\varepsilon,\sigma} - \lambda} g_u^{\varepsilon,\sigma} \phi_0^{\varepsilon,\sigma} + g_u^{\varepsilon,0} (L^{\varepsilon,\sigma} - \lambda)^{\dagger} (-f_v^{\varepsilon,\sigma} z) + g_v^{\varepsilon,\sigma} z = \lambda z, \tag{2.5}$$
$$z \in H^2(I) \cap H_N^1(I).$$

We introduce the following bilinear form on $H_N^1(I)$ associated with (2.5):

$$\begin{aligned} B^{\varepsilon,\sigma,\lambda}(z^1, z^2) = {} & \frac{1}{\sigma} \langle z_x^1, z_x^2 \rangle - \frac{1}{\zeta_0^{\varepsilon,\sigma} - \lambda} \langle -f_v^{\varepsilon,\sigma} z^1, \phi_0^{\varepsilon,\sigma} \rangle \langle g_u^{\varepsilon,\sigma} \phi_0^{\varepsilon,\sigma}, z^2 \rangle \\ & - \langle (L^{\varepsilon,\sigma} - \lambda)^{\dagger} (-f_v^{\varepsilon,\sigma} z^1), g_u^{\varepsilon,\sigma} z^2 \rangle - \langle g_v^{\varepsilon,\sigma} z^1, z^2 \rangle \\ & + \lambda \langle z^1, z^2 \rangle \quad \text{for } z^1, z^2 \in H_N^1(I). \end{aligned} \tag{2.26}$$

We shall show the boundedness and positivity of (2.26). Since $\lambda \in \Lambda_{1,\delta}$, $\lim_{\varepsilon \downarrow 0} \zeta_0^{\varepsilon,\sigma} = 0$ (Lemma 1.4) and $\int \phi_0^{\varepsilon,\sigma} \, dx = O(\sqrt{\varepsilon})$ (Corollary 1.3), we can see that there exists a $\varepsilon_\delta > 0$ such that the estimate

$$|\text{the second term of (2.26)}| \leqq \frac{c_1 \varepsilon}{\delta} \|z^1\|_{H^1} \|z^2\|_{H^1} \tag{2.27}$$

holds for $(\varepsilon, \sigma) \in \Omega_{\varepsilon_\delta, \sigma_0}$ and $\lambda \in \Lambda_{1,\delta}$, where $c_1(>0)$ does not depend on δ, (ε, σ), and λ. Therefore, using (2.27) and (2.7), we obtain the following:

$$\begin{aligned} |B^{\varepsilon,\sigma,\lambda}(z^1, z^2)| \leqq {} & \frac{1}{\sigma} \|z_x^1\|_{L^2} \|z_x^2\|_{L^2} + \frac{c_1 \varepsilon}{\delta} \|z^1\|_{H^1} \|z^2\|_{H^1} \\ & + c_2 \|z^1\|_{L^2} \|z^2\|_{L^2} + |\lambda| \, \|z^1\|_{L^2} \|z^2\|_{L^2}, \end{aligned} \tag{2.28}$$

holds for $(\varepsilon, \sigma) \in \mathring{\Omega}_{\varepsilon_\delta, \sigma_0}$ and $\lambda \in \Lambda_{1,\delta}$, where $c_2(>0)$ is independent of $(\varepsilon, \sigma) \in \Omega_{\varepsilon_0, \sigma_0}$ and $\lambda \in \Lambda_1$. Here $\mathring{\Omega}$ denotes the interior of the set. The inequality (2.28) shows the boundedness of $B^{\varepsilon,\sigma,\lambda}$.

We first consider real noncritical eigenvalues. We shall show that there exists a positive constant μ^* such that $B^{\varepsilon,\sigma,\lambda}$ satisfies the positivity property

$$|B^{\varepsilon,\sigma,\lambda}(z, z)| \geqq c_3 \|z\|_{H^1}^2 \tag{2.29}$$

for $(\varepsilon, \sigma) \in \mathring{\Omega}_{\varepsilon_\delta, \sigma_0}$ and $\lambda > -\mu^*$ with $\lambda \in \Lambda_{1,\delta}$, where the positive constants c_3 and μ^* do not depend on (ε, σ) and λ. The inequality (2.29) implies from the Lax-Milgram theorem that the set $\{\lambda \in \mathbb{R} \mid \lambda \in \Lambda_{1,\delta} \text{ and } \lambda > -\mu^*\}$ belongs to the resolvent of (LP) for $(\varepsilon, \sigma) \in \mathring{\Omega}_{\varepsilon_d, \sigma_0}$. By virtue of Lemma 2.2, we see that

$$\langle (L^{\varepsilon,\sigma} - \lambda)^{\dagger} (-f_v^{\varepsilon,\sigma} z), g_u^{\varepsilon,\sigma} z \rangle \xrightarrow[\varepsilon \downarrow 0]{} \left\langle \frac{-f_v^{*,\sigma} z}{f_u^{*,\sigma} - \lambda}, g_u^{*,\sigma} z \right\rangle \tag{2.30}$$

uniformly for $\|z\|_{H^1} \leqq M$, $0 \leqq \sigma < \sigma_0$, and $\lambda \in \Lambda_1$. Similarly, we have

$$\langle g_v^{\varepsilon,\sigma} z, z \rangle \xrightarrow[\varepsilon \downarrow 0]{} \langle g_v^{*,\sigma} z, z \rangle, \tag{2.31}$$

uniformly for $\|z\|_{H^1} \leqq M$ and $0 \leqq \sigma < \sigma_0$. Therefore, using the uniformity of the convergence of (2.30) and (2.31), and the estimate (2.27), we can see that if the limiting bilinear form $B^{*,\sigma,\lambda}$ defined by

$$B^{*,\sigma,\lambda}(z^1, z^2) = \frac{1}{\sigma} \langle z_x^1, z_x^2 \rangle - \left\langle \frac{-f_v^{*,\sigma} z^1}{f_u^{*,\sigma} - \lambda}, g_u^{*,\sigma} z^2 \right\rangle - \langle g_v^{*,\sigma} z^1, z^2 \rangle + \lambda \langle z^1, z^2 \rangle \tag{2.32}$$

satisfies the positivity property (2.29), then $B^{\varepsilon,\sigma,\lambda}$ also satisfy the same inequality with the appropriate change of constants c_3 and ε_δ.

After a simple computation, we obtain

$$B^{*,\sigma,\lambda}(z, z) = \frac{1}{\sigma}\|z_x\|^2_{L^2} + \left\langle \frac{1}{\lambda - f_u^{*,\sigma}}\{\lambda^2 - (f_u^{*,\sigma} + g_v^{*,\sigma})\lambda + \det{}^{*,\sigma}\}|z|^2, 1 \right\rangle. \tag{2.33}$$

Note that this corresponds to the reduced scalar eigenvalue problem (2.1). Recalling the assumptions (A.3)-(A.5), and $\lambda \in \Lambda_{1,\delta}$, we can see that there exist positive constants μ^* and c_4 such that

$$|\text{the second term of (2.33)}| \geqq c_4\|z\|_{L^2} \tag{2.34}$$

holds for $\lambda > -\mu^*$, where c_4 is independent of λ $(> -\mu^*)$ and σ with $0 \leqq \sigma < \sigma_0$. Combining the estimate (2.34) with (2.33), we easily see that $B^{*,\sigma,\lambda}$ satisfies the positivity property (2.29).

Next we consider the case where λ is a complex noncritical eigenvalue. Our goal is to show that there is a priori bound $-\mu^*$ such that $\operatorname{Re}\lambda < -\mu^*$ for small ε. First we note the following boundedness of complex noncritical eigenvalues.

SUBLEMMA 2.1. *If* $\lambda \in \Lambda_{1,\delta}$ *is a complex eigenvalue of* (LP) (*or* (2.5)), *then, we have*

$$|\lambda| \leqq M_c \quad \textit{for } (\varepsilon, \sigma) \in \mathring{\Omega}_{\varepsilon_0,\sigma_0},$$

where the positive constant M_c *does not depend on* (ε, σ).

Proof. Let z be the eigenfunction associated with λ. Then, the pair (λ, z) satisfies $B^{\varepsilon,\sigma,\lambda}(z, z) = 0$. Taking the Re- and Im- parts of this bilinear form, we have the following.

$$\begin{aligned} &\text{Re part: } \frac{1}{\sigma}\langle z_x, z_x\rangle - \operatorname{Re}\left\{\frac{1}{\zeta^{\varepsilon,\sigma} - \lambda}\langle -f_v^{\varepsilon,\sigma} z, \phi_0^{\varepsilon,\sigma}\rangle\langle g_u^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma}, z\rangle\right\} \\ &\qquad -\operatorname{Re}\langle (L^{\varepsilon,\sigma} - \lambda)^\dagger(-f_v^{\varepsilon,\sigma} z), g_u^{\varepsilon,\sigma} z\rangle \\ &\qquad -\langle g_v^{\varepsilon,\sigma} z, z\rangle + \operatorname{Re}\lambda\langle z, z\rangle = 0, \end{aligned} \tag{2.35}$$

$$\begin{aligned} &\text{Im part: } -\operatorname{Im}\left\{\frac{1}{\zeta_0^{\varepsilon,\sigma} - \lambda}\langle -f_v^{\varepsilon,\sigma} z, \phi_0^{\varepsilon,\sigma}\rangle\langle g_u^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma}, z\rangle \right. \\ &\qquad \left. + \langle (L^{\varepsilon,\sigma} - \lambda)^\dagger(-f_v^{\varepsilon,\sigma} z), g_u^{\varepsilon,\sigma} z\rangle\right\} + \operatorname{Im}\lambda\langle z, z\rangle = 0. \end{aligned} \tag{2.36}$$

Let us normalize z as $\|z\|_{L^2} = 1$. By virtue of (2.7), we can see from (2.36) that $\operatorname{Im}\lambda$ must be uniformly bounded for $(\varepsilon, \sigma) \in \mathring{\Omega}_{\varepsilon_0,\sigma_0}$. If not, the first term would remain bounded, while the second term is equal to $\operatorname{Im}\lambda$, which is a contradiction. As for $\operatorname{Re}\lambda$, it suffices to show that there exists a positive constant M_1 such that $\operatorname{Re}\lambda < M_1 < +\infty$, since $\lambda \in \Lambda_{1,\delta}$ (see (2.2) and (2.25)). We can prove this by applying a contradiction method to (2.35) again. In fact, suppose that there is a sequence of complex eigenvalues and their eigenfunctions (λ_n, z_n) with $(\varepsilon, \sigma) = (\varepsilon_n, \sigma_n) \in \mathring{\Omega}_{\varepsilon_0,\sigma_0}$ and $\|z_n\|_{L^2} = 1$ such that $\operatorname{Re}\lambda_n \uparrow +\infty$ as $n \uparrow +\infty$ as $n \uparrow \infty$. Then, in view of (2.35), we can see that $1/\sigma\langle (z_n)_x, (z_n)_x\rangle + \operatorname{Re}\lambda_n\langle z_n, z_n\rangle$ diverges to $+\infty$ as $n \uparrow \infty$, while all the other terms remain bounded for $(\varepsilon, \sigma) \in \mathring{\Omega}_{\varepsilon_0,\sigma_0}$, which violates (2.35). Thus, we obtain the conclusion of Sublemma 2.1.

COROLLARY 2.1. *Let* $\lambda \in \Lambda_{1,\delta}$ *be a complex eigenvalue of* (2.5), *and* z *be the associated eigenfunction with* $\|z\|_{L^2} = 1$. *Then, the following inequality holds*

$$1 \leqq \|z\|_{H^1} \leqq \sqrt{1 + \sigma M} \quad \textit{for } (\varepsilon, \sigma) \in \mathring{\Omega}_{\varepsilon_0,\sigma_0}, \tag{2.37}$$

where $M (> 0)$ *is independent of* ε *and* σ.

Proof. We know the uniform boundedness of $|\lambda|$, $\|(L^{\varepsilon,\sigma}-\lambda)^{\dagger}\|$, and partial derivatives $f_u^{\varepsilon,\sigma}, f_v^{\varepsilon,\sigma}$, etc., for $(\varepsilon,\sigma)\in\Omega_{\varepsilon_0,\sigma_0}$. Therefore, we easily obtain the following estimate from (2.35),

$$\frac{1}{\sigma}\|z_x\|^2_{L_2}\leqq \tilde{M}\|z\|^2_{L^2}\quad \text{for } (\varepsilon,\sigma)\in\mathring{\Omega}_{\varepsilon_0,\sigma_0},$$

where $\tilde{M}(>0)$ is independent of ε and σ, which leads to the conclusion.

Now, we shall show that there is a negative upper bound for the Re-parts of complex eigenvalues by using (2.35) and (2.36). Since z is normalized as $\|z\|_{L^2}=1$, $\|z\|_{H^1}\leqq M^*$, where M^* is independent of $(\varepsilon,\sigma)\in\mathring{\Omega}_{\varepsilon_0,\sigma_0}$ from Corollary 2.1.

First, we consider the limiting behavior of each term of (2.35). It follows from $\lambda\in\Lambda_{1,\delta}$, (1.28) and Corollary 1.3 that there exists a positive constant c_5 such that the inequality

$$\text{(2.38)}\qquad |\text{the second term of (2.35)}|\leqq\frac{c_5\varepsilon}{\delta}\|z\|^2_{H^1}\leqq\frac{c_5\varepsilon}{\delta}(M^*)^2$$

holds for $(\varepsilon,\sigma)\in\mathring{\Omega}_{\varepsilon_\delta,\sigma_0}$ and $\lambda\in\Lambda_{1,\delta}$, where c_5 does not depend on δ, (ε,σ) and λ. For the third term of (2.35), we can see from Lemma 2.2 that

$$\text{(2.39)}\qquad \{\text{the third term of (2.35)}\}\xrightarrow[\varepsilon\downarrow 0]{}\left\langle\frac{-f_u^{*,0}+\operatorname{Re}\lambda}{(f_u^{*,\sigma}-\operatorname{Re}\lambda)^2+(\operatorname{Im}\lambda)^2}(-f_v^{*,\sigma}z),\, g_u^{*,\sigma}z\right\rangle$$

uniformly for $\lambda\in\Lambda_{1,\delta}$, $0\leqq\sigma<\sigma_0$ and $\|z\|_{H^1}\leqq M^*$. Therefore, for small ε, we can rewrite (2.35) in the following form:

$$\begin{aligned}&\frac{1}{\sigma}\langle z_x, z_x\rangle+\left\langle\frac{-f_u^{*,\sigma}}{(f_u^{*,\sigma}-\operatorname{Re}\lambda)^2+(\operatorname{Im}\lambda)^2}(-f_v^{*,\sigma}z),\, g_u^{*,\sigma}z\right\rangle\\ &+\operatorname{Re}\lambda\left\langle\frac{-f_v^{*,\sigma}g_u^{*,\sigma}}{(f_u^{*,\sigma}-\operatorname{Re}\lambda)^2+(\operatorname{Im}\lambda)^2}|z|^2, 1\right\rangle-\langle g_v^{*,\sigma}|z|^2, 1\rangle\\ &+\operatorname{Re}\lambda+o(1)=0,\end{aligned}$$

where $o(1)$ denotes an infinitesimal term which goes to zero uniformly for $\lambda\in\Lambda_{1,\delta}$, $0\leqq\sigma<\sigma_0$ and $\|z\|_{H^1}\leqq M^*$. In the following, we use the same notation $o(1)$ for this type of infinitesimal term. Combining the second and the fourth terms of (2.40), we have

$$\text{(2.41)}\ 2\operatorname{Re}\lambda\left\langle\frac{f_u^{*,\sigma}g_v^{*,\sigma}}{(f_u^{*,\sigma}-\operatorname{Re}\lambda)^2+(\operatorname{Im}\lambda)^2}|z|^2, 1\right\rangle-\left\langle\frac{f_u^{*,\sigma}\det{}^{*,\sigma}+g_v^{*,\sigma}|\lambda|^2}{(f_u^{*,\sigma}-\operatorname{Re}\lambda)^2+(\operatorname{Im}\lambda)^2}|z|^2, 1\right\rangle.$$

After some computation, we obtain the following expression for $\operatorname{Re}\lambda$ from (2.40) together with (2.41),

$$\text{(2.42)}\qquad \operatorname{Re}\lambda=\frac{-\dfrac{1}{\sigma}\|z_x\|^2_{L^2}+\left\langle\dfrac{f_u^{*,\sigma}\det{}^{*,\sigma}+g_v^{*,\sigma}|\lambda|^2}{(f_u^{*,\sigma}-\operatorname{Re}\lambda)^2+(\operatorname{Im}\lambda)^2}|z|^2, 1\right\rangle+o(1)}{\left\langle\left(1+\dfrac{\det{}^{*,\sigma}+f_u^{*,\sigma}g_v^{*,\sigma}}{(f_u^{*,\sigma}-\operatorname{Re}\lambda)^2+(\operatorname{Im}\lambda)^2}\right)|z|^2, 1\right\rangle+o(1)}.$$

Recalling (A.3)-(A.5), $\lambda\in\Lambda_{1,\delta}(\subset\Lambda_1)$ and Sublemma 2.1, we can see that

$$\text{(2.43)}\quad 0<c_6<-\frac{f_u^{*,\sigma}\det{}^{*,\sigma}+g_v^{*,\sigma}|\lambda|^2}{(f_u^{*,\sigma}-\operatorname{Re}\lambda)^2+(\operatorname{Im}\lambda)^2},\ \left(1+\frac{\det{}^{*,\sigma}+f_u^{*,\sigma}g_v^{*,\sigma}}{(f_u^{*,\sigma}-\operatorname{Re}\lambda)^2+(\operatorname{Im}\lambda)^2}\right)<c_7$$

holds, where the positive constants c_6 and c_7 are independent of δ, $\lambda \in \Lambda_1$ and σ. Since $\|z\|_{L^2}^2 = 1$, it follows from (2.42) and (2.43) that there exist positive constants μ^* and ε_δ such that

$$\operatorname{Re} \lambda < -\mu^* \quad \text{for } 0 < \varepsilon < \varepsilon_\delta,$$

where $-\mu^*$ does not depend on δ and $(\varepsilon, \sigma) \in \mathring{\Omega}_{\varepsilon_\delta, \sigma_0}$. Thus, we have obtained a negative upper bound for complex noncritical eigenvalues.

So far, we only consider the case where $\sigma > 0$. For the limiting case $\sigma = 0$, we have to study the following eigenvalue problem instead of (2.5),

$$\int_I \left\{ \frac{\langle -f_v^{\varepsilon,0}\eta, \phi_0^{\varepsilon,0} \rangle}{\zeta_0^{\varepsilon,0} - \lambda} g_u^{\varepsilon,0} \phi_0^{\varepsilon,0} + g_u^{\varepsilon,0}(L^{\varepsilon,0} - \lambda)^\dagger(-f_v^{\varepsilon,0}\eta) + g_v^{\varepsilon,0}\eta \right\} dx = \lambda \eta, \tag{2.44}$$

where η is a constant function. Note that Lemma 2.1 holds also for $\sigma = 0$. If we compare (2.44) with (2.26), we can see that (2.44) is a special form of (2.26) when we set z^i = constant function ($i = 1, 2$). Therefore, the above proof for $\sigma > 0$ is essentially valid to the case $\sigma = 0$ (even simpler than before), and the conclusion of Proposition 2.1 holds for $\sigma = 0$ without any change. In fact, if we remove $(1/\sigma)\|z_x\|_{L^2}^2$ from (2.33) (or (2.42)) and put $z = \eta$, we obtain the key expressions to show Proposition 2.1 for $\sigma = 0$. We leave the details to the reader (see also [19]).

Thus, we have finished the proof of Proposition 2.1.

Remark 2.4. Reconsidering the above proof, we find that in the framework of nonlinearities where

(AI) $\qquad f_v^{*,\sigma} g_u^{*,\sigma} < 0 \quad$ on the reduced set $R_+ \cup R_-$

as well as (A.0)-(A.4) are satisfied, Proposition 2.1 can be proved under a weaker assumption than (A.5). In fact, for real noncritical eigenvalues, we can see from (2.33) that

$$\sup_{x \in I} \{ f_u^{*,\sigma} + g_v^{*,\sigma} \} < 0 \quad \text{for } 0 < \sigma < \sigma_0 (< \sigma_1^*) \tag{2.45}$$

is enough even without (AI) to guarantee (2.34). For complex eigenvalues, using (2.36), we obtain from (2.40) that

$$\operatorname{Re} \lambda \leqq \frac{1}{2} \left\{ -\frac{1}{\sigma} \|z_x\|_{L^2}^2 + \left\langle \left(\sup_{x \in I} f_u^{*,\sigma} + \sup_{x \in I} g_v^{*,\sigma} \right) |z|^2, 1 \right\rangle \right\} + o(1).$$

Consequently, if we assume that

$$\sup_{x \in I} f_u^{*,\sigma} + \sup_{x \in I} g_v^{*,\sigma} < 0 \quad \text{for } 0 < \sigma < \sigma_0 (< \sigma_1^*). \tag{2.46}$$

$\operatorname{Re} \lambda$ has a negative upper bound for small ε and $0 < \sigma < \sigma_0$. Since (2.46) implies (2.45), under (AI), we can replace (A.5) by the weaker condition (2.46). However, the condition (2.46) depends on σ, in fact, when $\sigma_0 \uparrow \sigma_1^*$, we can see from Remark 0.2 that $\sup_{x \in I} f_u^{*,\sigma} \uparrow 0$. Therefore, if $\sup_{(u,v) \in R_+ \cup R_-} g_v(u, v)$ is strictly positive, the valid region of (2.46) is restricted to the subinterval of $[0, \sigma_1^*)$.

As far as noncritical eigenvalues are concerned, the effect of the second term

$$\frac{\langle -f_v^{\varepsilon,\sigma} z, \phi_0^{\varepsilon,\sigma} \rangle}{\zeta_0^{\varepsilon,\sigma} - \lambda} g_u^{\varepsilon,\sigma} \phi_0^{\varepsilon,\sigma} \tag{2.47}$$

of (2.5) can be neglected, and therefore, we find that they are not dangerous to the stability of SPS1 as in Proposition 2.1. However, if $\lambda = \lambda(\varepsilon, \sigma)$ is a critical eigenvalue (i.e., $\lim_{\varepsilon \downarrow 0} \lambda(\varepsilon, \sigma) = 0$), then, the behavior of (2.47) becomes delicate in the sense that

(i) the denominator of (2.47) approaches to zero as $\varepsilon \downarrow 0$, and the infinitesimal order of $\zeta_0^{\varepsilon,\sigma}-\lambda$ is not a priori known;

(ii) $\phi_0^{\varepsilon,\sigma}$ does not have a limit function in L^2-sense as $\varepsilon \downarrow 0$.

A nice characterization of (2.47) as $\varepsilon \downarrow 0$ is certainly necessary to overcome these difficulties. We give first a heuristic argument how to know the asymptotic order of $\lambda(\varepsilon,\sigma)$ as $\varepsilon \downarrow 0$. We remind that $\phi_0^{\varepsilon,\sigma}$ decays with an exponential order as $\varepsilon \downarrow 0$ outside of any fixed neighborhood of the layer position $x_1^*(\sigma)$. Therefore, if the decaying order of $\zeta_0^{\varepsilon,\sigma}-\lambda$ is milder than it, we can see from (2.5) that the outer part of the limit eigenfunction is governed by (2.1). Namely, letting $z(\varepsilon,\sigma)$ be the corresponding eigenfunction to $\lambda(\varepsilon,\sigma)$, then the limit function $z^*=\lim_{\varepsilon\downarrow 0} z(\varepsilon,\sigma)$ belongs to $H_N^1(I)$ and satisfies (2.1) with $\lambda=0$ in each of the subintervals $[0,x_1^*(\sigma))$ and $(x_1^*(\sigma),1]$ in classical sense. (Note that all coefficients of (LP) have a jump discontinuity at only one point $x=x_1^*(\sigma)$ as $\varepsilon\downarrow 0$.) Then, z^* must be strictly convex in each subinterval due to the negativity of $\det^{*,\sigma}/f_u^{*,\sigma}$. Therefore, taking account of $z_x^*=0$ on ∂I, z_x^* cannot be continuous at $x=x_1^*(\sigma)$, and has a finite jump discontinuity. On the other hand, if we integrate (2.5) over a small neighbourhood $I_\kappa=(x_1^*(\sigma)-\kappa,\ x_1^*(\sigma)+\kappa)$ of the layer position $x_1^*(\sigma)$, we obtain

$$\frac{1}{\sigma}\{z_x(x_1^*(\sigma)+\kappa)-z_x(x_1^*(\sigma)-\kappa)\}+\frac{\langle -f_v^{\varepsilon,\sigma}z,\ \phi_0^{\varepsilon,\sigma}\rangle}{\zeta_0^{\varepsilon,\sigma}-\lambda}\int_{I_\kappa} g_u^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma}\,dx+O(\kappa)=0.$$

Consequently, we have

$$\text{(2.48)}\qquad \frac{1}{\sigma}[z_x^*]=\lim_{\kappa\downarrow 0}\lim_{\varepsilon\downarrow 0}-\{\text{integral of (2.47) over } I_\kappa\},$$

where $[\cdot]$ denotes the jump at $x=x_1^*(\sigma)$. Recalling Corollary 1.3 and (1.28), we can see that $\lambda(\varepsilon,\sigma)-\zeta_0^{\varepsilon,\sigma}$ must be $O(\varepsilon)$ as $\varepsilon\downarrow 0$, since the left-hand side of (2.48) is finite. Thus, we may take the asymptotic form of $\lambda(\varepsilon,\sigma)$ as

$$\text{(2.49)}\qquad \lambda(\varepsilon,\sigma)=\varepsilon\tau(\varepsilon,\sigma)\quad\text{with } \tau^{*,\sigma}\neq\sigma\hat{\zeta}_0^{*,\sigma},$$

where $\tau(\varepsilon,\sigma)$ is a continuous function of ε and σ, $\tau^{*,\sigma}=\tau(0,\sigma)$, and $\hat{\zeta}_0^{*,\sigma}$ is defined by (1.30). Using (1.28), we can rewrite (2.47) in the following form

$$\text{(2.50)}\qquad \frac{\langle -f_v^{\varepsilon,\sigma}z,\ \phi_0^{\varepsilon,\sigma}/\sqrt{\varepsilon}\rangle}{\sigma\hat{\zeta}_0(\varepsilon,\sigma)+\mathrm{E\hat{x}p}\,(\varepsilon,\sigma)-\tau(\varepsilon,\sigma)}g_u^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma}/\sqrt{\varepsilon},$$

where $\mathrm{E\hat{x}p}\,(\varepsilon,\sigma)=\mathrm{Exp}\,(\varepsilon,\sigma)/\varepsilon$ which still goes to zero with exponential order like (1.31). The following lemma gives a complete characterization of (2.50).

LEMMA 2.3 (*the second key lemma*).

$$\text{(a)}\qquad \frac{-f_v^{\varepsilon,\sigma}}{\sqrt{\varepsilon}}\phi_0^{\varepsilon,\sigma}\xrightarrow[\varepsilon\downarrow 0]{} c_1^*\delta^*\quad \textit{in } H^{-1}(I)\textit{-sense},$$

$$\text{(b)}\qquad \frac{g_u^{\varepsilon,\sigma}}{\sqrt{\varepsilon}}\phi_0^{\varepsilon,\sigma}\xrightarrow[\varepsilon\downarrow 0]{} c_2^*\delta^*\quad \textit{in } H^{-1}(I)\textit{-sense},$$

uniformly for $0\leqq\sigma<\sigma_0$, *where* $\delta^*=\delta(x-x_1^*(\sigma))$, *a Dirac's* δ*-function at* $x_1^*(\sigma)$, *and*

$$c_1^*=-\kappa^*\frac{d}{dv}J(v)|_{v=v^*}>0\quad (\textit{see}\ (\mathrm{A}.2)),$$

$$c_2^*=\kappa^*\{g(h_+(v^*),v^*)-g(h_-(v^*),v^*)\}>0\quad (\textit{see}\ (\mathrm{A}.4\mathrm{a})),$$

with

$$\kappa^{*-1} = \left\| \frac{d}{dy} \tilde{u}^*(y) \right\|_{L^2(\mathbb{R})}.$$

Remark 2.5. Note that each coefficient c_i^* $(i=1,2)$ of δ^* does not depend on σ.

Proof. In order to show that $\{-f_v^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma}/\sqrt{\varepsilon}\}_{\varepsilon>0}$ is a Dirac-sequence to $c_1^*\delta^*$, it suffices to prove the following. For an arbitrary interval $(a,b)\subset I$, it holds that

$$\lim_{\varepsilon\downarrow 0} \int_a^b -f_v^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma}/\sqrt{\varepsilon}\, dx = \begin{cases} 0 & \text{if } x_1^*(\sigma)\notin(a,b), \\ c_1^* & \text{if } x_1^*(\sigma)\in(a,b). \end{cases} \tag{2.51}$$

First, we consider the case where $x_1^*(\sigma)\notin(a,b)$. Using the stretched variable $y=(x-x_1(\varepsilon,\sigma))/\varepsilon$, we have

$$\int_a^b -f_v^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma}/\sqrt{\varepsilon}\, dx = \int_{(a-x_1(\varepsilon,\sigma))/\varepsilon}^{(b-x_1(\varepsilon,\sigma))/\varepsilon} \sqrt{\varepsilon}(-\tilde{f}_v^{\varepsilon,\sigma})\tilde{\phi}_0^{\varepsilon,\sigma}\, dy. \tag{2.52}$$

We can assume without loss of generality that $x^*(\sigma)<a<b\leqq 1$. The right-hand side is majorized as

$$|\text{the right-hand side of (2.52)}| \leqq \|-\tilde{f}_v^{\varepsilon,\sigma}\|_{L^\infty} \int_{(a-x_1(\varepsilon,\sigma))/\varepsilon}^{(b-x_1(\varepsilon,\sigma))/\varepsilon} \sqrt{\varepsilon}\tilde{\phi}_0^{\varepsilon,\sigma}\, dy. \tag{2.53}$$

Since $|x_1(\varepsilon,\sigma)-x_1^*(\sigma)|=o(1)$ as $\varepsilon\downarrow 0$ (see (16) and (17) in Appendix 1), we see that

$$(a-x_1(\varepsilon,\sigma))/\varepsilon \geqq \delta/\varepsilon \quad \text{for small } \varepsilon,$$

where δ is a positive constant independent of ε. Consequently, the right-hand side of (2.53) goes to zero by virtue of the exponentially decaying property of $\sqrt{\varepsilon}\tilde{\phi}_0^{\varepsilon,\sigma}(=\hat{\phi}_0^{\varepsilon,\sigma}$, see (1.24)), which completes the proof of the first part of (2.51).

Next, we consider the case where $x_1^*(\sigma)\in(a,b)$. In view of Corollary 1.1, Lemma 1.1 and Lemma 1.3, we have

$$\begin{aligned} -\tilde{f}_v^{\varepsilon,\sigma} &\xrightarrow[\varepsilon\downarrow 0]{} -\tilde{f}_v^{*,\sigma} \quad \text{in } C^2_{\text{c.u.}}\text{-sense} \quad \text{and} \\ \sqrt{\varepsilon}\tilde{\phi}_0^{\varepsilon,\sigma} &\xrightarrow[\varepsilon\downarrow 0]{} \kappa^*\frac{d}{dy}\tilde{u}^* \quad \text{in } C^2_{\text{c.u.}}\text{-sense.} \end{aligned} \tag{2.54}$$

Using the decaying property of $\sqrt{\varepsilon}\tilde{\phi}_0^{\varepsilon,\sigma}$again, we can see that for any $\gamma>0$, there exist positive constants M_γ and ε_γ such that

$$\left| \int_{|y|\geqq M_\gamma} \sqrt{\varepsilon}(-\tilde{f}_v^{\varepsilon,\sigma})\tilde{\phi}_0^{\varepsilon,\sigma}\, dy \right| < \frac{\gamma}{3},$$

$$\left| \int_{|y|\geqq M_\gamma} \kappa^*(-\tilde{f}_v^{*,\sigma})\frac{d}{dy}\tilde{u}^*\, dy \right| < \frac{\gamma}{3},$$

and from (2.54),

$$\left| \int_{|y|\leqq M_\gamma} \left\{ \sqrt{\varepsilon}(-\tilde{f}_v^{\varepsilon,\sigma})\tilde{\phi}_0^{\varepsilon,\sigma} - \kappa^*(-\tilde{f}_v^{*,\sigma})\frac{d}{dy}\tilde{u}^* \right\} dy \right| < \frac{\gamma}{3},$$

for $0<\varepsilon<\varepsilon_\gamma$. Thus, we obtain

$$\left| \int_{\tilde{I}} \sqrt{\varepsilon}(-\tilde{f}_v^{\varepsilon,\sigma})\tilde{\phi}_0^{\varepsilon,\sigma}\, dy - \int_{-\infty}^{+\infty} \kappa^*(-\tilde{f}_v^{*,\sigma})\frac{d}{dy}\tilde{u}^*\, dy \right| < \gamma \quad \text{for } 0<\varepsilon<\varepsilon_\gamma.$$

Since γ is arbitrary, we have

$$\begin{aligned}\lim_{\varepsilon\downarrow 0}\int_{\tilde{I}}\sqrt{\varepsilon}(-\tilde{f}_v^{\varepsilon,\sigma})\tilde{\phi}_0^{\varepsilon,\sigma}\,dy &= \int_{-\infty}^{+\infty}\kappa^*(-\tilde{f}_v^{*,\sigma})\frac{d}{dy}\tilde{u}^*\,dy\\ &= -\kappa^*\int_{h_-(v^*)}^{h_+(v^*)} f_v(s, v^*)\,ds\\ &= -\kappa^*\frac{d}{dv}J(v)\bigg|_{v=v^*}\\ &= c_1^*.\end{aligned}$$

Here we use the fact that $\tilde{u}^*$ is a strictly monotone increasing function. Consequently, we have proved (a) of Lemma 2.3. As for (b), the same argument works without any change except the constant c_2^*. The constant c_2^* is computed as follows:

$$\begin{aligned}c_2^* &= \lim_{\varepsilon\downarrow 0}\int_{\tilde{I}}\sqrt{\varepsilon}\,\tilde{g}_u^{\varepsilon,\sigma}\tilde{\phi}_0^{\varepsilon,\sigma}\,dy\\ &= \int_{-\infty}^{+\infty}\kappa^*\tilde{g}_u^{*,\sigma}\frac{d}{dy}\tilde{u}^*\,dy\\ &= \kappa^*\int_{h_-(v^*)}^{h_+(v^*)}\frac{d}{ds}g(s, v^*)\,ds\\ &= \kappa^*\{g(h_+(v^*), v^*) - g(h_-(v^*), v^*)\}.\end{aligned}$$

Finally, noting that all the above estimates do not depend on σ for $0 \leqq \sigma < \sigma_0$, the convergence results (a) and (b) are also uniform for $0 \leqq \sigma < \sigma_0$, which completes the proof of Lemma 2.3.

Remark 2.6. Lemma 2.3 also holds for (SL) in Remark 1.4.

Using Lemma 2.3, we have

$$(2.55)\qquad (2.50) \xrightarrow[\varepsilon\downarrow 0]{} \frac{c_1^* c_2^*\langle z^*, \delta^*\rangle}{\sigma\hat{\zeta}_0^{*,\sigma} - \tau^{*,\sigma}}\delta^* \quad \text{in } H^{-1}(I)\text{-sense.}$$

This characterization is a key to solve the problem $(\mathrm{P2})_{\mathrm{b}}$ at the beginning of this section. Our task is to determine the sign of $\tau^{*,\sigma}$. In the following, using (2.55), we shall derive a limiting eigenvalue problem of (2.5) as $\varepsilon \downarrow 0$, which we call the *singular limit eigenvalue problem* (SLEP), and show that $\tau^{*,\sigma}$ is uniquely determined to be a negative constant. The assumption (2.49) and SLEP will be justified in the next section as well as the uniquenesss and the simplicity of the critical eigenvalue. Since the convergence in (2.55) has a meaning in H^{-1}-sense, we rewrite (2.5) in a weak form:

$$(2.56)\qquad \begin{aligned}&-\frac{1}{\sigma}\langle z_x, \psi_x\rangle + \frac{\langle z, -f_v^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma}\rangle}{\zeta_0^{\varepsilon,\sigma} - \lambda}\langle g_u^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma}, \psi\rangle\\ &\qquad + \langle g_u^{\varepsilon,\sigma}(L^{\varepsilon,\sigma} - \lambda)^{\dagger}(-f_v^{\varepsilon,\sigma}z), \psi\rangle + \langle g_v^{\varepsilon,\sigma}z, \psi\rangle = \lambda\langle z, \psi\rangle,\\ &\qquad\qquad z \in H_N^1(I), \quad \forall\psi \in H^1(I).\end{aligned}$$

Using (2.55), Lemma 2.2 and $\lim_{\varepsilon\downarrow 0}\lambda(\varepsilon, \sigma) = 0$, we see that $z^* = \lim_{\varepsilon\downarrow 0} z(\varepsilon, \sigma)$ satisfy the following limit equation as $\varepsilon \downarrow 0$.

$$(\mathrm{SLEP})_{\mathrm{a}}\quad -\frac{1}{\sigma}\langle z_x^*, \psi_x\rangle + \frac{c_1^* c_2^*\langle z^*, \delta^*\rangle}{\sigma\hat{\zeta}_0^{*,\sigma} - \tau^{*,\sigma}}\langle\delta^*, \psi\rangle + \left\langle\frac{\det^{*,\sigma}}{f_u^{*,\sigma}}z^*, \psi\right\rangle = 0, \qquad z^* \in H_N^1(I),$$

for any $\psi \in H^1(I)$. Roughly speaking, the second term comes from the transition layer part, and the remaining ones represent the outer part of (2.5) as $\varepsilon \downarrow 0$, namely (2.1) with $\lambda = 0$. We call the above limit equation the *singular limit eigenvalue problem* (SLEP). Hereafter, we normalize the limit eigenfunction z^* as

$$\langle z^*, \delta^* \rangle = 1. \tag{2.57}$$

This normalization is always possible, since there are no nontrivial solutions of SLEP which satisfy $\langle z^*, \delta^* \rangle = 0$. We denote the solution of SLEP under (2.57) by the pair $(z^*, \tau^{*,\sigma}) \in H^1_N(I) \times \mathbb{R}$. It is easily seen that $(\text{SLEP})_a$ is equivalent to the following equations.

$$(\text{SLEP-1})_b \quad \begin{cases} \dfrac{1}{\sigma} z^*_{xx} + \dfrac{\det^{*,\sigma}}{f_u^{*,\sigma}} z^* = 0 & \text{in } [0, x_1^*(\sigma)) \cup (x_1^*(\sigma), 1], \\ z^*_x = 0 & \text{on } \partial I, \text{ and } z^* \text{ is continuous at } x = x_1^*(\sigma), \end{cases}$$

$$(\text{SLEP-2})_b \quad \frac{1}{\sigma}[z^*_x] = -\frac{c_1^* c_2^*}{\sigma \hat{\xi}_0^{*,\sigma} - \tau^{*,\sigma}},$$

where $[z^*_x]$ denotes the jump of z^*_x at $x = x_1^*(\sigma)$, namely,

$$[z^*_x] = \lim_{\delta \downarrow 0} \{ z^*_x(x_1^*(\sigma) + \delta) - z^*_x(x_1^*(\sigma) - \delta) \}.$$

Since $\det^{*,\sigma}/f_u^{*,\sigma}$ is strictly negative from (A.3) and (*A*.4) and smooth in each subinterval, there exists a unique solution of $(\text{SLEP-1})_b$ under (2.57), which is strictly convex and smooth in each subinterval (see Fig. 10). We denote this solution by $z_N^{*,\sigma}$. Using the relation $(\text{SLEP-2})_b$, $\tau^{*,\sigma}$ is also uniquely determined from $z_N^{*,\sigma}$, which we denote by $\tau_N^{*,\sigma}$. Thus, we obtain a unique solution $(z_N^{*,\sigma}, \tau_N^{*,\sigma})$ of $(\text{SLEP})_b$ under (2.57).

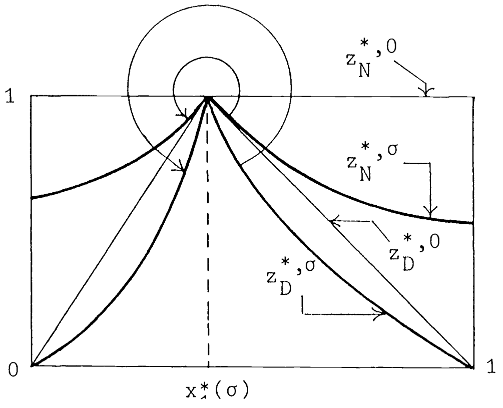

FIG. 10. *Solutions of* SLEP *and a comparison of jumps of* $(z_N^{*,\sigma})_x$ *and* $(z_D^{*,\sigma})_x$ *at* $x = x_1^*(\sigma)$.

In order to judge the sign of $\tau_N^{*,\sigma}$, the following observation is useful. Let $(\text{SLEP})_D$ denote the problem $(\text{SLEP})_b$ with replacing the boundary conditions $z^*_x = 0$ on ∂I by Dirichlet conditions $z^* = 0$ on ∂I. Then, we have the following.

LEMMA 2.4. $(\text{SLEP})_D$ *has a unique solution* $z_D^{*,\sigma}$ *with* $\tau^{*,\sigma} = 0$ *under* (2.57) (*see Fig.* 10).

Proof. By differentiating the SPS1 of the stationary problem (SP) with respect to x, we can see that $\lambda = 0$ is always an eigenvalue of (LP) under Dirichlet boundary conditions. In view of Remarks 1.5, 2.3 and 2.6, we see that all the above procedures to SLEP can be similarly done for Dirichlet boundary conditions, so that we obtain $(\mathrm{SLEP})_{\mathrm{D}}$. Therefore, $V_x^{*,\sigma}=\lim_{\varepsilon\downarrow 0} v(x, \varepsilon, \sigma)$ (see Theorem 1.1) becomes a solution of $(\mathrm{SLEP})_{\mathrm{D}}$ with $\tau^{*,\sigma}=0$, and from a normalization (2.57), $z_D^{*,\sigma}$ is given by

$$z_D^{*,\sigma}=\frac{V_x^{*,\sigma}}{V_x^{*,\sigma}(x_1^*(\sigma))}. \tag{2.58}$$

Now, a comparison of two solutions $(z_N^{*,\sigma}, \tau_N^{*,\sigma})$ and $(z_D^{*,\sigma}, 0)$ leads to the following (see Fig. 10).

LEMMA 2.5.

$$[(z_D^{*,\sigma})_x]<[(z_N^{*,\sigma})_x]<0. \tag{2.59}$$

Proof. By virtue of the negative definiteness of $\det^{*,\sigma}/f_u^{*,\sigma}$ and the positivity of $z_N^{*,\sigma}$ and $z_D^{*,\sigma}$, a simple comparison argument implies that

$$D_x^+ z_N^{*,\sigma}> D_x^+ z_D^{*,\sigma} \quad \text{and} \quad D_x^- z_N^{*,\sigma}< D_x^- z_D^{*,\sigma} \quad \text{at } x=x_1^*(\sigma),$$

where $D_x^+(D_x^-)$ denotes the right(left) x-derivative, which concludes (2.59).

In view of $(\mathrm{SLEP\text{-}2})_{\mathrm{b}}$, we can see from Lemma 2.5 that

$$\tau_N^{*,\sigma}<0 \quad \text{for } 0<\sigma<\sigma_0,$$

which shows the stability of SPS1. It is easy to see that $\tau_N^{*,\sigma}$ is a continuous function of σ for $0<\sigma<\sigma_0$, since $\det^{*,\sigma}/f_u^{*,\sigma}$ depends smoothly on σ in each subinterval and from (1.30).

Let us consider the limiting behavior of $\tau_N^{*,\sigma}$ as $\sigma\downarrow 0$. It is convenient to write $(\mathrm{SLEP})_{\mathrm{b}}$ in the following form.

$$z_{xx}^*+\sigma\frac{\det^{*,\sigma}}{f_u^{*,\sigma}}z^*=0 \quad \text{in each subinterval and } \langle z^*, \delta^*\rangle=1, \tag{2.60}$$

$$z_x^* \text{ (or } z^*)=0 \quad \text{on } \partial I \text{ and } z^* \text{ is continuous at } x=x_1^*(\sigma), \tag{2.61}$$

$$[z_x^*]=-\frac{\sigma c_1^* c_2^*}{\sigma\hat{\zeta}_0^{*,\sigma}-\tau^{*,\sigma}}. \tag{2.62}$$

We can see from the negativity of $\det^{*,\sigma}/f_u^{*,\sigma}$ and the boundary conditions that $z_N^{*,\sigma}$ and $z_D^{*,\sigma}$ satisfy $0\leqq z_N^{*,\sigma}, z_D^{*,\sigma}\leqq 1$. Therefore, noting that $|\det^{*,\sigma}/f_u^{*,\sigma}|<M$ for $0<\sigma<\sigma_0$, where M is independent of σ, we easily see from (2.60) that

$$(z_N^{*,\sigma})_{xx} \text{ and } (z_D^{*,\sigma})_{xx} \xrightarrow[\sigma\downarrow 0]{} 0 \quad \text{uniformly in each subinterval,}$$

$$(z_N^{*,\sigma})_x \xrightarrow[\sigma\downarrow 0]{} 0 \quad \text{uniformly in each subinterval.}$$

Using the boundary conditions, we can derive the following convergence:

$$z_N^{*,\sigma} \xrightarrow[\sigma\downarrow 0]{} 1 \quad \text{uniformly in } C^2\text{-sense in each subinterval,} \tag*{$(2.63)_{\mathrm{N}}$}$$

$$z_D^{*,\sigma} \xrightarrow[\sigma\downarrow 0]{} z_D^{*,0} \quad \text{uniformly in } C^2\text{-sense in each subinterval,} \tag*{$(2.63)_{\mathrm{D}}$}$$

where $z_D^{*,0}$ is a piecewise linear function as is shown in Fig. 10. Now, if we put $\psi=1$

in $(\mathrm{SLEP})_{\mathrm{a}}$, we obtain

$$\frac{c_1^* c_2^*}{\sigma\hat{\zeta}_0^{*,\sigma}-\tau_N^{*,\sigma}}+\left\langle\frac{\det^{*,\sigma}}{f_u^{*,\sigma}}z_N^{*,\sigma}, 1\right\rangle=0. \tag{2.64}$$

Therefore, using $(2.63)_{\mathrm{N}}$, we can see that $\tau_N^{*,\sigma}$ converges to $\tau_N^{*,0}$ as $\sigma\downarrow 0$, which is determined by the relation

$$-\frac{c_1^* c_2^*}{\tau_N^{*,0}}+\left\langle\frac{\det^{*,0}}{f_u^{*,0}}, 1\right\rangle=0. \tag{2.65}$$

On the other hand, starting from (2.44), we can derive the SLEP for the limiting case $\sigma=0$. It turns out after some computation that the SLEP for $\sigma=0$ is exactly the same as (2.65) (see also Nishiura and Fujii [19]). Thus, $\tau_N^{*,0}$ is a continuous function of σ up to $\sigma=0$, and $\tau_N^{*,0}$ is explicitly given by

$$\tau_N^{*,0}=\frac{c_1^* c_2^*}{\langle(\det^{*,0}/f_u^{*,0}), 1\rangle}. \tag{2.66}$$

We summarize the above results in the following theorem.

THEOREM 2.1. *The singular limit eigenvalue problem* (SLEP) *has a unique solution* $(z_N^{*,\sigma}, \tau_N^{*,\sigma})\in H_N^1(I)\times\mathbb{R}$ *under a normalization* (2.57) *such that*

(i) $z_N^{*,\sigma}$ *is smooth, strictly positive and convex in each of the subintervals* $[0, x_1^*(\sigma)]$ *and* $[x_1^*(\sigma), 1]$ (*see Fig.* 10),

(ii) $\tau_N^{*,\sigma}$ *is a continuous function of* σ, *and strictly negative for* $0\leqq\sigma<\sigma_0$. *Moreover,* $\tau_N^{*,0}=\lim_{\sigma\downarrow 0}\tau_N^{*,\sigma}$ *is given by* (2.66).

3. Justification of SLEP and the uniqueness of critical eigenvalue. In this section, we give a justification of SLEP and show the uniqueness and simplicity of the critical eigenvalue.

THEOREM 3.1. *There exists a positive constant* δ *such that* (2.5) *has a unique critical eigenvalue* $\lambda=\lambda_c(\varepsilon, \sigma)$ *in* B_δ *for small* ε. $\lambda_c(\varepsilon, \sigma)$ *is real, simple and takes the form* $\lambda_c(\varepsilon, \sigma)=\varepsilon\tau(\varepsilon, \sigma)$, *where* $\tau(\varepsilon, \sigma)$ *is a strictly negative continuous function for* $(\varepsilon, \sigma)\in\bar{\Omega}_{\varepsilon_0,\sigma_0}$. *Moreover,* $\tau(0, \sigma)$ *is just equal to* $\tau_N^{*,\sigma}$ *determined by* SLEP *in Theorem* 2.1.

This result combined with Proposition 2.1 guarantees that the negativity of $\tau_N^{*,\sigma}$ in Theorem 2.1 implies the stability of SPS1 for small $\varepsilon>0$.

The strategy to show Theorem 3.1 is to reduce the problem of finding critical eigenvalues of (2.5) to solve the algebra-like equation for λ by applying the inverse operator $K^{\varepsilon,\sigma,\lambda}$ (see Lemma 3.1) to (2.5).

Recalling Lemma 2.3, it is convenient to consider (2.5) in a weak form (2.56). First, we will define the operator $K^{\varepsilon,\sigma,\lambda}$, which is, roughly speaking, equal to

$$\left(-\frac{1}{\sigma}\frac{d^2}{dx^2}-g_u^{\varepsilon,\sigma}(L^{\varepsilon,\sigma}-\lambda)^{\dagger}(-f_v^{\varepsilon,\sigma}\cdot)-g_v^{\varepsilon,\sigma}\cdot+\lambda\cdot\right)^{-1}.$$

Let us introduce the bilinear form $\hat{B}^{\varepsilon,\sigma,\lambda}$ by

$$\hat{B}^{\varepsilon,\sigma,\lambda}(z^1, z^2)=\frac{1}{\sigma}\langle z_x^1, z_x^2\rangle-\langle\{g_u^{\varepsilon,\sigma}(L^{\varepsilon,\sigma}-\lambda)^{\dagger}(-f_v^{\varepsilon,\sigma}\cdot)+g_v^{\varepsilon,\sigma}-\lambda\}z^1, z^2\rangle \tag{3.1}$$

for any $z^i\in H_N^1(I)$ $(i=1, 2)$, which is equal to $B^{\varepsilon,\sigma,\lambda}$ (see (2.26)) after removing the second term of $B^{\varepsilon.\sigma,\lambda}$. For a given $h\in H^{-1}(I)$, we consider the equation for $z\in H_N^1(I)$:

$$\hat{B}^{\varepsilon,\sigma,\lambda}(z, \psi)=\langle h, \psi\rangle \quad \text{for any } \psi\in H_N^1(I). \tag{3.2}$$

If z is uniquely determined, we can define the mapping $K^{\varepsilon,\sigma,\lambda}$ as

$$K^{\varepsilon,\sigma,\lambda}h = z; \qquad H^{-1}(I) \to H^1_N(I). \tag{3.3}$$

We have the following result for $K^{\varepsilon,\sigma,\lambda}$.

LEMMA 3.1. *For any $\sigma_0(<\sigma_1^*)$, there exist positive constants ε_0 and δ_0 such that $K^{\varepsilon,\sigma,\lambda}$ is a well-defined uniformly bounded mapping from $H^{-1}(I)$ to $H^1_N(I)$ for $0 \leqq \varepsilon < \varepsilon_0$, $0 \leqq \sigma < \sigma_0$, and $\lambda \in \mathring{B}_{\delta_0}$, and depends continuously on (ε, σ) and analytically on λ in operator norm sense, respectively. Moreover, $K^{\varepsilon,0,\lambda}$ is the operator which maps h $(\in H^{-1}(I))$ to the constant function c_z defined by*

$$c_z = -\langle h, 1\rangle / \langle \{g_u^{\varepsilon,0}(L^{\varepsilon,0}-\lambda)^\dagger(-f_v^{\varepsilon,0}\,\cdot) + g_v^{\varepsilon,0} - \lambda\}1, 1\rangle. \tag{3.4}$$

Proof. First we consider the case where σ is positive. Using the similar arguments to obtain (2.28) and (2.29) in § 2, we can see that, for a given σ_0 $(<\sigma_1^*)$, there exist positive constants ε_0 and δ_0 such that

$$|\hat{B}^{\varepsilon,\sigma,\lambda}(z^1, z^2)| \leqq \left(\frac{1}{\sigma} + c_2 + |\lambda|\right)\|z^1\|_{H^1}\|z^2\|_{H^1} \tag{3.5}$$

and

$$|\hat{B}^{\varepsilon,\sigma,\lambda}(z, z)| \geqq \hat{c}_3\|z\|^2_{H^1} \tag{3.6}$$

hold for $0 \leqq \varepsilon < \varepsilon_0$, $0 < \sigma < \sigma_0$ and $\lambda \in \mathring{B}_{\delta_0}$, where c_2 and $\hat{c}_3$ are positive constants which are independent of ε, σ and λ. Note that ε_0 can be taken uniformly for $\lambda \in \mathring{B}_{\delta_0}$, since $\hat{B}^{\varepsilon,\sigma,\lambda}$ lacks the second term of (2.26). Therefore, it follows from the Lax-Milgram theorem that, for a given $h \in H^{-1}(I)$, there exists a unique $z \in H^1_N(I)$ such that

$$\hat{B}^{\varepsilon,\sigma,\lambda}(z, \psi) = \langle h, \psi\rangle \quad \text{for any } \psi \in H^1_N(I). \tag{3.7}$$

Thus, the generalized inverse operator $K^{\varepsilon,\sigma,\lambda}$

$$z = K^{\varepsilon,\sigma,\lambda}h; \quad H^{-1}(I) \to H^1_N(I)$$

is well defined, and it holds from (3.6) and (3.7) that

$$\|K^{\varepsilon,\sigma,\lambda}\| \leqq \hat{c}_3^{-1} \quad \text{for } 0 \leqq \varepsilon < \varepsilon_0, \quad 0 < \sigma < \sigma_0 \quad \text{and} \quad \lambda \in \mathring{B}_{\delta_0}, \tag{3.8}$$

where $\|K^{\varepsilon,\sigma,\lambda}\|$ denotes the operator norm of $K^{\varepsilon,\sigma,\lambda}$, i.e., $K^{\varepsilon,\sigma,\lambda}$ is uniformly bounded in this parameter region.

Next, we consider the parametric dependence of $K^{\varepsilon,\sigma,\lambda}$ on ε, σ and λ. From the definition of $K^{\varepsilon,\sigma,\lambda}$, we have

$$\hat{B}^{\varepsilon,\sigma,\lambda}(K^{\varepsilon,\sigma,\lambda}h, \psi) = \langle h, \psi\rangle = \hat{B}^{\varepsilon',\sigma',\lambda'}(K^{\varepsilon',\sigma',\lambda'}h, \psi)$$

for any $h \in H^{-1}(I)$ and $\psi \in H^1_N(I)$. Using this, we have the following equality

$$\begin{aligned} &\hat{B}^{\varepsilon,\sigma,\lambda}(K^{\varepsilon,\sigma,\lambda}h, \psi) - \hat{B}^{\varepsilon,\sigma,\lambda}(K^{\varepsilon',\sigma',\lambda'}h, \psi) \\ &\quad = \hat{B}^{\varepsilon',\sigma',\lambda'}(K^{\varepsilon',\sigma',\lambda'}h, \psi) - \hat{B}^{\varepsilon,\sigma,\lambda}(K^{\varepsilon',\sigma',\lambda'}h, \psi). \end{aligned} \tag{3.9}$$

The left-hand side of (3.9) is equal to

$$\hat{B}^{\varepsilon,\sigma,\lambda}(\{K^{\varepsilon,\sigma,\lambda} - K^{\varepsilon',\sigma',\lambda'}\}h, \psi).$$

Let $\psi = (K^{\varepsilon,\sigma,\lambda} - K^{\varepsilon',\sigma',\lambda'})h$, then, using the inequality (3.6), we obtain

$$|\hat{B}^{\varepsilon,\sigma,\lambda}(\{K^{\varepsilon,\sigma,\lambda} - K^{\varepsilon',\sigma',\lambda'}\}h, \{K^{\varepsilon,\sigma,\lambda} - K^{\varepsilon',\sigma',\lambda'}\}h)| \geqq \hat{c}_3\|(K^{\varepsilon,\sigma,\lambda} - K^{\varepsilon',\sigma',\lambda'})h\|^2_{H^1}. \tag{3.10}$$

On the other hand, the right-hand side of (3.9) is estimated from above for $\psi = (K^{\varepsilon,\sigma,\lambda} - K^{\varepsilon',\sigma',\lambda'})h$ as follows:

$$
\begin{aligned}
&|\text{the right-hand side of } (3.9)|\\
&\quad \leqq \left[\left| \frac{1}{\sigma} - \frac{1}{\sigma'} \right| \| K^{\varepsilon',\sigma',\lambda'} h \|_{H^1} \right.\\
&\qquad \left. + \| \{ (g_u^{\varepsilon',\sigma'} (L^{\varepsilon',\sigma'} - \lambda')^{\dagger} (-f_v^{\varepsilon',\sigma'} \cdot) + g_v^{\varepsilon',\sigma'} - \lambda') - (\text{without } ') \} K^{\varepsilon',\sigma',\lambda'} h \|_{L^2} \right]\\
&\qquad \times \| (K^{\varepsilon,\sigma,\lambda} - K^{\varepsilon',\sigma',\lambda'}) h \|_{H^1}.
\end{aligned}
\tag{3.11}
$$

Combining (3.10) with (3.11), we obtain the following inequality:

$$
\begin{aligned}
\| (K^{\varepsilon,\sigma,\lambda} - K^{\varepsilon',\sigma',\lambda'}) h \|_{H^1} &\leqq \hat{c}_3^{-1} \left| \frac{1}{\sigma} - \frac{1}{\sigma'} \right| \| K^{\varepsilon',\sigma',\lambda'} h \|_{H^1}\\
&\quad + \| \{ (g_u^{\varepsilon',\sigma'} (L^{\varepsilon',\sigma'} - \lambda')^{\dagger} (-f_v^{\varepsilon',\sigma'} \cdot) + g_v^{\varepsilon',\sigma'} - \lambda') - (\text{without } ') \} K^{\varepsilon',\sigma',\lambda'} h \|_{L^2}.
\end{aligned}
\tag{3.12}
$$

Note that when $\|h\|_{H^{-1}} \leqq 1$, we have $\|K^{\varepsilon',\sigma',\lambda'} h\|_{H^1} \leqq \hat{c}_3^{-1}$ from (3.8). Recalling that $(L^{\varepsilon,\sigma} - \lambda)^{\dagger}(-f_v^{\varepsilon,\sigma} \cdot)$ converges to $(-f_v^{*,\sigma} \cdot)/(f_u^{*,\sigma} - \lambda)$ as $\varepsilon \downarrow 0$ uniformly on a bounded set in $H^1(I)$ (see Lemma 2.2), L^2-continuity of the coefficients with respect to parameters up to $\varepsilon = 0$, and the resolvent formula in Remark 2.2, we can see from (3.12) that $K^{\varepsilon,\sigma,\lambda}$ depends continuously on (ε, σ), and analytically on λ in operator norm sense for $0 \leqq \varepsilon < \varepsilon_0$, $0 < \sigma < \sigma_0$ and $\lambda \in B_{\delta_0}$, respectively.

Finally, we consider the limiting behavior of $K^{\varepsilon,\sigma,\lambda}$ as $\sigma \downarrow 0$. Although the boundedness of $\hat{B}^{\varepsilon,\sigma,\lambda}$ breaks down in this limit (see (3.5)), we can recover it by dividing the solution space into the average free space and the constant function space as follows,

$$
z = c_z + \hat{z} \quad \text{and} \quad h = c_h + \hat{h},
\tag{3.13}
$$

where $c_z = \langle z, 1 \rangle$, $c_h = \langle h, 1 \rangle$ and $\hat{z}$ and $\hat{h}$ are average free parts of z and h, respectively. Let $\hat{H}_N^1(I)$ denote the average free space, namely,

$$
\hat{H}_N^1(I) = \{ \hat{\psi} \in H_N^1(I) \,|\, \langle \hat{\psi}, 1 \rangle = 0 \}.
$$

Substituting (3.13) into (3.2), and multiplying σ on both sides, we obtain for $\psi = \hat{\psi} \in \hat{H}_N^1(I)$,

$$
\begin{aligned}
&\langle \hat{z}_x, \hat{\psi}_x \rangle - \sigma \langle \{ g_u^{\varepsilon,\sigma} (L^{\varepsilon,\sigma} - \lambda)^{\dagger} (-f_v^{\varepsilon,\sigma} \cdot) + g_v^{\varepsilon,\sigma} + \lambda \} \hat{z}, \hat{\psi} \rangle\\
&\qquad = \sigma \langle \{ g_u^{\varepsilon,\sigma} (L^{\varepsilon,\sigma} - \lambda)^{\dagger} (-f_v^{\varepsilon,\sigma} \cdot) + g_v^{\varepsilon,\sigma} + \lambda \} c_z + \hat{h}, \hat{\psi} \rangle.
\end{aligned}
\tag{3.14}
$$

Noting that $\langle \hat{\psi}_x, \hat{\psi}_x \rangle$ is equivalent to H^1-norm in $\hat{H}_N^1$-space, we see that there exist a $\hat{\sigma}(>0)$ such that the left side of (3.14) is a positive bounded bilinear form for $0 \leqq \sigma < \hat{\sigma}$. Thus, we can solve (3.14) with respect to $\hat{z}$ as a function of c_z and $\hat{h}$ as $\hat{z} = \hat{z}(c_z, \hat{h}) \in \hat{H}_N^1(I)$ with the aid of the Lax-Milgram theorem. Furthermore, $\hat{z}$ satisfies

$$
\| \hat{z} \|_{\hat{H}_N^1} \leqq C \sigma (c_z + \| \hat{h} \|_{H^{-1}}),
\tag{3.15}
$$

where C is a positive constant independent of ε and σ. On the other hand, if we set $\psi = 1$ in (3.2), we have

$$
-\langle \{ g_u^{\varepsilon,\sigma} (L^{\varepsilon,\sigma} - \lambda)^{\dagger} (-f_v^{\varepsilon,\sigma} \cdot) + g_v^{\varepsilon,\sigma} - \lambda \} (c_z + \hat{z}), 1 \rangle = \langle c_h, 1 \rangle.
\tag{3.16}
$$

Substituting $\hat{z} = \hat{z}(c_z, \hat{h})$ into (3.16), we have an equation for c_z. Note that the coefficient of c_z in the left-hand side of (3.16) is strictly negative by virtue of Lemma 2.2, (A.3) and (A.4b) for $0 \leqq \varepsilon < \varepsilon_0$, $0 \leqq \sigma < \sigma_0$, and $\lambda \in B_{\delta_0}$. Here, we take ε_0 and δ_0 smaller, if necessary. In view of (3.15), we can see that (3.16) is uniquely solvable with respect to c_z for small $\hat{\sigma}$ as

$$c_z = c_z^{\varepsilon,\sigma,\lambda}(h). \tag{3.17}$$

Thus, $z = K^{\varepsilon,\sigma,\lambda} h$ takes the following form

$$z = c_z^{\varepsilon,\sigma,\lambda}(h) + \hat{z}(c_z^{\varepsilon,\sigma,\lambda}(h), \hat{h}) \tag{3.18}$$

for $0 \leqq \varepsilon < \varepsilon_0$, $0 \leqq \sigma < \hat{\sigma}$ and $\lambda \in B_{\delta_0}$.

Integrating the results from (3.15) to (3.18), we can see that

$$K^{\varepsilon,\sigma,\lambda} \xrightarrow[\sigma \downarrow 0]{} K^{\varepsilon,0,\lambda} \quad \text{in operator norm}$$

uniformly for $0 \leqq \varepsilon < \varepsilon_0$ and $\lambda \in B_{\delta_0}$, where $K^{\varepsilon,0,\lambda}$ is the operator which maps $h \in H^{-1}(I)$ to the constant function c_z defined by

$$c_z = -\langle h, 1\rangle / \langle \{ g_u^{\varepsilon,0}(L^{\varepsilon,0} - \lambda)^{\dagger}(-f_v^{\varepsilon,0} \cdot) + g_v^{\varepsilon,0} - \lambda \} \cdot 1, 1 \rangle, \tag{3.19}$$

which completes the proof of Lemma 3.1.

Remark 3.1. When $h \in L^2(I)$, $K^{\varepsilon,\sigma,\lambda} h$ belongs to $H^2(I) \cap H_N^1(I)$. Moreover, for positive ε, when h is smooth, so is $K^{\varepsilon,\sigma,\lambda}\ h$.

Now, we will derive a scalar equation for λ, which is equivalent to (2.56). Applying the operator $K^{\varepsilon,\sigma,\lambda}$ in Lemma 3.1 to (2.56), and dividing both denominator and numerator by ε, we have

$$z = \frac{\langle z, -f_v^{\varepsilon,\sigma} \phi_0^{\varepsilon,\sigma} / \sqrt{\varepsilon} \rangle}{(\zeta_0^{\varepsilon,\sigma} - \lambda)/\varepsilon} K^{\varepsilon,\sigma,\lambda}(g_u^{\varepsilon,\sigma} \phi_0^{\varepsilon,\sigma} / \sqrt{\varepsilon}), \tag{3.20}$$

which implies that z is a scalar multiple of $K^{\varepsilon,\sigma,\lambda}(g_u^{\varepsilon,\sigma} \phi_0^{\varepsilon,\sigma}/\sqrt{\varepsilon})$, namely, $z = \alpha K^{\varepsilon,\sigma,\lambda}(g_u^{\varepsilon,\sigma} \phi_0^{\varepsilon,\sigma}/\sqrt{\varepsilon})$ with α being a scalar constant. Substituting this into (3.20), we can see that (3.20) has a nontrivial solution z if and only if λ satisfies the following equation,

$$\left\langle K^{\varepsilon,\sigma,\lambda}\left(\frac{g_u^{\varepsilon,\sigma} \phi_0^{\varepsilon,\sigma}}{\sqrt{\varepsilon}} \right), \frac{-f_v^{\varepsilon,\sigma} \phi_0^{\varepsilon,\sigma}}{\sqrt{\varepsilon}} \right\rangle = \frac{\zeta_0^{\varepsilon,\sigma} - \lambda}{\varepsilon}. \tag{3.21}$$

It follows from Lemma 2.3 and Lemma 3.1 that the left-hand side of (3.21) is continuous with respect to (ε, σ), and analytic with respect to λ for $0 \leqq \varepsilon < \varepsilon_0$, $0 \leqq \sigma < \sigma_0$ and $\lambda \in B_{\delta_0}$. Therefore, recalling the asymptotic form of $\zeta_0^{\varepsilon,\sigma}$ (see (1.28) in Lemma 1.4), λ must be $O(\varepsilon)$ in order that (3.21) has a solution $\lambda = \lambda_c(\varepsilon, \sigma)$ with $\lambda_c(0, \sigma) = 0$. Hence, without loss of generality, we can set

$$\lambda = \varepsilon \tau(\varepsilon, \sigma), \tag{3.22}$$

where τ is a bounded continuous function for $(\varepsilon, \sigma) \in \bar{\Omega}_{\varepsilon_0,\sigma_0}$. Substituting (3.22) into (3.21), it is easily seen that (3.21) is equivalent to the following scalar equation for τ:

$$\begin{aligned} \mathscr{F}(\varepsilon, \sigma, \tau) = \tau - \sigma \tilde{\zeta}_0(\varepsilon, \sigma) - \hat{\text{Exp}}\,(\varepsilon, \sigma) \\ + \left\langle K^{\varepsilon,\sigma,\varepsilon\tau}\left(\frac{g_u^{\varepsilon,\sigma} \phi_0^{\varepsilon,\sigma}}{\sqrt{\varepsilon}} \right), \frac{-f_v^{\varepsilon,\sigma} \phi_0^{\varepsilon,\sigma}}{\sqrt{\varepsilon}} \right\rangle = 0. \end{aligned} \tag{3.23}$$

When $\varepsilon = 0$, there exists a unique solution $\tau_N^{*,\sigma}$ of $\mathscr{F}(0, \sigma, \tau) = 0$ for any σ with $0 \leqq \sigma < \sigma_0$, namely

$$\tau_N^{*,\sigma} = \sigma \hat{\zeta}_0^{*,\sigma} - c_1^* c_2^* \langle K^{0,\sigma,0} \delta^*, \delta^* \rangle. \tag{3.24}$$

Moreover, in view of (3.23), we can see from the uniform continuity with respect to σ that, for any $\kappa_0 > 0$, there exists an $\varepsilon_{\kappa_0} > 0$ such that, if $(\varepsilon, \sigma, \tau)$ is a solution of (3.23) with $0 \leqq \varepsilon < \varepsilon_{\kappa_0}$ and $0 \leqq \sigma < \sigma_0$ then τ must belong to the κ_0-neighbourhood of $\tau_N^{*,\sigma}$ in the complex plane. Recalling (SLEP)$_a$ in § 2, (2.57) and the definition of $K^{\varepsilon,\sigma,\lambda}$, $\tau_N^{*,\sigma}$ defined by (3.24) is just equal to $\tau_N^{*,\sigma}$ given in Theorem 2.1. On the other hand, since $\mathscr{F}(0, \sigma, \tau_N^{*,\sigma}) = 0$ and $(\partial\mathscr{F}/\partial\tau)(0, \sigma, \tau_N^{*,\sigma}) = 1$, we can apply the implicit function theorem to (3.23) and obtain a unique solution $\tau = \tau_c(\varepsilon, \sigma)$ with $\tau_c(0, \sigma) = \tau_N^{*,\sigma}$ in the appropriate region $0 \leqq \varepsilon < \varepsilon^*$, $0 \leqq \sigma < \sigma_0$ and $|\tau - \tau_N^{*,\sigma}| < \kappa^*$, where ε^* and κ^* do not depend on σ. If we take κ_0 to be smaller than κ^* and ε_0 to be $\min\{\varepsilon_{\kappa_0}, \varepsilon^*\}$, we can see from the above arguments that $\tau = \tau_c(\varepsilon, \sigma)$ is a unique solution of (3.23) for $0 \leqq \varepsilon < \varepsilon_0$ and $0 \leqq \sigma < \sigma_0$, which implies that

$$\lambda = \lambda_c(\varepsilon, \sigma) \overset{\text{def}}{\equiv} \varepsilon\tau_c(\varepsilon, \sigma) \tag{3.25}$$

is a unique solution of (3.21) for $0 \leqq \varepsilon < \varepsilon_0$, $0 \leqq \sigma < \sigma_0$ and $\lambda \in B_\delta$, where $0 < \delta \leqq \varepsilon_0\kappa_0$. Noting that $\mathscr{F}$ is a real operator, it is clear from the uniqueness that $\tau_c(\varepsilon, \sigma)$ is real.

Finally, we show the simplicity of the critical eigenvalue (3.25). Apparently, the geometric multiplicity of $\lambda_c(\varepsilon, \sigma)$ is equal to one, since the z-component of the eigenvector ${}^t(w_c, z_c)$ is uniquely determined by $z_c = K^{\varepsilon,\sigma,\varepsilon\tau_c(\varepsilon,\sigma)}(g_u^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma})$ up to a constant multiple, and so is the w-component through $w_c = (L^{\varepsilon,\sigma} - \lambda_c(\varepsilon, \sigma))^{-1}(-f_v^{\varepsilon,\sigma} z_c)$.

In order to show that the algebraic multiplicity is also equal to one, we introduce the adjoint operator of $\mathscr{L}^{\varepsilon,\sigma}$ (see (LP)) defined by

$$(\mathscr{L}^{\varepsilon,\sigma})^*\begin{pmatrix} w^* \\ z^* \end{pmatrix} = \begin{bmatrix} \varepsilon^2\dfrac{d^2}{dx^2} + f_u^{\varepsilon,\sigma} & g_u^{\varepsilon,\sigma} \\ f_v^{\varepsilon,\sigma} & \dfrac{1}{\sigma}\dfrac{d^2}{dx^2} + g_v^{\varepsilon,\sigma} \end{bmatrix}\begin{pmatrix} w^* \\ z^* \end{pmatrix} = \lambda^*\begin{pmatrix} w^* \\ z^* \end{pmatrix}, \tag{3.26}$$

with $\mathscr{D}((\mathscr{L}^{\varepsilon,\sigma})^*) = (H^2(I) \cap H_N^1(I))^2 (\subset (L^2(I))^2)$ into $(L^2(I))^2$. It is not difficult to verify that $(\mathscr{L}^{\varepsilon,\sigma})^*$ has the same isolated eigenvalue $\lambda^* = \lambda_c(\varepsilon, \sigma)$ with geometric multiplicity being equal to one. The associated eigenfunction is given by ${}^t(w_c^*, z_c^*) = {}^t((L^{\varepsilon,\sigma} - \lambda_c(\varepsilon, \sigma))^{-1}\{-g_u^{\varepsilon,\sigma}(K^{\varepsilon,\sigma,\lambda_c})^*\ (f_v^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma})\}, (K^{\varepsilon,\sigma,\lambda_c})^*(f_v^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma}))$, where $(K^{\varepsilon,\sigma,\lambda_c})^*$ is the generalized inverse from $H^{-1}(I)$ to $H_N^1(I)$ analogously defined as $K^{\varepsilon,\sigma,\lambda}$. From the closed range theorem, we have $(\mathscr{N}(\mathscr{L}^{\varepsilon,\sigma} - \lambda_c)^*)^\perp = \mathscr{R}(\mathscr{L}^{\varepsilon,\sigma} - \lambda_c)$, where $\mathscr{N}$ and $\mathscr{R}$ denotes the nullspace and range, respectively. Therefore, in order to show the simplicity of $\lambda_c(\varepsilon, \sigma)$, it suffices to prove

$$\left\langle\!\!\left\langle \begin{pmatrix} w_c \\ z_c \end{pmatrix}, \begin{pmatrix} w_c^* \\ z_c^* \end{pmatrix} \right\rangle\!\!\right\rangle \neq 0, \tag{3.27}$$

where $\langle\!\langle \cdot, \cdot \rangle\!\rangle$ denotes the inner product in $(L^2(I))^2$-space. Let us compute the left-hand side of (3.27). Using the eigenfunction expansion of $L^{\varepsilon,\sigma}$, we rewrite w_c as

$$\begin{aligned} w_c &= (L^{\varepsilon,\sigma} - \lambda_c)^{-1}\{-f_v^{\varepsilon,\sigma}K^{\varepsilon,\sigma,\lambda_c}(g_u^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma})\} \\ &= \frac{\langle -f_v^{\varepsilon,\sigma}K^{\varepsilon,\sigma,\lambda_c}(g_u^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma}), \phi_0^{\varepsilon,\sigma}\rangle}{\zeta_0^{\varepsilon,\sigma} - \lambda_c}\phi_0^{\varepsilon,\sigma} + (L^{\varepsilon,\sigma} - \lambda_c)^\dagger\{\cdot\} \\ &= \frac{\langle K^{\varepsilon,\sigma,\lambda_c}(g_u^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma}/\sqrt{\varepsilon}), -f_v^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma}/\sqrt{\varepsilon}\rangle}{\sigma\hat{\zeta}_0(\varepsilon, \sigma) - \tau_c}\phi_0^{\varepsilon,\sigma} + (L^{\varepsilon,\sigma} - \lambda_c)\dagger\{\cdot\}. \end{aligned} \tag{3.28}$$

Since $\|g_u^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma}\|_{H^{-1}} = O(\sqrt{\varepsilon})$ from Corollary 1.3, it follows from Lemma 3.1 that $\|K^{\varepsilon,\sigma,\lambda_c}(g_u^{\varepsilon,\sigma}\phi_0^{\varepsilon,\sigma})\|_{H^1} = O(\sqrt{\varepsilon})$, which shows that the second term of (3.28) is of $O(\sqrt{\varepsilon})$ due to the L^2-uniform boundedness of $(L^{\varepsilon,\sigma} - \lambda_c)^\dagger$ (see (2.7)). On the other hand, the first term of (3.28) is just equal to $\phi_0^{\varepsilon,\sigma}$, since $\lambda_c = \varepsilon\tau_c$ is a solution of (3.21). Therefore, the principal part of w_c for small ε is given by $\phi_0^{\varepsilon,\sigma}$, namely,

$$w_c = \phi_0^{\varepsilon,\sigma} + O(\sqrt{\varepsilon}) \quad \text{as } \varepsilon \downarrow 0 \text{ in } L^2\text{-sense.} \tag{3.29}$$

Note that the above computation also shows that

$$z_c = O(\sqrt{\varepsilon}) \quad \text{as } \varepsilon \downarrow 0 \text{ in } L^2\text{-sense.} \tag{3.30}$$

Similarly, we have the analogous result for the adjoint eigenfunction;

$$\left.\begin{array}{l} w_c^* = \phi_0^{\varepsilon,\sigma} + O(\sqrt{\varepsilon}) \\ z_c^* = O(\sqrt{\varepsilon}) \end{array}\right. \quad \text{as } \varepsilon \downarrow 0 \text{ in } L^2\text{-sense.} \tag{3.31}$$

Thus, using (3.29)-(3.31), we can see that the inner product (3.27) becomes

$$\left\langle\!\!\left\langle \begin{pmatrix} w_c \\ z_c \end{pmatrix}, \begin{pmatrix} w_c^* \\ z_c^* \end{pmatrix} \right\rangle\!\!\right\rangle = 1 + O(\varepsilon) \quad \text{for small } \varepsilon,$$

which concludes the simplicity of $\lambda_c(\varepsilon, \sigma)$ for small ε and finishes the proof of Theorem 3.1.

4. Concluding remarks—instability theorems. As mentioned in the Introduction, concerning the stability of SPS, and in particular that of mode 1 patterns, it has been widely believed that they are stable so long as they can be constructed. Also, "numerical evidences leave little doubt that the pattern is quite robust" (according to Conway [3]).

So far, our study has been concentrated on the stability of SPS of mode 1, from the viewpoint that "under what conditions SPS1 are stable solutions?" Our Main Theorem says that the above *belief* is *partially* correct, that we needed (A.5) as the stability condition of SPS1, together with the existence conditions (A.1)-(A.4).

We have an important remark here. If the direction of the inequality in (A.5) is reversed, then an instability theorem follows for SPS of mode 1.

Another possibility of instability is that the sign of dJ/dv at v^* is reversed in (A.2). Of course, this means a violation of our ⟨Existence Conditions⟩. However, it is not difficult to see that (i) SPS can still be constructed under such a reversed condition on dJ/dv at least for small σ, and that (ii) there can exist a nonlinearity satisfying the reversed condition on dJ/dv, without destroying the other existence conditions. In fact, we can construct a function $f(u, v)$ by an appropriate deformation around the central branch $h_0(v)$ so that $J(v)$ has three zeros at $v = \underline{v}^*$, v^*, and $\bar{v}^*$ as in Fig. 11, and $dJ/dv > (<)0$ at $v = v^*$ ($\underline{v}^*$ and $\bar{v}^*$), respectively. We remark that the mathematical structures of these two instabilities are not the same, namely, *the noncritical instability* for the first case and *the critical case* for the second case. More precisely, the instability occurs in two different ways as follows. Hereafter, let us fix σ to be an appropriate positive constant.

(1) Instability of noncritical type. We shall show that there exists a *real positive eigenvalue* of (LP) for small ε, if g_v satisfies the following:

$$\begin{gathered} \min_{(u,v)\in R_+\cup R_-} \{f_u + g_v\} > 0, \\ \min_{(u,v)\in R_+\cup R_-} \{(f_u + g_v)^2 - 4(f_u g_v - f_v g_u)\} > 0, \\ \min_{x\in I} \bar{\lambda}(x) > \max_{x\in I} \underline{\lambda}(x), \end{gathered} \tag{4.1}$$

where $\bar{\lambda}(x)$ and $\underline{\lambda}(x)$ ($\underline{\lambda}(x) < \bar{\lambda}(x)$) are two real positive solutions of

$$\lambda^2 - \{f_u^{*,\sigma}(x) + g_v^{*,\sigma}(x)\}\lambda + \det{}^{*,\sigma}(x) = 0.$$

Recall that $f_u^{*,\sigma}(x) = f_u(U^{*,\sigma}(x), V^{*,\sigma}(x))$ and so on.

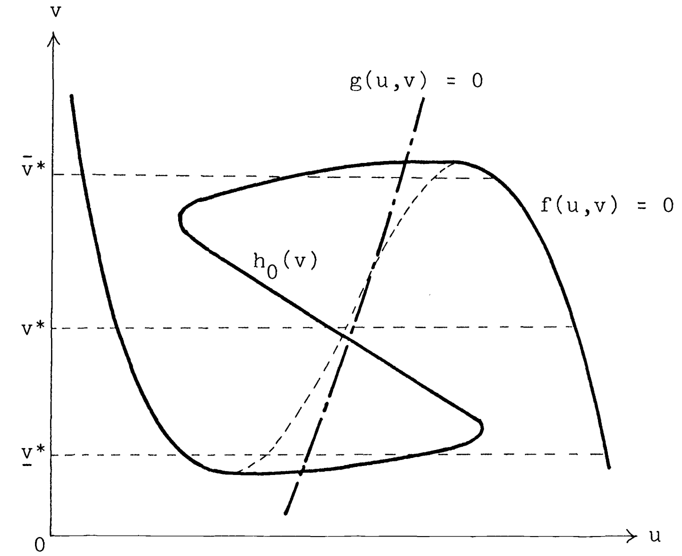

FIG. 11. *An example of the nonlinearity satisfying* $(dJ/dv)>0$ *at* $v=v^*$.

First, let us consider the following minimization problem for real λ associated with (2.33):

$$m(\sigma,\lambda)\overset{\text{def}}{=}\min_{z\in H^2(I)\cap H^1_N(I),\|z\|_{L^2}=1} B^{*,\sigma,\lambda}. \tag{4.2}$$

Suppose $m(\sigma,\lambda)$ is equal to zero and attained by $(z,\lambda)=(z^*,\lambda^*)$, then (z^*,λ^*) is a solution of the eigenvalue problem

$$\frac{1}{\sigma}z_{xx}-\frac{\det^{*,\sigma}-g_v^{*,\sigma}}{\lambda-f_u^{*,\sigma}}z=\lambda z. \tag{4.3}$$

Under the conditions (4.1), we can find a $\lambda_1>0$ such that

$$\frac{\lambda_1^2-(f_u^{*,\sigma}+g_v^{*,\sigma})\lambda_1+\det^{*,\sigma}}{\lambda_1-f_u^{*,\sigma}}<0 \quad \text{for any } x\in I,$$

while, for large $\lambda_2>0$, we have

$$\frac{\lambda_2^2-(f_u^{*,\sigma}+g_v^{*,\sigma})\lambda_2+\det^{*\sigma}}{\lambda_2-f_u^{*,\sigma}}>0 \quad \text{for any } x\in I.$$

Let $z=1$ in (4.2), we see that $m(\sigma,\lambda_1)<0$. On the other hand, it is clear that $m(\sigma,\lambda_2)>0$. Therefore, by using a continuity argument, it is easily seen that there exists a λ_0^* such that $m(\sigma,\lambda_0^*)=0$ with $0<\lambda_1<\lambda_0^*<\lambda_2$. This implies the existence of the real positive eigenvalue of (4.3). Applying a regular perturbation technique to (2.5) with the aid of $K^{\varepsilon,\sigma,\lambda}$ in Lemma 3.1, it is not difficult to obtain a real positive eigenvalue $\lambda=\lambda^*(\varepsilon,\sigma)$ with $\lambda^*(0,\sigma)=\lambda_0^*$ of (LP) for $\varepsilon>0$. We leave the details to the reader.

(2) Instability of critical type. If $dJ/dv(v^*)$ changes its sign from negative to positive, two important quantities also change signs. The first one is $\hat{\zeta}_0^{*,\sigma}$ (see (1.30)), which changes sign from positive to negative. The second one is the coefficient c_1^* of δ^* in Lemma 2.3, which becomes positive when $dJ/dv(v^*)>0$. In view of SLEP in § 2, we see that SLEP is invariant under the transformation from $(c_1^*, \hat{\zeta}_0^{*,\sigma}, \tau^{*,\sigma})$ to

$(-c_1^*, -\hat{\zeta}_0^{*,\sigma}, -\tau^{*,\sigma})$. Therefore, $\tau^{*,\sigma}$ takes a positive value when $dJ/dv(v^*) > 0$, which implies the existence of *the unstable real critical eigenvalue* which tends to zero from the positive side with $O(\varepsilon)$.

Thus, we have shown the following proposition.

PROPOSITION 4.1. *If the sign of* $g_v|_{R_+ \cup R_-}$ *(Stability Assumption* (A.5)) *or* $dJ/dv(v^*)$ ((A.2)) *is reversed,* SPS1 $U^{\varepsilon,\sigma}$ *becomes unstable in the following sense.*

(i) *If* $g_v > 0$ *on* $R_+ \cup R_-$ *and satisfies* (4.1), *then there exists a real eigenvalue* $\lambda^*(\varepsilon, \sigma)$, *which is strictly positive for small* ε.

(ii) *If* $dJ/dv(v^*) > 0$, *the unique critical eigenvalue* $\lambda_c(\varepsilon, \sigma)$, *which is real and simple, approaches to zero from the positive side with* $O(\varepsilon)$ *as* $\varepsilon \downarrow 0$, *namely,* $\lambda_c(\varepsilon, \sigma) \simeq \tau^{*,\sigma}\varepsilon(\tau^{*,\sigma} > 0)$.

Remark 4.1. For the limiting case $\sigma = 0$, the proof for the instability of critical type is also valid. While, for noncritical type, the same instability as in Proposition 4.1 occurs under weaker conditions than (4.1), namely,

$$\int_I (f_u^{*,0} + g_v^{*,0})\, dx > 0,$$

$$\left\{\int_I (f_u^{*,0} + g_v^{*,0})\, dx\right\}^2 - 4\int_I \det{}^{*,0}\, dx > 0.$$

This can be proved by making use of (2.44) in an analogous way.

Appendix 1. We show the outline of the construction of SPS1 and its parametric dependency in Theorem 1.1. The method here is essentially a modified version of Mimura, Tabata and Hosono [15]. However, this improves the original version at the three points:

(i) The σ-family of SPS1 is uniformly constructed with respect to σ up to $\sigma = 0$. (Note that the method in [15] breaks down as σ tends to 0.)

(ii) Although the smallness of σ is assumed in [15], our method enables us to construct SPS1 for any $\sigma \in [0, \sigma_1^*)$, thanks to the device by Ito [11].

(iii) Construction of SPS1 solutions proceeds in the function space $X_\varepsilon := C_\varepsilon^2 \times C^2$, as compared with $X_\varepsilon := C_\varepsilon^2 \times H^2$ in [15]. This is due to Hosono and Mimura [10].

A.1. Reduced problem. We begin with the C^1-matching solution of (RSP). For a given $x_1 \in (0, 1)$, we consider the following problem in each of the subintervals $I_{-x_1} = (0, x_1)$ and $I_{+x_1} = (x_1, 1)$:

$$\text{(1)} \qquad \begin{aligned} &\frac{1}{\sigma}(V_\pm)_{xx} + G_\pm(V_\pm) = 0, \qquad x \in I_{\pm x_1}, \\ &(V_-)_x(0) = 0 = (V_+)_x(1), \\ &V_-(x_1) = v^* = V_+(x_1), \end{aligned}$$

where $G_\pm(v) = g(h_\pm(v), v)$ for $v \in I_\pm$. It is a useful trick for the uniform construction up to $\sigma = 0$ to put

$$\text{(2)} \qquad V_\pm = v^* + \sigma W_\pm .$$

Substituting (2) into (1), we have

$$\text{(3)} \qquad \begin{aligned} &(W_\pm)_{xx} + G_\pm(v^* + \sigma W_\pm) = 0, \qquad x \in I_{\pm x_1}, \\ &(W_-)_x(0) = 0 = (W_+)_x(1), \\ &W_-(x_1) = 0 = W_+(x_1). \end{aligned}$$

The problem is to find an x_1 so that W_+ and W_- are matched in C^1-sense at $x=x_1$. Here we only consider the monotone increasing solution of (3). Using similar arguments as in [15] and [6], we can prove the following two lemmas.

LEMMA A.1. *Under* (A.0), (A.1) *and* (A.4), *there exists a uniquely determined positive constant* σ_1^* *and a unique* C^1*-function* $x_1^*(\sigma)$ *of* $\sigma \in [0, \sigma_1^*]$ *such that the function* $W^*(x;\sigma)$ *defined by*

$$W^*(x;\sigma)=\begin{cases} W_-^*(x;\sigma), & x\in \bar{I}_-^{*,\sigma}=[0, x_1^*(\sigma)], \\ W_+^*(x;\sigma), & x\in \bar{I}_+^{*,\sigma}=[x_1^*(\sigma), 1], \end{cases}$$

belongs to $C^1(\bar{I})$ *and depends continuously on* σ *in* $C^1(\bar{I})$*-topology for* $\sigma\in[0,\sigma_1^*]$ (*see* Fig. A.1), *where* $W_\pm^*(x;\sigma)$ *is the solution of* (3) *for* $x\in \bar{I}_\pm^{*,\sigma}$, *respectively. Moreover, as* $\sigma\downarrow 0$, $x_1^*(0)=\lim_{\sigma\downarrow 0} x_1^*(\sigma)$ *is given by*

$$x_1^*(0)=\frac{G_+(v^*)}{G_+(v^*)-G_-(v^*)}. \tag{4}$$

The constant σ_1^* *and the function* $x_1^*(\sigma)$ *are the same as appeared in Propositions* 1.1 *and* 1.2.

Remark A.1. When $\sigma=0$, $W_\pm^*(x;0)$ are quadratic functions of x in $I_\pm^{*,0}$.

For later use, we also construct reduced solutions which have perturbed matching points and values in C^0-sense.

LEMMA A.2. *For any* $\sigma_0\in[0,\sigma_1^*)$, *and small positive constants* δ_0 *and* ω_0, *let* $W_-=W_-(x;x_1,v,\sigma)=W_-(x;\delta,\omega,\sigma)$ *be the solution of*

$$\begin{aligned} &(W_-)_{xx}+G_-(v+\sigma W_-)=0, \qquad 0<x<x_1, \\ &(W_-)_x(0)=0, \\ &W_-(x_1^*(\sigma)+\delta)=0, \end{aligned}$$

for $(\delta,\omega,\sigma)\in\Gamma_0$, *where* $x_1=x_1^*(\sigma)+\delta$ *and* $v=v^*+\omega$, *and* $\Gamma_0=\{(\delta,\omega,\sigma)\in\mathbb{R}^3 \mid |\delta|<\delta_0, |\omega|<\omega_0, \sigma\in[0,\sigma_0)\}$. *Similarly, we can define* $W_+(x;\delta,\omega,\sigma)$. *See Fig.* A.1. *Then, we have*

(i) $W_\pm(x;\delta,\sigma)$ *depends continuously on* (δ,ω,σ) *in* C^k*-topology* $(k\geqq 2)$.

(ii) $$\begin{aligned} &\|W_-(x;\delta,\omega,\sigma)-W^*(x;\sigma)\|_{C^1([0,x_1^*(\sigma)+\delta])}\to 0 \\ &\|W_+(x;\delta,\omega,\sigma)-W^*(x;\sigma)\|_{C^1([x_1^*(\sigma)+\delta,1])}\to 0 \end{aligned} \quad \textit{as } \delta,\omega\to 0,$$

uniformly for $\sigma\in[0,\sigma_0)$.

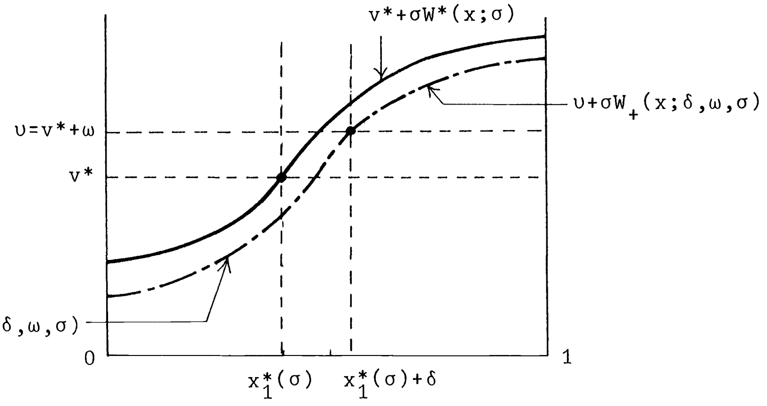

FIG. A.1. *Reduced solution which depends on parameters* δ *and* ω.

(iii) $\pm\dfrac{d}{d\delta}\left(\dfrac{\partial}{\partial x}W_{\pm}(\cdot\,;\delta,\omega,\sigma)\Big|_{x=x_1^*(\sigma)+\delta}\right)<0$ *for* $(\delta,\omega,\sigma)\in\Gamma_0$.

A.2. Approximate solutions in subintervals. We shall construct the solutions $(u_{\pm}, v_{\pm})$ of the following two problems:

$$\text{(5a)}\qquad \begin{aligned} &\varepsilon^2(u_-)_{xx}+f(u_-,v_-)=0,\\ &\frac{1}{\sigma}(v_-)_{xx}+g(u_-,v_-)=0, \end{aligned}\qquad x\in(0,x_1),\ x_1=x_1^*(\sigma)+\delta,$$

with the boundary conditions

$$\text{(5b)}\qquad \begin{aligned} &(u_-)_x(0)=0, && u_-(x_1)=h_0(v^*),\\ &(v_-)_x(0)=0, && v_-(x_1)=v^*+\omega, \end{aligned}$$

and

$$\text{(6a)}\qquad \begin{aligned} &\varepsilon^2(u_+)_{xx}+f(u_+,v_+)=0,\\ &\frac{1}{\sigma}(v_+)_{xx}+g(u_+,v_+)=0, \end{aligned}\qquad x\in(x_1,1),$$

with the boundary conditions

$$\text{(6b)}\qquad \begin{aligned} &(u_+)_x(1)=0, && u_+(x_1)=h_0(v^*),\\ &(v_+)_x(1)=0, && v_+(x_1)=v^*+\omega. \end{aligned}$$

Using the solution $W_{\pm}$ in Lemma A.2, we define $\hat{V}_{\pm}$ by

$$\text{(7)}\qquad \hat{V}_{\pm}(x;\delta,\omega,\sigma)=v^*+\omega+\sigma W_{\pm}(x;\delta,\omega,\sigma).$$

The 0th approximate solution (U_+, V_+) for (6) is defined as follows ((U_-, V_-) is analogously defined):

$$\text{(8a)}\qquad U_+(x;\delta,\omega,\varepsilon,\sigma)=h_+(\hat{V}_+(x;\delta,\omega,\sigma))+z_+(x;\delta,\omega,\varepsilon,\sigma),$$

$$\text{(8b)}\qquad V_+(x;\delta,\omega,\varepsilon,\sigma)=\hat{V}_+(x;\delta,\omega,\sigma)+\varepsilon^2\sigma Y_+(y),$$

where y is a stretched variable, namely $y=(x-x_1)/\varepsilon$. Here, Y_+ is defined by

$$Y_+(y)=\tilde{Y}(y)-\tilde{Y}(0)\zeta(x),$$

$$\tilde{Y}(y)=-\int_y^{+\infty}\int_\eta^{+\infty}\{g(h_+(\hat{V}_+(\eta',\delta,\omega,\sigma))+\tilde{z}_+(\eta',\delta,\omega,\varepsilon),v)$$
$$-g(h_+(\tilde{\hat{V}}_+(\eta',\delta,\omega,\sigma)),v)\}\,d\eta'\,d\eta,$$

where $\zeta(x)$ is a C^∞-cutoff function defined by

$$\zeta(x)=\begin{cases}1 & \text{for } x\in[0,\frac{1}{4}],\\ 0 & \text{for } x\in[\frac{1}{2},1].\end{cases}$$

Remark A.2. $Y_+(y)$ is uniformly bounded in C^2-sense for $(\varepsilon, \sigma) \in \Omega_{\varepsilon_0, \sigma_0}$, and z_+ is defined by

$$z_+(x;\, \delta, \omega, \varepsilon, \sigma) = z_+(x;\, x_1, \upsilon, \varepsilon) = \left\{ \tilde{z}_+^*\left(\frac{x-x_1}{\varepsilon};\, \upsilon\right) - h_+(\upsilon) \right\} \cdot \zeta\left(\frac{x-x_1}{1-x_1}\right),$$

where $\tilde{z}_+^*(y;\, \upsilon)$ is the layer correction term defined by the solution of

$$(9) \qquad \frac{d^2}{dy^2}\tilde{z} + f(\tilde{z}, \upsilon) = 0, \quad \tilde{z}(0) = h_0(v^*), \quad \tilde{z}(+\infty) = h_+(\upsilon).$$

The layer correction term $\tilde{z}_+^*$ satisfies the following.

LEMMA A.3 (*Fife* [4]). *The solution* $\tilde{z} = \tilde{z}_+^*(y;\, \upsilon)$ *of* (9) *exists uniquely and satisfies the following properties*:

(i) $\tilde{z}_+^*(y;\, \upsilon)$ *is monotone increasing and*

$$\left| \left\{ \left(\frac{d}{d\xi}\right)^j (\tilde{z}_+^*(y;\, \upsilon) - h_+(\upsilon)) \right\} \right| \leqq C \exp(-\kappa y) \qquad (j = 0, 1, 2),$$

where the positive constants C *and* κ *are independent of* ω *for* $|\omega| < \omega_0$ (*recall that* $\upsilon = v^* + \omega$).

$$\text{(ii)} \qquad \frac{1}{2}\left\{\frac{dz_+^*}{dy}(0;\, \upsilon)\right\}^2 = \int_{h_0(v^*)}^{h_+(\upsilon)} f(s, \upsilon)\, ds.$$

We seek the desired solution of (6) in the following form:

$$(10\text{a}) \qquad u_+ = U_+ + r_+ + \sigma \frac{d}{d\upsilon} h_+(\hat{V}_+(x;\, \delta, \omega, \sigma)) \cdot s_+,$$

$$(10\text{b}) \qquad v_+ = V_+ + \sigma s_+ = \upsilon + \sigma(W_+ + \varepsilon^2 Y_+ + s_+),$$

where (U_+, V_+) is defined by (8), and (r_+, s_+) is the unknown vector to be determined so that (u_+, v_+) becomes a true solution of (SP) in $(x_1, 1)$. Let us introduce several notations; $t = (r_+, s_+)$, $\Delta = (\delta, \omega, \sigma)$, $X_\varepsilon = C_{\varepsilon 0}^2 \times C_0^2$, and $Y = C^0 \times C^0$. We define the operator T from X_ε to Y by

$$(11) \qquad T(t, \varepsilon;\, \Delta) = \begin{pmatrix} \varepsilon^2 \dfrac{d^2}{dx^2} u_+ + f(u_+, v_+) \\ \dfrac{1}{\sigma} \dfrac{d^2}{dx^2} v_+ + g(u_+, v_+) \end{pmatrix}.$$

T is a continuously differentiable mapping of t for $(\varepsilon, \Delta) \in (0, \varepsilon_0) \times \Gamma_0$. Analogously as in Lemma 4.3 of [15], we can obtain the following lemma.

LEMMA A.4. *There exist positive constants* ε_0, δ_0 *and* ω_0 *such that the following estimates hold for* $(\varepsilon, \Delta) \in (0, \varepsilon_0) \times \Gamma_0$;

(i) $\|T(0, \varepsilon;\, \Delta)\|_Y \leqq K_0 \varepsilon$,

(ii) $\|T_t^{-1}(0, \varepsilon;\, \Delta)\|_{(Y, X_\varepsilon)} \leqq K_1 < +\infty$,

(iii) $\|T_t(t_1, \varepsilon;\, \Delta) - T_t(t_2, \varepsilon;\, \Delta)\|_{(X_\varepsilon, Y)} \leqq K_2 \|t_1 - t_2\|_{X_\varepsilon}$,

where K_i $(i = 1, 2)$ *are positive constants independent of* (ε, Δ).

Applying the generalized implicit function arguments (see [15] and [4]), we can find solutions of $T = 0$, namely, true solutions of (6) in the right-half interval $(x_1, 1)$.

THEOREM A.1. *There exist solutions* $t=t(\varepsilon;\Delta)=(r_+(\varepsilon;\Delta), s_+(\varepsilon;\Delta))$ *of* $T=0$ *for* $(\varepsilon;\Delta)\in(0,\varepsilon_0)\times\Gamma_0$ *such that* $t(\varepsilon;\Delta)$ *depends continuously on* $(\varepsilon;\Delta)$ *in* X_ε*-topology, and when* $\varepsilon\downarrow 0$, *it goes to zero with the asymptotic order as*

$$\|r_+\|_{C^2_{\varepsilon 0}}+\|s_+\|_{C^2_0}\leqq C\varepsilon,$$

where $C>0$ *is independent of* $(\varepsilon,\Delta)\in(0,\varepsilon_0)\times\Gamma_0$. *Moreover, if we denote the solution of* (6) *by* $(u_+(x;\delta,\omega,\varepsilon,\sigma), v_+(x;\delta,\omega,\varepsilon,\sigma))$, *then it satisfies*

$$\begin{aligned}&\lim_{\varepsilon\downarrow 0}\left(\varepsilon\frac{d}{dx}u_+(x;\delta,\omega,\varepsilon,\sigma)\big|_{x=x_1^*(\sigma)+\delta}\right)^2=\int_{h_0(v^*)}^{h_+(v)}f(s,v)\,ds\quad(v=v^*+\omega),\\(12)\qquad&\lim_{\varepsilon\downarrow 0}\left(\frac{1}{\sigma}\frac{d}{dx}v_+(x;\delta,\omega,\varepsilon,\sigma)\big|_{x=x_1^*(\sigma)+\delta}\right)=\frac{d}{dx}W_+(x;\delta,\omega,\sigma)\big|_{x=x_1^*(\sigma)+\delta}.\end{aligned}$$

In a similar fashion, we can construct the solution $(u_-(x;\delta,\omega,\varepsilon,\sigma), v_-(x;\delta,\omega,\varepsilon,\sigma))$ of (5).

A.3. Matching problem and the asymptotic behavior of δ(ε, σ) and ω(ε, σ). In order to obtain a solution of (SP) on the whole interval, we have to solve the C^1-matching problem at $x=x_1^*(\sigma)+\delta$. Let us introduce the matching functions (Φ,Ψ):

$$(13a)\quad \Phi(\delta,\omega,\varepsilon,\sigma)=\left(\varepsilon\frac{d}{dx}u_+(x_1^*(\sigma)+\delta,\delta,\omega,\varepsilon,\sigma)\right)^2-\left(\varepsilon\frac{d}{dx}u_-\ \text{(the same value)}\right)^2,$$

$$(13b)\quad \Psi(\delta,\omega,\varepsilon,\sigma)=\frac{1}{\sigma}\left\{\frac{d}{dx}v_+(x_1^*(\sigma)+\delta,\delta,\omega,\varepsilon,\sigma)-\frac{d}{dx}v_-\ \text{(the same value)}\right\}.$$

Note that the factor $1/\sigma$ is important to construct the solution up to $\sigma=0$. Analogously as in [15], Φ and Ψ can be extended to be a uniform continuous function for $(\varepsilon,\Delta)\in[0,\varepsilon_0)\times\Gamma_0$, and satisfy

$$(14)\qquad \begin{aligned}&\lim_{\varepsilon\downarrow 0}\Phi(0,0,\varepsilon,\sigma)=0\\&\lim_{\varepsilon\downarrow 0}\Psi(0,0,\varepsilon,\sigma)=0\end{aligned}\qquad\text{uniformly with respect to }\sigma.$$

Moreover, it follows from assumptions (A.2) and (A.4) that

$$(15)\qquad \lim_{\varepsilon\downarrow 0}\begin{pmatrix}\Phi_\delta & \Phi_\omega\\ \Psi_\delta & \Psi_\omega\end{pmatrix}_{\substack{\delta=0\\ \omega=0}}$$

becomes an invertible matrix as in [15]. Therefore, applying again the generalized implicit function theorem of [4], we obtain a solution $\delta=\delta(\varepsilon,\sigma)$ and $\omega=\omega(\varepsilon,\sigma)$ of $\Phi=0=\Psi$ such that they are continuous functions with respect to (ε,σ) up to $\varepsilon=0$, and

$$(16)\qquad \begin{aligned}&\delta=\delta(\varepsilon,\sigma)\xrightarrow[\varepsilon\downarrow 0]{}0\\&\omega=\omega(\varepsilon,\sigma)\xrightarrow[\varepsilon\downarrow 0]{}0\end{aligned}\qquad\text{uniformly with respect to }\sigma.$$

Substituting this solution $(\delta(\varepsilon,\sigma),\omega(\varepsilon,\sigma))$ into $(u_\pm, v_\pm)$, we obtain the SPS1 $U^{\varepsilon,\sigma}$ in Theorem 1.1 which satisfies (1.5)-(1.8).

Note that the matching point $x=x_1(\varepsilon,\sigma)$ is defined by

$$(17)\qquad x_1(\varepsilon,\sigma)=x_1^*(\sigma)+\delta(\varepsilon,\sigma).$$

As for the parametric dependency of $U^{\varepsilon,\sigma}$, the only problem is the continuity at $\varepsilon=0$. However, in view of Theorem A.1, (16) and the continuity of the reduced solution $(U^{*,\sigma}, V^{*,\sigma})$ with respect to σ in $L^2\times C^1$-topology, we can see that $U^{\varepsilon,\sigma}$ is a continuous function of (ε, σ) up to $\varepsilon=0$.

Appendix 2. We prove Lemma 2.1 by contradiction. Suppose that this lemma does not hold, we can choose a sequence $\{\varepsilon_n\}_{n\geqq 1}$ with $\lim_{n\downarrow\infty}\varepsilon_n=0$ such that $\zeta_0^{\varepsilon_n,\sigma}$ is the eigenvalue of (LP) for $n\geqq 1$. Let (w_n, z_n) be an associated eigenfunction with $\zeta_0^{\varepsilon_n,\sigma}$. Then, from the solvability condition of the first equation of (LP), we have

$$(18)\qquad \langle f_v^{\varepsilon_n,\sigma} z_n, \phi_0^{\varepsilon_n,\sigma}\rangle=0 \quad \text{for } n\geqq 1.$$

When (18) is satisfied, the general form of w_n is given by

$$(19)\qquad w_n=k_n\phi_0^{\varepsilon_n,\sigma}+(L^{\varepsilon_n,\sigma}-\zeta_0^{\varepsilon_n,\sigma})^{\dagger}(-f_v^{\varepsilon_n,\sigma}z_n), \qquad k_n;\ \text{real constant.}$$

Substituting (19) into the second equation of (LP), we obtain

$$(20)\qquad \frac{1}{\sigma}(z_n)_{xx}+g_u^{\varepsilon_n,\sigma}k_n\phi_0^{\varepsilon_n,\sigma}+g_u^{\varepsilon_n,\sigma}(L^{\varepsilon_n,\sigma}-\zeta_0^{\varepsilon_n,\sigma})^{\dagger}(-f_v^{\varepsilon_n,\sigma}z_n)+g_v^{\varepsilon_n,\sigma}z_n=\zeta_0^{\varepsilon_n,\sigma}z_n.$$

Recalling $K^{\varepsilon_n,\sigma,\zeta_0^{\varepsilon_n,\sigma}}$ exists and uniformly bounded for all $n\geqq 1$ (see Lemma 3.1), we can see that $k_n\neq 0$, otherwise $(w_n, z_n)=(0,0)$, which is a contradiction. Dividing (w_n, z_n) by $k_n\sqrt{\varepsilon}_n$, we have a new eigenvector $(\hat{w}_n, \hat{z}_n)$;

$$\hat{w}_n=w_n/k_n\sqrt{\varepsilon}_n=\phi_0^{\varepsilon_n,\sigma}/\sqrt{\varepsilon}_n+(L^{\varepsilon_n,\sigma}-\zeta_0^{\varepsilon_n,\sigma})^{\dagger}(-f_v^{\varepsilon_n,\sigma}\hat{z}_n)\qquad \hat{z}_n=z_n/k_n\sqrt{\varepsilon}_n.$$

Then, $\hat{z}_n$ satisfies (20) with replacing $k_n\phi_0^{\varepsilon_n,\sigma}$ by $\phi_0^{\varepsilon_n,\sigma}/\sqrt{\varepsilon}_n$ in the second term. Therefore, recalling that $\phi_0^{\varepsilon_n,\sigma}/\sqrt{\varepsilon_n}$ converges to the constant multiple of the Dirac-function δ^* (see Lemma 2.3), we can see that $\hat{z}^*=\lim_{n\uparrow\infty}\hat{z}_n$ exists in $H_N^1(I)$, and $\langle\hat{z}^*, \delta^*\rangle\neq 0$. On the other hand, it holds from the (18) and Lemma 2.3 that $\langle\hat{z}^*, \delta^*\rangle=0$, which is a contradiction, and completes the proof.

MULTIPLE STEADY STATES IN A BIOCHEMICAL SYSTEM*

CHUNQING LU†

Abstract. The differential equation

$$-s''+\sigma s/(1+s+ks^2)=0, \qquad 0<x<1,$$
$$s(0)=s(1)=s_0$$

for $k>0$ and for $\sigma>0$ governs the steady state in a reaction-diffusion equation which describes a substrate in a mono-enzymatic artificial membrane. We present a proof that for given $k>0$ there exists an $s^*>0$ (depending on k only) such that for $s_0>s^*$ and for any $\sigma>0$ there exist at most three positive solutions for this steady state problem.

Key words. enzyme, steady state, response function

AMS (MOS) subject classification. 92

1. Introduction. M. C. Duban [3] and J. P. Kernevez and D. Thomas [5], [8] introduced a nonlinear evolution equation in 1974 and 1975 which describes the diffusion and reaction of a substrate in a mono-enzymatic artificial membrane, when the enzyme is inhibited by an excess of substrate:

$$S_t-D_SS_{xx}+R(S)=0, \tag{1.0}$$

together with boundary conditions

$$S=S_0 \quad \text{at } x=0 \quad \text{and} \quad x=L \quad (L \text{ membrane thickness}),$$

and the given condition, where $S=S(x,t)$ represents the concentration of the substrate of the membrane, D_S is a constant, the coefficient of diffusion, and

$$R(S)=V_MS/[k_S+S(1+S/k_{SS})]$$

is the velocity due to the reaction where k_S is the Michaelis constant, k_{SS} the inhibition constant of S for the enzyme and V_M the maximal value of the reaction rate. Nondimensionalizing the quantities, one obtains the following equation:

$$\begin{aligned} &s_t-s_{xx}+\sigma F(s)=0, \quad 0<x<1, \quad t>0,\\ &s(0,t)=s(1,t)=s_0,\\ &s(x,0) \text{ given}\end{aligned} \tag{1.1}$$

where $s=S/k_S$, $F(s)=s/(1+s+ks^2)$ and $\sigma=(V_M/k_S)L^2$, $k=k_S/k_{SS}$ and $s_0=S_0/k_S$ are positive constants. Then the steady state equation associated with (1.1) is the two-point boundary value problem

$$-s''+\sigma F(s)=0, \qquad s(0)=s(1)=s_0. \tag{1.2}$$

J. P. Kernevez proved that for σ large enough and s_0 conveniently chosen, (1.2) admits at least three solutions, and presented numerical evidence that there are at most three solutions for any positive s_0, k and σ [6, pp. 64–73]. In 1976, C. M. Brauner and B. Nicolaenko [2] rewrote (1.2) in the following form:

$$\begin{aligned} &-u''+u/(\alpha^2+\beta\alpha u+k\beta^2u^2)=0, \qquad 0<x<1,\\ &u(0)=u(1)=1\end{aligned} \tag{1.3}$$

* Received by the editors June 3, 1985; accepted for publication (in revised form) October 22, 1986.

by defining $u=s/s_0$, $\alpha^2=1/\sigma$, $\beta=s_0\alpha$. They studied the stability of multiple solutions of (1.3) for sufficiently small $\alpha>0$, i.e., for σ large enough and s_0 conveniently chosen in problem (1.2) ([1], [2]). Their discussion is based on their claim that there exist at most three solutions for problem (1.3). However, they did not provide a proof for this.

In this paper we employ another change of variable and parameters from [1] in order to present a rigorous proof that for given $k>0$ there exists an $s^*=s^*(k)$ such that for $s_0>s^*$ and for any positive σ the steady state problem (1.2) admits no more than three solutions. The result we obtain here agrees with that of experiment and numerical analysis because it is known that in order to get multiple steady states we must have σ and s_0 sufficiently large [6, p. 97]. The change of parameters we introduce in (2.2) will let us study sufficiently small ε, which is related to $1/s_0$. The latter is proportional to the concentration on the edge of the membrane. Problems of a similar kind are treated in [4] and [9]. However, the nonlinearities are completely different and very little of the analysis is relevant here.

2. Formulation of the perturbation problem and the response function. We first make a change of variable $u(x)=s(x)/s_0$ where $s=s(x)$, s_0 satisfy (1.2). Then (1.2) becomes

$$\begin{aligned} &-u''+\sigma u/(1+s_0u+ks_0^2u^2)=0, \qquad 0<x<1,\\ &u(0)=u(1)=1. \end{aligned} \tag{2.1}$$

Next we introduce some new parameters β and ε by defining

$$\beta=s_0/\sqrt{\sigma}, \qquad \varepsilon=1/2ks_0, \tag{2.2}$$

where ε will be the perturbation parameter. Thus (2.1) becomes the following equation:

$$-u''+u/[k\beta^2(u^2+2\varepsilon u+4k\varepsilon^2)]=0, \qquad 0<x<1 \tag{2.3}$$

with $u(0)=u(1)=1$.

Our purpose is to prove that for given $k>0$ there exists an $\varepsilon_0>0$ such that 0 (2.3) has no more than three solutions for $0<\varepsilon<\varepsilon_0$ and for any $\beta>0$, where $\varepsilon_0=\varepsilon_0(k)$ depends on k only. Obviously, this means that for given $k>0$ there exists a value $s^*=s^*(k)$ such that (1.2) admits at most three solutions for all $s_0>s^*$ and any $\sigma>0$.

Multiplying (2.3) by u', we see that

$$[u'^2/2]'=uu'/[k\beta^2(u^2+2\varepsilon u+4k\varepsilon^2)]. \tag{2.4}$$

If we integrate both sides of (2.4) with respect to x, it follows that

$$[u'(x)]^2/2=\left(\frac{1}{k\beta^2}\right)\int_{u(1/2)}^{u(x)}\{u/(u^2+2\varepsilon u+4k\varepsilon^2)\}\,du+u'^2(\tfrac12)/2. \tag{2.5}$$

We claim that $u'(\frac12)=0$. Assume that $u=u(x)$ is any solution of (2.3) with $u(0)=u(1)=1$ (for the proof of the existence of such a solution for (2.3) see [7]). From (2.5), $u'(0)^2=u'(1)^2$. Since $u''(x)>0$, u is a convex function of x on $[0,1]$, so it must be that $u'(1)=-u'(0)$. Suppose $u'(1)=m$. Now we see that (2.3) with boundary conditions is equivalent to the same equation with initial conditions either $u(1)=1$, $u'(1)=m$ or $u(0)=1$, $u'(0)=-m$. Let $x=\frac12+z$ and $v(z)=u(\frac12+z)$, where x is in $[0,1]$ and z in $[-\frac12,\frac12]$. Then $v(z)$ satisfies

$$-v''+v/[k\beta^2(v+2\varepsilon v+4k\varepsilon^2)=0, \qquad -\tfrac12<z<\tfrac12 \tag{2.6}$$

with $v(-\frac12)=v(\frac12)=1$; moreover, $v'(\frac12)=-v'(-\frac12)=m$. It is easy to check that $v(-z)=w(z)$ is also a solution for (2.6) with the initial conditions. By the uniqueness of $v(z)$, one obtains $v(z)=v(-z)$, which implies that the $u(x)$ profile is symmetric with respect to $x=\frac{1}{2}$, and hence $u'(\frac{1}{2})=0$. It also follows that $u'(x)>0$ for $x>\frac{1}{2}$, $u'(x)<0$ for $x<\frac{1}{2}$ by the convexity of $u(x)$. One can see that the number of solutions of (2.3) will be determined by the number of values of $u(\frac{1}{2})$.

To determine which condition $u(\frac{1}{2})$ has to satisfy we begin with (2.5). Let $y=1/u(\frac{1}{2})$. Then for x in $(\frac{1}{2}, 1]$, $1/y<u(x)$ and

$$u'(x)=\left\{\left[\frac{2}{k\beta^2}\right]\int_{y^{-1}}^{u(x)}[s/(s^2+2\varepsilon s+4k\varepsilon^2)]\,ds\right\}^{1/2}. \tag{2.7}$$

Computing the integral in (2.7), we obtain

$$\begin{aligned}\int_{y^{-1}}^{u(x)}[s/(s^2+2\varepsilon s+4k\varepsilon^2)]\,ds&=\ln\{[\varepsilon+u(x)]^2+(4k-1)\varepsilon^2\}^{1/2}\\&\quad-\ln[(\varepsilon+y^{-1})^2+(4k-1)\varepsilon^2]^{1/2}+\varepsilon h_0(u(x),y)\end{aligned} \tag{2.8}$$

where

$$h_0(u(x),y)=-\int_{y^{-1}}^{u(x)}\{1/[(s+\varepsilon)^2+(4k-1)\varepsilon^2]\}\,ds. \tag{2.9}$$

Denote the right side of (2.8) by $K(\varepsilon, y, u(x))/2$. From (2.7) we have

$$u'/\sqrt{K}(\varepsilon, y, u)=1/(\beta\sqrt{k}). \tag{2.10}$$

Moreover,

$$\int_{u(1/2)}^{1}K^{-1/2}(\varepsilon, y, u)\,du=\frac{1}{(2\beta\sqrt{K})}. \tag{2.11}$$

For convenience, we make a change of variable as follows:

$$\varepsilon+u=(\varepsilon+1/y)\,e^{t^2},\qquad du=2(\varepsilon+y^{-1})t\,e^{t^2}\,dt.$$

Then (2.11) becomes

$$\begin{aligned}2(\varepsilon+y^{-1})\int_0^{v(\varepsilon,y)}&\{\ln[(1+\varepsilon y)^2e^{2t^2}+(4k-1)(\varepsilon y)^2]\\&-\ln[(1+\varepsilon y)^2+(4k-1)(\varepsilon y)^2]+2h(\varepsilon,y,t)\}^{-1/2}t\,e^{t^2}\,dt\\=\frac{1}{(2\beta\sqrt{k})}&\end{aligned} \tag{2.12}$$

where

$$h(\varepsilon,y,t)=-\varepsilon y\int_1^{(1+\varepsilon y)e^{t^2}-\varepsilon y}\{1/[(s+\varepsilon y)^2+(4k-1)\varepsilon^2y^2]\}\,ds, \tag{2.13}$$

$y\geqq 1$, and $v(\varepsilon, y)=\sqrt{\{\ln(\varepsilon+1)-\ln(\varepsilon+y^{-1})\}}$. Evidently, it is necessary to prove that, for given $k>0$, if ε is small enough, then for any $\beta>0$ there are no more than three y's satisfying (2.12). We denote the function on the left in (2.12) by $f_\varepsilon(y)$, which is called the response function, and then (2.12) becomes

$$f_\varepsilon(y)=1/(2\beta\sqrt{k}). \tag{2.14}$$

3. Notation and conventions. Since we only deal with nonnegative solutions of (2.3), we shall always assume that $u(x)>0$. From § 2, $y\geqq 1$. If we set $\varepsilon=0$ in (2.3), then we obtain the so-called reduced problem, and the corresponding response function will be denoted by $f_0(y)$. In the reduced problem, of course, we have

$$f_0(y) = (2\beta\sqrt{k})^{-1}. \tag{3.1}$$

Since we always fix $k > 0$, we shall omit the words "for given $k > 0$" in all our statements. Let G denote

$$\begin{aligned} G(\varepsilon, y, t) = {} & \ln[(1+\varepsilon y)^2 e^{2t^2} + (4k-1)(\varepsilon y)^2] \\ & - \ln[(1+\varepsilon y)^2 + (4k-1)(\varepsilon y)^2] + 2h(\varepsilon, y, t) \end{aligned} \tag{3.2}$$

where $h(\varepsilon, y, t)$ is given in (2.13).

We shall always denote the derivative of any function with respect to y by "prime," and with respect to t by "dot."

We now list some functions which are repeatedly used in the following sections:

$$v = v(\varepsilon, y) = \sqrt{\{\ln(1+\varepsilon) - \ln(y^{-1}+\varepsilon)\}},$$

$$f_\varepsilon(y) = 2(\varepsilon + y^{-1}) \int_0^v t\, e^{t^2} G^{-1/2}\, dt,$$

$$G_1 = G_1(\varepsilon, y, t) = \frac{\partial G}{\partial y},$$

$$G^{\bullet} = G^{\bullet}(\varepsilon, y, t) = \frac{\partial G}{\partial t},$$

$$G_1^{\bullet} = G_1^{\bullet}(\varepsilon, y, t) = \frac{\partial^2 G}{\partial t \partial y},$$

$$G_2 = G_2(\varepsilon, y, t) = \frac{\partial^2 G}{\partial y^2},$$

$$G^{\bullet\bullet} = G^{\bullet\bullet}(\varepsilon, y, t) = \frac{\partial^2 G}{\partial t^2},$$

$$F_\varepsilon(y) = f_\varepsilon''(y) + \{2 - [\varepsilon y(1 + 8k\varepsilon y + 4k(\varepsilon y)^2)][2(1+\varepsilon y)(1 + 2\varepsilon y + 4k\varepsilon^2 y^2)]^{-1}\} y f_\varepsilon'(y),$$

$$T_1 = T_1(\varepsilon, y, t) = (1+\varepsilon y)^2 e^{2t^2} + (4k-1)(\varepsilon y)^2,$$

$$T_2 = T_2(\varepsilon, y, t) = (1+\varepsilon y)^2 e^{2t^2} + 2(4k-1)\varepsilon y(1+\varepsilon y)\, e^{t^2} - (4k-1)(\varepsilon y)^2.$$

Elementary calculations show that

$$G_1 = 2\varepsilon[(1+\varepsilon y)\, e^{2t^2} + e^{t^2} + (4k-1)\varepsilon y]/T_1 - 4\varepsilon(1 + 2k\varepsilon y)/T_1(\varepsilon, y, 0),$$

$$G_1^{\bullet} = -4\varepsilon t\, e^{t^2} T_2 / T_1^2,$$

$$G^{\bullet} = 4t\, e^{t^2}(1+\varepsilon y)[(1+\varepsilon y)\, e^{t^2} - \varepsilon y] T_1^{-1},$$

$$\begin{aligned} G_2 = {} & 2\varepsilon^2 T_1^{-2}[-(1+\varepsilon y)^2 e^{4t^2} - 2(1+\varepsilon y)\, e^{3t^2} \\ & - (4k-1)(2\varepsilon y + 2\varepsilon^2 y^2 - 1)\, e^{2t^2} - 2(4k-1)\varepsilon y\, e^{t^2} - (4k-1)(\varepsilon y)^2] \\ & - 8\varepsilon^2 T_1^{-2}(\varepsilon, y, 0)(k - 1 - 4k\varepsilon y - 4k^2\varepsilon^2 y^2), \end{aligned}$$

$$\begin{aligned} G^{\bullet\bullet} = {} & 4(1+\varepsilon y)\, e^{t^2}[4t^2 e^{t^2}(1+\varepsilon y) + (1+\varepsilon y)\, e^{t^2} - 2t^2\varepsilon y - \varepsilon y] \cdot T_1^{-1} \\ & - 16(1+\varepsilon y)^3 t^2 e^{3t^2}[(1+\varepsilon y)\, e^{t^2} - \varepsilon y] T_1^{-2}. \end{aligned}$$

For simplicity, we shall only give the details in the case $k=\frac{1}{4}$ in this paper. We do indicate those quantities introduced below which depend on k in the general case. For $k\neq\frac{1}{4}$ the interested reader can refer to [7]. We see that if $k=\frac{1}{4}$, then

$$G=2t^2+2\varepsilon y(e^{-t^2}-1)/(1+\varepsilon y), \tag{3.3}$$

$$T_1=T_2=(1+\varepsilon y)^2\,e^{2t^2}, \tag{3.4}$$

$$G_1=-2\varepsilon(1-e^{-t^2})/(1+\varepsilon y)^2, \tag{3.5}$$

$$G^{\bullet}=4t(1+\varepsilon y-\varepsilon y\,e^{-t^2})/(1+\varepsilon y), \tag{3.6}$$

$$G_1^{\bullet}=-4\varepsilon t/\{(1+\varepsilon y)^2\,e^{t^2}\}, \tag{3.7}$$

$$G_2=4\varepsilon^2(1-e^{-t^2})/(1+\varepsilon y)^3, \tag{3.8}$$

$$G^{\bullet\bullet}=4\{(1+\varepsilon y)\,e^{t^2}+2\varepsilon yt^2-\varepsilon y\}/\{(1+\varepsilon y)\,e^{t^2}\}, \tag{3.9}$$

$$f_\varepsilon(y)=2(\varepsilon+y^{-1})\int_0^v t\,e^{t^2}G^{-1/2}\,dt, \tag{3.10}$$

$$\begin{aligned} f_\varepsilon'(y)&=(1+\varepsilon)/[(1+\varepsilon y)G^{1/2}(\varepsilon,y,v)]\\ &\quad-\left(\frac{2}{y^2}\right)\int_0^v t\,e^{t^2}G^{-1/2}\,dt-\left(\varepsilon+\frac{1}{y}\right)\int_0^v t\,e^{t^2}G_1G^{-3/2}\,dt, \end{aligned} \tag{3.11}$$

$$F_\varepsilon(y)=y^2f_\varepsilon''(y)+\{2-\varepsilon y/[2(1+\varepsilon y)]\}yf_\varepsilon'(y). \tag{3.12}$$

4. The reduced problem. At $\varepsilon=0$, $G=G(0,y,t)=2t^2$ and

$$f_0(y)=(\sqrt{2}/y)\int_0^{\sqrt{\ln y}} e^{t^2}\,dt, \tag{4.1}$$

$$f_0'(y)=1/[y\delta/\sqrt{(2\ln y)}]-(\sqrt{2}/y^2)\int_0^{\sqrt{\ln y}} e^{t^2}\,dt, \tag{4.2}$$

$$f_0''(y)=-2/[y^2\sqrt{(2\ln y)}]-1/[y^2\{\sqrt{(2\ln y)}\}^3]+\left(\frac{2\sqrt{2}}{y^3}\right)\int_0^{\sqrt{\ln y}} e^{t^2}\,dt, \tag{4.3}$$

$$F_0(y)=-1/[\sqrt{(2\ln y)}]^3<0 \tag{4.4}$$

for $y>1$. It follows that $f_0(y)$ has at most one critical point, the maximum. Thus the reduced problem admits at most two solutions for any $\beta>0$.

5. Outline of the argument. For our purpose it suffices to prove that there exists an $\varepsilon_0=\varepsilon_0(k)$ such that for ε in $(0,\varepsilon_0)$ and for $y>1$, $f_\varepsilon(y)$ has only two critical points; one is a local maximum and the other is a local minimum. In order to do this we shall prove the following.

THEOREM 1. *There exists an* $\varepsilon_1=\varepsilon_1(k)$ *such that for* ε *in* $(0,\varepsilon_1)$ *and* $y>1/\varepsilon^2$, $f_\varepsilon'(y)>0$.

THEOREM 2. *There exist constants $d = d(k)$, $Y_0 = Y_0(k)$ and $\varepsilon_2 = \varepsilon_2(k)$ such that for y in $[Y_0, d/\varepsilon]$ and ε in $(0, \varepsilon_2)$, $f_\varepsilon'(y) < 0$.*

THEOREM 3. *There exists an $\varepsilon_3 = \varepsilon_3(k)$ such that for $0 < \varepsilon < \varepsilon_3$ and y in $[d/\varepsilon, 1/\varepsilon^2]$, $F_\varepsilon(y) > 0$, where d is given in Theorem 2 and F_ε is listed in* § 2.

It is then clear that $f_\varepsilon(y)$ has only one critical point, the local minimum, for $y > Y_0$ if ε is small enough, because if $f_\varepsilon' = 0$, then by Theorem 3 and the expression of F_ε', $f_\varepsilon'' > 0$.

THEOREM 4. *There exists an $\varepsilon_4 = \varepsilon_4(k)$ such that for $0 < \varepsilon < \varepsilon_4$, $f_\varepsilon(y)$ has exactly one critical point, the local maximum, on $[1, Y_0]$, where Y_0 is given in Theorem 2.*

The technique used in proving Theorems 1-3 is to estimate the integrals which appear in the expressions of $f_\varepsilon'(y)$ and $F_\varepsilon(y)$ carefully. For Theorem 4, however, we shall compare $f_\varepsilon(y)$ with $f_0(y)$ for small ε.

Now if we set $\varepsilon_0 = \min\{\varepsilon_1, \varepsilon_2, \varepsilon_3, \varepsilon_4\}$, then all the conclusions of Theorems 1-4 hold, as desired.

6. The proofs of Theorems 1 and 2. Let δ be any constant such that $0 < \delta < v = v(\varepsilon, y)$. Then

$$\int_0^v t e^{t^2} G^{-1/2}\, dt = \int_0^\delta + \int_\delta^v, \qquad \int_0^v t e^{t^2} G^{-3/2} G_1\, dt = \int_0^\delta + \int_\delta^v. \tag{6.1}$$

By integration by parts,

$$\begin{aligned} \int_\delta^v t e^{t^2} G^{-1/2}\, dt &= (1+\varepsilon)y/[2(1+\varepsilon y)\sqrt{G}(\varepsilon, y, \delta)] \\ &\quad - e^{\delta^2}/[2\sqrt{G}(\varepsilon, y, \delta)] + \frac{1}{4}\int_\delta^v e^{t^2} G^{-3/2} G^{\cdot}\, dt. \end{aligned} \tag{6.2}$$

Substituting (6.1) and (6.2) into (3.11), we obtain

$$\begin{aligned} f_\varepsilon'(y) &= e^{\delta^2}/[y^2\sqrt{G}(\varepsilon, y, \delta)] - \left(\frac{1}{y^2}\right)\int_0^v t e^{t^2} G^{-3/2}[2G + (1+\varepsilon y) y G_1]\, dt \\ &\quad - \left(\frac{1}{y^2}\right)\int_0^v e^{t^2} G^{-3/2}[G^{\cdot}/2 + (1+\varepsilon y) y t G_1]\, dt. \end{aligned} \tag{6.3}$$

From (3.5) and (3.6),

$$\frac{G^{\cdot}}{2} + (1+\varepsilon y) y t G_1 = 2t/(1+\varepsilon y), \tag{6.4}$$

and then (6.3) becomes

$$\begin{aligned} f_\varepsilon'(y) &= e^{\delta^2}/[y^2\sqrt{G}(\varepsilon, y, \delta)] - \left(\frac{1}{y^2}\right)\int_0^\delta t e^{t^2} G^{-3/2}[2G + (1+\varepsilon y) y G_1]\, dt \\ &\quad - \frac{2}{y^2(1+\varepsilon y)}\int_\delta^v t e^{t^2} G^{-3/2}\, dt. \end{aligned} \tag{6.5}$$

LEMMA 6.1. *For given $\varepsilon y > 0$, $tG^{-3/2}(\varepsilon, y, t)$ is a decreasing function of t, where $t > 0$.*

Proof. $G^{\cdot} > 0$ for $t > 0$ and for given $\varepsilon y > 0$; hence from $G > 0$

$$(1/G)^{\cdot} < 0. \tag{6.6}$$

All we need is to have $(tG^{-1/2})^{\cdot} < 0$, which is equivalent to

$$(6.7) \qquad (t^2/G^{-1})^{\cdot} < 0 \quad \text{for } t > 0.$$

Notice that $(t^2/G^{-1})^{\cdot} = t(2G - tG^{\cdot})/G^2$ and $G = G^{\cdot} = 0$ at $t = 0$. Since

$$(2G - tG^{\cdot})^{\cdot} = G^{\cdot} - tG^{\cdot\cdot} = -8\varepsilon y t^3/(1+\varepsilon y) < 0$$

for $t > 0$, (6.7) holds. This proves the lemma.

LEMMA 6.2. *For each $c > 0$ there is a $Y(c)$ such that for $0 < a < 1$ and $Y > Y(c)$,*

$$(6.8) \qquad Y/[2\sqrt{\ln Y}] < \int_a^{\sqrt{\ln Y}} e^{t^2}\, dt < (\tfrac{1}{2} + c)Y/\sqrt{\ln Y}.$$

Also for each $b > 0$ there is a $W(b)$ such that for $W > W(b)$

$$(6.9) \qquad W/[2\sqrt{\ln W}] < \int_b^{\sqrt{\ln W}} e^{t^2}\, dt.$$

Proof. By integration by parts,

$$(6.10) \qquad \begin{aligned} \int_1^{\sqrt{\ln y}} e^{t^2}\, dt &= y/[2\sqrt{\ln y}] - e/2 + \frac{1}{2}\int_1^{\sqrt{\ln y}} e^{t^2}/t^2\, dt, \\ &\geqq y/[2\sqrt{\ln y}] - e/2 + \frac{1}{2}\int_1^2 e\, dt = y/[2\sqrt{\ln y}] \end{aligned}$$

for $Y \geqq e^4$, since $e^{t^2}/t^2 \geqq e$ for $t \geqq 1$. We then see that (6.10) implies the first inequality in (6.8) for $Y > e^4$. In the same way one can prove (6.9). The right half of the inequality (6.8) follows from

$$(6.11) \qquad \lim_{y\to\infty} \left\{ \int_0^{\sqrt{\ln y}} e^{t^2}\, dt / [y/\sqrt{\ln y}] \right\} = \frac{1}{2}. \qquad \text{Q.E.D.}$$

LEMMA 6.3. *There exist an $\varepsilon_{*1} = \varepsilon_{*1}(k)$ and a $\delta_1 = \delta_1(k)$ such that for t in $(0, \delta)$, where $0 < \delta < \delta_1$, and for $y > 1/\varepsilon^2$, where ε is in $(0, \varepsilon_{*1})$,*

$$2G + (1+\varepsilon y)yG_1 < 0.$$

Proof. Let $g = g(\varepsilon, y, t) = 2G + (1+\varepsilon y)yG_1$. Then $g(\varepsilon, y, 0) = 0$ for any $y > 0$ and $g^{\cdot} = 4t(2 + 2\varepsilon y - 3\varepsilon y/e^{t^2})/(1+\varepsilon y)$. Let $g_1(\varepsilon, y, t) = 2 + 2\varepsilon y - 3\varepsilon y\, e^{-t^2}$. Then for given $\varepsilon y > 0$, $g_1(\varepsilon, y, t) = 2 - \varepsilon y + g_1^{\cdot}(\varepsilon, y, \alpha)t$ for some $\alpha = \alpha(\varepsilon, y, t)$, with $0 < \alpha < t$. Take $\delta_1 = \sqrt{2}/2$ if $k = \frac{1}{4}$; then $g_1^{\cdot}(\varepsilon, y, \alpha) < 6\varepsilon yt\, e^{-t^2}$ for $0 < \alpha < t < \delta < \delta_1$. Thus

$$\begin{aligned} g_1(\varepsilon, y, t) &< 2 - 2\varepsilon y(1 - 3t^2 e^{-t^2}) < 2 - 2\varepsilon y(1 - 3\delta^2 e^{-\delta^2}) \\ &< 2 - 2(1 - 3\delta_1^2 e^{-\delta_1^2})/\varepsilon \end{aligned}$$

for $y > 1/\varepsilon^2$. Fix δ_1 and let ε tend to 0 to complete the proof. Q.E.D.

LEMMA 6.4. *For any $\delta > 0$ there is a $r = r(k, \delta)$ such that $G(\varepsilon, y, \delta) > r > 0$ for all $\varepsilon y > 0$.*

Proof. $\partial G(\varepsilon, y, t)/\partial(\varepsilon y) = G_1/\varepsilon < 0$ and $\lim_{\varepsilon y\to\infty} G(\varepsilon, y, \delta) = 2(\delta^2 - 1 + e^{-\delta^2}) > 0$. Q.E.D.

We now proceed with the proof of Theorem 1. First of all we set $\delta < \min\{\delta_1, 1\}$ and $\varepsilon < \varepsilon_{*1}$ in (6.5), where δ_1 and ε_{*1} are given in Lemma 6.3. Then by Lemmas 6.1

and 6.3 it follows that

$$(6.12)\qquad f'_\varepsilon(y) > e^{\delta^2}/[y^2\sqrt{G}(\varepsilon, y, \delta)] - 2/[y^2(1+\varepsilon y)] \int_\delta^v [\max(tG^{-3/2})]\, e^{t^2}\, dt.$$

Notice that $\max tG^{-3/2} = \delta G^{-3/2}(\varepsilon, y, \delta)$ for t in $[\delta, v]$ and $v < \sqrt{[\ln(1+\varepsilon) - \ln \varepsilon]}$ for $y > 1$. We then use $1/(1+\varepsilon y) < 3/(2\varepsilon y)$ in (6.12) and obtain that, for $\varepsilon < \varepsilon_{*1}$ and $y \geqq 1/\varepsilon^2$,

$$(6.13)\qquad y^2 G^{3/2}(\varepsilon, y, \delta) f'_\varepsilon(y) > e^{\delta^2} G(\varepsilon, y, \delta) - (3\delta/\varepsilon y) \int_0^{v_0(\varepsilon)} e^{t^2}\, dt$$

where $v_0(\varepsilon) = \sqrt{\{\ln(1+\varepsilon) - \ln \varepsilon\}}$. Let ε_{*2} be a number such that $v_0(\varepsilon) > Y(\frac{1}{2})$ for $\varepsilon < \varepsilon_{*2}$, where $Y(\frac{1}{2})$ is the value of $Y(c)$ at $c = \frac{1}{2}$ in Lemma 6.2. Denote the function on the left in (6.13) by $n(\varepsilon, y, \delta)$ and apply Lemmas 6.2 and 6.4 to show that

$$(6.14)\qquad n(\varepsilon, y, \delta) > r(k, \delta) - 3\delta(1+\varepsilon)/v_0(\varepsilon).$$

Since the choice for δ does not depend upon ε and $(1+\varepsilon)/v_0(\varepsilon)$ tends to 0 as $\varepsilon \to 0$, there exists $\varepsilon_{*3} = \varepsilon_{*3}(k)$ such that

$$(1+\varepsilon)/v_0(\varepsilon) < r(k, \delta)/6\delta.$$

Thus, setting $\varepsilon_1 = \min\{\varepsilon_{*1}, \varepsilon_{*2}, \varepsilon_{*3}\}$, we obtain Theorem 1.

To prove Theorem 2 we require the following lemma which will prove that the second term in the expression for $f'_\varepsilon(y)$ is negative.

LEMMA 6.5. *There exists a number $d = d(k)$ such that for εy in $(0, d]$ and $t > 0$, $2G + (1+\varepsilon y) y G_1 > 0$.*

Proof. We shall use the same notation as in the proof of Lemma 6.3. Since $g_1(0,0,0) = 2$, there is a number $d = d(k)$ such that $g_1(\varepsilon, y, 0) \geqq 0$ for εy in $[0, d]$ and $g_1(\varepsilon, y, 0) = 0$ at $\varepsilon y = d$. Also $\dot{g}_1(\varepsilon, y, t) > 0$ for $t > 0$ and $\varepsilon y > 0$. This implies the lemma.

Remark. In the case of $k = \frac{1}{4}$, $d = 2$.

Proof of Theorem 2. We first take d as in Lemma 6.5, and then set $\delta = 1$ in (6.5). Using Lemmas 6.1 and 6.6, we see that for $1 < y \leqq d/\varepsilon$,

$$(6.15)\qquad f'_\varepsilon(y) < e/[y^2\sqrt{G}(\varepsilon, y, 1)] - \{2v/[y^2(1+\varepsilon y)G^{3/2}(\varepsilon, y, v)]\} \int_1^v e^{t^2}\, dt.$$

Further, assume that $\varepsilon < 1/(2e^4)$. Then $v > 2$ for $y > 2e^4$ and hence from (6.10)

$$(6.16)\qquad \int_1^v e^{t^2}\, dt > (1+\varepsilon)y/[2v(1+\varepsilon y)].$$

This shows that for $\varepsilon < 1/(2e^4)$ and for $2e^4 \leqq y \leqq d/\varepsilon$

$$(6.17)\qquad f'_\varepsilon(y) < e/[y^2\sqrt{G}(\varepsilon, y, 1)] - (1+\varepsilon)/[y(1+\varepsilon y)^2 G^{3/2}(\varepsilon, y, v)].$$

Since $G(\varepsilon, y, 1) = 2 + 2\varepsilon y(1/e - 1)/(1+\varepsilon y) \geqq m(d)$, where $m(d) = 2 + 2d(1/e - 1)/(1+d)$, for $y < d/\varepsilon$, and $G(\varepsilon, y, v) < 2v^2 < 2\ln y$ for $y > 1$, it follows that for y in $[2e^4, d/\varepsilon]$,

$$(6.18)\qquad yf'_\varepsilon(y) < e/\sqrt{m}(d) - y/[(1+d)^2(2\ln y)^{3/2}].$$

Thus there exists an $\varepsilon_2 = \varepsilon_2(k)$ and $Y_0 = Y_0(k)$ such that $f'_\varepsilon(y) < 0$ for $0 < \varepsilon < \varepsilon_2$ and y in $[Y_0, d/\varepsilon]$, which is desired.

7. The proof of Theorem 3. To begin with, let δ be chosen as in the beginning of § 6. We start at (6.5). Then

$$\begin{aligned}
[y^2 f_\varepsilon'(y)]' &= 2y f_\varepsilon'(y) + y^2 f_\varepsilon''(y) \\
&= -e^{\delta^2} G_1(\varepsilon, y, \delta)/[2G^{3/2}(\varepsilon, y, \delta)] \\
&\quad - \int_0^\delta t\, e^{t^2} \{ G^{-3/2}[(3+2\varepsilon y)G_1 + (1+\varepsilon y) y G_2] \\
&\qquad - (\tfrac{3}{2}) G_1 G^{-5/2}[2G + (1+\varepsilon y) y G_1]\}\, dt \\
&\quad - (1+\varepsilon)/[(1+\varepsilon y)^3 G^{3/2}(\varepsilon, y, v)] \\
&\quad + [1/(1+\varepsilon y)^2] \int_\delta^v t\, e^{t^2} G^{-3/2}[2\varepsilon + 3(1+\varepsilon y) G_1 G^{-1}]\, dt,
\end{aligned} \tag{7.1}$$

$$\begin{aligned}
F_\varepsilon(y) &= [y^2 f_\varepsilon'(y)]' - \varepsilon y^2 f_\varepsilon'(y)/[2(1+\varepsilon y)] \\
&= -e^{\delta^2} G_1(\varepsilon, y, \delta)/[2G^{3/2}(\varepsilon, y, \delta)] \\
&\quad - \varepsilon\, e^{\delta^2}/[2(1+\varepsilon y)\sqrt{G}(\varepsilon, y, \delta) - (1+\varepsilon)/[(1+\varepsilon y)^3 G^{3/2}(\varepsilon, y, v)] \\
&\quad - \int_0^\delta t\, e^{t^2} \{ G^{-3/2}[(3+2\varepsilon y)G_1 + (1+\varepsilon y) y G_2 - \varepsilon[2G + yG_1(1+\varepsilon y)] \\
&\qquad \cdot (1+\varepsilon y)^{-1}/2] - (\tfrac{3}{2}) G_1 G^{-5/2}[2G + (1+\varepsilon y) y G_1]\}\, dt \\
&\quad + [3/(1+\varepsilon y)^2] \int_\delta^v t\, e^{t^2} G^{-3/2}[\varepsilon + (1+\varepsilon y) G_1 G^{-1}]\, dt.
\end{aligned} \tag{7.2}$$

We now define several functions which will be used in this section as follows:

$$\begin{aligned}
N = N(\varepsilon, y, t) &= (3+2\varepsilon y) G_1/G + y(1+\varepsilon y) G_2/G \\
&\quad - \varepsilon[2 + (1+\varepsilon y) y G_1/G]/(1+\varepsilon y)/2 \\
&\quad - 3G_1[2 + (1+\varepsilon y) G_1/G]/(2G), \\
M = M(\varepsilon, y, \delta) &= -e^{\delta^2} G_1(\varepsilon, y, \delta)/[2G^{3/2}(\varepsilon, y, \delta)] \\
&\quad - \varepsilon\, e^{\delta^2}/[2(1+\varepsilon y)\sqrt{G}(\varepsilon, y, \delta)], \\
Q = Q(\varepsilon, y, t) &= \varepsilon + (1-\varepsilon y) G_1/G.
\end{aligned} \tag{7.3}$$

Then rewrite (7.2) as

$$\begin{aligned}
F_\varepsilon(y) &= M - (1+\varepsilon)/[(1+\varepsilon y)\sqrt{G}(\varepsilon, y, v)]^3 \\
&\quad - \int_0^\delta t\, e^{t^2} N/\sqrt{G}\, \mathrm{dt} + [3/(1+\varepsilon y)^2] \int_\delta^v t\, e^{t^2} Q/G^{3/2}\, dt.
\end{aligned} \tag{7.4}$$

LEMMA 7.1. *G_1/G is an increasing function of $t > 0$ for any given $\varepsilon y > 0$.*

Proof. $(G_1/G)^{\cdot} = (GG_1^{\cdot} - G_1 G^{\cdot})/G^2 = G_1^{\cdot}(G - G_1 G^{\cdot}/G_1^{\cdot})/G^2$. Since $G_1^{\cdot} < 0$ and $G > 0$ for $\varepsilon y > 0$ and $t > 0$, it suffices to show that $G - G_1 G^{\cdot}/G_1^{\cdot} < 0$. It is clear that if $k = \frac{1}{4}$, then $G - G_1 G^{\cdot}/G_1^{\cdot} = 2(1 + t^2 - e^{t^2}) < 0$ for $t > 0$. The proof of Lemma 7.1 for $k = \frac{1}{4}$ is complete.

Considering that $Q(\varepsilon, y, 0) = 0$ and $Q^{\cdot} \geqq 0$, from Lemma 7.1 we have the following corollary.

COROLLARY 7.1. *$Q(\varepsilon, y, t) > 0$ for $t > 0$ and for any $\varepsilon y > 0$.*

Remark. Lemma 7.1 is the hardest lemma to prove if $k \neq \frac{1}{4}$, but it is true for any $k > 0$.

LEMMA 7.2. *There exists a number $b=b(k)>0$ such that for $\varepsilon y \geqq d$, where d is chosen as in Theorem 2, and for $t>b$, $Q(\varepsilon, y, t)>2/3y$.*

Proof. From the remark after the proof of Lemma 6.5, $d=2$ for $k=\frac{1}{4}$; hence $3\varepsilon y-2>0$ for $\varepsilon y \geqq d$. Define

$$p(\varepsilon y, t)=3yQ(\varepsilon, y, t)/[2(1+\varepsilon y)].$$

We see that $\lim_{\varepsilon y\to\infty} p(\varepsilon y, t)=3/2$ for fixed $t>0$. From Lemma 7.1, the function $\{p(\varepsilon y, t)-1/(1+\varepsilon y)\}$ has at most a single zero if y is given. Notice that $p(\varepsilon y, 1)=3\varepsilon y/[2e(1+\varepsilon y/e)]>3/(e+2)>1/(1+\varepsilon y)$ for $\varepsilon y \geqq d$ and $p(\varepsilon y, 0)=0$, and that $p(\varepsilon y, t)>0$. Then there is a $b=b(k)$ such that $0<b<1$ and $p(\varepsilon y, t)>1/(1+\varepsilon y)$ for $t>b$ and $\varepsilon y \geqq d$, which implies Lemma 7.2.

COROLLARY 7.2. *There is an $\tilde{\varepsilon}=\tilde{\varepsilon}(k)$ such that for $\varepsilon y>d$, where ε is in $(0, \tilde{\varepsilon})$ and d is chosen as in Theorem 2,*

$$-[(1+\varepsilon)/(1+\varepsilon y)]G^{-3/2}(\varepsilon, y, v)+3\int_b^v t\,e^{t^2}QG^{-3/2}\,dt>0, \tag{7.5}$$

where b is given as in Lemma 7.2.

Proof. Let $W=(\varepsilon+1)/(\varepsilon+1/y)$ in Lemma 6.2. Since $W(b)$ depends on $b=b(k)$, and $W>(1+\varepsilon)/[\varepsilon(1/d+1)]$ for $\varepsilon y \geqq d$, there is an $\tilde{\varepsilon}=\tilde{\varepsilon}(k)$ such that $W>(1+\varepsilon)/[\varepsilon(1/d+1)]>W(b)$ for all $\varepsilon y \geqq d$, where ε is in $(0, \tilde{\varepsilon})$. Hence by Lemma 6.2,

$$\int_b^v e^{t^2}\,dt>(1+\varepsilon)/[2v(1+\varepsilon y)]. \tag{7.6}$$

Using Lemmas 7.2 and 6.1, we obtain

$$3\int_b^v tG^{-3/2}Q\,e^{t^2}\,dt>2v/[yG^{3/2}(\varepsilon, y, v)]\int_b^v e^{t^2}\,dt. \tag{7.7}$$

From (7.6), the corollary is proved.

LEMMA 7.3. *For given $\varepsilon y>0$, there exists a $\delta_1=\delta_1(\varepsilon, y, k)$ such that for $0<t<\delta_1$, where δ is in $(0, \delta_1)$, $N(\varepsilon, y, t)<0$.*

Proof. Let $c_1(\varepsilon, y)=\lim_{t\to 0} G_1/G$ and $c_2(\varepsilon, y)=\lim_{t\to 0} G_2/G$. From (7.3),

$$N(\varepsilon, y, 0)=(1+2\varepsilon y)c_1(\varepsilon, y)+y(1+\varepsilon y)[c_2(\varepsilon, y)-c_1^2(\varepsilon, y)]<0.$$

In fact $c_1(\varepsilon, y)=-\varepsilon/(1+\varepsilon y)$, $c_2(\varepsilon, y)=2\varepsilon^2/(1+\varepsilon y)^2$ and hence $N(\varepsilon, y, 0)=-\varepsilon$ for $k=\frac{1}{4}$. For $k\neq\frac{1}{4}$ a tedious calculation shows that the lemma also holds.

LEMMA 7.4. *For given $\varepsilon y>0$, there exists a $\delta_2=\delta_2(\varepsilon, y, k)$ such that for δ in $(0, \delta_2)$*

$$M(\varepsilon, y, \delta)+[3/(1+\varepsilon y)^2]\int_{b/2}^{b} t\,e^{t^2}G^{-3/2}Q\,dt>0, \tag{7.8}$$

where $b>0$ is any constant.

Proof. Let $q(\varepsilon, y, k)$ be the second term on the left side of (7.8). By Corollary 7.1, $q(\varepsilon, y, k)>0$. From (7.3),

$$2M(\varepsilon, y, \delta)\,e^{-\delta^2}=[-G_1(\varepsilon, y, \delta)/G(\varepsilon, y, \delta)+c_1(\varepsilon, y)]/\sqrt{G}(\varepsilon, y, \delta) \tag{7.9}$$

where $c_1(\varepsilon, y)$ is in the proof of Lemma 7.3. By L'Hôpital's rule, $\lim_{\delta\to 0} M(\varepsilon, y, \delta)=0$. This completes the proof of Lemma 7.4.

We can now proceed to prove Theorem 3. First fix an ε in $(0, \tilde{\varepsilon})$, where $\tilde{\varepsilon}$ is chosen in Corollary 7.2. Second, for any given $y>d/\varepsilon$, where d is in Theorem 2, take b as in Lemma 7.2 (note that b is independent of ε). Then let $\delta=\min\{\delta_1, \delta_2\}/2$, where

δ_1 and δ_2 are given in Lemmas 7.3 and 7.4 respectively. By Corollaries 7.1 and 7.2 and Lemmas 7.3 and 7.4, we prove the theorem immediately, if we rewrite (7.4) as follows:

$$
\begin{aligned}
F_\varepsilon(y) = M(\varepsilon, y, \delta) &+ [3/(1+\varepsilon y)^2] \int_{b/2}^{b} t\, e^{t^2} G^{-3/2}\, Q\, dt \\
&- (1+\varepsilon)/[(1+\varepsilon y)^3 G^{3/2}(\varepsilon, y, v)] \\
&+ [3/(1+\varepsilon y)^2] \int_{b}^{v} t\, e^{t^2} G^{-3/2} Q\, dt \\
&+ \int_0^{\delta} t\, e^{t^2}(-N)/\sqrt{G}\, dt + [3/(1+\varepsilon y)^2] \int_0^{b/2} t\, e^{t^2} G^{-3/2} Q\, dt.
\end{aligned}
\tag{7.10}
$$

8. The proof of Theorem 4. From (3.11) and $v' = 1/[2vy(1+\varepsilon y)]$,

$$
\begin{aligned}
f''_\varepsilon(y) &= -2(1+\varepsilon)/[y^2(1+\varepsilon y)\sqrt{G}(\varepsilon, y, v)] \\
&\quad - (1+\varepsilon) G_1(\varepsilon, y, v)/[y(1+\varepsilon y) G^{3/2}(\varepsilon, y, v)] \\
&\quad - 1/[y^2(1+\varepsilon y)^2 G^{3/2}(\varepsilon, y, v)] \\
&\quad + \left(\frac{4}{y^3}\right) \int_0^v t\, e^{t^2}/\sqrt{G}\, dt + \left(\frac{2}{y^2}\right) \int_0^v t\, e^{t^2} G_1 G^{-3/2}\, dt \\
&\quad - \left(\varepsilon + \frac{1}{y}\right) \int_0^v [3G_1^2/(2G^{5/2}) - G_2/G^{3/2}]\, t\, e^{t^2}\, dt.
\end{aligned}
\tag{8.1}
$$

LEMMA 8.1. *As ε tends to* 0,

$$
\int_0^v t\, e^{t^2}/\sqrt{G}\, dt \to \frac{\sqrt{2}}{2} \int_0^{\sqrt{\ln y}} e^{t^2}\, dt,
\tag{8.2}
$$

$$
\int_0^v t\, e^{t^2} G_1 G^{-3/2}\, dt \to 0,
\tag{8.3}
$$

$$
\int_0^v t\, e^{t^2}(G_1^2 G^{-5/2} - G_2 G^{-3/2})\, dt \to 0
\tag{8.4}
$$

uniformly on $[1, E]$, *where* $E > 1$ *is any constant.*

Proof. From (3.1) or (3.3), we see that

$$
\frac{\partial G}{\partial \varepsilon} = \left(\frac{\partial G}{\partial y}\right) y/\varepsilon = \frac{G_1 y}{\varepsilon} < 0
\tag{8.5}
$$

for $t, \varepsilon, y > 0$. Thus $t\, e^{t^2}/\sqrt{G}$ monotonely increases as ε decreases for given $t > 0$ and for given $t \geqq 1$. By Dini's theorem,

$$
t\, e^{t^2}/\sqrt{G} \to \sqrt{2}\, e^{t^2}/2
\tag{8.6}
$$

uniformly on any compact set of (y, t) in R^2. In addition, $v \to \ln y$ uniformly on $[1, E]$, so that (8.2) holds. From (3.5) and (3.8), both G_1/t^2 and G_2/t^2 converge to 0 as ε tends to 0 uniformly on any compact set of (y, t) in R^2. Then considering that $t\, e^{t^2} G_1/G^{3/2} = (t\, e^{t^2}/\sqrt{G})(G_1/t^2)(t^2/G)$, we get (8.3). Similarly, one can prove (8.4). Q.E.D.

We then see that in order to determine the sign of $f'_\varepsilon(y)$ when y is near to $y = 1$ the integral terms in (3.11) are not important for small ε. For the first term in (3.11) we need the following lemma.

LEMMA 8.2. *$1/G(\varepsilon, y, v)$ decreases as ε decreases, and hence for $\varepsilon > 0$,*

$$1/\sqrt{G}(\varepsilon, y, v) > 1/\sqrt{(2 \ln y)}. \tag{8.7}$$

Proof. We see that

$$\begin{aligned} \frac{\partial G(\varepsilon, y, v(\varepsilon))}{\partial \varepsilon} &= G_1(\varepsilon, y, v)y/\varepsilon + \frac{\partial G(\varepsilon, y, v)}{\partial v} \cdot \frac{\partial v}{\partial \varepsilon} \\ &= G_1(\varepsilon, y, v)y/\varepsilon + G'(\varepsilon, y, v)/(2v)[1/(1+\varepsilon) - y/(1+\varepsilon y)] \qquad (8.8) \\ &= 2(1-y)(2+\varepsilon+\varepsilon y)/[(1+\varepsilon y)^2(1+\varepsilon)^2] < 0. \end{aligned}$$

At $\varepsilon = 0$, $G(\varepsilon, y, v) = 2 \ln y$, which implies the lemma.

LEMMA 8.3. *There exist two numbers E_1 and α_1 such that for y in $(1, E_1]$ and for α in $(0, \alpha_1]$*

$$1/[y(1+\alpha)\sqrt{(2 \ln y)}] - (2/y^2) \int_0^{\sqrt{\ln y}} e^{t^2}\, dt - 2\alpha > 0. \tag{8.9}$$

Proof. Denote the left side of (8.9) by $j(y, \alpha)$. Obviously, $j(y, \alpha)$ is continuous in $(1, E) \times (0, D)$ where $E > 1$ and $D > 0$ are constants. Because $\lim_{y \to 1} j(y, 0) = +\infty$ as y approaches 0, such an α_1 and E_1 exist. The lemma is proved.

LEMMA 8.4. *There exists an $\varepsilon_{-1} = \varepsilon_{-1}(k)$ such that for ε in $(0, \varepsilon_{-1})$ and y in $(1, E_1]$, where E_1 is chosen as in Lemma 8.3, $f'_\varepsilon(y) > 0$.*

Proof. By Lemma 8.1, there exists an $\varepsilon_{-1} = \varepsilon_{-1}(E_1, k)$ such that

$$\left(\frac{2}{y^2}\right) \int_0^v t e^{t^2}/\sqrt{G}\, dt < \alpha_1 + \left(\frac{\sqrt{2}}{y^2}\right) \int_0^{\sqrt{\ln y}} e^{t^2}\, dt, \tag{8.10}$$

$$\left(\varepsilon + \frac{1}{y}\right) \int_0^v t e^{t^2} G_1 G^{-3/2}\, dt < \alpha_1 \tag{8.11}$$

and $(1+\varepsilon)/[y(1+\varepsilon y)] > 1/[y(1+\alpha_1)]$ for ε in $(0, \varepsilon_{-1})$ and y in $(1, E_1]$, where α_1 is chosen as in Lemma 8.3. Then from (3.11), (8.10) and (8.9), we obtain the lemma.

LEMMA 8.5. *$f'_\varepsilon(y)$ and $f''_\varepsilon(y)$ converge to $f'_0(y)$ and $f''_0(y)$ respectively as ε tends to 0 uniformly on $[E_1, Y_0]$, where E_1 is given as in Lemma 8.4 and Y_0 in Theorem 2.*

Proof. We see that $(1+\varepsilon)/[y(1+\varepsilon y)\sqrt{G}(\varepsilon, y, v)]$ converges to $y/\sqrt{(2 \ln y)}$ uniformly on $[E_1, Y_0]$ as ε tends to 0; the rest follows by Lemma 8.1. Q.E.D.

COROLLARY 8.1. *As ε approaches 0, $F_\varepsilon(y)$ converges to $F_0(y)$ uniformly on $[E_1, Y_0]$.*

From Corollary 8.1, there is an $\varepsilon_{-2} = \varepsilon_{-2}(k)$ such that for (ε, y) in $(0, \varepsilon_{-2}) \times [E_1, Y_0]$, $F_\varepsilon(y) > 0$. To see this we take $\delta = (2 \ln Y_0)^{-3/2}/2$ in the definition of uniform convergence. Then such an ε_{-2} exists and for (ε, y) in $(0, \varepsilon_{-2}) \times [E_1, Y_0]$,

$$\begin{aligned} F_\varepsilon(y) < F_0(y) + \delta &= -(2 \ln y)^{-3/2} + (2 \ln Y_0)^{-3/2}/2 \\ &< -(2 \ln Y_0)^{-3/2}/2. \end{aligned}$$

Now, combining this fact and Lemma 8.4 and taking $\varepsilon_4 = \min\{\varepsilon_{-1}, \varepsilon_{-2}\}$, we have proved Theorem 4.

9. Comments. (i) If k is not equal to $\frac{1}{4}$, most calculations are very tedious. For example, the proof of Lemma 7.1 takes about 15 pages of computation! Nevertheless, the functions which appear in the above proofs for general $k > 0$ still have all the same properties as for $k = \frac{1}{4}$. Much of this has been checked using the symbolic manipulator Macsyma [7].

(ii) If we make a change of parameters as in [1], i.e., define $\beta = s_0/\sqrt{\sigma}$, $\varepsilon = 1/\sqrt{\sigma}$, then the corresponding problem becomes (1.3) with $u(0) = u(1) = 1$. The response function $f_\varepsilon(y, \beta)$ is a function of both y and β. In this case we need to determine the number of solutions of the equation

$$f_\varepsilon(y, \beta) = \frac{\sqrt{2}}{(4\beta\sqrt{k})}. \tag{9.1}$$

We may apply the same ideas to prove that, for given $k > 0$ and for given $\beta > 0$, there is an $\varepsilon_0 = \varepsilon_0(k, \beta)$ such that $f_\varepsilon(y, \beta)$ has exactly two critical points for ε in $(0, \varepsilon_0)$. Hence (1.3) admits no more than three solutions. This is to say that for σ large enough and s_0 conveniently chosen, problem (1.2) admits at most three solutions.

(iii) We can also study the stability of the steady states associated with problem (1.1) in the case where s_0 is large by using the Conley Index Theory or Morse Index Theorem. The conclusion is that if there exist three steady state solutions, then two of them are stable and the other is unstable (cf. [7]).

Acknowledgment. I wish to thank my advisor, Professor Stuart P. Hastings, for the suggestions he contributed to the thesis upon which this paper is based.

WEAK SOLUTIONS TO STEFAN PROBLEMS WITH PRESCRIBED CONVECTION*

JIM RULLA†

Abstract. This paper deals with the equation

$$w_t + \operatorname{div}(\mathbf{v}w - \nabla\alpha(w)) = g,$$

which is to hold in a smooth, bounded domain $G \subset \mathbb{R}^n$. The function $\alpha: \mathbb{R} \to \mathbb{R}$ is uniformly Lipschitz and nondecreasing, but may be identically zero. For certain smooth functions $\mathbf{v}: \bar{G} \to \mathbb{R}^n$ satisfying $\operatorname{div}(\mathbf{v}) \geqq 0$, there are integral solutions to the Cauchy problem associated with this equation, provided the boundary conditions on w are chosen appropriately. We prove that these integral solutions are weak solutions in the usual sense. Moreover, these weak solutions are unique; hence the notion of a weak solution is adequate for problems of this type.

Key words. Stefan problem, free boundary, convection, uniqueness

AMS(MOS) subject classifications. 35D05, 35K65, 35R35

1. Introduction and notation. Consider a mixture of crude oil and melted paraffin flowing through a pipe. As the temperature of the mixture falls, the paraffin solidifies, thus changing the thermal properties of the mixture. We shall develop a heat equation modeling this problem, and we shall prove existence and uniqueness of solutions (in an appropriate sense) to the evolution equation. In [5], Fasano, Primicerio and Rubenstein address this problem classically and obtain solutions if the free boundary is assumed to satisfy a simplifying assumption. Visintin, in [12], considers a similar class of equations and obtains existence results for weak solutions. His solutions are weaker than ours, however. In particular, we prove that solutions are bounded and Lipschitz continuous: $[0, T] \to L^1(G)$ (so the notion of an initial value makes sense in $L^1(G)$) while the similar class of problems yields solutions which are only measurable into L^∞ (hence the notion of initial value must be weakened). By interpolation, we prove that solutions are weak solutions in an L^2 sense. Moreover, these weak solutions are unique provided the data in the problem are appropriately regular; consequently, the notion of a weak solution is appropriate for this problem.

In § 2 of this paper, we present a brief derivation of the Stefan problem. In § 3, we find solutions to an appropriate stationary problem. The operator involved is a degenerate elliptic operator, and existence of solutions depends strongly on our making a suitable choice of boundary conditions. The properties of the solutions which we shall need follow from the uniqueness of solutions, which must be proven independently from the existence argument. In § 4, we prove the existence of integral solutions to the evolution equation and we show that these integral solutions are actually weak solutions. Finally, we prove in § 5 the uniqueness of these weak solutions. This proof mimics the uniqueness proof from § 3.

Let $G \subseteq \mathbb{R}^n$ be a bounded domain with smooth (C^2) boundary, ∂G, which we denote by S. We let $L^p(G)$ and $H^m(G)$ denote the usual Lebesgue and Hilbert spaces of measurable functions on G, and we omit the reference to the set G when such reference is unnecessary. We use the notation $C([0, T]; L^p)$ to denote the space of continuous functions from $[0, T]$ into L^p.

† Department of Mathematics, University of Texas, Austin, Texas 78712. Present address, Department of Mathematics, North Carolina State University, Raleigh, North Carolina 27695-8205.

We denote the spatial divergence and gradient operators, respectively, by div $(\cdot)$ and ∇. The spatial Laplace operator is denoted by Δ. A natural domain for the divergence operator is the space $\mathscr{E}$ defined by

$$\mathscr{E}=\{\mathbf{v}\in(L^2)^n \mid \operatorname{div}(\mathbf{v})\in L^2\}.$$

The space $(L^2)^n$ here is the n-fold product of $L^2(G)$. The trace operators γ_0 and γ_ν, which represent restricting scalar and normal components of vector valued functions, on G to S, respectively, are then related by

$$\int_G [\operatorname{div}(\mathbf{v})u+\mathbf{v}\cdot\nabla u]=\langle\gamma_\nu(\mathbf{v}),\ \gamma_0(u)\rangle$$

for all $\mathbf{v}\in\mathscr{E}$ and $u\in H^1$. The duality on the right takes place between $H^{1/2}(S)$ and its dual (cf. [11]). If $\boldsymbol{\nu}:S\to\mathbb{R}^n$ is the unit outward normal on S, then

$$\langle\gamma_\nu(\mathbf{v}),\ \gamma_0(u)\rangle=\int_S(\boldsymbol{\nu}\cdot\mathbf{v})u$$

provided $\mathbf{v}$ and u are smooth enough. In addition, $C^\infty(\bar{G})$ is dense in $\mathscr{E}$ (when $\mathscr{E}$ is supplied with its natural topology).

We shall split S into disjoint measurable subsets S_1 and S_2. If S_1 has positive (surface) measure, then the space

$$V\equiv\{v\in H^1(G) \mid \gamma_0(v)=0 \text{ a.e. (w.r.t. surface measure) on } S_1\}$$

is a Hilbert space with inner product

$$(u,v)_V\equiv\int_G\nabla u\cdot\nabla v.$$

We shall make use of the notation

$$\langle u,v\rangle\equiv\int_G uv$$

whenever the product $uv\in L^1$. We use the same notation if $\mathbf{u}\cdot\mathbf{v}\in L^1$, i.e.,

$$\langle\mathbf{u},\mathbf{v}\rangle=\int_G\mathbf{u}\cdot\mathbf{v}.$$

We conclude this section by recalling that a subset $\mathscr{A}$ of $L^1\times L^1$ is *accretive* provided

$$\|x_1-x_2\|_{L^1}\leqq\|(x_1+\lambda y_1)-(x_2+\lambda y_2)\|_{L^1}$$

for all pairs $[x_i,y_i]\in\mathscr{A}$ $(i=1,2)$ and all (sufficiently small) $\lambda>0$. This is equivalent to having

$$\int_G(y_1-y_2)\sigma\geqq0,$$

where σ is some measurable function on G chosen so that

$$\sigma\in\operatorname{sgn}(x_1-x_2)\quad\text{a.e. in } G.$$

The signum relation is given by

$$\operatorname{sgn}(s)=\begin{cases}\{1\}, & s>0,\\ [-1,1], & s=0,\\ \{-1\}, & s<0.\end{cases}$$

We view the set $\mathscr{A}$ as the graph of an operator, which we denote by $\mathscr{A}$. The operator $\mathscr{A}$ is *m-accretive* if, for every $\lambda > 0$ and every $f \in L^1$, there is a solution u to

$$u + \lambda \mathscr{A}(u) \ni f.$$

For a thorough treatment of m-accretive operators and the semigroups they generate, see [1, Chaps. 2 and 3]. We denote the *zero section* of a graph by a subscripted zero. If β is a graph, then $\beta_0(s)$ is the element of the set $\beta(s)$ which is closest to zero. For example,

$$\operatorname{sgn}_0(s) = \begin{cases} 1, & s > 0, \\ 0, & s = 0, \\ -1, & s < 0. \end{cases}$$

2. The formulation of the Stefan problem. We consider a fluid flowing through a bounded domain, $G \subseteq \mathbb{R}^n$, with a prescribed velocity $\mathbf{v} \in C^1(\bar{G}; \mathbb{R}^n)$. We shall make further restrictions on the velocity in § 3. Let $u(x)$ denote the temperature and $w(x)$ the enthalpy or heat energy of the fluid at the point $x \in G$. When the fluid changes phase, the enthalpy increases by an amount L per unit mass, while the temperature remains constant. The quantity L is the latent heat of the material. This fact suggests that the enthalpy, not the temperature, is the natural function to consider in problems of heat transfer (cf. [10]). If $c = c(u)$ is the heat capacity of the material (which depends on the phase and may be discontinuous) and $\xi \in [0, 1]$ is the fraction of the material in the more energetic phase, then a unit mass of the material has enthalpy

$$w = c(u)u + \xi L.$$

If the phase change occurs when $u = u_0$, then $\xi \in H(u - u_0)$, where $H(x) = \operatorname{sgn}^+(x)$ is the Heaviside graph. We may then write

$$w \in c(u)u + LH(u - u_0),$$

so w is given as a nondecreasing relation of u. In fact, we may invert this relation to obtain the temperature as a nondecreasing function of the enthalpy:

$$u = \theta(w).$$

If $k = k(u)$ denotes the conductivity of the material (which again depends on the phase and may be discontinuous), then the flux or flow of energy at any point in G is given by

$$\begin{aligned} \text{flux} &= \mathbf{v}w - k(u)\nabla u \\ &= \mathbf{v}w - \nabla \alpha(w), \end{aligned}$$

where $\alpha : \mathbb{R} \to \mathbb{R}$ is the antiderivative of $k \circ \theta$ with $\alpha(0) = 0$. We remark that α is nondecreasing and satisfies $\alpha'(s) = 0$ for $s \in [\theta_0^{-1}(u_0), \theta_0^{-1}(u_0) + L]$. The temperature u and $\alpha(w)$ are related by a one-to-one correspondence and we abuse the distinction by referring to $\alpha(w)$ as the temperature. We shall, naturally, require that $\alpha(w) \in H^1$. Notice that this requirement may force $\alpha(w) \notin H^2$ and $w \notin H^1$. In fact, since energy is conserved, the free boundary (where the two phases of material meet) advances at a speed proportional to the jump in the normal component of the flux across the boundary. In [8], Rubenstein comments on the adequacy of this model.

Let $\Omega = G \times (0, T)$ and divide Ω into three regions:

$$\Omega_0 = \{\alpha(w(x, t)) = u_0\},$$

$$\Omega_1 = \{\alpha(w(x, t)) < u_0\},$$

$$\Omega_2 = \{\alpha(w(x, t)) > u_0\}.$$

In each of these regions, energy is conserved, so

$$\frac{\partial w}{\partial t}+\operatorname{div}(\mathbf{v}w-\nabla\alpha(w))=g \quad \text{in } \Omega_j, \qquad j=0,1,2,$$

where g represents any external heat sources or sinks. If we multiply by a smooth function $\varphi\in C^\infty(\bar\Omega)$ and formally integrate by parts over each of the three regions, we get

$$\begin{aligned}\int_{\Omega_0}+\int_{\Omega_1}+\int_{\Omega_2}&\left[\frac{\partial w}{\partial t}+\operatorname{div}(\mathbf{v}w-\nabla\alpha(w))\right]\varphi\\ &=-\int_{\Omega}\left[w\frac{\partial\varphi}{\partial t}+\mathbf{v}w\cdot\nabla\varphi-\nabla\alpha(w)\cdot\nabla\varphi\right]\\ &\quad+\int_{\partial\Omega_1}+\int_{\partial\Omega_2}+\int_{\partial\Omega_3}\mathbf{N}\cdot(\mathbf{v}w-\nabla\alpha(w),w)\varphi.\end{aligned}$$

The vector N is the unit normal out of each of the regions $\Omega_j, j=0,1,2$, and $(\cdot,\cdot)$ denotes vectors in $\mathbb{R}^n\times\mathbb{R}$. The jump condition on the flux is equivalent to having the boundary integrals make a nonzero contribution only on $\partial\Omega$, not on any of the interior interfaces. We conclude that

$$\begin{aligned}&\int_{\Omega} g\varphi+w\frac{\partial\varphi}{\partial t}+\mathbf{v}w\cdot\nabla\varphi-\nabla\alpha(w)\cdot\nabla\varphi\\ &\quad=\int_0^T\int_{\partial G}(\mathbf{v}w-\nabla\alpha(w))\cdot\boldsymbol{\nu}\varphi+\int_G[\varphi(\cdot,T)w(\cdot,T)-\varphi(\cdot,0)w(\cdot,0)].\end{aligned}\tag{2.1}$$

If $\varphi\in C_0^\infty(\Omega)$, then we are led to the differential equation

$$\frac{\partial w}{\partial t}+\operatorname{div}(\mathbf{v}w-\nabla\alpha(w))=g.\tag{2.2a}$$

It is important to choose the boundary conditions on w carefully in order to be able to solve this problem. We let $S=S_1\cup S_2$, where S_1 and S_2 are disjoint, measurable subsets of $S=\partial G$. We require that

$$S_1\subseteq\{s\in S\,|\,\boldsymbol{\nu}(s)\cdot\mathbf{v}(s)\geqq 0\}$$

and

$$S_2\subseteq\{s\in S\,|\,\boldsymbol{\nu}(s)\cdot\mathbf{v}(s)\leqq 0\}$$

and that the measure of S_1 be nonzero. For a specified $g_1\in H^1$ and $\mathbf{g}_2\in\mathscr{C}$, we shall require that

$$\begin{aligned}&\gamma_0(\alpha(w))=\gamma_0(g_1)\quad\text{a.e. on } S_1,\\ &\langle\gamma_\nu(\mathbf{g}_2-(\mathbf{v}w-\nabla\alpha(w))),\gamma_0(v)\rangle=0\quad\text{for all } v\in V.\end{aligned}\tag{2.2b}$$

(Recall that $V=\{v\in H^1\,|\,\gamma_0(v)=0 \text{ a.e. on } S_1\}$.) Notice that we specify the *temperature* on S_1 and the normal component of the *flux* on S_2.

The last piece of data which we need to make the Cauchy problem well posed is the initial enthalpy

$$w(x,0)=w_0(x).\tag{2.2c}$$

3. The stationary problem. A standard approach to solving the Cauchy problem (2.2) is to define an operator $\mathcal{A}$ corresponding to the spatial derivatives $\operatorname{div}(\mathbf{v}(\cdot)-\nabla\alpha(\cdot))$ on an appropriate domain $D(\mathcal{A})$ of functions in some Banach space X which satisfy the boundary conditions (2.2b). One then proves that $\mathcal{A}$ is m-accretive on X and then applies the generation theorems of Crandall and Liggett [4] or Benilan [2], [1] to obtain "solutions" $w:[0, T]\to X$ to

$$
\begin{aligned}
&\frac{dw(t)}{dt}+\mathcal{A}(w(t))\ni g(t),\\
&w(0)=w_0.
\end{aligned}
\tag{3.1}
$$

If X is reflexive and the data $g(t)$ and w_0 are sufficiently well behaved, then $w(t)\in D(\mathcal{A})$ a.e. on $[0, T]$ and w satisfies (3.1) a.e. in $[0, T]$ (cf. [1]). It is easy to see by a formal computation, however, that $\mathcal{A}$ cannot be accretive on L^p for $p>1$. Since L^1 is not reflexive, the above regularity result fails, and "solutions" to (3.1) may satisfy $w(t)\notin D(\mathcal{A})$ for all $t\in[0, T]$. In addition, it is difficult to identify $D(\mathcal{A})$ if $G\subseteq\mathbb{R}^n$ with $n>1$. These observations motivate our search for weak solutions to (2.1), i.e., functions $w\in C([0, T]; L^2)$ satisfying $\alpha(w)-g_1\in L^2([0, T]; V)$ and

$$
\begin{aligned}
&\int_0^T \langle g,\varphi\rangle+\left\langle w,\frac{d\varphi}{dt}+\mathbf{v}\cdot\nabla\varphi\right\rangle-\langle\nabla\alpha(w),\nabla\varphi\rangle\,dt\\
&\qquad=\langle w(T),\varphi(T)\rangle-\langle w(0),\varphi(0)\rangle+\int_0^T\langle\gamma_\nu(\mathbf{g}_2),\gamma_0(\varphi)\rangle\,dt
\end{aligned}
\tag{3.2}
$$

for all appropriately smooth testing functions $\varphi:[0, T]\to V$.

In order to prove the existence of solutions to (3.2) we employ the following plan:

(1) Define an operator in $L^2\times L^2$ and prove that this operator is accretive when considered as a subset of $L^1\times L^1$.

(2) Prove that the closure of the operator in (1) is m-accretive in $L^1\times L^1$.

(3) Prove that the integral solutions generated by the operator in (2) are weak solutions (solutions to (3.2)).

Step (1) is similar in nature to the technique used in [3]. The uniqueness proof used in Step (1) contains the idea of the proof of uniqueness of weak solutions. Steps (2) and (3) consist primarily of applying the estimates found in Theorem 1 in an obvious way to obtain the necessary estimates.

Throughout the remainder of this discussion, we shall assume that the following "regularity" conditions are met:

The function $\alpha:\mathbb{R}\to\mathbb{R}$ is uniformly Lipschitz continuous with a derivative at all but finitely many points.

The functions $g_1, \mathbf{g}_2$ and g satisfy $g_1\in H^1(G)$, $\mathbf{g}_2\in\mathscr{E}$ and $g\in L^1([0, T]; L^\infty(G))$. We shall assume that $\gamma_0(g_1)\in L^\infty(S_1)$, that $\gamma_0(g_1)\in$ Range of (α) a.e. on S_1 and that $\gamma_0(g_1)$ satisfies $\|\alpha_0^{-1}(\gamma_0(g_1))\|_{L^\infty(S_1)}<\infty$, where α_0^{-1} is the zero section of the graph of α^{-1}. We also suppose that there is a constant M chosen so that

$$
\langle\gamma_\nu(\mathbf{g}_2),\gamma_0(v)\rangle\leqq M|\langle\gamma_\nu(\mathbf{v}),\gamma_0(v)\rangle|\quad\forall v\in V.
\tag{3.3}
$$

In particular, if $\mathbf{g}_2$ is smooth, this means that

$$
|\boldsymbol{\nu}\cdot\mathbf{g}_2|\leqq M|\boldsymbol{\nu}\cdot\mathbf{v}|\quad\text{a.e. on } S_2.
$$

The function $\mathbf{v}\in C^1(\bar{G};\mathbb{R}^n)$ satisfies $\operatorname{div}(\mathbf{v})\geqq 0$ in G. This means that the fluid may be incompressible ($\operatorname{div}(\mathbf{v})=0$) or that there may be sources of flow ($\operatorname{div}(\mathbf{v})\geqq 0$). Since the fluid will adhere to the sides of the pipe, we expect that $\mathbf{v}=\mathbf{0}$ on that portion of

S corresponding to the pipe. In fact, we shall only require that $\mathbf{v}=\mathbf{0}$ on the set $\partial S_1=\partial S_2$. We define the operator

$$\mathcal{A}_2(w)=\operatorname{div}(\mathbf{v}w-\nabla\alpha(w))$$

on the set

$$D(\mathcal{A}_2)=\{w\in L^2\,|\,\alpha(w)-g_1\in V,\ \mathcal{A}_2(w)\in L^2,\text{ and}$$
$$\langle\gamma_\nu(\mathbf{v}w-\nabla\alpha(w)-\mathbf{g}_2),\ \gamma_0(v)\rangle=0\ \forall v\in V\}.$$

THEOREM 1. *There is a constant* $\delta=\delta(\mathbf{v})$ *so that if* $\lambda\leqq\delta$ *and* $f\in L^\infty$, *then there is a unique* $w\in D(\mathcal{A}_2)$ *satisfying*

$$w+\lambda\mathcal{A}_2(w)=f \tag{3.4}$$

(*notice that* $\mathcal{A}_2$ *is single valued*; *hence equality holds rather than containment*). *If* w_1 *and* w_2 *satisfy* (3.4) *with* f *replaced by* f_1 *and* f_2, *respectively, then*

$$\|(w_1-w_2)^+\|_{L^1}\leqq\|(f_1-f_2)^+\|_{L^1}. \tag{3.5}$$

In particular, $\mathcal{A}_2$ *is accretive in* $L^1\times L^1$ *and the resolvent* $(I+\lambda\mathcal{A}_2)^{-1}$ *is order preserving. Finally, if* $\beta=\alpha^{-1}$,

$$K_1\equiv\min\left\{\beta_0\left(\operatorname*{ess\,inf}_{S_1}(\gamma_0(g_1))\right),-M\right\}\leqq 0$$

and

$$K_2\equiv\max\left\{\beta_0\left(\operatorname*{ess\,sup}_{S_1}(\gamma_0(g_1))\right),M\right\}\geqq 0,$$

then

$$\min\left\{\operatorname*{ess\,inf}_G(f),K_1\right\}\leqq w\leqq\max\left\{\operatorname*{ess\,sup}_G(f),K_2\right\} \tag{3.6}$$

a.e. in G.

Proof. We prove uniqueness of solutions first. Uniqueness of solutions to (3.4) follows from (3.5), but estimate (3.5) is established assuming that solutions to (3.4) are unique; therefore, we require an independent uniqueness proof.

Let w_1 and $w_2\in D(\mathcal{A}_2)$ satisfy (3.4). Then

$$(w_1-w_2)+\lambda\operatorname{div}(\mathbf{v}(w_1-w_2)-\nabla(\alpha(w_1)-\alpha(w_2)))=0$$

and $\alpha(w_1)-\alpha(w_2)\in V$. For any testing function $\varphi\in V$ we have

$$0=\int_G(w_1-w_2)\varphi-\lambda[\mathbf{v}(w_1-w_2)-\nabla(\alpha(w_1)-\alpha(w_2))]\cdot\nabla\varphi \tag{3.7}$$

since the boundary term in the integration by parts formula is zero. The proof of uniqueness follows by choosing an appropriate testing function φ. Readers familiar with the duality between H_0^1 and H^{-1} will recognize the similarity between the techniques used there and here.

Let $\varphi\in V$ be the solution to the mixed boundary value problem

$$-\Delta\varphi=w_1-w_2\in L^2,\qquad\frac{\partial\varphi}{\partial\nu}=0\quad\text{a.e. on }S_2.$$

Then $\varphi \in V$ and for all $v \in V$,

$$\int_G \nabla\varphi\cdot\nabla v=\int_G (w_1-w_2)v.$$

This problem is well posed (cf. [9]) and so $w_1=w_2$ if and only if $\varphi\equiv 0$.

With this choice of φ, (3.7) becomes

$$0=\int_G |\nabla\varphi|^2+\lambda(\Delta\varphi\mathbf{v})\cdot\nabla\varphi+\lambda(\alpha(w_1)-\alpha(w_2))(w_1-w_2) \tag{3.8}$$

since $\alpha(w_1)-\alpha(w_2)\in V$. The last term is nonnegative a.e. because α is nondecreasing. By the regularity theory for elliptic operators (cf. [9]), $\varphi\in H^2(G')$ for any $G'\subset G$ whose intersection with a neighborhood of ∂S_1 is void. If ψ is a smooth function in G with support $\subset \bar{G}'$, then $\psi\mathbf{v}\cdot\nabla\varphi\in H^1(G)$ and

$$\int_G \Delta\varphi(\psi\mathbf{v}\cdot\nabla\varphi)=\langle\gamma_\nu(\nabla\varphi),\gamma_0(\psi\mathbf{v}\cdot\nabla\varphi)\rangle-\int_G \nabla\varphi\cdot\nabla(\psi\mathbf{v}\cdot\nabla\varphi).$$

The boundary term is

$$\int_S (\boldsymbol{\nu}\cdot\nabla\varphi)\psi\mathbf{v}\cdot\nabla\varphi=\int_{S_1}(\boldsymbol{\nu}\cdot\nabla\varphi)\psi\mathbf{v}\cdot\nabla\varphi$$

because $\boldsymbol{\nu}\cdot\nabla\varphi=0$ on $S_2\cap\bar{G}'$. Suppose for the moment that φ is smooth in a neighborhood of $S_1\cap\bar{G}'$. Then $\nabla\varphi$ lies in the direction of $\pm\boldsymbol{\nu}$ on $\{s\in S_1|\nabla\varphi(s)\neq\mathbf{0}\}$ because $\varphi=0$ on S_1. In this case,

$$\int_S (\boldsymbol{\nu}\cdot\nabla\varphi)\psi\mathbf{v}\cdot\nabla\varphi=\int_{S_1}\boldsymbol{\nu}\cdot\mathbf{v}|\nabla\varphi|^2\psi.$$

This equality remains valid for $\varphi\in V\cap H^2(G')$ with $\partial\varphi/\partial\nu=0$ on S_2 by a simple approximation argument.

From the above computation, we have

$$\int_G \Delta\varphi(\psi\mathbf{v}\cdot\nabla\varphi)=\int_{S_1}\boldsymbol{\nu}\cdot\mathbf{v}|\nabla\varphi|^2\psi-\int_G \varphi_j[(\psi\mathbf{v}^i)_j\varphi_i+\psi\mathbf{v}^i\varphi_{ij}],$$

where $\mathbf{v}=(v^1,\cdots,v^n)$, $\varphi_j=\partial\varphi/\partial x_j$, and the summation over $1\leqq i,j\leqq n$ is implicit. The last integrand is

$$\varphi_j\varphi_{ij}\psi\mathbf{v}^i=\varphi_j\varphi_{ji}\psi\mathbf{v}^i=\tfrac{1}{2}\psi\mathbf{v}^i\,\partial_i(\varphi_j)^2=\tfrac{1}{2}\psi\mathbf{v}\cdot\nabla|\nabla\varphi|^2.$$

We integrate by parts to get

$$\begin{aligned}\int_G \varphi_j\psi\mathbf{v}^i\varphi_{ij}&=\int_S \frac{1}{2}\psi\mathbf{v}\cdot\boldsymbol{\nu}|\nabla\varphi|^2-\int_G \frac{1}{2}\operatorname{div}(\psi\mathbf{v})|\nabla\varphi|^2\\ &\leqq\int_{S_1}\frac{1}{2}\psi\mathbf{v}\cdot\boldsymbol{\nu}|\nabla\varphi|^2-\int_G \frac{1}{2}\operatorname{div}(\psi\mathbf{v})|\nabla\varphi|^2,\end{aligned}$$

provided $\psi\geqq 0$, since $\mathbf{v}\cdot\boldsymbol{\nu}\leqq 0$ on S_2. With this estimate, we have

$$\begin{aligned}\int_G \Delta\varphi(\psi\mathbf{v}\cdot\nabla\varphi)&\geqq\int_G \frac{1}{2}\operatorname{div}(\psi\mathbf{v})|\nabla\varphi|^2-(\psi\mathbf{v}^i)_j\varphi_j\varphi_i+\int_{S_1}\frac{1}{2}\boldsymbol{\nu}\cdot\mathbf{v}|\nabla\varphi|^2\psi\\ &\geqq\int_G \frac{1}{2}\operatorname{div}(\psi\mathbf{v})|\nabla\varphi|^2-(\psi\mathbf{v}^i)_j\varphi_j\varphi_i,\end{aligned}$$

provided $\psi\geqq 0$, because $\boldsymbol{\nu}\cdot\mathbf{v}\geqq 0$ on S_1.

Let $\varepsilon > 0$ and define

$$\sigma_\varepsilon^+(s) = \begin{cases} 1, & s > \varepsilon, \\ s/\varepsilon, & 0 \leqq s \leqq \varepsilon, \\ 0, & s < 0. \end{cases}$$

If we let $\psi \in \sigma_\varepsilon^+(|\mathbf{v}|^2 - \varepsilon)$, then the above calculations are valid, and $\psi\mathbf{v} \to \mathbf{v}$ boundedly in $\bar{G}$ as $\varepsilon \downarrow 0$. We calculate

$$\partial_j(\psi \mathbf{v}^i) = \frac{2\mathbf{v} \cdot \mathbf{v}_j \mathbf{v}^i}{\varepsilon} \chi_{\{0 \leqq |\mathbf{v}|^2 - \varepsilon \leqq \varepsilon\}} + \psi \mathbf{v}_j^i.$$

Both terms remain bounded and the sum tends to $\mathbf{v}_j^i$ a.e. as $\varepsilon \downarrow 0$. We apply the dominated convergence theorem to verify

$$\begin{aligned} \int_G \Delta\varphi(\mathbf{v} \cdot \nabla\varphi) &\geqq \int_G \frac{1}{2} \operatorname{div}(\mathbf{v})|\nabla\varphi|^2 - \mathbf{v}_j^i \varphi_i \varphi_j \\ &\geqq -K(\mathbf{v}) \int_G |\nabla\varphi|^2. \end{aligned} \tag{3.9}$$

We return now to estimate (3.8). Using (3.9), we have

$$0 \geqq \int_G |\nabla\varphi|^2 - \lambda K(\mathbf{v})|\nabla\varphi|^2 \geqq \frac{1}{2}\|\varphi\|_V^2$$

provided $\lambda K(\mathbf{v}) \leqq \frac{1}{2}$. We conclude that $\varphi \equiv 0$; hence $w_1 = w_2$.

Proof of existence. It is convenient to work with temperature rather than with enthalpy when proving existence of solutions. Let $\beta = \alpha^{-1}$ and assume for the moment that β is Lipschitz with Lipschitz constant μ. We begin by establishing estimates which are independent of μ.

Let $u = \alpha(w)$, so $w = \beta(u)$. Then $w \in D(\mathcal{A}_2)$ is a solution to (3.4) if and only if

$$u - g_1 \in V, \tag{3.10a}$$

$$\mathbf{v}\beta(u) - \nabla u \in \mathscr{E}, \tag{3.10b}$$

and

$$b(u, v) = \langle f, v \rangle \quad \text{for all } v \in V, \tag{3.10c}$$

where $b(u, v) \equiv \int_G [\beta(u)(v - \lambda\mathbf{v} \cdot \nabla v) + \lambda \nabla u \cdot \nabla v] + \lambda\langle \gamma_\nu(\mathbf{g}_2), \gamma_0(v)\rangle$.

LEMMA. *If* $f \in L^\infty$ *and* u *satisfies* (3.10), *then*

$$\min\left\{\operatorname*{ess\,inf}_G (f), K_1\right\} \leqq \beta(u) \leqq \max\left\{\operatorname*{ess\,sup}_G (f), K_2\right\} \quad \textit{a.e. in } G.$$

Proof. We shall establish the right inequality; the left inequality is proved in a similar manner.

Let K be chosen so that $\beta(K) \geqq K_2$, and set $v = \sigma_\varepsilon^+(u - K)$. Then $v \in V$ (cf. [6, p. 54]) and

$$\begin{aligned} \int_G (f - \beta(K))v = \int_G &\Big[(\beta(u) - \beta(K))v - \lambda\mathbf{v}[\beta(u) - \beta(K)] \cdot \nabla v + \lambda\nabla(u - K) \cdot \nabla v\Big] \\ &- \lambda \int_G [\mathbf{v}\beta(K) \cdot \nabla v] + \lambda\langle \gamma_\nu(\mathbf{g}_2), \gamma_0(v)\rangle. \end{aligned}$$

We calculate

$$\nabla v = (\nabla(u-K)/\varepsilon)\chi_{E_\varepsilon} \quad \text{a.e. in } G,$$

where χ_{E_ε} is the characteristic function of the set $E_\varepsilon = \{x \in G \mid 0 < u(x) - K < \varepsilon\}$. If we integrate the term in the second integral on the right by parts, we get

$$\begin{aligned}\|(f-\beta(K))^+\|_{L^1} &\geqq \int_G (f-\beta(K))\sigma_\varepsilon^+(u-K)\\ &\geqq \int_G \Big[(\beta(u)-\beta(K))v - \lambda\mathbf{v}\Big[\frac{\beta(u)-\beta(K)}{\varepsilon}\Big]\nabla(u-K)\chi_{E_\varepsilon}\\ &\qquad + \lambda\beta(K)\operatorname{div}(\mathbf{v})v\Big]\\ &\qquad + \lambda\langle\gamma_\nu(\mathbf{g}_2 - \mathbf{v}\beta(K)), \gamma_0(v)\rangle.\end{aligned}$$

The boundary term is nonnegative since $v \in V$, $v \geqq 0$, $\beta(K) \geqq M$, $\mathbf{v} \cdot \boldsymbol{\nu}\beta(K) \leqq 0$ on S_2, and condition (3.3) holds. We let $\varepsilon \downarrow 0$. Since β is Lipschitz, the second term on the right is dominated by a constant times a function which goes to zero boundedly on G. Hence this term tends to zero. The third term on the right is nonnegative since $v \geqq 0$, $\beta(K) \geqq 0$ and $\operatorname{div}(\mathbf{v}) \geqq 0$ a.e. in G. Finally, as $\varepsilon \downarrow 0$, v tends to $\operatorname{sgn}_0^+(u-K) = \operatorname{sgn}_0^+(\beta(u)-\beta(K))$ boundedly a.e. in G, so

$$\|(f-\beta(K))^+\|_{L^1} \geqq \|(\beta(u)-\beta(K))^+\|_{L^1}.$$

The lemma now follows by choosing $\beta(K) = \max\{\operatorname{ess\,sup}_G(f), K_2\}$. □

Let $\mathscr{B}: V \to V^*$, the dual of V, be the operator defined by

$$(\mathscr{B}y, v)_{V^*,V} = b(y+g_1, v).$$

If we prove that $\mathscr{B}$ is bounded, coercive, and Type-M, then there is a solution $y \in V$ to

$$(\mathscr{B}y, v)_{V^*,V} = \langle f, v\rangle \quad \text{for all } v \in V$$

(cf. [7]). The function $y + g_1 \equiv u$ is then the solution to (3.10).

We begin by estimating

$$\begin{aligned}|(\mathscr{B}y, v)_{V^*,V}| = |b(y+g_1, v)| &\leqq \|\beta(y+g_1)\|_{L^2} \cdot K\|v\|_V\\ &\quad + \lambda\|y+g_1\|_V \cdot \|v\|_V + \lambda\|\mathbf{g}_2\|_{\mathscr{G}} \cdot \|v\|_V,\end{aligned}$$

where $1 + \lambda\|\mathbf{v}\|_{L^\infty} = K$. Since β is Lipschitz and $\beta(0) = 0$,

$$\|\beta(y+g_1)\|_{L^2} \leqq \mu\|y+g_1\|_{L^2} \leqq \mu C\|y+g_1\|_V,$$

where C depends only on G (by Poincaré's lemma). We conclude that $\mathscr{B}$ is bounded.

Next, we observe that if $y_n \rightharpoonup y$ (converges weakly) in V, then $y_n \to y$ in L^2 and $\beta(y_n + g_1) \to \beta(y+g_1)$ in L^2 since β is Lipschitz. We conclude from the definition of $\mathscr{B}$ that $\mathscr{B}$ is weakly continuous, hence Type-M.

Finally, we want to prove that $\mathscr{B}$ is coercive. For $v \in V$, we have

$$\begin{aligned}(\mathscr{B}(v), v)_{V^*,V} &= \int_G [\beta(v+g_1)(v+g_1-\lambda\mathbf{v}\cdot\nabla(v+g_1)) + \lambda\nabla(v+g_1)\cdot\nabla v]\\ &\quad - \int_G [\beta(v+g_1)(g_1 - \lambda\mathbf{v}\cdot\nabla g_1)] + \lambda\langle\gamma_\nu(g_2), \gamma_0(v)\rangle.\end{aligned}$$

Let $B: \mathbb{R} \to \mathbb{R}$ be the antiderivative of β with $B(0) = 0$. Then $B(s) \geqq 0$ for all s since β

is nondecreasing and $\beta(0)=0$. Also,

$$-\lambda\int_V \mathbf{v}\beta(v+g_1)\cdot\nabla(v+g_1)=-\lambda\int_G \mathbf{v}\cdot\nabla B(v+g_1)$$
$$=-\lambda\langle\gamma_\nu(\mathbf{v}),\ \gamma_0(B(v+g_1))\rangle+\lambda\int_G \operatorname{div}(\mathbf{v})B(v+g_1)$$

provided $\beta(v+g_1)\in L^\infty(G)$ (so that $B(v+g_1)\in H^1$). In this case, the rightmost side is given by

$$-\lambda\int_S \mathbf{v}\cdot\boldsymbol{\nu}B(v+g_1)+\lambda\int_G \operatorname{div}(\mathbf{v})B(v+g_1)\geqq-\lambda\int_{S_1}\mathbf{v}\cdot\boldsymbol{\nu}B(g_1)$$

since $\mathbf{v}\cdot\boldsymbol{\nu}\leqq 0$ on S_2 and div ($\mathbf{v}$), $B(v+g_1)\geqq 0$. This estimate now follows for all $v\in V$ by approximation.

With this estimate we have

$$(3.11)\qquad (\mathcal{B}(v),v)_{V^*,V}\geqq c\|v+g_1\|_{L^2}^2+\frac{\lambda}{2}\|v\|_V^2-K(\|\beta(v+g_1)\|_{L^2}+1),$$

where $\beta(s)s\geqq cs^2$ (since $\alpha=\beta^{-1}$ is Lipschitz) and K is independent of μ. From this estimate, it is easy to see that $(\mathcal{B}(v),v)_{V^*,V}/\|v\|_V\to\infty$ as $\|v\|_V\to\infty$; hence $\mathcal{B}$ is coercive.

We require one further estimate before we consider the case of non-Lipschitz β. Suppose u_1 and u_2 satisfy (3.10) with f replaced, respectively, with f_1 and f_2. Then

$$\int_G (f_1-f_2)v=\int_G[\beta(u_1)-\beta(u_2)][v-\lambda\mathbf{v}\cdot\nabla v]+\lambda\nabla(u_1-u_2)\cdot\nabla v$$

for all $v\in V$. We take $v=\sigma_\varepsilon^+(u_1-u_2)$, let $\varepsilon\downarrow 0$ and argue as in the previous lemma to get

$$(3.12)\qquad \|(f_1-f_2)^+\|_{L^1}\geqq\|(\beta(u_1)-\beta(u_2))^+\|_{L^1},$$

since $[\beta(u_1)-\beta(u_2)]\operatorname{sgn}_0^+(u_1-u_2)=(\beta(u_1)-\beta(u_2))^+$.

Theorem 1 is now proved in the case of Lipschitz $\beta=\alpha^{-1}$. Notice that we have *not* made use of the uniqueness of solutions to (3.4) yet; uniqueness in this case follows from (3.5), which we have obtained independently from the uniqueness proof. Our development in § 2, however, indicates that $\beta=\alpha^{-1}$ is not a function, since $\alpha'(s)=0$ for s belonging to the interval corresponding to the energy during a phase change. We suppose now, therefore, that β is not Lipschitz and set

$$\alpha_\mu(s)=\alpha(s)+\frac{s}{\mu},$$

and

$$\beta_\mu(s)=\alpha_\mu^{-1}(s).$$

Then β_μ is Lipschitz with Lipschitz constant $\leqq\mu$ and $|\beta_\mu(s)|\leqq|\beta_0(s)|$ for all s. Let u_μ denote the solution to (3.10) with β replaced by β_μ. Then

$$\|\beta_\mu(u_\mu)\|_{L^\infty}\leqq\max\{-K_1,K_2,\|f\|_{L^\infty}\}$$

uniformly in μ by our lemma, and from our calculation (3.11) we see that $\|u_\mu\|_V$ must also be uniformly bounded. Choose a sequence $\{\mu_k\}$ tending to $+\infty$ so that

$$u_{\mu_k} \rightharpoonup u \quad \text{in } V,$$
$$u_{\mu_k} \to u \quad \text{in } L^2,$$

and

$$\beta_{u_k}(u_{\mu_k}) \rightharpoonup w \quad \text{in } L^2.$$

To prove that $\alpha(w) = u$, let $w_k = \beta_{\mu_k}(u_{\mu_k})$. Then

$$\alpha(w_k) = \alpha_{\mu_k}(w_k) - \frac{(w_k)}{\mu_k} = u_{\mu_k} - \frac{w_k}{\mu_k},$$

which tends to u as $k \to \infty$ since $\|w_k\|_{L^\infty}$ is bounded. We have

$$\begin{aligned}\|\alpha(w) - u\|_{L^2} &\leqq \|\alpha(w) - \alpha(w_k)\|_{L^2} + \|\alpha(w_k) - u_{\mu_k}\|_{L^2} + \|u_{\mu_k} - u\|_{L^2} \\ &= \|\alpha(w) - \alpha(w_k)\|_{L^2} + 1/\mu_k \|w_k\|_{L^2} + \|u_{\mu_k} - u\|_{L^2}.\end{aligned}$$

The last two terms tend to zero as $k \to \infty$. Since α is nondecreasing and Lipschitz, there is a constant $c > 0$ so that

$$\|\alpha(w) - \alpha(w_k)\|_{L^2}^2 \leqq c \int (w - w_k)(\alpha(w) - \alpha(w_k)).$$

Since $w_k \rightharpoonup w$ and $\alpha(w_k) \to u$ in L^2, this term tends to zero as well. The function w is the solution to (3.4) since u is the solution to (3.10). We know that the solution w is unique (!); hence every subsequence $\{u_{\mu_k}\}$ converges to u weakly in V and every subsequence $\{\beta_{\mu_k}(u_{u_k})\}$ converges to w weakly in L^2. This convergence is enough to guarantee that estimate (3.12) and the result of the lemma remain valid upon passage to the limit; hence (3.5) and (3.6) follow, and the theorem is proved. □

COROLLARY. *The operator $\mathcal{A} \equiv \bar{\mathcal{A}}_2^{L^1 \times L^1}$ (the closure in $L^1 \times L^1$ of the graph of $\mathcal{A}_2$) is m-accretive.*

Proof. The closure of an accretive operator is accretive, so we need only prove the existence of solutions $w \in D(\mathcal{A})$ to

$$w + \lambda \mathcal{A}(w) \ni f$$

for any choice of $f \in L^1$ and $\lambda > 0$. Define

$$f_n(x) = \begin{cases} n, & f(x) > n, \\ f(x), & -n \leqq f(x) \leqq n, \\ -n, & f(x) < -n. \end{cases}$$

Then $f_n \in L^\infty$, $f_n \to f$ in L^1 and there is a solution $w_n \in D(\mathcal{A}_2)$ to (3.4) with f replaced by f_n. Since

$$\|w_n - w_m\|_{L^1} \leqq \|f_n - f_m\|_{L^1},$$

the sequence $\{w_n\}$ is Cauchy in L^1. If $w_n \to w$, then the pairs $[w_n, (f_n - w_n)/\lambda] \in \mathcal{A}_2$ converge in $L^1 \times L^1$ to $[w, (f - w)/\lambda] \in \mathcal{A}$, and we have our solution. □

4. Weak solutions. There is a unique integral solution $w \in C([0, T]; L^1)$ to the Cauchy problem (3.1) by Benilan's theorem. We shall now prove that w satisfies (3.2) for all appropriate testing functions φ.

THEOREM 2. *Let $w(t) \in C([0, T]; L^1)$ be the solution to* (3.1) *and assume $w_0 \in L^\infty \cap D(\mathscr{A})$. Then $w(t)$ satisfies*

$$\begin{aligned}\min\left\{\operatorname*{ess\,inf}_G(w_0), K_1\right\} + \int_0^t \operatorname*{ess\,inf}_G(g^-(s))\,ds \leqq w(t)\\ \leqq \max\left\{\operatorname*{ess\,sup}_G(w_0), K_2\right\}\\ + \int_0^t \operatorname*{ess\,sup}_G(g^+(s))\,ds \quad \text{a.e. in } G.\end{aligned} \tag{4.1}$$

By interpolation, $w(t)$ is continuous into L^p for $1 \leqq p < \infty$. If $g(t) \equiv g \in L^\infty$, then $\alpha(w) - g_1 \in L^2(0, T; V)$, and $w(t)$ satisfies (3.2) *for all $\varphi \in C^1([0, T]; L^2) \cap L^2((0, T); V)$. If $g(t) \in L^1((0, T); L^\infty)$, then $\alpha(w)$ may fail to belong to $L^2(0, T; H^1)$, but $w(t)$ satisfies*

$$\begin{aligned}\int_0^T \langle g, \varphi\rangle + \left\langle w, \frac{d\varphi}{dt} + \mathbf{v}\cdot\nabla\varphi\right\rangle + \langle \alpha(w), \Delta\varphi\rangle\,dt\\ = \langle w(T), \varphi(T)\rangle - \langle w(0), \varphi(0)\rangle + \int_0^T \langle \gamma_\nu(g_2), \nu_0(\varphi)\rangle + \langle \gamma_\nu(\nabla\varphi), \gamma_0(g_1)\rangle\end{aligned} \tag{4.2}$$

for all $\varphi \in C^1([0, T]; L^2) \cap L^2((0, T); V \cap H^2)$ with $\partial\varphi(t)/\partial\nu = 0$ on S_2.

Proof. We consider first the case $g(t) \equiv g \in L^\infty$. The operator $\mathscr{A}_g$ defined on $D(\mathscr{A})$ by

$$\mathscr{A}_g(w) = \mathscr{A}(w) - g$$

is m-accretive in $L^1 \times L^1$. The integral solution to (3.1) in this case is obtained using the Crandall–Liggett generation theorem for the operator $\mathscr{A}_g$ (cf. [1, Chap. 3]). Let $I: L^1 \to L^1$ be the identity and for $\lambda > 0$ let $J_\lambda \equiv (I + \lambda\mathscr{A}_g)^{-1}$ be the resolvent of $\mathscr{A}_g$. Since $\mathscr{A}_g$ is m-accretive, J_λ is a contraction on L^1. If $[t]$ denotes the greatest integer less than or equal to t,

$$w(t) = \lim_{n\to\infty} J_{1/n}^{[tn]}(w_0),$$

where convergence is uniform in L^1 for $0 \leqq t \leqq T$. We calculate

$$f = J_\lambda(w) \Leftrightarrow f + \lambda\mathscr{A}(f) - \lambda g \ni w \Leftrightarrow f + \lambda\mathscr{A}(f) \ni w + \lambda g.$$

By (3.6),

$$\min\left\{\operatorname*{ess\,inf}_G(w_0 + \lambda g), K_1\right\} \leqq J_\lambda(w_0) \leqq \max\left\{\operatorname*{ess\,sup}_G(w_0 + \lambda g), K_2\right\}$$

a.e. in G. We iterate this estimate and use

$$\max\left\{\operatorname*{ess\,sup}_G(w_0 + \lambda g), K_2\right\} \leqq \max\left\{\operatorname*{ess\,sup}_G(w_0), K_2\right\} + \lambda \operatorname*{ess\,sup}_G(g^+)$$

to get

$$\begin{aligned}\min\left\{\operatorname*{ess\,inf}_G(w_0), K_1\right\} + \lambda[tn] \operatorname*{ess\,inf}_G(g^-)\\ \leqq J_\lambda^{[tn]}(w_0) \leqq \max\left\{\operatorname*{ess\,sup}_G(w_0), K_2\right\} + \lambda[tn] \operatorname*{ess\,sup}_G(g^+).\end{aligned}$$

Let $\lambda = 1/n$ and let $n \to \infty$ to obtain (4.1).

Since $w_0 \in L^\infty$, $J_\lambda(w_0) \in D(\mathscr{A}_2)$, the domain of our original operator in L^2. Let us define

$$w_n(t) = J_{1/n}^{[tn]}(w_0) \in D(\mathscr{A}_2).$$

Then $w_n(t)$ converges uniformly in L^1 (and in L^2 by interpolation) to the solution $w(t)$. Notice that since α is Lipschitz, $\alpha(w_n(t))$ converges uniformly in L^2 to $\alpha(w(t))$. Moreover,

$$w_n\left(t+\frac{1}{n}\right) = J_{1/n}^{[tn]+1}(w_0) = J_{1/n}J_{1/n}^{[tn]}(w_0) = J_{1/n}(w_n(t)),$$

and consequently,

$$n\left(w_n\left(t+\frac{1}{n}\right) - w_n(t)\right) = -\left(\mathscr{A}_2\left(w_n\left(t+\frac{1}{n}\right)\right) - g\right). \tag{4.3}$$

The function $\alpha(w_n(t+1/n)) - g_1 \in V$, so

$$\begin{aligned}\left\langle \mathscr{A}_2\left(w_n\left(t+\frac{1}{n}\right)\right), \alpha\left(w_n\left(t+\frac{1}{n}\right)\right) - g_1\right\rangle \\ = \left\|\alpha\left(w_n\left(t+\frac{1}{n}\right)\right) - g_1\right\|_V^2 + \left\langle \nabla g_1, \nabla\left(\alpha\left(w_n\left(t+\frac{1}{n}\right)\right) - g_1\right)\right\rangle \\ - \left\langle \mathbf{v}w_n\left(t+\frac{1}{n}\right), \nabla\left(\alpha\left(w_n\left(t+\frac{1}{n}\right)\right) - g_1\right)\right\rangle \\ = -\left\langle n\left(w_n\left(t+\frac{1}{n}\right) - w_n(t)\right) - g, \alpha\left(w_n\left(t+\frac{1}{n}\right)\right) - g_1\right\rangle.\end{aligned}$$

It is a consequence of the Crandall-Liggett generation theorem that

$$n\left\|w_n\left(t+\frac{1}{n}\right) - w_n(t)\right\|_{L^1} \leqq \sqrt{2}\|\mathscr{A}_g w_0\|_{L^1}. \tag{4.4}$$

Since $g_1 \in L^\infty \cap H^1$, it follows from the uniform boundedness of $\alpha(w_n)$ that

$$\left\|\alpha\left(w_n\left(t+\frac{1}{n}\right)\right) - g_1\right\|_V^2 \leqq K(\|\mathscr{A}_g w_0\|_{L^1} + 1)$$

by an application of Hölder's inequality. The constant K is independent of n. We let $n \to \infty$. Then some (indeed, every) subsequence of $\alpha(w_n(t+1/n))$ converges weakly in H^1 to $\alpha(w(t))$, so $\alpha(w) \in L^\infty([0, T]; H^1)$ and $\alpha(w(t)) - g_1 \in V$ for almost every $t \in [0, T]$. We conclude that $\alpha(w_n(t+1/n)) - g_1$ converges weakly to $\alpha(w(t)) - g_1$ in $L^2([0, T]; V)$.

From (4.3) and the definition of $\mathscr{A}_2$, we have

$$\begin{aligned}\int_0^{T-1/n} n\left\langle w_n\left(t+\frac{1}{n}\right) - w_n(t), \varphi(t)\right\rangle dt \\ = \int_0^{T-1/n} \Bigg[-\langle \gamma_\nu, (\mathbf{g}_2), \gamma_0(\varphi(t))\rangle \\ + \left\langle \mathbf{v}w_n\left(t+\frac{1}{n}\right) - \nabla\alpha\left(w_n\left(t+\frac{1}{n}\right)\right), \nabla\varphi(t)\right\rangle + \langle g, \varphi(t)\rangle\Bigg] dt.\end{aligned} \tag{4.5}$$

We perform the standard change of variables on the right so that the difference quotients are on φ rather than w_n, take the limit as $n \to \infty$ and use the convergence properties of w_n, $\alpha(w_n)$ and the smoothness of φ to obtain (3.2).

If $g(t)$ is a step function, then we obtain the integral solution $w(t)$ to (3.1) by successively solving

$$\frac{dw(t)}{dt} + \mathscr{A}(w(t)) \ni g(t), \qquad T_j < t \leqq T_{j+1},$$

where g is constant on the interval (T_j, T_{j+1}) and $w(0) = w_0$. It is obvious that equation (4.1) continues to hold in this case. If the test function $\varphi(t)$ satisfies $\partial\varphi(t)/\partial\nu = 0$ on S_2 for all $t \in [0, T]$, then (4.5) is equivalent to

$$\int_0^{T-1/n} n\left\langle w_n\left(t+\frac{1}{n}\right) - w_n(t), \varphi(t)\right\rangle dt$$

$$= -\int_0^{T-1/n} \Bigg[\langle \gamma_\nu(g_2), \gamma_0(\varphi(t))\rangle + \langle \gamma_\nu(\nabla\varphi(t)), \gamma_0(g_1)\rangle$$

$$- \left\langle \mathbf{v}w_n\left(t+\frac{1}{n}\right), \nabla\varphi(t)\right\rangle - \left\langle \alpha\left(w_n\left(t+\frac{1}{n}\right)\right), \Delta\varphi(t)\right\rangle - \langle g, \varphi(t)\rangle\Bigg] dt.$$

Letting $n \to \infty$ and arguing as in the previous case, we obtain (4.2).

Finally, if $g \in L^1([0, T]; L^\infty)$ is arbitrary, then we obtain our results by approximating g by step functions and noting that the approximating solutions satisfy (4.1) and (4.2). These solutions converge uniformly in $L^1([0, T]; L^1)$ and are uniformly bounded in L^∞; hence they converge weakly in $L^2([0, T]; L^2)$ by the dominated convergence theorem. Under these conditions, (4.1) and (4.2) continue to hold for the solution to (3.1) □

5. Uniqueness of weak solutions. If the solution $w(t)$ to (3.2) is Lipschitz into L^1 and bounded into L^∞, then by interpolation it is Hölder continuous into L^p, $1 \leqq p < \infty$, with Hölder exponent $1/p$. A sufficient condition for $w(t)$ to be Lipschitz is to have $g(t) \in W^{1,1}([0, T]; L^1)$ and $w_0 \in D(\mathscr{A})$ (cf. [1, p. 131]; the relevant part of the theorem is true in *any* Banach space). We now prove the uniqueness of Hölder continuous solutions to (3.2).

THEOREM 3. *Let $T_0 \in \mathbb{R}$ be any point for which both w_1 and w_2 are Hölder continuous from $[0, T_0]$ into L^2 and assume that $w_1(0) = w_2(0)$ a.e. in G and both w_1 and w_2 satisfy (3.2) for all $\varphi \in C^1([0, T_0]; L^2) \cap L^2([0, T_0]; V)$. Then*

$$w_1(T_0) = w_2(T_0) \quad \textit{a.e. in } G.$$

Proof. For all $T \leqq T_0$ and $\varphi \in C^1([0, T]; L^2) \cap L^2([0, T]; V)$,

$$\langle w_1(T) - w_2(T), \varphi(T)\rangle$$

$$= \int_0^T \left\langle w_1 - w_2, \frac{d\varphi}{dt} + \mathbf{v}\cdot\nabla\varphi\right\rangle - \langle \nabla(\alpha(w_1) - \alpha(w_2)), \nabla\varphi\rangle$$

$$= \int_0^T 2K\langle w_1 - w_2, \varphi\rangle + \left\langle w_1 - w_2, \frac{d\varphi}{dt} + \mathbf{v}\cdot\nabla\varphi - 2K\varphi\right\rangle - \langle \nabla(\alpha(w_1) - \alpha(w_2)), \nabla\varphi\rangle,$$

where $K \geqq K(\mathbf{v})$, the constant defined in (3.9). This equation is equivalent to

$$\begin{aligned}&\langle w_1(T)-w_2(T), \varphi(T)\rangle\\&\quad=\int_0^T e^{2K(T-t)}\left[\left\langle w_1(t)-w_2(t), \frac{d\varphi(t)}{dt}+\mathbf{v}\cdot\nabla\varphi(t)-2K\varphi(t)\right\rangle\right.\\&\qquad\qquad\left.-\langle\nabla(\alpha(w_1)(t)-\alpha(w_2)(t)), \nabla\varphi(t)\rangle\right]dt.\end{aligned}$$

In fact, this second equation follows from the first by the usual variation of parameters formula for solutions of nonhomogeneous, first order ordinary differential equations. Theorem 3 follows by choosing an appropriate testing function $\varphi(t)$.

Let $c=\|\alpha\|_{\mathrm{Lip}}^{-1}$ and define the linear operator $\mathscr{L}$ by

$$D(\mathscr{L})=\{v\in V\,|\,\Delta v\in L^2, \langle\gamma_\nu(\nabla v), \gamma_0(\psi)\rangle=0 \quad \text{for all } \psi\in V\}$$

and

$$\mathscr{L}(v)=-2Kv+\mathbf{v}\cdot\nabla v+\Delta v/c.$$

Then $-\mathscr{L}$ is elliptic, and for all $v\in D(\mathscr{L})$ and $\psi\in V$,

$$\langle-\mathscr{L}v, \psi\rangle=\int_G \nabla v\cdot\nabla\psi/c-\mathbf{v}\cdot\nabla v\psi+2Kv\psi.$$

Notice that $-\mathscr{L}$ is V-coercive since

$$\begin{aligned}\langle-\mathscr{L}v, v\rangle&=\frac{\|v\|_V^2}{c}+\int_G 2K(v)^2-\frac{1}{2}\mathbf{v}\cdot\nabla(v^2)\\&=\frac{\|v\|_V^2}{c}+\int_G 2K(v)^2+\frac{1}{2}\operatorname{div}(\mathbf{v})(v^2)-\frac{1}{2}\int_S \mathbf{v}\cdot\nu(v^2)\\&\geqq\frac{\|v\|_V^2}{c}\end{aligned}$$

by the choice of boundary conditions on v.

Since $w_1, w_2, \alpha(w_1)$ and $\alpha(w_2)$ are Hölder continuous into L^2, the backward heat equation

$$\begin{aligned}&\frac{d\varphi(t)}{dt}+\mathscr{L}\varphi(t)=(w_1(t)-w_2(t))-c(\alpha(w_1(t))-\alpha(w_2(t))), \qquad 0\leqq t\leqq T,\\&\varphi(T)=\varphi_T,\end{aligned}$$

with $\varphi_T\in D(\mathscr{L})$, is well posed. In fact, the theory of analytic semigroups provides a strong solution $\varphi(t)\in C^1([0, T]; L^2)\cap D(\mathscr{L})$ for all $t\in[0, T]$ (cf. [9]). We observe that

$$\begin{aligned}\|\varphi(t)\|_V^2=c\Bigg[&\left\langle\frac{d\varphi(t)}{dt}+\mathbf{v}\cdot\nabla\varphi(t)+c(\alpha(w_1(t))-\alpha(w_2(t)))-(w_1(t)-w_2(t)), \varphi(t)\right\rangle\\&-2K\|\varphi(t)\|_{L^2}^2\Bigg].\end{aligned}$$

Since $\varphi\in C^1([0, T]; L^2)$ and $w_1, w_2, \alpha(w_1)$ and $\alpha(w_2)$ are continuous into L^2, we conclude, using Hölder's inequality, that $\|\varphi(\cdot)\|_V$ is uniformly bounded on $[0, T]$; hence $\varphi\in L^2([0, T]; V)$.

With this testing function, we have

$$\begin{aligned}
&\langle w_1(T)-w_2(T),\varphi_T\rangle\\
&=\int_0^T e^{2K(T-t)}\Big[\Big\langle w_1(t)-w_2(t)-c(\alpha(w_1(t))-\alpha(w_2(t))),\frac{d\varphi(t)}{dt}+\mathbf{v}\cdot\nabla\varphi(t)-2K\varphi(t)\Big\rangle\\
&\qquad\qquad+c\Big\langle\alpha(w_1(t))-\alpha(w_2(t)),\frac{d\varphi(t)}{dt}+\mathscr{L}(\varphi(t))\Big\rangle\Big]\\
&=\int_0^T e^{2K(T-t)}\Big[\Big\langle\frac{d\varphi(t)}{dt}+\frac{\Delta\varphi(t)}{c}+\mathbf{v}\cdot\nabla\varphi(t)-2K\varphi(t),\frac{d\varphi(t)}{dt}+\mathbf{v}\cdot\nabla\varphi(t)-2K\varphi(t)\Big\rangle\\
&\qquad\qquad+c\langle\alpha(w_1(t))-\alpha(w_2(t)),w_1(t)-w_2(t)-c(\alpha(w_1(t))-\alpha(w_2(t)))\rangle\Big]\,dt.
\end{aligned}$$

The last term on the right is nonnegative since $c=\|\alpha\|_{\mathrm{Lip}}^{-1}$. We conclude that

$$\begin{aligned}
c\langle w_1(T)-w_2(T),\varphi(T)\rangle&\geqq\int_0^T e^{2K(T-t)}\Big\langle\Delta\varphi(t),\frac{d\varphi(t)}{dt}+\mathbf{v}\cdot\nabla\varphi(t)-2K\varphi(t)\Big\rangle\,dt\\
&\geqq\int_0^T e^{2K(T-t)}\Big[\Big\langle\Delta\varphi(t),\frac{d\varphi(t)}{dt}\Big\rangle+K\|\varphi(t)\|_V^2\Big]\,dt
\end{aligned}$$

by (3.9) and the identity $\langle\Delta\varphi,-\varphi\rangle=\|\varphi\|_V^2$. If we formally integrate the first term by parts, we obtain the identity

$$\begin{aligned}
\int_0^T e^{2K(T-t)}\Big\langle\Delta\varphi(t),\frac{d\varphi(t)}{dt}\Big\rangle\,dt&=-\int_0^T e^{2K(T-t)}\frac{d}{dt}\|\varphi(t)\|_V^2/2\,dt\\
&=\frac{e^{2K(T)}}{2}\|\varphi(0)\|_V^2-\tfrac{1}{2}\|\varphi_T\|_V^2\\
&\quad+\int_0^T e^{2K(T-t)}(-K\|\varphi(t)\|_V^2)\,dt.
\end{aligned}$$

In fact, this formal calculation yields a valid identity as may be verified by considering Riemann sums of the (continuous) integrand. Hence, we may estimate

$$2c\langle w_1(T)-w_2(T),\varphi_T\rangle\geqq-\|\varphi_T\|_V^2$$

or

$$\langle w_1(T)-w_2(T),(-2c)\varphi_T\rangle\leqq\|\varphi_T\|_V^2$$

for *any* choice of $\varphi_T\in D(\mathscr{L})$. But $D(\mathscr{L})$ is a subspace of $L^2(G)$, so if we take $\varepsilon\varphi_T$ in place of φ_T, divide by ε and let $\varepsilon\to0$, we get

$$\langle w_1(T)-w_2(T),\varphi_T\rangle=0$$

for all $\varphi_T\in D(\mathscr{L})$. Finally, $D(\mathscr{L})$ is dense in L^2, and we conclude that

$$w_1(T)=w_2(T)\quad\text{a.e. in }G.\qquad\square$$

AN INVERSE PROBLEM FOR A NONLINEAR ELLIPTIC DIFFERENTIAL EQUATION [*]

MICHAEL PILANT[†] AND WILLIAM RUNDELL[†]

Abstract. In this paper we determine the form of an unknown forcing term f in the equation $\Delta u = \gamma(x, y, u) + f(u)$ from overprescribed boundary data on a domain in R^2 by reformulating the problem as a fixed point problem in an appropriate function space. Given suitable restrictions on the growth of f and the boundary data we recover a unique f.

Key words. undetermined coefficient, overposed boundary data, convergent iteration scheme

AMS(MOS) subject classifications. 35R30, 35J25

1. Introduction.

This paper considers the elliptic differential equation

$$-\Delta u = \gamma(x, y) + f(u) \tag{1.1}$$

defined on bounded open domain Ω of $\mathbf{R}^2$, with smooth boundary $\partial\Omega$. The function $\gamma(x, y)$ is known, but $f(u)$ as well as $u(x, y)$ has to be determined. We shall assume that $\partial\Omega$ can be decomposed into two connected components, $\partial\Omega = \partial\Omega_1 \cup \partial\Omega_2$, and on $\partial\Omega_1$ we impose the boundary condition

$$\alpha\frac{\partial u}{\partial\nu} + \beta u = g_1, \qquad (x, y) \in \partial\Omega_1 \tag{1.2}$$

while on $\partial\Omega_2$ we give *both* Dirichlet *and* Neumann boundary data

$$\begin{aligned} \frac{\partial u}{\partial\nu} &= g_2, \\ u &= \theta, \end{aligned} \qquad (x, y) \in \partial\Omega_2. \tag{1.3}$$

Here ν is the inner normal to the curve $\partial\Omega$.

By this overposing of the data on part of the boundary we hope to recover the pair of functions $\langle u(x, y), f(u)\rangle$. Our result is to show that conditions can be given on the boundary data and the known forcing function $\gamma(x, y)$ in order to obtain a unique function $f(u)$, provided $f(u)$ is, in a sense to be defined, "sufficiently small."

We are thus able to obtain the exact nature of a nonlinear forcing function in Poisson's equation that is subject to a small but unknown perturbation depending only on the function $u(x, y)$. The maximum allowable size of the perturbation will depend on the data and the region Ω. Our method will lead to a construction of the function $f(u)$.

Problems such as the above have received recent attention, and we mention some related work. First however we note that there is an inherent limitation on the form of any right-hand side of (1.1) that can be recovered by measurements made only on the boundary. If $-\Delta u = f(x, y)$, where f depends on x and y, then even in this case of a linear equation the function f cannot be determined uniquely no matter what the imposed boundary data. To see this, suppose (u_1, f_1) is a solution of $-\Delta u_1 = f_1$ where both u_1 and $\partial u_1/\partial\nu$ are prescribed on the boundary $\partial\Omega$. Then if ϕ is *any*

[*] Received by the editors July 14, 1986; accepted for publication October 22, 1986.

[†] Department of Mathematics, Texas A& M University, College Station, Texas 77843.

smooth function of compact support in Ω, set $u_2 = u_1 + \phi$ and $f_2 = f_1 + \Delta\phi$, so that u_1 and u_2 agree with all their derivatives on $\partial\Omega$. If the pair (u_1, f_1) is a solution, so also is (u_2, f_2). Thus one cannot expect uniqueness regardless of how many derivatives of the function u are imposed on the boundary. If, however, one restricts the allowed dependence of the forcing function f in advance then uniqueness results are possible. For example if Ω is a square and $f = f(x)$ only, then f can be recovered by overposing both Dirichlet and Neumann data on one side. If the function f has a linear dependence on u with proportionality coefficient depending only on *one* of the space variables, $f = a(x)u$ say, then again f or in this case $a(x)$ can be recovered by conditions of the form (1.2), (1.3) (see [4]). The authors in [7] considered the parabolic equation $u_t - \Delta u = f(u)$, and conditions were given on the initial–boundary data to guarantee the existence of a unique function f, locally in time, but with no restrictions on size. In fact $f(u)$ was restricted only by the requirements of uniqueness for the forwards or direct problem, that is the problem of finding u if the operator and the forcing function were known. The techniques of the present paper will have considerable overlap with those of [7], in that we shall set up a mapping from the space of admissible functions $f(u)$ to the overposed data using an evaluation of (1.1) on the arc $\partial\Omega_2$. We shall show that a solution of our problem is equivalent to this map having a fixed point, and accomplish this by showing it to be a contraction on a suitable function space.

We remark that the related inverse problem of finding the unknown function $f(u)$ in $u_t - \Delta u = f(u)$, or of finding the conductivity $a(u)$ in $u_t - \nabla.a(u)\nabla u = f(u)$ has an extensive literature but the techniques of these papers are different from the ones proposed here; cf. [1], [2], [3], [5], [9].

The plan of this paper is as follows. The next section describes our notation and gives the assumptions on the data. The third section constitutes the main body of the paper and contains the existence and uniqueness result.

2. Notation and assumptions.

Denote by $C^{k,\alpha}(D)$ the usual Schauder space of functions whose kth order partial derivatives are Hölder continuous of order α, $0 < \alpha \leq 1$ on the set D. The usual norm on this space we shall denote by $\|\cdots\|_{k,\alpha}$, the set D being usually understood by the context.

We shall assume that the boundary $\partial\Omega$ of $\Omega \subset R_2$ is the union of two simply connected arcs $\partial\Omega_1$ and $\partial\Omega_2$, each of which lie in $C^{2,1}$. It will be convenient to paramerize the segment $\partial\Omega_2$ on which both Dirichlet and Neumann data is prescribed, by the variable t, $0 \leq t \leq 1$. We denote by (x_0, y_0) and (x_1, y_1) the corresponding endpoints of the arc $\partial\Omega_2$.

Our assumptions on the data shall be for two purposes. First, to guarantee the existence of a sufficiently smooth solution u to the direct problem, that is a function $u(x, y; f)$ satisfying

$$-\Delta u = \gamma(x, y) + f(u) \tag{2.1}$$

for a given $f(u)$ and subject to the primary boundary conditions

$$\alpha(x, y)\frac{\partial u}{\partial\nu} + \beta(x, y)\, u = g_1(x, y), \qquad (x, y) \in \partial\Omega_1, \tag{2.2}$$

$$\frac{\partial u}{\partial\nu} = g_2(x, y), \qquad (x, y) \in \partial\Omega_2. \tag{2.3}$$

Second, to ensure that our mapping from f to the overposed data

$$u = \theta(x,y), \qquad (x,y) \in \partial\Omega_2 \tag{2.4}$$

is well defined we need to guarantee that $u(x,y;f)$ attains both its minimum and maximum on $\partial\Omega_2$, and is a monotone function of the parameter t on $\partial\Omega_2$.

We shall denote by Λ_0 the smallest eigenvalue for the problem $-\Delta\phi = \lambda\phi$ on Ω, where ϕ is subject to the homogeneous primary boundary conditions (2.2) and (2.3). Since Ω is bounded it follows that $\Lambda_0 > 0$ provided that β not identically zero on $\partial\Omega_1$.

We shall assume that the boundary data satisfies:

A1. *$\alpha(x,y)$ and $\beta(x,y)$ lie in $C^{2,1}(\partial\Omega_1)$. In addition, $\alpha \geq 0, \beta > 0$ on $\partial\Omega_1$, and $\alpha = 0$ in a neighborhood of (x_0,y_0) and (x_1,y_1).* (That is, we have Dirichlet boundary conditions in a neighborhood of the endpoints of $\partial\Omega_1$.)

A2. $g_1 \in C^{2,1}(\partial\Omega_1)$,
$g_2 \in C^{2,1}(\partial\Omega_2)$,
$\theta \in C^{3,1}(\partial\Omega_2)$.

A3. *For $(x,y) \in \Omega$ the function $\gamma(x,y) \in C^{1,1}(\Omega)$.*

For a given $E > 0$ denote by S_E the ball in $C^{(1,1)}$ centered at the origin, that is

$$S_E := \{ f \mid f(0) = 0, \quad \|f\|_{1,1} \leq E \}. \tag{2.5}$$

With some restrictions on the value of E this set will form the admissible class of functions f. By a solution pair (u,f) to (2.1) – (2.4) we shall mean that,

(a) $f \in S_E$.
(b) $u \in C^{2,1}(\bar{\Omega})$.
(c) (2.1) – (2.4) hold.

We note that conditions A1 – A3 are sufficient to guarantee the existence of a unique solution to the direct problem (2.1) - (2.3) for any $f \in S_E$, provided $E < \Lambda_0$. This ensures that we avoid any eigenvalues of the linearized problem.

If σ and ν denote unit vectors in the tangential and normal directions on the boundary $\partial\Omega$, then for some functions $a(s)$ and $b(s)$ of the arc length s, and with $a^2 + b^2 = 1$,

$$\frac{\partial}{\partial x} = a\frac{\partial}{\partial\sigma} + b\frac{\partial}{\partial\nu}, \qquad \frac{\partial}{\partial y} = b\frac{\partial}{\partial\sigma} - a\frac{\partial}{\partial\nu}.$$

Thus in this coordinate system the Laplacian has principal part $\frac{\partial^2}{\partial\sigma^2} + \frac{\partial^2}{\partial\nu^2}$.

Let D_ν and D_σ denote the normal and tangential components of the Laplacian on the boundary $\partial\Omega$, that is

$$D_\nu = \frac{\partial^2}{\partial\nu^2} + c(s)\frac{\partial}{\partial\nu}$$

and

$$D_\sigma = \frac{\partial^2}{\partial\sigma^2} + d(s)\frac{\partial}{\partial\sigma}$$

where $c(s)$ and $d(s)$ are coefficients that depend only on the boundary $\partial\Omega$. For example if Ω is the unit circle then $D_\nu = \frac{\partial^2}{\partial r^2} + \frac{1}{r}\frac{\partial}{\partial r}$ and $D_\sigma = \frac{1}{r^2}\frac{\partial^2}{\partial\theta^2}$. For $f \in S_E$, and $u(x,y;f)$ the corresponding solution of the direct problem, (2.1) - (2.3), define the mapping $\mathbf{T}_\theta[f]$ by

$$\mathbf{T}_\theta[f] = \tilde{f}(\theta) = -\tilde{\gamma}(t) + D_\sigma\theta + D_\nu\{u(x,y;f)\} \tag{2.6}$$

where $\tilde{v}$ denotes the restriction of a function v to the boundary $\partial\Omega_2$. Equation (2.6) is precisely the projection of (1.1) onto the boundary $\partial\Omega_2$.

We shall say that the mapping $\mathbf{T}_\theta[f]$ has a *theta fixed point* f in S_E if for some f in this space

$$\mathbf{T}_\theta[f] = f(\theta).$$

Let the functions $\psi(x,y)$, $\psi_+(x,y)$ and $\psi_-(x,y)$ satisfy

$$-\Delta\psi = \gamma(x,y), \tag{2.7}$$
$$-\Delta\psi_+ = \gamma(x,y) + E\psi_+, \qquad (x,y)\in\Omega \tag{2.8}$$
$$-\Delta\psi_- = \gamma(x,y) - E\psi_-, \tag{2.9}$$

and be subject to the primary boundary conditions (2.2), (2.3).

In order to develop the properties we need of the mapping $\mathbf{T}_\theta[\ ]$, we will require that,

A4. *The functions* $\psi_\pm(x,y)$ *satisfy,*
$g_1(0)/\beta(0) = \psi_\pm(\pm_0, y_0) \le \psi_\pm(x,y) \le \psi_\pm(x_1,y_1) = g_1(1)/\beta(1)$ *for all* $(x,y)\in\bar{\Omega}$.

The overposed boundary data $\theta(t) = u\,|_{\partial\Omega_2}$ will be assumed to satisfy,

A5. $\|D_\sigma\{\theta-\psi\}\|_{1,1} < C_2$, *for some constant* C_2 *to be defined later.*
In addition, $\theta(0) = g_1(0)/\beta(0)$, $\theta(1) = g_1(1)/\beta(1)$, *and* $\theta(t)$ *is an increasing function of the parameter* t *on* $\partial\Omega_2$. *Furthermore,* $\theta(0)\le\theta(t)\le\theta(1)$.

The monotonicity assumption on $\theta(t)$ is necessary to recover $\tilde{f}$ from $\tilde{f}(\theta(t))$ in $\mathbf{T}_\theta[f]$. By $G = G(x,y,\xi,\eta)$ we denote the Green's function for the Laplacian on Ω subject to the primary boundary conditions (2.2) and (2.3).

We define the following quantitities, for $f\in S_E$ and $\|u\|_{1,1} < \infty$

$$C(\Omega,u) := \sup_{f\neq 0}\frac{\|\iint_\Omega D_\nu G f(u)\|_{1,1}}{\|f\|_{1,1}} \tag{2.10}$$

and

$$C_4(\Omega) := \sup_{h\neq 0}\frac{\|\iint_\Omega D_\nu G h(\xi,\eta)\|_{1,1}}{\|h\|_{1,1}}. \tag{2.11}$$

We can make the following observations:

First, let K be defined by

$$K[h] = \iint_\Omega D_\nu G h(\xi,\eta)\,d\xi\,d\eta. \tag{2.12}$$

By standard elliptic estimates [6], we have

$$\|K[h]\|_{1,1} \le C\|h\|_{1,1} \tag{2.13}$$

where C is a constant depending only on the domain Ω. C_4 is therefore the smallest such constant.

Secondly, from inequality (2.13) we have

$$\| \iint D_\nu Gf(u) \|_{1,1} \leq C_4(\Omega)\|f(u)\|_{1,1} \leq C_4(\Omega)\|f\|_{1,1}\|u\|^2_{1,1}$$

which implies that

$$C(\Omega, u) \leq C_4(\Omega)\|u\|^2_{1,1} \tag{2.14}$$

and that (2.10) is therefore well defined.

Thirdly, $K[h] = \iint D_\nu Gh$ may have a nontrivial kernel. To see this, consider the following example.

Let Ω be the unit square, and let $u(x,y)$ satisfy (2.1) with $\gamma = \gamma(y)$ together with the primary boundary conditions

$$\frac{\partial u(1,y)}{\partial x} = 0, \qquad \frac{\partial u(0,y)}{\partial x} = 0,$$

$$u(x,0) = 0, \qquad u(x,1) = 1,$$

along with the overposed condition

$$u(0,y) = \theta(y).$$

For this case note that

$$u_{xx}(0,y) = \iint_\Omega D_\nu Gh(\eta)d\xi d\eta = 0 \tag{2.15}$$

for any $h \in Lip_1$. This leads to the following inequality (where $u_0 = u_0(y)$):

$$\begin{aligned} C(\Omega,u) = \sup_{f \neq 0} \frac{\|Kf(u)\|_{1,1}}{\|f\|_{1,1}} &= \sup_{f\neq 0}\left\{ \frac{\| Kf(u) - Kf(u_0) \|_{1,1}}{\| f(u) - f(u_0) \|_{1,1}} \cdot \frac{\| f(u) - f(u_0) \|_{1,1}}{\|f\|_{1,1}} \right\} \\ &\leq C_4(\Omega) \sup_{f\neq 0} \frac{\|f(u) - f(u_0)\|_{1,1}}{\|f\|_{1,1}}. \end{aligned} \tag{2.16}$$

We have, in this case, $C(\Omega, u_0) = 0$.

We shall require that the constant $C(\Omega, u)$ satisfy :

A6. *$C(\Omega,u)$ defined in (2.10), is a continuous function of u, for $\|u\|_{2,1} < \infty$.* Note that from the above, there exists domains and primary boundary conditions on this domain for which $\mathbf{T}_\theta[\ ]$ reduces to the trivial mapping

$$\mathbf{T}_\theta[f] = -\tilde{\gamma}(t) + \theta''(t) = f(\theta(t))$$

from (2.6) and (2.15), and thus gives a direct determination of the function f without any iteration. The above conditions essentially restrict the allowable class of unknown functions $f(u)$ and the primary boundary data to be sufficiently small perturbations of such problems. Here sufficiently small means that the operator defined by (2.13) have norm less than one in a suitable space.

3. Existence and uniqueness. We shall prove the following result:

THEOREM. *If assumptions* A1 - A6 *hold, then for E sufficiently small, there exists a unique solution pair* $\langle u, f\rangle$ *of* (2.1) - (2.4).

We shall need some lemmas, the first shows that the mapping $\mathbf{T}_\theta[\,]$ is well defined, while the second shows the inverse problem of finding the function $f(u)$ is equivalent to finding a theta fixed point of $\mathbf{T}_\theta[f]$.

LEMMA 1. *If $u(x,y;f)$ denotes the solution of the direct problem then it takes its minimum and maximum at the points (x_0,y_0) and (x_1,y_1) on the boundary $\partial\Omega$.*

Proof. From A4, A5 and the maximum principle, [6, Chap. 9] applied to the functions u, ψ_+ and ψ_- we have that

$$\theta(0) \le \psi_-(x,y) \le u(x,y) \le \psi_+(x,y) \le \theta(1) \qquad \text{for } (x,y) \in \bar{\Omega}.$$

LEMMA 2. *Given $f \in S$ then $\langle u(x,y), f\rangle$ is a solution of* (2.1) - (2.4) *if and only if f is a theta fixed point of* $\mathbf{T}_\theta[f]$.

Proof. Let $\tilde{u}(t;f)$ and $\tilde{\gamma}(t)$ denote the restrictions of these functions to $\partial\Omega_2$. If $\langle f, u\rangle$ is a solution to (2.1) - (2.4), then for $t \in \partial\Omega_2$

$$\begin{aligned} f(\theta) &= f(\tilde{u}(t;f)) \\ &= D_\nu\{u\} + D_\sigma\{\tilde{u}\} - \tilde{\gamma}(t) \\ &= D_\nu\{u\} + D_\sigma\{\theta\} - \tilde{\gamma}(t) \\ &= \mathbf{T}_\theta[f] \end{aligned}$$

so that f is a theta fixed point of $\mathbf{T}_\theta[\,]$.

Since

$$\mathbf{T}_\theta[f] = -\tilde{\gamma}(t) + D_\sigma\{\theta\} + D_\nu\{u\}$$

where u is a solution of the direct problem, by evaluating (2.1) on $\partial\Omega_2$ we obtain $D_\nu\{u\} + D_\sigma\{\tilde{u}\} = \gamma + f(\tilde{u})$ and hence $D_\nu\{u\} = \tilde{\gamma}(t) + f(\tilde{u}) - D_\sigma\{\tilde{u}\}$. Combining this with the above equation in the case that f is a theta fixed point of $\mathbf{T}_\theta[f]$,

$$\mathbf{T}_\theta[f] = f(\theta) = D_\sigma\{\theta\} - D_\sigma\{\tilde{u}\} + f(\tilde{u})$$

for $t \in \partial\Omega_2$.

Setting $\sigma(t) = \tilde{u}(t;f) - \theta(t)$ for $t \in \partial\Omega_2$, we have

$$\begin{aligned} D_\sigma\{\sigma(t)\} &= D_\sigma\{\tilde{u}(t;f) - \theta(t)\} \\ &= f(\tilde{u}(t;f)) - f(\theta(t)). \end{aligned}$$

From A3, since $f \in S_E$, it follows that $D_\sigma\{\sigma\} = \xi_f(t)\,\sigma$ for some Lip_1 function $\xi_f(t)$ satisfying $|\xi_f| \le E$. From assumption A5 it follows that $\sigma(0) = \sigma(1) = 0$. If we let Λ_1 be the lowest eigenvalue for the operator D_σ on $\partial\Omega_2$ acting on functions that vanish at the endpoints (x_0,y_0) and (x_1,y_1), then if E is restricted to be less than Λ_1 it follows by comparison arguments from Sturm–Liouville theory that $\sigma(t) = 0$. Hence u satisfies (2.4).

LEMMA 3. $\mathbf{T}_\theta[\,]$ *maps a ball into itself in* $C^{1,1}$.

Proof. By definition

$$\begin{aligned}\tilde{f}(\theta(t)) = \mathbf{T}_\theta[f](t) &= -\gamma + D_\sigma[\theta] + D_\nu u(x,y;f)\\ &= D_\sigma[\theta-\psi] + D_\nu \iint_\Omega Gf(u)\\ &= D_\sigma[\theta-\psi] + \iint_\Omega Kf(u).\end{aligned}$$

Assume that $f(0)=0$ and $\|f\|_{1,1} \le E$. With respect to the $\|\ \|_{1,1}$ norm, on $[0,T]$, we have

$$\|\iint Kf(u)\|_{1,1} \le C(\Omega,u)\|f\|_{1,1}.$$

The domain of $\tilde{f}$ is not $[0,T]$, but $[\theta(0),\theta(T)] = [0,\theta(T)]$. We have the bound, which results from a transformation of variables:

$$\|f\|_{1,1,\,[\theta(0),\theta(1)]} \le C(T;\theta)\,\|f\|_{1,1,\,[0,1]}$$

where we have indicated the intervals over which the norms are taken. This immediately implies

$$\begin{aligned}\|\tilde{f}\|_{1,1} &\le C(T;\theta)\,\|\mathbf{T}_\theta[f]\|_{1,1}\\ &\le C(T;\theta)\Big[\|D_\sigma(\theta-\psi)\|_{1,1} + C(\Omega,u)\|f\|_{1,1}\Big].\end{aligned}$$

If $C(\Omega,u_0)=0$ then if $\|u-u_0\|_{1,1}$ is sufficiently small, we can satisfy

$$C(T,\theta).C(\Omega,u) < 1/2.$$

If $\|D_\sigma(\theta-\psi)\|_{1,1}$ is sufficiently small then

$$C(T,\theta)\|D_\sigma(\theta-\psi)\|_{1,1} < E/2$$

and consequently

$$\|\tilde{f}\|_{1,1} < E$$

and the Lemma is proved.

LEMMA 4. *If* $\|D_\sigma(\theta-\psi)\|_{1,1}$ *is sufficiently small, then* $\mathbf{T}_\theta[\,]$ *is a contraction on* Lip_1.

Proof. Under the hypotheses, $\mathbf{T}_\theta[\,]$ maps a ball into itself in $C^{1,1}$. Consequently, $\|f'\|_{0,1}$ is uniformly bounded. We therefore have the following:

$$\begin{aligned}\|\tilde{f}_1 - \tilde{f}_2\|_{1,1} &= \|\,\mathbf{T}_\theta[f_1] - \mathbf{T}_\theta[f_2]\,\|_{1,1}\\ &\le C(T,\theta)\,\|\iint D_\nu G\big(f_1(u_1) - f_2(u_2)\big)\,\|_{1,1}\\ &\le C(T,\theta)\,\|\,K[f_1(u_1) - f_1(u_2)]\,\|_{1,1} + C(\Omega,u_2)\|f_1 - f_2\|_{1,1}\\ &\le C(T,\theta)\,C_4(\Omega)\,E\,\|u_1 - u_2\|_{1,1} + C(\Omega,u_2)\|f_1 - f_2\|_{1,1}.\end{aligned}$$

The inequality

$$\|u_1 - u_2\|_{1,1} \leq C(\Omega)\|f_1 - f_2\|_{1,1} \tag{3.1}$$

with $C(\Omega) \to 0$ as $\mathrm{Vol}(\Omega) \to 0$ follows easily from estimates on lower norms of u. Consequently, if $\|u_2 - u_0\|_{1,1}$ is sufficiently small, and if the region is sufficiently small we conclude that

$$\|\tilde{f}_1 - \tilde{f}_2\|_{1,1} \leq \delta\|f_1 - f_2\|_{1,1} \tag{3.2}$$

and the lemma is proved.

The crucial estimate is that

$$C(T,\theta).C(\Omega,u_2) < 1. \tag{3.3}$$

This is essentially the requirement that $C(\Omega, u) \ll 1$ for some ball about u_0. This is guaranteed by the presence of a nontrivial kernel for the mapping $K = D_\nu G$ and continuity.

We now compute an a priori bound on the iterates of $\mathbf{T}_\theta[f]$ by the following argument. With $f_0 = 0$, and using (2.7)

$$\begin{aligned} \| f_0 - \mathbf{T}_\theta[f_0] \|_{1,1} &= \| \mathbf{T}_\theta[f_0] \|_{1,1} \\ &= \| -\tilde{\gamma}(t) + D_\sigma\{\theta\} + D_\nu\{\psi\} \|_{1,1} \\ &= \| D_\sigma\{\theta - \psi\} \|_{1,1} \\ &\leq C_2. \end{aligned}$$

Define the sequence $\{f_n\}$ for $n \geq 1$ by

$$f_{n+1} = \mathbf{T}_\theta[f_n], \qquad f_0 = 0, \tag{3.4}$$

From (3.2) we have since $\delta < 1$, and $f_0 = 0$

$$\begin{aligned} \|f_{n+1}\|_{1,1} = \|f_{n+1} - f_0\|_{1,1} &\leq \|f_{n+1} - f_n\|_{1,1} + \|f_n - f_{n-1}\|_{1,1} + \cdots + \|f_1 - f_0\|_{1,1} \\ &\leq (\delta^n + \delta^{n-1} + \ldots + \delta + 1)\| \mathbf{T}_\theta[f_0] - f_0 \|_{1,1} \\ &\leq \frac{1}{1-\delta} \| \mathbf{T}_\theta[0] \|_{1,1} \\ &\leq \frac{C_2}{1-\delta} \quad \equiv R. \end{aligned} \tag{3.5}$$

We require that the constant C_2 (appearing in A5), satisfy $C_2 < E(1-\delta)$ where δ is defined in equation (3.2). Therefore all the iterates lie in a ball of radius $R < E$ in Lip_1.

Since $\mathbf{T}_\theta[\;]$ is a contraction on S_E, the sequence $\{f_n\}_{n=1}^{\infty}$ converges to a unique theta fixed point in $C^{1,1}$ with $\|f\|_{1,1} \leq R$. This completes the proof of the theorem.

Some remarks on the assumptions should be made.

First on the specification of boundary conditions and the assumption A4. In order for the functions $\psi_\pm$ to achieve their maximum on the boundary $\partial\Omega$ at the ends of the arc $\partial\Omega_2$, for a given forcing function $\gamma(x,y)$ and error bound E, we require that the contribution from the boundary conditions (2.2) – (2.3) overcome the tendency for the forcing functions to create internal maxima or minima.

Second, other than for clarity of exposition, there is no reason to restrict ourselves to the Laplacian in equation (2.1). We could replace this equation by $Lu = \gamma(x,y) + f(u)$ where L is any uniformly elliptic operator with smooth coefficients on Ω. It is probable that extension could be made to the case where the unperturbed problem is quasilinear, by for example taking $\gamma = \gamma(x,y,u,\nabla u)$. We have performed a numerical simulation of the algorithm defined by (3.3) including the case of γ depending on u and ∇u, and found it to be quite robust and rapidly convergent. Some of the numerical implementations for this fixed point method may be found in [8].

Finally the extension to R^n can easily be made. The section of the boundary where the overposed data is specified would still have to be a one dimensional arc on the surface $\partial\Omega$ and contain the entire range of values of $u(\vec{x};f)$.
