ATTRACTORS FOR THE PENALIZED NAVIER–STOKES EQUATIONS*

B. BREFORT†, J. M. GHIDAGLIA† AND R. TEMAM†

Abstract. We consider the penalized form of the Navier–Stokes equations for a viscous incompressible fluid where the pressure and the incompressibility equation div $u = 0$ are suppressed and replaced by a penalty term in the momentum conservation equation. In this article we study the existence of an attractor for the penalized Navier–Stokes equation, this attractor describing the long-time behaviour of the solutions. Then we let the penalty parameter tend to zero and we show how the attractors of the penalized equations approximate the attractor of the exact equations.

Key words. attractors, Navier–Stokes equations, penalization

AMS(MOS) subject classifications. 35Q10, 65P05, 76D05

Introduction. The penalty method was introduced by Courant [5] in the context of the calculus of variations and has developed considerably. Besides the applications to the constrained variational problems and variational inequalities, this is now a useful tool for numerical computations in continuum fluid and solid mechanics. In particular its application to the Navier–Stokes equations which, as far as we know, was initiated in Temam [13], [14] is now commonly used in some areas of computational fluid dynamics, especially for the computations using the finite element methods in conjunction with quadrature formula (see for instance Bercovier [2], Bercovier and Engelman [3], Oden and Kikuchi [11], Oden and Jacquotte [12]).

With the increase of the computing power we are now at the point of being able to compute nonstationary flows; by this we mean the time periodic flows or the more complex (turbulent) flows which do appear, even if the driving forces are time-independent, after a Hopf bifurcation or a cascade of more complex bifurcations has occurred (Feigenbaum cascade of bifurcations, Ruelle–Takens bifurcations towards turbulence, ...). This new development in computational fluid dynamics will necessitate some improvement of our knowledge of the dynamics of the Navier–Stokes equations, and the problem that we address here pertains to this question.

Our aim in this article is to study the attractors for the penalized Navier–Stokes Equations (N.S.E.) and their convergence toward the universal attractor of the exact equations (cf. Foias and Temam [6], Temam [18], and the references therein). We restrict ourselves to the two-dimensional case and consider the flow in a bounded domain $\Omega \subset \mathbb{R}^2$; the N.S.E. of incompressible flows then reads

$$\frac{\partial u}{\partial t} - \nu \Delta u + (u \cdot \nabla) u + \operatorname{grad} p = f, \tag{0.1}$$

$$\operatorname{div} u = 0 \quad \text{in } \Omega \times (0, T) \tag{0.2}$$

where $u = u(x, t)$ is the velocity vector, $p = p(x, t)$ the pressure, $\nu > 0$ is the kinematic viscosity and f represents the volumic driving forces, for simplicity the constant density ρ was taken equal to 1.

For the penalized equation we suppress the pressure p and the incompressibility equation (0.2) and introduce in (0.1) a penalty term, (ν/ε) grad div u, $\varepsilon > 0$ the penalty

parameters. Hence we obtain[1]

$$\frac{\partial u_\varepsilon}{\partial t} - \nu\Delta u_\varepsilon + (u_\varepsilon \cdot \nabla)u_\varepsilon + \frac{1}{2}(\operatorname{div} u_\varepsilon)u_\varepsilon - \frac{\nu}{\varepsilon}\operatorname{grad}\operatorname{div} u_\varepsilon = f. \tag{0.3}$$

We have also introduced the supplementary nonlinear term $\frac{1}{2}(\operatorname{div} u_\varepsilon)u_\varepsilon$ which was proposed in [13], [14] to make (0.3) well set.

The equations (0.1), (0.2) (or (0.3)) are supplemented by boundary and initial conditions. For the boundary condition, two cases will be considered:

Either Ω is a smooth bounded domain of $\mathbb{R}^2$ with boundary Γ and we set

$$u = 0 \quad \text{on } \Gamma \times (0, T), \tag{0.4}$$

Or Ω is a square in $\mathbb{R}^2$, $\Omega = (0, L)^2$, and the boundary condition is the space periodicity for u and p

$$\begin{aligned} &\varphi(x_1, L, t) = \varphi(x_1, 0, t), \\ &\varphi(L, x_2, t) = \varphi(0, x_2, t), \\ &0 < x_1, x_2 < L, \quad t \in (0, T), \quad \varphi = u \text{ or } p. \end{aligned} \tag{0.5}$$

In this case we assume also that the average flow in Ω vanishes (cf. [6])

$$\int_\Omega u(x, t)\, dx = 0 \quad \forall t. \tag{0.6}$$

The initial condition is simply in all cases

$$u(x, 0) = u_0(x), \qquad x \in \Omega. \tag{0.7}$$

This article is organized as follows. In § 1 we recall the functional form of the exact and penalized N.S.E. and the results of existence, uniqueness and regularity of solutions in both cases (§ 1.1); § 1.2 contains a technical result on the penalized Stokes problem. Section 2 is devoted to the study of the attractors of the penalized N.S.E. (the penalization parameter ε being fixed). We derive uniform estimates for various norms of u and prove the existence of an absorbing set and a universal attractor $\mathscr{A}_\varepsilon$ for all $\varepsilon > 0$. Then § 3 deals with the convergence of the attractor $\mathscr{A}_\varepsilon$ to the universal attractor $\mathscr{A}$ of the exact Navier-Stokes equations when $\varepsilon \to 0$. Section 3.1 provides an appropriate result on convergence of attractors; § 3.2 recalls and improves the results of [13], [14] of convergence of the solutions u_ε of the penalized N.S.E. to the solution u of the exact N.S.E. Section 3.3 gives the main result of convergence of $\mathscr{A}_\varepsilon$ to $\mathscr{A}$. Finally § 3.4 shows how the dimension of $\mathscr{A}_\varepsilon$ can be compared to that of $\mathscr{A}$.

1. Survey and complements for the exact and penalized Navier–Stokes equations.

1.1. Functional setting. We denote by $L^2(\Omega)$ the space of square integrable functions on Ω, and by $H^m(\Omega)$ the Sobolev space of order m based on $L^2(\Omega)$ (m an integer), i.e., $H^m(\Omega)$ is the space of functions u in $L^2(\Omega)$ whose distribution derivatives of order $\leqq m$ are in $L^2(\Omega)$. We let $H_0^1(\Omega)$ denote the space of functions in $H^1(\Omega)$ whose trace on Γ vanishes and in the periodic case (0.5) $H^1_{\text{per}}(\Omega)$ represents the space of functions u in $H^1(\Omega)$ whose trace assumes the same values on corresponding points of Γ. Finally we set $\mathbb{L}^2(\Omega) = L^2(\Omega)^n$, $\mathbb{H}^1(\Omega) = H^1(\Omega)^n$, etc. $\cdots$, $n = 2$. The scalar products and norms on either $L^2(\Omega)$ or $\mathbb{L}^2(\Omega)$ are denoted

$$(u, v) = \int_\Omega u(x) \cdot v(x)\, dx, \qquad |u| = \{(u, u)\}^{1/2} \tag{1.1}$$

[1] The penalty parameter is written ε/ν instead of ε as in [14]. Hence ε is a nondimensional parameter.

and on $H_0^1(\Omega)$ or $\mathbb{H}_0^1(\Omega)$:

$$((u, v)) = \sum_{i=1}^{n} (D_i u, D_i v), \quad \|u\| = \{((u, u))\}^{1/2} \quad \left(D_i = \frac{\partial}{\partial x_i}\right). \tag{1.2}$$

We have the Poincaré inequality

$$|u| \leqq \frac{1}{\sqrt{\lambda_1}} \|u\| \quad \forall u \in H_0^1(\Omega) \text{ (or } \mathbb{H}_0^1(\Omega)), \tag{1.3}$$

where $\lambda_1 > 0$ is the first eigenvalue of the Laplace operator in $H_0^1(\Omega)$; (1.3) shows that $\|u\|$ is a norm on $H_0^1(\Omega)$ (or $\mathbb{H}_0^1(\Omega)$) which is equivalent to that of $H^1(\Omega)$ (or $\mathbb{H}^1(\Omega)$).

A similar remark holds in the space periodic case if we restrict ourselves to functions satisfying (0.6):

$$\dot{L}^2(\Omega) = \{u \in L^2(\Omega), u \text{ satisfies (0.6)}\},$$

$$\dot{H}^1(\Omega) = \{u \in H^1(\Omega), u \text{ satisfies (0.6)}\}, \cdots.$$

In particular we have

$$|u| \leqq \frac{1}{\sqrt{\lambda_1'}} \|u\| \quad \forall u \in H^1_{\text{per}}(\Omega) \text{ (or } \dot{\mathbb{H}}^1_{\text{per}}(\Omega)) \tag{1.4}$$

where $\lambda_1' = 4\pi^2/L^2$ is the first eigenvalue of the Laplace operator in $\dot{H}^1_{\text{per}}(\Omega)$ (or $\mathbb{H}^1_{\text{per}}(\Omega)$). This shows that in this case too $\|u\|$ is a norm on $\dot{H}^1_{\text{per}}(\Omega)$ (or $\mathbb{H}^1_{\text{per}}(\Omega)$) equivalent to that of $H^1(\Omega)$ (or $\mathbb{H}^1(\Omega)$).

The basic Hilbert space is $H \subset \mathbb{L}^2(\Omega)$; in the case (0.4) (cf. [15]),

$$H = \{u \in \mathbb{L}^2(\Omega), \operatorname{div} u = 0, u \cdot \underset{\sim}{\nu} = 0 \text{ on } \Gamma\}$$

where $\underset{\sim}{\nu}$ is the unit outward normal on Γ and in the case (0.5) (cf. [16]), H is the set of $u \in \mathbb{L}^2(\Omega)$ such that $\operatorname{div} u = 0$ and $u \cdot \underset{\sim}{\nu}$ take opposite values on corresponding points of Γ. We denote by A the unbounded operator in H with domain

$$D(A) = \{u \in \mathbb{H}^2(\Omega) \cap \mathbb{H}_0^1(\Omega), \operatorname{div} u = 0\} \quad \text{in the case (0.4)}, \tag{1.5}$$

$$D(A) = \{u \in \dot{\mathbb{H}}^2_{\text{per}}(\Omega), \operatorname{div} u = 0\} \quad \text{in the case (0.5)}, \tag{1.6}$$

and

$$Au = -P\Delta u \quad \forall u \in D(A),$$

where P is the projector in $\mathbb{L}^2(\Omega)$ onto H. The operator A is self-adjoint, >0 in H, and A is an isomorphism from $D(A)$ (endowed with the graph norm) onto H. Since by Rellich's theorem the embedding of $H^1(\Omega)$ into $L^2(\Omega)$ is compact, the embedding of $D(A)$ in H is compact and therefore A^{-1} is a compact self-adjoint operator in H. Thus there exists an orthonormal basis of H consisting of eigenvectors w_j of A (or A^{-1}),

$$\begin{cases} Aw_j = \lambda_j w_j \quad \text{(for (0.4))}, \\ Aw_j' = \lambda_j' w_j' \quad \text{(for (0.5))}, \\ 0 < \lambda_1 \leqq \lambda_2, \cdots, \qquad 0 < \lambda_1' \leqq \lambda_2', \cdots, \\ \lambda_j, \lambda_j' \to \infty \quad \text{as } j \to \infty. \end{cases} \tag{1.7}$$

We can define the powers A^α of A, $\alpha \in \mathbb{R}$. Of particular interest are the spaces $V = D(A^{1/2})$, $V' = D(A^{-1/2})$ = the dual of V, and [15], [16],

$$V = \{u \in \mathbb{H}_0^1(\Omega), \operatorname{div} u = 0\} \quad \text{(for (0.4))}, \tag{1.8}$$

$$V = \{u \in \mathbb{H}_{\text{per}}^1(\Omega), \operatorname{div} u = 0\} \quad \text{(for (0.5))}. \tag{1.9}$$

The space V is Hilbert for the scalar product $((u, v))$.

We are given $f \in \mathbb{L}^2(\Omega)^2$ and for $u, v \in V$ or $\mathbb{H}^1(\Omega)$, we denote by $B(u, v)$ the element of V' defined by

$$(B(u, v), w) = \sum_{i,j=1}^{2} \int_\Omega u_i (D_i v_j) w_j \, dx \quad \forall w \in V \tag{1.10}$$

and we set $B(u) = B(u, u)$.

Similarly for the penalized problems the basic spaces are $G = \mathbb{L}^2(\Omega)$ in the case (0.4), $= \dot{\mathbb{L}}^2(\Omega)$ in the case (0.5), and $W = \mathbb{H}_0^1(\Omega)$ (for (0.4)) or $\dot{\mathbb{H}}_{\text{per}}^1(\Omega)$ (for (0.5)). The operator A is replaced by $-\Delta$, $D(-\Delta) = \mathbb{H}_{\text{per}}^2(\Omega) \cap W$ and for $u, v \in \mathbb{H}^1(\Omega)$, we denote by $\mathcal{B}(u, v)$ and $\tilde{\mathcal{B}}(u, v)$ the elements of W' defined by

$$(\mathcal{B}(u, v), w) = \sum_{i,j=1}^{2} \int_\Omega u_i (D_i v_j) w_j \, dx \quad \forall w \in W, \tag{1.11}$$

$$\begin{aligned} (\tilde{\mathcal{B}}(u, v), w) &= (\mathcal{B}(u, v), w) + \frac{1}{2} \int_\Omega (\operatorname{div} u) v w \, dx \\ &= \text{(cf. [14], [15])} \\ &= \frac{1}{2} \sum_{i,j=1}^{2} \int_\Omega u_i \{(D_i v_j) w_j - v_j (D_i w_j)\} \, dx \quad \forall w \in W. \end{aligned} \tag{1.12}$$

We also set $\mathcal{B}(u) = \mathcal{B}(u, u)$, $\tilde{\mathcal{B}}(u) = \tilde{\mathcal{B}}(u, u)$.

The functional form of the exact N.S.E. is then (cf. [15], [16])

$$\frac{du}{dt} + \nu A u + B(u) = Pf \quad \text{in } V' \tag{1.13}$$

which we supplement with the initial condition (for initial value problems).

$$u(0) = u_0. \tag{1.14}$$

The penalized N.S.E. are written

$$\frac{du_\varepsilon}{dt} - \nu \Delta u_\varepsilon + \tilde{\mathcal{B}}(u_\varepsilon) - \frac{\nu}{\varepsilon} \operatorname{grad} \operatorname{div} u_\varepsilon = f \quad \text{in } W' \tag{1.15}$$

with an initial condition

$$u_\varepsilon(0) = u_{\varepsilon 0}. \tag{1.16}$$

We recall that for u_0 given in H (and $Pf \in H$), (1.13), (1.14) possesses a unique solution $u \in L^2(0, T, V) \cap \mathcal{C}([0, T]; H)$. In fact, [6], u is analytic from $]0, \infty[$ with values in $D(A)$ and if $u_0 \in V$ (instead of H), $u \in L^2_{\text{loc}}(0, \infty; D(A)) \cap \mathcal{C}([0, \infty[; V)$.

[2] We restrict ourselves to f independent of time since we consider only autonomous dynamical systems.

For (1.15), (1.16) similar results were proved in [13], [14]; there exists a unique solution $u_\varepsilon \in L^2(0, T, W) \cap L^\infty([0, T]; G)$ for all $T > 0$, of (1.15), (1.16). Also with the same methods as in [6], we find that u_ε is analytic in t from $(0, \infty)$ with values in $D(-\Delta)$ = the domain of $-\Delta$ in G (= a closed subspace of $\mathbb{H}^2(\Omega)$). Furthermore if $u_{\varepsilon 0} \in W$, then u_ε is in $L^2_{\text{loc}}(0, \infty; \mathbb{H}^2(\Omega)) \cap \mathscr{C}([0, \infty[; W)$. We denote by $S(t)$ the operator $u_0 \to u(t)$ which maps H into $D(A)$ for $t > 0$, and by $S_\varepsilon(t)$ the operator $u_{\varepsilon 0} \to u_\varepsilon(t)$ which maps $\mathbb{L}^2(\Omega)$ into $\mathbb{H}^2(\Omega)$. Each of the family of operators $\{S(t)\}_{t>0}$, $\{S_\varepsilon(t)\}_{t \geqq 0}$ enjoys the usual semigroup properties.

The results above are valid for each $\varepsilon > 0$ fixed. Concerning the passage to the limit $\varepsilon \to 0$ some convergence results of u_ε to u were proved in [13], [14]. We will recall and complete these results in § 3. We now finish this section with a technical result.

1.2. Comparison of two norms. We consider mainly in this section the case of Dirichlet boundary condition (0.4), while the space periodic case (0.5) is much easier and will be rapidly considered at the end of this section.

We recall [15] that, for $u \in D(A)$ (or even V) and $g \in H$, saying that $Av = g$ amounts to saying that there exists $q \in L^2(\Omega)$ such that

$$\begin{aligned} -\Delta v + \operatorname{grad} q &= g \quad \text{in } \Omega, \\ \operatorname{div} v &= 0 \quad \text{in } \Omega, \\ v &= 0 \quad \text{on } \Gamma. \end{aligned} \tag{1.17}$$

This is a Stokes problem. We can also consider a slightly more general Stokes problem

$$\begin{aligned} -\Delta v + \operatorname{grad} q &= g \quad \text{in } \Omega, \\ \operatorname{div} v &= h \quad \text{in } \Omega, \\ v &= 0 \quad \text{on } \Gamma. \end{aligned} \tag{1.18}$$

Now $g \in H$ or more generally $\mathbb{L}^2(\Omega)$, and for instance $h \in \dot{L}^2(\Omega)$. The results concerning (1.18) can be found in [15] and will be recalled when needed.

The penalized form of (1.17) is the following [15]; given $\varepsilon > 0$ and $g_\varepsilon \in \mathbb{L}^2(\Omega)$, we denote by v_ε the solution of

$$\begin{aligned} -\Delta v_\varepsilon - \frac{1}{\varepsilon} \operatorname{grad} \operatorname{div} v_\varepsilon &= g_\varepsilon \quad \text{in } \Omega, \\ v_\varepsilon &= 0 \quad \text{on } \Gamma. \end{aligned} \tag{1.19}$$

It is known that if $v \in V$ and $Av = g \in H$ then in fact $v \in D(A) = \mathbb{H}^2(\Omega) \cap V$ and $|Av|$ is a norm on $D(A)$ which is equivalent to that of $\mathbb{H}^2(\Omega)$. More generally for (1.18), if g is in $\mathbb{L}^2(\Omega)$ and h in $H^1(\Omega)$ then v is in $\mathbb{H}^2(\Omega)$, q in $H^1(\Omega)$ and there exists a constant C_1 depending only on Ω such that[3]

$$\|v\|_{\mathbb{H}^2(\Omega)} + |q|_{H^1(\Omega)} \leqq C_1(|g|_{\mathbb{L}^2(\Omega)} + |h|_{H^1(\Omega)}) \tag{1.20}$$

or equivalently with another constant C_2

$$|\Delta v|_{\mathbb{L}^2(\Omega)} + |\operatorname{grad} q|_{\mathbb{L}^2(\Omega)} \leqq C_2(|g|_{\mathbb{L}^2(\Omega)} + |\operatorname{grad} h|_{\mathbb{L}^2(\Omega)}). \tag{1.21}$$

For (1.19) the similar results are simple and follow immediately from the general results on elliptic systems (cf. Agmon, Douglis and Nirenberg [1]). For fixed $\varepsilon > 0$, if

[3] Here and in the sequel we make q unique by imposing the condition $\int_\Omega q(x)\, dx = 0$.

$g_\varepsilon \in \mathbb{L}^2(\Omega)$ and $v_\varepsilon \in \mathbb{H}_0^1(\Omega)$ satisfies (1.19) then in fact $v_\varepsilon \in \mathbb{H}^2(\Omega)$ and $|\mathcal{A}_\varepsilon v|$ is a norm on $\mathbb{H}^2(\Omega) \cap \mathbb{H}_0^1(\Omega)$, equivalent to that of $\mathbb{H}^2(\Omega)$; here we have written

$$\mathcal{A}_\varepsilon v = -\Delta v - \frac{1}{\varepsilon} \text{grad div } v \quad \forall v \in \mathbb{H}_0^1(\Omega).$$

Of course [1] provides only an equivalence of norms

$$|\mathcal{A}_\varepsilon v| \sim |v|_{\mathbb{H}^2(\Omega)} \tag{1.22}$$

with constants depending on ε (besides Ω). Our aim is now to show that one of the inequalities (1.22) is valid uniformly with respect to ε.

LEMMA 1.1. *There exists a constant $C_3 < \infty$, depending only on Ω and such that if $\varepsilon C_3 \leqq 1$*

$$|\Delta v| \leqq C_3 |\mathcal{A}_\varepsilon v| \quad \forall v \in \mathbb{H}^2(\Omega) \cap \mathbb{H}_0^1(\Omega). \tag{1.23}$$

Proof. Let $v \in \mathbb{H}^2(\Omega) \cap \mathbb{H}_0^1(\Omega)$ and let $g_\varepsilon = \mathcal{A}_\varepsilon v$. Taking the scalar product with v we obtain

$$\begin{aligned} \|v\|^2 + \frac{1}{\varepsilon} |\text{div } v|^2 &= (g_\varepsilon, v) \\ &\leqq |g_\varepsilon| |v| \leqq \frac{1}{\sqrt{\lambda_1}} |g_\varepsilon| \|v\| \\ &\leqq \frac{1}{2} \|v\|^2 + \frac{1}{2\lambda_1} |g_\varepsilon|^2. \end{aligned}$$

Hence

$$\|v\|^2 + \frac{1}{\varepsilon} |\text{div } v|^2 \leqq \frac{1}{\lambda_1} |g_\varepsilon|^2 = \frac{1}{\lambda_1} |\mathcal{A}_\varepsilon v|^2. \tag{1.24}$$

Now setting $q_\varepsilon = (1/\varepsilon) \text{ div } v$, we rewrite $\mathcal{A}_\varepsilon v = g_\varepsilon$ in the following manner

$$\begin{aligned} -\Delta v + \text{grad } q_\varepsilon &= g_\varepsilon, \\ \text{div } v &= h_\varepsilon. \end{aligned}$$

Using (1.21) we then find

$$|\Delta v| + |\text{grad } q_\varepsilon| \leqq C_2 (|g_\varepsilon| + |\text{grad } h_\varepsilon|)$$

or equivalently

$$|\Delta v| + \frac{1}{\varepsilon} |\text{grad div } v| \leqq C_2 (|g_\varepsilon| + |\text{grad div } v|)$$

and if

$$\varepsilon C_2 \leqq \tfrac{1}{2}, \tag{1.25}$$

$$|\Delta v| + \frac{1}{\varepsilon} |\text{grad div } v| \leqq 2C_2 |g_\varepsilon|. \tag{1.26}$$

This proves (1.23) with $C_3 = 2C_2$. We recall that $|\Delta v|$ and $|v|_{\mathbb{H}^2(\Omega)}$ are equivalent norms on $\mathbb{H}^2(\Omega) \cap \mathbb{H}_0^1(\Omega)$.

Remark 1.1. We infer also from (1.26) that

$$|\text{grad div } v| \leqq \varepsilon C_3 |\mathcal{A}_\varepsilon v|. \tag{1.27}$$

Remark 1.2. In the space periodic case, an inequality similar to (1.23) holds, for every $v \in \dot{\mathbb{H}}^2_{\text{per}}(\Omega)$. The proof is exactly the same as Lemma 1.1 and relies on the analogue of (1.21), which is much easier to prove in this case by using Fourier series expansions [16].

2. Attractors for the penalized equations. We derive in §§ 2.1 and 2.2 a series of uniform estimates on the solutions of the penalized N.S.E. We then introduce the absorbing sets and their universal attractor.

2.1. Uniform estimates in L^2. If u_ε is solution of (1.15), (1.16) then, taking the scalar product of (1.15) with u_ε in $\mathbb{L}^2(\Omega)$ we obtain

$$\frac{1}{2}\frac{d}{dt}|u_\varepsilon|^2 + \nu\|u_\varepsilon\|^2 + \frac{\nu}{\varepsilon}|\text{div } u_\varepsilon|^2 = (f, u_\varepsilon)$$

$$\leqq |f||u_\varepsilon| \leqq \frac{1}{\sqrt{\lambda_1}}|f|\,\|u_\varepsilon\|$$

$$\leqq \frac{\nu}{2}\|u_\varepsilon\|^2 + \frac{1}{2\nu\lambda_1}|f|^2.$$

We have used the property

$$(\tilde{\mathcal{B}}(u, v), v) = 0 \quad \forall u, v \in W \tag{2.1}$$

which follows easily from the second expression of $\tilde{\mathcal{B}}$ in (1.12). Therefore

$$\frac{d}{dt}|u_\varepsilon|^2 + \nu\|u_\varepsilon\|^2 + \frac{\nu}{\varepsilon}|\text{div } u_\varepsilon|^2 \leqq \frac{1}{2\lambda_1}|f|^2, \tag{2.2}$$

$$\frac{d}{dt}|u_\varepsilon|^2 + \nu\lambda_1|u_\varepsilon|^2 + \frac{\nu}{\varepsilon}|\text{div } u_\varepsilon|^2 \leqq \frac{1}{\nu\lambda_1}|f|^2, \tag{2.3}$$

from which we infer easily that

$$|u_\varepsilon(t)|^2 \leqq |u_{\varepsilon 0}|^2\, e^{-\nu\lambda_1 t} + \frac{1}{\nu^2\lambda_1^2}|f|^2(1 - e^{-\nu\lambda_1 t}), \tag{2.4}$$

$$\overline{\lim_{t\to\infty}}\ |u_\varepsilon(t)|^2 \leqq \frac{1}{\nu^2\lambda_1^2}|f|^2. \tag{2.5}$$

Returning then to (2.2) we obtain

$$\nu\int_t^{t+T}\left\{\nu\|u_\varepsilon\|^2 + \frac{1}{\varepsilon}|\text{div } u_\varepsilon|^2\right\} ds \leqq |u_{\varepsilon 0}|^2\, e^{-\nu\lambda_1 t} + \frac{T}{\nu\lambda_1}|f|^2 + \frac{|f|^2}{\nu^2\lambda_1^2}(1 - e^{-\nu\lambda_1 t}), \tag{2.6}$$

$$\overline{\lim_{t\to\infty}}\int_t^{t+T}\left\{\nu\|u_\varepsilon\|^2 + \frac{1}{\varepsilon}|\text{div } u_\varepsilon|^2\right\} ds \leqq \left(\frac{T}{\nu^2\lambda_1} + \frac{1}{\nu^3\lambda_1^2}\right)|f|^2. \tag{2.7}$$

Let ρ_0^2 denote the right-hand side of (2.5). It follows from (2.4) that if $|u_{\varepsilon 0}| \leqq \rho$, $\rho \geqq \rho_0$, then $|u_\varepsilon(t)| \leqq \rho$ for all $t > 0$, i.e., $S_\varepsilon(t)$ maps the ball of $\mathbb{L}^2(\Omega)$ centered at 0 of radius ρ into itself:

(2.8) For any $\rho \geqq \rho_0$ the ball of G centered at 0 of radius ρ is invariant for the semigroup $S_\varepsilon(t)$.

We note also that for $\rho > \rho_0$ any trajectory eventually enters into the ball of $\mathbb{L}^2(\Omega)$ centered at 0 of radius ρ. The time of entrance of $u_\varepsilon(t)$ into this ball is uniform for all the $u_{\varepsilon 0}$ such that

$$|u_{\varepsilon 0}| \leqq r_0\ (< \infty).$$

We recall that a set $\mathscr{C} \subset G$ is called an *absorbing set* for the semigroup $S_\varepsilon(t)$ if, for every bounded set $\mathscr{C}_0 \subset G$, there exists $t_0 = t_0(\mathscr{C}_0)$ such that

$$S_\varepsilon(t)\mathscr{C}_0 \subset \mathscr{C} \quad \forall t \geqq t_0(\mathscr{C}_0).$$

We then interpret the result above as follows:

(2.9) For any $\rho > \rho_0$, the ball of G centered at 0 of radius ρ is absorbing in G for the semigroup $S_\varepsilon(t)$.

The time of entrance of u_ε in this ball, depending on r_0, $\delta = \rho - \rho_0$ (and the data $\nu, \lambda_1, |f|$), $t = t_0(r_0, \delta)$ can be explicitly computed from (2.4) and we have

$$|u_\varepsilon(t)| \leqq \rho_0 + \delta \quad \text{for } t \geqq t_0(r_0, \delta),$$

$$\int_t^{t+T} \left(\|u_\varepsilon\|^2 + \frac{1}{\varepsilon}|\operatorname{div} u_\varepsilon|^2 \right) ds \leqq \frac{(\rho_0+\delta)^2}{\nu} + \frac{T}{\nu^2\lambda_1}|f|^2 \tag{2.10}$$

$$\forall T > 0, \quad \forall t \geqq t_0(r_0, \delta).$$

2.2. Uniform estimates in H^1. We now take the scalar product of (1.15) with $\mathscr{A}_\varepsilon u_\varepsilon$ in $\mathbb{L}^2(\Omega)$, the operator $\mathscr{A}_\varepsilon$ being defined in Lemma 1.1. We find

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\left(\|u_\varepsilon\|^2 + \frac{1}{\varepsilon}|\operatorname{div} u_\varepsilon|^2 \right) + \nu|\mathscr{A}_\varepsilon u_\varepsilon|^2 \\
&\quad = (f - \tilde{\mathscr{B}}(u_\varepsilon), \mathscr{A}_\varepsilon u_\varepsilon) \\
&\quad \leqq (|f| + |\tilde{\mathscr{B}}(u_\varepsilon)|)|\mathscr{A}_\varepsilon u_\varepsilon| \\
&\quad \leqq \frac{\nu}{4}|\mathscr{A}_\varepsilon u_\varepsilon|^2 + \frac{1}{\nu}|f|^2 + |\tilde{\mathscr{B}}(u_\varepsilon)|\,|\mathscr{A}_\varepsilon u_\varepsilon|.
\end{aligned}$$

We know (cf. [6], [16]) that there exists a constant C_4 depending only on Ω such that

$$|\mathscr{B}(\varphi, \psi)| \leqq \begin{cases} C_4|\varphi|^{1/2}|\Delta\varphi|^{1/2}\|\psi\|, \\ C_4|\varphi|^{1/2}\|\varphi\|^{1/2}\|\psi\|^{1/2}|\Delta\psi|^{1/2} \end{cases} \quad \forall \varphi, \psi \in \mathbb{H}^2(\Omega). \tag{2.11}$$

It can be proved exactly in the same manner that

$$|\tilde{\mathscr{B}}(\varphi, \psi)| \leqq \begin{cases} C_5\{|\varphi|^{1/2}|\Delta\varphi|^{1/2}\|\psi\| + \|\varphi\|\,|\psi|^{1/2}|\Delta\psi|^{1/2}\}, \\ C_5\{|\varphi|^{1/2}\|\varphi\|^{1/2}\|\psi\|^{1/2}|\Delta\psi|^{1/2} + \|\varphi\|\,|\psi|^{1/2}|\Delta\psi|^{1/2}\} \end{cases} \quad \forall \varphi, \psi \in \mathbb{H}^2(\Omega). \tag{2.12}$$

Thus

$$|\tilde{\mathscr{B}}(u_\varepsilon)| = |\tilde{\mathscr{B}}(u_\varepsilon, u_\varepsilon)| \leqq 2C_5|u_\varepsilon|^{1/2}\|u_\varepsilon\|\,|\Delta u_\varepsilon|^{1/2}.$$

We then apply (1.23) (cf. Lemma 1.1 and Remark 1.2 for the space periodic case) and we bound this expression by

$$2C_5C_3^{1/2}|u_\varepsilon|^{1/2}\|u_\varepsilon\|\,|\mathscr{A}_\varepsilon u_\varepsilon|^{1/2},$$

and

$$\begin{aligned}
|(\tilde{\mathscr{B}}(u_\varepsilon), \mathscr{A}_\varepsilon u_\varepsilon)| &\leqq 2C_5C_3^{1/2}|u_\varepsilon|^{1/2}\|u_\varepsilon\|\,|\mathscr{A}_\varepsilon u_\varepsilon|^{3/2} \\
&\leqq \text{(with Young Inequality)} \\
&\leqq \frac{\nu}{4}|\mathscr{A}_\varepsilon u_\varepsilon|^2 + \frac{C_1'}{\nu^3}|u_\varepsilon|^2\|u_\varepsilon\|^4,
\end{aligned}$$

where C_1' as well as the C_j, C_j', $\cdots$, is a constant depending only on Ω.[4]

Combining these estimates we arrive at

$$\frac{d}{dt}\left(\|u_\varepsilon\|^2+\frac{1}{\varepsilon}|\operatorname{div} u_\varepsilon|^2\right)+\nu|\mathscr{A}_\varepsilon u_\varepsilon|^2\leqq\frac{2}{\nu}|f|^2+\frac{2C_1'}{\nu^3}|u_\varepsilon|\,\|u_\varepsilon\|^4. \tag{2.13}$$

First we deduce from (2.13) that

$$\begin{aligned} &y'\leqq h+gy,\\ &y=\|u_\varepsilon\|^2+\frac{1}{\varepsilon}|\operatorname{div} u_\varepsilon|^2,\quad h=\frac{2}{\nu}|f|^2,\\ &g=\frac{2C_1'}{\nu^3}|u_\varepsilon|\,\|u_\varepsilon\|^2. \end{aligned} \tag{2.14}$$

We apply the Uniform Gronwall Lemma [8] that we recall below for the convenience of the reader and we obtain that $y(t)$ is bounded uniformly with respect to t (and ε) on $[t_0+T,+\infty)$. More precisely

$$\|u_\varepsilon(t)\|^2+\frac{1}{\varepsilon}|\operatorname{div} u_\varepsilon(t)|^2\leqq\rho_1\quad\forall t\geqq t_0(r_0,\delta)+T\quad\forall T>0 \tag{2.15}$$

with (cf. (2.9) and Lemma 2.1 below)

$$\begin{aligned} &\rho_1=\left(\frac{\alpha_3}{T}+\alpha_2\right)\exp(\alpha_1),\\ &\alpha_1=\frac{2C_1'}{\nu^3}(\rho_0+\delta)\alpha_3,\quad\alpha_2=\frac{2}{\nu}|f|^2,\quad\alpha_3=\frac{(\rho_0+\delta)}{\nu}+\frac{T}{\nu^2\lambda_1}|f|^2. \end{aligned} \tag{2.16}$$

Then we obtain from (2.13)

$$\int_t^{t+T}|\mathscr{A}_\varepsilon u_\varepsilon|^2\,ds\leqq\frac{\rho_1(1+\alpha_1)}{\nu}+\frac{T\alpha_2}{\nu}\quad\forall T>0,\quad\forall t\geqq t_0(r_0,\delta), \tag{2.17}$$

$$\int_t^{t+T}|\Delta u_\varepsilon|^2\,ds\leqq\frac{C_3^2}{\nu}\{\rho_1(1+\alpha_1)+T\alpha_2\}\quad\forall T>0,\quad\forall t\geqq t_0(r_0,\delta). \tag{2.18}$$

We infer from (2.15), as in (2.8) that

(2.19) The ball of W centered at 0 of radius ρ_1 (given by (2.16)) is absorbing in W for the semigroup $S_\varepsilon(t)$.

Remark 2.1. The bounds similar to (2.15), for $0\leqq t\leqq t_0+T$, and to (2.17) for $0\leqq t\leqq t_0$ are easily derived from (2.14) using the classical Gronwall Lemma. Like in (2.15) and (2.17) the bounds are independent on ε.

Remark 2.2. We observe that in (2.8) and (2.19) the absorbing sets are *independent* of ε.

We conclude with the Uniform Gronwall Lemma.

LEMMA 2.1. *Let g, h, y be three positive locally integrable functions on $]t_0,\infty[$; assume that y is absolutely continuous and*

$$\frac{dy}{dt}\leqq gy+h\quad\textit{for } t\geqq t_0, \tag{2.20}$$

$$\int_t^{t+T}g(s)\,ds\leqq\alpha_1,\quad\int_t^{t+T}h(s)\,ds\leqq\alpha_2,\quad\int_t^{t+T}y(s)\,ds\leqq\alpha_3\quad\forall t\geqq t_0, \tag{2.21}$$

[4] More precisely, these constants depend on the shape of Ω but not on its size, i.e., they are the same for instance for Ω and $\lambda\Omega$ for all $\lambda>0$, or $\Omega+a$ for all $a\in\mathbb{R}^2$.

where T, $\alpha_1, \alpha_2, \alpha_3$ are positive constants. Then

$$y(t+T) \leqq \left(\frac{\alpha_3}{T} + \alpha_2\right) \exp(\alpha_1) \quad \forall t \geqq t_0. \tag{2.22}$$

Proof. Assume that $t_0 \leqq t \leqq s < t+T$. We deduce from (2.20) that

$$\frac{d}{ds}\left(y(s) \exp\left(-\int_t^s g(\tau)\, d\tau\right)\right) \leqq h(s) \exp\left(-\int_t^s g(\tau)\, d\tau\right) \leqq h(s).$$

Then by integration between s and $t+T$

$$y(t+T) \leqq y(s) \exp\left(\int_s^{t+T} g(\tau)\, d\tau\right) + \left(\int_s^{t+T} h(\tau)\, d\tau\right) \exp\left(\int_s^{t+T} g(\tau)\, d\tau\right).$$

Integration of this last inequality with respect to s between t and $t+T$ gives precisely (2.22). □

2.3. Existence of the universal attractors. We denote by $\mathscr{C}_0$ the $\mathbb{L}^2$-absorbing set introduced in (2.9), i.e., the ball of G centered at 0 of radius $\rho > \rho_0$, and we consider its ω-limit set for the semigroup S_ε:

$$X_\varepsilon = \bigcap_{s \geqq 0} \overline{\bigcup_{t \geqq s} S_\varepsilon(t)\mathscr{C}_0}, \tag{2.23}$$

where the closures are taken in $\mathbb{L}^2(\Omega)$. It is easy to see that $\varphi \in X_\varepsilon$ if and only if there exists a sequence $t_m \to \infty$ and a sequence φ_m of elements of $\mathscr{C}_0$ such that

$$S_\varepsilon(t_m)\varphi_m \to \varphi \quad \text{in } \mathbb{L}^2(\Omega) \quad \text{as } m \to \infty. \tag{2.24}$$

Exactly as in the case of the Navier-Stokes equations [6] or by application of general results [19], we can prove the following.

THEOREM 2.1. *The set X_ε is included and bounded in $\mathbb{H}^2(\Omega)$, compact in $\mathbb{L}^2(\Omega)$ and connected.*

This set is a functional invariant set for the semigroup S_ε, i.e.,

$$S_\varepsilon(t)X_\varepsilon = X_\varepsilon \quad \forall t > 0 \ (\textit{and thus } \forall t \in \mathbb{R}). \tag{2.25}$$

This set is an attractor in G and W. Its basin of attraction is the whole space G (resp. W). It is the largest bounded attractor and the largest bounded invariant set for S_ε.

This attractor X_ε is called the universal attractor for the semigroup S_ε. Our aim will be, in § 3, to study its convergence to the universal attractor for the Navier-Stokes equations.

2.4. Remark on another perturbed equation. As indicated in the Introduction, the nonlinear term $\frac{1}{2}(\operatorname{div} u_\varepsilon)u_\varepsilon$ was introduced in order to have a well-set Cauchy problem for arbitrary large data f and u_0 and arbitrary ε. Now since we are interested here in small values of ε, it is interesting to observe that we can also obtain global existence for the equation

$$\frac{\partial v_\varepsilon}{\partial t} - \nu\Delta v_\varepsilon + (v_\varepsilon \cdot \nabla)v_\varepsilon - \frac{\nu}{\varepsilon}\nabla(\operatorname{div} v_\varepsilon) = f$$

with the same initial and boundary conditions as those on u_ε, namely (0.4) or (0.5) and (0.7), provided ε is small enough. More precisely we claim that if $v_{\varepsilon_0} \in G$ and

$$|v_{\varepsilon_0}| \leqq R$$

(where R is an arbitrary real number), then for

$$0<\varepsilon\leqq \operatorname{Min}\left(\frac{1}{2R^2},\frac{\nu^2}{4|f|^2}\right)$$

the solution v_ε (with $v_\varepsilon(0)=v_{\varepsilon_0}$) exists and is unique in the spaces $L^2(0,T;W)\cap \mathscr{C}([0,T];G)$ for all $T>0$. Moreover (compare to (2.4))

$$|v_\varepsilon(t)|^2\leqq |v_{\varepsilon_0}|^2\, e^{-\nu\lambda_1 t/2}+\frac{2|f|^2}{\nu^2\lambda_1^2}(1-e^{-\nu\lambda_1 t/2}).$$

This inequality is proved as (2.4), but since $b(v_\varepsilon,v_\varepsilon,v_\varepsilon)=-\frac{1}{2}\int_\Omega(\operatorname{div} v_\varepsilon)|v_\varepsilon|^2\,dx$ we have, instead of (2.3),

$$\frac{1}{2}\frac{d}{dt}|v_\varepsilon|^2+\nu\|v_\varepsilon\|^2+\frac{2\nu}{\varepsilon}|\operatorname{div} v_\varepsilon|^2\leqq\frac{|f|^2}{\nu\lambda_1}+\frac{1}{2}\int_\Omega(\operatorname{div} v_\varepsilon)|v_\varepsilon|^2\,dx.$$

The supplementary term in the right-hand side is bounded by

$$\left|\frac{1}{2}\int_\Omega(\operatorname{div} v_\varepsilon)|v_\varepsilon|^2\,dx\right|\leqq\frac{\nu}{2\varepsilon}|\operatorname{div} v_\varepsilon|^2+\frac{\varepsilon}{8\nu}\int_\Omega|v_\varepsilon|^4\,dx.$$

Then using the interpolation inequality recalled hereafter in (3.48), we see that

$$\frac{d}{dt}|v_\varepsilon|^2+\nu\left(1-\frac{\varepsilon}{2}|v_\varepsilon|^2\right)\|v_\varepsilon\|^2\leqq\frac{|f|^2}{\nu\lambda_1}.$$

By the choice of ε, $1-(\varepsilon/2)|v_\varepsilon(t)|^2>\frac{1}{2}$ at time $t=0$, and by Gronwall's Lemma technics it follows that this holds true for all $t>0$. This guarantees the existence of $v_\varepsilon(t)$ for all time and provides a uniform estimate on $|v_\varepsilon(t)|$ for $t\geqq 0$ and ε as above.

If we choose

$$R\geqq\frac{\sqrt{2}|f|}{\nu\lambda_1}$$

then for every ε, $0<\varepsilon\leqq 1/2R^2$, the ball of G centered at 0 of radius R is invariant for the semigroup $\Sigma_\varepsilon(t)$ ($\Sigma_\varepsilon(t)v_{\varepsilon_0}\equiv v_\varepsilon(t)$). Moreover any ball of G centered at 0 of radius R_0, $R_0>|f|/\nu\lambda_1$, is an absorbing set for the semigroup $\Sigma_\varepsilon(t)$ in the ball of G centered at 0 and of radius R.

The uniform estimates in H^1 for u_ε (i.e., (2.15) and also (2.17), (2.18)) can also be derived on the solutions v_ε using similar methods. It follows then by the same procedure that Theorem 2.1 can be extended to this case: the semigroup Σ_ε possesses a universal attractor in the ball of G centered at 0 of radius R (where R is a fixed number greater than $\sqrt{2}|f|/\nu$ and ε satisfies $0<\varepsilon\leqq 1/2R^2$).

3. Convergence to 0 of the penalty parameter. We recall a result on the convergence of attractors (§ 3.1). Then we recall some known results on the convergence of u_ε to u as $\varepsilon\to 0$ and give some complements (§ 3.2). Finally in § 3.3 we apply the results of §§ 3.1 and 3.2 and establish the convergence of the universal attractor of the penalized Navier-Stokes equations to that of the exact N.S.E.

3.1. A result on convergence of attractors. We give a result on convergence of attractors; for another form of this result see Foias and Temam [7]. Although the notations are the same as in the rest of the article, this § 3.1 is self-contained and independent.

We are given a Hilbert space G and a Hilbert subspace $H \subset G$ and we denote by P the projector in G onto H. We consider in H a semigroup of operators $\{S(t)\}_{t\geq 0}$ which possesses an attractor $\mathscr{A}$ attracting the whole space H.

We are also given a family of semigroups $\{S_\varepsilon(t)\}_{t\geq 0}$ which depends on a parameter ε, $0<\varepsilon\leq\varepsilon_0$. For each ε it is assumed that S_ε possesses an attractor $\mathscr{A}_\varepsilon$ which attracts the whole space G. Furthermore the following assumptions are made:

(3.1) There exists a fixed open bounded set of G, $\mathscr{U}$, which contains $\mathscr{A}$ and $\mathscr{A}_\varepsilon$ $\forall\varepsilon$, and is invariant by $S_\varepsilon(t)$ and $S(t)P$, ($S_\varepsilon(t)\mathscr{U}\subset\mathscr{U}$, $S(t)P\mathscr{U}\subset\mathscr{U}$, $\forall\varepsilon$, $\forall t>0$).

(3.2) For every bounded set $\mathscr{C}\subset G$ and every $t\in]0,\infty[$

$$\mathrm{Sup}_{u_1\in\mathscr{C}}\,|(I-P)S_\varepsilon(t)u_1|\to 0 \text{ as } \varepsilon\to 0.$$

(3.3) For every compact $I\subset]0,\infty[$

$$\mathrm{Sup}_{t\in I}\,|S_\varepsilon(t)v_1-S(t)Pv_1|\leq a(|v_1-Pv_1|)+b(\varepsilon)$$

uniformly with respect to v_1 in a compact of G, where $a(\alpha)$, $b(\alpha)$ are continuous increasing functions which tend to 0 as $\alpha\to 0$.[5]

PROPOSITION 3.1. *Under the above assumptions $\mathscr{A}_\varepsilon$ converges to $\mathscr{A}$ as $\varepsilon\to 0$ in the following sense*:

(3.4) *For every open neighborhood $\mathscr{V}$ of $\mathscr{A}$ there exists ε_1 depending on $\mathscr{V}$ and for $\varepsilon\leq\varepsilon_1$, $\mathscr{A}_\varepsilon\subset\mathscr{V}$.*

In particular $(I-P)\,\mathscr{A}_\varepsilon\to 0$ (in the above sense) as $\varepsilon\to 0$.

Proof. Let $\mathscr{V}_\alpha(\mathscr{A})$ denote the α-neighborhood of $\mathscr{A}$ in H, i.e., the union of open balls of radius α of H centered on $\mathscr{A}$. It is sufficient to show that for every α, there exists $\varepsilon_1=\varepsilon_1(\alpha)$ and $t_1=t_1(\alpha)$ such that, for $0<\varepsilon\leq\varepsilon_1(\alpha)$ and $t\geq t_1(\alpha)$,

$$S_\varepsilon(t)\mathscr{U}\subset\mathscr{V}_\alpha(\mathscr{A}). \tag{3.5}$$

Indeed the ω-limit set of $\mathscr{U}$ for S_ε, $\omega_\varepsilon(\mathscr{U})$ is equal to $\mathscr{A}_\varepsilon$[6] and (3.5) implies that

$$\omega_\varepsilon(\mathscr{U})=\mathscr{A}_\varepsilon\subset\mathscr{V}_\alpha(\mathscr{A}).$$

We now prove (3.5); there exists $r_0>0$ such that $(\mathscr{U}\supset)P\mathscr{U}\supset\mathscr{V}_{r_0}(\mathscr{A})$. Assuming that $\alpha>r_0$, and since $\mathscr{A}$ attracts $P\mathscr{U}$, we can find $t_1=t_1(\alpha)$ such that for $t\geq t_1/2$

$$S(t)P\mathscr{U}\subset\mathscr{V}_{\alpha/2}(\mathscr{A}). \tag{3.6}$$

We use (3.2) with $\mathscr{C}=\mathscr{U}$ and $t=t_1/2$ and we find that

$$\mathrm{Sup}_{u_0\in\mathscr{U}}\left|(I-P)S_\varepsilon\left(\frac{t_1}{2}\right)u_0\right|=\delta(\varepsilon)\to 0 \quad \text{as } \varepsilon\to 0. \tag{3.7}$$

We then use (3.3) with $I=[\frac{1}{2}t_1,\frac{3}{2}t_1]$, and $v_1=S_\varepsilon(\frac{1}{2}t_1)u_1$, $u_1\in\mathscr{U}$ and we obtain (note that $S(t_1/2)\mathscr{U}$ is a compact of G)

$$\mathrm{Sup}_{(1/2)t_1\leq t\leq(3/2)t_1}\,|S_\varepsilon(t)v_1-S(t)Pv_1|\leq a(|v_1-Pv_1|)+b(\varepsilon)\leq a(\delta(\varepsilon))+b(\varepsilon). \tag{3.8}$$

We can find $\varepsilon_1=\varepsilon_1(\alpha)$ such that $a(\delta(\varepsilon))+b(\varepsilon)\leq\alpha/2$ for every $\varepsilon\leq\varepsilon_1(\alpha)$. Then (3.6), (3.7) and (3.8) (with $v_1=S_\varepsilon(\frac{1}{2}t_1)u_1$, $u_1\in\mathscr{U}$) show that

$$S_\varepsilon(t)u_1\in\mathscr{V}_\alpha(\mathscr{A}) \quad \forall u_1\in\mathscr{U} \quad \forall t\in[t_1,2t_1] \quad \forall\varepsilon\leq\varepsilon_1(\alpha).$$

We have thus proved (3.5) for $t\in[t_1,2t_1]$.

---

[5] If (3.3) is satisfied with functions a, b which are not increasing, we can replace these functions by $\mathrm{Sup}_{0\leq r\leq\alpha}\,a(r)$, $\mathrm{Sup}_{0\leq r\leq\alpha}\,b(r)$ and (3.3) will be satisfied.

[6] $\mathscr{A}_\varepsilon=\omega_\varepsilon(\mathscr{A}_\varepsilon)\subset\omega_\varepsilon(\mathscr{U})$ since $\mathscr{A}_\varepsilon\subset\mathscr{U}$ and $\omega_\varepsilon(\mathscr{U})\subset\mathscr{A}_\varepsilon$ since $\mathscr{A}_\varepsilon$ attracts $\mathscr{U}$.

In order to prove (3.5) for $t > 2t_1$ we write such a t in the form $t = nt_1 + \tau$ for an appropriate integer n and $\tau \in [t_1, 2t_1]$. Then if $u_1 \in \mathcal{U}$,

$$S_\varepsilon(t)u_1 = S_\varepsilon(\tau)S_\varepsilon(nt_1)u_1. \tag{3.9}$$

Due to (3.1), $S_\varepsilon(nt_1)u_1 \in \mathcal{U}$ and (3.5) (which is valid for $\tau \in [t_1, 2t_1]$) implies that $S_\varepsilon(t)u_1 \in \mathcal{V}_\alpha(\mathcal{A})$, if $\varepsilon \leqq \varepsilon_1(\alpha)$.

The proposition is proved. □

This result will be applied to the Navier-Stokes equations, but before that we study the convergence of u_ε to u as $\varepsilon \to 0$.

3.2. Convergence of the solutions of the penalized problems. It was proved in [13], [14] that, if $u_\varepsilon(0) = u(0) \in H$ then u_ε converges to u_ε as $\varepsilon \to 0$, in the following sense:

$$u_\varepsilon \to u \quad \text{in } L^2(0, T; \mathbb{H}^1(\Omega)) \quad \text{and} \quad \mathscr{C}([0, T]; \mathbb{L}^2(\Omega)) \qquad \forall T < \infty. \tag{3.10}$$

Here we will improve this result and, in view of (3.2), (3.3), consider also the case where $u_\varepsilon(0) \notin H$.

We investigate the case where $u_\varepsilon(0)$—hereafter denoted u_1—is fixed and belongs to G, not necessarily to H. We use the a priori estimates of § 2 which are of course valid. We need only these estimates on a finite interval $[0, T]$. We infer from (2.4), (2.6) that

$$u_\varepsilon \text{ is bounded in } L^\infty(0, T; G) \cap L^2(0, T; W) \text{ independently of } \varepsilon, \tag{3.11}$$

$$\frac{1}{\sqrt{\varepsilon}} \operatorname{div} u_\varepsilon \text{ is bounded in } L^2(0, T; L^2(\Omega)) \text{ independently of } \varepsilon. \tag{3.12}$$

Then we use (2.13), (2.14) but in a slightly different manner than in § 2. We infer from (2.14) that

$$(ty)' \leqq th + (1 + tg)y = th + y + tgy. \tag{3.13}$$

Then by the classical Gronwall Lemma,

$$\begin{aligned} ty(t) &\leqq \left(\int_0^t sh(s) + y(s))\, ds \right) \exp\left(\int_0^t g(s)\, ds \right) \\ &\leqq \left(T \int_0^T h(s)\, ds + \int_0^T y(s)\, ds \right) \exp\left(\int_0^T g(s)\, ds \right). \end{aligned}$$

Due to (3.11), (3.12) and the expressions of y, g, h in (2.14), we conclude that

$$\|u_\varepsilon(t)\|^2 + \frac{1}{\varepsilon} |\operatorname{div} u_\varepsilon(t)|^2 \leqq \frac{K_1}{t} \quad \forall t \in [0, T] \tag{3.14}$$

where K_1 depends on the data (ν, f, u_1) but not on ε and t. Thus using again (2.13) in conjunction with (1.23) we obtain

$$\int_0^T t |\mathcal{A}_\varepsilon u_\varepsilon(t)|^2\, dt \leqq K_2, \tag{3.15}$$

$$\int_0^T t |\Delta u_\varepsilon(t)|^2\, dt \leqq K_2' \tag{3.16}$$

where K_2, K_2' depend on the data but not on ε.

Then we consider (1.15), which is valid in G for almost every t in $[0, T]$ and we project it on H. We find

$$\frac{d}{dt} P u_\varepsilon - \nu P \Delta u_\varepsilon + P\tilde{\mathcal{B}}(u_\varepsilon) = Pf. \tag{3.17}$$

The term involving grad div u_ε has been annihilated by P. With (2.15), (3.14), (3.16) we obtain

$$\frac{d}{dt}(tPu_\varepsilon) \text{ is bounded in } L^2(0, T; H) \text{ independently of } \varepsilon. \tag{3.18}$$

Because of (3.14), (3.16) and since P is continuous in $\mathbb{H}^m(\Omega)$ for all $m \in \mathbb{N}$ (cf. [15, Chap. I, Remark 1.6]), we have

$$tPu_\varepsilon \text{ is bounded in } L^2(0, T; \mathbb{H}^2(\Omega)) \cap L^\infty(0, T; \mathbb{H}^1(\Omega)) \text{ independently of } \varepsilon. \tag{3.19}$$

It follows from a compactness theorem in [15, Chap. III, § 2] that tPu_ε is relatively compact in $L^2(0, T; \mathbb{H}^1(\Omega))$; hence there exists a subsequence, still denoted ε, which tends to 0 such that

$$u_\varepsilon \to u \quad \text{in } L^2(0, T; \mathbb{H}^1(\Omega)) \quad \text{weakly}, \tag{3.20}$$

$$tPu \to tPu \quad \text{in } L^2(0, T; \mathbb{H}^1(\Omega)) \quad \text{strongly}, \tag{3.21}$$

$$\text{div } u_\varepsilon \to 0 \quad \text{in } L^2(0, T; \mathbb{L}^2(\Omega)) \quad \text{strongly}. \tag{3.22}$$

The term $(I - P)u_\varepsilon$ is the gradient of a function q_ε such that (cf. [15, Chap. I, Remark 1.6])

$$\begin{aligned} &\Delta q_\varepsilon = \text{div } u_\varepsilon \quad \text{in } \Omega, \\ &\frac{\partial q_\varepsilon}{\partial \nu} = 0 \quad \text{on } \Gamma \quad \text{in the case (0.4)}, \\ &q_\varepsilon \text{ is periodic in the case (0.5)}. \end{aligned} \tag{3.23}$$

Hence

$$|(I - P)u_\varepsilon|_{\mathbb{H}^1(\Omega)} \leqq |\text{grad } q_\varepsilon|_{\mathbb{H}^1(\Omega)} \leqq C_7 |\text{div } u_\varepsilon| \tag{3.24}$$

and due to (3.12), (3.21)

$$(I - P)u_\varepsilon \to 0 \quad \text{in } L^2(0, T; \mathbb{H}^1(\Omega)), \tag{3.25}$$

$$tu_\varepsilon \to tu \quad \text{in } L^2(0, T; \mathbb{H}^1(\Omega)) \quad \text{strongly}. \tag{3.26}$$

It is clear that u belongs to $L^2(0, T, V) \cap L^\infty(0, T; H)$ ($Pu = u$). The passage to the limit in (3.17) can be made by standard methods (cf. [15]) and we find at the limit that u satisfies (1.13). We can also deduce from (3.17) and (3.11) that $(d/dt)Pu_\varepsilon$ is bounded in $L^2(0, T; V')$ independently of ε. This implies that $u' \in L^2(0, T; V')$, $u \in \mathscr{C}([0, T]; H)$ and that

$$Pu_\varepsilon(t) \to u(t) \quad \text{as } \varepsilon \to 0 \text{ weakly in } V' \quad \forall t \in [0, T]. \tag{3.27}$$

In particular $u(0) = Pu_1$. We conclude that u is the unique solution of (1.13) satisfying $u(0) = Pu_1$ and that all the convergences above are valid for the whole sequence $\varepsilon \to 0$ and not only for a subsequence. We have thus proved the following proposition.

PROPOSITION 3.2. *When $\varepsilon \to 0$, the solution u_ε of* (1.15), (1.16) *such that $u_\varepsilon(0) = u_1 \in G$, converges to the solution u of* (1.13), (1.14) *such that $u(0) = u_0 = Pu_1$. The convergences hold in particular in the sense* (3.20), (3.25), (3.26).

If $u_1 \in G \setminus H$, $u_1 \neq u_0$, $u_\varepsilon(0)$ does not converge to $u(0)$ and a boundary layer appears near $t = 0$. However away from $t = 0$, on a compact subset of $]0, T]$, one can improve the convergence of u_ε to u; this will be discussed hereafter.

Before that we observe that (1.13) possesses a regularizing property, and although $u_0 \in H$, we have $u(t) \in V$ for all $t > 0$ (since $f \in H$). A classical energy inequality for (1.13) reads (cf. [16])

$$\frac{d}{dt}\|u\|^2 + \nu|Au|^2 \leqq \frac{2}{\nu}|f|^2 + \frac{c_1'}{\nu^3}|u|^2\|u\|^4 \tag{3.28}$$

where c_1' is an appropriate constant and after multiplication by t we obtain

$$\frac{d}{dt}(t\|u\|^2) + \nu t|Au|^2 \leqq \|u\|^2 + \frac{2t}{\nu}|f|^2 + \frac{c_1' t}{\nu^3}|u|^2\|u\|^4. \tag{3.29}$$

Thanks to the Gronwall inequality and the fact already known that $u \in L^2(0, T; V) \cap L^\infty(0, T; H)$ we infer from (3.29) that

$$\sqrt{t}u \in L^\infty(0, T; V) \cap L^2(0, T; D(A)). \tag{3.30}$$

After multiplication of (1.13) by t we see that

$$\frac{d}{dt}(tu) + \nu tAu + tB(u) = u + tPf \tag{3.31}$$

and we conclude from (3.30) and (2.11) that

$$\frac{d}{dt}(tu) \in L^2(0, T; H) \subset L^2(0, T; \mathbb{L}^2(\Omega)). \tag{3.32}$$

Considering then the Navier-Stokes equation itself, i.e., (0.1), we see after multiplication by t and utilization of (2.11), (3.30), (3.32) that

$$\text{grad}\,(tp) \in L^2(0, T; \mathbb{L}^2(\Omega)), \tag{3.33}$$

which implies

$$tp \in L^2(0, T; H^1(\Omega)). \tag{3.34}$$

We now improve the convergence of u_ε to u. We subtract (0.1) from (0.3) and set $v_\varepsilon = u_\varepsilon - u$, $q_\varepsilon = -\nu/\varepsilon \text{ div } u_\varepsilon - p$. We obtain

$$\frac{\partial v_\varepsilon}{\partial t} - \nu\Delta v_\varepsilon + \tilde{\mathcal{B}}(u_\varepsilon, v_\varepsilon) + \tilde{\mathcal{B}}(v_\varepsilon, u) + \text{grad}\, q_\varepsilon = 0, \tag{3.35}$$

and we then take the scalar product of this equation with v_ε in $\mathbb{L}^2(\Omega)$:

$$\frac{1}{2}\frac{d}{dt}|v_\varepsilon|^2 + \nu\|v_\varepsilon\|^2 + (\tilde{\mathcal{B}}(v_\varepsilon, u), v_\varepsilon) + (\text{grad}\, q_\varepsilon, v) = 0. \tag{3.36}$$

The first term involving $\tilde{\mathcal{B}}$ has disappeared due to (2.1) while the remaining term is majorized using the following inequality:

$$|(\tilde{\mathcal{B}}(\varphi, \psi), \theta| \leqq c_6\{|\psi|^{1/2}\|\varphi\|^{1/2}\|\psi\| + \|\varphi\||\psi|^{1/2}\|\psi\|^{1/2}\}|\theta|^{1/2}\|\theta\|^{1/2}. \tag{3.37}$$

This inequality is proved exactly as the similar inequality for $\tilde{\mathcal{B}}$ (cf. Remark 2.2 in [16]). It implies

$$\begin{aligned}|(\tilde{\mathcal{B}}(v_\varepsilon, u), v_\varepsilon)| &\leqq c_6\{|v_\varepsilon|\,\|v_\varepsilon\|\,\|u\| + |v_\varepsilon|^{1/2}\|v_\varepsilon\|^{3/2}|u|^{1/2}\|u\|^{1/2}\} \\ &\leqq \text{(with Schwarz and Young inequalities)} \\ &\leqq \frac{\nu}{2}\|v_\varepsilon\|^2 + \frac{c_2'}{\nu}\left(1 + \frac{1}{\nu^2}|u|^2\right)\|u\|^2|v_\varepsilon|^2.\end{aligned}$$

We have

$$(\text{grad } q_\varepsilon, v_\varepsilon) = -(q_\varepsilon, \text{div } v_\varepsilon)$$

$$= \frac{\nu}{\varepsilon}|\text{div } u_\varepsilon|^2 + (p, \text{div } u_\varepsilon)$$

$$\geqq \frac{\nu}{2\varepsilon}|\text{div } u_\varepsilon|^2 - \frac{\varepsilon}{2\nu}|p|^2.$$

Hence

$$\frac{d}{dt}|v_\varepsilon|^2 + \nu\|v_\varepsilon\|^2 + \frac{\nu}{\varepsilon}|\text{div } u_\varepsilon|^2 \leqq \frac{\varepsilon}{\nu}|p|^2 + g|v_\varepsilon|^2, \tag{3.38}$$

$$g = \frac{2c_2'}{\nu}\left(1 + \frac{1}{\nu^2}|u|^2\right)\|u\|^2. \tag{3.39}$$

We are going to show that (3.38) implies the following property which will allow us to prove (3.3):

(3.40) On every compact interval $I = [t_0, T]$, $0 < t_0 < T < \infty$, and for every $R > 0$, $\lim_{\varepsilon \to 0} \text{Sup}_{|u_1| \leqq R, t \in I} |S_\varepsilon(t)u_1 - S(t)Pu_1| = 0$.

The proof of this property relies on (3.38) and the fact that for every $t_0 > 0$, we have

$$\lim_{\varepsilon \to 0} \sup_{|u_1| \leqq R} |S_\varepsilon(t_0)u_1 - S(t_0)Pu_1| = 0. \tag{3.41}$$

Indeed, let us assume for the moment that (3.41) holds true. We notice that when u_1 belongs to G and $|u_1| \leqq R$, we have $|Pu_1| \leqq R$ and then since $u(t) = S(t)Pu_1$ satisfies the relation similar to (2.2)

$$\frac{d}{dt}|u|^2 + \nu\|u\|^2 \leqq \frac{|f|^2}{\nu\lambda_1},$$

it follows that there exists C_3 depending only on R, T, f, ν and Ω such that the norm of g (see (3.39)) in $L^1(0, T)$ is bounded by C_3. The same holds for the norm of tp in $L^2(0, T; H^1(\Omega))$ (see (3.34)) and we have ($|\varphi| \leqq \|\varphi\|_{H^1}$)

$$\text{Sup}_{|u_1| \leqq R} \int_0^T (t^2|p(t)|^2 + g(t))\, dt \leqq C_3 < \infty. \tag{3.42}$$

We return to (3.38) which implies

$$\frac{d}{dt}\left(|v_\varepsilon(t)|^2 \exp\left(-\int_0^t g(s)\, ds\right)\right) \leqq \frac{\varepsilon}{\nu}|p(t)|^2 \exp\left(-\int_0^t g(s)\, ds\right).$$

By integration between t_0 and t, we find

$$|v_\varepsilon(t)|^2 \leqq e^{C_3}\left\{|v_\varepsilon(t_0)|^2 + \frac{\varepsilon}{\nu}\int_{t_0}^t |p(s)|^2\, ds\right\} \quad \text{for } t_0 \leqq t \leqq T;$$

thus

$$|v_\varepsilon(t)|^2 \leqq e^{C_3}\left\{|v_\varepsilon(t_0)|^2 + \frac{\varepsilon C_3}{\nu t_0^2}\right\}, \qquad t_0 \leqq t \leqq T.$$

Keeping in mind that $v_\varepsilon(t) = S_\varepsilon(t)u_1 - S(t)Pu_1$, we see that (3.41) and this last estimate prove (3.40).

We proceed to the proof of (3.41). We argue by contradiction and assume that there exist $\delta > 0$ and a sequence $(\varepsilon_j, u_{1j}) \in \mathbb{R}_+^* \times G$ such that $|u_{1j}| \leqq R$, $\varepsilon_j \to 0$ as $j \to \infty$ and

$$|S_{\varepsilon j}(t_0)u_{1j} - S(t_0)Pu_{1j}| \geqq \delta > 0. \tag{3.43}$$

Since u_{1j} is bounded in G we can extract a weakly convergent subsequence, still denoted u_{1j}, such that $u_{1j} \to u_1$ in the weak topology of G. It can be shown with the methods used above that $S_{\varepsilon j}(\cdot)u_{1j}$ and $S(\cdot)Pu_{1j}$ converge to $S(\cdot)P_{u_1}$ for various topologies. In particular it follows from (2.15) that $S_{\varepsilon j}(t_0)u_{1j}$ is bounded in $\mathbb{H}^1(\Omega)$ and as in Proposition 3.2 it can be shown by compactness that $S_{\varepsilon j}(t_0)u_{1j}$ converges to $S(t_0)Pu_1$ in the norm of G, as $j \to \infty$. Similarly, $S(t_0)Pu_{1j}$ converges to $S(t_0)Pu_1$ in the norm of $G(H)$ as $j \to \infty$. These convergences contradict (3.43) and therefore (3.41) follows.

Remark 3.1. We have used (3.42), which is valid for the two boundary conditions (0.4) and (0.5). In fact, in the space periodic case, it can be proved that

$$\operatorname*{Sup}_{|v_1| \leqq R} \int_0^T (|p(t)|^2 + g(t))\, dt < \infty,$$

which is a stronger result and permits us to avoid the derivation of (3.34).

3.3. Convergence of the universal attractors. We now apply Proposition 3.1 to the convergence of the penalized attractors. The spaces G, H, the semigroups S, S_ε, will be the same as in the rest of the article. We must verify the assumptions (3.1) and (3.2). With (2.5), (2.8), (2.9) we see that any ball of G, centered at 0 of radius $\rho > \rho_0 = (1/\nu\lambda_1)|f|$ contains the attractor $\mathscr{A}_\varepsilon$ for all $\varepsilon > 0$, and is mapped into itself by $S_\varepsilon(t)$. It is proved (see for instance [18]) exactly as for (2.5) that

$$\overline{\lim_{t \to \infty}} |u(t)|^2 \leqq \frac{1}{\nu^2 \lambda_1^2} |f|^2,$$

when u is any solution of (1.13) (the exact Navier-Stokes equations) and thus $\mathscr{A}$ is contained in the ball of H centered at 0 of radius ρ. This shows that (3.1) is satisfied if we take $\mathscr{U}$ = the ball of G centered at 0 of radius $\rho > \rho_0$.

The proof of (3.2) follows from (3.14) and (3.23), (3.24):

$$|(I-P)S_\varepsilon(t)u_1| = |(I-P)u_\varepsilon(t)| \leqq C_7 |\operatorname{div} u_\varepsilon(t)| \leqq C_7 \sqrt{\frac{K_1 \varepsilon}{t}}.$$

It can be easily seen that K_1, as well as all the bounds in the estimates (3.11)-(3.16) depend only on r_1 when $u_1 \in G$ and $|u_1| \leqq r_1$, and not explicitly on u_1[7]; (3.2) is proved. Finally (3.3) follows readily from (3.40).

By application of Proposition 3.1 we obtain the following theorem.

THEOREM 3.1. *Let $\mathscr{A}_\varepsilon$ denote the universal attractor for the penalized Navier-Stokes equations and let $\mathscr{A}$ denote the universal attractor for the exact Navier-Stokes equations (in space dimension 2).*

Then, as $\varepsilon \to 0$, $\mathscr{A}_\varepsilon$ converges to $\mathscr{A}$ in the sense of (3.4) *and in particular $(I-P)\mathscr{A}_\varepsilon$ converges to* 0.

3.4. Remark on the dimensions. It was proved (Foiaş and Temam [6]) that the universal attractor $\mathscr{A}$ describing the long-time behavior of the exact N.S.E. is finite

[7] Everything follows from (2.4), where we write $|u_\varepsilon(0)|^2 = |u_1|^2 \leqq r_1^2$.

dimensional. In the two-dimensional case ([17]) the fractal[8] (and Hausdorff) dimension of $\mathscr{A}$ is $\leqq c_0(1+G)$, where c_0 is a universal constant and G is the nondimensional (Grashof) number

$$G=\frac{|f|}{\nu^2\lambda_1}. \tag{3.44}$$

In this section we apply a general result of Constantin, Foias and Temam [4] to the penalized N.S.E. and estimate in a similar fashion the dimension of $\mathscr{A}_\varepsilon$. We have the following theorem.

THEOREM 3.2. *The fractal (and Hausdorff) dimension of the universal attractor $\mathscr{A}_\varepsilon$ is $\leqq c_0(1+G+c_1\varepsilon G^2)$, where c_0 and c_1 are universal constants.*

The proof of this result is parallel to the one performed on Navier-Stokes equations in [4], [17], [18]. We just mention here the step of the proof which provides the result on the dimensions. For simplicity we consider the boundary condition (0.4). The space periodic case is totally similar. For $m\in\mathbb{N}^*$ we introduce a family $\{v^i\}_{i=1}^m$ in $\mathbb{H}_0^1(\Omega)$ which is *orthonormal* (o.n.) *in* $\mathbb{L}^2(\Omega)$. Let u_{ε_0} be an arbitrary point in $\mathscr{A}_\varepsilon$ and $\{u_\varepsilon\}$: $u_\varepsilon(t)=S_\varepsilon(t)u_{\varepsilon_0}$, be the solution of (1.15), (1.16). We form the quantity[9]

$$\sigma_m(u_{\varepsilon_0},\{v^i\},t)=\sum_{i=1}^m\left\{\nu\|v^i\|^2+\frac{\nu}{\varepsilon}|\operatorname{div} v^i|^2+\tilde{b}(v^i,u_\varepsilon(t),v^i)\right\} \tag{3.45}$$

and we set

$$q_m=\limsup_{t\to+\infty}\ \sup_{u_{\varepsilon_0}\in\mathscr{A}_\varepsilon}\frac{1}{t}\int_0^t\ \sup_{\{v^i\}_{i=1}^m \text{ o.n. in } \mathbb{L}^2}(-\sigma(u_{\varepsilon_0},\{v^i\},s))\,ds. \tag{3.46}$$

According to [4], if there exists some $m_0\in\mathbb{N}^*$ such that

$$q_{m_0}>0 \tag{3.47}$$

then $\mathscr{A}_\varepsilon$ has a finite fractal (and Hausdorff) dimension and

$$d_F(\mathscr{A}_\varepsilon)\leqq m_0\max_{1\leqq l\leqq m_0}\left(1-\frac{|q_l|}{q_{m_0}}\right). \tag{3.48}$$

Our aim now is to estimate (3.45) in order to obtain (3.47) for some $m_0\in\mathbb{N}^*$. We notice that, pointwise,

$$\left|\frac{1}{2}(\operatorname{div} v^i)u\cdot v^i\right|\leqq\frac{\nu}{\varepsilon}(\operatorname{div} v^i)^2+\frac{\varepsilon}{16\nu}|u|^2|v^i|^2; \tag{3.49}$$

therefore if we set

$$\rho(x)=\sum_{i=1}^m|v^i(x)|^2 \tag{3.50}$$

then thanks to successive applications of the Schwarz inequality we find that

$$|\tilde{b}(v_i,u_\varepsilon,v_i)|\leqq\|u_\varepsilon\|\,|\rho|+\frac{\nu}{\varepsilon}|\operatorname{div} v^i|^2+\frac{\varepsilon}{16\nu}\left(\int_\Omega|u_\varepsilon|^4\,dx\right)^{1/2}|\rho|. \tag{3.51}$$

[8] If $\mathscr{E}$ is a metric space, its fractal dimension (or capacity) $d_F(\mathscr{E})$ is defined as the lim sup as $r\to0^+$ of the ratio $N_2(\mathscr{E})/\log(1/r)$, where $N_r(\mathscr{E})$ is the minimum number of balls of radius r necessary to cover $\mathscr{E}$. The fractal dimension is always greater or equal to the Hausdorff dimension, the converse being false in general.

[9] This quantity occurs naturally when one considers the linearized flow around the trajectory $\{u_\varepsilon(t)\}$ on the attractor.

Returning to (3.45) we find that

$$\sigma_m(t) \geqq \nu\left(\sum_{i=1}^{m} |v^i\|^2\right) - \left(\|u_\varepsilon\| + \frac{\varepsilon}{16\nu}\left(\int_\Omega |u_\varepsilon|^4\, dx\right)^{1/2} |\rho|\right). \tag{3.52}$$

We set

$$\beta_\varepsilon \equiv \limsup_{t\to+\infty} \operatorname*{Sup}_{u_{\varepsilon_0}\in\mathscr{A}_\varepsilon} \left\{\frac{1}{t}\int_0^t \left(\|u_\varepsilon(s)\| + \frac{\varepsilon}{16\nu}\left(\int_\Omega |u_\varepsilon|^4\, dx\right)^{1/2}\right) ds\right\} \tag{3.53}$$

and then according to (3.52), (3.46) yields

$$q_m \geqq \nu\left(\sum_{i=1}^{m} \|v^i\|^2\right) - \beta_\varepsilon|\rho|. \tag{3.54}$$

We are going to use now the Lieb-Thirring inequality [9] (see also [19]) which is an improvement of the classical Gagliardo-Nirenberg-Sobolev inequality (see for instance [15, p. 291]):

$$\int_\Omega |\phi|^4\, dx \leqq 2|\phi|^2 \|\phi\|^2 \quad \forall \phi \in \mathbb{H}_0^1(\Omega). \tag{3.55}$$

According to the Lieb-Thirring inequality there exists a universal constant K (which is in particular independent of m) such that[10]

$$\int_\Omega \left(\sum_{i=1}^{m} |v^i(x)|^2\right)^2 dx \leqq K \sum_{i=1}^{m} \int_\Omega |\nabla v^i(x)|^2\, dx. \tag{3.56}$$

From (3.54) and (3.56), it follows that

$$q_m \geqq \frac{\nu}{K}|\rho|^2 - \beta_\varepsilon|\rho| \geqq \frac{\nu}{2K}|\rho|^2 - \frac{K}{2\nu}\beta_\varepsilon^2,$$

and since the $\{v^i\}$ are orthonormal in $\mathbb{L}^2(\Omega)$,

$$m = \int_\Omega \rho(x)\, dx \leqq |\rho||\Omega|^{1/2}$$

where $|\Omega|$ denotes the area of Ω. Hence

$$q_m \geqq \frac{\nu}{2K}\frac{m^2}{|\Omega|} - \frac{K}{2\nu}\beta_\varepsilon^2, \qquad m \geqq 1. \tag{3.57}$$

If we define m_0 by

$$m_0 - 1 < \frac{2K}{\nu}|\Omega|^{1/2}\beta_\varepsilon \leqq m_0, \tag{3.58}$$

then

$$-\frac{q_l}{q_{m_0}} \leqq 1 \quad \text{for } l = 1, \cdots, m_0 - 1$$

and from (3.48), it follows that

$$d_F(\mathscr{A}_\varepsilon) \leqq 2\left(1 + \frac{2K\beta_\varepsilon|\Omega|^{1/2}}{\nu}\right). \tag{3.59}$$

[10] Applying (3.55) to each of the v^i provides (3.56) with only a constant $K = K(m)$ and $K(m) \to \infty$ when $m \to \infty$.

It remains to estimate β_ε. According to (2.5) we have, for every $u_{\varepsilon_0} \in \mathscr{A}_\varepsilon$,

$$\limsup_{t\to+\infty} |u_\varepsilon(t)|^2 \leqq \frac{|f|^2}{\nu^2\lambda_1^2}, \tag{3.60}$$

and returning to (2.2) it follows by integration that

$$\limsup_{t\to+\infty} \frac{1}{t}\int_0^t \|u_\varepsilon(t)\|^2\, ds \leqq \frac{|f|^2}{\nu^2\lambda_1}. \tag{3.61}$$

Thanks to (3.55), we have

$$\int_\Omega |u_\varepsilon(x,t)|^4\, dx \leqq 2|u_\varepsilon(t)|^2\|u_\varepsilon(t)\|^2$$

and by (3.60), (3.61),

$$\limsup_{t\to+\infty} \frac{1}{t}\int_0^t \left(\int_\Omega |u_\varepsilon(x,s)|^4\, dx\right) ds \leqq 2\frac{|f|^2}{\nu^4\lambda_1^3}. \tag{3.62}$$

Now from (3.53) and (3.61), (3.62) it follows that

$$\beta_\varepsilon \leqq \frac{|f|}{\nu\lambda_1^{1/2}} + \frac{\sqrt{2}\varepsilon}{16}\frac{|f|^2}{\nu^3\lambda_1^{3/2}}. \tag{3.63}$$

With the definition (3.43) and according to (3.59) and (3.63) we deduce that

$$d_F(\mathscr{A}_\varepsilon) \leqq 2\left\{1+2K(\lambda_1|\Omega|)^{1/2}\left(G+\frac{\sqrt{2}}{16}\varepsilon G^2\right)\right\} \tag{3.64}$$

and since $\lambda_1|\Omega|$ is a nondimensional constant depending only on the shape of Ω, Theorem 3.2 follows in the case of homogeneous Dirichlet boundary conditions. As we indicated above, the computations are almost identical in the space periodic case and we omit them.

ON THE MOTION OF VISCOUS FLUIDS IN THE PRESENCE OF DIFFUSION*

PAOLO SECCHI†

Abstract. We consider the motion of a viscous incompressible fluid consisting of two components with a diffusion effect obeying Fick's law. We prove: (i) the existence for two-dimensional flows of a (unique) global solution if the diffusion coefficient λ is small; (ii) the convergence (as $\lambda \to 0$) for two- and three-dimensional motions towards the corresponding solutions of the Navier-Stokes system for nonhomogeneous fluids.

Key words. Navier-Stokes equations, nonlinear parabolic equations

AMS(MOS) subject classifications. 35Q10, 76R99

1. Statement of the problem and main results. Let Ω be a bounded domain in $\mathbb{R}^2$ or $\mathbb{R}^3$. Consider the motion in Ω of a viscous fluid consisting of two components, say, satured salt water and water. Let ρ_1, ρ_2 be the characteristic densities of the two components, $v^{(1)}(t,x)$ and $v^{(2)}(t,x)$ their velocities and $c(t,x)$, $d(t,x)$ the mass and volume concentration of the first fluid. The mean density of the mixture is $\rho(t,x) \equiv d\rho_1 + (1-d)\rho_2$ and the mean-volume and mean-mass velocities are $v(t,x) \equiv dv^{(1)} + (1-d)v^{(2)}$, $w(t,x) \equiv cv^{(1)} + (1-c)v^{(2)}$. Then the equations of motions are (see for instance Frank-Kamenestskii [3], Ignat'ev and Kuznetsov [4]):

$$\rho[\dot{w} + (w \cdot \nabla)w - b] - \mu \Delta w - (\mu + \mu')\nabla \operatorname{div} w = -\nabla \pi \quad \text{in } Q_T \equiv]0, T[\times \Omega,$$

$$\operatorname{div} v = 0 \quad \text{in } Q_T,$$

$$\dot{\rho} + \operatorname{div}(\rho w) = 0 \quad \text{in } Q_T,$$

where $\pi = \pi(t,x)$ is the (unknown) pressure, $b = b(t,x)$ is the external force field, μ and μ' ($\mu > 0, 3\mu' + 2\mu \geqq 0$) are the viscosity coefficients which are assumed to be constant. If the diffusion process obeys Fick's law

$$w = v - \lambda \frac{\nabla \rho}{\rho}$$

($\lambda > 0$ is the constant diffusion coefficient), we get

$$\begin{aligned} &\rho[\dot{v} + (v \cdot \nabla)v - b] - \mu \Delta v - \lambda[(v \cdot \nabla)\nabla\rho + (\nabla\rho \cdot \nabla)v] \\ &\quad + \nabla P + \frac{\lambda^2}{\rho}\left[(\nabla\rho \cdot \nabla)\nabla\rho - \frac{1}{\rho}(\nabla\rho \cdot \nabla\rho)\nabla\rho + \Delta\rho\nabla\rho\right] = 0 \quad \text{in } Q_T, \\ &\dot{\rho} + v \cdot \nabla\rho - \lambda\Delta\rho = 0 \quad \text{in } Q_T, \\ &\operatorname{div} v = 0 \quad \text{in } Q_T, \end{aligned} \tag{1.1}$$

where $P = \pi + \lambda v \cdot \nabla\rho - \lambda^2 \Delta\rho + \lambda(2\mu + \mu')\Delta \log \rho$ is the modified pressure. In addition, consider also the following initial and boundary conditions ($n = n(x)$ is the unit outward

normal to $\partial\Omega$):

$$
\begin{aligned}
&v = 0 && \text{on } \Sigma_T \equiv]0, T[\times \partial\Omega,\\
&\partial\rho/\partial n = 0 && \text{on } \Sigma_T,\\
&v|_{t=0} = v_0(x) && \text{in } \Omega,\\
&\rho|_{t=0} = \rho_0(x) && \text{in } \Omega.
\end{aligned} \tag{1.2}
$$

The initial density $\rho_0(x)$ is assumed to be a positive bounded function: $0 < m \leqq \rho_0(x) \leqq M$. In [6], [7], Kazhikhov and Smagulov study problem (1.1), (1.2) in the simplified case obtained from (1.1) by dropping the λ^2-terms. They prove the existence of a local (in time) solution (global in the bidimensional case) under the assumption

$$\lambda < \frac{2\mu}{\operatorname{osc} \rho_0}.$$

In [14], Smagulov and Utegenov study the asymptotic behavior as $t \to \infty$ of the solution of the simplified model; they also consider the problem of the behavior of the solution as $\lambda \to 0$. Local existence for the complete system (i.e., with the λ^2-terms), without any condition on λ, is proved by Secchi in [12] in the case $\Omega = \mathbb{R}^3$. More recently, Beirão da Veiga [2] has studied the complete problem (1.1), (1.2) in a bounded domain of $\mathbb{R}^3$. He has proved (with no assumption on λ) the existence of a (unique) local solution for every initial datum and external force field and the existence of a (unique) global solution if, as usual, the data are sufficiently small. In the present paper we consider the full system (1.1) and prove the existence of a (unique) global solution for the two-dimensional problem if λ/μ is sufficiently small. We need to introduce this condition in order to get the estimate of energy, necessary in our approach to obtain the global existence. Moreover we consider the behavior of the solution as $\lambda \to 0$. We prove that there exists a subsequence of solutions of (1.1), (1.2) converging towards a solution of the corresponding Navier-Stokes equations for nonhomogeneous incompressible fluids:

$$
\begin{aligned}
&\rho[\dot{v} + (v \cdot \nabla)v - b] - \mu\Delta v + \nabla P = 0 \quad \text{in } Q_T,\\
&\dot{\rho} + v \cdot \nabla\rho = 0 \quad \text{in } Q_T,\\
&\operatorname{div} v = 0 \quad \text{in } Q_T,\\
&v = 0 \quad \text{on } \Sigma_T,\\
&v|_{t=0} = v_0(x) \quad \text{in } \Omega,\\
&\rho|_{t=0} = \rho_0(x) \quad \text{in } \Omega.
\end{aligned} \tag{1.3}
$$

If the domain is two-dimensional the convergence is on every finite interval $[0, T]$. In the three-dimensional case, where the solution exists only in the small, the convergence is on a short time interval independent of λ. Concerning the Navier-Stokes equations for nonhomogeneous fluids see Antoncev and Kazhikhov [1], Kazhikhov [5], Ladyzhenskaja and Solonnikov [9]; see also Lions [10] and Simon [13]. We find the solution to the Navier-Stokes system in the same class of solutions of Kazhikhov.

Let us denote by $\| \ \|$ and $(\ , \ )$ the norm and the scalar product in $L^2(\Omega)$, by $| \ |_p$ the norm in $L^p(\Omega)$, $2 < p \leqq \infty$. We use the same notation for scalar and vector spaces.

Let $H^k(\Omega)$ be the usual Sobolev space and $\| \ \|_k$ its norm. Let $H_0^1(\Omega)$ be the closure of $C_0^\infty(\Omega)$ in $H^1(\Omega)$. We introduce the following functional spaces:

$$H_N^k \equiv \left\{ \rho \in H^k(\Omega): \frac{\partial \rho}{\partial n} = 0 \text{ on } \partial\Omega, \int_\Omega \rho(x)dx = \int_\Omega \rho_0(x)dx \right\}, \qquad k \geqq 2,$$

$$V \equiv \{v \in C_0^\infty(\Omega): \operatorname{div} v = 0 \text{ in } \Omega\},$$

$$H \equiv \{v \in L^2(\Omega): \operatorname{div} v = 0 \text{ in } \Omega, \ v \cdot n = 0 \text{ on } \partial\Omega\},$$

$$V \equiv \{v \in H_0^1(\Omega): \operatorname{div} v = 0 \text{ in } \Omega\}$$

(see for instance [8], [11], [15] for their properties). H and V are the closures of V in $L^2(\Omega)$ and $H_0^1(\Omega)$, respectively. Moreover $L^2(\Omega) = H \oplus G$, where $G \equiv \{\nabla p: p \in H^1(\Omega)\}$. Denoting by P_H the orthogonal projection of $L^2(\Omega)$ onto H, we define the operator $A \equiv -P_H \Delta$ on $D(A) \equiv H^2(\Omega) \cap V$. We have

$$(Au, v) = \sum_{i,j} (D_i u_j, D_i v_j) \quad \forall u \in D(A), \quad v \in V$$

where D_i means $\partial/\partial x_i$. The norms $\|\rho\|_2$, $\|\Delta\rho\|$ are equivalent in H_N^2, $\|\rho\|_3$, $\|\nabla\Delta\rho\|$ are equivalent in H_N^3 and $\|v\|_2$, $\|Av\|$ are equivalent in $D(A)$. We define $\|v\|_V^2 \equiv \sum_{i,j} (D_i v_j, D_i v_j)$; the norms $\|v\|_1$, $\|v\|_V$ are equivalent in V. If X is a Banach space, $L^2(0, T; X)$ will be the Banach space of X-valued measurable functions in $L^2(0, T)$, and $C(0, T; X)$ will be the Banach space of X-valued continuous functions on $[0, T]$. We set $L^2(Q_T) \equiv L^2(0, T; L^2(\Omega))$, $H^1(0, T; L^2(\Omega)) \equiv \{v \in L^2(Q_T)$ with $\dot{v} \in L^2(Q_T)\}$. In the sequel C will denote different constants depending at most on Ω and m, M, μ. Other constants will be indicated by C_0, C_1, C_2, $\cdots$. We prove the following results.

THEOREM A. *Let Ω be an open bounded set in $\mathbb{R}^2$ with boundary $\partial\Omega$ of class C^3. Suppose $v_0 \in V$, $\rho_0 \in H_N^2$ such that $0 < m \leqq \rho_0(x) \leqq M$ in Ω, $b \in L^2(Q_T)$. Then there exists $\lambda_0 > 0$ depending on Ω, m, M such that, if $\lambda/\mu < \lambda_0$, problem (1.1), (1.2) is uniquely solvable in Q_T. Moreover $v \in L^2(0, T; H^2(\Omega)) \cap C(0, T; V)$, $\dot{v} \in L^2(0, T; H)$, $\rho \in L^2(0, T; H_N^3) \cap C(0, T; H_N^2)$, $\dot{\rho} \in L^2(0, T; H^1(\Omega))$ and $m \leqq \rho(t, x) \leqq M$, $\nabla P \in L^2(Q_T)$.*

DEFINITION. We shall say that $(v, \rho, \nabla P)$ is a *generalized solution* of (1.3) if:

(i) $v \in L^2(0, T; H^2(\Omega)) \cap H^1(0, T; L^2(\Omega))$, $\rho \in L^\infty(Q_T)$, $\nabla P \in L^2(Q_T)$;

(ii) $(1.3)_1$, $(1.3)_3$–$(1.3)_5$ are satisfied in the usual strong sense and $(1.3)_2$, $(1.3)_6$ are satisfied in the following weak sense:

$$\int_0^T (\rho, \dot{\varphi} + v \cdot \nabla\varphi) \, dt + (\rho_0, \varphi(0, \cdot)) = 0 \tag{1.4}$$

for any $\varphi \in H^1(Q_T)$ such that $\varphi(T, x) = 0$.

THEOREM B. *Let Ω be an open bounded set in $\mathbb{R}^n$, $n = 2$ or 3, with $\partial\Omega$ of class C^3. Assume $v_0 \in V$, $\rho_0 \in H_N^2$ such that $0 < m \leqq \rho_0(x) \leqq M$, in Ω, $b \in L^2(Q_{T_0})$. Then there exist $T \in (0, T_0]$ (independent of λ) and a subsequence of $\{(v^\lambda, \rho^\lambda, \nabla P^\lambda)\}$ converging on $[0, T]$ in the topology indicated in (3.12), (3.13) to a generalized solution $(v, \rho, \nabla P)$ of (1.3). The function ρ satisfies $m \leqq \rho(t, x) \leqq M$ a.e. in Q_T. If $n = 2$, $T = T_0$.*

Remark. It is not known if generalized solutions of (1.3) are unique. In [9], Ladyzhenskaja and Solonnikov show the existence of a solution of (1.3) $v \in L^q(0, T; W_q^2(\Omega)) \cap W_q^1(0, T; L^q(\Omega))$, $\nabla P \in L^q(Q_T)$, $q > n$ $(n = 2, 3)$, $\rho \in C^1(\bar{Q}_T)$, provided that $v_0 \in W_q^{2-2/q}(\Omega)$, $\rho_0 \in C^1(\bar{\Omega})$, $b \in L^q(Q_T)$. Here T is sufficiently small in $n = 3$, arbitrary if $n = 2$. In this class of functions the uniqueness theorem holds. It is also

possible to prove that these smoother solutions (if the data are regular enough so that they exist) necessarily coincide with the generalized solutions. Hence, if the data are smooth enough, the uniqueness theorem holds also for generalized solutions. This implies the convergence of the whole sequence $\{(v^\lambda, \rho^\lambda, \nabla P^\lambda)\}$ to the solution $(v, \rho, \nabla P)$.

2. Proof of Theorem A. Let $(v, \rho, \nabla P)$ be a solution to problem (1.1), (1.2). We want to find some global a priori estimate for it. In view of the study of the next section (the convergence as $\lambda \to 0$), we shall explicitly point out every dependence on λ, also if, for the aim of this section, λ is considered fixed. We start with the estimates for the density. From $(1.1)_2$ and $(1.1)_3$, $(1.2)_1$, $(1.2)_2$ one has $d/dt \int_\Omega \rho\, dx = 0$; hence $\int_\Omega \rho\, dx = \int_\Omega \rho_0\, dx$. From the diffusion equation $(1.1)_2$, we have by the maximum principle

$$0 < m \leqq \rho(t, x) \leqq M, \qquad (t, x) \in Q_T, \tag{2.1}$$

for any $\lambda > 0$. Multiply $(1.1)_2$ by $-\lambda \Delta \rho$ and integrate over Ω. Then, by integrating by parts and using $(1.1)_3$, $(1.2)_1$, $(1.2)_2$, we obtain

$$\frac{\lambda}{2} \frac{d}{dt} \|\nabla \rho\|^2 + \lambda^2 \|\Delta \rho\|^2 + \lambda((\nabla \rho \cdot \nabla) v, \nabla \rho) = 0. \tag{2.2}$$

Using (2.1) and the interpolation inequality

$$|\nabla \rho|_4^2 \leqq C_0 \|\Delta \rho\| \, |\rho|_\infty, \tag{2.3}$$

where C_0 is a positive constant depending on Ω, we easily obtain

$$\frac{\lambda}{2} \frac{d}{dt} \|\nabla \rho\|^2 + \lambda^2 \|\Delta \rho\|^2 \leqq \varepsilon_1 \lambda^2 \|\Delta \rho\|^2 + \frac{C_0^2 M^2}{4 \varepsilon_1} \|v\|_V^2 \tag{2.4}$$

where ε_1 is a small positive parameter. From $(1.1)_1$ and $(1.1)_2$ we have, after suitable integrations by parts,

$$\begin{aligned} \frac{1}{2} \frac{d}{dt} (\rho v, v) &= (\rho b, v) - \mu \|v\|_V^2 - \lambda((v \cdot \nabla) v, \nabla \rho) \\ &\quad - \left(\frac{\lambda^2}{\rho} \left[(\nabla \rho \cdot \nabla) \nabla \rho - \frac{1}{\rho} (\nabla \rho \cdot \nabla \rho) \nabla \rho + \Delta \rho \nabla \rho \right], v \right). \end{aligned} \tag{2.5}$$

On the other hand, by integrating by parts, we have

$$-\left(\frac{\lambda^2}{\rho} (\nabla \rho \cdot \nabla) \nabla \rho, v \right) = \left(\frac{\lambda^2}{\rho} \Delta \rho \nabla \rho, v \right) + \left(\frac{\lambda^2}{\rho} (\nabla \rho \cdot \nabla) v, \nabla \rho \right) - \left(\frac{\lambda^2}{\rho^2} |\nabla \rho|^2 \nabla \rho, v \right).$$

Then (2.5) becomes

$$\frac{1}{2} \frac{d}{dt} (\rho v, v) + \mu \|v\|_V^2 = (\rho b, v) - \lambda((v \cdot \nabla) v, \nabla \rho) + \left(\frac{\lambda^2}{\rho} (\nabla \rho \cdot \nabla) v, \nabla \rho \right). \tag{2.6}$$

Set $c_0 = (M + m)/2$ so that $|\rho(t, x) - c_0| \leqq (M - m)/2$. We have

$$\begin{aligned} \lambda |((v \cdot \nabla) v, \nabla \rho)| &= \lambda |((v \cdot \nabla) v, \nabla (\rho - c_0))| \\ &= \lambda \left| \sum_{i,j} (D_i v_j, D_i v_j (\rho - c_0)) \right| \leqq \lambda \frac{M - m}{2} \|v\|_V^2. \end{aligned}$$

Moreover, by using (2.1), (2.3) and introducing a small parameter ε_2,

$$\left|\left(\frac{\lambda^2}{\rho}(\nabla\rho\cdot\nabla)v, \nabla\rho\right)\right| \leqq \varepsilon_2\lambda^2\|\Delta\rho\|^2+\frac{C_0^2M^2\lambda^2}{4\varepsilon_2 m^2}\|v\|_V^2.$$

Then (2.6) gives

$$\frac{1}{2}\frac{d}{dt}(\rho v, v)+\mu\|v\|_V^2 \leqq (\rho b, v)+\left(\frac{M-m}{2}\lambda+\frac{C_0^2M^2}{4\varepsilon_2 m^2}\lambda^2\right)\|v\|_V^2+\varepsilon_2\lambda^2\|\Delta\rho\|^2. \tag{2.7}$$

Now we have to balance (2.4) and (2.7) in a suitable way. We can proceed in the following way: We add (2.7) to (2.4) multiplied by $\alpha=\mu/2C_0^2M^2$ and set $\varepsilon_1=1/4$, $\varepsilon_2=\alpha/4$. Then there exists $\lambda_0>0$ sufficiently small depending on m, M, C_0 such that if $\lambda/\mu<\lambda_0$ we have

$$\frac{1}{2}\frac{d}{dt}[(\rho v, v)+\alpha\lambda\|\nabla\rho\|^2]+\frac{\alpha}{2}\lambda^2\|\Delta\rho\|^2+\frac{\mu}{4}\|v\|_V^2 \leqq (\rho b, v).$$

By Gronwall's lemma and (2.1), after some calculation, we get for any $\lambda<\lambda_0\mu$

$$\begin{aligned}\|v\|_{C(0,T;H)}+\lambda^{1/2}\|\nabla\rho\|_{C(0,T;L^2(\Omega))}+\lambda\|\Delta\rho\|_{L^2(Q_T)}+\|v\|_{L^2(0,T;V)}\\ \leqq C[\|v_0\|+\|\nabla\rho_0\|+T^{1/2}\|b\|_{L^2(Q_T)}].\end{aligned} \tag{2.8}$$

Now we shall prove a priori estimates for higher norms. From $(1.1)_2$ and $(1.2)_2$, we have

$$\frac{1}{2}\frac{d}{dt}\|\Delta\rho\|^2=\int_{\partial\Omega}\Delta\rho\frac{\partial\dot\rho}{\partial n}\,d\sigma-(\nabla\Delta\rho, \nabla\dot\rho)=(\nabla\Delta\rho, \nabla(v\cdot\nabla\rho-\lambda\Delta\rho)).$$

Integrating by parts and using $(1.1)_3$ and $(1.2)_1$, we obtain

$$(\nabla\Delta\rho, \nabla(v\cdot\nabla\rho))=((\nabla\Delta\rho\cdot\nabla)v, \nabla\rho)-\sum_{i,j,k}(D_jv_i, D_kD_i\rho D_kD_j\rho).$$

Then we have

$$\frac{\lambda^2}{2}\frac{d}{dt}\|\Delta\rho\|^2+\lambda^3\|\nabla\Delta\rho\|^2=\lambda^2((\nabla\Delta\rho\cdot\nabla)v, \nabla\rho)-\lambda^2\sum_{i,j,k}(D_jv_i, D_kD_i\rho D_kD_j\rho). \tag{2.9}$$

Using (2.3) and the interpolation inequality

$$|\nabla v|_4^2 \leqq C\|v\|_2\|\nabla v\| \leqq C\|Av\|\,\|v\|_V$$

we obtain

$$\lambda^2|((\nabla\Delta\rho\cdot\nabla)v, \nabla\rho)| \leqq \frac{\varepsilon_0}{4}\|Av\|^2+\frac{\varepsilon}{4}\lambda^3\|\nabla\Delta\rho\|^2+\frac{C}{\varepsilon_0\varepsilon^2}\|v\|_V^4+\frac{C}{\varepsilon_0\varepsilon^2}\lambda^4\|\Delta\rho\|^4$$

where ε_0 and ε are small positive parameters (say less than 1). On the other hand, by using the inequalities

$$\begin{aligned}|\nabla v|_3 &\leqq C\|v\|_2^{1/3}\|\nabla v\|^{2/3} \leqq C\|Av\|^{1/3}\|v\|_V^{2/3},\\ |\Delta\rho|_3 &\leqq C\|\nabla\Delta\rho\|^{2/3}|\rho|_\infty^{1/3},\end{aligned}$$

we have (since $ab \leqq \varepsilon a^{3/2}+(C/\varepsilon^2)b^3$)

$$\lambda^2\left|\sum_{i,j,k}(D_jv_i, D_kD_i\rho D_kD_j\rho)\right| \leqq \frac{\varepsilon_0}{4}\|Av\|^2+\frac{\varepsilon}{4}\lambda^3\|\nabla\Delta\rho\|^2+\frac{C}{\varepsilon_0\varepsilon^4}\|v\|_V^4. \tag{2.10}$$

We thus obtain

$$\frac{\lambda^2}{2}\frac{d}{dt}\|\Delta\rho\|^2+\lambda^3\|\nabla\Delta\rho\|^2 \leqq \frac{\varepsilon_0}{2}\|Av\|^2+\frac{\varepsilon}{2}\lambda^3\|\nabla\Delta\rho\|^2+\frac{C}{\varepsilon_0\varepsilon^4}\|v\|_V^4+\frac{C}{\varepsilon_0\varepsilon^2}\lambda^4\|\Delta\rho\|^4. \tag{2.11}$$

Now we turn to the estimate for the velocity. We obtain it by following the method used in [2]. If we take the projection P_H of $(1.1)_1$, we obtain

$$P_H(\rho\dot{v}) - \mu Av = F \tag{2.12}$$

where for the sake of brevity

$$F \equiv P_H\Big\{-\rho(v\cdot\nabla)v + \rho b + \lambda[(v\cdot\nabla)\nabla\rho + (\nabla\rho\cdot\nabla)v] - \frac{\lambda^2}{\rho}\Big[(\nabla\rho\cdot\nabla)\nabla\rho - \frac{1}{\rho}(\nabla\rho\cdot\nabla\rho)\nabla\rho + \Delta\rho\nabla\rho\Big]\Big\}.$$

In H take the inner product of (2.12) with $\dot{v} + (m\mu/4M^2)Av$. Since

$$(\dot{v}, Av) = \frac{1}{2}\frac{d}{dt}\|v\|_V^2,$$

we obtain

$$m\|\dot{v}\|^2 + \frac{\mu}{2}\frac{d}{dt}\|v\|_V^2 + \frac{m\mu^2}{4M^2}\|Av\|^2 \leqq \|F\|\,\|\dot{v}\| + \frac{m\mu}{4M^2}\|F\|\,\|Av\| + \frac{m\mu}{4M}\|\dot{v}\|\,\|Av\|,$$

from which we easily obtain

$$\mu\frac{d}{dt}\|v\|_V^2 + m\|\dot{v}\|^2 + \frac{m\mu^2}{4M^2}\|Av\|^2 \leqq \left(\frac{2}{m} + \frac{m}{2M^2}\right)\|F\|^2. \tag{2.13}$$

We have only to estimate the norm of F in $L^2(\Omega)$. By using Hölder's inequality and suitable interpolation inequalities, we obtain

$$\begin{aligned}\|F\|^2 \leqq{}& C\|v\|\,\|v\|_V^2\|Av\| + C\lambda^2\|v\|^{2/3}\|v\|_V^{4/3}\|\nabla\Delta\rho\|^{4/3} + C\lambda^2\|\Delta\rho\|\,\|Av\|\,\|v\|_V \\ &+ C\lambda^4\|\Delta\rho\|\,\|\nabla\Delta\rho\|^{3/2} + C\lambda^4\|\Delta\rho\|^4 + C\|b\|^2.\end{aligned}$$

After some calculation we then get from (2.13) the following estimate:

$$\begin{aligned}&\frac{d}{dt}\|v\|_V^2 + \frac{m}{\mu}\|\dot{v}\|^2 + \frac{m\mu}{4M^2}\|Av\|^2 \leqq \varepsilon_0\|Av\|^2 + \varepsilon\lambda^3\|\nabla\Delta\rho\|^2 \\ &\quad + C\left(\frac{1}{\varepsilon_0} + \frac{1}{\varepsilon^2}\right)(1+\|v\|^2)\|v\|_V^4 + C\left(\frac{1}{\varepsilon_0} + \frac{1}{\varepsilon^3}\right)\lambda^4\|\Delta\rho\|^4 + C\|b\|^2.\end{aligned} \tag{2.14}$$

Finally, adding (2.11) to (2.14) divided by 2, we have

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}[\|v\|_V^2 + \lambda^2\|\Delta\rho\|^2] + \frac{m}{2\mu}\|\dot{v}\|^2 + \frac{m\mu}{8M^2}\|Av\|^2 + \lambda^3\|\nabla\Delta\rho\|^2 \\ &\quad \leqq \varepsilon_0\|Av\|^2 + \varepsilon\lambda^3\|\nabla\Delta\rho\|^2 + \frac{C}{\varepsilon_0\varepsilon^4}(1+\|v\|^2)\|v\|_V^4 + \frac{C}{\varepsilon_0\varepsilon^3}\lambda^4\|\Delta\rho\|^4 + C\|b\|^2.\end{aligned}$$

By taking ε_0 and ε sufficiently small, we thus obtain

$$\begin{aligned}&\frac{d}{dt}[\|v\|_V^2 + \lambda^2\|\Delta\rho\|^2] + C[\|\dot{v}\|^2 + \|Av\|^2 + \lambda^3\|\nabla\Delta\rho\|^2] \\ &\quad \leqq C[(1+\|v\|^2)\|v\|_V^2 + \lambda^2\|\Delta\rho\|^2][\|v\|_V^2 + \lambda^2\|\Delta\rho\|^2] + C\|b\|^2.\end{aligned} \tag{2.15}$$

By (2.8) the function $(1+\|v\|^2)\|v\|_V^2 + \lambda^2\|\Delta\rho\|^2$ belongs to $L^1(0, T)$. This gives, for any

$\lambda < \lambda_0 \mu$, the following estimate:

$$\begin{aligned} &\|v\|_{C(0,T;V)} + \lambda \|\Delta\rho\|_{C(0,T;L^2(\Omega))} + \|\dot{v}\|_{L^2(0,T;H)} + \|Av\|_{L^2(0,T;H)} \\ &\quad + \lambda^{3/2} \|\nabla \Delta\rho\|_{L^2(Q_T)} \leqq K_1(\|v_0\|_V + \|\nabla\rho_0\| \\ &\quad + T^{1/2}\|b\|_{L^2(Q_T)}) \cdot [\|v_0\|_V + \|\Delta\rho_0\| + \|b\|_{L^2(Q_T)}] \end{aligned} \tag{2.16}$$

where K_1 is an increasing function of its argument depending also on m, M, μ, Ω. Finally, directly from $(1.1)_1$, we can obtain $\nabla P \in L^2(Q_T)$, and from $(1.1)_2$ we can obtain $\dot{\rho} \in L^2(0, T; H^1(\Omega))$. By using these estimates, it is possible to prove the existence in the large of a solution of (1.1), (1.2). For example, one can follow (with obvious modifications) the continuity method employed in [2]. Also the uniqueness can be proved as in [2].

Remark. If $b \in L^1(0, +\infty; L^2(\Omega)) \cap L^2(0, +\infty; L^2(\Omega))$ it is possible to get the existence of the solution on the whole interval $[0, +\infty)$. The assumption $b \in L^1(0, +\infty; L^2(\Omega))$ is necessary to obtain the estimate (2.8) for $T = +\infty$, with on the right $C[\|v_0\| + \|\nabla\rho_0\| + \|b\|_{L^1(0,+\infty;L^2(\Omega))}]$. Analogously, also (2.16) will be true for $T = +\infty$, with on the right

$$K_1(\|v_0\|_V + \|\nabla\rho_0\| + \|b\|_{L^1(0,+\infty;L^2(\Omega))}) \cdot [\|v_0\|_V + \|\Delta\rho_0\| + \|b\|_{L^2(0,+\infty;L^2(\Omega))}].$$

These estimates permit to extend the solution from every bounded interval $[0, T]$ to the whole interval $[0, +\infty)$.

3. Proof of Theorem B. Let us now consider the problem of the behavior of the solution to problem (1.1), (1.2) as $\lambda \to 0$. For the passage to the limit we need suitable estimates not depending on λ. We already proved these estimates in § 2 for the bidimensional case. Now, we shall prove them for the three-dimensional case. Let us denote by $(v^\lambda, \rho^\lambda, \nabla P^\lambda)$ the solution of (1.1), (1.2) (existence and uniqueness of this solution is proved in [2]). This solution exists in a short interval which is, a priori, dependent on λ. We shall see that one can find an interval not depending on λ; the convergence will be proved in this time interval. Assume $0 < \lambda \leqq \lambda_1$ with $\lambda_1 > 0$ arbitrary. We proceed as in § 2. From the diffusion equation we obtain

$$0 < m \leqq \rho^\lambda(t, x) \leqq M, \qquad (t, x) \in Q_T, \tag{3.1}$$

for any $\lambda > 0$. As in the bidimensional case we obtain (the analogue of (2.4)):

$$\frac{\lambda}{2}\frac{d}{dt}\|\nabla\rho^\lambda\|^2 + \lambda^2\|\Delta\rho^\lambda\|^2 \leqq \frac{\lambda^2}{2}\|\Delta\rho^\lambda\|^2 + C\|v^\lambda\|_V^2 \tag{3.2}$$

(observe that (2.3) is valid also for three-dimensional domains). From (2.9), by using (3.1) and the following interpolation inequalities

$$|\nabla v|_3 \leqq C\|\Delta v\|^{1/2}\|\nabla v\|^{1/2} \leqq C\|Av\|^{1/2}\|v\|_V^{1/2}, \tag{3.3}$$

$$|\nabla\rho|_6 \leqq C\|\nabla\Delta\rho\|^{1/3}|\rho|_\infty^{2/3}, \tag{3.4}$$

$$|D^2\rho|_3 \leqq C\|\nabla\Delta\rho\|^{2/3}|\rho|_\infty^{1/3}, \tag{3.5}$$

we get

$$\begin{aligned} \frac{\lambda^2}{2}\frac{d}{dt}\|\Delta\rho^\lambda\|^2 + \lambda^3\|\nabla\Delta\rho^\lambda\|^2 &\leqq \lambda^2\|\nabla\Delta\rho^\lambda\|\,|\nabla v^\lambda|_3|\nabla\rho^\lambda|_6 + C\lambda^2|\nabla v^\lambda|_3|D^2\rho^\lambda|_3^2 \\ &\leqq C\lambda^2\|\Delta v^\lambda\|^{1/2}\|\nabla v^\lambda\|^{1/2}\|\nabla\Delta\rho^\lambda\|^{4/3}|\rho^\lambda|_\infty^{2/3} \\ &\leqq \frac{\lambda^3}{4}\|\nabla\Delta\rho^\lambda\|^2 + \varepsilon\|Av^\lambda\|^2 + \frac{C}{\varepsilon^3}\|v^\lambda\|_V^6 \end{aligned} \tag{3.6}$$

where ε is a small parameter. Finally, consider the estimate (2.13), where instead of v and F we write v^λ and F^λ. By using (3.1), (3.3)-(3.5) and the Sobolev embedding theorem $H^1 \subset L^6$, we have

$$\|F^\lambda\|^2 \leqq C\|v^\lambda\|_V^3\|Av^\lambda\| + C\lambda^2\|v^\lambda\|_V^2\|\nabla\Delta\rho^\lambda\|^{4/3} + C\lambda^2\|Av^\lambda\|\,\|v^\lambda\|_V\|\nabla\Delta\rho^\lambda\|^{2/3} + C\lambda^4\|\nabla\Delta\rho^\lambda\|^{4/3}\|\Delta\rho^\lambda\|^2 + C\|b\|^2.$$

From this estimate we obtain (for $\varepsilon > 0$ small), after some calculation,

$$\begin{aligned}&\frac{d}{dt}\|v^\lambda\|_V^2 + C\|\dot v^\lambda\|^2 + C\|Av^\lambda\|^2 \\ &\qquad \leqq \varepsilon\|Av^\lambda\|^2 + \frac{\lambda^3}{2}\|\nabla\Delta\rho^\lambda\|^2 + \frac{C}{\varepsilon^3}\|v^\lambda\|_V^6 + \frac{C}{\varepsilon^3}\lambda^6\|\Delta\rho^\lambda\|^6 + C\|b\|^2\end{aligned} \tag{3.7}$$

where the constants C in the third and in the fourth term of the right side depend also on λ_1. Thus, from (3.6) and (3.7), it is possible to obtain the following estimate:

$$\begin{aligned}&\frac{d}{dt}[\|v^\lambda\|_V^2 + \lambda^2\|\Delta\rho^\lambda\|^2] + C\|\dot v^\lambda\|^2 + (C - 3\varepsilon)\|Av^\lambda\|^2 + \lambda^3\|\nabla\Delta\rho^\lambda\|^2 \\ &\qquad \leqq \frac{C}{\varepsilon^3}[\|v^\lambda\|_V^2 + \lambda^2\|\Delta\rho^\lambda\|^2]^3 + C\|b\|^2.\end{aligned} \tag{3.8}$$

Let ε be such that $C - 3\varepsilon > 0$. Then there exist $T' \in (0, T_0]$ and a constant C_1 depending only on m, M, μ, Ω, $\|v_0\|_V$, $\lambda_1\|\Delta\rho_0\|$ and $\|b\|_{L^2(Q_T)}$ such that

$$\begin{aligned}&\|v^\lambda\|_{C(0,T';V)} + \lambda\|\Delta\rho^\lambda\|_{C(0,T';L^2(\Omega))} + \lambda^{3/2}\|\nabla\Delta\rho^\lambda\|_{L^2(Q_{T'})} + \|\dot v^\lambda\|_{L^2(Q_{T'})} \\ &\qquad + \|Av^\lambda\|_{L^2(Q_{T'})} \leqq C_1,\end{aligned} \tag{3.9}$$

for any $0 < \lambda < \lambda_1$. From (3.2) we see that there exists a constant C_2, depending on the data of the problem as C_1, such that

$$\lambda^{1/2}\|\nabla\rho^\lambda\|_{C(0,T';L^2(\Omega))} \leqq C_2 \tag{3.10}$$

for any $0 < \lambda < \lambda_1$. Directly from $(1.1)_1$ we obtain

$$\|\nabla P^\lambda\|_{L^2(Q_{T'})} \leqq C_3 \tag{3.11}$$

where C_3 is a positive constant depending on the data as C_1.

The convergence as $\lambda \to 0$. From now on we treat both the two-dimensional and the three-dimensional cases together. Let T be arbitrary in the plane case and $T = T'$ in the spatial case. Since $\{v^\lambda\}$ is bounded in $L^2(0, T; H^2(\Omega)) \cap H^1(0, T; L^2(\Omega))$, it is bounded by interpolation in $C(0, T; H^1(\Omega)) \cap H^{1/2+\varepsilon}(0, T; H^{1-\varepsilon}(\Omega))$; hence from the Ascoli-Arzelà theorem it is compact in $C(0, T; H^{1-\varepsilon}(\Omega))$. Then there exists a subsequence, that we continue to denote by $\{v^\lambda\}$, and a function v such that

$$\begin{aligned}&v^\lambda \to v \quad \text{in } C(0, T; H^{1-\varepsilon}(\Omega)), \\ &v^\lambda \rightharpoonup v \quad \text{in } L^2(0, T; H^2(\Omega)) \text{ and in } H^1(0, T; L^2(\Omega)).\end{aligned} \tag{3.12}$$

From (2.1), (3.1) and the estimates on the pressures P^λ, we find two subsequences, again denoted by $\{\rho^\lambda\}$, $\{P^\lambda\}$, and two functions ρ, P such that

$$\begin{aligned}&\rho^\lambda \rightharpoonup^* \rho \quad \text{in } L^\infty(Q_T), \\ &\nabla P^\lambda \rightharpoonup \nabla P \quad \text{in } L^2(Q_T).\end{aligned} \tag{3.13}$$

First we pass to the limit in $(1.1)_2$, where instead of $(v, \rho, \nabla P)$ we consider $(v^\lambda, \rho^\lambda, \nabla P^\lambda)$. Take $\varphi \in H^1(Q_T)$ with $\varphi(T, x) = 0$. Then

$$0 = \int_0^T (\dot{\rho}^\lambda + v^\lambda \cdot \nabla \rho^\lambda - \lambda \Delta \rho^\lambda, \varphi)\, dt$$

$$= -\int_0^T (\rho^\lambda, \dot{\varphi} + v^\lambda \cdot \nabla \varphi)\, dt + \lambda \int_0^T (\nabla \rho^\lambda, \nabla \varphi)\, dt - (\rho_0, \varphi(0, \cdot));$$

using the strong convergence of v^λ and the weak-$*$ convergence of ρ^λ, estimates (2.8) and (3.10), one can pass to the limit as $\lambda \to 0$ in the right-hand side of this equation obtaining (1.4). Consider now $(1.1)_1$. By $(1.1)_2$ and some integrations by parts we obtain, for any $\phi \in C_0^\infty(Q_T)$,

$$\int_0^T (\rho^\lambda \dot{v}^\lambda + \rho^\lambda (v^\lambda \cdot \nabla) v^\lambda, \phi)\, dt = -\int_0^T (\rho^\lambda v^\lambda, \dot{\phi})\, dt - \int_0^T (\rho^\lambda (v^\lambda \cdot \nabla)\phi, v^\lambda)\, dt$$

(3.14)

$$+ \int_0^T ((\nabla \rho^\lambda \cdot \nabla) v^\lambda, \phi)\, dt + \lambda \int_0^T ((\nabla \rho^\lambda \cdot \nabla)\phi, v^\lambda)\, dt.$$

By (2.8), (2.16), (3.9) and (3.10) the last two terms can be estimated by

$$\lambda^{1/2} \lambda^{1/2} \|\nabla \rho^\lambda\|_{C(0,T;L^2(\Omega))} \|v^\lambda\|_{C(0,T;V)} \|\phi\|_{L^\infty(Q_T)} T$$

$$+ \lambda^{1/2} \lambda^{1/2} \|\nabla \rho^\lambda\|_{C(0,T;L^2(\Omega))} \|\nabla \phi\|_{L^\infty(Q_T)} \|v^\lambda\|_{C(0,T;L^2(\Omega))} T \leqq C_4 \lambda^{1/2},$$

going to zero as $\lambda \to 0$. By using the strong convergence v^λ and the weak-$*$ convergence of ρ^λ, we can pass to the limit in the other terms of (3.14) obtaining

$$\int_0^T (\rho^\lambda \dot{v}^\lambda + \rho^\lambda (v^\lambda \cdot \nabla) v^\lambda, \phi)\, dt \to -\int_0^T (\rho v, \dot{\phi})\, dt - \int_0^T (\rho (v \cdot \nabla)\phi, v)\, dt$$

for any $\phi \in C_0^\infty(Q_T)$. Consider now $\varphi = v \cdot \phi$; then $\varphi \in H^1(Q_T)$, $\varphi(T, x) = \varphi(0, x) = 0$. By (1.4) we have

$$-\int_0^T (\rho v, \dot{\phi})\, dt - \int_0^T (\rho (v \cdot \nabla)\phi, v)\, dt = \int_0^T (\rho \dot{v} + \rho (v \cdot \nabla) v, \phi)\, dt.$$

The convergence of $\int_0^T (\rho^\lambda b + \mu \Delta v^\lambda - \nabla P^\lambda, \phi)\, dt$ to the corresponding expression is direct. Consider the first term in λ in $(1.1)_1$. We have, by integration by parts and (3.10),

$$\left| \lambda \int_0^T ((v^\lambda \cdot \nabla) \nabla \rho^\lambda, \phi)\, dt \right| = \left| \lambda \int_0^T ((v^\lambda \cdot \nabla)\phi, \nabla \rho^\lambda)\, dt \right|$$

$$\leqq \lambda^{1/2} T \|\nabla \phi\|_{L^\infty(Q_T)} \|v\|_{L^\infty(0,T;L^2(\Omega))} \lambda^{1/2} \|\nabla \rho^\lambda\|_{L^\infty(0,T;L^2(\Omega))} \leqq C_4 \lambda^{1/2},$$

going to zero as $\lambda \to 0$. Concerning the second term in λ^2, we have, by using (3.4) and (3.9),

$$\left| \lambda \int_0^T \left(\frac{1}{(\rho^\lambda)^2} (\nabla \rho^\lambda \cdot \nabla \rho^\lambda) \nabla \rho^\lambda, \phi \right) dt \right| \geqq \lambda^{1/2} C \frac{M^2}{m^2} \|\phi\|_{L^2(Q_T)} \lambda^{3/2} \|\nabla \Delta \rho^\lambda\|_{L^2(Q_T)} \leqq C_5 \lambda^{1/2},$$

which goes to zero as $\lambda \to 0$. Also the other terms in λ, λ^2 go to zero as $\lambda \to 0$, as one can see with a direct calculation. Thus at the limit we obtain

$$\int_0^T (\rho \dot{v} + \rho (v \cdot \nabla) v - \rho b - \mu \Delta v + \nabla P, \phi)\, dt = 0$$

for any $\phi \in C_0^\infty(Q_T)$. This gives $(1.3)_1$. $(1.3)_3$ and the initial and boundary conditions $(1.3)_4$, $(1.3)_5$ are easily checked. The boundary condition $(1.2)_2$ on ρ^λ is lost.

THE EQUATIONS OF ONE-DIMENSIONAL UNSTEADY FLAME PROPAGATION: EXISTENCE AND UNIQUENESS*

B. LARROUTUROU†

Abstract. This paper deals with the mathematical analysis of a system of partial differential equations describing the time-dependent propagation of a planar flame front within the framework of the well-known isobaric approximation of slow combustion. The problem to be investigated takes the form of a nonlinear mixed initial-boundary value problem in an infinite one-dimensional domain. We show the existence and uniqueness of weak and classical solutions of this problem, depending on the assumptions on the initial data and on the nonlinear temperature dependence of the chemical reaction rates. The crucial point lies in the introduction of a Lagrangian space coordinate, which uncouples the reaction-diffusion equations for the combustion variables from the remaining hydrodynamical subsystem. The analysis then uses some classical arguments of functional analysis, such as the application of the theory of linear semigroups to nonlinear partial differential equations.

1. Introduction. The mathematical analysis of systems of ordinary or partial differential equations arising from the theory of gaseous combustion has received increasing attention in recent years: one can mention for instance several studies of the equations of the stationary planar flame (see [2], [8]) or of the two-dimensional zero Mach number model (see [6]), and in a different domain some mathematical works dealing with the existence and the asymptotic behaviour of the solutions of the Kuramoto–Sivashinsky equation for the flame front instabilities (see [1], [9]).

We present in this paper a new rigorous mathematical result which concerns the time-dependent one-dimensional flame propagation. More precisely, we consider the governing equations of an unsteady planar flame propagating in an infinite channel. These equations, which we recall in § 2, are written using the classical isobaric approximation for reacting flows in open domains (we first consider a simplified one-step chemical mechanism; the extension to chemically complex flames or to nonadiabatic flames is given at the end of the paper). With appropriate hypotheses on the initial data and on the temperature dependence of the reaction rate, we show the global existence and the uniqueness of both weak and classical solutions of the resulting initial-boundary value problem.

The crucial point in our analysis (and in fact the point which restricts our work to the one-dimensional case) lies in the introduction of a Lagrangian space coordinate. This change of coordinates has the effect of decoupling the reaction-diffusion equations for the combustion variables (temperature and mass fraction of the reactant) from the remaining equations for the hydrodynamical variables (density, velocity and pressure). The reactive diffusive system involving the temperature and the mass fraction takes the form of two coupled nonlinear heat equations and is known as the thermodiffusive model for the flame propagation. This parabolic system of partial differential equations is solved in a first step, using classical tools of nonlinear functional analysis such as semigroups generated by linear operators in functional spaces. The remaining subsystem for the hydrodynamical unknowns is then solved in a second step, the temperature

being considered given. This provides the existence and uniqueness of solutions of the Lagrangian system. In particular, the analysis shows that no initial data for the hydrodynamical variables need be given for the initial-boundary value problem to be well posed.

Owing to the strong regularizing effect of the heat equation, even a weak solution of the Lagrangian system is continuous. It is then straightforward to come back to the usual Eulerian coordinates, and to prove that similar existence and uniqueness results hold for the original Eulerian system of governing equations.

The paper is organized as follows: (1) Introduction; (2) Governing equations of the flame propagation; (3) Assumptions and main results; (4) Recalling some basic results from semigroup theory; (5) Existence and uniqueness for the combustion variables; (6) Existence and uniqueness for the hydrodynamical variables; (7) Back transformation to the Eulerian variables; (8) Extension to chemically complex flames.

2. Governing equations of the flame propagation.

2.1. Reactive flow equations in one dimension. We are interested in the description of a compressible heat-conducting chemically reacting gaseous mixture with the assumption of a one-dimensional geometry. For the sake of simplicity, we first assume a one-step chemical mechanism $nA \to nB$: the mixture is considered to be made of only two species, the reactant A and the product B. The extension to the case of a chemically complex flame will be investigated in § 8 below.

The reactive gas flow is then described with the usual variables ρ, u, P, T (denoting respectively the total density, velocity, pressure and temperature of the mixture) and an additional variable for the mixture composition, the mass fraction Y of the reactant A (ρY is the separate density of the reactant and $\rho(1-Y)$ is the density of the product). The time-dependent flow of this reactive mixture is then described by the following set of equations (see [5], [7], [14]):

$$
\begin{aligned}
&\rho_\tau + (\rho u)_\xi = 0,\\
&\rho u_\tau + \rho u u_\xi = -P_\xi,\\
&\rho c_p T_\tau + \rho u c_p T_\xi - (\lambda T_\xi)_\xi = Q\omega(Y, T) + P_\tau + uP_\xi,\\
&\rho Y_\tau + \rho u Y_\xi - (\rho D Y_\xi)_\xi = -m\omega(Y, T),\\
&\rho T = \frac{mP}{R},
\end{aligned}
\tag{2.1}
$$

where ξ and τ denote respectively the space and time variables; c_p is the specific heat at constant pressure of the mixture, λ the heat conductivity, D the diffusion coefficient of the reactant A, m its molecular mass and R is the universal gas constant. The effects of viscosity and gravity are neglected. Lastly, $Q(>0)$ is the amount of energy released by the exothermic chemical reaction per unit mass of the reactant, and $\omega(Y, T)$ is the rate at which this reaction proceeds. From the Arrhenius law and the law of mass action, this reaction rate is given by:

$$
\omega(Y, T) = B(T)\left(\frac{\rho Y}{m}\right)^n e^{-E/RT}, \tag{2.2}
$$

where E is the activation energy of the reaction (a constant), and $B(T)$ is some given function of T (which usually has a polynomial-type dependence on T).

2.2. Eulerian form of the flame propagation equations. For writing down the governing equations of the unsteady flame propagation, we will use the so-called

"classical approximation of combustion": the flame propagation is essentially a very subsonic, almost isobaric phenomenon. In other words, the Mach number M of the flow is very small and consequently the pressure variations are also small: $P(\xi, \tau) = P_0 + p(\xi, \tau)$, with $p/P_0 = O(M^2) \ll 1$. For this reason, we may set $P = P_0 = \text{Constant}$ everywhere except in the momentum equation (2.1b) (see [5], [7] for a more detailed discussion of this approximation). The system (2.1) then reduces to

$$\begin{aligned} &\rho_\tau + (\rho u)_\xi = 0, \\ &\rho c_p T_\tau + \rho u c_p T_\xi - (\lambda T_\xi)_\xi = Q\omega(Y, T), \\ &\rho Y_\tau + \rho u Y_\xi - (\rho D Y_\xi)_\xi = -m\omega(Y, T), \\ &\rho T = \frac{mP_0}{R}, \end{aligned} \tag{2.3}$$

$$\rho u_\tau + \rho u u_\xi = -p_\xi. \tag{2.4}$$

Some authors use the system (2.3) alone, replacing the momentum equation (2.4) by $P = P_0$ (see [14]). This is legitimate in one spatial dimension since the only role of the relation (2.4) is the calculation of the small pressure variation p. But this simplification is no more valid when the space dimension N is higher than one, since it eliminates N scalar momentum equations and only one variable p. For this reason we will mainly consider the full system (2.3), (2.4).

The flame propagation equations (2.3), (2.4) will be investigated with the following upstream and downstream boundary conditions:

$$Y(-\infty, t) = Y_u, \quad T(-\infty, t) = T_u, \quad u(-\infty, t) = u^0, \quad p(-\infty, t) = 0 \tag{2.5}$$

(where $Y_u > 0$, $T_u > 0$, $u^0 \in \mathbb{R}$ are given constants) in the fresh mixture, and:

$$Y(+\infty, t) = 0, \qquad T(+\infty, t) = T_b = T_u + \frac{Q}{c_p}\frac{Y_u}{m}, \tag{2.6}$$

in the burnt gases.

2.3. Lagrangian form of the governing equations. From now on we will assume that the Lewis number $\text{Le} = \lambda/\rho c_p D$ and the specific heat c_p are constant. We will also assume that the thermal conductivity of the mixture λ is proportional to the temperature T; this additional assumption will be discussed below, after the derivation of the Lagrangian equations.

We now derive an alternate formulation of the governing equations (2.3), (2.4) using the usual mass-weighted Lagrangian coordinate:

$$x = \int_{\xi(0,t)}^{\xi(x,t)} \rho(\xi', t)\, d\xi'. \tag{2.7}$$

Although the use of this transformation is classical, we detail the calculation for sake of completeness. Let us define a Lagrangian coordinate (i.e. a variable whose value, defined at time $\tau = 0$, remains constant during the flow for each fluid particle) by setting:

$$x = \int_0^{\xi} \rho(\xi', 0)\, d\xi'.$$

We also set $t = \tau$. Then $x(\xi, \tau)$ represents the Lagrangian coordinate of the particle which is located at the abscissa ξ at time τ and the last relation is to be read as

$x(\xi, 0) = \int_0^{\xi} \rho(\xi', 0)\, d\xi'$. Inversely, $\xi(x, t)$ is the position at time t of the fluid particle whose Lagrangian coordinate is x. Therefore we have, by definition:

$$\xi_t = u \quad \text{or} \quad \frac{\partial}{\partial t}\xi(x, t) = u[\xi(x, t), t].$$

We can then write:

$$\begin{aligned}\frac{d}{dt}\left[\int_{\xi(0,t)}^{\xi(x,t)} \rho(\xi', t)\, d\xi'\right] &= \frac{\partial \xi}{\partial t}(x, t)\rho[\xi(x, t), t] - \frac{\partial \xi}{\partial t}(0, t)\rho[\xi(0, t), t] \\ &\quad + \int_{\xi(0,t)}^{\xi(x,t)} \frac{\partial \rho}{\partial t}(\xi', t)\, d\xi' \\ &= (\rho u)[\xi(x, t), t] - (\rho u)[\xi(0, t), t] \\ &\quad + \int_{\xi(0,t)}^{\xi(x,t)} \frac{\partial \rho}{\partial t}(\xi', t)\, d\xi' \\ &= \int_{\xi(0,t)}^{\xi(x,t)} [\rho_t + (\rho u)_\xi](\xi', t)\, d\xi' = 0,\end{aligned}$$

whence:

$$\int_{\xi(0,t)}^{\xi(x,t)} \rho(\xi', t)\, d\xi' = \int_{\xi(0,0)}^{\xi(x,0)} \rho(\xi', 0)\, d\xi' = x,$$

which is exactly (2.7).

Differentiating (2.7) with respect to x gives:

$$1 = \rho \xi_x \quad \text{or} \quad \frac{\partial}{\partial x}\xi(x, t) = \frac{1}{\rho[\xi(x, t), t]}.$$

We then have in matrix form (writing simply $u(x, t)$ for $u[\xi(x, t), t]$):

$$\begin{pmatrix} \xi_x & \xi_t \\ \tau_x & \tau_t \end{pmatrix} = \begin{pmatrix} \rho^{-1} & u \\ 0 & 1 \end{pmatrix},$$

which implies:

$$\begin{pmatrix} x_\xi & x_\tau \\ t_\xi & t_\tau \end{pmatrix} = \begin{pmatrix} \rho & -\rho u \\ 0 & 1 \end{pmatrix}. \tag{2.8}$$

Remark 2.1. The mass balance equation (2.3a) has been crucial for introducing the new variable x. This amounts to noticing that a variable X satisfying $X_\xi = \rho$, $X_\tau = -\rho u$ (i.e. (2.8)) could have been introduced directly, since (2.3a) insures that $(\partial/\partial\tau)(X_\xi) = (\partial/\partial\xi)(X_\tau)$.

We can now derive the Lagrangian form of the flame propagation equations. For any quantity F we have $F_\tau = F_t - \rho u F_x$, $F_\xi = \rho F_x$, and the system (2.3), (2.4) becomes

$$\begin{aligned} &\rho_t + \rho^2 u_x = 0, \\ &u_t + p_x = 0, \\ &T_t = \frac{Q}{c_p}\frac{\omega}{\rho} + \frac{1}{c_p}(\lambda \rho T_x)_x, \\ &Y_t = -m\frac{\omega}{\rho} + (\rho^2 D Y_x)_x, \\ &\rho T = \frac{m P_0}{R}. \end{aligned} \tag{2.9}$$

To nondimensionalize these equations, we refer the mass fraction to $Y_0 = Y_u$, the temperature to $T_0 = T_b - T_u = (Q/c_p)(Y_u/m)$, the density to $\rho_0 = mP_0/RT_0$. Denoting $(\lambda\rho)_0$ the constant value of $\lambda\rho = (mP_0/R)(\lambda/T)$, we relate the time unit t_0 and the "Lagrangian unit" x_0 by: $x_0^2 = t_0(\lambda\rho)_0/c_p$. The velocity is then referred to $u_0 = x_0/\rho_0 t_0$ and the pressure variation to $p_0 = \rho_0 u_0^2$.

Setting $\Theta = T - T_u$ and denoting by $\hat{\Theta}$, $\hat{Y}$, $\hat{\rho}$, $\hat{u}$, $\hat{p}$ the nondimensionalized variables, we obtain the following expressions for the Lagrangian equations (2.9) and boundary conditions (2.5), (2.6):

$$\hat{\Theta}_t = \hat{\Theta}_{xx} + \Omega(\hat{Y}, \hat{\Theta}), \qquad \hat{Y}_t = \frac{1}{\mathrm{Le}}\hat{Y}_{xx} - \Omega(\hat{Y}, \hat{\Theta}), \tag{2.10}$$

$$(\hat{\Theta} + \alpha)\hat{\rho} = 1, \quad \hat{u}_x = \hat{\Theta}_t, \quad \hat{u}_t + \hat{p}_x = 0, \tag{2.11}$$

$$\hat{\Theta}(-\infty, t) = 0, \qquad \hat{\Theta}(+\infty, t) = 1,$$

$$\hat{Y}(-\infty, t) = 1, \qquad \hat{Y}(+\infty, t) = 0, \tag{2.12}$$

$$\hat{u}(-\infty, t) = \hat{u}^0, \qquad \hat{p}(-\infty, t) = 0,$$

where x and t now represent the nondimensionalized Lagrangian coordinates, $\alpha = T_u/(T_b - T_u)$ is a nondimensional heat release parameter, and $\Omega(\hat{Y}, \hat{\Theta}) = (Q/c_p)(R/mP_0)t_0(\omega/\hat{\rho})$ is the normalized reaction rate. In the sequel, we will assume using (2.2) that Ω is given by:

$$\Omega(\hat{Y}, \hat{\Theta}) = \hat{Y}^n f(\hat{\Theta}),$$

where f is a positive continuous function satisfying $f(0) = 0$.

Remark 2.2. The assumption $f(0) = 0$ is not fulfilled in view of the expression (2.2) of the reaction rate ω since $e^{-E/RT_u} \neq 0$. This is the well-known "cold boundary difficulty," on which a lot has already been said (see [5]). Let us just point out that this hypothesis is necessary for the mathematical problem (2.10), (2.12) to be well posed.

It should be emphasized here that the use of the Lagrangian coordinate (2.7) uncouples the equations (2.10) for the combustion field $(\hat{\Theta}, \hat{Y})$ (which take the form of a purely diffusive reaction system) from the equations (2.11) for the hydrodynamical variables $(\hat{\rho}, \hat{u}, \hat{p})$. Moreover, the form of these hydrodynamical equations leads one to think that no initial data for the density, velocity or pressure is needed to determine the profiles of these variables at positive time values: these hydrodynamical profiles $\hat{\rho}(\cdot, t)$, $\hat{u}(\cdot, t)$, $\hat{p}(\cdot, t)$ for $t > 0$ only depend on the temperature profiles $\hat{\Theta}(\cdot, t')$ for $t' \geqq 0$; we first have to study the nonlinear parabolic system (2.10), and (2.11) will be investigated in a second step.

Remark 2.3. The assumption $\lambda\rho = \text{Constant}$, or $\lambda/T = \text{Constant}$ only affects the expression of the diffusive terms in the temperature and mass fraction equations: these terms take the form $\hat{\Theta}_{xx}$ and $(1/\mathrm{Le})\hat{Y}_{xx}$ instead of $[(\lambda\rho)T_x]_x$ and $(1/\mathrm{Le})[(\lambda\rho)Y_x]_x$ where, in complete generality, $\lambda\rho$ is a function of T and Y. Nevertheless, it can be noticed that this hypothesis (which is rather classical in combustion theory, see [11]) does not change the preceding remarks about the nature of the Lagrangian system (2.10), (2.11). We hope to extend our mathematical analysis to the case of a nonconstant λ/T ratio in a forthcoming paper.

Remark 2.4. In the classical nondimensionalization of the Eulerian equations (2.3), (2.4) (see [5], [7]), the length and time scales ξ_0 and $\tau_0 = t_0$ are related to the thermal diffusion coefficient $(\lambda/\rho c_p)_0 = (\lambda\rho)_0/\rho_0^2 c_p$ and to the velocity unit u_0 by the

identities:

$$\frac{\xi_0^2}{\tau_0}=\frac{(\lambda\rho)_0}{\rho_0^2 c_p} \quad \text{and} \quad u_0=\frac{\xi_0}{\tau_0}.$$

In our case, the units used above to nondimensionalize the equations (2.9) have essentially been chosen in order to simplify the Lagrangian system (2.10), (2.11), which will play a crucial role in the sequel. Therefore, these units are not quite usual, and the above relations are replaced by:

$$\frac{\xi_0^2}{\tau_0}\left[\int_0^1 \hat{\rho}(\zeta,0)d\zeta\right]^2=\frac{(\lambda\rho)_0}{\rho_0^2 c_p} \quad \text{and} \quad u_0=\frac{\xi_0}{\tau_0}\int_0^1 \hat{\rho}(\zeta,0)\,d\zeta,$$

since $x_0=\int_0^{\xi_0}\rho(\xi',0)\,d\xi'=\rho_0\xi_0\int_0^1\hat{\rho}(\zeta,0)\,d\zeta$.

3. Assumptions and main results.

3.1. Statement of the problem. The aim of this paper is to investigate the following version of (2.10)-(2.12):

$$\begin{aligned}
&\Theta_t-\Theta_{xx}=\Omega(Y,\Theta)=Y^n f(\Theta),\\
&Y_t-\frac{Y_{xx}}{\mathrm{Le}}=-\Omega(Y,\Theta),\\
&(\Theta+\alpha)\rho=1, \qquad (3.1)\\
&u_x=\Theta_t \quad \text{for } x\in\mathbb{R},\ t\in\mathbb{R}_+,\\
&\Theta(x,0)=\Theta_0(x), \qquad Y(x,0)=Y_0(x),\\
&\Theta(-\infty,t)=0, \qquad \Theta(+\infty,t)=1,\\
&Y(-\infty,t)=1, \qquad Y(+\infty,t)=0, \qquad (3.2)\\
&u(-\infty,t)=u^0,\\
&u_t+p_x=0, \qquad p(-\infty,t)=0. \qquad (3.3)
\end{aligned}$$

We will also study the corresponding normalized Eulerian formulation in conservative form:

$$\begin{aligned}
&\rho_\tau+(\rho u)_\xi=0,\\
&(\rho u)_\tau+(\rho u^2)_\xi+p_\xi=0,\\
&(\rho\Theta)_\tau+(\rho u\Theta)_\xi-\left(\frac{\Theta_\xi}{\rho}\right)_\xi=\rho\Omega(Y,\Theta),\\
&(\rho Y)_\tau+(\rho u Y)_\xi-\frac{1}{\mathrm{Le}}\left(\frac{Y_\xi}{\rho}\right)_\xi=-\rho\Omega(Y,\Theta), \qquad (3.4)\\
&(\Theta+\alpha)\rho=1 \qquad \text{for } x\in\mathbb{R},\ t\in\mathbb{R}_+,\\
&\Theta(x,0)=\Theta_0(x), \qquad Y(x,0)=Y_0(x),\\
&\Theta(-\infty,t)=0, \qquad \Theta(+\infty,t)=1,\\
&Y(-\infty,t)=1, \qquad Y(+\infty,t)=0, \qquad (3.5)\\
&u(-\infty,t)=u^0, \qquad p(-\infty,t)=0.
\end{aligned}$$

It can be noticed here that initial data are prescribed only for the temperature and mass fraction (Θ, Y) and not for the hydrodynamical unknowns (ρ, u, p).

For the investigation of these two problems, we will mainly focus on two types of solutions, which we define precisely below.

DEFINITION 3.1. (Θ, Y, ρ, u, p) is a *weak solution* of problem (3.1)-(3.3) if the three following properties hold:

(1) $(\Theta, Y, \rho, u, p) \in [L^{\infty}_{\text{loc}}(\mathbb{R}\times\mathbb{R}_+)]^5$ and (Θ, Y, ρ, u, p) is a solution of (3.1)-(3.3a) in the sense of the distributions:

$$\int_{\mathbb{R}\times\mathbb{R}_+} [-\Theta\eta_t + \Theta\eta_{xx} - \Omega\eta] = \int_{\mathbb{R}} \Theta_0\eta(\cdot, 0),$$

$$\int_{\mathbb{R}\times\mathbb{R}_+} [-Y\eta_t + \frac{1}{\text{Le}} Y\eta_{xx} + \Omega\eta] = \int_{\mathbb{R}} Y_0\eta(\cdot, 0),$$

$$\int_{\mathbb{R}\times\mathbb{R}_+} [(\Theta+\alpha)\rho\eta - \eta] = 0,$$

$$\int_{\mathbb{R}\times\mathbb{R}_+} [u\eta_x - \Theta\eta_t] = \int_{\mathbb{R}} \Theta_0\eta(\cdot, 0),$$

$$\int_{\mathbb{R}\times\mathbb{R}_+} -[u\eta_t + p\eta_x] = \int_{\mathbb{R}} u(\cdot, 0)\eta(\cdot, 0) \quad \text{for any } \eta \in D(\mathbb{R}\times\mathbb{R}_+).$$

(2) The boundary conditions (3.2) hold in the classical sense for $t > 0$ and (3.3b) holds in the following weak sense:

$$\forall t > 0, \quad \exists p_1 \in L^2(\mathbb{R}), \quad \lim_{x\to-\infty} [p(x, t) - p_1(x)] = 0. \tag{3.6}$$

(3) The following inequalities (which are necessary from a physical standpoint) hold:

$$\Theta(x, t) \geqq 0, \quad 0 \leqq Y(x, t) \leqq 1 \quad \text{a.e. on } \mathbb{R}\times\mathbb{R}_+.$$

Moreover, $\Theta \in L^{\infty}_{\text{loc}}(\mathbb{R}_+, L^{\infty}(\mathbb{R}))$.

DEFINITION 3.2. A *weak solution* (Θ, Y, ρ, u, p) of problem (3.1)-(3.3) is a *smooth solution* if and only if:

(1) All the functions and all the partial derivatives appearing in the equations (3.1) and (3.3a) are continuous with respect to both variables x and t on $\mathbb{R}\times\mathbb{R}_+$;

(2) The boundary conditions (3.2) and (3.3b) are fulfilled in the classical sense for $t \geqq 0$.

Similar definitions hold for the solutions of (3.4), (3.5).

3.2. Assumptions and notation. Before stating the main hypotheses which will be used for investigating the two above problems, we need to introduce two functions γ and γ_1 of $C^{\infty}(\mathbb{R})$ satisfying

$$\begin{aligned} &\gamma = 0 \quad \text{on } (-\infty, -1], \quad 0 \leqq \gamma \leqq 1 \quad \text{on } [-1, 1], \quad \gamma = 1 \quad \text{on } [1, +\infty), \\ &\gamma_1 = 1 - \gamma. \end{aligned} \tag{3.7}$$

We will set:

$$\varphi_0(x) = \Theta_0(x) - \gamma(x), \qquad \psi_0(x) = Y_0(x) - \gamma_1(x). \tag{3.8}$$

The following assumptions will be used in the theorems stated below:

$$\begin{cases} \varphi_0 \in L^2(\mathbb{R}) \cap L^1(\mathbb{R}), \qquad \psi_0 \in L^2(\mathbb{R}) \cap L^1(\mathbb{R}); \\ \Theta_0 \in L^\infty(\mathbb{R}), \quad \Theta_0(x) \geqq 0 \quad \text{a.e.}, \\ Y_0(x) \in [0,1] \quad \text{a.e.}, \\ \mathrm{Le} > 0 \quad \text{and} \quad n \in \mathbb{N}^* \text{ are given}, \\ f \in C(\mathbb{R}_+, \mathbb{R}_+), \qquad f(0) = 0, \\ \forall \vartheta > 0, \quad f \text{ is Lipschitz-continuous on } [0, \vartheta]. \end{cases} \tag{3.9}$$

Moreover, we will sometimes need some of the following more technical hypotheses:

$$\exists C_f > 0, \quad \forall \vartheta \in \mathbb{R}_+, \qquad |f(\vartheta)| \leqq C_f |\vartheta|, \tag{3.10}$$

$$\varphi_0 \in H^2(\mathbb{R}), \qquad \psi_0 \in H^2(\mathbb{R}), \tag{3.11}$$

$$f \in C^1(\mathbb{R}_+, \mathbb{R}_+),$$

$$\exists \beta > \frac{1}{2}, \quad \overline{\lim_{\vartheta \to 0}} \frac{|f'(\vartheta)|}{\vartheta^\beta} < +\infty, \tag{3.12}$$

$$\exists \mu > \frac{3}{2\beta}, \quad \sup_{x \in \mathbb{R}_-} \Theta_0(x) |x|^\mu < +\infty, \tag{3.13}$$

$$\varphi_0 \in H^4(\mathbb{R}), \qquad \psi_0 \in H^4(\mathbb{R}), \tag{3.14}$$

$$\begin{aligned} &f \in C^2(\mathbb{R}_+, \mathbb{R}_+), \\ &\forall \vartheta > 0, \quad f_{xx} \text{ is Lipschitz-continuous on } [0, \vartheta]. \end{aligned} \tag{3.15}$$

From now on, we will denote $L^p = L^p(\mathbb{R})$, for $p \in [1, +\infty)$, and $\|\varphi\|_p = \|\varphi\|_{L^p}$ or $\|(\varphi, \psi)\|_p = \max(\|\varphi\|_{L^p}, \|\psi\|_{L^p})$. Furthermore, for $m \in \mathbb{N}^*$, we set $H^m = H^m(\mathbb{R}) = W^{m,2}(\mathbb{R})$.

3.3. Results concerning the Lagrangian formulation. The first of our theorems deals with the problem (3.1), (3.2) without the pressure variable.

THEOREM 3.3. *Assume that the hypotheses* (3.9) *and* (3.10) *hold. Then there exists a unique* weak solution (Θ, Y, ρ, u) *of* (3.1), (3.2) *in* $\mathbb{R} \times \mathbb{R}_+$ *satisfying*:

$$\Theta - \gamma, \; Y - \gamma_1 \in C(\mathbb{R}_+, L^2). \tag{3.16}$$

Furthermore, this solution satisfies:

$$\begin{aligned} &\Theta, Y, \rho \in C(\mathbb{R}_+, L^\infty) \cap C(\mathbb{R}_+^*, C^1(\mathbb{R})), \\ &\Theta - \gamma, \; Y - \gamma_1 \in C^1(\mathbb{R}_+^*, L^2), \\ &u \in C(\mathbb{R}_+^*, C(\mathbb{R}) \cap L^\infty). \end{aligned} \tag{3.17}$$

Concerning the complete system (3.1)-(3.3), we have the following two results.

THEOREM 3.4. *Assume that the hypotheses* (3.9)-(3.13) *hold. Then there exists a unique weak solution* (Θ, Y, ρ, u, p) *of* (3.1)-(3.3) *in* $\mathbb{R}\times\mathbb{R}_+$ *satisfying* (3.16). *Moreover this solution satisfies* (3.17).

THEOREM 3.5. *Assume that all the hypotheses* (3.9) *to* (3.15) *hold. Then there exists a unique smooth solution of* (3.1)-(3.3) *in* $\mathbb{R}\times\mathbb{R}_+$. *This solution satisfies*:

$$\begin{aligned} &\Theta, Y, \rho \in C(\mathbb{R}_+, C^3(\mathbb{R})) \cap C^1(\mathbb{R}_+, C^1(\mathbb{R})), \\ &u \in C(\mathbb{R}_+, C^2(\mathbb{R})) \cap C^1(\mathbb{R}_+, C(\mathbb{R})). \end{aligned} \tag{3.18}$$

These three theorems will be proved in §§ 5 and 6 below.

3.4. Results concerning the Eulerian formulation. Analogous results hold for the Eulerian problem (3.4), (3.5).

THEOREM 3.6. *Assume that the hypotheses* (3.9)-(3.13) *hold. Then there exists a unique weak solution* (Θ, Y, ρ, u, p) *of* (3.4), (3.5) *in* $\mathbb{R}\times\mathbb{R}_+$ *satisfying* (3.16) *and*:

$$u, \rho \in C(\mathbb{R}\times\mathbb{R}_+, \mathbb{R}).$$

Moreover, this solution satisfies (3.17).

THEOREM 3.7. *Assume that all the hypotheses* (3.9) *to* (3.15) *hold. Then there exists a unique smooth solution of* (3.4), (3.5) *in* $\mathbb{R}\times\mathbb{R}_+$. *This solution satisfies* (3.18).

The proof of these two last results is detailed in § 7.

4. Recalling some basic results from semigroup theory. In this section, we briefly recall some classical results from functional analysis which will be needed in the following sections. We refer the reader to [3], [4], [10], [15] for more details and for the proofs of these results.

4.1. Semigroups of linear operators. Let us first recall some basic definitions and results about maximal monotone linear operators.

Let H be a real Hilbert space and A be an unbounded linear operator defined on the subspace $D(A)\subset H$. The operator A is said to be maximal monotone if and only if:

$$\begin{aligned} &\forall u \in D(A), \quad (Au, u) \geqq 0, \\ &\forall v \in H, \quad \exists u \in D(A), \quad v = u + Au. \end{aligned} \tag{4.1}$$

The basic property is the theorem of Hille and Yosida.

THEOREM 4.1 (Hille and Yosida). *Let H be a real Hilbert space and A be a maximal monotone linear operator defined on the subspace $D(A)\subset H$. For $u_0\in D(A)$, the problem*:

$$\begin{aligned} &\frac{du}{dt} + Au = 0 \quad \text{for } t \geqq 0, \\ &u(0) = u_0 \end{aligned} \tag{4.2}$$

has a unique solution in $C(\mathbb{R}_+, D(A)) \cap C^1(\mathbb{R}_+, H)$.

Let $u(t)$ be the solution of (4.2) for $t\geqq 0$; we set $u(t) = R(t)u_0$, where $R(t)$ is a linear operator from $D(A)$ into H. Since it follows from (4.1) that $D(A)$ is a dense subspace of H, we can extend $R(t)$ to the whole space H; the resulting operator, which we still denote by $R(t)$, is (by definition) the linear semigroup generated by $-A$.

Let us finally recall that a maximal monotone operator A is self-adjoint if and only if, for all $(u, v)\in D(A)^2$, $(Au, v) = (u, Av)$.

4.2. Nonlinear equations. We are going to consider some problems of the form:

$$\begin{aligned} &\frac{du}{dt} + Au = F(u) \quad \text{for } t \geqq 0, \\ &u(0) = u_0, \end{aligned} \tag{4.3}$$

where A is a linear self-adjoint maximal monotone operator, $u_0 \in H$ and $F \in C(H, H)$. Before stating results about the existence of a solution of this problem, we specify which type of solution will be considered.

DEFINITION 4.2. u is a *classical solution* of (4.3) on an interval $[0, T)$ if and only if u satisfies (4.3) in the classical sense, i.e., with:

$$u \in C^1([0, T), H) \cap C([0, T), D(A)).$$

u is a *weak solution* of (4.3) on $[0, T)$ if and only if $u \in C([0, T), H)$ and:

$$\forall t \in [0, T), \quad u(t) = R(t)u_0 + \int_0^t R(t-s)F[u(s)]\, ds. \tag{4.4}$$

We can then state the following two theorems.

THEOREM 4.3. *Let H be a real Hilbert space and A be a linear self-adjoint maximal monotone operator defined on the subspace $D(A) \subset H$. Assume that F is a Lipschitz-continuous mapping from H into itself. Then for any $u_0 \in H$, there exists a unique weak solution of* (4.3) *in $\mathbb{R}_+$ and this solution u is classical on $\mathbb{R}_+^*$.*

Moreover, if $u_0 \in D(A)$, then u is a classical solution on $\mathbb{R}_+$.

THEOREM 4.4. *Let H be a real Hilbert space and A be a linear self-adjoint maximal monotone operator defined on the subspace $D(A) \subset H$. Assume that F is a Lipschitz-continuous mapping from any bounded subset of H into H. Then for any $u_0 \in H$, there exists $T_{\max} > 0$ such that a unique weak solution of* (4.3) *exists on $[0, T_{\max})$; this solution u is classical on $(0, T_{\max})$ and the following alternative holds:*

$$\begin{aligned} &\textit{Either:} \quad T_{\max} = +\infty, \\ &\textit{Or:} \quad \lim_{t \to T_{\max}} \|u(t)\|_H = +\infty. \end{aligned}$$

Moreover, if $u_0 \in D(A)$, then u is a classical solution on $[0, T_{\max})$.

4.3. Application to the heat equation. We now consider the case $H = L^2$, and the operator:

$$A: \begin{vmatrix} D(A) = H^2 \to L^2, \\ \varphi \to -\varphi_{xx}. \end{vmatrix}$$

Problem (4.3) then becomes a nonlinear heat equation; Theorems 4.3 and 4.4 apply to this case because of the following lemma.

LEMMA 4.5. *A is a self-adjoint maximal monotone operator.*

Let $S(t)$ be the semigroup generated by $-A$; the following properties of this semigroup will be useful in the sequel.

LEMMA 4.6. *The following properties hold for the semigroup $S(t)$:*

$$\forall p \in [1, \infty), \quad \forall \varphi \in L^2 \cap L^p, \quad \forall t \in \mathbb{R}_+, \quad \|S(t)\varphi\|_{L^p} \leqq \|\varphi\|_{L^p},$$
$$\forall \varphi \in L^2 \cap L^\infty, \quad S(\cdot)\varphi \in C[\mathbb{R}_+, L^\infty(\mathbb{R})].$$

LEMMA 4.7. *Let $u_0 \in L^2$. The following explicit expression holds for $S(t)u_0$:*

$$[S(t)u_0](x) = \frac{1}{\sqrt{4\pi t}} \int_{\mathbb{R}} u_0(y)\, e^{|x-y|^2/4t}\, dy. \tag{4.5}$$

5. Existence and uniqueness for the combustion variables.

5.1. Statement of the problem and main results. The aim of this section is to study the subsystem of the reaction-diffusion equations for the temperature and mass fraction:

$$\Theta_t - \Theta_{xx} = \Omega(Y, \Theta) = Y^n f(\Theta), \qquad Y_t - \frac{Y_{xx}}{\mathrm{Le}} = -\Omega(Y, \Theta) \quad \text{for } x \in \mathbb{R},\ t \in \mathbb{R}_+,$$

(5.1)

$$\Theta(x, 0) = \Theta_0(x), \qquad Y(x, 0) = Y_0(x),$$

$$\Theta(-\infty, t) = 0, \qquad \Theta(+\infty, t) = 1,$$

(5.2)

$$Y(-\infty, t) = 1, \qquad Y(+\infty, t) = 0.$$

Before stating the results concerning the existence and uniqueness of a solution of problem (5.1), (5.2) we introduce a new formulation of this problem. In order to apply some of the results recalled in the preceding section, we define new unknowns (φ, ψ) satisfying zero boundary condition; we therefore use the functions γ and γ_1 introduced in (3.7), define (φ_0, ψ_0) as in (3.8) and set:

$$\varphi(x, t) = \Theta(x, t) - \gamma(x), \qquad \psi(x, t) = Y(x, t) - \gamma_1(x). \tag{5.3}$$

Finally we extend the domain of definition of f by setting: $f \equiv 0$ on $\mathbb{R}_-$, and we define g by:

$$g(\xi) = \begin{cases} 0 & \text{if } \xi \leqq 0, \\ \xi^n & \text{if } \xi \geqq 0. \end{cases} \tag{5.4}$$

The system (5.1), (5.2) can now be rewritten as:

$$\varphi_t - \varphi_{xx} = f(\varphi + \gamma) g(\psi + \gamma_1) + \gamma_{xx},$$

$$\psi_t - \frac{\psi_{xx}}{\mathrm{Le}} = -f(\varphi + \gamma) g(\psi + \gamma_1) - \frac{\gamma_{xx}}{\mathrm{Le}}, \tag{5.5}$$

$$\varphi(x, 0) = \varphi_0(x), \qquad \psi(x, 0) = \psi_0(x),$$

$$\varphi(-\infty, t) = \varphi(+\infty, t) = \psi(-\infty, t) = \psi(+\infty, t) = 0. \tag{5.6}$$

The next lemma shows that problem (5.5) does belong to the general framework of the preceding section. Consider the linear operator:

$$A: \begin{vmatrix} D(A) = H^2 \times H^2 \to L^2 \times L^2, \\ (\varphi, \psi) \to \left(-\varphi_{xx}, -\frac{\psi_{xx}}{\mathrm{Le}} \right). \end{vmatrix}$$

We then have the following lemma.

LEMMA 5.1. *A is a maximal monotone self-adjoint operator.*

Proof. The proof is obvious from Lemma 4.5. □

Remark 5.2. Let S^2 be the continuous linear semigroup generated by $-A$. The two following properties follow easily from Lemma 4.6:

$$\forall p \in [1, \infty), \quad \forall (\varphi, \psi) \in L^2 \times L^2 \cap L^p \times L^p, \quad \forall t \in \mathbb{R}_+, \quad \| S^2(t)(\varphi, \psi) \|_p \leqq \| (\varphi, \psi) \|_p,$$

$$\forall (\varphi, \psi) \in L^2 \times L^2 \cap L^\infty \times L^\infty, \quad S^2(\cdot)(\varphi, \psi) \in C(\mathbb{R}_+, L^\infty \times L^\infty).$$

We can now make precise what the solutions of (5.5) may be, in view of Definitions 3.2 and 4.2. For the more general problem:

$$\begin{aligned} &\varphi_t - \varphi_{xx} = h_1(\varphi, \psi, x), \\ &\psi_t - \frac{\psi_{xx}}{\mathrm{Le}} = h_2(\varphi, \psi, x), \\ &\varphi(x, 0) = \varphi_0(x), \qquad \psi(x, 0) = \psi_0(x), \end{aligned} \tag{5.7}$$

we state the following.

DEFINITION 5.3. (φ, ψ) is a *weak solution* of (5.7) on $\mathbb{R}\times[0, T)$ if and only if:

$$\varphi, \psi \in C([0, T), L^2), \qquad H(\varphi, \psi) \in C([0, T), L^2 \times L^2),$$

$$\forall t \in [0, T), \quad (\varphi, \psi)(t) = S^2(t)(\varphi_0, \psi_0) + \int_0^t S^2(t-s) H[(\varphi, \psi)(s)]\, ds,$$

where $H(\varphi, \psi) = [h_1(\varphi, \psi, x), h_2(\varphi, \psi, x)]$.

A *weak solution* (φ, ψ) of (5.7) is a *classical solution* on the interval K of $\mathbb{R}_+$ if and only if:

$$\varphi, \psi \in C^1(K, L^2) \cap C(K, H^2).$$

A classical solution (φ, ψ) of (5.7) is a *smooth solution* if and only if (φ, ψ) and all the partial derivatives appearing in (5.7) are continuous with respect to both variables x and t.

DEFINITION 5.4. (Θ, Y) is a *weak* (resp., *classical, smooth*) solution of (5.1) on $\mathbb{R}\times[0, T)$ if and only if (Θ, Y) is related to a *weak* (resp., *classical, smooth*) solution (φ, ψ) of (5.5) on $\mathbb{R}\times[0, T)$ by (5.3), and satisfies:

$$\Theta \in L^\infty_{\mathrm{loc}}(\mathbb{R}_+, L^\infty),$$

$$\Theta(x, t) \geqq 0, \qquad 0 \leqq Y(x, t) \leqq 1 \quad \text{a.e. on } \mathbb{R}\times[0, T).$$

Remark 5.5. It is easily checked that a *weak solution* (φ, ψ) of (5.5) on $\mathbb{R}\times\mathbb{R}_+$ which is also a *classical solution* on $\mathbb{R}_+^*$ is a solution in the sense of the distributions. Let indeed $\eta \in D(\mathbb{R}\times\mathbb{R}_+)$. Assuming that $\mathrm{Supp}\,(\eta) \subset (-M, M)\times[0, T)$, we set: $K = (-M, M)\times[0, T)$ and $K_\varepsilon = (-M, M)\times(\varepsilon, T)$. Since (φ, ψ) is a classical solution on $\mathbb{R}\times K_\varepsilon$, φ, ψ and η are in $H^1(K_\varepsilon)$. We can then apply Green's formula to get:

$$\int_{K_\varepsilon} [-\varphi\eta_t - (\varphi+\gamma)\eta_{xx} - f(\varphi+\gamma)g(\psi+\gamma_1)\eta] = \int_{-M}^{M} \varphi(x, \varepsilon)\eta(x, \varepsilon)\, dx.$$

As $\varphi \in C([0, T), L^2)$, we can take the limit $\varepsilon \to 0$ in the last relation to get:

$$\int_K [-\varphi\eta_t - (\varphi+\gamma)\eta_{xx} - f(\varphi+\gamma)g(\psi+\gamma_1)\eta] = \int_{-M}^{M} \varphi_0(x)\eta(x, 0)\, dx,$$

which (together with the analogous relation for ψ) shows that (φ, ψ) is a solution of (5.5) in the sense of $D'(\mathbb{R}\times\mathbb{R}_+)$.

In the same way, a *weak solution* (Θ, Y) of (5.1) is a solution in the sense of distributions.

We are now ready to state the main results about problems (5.1), (5.2) and (5.5), (5.6). For the sake of simplicity, we are using both the new unknowns (φ, ψ) and the old ones (Θ, Y).

THEOREM 5.6. *Under the hypotheses* (3.9) *and* (3.10), *there exists a unique solution* (Θ, Y) *of problem* (5.1), (5.2). *The corresponding solution* (φ, ψ) *of* (5.5), (5.6) *satisfies*:

$$\varphi, \psi \in C(\mathbb{R}_+, L^2 \cap L^\infty) \cap C^1(\mathbb{R}_+^*, L^2) \cap C(\mathbb{R}_+^*, H^2).$$

COROLLARY 5.7. *Under the hypotheses* (3.9), (3.10) *and* (3.15), *the solution* (Θ, Y) *of* (5.1), (5.2) *is a smooth solution on* $\mathbb{R}\times\mathbb{R}_+^*$.

Moreover, if $\varphi_0, \psi_0 \in H^4$, (Θ, Y) *is a smooth solution on* $\mathbb{R}\times\mathbb{R}_+$.

5.2. A lemma for systems of type (5.5). We begin the proof of the above theorems with the next result, which will be used several times in the sequel.

LEMMA 5.8. *Let* f_0 *and* g_0 *be two bounded Lipschitz-continuous functions on* $\mathbb{R}$, *with* $f_0(0)=0$, $g_0(0)=0$; *consider the problem*:

$$\begin{aligned} &\varphi_t-\varphi_{xx}=f_0(\varphi+\gamma)g_0(\psi+\gamma_1)+\gamma_{xx},\\ &\psi_t-\frac{\psi_{xx}}{\mathrm{Le}}=-f_0(\varphi+\gamma)g_0(\psi+\gamma_1)-\frac{\gamma_{xx}}{\mathrm{Le}},\\ &\varphi(x,0)=\varphi_0(x),\qquad \psi(x,0)=\psi_0(x). \end{aligned} \tag{5.8}$$

For any $(\varphi_0, \psi_0)\in L^2\times L^2$, *the problem* (5.8) *has a unique solution* (φ, ψ) *in* $C(\mathbb{R}_+, L^2\times L^2)$; *this solution is a classical solution on* $\mathbb{R}_+^*$:

$$\varphi, \psi \in C(\mathbb{R}_+^*, H^2)\cap C^1(\mathbb{R}_+^*, L^2).$$

Proof. Define the mapping F_0 by:

$$F_0(\varphi,\psi)=\left[f_0(\varphi+\gamma)g_0(\psi+\gamma_1)+\gamma_{xx}, -f_0(\varphi+\gamma)g_0(\psi+\gamma_1)-\frac{\gamma_{xx}}{\mathrm{Le}}\right]$$

for $\varphi, \psi \in L^2$. In view of Theorem 4.3, it suffices to show that F_0 is a Lipschitz-continuous mapping from $L^2\times L^2$ into itself.

Let $h=f_0(\varphi+\gamma)g_0(\psi+\gamma_1)$. It is classical to show that $h\in L^2$ when $\varphi, \psi\in L^2$. Let us simply check that h is Lipschitz-continuous from $L^2\times L^2$ into L^2. Let M_f, M_g, L_f, L_g be real constants such that:

$$\forall \xi\in\mathbb{R},\quad |f_0(\xi)|\leqq M_f,\quad |g_0(\xi)|\leqq M_g,$$

$$\forall(\xi,\eta)\in\mathbb{R}^2,\quad |f_0(\xi)-f_0(\eta)|\leqq L_f|\xi-\eta|,\quad |g_0(\xi)-g_0(\eta)|\leqq L_g|\xi-\eta|.$$

For $\varphi_1, \psi_1\in L^2$, $\varphi_2, \psi_2\in L^2$, we have:

$$\begin{aligned} h_1-h_2&=f_0(\varphi_1+\gamma)g_0(\psi_1+\gamma_1)-f_0(\varphi_2+\gamma)g_0(\psi_2+\gamma_1)\\ &=f_0(\varphi_1+\gamma)[g_0(\psi_1+\gamma_1)-g_0(\psi_2+\gamma_1)]+g_0(\psi_2+\gamma_1)[f_0(\varphi_1+\gamma)-f_0(\varphi_2+\gamma)], \end{aligned}$$

whence:

$$\begin{aligned} \|h_1-h_2\|_2&\leqq M_fL_g\|\psi_1-\psi_2\|_2+M_gL_f\|\varphi_1-\varphi_2\|_2,\\ &\leqq[M_fL_g+M_gL_f]\|(\varphi_1-\varphi_2,\psi_1-\psi_2)\|_2, \end{aligned}$$

and the proof is complete. □

5.3. Uniqueness. The uniqueness of the solution (Θ, Y) of problem (5.1), (5.2) is a consequence of the following proposition.

PROPOSITION 5.9. *Let* $T>0$. *Under the hypotheses* (3.9), *there exists at most one solution of problem* (5.5) *in* $C([0,T), L^2\times L^2)\cap L^\infty([0,T), L^\infty\times L^\infty)$.

Proof. Let $T>0$, and let (φ_1,ψ_1) and (φ_2,ψ_2) be two solutions of (5.5), with $\varphi_i, \psi_i\in L^\infty([0,T), L^\infty)$ for $i=1,2$. Choosing $U\in\mathbb{R}$ such that $\|(\varphi_i,\psi_i)(t)\|_\infty\leqq U$ for $i=1,2$ and $t\in[0,T)$, we can consider two functions f_U and g_U satisfying:

(5.9) f_U is positive, bounded and Lipschitz-continuous on $\mathbb{R}$, $f_U(\xi)=f(\xi)$ if $|\xi|\leqq U$.

(5.10) g_U is positive, bounded and Lipschitz-continuous on $\mathbb{R}$, $g_U(\xi) = g(\xi)$ if $|\xi| \leqq U$.

(φ_1, ψ_1) and (φ_2, ψ_2) are then solutions of the following problem:

$$\begin{aligned} &\varphi_t - \varphi_{xx} = f_U(\varphi+\gamma) g_U(\psi+\gamma_1) + \gamma_{xx}, \\ &\psi_t - \frac{\psi_{xx}}{\mathrm{Le}} = -f_U(\varphi+\gamma) g_U(\psi+\gamma_1) - \frac{\gamma_{xx}}{\mathrm{Le}}, \\ &\varphi(x,0) = \varphi_0(x), \qquad \psi(x,0) = \psi_0(x). \end{aligned} \tag{5.11}$$

Applying Lemma 5.8, we get $(\varphi_1, \psi_1) = (\varphi_2, \psi_2)$, which ends the proof. □

5.4. Global existence. We show in this section the existence of a solution (Θ, Y) of problem (5.1), (5.2).

PROPOSITION 5.10. *Assume that the hypotheses* (3.9) *hold. Then there exists* $T_{\max} \in \mathbb{R}_+^* \cup \{+\infty\}$ *such that a solution* (Θ, Y) *of problem* (5.1), (5.2) *exists on* $\mathbb{R} \times [0, T_{\max})$. *Moreover,* (Θ, Y) *is a classical solution on* $(0, T_{\max})$, *and the following alternative holds*:

$$\begin{aligned} &\textit{Either}: \quad T_{\max} = +\infty, \\ &\textit{Or}: \quad \lim_{t \to T_{\max}} \|\Theta(t)\|_\infty = +\infty. \end{aligned} \tag{5.12}$$

The proof of this proposition is divided into two lemmas.

LEMMA 5.11. *Under the hypotheses* (3.9), *there exists* $T_{\max} \in \mathbb{R}_+^* \cup \{+\infty\}$ *such that a solution* (φ, ψ) *of problem* (5.5) *exists on* $\mathbb{R} \times [0, T_{\max})$. *Moreover, the following properties hold*:

$$\varphi, \psi \in C([0, T_{\max}), L^2) \cap C((0, T_{\max}), H^2) \cap C^1((0, T_{\max}), L^2), \tag{5.13}$$

$$\forall T < T_{\max}, \quad \varphi, \psi \in L^\infty([0, T), L^\infty), \tag{5.14}$$

$$\begin{aligned} &\textit{Either}: \quad T_{\max} = +\infty, \\ &\textit{Or}: \quad \lim_{t \to T_{\max}} \|(\varphi, \psi)(t)\|_\infty = +\infty. \end{aligned} \tag{5.15}$$

Proof. (a) Let us first show the existence of a solution on $\mathbb{R} \times [0, T)$ for small positive T. For $U \geqq \|(\varphi_0, \psi_0)\|_\infty + 2$, we define f_U and g_U as in (5.9), (5.10) above and consider again the problem (5.11). Lemma 5.8 applies again and gives a solution (φ_U, ψ_U). Denoting

$$F_U(\varphi_U, \psi_U) = \left[f_U(\varphi_U+\gamma) g_U(\psi_U+\gamma_1) + \gamma_{xx}, -f_U(\varphi_U+\gamma) g_U(\psi_U+\gamma_1) - \frac{\gamma_{xx}}{\mathrm{Le}} \right],$$

and using Remark 5.2, we get:

$$\begin{aligned} &(\varphi_U, \psi_U)(t) = S^2(t)(\varphi_0, \psi_0) + \int_0^t S^2(t-s) F_U[(\varphi_U, \psi_U)(s)]\, ds, \\ &\|(\varphi_U, \psi_U)(t)\|_\infty \leqq \|(\varphi_0, \psi_0)\|_\infty + \int_0^t \|F_U[(\varphi_U, \psi_U)(s)]\|_\infty\, ds. \end{aligned} \tag{5.16}$$

Since f_U, g_U and γ_{xx} are bounded, we can obviously find a constant C_U such that: for all $(\varphi_1, \psi_1) \in L^\infty \times L^\infty$, $\|F_U(\varphi_1, \psi_1)\|_\infty \leqq C_U$. This implies:

$$\|(\varphi_U, \psi_U)(t)\|_\infty \leqq \|(\varphi_0, \psi_0)\|_\infty + C_U t.$$

Let $t_U = 1/C_U$. For $t \in [0, t_U)$, we have

$$\|(\varphi_U, \psi_U)(t)\|_\infty \leqq \|(\varphi_0, \psi_0)\|_\infty + 1,$$

whence

$$\|\varphi_U(t)+\gamma\|_\infty \leqq \|(\varphi_0, \psi_0)\|_\infty + 2 \leqq U, \qquad \|\psi_U(t)+\gamma_1\|_\infty \leqq \|(\varphi_0, \psi_0)\|_\infty + 2 \leqq U.$$

This implies that (φ_U, ψ_U) is a solution of (5.5) on $\mathbb{R}\times[0, t_U)$; this solution satisfies:

$$\varphi_U, \psi_U \in C([0, t_U), L^2) \cap L^\infty([0, t_U), L^\infty),$$

and

$$\varphi_U, \psi_U \in C((0, t_U), H^2) \cap C^1((0, t_U), L^2).$$

(b) Since a solution of problem (5.5) exists locally in the neighbourhood $[0, t_U)$ of 0, it is classical to show the existence of a solution (φ, ψ) satisfying (5.13)-(5.15) on a maximal interval $[0, T_{\max})$. For sake of completeness we briefly recall the proof of (5.15): let us assume that $T_{\max} < +\infty$ and that there exists a sequence $(t_m)_{m\in\mathbb{N}}$ such that:

$$\begin{aligned} &\lim_{m\to\infty} t_m = T_{\max}, \\ &\exists V > 0, \quad \forall m \in \mathbb{N} \quad \|(\varphi, \psi)(t_m)\|_\infty \leqq V. \end{aligned} \tag{5.17}$$

Let $U = V+2$. For $m\in\mathbb{N}$, we can argue as in (a) above to show the existence of a solution of (5.5) on the interval $[t_m, t_m + t_U)$. Since t_U does not depend on m we can choose the latter so that: $t_m + t_U > T_{\max}$, which contradicts the assumption that $[0, T_{\max})$ is a maximal interval for the existence of a solution of (5.5). Formula (5.17) is therefore wrong and the alternative (5.15) holds. □

The solution (φ, ψ) of (5.5) defined in Lemma 5.11 satisfies the boundary conditions (5.6) on $(0, T_{\max})$. For $t\in(0, T_{\max})$, we have indeed $\varphi(\pm\infty, t) = \psi(\pm\infty, t) = 0$ since $\varphi, \psi \in H^1$ (see [3]).

We can now end the proof of Proposition 5.10 by using the maximum principle for parabolic partial differential equations.

LEMMA 5.12. *Let* (φ, ψ) *be the solution of* (5.5) *defined in Lemma* 5.11. *For* $(x, t)\in\mathbb{R}\times[0, T_{\max})$, *define*:

$$\Theta(x, t) = \varphi(x, t) + \gamma(x), \qquad Y(x, t) = \psi(x, t) + \gamma_1(x).$$

Then the following inequalities hold:

$$\Theta(x, t) \geqq 0, \quad 0 \leqq Y(x, t) \leqq 1 \quad \text{a.e. on } \mathbb{R}\times[0, T_{\max}). \tag{5.18}$$

Proof. (a) Let us first show that $Y \geqq 0$. This is essentially the maximum principle. For any function Z of $L^2_{\text{loc}}(\mathbb{R})$ we define as usual: $Z^- = \max(0, -Z)$, $Z^+ = \max(0, Z)$. For $t\in(0, T_{\max})$, it is known that $\psi^-(t)\in H^1$, $(\psi(t)+\gamma_1)^- \in H^1_{\text{loc}}(\mathbb{R})$ (see [12]). It follows easily from the properties (3.7) of γ and γ_1 that $(\psi(t)+\gamma_1)^- = Y^- \in H^1$. Since (φ, ψ) is a *classical solution* of (5.5) on $(0, T_{\max})$, we can write:

$$Y_t Y^- - \frac{Y_{xx} Y^-}{\text{Le}} = -f(\Theta) g(Y) Y^-.$$

But $g(Y) Y^- \equiv 0$ from (5.4); integrating the last relation by parts, we get:

$$\frac{d}{dt}\left[\frac{1}{2}\int_{\mathbb{R}} (Y^-)^2\right] + \frac{1}{\text{Le}}\int_{\mathbb{R}} [(Y^-)_x]^2 = 0,$$

whence

$$\frac{d}{dt}\left[\int_{\mathbb{R}} (Y^-)^2\right] \leqq 0 \quad \text{for } t\in(0, T_{\max}). \tag{5.19}$$

On the other hand, it can be checked easily that the mapping $\psi \to (\psi + \gamma_1)^-$ is continuous from L^2 into itself. Thus $Y^- \in C([0, T_{\max}), L^2)$. Since $\int_{\mathbb{R}} (Y^-)^2$ is decreasing on $(0, T_{\max})$ from (5.19) and $\int_{\mathbb{R}} [Y^-(t=0)]^2 = 0$ from (3.9), we obtain:

$$Y^-(t) \equiv 0 \quad \text{for } t \in [0, T_{\max}),$$

or equivalently:

$$Y(t) \geqq 0 \quad \text{for } t \in [0, T_{\max}).$$

(b) Using $(Y-1)^+$ and Θ^- instead of Y^- gives the other inequalities (5.18) as in (a) above. □

5.5. Regularity of the solution. Before showing that a global solution does exist (i.e. $T_{\max} = +\infty$), we can investigate the smoothness of the solution (Θ, Y) defined in Proposition 5.10; this is the aim of this section.

A first result concerning the regularity of the solution is the next lemma, which is an obvious consequence of Theorem 4.3 and Lemma 5.11.

LEMMA 5.13. *If* $(\varphi_0, \psi_0) \in H^2 \times H^2$, *the solution* (Θ, Y) *defined in Proposition* 5.10 *is a classical solution on* $[0, T_{\max})$.

Without any further assumption on f, we also have the following lemma.

LEMMA 5.14. *The solution* (Θ, Y) *defined in Proposition* 5.10 *satisfies*:

$$(\Theta, Y) \in C([0, T_{\max}), L^\infty). \tag{5.20}$$

Proof. Since the imbedding $H^2 \subset L^\infty$ is continuous, we already have: $(\Theta, Y) \in C((0, T_{\max}), L^\infty)$ from (5.13). Therefore we only have to show that:

$$\|(\varphi, \psi)(t) - (\varphi_0, \psi_0)\|_\infty \to 0 \quad \text{when } t \to 0. \tag{5.21}$$

We use again the notation of the proof of Lemma 5.11. Let $U > \|(\varphi_0, \psi_0)\|_\infty + 2$. For $t > 0$ small enough, (φ, ψ) is a solution of (5.11) and (5.16) implies:

$$\|(\varphi, \psi)(t) - (\varphi_0, \psi_0)\|_\infty \leqq \|S^2(\varphi_0, \psi_0) - (\varphi_0, \psi_0)\|_\infty + C_U t,$$

and formula (5.21) follows now immediately from Remark 5.2. □

The next proposition shows that, with the additional assumptions (3.15) on f, there exists a *smooth solution* of (5.1), (5.2).

PROPOSITION 5.15. *Under the hypotheses* (3.15) *on* f, *the solution* (Θ, Y) *of problem* (5.1), (5.2) *defined in Proposition* 5.10 *is a smooth solution on* $\mathbb{R} \times \mathbb{R}_+^*$. *The corresponding solution* (φ, ψ) *of* (5.5), (5.6) *satisfies*:

$$\varphi, \psi \in C((0, T_{\max}), H^4) \cap C^1((0, T_{\max}), H^2) \cap C^2((0, T_{\max}), L^2).$$

Remark 5.16. This regularity result holds without any assumption on the regularity of the initial data (φ_0, ψ_0)—only (3.9) is assumed. This is of course related to the strong regularizing effect of the heat equation.

COROLLARY 5.17. *Assume that the hypotheses* (3.15) *hold, and that* $\varphi_0, \psi_0 \in H^4$. *Then the solution* (Θ, Y) *of problem* (5.1), (5.2) *defined in Proposition* 5.10 *is a smooth solution on* $\mathbb{R} \times \mathbb{R}_+$. *The corresponding solution* (φ, ψ) *of* (5.5), (5.6) *satisfies*:

$$\varphi, \psi \in C([0, T_{\max}), H^4) \cap C^1([0, T_{\max}), H^2) \cap C^2([0, T_{\max}), L^2).$$

We begin the proof of Proposition 5.15 with two lemmas. Assuming (3.15), we first introduce two functions $\hat{f}$ and $\hat{g}$ satisfying:

$$\hat{f} \in C^2(\mathbb{R}, \mathbb{R}),$$
$$\forall \xi > 0, \quad \hat{f}_{xx} \text{ is Lipschitz-continuous on } [-\xi, \xi],$$
$$\forall \xi > 0, \quad \hat{f}(\xi) = f(\xi),$$
$$\hat{g}(\xi) = \xi^n,$$

and a mapping $\hat{F}$ defined by:

$$\hat{F}(\varphi, \psi) = \left[\hat{f}(\varphi + \gamma)\hat{g}(\psi + \gamma_1) + \gamma_{xx}, -\hat{f}(\varphi + \gamma)\hat{g}(\psi + \gamma_1) - \frac{\gamma_{xx}}{\mathrm{Le}} \right],$$

for $\varphi, \psi \in L^2$.

LEMMA 5.18. *Under the hypotheses* (3.9) *and* (3.15), *the mapping* $\hat{F}$ *is Lipschitz-continuous from any bounded subset of* $H^2 \times H^2$ *into* $H^2 \times H^2$.

Proof. (a) Let us first show that $\hat{F}(\varphi, \psi) \in H^2 \times H^2$ when $\varphi, \psi \in H^2$. For $\varphi, \psi \in H^2$, let $\hat{h} = \hat{f}(\varphi + \gamma)\hat{g}(\psi + \gamma_1)$, $M = \|(\varphi, \psi)\|_\infty$. We define: $M_f = \max_{[-M,M]} \hat{f}$, $M_g = \max_{[-M,M]} \hat{g}$, $L_f = \max_{[-M,M]} \hat{f}_x$, $L_g = \max_{[-M,M]} \hat{g}_x$. Thus $\hat{h} \in L^2$ as in the proof of Lemma 5.8. Furthermore, we have:

$$\hat{h}_x = \hat{f}_x(\varphi + \gamma)(\varphi_x + \gamma_x)\hat{g}(\psi + \gamma_1) + \hat{f}(\varphi + \gamma)\hat{g}_x(\psi + \gamma_1)(\psi_x + \gamma_{1_x}),$$
$$|\hat{h}_x| \leqq L_f M_g |\varphi_x + \gamma_x| + M_f L_g |\psi_x + \gamma_{1x}|,$$

which yields $\hat{h}_x \in L^2$. It can also be shown that $\hat{h}_{xx} \in L^2$, using the Sobolev continuous imbedding:

$$H^2 \subset W^{1,\infty}(\mathbb{R}),$$
$$\exists S > 0, \quad \forall \varphi \in H^2, \quad \|\varphi\|_{W^{1,\infty}} \leqq S \|\varphi\|_{H^2}.$$

(b) It is long but easy to check that, for any $M > 0$, $\hat{h}$ is Lipschitz-continuous from $\{(\varphi, \psi) \in H^2 \times H^2, \ \|(\varphi, \psi)\|_{H^2 \times H^2} \leqq M\}$ into H^2; the details are left to the reader. □

For $\varphi_1, \psi_1 \in L^2$, we now consider the problem:

$$\varphi_t - \varphi_{xx} = \hat{f}(\varphi + \gamma)\hat{g}(\psi + \gamma_1) + \gamma_{xx},$$
$$\psi_t - \frac{\psi_{xx}}{\mathrm{Le}} = -\hat{f}(\varphi + \gamma)\hat{g}(\psi + \gamma_1) - \frac{\gamma_{xx}}{\mathrm{Le}}, \tag{5.22}$$
$$\varphi(x, 0) = \varphi_1(x), \qquad \psi(x, 0) = \psi_1(x).$$

LEMMA 5.19. *Assume that* (3.9) *and* (3.15) *hold. Then there exist* $\hat{T}_{\max} \in \mathbb{R}_+^* \cup \{+\infty\}$ *such that a unique solution* $(\hat{\varphi}, \hat{\psi})$ *of problem* (5.22) *exists on* $\mathbb{R} \times [0, \hat{T}_{\max})$. *This solution satisfies*:

$$\hat{\varphi}, \hat{\psi} \in C((0, \hat{T}_{\max}), H^4) \cap C^1((0, \hat{T}_{\max}), H^2),$$

and the following alternative holds:

Either: $\hat{T}_{\max} = +\infty$,

Or: $\lim_{t \to \hat{T}_{\max}} \|(\hat{\varphi}, \hat{\psi})(t)\|_{H^2 \times H^2} = +\infty$.

Proof. From Lemma 5.18, it suffices to apply Theorem 4.4 with $H = H^2 \times H^2$, $D(A) = H^4 \times H^4$ and $F = \hat{F}$. □

We can now complete the proof of Proposition 5.15 and Corollary 5.17.

Proof. (a) Let (φ, ψ) be the solution of (5.5) defined in Lemma 5.11; for $\varepsilon \in (0, T_{\max})$, we set $(\varphi_1, \psi_1) = (\varphi, \psi)(t = \varepsilon) \in H^2 \times H^2$. Applying Lemma 5.19, we get a solution $(\hat{\varphi}, \hat{\psi})$ of (5.22), which is unique in $C((0, \hat{T}_{\max}), H^2 \times H^2)$. But it is straightforward to show that $(\varphi, \psi)(t+\varepsilon)$ is also a solution of (5.22) in $C([0, T_{\max} - \varepsilon), H^2 \times H^2)$. These two solutions coincide, and we get:

$$(\varphi, \psi)(t) = (\hat{\varphi}, \hat{\psi})(t-\varepsilon) \quad \text{for } t \in [\varepsilon, T_{\max}).$$

(b) Lemma 5.19 and (a) above obviously imply that the solution (φ, ψ) defined in Lemma 5.11 satisfies:

$$\varphi, \psi \in C((0, T_{\max}), H^4) \cap C^1((0, T_{\max}), H^2).$$

It suffices now to use the Sobolev continuous imbeddings $H^2 \subset C^1(\mathbb{R})$, $H^4 \subset C_3(\mathbb{R})$ to show that (φ, ψ) is a smooth solution of (5.5), (5.6) on $(0, T_{\max})$. To end the proof of Proposition 5.15, it remains to show that $\varphi, \psi \in C^2((0, T_{\max}), L^2)$, or equivalently that $\hat{F}(\varphi, \psi) \in C^1((0, T_{\max}), L^2 \times L^2)$; this is straightforward and is left to the reader. □

Before concluding this section, we state another lemma:

LEMMA 5.20. *Let (φ, ψ) be the solution of problem (5.5) defined in Lemma 5.11. Let $p \in [1, +\infty)$ and assume that $\varphi_0, \psi_0 \in L^p$. Then*

$$\forall t \in (0, T_{\max}), \qquad \varphi(t), \psi(t) \in L^p.$$

Proof. Let $T < T_{\max}$ and $t \in [0, T]$. We set $M = \max_{t \in [0,T]} \|\Theta(t)\|_\infty$ and define L_f such that:

$$\forall \xi \in [0, M], \qquad |f(\xi)| \leqq L_f \xi.$$

Denoting $\Omega = Y^n f(\Theta)$, we can write $\Omega \leqq L_f \Theta$ and $\Omega \leqq L_f M Y$ from (5.18). Then, using (3.7), we have:

$$\begin{aligned} \|\Omega\|_p^p &= \|\Omega\|_{L^p(-\infty,-1)}^p + \|\Omega\|_{L^p(-1,+1)}^p + \|\Omega\|_{L^p(1,\infty)}^p \\ &\leqq L_f^p \|\varphi\|_{L^p(-\infty,-1)}^p + L_f^p M^p \|\psi\|_{L^p(1,\infty)}^p + K \\ &\leqq K(\|\varphi\|_p^p + \|\psi\|_p^p + 1) \end{aligned}$$

(where K denotes a positive constant), whence:

$$\|\Omega\|_p \leqq K(\|\varphi\|_p + \|\psi\|_p + 1).$$

Using now (4.4) and Lemma 4.6, we have (we use the notation $\Omega(s)$ instead of $\Omega Y(., s), \Theta(., s)]$ for simplicity):

$$\varphi(t) = S(t)\varphi_0 + \int_0^t S(t-s)[\Omega(s) + \gamma_{zz}]\, ds,$$

$$\|\varphi(t)\|_p \leqq \|\varphi_0\|_p + \int_0^t (\|\Omega(s)\|_p + K)\, ds,$$

$$\|\varphi(t)\|_p \leqq K + K \int_0^t (\|\varphi(s)\|_p + \|\psi(s)\|_p + 1)\, ds.$$

Arguing in the same way for $\|\psi(t)\|_p$, we finally obtain:

$$\|\varphi(t)\|_p + \|\psi(t)\|_p \leqq K\left[1 + \int_0^t (\|\varphi(s)\|_p + \|\psi(s)\|_p)\, ds\right].$$

It suffices now to apply Gronwall's lemma and the proof is complete. □

Remark 5.21. With the hypotheses of Lemma 5.20, one could easily show that $(\varphi, \psi) \in C([0, T_{\max}), L^p)$.

5.6. Existence for all time. We now end this fifth section by showing that $T_{\max} = +\infty$.

PROPOSITION 5.22. *Under hypothesis* (3.10), *the solution* (Θ, Y) *of* (5.1), (5.2) *defined in Proposition* 5.10 *exists on* $\mathbb{R} \times \mathbb{R}_+$:

$$T_{\max} = +\infty. \tag{5.23}$$

Proof. For $p \in [1, +\infty)$ and $t \in (0, T_{\max})$, we can write, since (Θ, Y) is a *classical solution* on $(0, T_{\max})$:

$$\Theta_t \Theta^{p-1} - \Theta_{xx} \Theta^{p-1} = Y^n f(\Theta) \Theta^{p-1}.$$

Integrating by parts as in the proof of Lemma 5.12, we obtain:

$$\frac{1}{p} \frac{d}{dt} \left(\int_{\mathbb{R}} \Theta^p \right) \leqq \int_{\mathbb{R}} [Y^n f(\Theta) \Theta^{p-1}].$$

Formulae (3.10) and (5.18) now imply:

$$\frac{d}{dt} \left(\int_{\mathbb{R}} \Theta^p \right) \leqq C_f p \int_{\mathbb{R}} \Theta^p.$$

Let $t_0 \in (0, T_{\max})$. Applying Gronwall's lemma to the last inequality, we can write:

$$\int_{\mathbb{R}} \Theta(t)^p \leqq \int_{\mathbb{R}} \Theta(t_0)^p \, e^{pC_f(t-t_0)},$$

or:

$$\|\Theta(t)\| p \leqq \|\Theta(t_0)\|_p e^{C_f(t-t_0)}.$$

We can then take the limit $p \to \infty$ to get:

$$\|\Theta(t)\|_\infty \leqq \|\Theta(t_0)\|_\infty \, e^{C_f(t-t_0)},$$

which together with (5.12) implies $T_{\max} = +\infty$. □

Of course, from a physical standpoint, it can be thought that (5.23) holds even if (3.10) is not assumed, because of (5.12), since one may expect that the increase of the temperature is limited by the consumption of the reactant. Nevertheless, we have been able to prove rigorously the global existence of the solution only with the assumption (3.10), or in the following case.

LEMMA 5.23. *Assume that the hypotheses* (3.9) *hold. If moreover* $\mathrm{Le} = 1$, *then the solution* (Θ, Y) *of* (5.1), (5.2) *exists on* $\mathbb{R} \times \mathbb{R}_+$.

Proof. If $\mathrm{Le} = 1$, we can add the two equations (5.1) to get:

$$(Y + \Theta)_t - (Y + \Theta)_{xx} = 0.$$

A straightforward application of the maximum principle for parabolic partial differential equations yields:

$$\|(Y + \Theta)(t)\|_\infty \leqq \|(Y + \Theta)(0)\|_\infty,$$

and (5.23) follows again from (5.12). □

Remark 5.24. With the same hypothesis $\mathrm{Le} = 1$, it can be shown that $(Y + \Theta)$ converges towards 1 uniformly on $\mathbb{R}$ as t tends to $+\infty$:

$$\lim_{t \to +\infty} \| Y + \Theta - 1 \|_\infty = 0.$$

6. Existence and uniqueness for the hydrodynamical variables.

6.1. Statement of the problem and main results. We now want to consider the subsystem (2.11) for the hydrodynamical variables—density, velocity and pressure:

$$(\Theta+\alpha)\rho=1, \tag{6.1}$$

$$u_x=\Theta_t, \qquad u(-\infty, t)=u^0, \tag{6.2}$$

$$u_t+p_x=0, \qquad p(-\infty, t)=0. \tag{6.3}$$

Throughout this section, it will be assumed that hypotheses (3.9) and (3.10) hold. The solution (Θ, Y) of (5.1), (5.2) in $\mathbb{R}\times\mathbb{R}_+$ and the corresponding solution (φ, ψ) of (5.5), (5.6) are now considered given. We let $\Omega(y, t)=\Omega[Y(y, t), \Theta(y, t)]$.

We recall that the *weak* or *smooth solutions* of (6.1)-(6.3) are defined at the beginning of § 3 (in particular, the boundary condition (6.3b) is fulfilled in the sense of (3.6) for *weak solutions*). About problem (6.1)-(6.3), we are going to prove:

THEOREM 6.1. *Assume that the hypotheses* (3.9)-(3.13) *hold. Then there exists a unique weak solution* (ρ, u, p) *of* (6.1)-(6.3) *in* $\mathbb{R}\times\mathbb{R}_+$.

If moreover (3.14) *and* (3.15) *hold,* (ρ, u, p) *is a smooth solution on* $\mathbb{R}\times\mathbb{R}_+$.

In order to prove this result, we now solve the two problems (6.2) and (6.3) in sequence (solving (6.1) for the density ρ is an obvious task since $\Theta(x, t)+\alpha\geqq\alpha>0$ for all $(x, t)\in\mathbb{R}\times\mathbb{R}_+$).

6.2. Velocity.

PROPOSITION 6.2. *There exists a unique weak solution of* (6.2) *in* $\mathbb{R}\times\mathbb{R}_+$:

$$u(x, t)=u^0+\Theta_x(x, t)+\int_{-\infty}^{x}\Omega(y, t)\,dy \quad \textit{for } (x, t)\in\mathbb{R}\times\mathbb{R}_+ \tag{6.4}$$

and u is a smooth solution of (6.2) *in* $\mathbb{R}\times\mathbb{R}_+^*$.

Moreover, if $\varphi_0, \psi_0\in H^2$, *u is a smooth solution of* (6.2) *in* $\mathbb{R}\times\mathbb{R}_+$.

Proof. (a) Let $t>0$. Since (Θ, Y) is a *classical solution* of (5.1) in the neighbourhood of t, we have from (6.2):

$$u_x=\Theta_t=\Theta_{xx}+\Omega\in L^1_{\mathrm{loc}}(\mathbb{R}),$$

whence:

$$u(x, t)=u(0, t)+\Theta_x(x, t)-\Theta_x(0, t)+\int_0^x\Omega(y, t)\,dy.$$

Since we want a finite limit $u(-\infty, t)$ to exist, we only need to show that:

$$\int_{-\infty}^{0}\Omega(y, t)\,dy<+\infty. \tag{6.5}$$

But (3.10) and (5.18) imply: $\Omega(y, t)\leqq C_f\Theta(y, t)$ and (6.5) follows since (3.9) and Lemma 5.20 imply $\Theta(t)\in L^1(\mathbb{R}_-^*)$. We then obtain (6.4) for $t>0$ (we have $\Theta_x(-\infty, t)=0$ since $\Theta(t)\in H^2$).

(b) It is clear that the solution u defined by (6.4) for $t>0$ satisfies (6.2a) in the sense of $D'(\mathbb{R}\times\mathbb{R}_+)$. When $\varphi_0, \psi_0\in H^2$, we can argue as in (a) above for $t=0$ and obtain (6.4) for $t\geqq 0$. To show that u is then a *smooth solution* of (6.2), it remains to prove that $\int_{-\infty}^{x}\Omega(y, t)\,dy$ is continuous with respect to both variables x and t; this will be a consequence of the next lemma. □

Before studying the pressure problem (6.3), we state some results about the regularity of the velocity u.

LEMMA 6.3. *The solution u of* (6.2) *satisfies*:

$$u \in C(\mathbb{R}_+^*, C(\mathbb{R})) \cap C(\mathbb{R}_+^*, L^\infty).$$

If moreover $\varphi_0, \psi_0 \in H^2$, *then* $u \in C(\mathbb{R}_+, C(\mathbb{R}) \cap C(\mathbb{R}_+, L^\infty)$.

Proof. For $T>0$ define $M = \max_{t\in[0,T]} \|\Theta(t)\|_\infty$. For $t \in (0, T]$, we first have $u(t) \in L^\infty$, or equivalently $\Omega(t) \in L^1$ from the estimates:

$$\Omega(t) \leqq C_f \Theta(t) \in C(\mathbb{R}_+^*, L^1(\mathbb{R}_-^*)), \qquad \Omega(t) \leqq C_f M Y(t) \in C(\mathbb{R}_+^*, L^1(\mathbb{R}_+^*)).$$

These two inequalities can be written together in the form $\Omega(t) \leqq G(t)$ with $G(t) \in C(\mathbb{R}_+^*, L^1)$. The continuity of the integral $\int \Omega(y, t)\, dy$ with respect to the variable t is now a consequence of classical convergence results from integration theory. For the sake of completeness we sketch the arguments: arguing by contradiction, we assume that there exists a sequence (t_n) satisfying $t_n \to t_0 > 0$ and:

$$\|\Omega(t_n) - \Omega(t_0)\|_1 \geqq \varepsilon > 0. \tag{6.6}$$

Then from the converse of Lebesgue's bounded convergence theorem (see [3, p. 58]), there exists $G_0 \in L^1$ and a subsequence (t_{n_k}) such that $G(y, t_{n_k}) \leqq G_0(y)$ a.e. for all n_k. Since (5.20) proves that $\Omega(t_{n_k})$ converges pointwise towards $\Omega(t_0)$, Lebesgue's bounded convergence theorem now shows that $\Omega(t_{n_k})$ converges to $\Omega(t_0)$ in L^1, which contradicts (6.6) and ends the proof. □

LEMMA 6.4. *Assume that the hypotheses* (3.12) *hold and define* $v(x, t) = \int_{-\infty}^{x} \Omega(y, t)\, dy$. *Then*:

$$v \in C^1(\mathbb{R} \times \mathbb{R}_+^*, \mathbb{R}) \quad \text{and} \quad v_t(x, t) = \int_{-\infty}^{x} \Omega_t(y, t)\, dy.$$

Proof. Assumption (3.12) obviously implies:

$$\forall M > 0, \quad \exists K_M > 0, \quad \forall \vartheta \in [0, M] \quad |f'(\vartheta)| \leqq K_M \vartheta^\beta \tag{6.7}$$

(with $\beta > \frac{1}{2}$). Let again $T>0$ and $M = \max_{t\in[0,T]} \|\Theta(t)\|_\infty$. For $t \in [0, T]$ and $y \in \mathbb{R}$ we have:

$$\Omega_t = nY^{n-1} Y_t f(\Theta) + Y^n \Theta_t f'(\Theta),$$

whence:

$$|\Omega_t(t)| \leqq nC_f \Theta(t) |Y_t(t)| + K_M \Theta^\beta(t) |\Theta_t(t)|,$$

$$|\Omega_t(t)| \leqq K[\Theta^2 + Y_t^2 + \Theta^{2\beta} + \Theta_t^2](t) \in C(\mathbb{R}_+^*, L^1(\mathbb{R}_-^*)),$$

where K is a positive constant. The proof is then completed in a way similar to that of the previous lemma. □

The next result is now an obvious consequence of the above lemmas and of Proposition 5.15.

LEMMA 6.5. *Under hypotheses* (3.12) *and* (3.15), *the solution u of* (6.2) *satisfies*:

$$u \in C(\mathbb{R}_+^*, C^2(\mathbb{R})) \cap C^1(\mathbb{R}_+^*, C(\mathbb{R})).$$

If moreover $\varphi_0, \psi_0 \in H^4$, *then* $u \in C(\mathbb{R}_+, C^2(\mathbb{R})) \cap C^1(\mathbb{R}_+, C(\mathbb{R}))$.

6.3. Pressure. We now investigate the problem (6.3) for the pressure. We are going to prove the following.

PROPOSITION 6.6. *Assume that the hypotheses* (3.11)-(3.13) *hold and that* $\varphi_0, \psi_0 \in H^2$. *Then there exists a unique weak solution of* (6.3) *on* $\mathbb{R}\times\mathbb{R}_+$.

If moreover the hypotheses (3.14) *and* (3.15) *hold, there exists a unique smooth solution of* (6.3) *on* $\mathbb{R}\times\mathbb{R}_+$.

Proof. (a) If p is a solution of (6.3), we get from (6.4) and Lemma 6.4:

$$p_x = -\Theta_{xt} - \int_{-\infty}^{x} \Omega_t,$$

whence:

$$p = -\Theta_t - \int_{-\infty}^{x} \left[dy \int_{-\infty}^{y} \Omega_t \right],$$

or

$$p(x,t) = -\Theta_{xx}(x,t) - \Omega(x,t) - \int_{-\infty}^{x} \left[dy \int_{-\infty}^{y} \Omega_t(z,t)\, dz \right] \tag{6.8}$$

because of the boundary condition (6.3b).

Therefore, we need to prove that the last integral does exist when the assumptions (3.11)-(3.13) hold. This amounts to showing that $\Omega_t(y,t)$ vanishes at $-\infty$ at least as fast as some negative power of y. More precisely, we are going to show that:

$$\exists \varepsilon > 0, \quad \forall y < 0, \quad \int_{-\infty}^{y} |\Omega_t| \leqq \frac{1}{|y|^{1+\varepsilon}}. \tag{6.9}$$

We first need to introduce the functional space:

$$W_\nu = \{ w \in L^2 \cap L^\infty, \max_{y \in \mathbb{R}^*_-} |y^\nu w(y)| < +\infty \}$$

for $\nu > 0$, with the norm: $\|w\|_{W_\nu} = \|w\|_2 + \|w\|_\infty + \|y^\nu w\|_{L^\infty(\mathbb{R}^*_-)}$, and to state the next lemma, which is proved at the end of this section.

LEMMA 6.7. *Let* $\nu > 0$ *be given. If* $\varphi_0 \in W_\nu$, *then* $\varphi(t) \in W_\nu$ *for any* $t > 0$.

We now have:

$$|\Omega_t| = |Y^n f'(\Theta)\Theta_t + nY^{n-1} Y_t f(\Theta)| \leqq |f'(\Theta)||\Theta_t| + n|Y_t||f(\Theta)|.$$

Let $T > 0$ and $M = \max_{t\in[0,T]} \|\Theta(t)\|_\infty$. Since $(\Theta_t, Y_t) \in C([0,T], L^2 \times L^2)$, we can set $M' = \max_{t\in[0,T]} \|\Theta_t(t)\|_2$. For $t \in [0,T]$ and $y < 0$ we have:

$$\int_{-\infty}^{y} |f'(\Theta)||\Theta_t| \leqq \left[\int_{-\infty}^{y} f'(\Theta)^2 \right]^{1/2} \left[\int_{-\infty}^{y} \Theta_t^2 \right]^{1/2}$$

by the Cauchy-Schwarz inequality. Hence, using (6.7):

$$\int_{-\infty}^{y} |f'(\Theta)||\Theta_t| \leqq M' K_M \left[\int_{-\infty}^{y} \Theta^{2\beta} \right]^{1/2}.$$

As $\varphi_0 \in W_\mu$ with $\beta\mu > 3/2$ from (3.13), we can apply Lemma 6.7 to get:

$$\int_{-\infty}^{y} |f'(\Theta)||\Theta_t| \leqq K \left[\int_{-\infty}^{y} \frac{dz}{|z|^{2\beta\mu}} \right]^{1/2} \leqq \frac{K}{|y|^{\beta\mu - 1/2}}.$$

Since (6.7) implies $f(\Theta) \leqq K'_M \Theta^{\beta+1}$ we can argue in the same way for $\int_{-\infty}^{y} |f(\Theta)||Y_t|$ and (6.9) holds.

(b) It is straightforward to check that p defined by (6.8) is a solution of (6.3a) in the sense of $D'(\mathbb{R}\times\mathbb{R}_+)$ (it suffices to argue as in Remark 5.5 and to use Lemma 6.3 for the continuity of u in the neighbourhood of $t=0$). (u, p) is the unique *weak solution* of (6.3) in the sense of Definition 3.1. Furthermore, if (3.14) and (3.15) hold, (6.3a) is fulfilled in the classical sense and p is a *smooth solution* of (6.3). □

It remains now to prove Lemma 6.7. We begin the proof with a property of the linear semigroup $S(t)$ generated by the heat operator (see the end of § 4).

LEMMA 6.8. *Let $\nu>0$. The operator $S(t)$ maps W_ν into itself: for any $T>0$, there exists a positive constant M_T such that:*

$$\forall w_0\in W_\nu,\quad \forall t\in[0,T],\quad \|S(t)w_0\|_{W_\nu}\leqq M_T\|w_0\|_{W_\nu}.$$

Proof. Let $\nu>0$, $w_0\in W_\nu$, $T>0$, $t\in[0,T]$. Lemma 4.6 implies:

$$\|S(t)w_0\|_2+\|S(t)w_0\|_\infty\leqq\|w_0\|_2+\|w_0\|_\infty.$$

Therefore it remains to study $\|y^\nu S(t)w_0\|_{L^\infty(\mathbb{R}^*_\pm)}$.

Let $x<0$; we have from (4.5):

$$|x|^\nu S(t)w_0(x)=\frac{|x|^\nu}{\sqrt{4\pi t}}\int_{-\infty}^{x/2}w_0(y)\,e^{-|x-y|^2/4t}\,dy+\frac{|x|^\nu}{\sqrt{4\pi t}}\int_{x/2}^{+\infty}w_0(y)\,e^{-|x-y|^2/4t}\,dy.$$

Let us denote by $A(x)$ and $B(x)$ the two terms in the right-hand side of this relation. For $y\in(-\infty, x/2]$, we have:

$$|w_0(y)|\leqq\frac{\|w_0\|_{W_\nu}}{|y|^\nu}\leqq 2^\nu\frac{\|w_0\|_{W_\nu}}{|x|^\nu}.$$

Thus:

$$|A(x)|\leqq\frac{2^\nu}{\sqrt{4\pi t}}\|w_0\|_{W_\nu}\int_{\mathbb{R}}e^{-|x-y|^2/4t}\,dy=2^\nu\|w_0\|_{W_\nu}.$$

On the other hand, we also have:

$$|B(x)|\leqq\frac{|x|^\nu}{\sqrt{4\pi t}}\|w_0\|_\infty\int_{x/2}^{+\infty}e^{-|x-y|^2/4t}\,dy.$$

Setting $z=(y-x)/\sqrt{4t}$ and assuming $x<-4\sqrt{T}$, we obtain:

$$\begin{aligned}|B(x)|&\leqq\frac{|x|^\nu}{\sqrt{\pi}}\|w_0\|_\infty\int_{|x|/4\sqrt{t}}^{+\infty}e^{-z^2}\,dz\\&\leqq\frac{|x|^\nu}{\sqrt{\pi}}\|w_0\|_\infty\int_{|x|/4\sqrt{T}}^{+\infty}e^{-z^2}\,dz\leqq\frac{|x|^\nu}{\sqrt{\pi}}\|w_0\|_\infty\int_{|x|/4\sqrt{T}}^{+\infty}e^{-z}\,dz\\&\leqq\frac{|x|^\nu}{\sqrt{\pi}}e^{-|x|/4\sqrt{T}}\|w_0\|_\infty\leqq K\|w_0\|_\infty,\end{aligned}$$

and the proof is easily achieved. □

Proof of Lemma 6.7. Let $T>0$ and $M=\max_{t\in[0,T]}\|\Theta(t)\|_\infty$. For $t\in[0,T]$ we can write:

$$\begin{aligned}\|\Omega\|_\infty&\leqq C_f\|\Theta\|_\infty\leqq C_fM,\\\|\Omega(t)\|_2^2&\leqq\|\Omega(t)\|^2_{L^2(-\infty,-1)}+\|\Omega(t)\|^2_{L^2(-1,+1)}+\|\Omega(t)\|^2_{L^2(1,\infty)}\\&\leqq C_f^2\|\varphi(t)\|_2^2+2C_f^2M^2+C_f^2M^2\|\psi(t)\|_2\leqq K,\\\|y^\nu\Omega(t)\|_{L^\infty(\mathbb{R}^*_\pm)}&\leqq C_f\|y^\nu\Theta(t)\|_{L^\infty(\mathbb{R}^*_\pm)},\end{aligned}$$

whence: $\|\Omega(t)\|_{W_\nu}\leqq K(\|\varphi(t)\|_{W_\nu}+1)$, where K is a positive constant.

From (4.4) and (5.5), we have:

$$\varphi(t) = S(t)\varphi_0 + \int_0^t S(t-s)[\Omega(s) + \gamma_{xx}]\, ds.$$

Applying Lemma 6.8 yields:

$$\|\varphi(t)\|_{W_\nu} \leqq M_T \|\varphi_0\|_{W_\nu} + M_T \int_0^t \|\Omega(s) + \gamma_{xx}\|_{W_\nu}\, ds$$

$$\leqq K\left[1 + \int_0^t \|\varphi(s)\|_{W_\nu}\, ds\right].$$

It suffices now to apply Gronwall's lemma and the proof is complete. □

7. Back transformation to the Eulerian variables. We now want to show that the results of the preceding sections make it possible to show the existence of a solution for the Eulerian system (3.4), (3.5). Since the equivalence between *smooth solutions* of the two systems (3.1)–(3.3) and (3.4), (3.5) follows immediately from § 2, we only have to investigate the existence and uniqueness of a *weak solution* of (3.4), (3.5).

7.1. Coordinate transformation. We first need to study the change of variables between the Lagrangian and the Eulerian system. This is the aim of the next two lemmas.

LEMMA 7.1. *Assume that the hypotheses* (3.11), (3.13) *hold and let* (Θ, Y, ρ, u) *be the unique weak solution of* (3.1), (3.2). *Consider the mapping*:

$$T_{LE}: \left| \begin{array}{l} \mathbb{R}\times\mathbb{R}_+ \to \mathbb{R}\times\mathbb{R}_+, \\ (x, t) \to (\xi, \tau) \text{ defined as}: \end{array} \right.$$

$$\xi(x, t) = \int_0^t u(0, t')\, dt' + \int_0^x \frac{1}{\rho(x', t)}\, dx', \qquad \tau(x, t) = t. \tag{7.1}$$

T_{LE} is a bijection from $\mathbb{R}\times\mathbb{R}_+$ into itself. Furthermore, $T_{LE} \in C^1(\mathbb{R}\times\mathbb{R}_+^*, \mathbb{R}\times\mathbb{R}_+^*)$ and:

$$\xi_x(x, t) = \frac{1}{\rho(x, t)}, \qquad \xi_t(x, t) = u(x, t). \tag{7.2}$$

Proof. Since $u(0, t)$ and $1/\rho(x, t)$ are continuous functions on $\mathbb{R}\times\mathbb{R}_+$, the relations (7.1) define a mapping from $\mathbb{R}\times\mathbb{R}_+$ into itself. Moreover, we have $\xi_x = 1/\rho$ and, for $t > 0$:

$$\xi(x, t) = \int_0^t u(0, t')\, dt' + \int_0^x [\Theta(x', t) + \alpha]\, dx'.$$

It is clearly possible to differentiate under the second integral sign in this expression to get:

$$\xi_t(x, t) = u(0, t) + \int_0^x \Theta_t(x', t)\, dx' = u(0, t) + \int_0^x u_x(x', t)\, dx' = u(x, t).$$

On the other hand, we can easily define $T_{EL} = T_{LE}^{-1}$ by setting $T_{EL}(\xi, \tau) = (x, t)$ with:

$$x(\xi, \tau) = \int_{\xi_0(\tau)}^{\xi} \rho(\xi', \tau)\, d\xi', \qquad t(\xi, \tau) = t \tag{7.3}$$

where $\xi_0(\tau) = \int_0^\tau u(0, \tau')\, d\tau' [= \xi(0, \tau)]$. The end of the proof is now obvious and is omitted. □

We can use this lemma to define the following transformation: for any $\eta \in L^\infty_{\text{loc}}(\mathbb{R}\times\mathbb{R}_+)$ we define $\hat\eta \in L^\infty_{\text{loc}}(\mathbb{R}\times\mathbb{R}_+)$ by:

$$\hat\eta(\xi,\tau) = \eta[T_{EL}(\xi,\tau)] = \eta[x(\xi,\tau),\tau]. \tag{7.4}$$

We can then state the following.

LEMMA 7.2. *Assume that the hypotheses* (3.11)-(3.13) *hold and consider the transformation* $\eta \to \hat\eta$ *defined by* (7.4). *The following properties hold for* $p \in [1,+\infty]$ *and* $t_0 \in \mathbb{R}_+$:

$$\text{If } \eta \in C(\mathbb{R}_+, L^p) \quad \text{then } \hat\eta \in C(\mathbb{R}_+, L^p),$$
$$\text{If } \eta \in C(\mathbb{R}_+, C(\mathbb{R})) \quad \text{then } \hat\eta \in C(\mathbb{R}_+, C(\mathbb{R})),$$
$$\text{If } \eta(\pm\infty, t_0) = \eta_0 \quad \text{then } \hat\eta(\pm\infty, t_0) = \eta_0.$$

Moreover, similar properties hold for the derivatives:

$$\text{If } \eta \in C(\mathbb{R}_+, H^2) \quad \text{then } \hat\eta \in C(\mathbb{R}_+, H^2),$$
$$\text{If } \eta \in C(\mathbb{R}_+, C^2(\mathbb{R})) \quad \text{then } \hat\eta \in C(\mathbb{R}_+, C^2(\mathbb{R})),$$
$$\text{If } \eta \in C^1(\mathbb{R}_+, C(\mathbb{R})) \quad \text{then } \hat\eta \in C^1(\mathbb{R}_+, C(\mathbb{R})).$$

Proof. These properties are easy to check and their proofs are omitted. We simply indicate the expressions of the partial derivatives of η and $\hat\eta$ which will be useful in the sequel; (7.2) and (7.4) obviously imply:

$$\hat\eta_\xi = \rho\eta_x, \qquad \hat\eta_\tau = -\rho u\eta_x + \eta_t,$$
$$\eta_x = \frac{1}{\hat\rho}\hat\eta_\xi, \qquad \eta_t = \hat\eta_\tau + \hat u\hat\eta_\xi. \qquad \square$$

7.2. Equivalence between the Lagrangian and Eulerian formulations. We can now show the existence of a weak solution to the Eulerian system (3.4), (3.5).

PROPOSITION 7.3. *Assume that the assumptions* (3.11)-(3.13) *hold. Let* (Θ, Y, ρ, u, p) *be the unique weak solution of* (3.1)-(3.3) *and define* $(\hat\Theta, \hat Y, \hat\rho, \hat u, \hat p)$ *using* (7.2). *Then* $(\hat\Theta, \hat Y, \hat\rho, \hat u, \hat p)$ *is a weak solution of* (3.4), (3.5).

Proof. We only sketch the proof by studying the temperature equation. The weak solution satisfies (see Remark 5.5):

$$\int_{\mathbb{R}\times\mathbb{R}_+} [-\Theta\eta_t + \Theta_x\eta_x - \Omega\eta] = \int_{\mathbb{R}} \Theta(\cdot,0)\eta(\cdot,0), \tag{7.5}$$

for any $\eta \in D(\mathbb{R}\times\mathbb{R}_+)$. This relation also holds for $\eta \in D^1(\mathbb{R}\times\mathbb{R}_+)[\eta \in C^1(\mathbb{R}\times\mathbb{R}_+)$ with compact support], since $D(\mathbb{R}\times\mathbb{R}_+)$ is dense in $D^1(\mathbb{R}\times\mathbb{R}_+)$.

Let $\hat\eta \in D(\mathbb{R}\times\mathbb{R}_+)$ and let η be the unique function such that $\eta(x,t) = \hat\eta[T_{LE}(x,t)]$. Since $\eta \in D^1(\mathbb{R}\times\mathbb{R}_+)$, (7.5) holds. Using the change of coordinates (7.1) in (7.5) gives:

$$\int_{\mathbb{R}\times\mathbb{R}_+} \left[-\hat\rho\hat\Theta(\hat\eta_\tau + \hat u\hat\eta_\xi) + \hat\rho\frac{\hat\Theta_\xi}{\hat\rho}\frac{\hat\eta_\xi}{\hat\rho} - \hat\rho\hat\Omega\hat\eta \right] = \int_{\mathbb{R}} \hat\rho(\cdot,0)\hat\Theta(\cdot,0)\hat\eta(\cdot,0),$$

where we have used the Jacobian $\partial(x,t)/\partial(\xi,\tau) = \rho$. The last relation, which is true for any $\hat\eta \in D(\mathbb{R}\times\mathbb{R}_+)$, says that:

$$(\hat\rho\hat\Theta)_\tau + (\hat\rho\hat u\hat\Theta)_\xi - \left(\frac{\hat\Theta_\xi}{\hat\rho}\right)_\xi = \hat\rho\hat\Omega,$$

in the sense of the distributions in $\mathbb{R}\times\mathbb{R}_+$. $\square$

To end the proof of Theorem 3.6, we still need the following lemma.

LEMMA 7.4. *There exists at most one weak solution* $(\hat\Theta, \hat Y, \hat\rho, \hat u, \hat p)$ *of* (3.4), (3.5) *satisfying*:

$$\hat u \in C(\mathbb{R}\times\mathbb{R}_+, \mathbb{R}), \qquad \hat\rho \in C(\mathbb{R}\times\mathbb{R}_+, \mathbb{R}). \tag{7.6}$$

Proof. Let $(\hat{\Theta}, \hat{Y}, \hat{\rho}, \hat{u}, \hat{p})$ be a *weak solution* of (3.4), (3.5). Thanks to (7.6), the transformations (7.3) and (7.4) can be used to show (exactly as in the proof of Proposition 7.3) that $(\hat{\Theta}, \hat{Y}, \hat{\rho}, \hat{u}, \hat{p})$ corresponds to a *weak solution* (Θ, Y, ρ, u, p) of (3.1)-(3.3); the uniqueness then follows from §§ 5 and 6. □

Remark 7.5. The uniqueness of a *weak solution* of (3.4), (3.5) can also be proven without (7.6). In this case, the equivalence between Lagrangian locally bounded *weak solutions* and Eulerian locally bounded *weak solutions* still holds, but is less simple to prove (see [13]).

8. Extension to chemically complex flames. In this section we extend our analysis to the equations of a chemically complex flame propagating in a dilute premixed gaseous mixture.

8.1. Physical assumptions. We will assume that the mixture is made up of N components $A_1, A_2 \cdots A_N$, whose mass fractions are respectively $Y_1, Y_2 \cdots Y_N$. The last species A_N is chemically inert and the reactants and products are highly diluted in a bath of A_N:

$$\sum_{s=1}^{N-1} Y_s \ll Y_N. \tag{8.1}$$

It therefore makes sense to consider that the specific heat c_p and the thermal conductivity λ of the mixture are those of the inert. Also assuming that the matrix of the diffusion coefficients is diagonal (the diffusion flux for the sth component only depends on ∇Y_s), we obtain that all the species have equal diffusivities (see [5, p. 8]), a fairly classical assumption.

Let M be the number of irreversible chemical reactions taking place in the mixture. From $1 \leqq r \leqq M$, the rth reaction can be written as:

$$\sum_{s=1}^{N-1} \nu_{rs} A_s \rightarrow \sum_{s=1}^{N-1} \mu_{rs} A_s,$$

where the stoicheometric coefficients ν_{rs} and μ_{rs} are positive integers (ν_{rs} (resp., μ_{rs}) is equal to zero if the species A_s is not a reactant (resp., a product) in the rth reaction). Let ω_r be the rate at which this reaction proceeds (a relation analogous to (2.2) gives ω_r as a function of the temperature and the mass fractions Y_s).

We can now write the governing equations of the propagation of this chemically complex flame under the form:

$$\begin{aligned}
&\rho_\tau + (\rho u)_\xi = 0,\\
&\rho u_\tau + \rho u u_\xi = -p_\xi,\\
&\rho c_p T_\tau + \rho u c_p T_\xi - (\lambda T_\xi)_\xi = \sum_{r=1}^{M} Q_r \omega_r,\\
&\rho (Y_s)_\tau + \rho u (Y_s)_\xi - (\rho D (Y_s)_\xi)_\xi = m_s \sum_{r=1}^{M} (\mu_{rs} - \nu_{rs}) \omega_r \quad \text{for } 1 \leqq s \leqq N,\\
&\sum_{s=1}^{N} Y_s = 1,
\end{aligned} \tag{8.2}$$

$$\rho T = m_N \frac{P}{R}. \tag{8.3}$$

We have defined $\nu_{rN} = \mu_{rN} = 0$ for all r. The heat released by the rth reaction, which is no more assumed to be exothermic, is denoted by Q_r, and m_s is the molecular mass of the sth species; the other notation are defined as in § 2.

Remark 8.1. The form $\rho T = m_N(P/R)$ of the equation of state follows from the assumption (8.1). The perfect gas law gives the value $P_s = RT(\rho Y_s/m_s)$ for the partial pressure of each species. Using Dalton's law we get $P = \rho RT \sum_{s=1}^{N} (Y_s/m_s)$ for the total pressure P, and this last expression reduces to (8.3) in view of (8.1).

Assuming again that the Lewis number $\mathrm{Le} = \lambda/\rho c_p D$, the specific heat c_p and the ratio λ/T are constant, we can write a Eulerian and a Lagrangian normalized form of (8.2), (8.3) as follows:

$$
(8.4)\quad \begin{cases}
\rho_\tau + (\rho u)_\xi = 0, \\
(\rho u)_\tau + (\rho u^2)_\xi = -p_\xi, \\
(\rho\Theta)_\tau + (\rho u\Theta)_\xi - \left(\dfrac{\Theta_\xi}{\rho}\right)_\xi = \displaystyle\sum_{r=1}^{M} Q_r \rho \Omega_r, \\
(\rho Y_s)_\tau + (\rho u Y_s)_\xi - \dfrac{1}{\mathrm{Le}}\left[\dfrac{(Y_s)_\xi}{\rho}\right]_\xi = m_s \displaystyle\sum_{r=1}^{M} (\mu_{rs} - \nu_{rs})\rho\Omega_r \quad \text{for } 1 \leqq s \leqq N, \\
\displaystyle\sum_{s=1}^{N} Y_s = 1, \\
(\Theta + \alpha)\rho = 1.
\end{cases}
$$

$$
(8.5)\quad \begin{cases}
\Theta_t - \Theta_{xx} = \displaystyle\sum_{r=1}^{M} Q_r \Omega_r, \\
(Y_s)_t - \dfrac{(Y_s)_{xx}}{\mathrm{Le}} = m_s \displaystyle\sum_{r=1}^{M} (\mu_{rs} - \nu_{rs})\Omega_r \quad \text{for } 1 \leqq s \leqq N, \\
\displaystyle\sum_{s=1}^{N} Y_s = 1, \\
(\Theta + \alpha)\rho = 1, \\
u_x = \Theta_t, \\
u_t + p_x = 0.
\end{cases}
$$

The following boundary conditions are associated with the above systems:

$$
\begin{aligned}
&\Theta(-\infty) = 0, && \Theta(+\infty) = 1, \\
&Y_s(-\infty) = Y_{su}, && Y_s(+\infty) = Y_{sb}, \\
&u(-\infty) = u^0, && p(-\infty) = 0.
\end{aligned}
$$

Let us denote $\Omega_r = \prod_{s=1}^{N-1} Y_s^{\nu_{rs}} f_r(\Theta)$. Since we use time-independent boundary conditions, we have to assume that the two thermochemical states prescribed at the boundaries $-\infty$ and $+\infty$ correspond to equilibria, i.e.:

$$
\forall r \in \{1, 2 \cdots M\}, \quad f_r(0) = 0,
$$

$$
\forall r \in \{1, 2 \cdots M\}, \quad \prod_{s=1}^{N-1} Y_{sb}^{\nu_{rs}} = 0.
$$

It is then straightforward to extend to systems (8.4) and (8.5) the results stated in § 3 (with a change of unknowns similar to (5.3) and assumptions analogous to (3.9)-(3.15)). Stating in detail the hypotheses and the theorems would be too long, but there appears to be no new difficulty in applying the arguments of §§ 5-7 to systems (8.4) and (8.5).

Remark 8.2. The global existence and uniqueness results stated in § 3 are also easily extended to the case of the nonadiabatic propagation of a planar flame. In this case, the energy balance equation (2.3b) becomes:

$$\rho c_p T_\tau + \rho u c_p T_\xi - (\lambda T_\xi)_\xi = Q\omega(Y, T) - \kappa(T),$$

where $\kappa(T) \geqq 0$ represents the heat losses (see [5]; for instance $\kappa(T) \equiv k(T - T_{\text{ref}})$ if only conductive heat losses are considered). In Lagrangian coordinates, the energy equation (2.10a) reads as:

$$\Theta_t = \Theta_{xx} + \Omega(Y, \Theta) - \hat{\kappa}(\Theta),$$

with $\hat{\kappa}(\Theta) \geqq 0$, $\hat{\kappa}(0) = 0$, and the arguments presented in §§ 5 and 6 apply.

THE ACOUSTIC APPROXIMATION FOR COMPRESSIBLE FLOW IN THE PRESENCE OF A SURFACE UNDERGOING SMALL AMPLITUDE VIBRATIONS*

JEFFERY COOPER†

Abstract. Existence and uniqueness for short time is proved for the solutions of compressible isentropic flow in a bounded region with a moving boundary. These solutions have an asymptotic expansion in η, the amplitude of the boundary motion, as $\eta \to 0$. The leading term in this expansion is a constant flow in a fixed region, and the second term is a solution of the linear acoustic equations in the fixed region which satisfies an inhomogeneous boundary condition.

Key words. acoustics, moving boundary

AMS(MOS) subject classification. 35

1. Introduction. In this paper we shall make a rigorous derivation of the equation and boundary conditions which describe the acoustic waves produced and reflected by a vibrating surface when the amplitude of the vibrations is small. The sound waves produced by a loudspeaker are a typical example of this situation.

In most engineering textbooks, e.g., [3, p. 100], the derivation begins with the linear wave equation for the velocity potential, $\phi(x, t)$, $x \in \mathbb{R}^3$, $t \in \mathbb{R}$. Denote the moving 2-dimensional surface by $S(t)$ and assume that $S(t) = S_0 + r(t)$ where S_0 is a fixed surface and $r(t)$ is a displacement vector. Then the usual acoustic boundary condition would be

$$\frac{\partial \phi}{\partial n} = n \cdot \partial_t r \quad \text{on } S(t). \tag{1.1}$$

This boundary condition, however, leads to an ill-posed problem for the linear wave equation [1]. Acoustic engineers have found that the "correct" boundary condition for the linear wave equation is obtained by assuming that $S(t)$ oscillates about S_0 and that the wavelength of sound is much longer than the amplitude of the oscillations of $S(t)$. One then requires that

$$\frac{\partial \phi}{\partial n} = n \cdot \partial_t r \quad \text{on } S_0. \tag{1.2}$$

Recent work by Majda [2] and Schochet [5] for the nonlinear equations of compressible flow allow us to make a more systematic derivation of this boundary condition. In § 2 we prove the short-time existence of solutions of the equations of an isentropic, compressible gas in three space dimensions in a bounded region with a moving boundary. The boundary condition is that particles of the gas do not cross the moving boundary surface.

In § 3 we introduce a small parameter η which is a measure of the amplitude of the boundary motion. We then rigorously prove in Theorem 2 that the solution U_η of the nonlinear equations has an asymptotic expansion

$$U_\eta = U_0 + \eta U_1 + o(\eta) \quad \text{as } \eta \to 0$$

* Received by the editors September 2, 1986; accepted for publication (in revised form) January 23, 1987.

where U_0 is the state of zero velocity and constant density, and U_1 is the solution of the linearized acoustic equation with the boundary condition

$$n \cdot U_1 = n \cdot \partial_t r \quad \text{on } S_0.$$

When a velocity potential ϕ is introduced, this is precisely (1.2).

2. Nonlinear equations. For each $t \geqq 0$, let $\Omega(t)$ be a smoothly bounded open set of $\mathbb{R}^3$ with $\bar{\Omega}(t)$ compact. We set

$$Q = \bigcup_{t>0} \Omega(t) \times \{t\} \quad \text{and} \quad \Sigma = \bigcup_{t \geqq 0} \partial\Omega(t) \times \{t\}.$$

Set $Q_T = Q \cap \{0 < t < T\}$ and $\Sigma_T = \Sigma \cap \{0 \leqq t \leqq T\}$. The smoothness of the motion of the $\Omega(t)$ will come from assuming that there is a fixed, bounded, open set $\tilde{\Omega} \subset \mathbb{R}^3$, with $\partial\tilde{\Omega}$ smooth and a family of smooth mappings $x \to \phi(x, t) : \Omega(t) \to \tilde{\Omega}$, with inverse $y \to \psi(y, t) : \tilde{\Omega} \to \Omega(t)$, such that $(y, t) \to (\psi(y, t), t)$ extends to a diffeomorphism of an open neighborhood of $\tilde{\Omega} \times [0, \infty)$ onto an open neighborhood of $\bar{Q}$. $v = \partial_t \psi(\phi(x, t), t)$ is the velocity at a point $(x, t) \in \bar{Q}$, and we assume that

$$\sup_{\tilde{\Omega} \times [0, \infty)} |\partial_t \psi| < \infty. \tag{2.1}$$

Finally, we let $\nu = (\nu_x, \nu_t)$ be the space-time unit normal to Σ.

For a function $U : Q \to \mathbb{R}^p$, we shall let

$$\tilde{U}(y, t) = U(\psi(y, t), t)$$

when it is necessary to indicate that we are considering U in the coordinate system of $\tilde{Q}$. When no confusion will arise, we suppress the symbol $\tilde{}$ to simplify the notation.

We shall need the following spaces. $H^s(\tilde{\Omega})$, $s \geqq 0$, will denote the usual Sobolev space. Let $X_{m,T}$ be the space of functions U on Q such that

$$\tilde{U} \in \bigcap_{j=0}^{m} C^j([0, T]; H^{m-j}(\tilde{\Omega})).$$

We set

$$|||U(t)|||_m^2 = |||\tilde{U}(t)|||_m^2 = \sum_{j=0}^{m} \|\partial_t^j \tilde{U}(t)\|_{H^{m-j}(\tilde{\Omega})}^2$$

and give $X_{m,T}$ the norm

$$|||U|||_{m,T} = \sup_{0 \leqq t \leqq T} |||U(t)|||_m.$$

Finally, we let $Y_{\delta,T}$ $(0 < \delta < 1)$ denote the space of functions U on Q such that

$$\tilde{U} \in \bigcap_{j=0}^{2} C^j([0, T]; H^{3-\delta-j}(\tilde{\Omega}))$$

with the obvious norm.

Now we are ready to consider the following initial-boundary value problem in Q for the Euler equations of isentropic compressible flow:

$$\begin{aligned} &\partial_t \rho + (u \cdot \nabla)\rho + \rho(\nabla \cdot u) = 0 \\ &\rho[\partial_t u + (u \cdot \nabla)u] + c^2(\rho)\nabla\rho = 0 \end{aligned} \quad \text{in } Q, \tag{2.2}$$

$$\nu_t + \nu_x \cdot 4u = 0 \quad \text{on } \Sigma, \tag{2.3}$$

$$u(x, 0) = u_0(x), \quad \rho(x, 0) = \rho_0(x) \quad \text{in } \Omega(0). \tag{2.4}$$

Here ρ is the density and $u=(u_1, u_2, u_3)$ the velocity. If $P(\rho)$ denotes the pressure, then $c^2(\rho)=dP/d\rho$ is the sound speed. We assume that $c^2(\rho)$ is a smooth, increasing function of ρ with $c^2(\rho)>0$ for $\rho>0$. The model case is that of an ideal gas in which $P(\rho)=A\rho^\gamma$, with $A>0$ and $\gamma>1$. The boundary condition (2.3) means that the velocity of the fluid is tangential to Σ. That is, fluid particles do not cross the moving boundary surface.

We shall write the system (2.2) more concisely as

$$L(U)U=0 \tag{2.5}$$

where $U=(\rho, u)$. When we wish to study the equation in the coordinates of $\tilde{Q}$, we shall write it as

$$\tilde{L}(\tilde{U})\tilde{U}=0. \tag{2.6}$$

Before stating the existence theorem, we make the following assumptions about the initial data ρ_0 and u_0:

$$\rho_0, u_0 \in H^3(\Omega(0)), \tag{2.7}$$

(2.8) There is a constant $k_0>0$ such that $\rho_0(x)\geqq k_0$ in $\Omega(0)$.

Condition (2.8) makes sense because the Sobolev inequality in three dimensions ensures that functions in $H^3(\Omega(0))$ are continuous.

We must assume a compatibility condition of the initial date with the boundary condition at $t=0$. Using the equation (2.6), and the initial data $\tilde{U}_0=(\tilde{\rho}_0, \tilde{u}_0)$, one can calculate the putative derivates,

$$\text{“}\partial_t^i\tilde{U}(0)\text{”} \quad \text{for } i=0, 1, 2,$$

as in the Cauchy–Kowaleskaya Theorem. In fact, from (2.7) and the smoothness of the nonlinear functions of $\tilde{L}$, one can deduce that “$\partial_t^i\tilde{U}(0)$”$\in H^{3-i}(\tilde{\Omega})$ for $i=0, 1, 2$. Thus it makes sense to consider the restriction of “$\partial_t^i\tilde{U}(0)$” to $\partial\tilde{\Omega}$.

For a vector field $u:\bar{Q}\to\mathbb{R}^3$ we set $(\nu_t+\nu_x\cdot u)^{\sim}=(\nu_t+\nu_x\cdot u)(\psi(y, t), t)$. Then for all $y\in\partial\tilde{\Omega}$ we assume that the data ρ_0 and u_0 satisfy

$$\partial_t^i(\nu_t+\nu_x\cdot u)^{\sim}\big|_{t=0}=0 \quad \text{for } i=0, 1, 2 \tag{2.9}$$

where we use the putative derivatives “$\partial_t^i\tilde{U}(0)$” to evaluate (2.9).

Remark. In the original coordinates of Q, the condition (2.9) can be expressed as follows:

$$\partial_\tau^i(\nu_t+\nu_x\cdot u)\big|_{t=0}=0 \quad \text{for } i=0, 1, 2$$

where $\partial_\tau=\partial_t+\partial_t\psi\cdot\nabla$ is a tangential derivative to Σ.

THEOREM 1. *Assume that the initial data satisfy* (2.7), (2.8) *and* (2.9). *Then there is a* $T>0$ *such that there is a unique classical solution* $U=(\rho, u)$ *of* (2.2), (2.3) *and* (2.4) *on* Q_T. *T depends on* k_0, *on the* H^3 *norms of* (ρ_0, u_0) *and on the derivatives of* ψ *up to order* 3.

In addition, the solution $U\in Y_{\delta,T}\cap C^1(\bar{Q}_T)$ *for each* $\delta>0$ *and*

$$\partial_t^i\tilde{U}\in L^\infty(0, T; H^{3-j}(\tilde{\Omega}))$$

for $j=0, 1, 2, 3$.

The proof of Theorem 1 is only a slight modification of that of Schochet [5] for the initial-boundary value problem in a fixed domain. For completeness, we will sketch the several steps of the proof, and indicate where changes must be made to take the noncylindrical domain into account. For details we refer the reader to [5].

The first step is to approximate the initial data (ρ_0, u_0) by functions $(\rho_0^n, u_0^n) \in H^5(\Omega(0))$ such that

$$\text{(2.10)} \qquad \begin{aligned} &\text{(i)} \quad (\rho_0^n, u_0^n) \to (\rho_0, u_0) \quad \text{in } H^3(\Omega(0)), \\ &\text{(ii)} \quad u_0^n \text{ satisfies the compatibility condition (2.9) for } i = 0, 1, 2, 3. \end{aligned}$$

This can be done by the methods of [4].

The boundary condition (2.3) is characteristic for the equations (2.2). To apply the basic existence theorem in a bounded domain for quasilinear symmetric hyperbolic systems, we must add a term to the equations (2.2) which makes the boundary condition noncharacteristic. At the same time we must add a term to the right-hand side so that the initial data ρ_0^n and u_0^n still satisfy the compatibility conditions (2.9).

According to standard results on Sobolev spaces, there exists a function $Z^n \in H^5(Q)$ such that

$$\partial_t^k(\tilde{Z}_n)(0) = \text{“}\partial_t^k \tilde{u}^n(0)\text{”} \quad \text{for } 0 \leqq k \leqq 4.$$

We then consider the modified equations (for each $\varepsilon > 0$)

$$\text{(2.2)}_\varepsilon \qquad \begin{aligned} &\partial_t \rho + (u \cdot \nabla)\rho + \rho \cdot \nabla u = 0 \\ &\rho[\partial_t u + (u \cdot \nabla)u] + c^2(\rho)\nabla\rho + \varepsilon(\nu_x \cdot \nabla)u = \varepsilon(\nu_x \cdot \nabla)Z_n \end{aligned} \qquad \text{in } Q.$$

Here we have smoothly extended the vector field ν_x into Q.

We write the system $(2.2)_\varepsilon$ more compactly as

$$\text{(2.5)}_\varepsilon \qquad L_\varepsilon(U)U = \varepsilon\gamma_n, \qquad \gamma_n = (0, (\nu_x \cdot \nabla)Z_n).$$

Next we subtract off the nonhomogeneous boundary values. Set $\beta = (0, \partial_t\psi(\phi(x, t), t))$, and let $V = (\rho, v) = U - \beta$ so that $u = v + \partial_t\psi$. Then equation $(2.5)_\varepsilon$ becomes

$$\text{(2.11)} \qquad L_\varepsilon(V + \beta)V = F(\varepsilon, n)$$

where $F(\varepsilon, n) = \varepsilon\gamma_n - L_\varepsilon(V + \beta)\beta$.

The boundary and initial conditions are

$$\text{(2.12)} \qquad \nu_x \cdot v = 0 \quad \text{on } \Sigma,$$

$$\text{(2.13)} \qquad \rho(x, 0) = \rho_0^n(x), \quad v(x, 0) = v_0^n(x) - \partial_t\psi(\phi(x, 0), 0) \quad \text{in } \Omega(0).$$

We require v to satisfy the homogeneous boundary conditions (2.12) because $v + \partial_t\psi$ should satisfy (2.4) and $\nu_t + \nu_x \cdot \partial_t\psi = 0$ on Σ. The appropriate compatibility conditions on v are

$$\text{(2.14)} \qquad \partial_t^i(\nu_x \cdot v)^{\sim}|_{t=0} = 0, \qquad i = 0, 1, 2, 3.$$

These conditions are satisfied because the initial data u_0^n satisfies (2.9) for $i = 0, 1, 2, 3$.

If we multiply the first equation of $(2.2)_\varepsilon$ by $c^2(\rho)$ and the second by ρ, the system becomes symmetric hyperbolic. Then according to the existence theorem for symmetric hyperbolic quasilinear systems with noncharacteristic boundary, for each ε and n there exists a unique solution $V(\varepsilon, n) \in X_{4, T(\varepsilon, n)}$ of (2.11)–(2.13).

Our goal is to pass to the limit as $\varepsilon \to 0$ and $n \to \infty$. However, note that $|||V(\varepsilon, n)|||_{4, T(\varepsilon, n)}$ depends on $\|F(\varepsilon, n)\|_{H^4(\tilde{Q}_{T(\varepsilon, n)})}$, where $\tilde{Q}_T = \tilde{Q} \cap \{0 < t < T\}$. This norm, in turn, involves $\|Z_n\|_{H^5(\tilde{Q}_{T(\varepsilon, n)})}$. This latter norm may blow up as $u_0^n \to u_0$ in $H^3(\Omega(0))$. Thus for each $n = 1, 2, 3, \cdots$ we choose $\tilde{\varepsilon}(n)$ so that $\|F(\tilde{\varepsilon}(n), n)\|_{H^4(\tilde{Q}_{T(\varepsilon, n)})}$ remains bounded as $n \to \infty$. Finally, we set

$$\varepsilon(n) = \min\left\{\frac{1}{n}, \tilde{\varepsilon}(n)\right\}.$$

We shall write $V(n, t)$ for $V(\varepsilon(n), n, t)$, and $T(n)$ for $T(\varepsilon(n), n)$. When it is clear from context, we may suppress the index n for brevity.

By a continuation principle of [5], $V(n) \in X_{4,T}$ for any $T > 0$ such that $|||V(n, t)|||_3$ is bounded on $[0, T)$. Hence the desired convergence will follow provided that we can show there exists a $T > 0$ with $T(n) \geqq T$ for all n, and that

$$|||V(n)|||_{3,T} \leqq C \tag{2.15}$$

where C is independent of n.

We introduce the following auxilliary norms. For $\delta > 0$ sufficiently small, we set

$$Q_\delta(0, T) = \{(x, t) \in \bar{Q}(0, T): d(y = \phi(x, t), \tilde{\Sigma}) \leqq \delta\}.$$

Next, using suitable cutoff functions equal to 1 on neighborhoods of the boundary which cover Q_δ, we use local coordinates to define $|||V|||_{m,\tan}$. This norm contains no normal derivatives at the boundary Σ. On Q/Q_δ, $|||V|||_{m,\tan}$ and $|||V|||_m$ are equivalent.

Now for $U \in X_{3,T}$, $U = (\rho, u)$, we define

$$|||U(t)|||_{E_1}^2 = |||U(t)|||_2^2 + |||U(t)|||_{3,\tan}^2 + |||\nabla \times u|||_2^2.$$

Next we cover the boundary Σ_T by a finite family of sets $\hat{G}$ such that the image of $\hat{G}$ under the mapping $(x, t) \to (\phi(x, t), t)$ is a product set $\tilde{G} \times [0, T]$ where $\tilde{G}$ is open in $\mathbb{R}^3$. Furthermore, we assume that in each $\tilde{G}$, ψ can be expressed in local coordinates

$$x_1 = y_1, \quad x_2 = y_2, \quad x_3 = y_3 + l(y_1, y_2, t).$$

Set $\alpha(x_1, x_2, x_3, t) = x_3 - l(x_1, x_2, t)$.

In these local coordinates, $\Sigma \cap \hat{G} = \{y_3 = 0\}$ and $Q \cap \hat{G} = \{y_3 > 0\}$.

Next, for $U \in X_{3,T}$, $U = (\rho, u)$ and some $\hat{G}$, we consider

$$|||\partial_{y_3}(\rho, \nabla\alpha \cdot u)|||_{2,\hat{G}}$$

where $\nabla\alpha = (-\partial_{x_1} l, -\partial_{x_2} l, 1)$ and the seminorm is evaluated in the local coordinates of $\hat{G}$. Now we sum over the sets $\hat{G}$ and define

$$|||U(t)|||_{E_2}^2 = \sum_{\hat{G}} |||\partial_{y_3}(\rho, \nabla\alpha \cdot u)|||_{2,\hat{G}}^2.$$

The basic lemma for these norms is as follows.

LEMMA 1. *Assume δ so small that the sets $\hat{G}$ cover $Q_\delta(0, T)$. Then for $U \in X_{3,T}$*

$$|||U(t)|||_3 \leqq c(|||U(t)|||_{E_1} + |||U(t)|||_{E_2}). \tag{2.16}$$

The constant is independent of U, but depends on the choice of localizing sets. The proof is given in [5].

The proof of the estimate (2.15) can be organized into several lemmas. We shall use $H_1(s), H_2(s), \cdots, K_1(s), K_2(s), \cdots$, to denote positive, smooth increasing functions of $s \geqq 0$.

LEMMA 2. *Let $V(n) \in X_{4,T(n)}$ solve* (2.11), *$\varepsilon = \varepsilon(n)$. Then for each $n = 1, 2, 3, \cdots$,*

$$\frac{d}{dt}|||V(n, t)|||_{E_1}^2 \leqq H_1(|||V(n, t)|||_3), \qquad 0 \leqq t < T(n). \tag{2.17}$$

Proof. We can show that

$$\frac{d}{dt}|||V(n, t)|||_2^2 \leqq H_2(|||V(n, t)|||_3) \tag{2.18}$$

and

$$\frac{d}{dt}|||V(n, t)|||_{3,\tan}^2 \leqq H_3(|||V(n, t)|||_3) \tag{2.19}$$

using standard estimates for symmetric hyperbolic systems. In the case of (2.18), we do not make the usual integration by parts in the spatial variables.

The remaining term in the definition of $|||\ |||_{E_1}$ is $|||\nabla \times v|||_2$. Take the curl of the second equation of (2.11) and use the fact that $\nabla \times (\nabla \rho) = 0$. We deduce that $\nabla \times v$ satisfies

$$\rho[\partial_t(\nabla \times v) + (u \cdot \nabla)(\nabla \times v)] + \varepsilon(\nu_x \cdot \nabla)(\nabla \times v) = f \tag{2.20}$$

where f is a function of first derivatives of v and ρ. Because of the boundary condition satisfied by u, the left side of (2.19) is simply a transverse (to Σ) derivative in an exterior direction. Hence usual energy type estimates show that

$$\frac{d}{dt}|||\nabla \times v|||_2^2 \leqq H_4(|||V(n, t)|||_3) \tag{2.21}$$

for $0 \leqq t < T(n)$. We combine (2.18), (2.19) and (1.21) to arrive at (2.17).

When the boundary condition is noncharacteristic, it is possible, in an equation like (2.11), to solve for derivatives of V normal to Σ in terms of tangential derivates. However, in this case the boundary matrix of the system (2.2) has rank 2, so that we can only solve for normal derivatives of two components of V in (2.11) without obtaining terms of order $1/\varepsilon$. To see this, we change variables in (2.11) using the local coordinates of $\hat{G}$ introduced earlier. The first equation becomes

$$(\nabla \alpha \cdot u + \alpha_t)\partial_{y_3}\rho + \rho\partial_{y_3}(\nabla \alpha \cdot v) = f. \tag{2.22}$$

After changing variables, and taking scalar product with $\nabla \alpha$, the second equation becomes

$$\rho(\nabla \alpha \cdot u + \alpha_t)\partial_{y_3}(\nabla \alpha \cdot v) + c^2|\nabla \alpha|^2\partial_{y_3}\rho + \varepsilon(\nu_x \cdot \nabla \alpha)\partial_{y_3}(\nabla \alpha \cdot v) = g. \tag{2.23}$$

Here f and g contain terms which involve derivatives of ρ and v in the y_1, y_2, and t directions. Now

$$\nu = (\nabla \alpha, \alpha_t)(|\nabla \alpha|^2 + \alpha_t^2)^{-1/2}$$

so that

$$\nu_x \cdot \nabla \alpha = |\nabla \alpha|^2(|\nabla \alpha|^2 + \alpha_t^2)^{-1/2}.$$

We set $w = (\rho, (\nabla \alpha \cdot v))$. Then (2.22) and (2.23) can be written

$$\Lambda \partial_{y_3} w = (f, g)$$

where

$$\Lambda = \begin{bmatrix} \nabla \alpha \cdot u + \alpha_t & \rho \\ c^2|\nabla \alpha|^2 & \rho(\nabla \alpha \cdot u + \alpha_t) + \varepsilon|\nabla \alpha|^2(\alpha_t^2 + |\nabla \alpha|^2)^{-1/2} \end{bmatrix}.$$

We can solve for $\partial_{y_3} w$ provided $\det \Lambda \neq 0$. Now on the boundary Σ, we have $\nabla \alpha \cdot u + \alpha_t = 0$ because $(u, 1)$ is tangent to Σ. Furthermore, when $t = 0$, $\rho = \rho_0^n(x) \geqq k > 0$ on $\bar{\Omega}(0)$ for n sufficiently large because convergence in $H^3(\Omega(0))$ implies uniform convergence. Hence

$$\det \Lambda = -\rho c^2(\rho)|\nabla \alpha|^2 \leqq -kc^2(k) \equiv -\lambda_0 < 0$$

on $\partial\Omega(0)$ because $|\nabla \alpha|^2 = 1 + (\partial_{x_1} l)^2 + (\partial_{x_2} l)^2 \geqq 1$. For $(y, t) \in \tilde{Q}$,

$$|\tilde{\rho}(y, t) - \tilde{\rho}_0^n(y)| \leqq t \sup_{0 \leqq s \leqq t} |\partial_t \tilde{\rho}(y, s)| \tag{2.24}$$

so that

$$\tilde{\rho}(y, t) \geqq k - ct|||V|||_{3,t}$$

where c is independent of n, n sufficiently large.

Now the data u_0^n are bounded in $H^3(\Omega(0))$ so that $\sup_{\Omega(0)} |\nabla u_0^n|$ is bounded. For each n, u_0^n satisfies the boundary condition. Thus by choosing δ_* sufficiently small we can guarantee that $\sup_{Q_{\delta_*} \cap \{t=0\}} |\nabla \alpha \cdot u_0^n + \alpha_t| \leqq \varepsilon_1$ for any suitable ε_1. Choose ε_0 and ε_1 so that for $\varepsilon \leqq \varepsilon_0$, n sufficiently large, and $x \in Q_{\delta_*} \cap \{t=0\}$,

$$\det \Lambda < -\tfrac{1}{2}\lambda_0. \tag{2.25}$$

We assume further that δ_* is chosen so small that Q_{δ_*} is covered by the local coordinate neighborhoods $\hat{G}$. Then for points in $\hat{G}$,

$$\begin{aligned} |\nabla \alpha \cdot u + \alpha_t| &\leqq \varepsilon_1 + ct \sup_{0 \leqq s \leqq t} (|\partial_t^{\sim} u| + |\partial_t \alpha_t|) \\ &\leqq \varepsilon_1 + t[C_1|||V|||_{3,t} + C_2]. \end{aligned} \tag{2.26}$$

Combining (2.24), (2.25) and (2.26) we see that

$$\det \Lambda \leqq -\tfrac{1}{2}\lambda_0 + tK(|||V(n)|||_{3,t}). \tag{2.27}$$

We have thus proved the following.

LEMMA 3. *For each n sufficiently large, there is an $S(n)$, $0 < S(n) \leqq T(n)$ such that*

$$\det \Lambda \leqq -\tfrac{1}{4}\lambda_0 \quad \textit{for } 0 \leqq t \leqq S(n) \tag{2.28}$$

on Q_{δ_*}. $S(n)$ depends on $|||V(n)|||_{3,T(n)}$.

LEMMA 4. *For each n,*

$$\frac{d}{dt}|||V(n, t)|||_{E_1}^2 \leqq K_3(|||V(n, t)|||_{E_1}) \tag{2.29}$$

for $0 \leqq t < S(n)$. K_3 does not depend on n.

Proof. On $Q_{\delta_*} \cap \{0 \leqq t < S(n)\}$ we can solve (2.22) and (2.23) for $\partial_{y_3} w$ and thus arrive at the estimate

$$|||V(n, t)|||_{E_2} \leqq K_1(|||V(n, t)|||)_E \tag{2.30}$$

for $0 \leqq t < S(n)$. For details see Schochet [5]. Now combine (2.16), (2.17) and (2.30) to deduce (2.29).

Finally, to establish the uniform bound (2.15), we will use the following argument. Assume that $S(n) = \sup\{S: \det \Lambda(n, t) \leqq -\frac{1}{4}\lambda_0 \text{ on } [0, S)\}$. $S(n) \leqq T(n)$ where $[0, T(n))$ is the maximal interval of existence of $V(n)$. Suppose that $S(n) \to 0$ as $n \to \infty$. Now the differential inequality (2.29) implies that there is a uniform bound

$$|||V(n, t)|||_{E_1} \leqq C \tag{2.31}$$

on $0 \leqq t < S(n)$. From (2.16) and (2.30), we deduce that

$$|||V(n, t)|||_3 \leqq C \quad \text{for } 0 \leqq t < S(n). \tag{2.32}$$

Finally we insert (2.32) into (2.27) to deduce that

$$\det \Lambda(n, t) \leqq -\tfrac{1}{2}\lambda_0 + tK(C_1), \qquad 0 \leqq t < S(n).$$

But then $S(n) \to 0$ as $n \to \infty$ implies that $\det \Lambda(n, t) \leqq -(3/8)\lambda_0$ on $[0, S(n))$ for n sufficiently large. By continuity, we have $\det \Lambda(t, n) \leqq -\frac{1}{4}\lambda_0$ on some larger interval, which contradicts the maximality of $S(n)$.

The proof of Theorem 1 is completed exactly as in [5], in the coordinates of $\tilde{Q}$. We use (2.11) for indices n and m, to deduce

$$\begin{aligned}\tilde{L}_n(\tilde{V}(n)+\beta)[\tilde{V}(n)-\tilde{V}(m)]&\\ =[\tilde{L}_m(\tilde{V}(m)+\beta)-\tilde{L}_n(\tilde{V}(n)+\beta)]\tilde{V}(m)+\tilde{F}(n)-\tilde{F}(m)&\\ =[\tilde{L}_m(\tilde{V}(m)+\beta)-\tilde{L}_n(\tilde{V}(n)+\beta)](\tilde{V}(m)+\beta)+\varepsilon(n)\gamma_n-\varepsilon(m)\gamma_m&\end{aligned} \tag{2.33}$$

where we have used $F(n)$ to denote $F(\varepsilon_n, n)$ when $\varepsilon=\varepsilon(n)$.

Multiplication of (2.33) by $\tilde{V}(n)-\tilde{V}(m)$ and integration over $\tilde{\Omega}$, together with the Sobolev inequality and the bound (2.15) show that $\tilde{V}(n)$ converges in $C([0, T]; L^2(\tilde{\Omega}))$. Again using the bound (2.15) and an interpolation argument, we deduce that $\tilde{V}(n)$ converges in $Y_{\delta,T}$ for each $\delta>0$. This implies that $V(n)$ converges in $C^1(\bar{Q}_T)$, and hence converges to a solution of (2.2)-(2.4). The uniqueness of C^1 solutions is well known.

3. Small amplitude motion. Now consider the case of vanishingly small boundary motion. We assume that ψ has the form

$$\psi(y, t)=y+\eta r(y, t), \tag{3.1}$$

$$\sup_{\tilde{Q}}|\partial_t r(y, t)|<\infty \tag{3.2}$$

and $\eta>0$ is a small parameter. The boundary condition can be expressed as follows:

$$\nu_x\cdot(u-\eta\partial_t r)=0 \quad \text{on } \Sigma \tag{3.3}$$

because $\nu_t=-\nu_x\cdot\partial_t\psi=-\eta\nu_x\cdot\partial_t r$.

The initial conditions are more easily described in $\tilde{\Omega}$. We take initial data of the form

$$\tilde{\rho}_0(y)=\rho_0+\eta\tilde{f}(y) \tag{3.4}$$

where ρ_0 is a constant, $\rho_0>0$, and $\tilde{f}\in H^3(\tilde{\Omega})$. For the initial velocity we assume that

$$\tilde{u}_0(y)=\eta\tilde{g}(y, \eta) \tag{3.5}$$

where $\eta\to\tilde{g}(y, \eta)$ is continuous with values in $H^3(\tilde{\Omega})$ for $0\leqq\eta\leqq\eta_0$, some $\eta_0>0$. We assume that the compatibility condition (2.9) holds for each η, $0\leqq\eta\leqq\eta_0$.

By Theorem 1, for each $\eta>0$, there will exist a solution U_η of (2.2), (2.3) with initial data (3.4), (3.5). From the estimates of Theorem 1, we can see that there will be a common interval of existence $[0, T)$, $T>0$, for all $\eta\geqq 0$. For the purpose of this section, we write the system compactly as

$$L(U_\eta)U_\eta=0 \qquad \text{in } Q_T. \tag{3.6}$$

Now let $U_0(x, t)\equiv(\rho_0, 0)$ be the constant solution with $\eta=0$, and let $L_0\equiv L(U_0)$ be the operator of (3.6) with constant coefficients. The initial-boundary value problem for the linearized acoustic equations is ($U_1=(\rho_1, u_1)$):

$$L_0U_1=0 \quad \text{in } \tilde{Q}_T, \tag{3.7}$$

$$n\cdot(u_1(y, t)-\partial_t r(y, t))=0 \quad \text{for } y\in\partial\tilde{\Omega}, \tag{3.8}$$

$$U_1(y, 0)=(\tilde{f}(y), \tilde{g}(y)) \quad \text{in } \tilde{\Omega} \tag{3.9}$$

where $\tilde{g}(y) = \tilde{g}(y, \eta = 0)$. Here we use n as the exterior unit normal to $\partial\tilde{\Omega}$. The data $\tilde{g}(y)$ satisfies the compatibility condition

$$\partial_t^i (n \cdot u_1 - \tilde{g})|_{t=0} = 0 \quad \text{for } i = 0, 1, 2. \tag{3.10}$$

The putative derivatives "$\partial_t^i u(0)$" as computed from (3.7) are used to evaluate (3.10).

We are ready to state our main result.

THEOREM 2. *Let U_η be the solution of* (3.6). *Then the solution U_1 of* (3.7), (3.8) *and* (3.9) *lies in $X_{3,T}$ and*

$$U_\eta = U_0 + \eta U_1 + o(\eta) \quad \text{as } \eta \downarrow 0. \tag{3.11}$$

The convergence takes place in $Y_{\delta,T} \cap C^1(\bar{\tilde{Q}}_T)$ for each $\delta > 0$.

Proof. To see that $U_1 \in X_{3,T}$, apply the existence theory of § 2 to the linearized equation (3.7). Since the boundary data are smooth and the compatibility condition (2.9) is satisfied, we can conclude that $U_1 \in Y_{\delta,T}$ for each $\delta > 0$ and that

$$\partial_t^j U_1 \in L^\infty(0, T, H^{3-j}(\tilde{\Omega})), \qquad j = 0, 1, 2, 3.$$

However, multiplication of the first equation by $c^2(\rho_0)$ and the second by ρ_0 yields a symmetric hyperbolic system with constant coefficients and the theory of unitary groups may be used to improve the regularity to yield $U_1 \in X_{3,T}$.

Next we define $\hat{U}_\eta$ by setting $U_\eta = U_0 + \eta \hat{U}_\eta$. Then because U_0 is constant, $\hat{U}_\eta$ satisfies:

$$L(U_\eta)\hat{U}_\eta = 0 \quad \text{in } Q_T, \tag{3.12}$$

$$\nu_x \cdot (\hat{u}_\eta - \partial_t r) = 0 \quad \text{on } \Sigma_T, \tag{3.13}$$

$$\tilde{\hat{U}}_\eta(0) = (\tilde{f}(y), \tilde{g}(y, \eta)) \quad \text{in } \tilde{\Omega}, \tag{3.14}$$

$$\partial_t^i (\nu_x \cdot (\hat{u}_\eta - \partial_t r))\tilde{}\,|_{t=0} = 0, \qquad i = 0, 1, 2 \tag{3.15}$$

where "$\partial_t^i \tilde{\hat{U}}_\eta(0)$" is computed using (3.12).

If we write (3.12) as $L(U_0 + \eta\hat{U}_\eta)\hat{U}_\eta = 0$, we can apply the quasilinear theory of § 1 to deduce that

$$\hat{U}_\eta \quad \text{is bounded in } Y_{\delta,T} \tag{3.16}$$

independent of $\eta > 0$. It follows that

$$U_\eta \to U_0 \quad \text{as } \eta \to 0 \quad \text{in } Y_{\delta,T}. \tag{3.17}$$

To prove Theorem 2, we shall show that

$$\hat{U}_\eta \to U_1 \quad \text{in } Y_{\delta,T}. \tag{3.18}$$

From (3.7) and (3.12), we have that

$$L_0(U_1 - \hat{U}_\eta) = [L(U_\eta) - L_0]\hat{U}_\eta. \tag{3.19}$$

To find the boundary conditions satisfied by $U_1 - \hat{U}_\eta$, we introduce the 3×3 matrix

$$S_\eta = (\partial_x \phi_\eta)(x, t).$$

Then $S_\eta^\tau n = \lambda \nu_x$, where $\lambda = \lambda(\eta) > 0$. The boundary condition $\nu_x \cdot (\hat{u}_\eta - \partial_t r) = 0$ on Σ can be expressed as follows:

$$n \cdot S_\eta(\hat{u}_\eta - \partial_t r) = 0 \quad \text{on } \tilde{\Sigma}_T$$

to yield

$$n \cdot (u_1 - \hat{u}_\eta) = n \cdot (S_\eta - I)\hat{u}_\eta + n \cdot (I - S_\eta)\partial_t r \quad \text{on } \hat{\tilde{\Sigma}}_T. \tag{3.20}$$

The initial condition is

$$(U_1 - \hat{U}_\eta)(0) = (0, \tilde{g}(y, \eta = 0) - \tilde{g}(y, \eta)) \quad \text{in } \tilde{\Omega}. \tag{3.21}$$

Now we need to show that the right side of (3.19) tends to zero in $L^2(\tilde{Q}_T)$ as $\eta \to 0$. We shall need to write out the matrices of L:

$$\tilde{L}(U)V = A^0(U)\partial_t V + \sum_{j=1}^{3} A^j(U)\partial_{y_j} V.$$

Recalling that $L_0 V = L(U_0)V$, we see that for each t, $0 \leqq t \leqq T$

$$\begin{aligned}\|[L_0 - \tilde{L}(\tilde{U}_\eta)]\tilde{\hat{U}}_\eta\|_{L^2(\tilde{\Omega})} &\leqq \|A^0(U_0) - A^0(\tilde{U}_\eta)\|_{L^2(\tilde{\Omega})}\|\partial_t \tilde{\hat{U}}_\eta\|_{C^0} \\ &\quad + \sum_{j=1}^{3} \|A^j(U_0) - A^j(\tilde{U}_\eta)\|_{L^2(\tilde{\Omega})}\|\partial_{y_j}\tilde{\hat{U}}_\eta\|_{C^0} \\ &\leqq \text{Const.}\, \|U_0 - \tilde{U}_\eta\|_{L^2(\tilde{\Omega})}(\|\partial_t \tilde{\hat{U}}_\eta\|_{H^{2-\delta}} + \|\partial_{y_j}\tilde{\hat{U}}_\eta\|_{H^{2-\delta}})\end{aligned}$$

for some δ, $0 < \delta < \frac{1}{2}$. Then using (3.16) and (3.17) we see that in fact $[L_0 - L(\tilde{U}_\eta)]\tilde{\hat{U}}_\eta \to 0$ in $C([0, T]; L^2(\tilde{\Omega}))$.

The same bounds and the fact that $S_\eta \to I$ uniformly on $\tilde{\Sigma}_T$ imply that the right side of (3.20) converges to zero in $C([0, T]; H^1(\partial\hat{\Omega}))$. In addition, $\tilde{g}(y, \eta) \to \tilde{g}(y, 0)$ in $H^3(\tilde{\Omega})$ by hypothesis (3.5). Then by standard results for symmetric hyperbolic systems we deduce that

$$|||\hat{U}_\eta - U_1|||_{0,T} \to 0 \quad \text{as } \eta \to 0.$$

Since $\hat{U}_\eta - U_1$ is bounded in $Y_{\delta,T}$, we deduce by the usual interpolation argument that $\hat{U}_\eta - U_1 \to 0$ in $Y_{\delta',T}$ for each $\delta' > \delta$. This completes the proof of Theorem 2.

AN EXISTENCE THEOREM FOR SLIGHTLY COMPRESSIBLE MATERIALS IN NONLINEAR ELASTICITY*

P. CHARRIER†, B. DACOROGNA‡, B. HANOUZET† AND P. LABORDE†

Abstract. We show that if a hyperelastic material is slightly compressible, in this case the stored energy function is a function of the "modified invariants," then the existence results of Ball are still valid. We then study the behavior of the solutions when the compressibility tends to zero.

Key words. nonlinear elasticity, slightly compressible materials, polyconvexity, coercivity

AMS(MOS) subject classifications. 49, 73

Introduction. In an important article Ball [1] has established an existence theorem for nonlinear hyperelastic and compressible materials. Roughly speaking, it is shown that the problem

$$\text{(P)} \qquad \inf\left\{ I(u) = \int_\Omega W(\nabla u(x))\, dx,\ u = u_0 \text{ on } \partial\Omega_1,\ u \in W^{1,p}(\Omega; \mathbb{R}^3) \right\}$$

admits a solution; where $\Omega \subset \mathbb{R}^3$ is the reference configuration, $\partial\Omega_1$ is part of the boundary $\partial\Omega$, $u: \Omega \to \mathbb{R}^3$ and $\nabla u \in M^3_+$ (i.e., ∇u is a 3×3 matrix with $\det \nabla u > 0$), $W: M^3_+ \to \mathbb{R}$ is the stored energy function which is assumed to be *coercive* and *polyconvex* (for precise definitions see the next section).

In particular, if the material is isotropic then it is well known that W can be written as

$$W(F) = \Phi(i(F^T F)) \tag{0.1}$$

where $\Phi: (\mathbb{R}_+)^3 \to \mathbb{R}_+$ and $i(F)$ denotes the principal invariants of F, i.e., $i(F) = (i_1(F), i_2(F), i_3(F)) = (\operatorname{tr} F, \operatorname{tr}(\operatorname{adj} F), \det F)$.

It is the aim of this article to show that the theorem of Ball still holds, under some extra hypotheses, if one replaces the principal invariants by the so-called "modified invariants" i^* (cf. [7], [8]) defined as

$$i^*(F) = (i_1^*, i_2^*) = (i_1 i_3^{-1/3}, i_2 i_3^{-2/3}). \tag{0.2}$$

Let us be more precise and first explain the importance of the "modified invariants." In practice it is a hard problem to determine experimentally the function W (or Φ, if the material is isotropic) and for slightly compressible materials, one is led to proceed indirectly. One way of determining W may be as follows: first we make some experiments (such as simple traction, biaxial traction, simple shear, etc.) for which we can assume that the volume changes are negligible,

$$W^*(F) = W(F)_{|\det F = 1} \tag{0.3}$$

or for isotropic material

$$\Phi^*(i_1, i_2) = \Phi(i_1, i_2, 1).$$

* Received by the editors November 4, 1985; accepted for publication (in revised form) December 15, 1986.

However, since the material is actually slightly compressible, we assume that a strong pressure p leads to change of volumes and postulates that

$$p(\nabla u) = g(\det \nabla u). \tag{0.4}$$

It is then easy to show (cf. Proposition 1) that W must be in the following form:

$$W(F) = W^*((\det F)^{-1/3}F) + \int_1^{\det F} g(v)\, dv \tag{0.5}$$

or if the material is isotropic

$$\Phi(i_1, i_2, i_3) = \Phi^*(i_1^*, i_2^*) + \int_1^{\sqrt{i_3}} g(v)\, dv. \tag{0.5'}$$

However it is not obvious that such functions W (or Φ) remain *coercive* and *polyconvex* (the two crucial hypotheses in Ball's theorem). And indeed for the Mooney-Rivlin stored energy function $W^*(F) = \alpha|F|^2 + \beta|\text{adj } F|^2$, the polyconvexity is actually lost.

In the second section of this article we show (Theorem 5) that for a large class of materials including some of the Ogden materials (but not Mooney-Rivlin materials), W is coercive and polyconvex. Then, using the same techniques as in Ball [1], we show existence of minima when W satisfies (0.5).

In the last section we study the convergence of the minima when the compressibility tends to zero and, in particular, we show convergence to the incompressible case.

Finally, we should mention that this kind of rheology has been used for engineering purposes and for numerical computation of rubberlike materials; for more details we refer to Charrier and Pouyot [2] and Pouyot [9].

The article is divided as follows: § 1. Stored energy function of hyperelastic and slightly compressible materials; § 2. An existence theorem; § 3. Convergence to the incompressible case.

1. Stored energy function of hyperelastic and slightly compressible materials.

1.1. Notation. We start by recalling the usual framework of nonlinear elasticity (for references, see [10] or [3] for instance).

We denote by M^3 the set of 3×3 matrices and by

$$M^3_+ = \{A \in M^3 : \det A > 0\}. \tag{1.1}$$

We endow the space M^3 with the scalar product $A \cdot B = \text{tr}\,(AB^T)$ and we denote by $|A|$ the associated norm. We also denote by $i(A)$ the principal invariants of $A \in M^3$, i.e.,

$$i(A) = (i_1(A), i_2(A), i_3(A)) = (\text{tr } A, \text{tr (adj } A), \det A) \tag{1.2}$$

where adj A denotes the transpose of the matrix of cofactors of A.

Let $\Omega \subset \mathbb{R}^3$ be the reference configuration (Ω is a bounded open set), $u: \bar{\Omega} \to \mathbb{R}^3$ a deformation of the body satisfying $\det \nabla u > 0$, i.e., $F = \nabla u \in M^3_+$.

Let $T(u(x))$ be the Cauchy stress tensor defined on the deformed configuration $u(\bar{\Omega})$ and let $S(x)$ be the first Piola-Kirchhoff stress tensor defined as follows:

$$S(x) = \det(\nabla u(x))\, T(u(x))\, [(\nabla u(x))^T]^{-1}. \tag{1.3}$$

We also assume that the material under consideration is *hyperelastic* (and homogeneous), i.e., there exists $W: M^3_+ \to \mathbb{R}_+$ the *stored energy function* such that

$$S = W'(\nabla u) \tag{1.4}$$

where $W' \equiv (\partial W / \partial F_{i\alpha})_{1 \leqq i,\alpha \leqq 3}$.

The pressure is then equal to

$$p \equiv \tfrac{1}{3} \operatorname{tr} T = \tfrac{1}{3} (\det \nabla u)^{-1} W'(\nabla u) \cdot \nabla u. \tag{1.5}$$

If the material is also *isotropic* then W assumes the following form

$$W(\nabla u) = \Phi(i(\nabla u^T \nabla u)) \tag{1.6}$$

where $\Phi: (\mathbb{R}_+)^3 \to \mathbb{R}_+$.

As we mentioned in the Introduction, one way to construct the function Φ (or more generally W) is to determine at first

$$\Phi^*(i_1, i_2) = \Phi(i_1, i_2, 1) \tag{1.7}$$

(or $W^*(F) = W(F)_{|\det F = 1}$).

In the second step we postulate that pressure changes induce volume changes that are related in the following way:

$$p(\nabla u) \equiv g(\det \nabla u) \tag{1.8}$$

where $g: \mathbb{R}_+ \to \mathbb{R}_+$.

In Proposition 1 we show that relations (1.7) and (1.8) determine completely the function Φ (resp. W), once Φ^* (resp. W^*) and g are prescribed. And in fact we find

$$W(F) = W^*((\det F)^{-1/3} F) + G(\det F), \tag{1.9}$$

$$\Phi(i_1, i_2, i_3) = \Phi^*(i_3^{-1/3} i_1, i_3^{-2/3} i_2) + G(\sqrt{i_3}) \tag{1.9'}$$

where G is a primitive of g, i.e.,

$$G(x) = \int_1^x g(z)\, dz. \tag{1.10}$$

The identity (1.9') leads to the introduction of the so-called "*modified invariants*" (see Ogden [6], Penn [8])

$$i_1^* \equiv i_3^{-1/3} i_1 \quad \text{and} \quad i_2^* \equiv i_3^{-2/3} i_2. \tag{1.11}$$

1.2. Determination of the stored energy function. We can now state the proposition which shows (1.9) and (1.9').

PROPOSITION 1. *Part* 1. *Let* $W: M^3_+ \to \mathbb{R}_+$ *be differentiable and* $p: M^3_+ \to \mathbb{R}_+$ *be such that*

$$W'(F) \cdot F = 3 \det F p(F). \tag{1.12}$$

Let $g \in L^1_{\text{loc}}(0, +\infty)$. *The following conditions are then equivalent*:

(i) *For every* $F \in M^3_+$,

$$p(F) = g(\det F). \tag{1.13}$$

(ii) *There exists* $W^*: \{F \in M^3_+; \det F = 1\} \to \mathbb{R}_+$ *such that*

$$W(F) = W^*((\det F)^{-1/3} F) + \int_1^{\det F} g(z)\, dz. \tag{1.14}$$

Part 2. *Furthermore if* Φ *satisfies* (1.6) *then* (1.13) *is equivalent to the fact that there exists* $\Phi^*: \mathbb{R} \times \mathbb{R} \to \mathbb{R}_+$ *such that*

$$\Phi(i_1, i_2, i_3) = \Phi^*(i_1^*, i_2^*) + \int_1^{\sqrt{i_3}} g(z)\, dz \tag{1.14'}$$

where i_1^*, i_2^* *satisfy* (1.11).

Proof. Part 1. First suppose (ii). If W satisfies (1.14) then

$$\frac{d}{dt} W(tF)_{|t=1} = 3 \det F g(\det F)$$

and since (1.12) holds, we indeed have (1.13).

Conversely, assume that (i) holds and let

$$h(F) = W(F) - \int_1^{\det F} g(z)\, dz. \tag{1.15}$$

We then have

$$\begin{aligned} h'(F) \cdot F &= W'(F) \cdot F - (\operatorname{adj} F)^T F g(\det F) \\ &= 3 \det F(p(F) - g(\det F)) = 0. \end{aligned}$$

Therefore h is homogeneous of degree 0. Let W^* be the restriction of h on $\{F \in M^3 : \det F = 1\}$; then we immediately have (1.14). This completes Part 1.

Part 2. This is proved exactly in the same way. □

1.3. Choice of a rheology. We first start with a definition introduced by Ball [1].

DEFINITION. A function $W: M^3 \to \mathbb{R}_+$ is said to be *polyconvex* if there exists $w: M^3 \times M^3 \times \mathbb{R} \to \mathbb{R}_+$ convex, such that

$$W(F) = w(F, \operatorname{adj} F, \det F). \tag{1.16}$$

In the incompressible case a class of rheologies (i.e. stored energy functions) for isotropic materials is that of Ogden [6], where

$$W^*(F) = \sum_{i=1}^{M} a_i \operatorname{tr}(C^{\alpha_i/2}) + \sum_{i=1}^{N} b_i \operatorname{tr}((\operatorname{adj} C)^{\beta_i/2}) \tag{1.17}$$

where $C = F^T F$. If $a_i, b_i > 0$ and $\alpha_i, \beta_i \geqq 1$ then W^* defined as in (1.17) is polyconvex (cf. Ball [1]).

One can choose the coefficients in (1.17) such that W^* interpolate, with a reasonably good approximation, the experimental measurements.

We will also, marginally, consider W^* satisfying

$$W^*(F) = \sum_{i=1}^{M} a_i |F|^{\alpha_i} + \sum_{i=1}^{N} b_i |\operatorname{adj} F|^{\beta_i} \tag{1.17'}$$

with $a_i, b_i \geqq 0$ and $\alpha_i, \beta_i \geqq 1$, which is obviously polyconvex.

Note also that if $w^*: M^3 \times M^3 \to \mathbb{R}_+$ in (1.17) or (1.17') is such that

$$W^*(F) = w^*(F, \operatorname{adj} F) \tag{1.18}$$

then we have the following *coercivity* condition

$$w^*(F, G) \geqq K(|F|^\alpha + |G|^\beta) \tag{1.19}$$

where $K > 0$ is a constant and $\alpha = \max_{1 \leqq i \leqq M} \{\alpha_i\}$ and $\beta = \max_{1 \leqq j \leqq N} \{\beta_j\}$.

We now discuss the compressibility law. As we mentioned, we postulate that for slightly compressible materials the pressure p satisfies

$$p(\nabla u) = g(\det \nabla u). \tag{1.20}$$

We assume that if

$$G(x) = \int_1^x g(z)\, dz \tag{1.21}$$

then G satisfies

$$\begin{aligned} &G\colon (0,+\infty)\to[0,+\infty) \text{ is convex},\\ &\lim_{x\to 0^+} G(x)=+\infty,\\ &G(x)\geqq Cx^{\gamma} \text{ for some } C>0 \quad \text{and} \quad \gamma>1, \quad x \text{ large enough},\\ &G(x)=0 \quad \text{if and only if } x=1. \end{aligned} \tag{1.22}$$

A good example of compressibility law is, for every $F\in M^3_+$,

$$p(F)=g(\det F)=\frac{1}{2\varepsilon}\left(\det F-\frac{1}{\det F}\right), \tag{1.23}$$

which satisfies (1.22). In particular, if $\det F$ is close to 1 we have

$$p\sim\frac{1}{\varepsilon}(\det F-1)=\frac{1}{\varepsilon}\left(\frac{\rho}{\rho_0}-1\right)$$

where ρ_0 is the initial density and ρ is the density of the deformed body. This is usually considered as reasonable for numerous slightly compressible materials.

Therefore, consider a rheology of the form

$$W(F)=W^*(F)+G(\det F) \tag{1.24}$$

where W^* and G satisfy (1.17) and (1.22). We could also consider more general W^* (cf. (2.6) below). We seek deformations u such that $u=u_0$ on $\partial\Omega_1$ (where $\partial\Omega_1\subset\partial\Omega$) and which minimize the potential energy of the system (we suppose for simplicity that the material is homogeneous and that there are no external forces), i.e.,

$$I(v)=\int_\Omega W(\nabla v(x))\,dx \tag{1.25}$$

among all kinematically admissible deformations v which belong to

$$A_{\alpha\beta\gamma}=\{v\in W^{1,\alpha}(\Omega,\mathbb{R}^3),\ \operatorname{adj}\nabla v\in(L^\beta(\Omega))^9,\ \det\nabla v\in L^\gamma(\Omega)$$
$$\det\nabla v>0 \text{ a.e. and } u=u_0 \text{ on } \partial\Omega_1\}.$$

The methods and results of Ball [1] can then be applied as follows.

THEOREM (Ball). *Let $\alpha>3/2$, $\beta>1$, $1/\alpha+1/\beta<4/3$ and $\gamma>1$. If there exists $\tilde{u}\in A_{\alpha\beta\gamma}$ such that $I(\tilde{u})<\infty$ then there exists $u\in A_{\alpha\beta\gamma}$ so that*

$$I(u)=\inf\{I(v)\colon v\in A_{\alpha\beta\gamma}\}.$$

Remark 2. In the definition of $A_{\alpha\beta\gamma}$, if we assume $\alpha\geqq 2$, then there is no ambiguity in the definition of $\operatorname{adj}\nabla u$ since it is an L^1 function. However if $3/2<\alpha<2$, $\operatorname{adj}\nabla u$ is extended as a distribution by continuity denoted $\operatorname{Adj}\nabla u$ by Ball [1]. A similar remark is applicable to $\det\nabla u$.

It is the aim of this article to extend Ball's result to the case of a slightly compressible material which satisfy (cf. Proposition 1)

$$W(F)=W^*((\det F)^{-1/3}F)+G(\det F) \tag{1.26}$$

where W^* and G satisfy (1.17) and (1.22).

The theorem of Ball cannot be applied directly since, even if W^* is polyconvex and coercive when $\det F=1$, it is not, in general, the case for W satisfying (1.27). This will be investigated in the next section.

We end this section with some remarks.

Remark 3. (i) A simple example of stored energy function is the so-called Mooney-Rivlin rheology, i.e.,

$$W^*(F) = a \operatorname{tr} C + b \operatorname{tr} (\operatorname{adj} C) = a|F|^2 + b|\operatorname{adj} F|^2. \tag{1.27}$$

We shall see in the next section that, even though (1.27) is polyconvex the function

$$W(F) = a(\det F)^{-2/3}|F|^2 + b(\det F)^{-4/3}|\operatorname{adj} F|^2 + G(\det F) \tag{1.28}$$

is not polyconvex.

(ii) It is known (cf. Gurtin [4]) that in an isotropic material the constraint in the reference configuration is a pressure. The choice of a law of compressibility satisfying $G'(1) = g(1) = 0$ implies that the reference configuration is free of constraint and thus is a "natural" configuration.

2. An existence theorem.

2.1. Statement of the result. We consider a stored energy function W in the form

$$W(F) = w(F, \operatorname{adj} F, \det F) \equiv W^*((\det F)^{-1/3}F) + G(\det F) \tag{2.1}$$

where

$$W^*(F) = w^*(F, \operatorname{adj} F) \tag{2.2}$$

and w^* satisfies

$$w^*(F, H) = \sum_{i=1}^{M} a_i \operatorname{tr} (C^{\alpha_i/2}) + \sum_{j=1}^{N} b_j \operatorname{tr} (D^{\beta_j/2}) \tag{2.3}$$

with $a_i > 0$, $b_j > 0$, $C = F^TF$, $D = H^TH$ and

$$\begin{aligned} &\alpha_i \geqq \tfrac{3}{2}, \qquad i = 1, \cdots, M, \\ &\beta_j \geqq 3, \qquad j = 1, \cdots, N. \end{aligned} \tag{2.4}$$

We also assume that

$$G \text{ satisfies (1.22).} \tag{2.5}$$

Finally, if we let $\alpha = \max \{\alpha_i, 1 \leqq i \leqq M\}$ and $\beta = \max \{\beta_j, 1 \leqq j \leqq N\}$ we then assume

$$\begin{aligned} &p \equiv \frac{3\alpha\gamma}{\alpha + 3\gamma} > \frac{3}{2}, \\ &q \equiv \frac{3\beta\gamma}{2\beta + 3\gamma} \quad (\beta \geqq 3 \text{ and } \gamma > 1 \text{ imply } q > 1), \\ &\frac{1}{p} + \frac{1}{q} = \frac{1}{\alpha} + \frac{1}{\beta} + \frac{1}{\gamma} < \frac{4}{3}. \end{aligned} \tag{2.6}$$

For instance (2.6) is verified if $\alpha \geqq 2$, $\beta \geqq 3$, $\gamma > 2$.

Remark 4. The same results hold if instead of (2.3) w^* is of the form

$$w^*(F, G) = \sum_{i=1}^{M} a_i|F|^{\alpha_i} + \sum_{j=1}^{N} b_j|G|^{\beta_j}, \tag{2.3'}$$

and if we assume all the other hypotheses (2.1)-(2.6).

Recall that we want to minimize

$$I(v) \equiv \int_\Omega W(\nabla v(x))\, dx \tag{2.7}$$

over the space

$$A_{pq\gamma} = \{v \in W^{1,p}(\Omega; \mathbb{R}^3), \operatorname{adj} \nabla v \in (L^q(\Omega))^9, \det \nabla v \in L^\gamma(\Omega), \det \nabla v > 0 \text{ a.e. and } v = u_0 \text{ on } \partial\Omega_1\}. \tag{2.8}$$

The theorem can then be stated as follows.

THEOREM 5 (Existence Theorem). *Let W satisfy* (2.1)-(2.6) *and suppose that there exists $v \in A_{pq\gamma}$ such that $I(v) < \infty$, then there exists $\bar{u} \in A_{pq\gamma}$ so that*

$$I(\bar{u}) = \inf\{I(v): v \in A_{pq\gamma}\}.$$

In order to prove the above theorem, we proceed according to Ball [1] and we divide our proof in three steps. In the first one we discuss the polyconvexity of W, in the second one we study the coercivity of I in the space $A_{pq\gamma}$ and last, we pass to the limit on the minimizing sequence.

2.2. Polyconvexity of W.

PROPOSITION 6. *Let $\alpha > 0$, $\beta > 0$.*

(i) *Let*

$$W(F) = (|F|(\det F)^{-1/3})^\alpha; \tag{2.9}$$

then W is polyconvex if and only if $\alpha \geqq 3/2$.

(ii) *Let*

$$W(F) = (|\operatorname{adj} F|(\det F)^{-2/3})^\beta; \tag{2.10}$$

then W is polyconvex if and only if $\beta \geqq 3$.

(iii) *Let v_1, v_2, v_3 denote the principal stretches, i.e., the eigenvalues of $(F^TF)^{1/2}$ and let*

$$W(F) = \sum_{i=1}^{M} a_i \left(\sum_{k=1}^{3} v_k \delta^{-1/3} \right)^{\alpha_i} + \sum_{j=1}^{N} b_j \left(\sum_{j=1}^{3} v_{k+1} v_{k+2} \delta^{-2/3} \right)^{\beta_j} \tag{2.11}$$

where $\delta = \det F$ (with the notation $v_4 = v_1$ and $v_5 = v_2$) and $a_i, b_j > 0$. Furthermore if $\alpha_i \geqq 3/2$ and $\beta_j \geqq 3$ for every i, j then W is polyconvex.

Remark. It is interesting to note that, following the above proposition, the Mooney-Rivlin stored energy function

$$W^*(F) = a|F|^2 + b|\operatorname{adj} F|^2$$

does not lead to polyconvex W:

$$W(F) = a|F|^2(\det F)^{-2/3} + b|\operatorname{adj} F|^2(\det F)^{-4/3}$$

since $\alpha = 2$ and $\beta = 2$.

Proof. (i) *Step* 1. Let $h: \mathbb{R}_+ \times \mathbb{R}_+ \to \mathbb{R}$ be defined as

$$h(x, \delta) \equiv (x\delta^{-1/3})^\alpha. \tag{2.12}$$

It is then easy to show that h is convex if and only if $\alpha \geqq 3/2$. Let us remark now that

$$W(F) = w(F, \det F), \quad \text{where } w(F, \delta) = h(|F|, \delta). \tag{2.13}$$

If $\alpha \geqq 3/2$, polyconvexity of W is deduced from the convexity of h and the fact that $x \to h(x, \delta)$ is a nondecreasing function.

Step 2. It now remains to show that $\alpha \geqq 3/2$ is also necessary for W to be polyconvex. To prove this is slightly more involved. We first define for $F \in M^3_+$, $a, b \in \mathbb{R}^3$ such that $F + ta \otimes b \in M^3_+$ for every $t \in \mathbb{R}_+$ (where $a \otimes b \equiv (a_i b_j)_{1 \leqq i,j \leqq 3} \in M^3$):

$$\varphi(t) \equiv W(F + ta \otimes b) = (|F + ta \otimes b| (\det (F + ta \otimes b))^{-1/3})^{\alpha}. \tag{2.14}$$

It is then easy to show (cf. Ball [1]) that

$$W \text{ polyconvex implies } \varphi \text{ convex} \tag{2.15}$$

(a function W having the property that the associated φ is convex is called *rank one convex*).

In order to simplify the notation we let $\lambda_1, \cdots, \lambda_5$ be defined as

$$\begin{aligned} |F + ta \otimes b|^2 &= \lambda_1^2 t^2 + \lambda_2 t + \lambda_3^2, \\ \det (F + ta \otimes b) &= \lambda_4 t + \lambda_5 \end{aligned} \tag{2.16}$$

for every $t \in \mathbb{R}_+$ (observe that $\det (F + ta \otimes b)$ is linear in t).

Since $W \in C^2$, so is φ and an elementary computation leads to

$$\varphi''(t) = (\lambda_1^2 t^2 + \lambda_2 t + \lambda_3^2)^{(\alpha/2)-2} (\lambda_4 t + \lambda_5)^{-(\alpha/3)-2} \left[\lambda_1^4 \lambda_4^2 t^4 \left(\frac{2\alpha}{9} (2\alpha - 3) \right) + O(t^3) \right];$$

thus

$$\varphi''(t) \geqq 0 \quad \text{for every } t \in \mathbb{R}_+ \text{ implies } \alpha \geqq \tfrac{3}{2}$$

and consequently

$$W \text{ polyconvex implies } \alpha \geqq \tfrac{3}{2}.$$

(ii) The second part of the proposition is proved in exactly the same way.

(iii) In order to prove the third part we set

$$W(F) = \psi(v_1, v_2, v_3, v_2 v_3, v_1 v_3, v_1 v_2, v_1 v_2 v_3)$$

and use a result of Ball [1] which asserts that, if $\psi: (\mathbb{R}_+)^7 \to \mathbb{R}$ is convex and increasing in each of the first six variables, then W^* is polyconvex. It is clear that if $\alpha_i \geqq 3/2$ and $\beta_j \geqq 3$ then ψ has the required properties (as in the first part). □

2.3. Coercivity of the energy functional I. We now want to show that I defined in (2.7) is coercive over the space $A_{pq\gamma}$ introduced in (2.8).

PROPOSITION 7. *Let W satisfy* (2.1)-(2.6); *then there exists $K > 0$ such that for every $v \in A_{pq\gamma}$*

$$\begin{aligned} I(v) &= \int_\Omega W(\nabla v(x))\, dx \\ &= \int_\Omega w(\nabla v, \operatorname{adj} \nabla v, \det \nabla v)\, dx \\ &\geqq K(-1 + \|\nabla v\|_{L^p}^p + \|\operatorname{adj} \nabla v\|_{L^q}^q + \|\det \nabla v\|_{L^\gamma}^\gamma). \end{aligned} \tag{2.17}$$

Remark. The result is still valid if instead of (2.3) we have (2.3′).

Proof. It is easy to see that (2.3) implies that there exists $K > 0$ such that

$$w^*(F, H) \geqq K(|F|^\alpha + |H|^\beta) \tag{2.18}$$

where $\alpha = \max \{\alpha_i : 1 \leqq i \leqq M\}$ and $\beta = \max \{\beta_j : 1 \leqq j \leqq N\}$.

Let $\delta = \det F$ and use (2.5) to get that there exists $K > 0$ (we write K generically for constants):

$$G(\delta) \geqq K(\delta^\gamma - 1); \tag{2.19}$$

hence W and w defined by (2.1) satisfy the following coercivity condition:

$$w(F, H, \delta) \geqq K(|\delta^{-1/3} F|^\alpha + |\delta^{-2/3} H|^\beta + \delta^\gamma - 1). \tag{2.20}$$

We now apply Young's inequality to

$$|F|^p = |\delta^{-1/3} F|^p \delta^{p/3}. \tag{2.21}$$

So for every $\varepsilon > 0$ and $m > 1$, $1/m + 1/m' = 1$ we have

$$|F|^p \leqq \frac{\varepsilon^m}{m} |\delta^{-1/3} F|^{pm} + \frac{\varepsilon^{-m'}}{m'} \delta^{pm'/3}. \tag{2.22}$$

Choosing p as in (2.6), i.e.,

$$p = \frac{3\alpha\gamma}{\alpha + 3\gamma}$$

and m such that $pm = \alpha$, we indeed obtain $pm' = 3\gamma$ and hence

$$|F|^p \leqq \frac{p}{\alpha} \varepsilon^{\alpha/p} |\delta^{-1/3} F|^\alpha + \frac{p}{3\gamma} \varepsilon^{-3\gamma/p} \delta^\gamma. \tag{2.23}$$

Similarly if $q = 3\beta\gamma/(2\beta + 3\gamma)$ we get

$$|H|^q \leqq \frac{q}{\beta} \varepsilon^{\beta/q} |\delta^{-2/3} H|^\beta + \frac{2q}{3\gamma} \varepsilon^{-3\gamma/2q} \delta^\gamma. \tag{2.24}$$

Combining (2.20), (2.23) and (2.24) we have indeed obtained

$$w(F, H, \delta) \geqq K(|F|^p + |H|^q + \delta^\gamma - 1) \tag{2.25}$$

and thus proved the proposition. □

Remark 8. Observe that in the above proposition we have indeed used the coercivity of $w(F, H, \delta)$ (i.e. where the arguments (F, H, δ) are *independent*) as in (2.25), and not only the condition $W(F) = w(F, \operatorname{adj} F, \det F) \geqq K(|F|^p + |\operatorname{adj} F|^q + (\det F)^\gamma - 1)$, $F \in M^3_+$ which is, in general, weaker. In fact, the coercivity of $w(F, \operatorname{adj} F, \det F)$ does not seem to be sufficient to ensure the coercivity of $I(v)$ in $A_{pq\gamma}$ if $3/2 < p < 2$, since we do not know whether $\operatorname{adj} \nabla v$ (which is defined only as a distribution in L^q) coincides with the almost everywhere definition. However, if $p \geqq 2$ and $q \geqq p/(p-1)$, the coercivity of $w(F, \operatorname{adj} F, \det F)$ is sufficient to obtain that of $I(v)$ on $A_{pq\gamma}$ (see § 2.5, Theorem 5′).

2.4. Proof of Theorem 5. We first state a lemma proved by Ball [1].

LEMMA 9. *Let Ω be a bounded open set of $\mathbb{R}^3$ and let*

$$u_k \rightharpoonup u \; W^{1,p}(\Omega; \mathbb{R}^3).$$

(i) *If $p > \frac{3}{2}$, then*

$$\operatorname{adj} \nabla u_k \rightharpoonup \operatorname{adj} \nabla u \quad \text{in } (\mathscr{D}'(\Omega))^9.$$

(ii) *Furthermore, if $p > 1$ and*

$$\operatorname{adj} \nabla u_k \rightharpoonup \operatorname{adj} \nabla u \quad \text{in } (L^q(\Omega))^9, \qquad q > 1$$

with $(1/p)+(1/q)<\frac{4}{3}$ *then*

$$\det \nabla u_k \rightharpoonup \det \nabla u \quad \text{in } \mathscr{D}'(\Omega).$$

Remark. Recall that in the lemma we have used the notation of Remark 2.

Proof of Theorem 5. We may now proceed exactly as in the proof of Ball's Theorem. Let u_k be a minimizing sequence of $I(u)$ on $A_{pq\gamma}$. A version of Poincare's inequality ensures that

$$\int_\Omega |u_k(x)|^p \leqq K\left[\int_\Omega |\nabla u_k(x)|^p + \left(\int_{\partial\Omega_1} |u_0|\, ds\right)^p\right] \tag{2.26}$$

where K is a constant. Therefore combining (2.26) and Proposition 7, we find that (up to an extraction of a subsequence)

$$\begin{aligned} &u_k \rightharpoonup \bar{u} && \text{in } W^{1,p}(\Omega;\mathbb{R}^3),\\ &\operatorname{adj} \nabla u_k \rightharpoonup H && \text{in } (L^q(\Omega))^9,\\ &\det \nabla u_k \rightharpoonup \delta && \text{in } L^\gamma(\Omega). \end{aligned} \tag{2.27}$$

The above lemma ensures that $H = \operatorname{adj} \nabla \bar{u}$ and $\delta = \det \nabla \bar{u}$. Using Proposition 6 we get

$$\liminf_{k\to\infty} I(u_k) \geqq I(\bar{u}). \tag{2.28}$$

Moreover, $\bar{u} = u_0$ on $\partial\Omega_1$ and $\det \nabla \bar{u} > 0$ a.e. Since, by (2.28), $I(\bar{u}) < +\infty$, so $\bar{u} \in A_{pq\gamma}$. Thus $\bar{u}$ is a minimizer of the energy. □

In the next section we show that the coercivity condition may be slightly improved; and in the last section of the second part of this article we will also show that one can consider more general stored energy functions.

2.5. Optimal coercivity of the energy. Recall that

$$\begin{aligned} &W(F) = w(F, \operatorname{adj} F, \det F) = W^*((\det F)^{-1/3}F) + G(\det F),\\ &W^*(F) = w^*(F, \operatorname{adj} F) = \sum_{i=1}^{M} a_i \operatorname{tr}(C^{\alpha_i/2}) + \sum_{j=1}^{N} b_j \operatorname{tr}(\operatorname{adj} C)^{\beta_j/2}, \end{aligned} \tag{2.29}$$

where $C = F^T F$,

$$G(\delta) \geqq C\delta^\gamma \quad \text{for some } C>0 \text{ and } \gamma>1,\ \delta \text{ large enough.}$$

In Proposition 7 we have shown that

$$w(F, H, \delta) \geqq K(|F|^p + |H|^q + \delta^\gamma - 1) \tag{2.30}$$

provided

$$p \leqq \frac{3\alpha\gamma}{\alpha+3\gamma}, \qquad q \leqq \frac{3\beta\gamma}{2\beta+3\gamma} \tag{2.31}$$

where $\alpha = \max\{\alpha_i : 1 \leqq i \leqq M\}$ and $\beta = \max\{\beta_j : 1 \leqq j \leqq N\}$.

In fact, we have shown that for every $(x, y, \delta) \in (\mathbb{R}_+)^3$

$$(\delta^{-1/3}x)^\alpha + (\delta^{-2/3}y)^\beta + \delta^\gamma \geqq K(x^p + y^q + \delta^\gamma - 1). \tag{2.32}$$

The question is then whether we can improve p and q by assuming that $x = |F|$, $y = |\operatorname{adj} F|$ and $\delta = \det F$. This can indeed be done and we have the following optimal result.

PROPOSITION 10. *Let W be as above, then the following two statements are equivalent*:

(i) *There exists $K>0$ such that*

$$W(F)\geqq K(|F|^p+|\text{adj } F|^q+(\det F)^r-1)$$

for every $F\in M^3_+$;

(ii) $p\leqq\max\left(\dfrac{3\alpha\gamma}{\alpha+3\gamma},\dfrac{3\beta\gamma}{\beta+6\gamma}\right)$, $q\leqq\max\left(\dfrac{3\beta\gamma}{2\beta+3\gamma},\dfrac{3\alpha\gamma}{2\alpha+6\gamma}\right)$, $r\leqq\gamma$.

Proof. Let us suppose (ii) and prove (i).

We first show the following two inequalities:

(2.33) $\text{tr}(\text{adj } A)\leqq\text{tr } A^2$ for every $A\in M^3$,

(2.34) $\text{tr } A^{1/2}\leqq\text{tr adj } A$ for every symmetric positive matrix A with $\det A=1$.

Let a_k be the eigenvalues of A. It is obvious that

$$\text{tr}(\text{adj } A)=a_2a_3+a_1a_3+a_1a_2\leqq a_1^2+a_2^2+a_3^2=\text{tr } A^2,$$

and hence (2.33). Similarly,

$$(a_2a_3)^{-1/2}+(a_1a_3)^{-1/2}+(a_1a_2)^{-1/2}\leqq a_1^{-1}+a_2^{-1}+a_3^{-1}$$

and since $\det A=1=a_1a_2a_3$ we deduce that

$$\text{tr } A^{1/2}=a_1^{1/2}+a_2^{1/2}+a_3^{1/2}\leqq a_2a_3+a_1a_3+a_1a_2=\text{tr adj } A$$

and thus (2.34).

Let us define

$$C_*=(\det F)^{-2/3}F^TF=(\det F)^{-2/3}C,$$
$$\bar\alpha=\max\left(\alpha,\frac{\beta}{2}\right),\qquad\bar\beta=\max\left(\beta,\frac{\alpha}{2}\right).\tag{2.35}$$

Then using (2.33) and (2.34) we have

$$\text{tr}(C_*^{\alpha/2})\geqq\text{tr}(\text{adj } C_*^{\alpha/4}),\qquad\text{tr}(\text{adj } C_*^{\beta/2})\geqq\text{tr}(C_*^{\beta/4})\tag{2.36}$$

and thus

$$W(F)\geqq K(\text{tr } C_*^{\bar\alpha/2}+\text{tr}(\text{adj } C_*^{\bar\beta/2})+(\det F)^\gamma-1).\tag{2.37}$$

We now proceed exactly as in Proposition 7, where we have replaced α and β by $\bar\alpha$ and $\bar\beta$, and thus we get (i). Conversely, we now assume that W satisfies the coercivity (i) and we want to show that p, q and r are as in (ii). The condition on r is immediately deduced from (i) by choosing $F=\lambda I$ and letting $\lambda\to\infty$.

Furthermore, by letting v_1, v_2, v_3 be the principal stretches of F and $\delta=v_1v_2v_3$ we get from (i)

$$\sum_{i=1}^3(v_i\delta^{-1/3})^\alpha+\sum_{i=1}^3(v_iv_{i+1}\delta^{-2/3})^\beta+\delta^\gamma$$
$$\geqq K\left[\left(\sum_{i=1}^3v_i^2\right)^{p/2}+\left(\sum_{i=1}^3v_i^2v_{i+1}^2\right)^{q/2}+\delta^r-1\right]\tag{2.38}$$

where $v_4=v_1$.

Step 1. We let s_i be such that

$$v_i = e^{s_i} \quad \text{and} \quad s_1 \geqq s_2 \geqq s_3. \tag{2.39}$$

Then (2.38) is equivalent to (considering only the leading term)

$$\begin{aligned} &e^{(s_1-(1/3)(s_1+s_2+s_3))\alpha} + e^{(s_1+s_2-(2/3)(s_1+s_2+s_3))\beta} + e^{(s_1+s_2+s_3)\gamma} \\ &\geqq K(e^{s_1 p} + e^{(s_1+s_2)q} + e^{(s_1+s_2+s_3)r} - 1). \end{aligned} \tag{2.40}$$

Hence letting

$$s_1 = s, \quad s_2 = (1-\sigma_1)s, \quad s_3 = (1-\sigma_1-\sigma_2)s$$

we must have from (2.40)

$$\begin{aligned} &\max\left\{(2\sigma_1+\sigma_2)\frac{\alpha}{3}; (\sigma_1+2\sigma_2)\frac{\beta}{3}; (3-2\sigma_1-\sigma_2)\gamma\right\} \\ &\geqq \max\{p, (2-\sigma_1)q, (3-2\sigma_1-\sigma_2)r\} \end{aligned} \tag{2.41}$$

for every $\sigma_1, \sigma_2 \geqq 0$.

Step 2. In particular

$$p \leqq \bar{p} \equiv \min_{\alpha_1,\sigma_2\geqq 0}\left\{\max_{1\leqq i\leqq 3} l_i(\sigma_1, \sigma_2)\right\} \tag{2.42}$$

where

$$l_1 = (2\sigma_1+\sigma_2)\frac{\alpha}{3}, \qquad l_2 = (\sigma_1+2\sigma_2)\frac{\beta}{3}, \qquad l_3 = (3-2\sigma_1-\sigma_2)\gamma. \tag{2.43}$$

It now remains to show that

$$\bar{p} = \max\left\{\frac{3\alpha\gamma}{\alpha+3\gamma}, \frac{3\beta\gamma}{\beta+6\gamma}\right\}$$

to obtain (ii).

We need to consider three cases.

Case 1. $\alpha \geqq 2\beta$; then $l_1 \geqq l_2$ and hence

$$\bar{p} = \min_{\sigma_1,\sigma_2\geqq 0}\{\max\{l_1, l_3\}\}.$$

Observe that the line $l_1 = l_3$ divides the cone $\sigma_1 \geqq 0$, $\sigma_2 \geqq 0$ into two regions and that $\max\{l_1, l_3\}$ tends to $+\infty$ if σ_1 or σ_2 does. Therefore, the minimum of $\max\{l_1, l_3\}$ over $\sigma_1 \geqq 0$ and $\sigma_2 \geqq 0$ is attained at one of the extremal points. Comparing the different values of $\max\{l_1, l_3\}$ at these points we find

$$\bar{p} = \frac{3\alpha\gamma}{\alpha+3\gamma}.$$

Case 2. $\alpha \leqq \beta/2$, then $l_2 \geqq l_1$ and therefore

$$\bar{p} = \min_{\sigma_1,\sigma_2\geqq 0}\{\max\{l_2, l_3\}\}.$$

Repeating the above argument we find

$$\bar{p} = \frac{3\beta\gamma}{\beta+6\gamma}.$$

Case 3. $\beta/2 \leqq \alpha \leqq 2\beta$, one shows in a similar manner that $\max\{l_1, l_2, l_3\}$ attains its minimum over $\sigma_1 \geqq 0$, $\sigma_2 \geqq 0$ exactly at the point where $l_1 = l_2 = l_3$ and this minimum is then

$$\bar{p} = \frac{3\alpha\gamma}{\alpha + 3\gamma};$$

hence the result.

Step 3. It now remains to show that

$$q \leqq \max\left(\frac{3\beta\gamma}{2\beta + 3\gamma}, \frac{3\alpha\gamma}{2\alpha + 6\gamma}\right). \tag{2.44}$$

We again use (2.41) to get that

$$2q \leqq \min_{\sigma_1 \geqq 0, \sigma_2 \geqq 0} \left\{ \max_{1 \leqq i \leqq 3} \{l_i'(\sigma_1, \sigma_2)\} \right\} \equiv 2\bar{q} \tag{2.45}$$

where $l_i' = l_i + q\sigma_1$.

A procedure similar to that of step 2 shows that $\bar{q}$ is exactly $\max(3\beta\gamma/(2\beta + 3\gamma), 3\alpha\gamma/(2\alpha + 6\gamma))$. And this concludes the proof of the proposition. □

Combining Proposition 10 with Proposition 6, we obtain the following (exactly in the same way as Theorem 5).

THEOREM 5′ (Existence Theorem). *Hypotheses* (2.1)-(2.5) *are supposed to be satisfied and* (*instead of* (2.6))

$$\begin{aligned} \bar{p} &\equiv \max\left(\frac{3\alpha\gamma}{\alpha + 3\gamma}, \frac{3\beta\gamma}{\beta + 6\gamma}\right) \geqq 2, \\ \bar{q} &\equiv \max\left(\frac{3\beta\gamma}{2\beta + 3\gamma}, \frac{3\alpha\gamma}{2\alpha + 6\gamma}\right) \geqq \frac{\bar{p}}{\bar{p} - 1} \end{aligned} \tag{2.6′}$$

holds. Assume also that there exists $v \in A_{\bar{p}\bar{q}\gamma}$ *such that* $I(v) < \infty$; *then there exists* $\bar{u} \in A_{\bar{p}\bar{q}\gamma}$ *so that*

$$I(\bar{u}) = \inf\{I(v) : v \in A_{\bar{p}\bar{q}\gamma}\}.$$

2.6. Polyconvexity of a more general stored energy function. Up to now we have only considered stored energy functions constructed from the Ogden model (i.e., W^* satisfying (2.1)-(2.3)). We now consider the more general case

$$W(F) = \psi^*(v_k^*, v_{k+1}^*, v_{k+2}^*) + G(\delta) \tag{2.46}$$

where the v_k^* are the principal stretches of $(\det F)^{-1/3}F$ and $\delta = \det F$, and $\varphi(v_k, w_k)$ stands for $\varphi(v_1, v_2, v_3, w_1, w_2, w_3)$.

For notational purposes we pose $w_k = v_{k+1}v_{k+2}$. We also make the following hypotheses on ψ^*:

$$\begin{aligned} &\psi^*: ([0, +\infty))^6 \to \mathbb{R}_+ \text{ is increasing,} \\ &\tilde{\psi}^*: (v_k, w_k) \to \psi^*(v_k^{2/3}, w_k^{1/3}) \text{ is a convex function on } [0, +\infty)^6, \\ &\psi^*(v_k, w_k) \geqq K\left(\sum_{i=1}^{3} v_i^{\alpha} + \sum_{j=1}^{3} w_j^{\beta} - 1\right) \end{aligned} \tag{2.47}$$

and G satisfies (2.5). Then if

$$p \equiv \frac{3\alpha\gamma}{\alpha + 3\gamma} > \frac{3}{2}, \quad q \equiv \frac{3\beta\gamma}{2\beta + 3\gamma} > 1, \quad \frac{1}{p} + \frac{1}{q} < \frac{4}{3}, \quad \gamma > 1 \tag{2.48}$$

we have the following.

THEOREM 5″. *If there exists* $v \in A_{pq\gamma}$ *such that* $I(v) < \infty$ *then there exists* $\bar{u} \in A_{pq\gamma}$ *such that*

$$I(\bar{u}) = \inf\{I(u): u \in A_{pq\gamma}\}.$$

Proof. The only thing that remains to be checked is the polyconvexity of W. It is then sufficient (see Ball [1]) to show that

$$\psi(v_k, w_k, \tau) = \psi^*(\tau^{-1/3} v_k, \tau^{-2/3} w_k) + G(\tau) \tag{2.49}$$

is increasing in the first six variables and is convex. The first property follows from the fact that ψ^* is increasing. It thus remains to show the convexity of ψ, but this is obvious since we have from (2.47) and (2.49)

$$\psi(v_k, w_k, \tau) = \tilde{\psi}^*((\tau^{-1/3} v_k)^{3/2}(\tau^{-2/3} w_k)^3) + G(\tau). \tag{2.50}$$

Combining Proposition 6, the convexity of $\tilde{\psi}^*$ and G, we have indeed proved the theorem. □

Examples. (i) Ogden materials, considered in the preceding sections, represent a particular case of the above theorem.

(ii) However there are examples, not of Ogden type, satisfying (2.47), for instance,

$$\psi^*(v, w) = \sum_{i,j=1}^{3} a_{ij} v_i^{\alpha_i} v_j^{\alpha_j} + b_{ij} w_i^{\beta_i} w_j^{\beta_j} + c_{ij} v_i^{\alpha_i} w_j^{\beta_j}$$

with a_{ij}, b_{ij}, $c_{ij} \geqq 0$, $\alpha_i \geqq 3/2$ and $\beta_j \geqq 3$. If we also assume that the quadratic form on $\mathbb{R}^6$

$$f(x, y) = \sum_{i,j=1}^{3} (a_{ij} x_i x_j + b_{ij} y_i y_j + c_{ij} x_i y_j)$$

is positive definite. Therefore, the convexity of f and the fact that f is increasing imply that $\tilde{\psi}^*$ is so.

3. Convergence to the incompressible case. We conclude this article by showing that if in the above analysis we let the compressibility tend to zero we recover the incompressible case.

Let $\varepsilon > 0$ and

$$I_\varepsilon(v) = \int_\Omega W^*((\det \nabla v)^{-1/3} \nabla v)\, dx + \frac{1}{\varepsilon} \int_\Omega G(\det \nabla v)\, dx \tag{3.1}$$

where W^* and G satisfy (2.1)-(2.6).

Let us consider the problem

$$\inf\{I_\varepsilon(v): v \in A_{pq\gamma}\} \tag{P_ε}$$

and define

$$I_0(v) = \int_\Omega W^*((\det \nabla v)^{-1/3} \nabla v)\, dx. \tag{3.2}$$

We define the admissible set for the incompressible case as

$$K_{\alpha\beta} = \{v \in W^{1,\alpha}(\Omega; \mathbb{R}^3), \operatorname{adj} \nabla v \in (L^\beta(\Omega))^9, \det \nabla v = 1 \text{ and } v = u_0 \text{ on } \partial\Omega_1\}. \tag{3.3}$$

We will assume that $K_{\alpha\beta} \neq \varnothing$. Finally, let

$$\inf\{I_0(v): v \in K_{\alpha\beta}\}. \tag{P_0}$$

Remark. Note that $p < \alpha$ and $q < \beta$.

We now can state our last theorem.

THEOREM 11. *Under hypotheses* (2.1)-(2.6) *and the further assumption that* $G(1) = G'(1) = 0$ *and* $G''(t) \geqq c_0 > 0$, *then every sequence* $u_\varepsilon \in A_{pq\gamma}$ *of solutions of* (P_ε) *converges* (*up to the extraction of a subsequence*) *to a solution* $\bar{u} \in K_{\alpha\beta}$ *of* (P_0) *in the following sense*:

$$
\begin{aligned}
&u_\varepsilon \rightharpoonup \bar{u} \quad \text{in } W^{1,p}(\Omega;\mathbb{R}^3),\\
&\operatorname{adj}\nabla u_\varepsilon \rightharpoonup \operatorname{adj}\nabla \bar{u} \quad \text{in } (L^q(\Omega))^9,\\
&\det \nabla u_\varepsilon \to 1 \quad \text{in } L^2(\Omega) \quad \text{strongly},\\
&\lim_{\varepsilon\to 0} I_0(u_\varepsilon) = I_0(\bar{u}),\\
&\lim_{\varepsilon\to 0} \frac{1}{\varepsilon}\int_\Omega G(\det \nabla u_\varepsilon)\, dx = 0.
\end{aligned}
\tag{3.4}
$$

Remark. Similar results have been obtained by Pouyot [9] and Le Dret [5] for rheologies of the form $W_0(F) + (1/\varepsilon)G(\det F)$.

Proof. The existence of solutions u_ε of (P_ε) is obtained using Theorem 5; the existence of solutions u of (P_0) is a consequence of a theorem from Ball [1] for incompressible materials.

Let $w \in K_{\alpha\beta}$; then

$$
I_\varepsilon(u_\varepsilon) = I_0(u_\varepsilon) + \frac{1}{\varepsilon}\int_\Omega G(\det \nabla u_\varepsilon)\, dx \leqq I_\varepsilon(w) = I_0(w). \tag{3.5}
$$

Therefore u_ε is bounded in $A_{pq\gamma}$ and, after a possible extraction of a subsequence, we have

$$
\begin{aligned}
&\nabla u_\varepsilon \rightharpoonup \nabla \bar{u} \quad \text{in } L^p,\\
&\operatorname{adj}\nabla u_\varepsilon \rightharpoonup \operatorname{adj}\nabla \bar{u} \quad \text{in } L^q,\\
&\det \nabla u_\varepsilon \rightharpoonup \det \nabla \bar{u} \quad \text{in } L^\gamma.
\end{aligned}
\tag{3.6}
$$

Furthermore, taking into account the fact that $G(1) = G'(1) = 0$ and $G''(t) \geqq c_0 > 0$, we deduce that $c_0((t-1)^2/2) \leqq G(t)$. Hence in combination with (3.6) we get

$$
\det \nabla u_\varepsilon \to 1 \quad \text{in } L^2 \quad \text{strongly}. \tag{3.7}
$$

It remains to show that $\bar{u}$ is a solution of (P_0) and the last two equalities of (3.4). Let $\varepsilon_0 > 0$ be fixed and $0 < \varepsilon < \varepsilon_0$, we then have for $w \in K_{\alpha\beta}$

$$
I_{\varepsilon_0}(u_{\varepsilon_0}) \leqq I_{\varepsilon_0}(u_\varepsilon) \leqq I_\varepsilon(u_\varepsilon) \leqq I_\varepsilon(w) = I_0(w); \tag{3.8}
$$

thus

$$
I_0(\bar{u}) = I_{\varepsilon_0}(\bar{u}) \leqq \liminf_{\varepsilon\to 0} I_{\varepsilon_0}(u_\varepsilon) \leqq \limsup_{\varepsilon\to 0} I_{\varepsilon_0}(u_\varepsilon) \leqq I_0(w). \tag{3.9}
$$

This implies that $I_0(\bar{u}) < +\infty$ and hence $\bar{u} \in K_{\alpha\beta}$ and is a solution of (P_0). Replacing in (3.9) w by $\bar{u}$ we have immediately

$$
\lim_{\varepsilon\to 0} I_{\varepsilon_0}(u_\varepsilon) = I_0(\bar{u}) \tag{3.10}
$$

and returning to (3.8) we have indeed proved the theorem. □

PERTURBATION METHODS FOR SOLID DIFFUSION IN A STEFAN PROBLEM*

JOSEPH D. FEHRIBACH†

Abstract. Consider a one-dimensional, two-phase Stefan problem where one phase is a semi-infinite solid and the second, a semi-infinite liquid, and where the dependent variable represents a diffusive impurity concentration. Assume that the diffusion coefficient for the solid phase is much less than that for the liquid and that temperature is constant in space. In this paper, singular perturbation techniques are used to study this problem when the movement of the solid-liquid interface is governed by a thermodynamic perturbation in time which is large compared to the solid diffusion coefficient. Asymptotic expansions for the solid impurity concentration are given for solids that decay, grow, or have both periods of growth and decay. It is shown that when the thermodynamic perturbations lead to decay, the boundary layer in the solid impurity concentration is substantially narrower than in the absence of the thermodynamic perturbations. The significance of this narrowing is illustrated using the liquid-phase epitaxial decay of semiconductor crystals.

Key words. Stefan problems, singular perturbation expansions, solid diffusion, liquid-phase epitaxy, crystal growth

AMS(MOS) subject classifications. primary 35R35; secondary 35K05, 41A60

1. Introduction. Perturbation methods have long been a powerful tool for studying complex systems of partial differential equations. Here these methods are applied to an infinite, one-dimensional, two-phase Stefan problem modeling "impurity" diffusion, where one phase is a semi-infinite solid and the other is a semi-infinite liquid. The problem has two perturbation sources: a thermodynamic perturbation which is time dependent and which affects the phase interface, and a singular perturbation due to the small diffusion coefficient of the solid. The interaction between these perturbations is the mathematically interesting part of the problem.

Much work has already been done on the general class of problems known as Stefan problems (e.g., [1]–[4] and their references). That the problem in question (1.1) is well posed for at least some finite time was established (up to minor adjustments) by Fasano and Primicerio [5]. But while existence and uniqueness proofs hold for all $\varepsilon > 0$, the form of the solutions to nonsingular problems with $\varepsilon \simeq 1$ differs from that of the singular problems where $\varepsilon \ll 1$. Determining and analyzing solutions for singular problems is the main goal of this paper.

In its simplest form, the problem can be stated as follows: Let $S(t)$ be the position of the solid-liquid interface with the solid phase to the left of the interface, let $v(t)$ be the interface velocity, and let u represent the concentration of the diffusing species. Then

$$u_t = \varepsilon u_{xx}, \qquad x < S(t), \tag{1.1a}$$

$$u_t = u_{xx}, \qquad x > S(t), \tag{1.1b}$$

$$\text{Stefan Condition:} \qquad v(t)[u_+ - u_-] = \varepsilon(u_x)_- - (u_x)_+, \tag{1.1c}$$

$$\text{Thermodynamic Equilibrium Condition:} \qquad F(u_-, u_+; \omega(t)) = 0, \tag{1.1d}$$

(1.1e) $u(x, 0) = u_s^\infty, \quad x < 0,$

(1.1f) Initial Conditions: $u(x, 0) = u_l^\infty, \quad x > 0,$

(1.1g) $S(0) = 0.$

Here ε, $\omega \ll 1$, and F is a known system of two equations that is nonsingular at $\omega(t) = 0$ and that satisfies the condition that there exist uniquely u_s^e such that $F(u_s^e, u_l^\infty; 0) = 0$. This last condition assures that the only thermodynamic influence on the motion of the interface is the perturbation $\omega(t)$. For simplicity, this thermodynamic perturbation will be assumed affine-linear in time: $\omega(t) = \delta + \alpha t$. Thus the ambient temperature is constant in space and varies slowly in time. Also the symbols + and − indicate the limiting value on the left and right sides of the interface, respectively.

This Stefan problem (1.1) can be viewed as the instantaneous heat diffusion limit of the coupled heat-impurity diffusion problem often referred to as the alloy solidification problem [2, p. 14], [6]. It should be kept in mind, however, that the presence of a single diffusion field in (1.1) places the model closer to the classical Stefan problem than the "full" alloy solidification problem. The latter problem has been studied analytically by Rubinstein [1, pp. 52–60], [7], and numerical methods for the enthalpy formulation have been given by (among others) Crowley and Ockendon [8], Fix [18], and Bermudez and Saguez [19].

Ghez and Small [9], [10] have proposed (1.1) as a model for the formation of semiconductor crystals by liquid-phase epitaxy (LPE). In an LPE process, a solid semiconductor crystal substrate is placed under a liquid semiconductor solution. Depending primarily on the ambient temperature of the solid and liquid, the crystal will either grow or decay. In the absence of a time-dependent thermodynamic perturbation (i.e., when the ambient temperature is constant), Small and Ghez [9] solved this LPE problem using the well-known similarity solution. Their solution taking the time-dependent perturbation into account, however, is only valid for very small values of time where the thermodynamic perturbation is small [10].

Notation. For convenience, let "$\tau = Or(\varepsilon)$" mean

$$\text{“}\lim_{\varepsilon \to 0} \frac{|\tau|}{|\varepsilon|} = M\text{”}$$

for some constant $M > 0$. Also let inequalities have their obvious meanings, e.g., let $\tau > Or(\varepsilon)$ imply that τ tends to zero more slowly than ε. Note that $\tau \leq Or(\varepsilon)$ is equivalent to $\tau = O(\varepsilon)$.

The solution of Ghez and Small is valid when $\omega(t) < Or(\sqrt{\varepsilon})$. In the next section, perturbation methods are used to calculate asymptotic expansions when $\omega(t) > Or(\sqrt{\varepsilon})$ (i.e., when the thermodynamic perturbation dominates) for the Stefan problem (1.1) in the growth, decay, and mixed growth-decay cases. The analysis shows that in the presence of a purely linear time-dependent perturbation (i.e., $\delta = 0$), the decaying solution contains a boundary layer, the width of which narrows from $Or(\sqrt{\varepsilon})$ to $Or(\varepsilon)$ after an initial $Or(\sqrt{\varepsilon})$ time interval. In the affine case ($\delta \neq 0$), the width of the boundary layer is $Or(\varepsilon)$ for all time. The growth solution, on the other hand, may require fractionally iterated error functions, but will always contain a transition layer of width $Or(\sqrt{\varepsilon})$ buried in the solid. The solution for the mixed growth-decay case is obtained by combining the first two solutions.

In the third section, the results of § 2 are applied to the problem posed by Ghez and Small. Here the major result is that the boundary layer in a decaying crystal becomes so narrow as to effectively have disappeared altogether.

There have been a number of other applications of asymptotic methods to Stefan problems. Many applications are discussed by Crank [2, pp. 139–162]. Among these are two: Ockendon [11] considers heat diffusion problems with either small or large latent heat, and Stewartson and Waechter [12] have studied the inward freezing of a spherical liquid assuming a large latent heat. In addition Tayler [13, pp. 167–171] discusses the difficulties inherent in an asymptotic solution to a coupled heat-impurity diffusion problem where the solid diffusivity is assumed to be zero and the liquid diffusivity is assumed small. Finally it is worth noting the classical Mullins and Sekerka [14], [15] stability analysis describing dendrite formation (see also [16] and [17]).

Weak, variational, and numerical methods have also been applied to various Stefan problems, including those modeling impurity diffusion. Among the works discussing these methods are [2, pp. 245–249], [3], [8], [9], [18], and [19].

2. The Stefan problem. When F is independent of time (i.e., $\alpha = 0$), the Stefan problem (1.1) has a similarity solution regardless of the size of ε. In particular, if $\xi = x/2\sqrt{t}$, then this solution can be written in terms of error functions:

$$u(\xi) = u_s^\infty + (u_- - u_s^\infty)\frac{\operatorname{erfc}(-\xi/\sqrt{\varepsilon})}{\operatorname{erfc}(-\lambda/\sqrt{\varepsilon})}, \qquad \xi < \lambda,$$

$$u(\xi) = u_l^\infty + (u_+ - u_l^\infty)\frac{\operatorname{erfc}(\xi)}{\operatorname{erfc}(\lambda)}, \qquad \xi > \lambda$$

where $v(t) = \lambda/\sqrt{t}$ implies that the interface position is $\xi = \lambda$. The values for u_-, u_+, and λ are determined using the Stefan condition and the requirement that $F(u_-, u_+; \delta) = 0$.

At this point one is tempted to solve the time-dependent problem (i.e., $\alpha \neq 0$) by defining $\tau = \alpha t$ (hence $\omega(\tau) = \delta + \tau$) and treating τ as a perturbation of the similarity solution. This approach is essentially the one used by Ghez and Small [10] and elsewhere [20], [21]; it works well in the liquid, but leads to difficulties in the solid for $\tau \geq Or(\sqrt{\varepsilon})$. Specifically, if τ is viewed as a perturbation of the similarity solution and $u(\xi, \tau)$ is expanded in τ, then the first order term of the solution can be written in terms of a second iterated error function. In the liquid this term is $O(\tau)$, while in the solid it is $O(\tau/\sqrt{\varepsilon})$. Therefore a different approach is required in the solid for larger times. The idea is to apply singular perturbation methods leaving $u_-(\tau)$ and $\lambda(\tau)$ as arbitrary functions to be evaluated at the interface. Note that in terms of (ξ, τ), the interface position is $\xi = \Lambda(\tau)$, where

$$\Lambda(\tau) = \frac{1}{2\sqrt{\tau}}\int_0^\tau \frac{\lambda(s)}{\sqrt{s}}\,ds, \tag{2.0}$$

which reduces to $\Lambda = \lambda$ in the similarity case.

2.1. Solid decay. First consider the case when $\omega(\tau)$ causes the solid to decay, i.e., $\lambda(\tau) < 0$. For this case, it is useful to transform the differential equation in the solid into coordinates where the position of the solid-liquid interface is fixed. Therefore define $\zeta = \xi - \Lambda(\tau)$; (1.1a) then transforms to

$$4\tau\partial_\tau u(\zeta, \tau) = \varepsilon\partial_{\zeta\zeta}u(\zeta, \tau) + 2[\lambda(\tau) + \zeta]\partial_\zeta u(\zeta, \tau). \tag{2.1}$$

Since the coefficient of $\partial_\zeta u$ is always negative, there is a boundary layer at $\zeta = 0$. The outer solution deep in the solid is simply $u_{\text{out}}(\zeta, \tau) = u_s^\infty$. To find the inner solution,

define an inner variable:

$$Z = \frac{\zeta}{\varepsilon^p}$$

where p is chosen to balance the lowest order terms in ε in (2.1). At this point two cases develop: the first will be referred to as diffusive motion, the second, thermal decay.

LEMMA 2.1. *Assume that there exists uniquely* u_s^e *such that* $F(u_s^e, u_l^\infty; 0) = 0$ *and that* $(u_l^\infty - u_s^e) = Or(\varepsilon^0)$. *If* $\omega(\tau) \leqq Or(\sqrt{\varepsilon})$, *i.e.,* δ, $\tau \leq Or(\sqrt{\varepsilon})$, *then dominant balance for* (2.1) *implies* $p = \frac{1}{2}$. *If* $\omega(\tau) = Or(\varepsilon^q)$ *for* $0 \leqq q < \frac{1}{2}$, *then* $p = 1 - q$.

Proof. Expand $\lambda(\tau) = \lambda_0 + \lambda_1 \tau + O(\tau^2)$. For diffusive motion, the Stefan condition (1.1c) and $F(u_s^e, u_l^\infty; \omega(\tau)) = O(\sqrt{\varepsilon})$ imply $\lambda_0 = Or(\varepsilon^{1-p})$ and $\lambda_1 = O(\varepsilon^0)$. On setting $p = \frac{1}{2}$, all of the terms of (2.1) scale as $Or(\varepsilon^0)$. Similar balancing of the interface conditions and (2.1) in the case of thermal decay results in $p = 1 - q$. In this latter case, the lowest order terms of (2.1) are the term containing $\lambda(\tau)$ and the second derivative term.

Remarks. (1) Little is gained by considering cases where $\delta = Or(\varepsilon^r)$ for $0 < r < \infty$ since the *coefficients* of the thermal perturbation would not be expected to depend on the solid diffusivity. Therefore from here on, either $\delta = 0$ or $\delta = Or(\varepsilon^0)$.

(2) The above lemma has the following interpretation: When the motion of the interface is governed principally by diffusion, the relative slowness of this motion leads to a boundary layer in the solid of width $Or(\sqrt{\varepsilon})$. But in the presence of a thermal perturbation which is $Or(\varepsilon^q)$ for $0 \leq q < \frac{1}{2}$, the interface motion is relatively fast, and since the solid is decaying, the boundary layer is narrowed to $Or(\varepsilon^{1-q})$. If $\delta = Or(\varepsilon^0)$, then the boundary layer has width $Or(\varepsilon)$ for all τ. When $\delta = 0$, however, there is a transition from an initial period of diffusive motion for $\tau < Or(\sqrt{\varepsilon})$ to a period of thermal decay for $\tau > Or(\sqrt{\varepsilon})$. In this case, $\lambda_0 = 0$, and the width of the boundary layer then narrows from $Or(\sqrt{\varepsilon})$ during the initial period to $Or(\varepsilon)$ for large times, i.e., $\tau = Or(\varepsilon^0)$ (cf. Fig. 2.1).

(3) The direction of the diffusive motion (growth or decay) is determined by the Stefan condition, depending on the signs of $(u_+ - u_-)$ and $(u_x)_-$. For present purposes, this direction is not important.

Now since for all τ the function $\Lambda(\tau)$ depends on the value of $\lambda(s)$ near $s = 0$ (cf. (2.0)), the initial diffusive behavior influences the large-time behavior by affecting the position of the interface in the laboratory frame (i.e., in terms of ξ or x). However, as the next lemma establishes, if distances are measured in terms of ζ, one does not need the solution for the diffusive period to calculate the solution for the thermal period. The lemma follows immediately from the change of variables.

LEMMA 2.2. *Recall that* $\zeta = \xi - \Lambda(\tau)$. *When written in terms of* (ζ, τ), *for* $\tau > O(\sqrt{\varepsilon})$, *system* (1.1) *is independent of the initial diffusive period.*

A lowest order asymptotic solution valid for $\omega(\tau) > Or(\sqrt{\varepsilon})$ can now be calculated using a multiple time scaling. Recall that $\omega(\tau) = \delta + \tau$, and assume first that $\delta = 0$ and $\tau = Or(\varepsilon^q)$ for $0 \leqq q < \frac{1}{2}$. The correct inner variables in the solid are $Z = \zeta/\varepsilon^{1-q}$ and $\tilde{\tau} = \tau/\varepsilon^q$. Let $r = 1 - 2q$. On writing (2.1) in terms of $(Z, \tilde{\tau})$, one obtains the inner equation

$$4\varepsilon^r \tilde{\tau} \partial_{\tilde{\tau}} u_{\text{in}}(Z, \tilde{\tau}) = \partial_{ZZ} u_{\text{in}}(Z, \tilde{\tau}) + 2[\lambda(\tilde{\tau}\varepsilon^q) + \varepsilon^r Z] \partial_Z u_{\text{in}}(Z, \tilde{\tau}). \tag{2.2}$$

Now expand $u_{\text{in}}(Z, \tilde{\tau}) = u_{\text{in}}^0(Z, \tilde{\tau}) + O(\varepsilon^r)$. A priori $\lambda(\tilde{\tau})$ would also be expected to depend on ε. But because the interface conditions written in terms of the inner variables in the decay case are independent of ε (cf. (1.1c), (1.1d)), $\lambda(\tilde{\tau})$ is also independent of ε. On substituting the expansion for u_{in} into (2.2), solving the lowest order differential equation for u_{in}^0 and matching this solution with the outer solution deep in the solid,

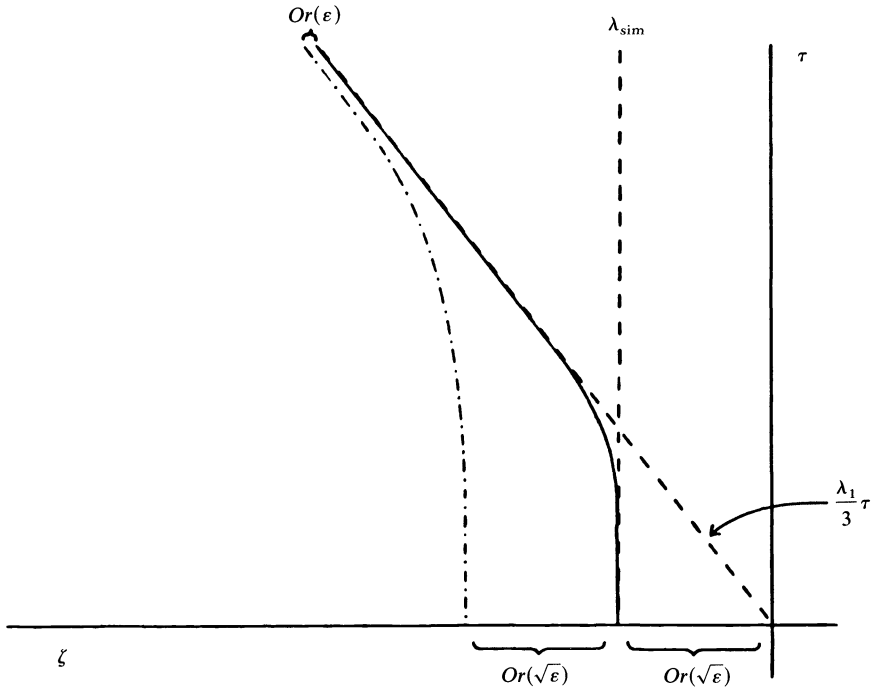

FIG. 2.1. *Transition from diffusive decay to thermal decay. The continuous line is the position of the interface and the dash-dot line shows the thickness of the boundary layer.* λ_{sim} *is the value of* λ *in the similarity solution, and* $(\lambda_1/3)\tau$ *is the interface position for large times.*

one obtains a lowest order solution $u^0(\zeta, \tau)$ valid uniformly in ζ for $\tau = Or(\varepsilon^q)$. On the other hand, if $\delta = Or(\varepsilon^0)$, the scaling of τ is not important and the above perturbation expansion can be carried out with $p = 1$. In either case, the following lemma is obtained.

LEMMA 2.3. *Assume that* $\omega(\tau) \geqq Or(\sqrt{\varepsilon})$. *Then to lowest order, the uniform (in* ζ*) solution of* (2.1) *is*

$$u^0(\zeta, \tau) = u_s^\infty + [u_-(\tau) - u_s^\infty]\, e^{-2\lambda(\tau)\zeta/\varepsilon} \tag{2.3}$$

where the functions $u_-(\tau)$ *and* $\lambda(\tau)$ *are determined by linearizing the interface conditions in* τ *(recall that F is assumed to be nonsingular).*

Note that even for $\delta = 0$, this lowest order solution is independent of q. The order of the next term in the expansion, however, is $1-2q$. Also note that the exponential factor in (2.3) would be present in every term of the expansion, regardless of the order.

2.2. Solid growth. Now consider the case when $\omega(\tau)$ causes the solid to grow, i.e., $\lambda(\tau) > 0$. In terms of (ξ, τ), (1.1a) is

$$4\tau \partial_\tau u(\xi, \tau) = \varepsilon \partial_{\xi\xi} u(\xi, \tau) + 2\xi \partial_\xi u(\xi, \tau). \tag{2.4}$$

Since the coefficient of $\partial_\xi u$ in (2.4) vanishes at $\xi = 0$, in the growth case a transition layer is buried in the growing solid. As in the decaying case, the goal is to find an asymptotic expansion for u in the solid for $\omega(\tau) > O(\sqrt{\varepsilon})$. But as before, if $\delta = 0$ there is an initial period when the motion of the interface is governed by diffusion. Since $\Lambda(\tau)$ depends on the value of λ in this initial period, and since for a growing solid $\Lambda(\tau)$ is the distance between the transition layer and the solid-liquid interface, it is

not possible to move to a reference frame where calculations can be made completely independent of the initial period. Since the length of this initial period is $O(\sqrt{\varepsilon})$, however, lowest order calculations can be made ignoring this period. Thus for large times, the position of the interface is

$$\xi = \Lambda(\tau) = \lambda_0 + \frac{\lambda_1}{3}\tau + O(\sqrt{\varepsilon}, \tau^2)$$

where λ_0 and λ_1 are determined by the interface conditions (1.1c, d) for $\tau > O(\sqrt{\varepsilon})$. Note that if $\delta = Or(\varepsilon^0)$, there is no diffusive period and therefore no $O(\sqrt{\varepsilon})$ error term.

Finding a uniform asymptotic solution for the solid in the growth case implies combining two outer solutions, one for $\xi < 0$, one for $0 < \xi < \Lambda(\tau)$, with an inner solution at $\xi = 0$. As before, the outer solution deep in the solid is simply $u_{\text{left}}(\xi, \tau) = u_s^\infty$.

Now consider the region between the transition layer and the interface, and let $u_r \equiv u_{\text{right}}$ be the outer solution in this region. To lowest order in ε, the outer equation corresponding to (2.4) is

$$2\tau \partial_\tau u_r^0(\xi, \tau) = \xi \partial_\xi u_r^0(\xi, \tau). \tag{2.5}$$

This equation simply indicates that u_r^0 is constant along the characteristic curves $\xi^2\tau = x = \text{constant}$. Let u_-^{00} and u_-^{01} be the interface constants for the solid solution, i.e., require that

$$u_r^0(\Lambda(t), t) = u_-^{00} + u_-^{01} t + O(t^2). \tag{2.6}$$

Then to lowest order in ε, $u_r(\xi, \tau)$ is found by solving $\xi^2\tau = (\Lambda(t))^2 t$ for t and substituting into (2.6). If $\Lambda(t)$ is approximated to $O(t^2)$, then the equation to be solved is a cubic with one real root. The resulting outer solution is then

$$u_r^0(\xi, \tau) = u_-^{00} + u_-^{01}[Q_+(\xi, \tau) + Q_-(\xi, \tau)]^2 + \text{HOT} \tag{2.7}$$

where HOT represents higher order terms and

$$Q_\pm(\xi, \tau) = \left[\frac{3\xi\sqrt{\tau}}{2\lambda_1} \pm \left[\frac{\lambda_0^3}{\lambda_1^3} + \frac{9\xi^2\tau}{4\lambda_1^2}\right]^{1/2}\right]^{1/3}. \tag{2.8}$$

Note that if $\delta = 0$, then $\lambda_0 = 0$ and (2.7) and (2.8) reduce to

$$u_r^0(\xi, \tau) = u_-^{00} + u_-^{01}\left[\frac{9\xi^2\tau}{\lambda_1^2}\right]^{1/3} + O(\tau^{2/3}).$$

Again the coefficients u_-^{00}, u_-^{01}, λ_0 and λ_1 are found using the interface conditions.

Now consider the inner equation near $\xi = 0$. By dominant balance, the appropriate inner equation is

$$4\tau \partial_\tau u_{\text{in}}(X, \tau) = \partial_{XX} u_{\text{in}}(X, \tau) + 2X \partial_X u_{\text{in}}(X, \tau) \tag{2.9}$$

where $X = \xi/\sqrt{\varepsilon}$. To lowest order in ε, the inner solution is essentially the similarity solution

$$u_{\text{in}}^0(X, \tau) = u_s^\infty + \tfrac{1}{2}[u_-^{00} - u_s^\infty] \operatorname{erfc}(-X).$$

This lowest order inner solution, however, may not be sufficient to construct a uniform solution which is $O(\varepsilon)$ or $O(\sqrt{\varepsilon})$ for all ξ since fractional powers of ε (other than $\sqrt{\varepsilon}$) may appear in the expansion. To determine if any such powers are present, the following lemma is needed. The lemma shows the effect on the inner solution of a nonconstant outer solution u_r satisfying (2.5). In particular note that higher order terms from the outer solution do not affect the lower order terms of the inner solution.

LEMMA 2.4. *Suppose that $u_{\text{in}}(X, \tau)$ is an inner solution satisfying* (2.9) *and suppose that u_-^{00}, u_s^{∞}, K, m, n and q are constants with $0 < q < m+n$. If $u_{\text{in}}(X, \tau)$ matches the outer solutions $u_{\text{left}}(\xi, \tau) = u_s^{\infty}$ on the left and $u_r(\xi, \tau) = u_-^{00} + K(\xi^2\tau)^q + O(\tau^m \varepsilon^n)$ on the right, then*

$$u_{\text{in}}(X, \tau) = u_s^{\infty} + \tfrac{1}{2}[u_-^{00} - u_s^{\infty}] \operatorname{erfc}(-X) + Kq(\varepsilon\tau)^q \operatorname{ierfc}^{2q}(-X) + O(\varepsilon^{m+n}, \varepsilon)$$

where $\operatorname{ierfc}^{2q}$ *is defined using an extension of the Dirichlet formula for repeated integrals*:

$$\operatorname{ierfc}^{2q}(X) \equiv \int_0^{\infty} s^{2q-1} \operatorname{erfc}(s+X)\, ds.$$

Remark. The function $\operatorname{ierfc}^{2q}$ can be thought of as a fractionally iterated error function. For $2q \in \mathbb{Z}^+$, it agrees (up to a factor of $\Gamma(2q)$) with the usual definition for an iterated error function. The function equivalently can be viewed as a convolution of $\operatorname{erfc}(X)$ with the generalized function x_+^{λ}. The definition can then be extended to include fractional derivatives when $q \leqq 0$ [22, p. 48].

Proof. Confirming that u_{in} satisfies the differential equation (2.9) is a simple application of integration by parts. Since the latter two terms in u_{in} both vanish as $X \to -\infty$, u_{in} correctly matches u_{left}. On the right, the sum of the first two terms asymptotically tends to u_-^{00}. As for the third term, fix β so that $0 \ll \beta \ll X$ and let $p = 2q - 1$. Then since $\operatorname{erfc}(-s) = 2 - \operatorname{erfc}(s)$,

$$\begin{aligned}\int_0^{\infty} s^p \operatorname{erfc}(s-X)\, ds &= \int_0^{2X} s^p \operatorname{erfc}(s-X)\, ds + \text{TS} \\ &= \frac{1}{q} X^{2q} + \int_0^{X} [(X+s)^p - (X-s)^p] \operatorname{erfc}(s)\, ds + \text{TS}\end{aligned}$$

where TS represents terms that are transcendentally small, i.e., terms which, as $X \to \infty$, tend to zero faster than X^{-n} for all n. But

$$\begin{aligned}\int_0^{X} [(X+s)^p - (X-s)^p] \operatorname{erfc}(s)\, ds &\leqq X^p \int_0^{\beta} \left[\left(1+\frac{t}{X}\right)^p - \left(1-\frac{t}{X}\right)^p\right] dt + \text{TS} \\ &\leqq pX^{p-1}\beta^2 + O(X^{p-3}).\end{aligned}$$

Hence for $X \gg 0$, $Kq(\varepsilon\tau)^q \operatorname{ierfc}^{2q}(-X)$ asymptotically approaches $K(\xi^2\tau)^q$. Finally terms which are $O(\varepsilon^n)$ in the outer solution match similar terms in the inner solution, while $O(\tau^m)$ terms in the outer solution correspond to $O(\varepsilon^m)$ terms in the inner solution. Also the term $\varepsilon \partial_{\zeta\zeta} u$ in (2.4) implies that the size of the next terms in the inner expansion will be at least $O(\varepsilon)$.

To construct a uniform solution for the growth case, the outer solutions must now be analyzed on the scale of the inner variable and matched to the appropriate inner solution. Let $u_m(X, \tau)$ be the right outer solution written on the scale of the inner variable. Two cases again arise: first when $\delta = 0$ so that $\lambda_0 = 0$, and second when $\delta = Or(\varepsilon^0)$ so that $\lambda_0 = Or(\varepsilon^0)$ also. In the first case, $u_m(X, \tau) = u_r(\xi, \tau)$, i.e.,

$$u_m(X, \tau) = u_-^{00} + u_-^{01} \varepsilon^{1/3} \left[\frac{9X^2\tau}{\lambda_1^2}\right]^{1/3} + O(\varepsilon^{2/3}), \qquad X > 0.$$

In the second case, in terms of the inner variable, (2.8) becomes

$$Q_{\pm}(\xi, \tau) = \pm\left[\frac{\lambda_0}{\lambda_1}\right]^{1/2} + \sqrt{\varepsilon}\, \frac{X\sqrt{\tau}}{2\lambda_0} + O(\varepsilon);$$

hence

$$u_m(X,\tau)=u_-^{00}+u_-^{01}\frac{\varepsilon X^2\tau}{\lambda_0^2}+O(\varepsilon^{3/2}),\qquad X>0.$$

Uniform solutions for the solid concentration can now be obtained by adding the inner and outer solutions, then subtracting the matching terms. When $\delta=0$, the inner solution is given by the Lemma 2.4 with $q=\frac{1}{3}$. The uniform solution for $\tau>Or(\sqrt{\varepsilon})$ in this case is thus

$$u(\xi,\tau)=u_s^\infty+\tfrac{1}{2}[u_-^{00}-u_s^\infty]\operatorname{erfc}(-\xi/\sqrt{\varepsilon})+u_-^{01}\left[\frac{\varepsilon\tau}{3\lambda_1^2}\right]^{1/3}\operatorname{ierfc}^{2/3}(-\xi/\sqrt{\varepsilon})+O(\sqrt{\varepsilon},\tau^{2/3}).$$

When $\delta=Or(\varepsilon^0)$, $q=1$. Hence in this case the terms of the inner solution which match the lowest order terms in τ and ε of the outer solution are higher order in ε. Therefore the uniform solution is

$$u(\xi,\tau)=u_s^\infty+\tfrac{1}{2}[u_-^{00}-u_s^\infty]\operatorname{erfc}(-\xi/\sqrt{\varepsilon})+u_-^{01}S(\xi,\tau)+O(\varepsilon,\tau^2)$$

where

$$S(\xi,\tau)=\begin{cases}0, & \xi\leqq 0,\\ [Q_+(\xi,\tau)+Q_-(\xi,\tau)]^2, & \xi>0.\end{cases}$$

2.3. Mixed growth-decay problems. Up until this point, in all of the problems analyzed, the thermal perturbation has caused either growth or decay for all values of τ. In this section attention will be given to mixed problems where the time-dependent and time-independent terms of $\omega(\tau)$ drive the interface in opposite directions.

Consider the case when the time-independent term induces growth while the time-dependent term induces decay (a similar argument can be given if the signs on the terms are reversed). Under these conditions, the crystal will initially grow since $\lambda_0>0$, but after a time the process will reverse to decay since $\lambda_1<0$. The turning point occurs when $\lambda(\tau)=0$ which (to $O(\sqrt{\varepsilon},\tau^2)$) corresponds to $\tau=\tau_{tp}\equiv-(\lambda_0/\lambda_1)$ and $\xi=\Lambda(\tau_{tp})=\frac{2}{3}\lambda_0$. The mixed solution is then found by combining a growth solution (similar to that of § 2.2) for $0\leqq\tau\leqq\tau_{tp}$ with a decay solution (similar to that of § 2.1) for $\tau\geqq\tau_{tp}$. The accuracy of these inequalities, however, is limited to $O(\sqrt{\varepsilon})$ since the rapid growth/decay approximation is not valid for an $O(\sqrt{\varepsilon})$ time interval around the turning point. Indeed this accuracy limit holds for all equalities and inequalities throughout this section.

The growth solution is again constant along the characteristic curves $\xi^2\tau=$ constant and again is found by solving $(\Lambda(t))^2t=\xi^2\tau$ for t and substituting into (2.6). In this case, however, when $\Lambda(\tau)$ is approximated to $O(t^2)$, the resulting cubic has three real roots. The appropriate root is the smallest of the three; using this value for t, one finds that the uniform solution in the solid for $0\leqq\tau\leqq\tau_{tp}$ is

$$u(\xi,\tau)=u_s^\infty+\tfrac{1}{2}[u_-^{00}-u_s^\infty]\operatorname{erfc}(-\xi/\sqrt{\varepsilon})+u_-^{01}R(\xi,\tau)+O(\varepsilon,\tau^2)\tag{2.10}$$

where u_-^{00} and u_-^{01} are determined as before by the interface conditions and where

$$R(\xi,\tau)=\begin{cases}0, & \xi\leqq 0,\\ \tfrac{1}{4}[Q_+(\xi,\tau)+Q_-(\xi,\tau)+\sqrt{-3}[Q_+(\xi,\tau)-Q_-(\xi,\tau)]]^2, & \xi>0.\end{cases}$$

Note that since in this case Q_+ and Q_- are complex conjugates, $R(\xi,\tau)$ is real and continuous at $\xi=0$. Also note that $-(\lambda_0/\lambda_1)$ is not only the value of τ for which $\lambda(\tau)=0$, but is also the maximum value of τ for which (2.4) can be solved using characteristics when λ_1 is negative. The solution for $\tau\leqq\tau_{tp}$ is illustrated in Fig. 2.2(a).

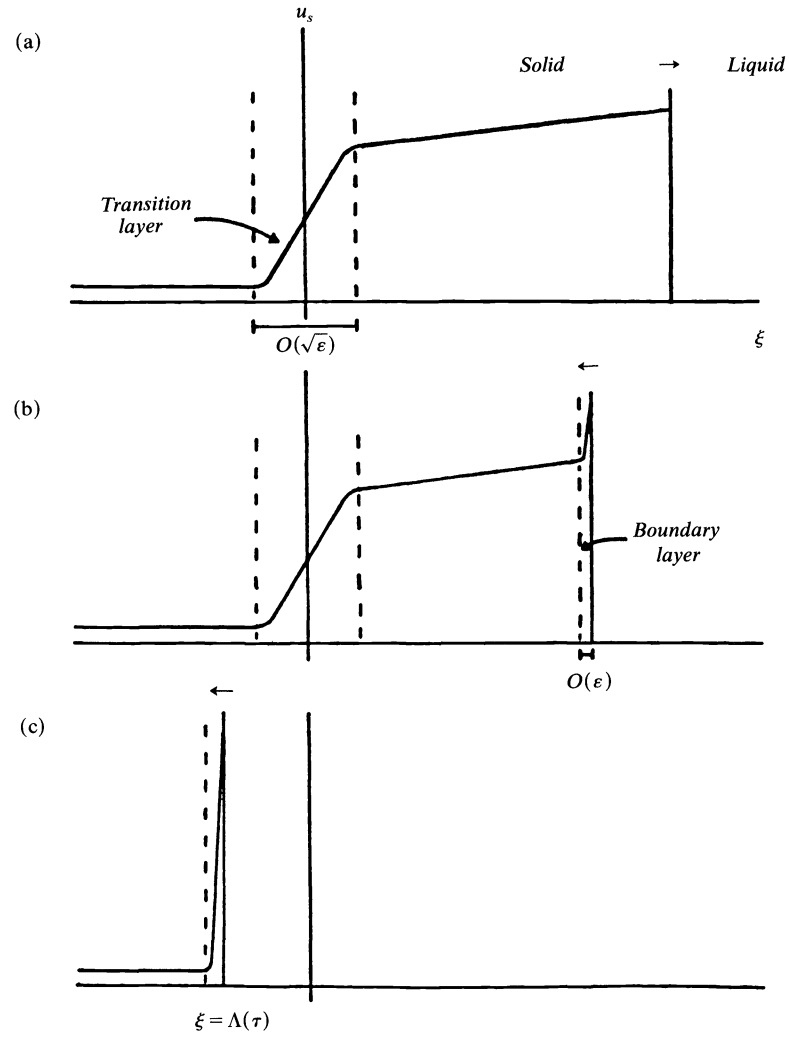

FIG. 2.2. *Mixed growth-decay case: When subject to both undercooling* ($T_0 < T_{sat}$) *and a temperature ramp* ($\sigma = 1$), (a) *the crystal initially grows,* (b) *then begins to decay,* (c) *finally resembling pure decay.*

At $\tau = \tau_{tp}$ growth ends and decay begins. Since $u(\xi, \tau_{tp})$ in the liquid is not constant, the decay solution of the previous section is not immediately applicable. The variation in u is $O(\tau_{tp})$, however, and can be viewed as a new perturbation of the interface concentrations. Therefore the formula for $u(\xi, \tau)$ in the solid is still determined by (2.4) using essentially the same argument as in § 2.1, except that the inner solution must now be matched to the growth solution given by (2.10) rather than to u_s^∞. The uniform solution for the solid valid beginning at $\tau = \tau_{tp}$ is thus

$$u(\xi, \tau) = u_s^\infty + \tfrac{1}{2}[u_-^{00} - u_s^\infty] \operatorname{erfc}(-\xi/\sqrt{\varepsilon}) + u_-^{01} R(\xi, \tau)$$
$$+ [u_{d-}^0(\tau) - u_-^{00} - u_-^{01} R(\Lambda(\tau), \tau)] 4 e^{-2\lambda_d(\tau)(\xi - \Lambda(\tau))/\varepsilon} + O(\sqrt{\varepsilon}, \tau^2)$$

where for $\tau > \tau_{tp}$, the coefficient functions $u_{d-}(\tau)$ and $\lambda_d(\tau)$ are respectively the interface concentration for the solid and the interface velocity during the decay period. These

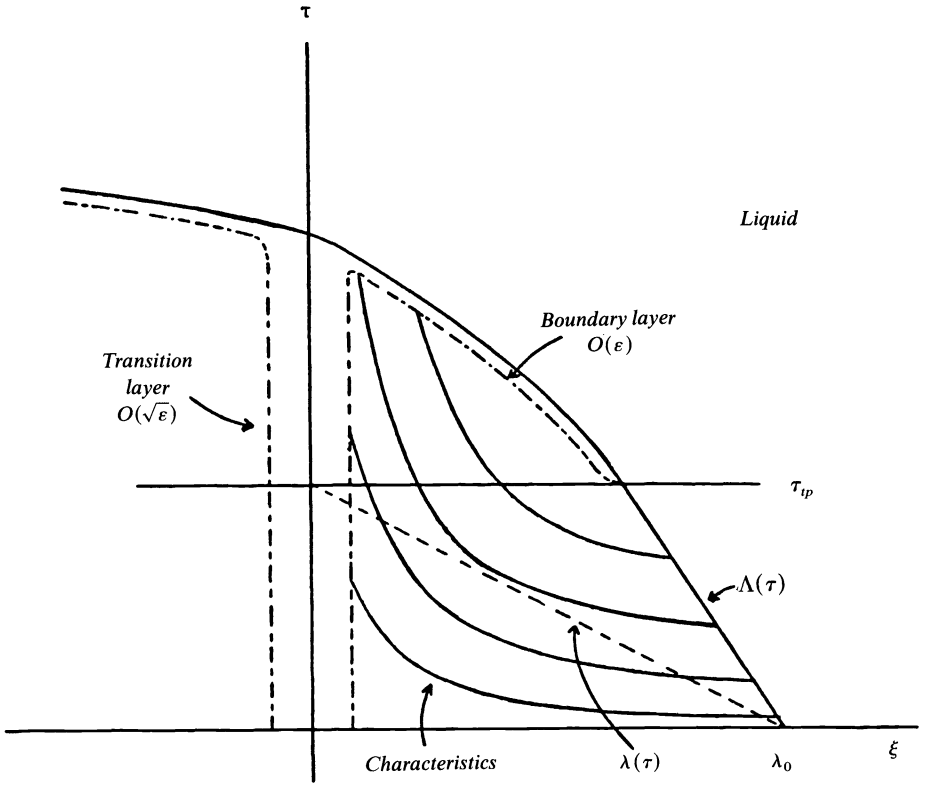

FIG. 2.3. *The interface, transition and boundary layers in the $\xi\tau$-plane.*

functions can be determined using the interface conditions and taking the new perturbation into account. Figure 2.2(b) illustrates this solution.

Let τ_0 be the value of τ such that $\Lambda(\tau_0) = 0$. For τ near τ_0 (i.e., for $\tau = \tau_0 \pm O(\sqrt{\varepsilon})$), the retreating interface moves across the transition layer. After this interval, the solution in the solid is then very similar to the solution given in the pure decay case (Fig. 2.2(c)): the general profiles of these solutions are the same, and the exact interface coefficients differ only due to the boundary perturbations in the liquid phase. Indeed because of the semi-infinite nature of this phase, the significance of these perturbations decreases with time, and this solution asymptotically approaches the solution of the pure decay case.

The regions for which the various solutions are valid are shown in Fig. 2.3. Note the relative widths of the transition and boundary layers.

3. The semiconductor problem. The results of the previous section will now be used to study the effects of a linear temperature ramp on the LPE decay of semiconductor crystals (applications to LPE growth or mixed growth-decay problems can also be made). This problem is somewhat more complicated than the one studied in § 2 since there are now several unknown concentrations to be found in each phase. Hence (1.1) is transformed to a coupled system of Stefan problems. To simplify notation and because of the particular interest in gallium-aluminum-arsenide (GaAlAs), the present discussion will focus on this semiconductor. It should be noted, however, that the results given here are applicable to any one-dimensional LPE process.

The principal assumptions in this model are that the problem is spacially one dimensional and that each phase is semi-infinite. Since (1.1) is classically well posed for sufficiently small thermal perturbations [5], there is no "mushy region" in the model. Thus the formation of dendrites or pits in the solid is not taken into account. Since GaAlAs crystals formed by LPE typically "grow smooth but decay rough" (cf. [23]-[25]), a model incorporating pit formation in the decaying case would be preferred. However, the physical implications of this model are still interesting. Also the semi-infinite assumption for the liquid is valid only for an initial period since the liquid is in fact of finite depth. (The depth of the solid is also finite, but the diffusion coefficient in this phase is so extremely small that the semi-infinite assumption for this phase is valid for any practical time.) Since numerical methods can only easily handle times outside of this initial period, however, the solution obtained by assuming a semi-infinite liquid can be used as a "starter solution" for an analytic-numerical scheme valid for a wide range of times [9].

The crystal structure for GaAlAs is face-centered cubic (or diamond) with tetrahedral bonding. Half of the lattice sites are occupied by arsenic atoms, the other half by either gallium or aluminum atoms. For the present model the aluminum atoms are viewed as diffusing across the gallium sites. In the semiconductor liquid, gallium serves as the solvent with aluminum and arsenic present in substantially smaller amounts. Hence aluminum and arsenic are viewed as the diffusing species in this phase.

Let the concentrations of the constituent species be measured in mole fractions for both the solid and liquid phases. Specifically, let u_i be the fraction of liquid made of the ith constituent and $u_{i,s}$ the fraction of the solid made of the ith constituent. To simplify notation, let the aluminum fraction of the solid be denoted u_s. Finally let D_s, D_{Al} and D_{As} be the diffusion coefficients for aluminum in the solid and aluminum and arsenic in the liquid. Equations (3.1) then govern these concentrations in both phases.

Partial Differential Equations:

Solid: $x < S(t)$:

$$u_{\mathrm{Ga},s} + u_s = \tfrac{1}{2}, \tag{3.1a}$$

$$\partial_t u_s(x, t) = D_s \partial_{xx} u_s(x, t), \tag{3.1b}$$

$$u_{\mathrm{As},s} = \tfrac{1}{2}. \tag{3.1c}$$

Liquid: $x > S(t)$:

$$u_{\mathrm{Ga}} + u_{\mathrm{Al}} + u_{\mathrm{As}} = 1, \tag{3.1d}$$

$$\partial_t u_{\mathrm{Al}}(x, t) = D_{\mathrm{Al}} \partial_{xx} u_{\mathrm{Al}}(x, t), \tag{3.1e}$$

$$\partial_t u_{\mathrm{As}}(x, t) = D_{\mathrm{As}} \partial_{xx} u_{\mathrm{As}}(x, t). \tag{3.1f}$$

Equations (3.1) are coupled at the solid-liquid interface by two Stefan conditions, one for arsenic, one for aluminum, and two thermodynamic equilibrium conditions that represent the continuity of chemical potentials across the phase interface and that are determined by the phase diagram for GaAlAs. As before, the initial conditions are that all of the concentrations be constant and that $S(0) = 0$.

Interface Conditions: $x = S(t)$:

Stefan Conditions:

$$v(t)[u_s(t) - u_{\mathrm{Al}}(t)] = D_{\mathrm{Al}} \partial_x u_{\mathrm{Al}}(t) - D_s \partial_x u_s(t), \tag{3.2a}$$

$$v(t)[\tfrac{1}{2} - u_{\mathrm{As}}(t)] = D_{\mathrm{As}} \partial_x u_{\mathrm{As}}(t). \tag{3.2b}$$

Equilibrium Conditions:

$$\mu_{Ga}(T, u) + \mu_{As}(T, u) = \mu_{GaAs}(T, u), \tag{3.2c}$$

$$\mu_{Al}(T, u) + \mu_{As}(T, u) = \mu_{AlAs}(T, u). \tag{3.2d}$$

Initial Conditions:

$$u_s(x, 0) = u_s^{\infty},$$
$$u_{Al}(x, 0) = u_{Al}^{\infty},$$
$$u_{As}(x, 0) = u_{As}^{\infty}.$$

The initial aluminum concentration in the solid is often (though not always) taken to be zero. The initial liquid concentrations are determined by the process used to prepare the liquid. Assume that the liquid is prepared at a saturation temperature T_{sat} to be uniformly in equilibrium with a solid whose aluminum concentration is u_s^e.

In (3.2c), (3.2d), μ_i represents the chemical potential of the ith species as a function of temperature and constituent concentrations. Assume that the temperature is ramped, i.e., let $T(t) = T_0 + rt$, where T_0 is the initial temperature and r is the ramping rate. Then $T(\delta, \tau) = T_{sat}(1 + \delta + \sigma\tau)$ where $\tau = |r|t/T_{sat}$, $\sigma = \operatorname{sgn}(r)$, and $\delta = (T_0 - T_{sat})/T_{sat}$. Here δ represents the relative difference between the initial temperature for the LPE process and the saturation temperature at which the liquid phase is prepared; this difference is referred to as undercooling.

The details of linearizing the interface conditions are discussed elsewhere [26, p. 27]. Roughly speaking, the results are that the GaAlAs crystal grows when $T < T_{sat}$ and decays when $T > T_{sat}$. Also the interface concentration for aluminum in the solid increases in time for $\sigma = 1$ and decreases for $\sigma = -1$.

Although the concentrations of the constituents in both phases can be determined, principal attention is given to the aluminum concentration in the solid. This concentration is of particular interest from the practical view of manufacturing devices. The goal is to form regions in the solid of high aluminum concentration sandwiched between regions having little or no aluminum. Ghez and Small [10] have speculated that an internal maximum in the aluminum concentration of the solid could be produced by a temperature ramp which caused the crystal to decay. Applying Lemma 2.3, however, one can see that this is not case. In particular, the presence of the exponential factor in (2.3) assures that no internal maximum is possible.

For GaAlAs, $D_{Al} \simeq D_{As} \simeq 10^{-5}$ cm^2/sec while reported values for D_s vary rather widely from 10^{-9} cm^2/sec to as low as 10^{-17} cm^2/sec [9]. Since in most LPE processes $D_s \leqq 10^{-12}$, the range for $\sqrt{\varepsilon}$ is approximately $10^{-6} \leqq \sqrt{\varepsilon} \leqq 10^{-4}$. Assume that $r =$ 10°C/min and that $T_0 = T_{sat} \simeq 850$°C (both of these assumptions are typical) [10]. For $\sqrt{\varepsilon} = 10^{-4}$, the condition that τ be larger than $\sqrt{\varepsilon}$ requires that t be greater than roughly 1 sec. Note that this restriction does not present a difficulty for the linearization of the interface conditions since $\tau \ll 1$ only implies that $t \ll 10^4$ sec. Now assume that the liquid phase is sufficiently thick so that the semi-infinite approximation is valid for both phases and that $u_s^e = 0.175$. Then $u_{Al}^{\infty} = 3.25 \times 10^{-3}$ and $u_{As}^{\infty} = 2.71 \times 10^{-2}$. If $u_s^{\infty} = 0.1$, then Fig. 3.1 illustrates the thermal decay solution for these parameter values when $t = 1$, 10, and 100 sec and shows how narrow the boundary layer becomes. Indeed since the figure spans only 100 A (20–50 atomic layers), the continuum model is breaking down, and one would expect no increase in the aluminum concentration in the interior of the solid for times much larger than 10 sec. For smaller values of D_s the boundary layer disappears even more rapidly. A temperature ramp of this sort

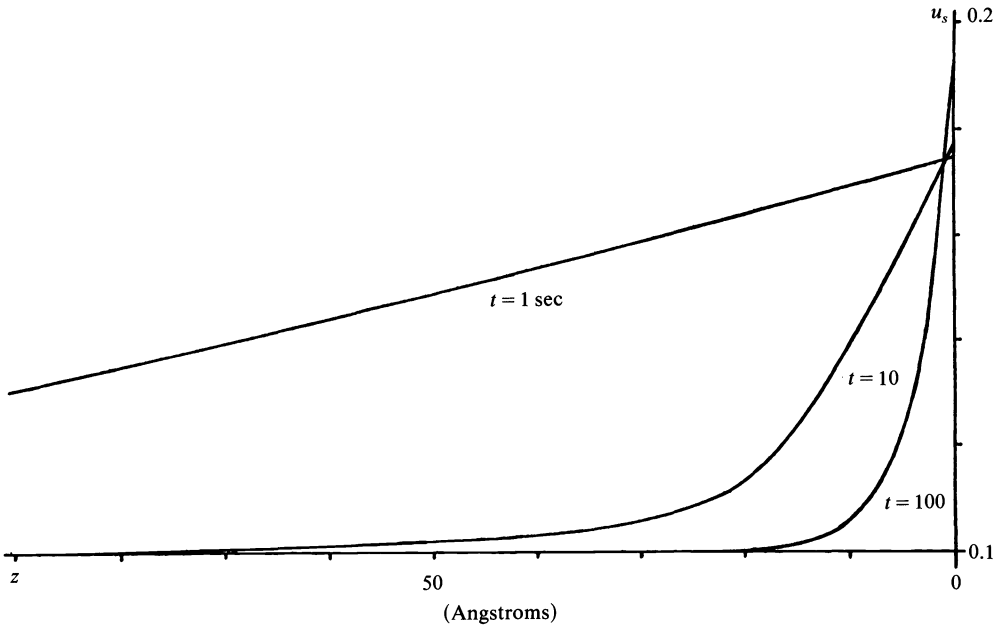

FIG. 3.1. *Graph of the long-time solution for temperature-ramp induced decay when* $T_0 = T_{sat} = 850°C$, $r = 10°C/min$, *and* $D_s = 10^{-13}$ cm^2/sec. *Note that* $z = 0$ *is the solid-liquid interface.*

would therefore not be useful in creating a shallow aluminum-rich region in an LPE crystal. From the solutions given in § 2, one sees that no other temperature ramp would create isolated aluminum-rich regions either.

Acknowledgments. My thanks go to David G. Schaeffer and Richard Ghez who have helped me greatly in this work.

BIFURCATION ANALYSIS OF REACTION-DIFFUSION EQUATIONS VI. MULTIPLY PERIODIC TRAVELLING WAVES*

JAMES C. ALEXANDER† AND GILES AUCHMUTY‡

Abstract. The bifurcation of periodic travelling-wave solutions of a system of reaction-diffusion equations from a trivial solution is studied. We allow general periodicity conditions and show that the resulting bifurcation is characterized by the wave vector **k** and a wave speed c. Criteria for the global branching of such solutions are described and the results are applied to the Brusselator.

Key words. reaction-diffusion equations, global bifurcation, travelling waves, multiparameter bifurcation, multiply periodic

AMS(MOS) subject classification. 35D30, 35K20, 35B32

1. Introduction.

In recent years a lot of work has been done applying bifurcation theory to describe various special classes of solutions of reaction-diffusion equations. The bifurcation of stationary and time-dependent solutions is well-known. More recently considerable work has been done in describing wave-like solutions in problems with rotational symmetry; see (Alexander [1986]; Alexander and Auchmuty [1979]; Auchmuty [1979]; Auchmuty [1984]; Auchmuty and Nicolis [1976]). In this paper we shall study the bifurcation of travelling-wave solutions which are periodic in space.

Consider the general reaction-diffusion system

$$\frac{\partial u_i}{\partial t} = D_i \Delta u_i + f_i(u_1, \ldots, u_m; \mu), \tag{1.1}$$

on $R^n \times (0, \infty)$. Here $i = 1, \ldots, m$ and $u_i(\mathbf{x}, t)$ generally models the concentration of the ith chemical species at a point $(\mathbf{x}, t)$ of space-time. The Laplacian Δ is

$$\Delta v = \sum_{j=1}^{n} \frac{\partial^2 v}{\partial x_j^2}$$

and the functions $f_i: R^{m+1} \to R$, depending on a parameter μ, define the kinetics of the system.

Our interest is in studying the bifurcation of travelling-wave solutions of (1.1) which are also periodic in space. That is, we seek solutions of (1.1) of the form

$$\mathbf{u}(\mathbf{x}, t) = \mathbf{v}(x_1 - c_1 t, x_2 - c_2 t, \ldots, x_n - c_n t), \tag{1.2}$$

where $\mathbf{v}$ is also periodic on R^n. It may be periodic in each variable separately or more generally we treat the case where

$$\mathbf{v}\left(\mathbf{x}+\sum_{j=1}^{n} k_j \mathbf{a}_j\right) = \mathbf{v}(\mathbf{x}) \tag{1.3}$$

for any n linearly independent vectors $\mathbf{a}_1, \mathbf{a}_2, \ldots, \mathbf{a}_n$ and any $\mathbf{k} = (k_1, k_2, \ldots, k_n) \in \mathbf{Z}^n$, the set of all n-tuples of integers.

The parameter μ will be regarded as the bifurcation parameter. In general, it need not occur in the kinetics but could arise elsewhere in the system, but this usually only causes minor changes in the analysis. It might appear that this is a bifurcation problem with $(n+1)$ parameters $(c_1, c_2, \ldots, c_n, \mu)$, but in fact there actually are only two parameters (c, μ), for bifurcation with a given wave vector $\mathbf{k} \in \mathbf{Z}^n$. This is described in section 4 where we give the general global bifurcation theorem. In sections 2 and 3 we formulate the problem mathematically as a fixed-point problem and then in section 5 we show how the analysis applies to the Brusselator in two and three space dimensions.

2. Description of the problem. Our interest is in studying the bifurcations of periodic travelling wave solutions of the reaction-diffusion system (1.1) from a trivial stationary solution. The pure reaction system may be written in vector form as

$$\frac{d\mathbf{u}}{dt} = \mathbf{f}(\mathbf{u}; \mu) \tag{2.1}$$

where $\mathbf{u}(t) = \big(u_1(t), u_2(t), \ldots, u_m(t)\big)^T$ and $\mathbf{f}(\mathbf{u}; \mu)$ has components $f_i(\mathbf{u}; \mu)$, $1 \le i \le m$. Here μ is a real parameter. We assume:

(F1) $\mathbf{f}: R^{m+1} \to R^m$ *is continuously differentiable and* $\mathbf{f}(\mathbf{0}; \mu) = \mathbf{0}$ *for all* $\mu \in R$.

Define $F(\mu) = \left(\frac{\partial f_i}{\partial u_j}(\mathbf{0}; \mu)\right)$ to be the Jacobian matrix of $\mathbf{f}(\,\cdot\,; \mu)$ at $\mathbf{u} = \mathbf{0}$. The assumption (F1) implies that $\mathbf{u}(\mathbf{x}, t) \equiv \mathbf{0}$ is a solution of (1.1) for all μ. It is called the *trivial solution* and we are interested in the bifurcation of certain wave-like solutions from it. For many particular systems, the trivial solution is not the zero solution, but a change of variables effects (F1).

Consider the problem of finding solutions of (1.1) of the form

$$\begin{aligned} \mathbf{u}(\mathbf{x}, t) &= \mathbf{v}(x_1 - c_1 t, x_2 - c_2 t, \ldots, x_n - c_n t) \\ &= \mathbf{v}(\mathbf{x} - \mathbf{c}t), \end{aligned} \tag{2.2}$$

where $\mathbf{c} = (c_1, c_2, \ldots, c_n)$ is non-zero, and $\mathbf{v}$ is periodic of period α_j in the jth variable, $1 \le j \le n$. Let $\mathbf{e}_j$ be the unit vector in R^n whose jth coordinate is 1 and all other coordinates are 0, and let $\xi_j = x_j - c_j t$. Then for any $\mathbf{k} = (k_1, k_2, \ldots, k_n) \in \mathbf{Z}^n$, one has

$$\mathbf{v}\left(\boldsymbol{\xi} + \sum_{j=1}^{n} k_j \alpha_j \mathbf{e}_j\right) = \mathbf{v}(\boldsymbol{\xi}) \qquad \text{for all } \boldsymbol{\xi} \in R^n. \tag{2.3}$$

Moreover if $\mathbf{v}$ is a solution of (1.1), then its components v_i are solutions of the semi-linear elliptic system

$$D_i \Delta v_i + \sum_{j=1}^{n} c_j \frac{\partial v_i}{\partial \xi_j} + f_i(v_1, v_2, \ldots, v_m) = 0. \tag{2.4}$$

Here $1 \le i \le m$, $\boldsymbol{\xi} \in R^n$ and $\mathbf{v}$ obeys the periodicity conditions (2.3). One may regard (2.3), (2.4) as an elliptic system defined on the domain $\overline{\Omega}_\alpha = [0, \alpha_1] \times [0, \alpha_2] \times \cdots [0, \alpha_n]$

subject to the periodic boundary conditions

$$\begin{aligned} &\mathbf{v}(\boldsymbol{\xi}) = \mathbf{v}(\boldsymbol{\xi} + \alpha_j \mathbf{e}_j) \qquad \text{for all } \boldsymbol{\xi} \in \overline{\Omega}_\alpha \text{ with } \xi_j = 0, \\ &\frac{\partial \mathbf{v}}{\partial \xi_k}(\boldsymbol{\xi}) = \frac{\partial \mathbf{v}}{\partial \xi_k}(\boldsymbol{\xi} + \alpha_j \mathbf{e}_j), \qquad 1 \le j, k \le n. \end{aligned} \tag{2.5}$$

Thus the problem of finding periodic travelling-wave solutions of the form (2.2) is equivalent to solving the boundary-value problem (2.4)–(2.5).

Note that the vectors $\alpha_j \mathbf{e}_j$, $1 \le j \le n$, generate a lattice in R^n, a discrete subgroup of maximal rank n. The periodicity condition can be phrased: if $\mathbf{x}, \mathbf{x}' \in R^n$ are in the same coset of the lattice, the solutions are equal at $\mathbf{x}$ and $\mathbf{x}'$. The lattice of the $\alpha \mathbf{e}_j$, $1 \le j \le n$, is a rectangular lattice. It is possible to work with more general lattices; that is, more general periodicity conditions. Let $\mathbf{a}_1, \mathbf{a}_2, \ldots, \mathbf{a}_n$ be n linearly independent points in R^n, and suppose $\mathbf{a}_i = (a_{i1}, a_{i2}, \ldots, a_{in})$. Let

$$\Omega_A = \left\{ \mathbf{x} \in R^n : \mathbf{x} = \sum_{j=1}^{n} \beta_j \mathbf{a}_j \text{ with } 0 \le \beta_j \le 1 \right\}.$$

Then Ω_A is an n-dimensional parallelepiped. When $n = 2$, it is a parallelogram with vertices $\mathbf{0}$, $\mathbf{a}_1$, $\mathbf{a}_2$, $\mathbf{a}_1 + \mathbf{a}_2$. We look for solutions of (1.2) subject to the "skewed" periodicity conditions (1.3). For example, suppose $\mathbf{a}_1 = (1, 1)$ and $\mathbf{a}_2 = (0, 2)$. Then (1.3) reads

$$\mathbf{v}(x_1 + 1, x_2 + 1) = \mathbf{v}(x_1, x_2 + 2) = \mathbf{v}(x_1, x_2).$$

Such solutions are of course defined on the quotient space of R^n by the lattice. This space is a skewed flat n-dimensional torus. Topologically it is the product of n circles, one for each periodicity condition.

Let A be the (nonsingular) matrix (a_{ij}) and let $B = A^{-1}$. For the example just above

$$A = \begin{pmatrix} 1 & 1 \\ 2 & 0 \end{pmatrix}, \qquad B = \frac{1}{2} \begin{pmatrix} 0 & 1 \\ 2 & -1 \end{pmatrix}.$$

Define $y_i = \sum_{j=1}^{n} b_{ij} x_j$, $1 \le i \le n$. Then $\mathbf{x} \in \overline{\Omega}_A$ if and only if $\mathbf{y} = B\mathbf{x} \in [0, 1]^n$, the cube of unit side in R^n. By the chain rule,

$$\frac{\partial u_i}{\partial x_j} = \sum_{k=1}^{n} b_{kj} \frac{\partial u_i}{\partial y_k},$$

so

$$\Delta_x u_i = \sum_{j=1}^{n} \sum_{k=1}^{n} \sum_{l=1}^{n} b_{kj} \frac{\partial^2 u_i}{\partial y_k \partial y_l} b_{lj} = \operatorname{tr} B^T D_y^2 u_i B = L_y u_i, \tag{2.6}$$

where $D_y^2 u_i = \left(\frac{\partial^2 u_i}{\partial y_k \partial y_l} \right)$ is the Hessian matrix of u_i with respect to y and $\operatorname{tr} A$ is the trace of A.

Now consider the problem of finding solutions of (1.1) of the form $\mathbf{u}(\mathbf{x}, t) = \mathbf{v}(\mathbf{y} - \mathbf{c}t)$ with $\mathbf{y} = B\mathbf{x}$ as above. Then if $\mathbf{z} = \mathbf{y} - \mathbf{c}t$,

$$D_i L_z v_i + \sum_{j=1}^{n} c_j \frac{\partial v_i}{\partial z_j} + f_i(v_1, v_2, \ldots, v_m; \mu) = 0 \tag{2.7}$$

on R^n, subject to (2.3) with each $\alpha_j = 1$ and with L_z defined by (2.6). Alternately one may regard (2.7) as an elliptic system defined on the domain $\overline{\Omega}_1 = [0, 1] \times [0, 1] \times \cdots \times [0, 1]$ and subject to the periodicity conditions

(2.8)
$$\left.\begin{aligned} \mathbf{v}(\mathbf{z}) &= \mathbf{v}(\mathbf{z}+\mathbf{e}_j) \\ \frac{\partial \mathbf{v}}{\partial z_k}(\mathbf{z}) &= \frac{\partial \mathbf{v}}{\partial z_k}(\mathbf{z}+\mathbf{e}_j) \end{aligned}\right\} \quad \text{for all } \mathbf{z} \in \Gamma_j = \{\mathbf{z} \in \partial\Omega_1 : z_j = 0\}, \quad 1 \le j,k \le n.$$

Our interest is in finding nontrivial solutions of either (2.4)–(2.5) or (2.7)–(2.8). Note that (2.4)–(2.5) can be put in the form (2.7)–(2.8) by letting $z_j = \xi_j/\alpha_j$ for $1 \le j \le n$. Thus we concentrate on the latter problem.

3. Fixed-point formulation. The system of equations (2.7)–(2.8) may be formulated as a fixed-point problem. Consider the problem of solving the scalar equation

$$w - L_z w = g \qquad \text{on } \Omega_1 \tag{3.1}$$

subject to the boundary conditions

$$\left.\begin{aligned} w(\mathbf{z}) &= w(\mathbf{z}+\mathbf{e}_j) \\ \frac{\partial w}{\partial z_k}(\mathbf{z}) &= \frac{\partial w}{\partial z_k}(\mathbf{z}+\mathbf{e}_j) \end{aligned}\right\} \quad \text{for all } \mathbf{z} \in \Gamma_j, \quad 1 \le j \le n. \tag{3.2}$$

Let $L^2(\Omega_1)$ be the usual Lebesgue space of all square-integrable complex-valued measurable functions on Ω_1. Let $H_p^1(\Omega_1)$ (resp. $H_p^2(\Omega_1)$) be the usual Sobolev space of all complex-valued functions on Ω_1 which are restrictions of periodic functions on R^n, locally in H^1 (resp. H^2) and of period 1 in each variable. Suppose $w \in L^2(\Omega_1)$. Then w has a Fourier expansion

$$w(\mathbf{z}) = \sum_{\mathbf{k}\in\mathbf{Z}^n} w_{\mathbf{k}} \exp(2\pi i\langle \mathbf{k}, \mathbf{z}\rangle), \tag{3.3}$$

where $\langle \mathbf{k}, \mathbf{z}\rangle = \sum_{j=1}^n k_j z_j$ and $w_{\mathbf{k}} = \int_{\Omega_1} w(\mathbf{z}) \exp(-2\pi i\langle \mathbf{k}, \mathbf{z}\rangle)\, dz$. From Parseval's theorem, w is in $L^2(\Omega_1)$ if and only if $\sum_{\mathbf{k}\in\mathbf{Z}^n} |w_{\mathbf{k}}|^2 < \infty$. For $\mathbf{k} = (k_1, k_2, \ldots, k_n)$

$$\frac{\partial w}{\partial z_j}(\mathbf{z}) = 2\pi i \sum_{\mathbf{k}\in\mathbf{Z}^n} k_j w_{\mathbf{k}} \exp(2\pi i\langle \mathbf{k}, \mathbf{z}\rangle) \quad \text{and}$$

$$\frac{\partial^2 w}{\partial z_i \partial z_j}(\mathbf{z}) = -4\pi^2 \sum_{\mathbf{k}\in\mathbf{Z}^n} k_i k_j w_{\mathbf{k}} \exp(2\pi i\langle \mathbf{k}, \mathbf{z}\rangle).$$

Thus, using Parseval's theorem again,

$$w \in H_p^1(\Omega_1) \quad \text{if and only if} \quad \sum_{\mathbf{k}\in\mathbf{Z}^n} (1+|k|^2)|w_{\mathbf{k}}|^2 < \infty \quad \text{and}$$

$$w \in H_p^2(\Omega_1) \quad \text{if and only if} \quad \sum_{\mathbf{k}\in\mathbf{Z}^n} (1+|k|^2)^2|w_{\mathbf{k}}|^2 < \infty,$$

where $|\mathbf{k}|^2 = \sum_{j=1}^n k_j^2$.

THEOREM 1. *Suppose $g \in L^2(\Omega_1)$. Then there is a unique $w \in H_p^2(\Omega_1)$ obeying (3.1)–(3.2) and the mapping $G: L^2(\Omega_1) \to H_p^2(\Omega_1)$ defined by $Gg = w$ is a continuous linear map.*

Proof. Take inner products of (3.1) with w. Then

$$\int_{\Omega_1} |w(\mathbf{z})|^2\, dz - \langle L_z w, w\rangle = \int_{\Omega_1} \overline{w}(\mathbf{z}) g(\mathbf{z})\, dz.$$

Now

$$-\langle L_z w, w\rangle = -\int_{\Omega_A} \Delta w(\mathbf{x})\overline{w}(\mathbf{x})|\det B|\,dx = |\det B|\int_{\Omega_A} |\nabla w(\mathbf{x})|^2\,dx \geq 0$$

by the Gauss-Green theorem. Also $I - L_z: H_p^2(\Omega_1) \to L^2(\Omega_1)$ is a closed densely-defined linear operator on $L^2(\Omega_1)$, and this inequality implies it is positive-definite. From the Lax-Milgram theorem, it has a continuous inverse and the result follows from standard elliptic operator theory.

Let $\mathcal{P}^0$ be the space of all continuous real-valued functions $\mathbf{u}: \overline{\Omega}_1 \to R$ which satisfy $\mathbf{u}(\mathbf{z}) = \mathbf{u}(\mathbf{z} + \mathbf{e}_j)$ for $\mathbf{z} \in \Gamma_j$. Similarly let $\mathcal{P}^1$ be the space of all continuously differentiable real-valued functions on $\overline{\Omega}_1$ which satisfy (3.2). Note that $\mathcal{P}^0$ and $\mathcal{P}^1$ are Banach spaces under the norms

$$\|\mathbf{u}\|_0 = \sup_{\mathbf{z}\in\overline{\Omega}_1} |\mathbf{u}(\mathbf{z})|,$$

$$\|\mathbf{u}\|_1 = \sup_{\mathbf{z}\in\overline{\Omega}_1} \left[|\mathbf{u}(\mathbf{z})| + \sum_{k=1}^{n} \left|\frac{\partial u}{\partial z_k}(\mathbf{z})\right|\right].$$

COROLLARY. *Suppose $g \in \mathcal{P}^0$. Then the solution w of* (3.1)–(3.2) *is in $\mathcal{P}^1$ and the map $G: \mathcal{P}^0 \to \mathcal{P}^1$ is a compact linear map.*

Proof. If $g \in \mathcal{P}^0$, then $g \in L^p(\Omega_1)$ for all p, $1 < p < \infty$. Hence from standard elliptic theory, $w \in W^{2,p}(\Omega_1)$ and $G: L^p(\Omega_1) \to W^{2,p}(\Omega_1)$ is continuous. If $p > n$, then $W^{2,p}(\Omega_1)$ is compactly embedded in $\mathcal{P}^1$. This proves the result.

It is worth noting that

$$\begin{aligned} L_z \exp(2\pi i\langle \mathbf{k}, \mathbf{z}\rangle) &= -4\pi^2 \sum_{m=1}^{n}\sum_{l=1}^{n}\left(\sum_{j=1}^{n} b_{mj}b_{lj}\right) k_m k_l \exp(2\pi i\langle \mathbf{k}, \mathbf{z}\rangle) \\ &= -4\pi^2\langle \mathbf{k}B, \mathbf{k}B\rangle \exp(2\pi i\langle \mathbf{k}, \mathbf{z}\rangle) \end{aligned} \tag{3.4}$$

where $\langle\cdot,\cdot\rangle$ is the usual inner product on R^n. Thus if $g(\mathbf{z}) = \sum_{\mathbf{k}\in\mathbf{Z}^n} g_{\mathbf{k}} \exp(2\pi i\langle \mathbf{k}, \mathbf{z}\rangle)$, an explicit representation for the solution w of (3.1)–(3.2) is

$$w(\mathbf{z}) = \sum_{\mathbf{k}\in\mathbf{Z}^n} \frac{g_{\mathbf{k}} \exp(2\pi i\langle \mathbf{k}, \mathbf{z}\rangle)}{1 + 4\pi^2\langle \mathbf{k}B, \mathbf{k}B\rangle}. \tag{3.5}$$

Let $X_1 = \{(v_1, v_2, \ldots, v_m) : v_j \in \mathcal{P}^1, 1 \leq j \leq m\}$ and define $\|\mathbf{v}\|_1 = \sum_{j=1}^{m} \|v_j\|_1$. Define $\mathcal{G}(\cdot, \mathbf{c}, \mu): X_1 \to X_1$ by

$$\mathcal{G}_j(\mathbf{v}, \mathbf{c}, \mu) == D_j^{-1} G\left[\sum_{k=1}^{m} c_k \frac{\partial v_j}{\partial z_k} + f_j(\mathbf{v}; u) + D_j v_j\right]. \tag{3.6}$$

From the corollary to theorem 1, we see any classical wave solution $(\mathbf{v}, \mathbf{c})$ of (2.7)–(2.8) is a fixed point of $\mathcal{G}(\cdot, \cdot, \mu)$ in $X_1 \times R^n$. That is, $(\mathbf{v}, \mathbf{c})$ is a solution of

$$\mathbf{v} = \mathcal{G}(\mathbf{v}, \mathbf{c}, \mu) \tag{3.7}$$

PROPOSITION 3.1. *$\mathcal{G}: X_1 \to X_1$, defined by* (3.6), *is a compact map. It is Fréchet differentiable and*

$$\left[D\mathcal{G}(\mathbf{0}, \mathbf{c}, \mu)h\right]_j = D_j^{-1} G\left(\sum_{k=1}^{m} c_k \frac{\partial h_j}{\partial z_k} + D_j h_j + \sum_{l=1}^{m} \frac{\partial f_j}{\partial v_l}(\mathbf{0}; \mu) h_l\right). \tag{3.8}$$

The proof of this is identical to that of Proposition 2 in (Auchmuty [1979]).

Equation (3.5) is a fixed-point problem for a compact map of the Banach space X_1 to itself which depends on $n+1$ parameters $(c_1, c_2, \ldots, c_n, \mu)$. For all $(\mathbf{c}, \mu) \in R^{n+1}$, we have $\mathbf{v} = \mathbf{0}$ is a solution of (3.7), so we look for global branches of solutions of (3.7) bifurcating from this basic solution.

4. Bifurcation results. The formulation of the last section enables us to use general functional analytic methods for bifurcation theory. We use global results, as described in (Alexander [1978]) or (Alexander and Fitzpatrick [1979]); of course local results are subsumed.

First it is worth noting that the possible bifurcation points for (3.5) can be characterized in terms of eigenvalues of $m \times m$ matrices. Given a lattice of periodicity conditions, let B be the associated matrix. For $\mathbf{k} \in \mathbf{Z}^n$, let $\lambda_{\mathbf{k}} = 4\pi^2 \langle \mathbf{k}B, \mathbf{k}B \rangle$ be the associated eigenvalue of the Laplacian. Let D be the diagonal matrix with entries D_i, $1 \le i \le n$, let $F(\mu)$ be the Jacobian of $f(\,\cdot\,, \mu)$ at $u = 0$, and define the $m \times m$ matrix

$$F_{\mathbf{k}}(\mu) = F(\mu) - \lambda_{\mathbf{k}} D. \tag{4.1}$$

PROPOSITION 4.1. *If $(\mathbf{0}, \hat{\mathbf{c}}, \hat{\mu})$ is a bifurcation point for (3.7) (or the system (2.7)–(2.8)), then there exists $\mathbf{k} \in \mathbf{Z}^n$ such that $F_{\mathbf{k}}(\hat{\mu})$ has purely imaginary eigenvalues.*

Proof. If $(\mathbf{0}, \hat{\mathbf{c}}, \hat{\mu})$ is a bifurcation point for (3.7), then from the implicit function theorem, 1 is an eigenvalue of $D\mathcal{G}(\mathbf{0}, \hat{\mathbf{c}}, \hat{\mu})$. Let h be the corresponding eigenfunction. From (3.8), h is a solution of

$$D_j\left(L_z h_j\right) + \sum_{l=1}^{n} \hat{c}_l \frac{\partial h_j}{\partial z_l} + \sum_{l=1}^{m} F_{jl}(\hat{\mu}) h_l = 0, \tag{4.2}$$

and satisfies periodicity conditions like (2.8). Expand h in a Fourier series:

$$h(\mathbf{z}) = \sum_{\mathbf{k} \in \mathbf{Z}^n} \mathbf{a}_{\mathbf{k}} \exp(2\pi i \langle \mathbf{k}, \mathbf{z} \rangle),$$

with each $\mathbf{a}_{\mathbf{k}}$ in C^m. From (3.4), for some $\mathbf{k} \in \mathbf{Z}^n$,

$$-\lambda_{\mathbf{k}} D \mathbf{a}_{\mathbf{k}} + 2\pi i \langle \hat{\mathbf{c}}, \mathbf{k} \rangle \mathbf{a}_{\mathbf{k}} + F(\hat{\mu}) \mathbf{a}_{\mathbf{k}} = 0$$

for some nonzero $\mathbf{a}_{\mathbf{k}}$. Thus $\pm 2\pi i \langle \hat{\mathbf{c}}, \mathbf{k} \rangle$ must be eigenvalues of $F_{\mathbf{k}}(\mu)$.

As usual, the necessary condition is not sufficient for bifurcation. Standard crossing and non-degeneracy conditions are needed. The situation is still more complicated. There are ostensively $n+1$ parameters, the n components of $\mathbf{c}$ and μ. Moreover there are a considerable number of degeneracies. For example, suppose the periodicity lattice is given by the unit vectors $\mathbf{e}_j$. Then all interchanges of coordinates preserve the problem and virtually all the eigenvalues are highly degenerate. It is possible to analyze the problem using equivariant bifurcation theory; however for travelling waves, we can obtain more information by dealing directly with the problem. In particular, we decompose it into simple bifurcation problems, one for each $\mathbf{k}$. We see directly that the solutions we obtain are plane-wave solutions. Generically in f, these are all the wave solutions on primary bifurcation branches. Let

$$\Delta_{\mathbf{k}} = \left\{ \mathbf{v} \in \mathcal{P}^1 : \mathbf{v}(\mathbf{z}) = \mathbf{v}(\mathbf{z} + \mathbf{z}') \text{ whenever } \langle \mathbf{z}', \mathbf{k} \rangle = 0 \right\}.$$

If $\mathbf{k} \neq \mathbf{0}$, $\Delta_{\mathbf{k}}$ is a proper closed subspace of $\mathcal{P}^1$. If $\mathbf{v} \in \Delta_{\mathbf{k}}$, there is a function $\tilde{\mathbf{v}}: R \to R^n$ which is periodic of period $k_0 = \gcd\{k_i : k_i \neq 0, 1 \le i \le n\}$, such that

$\mathbf{v}(\mathbf{z}) = \tilde{\mathbf{v}}(\langle \mathbf{k}, \mathbf{z}\rangle)$ for all $\mathbf{z} \in R^n$. Thus if $\tilde{c} = \langle \mathbf{c}, \mathbf{k}\rangle$, define

$$\mathbf{v}(\mathbf{y} - \mathbf{c}t) = \tilde{\mathbf{v}}(\langle \mathbf{k}, \mathbf{y} - \mathbf{c}t\rangle) = \tilde{\mathbf{v}}(\langle \mathbf{k}, \mathbf{y}\rangle - \tilde{c}t).$$

That is $\mathbf{u}(\mathbf{x}, t) = \tilde{\mathbf{v}}(\langle B^T\mathbf{k}, \mathbf{x}\rangle - \tilde{c}t)$. Wave solutions of (3.1) in $\Delta_{\mathbf{k}}$ are actually functions only of the scalar variable $\langle B^T\mathbf{k}, \mathbf{x}\rangle - \tilde{c}t$.

Let

$$\mathcal{S}_{\mathbf{k}} = \left\{(\mathbf{v}, \tilde{c}, \mu) \in \Delta_{\mathbf{k}} \times R^2 : \mathbf{v} = \mathcal{G}(\mathbf{v}, \mathbf{c}, \mu) \text{ holds with } \tilde{c} = \langle \mathbf{c}, \mathbf{k}\rangle\right\},$$

and let

$$\mathcal{S}_{0,\mathbf{k}} = \left\{(\mathbf{0}, c, \mu) : (c, \mu) \in R^2\right\}.$$

Thus $\mathcal{S}_{0,\mathbf{k}}$ is the set of trivial solutions of (3.7) in $\Delta_{\mathbf{k}}$ and $\mathcal{S}_{\mathbf{k}}$ is the set of all solutions of (3.7) in $\Delta_{\mathbf{k}}$. Let $\mathcal{C}$ be a maximal connected subset of $\mathcal{S}_{\mathbf{k}} \setminus \mathcal{S}_{0,\mathbf{k}}$ with $(\mathbf{0}, \hat{c}, \hat{\mu}) \in \overline{\mathcal{C}}$. We say there is a *global branch of solutions* of (3.7) in $\Delta_{\mathbf{k}}$ bifurcating at $(\mathbf{0}, \hat{c}, \hat{\mu})$ provided one or more of the following holds:

(i) $\mathcal{C}$ is unbounded in $\Delta_{\mathbf{k}} \times (0, \infty) \times R$ or,

(ii) there exists $(\mathbf{v}, 0, \hat{\mu}) \in \overline{\mathcal{C}}$ or,

(iii) there exists $(\tilde{c}, \tilde{\mu}) \neq (\hat{c}, \hat{\mu})$ such that $(\mathbf{0}, \tilde{c}, \tilde{\mu}) \in \overline{\mathcal{C}}$.

Our main result is the following bifurcation theorem. For convenience of application, the bifurcation criteria are stated in terms of the matrices $F_{\mathbf{k}}(\mu)$. Fix $\mathbf{k}$.

THEOREM 2. *Suppose f satisfies* (F1) *and that $\mathcal{G}$, X, $F_{\mathbf{k}}(\mu)$, and $\Delta_{\mathbf{k}}$ are as above. Suppose there exists $\hat{\mu} \in R$ and $\mathbf{k} \neq \mathbf{0}$ such that*

(i) (*nonsingularity*) *$F_{\mathbf{k}}(\hat{\mu})$ is nonsingular,*

(ii) (*nonresonance*) *$F_{\mathbf{k}}(\hat{\mu})$ has a pair of simple eigenvalues $\pm i\nu$ and no other integer multiple of $\pm i\nu$ is an eigenvalue of $F_{\mathbf{k}}(\hat{\mu})$,*

(iii) (*transversality*) *the continuation of $i\nu$ in μ crosses the imaginary axis as μ crosses $\hat{\mu}$.*

Then there is a global branch of travelling-wave solutions of (3.7) *in $\Delta_{\mathbf{k}}$ bifurcating at $(\mathbf{0}, \nu/2\pi, \hat{\mu})$. Moreover the solutions $v_i(\mathbf{z})$ are classical solutions of* (2.7)-(2.8).

Proof. Both the linear equations (4.2) and the nonlinear equations (2.7) and (3.7) respect $\Delta_{\mathbf{k}}$, so we can restrict the analysis to $\Delta_{\mathbf{k}}$. If $\mathbf{v} \in \Delta_{\mathbf{k}}$, then

$$\mathbf{v}(\mathbf{z}) = \sum_{l=-\infty}^{\infty} \mathbf{v}_l \exp(2\pi i l\langle \mathbf{k}, \mathbf{z}\rangle) = \tilde{\mathbf{v}}(\langle \mathbf{k}, \mathbf{z}\rangle),$$

and thus conditions (i)—(iii) and Theorem 1 of (Alexander and Fitzpatrick [1979]) imply the existence of a global branch of travelling-wave solutions of (3.7) in $\Delta_{\mathbf{k}}$ bifurcating from $(\mathbf{0}, \hat{c}, \hat{\mu})$. From Proposition 4.1, $\nu = 2\pi\hat{\mathbf{c}}$. If $\mathbf{v} \in \Delta_{\mathbf{k}}$, then $\mathbf{v} \in \mathcal{P}^1$ and hence $L_z v_i$ is continuous on Ω_1 from (2.7). Hence each v_i is in $W^{2,\infty}(\Omega_1)$ from usual elliptic theory. This implies that $L_z v_i \in W^{1,\infty}(\Omega_1)$ for each i and hence v_i is a classical solution of (2.7)–(2.8) as required. The proof is complete.

Comments.

1. The bifurcation conditions (i)–(iii) are of standard type and are generically valid.
2. These travelling waves have wave-fronts given by

$$\langle B^T\mathbf{k}, \mathbf{x}\rangle - ct = \text{constant},$$

   so the fronts are hyperplanes in R^n. Moreover these waves are periodic functions of t of period k_0/c.
3. When $\mathbf{k} = \mathbf{0}$ and $F_0(\hat{\mu})$ is singular, bifurcating steady states occur, while if $\mathbf{k} = \mathbf{0}$ and the other conditions of the theorem hold, standing waves bifurcate via a

straightforward Hopf bifurcation.

4. Note that although we originally sought solutions involving a vector of wave speeds $\mathbf{c} = (c_1, c_2, \ldots, c_n)$, it turns out that these bifurcating waves may be characterized by a scalar c. Thus although we originally had an $(n+1)$-parameter problem, the bifurcation analysis is a standard type involving only two parameters.
5. One can use the implicit function theorem to construct these waves near the bifurcation point and to first order they can be represented in terms of the real and imaginary parts of $\exp(2\pi i\langle \mathbf{k}, \mathbf{y} - \mathbf{c}t\rangle)$ multiplying the eigenvectors of $F_{\mathbf{k}}(\hat{\mu})$ associated with the eigenvalues $\pm i\nu$. More precisely, if the eigenvector of $F_{\mathbf{k}}(\hat{\mu})$ associated to $i\nu$ has components γ_i (defined up to a complex scalar), to first order the wave solutions have components

$$\epsilon|\gamma_1| \sin\left(\sum_{i=1}^{N} k_i y_i - \hat{\mathbf{c}}t + \arg\gamma_1\right), \ldots, \epsilon|\gamma_n| \sin\left(\sum_{i=1}^{N} k_i y_i - \hat{\mathbf{c}}t + \arg\gamma_n\right),$$

in terms of the $y_i = \sum_{j=1}^{n} b_{ij} x_j$, where ϵ is a parameter along the branch. These are harmonic in each component. The amplitude in the ith component is $\epsilon|\gamma_i|$ and the relative phases between components are the differences between the $\arg\gamma_i$.
6. Recall that the solutions could be defined on a quotient space of R^n, a torus, which is the product of n circles. The vector $\mathbf{k} = (k_1, \ldots, k_n)$ indexes a parallel family of circles on the torus which wind around k_i times in the ith direction. This family of circles is the direction of motion of the wave front. On perpendicular hyperplanes, the wave is constant. Indeed use of the function space $\Delta_{\mathbf{k}}$ reduces the analysis to bifurcation theory on the circle indexed by $\mathbf{k}$, which has radius $\sqrt{\sum_{i,j,l=1}^{N} b_{ji} b_{li} k_j k_l}$. In particular, local higher-order bifurcation analysis can be done, for example to determine the criticality of the bifurcating branch. The analysis here reduces to an analysis on a circle, such as in (Auchmuty and Nicolis [1976]). From the point of view of equivariant theory, the vectors $\mathbf{k}$ index the characters (irreducible representations) of the symmetry group $(S^1)^n$. Although there are other symmetries, these seem to be the ones relevant to travelling waves.
7. We have introduced the bifurcation parameter μ in the reaction term. This is the most common formulation. However, other parameters are also reasonable bifurcation parameters, in particular one or more of the diffusion coefficients d_i or even the size of the underlying torus (compare (Auchmuty [1982])).

5. Examples. Consider the problem of looking for periodic travelling-wave solutions of the Brusselators in two and three space dimensions. The Brusselator is a model chemical reaction whose analysis is described in (Nicolis and Prigogine [1977, part II]). It is often used as a test of machinery. The case of periodic one-dimensional waves was treated in (Auchmuty and Nicolis [1976]). The equations are

$$\begin{aligned} \frac{\partial X}{\partial t} &= D_1 \Delta X - (B+1)X + X^2 Y + A, \\ \frac{\partial Y}{\partial t} &= D_2 \Delta Y + BX - X^2 Y. \end{aligned} \tag{5.1}$$

For all A, B, $X(\mathbf{x}, t) \equiv A$, $Y(\mathbf{x}, t) \equiv B/A$ are solutions. Letting $u_1(\mathbf{x}, t) = X(\mathbf{x}, t) - A$, $u_2(\mathbf{x}, t) = Y(\mathbf{x}, t) - B/A$, we obtain

$$\begin{aligned} \frac{\partial u_1}{\partial t} &= D_1 \Delta u_1 + (B-1)u_1 + A^2 u_2 + h(u_1, u_2), \\ \frac{\partial u_2}{\partial t} &= D_2 \Delta u_2 - Bu_1 - A^2 u_2 - h(u_1, u_2), \end{aligned} \tag{5.2}$$

where h contains quadratic and cubic terms.

First we look for travelling-wave solutions of (5.2) in two space dimensions which are periodic of period 1 in x_1 and of period $l > 0$ in x_2. Let $\mathbf{u}(\mathbf{x}, t) = \mathbf{v}(x_1 - c_1 t, x_2 - c_2 t) = \mathbf{v}(\xi_1, \xi_2)$. Then on R^2

$$\begin{aligned} D_1 \Delta v_1 + (c \cdot \nabla) v_1 + f_1(v_1, v_2) &= 0, \\ D_2 \Delta v_2 + (c \cdot \nabla) v_2 + f_2(v_1, v_2) &= 0, \end{aligned} \tag{5.3}$$

where $c \cdot \nabla = c_1 \frac{\partial}{\partial \xi_1} + c_2 \frac{\partial}{\partial \xi_2}$, $f_1(v_1, v_2) = (B-1)v_1 + A^2 v_1 + h(v_1, v_2)$, and $f_2(v_1, v_2) = -Bv_1 - A^2 v_2 - h(v_1, v_2)$. The periodicity conditions are:

$$\mathbf{v}(\xi_1 + 1, \xi_2) = \mathbf{v}(\xi_1, \xi_2) = \mathbf{v}(\xi_1, \xi_2 + l) \qquad \text{for all } (\xi_1, \xi_2) \in R^2. \tag{5.4}$$

Let $z_1 = \xi_1$, $z_2 = \xi_2 / l$ and $\mathbf{v}(\xi_1, \xi_2) = \mathbf{w}(\xi_1, \xi_2 / l)$; then $\mathbf{w}$ obeys (2.3) and

$$d_i L w_i + (c \cdot \nabla) w_i + f_i(\mathbf{w}, B) = 0, \tag{5.5}$$

where

$$L = \frac{\partial^2}{\partial^2 z_1^2} + \frac{1}{l^2} \frac{\partial^2}{\partial^2 z_2^2}.$$

The parameter B plays the role of μ so the matrices $F_{\mathbf{k}}(B)$ are

$$\begin{aligned} F_{\mathbf{k}}(B) &= \begin{pmatrix} B-1 & A^2 \\ -B & -A^2 \end{pmatrix} - 4\pi^2 \left(k_1^2 + \frac{k_2^2}{l^2} \right) \begin{pmatrix} D_1 & 0 \\ 0 & D_2 \end{pmatrix} \\ &= \begin{pmatrix} B - 1 - \lambda_{\mathbf{k}} D_1 & A^2 \\ -B & -A^2 - \lambda_{\mathbf{k}} D_2 \end{pmatrix}, \end{aligned}$$

with $\lambda_{\mathbf{k}} = 4\pi^2 \left(k_1^2 + k_2^2 l^{-2} \right)$.

In the next two theorems we need the expression for $\Delta(\lambda_{\mathbf{k}}) = \det F_{\mathbf{k}}(B)$ when $F_{\mathbf{k}}(B) = 0$. It is

$$\Delta(\lambda_{\mathbf{k}}) = A^2 + \lambda_{\mathbf{k}}(D_1 - D_2)A^2 - \lambda_{\mathbf{k}}^2 D_2^2.$$

THEOREM 3. *Suppose* $\mathbf{k} = (k_1, k_2) \in \mathbf{Z}^2 \backslash \{(0,0)\}$ *and* $\Delta(\lambda_{\mathbf{k}}) > 0$. *Then there is a global branch of periodic travelling-wave solutions of* (5.3) *obeying* (5.4) *bifurcating at* $B_{\mathbf{k}} = 1 + A^2 + \lambda_{\mathbf{k}}(D_1 + D_2)$ *with* $\hat{c} = (2\pi)^{-1} \sqrt{\Delta(\lambda_{\mathbf{k}})}$. *The solutions on this branch have the form*

$$\mathbf{u}(\mathbf{x}, t) = \mathbf{v}(k_1 x_1 + k_2 l^{-1} x_2 - ct), \tag{5.6}$$

with $\mathbf{v}$,c *varying along the branch and* $\mathbf{v}$ *being a vector-valued function of period* 1.

Proof. This results from verifying the conditions of Theorem 2. At $B_{\mathbf{k}}$, (i) and (ii) hold trivially and (iii) holds by computation. Hence the result follows.

In the three-dimensional case a very similar result is true. Suppose we seek travelling-wave solutions which have period 1 in x_1, l_2 in x_2 and l_3 in x_3 with l_2, $l_3 > 0$.

THEOREM 4. *Suppose* $\mathbf{k} = (k_1, k_2, k_3) \in \mathbf{Z}^3 \backslash \{(0,0,0)\}$, $\lambda_{\mathbf{k}} = k_1^2 + k_2^2 l_2^{-2} + k_3^2 l_3^{-2}$, *and* $\Delta(\lambda_{\mathbf{k}}) > 0$. *Then there is a global branch of periodic travelling-wave solutions of* (5.3) *bifurcating at*

$$B_{\mathbf{k}} = 1 + A^2 + 4\pi^2 \lambda_{\mathbf{k}}(D_1 + D_2)$$

with $\hat{c} = (2\pi)^{-1} \sqrt{\Delta(\lambda_{\mathbf{k}})}$. *The solutions on this branch have the form*

$$\mathbf{u}(\mathbf{x}, t) = \mathbf{v}(k_1 x_1 + k_2 l_2^{-1} x_2 + k_3 l_3^{-1} x_3 - ct), \tag{5.7}$$

with $\mathbf{v},c$ *varying along the branch and* $\mathbf{v}$ *being a periodic vector-valued function of period* 1.

Proof. The only changes here are the new boundary conditions. The proof is the same as that for Theorem 3 and (5.7) is the analog of (5.6).

QUASILINEAR EVOLUTION EQUATIONS IN NONCLASSICAL DIFFUSION*

KENNETH KUTTLER† AND ELIAS AIFANTIS‡

Abstract. After describing the motivation leading to some nonclassical diffusion equations, we formulate a general abstract nonlinear evolution equation and establish existence of solutions. Then we return to the original equation and discuss particular initial-boundary value problems.

Key words. existence, modeling

AMS(MOS) subject classifications. 35A05, 35G30, 35K60, 35K70

Introduction. A general framework based on the approach of continuum mechanics has been proposed recently by Aifantis [1] for a systematic development of diffusion models. In this method, the diffusing substance is viewed as a continuum subject to two kinds of forces: an internal body force vector arising from its interaction with the matrix and a stress tensor that the diffusing substance exerts on itself.

By introducing constitutive equations for the stress tensor and the internal force vector, we can obtain classes of diffusion behavior which take into account viscosity and higher-order gradient effects. Various diffusion models are thus generated within a unified mathematical framework.

For example, if the stress tensor is assumed to depend on the concentration and the gradient of the flux, while the internal body force is viewed as a drag proportional to the flux, a pseudoparabolic partial differential equation of the type studied by Ting [2] is obtained. This yields a physically realistic model of diffusion for situations where the effects of viscosity cannot be ignored. Similarly, the equation of spinodal decomposition of Cahn [3] can be obtained within this general formalism by including second gradients of the solute concentration in the constitutive equation for the stress tensor to allow for long-range effects. For a further discussion of the method and the development of many other examples, we refer to [1].

A central problem in the development of these new models is to determine which of the resulting partial differential equations are well posed. This is not always obvious, especially if nonlinear or time dependent equations are being considered. In a preceding paper [4], the questions of existence and uniqueness were resolved for a class of linear partial differential equations resulting when the stress $\underset{\sim}{T}$ is a linear function of the concentration, its gradients up to second order, and the gradient of the flux, while the internal body force $\underset{\sim}{f}$ is a linear function of the flux. The corresponding constitutive equations are thus

$$\begin{aligned} \underset{\sim}{T} &= c_1\rho\underset{\sim}{1} + c_2 \operatorname{tr}(\nabla \underset{\sim}{j})\underset{\sim}{1} + c_3 \operatorname{tr}(\nabla^2\rho)\underset{\sim}{1}, \\ \underset{\sim}{f} &= -\underset{\sim}{\alpha}(\underset{\sim}{x}, t)\underset{\sim}{j}, \end{aligned} \tag{0.1}$$

where $\underset{\sim}{j}$ is the flux, ρ is the concentration, $\nabla \underset{\sim}{j}$ denotes the first gradient of j ($\nabla \underset{\sim}{j} = j_{i,j}$), $\nabla^2\rho$ the second gradient of ρ ($\nabla^2\rho = \rho_{,ij}$), tr is the trace and $\underset{\sim}{\alpha}(\underset{\sim}{x}, t)$ is a nonsingular

symmetric matrix. The spatial and temporal dependence of $\underset{\sim}{\alpha}$ models the inhomogeneity of the interaction between the solid and the diffusing substance. The reason for neglecting nonhydrostatic components in the expression for the stress tensor in $(0, 1)_1$ is also discussed in [4].

Next we introduce (0.1) into the balance equations of mass and momentum which, on neglecting inertia forces, take the form

$$\begin{aligned} &\rho_t + \operatorname{div} \underset{\sim}{j} = 0, \\ &\operatorname{div} \underset{\sim}{T} + \underset{\sim}{f} = 0. \end{aligned} \tag{0.2}$$

This operation yields the following linear evolution equation whose existence and uniqueness have been studied earlier [4].

$$\frac{\partial}{\partial t}(\rho - c_2 \operatorname{div} (\underset{\sim}{\alpha}^{-1}\nabla\rho)) = -c_1 \operatorname{div} (\underset{\sim}{\alpha}^{-1}\nabla\rho) - c_3 \operatorname{div} (\underset{\sim}{\alpha}^{-1}\nabla(\Delta\rho)). \tag{0.3}$$

In the present paper we consider a more general physical situation by allowing the constants c_1 and c_3 in $(0.1)_1$ to be functions of ρ. Roughly speaking, this means physically that we consider situations where the diffusion coefficient is concentration dependent. In this connection, our results are most suitable for problems in the nonlinear theory of spinodal decomposition, where c_2 vanishes identically. Thus our present expression for the stress $\underset{\sim}{T}$ takes the form

$$\underset{\sim}{T} = c_1(\rho)\underset{\sim}{1} + c_2 \operatorname{tr} (\nabla \underset{\sim}{j})\underset{\sim}{1} + c_3(\rho) \operatorname{tr} (\nabla^2\rho)\underset{\sim}{1}. \tag{0.4}$$

On substituting (0.4) in the balance laws (0.2), we find that ρ satisfies a partial differential equation of the form

$$\rho_t - c_2 \operatorname{div} (\underset{\sim}{\beta}(x, t)\nabla\rho_t) + \operatorname{div} (\underset{\sim}{\beta}\nabla(c_3(\rho)\Delta\rho)) + \operatorname{div} (\underset{\sim}{\beta}\nabla c_1(\rho)) = 0 \tag{0.5}$$

where $\underset{\sim}{\beta}(\underset{\sim}{x}, t) = \underset{\sim}{\alpha}^{-1}(\underset{\sim}{x}, t)$. As explained in [4], we could also have allowed c_1, c_2 and c_3 to depend on $\underset{\sim}{x}$ and t, but in any case, we would have arrived at an equation of the following general form:

$$\begin{aligned} &\frac{\partial}{\partial t}\Big(\rho - \sum_{ij} \partial_i(\tilde{D}_{ij}(\underset{\sim}{x}, t)\partial_j\rho)\Big) - \sum_{ij} \partial_i(D_{ij}(\underset{\sim}{x}, t; \rho)\partial_j\rho) \\ &\qquad + \sum_{|\alpha|,|\beta|\leqq 2} (-1)^{|\beta|} D^\beta(E_{\alpha\beta}(\underset{\sim}{x}, t; \rho)D^\alpha\rho) = h(\underset{\sim}{x}, t), \end{aligned} \tag{0.6}$$

where α, β are multi-indices [5], h is a source function and the rest of the coefficient functions are to be specified later. Since this extra generality does not create essential difficulties in the mathematical treatment, we will consider this last equation. We show that weak solutions to (0.6) exist by formulating a corresponding abstract problem and obtaining estimates that allow the use of a fixed point theorem.

The plan of the paper is as follows: Section 1 is a review of the linear version of these equations. Section 2 contains an abstract result, motivated by (0.6), which might be useful in other problems in the theory of nonlinear evolution equations. This result is used in § 3 to reduce the question of existence of weak solutions for (0.6) to the verification of a coercivity inequality. In § 4 we actually prove that this inequality holds. This way, we obtain the existence of solutions for (0.6) to some specific initial-boundary value problems. We use the standard notation for Banach spaces: If V is a Banach space, V' denotes its dual, $\to$ denotes strong convergence, and $\rightharpoonup$ denotes weak convergence. If i: $V \to W$ is an injection map, i^* denotes the dual map defined by

$$\langle i^* f, u\rangle = \langle f, iu\rangle = \langle f, u\rangle.$$

1. The linear equations. Before dealing with (0.6), we discuss briefly the main results of the earlier paper [4] in which D_{ij} and $E_{\alpha\beta}$ do not depend on ρ. In this earlier paper, the assumptions were

$$\begin{aligned} &\tilde{D}_{ij} = \tilde{D}_{ji}, \\ &\tilde{D}_{ij} \text{ is bounded, measurable and } C^1 \text{ in } t, \\ &\sum_{ij} \tilde{D}_{ij}\xi_i\xi_j \geqq 0 \quad \text{for } \xi = (\xi_1, \xi_2, \xi_3) \in R^3, \\ &D_{ij} \in L^\infty(\Omega \times [0, T]), \\ &E_{\alpha\beta} \in L^\infty(\Omega \times [0, T]), \end{aligned} \tag{1.1}$$

along with a coercivity inequality similar to (2.5) of the present paper.

Under these assumptions, existence, uniqueness and continuous dependence results were obtained for a large class of initial-boundary value problems associated with the linear version of (0.6). The existence part was based on the verification of this coercivity inequality which allowed the use of the main existence theorem of [6] or [11]. The uniqueness may be obtained as a special case of the uniqueness theorem of [6].

To be more specific, sufficient conditions were given for well-posedness of weak solutions of the following initial boundary value problems:

$$\frac{\partial}{\partial t}\left(\rho - \sum_{ij} \partial_i(\tilde{D}_{ij}(\underset{\sim}{x}, t)\partial_j\rho)\right) - \sum_{ij} \partial_i(D_{ij}(\underset{\sim}{x}, t)\partial_j\rho) + \Delta^2\rho = g(\underset{\sim}{x}, t), \tag{1.2.1}$$

$$\rho(\underset{\sim}{x}, 0) = \rho_0(\underset{\sim}{x}), \tag{1.2.2}$$

along with either the boundary conditions

$$\frac{\partial\rho}{\partial n}(\underset{\sim}{x}, t) = \frac{\partial w}{\partial n}(\underset{\sim}{x}, t), \qquad x \in \partial\Omega, \tag{1.2.3}$$

$$\frac{\partial}{\partial t}\left(\sum_{ij} \tilde{D}_{ij}\partial_j\rho n_i\right) + \sum_{ij} (D_{ij}\partial_i\rho)n_i - \frac{\partial(\Delta\rho)}{\partial n} = l, \qquad x \in \partial\Omega, \tag{1.2.4}$$

or the boundary conditions

$$\rho(\underset{\sim}{x}, t) = c(t) + w(\underset{\sim}{x}, t), \qquad x \in \partial\Omega, \tag{1.2.5}$$

$$\int_{\partial\Omega} \frac{\partial\rho}{\partial t}(\underset{\sim}{x}, t)\, ds = \int_{\partial\Omega} \frac{\partial w}{\partial n}(\underset{\sim}{x}, t)\, ds, \tag{1.2.6}$$

$$\int_{\partial\Omega} \left[\frac{\partial}{\partial t}\left(\sum_{ij} \tilde{D}_{ij}\partial_j\rho\right)n_i + \sum_{ij} D_{ij}\partial_j\rho n_i - \frac{\partial(\Delta\rho)}{\partial n}\right] ds = \int_{\partial\Omega} l(\underset{\sim}{x}, t)\, ds, \tag{1.2.7}$$

$$\Delta\rho(x, t) - k(x, t) = r(t) \tag{1.2.8}$$

where in (1.2.3)-(1.2.8), $r(t), c(t)$ are unknown functions and w and l are given functions.

In the present paper, we shall use the existence and uniqueness of solutions to an appropriate abstract version of the linear problem, along with a well-known generalization of the Brouer fixed point theorem, to establish the existence of solutions to initial-boundary value problems corresponding to (0.6). We shall show that, just as in the linear case, the verification of an appropriate inequality is sufficient.

2. The abstract equation. For the sake of both generality and simplicity in the presentation, we obtain existence of solutions to (0.6) as a special case of an abstract result. We introduce the following hypotheses and conventions:

(2.1) V, W are reflexive Banach spaces $V \subseteq W$, $\|v\|_V \geqq \|v\|_W$, so that $V \subseteq W \subseteq i^* W' \subseteq V'$.

On defining $B(t)$ as a continuous linear map from W to W', we will assume

$$\begin{aligned} &\langle B(t)u, u\rangle \geqq 0, \\ &\langle B(t)u, v\rangle = \langle B(t)v, u\rangle, \\ &t \to B(t)u \quad \text{is in } C^1(0, T; W'). \end{aligned} \tag{2.2}$$

We will also make use of the space

$$\begin{aligned} X = \{u \in L^2(0, T; V) \text{ such that} \\ (Bu)' \in L^2(0, T; V')\}\ \|u\|_X = \|u\|_{L^2(0,T;V)} + \|(Bu)'\|_{L^2(0,T;V')} \end{aligned} \tag{2.3}$$

where by $(Bu)'$ we mean a unique function in $L^2(0, T; V')$, such that

$$\int_0^T (Bu)'(t)\phi(t)\, dt = -\int_0^T i^* B(t)u(t)\phi'(t)\, dt \quad \text{for all } \phi \in C_0^\infty(0, T).$$

It follows that X is a reflexive Banach space.

For each $w \in L^2(0, T; V)$, let $A(w)$ be a continuous linear map from $L^2(0, T; V)$ to $L^2(0, T; V')$ satisfying the following property:

(2.4)
(i) $\sup\{\|A(w)\|,\ w \in L^2(0, T; V)\} = Q < \infty$,

(ii) If $u_n \rightharpoonup u$ in X and $v_n \rightharpoonup v$ in $L^2(0, T; V)$ then for some subsequence $u_{n'}$, $v_{n'}$, $A(u_{n'})v_{n'} \rightharpoonup A(u)v$ in $L^2(0, T; V')$.

Moreover, by introducing the definitions
(i) $B: L^2(0, T; W) \to L^2(0, T; W')$ is given by $B(t)u(t) = Bu(t)$,
(ii) $B': L^2(0, T; W) \to L^2(0, T; W')$ is given by $B'(t)u(t) = B'u(t)$,
we can postulate the following coercivity inequality:

$$2\langle A(w)u, u\rangle + \lambda\langle Bu, u\rangle + \langle B'u, u\rangle \geqq C_1 \|u\|^2_{L^2(0,T;V)}, \tag{2.5}$$

for some $\lambda \in \mathbb{R}$ independent of w and $C_1 > 0$.

Finally, for each $u \in L^2(0, T; V)$, let $f(u) \in L^2(0, T; V')$ satisfy the following properties:

(2.6)
(i) $\sup\{\|f(u)\|_{L^2(0,T;V')},\ u \in X\} = P < \infty$,

(ii) If $u_n \rightharpoonup u$ in X, then $f(u_{n'}) \rightharpoonup f(u)$ in $L^2(0, T; V')$, for some subsequence $u_{n'}$.

With these assumptions, we can state the main existence theorem.

THEOREM 1. *With* (2.1)-(2.6) *valid and* $u_0 \in V$, *there exists* $u \in X$ *such that*

$$\begin{aligned} &(Bu)' + A(u)u = f(u), \\ &i^* Bu(0) = i^* B(0)u_0. \end{aligned} \tag{2.7}$$

Proof. It follows from (2.5) and [6] that for each $w \in X$ there exists a unique solution $u \in X$ to the problem

$$\begin{aligned} &(Bu)' + A(w)(u) = f(w), \\ &i^* Bu(0) = i^* B(0) u_0. \end{aligned} \tag{2.8}$$

On denoting this solution by $\psi(w)$ we have $\psi : X \to X$.

Next we make use of three lemmas whose proof may be found in [6].

LEMMA 1. *For each $u \in X$,*

$$\langle (Bu)'(t), u(t)\rangle = \frac{1}{2}\left[\frac{d}{dt}\langle Bu(t), u(t)\rangle + \langle B'(t)u(t), u(t)\rangle\right] \text{ a.e.} \tag{2.9}$$

Moreover $\langle Bu(t), u(t)\rangle$ is equal to an absolutely continuous function a.e. and point evaluation of $i^* Bu(\cdot)$ is a continuous map from X to V'.

LEMMA 2. *For $u, v \in X$, $\langle Bu(t), v(t)\rangle$ equals an absolutely continuous function a.e. denoted by $\langle Bu, v\rangle(\cdot)$. Moreover, there exists a constant M such that*

$$|\langle Bu, v\rangle(t)| \leqq M \|u\|_X \|v\|_X \quad \text{for all } t \in [0, T]. \tag{2.10}$$

LEMMA 3. *If $i^* Bv(0) = 0$ for $v \in X$, then there exists a sequence $\{v_n\} \subseteq X$ such that $\|v - v_n\|_X \to 0$ and $v_n(t) = 0$ in some neighborhood of 0.*

As a consequence of Lemmas 1-3 we can establish the following results:

$$\begin{aligned} &\text{(i)} \quad \langle Bu, u\rangle(t) - \langle Bu, u\rangle(0) + \int_0^t \langle B'(s)u(s), u(s)\rangle \, ds \\ &\qquad + 2\int_0^t \langle A(w)u(s), u(s)\rangle \, ds = 2\int_0^t \langle f(w)(s), u(s)\rangle \, ds, \end{aligned} \tag{2.11}$$

$$\text{(ii)} \quad \langle Bu, u\rangle(0) = \langle B(0)u_0, u_0\rangle. \tag{2.12}$$

Relation (2.11) is obtained by multiplying $(2.8)_1$ by u, using Lemma 1 and integrating the result from 0 to t. Relation (2.12) is derived by first using Lemma 3 to obtain a sequence $\{u_n\} \subseteq X$ with $u_n(t) = u_0$ near 0 and converging to u in X, and then using Lemma 2 together with the inequality

$$\begin{aligned} |\langle Bu, u\rangle(0) - \langle B(0)u_0, u_0\rangle| &= |\langle Bu, u\rangle(0) - \langle Bu_n, u_n\rangle(0)| \\ &\leqq |\langle B(u_n - u), u_n\rangle(0)| + |\langle Bu, u_n - u\rangle(0)| \\ &\leqq M(\|u\|_X + \|u_n\|_X)\|u_n - u\|_X. \end{aligned} \tag{2.13}$$

With (2.11) and (2.12) valid and the use of (2.5) and (2.6), we can establish the following main inequality:

$$\begin{aligned} &\langle Bu, u\rangle(t) + C_1 \|u\|^2_{L^2(0,t;V)} \\ &\qquad \leqq \lambda \int_0^t \langle Bu(s), u(s)\rangle \, ds + 2P\|u\|_{L^2(0,t;V)} + \langle B(0)u_0, u_0\rangle. \end{aligned} \tag{2.14}$$

On subtracting $C_1\|u\|^2_{L^2(0,t;V)}$ from both sides, we first note that

$$2P\|u\|_{L^2(0,t;V)} - C_1\|u\|^2_{L^2(0,t;V)} \leqq \frac{P^2}{C_1}. \tag{2.15}$$

It then follows that

$$\langle Bu, u\rangle(t) \leqq \left(\langle B(0)u_0, u_0\rangle + \frac{P^2}{C_1}\right) e^{\lambda t} \tag{2.16}$$

by an application of Gronwall's inequality. Having thus established that $\langle Bu, u\rangle(t)$ is bounded uniformly for $t\in[0, T]$ independently of w, (2.14) implies that $\|\psi w\|_{L^2(0,T;V)}$ is bounded independently of w. It now follows from $(2.8)_1$, (2.4) and (2.6) that $\|\psi w\|_X$ is bounded independently of w. Moreover, if $N\geqq\sup\{\|\psi w\|_X, w\in X\}$ and $S=\{w\in X$ such that $\|w\|_X\leqq N\}$, it follows that $\psi: X\to S$.

As a final step in the proof of the theorem we establish the following.

LEMMA 4. *$\psi: X\to X$ is weakly continuous.*

Proof. Let $u_n\rightharpoonup u$ in X. If ψu_n fails to converge weakly to ψu, then by selecting a subsequence also denoted by u_n, we may assume $u_n\rightharpoonup u$ in X and $\psi u_n\rightharpoonup z\neq\psi u$ in X. By utilizing the definition of ψ

$$\begin{aligned}&(B(\psi u_n))'+A(u_n)\psi u_n=f(u_n),\\ &i^*B(\psi u_n)(0)=i^*B(0)u_0,\end{aligned}\tag{2.17}$$

and properties (2.4) and (2.6) together with Lemma 1, we obtain

$$\begin{aligned}&(Bz)'+A(u)z=f(u),\\ &i^*Bz(0)=i^*B(0)u_0.\end{aligned}\tag{2.18}$$

Obviously, (2.18) contradicts the assumption that $z\neq\psi u$; therefore ψ is weakly continuous and Lemma 4 is established.

Thus, the proof of Theorem 1 is now completed by invoking Tykhanov's fixed point theorem [7] which asserts that ψ has a fixed point in S.

3. The nonlinear partial differential equation. Here we apply the abstract result of § 2 to the question of existence of solutions for initial-boundary value problems associated with the generalized diffusion equation (0.6). We will assume the following general properties for the relevant coefficients:

$$\begin{aligned}&\text{(i)}\quad \tilde{D}_{ij}=\tilde{D}_{ji},\\ &\text{(ii)}\quad \tilde{D}_{ij}\text{ is bounded, measurable, and } C^1\text{ in } t,\\ &\text{(iii)}\quad \sum_{ij}\tilde{D}_{ij}\xi_i\xi_j\geqq 0\quad\text{for } \underset{\sim}{\xi}=(\xi_1,\xi_2,\xi_3)\in\mathbb{R}^3,\\ &\text{(iv)}\quad \sup\left\{\sum_{ij}|D_{ij}(t,x;r)|+\sum_{|\alpha|,|\beta|\leqq 2}|E_{\alpha\beta}(x,t;r)|,\ (x,t,r)\in\bar{\Omega}\times[0,T]\times\mathbb{R}\right\}<\infty,\\ &\text{(v)}\quad r\to D_{ij}(x,t;r)\text{ and }r\to E_{\alpha\beta}(x,t;r)\text{ are continuous and real valued}\end{aligned}\tag{3.1}$$

where Ω is a bounded open set in $\mathbb{R}^3$.

With these, and in order to cast (0.6) in the abstract form of (2.7), we let V be a closed subspace of $H^2(\Omega)$, $W=H^1(\Omega)$, $H=L^2(\Omega)$, and for $y\in L^2(0, T; H^2(\Omega))$ we let $\tilde{A}(y)$ be a continuous linear map from $L^2(0, T; V)$ to $L^2(0, T; V')$ defined by

$$\begin{aligned}\langle\tilde{A}(y)u, v\rangle=&\int_0^T\int_\Omega D_{ij}(x,t;y(t)(x))\partial_i u(t)(x)\partial_j v(t)(x)\,dx\,dt\\ &+\int_0^T\int_\Omega E_{\alpha\beta}(x,t;y(t)(x))D^\alpha u(t)(x)D^\beta v(t)(x)\,dx\,dt,\end{aligned}\tag{3.2}$$

and $B(t)$; $W\to W'$ defined by

$$\langle B(t)u, v\rangle=\int_\Omega u(x)v(x)+\tilde{D}_{ij}(x,t)\partial_i u(x)\partial_j v(x)\,dx,\tag{3.3}$$

where summation over repeated indices is assumed. With $B(t)$ given by (3.3), it is clear that (2.2) holds.

Having already specified definitions and hypotheses (2.1)-(2.3), we proceed by considering properties (2.4)-(2.6). Of these properties, (2.4) and (2.6) are verified in this section while the coercivity inequality (2.5) is examined in the next section. To do this we first prove the following lemma which is a generalization of a well-known result in [8, p. 57].

LEMMA 5. *If* $u_n \rightharpoonup 0$ *in* X, *then*

(i) $\lim_{n\to\infty} i^*Bu_n(t) = 0$ *in* V' *for each* $t \in [0, T)$,

(ii) $\lim_{n\to\infty} \langle Bu_n, u_n\rangle = 0$ *in* $L^1(0, T)$,

(iii) $\lim_{n\to\infty} u_n = 0$ *in* $L^2(0, T; H)$,

where each limit in (i)-(iii) *refers to the strong topology of the space indicated.*

Proof. We first note that $i^*Bu(\cdot)$ is an absolutely continuous function with values in V' since i^*Bu_n and $(i^*Bu_n)'$ are both in $L^2(0, T; V')$. Thus $i^*Bu_n(t)$ is well defined and

$$\begin{aligned} i^*Bu(t) &= -\frac{1}{s}\int_t^{t+s} (Bu_n)'(r)(t+s-r)\,dr + \frac{i^*}{s}\int_t^{t+s} Bu_n(r)\,dr \\ &= U_n + i^*V_n. \end{aligned} \tag{3.4}$$

Thus, for a given $\varepsilon > 0$, it follows that $\|U_n\|_{V'} \leqq \varepsilon$ for all n if s is small enough. With this choice for s and $w \in W$, we have

$$|\langle V_n, w\rangle_{W',W}| = \left|\int_0^T \left\langle B(r)\frac{1}{s}\chi_{[t,t+s]}(r)w, u_n(r)\right\rangle_{W'W} dr\right|. \tag{3.5}$$

Since $B(\cdot)(1/s)\chi_{[t,t+s]}(\cdot) \in L^2(0, T; W')$ and $u_n \rightharpoonup 0$ in $L^2(0, T; V)$, the right-hand side of (3.5) converges to 0. But $w \in W$ was arbitrary and therefore $V_n \rightharpoonup 0$ in W'. The inclusion map of V into W is compact and thus i^*V_n converges strongly to 0 in V'. This proves (i) since $\varepsilon > 0$ was arbitrary.

To prove (ii), let $\varepsilon > 0$ be given. If α is large enough, we have

$$\begin{aligned} \int_0^T \langle Bu_n(t), u_n(t)\rangle\,dt &\leqq \frac{\alpha^2}{2}\int_0^T \|i^*Bu_n(t)\|_{V'}^2\,dt + \frac{1}{2\alpha^2}\int_0^T \|u_n(t)\|_V^2\,dt \\ &\leqq \varepsilon + \frac{\alpha^2}{2}\int_0^T \|i^*Bu_n(t)\|_{V'}^2\,dt. \end{aligned} \tag{3.6}$$

In view of Lemma 1, the term $\|i^*Bu_n(t)\|_{V'}^2$ is bounded independently of t and n. Therefore, the Dominated Convergence Theorem [9] and (i) imply the convergence to zero of the last term of (3.6), and since ε was arbitrary, part (ii) follows. Part (iii) is clearly implied by (ii). This completes the proof of the lemma.

As a final step in establishing the validity of (2.4) and (2.6), we introduce the definitions

$$\begin{aligned} &\text{(i)} \quad A(v) = \tilde{A}(v+w), \\ &\text{(ii)} \quad f(v) = -\tilde{A}(w+v)w - i^*B'w - i^*Bw' + g, \end{aligned} \tag{3.7}$$

where w and w' are both in $L^2(0, T; H^2(\Omega))$, $v \in L^2(0, T; V)$, $g \in L^2(0, T; V')$ and i is the injection map of V into $H^2(\Omega)$. Then the following lemma can be established.

LEMMA 6. *Hypotheses* (2.4) *and* (2.6) *hold.*

Proof. By $(3.1)_4$, it is clear that there exists $Q < \infty$ such that $\|A(u)\| \leqq Q$ for all $u \in L^2(0, T; V)$. Now let $u_n \rightharpoonup u$ in X and let $v_n \rightharpoonup v$ in $L^2(0, T; V)$. From Lemma 5,

$\lim_{n\to\infty} \|u_n - u\|_{L^2(0,T;H)} = 0$. Therefore a subsequence of $\{u_n\}$ converges to u a.e. in t and x. Then (2.4) follows from the Dominated Convergence Theorem and $(3.1)_5$. Hypothesis (2.6) also holds by similar arguments.

In view of the above arguments, we have reduced the problem of existence of solutions to the abstract evolution equation (2.7) in the special context of § 3 to the verification of the coercivity inequality (2.5). This will be discussed in the next section. For the convenience of presentation, however, this inequality will be assumed to hold in the remaining part of this section in order to provide the explicit form of the partial differential equation that we are concerned with here.

To do this, we define $g \in L^2(0, T; V')$ to be given by the relation

$$\begin{aligned}\langle g, v\rangle = \int_0^T \Big[\int_\Omega h(t)(x)v(t)(x)\, dx + \int_{\partial\Omega} l(t)(x)v(t)(x)\, dA \\ + \int_{\partial\Omega} k(t)(x) \frac{\partial v(t)}{\partial n}(x)\, dA \Big]\, dt\end{aligned} \tag{3.8}$$

where $h \in L^2(0, T; H)$, $(k, l) \in L^2(0, T; L^2(\partial\Omega))$ and $\partial\Omega$ is assumed to be a smooth two-dimensional manifold. Since the trace map from $H^1(\Omega)$ to $L^2(\partial\Omega)$ is continuous, it is clear that g is in $L^2(0, T; V')$. On assuming that (2.5) holds, it follows that Theorem 1 implies the existence of $u \in X$ satisfying the equation

$$\begin{aligned}&-\int_0^T \int_\Omega [u(t)(x)v(x) + \tilde{D}_{ij}(x, t)\partial_i u(t)(x)\partial_j v(x)]\, dx\, \phi'(t)\, dt \\ &\quad + \int_0^T \int_\Omega D_{ij}(x, t; w(t)(x) + u(t)(x))\partial_i u(t)(x)\partial_j v(t)(x)\, dx\, \phi(t)\, dt \\ &\quad + \int_0^T \int_\Omega E_{\alpha\beta}(x, t; w(t)(x) + u(t)(x))D^\alpha u(t)(x) D^\beta v(x)\, dx\, \phi(t)\, dt \\ &= \int_0^T \int_\Omega h(t)(x)v(x)\, dx\, \phi(t)\, dt \\ &\quad + \int_0^T \int_{\partial\Omega} \left(l(t)(x)v(x) + k(t)(x) \frac{\partial v(x)}{\partial n} \right) dA\, \phi(t)\, dt \\ &\quad - \int_0^T \int_\Omega D_{ij}(x, t; w(t)(x) + u(t)(x))\partial_i w(t)(x)\partial_j v(x)\, dx\, \phi(t)\, dt \\ &\quad - \int_0^T \int_\Omega E_{\alpha\beta}(x, t; w(t)(x) + u(t)(x))D^\alpha w(t)(x) D^\alpha v(x)\, dx\, \phi(t)\, dt \\ &\quad + \int_0^T \int_\Omega [w(t)(x)v(x) + \tilde{D}_{ij}(x, t)\partial_i w(t)(x)\partial_j v(x)]\, dx\, \phi'(t)\, dt,\end{aligned} \tag{3.9}$$

together with the initial condition

$$i^* Bu(0) = i^* B(0)(u_0 - w(0)) \tag{3.10}$$

for all $v \in V$ and $\phi \in C_0^\infty(0, T)$ provided $u_0 - w(0) \in V$.

On restricting v to be in $C_0^\infty(\Omega)$ and letting $z = u + w$ we see that a measurable representative of z is a weak solution of the partial differential equation (0.6) subject to the initial condition $i^* Bz(0) = i^* B(0)u_0$. Stable boundary conditions are obtained by properly selecting the space V, while variational boundary conditions are obtained

by the use of the divergence theorem in (3.9). This leads to the formulation of a variety of initial-boundary value problems, representative examples of which are considered in the next section.

4. Boundary value problems. In this section we consider particular initial-boundary value problems pertaining to (0.6) and establish existence of weak solutions by utilizing the results derived earlier. As mentioned previously, our task has been reduced to the verification of the coercivity inequality (2.5). Here this is accomplished in relation to specific forms of the associated boundary conditions. Three different sets of such conditions are considered below. The first set corresponds to Dirichlet type and coercivity is obtained as a result of Garding's inequality. The other two examples include variational-type boundary conditions and coercivity is established by other means.

4.1. Dirichlet boundary conditions. We choose $V = H_0^2(\Omega)$ and assume that the coefficients $E_{\alpha\beta}$ for $|\alpha| = |\beta| = 2$ are independent of ρ and are continuous on $\bar{\Omega} \times [0, T]$. Moreover, we suppose that they obey the strong ellipticity condition

$$\sum_{|\alpha|,|\beta|=2} E_{\alpha\beta}(x, t)\underset{\sim}{\xi}^{\alpha}\underset{\sim}{\xi}^{\beta} \geqq C|\underset{\sim}{\xi}|^4 \quad \text{for all } \underset{\sim}{\xi} \in \mathbb{R}^3, \tag{4.1}$$

so that the conditions of Garding's inequality [5] are satisfied. It then follows that (2.5) holds.

Thus, we have obtained existence of a weak solution to (1.6), denoted by z, along with boundary and initial conditions of the form

$$\begin{aligned} &z(t) - w(t) \in H_0^2(\Omega) \text{ a.e.,} \\ &i^* Bz(0) = i^* B(0)u_0, \end{aligned} \tag{4.2}$$

where i is the injection map of V into W. In less abstract fashion, the boundary condition $(4.2)_1$ can be expressed as

$$\begin{aligned} &z(t, x) = w(t, x), \qquad x \in \partial\Omega, \\ &\partial_i z(t, x) = \partial_i w(t, x), \qquad x \in \partial\Omega, \end{aligned} \tag{4.3}$$

where w is the prescribed function defined earlier. Roughly speaking, (4.3) suggests that in contrast to second-order problems, both the function and its derivatives need to be specified on the boundary for this class of fourth-order problems. These problems may be viewed as pertinent to the later stages of the important metallurgical process of spinodal decomposition, where nonlinear effects dominate.

4.2. Variational boundary conditions. In discussing boundary conditions of variational type, we consider a simplified form of the diffusion equation (0.6) as follows:

$$\frac{\partial}{\partial t}(\rho - \Delta\rho) - \partial_i(D(\rho)\partial_i\rho) + \Delta^2\rho = h. \tag{4.4}$$

This corresponds to assuming that the stress coefficient $c_3(\rho)$ in (1.4) is a constant and the mobility coefficient $\underset{\sim}{\alpha}$ in $(1.1)_2$ is a scalar α. Physically, these assumptions mean that nonlinear effects are retained in the dependence of the usual diffusion coefficient D but not in the small correcting terms, due to viscosity and surface tension.

We let $u_0 \in V \equiv \{u \in H^2(\Omega)$ such that $\partial u/\partial n = 0$ on $\partial\Omega\}$, with $\partial\Omega$ smooth. Then by the well-known theorem on elliptic regularity [10], $I - \Delta$ is a one-to-one and onto mapping from V to $L^2(\Omega)$. It follows $(I - \Delta)^{-1}$ is continuous by the open mapping theorem [9]. Therefore, there exists a $K > 0$ such that the following inequality holds:

$$\|u\|_V = \|(I - \Delta)^{-1}(I - \Delta)u\|_V \leqq K\|(I - \Delta)u\|_{L^2(\Omega)} \leqq K(\|u\|_{L^2(\Omega)} + \|\Delta u\|_{L^2(\Omega)}). \tag{4.5}$$

Then $\langle A(v)u, y\rangle = \langle \tilde{A}(v+w)u, y\rangle$ is of the form

$$\int_0^T \int_\Omega D(v(t)(x)+w(t)(x))\partial_i u(t)(x)\partial_j y(t)(x)\, dx\, dt + \int_0^T \int_\Omega \Delta u(t)(x)\Delta y(t)(x)\, dx\, dt \tag{4.6}$$

where $w(\cdot)$ and $w'(\cdot)$ are both in $L^2(0, T; H^2(\Omega))$ and $D(\cdot)$ is bounded and continuous. Similarly, $\langle B(t)u, v\rangle$ is of the form

$$\langle B(t)u, v\rangle = \int_\Omega (uv + \nabla u \cdot \nabla v)\, dx. \tag{4.7}$$

As a result of (4.5), it is easy to see through (4.6) and (4.7) that (2.5) holds. This establishes existence of solutions to (3.9) specialized to the present context. Applying then the divergence theorem, we obtain the existence of $u \in X$ such that $z = u + w$ satisfies (4.4) and the integral condition

$$\int_{\partial\Omega} \frac{\partial}{\partial n}(z_t)v + D(z)\frac{\partial z}{\partial n}v + \Delta z\frac{\partial v}{\partial n} - v\frac{\partial(\Delta z)}{\partial n}\, dA = \int_{\partial\Omega}\left(lv + k\frac{\partial v}{\partial n}\right) dA \tag{4.8}$$

for almost all values of t and for all $v \in V$.

Therefore z solves

$$\frac{\partial}{\partial t}(z - \Delta z) - \partial_i(D(z)\partial_i z) + \Delta^2 z = h, \tag{4.9}$$

along with the initial condition

$$\lim_{t\to 0+} \int_\Omega (z(t) - u_0)v + \nabla(z(t) - u_0)\cdot\nabla v\, dx = 0 \quad \text{for all } v \in V \tag{4.10}$$

and the boundary conditions

$$\begin{aligned} &\frac{\partial z(t, x)}{\partial n} = \frac{\partial w(t, x)}{\partial n} \quad \text{a.e. } t \text{ and } x \in \partial\Omega, \\ &\frac{\partial z_t(t, x)}{\partial n} + D(z(t, x))\frac{\partial z(t, x)}{\partial n} - \frac{\partial(\Delta z(t, x))}{\partial n} = l(t, x) \quad \text{a.e. } t \text{ and } x \in \partial\Omega \end{aligned} \tag{4.11}$$

where $(4.11)_1$ is stable resulting from the choice of V and $(4.11)_2$ is of a variational type resulting from the divergence theorem.

The initial condition (4.10) can be expressed in a more conventional form by noting that for $u \in X$, $Bu(t)$ is a function in $C(0, T; W')$. It follows that $u \in C(0, T; W)$ and thus $z = (u + w) \in C(0, T; W)$. Therefore, the limit in (4.10) can be taken inside the integral giving

$$\int_\Omega (z(0) - u_0)v + \nabla(z(0) - u_0)\cdot\nabla v\, dx = 0 \quad \text{for all } v \in V. \tag{4.12}$$

If $z(0) - u_0 \in V$, it follows that the initial condition (4.12) takes the usual form,

$$z(0, \cdot) = u_0(\cdot). \tag{4.13}$$

The condition that $z(0, \cdot) - u_0(\cdot) \in V$ is equivalent to saying that $(\partial z/\partial n)(0, \cdot) = (\partial w/\partial n)(0, \cdot) = \partial u_0(\cdot)/\partial n$ on $\partial\Omega$; that is, the initial condition $u_0(\cdot)$ and the boundary condition at $t = 0$, $w(0, \cdot)$ are compatible.

Next, we turn to a second example pertaining again to (4.4) but we now let $V=\{u\in H^2(\Omega)$ such that $u(x)=0$ on $\partial\Omega\}$. By reasoning similar to that of the previous example, (2.5) is again satisfied. Thus, in this case, we obtain the existence of a weak solution to the problem

$$
\begin{aligned}
&\frac{\partial}{\partial t}(z-\Delta z)-\partial_i(D(z)\partial_i z)+\Delta^2 z=h,\\
&z(t,\cdot)=w(t,\cdot)\quad \text{on } \partial\Omega \text{ for a.e. } t,\\
&\Delta z(t,\cdot)=k(t,\cdot)\quad \text{on } \partial\Omega \text{ for a.e. } t,\\
&\lim_{t\to 0+}\int_\Omega (z(t)-u_0)v+\nabla(z(t)-u_0)\cdot\nabla v\,dx=0,\qquad v\in V.
\end{aligned}
\tag{4.14}
$$

As before, $z(\cdot)$ is in $C(0, T; W)$ and if $z(0)-u_0\in V$, the initial condition $(4.14)_4$ takes the usual form $z(0,\cdot)=u_0(\cdot)$. In this case, the condition that $z(0)-u_0\in V$ is equivalent to the requirement that $u_0(\cdot)=w(0,\cdot)$ on $\partial\Omega$.

Other examples could be considered in a similar manner. Questions of existence of solutions to (0.6) or its specializations may thus be resolved by considering the verification of (2.5); that is the coercivity of a family of bilinear forms. This question of coercivity has been extensively studied and we refer to [10] for further discussion.

A THEOREM OF LA SALLE–LYAPUNOV TYPE FOR PARABOLIC SYSTEMS*

RAY REDHEFFER†, REINHARD REDLINGER‡ AND WOLFGANG WALTER‡

Abstract. This paper deals with the boundary value problem for a nonlinear system of parabolic differential equations for $u = u(t, x)$

$$u_t = Lu + f(u) \quad \text{in } \Omega, \qquad u(0, x) \text{ given}, \qquad \frac{\partial u}{\partial \nu} = 0 \quad \text{on } \partial\Omega$$

under the assumption that a Lyapunov function $V(z)$ for the corresponding ordinary differential equation system $u' = f(t, u)$ exists. In the case where L is one and the same selfadjoint elliptic operator of second order for all components of u, the real-valued function $U(t, x) = V(u(t, x))$ satisfies a parabolic differential inequality

$$U_t \leqq LU - c|u_x|^2 \qquad (c > 0).$$

It follows that u exists globally and is bounded if $u(0, x)$ is bounded. The limit set Λ^+ (as $t \to \infty$) of any solution u is nonempty and compact, it consists of constant functions only, it is an invariant set for $u' = f(u)$, and $\dot{V} = V_z \cdot f$ vanishes on Λ^+ (analogue of La Salle's stability theorem for ordinary differential equations). The results are then extended to quasilinear systems where $Lu = (a_{ij}(x, u)u_{x_j})_{x_j}$. In the case where different elliptic operators are involved, $u_t^k = L^k u^k + f^k(u)$ $(k = 1, \cdots, n)$, it is assumed that $a_{ij}^k(x) = c^k(x)a_{ij}(x)$ with $c^k > 0$. A Lyapunov functional $U(t) = \int_\Omega V(u(t, x))\, dx$ is employed, but the boundedness of solutions has to be assumed or obtained by other means.

Key words. parabolic systems, Lyapunov function, asymptotic behavior, limit set

1. Introduction.

We begin by briefly reviewing the ODE case. Let

$$u'(t) = f(u(t)) \tag{1}$$

be an autonomous system of n ordinary differential equations in an open set $D \subset R^n$, where $f: D \to R^n$ is continuous and such that the initial-value problems for (1) are uniquely solvable. This holds, for example, if f is locally Lipschitz continuous. Here a C^1 function $V: D \to R$ such that the set $D_c = \{z \in D: V(z) \leqq c\}$ is a compact subset of D for every $c \in V(D)$ is called a *Lyapunov function* for (1). The function

$$\dot{V}(z) = V_z \cdot f := \sum_{i=1}^{n} f_i \frac{\partial V}{\partial z_i},$$

the derivative of V in the direction f, has the property that

$$\frac{d}{dt} V(u(t)) = \dot{V}(u(t))$$

for any solution u of (1). The latter expression is called "the derivative of V along a solution" and is denoted by $\dot{V}(u)$.

Let u be a solution of (1) existing for $t \geqq 0$. The set $\Lambda^+ = \Lambda^+(u)$ defined by

$$\Lambda^+(u) = \{z \in R^n: z = \lim u(t_k) \text{ for some sequence } t_k \to \infty\}$$

is called the positive limit set of u. Let $\dot{V}(z) \leqq 0$ for $z \in D$. Then each solution of (1) exists for all $t \geqq 0$, the set Λ^+ is a compact nonempty subset of D, and dist $(u(t), \Lambda^+) \to 0$ as $t \to \infty$. It follows from this latter statement that Λ^+ is not only contained in the set

$$W = \{z \in D: \dot{V}(z) = 0\}$$

but is contained in the largest subset of this set which is invariant under (1). The description of Λ^+ is usually referred to as *La Salle's stability theorem.* Although various ingredients for La Salle's theorem were available previously, starting with the pioneering work of Lyapunov, it appears that the complete result was first formulated by La Salle (cf. [11] and the references there given).

The primary subject of this paper is the parabolic system

$$u_t^k = Lu^k + f^k(u) \quad \text{in } J \times \Omega \quad (k = 1, 2, \cdots, n). \tag{2}$$

In short $u_t = Lu + f(u)$, where $u = (u^1, u^2, \cdots, u^n) = u(t, x)$, $x = (x_1, x_2, \cdots, x_m)$, J is an interval $(0, T]$ or $(0, \infty)$, Ω is a bounded open set in R^m with smooth boundary, and L is a selfadjoint elliptic operator with coefficients independent of t,

$$L\phi = \sum_{i,j=1}^{m} \frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial \phi}{\partial x_j}\right). \tag{3}$$

Note that we have the same elliptic part in all equations, so that L can be regarded as operating on the real-valued function ϕ or as operating componentwise on the vector-valued function u. For the most part we shall deal with the Neumann problem, in which the initial and boundary conditions are

$$u(0, x) = \bar{u}(x) \quad \text{in } \bar{\Omega}, \qquad \frac{\partial u}{\partial \nu} = 0 \quad \text{on } J \times \Gamma \tag{4}$$

where $\Gamma = \partial\Omega$ and $\partial/\partial\nu$ denotes the outer conormal derivative; that is,

$$\nu_i = \sum_{j=1}^{m} a_{ji} n_j,$$

where $n = (n_i)$ is the outer normal at $x \in \Gamma$. Our basic result, given explicitly in Theorems 1 and 2, can be roughly described as follows. If a convex Lyapunov function satisfying $\dot{V}(z) \leqq 0$ exists, then the parabolic case reduces to the ODE case. More precisely, solutions to (2), (4) exist for all $t \geqq 0$ and are bounded in $C^{2+\gamma}(\bar{\Omega})$ for some $\gamma > 0$. The limit set Λ^+ of any solution u, which is now a set in the space $C^{2+\gamma}$, consists of constant functions only. Considered as a subset of R^n, the limit set Λ^+ is an invariant set for the ODE (1) and the function $\dot{V}(z)$ vanishes on Λ^+. Hence Λ^+ is contained in the largest invariant subset (with respect to (1)) of the subset W defined above. It will be seen that

$$\text{dist}\,(u(t, \cdot), \Lambda^+) \to 0 \quad \text{as } t \to \infty,$$

where the distance is taken in the sense of the $C^{2+\gamma}$ norm. Hence, the largest invariant subset of W can be used to assess the asymptotic behavior not only for the ODE (1) but also for the PDEs (2) and (4).

As to method, our work relies heavily on the theory of parabolic differential inequalities. In the ODE case the function $U(t) = V(u(t))$ satisfies $U'(t) \leqq 0$ and hence is decreasing. The results of Lyapunov and their extension due to La Salle follow easily from this fact. In the parabolic case the corresponding real-valued function $U(t, x) = V(u(t, x))$ satisfies a parabolic inequality of the form

$$U_t \leqq LU - \alpha\beta|u_x|^2; \tag{5}$$

this fact is crucial for our method. Here α and β are positive constants such that $(a_{ij}) \geqq \alpha I_m$, $V_{zz} \geqq \beta I_n$, where I_k is the identity matrix of order k, V_{zz} is the Hessian of V, and the inequalities are interpreted in the sense of quadratic forms. The assumption $V_{zz} > 0$ is an additional requirement that is not needed in the ODE case.

The general problem considered here has a number of special cases that are of considerable interest in applications. Discussion of such cases can be found in the work of Alikakos [1]–[3], Chaffee [7], [8], Fleming [9], Hadeler [10], Leung [12], Mottoni, Orlandi and Tesei [13], Rothe [17], Webb [20] and in our own analysis of the prey-predator case [14]. These references make use of Lyapunov-type arguments, as we do, and [2] also indicates the importance of a condition of strict inequality such as $V_{zz} > 0$. We show by an example that, in fact, the weak inequality $V_{zz} \geqq 0$ is not sufficient.

2. Notation, assumptions and auxiliary theorems. Our basic notation is the same as in [14] but is briefly described for the reader's convenience. The Euclidean norm in R^m or R^n is denoted by $|\cdot|$. For a function $w: \bar{\Omega} \to R^n$ we set

$$\|w\|_0 = \sup |w(x)|, \quad [w]_\gamma = \sup \frac{|w(x) - w(y)|}{|x - y|^\gamma} \quad (x \neq y),$$

where $x \in \bar{\Omega}$, $y \in \bar{\Omega}$ and $0 < \gamma < 1$. Furthermore, $\|w\|_\gamma = \|w\|_0 + [w]_\gamma$. The spaces $C^\gamma(\bar{\Omega})$ or $C^{2+\gamma}(\bar{\Omega})$ consist of all functions with a finite norm $\|w\|_\gamma$ or

$$\|w\|_{2+\gamma} = \|w\|_0 + \sum_{i=1}^{m} \|D_i w\|_0 + \sum_{i,j=1}^{m} \|D_i D_j w\|_\gamma \qquad \left(D_i = \frac{\partial}{\partial x_i}\right),$$

respectively. The space $C^{1+\gamma}(\bar{\Omega})$ is defined similarly. Whenever a distinction between scalar- and vector-valued functions is not self-evident, we use notation such as $C^\gamma(\bar{\Omega}, R)$ or $C^{2+\gamma}(\bar{\Omega}, R^n)$. The gradient and Hessian of V are denoted by V_z and V_{zz}, respectively, and we set, by definition,

$$|u_x|^2 = \sum_{i=1}^{m} \sum_{k=1}^{n} |D_i u^k|^2.$$

We use a summation convention for repeated indices, the range of summation being from 1 to m or from 1 to n, as will be clear from the context. Thus, $L\phi = D_i(a_{ij} D_j \phi)$ and if $A = (a_{ij})$, $V_{zz} = (b_{ij})$, the inequalities $A \geqq \alpha I_m$, $V \geqq \beta I_n$ mean

$$a_{ij} \xi^i \xi^j \geqq \alpha |\xi|^2, \qquad b_{ij} \xi^i \xi^j \geqq \beta |\xi|^2$$

for $\xi \in R^m$ and for $\xi \in R^n$, respectively. The range of summation in the first case is from 1 to m and in the second, from 1 to n.

Concerning the domain Ω, the elliptic operator L, the function f and the initial value $\bar{u}$, we require the following:

(R1) Ω is a bounded, open, connected set in R^m with orientable boundary $\partial\Omega = \Gamma$ of class $C^{2+\gamma}$.

(R2) $D \subset R^n$ is open and $f: D \to R^n$ is locally Lipschitz continuous.

(R3) The matrix $A(x) = (a_{ij}(x))$ is of class $C^{1+\gamma}(\bar{\Omega})$ and $A \geqq \alpha I_m$ with $\alpha > 0$ constant.

(R4) $\bar{u}(x) \in C^{2+\gamma}(\bar{\Omega})$, $\partial \bar{u}/\partial \nu = 0$ on Γ, and $\bar{u}(x) \in D$ for $x \in \bar{\Omega}$.

If $u(t, x)$ is such that u, u_t, u_x and u_{xx} are continuous in $J \times \bar{\Omega}$, we write $u \in C^*(J)$. The following local existence theorem holds under the assumptions (R), and any other assumptions under which it holds would suffice for our purposes.

THEOREM 0. *Under the assumptions* (R) *the problem*

$$u_t = Lu + f(u), \qquad u(0, x) = \bar{u}(x), \qquad \frac{\partial u}{\partial \nu} = 0 \tag{6}$$

has a unique local solution $u \in C^*(J)$, $J = (0, T]$, $T > 0$. *The matrix* u_{xx} *is Hölder continuous in* x *and* $u(t, \cdot)$ *maps* $\bar{J}$ *continuously into* $C^{2+\gamma}(\bar{\Omega})$. *If an a priori estimate* $|u(t, x)| \leqq K$ *for* $0 \leqq t \leqq T$, $x \in \bar{\Omega}$ *can be established, where* K *is independent of* T, *then the solution exists for all* $t \geqq 0$ *and* $\sup_{t \geqq 0} \|u(t, \cdot)\|_{2+\gamma} < \infty$.

In (6) it is understood that the first equality holds in $J \times \Omega$ with $J = (0, \infty)$, the second in $\bar{\Omega}$, and the third in $J \times \Gamma$. To avoid unnecessary clutter, a similar convention is followed below.

The assertion of existence in Theorem 0 has been known for some time but prior to the investigation in [15], as far as we know, the global bound for $\|u\|_{2+\gamma}$ has been available only in special cases.

When $\|u\|_{2+\gamma}$ is bounded, the "path" $\{u(t, \cdot): t \geqq 0\}$ is a relatively compact subset of $C^2(\bar{\Omega})$. That is, for any sequence $t_k \to \infty$ there is a subsequence t_k^* such that $\lim_{k \to \infty} u(t_k^*, \cdot)$ exists as an element of $C^2(\bar{\Omega})$. By definition, the *limit set* Λ^+ is the set of all functions in $C^2(\bar{\Omega})$ that can be obtained as limits in this way. Characterization of Λ^+ is the object of the following investigation.

3. Statement of the main results. All the concepts needed for our principal theorem are now at hand.

THEOREM 1 (Global existence). *Assume that the assumptions* (R) *hold and that there exists a Lyapunov function* $V: D \to R$ *of class* C^2 *such that* $\dot{V}(z) \leqq 0$ *and such that* $V_{zz} \geqq \beta I_n$, *where* $\beta \geqq 0$ *is constant. Then* (6) *has exactly one solution* u *for each initial value* $\bar{u}$. *The solution exists for* $t \geqq 0$, *it belongs to* $C^*(0, \infty)$, *and it remains in a compact subset of* D. *The function* $u(t, \cdot)$ *is continuous and the orbit* $\{u(t, \cdot): 0 \leqq t < \infty\}$ *is bounded in the* $C^{2+\gamma}$ *norm.*

THEOREM 2 (Asymptotic behavior). *Under the assumptions of Theorem* 1, *with* $\beta > 0$, *the limit set* Λ^+ *of* u *is a nonempty compact subset of* $C^2(\bar{\Omega})$ *and it contains constant functions only. Considered as a subset of* R^n, *the limit set* Λ^+ *is an invariant set for the ordinary differential equation* $u' = f(u)$, *and* $\dot{V}$ *vanishes on* Λ^+.

The above results imply that

$$\operatorname{dist}(u(t, \cdot), \Lambda^+) \to 0 \quad \text{in } C^2(\bar{\Omega}) \quad \text{as } t \to \infty.$$

In particular, given any sequence $\{t_k\}$ with $t_k \to \infty$ there exists a subsequence $\{t_k^*\}$ and a constant $c \in R^n$ such that $\|u(t_k^*, \cdot) - c\|_2 \to 0$ as $k \to \infty$.

Before turning to the proof we indicate a possible source of misunderstanding. Since each element of Λ^+ is a constant c, and all the derivatives of c are of course 0, it might be thought that the partial differential equation implies $f(c) = 0$. (The uniformity of convergence does in fact give $Lu \to Lc = 0$ as $t = t_k \to \infty$.) Although existence of a "stationary point" c with $f(c) = 0$ was not postulated initially, it was pointed out by Professor Robert Greene of the University of California, Los Angeles that this is implied by the hypothesis of Theorem 2. Namely, $f(c) = 0$ at the point where V assumes its minimum; we omit the easy proof.

Nevertheless, the above conclusion "$c \in \Lambda^+ \Rightarrow f(c) = 0$" is false. Taking $n = 2$ let $u = (p, q)$ and consider the system

$$p_t = Lp + q, \qquad q_t = Lq - p, \qquad u(0, x) = (0, 1).$$

This system has the solution $u(t, x) = (\sin t, \cos t)$ and the hypothesis of Theorem 2 holds with $V(z) = |z|^2$. But no point $c \in \Lambda^+$ satisfies $f(c) = 0$.

Later we shall consider a similar problem for the scalar function $U = V(u)$ and here the elements $W \in \Lambda^+$ for U will satisfy $W_t = 0$ as well as $LW = 0$. The difference in the two cases is that in the scalar case we shall have $U(t, \cdot) \to c$ as $t \to \infty$ without restriction, while $u(t, \cdot) \to c$ holds only on the sequence $\{t_k\}$.

4. Existence of a limit. One of the most important lemmas needed for our theorem states that the solutions of $\phi_t \leqq L\phi$, $\phi_\nu \leqq 0$ have a constant limit, in general, as $t \to \infty$. In [14] the result is deduced first for the corresponding equation $\phi_t = L\phi$, $\phi_\nu = 0$ by consideration of the integrals

$$h(t) = \int_\Omega \phi(t, x)\, dx, \qquad k(t) = \int_\Omega \phi^2(t, x)\, dx.$$

Another method is briefly outlined as follows: Let (λ_n, ψ_n) be the sequence of characteristic values and functions for the problem

$$L\psi + \lambda\psi = 0, \qquad \psi_\nu = 0.$$

Then $\lambda_1 = 0$, $\psi_1 = 1$, and $\lambda_n > 0$ for $n > 1$. Also, by the spectral theorem,

$$\phi(0, x) = \sum_{n=1}^{\infty} b_n \psi_n(x) \Rightarrow \phi(t, x) = \sum_{n=1}^{\infty} b_n\, e^{-\lambda_n t} \psi_n(x),$$

where the coefficients b_n are bounded. Hence $\phi(t, x) \to b_1$ as $t \to \infty$, and indeed, with exponential rapidity. A comparison argument [14] now gives the result for the inequality, which we formulate as follows.

LEMMA 1. *Let ϕ be a bounded real-valued function of class $C^*(0, \infty)$ satisfying*

$$\phi_t \leqq L\phi, \quad \phi_\nu \leqq 0, \qquad \sup |\phi_t| < \infty, \qquad \sup |\phi_x| < \infty.$$

Then $\lim_{t\to\infty} \phi(t, x) = c$, where c is constant, and the convergence is uniform with respect to x.

Since the hypothesis on ϕ_t and ϕ_x in Lemma 1 forms the primary obstacle to extension of our theorem to quasilinear systems, we shall give an alternative proof, different from that in [14], which requires weaker assumptions and makes no use of existence theory. It will be seen that the crucial requirement is a condition of uniform continuity of ϕ, and, if the assertion of uniformity of the convergence is dropped, even this is needed only in each compact subset of Ω as $t \to \infty$.

5. Proof of Lemma 1. Let $\phi = M - e^{-\psi}$ where M is a sufficiently large constant; for example, $M = 1 + \sup \phi$. Then with $\phi_j = D_j\phi$, $\phi_{ij} = D_iD_j\phi$,

$$\phi_j = e^{-\psi}\psi_j, \qquad (a_{ij}\phi_j)_i = e^{-\psi}[(a_{ij}\psi_j)_i - a_{ij}\psi_i\psi_j]$$

and hence

$$\phi_t = e^{-\psi}\psi_t \leqq L\phi = e^{-\psi}(L\psi - a_{ij}\psi_i\psi_j)$$

or, in view of the hypothesis $(a_{ij}) \geqq \alpha I$,

$$\psi_t \leqq L\psi - \alpha|\psi_x|^2.$$

Let us now set

$$h(t) = \frac{1}{|\Omega|} \int \psi(t, x)\, dx.$$

Then by the divergence theorem

$$h'(t) \leqq -\frac{\alpha}{|\Omega|} \int |\psi_x(t, x)|^2\, dx.$$

It is readily checked that e^{ψ} (as well as $e^{-\psi}$) is bounded, and hence the boundedness of ϕ_t and ϕ_x ensures that ψ_t and ψ_x are also bounded. From the regularity conditions on Ω it follows that ψ is uniformly Lipschitz continuous. That is, there exists a constant L such that

$$|\psi(t, x)-\psi(s, y)| \leqq L(|s-t|+|x-y|) \quad \text{for } x, y \in \bar{\Omega} \text{ and } s, t \geqq 0.$$

Lemma 1 is therefore a consequence of Lemma 2.

LEMMA 2. *Assume that ψ is bounded and uniformly continuous in $(0, \infty)\times\Omega$ and that $\psi_x(t, \cdot) \in L_2(\Omega)$ for $t>0$. Suppose*

$$h(t)=\frac{1}{|\Omega|}\int \psi(t, x)\, dx \quad \textit{satisfies } h'(t) \leqq -\lambda \int |\psi_x(t, x)|^2\, dx,$$

where λ is a positive constant. Then $\lim_{t\to\infty} \psi(t, x)=c$, where c is constant, and the convergence is uniform with respect to x.

Proof of Lemma 2. Let

$$v(t, B)=\sup_{x\in B} \psi(t, x)-\inf_{x\in B} \psi(t, x) \quad \text{where } B \subset \Omega.$$

We show first that $v(t, B)\to 0$ as $t\to\infty$ for any closed ball $B\subset\Omega$. Assume that B has radius r and that $\operatorname{dist}(B, \Gamma)=\alpha>0$. Suppose that for a specified value t_0 we have $v(t_0, B)>3\varepsilon$. Then there are points $\xi, \eta \in B$ such that $|\psi(t_0, \xi)-\psi(t_0, \eta)|>2\varepsilon$. Since ψ is uniformly continuous there exists $\delta \leqq \alpha$ (independent of t_0) with the property that

$$|\psi(t, x)-\psi(t, y)|>\varepsilon \quad \text{for } |t-t_0|, |x-\xi|, |y-\eta|<\delta.$$

Assume for simplicity that $\xi_1 \neq \eta_1$ and let $p=(0, p')$, where $p'=(p_2, \cdots, p_n) \in R^{n-1}$, $|p'|<\delta$. Then

$$\varepsilon<|\psi(t, \xi+p)-\psi(t, \eta+p)| \leqq \int_{\xi_1}^{\eta_1} |\psi_x(t, s, p_2, \cdots, p_n)|\, ds.$$

Integrating over the ball B': $|p'|<\delta$ in R^{n-1}, we obtain

$$|B'|\varepsilon<\int_{B'}\int_{\xi_1}^{\eta_1} |\psi_x(t, x)|\, dx \leqq \left(\int_{\Omega} |\psi_x(t, x)|^2\, dx \cdot 2r|B'|\right)^{1/2},$$

where $|B'|=\omega_{n-1}\delta^{n-1}$ is the $(n-1)$-dimensional volume of B'. This inequality shows that

$$\int |\psi_x(t, x)|^2\, dx \geqq \frac{|B'|}{2r}\varepsilon^2 =: \beta \quad \text{for } (t-t_0)<\delta.$$

Hence $h' \leqq -\lambda\beta$, i.e., $h(t_0+\delta)-h(t_0-\delta)<-2\delta\lambda\beta$. If there existed a sequence (t_k), $t_k\to\infty$, such that $v(t_k, B)>3\varepsilon$, we would have $\lim_{t\to\infty} h(t)=-\infty$. Since h is bounded, this cannot happen, i.e., $v(t, B)<3\varepsilon$ for large t.

Now we show that $v(t, \Omega)\to 0$. Let $\varepsilon>0$ be given and let $\delta>0$ be such that $|\psi(t, x)-\psi(t, y)|<\varepsilon$ for $|x-y|<\delta$ and all t. Let B be a finite subset of Ω with the property that the δ-neighborhood of B covers Ω. By connecting the points of B with polygonal lines, we obtain a connected subset C of Ω with positive distance from Γ, say, $\operatorname{dist}(C, \Gamma)=2\alpha>0$. We cover C by a finite number of balls B_i with radius α and midpoint on C with the property that for each B_i there is a neighboring B_j such that $B_i \cap B_j \neq \varnothing$. Because $C_1 \cap C_2 \neq \varnothing$ implies $v(t, C_1 \cup C_2) \leqq v(t, C_1)+v(t, C_2)$, we get $v(t, C)\to 0$ as $t\to\infty$. Since each point of Ω is in the δ-neighborhood of C,

$$v(t, \Omega)<v(t, C)+2\varepsilon,$$

which shows that $v(t, \Omega)\to 0$ as $t\to\infty$.

Since h is decreasing and bounded, there exists

$$c = \lim_{t \to 0} h(t).$$

On the other hand, since $h(t)$ is a mean value, there exists $x_t \in \Omega$ such that $\psi(t, x_t) = h(t)$. The equation

$$|\psi(t, x) - h(t)| = |\psi(t, x) - \psi(t, x_t)| \leqq v(t)$$

now shows that $\psi(t, x) \to c$, and that the convergence is uniform with respect to x. This completes the proof of Lemma 2.

6. A matrix inequality. The trace of a square matrix A, written tr A, is the sum of its diagonal elements. According to a well-known lemma of Schur and Fejér, the following holds: Let A and D be square matrices of the same size with $A \geqq 0$, $D \geqq 0$, $D^T = D$. Then tr $AD \geqq 0$, with strict inequality if $A > 0$ and $D \neq 0$. Since this result is usually quoted for symmetric matrices only, let us briefly recall the proof. From $D \geqq 0$ and $D^T = D$ follows a representation $D = X^T X$, so that $d_{ij} = x_{ki} x_{kj}$. Thus,

$$\text{tr } AD = a_{ij} d_{ij} = a_{ij} x_{ki} x_{kj}.$$

For each fixed k the quadratic form on the right is $\geqq 0$, with strict inequality for at least one k if $A > 0$ and $X \neq 0$. This completes the proof.

We shall establish the following lemma.

LEMMA 3. *Let $A = (a_{ij})$, $B = (b_{ij})$ and $C = (c_{ij})$ be matrices of size m by m, n by n and n by m, respectively. Suppose further that $B = B^T$ and that $A \geqq \alpha I_m$, $B \geqq \beta I_n$ with $\alpha \geqq 0$ and $\beta \geqq 0$. Then*

$$\text{tr } AC^T BC = a_{ij} b_{kl} c_{ik} c_{jl} \geqq \alpha\beta |C|^2$$

where $|C|^2 = \sum_{i,j} (c_{ij})^2$.

For proof, let $D = C^T BC$. Then $x^T Dx = z^T Bz$ where $z = Cx$. This shows $D \geqq 0$ and the inequality tr $AC^T BC \geqq 0$ follows from the lemma of Schur and Fejér as quoted above. Now write $A = \bar{A} + \alpha I_m$, $B = \bar{B} + \beta I_n$ with $\bar{A} \geqq 0$ and $\bar{B} \geqq 0$ and consider the identity

$$(\bar{A} + \alpha I_m) C^T (\bar{B} + \beta I_n) C = \bar{A} C^T \bar{B} C + \alpha C^T \bar{B} C + \beta \bar{A} C^T C + \alpha\beta C^T C.$$

It follows from the earlier result that the traces of the first three matrices on the right are nonnegative, and hence

$$\text{tr } AC^T BC \geqq \alpha\beta \text{ tr } C^T C = \alpha\beta |C|^2.$$

7. The Lyapunov function. Let $V: D \to R$ be of class C^2 and let u be a solution of $u_t = Lu + f(u)$. The notation $V_k = \partial V(z)/\partial z_k$, $u_i^k = \partial u^k / \partial x_i$ are used, and similarly for higher derivatives. The gradient and Hessian of V are denoted by V_z and V_{zz}, respectively, so that $V_{zz} = \text{matrix } (V_{kl})$. As before, i and j run from 1 to n while k and l run from 1 to m. We are going to derive a differential inequality for the scalar function $U(t, x) = V(u(t, x))$ or, briefly, $U = V(u)$.

From

$$U_t = V_k u_t^k = V_k (a_{ij} u_i^k)_j + V_k f^k(u),$$

$$L(U) = (a_{ij} V_k u_i^k)_j = V_k (a_{ij} u_i^k)_j + a_{ij} V_{kl} u_i^k u_j^l,$$

it follows that

$$U_t = L(U) + \dot{V} - a_{ij} V_{kl} u_i^k u_j^l$$

where $\dot{V} = V_x \cdot f$ along the trajectory u. Applying Lemma 3 with $A = (a_{ij})$, $B = V_{xx}$ and $C = (u_i^k)$, we get the following lemma.

LEMMA 4. *Let $V: D \to R$ be a function of class C^2 satisfying*

$$V_{zz} \geqq \beta I, \qquad \dot{V} = V_z \cdot f(u) \leqq 0$$

where β is a positive constant and where u is a solution of $u_t = Lu + f(u)$. Then the scalar function $U = V(u)$ satisfies

$$U_t \leqq LU - \alpha\beta |u_x|^2.$$

It should be observed that the proof, based on Lemma 3, uses the fact that V_{zz} is symmetric, but does not require symmetry of the matrix A. The latter condition would be a serious restriction on the operator L.

8. Monotonicity and comparison. The following two lemmas are well known [14], [19] but are repeated here for logical completeness. They hold under much weaker assumptions regarding L, Ω and u than those necessary for existence theory. Rather than fully exploiting this fact, we point to it by introducing the space $C_0^*(J)$ of functions continuous in $\bar{J} \times \bar{\Omega}$ with derivatives u_t, u_x and u_{xx} continuous in $J \times \Omega$. As always, J is an interval $(0, T]$ or $(0, \infty)$.

LEMMA 5. *If the real-valued functions ϕ, $\psi \in C_0^*(J)$ satisfy*

$$\phi_t \leqq L\phi, \quad \psi_t \geqq L\psi, \quad \frac{\partial \phi}{\partial \nu} \leqq \frac{\partial \psi}{\partial \nu}, \quad \phi(0, x) \leqq \psi(0, x)$$

then $\phi \leqq \psi$ in $\bar{J} \times \bar{\Omega}$.

LEMMA 6. *If two solutions v, $u \in C_0^*(J, R^n)$ of $u_t = Lu + f(u)$ satisfy*

$$|u(0, x) - v(0, x)| \leqq \rho, \qquad \frac{\partial u}{\partial \nu} = \frac{\partial v}{\partial \nu}$$

and if for these solutions $|f(u) - f(v)| \leqq M|u - v|$, where M and ρ are constant, then $|u(t, x) - v(t, x)| \leqq \rho e^{Mt}$ in $\bar{J} \times \bar{\Omega}$.

9. Proof of Theorem 1. Let $\max V(\bar{u}(x)) = \eta$, where $\bar{u}$ is the initial value of u. Since Lemma 4 gives $U_t \leqq LU$, and since $\partial U / \partial \nu = 0$, we can apply Lemma 5 with $\phi = U$ and $\psi = \eta$. It follows that, as long as the solution exists, $U(t, x) \leqq \eta$ and hence $u(t, x) \in D_\eta$, where $D_\eta = \{z \in R^n : V(z) \leqq \eta\}$ is a compact subset of D (cf. the definition of Lyapunov function given in § 1). Theorem 1 now follows from Theorem 0.

10. Proof of Theorem 2. It is clear from the global estimate given in Theorem 1 that the set Λ^+ is nonempty and compact. Since $U_t \leqq LU$ by Lemma 4, and since the differential equation together with Theorem 0 shows that u_t and hence U_t are bounded, we can apply Lemma 1 to get

$$\lim_{t \to \infty} U(t, \cdot) = c, \qquad c \text{ constant.} \tag{7}$$

Let $\bar{w}$ be an arbitrary element of Λ^+, say $\lim u(t_k, \cdot) = \bar{w}$ as $k \to \infty$. Clearly $\bar{w}$ satisfies (R4). We denote by $w(t, x)$ the solution of (6) with initial value $\bar{w}$ and we set $W(t, x) = V(w(t, x))$, that is, $W = V(w)$. The proof of Theorem 1 gives $\bar{w}(x) \in D_\eta$, hence $w(t, x) \in D_\eta$ by the same proof, and we may assume, therefore, that $|f(u) - f(w)| \leqq M|u - w|$ for some constant M. From Lemma 6 we obtain the estimate

$$|u(t_k + t, x) - w(t, x)| \leqq \|u(t_k, \cdot) - \bar{w}\|_0 \, e^{Mt} \tag{8}$$

which implies $u(t_k+t, x)\to w(t, x)$ and $U(t_k+t, x)\to W(t, x)$ uniformly in x as $k\to\infty$. But the latter limit is constant by (7); hence $W(t, x)=c$ for all t and x. Now, Lemma 4 gives

$$W_t \leqq LW-\alpha\beta|w_x|^2$$

and, on the other hand, $W_t=LW=0$. Hence $w_x=0$. This shows that $w(t, x)$ and in particular $w(x)=w(0, x)$ are independent of x. In other words, $w=w(t)$ is a solution to the ordinary differential equation $w_t=f(w)$. It follows from (8) that $w(t)\in\Lambda^+$ for any positive t; in other words, Λ^+ is positively invariant. That Λ^+ is also negatively invariant, and that $\dot{V}(z)$ vanishes on Λ^+, are proved as in [14].

11. Remarks on the condition for V_{zz}. If the condition $V_{zz}>0$ is replaced by $V_{zz}\geqq 0$ Theorem 2 no longer follows even when $m=n=1$. To see this, let $f(u)$ be a smooth function such that $f(u)=u$ for $|u|\leqq 1$ and $f(u)=0$ for $|u|\geqq 2$. Also let $V(z)=0$ for $|z|\leqq 2$, $V(z)=(2-|z|)^4$ for $|z|\geqq 2$. Then the boundary value problem suggested for $n=m=1$ by

$$u_t=u_{xx}+f(u), \qquad (t, x)\in(0, \infty)\times(0, \pi)$$

has a solution $u(t, x)=\cos x$, which violates the conclusion of Theorem 2.

In many developments of the Lyapunov theory $V(z)$ is required to satisfy the additional condition

$$V(0)=0, \qquad V(z)>0 \quad \text{for } z\neq 0. \tag{9}$$

The first of these can be attained by adding a constant to V but the second is more restrictive. The condition is imposed to ensure stability of the zero solution, a consideration which has nothing to do with the problems addressed in this paper. (If we impose the additional condition $\dot{V}(z)<0$ for $z\neq 0$, as well as (9), then every solution with initial values satisfying $\bar{u}(x)\in D$ for $x\in\bar{\Omega}$ converges to the null solution in the $C^2(\Omega)$ norm, as $t\to\infty$, and the latter solution is stable. But this case excludes most of the more interesting applications of the La Salle stability theorem and it can be obtained in a much simpler way.)

If V is normalized so $\min V(z)=V(0)=0$, the hypothesis $V_{zz}>0$ ensures (9) automatically. The question arises whether (9) is sufficient for Theorem 2, without any condition on V_{zz}. We shall show that this is not the case. Considering the same equation as above, let f be a smooth function satisfying

$$f(u)=0, \quad u-4, \quad 0$$

on the intervals $u\leqq 2$, $3\leqq u\leqq 5$, $u\geqq 6$, respectively. Let $V(z)$ be a smooth function satisfying $V(z)>0$ for $z=0$ and $V(z)=z^2$, 2, z^2 on the intervals $z\leqq 1$, $2\leqq z\leqq 6$, $z\geqq 7$, respectively. Then all assumptions hold, except $V_{zz}>0$. Nevertheless the boundary value problem with initial value $\bar{u}(x)=4+\cos x$ has the solution $u=\bar{u}$ and Λ^+ contains only the function $\bar{u}$, which is certainly not constant. If $m=n=1$, a brief investigation suggests that $V_{zz}\geqq 0$ together with (9) is sufficient. Whether this holds in general is left as an open problem.

If $V(z)=f_1(z^1)+f_2(z^2)+\cdots+f_n(z^n)$ the condition $f_k''>0$ for $k=1, 2, \cdots, n$ ensures $V_{zz}>0$. Using this fact, one can show that Theorem 2 contains the main results of [14].

12. The quasilinear case. In this section we will indicate how to extend the above results to the quasilinear system ($k=1, 2, \cdots, n$)

$$u_t^k=\sum_{i,j=1}^{m}\frac{d}{dx_i}\left(a_{ij}(x, u)\frac{\partial u^k}{\partial x_j}\right)+f^k(u) \quad \text{in } J\times\Omega \tag{10}$$

subject to the initial and boundary condition (4). Instead of assumptions (R) we now require:

(R1′) Ω is a bounded domain in R^m with orientable boundary Γ of class C^{3-}.

(R2′) $D \subset R^n$ is open and $f: D \to R^n$ is locally of class C^{2-}.

(R3′) The matrix $A(x, u) = (a_{ij}(x, u))$ is of class $C^{3-}(\bar{\Omega} \times D)$ and $A \geqq \alpha I_m$ with $\alpha > 0$ constant.

(R4′) as (R4).

(R5′) For $x \in \Gamma$ the functions $a_{ij}(x, u)$ are independent of u.

Here, $C^{3-}(\bar{\Omega} \times D)$ denotes the space of all functions $\phi: \bar{\Omega} \times D \to R$ with Lipschitz continuous first and second partial derivatives; the symbols C^{3-} and C^{2-} are to be interpreted in a similar fashion.

Remark. It is sufficient for our purposes that (R3′) holds locally with respect to u.

Under the assumptions (R′) assertions analogous to those in Theorems 0, 1 and 2 can be proved for system (10). Hence, in particular, the asymptotic behavior for (10) is completely determined by the asymptotic behavior of the solutions to the system (1) of ordinary differential equations. Since, as has been noted above, the proofs of Theorems 1 and 2 can be easily adapted to the quasilinear setting, the main difficulty in establishing this result lies in the extension of Theorem 0 to (10).

We do not want to go into details about the proof at this place. Let us only say that local existence of a classical solution u for the boundary-value problem (10), (4) follows from [5, § 10]. Next, using reasoning similar to that employed in [16, § 4], an a priori bound (uniformly in t) for the functions $u(t, \cdot)$ in $C^{1+\alpha}(\bar{\Omega}, R^n)$ is established (any $0 < \alpha < 1$). This is sufficient to guarantee global existence of u. The statement about global boundedness of $\|u(t, \cdot)\|_{2+\gamma}$ then follows from [16, Thm. 8]. We have thus proved the following.

THEOREM 3. *Assume that the assumptions* (R′) *hold and that there exists a Lyapunov function* $V: D \to R$ *of class* C^2 *such that* $\dot{V}(z) \leqq 0$ *in* D *and such that* $V_{zz} \geqq \beta I_n$ *where* $\beta > 0$ *is constant. Then* (10), (4) *has exactly one solution* u *for each initial value* $\bar{u}$. *The solution exists for* $t \geqq 0$, *it belongs to* $C^*([0, \infty))$ *and it remains in a compact subset of* D. *The orbit* $\{u(t, \cdot): t \geqq 0\}$ *is bounded in the* $C^{2+\gamma}$ *norm.*

The limit set Λ^+ *of* u *is a nonempty compact subset of* $C^2(\bar{\Omega})$ *and it contains constant functions only. Considered as a subset of* R^n, Λ^+ *is an invariant set for the ordinary differential equation* $u' = f(u)$ *and* $\dot{V}$ *vanishes on* Λ^+.

13. Lyapunov functionals. We briefly describe an alternative approach. Assume that u is a bounded regular solution of (2), (4) with values in D, and that $V: D \to R$ is a Lyapunov function for the associated system (1) of ordinary differential equations with $V_{zz} \geqq \beta I_n$, where $\beta > 0$ is constant. Consider the Lyapunov functional

$$U(t) = \int_\Omega V(u(t, x))\, dx \quad \text{for } t \geqq 0.$$

We get

$$\begin{aligned} \dot{U}(t) = \frac{d}{dt} U(t) &= \int_\Omega V_k u_t^k \\ &= \int_\Omega V_k (a_{ij} u_j^k) i + V_k f^k \\ &= \int_\Omega V_k f^k - a_{ij} V_{kl} u_j^k u_i^l \\ &\leqq \int_\Omega V_k f^k - \alpha\beta |u_x|^2. \end{aligned}$$

Since the orbit $\{u(t,\cdot): t \geqq 0\}$ is relatively compact in $C^2(\bar{\Omega}, R^n)$ by [15], La Salle's principle implies that Λ^+ consists of constant functions only. Moreover, Λ^+ is an invariant set for (1) and $\dot{V}=0$ on Λ^+. This proves Theorem 2.

The same reasoning also applies to the system

$$(2^*) \qquad u_t^k = L^k u^k + f^k(u) \quad \text{in } J\times\Omega \quad (k=1,2,\cdots,n),$$

where the elliptic part

$$L^k\theta = (a_{ij}^k(x)\theta_j)_i$$

now may vary with k, provided we have $a_{ij}^k = c^k(x)a_{ij}(x)$ with functions $c^k(x) \in C^{1+\gamma}(\bar{\Omega})$ that are strictly positive in $\bar{\Omega}$. Moreover we suppose that

(α) (a_{ij}) is symmetric and $(c_k V_{kl})$ is positive definite for any $x \in \bar{\Omega}$, $u \in D$;

or that

(β) the matrix V_{zz} is of diagonal form.

This gives the following theorem.

THEOREM 2*. *Let u be a bounded regular solution of* (2), (4) *under the above hypotheses. Then the limit set Λ^+ of u is a nonempty compact subset of $C^2(\bar{\Omega})$ and it contains constant functions only. Moreover, Λ^+ is an invariant set for* (1) *and $\dot{V}$ vanishes on Λ^+.*

Theorem 2* generalizes a result of Alikakos [1, § 4], where the case $(a_{ij}) = I_m$, c_k constant is considered. The method of proof (integration with respect to some variables and derivation of a differential inequality for the resulting function) apparently was first used by Carleman [6] in his paper on the Denjoy conjecture.

14. Remarks on boundedness. It should be noted that in the preceding section boundedness of the solution u is used as a hypothesis. As shown above, for systems of type (2) an a priori bound for u can be derived directly from a differential inequality for the Lyapunov function. For system (2*) it seems that such a procedure is not possible. We mention instead the following two methods.

(i) *Comparison arguments.* Let $\alpha(t)$, $\beta(t):[0,\infty)\to R^n$ be a pair of upper and lower solutions for (2*), i.e., assume that $(k=1,2,\cdots,n;\ t>0)$

$$\alpha_t^k(t) \leqq f^k(z) \quad \text{for all } \alpha(t) \leqq z \leqq \beta(t), \quad z^k = \alpha^k(t),$$

$$\beta_t^k(t) \geqq f^k(z) \quad \text{for all } \alpha(t) \leqq z \leqq \beta(t), \quad z^k = \beta^k(t),$$

and that

$$\alpha(0) \leqq u(0,x) \leqq \beta(0) \quad \text{in } \bar{\Omega}.$$

Then $\alpha(t) \leqq u(t,x) \leqq \beta(t)$ for all $t \geqq 0$, $x \in \bar{\Omega}$. This is a special case of a general estimation theorem for parabolic systems (see [19, § 32]). In case α and β are constant it is sometimes called the method of "invariant rectangles."

(ii) *Functional analytic methods* (bootstrapping and feedback arguments). For these we refer the reader to the book by Rothe [18].

15. Historical remarks. As mentioned in the Introduction, a number of special cases of (2) have been treated in the literature. Our results contain those of [10], [12] and [14], and they generalize those of [20] from one to several space variables. The results of [17] are contained insofar as they deal with Neumann boundary conditions. Our results do not contain those of [17] for other boundary conditions, nor those of [7], [8], [9] or [13]. Reference [7] pertains to an unbounded x-domain, [8] and [9] involve nonlinearities depending on both x and u, and [13] has a functional acting on $u(t,\cdot)$. These references suggest possible directions in which our work might be

generalized. It would also be desirable to extend the results to equations with a lagging time variable.

BOUNDED SOLUTIONS OF VOLTERRA EQUATIONS*

JAN PRÜSS†

Abstract. The solvability behavior on the real line of linear integrodifferential equations in a general Banach space is considered and several applications to integral partial differential equations are given.

Key words. Volterra equations, Laplace transform, Fourier transform, Fourier-Carleman transform, admissibility, almost periodic solution, resolvents

AMS(MOS) subject classifications. 45N05, 45K05, 42A38

1. Introduction. It is well known that quite a few problems of applied mathematics lead to abstract equations of the following type:

$$u'(t) = Au(t) + \int_0^\infty dB(\tau)u(t-\tau) + f(t), \tag{1}$$

for example, problems in thermodynamics or elasticity theory for materials with memory, and in population dynamics, to mention a few. Here $u(t)$ denotes the state of the system at time t, A a closed linear operator in the state space, a Banach space X, with dense domain $D(A)$, $\{B(t)\}_{t\geqq 0}$ a family of closed linear operators in X with $D(B(t)) \supset D(A)$ for all $t \geqq 0$ such that $B \in BV(\mathbb{R}_+, \mathbb{B}(Y, X))$ (the space of $\mathbb{B}(Y, X)$-valued functions of bounded variation over $\mathbb{R}_+ = [0, \infty)$), where $Y = D(A)$ is normed by the graph norm of A and $\mathbb{B}(Y, X) = \{T: Y \to X : T \text{ linear and bounded}\}$, and f an X-valued function; w.l.o.g. we also assume that $B(\cdot)$ is left-continuous in $\mathbb{B}(Y, X)$ and satisfies $B(0) = B(0+) = 0$.

In recent years equations of type (1) have been the object of intensive study, mainly the local problem for (1) has been investigated, i.e., the history value problem. This means, given the history function $u_-(t)$ for $t \leqq 0$ and f, find the solution u such that $u(t) = u_-(t)$ for $t \leqq 0$ and (1) holds for $t \geqq 0$. Assuming well-behaved history values $u_-(t)$, this problem reduces to the initial value problem for

$$u'(t) = Au(t) + \int_0^t dB(\tau)u(t-\tau) + g(t), \qquad t \in \mathbb{R}_+, \tag{2}$$

where

$$g(t) = f(t) + \int_t^\infty dB(\tau)u_-(t-\tau).$$

The theory of (2) centers around the concepts "wellposedness" and "resolvent operator" and is well understood by now. It turns out that (2) is well posed if and only if there is a resolvent operator $S(t)$ for (2), and in this case the solution of (2) with initial value u_0 is represented by the variation of parameters formula

$$u(t) = S(t)u_0 + \int_0^t S(t-\tau)g(\tau)\, d\tau. \tag{3}$$

Furthermore, the relation

$$\hat{S}(\lambda) = (\lambda - A - \widehat{dB}(\lambda))^{-1} \tag{4}$$

for the Laplace-transform of S yields a Hille-Yosida type result for resolvents analogous to linear differential equations (cf., e.g., Grimmer and Prüss [7] or Prüss [13]).

However, there are other questions concerning (1) that call for a global theory of (1), e.g., the existence of periodic or almost periodic solutions in the case f has the corresponding property. It is the purpose of this note to present some results in this direction.

2. Admissibility. Let $f:\mathbb{R}\to X$ be continuous, $f\in C(X)$ for short. First we have to state what we mean by a solution of (1).

DEFINITION 1. $u\in C(X)$ is called a *solution* of (1) if $u\in C(Y)\cap C^1(X)$, $\sup_{t\leqq 0}|u(t)|_Y<\infty$ and (1) holds on $\mathbb{R}$.

Note that (1) is translation invariant; i.e., if u is a solution of (1), then $(T_\tau u)(t)=u(t+\tau)$ is also a solution of (1) with f replaced by $T_\tau f$. This property is not shared by (2). The analogue of "wellposedness" for (1) is the concept of an admissible subspace of $C_u(X)=\{f\in C(X): f$ bounded and uniformly continuous$\}$ which we have to introduce next. Since (1) is translation invariant, we only consider translation invariant subspaces $W\subset C_u(X)$.

DEFINITION 2. Let $W\subset C_u(X)$ be a closed translation invariant subspace. W is called *admissible* for (1), if for each $f\in W_0=W\cap C_u^1(X)$ there is a unique solution $u\in W_0\cap C_u(Y)$, and $(f_n)\subset W_0$, $f_n\to 0$ in W imply $u_n\to 0$ in W.

In case W is admissible for (1), the solution operator G is defined on the dense set W_0 according to the following:

$$(Gf)(t)=u(t),\qquad t\in\mathbb{R},\quad f\in W_0 \tag{5}$$

and can be extended to all of W, since G is bounded, i.e., $G\in\mathbb{B}(W)$. Due to the translation invariance of (1) and W, G enjoys the following properties.

(i) $T_\tau G=GT_\tau$ for all $\tau\in\mathbb{R}$;

(ii) $DG=GD$, where $D=d/dt$;

(iii) $G(\varphi * f)=\varphi * Gf$ for all $f\in W$, $\varphi\in L^1$.

Property (i) shows already that for $f\in W$ periodic or almost periodic the solution $u=Gf$ is periodic or almost periodic, also. Therefore the main problem is to obtain characterizations of admissibility of subspaces W which can be checked more easily. We are not able to do this for all subspaces W but for a large class which we introduce next.

DEFINITION 3. Let $f\in C_b(X)=\{f\in C(X): f$ bounded$\}$. The *Fourier-Carleman* transform of f is defined by

$$\hat f(\lambda)=\begin{cases}\displaystyle\int_0^\infty e^{-\lambda t}f(t)\,dt, & \operatorname{Re}\lambda>0,\\[2mm] \displaystyle-\int_{-\infty}^0 e^{-\lambda t}f(t)\,dt, & \operatorname{Re}\lambda<0;\end{cases} \tag{6}$$

$\hat f(\lambda)$ is holomorphic in $\mathbb{C}\setminus i\mathbb{R}$. Let $\rho(f)$ denote the set of all $\rho\in\mathbb{R}$ such that $\hat f(\lambda)$ admits analytic continuation to some ball $B_\varepsilon(i\rho)$; then $\sigma(f)=\mathbb{R}\setminus\rho(f)$ is called the *spectrum* of f.

For $\Lambda\subset\mathbb{R}$ closed we let

$$\Lambda(X)=\{f\in C_u(X):\sigma(f)\subset\Lambda\}; \tag{7}$$

it can be shown that $\Lambda(X)$ is a closed translation invariant subspace of $C_u(X)$ (cf. Katznelson [11]). This class of subspaces is, on the one hand, large enough for our purposes and, on the other hand, amenable to analysis, in particular to transform

theory, and therefore presents an efficient means to describe the solvability behavior of (1). Two special cases should be mentioned.

(i) $f \in C_b(X)$ is τ-periodic. Then

$$\hat{f}(\lambda) = (1 - e^{\lambda\tau})^{-1} \int_0^\tau e^{-\lambda t} f(t)\, dt \quad \text{for all } \operatorname{Re}\lambda \neq 0;$$

hence,

$$\sigma(f) = \left\{ \frac{2\pi n}{\tau} : n \in \mathbb{Z}, f_n \neq 0 \right\} \quad \text{where } f_n = \tau^{-1} \int_0^\tau e^{2\pi\, \mathrm{int}/\tau} f(t)\, dt$$

denotes the nth *Fourier-coefficient* of f.

(ii) $f \in C_b(X) \cap L^1(X)$. Then $\sigma(f) = \operatorname{supp} \tilde{f}$, where $\tilde{f}$ denotes the *Fourier-transform* of f; this generalizes to any $f \in C_b(X)$ if $\tilde{f}$ is understood in the sense of distributions: $\sigma(f) = \operatorname{supp} \tilde{D}_f$ (cf. Katznelson [11]).

We are now in a position to state the conditions necessary for the admissibility of the subspaces $\Lambda(X)$. In fact, *Fourier-transformation* of (1) formally yields the relation

$$\begin{aligned} &(i\rho - A - \widehat{dB}(i\rho))\tilde{u}(\rho) = \tilde{f}(\rho), \qquad \rho \in \mathbb{R}, \quad \text{i.e.,} \\ &\tilde{u}(\rho) = (i\rho - A - \widehat{dB}(i\rho))^{-1}\tilde{f}(\rho) = H(i\rho)\tilde{f}(\rho). \end{aligned} \tag{8}$$

Let

$$\Lambda_0 = \{\rho \in \mathbb{R} : i\rho - A - \widehat{dB}(i\rho) \text{ not invertible}\} \tag{9}$$

denote the (real) *spectrum* of (1); then we have

PROPOSITION 1. *Let $\Lambda(X)$ be admissible for* (1). *Then*

(i) $\Lambda \cap \Lambda_0 = \varnothing$ *and there is* $M \geqq 1$ *such that*

$$|H(i\rho)| \leqq M \quad \textit{and} \quad |AH(i\rho)| \leqq M(1 + |\rho|) \quad \textit{for all } \rho \in \Lambda;$$

(ii) $\sigma(Gf) = \sigma(f)$ *for each* $f \in \Lambda(X)$;

(iii) $\sigma(u) \subset \Lambda_0$ *for each solution* $u \in C_u^1(X) \cap C_u(Y)$ *of the homogeneous equation* (1) (*i.e.*, $f = 0$).

It is obvious that the conditions necessary for admissibility of $\Lambda(X)$ presented in Proposition 1(i) are much easier to check than the definition of admissibility, but unfortunately they are not in general sufficient as a counterexample shows, even for differential equations (cf. Greiner, Voigt and Wolff [6] and Prüss [13]).

3. The main results. In this section we present several results on the solvability of (1) and on the converse of Proposition 1(i). In particular, we obtain characterizations of the admissibility of the subspaces $\Lambda(X)$ introduced above for several important subclasses of (1). One of the main tools for this purpose is the following lemma.

LEMMA 1. *Suppose $\varphi \in L^1$ satisfies $\tilde{\varphi} \in C_0^\infty$ and $\Lambda_0 \cap \operatorname{supp} \tilde{\varphi} = \varnothing$. Then there is a unique $G_\varphi \in C_b^\infty(\mathbb{B}(X, Y)) \cap L^1(\mathbb{B}(X, Y))$ such that*

$$G_\varphi' = AG_\varphi + dB * G_\varphi + \varphi = G_\varphi A + G * dB + \varphi \tag{10}$$

holds on $\mathbb{R}$.

Fourier-transformation of (10) shows that G_φ is given by

$$G_\varphi(t) = (2\pi)^{-1} \int_{-\infty}^{\infty} H(i\rho)\tilde{\varphi}(\rho)\, e^{i\rho t}\, d\rho$$

which exists and belongs to $C_b^\infty(\mathbb{B}(X, Y))$ since φ has compact support. The main task in the proof of Lemma 1 is to show that $G_\varphi \in L^1(\mathbb{B}(X, Y))$ holds; this in turn follows from the generalization of classical Paley-Wiener Theorem which we state as follows.

LEMMA 2. *Suppose $K \in L^1(\mathbb{B}(X))$ is such that $I - \tilde{K}(\rho)$ is invertible for each $\rho \in \mathbb{R}$. Then there is a unique $L \in L^1(\mathbb{B}(X))$ such that*

$$L = K + K * L = K + L * K \tag{11}$$

holds in $L^1(\mathbb{B}(X))$.

For a proof of this result we refer to Hagedorn [9], Prüss [13] or Gripenberg [8].

By proper choice of φ Lemma 1 implies our first main result.

THEOREM 1. *Let $\Lambda \subset \mathbb{R}$ be closed and such that $\Lambda \cap \Lambda_0 = \emptyset$. Then (1) is uniquely solvable in $\Lambda(X)$ for each f from a dense subspace of $\Lambda(X)$. If, in addition, Λ is compact then $\Lambda(X)$ is admissible for (1) and there is a kernel $G_\Lambda \in C_b^\infty(\mathbb{B}(X, Y)) \cap L^1(\mathbb{B}(X, Y))$ such that the solution operator admits the representation*

$$(Gf)(t) = \int_{-\infty}^{\infty} G_\Lambda(\tau) f(t-\tau)\, d\tau, \qquad t \in \mathbb{R}, \tag{12}$$

for each $f \in \Lambda(X)$.

Theorem 1 shows that, in the case where $\Lambda \cap \Lambda_0 = \emptyset$, without any further assumption on A or B the solution operator G for (1) on $\Lambda(X)$ is already densely defined, and to obtain the admissibility of $\Lambda(X)$ it remains to prove its boundedness. The second part of Theorem 1 shows that the solution operator for (1) behaves very well on $\Lambda(X)$ for compact Λ. But this should not be surprising since each $f \in C_u(X)$ with $\sigma(f)$ compact admits an extension to an entire function, namely by $f(z) = (2\pi i)^{-1} \int_\Gamma \hat{f}(\lambda)\, e^{\lambda z}\, d\lambda$, where Γ denotes a Jordan curve surrounding the set $i\sigma(f)$ in the complex plane.

The next result on admissibility does not restrict $\Lambda \subset \mathbb{R}$ (besides $\Lambda \cap \Lambda_0 = \emptyset$ of course), but the class of operators A and $B(t)$.

THEOREM 2. *Suppose A generates an analytic semigroup and let $B \in BV(\mathbb{R}_+, \mathbb{B}(Y, X))$ be decomposed according to $B = B_1 + B_2 + B_3$ where $B_1 \in W^{1,1}_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{B}(Y, X))$, $B_2 \in BV(\mathbb{R}_+, \mathbb{B}(Y^\alpha, X))$ for some $\alpha < 1$, and $B_3 \in BV(\mathbb{R}_+, \mathbb{B}(Y, X))$ has sufficiently small variation. Then $\Lambda(X)$ is admissible for (1) iff $\Lambda \cap \Lambda_0 = \emptyset$. Moreover, in this case there is a kernel $G_\Lambda \in L^1(\mathbb{B}(X)) \cap L^\infty(\mathbb{B}(X))$, strongly continuous for $t \neq 0$, satisfying the jump relation $G_\Lambda(0+) - G_\Lambda(0-) = I$, such that the solution operator G for (1) is represented by (12) on $\Lambda(X)$.*

Here $Y^\alpha = D((\omega_0 - A)^\alpha)$ denotes the domain of the fractional power $(\omega_0 - A)^\alpha$ where $\omega_0 \geqq 0$ is chosen large enough; thus the assumption on B_2 means that B_2 is of "lower order." Note that the conditions for B are strong enough to imply compactness of Λ_0 as well as $\lim_{|\rho| \to \infty} |H(i\rho)| = 0$, therefore the other necessary conditions of Proposition 1(i) are automatically satisfied. Theorem 2 covers the so-called *parabolic case*; applications are given in § 6. It is an open question whether this result holds in the case where B is merely of bounded variation in $\mathbb{B}(Y, X)$; examples show that Λ_0 then need not be compact.

Our third result is concerned with A generating merely a C_0-semigroup. Then as the above-mentioned examples in [6] and [13] show, X must be a Hilbert space for Proposition 1(i) to be sufficient for admissibility. Also we have to assume more regularity as well as a certain decay of the kernel B which already implies existence of the resolvent for (2) (cf. [7]). In this case Λ_0 need not be compact as before, and here it still remains open whether the solution operator G admits a representation (12).

However, if in addition compactness of Λ_0 is assumed, then we show that such a kernel G_Λ does exist.

THEOREM 3. *Let $\Lambda \subset \mathbb{R}$ be closed, X a Hilbert space, A a generator of a C_0-semigroup in X and let $B \in W^{1,1}_{\mathrm{loc}}(\mathbb{R}_+, \mathbb{B}(Y, X))$ be such that*

(i) $|B'(t)x| \leqq b(t)|x|_Y$ *for* $x \in D(A)$, $\int_0^\infty (1+t)b(t)\,dt < \infty$;

(ii) $B'(\cdot)x \in BV(\mathbb{R}_+, X)$ *and* $\int_0^\infty (1+t)|dB'(t)x| < \infty$ *for each* $x \in D(A)$.

Then $\Lambda(X)$ is admissible for (1) iff $\Lambda \cap \Lambda_0 = \varnothing$ and there is some $M \geqq 1$, such that $|H(i\rho)| \leqq M$ and $|AH(i\rho)| \leqq M(1+|\rho|)$ for all $\rho \in \Lambda$. In this case for each $x \in X$ there is $g_x \in L^1(X) \cap L^2(X)$ such that $\tilde{g}_x(\rho) = H(i\rho)x$ holds for all $\rho \in \Lambda$.

If, in addition, Λ_0 is compact then there is $G_\Lambda : \mathbb{R} \to \mathbb{B}(X)$ strongly continuous for $t \neq 0$, such that $G_\Lambda(\cdot)x \in L^1(X) \cap L^\infty(X)$, $G_\Lambda(0+)x - G_\Lambda(0-)x = x$ and $\tilde{G}_\Lambda(\rho)x = H(i\rho)x$ on Λ for each $x \in X$.

4. Almost periodic solutions. Recall that a function $f \in C_b(X)$ is called *almost periodic* (a.p.) if $T_{\mathbb{R}} f = \{f(\tau + \cdot) : \tau \in \mathbb{R}\} \subset C_b(X)$ is relatively compact; the space $AP(X)$ of all a.p. functions is a closed subspace of $C_b(X)$. a.p. functions are uniformly continuous on $\mathbb{R}$ and their *Bohr-transform*

$$a(\rho, f) = \lim_{N \to \infty} N^{-1} \int_0^N e^{-i\rho t} f(t)\,dt, \qquad \rho \in \mathbb{R}$$

is well defined. The *exponent set* of f

$$\exp(f) = \{\rho \in \mathbb{R} : a(\rho, f) \neq 0\}$$

is at most countable and we have $\sigma(f) = \overline{\exp(f)}$.

This can be proved by means of Bochner's approximation theorem, which states that, given a fixed countable exponent set $\{\rho_j\}_1^\infty$, there are convergence factors $\gamma_{nj} \in \mathbb{R}$ with $\gamma_{nj} \to 1$ as $n \to \infty$ such that the trigonometric polynomials

$$f_n(t) = \sum_1^n \gamma_{nj} a(\rho_j, f)\, e^{i\rho_j t}$$

converge to f uniformly on $\mathbb{R}$, provided $\exp(f) \subset \{\rho_j\}_1^\infty$ (cf. Amerio and Prouse [1] for the proofs).

Recall also that a function $f \in C_u(X)$ is called *asymptotically almost periodic* (a.a.p.) if there is $g \in AP(X)$ such that $|f(t) - g(t)| \to 0$ for $t \to \infty$. Such g is unique since $a(\rho, f) = a(\rho, g)$ for $\rho \in \mathbb{R}$; it is called the a.p.-part of f and will be denoted by f_a. It is not difficult to verify that the space $AAP(X)$ of all a.a.p.-functions is a closed subspace of $C_u(X)$ and decomposes according to

$$AAP(X) = AP(X) \oplus C_0^+(X),$$

where

$$C_0^+(X) = \left\{ f \in C_u(X) : \lim_{t \to \infty} f(t) = 0 \right\}.$$

Thus for any $f \in APP(X)$ we have that $f = f_a + f_0$ with unique $f_a \in AP(X)$ and $f_0 \in C_0^+(X)$. Note that

$$C_l^+(X) = \left\{ f \in C_u(X) : \lim_{t \to \infty} f(t) = f(\infty) \text{ exists} \right\}$$

is a closed subspace of $AAP(X)$.

We are now in position to state our main result on a.p. and a.a.p. solutions.

THEOREM 4. *Let $W = \Lambda(X)$ be admissible for* (1) *and let G denote the corresponding solution operator. Then*

(i) $f \in AP(X)$, $\exp(f) \subset \Lambda$ *imply* $Gf \in AP(X)$, $\exp(Gf) = \exp(f)$ *and*

$$a(\rho, Gf) = H(i\rho)a(\rho, f) \quad \text{for all } \rho \in \mathbb{R}. \tag{13}$$

(ii) $f \in AAP(X)$, $\sigma(f) \subset \Lambda$ *imply* $Gf \in AAP(X)$, $(Gf)_a = Gf_a$, $(Gf)_0 = Gf_0$, *and* (13) holds.

(iii) $f \in C_l^+(X)$, $\sigma(f) \subset \Lambda$, $0 \in \Lambda$ *imply* $Gf \in C_l^+(X)$ *and*

$$(Gf)(\infty) = H(0)f(\infty). \tag{14}$$

It should be mentioned that Theorem 4(i) contains as special cases results on periodic solutions of (1) for periodic f. For instance, if $\Lambda = \{2\pi n/\tau : n \in \mathbb{Z}\}$ and $\Lambda(X)$ is admissible, then each τ-periodic function $f \in C(X)$ satisfies $\exp(f) = \sigma(f) \subset \Lambda$; hence there is precisely one τ-periodic solution u of (1) and, moreover, we have the relation

$$u_n = H(2\pi i n/\tau) f_n, \qquad n \in \mathbb{Z}$$

for the Fourier-coefficients of f and u.

5. Nonresonant equations. The results of §§ 2–4 can be applied to the study of the asymptotic behavior of bounded solutions of (2) and of the resolvent $S(t)$ of (2), provided (1) is *nonresonant*, which means that $W = C_u(X)$ is admissible for (1). Note that in this case Theorems 2 and 3 yield G_0 such that $\tilde{G}_0(\rho) = H(i\rho)$ for all $\rho \in \mathbb{R}$ and the kernel G_0 represents the solution operator by means of (10). More generally, we define the following.

DEFINITION 4. Suppose (1) is nonresonant and let G denote Green's operator for $W = C_u(X)$. An operator-valued function $G_0 : \mathbb{R} \to \mathbb{B}(X)$ is called *solution kernel* for (1) if $G_0(t)$ satisfies

(G1) $G_0(\cdot)x$ is continuous on $\mathbb{R}\setminus\{0\}$ for each $x \in X$;

(G2) $G_0(\cdot)x \in L^1(X) \cap L^\infty(X)$ for each $x \in X$;

(G3) $\tilde{G}_0(\rho) = H(i\rho)$ for each $\rho \in \mathbb{R}$;

(G4) $G_0(0+)x - G_0(0-)x = x$ for each $x \in X$.

Note that solution kernels are unique.

Suppose that (1) is nonresonant and admits the solution kernel $G_0(t)$. Let $S(t)$ be a resolvent for (2) of exponential growth, i.e.,

$$|S(t)| \leqq M e^{\omega t} \quad \text{for all } t \geqq 0 \tag{E}$$

holds with some $M \geqq 1$ and $\omega \in \mathbb{R}$, and suppose that the (complex) *spectrum* of (2)

$$\Sigma_0 = \{\lambda \in \mathbb{C} : \operatorname{Re}\lambda \geqq 0,\ \lambda - A - \widehat{dB}(\lambda) \text{ is not invertible}\}$$

is compact and that

$$|H(\lambda)| \leqq M \quad \text{for } \operatorname{Re}\lambda \geqq 0,\ \operatorname{dist}(\lambda, \Sigma_0) \geqq 1 \tag{15}$$

holds. Since $\hat{S}(\lambda) = H(\lambda)$ the inversion theorem for the Laplace-transform yields for $x \in D(A)$ and some $\omega_1 > \omega$

$$S(t)x = (2\pi i)^{-1} \lim_{N\to\infty} \int_{\omega_1 - Ni}^{\omega_1 + Ni} e^{\lambda t} H(\lambda) x \, d\lambda \quad \text{for } t \neq 0.$$

Thus, shifting the path of integration to the imaginary axis, we obtain

$$S(t)x = (2\pi)^{-1} \lim_{N\to\infty} \int_{-N}^{N} e^{i\rho t} H(i\rho) x \, d\rho + (2\pi i)^{-1} \int_\Gamma e^{\lambda t} H(\lambda) x \, d\lambda$$

where Γ denotes some Jordan curve contained in $\{\operatorname{Re}\lambda > 0\}$ and surrounding Σ_0. The inversion theorem for the Fourier-transform therefore yields

$$S(t)x = G_0(t)x + S_0(t)x \tag{16}$$

with

$$S_0(t) = (2\pi i)^{-1} \int_\Gamma e^{\lambda t} H(\lambda)\, d\lambda, \qquad t \in \mathbb{R}. \tag{17}$$

Note that $S_0 \in C^\infty(\mathbb{R}, \mathbb{B}(X, Y))$ and

$$S_0'(t) = AS_0(t) + \int_0^\infty dB(\tau) S_0(t-\tau) \quad \text{for } t \in \mathbb{R}.$$

In the case where $\Sigma_0 = \{\lambda_1, \cdots, \lambda_n\}$ is finite and each λ_j is a pole of finite multiplicity m_j, $S_0(t)$ can be evaluated by means of the calculus of residues to the result

$$S_0(t) = \sum_{j=1}^{n} e^{\lambda_j t} \sum_{m=1}^{m_j} H_{j,m} t^{m-1}/(m-1)!, \qquad t \in \mathbb{R} \tag{18}$$

for some $H_{j,m} \in \mathbb{B}(X, Y)$, i.e., $S_0(t)$ becomes a generalized exponential polynomial.

Property (G3) and the variation of parameters formula (3) now yield the following result.

THEOREM 5. *Suppose* (1) *is nonresonant and admits a solution kernel* $G_0(t)$. *Let* $S(t)$ *be a resolvent for* (2) *with* (E) *and suppose* Σ_0 *is compact and that* (15) *holds. Then*

$$S(t) = G_0(t) + S_0(t) \quad \textit{for all } t \in \mathbb{R}\setminus\{0\} \tag{16}$$

where $S_0 \in C^\infty(\mathbb{R}, \mathbb{B}(X, Y))$ *is given by* (17). *Any solution* $u \in C_u(\mathbb{R}_+, X)$ *of* (2) *with* $g = f$ *satisfies*

$$u(t) - (Gf)(t) \to 0 \quad \textit{as } t \to \infty;$$

in particular

(i) u *is a.a.p. if* $f \in AAP(X)$, *and* $a(\rho, u) = H(i\rho)a(\rho, f)$ *for all* $\rho \in \mathbb{R}$,

(ii) $u \in C_l^+(\mathbb{R}_+, X)$ *if* $f \in C_l^+(X)$, *and* $\lim_{t\to\infty} u(t) = H(0)f(\infty)$.

Combining Theorem 1 and Theorem 4 we obtain the following generalization of results of Friedman and Shinbrot [5] and Miller and Wheeler [12] concerning integrable resolvents of (2).

COROLLARY 1. *Suppose* $\Sigma_0 = \varnothing$. *Then*

(i) *if the assumptions of Theorem* 2 *are satisfied, the resolvent* $S(t)$ *of* (2) *exists and belongs to* $L^1(\mathbb{R}_+, \mathbb{B}(X)) \cap C_0(\mathbb{R}_+, \mathbb{B}(X))$;

(ii) *if the assumptions of Theorem* 3 *are satisfied, the resolvent* $S(t)$ *of* (2) *exists and* $S(t)x$ *belongs to* $L^1(\mathbb{R}_+, X) \cap C_0(\mathbb{R}_+, X)$ *for each* $x \in X$.

In either case each solution u *of* (2) *with* $g = f \in C_u(X)$ *asymptotically behaves like the solution* Gf *of* (1), *i.e.,* $u(t) - Gf(t) \to 0$ *as* $t \to \infty$.

6. Applications. (a) Consider the heat equation in materials with memory

$$\begin{aligned} &u_t(t, x) = \Delta u(t, x) + \int_0^\infty b(\tau)\Delta u(t-\tau)\, d\tau + f(t, x), \qquad t \in \mathbb{R}, \quad x \in \Omega, \\ &u(t, x) = 0, \qquad t \in \mathbb{R}, \quad x \in \partial\Omega, \end{aligned} \tag{19}$$

where $\Omega \in \mathbb{R}^N$ denotes a bounded domain with smooth boundary $\partial\Omega$ and $b \in L^1(\mathbb{R}_+)$ (cf., e.g., Coleman and Gurtin [2]).

We let $X = L^2(\Omega)$, $A = \Delta$ with $D(A) = W^{2,2}(\Omega) \cap W_0^{1,2}(\Omega)$. A is selfadjoint and negative definite hence analytic, and $\sigma(A) = \{\mu_j\}_1^\infty \subset (-\infty, 0)$. Formula (19) then becomes

$$u' = Au + b * Au + f \tag{20}$$

and clearly the assumptions of Theorem 2 are satisfied. To determine the spectra Σ_0 and Λ_0 of (20) note that $\lambda - A - \widehat{dB}(\lambda) = \lambda - (1 + \hat{b}(\lambda))A$ with domain $D(A)$ is invertible iff $1 + \hat{b}(\lambda) \neq 0$ and $\lambda(1 + \hat{b}(\lambda))^{-1} \notin \sigma(A)$, i.e., $\lambda \neq \mu_j(1 + \hat{b}(\lambda))$ for all j. With

$$\begin{aligned} &\chi_j(\lambda) = 1 + \hat{b}(\lambda) - \lambda/\mu_j, \qquad j \in \mathbb{N}, \\ &\chi_\infty(\lambda) = 1 + \hat{b}(\lambda) \end{aligned} \tag{21}$$

we therefore have

$$\Sigma_0 = \{\lambda \in \mathbb{C}: \operatorname{Re} \lambda \geqq 0, \chi_j(\lambda) = 0 \text{ for some } j \in \mathbb{N} \cup \{\infty\}\}$$

and

$$\Lambda_0 = \{\rho \in \mathbb{R}: \chi_j(i\rho) = 0 \text{ for some } j \in \mathbb{N} \cup \{\infty\}\};$$

Λ_0 and Σ_0 are compact, $\Sigma_0 \cap \{\operatorname{Re} \lambda > 0\}$ is at most countable, Λ_0 has Lebesgue-measure zero, and $\lambda_0 \in \Sigma_0$ with $\operatorname{Re} \lambda_0 > 0$ is a cluster point of Σ_0 iff $\chi_\infty(\lambda_0) = 0$. Theorem 2 applies, hence $\Lambda(X)$ is admissible for (20) iff $\Lambda \cap \Lambda_0 = \varnothing$, in particular, (20) is nonresonant iff $\chi_j(i\rho) \neq 0$ for all $\rho \in \mathbb{R}$, $j \in \mathbb{N} \cup \{\infty\}$. In this case there is a solution kernel $G_0 \in L^1(\mathbb{B}(X))$ for (20) and the resolvent $S(t)$ admits the decomposition $S(t) = G_0(t) + S_0(t)$ by Theorem 5. If we also have $\chi_\infty(\lambda) \neq 0$ for $\operatorname{Re} \lambda \geqq 0$, then Σ_0 is finite and

$$S_0(t) = \sum_{j=1}^{n} e^{\lambda_j t} \sum_{m=1}^{m_j} H_{j,m} t^{m-1}/(m-1)!$$

where m_j denotes the multiplicity of $\lambda_j \in \Sigma_0$. Finally, by Theorem 5 we have $S \in L^1(\mathbb{B}(X))$ iff $\chi_j(\lambda) \neq 0$ for all $\operatorname{Re} \lambda \geqq 0$ and $j \in \mathbb{N} \cup \{\infty\}$. This generalizes the results of Friedman and Shinbrot [5] and Miller and Wheeler [12].

(b) The following system of equations arise as linearizations of nonlinear equations at equilibrium points in population dynamics (cf. Cushing [3]):

$$\begin{aligned} &u_{jt}(t, x) = d_j \Delta u_j(t, x) + \sum_{k=1}^{n} \int_0^\infty db_{jk}(\tau) u_k(t - \tau, x), \qquad t \in \mathbb{R}, \quad x \in \Omega, \\ &d_j \frac{\partial u_j}{\partial \nu}(t, x) = 0, \quad x \in \partial\Omega, \quad j = 1, \cdots, n. \end{aligned} \tag{22}$$

Here $\Omega \in \mathbb{R}^N$ denotes again a bounded domain with smooth boundary and $\nu(x)$ the outer normal at $x \in \partial\Omega$. The solvability behavior of (22) is important for stability and bifurcation considerations for the nonlinear system.

Let $X = [L^2(\Omega)]^n$, $A = D \cdot \Delta = (\operatorname{diag} d_j)\Delta$, $d_j \geqq 0$ for all j, with domain $D(A) = \{u \in X: d_j u_j \in W^{2,2}(\Omega), d_j \partial u_j/\partial \nu = 0 \text{ on } \partial\Omega\}$ and let $B(t)$ be defined according to

$$(B(t)u)_j(x) = \sum_{k=1}^{n} b_{jk}(t) u_k(x), \qquad u \in X,$$

where $b_{jk} \in BV(\mathbb{R}_+)$. Then A is analytic and Theorem 2 is applicable. It therefore remains to compute Σ_0 and Λ_0. For this purpose let $\mu_0 = 0 > \mu_1 \geqq \mu_2 \geqq \cdots$ denote the eigenvalues of the Laplacian with Neumann boundary condition and e_j the corresponding eigenvectors. A simple calculation then yields

$$\Sigma_0 = \{\lambda \in \mathbb{C}: \operatorname{Re} \lambda \geqq 0, \chi_m(\lambda) = 0 \text{ for some } m \in \mathbb{N}_0\}$$

and

$$\Lambda_0 = \{\rho \in \mathbb{R}: \chi_m(i\rho) = 0 \text{ for some } m \in \mathbb{N}_0\}$$

where

$$\chi_m(\lambda) = \det(\lambda - \mu_m D - \widehat{dB}(\lambda)), \qquad m \in \mathbb{N}_0.$$

Note that $\chi_m(\lambda) \neq 0$ for $m \geqq m_0$, $\operatorname{Re}\lambda \geqq 0$; hence $\Sigma_0 \setminus \Lambda_0$ is countable and discrete. Λ_0 has Lebesgue-measure zero.

(c) The following problem arises in the theory of viscoelasticity (cf., e.g., Dafermos [4] and the references given there):

$$\begin{aligned} &v_{tt}(t,x) + \gamma v_t(t,x) = \Delta v(t,x) - (b * \Delta v)(t,x) + g(t,x), \qquad t \in \mathbb{R}, \quad x \in \Omega, \\ &\frac{\partial v}{\partial \nu}(t,x) + c(x)v(t,x) = 0, \qquad x \in \partial\Omega, \quad t \in \mathbb{R}, \end{aligned} \tag{23}$$

where Ω and ν are as before, $c \in C(\partial\Omega, \mathbb{R}_+)$, $c \not\equiv 0$ and $b \in W^{1,1}(\mathbb{R}_+, \mathbb{R})$ such that $\int_0^\infty t|b(t)|\,dt + \int_0^\infty t|b'(t)|\,dt < \infty$.

Let $H_0 = L^2(\Omega)$, $H_1 = W^{1,2}(\Omega)$, $H_2 = W^{2,2}(\Omega)$ and $\mathcal{A} = \Delta$ with domain $D(\mathcal{A}) = \{v \in H_2: \partial v/\partial\nu + cv = 0 \text{ on } \partial\Omega\}$; $\mathcal{A}$ is selfadjoint and negative definite in H_0 and $\sigma(A) = \{\mu_j\}_1^\infty \subset (-\infty, 0)$. Formula (23) then becomes the abstract second order equation

$$v'' + \gamma v' = \mathcal{A}v - b * \mathcal{A}v + g, \tag{24}$$

which can be reduced to (1) as usual. Let $X = H_1 \times H_0$, $u = (v, v')$, $f = (0, g)$ and

$$A = \begin{pmatrix} 0 & I \\ \mathcal{A} & -\gamma I \end{pmatrix}, \qquad B'(t) = \begin{pmatrix} 0 & 0 \\ -b(t)\mathcal{A} & 0 \end{pmatrix}$$

where $D(A) = D(\mathcal{A}) \times H_1$. It is well known that A generates a C_0-group in X and $B(t)$ meets the assumptions of Theorem 3. To compute the spectra Σ_0 and Λ_0 we note that

$$\lambda - A - \widehat{B'}(\lambda) = \begin{pmatrix} \lambda & -I \\ (\hat{b}(\lambda) - 1)\mathcal{A} & (\lambda + \gamma)I \end{pmatrix}$$

is invertible in X iff $(\lambda + \gamma)\lambda - (1 - \hat{b}(\lambda))\mathcal{A}$ is invertible in H_0; hence we obtain

$$\Sigma_0 = \{\lambda \in \mathbb{C}: \operatorname{Re}\lambda \geqq 0 \text{ and } \chi_m(\lambda) = 0 \text{ for some } m \in \mathbb{N} \cup \{\infty\}\}$$

and

$$\begin{aligned} &\Lambda_0 = \{\rho \in \mathbb{R}: \chi_m(i\rho) = 0 \text{ for some } m \in \mathbb{N} \cup \{\infty\}\}, \\ &\chi_m(\lambda) = 1 - \hat{b}(\lambda) - \lambda(\lambda + \gamma)/\mu_m, \qquad m \in \mathbb{N} \end{aligned}$$

where

$$\chi_\infty(\lambda) = 1 - \hat{b}(\lambda).$$

The representation

$$H(\lambda) = F(\lambda)\begin{pmatrix} (\lambda + \gamma)I & I \\ (1 - \hat{b}(\lambda))\mathcal{A} & \lambda I \end{pmatrix}, \qquad F(\lambda) = (\lambda(\lambda + \gamma) - (1 - \hat{b}(\lambda))\mathcal{A})^{-1}$$

yields the estimates

$$|H(i\rho)|_X \leqq M|\rho|\,|F(i\rho)|_{H_0}, \qquad |AH(i\rho)|_X \leqq M|\rho|^2|F(i\rho)|_{H_0}$$

for $|\rho| \to \infty$, $\rho \in \Lambda_0$, since it is well known that $H_1 = D((-\mathscr{A})^{1/2})$ holds (cf. Tanabe [15, Thm. 2.23]). On the other hand, we have

$$|F(i\rho)|_{H_0} \leqq [\inf_m |-\rho^2 + i\gamma\rho - (1-\hat{b}(i\rho))\mu_m|]^{-1}$$

$$\leqq |\rho|^{-1} \cdot |1-\hat{b}(i\rho)| / |-\rho \operatorname{Im} \hat{b}(i\rho) + \gamma \cdot (1 - \operatorname{Re} \hat{b}(i\rho))|.$$

The relation

$$-\rho \operatorname{Im} \hat{b}(i\rho) = \rho \int_0^\infty b(t) \sin \rho t \, dt = b(0) + \int_0^\infty b'(t) \cos \rho t \, dt = b(0) + \operatorname{Re} \widehat{b'}(i\rho)$$

yields

$$-\rho \operatorname{Im} \hat{b}(i\rho) + \gamma(1 - \operatorname{Re} \hat{b}(i\rho)) \to b(0) + \gamma \quad \text{as } |\rho| \to \infty;$$

hence we obtain

$$|F(i\rho)|_{H_0} \leqq C|\rho|^{-1} \cdot |b(0) + \gamma|^{-1} \quad \text{for } |\rho| \geqq \rho_0.$$

Therefore the estimates required in Theorem 3 are satisfied if $b(0) + \gamma \neq 0$, in particular Λ_0 is compact, and Theorem 3 shows that $\Lambda(X)$ is admissible iff $\Lambda \cap \Lambda_0 = \varnothing$, and (24) is nonresonant iff $\Lambda_0 = \varnothing$. It is easy to see that the latter is the case if, e.g., $\gamma \geqq 0$, $b(t) \geqq 0$ nonincreasing and $\int_0^\infty b(t)\, dt \neq 1$ holds. A calculation similar to the one above shows also that Σ_0 is compact and (13) holds, in the case $\gamma + b(0) > 0$, hence Theorem 5 yields the decomposition

$$S(t) = G_0(t) + S_0(t)$$

for the resolvent $S(t)$, where $S_0 \in C_b^\infty(\mathbb{R}, \mathbb{B}(X, Y)) \cap L^1(\mathbb{R}_-, \mathbb{B}(X, Y))$ and $G_0(\cdot)x$ is in $L^1(X)$ for each $x \in X$. Finally, for $\gamma \geqq 0$, $b(t) > 0$ nonincreasing, $b(0) > 0$ and $\int_0^\infty b(t)\, dt < 1$ we even obtain $\Sigma_0 = \varnothing$, hence $S(\cdot)x \in L^1(\mathbb{R}_+, X)$ for all $x \in X$; this result has been proved by Dafermos [4], assuming additionally that b is convex.

7. Proofs.

(a) *Proof of Lemma* 1.

Since $\tilde{\varphi}$ has compact support and $\Lambda_0 \cap \operatorname{supp} \tilde{\varphi} = \varnothing$, $H(i\rho)$ is bounded in $\mathbb{B}(X, Y)$ on $\operatorname{supp} \tilde{\varphi}$, and therefore G_φ defined by

$$G_\varphi(t) = (2\pi)^{-1} \int_{-\infty}^{\infty} H(i\rho)\tilde{\varphi}(\rho)\, e^{i\rho t}\, d\rho \tag{25}$$

belongs to $C_b^\infty(\mathbb{B}(X, Y))$.

(i) To obtain $G_\varphi \in L^1(\mathbb{B}(X, Y))$ suppose first that $\int_0^\infty (1+t^2)\, db(t) < \infty$ where $b(t) = \operatorname{Var} B|_0^t$ denotes the variation of B in $\mathbb{B}(Y, X)$. Then $\widehat{dB}(i\rho)$ is twice continuously differentiable, and so is $\Phi(\rho) = H(i\rho)\tilde{\varphi}(\rho)$ and $\Phi''(\rho)$ is bounded on $\mathbb{R}$. Partial integration in (25) now yields

$$G_\varphi(t) = -(2\pi)^{-1} t^{-2} \int_{-\infty}^{\infty} \Phi''(\rho)\, e^{i\rho t}\, ds \quad \text{for } t \neq 0$$

and so we obtain an estimate $|G(t)|_{X,Y} \leqq C(1+t^2)^{-1}$ for $t \in \mathbb{R}$, i.e., $G_\varphi \in L^1(\mathbb{B}(X, Y))$ holds.

(ii) For the general case we let $B_m(t) = B(t)$ for $t \leqq m$ and $B_m(t) = B(m)$ for $t \geqq m$; then $\widehat{dB}_m(i\rho)$ has moments of any order and $\widehat{dB}_m(\lambda) \to \widehat{dB}(\lambda)$ for $m \to \infty$ in $\mathbb{B}(Y, X))$ uniformly on $\operatorname{Re} \lambda \geqq 0$. Therefore the relation

$$i\rho - A - \widehat{dB}_m = (i\rho - A - \widehat{dB})[I - H(i\rho)(\widehat{dB}_m - \widehat{dB})] \tag{26}$$

shows that $H_m(i\rho) = (i\rho - A - \widehat{dB}_m)^{-1}$ exists on a fixed neighborhood N of supp $\tilde{\varphi}$, in the case where m is chosen large enough; note that $H(i\rho)$ is bounded in $\mathbb{B}(X, Y)$ on N. Equation (26) yields

$$H(i\rho) = H_m(i\rho) + H(i\rho)[\widehat{dB}(i\rho) - \widehat{dB}_m(i\rho)]H_m(i\rho);$$

hence

$$H(i\rho)\tilde{\varphi}(\rho) = H_m(i\rho)\tilde{\varphi}(\rho) + H(i\rho)\tilde{\varphi}(\rho)[\widehat{dB}(i\rho) - \widehat{dB}_m(i\rho)]H_m(i\rho)\tilde{\varphi}_1(\rho), \tag{27}$$

where $\tilde{\varphi}_1 \in C_0^\infty$ is such that $\tilde{\varphi}_1(\rho) \equiv 1$ on supp $\tilde{\varphi}$, $0 \leqq \tilde{\varphi} \leqq 1$, and supp $\tilde{\varphi}_1 \subset N$. By step (i) of this proof, there are G_m, $K_m \in C_b^\infty(\mathbb{B}(X, Y)) \cap L^1(\mathbb{B}(X, Y))$ such that $\tilde{G}_m(\rho) = H_m(i\rho)\tilde{\varphi}(\rho)$ and $\tilde{K}_m(\rho) = H_m(i\rho)\tilde{\varphi}_1(\rho)$ (choose N such that $N \cap \Lambda_0 = \varnothing$); let $K = (\widehat{dB} - \widehat{dB}_m) * K_m$ and observe that $K \in L^1(\mathbb{B}(X))$ holds. Now we have

$$\begin{aligned} I - \tilde{K} &= I - (\widehat{dB} - \widehat{dB}_m)\tilde{K}_m = I - (\widehat{dB} - \widehat{dB}_m)H_m\tilde{\varphi}_1 \\ &= (i\rho - A - \widehat{dB}\tilde{\varphi}_1 - \widehat{dB}_m(1 - \tilde{\varphi}_1))H_m \\ &= [I - (1 - \tilde{\varphi}_1)(\widehat{dB}_m - \widehat{dB})H](i\rho - A - \widehat{dB})H_m, \end{aligned}$$

i.e., $I - K(\rho)$ is invertible on $\mathbb{R}$, and Lemma 2 yields a solution $L \in L^1(\mathbb{B}(X))$ of (11). Therefore the equation $G_\varphi = G_m + G_\varphi * K$ whose Fourier-transform is (27) has the solution $G_\varphi = G_m + G_m * L$ which belongs to $L^1(\mathbb{B}(X, Y))$. Uniqueness of the Fourier-transform now gives the assertion of Lemma 1. □

(b) *Proof of Proposition* 1.

(i) Since for any $y \in X$, $\rho \in \mathbb{R}$, the function $f(t) = y\, e^{i\rho t}$ belongs to $C_u(X)$ and satisfies $\sigma(f) = \{\rho\}$, we have $f \in W_0 = \Lambda(X) \cap C_u^1(X)$ in the case where $\rho \in \Lambda$. Now, if $\Lambda(X)$ is admissible for (1), there is a solution $u = Gf$ of (1) and we obtain

$$u' = (Gf)' = Gf' = i\rho Gf = i\rho u;$$

hence $u(t) = x\, e^{i\rho t}$ for some $x \in D(A)$, and (1) implies $(i\rho - A - \widehat{dB}(i\rho))x = y$, i.e., $i\rho - A - \widehat{dB}(i\rho)$ is surjective. On the other hand, we have for some $M > 0$

$$|x| = |u|_0 = |Gf|_0 \leqq M|f|_0 = M|(i\rho - A - \widehat{dB}(i\rho))x|;$$

i.e., $i\rho - A - \widehat{dB}(i\rho)$ is bounded from below uniformly on Λ, and this yields $|H(i\rho)| \leqq M$ in $\mathbb{B}(X)$ on Λ, in particular $\Lambda \cap \Lambda_0 = \varnothing$. Since G is also bounded as a map from $\Lambda(X) \cap C_u^1(X)$ to $C_u(Y)$ by the closed graph theorem, we finally obtain

$$|AH(i\rho)y| = |Ax| \leqq |Gf|_{Y,0} \leqq M_1(|f'|_0 + |f|_0) \leqq M_1(1 + |\rho|)|y|;$$

i.e., the second estimate of Proposition 1(i) holds.

(ii) For the proof of (ii) and (iii) of Proposition 1 we shall need some properties of the spectrum of bounded functions which are collected in the following.

PROPOSITION 2. *Let $f, g \in C_b(X)$ and $K \in BV(\mathbb{B}(X, Z))$. Then*

(i) *$\sigma(f)$ is closed and $\neq \varnothing$ in case $f \neq 0$;*

(ii) *$\sigma(f + g) \subset \sigma(f) \cup \sigma(g)$;*

(iii) *$\sigma(f') \subset \sigma(f)$ for each $f \in C_b^1(X)$;*

(iv) *$\sigma(dK * f) \subset \sigma(f)$;*

(v) *$\Lambda \subset \mathbb{R}$ closed, $(f_n) \subset C_b(X)$ uniformly bounded, $\sigma(f_n) \subset \Lambda$ for each n, and $f_n \to f$ uniformly on compact sets imply $\sigma(f) \subset \Lambda$; i.e., $\sigma(\cdot)$ is lower semicontinuous;*

(vi) *$\sigma(f) = \operatorname{supp} \widehat{D_f}$, where $\widehat{D_f}$ denotes the Fourier-transform of the distribution D_f induced by f;*

(vii) *$\sigma_X(f) = \sigma_Y(f)$ for each $f \in C_b(Y)$, where $Y \to X$;*

(viii) *$\varphi * f = f$ for each $\varphi \in L^1$ such that $\tilde{\varphi} \equiv 1$ on $\sigma(f)$.*

Proofs for these properties can be found in Katznelson [11] in the case of scalar functions or Prüss [13] for the general case.

Now, let $\tilde{\varphi} \in C_0^\infty$ be such that $\operatorname{supp} \tilde{\varphi} \cap \sigma(f) = \emptyset$. Since $\sigma(\varphi * f) \subset \sigma(\varphi) \cap \sigma(f) = \operatorname{supp} \tilde{\varphi} \cap \sigma(f) = \emptyset$ we have $\varphi * f = 0$ and therefore

$$\langle \widetilde{D_{Gf}}, \tilde{\varphi} \rangle = \langle Gf, \tilde{\tilde{\varphi}} \rangle = (\varphi * Gf)(0) = G(\varphi * f)(0) = 0.$$

Hence we obtain $\sigma(Gf) = \operatorname{supp} \widetilde{D_{Gf}} \subset \sigma(f)$ by definition of the support of a distribution.

Conversely, suppose $f \in \Lambda(X) \cap C_u^1(X)$. Then by (1) we get

$$\sigma(f) = \sigma(u' - Au - dB * u) \subset \sigma_Y(u) = \sigma(u)$$

where $u = Gf$. For the general case let φ_n denote a Dirac-sequence, i.e., $\varphi_n \in C_0^\infty$, $\operatorname{supp} \varphi_n \subset (-n^{-1}, n^{-1})$, $\varphi_n \geqq 0$ and $\int_{-\infty}^{\infty} \varphi_n(t)\, dt = 1$ for each $n \in \mathbb{N}$. Then $f_n = \varphi_n * f$ is uniformly bounded, converges to f as $n \to \infty$ in $C_u(X)$ and $f_n \in \Lambda(X) \cap C_u^1(X)$ for each n. We therefore have

$$\sigma(f_n) \subset \sigma(Gf_n) = \sigma(G(\varphi_n * f)) = \sigma(\varphi_n * Gf) \subset \sigma(Gf);$$

hence $\sigma(f) \subset \sigma(Gf)$ by (v) and (i) of Proposition 2.

(iii) Suppose $u \in C_u(Y) \cap C_u^1(X)$ is a solution of equation (1) with $f = 0$ on $\mathbb{R}$, and let $\tilde{\varphi} \in C_0^\infty$ be such that $\Lambda_0 \cap \operatorname{supp} \tilde{\varphi} = \emptyset$. By Lemma 1, there is a solution $G_\varphi \in C_u^\infty(\mathbb{B}(X, Y)) \cap L^1(\mathbb{B}(X, Y))$ of (10). This implies

$$G_\varphi * Au + G_\varphi * dB * u = G_\varphi * u' = G'_\varphi * u = G_\varphi * Au + G_\varphi * dB * u + \varphi * u,$$

i.e., $\varphi * u \equiv 0$; hence

$$\langle \widetilde{D_u}, \tilde{\varphi} \rangle = \langle u, \tilde{\tilde{\varphi}} \rangle = (\varphi * u)(0) = 0,$$

which means $\sigma(u) = \operatorname{supp} \widetilde{D_u} \subset \Lambda_0$. □

(c) *Proof of Theorem* 1.

(i) Suppose $u_1, u_2 \in \Lambda(X) \cap C_u^1(X)$ are two solutions of (1) for the same $f \in \Lambda(X)$. Then $u = u_1 - u_2 \in \Lambda(X) \cap C_u^1(X)$ is a solution of the homogeneous equation (1). Hence by Proposition 1(iii) we have $\sigma(u) \subset \Lambda_0 \cap \Lambda = \emptyset$, i.e., $u = 0$ by Proposition 2(i). This shows that solutions are unique.

(ii) To obtain the existence of a solution for f from a dense subset of $\Lambda(X)$, let $\tilde{\varphi} \in C_0^\infty$ be such that $0 \leqq \tilde{\varphi} \leqq 1$, $\tilde{\varphi}(\rho) = 1$ for $|\rho| \leqq 1$, $\tilde{\varphi}(\rho) = 0$ for $|\rho| \geqq 2$ and consider $\varphi_n(t) = n\varphi(nt)$. Then $\{\varphi_n\}$ is an approximation of the identity, i.e., $\varphi_n * f \to f$ as $n \to \infty$ in $C_u(X)$. Hence it is sufficient to solve (1) for $\varphi_n * f$, $f \in \Lambda(X)$, $n \in \mathbb{N}$. But since $\sigma(\varphi_n * f) \subset \sigma(f) \cap \sigma(\varphi_n) \subset \Lambda \cap \{\rho \in \mathbb{R}: |\rho| \leqq 2n\}$ holds we only need to solve (1) for $f \in \Lambda(X)$ with $\sigma(f)$ compact; i.e., we may assume that $\Lambda \in \mathbb{R}$ is compact.

(iii) Suppose $\Lambda \subset \mathbb{R}$ is compact. Then we choose a cutoff function $\tilde{\varphi}_0 \in C_0^\infty$ such that $\tilde{\varphi}_0 \equiv 1$ for $\operatorname{dist}(\rho, \Lambda) \leqq \varepsilon$, $\tilde{\varphi}_0 \equiv 0$ for $\operatorname{dist}(\rho, \Lambda) \geqq 2\varepsilon$, $0 \leqq \tilde{\varphi}_0 \leqq 1$, where $\operatorname{dist}(\Lambda, \Lambda_0) \geqq 3\varepsilon$, and let $G_\Lambda \in C_b^\infty(\mathbb{B}(X, Y)) \cap L^1(\mathbb{B}(X, Y))$ denote the solution of (10) from Lemma 1. Then $u = G_\Lambda * f$ is a solution of (1) with inhomogeneity $\varphi_0 * f$ for each $f \in C_u(X)$ and we have $|u|_0 \leqq |G_\Lambda|_{L^1} |f|_0$. But for $f \in \Lambda(X)$ we obtain $\varphi_0 * f = f$ by Proposition 2(viii) and so u is already a solution of (1). This shows that $\Lambda(X)$ is admissible and G is represented by (12). □

(d) *Proof of Theorem* 4.

(i) Suppose $\Lambda(X)$ is admissible. Then if $\rho \in \Lambda$, as in (b) we obtain $G(a\, e^{i\rho t}) = H(i\rho) a\, e^{i\rho t}$ for each $a \in X$. Hence if $f(t) = \sum_{n=1}^N a_n\, e^{i\rho_n t}$ is a trigonometric polynomial with $\exp(f) = \{\rho_n\}_1^N \subset \Lambda$ we obtain $(Gf)(t) = \sum_{n=1}^N H(i\rho_n)\, a_n\, e^{i\rho_n t}$, i.e., (i) of Theorem 4 holds for trigonometric polynomials. The general case then follows by Bochner's approximation theorem mentioned above since G is bounded and the Bohr-transform is continuous.

(ii) If $f=f_a+f_0\in AAP(X)\cap\Lambda(X)$, then $T_nf\to f_a$ as $n\to\infty$ uniformly on compact subsets; hence by Proposition 2(v) and from $\sigma(T_nf)=\sigma(f)\subset\Lambda$ we obtain $\sigma(f_a)\subset\Lambda$ and so $\sigma(f_0)=\sigma(f-f_a)\subset\sigma(f)\cup\sigma(f_a)\subset\Lambda$, also. Since $\Lambda(X)$ is admissible we therefore obtain $Gf=Gf_a+Gf_0$ and $Gf_a\in AP(X)$ by step (i) of this proof; hence it remains to show that $Gf_0\in C_0^+(X)$ holds. As in (c), step (ii) it suffices to consider $f_0\in C_0^+(X)\cap\Lambda(X)$ with $\sigma(f_0)$ compact, i.e., w.l.o.g. Λ compact. But in this case Lemma 1 yields a kernel $G_\Lambda\in C_b^\infty(\mathbb{B}(X,Y))\cap L^1(\mathbb{B}(X,Y))$ such that $Gf=G_\Lambda*f$ for all $f\in\Lambda(X)$, and since $G_\Lambda\in L^1(\mathbb{B}(X,Y))$ we obtain $Gf\in C_0^+(X)$ for each $f\in C_0^+(X)\cap\Lambda(X)$.

(iii) This is a consequence of (ii) with $f_a(t)\equiv f(\infty)$. □

(e) *Proof of Theorem* 2.

(i) Since A is analytic, $(i\rho-A)^{-1}$ exists say for $|\rho|\geqq N_0$ and satisfies $|(i\rho-A)^{-1}|\leqq M/|\rho|$ for $|\rho|\geqq N_0$. The relation

$$i\rho-A-\widehat{dB}(i\rho)=(I-\widehat{dB}(i\rho)(i\rho-A)^{-1})(i\rho-A),\qquad |\rho|\geqq N_0,$$

then shows that $\Lambda_0\subset(-N,N)$ holds for some $N>0$. In fact, we have $B_1'\in L^1(\mathbb{B}(Y,X))$; hence $B_1'(i\rho)\to 0$ as $|\rho|\to\infty$, by the Riemann-Lebesgue Lemma, and so

$$|\widehat{B_1'}(i\rho)(i\rho-A)^{-1}|_{X,X}\leqq|\widehat{B_1'}(i\rho)|_{Y,X}\cdot|(i\rho-A)^{-1}|_{X,Y}\to 0\quad\text{as } |\rho|\to\infty.$$

Similarly,

$$|\widehat{dB_2}(i\rho)(i\rho-A)^{-1}|_{X,X}\leqq|\widehat{dB_2}(i\rho)|_{Y^\alpha,X}\cdot|(i\rho-A)^{-1}|_{X,Y^\alpha}\leqq C|\rho|^{\alpha-1}\quad\text{as } |\rho|\to\infty,$$

and finally

$$|\widehat{dB_3}(i\rho)(i\rho-A)^{-1}|_{X,X}\leqq|\widehat{dB_3}(i\rho)|_{Y,X}\cdot|(i\rho-A)^{-1}|_{X,Y}\leqq 1/4\quad\text{for } |\rho|\geqq N$$

since B_3 has sufficiently small variation by assumption. Thus w.l.o.g. we let $\Lambda\supset\{\rho\in\mathbb{R}\colon|\rho|\geqq N\}$.

Let $\tilde\varphi_0\in C^\infty$ be a cutoff function for Λ, i.e., $\tilde\varphi_0(\rho)=1$ for dist $(\rho,\Lambda)\leqq\varepsilon$, $\tilde\varphi_0(\rho)=0$ for dist $(\rho,\Lambda)\geqq 2\varepsilon$, $0\leqq\tilde\varphi_0\leqq 1$, where $3\varepsilon\leqq$ dist (Λ,Λ_0). Let $\tilde\varphi_1\in C^\infty$ denote another cutoff function such that $\tilde\varphi_1(\rho)=1$ for $|\rho|\geqq N+1$ and $\tilde\varphi_1(\rho)=0$ for $|\rho|\leqq N$, $0\leqq\tilde\varphi_1\leqq 1$. Then

$$G_1(t)=(2\pi)^{-1}\int_{-\infty}^{\infty}(1-\tilde\varphi_1(\rho))\tilde\varphi_0(\rho)H(i\rho)\,e^{i\rho t}\,d\rho$$

belongs to $C_b^\infty(\mathbb{B}(X,Y))\cap L^1(\mathbb{B}(X,Y))$ by Lemma 1 and so it remains to study

$$G_2(t)=(2\pi)^{-1}\int_{-\infty}^{\infty}\tilde\varphi_1(\rho)H(i\rho)\,e^{i\rho t}\,d\rho;$$

note that $\tilde\varphi_0(\rho)=1$ on supp $\tilde\varphi_1$.

(ii) Let $k_N(t)=2(\pi Nt^2)^{-1}\sin^2(Nt/2)$ denote Fejer's kernel, and let $B_N(t)=B_1(t)-k_N*B_1(t)+B_2(t)+B_3(t)$; note that $\widetilde{(k_N*B_1')}(\rho)=\widehat{k_N}(\rho)\cdot\widehat{B_1'}(i\rho)=0$ for $|\rho|\geqq N$, since $\widehat{k_N}(\rho)=(1-|\rho|/N)_+$ holds, i.e., $\widehat{dB_N}(\rho)=\widehat{dB}(i\rho)$ for $|\rho|\geqq N$. Next we choose $\omega>\omega_0$ sufficiently large and the equivalent norm $\|x\|_Y=|(\omega-A)x|$ on Y. Then the variation of B_N over $\mathbb{R}$ can be made arbitrarily small, since

$$B_1'-k_N*B_1'\to 0\quad\text{in } L^1(\mathbb{B}(Y,X))\quad\text{for } N\to\infty$$

and

$$\operatorname{Var}_{Y,X}B_2|_0^\infty=\operatorname{Var}_{Y^\alpha,X}B_2|_0^\infty\cdot|J|_{Y,Y^\alpha}\leqq\operatorname{Var}_{Y^\alpha,X}B_2|_0^\infty\cdot C\omega^{\alpha-1}\to 0$$

for $\omega\to\infty$, where $J\colon Y\to Y^\alpha$ denotes the natural embedding, and the variation of B_3 is arbitrarily small by assumption. The proof of Theorem 1 in [14] now shows that there is $G_{\omega,N}\in L^1(\mathbb{B}(X))\cap L^\infty(\mathbb{B}(X))$, strongly continuous for $t\neq 0$, satisfying the jump

relation $G_{\omega,N}(0+)-G_{\omega,N}(0-)=I$, such that $G_{\omega,N}(\rho)=(i\rho+\omega-A-\widehat{dB_N}(\rho))^{-1}$ holds. Note that Theorem 1 of [14] does not apply directly since the support of B_N is generally not contained in $\mathbb{R}_+$, however, the method of proof still works for this more general case. Thus the solution $H_{\omega,N}(\rho)=(i\rho+\omega-A-\widehat{dB_N}(\rho))^{-1}$ of the equation

$$H_{\omega,N}(\rho)=(i\rho+\omega-A)^{-1}+H_{\omega,N}(\rho)\widehat{dB_N}(\rho)(i\rho+\omega-A)^{-1} \tag{28}$$

is the Fourier-transform of $G_{\omega,N}\in L^1(\mathbb{B}(X))\cap L^\infty(\mathbb{B}(X))$.

(iii) Since $1-\tilde{\varphi}_1=\tilde{\Psi}_1$ is the Fourier-transform of some function $\Psi_1\in L^1$ we now also have that

$$\tilde{\varphi}_1 H_\omega=\tilde{\varphi}_1 H_{\omega,N}=H_{\omega,N}-(1-\tilde{\varphi}_1)H_{\omega,N}=\tilde{G}_{\omega,N}-\tilde{\Psi}_1\tilde{G}_{\omega,N}$$

is the Fourier-transform of $G_\omega=G_{\omega,N}-\Psi_1 * G_{\omega,N}$ and G_ω enjoys the same properties as $G_{\omega,N}$; note that $H_\omega(i\rho)=(i\rho+\omega-A-\widehat{dB}(i\rho))^{-1}$ coincides with $H_{\omega,N}(\rho)$ for $|\rho|\geqq N$ since $(k_N * B_1)\tilde{}\,(\rho)=0$ there. Finally to get from $H_\omega(i\rho)$ to $H(i\rho)$ we consider the equation

$$H(i\rho)=H_\omega(i\rho)+\omega H(i\rho)H_\omega(i\rho).$$

Choosing another cutoff function $\tilde{\varphi}_2\in C^\infty$ with $\tilde{\varphi}_2\equiv 1$ on supp $\tilde{\varphi}_1$, we then have

$$\tilde{\varphi}_1 H=\tilde{\varphi}_1 H_\omega+\omega\tilde{\varphi}_1 H\cdot\tilde{\varphi}_2 H_\omega,$$

where $\tilde{\varphi}_1 H_\omega$ and $\tilde{\varphi}_2 H_\omega$ are Fourier-transforms of functions from $L^1(\mathbb{B}(X))\cap L^\infty(\mathbb{B}(X))$, hence, by Lemma 2, $\tilde{\varphi}_1 H$ is the Fourier-transform of $G_2\in L^1(\mathbb{B}(X))\cap L^\infty(\mathbb{B}(X))$ with the desired properties, since

$$\begin{aligned} I-\omega\tilde{\varphi}_2 H_\omega&=(i\rho+\omega-A-\widehat{dB}-\omega\varphi_2)H_\omega\\ &=[I-\widehat{dB}(i\rho+\omega(1-\tilde{\varphi}_2)-A)^{-1}](i\rho+\omega(1-\tilde{\varphi}_2)-A)H_\omega \end{aligned}$$

is invertible for each $\rho\in\mathbb{R}$.

(iv) Up to this point we have obtained the kernel G_Λ with the desired properties and G_Λ represents the solution operator G by (12); $G_\Lambda\in L^1(\mathbb{B}(X))$ also implies $G\in\mathbb{B}(\Lambda(X))$. To derive the admissibility of $\Lambda(X)$ for (1), by Theorem 1, it thus remains to show that G is also bounded from $\Lambda(X)\cap C_u^1(X)$ to $C_u(Y)$, and for this in turn it suffices to prove that $\tilde{\varphi}_1(\rho)H(i\rho)/i\rho$ is the Fourier-transform of some $V\in L^1(\mathbb{B}(X, Y))$. Since $\tilde{\varphi}_1(\rho)/i\rho$ and $\tilde{\varphi}_1(\rho)H_\omega(i\rho)$ are Fourier-transforms of $L^1(\mathbb{B}(X))$-functions and

$$I-(\omega-A)^{-1}\tilde{\varphi}_2(\rho)\,\widehat{dB}(i\rho)=(\omega-A)^{-1}(\omega-A-\tilde{\varphi}_2(\rho)\,\widehat{dB}(i\rho))$$

is invertible for each $\rho\in\mathbb{R}$, Lemma 2 and the relation

$$\begin{aligned} \tilde{\varphi}_1 H_\omega(i\rho)/i\rho=(\omega-A)^{-1}\tilde{\varphi}_1(\rho)/i\rho-(\omega-A)^{-1}\tilde{\varphi}_1(\rho)H_\omega(i\rho)\\ +(\omega-A)^{-1}\tilde{\varphi}_2(\rho)\,\widehat{dB}(i\rho)\cdot\tilde{\varphi}_1(\rho)H_\omega(i\rho)/i\rho \end{aligned}$$

show that $\tilde{\varphi}_1 H_\omega/i\rho=\tilde{V}_\omega$ for some $V_\omega\in L^1(\mathbb{B}(X, Y))$. Finally, another application of Lemma 2 to

$$\tilde{\varphi}_1 H/i\rho=\tilde{V}_\omega+(\tilde{\varphi}_1 H/i\rho)\cdot\tilde{\varphi}_2\omega H_\omega$$

yields $V\in L^1(\mathbb{B}(X, Y))$ with $\tilde{V}(\rho)=\tilde{\varphi}_1(\rho)H(i\rho)/i\rho$.

The proof is now complete. □

(f) *Proof of Theorem* 3.

(i) The "only if" part is contained in Proposition 1(i). For the "if" part we note first that again dist $(\Lambda, \Lambda_0)\geqq 3\varepsilon>0$ for some $\varepsilon>0$ holds. In fact, the relation $\widehat{B'}(\lambda)=\lambda^{-1}\widehat{(dB')}(\lambda)$ together with the assumptions of Theorem 3 implies

$$|\widehat{B'}(i\rho)y|\leqq C|y|_Y/(1+|\rho|)\quad\text{for all } y\in D(A),\quad \rho\in\mathbb{R}, \tag{29}$$

and therefore

$$i\rho - A - \widehat{B'}(i\rho) = [I + i(\rho - \tau)H(i\tau) + (\widehat{B'}(i\tau) - \widehat{B'}(i\rho))H(i\tau)](i\tau - A - \widehat{B'}(i\tau))$$

shows the invertibility of $i\rho - A - B'(i\rho)$ on dist $(\rho, \Lambda) \leqq 3\varepsilon$. So we may choose a cutoff function $\tilde{\varphi} \in C^\infty$ such that $\tilde{\varphi}(\rho) = 1$ on dist$(\rho_1 \Lambda) \leqq \varepsilon$; w.l.o.g. we may also suppose that $\tilde{\varphi}(\rho) = 0$ for $\rho \in [-\varepsilon_0, \varepsilon_0]$ holds for some $\varepsilon_0 > 0$, otherwise choose another cutoff function $\tilde{\varphi}_1 \in C_0^\infty$ such that $\tilde{\varphi}_1 = 1$ on $[-\varepsilon_0, \varepsilon_0]$, $0 \leqq \tilde{\varphi}_1 \leqq 1$, and consider $(1 - \tilde{\varphi}_1)\tilde{\varphi}$ instead of $\tilde{\varphi}$. The part corresponding to $\tilde{\varphi}_1$

$$G_1(t) = (2\pi)^{-1} \int_{-\infty}^{\infty} \tilde{\varphi}_1(\rho)\tilde{\varphi}(\rho)H(i\rho)\, e^{i\rho t}\, d\rho$$

belongs to $C_b^\infty(\mathbb{B}(X, Y)) \cap L^1(\mathbb{B}(X, Y))$ by Lemma 1.

(ii) Let $\omega \in \mathbb{R}$ be large enough such that $|T(t)| \leqq M e^{(\omega - 1)t}$ for $t > 0$ and some $M > 1$, where $T(t)$ denotes the semigroup generated by A. Then $f_1(t) = h_0(t)\, e^{-\omega t} T(t)x$ as well as $f_2(t) = h_0(t)\, e^{-\omega t} T(t)^* x$ belong to $L^2(X)$, where $h_0(t)$ means Heaviside's function and the star indicates the adjoint. Since X is Hilbert, their Fourier-transforms $\tilde{f}_1(\rho) = (i\rho + \omega - A)^{-1}x$ and $\tilde{f}_2(\rho) = (i\rho + \omega - A)^{-1*}x$ belong to $L^2(X)$. By (29), $K(\rho) = \widehat{B'}(i\rho)H(i\rho)$ is $\mathbb{B}(X)$-continuous and uniformly bounded for dist $(\rho, \Lambda) \leqq 2\varepsilon$, and so the representation

$$H(i\rho)^* x = (I + \omega H(i\rho)^* + K(\rho)^*)(i\rho + \omega - A)^{-1*} x$$

yields $\tilde{\varphi} H^* x \in L^2(X)$, also. Hence there is $g_x^* \in L^2(X)$ such $\widetilde{g_x^*} = \tilde{\varphi} H^* x$. Similarly, the relation

$$A(i\rho + \omega - A)^{-1} x = (i\rho + \omega)(i\rho + \omega - A)^{-1} x - x$$

shows that $\tilde{\varphi}(\rho) A(i\rho + \omega - A)^{-1} x / i\rho$ as well as $\tilde{\varphi}(\rho) A^*(i\rho + \omega - A)^{-1*} x / i\rho$ also belong to $L^2(X)$, and so by means of

$$Hx = (I + \omega H)(i\rho + \omega - A)^{-1} x + H[i\rho \widehat{B'}(\omega - A)^{-1}](\omega - A)(i\rho + \omega - A)^{-1} x / i\rho$$

and

$$(AH)^* x = (I + \omega H^* + K^*) A^*(i\rho + \omega - A)^{-1*} x$$

we see by (29) that $\tilde{\varphi} Hx$ and $\tilde{\varphi}(AH)^* x / i\rho$ belong to $L^2(X)$ and so there are g_x, $f_x^* \in L^2(X)$ such that $\tilde{g}_x = \tilde{\varphi} Hx$ and $\widetilde{f_x^*} = \tilde{\varphi}(AH)^* x / i\rho$ hold in $L^2(X)$. Note that g_x, g_x^*, f_x^* are uniquely determined by $x \in X$ in $L^2(X)$, i.e., almost everywhere.

(iii) Next we show that g_x, g_x^*, f_x^* also belong to $L^1(X)$. Since B' has first moment by assumption, $H(i\rho)$ is differentiable for dist $(\rho, \Lambda) \leqq 2\varepsilon$ and with $\partial = \partial / \partial\rho$ we obtain

$$\partial H = H(i - \partial \widehat{B'})H = H(iH - K_1);$$

hence

$$\partial(\tilde{\varphi} H^* x) = \partial\tilde{\varphi} H^* x + \tilde{\varphi}\, \partial H^* x = \partial\tilde{\varphi} H^* x - (iH^* + K_1^*)\tilde{\varphi} H^* x$$

belongs to $L^2(X)$ since $K_1 = (\partial \widehat{B'})H = -i(B')\hat{}\, H$ is continuous and bounded for dist $(\rho, \Lambda) \leqq 2\varepsilon$. But this shows $t g_x^* \in L^2(X)$ and therefore

$$\int_{-\infty}^{\infty} |g_x^*(t)|\, dt = \int_{|t| \leqq 1} |g_x^*(t)|\, dt + \int_{|t| \geqq 1} t^{-1} |t g_x^*(t)|\, dt$$
$$\leqq |g_x^*|_{L^2} + \sqrt{2}\, |t g_x^*|_{L^2} < \infty,$$

i.e., $g_x^* \in L^1(X)$. Similarly, one also obtains g_x, $f_x^* \in L^1(X)$.

(iv) The mappings $x \to g_x$, $x \to g_x^*$, $x \to f_x^*$ from X to $L^1(X)$ are closed, linear and defined on all X; hence by the closed graph theorem, there is some $C > 0$ such that

$$|g_x|_{L_1} + |g_x^*|_{L^1} + |f_x^*|_{L^1} \leqq C|x| \quad \text{for all } x \in X.$$

To prove the boundedness of the solution operator G from $\Lambda(X)$ to $C_u(X)$ as well as from $\Lambda(X) \cap C_u^1(X)$ to $C_u(Y)$, it therefore suffices to show that the relations

$$\begin{aligned} (x, u(t)) &= \int_{-\infty}^{\infty} (g_x^*(t-\tau), f(\tau))\, d\tau, \qquad t \in \mathbb{R}, \quad x \in X, \\ (x, Au(t)) &= \int_{-\infty}^{\infty} (f_x^*(t-\tau), f'(\tau))\, d\tau, \qquad t \in \mathbb{R}, \quad x \in X \end{aligned} \tag{30}$$

hold for solutions $u \in \Lambda(X) \cap C_u^1(X) \cap C_u(Y)$ of (1) with $f \in \Lambda(X)$, $\sigma(f)$ compact, which exist by Theorem 1.

So let such f be given, choose another cutoff function $\tilde{\varphi}_0 \in C_0^\infty$ such that $\tilde{\varphi}_0(\rho) = 1$ on $\sigma(f)$ and let $G_0 \in C_b(\mathbb{B}(X, Y)) \cap L^1(\mathbb{B}(X, Y))$ from Lemma 1 such that $\tilde{G}_0 = \tilde{\varphi} H \cdot \tilde{\varphi}_0$. Then we have

$$\begin{aligned} (x, u(t)) = (x, G_0 * f(t)) &= \int_{-\infty}^{\infty} (G_0^*(t-\tau)x, f(\tau))\, d\tau \\ &= \int_{-\infty}^{\infty} ((g_x^* * \varphi_0)(t-\tau), f(\tau))\, d\tau = \int_{-\infty}^{\infty} (g_x^*(t-\tau), (\varphi_0 * f)(\tau))\, d\tau \\ &= \int_{-\infty}^{\infty} (g_x^*(t-\tau), f(\tau))\, d\tau \end{aligned}$$

since $\varphi_0 * f = f$ by Proposition 2 and $\widetilde{G_0^* x} = \tilde{\varphi} H^* x \tilde{\varphi}_0 = \widetilde{g_x^*} \cdot \tilde{\varphi}_0 = (g_x^* * \varphi_0)^{\sim}$; hence $G_0^* x = g_x^* * \varphi_0$ by uniqueness of the Fourier-transform. Similarly one obtains the second part of (30).

(v) Suppose Λ_0 is compact, then w.l.o.g. we may choose $\tilde{\varphi}$ such that $\tilde{\varphi}(\rho) = 1$ for $|\rho| \geqq N$, where N is sufficiently large. Since for $x \in D(A)$

$$i\rho H(i\rho)x - x = i\rho(H(i\rho)x - x/i\rho) = H(i\rho)Ax + H(i\rho)\widehat{B'}(i\rho)x$$

belongs to $L^2(X)$ asymptotically, we obtain from

$$\tilde{\varphi}(\rho)H(i\rho)x = \tilde{\varphi}(\rho)(H(i\rho)x - x/i\rho) + (\tilde{\varphi}(\rho) - 1)x/i\rho + x/i\rho$$

that $g_x(t)$ is continuous for $t \neq 0$ and that the jump relation $g_x(0+) - g_x(0-) = x$ is satisfied for each $x \in D(A)$. Also since $\tilde{\varphi} H^* x \in L^2(x)$ and $(i\rho + \omega - A)^{-1}x \in [L^\infty(X)]^{\sim}$ we derive from

$$(x^*, Hx) = (x^*, (i\rho + \omega - A)^{-1}x) + (H^* x, (\omega + \widehat{B'})(i\rho + \omega - A)^{-1}x) \in L^1(X)$$

the boundedness of $(x^*, g_x(t))$ for all $x, x^* \in X$. Hence $g_x(t)$ is bounded in t for each $x \in X$, and therefore continuous for $t \neq 0$ and $g_x(0+) - g_x(0-) = 0$ holds, by density of $D(A)$ in X. This shows that there is an operator-valued kernel $G_\Lambda(\cdot)$ representing $g_x(t)$ by $g_x(t) = G_\Lambda(t)x$. □

ON LIMIT STATES OF A LINEARIZED BOLTZMANN EQUATION*

MILAN MIKLAVČIČ†

Abstract. With methods of mean ergodic theory a very simple criterion for existence of limit states of linearized Boltzmann equation is proven.

Key words. linearized Boltzmann equation, ergodic theory

AMS(MOS) subject classifications. 45A05, 47A35

A linearized Boltzmann equation can under some conditions ([4], see also [1], [8]) be written in the form

$$\frac{du}{dt} + u = Bu$$

where B is typically a Markov operator on some L^1. The solution of this equation is $e^{-t}e^{Bt}u_0$ and one would like to know how the solution behaves as $t \to \infty$. In this paper this equation is considered in an arbitrary Banach space X and B is assumed to be a bounded linear operator on X such that $\sup_{n\geqq 0}\|B^n\| < \infty$. Let $N = \{x \in X \mid Bx = x\}$ and $R = \{x \in X \mid x = y - By \text{ for some } y \in X\}$.

THEOREM 1. *If $x \in X$, $x_0 \in X$, then the following statements are equivalent*:

(a) *There exist integers $n_1 < n_2 < \cdots$ such that $\lim_{i\to\infty} y((1/n_i)\sum_{k=0}^{n_i-1} B^k x) = y(x_0)$ for all $y \in X^*$.*

(b) *There exist $t_1, t_2, \cdots$ in $(0, \infty)$ such that $\lim_{i\to\infty} t_i = \infty$ and $\lim_{i\to\infty} y(e^{-t_i}e^{Bt_i}x) = y(x_0)$ for all $y \in X^*$.*

(c) $x_0 \in N$ *and* $x - x_0 \in \bar{R}$.

(d) $\lim_{n\to\infty} \|(1/n)\sum_{k=0}^{n-1} B^k x - x_0\| = 0$.

(e) $\lim_{t\to\infty} \|e^{-t}e^{Bt}x - x_0\| = 0$.

This theorem implies that all standard mean ergodic theorems (e.g. (2)) are applicable in the study of limits of $e^{-t}e^{Bt}x$! A simple and quite powerful criterion for existence of the limit is given by the following.

THEOREM 2. *If $x \in X$ and if the set $\{B^n x \mid n \geqq 0\}$ is weakly sequentially compact, then there exists $x_0 \in N$ such that*

$$\lim_{t\to\infty} \|e^{-t}e^{Bt}x - x_0\| = 0.$$

Proof. Let $C = \{B^n x \mid n \geqq 0\}$ and let C_1 be the convex hull of C. Since $(1/n)\sum_{k=0}^{n-1} B^k x \in C_1$ for $n \geqq 1$ and since C_1 is weakly sequentially compact [2, Krein-Šmulian Theorem] there exists $x_0 \in X$ such that part (a) of Theorem 1 is satisfied.

There are many ways of showing that the set $\{B^n x \mid n \geqq 0\}$ is weakly sequentially compact [2]. In [3], [5] conditions like strong (weak) constrictiveness (and some other conditions) are required; the following observation shows that these conditions are much more restrictive than those of Theorem 2. If $x \in X$, then the set $\{B^n x \mid n \geqq 0\}$ is weakly sequentially compact if and only if there exists a weakly compact set F (for this x!) such that $\lim_{n\to\infty} \operatorname{dist}(B^n x, F) = 0$.

If B is positive quasi-compact operator then even convergence rates can be estimated.

* Received by the editors March 31, 1986; accepted for publication February 9, 1987.

† Department of Mathematics, Michigan State University, East Lansing, Michigan 48824.

THEOREM 3. *Suppose that X is real Banach space and that X^+ is a closed subset of X with the following properties*:

(1) *If $x \in X^+$, $y \in X^+$, $\alpha \in [0, \infty)$ then $x+y \in X^+$ and $\alpha x \in X^+$;*

(2) *There exists $M_0 \in (0, \infty)$ such that for each $x \in X$ there exist $x_+ \in X^+$ and $x_- \in X^+$ which satisfy*

$$x = x_+ - x_-, \quad \|x_+\| \leqq M_0\|x\|, \quad \|x_-\| \leqq M_0\|x\|$$

and if $x = y_+ - y_-$ for some $y_+ \in X^+$, $y_- \in X^+$, then $y_+ - x_+ \in X^+$.

(3) *If $x \in X^+$, $y \in X^+$, then $\|x\| \leqq \|x+y\|$.*

Suppose also that T is bounded linear operator on X such that

(4) *$TX^+ \subset X^+$.*

(5) *$\lim_{n\to\infty} (1/n) y(T^n x) = 0$ for all $x \in X$ and all $y \in X^*$.*

(6) *$\|T^m - K\| < 1$ for some integer m and some compact linear operator K.*

Then there exist $a \in (0, \infty)$, $b \in (0, \infty)$ such that for every $x \in X$ there exists $x_0 \in X$ for which

$$\left\| \frac{1}{n} \sum_{k=0}^{n-1} T^k x - x_0 \right\| \leqq \frac{b}{n}\|x\|, \qquad \|e^{-t} e^{Tt} x - x_0\| \leqq b\|x\| \, e^{-at}$$

whenever $n \geqq 1$, $t > 0$.

Proof of Theorem 3 can be found in [7] and follows from the fact that $T^n x$ is actually asymptotically periodic for every $x \in X$ (see also [6]). Operators considered in [5] in connection with the Boltzmann equation satisfy above assumptions.

Proof of Theorem 1. Equivalence of statements (a), (c), (d) is well known [2]. It is obvious that (e) implies (b) and (c); it is enough to prove that (b) implies (c) and that (c) implies (e).

Let $M = \sup_{n\geqq 0} \|B^n\|$, $A = I - B$ and

$$F(t) = e^{-t} + e^{-t} \sum_{n=0}^{\infty} \frac{t^n}{n!} \left| \frac{t}{n+1} - 1 \right|.$$

Identities

$$e^{-At} = e^{-t} e^{Bt} = e^{-t} \sum_{n=0}^{\infty} \frac{t^n}{n!} B^n,$$

$$Ae^{-At} = e^{-t} + e^{-t} \sum_{n=0}^{\infty} \frac{t^n}{n!} \left(\frac{t}{n+1} - 1 \right) B^{n+1}$$

imply that for $t > 0$

$$\|e^{-At}\| \leqq M, \qquad \|Ae^{-At}\| \leqq MF(t).$$

A nasty but straightforward exercise gives that $\lim_{t\to\infty} F(t) = 0$.

Assume (b). Then for all $y \in X^*$

$$0 = \lim_{i\to\infty} y(Ae^{-At_i} x) = \lim_{i\to\infty} (A^* y)(e^{-At_i} x) = (A^* y)(x_0) = y(Ax_0);$$

hence, $Ax_0 = 0$. If $x - x_0 \notin \bar{R}$, then there exists $y_0 \in X^*$ such that $A^* y_0 = 0$ and $y_0(x - x_0) = 1$, which leads to the contradiction

$$1 = y_0(x - x_0) = (e^{-A^* t_i} y_0)(x - x_0) = y_0(e^{-At_i} x - x_0) = 0$$

and therefore $x - x_0 \in \bar{R}$ and (c) is true.

Assume (c). Pick $\varepsilon > 0$ and let $z \in X$ be such that $\|x - x_0 - Az\| < \varepsilon/(1+M)$; hence, for $t > 0$

$$\begin{aligned}\|e^{-At}x - x_0\| &\leqq \|e^{-At}(x - x_0 - Az)\| + \|Ae^{-At}z\| \\ &\leqq M\varepsilon/(1+M) + MF(t)\|z\|\end{aligned}$$

and this implies (e).

Acknowledgment. It is my pleasure to thank T. Y. Li for many illuminating discussions.

EXISTENCE, UNIQUENESS AND REGULARITY OF A TIME-PERIODIC PROBABILITY DENSITY DISTRIBUTION ARISING IN A SEDIMENTATION-DIFFUSION PROBLEM*

LUDWIG C. NITSCHE†‡, JOHANNES M. NITSCHE†‡ AND HOWARD BRENNER†§

Abstract. An analysis is presented of the one-dimensional convective-diffusive equation governing the temporal evolution and spatial distribution of the probability density $P(x, t)$ describing the sedimentation and diffusion of a nonneutrally buoyant Brownian particle in a vertical fluid-filled cylinder that is flipped over instantaneously at regular intervals. A time-periodic solution is sought by requiring that the initial spatial distribution recur after one complete period of the flipping motion. The periodicity condition is formulated both as an infinite matrix equation for the eigenfunction expansion coefficients of a possible recurring initial distribution, and as an integral equation of the second kind for the distribution itself. The kernel (infinite matrix) is shown to be square integrable (square summable), so that Fredholm theory applies. There exists a unique time-periodic solution whenever unity is not an eigenvalue of the integral (infinite matrix) operator. Regions in parameter space are identified in which existence and uniqueness are assured. It is shown that time-periodic solutions are analytic functions of the position coordinate at each time. A symmetry property of unique time-periodic solutions is established by deriving a simpler infinite matrix equation. Numerical examples show the appearance of recurring initial distributions.

Key words. sedimentation-diffusion, time-periodic solution, Fredholm theory, existence, uniqueness, regularity

1. Introduction.

Motivation. (Small) nonneutrally buoyant particles sedimenting under the influence of gravity in an otherwise quiescent viscous suspension ultimately settle to the bottom of the container. This phenomenon unfortunately eliminates the possibility of a leisurely experimental study of the physicochemical, colloidal or biophysical properties of individual particles in their supernatant fluid environment. While the suspension can, of course, be stirred to levitate the particles, the relatively large shear fields engendered by the stirring may fundamentally alter the intrinsic particle property being studied, e.g., the configuration of the body in the case of flexible or deformable particles. Even when this is not the case, the introduction of largely unknown velocity fields by the agitator may be expected to complicate the interpretation of any experimental results.

With these difficulties in mind, a novel scheme for achieving (time-average) nonsedimenting states for small nonneutrally buoyant particles has recently been proposed by Dill and Brenner [5], and further elaborated by Nadim, Cox and Brenner [15] and Davis and Brenner [4]. This involves placing the suspension into a *slowly* rotating horizontal circular cylinder, so that the suspension as a whole undergoes a rigid-body rotation upon which is superposed the Stokes settling velocity of each particle with respect to the fluid in its instantaneous locale. (*Slow* rotation assures the absence of centrifugal and Coriolis effects, whose presence would negate the theoretical basis of the proposed scheme.) This combined translational/rotational particle motion

relative to a space-fixed observer results in a closed, time-periodic particle trajectory, whose *net* motion over one period is identically zero [5]. (This same conclusion obtains [15] even when the sedimenting particle is small enough to undergo appreciable translational Brownian motion, whereupon its trajectory is now stochastic rather than deterministic—the former circumstance being the case of interest to us in the subsequent analysis.) Thus, despite the particle's continuous *relative* settling, it does not undergo any *net* settling relative to a space-fixed observer.

The underlying mechanism behind this class of "antisedimentation" devices is most readily visualized by imagining oneself to be a body-fixed observer, fixed in a reference frame that rotates with the fluid-filled cylinder. From this vantage point the otherwise constant, space-fixed gravity force vector acting on each particle is observed to be a time-periodic vector (of constant magnitude), whose average value over one period is the zero vector. In effect, it is this zero-valued mean which is the source of the state of levitation. It effectively nullifies the action of gravity [16].

In a specific context the class of such time-periodic, zero-mean sedimentation phenomena may be simulated, both physically and mathematically, by allowing the suspension to settle in a (nonrotating) vertical cylinder that is flipped over at periodic intervals. (Any sediment near to the bottom of the cylinder then suddenly finds itself near to the top, whereupon it must again settle through the entire length of the cylinder before reaching the bottom, et cycl.) An observer fixed in the cylinder walls will evidently observe the gravity-force vector to be time-periodic with zero mean. The physicomathematical question to be addressed here is whether or not this zero-mean, time-periodic external force will give rise to a zero-mean, time-periodic particle displacement—and hence a levitated particle state. More explicitly, we address this question in the specific circumstances of interest to us in applications, namely that the sedimenting particles be small enough to also undergo appreciable diffusion. Because of this small particle size, both particle and fluid inertial effects can be ignored, and the instantaneous particle settling velocity assigned its quasistatic Stokes law value.

Formulation of the physical problem. Consider the sedimentation and diffusion of a nonneutrally buoyant Brownian particle (or, equivalently, a dilute sedimenting suspension of identical nonhydrodynamically-interacting such particles) in a vertical fluid-filled cylinder of finite length l that is flipped over instantaneously at regular intervals Θ. In a reference frame fixed to the container the particle's settling velocity vector alternately points up and down. The analysis is simplified by considering a one-dimensional description, in which the only spatial coordinate is distance x parallel to the cylinder axis. Then the single-body probability density $P(x, t)$ for the particle position x at time t is governed by a standard one-dimensional convective-diffusion equation, together with no-flux boundary conditions at the ends $x = 0, l$ of the container, and an arbitrarily prescribed initial spatial distribution $f(x)$ at $t = 0$. These equations may be cast in the following dimensionless form (with x, t, P and f henceforth nondimensional):

$$\left.\begin{aligned}
&\frac{\partial P}{\partial t}+u(t)\frac{\partial P}{\partial x}=\frac{1}{b}\frac{\partial^2 P}{\partial x^2}, && 0<x<1, \quad t>0, && (1.1)\\
&\frac{\partial P}{\partial x}(0,t)-bu(t)P(0,t)=0, && t>0, && (1.2)\\
&\frac{\partial P}{\partial x}(1,t)-bu(t)P(1,t)=0, && t>0, && (1.3)\\
&P(x,0)=f(x), && 0<x<1, && (1.4)
\end{aligned}\right\}\ \mathscr{P}$$

where

$$u(t)=\begin{cases}1, & 0<t<T,\\ -1, & T<t<2T,\end{cases} \tag{1.5a}$$

$$u(t+2T)=u(t) \tag{1.5b}$$

and

$$\int_0^1 f(x)\,dx=1 \qquad \text{(normalization condition).} \tag{1.6}$$

The two positive nondimensional parameters appearing in this formulation are the Péclet number b and dimensionless half-period T, respectively defined as

$$b=lc/D, \tag{1.7}$$

$$T=\Theta c/l, \tag{1.8}$$

with l the container length, $c>0$ the Stokes' law settling speed of the particle, $D>0$ its Brownian diffusivity through the fluid, and Θ the time interval between successive overturnings.

Considering the time periodicity of the dimensionless particle settling velocity $u(t)$, it is natural to inquire whether or not problem $\mathcal{P}$ possesses a (square integrable) time-periodic solution; equivalently, does there exist an "initial" distribution $P(x,0)=f(x)$ which will recur at time $t=2T$? It is the purpose of this paper to prove the existence and uniqueness of time-periodic solutions for various ranges of the parameters b and T. Moreover, we address the question of regularity by showing that time-periodic solutions are analytic functions of x at each time t. We also establish a time-shifted symmetry property of unique time-periodic solutions. Illustrations are appended which show numerically-generated recurring initial distributions.

Although the literature on the general subject of time-periodic solutions of parabolic differential equations is considerable, the present problem seems not to have been treated before. Different types of boundary conditions have been considered; Dirichlet conditions seem to predominate. There have appeared many analyses of problems which, in contrast with the present problem $\mathcal{P}$, involve time periodicity only in the differential operator or only in the boundary conditions, but not in both (e.g. [11]). Extensive bibliographies are available in Cannon [2] and Vejvoda [21]. Differential equations which could reduce to an equation similar to (1.1), together with time-periodic boundary conditions involving the unknown function and a spatial derivative thereof, are considered by Farlow [6], [7], Heuss [9], Knolle [12], Mal'tsev [13], Prodi [17] and Šmulev [19], [20]. The principal differences between these analyses and the present one are that: (i) In contrast to (1.2) and (1.3), the boundary conditions in the aforementioned papers are of the conventional type, which require P and its normal (or oblique) derivative with a consistent orientation to have the same sign relationship at all points of the boundary; (ii) the time-periodic functions considered in the cited references generally must satisfy certain regularity conditions, whereas our time-periodic velocity $u(t)$ is discontinuous.

2. Equations for a time-periodic solution. A time-periodic solution of problem $\mathcal{P}$ is sought by requiring that the initial distribution $f(x)=P(x,0)$ recur after the system evolves through one complete period of the flipping motion; explicitly, $f(x)$ should satisfy

$$f(x)=P(x,0)=P(x,2T), \qquad 0\leqq x\leqq 1. \tag{2.1}$$

Since $u(t)$ is time independent during each half period, problem $\mathcal{P}$ may be subdivided into two constant-coefficient subproblems, $\mathcal{P}^+$ and $\mathcal{P}^-$. Thus, the probability density $P(x, t)$ is governed by the set of equations

$$\left.\begin{aligned}
&\frac{\partial P}{\partial t}+\frac{\partial P}{\partial x}=\frac{1}{b}\frac{\partial^2 P}{\partial x^2}, && 0<x<1, \quad 0<t<T, && (2.2)\\
&\frac{\partial P}{\partial x}(0, t)-bP(0, t)=0, && 0<t<T, && (2.3)\\
&\frac{\partial P}{\partial x}(1, t)-bP(1, t)=0, && 0<t<T, && (2.4)\\
&P(x, 0)=f(x), && 0<x<1, && (2.5)
\end{aligned}\right\} \mathcal{P}^+$$

where

$$\int_0^1 f(x)\,dx=1, \tag{2.6}$$

together with

$$\left.\begin{aligned}
&\frac{\partial P}{\partial t}-\frac{\partial P}{\partial x}=\frac{1}{b}\frac{\partial^2 P}{\partial x^2}, && 0<x<1, \quad T<t<2T, && (2.7)\\
&\frac{\partial P}{\partial x}(0, t)+bP(0, t)=0, && T<t<2T, && (2.8)\\
&\frac{\partial P}{\partial x}(1, t)+bP(1, t)=0, && T<t<2T. && (2.9)
\end{aligned}\right\} \mathcal{P}^-$$

Here, the initial distribution $P(x, T)$ for problem $\mathcal{P}^-$ is furnished by the solution of problem $\mathcal{P}^+$ at time $t=T$. It is redundant to demand satisfaction of the unit normalization condition (2.6) by $P(x, T)$ inasmuch as problem $\mathcal{P}^+$ conserves probability density (as do problems $\mathcal{P}^-$ and $\mathcal{P}$, also).

Problems $\mathcal{P}^+$ and $\mathcal{P}^-$ can be solved by separation of variables. Though both lead to the same discrete eigenvalue spectrum,

$$\lambda_0=0, \qquad \lambda_n=\frac{b}{4}+\frac{n^2\pi^2}{b} \quad \text{for } n=1, 2, 3, \cdots, \tag{2.10}$$

the sequence of eigenfunctions is, nevertheless, different for each. With $^+$ and $^-$ superscripts respectively distinguishing problems $\mathcal{P}^+$ and $\mathcal{P}^-$, the eigenfunctions $\phi_n^{\pm}(x)$ are given by

$$\phi_0^{\pm}(x)=\left(\frac{\pm b}{e^{\pm b}-1}\right)^{1/2} e^{\pm bx}, \tag{2.11a}$$

$$\phi_n^{\pm}(x)=\left(\frac{2}{b\lambda_n}\right)^{1/2}\left[n\pi\cos(n\pi x)\pm\frac{b}{2}\sin(n\pi x)\right] e^{\pm bx/2}, \qquad n\geqq 1, \tag{2.11b}$$

and satisfy the orthonormality condition

$$\int_0^1 \phi_m^{\pm}(x)\phi_n^{\pm}(x)\, e^{\mp bx}\,dx=\delta_{mn}, \qquad m, n\geqq 0. \tag{2.12}$$

Both sets of eigenfunctions are complete. A direct computation shows that the two kinds of eigenfunctions are related by the equation

$$\phi_n^-(x) = (-1)^n e^{-b/2}\phi_n^+(1-x) \tag{2.13}$$

for all $n \geqq 0$.

Subsequent analysis necessitates determining the expansion of each function $\phi_n^-(x)$ in terms of the set of functions $\{\phi_n^+(x)\}$ and conversely:

$$\phi_n^-(x) = \sum_{m=0}^{\infty} A_{mn}\phi_m^+(x), \tag{2.14}$$

$$\phi_n^+(x) = \sum_{m=0}^{\infty} B_{mn}\phi_m^-(x) \tag{2.15}$$

($n \geqq 0$), where

$$A_{mn} = \int_0^1 \phi_n^-(x)\phi_m^+(x)\, e^{-bx}\, dx, \tag{2.16}$$

$$B_{mn} = \int_0^1 \phi_n^+(x)\phi_m^-(x)\, e^{bx}\, dx \tag{2.17}$$

($m, n \geqq 0$). By making the substitution $x = 1 - y$ in (2.17), and utilizing (2.13) and (2.16), it can be shown that

$$B_{mn} = (-1)^{m+n} e^b A_{mn}. \tag{2.18}$$

Straightforward, albeit lengthy, computations yield:

$$A_{mn} = \frac{4\pi^2 b[1-(-1)^{m+n} e^{-b}](\lambda_m/\lambda_n)^{1/2} mn}{[b^2+(m+n)^2\pi^2][b^2+(m-n)^2\pi^2]}, \qquad m, n \geqq 1, \tag{2.19a}$$

$$A_{m0} = \left[\frac{2}{\lambda_m(1-e^{-b})}\right]^{1/2} [1-(-1)^m e^{-3b/2}] \frac{8\pi mb}{9b^2+4m^2\pi^2}, \qquad m \geqq 1, \tag{2.19b}$$

$$A_{0n} = e^{-b/2}\delta_{0n}, \qquad n \geqq 0. \tag{2.19c}$$

Explicit expressions for the B_{mn} can be obtained from (2.19) upon using the relation (2.18).

The preceding development permits derivation of the pertinent equations that a recurring initial distribution must necessarily satisfy. Start with some arbitrary initial distribution,

$$P(x, 0) = f(x) = \sum_{m=0}^{\infty} a_m\phi_m^+(x), \qquad 0 \leqq x \leqq 1, \tag{2.20}$$

where, for all $m \geqq 0$,

$$a_m = \int_0^1 f(x)\phi_m^+(x)\, e^{-bx}\, dx. \tag{2.21}$$

Correspondingly, the solution of problem $\mathcal{P}^+$ is given by the series

$$P(x, t) = \sum_{m=0}^{\infty} a_m\, e^{-\lambda_m t}\phi_m^+(x), \qquad 0 \leqq t \leqq T. \tag{2.22}$$

In particular,

$$P(x, T) = \sum_{m=0}^{\infty} a_m\, e^{-\lambda_m T}\phi_m^+(x). \tag{2.23}$$

Since $P(x, T)$ serves as the initial distribution for problem $\mathscr{P}^-$ it is convenient to expand it in terms of the $\phi_k^-(x)$ as

$$P(x, T) = \sum_{k=0}^{\infty} b_k \phi_k^-(x). \tag{2.24}$$

Here, for all $k \geqq 0$,

$$b_k = \int_0^1 P(x, T)\phi_k^-(x)\, e^{bx}\, dx. \tag{2.25}$$

Problem $\mathscr{P}^-$ possesses the solution

$$P(x, t) = \sum_{k=0}^{\infty} b_k\, e^{-\lambda_k(t-T)}\phi_k^-(x), \qquad T \leqq t \leqq 2T. \tag{2.26}$$

The function $f(x)$ is a recurring initial distribution if, and only if,

$$f(x) \equiv P(x, 2T) = \sum_{k=0}^{\infty} b_k\, e^{-\lambda_k T}\phi_k^-(x). \tag{2.27}$$

Introduction of (2.27) into (2.21) leads to the following expression for each coefficient a_m in terms of the coefficients b_k:

$$a_m = \sum_{k=0}^{\infty} A_{mk}\, e^{-\lambda_k T} b_k, \qquad m \geqq 0. \tag{2.28}$$

A similar combination of (2.23) and (2.25) gives

$$b_k = \sum_{n=0}^{\infty} B_{kn}\, e^{-\lambda_n T} a_n, \qquad k \geqq 0. \tag{2.29}$$

Equations (2.28) and (2.29) coalesce into the following infinite system of linear equations for the eigenfunction expansion coefficients a_m:

$$a_m = \sum_{n=0}^{\infty} \left[\sum_{k=0}^{\infty} A_{mk} B_{kn}\, e^{-(\lambda_k + \lambda_n)T} \right] a_n, \qquad m \geqq 0. \tag{2.30}$$

For $m = 0$, (2.30) reduces to the trivial identity $a_0 = a_0$, owing to (2.19c) and the corresponding equation for the B_{0n}. The system (2.30) therefore needs to be considered only for $m \geqq 1$; it may be rewritten as

$$a_m = \sum_{n=1}^{\infty} C_{mn} a_n + R_m a_0, \qquad m \geqq 1, \tag{2.31}$$

where

$$C_{mn} = \sum_{k=1}^{\infty} A_{mk} B_{kn}\, e^{-(\lambda_k + \lambda_n)T}, \tag{2.32}$$

$$R_m = A_{m0}\, e^{b/2} + \sum_{k=1}^{\infty} A_{mk} B_{k0}\, e^{-\lambda_k T} \qquad (m, n \geqq 1). \tag{2.33}$$

The coefficient a_0 of the expansion (2.20), which appears on the right-hand side of (2.31), must still be specified. Direct calculation gives

$$\int_0^1 \phi_m^+(x)\, dx = \left(\frac{e^b - 1}{b} \right)^{1/2} \delta_{0m}, \tag{2.34}$$

whence the normalization condition (2.6) involves only a_0, thereby yielding

$$a_0 = \left(\frac{b}{e^b - 1}\right)^{1/2}. \tag{2.35}$$

Equation (2.31) constitutes an infinite system of linear equations for the eigenfunction expansion coefficients a_n $(n \geqq 1)$ of the possible recurring initial distribution(s). The question of existence and uniqueness of a square integrable time-periodic solution of problem $\mathscr{P}$ is equivalent to the question of whether or not the infinite linear system (2.31) possesses a unique square summable solution.

There also exists an equivalent integral equation of the second kind for the recurring initial distributions themselves. This may be derived by first reformulating the solutions of problems $\mathscr{P}^+$ and $\mathscr{P}^-$ in terms of their respective Green's functions $G^+(x, t; \xi)$ and $G^-(x, t; \xi)$. In particular,

$$P(x, T) = \int_0^1 G^+(x, T; \xi) f(\xi)\, d\xi. \tag{2.36}$$

With this as the initial distribution for problem $\mathscr{P}^-$, we obtain

$$\begin{aligned} P(x, 2T) &= \int_0^1 G^-(x, 2T; \eta) P(\eta, T)\, d\eta \\ &= \int_0^1 G^-(x, 2T; \eta) \left[\int_0^1 G^+(\eta, T; \xi) f(\xi)\, d\xi \right] d\eta. \end{aligned} \tag{2.37}$$

Accordingly, the periodicity condition (2.1) may be expressed in the form

$$f(x) = P(x, 2T) = \int_0^1 H(x; \xi) f(\xi)\, d\xi, \tag{2.38}$$

where

$$H(x; \xi) = \int_0^1 G^-(x, 2T; \eta) G^+(\eta, T; \xi)\, d\eta. \tag{2.39}$$

Series representations for the Green's functions may be derived from (2.21), (2.22), (2.25) and (2.26). Using these, we ultimately obtain

$$H(x; \xi) = K(x; \xi) + Q(x), \tag{2.40}$$

where

$$K(x; \xi) = e^{-b\xi} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} B_{mn}\, e^{-(\lambda_m + \lambda_n)T} \phi_m^-(x) \phi_n^+(\xi), \tag{2.41}$$

$$Q(x) = \left(\frac{b}{1 - e^{-b}}\right) e^{-bx} + \left(\frac{b}{e^b - 1}\right)^{1/2} \sum_{m=1}^{\infty} B_{m0}\, e^{-\lambda_m T} \phi_m^-(x). \tag{2.42}$$

Substitution of (2.40) into (2.38) together with use of the normalization condition (2.6) leads to an integral equation of the second kind,

$$f(x) = \int_0^1 K(x; \xi) f(\xi)\, d\xi + Q(x), \tag{2.43}$$

for $f(x)$. The last step, whereby (2.38) is rewritten as the inhomogeneous equation (2.43), is analogous to our previous reduction of the homogeneous system (2.30) to the inhomogeneous system (2.31).

We remark that substitution of the series representations (2.20), (2.41) and (2.42) into (2.43) leads to the infinite system (2.31).

3. Existence and uniqueness of time-periodic solutions. Possible conclusions that can be drawn from the integral equation (2.43) necessarily depend upon the properties of the kernel $K(x;\xi)$ as well as those of the inhomogeneous term $Q(x)$. As shown a fortiori by our proof of Lemma 3.2 below, $K(x;\xi)$ is square integrable. Similar arguments establish that $Q(x)$ is also square integrable. It follows from these facts that the standard Fredholm theorems (cf. Mikhlin [14, pp. 1-3, 64-68], Courant and Hilbert [3, pp. 112-122, 152-153]) apply to (2.43).[1] A parallel theory (cf. Hilbert [10, pp. VI-VII], Courant and Hilbert [3, pp. 160-161]) applies to (2.31) because the infinite matrix $C=[C_{mn}]$ and inhomogeneous term $R=[R_m]$ are square summable. Thus, we conclude that there exists a unique (square integrable) recurring initial distribution (equivalently, a unique time-periodic solution) if unity is not an eigenvalue of the integral operator $\mathscr{L}_K=\int_0^1 d\xi\, K(x;\xi)$ or of the infinite matrix $C=[C_{mn}]$.[2] Accordingly, we are motivated to identify regions of the (b, T) parameter plane in which it is impossible for unity to be an eigenvalue. Two independent arguments are presented for this purpose.

LEMMA 3.1. *When*

$$T>2b^2/(b^2+4\pi^2), \tag{3.1}$$

problem $\mathscr{P}$ possesses a unique time-periodic solution.

Proof.[3] Suppose $a_0=0$. Equation (2.29) with $k=0$, in conjunction with (2.19c) and (2.18), then gives $b_0=0$. From (2.24), (2.12) and (2.23) there follows the Parseval identity

$$\sum_{n=1}^{\infty} b_n^2=\int_0^1 e^{bx}\left[\sum_{n=1}^{\infty} a_n e^{-\lambda_n T}\phi_n^+(x)\right]^2 dx, \tag{3.2}$$

in which the summations start from $n=1$ because $a_0=b_0=0$. Straightforward manipulation of the right-hand side, utilizing the bound $e^{bx}\leqq e^{2b}e^{-bx}$ $(0\leqq x\leqq 1)$ together with (2.12), gives

$$\sum_{n=1}^{\infty} b_n^2\leqq e^{2b}\sum_{n=1}^{\infty} a_n^2 e^{-2\lambda_n T}\leqq e^{2(b-\lambda_1 T)}\sum_{n=1}^{\infty} a_n^2. \tag{3.3}$$

A similar argument starting from (2.20), (2.12) and (2.27) shows that

$$\sum_{n=1}^{\infty} a_n^2\leqq e^{-2\lambda_1 T}\sum_{n=1}^{\infty} b_n^2. \tag{3.4}$$

Relations (3.3) and (3.4) can be combined to give

$$\sum_{n=1}^{\infty} a_n^2\leqq e^{2(b-2\lambda_1 T)}\sum_{n=1}^{\infty} a_n^2. \tag{3.5}$$

---

[1] Actually, square integrability of the kernel $K(x;\xi)$ is a sufficient condition for complete continuity of the integral operator. In turn, this property is all that is required (insofar as the integral operator is concerned) to insure the validity of the Fredholm theorems (see Hellinger and Toeplitz [8, p. 1399ff], Riesz and Sz.-Nagy [18, pp. 177-190]).

[2] An eigenvalue μ of the (integral/infinite matrix) operator $\mathscr{L}$ is defined by the equation $y=\mu\mathscr{L}y$, in which y is the corresponding eigenfunction/eigenvector.

[3] This argument was developed in an article by L.C. Nitsche entitled *Settling of a Brownian particle in a container which is flipped over at regular intervals.* (Term paper for the course "Macrotransport Processes," Catalog No. 10.54, Massachusetts Institute of Technology, Cambridge, Massachusetts, May 17, 1985.)

Suppose $T > b/(2\lambda_1) = 2b^2/(b^2+4\pi^2)$. Inequality (3.5) is then satisfied iff $a_n = 0$ for all $n \geqq 1$. Thus, $a_0 = 0 \Rightarrow a_n = 0$ for all $n \geqq 1$. This means that the homogeneous system corresponding to (2.31) has only the trivial solution, i.e., unity is not an eigenvalue of C. It follows as an immediate consequence that problem $\mathscr{P}$ possesses a unique time-periodic solution. Q.E.D.

Another development is based on the fact that the magnitude of an eigenvalue cannot be less than the reciprocal of any norm of the operator; thus, if a norm of the operator is less than unity, no eigenvalue can possibly equal unity. We use this fact in conjunction with a bound on the L^2 norm of $\mathscr{L}_K$ to prove the following lemma.

LEMMA 3.2. *If*

$$\Gamma(b, T) \overset{\text{def}}{=} (e^b-1)^4(\pi bT)^{-2}\, e^{-b(2+T)} \leqq 1, \tag{3.6}$$

then problem $\mathscr{P}$ possesses a unique time-periodic solution.

Proof.

$$\begin{aligned}
\|\mathscr{L}_K\|_2^2 &= \int_0^1 \int_0^1 [K(x;\xi)]^2\, d\xi\, dx \\
&= \int_0^1 \int_0^1 \left[\sum_{k=1}^{\infty} \sum_{l=1}^{\infty} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} B_{kl}B_{mn}\, e^{-(\lambda_k+\lambda_l+\lambda_m+\lambda_n)T} \right. \\
&\qquad \left. \cdot\, e^{-2b\xi}\phi_k^-(x)\phi_l^+(\xi)\phi_m^-(x)\phi_n^+(\xi) \right] d\xi\, dx \qquad (3.7) \\
&= \sum_{k=1}^{\infty} \sum_{l=1}^{\infty} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} B_{kl}B_{mn}\, e^{-(\lambda_k+\lambda_l+\lambda_m+\lambda_n)T} \\
&\qquad \cdot \left[\int_0^1 e^{-2b\xi}\phi_l^+(\xi)\phi_n^+(\xi)\, d\xi \right] \left[\int_0^1 \phi_k^-(x)\phi_m^-(x)\, dx \right].
\end{aligned}$$

From (2.17), together with the bound

$$|\phi_n^{\pm}(x)| \leqq 2^{1/2}\, e^{\pm bx/2}, \qquad 0 \leqq x \leqq 1, \quad n \geqq 1, \tag{3.8}$$

it follows that

$$|B_{mn}| \leqq 2b^{-1}(e^b-1), \qquad m, n \geqq 1. \tag{3.9}$$

Use of (3.8) and (3.9) in (3.7) gives

$$\begin{aligned}
\|\mathscr{L}_K\|_2^2 &\leqq (2/b)^4(e^b-1)^4\, e^{-2b} \sum_{k=1}^{\infty} \sum_{l=1}^{\infty} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} e^{-(\lambda_k+\lambda_l+\lambda_m+\lambda_n)T} \\
&= (2/b)^4(e^b-1)^4\, e^{-b(2+T)} \left[\sum_{k=1}^{\infty} e^{-(\pi^2 T/b)k^2} \right]^4.
\end{aligned}$$

Upon majorizing the series on the right-hand side by the appropriate definite integral, we obtain

$$\|\mathscr{L}_K\|_2^2 < \Gamma(b, T). \tag{3.10}$$

If $\Gamma(b, T) \leqq 1$, then $\|\mathscr{L}_K\|_2 < 1$, thereby assuring the existence and uniqueness of a time-periodic solution. Q.E.D.

Remark. If any norm of $\mathscr{L}_K$ is less than unity, then an iterative scheme starting from any initial distribution $w^{(0)}(x)$, namely

$$w^{(k+1)}(x) = \int_0^1 K(x;\xi)w^{(k)}(\xi)\, d\xi + Q(x), \tag{3.11}$$

converges in the corresponding function norm to the solution of (2.43). This iteration corresponds to the actual temporal evolution of the probability density as recorded by a stroboscopic device which records images only at the discrete times $t=0$, $2T, 4T, \cdots$. In particular, the convergence of the iterative scheme assures that the solution to problem $\mathcal{P}$, starting from any arbitrary initial distribution, approaches the time-periodic solution in the pertinent function norm as time $t\to\infty$.

Figure 1 summarizes the results of this section. It depicts the two curves respectively defined by

$$T=2b^2/(b^2+4\pi^2) \quad \text{(curve I)},$$

$$\Gamma(b, T)=1 \quad \text{(curve II)}.$$

We have established that there exists a unique time-periodic solution of problem $\mathcal{P}$ for (b, T) lying above curve I, on or above curve II, or both (corresponding to the shaded region in Fig. 1).

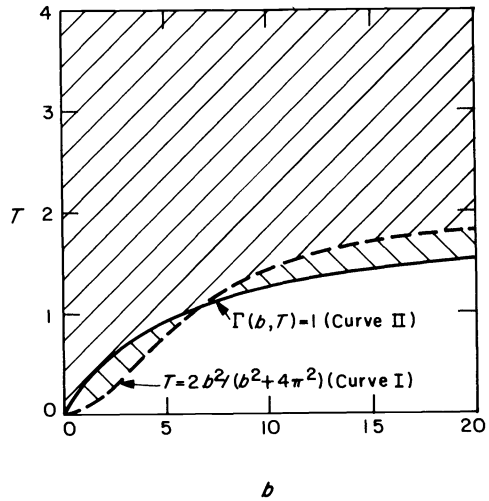

FIG. 1. *(b, T)-plane. Existence and uniqueness of a time-periodic solution of problem $\mathcal{P}$ are assured for (b, T) lying in the shaded region.*

Remark. By deriving a bound on the L^2 norm of the infinite matrix operator C, it can be shown that problem $\mathcal{P}$ possesses a unique time-periodic solution if b and T satisfy the condition

$$\Omega(b, T) \overset{\text{def}}{=} (e^b-1)^2(e^{2b}-1)(2\pi bT)^{-3/2}\, e^{-b(2+T)} \leqq 1.$$

The level curve given by $\Omega(b, T)=1$ is quantitatively similar to curve II. It is not shown in Fig. 1 because its inclusion would not enlarge the shaded region.

4. Regularity of time-periodic solutions. Conditions under which square integrable time-periodic solutions of problem $\mathcal{P}$ exist were established in § 3. We now briefly sketch the argument that leads to a much stronger regularity property of such solutions. The key observation is that at each time t, a time-periodic solution $P(x, t)$ possesses a series representation in which the coefficients multiplying the eigenfunctions $\phi_n^+(x)$ or $\phi_n^-(x)$ $(n\geqq 1)$ can be bounded by $[\mathcal{C}(b, T)\exp(-b\tau/4)]\exp[-(\pi^2\tau/b)n]$, where

$\tau > 0$.[4] This statement applies even at the flipping times. For example, of the two series representations $\sum_{n=0}^{\infty} a_n \phi_n^+(x)$ and $\sum_{n=0}^{\infty} b_n \exp(-\lambda_n T)\phi_n^-(x)$ for $P(x, 0) = P(x, 2T)$, the latter is the appropriate one to consider.

It is well known for trigonometric Fourier series that if the Fourier coefficients can be bounded by $A\vartheta^n$ (with $0 < \vartheta < 1$), then the series represents a function that is analytic in x on $[-\pi, \pi]$ (see, for example, Bary [1, pp. 82–83]). Minor modifications of Bary's proof establish the analogous result for the orthonormal sequences $\{\phi_n^+(x)\}$, $\{\phi_n^-(x)\}$ on the interval $[0, 1]$. With $A = \mathscr{C}(b, T)\exp(-b\tau/4)$ and $\vartheta = \exp(-\pi^2\tau/b)$ we obtain the following theorem.

THEOREM 4.1. *Any square integrable time-periodic solution of problem $\mathscr{P}$ is, in fact, an analytic function of x for all $x \in [0, 1]$ at each fixed time t.*

5. Further study of the infinite linear system (2.31). It has already been established that the eigenfunction expansion coefficients a_n $(n \geqq 1)$ of a possible recurring initial distribution must satisfy (2.31). We now exhibit a simpler infinite matrix equation for the expansion coefficients, and use it to establish a symmetry property of unique time-periodic solutions of problem $\mathscr{P}$.

THEOREM 5.1. *Provided that unity is not an eigenvalue of C, the unique solution of* (2.31) *is also determined uniquely by the simpler system*

$$a_m = \sum_{n=1}^{\infty} E_{mn} a_n + S_m a_0, \qquad m \geqq 1, \tag{5.1}$$

where

$$E_{mn} = (-1)^n e^{b/2} A_{mn} e^{-\lambda_n T} \qquad (m, n \geqq 1), \tag{5.2}$$

$$S_m = e^{b/2} A_{m0} \qquad (m \geqq 1). \tag{5.3}$$

Proof. Using (5.2) and (5.3), together with bounds that utilize (3.8) and (2.11a) in the Parseval identity corresponding to (2.14), it can be shown that $E = [E_{mn}]$ and $S = [S_m]$ are square summable. Thus, Fredholm theory applies to (5.1). Next, we note the equalities

$$C_{mn} = \sum_{k=1}^{\infty} E_{mk} E_{kn}, \tag{5.4}$$

$$R_m = S_m + \sum_{k=1}^{\infty} E_{mk} S_k, \tag{5.5}$$

which follow from (5.2), (5.3), (2.32), (2.33) and (2.18). The hypothesis that unity is not an eigenvalue of C, in conjunction with (5.4), leads to the conclusion that unity also fails to be an eigenvalue of E. Thus, (5.1) possesses a unique solution. Moreover, any solution of (5.1) also satisfies (2.31), as can be verified using (5.1), (5.4) and (5.5). Thus, the unique solutions of (5.1) and (2.31) are, in fact, one and the same. Q.E.D.

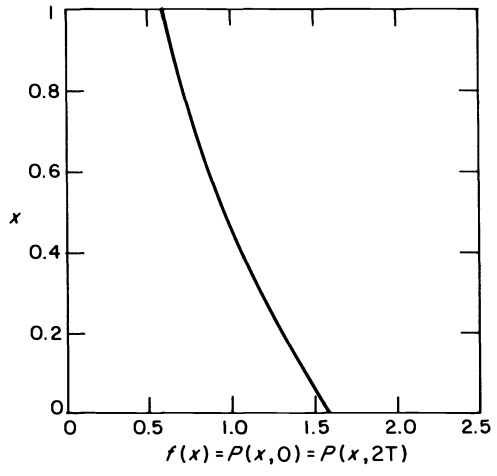
By considering the simpler system (5.1) we can establish the following time-shifted symmetry property of unique time-periodic solutions.

THEOREM 5.2. *Unique time-periodic solutions $P(x, t)$ of problem $\mathscr{P}$ satisfy*

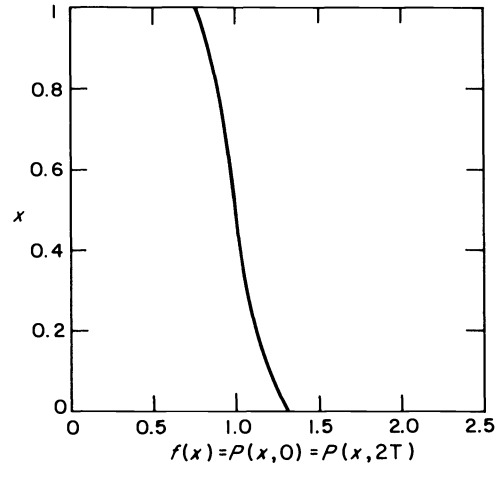
$$P(1 - x, t + T) = P(x, t). \tag{5.6}$$

---

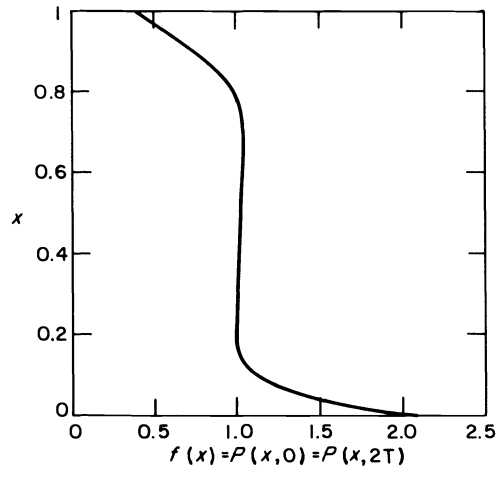
[4] We establish this bound by considering (2.22) for $0 < t \leqq T$ with $\tau = t$, and (2.26) for $T < t \leqq 2T$ with $\tau = t - T$. We then jointly utilize (2.10), the inequality $\exp[-(\pi^2\tau/b)n^2] \leqq \exp[-(\pi^2\tau/b)n]$ for $n \geqq 1$, and the fact that the a_n and b_n are certainly bounded, say by $\mathscr{C}(b, T)$.



(a)



(b)



(c)

FIG. 2. *Numerically generated recurring initial distributions*: (a) $b = 1$, $T = 1$; (b) $b = 1$, $T = 0.1$; (c) $b = 10$, $T = 0.1$.

Proof. We first derive a simple relation between the coefficients a_k and b_k for a unique time-periodic solution. By utilizing (2.29), (2.18), (2.19c), (5.2) and (5.3) we obtain

$$b_0 = e^{b/2} a_0, \quad b_k = (-1)^k e^{b/2} \left[\sum_{n=1}^{\infty} E_{kn} a_n + S_k a_0 \right] \quad \text{for } k \geqq 1. \tag{5.7}$$

For a unique time-periodic solution the coefficients a_n $(n \geqq 1)$ satisfy (5.1). Thus,

$$b_k = (-1)^k e^{b/2} a_k \tag{5.8}$$

for all $k \geqq 0$. This relation, together with (2.13), yields

$$b_k \phi_k^-(x) = a_k \phi_k^+(1-x). \tag{5.9}$$

From (2.22), (2.26) and (5.9) we conclude that a unique time-periodic solution $P(x, t)$ of problem $\mathcal{P}$ can be represented as follows:

$$P(x, t) = \begin{cases} \sum_{m=0}^{\infty} a_m e^{-\lambda_m t} \phi_m^+(x), & 0 \leqq t \leqq T, \\ \sum_{m=0}^{\infty} a_m e^{-\lambda_m (t-T)} \phi_m^+(1-x), & T \leqq t \leqq 2T. \end{cases} \tag{5.10}$$

The theorem is an immediate consequence of (5.10). Q.E.D.

Remark. It can be deduced from the preceding theorem that, in a laboratory reference frame, the probability density distributions for comparable times after each flip are all identical. This is in accordance with physical intuition.

6. Concluding remarks. In order to provide perspective for the appearance of time-periodic solutions of problem $\mathcal{P}$, we present in Figs. 2(a)-(c) examples of recurring initial distributions, generated numerically by solving finite sections of (5.1) for specific parameter values. These spatial distributions also represent the probability density at time $t = 2T$, confirming the expectation of an accumulation of probability density ("sediment") at the bottom of the container after the system has been left undisturbed for one half period. Figures 2(a) and 2(b) show the accumulation to be more pronounced for a larger than for a smaller value of T, again conforming to expectations, since the Brownian particle(s) will then have had more time in which to settle between successive overturnings.

Existence and uniqueness of time-periodic solutions have been proven for a certain region of the (b, T)-plane. One direction for future study is that of determining the eigenvalues and corresponding eigenvectors of the infinite matrix C (or E)—in particular, the first eigenvalue. This would furnish further information regarding conditions under which existence and uniqueness are assured.

REMARKS ON THE SECOND EIGENVALUE OF A SYMMETRIC SIMPLY CONNECTED PLANE REGION*

CHAO-LIANG SHEN†

Abstract. In this paper we study the second eigenfunctions of the fixed membrane eigenvalue problem on a symmetric domain. Using the notion of axially symmetric functions we prove a comparison theorem for two eigenvalues when the nodal sets of the corresponding eigenfunctions are known. This result implies that the second eigenvalues of certain membranes are nondegenerate.

Key words. eigenvalues, multiplicity, eigenfunctions, nodal set

AMS(MOS) subject classifications. 35B05, 35P99

1. Introduction. The purpose of this paper is to study the eigenspace of the second eigenvalue of a fixed membrane problem (§ 2), and to find a sufficient condition for the nondegeneracy of the second eigenvalue of a simply connected plane region, symmetric with respect to the x-, y-axes (§ 3). In § 3, using the notion of axially symmetric functions proposed by Payne, Weinberger and Weinstein [4], [5], [6], we prove a comparison theorem (Theorem 7) for two eigenvalues of a membrane when the nodal sets of the corresponding eigenfunctions are known. Using this result, we find that if f is continuous and strictly decreasing in $[0, a]$, $f(0)>0$, $f(a)=0$, but $x^2+[f(x)]^2$ is strictly increasing in $[0, a]$, then the second eigenvalue of the fixed membrane problem on the region $\bar{\Omega} := \{(x, y)\in\mathbb{R}^2: -a\leqq x\leqq a,\ -f(|x|)\leqq y\leqq f(|x|)\}$ is simple (Theorem 8).

2. A decomposition of the eigenspace of the second eigenvalue of a two-symmetric simply connected plane region. Ω shall denote a 2-symmetric simply connected plane region (i.e., Ω is separately symmetric with respect to the x-, y-axes). We shall use the following notation and terminology:

Let λ_2 be the second eigenvalue of the fixed membrane problem on Ω.

(1) If $u\in C^2(\Omega)\cap C(\bar{\Omega})$, $u=0$ on $\partial\Omega$, and $u\not\equiv 0$ such that $\Delta u+\lambda_2 u=0$, we shall call it a *second eigenfunction* of Ω.

(2) $E(\lambda_2)$ denotes the vector space consisting of 0 and second eigenfunctions.

(3) For $u\in E(\lambda_2)$, $u\not\equiv 0$, the set $N(u)=\{(x, y)\in\Omega: u(x, y)=0\}$ is called the *nodal line* (*nodal set*) of u. Any connected component of $\Omega\backslash N(u)$ is called a *nodal domain* of u. It is known that for $u\in E(\lambda_2)\backslash\{0\}$, u has exactly two nodal domains; the signs of u on these two nodal domains are different (see [1], [2]).

(4) $S(\lambda_2)=\{u\in E(\lambda_2)$: $u=0$, or $(0, 0)\in N(u)$ and $N(u)$ is symmetric with respect to $(0, 0)\}$.

(5) $\mathscr{F}(\lambda_2)=\{u\in E(\lambda_2)$: $u(x, y)=u(x, -y)=u(-x, y)$ for all (x, y) in $\Omega\}$.

(6) A function u in Ω is *2-symmetric* if $u(x, y)=u(x, -y)=u(-x, y)$ for all (x, y) in Ω. A subset N of Ω is *2-symmetric* if (x, y) in N implies that $(x, -y)$ and $(-x, y)$ are all in N.

It follows from the maximum principle for subharmonic functions that $N(u)$ cannot have isolated points. It is also known that critical nodal points are isolated (see [1, § 2]). Using these facts we see that for a second eigenfunction u, $N(u)$ is either a simple curve with end points on $\partial\Omega$ or a simple closed loop in Ω.

* Received by the editors March 21, 1986; accepted for publication (in revised form) March 24, 1987. This research was supported in part by National Science Council grant 75-0208-M007-23 of the Republic of China.

† Institute of Mathematics, National Tsing Hua University, Hsinchu, Taiwan 300, Republic of China.

We note that in general if we have a segment L in the nodal set $N(v)$ of an eigenfunction v of Ω, then L can be extended either to a (possibly self-intersected) curve in $N(v)$ with end points on $\partial\Omega$, or to a (possibly self-intersected) loop in $N(v)$. Since when nodal lines meet at a point they form an equiangular system with an even number of angles ([1, Thm. 2.5], [3, §§ 25.12, 25.13]), if we have an equiangular system in $N(v)$ at a nodal point P with $2j_0$ angles, then the eigenfunction v has at least j_0+1 nodal domains.

LEMMA 1. *For $u_1, u_2 \in E(\lambda_2)$, if $N(u_1) = N(u_2)$, then $u_1 = \alpha u_2$ for some $\alpha \in \mathbb{R}$.*

Proof. We know that any second eigenfunction has exactly two nodal domains. Let Ω_1 and Ω_2 be the nodal domains of u_1 and u_2. Then $u_i|_{\Omega_j}$ is a first eigenfunction of Ω_j (see [2]). Thus there exist real numbers α and β such that

$$u_1 = \alpha u_2 \quad \text{in } \Omega_1, \qquad u_1 = \beta u_2 \quad \text{in } \Omega_2.$$

Suppose $P \in \partial\Omega_1 \cap \partial\Omega_2 \cap \Omega$. Then

$$\frac{\partial u_1}{\partial \xi}(P) = \alpha \frac{\partial u_2}{\partial \xi}(P), \qquad \frac{\partial u_1}{\partial \xi}(P) = \beta \frac{\partial u_2}{\partial \xi}(P),$$

for any P, in any direction ξ. Since critical nodal points are isolated, there exist a nodal point P and a direction ξ such that $(\partial u_2/\partial \xi)(P) \neq 0$. Hence $\alpha = \beta$. □

THEOREM 2. *$S(\lambda_2)$ is a vector space.* $\dim_{\mathbb{R}} S(\lambda_2) \leqq 2$.

Proof. For $u \neq 0$ in $S(\lambda_2)$ let Ω_1 and Ω_2 be its nodal domains. Then Ω_1 and Ω_2 are congruent from the setting of $S(\lambda_2)$, and one is the reflection with respect to $(0, 0)$ of the other. Therefore it follows immediately from Lemma 1 that $u(x, y) = -u(-x, -y)$ for all (x, y) in Ω. This implies $S(\lambda_2)$ is a vector space.

Choose u_1, u_2 from $S(\lambda_2)\backslash\{0\}$ such that $u_1(x, y) \not\equiv u_1(x, -y)$ and $u_2(x, y) \not\equiv -u_2(x, -y)$. If no such u_1 exists, then for all u in $S(\lambda_2)$, $u(x, y) = u(x, -y) = -u(-x, -y)$ implies that $N(u)$ contains the y-axis portion (and hence is the y-axis portion) of Ω. Then Lemma 1 implies that $\dim S(\lambda_2) \leqq 1$. Similarly if no such u_2 exists, then $\dim S(\lambda_2) \leqq 1$. Assume both u_1 and u_2 do exist. Define

$$v_1(x, y) = u_1(x, y) - u_1(x, -y),$$
$$v_2(x, y) = u_2(x, y) + u_2(x, -y).$$

Then $N(v_1)$ (resp., $N(v_2)$) consists of the x-axis portion (resp., the y-axis portion) of Ω. For any u in $S(\lambda_2)$, by applying Lemma 1, we can find real numbers α, β such that $u(x, y) - u(x, -y) = \alpha v_1(x, y)$, $u(x, y) + u(x, -y) = \beta v_2(x, y)$. Thus u belongs to the span of v_1 and v_2. Therefore $\dim S(\lambda_2) \leqq 2$. (We also note that $\int_\Omega v_1 v_2 = 0$.) □

THEOREM 3. $\dim_{\mathbb{R}} \mathcal{F}(\lambda_2) \leqq 1$.

Proof. From its definition it is clear that $\mathcal{F}(\lambda_2)$ is a real vector space. Assume $\dim \mathcal{F}(\lambda_2) \geqq 2$. Then there would exist linearly independent u and v in $\mathcal{F}(\lambda_2)$. Since u and v are 2-symmetric, if $N(u)$ were not a loop in Ω, then, by the symmetry of u, $N(u)$ would be the x-axis or the y-axis portion of Ω. This is a contradiction to the 2-symmetry of u, since u has distinct signs on distinct nodal domains. Thus both $N(u)$ and $N(v)$ are 2-symmetric loops in Ω. Let Ω_u and Ω_v be the simply connected nodal domains of u and v, respectively. We may assume u and v have the same sign in $\Omega_u \cap \Omega_v$ (note that $(0, 0) \in \Omega_u \cap \Omega_v$), then we can find $\alpha \in \mathbb{R}_+$ such that $u(0, 0) - \alpha v(0, 0) = 0$. Since $u - \alpha v \neq 0$, $u - \alpha v$ is in $\mathcal{F}(\lambda_2)$. The previous argument implies that $N(u - \alpha v)$ is a 2-symmetric loop in Ω. Thus $(u - \alpha v)(0, 0) = 0$ leads to a contradiction unless $u - \alpha v = 0$. Hence $\dim_{\mathbb{R}} \mathcal{F}(\lambda_2) \leqq 1$. □

COROLLARY 4. *If $u, v \in E(\lambda_2)$ such that $N(u)$ and $N(v)$ are 2-symmetric simply closed loops in Ω, then there exists a real number α such that $u = \alpha v$, i.e., $N(u) = N(v)$.*

Proof. Since $N(u)$ and $N(v)$ are 2-symmetric loops in Ω, the nodal domains of u and v are 2-symmetric regions. By the 2-symmetry of the nodal domains and the simplicity of the first eigenvalue (recall that the restriction of u to any one of its two nodal domains is an eigenfunction of the first eigenvalue λ_2 of that domain), we see immediately that both u and v are 2-symmetric. Thus $u, v \in \mathcal{F}(\lambda_2)$. Since $\dim \mathcal{F}(\lambda_2) \leqq 1$, we are done. □

It is clear from the definitions of $\mathcal{F}(\lambda_2)$ and $S(\lambda_2)$ that for $u \in \mathcal{F}(\lambda_2)$, $v \in S(\lambda_2)$ we have $\int_\Omega uv = 0$.

THEOREM 5. $E(\lambda_2) = \mathcal{F}(\lambda_2) \oplus S(\lambda_2)$. *In particular* $\dim_{\mathbb{R}} E(\lambda_2) \leqq 3$.

Proof. For $u \in E(\lambda_2)$ define

$$u_A(x, y) = u(x, y) + u(-x, -y),$$

$$u_B(x, y) = u(x, y) - u(-x, -y),$$

and denote $E_A(\lambda_2) = \{u_A : u \in E(\lambda_2)\}$, $E_B(\lambda_2) = \{u_B : u \in E(\lambda_2)\}$. Then E_A is orthogonal to E_B in the L^2 sense. We note that $u_B(0, 0) = 0$, $u_B(-x, -y) = -u_B(x, y)$; thus $u_B \in S(\lambda_2)$. $u_A(x, y) = u_A(-x, -y)$. Next, for $u \in E_A(\lambda_2)$, define

$$u_C(x, y) = u(x, y) - u(x, -y),$$

$$u_D(x, y) = u(x, y) + u(x, -y).$$

Let $E_C(\lambda_2) = \{u_C : u \in E_A(\lambda_2)\}$, $E_D(\lambda_2) = \{u_D : u \in E_A(\lambda_2)\}$. Then $E_C(\lambda_2)$ is contained in $S(\lambda_2)$ (in fact, $E_C(\lambda_2) = \{0\}$). For $w \in E_D(\lambda_2)$, $w(x, y) = w(x, -y) = w(-x, -y)$; i.e., $w \in \mathcal{F}(\lambda_2)$. Summarizing the previous argument, we find that $E(\lambda_2) \subseteq \mathcal{F}(\lambda_2) \oplus S(\lambda_2)$. Thus $E(\lambda_2) = \mathcal{F}(\lambda_2) \oplus S(\lambda_2)$. $\dim_{\mathbb{R}} E(\lambda_2) \leqq 3$ follows immediately from Theorems 2 and 3. □

We note that we can employ the arguments in § 25.13 of [3] and the arguments similar to those given by Cheng in [1, Thm. 3.4] to derive the following multiplicity estimate: *Let $m_\Omega(n)$ denote the multiplicity of the nth eigenvalue λ_n of the fixed membrane problem on a bounded simply connected open region Ω in $\mathbb{R}^2$ with reasonably regular boundary. Then $m_\Omega(n) \leqq n(n+1)/2$.* The idea of the proof, as was pointed out by Cheng, is to show the order of vanishing of an nth eigenfunction u is at most $n-1$. Let P be a nodal point of u. We may assume that $P = (0, 0)$ and expand u in a neighborhood of $(0, 0)$ into the following Fourier-Bessel series:

$$u(r, \theta) = \sum_{m=0}^{\infty} J_m(\sqrt{\lambda_n} r)(a_m \cos m\theta + b_m \sin m\theta) \qquad (b_0 = 0).$$

Define the *order of vanishing* of u at $(0, 0)$ to be the largest integer k such that $u(0, 0) = 0$ and $du(0, 0) = 0, \cdots, d^{k-1}u(0, 0) = 0$. If $u(0, 0) = 0$ and $du(0, 0) = 0, \cdots, d^{n-1}u(0, 0) = 0$, then the coefficients $a_0, b_0, a_1, b_1, \cdots, a_{n-1}, b_{n-1}$ are all zeros. This implies that if j_0 is the first term so that $(a_{j_0}, b_{j_0}) \neq (0, 0)$, then $j_0 \geqq n$. For this j_0, say $a_{j_0} \neq 0$ ($b_{j_0} \neq 0$ is discussed similarly). Then $\cot(j_0\theta) = -b_{j_0}/a_{j_0}$ determines j_0 segments of $N(u)$ which intersect at $(0, 0)$ and form an equiangular system with $2j_0$ angles. This implies there are at least $j_0 + 1$ nodal domains (see the note we give before Lemma 1). $j_0 + 1 > n$, which is a contradiction to Courant's nodal domain theorem. Thus the order of vanishing of an nth eigenfunction of a plane fixed membrane problem is at most $n-1$. Then, by using Cheng's argument (on $\mathbb{R}^2$ the dimension of the space of constant coefficient partial differential operators of order less than or equal to $n-1$ is equal to $n(n+1)/2$), we can obtain $m_\Omega(n) \leqq n(n+1)/2$.

3. Comparing two eigenvalues when the nodal sets of the corresponding eigenfunctions are known. Let Ω be a simply connected plane region symmetric with respect to

the x-axis and the y-axis. Let ϕ, ψ be two eigenfunctions of Ω such that $N(\phi)$ lies on the x-axis and $N(\psi)$ lies on the y-axis. In this section we shall prove a comparison theorem (Theorem 7) which states that under certain conditions on $\partial\Omega$, we can compare the corresponding eigenvalues. Using this theorem we find that the second eigenvalues of certain plane regions are simple (Theorem 8).

THEOREM 6. *Let $\Omega = \Omega_f$ be a simply connected plane region with smooth boundary such that $\bar{\Omega}_f = \{(x, y): -a \leqq x \leqq a,\ -f(|x|) \leqq y \leqq f(|x|)\}$, where f is a continuous strictly decreasing function in $[0, a]$, $f(x) > 0$ in $[0, a)$, $f(a) = 0$, $f(0) = b$. Let g be the inverse function of f. Construct two four-dimensional domains Ω_1, Ω_2 as follows:*

$$\bar{\Omega}_1 = \{(x, y, z, w) \in \mathbb{R}^4: y^2 + z^2 + w^2 \leqq f(|x|)^2,\ -a \leqq x \leqq a\},$$

$$\bar{\Omega}_2 = \{(x, y, z, w) \in \mathbb{R}^4: x^2 + z^2 + w^2 \leqq g(|y|)^2,\ -b \leqq y \leqq b\}.$$

Then $\bar{\Omega}_1 \subseteq \bar{\Omega}_2$ if and only if $x^2 + [f(x)]^2$ is an increasing function in $[0, a]$. Furthermore, if $x^2 + [f(x)]^2$ is strictly increasing, then $\bar{\Omega}_1 \subsetneqq \bar{\Omega}_2$.

Proof. Since both $\bar{\Omega}_1$ and $\bar{\Omega}_2$ are simply connected, $\bar{\Omega}_1 \subseteq \bar{\Omega}_2$ if and only if $\partial\Omega_1 \subseteq \bar{\Omega}_2$. To show that $\bar{\Omega}_1 \subseteq \bar{\Omega}_2$, it is sufficient to prove that if $y^2 + r^2 = f(x)^2$, $(x \geqq 0,\ y \geqq 0)$, then $x^2 + r^2 \leqq g(y)^2$. For x, y, r such that $y^2 + r^2 = f(x)^2$, the inequality $x^2 + r^2 \leqq g(y)^2$ holds if and only if $x^2 + f(x)^2 - y^2 \leqq g(y)^2$; i.e., $x^2 + f(x)^2 \leqq y^2 + g(y)^2$. Since $0 \leqq y \leqq f(x)$ and f is strictly decreasing, $y = f(x_1)$ for some $x \leqq x_1 \leqq a$. Thus $\bar{\Omega}_1 \subseteq \bar{\Omega}_2$ if and only if $x^2 + [f(x)]^2$ is an increasing function. It is clear from the previous argument that if $x^2 + [f(x)]^2$ is strictly increasing, then $\bar{\Omega}_1 \neq \bar{\Omega}_2$. □

Example. Let $a > b > 0$ and let Ω be the ellipse $(x^2/a^2) + (y^2/b^2) < 1$. Then $\Omega = \Omega_f$, where $f = b\sqrt{1 - (x^2/a^2)}$ satisfies the conditions stated in Theorem 6.

Let Ω_f be as in Theorem 6, and let $x^2 + [f(x)]^2$ be strictly increasing in $[0, a]$. Suppose ϕ is an eigenfunction of Ω_f such that $N(\phi)$ lies on the x-axis, ψ is an eigenfunction of Ω_f such that $N(\psi)$ lies on the y-axis, and the corresponding eigenvalues of ϕ, ψ are λ, μ, respectively. Let $\phi = y\nu$. Then $\Delta\phi + \lambda\phi = 0$ implies that $(\partial^2\nu/\partial x^2) + (1/y^2)(\partial/\partial y)(y^2(\partial\nu/\partial y)) + \lambda\nu = 0$. If we denote $V(x, y_1, y_2, y_3) = \nu(x, y)$, where $y^2 = y_1^2 + y_2^2 + y_3^2$, then V is an axially symmetric function on the four-dimensional domain Ω_1 (the x-axis is the axis of symmetry of Ω_1). $(\partial^2/\partial x^2) + (1/y^2)(\partial/\partial y)(y^2(\partial/\partial y))$ is the axially symmetric Laplacian [4], [5], [6]. Since $V > 0$ in Ω_1, λ is the first eigenvalue of the four-dimensional membrane Ω_1 (with fixed boundary). Similarly μ is the first eigenvalue of the four-dimensional membrane Ω_2. Since $\bar{\Omega}_2 \supsetneqq \bar{\Omega}_1$, $\mu < \lambda$. Thus we obtain the following comparison theorem.

THEOREM 7. *Suppose $\Omega = \Omega_f$, f satisfies the conditions stated in Theorem 6, and $x^2 + [f(x)]^2$ is strictly increasing. Suppose ϕ and ψ are eigenfunctions of eigenvalues λ, μ, respectively, such that the nodal set of ϕ lies on the x-axis and the nodal set of ψ lies on the y-axis. Then $\lambda > \mu$.*

THEOREM 8. *Let f, Ω_f be as in Theorem 7. Then the second eigenvalue of the fixed membrane problem on Ω_f is simple; the eigenfunction is an odd function of x, even in y.*

Proof. Since Ω_f is convex in the x-direction and symmetric about the y axis, it follows from Payne's Theorem [4, Thm. I] that the second eigenfunction of Ω_f cannot have an interior closed nodal curve. Thus, by Theorem 5, $\dim E(\lambda_2) \leqq 2$. If $\dim E(\lambda_2) = 2$, then there is a second eigenfunction ϕ whose nodal curve lies on the x-axis, and there is another second eigenfunction ψ whose nodal curve lies on the y-axis; then Theorem 7 implies $\lambda_2 > \lambda_2$, which is absurd. □

Example. Let $\Omega = \{(x, y): (x^2/a^2) + (y^2/b^2) < 1\}$, $a > b$. Then $\Omega = \Omega_f$, where $f = b\sqrt{1 - (x^2/a^2)}$ and f satisfies the condition stated in Theorem 7. Thus the second eigenvalue λ_2 of Ω is simple and the nodal curve of corresponding eigenfunction lies

on the y-axis. Furthermore, Payne showed that $\lambda_2 \geqq [\pi/(4\int_\Omega x^2\,dx\,dy)]^{1/2} j_1^2$, where j_1 is the first positive zero of the Bessel function $J_1(x)$.

REGULARITY OF THE SOLUTION OF ELLIPTIC PROBLEMS WITH PIECEWISE ANALYTIC DATA. PART I. BOUNDARY VALUE PROBLEMS FOR LINEAR ELLIPTIC EQUATION OF SECOND ORDER*

I. BABUŠKA† AND B. Q. GUO‡

Abstract. This paper is the first in a series devoted to the analysis of the regularity of the solution of elliptic partial differential equations with piecewise analytic data. The present paper analyzes the case of linear, second order partial differential equation of elliptic type. It concentrates on the case when the domain $\Omega \subset \mathbf{R}^2$ is a polygon, boundary conditions are of changing type and coefficients are analytic on $\bar{\Omega}$. The main result states that the solution belongs to a countably normed space based on weighted Sobolev spaces of all orders with weights located in the vertices of the domain and at the points where the type of boundary conditions changes.

These results are essential for the design and the analysis of the *h-p* version of the finite element method for solving the elliptic differential equations of structural engineering (see [6], [11], [12]).

Key words. elliptic equation with piecewise analytic data, Dirichlet problem, corner singularities

AMS(MOS) subject classifications. 35B65, 35D10, 35G15, 35J05

1. The preliminaries.

1.1. Introduction. In applications, as for example in structural mechanics, the problems of elliptic partial differential equations are typically characterized by piecewise analytic input data. The boundary of the domain is piecewise analytic with corners and edges; the coefficients of the equation are piecewise analytic with interfaces having corners and edges. The type of boundary condition is abruptly changing but they are piecewise analytic, etc.

The regularity theory is typically developed in the framework of Sobolev spaces. We refer here, for example, to the survey [15] and to the monographs [10], [14] addressing the problem of the unsmooth boundary. We refer to [2] for more classical results. Results mentioned above do not characterize sufficiently accurately the class of solutions of problems of applications. The detailed knowledge of the properties of the solutions of problems of applications is essential for the design and analysis of effective numerical methods for solving these problems. We mention here, for example, the *h-p* version of the finite element method which was recently developed and is very successfully used in practice.[1] For more about the theory and practice of the *h-p* version we refer to [6], [17], [18].

The solution of the problem with piecewise analytic data is analytic with the exception of special areas of the domain, where the solution has singular character. Typically it happens in the neighborhood of the corners of the domain, places where the type of the boundary condition changes, etc.

This paper, which is the first one in a series of papers, deals with the problem of characterizing the regularity of the solution of the linear partial differential equation of elliptic type on a polygonal domain. It addresses the case of constant and analytic

coefficients. The main tool of the characterization of the solution is the theory of countably normed spaces based on weighted Sobolev spaces of all orders, where the weights are placed in the vertices of the domain. The main result is that the solution is from the set $B^2_\beta(\Omega)$ of functions which belong to the weighted Sobolev spaces $H^{k,2}_\beta(\Omega)$ for $k=2,\cdots$, and $\|u\|_{H^{k,2}_\beta(\Omega)} \leqq Cd^{k-2}(k-2)!$ with C and d independent of k. The main theorem of the paper is Theorem 2.1 addressing the case of the Poisson equation and its generalization for the general equation with analytic coefficients is given in Theorem 3.1. Theorem 3.1 can be further generalized for the case when the coefficients have singular behavior in the neighborhood of the corners too. (Problems of this type are important in applications when nonlinear equations are considered.) Section 1 gives basic notation and preliminaries. Section 2 deals with the regularity of the solution of the Poisson problem. Section 3 deals with the general equation and § 4, the Appendix, proves some technical lemmas used in the paper.

1.2. Notation. Throughout this paper we shall denote integers by i, j, k, l, m, n. By $\mathbf{R}^1$ and $\mathbf{R}^2$ we shall denote the one- and two-dimensional Euclidean space. If $Q \subset \mathbf{R}^1$, respectively, $Q \subset \mathbf{R}^2$, then $\bar{Q}$ denotes the closure of Q in $\mathbf{R}^1$, respectively, in $\mathbf{R}^2$.

By Ω we denote the polygonal domain in $\mathbf{R}^2$ with boundary $\partial\Omega = \Gamma$, the vertices A_i, $i=1,\cdots,M$, and Γ_i, $i=1,\cdots,M$ the open edges of $\partial\Omega$ connecting A_i and A_{i+1} ($A_1 = A_{M+1}$). Obviously we have $\partial\Omega = \bigcup_{i=1}^M \bar{\Gamma}_i$. By ω_i we denote the measure of the interior angle of Ω at A_i. We allow also $\omega_i = 2\pi$, and $\omega_i = \pi$ and the polygon Ω has hence to be understood in this generalized sense. Let further $\Gamma = \bar{\Gamma}^0 + \bar{\Gamma}^1$, $\Gamma^0 = \bigcup_{i\in\mathscr{D}} \bar{\Gamma}_i$, $\Gamma^1 = \Gamma - \Gamma^0$ where $\mathscr{D}$ is some subset of set $\{1, 2, \cdots, M\}$. Γ^0 will be sometimes referred to as Dirichlet boundary and Γ^1 as Neumann boundary.

By $H^m(\Omega)$ (resp. $H^m(Q)$), $m \geqq 0$, m integer, we denote the Sobolev space of functions with square integrable derivatives of order $\leqq m$ on Ω (resp. Q) furnished with the norm:

$$\|u\|^2_{H^m(\Omega)} = \sum_{0\leqq|\alpha|\leqq m} \|D^\alpha u\|^2_{L_2(\Omega)},$$

$$\alpha = (\alpha_1, \alpha_2), \quad \alpha_i \geqq 0, \quad \text{integers}, \quad i = 1, 2,$$

$$|\alpha| = \alpha_1 + \alpha_2,$$

$$D^\alpha u = \frac{\partial^{|\alpha|} u}{\partial x_1^{\alpha_1} \partial x_2^{\alpha_2}} = u_{x_1^{\alpha_1} x_2^{\alpha_2}}.$$

As usual $H^0(\Omega) = L_2(\Omega)$. Further let

$$H^1_0(\Omega) = \{u \in H^1(\Omega) \,|\, u = 0 \text{ on } \Gamma^0\}$$

and

$$|u|^2_{H^m(\Omega)} = \sum_{|\alpha|=m} \|D^\alpha u\|^2_{H^0(\Omega)},$$

$$|D^m u|^2 = \sum_{|\alpha|=m} |D^\alpha u|^2.$$

By $r_i(x) = |x - A_i|$, $i = 1, \cdots, M$, we shall denote the Euclidean distance between x and the vertex A_i of Ω. Let $\beta = (\beta_1, \beta_2, \cdots, \beta_M)$ be an M-tuple of real numbers, $0 < \beta_i < 1$, $i = 1, \cdots, M$. For any integer k let $\beta \pm k = (\beta_1 \pm k, \cdots, \beta_M \pm k)$. Further we denote $\Phi_\beta(x) = \prod_{i=1}^M r_i^{\beta_i}(x)$ and $\Phi_{\beta\pm k} = \prod_{i=1}^M r_i^{\beta_i \pm k}(x)$.

By $H_\beta^{m,l}(\Omega)$, $m \geqq l \geqq 0$, l an integer ($H_\beta^{m,0}(\Omega) = H_\beta^m(\Omega)$) we denote the completion of the set of all infinitely differentiable functions under the norm

$$\|u\|^2_{H_\beta^{m,l}(\Omega)} = \|u\|^2_{H^{l-1}(\Omega)} + \sum_{\substack{|\alpha|=k \\ k=l}}^{m} \| |D^\alpha u| \Phi_{\beta+k-l} \|^2_{L_2(\Omega)}, \qquad l \geqq 1,$$

$$\|u\|^2_{H_\beta^{m,0}(\Omega)} = \|u\|^2_{H_\beta^m(\Omega)} = \sum_{\substack{|\alpha|=k \\ k=0}}^{m} \| |D^\alpha u| \Phi_{\beta+k} \|^2_{L_2(\Omega)}, \qquad l = 0.$$

For $m = l = 0$ we shall write $H_\beta^{0,0}(\Omega) = L_\beta(\Omega)$. The space $H_\beta^{m,2}(\Omega)$ was introduced and widely used in [5].

For $0 < \delta \leqq \infty$, $0 < \omega \leqq 2\pi$ let

$$S = S_\delta^\omega = \{(r, \theta) \mid 0 < r < \delta, 0 < \theta < \omega\},$$

$$\mathscr{D}^\alpha u = \frac{\partial^{|\alpha|} u}{\partial r^{\alpha_1} \partial \theta^{\alpha_2}} = u_{r^{\alpha_1}\theta^{\alpha_2}}$$

and

$$|\mathscr{D}^m u|^2 = \sum_{|\alpha|=m} |r^{-\alpha_2} \mathscr{D}^\alpha u|^2.$$

For $0 < \beta < 1$, $m \geqq l \geqq 1$

$$\mathscr{H}_\beta^{m,l}(S) = \left\{ u \,\middle|\, \|u\|^2_{H^{l-1}(S)} + \sum_{l \leqq |\alpha| \leqq m} \|r^{\alpha_1 - l + \beta} \mathscr{D}^\alpha u\|^2_{L_2(S)} = \|u\|^2_{\mathscr{H}_\beta^{m,l}(S)} < \infty \right\},$$

and $m \geqq 0$

$$\mathscr{H}_\beta^{m,0}(S) = \left\{ u \,\middle|\, \sum_{0 \leqq |\alpha| \leqq m} \|r^{\alpha_1 + \beta} \mathscr{D}^\alpha u\|^2_{L_2(S)} = \|u\|^2_{\mathscr{H}_\beta^{m,0}(S)} < \infty \right\}.$$

Obviously

$$\mathscr{H}_\beta^{0,0}(S) = H_\beta^{0,0}(S) = \mathscr{L}_\beta(S)$$

and

$$\mathscr{H}_\beta^{1,1}(S) = H_\beta^{1,1}(S).$$

We will now show that $\mathscr{H}_\beta^{2,2}(S) = H_\beta^{2,2}(S)$.

LEMMA 1.1. *Let $0 < \delta < \infty$. Then the spaces $\mathscr{H}_\beta^{2,2}(S)$ and $H_\beta^{2,2}(S)$ with $\Phi_\beta = r^\beta$ are equivalent.*

Proof. Observe that

$$u_{x_1} = u_r \cos\theta - u_\theta \frac{\sin\theta}{r},$$

$$u_{x_1 x_1} = u_{rr} \cos^2\theta - u_{r\theta} \frac{\sin 2\theta}{r} + \frac{1}{r^2} u_{\theta^2} \sin^2\theta$$

$$+ \frac{1}{r} u_r \sin^2\theta + \frac{1}{r^2} u_\theta \sin 2\theta.$$

Hence

$$\|u_{x_1 x_1}\|_{\mathscr{L}_\beta(S)} \leqq \sum_{|\alpha|=2} \|r^{\alpha_1 - 2} \mathscr{D}^\alpha u\|_{\mathscr{L}_\beta(S)} + \sum_{|\alpha|=1} \|r^{\alpha_1 - 2} \mathscr{D}^\alpha u\|_{\mathscr{L}_\beta(S)}.$$

By Lemma A.2 (see Appendix) we have for $|\alpha|=1$

$$\|r^{\alpha_1-2}\mathscr{D}^{\alpha}u\|_{\mathscr{L}_\beta(S)} \leqq C(\delta)\left[\sum_{|\alpha'|=2}\|r^{\alpha_1'-2}\mathscr{D}^{\alpha'}u\|_{\mathscr{L}_\beta(S)}+\|u\|_{H^1(S)}\right]$$

and hence

$$\|u_{x_1x_1}\|_{\mathscr{L}_\beta(S)} \leqq C\|u\|_{\mathscr{H}^{2,2}_\beta(S)}.$$

Similarly, we have the same relation for $u_{x_1x_2}$ and $u_{x_2x_2}$, and hence $H^{2,2}_\beta(S)\subset\mathscr{H}^{2,2}_\beta(S)$. The other direction follows directly. □

Later we will investigate the case S^ω_δ when $\delta=\infty$. In this case we will write Q instead of S^ω_δ.

LEMMA 1.2. *Let Ω be the polygon, then for $j=0, 1$ we have*

$$\int_\Omega \Phi^2_{-1+\beta}|u_{x_1^{1-j}x_2^j}|^2\,dx_1\,dx_2 \leqq C\|u\|^2_{H^{2,2}_\beta(\Omega)}, \tag{1.1a}$$

$$\int_\Omega \Phi^2_{-1+\beta}r_i^{-2j}|u_{r_i^{1-j}\theta_i^j}|^2 r_i\,dr_i\,d\theta_i \leqq C\|u\|^2_{H^{2,2}_\beta(\Omega)}, \tag{1.1b}$$

where (r_i, θ_i) are polar coordinates with respect to A_i, $1\leqq i\leqq M$.

Proof. We can write

$$\Omega=\bigcup_{i=1}^{M} S^{\omega_i}_{\delta_i}(A_i)\cup R,$$

$$R=\Omega-\sum_{i=1}^{M} S^{\omega_i}_{\delta_i/2}(A_i)$$

where $S^{\omega_i}_{\delta_i}(A_i)\subset\Omega$ are sectors with the origin in A_i such that $S^{\omega_i}_{\delta_i}(A_i)\cap S^{\omega_i}_{\delta_j}(A_j)=\varnothing$ for $i\neq j$ and ω_i is the interior angle at A_i. Obviously (1.1a, b) hold on R. Lemma A.3 yields (1.1a) on $S^{\omega_i}_{\delta_i}(A_i)$, Lemma A.2 and Lemma 1.1 yield (1.1b) on $S^{\omega_i}_{\delta_i}(A_i)$. □

We also recall the spaces $W^k_\beta(S)$ introduced by Kondrat'ev (see [14], [15])

$$W^k_\beta(S)=\left\{u\,\middle|\,\sum_{0\leqq|\alpha|\leqq k}\|r^{\beta-k+\alpha_1}\mathscr{D}^{\alpha}u\|_{L_2(S)}=\|u\|^2_{W^k_\beta(S)}<\infty\right\}.$$

Finally let

$$D=\{\tau,\theta\,|\,-\infty<\tau<\infty, 0<\theta<\omega\}$$

and for $h>0$ and $k\geqq 0$ an integer define

$$\mathscr{H}^k_h(D)=\left\{u\,\middle|\,\sum_{0\leqq|\alpha|\leqq k}\int_D e^{2h\tau}|D^\alpha u|^2\,d\tau\,d\theta=\|u\|^2_{\mathscr{H}^k_h(D)}<\infty\right\}.$$

We will write also $\mathscr{H}^0_h(F)=\mathscr{L}_h(D)$.

1.3. The space $\psi^l_\beta(\Omega)$ and $B^l_\beta(\Omega)$. For l an integer $0\leqq l\leqq 2$ let

$$\psi^l_\beta(\Omega)=\{u(x)\,|\,u\in H^{m,l}_\beta(\Omega), m\geqq l\} \tag{1.2}$$

and

$$B^l_\beta(\Omega)=\{u(x)\,|\,u\in\psi^l_\beta(\Omega), \||D^\alpha u|\Phi_{\beta+k-l}\|_{L_2(\Omega)}\leqq Cd^{k-l}(k-l)! \text{ for } |\alpha|=k=l, l+1,\cdots, d\geqq 1, C \text{ independent of } k\}. \tag{1.3}$$

For $l=0$ we shall write $B_\beta(\Omega)$ instead $B^0_\beta(\Omega)$. Constants C and d in (1.3) depend on u.

The space $B^l_\beta(\Omega)$ was defined in Cartesian coordinates. There is also an equivalent definition of $B^l_\beta(\Omega)$ in polar coordinates.

Let (r_i, θ_i) be the polar coordinates with respect to A_i, $i = 1, \cdots, M$ as before.

THEOREM 1.1. *Let* $0 \leqq l \leqq 2$. *Then*

$$\| |D^\alpha u| \Phi_{k-l+\beta} \|_{L_2(\Omega)} \leqq C d^{k-l}(k-l)!, \qquad |\alpha| = k,\ k \geqq l \tag{1.4}$$

if and only if

$$\left(\int_\Omega |\mathscr{D}_i^{\alpha'} u|^2 r_i^{-2\alpha'_2} \Phi^2_{k'-l+\beta} r_i \, dr_i \, d\theta_i \right)^{1/2} \leqq C_i d_i^{k'-l}(k'-l)! \tag{1.5}$$

holds for all $l \leqq |\alpha'| = k' \leqq k$, $\alpha' = (\alpha'_1, \alpha'_2)$ *and* $i = 1, \cdots, M$. *By* $\mathscr{D}_i^\alpha u$ *we denoted differentiation with respect to the polar coordinates* (r_i, θ_i).

Proof. We first prove that if (1.4) holds then (1.5) holds for every $i = 1, \cdots, M$. To this end we fix i and will omit writing the index i. Then

$$u_{r^k} = \sum_{j=0}^{k} \binom{k}{j} u_{x_1^{k-j} x_2^j} \cos^{k-j}\theta \sin^j \theta. \tag{1.6}$$

Hence

$$\begin{aligned} \left(\int_\Omega |u_{r^k}|^2 \Phi^2_{k-l+\beta} r \, dr \, d\theta \right)^{1/2} &\leqq \sum_{j=0}^{k} \binom{k}{j} \| u_{x_1^{k-j} x_2^j} \Phi_{k-l+\beta} \|_{L_2(\Omega)} \\ &\leqq C_1 2^k d^{k-l}(k-l)! \\ &= C_2 (2d)^{k-l}(k-l)! \end{aligned} \tag{1.7}$$

and (1.5) is proven for $\alpha'_2 = 0$.

We show now by induction that for any $k \geqq 1$:

$$u_{\theta^k} = \sum_{m=1}^{k} r^m \sum_{j=0}^{m} \sum_{\substack{l_1, l_2 \geqq 0 \\ l_1 + l_2 = m}} a^{(k)}_{m,j,l_1,l_2} \sin^{l_1}\theta \cos^{l_2}\theta \, u_{x_1^{m-j} x_2^j}, \tag{1.8a}$$

$$A^{(k)}_m = \sum_{j=0}^{m} \sum_{\substack{l_1, l_2 \geqq 0 \\ l_1 + l_2 = m}} |a^{(k)}_{m,j,l_1,l_2}| \leqq 4^k \frac{k!}{m!}. \tag{1.8b}$$

Suppose that (1.8) holds for $k = n-1$. Then

$$\begin{aligned} u_{\theta^n} = \sum_{m=1}^{n-1} r^m \sum_{j=0}^{m} \sum_{\substack{l_1, l_2 \geqq 0 \\ l_1 + l_2 = m}} a^{(n-1)}_{m,j,l_1,l_2} \\ \cdot [-r \sin^{l_1+1}\theta \cos^{l_2}\theta \, u_{x_1^{m-j+1} x_2^j} + r \sin^{l_1}\theta \cos^{l_2+1}\theta \, u_{x_1^{m-j} x_2^{j+1}} \\ + (l_1 \sin^{l_1-1}\theta \cos^{l_2+1}\theta - l_2 \sin^{l_1+1}\theta \cos^{l_2-1}\theta) u_{x_1^{m-j} x_2^j}]. \end{aligned}$$

Comparing the coefficients we get

$$\begin{aligned} a^{(n)}_{m,j,l_1,l_2} = -a^{(n-1)}_{m-1,j,l_1-1,l_2} + a^{(n-1)}_{m-1,j-1,l_1,l_2-1} \\ + (l_1+2) a^{(n-1)}_{m,j,l_1+1,l_2-1} - (l_2+2) a^{(n-1)}_{m,j,l_1-1,l_2+1}. \end{aligned}$$

Thus

$$A^{(n)}_m \leqq 2(1+m) A^{(n-1)}_m + 2A^{(n-1)}_{m-1}.$$

Using the induction assumption we get for $n = k$ and $m \leqq k$

$$A^k_m \leqq 4^k \frac{k!}{m!}$$

and (1.8b) is proven.

Let $D = \max(1, \operatorname{diam}\Omega)$. Then for $k \geqq 1$, $0 \leqq l \leqq 1$

$$\left(\int_\Omega r^{-2k} |u_{\theta^k}|^2 \Phi^2_{k-l+\beta} r\, dr\, d\theta\right)^{1/2}$$

$$\leqq \sum_{m=1}^{k} \sum_{j=0}^{m} \sum_{\substack{l_1,l_2 \geqq 0 \\ l_1+l_2=m}}^{m} |a^{(k)}_{m,j,l_1,l_2}| D^{(k+1-l)(M-1)} \|\Phi_{m-l+\beta} u_{x_1^{m-j} x_2^j}\|_{L_2(\Omega)}$$

$$\leqq C D_1^{k-l} \sum_{m=1}^{k} A^{(k)}_m d^{m-l} (m-l)! \tag{1.9}$$

$$\leqq C D_2^{k-l} \sum_{m=1}^{k} 4^k \frac{k!}{m!} (m-l)!$$

$$\leqq C D_3^{k-l} (k-l)!$$

where C and D_3 are independent of k.

By Lemma 1.2 we have for $j = 0, 1$

$$\int_\Omega \Phi^2_{-1+\beta} |u_{x_1^{1-j} x_2^j}|^2\, dx \leqq C \|u\|^2_{H^{2,2}_\beta(\Omega)} \leqq C. \tag{1.10}$$

Hence (1.9) holds for all $k \geqq l$, $l \leqq 2$, and (1.5) holds for $\alpha_1' = 0$. Combining the arguments we have used above we get (1.5) in full generality.

(2) We will now show that if (1.5) holds for every i, then (1.4) holds too. First we will show that for any $k \geqq 1$

$$u_{x_1^k} = \sum_{m=1}^{k} \sum_{j=0}^{m} \sum_{\substack{l_1,l_2 \geqq 0 \\ l_1+l_2=k}} b^{(k)}_{m,j,l_1,l_2} \sin^{l_1}\theta \cos^{l_2}\theta\, r^{-(k-m+j)} u_{r^{m-j}\theta^j}, \tag{1.11a}$$

$$B^{(k)}_m = \sum_{j=0}^{m} \sum_{\substack{l_1,l_2 \geqq 0 \\ l_1+l_2=k}} |b^{(k)}_{m,j,l_1,l_2}| \leqq 5^k \frac{k!}{m!}. \tag{1.11b}$$

It is easy to check that (1.11) holds for $k = 0, 1$. Analogously as in the first part we get

$$b^{(k)}_{m,j,l_1,l_2} = b^{(k-1)}_{m-1,j,l_1,l_2-1} - b^{(k-1)}_{m-1,j-1,l_1-1,l_2}$$
$$-(l_1+2) b^{(k-1)}_{m,j,l_1,l_2-1} + (l_2+2) b^{(k-1)}_{m,j,l_1-1,l_2} - (k-m+j) b^{(k-1)}_{m,j,l_1,l_2-1}$$

and hence

$$B^{(k)}_m \leqq 2B^{(k-1)}_{m-1} + 2kB^{(k-1)}_m + kB^{(k-1)}_m \leqq 2B^{(k-1)}_{m-1} + 3kB^{(k-1)}_m.$$

Using the induction hypothesis we get (1.11b). Using (1.11) we get for $k \geqq l$ and $l \geqq 1$

$$\left(\int_\Omega |u_{x_1^k}|^2 \Phi^2_{k-l+\beta}\, dx\right)^{1/2} \leqq C D^{(k-l)} \sum_{m=1}^{k} B^{(k)}_m d^{m-l} (m-l)!$$
$$\leqq C D_2^{(k-l)} (k-l)! \tag{1.12}$$

where D_2 and C are independent of k. For $j = 0, 1$ we have by Lemma 1.2

$$\int_\Omega \Phi^2_{-1+\beta} r_i^{-2j} |u_{r_i^{1-j}\theta_i^j}|^2 r_i\, dr_i\, d\theta_i \leqq C \|u\|^2_{H^{2,2}_\beta(\Omega)} \leqq \tilde{C}.$$

Hence (1.12) holds for $0 \leqq l \leqq 2$, $k \geqq l$ and (1.4) holds for $\alpha_2 = 0$. The general case can be proven quite analogously. □

Theorem 1.1 yields an equivalent definition of $B^l_\beta(\Omega)$, $0 \leqq l \leqq 2$

$$B^l_\beta(\Omega) = \left\{ u \in \psi^l_\beta(\Omega) \left| \left(\int_\Omega r_i^{-2\alpha_2} \Phi^2_{k-l+\beta} |\mathscr{D}_i^\alpha u|^2 r_i \, dr_i \, d\theta_i \right)^{1/2} \leqq C d^{k-l} (k-l)! \right. \right. \tag{1.13}$$
$$\left. \text{for any } k \geqq l \text{ and } |\alpha| = k;\ C \text{ and } d \text{ independent of } k,\ i = 1, \cdots, M \right\}$$

where (r_i, θ_i) are polar coordinates with the origin in A_i and $\mathscr{D}_i^\alpha u = u_{r_i^{\alpha_1} \theta_i^{\alpha_2}}$. In what will follow both definitions will be used interchangeably.

Remark 1. Let $S = \{r, \theta \,|\, 0 < r < 1, 0 < \theta < \omega\}$. Then $u_1 = r^\alpha \sin\theta$ and $u_2 = r^\alpha \operatorname{lgr} \sin\theta$, $0 < \alpha < 1$ belong to $B^2_\beta(S)$, $\beta \in (1-\alpha, 1)$ but not to $B^2_{1-\alpha}(S)$.

1.4. The spaces $H^{m-1/2}(\gamma)$ and $H^{m-1/2,l-1/2}_\beta(\gamma)$. Let $Q \subset R^2$ be an open bounded set with a piecewise analytic boundary ∂Q and let γ be part of, or the whole boundary ∂Q. We define $H^{m-1/2}(\gamma)$, $m \geqq 1$ as the set of all functions φ on γ such that there exists $f \in H^m(\gamma)$, with $\varphi = f|_\gamma$. The norm is defined by

$$\|\varphi\|_{H^{m-1/2}(\gamma)} = \inf \|f\|_{H^m(Q)}$$

where the infimum is taken over all functions $f \in H^m(Q)$ with $f = \varphi$ on γ.

Suppose that $A_i \in \partial Q$ or $A_i \notin \bar{Q}$, $i = 1, 2, \cdots, M$, then we define the spaces $H^{m,l}_\beta(Q)$, $l \geqq 0$ as in § 1.2. Let $H^{m-1/2,l-1/2}_\beta(\gamma)$, $m \geqq 1$, $l \geqq 0$ be the set of all functions φ on γ such that there exists $f \in H^{m,l}_\beta(Q)$ with $\varphi = f|_\gamma$ and

$$\|\varphi\|_{H^{m-1/2,l-1/2}_\beta(\gamma)} = \inf \|f\|_{H^{m,l}_\beta(Q)}.$$

where the infimum is taken over all functions $f \in H^{m,l}_\beta(\Omega)$ such that $f|_\gamma = \varphi$.

By $L_2(\gamma)$ we denote the space of the square integrable functions on γ. We also define the space $B^l_\beta(Q)$, $0 \leqq l \leqq 2$ analogously as in (1.2) replacing Ω by Q. Finally let $B^{l-1/2}_\beta(\gamma)$, $0 \leqq l \leqq 2$, be the space of all functions φ for which there exists $f \in B^l_\beta(Q)$ such that $f = \varphi$ on γ.

Remark 2. Although $B^l_\beta(Q)$, $0 \leqq l \leqq 1$ is not a subspace of $H^1(Q)$ the trace of $f \in B^l_\beta(Q)$ on γ obviously exists.

Remark 3. The norms $\|\cdot\|_{H^{m-1/2}(\gamma)}$ and $\|\cdot\|_{H^{m-1/2,l-1/2}_\beta(\gamma)}$ obviously depend on Q.

Remark 4. In what will follow Q will often be the polygonal domain and γ some of its edges. Although the set $H^{m-1/2,l-1/2}_\beta(\gamma)$ is characterized only by β_i associated to the vertices of the edges γ, we are defining the space $H^{m-1/2,l-1/2}_\beta(\gamma)$ depending on $\beta = (\beta_1, \cdots, \beta_M)$.

2. Regularity of the solution of the Poisson problem on a polygonal domain. In this chapter we will discuss the regularity of the problem

$$\begin{aligned} -\Delta u &= f \quad \text{on } \Omega, \\ u &= g^0 \quad \text{on } \Gamma^0, \\ \frac{\partial u}{\partial n} &= g^1 \quad \text{on } \Gamma^1 \end{aligned} \tag{2.1}$$

where

$$\Gamma^0 = \bigcup_{i \in \mathscr{D}} \bar{\Gamma}_i, \qquad \Gamma^1 = \Gamma - \Gamma^0.$$

Γ^0 will be called the Dirichlet boundary, Γ^1 the Neumann boundary. If $\Gamma^0 = \Gamma$ (respectively $\Gamma^1 = \Gamma$), then we will speak about the Dirichlet (respectively Neumann) problem. If $\Gamma^0 \neq \Gamma$ and $\Gamma^1 \neq \Gamma$, then we will speak about the mixed problem. The main theorem of this chapter is:

THEOREM 2.1. *Let* $f \in B^0_\beta(\Omega)$, $g^i \in B^{3/2-i}_\beta(\Gamma^i)$, $i=0,1$, $\beta=(\beta_1,\cdots,\beta_M)$, $0<\beta_i<1$, $\beta_i>1-\pi/\omega_i$ (*respectively* $\beta_i>1-\pi/2\omega_i$ *if Dirichlet and Neumann boundary conditions are imposed on the edges* Γ_{i-1}, Γ_i, $\bar\Gamma_{i-1}\cap\bar\Gamma_i=A_i$) *and let* $\Gamma^0\neq\varnothing$. *Then the problem* (2.1) *has a unique solution* u *in* $H^1(\Omega)$ *and* $u\in B^2_\beta(\Omega)$. □

Remark 1. If $\Gamma^0=\varnothing$ then the theorem still holds provided that f and g satisfy the condition (2.38) and the uniqueness is understood modulo a constant function.

Remark 2. g^1 should be understood as the vector $g^1=(g^1_1, g^1_2,\cdots, g^1_p)$; p is an integer $\leqq M$ such that $g^1_l=G^1_l|_{\Gamma_{i_l}}$, $\cup_{l=1}^p \Gamma_{i_l}=\Gamma^1$, $G^1_l\in B^1_\beta(\Omega)$, and $\|G^1\|^2_{H^{k,1}_\beta(\Omega)}=\sum_{l=1}^p \|G^1_l\|^2_{H^{k,1}_\beta(\Omega)}$.

Remark 3. It can be seen from the proof of the theorem that if $f\in H^{k,0}_\beta(\Omega)$, $G^j\in H^{k+2-j,2-j}_\beta(\Omega)$, $j=0,1$, $\beta_i>1-\pi/\omega_i$, (respectively $\beta_i>1-\pi/2\omega_i$) and $k\geqq 0$, then the solution of (2.1) exists in $H^{k+2,2}_\beta$ and

$$\|u\|_{H^{k+2,2}_\beta(\Omega)}\leqq C(k)\left(\|f\|_{H^{k,0}_\beta(\Omega)}+\sum_{j=0,1}\|G^j\|_{H^{k+2-j,2-j}_\beta(\Omega)}\right)$$

which is a kind of the "shift" theorem. Usually the shift theorem is expressed in the terms of usual Sobolev spaces so that

$$u=w+\sum_{i=1}^{m(k)} C_i\varphi_i$$

where φ_i are singular functions and for w there is the same shift theorem as for the domain with smooth boundary and without specific estimates of various constants in dependence on k. Theorem 2.1 is related to the known results but the authors were unable to find the theorem characterizing the solution in the framework of the countable normed space $B^2_\beta(\Omega)$ which is essential for applications.

Remark 4. The singular functions φ_i are associated to the vertices A_i, $\varphi_i=r^\alpha 1g^q r\psi(\theta)$, $\alpha>0$, $q\geqq 0$ integer, and $\psi(\theta)$ is an analytic function of θ. (r,θ) are the polar coordinates with the origin at A_i. Function φ_i belongs to the same space $B^2_\beta(\Omega)$, $\beta\in(1-\alpha,1)$ independent of q (see Remark 1 in § 1).

Remark 5. The proof of the theorem utilizes simple expansions of the solution, although this reasoning is very special. This approach is used to illuminate the main idea which will be used in the second paper of the series in an abstract form without using explicitly the mentioned expansion argument.

2.1. Auxiliary problems on the cone and the strip. Let

$$Q=S^\omega_\infty=\{r,\theta\,|\,0<r<\infty,\ 0<\theta<\omega\},$$
$$\Gamma_1=\{r,\theta\,|\,0<r<\infty,\ \theta=0\},$$
$$\Gamma_2=\{r,\theta\,|\,0<r<\infty,\ \theta=\omega\},$$

and

$$D=\{\tau,\theta\,|\,-\infty<\tau<\infty,\ 0<\theta<\omega\},$$
$$\tilde\Gamma_1=\{\tau,\theta\,|\,-\infty<\tau<\infty,\ \theta=0\},$$
$$\tilde\Gamma_2=\{\tau,\theta\,|\,-\infty<\tau<\infty,\ \theta=\omega\}.$$

The spaces $\mathscr{K}^{k,l}_\beta(Q)$, $0\leqq l\leqq 2$ and $\mathscr{K}^k_h(D)$, $k\geqq 0$, we defined in § 1.2. Let $C^\infty_\#(Q)$ be the collection of infinitely differentiable functions on $\bar Q$ such that:

for any $u\in C^\infty_\#(Q)$ there exists a positive number $A=A(u)$ such that u vanishes on $Q-Q_A$ where $Q_A=\{(r,\theta)\,|\,1/A<r<A,\ 0<\theta<\omega\}$.

Analogously we denote by $C^\infty_{\#}(D)$ the collection of infinitely differentiable functions on $\bar{D}$ such that for any $u \in C^\infty_{\#}(D)$ there exists $A = A(u) > 0$ such that u vanishes on $D - D_A$ where $D_A = \{(\tau, \theta) \mid -A < \tau < A,\ 0 < \theta < \omega\}$. It is not difficult to show (see [12]):

LEMMA 2.1. *$C^\infty_{\#}(Q)$ (respectively $C^\infty_{\#}(D)$) is dense in $\mathcal{H}^{k,l}_\beta(Q)$ (respectively $\mathcal{H}^k_h(D)$), $k \geqq l \geqq 0$.* □

LEMMA 2.2. *The space $\mathcal{H}^{k,l}_\beta(Q)$ and $\mathcal{H}^k_h(D)$ are complete.* □

Consider now the following problem on Q,

$$
\begin{aligned}
&-\Delta u = -\left(\frac{\partial^2 u}{\partial r^2} + \frac{1}{r}\frac{\partial u}{\partial r} + \frac{1}{r^2}\frac{\partial^2 u}{\partial \theta^2}\right) = f \quad \text{on } Q, \\
&u|_{\theta=0} = g^0 = G^0|_{\theta=0}, \\
&\left.\frac{\partial u}{\partial n}\right|_{\theta=\omega} = g^1 = G^1|_{\theta=\omega}
\end{aligned}
\tag{2.2}
$$

where g^0 and g^1 are the traces of functions G^0 and G^1 defined on Q. Introducing new variable

$$\tau = \ln \frac{1}{r}$$

we transform the problem (2.2) into the problem on D

$$-\left(\frac{\partial^2 \tilde{u}}{\partial \tau^2} + \frac{\partial^2 \tilde{u}}{\partial \theta^2}\right) = \tilde{f}(\tau, \theta), \tag{2.3a}$$

$$
\begin{aligned}
&\tilde{u}|_{\theta=0} = \tilde{g}^0 = \tilde{G}^0|_{\theta=0}, \\
&\left.\frac{\partial \tilde{u}}{\partial \theta}\right|_{\theta=\omega} = \tilde{g}^1 = \tilde{G}^1|_{\theta=\omega}
\end{aligned}
\tag{2.3b}
$$

where

$$
\begin{aligned}
&\tilde{u}(\tau, \theta) = u(e^{-\tau}, \theta), \tilde{f}(\tau, \theta) = e^{-2\tau} f(e^{-\tau}, \theta), \\
&\tilde{G}^l(\tau, \theta) = e^{-l\tau} G^l(e^{-\tau}, \theta), \qquad l = 0, 1.
\end{aligned}
$$

LEMMA 2.3. *Let $f \in \mathcal{L}_h(D)$, $\tilde{G}^i \in \mathcal{H}^{2-i}_h(D)$, $i = 0, 1$, $0 < h < \pi/2\omega$, then the solution $\tilde{u}$ of (2.3) exists in $\mathcal{H}^2_h(D)$, is unique and for $0 \leqq |\alpha| \leqq 2$:*

$$
\begin{aligned}
\|D^\alpha \tilde{u}\|^2_{\mathcal{L}_h(D)} &= \int_D e^{2h\tau} |D^\alpha \tilde{u}|^2 \, d\tau \, d\theta \\
&\leqq C\left[\|\tilde{f}\|^2_{\mathcal{L}_h(D)} + \sum_{i=0}^{1} \|\tilde{G}^i\|^2_{\mathcal{H}^{2-i}_h(D)}\right],
\end{aligned}
\tag{2.4}
$$

where

$$D^\alpha \tilde{u} = \frac{\partial^{|\alpha|} \tilde{u}}{\partial \tau^{\alpha_1} \partial \theta^{\alpha_2}}$$

and C is independent of $\tilde{f}$ and $\tilde{G}^i$.

Proof. (1) Because of Lemmas 2.1 and 2.2, we may assume that $\tilde{f}, \tilde{G}^i \in C^\infty_{\#}(D)$. Denote by $\hat{f}(\lambda, \theta) = \mathcal{F}(\tilde{f}) = 1/\sqrt{2\pi} \int_{-\infty}^{+\infty} e^{-i\lambda\tau} f(\tau, \theta)\, d\tau$, $\hat{G}^i(\lambda, \theta) = \mathcal{F}(\tilde{G}^i)$ the Fourier transform (in τ) of $\tilde{f}$ and $\tilde{G}^i$.

Because $\tilde{f}, \tilde{G}^i \in C^\infty_{\#}(D)$ the Fourier transform for all λ. By the basic properties of the Fourier transform we get with $\lambda = \xi + ih$, $-\infty < \xi < \infty$:

$$
\begin{aligned}
&-\frac{\partial \hat{u}}{\partial \theta^2}(\lambda, \theta) + \lambda^2 \hat{u}(\lambda, \theta) = \hat{f}(\lambda, \theta) \quad \text{for } \theta \in I = (0, \omega), \\
&\hat{u}(\lambda, \theta)|_{\theta=0} = \hat{g}^0 = \hat{G}^0(\lambda, \theta)|_{\theta=0}, \\
&\frac{\partial \hat{u}}{\partial \theta}(\lambda, \theta)|_{\theta=0} = \hat{g}^1 = \hat{G}^1(\lambda, \theta)|_{\theta=\omega}.
\end{aligned}
\tag{2.5}
$$

The boundary value problem for the ordinary differential equation

$$-\hat{u}''+\lambda^2\hat{u}=0,$$

$$\hat{u}|_{\theta=0}=\frac{\partial\hat{u}}{\partial\theta}\bigg|_{\theta=\omega}=0$$

has eigenvalues $\lambda_k=i(\pi/\omega)(k-\frac{1}{2})$, $k=1, 2, \cdots$, and corresponding eigenfunctions $u_k=\sin(\pi/\omega)(k-\frac{1}{2})\theta$. Hence for $0<h<\pi/2\omega$ (2.5) always has a unique solution and by [3], [14] (formula (1.14))

$$\begin{aligned}\|\hat{u}\|^2_{H^2(I)}+|\lambda|^4\|\hat{u}\|^2_{L_2(I)}\leqq C[&\|\hat{f}\|^2_{L_2(I)}+\|\hat{G}^0\|^2_{H^2(I)}+\|\hat{G}^1\|^2_{H^1(I)}\\&+|\lambda|^3|\hat{G}^0(\lambda,0)|^2+|\lambda||\hat{G}^1(\lambda,\omega)|^2].\end{aligned}\tag{2.6}$$

It follows from the basic property of the Fourier transform that for any integer s, $s\leqq k$ and for any F in the set of admissible functions

$$\begin{aligned}\int_0^\omega\int_{-\infty}^{+\infty}\left|\frac{\partial^k F(\tau,\theta)}{\partial\tau^s\partial\theta^{k-s}}\right|^2 e^{2h\tau}\,d\tau\,d\theta&=\int_0^\omega\left(\int_{-\infty}^{\infty}\left|e^{h\tau}\frac{\partial^k F(\tau,\theta)}{\partial\tau^s\partial\theta^{k-s}}\right|^2 d\tau\right)d\theta\\&=\int_0^\omega\int_{-\infty+ih}^{\infty+ih}|\lambda|^{2s}\left|\frac{\partial^{k-s}\hat{F}(\lambda,\theta)}{\partial\theta^{k-s}}\right|^2 d\lambda\,d\theta.\end{aligned}\tag{2.7}$$

Hence for $\tilde{u}=\mathscr{F}^{-1}(\hat{u})$ we get

$$\int_D e^{2h\tau}\left|\frac{\partial^2\tilde{u}}{\partial\theta^2}\right|^2 d\tau\,d\theta=\int_{-\infty+ih}^{\infty+ih}\left\|\frac{\partial^2\hat{u}}{\partial\theta^2}\right\|^2_{L_2(I)}d\lambda,\tag{2.8}$$

$$\int_D e^{2h\tau}\left|\frac{\partial^2\tilde{u}}{\partial\tau^2}\right|^2 d\tau\,d\theta=\int_{-\infty+ih}^{\infty+ih}|\lambda|^4\|\hat{u}\|^2_{L_2(I)}\,d\lambda.\tag{2.9}$$

By the interpolation space theorem [8]

$$\begin{aligned}|\lambda|^2\left\|\frac{\partial\hat{u}}{\partial\theta}\right\|^2_{L_2(I)}&\leqq|\lambda|^2\|\hat{u}\|^2_{H^1(I)}\leqq C|\lambda|^2\|\hat{u}\|_{L_2(I)}\|\hat{u}\|_{H^2(I)}\\&\leqq C|\lambda|^2\|\hat{u}\|_{L_2(I)}\left(\|\hat{u}\|_{L_2(I)}+\left\|\frac{\partial\hat{u}}{\partial\theta}\right\|_{L_2(I)}+\left\|\frac{\partial^2\hat{u}}{\partial\theta^2}\right\|_{L_2(I)}\right)\\&\leqq C\left(\left(\left(1+\frac{C}{2}\right)|\lambda|^2+\frac{1}{2}|\lambda|^4\right)\|\hat{u}\|^2_{L_2(I)}+\frac{1}{2C}|\lambda|^2\left\|\frac{\partial\hat{u}}{\partial\theta}\right\|^2_{L_2(I)}+\frac{1}{2}\left\|\frac{\partial^2\hat{u}}{\partial\theta^2}\right\|^2_{L_2(I)}\right)\\&\leqq C_1\left(|\lambda|^4\|\hat{u}\|^2_{L_2(I)}+\left\|\frac{\partial^2\hat{u}}{\partial\theta^2}\right\|^2_{L_2(I)}\right)\end{aligned}$$

where C_1 depends on h but not on λ and $\hat{u}$. Hence

$$\begin{aligned}\int_D e^{2h\tau}\left|\frac{\partial^2\tilde{u}}{\partial\tau\partial\theta}\right|^2 d\tau\,d\theta&=\int_{-\infty+ih}^{\infty+ih}|\lambda|^2\left\|\frac{\partial\hat{u}}{\partial\theta}\right\|^2_{L_2(I)}d\lambda\\&\leqq C_1\int_{-\infty+ih}^{\infty+ih}\left(|\lambda|^4\|\hat{u}\|^2_{L_2(I)}+\left\|\frac{\partial^2\hat{u}}{\partial\theta^2}\right\|^2_{L_2(I)}\right)d\lambda.\end{aligned}\tag{2.10}$$

We have also

$$\int_{-\infty+ih}^{\infty+ih} (\|\hat{f}\|^2_{L_2(I)} + \|\hat{G}^0\|^2_{H^2(I)} + \|\hat{G}^1\|^2_{H^1(I)})\, d\lambda \tag{2.11}$$
$$= \int_D e^{2h\tau}\left(|\tilde{f}|^2 + \sum_{l=0}^{2}\left|\frac{\partial^l \tilde{G}^0}{\partial\theta^l}\right|^2 + \sum_{l=0}^{1}\left|\frac{\partial^l \tilde{G}^1}{\partial\theta^l}\right|^2\right) d\tau\, d\theta,$$

$$\int_{-\infty+ih}^{\infty+ih} |\lambda|^3 |\hat{G}^0(\lambda, 0)|^2\, d\lambda \leqq C\|e^{h\tau}\tilde{G}^0(\lambda, 0)\|^2_{H^{3/2}(\mathbf{R}_1)} \tag{2.12}$$
$$\leqq C\|e^{h\tau}\tilde{G}^0(\lambda, \theta)\|^2_{H^2(D)},$$

$$\int_{-\infty+ih}^{\infty+ih} |\lambda|\,|\hat{G}^1(\lambda, \omega)|^2\, d\lambda \leqq C\|e^{h\tau}\tilde{G}^1(\lambda, \omega)\|^2_{H^{1/2}(\mathbf{R}_1)} \tag{2.13}$$
$$\leqq C\|e^{h\tau}\tilde{G}^1(\lambda, \theta)\|^2_{H^1(D)}.$$

Hence from (2.6) using (2.8)-(2.13) we get for $|\alpha| = 2$;

$$\int_D e^{2h\tau}|D^\alpha \tilde{u}|^2\, d\tau\, d\theta \leqq C\left[\|\tilde{f}\|^2_{L_h(D)} + \sum_{i=0}^{1}\|\tilde{G}^i\|^2_{\mathscr{H}_h^{2-i}(D)}\right]. \tag{2.14}$$

For $l = 0, 1$ we have

$$\int_D e^{2h\tau}\left|\frac{\partial^l \tilde{u}}{\partial\tau^l}\right|^2 d\tau\, d\theta = \int_{-\infty+ih}^{\infty+ih} |\lambda|^{2l}\|\hat{u}\|^2_{L_2(I)}\, d\lambda$$
$$\leqq h^{-2l}\int_{-\infty+ih}^{\infty+ih} |\lambda|^4\|\hat{u}\|^2_{L_2(I)}\, d\lambda \tag{2.15}$$
$$\leqq Ch^{-2l}\left(\|\tilde{f}\|^2_{H_h(D)} + \sum_{i=0}^{1}\|\tilde{G}^i\|^2_{\mathscr{H}_h^{2-i}(D)}\right),$$

$$\int_D e^{2h\tau}\left|\frac{\partial\tilde{u}}{\partial\theta}\right|^2 d\tau\, d\theta = \int_{\infty-ih}^{\infty+ih} |\hat{u}|^2_{H^1(I)}\, d\lambda$$
$$\leqq h^{-2}\int_{-\infty+ih}^{\infty+ih} |\lambda|^2|\hat{u}|^2_{H^1(I)}\, d\lambda \tag{2.16}$$
$$\leqq Ch^{-2}\left(\|\tilde{f}\|^2_{\mathscr{L}_h(D)} + \sum_{i=0}^{1}\|\tilde{G}^i\|^2_{\mathscr{H}_h^{2-i}(D)}\right)$$

and (2.4) is proven.

(2) Let $\tilde{u} \in \mathscr{H}_h^2(D)$ and

$$\Delta\tilde{u} = 0 \quad \text{in } D,$$
$$\tilde{u}|_{\theta=0} = \left.\frac{\partial\tilde{u}}{\partial\theta}\right|_{\theta=\omega} = 0.$$

Hence we can write

$$\tilde{u}(\tau, \theta) = \sum_{j=1}^{\infty} a_j(\tau)\sin\frac{\pi\theta}{\omega}\left(j - \frac{1}{2}\right), \tag{2.17}$$

$$a_j(\tau) = \frac{2}{\omega}\int_0^\omega \tilde{u}(\tau, \theta)\sin\frac{\pi\theta}{\omega}\left(j - \frac{1}{2}\right) d\theta, \tag{2.18}$$

$$a_j''(\tau)=\frac{2}{\omega}\int_0^{\omega}\frac{\partial^2\tilde{u}(\tau,\theta)}{\partial\tau^2}\sin\frac{\pi\theta}{\omega}\left(j-\frac{1}{2}\right)d\theta$$

$$=\left(\frac{\pi}{\omega}\left(j-\frac{1}{2}\right)\right)^2 a_j(\tau).$$

Because for each j, $j=1, 2, \cdots$, $a_j(\tau)$ satisfies

$$a_j''(\tau)-\left(\frac{\pi}{\omega}\left(j-\frac{1}{2}\right)\right)^2 a_j(\tau)=0$$

we have

$$a_j(\tau)=c_j\,e^{-(\pi/\omega)(j-1/2)\tau}+d_j\,e^{(\pi/\omega)(j-1/2)\tau}. \tag{2.19}$$

For $A>0$ arbitrary

$$\infty>\int_{D_A}e^{2h\tau}|\tilde{u}|^2\,d\tau\,d\theta$$

$$=\int_{-A}^{A}\left(\int_0^{\omega}\left(\sum_{j=1}^{\infty}a_j(\tau)\sin\frac{\pi\theta}{\omega}\left(j-\frac{1}{2}\right)\right)^2 d\theta\right)e^{2h\tau}\,d\tau$$

$$=\int_{-A}^{+A}\frac{\omega}{2}\sum_{j=1}^{\infty}|a_j(\tau)|^2\,e^{2h\tau}\,d\tau$$

$$=\frac{\omega}{2}\sum_{j=1}^{\infty}\int_{-A}^{+A}|a_j(\tau)|^2\,e^{2h\tau}\,d\tau.$$

For $j=1$

$$|a_1(\tau)|^2=c_1^2\,e^{-(\pi/\omega)\tau}+d_1^2\,e^{(\pi/\omega)\tau}+2c_1d_1$$

and hence

$$\int_{-A}^{A}|a_1(\tau)|^2\,e^{2h\tau}\,d\tau=2c_1d_1\frac{1}{2h}(e^{2hA}-e^{-2hA})+\frac{c_1^2}{(2h-\pi/\omega)}(e^{(2h-\pi/\omega)A}-e^{-(2h-\pi/\omega)A})$$

$$+\frac{d_1^2}{(2h+\pi/\omega)}(e^{(2h+\pi/\omega)A}-e^{-(2h+\pi/\omega)A})$$

and

$$\infty>\lim_{A\to\infty}\int_{-A}^{+A}|a_1(\tau)|^2\,e^{2h\tau}\,d\tau$$

$$=\lim_{A\to\infty}\left(\frac{c_1d_1}{h}\,e^{2hA}+\frac{c_1^2}{(\pi/\omega-2h)}\,e^{|(\pi/\omega-2h)|A}+\frac{d_1^2}{(2h+\pi/\omega)}\,e^{(2h+\pi/\omega)A}\right).$$

Hence c_1, $d_1=0$. Similarly we get $c_j=d_j=0$ for all $1\leqq j<\infty$, which implies the uniqueness of the solution of (2.3) in $\mathcal{H}_h^2(D)$. □

We have not explicitly used in the proof of Lemma 2.3 the assumption $h<\pi/2\omega$. We have used only $h>0$ and $h\neq\pi/2\omega(k-\frac{1}{2})$, $k=1, 2, \cdots$. The assumption $h<\pi/2\omega$ is essential in the next lemma.

LEMMA 2.4. *Let the assumptions of Lemma* 2.3 *hold. Let, in addition,* $\tilde{f}(\tau, \theta) = 0$, $\tilde{G}^i(\tau, \theta) = 0$ *for* $\tau < 0$. *Then for* $\varepsilon > 0$ *and* $0 \leqq \gamma = h + (\pi/2\omega) - \varepsilon$, $\tilde{D} = \{\tau, \theta \,|\, -\infty < \tau < 0, 0 < \theta < \omega\}$ *one has*

$$\int_{\tilde{D}} |D^\alpha \tilde{u}|^2 \, e^{2(h-\gamma)\tau} \, d\tau \, d\theta \leqq C(\varepsilon) \int_{\tilde{D}} |D^\alpha \tilde{u}|^2 \, e^{2h\tau} \, d\tau \, d\theta, \qquad |\alpha| \leqq 2. \tag{2.20}$$

Proof. Equations (2.17)-(2.19), hold, and

$$\infty > \int_{\tilde{D}} |\tilde{u}|^2 \, e^{2h\tau} \, d\tau \, d\theta = \frac{\omega}{2} \int_{-\infty}^{0} \sum_{j=1}^{\infty} |a_j(\tau)|^2 \, e^{2h\tau} \, d\tau.$$

Hence for $A > 0$ arbitrary

$$\int_{-A}^{0} |a_j(\tau)|^2 \, e^{2h\tau} \, d\tau = 2c_j d_j (1 - e^{-2hA}) + \frac{c_j^2}{2(h - (\pi/\omega)(j - \frac{1}{2}))} (1 - e^{-2(h-(\pi/\omega)(j-1/2))A})$$
$$+ \frac{d_j^2}{2(h + (\pi/\omega)(j - \frac{1}{2}))} (1 - e^{-2(h+(\pi/\omega)(j-1/2))A}).$$

Since $0 < h < \pi/2\omega$ and $A > 0$ is arbitrary we have $c_j = 0$, $j = 1, 2, \cdots$ and

$$\int_{-A}^{0} |a_j(\tau)|^2 \, e^{2h\tau} \, d\tau = \frac{d_j^2}{2(h + (\pi/\omega)(j - \frac{1}{2}))} (1 - e^{-2(h+(\pi/\omega)(j-1/2))A}),$$

$$\int_{-A}^{0} |a_j(\tau)|^2 \, e^{2(h-\gamma)\tau} \, d\tau = \frac{d_j^2}{2(h - \gamma + (\pi/\omega)(j - \frac{1}{2}))} (1 - e^{-2(h-\gamma+(\pi/\omega)(j-\frac{1}{2}))A}).$$

If $0 \leqq \gamma = h + \pi/2\omega - \varepsilon$, $\varepsilon > 0$ then

$$\int_{\tilde{D}} |\tilde{u}(\tau, \theta)|^2 \, e^{2(h-\gamma)\tau} \, d\tau \, d\theta = \int_{\tilde{D}} |\tilde{u}(\tau, \theta)|^2 \, e^{2(-\pi/2\omega+\varepsilon)\tau} \, d\tau \, d\theta$$
$$= \frac{\omega}{2} \lim_{A \to \infty} \sum_{j=1}^{\infty} \frac{d_j^2 (1 - e^{-2((\pi/\omega)(j-1)+\varepsilon)A})}{2(\varepsilon + (\pi/\omega)(j-1))}$$
$$\leqq C \frac{\omega}{2} \sum_{j=1}^{\infty} \frac{d_j^2}{2(h + (\pi/\omega)(j - \frac{1}{2}))}$$
$$= C \int_{\tilde{D}} |\tilde{u}|^2 \, e^{2h\tau} \, d\tau \, d\theta.$$

Similarly we have for $|\alpha| \leqq 2$

$$\int_{\tilde{D}} |D^\alpha \tilde{u}|^2 \, e^{2(h-\gamma)\tau} \, d\tau \, d\theta \leqq C \int_{\tilde{D}} |D^\alpha \tilde{u}|^2 \, e^{2h\tau} \, d\tau \, d\theta. \qquad \square$$

Lemmas 2.3 and 2.4 address the regularity of the problem (2.3) when on Γ_1, respectively, Γ_2, the Dirichlet respectively the Neumann condition has been given. The same statement holds if on Γ_1 and Γ_2 the Dirichlet or Neumann condition are given.

LEMMA 2.5. *Let* $\tilde{f} \in \mathcal{H}_h(D)$, $\tilde{G}^0 \in \mathcal{H}_h^2(D)$ *(respectively* $\tilde{G}^1 \in \mathcal{H}_h^1(D)$*),* $0 < h < \pi/\omega$. *Then the Dirichlet (respectively Neumann) problem*

$$-\left(\frac{\partial^2 \tilde{u}}{\partial \tau^2} + \frac{\partial^2 u}{\partial \theta^2}\right) = \tilde{f}(\tau, \theta), \tag{2.21a}$$

$$\tilde{u}\Big|_{\substack{\theta=0 \\ \theta=\omega}} = \tilde{g}^0 = \tilde{G}^0\Big|_{\substack{\theta=0 \\ \theta=\omega}} \tag{2.21b}$$

(*respectively*)

$$\left.\frac{\partial \tilde{u}}{\partial n}\right|_{\substack{\theta=0\\ \theta=\omega}} = \tilde{g}^1 = \tilde{G}^2\Big|_{\substack{\theta=0\\ \theta=\omega}}, \tag{2.21c}$$

has a unique solution in $\mathscr{H}^2_h(D)$ *and for* $0 \leqq |\alpha| \leqq 2$

$$\|D^\alpha \tilde{u}\|^2_{\mathscr{L}_h(D)} \leqq C[\|\tilde{f}\|^2_{\mathscr{L}_h(D)} + \|\tilde{G}^0\|^2_{\mathscr{H}^2_h(D)} \quad (\textit{respectively } \|\tilde{G}^1\|^2_{\mathscr{H}^1_h(D)})]. \tag{2.22}$$

If in addition $\tilde{f} = 0$, $\tilde{G}^0$ (*respectively* $\tilde{G}^1$) $= 0$ *for* $\tau < 0$ *then for* $0 \leqq \gamma = h + \pi/\omega - \varepsilon$, $\varepsilon > 0$, $0 \leqq |\alpha| \leqq 2$

$$\int_{\tilde{D}} |D^\alpha \tilde{u}^*|^2 \, e^{2(h-\gamma)\tau} \, d\tau \, d\theta \leqq C \int_{\tilde{D}} |D^\alpha \tilde{u}|^2 \, e^{2h\tau} \, d\tau \, d\theta \tag{2.23}$$

where $\tilde{u}^*(\tau, \theta) = \tilde{u}(\tau, \theta)$, *for the Dirichlet problem and*

$$\tilde{u}^*(\tau, \theta) = \tilde{u}(\tau, \theta) - \frac{1}{\omega} \int_0^\omega \tilde{u}(\tau, \theta) \, d\theta$$

for the Neumann problem. □

The proof is quite the same. In the case of Neumann conditions it is enough to realize that a similar summation as in (2.17) is for $j = 0, 1, 2, \cdots$.

LEMMA 2.6. *Let* $f \in \mathscr{L}_\beta(Q)$, $g^i \in \mathscr{H}^{2-i,2-i}_\beta(Q)$, $i = 0, 1$, $0 < \beta < 1$, $\beta > 1 - \pi/2\omega$ *and let* $f = G^i = 0$ *for* $r \geqq 1$; *then the mixed problem*

$$-\Delta u = f(r, \theta), \tag{2.24a}$$

$$u|_{\theta=0} = g^0 = G^0|_{\theta=0}, \qquad \left.\frac{\partial u}{\partial n}\right|_{\theta=\omega} = \frac{1}{r}\left.\frac{\partial u}{\partial \theta}\right|_{\theta=\omega} = g^1 = G^1|_{\theta=\omega} \tag{2.24b}$$

has a solution such that

(i) $(u - G^0) \in W^2_\beta(Q)$, $u \in \mathscr{H}^{2,2}_\beta(S_1)$,

(ii) $\|\mathscr{D}^1 u\|_{H^0(Q)} < \infty$,

(iii) *there exists a constant* C *independent of* u, f, G^i *such that for* $|\alpha| \leqq 2$

$$\|u\|^2_{\mathscr{H}^{2,2}_\beta(S_1)} \leqq C\left[\|f\|^2_{\mathscr{L}_\beta(Q)} + \sum_{i=0}^{1} \|G^i\|^2_{\mathscr{H}^{2-i,2-i}_\beta(Q)}\right] \tag{2.25}$$

where $Q = \{r, \theta \,|\, 0 < r < \infty, 0 < \theta < \omega\}$ *and* $S_1 = \{r, \theta \,|\, 0 < r < 1, 0 < \theta < \omega\}$.

Proof. First assume that $G^0 = 0$. Let $0 < h = 1 - \beta < \pi/2\omega$ and $\tau = \ln(1/r)$. Then we have for $\tilde{f}(\tau, \theta) = e^{-2\tau} f(e^{-\tau}, \theta)$ and $\tilde{G}^1(\tau, \theta) = e^{-\tau} G^1(e^{-\tau}, \theta)$

$$\begin{aligned} \int_D e^{2h\tau} |\tilde{f}(\tau, \theta)|^2 \, d\tau \, d\theta &= \int_D e^{-2(2-h)\tau} |f(e^{-\tau}, \theta)|^2 \, d\tau \, d\theta \\ &= \int_Q r^{2\beta} |f(r, \theta)|^2 r \, dr \, d\theta \\ &= \|f\|^2_{\mathscr{L}_\beta(Q)}, \end{aligned} \tag{2.26a}$$

$$\begin{aligned} \int_D e^{2h\tau} |\tilde{G}^1(\tau, \theta)|^2 \, d\tau \, d\theta &= \int_Q r^{2(\beta-1)} |G^1(r, \theta)|^2 r \, dr \, d\theta \\ &= \int_{S_1 \cup Q_2} r^{2(\beta-1)} |G^1(r, \theta)|^2 r \, dr \, d\theta \end{aligned} \tag{2.26b}$$

where we denoted

$$Q_2 = \{(r, \theta) \mid 1 \leqq r < \infty, 0 < \theta < \omega\}.$$

By Lemma A.2 (see Appendix)

$$\int_{S_1} r^{2(\beta-1)} |G^1|^2 r\, dr\, d\theta \leqq C\left[\sum_{|\alpha|=1} \int_{S_1} r^{2(\beta+\alpha_1-1)} |\mathscr{D}^\alpha G^1|^2 r\, dr\, d\theta + \int_{S_1} |G^1|^2 r\, dr\, d\theta\right]$$

and

$$\int_{Q_2} r^{2(\beta-1)} |G^1|^2 r\, dr\, d\theta \leqq \int_{Q_2} |G^1|^2 r\, dr\, d\theta.$$

Hence

$$\|\tilde{G}^1\|_{\mathscr{L}_h(D)} \leqq C \|G^1\|_{H^{1,1}_\beta(Q)}$$

and for $\alpha_1 + \alpha_2 = 1$

$$\int_D e^{2h\tau} |\tilde{G}^1_{\tau^{\alpha_1}\theta^{\alpha_2}}|^2\, d\tau\, d\theta = \int_Q r^{2(\alpha_1-1+\beta)} |G^1_{r^{\alpha_1}\theta^{\alpha_2}}|^2 r\, dr\, d\theta.$$

Therefore

$$\|\tilde{G}^1\|_{\mathscr{H}^1_h(D)} \leqq C \|G^1\|_{\mathscr{H}^{1,1}_\beta(Q)}. \tag{2.27}$$

Using (2.26) and (2.27) and Lemma 2.3 we see that the equation

$$\begin{aligned} &-(\tilde{u}_{\tau\tau} + \tilde{u}_{\theta\theta}) = \tilde{f} \quad \text{in } D, \\ &\tilde{u}|_{\theta=0} = 0, \\ &\left.\frac{\partial \tilde{u}}{\partial \theta}\right|_{\theta=\omega} = \tilde{G}^1|_{\theta=\omega} \end{aligned} \tag{2.28}$$

has the unique solution $\tilde{u} \in \mathscr{H}^2_h(D)$ and (2.4) holds. Let $u = \tilde{u}(\ln(1/r), \theta)$, then u satisfies (2.24) and for $|\alpha| \leqq 2$

$$\begin{aligned} \int_Q r^{2(\alpha_1-2+\beta)} |u_{r^{\alpha_1}\theta^{\alpha_2}}|^2 r\, dr\, d\theta &\leqq C \sum_{|\alpha|\leqq 2} \int_D e^{2h\tau} |\tilde{u}_{\tau^{\alpha_1}\theta^{\alpha_2}}|^2\, d\tau\, d\theta \\ &\leqq C[\|\tilde{f}\|^2_{\mathscr{L}_h(D)} + \|\tilde{G}^1\|^2_{\mathscr{H}^1_h(D)}] \\ &= C[\|f\|^2_{\mathscr{L}_\beta(Q)} + \|G^1\|^2_{\mathscr{H}^{1,1}_\beta(Q)}]. \end{aligned} \tag{2.29}$$

Hence $u \in W^2_\beta(Q)$ and (2.25) is proven for $G^0 = 0$. For $G^0 \neq 0$ we define $w = u - G^0$; then

$$\begin{aligned} &-\Delta w = f + \Delta G^0 = \bar{f}, \\ &w|_{\theta=\omega} = 0, \\ &\frac{1}{r}\left.\frac{\partial w}{\partial \theta}\right|_{\theta=\omega} = \left(G^1 - \frac{1}{r}\frac{\partial G^0}{\partial \theta}\right)\Bigg|_{\Gamma_2} = \bar{G}^1|_{\Gamma_2}. \end{aligned}$$

Applying now (2.29) (respectively (2.25)) to this case we get $w \in W^2_\beta(Q)$ and

$$\begin{aligned} \|w\|^2_{\mathscr{H}^{2,2}_\beta(S_1)} &\leqq C[\|\bar{f}\|^2_{\mathscr{L}_\beta(Q)} + \|\bar{G}^1\|^2_{\mathscr{H}^{1,1}_\beta(Q)}] \\ &\leqq C\left[\|f\|^2_{\mathscr{L}_\beta(Q)} + \sum_{i=0,1} \|G^i\|^2_{\mathscr{H}^{2-i,2-i}_\beta(Q)}\right] \end{aligned}$$

which proves (2.25) in full generality.

Let us prove now that $\|\mathscr{D}^1 u\|_{H^0(Q)} < \infty$. Equation (2.25) shows that $\|\mathscr{D}^1 u\|_{H^0(S_1)} < \infty$; hence we have to prove only that

$$\|\mathscr{D}^1 u\|_{H^0(Q_2)}, \qquad Q_2 = Q - \bar{S}_1.$$

We have by Lemma 2.4 for $h = 1-\beta$ and $0 \leqq \gamma = \pi/2\omega + h - \varepsilon$, $\varepsilon > 0$, $|\alpha| \leqq 2$

$$\int_{Q_2} |\mathscr{D}^\alpha u|^2 r^{2(\alpha_1 - 2 + \beta) + 2\gamma} r\, dr\, d\theta = \int_{\tilde{D}} |D^\alpha \tilde{u}|^2 \, e^{2(h-\gamma)\tau}\, d\tau\, d\theta < \infty. \tag{2.30}$$

Particularly for $\alpha_1 + \alpha_2 = 1$ and $0 < \varepsilon < \pi/2\omega$ we have

$$\begin{aligned} \int_{Q_2} |u_r|^2 r\, dr\, d\theta &\leqq \int_{Q_2} |u_r|^2 r^{2(-1+\beta+1-\beta+(\pi/2\omega)-\varepsilon)} r\, dr\, d\theta \\ &\leqq \int_{Q_2} |u_r|^2 r^{2(\alpha_1 - 2 + \beta) + 2\gamma} r\, dr\, d\theta < \infty \end{aligned} \tag{2.31}$$

and

$$\begin{aligned} \int_{Q_2} \frac{1}{r^2} |u_\theta|^2 r\, dr\, d\theta &\leqq \int_{Q_2} |u_\theta|^2 r^{2(-2+\beta+(1-\beta)+(\pi/2\omega)-\varepsilon)} \\ &\leqq \int_{Q_2} |u_\theta|^2 r^{2(\alpha_1 - 2 + \beta) + 2\gamma} r\, dr\, d\theta < \infty \end{aligned} \tag{2.32}$$

and (ii) of Lemma 2.6 is proven. □

Analogously we have the following.

LEMMA 2.7. *Let* $f \in \mathscr{L}_\beta(Q)$, $G^i \in \mathscr{H}_\beta^{2-i,2-i}(Q)$, $i = 0,\ 1$, $0 < \beta < 1$, $\beta > 1 - (\pi/\omega)$ $f = G^i = 0$ *for* $r > 1$, *then the Dirichlet (respectively Neumann) problem*

$$-\Delta u = f(r, \theta), \tag{2.33a}$$

$$u|_{\theta = 0,\omega} = g^0 = G^0|_{\theta = 0,\omega}$$
$$\left(\textit{respectively} \left.\frac{\partial u}{\partial n}\right|_{\theta = 0,\omega} = g^1 = G^1|_{\theta = 0,\omega} \right) \tag{2.33b}$$

has a solution such that

(i) $(u - G^0) \in W_\beta^2(Q)$ *(respectively* $u \in W_\beta^2(Q)$*)*, $u \in \mathscr{H}_\beta^{2,2}(S_1)$, *and*

(ii) $\|\mathscr{D}^1 u^*\|_{H^0(Q)} < \infty$

where $u^*(r, \theta) = u(r, \theta) - 1/\omega \int_0^\omega u(r, \theta)\, d\theta$ *for the Neumann problem,*

(iii) (2.25) *holds with* $G^1 = 0$ *(respectively* $G^0 = 0$*).*

Let us now prove the following.

LEMMA 2.8. *Let* $u \in \tilde{H}^1(Q) = \{u \mid \int_Q |\mathscr{D}^1 u|^2 r\, dr\, d\theta < \infty,\ u|_{\Gamma^0} = 0\}$ *and* $u = 0$ *for* $r > 1$ *be the solution of the problem*

$$-\Delta u = f,$$
$$u|_{\Gamma^0} = G^0|_{\Gamma^0},$$
$$\left.\frac{\partial u}{\partial n}\right|_{\Gamma^1} = G^1|_{\Gamma^1}$$

with $f \in \mathscr{L}_\beta(Q)$, $G^i \in \mathscr{H}_\beta^{2-i,2-i}(Q)$, f *and* G^i *vanish for* $r > 1$, $i = 0,\ 1$, $0 < \beta < 1$, $\beta > 1 - \pi/2\omega$ *for the mixed problem and* $\beta > 1 - \pi/\omega$ *for the Dirichlet and Neumann problem, where* Γ^0 *is the union of the edges of* Q, *or the empty set,* $\Gamma^1 = \partial Q - \Gamma^0$.

Further let $w \in W^2_\beta(Q)$ *be the solution of the same problem given in Lemmas* 2.6 *and* 2.7. *Then* $u = w$ *if* $\Gamma^0 \neq \emptyset$ (*i.e. for the Dirichlet or mixed problem*) *and* $u = w + C$ *if* $\Gamma^0 = \emptyset$ (*i.e. Neumann problem*).

Proof. We first prove the lemma for the Dirichlet problem. We may assume $G^0 = 0$. Since $\|\mathscr{D}^1 w\|_{H^0(Q)} < \infty$ by Lemma 2.7, we have for every $v \in \tilde{H}^1_0(Q) = \{v | \int_Q |\mathscr{D}^1 v|^2 r\, dr\, d\theta < \infty,\ v|_{\Gamma^0} = 0,\ v = 0 \text{ for } r > A(v)\}$

$$\int_Q \left(w_r v_r + \frac{1}{r^2} w_\theta v_\theta \right) r\, dr\, d\theta = \int_Q \left(u_r v_r + \frac{1}{r^2} u_\theta v_\theta \right) r\, dr\, d\theta$$

and hence

$$\int_Q \left((w_r - u_r) v_r + \frac{1}{r^2} (w_\theta - u_\theta) v_\theta \right) r\, dr\, d\theta = 0.$$

Because $\tilde{H}^1_0(Q)$ is dense in $\tilde{H}^1(Q)$ the equality holds also for $v = w - u$. This immediately gives $w = u + C$ and obviously $C = 0$. Now we prove the lemma for the Neumann problem.

Let $u^* = u - 1/\omega \int_0^\omega u(r, \theta)\, d\theta = u - b_0(r)$ and $w^* = w - \int_0^\omega (1/\omega) w(r, \theta)\, d\theta = w - a_0(r)$. Then by Lemma 2.7 $\|\mathscr{D}^1 w^*\|_{H^0(Q)} < \infty$. Let

$$\tilde{\tilde{H}}^1_0(Q) = \left\{ u \,\middle|\, \int_Q |\mathscr{D}^1 u|^2 r\, dr\, d\theta < \infty, \int_0^\omega u(r, \theta)\, d\theta = 0 \right\}.$$

Then for any $v \in \tilde{\tilde{H}}^1_0(Q)$ having bounded support

$$\begin{aligned} \int_Q \left(u_r v_r + \frac{1}{r^2} u_\theta v_\theta \right) r\, dr\, d\theta &= \int_Q \left(u^*_r v_r + \frac{1}{r^2} u^*_\theta v_\theta \right) r\, dr\, d\theta \\ &= \int_Q \left(w_r v_r + \frac{1}{r^2} w_\theta v_\theta \right) r\, dr\, d\theta \\ &= \int_Q \left(w^*_r v_r + \frac{1}{r^2} w^*_\theta v_\theta \right) r\, dr\, d\theta \end{aligned}$$

and hence

$$\int_Q \left((u^*_r - w^*_r) v_r + \frac{1}{r^2} (u^*_\theta - w^*_\theta) v_\theta \right) r\, dr\, d\theta = 0.$$

Since the set of $v \in \tilde{\tilde{H}}^1_0(Q)$ having bounded support is dense in $\tilde{\tilde{H}}^1_0(Q)$ we get $u^* - w^* = C$. Thus

$$u - w = u^* - w^* = a_0(r) - b_0(r) = C(r)$$

and because u, w solve the same problem and obviously $\partial C/\partial\theta = 0$, we get

$$\int_Q C_r v_r r\, dr\, d\theta = 0$$

for any $v \in H = \{v | \int_Q |\mathscr{D}^1 v|^2 r\, dr\, d\theta < \infty$, hence $C(r) = C_1 + C_2 \log(1/r)$; but $C(r) = (u - w) \in H^1(S_1)$ by Lemma 2.7, and hence $C_2 = 0$ and $u - w = C_1$. □

2.2. The regularity of the solution on a polygonal domain Ω.

LEMMA 2.9. *Let* $g = G|_\gamma \in H^{1/2,1/2}_\beta(\gamma)$ *where* γ *is the edge of* $\partial\Omega$. *Then* $(\Phi_{\beta/2} G)|_\gamma \in L_2(\gamma)$.

Proof. Let $\Gamma_i = \gamma$ be the edge connecting the vertices A_{i+1} and A_i, let A_i be placed at the origin and Γ_i lies on the x_1-axis. Assume that $S_\delta^{\omega_i} \subset \Omega$. It is sufficient to prove that on $\int_0^\delta r^\beta |G(x_1, 0)|^2 \, dx_1 < \infty$ with $\beta = \beta_i$.

Let $F = r^\beta G$. Then

$$F_{x_i} = r^\beta G_{x_i} + \beta r^{\beta-1} \frac{x_i}{r} G.$$

By Lemma A.3 of the Appendix

$$\|F_{x_i}\|_{\mathscr{L}_\beta(S_\delta^{\omega_i})} \leqq C \|G\|_{H_\beta^{1,1}(\Omega)}$$

and hence

$$\|F\|_{H^1(S_\delta^{\omega_i})} \leqq C \|G\|_{H_\beta^{1,1}(\Omega)}.$$

By the imbedding theorem $F \in L_p(I_\delta)$ for any $p > 1$, $I_\delta = (0, \delta)$ (see [1]), and

$$\|F\|_{L_p(I_\delta)} \leqq C \|F\|_{H^1(S_\delta^{\omega_i})} \leqq C \|G\|_\beta^{1,1}(\Omega).$$

Hence

$$\begin{aligned} \|r^{\beta/2} G\|_{L_2(I_\delta)}^2 &= \int_{I_\delta} r^{-\beta} |F|^2 \, dx_1 \\ &\leqq C \left(\int_{I_\delta} r^{-\beta q} \, dx_1 \right)^{1/q} \left(\int_{I_\delta} |F|^{2p} \right)^{1/p} \\ &\leqq C \|F\|_{L_{2p}(I_\delta)}^2 \leqq C \|F\|_{H^1(S_\delta^{\omega_i})}^2 \leqq C \|G\|_{H_\beta^{1,1}(\Omega)}^2 \end{aligned}$$

where $1/p + 1/q = 1$ and $\beta q < 1$, $p > 1$, $q > 1$. □

LEMMA 2.10. *Let $f \in \mathscr{L}_\beta(\Omega)$. Then $\int_\Omega fv \, dx$ is a linear continuous functional on $H^1(\Omega)$ and $\|f\|_{(H^1(\Omega))'} \leqq C \|f\|_{\mathscr{L}_\beta(\Omega)}$.*

The proof follows easily from the Schwarz inequality and imbedding theorem. See also [12]. □

LEMMA 2.11. *Let $f \in \mathscr{L}_\beta(\Omega)$, $G^i \in H_\beta^{2-i,2-i}(\Omega)$ $i = 0, 1$ and $|\Gamma^0| \neq 0$. Then*

$$\begin{aligned} &-\Delta u = f, \\ &u|_{\Gamma^0} = g^0 = G^0|_{\Gamma^0}, \\ &\left.\frac{\partial u}{\partial n}\right|_{\Gamma^1} = g^1 = G^1|_{\Gamma^1} \end{aligned} \tag{2.34}$$

has the unique solution $u \in H^1(\Omega)$ (in the weak sense) and

$$\|u\|_{H^1(\Omega)} \leqq C \left[\|f\|_{\mathscr{L}_\beta(\Omega)} + \sum_{i=0,1} \|G^i\|_{H_\beta^{2-i,2-i}(\Omega)} \right]. \tag{2.35}$$

Proof. Without loss of generality we can assume that $G^0 = 0$ because $\Delta G^0 \in \mathscr{L}_\beta(\Omega)$ and $\partial G^0 / \partial x_i \in H_\beta^{1,1}(\Omega)$. Applying Lemma 2.10 it suffices to show that

$$\int_{\Gamma^1} g^1 v \, dx$$

is a linear functional on $H^1(\Omega)$.

We have

$$\int_{\Gamma^1} g^1 v \, ds = \int_{\Gamma^1} r^{\beta/2} g^1 r^{-\beta/2} v \, ds, \tag{2.36}$$

$$\int_{\Gamma^1} r^{-\beta} v^2 \, ds \leqq \left(\int_{\Gamma^1} r^{-\beta p} \, ds \right)^{1/p} \left(\int_{\Gamma^1} |v|^{2q} \, dx \right)^{1/q} \leqq C \|v\|_{H^1(\Omega)}^2 \tag{2.37}$$

and (2.36) together with Lemma 2.9 and (2.37) shows that

$$\left| \int_{\Gamma^1} g^1 v \, ds \right| \leqq C \| G^1 \|_{H_\beta^{1,1}(\Omega)} \| v \|_{H^1(\Omega)}.$$

The Lax-Milgram lemma yields (2.35) and the uniqueness. □

Remark. If $|\Gamma^0| = 0$ and

$$\int_\Omega f \, dx + \int_{\Gamma^1} g^1 \, ds = 0, \tag{2.38}$$

then Lemma 2.11 holds in the factor space modulo a constant.

Proof of Theorem 2.1. Consider the polygonal domain shown in Fig. 2.1. Let

$$S_{i,\delta_i} = \{ r_i, \theta_i \,|\, 0 < r_i < \delta_i, 0 < \theta_i < \omega_i \} \subset \Omega$$

where (r_i, θ_i) are the polar coordinates with respect to the vertex A_i. (See Fig. 2.2.)

Let $\delta_i < 1$, be such that $S_{i,2\delta_i} \cap S_{j,2\delta_j} = \varnothing$ for $i \neq j$, $i, j = 1, \cdots M$. By Lemma 2.11 there is a unique solution of (2.1) in $H^1(\Omega)$. By Theorem 5.7.1, 5.7.1′ and 6.6.1 of [16], u is analytic in Ω and on Γ_i, $1 \leqq i \leqq M$ (because f and g^i are analytic functions in Ω

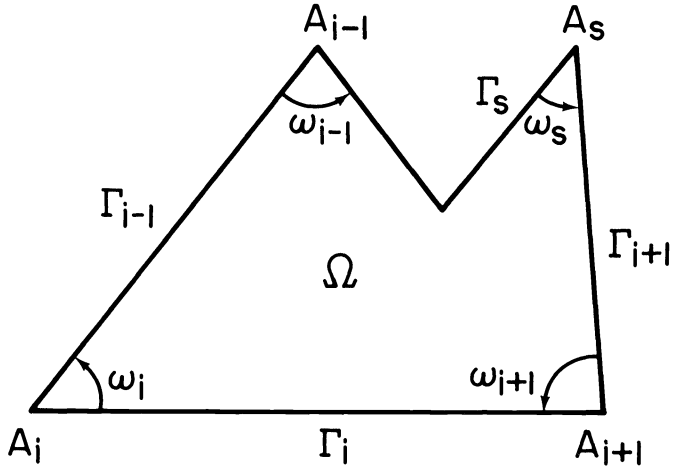

FIG. 2.1. *The polygonal domain.*

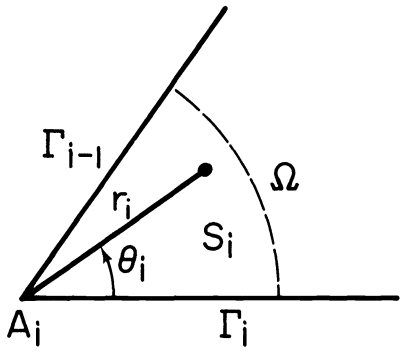

FIG. 2.2. *The scheme of coordinates* (r_i, θ_i).

and on Γ_i by our assumption). Hence Theorem 2.1 holds on $\Omega - \bigcup_{i=1}^{M} S_{i,\delta_i/4}$, and in particular we have for $|\alpha| = k$, $k \geqq 2$

$$\|r_i^{\alpha_1} \mathscr{D}^\alpha u\|_{\mathscr{L}_{\beta_i}(S_{i,\delta_i} - S_{i,\delta_i/2})} \leqq C_{i,0} d_{i,0}^{k-2} (k-2)!. \tag{2.39}$$

Hence, it is sufficient to prove that in each sector $S_{i,\delta_i/2}$, $1 \leqq i \leqq M$ and $|\alpha| = k$, $k \geqq 2$ we have

$$\|r_i^{\alpha_1 - 2} \mathscr{D}^\alpha u\|_{L_{\beta_i}(S_{i,\delta i/2})} \leqq L_i D_i^{k-2} P_i^{\alpha_2} (k-2)! \tag{2.40}$$

with L_i, D_i, P_i independent of k (see also Theorem 1.1 and (1.13)). There are three cases to be considered:

(i) $\Gamma_1 \subset \Gamma^0$, $\Gamma_{i-1} \subset \Gamma^1$,
(ii) Γ_i, $\Gamma_{i-1} \subset \Gamma^0$,
(iii) Γ_i, $\Gamma_{i-1} \subset \Gamma^1$.

We may assume that A_i is located at the origin and Γ_i lies on x_i-axes. To simplify the notation we will write $S_{i,\delta_i} = S_\delta$ and $\beta_i = \beta$, etc.

We will prove case (i) only. The proof for the other two cases is analogous.

Obviously the solution of problem (2.1) satisfies

$$\begin{aligned} &-\Delta u = f, \\ &u|_{\tilde{\Gamma}_i} = G^0|_{\tilde{\Gamma}_i}, \\ &\left.\frac{\partial u}{\partial n}\right|_{\tilde{\Gamma}_{i-1}} = G^1|_{\tilde{\Gamma}_{i-1}} \end{aligned} \tag{2.41}$$

where

$$\tilde{\Gamma}_l = \Gamma_l \cap S_\delta, \qquad l = i-1, i.$$

Let

$$\begin{aligned} &\varphi_0 \in C^\infty(R_+^1), \\ &\varphi_0(x) = 1 \quad \text{for } 0 \leqq x \leqq \tfrac{1}{2}, \\ &\varphi_0(x) = 0 \quad \text{for } x \geqq 1, \\ &\varphi_\delta(r) = \varphi_0\left(\frac{r}{\delta}\right) = \varphi(r). \end{aligned}$$

Denote

$$v = \varphi u.$$

Then, by zero extension outside S_δ, function v is defined on the infinite sector $Q = \{(r, \theta) \mid 0 < r < \infty,\ 0 < \theta < \omega\}$ and v satisfies

$$\begin{aligned} &-\Delta v = \varphi f + 2\nabla\varphi\nabla u + u\Delta\varphi = \tilde{f}, \\ &v|_{\theta=0} = \varphi G^0|_{\theta=0} = \tilde{G}^0|_{\theta=0}, \\ &\left.\frac{\partial v}{\partial n}\right|_{\theta=\omega} = \frac{1}{r}\left.\frac{\partial v}{\partial \theta}\right|_{\theta=\omega} = \varphi G^1|_{\theta=\omega} = \tilde{G}^1|_{\theta=\omega}. \end{aligned} \tag{2.42}$$

Obviously $v \in H^1(Q)$ and $\tilde{f}$, $\tilde{G}^0$, $\tilde{G}^1 = 0$ for $r > 1$. Denote by w the solution of (2.24) mentioned in Lemma 2.6. Then using Lemma 2.8 we see that $v = w$ and hence by (2.25)

$$\begin{aligned} \|v\|_{\mathscr{H}_\beta^{2,2}(S_\delta)} &\leqq C[\|\tilde{f}\|_{\mathscr{L}_\beta(Q)} + \|\tilde{G}^0\|_{\mathscr{H}_\beta^{2,2}(Q)} + \|\tilde{G}^1\|_{\mathscr{H}_\beta^{1,1}(Q)}] \\ &\leqq C\left[\|\tilde{f}\|_{\mathscr{L}_\beta(S_\delta)} + \sum_{l=0}^{1} \|\tilde{G}^l\|_{\mathscr{H}_\beta^{2-l,2-l}(S_\delta)}\right]. \end{aligned} \tag{2.43}$$

In (2.43) we have used the fact that $\varphi = 0$ for $r > \delta$. Because $\nabla\varphi = \Delta\varphi = 0$ for $0 < r < \delta/2$ and $r > \delta$ we have

$$\|\nabla\varphi\nabla u\|_{\mathscr{L}_\beta(S_\delta)} \leqq C\|u\|_{\mathscr{H}^{1,1}_\beta(S_\delta - S_{\delta/2})} \leqq C_1,$$

$$\|u\Delta\varphi\|_{\mathscr{L}_\beta(S_\delta)} \leqq C\|u\|_{\mathscr{L}_\beta(S_\delta - S_{\delta/2})} \leqq C_1.$$

Because $f \in B^0_\beta(\Omega)$, $G^i \in B^{2-i}_\beta(\Omega)$ we get immediately from (2.43)

$$\begin{aligned}\|u\|_{\mathscr{H}^{2,2}_\beta(S_{\delta/2})} &= \|v\|_{\mathscr{H}^{2,2}_\beta(S_{\delta/2})} \leqq \|v\|_{\mathscr{H}^{2,2}_\beta(S_\delta)} \\ &\leqq C_2\left\{\|f\|_{\mathscr{L}_\beta(S_\delta)} + \sum_{l=0}^{1}\|G^l\|_{\mathscr{H}^{2-l,2-l}_\beta(S_\delta)} + \|u\|_{\mathscr{H}^{1,1}_\beta(S_\delta - S_{\delta/2})}\right\}\end{aligned} \tag{2.44}$$

with C_2 dependent on δ and φ. Hence (2.40) holds for $|\alpha| = 2$. Let

$$v_k = r^k u_{r^k}, \qquad k \geqq 2. \tag{2.45}$$

Then

$$\begin{aligned}&-\Delta v_k = r^{k-2}(r^2 f)_{r^k} \quad \text{in } S_\delta, \\ &v_k|_{\theta=0} = r^k G^0_{r^k}|_{\theta=0}, \\ &\left.\frac{\partial v_k}{\partial n}\right|_{\theta=\omega} = \frac{1}{r}\left.\frac{\partial v_k}{\partial\theta}\right|_{\theta=\omega} = (r^k G^1_{r^k} + kr^{k-1}G^1_{r^{k-1}})|_{\theta=\omega}.\end{aligned} \tag{2.46}$$

Let $w_k = \varphi v_k$. Then

$$-\Delta w_k = -\varphi\Delta v_k - 2\nabla\varphi\nabla v_k - v_k\Delta\varphi$$

and

$$\begin{aligned}&w_k|_{\theta=0} = r^k G^0_{r^k}|_{\theta=0}, \\ &\left.\frac{\partial w_k}{\partial n}\right|_{\theta=\omega} = \frac{1}{r}\left.\frac{\partial w_k}{\partial\theta}\right|_{\theta=\omega} = \varphi(r^k G^1_{r^k} + kr^{k-1}G^1_{r^{k-1}})|_{\theta=\omega}.\end{aligned}$$

Hence analogously as before

$$\begin{aligned}\|v_k\|_{\mathscr{H}^{2,2}_\beta(S_{\delta/2})} \leqq C[&\|r^{k-2}(r^2 f)_{r^k}\|_{\mathscr{L}_\beta(S_\delta)} + \|v_k\|_{\mathscr{H}^{1,1}_\beta(S_\delta - S_{\delta/2})} + \|v_k\|_{\mathscr{L}_\beta(S_\delta - S_{\delta/2})} \\ &+ \|r^k G^0_{r^k}\|_{\mathscr{H}^{2,2}_\beta(S_\delta)} + \|r^k G^1_{r^k}\|_{\mathscr{H}^{1,1}_\beta(S_\delta)} + k\|r^{k-1}G^1_{r^{k-1}}\|_{\mathscr{H}^{1,1}_\beta(S_\delta)}].\end{aligned} \tag{2.47}$$

Because $f \in B^0_\beta(\Omega)$, $G^l \in B^{2-i}_\beta(\Omega)$ we have

$$\|r^{k-2}(r^2 f)_{r^k}\|_{\mathscr{L}_\beta(S_\delta)} \leqq C_3 d_3^k k!, \tag{2.48a}$$

$$\|r^k G^i_{r^k}\|_{\mathscr{H}^{2-i,2-i}_\beta(S_\delta)} \leqq C_4 d_4^k k!, \tag{2.48b}$$

$$k\|r^{k-1}G^1_{r^{k-1}}\|_{\mathscr{H}^{1,1}_\beta(S_\delta)} \leqq C_5 d_5^k k!. \tag{2.48c}$$

Using (2.39) we get

$$\|v_k\|_{\mathscr{H}^{1,1}_\beta(S_\delta - S_{\delta_2})} \leqq C d_0^{k-1}(k-1)!,$$

$$\|v_k\|_{\mathscr{H}^0_\beta(S_\delta - S_{\delta/2})} \leqq C d_0^{k-2}(k-2)!$$

with C independent of k (depending on δ). Hence

$$\|v_k\|_{\mathscr{H}^{2,2}_\beta(S_{\delta/2})} \leqq C_6 d_6^k k! \tag{2.49}$$

with C_6 and d_6 independent of k, L, D and P. Assume now by induction that (2.40) holds for $k' < k$. Then we get using (2.49)

$$\begin{aligned}\|r^k u_{r^{k+2}}\|_{\mathcal{L}_\beta(S_{\delta/2})} &\leqq C_6 d_6^k k! + 2kLD^{k-1}(k-1)! + k(k-1)LD^{k-2}(k-2)! \\ &\leqq LD^k k!\end{aligned} \tag{2.50a}$$

provided that D and L are large enough. Further $P > 1$, e.g., $P = 2$

$$\|r^{k-1} u_{r^{k+1}\theta}\|_{\mathcal{L}_\beta(S_{\delta/2})} \leqq C_6 d_6^k k + k(k-1)! LD^{k-1} P \leqq LD^k Pk! \tag{2.50b}$$

$$\|r^{k-2} u_{r^k\theta^2}\|_{\mathcal{L}_\beta(S_{\delta/2})} \leqq C_6 d_6^6 k! < LK^k P^2 k!. \tag{2.50c}$$

Inequalities (2.50) yield (2.40) with $\alpha_1 \geqq 2$ and $\alpha_2 \leqq 2$.

Let us now prove (2.40) by induction with respect to α_2. Let $v = r^{\alpha_1} u_{r^{\alpha_1}\theta^{\alpha_2-2}}$, $\alpha_2 \geqq 2$, $\alpha_1 + \alpha_2 = k$, $\alpha_1 \geqq 2$. Then

$$-\Delta v = r^{\alpha_1-2}(r^2 f_{\theta^{\alpha_2-2}})_{r^{\alpha_1}}$$

and also

$$-\Delta v = -r^{\alpha_1-2} u_{r^{\alpha_1}\theta^{\alpha_2}} - (2\alpha_1+1) r^{\alpha_1-1} u_{r^{\alpha_1+1}\theta^{\alpha_2-2}} - \alpha_1^2 r^{\alpha_1-2} u_{r^{\alpha_1}\theta^{\alpha_2-2}} - r^{\alpha_1} u_{r^{\alpha_1+2}\theta^{\alpha_2-2}}.$$

Hence

$$\begin{aligned}\|r^{\alpha_1-2} u_{r^{\alpha_1}\theta^{\alpha_2}}\|_{\mathcal{L}_\beta(S_{\delta/2})} \leqq{}& \|r^{\alpha_1-2}(r^2 f_{\theta^{\alpha_2-2}})_{r^{\alpha_1}}\|_{\mathcal{L}_\beta(S_{\delta/2})} \\ &+ (2\alpha_1+1)\|r^{\alpha_1-1} u_{r^{\alpha_1+1}\theta^{\alpha_2-2}}\|_{\mathcal{L}_\beta(S_{\delta/2})} \\ &+ \alpha_1^2 \|r^{\alpha_1-2} u_{r^{\alpha_1}\theta^{\alpha_2-2}}\|_{\mathcal{L}_\beta(S_{\delta/2})} \\ &+ \|r^{\alpha_1} u_{r^{\alpha_1+2}\theta^{\alpha_2-2}}\|_{\mathcal{L}_\beta(S_{\delta/2})}.\end{aligned} \tag{2.51}$$

Because $f \in B_\beta^0(\Omega)$ we have

$$\|r^{\alpha_1-2}(r^2 f_{\theta^{\alpha_2-2}})_{r^{\alpha_1}}\|_{\mathcal{L}_\beta(S_{\delta/2})} \leqq C_3 d_3^{k-2}(k-2)!. \tag{2.52}$$

By the induction assumption

$$\|r^{\alpha_1-1} u_{r^{\alpha_1+1}\theta^{\alpha_2-2}}\|_{\mathcal{L}_\beta(S_{\delta/2})} \leqq LD^{k-3} P^{\alpha_2-2}(k-3)!, \tag{2.53a}$$

$$\|^{\alpha_1} u_{r^{\alpha_1+2}\theta^{\alpha_2-2}}\|_{\mathcal{L}_\beta(S_{\delta/2})} \leqq LD^{k-2} P^{\alpha_2-2}(k-2)!, \tag{2.53b}$$

$$\|r^{\alpha_1-2} u_{r^{\alpha_1}\theta^{\alpha_2-2}}\|_{\mathcal{L}_\beta(S_{\delta/2})} \leqq LD^{k-4} P^{\alpha_2-2}(k-4)!. \tag{2.53c}$$

Hence from (2.47)

$$\begin{aligned}\|r^{\alpha_1-2} u_{r^{\alpha_1}\theta^{\alpha_2}}\|_{\mathcal{L}_\beta(S_{\delta/2})} &\leqq (k-2)![C_3 d_3^{k-2} + LD^{k-2} P^{\alpha_2-2} + LD^{k-3} P^{\alpha_2-2}(2\alpha_1+1) \\ &\qquad + LD^{k-4} P^{\alpha_2-2} \alpha_1^2] \\ &\leqq LD^{k-2} P^{\alpha_2}(k-2)!\end{aligned} \tag{2.54}$$

provided that L, D and P are sufficiently large. Similarly we can prove (2.40) for $\alpha_2 \geqq 2$, $\alpha_1 = 0, 1$.

Theorem 2.1 is proven for the case (i). The other cases are analogous.

Combining our results for every vertex we easily complete the proof. □

3. Regularity of the solution of the elliptic equation in a polygonal domain Ω. In § 2 we analyzed the problem of the regularity of the solution of the Poisson problem on a polygonal domain. In this section we will consider the general case of the elliptic equation of second order with analytic coefficients.

3.1. The problem and its basic properties. Let

$$L(u) = -\sum_{i,j=1}^{2} (a_{i,j}u_{x_i})_{x_j} + \sum_{i=1}^{2} b_i u_{x_i} + cu. \tag{3.1}$$

Let us consider the problem

$$\begin{aligned} &L(u) = f \quad \text{in } \Omega, \\ &u|_{\Gamma^0} = g^0 = G^0|_{\Gamma^0}, \\ &\left.\frac{\partial u}{\partial n_c}\right|_{\Gamma^1} = g^1 = G^1|_{\Gamma^1} \quad \text{on } \Gamma^1 \end{aligned} \tag{3.2}$$

where

$$\Gamma^0 = \bigcup_{i=\mathscr{D}} \bar{\Gamma}_i, \qquad \Gamma^1 = \Gamma - \Gamma^0,$$

and n_c is the conormal.

Let Ω be the polygonal domain in $\mathbf{R}^2$ and Γ_i be the open edge of $\partial\Omega$ (see § 2.1).

About f and g^i, $i=0, 1$ we will make the same assumptions as in Theorem 2.1 but replacing ω_i by $\omega_i^* \in (0, 2\pi]$, which will be defined later. About the operator L we will assume that

(i) $a_{i,j} = a_{j,i}$, b_i, c are analytic function on $\bar{\Omega}$,

(ii)

$$\sum_{l,j=1}^{2} a_{i,j}\xi_i\xi_j \geqq \mu_0(\xi_1^2 + \xi_2^2), \qquad \mu_0 > 0, \tag{3.3}$$

i.e., the operator is strongly elliptic.

(iii) Denote (see § 1.2)

$$H_0^1(\Omega) = \{u \in H^1(\Omega) \,|\, u = 0 \text{ on } \Gamma^0\}$$

and

$$B(u, v), \quad u \in H_0^1(\Omega), \quad v \in H_0^1(\Omega)$$

the bilinear form

$$B(u, v) = \int_\Omega (a_{i,j}u_{x_i}v_{x_j} + b_i u_{x_i} v + cuv)\, dx. \tag{3.4}$$

Assume that

$$\inf_{\substack{\|u\|_{H^1(\Omega)}=1 \\ u \in H_0^1(\Omega)}} \sup_{\substack{\|v\|_{H^1(\Omega)}=1 \\ v \in H_0^1(\Omega)}} |B(u, v)| \geqq \gamma > 0, \tag{3.5a}$$

and for any $v \in H_0^1(\Omega)$, $v \neq 0$

$$\sup_{\substack{\|u\|_{H^1(\Omega)}=1 \\ u \in H_0^1(\Omega)}} |B(u, v)| > 0. \tag{3.5b}$$

Conditions (i), (ii) guarantee the existence and uniqueness of $u \in H_0^1(\Omega)$ such that

$$B(u, v) = F(v) \tag{3.6}$$

holds for any $v \in H_0^1(\Omega)$ for any $F(v) \in H_0^1(\Omega))'$, i.e., $F(v)$ being a linear functional on $H_0(\Omega)$. In addition we have

$$\|u\|_{H^1(\Omega)} \leqq C\|F\|_{(H_0^1(\Omega))'} \tag{3.7}$$

with C independent of F.

For the proof see e.g. [4, p. 112]. Hence we have

LEMMA 3.1. *Let* $f \in \mathscr{L}_\beta(\Omega) = H_\beta^{0,0}(\Omega)$, $G^i \in H_\beta^{2-i,2-i}(\Omega)$ *and* $|\Gamma^0| \neq 0$, $\beta = (\beta_1, \cdots, \beta_M)$, $0 < \beta_i < 1$. *Then* (3.2) *has the unique solution* $u \in H^1(\Omega)$ (*in the weak sense*) *and*

$$\|u\|_{H^1(\Omega)} \leqq C[\|f\|_{\mathscr{L}_\beta(\Omega)} + \sum_{i=0,1} \|G^i\|_{H_\beta^{2-i,2-i}(\Omega)}].$$

The proof is completely analogous to the proof of Lemma 2.11, only replacing the Lax-Milgram lemma by its generalized form based on (3.5), (3.6), (3.7).

Remark 1. Condition (3.5a) and (3.5b) exclude the case when $\Gamma^0 = \varnothing$. Nevertheless this case which occurs in the case of Neumann problem and $b_i = c = 0$ can be treated in the usual way by restricting of $H_0^1(\Omega)$ to a modulo space.

LEMMA 3.2. *Let* L^0 *be the operator* (3.1) *with* $a_{i,j}^0 = a_{j,i}^0$ *constants and* $b_i = c = 0$. *Let* M *be the linear transformation*

$$\begin{aligned} &\xi_1 = (a_{1,2}^0 x_1 - a_{1,1}^0 x_2)/\sqrt{a_{1,1}^0}A, \qquad A = (a_{1,1}^0 a_{2,2}^0 - |a_{1,2}^0|^2)^{1/2}, \\ &\xi_2 = x_1/\sqrt{a_{1,1}^0} \end{aligned} \tag{3.8}$$

and $\tilde{u}(\xi_1, \xi_2) = u(x_1(\xi_1, \xi_2), x_2(\xi_1, \xi_2))$. *Then*

$$L^0 u = (-\Delta \tilde{u})$$

and the conormal n_c *in* (x_1, x_2) *transforms into the normal* n *in* (ξ_1, ξ_2). □

The lemma follows easily by simple computation.

The transformation M maps the polygonal domain Ω into the polygonal domain Ω^* with interior angles ω_i^*, $\omega_i^* = M(\omega_i)$.

Now let L be the general operator (3.1). By assumption the coefficients $a_{i,j}$ are analytic on $\bar{\Omega}$. Hence we can define mappings M_k associated to the vertices A_k with $a_{i,j}^0 = a_{i,j}(A_k)$ and set $\omega_k^* = M(\omega_k)$.

3.2. The regularity of the solution. The main theorem of this chapter is as follows.

THEOREM 3.1. *Let* $f \in B_\beta^0(\Omega)$, $g^l \in B_\beta^{3/2-l}(\Gamma^l)$, $l = 0, 1$, $\beta = (\beta_1, \cdots, \beta_M)$, $0 < \beta_i < 1$, $\beta_i > 1 - \pi/\omega_1^*$ (*respectively* $\beta_i > 1 - \pi/2\omega_i^*$ *if Dirichlet and Neumann boundary conditions are imposed on the edges* Γ_i *and* Γ_{i-1}, $\bar{\Gamma}_i \cap \bar{\Gamma}_{i-1} = A_i$) *and* $\Gamma^0 \neq \varnothing$. *Then problem* (3.1) *has a unique solution in* $H^1(\Omega)$ *and* $u \in B_\beta^2(\Omega)$.

Proof. The main idea of the proof is the same as in Theorem 2.1, namely that in the neighborhood of every vertex A_i the inequality (2.40) holds. By Theorem 5.7.1, 5.7.1′ and 6.6.1 of [16] u is analytic in Ω and on (open) Γ_i, $1 \leqq i \leqq M$.

Let the mapping M_l map Ω into Ω^* with the vertex A_l mapped into the origin and the edge Γ_l being mapped into Γ_l^* lying on the ξ_1 axis. Defining $\tilde{u}(\xi_1, \xi_2) = u(M_l^{-1}(\xi_1, \xi_2))$ we have

$$L^*(\tilde{u}) = \tilde{f} \tag{3.9}$$

where

$$L^*(\tilde{u}) = -\Delta \tilde{u} - \sum_{i,j=1}^{2} \tilde{a}_{i,j} \tilde{u}_{\xi_i \xi_j} + \sum_{j=1}^{2} \tilde{b}_j \tilde{u}_{\xi_j} + \tilde{c}\tilde{u} \tag{3.10}$$

with $\tilde{a}_{i,j}(0, 0) = 0$, and $\tilde{a}_{i,j}$, $\tilde{b}_j$ and $\tilde{c}$ are analytic functions in $\bar{\Omega}^*$.

Let $S=\{r, \theta \mid 0<r<\delta_l, 0<\theta<\omega_l^*\}$, $\delta_l=\delta<1$ and $S\subset\Omega^*$. Let us analyze in detail the case Γ_{l-1}^*, $\Gamma_l^*\subset\Gamma^{0*}$. (Let us write further Γ_l instead of Γ_l^*.) We have

$$
\begin{aligned}
&L^*(\tilde{u})=\tilde{f} \quad \text{on } S,\\
&\tilde{u}|_{\tilde{\Gamma}_l\cup\tilde{\Gamma}_{l-1}}=G^0|_{\tilde{\Gamma}_l\cup\tilde{\Gamma}_{l-1}}
\end{aligned}
\tag{3.11}
$$

where $\tilde{\Gamma}_l=\Gamma_l\cap S$. Without a loss of generality we assume that $G^0=0$ (if not we set $v=u-G^0$). We rewrite (3.10) by replacing $\tilde{u}$, $\tilde{a}_{i,j}$, $\tilde{b}_j$, $\tilde{c}$, $\tilde{f}$ by u, $a_{i,j}$, b_j, c, f, and (ξ_1, ξ_2) by (x_1, x_2). Then

$$
-\Delta u=f_1=f+\sum_{i,j=1}^{2} a_{i,j}u_{x_ix_j}-\sum_{j=1}^{2} b_ju_{x_j}-cu, \qquad u|_{\tilde{\Gamma}_l\cup\tilde{\Gamma}_{l-1}}=0. \tag{3.12}
$$

By Theorem 2.1 (see (2.44)) we have for $\beta_l>1-\pi/\omega_l^*$ and $\delta_1<\delta/2$

$$
\|u\|_{\mathscr{H}_\beta^{2,2}(S_{\delta_1})}\leqq C_0(\|f_1\|_{\mathscr{L}_\beta(S_\delta)}+\|u\|_{H^1(S_\delta-S_{\delta/2})}) \tag{3.13}
$$

where for simplicity we set $\beta=\beta_l$. Since $a_{i,j}(0,0)=0$ and $a_{i,j}$ are analytic in $\bar{\Omega}^*$ we have $|a_{i,j}|\leqq C_1 r$ in $\bar{S}_\delta$ and hence

$$
\|a_{i,j}u_{x_ix_j}\|_{\mathscr{L}_\beta(S_{\sigma_1})}\leqq C_1\delta_1\|u_{x_ix_j}\|_{\mathscr{L}_\beta(S_{\delta_1})}. \tag{3.14}
$$

One has

$$
u_{x_1}=u_r\cos\theta-u_\theta\frac{\sin\theta}{r},
$$

$$
u_{x_1^2}=u_{r^2}\cos^2\theta-u_{r\theta}\frac{\sin 2\theta}{r}+\frac{1}{r^2}u_{\theta^2}\sin^2\theta+\frac{1}{r}u_r\sin^2\theta+\frac{1}{r^2}u_\theta\sin 2\theta
$$

and similar expressions for $u_{x_1x_2}$ and $u_{x_2^2}$. Using Lemma A.2 scaled to the sector S_{δ_1} we get for $|\alpha|=1$

$$
\|r^{\alpha_1-2}\mathscr{D}^\alpha u\|_{\mathscr{L}_\beta(S_{\delta_1})}\leqq\tilde{C}_2\Big(\sum_{|\alpha'|=2}\|r^{\alpha_1'-2}\mathscr{D}^{\alpha'}u\|_{\mathscr{L}_\beta(S_{\delta_1})}+\|u\|_{H^1(S_{\delta_1})}\Big)
$$

with $\tilde{C}_2\geqq 1$ independent of δ_1.

Hence

$$
\begin{aligned}
\|u_{x_1^2}\|_{\mathscr{L}_\beta(S_{\delta_1})}&\leqq C_2\Big(\sum_{|\alpha|=2}\|r^{\alpha_1-2}\mathscr{D}^\alpha u\|_{\mathscr{L}_\beta(S_{\delta_1})}+\|u\|_{H^1(S_{\delta_1})}\Big)\\
&\leqq C_2\|u\|_{\mathscr{H}_\beta^{2,2}(S_{\delta_1})}.
\end{aligned}
\tag{3.15}
$$

Analogously it can be readily proven that (3.15) holds for $u_{x_ix_j}$, $i=1, 2$.

Using (3.14) in (3.15) we get

$$
\begin{aligned}
\sum_{i,j=1}^{2}\|a_{i,j}u_{x_ix_j}\|_{\mathscr{L}_\beta(S_{\delta_1})}&\leqq C_2C_1\delta_1\|u\|_{\mathscr{H}_\beta^{2,2}(S_{\delta_1})}\\
&=C_3\delta_1\|u\|_{\mathscr{H}_\beta^{2,2}(S_{\delta_1})}
\end{aligned}
\tag{3.16}
$$

where C_3 is independent of u and δ_1. Let us select δ_1 so that $C_0C_3\delta_1<\frac{1}{2}$. Then we get from (3.13)-(3.16)

$$
\|u\|_{\mathscr{H}_\beta^{2,2}(S_{\delta_1})}\leqq C_0[\|f\|_{\mathscr{L}_\beta(\delta)}+\|u\|_{H^1(S_\delta-S_{\delta/2})}+\|u\|_{H^2(S_\delta-S_{\delta/1})}]+C_0C_3\delta_1\|u\|_{\mathscr{H}_\beta^{2,2}(S_{\delta_1})}. \tag{3.17}
$$

Hence

$$
\|u\|_{\mathscr{H}_\beta^{2,2}(S_{\delta_1})}\leqq C_4[\|f\|_{\mathscr{L}_\beta(\delta)}+\|u\|_{H^1(S_\delta)}+\|u\|_{H^2(S_\delta-S_{\delta_1})}]. \tag{3.18}
$$

Because u is analytic we have for any $|\alpha| = k$

$$\|D^\alpha u\|_{L_2(S_\delta - S_{\delta_1})} \leqq C_5 d_5^k k! \tag{3.19}$$

and we have also $u \in H^1(S_\delta)$. Hence $u \in \mathscr{H}^{2,2}_\beta(S_{\delta_1})$.

Let now $v_k = r^k u_{r^k}$, $k \geqq 1$. Then

$$\begin{aligned} -\Delta v_k &= f_k = f_k^{(1)} + f_k^{(2)} \quad \text{on } S_{\delta_1}, \\ v_k|_{\tilde{\Gamma}_l \cup \tilde{\Gamma}_{l-1}} &= 0 \end{aligned} \tag{3.20}$$

where

$$f_k^{(1)} = r^{k-2}(r^2 f)_{r^k}, \tag{3.21a}$$

$$f_k^{(2)} = r^{k-2}\left(r^2 \sum_{l,j=1}^{2} a_{i,j} u_{x_i x_j} - r^2 \sum_{j=1}^{2} b_j u_{x_j} - r^2 c u \right)_{r^k}. \tag{3.21b}$$

As before we have

$$\|v_k\|_{\mathscr{H}^{2,2}_\beta(S_{\delta_1})} \leqq C_0(\|f_k\|_{\mathscr{L}_\beta(S_\delta)} + \|v_k\|_{H^1(S_\delta - S_{\delta/2})}). \tag{3.22}$$

Since by assumption $f \in B^0_\beta(\Omega)$ there exist constants C_f, d_f such that

$$\|f_k^{(1)}\|_{\mathscr{L}_\beta(S_\delta)} \leqq C_f d_f^k d!. \tag{3.23}$$

Because the coefficients $a_{i,j}$, b_j, c are analytic in $\bar{\Omega}$ there exist constants C_6, d_6 such that for $|\alpha| = k > 0$

$$\begin{aligned} |D^\alpha a_{i,j}| &\leqq C_6 d_6^k k!, \\ |D^\alpha b_j| &\leqq C_6 d_6^k k!, \\ |D^\alpha c| &\leqq C_6 d_6^k k!. \end{aligned} \tag{3.24}$$

Hence for $0 \leqq k - m \leqq 2$

$$|(r^2 a_{i,j})_{r^{k-m}}| \leqq \tilde{C}_6 r^{(2-k+m)} d_6^{(2-k+m)}$$

and for $k - m \geqq 2$

$$|(r^2 a_{i,j})_{r^{k-m}}| \leqq \tilde{C}_6 d_6^{k-m}(k-m)!.$$

Therefore for $i, j = 1, 2$

$$\begin{aligned} \|r^{k-2}(r^2 a_{i,j} u_{x_i x_j})_{r^k}\|_{\mathscr{L}_\beta(S_{\delta_1})} &\leqq \sum_{m=0}^{k} \binom{k}{m} \|r^{k-2}(r^2 a_{i,j})_{r^{k-m}} (u_{x_i x_j})_{r^m}\|_{\mathscr{L}_\beta(S_{\delta_1})} \\ &\leqq C_1 \delta_1 \|r^k u_{x_i x_j r^k}\|_{\mathscr{L}_\beta(S_{\delta_1})} \\ &\quad + \sum_{m=0}^{k-1} \binom{k}{m} \tilde{C}_6 d_6^{k-m}(k-m)! \|r^{k-2+\xi(m,k)} u_{x_i x_j r^m}\|_{\mathscr{L}_\beta(S_{\delta_1})} \end{aligned} \tag{3.25}$$

where

$$\begin{aligned} \xi(m, k) &= 2 - k + m \quad \text{for } 0 < k - m \leqq 2, \\ \xi(m, k) &= 0 \qquad\qquad\ \ \text{for } k - m > 2. \end{aligned}$$

Obviously

$$|\mathscr{D}^2 v_k| \leqq r^k |\mathscr{D}^2 u_{r^k}| + 2k|r^{k-1} u_{r^{k+1}}| + k(k-1)|r^{k-2} u_{r^k}| \tag{3.26}$$

and by (A.10) of Lemma A.4 we get

$$\begin{aligned}(3.27)\qquad &\|r^k u_{x_i x_j r^k}\|_{\mathscr{L}_\beta(S_{\delta_1})}\\ &\leqq \|v_k\|_{\mathscr{H}^{2,2}_\beta(S_{\delta_1})} + C_7 k!\left(\sum_{\substack{2\leqq|\alpha|\leqq k+1\\ 0\leqq\alpha_2\leqq 2}} \frac{k-|\alpha|+3}{(|\alpha|-2)!}\|r^{\alpha_1-2}\mathscr{D}^\alpha u\|_{\mathscr{L}_\beta(S_{\delta_1})} + \|u\|_{H^1(S_{\delta_1})}\right).\end{aligned}$$

For $m\leqq k-1$, by (A.11) of Lemma A.4

$$\begin{aligned}(3.28)\qquad &\|r^{k-2+\xi(m,k)} u_{x_i x_j r^m}\|_{\mathscr{L}_\beta(S_{\delta_1})}\\ &\leqq C_7 m!\left(\sum_{\substack{2\leqq|\alpha|\leqq m+2\\ 0\leqq\alpha_2\leqq 2}} \frac{(m-|\alpha|+3)}{(|\alpha|-2)!}\|r^{\alpha_1-2}\mathscr{D}^\alpha u\|_{\mathscr{L}_\beta(S_{\delta_1})} + \|u\|_{H^1(S_{\delta_1})}\right).\end{aligned}$$

Hence

$$\begin{aligned}(3.29)\qquad &\sum_{m=0}^{k-1}\binom{k}{m}\|r^{k-2}(r^2 a_{ij})_{r^{k-m}}(u_{x_i x_j})_{r^m}\|_{\mathscr{L}_\beta(S_{\delta_1})}\\ &\leqq C_7 k!\sum_{m=0}^{k-1} d_7^{k-m}\left(\sum_{2\leqq|\alpha|\leqq m+2}\frac{(m-|\alpha|+3)}{(|\alpha|-2)!}\|r^{\alpha_1-2}\mathscr{D}^\alpha u\|_{\mathscr{L}_\beta(S_{\delta_1})} + \|u\|_{H^1(S_{\delta_1})}\right).\end{aligned}$$

Similarly

$$\begin{aligned}(3.30)\qquad &\left\|r^{k-2}\left(r^2\sum_{j=1}^{2} b_j u_{x_j} + r^2 cu\right)_{r^k}\right\|_{\mathscr{L}_\beta(S_{\delta_1})}\\ &\leqq C_7 k!\left(\sum_{m=0}^{k} d_7^k \sum_{\substack{2\leqq|\alpha|\leqq m+1\\ 0\leqq\alpha_2\leqq 1}}\frac{1}{(|\alpha|-1)!}\|r^{\alpha_1-2}\mathscr{D}^\alpha u\|_{\mathscr{L}_\beta(S_{\delta_1})} + \|u\|_{H^1(S_{\delta_1})}\right).\end{aligned}$$

Thus

$$\begin{aligned}(3.31)\qquad &\|v_k\|_{\mathscr{H}^{2,2}_\beta(S_{\delta_1})} \leqq C_0 C_1\delta_1\|v^k\|_{\mathscr{H}^{2,2}_\beta(S_{\delta_1})}\\ &+ C(\delta)k!\left[\left(\sum_{\substack{2\leqq|\alpha|\leqq k+1\\ 0\leqq\alpha_2\leqq 2}}\frac{k-|\alpha|+3}{(|\alpha|-2)!}\|r_1^{\alpha_1-2}\mathscr{D}^\alpha u\|_{\mathscr{L}_\beta(S_{\delta_1})}\right.\right.\\ &+ \|u\|_{H^1(S_{\delta_1})} + \sum_{m=0}^{k-1} d_7^{k-m}\sum_{\substack{2\leqq|\alpha|\leqq m+2\\ 0\leqq\alpha_2\leqq 2}}\frac{(m-|\alpha|+3)}{(|\alpha|-2)!}\|r^{\alpha_1-2}\mathscr{D}^\alpha u\|_{\mathscr{L}_\beta(S_{\delta_1})}\\ &+ \sum_{m=0}^{k} d_7^{k-m}\sum_{\substack{2\leqq|\alpha|\leqq m+1\\ 0\leqq\alpha_2\leqq 1}}\frac{1}{(|\alpha|-1)!}\|r^{\alpha_1-2}\mathscr{D}^\alpha u\|_{\mathscr{L}_\beta(S_{\delta_1})}\\ &\left.\left. + C_f d_f^k k! + \|u\|_{H^{k+2}(S_\delta - S_{\delta_1})}\right)\right].\end{aligned}$$

Assuming by induction that (2.40) holds for $\alpha_2\leqq 2$ and $|\alpha|\leqq k-1$ and realizing that for $C_0C_1\delta_1<\frac{1}{2}$ we get (2.40) for $|\alpha|=k$, $\alpha_2\leqq 2$ provided that L and D are sufficiently large.

The same argument as has been used in § 2 yields (2.40) for $\alpha_2 > 2$. So far we have assumed that $(\Gamma_{l-1} \cup \Gamma_l) \subset \Gamma^0$. In the case $\Gamma_l \subset \Gamma^1$, $\Gamma_{l-1} \subset \Gamma^0$ we proceed analogously. We have

$$-\Delta u = f + \sum_{i,j=1}^{2} a_{i,j} u_{x_i x_j} - \sum_{j=1}^{2} b_j u_{x_j} - cu = f_1 \quad \text{on } S_{\delta_1}, \quad u|_{\tilde{\Gamma}_{l-1}} = 0,$$

$$\left.\frac{\partial u}{\partial n}\right|_{\tilde{\Gamma}_l} = \left[\frac{\partial u}{\partial n_c} - (a_{1,2} u_{x_1} + a_{2,2} u_{x_2})\right]\Bigg|_{\tilde{\Gamma}_l}$$

$$= G^1|_{\tilde{\Gamma}_l} - (a_{1,2} u_{x_1} + a_{2,2} u_{x_2})| = \tilde{G}^1|_{\tilde{\Gamma}_l}$$

with $a_{i,j}(0,0) = 0$. By (2.44) we have

$$\|u\|_{\mathscr{K}^{2,2}_{\beta}(S_{\delta_1})} \leqq C(\|f_1\|_{\mathscr{L}_{\beta}(S_\delta)} + \|G^1\|_{\mathscr{K}^{1,1}_{\beta}(S_\delta)} + \delta_1 \|u\|_{\mathscr{K}^{2,2}_{\beta}(S_{\delta_1})} + \|u\|_{H^1(S_\delta)} + \|u\|_{H^2(S_\delta - S_{\delta_1})})$$

and the proof is very similar as before. The same arguments hold for the case $(\Gamma_l \cup \Gamma_{l-1}) \subset \Gamma^1$. Combining the results for every vertex we get our theorem. □

Remark 2. In the proof that $u \in B^2_{\beta}(\Omega)$ we have only assumed that the solution exists. The other conditions, namely (3.4) and (3.5), only guarantee this existence.

We have assumed that the coefficients $a_{i,j}$, b_j, c are analytic on $\bar{\Omega}$. This assumption can be weakened. For example, we can assume that $a_{i,j}$, b_j, c are analytic on $\bar{\Omega} - \cup_{j=1}^{M} A_j$ and in the neighborhood of A_l, $l = 1, \cdots, M$

$$|D^\alpha (a_{i,j} - a_{i,j}(A_l))| \leqq C d^k k! r_l^{\varepsilon_l^a - k},$$

$$|D^\alpha b_j| \leqq C d^k k! r_l^{\varepsilon_l^b - k - 1},$$

$$|D^\alpha c| \leqq C d^k k! r_l^{\varepsilon_l^c - k - 2},$$

with arbitrary $\varepsilon_l^a > 0$, $\varepsilon_l^b > 0$, $\varepsilon_l^c > 0$, $\varepsilon_l^c + \beta_l > 1$, and $k = |\alpha|$. Nevertheless we will not go in further detail although this case plays an important role when nonlinear problem is studied.

4. Appendix.

LEMMA A.1. *One has the inequality*

$$\text{(A.1)} \qquad \int_0^1 t^{\alpha-2}[z(t) - a]^2 \, dt \leqq C(\alpha) \int_0^1 t^\alpha \left(\frac{dz}{dt}\right)^2 dt, \qquad \alpha \neq 1$$

where for $\alpha < 1$, $z(t)$ *is continuous on* $(0, 1]$, *and* $a = z(0)$; *for* $\alpha > 1$, $z(t)$ *is continuous on* $(0, 1]$, *and* $a = z(1)$.

Proof. For $\alpha < 1$, we have by Theorem 2.53 of [13]

$$\int_0^1 s^{-2} |w(s)|^2 \, ds \leqq C\left[\int_0^1 |w'(s)|^2 \, ds + w^2(1)\right], \qquad w(0) = 0.$$

Because $|w(1)|^2 \leqq \int_0^1 |w'(s)|^2 \, ds$ we have

$$\int_0^1 s^{-2} |w(s)|^2 \, ds \leqq C \int_0^1 |w'(s)|^2 \, ds.$$

Setting $w(t) = z(t) - z(0)$ and $s = t^{1-\alpha}$ we get

$$\int_0^1 t^{\alpha-2} (z(t) - z(0))^2 \, dt \leqq C \int_0^1 t^\alpha |z'(t)|^2 \, dt.$$

For $\alpha > 1$ we use Theorem 2.53 of [13]

$$\int_0^\infty s^{-2} |w(s)|^2 \, ds \leqq 4 \int_0^\infty |w'(s)|^2 \, ds, \qquad w(0) = 0.$$

Setting $t = s^{1/(1-\alpha)}$, $w(s) = z(s^{1/(1-\alpha)}) - z(1)$ for $s > 1$ and $w(s) = 0$ for $s \leqq 1$. Then we get (A.1).

LEMMA A.2. *Let* $S_\delta = \{r, \theta \mid 0 < r < \delta, 0 < \theta < \omega\}$. *Then for* $0 < \beta < 1$:

(i)

$$\|r^{-1}u\|^2_{\mathscr{L}_\beta(S_1)} \leqq C\left[\sum_{|\alpha|=1} \|r^{\alpha_1 - 1}\mathscr{D}^\alpha u\|_{\mathscr{L}_\beta(S_1)} + \|u\|^2_{L_2(S_1 - S_{1/2})}\right]; \tag{A.2}$$

(ii) *for* $|\alpha| = 1$

$$\|r^{\alpha_1 - 2}\mathscr{D}^\alpha u\|^2_{\mathscr{L}_\beta(S_1)} \leqq C\left[\sum_{|\alpha'|=2} \|r^{\alpha_1' - 2}\mathscr{D}^{\alpha'} u\|^2_{\mathscr{L}_\beta(S_1)} + \|u\|^2_{H^1(S_1)}\right]. \tag{A.3}$$

Proof. The proof is similar to the one of [5].

(1) Let

$$\bar{u}(r) = \frac{1}{\omega}\int_0^\omega u(r, \theta)\, d\theta;$$

then

$$\bar{u}_r(r) = \frac{1}{\omega}\int_0^\omega u_r(r, \theta)\, d\theta$$

and hence

$$\int_0^1 r^{2\beta+1}|\bar{u}_r(r)|^2\, dr \leqq C\|u_r\|^2_{\mathscr{L}_\beta(S_1)}.$$

Using (A.1) we get

$$\int_0^1 r^{2\beta-1}|\bar{u}(r) - a|^2\, dr \leqq C\|u_r\|^2_{\mathscr{L}_\beta(S_1)}$$

where $a = \bar{u}(1)$, and by the imbedding theorem

$$|a|^2 \leqq C\int_{1/2}^1 (\bar{u}^2 + \bar{u}_r^2)\, dr.$$

Hence

$$\int_0^1 r^{2\beta-1}|\bar{u}(r)|^2\, dr \leqq C[\|u_r\|^2_{\mathscr{L}_\beta(S_1)} + \|u\|^2_{L_2(S_1 - S_{1/2})}]$$

and

$$\|r^{-1}\bar{u}\|^2_{\mathscr{L}_\beta(S_1)} \leqq C[\|u_r\|^2_{\mathscr{L}_\beta(S_1)} + \|u\|^2_{L_2(S_1 - S_{1/2})}]. \tag{A.4}$$

Further for almost all r, φ we get

$$u(r, \varphi) - u(r, \psi) = \int_\psi^\varphi u_\theta(r, \theta)\, d\theta$$

and therefore

$$\begin{aligned} |u(r, \ ) - \bar{u}(r)| &= |\omega^{-1}\int_0^\omega d\psi \int_\psi^\varphi u_\theta(r, \theta)\, d\theta| \\ &\leqq C\left[\int_0^\omega |u_\theta(r, \theta)|^2\, d\theta\right]^{1/2} \end{aligned}$$

and

$$\int_0^\omega |u(r,\varphi)-\bar{u}(r)|^2\,d\theta \leqq C\int_0^\omega |u_\theta(r,\theta)|^2\,d\theta.$$

Hence

$$\int_{S_1} r^{2\beta-2}|u(r,\varphi)-\bar{u}(r)|^2 r\,dr\,d\varphi \leqq C\int_{S_1} r^{2\beta-2}|u_\theta(r,\theta)|^2 r\,dr\,d\theta. \tag{A.5}$$

Combining (A.4) and (A.5) we get (A.2).

(2) Let $v=u_r$. Then using (A.2) we have

$$\|r^{-1}u_r\|^2_{\mathscr{L}_\beta(S_1)} \leqq C[\|u_{rr}\|^2_{\mathscr{L}_\beta(S_1)}+\|r^{-1}u_{r\theta}\|^2_{\mathscr{L}_\beta(S_1)}+\|u_r\|^2_{L_2(S_1-S_{1/2})}]$$

which is (A.3) for $\alpha_1=1$, $\alpha_2=0$. Now let $v=u_\theta$ and repeat our argument. Let

$$\bar{v}^2(r)=\frac{1}{\omega}\int_0^\omega v(r,\theta)\,d\theta.$$

Then

$$\bar{v}^2(r) \leqq C\int_0^\omega v^2(r,\theta)\,d\theta,$$

$$\bar{v}'(r)=\frac{d\bar{v}}{dr}(r)=\frac{1}{\omega}\int_0^\omega u_{r\theta}\,d\theta$$

and

$$\bar{v}'^2(r) \leqq C\int_0^\omega (u^2_{r\theta})\,d\theta.$$

Hence

$$\int_0^1 \bar{v}'^2(r)r^{-1+2\beta}\,dr \leqq C\int_0^1\int_0^\omega (u^2_{r\theta})r^{-2+2\beta}r\,dr\,d\theta$$
$$\leqq C\sum_{|\alpha'|=2}\|r^{\alpha_1'-2}\,^{\alpha'}u\|^2_{\mathscr{L}_\beta(S_1)}<\infty,$$

and therefore $\bar{v}(r)$ is continuous on $[0,1]$. We also have

$$\int_0^1 \bar{v}^2(r)\frac{1}{r}\,dr \leqq \|u\|^2_{H^1(S_1)}<\infty$$

and hence $\bar{v}(0)=0$.

Using now Lemma A.1 we have

$$\int_0^1 r^{2\beta-3}|\bar{v}(r)|^2\,dr \leqq C\int_0^1 r^{2\beta-1}|\bar{v}_r(r)|^2\,dr$$
$$\leqq C\|r^{-1}u_{r\theta}\|^2_{\mathscr{L}_\beta(S_1)}$$

and hence

$$\|r^{-2}\bar{v}^2(r)\|_{\mathscr{L}_\beta(S_1)} \leqq C\|r^{-1}u_{r\theta}\|_{\mathscr{L}_\beta(S_1)}. \tag{A.6}$$

Analogously as before

$$\int_0^\omega |v(r,\varphi)-\bar{v}(r)|^2\,d\varphi \leqq C\int_0^\omega |v_\theta|^2\,d\varphi$$
$$\leqq C\int_0^\omega |u_{\theta\theta}|^2\,d\varphi$$

and

$$\int_{S_1} r^{2(\beta-2)}|v(r,\varphi)-\bar{v}(r)|^2 r\,dr\,d\varphi \leqq C\int_{S_1} r^{2(\beta-2)}|u_{\theta\theta}|^2 r\,dr\,d\varphi. \tag{A.7}$$

Combining (A.6) and (A.7) we get (A.3).

LEMMA A.3. *For $0<\beta<1$ one has*

$$\|r^{-1}u\|^2_{\mathscr{L}_\beta(S_1)} \leqq C\left[\sum_{|\alpha|=1}\|D^\alpha u\|^2_{\mathscr{L}_\beta(S_1)}+\|u\|^2_{L_2(S_1-S_{1/2})}\right]. \tag{A.8}$$

For $|\alpha|=1$

$$\|r^{-1}D^\alpha u\|_{\mathscr{L}_\beta(S_1)} \leqq C\left[\sum_{|\alpha'|=2}\|D^{\alpha'}u\|^2_{\mathscr{L}_\beta(S_1)}+\|u\|^2_{H^1(S_1-S_{1/2})}\right]. \tag{A.9}$$

Proof. Because

$$\sum_{|\alpha|=1}\|D^\alpha u\|^2_{\mathscr{L}_\beta(S_1)}=\sum_{|\alpha|=1}\|r^{\alpha_1-1}\mathscr{D}^\alpha u\|^2_{\mathscr{L}_\beta(S_1)},$$

(A.8) follows immediately from (A.2). Let $v=D^\alpha u$. Then (A.9) follows immediately from (A.8). □

LEMMA A.4. *Let $S=\{r,\theta\,|\,0<r<\delta, 0<\theta<\omega\}$. Then for $k>0$, $i,j=1,2$*

$$\begin{aligned}\|r^k u_{x_ix_jr^k}\|_{\mathscr{L}_\beta(S)} &\leqq \|r^k|\mathscr{D}^2 u_{r^k}|\,\|_{\mathscr{L}_\beta(S)}\\ &\quad + Ck!\left[\sum_{\substack{2\leqq|\alpha|\leqq k+1\\ 0\leqq\alpha_2\leqq 2}}\frac{(k-|\alpha|+3)}{(|\alpha|-2)!}\|r^{\alpha_1-2}\mathscr{D}^\alpha u\|_{\mathscr{L}_\beta(S)}+\|u\|_{H^1(S)}\right]\end{aligned} \tag{A.10}$$

and for $m\leqq k-1$, $k\geqq 1$, $i,j=1,2$

$$\|r^{k-2+\xi(m,k)}u_{x_ix_jr^m}\|_{\mathscr{L}_\beta(S)} \leqq Cm!\left(\sum_{\substack{2\leqq|\alpha|\leqq m+2\\ 0\leqq\alpha_2\leqq 2}}\frac{m-|\alpha|+3}{(|\alpha|-2)!}\|r^{\alpha_1-2}\mathscr{D}^\alpha u\|_{\mathscr{L}_\beta(S)}+\|u\|_{H^1(S)}\right) \tag{A.11}$$

where

$$\begin{aligned}&\xi(m,k)=2-k+m \quad \text{for } 0<k-m\leqq 2,\\ &\xi(m,k)=0 \quad\qquad\ \text{for } k-m>2\end{aligned}$$

and C is independent of u, but depends on δ and ω.

Proof. We will prove (A.10) only for $i=j=1$. Proof of the other two cases is completely analogous. We have

$$u_{x_1^2}=u_{r^2}\cos^2\theta-u_{r\theta}\frac{\sin 2\theta}{r}+\frac{1}{r^2}u_{\theta^2}\sin^2\theta+\frac{1}{r}u_r\sin^2\theta+\frac{1}{r^2}u_\theta\sin 2\theta.$$

Hence

$$\begin{aligned}r^k u_{x_1^2r^k} &= r^k\left(u_{r^{2+k}}\cos^2\theta-u_{r^{k+1}\theta}\frac{\sin 2\theta}{r}+\frac{1}{r^2}u_{r^k\theta^2}\sin^2\theta\right)\\ &\quad -\sin 2\theta\sum_{l=0}^{k-1}(-1)^{k-l}\binom{k}{l}(k-l)!\,r^{l-1}u_{r^{l-1}\theta}\\ &\quad +\sin^2\theta\sum_{l=0}^{k-1}(-1)^{k-l}\binom{k}{l}(k-l+1)!\,r^{l-2}u_{r^l\theta^2}\\ &\quad +\sin^2\theta\sum_{l=0}^{k}(-1)^{k-l}\binom{k}{l}(k-l)!\,r^{l-1}u_{r^{l+1}}\end{aligned} \tag{A.12}$$

$$+\sin^2\theta \sum_{l=0}^{k} (-1)^{k/l}\binom{k}{l}(k-l+1)!\, r^{l-2}u_{r^l\theta}$$

which yields

$$\begin{aligned}
\|r^k u_{x_1^2 r^k}\|_{\mathscr{L}_\beta(S)} &\leqq \|r^k|\mathscr{D}^2 u_{r^k}|\,\|_{\mathscr{L}_\beta(S)} \\
&\quad + k!\Bigg(\sum_{l=0}^{k-1}\frac{1}{l!}\|r^{l-1}u_{r^{l+1}\theta}\|_{\mathscr{L}_\beta(S)} + \sum_{l=0}^{k-1}\frac{(k-l+1)}{l!}\|r^{l-2}u_{r^l\theta^2}\|_{\mathscr{L}_\beta(S)} \\
&\quad + \sum_{l=0}^{k-1}\frac{1}{l!}\|r^{l-1}u_{r^{l+1}}\|_{\mathscr{L}_\beta(S)} + \sum_{l=0}^{k-1}\left(\frac{k-l+1}{l!}\right)\|r^{l-2}u_{r^l\theta}\|_{\mathscr{L}_\beta(S)}\Bigg) \qquad \text{(A.13)} \\
&\leqq \|r^2|\mathscr{D}^2 u_{r^k}|\,\|_{\mathscr{L}_\beta(S)} + Ck!\Bigg(\sum_{\substack{2\leqq|\alpha|\leqq k+1 \\ \alpha_2\geqq 2}}\frac{(k-|\alpha|+3)}{(|\alpha|-2)!}\|r^{\alpha_1-2}\mathscr{D}^\alpha u\|_{\mathscr{L}_\beta(S)} \\
&\quad + \|r^{-1}u_r\|_{\mathscr{L}_\beta(S)} + \|r^{-2}u_\theta\|_{\mathscr{L}_\beta(S)}\Bigg).
\end{aligned}$$

Equation (A.13) combined with Lemma 2 yields (A.10).

The proof of (A.11) is quite analogous. □

A GENERALIZED DIRICHLET PRINCIPLE FOR SECOND ORDER NONSELFADJOINT ELLIPTIC OPERATORS*

ROSS G. PINSKY†

Abstract. The classical Dirichlet principle states that if the spectrum of $L=\frac{1}{2}\Delta - V$ on a smooth bounded domain $D\subset R^n$ with the Dirichlet boundary condition on ∂D is negative, then the unique solution ϕ_0 of $L\phi_0=0$ in D with $\phi_0=f$ on ∂D, for a smooth function f, minimizes a certain energy integral. This may be easily extended to the operator $L=\frac{1}{2}\nabla\cdot a\nabla + a\nabla Q\cdot\nabla - V$. Now L is selfadjoint with respect to the density e^{2Q}. In this paper, we generalize this result to nonselfadjoint operators on bounded domains. We consider the solution ϕ_0 to $L\phi_0=(\frac{1}{2}\nabla\cdot a\nabla + b\cdot\nabla - V)\phi_0=0$ in D and $\phi_0=f\geqq 0$ on ∂D under the assumption $\operatorname{Re}(\sigma(L))<0$ for L with the Dirichlet boundary condition on ∂D.

Key words. second order nonselfadjoint elliptic operator, Dirichlet principle, mini-max formula

AMS(MOS) subject classification. 35J

1. Introduction. Consider the Dirichlet problem in a smooth bounded domain D, that is,

$$\frac{1}{2}\Delta u = 0 \text{ in } D \text{ and } u=f \text{ on } \partial D \text{ for } f\in W^{1,2}(D). \tag{1.1}$$

The classical Dirichlet or energy principle states that

$$\lambda_0 = \inf_{\substack{\phi=f \text{ on } \partial D \\ \phi\in W^{1,2}(D)}} \int_D \frac{1}{2}|\nabla\phi|^2\,dx \quad \text{is attained uniquely at } \phi=\phi_0$$

where ϕ_0 is the unique solution to (1.1). More generally, if V is smooth and the lead eigenvalue of the operator $\frac{1}{2}\Delta - V$ with the Dirichlet boundary condition on ∂D is negative, then

$$\lambda_0 = \inf_{\substack{\phi=f \text{ on } \partial D \\ \phi\in W^{1,2}(D)}} \int (\tfrac{1}{2}|\nabla\phi|^2 + V\phi^2)\,dx \text{ is attained uniquely at } \phi=\phi_0$$

where ϕ_0 uniquely solves $\frac{1}{2}\Delta\phi_0 - V\phi_0=0$ in D with $\phi_0=f$ on ∂D. In fact, if Q is a smooth function and $a(x)$ is a positive definite matrix at each $x\in R^n$ with smooth entries a_{ij}, then the above result can easily be extended to the case $L=\frac{1}{2}\nabla\cdot a\nabla + a\nabla Q\cdot\nabla - V\equiv L_0 - V$. Now the Dirichlet principle states that if the lead eigenvalue of L with the Dirichlet boundary condition is negative, then

$$\lambda_0 = \inf_{\substack{\phi=f \text{ on } \partial D \\ \phi\in W^{1,2}(D)}} \left[\int_D \left(\frac{1}{2}\nabla\phi a\nabla\phi + V\phi^2\right) e^{2Q}\,dx\right] \tag{1.2}$$

is attained uniquely at $\phi=\phi_0$ where ϕ_0 uniquely solves $L\phi_0=0$ in D with $\phi_0=f$ on ∂D. Now, if we replace the first order term, $a\nabla Q\cdot\nabla$, by $b\cdot\nabla$ where $a^{-1}b$ is not a gradient, then the problem is no longer selfadjoint and although a unique solution to the Dirichlet problem still exists, it is not representable as the solution to a simple variational problem as above.

In this paper we will extend this variational principle to the nonselfadjoint case. It turns out that in the nonselfadjoint case, one must consider a mini-max variational formula rather than a standard one.

In order to see how the minimax formula was arrived at, we need to discuss briefly the classical Rayleigh-Ritz formula and its generalization to nonselfadjoint operators. The classical Rayleigh-Ritz variational formula for the largest eigenvalue of the operator $L=\frac{1}{2}\Delta - V$ for a smooth function V on a smooth domain $D\subset R^n$ with the Dirichlet (Neumann) boundary condition on ∂D may be given as follows: the largest eigenvalue λ_0 satisfies

$$\lambda_0 = \inf_{\substack{\|\phi\|=1 \\ \phi=0 \text{ on } \partial D \\ \phi\in W^{1,2}(D)}} \int_D \left(\frac{1}{2}|\nabla\phi|^2 + V\phi^2\right) dx \qquad \left(\lambda_0 = \inf_{\substack{\|\phi\|=1 \\ \phi\in W^{1,2}(D)}} \int_D \left(\frac{1}{2}|\nabla\phi|^2 + V\phi^2\right) dx\right),$$

where $\|\phi\| = (\int_D \phi^2\, dx)^{1/2}$. Furthermore, the infimum is attained uniquely at ϕ_0, where ϕ_0 is the eigenfunction corresponding to λ_0. In fact, again, if Q is a smooth function and $a(x)$ is a positive definite matrix at each $x\in R^n$ with smooth entries a_{ij}, then the above result can easily be extended to the case $L=\frac{1}{2}\nabla\cdot a\nabla + a\nabla Q\cdot\nabla - V \equiv L_0 - V$ with either the Dirichlet or the conormal boundary condition, $na\nabla\phi = 0$ on ∂D, where n is the outward unit normal. L is now selfadjoint with respect to the density e^{2Q}, and the variational formula is given by

$$\lambda_0 = \inf_{\substack{\|\phi\|=1 \\ \phi=0 \text{ on } \partial D \\ \phi\in W^{1,2}(D)}} \int_D \left(\frac{1}{2}\nabla\phi a\nabla\phi + V\phi^2\right) e^{2Q}\, dx \quad \text{in the Dirichlet case,}$$

(1.3)

$$\lambda_0 = \inf_{\substack{\|\phi\|=1 \\ \phi\in W^{1,2}(D)}} \int_D \left(\frac{1}{2}\nabla\phi a\nabla\phi + V\phi^2\right) e^{2Q}\, dx \quad \text{in the conormal case,}$$

where $\|\phi\| = (\int_D \phi^2\, e^{2Q}\, dx)^{1/2}$. The infimum is attained uniquely at ϕ_0, where ϕ_0 is the eigenfunction corresponding to λ_0. As before, if we change the first order term in L_0 from $a\nabla Q\cdot\nabla$ to $b\cdot\nabla$, where $a^{-1}b$ is not a gradient, then the operator L is no longer selfadjoint. However, L is still semibounded and has a compact resolvent; consequently the Krein-Rutman theory of positive operators [4] guarantees that $\sup(\mathrm{Re}\,(\sigma(L)))$ occurs at a real eigenvalue. Yet the classical theory does not give a variational formula for the eigenvalue.

In the nonselfadjoint setting, Donsker and Varadhan [1] and Holland [3] have obtained for the Dirichlet case and the conormal case respectively, a mini-max variational formula for $\lambda_0 = \sup(\mathrm{Re}\,(\sigma(L)))$. Now, in the selfadjoint case, comparing (1.2) and (1.3), one sees that the same functional, $\int(\frac{1}{2}\nabla\phi a\nabla\phi + V\phi^2)\, e^{2Q}\, dx$, is varied in both the Rayleigh-Ritz formula and the Dirichlet principle. The only difference is the particular subdomain of $W^{1,2}(D)$ over which the variation is taken. Thus, to generalize the Dirichlet principle, we were led to consider the functional that was obtained by Donsker and Varadhan and by Holland, and then to find the appropriate boundary conditions.

2. Statement and proof of theorem. Let $L = L_0 - V$ with $L_0 = \frac{1}{2}\nabla\cdot a\nabla + b\cdot\nabla$ in a bounded domain $D\subset R^n$ where $a(x)$ is a positive definite $n\times n$ matrix for all $x\in\bar{D}$ with entries $a_{ij}\in C^{1,\alpha}(\bar{D})$, b is an n-vector with components $b_i\in C^{1,\alpha}(\bar{D})$, $V\in C^{\alpha}(\bar{D})$ and ∂D is a $C^{2,\alpha}$-boundary. Let $\tilde{L} = \frac{1}{2}\nabla\cdot a\nabla - b\cdot\nabla - \nabla\cdot b - V$ be the formal adjoint to L. We will assume that the spectrum of the operator L with the Dirichlet boundary condition on ∂D satisfies $\mathrm{Re}\,(\sigma(L)) < 0$. Since $\sigma(\tilde{L}) = \sigma(L)$, we also have $\mathrm{Re}\,(\sigma(\tilde{L})) < 0$. Then, since $Lu = 0$ with $u = 0$ on ∂D and $\tilde{L}\tilde{u} = 0$ with $\tilde{u} = 0$ on ∂D have only the trivial solution, there exist unique solutions in $C^{2,\alpha}(\bar{D})$ of $Lu = 0$ in D with $u = f$ on ∂D and of $\tilde{L}\tilde{u} = 0$ in D with $\tilde{u} = \tilde{f}$ on ∂D, for each f and each $\tilde{f}$ in $C^{2,\alpha}(\bar{D})$ [2, Thm. 6.15]. In

particular, let ϕ_0 solve $L\phi_0 = 0$ in D with $\phi_0 = f$ on ∂D and let $\tilde{\phi}_0$ solve $\tilde{L}\tilde{\phi}_0 = 0$ in D with $\tilde{\phi}_0 = fe^{2k}$ on ∂D, where $k \in C^{2,\alpha}(\bar{D})$. From here on, we will assume that $f \geqq 0$ and $f \not\equiv 0$. Define $\partial D_1 = \partial D \cap \{f = 0\}$. We have

PROPOSITION 2.1. (a) *$\phi_0 > 0$ in D and $\tilde{\phi}_0 > 0$ in D;*

(b) *$\nabla\phi_0 \cdot n < 0$ on ∂D_1 and $\nabla\tilde{\phi}_0 \cdot n < 0$ on ∂D_1, where n is the outward unit normal.*

Proof. This generalized maximum principle follows from Theorem 10 in [7], Theorem 6.15 in [2] and the fact that $\operatorname{Re}(\sigma(L)) = \operatorname{Re}(\sigma(\tilde{L})) < 0$.

Proposition 2.1 gives us the following.

PROPOSITION 2.2. $(\phi_0\tilde{\phi}_0)^{1/2} \in W^{1,2}(D)$.

Proof. From Proposition 2.1, it follows that

$$0 < \inf_{x \in D} \frac{\tilde{\phi}_0(x)}{\phi_0(x)} \leqq \sup_{x \in D} \frac{\tilde{\phi}_0(x)}{\phi_0(x)} < \infty.$$

This is enough to show that in fact $(\phi_0\tilde{\phi}_0)^{1/2} \in C^1(\bar{D})$.

We now present a generalized Dirichlet or energy principle for ϕ_0. Actually, we obtain a family of mini-max variational principles—one for each k, where k is as above. In the selfadjoint case, that is, the case $a^{-1}b = \nabla Q$, our Dirichlet principle will reduce to the classical one if and only if $k = Q$ on $\partial D - \partial D_1$. (See Remark 3 after the statement of the theorem for a proof of this.) It does not seem possible to give just one mini-max variational principle, which reduces to the classical one simultaneously for every selfadjoint case.

THEOREM. *Let $L = L_0 - V \equiv \frac{1}{2}\nabla \cdot a\nabla + b \cdot \nabla - V$ on a bounded region $D \subset R^n$ with $C^{2,\alpha}$-boundary ∂D. Also let $\tilde{L} = \tilde{L}_0 - V \equiv \frac{1}{2}\nabla \cdot a\nabla - b \cdot \nabla - \nabla \cdot b - V$ be the adjoint to L. Assume that the $n \times n$ matrix a has entries $a_{ij} \in C^{1,\alpha}(\bar{D})$, that the n-vector b has components $b_i \in C^{1,\alpha}(\bar{D})$, that $V \in C^{\alpha}(\bar{D})$ and that f and k are in $C^{2,\alpha}(\bar{D})$ with $f \geqq 0$ and $f \not\equiv 0$ on ∂D. Define $\partial D_1 = \partial D \cap \{f = 0\}$. Assume $\operatorname{Re}(\sigma(L)) < 0$ where L is the above operator with the Dirichlet boundary condition on ∂D, and let ϕ_0 and $\tilde{\phi}_0$ be the unique solutions to $L\phi_0 = 0$ in D with $\phi_0 = f$ on ∂D and to $\tilde{L}\tilde{\phi} = 0$ in D with $\tilde{\phi}_0 = fe^{2k}$ on ∂D. Then the mini-max variational formula*

$$\lambda_0^{(k)} = \inf_{\substack{g = fe^k \text{ on } \partial D \\ g \in W^{1,2}(D) \\ (\operatorname{dist}(x, \partial D_1))^{-1} g(x) \in L^{\infty}(D)}} \sup_{\substack{h = k \text{ on } \partial D - \partial D_1 \\ h \in W^{1,2}(D, g^2\,dx)}} \left[\frac{1}{2} \int_D \left(\frac{\nabla g}{g} - a^{-1}b \right) a \left(\frac{\nabla g}{g} - a^{-1}b \right) g^2\,dx \right.$$

$$\left. - \frac{1}{2} \int_D (\nabla h - a^{-1}b) a (\nabla h - a^{-1}b) g^2\,dx + \int Vg^2\,dx \right] \tag{2.1}$$

is attained for a unique pair,

$$(g_0, h_0) \in \{(g, h) : g \in W^{1,2}(D), (\operatorname{dist}(x, \partial D_1))^{-1} g(x)) \in L^{\infty}(D), h \in W^{1,2}(D, g^2\,dx)\},$$

and in fact $g_0 = (\phi_0\tilde{\phi}_0)^{1/2}$ and $h_0 = \frac{1}{2}\log \tilde{\phi}_0/\phi_0$. Thus

$$\lambda_0^{(k)} = \frac{1}{2} \int_D \left(\frac{1}{2} \frac{\nabla\tilde{\phi}_0}{\tilde{\phi}_0} + \frac{1}{2} \frac{\nabla\phi_0}{\phi_0} - a^{-1}b \right) a \left(\frac{1}{2} \frac{\nabla\tilde{\phi}_0}{\tilde{\phi}_0} + \frac{1}{2} \frac{\nabla\phi_0}{\phi_0} - a^{-1}b \right) \phi_0\tilde{\phi}_0\,dx$$

$$- \frac{1}{2} \int_D \left(\frac{1}{2} \frac{\nabla\tilde{\phi}_0}{\tilde{\phi}_0} - \frac{1}{2} \frac{\nabla\phi_0}{\phi_0} - a^{-1}b \right) a \left(\frac{1}{2} \frac{\nabla\tilde{\phi}_0}{\tilde{\phi}_0} - \frac{1}{2} \frac{\nabla\phi_0}{\phi_0} - a^{-1}b \right) \phi_0\tilde{\phi}_0\,dx \tag{2.2a}$$

$$+ \int_D V\phi_0\tilde{\phi}_0\,dx.$$

In the special case $\{f = 0 \text{ or } f = 1\} \cap \partial D = \partial D$, then

$$\lambda_0^{(k)} = \int_D \left(\frac{1}{2} \frac{\nabla\phi_0 a \nabla\phi_0}{\phi_0^2} + V \right) \phi_0\tilde{\phi}_0\,dx. \tag{2.2b}$$

Formula (2.2b) *also holds for arbitrary* f *in the selfadjoint case* $a^{-1}b = \nabla Q$ *if* $Q = k$ *on* $\partial D - \partial D_1$.

Furthermore, the mini-max principle in (2.1) *may be converted to the following minimum principle*:

$$\mu_0^{(k)} = \inf_{\substack{g = fe^k \text{ on } \partial D \\ g \in W^{1,2}(D) \\ (\operatorname{dist}(x, \partial D_1))^{-1} g(x) \in L^\infty(D)}} \inf_{\substack{z = (z_1, \cdots, z_n) \in C^1(D) \\ \nabla \cdot (g^2 z) = 0 \text{ in } D}} \left[\frac{1}{2} \int_D \left(\frac{\nabla g}{g} - a^{-1} b \right) a \left(\frac{\nabla g}{g} - a^{-1} b \right) g^2 \, dx \right. \tag{2.3}$$

$$\left. + \int_D \left(\frac{1}{2}(zaz) + z(b - a \nabla k) \right) g^2 \, dx \right]$$

is attained uniquely at the pair (g_0, z_0), *where* $z_0 = \nabla h_0 - a^{-1} b$ *and* g_0 *and* h_0 *are as defined above. Moreover,* $\mu_0^{(k)} = \lambda_0^{(k)}$.

Before proving the theorem, we make a number of comments.

Remark 1. The theorem ought to hold without the condition $(\operatorname{dist}(x, \partial D_1))^{-1} g(x) \in L^\infty(D)$. Unfortunately, our proof requires this technical condition.

Remark 2. The smoothness conditions on a, b, V, D, f and k may be ignored as long as it is known that (possibly weak) solutions $\phi_0 > 0$ and $\tilde{\phi}_0 > 0$ exist in $W^{1,2}(D)$ and that $(\phi_0 \tilde{\phi}_0)^{1/2}$ is in $W^{1,2}(D)$. The only change now is that the condition $(\operatorname{dist}(x, \partial D_1))^{-1} g(x) \in L^\infty(D)$ should be replaced by $\phi_0^{-1} g \in L^\infty(D)$. It is true that in the proof, we integrate by parts and use the assumption that ϕ_0 and $\tilde{\phi}_0$ are C^2-functions. However, this is merely a convenience.

Remark 3. In the selfadjoint case, we have $a^{-1} b = \nabla Q$. This implies that $Q \in C^{2,\alpha}(\bar{D})$. Thus, it is always possible to pick k such that $k = Q$ on $\partial D - \partial D_1$ (in fact one might as well pick $k \equiv Q$). We noted, prior to stating the theorem, that only in the case $k = Q$ on $\partial D - \partial D_1$ will the variational principle reduce to the classical one given in (1.2). To see this note that only in this case will

$$\inf_{\substack{h = k \text{ on } \partial D - \partial D_1 \\ h \in W^{1,2}(D, g^2 dx)}} \left[\int_D (\nabla h - \nabla Q) a (\nabla h - \nabla Q) g^2 \, dx \right] = 0 \quad \text{for all } g \in W^{1,2}(D).$$

If this above expression is zero for all $g \in W^{1,2}(D)$, then it is easy to see that the condition $(\operatorname{dist}(x, \partial D_1))^{-1} g(x) \in L^\infty(D)$ is no longer needed. Thus (2.1) reduces to

$$\lambda_0^{(k)} = \inf_{\substack{g \in fe^k \text{ on } \partial D \\ g \in W^{1,2}(D)}} \left[\frac{1}{2} \int_D \left(\frac{\nabla g}{g} - \nabla Q \right) a \left(\frac{\nabla g}{g} - \nabla Q \right) g^2 \, dx + \int_D V g^2 \, dx \right]$$

$$= \inf_{\substack{u = f \text{ on } \partial D \\ u \in W^{1,2}(D)}} \left[\frac{1}{2} \int (\nabla u a \nabla u) \, e^{2Q} \, dx + \int_D V u^2 \, e^{2Q} \, dx \right],$$

where we have made the substitution $g = ue^Q$. This is (1.2). Furthermore (2.2b) now becomes

$$\lambda_0^{(k)} = \frac{1}{2} \int_D (\nabla \phi_0 a \nabla \phi_0) \, e^{2Q} \, dx + \int_D V \phi_0^2 \, e^{2Q} \, dx,$$

since $h_0 = Q$ and $\tilde{\phi}_0 / \phi_0 = e^{2Q}$.

Remark 4. Since ∂D may be composed of two disconnected pieces (D an annulus, for example), the special case $\{f = 0 \text{ or } f = 1\} \cap \partial D = \partial D$ does not only include the

trivial cases $f \equiv 0$ on ∂D and $f \equiv 1$ on ∂D. We note the reduction of (2.2a) to (2.2b) for two reasons. First of all, if $V \geqq 0$, then excluding the selfadjoint case $a^{-1}b = \nabla Q$ for some Q satisfying $Q = k$ on ∂D (see Remark 3), it is clear from (2.1) that only in the case $\{f = 0 \text{ or } f = 1\} \cap \partial D = \partial D$ can one guarantee by inspection that $\lambda_0^{(k)} \geqq 0$. This is reflected in (2.2a) and (2.2b). Also, in a probabilistic application of this theorem, which appears in [6], we need the form appearing in (2.2b).

Remark 5. This generalized Dirichlet principle is less general than the classical one since it requires that the boundary values be nonnegative. Indeed, if f changes sign, then ϕ_0 and $\tilde{\phi}_0$ may change sign and, consequently, neither g_0 nor h_0 is defined. However, this restriction is not too severe. For example, if $V = 0$ and if $\hat{\phi}_0$ satisfies $L\hat{\phi}_0 = 0$ on D and $\hat{\phi}_0 = \hat{f}$ on ∂D, for a general $\hat{f}$, then for sufficiently large M, $\phi_0 \equiv \hat{\phi}_0 + M$ satisfies $L\phi_0 = 0$ on D with $\phi_0 = f \equiv \hat{f} + M \geqq 0$ on ∂D. Thus $\hat{\phi}_0$ may be described as $\phi_0 - M$ where ϕ_0 has a generalized Dirichlet principle associated with it.

Proof. For $g \in W^{1,2}(D)$ satisfying $g = fe^k$ on ∂D, let

$$H_g(h) = \frac{1}{2} \int_D (\nabla h - a^{-1}b) a (\nabla h - a^{-1}b) g^2 \, dx.$$

First we show that

$$\inf_{\substack{h = k \text{ on } \partial D - \partial D_1 \\ h \in W^{1,2}(D, g^2\,dx)}} H_g(h) \quad \text{is attained at a unique } h = h_g \in W^{1,2}(D, g^2\,dx).$$

Actually, the proof is almost identical to a special case of the proof of a result which can be found in [5, pp. 688-690]. For completeness, we will give a proof although we will not write down all the details. By the Schwarz inequality, it is easy to obtain $H_g(h) \geqq c_1 \int_D |\nabla h|^2 g^2 \, dx - c_2$ for positive constants c_1 and c_2. Thus if $\{h_n\}$ is a minimizing sequence, then $\int_D |\nabla h_n|^2 g^2 \, dx$ is bounded independent of n. This, coupled with the fact that $h_n = k$ on $\partial D - \partial D_1$ gives weak compactness in $W^{1,2}(D, g^2\,dx)$. Now $H_g(h)$ is lower semicontinuous under weak convergence since the norm is lower semicontinuous under weak convergence. Thus, in fact, any limit $\hat{h}$ of a subsequence $\{h_n\}$ must be a minimizer. Varying $H_g(h)$ at $\hat{h}$ gives

$$\int_D (\nabla \hat{h} - a^{-1}b) a \nabla q g^2 \, dx = 0, \tag{2.4}$$

for all $q \in W^{1,2}(D, g^2\,dx)$ satisfying $q = 0$ on $\partial D - \partial D_1$. Now if $\tilde{h}$ is also a minimizer, then (2.4) also holds with $\tilde{h}$ in place of $\hat{h}$. Subtracting gives $\int_D (\nabla \hat{h} - \nabla \tilde{h}) a \nabla q g^2 \, dx = 0$. Substituting $q = \hat{h} - \tilde{h}$ shows that $\nabla \hat{h} - \nabla \tilde{h} = 0$ a.e. $[g^2\,dx]$, and since $\hat{h} = \tilde{h} = k$ on $\partial D - \partial D_1$, we have $\hat{h} = \tilde{h}$ a.e. $[g^2\,dx]$. This completes the proof. We will denote the minimizer by h_g.

Consider $g = g_0 \equiv (\phi_0 \tilde{\phi}_0)^{1/2}$. By Proposition 2.2, $g_0 \in W^{1,2}(D)$. We claim that $h_0 \equiv h_{g_0} = \frac{1}{2} \log (\tilde{\phi}_0 / \phi_0)$. Note that h_0 satisfies the appropriate boundary conditions since $\phi_0 = f$ and $\tilde{\phi}_0 = fe^{2k}$ on ∂D. We must check that (2.4) is satisfied with $\hat{h}$ replaced by h_0. From the fact that $L\phi_0 = 0$ and $\tilde{L}\tilde{\phi}_0 = 0$, one can check that h_0 satisfies

$$\nabla \cdot a \nabla h_0 + 2 \frac{\nabla g_0}{g_0} \nabla h_0 = \nabla \cdot b + 2 \frac{\nabla g_0}{g_0} b. \tag{2.5}$$

Integrating the left-hand side of (2.4) by parts and using (2.5), one sees that (2.4) is indeed satisfied with $\hat{h} = h_0$.

Now, for $g \in W^{1,2}(D)$, let $\gamma = g^2$ and define for γ and for $h \in W^{1,2}(D, \gamma\,dx)$, $\psi(h, \gamma) = \frac{1}{2}\int_D (\nabla h - a^{-1}b)a(\nabla h - a^{-1}b)\gamma\,dx$. Also define

$$J(\gamma) = \psi(\tfrac{1}{2}\log\gamma, \gamma) - \inf_{\substack{h=k \text{ on } \partial D - \partial D_1 \\ h \in W^{1,2}(D, \gamma\,dx)}} \psi(h, \gamma) + \int_D V\gamma\,dx.$$

Then the right-hand side of (2.1) may be written as

$$\inf_{\substack{\gamma = f^2 e^{2k} \text{ on } \partial D \\ \gamma^{1/2} \in W^{1,2}(D) \\ (\operatorname{dist}(x, \partial D_1))^{-1}\gamma^{1/2}(x) \in L^\infty(D)}} J(\gamma).$$

To show that (a) the mini-max in (2.1) is attained at some pair (g, h_g); (b) the pair is unique; and (c) the pair is given by (g_0, h_0), it obviously suffices to show that $J(\gamma_0) < J(\gamma_1)$ for all $\gamma_1 \neq \gamma_0 \equiv g_0^2$ that satisfy $\gamma_1 = f^2 e^{2k}$ on ∂D, $\gamma_1^{1/2} \in W^{1,2}(D)$ and $(\operatorname{dist}(x, \partial D_1))^{-1}\gamma_1^{1/2}(x) \in L^\infty(D)$. To do this, we will show that $M(p) \equiv J(\gamma_p)$ is strictly convex on $[0, 1]$ and satisfies $M'(0) = 0$, where $\gamma_p = p\gamma_1 + (1-p)\gamma_0$.

Now

$$M(p) = J(\gamma_p) = \psi\left(\frac{1}{2}\log\gamma_p, \gamma_p\right) + \left(-\inf_{\substack{h=k \text{ on } \partial D - \partial D_1 \\ h \in W^{1,2}(D, \gamma_p dx)}} \psi(h, \gamma_p)\right) + \int_D V\gamma_p\,dx$$

and it is easy to see that the second term on the right-hand side is convex in p (the p appearing in the domain over which the infimum is calculated causes no problem). Since the third term on the right-hand side is linear, to show strict convexity we need only show that $(d^2/dp^2)(\psi(\frac{1}{2}\log\gamma_p, \gamma_p)) > 0$ for $p \in [0, 1]$. We have

$$\psi\left(\frac{1}{2}\log\gamma_p, \gamma_p\right) = \frac{1}{2}\int_D \frac{(\frac{1}{2}\nabla\gamma_p - a^{-1}b\gamma_p)a(\frac{1}{2}\nabla\gamma_p - a^{-1}b\gamma_p)}{\gamma_p}\,dx$$

and

$$\frac{d^2}{dp^2}\left(\psi\left(\frac{1}{2}\log\gamma_p, \gamma_p\right)\right) = \int_D \left(\frac{\nabla(\gamma_1 - \gamma_0) - a^{-1}b(\gamma_1 - \gamma_0)}{\gamma_p^{1/2}} - \frac{\nabla\gamma_p - a^{-1}b\gamma_p(\gamma_1 - \gamma_0)}{\gamma_p^{3/2}}\right)$$
$$\cdot a\left(\frac{\nabla(\gamma_1 - \gamma_0) - a^{-1}b(\gamma_1 - \gamma_0)}{\gamma_p^{1/2}} - \frac{\nabla\gamma_p - a^{-1}b\gamma_p(\gamma_1 - \gamma_0)}{\gamma_p^{3/2}}\right) dx \geqq 0.$$

Equality occurs if and only if

$$\frac{\nabla(\gamma_1 - \gamma_0) - a^{-1}b(\gamma_1 - \gamma_0)}{\gamma_p^{1/2}} = \frac{\nabla\gamma_p - a^{-1}b\gamma_p(\gamma_1 - \gamma_0)}{\gamma_p^{3/2}},$$

that is, only if $(\nabla(\gamma_1 - \gamma_0))/\gamma_1 - \gamma_0 = \nabla p/\gamma_p$. For this to occur for even one fixed p requires that γ_1 be a multiple of γ_0, which is impossible since by assumption $\gamma_1 \not\equiv \gamma_0$ and $\gamma_1 = \gamma_0 = f^2 e^{2k}$ on ∂D. This proves the strict convexity.

We now prove that $M'(0) = 0$. Let $h_p \in W^{1,2}(D, \gamma_p)$ be the function at which

$$\inf_{\substack{h=k \text{ on } \partial D - \partial D_1 \\ h \in W^{1,2}(D, \gamma_p)}} \int_D (\nabla h - a^{-1}b)a(\nabla q - a^{-1}b)\gamma_p\,dx$$

is attained. From (2.4), h_p satisfies

$$\int (\nabla h_p - a^{-1}b)a\nabla q\gamma_p\,dx = 0, \tag{2.6}$$

for all $q \in W^{1,2}(D, \gamma_p\, dx)$ satisfying $q = 0$ on $\partial D - \partial D_1$. We will show that

$$\nabla h_0' \equiv \lim_{\varepsilon \to 0} \frac{\nabla h_\varepsilon - \nabla h_0}{\varepsilon} \tag{2.7}$$

exists as a weak limit in $L^2(D, \gamma_0\, dx)$. Then we have

$$\begin{aligned} M(p) = &\frac{1}{2}\int_D \frac{(\tfrac{1}{2}\nabla\gamma_p - a^{-1}b\gamma_p)a(\tfrac{1}{2}\nabla\gamma_p - a^{-1}b\gamma_p)}{\gamma_p}\, dx \\ &-\frac{1}{2}\int_D (\nabla h_p - a^{-1}b)a(\nabla h_p - a^{-1}b)\gamma_p\, dx + \int_D V\gamma_p\, dx \end{aligned} \tag{2.8}$$

and, formally,

$$\begin{aligned} M'(0) = &\int_D \left[\frac{(\tfrac{1}{2}\nabla(\gamma_1 - \gamma_0) - a^{-1}b(\gamma_1 - \gamma_0))a(\tfrac{1}{2}\nabla\gamma_0 - a^{-1}b\gamma_0)}{\gamma_0}\right. \\ &\left. -\frac{(\tfrac{1}{2}\nabla\gamma_0 - a^{-1}b\gamma_0)a(\tfrac{1}{2}\nabla\gamma_0 - a^{-1}b\gamma_0)(\gamma_1 - \gamma_0)}{2\gamma_0^2}\right] dx \\ &-\int_D (\nabla h_0 - a^{-1}b)a(\nabla h_0')\gamma_0\, dx \\ &-\frac{1}{2}\int_D (\nabla h_0 - a^{-1}b)a(\nabla h_0 - a^{-1}b)(\gamma_1 - \gamma_0)\, dx + \int_D V(\gamma_1 - \gamma_0)\, dx. \end{aligned} \tag{2.9}$$

Under the assumption that (2.7) and (2.9) hold rigorously, we will show that $M'(0) = 0$. Then we will go back and prove (2.7) and (2.9). The term $\int_D (\nabla h_0 - a^{-1}b)a(\nabla h_0')\gamma_0\, dx = 0$ by (2.6) and (2.7). Thus (2.9) becomes

$$\begin{aligned} M'(0) = &\int_D \left[\frac{(\tfrac{1}{2}\nabla(\gamma_1 - \gamma_0) - a^{-1}b(\gamma_1 - \gamma_0))a(\tfrac{1}{2}\nabla\gamma_0 - a^{-1}b\gamma_0)}{\gamma_0}\right. \\ &\left. -\frac{(\tfrac{1}{2}\nabla\gamma_0 - a^{-1}b\gamma_0)a(\tfrac{1}{2}\nabla\gamma_0 - a^{-1}b\gamma_0)(\gamma_1 - \gamma_0)}{2\gamma_0^2}\right] dx \\ &-\frac{1}{2}\int_D (\nabla h - a^{-1}b)a(\nabla h_0 - a^{-1}b)(\gamma_1 - \gamma_0)\, dx \\ &+\int_D V(\gamma_1 - \gamma_0)\, dx. \end{aligned} \tag{2.10}$$

From the fact that $\phi_0 = g_0\, e^{-h_0}$ and $\tilde{\phi}_0 = g_0\, e^{h_0}$, one can verify that $\gamma_0 = g_0^2$ satisfies

$$\frac{1}{2}\nabla \cdot a\nabla\gamma_0 - \frac{1}{4}\frac{\nabla\gamma_0 a\nabla\gamma_0}{\gamma_0} + \gamma_0(\nabla h_0 a\nabla h_0 - \nabla \cdot b - 2\nabla h_0 b) - V\gamma_0 = 0. \tag{2.11}$$

Now (2.9) arises as the variation of (2.8) in the direction $\gamma_1 - \gamma_0$. If we set $q = \gamma_1 - \gamma_0$ in (2.9), and then integrate by parts and use (2.11) and the fact that $q = 0$ on ∂D, we obtain $M'(0) = 0$.

It remains to show (2.7) and (2.9). First we show (2.7). Since $\int_D (\nabla h_p - b)a(\nabla h_p - b)\gamma_p\, dx$ is bounded independent of p, it is clear that

$$\overline{\lim_{p \to 0}} \int_D |\nabla h_p|^2 \gamma_0\, dx < \infty. \tag{2.12}$$

By the assumption that $(\operatorname{dist}(x, \partial D_1))^{-1}\gamma_1^{1/2}(x) \in L^\infty(D)$ and by Proposition 2.1, (2.12) guarantees that

$$\overline{\lim_{p \to 0}} \int_D |\nabla h_p|^2 \gamma_1\, dx < \infty. \tag{2.13}$$

From (2.6), we have $\int_D (\nabla h_p - a^{-1}b)a\nabla q\gamma_p\,dx = 0$ for $0<p<1$ and $\int(\nabla h_0 - a^{-1}b)a\nabla q\gamma_0\,dx = 0$ for all $q \in W^{1,2}(D, \gamma_0\,dx)$ satisfying $q=0$ on $\partial D - \partial D_1$. Subtracting, we obtain

$$\int_D (\nabla h_p - \nabla h_0)a\nabla q\gamma_0\,dx + p\int_D (\nabla h_p - b)a\nabla q(\gamma_1-\gamma_0)\,dx = 0. \tag{2.14}$$

From (2.12), (2.13) and (2.14), we have

$$\lim_{p\to 0}\int_D (\nabla h_p - \nabla h_0)a\nabla q\gamma_0\,dx = 0, \tag{2.15}$$

for all $q \in W^{1,2}(D, \gamma_0\,dx)$ satisfying $q=0$ on $\partial D - \partial D_1$. Since $h_p - h_0$ also satisfies $h_p - h_0 \in W^{1,2}(D, \gamma_0\,dx)$ and $h_p - h_0 = 0$ on $\partial D - \partial D_1$, (2.15) guarantees that $\nabla h_p \to \nabla h_0$ weakly in $L^2(D, \gamma_0\,dx)$. Using this fact, we see from (2.14) that

$$\lim_{p\to 0}\int_D \left(\frac{\nabla h_p - \nabla h_0}{p}\right) a\nabla q\gamma_0\,dx = -\int_D (\nabla h_0 - b)a\nabla q(\gamma_1-\gamma_0)\,dx.$$

This shows that $(\nabla h_p - \nabla h_0)/p \to (\nabla h_0 - b)(\gamma_0-\gamma_1)/\gamma_0 \equiv \nabla h_0'$ weakly in $L^2(D, \gamma_0\,dx)$ and proves (2.7).

To show (2.9), we must show that

$$\begin{aligned}
&\lim_{p\to 0}\frac{1}{p}\Bigg[\int (\nabla h_p - a^{-1}b)a(\nabla h_p - a^{-1}b)\gamma_p\,dx \\
&\qquad - \int_D (\nabla h_0 - a^{-1}b)a(\nabla h_0 - a^{-1}b)\gamma_0\,dx\Bigg] \\
&= 2\int_D (\nabla h_0 - a^{-1}b)a(\nabla h_0')\gamma_0\,dx \\
&\qquad + \int_D (\nabla h_0 - a^{-1}b)a(\nabla h_0 - a^{-1}b)(\gamma_1-\gamma_0)\,dx.
\end{aligned} \tag{2.16}$$

We have

$$\begin{aligned}
&\frac{1}{p}\Bigg[\int_D (\nabla h_p - a^{-1}b)a(\nabla h_p - a^{-1}b)\gamma_p\,dx \\
&\qquad - \int_D (\nabla h_0 - a^{-1}b)a(\nabla h_0 - a^{-1}b)\gamma_0\,dx\Bigg] \\
&= \frac{1}{p}\int_D \Big[(\nabla h_p - a^{-1}b)a(\nabla h_p - a^{-1}b) - (\nabla h_0 - a^{-1}b)a(\nabla h_0 - a^{-1}b)\Big]\gamma_0\,dx \\
&\qquad + \int_D (\nabla h_p - a^{-1}b)a(\nabla h_p - a^{-1}b)(\gamma_1-\gamma_0)\,dx \\
&= \frac{1}{p}\int_D ((\nabla h_p - a^{-1}b) + (\nabla h_0 - a^{-1}b))a((\nabla h_p - a^{-1}b) \\
&\qquad\qquad - (\nabla h_0 - a^{-1}b))\gamma_0\,dx \\
&\qquad + \int_D (\nabla h_p - a^{-1}b)a(\nabla h_p - a^{-1}b)(\gamma_1-\gamma_0)\,dx \\
&= \int_D ((\nabla h_p - a^{-1}b) + (\nabla h_0 - a^{-1}b))a\left(\frac{\nabla h_p - \nabla h_0}{p}\right)\gamma_0\,dx
\end{aligned} \tag{2.17}$$

$$+\int_D (\nabla h_p - a^{-1}b)a(\nabla h_p - a^{-1}b)(\gamma_1 - \gamma_0)\,dx.$$

Since $(\nabla h_p - \nabla h_0)/p$ converges weakly in $L^2(D, \gamma_0\,dx)$, $\nabla h_p \to \nabla h_0$ strongly in $L^2(D, \gamma_0\,dx)$. By Proposition 2.1 and the assumption $(\text{dist}\,(x, \partial D_1))^{-1}\gamma_1^{1/2}(x) \in L^\infty(D)$, we also have $\nabla h_p \to \nabla h_0$ strongly in $L^2(D, \gamma_1\,dx)$. The weak convergence of $(\nabla h_p - \nabla h_0)/p$ to $\nabla h_0'$ in $L^2(D, \gamma_0\,dx)$ and the strong convergence of ∇h_p to ∇h_0 in $L^2(D, \gamma_0\,dx)$ and in $L^2(D, \gamma_1\,dx)$ show that as $p \to 0$, the right-hand side of (2.17) converges to the right-hand side of (2.16). This verifies (2.16).

Now we derive (2.2a) and (2.2b). We obtain (2.2a) simply by substituting $g_0 = (\phi_0\tilde{\phi}_0)^{1/2}$ and $h_0 = \frac{1}{2}\log(\tilde{\phi}_0/\phi_0)$ in (2.1). For the case $a^{-1}b = \nabla Q$ and $Q = k$ on ∂D, (2.2b) was proven in Remark 3. We now show that (2.2b) holds in the case $\{f = 0$ or $f = 1\} \cap \partial D = \partial D$. By (2.4), we have

$$\int_D (\nabla h_0 - a^{-1}b)a\nabla q g^2\,dx = 0,$$

for all $q \in W^{1,2}(D, g^2\,dx)$ satisfying $q = 0$ on $\partial D - \partial D_1$. Because of the condition on f, we may pick $q = \log g_0 - h_0$ to obtain

$$\int (\nabla h_0 - a^{-1}b)a\left(\frac{\nabla g_0}{g} - \nabla h_0\right)g_0^2\,dx = 0. \tag{2.18}$$

From (2.18) we have

$$\begin{aligned}\frac{1}{2}\int_D (\nabla h_0 - a^{-1}b)a(\nabla h_0 - a^{-1}b)g_0^2\,dx &= \int_D g_0\nabla g_0 a\nabla h_0\,dx - \int_D g_0 b\nabla g_0\,dx \\ &\quad -\frac{1}{2}\int_D (\nabla h_0 a\nabla h_0)g_0^2\,dx \\ &\quad +\frac{1}{2}\int_D (ba^{-1}b)g_0^2\,dx.\end{aligned}$$

Substituting this in (2.1), we obtain

$$\begin{aligned}&\frac{1}{2}\int_D \left(\frac{\nabla g_0}{g_0} - a^{-1}b\right)a\left(\frac{\nabla g_0}{g_0} - a^{-1}b\right)g_0^2\,dx - \int_D g_0\nabla g_0 a\nabla h_0\,dx + \int_D g_0 b\nabla g_0\,dx \\ &\qquad +\frac{1}{2}\int_D (\nabla h_0 a\nabla h_0)g_0^2\,dx - \frac{1}{2}\int_D (ba^{-1}b)g_0^2\,dx + \int_D Vg_0^2\,dx \\ &= \frac{1}{2}\int_D (\nabla g_0 - g_0\nabla h_0)a(\nabla g_0 - g_0\nabla h_0)\,dx + \int_D Vg_0^2\,dx \\ &= \int_D \left(\frac{1}{2}\frac{(\nabla\phi_0 a\nabla\phi_0)}{\phi_0^2} + V\right)\phi_0\tilde{\phi}_0\,dx,\end{aligned}$$

since

$$g_0 = (\phi_0\tilde{\phi}_0)^{1/2} \quad \text{and} \quad h_0 = \frac{1}{2}\log\frac{\tilde{\phi}_0}{\phi_0}.$$

We now turn to (2.3). Let $R_g(z) = \int_D (\frac{1}{2}zaz + z(b - a\nabla k))g^2\,dx$. Essentially the same proof as that used to prove the existence of a unique minimizer $h = h_g$ of $H_g(h)$ at the

beginning of the proof of the theorem shows that there exists a unique $\hat{z} = (\hat{z}_1, \cdots, \hat{z}_n) \in L^2(D, g^2\,dx)$ which is a weak solution of $\nabla \cdot (g^2 z) = 0$ in D and which satisfies

$$R_g(\hat{z}) = \inf_{\substack{z \in C^1(D) \\ \nabla \cdot (g^2 z) = 0 \text{ in } D}} R_g(z).$$

This proof also shows that $\hat{z}$ is the unique solution to

$$\int_D q(a\hat{z} + b - a\nabla k) g^2\,dx = 0, \tag{2.19}$$

for every $q \in L^2(D, g^2\,dx)$ which is a weak solution to $\nabla \cdot (g^2 q) = 0$ in D.

In order to complete the proof of (2.3), it is enough to show for each $g \in W^{1,2}(D)$ satisfying $g = fe^k$ on ∂D, that

(i) $\hat{z} = \nabla h_g - a^{-1}b$, where h_g minimizes $H_g(h)$ over $h \in W^{1,2}(D, g^2\,dx)$ satisfying $h = k$ on $\partial D - \partial D_1$, and that

(ii) $R_g(\hat{z}) = -\frac{1}{2}\int_D (\nabla h_g - a^{-1}b) a (\nabla h_g - a^{-1}b) g^2\,dx$.

To show that (i) holds, simply substitute $\hat{z} = \nabla h_g - a^{-1}b$ in (2.19), integrate by parts and use the condition on q and the boundary condition on h. Now (ii) follows by substituting $q = \hat{z} = \nabla h_g - a^{-1}b$ in (2.19).

ON THE DETERMINATION OF A FUNCTION FROM SPHERICAL AVERAGES*

LARS-ERIK ANDERSSON†

Abstract. Let f be a function $f:\mathbb{R}^{n+1}\to\mathbb{R}$ which is even in the last variable, i.e., such that $f(x,-y)=f(x,y)$ where $x\in\mathbb{R}^n$, $y\in\mathbb{R}$. The mapping R is defined by $f\mapsto Rf=g$ where $g(x,r)$ is the average of f over a sphere with radius r and center at a point $(x,0)$ in the hyperplane $y=0$. The problem to invert the mapping R is studied. Extending the domain of the mapping R to the class of tempered distributions, we give a characterization of the range of R and prove that the inverse mapping R^{-1} exists and is continuous in the topology of distributions. An inversion formula, first discovered by J. Fawcett, is obtained in terms of Fourier transforms and a Sobolev estimate for the inverse mapping is given. Next, inversion methods using only values of g on some bounded set are studied. First a uniqueness theorem of Courant and Hilbert is generalized to distributions. Inversion formulas involving partial Fourier transforms are given and a numerical inversion procedure is proposed.

Key words. inverse problem, spherical averages, generalized Radon transform, ill-posed

AMS(MOS) subject classification. 44A15

Introduction. Consider functions $f:\mathbb{R}^{n+1}\to\mathbb{R}$ which are even in the last variable, i.e., such that $f(x,-y)=f(x,y)$ where $x\in\mathbb{R}^n$, $y\in\mathbb{R}$. Define the mapping $f\mapsto Rf=g$ by letting $g(x,r)$ be the average of f over a sphere with radius r and center at the point $(x,0)$ in the hyperplane $y=0$. Consequently,

$$g(x,r)=\frac{1}{\omega_n}\int_{S^n} f(x+r\xi,r\eta)\,dS_n(\xi,\eta),$$

where S^n is the unit sphere $\{(\xi,\eta):|\xi|^2+\eta^2=1\}$ in $\mathbb{R}^{n+1}$, dS_n is the surface measure on a sphere and ω_n is the area of S^n. The domain of this mapping R will be specified later.

The problem of inverting the mapping R, i.e., to determine the function f when g is known, which is the subject of this paper, has been treated by several authors. The uniqueness of the solution f in the class of continuous functions was proved by Courant and Hilbert [2]. Employing essentially the same technique as Courant and Hilbert, Lavrentiev et al. [9] have given inversion methods as well as a characterization of the range of R. Unfortunately, these methods are difficult to use numerically. In a recent paper Fawcett [3] has given an inversion method using Fourier–Hankel transformation and a so-called back projection operator. He thus provides a method to solve the global problem, i.e., to determine $f(x,y)$ for all $(x,y)\in\mathbb{R}^{n+1}$ when $g(x,r)$ is known for all $x\in\mathbb{R}^n$, $r>0$.

The inversion problem for the mapping R, belongs to the same class of problems as the inversion problems for the classical Radon transform and its generalizations (see for instance Helgason [4]). The problem that is studied in the present paper is of interest in several applications, for example in image processing of so-called synthetic aperture radar (SAR) data, when using wavelengths of the magnitude 3–30 m. In such a situation, when the wavelength is considerably larger than the dimension of the antenna, the emitted radar signal is spread more or less uniformly in all directions, and then the problem of inverting spherical averages enters naturally in the analysis. For a more detailed account of this application we refer to [5]–[7].

Other interesting applications are found in connection with inverse problems for hyperbolic partial differential equations. One example is the linearized inverse scattering problem in acoustics as described by Cohen and Bleistein [1]. Surveys of these applications are given by Lavrentiev et al. [9] and by Romanov [11].

One of the main results of the present work, given in § 2, is a rigorous derivation of Fawcett's inversion formula under very general conditions on f and g. Our (slightly different) version of the formula is given completely in terms of Fourier transforms. In § 4 we turn instead to the local inversion problem, i.e., how to determine f when $g(x, r)$ is known in some region $|x| < A \leqq \infty$, $0 < r < B < \infty$. Using the theory of § 2, we first deduce a theorem of uniqueness which is a generalization of Courant's to the case when f is allowed to be a distribution. In § 5 we give inversion formulas for the local problem in terms of integral equations involving partial Fourier transforms of f and g. We also discuss the range of the mapping R in the local case and the ill-posedness of the problem, and propose an inversion procedure.

1. Some notation and definitions. By $\mathcal{S}(\mathbb{R}^n)$ we mean the so-called Schwartz class of infinitely differentiable functions φ for which the norms $\|\varphi\|_N = \sup\{|x|^k |D^\alpha \varphi(x)| : 0 \leqq k \leqq N,\ 0 \leqq |\alpha| \leqq N,\ x \in \mathbb{R}^n\}$ are finite for all $N \geqq 0$. Here $\alpha = (\alpha_1, \alpha_2, \cdots, \alpha_n)$ is a multiindex. $\mathcal{S}(\mathbb{R}^n)$ is given the topology which is induced by these norms.

$$\mathcal{S}_e(\mathbb{R}^{n+1}) = \{\psi \in \mathcal{S}(\mathbb{R}^{n+1}) : \psi(x, -y) = \psi(x, y),\ \forall x \in \mathbb{R}^n,\ y \in \mathbb{R}\}.$$

For convenience we will in this paper consider the functions $g(x, r)$ where $x \in \mathbb{R}^n$, $r \geqq 0$, to be defined on $\mathbb{R}^n \times \mathbb{R}^{n+1}$ and to depend radially on the last $n+1$ variables. We therefore introduce

$$\mathcal{S}_r(\mathbb{R}^n \times \mathbb{R}^{n+1}) = \{\varphi \in \mathcal{S}(\mathbb{R}^{2n+1}) : \varphi(x, z) = \varphi(x, Uz),\ \forall x \in \mathbb{R}^n,\ z \in \mathbb{R}^{n+1}$$
$$\text{and for all orthonormal transformations } U\}.$$

$\mathcal{S}_r(\mathbb{R}^n \times \mathbb{R}^{n+1})$ is thus the subspace of functions in $\mathcal{S}(\mathbb{R}^{2n+1})$ which depend radially on the last $n+1$ variables. $\mathcal{S}_e(\mathbb{R}^{n+1})$ and $\mathcal{S}_r(\mathbb{R}^n \times \mathbb{R}^{n+1})$ are given the same topology as $\mathcal{S}(\mathbb{R}^{n+1})$ and $\mathcal{S}(\mathbb{R}^{2n+1})$, respectively. $\mathcal{S}'(\mathbb{R}^n)$, the class of tempered distributions on $\mathbb{R}^n$, is by definition the set of all continuous linear functionals on $\mathcal{S}(\mathbb{R}^n)$. $\mathcal{S}'(\mathbb{R}^n)$ is given the weak topology. $\langle f, \psi\rangle$ denotes the value of $f \in \mathcal{S}'(\mathbb{R}^n)$ at $\psi \in \mathcal{S}(\mathbb{R}^n)$. $\mathcal{S}'_e(\mathbb{R}^{n+1}) = \{f \in \mathcal{S}'(\mathbb{R}^{n+1}) : \langle f, \psi\rangle = 0$ whenever $\psi(x, -y) = -\psi(x, y)$ for all $x, y\}$, i.e., $\mathcal{S}'_e(\mathbb{R}^{n+1})$ is the subspace of tempered distributions that are even in the last variable. $\mathcal{S}'_r(\mathbb{R}^n \times \mathbb{R}^{n+1}) = \{g \in \mathcal{S}'(\mathbb{R}^{2n+1}) : \langle g, \varphi\rangle = 0$ whenever $\int_{|z|=r} \varphi(x, z)\, dS_n(z) = 0$ for all $x \in \mathbb{R}^n$ and $r > 0\}$, i.e., $\mathcal{S}'_r(\mathbb{R}^n \times \mathbb{R}^{n+1})$ is the subspace of tempered distributions which depend radially on the last $n+1$ variables. $\mathcal{S}'_e(\mathbb{R}^{n+1})$ and $\mathcal{S}'_r(\mathbb{R}^n \times \mathbb{R}^{n+1})$ may also be identified with the class of continuous linear functionals on $\mathcal{S}_e(\mathbb{R}^{n+1})$ and $\mathcal{S}_r(\mathbb{R}^n \times \mathbb{R}^{n+1})$ respectively. In the following we will occasionally write $\mathcal{S}$, $\mathcal{S}_e$, $\mathcal{S}_r$, etc., instead of $\mathcal{S}(\mathbb{R}^n)$, $\mathcal{S}_e(\mathbb{R}^{n+1})$, $\mathcal{S}_r(\mathbb{R}^n \times \mathbb{R}^{n+1})$. Fourier transformation is defined by $\mathcal{F}\varphi(\sigma) = \hat{\varphi}(\sigma) = \int_{\mathbb{R}^n} e^{-i\langle\sigma, x\rangle} \varphi(x)\, dx$, $\mathcal{F}^{-1}\hat{\varphi}(x) = \varphi(x) = (1/(2\pi)^n) \int_{\mathbb{R}^n} e^{i\langle\sigma, x\rangle} \hat{\varphi}(\sigma)\, d\sigma$ when $\varphi \in \mathcal{S}(\mathbb{R}^n)$ and by $\langle -\hat{f}, \hat{\varphi}\rangle = (2\pi)^n \langle f, \varphi\rangle$ when $f \in \mathcal{S}'(\mathbb{R}^n)$.

We note that Fourier transformation gives isomorphisms

$$\mathcal{F}: \mathcal{S} \to \mathcal{S}, \qquad \mathcal{F}: \mathcal{S}' \to \mathcal{S}',$$
$$\mathcal{F}: \mathcal{S}_e \to \mathcal{S}_e, \qquad \mathcal{F}: \mathcal{S}'_e \to \mathcal{S}'_e,$$
$$\mathcal{F}: \mathcal{S}_r \to \mathcal{S}_r, \qquad \mathcal{F}: \mathcal{S}'_r \to \mathcal{S}'_r.$$

If $\varphi, \psi \in \mathcal{S}(\mathbb{R}^n)$ then $\varphi * \psi(x) = \int_{\mathbb{R}^n} \varphi(x - z)\psi(z)\, dz$ is the convolution. $(\varphi * \psi)\hat{} = \hat{\varphi}\hat{\psi}$. If $f \in \mathcal{S}'(\mathbb{R}^n)$ then $f * \varphi$ is defined by $\langle f * \varphi, \psi\rangle = \langle f, \check{\bar{\varphi}} * \psi\rangle$. Here $\check{\varphi}$ is defined by

$\check{\varphi}(x)=\varphi(-x)$ and $\bar{\varphi}$ denotes the complex conjugate of φ. Elements of $\mathcal{S}_e(\mathbb{R}^{n+1})$ or $\mathcal{S}'_e(\mathbb{R}^{n+1})$ will be denoted by, for example, $\psi(x, y)$ or $f(x, y)$ and their Fourier transforms by $\hat{\psi}(\sigma, \omega)$ or $\hat{f}(\sigma, \omega)$. Here $x, \sigma \in \mathbb{R}^n$ and $y, \omega \in \mathbb{R}$.

Elements of $\mathcal{S}_r(\mathbb{R}^n \times \mathbb{R}^{n+1})$ or $\mathcal{S}'_r(\mathbb{R}^n \times \mathbb{R}^{n+1})$ are written, for example, $\varphi(x, r)$ or $g(x, r)$ and their Fourier transforms $\hat{\varphi}(\sigma, \rho)$ or $\hat{g}(\sigma, \rho)$. Here $x, \sigma \in \mathbb{R}^n$ and $r, \rho \in \mathbb{R}$, r and $\rho \geqq 0$. In § 5 we use the notation ψ^*, φ^*, etc. for the partial Fourier transform with respect to the n first variables.

$$\psi^*(\sigma, y)=\int_{\mathbb{R}^n} e^{-i\langle\sigma,x\rangle}\psi(x, y)\,dx, \qquad \varphi^*(\sigma, r)=\int_{\mathbb{R}^n} e^{-i\langle\sigma,x\rangle}\varphi(x, r)\,dx$$

when $\psi \in \mathcal{S}_e$ and $\varphi \in \mathcal{S}_r$.

$$\langle f^*, \psi^*\rangle=(2\pi)^n\langle f, \psi\rangle \quad \text{and} \quad \langle g^*, \varphi^*\rangle=(2\pi)^n\langle g, \varphi\rangle$$

when $f \in \mathcal{S}'_e$ and $g \in \mathcal{S}'_r$.

Note that $\psi \in \mathcal{S}_e \Leftrightarrow \psi^* \in \mathcal{S}_e$, $f \in \mathcal{S}'_e \Leftrightarrow f^* \in \mathcal{S}'_e$, $\varphi \in \mathcal{S}_r \Leftrightarrow \varphi^* \in \mathcal{S}_r$ and $g \in \mathcal{S}'_r \Leftrightarrow g^* \in \mathcal{S}'_r$. In § 5 we also use J_ν and I_ν to denote respectively the ordinary and the modified Bessel functions of the first kind and of order ν. See Magnus and Oberhettinger [10]. $(\mathcal{L}f)(p)=\tilde{f}(p)=\int_0^\infty e^{-pt}f(t)\,dt$ denotes the Laplace transform of the function f. Finally $[x]$ denotes the integer part of x.

2. An inversion formula for the global problem. It is almost obvious that the relation

$$g(x, r)=\frac{1}{\omega_n}\int_{S^n} f(x+r\xi, r\eta)\,dS_n(\xi, \eta)=Rf(x, r)$$

defines a linear, continuous mapping

$$R: \mathcal{S}_e(\mathbb{R}^{n+1}) \to \mathcal{S}'_r(\mathbb{R}^n \times \mathbb{R}^{n+1}).$$

Note, however, that in general, $Rf \notin L^1(\mathbb{R}^{2n+1})$ or $L^2(\mathbb{R}^{2n+1})$ when $f \in \mathcal{S}_e(\mathbb{R}^{n+1})$, not even if f has compact support. Now $\mathcal{S}_e(\mathbb{R}^{n+1})$ may also be thought of as a linear subspace of $\mathcal{S}'_e(\mathbb{R}^{n+1})$, equipped with the topology of $\mathcal{S}'_e(\mathbb{R}^{n+1})$. It is well known, then, that $\mathcal{S}_e(\mathbb{R}^{n+1})$ is dense in $\mathcal{S}'_e(\mathbb{R}^{n+1})$.

THEOREM 2.1. *If $\mathcal{S}_e(\mathbb{R}^{n+1})$ is given the topology of $\mathcal{S}'_e(\mathbb{R}^{n+1})$ then the mapping*

$$R: \mathcal{S}_e(\mathbb{R}^{n+1}) \to \mathcal{S}'_r(\mathbb{R}^n \times \mathbb{R}^{n+1})$$

is continuous and can, by continuity, be extended to a mapping (with abuse of notation)

$$R: \mathcal{S}'_e(\mathbb{R}^{n+1}) \to \mathcal{S}'_r(\mathbb{R}^n \times \mathbb{R}^{n+1}).$$

Further, the range of this extended mapping R is the closed subspace

$$\mathcal{S}'_{r,\mathrm{cone}}(\mathbb{R}^n \times \mathbb{R}^{n+1})=\{g \in \mathcal{S}'_r(\mathbb{R}^n \times \mathbb{R}^{n+1}): \operatorname{supp} \hat{g} \subset \{(\sigma, \rho): \rho \geqq |\sigma|\}\}$$
$$\subset \mathcal{S}'_r(\mathbb{R}^n \times \mathbb{R}^{n+1}).$$

R is one-to-one and the inverse mapping

$$R^{-1}: \mathcal{S}'_{r,\mathrm{cone}}(\mathbb{R}^n \times \mathbb{R}^{n+1}) \to \mathcal{S}'_e(\mathbb{R}^{n+1})$$

is continuous. Moreover, if $g=Rf$ and if $\hat{f}$ or $\hat{g}$ are in some open set equal to ordinary integrable functions $\hat{f}(\sigma, \omega)$ or $\hat{g}(\sigma, \rho)$, then

$$\hat{g}(\sigma, \rho)=\begin{cases}\dfrac{2}{\omega_n}\dfrac{1}{\rho^{n-1}}\dfrac{\hat{f}(\sigma, \sqrt{\rho^2-|\sigma|^2})}{\sqrt{\rho^2-|\sigma|^2}} & \text{for } \rho>|\sigma|,\\ 0 & \text{for } 0 \leqq \rho<|\sigma|\end{cases}$$

and conversely we have the inversion formula

$$\hat{f}(\sigma, \omega)=\frac{\omega_n}{2}\cdot|\omega|(|\sigma|^2+\omega^2)^{(n-1)/2}\hat{g}(\sigma, \sqrt{|\sigma|^2+\omega^2}).$$

The proof of Theorem 2.1 will be divided into several steps arranged in the paragraphs (a) through (i) below.

(a) PROPOSITION 2.2. *There exists a linear and continuous dual mapping*

$$R^*: \mathcal{S}_r(\mathbb{R}^n \times \mathbb{R}^{n+1}) \to \mathcal{S}_e(\mathbb{R}^{n+1})$$

such that $\langle Rf, \varphi\rangle = \langle f, R^*\varphi\rangle$ *for all* $f \in \mathcal{S}_e(\mathbb{R}^{n+1})$ *and* $\varphi \in \mathcal{S}_r(\mathbb{R}^n \times \mathbb{R}^{n+1})$. *Further*

$$R^*\varphi(x, y) = \int_{\mathbb{R}^n} \varphi(z, \sqrt{|z-x|^2+y^2})\, dz$$

and

$$(R^*\varphi)\hat{}(\sigma, \omega) = \hat{\varphi}(\sigma, \sqrt{|\sigma|^2+\omega^2})$$

for all (x, y) *and* $(\sigma, \omega) \in \mathbb{R}^{n+1}$.

Proof.

$$\begin{aligned}
\langle Rf, \varphi\rangle &= \int_{\mathbb{R}^n} \int_0^\infty \bar{\varphi}(x, r) r^n\, dr\, dx \int_{S^n} f(x + r\xi, r\eta)\, dS_n(\xi, \eta) \\
&= \int_{\mathbb{R}^n} dx \int_0^\infty \int_{S^n} \bar{\varphi}(x, r) f(x + r\xi, r\eta) r^n\, dr\, dS_n(\xi, \eta) \\
&= \{z = r\xi,\ y = r\eta\} \\
&= \int_{\mathbb{R}^n} dx \int_{\mathbb{R}^{n+1}} \bar{\varphi}(x, \sqrt{|z|^2+y^2}) f(x+z, y)\, dz\, dy \\
&= \int_{\mathbb{R}^n} dx \int_{\mathbb{R}^{n+1}} \bar{\varphi}(x, \sqrt{|z-x|^2+y^2}) f(z, y)\, dz\, dy \\
&= \int_{\mathbb{R}^{n+1}} f(z, y)\, dz\, dy \int_{\mathbb{R}^n} \bar{\varphi}(x, \sqrt{|x-z|^2+y^2})\, dx \\
&= \int_{\mathbb{R}^{n+1}} f(x, y)\, dx\, dy \int_{\mathbb{R}^n} \bar{\varphi}(z, \sqrt{|z-x|^2+y^2})\, dz = \langle f, R^*\varphi\rangle
\end{aligned}$$

where, by definition, we take

$$R^*\varphi(x, y) = \int_{\mathbb{R}^n} \varphi(z, \sqrt{|z-x|^2+y^2})\, dz.$$

The changing of the order of integration is easily justified by the fact that $f \in \mathcal{S}_e$ and $\varphi \in \mathcal{S}_r$. Obviously $R^*\varphi \in \mathcal{S}'_e(\mathbb{R}^{n+1})$. We have to prove that, actually, $R^*\varphi \in \mathcal{S}_e(\mathbb{R}^{n+1})$ and that the mapping R^* is continuous. To this end we first calculate the Fourier transform $(R^*\varphi)\hat{}(\sigma, \omega)$.

$$\begin{aligned}
(R^*\varphi)\hat{}(\sigma, \omega) &= \int_{\mathbb{R}^{n+1}} e^{-i(\langle \sigma, x\rangle + \omega y)}\, dx\, dy \int_{\mathbb{R}^n} \varphi(z, \sqrt{|x-z|^2+y^2})\, dz \\
&= \int_{\mathbb{R}^n} e^{-i\langle \sigma, z\rangle}\, dz \int_{\mathbb{R}^{n+1}} e^{-i(\langle \sigma, x-z\rangle + \omega y)} \varphi(z, \sqrt{|x-z|^2+y^2})\, dx\, dy \\
&= \int_{\mathbb{R}^n} e^{-i\langle \sigma, z\rangle}\, dz \int_{\mathbb{R}^{n+1}} e^{-i(\langle \sigma, x\rangle + \omega y)} \varphi(z, \sqrt{|x|^2+y^2})\, dx\, dy \\
&= \hat{\varphi}(\sigma, \sqrt{|\sigma|^2+\omega^2}).
\end{aligned}$$

Here, again the change in the order of integration is easily justified since the integrals are absolutely convergent.

LEMMA 2.3. *If* $\hat{\varphi} \in \mathcal{S}_r$ *then* $(R^*\varphi)^\wedge \in \mathcal{S}_e$. *The mapping* $\mathcal{F} \circ R^* \circ \mathcal{F}^{-1}: \mathcal{S}_r \to \mathcal{S}_e$ *is continuous.*

Proof. $\hat{\varphi}(\sigma, \rho)$ may be written $\hat{\varphi}(\sigma, \rho) = \hat{\psi}(\sigma, z, \omega)$ where $\hat{\psi} \in \mathcal{S}(\mathbb{R}^{2n+1})$, $\sigma \in \mathbb{R}^n$, $z \in \mathbb{R}^n$, $\omega \in \mathbb{R}$ and $\rho = \sqrt{|z|^2 + \omega^2}$. Then $(R^*\varphi)^\wedge(\sigma, \omega) = \hat{\varphi}(\sigma, \sqrt{|\sigma|^2 + \omega^2}) = \hat{\psi}(\sigma, \sigma, \omega)$. Using the chain rule, it is easy to verify that $(R^*\varphi)^\wedge \in \mathcal{S}_e$ and that the mapping $\mathcal{F} \circ R^* \circ \mathcal{F}^{-1}$ is continuous.

It follows immediately from the lemma that $R^*\varphi \in \mathcal{S}_e$ whenever $\varphi \in \mathcal{S}_r$ and that the mapping

$$R^*: \mathcal{S}_r(\mathbb{R}^n \times \mathbb{R}^{n+1}) \to \mathcal{S}_e(\mathbb{R}^{n+1})$$

is continuous. This finishes the proof of Proposition 2.2.

(b) For $f \in \mathcal{S}'_e(\mathbb{R}^{n+1})$ we now define $Rf \in \mathcal{S}'_r(\mathbb{R}^n \times \mathbb{R}^{n+1})$ by the equality

$$\langle Rf, \varphi \rangle = \langle f, R^*\varphi \rangle, \quad \varphi \in \mathcal{S}_r(\mathbb{R}^n \times \mathbb{R}^{n+1}),$$

i.e., by $Rf = f \circ R^*$. From the continuity of R^* it is clear that Rf is an element of $\mathcal{S}'_r$ for every $f \in \mathcal{S}'_e$. The continuity of the extended mapping

$$R: \mathcal{S}'_e \to \mathcal{S}'_r$$

follows trivially from the definition.

(c) We will also need the following extension lemma of Whitney type.

EXTENSION LEMMA 2.4. *There exists a continuous linear mapping*

$$\mathcal{E}: \mathcal{S}_e(\mathbb{R}^{n+1}) \to \mathcal{S}_r(\mathbb{R}^n \times \mathbb{R}^{n+1})$$

such that for all $\psi \in \mathcal{S}_e(\mathbb{R}^{n+1})$

$$(\mathcal{E}\psi)^\wedge(\sigma, \rho) = \hat{\psi}(\sigma, \sqrt{\rho^2 - |\sigma|^2}) \quad \text{for } \rho \geqq |\sigma|.$$

Postponing the proof of this lemma, we first note that the following corollary follows immediately.

COROLLARY 2.5. $(R^*\mathcal{E}\psi)^\wedge(\sigma, \omega) = \hat{\psi}(\sigma, \omega)$ *for all* $\psi \in \mathcal{S}_e$, *i.e.,* $R^*\mathcal{E} = id_{\mathcal{S}_e}$. *The mapping* $R^*: \mathcal{S}_r \to \mathcal{S}_e$ *is onto. If* $\varphi \in \mathcal{S}_r$ *then* $(\mathcal{E}R^*\varphi)^\wedge(\sigma, \rho) = \hat{\varphi}(\sigma, \rho)$ *for* $\rho \geqq |\sigma|$.

(d) PROPOSITION 2.6. *The mapping*

$$R: \mathcal{S}'_e(\mathbb{R}^{n+1}) \to \mathcal{S}'_r(\mathbb{R}^n \times \mathbb{R}^{n+1})$$

is one-to-one.

Proof. Suppose that $Rf = 0$ and let $\psi \in \mathcal{S}_e$ be arbitrary. Then by Corollary 2.5

$$\langle f, \psi \rangle = \langle f, R^*\mathcal{E}\psi \rangle = \langle Rf, \mathcal{E}\psi \rangle = 0.$$

Consequently $f = 0$ which finishes the proof.

(e) PROPOSITION 2.7. *If* $f \in \mathcal{S}'_e$ *and* $g = Rf$ *then* $\langle f, \psi \rangle = \langle g, \mathcal{E}\psi \rangle$ *for all* $\psi \in \mathcal{S}_e$.

This was already proved in the previous proposition.

(f) PROPOSITION 2.8. *For every* $f \in \mathcal{S}'_e$ *we have* $g = Rf \in \mathcal{S}'_{r,\text{cone}}$.

Proof. Let φ be arbitrary such that $\varphi \in \mathcal{S}_r$ and supp $\hat{\varphi} \subset \{(\sigma, \rho): 0 \leqq \rho < |\sigma|\}$. Then $\langle Rf, \varphi \rangle = \langle f, R^*\varphi \rangle = (2\pi)^{-(n+1)} \langle \hat{f}, (R^*\varphi)^\wedge \rangle$. Since $(R^*\varphi)^\wedge(\sigma, \omega) = \hat{\varphi}(\sigma, \sqrt{|\sigma|^2 + \omega^2}) = 0$ for all $(\sigma, \omega) \in \mathbb{R}^{n+1}$ we deduce that $\langle Rf, \varphi \rangle = 0$ which finishes the proof.

LEMMA 2.9. *If* $\hat{g} \in \mathcal{S}'_r$, $\hat{h} \in \mathcal{S}_r$ *and if* supp $\hat{g} \subset \{(\sigma, \rho): \rho \geqq |\sigma|\}$ *and* supp $\hat{h} \subset \{(\sigma, \rho): \rho \leqq |\sigma|\}$ *then* $\langle \hat{g}, \hat{h} \rangle = 0$.

Proof. Choose $\varphi \in C_0^\infty(\mathbb{R}^{n+1})$ such that $\varphi(0)=1$ and take $\varphi_n(x)=\varphi(x/n)$. Then, if we let $\hat{h}_n=\varphi_n\hat{h}$, $\hat{h}_n\to\hat{h}$ in $\mathcal{S}(\mathbb{R}^{n+1})$ and supp $\hat{h}_n$ is compact. By [8, Thm. 2.3.3], $\langle\hat{g},\hat{h}_n\rangle=0$. Consequently $\langle\hat{g},\hat{h}\rangle=\lim_{n\to\infty}\langle\hat{g},\hat{h}_n\rangle=0$ and the proof is complete.

(g) PROPOSITION 2.10. *For every $g\in\mathcal{S}'_{r,\text{cone}}$ there exists an $f\in\mathcal{S}'_e$ such that $g=Rf$.*

Proof. Let $g\in\mathcal{S}'_{r,\text{cone}}$ be given. Now, since the mapping $\mathcal{E}$ is continuous, the relation

$$\langle f,\psi\rangle=\langle g,\mathcal{E}\psi\rangle$$

with $\psi\in\mathcal{S}_e$ arbitrary, defines a distribution $f\in\mathcal{S}'_e$. We shall prove that $g=Rf$. Using that supp $\hat{g}\subset\{(\sigma,\rho)\colon \rho\geqq|\sigma|\}$, Corollary 2.5 and Lemma 2.9 we have

$$\langle g,\varphi\rangle=(2\pi)^{-(n+1)}\langle\hat{g},\hat{\varphi}\rangle=(2\pi)^{-(n+1)}\langle\hat{g},(\mathcal{E}R^*\varphi)\hat{}\,\rangle=\langle g,\mathcal{E}R^*\varphi\rangle.$$

By the definition of f this last expression equals $\langle f,R^*\varphi\rangle=\langle Rf,\varphi\rangle$. Therefore $\langle g,\varphi\rangle=\langle Rf,\varphi\rangle$ for all $\varphi\in\mathcal{S}_r$, i.e., $g=Rf$.

PROPOSITION 2.11. *If $g_n\in\mathcal{S}'_{r,\text{cone}}$, $g_n\to g\in\mathcal{S}'_r$ and if $Rf_n=g_n$ then $f_n\to f$ where $Rf=g$, i.e., the inverse mapping is continuous.*

Proof. By Proposition 2.7 $\langle f_n,\psi\rangle=\langle g_n,\mathcal{E}\psi\rangle$ for all $\psi\in\mathcal{S}_r$. Since $\mathcal{S}'_{r,\text{cone}}$ is closed $g\in\mathcal{S}'_{r,\text{cone}}$ and $g=Rf$ for some $f\in\mathcal{S}'_e$. Now

$$\langle f_n,\psi\rangle\to\langle g,\mathcal{E}\psi\rangle=\langle f,\psi\rangle.$$

(h) Let $U\subset\{(\sigma,\rho)\colon\rho>|\sigma|\}\subset\mathbb{R}^{2n+1}$ be an open set of the form $U=\{(\sigma,\rho)\colon\sigma\in V,0<a<\rho<b\}$ where $V\subset\mathbb{R}^n$ is open. Let $U'\subset\mathbb{R}^{n+1}$ be the image of U under the mapping $(\sigma,\rho)\mapsto(\sigma,\sqrt{\rho^2-|\sigma|^2})$. It is easy to see that U' is open and that U is the inverse image of U' under the same mapping. Further consider the mappings $\hat{\varphi}\mapsto(R^*\varphi)\hat{}\,=\hat{\psi}$ and $\hat{\psi}\mapsto(\mathcal{E}\psi)\hat{}\,=\hat{\varphi}$. It is rather easy to see that they establish a one-to-one correspondence between all $\hat{\varphi}\in\mathcal{S}_r$ with supp $\hat{\varphi}\subset U$ and all $\hat{\psi}\in\mathcal{S}_e$ with supp $\hat{\psi}\subset U'$.

Now suppose that the distribution $\hat{g}=(Rf)\hat{}$ is on U equal to some integrable function $\hat{g}(\sigma,\rho)$. Then

$$\begin{aligned}\langle\hat{g},\hat{\varphi}\rangle&=\omega_n\int_{\mathbb{R}^n}\int_{|\sigma|}^{\infty}\hat{g}(\sigma,\rho)\bar{\hat{\varphi}}(\sigma,\rho)\rho^n\,d\rho\,d\sigma=\{\text{substitute }\omega=\sqrt{\rho^2-|\sigma|^2}\}\\&=\frac{\omega_n}{2}\int_{\mathbb{R}^{n+1}}\hat{g}(\sigma,\sqrt{|\sigma|^2+\omega^2})(|\sigma|^2+\omega^2)^{(n-1)/2}|\omega|\bar{\hat{\varphi}}(\sigma,\sqrt{|\sigma|^2+\omega^2})\,d\sigma\,d\omega\\&=\langle\hat{f},(R^*\varphi)\hat{}\,\rangle.\end{aligned}$$

Taking $\psi=R^*\varphi$ we have

$$\langle\hat{f},\hat{\psi}\rangle=\frac{\omega_n}{2}\int_{\mathbb{R}^{n+1}}\hat{g}(\sigma,\sqrt{|\sigma|^2+\omega^2})(|\sigma|^2+\omega^2)^{(n-1)/2}|\omega|\bar{\hat{\psi}}(\sigma,\omega)\,d\sigma\,d\omega$$

where $\hat{\psi}$ with supp $\hat{\psi}\subset U'$ is arbitrary. We conclude that

$$\hat{f}(\sigma,\omega)=\frac{\omega_n}{2}|\omega|(|\sigma|^2+\omega^2)^{(n-1)/2}\hat{g}(\sigma,\sqrt{|\sigma|^2+\omega^2})$$

for $(\sigma,\omega)\in U'$. This is our inversion formula. Next suppose that the distribution $\hat{f}$ is on U' equal to some integrable function $\hat{f}(\sigma,\omega)$. By Proposition 2.7 we have, if supp $\hat{\psi}\subset U'$,

$$\begin{aligned}\langle\hat{g},(\mathcal{E}\psi)\hat{}\,\rangle=\langle\hat{f},\hat{\psi}\rangle&=\int_{\mathbb{R}^{n+1}}\hat{f}(\sigma,\omega)\bar{\hat{\psi}}(\sigma,\omega)\,d\sigma\,d\omega=\{\text{substitute }\rho=\sqrt{|\sigma|^2+\omega^2}\}\\&=\frac{2}{\omega_n}\cdot\omega_n\int_{\mathbb{R}^n}\int_{|\sigma|}^{\infty}\frac{\hat{f}(\sigma,\sqrt{\rho^2-|\sigma|^2})}{\sqrt{\rho^2-|\sigma|^2}}\,\frac{\bar{\hat{\psi}}(\sigma,\sqrt{\rho^2-|\sigma|^2})}{\rho^{n-1}}\rho^n\,d\rho\,d\sigma.\end{aligned}$$

Since $\hat{\psi}(\sigma, \sqrt{\rho^2-|\sigma|^2}) = (\mathscr{E}\psi)\hat{}(\sigma, \rho)$ we have, introducing $\varphi = \mathscr{E}\psi$,

$$\langle \hat{g}, \hat{\varphi} \rangle = \frac{2}{\omega_n} \omega_n \int_{\mathbb{R}^n} \int_{|\sigma|}^{\infty} \frac{\hat{f}(\sigma, \sqrt{\rho^2-|\sigma|^2})}{\rho^{n-1}\sqrt{\rho^2-|\sigma|^2}} \bar{\varphi}(\sigma, \rho) \rho^n \, d\rho \, d\sigma$$

whence we conclude that

$$\hat{g}(\sigma, \rho) = \frac{2}{\omega_n} \frac{\hat{f}(\sigma, \sqrt{\rho^2-|\sigma|^2})}{\rho^{n-1}\sqrt{\rho^2-|\sigma|^2}} \quad \text{for } (\sigma, \rho) \in U.$$

(i) To complete the proof of Theorem 2.1 it remains to prove the extension lemma. For that purpose we need a few sublemmata.

LEMMA 2.12. *The mapping* $A: \mathscr{S}_e(\mathbb{R}^{n+1}) \to C^\infty(\mathbb{R}^{n+1})$, *given by* $A\varphi(x, y) = (1/y)\varphi'_y(x, y)$ *has its range in* $\mathscr{S}_e(\mathbb{R}^{n+1})$ *and is a continuous mapping,*

$$A: \mathscr{S}_e(\mathbb{R}^{n+1}) \to \mathscr{S}_e(\mathbb{R}^{n+1}).$$

Proof. Considering Fourier transforms we may equivalently prove that the mapping

$$\hat{\varphi}(\sigma, \omega) \to \int_{\omega}^{\infty} s\hat{\varphi}(\sigma, s) \, ds$$

is a continuous mapping from $\mathscr{S}_e$ *to* $\mathscr{S}_e$. This is almost obvious.

Let us now consider functions $\psi(\sigma, t)$ defined for $t > |\sigma|^2$ in $\mathbb{R}^{n+1}$, which are C^∞ and such that the norms

$$\|\psi\|_{\mathrm{par},M} = \sup \left\{ (t^2+|\sigma|^2)^m \left| \frac{\partial^{\alpha+|\beta|}}{\partial t^\alpha \, \partial \sigma^\beta} \psi(\sigma, t) \right| : t > |\sigma|^2, 0 \leqq m \leqq M, 0 \leqq \alpha + |\beta| \leqq M \right\}$$

are finite. The linear space of such functions with the topology given by these norms is denoted by $\mathscr{S}_{\mathrm{par}}(\mathbb{R}^{n+1})$.

LEMMA 2.13. *The mapping*

$$B: \mathscr{S}_e(\mathbb{R}^{n+1}) \to \mathscr{S}_{\mathrm{par}}(\mathbb{R}^{n+1})$$

given by $B\varphi(\sigma, t) = \varphi(\sigma, \sqrt{t-|\sigma|^2})$ *is linear and continuous.*

Proof. If $\psi(\sigma, t) = B\varphi(\sigma, t) = \varphi(\sigma, \sqrt{t-|\sigma|^2})$ then

$$\frac{\partial \psi}{\partial t}(\sigma, t) = \frac{1}{2\sqrt{t-|\sigma|^2}} \frac{\partial \varphi}{\partial \omega}(\sigma, \sqrt{t-|\sigma|^2}) = \frac{1}{2}\left(\frac{1}{\omega} \frac{\partial \varphi}{\partial \omega}(\sigma, \omega) \right)_{\omega = \sqrt{t-|\sigma|^2}}.$$

Consequently $(\partial/\partial t)(B\varphi) = \frac{1}{2} BA\varphi$ where A is the mapping in Lemma 2.12. Further

$$\frac{\partial \psi}{\partial \sigma_i} = \frac{\partial \varphi}{\partial \sigma_i}(\sigma, \sqrt{t-|\sigma|^2}) - \frac{\sigma_i}{\sqrt{t-|\sigma|^2}} \frac{\partial \varphi}{\partial \omega}(\sigma, \sqrt{t-|\sigma|^2})$$

i.e. $(\partial/\partial\sigma_i)(B\varphi) = B((\partial\varphi/\partial\sigma_i) - \sigma_i A\varphi) = BC_i\varphi$ where the mapping $C_i: \mathscr{S}(\mathbb{R}^{n+1}) \to \mathscr{S}(\mathbb{R}^{n+1})$ defined by $C_i\varphi(\sigma, \omega) = \partial\varphi/\partial\sigma_i(\sigma, \omega) - \sigma_i A\varphi(\sigma, \omega)$ is continuous. Further we see that $AC_i = C_i A$ which implies that

$$\frac{\partial^{\alpha+|\beta|}}{\partial t^\alpha \partial \sigma^\beta} B\varphi = \frac{1}{2^\alpha} BA^\alpha C^\beta \varphi.$$

Here $C^\beta = C_1^{\beta_1} C_2^{\beta_2} \cdots C_n^{\beta_n}$. Then

$$(t^2+|\sigma|^2)^m \frac{\partial^{\alpha+|\beta|}}{\partial t^\alpha \partial \sigma^\beta} \psi(\sigma, t) = \frac{1}{2^\alpha} B(((\omega^2+|\sigma|^2)^2+|\sigma|^2)^m A^\alpha C^\beta)\varphi.$$

Using the estimate

$$\sup_{t>|\sigma|^2} |B\varphi(\sigma, t)| < K_0 \sup_{(\sigma,\omega)\in\mathbb{R}^{n+1}} |\varphi(\sigma, \omega)|$$

and the continuity of A and C we obtain

$$\sup\left\{(t^2+|\sigma|^2)^m \left|\frac{\partial^{\alpha+|\beta|}}{\partial t^\alpha \partial\sigma^\beta}\psi(\sigma, t)\right| : t>|\sigma|^2, 0\leqq\alpha+|\beta|\leqq M, 0\leqq m\leqq M\right\}$$
$$\leqq K_M \sup\left\{(|\sigma|^2+\omega^2)^m \left|\frac{\partial^{\alpha+|\beta|}}{\partial\omega^\alpha\partial\sigma^\beta}\varphi(\sigma,\omega)\right| : (\sigma,\omega)\in\mathbb{R}^{n+1},\right.$$
$$\left. 0\leqq\alpha+|\beta|\leqq M', 0\leqq m\leqq M'\right\}$$

for some constants K_M and M'. This proves that B is continuous.

LEMMA 2.14. *There exists a linear continuous mapping*

$$\mathcal{G}: \mathcal{S}_{\text{par}}(\mathbb{R}^{n+1}) \to \mathcal{S}(\mathbb{R}^{n+1})$$

such that $\mathcal{G}\psi(\sigma, t) = \psi(\sigma, t)$ *for* $t>|\sigma|^2$.

Proof. Following the method used in Chapter VI in the book by Stein [12] we first introduce a function $h(\lambda)$ with the following properties. $h(\lambda)$ is defined for $\lambda\geqq 1$, $h(\lambda)$ is rapidly decreasing at ∞, i.e., $h(\lambda)=O(\lambda^{-N})$ as $\lambda\to\infty$ for all N and, finally, $\int_1^\infty h(\lambda)\,d\lambda=1$, $\int_1^\infty \lambda^n h(\lambda)\,d\lambda=0$ for $n=1, 2, \cdots$. Then define the extension $\mathcal{G}\psi$ by

$$\mathcal{G}\psi(\sigma, t)=\begin{cases}\displaystyle\int_1^\infty \psi(\sigma, t+2\lambda(|\sigma|^2-t))h(\lambda)\,d\lambda & \text{for } t<|\sigma|^2,\\ \psi(\sigma, t) & \text{for } t>|\sigma|^2,\\ \displaystyle\lim_{t\searrow|\sigma|^2}\psi(\sigma, t) & \text{for } t=|\sigma|^2.\end{cases}$$

Now, by the arguments in [12, pp. 185–186] it follows that $\psi\in\mathcal{S}_{\text{par}}(\mathbb{R}^{n+1})\Rightarrow\mathcal{G}\psi\in C^\infty(\mathbb{R}^{n+1})$. To prove the continuity we proceed as follows.

If $t\geqq|\sigma|^2$ then $\psi(\sigma, t)=\psi(\sigma, t+)$.

If $t<|\sigma|^2$ and $|\alpha|+\beta=M$ then it easily follows that

$$\frac{\partial^{|\alpha|+\beta}}{\partial\sigma^\alpha\partial t^\beta}\mathcal{G}\psi(\sigma, t)=\sum_{m=0}^{M}\int_1^\infty p_m\left(\sigma, \frac{\partial}{\partial\sigma}, \frac{\partial}{\partial t}\right)\psi(\sigma, t^*)\lambda^m h(\lambda)\,d\lambda$$

where $t^*=t^*(\sigma, t, \lambda)=t+2\lambda(|\sigma|^2-t)$ and $p_m(\cdot,\cdot,\cdot)$ is a three-variable polynomial of degree less than or equal to m. Multiplying by $(|\sigma|^2+t^2)^{N/2}$ and taking the supremum when $t<|\sigma|^2$ we obtain, for some constant C_M

$$\|\mathcal{G}\psi\|_N \leqq C_M \|\psi\|_{\text{par},M+N} \sum_{m=0}^{M}\int_1^\infty \lambda^m|h(\lambda)|\,d\lambda.$$

Since h is rapidly decreasing, all the integrals are finite. This proves the continuity of the mapping $\mathcal{G}: \mathcal{S}_{\text{par}}(\mathbb{R}^{n+1})\to\mathcal{S}(\mathbb{R}^{n+1})$.

LEMMA 2.15. *The mapping*

$$K: \mathcal{S}(\mathbb{R}^{n+1})\to\mathcal{S}_r(\mathbb{R}^n\times\mathbb{R}^{n+1})$$

given by $K\psi(\sigma, \rho)=\psi(\sigma, \rho^2)$ *is linear and continuous.*

Proof. If $\rho^2=|\xi|^2$, $\xi\in\mathbb{R}^{n+1}$ and $\varphi(\sigma, \xi)=\psi(\sigma, \rho^2)$ then

$$\frac{\partial^{|\alpha|+|\beta|}}{\partial\sigma^\alpha\partial\xi^\beta}\varphi(\sigma, \xi)=\sum_{0\leqq l\leqq|\beta|}P_{\alpha,l}(\xi)\frac{\partial^{|\alpha|+l}}{\partial\sigma^\alpha\partial\omega^l}\psi(\sigma, |\xi|^2)$$

where $P_{\alpha,l}(\xi)$ are polynomials in $\xi_1, \xi_2, \cdots, \xi_{n+1}$. From this it follows that K is continuous.

Now combining Lemmata 2.13, 2.14 and 2.15, we see that the mapping

$$\mathscr{E} = \mathscr{F} \circ K \circ \mathscr{G} \circ B \circ \mathscr{F}^{-1}$$

satisfies the requirements of the extension lemma. This finally completes the proof of Theorem 2.1.

Remark 2.16. In case $\hat{f}$ or $\hat{g}$ are not locally equal to integrable functions, an inversion formula is still supplied by the relation

$$\langle f, \varphi \rangle = \langle g, \mathscr{E}\varphi \rangle$$

given in Proposition 2.7. This may also be written $\langle f, \varphi \rangle = \langle \mathscr{E}^* g, \varphi \rangle$ or

$$f = \mathscr{E}^* g \quad \text{where } \mathscr{E}^* : \mathscr{S}'_r \to \mathscr{S}'_e.$$

Consequently $R\mathscr{E}^* g = g \Leftrightarrow \hat{g} \in \mathscr{S}'_{r,\text{cone}}$ and $\mathscr{E}^* Rf = f$ for all $f \in \mathscr{S}'_e$.

3. A Sobolev estimate.

DEFINITION. $\mathscr{H}^\alpha(\mathbb{R}^n)$ is the set of all distributions f in $\mathscr{S}'(\mathbb{R}^n)$ such that $\hat{f}$ has a representative which is a locally integrable function with the norm $\|f\|_\alpha = \{\int_{\mathbb{R}^n} (1+|\xi|^2)^\alpha |\hat{f}(\xi)|^2 \, d\xi\}^{1/2} < \infty$.

THEOREM 3.1. *If $g = Rf$ then*

$$\|f\|_\alpha < \sqrt{\frac{\omega_n}{2}} \|g\|_{\alpha+1/2}.$$

Proof. By the inversion formula

$$\hat{f}(\sigma, \omega) = \frac{\omega_n}{2} |\omega| (|\sigma|^2 + \omega^2)^{(n-1)/2} \hat{g}(\sigma, \sqrt{|\sigma|^2 + \omega^2})$$

we have

$$\begin{aligned}
&\int_{\mathbb{R}^{n+1}} (1+|\sigma|^2+\omega^2)^\alpha |\hat{f}(\sigma,\omega)|^2 \, d\sigma \, d\omega \\
&= \frac{\omega_n^2}{4} \int_{\mathbb{R}^{n+1}} (1+|\sigma|^2+\omega^2)^\alpha \omega^2 (|\sigma|^2+\omega^2)^{n-1} |\hat{g}(\sigma, \sqrt{|\sigma|^2+\omega^2})|^2 \, d\sigma \, d\omega \\
&= \{\text{substitute } \rho = \sqrt{|\sigma|^2+\omega^2}\} \\
&= \frac{\omega_n^2}{2} \int_{\mathbb{R}^n} \int_{|\sigma|}^\infty (1+\rho^2)^\alpha (\rho^2 - |\sigma|^2) \rho^{n-1} \frac{|\hat{g}(\sigma,\rho)|^2}{\sqrt{\rho^2-|\sigma|^2}} \rho \, d\rho \, d\sigma \\
&= \frac{\omega_n^2}{2} \int_{\mathbb{R}^n} \int_{|\sigma|}^\infty (1+\rho^2)^\alpha \sqrt{\rho^2-|\sigma|^2} |\hat{g}(\sigma,\omega)|^2 \rho^n \, d\rho \, d\sigma \\
&\leqq \frac{\omega_n^2}{2} \int_{\mathbb{R}^n} \int_{|\sigma|}^\infty (1+\rho^2+|\sigma|^2)^{\alpha+1/2} |\hat{g}(\sigma,\rho)|^2 \rho^n \, d\rho \, d\sigma \\
&= \frac{\omega_n}{2} \|g\|^2_{\alpha+1/2}.
\end{aligned}$$

Before proceeding to the local problem we remark that several reformulations of the inversion formula

$$\hat{f}(\sigma, \omega) = \frac{\omega_n}{2} |\omega| (|\sigma|^2 + \omega^2)^{(n-1)/2} \hat{g}(\sigma, \sqrt{|\sigma|^2 + \omega^2})$$

are possible. Taking inverse Fourier transforms and using the formula of Proposition 2.2, we obtain $f = c_n H_y(\partial/\partial y)\Delta^{(n-1)/2} R^* g$ which is also given by Fawcett [3]. Here H_y is the Hilbert transform with respect to y, Δ is the Laplacian $\Delta = \Delta_x + (\partial^2/\partial y^2)$ and c_n is a constant. However, if we introduce the pseudodifferential operator K defined by $(Kg)\hat{}(\sigma, \rho) = \sqrt{\rho^2 - |\sigma|^2}\, \rho^{n-1} \hat{g}(\sigma, \rho)$ then also $f = c_n R^* K g$.

Here, as is easily seen, K is a continuous mapping from the subspace $\mathcal{H}^\alpha \cap \mathcal{S}'_{r,\text{cone}}$ to $\mathcal{H}^{\alpha+n} \cap \mathcal{S}'_r$ and R^* is a continuous mapping from $\mathcal{H}^{\alpha+n} \cap \mathcal{S}'_r$ to $\mathcal{H}^{\alpha+1/2}$.

This formula might be more useful for numerical purposes than Fawcett's. One difficulty in using any of these formulas numerically will probably be the fact that the calculation of R^* requires an integration over an unbounded domain.

4. Uniqueness for the local problem. In this section we will extend a theorem of uniqueness for the local problem, proved by Courant and Hilbert [2] for continuous functions f.

Let $x_0 \in \mathbb{R}^n$, $\varepsilon > 0$ and $B > 0$ be given.

THEOREM 4.1. *Let $f \in \mathcal{S}'_e(\mathbb{R}^{n+1})$ and suppose that $g = Rf$ is equal to zero on the open set $U_{B,\varepsilon} = \{(x, r): |x - x_0| < \varepsilon,\ 0 \leqq r < B\} \subset \mathbb{R}^n \times \mathbb{R}^{n+1}$. Then $f = 0$ on the open set $V_B = \{(x, y): |x - x_0|^2 + y^2 < B^2\} \subset \mathbb{R}^{n+1}$. Also $g = 0$ in the open double cone $W_B = \{(x, r): |x - x_0| + r < B\}$.*

We first note that the assumption that f is a *tempered* distribution is inessential in the sense that any distribution defined on an open set $U_{B',\varepsilon'} \supset U_{B,\varepsilon}$ is, when restricted to $U_{B,\varepsilon}$, equal to the restriction of some *tempered* distribution to $U_{B,\varepsilon}$. We also see that we may take $x_0 = 0$ without loss of generality.

LEMMA 4.2. *Let $\varphi \in \mathcal{S}_r$, $\psi = R^*\varphi$, $f \in \mathcal{S}'_e$ and $g = Rf$. Then $g * \varphi = R(f * \psi)$.*

Proof. Consider the continuous mapping $f \mapsto R(f * (R^*\varphi)) - (Rf) * \varphi = h$ from $\mathcal{S}'_e$ to $\mathcal{S}'_r$.

Using the inversion formula of Theorem 2.1 and the formula for $(R^* \varphi)\hat{}$ in Proposition 2.2 it follows that $\hat{h} = 0$ if $f \in \mathcal{S}_r$, i.e., that the mapping is identically zero on the dense subspace $\mathcal{S}_e \subset \mathcal{S}'_e$. By continuity it follows that $R(f * (R^*\varphi)) - (Rf) * \varphi = 0$ for all $f \in \mathcal{S}'_e$ which proves the lemma.

Proof of Theorem 4.1. The first part of the proof is merely a reproduction of Courant's proof and is included for the convenience of the reader. Let $f \in C^\infty(\mathbb{R}^{n+1})$ and $g = Rf$. Obviously $g \in C^\infty(\mathbb{R}^n \times \mathbb{R}^{n+1})$. Take

$$G(x, r) = \omega_n \int_0^r g(x, s) s^n \, ds = \int_{|\xi|^2 + \eta^2 \leqq r^2} f(x + \xi, \eta) \, d\xi \, d\eta,$$

$$\begin{aligned} G'_{x_i}(x, r) &= \int_{|\xi|^2 + \eta^2 \leqq r^2} f'_{x_i}(x + \xi, \eta) \, d\xi \, d\eta \\ &= \int_{|\xi|^2 + \eta^2 \leqq r^2} f'_{\xi_i}(x + \xi, \eta) \, d\xi \, d\eta \\ &= \frac{1}{r} \int_{|\xi|^2 + \eta^2 = r^2} f(x + \xi, \eta) \xi_i \, dS_n. \end{aligned}$$

Now

$$\begin{aligned} R(x_i f)(x, r) &= \frac{1}{r^n \omega_n} \int_{|\xi|^2 + \eta^2 = r^2} f(x + \xi, \eta)(x_i + \xi_i) \, dS_n \\ &= x_i g(x, r) + \frac{r^{1-n}}{\omega_n} G'_{x_i}(x, r) \\ &= x_i g(x, r) + r^{1-n} \frac{\partial}{\partial x_i} \int_0^r g(x, s) s^n \, ds = D_i g(x, r). \end{aligned}$$

Consequently $R(x_i f) = D_i g$ where the linear operator D_i is defined by the previous expression. Repeating, we obtain $R(p(x)f) = p(D)g$ where p is any n-variable polynomial. Further

$$R(p(x)f)(x, r) = \frac{1}{r^n \omega_n} \int_{|\xi|^2+\eta^2=r^2} p(x+\xi) f(x+\xi, \eta)\, dS_n$$

$$= \frac{1}{r^{n-1}\omega_n} \int_{|\xi|\leqq r} p(x+\xi) \frac{f(x+\xi, \sqrt{r^2-|\xi|^2})}{\sqrt{r^2-|\xi|^2}}\, d\xi.$$

Now if $g = 0$ in $U_{B,\varepsilon}$ then obviously $p(D)g = 0$ in $U_{B,\varepsilon}$. Then

$$\int_{|\xi|\leqq r} p(x+\xi) \frac{f(x+\xi, \sqrt{r^2-|\xi|^2})}{\sqrt{r^2-|\xi|^2}}\, d\xi = 0$$

for every fixed point $(x, r) \in U_{B,\varepsilon}$ and every polynomial p. For x and r fixed, select a sequence p_n of polynomials such that $p_n(x+\xi) \to f(x+\xi, \sqrt{r^2-|\xi|^2})$ uniformly for $|\xi| \leqq r$. It follows that $f = 0$ in V_B and that $g = 0$ in W_B.

To proceed to the case when $f \in \mathscr{S}'_e$ we select a sequence of mollifiers $\varphi_n \in \mathscr{S}_r$ such that supp $\varphi_n \subset \{(x, r)\colon |x| < 1/n,\ 0 \leqq r < 1/n\}$ and such that $\varphi_n * g \to g$ for all $g \in \mathscr{S}'_r$. Taking $\psi_n = R^* \varphi_n$ it follows easily that supp $\psi_n \subset \{(x, y)\colon |x| < 2/n,\ 0 \leqq y < 1/n\}$. From Lemma 4.2 we conclude that $R(f * \psi_n) = g * \varphi_n \to g$ in the topology of $\mathscr{S}'_r$. Since R^{-1} is continuous we have $f * \psi_n \to f$ in the topology of $\mathscr{S}'_e$. Moreover, $g * \varphi_n$ and $f * \psi_n$ are in C^∞, $g * \varphi_n = 0$ in a sequence $U_{B_n,\varepsilon_n} \subset U_{B,\varepsilon}$ of open sets such that $B_n \to B$, $\varepsilon_n \to \varepsilon$. Then by the previous result $f * \psi_n = 0$ in the sequence $V_{B_n} \subset V_B$ of open sets. Since $f * \psi_n \to f$ as $n \to \infty$ in the sense of distributions it follows that $f = 0$ in V_B. Then also $g = 0$ in W_B and the proof is complete.

COROLLARY 4.3. *If $g = 0$ in a strip $\{(x, r)\colon |x - x_0| < \varepsilon,\ 0 \leqq r < \infty\}$ then $g = 0$ everywhere.*

Proof. Let $B \to \infty$ in Theorem 4.1.

5. Inversion formulas for the local problem. We will start by investigating the mapping R when f and g are of the form $f(x, y) = F(y)\, e^{i\langle\sigma,x\rangle}$ and $g(x, r) = G(r)\, e^{i\langle\sigma,x\rangle}$. The resulting equations have somewhat different form for even and odd values of n.

THEOREM 5.1. *Let $f(x, y) = F(y)\, e^{i\langle\sigma,x\rangle}$ where $F(y)$ is continuous for $0 \leqq y < B \leqq \infty$. Then $g = Rf$ is of the form $g(x, r) = G(r)\, e^{i\langle\sigma,x\rangle}$ where*

$$(1)\quad \left(\frac{|\sigma|}{2}\right)^{n-1} \frac{\sqrt{\pi}}{2\Gamma((n+1)/2)} r^{n-1} G(r) = \int_0^r F(y)(r^2-y^2)^{(n-2)/4} J_{(n-2)/2}(|\sigma|\sqrt{r^2-y^2})\, dy$$

for $0 \leqq r < A$.

Further $r^k G^{(k)}(r)$ is continuous on $[0, B)$ for $0 \leqq k \leqq n/2$. We have also for $n = 2m$, $m \geqq 1$

$$(2)\quad \frac{d}{dr}\left(\frac{1}{2r}\frac{d}{dr}\right)^{m-1} (r^{2m-1} G(r)) = \frac{2\Gamma(m+\frac{1}{2})}{\sqrt{\pi}} \left\{ F(r) - |\sigma| r \int_0^r F(y) \frac{J_1(|\sigma|\sqrt{r^2-y^2})}{\sqrt{r^2-y^2}}\, dy \right\}$$

and for $n = 2m+1$, $m \geqq 0$

$$(3)\quad \left(\frac{1}{2r}\frac{d}{dr}\right)^m (r^{2m} G(r)) = \frac{2\Gamma(m+1)}{\pi} \int_0^r \frac{\cos(|\sigma|\sqrt{r^2-y^2})}{\sqrt{r^2-y^2}} F(y)\, dy.$$

In particular for $n=1$ we have

$$\frac{\pi}{2}G(r)=\int_0^r F(y)\frac{\cos(\sigma\sqrt{r^2-y^2})}{\sqrt{r^2-y^2}}\,dy \tag{4}$$

and for $n=2$

$$rG(r)=\int_0^r F(y)J_0(|\sigma|\sqrt{r^2-y^2})\,dy_1, \tag{5}$$

$$\frac{d}{dr}(rG(r))=F(r)-r|\sigma|\int_0^r F(y)\frac{J_1(|\sigma|\sqrt{r^2-y^2})}{\sqrt{r^2-y^2}}\,dy. \tag{6}$$

Proof.

$$\begin{aligned}
g(x,r)&=\frac{1}{\omega_n r^n}\int_{|\xi|^2+\eta^2=r^2} F(\eta)\,e^{i\langle\sigma,x+\xi\rangle}\,dS_n(\xi,\eta)\\
&=\frac{1}{\omega_n r^n}\,e^{i\langle\sigma,x\rangle}\int_{|\xi|^2+\eta^2=r^2} F(\eta)\,e^{i\langle\sigma,\xi\rangle}\,dS_n(\xi,\eta)\\
&=\left\{dS_n=\frac{r}{|\eta|}\,d\xi,\ |\eta|=\sqrt{r^2-|\xi|^2}\right\}\\
&=\frac{2}{\omega_n r^{n-1}}\,e^{i\langle\sigma,x\rangle}\int_{|\xi|\leqq r}\frac{F(\sqrt{r^2-|\xi|^2})}{\sqrt{r^2-|\xi|^2}}\,e^{i\langle\sigma,\xi\rangle}\,d\xi.
\end{aligned}$$

Hence

$$\frac{\omega_n}{2}r^{n-1}G(r)=\int_{|\xi|\leqq r}\frac{F(\sqrt{r^2-|\xi|^2})}{\sqrt{r^2-|\xi|^2}}\,e^{i\langle\sigma,\xi\rangle}\,d\xi.$$

For $n=1$ we easily obtain (4). For $n\geqq 2$ we introduce polar coordinates $\xi=sx$, $x\in S^{n-1}$, $0\leqq s\leqq r$, $d\xi=s^{n-1}\,ds\,dS_{n-1}(x)$. Then

$$\frac{\omega_n}{2}r^{n-1}G(r)=\int_0^r\frac{F(\sqrt{r^2-s^2})}{\sqrt{r^2-s^2}}s^{n-1}\,ds\int_{S^{n-1}}e^{is\langle\sigma,x\rangle}\,dS_{n-1}(x).$$

Taking $\langle\sigma,x\rangle=|\sigma|\cos v$ we have by Fubini's theorem

$$\begin{aligned}
\int_{S^{n-1}}e^{is\langle\sigma,x\rangle}\,dS_{n-1}(x)&=\int_0^\pi e^{is|\sigma|\cos v}\omega_{n-2}(\sin v)^{n-2}\,dv\\
&=2\omega_{n-2}\int_0^{\pi/2}\cos(s|\sigma|\cos v)(\sin v)^{n-2}\,dv\\
&=\text{(see Magnus and Oberhettinger [10])}\\
&=\omega_{n-2}\sqrt{\pi}\,\Gamma\left(\frac{n-1}{2}\right)J_{(n-2)/2}(s|\sigma|)\left(\frac{2}{|\sigma|}\right)^{n/2-1}.
\end{aligned}$$

If we insert this in the previous formula and use that $\omega_n/\omega_{n-2}=2\pi(n-1)$ we obtain (1).

Next if we consider $H(r)=r^{(n-1)/2}G(\sqrt{r})$ and $K(y)=F(\sqrt{y})/2\sqrt{y}$ (1) may be rewritten

$$\left(\frac{|\sigma|}{2}\right)^{(n-2)/2}\frac{\sqrt{\pi}}{2\Gamma((n+1)/2)}H(r)=\int_0^r K(s)(r-s)^{(n-2)/4}J_{(n-2)/4}(|\sigma|\sqrt{r-s})\,ds.$$

Taking Laplace transforms we have (see [10])

$$\frac{\sqrt{\pi}}{2\Gamma((n+1)/2)}\tilde{H}(p)=\tilde{K}(p)\frac{e^{-|\sigma|^2/4p}}{p^{n/2}}.$$

If $n=2m$ then

$$\frac{\sqrt{\pi}}{2\Gamma(m+\frac{1}{2})}p^m\tilde{H}(p)=\tilde{K}(p)\,e^{-|\sigma|^2/4p}.$$

Now

$$\frac{e^{-|\sigma|^2/4p}}{p}=\mathscr{L}(J_0(|\sigma|\sqrt{t}))$$

and so

$$e^{-|\sigma|^2/4p}=1+\mathscr{L}\left(\frac{d}{dt}J_0(|\sigma|\sqrt{t})\right)=1-\mathscr{L}\left(\frac{|\sigma|}{2}\frac{J_1(|\sigma|\sqrt{t})}{\sqrt{t}}\right).$$

Consequently

$$\frac{\sqrt{\pi}}{2\Gamma(m+\frac{1}{2})}p^m\tilde{H}(p)=\tilde{K}(p)-\frac{|\sigma|}{2}\tilde{K}(p)\cdot\mathscr{L}\left(\frac{J_1(|\sigma|\sqrt{t})}{\sqrt{t}}\right)(p).$$

Further by the equality

$$\frac{\sqrt{\pi}}{2\Gamma(m+\frac{1}{2})}\tilde{H}(p)=\tilde{K}(p)\frac{e^{-|\sigma|^2/4p}}{p^m}$$

it follows that $H^{(k)}(0)=\lim_{p\to+\infty}p^{k+1}\tilde{H}(p)=0$ for $k=0,1,\cdots,m-1$.

Now, inverting the Laplace transform we have

$$\frac{\sqrt{\pi}}{2\Gamma(m+\frac{1}{2})}H^{(m)}(r)=K(r)-\frac{|\sigma|}{2}\int_0^r K(s)\frac{J_1(|\sigma|\sqrt{r-s})}{\sqrt{r-s}}\,ds.$$

If we substitute $s=y^2$, $ds=2y\,dy$ and replace r by r^2 we have

$$\frac{\sqrt{\pi}}{2\Gamma(m+\frac{1}{2})}H^{(m)}(r^2)=K(r^2)-|\sigma|\int_0^r K(y^2)\frac{J_1(|\sigma|\sqrt{r^2-y^2})}{\sqrt{r^2-y^2}}y\,dy$$

whence we easily obtain (2). It also follows that $r^kG^{(k)}(r)$ is continuous on $[0, B)$ for $0\leqq k\leqq m$.

Next if $n=2m+1$ we have

$$\frac{\sqrt{\pi}}{2\Gamma(m+1)}p^m\tilde{H}(p)=\tilde{K}(p)\frac{e^{-|\sigma|^2/4p}}{p^{1/2}}.$$

Using that

$$\mathscr{L}^{-1}\left(\frac{e^{-|\sigma|^2/4p}}{p^{1/2}}\right)=\frac{1}{\sqrt{\pi}}\left(\frac{\cos(|\sigma|\sqrt{t})}{\sqrt{t}}\right)$$

and an argument similar to the preceding one we may obtain (3) and the statement about continuity for $r^kG^{(k)}(r)$. The proof of Theorem 5.1 is complete. We note that it is of course possible to obtain formulas for

$$\frac{d}{dr}\left(\frac{1}{2r}\frac{d}{dr}\right)^k(r^{n-1}G(r))\quad\text{for every } k \text{ with } 0\leqq k\leqq\left[\frac{n}{2}\right].$$

THEOREM 5.2. *If $g(x, r)=G(r)\,e^{i\langle\sigma,x\rangle}$ and if $r^kG^{(k)}(r)$ is continuous for $0\leqq r<B$ and $0\leqq k\leqq[n+1/2]$ then $g=Rf$ for some function $f(x, y)=F(y)\,e^{i\langle\sigma,x\rangle}$ where $F(y)$ is continuous for $0\leqq y<B$.*

For $n=2m$, $m\geqq 1$ we have

$$\frac{2\Gamma(m+\frac{1}{2})}{\sqrt{\pi}}F(y)=a(y)-|\sigma|y\int_0^y a(r)\frac{I_1(|\sigma|\sqrt{y^2-r^2})}{\sqrt{y^2-r^2}}\,dr \tag{7}$$

where

$$a(r)=\frac{d}{dr}\left(\frac{1}{2r}\frac{d}{dr}\right)^{m-1}(r^{2m-1}G(r)).$$

For $n=2m+1$, $m\geqq 0$ we have

$$F(y)=G(0)\cosh(|\sigma|y)+\frac{1}{\Gamma(m+1)}y\int_0^y b(r)\frac{\cosh(|\sigma|\sqrt{y^2-r^2})}{\sqrt{y^2-r^2}}\,dr \tag{8}$$

where

$$b(r)=\frac{d}{dr}\left(\frac{1}{2r}\frac{d}{dr}\right)^{m}(r^{2m}G(r)).$$

In particular for $n=1$

$$F(y)=G(0)\cosh(\sigma y)+y\int_0^y G'(r)\frac{\cosh(\sigma\sqrt{y^2-r^2})}{\sqrt{y^2-r^2}}\,dr \tag{9}$$

and for $n=2$,

$$F(y)=\frac{d}{dy}(yG(y))-|\sigma|y\int_0^y\frac{d}{dr}(rG(r))\frac{I_1(|\sigma|\sqrt{y^2-r^2})}{\sqrt{y^2-r^2}}\,dr. \tag{10}$$

Proof. Recalling the proof of Theorem 5.1 we see that to find a function $f(x, y)=F(y)\,e^{i\langle\sigma,x\rangle}$ satisfying $g=Rf$ is equivalent to solving (1) of Theorem 5.1 for F. Now this equation is, with the previous notation, equivalent to

$$\frac{2\Gamma((n+1)/2)}{\sqrt{\pi}}\tilde{K}(p)=p^{n/2}H(p)\,e^{|\sigma|^2/4p}.$$

If $n=2m$ then

$$\frac{2\Gamma(m+\frac{1}{2})}{\sqrt{\pi}}\tilde{K}(p)=p^{m}H(p)\,e^{|\sigma|^2/4p}.$$

Arguing as in the proof of Theorem 5.1, we obtain

$$\frac{2\Gamma(m+\frac{1}{2})}{\sqrt{\pi}}\tilde{K}(p)=p^{m}H(p)-p^{m}H(p)\mathcal{L}\left(\frac{|\sigma|}{2}\frac{I_1(|\sigma|\sqrt{t})}{\sqrt{t}}\right)$$

where we have used that

$$\mathcal{L}(I_0(|\sigma|\sqrt{t}))=\frac{e^{|\sigma|^2/4p}}{p},$$

$$e^{|\sigma|^2/4p}=1+\mathcal{L}\left(\frac{d}{dt}I_0(|\sigma|\sqrt{t})\right)$$

$$=1-\mathcal{L}\left(\frac{|\sigma|}{2}\frac{I_1(|\sigma|\sqrt{t})}{\sqrt{t}}\right).$$

Now $r^{m-1}G^{(m-1)}(r)$ is continuous on $[0, B)$ which implies that $H(0)=H'(0)=\cdots=H^{(m-1)}(0)=0$ and that $p^mH(p)=\mathcal{L}H^{(m)}(t)$. Inverting the Laplace transform, we easily

obtain (7) and the argument is complete for $n=2m$. Next, if $n=2m+1$ then

$$\frac{2\Gamma(m+1)}{\sqrt{\pi}}\tilde{K}(p)=p^{m+1}H(p)\frac{e^{|\sigma|^2/4p}}{p^{1/2}}.$$

Using that

$$\frac{e^{|\sigma|^2/4p}}{p^{1/2}}=\frac{1}{\sqrt{\pi}}\mathscr{L}\left(\frac{\cosh(|\sigma|\sqrt{t})}{\sqrt{t}}\right)$$

and that $H^{(m)}(0)=\Gamma(m+1)G(0)$ we obtain (8) after arguments similar to those previously used and the proof is finished.

THEOREM 5.3. *Let $g=Rf$ for some distribution $f\in\mathscr{S}'_e(\mathbb{R}^{n+1})$ and assume that the distribution g^* is for $0<r<B$ equal to a function $g^*(\sigma,r)$ such that $r^k(\partial/\partial r)^k g^*(\sigma,r)$ is continuous on $\mathbb{R}^n\times[0,B)\subset\mathbb{R}^{n+1}$ for $0\leqq k\leqq[(n+1)/2]$. Then the distribution f^* is on $\mathbb{R}^n\times[0,B)\subset\mathbb{R}^{n+1}$ equal to a continuous function $f^*(\sigma,y)$. Moreover, we have for $n=2m$ the inversion formula*

$$\frac{2\Gamma(m+\frac{1}{2})}{\sqrt{\pi}}f^*(\sigma,y)=a^*(\sigma,y)-|\sigma|y\int_0^y a^*(\sigma,r)\frac{I_1(|\sigma|\sqrt{y^2-r^2})}{\sqrt{y^2-r^2}}\,dr \tag{11}$$

where

$$a^*(\sigma,r)=\frac{\partial}{\partial r}\left(\frac{1}{2r}\frac{\partial}{\partial r}\right)^{m-1}(r^{2m-1}g^*(\sigma,r))$$

and for $n=2m+1$

$$f^*(\sigma,y)=g^*(\sigma,0)\cosh(|\sigma|y)+\frac{1}{\Gamma(m+1)}y\int_0^y b^*(\sigma,r)\frac{\cosh(|\sigma|\sqrt{y^2-r^2})}{\sqrt{y^2-r^2}}\,dr \tag{12}$$

where

$$b^*(\sigma,y)=\frac{\partial}{\partial r}\left(\frac{1}{2r}\frac{\partial}{\partial r}\right)^{m}(r^m g^*(\sigma,r)).$$

In particular

$$f^*(\sigma,y)=g^*(\sigma,0)\cosh(\sigma y)+y\int_0^y\frac{\partial g^*}{\partial r}(\sigma,r)\frac{\cosh(\sigma\sqrt{y^2-r^2})}{\sqrt{y^2-r^2}}\,dr$$

for $n=1$ and

$$f^*(\sigma,y)=\frac{\partial}{\partial y}(yg^*(\sigma,y))-|\sigma|y\int_0^y\frac{\partial}{\partial r}(rg^*(\sigma,r))\frac{I_1(|\sigma|\sqrt{y^2-r^2})}{\sqrt{y^2-r^2}}\,dr$$

for $n=2$.

Proof. Let us for $(\sigma,r)\subset\mathbb{R}^n\times[0,B)$ define a function $h^*(\sigma,r)$ by replacing f^* in (11) or (12) above, by h^*. Then h^* is continuous on $\mathbb{R}^n\times[0,B)$. Moreover, inverting these integral equations, we obtain

$$\left(\frac{|\sigma|}{2}\right)^{n-1}\frac{\sqrt{\pi}}{2\Gamma((n+1)/2)}g^*(\sigma,r)=\int_0^y h^*(\sigma,r)(r^2-y^2)^{(n-2)/4}J_{(n-2)/2}(|\sigma|\sqrt{r^2-y^2})\,dy$$

for $(\sigma,r)\in\mathbb{R}^n\times[0,B)$. Reverting the deduction in the proof of Theorem 5.1, we find that

$$\frac{\omega_n}{2}r^{n-1}g^*(\sigma,r)=\int_{|x|\leqq r}\frac{h^*(\sigma,\sqrt{r^2-|x|^2})}{\sqrt{r^2-|x|^2}}e^{i\langle\sigma,x\rangle}\,dx$$

for $(\sigma,r)\in\mathbb{R}^n\times[0,B)$.

Next suppose that $\varphi \in \mathcal{S}_r$. Then

$$\begin{aligned}(R^*\varphi)^*(\sigma, y) &= \int_{\mathbb{R}^n} e^{-i\langle\sigma,x\rangle}\,dx \int_{\mathbb{R}^n} \varphi(z, \sqrt{|x-z|^2+y^2})\,dz \\ &= \int_{\mathbb{R}^n} e^{-i\langle\sigma,z\rangle}\,dz \int_{\mathbb{R}^n} e^{-i\langle\sigma,x-z\rangle}\varphi(z, \sqrt{|x-z|^2+y^2})\,dx \\ &= \int_{\mathbb{R}^n} e^{-i\langle\sigma,z\rangle}\,dz \int_{\mathbb{R}^n} e^{-i\langle\sigma,x\rangle}\varphi(z, \sqrt{|x|^2+y^2})\,dx \\ &= \int_{\mathbb{R}^n} e^{-i\langle\sigma,x\rangle}\,dx \int_{\mathbb{R}^n} e^{-i\langle\sigma,z\rangle}\varphi(z, \sqrt{|x|^2+y^2})\,dz \\ &= \int_{\mathbb{R}^n} e^{-i\langle\sigma,x\rangle}\varphi^*(\sigma, \sqrt{|x|^2+y^2})\,dx.\end{aligned}$$

To proceed we introduce the following subspaces of $\mathcal{S}_e$ and $\mathcal{S}_r$.

$$\mathcal{S}_{e,B} = \{\psi^* \in \mathcal{S}_e\colon \psi^*(\sigma, y) = 0 \text{ if } |y| \geqq B\}$$

and

$$\mathcal{S}_{r,B} = \{\varphi \in \mathcal{S}_r\colon \varphi(x, r) = 0 \text{ for } r \geqq B\}.$$

Consider the mapping

$$R^*\colon \mathcal{S}_r \to \mathcal{S}_e$$

with

$$(R^*\varphi)^*(\sigma, y) = \int_{\mathbb{R}^n} e^{-i\langle\sigma,x\rangle}\varphi^*(\sigma, \sqrt{|x|^2+y^2})\,dx.$$

It is obvious that $R^*\varphi \in \mathcal{S}_{e,B}$ if $\varphi \in \mathcal{S}_{r,B}$.

LEMMA 5.4. $\overline{R^*(\mathcal{S}_{r,B})} = \mathcal{S}_{e,B}$.

Proof. Suppose, on the contrary, that $\overline{R^*(\mathcal{S}_{r,B})} \neq \mathcal{S}_{e,B}$. Then, according to the Hahn-Banach theorem (see [13, Chap. IV]) there exists some $f \in \mathcal{S}'_e$ and some $\psi \in \mathcal{S}_{e,B}$ such that $\langle f, R^*\varphi\rangle = 0$ for all $\varphi \in \mathcal{S}_{r,B}$ and so that $\langle f, \psi\rangle \neq 0$. Let $g = Rf$. Then $\langle g, \varphi\rangle = \langle f, R^*\varphi\rangle = 0$ for all $\varphi \in \mathcal{S}_{r,B}$. Consequently $g = 0$ for $r < B$ and by Theorem 4.1 we conclude that $f = 0$ for $|y| < B$. This contradicts that $\langle f, \psi\rangle \neq 0$ and the lemma is proved. Now suppose that $\varphi^* \in \mathcal{S}_{r,B}$. Then, using the previous relation between g^* and h^*,

$$\begin{aligned}\langle g^*, \varphi^*\rangle &= \omega_n \int_{\mathbb{R}^n} \int_0^\infty g^*(\sigma, r)\varphi^*(\sigma, r) r^n\,dr\,d\sigma \\ &= 2\int_{\mathbb{R}^n} \int_0^\infty \varphi^*(\sigma, r) r\,dr\,d\sigma \int_{|x|\leqq r} \frac{h^*(\sigma, \sqrt{r^2-|x|^2})}{\sqrt{r^2-|x|^2}}\, e^{i\langle\sigma,x\rangle}\,dx \\ &= 2\int_{\mathbb{R}^n} dx \int_{\mathbb{R}^n} e^{i\langle\sigma,x\rangle}\,d\sigma \int_{|x|}^\infty \frac{h^*(\sigma, \sqrt{r^2-|x|^2})}{\sqrt{r^2-|x|^2}}\varphi^*(\sigma, r) r\,dr \\ &= \{\text{substitute } r = \sqrt{|x|^2+y^2},\ y = \sqrt{r^2-|x|^2}\} \\ &= \int_{\mathbb{R}^n} dx \int_{\mathbb{R}^n} e^{i\langle\sigma,x\rangle}\,d\sigma \int_{\mathbb{R}} h^*(\sigma, y)\varphi^*(\sigma, \sqrt{|x|^2+y^2})\,dy \\ &= \int_{\mathbb{R}^{n+1}} h^*(\sigma, y)\,d\sigma\,dy \int_{\mathbb{R}^n} e^{i\langle\sigma,x\rangle}\varphi^*(\sigma, \sqrt{|x|^2+y^2})\,dx \\ &= \int_{\mathbb{R}^{n+1}} h^*(\sigma, y)(R^*\varphi)^*(\sigma, y)\,d\sigma\,dy.\end{aligned}$$

However, we also have $\langle g^*, \varphi^* \rangle = \langle f^*, (R^*\varphi)^* \rangle$ whence

$$\langle f^*, (R^*\varphi)^* \rangle = \int_{\mathbb{R}^{n+1}} h^*(\sigma, y)(R^*\varphi)^*(\sigma, y)\, d\sigma\, dy.$$

From the lemma it now follows easily that f^* is for $0 \leqq y < B$ equal to the function $h^*(\sigma, y)$. By the definition of h^* this completes the proof of Theorem 5.3.

We remark again that for $n = 1$ and 2 the direct formula and the inversion formula have the following form.

For $n = 1$

$$\frac{\pi}{2} g^*(\sigma, r) = \int_0^r f^*(\sigma, y) \frac{\cos(\sigma\sqrt{r^2 - y^2})}{\sqrt{r^2 - y^2}}\, dy,$$

$$f^*(\sigma, y) = g^*(\sigma, 0)\cosh(\sigma y) + y \int_0^y \frac{\partial g^*}{\partial r}(\sigma, r) \frac{\cosh(\sigma\sqrt{y^2 - r^2})}{\sqrt{y^2 - r^2}}\, dr.$$

For $n = 2$

$$rg^*(\sigma, r) = \int_0^r f^*(\sigma, y) J_0(|\sigma|\sqrt{r^2 - y^2})\, dy,$$

$$f^*(\sigma, y) = \frac{\partial}{\partial y}(yg^*(\sigma, y)) - |\sigma| y \int_0^y \frac{\partial}{\partial r}(rg^*(\sigma, r)) \frac{I_1(|\sigma|\sqrt{y^2 - r^2})}{\sqrt{y^2 - r^2}}\, dr.$$

COROLLARY 5.5. *Let $g = Rf$ for some distribution $f \in \mathcal{S}'_e(\mathbb{R}^{n+1})$ and assume that the distribution g^* is for $0 < r < B$ and $\sigma \in \Sigma$, where $\Sigma \subset \mathbb{R}^n$ is an open set, equal to a function $g^*(\sigma, r)$ such that $r^k(\partial/\partial r)^k g^*(\sigma, r)$ is continuous on $\Sigma \times [0, B) \subset \mathbb{R}^{n+1}$ for $0 \leqq k \leqq [(n+1)/2]$. Then the distribution f^* is on $\Sigma \times [0, B) \subset \mathbb{R}^{n+1}$ equal to a continuous function $f^*(\sigma, y)$ and the previously given inversion formulas are valid. In particular if $g^*(\sigma, r) = 0$ on $\Sigma \times [0, B)$ then so is $f^*(\sigma, y)$.*

The proof is omitted.

Finally we will demonstrate a theorem concerning the local range of the operator R. The proof of this theorem also suggests a procedure for the inversion of the operator R. However, for numerical purposes the given procedure may not be directly useful. For simplicity we formulate the theorem for $n = 2$.

THEOREM 5.6. *Let $n = 2$ and suppose that $g(x, r)$ and $rg'_r(x, r)$ are continuous in the set*

$$\{(x, r): 0 \leqq x_i \leqq a_i,\ i = 1, 2,\ 0 \leqq r \leqq B\} = K.$$

Then, given any $\varepsilon > 0$, there exists a function $h(x, r)$ such that

$$\sup_{(x,r) \in K} \{|g(x, r) - h(x, r)| + r|g'_r(x, r) - h'_r(x, r)|\} < \varepsilon$$

and such that $h = Rf$ for some function $f(x, y)$ which is continuous for $x \in \mathbb{R}^n$, $0 \leqq y \leqq B$.

Proof. First extend $g(x, r)$ to an even function in x by requiring that $g(\pm x_1, \pm x_2, r) = g(x_1, x_2, r)$. Then extend g periodically in x by the condition $g(x_1 + 2a_1, x_2, r) = g(x_1, x_2 + 2a_2, r) = g(x_1, x_2, r)$. Now we can find a function $h(x, r) = \sum g_\sigma(r)\, e^{i\langle \sigma, x \rangle}$ with the following properties. h is a trigonometric polynomial in (x_1, x_2) with the same periodicity as g. The coefficients $g_\sigma(r)$ are continuously differentiable for $0 \leqq r \leqq B$ and $\sup_{(x,r) \in K} (|g - h| + r|g'_r - h'_r|) < \varepsilon$. Now, in order to determine the

function f, we simply take $f(x, y) = \sum_\sigma f_\sigma(y)\, e^{i\langle\sigma, x\rangle}$ where

$$f_\sigma(y) = \frac{d}{dy}(yg_\sigma(y)) - |\sigma| y \int_0^y \frac{d}{dr}(rg_\sigma(r)) \frac{I_1(|\sigma|\sqrt{y^2 - r^2})}{\sqrt{y^2 - r^2}}\, dr.$$

Then according to Theorem 5.2 $h = Rf$ and the proof is finished.

In the previous proof we note that since $I_1(t)$ has exponential growth as $t \to \infty$ the formula for $f_\sigma(y)$ will give an amplification of terms g_σ with large frequencies $|\sigma|$. Although by choosing some limit for the bandwidth one may try to control the ill-posedness of the inversion problem, the required cut-off bandwidth will probably be so small that the method would not be directly useful.

6. Conclusions. In § 2 we have given a solution of the global inversion problem by means of Fourier transformation under very general and precise conditions on f and g. The inversion formula that is given is suitable for numerical purposes in many problems.

In § 3 we have a Sobolev estimate for the function f, and a reformulation of the form $f = c_n R^* K(Rf)$, where K is a certain pseudodifferential operator and R^* is the backprojection operator. This formula differs from the one given by Fawcett [3] which is of the form $f = c_n K R^* Rf$.

In § 4 we have, using the theory of § 2, extended a uniqueness theorem for the local problem to distributions.

In § 5 we gave inversion formulas for the local problem in terms of partial Fourier transforms with respect to the first n variables. These formulas are closely related to similar inversion formulas for the ordinary Radon transform, given in terms of integral equations involving Chebyshev polynomials of the first kind (see for instance the article by A. M. Cormack in [14]), and suffer from the same numerical limitations. Perhaps some modified version analogous to the one suggested in [14] might prove to be more efficient. Finally, considering Theorem 5.6, it is remarkable that the condition supp $\hat{g} \subset \{(\sigma, \rho)\colon \rho \geqq |\sigma|\}$ given in § 2 does not prevent the functions $g(x, r)$ from taking virtually arbitrary values in a bounded set $\{(x, r)\colon 0 \leqq x_i \leqq a_i,\ 0 \leqq r \leqq B\}$.

Acknowledgments. Dr. Hans Hellsten, National Defence Research Institute, Sweden, introduced me to the longwavelength SAR theory and to the problem of inverting spherical average for which I thank him. Anonymous referees have helped to improve the paper by helpful suggestions.

DEGREE OF APPROXIMATION OF REAL FUNCTIONS BY RECIPROCALS OF REAL AND COMPLEX POLYNOMIALS*

A. L. LEVIN† AND E. B. SAFF‡

Abstract. Let $E^c_{on}(f; I)(E^r_{on}(f; I))$ denote the error in best uniform approximation of a real continuous function f on a closed interval I by reciprocals of polynomials of degree $\leqq n$ with complex (real) coefficients. We investigate the rate at which $E^c_{on}(f; I)$ (or $E^r_{on}(f; I)$ provided $f \geqq 0$) can decrease. For example, we prove a Jackson type theorem and also present a class of functions for which reciprocal polynomial approximation is significantly better than polynomial approximation.

Key words. uniform approximation, reciprocals of polynomials, Jackson theorem

AMS(MOS) subject classifications. 41A20, 41A17

1. Introduction. For any real continuous function f on a closed interval I, let $E^r_{on}(f; I)$ and $E^c_{on}(f; I)$ denote the errors in best Chebyshev (uniform) approximation of f on I by reciprocals of polynomials of degree $\leqq n$ with real and complex coefficients respectively.

If f changes its sign on I, then obviously $E^r_{on}(f; I)$ does not approach zero as $n \to \infty$. On the other hand, a result of Walsh [8, Thm. IV] implies that any continuous function on I can be approximated arbitrarily close by reciprocals of *complex* polynomials; that is, $E^c_{on}(f; I) \to 0$. The aim of this paper is to investigate the rate at which $E^c_{on}(f; I)$ can decrease. For example, we prove a Jackson type theorem (Theorem 2.1) and also present a class of functions for which reciprocal polynomial approximation is significantly better than polynomial approximation (of the same degree).

Most of our results are formulated for the case $I = [-1, 1]$ but can be easily restated for an arbitrary finite interval. We also present some examples of approximation on the real line and on the unit disk.

The paper is organized as follows. In § 2 we state and discuss our main results. The proofs of these results are presented in §§ 3-6.

2. Main results. Our first result is the following Jackson type theorem.

THEOREM 2.1. *There exists an absolute constant M such that for any real $f \in C[-1, 1]$,*

$$E^c_{on}(f; [-1, 1]) \leqq M\omega(f; n^{-1}), \qquad n = 1, 2, 3, \cdots, \tag{2.1}$$

where $\omega(f; \delta)$ denotes the modulus of continuity of f on $[-1, 1]$.

Moreover, if f does not change its sign on $[-1, 1]$, then one can replace E^c_{on} by E^r_{on}:

$$E^r_{on}(f; [-1, 1]) \leqq M\omega(f; n^{-1}), \qquad n = 1, 2, 3, \cdots. \tag{2.2}$$

We remark that the estimate (2.1) follows from the estimate (2.2) and (via the usual Jackson theorem) from the following general result.

THEOREM 2.2. *For any real $f \in C[-1, 1]$,*

$$E^c_{0,3n}(f; [-1, 1]) \leqq 5(E^r_{on}(|f|; [-1, 1]) + E^r_{no}(f; [-1, 1])), \tag{2.3}$$

where $E^r_{no}(f;[-1,1])$ *stands for the error in best Chebyshev approximation of* f *by polynomials of degree* $\leqq n$.

From Theorem 2.1 we obtain as a special case that

$$E^r_{on}(|x|^\alpha;[-1,1]) \leqq Mn^{-\alpha}, \qquad 0<\alpha\leqq 1. \tag{2.4}$$

For $0<\alpha<1$, this improves a result of Lungu [5]. For the case $\alpha=1$, the estimate (2.4) was proved by Newman and Reddy [6]. It turns out that the method of [6] can be modified to establish the estimate (2.4) for any $\alpha>0$. Since the matching lower bounds are also available (see Lungu [5]) we obtain the following result.

THEOREM 2.3. *For any* $\alpha>0$, *there exist positive constants* A_α, B_α *such that for any* $n=1,2,3,\cdots$, *the following hold*:

$$A_\alpha n^{-\alpha} \leqq E^c_{on}(|x|^\alpha;[-1,1]) \leqq E^r_{on}(|x|^\alpha;[-1,1]) \leqq B_\alpha n^{-\alpha}, \tag{2.5}$$

$$A_\alpha n^{-\alpha} \leqq E^c_{on}(|x|^\alpha \operatorname{sgn}(x);[-1,1]) \leqq B_\alpha n^{-\alpha}, \tag{2.6}$$

$$A_\alpha n^{-2\alpha} \leqq E^r_{on}(x^\alpha;[0,1]) \leqq B_\alpha n^{-2\alpha}. \tag{2.7}$$

Moreover, the constants A_α, B_α *may be written in the form* $A_\alpha=A^{-\alpha}$, $B_\alpha=C(B\alpha)^\alpha$, *where* A, B, C *are absolute constants* >1.

Note that the upper bound in (2.6) follows from that in (2.5) and (via Jackson's Theorem) from Theorem 2.2. The upper bound in (2.7) follows from that in (2.5) by the standard substitution $x\to x^2$.

The lower bounds in (2.5), (2.6) show that the estimate given in Theorem 2.1 is, in general, the least possible. Moreover, by considering the function $f(x)=x$, it is easy to see that no estimate of the kind $E^c_{on}(f;[-1,1])\leqq Mn^{-k}\omega(f^{(k)};n^{-1})$ (the analogue of Jackson's Theorem for differentiable functions) can be obtained. To get estimates better than $O(n^{-1})$ one has to make some assumptions concerning the zeros of f. The simplest theorem of this kind is the following one.

THEOREM 2.4. *Let* $f(\not\equiv 0)$ *be real-valued and analytic on* $[-1,1]$ *and assume* f *vanishes somewhere on* $[-1,1]$. *Denote by* r *the smallest order of the zeros of* f *in* $(-1,1)$ *and, by* s, *the smallest order of the zeros of* f *at* ±1 (*either* r *or* s *may be zero but not both*). *Define* k *by*

$$k:=\begin{cases} r & \text{if } s=0,\\ 2s & \text{if } r=0,\\ \min(r,2s) & \text{if } r>0,\quad s>0.\end{cases}$$

Then there exist positive constants $A(f)$, $B(f)$ *such that*

$$A(f)n^{-k} \leqq E^c_{on}(f;[-1,1]) \leqq B(f)n^{-k}, \qquad n=1,2,3,\cdots. \tag{2.8}$$

Moreover, the same estimates hold for $E^r_{on}(f;[-1,1])$ *provided* f *does not change sign on* $[-1,1]$.

Remark. The situation is more delicate if f is differentiable and does not change sign on $[-1,1]$. It may be true that in this case one can obtain the estimate $E^r_{on}(f;[-1,1])\leqq Mn^{-1}\omega(f';n^{-1})$ without any further assumptions on the structure of f. Even so, since $E^r_{on}(x^2;[-1,1])\neq 0$, no further refinement involving the modulus of continuity of higher derivatives is possible.

Our next result exhibits a class of functions that can be approximated by reciprocals of polynomials much better than by polynomials (of the same degree). The common feature of functions of this class is that they vanish on a set of intervals but not at

isolated points. To demonstrate why such functions are "well approximable" by reciprocals of polynomials, consider the following example. Let

$$x_+ := \begin{cases} x, & x \geqq 0, \\ 0, & x < 0. \end{cases}$$

Then, from the well-known degree of polynomial approximation to $|x|$, we have $E_{no}(x_+; [-1, 1]) \geqq Cn^{-1}$. On the other hand, we can find a real polynomial $p_n(x)$ such that (see (2.7)) $|x - 1/p_n(x)| \leqq An^{-2}$ for $0 \leqq x \leqq 1$. In particular, $p_n(0) \geqq A^{-1}n^2$. It can be shown that $p_n(x)$ is monotonic on $(-\infty, 0)$ and consequently $p_n(x) \geqq A^{-1}n^2$ for $x < 0$. It follows that

$$|x_+ - 1/p_n(x)| = 1/p_n(x) < An^{-2} \quad \text{for } x < 0,$$

and we obtain

$$E^r_{on}(x_+; [-1, 1]) \leqq An^{-2}.$$

We now formulate the general result.

THEOREM 2.5. *Let $[a_j, b_j], j = 1, 2, \cdots, N$ ($N \geqq 1$), be mutually disjoint subintervals of $[-1, 1]$. For each j, let $f_j \in C^3[a_j, b_j]$ be real-valued and satisfy $f_j(a_j) = f_j(b_j) = 0$, $f_j'(a_j + 0) \neq 0$, $f_j'(b_j - 0) \neq 0$, and assume that $f_j \neq 0$ in (a_j, b_j). Define the function f on $[-1, 1]$ by*

$$f(x) := \begin{cases} f_j(x) & a_j \leqq x \leqq b_j, \quad j = 1, 2, \cdots, N, \\ 0 & \text{otherwise.} \end{cases}$$

Then

$$E^c_{on}(f; [-1, 1]) \leqq A(f)n^{-2}, \qquad n = 1, 2, 3, \cdots. \tag{2.9}$$

Further, if f does not change sign on $[-1, 1]$ then $E^r_{on}(f; [-1, 1]) \leqq A(f)n^{-2}$.

Notice that if $N \geqq 2$ or if $N = 1$ and $[a_1, b_1] \neq [-1, 1]$, then f is not differentiable somewhere in $(-1, 1)$ and consequently $E_{no}(f; [-1, 1]) \neq O(n^{-1-\varepsilon})$ for any $\varepsilon > 0$.

So far we have discussed the direct theorems. What about inverse results? To have any chance of proving that f is differentiable on $[-1, 1]$, we have to assume at least (in view of Theorem 2.5) that $E^c_{on}(f; [-1, 1]) = o(n^{-2})$. Under some additional assumptions on the behavior of f near its zeros we can then prove the differentiability of f. For example, if f is piecewise continuously differentiable on $[-1, 1]$ and satisfies $E^c_{on}(f; [-1, 1]) = o(n^{-2})$, then f is continuously differentiable on $[-1, 1]$. At present, the proper formulation of an inverse theorem for differentiable functions is not clear. We confine ourselves to the following Bernstein type result, which was essentially proved by J. L. Walsh [8].

THEOREM 2.6. *For any complex-valued function $f(\not\equiv 0)$ on $[-1, 1]$, the following conditions are equivalent:*

(i) $\limsup_{n\to\infty} \{E^c_{on}(f; [-1, 1])\}^{1/n} < 1$.

(ii) *f is analytic on $[-1, 1]$ and does not vanish there.*

Our final result deals with approximation on the real axis.

THEOREM 2.7. *Let $K(x)$, $L(x)$ be real polynomials of degrees k and l respectively, with $k \leqq l - 1$. If $L(x) \neq 0$ for x real, then*

$$E^r_{on}(|K(x)|/L(x); \mathbb{R}) = O(n^{(k/l)-1}), \tag{2.10}$$

$$E^c_{on}(K(x)/L(x); \mathbb{R}) = O(n^{(k/l)-1}). \tag{2.11}$$

Furthermore, if $K(x)$ does not change sign for $x \in \mathbb{R}$ then

$$E^r_{on}(K(x)/L(x); \mathbb{R}) = O(n^{(2k/l)-2}). \tag{2.12}$$

For the special case $K(x)=x$, $L(x)=1+x^{2m}$, the estimates (2.10), (2.12) were proved by Newman and Reddy [6]. The lower bounds obtained in [6] show that the estimates of Theorem 2.7 are, in general, the best possible.

3. Jackson type theorems.

Proof of Theorem 2.1. To prove the estimate (2.1) it suffices to prove the corresponding estimate for the case of approximation of 2π-periodic functions on the interval $[-\pi, \pi]$ by reciprocals of trigonometric polynomials of degree n. In what follows we use the notation and the estimates that appear in the book of Lorentz [4, p. 55-56].

For any 2π-periodic function g, let

$$J_n(g; x) := \int_{-\pi}^{\pi} g(x+t)K_n(t)\,dt$$

be the Jackson operator. Since

$$\int_{-\pi}^{\pi} K_n(t)\,dt = 1, \quad \int_{-\pi}^{\pi} |t|^k K_n(t)\,dt = O(n^{-k}), \quad k = 1, 2,$$

we obtain that

$$\int_{-\pi}^{\pi} |g(x+t)-g(x)|K_n(t)\,dt \leqq c_1\omega(g; n^{-1}) \tag{3.1}$$

and that

$$\int_{-\pi}^{\pi} |g(x+t)-g(x)|^2 K_n(t)\,dt \leqq c_2[\omega(g; n^{-1})]^2, \tag{3.2}$$

where c_1, c_2 are absolute constants.

Consider now the function

$$f_\varepsilon(x) := f(x) + i\varepsilon, \tag{3.3}$$

where f is a given real 2π-periodic function and $\varepsilon > 0$ will be chosen later. Since f is real, $1/f_\varepsilon$ is continuous on $[-\pi, \pi]$. Furthermore,

$$\omega(f_\varepsilon; n^{-1}) = \omega(f; n^{-1}) \tag{3.4}$$

and

$$|1/f_\varepsilon(x)| \leqq 1/\varepsilon, \qquad -\pi \leqq x \leqq \pi. \tag{3.5}$$

Define the trigonometric polynomial p_n of degree $\leqq n$ by

$$p_n(x) := J_n(1/f_\varepsilon; x).$$

Then

$$\begin{aligned} |1/f_\varepsilon(x) - p_n(x)| &\leqq \int_{-\pi}^{\pi} |1/f_\varepsilon(x) - 1/f_\varepsilon(x+t)|K_n(t)\,dt \\ &= \int_{-\pi}^{\pi} \frac{|f_\varepsilon(x+t)-f_\varepsilon(x)|}{|f_\varepsilon(x)f_\varepsilon(x+t)|} K_n(t)\,dt. \end{aligned}$$

Hence,

$$|1-f_\varepsilon(x)p_n(x)| \leqq \int_{-\pi}^{\pi} |f_\varepsilon(x+t)-f_\varepsilon(x)| \frac{1}{|f_\varepsilon(x+t)|} K_n(t)\,dt$$

$$\leqq \frac{1}{\varepsilon} c_1\omega(f_\varepsilon; n^{-1}) = \frac{1}{\varepsilon} c_1\omega(f; n^{-1})$$

by (3.1), (3.4) and (3.5).

The choice

$$\varepsilon = 2c_1\omega(f; n^{-1}) \tag{3.6}$$

therefore yields

$$|f_\varepsilon(x)p_n(x)| \geqq \tfrac{1}{2}, \qquad -\pi \leqq x \leqq \pi. \tag{3.7}$$

In particular, $p_n \neq 0$ on $[-\pi, \pi]$. Now

$$|f_\varepsilon(x)-1/p_n(x)| = |1/f_\varepsilon(x)-p_n(x)| \cdot |f_\varepsilon(x)/p_n(x)|$$

$$\leqq \int_{-\pi}^{\pi} \frac{|f_\varepsilon(x+t)-f_\varepsilon(x)|}{|f_\varepsilon(x)f_\varepsilon(x+t)|} \cdot \left|\frac{f_\varepsilon(x)}{p_n(x)}\right| \cdot K_n(t)\,dt$$

$$\leqq 2\int_{-\pi}^{\pi} |f_\varepsilon(x+t)-f_\varepsilon(x)| \cdot \left|\frac{f_\varepsilon(x)}{f_\varepsilon(x+t)}\right| K_n(t)\,dt \quad \text{(by (3.7))}$$

$$\leqq 2\int_{-\pi}^{\pi} |f_\varepsilon(x+t)-f_\varepsilon(x)| K_n(t)\,dt$$

$$+2\int_{-\pi}^{\pi} \frac{|f_\varepsilon(x+t)-f_\varepsilon(x)|^2}{|f_\varepsilon(x+t)|} K_n(t)\,dt$$

$$\leqq 2c_1\omega(f_\varepsilon; n^{-1}) + \frac{2}{\varepsilon}\int_{-\pi}^{\pi} |f_\varepsilon(x+t)-f_\varepsilon(x)|^2 K_n(t)\,dt$$

by (3.1) and (3.5). Thus, from (3.2), (3.4) and (3.6) we deduce that

$$|f_\varepsilon(x)-1/p_n(x)| \leqq (2c_1+c_2/c_1)\omega(f; n^{-1}).$$

This yields (see (3.3), (3.6)) the first part of Theorem 2.1.

For the second part, we suppose that $f \geqq 0$ on $[-\pi, \pi]$ and set

$$f_\varepsilon(x) := f(x)+\varepsilon. \tag{3.3'}$$

Then the polynomial $J_n(1/f_\varepsilon; x)$ will have real coefficients. The rest of the proof remains the same. □

Remark. Although it does not follow immediately from the above argument, Theorem 2.1 holds, more generally, for any *complex-valued* continuous function f on $[-1, 1]$. The proof of this fact will appear in [2]. Moreover, for a special class of functions f, our methods can be adapted to obtain a Jackson-type theorem for approximation by reciprocal polynomials on the unit disk $|z| \leqq 1$. For example, in [3] we prove that

$$E^c_{on}((z-1)^\alpha; |z| \leqq 1) \leqq Mn^{-\alpha}, \qquad 0 < \alpha \leqq 1.$$

We now proceed to the proof of Theorem 2.2, which uses an idea of Trefethen [7].

LEMMA 3.1. *Let p_n be a real polynomial of degree $\leqq n$. Then*

$$E^c_{0,3n}(p_n; I) \leqq 4E^r_{on}(|p_n|; I).$$

Proof. Let q_n be a real polynomial of degree $\leqq n$ satisfying

$$\max_{x\in I}\big||p_n(x)|-1/q_n(x)\big| = E^r_{on}(|p_n|;\, I) =: \varepsilon.$$

Then

$$|p_n^2(x)-1/q_n^2(x)| \leqq \varepsilon(2|p_n(x)|+\varepsilon), \qquad x\in I.$$

Define the complex polynomial Q_{3n} of degree $\leqq 3n$ by

$$Q_{3n}(x) := (p_n(x)-i\varepsilon)q_n^2(x).$$

Then

$$\begin{aligned}|p_n(x)-1/Q_{3n}(x)| &\leqq \left|p_n(x)-\frac{p_n^2(x)}{p_n(x)-i\varepsilon}\right| \\ &\quad+\left|\frac{p_n^2(x)}{p_n(x)-i\varepsilon}-\frac{1}{(p_n(x)-i\varepsilon)q_n^2(x)}\right| \\ &\leqq \varepsilon\left|\frac{ip_n(x)}{p_n(x)-i\varepsilon}\right|+\varepsilon\frac{2|p_n(x)|+\varepsilon}{|p_n(x)-i\varepsilon|}\leqq 4\varepsilon,\end{aligned}$$

since p_n is real. □

Proof of Theorem 2.2. Let p_n be any real polynomial of degree $\leqq n$. With obvious simplification of notation we obtain the following:

$$\begin{aligned}E^c_{0,3n}(f) &\leqq \|f-p_n\|+E^c_{0,3n}(p_n) \\ &\leqq \|f-p_n\|+4E^r_{on}(|p_n|) \quad \text{(by Lemma 3.1)} \\ &\leqq \|f-p_n\|+4[E^r_{on}(|f|)+\|\,|f|-|p_n|\,\|] \\ &\leqq 5\|f-p_n\|+4E^r_{on}(|f|).\end{aligned}$$

Hence, on choosing p_n such that $\|f-p_n\| = E^r_{no}(f)$, Theorem 2.2 follows. □

4. Approximation of powers of x. The lower bounds for $E^r_{on}(|x|^\alpha;[-1,1])$ and for $E^r_{on}(x^\alpha;[0,1])$ were proved (for $0<\alpha\leqq 1$) by Lungu [5]. The proof for other cases is exactly the same. For the proof of the upper bounds it suffices to show (as we mentioned in the Introduction) that

$$E^r_{on}(|x|^\alpha;[-1,1]) \leqq B_\alpha n^{-\alpha}, \qquad \alpha>0. \tag{4.1}$$

Following an idea in Newman and Reddy [6], we consider the kernel

$$\varphi_n(t) := t^{\alpha-1}\left(\frac{T_n(t)}{t}\right)^{2k} \tag{4.2}$$

where n is odd, k is the smallest integer satisfying $k\geqq\alpha$ and T_n denotes the nth degree Chebyshev polynomial of the first kind. Define

$$p(x) := \frac{1}{Cx^\alpha}\int_0^x \varphi_n(t)\,dt, \qquad x>0 \tag{4.3}$$

where $C := \int_0^1 \varphi_n(t)\,dt$.

Clearly, $p(x)$ is an even polynomial of degree $2k(n-1)$. By evenness we consider only $x\in[0,1]$. Write

$$\frac{1}{p(x)}-x^\alpha = \frac{x^\alpha\int_x^1\varphi_n(t)\,dt}{\int_0^x\varphi_n(t)\,dt}. \tag{4.4}$$

As in [6] we make use of the estimates $|T_n(t)/t| \leqq n$, $|T_n(t)/t| \leqq 1/t$ for $0 < t \leqq 1$ and $|T_n(t)/t| \geqq 2n/\pi$ for $0 \leqq t \leqq \sin(\pi/2n)$. It follows that

$$\varphi_n(t) \leqq n^{2k} t^{\alpha-1}, \quad \varphi_n(t) \leqq t^{\alpha-1-2k} \quad \text{for } 0 < t \leqq 1,$$

and

$$\varphi_n(t) \geqq \left(\frac{2}{\pi}\right)^{2k} n^{2k} t^{\alpha-1} \quad \text{for } 0 < t \leqq \sin\left(\frac{\pi}{2n}\right).$$

We consider now two cases.

Case 1. Suppose $0 \leqq x \leqq \sin(\pi/2n)$. In this case, we have

$$\int_x^1 \varphi_n(t)\,dt \leqq \int_0^{1/n} + \int_{1/n}^1 \leqq \int_0^{1/n} n^{2k} t^{\alpha-1}\,dt + \int_{1/n}^1 t^{\alpha-1-2k}\,dt$$

$$\leqq \frac{1}{\alpha} n^{2k-\alpha} + \frac{1}{2k-\alpha} n^{2k-\alpha}$$

$$\leqq \frac{2}{\alpha} n^{2k-\alpha} \quad \text{since } k \geqq \alpha.$$

Also,

$$\int_0^x \varphi_n(t)\,dt \geqq \int_0^x \left(\frac{2}{\pi}\right)^{2k} n^{2k} t^{\alpha-1}\,dt = \left(\frac{2}{\pi}\right)^{2k} n^{2k} \cdot \frac{1}{\alpha} x^{\alpha}.$$

It now follows from (4.4) that

$$0 < \frac{1}{p(x)} - x^{\alpha} \leqq 2\left(\frac{\pi}{2}\right)^{2k} n^{-\alpha}, \qquad 0 \leqq x \leqq \sin\left(\frac{\pi}{2n}\right). \tag{4.5}$$

Case 2. Suppose $\sin(\pi/2n) \leqq x \leqq 1$. In this case, we have

$$\int_x^1 \varphi_n(t)\,dt \leqq \int_x^1 t^{\alpha-1-2k}\,dt < \int_x^{\infty} t^{\alpha-1-2k}\,dt$$

$$= \frac{1}{2k-\alpha} x^{\alpha-2k} \leqq \frac{1}{\alpha} x^{\alpha-2k} \quad \text{since } k \geqq \alpha.$$

Hence,

$$x^{\alpha} \int_x^1 \varphi_n(t)\,dt \leqq \frac{1}{\alpha} x^{2(\alpha-k)} \leqq \frac{1}{\alpha} \left(\sin\frac{\pi}{2n}\right)^{2(\alpha-k)} \leqq \frac{1}{\alpha} n^{2(k-\alpha)}.$$

Also,

$$\int_0^x \varphi_n(t)\,dt \geqq \int_0^{\sin(\pi/2n)} \varphi_n(t)\,dt \geqq \int_0^{\sin(\pi/2n)} \left(\frac{2}{\pi}\right)^{2k} n^{2k} t^{\alpha-1}\,dt$$

$$= \left(\frac{2}{\pi}\right)^{2k} n^{2k} \frac{1}{\alpha} \left(\sin\frac{\pi}{2n}\right)^{\alpha} \geqq \frac{1}{\alpha} \left(\frac{2}{\pi}\right)^{2k} n^{2k-\alpha}.$$

It follows that

$$0 < \frac{1}{p(x)} - x^{\alpha} \leqq \left(\frac{\pi}{2}\right)^{2k} n^{-\alpha}, \qquad \sin\left(\frac{\pi}{2n}\right) \leqq x \leqq 1. \tag{4.6}$$

From (4.5) and (4.6) it follows that

$$E^r_{0,2k(n-1)}(|x|^{\alpha}; [-1, 1]) \leqq 2(\pi/2)^{2k} n^{-\alpha}$$

(recall that $p(x)$ is of degree $2k(n-1)$). Using a standard technique, the last inequality implies (4.1) with a constant B_α of the form $C(B\alpha)^\alpha$, where $B, C>1$ are absolute constants. Analyzing the proof of lower bounds given in Lungu [5], we see that A_α may be taken of the form $A^{-\alpha}$, where $A>1$ is an absolute constant. The proof of Theorem 2.3 is complete. □

An appropriate change of variable yields the following corollary.

COROLLARY 4.1. *For any $a\in[-1,1]$ and for any $\alpha>0$ there exist constants c_1, c_2 (depending on a, α) such that*

$$c_1 n^{-\alpha} \leqq E^r_{on}(|x-a|^\alpha;[-1,1]) \leqq c_2 n^{-\alpha} \quad \text{if } |a|<1, \tag{4.7}$$

$$c_1 n^{-2\alpha} \leqq E^r_{on}(|x-a|^\alpha;[-1,1]) \leqq c_2 n^{-2\alpha} \quad \text{if } |a|=1. \tag{4.8}$$

The same estimates hold for $E^c_{on}(|x-a|^\alpha \operatorname{sgn}(x-a);[-1,1])$.

We conclude this section with a simple lemma. This lemma together with Corollary 4.1 enable us to obtain upper bounds for $E_{on}(f;[-1,1])$, where f is a finite product of functions of type $|x-a|^\alpha$ or $|x-a|^\alpha \operatorname{sgn}(x-a)$.

LEMMA 4.2. *For any complex-valued continuous functions f, g, on I, there is a constant K (independent of n) such that*

$$E_{0,2n}(fg;I) \leqq K(E_{on}(f;I)+E_{on}(g;I)), \tag{4.9}$$

where E_{om} stands for E^r_{om} or for E^c_{om}.

Proof. Choose the polynomials p_n, q_n such that

$$\left\| f-\frac{1}{p_n}\right\| = E_{on}(f;I), \qquad \left\| g-\frac{1}{q_n}\right\| = E_{on}(g;I),$$

where $\|\cdot\|$ denotes the uniform norm on I. Since

$$\begin{aligned}\left\| fg-\frac{1}{p_nq_n}\right\| &= \left\| \left(f-\frac{1}{p_n}\right)g+\frac{1}{p_n}\left(g-\frac{1}{q_n}\right)\right\| \\ &\leqq \|g\|E_{on}(f;I)+2\|f\|E_{on}(g,I),\end{aligned}$$

the result follows. □

5. Well-approximable functions (Proof of Theorem 2.5). The proof of Theorem 2.5 given in this section will be split into several lemmas. We shall use the following notation:

$$f(x)_+ = \begin{cases} f(x) & \text{if } f(x)\geqq 0, \\ 0 & \text{otherwise.}\end{cases}$$

LEMMA 5.1. *For any $\alpha>0$ and for any $n=1,2,3,\cdots$,*

$$E^r_{on}(x_+^\alpha;[-1,1]) \leqq E^r_{on}(x_+^\alpha;(-\infty,1]) \leqq B_\alpha n^{-2\alpha}. \tag{5.1}$$

Proof. We consider the kernel $\varphi_n(t)$ and the polynomial $p(x)$ as in the proof of Theorem 2.3 (see formulas (4.2), (4.3)) with α replaced by 2α. From the proof of Theorem 2.3 we obtain that

$$\left| x^{2\alpha}-\frac{1}{p(x)}\right| \leqq B_\alpha n^{-2\alpha}, \qquad 0\leqq x\leqq 1.$$

Recall that $p(x)$ is an even polynomial of degree $2k(n-1)$, where k is the smallest integer satisfying $k\geqq 2\alpha$. Define the polynomial $Q(x)$ by $Q(x):=p(\sqrt{x})$. Then

$$|x^\alpha - 1/Q(x)| \leqq B_\alpha n^{-2\alpha}, \qquad 0\leqq x\leqq 1. \tag{5.2}$$

Since $T_n(t)/t$ has the form $(-1)^{(n-1)/2}\sum_{j=0}^{(n-1)/2}(-1)^j a_j t^{2j}$, $a_j>0$, the polynomial $[T_n(t)/t]^{2k}$ has a similar form (except that the factor preceding the summation is now 1). Hence the polynomial $p(x)$ is of the form $\sum_{j=0}^{k(n-1)}(-1)^j b_j x^{2j}$, $b_j>0$, and therefore $Q(x)$ has the form

$$Q(x)=\sum_{j=0}^{k(n-1)}(-1)^j b_j x^j, \qquad b_j>0.$$

It follows that $Q(x)>Q(0)$ for x negative and we obtain from (5.2) that

$$0<1/Q(x)<1/Q(0)<B_\alpha n^{-2\alpha}, \qquad -\infty<x<0.$$

Hence,

$$|x_+^\alpha-1/Q(x)|\leqq B_\alpha n^{-2\alpha}, \qquad -\infty<x\leqq 1. \qquad \square$$

LEMMA 5.2. *Let p be a real polynomial. Then*

$$E_{on}^r(p_+;[-1,1])\leqq cn^{-2}\|p_+\|(\deg p)^2, \tag{5.3}$$

where c is an absolute constant and $\|\cdot\|$ denotes the uniform norm on $[-1,1]$.

Proof. By the proof of Lemma 5.1, there exists a polynomial $q_m(x)$ of degree m such that

$$|x_+-1/q_m(x)|\leqq cm^{-2}, \qquad -\infty<x\leqq 1. \tag{5.4}$$

Let $\deg p=:k$ and define the polynomial $Q_{mk}(x)$ of degree mk by

$$Q_{mk}(x)=\frac{1}{\|p_+\|}q_m(p(x)/\|p_+\|).$$

The substitution $x\to p(x)/\|p_+\|$ in (5.4) yields:

$$\|p_+(x)-1/Q_{mk}(x)\|\leqq cm^{-2}\|p_+\|=c(mk)^{-2}\|p_+\|k^2.$$

Hence the lemma is established for n of the form mk. The result for arbitrary n follows by a standard technique. $\square$

LEMMA 5.3. *Let f be a nonvanishing real continuous function on $[-1,1]$. Then*

$$c_1E_{no}^r(1/f;[-1,1])\leqq E_{on}^r(f;[-1,1])\leqq c_2E_{no}^r(1/f;[-1,1]), \tag{5.5}$$

where $c_1>0$, $c_2>0$ depend on f.

The proof of Lemma 5.3 is straightforward.

LEMMA 5.4. *For any $0<a<1$, there is a constant c (depending on a) such that*

$$E_{on}^r((|x|-a)_+;[-1,1])\leqq cn^{-2}. \tag{5.6}$$

Proof. It suffices to prove that

$$E_{on}^r((\sqrt{x}-a)_+;[0,1])\leqq cn^{-2}.$$

To show this write

$$(\sqrt{x}-a)_+=(x-a^2)_+\frac{1}{\sqrt{x}+a}.$$

From Lemma 5.1 it follows (by linear transformation of the variable) that

$$E_{on}^r((x-a^2)_+;[0,1])\leqq cn^{-2}. \tag{5.7}$$

Further, we can extend the function $1/(\sqrt{x}+a)$, $x \geqq a^2$, to the interval $[0, 1]$ in such a way that the resulting function, $g(x)$ say, will belong to $C^2[0, 1]$ and will be positive on $[0, 1]$. By Lemma 5.3 and by Jackson's Theorem for differentiable functions (see e.g. [4, p. 57]) we obtain that

$$E^r_{on}(g; [0, 1]) \leqq cn^{-2}. \tag{5.8}$$

Since $(x-a^2)_+ g(x) = (\sqrt{x}-a)_+$ on $[0, 1]$, the inequalities (5.7), (5.8) and Lemma 4.2 yield the desired estimate. □

LEMMA 5.5. *For any $0<a<1$ there is a constant c (depending on a) such that*

$$E^c_{on}((|x|-a)_+ \operatorname{sgn}(x); [-1, 1]) \leqq cn^{-2}. \tag{5.9}$$

Proof. Write

$$(|x|-a)_+ \operatorname{sgn}(x) = x^3(|x|-a)_+|x|^{-3},$$

and extend the function $|x|^{-3}$, $|x| \geqq a$, to the interval $[-1, 1]$ as a twice differentiable positive function. The lemma now follows (as in the proof of Lemma 5.4) from Theorem 2.3, Lemma 4.2 and Lemma 5.4. □

Using the proof similar to that of Lemma 5.2 we obtain the following.

LEMMA 5.6. *Let $p(x)$ be a real polynomial and let $0<a<\|p\|$, where $\|\cdot\|$ denotes the uniform norm on $[-1, 1]$. Then*

$$E^c_{on}((|p(x)|-a)_+ \operatorname{sgn} p(x); [-1, 1]) \leqq cn^{-2}\|p\|(\deg p)^2, \tag{5.10}$$

where c depends only on a.

Proof of Theorem 2.5. We first consider the case when all functions f_j are of the same sign (positive, say). Define the polynomial $p(x)$ by

$$p(x) := -\prod_{j=1}^{N} (x-a_j)(x-b_j).$$

Then $p(x)>0$ on each interval (a_j, b_j). It follows that the function

$$g_j(x) := f_j(x)/p(x), \qquad x \in [a_j, b_j],$$

is positive on $[a_j, b_j]$ and belongs to $C^2[a_j, b_j]$. We can find now a function $G(x) \in C^2[-1, 1]$ that is positive on $[-1, 1]$ and coincides with g_j on $[a_j, b_j]$, $j=1, 2, \cdots, N$. Since $p(x) \leqq 0$ whenever $f(x)=0$, we can write

$$f(x) = p_+(x)G(x).$$

By Lemma 5.2,

$$E^r_{on}(p_+; [-1, 1]) \leqq cn^{-2}$$

(c depends on f) and by Lemma 5.3

$$E^r_{on}(G; [-1, 1]) \leqq cn^{-2},$$

since $1/G$ is twice differentiable. Applying Lemma 4.2 we obtain that

$$E^r_{on}(f; [-1, 1]) \leqq c(f)n^{-2}.$$

For the general case, when the f_j are of arbitrary signs, define the function φ on $\bigcup_{j=1}^{N} [a_j, b_j]$ by

$$\varphi(x) := \begin{cases} f_j(x)+\frac{1}{2} & \text{if } f_j>0, \\ f_j(x)-\frac{1}{2} & \text{if } f_j<0. \end{cases}$$

Then

$$(|\varphi(x)|-\tfrac{1}{2}) \operatorname{sgn} \varphi(x) = f_j(x), \qquad x \in [a_j, b_j], \quad j=1, 2, \cdots, N. \tag{5.11}$$

Next, we claim that there is a polynomial $P(x)$ of some fixed but large degree, such that

(i) $|P(x)|<\frac{1}{2}$ for $x\in[-1,1]\setminus\bigcup_{j=1}^{N}[a_j,b_j]$,

(ii) $|P(x)|>\frac{1}{2}$ for $x\in(a_j,b_j)$, $j=1,2,\cdots N$,

(iii) $P(a_j)=P(b_j)=\begin{cases}\frac{1}{2} & \text{if } f_j>0,\\ -\frac{1}{2} & \text{if } f_j<0.\end{cases}$

This can be seen as follows. The function φ satisfies conditions (ii), (iii). Extend it to $[-1,1]$ in such a way that it will satisfy (i) and will belong to $C^3[-1,1]$. Now approximate φ simultaneously with φ' by a polynomial P that interpolates φ, φ' at a_j, b_j, $j=1,2,\cdots,N$. If the degree of P is large enough, the norms $\|\varphi-P\|$, $\|\varphi'-P'\|$ will be arbitrarily small (see Chalmers and Taylor [1, pp. 55-56]). From this it follows easily that P will satisfy (i)-(iii).

From this construction we obtain that the function

$$g(x)=\frac{(|\varphi(x)|-\frac{1}{2})\operatorname{sgn}\varphi(x)}{(|P(x)|-\frac{1}{2})\operatorname{sgn}P(x)}$$

is positive on $[a_j,b_j]$, $j=1,2,\cdots,N$ and has there two continuous derivatives. Extend g to $[-1,1]$ preserving its sign and the differentiability. From (5.11) and from the definition of g we obtain that

$$[(|P(x)|-\tfrac{1}{2})_+\operatorname{sgn}P(x)]g(x)=f(x),\qquad -1\leqq x\leqq 1.$$

By Lemma 5.3 and Jackson's Theorem,

$$E^c_{on}(g;[-1,1])\leqq cn^{-2}.$$

Also, by Lemma 5.6,

$$E^c_{on}((|P(x)|-\tfrac{1}{2})_+\operatorname{sgn}P(x);[-1,1])\leqq cn^{-2}.$$

Finally, Lemma 4.2 yields

$$E^c_{on}(f;[-1,1])\leqq cn^{-2}.$$ □

6. Approximation of analytic functions (Proofs of Theorems 2.4 and 2.6).

Proof of Theorem 2.4. If $f(\not\equiv 0)$ is real analytic on $[-1,1]$, we can write

$$f(x)=(x+1)^{a_1}(x-1)^{a_2}\prod_{j=1}^{N}(x-x_j)^{b_j}\cdot g(x), \tag{6.1}$$

where $a_1,a_2,b_1,\cdots,b_N$ are nonnegative integers, $|x_j|<1$ for $j=1,2,\cdots,N$ and g is real analytic and nonvanishing on $[-1,1]$. By Corollary 4.1, we have $E^r_{on}((x+1)^{a_1};[-1,1])\leqq cn^{-2a_1}$, $E^r_{on}((x-1)^{a_2};[-1,1])\leqq cn^{-2a_2}$, $E^c_{on}((x-x_j)^{b_j};[-1,1])\leqq cn^{-b_j}$. Also, by Lemma 5.3 and by Bernstein's Theorem (cf. [4, p. 76]),

$$\limsup_{n\to\infty}[E^c_{on}(g;[-1,1])]^{1/n}<1.$$

Applying Lemma 4.2 we obtain the estimate

$$E^c_{on}(f;[-1,1])\leqq cn^{-k},$$

where k is defined in Theorem 2.4.

For the lower bound in (2.8) we write $f(x)=(x-x_j)^{b_j}\varphi_j(x)$, where $\varphi_j(x_j)\neq 0$ and apply the argument in Lungu [5] to obtain $E^c_{on}(f;[-1,1])\geqq cn^{-b_j}$, $j=1,2,\cdots,N$. We omit the details. □

Concerning Theorem 2.6, Walsh [8] proves the corresponding result for approximation on a Jordan region. He asserts that the result is also true for Jordan arcs, but does not provide the proof. For completeness we provide the details.

Proof of Theorem 2.6. The implication (ii)$\Rightarrow$(i) is trivial (apply Lemma 5.3 and Bernstein's Theorem). Assume now that

$$\limsup_{n\to\infty} (E_{on}^{c}(f;[-1,1]))^{1/n} = q < 1,$$

and let $P_n(x)$, $n = 1, 2, 3, \cdots$, be polynomials for which

$$\|f - 1/P_n\| = E_{on}^{c}(f;[-1,1]).$$

It suffices to prove that $f \neq 0$ on $[-1,1]$, since then Lemma 5.3 and Bernstein's Theorem will imply the analyticity of f on $[-1,1]$. Suppose that f vanishes somewhere on $[-1,1]$. Since $f \not\equiv 0$, we can find an interval $I \subset [-1,1]$ such that $f \neq 0$ inside I but vanishes at one of its endpoints. Assume, for simplicity, that $I = [-\delta, \delta]$, $\delta < 1$, and $f(\delta) = 0$. Then

$$\limsup_{n\to\infty} |1/P_n(\delta)|^{1/n} \leqq q,$$

which implies that

$$\liminf_{n\to\infty} |P_n(\delta)|^{1/n} \geqq 1/q. \tag{6.2}$$

Pick $\delta_1 < \delta$. Since $f \neq 0$ on $[-\delta_1, \delta_1]$, there exists a constant $M = M(\delta_1)$ such that $|P_n(x)| \leqq M$ for $n = 1, 2, 3, \cdots$, and for $x \in [-\delta_1, \delta_1]$. Then (cf. [4, p. 43])

$$|P_n(\delta)| \leqq M\left(\frac{1+\sqrt{1-(\delta_1/\delta)^2}}{\delta_1/\delta}\right)^n.$$

It follows that

$$\liminf_{n\to\infty} |P_n(\delta)|^{1/n} \leqq \frac{1+\sqrt{1-(\delta_1/\delta)^2}}{\delta_1/\delta} < \frac{1}{q},$$

provided δ_1 is close enough to δ. This contradicts (6.2). □

7. Approximation on the real line.

Proof of Theorem 2.7. Consider the polynomial $p(x)$ defined by formulae (4.2) and (4.3) with $\alpha = 1$, $k = 1$. By the proof in § 4, we obtain that p is a polynomial of degree $2(n-1)$ satisfying

$$||x| - 1/p(x)| \leqq An^{-1} \quad \text{for } -1 \leqq x \leqq 1. \tag{7.1}$$

From (4.4) we also obtain that

$$0 < |x| - 1/p(x) < |x| \quad \text{for } |x| > 1. \tag{7.2}$$

For $T > 0$, set

$$F_T := \{x \in \mathbb{R}: |K(x)| \leqq \|K\|_{[-T,T]}\}.$$

Then we obtain by the substitution $x \to |K(x)|/\|K\|_{[-T,T]}$ in (7.1), (7.2) that

$$\left||K(x)| - \frac{1}{q(x)}\right| \leqq \begin{cases} An^{-1}\|K\|_{[-T,T]} & \text{if } x \in F_T, \\ |K(x)| & \text{if } x \in \mathbb{R}\setminus F_T, \end{cases} \tag{7.3}$$

where $q(x) := \|K\|_{[-T,T]}^{-1} p(K(x)/\|K\|_{[-T,T]})$ is a polynomial of degree $\leqq 2k(n-1)$. Dividing (7.3) by $L(x)$ and setting $a := \min_{\mathbb{R}} |L(x)| > 0$, we obtain that

$$\left| \frac{|K(x)|}{L(x)} - \frac{1}{r(x)} \right| \leqq \begin{cases} Aa^{-1}n^{-1}\|K\|_{[-T,T]} & \text{if } x \in F_T, \\ |K(x)|/L(x) & \text{if } x \in \mathbb{R}\setminus F_T, \end{cases}$$

where $r(x) := q(x)L(x)$ is a polynomial of degree $2k(n-1)+l$. For T large enough we have $\|K\|_{[-T,T]} = O(T^k)$ and $|K(x)/L(x)| = O(T^{k-l})$ uniformly for $x \in \mathbb{R}\setminus F_T$ and consequently

$$E^r_{0,2k(n-1)+l}(|K(x)|/L(x); \mathbb{R}) = O(T^k)n^{-1} + O(T^{k-l}).$$

When we choose $T = n^{1/l}$ we obtain the first assertion of Theorem 2.7.

For the third assertion we assume that $K(x) \geqq 0$, $L(x) > 0$ on $\mathbb{R}$ and make use of the polynomial $\tilde{p}(x) := p(\sqrt{x})$, where p is defined by (4.2) and (4.3) with $\alpha = 2$, $k = 2$. Then

$$|x - 1/p(x)| \leqq \begin{cases} An^{-2} & \text{if } 0 \leqq x \leqq 1, \\ x & \text{if } x > 1, \end{cases}$$

and we can repeat the above proof choosing eventually $T = n^{2/l}$.

It remains to prove the second assertion of Theorem 2.7 (formula (2.11)). Let p be the polynomial satisfying (7.1)-(7.2). Using the method of the proof of Lemma 3.1 we see that when we choose

$$\tilde{p}(x) = (x - i\varepsilon)p^2(x), \qquad \varepsilon := E^r_{on}(|x|; [-1, 1]), \tag{7.4}$$

we obtain

$$|x - 1/\tilde{p}(x)| \leqq An^{-1} \quad \text{for } |x| \leqq 1. \tag{7.5}$$

For $|x| > 1$ we have

$$|1/\tilde{p}(x)| = \frac{1}{|x - i\varepsilon|} \frac{1}{p^2(x)} \leqq \frac{|x|^2}{|x - i\varepsilon|} \leqq |x| \quad \text{(by (7.2))}.$$

Hence

$$|x - 1/\tilde{p}(x)| \leqq 2|x| \quad \text{for } |x| > 1. \tag{7.6}$$

Using (7.5) and (7.6) the proof can be completed as above. □

THE NEWTONIAN GRAPH OF A COMPLEX POLYNOMIAL*

MICHAEL SHUB†, DAVID TISCHLER‡ AND ROBERT F. WILLIAMS§

Abstract. In a recent paper [4] Smale posed as an important problem in complexity theory, characterization of the graph G_f of the Newtonian vector field N_f for a complex polynomial f. Such graphs are known to be connected and acyclic and Smale conjectured that these two properties completely characterize them. The purpose of this paper is to prove this conjecture, after adding an additional hypothesis (part 3 of the definition of "dynamic graph," § 2). In additon we give an example and prove a proposition to show this is necessary (see "Counterexamples" in § 2).

We present the proof as Theorem C in § 5 using the topological characterization of analytic maps given by Stöilow [5] in 1929. Bill Thurston pointed us in this direction, though considering the fact that G. T. Whyburn was the major professor of one of us, we should not have needed this help. In addition we present direct proofs of three special cases as Theorem A, Theorem B and Example 7. While this was being written an independent proof was given in the generic case (Theorem A) in [2].

Sections 1 and 2 are devoted to basic properties and to a list of examples designed to acquaint the reader (and the writers) with various aspects of Newtonian Graphs.

Key words. polynomial, root, Newtonian vector field, Newtonian Graph

AMS(MOS) subject classifications. 58F, 65H, 68Q

1. The Newtonian vector field. Given a smooth map $f: \mathbf{R}^n \to \mathbf{R}^n$ the Newtonian vector field for f, N_f, is defined by

$$N_f(x) = -(Df_x)^{-1}(f(x)).$$

Let $\phi_t: \mathbf{R}^n \to \mathbf{R}^n$ be the corresponding flow. Then a computation carried out below using the chain rule shows that $f(\phi_t(x)) = e^{-t}f(x)$. Thus f maps orbits of ϕ_t into rays pointing toward 0. This is essentially the geometric content to Newton's method for seeking zeros of f.

Alternatively, one defines

$$V_f(x) = -\tfrac{1}{2}\operatorname{grad} \|f(x)\|^2 = -(Df_x)^{\mathrm{tr}} f(x).$$

For conformal maps, and in particular analytic maps, of one complex variable (by the Cauchy-Riemann equations) the inverse of a matrix and its transpose differ only by a scalar multiple. Therefore, the vector fields V_f and N_f also differ only by a scalar multiple, except where $(Df)^{-1}$ is undefined.

We next collect some facts for f a polynomial of one complex variable:

1. N_f or V_f have the same solution curves as

(a) $-f(z)\bar{f}'(z)$ or

(b) $-\sum (z-a_j)/|z-a_j|^2$, $\{a_j\}$ the zeros of f.

Thus the field is the sum of forces toward a_j, each inversely proportional to the distance from a_j.

To see (a),

$$N_f(z) = -\frac{f(z)}{f'(z)} \cdot \frac{\bar{f}'(z)}{\bar{f}'(z)} = -(1/|f'(z)|^2) f(z)\bar{f}'(z)$$

§ Department of Mathematics, Northwestern University, Evanston, Illinois 60201.

so that N_f differs from $-f(z)\bar{f}'(z)$ only by the scalar function $|f'(z)|^{-2}$. Note however that this scalarization converts poles of N_f to zeros of V_f.

(b)
$$-f/f' = -[(\log f)']^{-1} = -\left[\sum \frac{1}{z-a_i}\right]^{-1}$$
$$= -\left[\sum \frac{\overline{z-a_i}}{|z-a_i|^2}\right]^{-1} = -\frac{\bar{A}}{\bar{A}}\left[\sum \frac{\overline{z-a_i}}{|z-a_i|^2}\right]^{-1}$$
$$= \left(-\sum \frac{z-a_i}{|z-a_i|^2}\right)(1/|A|^2),$$

where $A = \sum \overline{z-a_i}/|z-a_i|^2$.

2. Properties of N_f and V_f:

(a) $f(\phi_t(x)) = e^{-t}f(x)$

(b) N_f and V_f have attractors (sinks) at the zeros a_j of f.

(c) The only other rest points of V_f are the zeros θ_j of f':

(i) generic zeros of f' are hyperbolic saddles of V_f;

(ii) at multiple zeros of f' V_f has multipronged saddles ("monkey saddles" and worse);

(iii) For θ a zero of f', the orbits leaving θ, called together the unstable manifold $W^u(\theta)$, consist of n algebraic curves emanating from θ at equal angles because $f(z) = c_1 + c_2(z-\theta)^n +$ higher order terms, $c_2 \neq 0$.

(d) Multiple zeros a of f have no geometric effect on the corresponding sinks. Only the *velocity* of the flow toward a is increased.

(e) (Gauss-Lucas Theorem). The convex hull of the sinks $\{a_j\}$ contains the saddles $\{\theta_j\}$. The flow of N_f or V_f is inwardly transverse to any convex curve containing the $\{a_j\}$.

Proof of 2. To prove (a) we compute

$$\frac{d}{dt} f(\phi_t(x)) = Df(\phi_t(x)) \cdot \frac{d}{dt}\phi_t(x)$$
$$= Df(\phi_t(x)) \cdot (-Df(\phi_t(x)))^{-1} \cdot f(\phi_t(x))$$
$$= -f(\phi_t(x)).$$

Thus $f(\phi_t(x)) = \rho_t$ where

$$\frac{d\rho}{dt} = -\rho \quad \text{at } t = 0, \quad \rho = f(x)$$

which has $e^{-t}f(x)$ as solutions.

Parts (b) and (d) follow from the "attracting force" version of N_f, $-\sum(z-a_j)/|z-a_j|^2$. Similarly, if all the a_j are on the side of a line, the vector field is transverse to this line, which proves the second part of (e). The first part follows from the second part.

The form $-f(z)\bar{f}'(z)$ shows that the zeros of f and f' are the only rest points. Part (a) implies (c)(ii)-(c)(iii); the inverse image of a directed line under the map $z \to c_1 + c_2(z-\theta)^n +$ h.o.t. consists of $2n$ directed curves pointing alternatively toward and away from θ, with tangents evenly spaced at θ.

In fact, property 2(a) is proven for general $C^1 f$ and 2(b) is true for simple zeros of $C^1 f$ since at such points the derivative of N_f is $-I$.

When $f'(\theta)=0$, $DV_f(\theta)(w)=-\overline{f''(\theta)w}f(\theta)$. If $f(\theta)\neq 0$ and $f''(\theta)\neq 0$ then the 2×2 real matrix representing this linear transformation has strictly negative determinant and trace 0. Thus the eigenvalues of $DV_f(\theta)$ are real and have opposite sign.

We have borrowed here from [3] and [1] where a desingularization of Newton's method is discussed in more variables as well.

2. Newtonian graphs and special terminology. Let f be a complex polynomial with $\{a_j\}$ its zeros and $\{\theta_k\}$ the zeros of f' which are not zeros of f. Let $V_f=-f(z)\overline{f'(z)}$ be the gradient vector field of f as in § 1. Let $W^u(\theta_k)$ be the "unstable manifold" of θ_j, i.e., the union of all solutions which limit on θ_k as $t\to-\infty$. Note that they in turn limit on some a_j or some other θ_k, as $t\to+\infty$. Define

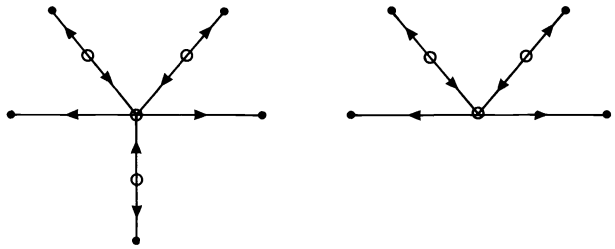
$$G_f=\{a_j\}\smile\{\theta_j\}\smile W^u(\theta_j).$$

Then G_f is a finite graph with distinguished vertices a_j, θ_k and directed "edges" $W^u(\theta_k)$.

For nonrepeated zeros θ_k of f', $W^u(\theta_k)\smile\{\theta_k\}$ is a smooth curve but in degenerated cases $W^u(\theta_k)$ consists of 3 or more prongs.

The sinks a_j of G_f have weights α_j where α_j is the multiplicity of a_j.

Counterexamples. CE1 below is not homeomorphic to any Newtonian graph G_f, f a polynomial. CE2 is not isotopic to any such G_f.



CE1 CE2

These facts follow from the general proposition.

PROPOSITION. *For f any complex polynomial and v a vertex of G_f at most one incoming edge can lie between any two outgoing edges.*

Proof. Suppose the contrary. Then choose a small circle J around v and note that it passes through points A, B, C, D where

(i) $A<B<C<D$ on J;

(ii) there is no other point of $J\frown$ (outgoing edge) between A and D on J;

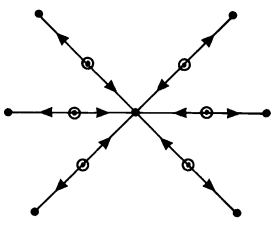
(iii) A and D lie on rays beginning at v;

(iv) B and C lie on rays terminating at v.

Then f has a singularity at v (of index $\geqq 2$) and f maps the open arc (B, C) of J completely around $f(v)$ since it intersects the ray $\{mf(v)\,|\,m \text{ real } m>1\}$ in the two points $f(B), f(C)$. $f|(B, C)$ does not intersect the ray $\{mf(v)\,|\,m \text{ real}, 0<m<1\}$ which is a contradiction.

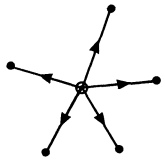
Examples. In our sketches we indicate the weights only if different from 1.

1. z^n-z $n=7$



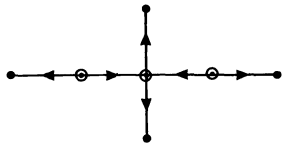
2. Real roots

3. $z^d - 1$ $d = 5$

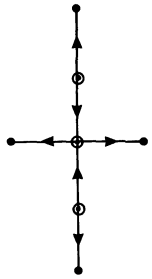


multiple saddle or
unstable star with 5 prongs.

4. $(z^2 + a^2)(z^2 - b^2)$ saddle connections



$a < b$

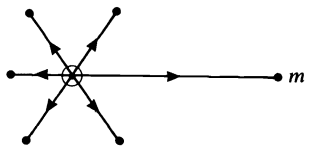


$a > b$

5. $z^n(z-c)^m$

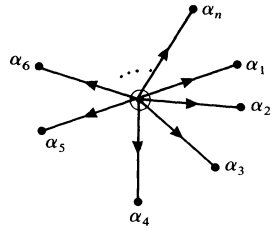
sinks of weights n and m.

6. There is a polynomial P, monic and of degree n such that $((z-c)^m P)' = (n+m)(z-c)^{m-1} z^n$ m, n positive integers. (This is proved in Lemma 4.1; we sketch the graph for such a P, where $n = 5$ next.)



$n = 5$

7. Given positive integers $\alpha_1, \cdots, \alpha_n$ there is a polynomial of degree $\alpha_1 + \cdots + \alpha_n$ with graph

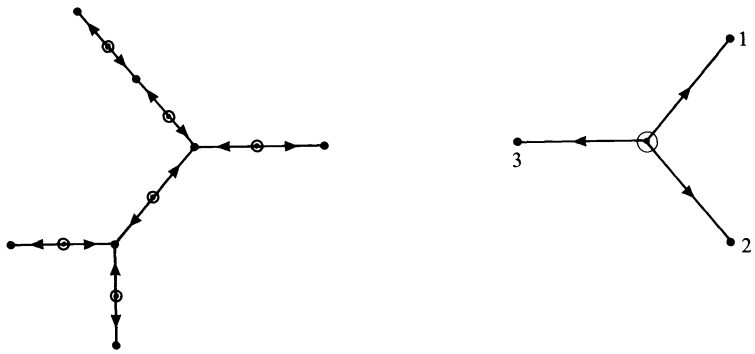


unstable star with weights

Remark. For any complex polynomial f, the graph G_f is connected and acyclic.

Proof. A cycle in the graph, G_f, would bound a finite region in the plane, but this contradicts 2(a). The flow is a gradient flow with ∞ as the only source. Thus the plane is the union of G_f and $W^u(\infty)$, the unstable manifold of ∞. Thus G_f has the homotopy type of the plane (or a point) and so G_f is connected.

Remark. Any connected acyclic finite graph can be embedded in the plane, and sometimes in distinct-*nonisotopic* ways. Embeddings $f: G \to \mathbf{R}^2$ and $g: G \to \mathbf{R}^2$ are *isotopic* provided there is a continuous 1-parameter family f_t, $0 \leqq t \leqq 1$ such that $f_0 = f$, $f_1 = g$ and f_t is an embedding of G for each t, $0 \leqq t \leqq 1$. This last property, that each f_t be an embedding, distinguishes isotopy from homotopy; were it to be dropped, one could reverse the orientation of the next two examples, by pushing one of the legs through another one. The following two examples have two isotopy classes of embedding determined by the cyclic order at the circled vertices.



PROPOSITION. *Generically V_f is structurally stable, having*

(a) *hyperbolic saddles,*

(b) *no saddle connections, and*

(c) *all weights* $= 1$.

Proof. Generically f and f' have no repeated zeros which proves (a) and (c). Any one saddle connection can be removed by an arbitrarily small perturbation of one of the vertices involved, noting for example that a saddle connection implies that two critical values lie on the same ray. Thus proceeding one at a time, one can remove all saddle connections by a perturbation so small as not to effect those already broken. Structural stability now follows from Peixoto's theorem (see Palis-de Melo [8]).

In order for an abstract finite acyclic graph to be the Newtonian graph of a complex polynomial, it must have certain properties best described in dynamical terms.

By a *dynamic graph* we mean a finite directed graph with two types of vertices, which we call *saddles* and *sinks* subject to the following conditions:

1) At a sink, all edges are directed inward (i.e., toward the sink).

2) Saddles have at least two outwardly directed edges.

3) At a saddle, any two adjacent outwardly directed edges have at most one inwardly directed edge between them. (Each such edge must then connect two saddles, and is thus called a *saddle connection.*)

4) Each sink has a weight which is a positive integer, often 1. The weights have no effect on the geometry of a dynamic graph.

It follows that a dynamic graph falls into natural units each consisting of a saddle together with all edges directed away from it. These will be called *unstable stars* or *k-prongs* where k is the number of issuing edges, $k = 2, 3, \cdots$. A 2-prong is also called a *hyperbolic saddle.*

3. The generic case. Our first theorem is a special case of each of the two others, but its proof is easy. In addition, while this was being written, other authors [2] have found a proof independently of this part of our results.

THEOREM A. *Given an acyclic dynamic graph with all saddles hyperbolic, no saddle connections and all weights* $= 1$, *there is a complex polynomial* f *whose graph* G_f *is isotopic to* G.

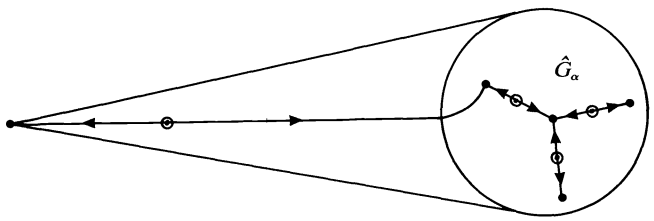
Proof. First, there exist sinks $v_0, v_1, \cdots, v_m \in G$, and subgraphs $G_\alpha \subset G$ such that for each α, $v_\alpha \in G_\alpha$ and $G_{\alpha+1}$ consists of G_α together with one additional hyperbolic saddle having v_α as one of its 2 sinks.

We proceed by induction on α. The graph $\{v_0\}$ is realized by the polynomial z. Thus assume we have a generic polynomial P_α such that the graph $\hat{G}_\alpha$ of P_α is isotopic to G_α. Let D be a (round) disk containing the zeros of P_α. Then $D \supset \hat{G}_\alpha$ and the field V_{P_α} is inwardly transverse to the boundary ∂D of D.

Let $f(z) = P_\alpha(\lambda(z-c))$ where $|\lambda| = 1$ and c is real. Note that the graph of f is conjugate to $\hat{G}_\alpha$ by a linear conjugacy: $f'(z) = \lambda P'_\alpha(\lambda(z-c))$ so that $V_f(z) = -\bar{\lambda} P_\alpha(\lambda(z-c))\bar{P}'_\alpha(\lambda(z-c)) = \bar{\lambda} V_{P_\alpha}(\lambda(z-c))$ which gives $V_f(z) = \lambda^{-1} V_{P_\alpha}(\lambda(z-c))$.

Let $g(z) = zf(z)$. We claim that for c sufficiently large and certain λ, $|\lambda| = 1$, the graph of g is isotopic to $G_{\alpha+1}$. In fact the field V_g on D differs from V_f only by the summand $-1/z$ and this is essentially constant $= -1/c$. Thus for $c \gg 1$, the part of the graph of g related to the zeros and saddles of f is isotopic to $\hat{G}_\alpha$ by structural stability.

Note that the "ice-cream cone" region sketched below contains the zeros of g and hence the dynamics of G_g. It follows that the graph G_g of g consists of $\hat{G}_\alpha$ together with a single edge added and that for c large, the saddle of this new edge is outside D.



Now as λ varies in the unit circle, the disk D and the dynamics of V_{P_α} rotates through a full circle as well, by structural stability. Thus our new edge arrives at any one of the entering orbits, for the appropriate choice of λ. This is important below, but here we have more leeway, because there is an open set of orbits limiting on the

sink v_α, and have the correct deployment with respect to $\hat{G}_\alpha$. Thus for some choice of λ the graph G_g of g is isotopic to $G_{\alpha+1}$.

This completes the inductive step and the proof of Theorem A.

4. Nongeneric saddles and Theorem B. The purpose of this section is to prove Thoerem B. This uses the fact that our example 6 is the Newtonian graph of a complex polynomial which we prove as Lemma 4.1. Example 6 is used in the proof of Theorem B (implicitly) and in example 7, below.

LEMMA 4.1. *Given integers m, n and $c \in \mathbf{C}$, there exists a monic polynomial P of degree $n+m$ such that $P(0) \neq 0$ for $c \neq 0$ and $((z-c)^m P(z))' = (n+m)z^n(z-c)^{m-1}$.*

Proof. This linear ODE reduces to $(z-c)P' + mP = (n+m)z^n$. We try a solution of the form $P = z^n + \sum_{i=0}^{n-1} b_i z^i$ and note that the coefficient of z^n is $n+m$ on both sides. Proceeding downward, for $j = n-1,\ n-2, \cdots, 0$ one has the formulas $jb_j - c(j+1)b_{j+1} + mb_j = 0$ for the coefficient of z^j. Thus

$$b_j = \frac{c(j+1)}{m+j} b_{j+1}$$

gives our solution, which terminates with b_0 as $b_{-1} = 0$.

THEOREM B. *Given an oriented acyclic embedded dynamic graph G with no saddle connections and all weights 1, there exists a polynomial f with graph G_f isotopic to G.*

Proof. We proceed as before with v_α, $G_\alpha \subset G$ by induction on α. Here, however, $G_{\alpha+1}$ is G_α with a *multiple saddle* attached at $v_\alpha \in G_\alpha$. Suppose then that P_α is a polynomial yielding the graph G_α and that D is a disk around 0 containing all G_α (as above) and w, the field of P_α transverse to ∂D. Let $f(z) = P_\alpha(\lambda(z-c))$. For simplicity we assume 0 is a zero of P_α and set $f(z) = P_\alpha(\lambda(z-c))$.

Now $G_{\alpha+1}$ is G_α with a saddle edge added at the vertex v_α. Say the new unstable star has $(n+1)$ exiting edges, for some $n \geqq 1$. Then we want our next polynomial g to have derivative $z^n f'(z)$, or $g(z) = \int_c^z w^n f'(w)\,dw$, some $c \in \mathbf{C}$ which we choose to be real. Here we use the same c as that in $f(z) = P_\alpha(\lambda(z-c))$. Then integrating by parts,

$$g(z) = z^n f(z) - n \int_c^z w^{n-1} f(w)\, dw,$$

as $f(c) = 0$.

Then the gradient field for g is given by

$$V_g = -|z|^{2n} f(z)\bar{f}'(z) + n\bar{z}^n \bar{f}'(z) \int_c^z w^{n-1} f(w)\, dw.$$

Now near c we scalarize to $V_g/|z|^{2n}$ which gives

$$-f(z)\bar{f}'(z) + \frac{n\bar{f}'(z)}{z^n} \int_c^z w^{n-1} f(w)\, dw,$$

so that we have our given field with an error term,

$$E = \frac{n\bar{f}'(z)}{z^n} \int_c^z w^{n-1} f(w)\, dw.$$

Then one can estimate E on D_c by

$$|E| \leqq \frac{n(c+\delta)^{n-1} |f'(z) f(\zeta)| \delta}{(c-\delta)^n} \quad \text{some } z, \zeta \in D_c$$

which goes to 0 for large c, where $\delta =$ diameter of D.

Next to check the C^1 part of the error, we note that E is differentiable as a map from $\mathbf{R}^2$ to $\mathbf{R}^2$, as conjugation is real analytic. Hence

$$E' = \frac{nz^{n-1}\bar{f}'(z)f(z)}{z^n} + \frac{n\bar{f}''(w)\int_c^z w^{n-1}f(w)\,dw}{z^n} - \frac{n^2\bar{f}'(z)\int_c^z w^{n-1}f(w)\,dw}{z^{n+1}}.$$

These clearly go to zero on D_c as $c \to \infty$. Thus the field of g on the disk is near that $f(\lambda(c-z))$ and has exactly the same saddles. It follows that for c large enough, the graph G_g is isotopic to G_α with an unstable star of $n+1$ prongs added.

But just as in the proof of Theorem A, we can choose λ so that this last edge is added in the correct "angle."

This completes the proof of Theorem B.

PROPOSITION (*Example* 7). *For any (integral) weights $\alpha_1, \cdots, \alpha_k$ there is an unstable star with these weights. Equivalently, there is a solution $a_1, a_2, \cdots, a_k$, $a_i \neq 0$ of the equation*

$$\left(\prod_{n=1}^{k}(z-a_n)^{\alpha_n}\right)' = (\alpha_1 + \cdots + \alpha_k)z^{k-1}\prod_{n=1}^{k}(z-a_n)^{\alpha_n - 1}.$$

Furthermore, any cyclic ordering of the weights (see the above remark) can be realized.

Proof. This ODE leads to an unstable star with weight α_i at a_i, provided it has a solution with the a_i distinct. To solve it is equivalent to solving a set of $k-1$ equations in k unknowns, which we augment by one equation.

$$(j)\quad \sum_{n=1}^{k}\alpha_n \sum_{\substack{i_1<i_2<\cdots<i_j \\ i_\alpha \neq i_n}} a_{i_1}a_{i_2}\cdots a_{i_j} = 0, \qquad j = 1, 2, \cdots, k-1;$$

$$a_k - 1 = 0.$$

Now the function $F_\alpha : \mathbf{C}^k \to \mathbf{C}^k$ defined by the left-hand sides, where $\alpha = \alpha_1, \cdots, \alpha_k$ is a proper map and has a positive Jacobian (see [1, p. 294]). Thus F_α can be extended to the $2k$-sphere $\mathbf{C}^k \cup \{\infty\}$ so that it has a solution $a_1, \cdots, a_k$.

In fact, by counting degrees we see that there are $(k-1)!$ solutions. To see that these contain all of the isotopy classes we need a homotopy argument. First, we may as well suppose that the α_n's are numbered in their desired cyclic order. Next let $\alpha(t)$ be a path, $0 \leqq t \leqq 1$, where

$$\alpha(0) = (1, 1, \cdots, 1) \quad \text{and}$$

$$\alpha(1) = (\alpha_1, \alpha_2, \cdots, \alpha_k) \quad \text{and}$$

$$\alpha_i(t) \neq \alpha_j(t) \quad \text{for } i \neq j \text{ and } 0 < t < 1.$$

Now by Lemma 4.1, above, there is a singular graph of weights $1, 1, \cdots, 1$, that is, the regular unstable star of k petals, and thus there is a solution $a_n(0)$ $n = 1, \cdots, k$ of the equation $F_{\alpha(0)} = 0$. Then $F_{\alpha(t)}$ is an analytic isotopy of this algebraic function, so there is a unique arc of solutions $\{a_n(t)\}$ to the equations $F_{\alpha(t)} = 0$. This gives a 1-parameter path of functions $f_t(z) = \prod_1^k (z-a_n)^{a_n}$, and Newtonian graphs G_t, whose end G_1 has its weights in the correct order as G_t is an isotopy of graphs. The weights $\{\alpha_n(t)\}$ do vary with t, of course, but G_t is an isotopy of the graphs if we disregard weights. One could also interpret G_t as an isotopy of weighted graphs. The $f_t(z)$ are proper and their Newtonian graphs are acyclic, connected, etc.

5. The general case via Stöilow's theorem.

THEOREM C. *Given an acyclic dynamic graph $G \subset \mathbf{R}^2$ there is a polynomial f such that the Newton graph G_f is isotopic to f.*

DEFINITIONS (see Whyburn [7]). A map $f: X \to Y$ is *light* if $f^{-1}(y)$ is finite (or totally disconnected; for surfaces X, Y it comes to the same thing) for each $y \in Y$ and *open* provided $f(u)$ is open for each open set $U \subset X$. In these terms there is the classical (1929) result as follows.

STÖILOW'S THEOREM [7, p. 103]. *If $f: M^2 \to \mathbf{C}$ is a light open map from the surface $M(\partial M = \varnothing)$ to the complex plane then there is an analytic function $\phi: R \to \mathbf{C}$, R a Riemann surface and a homeomorphism $h: R \to M^2$ such that $\phi = f \circ h$.*

We next outline the proof of Theorem C. We construct a light open map $f: \mathbf{R}^2 \to \mathbf{C}$ such that

(a) f is zero only at the sinks $v \in G$ and has degree m at v, m the weight of the sink v.

(b) The degree of f at a saddle θ is $k = k(\theta)$ where θ is a k-prong in G.

(c) f has no points of degree >1 except as in (a) and (b).

(d) The f-image of each directed edge is a (straight) ray pointed toward the origin in $\mathbf{C}$.

(e) f is proper.

Now applying Stöilow's theorem we obtain an analytic map $\phi: R \to \mathbf{C}$, and a homeomorphism $h: R \to \mathbf{R}^2$. Now R must be $\mathbf{C}$ or the interior of a disk in $\mathbf{C}$. But the latter case is ruled out as ϕ is proper. Then ϕ is a polynomial since it is entire and has poles only at ∞. But G_ϕ is just $h^{-1}(G)$ by our construction. That is, the zeros occur only at the sinks of $h^{-1}(G)$ and the other singular points are $\phi(h^{-1}(\theta))$, θ a saddle of G. Finally the solution curves of V_ϕ being those curves which map onto rays of $\mathbf{C}$ pointing toward the origin, include the directed edges of $h^{-1}(G)$.

This completes the proof of Theorem C; it remains only to construct the light open map f satisfying (a)-(e).

Construction of f. The construction will use induction on the number of saddle points in G.

Suppose there are no saddle points in the graph G. Then G consists of one root of weight m. In this case $G_f = G$ for $f(z) = z^m$.

We make the induction hypothesis that such f exist is true for dynamic graphs with less than or equal to n saddle points.

An equivalent form of the induction hypothesis which will be convenient is the following. Let G be a dynamic graph with less than or equal to n saddle points. For any disc D containing G there exists a light open map f such that (1) $f(D) = D_1 = \{z \mid |z| \leqq 1\}$, (2) f is a covering map from the boundary of D onto the boundary of D_1 and (3) f satisfies (a), (b), (c), (d) relative to G.

In order to see that the second form of the induction hypothesis follows from the first, observe that a large enough disc $\{z \mid |z| \leqq R\}$ in the range of f has for preimage a disc containing D. Adjusting f by an isotropy in the domain and by a radial isotopy in the range gives $f: D \to D_1$ with the desired G_f.

Suppose we have a dynamic graph G which is connected and acyclic, with $n+1$ saddle points. The points of G are partially ordered by the directed edges. Choose a saddle point θ at which no edge terminates. Let $\{\gamma_i\}$, $1 \leqq i \leqq k$ be the edges emanating from θ. For each γ_i, $G - \{\text{interior of } \gamma_i\}$ is the union of two dynamic graphs. Let G_i be the component of $G - \{\text{interior of } \gamma_i\}$ not containing θ. Let $\{D_i\}$, $1 \leqq i \leqq k$, be a family of pairwise disjoint discs such that D_i contains G_i, $\partial D_i \cap \gamma_i$ is a single point p_i in the interior of γ_i, and $D_i \cap \gamma_j = \phi$ for $i \neq j$. Such discs D_i can be found by taking small neighborhoods of the G_i. Since G_i is connected and acyclic, by the induction hypothesis there is a light open map $f_i: D_i \to D_1$ such that $G_i = G_{f_i}$.

Denote by q_i the terminal end of γ_i.

LEMMA. *We can alter γ_i by an isotopy so that $f(q_i) = \lambda_i \cdot f(p_i)$, for some real number $\lambda_i \geqq 0$, and so that the part of γ_i from p_i to q_i is mapped by f_i onto the radial segment from $f_i(p_i)$ to $f_i(q_i)$. Furthermore, we can assume that $f_i(p_i) = 1$ for $1 \leqq i \leqq k$.*

Proof of Lemma. Let $\{\theta_j^i\}$ be the saddle points of f_i. Then $f_i(G_i)$ is the star formed by the union of the radial segments from $f(\theta_j^i)$ to 0. We consider separately two cases: (1) q_i is a saddle of G_i and (2) q_i is a sink of G_i. In case 1, there is a unique radial segment J from a point of the circle $\{z \mid |z| = 1\}$ to $f(q_i)$. Let I be the union of all curves in $f_i^{-1}(J)$ that terminate at the saddle point q_i. There is one and only one such curve between each pair of successive edges emanating from q_i. If J contains some $f(\theta_j^i)$ then one of the curves of I will contain an edge of G_i which terminates at q_i. Suppose γ_i arrives at q_i between the two successive outward edges e_0, e_1. By property 3 of the definition of a saddle connection for the dynamic graph G, no edge of G_i can arrive at q_i between e_0 and e_1. Let $I_{0,1}$ be the curve in I that arrives between e_0 and e_1. Then $I_{0,1}$ does not contain an edge of G_i. Since G_i is connected and acyclic γ_i can be isotoped (that is, G can be isotoped, fixing $G - \gamma_i$) so that γ_i agrees with $I_{0,1}$ in D_i.

In case 2, γ_i arrives at the sink q_i and $f_i(\gamma_i \cap D_i)$ is a topological line segment proceeding from 0 to some point $p_i' \in \partial D$. Of course the map f_i, which we know exists, is only weakly related to the arc γ_i since γ_i is *not* a part of the graph G_i. We construct a more appropriate arc as follows. Choose a point p_i' near q_i in the correct "angle" or cone at q_i. Then $f(p_i') \neq 0$; let J be the line interval from 0 to $f(p_i')$. Then there is a unique lifting of J to an arc I_γ joining p_i' to q_i. This arc lifting property is essentially trivial to understand since we know f_i is a branched covering.

Let R_i be the rotation of $\mathbf{C}$ centered at $z = 0$ such that $R_i(f(p_i)) = 1$. Define $\bar{f}_i = R_i \circ G_i$. Note that $G_{\bar{f}_i} = G_f$ because R_i preserves radial lines. This completes the proof of the lemma.

We now have the situation pictured in Fig. 5.1, which we can think of as a map f defined on the union of the disks $D_1, \cdots, D_i$. Thus it is a simple matter to define a star-shaped disk D_δ^* bounded by the dotted lines in Fig. 5.1 and small arcs on the disks $D_1, \cdots, D_i$. This disk D^* is in turn mapped into the disk D' bounded by the dotted line $A = F(A_i)$ and a small arc of D, by a covering map, branched at $F(\theta)$ (see Fig. 5.2). The resulting map F is a light open map having the appropriate properties except that it is defined only on a compact disk $D_0 = D^* \cup D_1 \cup \cdots \cup D_i$. But since $F(D_0) = D \cup D'$ is a covering on the boundary, it is a simple matter to extend it to the whole plane by a covering map. This completes the induction and thus the proof of Theorem C.

A MODEL EQUATION FOR VISCOELASTICITY WITH A STRONGLY SINGULAR KERNEL*

WILLIAM J. HRUSA† AND MICHAEL RENARDY‡

Abstract. In much of the mathematical work on nonlinear viscoelasticity it is assumed that the kernel (or memory function) is smooth on $[0, \infty)$. There are, however, theoretical and experimental indications that certain viscoelastic materials may be described by equations involving kernels that are singular at zero. In this paper we establish local (in time) existence of smooth solutions to a nonlinear integrodifferential equation with a singular kernel. This equation provides a model for the motion of a certain class of viscoelastic materials. Our analysis is based on energy estimates and properties of positive definite kernels.

Key words. singular kernels, viscoelasticity, local existence, energy estimates

AMS(MOS) subject classifications. 35Q99, 45K05, 73F15

1. Introduction and statement of results. Over the last decade, a significant amount of effort has been devoted to the study of nonlinear integrodifferential equations that model motions of viscoelastic materials. Most of the results obtained so far concern equations with kernels that are smooth on $[0, \infty)$. There are, however, theoretical and experimental indications that certain viscoelastic materials may be described by equations involving kernels that are singular at zero. (See, e.g., [5], [16], [18], [27], [31].) A number of interesting questions are directly linked to behavior of the kernel near zero.

Recent work on linear equations with constant coefficients ([4], [10], [14], [23], [24]) shows that singular kernels lead to smoothing of solutions. One therefore expects that nonlinear equations with singular kernels should have "nicer" existence properties than those with regular kernels. However, singular kernels lead to significant technical complications, and even questions of local existence become very delicate.

In this paper, we study the model problem

$$(1.1)_1 \qquad u_{tt}(x,t) = \chi(u_x(x,t))_x + \int_0^t a(t-\tau)\psi(u_x(x,\tau))_{x\tau}\, d\tau + f(x,t), \qquad x \in [0,1], \quad t \geqq 0,$$

$$(1.1)_2 \qquad u(0,t) = u(1,t) = 0, \qquad t \geqq 0,$$

$$(1.1)_3 \qquad u(x,0) = u_0(x), \quad u_t(x,0) = u_1(x), \quad x \in [0,1].$$

Here χ, $\psi : \mathbb{R} \to \mathbb{R}$ are assigned smooth functions, $a : (0, \infty) \to \mathbb{R}$ is a given kernel, f is a known forcing function, and u_0, u_1 are prescribed initial data. The unknown function u represents displacement. On physical grounds, it is natural to assume that a is positive, decreasing and convex, and that $\psi' > 0$. If the material in question is a fluid then $\chi' \equiv 0$, while for a solid, χ' generally is positive near equilibrium, but may change signs globally.

For physical problems arising in viscoelasticity, the integral in $(1.1)_1$ would extend from $-\infty$ to t and the history of u prior to time $t = 0$ would also be prescribed. This

type of problem can be put in the form (1.1) by incorporating the part of the integral from $-\infty$ to 0 into the forcing term f. However, if the kernel a is singular then in order to ensure that the original history value problem is equivalent to the initial value problem (1.1) we must require that the limit as $t\uparrow 0$ of the given history is equal to u_0.

The behavior of smooth solutions of (1.1) (and of similar problems) is well understood when a is smooth on $[0, \infty)$, i.e., a, $a' \in AC[0, \infty)$. The situation can be described roughly as follows: if $\chi' + a(0)\psi' > 0$ and the data (u_0, u_1, f) are sufficiently regular, then (1.1) has a unique classical solution on a maximal time interval $[0, T_0)$. Under some additional assumptions (which are physically motivated) the solution of (1.1) exists globally in time, provided that the data are suitably small. On the other hand, if the data are too large then the solution will develop singularities in finite time. See, e.g., [2], [3], [9], [11], [12], [25], [28], [30], as well as the recent monograph [26] and the references cited therein.

The local existence result mentioned above can be established by a relatively simple iteration procedure that requires $\chi' + a(0)\psi' > 0$, but is otherwise insensitive to sign conditions on a and ψ. As explained in [15], [25], this procedure cannot work unless $a'(0^+)$ is finite.

The main effects of a kernel which is smooth on $[0, \infty)$ are exemplified by the special case

$$a(t) = \mu e^{-\lambda t} \tag{1.2}$$

with μ, $\lambda > 0$. When a is given by (1.2), the integrodifferential equation $(1.1)_1$ can be converted to the partial differential equation

$$u_{ttt} + \lambda u_{tt} = (\chi(u_x) + \mu\psi(u_x))_{xt} + \lambda\chi(u_x)_x + f_t + \lambda f, \tag{1.3}$$

which is studied in [7], [13]. We note that if $\chi' + \mu\phi' > 0$ then (1.3) is hyperbolic.

If we formally take a to be the Dirac delta function, then $(1.1)_1$ becomes

$$u_{tt} = \chi(u_x)_x + (\psi'(u_x)u_{xt})_x + f. \tag{1.4}$$

If $\psi' > 0$ then the initial-boundary value problem (1.4), $(1.1)_2$, $(1.1)_3$ is well posed (locally in time)—irrespective of the sign and size of χ'. Moreover, under reasonable assumptions on χ and ψ, (1.4), $(1.1)_2$, $(1.1)_3$ has a globally defined classical solution, even if the data are large ([1], [8], [17], [20]). (There are large-data global existence results for (1.4) that permit χ' to be negative. However, positivity of χ' is needed to ensure asymptotic stability.)

Although (1.4) is parabolic, solutions generally do not have more spatial regularity than the data, due to the presence of stationary singularities. Indeed, in the special case when $\chi \equiv 0$ and $\psi(\xi) = \xi$ the solution of (1.4), $(1.1)_2$, $(1.2)_3$ is given by

$$u(x, t) = u_0(x) + \int_0^t v(x, s)\, ds, \tag{1.5}$$

where v satisfies the heat equation and hence is analytic. The spatial regularity of the function u in (1.5) is precisely the same as that of u_0. In contrast with the situation concerning shocks and nonlinear hyperbolic equations, stationary singularities in solutions of (1.4) do not form on their own. In other words, such singularities originate solely from singularities in the data.

If the kernel is a function, but has a singularity at zero, we except $(1.1)_1$ to behave in an intermediate fashion, somewhere between a damped hyperbolic equation (such as (1.3)) and the parabolic equation (1.4). Some results of this nature have been established for linear problems, but relatively little is known about nonlinear equations with singular kernels.

In an earlier paper [15], we studied a problem quite similar to (1.1) under hypotheses which permit $a'(0^+) = -\infty$, but require $a(0^+)$ to be finite. (The problem considered in [15] is not exactly of the form (1.1). However, under the assumptions made in [15], the problem studied there is essentially equivalent to (1.1).) We establish here a local existence theorem for (1.1) that permits the kernel a to have an integrable singularity at zero. On the other hand, we also impose stronger monotonicity assumptions on a than those needed in [15].

Our proof employs the same basic strategy as in [15], i.e., a contraction argument based on energy estimates. However, a different function space is used and an inequality of Staffans [29] is exploited to obtain a modified chain of energy estimates.

A global existence theorem (which allows $a'(0^+) = -\infty$, but requires $a(0^+)$ to be finite) is also proved in [15] for bounded intervals and extended to unbounded intervals in [12]. This result requires the data to be small, and it is not known whether solutions develop singularities in finite time if $a'(0^+) = -\infty$ and the data are large. The problem of global existence when $a(0^+) = +\infty$ is currently under investigation (see "Note added in proof").

The only other existence results for nonlinear problems with singular kernels that we know of are the works of Londen [19] and Engler [6]. Londen establishes the existence of weak solutions to an abstract integrodifferential equation. His existence theorem can be applied to (1.1) in the special case when χ is a scalar multiple of ψ. Engler establishes the existence of weak solutions to the equations of motion for a class of viscoelastic fluids.

Concerning the kernel a we require

(a)
$$a \in L^1(0, \infty),$$
$$a \geqq 0, \qquad a' \leqq 0, \qquad a'' \geqq 0, \qquad a''' \leqq 0,$$

and we make the following assumptions of smoothness:

(s1) $$\chi, \psi \in C^3(\mathbb{R});$$

(s2) $$u_0 \in H^3(0, 1), \qquad u_1 \in H^2(0, 1);$$

(s3) $$f, f_x, f_{xx} \in L^2_{\text{loc}}([0, \infty); L^2(0, 1)).$$

In order to obtain a smooth solution of (1.1) we need the data (u_0, u_1 and f) to be compatible with the boundary conditions; for technical reasons we make the following rather strong compatibility assumption:

(c)
$$u_0(0) = u_0(1) = u_1(0) = u_1(1) = 0,$$
$$u_0''(0) = u_0''(1) = 0,$$
$$f(0, t) = f(1, t) = 0 \quad \text{a.e. } t \geqq 0,$$

which guarantees that the data admit smooth, spatially periodic, odd extensions (of period 2). Finally, in order to ensure the evolutionarity of equation (1.1) we require

(e) $$\psi'(\xi) > 0, \quad \chi'(\xi) + a(0^+)\psi'(\xi) > 0 \quad \forall \xi \in \mathbb{R}.$$

Observe that if $a(0^+) = +\infty$ then (e) imposes no restrictions on χ'. In this regard, when $a(0^+) = +\infty$ the memory term in $(1.1)_1$ has the same effect as the Newtonian viscosity $(\psi'(u_x)u_{xt})_x$.

The hypotheses of primary interest are (a) and (e). The inequalities in (a) are assumed to hold in the sense of distributions. Of course this guarantees that the kernel a has a certain amount of smoothness on $(0, \infty)$ in the classical sense. More precisely, it follows from (a) that $a \in C^1(0, \infty)$ and that a' is locally Lipschitz continuous on

$(0, \infty)$. The main difference between (a) and the corresponding assumption in [15] can be described roughly as follows: in [15] it is also required that $a' \in L^1(0, \infty)$ (and hence that $a(0^+)$ is finite), but no condition on a''' is needed.

Our main result is the following theorem.

THEOREM. *Assume that* (a), (s1)-(s3), (c) *and* (e) *hold. Then the initial-boundary value problem* (1.1) *has a unique solution u on a maximal time interval* $[0, T_0)$, $T_0 > 0$, *with*

$$u, u_x, u_t, u_{xx}, u_{xt}, u_{xxx}, u_{xxt} \in L^\infty_{\mathrm{loc}}([0, T_0); L^2(0, 1)), \tag{1.6}_1$$

$$u_{tt}, u_{xtt} \in L^2_{\mathrm{loc}}([0, T_0); L^2(0, 1)). \tag{1.6}_2$$

Moreover, if

$$\operatorname*{ess\text{-}sup}_{t \in [0, T_0)} \int_0^1 \{u_{xxx}^2 + u_{xxt}^2\}(x, t)\, dx + \int_0^{T_0} \int_0^1 u_{xtt}^2(x, t)\, dx\, dt < \infty, \tag{1.7}$$

then $T_0 = \infty$.

Remarks. (1) It follows from (1.6) and standard embedding theorems that u, u_x, u_t, u_{xx} and u_{xt} are continuous on $[0, 1] \times [0, T_0)$. Moreover, since f vanishes at the endpoints, one can show that the solution satisfies $u_{xx}(0, t) = u_{xx}(1, t) = 0$ for all $t \in [0, T_0)$.

(2) A similar existence theorem holds for the pure initial value problem on all of space.

(3) The question of optimal regularity of the solution of (1.1) appears to be rather delicate. One expects that a singularity in a will lead to smoothing in the temporal direction. However, one should not expect spatial smoothing because equation $(1.1)_1$ permits stationary singularities.

The paper is organized as follows. In § 2 we discuss some preliminary material concerning the kernel. Then in § 3, we establish an existence theorem for a linear integrodifferential equation with variable coefficients. Finally, in § 4, we use the results of § 3 to prove the theorem stated above. In §§ 3 and 4 we emphasize those features of our proofs that differ from [15]; details of arguments that are very similar to ones in [15] will be omitted.

2. Preliminaries. This section contains some preliminary material that is needed for the proof of our theorem. Let X be a Hilbert space with inner product $\langle \cdot, \cdot \rangle$ and associated norm $\| \cdot \|$. For each $b \in L^1_{\mathrm{loc}}[0, \infty)$, $T > 0$, and $\Phi \in L^2([0, T]; X)$ we set

$$Q(\Phi, t, b) := \int_0^t \left\langle \Phi(s), \int_0^s b(s - \tau)\Phi(\tau)\, d\tau \right\rangle ds \quad \forall t \in [0, T]. \tag{2.1}$$

We denote by $H^1([0, T]; X)$ the set of all $\Phi \in L^2([0, T]; X)$ such that $\Phi' \in L^2([0, T]; X)$, where Φ' is the (distributional) derivative of Φ.

Our energy estimates make crucial use of several properties of positive definite kernels. For the sake of completeness we recall a few basic concepts. A real-valued function $b \in L^1_{\mathrm{loc}}[0, \infty)$ is said to be positive definite (or of positive type) if

$$\int_0^t v(s) \int_0^s b(s - \tau)v(\tau)\, d\tau\, ds \geqq 0 \qquad \forall t \geqq 0 \tag{2.2}$$

for every $v \in C[0, \infty)$; b is called strongly positive definite if there is a $\lambda > 0$ such that the function $t \to b(t) - \lambda e^{-t}$ is positive definite. As the terminology suggests, every strongly positive definite kernel is positive definite.

The definition of a positive definite function is not easy to check directly. We quote a well-known sufficient condition. If $b \in L^1_{\mathrm{loc}}[0, \infty)$ satisfies

$$b \geqq 0, \qquad b' \leqq 0, \qquad b'' \geqq 0, \tag{2.3}$$

then b is positive definite; if, in addition, the measure b'' has a nontrivial absolutely continuous component, then b is strongly positive definite. We note that if b is positive definite and $\Phi \in L^2([0, T]; X)$ then

$$Q(\Phi, t, b) \geqq 0 \quad \forall t \in [0, T]. \tag{2.4}$$

See, for example, [22], [29] for more information on these matters.

In our existence proof for the linearized problem we shall employ "shifted" kernels. For each $\delta > 0$ we defined $a_\delta : [0, \infty) \to \mathbb{R}$ by

$$a_\delta(s) := a(s + \delta) \quad \forall s \geqq 0. \tag{2.5}$$

It follows from (a) and (2.5) that

$$a_\delta \geqq 0, \qquad a_\delta' \leqq 0, \qquad a_\delta'' \geqq 0, \qquad a_\delta''' \leqq 0, \tag{2.6}$$

$$a_\delta, a_\delta', a_\delta'' \in L^1(0, \infty) \tag{2.7}$$

and

$$\|a_\delta\|_{L^1} \leqq \|a\|_{L^1} \tag{2.8}$$

for every $\delta > 0$. Observe that $a_\delta \to a$ pointwise (and in L^1) as $\delta \downarrow 0$. The use of shifted kernels is not essential, but it provides a simple way of constructing approximate problems which are known to have solutions.

In view of (2.8), the following estimate is an immediate consequence of an inequality of Staffans. (See Lemma 1 and Theorem 2(iii) of [29].)

LEMMA 1. *Assume that* (a) *holds and let* $A := 5\|a\|_{L^1}$. *Then, for every* δ, $T > 0$, *and* $\Phi \in L^2([0, T]; X)$ *we have*

$$\int_0^t \left\| \int_0^s a_\delta(s - \tau)\Phi(\tau)\, d\tau \right\|^2 ds \leqq A \cdot Q(\Phi, t, a_\delta) \quad \forall t \in [0, T]. \tag{2.9}$$

Lemma 1 of [29] is formulated for the case when Φ is a continuous scalar-valued function. However, the same proof applies under the present circumstances.

The next result provides a useful lower bound for $Q(\Phi', t, a_\delta)$.

LEMMA 2. *Assume that* (a) *holds and let* δ_0, $\varepsilon > 0$ *be given. Then there is a constant* $C = C(\delta_0, \varepsilon)$ *such that for every* $T > 0$, $\delta \in (0, \delta_0]$, *and* $\Phi \in H^1([0, T]; X)$ *we have*

$$\begin{aligned} Q(\Phi', t, a_\delta) \geqq{}& \frac{1}{2}(a(\delta_0) - \varepsilon)\|\Phi(t) - \Phi(0)\|^2 \\ & - C \int_0^t \|\Phi(s) - \Phi(0)\|^2\, ds \quad \text{a.e. } t \in [0, T]. \end{aligned} \tag{2.10}$$

Proof. It is clear that the conclusion of the lemma holds if $a(\delta_0) = 0$, so we assume that $a(\delta_0) > 0$. We note that a_{δ_0} is then strongly positive definite and that $a_{\delta_0}, a_{\delta_0}' \in L^1(0, \infty)$.

By virtue of Lemma 2.3 of [15], there is a constant $C = C(\delta_0, \varepsilon)$ such that for every $T > 0$ and every $\Phi \in H^1([0, T]; X)$ we have

$$\begin{aligned} Q(\Phi', t, a_{\delta_0}) \geqq{}& \left(\frac{1}{2}a(\delta_0) - \varepsilon\right)\|\Phi(t) - \Phi(0)\|^2 \\ & - C \int_0^t \|\Phi(s) - \Phi(0)\|^2\, ds \quad \forall t \in [0, T]. \end{aligned} \tag{2.11}$$

(To apply the results of [15], we set $\Phi(t)=\Phi(0)$ for $t<0$, put $u(t)=\Phi(t)-\Phi(0)$, use a_{δ_0} in place of a, and let $h\downarrow 0$.) It follows from (a) and (2.5) that $a_\delta - a_{\delta_0}$ is positive definite for all $\delta\in(0,\delta_0]$ and consequently

$$Q(\Phi', t, a_\delta)\geqq Q(\Phi', t, a_{\delta_0}) \quad \forall \delta\in(0,\delta_0]. \tag{2.12}$$

This completes the proof.

3. Linear problem. The proof of our theorem is based on an iteration scheme which involves linear problems of the form

$$u_{tt}(x,t)=\gamma(x,t)u_{xx}(x,t)+\int_0^t a(t-\tau)[\beta(x,\tau)u_{xx}(x,\tau)]_\tau\,d\tau+f(x,t) \tag{3.1}_1$$
$$\forall x\in[0,1],\ t\in[0,T],$$

$$u(0,t)=u(1,t)=0, \tag{3.1}_2$$

$$u(x,0)=u_0(x),\ u_t(x,0)=u_1(x). \tag{3.1}_3$$

In this section we establish existence and an a priori estimate for (3.1). Concerning the coefficients γ and β we assume

$$\gamma,\gamma_x,\gamma_t,\gamma_{xx},\gamma_{xt},\beta,\beta_x,\beta_t,\beta_{xx},\beta_{xt}\in L^\infty([0,T];L^2(0,1)), \quad \gamma_{tt},\beta_{tt}\in L^2([0,T];L^2(0,1)); \tag{s1*}$$

$$\beta(x,t)\geqq\underline{\beta}>0,\ \gamma(x,t)+a(0^+)\beta(x,t)\geqq\underline{\lambda}>0 \quad \forall x\in[0,1],\ t\in[0,T]; \tag{e*}$$

$$\gamma_x(0,t)=\gamma_x(1,t)=\beta_x(0,t)=\beta_x(1,t)=0 \quad \forall t\in[0,T]. \tag{c*}$$

Our assumptions on the kernel and the data are the same as for the nonlinear problem.

For the purpose of stating an a priori estimate we define

$$U_0:=\int_0^1\{u_0'''(x)^2+u_1''(x)^2\}\,dx, \tag{3.2}$$

$$F:=\int_0^T\int_0^1 f_{xx}^2(x,t)\,dx\,dt, \tag{3.3}$$

$$B:=\int_0^1\{\gamma^2+\gamma_x^2+\beta^2+\beta_x^2\}(x,0)\,dx, \tag{3.4}$$

$$\Gamma:=\operatorname*{ess\text{-}sup}_{t\in[0,T]}\int_0^1\{\gamma^2+\gamma_x^2+\gamma_t^2+\gamma_{xx}^2+\gamma_{xt}^2+\beta^2+\beta_x^2+\beta_t^2+\beta_{xx}^2+\beta_{xt}^2\}(x,t)\,dx. \tag{3.5}$$

LEMMA 3. *Let $T>0$ be given and assume that* (a), (s1*), (s2), (s3), (c), (c*) *and* (e*) *hold. Then, the initial boundary value problem* (3.1) *has a unique solution u with*

$$u,u_x,u_t,u_{xx},u_{xt},u_{xxx},u_{xxt}\in L^\infty([0,T];L^2(0,1)), \tag{3.6}_1$$

$$u_{tt},u_{xtt}\in L^2([0,T];L^2(0,1)). \tag{3.6}_2$$

Moreover, this solution obeys the a priori estimate

$$\operatorname*{ess\text{-}sup}_{t\in[0,T]}\int_0^1\{u_{xxx}^2+u_{xxt}^2\}(x,t)+\int_0^T\int_0^1 u_{xtt}^2(x,t)\,dx\,dt \leqq K\{F+(1+B+BT)U_0\}\exp[K(1+\Gamma)T], \tag{3.7}$$

where K is a constant that depends on $\underline{\beta}$ and $\underline{\lambda}$, but is independent of U_0, F, B, Γ and T.

Proof. We use the shifted kernels a_δ (which are smooth on $[0,\infty)$) in place of a to construct approximate solutions $u^{(\delta)}$. We shall also approximate f by functions with more temporal regularity so that standard theory of equations with smooth kernels can be used to solve for the $u^{(\delta)}$. Let us set

$$f(x,t)=f(x,-t) \quad \text{for } t<0 \tag{3.8}$$

and

$$f^{(\delta)}(x,t):=\int_{-\infty}^{\infty} J_\delta(t-\tau)f(x,\tau)\,d\tau \tag{3.9}$$

where J_δ is a standard mollifier on $\mathbb{R}$.

We replace (3.1) with

$$u_{tt}^{(\delta)}(x,t)=\gamma(x,t)u_{xx}^{(\delta)}(x,t)+\int_0^t a_\delta(t-\tau)[\beta u_{xx}^{(\delta)}]_t(x,\tau)\,d\tau+f^{(\delta)}(x,t), \tag{3.10}$$

$$x\in[0,1], \quad t\in[0,T],$$

$$u^{(\delta)}(0,t)=u^{(\delta)}(1,t)=0, \tag{3.10}$$

$$u^{(\delta)}(x,0)=u_0(x), \qquad u_t^{(\delta)}(x,0)=u_1(x), \tag{3.10}$$

and we choose $\delta_0>0$ and small enough so that

$$\underline{\alpha}:=\inf_{\substack{x\in[0,1]\\ t\in[0,T]}}[\gamma(x,t)+a(\delta_0)\beta(x,t)]>0. \tag{3.11}$$

Observe that

$$\gamma(x,t)+a_\delta(0)\beta(x,t)\geqq\underline{\alpha} \quad \forall x\in[0,1], \quad t\in[0,T], \quad \delta\in(0,\delta_0]. \tag{3.12}$$

An integration by parts in (3.10)$_1$ produces

$$\begin{aligned} u_{tt}^{(\delta)}(x,t)&=[\gamma+a_\delta(0)\beta]u_{xx}^{(\delta)}(x,t)+\int_0^t a_\delta'(t-\tau)[\beta u_{xx}^{(\delta)}](x,\tau)\,d\tau \\ &=f^{(\delta)}(x,t)+a_\delta(t)\beta(x,0)u_0''(x). \end{aligned} \tag{3.13}$$

It follows from a standard argument (cf., e.g., [26]) that for each $\delta\in(0,\delta_0]$, the initial-boundary value problem (3.13), (3.10)$_2$, (3.10)$_3$ has a unique solution $u^{(\delta)}$ with

$$u^{(\delta)}, u_x^{(\delta)}, u_t^{(\delta)}, u_{xx}^{(\delta)}, u_{xt}^{(\delta)}, u_{tt}^{(\delta)}, u_{xxx}^{(\delta)}, u_{xxt}^{(\delta)}, u_{xtt}^{(\delta)}, u_{ttt}^{(\delta)}\in C([0,T];L^2(0,1)). \tag{3.14}$$

Moreover, this solution satisfies

$$u_{xx}^{(\delta)}(0,t)=u_{xx}^{(\delta)}(1,t)=0 \quad \forall t\in[0,T]. \tag{3.15}$$

It is clear that $u^{(\delta)}$ is also a solution of (3.10). Our objective is to obtain a priori bounds for $u^{(\delta)}$ that guarantee the existence of a sequence $\{\delta_n\}_{n=1}^\infty$ tending to zero such that $u^{(\delta_n)}$ converges to a solution of (3.1). For the purpose of obtaining these bounds, we shall extend $u^{(\delta)}$, u_0, u_1, $f^{(\delta)}$, γ and β periodically in space, in such a way that the extended functions are smooth and (3.10)$_1$, (3.10)$_3$ hold for all $x\in\mathbb{R}$. This will allow us to employ spatial difference operators.

We extend $u^{(\delta)}$, u_0, u_1 and $f^{(\delta)}$ (spatially) to be odd periodic functions of period 2, and we extend γ and β to be even periodic functions of period 2. By virtue of (c) and (c*), the extended functions have the same regularity as the original functions. Moreover, (3.10)$_1$ and (3.10)$_3$ are satisfied for all $x\in\mathbb{R}$.

In the estimates that follow we use K to denote a generic positive constant that can be chosen independently of U_0, F, B, Γ, T and δ. Moreover, to simplify the notation we suppress the superscript δ on u and f. We note that the elementary inequality

$$|CD| \leqq \eta C^2 + \frac{1}{4\eta} D^2 \quad \forall C, D \in \mathbb{R}, \eta > 0 \tag{3.16}$$

will be exploited in several places.

For each $h > 0$, we define the spatial difference operator D_h by

$$(D_h v)(x, t) := v(x+h, t) - v(x, t). \tag{3.17}$$

Applying D_h to $(3.10)_1$ we obtain

$$D_h u_{tt} = D_h[\gamma u_{xx}] + \int_0^t a_\delta(t-\tau) D_h[(\beta u_{xx})_t](x, \tau)\, d\tau + D_h f. \tag{3.18}$$

We multiply (3.18) by $D_h[(\beta u_{xx})_t]$ and integrate over space and time. After several integrations by parts we let $h \downarrow 0$ and obtain

$$\begin{aligned} &\frac{1}{2}\int_0^1 \{\beta u_{xxt}^2 + \beta\gamma u_{xxx}^2\}(x, t)\, dx + \lim_{h\downarrow 0} \frac{1}{h^2} Q(D_h[(\beta u_{xx})_t], t, a_\delta) \\ &\qquad = \int_0^t \int_0^1 (\beta_t u_{xx})_x u_{xtt}(x, s)\, dx\, ds + R_1(t) \quad \forall t \in [0, T], \end{aligned} \tag{3.19}$$

where Q is given by (2.1) with $X := L^2(0, 1)$ and R_1 is given by

$$\begin{aligned} R_1(t) = &\frac{1}{2}\int_0^1 \{\beta u_{xxt}^2 + \beta\gamma u_{xxx}^2\}(x, 0)\, dx \\ &+ \int_0^t \int_0^1 \left\{\frac{1}{2}\beta_t u_{xxt}^2 + \frac{1}{2}\beta\gamma_t u_{xxx}^2 - \frac{1}{2}\beta_t \gamma u_{xxx}^2 \right. \\ &\quad - \beta_x \gamma u_{xxx} u_{xxt} + \beta\gamma_x u_{xxx} u_{xxt} - \beta_t \gamma_x u_{xx} u_{xxx} + \beta\gamma_{xx} u_{xx} u_{xxt} \\ &\quad \left. - \beta_{xt}\gamma u_{xx} u_{xxx} - \beta_{xt}\gamma_x u_{xx}^2 + \beta f_{xx} u_{xxt} + \beta_t f_{xx} u_{xx} \right\}(x, s)\, dx\, ds. \end{aligned} \tag{3.20}$$

It is not evident a priori that $\lim_{h\downarrow 0}(1/h^2)\ Q(D_h[(\beta u_{xx})_t], t, a_\delta)$ exists for a.e. $t \in [0, T]$. However, the limits of each of the other terms involved in the derivation of (3.19) exist for a.e. $t \in [0, T]$. Consequently, the limit in question exists for a.e. $t \in [0, T]$.

We choose ε sufficiently small and apply Lemma 2 (and some straightforward calculations) to conclude that the left side of (3.19) is bounded below by

$$\int_0^1 \left\{\frac{1}{2}\underline{\beta} u_{xxt}^2 + \frac{1}{4}\underline{\alpha\beta} u_{xxx}^2\right\}(x, t)\, dx - K \cdot R_2(t) \tag{3.21}$$

where

$$\begin{aligned} R_2(t) := &\int_0^1 \{[(\beta u_{xx})_x(x, 0)]^2 + \beta_x^2 u_{xx}^2(x, t)\}\, dx \\ &+ \int_0^t \int_0^1 [(\beta u_{xx})_x(x, s) - (\beta u_{xx})_x(x, 0)]^2\, dx\, ds. \end{aligned} \tag{3.22}$$

It therefore follows from (3.19) that

$$\int_0^1 \{u_{xxx}^2 + u_{xxt}^2\}(x, t)\, dx \leqq K \cdot R_1(t) + K \cdot R_2(t) + K \int_0^t \int_0^1 (\beta_t u_{xx})_x u_{xtt}(x, s)\, dx\, ds. \tag{3.23}$$

We now divide (3.18) by h and employ Lemma 1 to conclude that

$$\begin{aligned} &\frac{1}{h^2} \int_0^t \int_0^1 [D_h u_{tt} - D_h(\gamma u_{xx}) - D_h f]^2(\cdot, s)\, dx\, ds \\ &\leqq \frac{1}{h^2} \int_0^t \int_0^1 \left(\int_0^s a_\delta(s-\tau) D_h[(\beta u_{xx})_t](\cdot, \tau)\, d\tau \right) dx\, ds \\ &\leqq \frac{A}{h^2} Q(D_h[(\beta u_{xx})_t], t, a_\delta). \end{aligned} \tag{3.24}$$

Letting $h \downarrow 0$ in (3.24) we obtain

$$\int_0^t \int_0^1 [u_{xtt} + (\gamma u_{xx})_x - f_x]^2(x, s)\, dx\, ds \leqq A \cdot \lim_{h \downarrow 0} \frac{1}{h^2} Q(D_h[(\beta u_{xx})_t], t, a_\delta). \tag{3.25}$$

It follows easily from (3.25) that

$$\int_0^t \int_0^1 u_{xtt}^2(x, s)\, dx\, ds \leqq K \cdot R_3(t) + K \cdot \lim_{h \downarrow 0} \frac{1}{h^2} Q(D_h[(\beta u_{xx})_t], t, a) \tag{3.26}$$

where

$$R_3(t) := \int_0^t \int_0^1 \{[(\gamma u_{xx})_x]^2 + f_x^2\}(x, s)\, dx\, ds. \tag{3.27}$$

The combination of (3.19), (3.23) and (3.25) yields the estimate

$$\begin{aligned} &\int_0^1 \{u_{xxx}^2 + u_{xxt}^2\}(x, t)\, dx + \int_0^t \int_0^1 u_{xtt}^2(x, s)\, dx\, ds \\ &\leqq K\{R_1(t) + R_2(t) + R_3(t)\} + K \int_0^t \int_0^1 (\beta_t u_{xx})_x u_{xtt}(x, s)\, dx\, ds. \end{aligned} \tag{3.28}$$

We apply (3.16) (with η sufficiently small) to the integrand on the right of (3.28) to obtain

$$\int_0^1 \{u_{xxx}^2 + u_{xxt}^2\}(x, t)\, dx + \int_0^t \int_0^1 u_{xtt}^2(x, s)\, dx\, ds \leqq K\{R_1(t) + R_2(t) + R_3(t) + R_4(t)\} \tag{3.29}$$

with

$$R_4(t) := \int_0^t \int_0^1 [(\beta_t u_{xx})_x]^2(x, s)\, dx\, ds. \tag{3.30}$$

To proceed further, we introduce

$$E[u](t) := \operatorname*{ess\text{-}sup}_{s \in [0,t]} \int_0^1 \{u_{xxx}^2 + u_{xxt}^2\}(x, s)\, ds. \tag{3.31}$$

Using calculations similar to those on pages 209–211 of [15] to bound the remainder terms $R_i(t)$, we arrive at the following estimate:

$$E[u](t)+\int_0^t\int_0^1 u_{xtt}^2(x,s)\,dx\,ds \leqq K\{F+(1+B+BT)U_0\} + K(1+\Gamma)\int_0^t E[u](s)\,ds. \tag{3.32}$$

(In our deviation of (3.32) we have exploited Poincaré's inequality; this is not essential, but it leads to a slightly simpler estimate.) Gronwall's inequality applied to (3.32) yields

$$E[u](T)+\int_0^T\int_0^1 u_{xtt}^2(x,s)\,dx\,ds \leqq K\{F+(1+B+BT)U_0\}\exp[K(1+\Gamma)T]. \tag{3.33}$$

It follows from (3.33) that $u_{xxx}^{(\delta)}$, $u_{xxt}^{(\delta)}$ are bounded in $L^\infty([0,T];L^2(0,1))$ and $u_{xtt}^{(\delta)}$ is bounded in $L^2([0,T];L^2(0,1))$ independently of δ. Therefore, there is a function $u:[0,1]\times[0,T]\to\mathbb{R}$ and sequence $\delta_n\downarrow 0$ such that

$$u^{(\delta_n)}, u_x^{(\delta_n)}, u_t^{(\delta_n)}, u_{xx}^{(\delta_n)}, u_{xt}^{(\delta_n)}, u_{xxx}^{(\delta_n)}, u_{xxt}^{(\delta_n)} \to u, u_x, \text{ etc.} \quad \text{weakly * in } L^\infty([0,T];L^2(0,1)), \tag{3.34}_1$$

$$u_{tt}^{(\delta_n)}, u_{xtt}^{(\delta_n)} \to u_{tt}, u_{xtt} \quad \text{weakly in } L^2([0,T];L^2(0,1)). \tag{3.34}_2$$

It follows from (3.34) and the convergence properties of a_δ and $f^{(\delta)}$ that u is a solution of (3.1) and that u satisfies the estimate (3.33). The uniqueness of a solution with the regularity (3.6) follows from a straightforward argument.

4. Proof of the theorem. For $M, T>0$ we denote by $Z(M,T)$ the set of all functions $w:[0,1]\times[0,T]\to\mathbb{R}$ satisfying

$$w, w_x, w_t, w_{xx}, w_{xt}, w_{xxx}, w_{xxt} \in L^\infty([0,T];L^2(0,1)), \tag{4.1}_1$$

$$w_{tt}, w_{xtt} \in L^2([0,T];L^2(0,1)), \tag{4.1}_2$$

$$w(0,t)=w(1,t)=0 \quad \forall t\in[0,T], \tag{4.1}_3$$

$$w_{xx}(0,t)=w_{xx}(1,t)=0 \quad \forall t\in[0,T], \tag{4.1}_4$$

$$w(x,0)=u_0(x) \quad \forall x\in[0,1], \tag{4.1}_5$$

$$\operatorname*{ess\text{-}sup}_{t\in[0,T]}\int_0^1\{w_{xxx}^2+w_{xxt}^2\}(x,t)\,dx+\int_0^T\int_0^1 w_{xtt}^2(x,t)\,dx\,dt \leqq M^2. \tag{4.1}_6$$

We note that $Z(M,T)$ is nonempty if M is sufficiently large.

We assume temporarily that

$$\inf_{\xi\in\mathbb{R}}\psi'(\xi)>0, \qquad \inf_{\xi\in\mathbb{R}}[\chi'(\xi)+a(0^+)\psi'(\xi)]>0. \tag{4.2}$$

(As in [15], this assumption will be removed later.) Identifying γ with $\chi'(w_x)$ and β with $\psi'(w_x)$, it follows from Lemma 3 that for $w\in Z(M,T)$, the initial value problem

$$u_{tt}(x,t)=\chi'(w_x)u_{xx}(x,t)+\int_0^t a(t-\tau)[\psi'(w_x)u_{xx}(x,\tau)]_\tau\,d\tau+f(x,t), \quad x\in[0,1], \quad t\in[0,T], \tag{4.3}_1$$

$$u(0,t)=u(1,t)=0, \quad t\in[0,T], \tag{4.3}_2$$

$$u(x,0)=u_0(x), \quad u_t(x,0)=u_1(x), \quad x\in[0,1], \tag{4.3}_3$$

has a unique solution satisfying (3.6). By virtue of (4.2), the corresponding $\underline{\beta}$ and $\underline{\lambda}$ can be chosen independently of M and T.

Let S be the mapping that carries $w \in Z(M, T)$ into the solution of (4.1). We want to show that for appropriately chosen M and T, S has a unique fixed point in $Z(M, T)$; such a fixed point is obviously a solution of (1.1) on $[0, 1]\times[0, T]$.

Existence of the desired fixed point will be established by means of the contraction mapping principle. For this purpose we equip $Z(M, T)$ with the complete metric ρ defined by

$$\rho(w, \bar{w})^2 := \max_{t\in[0,T]} \int_0^1 \{(w_{xx} - \bar{w}_{xx})^2 + (w_{xt} - \bar{w}_{xt})^2\}(x, t)\, dx + \int_0^T \int_0^1 (\bar{w}_{tt} - \bar{w}_{tt})^2(x, t)\, dx\, dt. \tag{4.4}$$

It follows from the definition of $Z(M, T)$ and the a priori estimate of Lemma 3 that S maps $Z(M, T)$ into itself if M is sufficiently large and T is sufficiently small relative to M.

Let M, $T>0$ and w, $\bar{w} \in Z(M, T)$ be given and put $u := Sw$, $\bar{u} := S\bar{w}$, $W := w - \bar{w}$, $U := u - \bar{u}$. A simple calculation shows that U satisfies

$$U_{tt} = \chi'(w_x) U_{xx} + [\chi'(w_x) - \chi'(\bar{w}_x)]\bar{u}_{xx} + \int_0^t a(t-\tau)[\psi'(w_x) U_{xx}(x, \tau) + (\psi'(w_x) - \psi'(\bar{w}_x))\bar{u}_{xx}(x, \tau)]_\tau\, d\tau, \tag{4.5}_1$$

$$U(0, t) = U(1, t) = 0, \tag{4.5}_2$$

$$U(x, 0) = U_t(x, 0) = 0. \tag{4.5}_3$$

To show that S is contractive we first multiply $(4.5)_1$ by Φ_t, where

$$\Phi := \psi'(w_x) U_{xx} + [\psi'(w_x) - \psi'(\bar{w}_x)]\bar{u}_{xx}, \tag{4.6}$$

integrate the resulting equation over space and time, and exploit Lemma 2 (as in § 3). This yields an estimate for

$$\int_0^1 \{U_{xx}^2 + U_{xt}^2\}(x, t)\, dx + Q(\Phi_t, t, a). \tag{4.7}$$

We then apply Lemma 1 to $(4.5)_1$ to obtain an estimate for

$$\int_0^T \int_0^1 U_{tt}^2(x, t)\, dx\, dt. \tag{4.8}$$

Combining the estimates obtained for the quantities in (4.7) and (4.8) and employing calculations very similar to those in § 4 of [15] we obtain an inequality of the form

$$\rho(Sw, S\bar{w}) \leqq P(M, T) \exp[R(M, T)] \tag{4.9}$$

(valid for M large and T small) where P, $R:[0, \infty)\times[0, \infty)\to[0, \infty)$ are continuous functions with $P(M, 0) = 0 \forall M > 0$. If we fix M sufficiently large and then choose T sufficiently small relative to M then S maps $Z(M, T)$ into itself, and (4.9) guarantees that S is strictly contractive with respect to ρ. The rest of the proof can be carried out as in [15], and we omit the details.

Note added in proof. A forthcoming article of M. Renardy ("Coercive estimates and existence of solutions for a model of one-dimensional viscoelasticity with a nonintegrable memory function," submitted to *J. Integral Equations Appl.*) develops

an alternative existence proof based on coercive properties of the linearized problem. Global existence for small data and local existence for large data are established for an equation of motion more general than $(1.1)_1$. Roughly speaking, the analogue of the kernel a is required to have a singularity at zero that is at least as strong as a negative power of t.

UNIFORM L^1 BEHAVIOR FOR THE SOLUTION OF A VOLTERRA EQUATION WITH A PARAMETER*

RICHARD NOREN†

Abstract. Consider the (scalar) initial value problem

$$\text{(P)} \qquad u_t(t,\lambda)+\lambda\int_0^t (d+a(t-\tau))u(\tau,\lambda)\,d\tau=0, \qquad u(0,\lambda)=1,$$

where $d\geqq 0$ is a constant, $\lambda\geqq 1$ is a parameter, and the subscript denotes differentiation with respect to t. The kernel $a\in L^1_{\text{loc}}[0,\infty)$ is assumed to be nonnegative, nonincreasing and convex. Let $u(t,\lambda)$ be the solution of (P) and define

$$w(t)=\sup_{\lambda\geqq 1}|u_{tt}(t,\lambda)\lambda^{-1}|.$$

Sufficient conditions (and weaker necessary conditions) concerning the kernel $a(t)$ are established in order that

$$\lim_{t\to\infty} w(t)=0 \quad \text{and} \quad \int_0^\infty w(t)\,dt<\infty.$$

Implications of the results are studied regarding solutions of the abstract initial value problem

$$\mathbf{y}'(t)+\int_0^t (d+a(t-s))\mathbf{L}\mathbf{y}(s)=\mathbf{f}(t), \qquad t>0, \quad \mathbf{y}(0)=\mathbf{x},$$

where $\mathbf{L}$ is a self-adjoint densely defined linear operator on a Hilbert space H with $\mathbf{L}\geqq\mathbf{I}$.

Key words. Volterra equation, uniform, Hilbert space, parameter, Fourier transform

AMS(MOS) subject classification. 45

1. Introduction. We study the solution $u=u(t)=u(t,\lambda)$ of the (scalar) initial value problem

$$\text{(1.1)} \qquad u'(t)+\lambda\int_0^t (d+a(t-\tau))u(\tau)\,d\tau=0, \quad u(0)=1, \quad t\geqq 0 \quad \left(' =\frac{d}{dt}\right)$$

where $\lambda\geqq 1$ is a parameter. Assuming that

(1.2) $d\geqq 0$ is a constant, $a\in L^1_{\text{loc}}[0,\infty)$ is nonnegative, nonincreasing, convex and $0=a(\infty)<a(0+)\leqq\infty$,

we give necessary conditions (and weaker sufficient conditions) concerning the kernel $a(t)$ in order that

(1.3) (i) $\displaystyle\int_0^\infty w(t)\,dt<\infty$, and

(ii) $\displaystyle\lim_{t\to\infty} w(t)=0$

hold where $w(t)\equiv\sup_{\lambda\geqq 1}|u''(t,\lambda)\lambda^{-1}|$. The necessary conditions are stated in Theorems 2.1 and 2.2. The main theorem that gives sufficient conditions is Theorem 2.5.

* Received by the editors April 7, 1986; accepted for publication (in revised form) May 12, 1987. This paper is based on the author's Ph.D. thesis, written at Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061.

The parameter problem (1.1) arises in the study of the Hilbert space problem

$$y'(t)+\int_0^t (d+a(t-\tau))Ly(\tau)\,d\tau=f(t), \qquad t\geqq 0, \quad y(0)=y_0, \tag{1.4}$$

where L is a self-adjoint linear operator, defined on a dense domain D of Hilbert space H, whose spectrum is contained in $[1,\infty)$. Let

$$U(t)\equiv\int_1^\infty u(t,\lambda)\,dE_\lambda,$$

where u is the solution of (1.1) and $\{E_\lambda\}$ is the spectral family corresponding to L. The function f belongs to the class of locally Bochner integrable functions from $[0,\infty)$ to H.

Carr and Hannsgen establish the resolvent formula

$$y(t)=U(t)y_0+\int_0^t U(t-\tau)f(\tau)\,d\tau \tag{1.5}$$

for (1.4). They also give sufficient conditions in order that

$$\int_0^\infty \|U(t)\|\,dt<\infty \quad \text{and} \quad \int_1^\infty \|V(t)L^{-1/2}\|\,dt<\infty \tag{1.6}$$

hold, where $V(t)\equiv\int_1^\infty u'(t,\lambda)\,dE_\lambda$, and $\|\ \|$ denotes the operator norm for linear operators from H to H (see [2], [3]). In particular, (1.6) holds when $a(t)$ satisfies (1.2) and

$$-a' \text{ is convex.} \tag{1.7}$$

The main work in their proof is to show that the two inequalities

$$\text{(i)} \quad \int_0^\infty \sup_{\lambda\geqq 1}|u(t,\lambda)|\,dt<\infty, \text{ and} \tag{1.8}$$

$$\text{(ii)} \quad \int_0^\infty \sup_{\lambda\geqq 1}|u'(t,\lambda)\lambda^{-1/2}|\,dt<\infty$$

hold. Then (1.6) follows by the functional calculus. See [2], [3] for a discussion (with references and an example) of applications of (1.5) to problems in viscoelasticity.

The condition (1.3) implies that

$$\int_0^\infty W(t)L^{-1}\,dt<\infty \quad \text{and} \quad \lim_{t\to\infty} W(t)L^{-1}=0$$

hold where $W(t)\equiv\int_1^\infty u''(t,\lambda)\,dE_\lambda$. We show that (1.3) holds for wide classes of kernels. In particular, Theorem 2.4(ii) below shows that (1.3)(ii) holds if $a(t)$ satisfies (1.2) and (1.7), while Theorem 2.5 below implies that (1.3)(i) holds when $a(t)$ satisfies (1.2), (1.7) and one of the following: $a(0+)<\infty$, $a(t)=t^{-p}$, $0<p<1$, $a(t)=-\log t$ (small t), $a(t)=t^{-1}(-\log t)^{-q}$ (small t), $q>2$. Theorem 2.2 below shows that when (1.2) holds, then

$$\int_0^1 (-\log t)a(t)\,dt<\infty \tag{1.9}$$

is necessary for (1.3)(i) to hold. No analogous growth restriction is necessary for (1.8) to hold. We note that (1.9) rules out the locally integrable kernel $a(t)=t^{-1}(-\log t)^{-q}$ (small t), for $1<q\leqq 2$.

The simple example $a(t)=e^{-t}$ shows the need for the scaling factor $\lambda^{-1/2}$ in (1.8)(ii) and λ^{-1} in the definition of $w(t)$. In this case, (1.1) reduces to the equation $u''(t)+u'(t)+\lambda u(t)=0$, $u(0)=1$, $u'(0)=0$, and the solution is

$$u(t,\lambda)=e^{-t/2}\left(\cos \mu t+\frac{1}{2\mu}\sin \mu t\right),$$

where $\mu=(4\lambda-1)^{1/2}/2$. Differentiation shows the need to scale u', u'' by $\lambda^{-1/2}$, λ^{-1}, respectively, before taking the supremum over $\lambda \geqq 1$, in order to obtain a finite valued function of t.

Equation (1.1) is studied to establish (1.6) for more general classes of kernels in [6] and [12], with application to viscoelasticity given in [6]. The related problem of how the solution $u=u(t,\lambda)$ of (1.1) behaves as $\lambda \to \infty$ is studied in [7]. (The answer depends on whether $a'(0+)$ is finite or not. For $a(t)$ satisfying (1.2) and (1.7), $\lim_{\lambda\to\infty} u(t,\lambda)=0$ if and only if $-a'(0+)=\infty$.)

We remark that quasilinear versions of (1.4) have been under active study in recent years. See, e.g., [9] and [10] and the references therein.

In § 2 we give explicit statements of our results for (1.1). In § 3 we state applications in Hilbert space and give an example. The last two sections contain the proofs.

2. Statement of results for (1.1). Throughout this paper we assume that $d+a(t)$ satisfies (1.2). The assumptions we use to prove (1.3) involve a sufficient transform condition which then implies a (stronger) direct sufficient condition. We denote the Fourier transform of a by

$$\hat{a}(\tau)\equiv\int_0^\infty e^{-i\tau t}\,a(t)\,dt\equiv\phi(\tau)-i\tau\theta(\tau),\qquad \tau>0. \tag{2.1}$$

By Lemma 1 in [13], $\hat{a}$ is in $C^1(0,\infty)$ and by [4], ϕ and θ are nonnegative. Formally, we have

$$\hat{u}_{tt}(\tau,\lambda)=\frac{-i\tau D(\tau)}{D(\tau,\lambda)}\quad \text{for } \tau>0,\quad \lambda\geqq 1, \tag{2.2}$$

where $\hat{u}_{tt}(\tau,\lambda)\equiv\int_0^\infty e^{-i\tau t}\,u''(t,\lambda)\,dt$, and

$$D(\tau,\lambda)\equiv D(\tau)+i\tau\lambda^{-1}\equiv\hat{a}(\tau)-i\,d\tau^{-1}+i\tau\lambda^{-1}, \tag{2.3}$$

so $u''(\cdot,\lambda)$ is not in $L^1(0,\infty)$ if $D(\tau,\lambda)=0$ for some τ. By [4],

$$\phi(\tau)>0,\qquad \tau>0, \tag{2.4}$$

unless $a(t)$ is piecewise linear with changes of slope only at integral multiples of a fixed number t_0 (taken as large as possible) and τ is an integral multiple of $2\pi/t_0$. In all other cases, $D(\tau,\lambda)\neq 0$ for $\tau>0$, and Theorem 2 of [13] yields $u''(t,\lambda)$ is in $L^1(0,\infty)$ and (2.2) holds. Throughout this paper we restrict ourselves to this case by assuming (2.4). Note that (1.7) with (1.2) implies (2.4).

To give our first necessary condition for (1.3)(i), we introduce the continuous, strictly increasing function $\omega=\omega(\lambda)$, defined on some interval $[\lambda_0,\infty)$ by the formula

$$\lambda^{-1}=\theta(\omega)+d\omega^{-2}, \tag{2.5}$$

where $\omega(\lambda_0)=\rho>0$. Extend ω to $[1,\infty)$ (if $\lambda_0>1$) by defining $\omega(\lambda)=\rho$ on $[1,\lambda_0]$ (see [3]). By (2.2) and (2.5), it follows that

$$\int_0^\infty |u''(t,\lambda)|\lambda^{-1}\,dt\geqq\theta(\omega)|\hat{u}_{tt}(\omega)|\geqq\frac{\theta(\omega)\omega^2}{\lambda\phi(\omega)}\geqq\frac{\omega^2\theta^2(\omega)}{\phi(\omega)}.$$

This establishes our first result.

THEOREM 2.1. *If* (1.2) *and* (1.3)(i) *hold, then*

$$\limsup_{\tau\to\infty}\frac{(\tau\phi(\tau))^2}{\phi(\tau)}<\infty. \tag{2.6}$$

We now state our other necessary condition for (1.3)(i).

THEOREM 2.2. *If* (1.2) *and* (1.3)(i) *hold, then*

$$\int_0^1(-\log t)a(t)\,dt<\infty. \tag{2.7}$$

Define

$$C(\lambda)=\frac{[\omega^*\theta(\omega^*)]^2}{\phi(\omega^*)}, \tag{2.8}$$

where $\omega^*=\omega^*(\lambda)$ *is defined to be any number in* $[\omega/2,2\omega]$ *such that* $\phi(\omega^*)=\min_{\omega/2\leqq\tau\leqq2\omega}\phi(\tau)$.

We may now give sufficient transform conditions for (1.3)(i).

THEOREM 2.3. (i) *Suppose that* (1.2), (2.4), (2.7) *and*

$$\sup_{\lambda\geqq1}\frac{C(\lambda)}{A(\lambda/\sigma^2)}<\infty \tag{2.9}$$

are satisfied, where A *and* $\sigma=\sigma(\lambda)$ *are defined by*

$$A(x)=\int_0^x a(t)\,dt \tag{2.10}$$

and

$$\lambda^{-1}=\sigma^{-1}A(\sigma^{-1}). \tag{2.11}$$

Then $\int_0^1 w(t)\,dt<\infty$.

(ii) *Assume that* (1.2), (2.4) *and* (2.6) *are satisfied. Let* $a(t)=b(t)+c(t)$ *where* $b(t)$ *and* $c(t)$ *both satisfy the conditions stated for* $a(t)$ *in* (1.2), *except that* $b(0+)=0$ *or* $c(0+)=0$ *is permitted* (*but not both*). *Assume that*

$$\int_1^\infty\frac{b(t)}{t}\,dt<\infty \text{ and } -c' \text{ is convex.} \tag{2.12}$$

Then it follows that $\int_1^\infty w(t)\,dt<\infty$.

Combining the two parts of the above theorem and noting that (2.9) implies (2.6) yields the following result.

COROLLARY. *If* (1.2), (2.4), (2.7), (2.9) *and* (2.12) *hold, then* (1.3)(i) *holds.*

For purposes of comparison, we restate the transform conditions sufficient for (1.8)(i), (ii) to hold (see [2], [3]).

THEOREM A. *Suppose* (1.2), (2.4) *and* (2.12) *hold. Then* (1.8)(i) *holds if and only if*

$$\limsup_{\tau\to\infty}\frac{\phi(\tau)}{\phi(\tau)}<\infty. \tag{2.13}$$

THEOREM B. *Suppose* (1.2), (2.4) *and* (2.12) *hold.*

(i) *Then* (1.8)(ii) *implies that*

$$\limsup_{\tau\to\infty}\frac{\tau\theta(\tau)^{3/2}}{\phi(\tau)}<\infty. \tag{2.14}$$

(ii) *Then*

$$\limsup_{\tau\to\infty}\frac{\tau\theta(\tau)^{3/2-\varepsilon}}{\phi(\tau)}<\infty \quad \textit{for some } \varepsilon>0, \quad 0<\varepsilon<\frac{1}{2}, \tag{2.15}$$

implies that (1.8)(ii) *holds.*

Note that (2.9)→(2.6)→(2.14)→(2.13), and none of these implications may be reversed. See [3] for all but one of these facts; the fact that (2.9)→(2.6) may not be reversed is contained in [11]. Also, note that $\lim_{\lambda\to\infty}\sigma^2/\lambda = a(0+)$, by (2.11), therefore (2.6) and (2.9) are equivalent when $a(0+)<\infty$.

Although the direct conditions in Theorem 2.4(ii) and Theorem 2.5 below are slightly stronger than the transform conditions in Theorem 2.4(i) and the above corollary, they are generally much easier to check.

THEOREM 2.4. (i) *Suppose that* (1.2), (2.4) *and* (2.6) *hold. Then* (1.3)(ii) *holds.*

(ii) *Suppose that* (1.2) *and* (1.7) *hold. Then* (1.3)(ii) *holds.*

Define the functions

$$B(x)=\int_0^x -sa'(s)\,ds, \qquad x>0, \tag{2.16}$$

and

$$A_1(x)=\int_0^x sa(s)\,ds, \qquad x>0. \tag{2.17}$$

THEOREM 2.5. *Assume that* (1.2) *and* (1.7) *are satisfied.*

(a) *If* $a(0+)<\infty$, *then* (1.3)(i) *holds.*

(b) *If in addition* (2.7) *and any one of the following holds*:

(i) *There exist constants* $c_1, c_2>0$ *such that*

$$c_1\tau A_1(\tau^{-1})\leqq B(\tau^{-1})\leqq c_2\tau A_1(\tau^{-1}), \qquad \rho/2\leqq\tau, \tag{2.18}$$

(ii)

$$\lim_{\tau\to\infty}\frac{\tau A_1(\tau^{-1})}{A(\tau^{-1})}=0, \tag{2.19}$$

(iii)

$$\lim_{\tau\to\infty}\frac{B(\tau^{-1})}{A(\tau^{-1})}=0, \frac{a^2(t)}{-a'(t)} \textit{ is increasing for small } t, \textit{ and}$$

$$\int_0^{\varepsilon}\frac{a^2(t)}{-ta'(t)}\,dt<\infty \quad \textit{for some } \varepsilon>0,$$

(iv)

$$\lim_{\tau\to\infty}\frac{B(\tau^{-1})}{A(\tau^{-1})}=0 \quad \textit{and} \quad \frac{\tau A^3(\tau^{-1})}{B(\tau^{-1})}\leqq M<\infty \quad \textit{for } \rho/2\leqq\tau,$$

then (1.3)(i) *follows.*

The four cases in part (b) say roughly this about $\hat{a}(\tau)$: (i) Re $\hat{a}$ and Im $\hat{a}$ have the same order of magnitude as $\tau\to\infty$; (ii) Im $\hat{a}(\tau)$ is smaller than Re $\hat{a}(\tau)$ as $\tau\to\infty$; (iii) and (iv) Re $\hat{a}(\tau)$ is smaller than Im $\hat{a}(\tau)$ as $\tau\to\infty$. This is shown in the discussion preceding the proof of Theorem 2.5. An easy calculation shows that if $a(t)=t^{-p}$, $0<p<1$, then (b)(i) applies. If $a(t)=t^{-1}(-\log t)^{-q}$ (small t), $q>2$, then (b)(ii) applies. If $a(t)=(-\log t)$ (small t), then both (b)(iii) and (iv) apply.

The kernel

$$a(t)=\sum_{k=0}^{\infty} a_k(x_k-t)^2 X_{[0,x_k)}(t),$$

with $a_k=2^{11\times 2^{2k}}$, $x_k=2^{-4\times 2^{2k}}$, $k=0,1,2,\cdots$, is an example satisfying (1.2), (1.7) (and therefore (2.6) by Lemma 2.2(iii) of [1]) and (2.7), but neither Theorem 2.5 nor the corollary to Theorem 2.3 applies. However a modification of the proof of Theorem 2.3 shows that (1.3)(i) holds with this example (see [11]).

We close this section with the following.

CONJECTURE. Assume that (1.2), (1.7) and (2.7) are satisfied. Then (1.3)(i) holds.

3. Results in a Hilbert space. In this section, we shall see that the operator $W(t)=\int_0^\infty u''(t,\lambda)\,dE_\lambda$ may be used to solve a variant of (1.4) when (1.3)(i) holds. Then we will discuss an example of a weakly nonlinear problem where the behavior of the solution can be studied if (1.3)(i) holds.

We begin with the relation between W, V and U.

THEOREM 3.1. *Suppose* (1.2) *and* (2.6) *hold. Then for* $t>0$, $W(t)L^{-1}$ *is a bounded operator on* H *which is strongly continuous on* $(0,\infty)$. *Moreover,*

$$W(t)y=\frac{d}{dt}V(t)y=\frac{d^2}{dt^2}U(t)y, \qquad t\geqq 0, \quad y\in D.$$

Now consider the following variant of (1.4):

$$z'(t)+\int_0^t (d+a(t-s))[Lz(s)+g(s)]\,ds=f(t), \qquad t\geqq 0, \quad z(0)=z_0, \tag{3.1}$$

where $z_0\in D, f\in C([0,\infty);H)$ with $f(t)\in D(t\geqq 0)$, $Lf\in B^1_{\mathrm{loc}}([0,\infty);H)$ and $g\in B^\infty_{\mathrm{loc}}([0,\infty);D)$.

THEOREM 3.2. *Assume that* z_0, f *and* g *are as above. If* (1.3)(i) *holds, then the function* $z=z(t)$ *given by*

$$z(t)=\int_0^t W(t-s)L^{-1}G(s)\,ds \qquad \left(G(s)\equiv\int_0^s g(x)\,dx\right)$$

is the unique solution of (3.1).

The proofs of these theorems are analogous to those given in [3] and will therefore be omitted. The results of Carr and Hannsgen concerning weakly nonlinear problems also hold in the present setting. We illustrate this with a simple example.

Consider the solution $U=U(t,x)$ of

$$\begin{aligned} &U_t(x,t)+\int_0^t (d+a(t-s))(U_{xx}(s,x)+U^2(s,x)\alpha(s))\,ds=F(t,x),\\ &U(t,0)=U(t,\pi)=0, \quad t\geqq 0, \quad U(0,x)=U_0(x), \end{aligned} \tag{3.2}$$

where $\alpha\in L^1_{\mathrm{loc}}[0,\infty)$ and $\left|\int_0^t \alpha(s)\,ds\right|\leqq M<\infty$ for some M independent of $t>0$. If

$$\int_0^\pi U_0^2(x)+U_0''^2(x)\,dx<\infty$$

and one of the two quantities

$$\int_0^\infty\left\{\int_0^\pi |F(t,x)|^2\,dx\right\}^{1/2}dt, \qquad \operatorname*{ess\,sup}_{0<t<\infty}\int_0^\pi |F(t,x)|^2\,dx,$$

are sufficiently small, then (3.2) has a unique solution U such that

$$\operatorname*{ess\,sup}_{0<t<\infty} \int_0^\pi U^2(t,x)+U_{xx}^2(t,x)\,dx<\infty.$$

The details are worked out in the same way as those in the example given in [3] and therefore will be omitted here.

4. Proofs. For the remainder of the paper M will denote a positive constant whose exact value may change each time it appears.

Proof of Theorem 2.2. If we make a change of variable in the integrand of (1.1) and then differentiate the result we obtain

$$-u''(t)\lambda^{-1}=a(t)+du(t)+\int_0^t a(\tau)u'(t-\tau)\,d\tau, \qquad t>0. \tag{4.1}$$

The next lemma gives an important estimate on the integral term in (4.1).

LEMMA 4.1. *Suppose that* (1.2) *and* (2.4) *hold. Then there exist constants* $N_1, N_2>0$ *such that*

$$N_1\frac{\sigma^2}{\lambda}\leqq\sup_{t>0}\left|\int_0^t u'(t-\tau)a(\tau)\,d\tau\right|\leqq N_2\frac{\sigma^2}{\lambda}, \qquad \lambda\geqq 1. \tag{4.2}$$

The proof of the lemma relies on [3, Thm. 2.2] which says that, under the assumptions (1.4) and (2.4),

$$\frac{1}{k}\sigma\leqq\sup_{t>0}|u_t(t,\lambda)|\leqq k\sigma, \qquad \lambda\geqq 1, \tag{4.3}$$

holds for some constant k. The proof of (4.3) also contains the inequality

$$u(t,\lambda)\geqq\frac{1}{2} \quad \text{for } 0\leqq t\leqq\frac{1}{2\sigma(8+dC_2)}\equiv 2T, \tag{4.4}$$

where C_2 is a positive constant. In [5] it was shown that (1.2) implies

$$|u(t,\lambda)|\leqq 1, \qquad t\geqq 0, \quad \lambda\geqq 1. \tag{4.5}$$

If $t\leqq 1/\sigma$, use (4.2) and (2.11) to obtain

$$\left|\int_0^t u'(t-\tau)a(\tau)\,d\tau\right|\leqq M\sigma A(t)\leqq M\sigma A(\sigma^{-1})=M\sigma^2/\lambda. \tag{4.6}$$

If $1/\sigma<t$, we use (4.6), (2.11) and (4.5) to obtain

$$\begin{aligned}\left|\int_0^t u'(t-\tau)a(\tau)\,d\tau\right| &\leqq M\sigma^2/\lambda+\left|\int_{1/\sigma}^t u'(t-\tau)a(\tau)\,d\tau\right| \\ &= M\sigma^2/\lambda+\left|-a(t)+a(\sigma^{-1})u(t-\sigma^{-1})+\int_{1/\sigma}^t a'(\tau)u(t-\tau)\,d\tau\right| \\ &\leqq M\sigma^2/\lambda+2a(\sigma^{-1})\leqq M\sigma^2/\lambda.\end{aligned}$$

Taken with (4.6), we have shown that the second inequality in (4.2) holds. For the other inequality, we will need the inequality

$$2^{-3/2}A(\tau^{-1})\leqq|\hat{a}(\tau)|\leqq 4a(\tau^{-1}), \qquad \tau>0, \tag{4.7}$$

which is established in [13]. Now we let $T \leqq t \leqq 2T$, and use (1.1), (4.4) and (4.7) to obtain

$$\begin{aligned}\left|\int_0^t u'(t-\tau)a(\tau)\,d\tau\right| &= \left|\lambda \int_0^t \int_0^\tau u(\tau-s)a(s)\,ds\,a(t-\tau)\,d\tau\right| \\ &\geqq \frac{\lambda}{2}\int_{t/2}^t a(t-\tau)\int_0^t a(s)\,ds\,d\tau \\ &\geqq \frac{\lambda}{2}\left[\int_0^{T/2} a(s)\,ds\right]^2 \\ &\geqq M\lambda\left[\int_0^{1/\sigma} a(s)\,ds\right]^2 = M\sigma^2/\lambda,\end{aligned} \tag{4.8}$$

where the last inequality follows by a change of variables and (1.2). This proves the lemma.

To prove Theorem 2.2, we use (1.2), (4.5), the definition of $w(t)$ and (4.1) to observe that $\int_0^1 w(t)\,dt < \infty$ if and only if

$$\int_0^1 \sup_{\lambda \geqq 1}\left|\int_0^t a(\tau)u'(t-\tau)\,d\tau\right| dt < \infty.$$

By (4.8), it follows that

$$\begin{aligned}\left|\int_0^t a(\tau)u'(t-\tau)\,d\tau\right| &\geqq M\sigma^2/\lambda = M\sigma\int_0^{1/\sigma} a(s)\,ds \\ &\geqq \frac{M}{4(8+dC_2)t}\int_0^{2t(8+dC_2)} a(s)\,ds \\ &\geqq \frac{M}{t}\int_0^t a(s)\,ds\end{aligned}$$

for $T \leqq t \leqq 2T$. By (2.11), it follows that $\sigma \to \infty$ as $\lambda \to \infty$, and then $T \to 0$ as $\lambda \to \infty$. Therefore, for each t in $(0, \varepsilon)$ (for some $\varepsilon > 0$), there exists T with $T \leqq t \leqq 2T$. Thus the inequality $\int_0^1 w(t)\,dt < \infty$ implies that $\int_0^\varepsilon t^{-1}\int_0^t a(s)\,ds\,dt < \infty$, and then we have

$$\infty > \int_0^1 t^{-1}\int_0^t a(s)\,ds\,dt = \int_0^1 -\log sa(s)\,ds.$$

This completes the proof of Theorem 2.2.

Proof of Theorem 2.3. Except for minor details, the proof of (ii) is the same as the corresponding proofs in [2] and [3] and we will therefore not give it here. (The proof is given in [11].)

To prove (i), we will need the inequalities

$$\omega \leqq C_1\sigma, \quad \lambda \leqq C_2\sigma^2, \quad \lambda \geqq 1, \quad C_1, C_2 > 0 \quad (C_1 > 12), \tag{4.9}$$

from [3], which hold when $a(\cdot)$ satisfies (1.2). (Recall that ω is defined in (2.5).) We will also use the inequality

$$\int_0^{kx} a(s)\,ds \geqq k\int_0^x a(s)\,ds, \qquad 0 < k < 1, \quad 0 < x < \infty, \tag{4.10}$$

which follows by (1.2) and a change of variables. Finally, we will need the next lemma which will be used for Theorem 2.4 as well. We defer the proof to § 5.

LEMMA 4.2. *Under the assumptions* (1.2) *and* (2.4), *it follows that*

$$|u_{tt}(t,\lambda)\lambda^{-1}| \leqq Mt^{-1}(\sigma/\lambda + C(\lambda)) \quad \text{for } \lambda \geqq 1, \quad t > 0. \tag{4.11}$$

Now we partition $S \equiv \{(t,\lambda): t \geqq 0, \lambda \geqq 1\}$ into $S_1 \cup S_2$ where $S_1 \equiv S \cap \{(t,\lambda): \sigma^2/\lambda \leqq a(t)\}$ and $S_2 \equiv S \cap \{(t,\lambda): \sigma^2/\lambda > a(t)\}$. On S_1, we use (4.1), (4.2) and (4.5) to obtain

$$|u_{tt}(t,\lambda)\lambda^{-1}| \leqq a(t) + d + M\sigma^2/\lambda \leqq (1+M)a(t) + d \in L^1(0,1).$$

On S_2, we use (4.1), (4.2), (4.5) and (4.9) to obtain

$$|u_{tt}(t,\lambda)\lambda^{-1}| \leqq a(t) + d + M\sigma^2/\lambda \leqq (M+1+C_2 d)\sigma^2/\lambda.$$

Now partition S_2 into $S_2 = S_3 \cup S_4$ where

$$S_3 \equiv \{(t,\lambda): |u_{tt}(t,\lambda)\lambda^{-1}| \leqq t^{-1/2}\} \cap S_2,$$

and

$$S_4 \equiv \{(t,\lambda): t^{-1/2} < |u_{tt}(t,\lambda)\lambda^{-1}|\} \cap S_2.$$

On S_3, $|u_{tt}(t,\lambda)\lambda^{-1}| \leqq t^{-1/2} \in L^1(0,1)$. On S_4, we use (4.11) to observe that

$$t^{-1/2} < |u_{tt}(t,\lambda)\lambda^{-1}| \leqq \frac{M}{t}(C(\lambda) + \sigma/\lambda).$$

Thus, on S_4 we have

$$\frac{t}{\sigma/\lambda + C(\lambda)} \leqq Mt^{1/2} \quad \text{and} \quad |u_{tt}(t,\lambda)\lambda^{-1}| \leqq M\sigma^2/\lambda. \tag{4.12}$$

Define $h(x) = xA(x^{-1})$ and $g(x) = 1/A(x^{-1})$. Clearly $g(x)$ is nondecreasing. To see that $h(x)$ is nondecreasing, we write

$$h'(x) = A(x^{-1}) - x^{-1}a(x^{-1}) \geqq 0.$$

Thus, on S_4 it follows that

$$\begin{aligned} |u_{tt}(t,\lambda)\lambda^{-1}| &= h(|u_{tt}(t,\lambda)|\lambda^{-1})g(|u_{tt}(t,\lambda)|\lambda^{-1}) \\ &\leqq h\left(\frac{M}{t}(C(\lambda)+\sigma/\lambda)\right) g(M\sigma^2/\lambda) \\ &\leqq \frac{M(C(\lambda)+\sigma/\lambda)A(t^{1/2})}{A(\lambda/\sigma^2)t} \\ &\leqq \frac{M}{t}A(t^{1/2}) \in L^1(0,1), \end{aligned}$$

where the first inequality follows from (4.11), (4.12) and monotonicity, the second inequality is a consequence of (4.12) and (4.10), the last inequality follows from (2.9) and the estimate,

$$\frac{\sigma/\lambda}{A(\lambda/\sigma^2)} = \frac{A(\sigma^{-1})}{A(\sigma^{-1}\lambda/\sigma)} \leqq \frac{A(\sigma^{-1})}{A(M\sigma^{-1})} \leqq M \tag{4.13}$$

(we use (4.10) and (4.11) to obtain (4.13)) and a simple calculation using (2.7) shows that $t^{-1}A(t^{1/2}) \in L^1(0,1)$. This proves Theorem 2.3.

Proof of Theorem 2.4. Theorem 2.4(i) follows immediately from Lemma 4.2 because $\sigma/\lambda = A(\sigma^{-1})$ is bounded. In [14], Staffans proved that for $a \in L^1(0,\infty)$, (1.2) and (1.7) imply (2.6). In his thesis [1], Carr relaxed this showing that (1.2) and (1.7) imply (2.6). This result, along with Theorem 2.4(i), proves Theorem 2.4(ii).

Discussion and proof of Theorem 2.5. Before proving Theorem 2.5 we give a preliminary estimate and make some comments. To do this we will need the following inequalities: Assuming (1.2) and (1.7), it then follows that

$$CB(\tau^{-1}) \leqq \phi(\tau) \leqq KB(\tau^{-1}), \qquad \tau > 0, \tag{4.14}$$

where C, K are positive constants. Assuming (1.2), it then follows that

$$\text{(i)}\quad \tfrac{1}{5}A_1(\omega^{-1}) \leqq \lambda^{-1} \leqq C_1 A_1(\omega^{-1}), \qquad \lambda \geqq 1, \tag{4.15}$$

$$\text{(ii)}\quad \tfrac{1}{5}A_1(\tau^{-1}) \leqq \theta(\tau) \leqq 12A_1(\tau^{-1}), \qquad \tau > 0.$$

The inequalities (4.14) and (4.15) are shown in [7] and [3], respectively.

In the following we assume that (1.2) and (1.7) are satisfied. Using (4.7), (4.15) and (4.14) we obtain

$$\begin{aligned} 8^{-1}A^2(\tau^{-1}) \leqq |\hat{a}(\tau)|^2 = \phi^2(\tau) + \tau^2\theta^2(\tau) &\leqq (12B(\tau^{-1}))^2 + \tau^2(12A_1(\tau^{-1}))^2 \\ &\leqq 144(B(\tau^{-1}) + \tau A_1(\tau^{-1}))^2. \end{aligned}$$

Hence,

$$2^{-3/2}A(\tau^{-1}) \leqq 12(B(\tau^{-1}) + \tau A_1(\tau^{-1})).$$

Also, we have

$$\begin{aligned} (4A(\tau^{-1}))^2 \geqq |\hat{a}(t)|^2 = \phi^2(\tau) + \tau^2\theta^2(\tau) &\geqq (5^{-1}B(\tau^{-1}))^2 + \tau^2(5^{-1}A_1(\tau^{-1}))^2 \\ &\geqq 50^{-1}(B(\tau^{-1}) + \tau A_1(\tau^{-1}))^2. \end{aligned}$$

Hence,

$$4A(\tau^{-1}) \geqq 50^{-1/2}(B(\tau^{-1}) + \pi A_1(\tau^{-1})).$$

Combining these into one inequality yields

$$A(\tau^{-1}) \leqq (1152)^{1/2}(B(\tau^{-1}) + A_1(\tau^{-1})) \leqq 960A(\tau^{-1}). \tag{4.16}$$

In view of (4.7), (4.14) and (4.15), the behavior of $|\hat{a}(\tau)|$, $\phi(\tau) = \operatorname{Re}\hat{a}(\tau)$ and $\tau\theta(\tau) = |\operatorname{Im}\hat{a}(\tau)|$, as $\tau \to \infty$, is like that of $A(\tau^{-1})$, $B(\tau^{-1})$ and $\tau A_1(\tau^{-1})$, respectively.

In view of (4.16), condition (i) in Theorem 2.5(b) corresponds to the case where $|\hat{a}(\tau)|$, $\operatorname{Re}\hat{a}(\tau)$ and $|\operatorname{Im}\hat{a}(\tau)|$ have the same order as $\tau \to \infty$. Theorem 2.5(b)(ii) corresponds to the case where $|\operatorname{Im}\hat{a}(\tau)|$ is small compared to $|\hat{a}(\tau)|$ as $\tau \to \infty$, $|\hat{a}(\tau)|$ and $\operatorname{Re}\hat{a}(\tau)$ having the same order as $\tau \to \infty$. Theorem 2.5(b)(iii) and (iv) are both in the case where $|\operatorname{Im}\hat{a}(\tau)|$ and $|\hat{a}(\tau)|$ have the same order as $\tau \to \infty$ and $\operatorname{Re}\hat{a}(\tau)$ is small by comparison, as $\tau \to \infty$. To treat this case the additional assumptions $a^2(t)/-a'(t)$ is increasing for small t and $a^2(t)/-ta'(t) \in L^1(0,\varepsilon)$ for some ε are made in (iii), and in (iv) the extra assumption we use is $\omega A^3(\omega^{-1})/B(\omega^{-1}) < \infty$ for ω in $(\rho/2,\infty)$.

For the proof of Theorem 2.5(a), we differentiate (1.1), multiply both sides by λ^{-1} and estimate using (4.5) to obtain

$$\begin{aligned} |u_{tt}(t,\lambda)\lambda^{-1}| &\leqq (d + a(0+))|u(t,\lambda)| + \int_0^t -a'(t-\tau)|u(\tau,\lambda)|\,d\tau \\ &\leqq d + 2a(0+). \end{aligned}$$

To complete the proof, we use this bound on $(0, 1)$ and Theorem 2.3(ii) with the fact, mentioned above, that (1.2) and (1.7) imply (2.6).

Let us turn to the proof of (b). By (2.11), (4.9), (4.15) and (4.10), there exists a constant K such that

$$\frac{1}{\sigma}=\frac{1}{\lambda A(\sigma^{-1})_-}\leqq\frac{A_1(\omega^{-1})}{5A(\sigma^{-1})}\geqq\frac{KA_1(\omega^{-1})}{A(\omega^{-1})}. \tag{4.17}$$

In case (i), use (4.16), (4.17) and (2.18) to obtain

$$\frac{1}{\sigma}\geqq\frac{KA_1(\omega^{-1})}{A(\omega^{-1})}\geqq\frac{MA_1(\omega^{-1})}{B(\omega^{-1})+\omega A_1(\omega^{-1})}\geqq\frac{MA_1(\omega^{-1})}{\omega A_1(\omega^{-1})}=\frac{M}{\omega}. \tag{4.18}$$

Partition the set $S\equiv\{(t,\lambda)\colon 0\leqq t\leqq 1,\ \lambda\geqq 1\}$ into

$$S_1\equiv S\cap\{(t,\lambda)\colon t\leqq\sigma^{-1}\}\quad\text{and}\quad S_2\equiv S\cap\{(t,\lambda)\colon t>\sigma^{-1}\}.$$

For (t,λ) in S_1 use (4.1), (4.3), (4.5) and (2.7) to make the estimate

$$|u_{tt}(t,\lambda)\lambda^{-1}|\leqq a(t)+d+K\sigma\int_0^t a(\tau)\,d\tau\leqq a(t)+d+t^{-1}\int_0^t a(\tau)\,d\tau\in L^1(0,1).$$

For (t,λ) in S_2, we use (4.11), (4.14) and (4.15) to obtain

$$\begin{aligned}|u_{tt}(t,\lambda)\lambda^{-1}|&\leqq\frac{M}{t}\left(\frac{\sigma}{\lambda}+C(\lambda)\right)\leqq\frac{M}{t}\left(A(\sigma^{-1})+\frac{[\omega^*A_1(\omega^{*-1})]^2}{B(\omega^{*-1})}\right)\\&\equiv\frac{M}{t}(I_1+I_2).\end{aligned}$$

By the definition of S_2 and by (2.7), it follows that

$$t^{-1}I_1\leqq t^{-1}\int_0^t a(s)\,ds\in L^1(0,1).$$

By (4.7), (2.18), (2.7), (4.10) and (4.18), it follows that

$$\begin{aligned}t^{-1}I_2&\leqq M\omega^*A_1(\omega^{*-1})\leqq Mt^{-1}A(2\omega^{-1})\leqq Mt^{-1}A(\sigma^{-1})\\&\leqq Mt^{-1}A(t)\in L^1(0,1).\end{aligned}$$

Therefore $\int_0^1 w(t)\,dt<\infty$. With Theorem 2.3(ii), this completes the proof of Theorem 2.5(b)(ii).

To prove (b)(ii), we will show that (2.9) is satisfied and then Theorem 2.3(i) and (ii) yield (1.3)(i). Now we use (4.15) and (2.11) to write

$$\frac{\lambda}{\sigma^2}=\frac{1}{\lambda A^2(\sigma^{-1})}\geqq\frac{A_1(\omega^{-1})}{5A^2(\sigma^{-1})}=\omega^{-1}\frac{A_1(\omega^{-1})}{5\omega^{-1}A^2(\sigma^{-1})}\equiv\omega^{-1}L(\lambda).$$

There are two possibilities: $L(\lambda)\geqq 1$ or $L(\lambda)<1$.

For $L(\lambda)\geqq 1$, we have $A(\lambda/\sigma^2)\geqq A(\omega^{-1})$. Now we use (2.8), (4.14), (4.15), (4.16) and (2.19) to obtain

$$\begin{aligned}\frac{C(\lambda)}{A(\lambda/\sigma^2)}&\leqq\frac{M\omega^{*2}A_1^2(\omega^{*-1})}{A(\lambda/\sigma^2)B(\omega^{*-1})}\\&\leqq\frac{M\omega^{*2}A_1^2(\omega^{*-1})}{A(\omega^{-1})B(\omega^{*-1})}\\&=M\left(\frac{\omega^*A_1(\omega^{*-1})}{A(\omega^{*-1})}\right)\left(\frac{\omega^*A_1(\omega^{*-1})}{B(\omega^{*-1})}\right)\leqq M.\end{aligned}$$

We have shown that

$$\sup_{L(\lambda)\geqq 1}\frac{C(\lambda)}{A(\lambda/\sigma^2)}<\infty.$$

For $L(\lambda)<1$, (4.10) implies that

$$A(\lambda/\sigma^2)\geqq A(\omega^{-1}L(\lambda))\geqq L(\lambda)A(\omega^{-1});$$

then (4.16), (4.9) and (4.10) yield

$$\begin{aligned}\frac{\omega^{*2}A_1^2(\omega^{*-1})}{B(\omega^{*-1})A(\lambda/\sigma^2)}&\leqq\frac{\omega^{*2}A_1^2(\omega^{*-1})}{B(\omega^{*-1})A(\omega^{-1})L(\lambda)}\\&=\frac{5\omega^{*2}A_1^2(\omega^{*-1})\omega^{-1}A^2(\sigma^{-1})}{B(\omega^{*-1})A(\omega^{-1})A_1(\omega^{-1})}\\&\leqq\frac{M\omega A_1^2(\omega^{-1})A^2(\omega^{-1})}{B(\omega^{-1})A(\omega^{-1})A_1(\omega^{-1})}\\&\leqq M\omega A_1(\omega^{-1})\leqq M,\end{aligned}$$

where we have used the following easily obtained inequalities:

$$A_1(2x)\leqq 4A_1(x)\quad\text{and}\quad B(2x)\leqq 4B(x),\quad x>0. \tag{4.19}$$

This shows that

$$\sup_{L(\lambda)<1}\frac{C(\lambda)}{A(\lambda/\sigma^2)}<\infty,$$

which establishes (2.9) and finishes the proof.

To prove (iii) we use (4.16), (4.17) and the assumption of (iii) to obtain

$$\sigma^{-1}\geqq\frac{KA_1(\omega^{-1})}{A(\omega^{-1})}\geqq\frac{M\omega^{-1}A(\omega^{-1})}{A(\omega^{-1})}=M\omega^{-1}. \tag{4.20}$$

Thus $\sigma^{-1}\geqq M\omega^{-1}$ as in (4.18) and the rest of the proof follows exactly as in the lines following (4.18) except for the term $t^{-1}I_2$ which we shall treat next. By (4.19) and integration by parts, we have

$$\begin{aligned}t^{-1}I_2&\leqq Mt^{-1}\frac{\omega^{*2}A_1^2(\omega^{*-1})}{B(\omega^{-1})}\leqq Mt^{-1}\frac{\omega^2A_1^2(\omega^{-1})}{B(\omega^{-1})}\\&=\frac{Mt^{-1}\omega^2}{2B(\omega^{-1})}\left(\omega^{-2}a(\omega^{-1})+\int_0^{\omega^{-1}}-s^2a'(s)\,ds\right)^2\\&\leqq Mt^{-1}\left(\frac{a^2(\omega^{-1})}{\omega^2B(\omega^{-1})}+\frac{\omega^2\left(\int_0^{\omega^{-1}}-s^2a'(s)\,ds\right)^2}{B(\omega^{-1})}\right)\\&\equiv Mt^{-1}(J_1+J_2).\end{aligned}$$

By definition of S_2, (4.20) and assumption (iii), we have

$$\begin{aligned}t^{-1}J_1&\leqq M\frac{a^2(\omega^{-1})}{-ta'(\omega^{-1})}\\&\leqq\frac{Ma^2(M_1t)}{-ta'(M_1t)}\in L^1\left(0,\frac{\varepsilon}{M_1}\right)\quad(\text{some } M_1>0).\end{aligned}$$

Also,

$$\begin{aligned} t^{-1}J_2 &\leqq \frac{M\omega^2 \int_0^{\omega^{-1}} -sa'(s)\,ds \int_0^{\omega^{-1}} -s^3a'(s)\,ds}{tB(\omega^{-1})} \\ &= \frac{M\omega^2 \int_0^{\omega^{-1}} -s^3a'(s)\,ds}{t} \\ &\leqq Mt^{-1}\int_0^{\omega^{-1}} -sa'(s)\,ds \\ &\leqq Mt^{-1}\int_0^{t} -sa'(s)\,ds \\ &\leqq Mt^{-1}A(t) \in L^1(0,1), \end{aligned}$$

where we have used the Cauchy-Schwarz inequality, the definition of S_2 (4.20), (4.19) and (2.7). Note that on $[\varepsilon/M_1, 1]$, (4.1) can be used to show that

$$|u_{tt}(t,\lambda)\lambda^{-1}| \leqq a(\varepsilon/M_1) + d + 2a(\varepsilon/M_1) \leqq M.$$

Together with Theorem 2.3, this finishes the proof of (iii).

To prove (iv), we will show that (2.9) holds and then Theorem 2.3 applies, finishing the proof. To do this use (4.15), (2.11), (4.9), (4.14), (4.16), (4.10) and (4.19) to obtain

$$\begin{aligned} \frac{\omega^{*2}\theta^2(\omega^*)}{\theta(\omega^*)A(\lambda/\sigma^2)} &\leqq \frac{\omega^{*2}A_1^2(\omega^{*-1})}{B(\omega^{*-1})A(\lambda/\sigma^2)} \leqq \frac{MA^2(\omega^{*-1})}{B(\omega^{*-1})A(\lambda/\sigma^2)} \\ &\leqq \frac{MA^2(\omega^{-1})}{B(\omega^{-1})\lambda/\sigma^2 A(1)} \leqq \frac{MA^2(\omega^{-1})A^2(\sigma^{-1})}{B(\omega^{-1})A_1(\omega^{-1})} \\ &\leqq \frac{MA^4(\omega^{-1})}{B(\omega^{-1})A_1(\omega^{-1})} \leqq \frac{M\omega A^3(\omega^{-1})}{B(\omega^{-1})} \\ &\leqq \frac{M\omega A^3(\omega^{-1})}{B(\omega^{-1})} \leqq M. \end{aligned}$$

This finishes the proof of Theorem 2.5.

5. Proof of Lemma 4.2. When (1.2) and (2.4) hold, we have the inversion formula

$$\pi u_{tt}(t,\lambda) = \operatorname{Re}\frac{1}{t\lambda}\int_0^\infty e^{i\tau t}\left(\frac{i\tau^2 D'(\tau) + \lambda D(\tau)^2}{D(\tau,\lambda)^2}\right) d\tau, \qquad t \geqq 0, \quad \lambda \geqq 1, \tag{5.1}$$

where the integral is absolutely convergent at both $\tau = 0$ and $\tau = \infty$. This was established in [11]. Thus, we have that

$$|u_{tt}(t,\lambda)\lambda^{-1}| \leqq \frac{1}{t\lambda^2}\int_0^\infty \left|\frac{\tau^2 D'(\tau)}{D(\tau,\lambda)^2}\right| + \left|\frac{\lambda D(\tau)^2}{D(\tau,\lambda)^2}\right| d\tau. \tag{5.2}$$

But, (5.19) and (5.21) of [3] and Lemma 1 of [13] imply that

$$|D(\tau,\lambda)| \geqq \max\left\{\phi(\tau), \frac{d-\tau^2}{\tau}\right\} \geqq \frac{1}{M\tau}, \qquad 0 < \tau \leqq \rho, \quad d > 0, \tag{5.3}$$

$$|D(\tau,\lambda)| \geqq \max\{2^{-3/2}A(\tau^{-1}) - \tau, \phi(\tau)\} \geqq M, \qquad 0 < \tau \leqq \rho, \quad d = 0, \tag{5.4}$$

and

$$|\hat{a}'(\tau)| \leqq 40A_1(\tau^{-1}), \qquad \tau > 0. \tag{5.5}$$

We use (5.3) and (5.5) to obtain (for $d > 0$)

$$\begin{aligned}\int_0^\rho \left|\frac{D(\tau)}{D(\tau,\lambda)}\right|^2 d\tau &= \int_0^\rho \left|1-\frac{i\tau}{\lambda D(\tau,\lambda)}\right|^2 d\tau \\ &\leqq \int_0^\rho 2+\frac{2\tau^2}{\lambda^2|D(\tau,\lambda)|^2}\, d\tau \\ &\leqq 2\rho+\frac{M}{\lambda^2}\int_0^\rho \frac{\tau^2}{\tau^{-2}}\, d\tau \leqq M\end{aligned}$$

and

$$\int_0^\rho \left|\frac{\tau^2 D'(\tau)}{D(\tau,\lambda)^2}\right| d\tau \leqq M\int_0^\rho \frac{\tau^2(\tau^{-2})}{\tau^{-2}}\, d\tau \leqq M.$$

When $d = 0$, we use (5.4) to obtain

$$\int_0^\rho \left|\frac{D(\tau)}{D(\tau,\lambda)}\right|^2 d\tau \leqq \int_0^\rho 2+\frac{2\tau^2}{\lambda^2|D(\tau,\lambda)|^2}\, d\tau \leqq 2\rho+\frac{M}{\lambda^2}\int_0^\rho \tau^2\, d\tau \leqq M.$$

Also,

$$\int_0^\rho \left|\frac{\tau^2 D'(\tau)}{D(\tau,\lambda)^2}\right| d\tau \leqq M\int_0^\rho \frac{\tau A(\tau^{-1})\, d\tau}{(\max\{2^{-3/2}A(\tau^{-1})-\tau,\, \phi(\tau)\})^2} \leqq M,$$

where we have used

$$\lim_{\tau\to 0} \tau A(\tau^{-1}) = 0$$

and

$$0 < 8^{-1}\left(\int_0^\infty a(s)\, ds\right)^2 = \lim_{\tau\to 0+} (2^{-3/2}A(\tau^{-1})-\tau)^2 \leqq \infty.$$

Therefore, we have

$$\frac{1}{\lambda^2 t}\int_0^\rho \left|\frac{\tau^2 D'(\tau)}{D(\tau,\lambda)^2}\right| + \left|\frac{\lambda D^2(\tau)}{D(\tau,\lambda)^2}\right| d\tau \leqq Mt^{-1}\sigma/\lambda. \tag{5.6}$$

For our estimates on (ρ, ∞) we will need the inequalities

$$\tau\lambda^{-1} \leqq M|D(\tau,\lambda)|, \qquad 2\omega \leqq \tau < \infty, \tag{5.7}$$

$$A(\tau^{-1}) \leqq M|D(\tau,\lambda)|, \qquad \rho/2 \leqq \tau \leqq \omega/2, \quad 2\omega \leqq \tau < \infty, \tag{5.8}$$

$$\lambda \leqq M\omega^2, \qquad \lambda \geqq 1, \tag{5.9}$$

$$MA(\tau^{-1}) \leqq \phi(\omega^*)+\omega^*\theta(\omega^*), \qquad \omega/2 \leqq \tau \leqq 2\omega, \tag{5.10}$$

$$\phi^2(\tau)+\frac{|\tau-\omega|^2}{\lambda^2} \leqq M|D(\tau,\lambda)|^2, \qquad \tau \leqq \rho/2, \tag{5.11}$$

which are contained in [3].

First we use (5.7), (2.11), (4.10), (5.5) and the Fubini theorem to obtain

$$\int_{2C_1\sigma}^{\infty} \left|\frac{\tau^2 D'(\tau)}{D(\tau,\lambda)^2}\right| d\tau \leqq \lambda^2 M \int_{2C_1\sigma}^{\infty} (d\tau^{-2} + A_1(\tau^{-1}))\, d\tau$$

$$\leqq \lambda^2 M \left(\sigma^{-1} + \int_{2C_1\sigma}^{\infty}\int_0^{1/\tau} sa(s)\, ds\, d\tau\right)$$

$$\leqq M\lambda^2 \left(\sigma/\lambda + \int_0^{1/2C_1\sigma} a(s)\, ds\right) \leqq M\lambda\sigma.$$

Also, by (5.7), (4.10) and (4.7), it follows that

$$\int_{2C_1\sigma}^{\infty} \left|\frac{D(\tau)}{D(\tau,\lambda)}\right|^2 d\tau \leqq M\lambda^2 \int_{2C_1\sigma}^{\infty} \frac{A^2(\tau^{-1})}{\tau^2}\, d\tau$$

$$\leqq M\lambda^2 \int_{2C_1\sigma}^{\infty} \tau^{-2}\, d\tau A^2(\sigma^{-1}/2C_1)$$

$$\leqq M\lambda^2 \sigma^{-1} A^2(\sigma^{-1}) = M\sigma.$$

Therefore, we have

$$\frac{1}{t\lambda^2}\int_{2C_1\sigma}^{\infty} \left|\frac{\tau^2 D'(\tau)}{D(\tau,\lambda)^2}\right| + \left|\frac{\lambda D(\tau)^2}{D(\tau,\lambda)^2}\right| d\tau \leqq \frac{M\sigma}{t\lambda}. \tag{5.12}$$

Next we use (5.8), (5.5), (4.10) and (2.11) to obtain

$$\lambda^{-2}\left(\int_\rho^{\omega/2} + \int_{2\omega}^{2C_1\sigma}\right) \left|\frac{\tau^2 D'(\tau)}{D(\tau,\lambda)^2}\right| d\tau \leqq M\lambda^{-2} \int_\rho^{2C_1\sigma} \frac{\tau^2(d\tau^{-2} + A_1(\tau^{-1}))}{A(\tau^{-1})^2}\, d\tau$$

$$\leqq M\lambda^{-2} \int_\rho^{2C_1\sigma} A^{-2}(\tau^{-1}) + \tau A^{-1}(\tau^{-1})\, d\tau$$

$$\leqq M\lambda^{-2}(\sigma A^{-2}(1/2C_1\sigma) + \sigma^{-2}A^{-1}(1/2C_1\sigma))$$

$$\leqq M\lambda^{-2}(\sigma A^{-2}(\sigma^{-1}) + \sigma^2 A^{-1}(\sigma^{-1}))$$

$$= M(\sigma^{-1} + \sigma/\lambda) \leqq M\sigma/\lambda,$$

where the last inequality is due to the fact that $0 < a(0+) = \lim_{\sigma\to\infty} \sigma^2/\lambda \leqq \infty$. Also, by (5.8), (4.9) and monotonicity of the function $h(x) = x/A(x^{-1})$, we have

$$\lambda^{-1}\int_\rho^{\omega/2} \left|\frac{D(\tau)}{d(\tau,\lambda)}\right|^2 d\tau \leqq \lambda^{-1}\int_\rho^{\omega/2} 2 + \frac{2\tau^2}{\lambda^2|D(\tau,\lambda)|^2}\, d\tau$$

$$\leqq \omega/\lambda + M\lambda^{-3}\int_\rho^{\omega/2} \frac{\tau^2}{A^2(\tau^{-1})}\, d\tau$$

$$\leqq M\left(\frac{\sigma}{\lambda} + \frac{\omega\sigma^2}{\lambda^3 A^2(1/2C_1\sigma)}\right)$$

$$\leqq M\left(\frac{\sigma}{\lambda} + \frac{\sigma^3}{\lambda^3 A^2(\sigma^{-1})}\right) \leqq M\sigma/\lambda.$$

Also, by (4.7), (5.8), (5.9), and (4.10), it follows that

$$\lambda^{-1}\int_{2\omega}^{2C_1\sigma}\left|\frac{D(\tau)}{D(\tau,\lambda)}\right|^2 d\tau \leqq M\lambda^{-1}\int_{2\omega}^{2C_1\sigma}\frac{(A(\tau^{-1})+d\tau^{-2})^2}{A^2(\tau^{-1})}\,d\tau$$

$$= M\lambda^{-1}\int_{2\omega}^{2C_1\sigma}\left(1+\frac{d}{\tau^2 a(\tau^{-1})}\right)^2 d\tau$$

$$\leqq M\frac{\sigma}{\lambda}\left(1+\frac{1}{\omega^2 A(\sigma^{-1})}\right)^2$$

$$\leqq M\frac{\sigma}{\lambda}(1+\sigma^{-1})^2 \leqq M\frac{\sigma}{\lambda}.$$

Thus, we have the estimate

$$\frac{1}{t\lambda^2}\left(\int_{\rho/2}^{\omega/2}+\int_{2\omega}^{2C_1\sigma}\right)\left(\left|\frac{\tau^2 D'(\tau)}{D(\tau,\lambda)^2}\right|+\left|\frac{\lambda D(\tau)^2}{D(\tau,\lambda)^2}\right|\right)d\tau \leqq \frac{M}{t}\frac{\sigma}{\lambda}. \tag{5.13}$$

On the interval $(\omega/2, 2\omega)$, we use (5.11), (5.5), (4.9), (5.10) and (4.15) to obtain

$$\lambda^{-2}\int_{\omega/2}^{2\omega}\left|\frac{\tau^2 D'(\tau)}{D(\tau,\lambda)^2}\right|d\tau \leqq M\lambda^{-2}\int_{\omega/2}^{2\omega}\frac{\tau A(\tau^{-1})\,d\tau}{\phi^2(\tau)+((\tau-\omega)/\lambda)^2}$$

$$\leqq M\int_{\omega/2}^{2\omega}\frac{\tau\,d\tau}{(\phi(\omega^*)\lambda)^2+|\tau-\omega|^2}A(2\omega^{-1})$$

$$\leqq M\int_{\omega/2}^{2\omega}\frac{\tau\,d\tau}{(\phi(\omega^*)\lambda)^2+|\tau-\omega|^2}A(2\omega^{-1})$$

$$\leqq M\omega^*\int_{\omega/2}^{2\omega}\frac{d\tau}{(\phi(\omega^*)\lambda)^2+|\tau-\omega|^2}(\phi(\omega^*)+\omega^*\theta(\omega^*))$$

$$\leqq M\frac{\omega^*(\phi(\omega^*)+\omega^*\theta(\omega^*))}{\lambda\phi(\omega^*)}$$

$$\leqq M\left(\frac{\sigma}{\lambda}+\frac{(\omega^*\theta(\omega^*))^2}{\phi(\omega^*)}\right).$$

Also, by (4.9), (5.11) and (4.15), we may write

$$\lambda^{-1}\int_{\omega/2}^{2\omega}\left|\frac{D(\tau)}{D(\tau,\lambda)}\right|^2 d\tau = \lambda^{-1}\int_{\omega/2}^{2\omega}\left|1-\frac{i\tau\lambda^{-1}}{D(\tau,\lambda)}\right|^2$$

$$\leqq 2\lambda^{-1}\int_{\omega/2}^{2\omega}1+\frac{\tau^2\lambda^{-2}}{|D(\tau,\lambda)|^2}\,d\tau$$

$$\leqq M\lambda^{-1}\int_{\omega/2}^{2\omega}1+\frac{\tau^2\lambda^{-2}}{\phi^2(\tau)+|(\tau-\omega)/\lambda|^2}\,d\tau$$

$$\leqq M\lambda^{-1}\int_{\omega/2}^{2\omega}1+\frac{\tau^2}{(\lambda\phi(\omega^*))^2+|\tau-\omega|^2}\,d\tau$$

$$\leqq M\left(\frac{\omega}{\lambda}+\frac{\omega^2}{\phi(\omega^*)\lambda^2}\right)$$

$$\leqq M\left(\frac{\sigma}{\lambda}+\frac{(\omega^*\theta(\omega^*))^2}{\phi(\omega^*)}\right).$$

These two estimates on $(\omega/2, 2\omega)$ together with (5.13), (5.12), (5.6) and (5.2) yield (4.11) (see (2.8)), thus proving Lemma 4.2.

Acknowledgment. The author thanks Professor Kenneth B. Hannsgen for many enlightening discussions on this material.

HOMOGENIZATION OF STATIONARY FLOW OF MISCIBLE FLUIDS IN A DOMAIN WITH A GRAINED BOUNDARY*

A. MIKELIĆ† AND I. AGANOVIĆ‡

Abstract. The purpose of this paper is to obtain phenomenological equations for stationary miscible displacement in a domain with a grained boundary (porous medium), with the help of homogenization of fluid mechanics equations. It is assumed that the viscosity of the mixture depends on the concentration of the solvent.

Key words. homogenization, miscible flow, porous medium

AMS(MOS) subject classifications. 35B40, 76S05

1. Introduction. In this paper we consider the homogenization of fluid mechanics equations of stationary miscible flow through a porous medium, assuming that the viscosity of the mixture depends on the concentration of the solvent.

We use the standard notation required for the homogenization method. Let $Y=]0,1[^n$, $n=2$ or 3; let $\mathcal{O}\subset Y$ be an open set strictly included in Y and locally placed on one side of its boundary $S\in C^\infty$ and $Y^*=Y\setminus\bar{\mathcal{O}}$. For $k\in Z^n$, we define $Y_k=Y+k$, $\mathcal{O}_k=\mathcal{O}+k$. Let $\Omega\subset\mathbf{R}^n$ be a bounded domain locally placed on one side of its boundary $\Gamma\in C^2$. For sufficiently small $\varepsilon>0$, we consider the sets

$$T_\varepsilon=\{k\in\mathbf{Z}^n:\ \varepsilon Y_k\subset\Omega\},\qquad K_\varepsilon=\{k\in\mathbf{Z}^n:\ \varepsilon Y_k\cap\Gamma\neq\varnothing\},$$

and define

$$\mathcal{O}_\varepsilon=\bigcup_{k\in T_\varepsilon}\varepsilon\mathcal{O}_k,\ S_\varepsilon=\partial\mathcal{O}_\varepsilon,\ \Omega_\varepsilon=\Omega\setminus\bar{\mathcal{O}}_\varepsilon.$$

Obviously, $\partial\Omega_\varepsilon=\Gamma\cup S_\varepsilon$. The domains $\mathcal{O}_\varepsilon$ and Ω_ε represent, respectively, the solid and fluid part of the porous medium Ω. We consider the Stokes flow of a mixture of two incompressible fluids in the domain Ω_ε, upon stationary diffusion of one of them (solvent) into the other.

Notation. v^ε, p^ε = the velocity and the pressure of the mixture, respectively; s^ε = the concentration of the solvent; $\varepsilon^2\mu(s^\varepsilon)$ = the viscosity of the mixture; f = the density of the external body force; $d=\text{const}>0$ = the diffusion coefficient of the mixture.

Taking into account the simplest model of diffusion, for the velocity, the pressure and the concentration we have the following equations and boundary conditions (e.g., [6]):

$$-\nabla p^\varepsilon+\varepsilon^2\operatorname{div}(\mu(s^\varepsilon)\nabla v^\varepsilon)+f=0\quad\text{in }\Omega_\varepsilon, \tag{1.1}$$

$$\operatorname{div} v^\varepsilon=0\quad\text{in }\Omega_\varepsilon, \tag{1.2}$$

$$v^\varepsilon=h\quad\text{on }\Gamma,\qquad v^\varepsilon=0\quad\text{on }S_\varepsilon, \tag{1.3}$$

$$-d\Delta s^\varepsilon+v^\varepsilon\cdot\nabla s^\varepsilon=0\quad\text{in }\Omega_\varepsilon, \tag{1.4}$$

$$s^\varepsilon=g\quad\text{on }\Gamma,\qquad\frac{\partial s^\varepsilon}{\partial\nu}=0\quad\text{on }S_\varepsilon. \tag{1.5}$$

Here h and g are given functions and ν denotes the unit vector of the outward normal on the boundary of a domain. We assume that

$$\mu \in C^1([0,1]), \quad \mu > 0 \quad \text{on } [0,1], \tag{1.6}$$

$$f \in (C(\bar{\Omega}))^n, \tag{1.7}$$

$$h \in (C^2(\bar{\Omega}))^n, \qquad \int_\Gamma h \cdot \nu \, d\Gamma = 0, \tag{1.8}$$

$$g \in C^2(\bar{\Omega}), \qquad 0 \leqq g \leqq 1 \text{ on } \bar{\Omega}, \tag{1.9}$$

and consider μ extended to $\mathbf{R}$ as follows:

$$\mu(s) = \begin{cases} \mu(0), & s < 0, \\ \mu(1), & s > 1. \end{cases}$$

By use of the Leray-Schauder Fixed Point Theorem and the Maximum Principle, one can prove the following result.

THEOREM 1.1. *Under the assumptions* (1.6)-(1.9), *the problem* (1.1)-(1.5) *has at least one solution*

$$(v^\varepsilon, p^\varepsilon, s^\varepsilon) \in (H^1(\Omega_\varepsilon))^n \times (L^2(\Omega_\varepsilon)/\mathbf{R}) \times (H^1(\Omega_\varepsilon) \cap C(\bar{\Omega}_\varepsilon)); \tag{1.10}$$

the inequality

$$0 \leqq s^\varepsilon \leqq 1 \quad \text{a.e. in } \Omega_\varepsilon \tag{1.11}$$

holds true for each solution.

We shall prove that the limit of solutions (1.10) (as ε tends to zero) satisfies the equations and boundary conditions of the simplest phenomenological model of miscible flow through a porous medium (e.g., [3]).

2. Macroscopic and constitutive equations. In this section, $C > 0$ denotes a generic constant which does not depend on ε and has possibly different values at different places.

LEMMA 2.1. *Let* $(v^\varepsilon, p^\varepsilon, s^\varepsilon)$ *be a solution to problem* (1.1)-(1.5), *and*

$$\tilde{v}^\varepsilon = \begin{cases} v^\varepsilon & \text{in } \Omega_\varepsilon, \\ 0 & \text{in } \mathcal{O}_\varepsilon. \end{cases}$$

Then

$$\|\nabla \tilde{v}^\varepsilon\|_{(L^2(\Omega))^{n^2}} \leqq \frac{C}{\varepsilon},$$

$$\|\tilde{v}^\varepsilon\|_{(L^2(\Omega))^n} \leqq C.$$

There exists the extension $\tilde{p}^\varepsilon \in L^2(\Omega)/\mathbf{R}$ *of the function* p^ε, *such that*

$$\|\tilde{p}^\varepsilon\|_{L^2(\Omega)} \leqq C.$$

LEMMA 2.2. *Under the notation of the preceding lemma, there exist subsequences of* $\{\tilde{v}^\varepsilon\}$ *and* $\{\tilde{p}^\varepsilon\}$ (*denoted again by* $\{\tilde{v}^\varepsilon\}, \{\tilde{p}^\varepsilon\}$) *and functions* $v \in (L^2(\Omega))^n$, $p \in L^2(\Omega)/\mathbf{R}$, *such that*

$$\tilde{v}^\varepsilon \to v \quad \text{weakly in } L^2(\Omega),$$

$$\tilde{p}^\varepsilon \to p \quad \text{strongly in } L^2(\Omega)/\mathbf{R},$$

as $\varepsilon \to 0$. *The function* v *satisfies the following* (*macroscopic*) *equation and boundary condition*:

$$\operatorname{div} v = 0 \quad \text{in } \Omega,$$

$$v \cdot h = \nu \cdot h \quad \text{on } \Gamma.$$

LEMMA 2.3. *Under the notation of Lemma* 2.1, *there exist the extension* $\tilde{s}^\varepsilon \in H^1(\Omega) \cap L^\infty(\Omega)$ *of the function* s^ε, *such that*

$$\|\tilde{s}^\varepsilon\|_{H^1(\Omega)} \leqq C,$$

$$\|\tilde{s}^\varepsilon\|_{L^\infty(\Omega)} \leqq C.$$

Let

$$\tilde{\sigma}^\varepsilon = \begin{cases} \sigma^\varepsilon = d\nabla s^\varepsilon & \text{in } \Omega_\varepsilon, \\ 0 & \text{in } \mathcal{O}_\varepsilon. \end{cases}$$

Then

$$\|\tilde{\sigma}^\varepsilon\|_{(L^2(\Omega))^n} \leqq C,$$

$$\operatorname{div} \tilde{\sigma}^\varepsilon - \tilde{v}^\varepsilon \cdot \nabla \tilde{s}^\varepsilon = 0 \quad \text{in } \Omega.$$

LEMMA 2.4. *Under the notation of the preceding lemma, there exist subsequences of* $\{\tilde{s}^\varepsilon\}$, $\{\tilde{\sigma}^\varepsilon\}$ (*denoted again by* $\{\tilde{s}^\varepsilon\}$, $\{\tilde{\sigma}^\varepsilon\}$) *and functions* $s \in H^1(\Omega) \cap L^\infty(\Omega)$, $\sigma \in (L^2(\Omega))^n$, *such that*

$$\tilde{s}^\varepsilon \to s \quad \text{weakly in } H^1(\Omega) \text{ and weakly* in } L^\infty(\Omega),$$

$$\tilde{\sigma}^\varepsilon \to \sigma \quad \text{weakly in } L^2(\Omega),$$

as $\varepsilon \to 0$. *The functions* s *and* σ *satisfy the following* (*macroscopic*) *equation and boundary condition*:

$$\operatorname{div} \sigma - v \cdot \nabla s = 0 \quad \text{in } \Omega,$$

$$s = g \quad \text{on } \Gamma.$$

Let $q \in (H^1(Y^*))^n/\mathbf{R}$ *be the solution to the problem*

$$\Delta q = 0 \quad \text{in } Y^*,$$

$$(\nabla q + I)\nu = 0 \quad \text{on } S,$$

q *is* Y*-periodic*

(*where* I *denotes the unity matix*), *and*

$$A = \int_{Y^*} \nabla q \, dy, \quad \theta = \operatorname{meas} Y^*,$$

$$D = d(\theta I + A).$$

LEMMA 2.5. *The functions* s *and* σ, *defined by Lemma* 2.4, *satisfy the following* (*constitutive*) *equation*:

$$\sigma = D\nabla s.$$

The proofs of Lemmas 2.1-2.5 can be performed by adapting the method of L. Tartar, applied in the linear case (see [8, Appendix], [4] and [7]).

Let $(w^i, \pi^i) \in (H^1(Y^*))^n \times (L^2(Y^*)/\mathbf{R})(i = 1, \cdots, n)$ be the solution to the problem

$$-\nabla \pi^i + \Delta w^i + e^i = 0 \quad \text{in } Y^*, \tag{2.1}$$

$$\operatorname{div} w^i = 0 \quad \text{in } Y^*, \tag{2.2}$$

$$w^i = 0 \quad \text{on } S, \tag{2.3}$$

$$w^i, \pi^i \quad \text{are } Y\text{-periodic} \tag{2.4}$$

and

$$K = (K_{ij}), \qquad K_{ij} = \int_{Y^*} (w^i)_j \, dy.$$

In the sequel, we consider w^i extended by zero to $\mathcal{O}$.

LEMMA 2.6. *The functions v, p and s, defined by Lemmas* 2.2 *and* 2.4, *satisfy the following* (*constitutive*) *equation* (*Darcy's law*):

$$v = \frac{1}{\mu(s)} K(f - \nabla p). \tag{2.5}$$

Proof. Let

$$w^{i,\varepsilon}(x) = w^i\left(\frac{x}{\varepsilon}\right), \quad \pi^{i,\varepsilon}(x) = \pi^i\left(\frac{x}{\varepsilon}\right), \quad i = 1, \cdots, n.$$

As a consequence of the basic lemma on periodic extension [8, p. 57], we obtain that

$$(w^{i,\varepsilon})_j \to K_{ij} \quad \text{weakly in } L^2(\Omega), \tag{2.6}$$

as $\varepsilon \to 0$. Using the regularity of the functions w^i and π^i we obtain the inequalities

$$\|w^{i,\varepsilon}\|_{(L^\infty(\Omega_\varepsilon))^n} \leqq C, \tag{2.7}$$

$$\|\nabla w^{i,\varepsilon}\|_{(L^\infty(\Omega_\varepsilon))^{n^2}} \leqq \frac{C}{\varepsilon}, \tag{2.8}$$

$$\|\pi^{i,\varepsilon}\|_{L^\infty(\Omega_\varepsilon)} \leqq C. \tag{2.9}$$

(Here we consider $\pi^{i,\varepsilon}$ extended in a simple way to $\varepsilon\mathcal{O}_{-k}$, $k \in K_\varepsilon$.) The functions $w^{i,\varepsilon}$, $\pi^{i,\varepsilon}$ satisfy the equations

$$-\varepsilon \nabla \pi^{i,\varepsilon} + \varepsilon^2 \Delta w^{i,\varepsilon} + e^i = 0 \quad \text{in } \Omega_\varepsilon \setminus \bigcup_{k \in K_\varepsilon} \varepsilon \bar{\mathcal{O}}_k, \tag{2.10}$$

$$\operatorname{div} w^{i,\varepsilon} = 0 \quad \text{in } \Omega_\varepsilon \setminus \bigcup_{k \in K_\varepsilon} \varepsilon \bar{\mathcal{O}}_k. \tag{2.11}$$

Under the notation of Lemma 2.1 and Lemma 2.3, for $\varphi \in \mathscr{D}(\Omega)$ we have (because of (1.1) and (2.10))

$$\int_\Omega (-\nabla \tilde{p}^\varepsilon + \varepsilon^2 \operatorname{div}(\mu(\tilde{s}^\varepsilon)\nabla \tilde{v}^\varepsilon) + f) \cdot w^{i,\varepsilon}\varphi \, dx = 0,$$

$$\int_\Omega \mu(\tilde{s}^\varepsilon)(-\varepsilon \nabla \pi^{i,\varepsilon} + \varepsilon^2 \Delta w^{i,\varepsilon} + e^i) \cdot \tilde{v}^\varepsilon \varphi \, dx = 0.$$

(Here we have assumed that ε is sufficiently small, so that $\operatorname{supp} \varphi \cap \varepsilon \mathscr{O}_k = \varnothing$ for $k \in K_\varepsilon$.) Subtracting these equations and performing the integation by parts (and using (1.2), (1.3) and (2.11)), we obtain

$$J^\varepsilon_{0,i} + \varepsilon J^\varepsilon_{1,i} + \varepsilon^2 J^\varepsilon_{2,i} = 0, \qquad i = 1, \cdots, n, \tag{2.12}$$

where

$$J^\varepsilon_{0,i} = \int_\Omega (\tilde{p}^\varepsilon w^{i,\varepsilon} \cdot \nabla \varphi + f \cdot w^{i,\varepsilon}\varphi - \mu(\tilde{s}^\varepsilon)\, e^i \cdot \tilde{v}^\varepsilon \varphi) \, dx,$$

$$J^\varepsilon_{1,i} = -\int_\Omega \pi^{i,\varepsilon} \tilde{v}^\varepsilon \cdot \nabla(\mu(\tilde{s}^\varepsilon)\varphi) \, dx,$$

$$J^\varepsilon_{2,i} = \int_\Omega (\mu(\tilde{s}^\varepsilon)\varphi \tilde{v}^\varepsilon \cdot (\nabla w^{i,\varepsilon})\nabla \tilde{s}^\varepsilon + \mu(\tilde{s}^\varepsilon)\tilde{v}^\varepsilon \cdot (\nabla w^{i,\varepsilon})\nabla \varphi$$
$$- \mu(\tilde{s}^\varepsilon) w^{i,\varepsilon} \cdot (\nabla \tilde{v}^\varepsilon)\nabla \varphi) \, dx.$$

Using (2.6)-(2.9) and Lemmas 2.1-2.4, we find that

$$J^\varepsilon_{0,i} \to \int_\Omega (p(K\nabla \varphi)_i + (Kf)_i \varphi - \mu(s) v_i \varphi) \, dx,$$

as $\varepsilon \to 0$, and

$$J^\varepsilon_{1,i} \leqq C, \qquad J^\varepsilon_{2,i} \leqq \frac{C}{\varepsilon}.$$

Now (2.5) follows from (2.12).

3. The homogenized problem and convergence theorem. Taking into account Lemmas 2.2, 2.4, 2.5 and 2.6, we conclude that (v, p, s) is a solution to the following homogenized problem:

$$\operatorname{div} v = 0 \quad \text{in } \Omega, \tag{3.1}$$

$$v = \frac{1}{\mu(s)} K(f - \nabla p) \quad \text{in } \Omega, \tag{3.2}$$

$$v \cdot \nu = h \cdot \nu \quad \text{on } \Gamma, \tag{3.3}$$

$$\operatorname{div}(D\nabla s) - v \cdot \nabla s = 0 \quad \text{in } \Omega, \tag{3.4}$$

$$s = g \quad \text{on } \Gamma. \tag{3.5}$$

Because of (1.6), the inequality

$$0 \leqq s \leqq 1 \quad \text{a.e. in } \Omega \tag{3.6}$$

holds true.

LEMMA 3.1 ([8, p. 139], [2, p. 149]). *The matrices K and D are symmetric and positive definite.*

LEMMA 3.2 ([1, p. 231]). *Let w be the solution to the problem*

$$\operatorname{div}(w+F)=0 \quad \text{in } \Omega,$$
$$w=0 \quad \text{on } \Gamma,$$

and, for $r>1$,

$$\Phi_r(F)=\frac{\|\nabla w\|_{L^r(\Omega)}}{\|F\|_{L^r(\Omega)}}.$$

Then

$$\alpha_r=\alpha_r(\Omega)=\sup_{0\neq F\in L^r(\Omega)}\Phi_r(F)<\infty.$$

LEMMA 3.3. *Let the function μ satisfy the condition*

$$\operatorname{osc}\mu<\frac{1}{\alpha_3}\max\mu, \tag{3.7}$$

and let (v, p, s) be a solution to the problem (3.1)-(3.5). *Then $p\in W_3^1(\Omega)$, and there exists a constant $\beta>0$ (depending on Ω, $\mathcal{O}$ and μ), such that for each f and h the inequality*

$$\|\nabla p\|_{(L^3(\Omega))^n}\leqq\beta(\|f\|_{(L^3(\Omega))^n}+\|h\cdot\nu\|_{L^e(\Gamma)})$$

holds true.

Proof. The conclusion follows from Lemma 3.1 and the results of the book [1, Thm. 4.2, p. 234], where the constant β is defined.

THEOREM 3.1. *Let the function μ satisfy the condition* (3.7). *Then there exists a constant $\gamma>0$ (depending on Ω, $\mathcal{O}$, d and μ) such that under the assumption*

$$\|f\|_{(L^3(\Omega))^n}+\|h\cdot\nu\|_{L^3(\Gamma)}<\gamma, \tag{3.8}$$

problem (3.1)-(3.5) *has only one solution*:

$$(v, p, s)\in(L^2(\Omega))^n\times(L^2(\Omega)/\mathbf{R})\times(H^1(\Omega)\cap L^\infty(\Omega)).$$

Proof. Let (v^i, p^i, s^i), $i=1, 2$ be solutions and $v=v^1-v^2$, $p=p^1-p^2$, $s=s^1-s^2$. These functions satisfy the following equations and boundary conditions:

$$\operatorname{div} v=0 \quad \text{in } \Omega, \tag{3.9}$$

$$v=-\frac{1}{\mu(s_1)}K\nabla p+\frac{\mu(s_2)-\mu(s_1)}{\mu(s_1)\mu(s_2)}K(f-\nabla p_2) \quad \text{in } \Omega, \tag{3.10}$$

$$v\cdot\nu=0 \quad \text{on } \Gamma, \tag{3.11}$$

$$\operatorname{div}(D\nabla s)-v_1\cdot\nabla s-v\cdot\nabla s_2=0 \quad \text{in } \Omega, \tag{3.12}$$

$$s=0 \quad \text{on } \Gamma. \tag{3.13}$$

In the sequel, $C_k>0$ $(k=1, \cdots, 5)$ denotes a generic constant, depending generally on Ω, $\mathcal{O}$, d and μ. By use of (3.6) and Lemma 3.1, from (3.9)-(3.13) we obtain the

inequalities

$$\begin{aligned} &\|\nabla p\|_{(L^2(\Omega))^n} \leqq C_1 \|s(f-\nabla p_2)\|_{(L^2(\Omega))^n}, \\ &\|\nabla s\|_{(L^2(\Omega))^n} \leqq C_2 \|s(f-\nabla p_2)\|_{(L^2(\Omega))^n}. \end{aligned} \tag{3.14}$$

Using the inequality

$$\|s\|_{L^6(\Omega)} \leqq C_3 \|\nabla s\|_{L^2(\Omega)} \tag{3.15}$$

and Lemma 3.3, we obtain

$$\|s(f-\nabla p_2)\|_{(L^2(\Omega))^n} \leqq C_4(\|f\|_{(L^3(\Omega))^n} + \|h \cdot \nu\|_{L^3(\Gamma)})\|\nabla s\|_{(L^2(\Omega))^n}. \tag{3.16}$$

Let $s \neq 0$; from (3.15) and (3.16) we conclude that

$$1 \leqq C_5(\|f\|_{(L^3(\Omega))^n} + \|h \cdot \nu\|_{L^3(\Gamma)}).$$

Let $\gamma = 1/C_5$; assuming (3.8), we obtain a contradiction. Therefore $s = 0$ and, because of (3.14), $\nabla p = 0$; from (3.10) we obtain $v = 0$.

THEOREM 3.2. *Let μ, f and h satisfy the conditions* (3.7) *and* (3.8). *Let $(v^\varepsilon, p^\varepsilon, s^\varepsilon)$ and (v, p, s) be solutions to problem* (1.1)-(1.5) *and problem* (3.1)-(3.5), *respectively. Then there exist extensions $\tilde{v}^\varepsilon$, $\tilde{p}^\varepsilon$ and $\tilde{s}^\varepsilon$ of the functions v^ε, p^ε and s^ε, respectively, such that*

$$\begin{aligned} &\tilde{v}^\varepsilon \to v \quad \textit{weakly in } (L^2(\Omega))^n, \\ &\tilde{p}^\varepsilon \to p \quad \textit{strongly in } L^2(\Omega), \\ &\tilde{s}^\varepsilon \to s \quad \textit{strongly in } L^2(\Omega), \end{aligned}$$

as $\varepsilon \to 0$.

Proof. Because of Theorem 3.1, the functions v, p and s are unique cluster points of $\{\tilde{v}^\varepsilon\}$, $\{\tilde{p}^\varepsilon\}$ and $\{\tilde{s}^\varepsilon\}$, respectively. Therefore, the conclusion follows immediately from Lemmas 2.2 and 2.4.

Acknowledgments. The authors would like to thank the referees for their very useful comments. The first author is grateful to Professor F. Murat (University Pierre et Marie Curie, Paris) for his illuminating discussion on the subject, which indicated how to shorten the proofs and how to treat the more general case with matrix viscosity and diffusion coefficients.

THE NEUMANN PROBLEM FOR NONLINEAR SECOND ORDER SINGULAR PERTURBATION PROBLEMS*

BENOIT PERTHAME† AND RICHARD SANDERS‡

Abstract. Singularly perturbed second order elliptic partial differential equations with Neumann boundary conditions arise in many areas of application. These problems rarely have smooth limit solutions. In this paper, we characterize the limit solution for a wide class of such problems. We also give an abstract rate of convergence theorem and apply the abstract theorem to certain finite difference approximations.

Key words. singular perturbation, viscosity solution, viscosity inequalities

AMS(MOS) subject classifications. 35F30, 65M15

1. Introduction. In this paper, we study the singular perturbation problem for partial differential equations which have the form

$$(NP_\varepsilon)\qquad \begin{aligned} -\varepsilon\Delta u_\varepsilon + H(x, u_\varepsilon, \nabla u_\varepsilon) &= 0, \qquad x\in\Omega,\\ \frac{\partial u_\varepsilon}{\partial n}(x) &= \gamma(x), \qquad x\in\partial\Omega, \end{aligned}$$

where Ω is a bounded domain in $\mathbf{R}^d$, n is Ω's outward unit normal, u_ε is a scalar unknown and H is a continuous function on $\bar{\Omega}\times\mathbf{R}\times\mathbf{R}^d$. One application that motivates the study of singular perturbation problems of the form (NP_ε) is found in the theory of optimal stochastic control. There, H depends on the deterministic part of a stochastic ODE, a control space and a specified cost function. u_ε can be identified as the optimal cost function. The positive parameter ε in (NP_ε) can be regarded as the intensity of noise in the dynamics equation. Control problems whose trajectories reflect at a boundary give rise to Neumann problems of the type studied here; see [1] or [17] for a detailed treatment of this topic. One could ask, for instance, is the optimal cost function of a stochastic control problem related to the optimal cost of its associated deterministic problem? Are the two close in any way when the noise is small?

As $\varepsilon\downarrow 0$, it is well known that solutions of (NP_ε) do not generally converge to a classical solution of

$$(NP_0)\qquad \begin{aligned} H(x, u, \nabla u) &= 0, \qquad x\in\Omega,\\ \frac{\partial u}{\partial n}(x) &= \gamma(x), \qquad x\in\partial\Omega. \end{aligned}$$

Indeed, (NP_0) does not generally admit a C^1 solution, as can easily be seen by considering the simple example

$$\begin{aligned} \frac{du}{dx} + u &= 0, \qquad x\in[0,1],\\ \frac{du}{dx}(0) &= 0, \qquad \frac{du}{dx}(1) = 1. \end{aligned}$$

This example is clearly overdetermined and here the data at 0 is not compatible with the data at 1. For this reason, a more general class of solutions to (NP_0) must be sought.

A new notion of continuous weak solutions to equations of Hamilton–Jacobi type has recently been introduced. In [4] and [5], M. G. Crandall and P. L. Lions have developed techniques that have been extremely successful in establishing a number of new results concerning continuous, but not necessarily differentiable, weak solutions to first order, fully nonlinear, partial differential equations. In their work, Crandall and Lions have utilized the "vanishing viscosity method," so named because of the link to the classical technique of vanishing viscosity from fluid mechanics, and they show that the method of vanishing viscosity gives rise to a specific notion of a "viscosity" weak solution.

In [15], and here as well, the notion of a viscosity solution for the generally overdetermined Neumann problem (NP_0) is given and is shown to include all L^∞ ε-limits of solutions to (NP_ε). All L^∞ ε-limits are shown to satisfy the so-called viscosity inequalities of § 2; additional details in this direction can be found in [15]. Remarkably (with additional hypotheses of course), these viscosity inequalities uniquely determine all such limits. In § 3, we introduce what we call "approximate viscosity solutions" and we show there that any reasonable approximate viscosity solution is approximately equal to the viscosity solution of (NP_0). More precisely, we give an abstract minimal rate-of-convergence theorem, Theorem 2, for approximate viscosity solutions to (NP_0). We also show that this rate is essentially sharp. A particular application of Theorem 2 gives an easy to determine measure of how far the solution of (NP_ε) can be away from the viscosity solution of (NP_0). In § 4, the abstract rate-of-convergence theorem of § 3 is applied to numerical approximations which are obtained from a class of finite difference schemes. Moreover, we show in § 4 that these schemes have "computable" solutions and we motivate how they can be obtained.

The reader is encouraged to see [2], [18] and [19] where similar results as those above are obtained for divergence form singular perturbation problems with mixed or Dirichlet boundary conditions. See also [6], [7] and [21] for a further treatment of approximations for time-dependent Hamilton–Jacobi equations without spatial boundaries.

2. Viscosity solutions. As mentioned in the previous section, as $\varepsilon \downarrow 0$, the corresponding solutions to (NP_ε) do not in general converge to a classical C^1 solution of (NP_0). In this section we offer a characterization of viscous limits to (NP_0) and we show that this characterization often allows for only one solution in the class of continuous functions. Throughout, we shall assume that Ω is a bounded domain in $\mathbf{R}^d$ which has a C^2 boundary $\partial\Omega$. The *outward* normal of Ω at a point $x \in \partial\Omega$ will be denoted by $n(x)$ and we write the outward normal derivative of φ at $x \in \partial\Omega$ as $(\partial\varphi/\partial n)(x)$.

We should like to mention that previous to the writing of this paper P. L. Lions had introduced the same viscosity characterization of solutions to (NP_0) as we give below (see [15]). For this reason, we borrow much of the notation and hypotheses of [15] and in this section we omit all proofs but those which motivate the results of the next sections.

We now state the viscosity characterization (see Proposition 1) of continuous weak solutions to (NP_0).

DEFINITION 1. Suppose that $H(x, u, p) \in C(\bar{\Omega} \times \mathbf{R} \times \mathbf{R}^d)$ and $u(x) \in C(\bar{\Omega})$. We say that:

(a) $u(x)$ is a *viscosity subsolution* of (NP_0) if for all test functions $\varphi \in C^1(\mathbf{R}^d)$

with $(\partial\varphi/\partial n)(x) \geqq \gamma(x)$, we have

$$H(x_0, u(x_0), \nabla\varphi(x_0)) \leqq 0,$$

where $x_0 \in \bar{\Omega}$ satisfies

$$u(x_0) - \varphi(x_0) = \max_{x\in\bar{\Omega}} (u(x) - \varphi(x)).$$

(b) $u(x)$ is a *viscosity supersolution* of (NP_0) if for all test functions $\varphi \in C^1(\mathbf{R}^d)$ with $(\partial\varphi/\partial n)(x) \leqq \gamma(x)$, we have

$$H(x_0, u(x_0), \nabla\varphi(x_0)) \geqq 0,$$

where $x_0 \in \bar{\Omega}$ satisfies

$$u(x_0) - \varphi(x_0) = \min_{x\in\bar{\Omega}} (u(x) - \varphi(x)).$$

(c) $u(x)$ is a *viscosity solution* of (NP_0) if it satisfies both (a) and (b) above.

The fact that our test functions are required to satisfy $(\partial\varphi/\partial n)(x) \geqq \gamma(x)$ (resp. $(\partial\varphi/\partial n)(x) \leqq \gamma(x)$), in our definition of viscosity subsolution (resp. supersolution), may at first seem superfluous. This is, however, precisely the mechanism that "sees" the Neumann boundary conditions when vanishing viscosity is taken into account (see Proposition 1 below).

Remark 2.1. Any C^1 solution of (NP_0) is also a viscosity solution. This fact is nontrivial only for the case when $\max(u-\varphi)$ or $\min(u-\varphi)$ is attained for some $x_0 \in \partial\Omega$. To see that u must indeed be a viscosity subsolution, take an arbitrary $\varphi \in C^1(\mathbf{R}^d)$ with $(\partial\varphi/\partial n)(x) \geqq \gamma(x)$. First choose a sequence $\{\varphi_m\}$, such that for every m, $\varphi_m(x_0) = \varphi(x_0)$, $\varphi_m(x) > \varphi(x)$ for $x \neq x_0$, $(\partial\varphi_m/\partial n)(x) \geqq (\partial\varphi/\partial n)(x)$ and with $\varphi_m \to \varphi$ in C^1 as $m \to \infty$. We then have that $(u-\varphi)(x_0) = \max(u-\varphi_m)$ and x_0 is the point where the *strict* maximum of $u-\varphi_m$ is attained. Next, for any fixed m, choose a sequence $\{\varphi_m^n\}$ such that $(\partial\varphi_m^n/\partial n)(x) > (\partial\varphi_m/\partial n)(x)$ and with $\varphi_m^n \to \varphi_m$ in C^1 as $n \to \infty$. Denoting by x_n the points where $\max(u-\varphi_m^n)$ is attained, we must have that $x_n \to x_0$ as $n \to \infty$. This is true because $(u-\varphi_m)(x_0)$ is a strict maximum of $u-\varphi_m$. For $x \in \partial\Omega$, we also have that $(\partial/\partial n)(u-\varphi_m^n)(x) < 0$, which implies $x_n \in \Omega^0$. Therefore, since now x_n is an interior maximum of $u-\varphi_m^n$, $\nabla u(x_n) = \nabla\varphi_m^n(x_n)$, and so by taking limits we have

$$H(x_0, u(x_0), \nabla\varphi(x_0)) = \lim_{m,n} H(x_n, u(x_n), \nabla\varphi_m^n(x_n)) = 0.$$

Remark 2.2. Obviously, the converse of Remark 2.1 is false. That is, a smooth viscosity solution need not satisfy the boundary conditions of (NP_0).

PROPOSITION 1. *Let $u_\varepsilon \in C^2(\bar{\Omega})$ be a solution of (NP_ε) and suppose that $\varphi \in C^2(\bar{\Omega})$. Then*:

(a) *For $(\partial\varphi/\partial n)(x) \geqq \gamma(x)$ and $u_\varepsilon(x_0) - \varphi(x_0) = \max_{x\in\bar{\Omega}}(u_\varepsilon(x) - \varphi(x))$ we have that $H(x_0, u_\varepsilon(x_0), \nabla\varphi(x_0)) \leqq \varepsilon\Delta\varphi(x_0)$.*

(b) *For $(\partial\varphi/\partial n)(x) \leqq \gamma(x)$ and $u_\varepsilon(x_0) - \varphi(x_0) = \min_{x\in\bar{\Omega}}(u_\varepsilon(x) - \varphi(x))$ we have that $H(x_0, u_\varepsilon(x_0), \nabla\varphi(x_0)) \geqq \varepsilon\Delta\varphi(x_0)$.*

If in addition, we have that $u_\varepsilon \to u$ in $L^\infty(\bar{\Omega})$ for some sequence $\varepsilon \downarrow 0$, then:

(c) *$u = \lim_\varepsilon u_\varepsilon$ is a viscosity solution, that is, u satisfies Definition* 1(c).

The proof of Proposition 1 can be found in [15]; however, the interested reader can easily reproduce its proof by taking limits as in Remark 2.1.

Before stating the main result of this section, we give a simple lemma.

LEMMA 1. *Let Ω be a bounded domain in $\mathbf{R}^d$ having a C^2 boundary $\partial\Omega$. Then*
(a) *There exists a constant $C_\Omega < \infty$ such that for all $x \in \partial\Omega$,*

$$C_\Omega \geqq \sup_{y \in \bar{\Omega}} \left(\frac{-(x-y)\cdot n(x)}{|x-y|^2} \right).$$

(b) *There exists a function $w \in C^2(\bar{\Omega})$ such that*

$$\frac{\partial w}{\partial n}(x) = \max(C_\Omega, 0), \quad x \in \partial\Omega,$$

$$|\nabla w(x)| \leqq \max(C_\Omega, 0), \quad x \in \bar{\Omega}.$$

Proof. $C_\Omega = w(x) \equiv 0$ would suffice in the case of convex Ω. For nonconvex Ω, (a) is shown in [12]. (b) can be shown by constructing a particular example. Under the hypotheses of the lemma, it is known that the distance function $d(x) = d(x; \partial\Omega)$ is C^2 in a neighborhood of $\partial\Omega$ [23], [10]. That is, $d(x) \in C^2(\Omega_\tau)$, where $\Omega_\tau = \{x \in \bar{\Omega}: d(x) < \tau\}$ and $\tau > 0$ is chosen sufficiently small. Set $0 < \tau_0 < \tau$ and verify that

$$w(x) = \begin{cases} \dfrac{C_\Omega}{3\tau_0^2}(\tau_0 - d(x))^3 & \text{if } x \in \bar{\Omega}_{\tau_0}, \\ 0 & \text{if } x \in \bar{\Omega}\Omega_{\tau_0}, \end{cases}$$

is a particular example that satisfies (b).

Now, consider the following set of assumptions.

Assumption A. $H(x, u, p)$ is strictly increasing in u for all $x \in \bar{\Omega}$ and uniformly for $p \in \mathbf{R}^d$. That is, for all $R > 0$ and $-R \leqq v \leqq u \leqq R$, there exists a $\mu_R > 0$ such that

$$H(x, u, p) - H(x, v, p) \geqq \mu_R(u - v).$$

Assumption B. Let $\alpha, \beta \in \mathbf{R}^d$ satisfy $|\alpha|, |\beta| \leqq \max(C_\Omega, 0)$, where C_Ω is as defined in the previous lemma. Then, for all such α, β and all $x \in \bar{\Omega}$, $x + \xi \in \bar{\Omega}$, all $|u| \leqq R$ and any $\lambda > 1$, assume that

$$\left| H\left(x + \xi, u, \lambda\xi + \frac{\lambda}{2}|\xi|^2\alpha + O(\xi)\right) - H\left(x, u, \lambda\xi + \frac{\lambda}{2}|\xi|^2\beta\right) \right| \leqq \omega_R(\lambda|\xi|^2 + |\xi|),$$

where $\omega_R(s)$ is some function such that $\lim_{s \downarrow 0} \omega_R(s) = 0$.

Remark 2.3. Assumptions A and B are standard (see [5], [8] and [15]). In the following theorem, Assumption B may always be relaxed so that $\alpha = \beta \equiv 0$ and $0(\xi) \equiv 0$ except for x in a neighborhood of $\partial\Omega$. Assuming additional regularity on the class of solutions allows Assumption B to be neglected entirely.

THEOREM 1. *Suppose that $H(x, u, p) \in C(\bar{\Omega} \times \mathbf{R} \times \mathbf{R}^d)$ and that it satisfies Assumption* A *above. Let $u \in C(\bar{\Omega})$ be a viscosity subsolution of (NP_0) and let $v \in C(\bar{\Omega})$ be a viscosity supersolution of (NP_0). Finally, assume one from the following three sets of hypotheses*:

(i) *Ω is convex and Assumption* B *holds with $\alpha = \beta \equiv 0$.*

(ii) *Assumption* B *is satisfied.*

(iii) *Either u or v is Lipschitz continuous.*

We then have that

$$\max_{x \in \bar{\Omega}} (u(x) - v(x)) \leqq 0.$$

Obviously, establishing this result would imply that a viscosity *solution* to (NP_0) is unique in the specified class of functions.

Proof. Given a $\delta > 0$, define the function $\phi^\delta(x, y)$ by

$$\phi^\delta(x, y) = \rho(x)\rho(y)|x-y|^2/\delta, \tag{2.1}$$

where $\rho(x) = \exp(w(x))$ and $w(x)$ satisfies the second conclusion of Lemma 1. For $x \in \partial\Omega$ and any fixed $y_0 \in \bar{\Omega}$, observe that

$$\frac{\partial}{\partial n_x}\phi^\delta(x, y_0) = \phi^\delta(x, y_0)\left\{\frac{\partial w}{\partial n}(x) + \frac{2(x-y_0)\cdot n}{|x-y_0|^2}\right\},$$

and Lemma 1 implies that the bracketed term above is nonnegative. Therefore,

$$\frac{\partial}{\partial n_x}\phi^\delta(x, y_0) \geqq 0$$

and, similarly, for $y \in \partial\Omega$ and any fixed $x_0 \in \bar{\Omega}$

$$\frac{\partial}{\partial n_y}\phi^\delta(x_0, y) \geqq 0.$$

Now, choose $\psi \in C^2(\bar{\Omega})$ such that $(\partial\psi/\partial n)(x) = \gamma(x)$. By the construction above, we have that for any fixed $y_0 \in \bar{\Omega}$

$$\phi_1(x) = \phi^\delta(x, y_0) + \psi(x)$$

is an admissible test function according to Definition 1(a) and similarly for fixed $x_0 \in \bar{\Omega}$

$$\phi_2(y) = -\phi^\delta(x_0, y) + \psi(y)$$

is admissible according to Definition 1(b).

The next step is to note the obvious inequality

$$\max_{x\in\bar{\Omega}}(u(x)-v(x)) \leqq \max_{\substack{x\in\bar{\Omega}\\ y\in\bar{\Omega}}}(u(x)-v(y)-(\phi^\delta(x, y)+\psi(x)-\psi(y))). \tag{2.2}$$

We denote by x_δ, y_δ the points in $\bar{\Omega}$ where the right-hand side of (2.2) is attained and we rewrite (2.2) as

$$\max_{x\in\bar{\Omega}}(u(x)-v(x)) \leqq u(x_\delta)-v(y_\delta)-(\phi^\delta(x_\delta, y_\delta)+\psi(x_\delta)-\psi(y_\delta)). \tag{2.3}$$

Using (2.3), we easily arrive at

$$\begin{aligned}\phi^\delta(x_\delta, y_\delta) &\leqq |u(x_\delta)-u(y_\delta)| + |\psi(x_\delta)-\psi(y_\delta)|,\\ \phi^\delta(x_\delta, y_\delta) &\leqq |v(x_\delta)-v(y_\delta)| + |\psi(x_\delta)-\psi(y_\delta)|,\end{aligned} \tag{2.4}$$

and recalling the definition of $\phi^\delta(x, y)$, (2.4) gives us that

$$|x_\delta - y_\delta| \leqq \text{const.}\sqrt{\delta}. \tag{2.5}$$

Furthermore, since u, (or v), and ψ are continuous, (2.4) combined with (2.5) shows that

$$\lim_{\delta\downarrow 0}\phi^\delta(x_\delta, y_\delta) = 0. \tag{2.6}$$

The object now is to show that the right-hand side of (2.2) can be made arbitrarily small by choosing δ sufficiently small. From above, we see that the test functions defined as

$$\begin{aligned}\phi_1(x) &= v(y_\delta) - \psi(y_\delta) + \phi^\delta(x, y_\delta) + \psi(x),\\ \phi_2(y) &= u(x_\delta) - \psi(x_\delta) - \phi^\delta(x_\delta, y) + \psi(y),\end{aligned}$$

are admissible according to Definition 1(a) and Definition 1(b), respectively. Inserting these into Definition 1, and using the fact that u is a viscosity subsolution and v is a viscosity supersolution, allows us to conclude that

$$H(x_\delta, u(x_\delta), \nabla_x \phi_1(x_\delta)) \leqq 0$$

and

$$H(y_\delta, v(y_\delta), \nabla_y \phi_2(y_\delta)) \geqq 0$$

because x_δ satisfies

$$u(x_\delta) - \phi_1(x_\delta) = \max_{x \in \bar{\Omega}} (u(x) - \phi_1(x))$$

and y_δ satisfies

$$v(y_\delta) - \phi_2(y_\delta) = \min_{y \in \bar{\Omega}} (v(y) - \phi_2(y)).$$

Combining the inequalities above and rearranging, we obtain

$$\begin{aligned} &H(x_\delta, u(x_\delta), \nabla_x \phi_1(x_\delta)) - H(x_\delta, v(y_\delta), \nabla_x \phi_1(x_\delta)) \\ &\quad \leqq H(y_\delta, v(y_\delta), \nabla_y \phi_2(y_\delta)) - H(x_\delta, v(y_\delta), \nabla_x \phi_1(x_\delta)). \end{aligned} \tag{2.7}$$

By a direct calculation, the right-hand side of (2.7) can be written as

$$\begin{aligned} &H\left(y_\delta, v(y_\delta), \lambda(x_\delta - y_\delta) + \frac{\lambda}{2}|x_\delta - y_\delta|^2 \beta + \nabla \psi(y_\delta)\right) \\ &\quad - H\left(x_\delta, v(y_\delta), \lambda(x_\delta - y_\delta) + \frac{\lambda}{2}|x_\delta - y_\delta|^2 \alpha + \nabla \psi(x_\delta)\right), \end{aligned} \tag{2.8}$$

where

$$\lambda = 2\rho(x_\delta)\rho(y_\delta)/\delta, \quad \alpha = \nabla w(x_\delta), \quad \beta = \nabla w(y_\delta).$$

(Recall from Lemma 1 that if Ω is convex we may assume that $\alpha = \beta \equiv 0$ and $\rho(x) = \rho(y) \equiv 1$.) Assumption B allows (2.8) to be bounded above by

$$\omega_R(\lambda |x_\delta - y_\delta|^2 + |x_\delta - y_\delta|), \tag{2.9}$$

where $R = \max(|u|_\infty, |v|_\infty)$.

To complete the proof of conclusions (i) and (ii), we again use inequality (2.3) to write

$$\max_{x \in \bar{\Omega}} (u(x) - v(x)) \leqq u(x_\delta) - v(y_\delta) + |\psi(x_\delta) - \psi(y_\delta)|,$$

which is bounded above by

$$\max((u(x_\delta) - v(y_\delta)), 0) + |\psi(x_\delta) - \psi(y_\delta)|. \tag{2.10}$$

Assumption A applied to the left-hand side of (2.7) combined with (2.8) and (2.9), allows us to bound (2.10) by

$$\frac{1}{\mu_R} \omega_R(\lambda |x_\delta - y_\delta|^2 + |x_\delta - y_\delta|) + |\psi(x_\delta) - \psi(y_\delta)|. \tag{2.11}$$

Recalling that $\lambda |x_\delta - y_\delta|^2 = 2\phi^\delta(x_\delta, y_\delta)$, (2.6) along with (2.5) show that (2.11) tends to zero as δ tends to zero, thereby proving that

$$\max_{x \in \bar{\Omega}} (u(x) - v(x)) \leqq 0.$$

To establish (iii), observe that if u (or v) is Lipschitz continuous, inequality (2.4) leads to an improvement of (2.5). That is, we may conclude that

$$|x_\delta - y_\delta| \leqq \text{const. } \delta. \tag{2.12}$$

This improved estimate implies that the p term of $H(\cdot, \cdot, p)$ in (2.8) remains bounded. Therefore, conclusion (iii) follows by noting the uniform continuity of $H(x, u, p)$ on a compact subset of $\bar{\Omega} \times \mathbf{R} \times \mathbf{R}^d$.

Remark 2.4. The combined results of Proposition 1 and Theorem 1 imply that *if* the family $\{u_\varepsilon\}_{\varepsilon>0}$ of solutions to (NP_ε) is relatively compact in L^∞, then $\lim_{\varepsilon \downarrow 0} u_\varepsilon$ exists in L^∞. For further results concerning the compactness of $\{u_\varepsilon\}_{\varepsilon>0}$ see [13] or [14].

3. Viscosity approximations and a rate of convergence. In this section we consider the rate at which certain approximations converge to the viscosity solution of (NP_0). We show in a precise sense below that if an approximation "almost" satisfies the viscosity inequalities of Definition 1, then the approximation is "almost" equal to its associated viscosity limit solution. The abstract rate of convergence theorem given in this section is then applied in § 4 to particular approximations generated by a class of numerical schemes.

Before making a precise statement of "almost satisfies the viscosity inequalities," recall the definitions of the test functions used in the proof of Theorem 1:

$$\phi^\delta(x, y) = \rho(x)\rho(y)|x - y|^2/\delta, \tag{3.1}$$

where $\delta > 0$, $\rho(x) = \exp(w(x))$ and $w(x)$ satisfies the second conclusion of Lemma 1. Also recall the function ψ, which satisfies

$$\begin{aligned} &\psi(x) \in C^2(\bar{\Omega}), \\ &\Delta\psi = 0 \quad \text{in } \Omega, \\ &\frac{\partial \psi}{\partial n}(x) = \gamma(x) \quad \text{on } \partial\Omega, \end{aligned} \tag{3.2}$$

and the specific test functions

$$\phi_1(x) = \phi^\delta(x, y_0) + \psi(x), \tag{3.3a}$$

$$\phi_2(y) = -\phi^\delta(x_0, y) + \psi(y), \tag{3.3b}$$

where x_0, y_0 are arbitrary fixed points in $\bar{\Omega}$. Notice that $\nabla\psi$ is uniquely determined by (3.2).

We now give the following definition.

DEFINITION 2. Suppose that $H(x, u, p) \in C(\bar{\Omega} \times \mathbf{R} \times \mathbf{R}^d)$ and $u_\varepsilon \in C(\bar{\Omega})$. We say that:

(a) u_ε is an *approximate viscosity subsolution of order* ε to (NP_0) if there exists a family of test functions of the form (3.3a) so that

$$H(x_0, u_\varepsilon(x_0), \nabla_x \phi_1(x_0)) \leqq \varepsilon \Delta_x \phi_1(x_0) + \underline{C}\varepsilon,$$

where $x_0 \in \bar{\Omega}$ satisfies

$$u_\varepsilon(x_0) - \phi_1(x_0) = \max_{x \in \bar{\Omega}} (u_\varepsilon(x) - \phi_1(x))$$

and $\underline{C}$ is some fixed constant.

(b) u_ε is an *approximate viscosity supersolution of order* ε to (NP_0) if there exists a family of test functions of the form (3.3b) so that

$$H(y_0, u_\varepsilon(y_0), \nabla_y \phi_2(y_0)) \geqq \varepsilon \Delta_y \phi_2(y_0) - \underline{C}\varepsilon,$$

where $y_0 \in \bar{\Omega}$ satisfies

$$u_\varepsilon(y_0) - \phi_2(y_0) = \min_{x \in \bar{\Omega}} (u_\varepsilon(x) - \phi_2(x)).$$

(c) u_ε is an *approximate viscosity solution of order* ε if it satisfies both (a) and (b) above.

In the proof of Theorem 1 we showed that $(\partial \phi_1 / \partial n_x)(x) \geqq \gamma(x)$ and $(\partial \phi_2 / \partial n_y)(y) \leqq \gamma(y)$; therefore, the statement of Proposition 1 implies that if u_ε is a C^2 solution of (NP_ε), then it is also an approximate viscosity solution of (NP_0) as defined above.

With Definition 2, we now state the following.

THEOREM 2. *In addition to Assumption* A *of Theorem* 1, *assume for ease of presentation that* $\gamma(x) \equiv 0$. *Furthermore, assume that* (NP_0) *admits a Lipschitz continuous viscosity solution* u, *with say Lipschitz constant* L, *and assume that* $H(x, u, p)$ *is locally Lipschitz continuous. Then, for any approximate viscosity solution to* (NP_0), *say* u_ε, *we have that*

$$|u_\varepsilon - u|_\infty \leqq \frac{1}{\mu_{R_0}} [(8dL_H L(1 + 2C_\Omega L)\varepsilon)^{1/2} + O(\varepsilon)]$$

where

$$R_0 = \sup_{1 \geqq \varepsilon > 0} |u_\varepsilon|_\infty,$$

$$L_H = \sup_{\substack{x_1, x_2 \in \bar{\Omega} \\ |u| \leqq R_0 \\ |P_1|, |P_2| \leqq 3L}} \left[\frac{|H(x_1, u, P_1) - H(x_2, u, P_2)|}{|x_1 - x_2| + |P_1 - P_2|} \right].$$

The definition of C_Ω *is given in Lemma* 1.

Remark 3.1. We may replace the assumption that (NP_0) admits a Lipschitz continuous viscosity solution by the assumption that u_ε is Lipschitz continuous, uniformly in $\varepsilon > 0$.

Remark 3.2. The interested reader can easily modify the following proof to include inhomogeneous boundary data to obtain the same $\sqrt{\varepsilon}$ rate of convergence. Relaxing the hypothesis on $H(x, u, p)$ and the regularity of u can also be done to obtain a more general (and slower) rate of convergence. This, however, will not be done here.

Proof of Theorem 2. Mimicking the proof of Theorem 1, we arrive at the analogue of inequality (2.7):

$$\begin{aligned} &H(x_\delta, u_\varepsilon(x_\delta), \nabla_x \phi_1(x_\delta)) - H(x_\delta, u(y_\delta), \nabla_x \phi_1(x_\delta)) \\ &\quad \leqq H(y_\delta, u(y_\delta), \nabla_y \phi_2(y_\delta)) - H(x_\delta, u(y_\delta), \nabla_x \phi_1(x_\delta)) + \varepsilon \Delta_x \phi_1(x_\delta) + \underline{C}\varepsilon, \end{aligned} \tag{3.4}$$

where $\nabla_x \phi_1$ and $\nabla_y \phi_2$ are given by (3.3) (with $\psi \equiv 0$) and x_δ and y_δ are as in (2.3). Recalling (2.4) and using the fact that u (or u_ε) is Lipschitz continuous, we have that

$$\phi^\delta(x_\delta, y_\delta) \leqq |u(x_\delta) - u(y_\delta)| \leqq L|x_\delta - y_\delta|, \tag{3.5}$$

or

$$(\phi^\delta(x_\delta, y_\delta) \leqq |u_\varepsilon(x_\delta) - u_\varepsilon(y_\delta)| \leqq L|x_\delta - y_\delta|),$$

which, with the definition of ϕ^δ, gives us that

$$|x_\delta - y_\delta| \leqq \frac{L}{\rho(x_\delta)\rho(y_\delta)} \delta. \tag{3.6}$$

Furthermore, a direct calculation shows that

$$|\nabla_x \phi_1(x) - \nabla_y \phi_2(y)| \leqq 2C_\Omega \phi^\delta(x, y),$$

where C_Ω is as in Lemma 1. This inequality, along with (3.5) shows that

$$|\nabla_x \phi_1(x_\delta) - \nabla_y \phi_2(y_\delta)| \leqq 2C_\Omega L|x_\delta - y_\delta|. \tag{3.7}$$

Returning now to inequality (3.4), we use (3.7), Assumption A and the fact that H is (locally) Lipschitz continuous to obtain

$$\mu_{R_0} \max((u_\varepsilon(x_\delta) - u(y_\delta)), 0) \leqq L_H(1 + 2C_\Omega L) \cdot |x_\delta - y_\delta| + \varepsilon \Delta_x \phi_1(x_\delta) + \underline{C}\varepsilon.$$

Calculating $\Delta_x \phi_1$ and inserting (3.6) into the right-hand side above, we find that

$$\begin{aligned} &\mu_{R_0} \max((u_\varepsilon(x_\delta) - u(y_\delta)), 0) \\ &\leqq \left[2d\varepsilon \left(\frac{\rho(x_\delta)\rho(y_\delta)}{\delta} \right) + \hat{L}L \left(\frac{\delta}{\rho(x_\delta)\rho(y_\delta)} \right) \right] + \text{const.}\,(\varepsilon + \varepsilon\delta), \end{aligned} \tag{3.8}$$

where $\hat{L} = L_H(1 + 2C_\Omega L)$. By setting

$$\frac{\delta}{\rho(x_\delta)\rho(y_\delta)} = \left(\frac{2d}{\hat{L}L} \varepsilon \right)^{1/2},$$

which can be done for $\hat{L}L \neq 0$ by the continuity of the left-hand side with respect to δ, we minimize the bracketed term in (3.8). This yields

$$\mu_{R_0} \max((u_\varepsilon(x_\delta) - u(y_\delta)), 0) \leqq (8d\hat{L}L\varepsilon)^{1/2} + \text{const.}\,(\varepsilon + \varepsilon^{3/2}),$$

and using the fact that

$$\max_{x \in \bar{\Omega}} (u_\varepsilon(x) - u(x)) \leqq u_\varepsilon(x_\delta) - u(y_\delta),$$

as done in the proof of Theorem 1, we have established the desired result for $\max(u_\varepsilon - u)$.

An identical estimate can be obtained for $\max(u - u_\varepsilon)$ by a similar argument and so the proof of Theorem 2 is complete.

Remark 3.3. When the domain Ω is convex and $\psi \equiv 0$, the term $O(\varepsilon)$ in the estimate of Theorem 2 is precisely $\underline{C}\varepsilon$. In addition, if the approximate viscosity solution is the solution of (NP_ε), the constant $\underline{C}$ is zero.

Next, we show that the order of the rate of convergence obtained above cannot in general be improved. To see this, consider the example

$$\begin{aligned} &-\varepsilon \frac{d^2 u_\varepsilon}{dx^2} + u_\varepsilon = 0, \\ &\frac{du_\varepsilon}{dx}(0) = 0, \qquad \frac{du_\varepsilon}{dx}(1) = 1. \end{aligned} \tag{3.9}$$

The exact solution of (3.9) is given by

$$u_\varepsilon(x) = \sqrt{\varepsilon}\, \cosh(x/\sqrt{\varepsilon}) / \sinh(1/\sqrt{\varepsilon})$$

and it is an easy exercise to show that $u_\varepsilon \to 0$ uniformly as $\varepsilon \downarrow 0$. In fact, one easily finds that

$$|u_\varepsilon - 0|_\infty = \sqrt{\varepsilon}\{1 + O(\exp(-2/\sqrt{\varepsilon}))\},$$

which is exactly the order obtained by Theorem 2. We should mention, however, that the rate constant of Theorem 2 is not the best possible.

We conclude this section by analyzing the specific example:

$$
\begin{aligned}
&-\varepsilon\frac{d^2u_\varepsilon}{dx^2}+\left(\frac{1}{2}\frac{du_\varepsilon}{dx}\right)^2+u_\varepsilon=0,\\
&\frac{du_\varepsilon}{dx}(0)=\gamma_0, \qquad \frac{du_\varepsilon}{dx}(1)=-\gamma_0.
\end{aligned}
\tag{3.10}
$$

Setting $\varepsilon=0$ and solving the reduced differential equation, we find that $u=\lim_\varepsilon u_\varepsilon$ should be built from functions having the form $-(x-c)^2$ and 0. The objective now is to piece things together in such a way that the constructed function satisfies the viscosity inequalities of Definition 1.

We have three basic cases (which depend on γ_0). Set

$$
u_L(x)=-\left(x-\frac{\gamma_0}{2}\right)^2, \qquad u_R(x)=-\left(x+\frac{\gamma_0}{2}-1\right)^2,
$$

and note that u_L satisfies the left boundary condition of (3.10) and u_R satisfies the right boundary conditions.

Case 1. For $1\geqq\gamma_0\geqq 0$, consider the candidate limit solution:

$$
u_1(x)=\begin{cases} u_L(x), & 0\leqq x\leqq\dfrac{\gamma_0}{2},\\[2ex] 0, & \dfrac{\gamma_0}{2}\leqq x\leqq 1-\dfrac{\gamma_0}{2},\\[2ex] u_R(x), & 1-\dfrac{\gamma_0}{2}\leqq x\leqq 1.\end{cases}
$$

The analysis of this case is trivial since $u_1(x)$ is a classical C^1 solution to the reduced problem. By Remark 2.1, it must therefore be a viscosity solution.

Case 2. For $\gamma_0>1$, consider the candidate limit solution:

$$
u_2(x)=\begin{cases} u_L(x), & 0\leqq x\leqq\frac{1}{2},\\ u_R(x), & \frac{1}{2}\leqq x\leqq 1.\end{cases}
$$

Obviously, we need only check the viscosity inequalities at $x_0=\frac{1}{2}$, the corner of u_2. In this case, however, $\min(u_2-\phi)$ cannot occur at $x_0=\frac{1}{2}$ for any C^1 function ϕ. If $\max(u_2-\phi)$ occurs at $x_0=\frac{1}{2}$, it is easy to check that we must have $(u_L)_x(\frac{1}{2})\geqq\phi_x(\frac{1}{2})\geqq(u_R)_x(\frac{1}{2})$. Computing these derivatives, we have that all possible values of $\phi_x(\frac{1}{2})$ lie in the interval $[1-\gamma_0,\ \gamma_0-1]$, in which case

$$
(\tfrac{1}{2}\phi_x(\tfrac{1}{2}))^2+u_2(\tfrac{1}{2})=(\tfrac{1}{2}\phi_x(\tfrac{1}{2}))^2-(\tfrac{1}{2}(1-\gamma_0))^2\leqq 0.
$$

Therefore, u_2 is a viscosity solution.

Case 3. For $\gamma_0<0$, consider the candidate:

$$
u_3(x)=0.
$$

Here, u_3 does not take on its boundary condition at $x=0$ or at $x=1$. However, $\max(u_3-\phi)$ cannot occur at $x=0$ for any admissible test function, $(\partial\phi/\partial n(0)\geqq-\gamma_0)$. If on the other hand, $\min(u_\varepsilon-\phi)$ is attained at $x_0=0$, we must have that $\phi_x(0)$ lies in $[\gamma_0, 0]$ and in this case

$$
(\tfrac{1}{2}\phi_x(0))^2+u_3(0)\geqq 0.
$$

A similar argument shows that u_3 satisfies the viscosity inequalities if $\max(u_3-\phi)$ is attained at $x_0=1$.

In these specific examples, we have demonstrated that these candidate limit solutions are viscosity solutions of (3.10) since they satisfy Definition 1(c). They are furthermore Lipschitz continuous and so by Proposition 1 and Remark 3.2 of Theorem 2, they satisfy $|u_\varepsilon - u|_\infty \leqq \text{const.}\sqrt{\varepsilon}$ where u_ε is the exact solution of problem (3.10). However, for these examples (as well as other nonlinear examples) there is evidence that indicates a convergence rate faster than the $\sqrt{\varepsilon}$, [3]. We believe that there is a yet undiscovered mechanism that links certain nonlinearities in H to diffusion which often gives rise to a faster rate of convergence than Theorem 2 predicts.

4. Numerical approximations. In this section, we introduce and analyze a class of numerical schemes that generate approximations of the viscosity *limit* solution to the one-dimensional version of (NP_ε), which we write here as:

$$\begin{aligned} &-\varepsilon\frac{d^2u_\varepsilon}{dx^2}+H\left(x, u_\varepsilon, \frac{du_\varepsilon}{dx}\right)=0, \\ &-\frac{du_\varepsilon}{dx}(0)=\gamma_0, \qquad \frac{du_\varepsilon}{dx}(1)=\gamma_1. \end{aligned} \tag{4.1}$$

Throughout this section, we make the following assumptions concerning $H(x, u, p)$, which for ease of presentation only, is assumed C^1 smooth.

Assumption A′. For all $x\in[0,1]$, $|u|=R$ and $|P|\leqq K$, there exists a $\mu_K>0$ and an $0\leqq\eta_1<1$, such that

$$\frac{\partial}{\partial u}H(x, u, p)\geqq \mu_K/(\max(R,1))^{\eta_1}.$$

Assumption B′. For all $x\in[0,1]$ and $|p|=K$, there exists an $0\leqq\eta_2<1$ and a constant $C(|u|)$ such that

$$\left|\frac{\partial}{\partial x}H(x, u, p)\right| \leqq \mu_K(\max(K,1))^{\eta_2}C(|u|).$$

Assumption A′ is merely a refined version of Assumption A of § 2. Assumption B′ guarantees that the viscosity limit solution of (4.1) is Lipschitz continuous and therefore supercedes Assumption B of § 2.

The numerical approximations that are considered here are built from a piecewise linear interpolation of grid values $\{u_j\}_{j=0}^J$. That is, we partition the interval $[0,1]$ as $\bigcup_{j=0}^{J-1}[x_j, x_{j+1}]$, where we shall assume that

$$2(x_j-x_{j-1})\geqq(x_{j+1}-x_j)\geqq\tfrac{1}{2}(x_j-x_{j-1}),$$

and then define $u^\Delta(x)$ by

$$u^\Delta(x)=\sum_{j=0}^{J}u_jT_j(x), \tag{4.2}$$

where

$$T_j(x)=\begin{cases}(x-x_{j-1})/(x_j-x_{j-1}) & \text{if } x\in[x_{j-1}, x_j],\\ (x_{j+1}-x)/(x_{j+1}-x_j) & \text{if } x\in[x_j, x_{j+1}],\\ 0 & \text{otherwise.}\end{cases}$$

In (4.2) the superscript Δ is to represent a measure of grid refinement and we set it equal to $\max_{0\leqq j\leqq J-1}(x_{j+1}-x_j)$. For each $0\leqq j\leqq J$, the grid values u_j are required to

satisfy the difference scheme

$$\begin{aligned} &\bar{H}(x_j, u_j, D^+u_j, D^-u_j) = 0, \\ &-D^-u_0 = \gamma_0, \qquad D^+u_J = \gamma_1, \end{aligned} \tag{4.3}$$

where $D^+u_j = (u_{j+1} - u_j)/(x_{j+1} - x_j)$, $D^-u_j = (u_j - u_{j-1})/(x_j - x_{j-1})$, and $\bar{H}(x, u, p_1, p_2)$ is some difference operator that does not explicitly depend on any grid parameter. $\bar{H}(x, u, p_1, p_2)$ is assumed to be locally Lipschitz continuous and it is also assumed to satisfy three basic properties.

Property 1. $\bar{H}(x, u, p_1, p_2)$ is consistent with $H(x, u, p)$. That is, $\bar{H}(x, u, p, p) = H(x, u, p)$.

Property 2. $\bar{H}(x, u, p_1, p_2)$ is nonincreasing in the p_1 argument and nondecreasing in the p_2 argument.

Property 3. For all $|p_1| \leqq K$ and $|p_2| \leqq K$, $\bar{H}(x, u, p_1, p_2)$ satisfies Assumption A′ above.

Of course, Property 3 simply says that $\bar{H}(x, u, p_1, p_2)$ is strictly increasing in u at the rate prescribed by Assumption A′. We now give the following theorem.

THEOREM 3. *With Assumptions* A′ *and* B′ *above, suppose that* u^Δ *comes from scheme* (4.3), *where* $\bar{H}(x, u, p_1, p_2)$ *satisfies Properties* 1, 2 *and* 3. *Then,* (4.3) *generates a unique approximate solution* u^Δ, *and moreover* u^Δ *converges to* $u = \lim_\varepsilon u_\varepsilon$ *at least as fast as*

$$|u^\Delta - u|_\infty \leqq \text{const.} \sqrt{\Delta},$$

where above, u *is the viscosity* <u>*limit*</u> *solution of* (4.1) *and* $\Delta = \max_{0 \leqq j \leqq J-1} (x_{j+1} - x_j)$.

Remark 4.1. In fact, the hypotheses of Theorem 3 guarantees that $\lim_\varepsilon u_\varepsilon$ exists. This is seen by checking that in the present situation the derivative of u_ε remains uniformly bounded for $\varepsilon > 0$. The Arzela-Ascoli theorem combined with the results of Proposition 1 should now make the remark obvious.

Before proving Theorem 3, we give two examples of finite difference operators which satisfy Properties 1, 2 and 3. Furthermore, we show that the rate above is the best possible under the hypotheses of Theorem 3.

Example 1. The Lax-Friedrichs difference operator [11], [20], is based upon approximating $H(x, u, du/dx)$ by a convex combination of $H(x, u, D^+u)$ and $H(x, u, D^-u)$ along with the introduction of an artificial numerical viscosity term. To be more specific, $\bar{H}$ is given by

$$\bar{H}(x, u, p_1, p_2) = \theta H(x, u, p_1) + (1 - \theta) H(x, u, p_2) - c(p_1 - p_2),$$

where θ is chosen in $[0, 1]$ and

$$c \geqq \max\,(\theta \sup H_p, (\theta - 1) \inf H_p, 0).$$

Clearly, this difference operator satisfies Properties 1, 2 and 3 above. Moreover, if $H_p \geqq 0$ (resp. $H_p \leqq 0$), we could have chosen $\theta = 0$ (resp. $\theta = 1$), and $c = 0$, thus giving a scheme based on backward (resp. forward) differencing.

Example 2. The Godunov difference operator ([9], [20]) is given by

$$\bar{H}(x, u, p_1, p_2) = \begin{cases} \min\limits_{v \in [p_2, p_1]} H(x, u, v) & \text{if } p_2 < p_1, \\ \max\limits_{v \in [p_1, p_2]} H(x, u, v) & \text{if } p_1 \leqq p_2. \end{cases}$$

This difference operator clearly satisfies Properties 1 and 2, and a straightforward exercise will verify that it satisfies Property 3 as well. Again, when $H(x, u, p)$ is monotone in p, the scheme reduces to either a backward or a forward difference scheme.

Next, we show that the rate of convergence of Theorem 3 is sharp. We again consider the trivial example (3.9) and we approximate its viscosity limit solution ($u=0$) by the Lax–Friedrichs difference scheme; however, we intentionally add too much numerical viscosity (we take $c=1$ rather than the allowable $c=0$). Setting $x_{j+1}-x_j=h$, where $h=1/J$, u_j is required to satisfy:

$$\begin{aligned} &-(D^+u_j-D^-u_j)+u_j=0,\\ &D^-u_0=0, \qquad D^+u_J=1. \end{aligned} \tag{4.4}$$

One easily computes the exact solution of (4.4)

$$u_j=\frac{h}{\alpha_2^{J+1}-\alpha_1^{J+1}}\left[\frac{1}{1-\alpha_1}\alpha_1^{j+1}+\frac{1}{\alpha_2-1}\alpha_2^{j+1}\right],$$

where

$$\alpha_1=1+\frac{h}{2}-\sqrt{h}\cdot\left(1+\frac{h}{4}\right)^{1/2}, \qquad \alpha_2=1+\frac{h}{2}+\sqrt{h}\cdot\left(1+\frac{h}{4}\right)^{1/2},$$

and furthermore, since $u_j\geqq 0$, we have that

$$|u^\Delta-u|_\infty\geqq u_J\geqq\frac{h}{\alpha_2-1}.$$

Finally, calculating the right-hand side above, we arrive at

$$|u^\Delta-u|_\infty\geqq\sqrt{h}\left(\frac{\sqrt{h}}{2}+\left(1+\frac{h}{4}\right)^{1/2}\right)^{-1}=\sqrt{h}+O(h),$$

which is exactly the rate of Theorem 3.

We shall prove Theorem 3 via three lemmas.

LEMMA 2. *Assume that $\bar H(x,u,p_1,p_2)$ satisfies Properties* 1, 2 *and* 3 *above. Then, if the difference scheme* (4.3) *had a solution, say u^Δ, u^Δ is bounded and has a bounded Lipschitz constant, uniformly in $\Delta>0$.*

Proof. We first prove that u^Δ must be uniformly bounded. Suppose that $\max_{0\leqq j\leqq J}u_j\geqq 0$ is attained for some $1\leqq j_0\leqq J-1$. Since at an interior maximum $D^+u_{j_0}\leqq 0\leqq D^-u_{j_0}$, (4.3) and Property 2 imply that

$$\bar H(x_{j_0},u_{j_0},0,0)\leqq\bar H(x_{j_0},u_{j_0},D^+u_{j_0},D^-u_{j_0})=0.$$

Therefore, we have from Property 3 that

$$\mu_0 u_{j_0}\leqq(\max(u_{j_0},1))^{\eta_1}|\bar H(x_{j_0},0,0,0)|.$$

Similarly, if $\max_{0\leqq j\leqq J}u_j\geqq 0$ is attained at $j=0$ or $j=J$, we would have that

$$\mu_{|\gamma_0|}u_0\leqq(\max(u_0,1))^{\eta_1}|\bar H(0,0,0,-\gamma_0)|$$

or

$$\mu_{|\gamma_1|}u_J\leqq(\max(u_J,1))^{\eta_1}|\bar H(1,0,\gamma_1,0)|,$$

which proves that $u^\Delta(x)$ must be bounded above independent of $\Delta>0$. An identical argument would show that $\min_{0\leqq j\leqq J}u_j$ must be bounded below independent of $\Delta>0$.

Next, we show that $|D^+u_j|$ must be uniformly bounded. Suppose that $\max_{0\leqq j\leqq J-1} D^+u_j \geqq \max(-\gamma_0, \gamma_1, 0)$ is attained at j_0. Again using (4.3), we must have that

$$\begin{aligned} 0 &= \bar{H}(x_{j_0+1}, u_{j_0+1}, D^+u_{j_0+1}, D^+u_{j_0}) - \bar{H}(x_{j_0}, u_{j_0}, D^+u_{j_0}, D^+u_{j_0-1}) \\ &\geqq \bar{H}(x_{j_0+1}, u_{j_0+1}, D^+u_{j_0}, D^+u_{j_0}) - \bar{H}(x_{j_0}, u_{j_0}, D^+u_{j_0}, D^+u_{j_0}) \\ &= H(x_{j_0+1}, u_{j_0+1}, D^+u_{j_0}) - H(x_{j_0}, u_{j_0}, D^+u_{j_0}). \end{aligned}$$

Setting $K = D^+u_{j_0} \geqq 0$, we have from above and Property 3 that

$$\mu_K K \leqq \left|\frac{\partial}{\partial x} H(\xi, u_{j_0}, K)\right| (\max(|u_{j_0}|, 1))^{\eta_1},$$

and this inequality combined with Assumption B′ implies that

$$K \leqq (\max(K, 1))^{\eta_2} C(|u_{j_0}|)(\max(|u_{j_0}|, 1))^{\eta_1}.$$

Therefore, D^+u_j is bounded above, again independent of $\Delta > 0$. A similar argument would show that D^+u_j is bounded below independent of $\Delta > 0$. This proves the lemma.

LEMMA 3. *Assume that $\bar{H}(x, u, p_1, p_2)$ satisfies Properties* 1, 2 *and* 3. *Then, the difference scheme* (4.3) *has a unique solution.*

Proof. Consider the map $F_\nu : \mathbf{R}^{J+1} \to \mathbf{R}^{J+1}$, defined by

$$(F_\nu(u))_j = u_j - \nu \bar{H}(x_j, u_j, D^+u_j, D^-u_j), \tag{4.5}$$

for $0 \leqq j \leqq J$, where $-D^-u_0 = \gamma_0$ and $D^+u_J = \gamma_1$. We show below that F_ν has a unique fixed point and obviously this fixed point is the desired solution of difference scheme (4.3). We may assume that $\bar{H}(x, u, p_1, p_2)$ above is globally Lipschitz continuous, since $\bar{H}$ could be modified in a smooth way outside the bounded a priori domain established by the previous lemma.

We now claim that $(F_\nu(u))_j$ is a nondecreasing function in u_{j-1}, u_j and u_{j+1}, provided that ν is chosen sufficiently small. Assume for simplicity that $\bar{H}$ is smooth. We then find upon differentiating that

$$\frac{\partial}{\partial u_{j-1}}(F_\nu(u))_j = \nu \bar{H}_{p_2}/(x_j - x_{j-1}) \qquad \text{for } 1 \leqq j \leqq J,$$

$$\frac{\partial}{\partial u_{j+1}}(F_\nu(u))_j = -\nu \bar{H}_{p_1}/(x_{j+1} - x_j) \qquad \text{for } 0 \leqq j \leqq J-1,$$

and Property 2 implies that these quantities are nonnegative. Furthermore,

$$\frac{\partial}{\partial u_j}(F_\nu(u))_j = 1 - \nu\{\bar{H}_u - \bar{H}_{p_1}/(x_{j+1} - x_j) + \bar{H}_{p_2}/(x_j - x_{j-1})\}, \tag{4.6}$$

for $1 \leqq j \leqq J-1$, and $\bar{H}_{p_2} = 0$ for $j = 0$ and $\bar{H}_{p_1} = 0$ for $j = J$. Therefore, since $\bar{H}$ is assumed to be globally Lipschitz continuous, we can choose ν small enough so that these derivatives are nonnegative as well.

Next, we show that F_ν has the fixed-point property for ν as above (ν should be thought of as an artificial time parameter and the restriction on ν imposed in (4.6) as a CFL condition). Let $u \in \mathbf{R}^{J+1}$ and $v \in \mathbf{R}^{J+1}$ and define $\tau = v - u$. Now consider

$$F_\nu(v) - F_\nu(u) = F_\nu(u + \tau) - F_\nu(u). \tag{4.7}$$

Setting $\tau_M = \max(\max_{0\leqq j\leqq J} \tau, 0)$, we have by the claim above, that

$$(F_\nu(u + \tau) - F_\nu(u))_j \leqq (F_\nu(u + \tau_M \vec{1}) - F_\nu(u))_j. \tag{4.8}$$

Now, recalling the definition of F_ν in (4.5), we see that the right-hand side of (4.8) is equal to

$$\tau_M - \nu(\bar{H}(x_j, u_j + \tau_M, D^+u_j, D^-u_j) - \bar{H}(x_j, u_j, D^+u_j, D^-u_j)),$$

which by Property 3 is bounded above by

$$\tau_M(1 - \nu\hat{\mu}),$$

where $\hat{\mu}$ is the appropriate positive constant of Property 3 governed by the a priori domain of Lemma 2. Setting $\tau_m = \min(\min_{0\leqq j\leqq J} \tau, 0)$ and repeating the argument above, we find that

$$\tau_m(1 - \nu\hat{\mu}) \leqq (F_\nu(v) - F_\nu(u))_j \leqq \tau_M(1 - \nu\hat{\mu}). \tag{4.9}$$

Therefore, the Banach fixed-point theorem guarantees a unique fixed point of F_ν, for ν sufficiently small, which is the desired result.

Remark 4.2. Inequality (4.9) tells us that implementing an artificial time method, $(u^{n+1} = F_\nu(u^n))$, to obtain a solution of difference scheme (4.3), converges at an l^∞ rate of $e^{-\hat{\mu}t}$. This, of course, is computationally slow in light of the increment restriction imposed by (4.6). We recommend a few iterations of artificial time to pull the initial approximation into the l^∞ domain of attraction for Newton's method, which with some "smoothness," converges at a much faster quadratic rate.

The next lemma is crucial to establish the fact that u^Δ satisfies the approximate viscosity inequalities.

LEMMA 4. *Suppose* $\phi(x) = \kappa|x - y|^2 + \psi(x)$, *where* $y \in [0, 1]$ *is fixed,* κ *is a constant and* $\psi(x)$ *is an affine function with* $-\psi'(0) = \gamma_0$ *and* $\psi'(1) = \gamma_1$. *Then*:

(a) *If* $\kappa \geqq 0$ *and* $\max_{x\in[0,1]}(u^\Delta(x) - \phi(x))$ *is attained for some* $\xi \neq x_j$, $0 \leqq j \leqq J$, *we have* $D^+u_{j_0} - D^-u_{j_0} \leqq \Delta \cdot \phi_{xx}(\xi)$, *where* x_{j_0} *is the nearest grid point to* ξ.

(b) *If* $\kappa \leqq 0$ *and* $\min_{x\in[0,1]}(u^\Delta(x) - \phi(x))$ *is attained for some* $\xi \neq x_j$, $0 \leqq j \leqq J$, *we have* $D^+u_{j_0} - D^-u_{j_0} \geqq \Delta \cdot \phi_{xx}(\xi)$, *where* x_{j_0} *is the nearest grid point to* ξ.

Proof. We prove (a) only since the proof of (b) is identical. Let x_{j_0} be the nearest grid point to ξ. We have three basic cases to examine: $x_{j_0} = 0$, $x_{j_0} = 1$ and $0 < x_{j_0} < 1$.

Case 1. When $x_{j_0} = 0$, we must have $D^+u_0 = \phi_x(\xi)$ since $\xi \in (0, x_1)$ is where the maximum of $u^\Delta - \phi$ occurs. However, because ϕ is quadratic, $\phi_x(\xi) = \phi_x(0) + \xi\phi_{xx}(\xi)$. Therefore, $D^+u_0 = \xi\phi_{xx}(\xi) + \phi_x(0) \leqq \xi\phi_{xx}(\xi) - \gamma_0$.

Case 2. The case when $x_{j_0} = 1$ is identical to Case 1 above.

Case 3. Suppose now that $\xi \in (x_{j_0-1}, x_{j_0})$ and choose an arbitrary $\tau \in (x_{j_0}, x_{j_0+1})$ (if, on the other hand, $\xi \in (x_{j_0}, x_{j_0+1})$ the argument below is essentially the same). Using the definition of u^Δ and the fact that $(u^\Delta - \phi)(\xi)$ is maximum, we have that

$$\begin{aligned} &u_{j_0} + D^-u_{j_0}(\xi - x_{j_0}) - \phi(\xi) \geqq u_{j_0} + D^+u_{j_0}(\tau - x_{j_0}) - \phi(\tau), \\ &D^-u_{j_0} = \phi_x(\xi). \end{aligned} \tag{4.10}$$

Therefore, a simple calculation will show that (4.10) implies

$$D^+u_{j_0} - D^-u_{j_0} \leqq \frac{\phi_x(\xi)(\xi - \tau) + \phi(\tau) - \phi(\xi)}{\tau - x_{j_0}}. \tag{4.11}$$

Taylor's theorem allows us to write the right-hand side of (4.11) as

$$\frac{1}{2}\left[\frac{(\tau - \xi)^2}{\tau - x_{j_0}}\right]\phi_{xx}(\xi).$$

Recall that we have assumed our grid satisfies the constraint $(x_{j+1}-x_j)\geqq\frac{1}{2}(x_j-x_{j-1})$. This allows us to minimize the bracketed term above by choosing $\tau=2x_j-\xi$. Doing this, we have

$$D^+u_{j_0}-D^-u_{j_0}\leqq 2(x_{j_0}-\xi)\phi_{xx}(\xi),$$

and since x_{j_0} is the *nearest* grid point to ξ, the proof is complete.

Proof of Theorem 3. The proof of the theorem is complete (Lemmas 2 and 3), except for showing that u^Δ satisfies the approximate viscosity inequalities of Definition 2. With this in mind, set $\phi_1(x)=|x-y_0|^2/\delta+\psi(x)$, where $y_0\in[0,1]$, is fixed and $\psi(x)$ is affine, with $\psi'(0)=-\gamma_0$ and $\psi'(1)=\gamma_1$ (as in Definition 2(a)). Suppose now that $u^\Delta-\phi_1$ is maximum at $\xi\in[0,1]$. To show that u^Δ is an approximate viscosity subsolution, we must verify that

$$H(\xi, u^\Delta(\xi), \phi_{1x}(\xi))\leqq(K\cdot\Delta)\cdot\phi_{1xx}(\xi)+C\Delta, \tag{4.12}$$

where K is some constant, independent of Δ, and as always in this section, $\Delta=\max_{0\leqq j\leqq J-1}(x_{j+1}-x_j)$.

Using difference scheme (4.3) and Property 1, we have that for every $0\leqq j\leqq J$

$$H(\xi, u^\Delta(\xi), \phi_{1x}(\xi))=\bar H(\xi, u^\Delta(\xi), \phi_{1x}(\xi), \phi_{1x}(\xi))-\bar H(x_j, u_j, D^+u_j, D^-u_j),$$

and we rewrite this identity as

$$\begin{aligned}H(\xi, u^\Delta(\xi), \phi_{1x}(\xi))=&[\bar H(x_j, u_j, \phi_{1x}(\xi), \phi_{1x}(\xi))-\bar H(x_j, u_j, D^+u_j, D^-u_j)]\\&+[\bar H(\xi, u^\Delta(\xi), \phi_{1x}(\xi), \phi_{1x}(\xi))\\&\quad-\bar H(x_j, u_j, \phi_{1x}(\xi), \phi_{1x}(\xi))].\end{aligned} \tag{4.13}$$

The second term on the right-hand side of (4.13) is bounded above by

$$L_x|\xi-x_j|+L_uL|\xi-x_j|, \tag{4.14}$$

where L_x and L_u are the Lipschitz constants of $\bar H$ in the x and u arguments, respectively, and L is the Lipschitz constant of u^Δ. The first term on the right-hand side of (4.13) can be written as

$$\bar H_{p_1}\cdot(\phi_{1x}(\xi)-D^+u_j)+\bar H_{p_2}\cdot(\phi_{1x}(\xi)-D^-u_j), \tag{4.15}$$

where, again, we have assumed that $\bar H$ is smooth for simplicity.

If $\xi=x_{j_0}$ for some $0\leqq j_0\leqq J$, we have nothing to prove since it is an easy exercise to determine that in this case $D^+u_{j_0}\leqq\phi_{1x}(\xi)\leqq D^-u_{j_0}$ when x_{j_0}, $(=\xi)$, is a maximizer of $u^\Delta-\phi_1$. (Recall by the definition of ϕ_1 that $\phi_1(0)\leqq D^-u_0$ and $\phi_{1x}(1)\geqq D^+u_J$ in the event that $\xi=0$ or 1.) Therefore setting $j=j_0$ in (4.15) and recalling Property 2 (which says that $\bar H_{p_1}\leqq 0\leqq\bar H_{p_2}$), verifies the approximate viscosity inequality of Definition 2(a) here in a trivial way.

If, on the other hand, $\xi\neq x_j$ for all $0\leqq j\leqq J$, take x_{j_0} to be the nearest grid point to ξ. Set $j=j_0$ in (4.15) and insert the identity $\phi_{1x}(\xi)=D^-u_{j_0}$, (or $\phi_{1x}(\xi)=D^+u_{j_0}$) into it. Using the result of Lemma 4 allows us to combine (4.15) with (4.13) to arrive at

$$H(\xi, u^\Delta(\xi), \phi_{1x}(\xi))\leqq(K\cdot\Delta)\cdot\phi_{1xx}(\xi)+C\Delta,$$

where $K=\max(-H_{p_1}, H_{p_2})$ and C is given by $\frac{1}{2}(L_x+L_uL)$.

An identical argument will show that u^Δ is an approximate viscosity supersolution, (see Definition 2(b)), and so by applying the abstract result of Theorem 2, the proof of Theorem 3 is complete.

STABILITY AND INSTABILITY FOR SOLUTIONS OF BURGERS' EQUATION WITH A SEMILINEAR BOUNDARY CONDITION*

HOWARD A. LEVINE†

Abstract. In this paper, we present several results concerning the long-time behavior of positive solutions of Burgers' equation $u_t = u_{xx} + \varepsilon u u_x$, $0 < x < 1$, $t > 0$, $u(x, 0)$ given, subject to one of two pairs of boundary conditions: (A) $u(0, t) = 0$, $u_x(1, t) = au^p(1, t)$, $t > 0$, or (B) $u(1, t) = 0$, $u_x(0, t) = -au^p(0, t)$, where $0 < p < \infty$. A complete stability-instability analysis is given. It is shown that some solutions can blow up in finite time. Generalizations replacing $\varepsilon u u_x$ by $(f(u))_x$ and au^p by $g(u)$ are discussed.

Key words. Burgers' equation, stability, instability

AMS(MOS) subject classifications. 35K05, 35K20, 35K55, 35K60, 76E99

1. Introduction. In this paper, we consider two nonstandard initial-boundary value problems for Burgers' equation, namely

$$\text{(A)}\qquad \begin{aligned} &u_t = u_{xx} + \varepsilon u u_x && \text{on } (0, 1) \times (0, \infty),\\ &u_x(1, t) = au^p(1, t) && \text{on } (0, \infty),\\ &u(0, t) = 0 && \text{on } (0, \infty),\\ &u(x, 0) = u_0(x) \text{ prescribed} && \text{on } [0, 1] \end{aligned}$$

and

$$\text{(B)}\qquad \begin{aligned} &u_t = u_{xx} + \varepsilon u u_x && \text{on } (0, 1) \times (0, \infty),\\ &u(1, t) = 0 && \text{on } (0, \infty),\\ &-u_x(0, t) = au^p(0, t) && \text{on } (0, \infty),\\ &u(x, 0) = u_0(x) && \text{on } [0,1]. \end{aligned}$$

Here $p > 0$, ε, $a > 0$, while u^p is defined as $|u|^{p-1}u$. We observe that in this case $\tilde{u}(x, t) = -u(1 - x, t)$ defines a one-to-one, onto correspondence between the solutions of (A) and those of (B). This observation permits us to construct all the stationary solutions of (A) (or (B)) for all real ε, if we know only the positive stationary solutions of (A) and (B) for $\varepsilon \geqq 0$. (Nontrivial stationary solutions of (A) and (B) are necessarily of one sign.)

Our interest in these problems is twofold. First, when $\varepsilon = 0$, (A) and (B) are essentially the same problem. They have been studied from the point of view of potential well-theory (in several space dimensions) in a recent series of papers [6], [7]. The arguments used therein establish the existence of a potential well for which solutions starting in the well remain in the well and for which solutions starting in the exterior of the well are unstable and, indeed, fail to exist for all time. However, when $\varepsilon \neq 0$, such arguments, which demand the existence of a potential energy functional, cannot be applied to problems (A) and (B), for which no such functional exists.

† Department of Mathematics, Iowa State University, Ames, Iowa 50011.

Second, in [1], [15], the authors have obtained partial results and done some numerical experiments for

$$\text{(C)}\qquad \begin{aligned} &u_t = u_{xx} + \varepsilon u u_x + a u^p && \text{in } (0,1)\times(0,\infty),\\ &u(0,t) = u(1,t) = 0 && \text{on } (0,\infty),\\ &u(x,0) \text{ prescribed} && \text{on } [0,1]. \end{aligned}$$

It has been observed in [6], [7] that with $\varepsilon = 0$, potential well theory for (C) closely parallels that for (A) (even in several space dimensions). We might therefore expect that when $\varepsilon > 0$, the study of (A) or (B) might provide additional insight into the behavior of solutions of (C).

Although this is true in some generalized sense, the analysis of the bifurcation diagram for (C) is much less well understood than those for (A) or (B). However, numerical calculations show that it is closer to (B) than to (A) in structure.

Our results are in the spirit of the framework considered by Hirsch [3] and Matano [9], [10] for strongly order preserving systems. However, application of their general results to our problem is complicated by the presence of the nonlinear term in the boundary condition. Also we make very strong use of the qualitative dependence of the stationary solutions upon ε, which is probably special to the one space dimensional character of our problem. We hope to pursue this matter in a later work.

Some (but not all) of our local existence results have been obtained by Amann [14], in a more general setting. However, we include these proofs here to make our work self-contained.

The plan of the paper is as follows. In § 2, we characterize the set of nonnegative stationary solutions for a generalization of (A), (B). We then obtain the set of stationary solutions of (A), (B) and give the bifurcation diagrams. Verification of the nature of the diagrams is given in Appendix I. In the third section we examine the questions of stability and unstability of the set of stationary solutions. Finally we briefly discuss the question of local existence and continuation in § 4.

2. Stationary solutions. Here we consider stationary solutions for

$$(\text{A}_1)\qquad \begin{aligned} &u_t = u_{xx} + (f(u))_x && \text{on } (0,1)\times(0,\infty),\\ &u_x(1,t) = g(u(1,t)) && \text{on } (0,\infty),\\ &u(0,t) = 0 && \text{on } (0,\infty),\\ &u(x,0) = u_0(x) && \text{on } [0,1] \end{aligned}$$

and

$$(\text{B}_1)\qquad \begin{aligned} &u_t = u_{xx} + (f(u))_x && \text{on } (0,1)\times(0,\infty),\\ &u(1,t) = 0 && \text{on } (0,\infty),\\ &-u_x(0,t) = g(u(0,t)) && \text{on } (0,\infty),\\ &u(x,0) = u_0(x) && \text{on } [0,1], \end{aligned}$$

where f, g are real valued, continuously differentiable functions defined on R^1 with $f(0) = g(0) = 0$ and where $ug(u) > 0$ if $u \neq 0$. We will impose additional hypotheses below. However, these will include the choice $f(u) = \varepsilon u^2/2$, $g(u) = a|u|^{p-1}u$ with $p > 0$. We shall focus on the behavior of nonnegative solutions of (A_1), (B_1) and their corresponding stationary problems.

The following lemma is a simple consequence of the first and second maximum principles for elliptic equations. No particular sign assumptions need be placed on f', f'', g.

LEMMA 2.1. *Let f be twice continuously differentiable. Nonzero stationary solutions of* (A_1) *and* (B_1) *cannot change sign. Positive solutions $w(x)$ of* (A_1) *satisfy* $w'(x)>0$ *on* $[0,1]$, *while positive solutions of* (B_1) *satisfy* $w'(x)<0$ *on* $[0,1]$.

Proof. The first statement follows from the maximum principle. For the first part of the second statement, we must have $w'(0)\geqq 0$. This inequality is strict unless $w\equiv 0$. If w' changed sign on $[0,1)$, w would have an interior maximum which cannot happen unless $w=$ constant $=0$. If $w'(1)=0$, then, from the Hopf second principle, $w(x)\equiv w(1)$ and consequently $w(x)\equiv 0$. If, for some $x_0\in(0,1)$ $w'(x_0)=0$ and $w'(x)\geqq 0$ otherwise, then $w''(x_0)=0$ also. However $v=w'$ then satisfies $v''+f'(w)v'+f''(w)v^2=0$ with $v(x_0)=v'(x_0)=0$. By uniqueness, $v\equiv 0$ and again $w(x)\equiv w(1)$.

A similar argument holds for the second part of the second statement. □

THEOREM 2.1A. *Let $f'>0$ for $u>0$. Let $w(x)$ be a positive stationary solution of* (A_1), C^2 *on* $(0,1)$ *and* C^1 *on* $[0,1]$. *Let $w_1\equiv w(1)$. Then*

$$\int_0^{w(x)}\frac{d\sigma}{g(w_1)+f(w_1)-f(\sigma)}=x \tag{2.1}$$

for $0\leqq x\leqq 1$. Conversely, if $w_1>0$ solves

$$\int_0^{w_1}\frac{d\sigma}{g(w_1)+f(w_1)-f(\sigma)}=1, \tag{2.2}$$

and w solves (2.1) *with this degree of smoothness, with $w(1)=w_1$, then w is a positive stationary solution of* (A_1).

THEOREM 2.1B. *Let $f\geqq 0$ for $u\geqq 0$. Let $w(x)$ be a positive stationary solution of* (B_1), C^2 *on* $(0,1)$ *and* C^1 *on* $[0,1]$. *Let $w_0=w(0)$. Then*

$$\int_0^{w(x)}\frac{d\sigma}{g(w_0)-f(w_0)+f(\sigma)}=1-x \tag{2.3}$$

for $0\leqq x\leqq 1$ and $g(w_0)-f(w_0)>0$. Conversely, if $w(0)=w_0>0$, $g(w_0)-f(w_0)>0$, w_0 solves

$$\int_0^{w_0}\frac{d\sigma}{g(w_0)-f(w_0)+f(\sigma)}=1, \tag{2.4}$$

w solves (2.3) *with this degree of smoothness, and $w(0)=w_0$, then w is a positive stationary solution of* (B_1).

Proof. To prove the first of these, we note that (2.1) and (2.2) follow from

$$w''(x)+(f(w(x)))'=0, \qquad 0<x<1,$$

$$w(0)=-w'(1)+g(w(1))=0,$$

after noting that $w'(x)=-f(w(x))+f(w_1)+g(w_1)>0$ and a second quadrature.

For the converse, we observe that if $w(\cdot)$ satisfies (2.1), then $w(x)<w_1$ if $x<1$. To see this, suppose that $w(\bar{x})\geqq w_1$ for some $\bar{x}\in[0,1)$. If $h(\sigma)\equiv g(w_1)+f(w_1)-f(\sigma)$ has no roots, then $h(\sigma)>0$ and

$$1=\int_0^{w_1}\frac{d\sigma}{h(\sigma)}\leqq\int_0^{w(\bar{x})}\frac{d\sigma}{h(\sigma)}=\bar{x}$$

so that $\bar{x}=1$. If $h(\sigma)$ has a root, say $\bar{\sigma}$, then this root is unique. Moreover, $\bar{\sigma}>\sup\{w(x)\,|\,0\leqq x\leqq 1\}$; otherwise there would be $\bar{x}\in(0,1)$ with $\bar{\sigma}=w(\bar{x})$. But $h(\sigma)=f(\bar{\sigma})-f(\sigma)\approx f'(\bar{\sigma})(\bar{\sigma}-\sigma)$ so that

$$\bar{x}=\int_0^{w(\bar{x})}\frac{d\sigma}{h(\sigma)}=\int_0^{\bar{\sigma}}\frac{d\sigma}{f(\bar{\sigma})-f(\sigma)}=+\infty.$$

Thus $w(x)\leqq\bar{\sigma}-\delta$ for some $\delta>0$ and all $x\in[0,1]$. Therefore we may differentiate (2.1) to find that $w'(x)+f(w(x))=g(w_1)+f(w_1)$ and $w''(x)+(f(w(x)))'=0$. Thus $w'(1)=g(w_1)$. Also, if $\bar{x}\in[0,1)$ is such that $w(1)<w(\bar{x})<\bar{\sigma}$, then by the argument above we find again that $\bar{x}\geqq 1$, which is impossible. Therefore $w(x)\leqq w_1$ and thus $w'(x)\geqq f(w_1)-f(w(x))\geqq 0$. Thus $w(0)\equiv\lim_{x\to 0^+}w(x)$ exists and, by (2.1), must be zero. □

The proof of Theorem 2.1B is similar. We note that if w is a stationary solution, then the conservation law $w'(x)+f(w(x))=$ constant yields (since $f(0)=0$), $f(w(0))-g(w(0))=w'(1)$ which is negative by the lemma.

Equations (2.2) and (2.4) can have several solutions, each corresponding to a stationary solution. With somewhat further restrictions on f, g we can prove that these solutions are ordered.

THEOREM 2.2A. *Let u_1, v_1 be solutions of* (2.2) *with $u_1>v_1>0$. Let $u(x)$, $v(x)$ be the corresponding solutions of* (2.1) *with $u(1)=u_1$, $v(1)=v_1$. Suppose that $f(u_1)+g(u_1)>f(v_1)+g(v_1)$ (which holds if $f+g$ is strictly increasing). Then $u(x)>v(x)$ for x in* $(0,1]$.

THEOREM 2.2B. *Let u_0, v_0 be solutions of* (2.4) *with $u_0>v_0>0$, $g(u_0)-f(u_0)>0$, $g(v_0)-f(v_0)>0$ and let $u(x)$, $v(x)$ denote the corresponding solutions of* (2.3). *If f' is strictly increasing, then $u(x)>v(x)$ on* $[0,1)$.

Theorem 2.2B is an easy consequence of the maximum principle. If $w(x)=u(x)-v(x)$, then $w(0)>0$, $w(1)=0$ and, on $(0,1)$,

$$w''+f'(u)w'+(f'(u)-f'(v))v'=0. \tag{2.5}$$

Since $v'<0$ and f' is strictly increasing, the usual arguments show that w cannot have an interior negative minimum. Therefore $w\geqq 0$. If w had an interior zero at x_0, it would also have a positive maximum on $(x_0,1)$. However from (2.5) we see that this is false also.

(The hypotheses on f, g *do not* imply that there are any solutions at all of (2.2), (2.4).)

To prove Theorem 2.2A, we see from the conservation laws that for any $x\in(0,1)$

$$u_x(0)=g(u_1)+f(u_1)=u_x(x)+f(u(x))$$

and

$$v_x(0)=g(v_1)+f(v_1)=v_x(x)+f(v(x)).$$

From the hypothesis we find $u_x(0)>v_x(0)$. Since $u(0)=v(0)=0$, $u(x)>v(x)$ in a neighborhood of $x=0$. If $\bar{x}$ is the first point in $(0,1]$ where $u(\bar{x})=v(\bar{x})$, we see from the above that $u_x(\bar{x})>v_x(\bar{x})$. This inequality holds in a left open neighborhood of $\bar{x}$, say $(\bar{x}-\delta,\bar{x}]$. But then we obtain a contradiction from

$$0=u(\bar{x})-v(\bar{x})=\int_{\bar{x}-\delta}^{\bar{x}}(u_x(x)-v_x(x))\,dx+[u(\bar{x}-\delta)-v(\bar{x}-\delta)]. \tag{2.6}$$

□

Example 2.1. $f(u)=\frac{1}{2}\varepsilon u^2$, $g(u)=a|u|^{p-1}u$, a, $\varepsilon>0$. In this case, (2.2) is equivalent to

$$F(w_1)\equiv\int_0^1\frac{d\sigma}{(2a/\varepsilon)w_1^{p-2}+1-\sigma^2}=\frac{1}{2}\varepsilon w_1. \tag{2.7}$$

We find that for $p=2$ there is one solution for all $\varepsilon>0$. For $p>2$, $F'(w_1)<0$, $F(w_1)\to+\infty$ as $w_1\downarrow 0$ and $F(w_1)\to 0$ as $w_1\to+\infty$ so that there is only one solution for all $\varepsilon>0$ in this case also. If $1<p<2$, we set $v_1=(2a/\varepsilon)w_1^{p-2}$, $\delta=a^{1/(2-p)}(\varepsilon/2)^{(p-1)/(p-2)}$ and seek the number of positive solutions of

$$Q(v_1)\equiv v_1\int_0^1\frac{d\sigma}{v_1+(1-\sigma^2)}=\delta v_1^{(p-1)/(p-2)}\equiv R(v_1).$$

It is easy to see that $Q(0)=0$, $Q'(v_1)>0$, $Q(+\infty)=1$ while $R'(v_1)<0$, $R(v_1)\to 0$ as $v_1\to+\infty$, $R(v_1)\to+\infty$ as $v_1\to 0^+$. Therefore problem (A) has exactly one positive stationary solution for all $a>0$, $\varepsilon>0$ in this case also.

The case $p=1$ must be treated separately. We observe that when $p=1$, we must solve $Q(v)=a$. Therefore there is one and only one positive stationary solution when $0<a<1$ and none when $a\geqq 1$.

The case $0<p<1$ is more difficult. We try to solve

$$\phi(v_1)=v_1^{1/(2-p)}\int_0^1\frac{d\sigma}{v_1+(1-\sigma^2)}=\delta$$

where, after an abuse of notation, we let

$$\phi(\alpha)=\tfrac{1}{2}(\alpha^2-1)^q\alpha^{-1}\ln((\alpha+1)/(\alpha-1))$$

on $(1,\infty)$, with $q=1/(2-p)$ and $\alpha=(v_1+1)^{1/2}$. It is easily seen that $\frac{1}{2}<q<1$ and that

$$\phi'(\alpha)=\tfrac{1}{2}(\alpha^2-1)^{q-1}\alpha^{-2}K(\alpha)$$

where

$$K(\alpha)=[(2q-1)\alpha^2+1]\ln((\alpha+1)/(\alpha-1))-2\alpha$$

and that

$$\tfrac{1}{2}K'(\alpha)=(2q-1)\alpha\ln((\alpha+1)/(\alpha-1))-2q\alpha^2/(\alpha^2-1).$$

We see that, as $\alpha\to+\infty$, $K'(\alpha)/2\alpha\sim 2(q-1)\alpha/(\alpha^2-1)<0$ and that

$$\left(\frac{K'(\alpha)}{2\alpha}\right)'=\frac{1}{(\alpha^2-1)^2}[2(1-q)\alpha^2+(6q-2)]$$

which is positive. Therefore K' is negative on $(1,\infty)$. However $\lim_{\alpha\to 1^+}K(\alpha)=+\infty$ while $K(\alpha)\sim 4(q-1)\alpha$ (<0) as $\alpha\to\infty$. Therefore K has exactly one sign change and ϕ first increases and then decreases on $(1,\infty)$. We note also that $\lim_{\alpha\to 1^+}\phi(\alpha)=0$ and, by L'Hopital's rule $\phi(\alpha)\approx(2/(2q-1))\alpha^{-2(1-q)}$ as $\alpha\to+\infty$ so that $\lim_{\alpha\to+\infty}\phi(\alpha)=0$. Thus the equation $\phi(\alpha)=\delta$ has zero, one or two solutions accordingly as

$$\varepsilon>2(\bar{\phi})^{(p-2)/(p-1)}a^{1/(p-1)},\qquad \varepsilon=2(\bar{\phi})^{(p-2)/(p-1)}a^{1/(p-1)}$$

or

$$\varepsilon<2(\bar{\phi})^{(p-2)/(p-1)}a^{1/(p-1)}$$

where

$$\bar{\phi}=\max_{1<\alpha<\infty}\phi(\alpha).$$

For (2.4) we have, in this case,

$$F(w_0)=\int_0^1\frac{d\sigma}{(2a/\varepsilon)w_0^{p-2}-1+\sigma^2}=\frac{1}{2}\varepsilon w_0 \tag{2.8}$$

with the additional condition that

$$(2a/\varepsilon)w_0^{p-2} > 1.$$

In this case, it is convenient to define

$$\beta = (2a/\varepsilon)w_0^{p-2} - 1$$

and seek positive solutions of

$$G(\beta) \equiv \int_0^1 \frac{d\sigma}{\beta + \sigma^2} = \delta(\beta+1)^{1/(p-2)} \equiv H(\beta) \tag{2.9}$$

with δ as above. If $p \geqq 2$, we see as above that there is exactly one positive solution of (2.9) and hence (2.8). On the other hand, if $1 < p < 2$, we examine the equation (with $\alpha^2 = \beta$, $\alpha > 0$)

$$I(\alpha) \equiv \frac{(\alpha^2+1)^{1/(2-p)}}{\alpha} \tan^{-1}\left(\frac{1}{\alpha}\right) = \delta.$$

We see that with $q = 1/(2-p)$,

$$I'(\alpha) = (\alpha^2+1)^{q-1}\alpha^{-2}K(\alpha)$$

where

$$K(\alpha) = ((2q-1)\alpha^2 - 1)\tan^{-1}(1/\alpha) - \alpha.$$

We have

$$K'(\alpha) = 2(2q-1)\alpha \tan^{-1}(1/\alpha) - 2q\alpha^2/(\alpha^2+1).$$

Moreover, $K'(\alpha) > 0$ on $(0, \infty)$ while

$$K(\alpha) \to \frac{-\pi}{2} \quad \text{as } \alpha \to 0^+$$

and

$$K(\alpha) \sim [2(p-1)/(2-p)]\alpha$$

as $\alpha \to +\infty$. Therefore $I'(\alpha)$ changes sign exactly once on $(0, \infty)$, $I(\alpha) \to +\infty$ as $\alpha \to 0^+$ and as $\alpha \to +\infty$. Therefore (2.9) has zero, one or two solutions according to whether

$$\varepsilon < 2(\bar{I})^{-(2-p)/(p-1)}a^{1/(p-1)}, \qquad \varepsilon = 2(\bar{I})^{-(2-p)/(p-1)}a^{1/(p-1)}$$

or

$$\varepsilon > 2(\bar{I})^{-(2-p)/(p-1)}a^{1/(p-1)}$$

where

$$\bar{I} = \min_{0<\alpha<\infty} I(\alpha).$$

When $p = 1$, the situation is somewhat different than the case $p > 1$. We must solve (with $\delta = a$ when $p = 1$)

$$J(\alpha) \equiv \tan^{-1}(1/\alpha) - \delta\alpha/(\alpha^2+1) = 0.$$

It is easy to see that when $\delta \in (0, 1]$, $J'(\alpha) < 0$ and the range of J is $(0, \pi/2)$ so that we have no positive stationary solutions in this case. If $\delta > 1$, then $J'(\alpha)$ has a unique positive root at $\bar{\alpha} = [(\delta+1)/(\delta-1)]^{1/2}$ while $J'(\alpha) > 0$ if $\alpha > \bar{\alpha}$ and $J'(\alpha) < 0$ if $\alpha < \bar{\alpha}$.

Since $\bar{\alpha}$ corresponds to a negative minimum of J, we see that there is a unique solution of $J(\alpha)=0$ in $(0, \bar{\alpha})$ and none on $[\bar{\alpha}, \infty)$. Thus, when $a \geqq 1$ there is a unique positive stationary solution for all $\varepsilon > 0$. Otherwise there is none.

In the case $0<p<1$, $K(\alpha) \to -\infty$ as $\alpha \to +\infty$. We write $K'(\alpha) = \alpha Q(\alpha)$ where

$$Q'(\alpha) = \frac{2}{(\alpha^2+1)^2}[(1-q)\alpha^2 - (3q-1)].$$

We see that Q' changes sign from $-(6q-2)$ near $\alpha = 0$ to nearly $2(1-q)\alpha^2/(\alpha^2+1)^2$ for α large. Therefore since $Q(\alpha) \to (2q-1)\pi$ as $\alpha \to 0^+$ and zero at $\alpha = +\infty$, Q changes sign exactly once and hence so does $K'(\alpha)$. The unique root of K' will correspond to a maximum of $K(\alpha)$. Calling this root $\bar{\alpha}$, we have

$$(2q-1)\tan^{-1}(1/\bar{\alpha}) = q\bar{\alpha}/(\bar{\alpha}^2+1).$$

We find

$$K(\bar{\alpha}) = \frac{-1}{(2q-1)(\bar{\alpha}^2+1)} \cdot [(1-q)(2q-1)\bar{\alpha}^3 + (3q-1)\bar{\alpha}]$$

which is negative.

Therefore $K(\alpha)<0$ and $I'(\alpha)<0$. Since $I(\alpha) \sim \alpha^{-2(1-q)}$ as $\alpha \to +\infty$, we see that in this case $I(\alpha) = \delta$ has exactly one solution when $0<p<1$.

The bifurcation diagrams then have the form indicated in Figs. 1.1, 1.2, 2.1 and 2.2. In Appendix II we establish the qualitative shapes of the curves in Figs. 1.1, 1.2, 2.1 and 2.2.

3. Stability-instability-global nonexistence. Here we examine the questions of stability and instability for the time dependent problems (A_1), (B_1) with particular attention focused on (A), (B). We shall assume all solutions are C^2 in x and C^1 in t on $(0, 1)\times(0, T) \equiv D_T$ and continuous in the parabolic cylinder $[0, 1]\times[0, T) \equiv D_T \cup \Gamma_T$. We shall assume f is C^2, for convenience. (See Appendix I.)

LEMMA 3.1A. *Suppose that f' is increasing and that either $g(u)/u$ is bounded in a neighborhood of $u=0$ or else that $u>0$ on $\{1\}\times[0, T)$. Let $u(x, t)$ solve (A_1). If $u(x, 0)>0$ on $(0, 1]$, then $u>0$ on $D_T \cup \Gamma_T$ except at $x=0$. Suppose also that $g(u)/u$ is increasing on $(0, \infty)$. If $w(x)$ is a positive stationary solution of (A_1), $\sigma \in [0, 1)$, and $u(x, 0) \leqq (1-\sigma)w(x)$, then $u(x, t) \leqq (1-\sigma)w(x)$. If $u(x, 0) \geqq (1+\sigma)w(x)$, for some $\sigma>0$, then $u(x, t) \geqq (1+\sigma)w(x)$ on $D_T \cup \Gamma_T$.*

Proof. If u had a negative minimum in $\bar{D}_{T-\delta}$ for some $\delta > 0$, then for any $\lambda, \mu > 0$, $v = e^{-(\lambda x+\mu t)}u$ also would have a negative minimum in $\bar{D}_{T-\delta}$. We choose λ so large that

$$\lambda > \sup\{g(u(1, t))/u(1, t) \,|\, 0 \leqq t \leqq T-\delta\}$$

and then choose μ so large that

$$\mu > \lambda^2 + \lambda \sup\{f'(u(x, t)) \,|\, (x, t) \in \bar{D}_{T-\delta}\}.$$

Then for v we have, in $D_{T-\delta}$,

$$v_t = v_{xx} + (2\lambda + f'(u))v_x + (\lambda f'(u) + \lambda^2 - \mu)v$$

while

$$v_x = (g(u)/u - \lambda)v$$

when $x=1$ and $0<t \leqq T-\delta$. From the first of these, a negative minimum cannot occur in $D_{T-\delta}$ or at $t = T-\delta$ and $0<x<1$, while from the second it cannot occur on $x=1$, $0<t \leqq T-\delta$. Since it cannot occur at $x=0$, we have $u(x, t)>0$ in $\bar{D}_{T-\delta}$ except at $x=0$.

To prove the second statement, we let $v(x)=(1-\sigma)w(x)$ and note that

$$\begin{aligned} v_{xx}+f'(v)v_x &\leqq (1-\sigma)[w_{xx}+f'((1-\sigma)w)w_x] \\ &\leqq (1-\sigma)[w_{xx}+f'(w)w_x] \\ &\leqq 0 \end{aligned} \tag{3.1}$$

since $w_x>0$ on $[0,1]$ and f' is assumed increasing. Moreover on $x=1$,

$$\begin{aligned} v_x-g(v) &= (1-\sigma)g(w)-g((1-\sigma)w) \\ &= (1-\sigma)w[g(w)/w-g((1-\sigma)w)/((1-\sigma)w)] \\ &\geqq 0. \end{aligned} \tag{3.2}$$

We now set

$$\psi(x,t)=e^{(\lambda x+\mu t)}(v(x)-u(x,t)).$$

We find that in $D_{T-\delta}$

$$\psi_t \geqq \psi_{xx}+(-2\lambda+f'(v))\psi_x+[\lambda^2-\mu-\lambda f'(v)+f''(\xi)u_x]\psi$$

and at $x=1$, $0<t\leqq T-\delta$, we have

$$\psi_x \geqq (g'(\eta)+\lambda)\psi.$$

We choose λ, μ to make the coefficients of ψ in these last two inequalities negative. Therefore, if ψ has a negative minimum in $D_{T-\delta}$, it must occur at $x=0$ or at $(1,0)$. At $(1,0)$, however, $\psi(1,0)\geqq 0$. Therefore $\psi\geqq 0$ and the second statement is proved. An argument similar to the above shows us that if $u(x,0)\geqq(1+\sigma)w(x)$, then $u(x,t)\geqq(1+\sigma)w(x)$ on $D_T\cup\Gamma_T$.

We then have, in consequence of the local existence and continuation results, the following theorem.

THEOREM 3.2A. *Let $f+g$ be strictly increasing on $[0,\infty)$. Suppose also that f' is strictly increasing and $g(u)/u$ is increasing on $[0,\infty)$ and that the roots of* (2.2) *are isolated. Then there is at most one positive stationary solution of* (A_1), *call it $w(x)$. Moreover, if $u(\cdot,\cdot)$ solves* (A_1) *on $D_T\cup\Gamma_T$ and $0\leqq u(x,0)\leqq(1-\sigma)w(x)$ on $[0,1]$, then we may take $T=+\infty$ and $0\leqq u(x,t)\leqq(1-\sigma)w(x)$ for all $x\in[0,1]$, $t\in[0,\infty)$. Therefore the null solution is stable from above and $w(x)$ is unstable from below and above (when it exists).*

Proof. Let w_1, w_2 be two stationary solutions of (A_1) with $0<w_1(1)<w_2(1)$ and assume that there are no solutions of (2.2) in $(w_1(1), w_2(1))$. By Theorem 2.1A, we have $w_1(x)<w_2(x)$ on $(0,1]$. Moreover, $w_i'(x)>0$ for $i=1,2$ on $[0,1]$ by Lemma 2.1. With $q(x)=w_1'(x)/w_2'(x)$, we have $q'(x)=(f'(w_2)-f'(w_1))q>0$ on $(0,1]$. From this it follows that $w_1'(0)\leqq w_2'(0)$ which, by uniqueness, must be strict. Moreover,

$$0<\frac{w_1'(1)}{w_2'(1)}=\frac{g(w_1(1))}{g(w_2(1))}=\frac{g(w_1(1))/w_1(1)}{g(w_2(1))/w_2(1)}\cdot\frac{w_1(1)}{w_2(1)}\leqq\frac{w_1(1)}{w_2(1)}<1.$$

Set $\gamma_i=1-w_1'(i)/w_2'(i)$, $i=0,1$. Then $\gamma_i\in(0,1)$ and, on $(0,1]$,

$$(1-\gamma_0)w_2(x)<w_1(x)<(1-\gamma_1)w_2(x).$$

Let $u(x,t)$ solve (A_1) with $u(x,0)=(1-\gamma_1)^{1/2}w_2(x)$. Then

$$(1-\gamma_1)^{-1/2}w_1(x)<u(x,0)\leqq(1-\gamma_1)^{1/2}w_2(x).$$

By the lemma and this inequality,

$$(1-\gamma_1)^{-1/2}w_1(x)\leqq u(x,t)\leqq(1-\gamma_1)^{1/2}w_2(x)$$

on $D_T \cup \Gamma_T$. From this a priori bound and the continuation theorems below, $T = +\infty$. Since $u_t \leqq 0$ on $[0, 1] \times [0, \infty)$ (see Appendix I) $\lim_{t\to\infty} u(x, t) = \phi(x)$ exists and

$$w_1(x) < (1-\gamma_1)^{-1/2} w_1(x) \leqq \phi(x) \leqq (1-\gamma_1)^{1/2} w_2(x) < w_2(x)$$

on $(0, 1]$. Let

$$F(x, t) = \int_0^1 G(x, y) u(y, t)\, dy$$

where

$$G(x, y) = \begin{cases} x & \text{if } 0 \leqq x \leqq y \leqq 1, \\ y & \text{if } 0 \leqq y \leqq x \leqq 1. \end{cases}$$

Then $\lim_{t\to\infty} F(x, t) = \int_0^1 G(x, y)\phi(y)\, dy$ and is finite. If we calculate F_t, we see that

$$\begin{aligned} F_t(x, t) &= \int_0^1 G(x, y) u_t(y, t)\, dy \\ &= -u(x, t) - \int_0^x f(u(y, t))\, dy + x[g(u(1, t)) + f(u(1, t))] \\ &\to -\left[\phi(x) + \int_0^x f(\phi(y))\, dy\right] + x[g(\phi(1)) + f(\phi(1))] \end{aligned}$$

as $t \to \infty$. This limit, which is nonpositive, is in fact zero for $x \in [0, 1]$; otherwise F would not have a finite limit as $t \to +\infty$. Therefore,

$$\phi(x) + \int_0^x f(\phi(y))\, dy = x[g(\phi(1)) + f(\phi(1))]$$

and hence ϕ is a stationary solution of (A_1) with $\phi(1) \in (w_1(1), w_2(1))$, which is the desired contradiction. (If $g(u)/u$ is strictly increasing, then one can relax the condition that the roots of (2.2) are isolated. It then follows that

$$w_1(1)/w_2(1) < 1 - \gamma_1 = w_1'(1)/w_2'(1) < w_1(1)/w_2(1)$$

which is a contradiction and the rest of the argument may be omitted.)

The second statement of the theorem follows from the lemma and the continuation theorems. The null solution is therefore stable from above in the class of continuous functions on $[0, 1]$ vanishing at $x = 0$ while $w(x)$ is unstable from above and below in this class. □

Although the positive stationary solution is unstable (when it exists), there remains the question of the long-time behavior of solutions of (A_1) when $u(x, 0) > w(x)$.

LEMMA 3.3A. *Suppose that* $f'(u) \geqq 0$, $g(u) \geqq 0$ *for* $u \geqq 0$ *and that* $u(x, t)$ *is a nonnegative solution of* (A_1) *on* $D_T \cup \Gamma_T$ *with* $u_x(x, 0) \geqq 0$ *and* $u_x(1, 0) = g(u(1, 0))$. *Then* $u_x(x, t) \geqq 0$ *on* $D_T \cup \Gamma_T$ *and consequently,*

$$u(x, t) \geqq v(x, t)$$

where v *solves*

$$(C_1) \qquad \begin{aligned} &v_t = v_{xx}, && 0 < x < 1, \quad 0 < t < T, \\ &v(0, t) = 0, \\ &v_x(1, t) = g(v(1, t)), && 0 \leqq t < T, \\ &v(x, 0) \leqq u(x, 0), && 0 \leqq x \leqq 1. \end{aligned}$$

Proof. Since $u_x \geqq 0$ on the parabolic boundary and satisfies a linear parabolic equation, $u_x \geqq 0$ in $D_t \cup \Gamma_T$. It follows that $u_t \geqq u_{xx}$ in D_T so that $w = u - v$ satisfies

$w_{xx} - w_t \leqq 0$ in D_T, $w \geqq 0$ when $t = 0$, $w = 0$ on $x = 0$, $w_x = A(x, t)w$ on $x = 1$ where $A(x, t) \equiv (g(u) - g(v))/(u - v)$. By the maximum principle again, $w \geqq 0$. □

LEMMA 3.4A. *Define* $G(u) = \int_0^u g(y)\, dy$ *and suppose that* g *satisfies the structure condition*

$$(p+1)G(u) \leqq ug(u) \tag{3.3}$$

on R^1 *where* $p > 1$ *is given. Let* $v(x, 0) \equiv v_0(x)$. *If* $v_0(x) \geqq 0$, $v_0'(x) \geqq 0$ *and*

$$v_0'(1) = g(v_0(1)), \tag{3.4}$$

$$v_0(0) = 0, \tag{3.5}$$

$$\frac{1}{2}\int_0^1 (v_0'(x))^2\, dx < G(v_0(1)), \tag{3.6}$$

then the solution of (C_1) *blows up in finite time; i.e.,* $T < \infty$ *and*

$$\lim_{t \uparrow T^-} \sup_{0 \leqq x \leqq 1} v(x, t) = +\infty.$$

Proof. The solution (which is nonnegative) fails to be global by the concavity arguments given in [8]. If the solution remains bounded on $\bar{D}_T$, then by the continuation arguments below, it may be continued to $\bar{D}_{T+\delta}$ for some $\delta > 0$. Hence v blows up pointwise in finite time. □

(A variant of this result can be obtained from [13] provided g' exists, an assumption not needed here.)

THEOREM 3.5A. *Let* u *solve* (A_1) *with* $u(x, 0) = v_0(x)$ *and* f, g *as in the preceding lemmas. Then* $u(x, t)$ *blows up in finite time.*

Proof. By Lemmas 3.3A, 3.4A u cannot exist for all time. By the continuation theorems it is continuable if it is bounded on $\bar{D}_T$. Therefore u blows up pointwise in finite time. □

Example 3.1. Suppose $f(u) = \varepsilon u^2/2$, $g(u) = au^p$, $p > 1$. In order to construct such a v_0 as required in Lemma 3.4A, we let

$$v_0(x) = A[(r^2 - (\alpha - x)^2)^{1/2} - (r^2 - \alpha^2)^{1/2}] \tag{3.7}$$

where A, α, r are positive and $r > \alpha > 1$. The constants A, α, r are to be chosen below. Notice that $v_0(0) = 0$, $v_0(x) > 0$ on $(0, 1]$ and $v_0'(x) = A(\alpha - x)(r^2 - (\alpha - x)^2)^{-1/2} > 0$. For any α, r define A by the condition $v_0'(1) = av_0^p(1)$, i.e., by

$$\frac{aA^{p-1}(2\alpha - 1)^p}{[(r^2 - \alpha^2)^{1/2} + (r^2 - (\alpha - 1)^2)^{1/2}]^p} = \frac{\alpha - 1}{(r^2 - (\alpha - 1)^2)^{1/2}}.$$

The final condition of Lemma 3.4A then holds if and only if

$$\frac{a}{p+1} v_0^{p+1}(1) = \frac{(\alpha - 1)(2\alpha - 1) \cdot A^2}{(r^2 - (\alpha - 1)^2)^{1/2}[(r^2 - \alpha^2)^{1/2} + (r^2 - (\alpha - 1)^2)^{1/2}]} \cdot \frac{1}{p+1}$$

$$> \frac{1}{2}\int_0^1 (v_0'(x))^2\, dx = \frac{1}{2}\left\{\frac{1}{2} r \ln\left[\frac{(r - \alpha + 1)(r + \alpha)}{(r + \alpha - 1)(r - \alpha)}\right] - 1\right\} \cdot A^2$$

which will hold if $r > \alpha^2 \gg 1$. One uses the approximation (valid for x small) $\ln(1 + x) \approx x - x^2/2 + x^3/3$ to verify this.

There is a second form of an instability-stability result for (A_1). Somewhat stronger regularity is required however. (See Appendix I.)

THEOREM 3.6A. *In* (A_1) *replace* f *by* εf *where* $\varepsilon \geqq 0$ *is a parameter. Suppose that* $\varepsilon f + g$ *and* f *are* C^1 *increasing functions on* $[0, \infty)$ *with* $f' > 0$ *for* $u > 0$. *Let* $w(x, \varepsilon)$ *be a* C^1 *(in* ε*) branch of positive solutions on some* ε *interval and let* $w_1(\varepsilon) \equiv w(1, \varepsilon)$. *If* $w_1'(\varepsilon) > 0$ *on this branch, the solutions are stable while if* $w_1'(\varepsilon) < 0$ *on this branch, the solutions are unstable. (Here* $w_1'(\varepsilon) \equiv \partial w(1, \varepsilon)/\partial \varepsilon$.)

Proof. We know that

$$x = \int_0^{w(x,\varepsilon)} \frac{d\sigma}{g(w_1(\varepsilon)) + \varepsilon(f(w_1(\varepsilon)) - f(\sigma))} \tag{3.8}$$

on $[0, 1]$. Differentiating with respect to ε, we obtain

$$\begin{aligned} &\{g(w_1(\varepsilon)) + \varepsilon[f(w_1(\varepsilon)) - f(w(x, \varepsilon))]\}^{-1} \frac{\partial w}{\partial \varepsilon}(x, \varepsilon) \\ &= \int_0^{w(x,\varepsilon)} \{[g'(w_1) + \varepsilon f'(w_1)]w_1'(\varepsilon) + (f(w_1) - f(\sigma))\} \frac{d\sigma}{D^2(\sigma)} \end{aligned} \tag{3.9}$$

where $D(\sigma)$ is the denominator in (3.8). Thus, if $w_1'(\varepsilon) > 0$, $\partial w(x, \varepsilon)/\partial \varepsilon > 0$ on $(0, 1]$. Therefore $w(x, \varepsilon_1) < w(x, \varepsilon_2)$ on $[0, 1)$ if $[\varepsilon_1, \varepsilon_2]$ is contained in the domain of this branch. Also $w_x(x, \varepsilon_i) > 0$ on $[0, 1]$.

Suppose that $u(x, t, \varepsilon_1)$ is a solution of (A_1) with $u(x, 0, \varepsilon_1) = w(x, \varepsilon_2)$. Then, on $(0, 1)$,

$$\begin{aligned} u_t(x, 0, \varepsilon_1) &= w_{xx}(x, \varepsilon_2) + \varepsilon_1 f'(w(x, \varepsilon_2)) \cdot w_x(x, \varepsilon_2) \\ &< w_{xx}(x, \varepsilon_2) + \varepsilon_2 f'(w(x, \varepsilon_2)) \cdot w_x(x, \varepsilon_2) \\ &= 0. \end{aligned}$$

Therefore since u_t satisfies a linear problem with homogeneous boundary data, $u_t < 0$ on $D_T \cup \Gamma_T$ except at $x = 0$ and

$$w(x, \varepsilon_1) < u(x, t, \varepsilon_1) < w(x, \varepsilon_2). \tag{3.10}$$

(The first inequality follows from standard comparison theorems. Note that u and the w's satisfy the same boundary conditions.) Thus, from the continuation theorems and (3.10), $T = \infty$ and

$$\phi(x, \varepsilon_1) \equiv \lim_{t \to \infty} u(x, t, \varepsilon_1)$$

exists. From (3.10), $w(x, \varepsilon_1) \leqq \phi(x, \varepsilon_1) < w(x, \varepsilon_2)$ so that, letting $\varepsilon_2 \downarrow \varepsilon_1$, we obtain $\phi(x, \varepsilon_1) = w(x, \varepsilon_1)$. This suffices to show that $w(x, \varepsilon_1)$ is stable from above. Similarly, with $\varepsilon_1 > \varepsilon_2$, one easily shows that $w(x, \varepsilon_1)$ is stable from below.

In the second case, from $w_1'(\varepsilon) < 0$ on $[\varepsilon_1, \varepsilon_2]$ we have that $w(1, \varepsilon_2) < w(1, \varepsilon_1)$ and consequently $w(x, \varepsilon_2) < w(x, \varepsilon_1)$ is a left open neighborhood of $x = 1$.

Suppose that $u(x, t, \varepsilon_2)$ is a solution of (A_1) with $u(x, 0, \varepsilon_2) = w(x, \varepsilon_1)$. Then since $f' > 0$, $w_x \geqq 0$, on $(0, 1)$,

$$\begin{aligned} u_t(x, 0, \varepsilon_2) &= w_{xx}(x, \varepsilon_1) + \varepsilon_2 f'(w(x, \varepsilon_1))w_x(x, \varepsilon_1) \\ &> w_{xx}(x, \varepsilon_1) + \varepsilon_1 f'(w(x, \varepsilon_1))w_x(x, \varepsilon_1) = 0. \end{aligned}$$

Since u_t is nonnegative at $x = 0$ and satisfies a homogeneous linear condition at $x = 1$, $u_t > 0$ in D_T. Therefore u is increasing in t. Hence $w(x, \varepsilon_2)$ is unstable from above. A similar argument with $\varepsilon_1 > \varepsilon_2$ shows that $w(x, \varepsilon_2)$ is unstable from below. □

We have the following corollary of Theorem 3.6A.

COROLLARY 3.7A. *Let f, g be as in the preceding theorem. If $g'(w_1(0))<1$, the branch of stationary solutions emanating from $\varepsilon=0$ is stable while if $g'(w_1(0))>1$, it is unstable.*

Proof. We need to compute $w_1'(\varepsilon)$ on such branches. Setting $x=1$ in (3.9), we find that

$$\left[1-g(w_1)(g'(w_1)+\varepsilon f'(w_1))\int_0^{w_1(\varepsilon)}\frac{d\sigma}{D^2(\sigma)}\right]w_1'(\varepsilon) = g(w_1)\int_0^{w_1(\varepsilon)}\frac{[f(w_1)-f(\sigma)]}{D^2(\sigma)}\,d\sigma \tag{3.11}$$

where $D(\sigma)$ denotes the denominator in (3.8). When $\varepsilon=0$, $g(w_1(0))=w_1(0)$. We find from (3.11) that

$$[1-g'(w_1(0))]w_1'(0)=\frac{1}{w_1(0)}\int_0^{w_1(0)}[f(w_1(0))-f(\sigma)]\,d\sigma. \tag{3.12}$$

Therefore $w_1'(0)<0$ or $w_1'(0)>0$, accordingly $g'(w_1(0))>1$ or $g'(w_1(0))<1$. From (3.11), it follows that the sign of $w_1'(\varepsilon)$ cannot change along the branch unless the coefficient of $w_1'(\varepsilon)$ changes sign. Since the product is strictly positive, $w_1'(\varepsilon)$ will be of constant sign. □

As an example, with $f(u)=\frac{1}{2}\varepsilon u^2$, $g(u)=au^p$, we find that $w_1(0)=a^{-1/(p-1)}$ and

$$1-g'(w_1(0))=1-p. \tag{3.13}$$

Thus, positive solutions of (A) are unstable if $p>1$. From Theorem 3.2A, the zero solution is stable. For $0<p<1$, on the branch emanating from $(0, w_1(0))$, we have $w_1'(\varepsilon)>0$. Therefore stationary solutions are stable on this branch. For $w_1'(\varepsilon)<0$ (the upper branch in Figs. 1.1 and 1.2 with $0<p<1$) the stationary solutions are unstable.

There remains only the question of the stability of the positive solution when $p=1$ and the stability of the null solution when $0<p\leqq 1$. When $p=1$ and $0<a<1$, we see from Example 2.1 that $w_1(\varepsilon)=2a/(\varepsilon v_1(a))$. Thus $w_1'(\varepsilon)<0$ and the branch of positive solutions is unstable. Therefore, from Theorem 3.2A, the null solution is stable.

In order to demonstrate the instability of the null solution when $p=1$ and $a>1$ or when $0<p<1$, suppose $u_0(x)>0$ on $(0,1]$ and $u_0(0)=0$, $u_0'(1)\geqq au_0^p(1)$. Choose $\lambda>0$, $\delta>0$ so small that

$$a\geqq \delta^{1-p}\lambda\coth(\lambda)(\sinh(\lambda))^{1-p},$$

$$u_0(x)\geqq \delta\sinh(\lambda x).$$

Then

$$v(x,t)=\delta\sinh(\lambda x) \tag{3.14}$$

is a subsolution. That is, $v_{xx}+\varepsilon vv_x\geqq 0$, $v_x(1,t)\leqq a(v(1,t))^p$. Therefore $u(x,t)\geqq \delta\sinh(\lambda x)$ for all t in the existence interval and hence zero is unstable from above. (When $a=1$, use $v=\delta x$.)

We next turn our attention to (B_1). As noted earlier, the structure conditions on f, g are somewhat different in this problem. There are parallel results however.

LEMMA 3.1B. *Let $f'(u)$ be increasing. Let $g(u)/u$ be bounded in a neighborhood of $u=0$ or $u>0$ on $\{0\}\times[0,T)$. Let u be a solution of (B_1) on $D_T\cup\Gamma_T$. If $u(x,0)>0$ on $[0,1)$, then $u>0$ on $D_T\cup\Gamma_T$ except at $x=1$. Suppose that $g(u)/u$ is decreasing on $(0,\infty)$. Suppose that $w(x)$ is a positive stationary solution of (B_1) and $u(x,0)\leqq(1+\sigma)w(x)$ on $[0,1]$, then $u(x,t)\leqq(1+\sigma)w(x)$ on $D_T\cup\Gamma_T$, while if $u(x,0)\geqq(1-\sigma)w(x)$ on $[0,1]$, then $u(x,t)\geqq(1-\sigma)w(x)$ on $D_T\cup\Gamma_T$.*

Proof. The proof of the lemma proceeds (mutatis mundanis) in the same manner as that of Lemma 3.1A. We note that this time $w'(x)<0$ on $[0,1]$. Therefore, with $v(x)=(1-\sigma)w(x)$ $(0<\sigma<1)$ we have

$$\begin{aligned} v_{xx}+f'(v)v_x &= (1-\sigma)[w_{xx}+f'((1-\sigma)w)w_x] \\ &= (1-\sigma)w_x[f'((1-\sigma)w)-f'(w)] \\ &\geqq 0. \end{aligned} \tag{3.15}$$

While at $x=0$,

$$\begin{aligned} v_x+g(v) &= g((1-\sigma)w)-(1-\sigma)g(w) \\ &= (1-\sigma)w[g((1-\sigma)w)/(1-\sigma)w-g(w)/w] \\ &\leqq 0. \end{aligned} \tag{3.16}$$

The inequalities (3.15) and (3.16) are reversed for $v(x)$ when $v(x)=(1+\sigma)w(x)$. □

THEOREM 3.2B. *Let f', $-g(u)/u$ be increasing on $[0,\infty)$ with f', g strictly increasing. Suppose that the roots of* (2.4) *are isolated and satisfy the conditions of Theorem* 2.1B. *Then there is at most one positive stationary solution $w(x)$ of* (B_1) *and it is stable. The null solution is unstable from above.*

Proof. The stability and instability follow from Lemma 3.1B and the continuation theorems below. Let w_1, w_2 be two positive stationary solutions and suppose $w_1(x)<w_2(x)$ on $[0,1)$ and that there are no roots of (2.4) in $(w_1(0), w_2(0))$. It follows from Lemma 2.1 that $w_i'(x)<0$ on $[0,1]$. Exactly as in the proof of Theorem 3.2A, there is a constant $\gamma_0=1-w_1'(0)/w_2'(0)$ in $(0,1)$ such that

$$w_1(x)<(1-\gamma_0)w_2(x).$$

(If $\gamma_0=0$, then $w_1'(0)=w_2'(0)$ or $g(w_1(0))=g(w_2(0))$. Then $w_1(0)=w_2(0)$ and $w_1\equiv w_2$. If $\gamma_0=1$, then $w_1'(0)=0=g(w_1(0))=0$ and hence $w_1(0)=0$. Then $w_1\equiv 0$.) Let $\delta>0$ such that

$$(1-\gamma_0)w_2(0)<(1+\delta)w_1(0)<w_2(0).$$

If we set

$$\begin{aligned} v(x) &= ((1+\delta)/(1-\gamma_0))w_1(x)-w_2(x) \\ &\equiv (1+\bar{\delta})w_1(x)-w_2(x), \end{aligned}$$

then $v(0)>0$, $v(1)=0$ and

$$\begin{aligned} v''(x) &= -(1+\delta)f'(w_1)w_1'+f'(w_2)w_2' \\ &< -f'(w_2)v'(x). \end{aligned}$$

Consequently v cannot have a minimum on $(0,1)$ and $v(x)>0$ on $[0,1)$. Therefore

$$(1+\delta)w_1(x)>(1-\gamma_0)w_2(x).$$

If we let u solve (B_1) with $u(x,0)=(1+\delta)w_1(x)$, then, by the lemma $u(x,t)>0$ except at $x=1$ on $D_T\cup\Gamma_T$ and by the first and second maximum principles

$$u(x,t)<(1+\delta)w_1(x)$$

on D_T and Γ_T. The lemma assures us that for all x, t

$$u(x,t)>(1-\gamma_0)w_2(x).$$

Therefore, by the continuation theorems, we may take $T=+\infty$. However, by the lemma $u(x,t)\leqq u(x,0)$ on $[0,1]$ so that $u_t\leqq 0$ for all t (see Appendix I) and hence $\lim_{t\to\infty} u(x,t)=\phi(x)$ exists for all $x\in[0,1]$. Exactly as in Theorem 3.2A, we easily establish that ϕ is a stationary solution and hence $\phi(0)$ is a root of (2.4). Since

$$w_1(0)<(1-\gamma_0)w_2(0)<\phi(0)<(1+\delta)w_1(0)<w_2(0),$$

we have reached the desired contradiction. □

As in Theorem 3.2A, if $-g(u)/u$ is strictly increasing, the proof may be shortened and the zeros of (2.4) need not be assumed to be isolated.

The choice $f(u)=\frac{1}{2}\varepsilon u^2$, $g(u)=au^p$, $a>0$, $0<p<1$, together with the observations in Example 2.1, provides an illustration of this result.

Sometimes solutions of (B_1) can blow up in finite time.

LEMMA 3.3B. *Suppose that $g(u)\geqq 0$ and that u solves (B_1) on $D_T\cup\Gamma_T$ with $u(x,0)>0$ on $[0,1)$. Then $u(x,t)>0$ on $D_T\cup\Gamma_T$ except at $x=1$. If $u_x(x,0)\leqq 0$, then $u_x(x,t)\leqq 0$ while if $u_t(x,0)\geqq 0$ then $u_t(x,t)\geqq 0$ on $D_T\cup\Gamma_T$.*

The proof of this rests on straightforward applications of the maximum principle and is omitted.

LEMMA 3.4B. *Let $f'\geqq 0$ and define $f_1(u)=\int_0^u f(\eta)\,d\eta$, $G(u)=\int_0^u g(\eta)\,d\eta$. Suppose that u solves (B_1) on $D_T\cup\Gamma_T$ and that the hypotheses of Lemma 3.3B hold. Define, for $t\leqq T$,*

$$F(t)=\int_0^t\int_0^1 u^2(x,\eta)\,dx\,d\eta+(T^*-t)\int_0^1 u^2(x,0)\,dx+\beta(t+t_0)^2 \tag{3.17}$$

where t_0, β, T^* are positive constants with $T^*\geqq T$. Then, for any $\alpha>0$, on $[0,T)$, we have,

$$\begin{aligned} FF''-(\alpha+1)(F')^2\geqq 4(\alpha+1)F\Big[G(u(0,0))-\frac{1}{2}\int_0^1 u_x^2(x,0)\,dx \\ -(2\alpha+1)\beta/(2\alpha+2)\Big]+2FQ(u(0,t)) \end{aligned} \tag{3.18}$$

where

$$Q(v)=vg(v)-2(\alpha+1)G(v)+f_1(v)-vf(v).$$

Proof. The proof is a straightforward calculation, variants of which can be found in [7], for example (in the case $f=0$). We find

$$\begin{aligned} FF''-(\alpha+1)(F')^2&=4(\alpha+1)S^2+2FQ(u(0,t)) \\ &\quad+4(\alpha+1)F\Big[G(u(0,0))-\frac{1}{2}\int_0^1 u_x^2(x,0)\,dx \\ &\quad-(2\alpha+1)\beta/(2\alpha+2)\Big] \\ &\quad-4(\alpha+1)F\cdot\int_0^t\int_0^1 u_xu_\eta f'(u)\,dx\,d\eta \end{aligned} \tag{3.19}$$

where

$$\begin{aligned} S^2=&\Big(\int_0^t\int_0^1 u^2\,dx\,d\eta+\beta(t+t_0)^2\Big)\Big(\int_1^t\int_0^1 u_\eta^2\,dx\,d\eta+\beta\Big) \\ &-\Big(\int_0^t\int_0^1 uu_\eta\,dx\,d\eta+\beta(t+t_0)\Big)^2. \end{aligned}$$

□

In view of the preceding lemma, we see that the double integral on the right of (3.19) is nonpositive and (3.18) follows immediately.

THEOREM 3.5B. *Let u solve* (B_1) *with f, g as in the above lemmas. Assume that*

$$u(x,0)>0 \quad \text{on } [0,1), \quad u(1,0)=0, \tag{3.20}$$

$$u_t(x,0)\geqq 0 \quad \text{on } (0,1), \tag{3.21}$$

$$u_x(x,0)\leqq 0 \quad \text{on } (0,1), \tag{3.22}$$

$$\frac{1}{2}\int_0^1 u_x^2(x,0)\,dx < G(u(0,0)), \tag{3.23}$$

$$\text{There is } \alpha>0 \text{ such that } Q(v)\geqq 0, \tag{3.24}$$

$$-u_x(0,0)=g(u(0,0)). \tag{3.25}$$

Then u cannot exist for all time.

Proof. If we can establish the theorem, the continuation theorems below permit the conclusion that u blows up in finite time. By choosing β such that

$$0<\beta\leqq\frac{2(\alpha+1)}{2\alpha+1}\cdot\left[G(u(0,0))-\frac{1}{2}\int_0^1 u_x^2(x,0)\,dx\right],$$

and noting (3.24) we see that $FF''-(\alpha+1)(F')^2\geqq 0$ on $[0,T)$ and therefore $(F^{-\alpha})''\leqq 0$ there. If $T=\infty$, T^* will be at our disposal. We find that $F^{-\alpha}$ has a zero at some value $\bar{t}\leqq F(0)/\alpha F'(0)$, provided $F(0)/\alpha F'(0)$ does not exceed T^*. These conditions are satisfied if we take $t_0=\alpha T^*$ and

$$T^*=(\alpha^2\beta)^{-1}\int_0^1 u^2(x,0)\,dx$$

while then $\bar{t}\leqq T^*$. □

Example 3.2. Let $f(u)=\frac{1}{2}\varepsilon u^2$, $g(u)=au^p$ and

$$u(x,0)=\frac{A[(\gamma-x)^2-(\gamma-1)^2]}{\sqrt{r^2-(\gamma-1)^2}+\sqrt{r^2-(\gamma-x)^2}}$$

where $A>0$, $r>\gamma>1$. We shall choose A, γ, r so that (3.20)-(3.25) hold. Clearly $u(1,0)=0$ and $u(x,0)>0$ on $[0,1)$. Also $u_x(x,0)=-A(\gamma-x)/(r^2-(\gamma-x)^2)^{1/2}<0$. We choose A so that (3.25) holds, i.e.,

$$A=\left[\frac{\gamma}{a(2\gamma-1)^p\sqrt{r^2-\gamma^2}}(\sqrt{r^2-\gamma^2}+\sqrt{r^2-(\gamma-1)^2})^p\right]^{1/(p-1)}.$$

If r, $\gamma\gg 1$ and $r\gg\gamma$, then

$$A\approx a^{-1/(p-1)}(r^2-\gamma^2)^{1/2}/\gamma.$$

In order to check that $u_t(x,0)\geqq 0$, we compute

$$\begin{aligned}W(x)&\equiv u_{xx}(x,0)+\varepsilon u(x,0)u_x(x,0)\\&=\frac{A}{\sqrt{r^2-(\gamma-x)^2}}\left[\frac{r^2}{(r^2-(\gamma-x)^2)}-\frac{\varepsilon A(2\gamma-x-1)(1-x)(\gamma-x)}{\sqrt{r^2-(\gamma-1)^2}+\sqrt{r^2-(\gamma-x)^2}}\right].\end{aligned}$$

Since $(\gamma-1)^2\leqq(\gamma-x)^2<\gamma^2$ on $[0,1]$, we find that

$$W(x)\geqq\frac{A}{(r^2-(\gamma-x)^2)^{3/2}}[r^2-\varepsilon\gamma^2\sqrt{r^2-(\gamma-1)^2}].$$

For $r, \gamma \gg 1$ and $r \gg \gamma$, the factor in brackets is larger than $\frac{1}{2}r^2$. Conditions (3.20), (3.21), (3.22) and (3.25) thus hold.

Condition (3.23) is verified exactly as in Example 3.1. We note that

$$\frac{a(u(0,0))^{p+1}}{p+1} = \frac{-u_x(0,0)u(0,0)}{(p+1)} \approx \frac{A^2\gamma^2}{(r^2-\gamma^2)(p+1)}$$

while

$$\frac{1}{2}\int_0^1 u_x^2(x,0)\,dx = \frac{A^2}{2}\left\{-1+\frac{r}{2}\ln\left[\frac{(r-\gamma+1)(r+\gamma)}{(r+\gamma-1)(r-\gamma)}\right]\right\}.$$

In order to check (3.24) we see that for $u>0$,

$$Q(u) = a(1-2(\alpha+1)/(p+1))u^{p+1} - \tfrac{1}{3}\varepsilon u^3.$$

For $p=2$, $Q(u)\geqq 0$ for $u\geqq 0$ provided $a>\varepsilon$. For $p>2$, $Q(u)$ is positive to the right of

$$\bar{u} = \left(\frac{\varepsilon}{3}\frac{(p+1)}{(p-1)}\right)^{1/(p-2)} a^{-1/(p-2)}.$$

Since $u_t(0,t)\geqq 0$, $u(0,t)\geqq \bar{u}$ and $Q(u)\geqq 0$ provided

$$u(0,0)\geqq \bar{u}$$

which in turn holds for $r, \gamma \gg 1$, $0<r\gg\gamma$ if

$$a > \left(\frac{\varepsilon(p+1)}{3(p-1)}\right)^{p-1}.$$

The question of finite time blow up remains open if $\varepsilon \gg a$.

We next replace f by εf in (B_1). We prove the following.

THEOREM 3.6B. *Let $f'>0$ on $(0,\infty)$ and suppose that $w(x,\varepsilon)$ is a C^1 branch of positive stationary solutions of (B_1) with f replaced by εf along which $g(w_0)-\varepsilon f(w_0)>0$ $(w_0(\varepsilon)\equiv w(0,\varepsilon))$. If $w_0'(\varepsilon)=\partial w(0,\varepsilon)/\partial\varepsilon>0$, this is a branch of unstable stationary solutions. If $f''\geqq 0$ and $w_0'(\varepsilon)<0$, this is a branch of stable stationary solutions.*

Proof. Suppose $w_0'(\varepsilon)>0$. Then if $\varepsilon_1<\varepsilon_2$, $w(x,\varepsilon_1)<w(x,\varepsilon_2)$ in a neighborhood of $x=0$. Then, with $u(x,t,\varepsilon_1)$ a solution of (B_1) with $\varepsilon=\varepsilon_1$ such that $u(x,0,\varepsilon_1)=w(x,\varepsilon_2)$, we find that on $(0,1)$,

$$\begin{aligned} u_t(x,0,\varepsilon_2) &= w''+\varepsilon_1 f'(w)w' \\ &= w''+\varepsilon_2 f'(w)w'+(\varepsilon_1-\varepsilon_2)f'(w)w' \\ &> 0 \end{aligned}$$

since $w'<0$, $f'>0$ and $\varepsilon_1-\varepsilon_2<0$. From this we conclude as before, that $u_t(x,t)>0$ on $D_T\cup\Gamma_T$ and hence that $w(x,\varepsilon_1)$ is unstable from above. A similar argument with $u(x,0,\varepsilon_2)=w(x,\varepsilon_1)$ shows that $w(x,\varepsilon_2)$ is unstable from below.

Suppose next that $w_0'(\varepsilon)<0$. Then $v(x)\equiv\partial w(x,\varepsilon)/\partial\varepsilon$ solves, on $(0,1)$,

$$v''+\varepsilon f'(w)v'+\varepsilon w'f''(w)v = -f'(w)w' > 0,$$

since $f'(w)>0$ if $w>0$ and $w'<0$ on $[0,1]$. Therefore, since $v(0)<0$, $v(1)=0$, $v(x)<0$ on $[0,1)$. It follows that if $0<\varepsilon_1<\varepsilon_2$ on the branch, then $w(x,\varepsilon_1)>w(x,\varepsilon_2)$ on $[0,1)$. Again, with $u(x,0,\varepsilon_1)=w(x,\varepsilon_2)$, we find that

$$\begin{aligned} u_t(x,0,\varepsilon_1) &= w''+\varepsilon_1 f'(w)w' \\ &= w''+\varepsilon_2 f'(w)w'-(\varepsilon_2-\varepsilon_1)f'(w)w' \\ &> 0 \end{aligned}$$

and consequently on $D_T \cup \Gamma_T$, by this and comparison

$$w(x, \varepsilon_2) \leqq u(x, t, \varepsilon_1) \leqq w(x, \varepsilon_1).$$

(Again note that u and the w's satisfy the same boundary conditions.) Thus, we may take $T = +\infty$ and $\lim_{t\to\infty} u(x, t, \varepsilon_1) = \phi(x, \varepsilon_1)$ exists. Moreover, $w(x, \varepsilon_2) \leqq \phi(x, \varepsilon_1) \leqq w(x, \varepsilon_1)$. Letting ε_2 decrease to ε_1, $\phi(x, \varepsilon_1) = w(x, \varepsilon_1)$. This shows that $w(x, \varepsilon_1)$ is stable from below. A similar argument shows that $w(x, \varepsilon_2)$ is stable from above. □

From (2.4), in this case, we have

$$1 = \int_0^{w_0(\varepsilon)} \frac{d\sigma}{g(w_0(\varepsilon)) + \varepsilon(f(\sigma) - f(w_0(\varepsilon)))}. \tag{3.26}$$

Differentiating with respect to ε along a branch of solutions of (2.4), we find

$$\left\{1 - [g'(w_0) - \varepsilon f'(w_0)]g(w_0) \int_0^{w_0(\varepsilon)} \frac{d\sigma}{D^2(\sigma)}\right\} w_0'(\varepsilon) = g(w_0) \int_0^{w_0(\varepsilon)} \frac{[f(\sigma) - f(w_0)]}{D^2(\sigma)}\, d\sigma$$

where $D(\sigma)$ is the denominator in (3.26). If the branch is defined on an interval $[0, \varepsilon_0)$, we have, at $\varepsilon = 0$,

$$[1 - g'(w_0(0))]w_0'(0) = -\frac{1}{w_0(0)} \int_0^{w_0(0)} [f(w_0(0)) - f(\sigma)]\, d\sigma$$

because again $g(w_0(0)) = w_0(0)$.

Thus, the corollary dual to Corollary 3.7A is the following.

COROLLARY 3.7B. *Let f, g be as in the preceding theorem. If $g'(w_1(0)) > 1$, the branch of stationary solutions emanating from $\varepsilon = 0$ is unstable, while if $g'(w_1(0)) < 1$, this branch is stable.*

The convexity of f in Theorem 3.6B is not necessary.

COROLLARY 3.8B. *Let $f' > 0$ on $(0, \infty)$, and suppose that $w_0'(\varepsilon) < 0$ on some C^1 branch $w(x, \varepsilon)$ of stationary solutions of (B_1) with f replaced by εf. If $g'(w_0(\varepsilon)) - \varepsilon f'(w_0(\varepsilon)) > 0$ along this branch, then the branch consists only of stable stationary solutions.*

Proof. It suffices to show that $\partial w(x, \varepsilon)/\partial\varepsilon < 0$. However, we must have

$$1 - x = \int_0^{w(x,\varepsilon)} \frac{d\sigma}{g(w_0) - \varepsilon f(w_0) + \varepsilon f(\sigma)} \tag{3.27}$$

along such a C^1 branch of stationary solutions and therefore

$$[g(w_0(\varepsilon)) - \varepsilon f(w_0(\varepsilon)) + \varepsilon f(w(x, \varepsilon))]^{-1} \frac{\partial w(x, \varepsilon)}{\partial \varepsilon}$$

$$= \int_0^{w(x,\varepsilon)} \{[g'(w_0) - \varepsilon f'(w_0)]w_0'(\varepsilon) + [f(\sigma) - f(w_0)]\} \frac{d\sigma}{D^2(\sigma)}$$

where $D(\sigma)$ is the denominator in (3.27). By hypothesis, the integrand in the integral is negative while the coefficient of $\partial w/\partial\varepsilon$ is positive. □

As an example, we again take $\varepsilon f(u) = \frac{\varepsilon}{2}u^2$, $g(u) = au^p$, $u \geqq 0$. We find again that $w_0(0) = a^{-1/(p-1)}$ and

$$1 - g'(w_0(0)) = 1 - p.$$

Thus, if $p > 1$, the branch of positive solutions emanating from zero is unstable. For $p > 2$, this branch exists for all $\varepsilon > 0$. Therefore, for all $\varepsilon > 0$, the null solution is stable from above. For $1 < p < 2$, the upper branch is stable since $w_0'(\varepsilon) < 0$ there. When $0 < p < 1$, $w_0'(\varepsilon) < 0$ and the branch of positive solutions (which also exists for all $\varepsilon > 0$) is stable. Thus, by Theorem 3.2B, in this case the null solution is unstable from above.

There remains only the question of the stability of the positive solution when $p=1$ and $a \geqq 1$ and of the null solution when $1 \leqq p \leqq 2$. (For $1<p<2$ we have this stability for $\varepsilon < \varepsilon(p)$.) When $p=1$ and $a \geqq 1$, we find from Example 2.1 that

$$w_0(\varepsilon) = 2a(\alpha_J^2+1)/\varepsilon$$

where α_J is the unique root of $J(\alpha)$. Therefore $w_0'(\varepsilon)<0$ and this is a branch of stable stationary solutions. Again by Theorem 3.2B, it follows that the null solution is unstable in this case.

When $p=1$ and $a<1$ or when $p>1$, set, for $\lambda>0$, $\delta>0$

$$v(x, t) = \delta \sin((1-x)\lambda)\, e^{-\lambda^2 t}.$$

Then one easily checks that $v_{xx}+\varepsilon v v_x \leqq v_t$ and that $v_x(0, t) \leqq -av^p(0, t)$ provided that $\lambda, \delta > 0$ satisfy

$$a \leqq \lambda \cot \lambda \cdot (\delta \sin \lambda)^{-(p-1)}.$$

If $u_0(x) \leqq \delta \sin((1-x)\lambda)$, it then follows that $u(x, t) \leqq v(x, t)$ and the null solution is thus stable from above (indeed asymptotically stable from above).

Finally, it is perhaps worth noting that for both (A) and (B) when $a=0$, there are no nontrivial stationary solutions. It is not difficult to show that the null solution is asymptotically stable.

4. Local existence and continuation. In this section we shall establish the existence of solutions of (A_1) and (B_1) on $D_T \cup \Gamma_T$ for sufficiently small T and certain initial values. This result follows from results in [2]. However, we include an elementary proof here for completeness.

We assume that f, g are defined on R^1, that $g(u)>0$ for $u>0$ and that $f(0)=g(0)=0$. We shall also assume that f is uniformly Lipschitz in compact subsets of R^1, that g is continuous and is uniformly Lipschitz on compact subsets of $R^1-\{0\}$. (This last restriction is necessary to include functions such as $g(u)=|u|^{p-1}u$ where $0<p<1$.) We shall also define

$$f_M \equiv \sup_{|u| \leqq M} |f(u)| \tag{4.1}$$

and

$$g_M \equiv \sup_{|u| \leqq M} |g(u)|. \tag{4.2}$$

We shall discuss problem (A_1). The arguments for (B_1) are similar and are omitted.

Let $G(x, y; t)$ denote Green's function for

$$\mathbf{L}u = u_t - u_{xx}, \qquad \sigma < x < 1, \quad t>0$$

with boundary conditions

$$u(0, t) = u_x(1, t) = 0, \qquad t>0,$$

i.e.,

$$G(x, y; t) = 2\sum_{n=1}^{\infty} \sin(\lambda_n x) \sin(\lambda_n y)\, e^{-\lambda_n^2 t}$$

where $\lambda_n = \frac{1}{2}(2n-1)\pi$. Then $G_x(1, y; t) = G_y(x, 1; t) = G(0, y; t) = G(x, 0; t) = 0$ and u is a solution of (A_1) on $[0, 1] = [0, T)$ if and only if for (x, t) $[0, 1] \times [0, T)$,

$$u(x,t) = \int_0^1 G(x, y; t) u_0(y)\, dy - \int_0^t \int_0^1 G_y(x, y; t-\eta) f(u(y, \eta))\, dy\, d\eta$$

$$+ \int_0^t G(x, 1; t-\eta)[f(u(1, \eta)) + g(u(1, \eta))]\, d\eta \tag{4.3}$$

$$\equiv \mathbf{T}u(x, t).$$

In order to show that (4.3) is solvable for sufficiently small T, we use a contraction mapping argument. We define

$$u_1(x, t) = 0 \tag{4.4}_1$$

and then, iteratively define

$$u_{n+1}(x, t) = \mathbf{T}u_n(x, t). \tag{4.4}_2$$

THEOREM 4.1. *Let the initial datum for problem* (A_1) *be continuous on* $[0, 1]$ *and satisfy*

$$0 < d_1 < \int_0^1 G(1, y; t) u_0(y)\, dy \tag{4.5}$$

for $0 \leqq t \leqq 1$, *say. Then for sufficiently small* T, (A_1) *has a unique solution which satisfies*

$$u(1, t) \geqq d_1/2 \tag{4.6}$$

on $[0, T]$. *The solution is* C^1 *in* t *and* c^2 *in* x *on* $(0, 1) \times (0, T)$ *and continuous on* $\bar{D}_T$. (*If* g *is uniformly Lipschitz continuous on compact subsets of* R^1, (4.5) *and* (4.6) *may be omitted.*)

Proof. The proof is fairly standard. We shall only sketch the arguments.

First, define

$$d_2 = \sup_{0 \leqq x \leqq 1} |u_0(x)|,$$

$$\mu(t) = \sup_{\substack{0 \leqq x \leqq 1 \\ 0 \leqq t' \leqq t}} \int_0^{t'} G(x, 1; t' - \eta)\, d\eta,$$

$$\nu(t) = \sup_{\substack{0 \leqq x \leqq 1 \\ 0 \leqq t' \leqq t}} \int_0^{t'} \int_0^1 |G_y(x, y; t' - \eta)|\, dy\, d\eta.$$

Clearly $\mu(t) \to 0$ monotonically as $t \to 0^+$. Inspection of the principle part of G shows us that the same is true for $\nu(t)$. For fixed $M > d_2$, choose T so small that $T \leqq 1$ and

$$\nu(T) f_M + \mu(T)(f_M + g_M) < \max(M - d_2, \tfrac{1}{2} d_1), \tag{4.7}$$

$$\beta_1 \equiv \nu(T) \cdot \sup_{|\xi| \leqq M} |f'(\xi)| < 1, \tag{4.8}$$

$$\beta_2 \equiv \mu(T)\left(\sup_{|\xi| \leqq M} |f'(\xi)| + \sup_{\substack{d_1/2 \leqq \xi_1 < \xi_2 \leqq M \\ -M \leqq \xi_2 < \xi_1 < -d_1/2}} |g(\xi_2) - g(\xi_1)| / |\xi_2 - \xi_1| \right) < 1. \tag{4.9}$$

It then follows from $(4.4)_1$, $(4.4)_2$, (4.7) and induction that on $\bar{D}_T$

$$\|u_n\|_{\bar{D}_T} \equiv \sup_{\bar{D}_T} |u_n(x, t)| \leqq M \tag{4.10}$$

for all $n = 1, 2, \cdots$. Moreover, on $x = 1$, we have from $(4.4)_2$ and (4.7),

$$u_n(1, t) \geqq \tfrac{1}{2} d_1 \tag{4.11}$$

for $n = 2, 3, \cdots$. A standard estimate then shows us that

$$\begin{aligned} \delta_n &\equiv \| u_{n+1}(1, \cdot) - u_n(1, \cdot) \|_{[0,T]} \\ &\equiv \sup_{0 \leqq t \leqq T} |u_{n+1}(1, t) - u_n(1, t)| < \beta_2 \delta_{n-1} \end{aligned} \tag{4.12}$$

and therefore

$$\delta_n < \beta_2^{n-1} \delta_1 . \tag{4.13}$$

From this it follows that the boundary values $u_n(1, t)$ are uniformly convergent. (From (4.4) $u_n(0, t) \equiv 0$.)

Again, a standard argument shows that if

$$\gamma_n \equiv \| u_{n+1} - u_n \|_{\bar{D}_T}, \tag{4.14}$$

then

$$\gamma_{n+1} \leqq \beta_1 \gamma_n + \delta_n . \tag{4.15}$$

Letting

$$\beta_3 = \max (\beta_1, \beta_2) < 1$$

we obtain from (4.13), (4.15) and the discrete version of Gronwall's inequality

$$\gamma_{n+1} \leqq \gamma_1 \beta_1^n + n \delta_1 \beta_3^{n-1} . \tag{4.16}$$

Therefore $\{u_n\}$ is uniformly convergent on $\bar{D}_T$ and

$$u(x, t) = \lim_{n \to \infty} u_n(x, t) \tag{4.17}$$

solves (4.3) with $u(1, t) \geqq \frac{1}{2} d_1$.

The asserted interior regularity follows from the properties of G and the continuity of u in $\bar{D}_T$. We omit the (standard) arguments.

A similar statement and argument holds for (B_1).

This result allows us to establish a precise version of the statement "If $|u| \leqq M$ on $\bar{D}_T$ and $u(1, T) > 0$ and u is a classical solution of (A_1) on $D_T \cup \Gamma_T$, then u may be continued as a classical solution on $D_{T+\delta} \cup \Gamma_{T+\delta}$ for some $\delta > 0$, with $u(1, t) > 0$ on $[T, T + \delta)$."

Appendix I. We have used, in Theorems 3.2A, B, 3.6A, B, the maximum principle applied to u_t in a rather cavalier fashion. Here we will state and sketch the proof of the precise result. It is similar to that of Lemma 2.3 of [5]. We shall only state it for solutions of (A_1) although it is true for solutions of (B_1) also. A weak form of the first statement was used in Theorems 3.2A, B while second was applied in Theorems 3.6A, B.

THEOREM. *Let f be C^2 on R^1 and g be C^1 except possibly at $u = 0$. Let u solve (A_1) in D_T, be C^2 in x, C^1 in t in D_T and continuous in $D_T \cup \Gamma_T$.*

(a) *If*

(H_1) $\quad u(x, t) > u(x, 0) > 0$ $(0 < u(x, t) < u(x, 0))$ *in $D_T \cup \Gamma_T$ except at $x = 0$,*

then $u_t(x, t) > 0$ (< 0) in D_T and on $x = 1$, $0 < t < T$.

(H_2) (i) *If either* $g'(0)$ *exists or* $u>0$ *on* $x=1$, $0\leqq t<T$,
(ii) u_t *is continuous in* D_T *up to* $t=0$ *on* $(0,1)$,
(iii) $u_x(1,0)=g(u(1,0))$ (*corner compatibility*),
(iv) u_t *is continuous in* D_T *up to* $x=0$ *and* $x=1$ *for* $0<t<T$,
(v) $u_t(x,0)>0$ (<0) *on* $(0,1]$, $u_t(0,0)\geqq 0$ $(\leqq 0)$,

then $u_t(x,t)>0$ (<0) *in* D_T *and on* $x=1$.

Proof. We dispense with the second statement first. Corner compatibility assures us that u_t is continuous in $\bar{D}_{T-\delta}$ for all small $\delta>0$, except possibly at $(0,0)$. Let $v=u_t$. Then we have

$$v_t=v_{xx}+f'(u)v_x+u_xf''(u)v \quad \text{in } D_T,$$
$$v_x=g'(u)v, \qquad x=1, \quad 0<t<T,$$
$$v(0,t)=0, \qquad 0<t<T,$$
$$v(0,x)>0, \qquad 0<x<1,$$

while $v(0,0)\geqq 0$. It follows from arguments similar to those used to prove Lemmas 3.1A, 3.2B that v cannot have a nonpositive minimum in $\bar{D}_{T-\delta}$ except at $(0,0)$. Therefore $v(x,t)>0$ in D_T and on $x=1$.

The proof of the first part is more difficult. To prove it we work in $\bar{D}_{T-\delta}$ and let $0<h<\delta/2$. We let

$$v(x,t)=u(x,t+h)-u(x,t).$$

Then $v(0,t)=0$ if $0<t<T$, $v(x,0)>0$ on $(0,1]$ and v satisfies

$$v_t=v_{xx}+f'(u(x,t+h))v_x+f''(\xi(x,t,h))u_xv$$

where ξ is between $u(x,t+h)$ and $u(x,t)$, while for $0<t\leqq T-\delta$,

$$v_x=g'(\eta(1,t))v$$

where η is between $u(1,t+h)$ and $u(1,t)$. The hypotheses are such that the coefficients of v, v_x are bounded in $\bar{D}_{T-\delta}$ and therefore, by the first and second maximum principles, $v\geqq 0$ in $\bar{D}_{T-\delta}$. It follows that $u_t\geqq 0$ wherever it exists. By interior regularity, u_t exists in D_T and by boundary regularity arguments, u_t exists on $x=1$, $0<t<T$.

Now $\psi=u_t$ satisfies, $\psi\geqq 0$ and

$$\psi_t=\psi_{xx}+f'(u)\psi_x+f''(u)\psi,$$

in $D_{T-\delta}$,

$$\psi_x=g'(u)\psi$$

at $x=1$, $0<t\leqq T-\delta$,

$$\psi(0,t)=0$$

for $0<t\leqq T-\delta$ and

$$\psi(x,0)\geqq 0$$

on $(0,1)$. Therefore $\psi>0$ in $D_{T-\delta}$ unless $\psi\equiv 0$ by the strong maximum principle. But then $\psi\equiv 0$ implies $u(x,0)\equiv u(x,t)$. □

Appendix II. Here we shall establish the signs of $w_1'(\varepsilon)$, $w_0'(\varepsilon)$ along the various stationary solution branches for problems (A), (B). These are crucial in determining the stability of these branches.

In the case of Figs. 1.1 and 1.2, we write (2.7) in the form

$$w = F(w, \varepsilon) = \int_0^1 \frac{d\sigma}{aw^{p-2} + \frac{1}{2}\varepsilon(1-\sigma^2)} \tag{1.1A}$$

where we have agreed to drop the subscript on w_1. When $1 \leqq p < \infty$, $w = w(\varepsilon)$ and we may differentiate implicitly to obtain

$$\frac{dw}{d\varepsilon} = \frac{F\varepsilon}{1 - F_w} \tag{1.2A}$$

we see that

$$F_\varepsilon(w, \varepsilon) = -\frac{1}{2}\int_0^1 \frac{(1-\sigma^2)\, d\sigma}{D^2(\sigma)} < 0 \tag{1.3A}$$

where $D(\sigma)$ is the denominator in the integrand in (1.1A). Using (1.1A) we may calculate F_w in a similar manner. We find that with

$$X = \frac{\varepsilon}{2a} w^{2-p}, \tag{1.4A}$$

we have

$$\frac{dw}{d\varepsilon} = -\frac{w^2 \int_0^1 (1-\sigma^2)\, d\sigma / D^2(\sigma, X)}{2\int_0^1 d\sigma / D(\sigma, X)} \cdot \left[\int_0^1 \frac{[(p-1) + X(1-\sigma^2)]}{D^2(\sigma, X)}\, d\sigma\right]^{-1} \tag{1.5A}$$

provided the integral in brackets does not vanish. We have set

$$D(\sigma, X) = 1 + X(1-\sigma^2). \tag{1.6A}$$

Thus, when $1 \leqq p < \infty$, $w'(\varepsilon) < 0$. Moreover, in this case,

$$\lim_{\varepsilon \to \infty} w(\varepsilon) = 0. \tag{1.7A}$$

This follows from the Dominated Convergence Theorem. Let $\bar{w}$ denote this limit. From (1.1A) we have

$$\bar{w} = \lim_{\varepsilon \to \infty} \int_0^1 \frac{d\sigma}{aw^{p-2}(\varepsilon) + \frac{1}{2}\varepsilon(1-\sigma^2)} = 0$$

if $\bar{w}^{(p-2)} > 0$, which is impossible.

If $0 < p < 1$, the bracketed integral in (1.5A) can vanish. Therefore we view $\varepsilon = \varepsilon(w)$. We know in this case, from the discussion in the example of § 2, that this function is bounded with bound $\varepsilon(p)$ and defined on some interval $[a^{-1/(p-1)}, B)$. However, we may take $B = +\infty$, since as $\varepsilon \to 0$, one of the solution branches $w_1(\varepsilon)$ of equation (2.8) satisfies

$$\lim_{\varepsilon \to 0^+} \varepsilon w_1^{(p-2)} = 0.$$

This tells us that $w_1(\varepsilon) \to +\infty$ as $\varepsilon \to 0$. Thus $B = \infty$ and the variable X in (1.4A) ranges over $(0, \infty)$.

Therefore, we may write

$$\frac{d\varepsilon}{dw} = -\frac{2\int_0^1 (1-\sigma^2)\, d\sigma / D^2(\sigma, X)}{w^2 \int_0^1 d\sigma / D(\sigma, X)} \cdot \left[\int_0^1 \frac{(p-1) + X(1-\sigma^2)}{D^2(\sigma, X)}\, d\sigma\right]. \tag{1.8A}$$

The bracketed integral can (and does) change sign exactly once. Therefore we find that for small X, on the upper branch in Figs. 1.1 and 1.2, $dw/d\varepsilon < 0$ while $dw/d\varepsilon > 0$ on the lower branch.

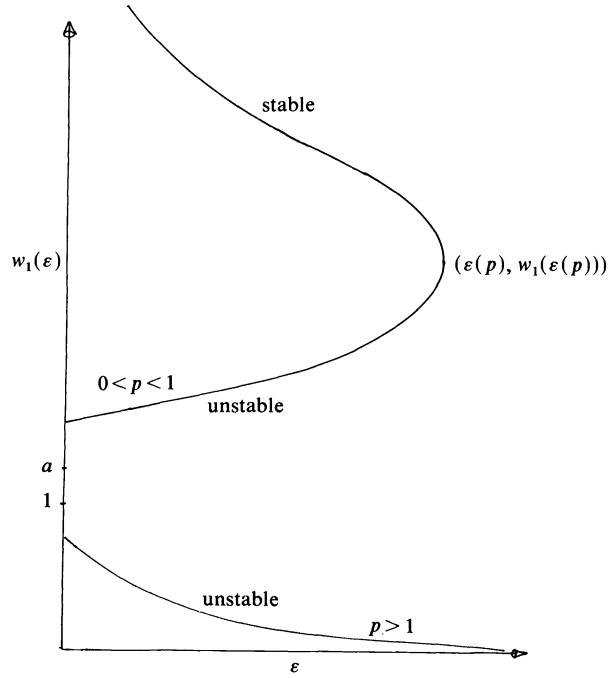

FIG. 1.1. $w_1(\varepsilon)$ *where* $w'(1) = aw^p(1)$, $a > 1$ *and* $w_1(0) = a^{-1/(p-1)}$.

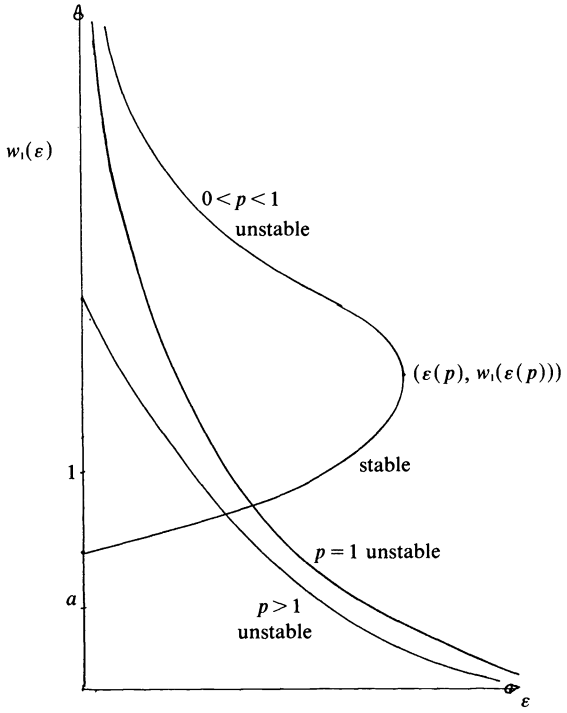

FIG. 1.2. *Same as for Fig.* 1.1 *except* $0 < a < 1$.

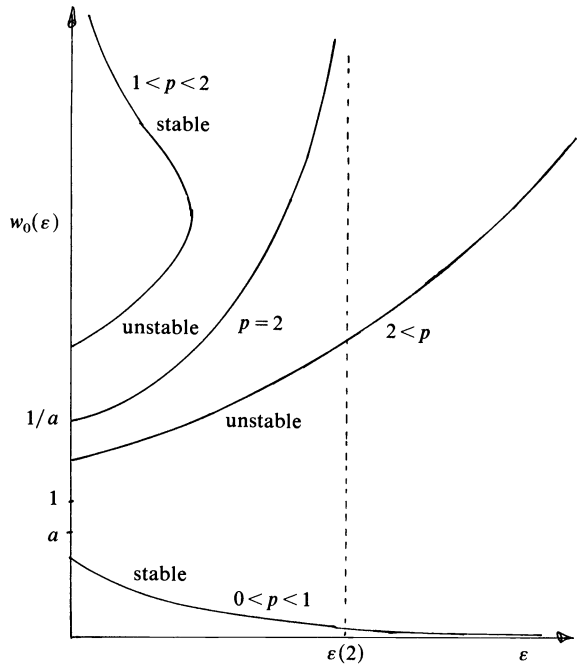

FIG. 2.1. $w_0(\varepsilon)$ *where* $w'(0) = -aw^p(0)$, $0 < a < 1$ *and* $w_0(0) = a^{-1/(p-1)}$.

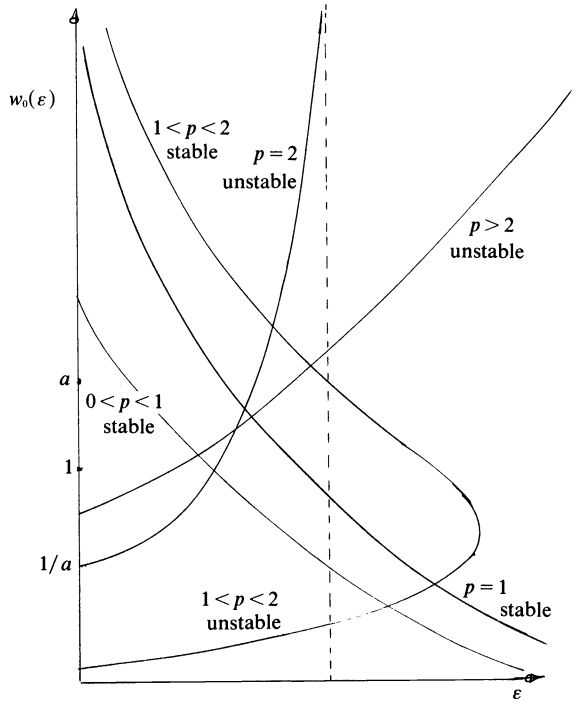

FIG. 2.2. *Same as Fig.* 2.1 *except* $a > 1$.

For problem (B), the argument is similar. In the cases $2 \leqq p < \infty$ and $0 < p \leqq 1$, we have

$$\frac{dw}{d\varepsilon} = -\frac{w^2 \int_0^1 (1-\sigma^2)\, d\sigma / D(\sigma, X)}{2 \int_0^1 d\sigma / D^2(\sigma, X)} \cdot \left[\int_0^1 \frac{(1-p)+X(1-\sigma^2)}{D^2(X, \sigma)}\, d\sigma \right]^{-1}$$

where now $X \in (0, 1)$. Clearly,

$$1-p < (1-p)+X(1-\sigma^2) < 2-p-\sigma^2$$

for X in this range. Thus, if $p \geqq 2$, $dw/d\varepsilon > 0$ while if $0 < p \leqq 1$, $dw/d\varepsilon < 0$. In the case $1 < p < 2$, the argument is similar to that of problem (A) for the case $0 < p < 1$.

It is possible to establish, at least in some cases, the precise curvatures in Figs. 1.1, 1.2, 2.1 and 2.2. However, such an analysis appears to add nothing to the stability results so we omit it.

Acknowledgments. The author would like to thank A. Majda for posing the question of blow up for solutions of (C). He also thanks H. Amann, J. Anderson, G. Lieberman and P. Sacks for several useful conversations, and is indebted to the referee for bringing [13], [14] to his attention.

STRONG SOLUTIONS OF A QUASILINEAR WAVE EQUATION WITH NONLINEAR DAMPING*

DANG DINH ANG† AND A. PHAM NGOC DINH‡

Abstract. We study the following initial and boundary value problem

$$u_{tt} - \Delta u_t - \sum_{i=1}^{N} \sigma_i'(u_{x_i}) u_{x_i x_i} + |u_t|^\alpha \operatorname{sgn} u_t = 0,$$

$$0 < \alpha < 1 \quad (x, t) \quad \text{in } \Omega \times]0, T[,$$

$$u = 0 \quad \text{on } \partial\Omega,$$

$$u(x, 0) = u_0(x), \qquad u_t(x, 0) = u_1(x)$$

where Ω is a bounded domain in R^N with a sufficiently regular boundary $\partial\Omega$. In § 1, it is proved that for u_0 in $H_0^1(\Omega)$, u_1 in $L_2(\Omega)$, σ_i in $C(\mathbb{R}, \mathbb{R})$ nondecreasing and inducing mappings of $L_2(\Omega)$ into itself, taking bounded sets into bounded sets, the problem admits a global weak solution. If, in addition, the σ_i's are assumed locally Lipschitzian, then the solution is unique.

In § 2, it is proved that for $N = 1$, u_0 in $H_0^1(\Omega) \cap H^2(\Omega)$, u_1 in $L_2(\Omega)$ and σ_i in $C^1(\mathbb{R}, \mathbb{R})$ with $\sigma_i' > 0$ nondecreasing and locally Hölder continuous, there exists a unique strong solution u of the initial and boundary value problem with the following properties: $t \to u(t)$ is continuous on $t \geqq 0$ to $H_0^1(\Omega) \cap H^2(\Omega)$, is continuously differentiable on $t > 0$ to $H_0^1(\Omega) \cap H^2(\Omega)$, is continuously differentiable on $t \geqq 0$ to $L_2(\Omega)$, and is twice continuously differentiable on $t > 0$ to $L_2(\Omega)$.

Introduction. We shall consider the following nonlinear initial and boundary value problem

$$u_{tt} - \Delta u_t - \frac{\partial}{\partial x_i} \sigma_i(u_{x_i}) + f(u_t) = 0, \qquad (x, t) \in \Omega \times]0, T[, \tag{0.1}$$

$$u = 0 \quad \text{on } \partial\Omega, \tag{0.2}$$

$$u(x, 0) = u_0(x), \qquad u_t(x, 0) = u_1(x) \tag{0.3}$$

where

$$f(u_t) = |u_t|^\alpha \operatorname{sgn} u_t, \qquad 0 < \alpha < 1, \qquad u_t = \frac{\partial u}{\partial t}, \qquad u_{x_i} = \frac{\partial u}{\partial x_i}.$$

In (0.1), Ω is a bounded domain in R^N with a sufficiently smooth boundary $\partial\Omega$, and σ_i, $i = 1, \cdots, N$ are continuous functions, satisfying certain monotonic and other conditions to be specified later.

Equations of the type (0.1), with $f = 0$, were given the first systematic treatment by Greenberg, MacCamy and Mizel [9] in the case of space dimension $N = 1$. They were proposed by the authors [6] as field equations governing the longitudinal motion of a viscoelastic bar obeying the nonlinear Voight model. Since the appearance of the work of Greenberg, MacCamy and Mizel, there has been a rather impressive literature on equations of the type (0.1) above, e.g., Caughey and Ellison [2], Clements [3], [4], Dafermos [5], Kozhanov, Larkin and Janenko [10], Yamada [16], [17], to name but a few. Of particular relevance to the present paper are the works of Clements and of

Webb [15]. The paper of Yamada [17] should also be consulted for reference. The remainder of the paper consists of two sections. In § 1, it is proved that for each given interval $]0, T[$, there exists a unique weak solution of (0.1)-(0.3) on the interval, under certain monotonic and other conditions on the σ_i's.

The method used here is a combination of compactness and monotonicity; such a method has enabled us to avoid the smoothness conditions as imposed, e.g., in Clements [3] (while the solution obtained here is weaker). For uniqueness, the σ_i's should satisfy certain contractive properties. In § 2, it is proved that for $N=1$, u_0 in $H_0^1(\Omega)\cap H^2(\Omega)$, u_1 in $L_2(\Omega)$ and σ_i in $C^1(\mathbb{R},\mathbb{R})$ with σ_i' locally Hölder continuous and positive, a unique strong solution of (0.1)-(0.3) exists for $t>0$. Note that the derivatives σ_i' are not used to satisfy any Lipschitzian condition. As a consequence, the usual method using semigroup theory to formulate the problem (0.1)-(0.3) as an integral equation and solve it by means of the contraction principle would not work in our case. Instead, we have found it efficient to use a combination of Galerkin approximation and analytic semigroup theory. The Galerkin method gives us a weak solution, which will be proved to be a strong solution, using Pazy's results on analytic semigroups [13].

1. Let

$$L_2 = L_2(\Omega), \quad H_0^1 = H_0^1(\Omega), \quad H^2 = H^2(\Omega).$$

Here $H_0^1(\Omega)$ and $H^2(\Omega)$ denote the usual Sobolev spaces on Ω. Let $\langle\ \cdot\ \rangle$ denote either the L_2-inner product or the paring of a continuous linear functional with an element of a function space. Let $\|\cdot\|_X$ be a norm on a Banach space X and let X^* be its dual. We denote by $L_p(0, T; X)$, $1\leqq p\leqq\infty$, the space of functions f on $[0, T]$ to X such that

$$\|f\|_{L_P(0,T;X)} = \left(\int_0^T \|f(t)\|_X^P\, dt\right)^{1/p} \quad \text{for } 1\leqq p<\infty,$$

$$\|f\|_{L_\infty(0,T;X)} = \operatorname{ess\,sup} \|f(t)\|_X \quad \text{for } p=\infty.$$

Then we have the following.

THEOREM 1 (Weak solution). *Let σ_i, $i=1,\cdots,N$ be real-valued functions satisfying the following*:

(1.1) *σ_i in $C(\mathbb{R},\mathbb{R})$, nondecreasing, $\sigma_i(0)=0$ each $\bar\sigma_i: L_2\to L_2$, where $\bar\sigma_i f=\sigma_i\circ f$ for f in L_2*

(1.2) *takes bounded sets into bounded sets and*

(1.3) *is locally Lipschitzian*

(1.4) *u_0 in H_0^1 and u_1 in L_2.*

Then for each $T>0$, the initial and boundary value problem (0.1)-(0.3) *admits a unique weak solution $u(\cdot)$ on $]0, T[$ with the following properties*:

(1.5) *u in $L_\infty(0, T; H_0^1)$ and u_t in $L_\infty(0, T; L_2)\cap L_2(0, T; H_0^1)$,*

(1.6) *$u(\cdot)$ locally Hölder continuous on $[0, T[$ to H_0^1.*

Remark 1. If σ_i is in $C^1(R, R)$ with a bounded derivative as in [3], then obviously σ_i satisfies (1.2).

Proof. The proof is a combination of compactness and monotony arguments, and consists of several steps. Step 1 is devoted to constructing Galerkin approximations and establishing a priori estimates. Step 2 is concerned with existence of the solution,

which will result from appropriate limiting processes. The final Step 3 will settle the question of uniqueness.

Step 1. Consider a special basis of H_0^1: $w_1, \cdots, w_n, \cdots$ formed by the eigenfunctions of Laplacian Δ on H_0^1. Let $(w_1, \cdots, w_n)$ be the linear space generated by $w_1, \cdots, w_n$. Let

$$u^{(n)}(t) = \sum_{k=1}^{n} c_{k,n}(t) w_k \tag{1.7}$$

be a solution of the following system:

$$\begin{aligned} &\langle u_{tt}^{(n)}(t), w_k\rangle + \sum_{i=1}^{N} \langle \sigma_i(u_{x_i}^{(n)}(t)), w_{k,x_i}\rangle - \langle \Delta u_t^{(n)}(t), w_k\rangle \\ &\qquad + \langle f(u_t^{(n)}(t)), w_k\rangle = 0, \end{aligned} \tag{1.8}$$

$$u^{(n)}(0) = u_{0n}, \qquad u_t^{(n)}(0) = u_{1n} \tag{1.9}$$

where $1 \leqq k \leqq n$

$$u_{0n} \to u_0 \quad \text{in } H_0^1,$$

$$u_{1n} \to u_1 \quad \text{in } L_2.$$

Note that such a solution $u^{(n)}(t)$ clearly exists on a sufficiently small interval $[0, T_n[$. Note also that the a priori estimates which follow allow us to take T_n equal to T.

A priori estimates. Let us multiply each equation of (1.8) by $\dot{c}_{k,n}(t)$, sum up and integrate with respect to the time variable from 0 to t. Then, we shall have, after some rearrangements

$$\begin{aligned} &\|u_t^{(n)}(t)\|^2 + 2\int_0^t \|\nabla u_t^{(n)}(s)\|^2\, ds + 2\sum_1^N \int_\Omega h_i(u_{x_i}^{(n)}(t))(x)\, dx \\ &\qquad + 2\int_0^t \langle f(u_t^{(n)}(s)), u_t^{(n)}(s)\rangle\, ds \\ &\qquad = \|u_{1n}\|^2 + 2\sum_1^N \int_\Omega h_i(u_{0n,x_i})(x)\, dx \end{aligned} \tag{1.10}$$

where

$$h_i(z) = \int_0^z \sigma_i(s)\, ds, \tag{1.11}$$

since we have the formula

$$\frac{d}{dt}\int_\Omega h_i(u_{x_i}^{(n)}(t))\, dx = -\left\langle \frac{\partial}{\partial x_i}\sigma_i(u_{x_i}^{(n)}(t)), u_t^{(n)}(t)\right\rangle,$$

$u_t^{(n)}(x, t)$ being equal to 0 on $\partial\Omega$.

By (1.1)

$$\int_\Omega h_i(u_{x_i}^{(n)}(t))(x)\, dx \geqq 0, \qquad i = 1, \cdots, N. \tag{1.12}$$

By (1.2),

$$0 \leqq \int_\Omega h_i(u_{0n,x_i})(x)\, dx \leqq C \tag{1.13}$$

where C is a constant independent of n.

Noting that

$$\langle f(v), v\rangle \geqq 0 \tag{1.14}$$

it follows from (1.10) that

$$\|u_t^{(n)}(t)\|^2 + \int_0^t \|\nabla u_t^{(n)}(s)\|^2\, ds \leqq C, \qquad 0 \leqq t \leqq T_n \tag{1.15}$$

where C is independent of n.

From (1.15), we deduce that, in particular, $t \to \nabla u^{(n)}(t)$ is Hölder continuous on $[0, T]$ and that

$$\|\nabla u^{(n)}(t)\| \leqq M_T, \qquad 0 \leqq t \leqq T \quad \text{for all } n \tag{1.16}$$

where M_T depends on T.

Define

$$\begin{aligned} &A: H_0^1 \to H^{-1}(\Omega) = H^{-1} \quad \text{(the dual of } H_0^1\text{)},\\ &Au: -\sum_1^N \sigma_i(u_{x_i})_{x_i}. \end{aligned} \tag{1.17}$$

Then

$$\langle Au, v\rangle = \sum_1^N \langle \sigma_i(u_{x_i}), v_{x_i}\rangle, \qquad u, v \text{ in } H_0^1.$$

Therefore,

$$|\langle Au^{(n)}(t), v\rangle| \leqq \left(\sum_1^N \|\sigma_i(u_{x_i}^{(n)}(t))\|^2\right)^{1/2} \|v\|_{H_0^1}. \tag{1.18}$$

By (1.16) and (1.2), it follows that

$$\|Au^{(n)}(t)\|_* \leqq M_T, \qquad 0 \leqq t \leqq T \tag{1.19}$$

where $\|\cdot\|_*$ is the dual norm on H^{-1}.

On the other hand, we have

$$\|f(u_t^{(n)}(t)\| \leqq C, \qquad 0 \leqq t \leqq T \tag{1.20}$$

(since Ω is bounded and $0 < \alpha < 1$).

We need an estimate on the $u_{tt}^{(n)}$. From the approximated problem

$$u_{tt}^{(n)}(t) - \Delta u_t^{(n)}(t) + Au^{(n)}(t) + f(u_t^{(n)}(t)) = 0, \tag{1.21}$$

we can deduce the following for each $v \in H_0^1$:

$$|\langle u_{tt}^{(n)}(t), v\rangle| \leqq (\|\nabla u_t^{(n)}(t)\| + \|Au^{(n)}(t)\|_* + \|f(u_t^{(n)}(t))\|)\|v\|_{H^1}. \tag{1.22}$$

By (1.15), (1.19) and (1.20) it follows that

$$\int_0^T \|u_{tt}^{(n)}(t)\|_{H^{-1}}^2\, dt \leqq 2\int_0^T (\|\nabla u_t^{(n)}(t)\|^2 + M_T)\, dt \leqq M_T. \tag{1.23}$$

The M_T always indicates constants independent of n, but depending on T. Therefore,

$$\int_0^T \|u_{tt}^{(n)}(t)\|_{H^{-1}}^2\, dt \leqq M_T, \qquad 0 \leqq t \leqq T \quad \text{for all } n. \tag{1.24}$$

Consequently,

$$\int_0^T \|\Delta u_t^{(n)}(t)\|_{H^{-1}}^2 \, dt \leqq M_T, \qquad 0 \leqq t \leqq T \quad \text{for all } n. \tag{1.25}$$

By (1.16), (1.15), (1.24), (1.19) and (1.20), we can extract a subsequence of $u^{(n)}$ still denoted by $u^{(n)}$, such that

$$u^{(n)} \to u \text{ in } L_\infty(0, T; H_0^1) \text{ weak } *, \tag{1.26}$$

$$\nabla u_t^{(n)} \to \nabla u_t \text{ in } L_2(0, T; L_2) \text{ weak}, \tag{1.27}$$

$$u_{tt}^{(n)} \to u_{tt} \text{ in } L_2(0, T; H^{-1}) \text{ weak}, \tag{1.28}$$

$$Au^{(n)} \to \xi \text{ in } L_\infty(0, T; H^{-1}) \text{ weak } *, \tag{1.29}$$

$$f(u_t^{(n)}) \to \chi \text{ in } L_\infty(0, T; L_2) \text{ weak } *. \tag{1.30}$$

Using a lemma on compactness [12] applied to (1.26) and (1.27), on the one hand, and to (1.27) and (1.28), on the other hand, we can extract from the sequence $\{u^{(n)}\}$ a subsequence, still denoted by $\{u^{(n)}\}$, such that

$$u^{(n)} \to u \text{ strongly in } L_2(Q) \text{ with } Q = \Omega \times]0, T[, \tag{1.31}$$

$$u_t^{(n)} \to u_t \text{ strongly in } L_2(Q). \tag{1.32}$$

Step 2. *Existence of a solution through a limiting process.* Letting $n \to \infty$ in (1.8), we find from (1.26)-(1.30) that u satisfies the equation

$$\begin{aligned} &\frac{d}{dt}\langle u_t(t), v\rangle + \langle \nabla u_t(t), \nabla v\rangle + \langle \xi(t), v\rangle + \langle \chi(t), v\rangle \\ &\quad = 0 \quad \text{a.e. } t \text{ in }]0, T[\quad \text{for all } v \text{ in } H_0^1. \end{aligned} \tag{1.33}$$

The initial conditions are satisfied since

(1.34) $u^{(n)}$ and u are in $C(0, T; L_2)$ implying that $u_n(0) = u_{0n} \to u(0)$ strongly in L_2 and hence $u(0) = u_0$, and

(1.35) $\langle u_t^{(n)}(t), w_k\rangle$ and $\langle u_t(t), w_k\rangle$ are in $C(0, T; \mathbb{R})$ implying that $\langle u_t^{(n)}(0) - u_t(0), w_k\rangle \to 0$ for $n \to \infty$ and hence $u_t(0) = u_1$.

So, we shall have proved the existence of a weak or distributional solution of (0.1)-(0.3) once we have shown that

$$\xi = Au \quad \text{and} \quad \chi = f(u_t). \tag{1.36}$$

We shall require the following two lemmas the proofs of which are immediate.

LEMMA 1. *The operator A defined in* (1.17) *is a monotone and hemicontinuous operator from* H_0^1 *to* H^{-1}, *i.e.*,

(i) $\langle Au - Av, u - v\rangle \geqq 0$ *for all* u, v *in* H_0^1,

(ii) *the map* $s \to \langle A(u + sv), w\rangle$ *is continuous on* $\mathbb{R}$ *to* $\mathbb{R}$.

LEMMA 2. *The function* $u \to f(u)$ *generates a monotone and hemicontinous operator on* L_2 *to* L_2.

We can now complete the existence proof.

Let

$$\xi_n(t) = \int_0^t \langle Au^{(n)}(s) - Av(s), u^{(n)}(s) - v(s)\rangle \, ds, \qquad 0 \leqq t < T. \tag{1.37}$$

We have, since A is monotone,

$$\xi_n \geqq 0 \quad \text{for all } v \text{ in } L_2(0, T; H_0^1).$$

From the relation

$$\begin{aligned}\int_0^t \langle Au^{(n)}(s), u^{(n)}(s)\rangle\, ds = &-\int_0^t \langle u_{tt}^{(n)}(s), u^{(n)}(s)\rangle\, ds \\ &-\frac{1}{2}\|\nabla u^{(n)}(t)\|^2+\frac{1}{2}\|u_{0n}\|^2_{H_0^1} \\ &-\int_0^t \langle f(u_t^{(n)}(s)), u^{(n)}(s)\rangle\, ds\end{aligned} \tag{1.38}$$

we obtain by passing to the limit

$$\begin{aligned}&\limsup_{n\to\infty} \int_0^t \langle Au^{(n)}(s), u^{(n)}(s)\rangle\, ds \\ &\quad\leqq -\frac{1}{2}\|\nabla u(t)\|^2+\frac{1}{2}\|u_0\|^2_{H_0^1} \\ &\quad\quad -\int_0^t \langle \chi(s), u(s)\rangle\, ds+\limsup_{n\to\infty}\left\{-\int_0^t \langle u_{tt}^{(n)}(s), u^{(n)}(s)\rangle\right\} ds\end{aligned} \tag{1.39}$$

a.e. t in $]0, T[$.

u satisfies the equation

$$u_{tt}-\Delta u_t+\xi+\chi=0, \tag{1.40}$$

which has a meaning in $L_2(0, T; H^{-1})$ as can be seen from (1.25) and (1.28)-(1.30).

Taking the inner product of (1.40) with u which belongs to $L_\infty(0, T; H_0^1)$, integrating with respect to the time variable from s to t, we obtain

$$\begin{aligned}&\int_s^t \langle u_{tt}(t), u(t)\rangle\, dt+\int_s^t \langle \xi(t), u(t)\rangle\, dt \\ &\quad=\frac{1}{2}(\|\nabla u(s)\|^2-\|\nabla u(t)\|^2)-\int_s^t \langle \chi(t), u(t)\rangle\, dt.\end{aligned} \tag{1.41}$$

From (1.41) we have, passing to the limit as $s\to 0$:

$$\begin{aligned}&\int_0^t \langle u_{tt}(t), u(t)\rangle\, dt+\int_0^t \langle \xi(t), u(t)\rangle\, dt \\ &\quad\geqq\frac{1}{2}(\|u_0\|^2_{H_0^1}-\|\nabla u(t)\|^2)-\int_0^t \langle \chi(t), u(t)\rangle\, dt.\end{aligned} \tag{1.42}$$

Then, by virtue of (1.42), the inequality (1.39) can be rewritten as

$$\begin{aligned}\limsup_{n\to\infty} \int_0^t \langle Au^{(n)}(s), u^{(n)}(s)\rangle\, ds \leqq &\int_0^t \langle \xi(s), u(s)\rangle\, ds \\ &+\int_0^t \langle u_{tt}(s), u(s)\rangle\, ds \\ &+\limsup_{n\to\infty}\left(-\int_0^t \langle u_{tt}^{(n)}(s), u^{(n)}(s)\rangle\, ds\right)\end{aligned} \tag{1.43}$$

a.e. t in $]0, T[$.

Integrating by parts, we have the relation

$$\int_0^t \langle u_{tt}^{(n)}(s), u^{(n)}(s)\rangle\, ds = -\int_0^t \|u_t^{(n)}(s)\|^2\, ds + \langle u^{(n)}(t), u_t^{(n)}(t)\rangle - \langle u_{0n}, u_{1n}\rangle \quad \text{for all } t \text{ in } [0, T[. \tag{1.44}$$

Passing to the limit in (1.44), we finally obtain

$$\lim_{n\to\infty} \int_0^t \langle u_{tt}^{(n)}(s), u^{(n)}(s)\rangle\, ds = -\int_0^t \|u_t(s)\|^2\, ds + \langle u(t), u_t(t)\rangle - \langle u_0, u_1\rangle = \int_0^t \langle u_{tt}(s), u(s)\rangle\, ds \quad \text{a.e. } t \text{ in } [0, T[\tag{1.45}$$

since

$$\lim_{n\to\infty} \langle u^{(n)}(t), u_t^{(n)}(t)\rangle = \langle u(t), u_t(t)\rangle \quad \text{a.e. } t \text{ in } [0, T[\tag{1.46}$$

as can be seen from (1.31) and (1.32).

Therefore,

$$\limsup_{n\to\infty} \int_0^t \langle Au^{(n)}(s), u^{(n)}(s)\rangle\, ds \leqq \int_0^t \langle \xi(s), u(s)\rangle\, ds \quad \text{a.e. } t \text{ in } [0, T[\tag{1.47}$$

which implies that

$$0 \leqq \int_0^T \langle \xi(t) - Av(t), u(t) - v(t)\rangle\, dt \quad \text{for all } v \text{ in } L_2(0, T; H_0^1). \tag{1.48}$$

In (1.48), if we choose $v = u - sw$ with $s \geqq 0$ and w in $L_2(0, T; H_0^1)$ and use the hemicontinuity of A, then we get

$$\xi = Au. \tag{1.49}$$

Now, from (1.30) and (1.32) we have

$$\lim_{n\to\infty} \int_0^T \langle f(u_t^{(n)}(s)), u_t^{(n)}(s)\rangle\, ds = \int_0^T \langle \chi(s), u_t(s)\rangle\, ds. \tag{1.50}$$

Using Lemma 2, we conclude that

$$\chi = f(u_t). \tag{1.51}$$

The existence proof is completed. Now, it is clear that

$$\|\nabla u(t) - \nabla u(t')\| \leqq |t - t'|^{1/2} \left(\int_0^T \|\nabla u_t(s)\|^2\, ds \right)^{1/2} \tag{1.52}$$

and hence, that $t \to u(t)$ is Hölder continuous from $[0, T[$ to H_0^1.

Step 3. *Uniqueness proof.* Let u and v be two weak solutions of the problem (0.1)-(0.3). Then $w = u - v$ is a weak solution of the problem

$$w_{tt} - \Delta w_t - \Delta w + f(u_t) - f(v_t) = \sum_{i=1}^N (\sigma_i(u_{x_i}) - \sigma_i(v_{x_i}))_{x_i} - \Delta w, \tag{1.53}$$

$$w(0) = 0 = w_t(0), \tag{1.54}$$

$$w = 0 \quad \text{on } \partial\Omega. \tag{1.55}$$

Multiplying (1.53) by w_t and integrating over Ω, we obtain

$$\frac{1}{2}\frac{d}{dt}(\|w_t(t)\|^2+\|\nabla w(t)\|^2)+\|\nabla w_t(t)\|^2+\langle f(u_t(t))-f(v_t(t)),\, u_t(t)-v_t(t)\rangle$$
$$(1.56)\qquad =\sum_{i=1}^{N}\langle \sigma_i(u_{x_i}(t))-\sigma_i(v_{x_i}(t)),\, w_{tx_i}(t)\rangle+\langle \nabla w(t), \nabla w_t(t)\rangle.$$

Using (1.3) and the monotonicity of f, we get from (1.56)

$$(1.57)\qquad \frac{1}{2}\frac{d}{dt}(\|\nabla w_t(t)\|^2+\|\nabla w(t)\|^2)\leqq a\|\nabla w(t)\|^2$$

for some $a>0$. From (1.57) we deduce that

$$(1.58)\qquad \|w_t(t)\|^2+\|\nabla w(t)\|^2=0$$

Thus $w=0$.

The proof of the theorem is completed.

2. We shall consider the problem of global existence of strong solutions of (0.1)-(0.3). To this end, we shall have to strengthen conditions on the initial data and on the σ_i's. The role of the space dimension is important in this connection, and, in order to simplify matters, we shall limit ourselves to $N=1$. With the latter restriction, it will be sufficient, from our point of view, to place the following requirements on the initial data on the coefficients of the field equation:

$$(2.1)\qquad u_0 \quad \text{in } H_0^1\cap H^2, \qquad u_1 \quad \text{in } L_2,$$

$$(2.2)\qquad \sigma_i \text{ in } C^1(\mathbb{R},\mathbb{R}),\ \sigma_i'>0,\ \sigma_i(0)=0 \text{ and } \sigma_i' \text{ locally Hölder continuous.}$$

Then, we have the following.

THEOREM 2. *Let $N=1$ and let* (2.1) *and* (2.2) *hold. Then, there exists a unique solution $u(\cdot)$ of* (0.1)-(0.3) *with the following properties*:

$$(2.3)\qquad t\to u(t) \text{ is continuously on } t\geqq 0 \text{ to } H_0^1\cap H^2, \text{ continuously differentiable on } t>0 \text{ to } H_0^1\cap H^2;$$

$$(2.4)\qquad t\to u(t) \text{ is continuously differentiable on } t\geqq 0 \text{ to } L_2 \text{ and twice continuously differentiable on } t>0 \text{ to } L_2;$$

$$(2.5)\qquad t\to \Delta u(t) \text{ is continuously differentiable on } t>0 \text{ to } L_2.$$

Proof. The idea of the proof is as follows. We take the weak solution w of (0.1)-(0.3) (which will presently be shown to exist), and then, using the analytic theory of semigroup, we shall prove that w is in fact the strong solution of the theorem. The proof consists of two steps. In Step 1, we shall establish the existence of a unique weak solution on R_+. In Step 2, we shall prove that such a solution is in fact a strong solution.

Step 1. We shall only sketch the proof since it is very similar to (in fact considerably simpler than) the proof of theorem 1. According to the a priori estimates already obtained in the proof of Theorem 1, we had

$$(2.6)\qquad \|u_t^{(n)}(t)\|\leqq M \quad \text{for all } n \text{ and } 0\leqq t\leqq T_n,$$

$$(2.7)\qquad \int_0^t \|\nabla u_t^{(n)}(s)\|^2\, ds\leqq M \quad \text{for all } n \text{ and } 0\leqq t\leqq T_n$$

where $u^{(n)}(t)$ is a Galerkin approximate solution of (0.1)-(0.3) as in the proof of Theorem 1, and $[0, T_n[$ is its interval of existence. Now, using the hypothesis that u_0 be in $H_0^1 \cap H^2$, we have the following bound on $\Delta u^{(n)}$:

$$\|\Delta u^{(n)}(t)\| \leqq M \quad \text{for all } n \text{ and } 0 \leqq t \leqq T_n. \tag{2.8}$$

Note that we can take $T_n = T$ for all n, where T is an arbitrary positive number. Since $N = 1$, we have

$$\|\nabla u^{(n)}(t)\|_\infty \leqq K \|\Delta u^{(n)}(t)\| \quad \text{for all } t \leqq T \tag{2.9}$$

where K is independent of n and t; from (2.9) and (2.8) we deduce that, in particular.

$$\|\nabla u^{(n)}(t)\|_\infty \leqq KM \quad \text{for all } t \text{ in } [0, T]. \tag{2.10}$$

By passing to the limit much as in the proof of Theorem 1, this time using the inequality (2.10), we conclude that there exists a weak solution w of (0.1)-(0.3) on $]0, T[$ with the following properties:

$$\|\Delta w(t)\| \leqq M \quad \text{for all } 0 \leqq t \leqq T, \tag{2.11}$$

$$\|w_t(t)\| \leqq M \quad \text{for all } 0 \leqq t \leqq T, \tag{2.12}$$

$$\int_0^t \|\nabla w_t(s)\|^2 \, ds \leqq M \quad \text{for all } 0 \leqq t \leqq T. \tag{2.13}$$

Uniqueness is proved in a standard manner, much as in the proof of Theorem 1. We conclude that there exists a unique weak solution w on R_+ with the same bounds as in (2.11)-(2.13).

Step 2. Let w be the weak solution of (0.1)-(0.3) on $\mathbb{R}_+$ as in Step 1. Then w is the solution of the following (equivalent) equation

$$w_t = \Delta w + u_1 - \Delta u_0 + G(w) + F(w) \tag{2.14}$$

where

$$G(w(t)) = \int_0^t H(w(s)) \, ds, \qquad F(w(s)) = -\int_0^t f(w_t(s)) \, ds. \tag{2.15}$$

Here

$$H(w) = \sigma'(w_x) w_{xx}. \tag{2.16}$$

Since (2.14) is equivalent to (0.1)-(0.3), w is its unique solution. Consider the differential equation

$$u_t = \Delta u + u_1 - \Delta u_0 + G(w) + F(w) \tag{2.17}$$

with the initial condition

$$u(0) = u_0. \tag{2.18}$$

Let $S(t)$ be the semigroup on L_2 generated by the Laplacian $\Delta(\operatorname{dom} \Delta = H_0^1 \cap H^2)$. Note that $S(t)$ is in fact an analytic semi-group, a fact which will be crucial for what follows. The solution of (2.17)-(2.18) is given by

$$\begin{aligned} u(t) = S(t)u_0 + \int_0^t S(t-s)(u_1 - \Delta u_0) \, ds \\ + \int_0^t S(t-s)(G(w(s)) + F(w(s))) \, ds. \end{aligned} \tag{2.19}$$

From (2.19), we get

$$\Delta u(t) = S(t)\Delta u_0 + S(t)(u_1 - \Delta u_0) - u_1 + \Delta u_0 + \int_0^t S(t-s)(H(w(s)) - F(w_t(s)))\, ds - G(w(t)) - F(w(t)). \tag{2.20}$$

We note from (2.20) that $\Delta u(t)$ is continuous on $t \geqq 0$, and hence, by (2.17) that $u_t(t)$ is continuous on $t \geqq 0$. From now on we shall use freely Pazy's results on analytic semigroups [13]. Since $S(t)$ is an analytic semigroup, we deduce from (2.20) that $t \to \Delta u(t)$ is Hölder continuous, and hence, by (2.17), $t \to u_t(t)$ is also Hölder continuous on $t > 0$ to L_2. Now, by the uniqueness of w as a solution of (2.14), we see that $u = w$. Thus, $w(\cdot)$ and $w_t(\cdot)$ are Hölder continuous. Thus $f(w_t(\cdot))$ is Hölder continuous. By (2.9), the Hölder continuity of σ_i' and by the Hölder continuity of $\Delta w(\cdot)$ noted above, it follows that $H(w(\cdot))$ is Hölder continuous. Thus, it follows from Pazy's results that $t \to \Delta w(t)$ is continuously differentiable on $t > 0$ to L_2, and that, similarly by (2.17), $t \to w_t$ is continuously differentiable on $t > 0$ to L_2. Thus w is the (unique) strong solution of (0.1)-(0.3) in the sense that it satisfies (2.3)-(2.5) (with $w = u$). This completes the proof of the theorem.

Remark 2. It was established in the course of the proof that the strong solution w satisfies the following inequalities (cf. (2.11)-(2.13)):

$$\|\Delta w(t)\| \leqq M \quad \text{for all } t \geqq 0, \tag{2.21}$$

$$\|w_t(t)\| \leqq M \quad \text{for all } t \geqq 0, \tag{2.22}$$

$$\int_0^t \|\nabla w_t(s)\|^2\, ds \leqq M \quad \text{for all } t \geqq 0. \tag{2.23}$$

Acknowledgement. The authors wish to thank the referee of this paper for his constructive and useful remarks.

DENSE SETS AND FAR FIELD PATTERNS FOR THE VECTOR HELMHOLTZ EQUATION UNDER TRANSMISSION BOUNDARY CONDITIONS*

PETER WILDE† AND ACHIM WILLERS†

Abstract. We study the set of far field patterns which are generated by entire incident fields scattered by a bounded penetrable obstacle. Necessary and sufficient conditions are given for the set to be dense in the set of all square integrable vector fields defined on the unit sphere and it is shown how these results can be generalized to Sobolev spaces and to classical function spaces.

Key words. far field pattern, scattering theory, Helmholtz equation, Fredholm integral equation

AMS(MOS) subject classifications. 78A45, 35J05, 45B05

1. Introduction. In the theory of direct problems in acoustic and electromagnetic scattering by bounded obstacles it is shown how the solution of a boundary value problem and the related far field corresponding to an incident field and to a given obstacle can be calculated. For further details see Colton and Kress [4].

Wilde [10], [11] has investigated the more general direct problem of electromagnetic scattering by a penetrable physical medium. To follow his considerations, let D_i be a bounded, simply connected domain in $\mathbb{R}^3$ with boundary S belonging to the class C^2 and define $D_e := \mathbb{R}^3 \setminus \overline{D_i}$. We assume that the normal vector n to S is directed into the exterior domain. To simplify notation, for any domain G with boundary ∂G of class C^2 we introduce the linear space of vector fields

$$F(G) := \{H : \bar{G} \to \mathbb{C}^3 \mid H \in C^2(G) \cap C(\bar{G}), \text{ curl } H, \text{ div } H \in C(\bar{G})\}.$$

Given an exterior wavenumber $\kappa_e > 0$, an interior wave number $\kappa_i \neq 0$ with $\operatorname{Im}(\kappa_i) \geqq 0$ and an entire solution H^i of the vector Helmholtz equation $\Delta H^i + \kappa_e^2 H^i = 0$ as incident field we consider the **magnetic transmission problem TH(m)** and the **electric transmission problem TH(e).**

Problem TH(m). Find two vector fields $H_e = H^i + H^s \in F(D_e)$ and $H_i \in F(D_i)$ satisfying the vector Helmholtz equations

$$\Delta H_e + \kappa_e^2 H_e = 0 \quad \text{in } D_e, \qquad \Delta H_i + \kappa_i^2 H_i = 0 \quad \text{in } D_i, \tag{1.1}$$

the *magnetic transmission conditions*

$$\begin{aligned} [n, H_e] \quad &- \quad [n, H_i] \quad = 0, \\ \operatorname{div} H_e \quad &- \quad \operatorname{div} H_i \quad = 0, \\ \beta_e[[\operatorname{curl} H_e, n], n] &- \beta_i[[\operatorname{curl} H_i, n], n] = 0, \\ \alpha_e(n, H_e) \quad &- \quad \alpha_i(n, H_i) \quad = 0 \quad \text{on } S \end{aligned} \tag{1.2}$$

and the *radiation condition*

$$[\operatorname{curl} H^s, \hat{x}] + \hat{x} \operatorname{div} H^s - \iota \kappa_e H^s = o(1/|x|), \qquad |x| \to \infty, \tag{1.3}$$

uniformly for all directions $\hat{x} := x/|x|$, where $\iota := \sqrt{-1}$ is the imaginary unit and $\beta_e, \beta_i, \alpha_e, \alpha_i \in \mathbb{C}\backslash\{0\}$ are given complex numbers. H^s is called the scattered field.

By (a, b), $[a, b]$, and (a, b, c) we denote the scalar product, vector product, and triple scalar product of the vectors $a, b, c \in \mathbb{C}^3$, respectively.

In electromagnetic scattering the transmission parameters $\beta_e, \beta_i, \alpha_e$ and α_i are related to the dielectric constants, the permeability, the electric and magnetic conductivity, and to the frequency of the incoming wave (cf. Wilde [11]).

The problem obtained by replacing the magnetic transmission conditions (1.2) by the *electric transmission conditions*

$$\begin{aligned} \beta_e^{-1}[n, H_e] &- \beta_i^{-1}[n, H_i] = 0, \\ \alpha_e^{-1} \operatorname{div} H_e &- \alpha_i^{-1} \operatorname{div} H_i = 0, \\ [[\operatorname{curl} H_e, n], n] &- [[\operatorname{curl} H_i, n], n] = 0, \\ (n, H_e) &- (n, H_i) = 0 \quad \text{on } S \end{aligned} \tag{1.4}$$

is called **Problem TH(e).**

The corresponding inverse problem, i.e., to determine the shape of the penetrable scattering obstacle by measuring the scattered fields, is in many cases of more interest for physical application. Recently, Colton and Monk [6] presented an optimization scheme for solving the inverse scalar transmission problem. It is based on the decomposition of the space of all square integrable functions defined on the unit sphere into the set of all far field patterns corresponding to all incoming plane waves and a finite dimensional space of Herglotz kernels. This decomposition theorem, obtained by Kirsch [8], is equivalent to the assertion that, under certain circumstances, the class of far field patterns corresponding to a fixed scattering obstacle and all entire incident fields is dense in the set of all square integrable functions defined on the unit sphere.

Therefore, the classification of the class of far field patterns corresponding to the scattering of time harmonic incident fields by a penetrable bounded obstacle is one of the basic problems in inverse scattering theory for acoustics, electromagnetics and elastodynamics. Far field patterns for acoustic and electromagnetic scattering problems have been considered by many authors, e.g., Colton [1], Colton and Kirsch [2], [3], Colton and Kress [5], Kirsch [8] and Willers [12]. We shall carry out an analogous investigation for the transmission problems for the vector Helmholtz equations. Wilde [11] has shown that transmission problems for the vector Helmholtz equation are slight generalizations of transmission problems for the Maxwell equation. This may be the first step in solving the corresponding inverse problem.

As opposed to the authors mentioned above we shall only use integral equations in classical function spaces and avoid the theory of generalized boundary value problems.

In order to reduce the transmission problems to integral equations of the second kind we introduce the function spaces

$$C_T^{0,\alpha}(S) := \{a : S \to \mathbb{C}^3 | (a, n) = 0, a \in C^{0,\alpha}(S)\},$$

$$C_D^{0,\alpha}(S) := \{a \in C_T^{0,\alpha}(S) | \operatorname{Div} a \in C^{0,\alpha}(S)\},$$

$$P_\uparrow^{0,\alpha}(S) := C_D^{0,\alpha}(S) \times C^{0,\alpha}(S) \times C_T^{0,\alpha}(S) \times C^{0,\alpha}(S),$$

$$P_\downarrow^{0,\alpha}(S) := C_T^{0,\alpha}(S) \times C^{0,\alpha}(S) \times C_D^{0,\alpha}(S) \times C^{0,\alpha}(S),$$

and equip $C^{0,\alpha}(S)$, $C_T^{0,\alpha}(S)$ with the usual Hölder norms, $C_D^{0,\alpha}(S)$ with the norm $\|a\|_{1,\alpha} := \|a\|_\alpha + \|\operatorname{Div} a\|_\alpha$ and $P_\uparrow^{0,\alpha}(S)$, $P_\downarrow^{0,\alpha}(S)$ with the product norms. Furthermore,

we define the integral operators $\mathbf{M_m}, \mathbf{M_e}: \mathrm{P}_{\uparrow}^{0,\alpha}(S) \to P_{\uparrow}^{0,\alpha}(S)$, $\mathbf{M}'_{\mathbf{m}}, \mathbf{M}'_{\mathbf{e}}: P_{\downarrow}^{0,\alpha}(S) \to P_{\downarrow}^{0,\alpha}(S)$ by

$$\mathbf{M_m} := \begin{pmatrix} (I+L_e)\Omega_e + (I-L_i)\Omega_i & R_e - R_i \\ -\Gamma_e Q_e \Omega_e + \Gamma_i Q_i \Omega_i & \Gamma_e(I-L'_e) + \Gamma_i(I+L'_i) \end{pmatrix},$$

$$\mathbf{M}'_{\mathbf{m}} := \begin{pmatrix} \Omega_e(I+L'_e) + \Omega_i(I-L'_i) & -\Omega_e Q_e \Gamma_e + \Omega_i Q_i \Gamma_i \\ R_e - R_i & (I-L_e)\Gamma_e + (I+L_i)\Gamma_i \end{pmatrix},$$

$$\mathbf{M_e} := \begin{pmatrix} \Gamma_e^{-1}(I+L_e) + \Gamma_i^{-1}(I-L_i) & \Gamma_e^{-1} R_e \Omega_e - \Gamma_i^{-1} R_i \Omega_i \\ -Q_e + Q_i & (I-L'_e)\Omega_e + (I+L'_i)\Omega_i \end{pmatrix},$$

$$\mathbf{M}'_{\mathbf{e}} := \begin{pmatrix} (I+L'_e)\Gamma_e^{-1} + (I-L'_i)\Gamma_i^{-1} & -Q_e + Q_i \\ \Omega_e R_e \Gamma_e^{-1} - \Omega_i R_i \Gamma_i^{-1} & \Omega_e(I-L_e) + \Omega_i(I+L_i) \end{pmatrix},$$

where the 2×2 matrix operators L_e, L'_e, R_e, Q_e and L_i, L'_i, R_i, Q_i are the operators L, L', R, Q from [4, pp. 132, 138], [11] with respect to the wave numbers κ_e, κ_i, respectively, and where $\Gamma_e, \Omega_e, \Gamma_i, \Omega_i$ are given by

$$\Gamma_j := \begin{pmatrix} \beta_j I & 0 \\ 0 & \alpha_j I \end{pmatrix}, \qquad \Omega_j := \sigma_j \begin{pmatrix} \kappa_j^2 I & 0 \\ 0 & I \end{pmatrix}, \qquad j = e, i,$$

with

$$\sigma_j := \begin{cases} 1 & \text{if } \mathrm{Re}\,(\kappa_j) \geqq 0, \\ -1 & \text{otherwise,} \end{cases} \qquad j = e, i.$$

Note that the operators $\mathbf{M_m}, \mathbf{M}'_{\mathbf{m}}$ and the operators $\mathbf{M_e}, \mathbf{M}'_{\mathbf{e}}$ are adjoint with respect to the nondegenerate bilinear form

$$\langle \cdot, \cdot \rangle : P_{\uparrow}^{0,\alpha}(S) \times P_{\downarrow}^{0,\alpha}(S) \to \mathbb{C},$$

$$\langle \chi, \chi_0 \rangle := \int_S \{(a, a_0) + \lambda\lambda_0 + (b, b_0) + \delta\delta_0\}\, ds,$$

$\chi := (a, \lambda, b, \delta)^T \in P_{\uparrow}^{0,\alpha}(S)$, $\chi_0 := (a_0, \lambda_0, b_0, \delta_0)^T \in P_{\downarrow}^{0,\alpha}(S)$.

Before starting our analysis we summarize some results obtained by Wilde [11]. In these theorems $\Phi_i(x, y)$ and $\Phi_e(x, y)$ denote the fundamental solution

$$\Phi(x, y) := \frac{\exp(\iota\kappa|x-y|)}{4\pi|x-y|}, \qquad x, y \in \mathbb{R}^3, \quad x \neq y,$$

of the scalar Helmholtz equation with respect to the wave numbers κ_i and κ_e.

THEOREM 1.1. (i) *If* $\chi_m := (a, \lambda, b, \delta)^T \in P_{\uparrow}^{0,\alpha}(S)$ *is a solution of the integral equation*

$$\mathbf{M_m}\chi_m = f_m$$

with $f_m := 2(-[n, H^i], -\mathrm{div}\, H^i, \beta_e[[\mathrm{curl}\, H^i, n], n], \alpha_e(n, H^i))^T$, *then the fields*

$$H_i(x) := \mathrm{curl}_x \int_S a(y)\Phi_i(x, y)\, ds(y) - \int_S n(y)\lambda(y)\Phi_i(x, y)\, ds(y)$$

$$+ \sigma_i \kappa_i^2 \int_S [n(y), b(y)]\Phi_i(x, y)\, ds(y)$$

$$+ \sigma_i\, \mathrm{grad}_x \int_S \delta(y)\Phi_i(x, y)\, ds(y), \qquad x \in D_i,$$

$$H^s(x) := \operatorname{curl}_x \int_S a(y)\Phi_e(x,y)\,ds(y) - \int_S n(y)\lambda(y)\Phi_e(x,y)\,ds(y) + \sigma_e\kappa_e^2 \int_S [n(y), b(y)]\Phi_e(x,y)\,ds(y) + \sigma_e \operatorname{grad}_x \int_S \delta(y)\Phi_e(x,y)\,ds(y), \qquad x \in D_e, \tag{1.5}$$

are a solution of the magnetic transmission problem.

(ii) *If the homogeneous magnetic transmission problem admits only the trivial solution then the operators* $\mathbf{M_m}$ *and* $\mathbf{M'_m}$ *are invertible and the Problem* $TH(m)$ *is uniquely solvable.*

THEOREM 1.2. (i) *If* $\chi_e := (a, \lambda, b, \delta)^T \in P_\uparrow^{0,\alpha}(S)$ *is a solution of the integral equation*

$$\mathbf{M_e}\chi_e = f_e$$

with $f_e := 2(-\beta_e^{-1}[n, H^i], -\alpha_e^{-1} \operatorname{div} H^i, [[\operatorname{curl} H^i, n], n], (n, H^i))^T$, *then the fields*

$$H_i(x) := \operatorname{curl}_x \int_S a(y)\Phi_i(x,y)\,ds(y) - \int_S n(y)\lambda(y)\Phi_i(x,y)\,ds(y) + \sigma_i\kappa_i^2 \int_S [n(y), b(y)]\Phi_i(x,y)\,ds(y) + \sigma_i \operatorname{grad}_x \int_S \delta(y)\Phi_i(x,y)\,ds(y), \qquad x \in D_i,$$

$$H^s(x) := \operatorname{curl}_x \int_S a(y)\Phi_e(x,y)\,ds(y) - \int_S n(y)\lambda(y)\Phi_e(x,y)\,ds(y) + \sigma_e\kappa_e^2 \int_S [n(y), b(y)]\Phi_e(x,y)\,ds(y) + \sigma_e \operatorname{grad}_x \int_S \delta(y)\Phi_e(x,y)\,ds(y), \qquad x \in D_e, \tag{1.6}$$

are a solution of the electric transmission problem.

(ii) *If the homogeneous electric transmission problem admits only the trivial solution then the operators* $\mathbf{M_e}$ *and* $\mathbf{M'_e}$ *are invertible and the Problem* $TH(e)$ *is uniquely solvable.*

2. Dense sets and far field patterns. To start our investigations we prove an integral equation based on the representation theorem.

LEMMA 2.1. *Let the incident field* H^i *be an entire solution of the vector Helmholtz equation and let* H^s *be the scattered field under magnetic transmission conditions. Then the Cauchy data* $\chi_m^D := (\beta_e[[\operatorname{curl} H_e, n], n], \alpha_e(n, H_e), [n, H_e], \operatorname{div} H_e)^T$, *on* S, *of the exterior field satisfy the integral equation*

$$\mathbf{M'_e}\chi_m^D = f_m^D \tag{2.1}$$

with $f_m^D := 2([[\operatorname{curl} H^i, n], n], (n, H^i), \sigma_e\kappa_e^2[n, H^i], \sigma_e \operatorname{div} H^i)^T \in P_\downarrow^{0,\alpha}(S)$.

Proof. From the investigations of Colton and Kress [4] we obtain

$$\begin{pmatrix} [n, H_e] \\ \operatorname{div} H_e \end{pmatrix} - L_e \begin{pmatrix} [n, H_e] \\ \operatorname{div} H_e \end{pmatrix} + R_e \begin{pmatrix} [[\operatorname{curl} H_e, n], n] \\ (n, H_e) \end{pmatrix} = 2 \begin{pmatrix} [n, H^i] \\ \operatorname{div} H^i \end{pmatrix}, \tag{2.2}$$

$$-\begin{pmatrix}[n, H_i]\\ \operatorname{div} H_i\end{pmatrix} - L_i\begin{pmatrix}[n, H_i]\\ \operatorname{div} H_i\end{pmatrix} + R_i\begin{pmatrix}[[\operatorname{curl} H_i, n], n]\\ (n, H_i)\end{pmatrix} = 0, \tag{2.3}$$

$$\begin{pmatrix}[[\operatorname{curl} H_e, n], n]\\ (n, H_e)\end{pmatrix} - Q_e\begin{pmatrix}[n, H_e]\\ \operatorname{div} H_e\end{pmatrix} + L'_e\begin{pmatrix}[[\operatorname{curl} H_e, n], n]\\ (n, H_e)\end{pmatrix} = 2\begin{pmatrix}[[\operatorname{curl} H^i, n], n]\\ (n, H^i)\end{pmatrix}, \tag{2.4}$$

$$-\begin{pmatrix}[[\operatorname{curl} H_i, n], n]\\ (n, H_i)\end{pmatrix} - Q_i\begin{pmatrix}[n, H_i]\\ \operatorname{div} H_i\end{pmatrix} + L'_i\begin{pmatrix}[[\operatorname{curl} H_i, n], n]\\ (n, H_i)\end{pmatrix} = 0. \tag{2.5}$$

Inserting the transmission conditions into (2.3) and (2.5) we deduce

$$\begin{pmatrix}[n, H_e]\\ \operatorname{div} H_e\end{pmatrix} + L_i\begin{pmatrix}[n, H_e]\\ \operatorname{div} H_e\end{pmatrix} - R_i\Gamma_i^{-1}\Gamma_e\begin{pmatrix}[[\operatorname{curl} H_e, n], n]\\ (n, H_e)\end{pmatrix} = 0, \tag{2.6}$$

$$\Gamma_i^{-1}\Gamma_e\begin{pmatrix}[[\operatorname{curl} H_e, n], n]\\ (n, H_e)\end{pmatrix} + Q_i\begin{pmatrix}[n, H_e]\\ \operatorname{div} H_e\end{pmatrix} - L'_i\Gamma_i^{-1}\Gamma_e\begin{pmatrix}[[\operatorname{curl} H_e, n], n]\\ (n, H_e)\end{pmatrix} = 0. \tag{2.7}$$

Adding (2.7) and (2.4) we obtain the first part of (2.1). To prove the second part we have to multiply (2.2) by Ω_e and (2.6) by Ω_i and add the equations. □

Now we write some definitions that we need in order to formulate the main theorem of this paper.

DEFINITION 2.2. κ_e is called an *eigenvalue of the magnetic transmission problem* if there exist nontrivial vector fields $G, W \in F(D_i)$ satisfying the vector Helmholtz equations

$$\Delta W + \kappa_e^2 W = 0 \quad \text{in } D_i, \qquad \Delta G + \kappa_i^2 G = 0 \quad \text{in } D_i, \tag{2.8}$$

and the boundary conditions

$$\begin{aligned} [n, W] \quad &- \quad [n, G] \quad = 0, \\ \operatorname{div} W \quad &- \quad \operatorname{div} G \quad = 0, \\ \beta_e[[\operatorname{curl} W, n], n] &- \beta_i[[\operatorname{curl} G, n], n] = 0, \\ \alpha_e(n, W) \quad &- \quad \alpha_i(n, G) \quad = 0 \qquad \text{on } S. \end{aligned} \tag{2.9}$$

The field W is called the *corresponding eigenfunction.* κ_e is called an *eigenvalue of the electric transmission problem* if we have

$$\begin{aligned} \beta_e^{-1}[n, W] \quad &- \quad \beta_i^{-1}[n, G] \quad = 0, \\ \alpha_e^{-1} \operatorname{div} W \quad &- \quad \alpha_i^{-1} \operatorname{div} G \quad = 0, \\ [[\operatorname{curl} W, n], n] &- [[\operatorname{curl} G, n], n] = 0, \\ (n, W) \quad &- \quad (n, G) \quad = 0 \qquad \text{on } S \end{aligned} \tag{2.10}$$

instead of (2.9).

Such eigenvalues may exist. This is shown by the following example.

Example 2.3. In the special case where S is the unit sphere in $\mathbb{R}^3$ we define

$$G(x) := \frac{\sin \kappa_e}{\kappa_i^3 \kappa_e} \operatorname{grad}\left(\frac{\sin \kappa_i |x|}{|x|}\right), \qquad x \in D_i,$$

$$W(x) := \frac{\sin \kappa_i}{\kappa_e^3 \kappa_i} \operatorname{grad}\left(\frac{\sin \kappa_e |x|}{|x|}\right), \qquad x \in D_i,$$

where κ_e and κ_i are different solutions of the equation $\tan t = t$.

Now $\{G, W\}$ is a solution of (2.8) and from

$$G(x) = \frac{\sin \kappa_e}{\kappa_e}\left(\frac{\kappa_i \cos \kappa_i|x|}{|x|} - \frac{\sin \kappa_i|x|}{|x|^2}\right)\hat{x},$$

$$W(x) = \frac{\sin \kappa_i}{\kappa_i}\left(\frac{\kappa_e \cos \kappa_e|x|}{|x|} - \frac{\sin \kappa_e|x|}{|x|^2}\right)\hat{x},$$

we easily see that the homogeneous boundary conditions (2.9) are satisfied.

On the other hand it can be shown that under certain assumption on κ_e, κ_i, α_e, α_i, β_e, and β_i the boundary value problem (2.8), (2.10) admits only the trivial solution.

Example 2.4. Let the following relations be fulfilled:

$$\gamma := \frac{\alpha_e}{\alpha_i} = \frac{\overline{\beta_e}}{\overline{\beta_i}} \quad \text{with } \gamma \notin \mathbb{R}, \quad \kappa_e > 0 \quad \text{and Re}\,(\kappa_i) = 0.$$

Then the first vector Green's theorem yields

$$\begin{aligned}\int_D \{-\kappa_e^2|W|^2 + |\text{curl } W|^2 + |\text{div } W|^2\}\, dx &= \int_S \{(n, \bar{W}, \text{curl } W) + (n, \bar{W})\, \text{div } W\}\, ds \\ &= \bar{\gamma} \int_S \{(n, \bar{G}, \text{curl } G) + (n, \bar{G})\, \text{div } G\}\, ds \\ &= \bar{\gamma} \int_D \{-\kappa_i^2|G|^2 + |\text{curl } G|^2 + |\text{div } G|^2\}\, dx\end{aligned}$$

and we obtain $G = W = 0$.

DEFINITION 2.5. An entire solution W of the vector Helmholtz equation is called a *Herglotz field* if

$$\lim_{r\to\infty} \frac{1}{r} \int_{|x|\leq r} |W(x)|^2\, dx < \infty.$$

Let $\mathbf{Y}$ be the set of all square integrable vector fields defined on the unit sphere. Applying the results of Hartman and Wilcox [7] to each coordinate of W we obtain Lemma 2.6.

LEMMA 2.6. *An entire solution W of the vector Helmholtz equation $\Delta W + \kappa^2 W = 0$ is a Herglotz field if and only if there exists a vector field $w \in \mathbf{Y}$ such that W has the representation*

$$W(x) = \int_{|\hat{y}|=1} w(\hat{y})\, e^{i\kappa(x,\hat{y})}\, ds(\hat{y}), \qquad x \in \mathbb{R}^3.$$

Furthermore, w is uniquely determined by W.

By using the representation theorem for solutions of the vector Helmholtz equation Colton and Kress [4] have shown the relation

$$H^s(x) = \frac{e^{i\kappa_e|x|}}{4\pi|x|} F(\hat{x}) + O\left(\frac{1}{|x|^2}\right), \qquad |x| \to \infty,$$

uniformly for all directions $\hat{x} \in \mathbb{R}^3$, where the vector field F is defined by

$$F(\hat{x}) := \iota\kappa_e \int_S [\hat{x}, [n(y), H_e(y)]]\, e^{-\iota\kappa_e(\hat{x},y)}\, ds(y)$$
$$- \int_S n(y)\, \operatorname{div} H_e(y)\, e^{-\iota\kappa_e(\hat{x},y)}\, ds(y)$$
$$- \int_S [\operatorname{curl} H_e(y), n(y)]\, e^{-\iota\kappa_e(\hat{x},y)}\, ds(y)$$
$$- \iota\kappa_e \int_S \hat{x}(n(y), H_e(y))\, e^{-\iota\kappa_e(\hat{x},y)}\, ds(y), \qquad \hat{x} \in \Gamma,$$

where Γ denotes the unit sphere in $\mathbb{R}^3$. Furthermore, they have shown that $F = 0$ implies $H^s = 0$. The vector field F is called the *far field pattern* of the scattered field H^s.

Now we are able to prove a theorem on the set $\mathbf{F}^{\mathbf{m}}_{\kappa_e}$ of far field patterns corresponding to all entire incident fields under magnetic transmission conditions.

THEOREM 2.7. *If the homogeneous magnetic transmission problem has only the trivial solution, then we have*:

If κ_e is not an eigenvalue of the electric transmission problem, then $\mathbf{F}^{\mathbf{m}}_{\kappa_e}$ is dense in $\mathbf{Y}$. If κ_e is an eigenvalue of the electric transmission problem, then $\mathbf{F}^{\mathbf{m}}_{\kappa_e}$ is dense in $\mathbf{Y}$ if and only if none of the corresponding eigenfunctions is a Herglotz field.

Proof. Let $\mathbf{F}^{\mathbf{m}}_{\kappa_e}$ be dense in $\mathbf{Y}$ and let W be a Herglotz field which is an eigenfunction in D_i. W has a representation of the form

$$W(x) := \int_{|\hat{y}|=1} \overline{w(\hat{y})}\, e^{-\iota\kappa_e(x,\hat{y})}\, ds(\hat{y}), \qquad x \in \mathbb{R}^3, \tag{2.11}$$

for some $w \in \mathbf{Y}$.

If $F \in \mathbf{F}^{\mathbf{m}}_{\kappa_e}$ is a given far field pattern and H_e, H_i is the corresponding solution of the magnetic transmission problem in D_e, D_i, respectively, then from the second vector Green's theorem we obtain

$$\int_{|\hat{x}|=1} (\overline{w(\hat{x})}, F(\hat{x}))\, ds(\hat{x})$$
$$= \int_S (n, H_e, \operatorname{curl} W)\, ds + \int_S (n, H_e) \operatorname{div} W\, ds$$
$$- \int_S (n, W, \operatorname{curl} H_e)\, ds - \int_S (n, W) \operatorname{div} H_e\, ds$$
$$= \int_S (n, H_i, \operatorname{curl} G)\, ds + \int_S (n, H_i) \operatorname{div} G\, ds$$
$$- \int_S (n, G, \operatorname{curl} H_i)\, ds - \int_S (n, G) \operatorname{div} H_i\, ds = 0.$$

Now the density of $\mathbf{F}^{\mathbf{m}}_{\kappa_e}$ in $\mathbf{Y}$ implies $w = 0$ and therefore $W = 0$.

Conversely, suppose that there exists a vector field $w \in \mathbf{Y}$ such that

$$\int_{|\hat{x}|=1} (\overline{w(\hat{x})}, F(\hat{x}))\, ds(\hat{x}) = 0$$

for all $F \in \mathbf{F}^{\mathbf{m}}_{\kappa_e}$.

Defining W as in (2.11) and using the integral equation (2.1), we obtain

$$
\begin{aligned}
0 &= \int_{|\hat{x}|=1} \overline{(w(\hat{x}), F(\hat{x}))}\, ds(\hat{x}) \\
&= \int_S (n, H_e, \operatorname{curl} W)\, ds + \int_S (n, H_e) \operatorname{div} W ds - \int_S (n, W, \operatorname{curl} H_e)\, ds \\
&\quad - \int_S (n, W) \operatorname{div} H_e\, ds \\
&= \left\langle \begin{pmatrix} \beta_e[[\operatorname{curl} H_e, n], n] \\ \alpha_e(n, H_e) \\ [n, H_e] \\ \operatorname{div} H_e \end{pmatrix}, \begin{pmatrix} \beta_e^{-1}[n, W] \\ \alpha_e^{-1} \operatorname{div} W \\ -[[\operatorname{curl} W, n], n] \\ -(n, W) \end{pmatrix} \right\rangle \qquad (2.12) \\
&= 2 \left\langle (\mathbf{M}_e')^{-1} \begin{pmatrix} [[\operatorname{curl} H^i, n], n] \\ (n, H^i) \\ \sigma_e \kappa_e^2 [n, H^i] \\ \sigma_e \operatorname{div} H^i \end{pmatrix}, \begin{pmatrix} \beta_e^{-1}[n, W] \\ \alpha_e^{-1} \operatorname{div} W \\ -[[\operatorname{curl} W, n], n] \\ -(n, W) \end{pmatrix} \right\rangle \\
&= \langle (\mathbf{M}_e')^{-1} f_m^D, g \rangle = \langle f_m^D, \mathbf{M}_e^{-1} g \rangle,
\end{aligned}
$$

where g is given by $g := (\beta_e^{-1}[n, W], \alpha_e^{-1} \operatorname{div} W, -[[\operatorname{curl} W, n], n], -(n, W))^T$ and f_m^D was defined in (2.1). With $\chi_e := (a, \lambda, b, \delta)^T := -2\mathbf{M}_e^{-1} g$ we define vector fields G^s and G_i as in (1.6). We observe that G_i and $G_e := G^s + W$ form a solution of *Problem TH*(e). Defining

$$
v_k^m(x) := h_k^{(1)}(\kappa_e |x|)\, Y_k^m(\hat{x}), \qquad u_k^m(x) := j_k(\kappa_e |x|)\, Y_k^m(\hat{x}),
$$

where $h_k^{(1)}$ denote the spherical Hankel function of the first kind of order k, j_k the spherical Bessel function of order k and Y_k^m the spherical harmonics of order k, $k = 0, 1, 2, \cdots$, $m = -k, \cdots, k$, and using the expansion $\Phi_e(x, y) = \iota\kappa_e \sum_{k=0}^{\infty} \sum_{m=-k}^{k} v_k^m(x) u_k^m(y)$, $|y| < |x|$, for all sufficiently large $|x|$ and every unit vector c, we obtain

$$
\begin{aligned}
(c, G^s(x)) &= \int_S (a(y), \operatorname{curl}_y \{c\Phi_e(x, y)\})\, ds(y) \\
&\quad - \int_S (c, n(y))\lambda(y)\Phi_e(x, y)\, ds(y) \\
&\quad + \sigma_e \kappa_e^2 \int_S (c, n(y), b(y))\Phi_e(x, y)\, ds(y) \\
&\quad - \sigma_e \int_S \delta(y) \operatorname{div}_y \{c\Phi_e(x, y)\}\, ds(y) \\
&= -\iota\kappa_e \sum_{k=0}^{\infty} \sum_{m=-k}^{k} v_k^m(x) 2\langle R_k^m, \mathbf{M}_e^{-1} g \rangle,
\end{aligned}
$$

where $R_k^m := ([[\operatorname{curl} E_k^m, n], n], (n, E_k^m), \sigma_e \kappa_e^2 [n, E_k^m], \sigma_e \operatorname{div} E_k^m)^T$ and $E_k^m := c u_k^m$.

Since in (2.12) we can especially choose $H^i = E_k^m$ as incident fields, it follows from the analyticity of G^s that G^s vanishes in D_e. Thus W is an eigenfunction of the electric transmission problem and the proof is completed by the second part of Lemma 2.6. □

Denoting with $\mathbf{F}^{e}_{\kappa_e}$ the set of far field patterns corresponding to all entire incident fields under electric transmission conditions we are able to prove the following theorem in an analogous way.

THEOREM 2.8. *If the homogeneous electric transmission problem has only the trivial solution, then we have*:

If κ_e is not an eigenvalue of the magnetic transmission problem, then $\mathbf{F}^{e}_{\kappa_e}$ is dense in $\mathbf{Y}$. If κ_e is an eigenvalue of the magnetic transmission problem, then $\mathbf{F}^{e}_{\kappa_e}$ is dense in $\mathbf{Y}$ if and only if none of the corresponding eigenfunctions is a Herglotz field.

Remark 2.9. Sufficient conditions for Problem TH(m) and Problem TH(e) to have at most one solution are given in [10], [11].

3. Far field patterns in Sobolev spaces. In this section we shall briefly discuss the denseness of far field patterns in Sobolev spaces.

Analogous to Nečas [9] for $r \in (0, 1)$ we define the Sobolev space $\mathbf{Y}^r$ to be the completion of the set of continuous differentiable vector fields defined on the unit sphere with respect to the inner product

$$(v, w)_r := \int_{|\hat{x}|=1} (v(\hat{x}), \overline{w(\hat{x})})\, ds(\hat{x}) + \int_{|\hat{z}|=1} \int_{|\hat{x}|=1} \frac{(v(\hat{x}) - v(\hat{z}), \overline{w(\hat{x})} - \overline{w(\hat{z})})}{|\hat{x} - \hat{z}|^{2r+2}}\, ds(\hat{x})\, ds(\hat{z}).$$

Now, motivated by Lemma 2.6, we generalize Definition 2.5 in the following way.

DEFINITION 3.1. An entire solution W of the vector Helmholtz equation $\Delta W + \kappa^2 W = 0$ is called a *Herglotz field of index r* if there exists a vector field $w \in \mathbf{Y}^r$ such that W has the representation

$$W(x) = \sum_{j=1}^{3} (w, e_j\, e^{-\iota\kappa(x, \cdot)})_r\, e_j, \qquad x \in \mathbb{R}^3,$$

where $e_j, j = 1, 2, 3$, denote the Cartesian unit coordinate vectors.

Using this definition we can state a theorem analogous to Theorem 2.7.

THEOREM 3.2. *If the homogeneous magnetic transmission problem has only the trivial solution, then we have*:

If κ_e is not an eigenvalue of the electric transmission problem, then $\mathbf{F}^{m}_{\kappa_e}$ is dense in $\mathbf{Y}^r$. If κ_e is an eigenvalue of the electric transmission problem, then $\mathbf{F}^{m}_{\kappa_e}$ is dense in $\mathbf{Y}^r$ if and only if none of the corresponding eigenfunctions is a Herglotz field of index r.

Proof. Let $F \in \mathbf{F}^{m}_{\kappa_e}$ be a given far field pattern and H_e the corresponding solution of the magnetic transmission problem in D_e. If W has the representation

$$W(x) = \sum_{j=1}^{3} (\bar{w}, e_j\, e^{\iota\kappa(x, \cdot)})_r\, e_j, \qquad x \in \mathbb{R}^3,$$

for some $w \in \mathbf{Y}^r$, then by interchanging the order of integration we obtain

$$(F, w)_r = \int_S (n, H_e, \operatorname{curl} W)\, ds + \int_S (n, H_e) \operatorname{div} W\, ds - \int_S (n, W, \operatorname{curl} H_e)\, ds - \int_S (n, W) \operatorname{div} H_e\, ds.$$

The rest of the proof is exactly the same as in Theorem 2.7. □

Analogous considerations are possible as well for the electric transmission problem as for arbitrary $r > 0$. Furthermore, using Sobolev's embedding theorems, we are able to consider the denseness of far field patterns in the sets of continuous and Hölder continuous functions, also.

Finally we emphasize that we had not to require the boundary S to be smoother than C^2 throughout this paper.

SOME REMARKS ABOUT THE MORSE LEMMA IN INFINITE DIMENSION*

MICHEL CROUZEIX†, GIUSEPPE GEYMONAT‡, AND GENEVIÈVE RAUGEL§

Abstract. We prove a Morse lemma for functionals that are of class C^2 (in a weak sense) on a Banach space. We also give a splitting lemma for C^2 functionals.

Key words. Morse lemma, splitting lemma, critical point, minima

AMS(MOS) subject classification. 58E05

1. Introduction. In this paper we prove a Morse lemma that, in some ways, improves Golubitsky and Marsden's theorem [5] as well as that of Tromba [12]. Indeed we relax the C^3-regularity condition required in [5] for the functional; under assumptions that are slightly different from those of Golubitsky and Marsden, we show that, when the functional is of class C^1 and admits a gradient which is "generator-differentiable" in the sense of Hugues and Marsden [6], it is equal to its quadratic part up to a homeomorphism, which is "C^1-generator-differentiable" in the sense of [6]. Furthermore we give a "splitting lemma" which is useful in the study of bifurcation problems and is true for C^2 functionals; it also contains a generalization of the "generalized Morse lemma" of Mawhin and Willem [10]. Actually, we have two things in mind here: the first is to complete the papers of Golubitsky and Marsden [5] and of Buchner, Marsden and Schecter [1]; the second is to give results that are applicable to elliptic variational problems (which have only few regularity properties) and also, after some minor modifications, to their approximate (or discrete) versions. In order to easily extend our results to approximate problems, we have used elementary and rough enough tools in our proofs; for instance, *the change of variables in our Morse lemma is given by an explicit formula*, which can be easily adapted to the approximate case. As the generalization to the approximate case is somewhat technical, we shall not give it here. (For the statement and the proof of the approximate splitting lemma, we refer the reader to [11].)

An outline of the paper is as follows. In § 2 we state and prove our generalization of the Morse lemma (see Theorem 2.1) as well as parametrized versions of it; we also give an example of application. Section 3 is devoted to the proof of the splitting lemma; moreover, we describe the relationship of the splitting lemma with the Morse lemma.

2. The Morse lemma.

2.1. Let X be a (real) Banach space equipped with the norm $\|\cdot\|_X$ and let H be a Hilbert space such that X is included in H with a continuous and dense imbedding. We denote by $\langle\cdot,\cdot\rangle$ the inner product of H and by $\|\cdot\|_H$ the associated norm. We identify the space H with its dual space so that we obtain the continuous imbeddings: $X \hookrightarrow H \hookrightarrow X'$. We also introduce a functional f on X as well as a continuous linear operator T from X into X, (which will be the second derivative of f at the point 0).

We assume that T and f satisfy the following hypotheses:

(H.1) T is an isomorphism of X onto X and is a symmetric operator with respect

to the inner product $\langle \cdot, \cdot \rangle$, i.e.,

$$\forall x \in X \quad \forall y \in X \quad \langle Tx, y \rangle = \langle x, Ty \rangle; \tag{2.1}$$

(H.2) there exists a neighbourhood $\mathcal{V}$ of 0 in X such that $f \in C^1(\mathcal{V}; \mathbb{R})$ and

$$f(0) = 0, \qquad Df(0) = 0; \tag{2.2}$$

(H.3) $Df(x) \in C^0(\mathcal{V}; H)$ and converges to Tx in the following way:

$$\forall x \in \mathcal{V} \quad \|Df(x) - Tx\|_H = \|x\|_H \varepsilon_1(x), \tag{2.3}$$

where

$$\lim_{\|x\|_X \to 0} \varepsilon_1(x) = 0. \tag{2.4}$$

(In order to simplify our notation, we set $\varepsilon_1(0) = 0$.)

The assumption (H.3) actually means that f admits a gradient relative to $\langle \cdot, \cdot \rangle$ that takes its values in H and is generator-differentiable at 0 in the sense of Hugues and Marsden [6]. Let us recall that a mapping F from an open set $\mathcal{U}$ in X into H is "generator-differentiable" if, for any x in $\mathcal{U}$, there exists a continuous linear operator $DF(x)$ from X into H such that

$$\frac{\|F(x+h) - F(x) - DF(x) \cdot h\|_H}{\|h\|_H} \to 0 \quad \text{as } \|h\|_X \to 0.$$

If X and Y are two normed vector spaces, let us denote by $\mathcal{L}(X; Y)$ the space of all continuous linear operators from X into Y and by $\mathcal{L}(X)$ the space $\mathcal{L}(X; X)$.

Now we may state the following main result.

THEOREM 2.1. *Assume that the hypothesis* (H.1) *is satisfied. Then the assumptions* (H.2) *and* (H.3) *hold if and only if there exists a homeomorphism* Φ *of a neighbourhood* $\tilde{\mathcal{V}}$ *of* 0 *in* X *onto a neighbourhood* $\mathcal{W}$ *of* 0 *in* X *satisfying*:

$$\forall x \in \tilde{\mathcal{V}} \quad f(x) = \tfrac{1}{2}\langle T\Phi(x), \Phi(x) \rangle, \tag{2.5}$$

$$\Phi \in C^0(\tilde{\mathcal{V}}; X) \cap C^1(\tilde{\mathcal{V}} - \{0\}; X), \tag{2.6}$$

$$\Phi(0) = 0, \qquad D\Phi(0) = Id_H, \tag{2.7}$$

$$D\Phi \in C^0(\tilde{\mathcal{V}}; \mathcal{L}(H)). \tag{2.8}$$

In Remark 2.3, we shall show that, if the assumptions (H.2) and (H.3) hold, the homeomorphism Φ obtained above is actually C^1-generator-differentiable (let us recall that a mapping F from an open set $\mathcal{U}$ into H is C^1-generator-differentiable if it is generator-differentiable and $DF(x)$ belongs to $C^0(\mathcal{U}; \mathcal{L}(X; H))$).

Theorem 2.1 together with the implicit function theorem give us the following corollary, at once.

COROLLARY 2.2. *Assume that the hypothesis* (H.1) *is true and that* $X = H$. *Then the assumptions* (H.2) *and* (H.3) *hold if and only if there exists a* C^1*-diffeomorphism* Φ *of a neighbourhood* $\tilde{\mathcal{V}}$ *of* 0 *in* X *onto a neighbourhood* $\mathcal{W}$ *of* 0 *in* X *satisfying the properties* (2.5) *and* (2.7).

Let us point out that the mapping Φ, given in Theorem 2.1, is not the same as that of Golubitsky and Marsden.

Now let us replace the hypothesis (H.3) by the following hypothesis:

(H.3 bis) $Df(x) \in C^0(\mathcal{V}; H)$ and converges to Tx in the following way:

(2.3 bis) $$\forall x \in \mathcal{V} \quad \begin{cases} |f(x) - \frac{1}{2}\langle Tx, x\rangle| = \|x\|_H^3 \eta_2(x), \\ \|Df(x) - Tx\|_{X'} = \|x\|_H^2 \varepsilon_2(x), \end{cases}$$

where

(2.4 bis) $$\forall x \in \mathcal{V} \quad \eta_2(x) + \varepsilon_2(x) \leqq C,$$

C being a positive constant.

THEOREM 2.3. *Assume that the hypotheses* (H.1), (H.2) *and* (H.3 bis) *hold. Then there exists a* C^1*-diffeomorphism* Φ *of a neighbourhood* $\tilde{\mathcal{V}}$ *of* 0 *in* X *onto a neighbourhood* $\mathcal{W}$ *of* 0 *in* X *such that* (2.5) *and* (2.7) *are satisfied.*

Let us make a few remarks before proving Theorem 2.1 and Theorem 2.3.

Remark 2.1. Let us recall that Golubitsky and Marsden [5] proved that, if the assumptions

(A.1) there exists a neighbourhood $\mathcal{V}$ of 0 in X such that $f \in C^3(\mathcal{V}; \mathbb{R})$ and f admits a gradient ∇f relative to $\langle \cdot, \cdot \rangle$ that belongs to $C^2(\mathcal{V}; X)$, i.e.,

(2.9) $$\forall x \in \mathcal{V} \quad \forall x' \in X \quad Df(x)x' = \langle \nabla f(x), x' \rangle \quad \text{with } \nabla f \in C^2(\mathcal{V}; X)$$

and

(A.2) $f(0) = 0$, $Df(0) = 0$, $D^2 f(0) = T$, where T is an isomorphism of X onto X,

hold, there exists a C^1-diffeomorphism ψ of a neighbourhood N of 0 in X onto a neighbourhood M of 0 in X, satisfying:

(2.10) $$\forall x \in N \quad f(x) = \tfrac{1}{2}\langle T\psi(x), \psi(x)\rangle.$$

The conditions required for the existence of a homeomorphism Φ of a neighbourhood $\tilde{\mathcal{V}}$ of 0 in X onto a neighbourhood $\mathcal{W}$ of 0 in X satisfying (2.5) and (2.7) are weaker than the conditions (A.1) and (A.2); in particular, we need C^2-regularity assumptions at most. Indeed, using Lemma 2.4 below, the reader will at once see that the hypotheses (H.1)-(H.3) are satisfied if the assumption (A.2) holds and if f and Df belong to $C^2(\mathcal{V}; \mathbb{R})$ and $C^1(\mathcal{V}; X)$, respectively.

As stated in Theorem 2.3, the homeomorphism Φ becomes a C^1-diffeomorphism when we replace the hypothesis (H.3) by the hypothesis (H.3 bis). Note that the condition (H.3 bis) is a kind of three times differentiability assumption at 0. But the assumptions (A.1) and (A.2) are neither weaker, nor stronger than the conditions (H.1), (H.2) and (H.3 bis). For instance, if $X = C^0([0, 1])$, $H = L^2(0, 1)$ (provided with its usual inner product) and $f(x) = \int_0^1 [(x(t))^2 + (x(t))^3]\, dt$, the assumptions (A.1) and (A.2) are clearly satisfied, while the condition (H.3 bis) fails; conversely, if we keep the same spaces X and H and if $f(x) = \int_0^1 (x(t))^2\, dt + [\int_0^1 g(t)x(t)\, dt]^3$, where $g \in L^2(0, 1)$, but $g \notin C^0([0, 1])$, the conditions (H.1), (H.2) and (H.3 bis) hold, but (A.1) is not satisfied.

Finally, let us remark that the hypothesis (H.3 bis) holds if, for instance,

(2.11) $$\|Df(x) - Tx\|_H = \|x\|_H^2 \tilde{\varepsilon}_2(x),$$

where, for any x in $\mathcal{V}$, $\tilde{\varepsilon}_2(x) \leqq C$.

Now let us state an auxiliary result which will be useful in the proof of Theorem 2.1.

LEMMA 2.4. *If A is a continuous linear operator from X into X and satisfies*

$$\forall x \in X \quad \forall y \in X \quad \langle Ax, y\rangle = \langle Ay, x\rangle, \tag{2.12}$$

it extends into a continuous linear operator from H into H, still denoted by A, and the inequalities

$$\|A\|_{\mathscr{L}(H)} \leqq \rho_X(A) \leqq \|A\|_{\mathscr{L}(X)}, \tag{2.13}$$

hold, where $\rho_X(A)$ is the spectral radius of A considered as an operator from X into X.

The proof of Lemma 2.4 can be found in [4, Vol. I, p. 346] or in [8], for instance.

Remark 2.2. Lemma 2.4 implies in particular that, if T is an isomorphism of X onto X, it can be extended into an isomorphism of H onto H.

Proof of Theorem 2.1. (1) Assume that there exists a homeomorphism Φ of $\tilde{\mathscr{V}}$ onto $\mathscr{W}$ satisfying (2.5)–(2.8), and that (H.1) holds. Without any loss of generality we may assume that $\tilde{\mathscr{V}}$ is path-connected. Using the properties (2.6) to (2.8) together with a Taylor formula, we at once show that

$$\forall x \in \tilde{\mathscr{V}} \quad \|\Phi(x)\|_H \leqq C\|x\|_H, \tag{2.14}$$

where $C > 0$ is a constant independent of h, and that,

$$\forall x \in \tilde{\mathscr{V}} \quad \|\Phi(x) - x\|_H = \|x\|_H \varepsilon_3(x), \tag{2.15}$$

where

$$\lim_{\|x\|_X \to 0} \varepsilon_3(x) = 0. \tag{2.16}$$

Owing to the property (2.5), we may write

$$Df(x) = (D\Phi(x))^t T\Phi(x), \tag{2.17}$$

which implies, due to (2.8), that $f \in C^1(\tilde{\mathscr{V}}; \mathbb{R})$ and $Df \in C^0(\tilde{\mathscr{V}}; H)$. From (2.17) we also derive:

$$Df(x) - Tx = (D\Phi(x) - Id_H)^t T\Phi(x) + T(\Phi(x) - x). \tag{2.18}$$

Equality (2.18) together with the properties (2.8), (2.15) and (2.16) give us the conditions (2.3) and (2.4).

(2) Now assume that the hypotheses (H.1) to (H.3) hold. First of all, let us remark that, thanks to the hypothesis (H.3), we have:

$$\begin{aligned} |f(x) - \tfrac{1}{2}\langle Tx, x\rangle| &= \left| \int_0^1 \langle Df(sx) - T(sx), x\rangle \, ds \right| \\ &\leqq \|x\|_H^2 \int_0^1 s\varepsilon_1(sx) \, ds, \end{aligned}$$

or

$$|f(x) - \tfrac{1}{2}\langle Tx, x\rangle| \leqq \|x\|_H^2 \varepsilon_4(x) \tag{2.19}$$

where

$$\lim_{\|x\|_X \to 0} \varepsilon_4(x) = 0 \quad \text{and} \quad \varepsilon_4(0) = 0. \tag{2.20}$$

As by Lemma 2.4 and the hypothesis (H.1) (see Remark 2.2), T^{-1} belongs to $\mathscr{L}(H)$, we infer from (2.19) and (2.20) that there exists a (convex) neighbourhood V of 0 in X such that

$$\forall x \in V \quad |(2f(x) - \langle Tx, x\rangle)\langle T^{-1}x, x\rangle| \leqq \tfrac{1}{2}\|x\|_H^4, \tag{2.21}$$

which allows us to define the function α in $C^0(V;\mathbb{R})\cap C^1(V-\{0\};\mathbb{R})$ by

$$\alpha(x)=\frac{2f(x)-\langle Tx,x\rangle}{\sqrt{\|x\|_H^4+(2f(x)-\langle Tx,x\rangle)\langle T^{-1}x,x\rangle}+\|x\|_H^2}\quad\text{for } x\neq 0,$$
$$\alpha(0)=0. \tag{2.22}$$

Indeed, by (2.19) to (2.21), we get

$$\forall x\in V\quad |\alpha(x)|\leqq 2\varepsilon_4(x). \tag{2.23}$$

Furthermore, the function α satisfies, for all x in V,

$$2\alpha(x)\|x\|_H^2+\alpha(x)^2\langle T^{-1}x,x\rangle=2f(x)-\langle Tx,x\rangle, \tag{2.24}$$

so that we obtain,

$$\forall x\in V\quad f(x)=\tfrac{1}{2}\langle T\Phi(x),\Phi(x)\rangle, \tag{2.25}$$

where

$$\Phi(x)=x+\alpha(x)T^{-1}x. \tag{2.26}$$

(Let us point out that the mapping Φ is given by an explicit formula.)

Clearly the properties (2.6) and (2.7) are satisfied. We also have for $x\neq 0$ in V,

$$D\Phi(x)=Id+\alpha(x)T^{-1}+\langle D\alpha(x),\cdot\rangle T^{-1}x, \tag{2.27}$$

where, thanks to a differentiation of (2.24) with respect to x, $D\alpha(x)$ may be written as

$$D\alpha(x)=\frac{1}{\|x\|_H^2+\alpha(x)\langle T^{-1}x,x\rangle}(Df(x)-Tx-2\alpha(x)x-\alpha(x)^2T^{-1}x). \tag{2.28}$$

Therefore $D\alpha$ is in the space $C^0(V-\{0\};H)$ and $D\Phi$ obviously belongs to $C^0(V-\{0\};\mathscr{L}(H))$. Moreover, from the equality (2.27), we deduce that, for $x\neq 0$ in V,

$$\|D\Phi(x)-Id\|_{\mathscr{L}(H)}\leqq|\alpha(x)|\,\|T^{-1}\|_{\mathscr{L}(H)}+\|D\alpha(x)\|_H\,\|T^{-1}x\|_H. \tag{2.29}$$

Using (2.28) together with the hypothesis (H.3) and the property (2.23), we at once prove that, for $x\neq 0$ in V,

$$\|D\alpha(x)\|_H\,\|T^{-1}x\|_H\leqq C\|T^{-1}\|_{\mathscr{L}(H)}(\varepsilon_1(x)+\varepsilon_4(x)). \tag{2.30}$$

Finally from (2.29) and (2.30), we derive that $\|D\Phi(x)-Id\|_{\mathscr{L}(H)}$ tends to 0 as $\|x\|_X$ tends to 0, and the property (2.8) holds.

Now it remains to prove that Φ is a homeomorphism of a neighbourhood $\tilde{\mathscr{V}}$ of 0 in X onto a neighbourhood $\mathscr{W}$ of 0 in X. Let $\eta_0>0$ be a real number such that

$$\{x\in X;\ \|x\|_X<\eta_0\}\subset V, \tag{2.31}$$

and that we have, for $\|x\|_X<\eta_0$,

$$|\alpha(x)|\,\|T^{-1}\|_{\mathscr{L}(X)}<\tfrac{1}{2} \tag{2.32}$$

and

$$\|D\Phi(x)-Id\|_{\mathscr{L}(H)}<\tfrac{1}{2}. \tag{2.33}$$

We set

$$\tilde{\mathscr{V}}=\{x\in X;\ \|x\|_X<\eta_0\}\quad\text{and}\quad\mathscr{W}=\Phi(\tilde{\mathscr{V}}).$$

As

$$x-y=\Phi(x)-\Phi(y)-(\Phi(x)-\Phi(y)-(x-y)),$$

by (2.33), we obtain, for x and y in $\tilde{\mathcal{V}}$,

$$\|x-y\|_H \leqq 2\|\Phi(x)-\Phi(y)\|_H, \tag{2.34}$$

which proves that Φ is a one-to-one mapping from $\tilde{\mathcal{V}}$ onto $\mathcal{W}$. Let us now show that Φ^{-1} is a continuous mapping from $\mathcal{W}$ into $\tilde{\mathcal{V}}$. From the equation,

$$(\alpha(x)-\alpha(y))T^{-1}x=\Phi(x)-\Phi(y)-(Id_X+\alpha(y)T^{-1})(x-y),$$

we deduce, using the property (2.32) and the inequality (2.13) of Lemma 2.4, that

$$|\alpha(x)-\alpha(y)|\,\|T^{-1}x\|_H \leqq \|\Phi(x)-\Phi(y)\|_H+\tfrac{3}{2}\|x-y\|_H,$$

which becomes, owing to (2.34),

$$|\alpha(x)-\alpha(y)|\,\|T^{-1}x\|_H \leqq 4\|\Phi(x)-\Phi(y)\|_H. \tag{2.35}$$

But $x-y$ can be written as

$$x-y=\Phi(x)-\Phi(y)-\alpha(y)T^{-1}(x-y)-(\alpha(x)-\alpha(y))T^{-1}x,$$

so that, by (2.32),

$$\|x-y\|_X \leqq \|\Phi(x)-\Phi(y)\|_X+\tfrac{1}{2}\|x-y\|_X+|\alpha(x)-\alpha(y)|\,\|T^{-1}x\|_X. \tag{2.36}$$

From (2.35) and (2.36) we infer, for $x\neq 0$,

$$\|x-y\|_X \leqq 2\|\Phi(x)-\Phi(y)\|_X+8\frac{\|T^{-1}x\|_X}{\|T^{-1}x\|_H}\|\Phi(x)-\Phi(y)\|_X,$$

or

$$\|x-y\|_X \leqq C(x)\|\Phi(x)-\Phi(y)\|_X. \tag{2.37}$$

Inequality (2.37) proves that the mapping Φ^{-1} is continuous from X into X at the point $\Phi(x)$, for $x\neq 0$. But

$$y=\Phi(y)-\alpha(y)T^{-1}y,$$

so that, by using the property (2.32) again, we obtain

$$\|y\|_X \leqq 2\|\Phi(y)\|_X,$$

which proves that Φ^{-1} is continuous at the point 0.

Now we have shown that Φ is a homeomorphism of $\tilde{\mathcal{V}}$ onto $\mathcal{W}$; it remains to prove that $\mathcal{W}$ is a neighbourhood of 0 in X. To this end we are going to check that $\mathcal{W}\supset\frac{1}{2}\tilde{\mathcal{V}}$.

Let $y\neq 0$ be an element of X such that $\|y\|_X<\frac{1}{2}\eta_0$. We introduce the sequence $(x_n)_n$ defined by

$$\begin{aligned} &\text{(a)}\quad x_0=y,\\ &\text{(b)}\quad x_{n+1}=y-\alpha(x_n)T^{-1}x_n\equiv y-(\Phi(x_n)-x_n). \end{aligned} \tag{2.38}$$

Obviously x_n belongs to X, for all n; using the property (2.32), one also proves, by induction on n, that x_n belongs to $\tilde{\mathcal{V}}$, for all n. The relation (2.38)(b) implies, thanks to the property (2.33),

$$\|x_{n+1}-x_n\|_H<\tfrac{1}{2}\|x_n-x_{n-1}\|_H. \tag{2.39}$$

Therefore, we get, for all $n\in\mathbb{N}$,

$$\|x_{n+1}-x_n\|_H<\frac{1}{2^n}\|y\|_H. \tag{2.40}$$

From (2.40) it follows that $(x_n)_n$ is a Cauchy sequence in H. Hence, $(x_n)_n$ converges in the space H to an element $x \in H$. By (2.32), we have

$$\|y\|_H \leqq \|x_{n+1}\|_H + \tfrac{1}{2}\|x_n\|_H,$$

and also

$$\|x\|_H \geqq \tfrac{2}{3}\|y\|_H, \tag{2.41}$$

which means that $x \neq 0$. Furthermore, using the following equality

$$-(\alpha(x_{n+1}) - \alpha(x_n))T^{-1}x_n = (x_{n+2} - x_{n+1}) + \alpha(x_{n+1})T^{-1}(x_{n+1} - x_n), \tag{2.42}$$

as well as the properties (2.32) and (2.40), we obtain

$$|\alpha(x_{n+1}) - \alpha(x_n)|\,\|T^{-1}x_n\|_H \leqq \frac{1}{2^n}\|y\|_H.$$

Therefore, as x is not equal to zero, we get, thanks to Lemma 2.4,

$$|\alpha(x_{n+1}) - \alpha(x_n)| \leqq \frac{C(x)}{2^n}\|y\|_H, \tag{2.43}$$

where $C(x)$ is a positive constant (depending on x). From the equality

$$x_{n+1} - x_n = \alpha(x_n)T^{-1}(x_{n-1} - x_n) - (\alpha(x_n) - \alpha(x_{n-1}))T^{-1}x_{n-1}$$

we derive, thanks to the properties (2.32) and (2.43), that

$$\|x_{n+1} - x_n\|_X \leqq \frac{1}{2}\|x_n - x_{n-1}\|_X + \frac{C^*(x)}{2^n}, \tag{2.44}$$

where $C^*(x) > 0$ is a constant (depending on x). Therefore, we obtain, for all $n \in \mathbb{N}$,

$$\|x_{n+1} - x_n\|_X \leqq \frac{1}{2^n}\|x_1 - y\|_X + \frac{nC^*(x)}{2^n}, \tag{2.45}$$

which proves that $(x_n)_n$ is a Cauchy sequence in X. Therefore x belongs to $\tilde{V}$ and the relation (2.38)(b) gives us:

$$x = y - \alpha(x)T^{-1}x,$$

i.e.,

$$y = \Phi(x).$$

Proof of the Theorem 2.3. Part (2) in the proof of Theorem 2.1 may be followed up to (2.28); according to the implicit function theorem, we have only to prove that Φ belongs to $C^1(V; X)$ and even that $\|D\Phi(x) - Id_X\|_{\mathcal{L}(X)}$ tends to 0 as $\|x\|_X$ tends to 0.

Taking into account the equality (2.27), we get:

$$\|D\Phi(x) - Id\|_{\mathcal{L}(X)} \leqq |\alpha(x)|\,\|T^{-1}\|_{\mathcal{L}(X)} + \|D\alpha(x)\|_{X'}\|T^{-1}x\|_X. \tag{2.46}$$

Using (2.28) together with the hypothesis (H.3 bis), we at once prove that, for $x \neq 0$ in V,

$$\|D\alpha(x)\|_{X'} \leqq C(|\varepsilon_2(x)| + |\eta_2(x)|), \tag{2.47}$$

where $C > 0$ is a constant independent of x. From (2.46) and (2.47) it immediately follows that $\|D\Phi(x) - Id\|_{\mathcal{L}(X)}$ tends to 0 as $\|x\|_X$ tends to 0.

Remark 2.3. Let us recall that a mapping F from an open set $\mathcal{U}$ in X into H is "generator-differentiable" if, for any x in $\mathcal{U}$, there exists a continuous linear operator $DF(x)$ from X into H such that

$$\frac{\|F(x+h)-F(x)-DF(x)\cdot h\|_H}{\|h\|_H}\to 0 \quad \text{as } \|h\|_X\to 0. \tag{2.48}$$

F is said to be "C^1-generator-differentiable" if, moreover, $DF(x)$ belongs to $C^0(\mathcal{U};\mathcal{L}(X;H))$. J. Marsden has asked one of the authors if the homeomorphism Φ constructed in Theorem 2.1 is C^1-generator-differentiable. The answer is positive. As we have already proved that $D\Phi(x)$ belongs to $C^0(\mathcal{V};\mathcal{L}(H))$, it remains only to show that (2.48) holds for $F=\Phi$. But

$$\begin{aligned}\Phi(x+h)-\Phi(x)-D\Phi(x)h &= \alpha(x+h)T^{-1}h\\ &\quad+(\alpha(x+h)-\alpha(x)-\langle D\alpha(x),h\rangle)T^{-1}x,\end{aligned} \tag{2.49}$$

which implies, at the point $x\neq 0$, that

$$\begin{aligned}&\frac{\|\Phi(x+h)-\Phi(x)-D\Phi(x)h\|_H}{\|h\|_H}\\ &\leqq|\alpha(x+h)|\,\|T^{-1}\|_{\mathcal{L}(H)}+\frac{\left|\int_0^1\langle D\alpha(x+sh)-D\alpha(x),h\rangle\,ds\right|}{\|h\|_H}\end{aligned} \tag{2.50}$$

and also, because $D\alpha$ belongs to $C^0(V-\{0\},H)$, that

$$\begin{aligned}&\frac{\|\Phi(x+h)-\Phi(x)-D\Phi(x)h\|_H}{\|h\|_H}\\ &\leqq|\alpha(x+h)|\,\|T^{-1}\|_{\mathcal{L}(H)}+\sup_{0\leqq s\leqq 1}\|D\alpha(x+sh)-D\alpha(x)\|_H.\end{aligned} \tag{2.51}$$

From (2.51), we at once infer that (2.48) holds for $x\neq 0$. At the point $x=0$, (2.49) gives us:

$$\frac{1}{\|h\|_H}\|\Phi(h)-D\Phi(0)h\|_H\leqq|\alpha(h)|\,\|T^{-1}\|_{\mathcal{L}(H)},$$

and (2.48) still holds.

Remark 2.4. Assume that f and the inner product $\langle\cdot,\cdot\rangle$ are invariant with respect to the group representation $R:\Gamma\to GL(X)$, where Γ is a group. Then it is an easy matter to prove that the homeomorphism Φ is equivariant with respect to the representation R.

2.2. Let us now turn to parametrized versions of the second part of Theorem 2.1. Let $f(x,\lambda)$ be a functional defined on $X\times\Lambda$ where Λ is a Banach space. Assume that f satisfies the following hypotheses:

(B.1) There exist two neighbourhoods $\mathcal{V}_1$ of 0 in X and $\mathcal{V}_2$ of 0 in Λ such that $f\in C^1(\mathcal{V}_1\times\mathcal{V}_2;\mathbb{R})$ and $D_xf\in C^0(\mathcal{V}_1\times\mathcal{V}_2;H)$; furthermore $f(0,\lambda)=0$ and $D_xf(0,\lambda)=0$;

(B.2) There exists a continuous mapping $\lambda\to T_\lambda$ of $\mathcal{V}_2$ into $\mathcal{L}(H)$; moreover, $\forall\lambda\in\mathcal{V}_2$, T_λ is a symmetric operator (with respect to the inner product $\langle\cdot,\cdot\rangle$ of H) and, for $\lambda=0$, $T\equiv T_0$ is an isomorphism of X onto X;

(B.3) For all (x,λ) in $\mathcal{V}_1\times\mathcal{V}_2$, one has

$$\|D_xf(x,\lambda)-T_\lambda x\|_H\leqq\|x\|_H\varepsilon_1(x), \tag{2.52}$$

where

$$\lim_{\|x\|_X \to 0} \varepsilon_1(x) = 0.$$

PROPOSITION 2.5. *Assume that the hypotheses* (B.1), (B.2) and (B.3) *hold. Then there exists a homeomorphism* $\Psi(x, \lambda) = (\varphi(x, \lambda), \lambda)$ *of a neighbourhood* $\mathcal{V}$ *of* $(0, 0)$ *in* $X \times \Lambda$ *onto a neighbourhood* $\mathcal{W}$ *of* $(0, 0)$ *in* $X \times \Lambda$ *satisfying*

$$\forall (x, \lambda) \in \mathcal{V} \quad f(x, \lambda) = \tfrac{1}{2}\langle T_\lambda \varphi(x, \lambda), \varphi(x, \lambda)\rangle, \tag{2.53}$$

$$\varphi(0, \lambda) = 0, \qquad D_x\varphi(0, \lambda) = Id_H, \tag{2.54}$$

$$D_x\varphi \in C^0(\mathcal{V}; \mathcal{L}(H)). \tag{2.55}$$

Proof. Here we introduce the function $\alpha(x, \lambda)$ given by:

$$\alpha(0, \lambda) = 0 \quad \text{and, for } x \neq 0,$$

$$\alpha(x, \lambda) = \frac{2f(x, \lambda) - \langle T_\lambda x, x\rangle}{\sqrt{\langle T_\lambda T^{-1}x, x\rangle^2 + (2f(x, \lambda) - \langle T_\lambda x, x\rangle)\langle T_\lambda T^{-1}x, T^{-1}x\rangle} + \langle T_\lambda T^{-1}x, x\rangle} \tag{2.56}$$

and we set

$$\varphi(x, \lambda) = x + \alpha(x, \lambda) T^{-1}x. \tag{2.57}$$

Then, arguing as in the proof of Theorem 2.1, we show that $\Psi(x, \lambda)$ is a homeomorphism of $\mathcal{V}$ onto $\mathcal{W}$ and satisfies (2.53), (2.54) and (2.55). (The only difference is that here one has to check that $\Psi(x, \lambda)$ and $\Psi^{-1}(x, \lambda)$ are continuous mappings in λ; but this does not involve any difficulty.) □

Let $\tilde{\mathcal{V}}_1$ and $\tilde{\mathcal{V}}_2$ be two neighbourhoods of 0 in X and Λ, respectively, such that $\tilde{\mathcal{V}}_1 \times \tilde{\mathcal{V}}_2 \subset \mathcal{V}$; one can prove as in Remark 2.3 that, for $\lambda \in \tilde{\mathcal{V}}_2$, $\varphi(\cdot, \lambda)$: $x \in \tilde{\mathcal{V}}_1 \mapsto \varphi(x, \lambda)$ is C^1-generator differentiable.

From Proposition 2.5 one deduces at once the following result.

THEOREM 2.6. *Assume that the hypotheses* (B1), (B2) *and* (B3) *hold*; *assume furthermore that* $T_\lambda \in C^0(\mathcal{V}_2; \mathcal{L}(X))$. *Then there exists a homeomorphism* $\Psi^*(x, \lambda) = (\varphi^*(x, \lambda), \lambda)$ *of a neighbourhood* $\mathcal{V}^*$ *of* $(0, 0)$ *in* $X \times \Lambda$ *onto a neighbourhood* $\mathcal{W}^*$ *of* $(0, 0)$ *in* $X \times \Lambda$ *satisfying*:

$$\forall (x, \lambda) \in \mathcal{V}^* \quad f(x, \lambda) = \tfrac{1}{2}\langle T\varphi^*(x, \lambda), \varphi^*(x, \lambda)\rangle; \tag{2.58}$$

$$\varphi^*(0, \lambda) = 0, \qquad D_x\varphi^*(0, 0) = Id_X, \tag{2.59}$$

and

$$D_x\varphi^* \in C^0(\mathcal{V}^*; \mathcal{L}(H)). \tag{2.60}$$

Proof. The operator T_λ can be written as

$$T_\lambda = T(Id + T^{-1}(T_\lambda - T)).$$

There exists a neighbourhood $\mathcal{N}_2$ of 0 in Λ such that, for $\lambda \in \mathcal{N}_2$,

$$\|T^{-1}(T_\lambda - T)\|_{\mathcal{L}(X)} \leqq \tfrac{1}{2} \quad \text{and} \quad \|T^{-1}(T_\lambda - T)\|_{\mathcal{L}(H)} \leqq \tfrac{1}{2}.$$

Then we introduce the operator:

$$L_\lambda = Id + \sum_{k=1}^{\infty} c_k (T^{-1}(T_\lambda - T))^k, \tag{2.61}$$

where the real numbers c_k, $1 \leqq k \leqq \infty$, are defined by

$$(1 + x)^{1/2} = 1 + c_1 x + \cdots + c_k x^k + \cdots \quad \text{for } |x| < 1.$$

For λ in $\mathcal{N}_2$, L_λ is well defined by (2.61) and is an isomorphism of X onto X and of H onto H. Moreover, L_λ and $(L_\lambda)^{-1}$ belong to $C^0(\mathcal{N}_2; \mathcal{L}(X) \cap \mathcal{L}(H))$. One easily checks that

$$T_\lambda = L_\lambda^t T L_\lambda. \tag{2.62}$$

The mapping φ^* defined by

$$\varphi^*(x, \lambda) = L_\lambda \varphi(x, \lambda), \tag{2.63}$$

where φ is given by Proposition 2.5, clearly satisfies the requirements of Theorem 2.6. □

2.3. *Example.* We consider the functional

$$f(u, \lambda) = \int_\Omega a(\partial_0 u(x), \partial_1 u(x), \partial_2 u(x), x, \lambda)\, dx, \tag{2.64}$$

where Ω is a bounded open subset of $\mathbb{R}^2$ with a smooth enough boundary, $x = (x_1, x_2)$ is a generic point in $\mathbb{R}^2$, λ is a real parameter and where $\partial_0 u = u$, $\partial_i u = \partial u / \partial x_i$, for $i = 1, 2$. We assume that the function a belongs to the space $C^2(\mathbb{R}^6; \mathbb{R})$ and can be written as

$$a(u_0, u_1, u_2, x, \lambda) = \sum_{i,j=0}^{2} a_{ij}(u_0, u_1, u_2, x, \lambda) u_i u_j$$

where $a_{ij} \in C^0(\mathbb{R}^6; \mathbb{R})$ and $a_{ij} = a_{ji}$, for $i \neq j$. The above equality means that the function a and its first partial derivatives (with respect to u_0, u_1 and u_2) vanish at the points $(0, 0, 0, x, \lambda) \equiv (0, x, \lambda)$. We suppose that there exists a real number $\alpha > 0$ such that

$$\forall \xi \in \mathbb{R}^2 \quad \sum_{i,j=0}^{2} a_{ij}(0, x, 0) \xi_i \xi_j \geqq 2\alpha \sum_{i=1}^{2} \xi_i^2 \tag{2.65}$$

and that

$$\left.\begin{array}{l} u \in H_0^1(\Omega) \quad \text{and} \quad \forall v \in H_0^1(\Omega) \\ \displaystyle\int_\Omega \sum_{i,j=0}^{2} a_{ij}(0, x, 0) \partial_i u \partial_j v\, dx = 0 \end{array}\right\} \Rightarrow u = 0. \tag{2.66}$$

We set $X = H_0^1(\Omega) \cap W^{1,\infty}(\Omega)$, $H = H_0^1(\Omega)$, $\Lambda = \mathbb{R}$. We now introduce the following inner product on H:

$$\langle u, v \rangle = 2 \int_\Omega \sum_{i,j=0}^{2} a_{ij}(0, x, 0) \partial_i u \partial_j v\, dx + \beta \int_\Omega uv\, dx, \tag{2.67}$$

where $\beta > 0$ is a real number such that, for all v in $H_0^1(\Omega)$,

$$\langle v, v \rangle \geqq \alpha \int_\Omega \sum_{i=0}^{2} (\partial_i v)^2\, dx.$$

The assumption (2.65) insures the existence of such a number β. We are now able to formulate our last assumption; we suppose that the operator $G \in \mathcal{L}(H)$ given by

$$\left.\begin{array}{l} Gu \in H_0^1(\Omega) \quad \text{and} \quad \forall v \in H_0^1(\Omega), \\ \langle Gu, v \rangle = \displaystyle\int_\Omega uv\, dx, \end{array}\right. \tag{2.68}$$

is a compact operator of $\mathcal{L}(X)$. (This property is true in particular if the coefficients $a_{ij}(0, x, 0)$ belong to the Hölder space $C^\delta(\Omega)$ for $0 < \delta \leqq 1$.) Let us verify that the above

functional f satisfies the hypotheses (B.1), (B.2) and (B.3). It is clear that f belongs to $C^2(X\times\Lambda;\mathbb{R})$. We introduce the linear operators T_λ defined by

$$T_\lambda u\in H_0^1(\Omega) \quad \text{and, for all } v \text{ in } H_0^1(\Omega),$$

$$\langle T_\lambda u, v\rangle = 2\int_\Omega \sum_{i,j=0}^{2} a_{ij}(0,x,\lambda)\partial_i u\partial_j v\,dx.$$

It is not difficult to prove that the property (B.1) is satisfied, T_λ belongs to $C^0(\mathbb{R};\mathscr{L}(H))$ and (B.3) holds. In order to prove (B.2), it remains to prove that $T\equiv T_0\in\mathscr{L}(X)$ and is an isomorphism of X onto X. We remark that $T=Id-\beta G$. As G is a compact operator of $\mathscr{L}(X)$, the assumption (2.66) implies that T is an isomorphism of X onto X. Thus the hypotheses (B.1), (B.2) and (B.3) are satisfied and the Proposition 2.5 applies.

3. The splitting lemma.

3.1. Now we give the splitting lemma which allows us to replace infinite-dimensional problems by finite-dimensional ones. In particular, it allows us to reduce the study of the minima of a C^2 functional defined on a infinite-dimensional Banach space to the study of the minima of a functional defined on a finite-dimensional space. But, contrary to Magnus [9] and to Golubitsky and Marsden [5], we need not use the Morse lemma in our proofs. However, at the end of the section we shall show how to use our Morse lemma (Theorem 2.6) in the proof.

We keep the notation of § 2. Let $f(x,\lambda)$ be a functional defined on $X\times\Lambda$ where Λ is a Banach space. Assume that the following properties hold:

(h.1) $\quad f\in C^p(X\times\Lambda;\mathbb{R})$ and $D_x f\in C^p(X\times\Lambda;X)$ with $p\geqq 1$,

(h.2) $\quad D_x f(0,0)=0$,

and

(h.3) there exist two closed subspaces Z and V of X satisfying

(3.1) $\quad X=Z\oplus V$, where V and Z are orthogonal with respect to the inner product $\langle\cdot,\cdot\rangle$,

and the restriction $\tilde{T}$ of $T\equiv D_{xx}^2 f(0,0)$ to Z is an isomorphism of Z onto Z.

Remark 3.1. The condition (3.1) holds, for instance, if T is a Fredholm operator from X into X of index 0 (with $V=\operatorname{Ker} T$ and $Z=\operatorname{Im} T$).

Let F be the C^p mapping from $Z\times V\times\Lambda$ into Z defined by

$$F(z;v,\lambda)=P_Z D_x f(z+v,\lambda), \tag{3.2}$$

where P_Z denotes the linear projector from X onto Z corresponding to the decomposition $X=Z\oplus V$. We remark that $F(0;0,0)=0$ and that $D_z F(0;0,0)=\tilde{T}$ is an isomorphism of Z onto Z; therefore, by applying the implicit function theorem, we obtain the following result.

LEMMA 3.1. *There exist three neighbourhoods $\mathscr{Z}$, $\mathscr{V}$ and $\mathscr{L}$ of 0 in Z, V and Λ, respectively, and, for any $(v,\lambda)\in\mathscr{V}\times\mathscr{L}$, a unique element $H(v,\lambda)\in\mathscr{Z}$ such that*

$$P_Z D_x f(H(v,\lambda)+v,\lambda)=0. \tag{3.3}$$

Moreover the mapping H belongs to $C^p(\mathscr{V}\times\mathscr{L};Z)$ and satisfies

$$H(0,0)=0, \qquad D_v H(0,0)=0. \tag{3.4}$$

Now, if $V\neq\{0\}$, we introduce the following "splitting"; we set, for $(v,\lambda)\in\mathscr{V}\times\mathscr{L}$,

$$\begin{aligned} f_V(v,\lambda) &= f(H(v,\lambda)+v,\lambda), \\ f_Z(z;v,\lambda) &= f(z+H(v,\lambda)+v,\lambda)-f_V(v,\lambda). \end{aligned} \tag{3.5}$$

Of course,

$$f(z+H(v,\lambda)+v,\lambda)=f_Z(z;v,\lambda)+f_V(v,\lambda). \tag{3.6}$$

Remark 3.2. For any $(v,\lambda)\in\mathcal{V}\times\mathcal{L}$, we have

$$f_Z(0;v,\lambda)=0; \tag{3.7}$$

and, as V and Z are orthogonal with respect to $\langle\cdot,\cdot\rangle$, (3.3) implies, for any $(v,\lambda)\in\mathcal{V}\times\mathcal{L}$,

$$\forall z^*\in Z,\quad D_z f_Z(0;v,\lambda)z^*=0, \tag{3.8}$$

and

$$\forall v^*\in V\quad D_v f_V(v,\lambda)w=\langle D_x f(H(v,\lambda)+v,\lambda),w\rangle. \tag{3.9}$$

Moreover, f_Z and $D_z f_Z$ belong to $C^p(\mathcal{X}\times\mathcal{V}\times\mathcal{L};\mathbb{R})$ and $C^p(\mathcal{X}\times\mathcal{V}\times\mathcal{L};X)$, respectively; and f_V and $D_v f_V$ belong to $C^p(\mathcal{V}\times\mathcal{L};\mathbb{R})$ and $C^p(\mathcal{V}\times\mathcal{L};X)$, respectively.

THEOREM 3.2. *For any $\lambda\in\mathcal{L}$, the mapping $v\to H(v,\lambda)+v$ is a bijection between the critical points of $f_V(\cdot,\lambda)$ in $\mathcal{V}$ and those of $f(\cdot,\lambda)$ in $\mathcal{X}\oplus\mathcal{V}$.*

Proof. It is an obvious consequence of Lemma 3.1 and of relation (3.9).

Now we introduce the additional hypothesis:

(h.4) The operator T is positive on Z, i.e.,

$$\forall z\in Z\quad \langle Tz,z\rangle\geqq 0. \tag{3.10}$$

LEMMA 3.3. *Assume that the hypotheses* (h.1), (h.2), (h.3) *and* (h.4) *hold. Then we can choose the neighbourhoods $\mathcal{X}$, $\mathcal{V}$, $\mathcal{L}$ in Lemma* 3.1 *in such a way that*

$$\forall(z,v,\lambda)\in\mathcal{X}\times\mathcal{V}\times\mathcal{L}\quad \text{with } z\neq 0,\quad f_Z(z;v,\lambda)>0. \tag{3.11}$$

Proof. Using a Taylor formula, we show, thanks to (3.7) and (3.8), that there exists a real number $t\in]0,1[$, depending on z, v and λ, such that

$$f_Z(z;v,\lambda)=\tfrac{1}{2}\langle D^2_{zz}f_Z(tz;v,\lambda)z,z\rangle$$

or also

$$f_Z(z;v,\lambda)=\tfrac{1}{2}\langle Tz,z\rangle+\tfrac{1}{2}\langle B_t z,z\rangle, \tag{3.12}$$

where

$$B_t=D^2_{xx}f(tz+H(v,\lambda)+v,\lambda)-T. \tag{3.13}$$

The Cauchy-Schwarz inequality

$$\langle Ty,z\rangle^2\leqq\langle Ty,y\rangle\langle Tz,z\rangle,$$

with $y=\tilde{T}^{-1}z$, $z\in Z$, implies

$$\langle Tz,z\rangle\langle\tilde{T}^{-1}z,z\rangle\geqq\|z\|_H^4;$$

therefore, thanks to Lemma 2.4, we obtain

$$\forall z\in Z\quad \langle Tz,z\rangle\geqq\frac{\|z\|_H^2}{\|\tilde{T}^{-1}\|_{\mathcal{L}(Z)}}. \tag{3.14}$$

On the other hand, using Lemma 2.4 once more, we get

$$|\langle B_t z, z\rangle| \leqq \|B_t\|_{\mathscr{L}(X)} \|z\|_H^2. \tag{3.15}$$

Now we at once deduce the property (3.11) from (3.14) and (3.15) by choosing the neighbourhoods $\mathscr{Z}$, $\mathscr{V}$ and $\mathscr{L}$, introduced in Lemma 3.1, in such a way that

$$\forall t \in [0,1] \quad \forall (z, v, \lambda) \in \mathscr{Z} \times \mathscr{V} \times \mathscr{L} \quad \|B_t\|_{\mathscr{L}(X)} < \frac{1}{\|\tilde{T}^{-1}\|_{\mathscr{L}(Z)}}. \tag{3.16}$$

The following theorem is an obvious consequence of Theorem 3.2 and the previous lemma.

THEOREM 3.4. *Assume that the hypotheses* (h.1), (h.2), (h.3) *and* (h.4) *hold and that the neighbourhoods $\mathscr{Z}$, $\mathscr{V}$, $\mathscr{L}$ are chosen in such a way that* (3.11) *is satisfied. Then, for any $\lambda \in \mathscr{L}$, the mapping $v \to H(v, \lambda) + v$ is a bijection between the minima of $f_V(\cdot, \cdot)$ in $\mathscr{V}$ and those of $f(\cdot, \lambda)$ in $\mathscr{Z} \oplus \mathscr{V}$.*

3.2. A few comments. (1) We can also prove Lemma 3.3 and Theorem 3.4 by using the Morse lemma given in § 2. Indeed, applying the Theorem 2.6 to the function f_Z, we obtain the following result.

THEOREM 3.5. *Assume that the hypotheses* (h.1), (h.2), (h.3) *hold. Then there exists a homeomorphism $\Psi^*(z, v, \lambda) = (\varphi^*(z, v, \lambda), v, \lambda)$ of a neighourhood $\mathscr{Z}^* \times \mathscr{V}^* \times \mathscr{L}^*$ of 0 in $Z \times V \times \Lambda$ onto another neighbourhood of 0 in $Z \times V \times \Lambda$ satisfying*

$$\forall (z, v, \lambda) \in \mathscr{Z}^* \times \mathscr{V}^* \times \mathscr{L}^* \quad f_Z(z, v, \lambda) = \tfrac{1}{2}\langle T\varphi^*(z, v, \lambda), \varphi^*(z, v, \lambda)\rangle \tag{3.17}$$

and

$$\varphi^*(0, v, \lambda) = 0, \qquad D_z\varphi^*(0, v, \lambda) = Id_Z. \tag{3.18}$$

(Let us remark that Theorem 3.5 is a generalization of the "generalized Morse lemma" of Mawhin and Willem [10].)

Now Lemma 3.3 is a direct consequence of Theorem 3.5 and of the hypothesis (h.4).

Of course this second proof of Lemma 3.3 is shorter. Nevertheless the first method of proof admits more generalizations than the second one and is well adapted to approximate problems encountered in numerical analysis (see [11, Chap. II] for such a generalization). In particular, the first method of proof enables us to show Theorem 3.4 when $\nabla f(0, 0)$ is near zero, but does not vanish (see [11, Chap. II]).

(2) When $V = \operatorname{Ker} T$ and $Z = \operatorname{Im} T$, the Theorem 3.2 is the variational counterpart of the Lyapunov-Schmidt procedure on the Euler equation $D_x f(x, \lambda) = 0$ and, of course, the two procedures give the same change of coordinates. But our point of view also gives a bijection between the minima of $f_V(\cdot, \lambda)$ and those of $f(\cdot, \lambda)$. In [2], a simplified procedure for the computation of the Taylor expansion of $f_V(\cdot, \lambda)$ is given: it uses the Faa di Bruno formula.

(3) Examples of applications of the splitting lemma can be found in [1], [2], [3] and [9]. The splitting lemma is especially useful in the problems of elasticity. In [11, Chap. III], one applies the splitting lemma and its discrete version to the elasticity problem studied in [3] and to its approximation, respectively.

BOUNDS FOR THE TAILS OF SHARP-CUTOFF FILTER KERNELS*

B. F. LOGAN†

Abstract. In communication theory, it is convenient to deal with bandlimited signals obtained by convolving an arbitrary bounded function with a filter kernel $k(t; \alpha, \beta)$ whose Fourier transform is 1 over the interval $(-\alpha, \alpha)$, and vanishes outside the interval $(-\beta, \beta)$, $0 < \alpha < \beta < \infty$. For α/β near 1, the sharp-cutoff case, the L_1-norm of the kernel must be large. In this paper, estimates are given for $\int_{|t|>T} |k(t; \alpha, \beta)|\, dt$, the norm in the tails of the kernel, which show that T must grow like $(\beta - \alpha)^{-1}$ as $\alpha \to \beta$ in order for the norm in the tails to be (say) less than 1. This result confirms a conjecture of J. C. Lagarias and A. M. Odlyzko who used such filter kernels in a method for computing $\pi(x)$, the number of primes not exceeding x.

Key words. bandlimiting, Lebesgue constants, L_1-norm

AMS(MOS) subject classification. 42A05

The notion of bandlimiting time signals by ideal filtering is pervasive in communication theory, owing to the fact that the resulting signal can be represented by a countable number of data or "samples". For a suitable class of signals, e.g., L_2, this bandlimiting can be accomplished (in theory) by convolving the signal with the filter kernel

$$k(t) = \frac{\sin \alpha t}{\pi t}. \tag{1}$$

However, this kernel is not L_1 (absolutely integrable) so the convolution with arbitrary bounded signals is not always defined. In order for a kernel to belong to L_1, it is necessary that its Fourier transform be continuous and tend to zero at $\pm\infty$. Here we consider filters characterized by kernels $k(t; \alpha, \beta)$ in L_1 whose Fourier transforms $\hat{k}$ satisfy

$$\hat{k}(\omega; \alpha, \beta) = \int_{-\infty}^{\infty} k(t; \alpha, \beta)\, e^{-i\omega t}\, dt = \begin{cases} 1 & \text{for } -\alpha \leqq \omega \leqq \alpha, \\ 0 & \text{for } |\omega| \geqq \beta \end{cases} \tag{2}$$

where $0 < \alpha < \beta < \infty$. The collection of such kernels will be denoted by $K(\alpha, \beta)$. If $(\beta - \alpha)$, the "cut-off interval," is small compared to $(\beta + \alpha)$ or, say α, then it is quite easy to show that the L_1 norm of $k(t; \alpha, \beta)$ must be large. J. C. Lagarias and A. M. Odlyzko [1], in using sharp cutoff filters in a method to compute $\pi(x)$, the number of primes not exceeding x, raised the following question concerning the norm in the tails of the kernels. If $\alpha \to \beta$, how small can one take T (depending on α and β) such that (for the best choice of $k(t; \alpha, \beta)$)

$$\int_{|t|>T} |k(t; \alpha, \beta)|\, dt \leqq 1. \tag{3}$$

They conjectured that $(\beta - \alpha)T$ could not tend to zero with (3) holding for any k in $K(\alpha, \beta)$. We show here that the conjecture is true. One would really like to determine

$$m_T(\alpha, \beta) = \inf_{k \in K(\alpha,\beta)} \int_{|t|>T} |k(t; \alpha, \beta)|\, dt. \tag{4}$$

This appears to be a very difficult problem to solve (except in special cases with $T = 0$), but inequalities are fairly simple to obtain which answer the question at hand.

* Received by the editors October 14, 1986; accepted for publication April 12, 1987.
† AT&T Bell Laboratories, Murray Hill, New Jersey 07974.

It is convenient to rescale the kernels so that they may be described in terms of one parameter λ. We denote by $K_\lambda = K(\lambda-1, \lambda+1)$ the collection of kernels $k(t)$ in L_1 whose Fourier transforms $\hat{k}$ satisfy

$$\hat{k}(\omega) = \int_{-\infty}^{\infty} k(t)\, e^{-i\omega t}\, dt = \begin{cases} 1 & \text{for } -(\lambda-1) \leqq \omega \leqq \lambda - 1, \\ 0 & \text{for } |\omega| \geqq \lambda + 1 \end{cases} \tag{5}$$

where $\lambda > 1$. The "cut-off interval" is now fixed at 2, and we are interested in the case where $\lambda \to \infty$. We wish to obtain inequalities for the quantity defined by

$$\mu(\lambda, c) = \inf_{k \in K_\lambda} \int_{|t|>c} |k(t)|\, dt. \tag{6}$$

Now any kernel in L_1 of the form

$$k(t) = g(t)\frac{\sin \lambda t}{\pi t}, \qquad \lambda > 1 \tag{7}$$

where the Fourier transform of g vanishes outside $[-1, 1]$ and $g(0) = 1$, belongs to K_λ. This is not the most general representation for kernels in k_λ, but it suffices for obtaining an upper bound for $\mu(\lambda, c)$. Let $B(1)$ denote the collection of functions g which are restrictions to the real line of entire functions of exponential type 1, which, in engineering terminology, are the bandlimited functions whose (generalized) Fourier transforms vanish outside $[-1, 1]$. Then from (6) and (7) we have

$$\mu(\lambda, c) \leqq \inf_{\substack{g \in B(1) \\ g(0)=1}} \frac{1}{\pi} \int_{|t|>c} \frac{|g(t)|}{|t|} \cdot |\sin \lambda t|\, dt. \tag{8}$$

It has been shown elsewhere [2] that

$$\inf_{\substack{g \in B(1) \\ g(0)=1}} \frac{1}{\pi} \int_{|t|>c} \frac{|g(t)|}{|t|}\, dt = \frac{2}{\pi} \log \frac{1+e^{-c}}{1-e^{-c}}, \tag{9}$$

the extremal function in (9) being

$$g(t) = g(t; c) = \frac{c}{\sinh c} \frac{\sin \sqrt{t^2 - c^2}}{\sqrt{t^2 - c^2}}. \tag{10}$$

Thus we have

$$\mu(\lambda, c) < \frac{2}{\pi} \log \frac{1+e^{-c}}{1-e^{-c}}. \tag{11}$$

In (8) we can expand $|\sin \lambda t|$ in a Fourier series (absolutely convergent)

$$|\sin \lambda t| = \frac{2}{\pi} - a_1 \cos 2\lambda t - a_2 \cos 4\lambda t - \cdots, \tag{12}$$

and then as $\lambda \to \infty$ only the constant term $2/\pi$ will contribute to the integral, provided $c > 0$ is fixed. We have equality in (9) for $g(t) = g(t; c)$; hence

$$\mu(\lambda, c) \leqq \frac{1}{\pi} \int_{|t|>c} \frac{|g(t; c)|}{|t|} \cdot |\sin \lambda t|\, dt \sim \frac{4}{\pi^2} \log \frac{1+e^{-c}}{1-e^{-c}} \qquad (\lambda \to \infty), \quad (c > 0). \tag{13}$$

It is believed that this is the correct asymptotic behavior of $\mu(\lambda; c)$ as $\lambda \to \infty$, with c held fixed, $c > 0$, but we will not attempt to prove that here. (It would be true if the extremal function had the simple form (7) for all c and λ, or tended in norm to that form as $\lambda \to \infty$.)

Now lower bounds for $\mu(\lambda, c)$ are more difficult to obtain. What we need here are functions $s(t; \lambda, c)$ of unit norm in L_∞ which vanish over $(-c, c)$ and have spectral gaps $(-\lambda_2, -\lambda_1)$ and (λ_1, λ_2), where

$$\lambda_1 = \lambda - 1, \quad \lambda_2 = \lambda + 1 \quad (\lambda > 1).$$

Such functions $s(t; \lambda, c)$ have the representation

$$s(t; \lambda, c) = f(t) + h(t), \tag{14}$$

where $s(t; \lambda, c) = 0$, $|t| \leqq c$, $\sup_t |s(t; \lambda, c)| = 1$, and $f(t)$ is a bounded bandlimited function whose "Fourier transform" vanishes outside $[-\lambda_1, \lambda_1]$, and $h(t)$ is a bounded high-pass function whose "Fourier transform" vanishes over $(-\lambda_2, \lambda_2)$. Since the Fourier transform of any kernel k in K_λ is 1 over the interval $[-\lambda_1, \lambda_1]$ and vanishes outside $(-\lambda_2, \lambda_2)$, the convolution of $s(t; \lambda, c)$ in (14) with $k(t)$ [or $k(-t)$] simply gives $f(t)$, rejecting $h(t)$. In particular,

$$\int_{-\infty}^{\infty} k(t)s(t; \lambda, c)\, dt = \int_{|t| \geqq c} k(t)s(t; \lambda, c)\, dt = f(0), \qquad k \in K_\lambda \tag{15}$$

gives the inequality

$$|f(0)| \leqq \int_{|t| > c} |k(t)|\, dt, \qquad k \in K_\lambda. \tag{16}$$

Thus we would like to find $s(t; \lambda, c)$ of the form (14), where $f(0)$ is as large as possible. This presents another difficult problem except in the case $c = 0$, $\lambda = n$, where n is an integer not less than 2. In this case the optimal function is

$$s(t; n, 0) = \operatorname{sgn}\left\{\frac{\sin nt}{\sin t}\right\}, \qquad n \geqq 2 \tag{17}$$

and the kernel of minimal norm in K_n is

$$k_n(t; 0) = \frac{\sin t}{t}\frac{\sin nt}{\pi t}. \tag{18}$$

To see this, we first note that

$$s(t + \pi; n, 0) = (-1)^{n-1} s(t; n, 0). \tag{19}$$

So in the case where n is odd ($\geqq 3$), $s(t; n, 0)$ has period π and a Fourier series of the form

$$s(t; n, 0) = b_0(n) + 2\sum_{k=1}^{\infty} b_{2k}(n) \cos 2kt, \quad n \text{ odd} \geqq 3. \tag{20}$$

In the case where n is even ($\geqq 2$), $s(t; n, 0)$ has period 2π but, in accord with (19), has only odd harmonics

$$s(t; n, 0) = 2\sum_{k=0}^{\infty} b_{2k+1}(n) \cos (2k+1)t, \quad n \text{ even} \geqq 2. \tag{21}$$

In either case, $s(t; n, 0)$ has the spectral gaps $(n-1, n+1)$ and $(-n-1, -n+1)$. So if k is any kernel in K_n we have

$$\begin{aligned} \int_{-\infty}^{\infty} s(t; n, 0)k(t)\, dt &= \int_{-\infty}^{\infty} s(t; n, 0)k_n(t; 0)\, dt \\ &= \int_{-\infty}^{\infty} |k_n(t; 0)|\, dt = \int_{-\infty}^{\infty} \frac{\sin^2 t}{\pi t^2}\left|\frac{\sin nt}{\sin t}\right| dt \leqq \int_{-\infty}^{\infty} |k(t)|\, dt. \end{aligned} \tag{22}$$

Now note in the next-to-last integral in (22), on expanding the periodic function $|\cdot|$ (period π) in a Fourier series, that only the constant term contributes to the integral. Thus we obtain the result

$$\mu(n,0)=\frac{2}{\pi}\int_0^{\pi/2}\left|\frac{\sin nt}{\sin t}\right|dt, \qquad n\geqq 1$$
$$=\frac{4}{\pi^2}\log n+O(1), \qquad n\to\infty. \tag{23}$$

(See "Lebesgue Constants," [3, p. 67].)

Now if $k(t)$ belongs to $K_\lambda = K(\lambda-1,\lambda+1)$, then $ak(at)$ belongs to $K(a(\lambda-1), a(\lambda+1))$. So setting

$$a=\frac{\alpha}{\lambda-1}, \quad \frac{\lambda+1}{\lambda-1}=\frac{\beta}{\alpha} \quad \text{or} \quad \lambda=\frac{\beta+\alpha}{\beta-\alpha},$$

we see that the connection between $m_T(\alpha,\beta)$ defined in (4) and $\mu(\lambda, c)$ defined in (6) is

$$m_T(\alpha,\beta)=\mu\left(\frac{\beta+\alpha}{\beta-\alpha},(\beta-\alpha)\frac{T}{2}\right). \tag{24}$$

Now we wish to show that $m_T(\alpha,\beta)\to\infty$ as $\alpha\to\beta$ if $(\beta-\alpha)T\to 0$; i.e., we need a lower bound for $\mu(\lambda, c)$ for small c and large λ.

For fixed c, it would seem that $\mu(\lambda, c)$ should be an increasing function of λ. We are not able to show that here, but we only need the "quasi-monotonicity" (29) to obtain the desired result from lower bounds for $\mu(n, c)$, $c<\pi/2$.

First suppose $n\leqq\lambda<n+1$ (n an integer $\geqq 2$). Then if $k_\lambda(t)$ belongs to $K(\lambda-1, \lambda+1)$, the dilation

$$k_n(t)=\frac{n+1}{\lambda+1}k_\lambda\left(\frac{n+1}{\lambda+1}t\right) \tag{25}$$

belongs to $K((n+1)(\lambda-1)/(\lambda+1), n+1)\subseteq K(n-1, n+1)=K_n$. We have

$$\inf_{k_\lambda\in K_\lambda}\int_{|t|>c}|k_\lambda(t)|\,dt=\mu(\lambda, c). \tag{26}$$

Using (25) we have

$$\int_{|t|>c}|k_n(t)|\,dt=\int_{|t|>c}\frac{n+1}{\lambda+1}\left|k_\lambda\left(\frac{n+1}{\lambda+1}t\right)\right|dt\geqq\mu(n, c) \qquad (n\leqq\lambda<n+1). \tag{27}$$

Thus

$$\int_{|t|>(n+1)c/(\lambda+1)}|k_\lambda(t)|\,dt\geqq\mu(n, c);$$

whence follows

$$\mu\left(\lambda,\frac{n+1}{\lambda+1}c\right)\geqq\mu(n, c), \qquad n\leqq\lambda<n+1, \tag{28}$$

or

$$\mu(\lambda, c)\geqq\mu\left(n,\frac{\lambda+1}{n+1}c\right), \qquad n\leqq\lambda<n+1. \tag{29}$$

It is sufficient then to show that

$$\mu(n, c) > \frac{2}{\pi}\int_c^{\pi/2} \left|\frac{\sin nt}{\sin t}\right| dt, \qquad n \geqq 2, \quad 0 < c < \frac{\pi}{2}. \tag{30}$$

To obtain the last result, define the periodic function

$$\begin{aligned} \sigma_n(t; c) &= \operatorname{sgn}\left\{\frac{\sin nt}{\sin t}\right\}, \qquad c \leqq t \leqq \pi - c \\ &= 0, \qquad -c < t < c, \end{aligned} \tag{31}$$

$$\sigma_n(t+\pi; c) = (-1)^{n-1}\sigma_n(t; c), \qquad -\infty < t < \infty. \tag{31a}$$

That is, we obtain $\sigma_n(t; c)$ by subtracting from $s(t; n, 0)$, defined in (17), its restriction to the intervals $(-c, c)$ modulo π. For n either odd or even, $\sigma_n(t; c)$ has the same form of Fourier series as $s_n(t; n, 0)$. In particular $\sigma_n(t; c)$ has spectral gaps $(n-1, n+1)$ and $(-n-1, -n+1)$. Hence for any k in K_n, we have

$$\int_{-\infty}^{\infty} k(t)\sigma_n(t; c)\, dt = \int_{-\infty}^{\infty} \frac{\sin nt}{\pi t}\frac{\sin t}{t}\sigma_n(t; c)\, dt. \tag{32}$$

So, since $|\sigma_n(t; c)| \leqq 1$ for $|t| > c$, vanishing over $(-c, c)$ and translates of this interval, we have for $c > 0$

$$\begin{aligned} \int_{|t|>c} |k(t)|\, dt &> \left|\int_{-\infty}^{\infty} k(t)\sigma_n(t; c)\, dt\right| \\ &= \int_{|t|>c} \frac{\sin nt}{\pi t}\frac{\sin t}{t}\sigma_n(t; c)\, dt \\ &= \int_{|t|>c} \frac{\sin^2 t}{\pi t^2}\frac{\sin nt}{\sin t}\sigma_n(t; c)\, dt \\ &= \frac{2}{\pi}\int_c^{\pi/2} \left|\frac{\sin nt}{\sin t}\right| dt \qquad \left(k \in K_n, 0 < c < \frac{\pi}{2}\right). \end{aligned} \tag{33}$$

Thus

$$\mu(n, c) > \frac{2}{\pi}\int_c^{\pi/2} \left|\frac{\sin nt}{\sin t}\right| dt \sim \frac{4}{\pi^2}\log\left(\cot\frac{c}{2}\right), \qquad n \to \infty, \quad 0 < c < \frac{\pi}{2}. \tag{34}$$

Now if $0 < c < \varepsilon$ for any positive $\varepsilon < \pi/2$, we have

$$\mu(\lambda, c) > \mu(\lambda, \varepsilon). \tag{35}$$

Recalling the relation (24) between $m_T(\alpha, \beta)$ and $\mu(\lambda, c)$, and the inequalities (29) and (34), we see that if T is "little-oh" of $(\beta - \alpha)^{-1}$ as $\alpha \to \beta$, then $m_T(\alpha, \beta) \to \infty$.

SOME ISOPERIMETRIC INEQUALITIES FOR THE LEVEL CURVES OF CAPACITY AND GREEN'S FUNCTIONS ON CONVEX PLANE DOMAINS*

MARCO LONGINETTI†

Abstract. The perimeter and the area of the convex level sets of capacity and Green's functions in convex plane domains are shown to satisfy sharp differential inequalities. Isoperimetric inequalities for capacity problems for optimal conductors are derived.

Key words. level set analysis, isoperimetric inequalities, capacity and Green's function, convexity

AMS(MOS) subject classifications. 31A15, 31A05, 35B50, 52A40

1. Introduction. The purpose of this paper is to show how convexity properties lead to sharp estimates for geometric quantities related to level curves of solutions to some classical partial differential equations.

We denote by $L(t)$ and $a(t)$ the perimeter and the area, respectively, of the domain bounded by a closed level curve $\{u=t\}\equiv\{x\colon u(x)=t\}$, where u is a real function on a plane domain.

We start by considering the solution u of the following capacity problem in a convex plane ring $D=D_0-\bar{D}_1$, where $D_1\subset D_0$ and D_0 and D_1 are plane convex domains:

$$\begin{aligned}&\Delta u=0 \quad \text{in } D,\\ &u=t_0 \quad \text{on } \partial D_0, \qquad u=t_1 \quad \text{on } \partial D_1,\end{aligned} \tag{1.1}$$

with

$$t_0 \text{ and } t_1 \text{ real constants.} \tag{1.2}$$

We derive isoperimetric inequalities involving the geometric quantities $L(t)$ and $a(t)$ related to the level curve $\{u=t\}$.

In Theorem 3.1 we prove that

(i) $\log L(t)$ *is a convex function of* t, and

(ii) $\log|a'(t)|$ *is a convex function of* t.

In the sequel ϕ is called logarithmic convex (concave) if $\log|\phi|$ is convex (concave).

In Theorems 4.1 and 4.2 we derive from (i) and (ii) further inequalities for the level sets of Green's function g for the Laplacian in a plane convex domain D. More specifically, if $\mu(t)$ is the distribution function of g, i.e., the area of the level set $\{g\geqq t\}$, we prove in Theorem 4.1 that:

(iii) $\log\mu(t)$ *is a convex function of* t.

In Theorem 4.2 a sharp upper bound for the length $L(t)$ of the level curves of g is obtained, namely, if L_0 is the perimeter of D:

(iv) $L(t)\leqq L_0\exp(-2\pi t)$.

In Theorem 3.2 we establish properties similar to (i)–(ii) for the following problem:

$$\begin{aligned}&\operatorname{div}(|\nabla u|^{p-2}\nabla u)=0 \quad \text{in } D,\\ &u=t_0 \quad \text{on } \partial D_0, \quad u=t_1 \quad \text{on } \partial D_1, \quad p>1.\end{aligned} \tag{1.3}$$

In Theorem 3.3 we give an explicitly sharp differential inequality for the length $L(t)$ of the level curves of the solution u to the following problem:

$$\begin{aligned} &\Delta u = f(u) \quad \text{in } D, \\ &u = t_0 \quad \text{on } \partial D_0, \quad u = t_1 \quad \text{on } \partial D_1, \quad t_0 < t_1, \\ &\text{with } f \geqq 0, \text{ and } f \text{ monotone nondecreasing.} \end{aligned} \tag{1.4}$$

In Theorem 3.4 we derive a sharp upper bound for the function $L(t)$ related to the solutions of problems (1.3) and (1.4). Furthermore in Theorem 3.5 we derive a sharp upper bound for the area $a(t)$ related to the solutions of problems (1.1), (1.3) in the case where D_1 is a circle.

Finally in § 5 we derive isoperimetric inequalities for the capacity problems (1.1)-(1.4) in the case where u satisfies the Bernoulli condition on the outside boundary ∂D_0, i.e.,

$$|\nabla u| = \text{const} > 0 \quad \text{on } \partial D_0. \tag{1.5}$$

Usually classical isoperimetric inequalities for the distribution function of Green's function or of solutions to elliptic equations are established by analysis and symmetrization arguments on the level sets (see [2]). Here we use arguments which stress the convexity properties of the function u. In fact in [5] and [7] it is proved, for an arbitrary dimension, that the solution u to (1.3) or (1.4), respectively, has convex level surfaces. An improvement for the problem (1.4) in dimension two is given in [4]. Strict convexity properties of Green's function g in a plane convex domain are shown in [4].

An interesting approach to a plasma physics problem [6] shows convexity properties of the level lines of harmonic functions which imply differential inequalities which supplement (i) and (ii).

The principal idea in the present paper is the introduction of a special coordinate system related to the convex level curves of u. More precisely, we consider the coordinates (θ, t) where t is the "level" of the curves $\{u = t\}$ and $(\cos\theta, \sin\theta)$ is the direction of the exterior normal vector to the level curve $\{u = t\}$. Furthermore we consider also the support function h of any level curve $\{u = t\}$ and rewrite any geometric quantity such as $L(t)$, $a(t)$, $|\nabla u|$ and the curvature K of $\{u = t\}$, in terms of h and its derivatives with respect to the curve parameters (θ, t). When u satisfies an elliptic differential equation, calculus arguments show that h is a solution to a nonlinear elliptic equation in (θ, t) coordinates. By analyzing this equation we obtain the sharp differential inequalities for $L(t)$ and $a(t)$, corresponding to (i)-(iv).

2. Support function. In this paragraph we start by recalling the geometric definition and the principal properties of the support function h of a plane convex domain D. For the necessary proofs and other details we refer the reader to [3]. Next we consider a family of support functions associated with a family of convex level curves of a given function u and show how certain geometric properties are defined in terms of derivatives of h.

Let D be a plane convex domain, and let us choose the origin of the coordinates inside D. Let us consider the exterior normal vector to ∂D at (x_1, x_2) given by $n = (\cos\theta, \sin\theta)$, for $\theta \in S \equiv [0, 2\pi)$. The distance from the origin to the support line r supporting ∂D at (x_1, x_2) orthogonal to n is given by the *support function*

$$h(\theta) = x_1 \cos\theta + x_2 \sin\theta. \tag{2.1}$$

If D is strictly convex r supports ∂D at only one point (x_1, x_2), h is of class $\mathscr{C}^1$ and the derivative of h with respect to θ is given by

$$h'(\theta) = -x_1 \sin\theta + x_2 \cos\theta. \tag{2.2}$$

If ∂D is $\mathscr{C}^2$ and has strictly positive curvature, then h is of class $\mathscr{C}^2$ also and

$$h(\theta) + h''(\theta) = R(\theta) > 0, \tag{2.3}$$

where $R(\theta)$ is the radius of curvature of ∂D.

For the proofs of the previous statements we refer the reader to [3, p. 18] and to [9, p. 3] where the formulas

$$L = \int_s R(\theta)\, d\theta = \int_s h(\theta)\, d\theta, \tag{2.4}$$

$$A = \frac{1}{2}\int_s h(\theta) R(\theta)\, d\theta, \tag{2.5}$$

for the perimeter L and the area A of D, respectively, also appear.

Let us now consider a real function u with strictly convex level curves in a domain D. Let us suppose also that u is of class $\mathscr{C}^2$ and that the derivative u_n of u along the outward normal to the level curve $\{u = t\}$ does not vanish at any point in D. For any value t in the range of u we consider the corresponding level curve of u: $\gamma_t \equiv \{u = t\}$, and for fixed t let $h(\theta, t)$ be the support function of the convex domain D_t bounded by γ_t. Furthermore, let $L(t)$, $a(t)$ and $R(\cdot, t)$ be the perimeter, the area and the radius of curvature of D_t, respectively. Partial derivatives are denoted by subscripts.

Of course by (2.1)-(2.3) the following equalities hold:

$$h(\theta, t) = x_1 \cos\theta + x_2 \sin\theta, \qquad (x_1, x_2) \in \gamma_t, \tag{2.6}$$

$$h_\theta(\theta, t) = -x_1 \sin\theta + x_2 \cos\theta, \qquad (x_1, x_2) \in \gamma_t, \tag{2.7}$$

$$h(\theta, t) + h_{\theta\theta}(\theta, t) = R(\theta, t) > 0 \tag{2.8}$$

where (x_1, x_2) is the unique point on γ_t with normal exterior vector $(\cos\theta, \sin\theta)$. Conversely, for any point (x_1, x_2) in D we can find θ and t by using,

$$(\cos\theta, \sin\theta) = \pm \nabla u(x_1, x_2)/|\nabla u(x_1, x_2)|, \tag{2.9}$$

$$t = u(x_1, x_2). \tag{2.10}$$

The + or − sign in (2.9) are given by the sign u_n. Moreover by (2.4) and (2.5) we have

$$L(t) = \int_s R(\theta, t)\, d\theta = \int_s h(\theta, t)\, d\theta, \tag{2.11}$$

$$a(t) = \frac{1}{2}\int_s h(\theta, t) R(\theta, t)\, d\theta. \tag{2.12}$$

We now show that certain classical expressions involving the partial derivatives of u with respect to x_1 and x_2 can be rewritten as derivatives of h with respect to θ and t. More precisely we have the following.

PROPOSITION 2.1. *If u has strictly convex level curves and its normal derivative u_n does not vanish at any point on D, then*

$$u_n = (h_t)^{-1}, \tag{2.13}$$

$$\Delta u = [-h_{tt} + (h_{\theta t}^2 + h_t^2) R^{-1}] h_t^{-3}. \tag{2.14}$$

Proof. We differentiate (2.6) and (2.10) with respect to t to get

$$h_t = \frac{\partial x_1}{\partial t}\cos\theta + \frac{\partial x_2}{\partial t}\sin\theta,$$

$$1 = u_{x_1}\frac{\partial x_1}{\partial t} + u_{x_2}\frac{\partial x_2}{\partial t};$$

expression (2.13) then follows with the use of (2.9). On the other hand, by differentiating (2.7) with respect to the exterior normal direction $n = (\cos\theta, \sin\theta)$, we get

$$h_{\theta t}\cdot t_n + h_{\theta\theta}\cdot\theta_n = -\frac{\partial x_1}{\partial n}\sin\theta - x_1\cos\theta\cdot\theta_n + \frac{\partial x_2}{\partial n}\cos\theta - x_2\sin\theta\cdot\theta_n. \tag{2.15}$$

By using (2.6), (2.13) and the fact that

$$t_n = u_n, \quad \frac{\partial x_1}{\partial n} = \cos\theta, \quad \frac{\partial x_2}{\partial n} = \sin\theta, \tag{2.16}$$

we can rewrite (2.15) in the form

$$h_{\theta t}\cdot h_t^{-1} + h_{\theta\theta}\cdot\theta_n = -h\cdot\theta_n.$$

So by solving for θ_n and using (2.8) we derive that the curvature of the orthogonal trajectories is given by

$$\theta_n = -h_{\theta t}h_t^{-1}R^{-1}. \tag{2.17}$$

Differentiating (2.13) with respect to n yields

$$U_{nn} = -(h_{tt}t_n + h_{\theta t}\theta_n)h_t^{-2}, \tag{2.18}$$

and so from (2.13) and (2.17) it follows that

$$U_{nn} = (-h_{tt} + h_{\theta t}^2 R^{-1})h_t^{-3}. \tag{2.19}$$

Now (2.14) follows from (2.13) and the following expression for the Laplacian in terms of normal derivatives of u and of the curvature $K = R^{-1}$ of the level curves of u:

$$\Delta u = u_{nn} + Ku_n. \qquad \square$$

3. Capacity functions in convex rings. We start by considering a harmonic function u with closed convex level curves $\gamma_t = \{x: u(x) = t\}$ in a convex ring D.

THEOREM 3.1. *If u is a solution to* (1.1)-(1.2), *then $L(t)$ is a logarithmic convex function in t, i.e.,*

$$L''L - (L')^2 \geqq 0, \tag{3.1}$$

and $|a'(t)|$ is a logarithmic convex function in t, i.e.,

$$a'''a' - (a'')^2 \geqq 0. \tag{3.2}$$

Moreover, equality holds in (3.1) *or* (3.2) *for some t if and only if all the level curves of u in D are concentric circles.*

Proof. Under the assumption that D_0 and D_1 are two convex domains bounding the convex level curves, $\{u = t_0\}$ and $\{u = t_1\}$, J. Lewis (cf. [7]) has proved that the function u has the following properties:

(a) $\{u = t\}$ is a strictly convex curve in D,

(b) $|\nabla u| \neq 0$ in D.

Therefore we can consider as in the previous section the support function $h(\theta, t)$ of the level curves of u.

We can suppose that $t_0 < t_1$, for substituting $-u$ for u leaves the inequalities (3.1) and (3.2) unchanged.

By (2.14) the following equality holds:

$$h_{tt} = (h_t^2 + h_{t\theta}^2) R^{-1} - h_t^{+3} \Delta u. \tag{3.3}$$

Since u is harmonic, we derive that

$$h_{tt} \geqq h_t^2 R^{-1}. \tag{3.4}$$

Moreover, by differentiating (2.11) with respect to t we get

$$L'(t) = \int_s h_t(\theta, t)\, d\theta, \tag{3.5}$$

$$L''(t) = \int_s h_{tt}(\theta, t)\, d\theta. \tag{3.6}$$

So from (3.4) it follows that

$$L''(t) \geqq \int_s h_t^2(\theta, t) R^{-1}(\theta, t)\, d\theta. \tag{3.7}$$

By Schwarz's inequality we have

$$\left(\int_s h_t\, d\theta \right)^2 \leqq \left(\int_s h_t^2 R^{-1}\, d\theta \right) \cdot \left(\int_s R\, d\theta \right). \tag{3.8}$$

So from (3.5), (3.6) and (2.11) we obtain (3.1). Equality in (3.1) holds for some $\tau \in (t_0, t_1)$ if and only if equality holds in (3.4) and (3.8) for $t = \tau$. This implies that

$$\begin{aligned} &h_{\theta t}(\cdot, \tau) \equiv 0 \quad \textit{on } S, \\ &h_t(\cdot, \tau) \textit{ is proportional to } R(\cdot, \tau) \textit{ on } S. \end{aligned} \tag{3.9}$$

Equivalently, we can say that

$$h_t(\cdot, \tau) \textit{ and } R(\cdot, \tau) \textit{ are constant on } S. \tag{3.10}$$

From (3.10) it then follows that $\{u = \tau\}$ is a circle and $|\nabla u| = |h_t|^{-1}$ is constant on $\{u = \tau\}$. From unique analytic continuation arguments it follows that any level curve of u is a circle concentric to D_τ.

Now we establish (3.2). By differentiating (2.8) and (2.12) with respect to t, we have

$$R_t = h_t + h_{\theta\theta t},$$

and

$$a'(t) = \frac{1}{2} \int_s (h_t R + h R_t)\, d\theta,$$

respectively. Replacing R_t we get

$$a'(t) = \frac{1}{2} \int_s (h_t R + h h_t + h h_{\theta\theta t})\, d\theta.$$

Integrating the last term in the previous integral two times by parts with respect to θ and using (2.8) yields

$$a'(t) = \int_s h_t R\, d\theta. \tag{3.11}$$

By differentiating (3.11) it follows that

$$a''(t) = \int_s (h_t R_t + R h_{tt})\, d\theta, \tag{3.12}$$

and using (3.3) it turns out that

$$a''(t) = \int_s (h_t h_{t\theta\theta} + 2h_t^2 + h_{t\theta}^2)\, d\theta - \int_s (R h_t^3\, \Delta u)\, d\theta.$$

Integrating the first term in the integral above by parts, we have

$$a''(t) = 2\int_s h_t^2\, d\theta - \int_s (R h_t^3\, \Delta u)\, d\theta \tag{3.13}$$

and so having used the fact that $\Delta u = 0$ we derive

$$a'''(t) = 4\int_s h_t h_{tt}\, d\theta. \tag{3.14}$$

Let us now observe that from (2.13) we have $h_t < 0$; therefore, from (3.4) and (3.14), it follows that

$$a'''(t) \leqq 4\int_s h_t^3 R^{-1}\, d\theta. \tag{3.15}$$

But Schwarz's inequality implies

$$\left(\int_s h_t^2\, d\theta\right)^2 \leqq \left(\int_s |h_t^3| R^{-1}\, d\theta\right) \cdot \left(\int_s |h_t| R\, d\theta\right). \tag{3.16}$$

So putting together (3.11), (3.13), (3.15), (3.16) we obtain (3.2). Moreover equality holds in (3.2) if and only if equality holds in (3.16) and (3.4), i.e., if (3.10) holds for some τ. The same previous analytic continuation argument completes the proof. □

The arguments of the previous theorem can also be applied to the solution u of the capacity problems (1.3) to obtain the following theorem.

THEOREM 3.2. *If u is a solution of* (1.3), *then the length $L(t)$ satisfies*

$$L \cdot L'' - \frac{1}{p-1}(L')^2 \geqq 0, \tag{3.17}$$

i.e., $(1/\alpha)L^\alpha$ is a convex function for $\alpha = (p-2)/(p-1)$, $p \neq 2$. Moreover the function $a(t)$ satisfies

$$a''' a' - \frac{2}{p}(a'')^2 \geqq 0, \tag{3.18}$$

i.e., $(1/\beta)|a'|^\beta$ is a convex function for $\beta = (p-2)/p$, $p \neq 2$. Equality holds in (3.17) *or* (3.18) *for some t if and only if all the level curves of u are concentric circles.*

Proof. Using normal coordinates, (1.3) becomes

$$\Delta u + (p-2)u_{nn} = 0. \tag{3.19}$$

So by (2.14) and (2.19) we have that

$$h_{tt} = \left(\frac{1}{p-1}h_t^2 + h_{\theta t}^2\right) R^{-1}, \tag{3.20}$$

from which it follows that

$$h_{tt} \geqq \frac{1}{p-1} h_t^2 R^{-1}. \tag{3.21}$$

If we now replace (3.4) by (3.21), then arguments along the lines of the previous theorem establish (3.17) and (3.18). □

Remark. By (3.3) the inequality (3.4) holds for any subharmonic function u with convex level curves and negative exterior normal derivative. So under this assumption the inequality (3.1) holds; moreover, by (3.12) and (3.3) one can show that $a'' > 0$.

Let us now consider the solution u to (1.4).

THEOREM 3.3. *If u is a solution to* (1.4), *then*

$$[\log L(t)]'' \geqq \frac{1}{4\pi^2} \cdot f(t) \cdot \frac{|L'(t)|^3}{L(t)}. \tag{3.22}$$

Equality in (3.22) *holds for some τ if and only if $\{u = \tau\}$ is a circle and $|\nabla u|$ is constant on $\{u = \tau\}$.*

Proof. Caffarelli and Friedman (cf. [4]) proved that u has strictly convex level curves. Moreover, $u_n = h_t^{-1} < 0$ since $t_0 < t_1$. So by (3.3) we get

$$h_{tt} \geqq h_t^2 R^{-1} + f(t)|h_t|^{+3}.$$

By integrating the above inequality on S and by using Holder's inequality for the last term, the same arguments in the proof of (3.1) prove (3.22). □

We now show that (3.17) (respectively (3.22)) leads to a sharp upper bound for the length $L(t)$ of the level curves of the solution u to (1.3) (respectively (1.4)).

Let $\tilde{D}_0$ and $\tilde{D}_1$ be two concentric circles with the same perimeters as D_0 and D_1. We consider the radial solutions v to (1.3) or to (1.4) with the following boundary conditions:

$$v = t_0 \quad \text{on } \partial\tilde{D}_0, \qquad v = t_1 \text{ on } \partial\tilde{D}_1. \tag{3.23}$$

We call v the *L-symmetrization* of u in $D_0 - D_1$.

THEOREM 3.4. *If u is a solution of* (1.3) *or* (1.4) *satisfying* (1.2) *and v is the L-symmetrization of u, then*

$$L(t) \leqq l(t) \tag{3.24}$$

where $l(t)$ is the perimeter of the level circles $\{v = t\}$.

Proof. We first consider the problem (1.3). By (3.23) we have

$$l(t_0) = L(t_0), \qquad l(t_1) = L(t_1).$$

Moreover by Theorem 3.2 we get that $l(t)$ satisfies

$$l(t) \cdot l''(t) - \frac{1}{p-1} l'(t)^2 = 0, \qquad t \in (t_0, t_1). \tag{3.25}$$

Similarly for the problem (1.4) we get

$$[\log l(t)]'' = \frac{1}{4\pi} f(t) \cdot \frac{|l'(t)|^3}{l(t)}, \qquad t \in (t_0, t_1). \tag{3.26}$$

By comparing (3.25) and (3.26) with (3.17) and (3.22), respectively, and by standard comparison theorems for differential inequalities (cf. [8]), we prove (3.24). □

We now wish to establish an upper bound for the area $a(t)$ in the problem (1.31). So let D_0^* and D_1^* be two concentric circles with the same area as D_0 and D_1. Let w be the radial solution to (1.3), with the following boundary conditions:

$$w = t_0 \quad \text{on } \partial D_0^*, \qquad w = t_1 \quad \text{on } \partial D_1^*.$$

We call w the *a-symmetrization of u in* $D_0 - D_1$.

THEOREM 3.5. *Let u be a solution of* (1.3) *and let w be the a-symmetrization of u. If*

(3.27) $$D_1 \text{ is a circle,}$$

then for any $p > 1$

(3.28) $$a''a - \frac{p}{2(p-1)}(a')^2 \geqq 0$$

and

(3.29) $$a(t) \leqq A(t),$$

where $A(t)$ *is the area of the level circle* $\{w = t\}$.

Proof. First we prove (3.28) and (3.29) for $p = 2$. Let us set

(3.30) $$M(t) = \frac{a''(t) \cdot a(t) - (a'(t))^2}{a(t)}.$$

By differentiating, (3.30) becomes

$$M' \equiv a''' - 2\frac{a'a''}{a} + \frac{(a')^3}{a^2}.$$

Since $a' < 0$, we get from (3.2) that

$$a''' \leqq \frac{(a'')^2}{a'}$$

and so

$$M' \leqq \frac{(a'')^2}{a'} - 2\frac{a'a''}{a} + \frac{(a')^3}{a^2}$$

$$= \frac{a''}{a}\left(\frac{a''a - (a')^2}{a'}\right) + \frac{a'}{a}\left(\frac{(a')^2 - a''a}{a}\right) \equiv \frac{M^2}{a'},$$

from which it follows that

(3.31) $$M'(t) \leqq 0.$$

Let us now compute $M(t_1)$. By (2.12), (3.11) and (3.13) we get

$$a \cdot M \equiv \left(\int_s h_t^2 \, d\theta\right) \cdot \left(\int_s hR \, d\theta\right) - \left(\int_s h_t R \, d\theta\right)^2.$$

By assumption (3.27) we have $R(\cdot, t_1) \equiv$ constant, say R_1, and so

$$\frac{aM(t_1)}{R_1^2} = 2\pi\left(\int_s h_t^2(\theta, t_1) \, d\theta\right) - \left(\int_s h_t(\theta, t_1) \, d\theta\right)^2.$$

Schwarz's inequality implies that

$$M(t_1) \geqq 0.$$

So by (3.31) we get $M(t) \geqq 0$, and (3.28) follows from (3.30) for $p=2$; by standard comparison theorems (cf. [8]), (3.28) implies (3.29).

For $p>1$, $p \neq 2$, by replacing (3.30) with

$$M \equiv \left[a''a - \frac{p}{2(p-1)}(a')^2 \right] a^{-\alpha}$$

where $\alpha = 1/(p-1)$, we can establish (3.28) and (3.29) by using arguments similar to those for the case $p=2$. □

Remark. In Theorem 5.2 we prove that for $p=2$, in the case where (3.27) is replaced by the Bernoulli condition (1.5), the opposite inequality of (3.28) holds. So in general assumption (3.27) is essential for inequalities (3.28) and (3.29) to hold.

4. Isoperimetric inequalities for Green's function. Usually the point of departure in level set-analysis of a function u is the coarea formula (cf. [2, p. 52]):

$$|\mu'(t)| = \oint_{u=t} \frac{ds}{|\nabla u|}, \tag{4.1}$$

where $\mu(t)$ is the distribution function of u, i.e., the Lebesgue measure of the level set $\{u \geqq t\}$. Moreover, applying Schwarz's inequality to (3.25), the following inequality is usually considered:

$$|\mu'(t)| \geqq \left(\oint_{u=t} ds \right)^2 \Big/ \oint_{u=t} |\nabla u| \, ds. \tag{4.2}$$

Let us now consider Green's functions of the Laplace operator in a plane domain D. It is of the form

$$g(x, y) = \frac{1}{2\pi} \log \frac{R(y)}{|x-y|} + H(x, y), \tag{4.3}$$

where H is determined such that for fixed $y \in D$ we have the following:

(i) $g(x, y) = 0$ for $x \in \partial D$,

(ii) $H(\cdot, y)$ is harmonic in D and continuous in $\bar{D}$,

(iii) $H(y, y) = 0$.

$R(y)$ is called the *conformal radius* of D with respect to y. Let us define D^* as the circle with the same area as D and with center at the origin of the coordinates and radius R^*. Let D_y be a concentric circle to D^*, with radius $R_y = R(y)$. We consider the functions g^* and g_y given by

$$\begin{aligned} g^*(x) &= \frac{1}{2\pi} \log \frac{R^*}{|x|}, \\ g_y(x) &= \frac{1}{2\pi} \log \frac{R_y}{|x|}, \end{aligned} \tag{4.4}$$

respectively. For fixed y, we denote the distribution functions of $g(\cdot, y)$, g^*, g_y, by $\mu(t)$, $\mu_*(t)$ and $\mu_y(t)$, respectively. By (4.3), (4.4) it follows that

$$\begin{aligned} \mu(t) &= \pi (R_y)^2 \exp(-4\pi t) + o(\exp(-4\pi t)), \\ \mu_*(t) &= \pi (R^*)^2 \exp(-4\pi t), \\ \mu_y(t) &= \pi (R_y)^2 \exp(-4\pi t). \end{aligned} \tag{4.5}$$

Since $\oint |\nabla g| \, ds = 1$ on any level curve of g, it follows from (4.2) that

$$|\mu'(t)| \geqq L^2(t). \tag{4.6}$$

From the classical isoperimetric inequality we derive

$$|\mu'(t)| \geqq 4\pi\mu(t), \tag{4.7}$$

and by integration (see also [2])

$$\mu_y(t) \leqq \mu(t) \leqq \mu_*(t). \tag{4.8}$$

If D is a convex plane domain the following theorem is an improvement of the inequality (4.7).

THEOREM 4.1. *Let D be a convex plane domain and let y be a fixed point in D, then the following differential inequalities hold*:

$$\mu'''\mu' - (\mu'')^2 \geqq 0, \tag{4.9}$$

i.e., $\log|\mu'|$ *is a convex function*;

$$\mu''\mu - (\mu')^2 \geqq 0, \tag{4.10}$$

i.e., $\log\mu$ *is a convex function*; *and*

$$\mu'' \geqq 4\pi|\mu'|. \tag{4.11}$$

Moreover D is a circle with center at y if and only if equality holds in (4.9), (4.10) *or* (4.11) *for some t.*

Proof. In [4] the authors prove that g has strictly convex level curves, so (4.9) follows directly from Theorem 3.1. To prove (4.10) we can repeat similar arguments to those in the proof of (3.28). Another proof of (4.10) follows by considering a sequence $u^{(m)}$ of harmonic functions in $D - D^{(m)}$, satisfying

$$u^{(m)} = 0 \quad \text{on } \partial D, \qquad u^{(m)} = C^{(m)} \quad \text{on } \partial D^{(m)},$$

where $D^{(m)}$ is a circle with center at y and such that

$$\oint_{\partial D^{(m)}} |\nabla u^{(m)}|\, ds = 1.$$

Indeed it is easy to see that $u^{(m)}$ approaches g when $C^{(m)} \to \infty$. Now by applying Theorem 3.5 to $u^{(m)}$ we get that any distribution function $a^{(m)}$ of $u^{(m)}$ is logarithmic convex. Since $\mu = \lim_{m\to\infty} a^{(m)}$, we derive that μ is also logarithmic convex. This proves (4.10).

Finally (4.11) follows from (4.7) and (4.10). This concludes the proof. □

The following corollary follows directly from (4.10), by applying standard comparison theorems for differential inequalities (cf. [8]).

COROLLARY 4.1. *Let $0 \leqq t_0 < t_1$ be fixed constants, and y a fixed point in D. Let D_0 and D_1 be the level sets $\{g \geqq t_0\}$ and $\{g \geqq t_1\}$, respectively. If w is the a-symmetrization of g in $D_0 - D_1$, then*

$$\mu(t) \leqq A(t) \quad \text{for } t \in (t_0, t_1), \tag{4.12}$$

where $A(t)$ is the area of the circle $\{w = t\}$.

We now wish to establish a lower and an upper bound for the length $L(t)$ of the level curves $\{g = t\}$.

Of course from the left-hand inequality in (4.8) and the classic isoperimetric inequality we get

$$2\pi R_y \exp(-2\pi t) \leqq L(t). \tag{4.13}$$

Unfortunately a similar argument does not apply to the right-hand inequality in (4.9) which will give an upper bound for $L(t)$. However, in the following theorem we give an upper bound for $L(t)$ which only depends on the perimeter L_0 of D.

THEOREM 4.2. *Let D be a convex plane domain with perimeter L_0 and let y be a fixed point in D. Then L is logarithmic convex and*

$$L(t) \leqq L_0 \exp(-2\pi t). \tag{4.14}$$

Equality holds in (4.14) *if and only if D is a circle centered at y.*

Proof. As in the proof of the previous theorem we have that g has strictly convex level curves. So Theorem 3.1 applies and $\log L$ is convex. Moreover, by (4.8) it follows that

$$\log \mu_y \leqq \log \mu \leqq \log \mu_*.$$

Since $\log \mu$ is convex and $\log \mu_y$, $\log \mu_*$ are linear functions with slope -4π, it follows that

$$\lim_{t\to+\infty} \frac{\mu'(t)}{\mu(t)} = -4\pi.$$

From (4.5) and the previous equality we have that

$$\lim_{t\to+\infty} \frac{|\mu'(t)|}{\exp(-4\pi t)} = 4\pi^2 R_y^2,$$

and so from (4.6),

$$\lim_{t\to+\infty} \frac{L(t)}{\exp(-2\pi t)} \leqq 2\pi R_y.$$

By logarithmic convexity properties of L and the previous equality we derive (4.14). □

5. Optimal conductors. In [10] the following result is proved: given a convex domain D_1 and a constant $\gamma > 0$ there exists a unique convex domain $D_0 \supset D_1$, such that the solution u to (1.1), (1.2) satisfies the Bernoulli condition:

$$|\nabla u| = \gamma \quad \text{on } \partial D_0. \tag{5.1}$$

This problem arises in optimal conductors and in some classic free boundary problems (see [1]).

The results of § 3 can be applied to obtain isoperimetric inequalities for the *optimal conductor* $D_0 - D_1$. For simplicity, let $t_0 = 0$, $t_1 = 1$ in (1.2). So the logarithmic capacity of $D_0 - D_1$ is given by

$$C = \oint_{\partial D_0} |\nabla u| \, ds, \tag{5.2}$$

and the constant γ in (5.1) is given by

$$\gamma = C/L_0, \tag{5.3}$$

where L_0 is the perimeter of ∂D_0.

THEOREM 5.1. *Let L_0, L_1 be the perimeter, and A_0, A_1 be the area of D_0 and D_1, respectively.*

The logarithmic capacity C of the optimal conductor $D_0 - D_1$ satisfies the following inequalities:

$$\frac{1}{C} \geqq \frac{1}{2\pi} \log \frac{L_0}{L_1}, \tag{5.4}$$

$$\frac{1}{C} \leqq \frac{1}{4\pi} \log \left[\frac{L_0^2}{L_0^2 - 4\pi(A_0 - A_1)} \right]. \tag{5.5}$$

Equality holds in (5.4) *or* (5.5) *if and only if $D_0 - D_1$ is a circular annulus.*

Proof. By logarithmic convexity of the function $L(t)$, Theorem 3.1, we have

$$\log L(1) \geqq \log L(0) + \frac{L'(0)}{L(0)}. \tag{5.6}$$

Moreover by (3.5), (5.1)-(5.3) we have

$$\frac{L'(0)}{L(0)} = -\frac{2\pi}{C}. \tag{5.7}$$

Now (5.4) follows by (5.6) and (5.7).

Similarly by Theorem 3.2 we derive

$$\log |a'(t)| \geqq \log |a'(0)| + \frac{a''(0)}{a'(0)} \cdot t \tag{5.8}$$

and from (3.11), (3.12) we have

$$|a'(0)| = \frac{L_0^2}{C}, \qquad a''(0) = \frac{4\pi L_0^2}{C^2}. \tag{5.9}$$

So by integrating (5.8) and by the equalities above, we get

$$A_0 - A_1 \geqq \frac{L_0^2}{4\pi}\left[1 - \exp\left(-\frac{4\pi}{C}\right)\right].$$

Inequality (5.5) is proved now by solving for $1/C$ in the inequality above. □

Remark 5.1. The length L_0 in (5.4) and (5.5) is not explicitly given, since L_0 is the length of the free boundary ∂D_0.

Moreover, by computation one can show that the upper bound given in (5.5) for $1/C$ is less than in Carleman's inequality:

$$\frac{1}{C} \leqq \frac{1}{4\pi} \log \frac{A_0}{A_1}. \tag{5.10}$$

In the following theorem we give an explicit isoperimetric inequality for the free boundary ∂D_0.

THEOREM 5.2. *If u is a solution to* (1.1), (1.2), *satisfying* (5.1), *then*

$$L_0^2 - 4\pi A_0 \leqq L_1^2 - 4\pi A_1. \tag{5.11}$$

Moreover, the following differential inequalities hold:

$$(L^2 - 4\pi a)' \geqq 0, \tag{5.12}$$

$$a''a - (a')^2 \leqq 0, \tag{5.13}$$

i.e., a is a logarithmic concave function. Equality holds in (5.11), (5.12) *or* (5.13) *if and only if D_1 is a circle.*

Proof. We obtain (5.11) by comparing the two terms on the right-hand side of (5.4) and (5.5). More simply, (5.11) follows by (5.12) which we now prove. In fact, let us set

$$G(t) \equiv L^2(t) - 4\pi a(t). \tag{5.14}$$

Since $\log L$ is convex (Theorem 3.1) we have that L'/L is increasing and by (5.7)

$$L'(t) \geqq \frac{-2\pi}{C} L(t). \tag{5.15}$$

So by (5.14)

$$G'(t) \geqq -4\pi\left[\frac{L^2(t)}{C} + a'(t)\right].$$

Inequality (5.12) follows now from (4.2) and the inequality above.

Finally to prove (5.13) we consider the function M defined by (3.30). By (5.9) we have

$$M(0) = \left(4\pi\frac{L_0^2}{C^2}A_0 - \frac{L_0^4}{C^2}\right)\frac{1}{A_0}.$$

So by classical isoperimetric inequality $M(0) \leqq 0$ and by (3.31) we derive $M(t) \leqq 0$, which implies (5.13). □

Finally, let us observe that: for the solution u to (1.4), and satisfying (5.1), the inequalities (5.4) and (5.12) hold. (5.4) and (5.13) also can be extended in a suitable form to the problems (1.3) satisfying the Bernoulli condition (5.1).

Acknowledgments. The author wishes to thank Cornell University for its hospitality and Professor L. E. Payne for his advice and the several fruitful discussions about the problems presented here.

STARLIKE FUNCTIONS AND LINEAR FUNCTIONS OF A DIRICHLET DISTRIBUTED VECTOR*

JYH-MING JIANG†

Abstract. It is shown that under specific conditions the limiting distribution of $\sum_{i=1}^{k} u_i z_i$ will be a uniform distribution on the unit disk where $z_1, \cdots, z_k$ are increasingly dense points on the unit circle and $\mathbf{u} = (u_1, \cdots, u_k)$ has a Dirichlet distribution. More general circularly symmetric distributions are also obtained as such limits. This is motivated by a new representation of starlike functions as expectations over the unit disk. A new kind of characteristic function and its convergence theorem are used.

Key words. Dirichlet distribution, spherical distributions, Carlson's R, convergence theorem about d-transformation, d-characteristic function

AMS(MOS) subject classifications. primary 60E10; secondary 30C45

1. Introduction. The study of univalent and starlike functions of a complex variable provides a motivation in § 2 for the problem of the limiting distribution of a linear function of a Dirichlet vector. This problem is also of intrinsic interest in probability theory as the distribution of the empirical mean of a Dirichlet random process on the circle as index set. In § 3, we define new kinds of characteristic functions. We show that they have properties similar to the properties of the traditional characteristic function. We use these properties in § 4 to determine the limiting distribution of a linear function of a Dirichlet vector, under some regularity conditions, as the coefficients grow increasingly dense on the unit circle.

2. Motivation. Let S be the full class of functions that are analytic on the open unit disk, one-to-one and normalized (i.e., $f(\zeta) = \zeta + a_2\zeta^2 + a_3\zeta^3, \cdots$, where ζ is a complex variable, $f(0) = 0$, and $f'(0) = 1$). The recently proved theorem of Bieberbach (de Branges (1985)) states that if $f \in S$, then $|a_n| \leqq n$ for $n = 0, 1, 2, \cdots$. Further define f as a *starlike* function if and only if tw belongs to the range of f for any $t \in [0, 1]$ and any w in the range of f. If we let S_t be the set of starlike functions, then S_t is a subset of S. We have the following well-known representation theorem (see Schober (1975, Thm. 2.13, p. 12)).

THEOREM 2.1.

$$s \in S_t \Leftrightarrow s(\zeta) = \zeta \cdot \exp \int_0^{2\pi} -2 \log [1 - (\exp (i\theta))\zeta] \, d\nu(\theta) \tag{2.1}$$

where ν is some probability measure on $[0, 2\pi)$.

Consider the case that the measure ν is discrete (the corresponding functions s are dense in S_t), and assume that

$$\nu(\{\theta_j\}) = t_j, \quad 1 \leqq j \leqq k, \quad t_j > 0 \quad \text{and} \quad \sum_{j=1}^{k} t_j = 1.$$

We then have

$$\frac{s(\zeta)}{\zeta} = \prod_{j=1}^{k} (1 - z_j\zeta)^{-2t_j} \tag{2.2}$$

where $z_j = \exp (i\theta_j)$. We shall derive a new representation for such $s(\zeta)$.

DEFINITIONS. The random vector $\mathbf{u}$ is said to have the Dirichlet distribution $D(\mathbf{b})$ with parameter $\mathbf{b}=(b_1, \cdots, b_k)'$, where every $b_i>0$, if $\mathbf{u}$ has the density in any $k-1$ of its coordinates,

$$f(\mathbf{u}; \mathbf{b}) = B^{-1}(\mathbf{b}) \cdot \prod_{i=1}^{k} u_i^{b_i-1}, \tag{2.3a}$$

for all $\mathbf{u}$ in the probability simplex $\{\mathbf{u}$: each $u_i \geqq 0$, $u_\cdot = 1\}$, where $u_\cdot = u_1 + \cdots + u_k$, and

$$B(\mathbf{b}) = \prod_{i=1}^{k} \Gamma(b_i)/\Gamma(b_\cdot).$$

Following Carlson (1977), define $R_n(\mathbf{b}, \mathbf{z})$ as the nth moment of the random variable $\theta = \sum_{j=1}^{k} u_j z_j$, where $\mathbf{u} \sim D(\mathbf{b})$,

$$R_n(\mathbf{b}, \mathbf{z}) = \underset{u|b}{E}\, \theta^n = \underset{u|b}{E} (\mathbf{u} \cdot \mathbf{z})^n. \tag{2.3b}$$

For a discussion of the relationship between Carlson's R functions and starlike functions see Carlson and Shaffer (1984).

LEMMA 2.2 (Carlson (1977, p. 143)). *Let $\mathbf{b} \in R^k$, $\mathbf{z} \in C^k$, $t \in C$ (R is the real line, C is the complex plane and R^k and C^k are the kth Cartesian power of R and C, respectively). Assume that $\max_{1 \leqq j \leqq k} |tz_j| < 1$. Then*

$$f_k(t) \equiv \prod_{j=1}^{k} (1 - itz_j)^{-b_j} = \sum_{n=0}^{\infty} i^n \cdot t^n \cdot \frac{(b_\cdot, n)}{n!} R_n(\mathbf{b}, \mathbf{z}), \tag{2.4}$$

using Appell's notation,

$$(b_\cdot, n) = \Gamma(b_\cdot + n)/\Gamma(b_\cdot) = b_\cdot(b_\cdot + 1) \cdots (b_\cdot + n - 1).$$

The following lemma can be proved by using the previous lemma and the following equation:

$$(1-y)^{-a} = \sum_{n=0}^{\infty} \frac{(a, n)}{n!} y^n, \tag{2.5}$$

for every real number a and $|y| < 1$.

LEMMA 2.3. *Let μ_b be a Dirichlet measure with parameter $\mathbf{b} = (2t_1, 2t_2, \cdots, 2t_k)'$, where t_j's > 0, and $\sum t_j = 1$. Then for any ζ in the unit disk, if $\mathbf{z} = (z_1, \cdots, z_k)'$ and the z_j's are points on the unit circle,*

$$\prod_{j=1}^{k} (1 - z_j\zeta)^{-2t_j} = \int_E [1 - (\mathbf{u} \cdot \mathbf{z})\zeta]^{-2}\, d\mu_b(\mathbf{u}), \tag{2.6}$$

where E is the probability simplex $\{\mathbf{u}$: each $u_i \geqq 0$, $u_\cdot = 1\}$.

By Lemma 2.3 and Theorem 2.1,

$$\zeta \cdot \int_E [1 - (\mathbf{u} \cdot \mathbf{z})\zeta]^{-2}\, d\mu_b(u) \tag{2.7}$$

is a starlike function for the case of discrete ν (2.1) and $b_\cdot = 2$. We remark that Bieberbach's theorem is straightforward for any function (2.7). This motivates our consideration of the following problems.

Our aim is to find the limiting distribution of $\mathbf{u}_{k*} \cdot \mathbf{z}_{k*} = \sum_{j=1}^{k} u_{kj} z_{kj}$ as $k \to \infty$, where $\mathbf{u}_{k*} \sim D(\mathbf{b}_{k*})$ and the z_{kj}'s are points on the unit circle. If the set of z_{kj}'s for specified k becomes dense on the circle as k increases, then our Dirichlet distribution has a

Dirichlet random process on the circle as limit in distribution (Ferguson (1973)). Thus the limiting distribution of our random sum is also of interest as the distribution of the empirical mean of a Dirichlet random process.

3. *d*-characteristic functions. Lord (1954) shows that a spherical distribution is determined by its marginal distribution. We shall show that under specific conditions, the limiting distribution of $\mathbf{u}_{k*} \cdot \mathbf{z}_{k*}$ is spherically symmetric. Therefore, we need only to find the limiting distribution of the real part of $\mathbf{u}_{k*} \cdot \mathbf{z}_{k*}$ (that is, $\mathbf{u}_{k*} \cdot \mathbf{x}_{k*}$ where each $z_{kj} = x_{kj} + iy_{kj}$).

One traditional method of finding the limiting distribution of a sequence of random variables is to find the limit of the corresponding (traditional) characteristic functions. But this method seems overly complicated for dealing with our problems. Therefore, we use the following alternative characteristic functions. For convenience, we shall call these *d*-characteristic functions.

Let

$$g(t;\, W, d) = \underset{W}{E}[(1 - itW)^{-d}], \qquad |t| < 1, \quad d > 0, \tag{3.1}$$

where W is any random variable on $[-1, 1]$. More generally, for any finite measure μ with supports in $[-a, a]$, we define the *d-transformation* of μ as

$$\hat{\mu}^d(t) = \int_{-a}^{a} (1 - itx)^{-d}\, d\mu(x), \qquad |t| < a^{-1}, \quad d > 0, \tag{3.2}$$

where a is a positive real number. We will show there is a one-to-one correspondence between $\hat{\mu}^d(t)$ and μ.

LEMMA 3.1. *For any finite measures μ and ν with supports in $[-a, a]$ and any positive real number d, if we have*

$$\hat{\mu}^d(t) = \hat{\nu}^d(t), \tag{3.3}$$

for all $|t| < a^{-1}$, then $\mu = \nu$.

Proof. Expand the integrands by (2.5), equation (3.3) is then equivalent to the following equation:

$$\sum_{n=0}^{\infty} \frac{(d, n)}{n!} i^n \cdot t^n \cdot \int_{-a}^{a} x^n\, d\mu(x) = \sum_{n=0}^{\infty} \frac{(d, n)}{n!} i^n \cdot t^n \cdot \int_{-a}^{a} x^n\, d\nu(x),$$

for all $|t| < a^{-1}$. If we regard t as variable, then after equating (for each n) the corresponding coefficients of t^n in the two sums, we have

$$\int_{-a}^{a} P(x)\, d\mu(x) = \int_{-a}^{a} P(x)\, d\nu(x), \tag{3.4}$$

where $P(x)$ is any polynomial function, and similarly for any continuous function. This implies that $\mu = \nu$.

LEMMA 3.2. *If* $\mathbf{u}_{k*} \sim D(\mathbf{b}_{k*})$, $\mathbf{u}_{k*} = (u_{k1}, \cdots, u_{kk})'$, $\mathbf{b}_{k*} = (b_{k1}, \cdots, b_{kk})'$, $b_{k\cdot} = \sum_{j=1}^{k} b_{kj}$ *and* $W_k = \mathbf{u}_{k*} \cdot \mathbf{x}_{k*}$, *then*

$$g(t; W_k, d) = R_{-d}(\mathbf{b}_{k*};\, 1 - itx_{k1}, \cdots, 1 - itx_{kk}) \tag{3.5}$$

where g is defined by (3.1).

Proof.

$$g(t; W_k, d) = \underset{u_{k*}|b_{k*}}{E}\left(1 - it\left(\sum_{j=1}^{k} u_{kj}x_{kj}\right)\right)^{-d}$$

$$= \underset{u_{k*}|b_{k*}}{E}\left(\sum_{j=1}^{k} u_{kj}(1 - itx_{kj})\right)^{-d}$$

$$= R_{-d}(\mathbf{b}_{k*}; 1 - itx_{k1}, \cdots, 1 - itx_{kk}).$$

The last identity follows from the definition (2.3b).

The following corollary can be shown by formula (6.6.5) in Carlson (1977).

COROLLARY 3.3. *Let* $c = b_{k\cdot} = \sum_{j=1}^{k} b_{kj}$, *then*

$$g(t; W_k, c) = \prod_{j=1}^{k} (1 - itx_{kj})^{-b_{kj}}. \tag{3.6}$$

We give the important convergence theorem about d-transformations. This is analogous to the corresponding convergence theorem for the Fourier transformations. Before we state the theorem, we need to give the following definitions and lemma.

DEFINITIONS. Let Ω be a measured space, μ is a measure on Ω. Then μ is called a *subprobability measure* (s.p.m.) if $\mu(\Omega) \leqq 1$. An interval (a, b) is called a *continuity interval* of μ if and only if $\mu(a, b) = \mu[a, b]$; in other words neither a nor b is an atom of μ. A sequence $\{\mu_n, n \geqq 1\}$ of s.p.m.'s is said to *converge vaguely* to an s.p.m. μ if and only if for every continuity interval $(a, b]$ of μ, we have $\mu_n(a, b] \to \mu(a, b]$. This will be denoted by $\mu_n \xrightarrow{v} \mu$.

LEMMA 3.4. *If* μ *and the* μ_n*'s are* s.p.m. *with supports in* $[-a, a]$ *and* $\mu_n \xrightarrow{v} \mu$, *then*

$$\hat{\mu}_n^d(t) \to \hat{\mu}^d(t) \quad \forall d > 0 \quad \textit{and} \quad |t| < a^{-1}, \tag{3.7}$$

where $\hat{\mu}$ *is defined by* (3.2).

Proof. By Theorem 4.4.1 of Chung (1974), we have

$$\int_R (1 - itx)^{-d}\, d\mu_n(x) \to \int_R (1 - itx)^{-d}\, d\mu(x) \quad \forall d > 0 \quad \text{and} \quad |t| < a^{-1}.$$

Given d, then by Lemma 3.1, subprobability measures have a one-to-one correspondence with their d-transforms.

Now, we are ready to give the following convergence theorem.

THEOREM 3.5. *Given* d, *assume the subprobability measures* $\mu, \mu_1, \mu_2, \cdots$ (*with supports in* $[-a, a]$) *correspond to* $\hat{\mu}^d(t), \hat{\mu}_1^d(t), \hat{\mu}_2^d(t), \cdots$, *respectively. If for all* $|t| < a^{-1}$

$$\hat{\mu}_n^d(t) \to \hat{\mu}^d(t) \quad \textit{as } n \to \infty, \tag{3.8}$$

then

$$\mu_n \xrightarrow{v} \mu \quad \textit{as } n \to \infty. \tag{3.9}$$

Proof. For any s.p.m. sequence $\{\mu_n\}$, by Theorem 4.3.3 of Chung (1974), there is a subsequence that converges vaguely to an s.p.m. say $\mu_{n_k} \xrightarrow{v} \lambda$, as $n_k \to \infty$. Then by Lemma 3.4, $\hat{\mu}_{n_k}^d(t) \to \hat{\lambda}^d(t)$, for all $|t| < a^{-1}$. By (3.8), we also have $\hat{\mu}_{n_k}^d(t) \to \hat{\mu}^d(t)$, for all $|t| < a^{-1}$. Therefore, we have $\hat{\lambda}^d(t) = \hat{\mu}^d(t)$, for all $|t| < a^{-1}$. By the uniqueness property of Lemma 3.1, we have $\lambda = \mu$. Therefore, we have $\mu_{n_k} \xrightarrow{v} \mu$, as $n_k \to \infty$. If there is another vaguely convergent subsequence of $\{\mu_n\}$ converging to ψ, then, by the same arguments as above, $\psi = \mu$. By Theorem 4.3.4 of Chung (1974), this proves $\mu_n \xrightarrow{v} \mu$.

4. Limiting distributions. Before proceeding with an application of Theorem 3.5, we need to have the following definitions and lemmas. Define a sequence of random variables $\{X_n\}$ to converge in distribution to X if and only if the sequence $\{\mu_n\}$ of corresponding probability measures converges vaguely to the probability measure μ of X.

Regularity conditions. Given $c>0$, $b=\{b_{kj}: k\geqq 2 \text{ and } 1\leqq j\leqq k\}$ and $z=\{z_{kj}: k\geqq 2 \text{ and } 1\leqq j\leqq k\}$. If b satisfies the following properties:

(A) $b_{k.}\equiv \sum_{j=1}^{k} b_{kj}=c \quad \forall k\geqq 2,$

(B) $B_k\equiv \max_{1\leqq j\leqq k} b_{kj}\to 0 \quad \text{as } k\to\infty,$

and z satisfies the following properties:

(C) z_{kj} lies on the unit circle with center at $(0,0)$,

(D) $\theta_{k,j-1}\leqq \arg z_{kj}<\theta_{kj}$, $1\leqq j\leqq k$ and for all $k\geqq 2$,

where $\theta_{k0}=0$, $\theta_{kj}=(2\pi/c)\sum_{m=1}^{j} b_{km}$ and $\arg z_{kj}$ denotes the argument of z_{kj}, then we say that b and z satisfy *the regularity conditions.* Notice that condition (B) is needed for the next lemma in the transition from a Riemann sum to an integral.

LEMMA 4.1. *If* $\mathbf{u}_{k*}\sim D(\mathbf{b}_{k*})$, $W_k^{\phi}=\mathbf{u}_{k*}\cdot \mathbf{z}_{k*}^{\phi}$ *and the regularity conditions* (A)-(D) *hold, where* $z_{kj}^{\phi}=\cos(\arg z_{kj}-\phi)$, *we then have*

$$\lim_{k\to\infty} g(t; W_k^{\phi}, c)=\left[\frac{2}{1+\sqrt{1+t^2}}\right]^c, \tag{4.1}$$

where g is defined by (3.1).

Proof. By Corollary 3.3, we have

$$g(t; W_k^{\phi}, c)=\prod_{j=1}^{k}(1-it\cos(\arg z_{kj}-\phi))^{-b_{kj}}.$$

Therefore,

$$\begin{aligned}\lim_{k\to\infty} g(t; W_k^{\phi}, c)&=\exp\left(-\lim_{k\to\infty}\sum_{j=1}^{k} b_{kj}\ln(1-it\cos(\arg z_{kj}-\phi))\right)\\&=\exp\left(-\frac{c}{2\pi}\int_0^{2\pi}\ln(1-it\cos(\theta-\phi))\,d\theta\right)\\&=\left[\exp\left(-(2\pi)^{-1}\int_0^{2\pi}\ln(1-it\cos\theta)\,d\theta\right)\right]^c.\end{aligned}$$

Since $\ln(1-it\cos\theta)=\ln|1-it\cos\theta|+i\arg(1-it\cos\theta)$ and $\arg(1-it\cos\theta)=\arg(1-it\cos(2\pi-\theta))$, we have

$$\begin{aligned}\int_0^{2\pi}\ln(1-it\cos\theta)\,d\theta&=\frac{1}{2}\int_0^{2\pi}\ln(1+t^2\cos^2\theta)\,d\theta\\&=2\pi\ln\frac{1+\sqrt{1+t^2}}{2}.\end{aligned}$$

The last identity is obtained by Formula 322.12b of Gröbner and Hofreiter (1973).

If we rotate axes counterclockwise through an angle ϕ, where $0\leqq\phi<\pi$, then z_{kj}^{ϕ} will be the projection of z_{kj} on the new first coordinate. Therefore, W_k^{ϕ} is the first coordinate with respect to rotated axes through an angle ϕ (counterclockwise) and

$W_k^0 = \mathbf{u}_{k*} \cdot \mathbf{x}_{k*}$. Notice that (4.1) holds for any real numbers c and the right-hand side of (4.1) does not depend on ϕ; that is, the limiting function of c-characteristic functions, $g(t; W_k^\phi, c)$, does not depend on ϕ, the angle corresponding to the transform of the marginal distribution W_k^0 under the regularity condition (A)-(D).

In the next lemma, we show that $\mathbf{V} = (X, Y)'$ has a spherical distribution if the first coordinate of any rotational transform of $\mathbf{V}$ has the same distribution as X. Therefore, under the regularity conditions (A)-(D), Lemma 4.1 together with the next lemma show that if $\mathbf{u}_{k*} \cdot \mathbf{z}_{k*}$ has a limiting distribution this limiting distribution is a spherical distribution.

LEMMA 4.2. *If the distribution of* $W^\phi = X \cos\phi + Y \sin\phi$, *where* $0 \leqq \phi < 2\pi$, *does not depend on* ϕ *(that is,* $W^{\phi_1} \sim W^{\phi_2}$ *for* $\phi_1 \neq \phi_2$*), then* $\mathbf{V} = (X, Y)'$ *has a spherical distribution.*

Proof. For any $\mathbf{t} = (t_1, t_2)' \neq \mathbf{0}$, there is one and only one pair (ρ, ϕ) such that $t_1 = \rho \cos\phi$, $t_2 = \rho \sin\phi$, $\rho > 0$ and $0 \leq \phi < 2\pi$. The characteristic function of $\mathbf{V} = (X, Y)'$ is

$$\begin{aligned} c(\mathbf{t}) &= E[\exp(i(t_1 X + t_2 Y))] \\ &= E[\exp(i\rho(X \cos\phi + Y \sin\phi))] \\ &= E[\exp(i\rho W^\phi)]. \end{aligned}$$

Since W^ϕ's have the same distribution for any ϕ, $c(\mathbf{t})$ depends on $\mathbf{t}$ only through ρ. But $\rho^2 = t_1^2 + t_2^2$, i.e., $\rho = (\mathbf{t}'\mathbf{t})^{1/2}$, and V has a spherical distribution if and only if $c(\mathbf{t})$ depends on $\mathbf{t}$ only through $\mathbf{t}'\mathbf{t}$. This completes the proof.

LEMMA 4.3. *Let* $\mathbf{V}_1 = (X_1, Y_1)'$ *and* $\mathbf{V}_2 = (X_2, Y_2)'$ *be two random vectors, whose first coordinates with respect to rotated axes through an angle* ϕ *are* W_1^ϕ *and* W_2^ϕ, *respectively, where* $0 \leqq \phi < 2\pi$. *We further assume that* $W_1^\phi \sim W_2^\phi$ *for any* ϕ. *Then* $\mathbf{V}_1 \sim \mathbf{V}_2$.

Proof. We denote the characteristic functions of $\mathbf{V}_1$ and $\mathbf{V}_2$ as $c_1(\mathbf{t})$ and $c_2(\mathbf{t})$, respectively. By the uniqueness of the characteristic function, we will complete the proof by showing that $c_1(\mathbf{t}) = c_2(\mathbf{t})$, for any real number pair $\mathbf{t}$. For any $\mathbf{t} = (t_1, t_2)' \neq 0$, there is one and only one pair (ρ, ϕ) such that $t_1 = \rho \cos\phi$, $t_2 = \rho \sin\phi$, $\rho > 0$ and $0 \leq \phi < 2\pi$. We have

$$c_j(\mathbf{t}) = E[\exp(i\rho W_j^\phi)] \quad \text{for } j = 1, 2.$$

But, since $W_1^\phi \sim W_2^\phi$, we therefore have $c_1(\mathbf{t}) = c_2(\mathbf{t})$.

LEMMA 4.4. *For any* $c > 0$, *let* $\tilde{Z} = (X, Y)'$ *be a vector random variable on the unit disk with its probability density function*

$$(c/\pi)(1 - x^2 - y^2)^{c-1}, \qquad 0 \leqq x^2 + y^2 < 1. \tag{4.2}$$

Furthermore, let $\tilde{Z}^\phi$ *be the first coordinate with respect to rotated axes through an angle* ϕ *(i.e.,* $\tilde{Z}^\phi = X \cos\phi + Y \sin\phi$*), where* $0 \leqq \phi < 2\pi$. *Then the c-characteristic function of* $\tilde{Z}^\phi$ *is*

$$g(t; \tilde{Z}^\phi, c) = \left[\frac{2}{1 + (1 + t^2)^{1/2}}\right]^c. \tag{4.3}$$

Proof. Without loss of generality, we need only to prove that (4.3) holds for $\phi = 0$, that is,

$$g(t; X, c) = \left[\frac{2}{1 + (1 + t^2)^{1/2}}\right]^c.$$

The probability density function of X is

$$2\int_0^{(1-x^2)^{1/2}}\left(\frac{c}{\pi}\right)(1-x^2-y^2)^{c-1}\,dy=\left(\frac{c}{\pi}\right)(1-x^2)^{c-1/2}\int_0^1 t^{-1/2}(1-t)^{c-1}\,dt$$

$$=(4\pi)(1-x^2)^{c-1/2}B\left(\frac{1}{2},c\right)$$

$$=(1-x^2)^{c-1/2}\Big/B\left(c+\frac{1}{2},\frac{1}{2}\right),\qquad -1<x<1.$$

The first identity follows by letting $y=t^{1/2}(1-x^2)^{1/2}$. The c-characteristic function of X is

$$g(t;X,c)=\int_{-1}^1\left\{(1-x^2)^{c-1/2}\Big/\left[(1-itx)^c\cdot B\left(c+\frac{1}{2},\frac{1}{2}\right)\right]\right\}dx$$

$$=R_{-c}\left(c+\frac{1}{2},c+\frac{1}{2};1+it,1-it\right)$$

$$=\left[\frac{2}{1+(1+t^2)^{1/2}}\right]^c.$$

The second and third identities can be obtained by using Exercises 5.1-3 and 6.10-12 in Carlson (1977). This completes the proof.

We have the following theorem on limiting distributions of linear combinations of Dirichlet vectors under the regularity conditions.

THEOREM 4.5. *Under the regularity conditions, the sequence of the random quantities* $\sum_{j=1}^k u_{kj}z_{kj}$, *where* $\mathbf{u}_{k*}\sim D(\mathbf{b}_{k*})$, *converges in distribution to a spherical distribution having probability density function* (4.2).

Proof. By Lemma 4.1, Lemma 4.4 and Theorem 3.5, the sequence of the distributions of the real part of $\sum_{j=1}^k u_{kj}z_{kj}$ converges in distribution to the marginal distribution of a distribution having probability density function (4.2). By Lemma 4.1 and Lemma 4.2, the limiting distribution has a spherical distribution. Lord (1954) shows that a spherical distribution is determined by its marginal distribution. This completes the proof.

An alternative proof is given directly by Lemma 4.1, Lemma 4.4, Theorem 3.5 and Lemma 4.3.

COROLLARY 4.6. *Assume the regularity conditions hold and denote* $V_c=\lim_{k\to\infty}\sum_{j=1}^k u_{kj}z_{kj}$, *where* $c=b_{k\cdot}$. *Then*

(a) V_1 *follows a uniform distribution on the unit disk with center* $(0,0)$.

(b) V_2 *follows the circularly symmetric distribution on the unit disk with probability density function*

$$f(x,y)=(2/\pi)(1-r^2),\qquad 0\leqq r<1,$$

where $r^2=x^2+y^2$.

(c) *Consider the limits in distributions,*

$$\lim_{c\to 0}V_c=U,\qquad \lim_{c\to\infty}V_c=V.$$

Then U has a uniform distribution on the unit circle and V has a point mass on the origin $(0,0)$.

COROLLARY 4.7. *If we have, for all k,*

$$b_{kj}=1/k,\qquad 1\leqq j\leqq k\qquad \text{so } b_{k\cdot}\equiv 1, \tag{4.4}$$

and $z_{k1}, z_{k2}, \cdots, z_{kk}$ are the kth roots of unity, then the limiting distribution of $\sum_{j=1}^{k} u_{kj} z_{kj}$, where $\mathbf{u}_{k*} \sim D(\mathbf{b}_{k*})$, will be a uniform distribution on the unit disk with its center at the origin.

Define the probability measure $\upsilon(v)$ on the unit disk by

$$d\upsilon(v) = (2/\pi)(1 - x_1^2 - x_2^2)\, dx_1\, dx_2$$

where $v = x_1 + ix_2$. By (2.7), Corollary 4.6(b) and the regularity conditions, we have the following theorem.

THEOREM 4.8. *The starlike function with representation* (2.1) *with uniform measure ν can be expressed by*

$$\zeta \cdot \int_{\Omega} (1 + v\zeta)^{-2}\, d\vartheta(v). \tag{4.5}$$

The more general starlike functions with representation (2.1) in terms of a more general measure ν would seem to be amenable to study through the Dirichlet random process, a random set function parameterized by a general probability measure (Ferguson (1973)).

Acknowledgments. I am deeply grateful to my adviser, James M. Dickey, for suggesting the problem and providing stimulating advice, encouragement, and helpful comments. I would also like to thank Louis Brickman and Benton Jamison for their help, and a referee for very helpful comments that led to considerable improvement of this paper.

ON THE REDUCTION OF CONNECTION PROBLEMS FOR DIFFERENTIAL EQUATIONS WITH AN IRREGULAR SINGULAR POINT TO ONES WITH ONLY REGULAR SINGULARITIES, II*

W. BALSER†, W. B. JURKAT‡, AND D. A. LUTZ§

Abstract. Our purpose is to investigate lateral and central connection problems for systems of linear differential equations near an irregular singularity. In Part I [SIAM J. Math. Anal., 12 (1981), pp. 691–721] we showed how the lateral connection problem can be solved using some associated functions constructed from a formal fundamental solution. Here, we generalize the associated functions by introducing a complex parameter and show how certain values of these functions can be used to construct solutions in so-called Floquet form. We also show how the coefficients of the formal series can be asymptotically represented using other associated functions and how the central connection problems for the Floquet solution can be solved. We conclude with an application of the main results to the global solution of a rationalized form of Mathieu's equation that has two irregular singularities.

Key words. connection problems, irregular singularity, Floquet solutions

AMS(MOS) subject classifications. 34A20, 34C20

Introduction. We consider systems of linear differential equations of the form

$$x' = A(z)x = \left(\sum_0^\infty A_p z^{-p}\right)x, \tag{0.1}$$

where x is an n-dimensional column vector, the leading coefficient matrix A_0 has all distinct eigenvalues $\lambda_1, \cdots, \lambda_n$, and the power series converges for $|z| > a \geqq 0$. We will refer to these later on as our *basic assumptions.*

The classical theory of differential equations near an irregular singularity (see [4] or [18]) asserts that there exist *formal* fundamental solutions and two types of actual solutions that we term normal solutions and solutions in *Floquet form.* The global solution of (0.1) involves determining how the normal solutions are related to each other (lateral connection problem) and how the normal solutions are related to solutions in Floquet form (central connection problem). Our purpose here is to show how these connection problems can be solved with the aid of some *associated functions* that are constructed using the formal solutions.

Of these types of solutions, the formal ones are by far the easiest to construct (in general). There exist, as is well known, formal fundamental solutions of the form

$$H(z) = F(z)z^{\Lambda'} e^{\Lambda z}, \qquad F(z) = \sum_0^\infty F_p z^{-p}, \tag{0.2}$$

where $\Lambda = \operatorname{diag}\{\lambda_1, \cdots, \lambda_n\}$, F_0 is any invertible matrix satisfying $F_0^{-1}A_0F_0 = \Lambda$, $\Lambda' = \operatorname{diag}\{F_0^{-1}A_1F_0\} \equiv \operatorname{diag}\{\lambda_1', \cdots, \lambda_n'\}$, the coefficients F_p are uniquely determined for $p \geqq 1$ (once F_0 is selected), and they can be calculated in a straightforward, recursive manner using only arithmetical operations. In what follows, we will assume that such a (fixed) formal fundamental solution has been constructed and we will base our subsequent discussion and calculations on it.

Next, using the classical asymptotic existence theorem, one can show that there is a family of actual solutions $\{X_\nu(z)\}$ (which we call normal solutions) and a covering of the Riemann surface of $\log z$, $|z|>a$, by sectorial regions $\{S_\nu\}$ (which are slightly larger than half-planes) such that $X_\nu(z)\cong H(z)$ as $z\to\infty$, $z\in S_\nu$, for every integer ν, and the $X_\nu(z)$ are even uniquely determined (individually) by this condition. (In Part I of this paper, reference [1], we showed how normal solutions can be constructed either using Laplace transforms of the associated functions or by summing the formal series as a factorial series.)

Finally, a well-known classical result (analogous to Floquet's theorem for differential equations with periodic coefficients) asserts that every fundamental solution $X(z)$ may be expressed in the form

$$X(z)=L(z)z^M, \tag{0.3}$$

where $L(z)=\sum_{-\infty}^{+\infty} L_p z^p$ is single-valued and analytic in $a<|z|<\infty$, and the constant matrix M is called a *monodromy matrix.* We say that such a solution is expressed in *Floquet form.*

In light of these facts, it is natural to consider the following *connection problems,* which explain the global behavior of solutions:

(i) Given two consecutive normal solutions, determine the constant matrices V_ν (called the *Stokes' multipliers*) that satisfy

$$X_{\nu-1}(z)=X_\nu(z)V_\nu.$$

(ii) Given a solution $X(z)$ in Floquet form, determine its asymptotic as $z\to\infty$, $z\in S_\nu$, i.e., find the *central connection factors* Ω_ν defined by

$$X(z)=X_\nu(z)\Omega_\nu.$$

(iii) Given a fundamental solution matrix with a known asymptotic near ∞, say one of the normal solutions, express it in Floquet form, i.e., determine a monodromy matrix and the corresponding Laurent coefficients.

Using the fact that the normal solutions (and hence the Stokes' multipliers are uniquely determined by the selected $H(z)$, one can conclude that there should exist relations (at least in an abstract sense) between the quantities in $H(z)$ and the Stokes' multipliers. Likewise, since a selected actual solution (say in Floquet form) and $H(z)$ uniquely determine the central connection factors, there ought to exist relations between these quantities as well. Our objective is to construct some concrete relations of these types; more specifically, our main results concern representation formulas for the formal and Laurent coefficients, which can be applied to solve the connection problems.

The derivation of these results depends upon developing and applying properties of some generalizations of the associated functions we have considered in [1]. They not only interpolate the coefficients in the formal series, but are also a natural and convenient way of assembling the information present in the formal solution that is relevant for our problems. The particular associated functions we construct now also involve a complex parameter s, corresponding to the "shifted" equations

$$x_s'=(A(z)-sz^{-1}I)x_s$$

that are obtained from (0.1) by the transformation $x=x_s z^s$. In addition to studying their analytic properties and connection phenomena in the variable t, we also require their analytic and asymptotic properties with respect to s.

Aside from this direct role that the parameter plays in our results, it also has a more indirect, unifying role through the discussion of a nonstandard type of difference

equation which the associated functions satisfy and whose appearance we motivate as follows.

For the often-studied case of the "two-term" differential equation

$$x' = (A_0 + A_1 z^{-1})x, \tag{0.4}$$

one constructs the corresponding system of linear difference equations (in the variable s and parameter t)

$$s\xi(s+1, t) + t\xi(s, t) = A_0\xi(s, t) + A_1\xi(s+1, t), \tag{0.5}$$

which has central importance because both the columns of the coefficients F_p in the formal series as well as the columns of the Laurent coefficients L_p (in case A_1 has incongruent (mod 1) eigenvalues) are special solutions for appropriate values of s and t. For example, for a suitable solution ξ of (0.5), $\xi(\lambda_k' - p + 1, \lambda_k) = f_k(p)$, the kth column of F_p, while (for a generally different ξ) $\xi(\mu_j + p + 1, 0) = l_j(p)$, the jth column of L_p (when $\mu_1, \cdots, \mu_n$ are the eigenvalue of A_1 and $M = \operatorname{diag}\{\mu_1, \cdots, \mu_n\}$). Using this correspondence, Okubo [15] and Kohno [14] have derived relationships between the coefficients of the formal series, the Laurent coefficients, and the central connection factors. (See also Hopf [8] and Knobloch [12].) R. Schäfke [17] has also considered connection problems for (0.4) and has derived relations which involve both the lateral and central connection problems. Some of our results may be thought of as extensions of these to the "general" case (0.1). Our methods are closer to Schäfke's than Okubo and Kohno's, which rely much more heavily on the interplay with the difference equation.

For a "general" equation (0.1), one can also analogously consider the "difference equation" (in the variable s and parameter t)

$$s\xi(s+1, t) + t\xi(s, t) = \sum_0^\infty A_\nu \xi(s+\nu, t). \tag{0.6}$$

Even in this case it is easy to see that both $f_k(p)$ and $l_j(p)$ are (at least in a formal sense) solutions of (0.6). While the vectors $f_k(p)$ can still be recursively calculated from (0.6) (note that the series on the right-hand side terminates because $f_k(p) = 0$ for $p < 0$), the same is not true for the coefficients $l_j(p)$ of the Laurent series. This happens because, in general, the Laurent series is a doubly infinite series and one is led to an infinite system of coupled linear equations for which no procedure to recursively calculate the terms is known. Von Koch [13] has applied the theory of infinite determinants to the study of these equations, leading to an approximation of a Floquet-type solution, but his method appears to differ substantially from the approach we take to construct Floquet solutions. (On the other hand, our approach is restricted to equations with a pole type singularity, while the procedure of von Koch applies, in principle, to cases where $A(z) = \sum_{-\infty}^{\infty} A_p z^{-p}$.)

Analogous to the case of (0.5), we call (0.6) a *difference equation of modified first order.* In contrast to (0.5) where the asymptotic theory of linear difference equations applies, it is somewhat surprising that certain explicit solutions of (0.6) can be constructed that have a known asymptotic, both as $\operatorname{Re} s \to +\infty$ (Proposition 4) and $\operatorname{Re} s \to -\infty$ (Proposition 5). In fact, the connection problems we consider can all be rephrased in terms of connection problems for particular solutions of (0.6). But the difference equation plays a more indirect role in our development because it may have many other solutions than the ones we consider, which seem to have no relevance to the differential equation. One reason behind the fact that we can construct particular solutions to (0.6) and discuss their complete analytic and asymptotic behavior is that

there exists a Birkhoff reduction (see, e.g., [1] for the definition) taking (0.1) into some equation of the form (0.4) (but not with the same A_0 and A_1). The Birkhoff transformation can be carried over to relate certain solutions of (0.6) and corresponding ones of (0.5). But solutions of (0.6) that grow too rapidly (as $\operatorname{Re} s \to +\infty$) cannot be thus transformed and one can see that only a certain n-dimensional subspace of solutions of (0.6) can actually correspond to solutions of (0.5).

As a final remark, we wish to alert the reader to the following situation: The values of the analytic continuations of the associated functions and the constants entering their connection relations play a key role in our calculations. Since the associated functions have, in general, branch points at $\lambda_1, \cdots, \lambda_n$, it is necessary before making their continuations to cut the plane near these points and specify a value for $\arg(t-\lambda_k)$ for t close to λ_k. The values are then strongly dependent on which system of cuts is used. For each particular application, we choose a system of cuts that most easily allows the quantities entering the relations to be identified as, for example, certain Stokes' multipliers or central connection factors. Thus in §§ 2–5 we use one type of cuts for the lateral connection problem, whereas in §§ 6 and 7 we use another type for the central connection problem. Both of these differ from the systems of cuts we used in [1], which were particularly convenient for integral representations.

1. Some relations between the connection matrices. Throughout this paper we consider a fixed, but arbitrary, differential equation (0.1) satisfying our basic assumptions in the Introduction. We also make a fixed, but arbitrary, selection of an enumeration of the eigenvalues $\lambda_1, \cdots, \lambda_n$ of A_0 and consider any fixed formal fundamental solution matrix $H(z)$ of the form (0.2). Such an $H(z)$ always exists and is unique up to a constant invertible diagonal right-hand factor D. The freedom in the choice of $H(z)$ corresponds exactly to the choice of F_0.

Letting $\{X_\nu(z)\}$ denote the normal solutions corresponding to $H(z)$ and (V_ν), the associated Stokes' multipliers, one sees that the *circuit factor* $e^{2\pi i M_\nu}$ for $X_\nu(z)$ (defined by $X_\nu(z\,e^{2\pi i}) = X_\nu(z)\,e^{2\pi i M_\nu}$) is given by

$$e^{2\pi i M_\nu} = e^{2\pi i \Lambda'} V_{\nu+m} \cdots V_{\nu+1} \tag{1.1}$$

(compare [3, Part II, Prop. 4]).

Remark 1.1. If we fix an arbitrary system $\mathcal{R}$ of representatives modulo one for the complex numbers, then there always exists a matrix M_ν having its eigenvalues in $\mathcal{R}$, such that (1.1) holds, and in fact M_ν is unique (to see the uniqueness, one can use a proposition in [10, p. 38]). From $V_{\nu+m} = e^{-2\pi i \Lambda'} V_\nu\, e^{2\pi i \Lambda'}$ [10] we conclude

$$e^{2\pi i M_\nu} = V_\nu\, e^{2\pi i M_{\nu-1}} V_\nu^{-1},$$

i.e., a possible choice for $M_{\nu-1}$ having eigenvalues in $\mathcal{R}$ is $V_\nu^{-1} M_\nu V_\nu$, and from the uniqueness stated above we conclude that

$$M_{\nu-1} = V_\nu^{-1} M_\nu V_\nu \quad \text{for every } \nu. \tag{1.2}$$

According to (1.2), the Jordan canonical form of M_ν is independent of ν and may be denoted by M. Then M is unique, if we choose it to be upper triangular and assume its blocks ordered according to some arbitrarily fixed rule (see [10], p. 34). If we replace $H(z)$ by $H(z)\,D$ (with D as above), then V_ν resp. M_ν are replaced by $D^{-1} V_\nu D$ resp. $D^{-1} M_\nu D$; hence, M is even independent of the choice of $H(z)$ and therefore *corresponds uniquely to the differential equation* (0.1).

According to the above construction, there exists a fundamental solution matrix $X(z)$ for (0.1) having M as a monodromy matrix, i.e.,

$$L(z) = X(z) z^{-M} \tag{1.3}$$

is single-valued and analytic in $|z|>a$. Such a fundamental solution is determined up to a constant, invertible, right-hand factor C that commutes with M (using again the proposition in [10, p. 38] or Lemma 1 of [3, Part I]). For each such $X(z)$, there exists (for every integer ν) a constant invertible matrix Ω_ν called the νth central connection factor of $X(z)$ such that

$$X(z)=X_\nu(z)\Omega_\nu, \qquad |z|>a. \tag{1.4}$$

(If $X(z)$ is replaced by $X(z)C$ with C as above, the Ω_ν is to be replaced by $\Omega_\nu C$.)

Remark 1.2. It follows immediately from the preceding discussion that the knowledge of the matrices

$$e^{2\pi i\Lambda'}, V_{\nu+1}, \cdots, V_{\nu+m}$$

for any fixed, but arbitrary, ν determines a solution $X(z)$ in Floquet form and its central connection factors up to within their natural degree of freedom. To see this, let M_ν denote the unique matrix satisfying (1.1) (with its eigenvalues coming from $\mathcal{R}$). If ν_0 is an arbitrarily fixed integer and Ω_{ν_0} is any invertible matrix satisfying

$$M=\Omega_{\nu_0}^{-1}M_{\nu_0}\Omega_{\nu_0},$$

define

$$X(z)=X_{\nu_0}(z)\Omega_{\nu_0}, \qquad |z|>a.$$

Then (1.4) determines the matrices Ω_ν for every integer ν, and it is clear from the definition of V_ν that

$$\Omega_\nu = V_\nu\Omega_{\nu-1} \tag{1.5}$$

for every integer ν. From the definition of M we find that $L(z)=X(z)z^{-M}$ is single-valued and analytic in $|z|>a$; hence, it has a Laurent expansion. We shall show later (in §§ 6 and 7) how the Laurent coefficients may be calculated using generalizations of the associated functions considered in [1].

Since M is selected in some particular Jordan form with its eigenvalues from a fixed system of representatives modulo one, then Ω_ν satisfying

$$e^{2\pi iM}=\Omega_\nu^{-1}\,e^{2\pi iM_\nu}\Omega_\nu$$

is determined up to a right-hand invertible factor that commutes with $e^{2\pi iM}$ (i.e. with M). This corresponds exactly to the freedom in the choice of a fundamental solution $X(z)$ for which $X(z)z^{-M}$ is single-valued.

It is clear from (1.4) and the definition of V_ν that the knowledge of two consecutive central connection factors determines a Stokes' multiplier. We now show that any *one* central connection factor Ω_ν together with the knowledge of the circuit factor $e^{2\pi iM}$ determine *all* the Stokes' multipliers and consequently *all* the other Ω_l.

PROPOSITION 1. *Consider a fixed, but arbitrary, differential equation* (0.1) *satisfying our basic assumptions and any selected formal fundamental solution matrix* $H(z)$ *as above. Let* $X(z)$ *denote an arbitrary fundamental solution matrix of* (0.1) *and assume that the circuit factor* $e^{2\pi iM}$ (*with* M *not necessarily in canonical form*) *is known along with one central connection factor* Ω_ν *for any fixed, but arbitrary integer* ν. *Then the formal circuit factor* $e^{2\pi i\Lambda'}$ *and all the normalized Stokes' multipliers* V_l, $-\infty<l<+\infty$, *can be explicitly computed*; *hence, all the remaining central connection factors* Ω_l *can be explicitly computed* (*without using the differential equation*).

Proof. Using (1.4) with $z=z_0$ and $z=z_0\,e^{2\pi i}$ we obtain

$$\Omega_\nu\,e^{2\pi iM}\Omega_\nu^{-1}=e^{2\pi iM_\nu}=e^{2\pi i\Lambda'}V_{\nu+m}\cdots V_{\nu+1}. \tag{1.6}$$

For convenience in this argument, we may assume that $\lambda_1, \cdots, \lambda_n$ are enumerated so that (with $\mu = m/2$) the matrices $V_{\nu+m}, \cdots, V_{\nu+\mu+1}$ are all upper triangular while $V_{\nu+\mu}, \cdots, V_{\nu+1}$ are all lower triangular (cf. [1, § 3]). Then

$$U = V_{\nu+m} \cdots V_{\nu+\mu+1}, \quad \text{resp. } L = V_{\nu+\mu} \cdots V_{\nu+1},$$

are also upper, resp. lower, triangular matrices and both have all ones on the diagonal (since all the V_l have ones on the diagonal), hence (1.6) shows that $\Omega_\nu e^{2\pi i M} \Omega_\nu^{-1}$ can be factored as $e^{2\pi i \Lambda'} UL$. Whenever such a factorization is possible, it can easily be shown that the factors are unique since the diagonals of U and L are prescribed. Moreover, the factors $e^{2\pi i \Lambda'}$, U and L can be explicitly calculated using only arithmetical operations (see [6, p. 33] for the explicit formulas). From U and L, all the components $V_{\nu+m}, \cdots, V_{\nu+1}$ can be uniquely calculated (see [10, p. 80]) and using

$$V_{l+m} = e^{-2\pi i \Lambda'} V_l e^{2\pi i \Lambda'} \tag{1.7}$$

for every integer l, we obtain the complete collection of Stokes' multipliers and consequently all the other Ω_l from (1.5).

Remark 1.3. As mentioned in the Introduction, for a differential equation (0.4) one can always calculate a Floquet solution in a straightforward manner since 0 is a singularity of the first kind. In such a case the central connection problem is reduced to the calculation of a corresponding matrix Ω_ν for any fixed integer ν. Proposition 1 then tells us that all the lateral connection matrices and all the other central connection matrices can be explicitly calculated with arithmetical operations.

Suppose that a fixed solution $X(z) = L(z) z^M$ in Floquet form is known, say with M in a particular Jordan canonical form and whose eigenvalues come from a fixed system of representatives. If we also know one of the matrices M_ν (for some fixed integer ν), then (1.6) was seen to determine Ω_ν up to a right-hand invertible factor that commutes with M, and the computation of Ω_ν modulo this freedom is an algebraic problem. Moreover, as a consequence of Abel's formula

$$z^{\operatorname{tr} M} \det L(z) = c\, e^{z \operatorname{tr} A_0} z^{\operatorname{tr} \Lambda'} \exp\left[-\sum_2^\infty \operatorname{tr} A_\nu \frac{z^{-\nu+1}}{\nu - 1} \right], \tag{1.8}$$

(with a nonzero constant c) we now show that $\det \Omega_\nu$ is also determined.

PROPOSITION 2. *Consider a fixed, but arbitrary, differential equation* (0.1), *a selected formal fundamental solution* $H(z)$ *as above, and a given solution* $X(z) = L(z) z^M$. *If* Ω_ν *satisfies* (1.4), *then*

$$z^{\operatorname{tr} M} \det L(z) = \det F_0 \det \Omega_\nu z^{\operatorname{tr} \Lambda'} e^{z \operatorname{tr} A_0} \exp\left[-\sum_2^\infty \operatorname{tr} A_\nu \frac{z^{-\nu+1}}{\nu - 1} \right].$$

Proof. From (0.3) we have

$$\det X(z) = \det X_\nu(z) \det \Omega_\nu, \quad z \in S_\nu,$$

while from Abel's formula (1.8) we find (for a suitable constant $c_\nu \neq 0$)

$$\det X_\nu(z) = c_\nu\, e^{z \operatorname{tr} A_0} z^{\operatorname{tr} \Lambda'} \exp\left[-\sum_2^\infty \operatorname{tr} A_\nu \frac{z^{-\nu+1}}{\nu^{-1}} \right]. \tag{1.9}$$

Hence $c = c_\nu \det \Omega_\nu$. To evaluate the constants, first note that

$$\det X_\nu(z) \cong z^{\operatorname{tr} \Lambda'} e^{\operatorname{tr} \Lambda z} \det F(z) \quad \text{as } z \to \infty \text{ in } S_\nu;$$

hence observing $\operatorname{tr} A_0 = \operatorname{tr} \Lambda$ we obtain

$$c_\nu = \det F_0 \quad \text{for all } \nu.$$

This completes the proof.

Remark 1.4. In the special case that $A(z) = \Lambda + A_1 z^{-1}$ and A_1 has incongruent (but possibly equal) eigenvalues μ_i, $1 \leqq i \leqq n$ (modulo one), then M may either be selected to be equal to A_1 or to a particular Jordan canonical form of A_1. In both cases

$$L(z) = \sum_0^\infty L_p z^p$$

with L_0 invertible. In case $M = A_1$ a natural selection for L_0 is I while if M is a particular Jordan canonical form we could select L_0 to consist of certain eigenvectors and generalized eigenvectors of A_1 having determinant also equal to one. Then using

$$\operatorname{tr} M = \sum_1^n \mu_i = \sum_1^n \lambda_j'$$

and letting $z \to 0$ as in the statement of Proposition 2 we obtain

$$1 = \det L_0 = \det F_0 \det \Omega_\nu \quad \text{for all } \nu.$$

If we also select $\det F_0 = 1$, then

$$\det \Omega_\nu = 1 \quad \text{for all } \nu.$$

From the fact that the matrices $e^{2\pi i M}$ and $e^{2\pi i \Lambda'} V_{\nu+m} \cdots V_{\nu+1}$ are similar, one can derive some other interesting relations which explain in a certain quantitative sense how the presence of nontrivial Stokes' multipliers accounts for the difference between the *formal circuit factor* $e^{2\pi i \Lambda'}$ and an *actual circuit factor* $e^{2\pi i M}$. To see this, observe that because of the similarity,

$$\sigma_k(e^{2\pi i M}) = \sigma_k(e^{2\pi i \Lambda'} V_{\nu+m} \cdots V_{\nu+1}), \tag{1.10}$$

where σ_k denotes the kth symmetric function of the matrix (i.e. $\pm$ kth coefficient in the characteristic polynomial). For $k = n$ this gives the obvious relation $\det(e^{2\pi i M}) = \det(e^{2\pi i \Lambda'} V_{\nu+m} \cdots V_{\nu+1})$, which implies

$$\sum_1^n \mu_i \equiv \sum_1^n \lambda_j' \pmod 1,$$

but for $1 \leqq k \leqq n-1$ the equations contain some deeper and more interesting information. For example, in the case of a "two-term" differential equation (0.4), recall that if A_1 has all incongruent (but possibly equal) eigenvalues (modulo one), then a choice for M is A_1 itself. Hence (1.10) can be written as

$$\sigma_k(e^{2\pi i A_1}) = \sigma_k(e^{2\pi i \Lambda'} V_{\nu+m} \cdots V_{\nu+1}), \qquad k = 1, 2, \cdots, n. \tag{1.11}$$

Even if A_1 has congruent eigenvalues modulo one, we claim that (1.11) still holds by analytic perturbation because the quantities on both sides of the equation are analytic functions of the entries of A_1 (when A_0, F_0 and the diagonal Λ' are fixed and the off-diagonal elements of A_1 are allowed to vary) and in this way one can always arrange for A_1 to have incongruent eigenvalues.

In the special case of (1.10) when $n=2$ and $k=1$, one can rewrite the equation by introducing an auxiliary parameter

$$\mu=\mu_1-\frac{\lambda_1'+\lambda_2'}{2}, \qquad -\mu=\mu_2-\frac{\lambda_1'+\lambda_2'}{2}$$

(where we use that $\mu_1+\mu_2=\lambda_1'+\lambda_2'$), and letting

$$V_2=\begin{bmatrix}1 & c_2\\ 0 & 1\end{bmatrix}, \qquad V_1=\begin{bmatrix}1 & 0\\ c_1 & 1\end{bmatrix}$$

(here we assume that λ_1 and λ_2 are ordered lexicographically). Then a short calculation shows that

$$2\cos 2\pi\mu=2\cos\pi(\lambda_2'-\lambda_1')+c_1c_2\,e^{\pi i(\lambda_1'-\lambda_2')}, \tag{1.12}$$

and using the explicit expressions for c_1, c_2 in terms of some invariants γ, γ' that are related to the asymptotic of the coefficients in the formal series (see [10, p. 182]), we see that (1.12) can be expressed as

$$\cos 2\pi\mu=\cos\pi(\lambda_2'-\lambda_2')-2\pi^2\gamma\gamma'. \tag{1.13}$$

This equation, which played a key role in the inverse (matching) problem of constructing a two-term equation with prescribed invariants (see [11, § 7]), was called for obvious reasons the "cosine equation." Thus the equations (1.11) are natural generalizations of this equation for larger-dimensional systems of differential equations.

2. Asymptotic behavior of the coefficients in a formal solution. In this section we consider a fixed, but arbitrary, differential equation (0.1) that satisfies our basic assumptions and a fixed, but arbitrary, formal fundamental solution matrix $H(z)$ of the form (0.2). We also assume that a scalar shift $x=z^\gamma\hat{x}$ has been made with an appropriate (real or complex) number γ so that

$$\Lambda'=\operatorname{diag}\{F_0^{-1}A_1F_0\}=\operatorname{diag}\{\lambda_1',\cdots,\lambda_n'\}$$

has the property that (for each $j=1,2,\cdots,n$) λ_j' is not an integer and $\operatorname{Re}\lambda_j'<0$.

Recall from [1, p. 693] that for each integer k, $1\leqq k\leqq n$, associated functions $y_k(t)$ were constructed as

$$y_k(t)=\sum_{p=0}^{\infty} f_k(p)\Gamma(\lambda_k'+1-p)(t-\lambda_k)^{p-\lambda_k'-1},$$

where $f_k(p)$ denotes the kth column of F_p and the series converges for $|t-\lambda_k|$ sufficiently small. Since for each natural number p the function

$$(t-\lambda_k)^{\lambda_k'-p}y_k(t)$$

is single-valued and analytic in a small deleted neighborhood of λ_k, we obtain (integrating in the positive direction and for $\varepsilon>0$ sufficiently small) from Cauchy's theorem

$$f_k(p)\Gamma(\lambda_k'+1-p)=\frac{1}{2\pi i}\oint_{|t-\lambda_k|=\varepsilon}(t-\lambda_k)^{\lambda_k'-p}y_k(t)\,dt. \tag{2.1}$$

To determine the explicit asymptotic behavior of the integral as $p\to+\infty$, we require knowledge of the function $y_k(t)$ away from the point λ_k. Since (see [1, § 4.2]) $y_k(t)$ is analytic everywhere in the finite complex t-plane, except for possible branch points at λ_j, $1\leqq j\leqq n$, in order to have a definite means for the analytic continuation of $y_k(t)$ outside of $|t-\lambda_k|<\varepsilon$ we will cut the plane at each of these points along rays in certain

directions extending to ∞. Such a direction η is called admissible (with respect to λ_j) if the cut $\arg(t-\lambda_j)=\eta$ contains no point λ_l, $l\neq j$. It is also natural to make the cuts nonintersecting so that all points are accessible without having to cross any of the cuts.

One method of making cuts that was convenient for the purposes in [1] is to make all the cuts have the same direction; we spoke of these as "parallel cuts." For our present purposes it is natural to make the following "star-shaped" systems of cuts:

Let k be a fixed, but arbitrary integer, $1\leqq k\leqq n$, and let η be any fixed, admissible direction (with respect to λ_k). Then we make a cut from λ_k to ∞ along $\arg(t-\lambda_k)=\eta$, and from each point λ_j we cut along

$$\arg(t-\lambda_j)=\eta_{jk}=\arg(\lambda_j-\lambda_k)\in(\eta-2\pi,\eta),\qquad j\neq k,\quad 1\leqq j\leqq n,$$

if η_{jk} is admissible with respect to λ_j, i.e., if no other λ_l lies on $\arg(t-\lambda_j)=\eta_{jk}$; otherwise, turn the cut slightly to the right so that it becomes admissible with respect to λ_j. Along the right border of each cut (looking toward ∞) we select

$$\arg(t-\lambda_j)=\eta_{jk}-0,\quad \text{resp., } \arg(t-\lambda_k)=\eta-0$$

and we use this choice of the argument in identifying the branch of $\log(t-\lambda_j)$, resp., $\log(t-\lambda_k)$, to be used in defining nonintegral powers of $(t-\lambda_j)$, resp., $(t-\lambda_k)$. We denote the complex t-plane with this system of cuts and choices of the arguments by $\mathcal{P}_{k,\eta}$.

It is easy to check that the proof of Theorem 1 in [1, § 4.2] extends to $\mathcal{P}_{k,\eta}$; hence, the associated function $y_k(t)=y_k(t;\eta)$ can be analytically continued to all of $\mathcal{P}_{k,\eta}$ and there exist constants $c_{jk}=c_{jk}(\eta)$ such that

$$y_k(t)=c_{jk}y_j(t)+\operatorname{reg}(t-\lambda_j),\qquad t\in\mathcal{P}_{k,\eta},\tag{2.2}$$

where $y_j(t)=y_j(t;\eta_{jk})$ is the analytic continuation (in $\mathcal{P}_{k,\eta}$) of the function defined near λ_j by the convergent series with the meaning for the nonintegral power as above. Note that these functions and constants depend upon the choice of the cuts, but to simplify the notation we do not specifically display that dependence. (These functions and constants also generally differ from the analogous quantities treated in [1] in the case of parallel cuts but for which we use the same notation.)

In order to show how the constants c_{jk} are related to certain Stokes' multipliers, we recall from Theorem 2 of [1, pp. 714–715] that for any fixed integer ν and any α between the critical rays $\eta_{\nu+1}$ and η_ν (see [1, § 3.1] for the definition of critical rays) we have

$$x_{\nu,j}(z)=\frac{1}{2\pi i}\int_{\gamma_j(\alpha)}e^{zt}y_j(t)\,dt,\qquad z\in\mathcal{S}(\alpha),\quad 1\leqq j\leqq n,$$

where

$$\mathcal{S}(\alpha)=\left\{\operatorname{Re}(z\,e^{i\alpha})<-a;\ \frac{\pi}{2}-\alpha<\arg z<\frac{3\pi}{2}-\alpha\right\},$$

and $\gamma_j(\alpha)$ denotes the loop encircling the ray $\arg(t-\lambda_j)=\alpha$ in the positive direction and such that no λ_l, $l\neq j$, is contained on or inside this loop. We also take $\arg(t-\lambda_j)\in(\alpha-2\pi,\alpha)$ for t on this loop. Since we are assuming $\operatorname{Re}\lambda_j'<0$, we may deform this loop integral into a ray integral as

$$x_{\nu,j}(z)=\frac{1-e^{2\pi i\lambda_j'}}{2\pi i}\int_{\lambda_j}^{\infty(\alpha)}e^{zt}y_j(t)\,dt,\qquad z\in\mathcal{S}(\alpha),\quad 1\leqq j\leqq n,\tag{2.3}$$

if we integrate along $\arg(t-\lambda_j)=\alpha$ and define $y_j(t)$ consistent with this selection of $\arg(t-\lambda_j)$.

Now let ν denote any fixed, but arbitrary, integer satisfying $\eta - 2\pi < \eta_\nu < \eta$ and let α, $\tilde{\alpha}$ be selected close to each other and satisfy

$$\eta_{\nu+1} < \alpha < \eta_\nu < \tilde{\alpha} < \eta_{\nu-1}.$$

Then from (2.3) we have for $z \in \mathcal{S}(\alpha) \cap \mathcal{S}(\tilde{\alpha}) \subset S(\tau_\nu - \pi, \tau_\nu)$

$$x_{\nu-1,k}(z) - x_{\nu,k}(z) = \frac{1 - e^{2\pi i \lambda_k'}}{2\pi i} \left\{ \int_{\lambda_k}^{\infty(\alpha)} - \int_{\lambda_k}^{\infty(\tilde{\alpha})} \right\} e^{zt} y_k(t)\, dt$$

and the selection of the branch of $y_k(t)$ in the integrals coincides with the selection in $\mathcal{P}_{k,\eta}$, provided we take α and $\tilde{\alpha}$ sufficiently close to η_ν (note that if for several $j \neq k$ we have $\arg(\lambda_j - \lambda_k) = \eta_\nu$, then without loss of generality we may assume that the cuts from those λ_j to ∞ do not intersect with the ray $\arg(t - \lambda_k) = \alpha$). It is easily seen from the definition of critical rays that those indices $j \neq k$ satisfying $\eta_\nu = \eta_{jk}$ are precisely the ones for which λ_j lies on $\arg(t - \lambda_k) = \eta_{jk}$. From the definition of the position set ρ_ν (see [1, § 3.1]) we conclude that this happens iff $(j, k) \in \rho_\nu$. For all these j the cuts from λ_j to ∞ have the same direction $\eta_\nu - \varphi = \alpha$, and with the help of Cauchy's theorem we conclude (using (2.2)) (for k as above)

$$\begin{aligned} x_{\nu-1,k}(z) - x_{\nu,k}(z) &= \frac{e^{2\pi i \lambda_k'} - 1}{2\pi i} \sum_{\substack{j \\ (j,k) \in \rho_\nu}} \int_{\gamma_j(\alpha)} e^{zt} y_k(t)\, dt \\ &= (e^{2\pi i \lambda_k'} - 1) \sum_{\substack{j \\ (j,k) \in \rho_\nu}} c_{jk} \frac{1}{2\pi i} \int_{\gamma_j(\alpha)} e^{zt} y_j(t)\, dt \\ &= (e^{2\pi i \lambda_k'} - 1) \sum_{\substack{j \\ (j,k) \in \rho_\nu}} c_{jk} x_{\nu,j}(z). \end{aligned}$$

Comparing this to $X_{\nu-1}(z) = X_\nu(z) V_\nu$, we find that for every j with $(j, k) \in \rho_\nu$ the constant $(e^{2\pi i \lambda_k'} - 1) c_{jk}$ coincides with the element of V_ν in the (j, k) position. We denote this element by v_{jk} (note that in a sense, this does not depend upon ν as long as we restrict to such ν with $\eta - 2\pi < \eta_\nu < \eta$, since then to every $j \neq k$ there exists exactly one such ν for which $(j, k) \in \rho_\nu$), and we then have for every fixed k, $1 \leqq k \leqq n$,

$$c_{jk} = (e^{2\pi i \lambda_k'} - 1)^{-1} v_{jk}, \qquad j \neq k, \quad 1 \leqq j \leqq n. \tag{2.4}$$

Now consider loops in $\mathcal{P}_{k,\eta}$ which we denote by $l_j(R)$ $(1 \leqq j \leqq n, j \neq k)$, and which have the following properties.

The loop $l_j(R)$ (for sufficiently large $R > 0$) extends from the point on the left border of the cut from λ_j to ∞ (looking towards ∞) for which $|t - \lambda_k| = R$ to the corresponding point on the right border, encircling the point λ_j in the positive direction and no other one of the points $\lambda_1, \cdots, \lambda_n$.

Then deforming the contour in (2.1), using (2.2), (2.4) and observing that

$$(t - \lambda_k)^{\lambda_k' - p} \operatorname{reg}(t - \lambda_j)$$

is holomorphic on $l_j(R)$ and its interior, we obtain

$$f_k(p) = \sum_{j \neq k} v_{jk} \varphi_{kj}(R, p) + I_k(R, p), \tag{2.5}$$

where

$$\begin{aligned} \varphi_{kj}(R, p) &= \{2\pi i \Gamma(\lambda_k' + 1 - p)(1 - e^{2\pi i \lambda_k'})\}^{-1} \int_{l_j(R)} (t - \lambda_k)^{\lambda_k' - p} y_j(t)\, dt \\ &= \frac{\Gamma(p - \lambda_k')}{(2\pi i)^2} e^{\pi i (p - \lambda_k')} \int_{l_j(R)} (t - \lambda_k)^{\lambda_k' - p} y_j(t)\, dt, \end{aligned} \tag{2.6}$$

and

$$I_k(R,p)=(2\pi i\Gamma(\lambda_k'+1-p))^{-1}\int_{|t-\lambda_k|=R}(t-\lambda_k)^{\lambda_k'-p}y_k(t)\,dt. \tag{2.7}$$

Note that in the integral representation of $I_k(R,p)$ the integration actually takes place over a set of $(n-1)$ disjoint segments on $|t-\lambda_k|=R$, and since $y_k(t)$ is bounded on each such segment, it is easy to see that for R as above (fixed) and every $\varepsilon>0$ (small)

$$I_k(R,p)=\Gamma(p)O((R-\varepsilon)^{-p})\quad \text{as } p\to\infty. \tag{2.8}$$

Since $\operatorname{Re}\lambda_j'<0$, the function $y_j(t)$ is integrable at λ_j, and deforming the contour of integration in (2.6) yields

$$\varphi_{kj}(R,p)=(1-e^{2\pi i\lambda_j'})\frac{\Gamma(p-\lambda_k')}{(2\pi i)^2}\,e^{\pi i(p-\lambda_k')}\int_{\lambda_j}^{\lambda_j+t_{jk}}(t-\lambda_k)^{\lambda_k'-p}y_j(t)\,dt,$$

where the integration takes place along the *right border* of the cut and accordingly $|t_{jk}|=R$, $\arg t_{jk}=\eta_{jk}-\varepsilon_{jk}$ with a suitably chosen small $\varepsilon_{jk}>0$. To find the asymptotic behavior of $\varphi_{jk}(R,p)$ as $p\to\infty$, we may (with the help of Cauchy's theorem) replace the integral from λ_j to λ_j+t_{jk} by a sum of two integrals from λ_j to $\lambda_j+\rho\exp[i\eta_{jk}]$ resp. from $\lambda_j+\rho\exp[i\eta_{jk}]$ to λ_j+t_{jk} (with sufficiently small $\rho>0$). Since ε_{jk} was taken small, the second integral may be easily estimated as $O((|\lambda_j-\lambda_k|+\rho/2)^{-p})$ as $p\to\infty$. In the first integral, we make the change of variable

$$t=t(s)=\lambda_j+(e^s-1)(\lambda_j-\lambda_k),\qquad 0\leqq s\leqq\delta=\log(1+\rho/|\lambda_j-\lambda_k|)$$

(with $\arg(\lambda_j-\lambda_k)=\arg(t-\lambda_j)=\eta_{jk}$), and we obtain

$$\int_{\lambda_j}^{\lambda_j+\rho e^{i\eta_{jk}}}(t-\lambda_k)^{\lambda_k'+p}y_j(t)\,dt=(\lambda_j-\lambda_k)^{\lambda_k'-p+1}\int_0^{\delta}e^{-s(p-\lambda_k'-1)}y_j(t(s))\,ds.$$

Expanding $e^{s(\lambda_k'+1)}y_j(t(s))$ in the variable s (for s close to 0, i.e., t close to λ_j) and using a standard result on the asymptotics of Laplace integrals (see, e.g., Doetsch [5]), we find that

$$\int_{\lambda_j}^{\lambda_j+\rho e^{i\eta_{jk}}}(t-\lambda_k)^{\lambda_k'+p}y_j(t)\,dt\cong(\lambda_j-\lambda_k)^{\lambda_k'-\lambda_j'-p}p^{\lambda_j'}\sum_0^{\infty}\tilde g_{kj}(m)p^{-m}$$

as $p\to\infty$ (with coefficients $\tilde g_{kj}(m)$ that can be computed from the coefficients of the expansion of $e^{s(\lambda_k'+1)}y_j(t(s))$; in particular $\tilde g_{kj}(0)=f_j(0)\Gamma(1+\lambda_j')\Gamma(-\lambda_j')$). The second integral has been shown to be *asymptotically negligible compared to the first* (by that we mean if we multiply with $(\lambda_j-\lambda_k)^{p-\lambda_k'+\lambda_j'}p^{-\lambda_j'}$, i.e., with the inverse of the explicit terms in the asymptotic obtained above, then the resulting function is asymptotically zero). Hence observing that $p^{\lambda_k'}\Gamma(p-\lambda_k')/\Gamma(p)$ has an asymptotic power series expansion in p^{-1} with leading term one, we obtain

$$\varphi_{kj}(R,p)\cong\Gamma(p)(\lambda_k-\lambda_j)^{\lambda_k'-\lambda_j'-p}p^{\lambda_j'-\lambda_k'}\sum_0^{\infty}g_{kj}(m)p^{-m}$$

with $\arg(\lambda_k-\lambda_j)=\arg(\lambda_j-\lambda_k)-\pi=\eta_{jk}-\pi$, and

$$\begin{aligned}g_{kj}(0)&=\tilde g_{kj}(0)(1-e^{2\pi i\lambda_j'})\,e^{-\pi i\lambda_j'}/(2\pi i)^2\\&=f_j(0)/(2\pi i).\end{aligned}$$

We formalize the results of the preceding discussion as follows:

PROPOSITION 3. *Let a differential equation* (0.1) *satisfying our basic assumptions and an arbitrarily selected formal fundamental solution* $H(z)$ *of the form* (0.2) *be given. Then for every fixed* k, $1 \leqq k \leqq n$, *the coefficients* $f_k(p)$ *can be represented as a linear combination of* $n-1$ *terms, each having a known asymptotic as* $p \to \infty$, *plus an error term which is asymptotically negligible compared to the other terms.*

More precisely, if $\lambda_j' \not\equiv 0 \pmod 1$ *and* $\operatorname{Re} \lambda_j' < 0$, *and if* η *is an arbitrarily fixed admissible direction (with respect to* λ_k*), then for* $R > 0$ *sufficiently large*

$$f_k(p) = \sum_{j \neq k} v_{jk} \varphi_{kj}(R, p) + I_k(R, p), \qquad p \geqq 0, \tag{2.9}$$

where $\varphi_{kj}(R, p)$ *and* $I_k(R, p)$ *are given by* (2.6) *and* (2.7), *and* v_{jk} *is the element in the* (j, k) *position of* V_ν, *with* ν *determined by*

$$\eta_\nu = \eta_{jk} = \arg(\lambda_j - \lambda_k) \in (\eta - 2\pi, \eta).$$

As $p \to \infty$, *we have (for sufficiently small* $\varepsilon > 0$)

$$I_k(R, p) = \Gamma(p) O((R - \varepsilon)^{-p}),$$

$$\varphi_{kj}(R, p) \cong \Gamma(p)(\lambda_k - \lambda_j)^{\lambda_k' - \lambda_j' - p} p^{\lambda_j' - \lambda_k'} \sum_{m=0}^{\infty} g_{kj}(m) p^{-m}, \tag{2.10}$$

with $\arg(\lambda_k - \lambda_j) = \eta_{jk} - \pi$ *and* $g_{kj}(0) = f_j(0)/(2\pi i)$.

Remark 2.1. While for the proof of Proposition 3 we required that $\lambda_j' \not\equiv 0 \pmod 1$ and $\operatorname{Re} \lambda_j' < 0$ for all $j = 1, 2, \cdots, n$, we observe that since a scalar shift of the differential equation does not change the $f_k(p)$ or the asymptotic (2.10), then these assumptions are not required for the existence of such an asymptotic for the formal coefficients $f_k(p)$ as $p \to \infty$. On the other hand, the assumption that $\lambda_j' \not\equiv 0 \pmod 1$ is necessary for the representation of $\varphi_{kj}(R, p)$ since if $\lambda_j' \equiv 0 \pmod 1$ then $y_j(t)$ does not exist.

Remark 2.2. The parameter R in (2.9) can be any sufficiently large real number. In the special case of a two-term differential equation (0.4), each function $y_j(t)$ grows no faster than a fixed power of t as $t \to \infty$ (when $|\arg t|$ is restricted to a bounded interval), hence for all p sufficiently large we may let $R \to +\infty$ in (2.6). Since $I_k(R, p) \to 0$ as $R \to +\infty$ (also for p large enough), one obtains an analogous formula to (2.9) without error term with the functions

$$\varphi_{kj}(p) = \varphi_{kj}(\infty, p)$$

having the same asymptotic (2.10). For a general differential equation (0.1), this argument does not apply since the functions $y_j(t)$ may have exponential growth as $t \to \infty$ and the loop integrals to ∞ may fail to converge. While there are several artificial ways to incorporate the error term by redefining the functions φ_{kj}, there seems to be no natural or simple way to do it. In § 5 we will obtain an analogous formula to (2.9) without error term but using some other functions, which in the case of a "two-term" equation (0.4) reduce to $\varphi_{kj}(\infty, p)$.

Remark 2.3. For each fixed k, $1 \leqq k \leqq n$, one may use the asymptotic development of the terms in (2.9) to calculate certain v_{jk} (to within any prescribed degree of accuracy). The j correspond to the highest level exponential terms, namely those $j \neq k$ for which $|\lambda_j - \lambda_k|$ is minimal. For each fixed k there is generally only one λ_j closest to λ_k, but should there be several at the same minimal distance, all the corresponding v_{jk} can be calculated in the following manner: First observe that without loss of generality we may assume A_0 is diagonal and $F_0 = I$. If $\operatorname{Re} \lambda_j'$ are all distinct, then the v_{jk} can be calculated successively starting with the j corresponding to $\max \operatorname{Re} \lambda_j'$. In doing this it is important to observe that the vectors $g_{kj}(m)$ can be explicitly calculated for each

$m \geqq 0$, hence the functions $\varphi_{kj}(R, p)(\lambda_k - \lambda_j)^{p+\lambda_j'-\lambda_k'}/\Gamma(p)$ can be calculated up to $O(p^{-N})$ for any N and p sufficiently large. In the antithetical case where $\operatorname{Re} \lambda_j'$ are all equal, then one v_{jk} can be calculated from each component by noticing that (aside from the leading terms which all have the same modulus) one term (corresponding to the unit vectors in F_0) grows like $p^{\operatorname{Re}(\lambda_j'-\lambda_k')}$ times a constant (which we want to determine) and all other terms grow at most like $p^{\operatorname{Re}(\lambda_j'-\lambda_k')-1}$. In the general case, one may put both arguments together, first calculating the v_{jk} for which $\operatorname{Re}(\lambda_j'-\lambda_k')$ is largest, and then proceeding to calculate the others as indicated.

3. Some interpolating functions for the coefficients of the formal series and their analytic and asymptotic properties. In the remaining sections we will consider a fixed differential equation satisfying only our basic assumptions and we assume that a fixed formal fundamental solution $H(z)$ of the form (0.2) has been constructed. For the purpose of extending and improving upon the representation (2.9) for the formal coefficients, we will consider now some generalizations of the associated functions $y_k(t)$, which are also natural interpolants of the formal coefficients. For $|t-\lambda_j|$ sufficiently small and all complex numbers s, we define

$$\xi_j(s, t) = \sum_{l=0}^{\infty} \frac{f_j(l)(\lambda_j - t)^{l+s-\lambda_j'-1}}{\Gamma(l+s-\lambda_j')}. \tag{3.1}$$

Observe that $\xi_j(\lambda_j'-p+1, \lambda_j) = f_j(p)$, while for each fixed $s \not\equiv \lambda_j' \pmod 1$, the function

$$2\pi i(1-e^{2\pi i(s-\lambda_j')})^{-1}\xi_j(s, t)$$

is the associated function $y_j(t)$ corresponding to the "shifted" differential equation

$$x' = (A(z) - sz^{-1}I)x$$

(if we define the powers of $(\lambda_j - t)$ and $(t-\lambda_j)$ using $\arg(\lambda_j - t) = \arg(t-\lambda_j) + \pi$). Hence, one sees (for such s) from the analytic properties of $y_j(t)$, that $\xi_j(s, t)$ may be continued analytically along every path avoiding the points $\lambda_1, \cdots, \lambda_n$, where the function generally has a branch-type singularity. To obtain a single-valued function it is therefore appropriate to cut the complex t-plane from each point $\lambda_1, \cdots, \lambda_n$ to ∞ and we choose to do this with a "star-shaped" system of cuts almost identical to what we did in § 2; however, here we do not require the cuts to be turned slightly if more than two of the λ_j's lie on the same straight line. Specifically, if j is any fixed but arbitrary integer, $1 \leqq j \leqq n$, and η is any fixed but arbitrary admissible value, we cut the t-plane from λ_j to ∞ along $\arg(t-\lambda_j) = \eta$ and from each λ_k, $k \neq j$, we cut along $\arg(t-\lambda_k) = \arg(\lambda_k - \lambda_j)$. For t not on the cut from λ_j we select

$$\arg(\lambda_j - t) \in (\eta - \pi, \eta + \pi) \tag{3.2}$$

in defining the powers of $\lambda_j - t$ and we denote the t-plane with this system of cuts and choice of the argument by $\mathcal{P}_{j,\eta}$.

For values of $s \equiv \lambda_j' \pmod 1$, the functions $\xi_j(s, t)$ are related to the derivatives or integrals of the function $\psi_j(t-\lambda_j)$ we constructed in [1, § 5]. To determine the analytic properties of $\xi_j(s, t)$ for this set of values, one could modify that discussion (in particular, see (5.9) in [1]) from the case of parallel cuts to the present star-shaped system. But the analytic continuation can also be obtained through an analogous formula (3.5) required here for another purpose, so we will give an independent argument in this case.

From the recursion relations for the coefficients $f_j(p)$ one can show that $\xi_j(s, t)$ at least formally satisfies the difference equation (0.6). To see that it is, in fact, a

solution one requires knowledge of the growth of $\xi_j(s, t)$ as $\operatorname{Re} s \to +\infty$ to establish the convergence of the infinite series. Such an estimate follows from an explicit asymptotic for $\xi_j(s, t)$ as $\operatorname{Re} s \to +\infty$.

We now formalize these analytic and asymptotic properties of the generalized associated function $\xi_j(s, t)$ as follows.

PROPOSITION 4. *In the situation described above, the function $\xi_j(s, t)$ defined by* (3.1) *is analytic in both variables for $t \in \mathcal{P}_{j,\eta}$ and all complex numbers s. Moreover, for every natural number N,*

$$\frac{\Gamma(N+s-\lambda_j')}{(\lambda_j-t)^{N+s-\lambda_j'-1}}\left\{\xi_j(s, t)-\sum_{l=0}^{N-1} f_j(l)\frac{(\lambda_j-t)^{l+s-\lambda_j'-1}}{\Gamma(l+s-\lambda_j')}\right\}=O(1) \tag{3.3}$$

as $\operatorname{Re} s \to +\infty$, *where the O-constant is uniform with respect to* $\operatorname{Im} s$ *and locally uniform with respect to t. Finally, the function $\xi_j(s, t)$ satisfies the difference equation*

$$s\xi_j(s+1, t)+t\xi_j(s, t)=\sum_{k=0}^{\infty} A_k\xi_j(s+k, t) \tag{3.4}$$

for $s \in \mathbb{C}$ and $t \in \mathcal{P}_{j,\eta}$, where the series on the right-hand side of (3.4) *is absolutely convergent due to* (3.3).

Proof. For arbitrary natural numbers $N > \operatorname{Re}(\lambda_j' - \tilde{s})$ and complex numbers s, $\tilde{s}$ satisfying $\operatorname{Re}(s-\tilde{s})>0$, one can show by integrating the expansion of $\xi_j(\tilde{s}, u)$ termwise and using a modified form of the standard beta-integral (cf. [1, p. 711]) that for $|t-\lambda_j|$ sufficiently small

$$\begin{aligned}\xi_j(s, t)=&\sum_{l=0}^{N-1} f_j(l)(\lambda_j-t)^{l+s-\lambda_j'-1}/\Gamma(l+s-\lambda_j')\\&-\int_{\lambda_j}^{t}\frac{(u-t)^{s-\tilde{s}-1}}{\Gamma(s-\tilde{s})}\left\{\xi_j(\tilde{s}, u)-\sum_{l=0}^{N-1} f_j(l)\frac{(\lambda_j-u)^{l+\tilde{s}-\lambda_j'-1}}{\Gamma(l+\tilde{s}-\lambda_j')}\right\}du\end{aligned} \tag{3.5}$$

(if one integrates along the straight line segment from λ_j to t and defines the power of $(u-t)$ according to $\arg(u-t)=\arg(\lambda_j-t)$). This formula, first established for $|t-\lambda_j|$ sufficiently small, now can be used to analytically continue $\xi_j(s, t)$ everywhere as long as the right-hand side is analytic. In particular, for $\tilde{s} \not\equiv \lambda_j' \pmod 1$ we have seen above that $\xi_j(\tilde{s}, u)$ is analytic for $u \in \mathcal{P}_{j,\eta}$, hence selecting any such $\tilde{s}$ so that $\operatorname{Re}(s-\tilde{s})>0$, we conclude that $\xi_j(s, t)$ is analytic for $t \in \mathcal{P}_{j,\eta}$ and any fixed s. (Note that since $\mathcal{P}_{j,\eta}$ is star-shaped we can reach any $t \in \mathcal{P}_{j,\eta}$ along straight line segments from λ_j.) Moreover, for any fixed value of $t \in \mathcal{P}_{j,\eta}$, the analyticity of $\xi_j(s, t)$ with respect to s also follows from (3.5) (taking any fixed $\tilde{s}$ with $\operatorname{Re}(s-\tilde{s})>0$).

To prove (3.3) we select $\tilde{s}=\lambda_j'$ in the integral on the right-hand side of (3.5) (hence N may be any natural number) and obtain by an $(N-1)$-fold partial integration that

$$\begin{aligned}&-\int_{\lambda_j}^{t}\frac{(u-t)^{s-\lambda_j'-1}}{\Gamma(s-\lambda_j')}\left\{\xi_j(\lambda_j', u)-\sum_{l=1}^{N-1}\frac{f_j(l)(\lambda_j-u)^{l-1}}{\Gamma(l)}\right\}du\\&\quad=(-1)^N\int_{\lambda_j}^{t}\frac{(u-t)^{s+N-\lambda_j'-2}}{\Gamma(s+N-\lambda_j'-1)}\left\{\left(\frac{d}{du}\right)^{N-1}\xi_j(\lambda_j', u)\right\}du\\&\quad=\frac{(\lambda_j-t)^{s+N-\lambda_j'-1}}{\Gamma(s+N-\lambda_j')}f_j(N)\\&\qquad+(-1)^{N+1}\int_{\lambda_j}^{t}\frac{(u-t)^{s+N-\lambda_j'-1}}{\Gamma(s+N-\lambda_j')}\left\{\left(\frac{d}{du}\right)^{N}\xi_j(\lambda_j', u)\right\}du\end{aligned}$$

for every natural number N and every complex s with $\operatorname{Re}(s-\lambda_j')>0$. Letting $\lambda_j - t = |\lambda_j - t|\, e^{i\varphi}$, it follows that the straight line from λ_j to t can be parametrized by

$$u - t = e^{i\varphi}|\lambda_j - t|(1-x) \quad \text{for } 0 \leqq x \leqq 1.$$

Making use of (3.5) (with $\tilde{s} = \lambda_j'$), we see that the left-hand side of (3.3) may be expressed as

$$f_j(N) + (-1)^N(\lambda_j - t)\int_0^1 (1-x)^{s+N-\lambda_j'-1}\left\{\left(\frac{d}{du}\right)^N \xi_j(\lambda_j', u)\right\} dx.$$

If K_t denotes the maximum of $\|(d/du)^N\, \xi_j(\lambda_j', u)\|$ for u between λ_j and t, then the left-hand side of (3.3) is less than or equal to

$$\|f_j(N)\| + |\lambda_j - t| K_t / \operatorname{Re}(s + N - \lambda_j')$$

which is clearly bounded (as $\operatorname{Re} s \to \infty$) by a number which is independent of $\operatorname{Im} s$ and locally uniform in t (for $t \in \mathcal{P}_{j,\eta}$). This proves (3.3).

To prove (3.4), first observe that the series converges absolutely, according to (3.3). For $|t - \lambda_j|$ sufficiently small one can prove (3.4) by substituting the expansions for the functions $\xi_j(s+k, t)$ into (3.4) and equating like powers of $\lambda_j - t$ (using the recursion formulas for the coefficients $f_j(l)$). For the other $t \in \mathcal{P}_{j,\eta}$, formula (3.4) holds by means of analytic continuation with respect to t.

Remark 3.1. The asymptotic result (3.3) can be expressed as a more familiar type of asymptotic power series in s^{-1} times certain explicit functions of s as follows: Using the usual interpretation for $\cong$, we rewrite (3.3) as

$$\xi_j(s, t) \cong \frac{(\lambda_k - t)^{s-\lambda_j'-1}}{\Gamma(s)} \sum_0^\infty f_j(l)(\lambda_j - t)^l \frac{\Gamma(s)}{\Gamma(l+s-\lambda_j')}, \qquad \operatorname{Re} s \to \infty.$$

(Note that this converges for $|t - \lambda_j|$ sufficiently small, but in general is only an asymptotic series.)

From the known asymptotic expression

$$\frac{\Gamma(s)}{\Gamma(s-\lambda_j'+l)} \cong s^{\lambda_j'} \sum_{\nu=l}^\infty c_{\nu,l}(\lambda_j') s^{-\nu} \quad \text{as } \operatorname{Re} s \to +\infty$$

(where the coefficients $c_{\nu,l}(\lambda_j')$ can be expressed in terms of Bernoulli numbers; see e.g., [16, p. 111]), we also have

$$\xi_j(s, t) \cong \frac{(\lambda_j - t)^{s-\lambda_j'-1}}{\Gamma(s)} s^{\lambda_j'} \sum_{\nu=0}^\infty s^{-\nu} \sum_{l=0}^\nu c_{\nu,l}(\lambda_j') f_j(l)(\lambda_k - t)^l. \tag{3.6}$$

Remark 3.2. M. Hukuhara [9] and R. Schäfke [17, p. 27] have obtained the asymptotic behavior of functions related to $\xi_j(s, t)$ for the two-term differential equation (0.4). Schäfke's asymptotic formula is expressed in a manner that could be considered an "asymptotic factorial series."

4. Solutions of the difference equation having a known asymptotic as $\operatorname{Re} s \to -\infty$. We have seen in the previous section that the associated functions $\xi_j(s, t)$ are solutions of (0.6) having a known asymptotic behavior as $\operatorname{Re} s \to +\infty$. For the special case of difference equations (0.5), one may construct formal solutions and use the asymptotic theory to conclude that there also exist solutions having the formal solutions as their asymptotic as $s \to \infty$ in appropriate half-planes. For the general case of (0.6), where no such formal solutions and asymptotic theory are known, it is therefore somewhat surprising that we nevertheless can construct some explicit solutions with a known

asymptotic as $\operatorname{Re} s \to -\infty$. These functions turn out to be related to the functions $y^*(t)$ we constructed in [1], § 1 and in this section we want to investigate their analytic and asymptotic properties. To construct these functions, let τ denote any fixed real number, let R denote any real number larger than a, and let $\gamma(\tau)$ be the loop-contour coming from ∞ along the ray $\arg z = \tau - 2\pi$ to the point $z_0 = R \exp[i(\tau - 2\pi)]$, then along the circle $|z| = R$ (in positive direction) to the point $z_0 e^{2\pi i}$, and back to ∞ along $\arg z = \tau$. For each fixed but arbitrary integer ν and each τ satisfying

$$\tau_\nu - \pi < \tau < \tau_{\nu+1},$$

we define

$$\xi^*(s, t; \nu) = \frac{1}{2\pi i} \int_{\gamma(\tau)} X_\nu(z) z^{-s} e^{-zt} (I - e^{2\pi i(sI - M_\nu)})^{-1} \, dz, \tag{4.1}$$

whenever the inverse matrix exists and the integral converges. Recall (§ 1) that the eigenvalues of M_ν are independent of ν and coincide with the eigenvalues of M. We label them as $\mu_1, \cdots, \mu_n$ (in some fixed, but arbitrary, ordering and repeated according to their multiplicity) and remark that $I - \exp[2\pi i(sI - M_\nu)]$ is invertible iff

$$s \not\equiv \mu_k \pmod 1, \qquad 1 \leqq k \leqq n. \tag{4.2}$$

In order to see for which values of t the integral in (4.1) converges, it is best to interpret the improper integral in the sense of its Cauchy principle value, i.e., we think of the two ray paths in $\gamma(\tau)$ as truncated at a common distance ρ and then let ρ tend to ∞. Observing that

$$X_\nu(z e^{-2\pi i})(z e^{-2\pi i})^{-s} = X_\nu(z) z^{-s} \exp[2\pi i(sI - M_\nu)],$$

it follows that (4.1) may be rewritten (using a change of variable) into a completely equivalent form as

$$\begin{aligned} \xi^*(s, t; \nu) = {} & \frac{1}{2\pi i} \int_{\gamma_1} X_\nu(z) z^{-s} e^{-zt} \, dz (I - \exp[2\pi i(sI - M_\nu)])^{-1} \\ & + \frac{1}{2\pi i} \int_{\gamma_2} X_\nu(z) z^{-s} e^{-zt} \, dz, \end{aligned} \tag{4.3}$$

where $\gamma_1 = \gamma_1(R, \tau)$ denotes the circular path $z = \operatorname{Re}^{i\varphi}$, $\tau - 2\pi \leqq \varphi \leqq \tau$, and $\gamma_2 = \gamma_2(R, \tau)$ is the ray $z = \rho e^{i\tau}$, $R \leqq \rho < \infty$. Due to the asymptotic expansion of $X_\nu(z)$ (as $z \to \infty$ in $S_\nu = S(\tau_\nu - \pi, \tau_{\nu+1})$), we see that for each j, $1 \leqq j \leqq n$, the jth column of the second integral in (4.3) converges for t satisfying

$$-\pi/2 < \arg(t - \lambda_j) + \tau < \pi/2, \tag{4.4}$$

while the first integral is an entire function of t. Therefore, $\xi^*(s, t; \nu)$ exists for every s satisfying (4.2) and t with

$$-\pi/2 < \arg(t - \lambda_l) + \tau < \pi/2, \qquad 1 \leqq l \leqq n. \tag{4.5}$$

Note that the value of the integral in (4.1) does not depend upon the choice of τ (as long as $\tau \in (\tau_\nu - \pi, \tau_{\nu+1})$ and (4.5) holds).

Letting $\xi_j^*(s, t; \nu)$ denote the jth column of $\xi^*(s, t; \nu)$ $(1 \leqq j \leqq n)$ and recalling that the Stokes' rays $\arg z = \tau_\nu$ and the critical values η_ν are related by

$$\eta_\nu + \tau_\nu = 3\pi/2 \quad \text{for every } \nu, \tag{4.6}$$

we now describe the properties of these functions in the following.

PROPOSITION 5. *Consider a differential equation* (0.1) *that satisfies our basic assumptions, a formal fundamental solution* $H(z)$, *an integer* ν, *and an index* $j(1 \leqq j \leqq n)$ *to be given, and let* $\xi_j^*(s, t; \nu)$ *denote the* j*th column of* (4.1). *Then for every* s *satisfying* (4.2), *the function* $\xi_j^*(s, t; \nu)$ *is analytic for* t *in the sector* (*on the Riemann surface of* $\log(t-\lambda_j)$)

$$\eta_{\nu+1} - 2\pi < \arg(t-\lambda_j) < \eta_\nu \tag{4.7}$$

and satisfies there the difference equation

$$s\xi_j^*(s+1, t; \nu) + t\xi_j^*(s, t; \nu) = \sum_{k=0}^{\infty} A_k \xi_j^*(s+k, t; \nu). \tag{4.8}$$

Moreover, for every (*fixed*) t *satisfying* (4.7), $\xi_j^*(s, t; \nu)$ *is meromorphic in* s *and may have poles only at the points*

$$s \equiv \mu_k \pmod 1, \qquad 1 \leqq k \leqq n. \tag{4.9}$$

Finally, if M_δ (*for sufficiently small* $\delta > 0$) *denotes the* s*-plane with* δ*-neighborhoods of the points in* (4.9) *deleted, then for every* t *satisfying*

$$\eta_{\nu+1} - 3\pi/2 < \arg(t-\lambda_j) < \eta_\nu - \pi/2$$

and every natural number N *we have*

$$\begin{aligned} &2\pi i \xi_j^*(s, t; \nu) - \sum_{l=0}^{N-1} f_j(l)\Gamma(1+\lambda_j' - s - l)(t-\lambda_j)^{l+s-\lambda_j'-1} \\ &\quad = O((t-\lambda_j)^{N+s-\lambda_j'-1}\Gamma(1+\lambda_j' - s - N)) \quad \text{as } \operatorname{Re} s \to -\infty, \quad s \in M_\delta, \end{aligned} \tag{4.10}$$

where the O-constant is locally uniform with respect to Im s *and* t.

Proof. For every $\tau \in (\tau_\nu - \pi, \tau_{\nu+1})$, we see from (4.3) that $\xi_j^*(s, t; \nu)$ (for every fixed s with (4.2)) is analytic in t in the sector given by (4.4), and by varying τ we can analytically continue $\xi_j^*(s, t; \nu)$ with respect to s. Since τ was taken arbitrarily from the interval $(\tau_\nu - \pi, \tau_{\nu+1})$, we see that $\xi_j^*(s, t; \nu)$ is analytic for t satisfying (4.7).

If t is now fixed and satisfies (4.7), while τ is selected in $(\tau_\nu - \pi, \tau_{\nu+1})$ such that (4.4) holds, then the jth column of the second integral in (4.3) is easily seen to be an entire function of s. Hence it follows from (4.3) that since

$$\int_{\gamma_1} X_\nu(z) z^{-s} e^{-zt}\, dz$$

is an entire function of s, the only singularities of $\xi_j^*(s, t; \nu)$ (with respect to s) are among the points where

$$I - \exp[2\pi i(sI - M_\nu)]$$

is not invertible, i.e., the points satisfying (4.9). At such points $\xi_j^*(s, t; \nu)$ has at worst a pole-type singularity.

To prove (4.8), we simply insert (4.1), or the equivalent form (4.3) (with s replaced by $s+k$) into the series on the right of (4.8), interchange the order of summation and integration and then integrate by parts using (0.1). To justify the interchange of the order of integration and summation and show the absolute convergence of the series, estimate (4.3) to obtain (for fixed t)

$$\xi_j^*(s+k, t; \nu) = O(R^{-k}) \quad \text{as } k \to \infty$$

and use $R > a$.

To prove (4.10), let δ, M_δ, N and t be given as in the final statement of the proposition. Note that for the t values satisfying

$$\eta_{\nu+1} - 3\pi/2 < \arg(t-\lambda_j) < \eta_\nu - \pi/2,$$

we may take $\tau = -\arg(t-\lambda_j)$ in (4.3). Defining now

$$r^{(N)}(s,t) = 2\pi i \xi_j^*(s,t;\nu) - \sum_{l=0}^{N-1} f_j(l)\Gamma(\lambda_j'+1-l-s)(t-\lambda_j)^{l+s-\lambda_j'-1}$$

and using (4.3) with the identity

$$(t-\lambda_j)^{-\alpha}\Gamma(\alpha) = \int_0^{\infty(\tau)} z^{\alpha-1} e^{-z(t-\lambda_j)}\, dz \quad \text{for } \operatorname{Re}\alpha > 0,$$

we obtain (for $-\operatorname{Re} s$ sufficiently large)

$$r^{(N)}(s,t) = r_1(s,t) + r_2^{(N)}(s,t) - r_3^{(N)}(s,t),$$

where $r_1(s,t)$ denotes the jth column of the first term on the right-hand side of (4.3),

$$r_2^{(N)}(s,t) = \int_{\operatorname{Re}^{i\tau}}^{\infty(\tau)} \left\{ x_{\nu,j}(z) - z^{\lambda_j'} e^{\lambda_j z} \sum_0^{N-1} f_j(l) z^{-l} \right\} z^{-s} e^{-zt}\, dz,$$

and

$$r_3^{(N)}(s,t) = \int_0^{\operatorname{Re}^{i\tau}} \left\{ \sum_0^{N-1} f_j(l) z^{-l} \right\} z^{\lambda_j'-s} e^{-z(t-\lambda_j)}\, dz.$$

Making the change of variable $x = z(t-\lambda_j)$ (hence $\arg x = 0$ due to the choice of τ), and using the asymptotic of $x_{\nu,j}(z)$, the jth column of the normal solution $X_\nu(z)$, for $z \to \infty$, $z \in \mathcal{S}_\nu$, we obtain

$$(t-\lambda_j)^{\lambda_j'+1-N-s} r_2^{(N)}(s,t) = \int_{R|t-\lambda_j|}^{\infty} x^{\lambda_j'-N-s} e^{-x} b(x)\, dx,$$

where $b(x)$ is bounded for $R|t-\lambda_j| \leqq x < \infty$, say by the constant K which is independent of t. Hence

$$\left\| \frac{r_2^{(N)}(s,t)(t-\lambda_j)^{\lambda_j'+1-N-s}}{\Gamma(\lambda_j'-s-N+1)} \right\| \leqq K \left| \frac{\Gamma(\operatorname{Re}(\lambda_j'-s)-N+1)}{\Gamma(\lambda_j'-s-N+1)} \right|. \tag{4.11}$$

Letting $\lambda_j' - s - N + 1 = x + iy$ with $x, y \in \mathbb{R}$, and using

$$\frac{\Gamma(x)}{\Gamma(x+iy)} \cong x^{-iy}(1+O(1)) \quad \text{as } x \to +\infty,$$

we see that the right-hand side of (4.11) is bounded by a constant that is locally uniform with respect to $\operatorname{Im} s$ and t. For the other two components of $r^{(N)}(s,t)$, one easily estimates that as $\operatorname{Re} s \to -\infty$,

$$\|r_1(s,t)\| \leqq \tilde{K}^{\operatorname{Re} s}, \qquad \|r_3^{(N)}(s,t)\| \leqq \tilde{K}^{\operatorname{Re} s}$$

for a suitably small constant $\tilde{K}$ that may be taken both independent of $\operatorname{Im} s$ and t as long as both vary locally so that $s \in M_\delta$ and $\arg(t-\lambda_j) \in (\eta_{\nu+1} - 3\pi/2, \eta_\nu - \pi/2)$. These statements then prove (4.10).

Remark 4.1. In Proposition 5 we have observed that $\xi^*(s, t; \nu)$ has possible poles (in the variable s) at the points $s \equiv \mu_k \pmod 1$, $1 \leqq k \leqq n$. To attach a meaning to the residues of $\xi^*(s, t; \nu)$ at these points, let us assume that t satisfying (4.3) is fixed and, moreover, to simplify the situation we assume that $e^{2\pi i M_\nu}$ has all distinct eigenvalues, i.e., the eigenvalues of M_ν are incongruent modulo one and are denoted by $\mu_1, \cdots, \mu_n$. Let Ω_ν be any invertible matrix satisfying

$$\Omega_\nu^{-1} \exp [2\pi i M_\nu] \Omega_\nu = \exp [2\pi i M]$$

and let $X(z) = X_\nu(z)\Omega_\nu$. Then as we observed in § 1, $X(z)z^{-M} = L(z)$ is single-valued for $a < |z| < \infty$. From (4.1), (1.4) we conclude that

$$\xi^*(s, t; \nu)\Omega_\nu = \frac{1}{2\pi i} \int_{\gamma(\tau)} L(z) z^{M-sI} e^{-zt} (I - e^{2\pi i(sI-M)})^{-1} \, dz.$$

For each fixed $j (1 \leqq j \leqq n)$ and p(integer) we find that all but the jth column of $\xi^*(s, t; \nu)\Omega_\nu$ are analytic (in s) at $s = \mu_j + p + 1$, while the jth column has a first order pole there and its residue is equal to

$$-\frac{1}{(2\pi i)^2} \int_{\gamma(\tau)} l_j(z) z^{-p-1} e^{-zt} \, dz = \frac{-1}{2\pi i} b_j(p, t),$$

if $l_j(z)$ denotes the jth column of $L(z)$, and $b_j(p, t)$ is the pth Laurent coefficient of $l_j(z)\, e^{-zt}$. This shows (under the additional assumptions made above) that the residues of $\xi^*(s, t; \nu)$ at the points $s \equiv \mu_j \pmod 1$ $(j = 1, \cdots, n)$ can be expressed in terms of the Laurent coefficients of $L(z)\, e^{-zt}$.

5. Lateral connection problems for (0.1) and (0.6) and a representation for the coefficients in a formal solution. We have seen in §§ 3 and 4 that the functions $\xi_k(s, t)$, $1 \leqq k \leqq n$, resp., $\xi_j^*(s, t; \nu)$, $1 \leqq j \leqq n$, are particular solutions of (0.6) having known asymptotics as $\operatorname{Re} s \to +\infty$, resp., $\operatorname{Re} s \to -\infty$. In the special case of (0.5) where the solution space is n-dimensional, one can conclude from the theory of difference equations that since these systems of solutions are both fundamental (this follows from the asymptotics), then these systems of functions are linearly related using certain one-periodic functions of s as coefficients (which could, in principle, also depend upon t). Equations such as (0.6), however, generally have many more than n linearly independent solutions, so no similar conclusion can be reached in the general case on the basis of the theory of difference equations alone.

We will nevertheless show in this section that these two systems of solutions for (0.6) do satisfy certain linear connection relations (5.2) and that the coefficients in these relations involve the Stokes' multipliers for the normal solutions of (0.1). We also show that (5.2) can be interpreted as yielding both a generalization and an improvement of the representation formulas for the formal coefficients we obtained in § 2 (2.5).

The function $\xi_k(s, t)$ was shown to be analytic for t in the star-shaped region $\mathcal{P}_{k,\eta}$ while the functions $\xi_j^*(s, t; \nu)$, $1 \leqq j \leqq n$, were shown to be analytic in

$$\bigcap_{j=1}^{n} \{t: \arg (t - \lambda_j) \in (\eta_{\nu+1} - 2\pi, \eta_\nu)\}.$$

For the purpose of comparing them we first need a common region where they are both defined; second, we would like (if possible) to also be able to use the asymptotic (4.10). With these objectives in mind, we now select a particular integer $\nu = \nu_j$ for each column $\xi_j^*(s, t; \nu)$ as follows.

Let k be any fixed integer, $1 \leqq k \leqq n$, and let η denote any fixed admissible value. If $j = k$ we choose $\nu_j = \nu$ satisfying

$$\eta_{\nu+1} < \eta < \eta_\nu,$$

while for each $j \neq k$ the integer ν_j is determined by

$$\eta < \eta_{\nu_j} < \eta + 2\pi \quad \text{and} \quad (j, k) \in \rho_{\nu_j}. \tag{5.1}$$

Note that ν_j depends upon both k and η but to simplify the notation we will not usually display that dependence. From the definition of ρ_{ν_j} (see [1, p. 699]) it is clear that (5.1) uniquely determines ν_j and one also sees that

$$\eta_{\nu_j} = 3\pi/2 - \tau_{\nu_j}$$

is a possible choice for $\arg(\lambda_j - \lambda_k)$, hence the region $\mathcal{P}_{k,\eta}$ can be considered part of the sector

$$\eta_{\nu_j+1} - 2\pi < \arg(t - \lambda_j) < \eta_{\nu_j}.$$

Therefore from Proposition 5 the function $\xi_j^*(s, t; \nu_j)$ (for every s satisfying (4.2)) is an analytic function in $\mathcal{P}_{k,\eta}$, $1 \leqq j \leqq n$, $j \neq k$. By similar arguments the same is true for $j = k$. To simplify the notation, we will mainly write $\xi_j^*(s, t)$ instead of $\xi_j^*(s, t; \nu_j)$, but it is important to keep in mind how these functions depend upon $\nu_j = \nu_j(k, \eta)$. We now state the connection relations between these two systems of functions as follows.

THEOREM 1. *Let a differential equation* (0.1) *satisfying our basic assumptions, a selected formal fundamental solution* $H(z)$, *any fixed index* k, $1 \leqq k \leqq n$, *and any fixed, admissible value* η *be given. Let* $\xi_k(s, t)$ *denote the analytic continuation into the cut plane* $\mathcal{P}_{k,\eta}$ *of the function* $\xi_k(s, t)$ *defined locally by* (3.1) *and let* $\xi_j^*(s, t) = \xi_j^*(s, t; \nu_j)$ *be defined by* (4.1) *with* ν_j *determined as above,* $1 \leqq j \leqq n$. *Then for every* s *satisfying* (4.2) *and* $t \in \mathcal{P}_{k,\eta}$ *we have*

$$\xi_k(s, t) = \sum_{\substack{j=1 \\ j \neq k}}^{n} v_{jk} \xi_j^*(s, t) + (1 - e^{2\pi i(s - \lambda_k')}) \xi_k^*(s, t), \tag{5.2}$$

where $v_{jk} = v_{jk}(\eta)$ *is the element in the* (j, k) *position of the Stokes' multiplier* V_{ν_j}.

Remark 5.1. This result extends Theorem 3.2.3 of R. Schäfke [17] from the "two-term" equation (0.4) (and the assumption that the position sets ρ_ν contain just a single pair) to the "general case" (0.1). Also in the case of (0.4), Schäfke has shown that essentially the same functions as $\xi_j^*(s, t)$ can be expressed as certain Mellin-type integral transforms of $\xi_j(s, t)$ (or equivalently of the $y_j(t)$) with either ray or loop paths (see [17, Def. 1.2.3 and Thm. 1.2.6]). As we remarked in § 2, in this case one can also take $R = \infty$ and $I_k(R, p) \equiv 0$ in (2.5). Then for the special choice in (5.2) of $s = \lambda_k' - p + 1$ and $t = \lambda_k$, one sees that (5.2) reduces to (2.5).

Remark 5.2. For the general case of (0.1), the function $\xi_j(s, t)$ may have exponential growth as $|t| \to \infty$, and we have no representation for $\xi_j^*(s, t)$ as an integral transform of $\xi_j(s, t)$.

Remark 5.3. Using (5.2) and the properties of $\xi_j^*(s, t)$ from Proposition 5, one sees that $\xi_j^*(s, t)$ satisfies

$$\xi_k^*(s, t) = (1 - e^{2\pi i(s - \lambda_k')})^{-1} \xi_k(s, t) + \operatorname{reg}(t - \lambda_k)$$

and

$$\xi_j^*(s, t) = \operatorname{reg}(t - \lambda_k) \quad \text{for all } k \neq j.$$

Again in the case of (0.4), since the functions $\xi_j(s, t)$ and $\xi_j^*(s, t)$, $1 \leqq j \leqq n$, are solutions of the same "shifted" associated differential equation

$$\frac{d\xi}{dt} = (A_0 - tI)^{-1}(A_1 - (s-1)I)\xi,$$

one can show that (under the additional assumption that $\lambda_j' \not\equiv 0 \pmod 1$) these conditions uniquely characterize the solutions ξ_j^*. Hence it follows (using that $2\pi i(1 - e^{2\pi i(s-\lambda_j')})^{-1}\xi_j(s, t)$ is the associated function $y_j(t)$ corresponding to the shifted equation) that

$$\xi_j^*(s, t) = (2\pi i)^{-1} y_j^*(t),$$

where $y_j^*(t)$ corresponds to the shifted differential equation (under an appropriate condition on s to guarantee its existence). It can be shown using arguments as in the proof of Proposition 6 in the next section that this is also true for (0.1).

Proof. We assume throughout that s is fixed, but arbitrary, and satisfies (4.2). First observe that it is sufficient to prove (5.2) for all t satisfying $\arg(t - \lambda_k) = \eta - \varepsilon/2$, $|t - \lambda_k| \geqq \rho$ (for some fixed and sufficiently small $\varepsilon > 0$ and some fixed and sufficiently large ρ), since then it holds for every $t \in \mathcal{P}_{k,\eta}$ by analytic continuation. If ρ is taken sufficiently large (while $\varepsilon > 0$ is fixed), one sees that for such t we have

$$\eta - \varepsilon < \arg(t - \lambda_j) < \eta, \qquad 1 \leqq j \leqq n, \tag{5.3}$$

and we will, from now on, also consider t fixed (as above).

Let ν_0 be such that $\eta_{\nu_0+m} < \cdots < \eta_{\nu_0+1}$ are precisely all the critical values in $(\eta, \eta + 2\pi)$, i.e.,

$$\tau_{\nu_0} \leqq -\eta - \pi/2 < \tau_{\nu_0+1} < \cdots < \tau_{\nu_0+m} < -\eta + 3\pi/2 \leqq \tau_{\nu_0+m+1}.$$

Then we claim that for every ν, $\nu_0 + 1 \leqq \nu \leqq \nu_0 + m$, there exists a $\tau(\nu) \in (\tau_\nu - \pi, \tau_{\nu+1})$ such that (4.5) holds with $\tau(\nu)$ in place of τ, hence $\xi^*(s, t; \nu)$ may be represented by (4.1) with $\tau = \tau(\nu)$. To see this, note that for t as above,

$$\tau + \arg(t - \lambda_j) \in (\eta + \tau - \varepsilon, \eta + \tau),$$

and we just need to show that there exists a $\tau(\nu) \in (\tau_\nu - \pi, \tau_{\nu+1})$ such that

$$[\tau(\nu) + \eta - \varepsilon, \tau(\nu) + \eta] \subset (-\pi/2, \pi/2).$$

But this follows immediately from the above inequalities.

For every $j \neq k$, $1 \leqq j \leqq n$, the corresponding ν_j lies between $\nu_0 + 1$ and $\nu_0 + m$, and the sum of those $v_{jk}\xi_j^*(s, t; \nu_j)$ for which ν_j is some fixed value ν, $\nu_0 + 1 \leqq \nu \leqq \nu_0 + m$, equals the kth column of $\xi^*(s, t; \nu)(V_\nu - I)$. Consequently, the sum of all the terms $v_{jk}\xi_j^*(s, t; \nu_j)$ $(j \neq k)$ is the kth column of

$$\sum_{\nu=\nu_0+1}^{\nu_0+m} \xi^*(s, t; \nu)(V_\nu - I)$$

$$= \sum_{\nu=\nu_0+1}^{\nu_0+m} \frac{1}{2\pi i} \int_{\gamma(\tau(\nu))} X_\nu(z) z^{-s} e^{-zt}\, dz (I - e^{2\pi i(sI - M_\nu)})^{-1}(V_\nu - I).$$

It easily follows from (1.2) that for every ν

$$(I - e^{2\pi i(sI - M_\nu)})^{-1} V_\nu = V_\nu (I - e^{2\pi i(sI - M_{\nu-1})})^{-1},$$

hence by means of $X_\nu(z)V_\nu = X_{\nu-1}(z)$ we obtain

$$\sum_{\nu=\nu_0+1}^{\nu_0+m} \xi^*(s, t; \nu)(V_\nu - I)$$

$$= \sum_{\nu=\nu_0}^{\nu_0+m-1} \frac{1}{2\pi i} \int_{\gamma(\tau(\nu+1))} X_\nu(z) z^{-s} e^{-zt}\, dz (I - e^{2\pi i(sI - M_\nu)})^{-1}$$

$$- \sum_{\nu=\nu_0+1}^{\nu_0+m} \frac{1}{2\pi i} \int_{\gamma(\tau(\nu))} X_\nu(z) z^{-s} e^{-zt}\, dz (I - e^{2\pi i(sI - M_\nu)})^{-1}.$$

Turning the path of integration continuously in any one of the above integrals does not change its value provided that it still converges. In view of our choice of t, all the above integrals along a $\gamma(\tau)$ converge for $\eta - \varepsilon + \tau \in (-\pi/2, \pi/2)$. Hence we find for $\nu = \nu_0+1, \cdots, \nu_0+m-1$ that corresponding terms of the above two sums are equal, and we therefore obtain

$$\sum_{\nu=\nu_0+1}^{\nu_0+m} \xi^*(s, t; \nu)(V_\nu - I)$$

$$= \frac{1}{2\pi i} \int_{\gamma(\tau(\nu_0+1))} X_{\nu_0}(z) z^{-s} e^{-zt}\, dz (I - e^{2\pi i(sI - M_{\nu_0})})^{-1}$$

$$- \frac{1}{2\pi i} \int_{\gamma(\tau(\nu_0+m))} X_{\nu_0+m}(z) z^{-s} e^{-zt}\, dz (I - e^{2\pi i(sI - M_{\nu_0+m})})^{-1}.$$

Since the largest integer ν for which $\eta_\nu > \eta$ has been denoted by ν_k, we find $\nu_k = \nu_0 + m$; hence, $\xi_k^*(s, t)$ is the kth column of

$$\xi^*(s, t; \nu_k) = \frac{1}{2\pi i} \int_{\gamma(\tau(\nu_0+m))} X_{\nu_0+m}(z) z^{-s} e^{-zt}\, dz (I - e^{2\pi i(sI - M_{\nu_0+m})})^{-1}.$$

Using the identities

$$(I - e^{2\pi i(sI - M_{\nu_0+m})})^{-1} e^{2\pi i(sI - \Lambda')} = e^{2\pi i(sI - \Lambda')} (I - e^{2\pi i(sI - M_{\nu_0})})^{-1}$$

and

$$X_{\nu_0+m}(z) = X_{\nu_0}(z e^{-2\pi i}) e^{2\pi i \Lambda'},$$

we find

$$\xi^*(s, t; \nu_k) e^{2\pi i(sI - \Lambda')}$$

$$= \frac{1}{2\pi i} \int_{\gamma(\tau(\nu_0+m)-2\pi)} X_{\nu_0}(z) z^{-s} e^{-zt}\, dz (I - e^{2\pi i(sI - M_{\nu_0})})^{-1}.$$

The proof will be completed once we show that $\xi_k(s, t)$ is the kth column of

$$\frac{1}{2\pi i} \left\{ \int_{\gamma(\tau)} - \int_{\gamma(\tilde{\tau})} \right\} X_{\nu_0}(z) z^{-s} e^{-zt}\, dz (I - e^{2\pi i(sI - M_{\nu_0})})^{-1}, \tag{5.4}$$

where $\tau = \tau(\nu_0+1)$ and $\tilde{\tau} = \tau(\nu_0+m) - 2\pi$. To see this, recall that by definition $\tau(\nu)$ was taken from

$$(\tau_\nu - \pi, \tau_{\nu+1}) \cap (-\pi/2 - \eta + \varepsilon/2, \pi/2 - \eta + \varepsilon/2) \quad \text{for } \nu = \nu_0+1, \cdots, \nu_0+m,$$

and since Stokes' rays occur in opposite pairs, then $\tau_{\nu_0} + \eta > -3/2\pi$ and $\tau_{\nu_0+1} + \eta < \pi/2$. Hence, we may take $\tau = \tau_{\nu_0+1} - \delta$ and $\tilde{\tau} = \tau_{\nu_0} - \pi + \delta$ for sufficiently small $\delta > 0$. Since

the integrals in (5.4) do not change their values when we continuously deform the paths of integration (provided that the integrals still converge), we find that we may replace $\gamma(\tau)$ by $\beta_{\nu_0}(\delta)$ and $\gamma(\tilde{\tau})$ by $\beta_{\nu_0-m}(\delta)$. (See [2, p. 156] for a definition of these paths.) Note that now the value of the integrand in the second integral is actually taken on the next higher sheet of the Riemann surface, so the change of variable $z = \tilde{z}\, e^{-2\pi i}$ in the second integral gives

$$\frac{1}{2\pi i}\int_{\beta_{\nu_0}(\delta)} X_{\nu_0}(z) z^{-s}\, e^{-zt}\, dz\, e^{2\pi i(sI - M_{\nu_0})}.$$

Hence we see that (5.4) equals

$$\frac{1}{2\pi i}\int_{\beta_{\nu_0}(\delta)} X_{\nu_0}(z) z^{-s}\, e^{-zt}\, dz. \tag{5.5}$$

In order to see that the kth column of (5.5) is $\xi_k(s, t)$, one may either consider inverting the Laplace transform representation for the normal solutions (e.g. (2.3)) and deform the path of integration, or else one may verify that the asymptotic for $X_{\nu_0}(z)$ can be substituted and term-wise integrated for $|t - \lambda_k|$ sufficiently small to obtain the expansion (3.1). Compare [2, pp. 157–159] where the latter procedure is carried out in a more general setting.

Remark 5.4. We wish to point out again that in the course of the proof we have obtained the following integral representation: For every fixed integer k, $1 \leqq k \leqq n$, every fixed integer ν, and all sufficiently small $\delta > 0$

$$\xi_k(s, t) = \frac{1}{2\pi i}\int_{\beta_\nu(\delta)} x_{\nu,k}(z) z^{-s}\, e^{-zt}\, dz$$

for t satisfying $\eta_{\nu+1} + \delta < \arg(t - \lambda_k) < \eta_\nu - \delta$ and all complex numbers s. If we restrict to t (in the above sector) with $|t|$ sufficiently large, then

$$\xi_k(s, t) = \frac{1}{2\pi i}\int_{\gamma(\tau)} x_{\nu,k}(z) z^{-s}\, e^{-zt}\, dz$$

for all τ with

$$-\pi/2 < \arg(t - \lambda_j) + \tau < \pi/2.$$

Remark 5.5. In order to solve the system of equations (5.2) for the elements v_{jk}, one must analytically continue the functions ξ_k and $\xi_j^*(1 \leqq j \leqq n)$ to some parameter values s, t with s satisfying (4.2), $t \in \mathcal{P}_{k,\eta}$, and such that

$$\det[\xi_1^*, \cdots, \xi_n^*](s, t) \neq 0.$$

It is easy to see using (4.10) that for $-\operatorname{Re} s$ sufficiently large the above determinant will be nonzero from the linear independence of the vectors $f_1(0), \cdots, f_n(0)$. For the purpose of simplifying the numerical calculations involved, it is reasonable to try to find some particularly convenient parameter values where we might either know exact values for the functions involved or be able to use their asymptotic. That there are such convenient parameter values which are also at the same time compatible with all the other requirements is not immediately obvious. But from our choice of the cuts it follows that we may specialize (5.2) in the following way to obtain a simpler relation.

For fixed k and for all $j \neq k$, $1 \leqq j \leqq n$ we observe that $\xi_j^*(s, t)$ is analytic at $t = \lambda_k$ and

$$-\arg(\lambda_k - \lambda_j) \in (\tau_{\nu_j} - \pi, \tau_{\nu_j+1})$$

according to the definition of ν_j (if consistent with the selection of $\arg(t-\lambda_j)$ for $t \in \mathcal{P}_{k,\eta}$ we take $\arg(\lambda_k-\lambda_j) \in (\eta_{\nu_j}-2\pi, \eta_{\nu_j})$). Hence we may put $t=\lambda_k$ in $\xi_j^*(s,t)$ and also use the asymptotic (4.10). Note that $\xi_k(s,t)$ does not exist when $t=\lambda_k$ for all values of s, but for the particular choice of $s=\lambda_k'-p+1$, where p is an arbitrary nonnegative integer, it follows directly from (3.1) that

$$\xi_k(\lambda_k'-p+1, \lambda_k) = f_k(p). \tag{5.6}$$

Defining now the functions $\alpha_j(s)=\alpha_j(s;k,\eta)=\xi_j^*(s,\lambda_k)$, note that the choice $s=\lambda_k'-p+1$ satisfies (4.2) if $\lambda_k' \not\equiv \mu_j \bmod 1$ $(1 \leqq j \leqq n)$. With these selections, we obtain as a special case of (5.2) the following.

COROLLARY 1. *For arbitrary, but fixed, admissible η and k, $1 \leqq k \leqq n$, assume $\lambda_k' \not\equiv \mu_j \bmod 1$, $1 \leqq j \leqq n$. Then*

$$f_k(p) = \sum_{\substack{j=1 \\ j \neq k}}^{n} v_{j,k}\alpha_j(\lambda_k'-p+1), \qquad p \geqq 0. \tag{5.7}$$

Remark 5.6. The functions $\alpha_j(\lambda_k'-p+1)$ have the asymptotic

$$\alpha_j(\lambda_k'-p+1) \cong \Gamma(p)(\lambda_k-\lambda_j)^{\lambda_k'-\lambda_j'-p}p^{\lambda_j'-\lambda_k'}\sum_{m=0}^{\infty} g_{kj}(m)p^{-m} \tag{5.8}$$

as $p \to +\infty$, where $g_{kj}(0)=f_j(0)/(2\pi i)$ and in defining the nonintegral power of $(\lambda_k-\lambda_j)$ we take $\arg(\lambda_k-\lambda_j)$ as above. If the asymptotic (5.8) for each of the $\alpha_j(\lambda_k'-p+1)$ is substituted into (5.7), we see that the right-hand side has a multi-level asymptotic representation as $p \to +\infty$ where the different levels are distinguished by the different exponential orders of growth $(\lambda_k-\lambda_j)^{-p}$ for $j \neq k$. For each fixed value of k, generally one level dominates and the corresponding coefficient $v_{j,k}$ can be calculated directly as a limit of the formal coefficients $f_k(p)$ after dividing out the main terms in the asymptotic. This extends results of Jurkat, Lutz and Peyerimhoff [11], who treated the case $n=2$, and R. Schäfke [17] who treated the "two-term" equation (0.4) for general n. Also see [7], where an equivalent result is obtained for a scalar second order equation that is already a special case of the results in [11].

To calculate the remaining coefficients $v_{j,k}$ $(n>2)$ one could either try to use (5.7) by calculating appropriate values for the functions $\alpha_j(\lambda_k'-p+1)$ or one could return to (5.2) and make another selection for t that would make other terms in the asymptotic dominate. For certain configurations of the eigenvalues $\lambda_1, \cdots, \lambda_n$ it is possible to choose appropriate t-values for which the asymptotic (4.10) is still valid and preselected terms will dominate the asymptotic. In using (5.2) it is of course necessary to perform the analytic continuation of the functions $\xi_k(s,t)$ possibly outside of the circle of convergence of its local power series expansion. If this is done for certain values of s, then either the difference equation (0.6) or the integral representation (3.5) may be used to calculate values of the analytic continuation of $\xi_j(s,t)$ at a set of points with $\operatorname{Re} s \to -\infty$.

In any case, one may view the functions $\xi_k(s,t)$ as a natural interpolation of the coefficients $f_k(p)$ of the formal solution vectors, and by performing the analytic continuation of these functions to certain values of the parameters one may be able to solve (5.2) for the lateral connection coefficients.

6. The central connection problem and representation of solutions in Floquet form. Our goals in this section and the next one are to investigate the relations between the Laurent coefficients of the single-valued part of a solution (vector or matrix) expressed in Floquet form (0.3) and the central connection coefficients linking that

solution with the normal solutions. The main formula expresses the Laurent coefficients (of a shifted equation) as a linear combination of the associated functions (and possibly their derivatives) evaluated at certain points times certain central connection coefficients. Two types of applications are indicated: if the Laurent coefficients would be known, the formulas may be used to calculate central connection coefficients; if the Stokes' multipliers would be known, then the Laurent coefficients of a solution in Floquet form can be calculated.

For our purposes it is convenient to introduce some different systems of cuts from the ones we used previously for the lateral connection problem. We wish to point out to the reader that for *any* fixed system of cuts from the points $\lambda_1, \cdots, \lambda_n$ and any fixed selection of $\arg(t-\lambda_j)$ for t close to λ_j, associated functions may be defined locally by (3.1) and continued analytically into all of the simply connected domain determined by the cuts. The values of the resulting continuations at various points may depend, however, on the location of the cuts. The main reason for preferring certain systems of cuts over others involves the ability to easily identify quantities arising from the continuations of the associated functions with some natural quantities corresponding to the differential equation, such as Stokes' multipliers.

Let λ denote any fixed, but arbitrary, complex number satisfying $\lambda \neq \lambda_j$, $1 \leqq j \leqq n$, and let θ denote any fixed, but arbitrary, real number satisfying

$$\theta \not\equiv \arg(\lambda_j - \lambda) \pmod{2\pi}, \qquad 1 \leqq j \leqq n.$$

For each such pair (λ, θ), which we henceforth call *admissible*, we cut the t-plane from λ to ∞ along $\arg(t-\lambda) = \theta$, and for t not on the cut we define

$$\arg(t-\lambda) \in (\theta - 2\pi, \theta).$$

Denoting $\theta_j = \arg(\lambda_j - \lambda) \in (\theta - 2\pi, \theta)$, $1 \leqq j \leqq n$, we call a λ-value *generic* if all the θ_j are *distinct*. In such a case we also make a cut from each point λ_j to λ along the straight line segment and denote the t-plane with these cuts by $\mathcal{P}_{\lambda,\theta}$. (Later on it will be important to discuss nongeneric values of λ, for which the cuts are then somewhat more complicated to arrange.) In order to define the associated functions $\xi_j(s, t)$ for $t \in \mathcal{P}_{\lambda,\theta}$, it is sufficient to select a branch of $\arg(\lambda_j - t)$, and we do this here by requiring

$$\theta_j < \arg(\lambda_j - t) < \theta_j + 2\pi, \qquad 1 \leqq j \leqq n.$$

If for a certain (fixed) generic value λ, and a given θ there exists a (necessarily unique) integer ν such that

$$\eta_{\nu+1} < \theta < \eta_\nu \quad \text{and} \quad \eta_{\nu+1} < \theta_j + \pi < \eta_\nu, \qquad 1 \leqq j \leqq n, \tag{6.1}$$

then the system of cuts is called *almost parallel*. (Here the numbers η_ν, the so-called *critical values*, are all numbers of the form $\arg(\lambda_j - \lambda_k)$, $j \neq k$; see [1, § 3.1].) This property depends both on the geometry of the numbers $\lambda_1, \cdots, \lambda_n$ as well as the choice of λ and θ. We observe that for any (fixed) set of distinct complex numbers $\lambda_1, \cdots, \lambda_n$ and any θ that is not one of the critical values, there always exists a generic λ, $|\lambda|$ sufficiently large, such that the system of cuts is almost parallel.

If $X(z)$ is any fundamental solution matrix for (0.1), we define

$$\Phi(s, t; \theta) = \Phi(s, t) = \frac{1}{2\pi i} \int_{\gamma(\tau)} X(z) z^{-s} e^{-zt}\, dz, \tag{6.2}$$

with $\gamma(\tau)$ as in (4.1), $\tau = \pi - \theta$, $s \in \mathbb{C}$, arbitrary, $t \in \mathcal{P}_{\lambda,\theta}$, and $|t|$ sufficiently large. Clearly the integral converges when $|t|$ is sufficiently large and $\arg t = \theta - \pi$ (using the asymptotic behavior of solutions). From (1.4) and the integral representation of $\xi_j(s, t)$

derived in the proof of Theorem 1, one sees that the columns of $\Phi(s, t)$ may be expressed as certain linear combinations of appropriate analytic continuations of $\xi_1(s, t), \cdots, \xi_n(s, t)$ in $\mathcal{P}_{\lambda,\theta}$. It follows that $\Phi(s, t)$ may be continued analytically (in t) to all of $\mathcal{P}_{\lambda,\theta}$. Moreover, since the vectors $\xi_1(s, t), \cdots, \xi_n(s, t)$ are all solutions of (0.6) we see that the columns of $\Phi(s, t)$ are also solutions of (0.6). We next consider the behavior of the columns $\varphi_j(s, t)$ of $\Phi(s, t)$ near the singularities $\lambda_1, \cdots, \lambda_n$ and see how the central connection factors enter into these relations. This result we now state as follows.

PROPOSITION 6. *Let a differential equation* (0.1) *satisfying our basic assumptions and a fixed formal fundamental solution be given, consider an admissible pair* (λ, θ) *for which the corresponding system of cuts is almost parallel, and let* ν *denote the unique integer satisfying* (6.1). *Then the following statements hold*:

(a) *There exists a unique matrix* $C(s) = [c_{kj}(s)]$ *of entire, one-periodic functions of* s *satisfying*

$$\xi_j(s, t) = \xi_k(s, t)(1 - e^{2\pi i(s-\lambda_k')})^{-1} c_{kj}(s) + \operatorname{reg}(t - \lambda_k) \tag{6.3}$$

for $t \in \mathcal{P}_{\lambda,\theta}$, $s \not\equiv \lambda_k' \pmod 1$, $1 \leqq j, k \leqq n$. *Moreover,* $C(s)$ *can be expressed in terms of the Stokes' multipliers as*

$$C(s) = V_\nu \cdots V_{\nu-\mu+1} - e^{2\pi i(sI-\Lambda')}(V_{\nu-\mu} \cdots V_{\nu-m+1})^{-1}, \qquad \mu = m/2. \tag{6.4}$$

(b) *If* $X(z)$ *is a fundamental solution for* (0.1) *and* $\Phi(s, t) = [\varphi_1(s, t), \cdots, \varphi_n(s, t)]$ *is defined by* (6.2), *then there exists a unique matrix* $\Delta(s) = [\delta_{kj}(s)]$ *of entire, one-periodic functions of* s *such that*

$$\varphi_j(s, t) = \xi_k(s, t)(1 - e^{2\pi i(s-\lambda_k')})^{-1} \delta_{kj}(s) + \operatorname{reg}(t - \lambda_k) \tag{6.5}$$

for $t \in \mathcal{P}_{\lambda,\theta}$, $s \not\equiv \lambda_k' \pmod 1$, $1 \leqq j, k \leqq n$. *Finally, if* $X(z) = X_\nu(z)\Omega_\nu$, *where* $X_\nu(z)$ *denotes the* ν*th normal solution, then*

$$\Delta(s) = C(s)\Omega_{\nu-\mu} = \Omega_\nu(I - e^{2\pi i(sI-M)}), \tag{6.6}$$

where $e^{2\pi iM}$ *denotes the circuit factor for* $X(z)$.

Remark 6.1. In [1] we proved a formula (see Theorem 1, § 4.2) corresponding to (6.3) for the associated functions $y_j(t)$ in the case of parallel cuts and it is readily seen that the same proof may be used to show existence (and uniqueness) of $C(s)$, $\Delta(s)$ satisfying (6.3), (6.5) for all systems of cuts that occur in §§ 6 and 7. The expressions (6.4), (6.6), however, generally depend on the particular system of cuts (since the analytic continuations of $\xi_j(s, t)$, $\varphi_j(s, t)$ depend upon the location of the cuts). We will discuss the dependence of $C(s)$, $\Delta(s)$ on the selection of the cuts in § 7, and it may be seen from the proof given there that even the existence of these matrices may be obtained along with expressions explaining how they change, provided the existence was proven in a particular situation, say the case of almost parallel cuts. To keep the statements in Lemma 1 (§ 7) as simple as possible, we will, however, take the existence of $C(s)$, $\Delta(s)$ for granted.

Proof. The uniqueness of $C(s)$, $\Delta(s)$ is immediate since for every j, $k \in \{1, 2, \cdots, n\}$, equation (6.3), resp. (6.5), holds for at most one entire function $c_{kj}(s)$, resp. $\delta_{kj}(s)$; observe that for $s \not\equiv \lambda_k' \pmod 1$ no nonzero constant multiple of $\xi_k(s, t)$ can be single-valued at λ_k.

To show (6.4), note that as a consequence of (6.1), for every j, $1 \leqq j \leqq n$, none of the cuts in $\mathcal{P}_{\lambda,\theta}$ intersects the sector

$$\eta_{\nu+\mu+1} = \eta_{\nu+1} - \pi < \arg(t - \lambda_j) < \eta_\nu - \pi = \eta_{\nu+\mu}, \tag{6.7}$$

and from the Remark 5.4, we have for t as above and arbitrary complex s,

$$\xi_j(s, t) = \frac{1}{2\pi i} \int_{\beta_{\nu-\mu}(\delta)} x_{\nu-\mu,j}(z) z^{-s} e^{-zt}\, dz.$$

For $j = 1, 2, \cdots, n$, note that the sectors (6.7) have a nonempty intersection and for such t we may replace $\beta_{\nu-\mu}(\delta)$ by $\gamma(\tau)$ with $\tau = \pi - \theta$ (θ as in (6.1)) to obtain

$$\xi(s, t) = \frac{1}{2\pi i} \int_{\gamma(\tau)} X_{\nu-\mu}(z) z^{-s} e^{-zt}\, dz. \tag{6.8}$$

Therefore from (6.2) and $X(z) = X_{\nu-\mu}(z)\Omega_{\nu-\mu}$ we obtain

$$\Phi(s, t) = \xi(s, t)\Omega_{\nu-\mu} \quad \text{for } t \in \mathcal{P}_{\lambda,\theta} \text{ and } s \in \mathbb{C}. \tag{6.9}$$

Using (6.9) we see that statement (a) in Proposition 6 implies (b) and the first equality in (6.6). From (6.4), (1.1), (1.5) and (1.6), it is easy to establish the second equality in (6.6). (Note that (1.1), (1.5), (1.6) do not depend upon M being in Jordan form.) To prove (a) and (6.4) we will show that they hold under the additional assumption (4.2) and then extend the formulas to the discrete set of values $s \equiv \mu_k \pmod 1$ using (3.5) and arguing as in the proof of Lemma 2′ in [1, p. 711].

Now assuming (4.2), let τ be as above and define

$$\xi^*(s, t) \equiv \xi^*(s, t; \nu)$$

by (4.1) (for $t \in \mathcal{P}_{\lambda,\theta}$ and satisfying (4.5)). Using (4.1), (6.8) and $X_{\nu-\mu} = X_\nu V_\nu \cdots V_{\nu-\mu+1}$, we obtain

$$\begin{aligned} \xi(s, t) &= \xi^*(s, t)(I - e^{2\pi i(sI - M_\nu)}) V_\nu \cdots V_{\nu-\mu+1} \\ &= \xi^*(s, t)\tilde{C}(s) \end{aligned} \tag{6.10}$$

with $\tilde{C}(s)$ defined by (6.4). It remains to show that these quantities are the same as in (6.3). Using Proposition 5 we conclude that

$$\xi^*(s, t) = [\xi_1^*(s, t), \cdots, \xi_n^*(s, t)]$$

can be analytically continued (with respect to t) into $\mathcal{P}$ (again use (6.1)) and

$$\xi_j^*(s, t) = \operatorname{reg}(t - \lambda_k), \qquad j \neq k, \quad 1 \leqq j, k \leqq n.$$

Hence for each such j, $1 \leqq j \leqq n$, we have by (6.10)

$$\xi_j(s, t) = \xi_k^*(s, t)\tilde{c}_{kj}(s) + \operatorname{reg}(t - \lambda_k), \qquad 1 \leqq k \leqq n,$$

which implies, in particular, for $j = k$ and $s \not\equiv \lambda_k' \pmod 1$ that

$$\xi_k^*(s, t) = \xi_k(s, t)(1 - e^{2\pi i(s - \lambda_k')})^{-1} + \operatorname{reg}(t - \lambda_k), \qquad 1 \leqq k \leqq n.$$

Here we have used that $V_\nu \cdots V_{\nu-\mu+1}$ and $(V_{\nu-\mu} \cdots V_{\nu-m+1})^{-1}$ both have ones along the diagonal, hence $c_{kk}(s) = 1 - e^{2\pi i(s - \lambda_k')}$. These formulas imply $\tilde{C} = C$, hence we obtain statement (a) with $C(s)$ as in (6.4), and this completes the proof.

Now consider a fundamental solution matrix in Floquet form, say $X(z) = L(z)z^M$, where M is an upper triangular matrix in Jordan canonical form. Since by an appropriate permutation of the columns of $X(z)$ (which corresponds to a permutation similarity of M) we can arrange any block of M to come first, and since it is notationally convenient to consider just the columns corresponding to the first block, we now restrict ourselves to that case without loss of generality. Let μ, resp. n_1, denote the eigenvalue, resp. dimension, of the first block and let $l_j(z)$, $1 \leqq j \leqq n_1$, denote the first n_1 columns of $L(z)$.

If (λ, θ) is an admissible pair with λ generic, let $t \in \mathcal{P}_{\lambda,\theta}$ with $\arg t = \theta - \pi$. For such t with $|t|$ sufficiently large (and $\gamma(\tau)$, τ as in (6.2)) we define

$$b_j(s,t) = \frac{1}{2\pi i} \int_{\gamma(\tau)} l_j(z) z^{-s-1} e^{-zt}\, dz, \qquad 1 \leqq j \leqq n_1, \tag{6.11}$$

which converges for all complex numbers s. (Note that $b_j(s,t)$ also depends on λ, θ but we do not explicitly display that here.) To discuss the analytic behavior in the t-variable, write

$$L(z) = X(z) z^{-M} = X(z)\, e^{-M \log z}$$

from which we obtain (with x_j denoting the jth column of X)

$$l_j(z) = z^{-\mu} \sum_{k=0}^{j-1} \frac{(-\log z)^k}{k!} x_{j-k}(z), \qquad 1 \leqq j \leqq n_1.$$

Inserting this into (6.11) and comparing with (6.2) we have

$$b_j(s,t) = \sum_{k=0}^{j-1} \frac{1}{k!} \left(\frac{\partial}{\partial s}\right)^k \varphi_{j-k}(\mu + s + 1, t), \qquad 1 \leqq j \leqq n_1. \tag{6.12}$$

This holds first for $|t|$ sufficiently large, $\arg t = \theta - \pi$, and all $s \in \mathbb{C}$, but using the analyticity of $\Phi(s,t)$ for all s and $t \in \mathcal{P}_{\lambda,\theta}$ we see that $b_j(s,t)$ can be continued analytically for all $t \in \mathcal{P}_{\lambda,\theta}$.

If s is an integer, it follows from (6.11) that $b_j(s,t)$ is the sth Laurent coefficient of $l_j(z)\, e^{-zt}$ (for fixed t); hence $b_j(s,t)$ is an entire function of t when s is an integer. In particular, we may select $t = \lambda$ and define

$$b_j(p) = b_j(p, \lambda)$$

for every integer p and $j = 1, 2, \cdots, n_1$. (Note that whereas $b_j(s,t)$ may depend on θ, $b_j(p)$ is clearly independent of θ.) As a consequence of interpreting $b_j(p)$ as the pth Laurent coefficient of $l_j(z)\, e^{-z\lambda}$ we obtain

$$l_j(z)\, e^{-z\lambda} = \sum_{p=-\infty}^{+\infty} b_j(p) z^p, \qquad 1 \leqq j \leqq n_1,$$

with the series converging absolutely for $|z| > a$ and uniformly for $a < R_1 \leqq |z| \leqq R_2 < +\infty$. Since $l_j(z)\, e^{-z\lambda}$ is at most of (exponential) order one and finite type as $z \to \infty$ then it is permissible to substitute the series into (6.11) and termwise integrate. To see this note that $\gamma(\tau)$ consists of two ray paths to ∞ along $\arg z = \tau$, $\tau - 2\pi$ and a circular segment. Termwise integration along the circular segment is justified by uniform convergence while termwise integration along the rays is justified for $|t - \lambda|$ sufficiently large and $\arg(t - \lambda) = \theta$ by the dominated convergence theorem. This yields

$$b_j(s,t) = \sum_{-\infty}^{+\infty} b_j(p)(\lambda - t)^{s-p} / \Gamma(1 + s - p), \qquad 1 \leqq j \leqq n_1, \tag{6.13}$$

for arbitrary s and t as above. But then the series automatically converges for all $|t - \lambda|$ sufficiently large, $t \in \mathcal{P}$ by analyticity of $b_j(s,t)$ and we have (6.13) for all such t (provided $\arg(\lambda - t) \in (\theta - \pi, \theta + \pi)$).

In order to establish our main formula which represents $b_j(p)$ in terms of the associated functions, we need an interpretation for $\xi_j(s, \lambda)$ (as well as its derivatives with respect to s) at points $s = p + \mu + 1$, where p is an integer and μ is the eigenvalue of M for the first block. To do this, we define

$$\left(\frac{\partial}{\partial s}\right)^k \xi_j(s, \lambda)$$

to be the analytic continuation of $(\partial/\partial s)^k \xi_j(s, t)$ along the segment $\arg(\lambda_j - t) = \theta_j$ ($k \geqq 0$, $1 \leqq j \leqq n_1$), which can always be performed all the way to $t = \lambda$ since we have assumed λ to be generic. We now state the representation result as follows.

THEOREM 2. *Under the same assumptions and notation as in Proposition* 6, *let* $X(z) = L(z) z^M$ *denote a fundamental solution matrix for* (0.1) *in Floquet form. Moreover, let* $b_j(p)$ *denote the pth Laurent coefficient of the vector* $l_j(z)\, e^{-z\lambda}$, *where* $l_j(z)$ *denotes the jth column of* $L(z)$. *Then* $b_j(p)$ *can be represented as a linear combination of the associated functions* (*and their derivatives with respect to* s) *with coefficients from the central connection matrix* Ω_ν. *More precisely, if* M *is in upper triangular Jordan canonical form with first block having the eigenvalue* μ *and size* n_1, *then for every integer* p *and* $j = 1, 2, \cdots, n_1$,

$$b_j(p) = \sum_{q=0}^{j-1} \frac{1}{q!} \sum_{k=1}^{n} \omega_{k,j-q}^{(\nu)} \left(\frac{\partial}{\partial s}\right)^q \xi_k(s, \lambda)\Big|_{s=p+\mu+1}, \tag{6.14}$$

where $\Omega_\nu = (\omega_{jk}^{(\nu)})$.

Proof. From (6.13) we have for each fixed, but arbitrary, integer p, for each fixed $s \not\equiv 0 \pmod 1$, and for R sufficiently large

$$b_j(p) = -\frac{\Gamma(1+s-p)}{2\pi i} \int_{|t-\lambda|=R} (\lambda - t)^{p-s-1} b_j(s, t)\, dt, \qquad 1 \leqq j \leqq n_1.$$

For those s such that $p > \operatorname{Re} s$, we may deform the contour into a sum of loops $\alpha_k(\lambda)$, where $\alpha_k(\lambda)$ is a simple closed path beginning at λ and proceeding toward λ_k close to the right border of the cut $\arg(t - \lambda) = \theta_k$, encircling λ_k, and proceeding back to λ close to the left border of the cut. No other λ_l, $l \neq k$, should lie on $\alpha_k(\lambda)$ or in the interior of the region bounded by it.

Then using also (6.12) we obtain

$$\begin{aligned} &-\frac{2\pi i}{\Gamma(1+s-p)} b_j(p) \\ &\quad = \sum_{q=0}^{j-1} \frac{1}{q!} \sum_{k=1}^{n} \int_{\alpha_k(\lambda)} (\lambda - t)^{p-s-1} \left(\frac{\partial}{\partial s}\right)^q \varphi_{j-q}(\mu + s + 1, t)\, dt. \end{aligned} \tag{6.15}$$

For fixed, but arbitrary, p, λ, q, j and k as above, and arbitrary complex numbers s and $\tilde{s}$, $s \not\equiv 0 \pmod 1$, consider the integral

$$\begin{aligned} &-\frac{\Gamma(1+s-p)}{2\pi i} \int_{\alpha_k(\lambda)} (\lambda - t)^{p-s-1} \left(\frac{\partial}{\partial \tilde{s}}\right)^q \varphi_{j-q}(\tilde{s}, t)\, dt \equiv I(s, \tilde{s}) \\ &\quad = \left(\frac{\partial}{\partial \tilde{s}}\right)^q \left[-\frac{\Gamma(1+s-p)}{2\pi i} \int_{\alpha_k(\lambda)} (\lambda - t)^{p-s-1} \varphi_{j-q}(\tilde{s}, t)\, dt \right]. \end{aligned}$$

Using (6.5) and Cauchy's theorem, one may replace $\varphi_{j-q}(\tilde{s}, t)$ by $\xi_k(\tilde{s}, t)(1 - e^{2\pi i(\tilde{s} - \lambda_k')})^{-1} \delta_{k, j-q}(\tilde{s})$ in the above integral (without changing its value). We claim that

then it follows that

$$I(s,\tilde{s}) = (1-e^{2\pi i s})^{-1}\left(\frac{\partial}{\partial\tilde{s}}\right)^q [\delta_{k,j-q}(\tilde{s})\xi_k(p-s+\tilde{s},\lambda)]. \tag{6.16}$$

To see this, first assume that in addition $\operatorname{Re}(\tilde{s}-\lambda_k')>0$. Then the integral converges at λ_k and the path $\alpha_k(\lambda)$ may be deformed to consist of two paths along the line segment from λ to λ_k, resp., from λ_k to λ, along the right, resp., left, borders of the cut. Using (3.1) one sees that the integrand on the left border is $e^{2\pi i(\tilde{s}-\lambda_k')}$ times the value on the right border, hence

$$I(s,\tilde{s}) = \left(\frac{\partial}{\partial\tilde{s}}\right)^q\left[-\frac{\Gamma(1+s-p)}{2\pi i}\delta_{k,j-q}(\tilde{s})\int_\lambda^{\lambda_k}(\lambda-u)^{p-s-1}\xi_k(\tilde{s},u)\,du\right],$$

where the integration takes place along the border with $\arg(\lambda_k-u)=\theta_k$, hence $\arg(\lambda-u)=\theta_k+\pi$. Comparing the above integral with (3.5) (taking $t=\lambda$ and $N=0$) we obtain

$$I(s,\tilde{s}) = \left(\frac{\partial}{\partial\tilde{s}}\right)^q\left[\frac{\Gamma(1+s-p)\Gamma(p-s)}{2\pi i}e^{i\pi(p-s)}\delta_{k,j-q}(\tilde{s})\xi_k(p-s+\tilde{s},\lambda)\right]$$

from which (6.16) immediately follows under the additional assumption that $\operatorname{Re}(\tilde{s}-\lambda_k')>0$. But since both $I(s,\tilde{s})$ and the right-hand side of (6.16) are entire functions of $\tilde{s}$, then (6.16) holds for all $\tilde{s}$. We also remark that in the same manner one can use (3.5) to show that

$$\begin{aligned}&-\frac{\Gamma(1-s)}{2\pi i}[1-e^{2\pi i(\tilde{s}-\lambda_k')}]^{-1}\int_{\alpha_k(\lambda)}(\lambda-t)^{s-1}\xi_k(\tilde{s},t)\,dt\\ &\quad=(1-e^{-2\pi i s})^{-1}\xi_k(s+\tilde{s},\lambda)\end{aligned} \tag{6.17}$$

for all $\tilde{s}\not\equiv\lambda_k'\pmod 1$ and $\operatorname{Re}s>0$, $s\not\equiv 0\pmod 1$.

Now returning to (6.15) and using (6.16) together with (6.6) note that in the case $j=1$ (hence $q=0$) we obtain (6.14). To complete the proof in the remaining cases we obtain from (6.15) and (6.16)

$$b_j(p) = \beta_j(p-s,\mu+s+1)(1-e^{2\pi i s})^{-1} \qquad (1\leqq j\leqq n_1)$$

with β_j defined by

$$\begin{aligned}\beta_j(p-s,\tilde{s}) &= \sum_{q=0}^{j-1}\frac{1}{q!}\sum_{k=1}^{n}\left(\frac{\partial}{\partial\tilde{s}}\right)^q[\delta_{k,j-q}(\tilde{s})\xi_k(p-s+\tilde{s},\lambda)]\\ &= \sum_{\tau=0}^{j-1}\frac{1}{\tau!}\sum_{k=1}^{n}\left(\frac{\partial}{\partial\tilde{s}}\right)^\tau\xi_k(p-s+\tilde{s},\lambda)\sum_{q=0}^{j-\tau-1}\frac{1}{q!}\left(\frac{\partial}{\partial\tilde{s}}\right)^q\delta_{k,j-\tau-q}(\tilde{s})\end{aligned}$$

(use Leibnitz's Rule to differentiate the product). Computing the first Jordan block of $e^{-2\pi i M}$ explicitly, we conclude from (6.6)

$$\delta_{kj}(\tilde{s}) = \omega_{kj}^{(\nu)} - e^{2\pi i(\tilde{s}-\mu)}\sum_{\sigma=0}^{j-1}\frac{(-1)^\sigma(2\pi i)^\sigma}{\sigma!}\omega_{k,j-\sigma}^{(\nu)} \qquad (1\leqq k\leqq n,\ 1\leqq j\leqq n_1),$$

and after some calculation (using a simple binomial identity) we obtain

$$\sum_{q=0}^{j-\tau-1}\frac{1}{q!}\left(\frac{\partial}{\partial\tilde{s}}\right)^q\delta_{k,j-\tau-q}(\tilde{s}) = (1-e^{2\pi i(\tilde{s}-\mu)})\omega_{k,j-\tau}^{(\nu)} \qquad (1\leqq k\leqq n,\ 1\leqq j-\tau\leqq n_1).$$

This implies for $j=1,\cdots,n_1$

$$\beta_j(p-s,\tilde{s}) = (1-e^{2\pi i(\tilde{s}-\mu)})\sum_{\tau=0}^{j-1}\frac{1}{\tau!}\sum_{k=1}^{n}\omega_{k,j-\tau}^{(\nu)}\left(\frac{\partial}{\partial\tilde{s}}\right)^\tau\xi_k(p-s+\tilde{s},\lambda).$$

This is easily seen to complete the proof.

Remark 6.2. For $j=1$, (6.14) reduces to

$$b_1(p)=\sum_{k=1}^{n}\omega_{k1}^{(\nu)}\xi_k(p+\mu+1,\lambda)$$

and from the asymptotic (3.3) we see that for p (positive) sufficiently large

$$\det[\xi_1(p+\mu+1,\lambda),\cdots,\xi_n(p+\mu+1,\lambda)]\neq 0. \tag{6.18}$$

Hence if the vector $b_1(p)$ would be known for one such value of p and if the analytic continuation of the $\xi_k(s,t)$ is performed, then the first column of Ω_ν can be calculated by solving the system of linear equations. For $j=2$ we obtain

$$b_2(p)-\sum_{k=1}^{n}\omega_{k1}^{(\nu)}\frac{\partial}{\partial s}\xi_k(s,\lambda)\Big|_{s=p+\mu+1}=\sum_{k=1}^{n}\omega_{k2}^{(\nu)}\xi_k(p+\mu+1,\lambda)$$

and if the left-hand side is now considered as known for some p satisfying (6.18), then the second column of Ω_ν may be calculated. Continuing in this manner (through this block of M and corresponding formulas for the others) one sees that if for each eigenvalue μ of M, (6.18) would hold for a value of p and the corresponding coefficients $b_j(p)$ would be known, and if the appropriate analytic continuations of the associated functions and their derivatives would be performed, then the central connection factor Ω_ν can be calculated.

We also remark that using the asymptotic (3.3) for $\xi_k(p+\mu+1,\lambda)$ as $p\to+\infty$ one sees that $b_1(p)$ is a sum of n terms, each having an asymptotic that consists of the common factor $1/\Gamma(p)$ times (different) exponentials in powers of p, and asymptotic power series in $1/p$. Using these asymptotics, one sees that if we would know the sequence $\{b_1(p)\}$ asymptotically in this sense as $p\to+\infty$ then (generally) one element of the column $\omega_{k1}^{(\nu)}$, $1\leqq k\leqq n$, can be calculated as a limit, corresponding to the value of k for which $|\lambda_k-\lambda|$ is the smallest.

The other columns $b_j(p)$, $j>1$, also have asymptotic representations as $p\to+\infty$ that consist of a sum of terms of the above type times various powers of $\log p$ (up to the $(j-1)$st power). This is obtained from (3.3) by differentiating with respect to s and using

$$\frac{\Gamma'(p)}{\Gamma(p)}=\Psi(p)\cong\log p-\frac{1}{2p}-\sum_{1}^{\infty}B_{2m}p^{-2m}/2m.$$

Remark 6.3. Using formula (6.10) and the knowledge of the asymptotic (4.10) for the functions $\xi_j^*(s,t)$, one could also try using (6.14) to obtain an asymptotic representation for $b_j(p)$ as $p\to-\infty$. But the leading terms of such an asymptotic would consist of $\Gamma(-p)$ times exponentials and powers of p whereas we know from the differential equation (0.1) that the Laurent coefficients can grow at most exponentially as $p\to-\infty$ since the series converges for $|z|>a$. Hence the leading terms all cancel leaving no apparent asymptotic structure for the Laurent coefficients corresponding to negative powers of z. This is indicated by the fact that, as a consequence of Birkhoff's reduction theorem, every equation (0.1) may be transformed into an equation (0.4) for which all Laurent coefficients with sufficiently small negative indices have to vanish identically.

7. The nongeneric cases; dependence of the matrices $C(s)$ and $\Delta(s)$ on the selection of λ. In the previous section we have considered the case of generic λ (in fact only the situation with almost parallel cuts) and from Remark 6.2 one may see that it may be advantageous from a computational standpoint to select several different generic

values of λ in a single problem. This makes it necessary to understand how the quantities appearing in the previous section depend upon the choice of λ, and in particular, to see what happens in the case of nongeneric values of λ.

Again consider an admissible pair (λ, θ) with the t-plane cut from λ to ∞ along $\arg(t-\lambda)=\theta$, and define $\arg(t-\lambda)\in(\theta-2\pi, \theta)$ for t not on the cut. If $\theta_j = \arg(\lambda_j-\lambda)\in(\theta-2\pi, \theta)$, let σ denote any permutation of $1, 2, \cdots, n$ such that

$$\theta-2\pi<\theta_{\sigma(1)}\leqq\theta_{\sigma(2)}\leqq\cdots\leqq\theta_{\sigma(n)}<\theta. \tag{7.1}$$

In the case that λ is generic, inequality holds everywhere in (7.1) and σ is uniquely determined by (λ, θ). Furthermore, σ has the following geometric interpretation: If we move along a circular arc $t-\lambda=\varepsilon e^{i\varphi}$ (with $\varepsilon>0$ and small, $\varphi\in(\theta-2\pi, \theta)$) in the positive sense, then we first cross the cut from λ to $\lambda_{\sigma(1)}$, then from λ to $\lambda_{\sigma(2)}$, etc.

If λ is *exceptional* (i.e., nongeneric), then (7.1) holds for several permutations. Letting σ denote any such (fixed) permutation, we now wish to show that there exists a system of cuts for which the above interpretation still applies (and which coincides with the system in § 6 in case λ is generic). We construct these cuts as follows.

If there is only one point λ_k on the ray $\arg(t-\lambda)=\theta_k$, we cut from λ to λ_k along the straight line segment. Otherwise, let j and l $(1\leqq j<j+l\leqq n)$ be such that (with the conventions $\theta_{\sigma(0)}=\theta-2\pi$, $\theta_{\sigma(n+1)}=\theta$)

$$\theta_{\sigma(j-1)}<\theta_{\sigma(j)}=\theta_{\sigma(j+1)}=\cdots=\theta_{\sigma(j+l)}<\theta_{\sigma(j+l+1)}.$$

Then the points $\lambda_{\sigma(j)}, \cdots, \lambda_{\sigma(j+l)}$ and no others lie on the ray $\arg(t-\lambda)=\theta_{\sigma(j)}\equiv\hat{\theta}$. We wish to cut from λ to $\lambda_{\sigma(j)}$, λ to $\lambda_{\sigma(j+1)}$, etc., by a set of nonselfintersecting polygonal arcs (meeting only at λ) such that the directed line segments constituting these arcs all have direction in $(\hat{\theta}-\varepsilon, \hat{\theta}+\varepsilon)$, where ε is any sufficiently small positive number (so that these arcs will not cross any of those from λ to λ_k for $k<j$ or $k>j+l$). First make a polygonal cut from λ to $\lambda_{\sigma(j)}$ (satisfying the above restriction) so that all points λ_k on the ray $\arg(t-\lambda)=\hat{\theta}$ which are closer to λ than $\lambda_{\sigma(j)}$ lie to the *left* of the arc. Next make a cut from λ to $\lambda_{\sigma(j+1)}$ starting out from λ slightly to the left of the previous cut and staying always to the right of all points λ_k closer to λ that $\lambda_{\sigma(j+1)}$ (except that the cut must pass to the left of $\lambda_{\sigma(j)}$ if $\lambda_{\sigma(j+1)}$ is further out than $\lambda_{\sigma(j)}$). (For the point on the ray $\arg(t-\lambda)=\hat{\theta}$ that is closest to λ we will cut along the straight line segment.) Continuing in this manner, we always begin the next cut slightly to the left of the previous one and stay to the right of all points that have not already been treated. This procedure then gives us a system of cuts so that when we traverse (in the positive sense) a circular arc close to λ with argument close to $\hat{\theta}$, we first encounter the cut from λ to $\lambda_{\sigma(j)}$, then from λ to $\lambda_{\sigma(j+1)}$, etc., and finally the one from λ to $\lambda_{\sigma(j+l)}$.

Remark 7.1. Given an admissible pair (λ, θ) and a permutation σ satisfying (7.1), we call any system of cuts of the type described above a *canonical system corresponding to the data* λ, θ, σ. (Note that in the generic case there is a unique system, whereas in the exceptional cases there are infinitely many possible systems. However, if we would call two systems *equivalent* when one can be homotopically deformed into the other without crossing any of the points $\lambda_1, \cdots, \lambda_n$ or the cut from λ to ∞, then the permutation uniquely specifies a system of cuts up to equivalence.) We also remark that given a canonical system, it would, of course, be possible to select an enumeration of $\lambda_1, \cdots, \lambda_n$ so that the cuts in $(\theta-2\pi, \theta)$ occur in their natural order, but this ordering clearly depends on the location of λ. Since we wish to discuss different choices of λ for the same $\lambda_1, \cdots, \lambda_n$, that point of view would not be convenient here.

In either case (generic or exceptional) we will use the symbol $\mathscr{P}=\mathscr{P}(\lambda, \theta, \sigma)$ for the t-plane with a specified canonical system of cuts.

Given any canonical system of cuts, one sees that the region

$$\theta_j + \pi/2 < \arg(\lambda_j - t) < \theta_j + 3\pi/2, \qquad |t - \lambda_j| < \varepsilon$$

(for sufficiently small $\varepsilon > 0$) is contained in $\mathcal{P}$ for every $j = 1, 2, \cdots, n$. Hence for such t we may define $\xi_j(s, t)$ by (3.1) and analytically continue it (with respect to t) into all of $\mathcal{P}$. Likewise, for $t \in \mathcal{P}$ we may use (6.2) to define $\Phi(s, t)$ and for the same reasons as stated there and in Remark 6.1, Proposition 6 holds for these functions as well, except for the expressions (6.4) and (6.6), which depend upon the assumption that the cuts are almost parallel (with ν determined by (6.1)). Our goal is to determine how the permutation σ influences the expressions for $C(s)$ and $\Delta(s)$ in (6.4) and (6.6) and to show in the process how to calculate all the matrices $C(s)$ and $\Delta(s)$ if they are known for a single admissible pair λ, θ.

As preparation for this, we consider the following rather general situation: Given an admissible pair (λ, θ) and a canonical system of cuts corresponding to a permutation σ, let $\mathcal{P}_{\lambda,\theta,\sigma} = \mathcal{P}$ denote the plane with these cuts and assume h and l are such that $\arg(\lambda_h - \lambda) = \arg(\lambda_l - \lambda)$ and the cut from λ to λ_l *immediately follows* the cut from λ to λ_h, i.e., $\sigma(l) = \sigma(h+1)$. Then there exists a polygonal cut π in $\mathcal{P}$ (of the type described above) from λ to λ_l that *immediately precedes* the cut from λ to λ_h such that the union of π and the original cut from λ to λ_l is a closed Jordan curve containing λ_h in its interior and *none* of the other λ_k, $k \neq h$.

Let $\tilde{\mathcal{P}}$ denote the t-plane with the same system of cuts as in $\mathcal{P}$, but the original cut from λ to λ_l is replaced by π, and let $\tilde{\xi}_j(s, t)$ and $\tilde{\varphi}_j(s, t)$ denote the corresponding analytic continuations (with respect to $t \in \tilde{\mathcal{P}}$) of the functions given locally by (3.1), (6.2). (We continue to use the notation $\xi_j(s, t)$, $\varphi_j(s, t)$ for the analytic continuations of the same germs in $\mathcal{P}$.) Let $\tilde{C}(s)$ and $\tilde{\Delta}(s)$ denote the unique matrices associated with these functions (by Proposition 6). We state the relation between these matrices and the original ones now as follows.

LEMMA 1. *In the situation described above, suppose that λ_l and λ_h are such that the cut from λ to λ_l lies on the left-hand side of the cut from λ to λ_h (case* I*). Then*

$$\tilde{C}(s) = (I - c_{hl}(s)E_{hl})C(s)(I + e^{2\pi i(\lambda_l' - s)}c_{lh}(s)E_{lh}) \tag{7.2}$$

and

$$\tilde{\Delta}(s) = (I - c_{hl}(s)E_{hl})\Delta(s), \tag{7.3}$$

where E_{hl} denotes the $n \times n$ matrix, in which all entries are zero except for a one in the (h, l) position.

If the cut from λ to λ_l lies on the right-hand side of the cut from λ to λ_h (case II*) we have*

$$\tilde{C}(s) = (I + e^{2\pi i(\lambda_l' - s)}c_{hl}(s)E_{hl})C(s)(I - c_{lh}(s)E_{lh}) \tag{7.4}$$

and

$$\tilde{\Delta}(s) = (I + e^{2\pi i(\lambda_l' - s)}c_{hl}(s)E_{hl})\,\Delta(s). \tag{7.5}$$

Proof. We give the proof only for case I; the proof in case II follows similarly. For fixed j, k, $1 \leqq j, k \leqq n$, we will choose a path in $\tilde{\mathcal{P}}$ from λ_j to λ_k along which we will analytically continue our functions. If neither j nor k equals h or else if $j = k = h$, then the path may be chosen so that it does not cross the cut from λ to λ_h (in $\mathcal{P}$); hence $\xi_j(s, t)$ and $\tilde{\xi}_j(s, t)$ (which are equal by definition for t close to λ_j and arbitrary s) remain equal as t approaches λ_k along this path. Hence $\tilde{c}_{kj}(s) = c_{kj}(s)$.

Next consider $k = h$, $j \neq h$. Then using the fact that the cut from λ to λ_h lies to the right of the cut from λ to λ_l, one sees that there exists such a path (in $\mathcal{P}$) crossing the cut from λ to λ_l exactly once and in the positive sense (i.e., the selected branch of $\arg(t-\lambda_l)$ jumps by -2π as the cut is crossed). Furthermore, we may also take the crossing point close to λ_l. Since for $s \not\equiv \lambda_l' \pmod 1$, $t \in \mathcal{P}$

$$\xi_j(s, t) = \xi_l(s, t) c_{lj}(s)(1 - e^{2\pi i(s-\lambda_l')})^{-1} + \operatorname{reg}(t-\lambda_l),$$

and since (using (3.1)) the analytic continuation of $\xi_l(s, t)$ across the cut from λ to λ_l in the positive sense is given by

$$\xi_l(s, t)\, e^{2\pi i(s-\lambda_l')},$$

then the analytic continuation of $\xi_j(s, t)$ along the path to a point close to λ_h is given by

$$\xi_j(s, t) - \xi_l(s, t) c_{lj}(s).$$

But since $\xi_j(s, t)$ and $\tilde{\xi}_j(s, t)$ have the same local definition near λ_j and the above path stays in $\tilde{\mathcal{P}}$, then the above value is by definition $\tilde{\xi}_j(s, t)$. Hence

$$\tilde{\xi}_j(s, t) = \xi_j(s, t) - \xi_l(s, t) c_{lj}(s),$$

for t close to λ_h. This expression has been shown for $s \not\equiv \lambda_l' \pmod 1$, but since all the terms on both sides are entire functions of s, it remains valid for all complex s. Using this and the relations (6.3) we obtain

$$\tilde{c}_{hj}(s) = c_{hj}(s) - c_{hl}(s) c_{lj}(s), \qquad j \neq h, \quad 1 \leqq j \leqq n. \tag{7.6}$$

Last, we consider the case $j = h$, $k \neq h$. Then there is a path (in $\mathcal{P}$) from λ_h to λ_k that crosses the cut from λ to λ_l exactly once and in the negative sense (also crossing close to λ_l). Using the same reasoning as above, the analytic continuation of $\xi_k(s, t)$ along this path to a point near λ_k is given by

$$\xi_h(s, t) + \xi_l(s, t) c_{lh}(s)\, e^{2\pi i(\lambda_l' - s)},$$

and comparing this with the analytic continuation in $\tilde{\mathcal{P}}$ we find

$$\tilde{\xi}_h(s, t) = \xi_h(s, t) + \xi_l(s, t) c_{lh}(s)\, e^{2\pi i(\lambda_l' - s)}.$$

Using this and the relations (6.3) we obtain

$$\tilde{c}_{kh}(s) = c_{kh}(s) + c_{kl}(s) c_{lh}(s)\, e^{2\pi i(\lambda_l' - s)}, \qquad k \neq h, \quad 1 \leqq k \leqq n. \tag{7.7}$$

From (7.6), (7.7) and the definition $c_{jj} = 1 - e^{2\pi i(s-\lambda_j')}$, we obtain (7.2).

In a similar manner, observe that for every j, $1 \leqq j \leqq n$, $\tilde{\varphi}_j(s, t) = \varphi_j(s, t)$ for t close to λ_k, $k \neq h$, $1 \leqq k \leqq n$ (since φ_j, $\tilde{\varphi}_j$ have the same definition for $|t|$ large, $\arg t = \theta - \pi$, and all points λ_j for $j \neq h$ are accessible from such points in both $\mathcal{P}$ and $\tilde{\mathcal{P}}$). But for t close to λ_h, we have (using (6.5))

$$\tilde{\varphi}_j(s, t) = \varphi_j(s, t) - \xi_l(s, t)\, \delta_{lj}(s).$$

This implies (for $j = 1, 2, \cdots, n$) that

$$\tilde{\delta}_{kj}(s) = \delta_{kj}(s), \qquad k \neq h, \quad 1 \leqq k \leqq n,$$

and

$$\tilde{\delta}_{hj}(s) = \delta_{hj}(s) - c_{hl}(s)\, \delta_{lj}(s),$$

which yields (7.3). This completes the proof of case I and the lemma.

We now return to the question of how the permutation σ affects the matrices $C(s)$ and $\Delta(s)$. Corresponding to a fixed, but arbitrary, canonical system of cuts, let σ denote the permutation. We define two sets σ^+ and σ^- of ordered pairs (j, k) according to the rule

$$(7.8) \qquad \begin{aligned} &(j, k) \in \sigma^+ \quad \text{iff } \sigma^{-1}(j) > \sigma^{-1}(k), \\ &(j, k) \in \sigma^- \quad \text{iff } (k, j) \in \sigma^+. \end{aligned}$$

One may think of σ^+ as defining a complete ordering of the numbers $1, 2, \cdots, n$; in case of almost parallel cuts, the ordering coincides with the dominance relation in $S'_{\nu+1} = S(\tau_\nu, \tau_{\nu+1})$ for ν as in (6.1). (Compare [1, § 3.1] for the notation and interpretation of the dominance relation in terms of the ordering of the cuts.) The purpose of σ^+ and σ^- is to provide (in the general case) the structure that allows $C(s)$ to be decomposed in a manner similar to (6.4). We state our main result in this section as follows.

THEOREM 3. *Let a differential equation* (0.1), *a formal fundamental solution matrix* $H(z)$, *a solution* $X(z)$ *in Floquet form, an admissible pair* (λ, θ) *and a canonical system of cuts be given. (Consider all of the above fixed, but arbitrary, subject to our assumptions and natural restrictions.) If* σ *denotes the permutation induced by the cuts, let* $\sigma^\pm$ *be defined by* (7.8). *Then Proposition* 6 *extends to this situation as follows.*

(i) *There exist unique constant (i.e., independent of* s*) matrices* $C^+ = C^+[\sigma]$, *resp.* $C^- = C^-[\sigma]$ *having ones along their diagonals and nonzero off-diagonal elements only in positions* $(j, k) \in \sigma^+$, *resp.* $(j, k) \in \sigma^-$ *and such that*

$$(7.9) \qquad C(s) = C^- - e^{2\pi i(sI - \Lambda')} C^+.$$

(ii) *There is a unique constant invertible matrix* $\Omega = \Omega[\sigma]$ *such that*

$$(7.10) \qquad \Delta(s) = \Omega(I - e^{2\pi i(sI - M)}) \quad \textit{with } M \textit{ as in } (0.3).$$

(iii) *If we define*

$$(7.11) \qquad e^{2\pi i M[\sigma]} = C^-[\sigma](C^+[\sigma])^{-1} e^{2\pi i \Lambda'},$$

then

$$(7.12) \qquad e^{2\pi i M[\sigma]} = \Omega[\sigma] e^{2\pi i M} \Omega^{-1}[\sigma].$$

Proof. First observe that slight changes in θ do not affect the validity of statements (a) and (b) in Proposition 6 nor the form of $C(s)$ or $\Delta(s)$. Hence we may assume without loss of generality that $\theta \neq \eta_\nu$ (for every integer ν) and at the same time that none of the points $\lambda_1, \cdots, \lambda_n$ lie on the straight line through λ with direction θ. (This line we denote by g.) Consider such a straight line g now to be fixed and think of varying λ along g, observing that all pairs (λ, θ) are admissible for all $\lambda \in g$. For λ sufficiently far out (and on the proper side of g), the cuts can be seen to be almost parallel and in this situation it follows from Proposition 6 that statement (i) holds if we take

$$C^- = V_\nu \cdots V_{\nu-\mu+1} \quad \text{and} \quad C^+ = (V_{\nu-\mu} \cdots V_{\nu-m+1})^{-1}.$$

(Compare with [1, § 3], to see that $C^\pm$ have the required form.) Moreover, using (6.6) and (1.6) we see that (ii) and (iii) hold with $\Omega[\sigma] = \Omega_\nu$ and $M[\sigma] = M_\nu$ since

$$C^-(C^+)^{-1} e^{2\pi i \Lambda'} = e^{2\pi i \Lambda'} V_{\nu+m} \cdots V_{\nu+1} = e^{2\pi i M_\nu}$$

(using that for every integer l, $V_{l+m} = e^{-2\pi i \Lambda'} V_l e^{2\pi i \Lambda'}$).

Note that as λ moves along g in an interval containing only *generic values*, then using (6.3) and (6.5) it is easy to see that $c_{kj}(s)$ and $\delta_{kj}(s)$ do not change. Because of the choice of g, the only nongeneric points on g are isolated and there are only finitely many of them. So to establish the validity of (7.9), (7.10) and (7.12) it suffices to consider what changes take place in $C(s)$, $\Delta(s)$ for generic values of λ and $\tilde{\lambda}$ in adjacent open intervals that are separated by an exceptional value $\hat{\lambda}$.

Let the permutations corresponding to the cuts from λ, resp., $\tilde{\lambda}$, be denoted by σ, resp. $\tilde{\sigma}$, and note that since $\hat{\lambda}$ is the only exceptional value between λ and $\tilde{\lambda}$, then both

$$(\hat{\lambda}, \theta, \sigma) \quad \text{and} \quad (\hat{\lambda}, \theta, \tilde{\sigma})$$

are admissible data (in the sense that they correspond to systems of cuts of the type discussed above). Also note that with respect to the points λ_h, λ_l with $\arg(\lambda_h - \lambda) = \arg(\lambda_l - \lambda)$, the difference between σ and $\tilde{\sigma}$ corresponds to a reversal of the ordering of the cuts. There are only finitely many such rays emanating from $\hat{\lambda}$ containing points which are thus affected and the permutation taking σ to $\tilde{\sigma}$ acts separately on the cuts corresponding to each of the rays. Observe that in the limiting situation as $\lambda \to \hat{\lambda}$, the elements in $C(s)$ and $\Delta(s)$ depend only on the permutation σ and not on the specific cuts used in the limiting situation $(\hat{\lambda}, \theta, \sigma)$, since all points $\lambda_1, \cdots, \lambda_n$ are accessible to each other and λ by paths lying in both planes. To now see what changes take place between $(\hat{\lambda}, \theta, \sigma)$ and $(\hat{\lambda}, \theta, \tilde{\sigma})$, observe that there exists a sequence of permutations taking σ into $\tilde{\sigma}$ corresponding to systems of cuts such that for two consecutive systems of cuts the situation of Lemma 1 applies. Hence to show that the conclusions of Theorem 3 hold for $(\hat{\lambda}, \theta, \tilde{\sigma})$ (and consequently for $(\tilde{\lambda}, \theta, \tilde{\sigma})$) it is sufficient to prove the following.

LEMMA 2. *In the situation of Lemma* 1, *let* σ, *resp.* $\tilde{\sigma}$, *denote the permutations corresponding to* $\mathcal{P}$, *resp.*, $\tilde{\mathcal{P}}$, *satisfying the aforementioned conditions and let* $\sigma^{\pm}$, $\tilde{\sigma}^{\pm}$ *be determined by* (7.8). *Furthermore, assume that the conclusions of Theorem* 3 *hold for* $\hat{\lambda}$, θ, σ (*with matrices denoted* $C(s)$, $C^{\pm}$, $\Delta(s)$, Ω). *Then for* $\hat{\lambda}$, θ, $\tilde{\sigma}$ *we have*

$$\tilde{C}(s) = \tilde{C}^{-} - e^{2\pi i(sI - \Lambda')}\tilde{C}^{+}, \tag{7.13}$$

$$\tilde{\Delta}(s) = \tilde{\Omega}(I - e^{2\pi i(sI - M)}), \tag{7.14}$$

and

$$\tilde{\Omega}\, e^{2\pi i M}\tilde{\Omega}^{-1} = \tilde{C}^{-}(\tilde{C}^{+})^{-1}\, e^{2\pi i \Lambda'}, \tag{7.15}$$

where (*in case* $(h, l) \in \sigma^{-}$) *we have*

$$\tilde{C}^{+} = (I - c_{hl}^{-}\, e^{2\pi i(\lambda_h' - \lambda_l')}E_{hl})C^{+}(I - c_{lh}^{+}E_{lh}), \tag{7.16}$$

$$\tilde{C}^{-} = (I - c_{hl}^{-}E_{hl})C^{-}(I - c_{lh}^{+}E_{lh}), \tag{7.17}$$

and

$$\tilde{\Omega} = (I - c_{hl}^{-}E_{hl})\Omega, \tag{7.18}$$

whereas (*in case* $(h, l) \in \sigma^{+}$) *we have*

$$\tilde{C}^{+} = (I - c_{hl}^{+}E_{hl})C^{+}(I - c_{lh}^{-}E_{lh}), \tag{7.19}$$

$$\tilde{C}^{-} = (I - e^{2\pi i(\lambda_l' - \lambda_h')}c_{hl}^{+}E_{hl})C^{-}(I - c_{lh}^{-}E_{lh}), \tag{7.20}$$

and

$$\tilde{\Omega} = (I - e^{2\pi i(\lambda_l' - \lambda_h')}c_{hl}^{+}E_{hl})\Omega. \tag{7.21}$$

Hence $\tilde{C}^{+}$, *resp.* $\tilde{C}^{-}$ *have ones on their main diagonals and nonzero off-diagonal elements only for positions in* $\tilde{\sigma}^{+}$, *resp.* $\tilde{\sigma}^{-}$.

Proof. We will restrict ourselves to the case $(h, l) \in \sigma^-$; the other case follows analogously. Observe that $(h, l) \in \sigma^-$ corresponds to case I of Lemma 1, since $\sigma^{-1}(l) > \sigma^{-1}(h)$ means that the cut from λ to λ_l comes after the cut from λ to λ_h (when traversing an arc close to λ in the positive sense). From (7.9) we find $c_{hl}(s) = c_{hl}^-$, $c_{lh}(s) = -e^{2\pi i(s-\lambda_l)} c_{lh}^+$. From (7.2) we therefore find (7.13) (if we define $\tilde{C}^{\pm}$ by (7.16), (7.17). Moreover, (7.14) and (7.15) follow immediately, using (7.3), (7.10), (7.16), (7.17), (7.18). It remains to show that $\tilde{C}^+$, $\tilde{C}^-$ (defined by (7.16), (7.17)) again have ones along the diagonal and nonzero off-diagonal terms only in positions $(j, k) \in \tilde{\sigma}^+$ resp. $(j, k) \in \tilde{\sigma}^-$. In order to do so, observe that re-enumerating the points $\lambda_1, \cdots, \lambda_n$ corresponds to applying the same permutation similarity transform to $C(s)$ and $\tilde{C}(s)$ (hence to $C^{\pm}$ and $\tilde{C}^{\pm}$). So for the purpose of simplifying the arguments, we may assume (without loss of generality) that $\lambda_1, \cdots, \lambda_n$ are enumerated according to the ordering of the cuts in $\mathcal{P}$ (from right to left when looking toward λ). In this case $(j, k) \in \sigma^+$ iff $j < k$, i.e., C^+ is upper triangular and C^- lower triangular. Moreover, the selection of cuts and the fact that we consider the case $(h, l) \in \sigma^-$ implies $h = l+1$. Hence it follows easily from (7.16), (7.17) that $\tilde{C}^+$ (resp. $\tilde{C}^-$) has ones along the diagonal and a zero in the (l, h) (resp. (h, l)) position, and the only nonzero element below (above) the diagonal may occur in the (h, l) (resp. (l, h)) position. This completes the proof.

8. Applications and final remarks. Finally, we will discuss how the previous results may be used to solve the central connection problem, in the case of an arbitrary admissible (λ, θ) (λ generic). For a solution $X(z) = L(z) z^M$ in Floquet form with monodromy matrix M in upper triangular Jordan form, let $\Delta(s) = \Omega(I - e^{2\pi i(sI - M)})$ be as in Theorem 3. If $b_j(p)$, μ, n_1 are as in Theorem 2, then the proof of that theorem also applies to situations of arbitrary generic λ (where the cuts generally are not almost parallel), and we find for arbitrary p and $j = 1, \cdots, n_1$:

$$b_j(p) = \sum_{q=0}^{j-1} \frac{1}{q!} \sum_{k=1}^{n} \omega_{k, j-q} \left(\frac{\partial}{\partial s}\right)^q \xi_k(s, \lambda) \Big|_{s=p+\mu+1}. \tag{8.1}$$

This expression and the corresponding formulas for the remaining blocks of M allow the following interpretations:

(a) If a monodromy matrix M in Jordan form and one Laurent coefficient $B(p) = [b_1(p), \cdots, b_n(p)]$ of a corresponding solution in Floquet form are known, and if the matrix $\xi(s, \lambda)$ is invertible (at least) for $s = p + \mu_j + 1$, $1 \leqq j \leqq n$, then the matrix $\Omega = [\omega_{kj}]$ can be uniquely computed from (8.1) and the corresponding formulas for the remaining blocks of M. Moreover, from (7.12), (7.11), (7.9) we can, successively, compute C^-, C^+, $C(s)$, and with the help of Lemma 1 we can explicitly see how $C(s)$ (and $\Delta(s)$) changes with respect to λ so that in the end we may compute the corresponding matrices for a situation of almost parallel cuts. Using Proposition 6 we can then compute all the Stokes' multipliers and all the central connection matrices. We wish to emphasize that all the computations required above are merely matrix algebraic operations, except for the evaluation of $\xi(s, t)$ (and its s-derivatives) at the point $t = \lambda$. In case the so-called "pentagonal condition" holds, i.e.,

$$|\lambda_j - \lambda| < |\lambda_j - \lambda_k| \qquad (k \neq j, 1 \leqq j, k \leqq n),$$

then for every $j = 1, \cdots, n$, the series (3.1) converges at $t = \lambda$ and may therefore be used directly to evaluate $\xi(s, \lambda)$. Generally one has to analytically continue $\xi(s, t)$ (along a straight line) to the point $t = \lambda$. This can be done by explicit summability methods or by rewriting (3.1) as a convergent generalized factorial series in s. (See R.

Schäfke [17] whose proof, given only for an equation (0.4), also carries over to equations of the form (0.1).) Concerning the invertibility of $\xi(s, \lambda)$, we may use either the asymptotic obtained in (3.3) to see that $\xi^{-1}(s, \lambda)$ exists for Re s sufficiently large, or, in the case of an equation (0.4) we can explicitly compute the determinant of $\xi(s, t)$ (using both the difference and the differential equation for $\xi(s, t)$ and its asymptotic; compare Hukuhara [9] for details):

$$\det \xi(s, t) = \prod_1^n \frac{(\lambda_j - t)^{s-\lambda_j'-1}}{\Gamma(s-\mu_j)}. \tag{8.2}$$

Consequently, if we assume that A_1 has n eigenvalues $\mu_1, \cdots, \mu_n$ incongruent modulo one, then $\xi(s, \lambda)$ is invertible for the values $s = \mu_j + 1$ $(1 \leqq j \leqq n)$. Hence if $X(z) = L(z)z^M$ (with $M = \operatorname{diag}[\mu_1, \cdots, \mu_n]$, $L(z)\, e^{-\lambda z} = \sum_0^\infty B(p)z^p$) is a given solution in Floquet form, then (8.1) (and the corresponding formulas for the other—one-dimensional—Jordan blocks of M) imply (with $p = 0$)

$$b_j(0) = \sum_{k=1}^n \omega_{k,j}\xi_k(\mu_j + 1, \lambda) \qquad (1 \leqq j \leqq n),$$

and solving these systems of linear equations gives Ω explicitly. Kohno [14], under the additional assumption of a pentagonal condition (and considering only the case $\lambda = 0$), derived an analogous result (even for equations having a singularity of larger rank at ∞ and a somewhat more general structure for the formal solution, but zero, the only finite singularity, being of first kind). To remove the assumptions of a pentagonal condition from Kohno's results, it has been observed by Sibuya [24] that one should in some sense analytically continue the functions in Kohno's formulas. One natural way to do this involves continuing the functions $\xi_j(s, t)$ with respect to t to a convenient value λ and then one needs to know how the connection constants depend upon the choice of λ.

(b) Using the freedom in the selection of a solution in Floquet form (corresponding to some fixed M), the result (a) has the following "converse": Suppose that the Stokes' multipliers are known, then one can compute the matrix $C(s)$ (and vice versa) corresponding to our selected admissible pair (λ, θ). From (7.9) we then compute C^+, C^-. If Ω is *any* invertible constant matrix for which

$$\Omega^{-1}C^-(C^+)^{-1}\, e^{2\pi i\Lambda'}\Omega = e^{2\pi iM}$$

with M in upper triangular Jordan form, then by (8.1) and the corresponding formulas for the other blocks of M we *define* $B(p) = [b_1(p), \cdots, b_n(p)]$, for arbitrary integer p. The matrix

$$X(z) = L(z)z^M, \qquad L(z)\, e^{-z\lambda} = \sum_{-\infty}^{\infty} B(p)z^p$$

then is a fundamental solution of (0.1) in Floquet form whose central connection coefficients can be explicitly computed in terms of Ω (following the same steps as in (a)).

As a result of the preceding discussion, we now formulate Theorem 4.

THEOREM 4. *Consider a differential equation* (0.1) *satisfying our basic assumptions, any selected formal fundamental solution matrix* $H(z)$ *as in* (0.2), *and any admissible pair* (λ, θ), with λ *a generic value. Then the following statements hold*:

(a) *If a monodromy matrix* M (*in upper triangular Jordan canonical form*) *and the* p*th Laurent coefficient* $B(p)$ *of* $L(z)\, e^{-z\lambda}$ (*for a solution* $X(z) = L(z)z^M$ *in Floquet form*) *are known* (*with fixed* p, *sufficiently large*), *then the matrix* $\Omega = \Delta(s)\ (I - e^{2\pi i(sI-M)})^{-1}$ *can be explicitly computed from systems of linear equations involving* $B(p)$ *and* $\xi(s, \lambda)$

together with its derivatives with respect to s, for values $s = p + \mu_j + 1$ $(1 \leqq j \leqq n)$. *Moreover, from* Ω *one can explicitly compute all the Stokes' multipliers and central connection matrices, using only arithmetical operations.*

(*b*) *If all the Stokes' multipliers (or equivalently,* $C(s)$*) have been calculated from the global behavior of* $\xi(s, t)$, *and if* Ω *is any invertible matrix for which*

$$\Omega^{-1} C^{-} (C^{+})^{-1} e^{2\pi i \Lambda'} \Omega = e^{2\pi i M}$$

with M in upper triangular Jordan form, then defining $B(p)$ *by* (8.1) *resp. the corresponding formulas for the other blocks of M, the matrix*

$$X(z) = L(z) z^{M}, \qquad L(z)\, e^{-z\lambda} = \sum_{-\infty}^{\infty} B(p) z^{p},$$

is a fundamental solution of (0.1) *in Floquet form, and its central connection coefficients may be explicitly computed from* Ω, *using the same procedure as in* (a).

9. An example. Consider the scalar, second-order differential equation

$$\frac{d^2y}{dz^2} + \frac{1}{z}\frac{dy}{dz} + \left(h^2 - \frac{\tilde{\lambda}}{z^2} + \frac{h^2}{z^4}\right) y = 0, \tag{9.1}$$

which we write in equivalent system form as

$$\frac{d}{dz}\begin{pmatrix} y \\ dy/dz \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ -h^2 + \tilde{\lambda}/z^2 - h^2/z^4 & -1/z \end{pmatrix} \begin{pmatrix} y \\ dy/dz \end{pmatrix} \equiv A(z) \begin{pmatrix} y \\ dy/dz \end{pmatrix}. \tag{9.2}$$

It is well known that (9.1) is related to Mathieu's differential equation

$$\frac{d^2\tilde{y}}{d\theta^2} + (\tilde{\lambda} - 2h^2 \cos 2\theta)\tilde{y} = 0 \tag{9.3}$$

through the change of variable $z = e^{i\theta}$ and $y(z) = \tilde{y}(\theta)$. The quantities h and $\tilde{\lambda}$ are complex parameters with $h \neq 0$: We use the same notation as in Meixner and Schäfke [22] except we have been forced to replace their λ by $\tilde{\lambda}$, since λ has already a special meaning for us from §§ 6–8.

Traditionally, it has been more popular [22] to treat (9.3) using Floquet's theory for periodic differential equations rather than (9.1) or (9.2), which are meromorphic differential equations having irregular singularities at 0 and ∞. Our goal is to apply the preceding theory to represent a fundamental matrix for (9.2) in Floquet form, that is, as a convergent Laurent series times a matrix power z^M. In terms of (9.3) this corresponds to calculating the Fourier expansion for the periodic part of a Floquet solution as well as the Floquet exponents. The formulas we derive here are not intended to supplant or duplicate the rather extensive literature on Mathieu functions, much of which is motivated by applications to eigenfunction expansions, but instead to indicate how the results of this paper could be applied to an interesting differential equation with multiple irregular singularities.

Near ∞, we select for (9.2) the formal fundamental solution matrix

$$H(z) = F(z) z^{\Lambda'} e^{\Lambda z}, \tag{9.4}$$

where $\Lambda = \operatorname{diag}\{ih, -ih\}$, $\Lambda' = \operatorname{diag}\{-\frac{1}{2}, -\frac{1}{2}\}$, $F(z) = \sum_0^{\infty} F_p z^{-p}$ with

$$F_0 = \begin{pmatrix} 1 & 1 \\ ih & -ih \end{pmatrix},$$

and h is selected so that $-\pi < \arg h \leqq 0$, replacing h by $-h$ if necessary. This selection corresponds to ordering the pair $(ih, -ih)$ lexicographically (in decreasing order, first by real, then imaginary parts).

In the study of (9.3) it is convenient to use its special form and periodicity to minimize the required calculations. For (9.1) this corresponds to its invariance with respect to each of the substitutions $z \to z e^{\pi i}$ and $z \to 1/z$. For (9.2) this implies that if $X(z)$ is a fundamental solution matrix (actual or formal), then

$$\operatorname{diag}\{1, -1\}X(z e^{\pi i}) \quad \text{and} \quad \operatorname{diag}\{1, -1/z^2\}X(1/z)$$

also are fundamental solutions. (We remark that all solutions are considered to be defined on the Riemann surface of $\log z$ with $\arg z$ selected consistent with the treatment in the earlier sections.)

It follows that there exists a constant, invertible matrix C such that

$$\operatorname{diag}\{1, -1\}H(z e^{\pi i}) = H(z)C \tag{9.5}$$

and using (9.4) we find that

$$C = \begin{pmatrix} 0 & -i \\ -i & 0 \end{pmatrix}$$

and

$$\operatorname{diag}\{1, -1\}F(-z) = F(z)\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}. \tag{9.6}$$

Also, since

$$\begin{aligned} \hat{H}(z) &= \operatorname{diag}\{1, -1/z^2\}H(1/z) \\ &= \operatorname{diag}\{1, -1/z^2\}F(1/z)z^{-\Lambda'} e^{\Lambda z^{-1}} \end{aligned}$$

is a formal fundamental solution, we may select this $\hat{H}(z)$ as our formal fundamental solution near $z = 0$.

The Stokes' rays for (9.2) with respect to the singularity at ∞ are those rays $\arg z = \tau$ for which $\operatorname{Re}(2ihz)$ changes sign. We let

$$\tau_0 = -\arg h \quad \text{and define } \tau_\nu = \tau_0 + \nu\pi$$

for all integers ν. Let $X_\nu(z)$ denote the νth normal solution (with respect to the singularity at ∞ and our selected $(H(z))$ and let (V_ν) denote the corresponding system of Stokes' multipliers.[1] From

$$X_\nu(z) \cong H(z), \quad z \to \infty, \quad \arg z \in (\tau_{\nu-1}, \tau_{\nu+1}),$$

we have (using (9.5))

$$\operatorname{diag}\{1, -1\}X_\nu(z e^{\pi i})C^{-1} \cong H(z), \quad z \to \infty, \quad \arg z \in (\tau_{\nu-2}, \tau_\nu),$$

hence (by uniqueness of the normal solutions)

$$X_{\nu-1}(z) = \operatorname{diag}\{1, -1\}X_\nu(z e^{\pi i})C^{-1} \quad \text{and} \quad V_{\nu-1} = CV_\nu C^{-1} \tag{9.7}$$

for all ν, i.e.,

$$V_{\nu-1} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} V_\nu \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}. \tag{9.8}$$

[1] Normal solutions can be represented, for example, as Laplace integrals using results of A. Erdélyi [19], [20].

In particular, due to the ordering of $(ih, -ih)$, we have

$$V_0 = \begin{pmatrix} 1 & 0 \\ v & 1 \end{pmatrix} \quad \text{and} \quad V_1 = \begin{pmatrix} 1 & v \\ 0 & 1 \end{pmatrix},$$

where v is a complex constant.

Define $\hat{X}_\nu(z) = \operatorname{diag}\{1, -1/z^2\} X_\nu(1/z)$, where we select $\arg(1/z) = -\arg z$. Then the Stokes' rays with respect to the singularity at $z = 0$ are those rays for which $\operatorname{Re}(2ihz^{-1})$ changes sign. To simplify the notation we can enumerate them as $\hat{\tau}_\nu = -\tau_\nu$ and note that $\arg z \in (\tau_{\nu-1}, \tau_{\nu+1})$ iff $\arg(1/z) \in (\hat{\tau}_{\nu-1}, \hat{\tau}_{\nu+1})$. It follows that $\hat{X}_\nu(z)$ is the νth normal solution (at 0 with respect to the selected $\hat{H}(z)$ and the Stokes' multipliers at 0 are exactly the same as the V_ν).

Hence there is just one quantity v that determines all the Stokes' multipliers at 0 and ∞; to calculate v we apply (5.7), which in this case reduces to

$$f_1(p) = v\alpha_2(\lambda_1' - p + 1) \tag{9.9}$$

with $\alpha_2(\lambda_1' - p + 1) \cong \Gamma(p)(2ih)^{-p}(f_2(0)/(2\pi i) + o(1))$ as $p \to +\infty$.[2] In using Corollary 1 we take $\eta = \eta_1 = \arg(ih) \in (-\pi/2, \pi/2]$, $\eta_0 = \eta_1 + \pi$, and also assume that $\lambda_1' \not\equiv \mu_j \pmod 1$.

Recalling our selection for F_0, this implies

$$v = -\frac{2\pi}{h} \lim_{p \to +\infty} \frac{f_{21}(p)(2ih)^p}{\Gamma(p)}, \tag{9.10}$$

where $f_1(p) = (f_{11}(p), f_{21}(p))^T$. We remark also that from the results in § 2 as well as in [11], (9.10) holds without the extra assumption on λ_1', while the construction of the function $\alpha_2(\cdot)$ and (9.9) depend upon that assumption. (The case when $\lambda_1' \equiv \mu_j \pmod 1$ will be seen shortly to be an especially simple one.)

The coefficients $f_1(p)$ are easily seen to satisfy

$$(2ihp) f_{11}(p) = ((p - 1/2)^2 - \tilde{\lambda}) f_{11}(p-1) + h^2 f_{11}(p-3), \qquad p \geqq 1 \tag{9.11}$$

and

$$f_{21}(p+1) = -(p + 1/2) f_{11}(p) + ih f_{11}(p+1), \qquad p \geqq -1 \tag{9.12}$$

with $f_{11}(-2) = f_{11}(-1) = 0$ and $f_{11}(0) = 1$. Defining $d(p) = (2ih)^p f_{11}(p)$, $p \geqq -2$, one sees that $(p+1)\, d(p+1) = (p + \frac{1}{2} + \beta)\,(p + \frac{1}{2} - \beta)\, d(p) - 4h^4\, d(p-2)$, $p \geqq 0$, where $\beta^2 \equiv \tilde{\lambda}$. Also defining

$$c(p) = d(p) \frac{\Gamma(p+1)}{\Gamma(p + \frac{1}{2} + \beta)\Gamma(p + \frac{1}{2} - \beta)} \quad \text{for } p \geqq 0,$$

one sees that

$$c(p+1) = c(p) - \frac{4h^4 \Gamma(p+1)\, d(p-2)}{\Gamma(p + \frac{3}{2} + \beta)\Gamma(p + \frac{3}{2} - \beta)}, \qquad p \geqq 0,$$

which implies that

$$c(p) = c(0) - 4h^4 \sum_{j=0}^{p-1} \frac{\Gamma(j+1)\, d(j-2)}{\Gamma(j + \frac{3}{2} + \beta)\Gamma(j + \frac{3}{2} - \beta)}, \qquad p \geqq 0.$$

Since $\Gamma(p + \frac{1}{2} + \beta)\Gamma(p + \frac{1}{2} - \beta)/\Gamma(p+1) \cong \Gamma(p)$ as $p \to +\infty$, we conclude from (9.10) that

$$v = 2\pi i \lim_{p \to +\infty} \frac{f_{11}(p)(2ih)^p}{\Gamma(p)} = 2\pi i \lim_{p \to +\infty} c(p),$$

[2] Also see [21] where the case of a scalar, second-order differential equation is described in detail.

where we have used that the first limit exists also from (9.9). (Also see [21], where the matrix formulas have been translated to the scalar case.) Hence it follows that

$$\frac{v}{2\pi i}=\frac{1}{\Gamma(\frac{1}{2}+\beta)\Gamma(\frac{1}{2}-\beta)}-4h^4\sum_{j=0}^{\infty}\frac{\Gamma(j+3)\,d(j)}{\Gamma(j+\frac{7}{2}+\beta)\Gamma(j+\frac{7}{2}-\beta)}$$

and since the $d(j)$ are easily seen to be polynomials in $\beta^2=\tilde{\lambda}$ and h^4 and of order $O(\Gamma(j))$ as $j\to\infty$, then the above series can be shown to converge compactly with respect to both variables, hence to an entire function in $\tilde{\lambda}$ and h^4. Note that the Stokes' factors are not defined for $h=0$, but the function v has a removable singularity there, in any case.

In terms of the Stokes' multipliers, one can construct a circuit factor for $X_{-1}(z)$ as $-V_1V_0$, hence the most general circuit factor is given by

$$\Omega^{-1}(-V_1V_0)\Omega=\Omega^{-1}\begin{pmatrix}-1-v^2 & -v\\ -v & -1\end{pmatrix}\Omega\equiv e^{2\pi iM}, \tag{9.13}$$

where Ω is an invertible matrix. To put $e^{2\pi iM}$ in Jordan form, use an auxiliary parameter μ defined (up to sign and modulo 2) by the equation

$$2i\cos\pi\mu=v.$$

For every possible fixed selection of μ, the values $x_1=e^{2\pi i\mu}$, $x_2=e^{-2\pi i\mu}$ then are the roots of

$$x^2+(2+v^2)x+1=0 \tag{9.14}$$

(hence are the eigenvalues of $e^{2\pi iM}$). The roots are equal in the cases $v=0$, resp. $v^2=-4$, in which cases they are -1, resp. 1. Both special cases are of particular interest: In case $v=0$, i.e., 2μ an odd integer, both columns of $F(z)$ converge, and a solution in Floquet form is given by $H(z)$. In case $v^2=-4$, i.e., μ an integer, a Jordan canonical form for $e^{2\pi iM}$ is

$$\begin{pmatrix}1 & 1\\ 0 & 1\end{pmatrix},$$

and M can be selected as

$$M=\begin{pmatrix}0 & (2\pi i)^{-1}\\ 0 & 0\end{pmatrix}.$$

When $v^2\neq -4$, we select Ω as

$$\Omega=\begin{pmatrix}e^{i\pi\mu} & e^{-i\pi\mu}\\ -i & -i\end{pmatrix}, \tag{9.15}$$

and we may take $M=\operatorname{diag}\{\mu,-\mu\}$ in (9.13); but every selection $M=\operatorname{diag}\{\mu_1,\mu_2\}$, with $e^{2\pi i\mu_j}=x_j$, $j=1,2$, will also satisfy (9.13). When $v^2=-4$ we may select

$$\Omega=\begin{pmatrix}1 & 0\\ \mp i & \pm i/2\end{pmatrix}\quad\text{in case } v=\pm 2i. \tag{9.16}$$

To calculate the Laurent coefficients, we first construct the associated functions

$$\xi_1(s,t)=\sum_0^{\infty}\frac{f_1(l)(ih-t)^{l+s-1/2}}{\Gamma(l+s+\frac{1}{2})}\quad\text{and}\quad\xi_2(s,t)=\sum_0^{\infty}\frac{f_2(l)(-ih-t)^{l+s-1/2}}{\Gamma(l+s+\frac{1}{2})},$$

where (consistent with the discussion in § 6) we may choose $\lambda = 0$ and cut the complex t-plane from $\pm ih$ to 0 along the line segments and from 0 to ∞ along $\arg(ih) + 3\pi/2 \equiv \theta$, with $\theta_1 = \arg(ih) \in (-\pi/2, \pi/2]$.

For t in the cut plane, denoted $\mathcal{P}$, we select

$$\arg(ih - t) \in (\theta_1, \theta_1 + 2\pi) \quad \text{and} \quad \arg(-ih - t) \in (\theta_1 + \pi, \theta_1 + 3\pi)$$

(for t close to ih, resp. $-ih$) to define the nonintegral powers. The identity (9.6) has the following interpretation for the associated functions.

Replacing t by $-t$ in the definition of $\xi_1(s, t)$ and using (9.6), we have

$$(ih + t)^{1/2-s}\xi_1(s, -t) = \operatorname{diag}\{1, -1\}(-ih - t)^{1/2-s}\xi_2(s, t) \tag{9.17}$$

for t such that $t, -t \in \mathcal{P}$. For $t \in \mathcal{P}$ with $\operatorname{Re}(te^{-i\theta_1}) < 0$ we find $\arg(-ih - t) = \pi + \arg(ih + t)$; hence

$$\xi_1(s, -t) = e^{i\pi(1/2-s)} \operatorname{diag}\{1, -1\}\xi_2(s, t).$$

Using the above relations in

$$\xi_1(s, t) = c_{21}(s)(1 - e^{2\pi i(s-1/2)})^{-1}\xi_2(s, t) + \operatorname{reg}(t + ih)$$

with $t \to -t$, one sees that

$$c_{12}(s) = c_{21}(s)\, e^{2\pi i(s-1/2)} = -c_{21}(s)\, e^{2\pi i s},$$

which agrees with (6.4) when we take $\nu = -2$ in (6.1).

Note that the above choice of $\lambda = 0$ is generic (in the sense of § 6) but the system of cuts is *not* almost parallel. This choice for λ is especially convenient, however, because both power series converge absolutely there (like geometric series) and the Laurent coefficients are produced directly rather than multiplied by the power series for $e^{-\lambda z}$ if $\lambda \neq 0$.

To apply formula (8.1), let μ_1, μ_2 be defined as above and let

$$\xi_k(p + \mu_j + 1, 0) = \sum_{l=0}^{\infty} \frac{f_k(l)[(-1)^{k+1}(ih)]^{l+p+\mu_j+1/2}}{\Gamma(l + p + \mu_j + 1)}$$

for $j, k = 1, 2$ and $p \in \mathbb{Z}$. (Note that in defining the nonintegral powers above, we must select the "forbidden" values $\arg(ih) = \theta_1$ and $\arg(-ih) = \pi + \theta_1$ according to the discussion preceding the statement of Theorem 2.)

In case $v^2 \neq -4$, take $\Omega = (\omega_{kj})$ as in (9.15) and form

$$l_j(p) \equiv b_j(p, 0) = \omega_{1j}\xi_1(p + \mu_j + 1, 0) + \omega_{2j}\xi_2(p + \mu_j + 1, 0) \quad \text{for } j = 1, 2. \tag{9.18}$$

Then from Theorem 4(b), $\sum_{-\infty}^{+\infty} [l_1(p), l_2(p)]z^{pI+M}$ *is a fundamental solution matrix for* (9.2) *in Floquet form.*

If $v^2 = -4$, then $\mu_1 = 0$ is a double root and we calculate $\xi_k(p + 1, 0)$, $k = 1, 2$, just as above and also

$$\frac{\partial}{\partial s}\xi_k(s, 0)\bigg|_{s=p+1} = \sum_{l=0}^{\infty} \frac{f_k(l)[(-1)^{k+1}ih]^{l+p+1/2}}{\Gamma(l + p + \frac{3}{2})} \log((-1)^{k+1}ih)$$

$$- \sum_{l=0}^{\infty} \frac{f_k(l)[(-1)^{k+1}ih]^{l+p+1/2}}{(\Gamma(l + p + \frac{3}{2}))^2}\Gamma'(l + p + \tfrac{3}{2}), \qquad k = 1, 2.$$

Then using Ω as in (9.16) and forming (according to (6.14))

$$l_1(p) = \xi_1(p + 1, 0) \mp i\xi_2(p + 1, 0)$$

and

$$l_2(p) = \pm\frac{i}{2}\xi_2(p+1,0) + \frac{\partial}{\partial s}\xi_1(p+1,0) \mp i\frac{\partial}{\partial s}\xi_2(p+1,0),$$

we obtain a solution for (9.2) *in Floquet form for the case* $v^2 = -4$ *as*

$$\sum_{-\infty}^{+\infty} [l_1(p), l_2(p)]z^p \begin{bmatrix} 1 & \log z/2\pi i \\ 0 & 1 \end{bmatrix}.$$

While we have constructed the Laurent coefficients L_p by the preceding infinite series for each integer p, it is interesting and useful to observe that because of the symmetries and special form of (9.2), it is only required to calculate a few such (transcendental) quantities in this manner; the remaining ones can then all be calculated recursively from the difference equation (0.6) and the symmetries as we now describe in the "main" case $v^2 \neq 0, -4$ (which corresponds to the nonperiodic case for (9.3)).

Let $X(z) = L(z)z^M$ denote the solution in Floquet form constructed above, where for definiteness we take

$$M = \operatorname{diag}\{\mu_1, -\mu_1\},$$

where $\mu_1 = \mu + k$, with μ denoting any *fixed* solution of $2i\cos\pi\mu = v$ and k denoting an integer. Then $2i\cos\pi\mu_1 = (-1)^k v$ and we will see below how the integer k affects the parity of the functions in $L(z)$. Observe that in our case ($v^2 \neq 0, -4$), $2\mu_1$ is not an integer.

Since

$$\operatorname{diag}\{1,-1\}X(z\,e^{\pi i}) = \operatorname{diag}\{1,-1\}L(-z)\,e^{\pi i M}z^M$$

is also a fundamental solution matrix for (9.2), there exists a constant, invertible matrix R such that

$$\operatorname{diag}\{1,-1\}L(-z)\,e^{\pi i M}z^M = L(z)z^M R,$$

from which it follows that $z^M R z^{-M}$ is single-valued. Since $2\mu_1$ is not an integer, it follows (see [10, p. 38]) that R is diagonal and

(9.19) $$\operatorname{diag}\{1,-1\}L(-z) = L(z)D \quad \text{where } D = \operatorname{diag}\{d_1, d_2\} = R\,e^{-\pi i M}.$$

Letting $L(z) = (\sum_{-\infty}^{+\infty} l_{ij}(p)z^p)$, $1 \leqq i, j \leqq 2$, it follows that for each integer p,

(9.20) $$(-1)^p l_{1j}(p) = d_j l_{1j}(p) \quad \text{and} \quad (-1)^{p+1} l_{2j}(p) = d_j l_{2j}(p),$$

$j = 1, 2$. Moreover, from Jacobi's identity one has $\det X(z) = \det L(z) = cz^{-1}$ for some nonzero constant c; hence from (9.19) $\det D = d_1 d_2 = 1$. Since neither column of $L(z)$ can be identically zero, it follows that either $d_1 = d_2 = 1$ and

(9.21) $$l_{1j}(2p+1) = 0, \quad l_{2j}(2p) = 0 \quad \text{for } j = 1, 2 \text{ and all } p$$

or $d_1 = d_2 = -1$ and

(9.22) $$l_{1j}(2p) = 0, \quad l_{2j}(2p+1) = 0 \quad \text{for } j = 1, 2 \text{ and all } p.$$

Which one of these cases occurs depends upon $k = \mu_1 - \mu$ being even or odd, as we will now see. From (9.17), setting $t = 0$ and recalling that in this event one must have $\arg(-ih) = \arg(ih) + \pi$ according to Theorem 2, we find

$$\xi_2(s,0) = \operatorname{diag}\{1,-1\}\,e^{i\pi(s-1/2)}\xi_1(s,0).$$

Using (9.18) and (9.15), it follows that

(9.23) $$l_1(p) = e^{i\pi\mu}\operatorname{diag}\{1 + e^{i\pi(p+\mu_1-\mu)}, 1 - e^{i\pi(p+\mu_1-\mu)}\}\xi_1(p+\mu_1+1,0);$$

hence (9.21) holds iff $\mu_1 - \mu$ is even while (9.22) holds iff $\mu_1 - \mu$ is odd.

The difference equation (0.6) for the first column of L_p in this case reduces to

$$[(p+\mu)^2-\tilde{\lambda}]l_{11}(p)+h^2l_{11}(p-2)+h^2l_{11}(p+2)=0 \tag{9.24}$$

and

$$l_{21}(p)=(\mu+p+1)l_{11}(p+1). \tag{9.25}$$

Hence one sees that if $l_{11}(p)$ and $l_{11}(p+2)$ are known for some value of p such that at least one of them is different from zero, then all the coefficients in the first column of $X(z)$ can be calculated recursively.

To generate the second column, one can use the fact that

$$\operatorname{diag}\{1, -1/z^2\}X(1/z)$$

is also a fundamental solution matrix, hence there exists an invertible, constant matrix P such that

$$\operatorname{diag}\{1, -1/z^2\}L(1/z)z^{-M}=L(z)z^MP.$$

From the single-valuedness of z^MPz^M and recalling 2μ is not an integer, one sees $\operatorname{diag} P=0$ and

$$\operatorname{diag}\{1, -1/z^2\}L(1/z)=L(z)P \quad \text{with } P=\begin{bmatrix}0 & \rho_2\\ \rho_1 & 0\end{bmatrix}. \tag{9.26}$$

Setting $z=1$ and taking the determinant, we have $\rho_1\rho_2=1$. Hence from (9.25) it follows that

$$l_{11}(p)=\rho_1l_{12}(-p) \quad \text{and} \quad -l_{21}(p)=\rho_1l_{22}(-p-2) \tag{9.27}$$

for all integers p.

Since for all p sufficiently large, it follows from the asymptotic (3.3) that the first component of $\xi_1(p+\mu_1+1, 0)$ is different from zero, then from the preceding discussion of the two cases (9.21) and (9.22), if we would select $k=0$, then $l_{11}(2n)\neq 0$ for all n sufficiently large. From (9.24) one sees that if two values $l_{11}(p)$, $l_{11}(p+2)$ would be zero, all the $l_{11}(p+2m)$ would be zero, hence if we are in case (9.21) then at least one of $l_{11}(p)$, $l_{11}(p+2)$ is different from zero for every even integer p. If $l_{11}(p)\neq 0$, then ρ_1 can be determined from (9.27) (by calculating $l_{12}(-p)$) and then all the other entries of the second column of $L(z)$ as well. On the other hand, if we just want *some* fundamental solution matrix in Floquet form, we could select $\rho_1=\rho_2=1$, which corresponds to multiplying the second column of $L(z)$ by a scalar, nonzero, constant (and also corresponds to changing the second column of the selected Ω in (9.15) by the same scalar factor). Since that Ω was not selected for any special purpose other than concreteness, if one just wants *a* fundamental solution in Floquet form, that point of view would be appropriate.

Hence we see that to calculate some solution for (9.2) in Floquet form according to this method, one must calculate three scalar quantities v, $l_{11}(p)$, $l_{11}(p+2)$, which are defined as the limits of infinite series. All other quantities in a Floquet solution can be recursively generated from these.

ASYMPTOTIC INTEGRATION OF A PERTURBED CONSTANT COEFFICIENT DIFFERENTIAL EQUATION UNDER MILD INTEGRAL SMALLNESS CONDITIONS*

WILLIAM F. TRENCH†

Abstract. The problem of asymptotic behavior of solutions of an nth order linear differential equation is reconsidered, and a result obtained by Hartman and Wintner under integral smallness conditions on the perturbing terms which require absolute integrability is shown to hold under weaker integrability conditions requiring only ordinary (perhaps conditional) convergence of some of the improper integrals that occur. The estimates of the asymptotic behavior of solutions of the perturbed equation are also sharper than in the classical result.

Key words. linear perturbations, asymptotic behavior, integral smallness conditions

AMS(MOS) subject classifications. 34C10, 34D10, 34E10

1. Introduction.

We consider the scalar equation

$$x^{(n)}+a_1x^{(n-1)}+\cdots+a_kx^{(n-k)}+P_1(t)x^{(n-1)}+\cdots+P_n(t)x=f(t), \qquad t>0, \tag{1.1}$$

where $a_1,\cdots,a_k$ are complex constants, with

$$1\leqq k\leqq n-1, \qquad a_k\neq 0. \tag{1.2}$$

It is assumed through that $P_1,\cdots,P_n$, and f are complex-valued and continuous on $(0,\infty)$. We give conditions on them which imply that (1.1) has a solution which behaves asymptotically like a given polynomial of degree $<n-k$.

The following theorem of Hartman and Wintner [1, Thm. 17.3, p. 316] addresses this question. (We use "o" and "O" in the standard way to denote behavior as $t\to\infty$.)

THEOREM 1. *Suppose that the polynomial*

$$Q(\lambda)=\lambda^k+a_1\lambda^{k-1}+\cdots+a_k$$

has no purely imaginary zeros, and that

$$\int^{\infty}|P_j(t)|t^q\,dt<\infty, \qquad 1\leqq j\leqq k+1, \tag{1.3}$$

and

$$\int^{\infty}|P_j(t)|t^{j-k-1+q}\,dt<\infty, \qquad k+2\leqq j\leqq n, \tag{1.4}$$

for some $q\geqq 0$. Then, for each $l=0,1,\cdots,n-k-1$, the equation

$$x^{(n)}+a_1x^{(n-1)}+\cdots+a_kx^{(n-k)}+P_1(t)x^{(n-1)}+\cdots+P_n(t)x=0, \qquad t>0, \tag{1.5}$$

has a solution x_l such that

$$\left(x_l(t)-\frac{t^l}{l!}\right)^{(r)}=\begin{cases} o(t^{l-r-q}), & 0\leqq r\leqq n-k-1,\\ o(t^{-n+l+k+1-q}), & n-k\leqq r\leqq n-1.\end{cases}$$

Prevatt [3] has obtained the conclusion of Theorem 1 under weaker integrability conditions on $|P_1|,\cdots,|P_n|$, and Hartman [2] has recently extended Prevatt's results

* Received by the editors March 31, 1986; accepted for publication (in revised form) December 22, 1986.
† Department of Mathematics, Trinity University, San Antonio, Texas 78284.

to the case where $Q(\lambda)$ may have purely imaginary zeros. Here we retain the assumption that $Q(\lambda)$ has no purely imaginary zeros, and we obtain results which imply the conclusion of Theorem 1 under integral smallness conditions on $P_1, \cdots, P_n$ and f which allow conditional convergence of some (in some cases all) of the improper integrals involved. We also give more precise estimates of the asymptotic behavior of the desired solutions.

The results obtained here are anaolgous to those obtained in [8] for the equation

$$x^{(n)} + P_1(t)x^{(n-1)} + \cdots + P_n(t)x = f(t) \tag{1.6}$$

(see also [7]); however, the condition (1.2) necessitates a distinctly nontrivial extension of the methods used in [7] and [8]. (For example, see Lemma 1 and its proof.)

In work related to the present paper in the sense that the integrability conditions on $P_1, \cdots, P_n$, and f are stated in terms of possibly conditional convergence, Šimša [4]-[6], has studied (1.1) with $k = n$, regarding it as a perturbation of the constant coefficient equation

$$x^{(n)} + a_1 x^{(n-1)} + \cdots + a_n x = 0.$$

The author [9] has also considered this problem.

2. The main theorem. It is to be understood below that improper integrals appearing in hypotheses are assumed to converge, and that the convergence may be conditional unless, of course, the integrand is necessarily nonnegative.

It is convenient to collect some technical definitions in the following standing assumption, which holds throughout the paper.

Assumption A. Let

$$Q(\lambda) = (\lambda - \lambda_1)^{d_1} \cdots (\lambda - \lambda_L)^{d_L} \tag{2.1}$$

where $\lambda_l = \mu_l + i\nu_l$ are distinct, $\mu_l \neq 0$ $(1 \leqq l \leqq L)$, and $\mu_1 \leqq \mu_2 \leqq \cdots \leqq \mu_L$. Let N be the unique integer in $\{1, \cdots, L+1\}$ such that

$$\mu_l < 0 \quad \text{if } 1 \leqq l \leqq N-1 \tag{2.2}$$

and $\mu_l > 0$ if $N \leqq l \leqq L$. Suppose that p is a given polynomial of degree $< n-k$, and define

$$g = f - \sum_{j=k+1}^{n} P_j p^{(n-j)}. \tag{2.3}$$

Let m be an integer in $\{0, \cdots, n-k-1\}$. Let ϕ be continuous, positive, and nonincreasing on $[a, \infty)$ for some $a > 0$. If $m \neq 0$, suppose that $t^{\gamma}\phi(t)$ is nondecreasing for some $\gamma < 1$. If $N \geqq 2$ (so that (2.2) is nonvacuous), let there be a number α such that $0 < \alpha < -\mu_{N-1}$ and $e^{\alpha t}t^{-n+m+k+1}\phi(t)$ is nondecreasing on $[a, \infty)$.

The following is our main theorem.

THEOREM 2. *Suppose that Assumption* A *holds, that*

$$\int_t^{\infty} s^{n-m-k-1} g(s)\, ds = O(\phi(t)), \tag{2.4}$$

and that

$$I_j(t) = \int_t^{\infty} |P_j(s)|\phi(s)\, ds = o(\phi(t)), \qquad 1 \leqq j \leqq k+1. \tag{2.5}$$

Suppose further that

$$F_j(t)=\int_t^\infty P_j(s)\,ds=o(t^{-j+k+1}),\qquad k+2\leqq j\leqq n, \tag{2.6}$$

and that

$$I_j(t)=\int_t^\infty |F_j(s)|s^{j-k-2}\phi(s)\,ds=o(\phi(t)),\qquad k+2\leqq j\leqq n. \tag{2.7}$$

Then (1.1) *has a solution* $\hat{x}$ *such that*

$$\hat{x}^{(r)}(t)-p^{(r)}(t)=\begin{cases}O(\phi(t)t^{m-r}), & 0\leqq r\leqq n-k-1,\\ O(\phi(t)t^{-n+m+k+1}), & n-k\leqq r\leqq n-1.\end{cases} \tag{2.8}$$

Moreover, if (2.4) *can be replaced by*

$$\int_t^\infty s^{n-m-k-1}g(s)\,ds=o(\phi(t)), \tag{2.9}$$

then (2.8) *can be replaced by*

$$\hat{x}^{(r)}(t)-p^{(r)}(t)=\begin{cases}o(\phi(t)t^{m-r}), & 0\leqq r\leqq n-k-1,\\ o(\phi(t)t^{-n+m+k+1}), & n-k\leqq r\leqq n-1.\end{cases} \tag{2.10}$$

The proof uses the Banach contraction principle. It is convenient to introduce the new dependent variable $h=x-p$, which transforms (1.1) into

$$Q(D)h^{(n-k)}=g-Mh, \tag{2.11}$$

with g as in (2.3) and

$$Mh=\sum_{j=1}^{n}P_jh^{(n-j)}. \tag{2.12}$$

We will construct a transformation $\mathcal{T}$ which, for t_0 sufficiently large, is a contraction of the Banach space $B(t_0)$ consisting of functions h in $C^{(n-1)}[t_0,\infty)$ such that

$$h^{(r)}(t)=\begin{cases}O(\phi(t)t^{m-r}), & 0\leqq r\leqq n-k-1,\\ O(\phi(t)t^{-n+m+k+1}), & n-k\leqq r\leqq n-1,\end{cases} \tag{2.13}$$

with norm

$$\|h\|=\sup_{t\geqq t_0}(\phi(t))^{-1}\left[\sum_{r=0}^{n-k-1}t^{r-m}|h^{(r)}(t)|+t^{n-m-k-1}\sum_{r=n-k}^{n-1}|h^{(r)}(t)|\right]. \tag{2.14}$$

For reference below, we define

$$B_0(t_0)=\{h\in B(t_0)|\ (2.13)\text{ holds with ``}O\text{'' replaced by ``}o\text{''}\}. \tag{2.15}$$

If $\hat{h}$ is a solution of (2.11) which is in $B(t_0)$, then the function

$$\hat{x}=p+\hat{h} \tag{2.16}$$

is a solution of (1.1) on $[t_0,\infty)$ (which can be continued over $(0,\infty)$), and $\hat{x}$ has the desired asymptotic behavior (2.8); moreover, if $\hat{h}\in B_0(t_0)$, then $\hat{x}$ satisfies (2.10). Therefore, we wish to construct $\mathcal{T}$ so that if $\mathcal{T}\hat{h}=\hat{h}$, then $\hat{h}$ satisfies (2.11).

To this end, let $A_1, \cdots, A_L$ be the uniquely defined polynomials such that $\deg A_l < d_l$ (see (2.1)) and

$$\sum_{l=1}^{L} [A_l(t)e^{\lambda_l t}]^{(r)}|_{t=0} = \delta_{r,k-1}, \qquad 0 \leqq r \leqq k-1. \tag{2.17}$$

If $v \in C[t_0, \infty)$, define $\mathscr{L}_1 v$ formally by

$$(\mathscr{L}_1 v)(t) = \sum_{l=1}^{N-1} \int_{t_0}^{t} A_l(t-\tau)e^{\lambda_l(t-\tau)}v(\tau)\,d\tau - \sum_{l=N}^{L} \int_{t}^{\infty} A_l(t-\tau)\,e^{\lambda_l(t-\tau)}v(\tau)\,d\tau.$$

Then formal differentiation and (2.17) imply that

$$\begin{aligned}(\mathscr{L}_1 v)^{(r)}(t) = &\sum_{l=1}^{N-1} \int_{t_0}^{t} A_{lr}(t-\tau)\,e^{\lambda_l(t-\tau)}v(\tau)\,d\tau \\ &- \sum_{l=N}^{L} \int_{t}^{\infty} A_{lr}(t-\tau)\,e^{\lambda_l(t-\tau)}v(\tau)\,d\tau, \qquad 0 \leqq r \leqq k-1,\end{aligned} \tag{2.18}$$

and that

$$Q(D)\mathscr{L}_1 v = v, \tag{2.19}$$

where A_{lr} is the polynomial defined by

$$A_{lr}(t) = e^{-\lambda_l t}[A_l(t)\,e^{\lambda_l t}]^{(r)}, \qquad 0 \leqq r \leqq k-1.$$

If $w \in C[t_0, \infty)$, define $\mathscr{L}_2 w$ formally by

$$(\mathscr{L}_2 w)(t) = \int_{t}^{\infty} \frac{(t-s)^{n-k-1}}{(n-k-1)!}\,w(s)\,ds \quad \text{if } m = 0 \tag{2.20}$$

or by

$$(\mathscr{L}_2 w)(t) = \int_{t_0}^{t} \frac{(t-\lambda)^{m-1}}{(m-1)!}\,d\lambda \int_{\lambda}^{\infty} \frac{(\lambda-s)^{n-k-m-1}}{(n-k-m-1)!}\,w(s)\,ds \quad \text{if } 1 \leqq m \leqq n-k-1. \tag{2.21}$$

In either case,

$$(\mathscr{L}_2 w)^{(n-k)} = -w. \tag{2.22}$$

Now define

$$G = \mathscr{L}_2(\mathscr{L}_1 g) \quad \text{(see (2.3))}, \tag{2.23}$$

$$\mathscr{L}h = \mathscr{L}_2(\mathscr{L}_1(Mh)) \quad \text{(see (2.12))}, \tag{2.24}$$

and

$$\mathscr{T}h = -G + \mathscr{L}h. \tag{2.25}$$

Formal manipulations using (2.19) and (2.22) show that

$$Q(D)(\mathscr{T}h)^{(n-k)} = g - Mh;$$

therefore, a fixed point (function) $\hat{h}$ of $\mathscr{T}$ satisfies (2.11). We will show that $\mathscr{T}$ is a contraction of $B(t_0)$, and therefore has a fixed point in $B(t_0)$, provided that t_0 is sufficiently large. It is convenient to present the lengthy proof of this assertion in a series of lemmas.

LEMMA 1. *Suppose that v is complex-valued and continuous on $[t_0, \infty)$ with $t_0 \geqq a > 0$, and that $\int^\infty t^q v(t)\,dt$ converges for some nonnegative integer q. Let*

$$\psi(t) = \sup_{\tau \geqq t} \left| \int_\tau^\infty s^q v(s)\,ds \right|. \tag{2.26}$$

Let $\lambda = \mu + i\nu$ be a complex number and X be a polynomial. Then

(i) *If $\mu > 0$, the functions*

$$f_1(t) = \int_t^\infty X(t-\tau)\, e^{\lambda(t-\tau)} v(\tau)\,d\tau \tag{2.27}$$

and

$$f_2(t) = \int_t^\infty s^q\,ds \int_s^\infty X(s-\tau)\, e^{\lambda(s-\tau)} v(\tau)\,d\tau = \int_t^\infty s^q f_1(s)\,ds \tag{2.28}$$

are defined on $[t_0, \infty)$ and satisfy the inequalities

$$|f_1(t)| \leqq K_1 t^{-q} \psi(t), \qquad t \geqq t_0, \tag{2.29}$$

$$|f_2(t)| \leqq K_2 \psi(t), \qquad t \geqq t_0, \tag{2.30}$$

where K_1 and K_2 are constants which depend only on λ and X.

(ii) *If $\mu < 0$, suppose that $\psi(t) = 0(\phi(t))$, where ϕ is nonincreasing and continuous on $[a, \infty)$, and $e^{\alpha t} t^{-q} \phi(t)$ in nondecreasing on $[a, \infty)$ for some α such that*

$$0 < \alpha < -\mu. \tag{2.31}$$

Let

$$\psi_1(t) = \sup_{\tau \geqq t} \frac{\psi(t)}{\phi(t)}, \tag{2.32}$$

and define

$$f_3(t) = \int_{t_0}^t X(t-\tau)\, e^{\lambda(t-\tau)} v(\tau)\,d\tau. \tag{2.33}$$

Then

$$|f_3(t)| \leqq K_3 \psi_1(t_0) t^{-q} \phi(t), \qquad t \geqq t_0, \tag{2.34}$$

where K_3 is a constant depending only on X and λ, and the function

$$f_4(t) = \int_t^\infty s^q\,ds \int_{t_0}^s X(s-\tau)\, e^{\lambda(s-\tau)} v(\tau)\,d\tau = \int_t^\infty s^q f_3(s)\,ds \tag{2.35}$$

is defined on $[t_0, \infty)$, and it satisfies the inequality

$$|f_4(t)| \leqq K_4 \psi_1(t_0) \phi(t), \qquad t \geqq t_0, \tag{2.36}$$

where K_4 is a constant depending only on X and λ.

Finally, if

$$\psi(t) = o(\phi(t)), \tag{2.37}$$

then

$$f_3(t) = o(t^{-q}\phi(t)) \tag{2.38}$$

and

$$f_4(t) = o(\phi(t)). \tag{2.39}$$

The lengthy proof of this lemma is given in § 4.

(Note that because of (2.29) and (2.30), (2.37) implies that $f_1(t) = o(t^{-q}\phi(t))$ and $f_2(t) = o(\phi(t))$.)

LEMMA 2. *Suppose that ϕ and m are as in Assumption* A *and $w \in C[t_0, \infty)$ for some $t_0 \geqq a$. Suppose also that $\int^\infty t^{n-m-k-1}w(t)\,dt$ converges, and that*

$$\int_t^\infty s^{n-m-k-1}w(s)\,ds = O(\phi(t)). \tag{2.40}$$

Define

$$\rho(t) = \sup_{\tau \geqq t} (\phi(\tau))^{-1} \left| \int_\tau^\infty s^{n-k-m-1}w(s)\,ds \right|. \tag{2.41}$$

Then $\mathscr{L}_2 w \in C^{(n-k)}[t_0, \infty)$ (see (2.20) *and* (2.21)), *and there is a constant K which does not depend on w or t_0 such that*

$$|(\mathscr{L}_2 w)^{(r)}(t)| \leqq K\rho(t_0)\phi(t)t^{m-r}, \qquad t \geqq t_0, \quad 0 \leqq r \leqq n-k-1. \tag{2.42}$$

Moreover, if

$$\lim_{t\to\infty} \rho(t) = 0, \tag{2.43}$$

then

$$(\mathscr{L}_2 w)^{(r)}(t) = o(\phi(t)t^{m-r}), \qquad 0 \leqq r \leqq n-k-1. \tag{2.44}$$

This lemma follows immediately from Lemma 1 of [8]. Since its conclusion follows trivially from the assumption that

$$\int^\infty s^{n-k-m-1}|w(s)|\,ds < \infty,$$

it is important to emphasize here that the covergence in (2.40) may be conditional. (Note: The existence of the constant γ in Assumption A is required for this lemma.)

LEMMA 3. *Suppose that v is complex-valued and continuous on $[t_0, \infty)$ with $t_0 \geqq a$, and that $\int^\infty t^{n-m-k-1}v(t)\,dt$ converges. Let*

$$\psi(t) = \sup_{\tau \geqq t} \left| \int_\tau^\infty s^{n-m-k-1}v(s)\,ds \right| = O(\phi(t)), \tag{2.45}$$

and define ψ_1 as in (2.32). *Then the function*

$$u = \mathscr{L}_2(\mathscr{L}_1 v) \tag{2.46}$$

is in $B(t_0)$, and

$$\|u\| \leqq W\psi_1(t_0), \tag{2.47}$$

where W is a constant independent of t_0 and v. Moreover, if

$$\psi(t) = o(\phi(t)), \tag{2.48}$$

then

$$u \in B_0(t_0) \quad (\textit{see } (2.15)). \tag{2.49}$$

Proof. From (2.18), $\mathscr{L}_1 v$ and its first $k-1$ derivatives are linear combinations of integrals of the forms (2.27) and (2.33) with $X = A_{lr}$: hence, Lemma 1 with $q = n-m-k-1$ (specifically, (2.29), (2.32) and (2.34)) implies that $\mathscr{L}_1 v \in C^{(k-1)}[t_0, \infty)$, and that

$$|(\mathscr{L}_1 v)^{(j)}(t)| \leqq \alpha_1 \psi_1(t_0)\phi(t)t^{-n+m+k+1}, \qquad 0 \leqq j \leqq k-1, \tag{2.50}$$

where α_1 is a constant independent of t_0 and v. Lemma 1 also implies that $\int^\infty t^{n-m-k-1}(\mathscr{L}_1 v)(t)\,dt$ converges (since it is a linear combination of integrals of the forms (2.28) and (2.35), again with $q = n-m-k-1$ and $X = A_{lr}$), and that

$$\left| \int_t^\infty s^{n-m-k-1}(\mathscr{L}_1 v)(s)\,ds \right| \leqq \alpha_2 \psi_1(t_0)\phi(t), \qquad t \geqq t_0, \tag{2.51}$$

where α_2 is a constant independent of t_0 and v. (See (2.30), (2.32), and (2.36).)

Now we apply Lemma 2 with $w = \mathscr{L}_1 v$. Then (2.51) implies (2.40) and (2.41), with $\rho(t) \leqq \alpha_2 \psi_1(t_0)$. Recalling (2.46), we now see from (2.42) with $w = \mathscr{L}_1 v$ that

$$|u^{(r)}(t)| \leqq K\alpha_2 \psi_1(t_0)\phi(t)t^{m-r}, \qquad 0 \leqq r \leqq n-k-1. \tag{2.52}$$

Moreover, since

$$u^{(n-k+j)} = -(\mathscr{L}_1 v)^{(j)}, \qquad 0 \leqq j \leqq k-1 \tag{2.53}$$

(from (2.22) with $w = \mathscr{L}_1 v$), (2.50) implies that

$$|u^{(r)}(t)| \leqq \alpha_1 \psi_1(t_0)\phi(t)t^{-n+m+k+1}, \qquad n-k \leqq r \leqq n-1. \tag{2.54}$$

Now (2.14), (2.52) and (2.54) imply (2.47), with $W = \max\{\alpha_1, K\alpha_2\}$.

It remains only to show that (2.48) implies (2.49). From the closing paragraph of Lemma 1, (2.48) implies that

$$(\mathscr{L}_1 v)^{(j)}(t) = o(\phi(t)t^{-n+m+k+1}), \qquad 0 \leqq j \leqq k-1,$$

and therefore

$$u^{(r)}(t) = o(\phi(t)t^{-n+m+k+1}), \qquad n-k \leqq r \leqq n-1, \tag{2.55}$$

because of (2.53). The closing paragraph of Lemma 1 also implies that

$$\int_t^\infty s^{n-m-k-1}(\mathscr{L}_1 v)(s)\,ds = o(\phi(t)),$$

because of (2.48). Therefore, (2.43) holds if $w = \mathscr{L}_1 v$ in (2.41), and so

$$u^{(r)}(t) = o(\phi(t)t^{m-r}), \qquad 0 \leqq r \leqq n-k-1, \tag{2.56}$$

from (2.44). Since (2.55) and (2.56) are equivalent to (2.49), this completes the proof of Lemma 3.

LEMMA 4. *Suppose that the assumptions of Theorem 2 hold, and let $\mathscr{L}$ be as defined in* (2.24). *Suppose also that $h \in B(t_0)$ for some $t_0 \geqq a$. Then $\mathscr{L}h \in B_0(t_0)$ and*

$$\|\mathscr{L}h\| \leqq W\sigma(t_0)\|h\|, \tag{2.57}$$

where σ is defined on $[a, \infty)$,

$$\lim_{t\to\infty} \sigma(t) = 0, \tag{2.58}$$

and W is as in (2.47).

Proof. We first consider the integral

$$J(t;h)=\int_t^\infty s^{n-m-k-1}(Mh)(s)\,ds$$

$$=\sum_{j=1}^{n}\int_t^\infty s^{n-m-k-1}P_j(s)h^{(n-j)}(s)\,ds. \tag{2.59}$$

We will show that the integrals in this sum converge, and estimate them. We remind the reader that $\|h\|$ is defined in (2.14).

From (2.5),

$$\left|\int_t^\infty s^{n-m-k-1}P_j(s)h^{(n-j)}(s)\,ds\right|\leqq\|h\|I_j(t),\qquad 1\leqq j\leqq k+1. \tag{2.60}$$

If $k+2\leqq j\leqq n$, then integration by parts yields

$$\int_t^\infty s^{n-m-k-1}P_j(s)h^{(n-j)}(s)\,ds$$

$$=t^{n-m-k-1}h^{(n-j)}(t)F_j(t)+\int_t^\infty F_j(s)[s^{n-m-k-1}h^{(n-j)}(s)]'\,ds\quad\text{(see (2.6))}. \tag{2.61}$$

To justify this we first observe that

$$\lim_{T\to\infty}T^{n-m-k-1}h^{(n-j)}(T)F_j(T)=0,\qquad k+2\leqq j\leqq n,$$

because of (2.6) and (2.13). Moreover, since (2.13) and (2.14) imply that

$$|[s^{n-m-k-1}h^{(n-j)}(s)]'|\leqq(n-m-k)\|h\|\phi(s)s^{j-k-2},\qquad k+2\leqq j\leqq n, \tag{2.62}$$

(2.7) implies that the integral on the right side of (2.61) converges (absolutely). We now conclude that $J(t;h)$ exists on $[t_0,\infty)$ if $h\in B(t_0)$; moreover, (2.59), (2.60), (2.61) and (2.62) imply that $|J(t;h)|\leqq\|h\|\Gamma(t)$, where

$$\Gamma(t)=\sum_{j=1}^{k+1}I_j(t)+(n-m-k)\sum_{j=k+1}^{n}I_j(t)+\phi(t)\sum_{j=k+2}^{n}t^{j-k-1}|F_j(t)|.$$

(See (2.6) and (2.7).) Now define $\sigma(t)=\sup_{\tau\geqq t}\Gamma(\tau)/\phi(\tau)$, and note that σ satisfies (2.58), because of (2.5), (2.6) and (2.7).

We now apply Lemma 3 with $v=Mh$; then the function ψ defined in (2.45) satisfies the inequality

$$\psi(t)\leqq\|h\|\Gamma(t)=o(\phi(t)).$$

Since $u=\mathscr{L}h$ in (2.46) when $v=Mh$ (see (2.24)), we conclude that $\mathscr{L}h\in B_0(t_0)$, and (2.47) with $\psi_1=\sigma\|h\|$ implies (2.57). This proves Lemma 4.

We can now complete the proof of Theorem 2. From (2.4) and Lemma 3 (with $v=g$), G as defined in (2.23) is also in $B(t_0)$. Now (2.25) and Lemma 4 imply that $\mathscr{T}(B(t_0))\subset B(t_0)$; moreover, $\mathscr{T}$ is obviously a contraction if $\mathscr{L}$ is, and the latter is so if

$$\sigma(t_0)<1/W\quad\text{(see (2.57))}. \tag{2.63}$$

From (2.58), we can choose t_0 to satisfy (2.63). By the contraction mapping principle, there is an $\hat{h}$ in $B(t_0)$ such that $\mathscr{T}\hat{h}=\hat{h}$; hence, $\hat{x}$ as defined in (2.16) satisfies (1.1) and (2.8).

Now suppose that (2.9) holds. Then Lemma 3 implies that $G \in B_0(t_0)$. Since $\mathscr{L}\hat{h} \in B_0(t_0)$ (by Lemma 4) and

$$\hat{h} = -G + \mathscr{L}\hat{h} \quad \text{(see (2.25))},$$

it now follows that $\hat{h} \in B_0(t_0)$. This and (2.16) imply (2.10), which completes the proof of Theorem 2.

3. Corollaries. If $P \in C[a, \infty)$ and $\int^\infty |P(t)|\, dt < \infty$, then obviously

$$\int_t^\infty |P(s)|\phi(s)\, ds = o(\phi(t))$$

if ϕ is nonincreasing. Also, if $\int^\infty t^\alpha |P(t)|\, dt < \infty$ for some $\alpha > 0$, then

$$\int_t^\infty P(s)\, ds = o(t^{-\alpha}) \quad \text{and} \quad \int^\infty t^{\alpha-1} \left| \int_t^\infty P(\tau)\, d\tau \right| dt < \infty$$

(see Corollary 3 of [8]), which in turn implies that

$$\int_t^\infty s^{\alpha-1} \left| \int_s^\infty P(\tau)\, d\tau \right| \phi(s)\, ds = o(\phi(t))$$

if ϕ is nonincreasing. Since the converses of these statements are false, the integrability conditions (1.3) and (1.4)—even with $q = 0$—are stronger than (2.5), (2.6) and (2.7).

We remind the reader that Assumption A is still in force.

COROLLARY 1. *Let l be an integer in $\{0, 1, \cdots, n-k-1\}$, and suppose that*

$$\int_t^\infty s^{j-k-1} P_j(s)\, ds = O(t^{-q}), \qquad n-l \leqq j \leqq n, \tag{3.1}$$

for some $q \geqq 0$ such that

$$q \neq 0, 1, \cdots, l. \tag{3.2}$$

Let

$$\int_t^\infty P_j(s)\, ds = o(t^{-j+k+1}), \qquad k+2 \leqq j \leqq n-l-1, \tag{3.3}$$

and define

$$\beta = \begin{cases} q - [q] & \text{if } l \geqq [q] \ (= \text{integer part of } q), \\ q - l & \text{if } l < [q]. \end{cases} \tag{3.4}$$

Finally, suppose that

$$\int_t^\infty |P_j(s)| s^{-\beta}\, ds = o(t^{-\beta}), \qquad 1 \leqq j \leqq k+1. \tag{3.5}$$

Then (1.5) *has a solution x_l such that*

$$\left(x_l(t) - \frac{t^l}{l!}\right)^{(r)} = \begin{cases} O(t^{l-r-q}), & 0 \leqq r \leqq n-k-1, \\ O(t^{l-n+k+1-q}), & n-k \leqq r \leqq n-1. \end{cases} \tag{3.6}$$

Moreover, if (3.1) *can be replaced by*

$$\int_t^\infty P_j(s)\, ds = o(t^{-j+k+1-q}), \qquad n-l \leqq j \leqq n, \tag{3.7}$$

then (3.6) *can be replaced by*

$$\left(x_l(t)-\frac{t^l}{l!}\right)^{(r)}=\begin{cases}o(t^{l-r-q}), & 0\leqq r\leqq n-k-1,\\ o(t^{l-n+k+1-q}), & n-k\leqq r\leqq n-1.\end{cases} \tag{3.8}$$

Proof. We start by observing that if $0<a<b$ and

$$\int_t^\infty P(s)\,ds=O(t^{-b}), \tag{3.9}$$

then

$$\int_t^\infty s^aP(s)\,ds=O(t^{a-b}). \tag{3.10}$$

If $f=0$ (as in (1.5)) and $p(t)=t^l/l!$, then

$$g(t)=-\sum_{j=n-l}^{n}P_j(t)\frac{t^{l-n+j}}{(l-n+j)!} \tag{3.11}$$

(see (2.3)); hence, (3.1) implies that

$$\int_t^\infty s^{n-m-k-1}g(s)\,ds=O(t^{l-m-q})$$

if $l-m<q$. We now apply Theorem 2 with

$$m=\max\{0,\,l-[q]\} \tag{3.12}$$

and

$$\phi(t)=O(t^{l-m-q})=O(t^{-\beta}), \tag{3.13}$$

with β as in (3.4). (Note that if $m>0$, then $\beta=q-[q]<1$, and ϕ as in (3.13) satisfies Assumption A with $\gamma=\beta$.)

Now (3.1), (3.2) and (3.3) imply (2.6), and (3.5) is the same as (2.5) with $\phi(t)=t^{-\beta}$. Since (3.2) and (3.4) imply that $\beta>0$, (2.6) automatically implies (2.7) with ϕ as in (3.13), without any absolute integrability assumptions on $P_{k+2},\cdots,P_n$. Now Theorem 2 implies that (1.5) has a solution x_l such that

$$\left(x_l(t)-\frac{t^l}{l!}\right)^{(r)}=\begin{cases}O(t^{m-r-\beta}), & 0\leqq r\leqq n-k-1,\\ O(t^{m-n+k+1-\beta}), & n-k\leqq r\leqq n-1,\end{cases}$$

which, in view of (3.4) and (3.12), is equivalent to (3.6).

If (3.9) holds with "O" replaced by "o", then so does (3.10). From Theorem 2, this also implies the assertion concerning (3.7) and (3.8).

We now consider the exceptional cases where (3.2) is not satisfied.

COROLLARY 2. *Let q and l be integers, with $0\leqq q\leqq l\leqq n-k-1$. Suppose that the integrals*

$$\int^\infty t^{j-k-1+q}P_j(t)\,dt, \qquad n-l\leqq j\leqq n, \tag{3.14}$$

converge, that (3.3) *holds, that*

$$\int^\infty |P_j(t)|\,dt<\infty, \qquad 1\leqq j\leqq k+1, \tag{3.15}$$

and that

$$\int^\infty t^{j-k-2}|F_j(t)|\,dt<\infty \tag{3.16}$$

for $k+2\leqq j\leqq n-l-1$. *Then* (1.5) *has a solution* x_l *which satisfies* (3.8) *if* $q>0$. *If* $q=0$, *the same conclusion is valid if the above assumptions hold and, in addition,* (3.16) *also holds for* $n-l\leqq j\leqq n$.

Proof. Now (3.14) implies that $\int^\infty t^{n-m-k-1}g(t)\,dt$ converges (see (3.11)) with $m=l-q$, and that (3.7) holds. We apply Theorem 2 with $\phi=1$, in which case (2.5) is equivalent to (3.15). Also, (2.7) is then equivalent to (3.16) for $k+2\leqq j\leqq n$. Since the convergence of (3.14) implies (3.7), which automatically implies (3.16) for $n-l\leqq j\leqq n$, the proof is complete.

Corollaries 1 and 2 imply the following corollary, which in turn implies Theorem 1.

COROLLARY 3. *Suppose that the integrals*

$$\int^\infty t^{j-k-1+q}P_j(t)\,dt, \qquad k+1\leqq j\leqq n, \tag{3.17}$$

converge for some $q\geqq 0$. *Suppose also that*

$$\int_t^\infty |P_j(s)|s^{[q]-q}\,ds=o(t^{[q]-q}), \qquad 1\leqq j\leqq k+1. \tag{3.18}$$

Then the conclusions of Theorem 1 *hold if either* (i) $q>0$; *or* (ii) $q=0$ *and*

$$\int^\infty s^{j-k-2}\left|\int_s^\infty P_j(\tau)\,d\tau\right|ds<\infty, \qquad k+2\leqq j\leqq n. \tag{3.19}$$

It is important to note that (3.17) implies (3.19) if $q>0$; therefore, it is not necessary to assume (3.19) in this case.

Corollary 1 implies that if

$$\int_t^\infty s^{j-k-1}P_j(s)\,ds=O(\phi(t)), \qquad k+1\leqq j\leqq n, \tag{3.20}$$

where $\phi(t)\to 0$ as $t\to\infty$ like some positive power of $1/t$, then (1.5) has solutions $x_l(t)\sim t^l/l!$ $(0\leqq l\leqq n-k-1)$, without any further integrability assumptions on $P_{k+1},\cdots,P_n$, provided that $P_1,\cdots,P_k$ satisfy (2.5). The following corollary shows that this conclusion remains valid even if ϕ decays more slowly than this.

COROLLARY 4. *Suppose that* ϕ *is as in Assumption* A, *and also that* $t^\gamma\phi(t)$ *is eventually nondecreasing for* $\gamma<1$, *and*

$$\int_t^\infty \frac{\phi^2(s)}{s}\,ds=o(\phi(t)). \tag{3.21}$$

Suppose also that (2.5) *and* (3.20) *hold. Then* (1.5) *has solutions* $x_0,\cdots,x_{n-k-1}$ *such that*

$$\left(x_l(t)-\frac{t^l}{l!}\right)^{(r)}=\begin{cases}O(\phi(t)t^{l-r}), & 0\leqq r\leqq n-k-1,\\ O(\phi(t)t^{-n+l+k+1}), & n-k\leqq r\leqq n-1.\end{cases} \tag{3.22}$$

Moreover, if (3.20) *holds with "*O*" replaced by "*o*," then so does* (3.22).

Proof. For each $l=0,1,\cdots,n-k-1$, we apply Theorem 2 with $p(t)=t^l/l!$ and $m=l$. The assumption (3.20) implies (2.4) and also that

$$F_j(t)=\int_t^\infty P_j(s)\,ds=O(\phi(t)t^{-j+k+1}), \qquad k+2\leqq j\leqq n.$$

This implies (2.6) and (2.7) (the latter because of (3.21)), which completes the proof.

A similar argument yields the following related corollary.

COROLLARY 5. *Let ϕ be as in Corollary* 4, *except that* (3.21) *is replaced by*

$$\int_t^\infty \frac{\phi^2(s)}{s}\,ds = O(\phi(t)).$$

Suppose also that (2.5) *holds, and that*

$$\int_t^\infty s^{j-k-1}P_j(s)\,ds = o(\phi(t)), \qquad k+1 \leqq j \leqq n.$$

Then (1.5) *has solutions $x_0, \cdots, x_{n-k-1}$ which satisfy* (3.22) *with "O" replaced by "o."*

Remark 1. Although we have assumed (1.2) throughout, our results are also valid for (1.6), which corresponds to the case where $k=0$, provided that obviously vacuous conditions (i.e., those involving $0 \leqq j \leqq k-1$ and $n-k \leqq r \leqq n-1$) are ignored. To see this, one has only to modify (in fact, simplify) the arguments as follows:

(a) Omit the now vacuous assumptions on the zeros of $Q(\lambda)$.

(b) Let $\mathscr{L}_1$ be the identity operator; i.e., $\mathscr{L}_1 v = v$.

(c) Omit Lemma 1.

Viewed in this way, the present results improve on those in [7] and [8], since we assumed in those papers that $\int^\infty |P_1(t)|\,dt < \infty$, which is stronger that (2.5), (3.5) and (3.18) with $k=0$ and $j=1$.

Remark 2. While preparing this paper the author discovered errors in [7] and [8], caused by his overlooking the need for special treatment of the exceptional cases where (3.2) does not hold. Theorem 2 of [7] requires the additional assumption that

$$\int^\infty \left| \int_t^\infty p_l(\tau)\,d\tau \right| t^{l-2}\,dt < \infty, \qquad 2 \leqq l \leqq n-r-1$$

(the notation here is that of [7]). Our present Corollary 2 (with $k=0$) extends this corrected result. Example 1 of [8] requires the additional assumption that $\alpha \neq 1, \cdots, n-1$. (The notation here is that of [8].) Corollary 1 (with $k=0$) extends this corrected result, and Corollary 2 deals with the excluded cases where $\alpha = 1, \cdots, n-1$.

4. Appendix. Proof of Lemma 1. We assume throughout that $t \geqq t_0 \geqq a$. If

$$V_r(t) = \int_t^\infty s^r v(s)\,ds, \qquad 0 \leqq r \leqq q, \tag{4.1}$$

then (2.26) implies that

$$|V_q(t)| \leqq \psi(t), \tag{4.2}$$

and by writing $s^r v(s) = s^{r-q}(s^q v(s))$, integrating by parts, and again invoking (2.26), we find that

$$|V_r(t)| \leqq 2t^{r-q}\psi(t), \qquad 0 \leqq r \leqq q-1. \tag{4.3}$$

Proof of (i). Now suppose that $\mu > 0$. If $t_0 \leqq s \leqq T$, then integration by parts shows that

$$\int_T^\infty X(s-\tau)\,e^{\lambda(s-\tau)}v(\tau)\,d\tau = X(s-T)\,e^{\lambda(s-T)}V_0(T) + \int_T^\infty V_0(\tau)[X(s-\tau)\,e^{\lambda(s-\tau)}]'\,d\tau.$$

Hence, (4.3) implies that

$$\left| \int_T^\infty X(s-\tau)\,e^{\lambda(s-\tau)}v(\tau)\,d\tau \right| \leqq T^{-q}\psi(T)\hat{X}(T-s)\,e^{\mu(s-T)}, \qquad t_0 \leqq s \leqq T, \tag{4.4}$$

where $\hat{X}$ is a polynomial with nonnegative coefficients determined by X and λ. Setting $s = T = t$ in (4.4) yields (2.29), with $K_1 = \hat{X}(0)$.

To prove (2.30), we consider the integral

$$I(t, T) = \int_t^T s^q f_1(s)\, ds = I_1(t, T) + I_2(t, T), \tag{4.5}$$

where

$$I_1(t, T) = \int_t^T s^q\, ds \int_s^T X(s-\tau)\, e^{\lambda(s-\tau)} v(\tau)\, d\tau \tag{4.6}$$

and

$$I_2(t, T) = \int_t^T s^q\, ds \int_T^\infty X(s-\tau)\, e^{\lambda(s-\tau)} v(\tau)\, d\tau. \tag{4.7}$$

From (4.4) and (4.7),

$$\begin{aligned} |I_2(t, T)| &\leqq \psi(T) \int_t^T \hat{X}(T-s)\, e^{\mu(s-T)}\, ds \\ &< \psi(T) \int_0^\infty \hat{X}(\eta)\, e^{-\mu\eta}\, d\eta; \end{aligned}$$

hence,

$$\lim_{T\to\infty} I_2(t, T) = 0. \tag{4.8}$$

Changing the order of integration in (4.6) yields

$$I_1(t, T) = \int_t^T \Gamma(t, \tau) v(\tau)\, d\tau, \tag{4.9}$$

where

$$\Gamma(t, \tau) = \int_t^\tau s^q X(s-\tau)\, e^{\lambda(s-\tau)}\, ds. \tag{4.10}$$

Repeated integration by parts shows that

$$\Gamma(t, \tau) = \sum_{r=0}^{q} [X_r(0)\tau^r - t^r X_r(t-\tau)\, e^{\lambda(t-\tau)}], \tag{4.11}$$

where $X_0, \cdots, X_q$ are polynomials determined by X and λ. Substituting (4.11) into (4.9), we obtain $I(t, T)$ in terms of integrals which converge as $T \to \infty$; therefore, (4.5), (4.8) and (4.11) imply that the integral $f_2(t) = I(t, \infty)$ (see (2.28)) converges, and that

$$f_2(t) = \sum_{r=0}^{q} X_r(0)\, V_r(t) - \sum_{r=0}^{q} t^r \int_t^\infty X_r(t-\tau)\, e^{\lambda(t-\tau)} v(\tau)\, d\tau \tag{4.12}$$

(see (4.1)). Replacing X by X_r in (4.4) and letting $s = T = t$ shows that

$$\left| \int_t^\infty X_r(t-\tau)\, e^{\lambda(t-\tau)} v(\tau)\, d\tau \right| \leqq K_{1r} t^{-q} \psi(t),$$

where K_{1r} is a constant determined by λ and X_r (and therefore by X). This, (4.2), (4.3) and (4.12) imply (2.30) for suitable K_2, a constant determined by X and λ. This proves (i).

Proof of (ii). Now suppose that $\mu < 0$. Integrating (2.33) by parts yields

$$f_3(t) = V_0(t_0)X(t-t_0)\, e^{\lambda(t-t_0)} - X(0)\, V_0(t) + \int_{t_0}^{t} V_0(\tau)[X(t-\tau)\, e^{\lambda(t-\tau)}]'\, d\tau.$$

Therefore, from (4.3) with $r = 0$,

$$\begin{aligned} |f_3(t)| \leqq 2t_0^{-q}\psi(t_0)|X(t-t_0)|\, e^{\mu(t-t_0)} + 2|X(0)|\psi(t)t^{-q} \\ + 2\int_{t_0}^{t} \psi(\tau)\tau^{-q}\tilde{X}(t-\tau)\, e^{\mu(t-\tau)}\, d\tau \end{aligned} \tag{4.13}$$

where $\tilde{X}$ is a polynomial with positive coefficients determined by X and λ. Now (2.32) and our assumptions on α and ϕ imply that

$$\psi(\tau)\tau^{-q} \leqq \psi_1(t_0)\, e^{\alpha(t-\tau)}\phi(t)t^{-q}, \qquad t \geqq \tau \geqq t_0.$$

This and (4.13) imply (2.34), with

$$K_3 = 2\left[|X(0)| + \sup_{\xi \geqq 0}|X(\xi)|\, e^{(\alpha+\mu)\xi} + \int_0^{\infty} \tilde{X}(\eta)\, e^{(\alpha+\mu)\eta}\, d\eta\right],$$

which is finite, because of (2.31).

To see that (2.37) implies (2.38), observe from (2.33) that if $t_0 \leqq t_1 \leqq t$, then

$$f_3(t) = \int_{t_0}^{t_1} X(t-\tau)\, e^{\lambda(t-\tau)}v(\tau)\, d\tau + \int_{t_1}^{t} X(t-\tau)\, e^{\lambda(t-\tau)}v(\tau)\, d\tau. \tag{4.14}$$

For fixed t_1,

$$\left|\int_{t_0}^{t_1} X(t-\tau)\, e^{\lambda(t-\tau)}v(\tau)\, d\tau\right| \leqq M(t_0, t_1)\, Y(t)\, e^{\mu t}, \tag{4.15}$$

where

$$M(t_0, t_1) = \max\{|v(\tau)|\,|\, t_0 \leqq \tau \leqq t_1\}$$

and Y is a polynomial, while

$$\left|\int_{t_1}^{t} X(t-\tau)\, e^{\lambda(t-\tau)}v(\tau)\, d\tau\right| \leqq K_3\psi_1(t_1)t^{-q}\phi(t), \qquad t \geqq t_1. \tag{4.16}$$

(Since this integral has the same form as $f_3(t)$ in (2.33), with t_0 replaced by t_1, (4.16) is obtained as was (2.34).)

Our assumptions on ϕ and α imply that

$$Y(t)\, e^{\mu t} = o(t^{-q}\phi(t)).$$

Therefore, (4.14), (4.15) and (4.16) imply that

$$\overline{\lim_{t\to\infty}}\, (t^{-q}\phi(t))^{-1}|f_3(t)| \leqq K_3\psi_1(t_1), \qquad t_1 \geqq t_0.$$

Since (2.32) and (2.37) imply that $\lim_{t_1\to\infty}\psi_1(t_1) = 0$, we now see that (2.37) implies (2.38).

For reference below, we observe here that

$$\lim_{t\to\infty} t^q f_3(t) = 0 \tag{4.17}$$

in any case. This is obvious from (2.34) if $\phi(t)=o(1)$. If $\lim_{t\to\infty}\phi(t)>0$, then (2.26) implies (2.37), which implies (2.38) and, therefore, (4.17).

To prove (2.36), consider the integral

$$J(t,T)=\int_t^T s^q f_3(s)\,ds=\int_t^T s^q\,ds\int_{t_0}^s X(s-\tau)\,e^{\lambda(s-\tau)}v(\tau)\,d\tau.$$

Reversing the order of integration yields

$$J(t,T)=\int_{t_0}^t v(\tau)\,d\tau\int_t^T s^qX(s-\tau)\,e^{\lambda(s-\tau)}\,ds+\int_t^T v(\tau)\,d\tau\int_\tau^T s^qX(s-\tau)\,e^{\lambda(s-\tau)}\,ds.$$

Manipulating the limits of integration here shows that

$$J(t,T)=H(t)-H(T).$$

where

$$H(t)=\int_{t_0}^t \Gamma(t,\tau)v(\tau)\,d\tau\quad\text{(see (4.10)).}$$

Therefore, from (4.11),

$$H(t)=\sum_{r=0}^q X_r(0)\int_{t_0}^t \tau^r v(\tau)\,d\tau-\sum_{r=0}^q t^r\int_{t_0}^t X_r(t-\tau)\,e^{\lambda(t-\tau)}v(\tau)\,d\tau. \tag{4.18}$$

The integrals on the right converge as $t\to\infty$. Moreover, since the integrals in the second sum are of the same form as $f_3(t)$ (see (2.33)), (4.17) implies that this sum approaches zero as $t\to\infty$; hence,

$$H(\infty)=\lim_{T\to\infty}H(T)=\sum_{r=0}^q X_r(0)\int_{t_0}^\infty \tau^r v(\tau)\,d\tau. \tag{4.19}$$

Since $f_4(t)=H(\infty)-H(t)$, we now see from (4.1), (4.18) and (4.19) that

$$f_4(t)=\sum_{r=0}^q X_r(0)V_r(t)+\sum_{r=0}^q t^r\int_{t_0}^t X_r(t-\tau)\,e^{\lambda(t-\tau)}v(\tau)\,d\tau. \tag{4.20}$$

Recalling (2.32), (4.2), (4.3) and, again, that the integrals in the second sum here are of the same form as $f_3(t)$, and therefore satisfy an inequality like (2.34), we see from (4.20) that (2.36) holds for a suitable constant K_4 which is ultimately determined by X and λ.

Finally, suppose that (2.37) holds. Then obviously $V_r(t)=o(\phi(t))$, from (4.2) and (4.3). Moreover,

$$\int_{t_0}^t X_r(t-\tau)\,e^{\lambda(t-\tau)}v(\tau)\,d\tau=o(t^{-q}\phi(t)),$$

as can be seen by replacing X with X_r in (2.33) and applying the argument that led to (2.38). Now (4.20) implies (2.39), which completes the proof of Lemma 1.

AN EXTENSION OF A THEOREM OF PERRON*

JAROMÍR ŠIMŠA†

Abstract. We give sufficient conditions for a linear differential equation of order n to have a solution whose logarithmic derivative is asymptotically in a small neighbourhood of a given constant. This asymptotic behavior is specified by means of a general comparison function φ. An appropriate formulation of the growth properties of φ is introduced. The differential equation is regarded as a perturbation of some constant coefficient equation. Our smallness conditions permit conditional convergence of some corresponding improper integrals.

Key words. ordinary linear differential equations, linear perturbations, asymptotic integration

AMS(MOS) subject classification. 34E99

1. Introduction and main theorem. We study the behavior for large t of the solutions of a scalar differential equation

$$x^{(n)}+[a_1+p_1(t)]x^{(n-1)}+\cdots+[a_n+p_n(t)]x=0 \qquad (t\geqq 0,\ n\geqq 2), \tag{1}$$

where a_k are constants and p_k are continuous on $[0,\infty)$. We assume throughout that a_k, p_k and x are real- or complex-valued. The symbols $\langle\langle O\rangle\rangle$ and $\langle\langle o\rangle\rangle$ refer to behavior as $t\to\infty$.

Perron [4] showed that if

$$p_k(t)=o(1) \qquad (1\leqq k\leqq n), \tag{2}$$

then (1) has a solution x_0 satisfying

$$\frac{x_0^{(k)}(t)}{x_0(t)}=\lambda_0^k+o(1) \qquad (1\leqq k\leqq n-1), \tag{3}$$

provided that λ_0 is a simple root of

$$\lambda^n+a_1\lambda^{n-1}+\cdots+a_{n-1}\lambda+a_n=0 \tag{4}$$

and $\operatorname{Re}\lambda_j\neq\operatorname{Re}\lambda_0$, for any other root λ_j of (4). Hartman and Wintner [3] have showed that Perron's conclusion remains valid if (2) is relaxed to

$$\sup_{s\geqq t}(1+s-t)^{-1}\int_t^s|p_k(r)|\,dr=o(1) \qquad (1\leqq k\leqq n) \tag{5}$$

(see also [1, Thm. 17.4]).

In this paper, we obtain another extension of Perron's Theorem. Namely, we give sufficient conditions for (1) to have a solution x_0 satisfying

$$\frac{x_0^{(k)}(t)}{x_0(t)}=\lambda_0^k+o(\varphi(t)) \qquad (1\leqq k\leqq n-1), \tag{6}$$

where the function φ is positive, continuous and nonincreasing on $[T,\infty)$, for some real T. Of course, due to the behavior of φ, we impose a new restriction on the roots of (4). In the case $\varphi=1$, when (6) becomes (3), our result is stronger than that of Hartman and Wintner mentioned above, because of the considerable weakening of (5).

Before we state the main theorem, we introduce the following notation. Assuming the function φ to be as above, we define

$$m_\varphi = \sup\{\alpha: e^{\alpha t}\varphi(t) \text{ is nonincreasing on } [T_\alpha, \infty) \text{ for some } T_\alpha \geqq T\} \tag{7}$$

and

$$M_\varphi = \inf\{\alpha: e^{\alpha t}\varphi(t) \text{ is nondecreasing on } [T_\alpha, \infty) \text{ for some } T_\alpha \geqq T\}, \tag{8}$$

where M_φ is meant to be ∞, if the set in (8) is empty. Obviously, it holds that $0 \leqq m_\varphi \leqq M_\varphi \leqq \infty$.

THEOREM 1. *Let λ_0 be a root of* (4) *such that*

$$\operatorname{Re}(\lambda_0 - \lambda_j) \notin [m_\varphi, M_\varphi] \tag{9}$$

for any zero λ_j of the polynomial

$$Q(\lambda) = (\lambda - \lambda_0)^{-1}(\lambda^n + a_1\lambda^{n-1} + \cdots + a_{n-1}\lambda + a_n). \tag{10}$$

(*Thus λ_0 need not be simple if $m_\varphi > 0$.*) *Suppose that*

$$\sup_{s \geqq t} (1+s-t)^{-1} \int_t^s |p_1(r)|\varphi(r)\, dr = o(\varphi(t)), \tag{11}$$

$$\sup_{s \geqq t} (1+s-t)^{-1} \left| \int_t^s p_k(r)\, dr \right| = o(1) \qquad (2 \leqq k \leqq n) \tag{12}$$

and

$$\sup_{s \geqq t} (1+s-t)^{-1} \left| \int_t^s f(r)\, dr \right| = o(\varphi(t)), \tag{13}$$

where

$$f(t) = \sum_{k=1}^{n} \lambda_0^{n-k} p_k(t) \qquad (0 \leqq t < \infty). \tag{14}$$

Then (1) *has a solution x_0 satisfying* (6). *This conclusion remains valid if* (12) *is relaxed to*

$$\sup_{s \geqq t} (1+s-t)^{-1} \left| \int_t^s (p_k(r) - q_k(r))\, dr \right| = o(1) \qquad (2 \leqq k \leqq n), \tag{15}$$

where q_k are some continuous functions satisfying

$$\sup_{s \geqq t} (1+s-t)^{-1} \int_t^s |q_k(r)|\varphi(r)\, dr = o(\varphi(t)) \qquad (2 \leqq k \leqq n). \tag{16}$$

Remark 1. A mild condition like (12) previously appeared in Hartman's work [2]. The result there is that if λ_0 and p are real-valued, $\lambda_0 \neq 0$ and if p is continuous on $[0, \infty)$, then the condition

$$\sup_{s \geqq t} (1+s-t)^{-1} \left| \int_t^s p(r)\, dr \right| = o(1)$$

is necessary and sufficient for the equation $x'' - (\lambda_0^2 + p(t))x = 0$ to have a solution x_0 satisfying (3) with $n = 2$ (see also [1, Exer. 17.3]).

Remark 2. The statement of Theorem 1 can be simplified if $m_\varphi > 0$ or, more generally, if $\varphi \in L_1$ and

$$\int_t^\infty \varphi(s)\, ds = O(\varphi(t)). \tag{17}$$

Then (6) is equivalent to

$$x_0^{(k)}(t) = [c\lambda_0^k + o(\varphi(t))]\, e^{\lambda_0 t} \qquad (0 \leqq k \leqq n-1), \tag{18}$$

where $c \neq 0$ is a constant, while (11), (13) and (16) mean that the integrals

$$\int_t^\infty |p_1(s)|\varphi(s)\, ds, \quad \int_t^\infty f(s)\, ds, \quad \int_t^\infty |q_k(s)|\varphi(s)\, ds \qquad (2 \leqq k \leqq n) \tag{19}$$

exist and are $o(\varphi(t))$. The proof of these assertions is given in the end of § 2.

2. Preliminary lemmas. The following lemmas will be used to prove Theorem 1 in § 3 and its corollaries in § 4.

LEMMA 1. *Suppose that h is in $C[T, \infty)$ and φ is positive and nonincreasing on $[T, \infty)$. If*

$$\sup_{s \geqq t} (1+s-t)^{-1} \left| \int_t^s h(r)\, dr \right| \leqq K_0 \psi(t) \qquad (T \leqq t < \infty) \tag{20}$$

holds with $K_0 = 1$, then the integral $\int^\infty h(t)\, e^{\gamma t}\, dt$ converges and satisfies

$$\left| \int_t^\infty h(s)\, e^{\gamma s}\, ds \right| \leqq K_1\, e^{\gamma t} \psi(t) \qquad (T \leqq t < \infty), \tag{21}$$

where the constant K_1 depends on γ only, for any $\gamma < 0$. Conversely if the integral $\int^\infty h(t)\, e^{\gamma t}\, dt$ converges and satisfies (21) *with $K_1 = 1$, for some $\gamma \leqq 0$, then* (20) *holds with a constant K_0 which depends on γ only.*

Proof. Denote

$$H(s) = \int_t^s h(r)\, dr$$

and suppose that $|H(s)| \leqq (1+s-t)\psi(t)$ for any $s \geqq t$. If $\gamma < 0$, then $H(s)e^{\gamma s} \to 0$ $(s \to \infty)$ and

$$\begin{aligned} \int_t^\infty |H(s)|\, e^{\gamma s}\, ds &\leqq \psi(t) \int_t^\infty (1+s-t)\, e^{\gamma s}\, ds \\ &= \psi(t)\, e^{\gamma t} \int_0^\infty (1+r) e^{\gamma r}\, dr. \end{aligned}$$

Consequently, we can let $r \to \infty$ in

$$\int_t^r h(s)\, e^{\gamma s}\, ds = (H(s)\, e^{\gamma s})\Big|_t^r - \gamma \int_t^r H(s)\, e^{\gamma s}\, ds$$

and conclude that $\int^\infty h(t)\, e^{\gamma t}\, dt$ converges and (21) holds if

$$K_1 = |\gamma| \int_0^\infty (1+r)\, e^{\gamma r}\, dr.$$

Conversely, denote

$$H_1(t) = \int_t^\infty h(s)\, e^{\gamma s}\, ds \quad \text{and} \quad H_2(t) = \sup_{s \geqq t} |H_1(s)|\, e^{-\gamma s},$$

and suppose that $H_2(t) \leqq \psi(t)$ for some $\gamma \leqq 0$. Integration by parts yields

$$\left| \int_t^s h(r)\, dr \right| = \left| (-H_1(r)\, e^{-\gamma r})|_t^s - \gamma \int_t^s H_1(r)\, e^{-\gamma r}\, dr \right|$$

$$\leqq 2H_2(t) + |\gamma| \int_t^s H_2(r)\, dr \leqq [2 + |\gamma|(s-t)]\psi(t)$$

for any $s \geqq t$. Consequently, (20) holds if K_0 is an upper bound of $(1+r)^{-1}(2+|\gamma|r)$ for $r \geqq 0$. This completes the proof of Lemma 1.

LEMMA 2. *Lemma* 1 *remains valid if* (20) *and* (21) *are replaced by*

$$\sup_{s \geqq t} [1 + \log(s/t)]^{-1} \left| \int_t^s h(r)\, dr \right| \leqq K_0 \psi(t) \qquad (T \leqq t < \infty)$$

and

$$\left| \int_t^\infty h(s) s^\gamma\, ds \right| \leqq K_1 t^\gamma \psi(t) \qquad (T \leqq t < \infty),$$

respectively.

Proof. Substituting $u = \log r$ yields

$$\int_t^s h(r)\, dr = \int_{\log t}^{\log s} h(e^u)\, e^u\, du, \quad \text{and}$$

$$\int_t^\infty h(r)\, r^\gamma\, dr = \int_{\log t}^\infty h(u)\, e^{(\gamma+1)u}\, du.$$

Thus Lemma 2 follows from Lemma 1, with $\psi(t)$ and $h(t)$ replaced by $\psi(e^t)$ and $e^t h(t)$, respectively.

LEMMA 3. *Assume that* σ *and* ψ *are nonnegative functions in* $C[t_0, \infty)$, σ *is nonincreasing,* B *is a polynomial with nonnegative coefficients and* $\gamma \neq 0$ *is a real constant. Define*

$$w(t) = \int_t^\infty e^{-|\gamma|s} B(s)\, ds \qquad (t \geqq 0). \tag{22}$$

If $\gamma > 0$ *and* $e^{\gamma t}\psi(t)$ *is nonincreasing on* $[t_0, \infty)$, *then*

$$\int_t^\infty B(s-t)\sigma(s)\psi(s)\, ds \leqq w(0)\sigma(t)\psi(t) \qquad (t \geqq t_0). \tag{23}$$

If $\gamma < 0$ *and* $e^{\gamma t}\psi(t)$ *is nondecreasing on* $[t_0, \infty)$, *then*

$$\int_{t_0}^t B(t-s)\sigma(s)\psi(s)\, ds \leqq [w(t-t_1)\sigma(t_0) + w(0)\sigma(t_1)]\psi(t) \qquad (t \geqq t_0), \tag{24}$$

where $t_1 = (t_0 + t)/2$.

Proof. If $\gamma > 0$ and $\psi(s) \leqq \psi(t)\, e^{\gamma(t-s)}$ for any $s \geqq t$, then the integral in (23) does not exceed

$$\sigma(t)\psi(t) \int_t^\infty e^{\gamma(t-s)} B(s-t)\, ds = w(0)\sigma(t)\psi(t).$$

If $\gamma<0$ and $\psi(s)\leqq\psi(t)\,e^{\gamma(t-s)}$, for any s in $[t_0, t]$, then the integral in (24) does not exceed

$$\psi(t)\left[\sigma(t_0)\int_{t_0}^{t_1} e^{\gamma(t-s)}B(t-s)\,ds+\sigma(t_1)\int_{t_1}^{t} e^{\gamma(t-s)}B(t-s)\,ds\right],$$

where $t_1=(t_0+t)/2$. Thus (24) holds, because

$$\int_{t_3}^{t_2} e^{\gamma(t-s)}B(t-s)\,ds\leqq\int_{-\infty}^{t_2} e^{\gamma(t-s)}B(t-s)\,ds=\hat{w}(t-t_2),$$

whenever $t_3\leqq t_2\leqq t$. This completes the proof of Lemma 3.

Before we state the last lemma of this section, we introduce a factor smallness condition as in [6, p. 763].

DEFINITION 1. Let $\sigma(t_0, t)$ be a real function defined for all t_0 and t, $T\leqq t_0<\infty$, which is nonincreasing in t and $\sigma(t_0, t)\to 0$ as $t\to\infty$ for any $t_0\geqq T$. If in addition $\sigma(t_0, t_0)\to 0$ as $t_0\to\infty$, then we sat that σ is of type (*).

LEMMA 4. *Assume that A is a polynomial, ψ_1, ψ_2 and p are in $C[T,\infty)$, ψ_1 and ψ_2 are positive, the integral $\int^\infty p(t)\,dt$ converges (perhaps conditionally) and satisfies*

$$\sigma(t)=\sup_{s\geqq t}(\psi_1(s))^{-1}\left|\int_s^\infty p(r)\,dr\right|\to 0\qquad(t\to\infty). \tag{25}$$

Assume also K is a function in $C^1[t_0,\infty)$ satisfying $|K^{(j)}(t)|\leqq K_0\psi_2(t)$, where K_0 is a constant, $t\geqq t_0$ and $j=0, 1$, for some $t_0\geqq T$. Denote $\psi=\psi_1\psi_2$.

(i) *If $e^{\gamma t}\psi(t)$ is nonincreasing on $[t_0,\infty)$, for some $\gamma>0$, then the integral $\int^\infty A(t-s)K(s)p(s)\,ds$ converges and satisfies*

$$\left|\int_t^\infty A(t-s)K(s)p(s)\,ds\right|\leqq K_0C\sigma(t)\psi(t)\qquad(t\geqq t_0), \tag{26}$$

where C is a constant which depends only on A and γ.

(ii) *If $e^{\gamma t}\psi(t)$ is nondecreasing on $[t_0,\infty)$ for some $\gamma<0$, then*

$$\left|\int_{t_0}^t A(t-s)K(s)p(s)\,ds\right|\leqq K_0\sigma_1(t_0, t)\psi(t)\quad(t\geqq t_0), \tag{27}$$

where σ_1 is of type (*) and depends only on σ, A and γ.

Proof. Our assumptions on K imply that

$$|(A(t-s)K(s))'|\leqq K_0B(|t-s|)\psi_2(s)\qquad\left(s, t\geqq t_0, '=\frac{d}{ds}\right), \tag{28}$$

where B is a polynomial with nonnegative coefficients which satisfies $B(s)\geqq|A(s)|+|A'(s)|$ for any $s\geqq 0$. From (25),

$$|P(t)|\leqq\sigma(t)\psi_1(t)\quad\text{where } P(t)=\int_t^\infty p(s)\,ds \text{ and } t\geqq t_0. \tag{29}$$

(i) Integration by parts yields

$$\int_t^\infty A(t-s)K(s)p(s)\,ds=A(0)K(t)P(t)+\int_t^\infty(A(t-s)K(s))'P(s)\,ds. \tag{30}$$

Lemma 3, (28) and (29) imply that the integral on the right side of (30) converges absolutely, and that (26) holds with $C=|A(0)|+w(0)$, where w is as in (22).

(ii) Integration by parts yields

$$(31)\quad \int_{t_0}^{t} A(t-s)K(s)p(s)\,ds = -A(t-s)K(s)P(s)\big|_{t_0}^{t} + \int_{t_0}^{t} (A(t-s)K(s))'P(s)\,ds.$$

If $t_0 \leqq s \leqq t$, then our assumptions on K and γ, (28) and (29) imply that

$$(32)\quad \begin{aligned} |A(t-t_0)K(t_0)P(t_0)| &\leqq K_0 B(t-t_0)\sigma(t_0)\psi(t_0) \\ &\leqq K_0 B(t-t_0)\sigma(t_0)\, e^{\gamma(t-t_0)}\psi(t) \end{aligned}$$

and

$$(33)\quad |(A(t-s)K(s))'P(s)| \leqq K_0 B(t-s)\sigma(s)\psi(s).$$

Now Lemma 3, (29) and (31)-(33) imply that (27) holds, with σ_1 given by

$$\begin{aligned} \sigma_1(t_0, t) = \sigma(t_0)[w(t-t_1) &+ \sup_{s \geqq t-t_0} e^{\gamma s} B(s)] \\ &+ \sigma(t_1)w(0) + \sigma(t)|A(0)|, \end{aligned}$$

where $t_1 = (t+t_0)/2$ and w is as in (22). Obviously, σ_1 is of type (*) and depends only on σ, A and γ. This completes the proof of Lemma 4.

We finish this section by proving the assertions of Remark 2 in § 1. First we show that $m_\varphi > 0$ implies (17). Indeed, if $e^{\gamma t}\varphi(t)$ is nonincreasing on $[T\gamma, \infty)$ for some $\gamma > 0$ (see (7)), then

$$\int_t^\infty \varphi(s)\,ds \leqq \int_t^\infty \varphi(t)\, e^{\gamma(t-s)}\,ds = \gamma^{-1}\varphi(t) \qquad (t \geqq T\gamma).$$

To prove (18), we need only to show that

$$(34)\quad x_0(t) = [c + o(\varphi(t))]\, e^{\lambda_0 t},$$

because (6) and (34) easily imply (18). Integrating (6) with $k=1$, we obtain

$$x_0(t) = x_0(t_0) \exp\left[\lambda_0(t-t_0) + \int_{t_0}^{t} o(\varphi(s))\,ds\right],$$

which proves (34), because of (17). Finally, we verify that (11), (13) and (16) imply the assertion on the integrals (19). (The converse is true by Lemma 1 with $\gamma = 0$, without supposing (17).) It suffices to show that the integral $\int^\infty h(t)\,dt$ converges and satisfies

$$(35)\quad \int_t^\infty h(s)\,ds = o(\varphi(t)),$$

provided that (17) holds and

$$(36)\quad \sup_{s \geqq t} (1+s-t)^{-1} \left| \int_t^s h(r)\,dr \right| = o(\varphi(t)).$$

To see this, observe that Lemma 1 and (36) imply that

$$(37)\quad H_1(t) = \int_t^\infty e^{\gamma s} h(s)\,ds = o(e^{\gamma t}\varphi(t))$$

if γ is a negative constant. From (17) and (37), we can let $r \to \infty$ in

$$\int_t^r h(s)\,ds = -H_1(s)\, e^{-\gamma s}\big|_t^r - \gamma \int_t^r H_1(s)\, e^{-\gamma s}\,ds$$

and conclude that (35) holds.

3. Asymptotic integration. This section contains the proof of Theorem 1, stated in § 1. The method of asymptotic integration is similar to that of [6], and we do not repeat some arguments given there.

We prove Theorem 1 assuming the function φ to satisfy

$$\varphi(t) = o(1). \tag{38}$$

(The case that $\lim_{t\to\infty} \varphi(t) > 0$ is discussed in the end of this section.) Furthermore, it suffices to assume that $\lambda_0 = 0$, otherwise $x \exp(-\lambda_0 t)$ is introduced as a new dependent variable in (1). However, due to this change, (12) may fail to hold, because (11) does not imply (12) with $k = 1$. Therefore, we give the proof with (12) replaced by the weaker assumption (15).

Let λ_j $(1 \leqq j \leqq L)$ be all distinct zeros of the polynomial $Q(\lambda) = \lambda^{n-1} + a_1\lambda^{n-2} + \cdots + a_{n-1}$ (see (10) with $\lambda_0 = a_n = 0$), and let $\operatorname{Re}\lambda_1 \leqq \operatorname{Re}\lambda_2 \leqq \cdots \leqq \operatorname{Re}\lambda_L$. From (9) with $\lambda_0 = 0$, there exists an integer $N (0 \leqq N \leqq L)$ such that

$$\operatorname{Re}\lambda_j + M_\varphi < 0 \quad (0 < j \leqq N), \qquad \operatorname{Re}\lambda_j + m_\varphi > 0 \quad (N < j \leqq L). \tag{39}$$

Now we introduce the new dependent variable u in (1) by $x' = ux$. Then

$$x^{(k)} = (u^{(k-1)} + g_k[u])x \qquad (1 \leqq k \leqq n), \tag{40}$$

where $g_k[u]$ are nonlinear expressions which have been described in detail in [6, p. 759]. Substituting (40) into (1) with $a_n = 0$, we obtain

$$Q(D)u = -p_n - R[u] \qquad \left(D = \frac{d}{dt}\right) \tag{41}$$

where

$$R[u] = \sum_{k=1}^{n-1} p_k u^{(n-k-1)} + \sum_{k=0}^{n-1} a_k g_{n-k}[u] + \sum_{k=1}^{n-1} p_k g_{n-k}[u] \qquad (a_0 = 1). \tag{42}$$

What follows is the standard variation of constants, applied to (41). Let $U(t)$ be the unique solution of $Q(D)u = 0$ that satisfies $D^i U(0) = 0 (0 \leqq i \leqq n-3)$ and $D^{n-2}U(0) = 1$. Then there exist solutions U_1 and U_2 of $Q(D)u = 0$ such that $U = U_1 + U_2$ and

$$D^i U_1(t) = \sum_{j=1}^{N} A_{ji}(t)\, e^{\lambda_j t}, \qquad D^i U_2(t) = \sum_{j=N+1}^{L} A_{ji}(t)\, e^{\lambda_j t} \tag{43}$$

where A_{ji} are polynomials. If we define

$$\mathscr{L}h(t) = \int_{t_0}^{t} U_1(t-s)h(s)\, ds - \int_{t}^{\infty} U_2(t-s)h(s)\, ds \tag{44}$$

for any continuous h and some $t_0 \geqq T$, then routine computations show that

$$D^i\mathscr{L}h(t) = \int_{t_0}^{t} D^i U_1(t-s)h(s)\, ds - \int_{t}^{\infty} D^i U_2(t-s)h(s)\, ds \qquad (0 \leqq i \leqq n-2) \tag{45}$$

and $Q(D)\mathscr{L}h = h$, provided that the improper integrals in (45) converge. Consequently, (41) can be converted into an integral equation

$$u = -\mathscr{L}p_n - \mathscr{L}R[u]. \tag{46}$$

The solution of (46) will be found as a fixed point (function) of the mapping

$$\mathscr{T}u = -\mathscr{L}p_n - \mathscr{L}R[u] \tag{47}$$

in the set $\mathcal{B}(t_0)$ of all functions u in $C^{n-2}[t_0, \infty)$ satisfying

$$D^k u(t) = O(\varphi(t)) \qquad (0 \leqq k \leqq n-2) \tag{48}$$

which is a Banach space with norm

$$\|u\| = \sup_{t \geqq t_0} \max_{0 \leqq k \leqq n-2} (\varphi(t))^{-1} |D^k u(t)|. \tag{49}$$

We will show that $\mathcal{T}$ is a contraction mapping of the closed sphere

$$\mathcal{S}(t_0) = \{u \in \mathcal{B}(t_0) : \|u\| \leqq 1\}$$

into itself if t_0 is sufficiently large.

In the following, assume that $t \geqq t_0$. From (49),

$$|D^k u(t)| \leqq \|u\| \varphi(t) \qquad (0 \leqq k \leqq n-2), \tag{50}$$

for any u in $\mathcal{B}(t_0)$. Moreover, there exists a universal constant C such that the estimates

$$|g_k[\tilde{u}](t) - g_k[\tilde{\tilde{u}}](t)| \leqq C \|\tilde{u} - \tilde{\tilde{u}}\| \varphi^2(t) \qquad (1 \leqq k \leqq n) \tag{51}$$

and

$$|g_k'[\tilde{u}](t) - g_k'[\tilde{\tilde{u}}](t)| \leqq C \|\tilde{u} - \tilde{\tilde{u}}\| \varphi^2(t) \qquad (1 \leqq k \leqq n-1) \tag{52}$$

hold for any functions $\tilde{u}$, $\tilde{\tilde{u}}$ in $\mathcal{S}(t_0)$. The last can be proved in the same way as in [6, p. 764], where the case $\varphi(t) = t^{-q}$ was considered.

We assume henceforth that t_0 is so large that $\exp[-(\operatorname{Re} \lambda_j + \gamma)t]\psi(t)$ is nondecreasing on $[t_0, \infty)$ if $1 \leqq j \leqq N$, and that $\exp[-(\operatorname{Re} \lambda_j - \gamma)t]\psi(t)$ is nonincreasing on $[t_0, \infty)$ if $N+1 \leqq j \leqq L$, for some positive γ (see (7), (8) and (39)).

LEMMA 5. *The functions $\mathcal{L}p_n$ and $\mathcal{L}R[u]$ exist and are in $C^{n-1}[t_0, \infty)$ for any u in $\mathcal{S}(t_0)$. Moreover, there exists a function σ of type* (*) *(see Definition* 1 *in* § 2*) such that the estimates*

$$|\mathcal{D}^i \mathcal{L}p_n(t)| \leqq \sigma(t_0, t)\varphi(t) \qquad (0 \leqq i \leqq n-2), \tag{53}$$

and

$$|D^i \mathcal{L}R[\tilde{u}](t) - D^i \mathcal{L}R[\tilde{\tilde{u}}](t)| \leqq \|\tilde{u} - \tilde{\tilde{u}}\| \sigma(t_0, t)\varphi(t) \qquad (0 \leqq i \leqq n-2) \tag{54}$$

hold for any $\tilde{u}$, $\tilde{\tilde{u}}$ in $\mathcal{S}(t_0)$.

Proof. Lemma 1, (11), (13) with $f = p_n$ (see (14) with $\lambda_0 = 0$), (15) and (16) imply that

$$\int_t^\infty |p_1(s)|\varphi(s)\, e^{cs}\, ds = o(\varphi(t)\, e^{ct}), \tag{55}$$

$$\int_t^\infty (p_k(s) - q_k(s))\, e^{cs}\, ds = o(e^{ct}) \qquad (2 \leqq k \leqq n), \tag{56}$$

$$\int_t^\infty |q_k(s)|\varphi(s)\, e^{cs}\, ds = o(\varphi(t)\, e^{ct}) \qquad (2 \leqq k \leqq n), \tag{57}$$

and

$$\int_t^\infty p_n(s)\, e^{cs}\, ds = o(\varphi(t)\, e^{ct}), \tag{58}$$

where c is a negative constant. (The integrals in (56) and (58) may converge conditionally.) From (43) and (45),

$$D^i\mathscr{L}h(t)=\sum_{j=1}^{N} e^{\lambda_j t}\int_{t_0}^{t} e^{-\lambda_j s}A_{ji}(t-s)h(s)\,ds - \sum_{j=N+1}^{L} e^{\lambda_j t}\int_{t}^{\infty} e^{-\lambda_j s}A_{ji}(t-s)h(s)\,ds \qquad (0\leqq i\leqq n-2). \tag{59}$$

To prove (53) and (54), we estimate each of the integrals in (59), for $h=p_n$ and for $h=R[\tilde{u}]-R[\tilde{\tilde{u}}]$, using Lemmas 3 and 4. To avoid unnecessary repetition, we note before that the estimates of $|K^{(j)}(t)|$ and the integrability condition on p follow from (50)-(52) and (55)-(58). For the monotonic property of ψ see the sentence preceding the statement of Lemma 5.

First observe that (53) follows from (59) with $h=p_n$ and from Lemma 4, with $p(t)=p_n(t)\,e^{ct}$, $\psi_1(t)=e^{ct}\varphi(t)$, $\psi_2(t)=\exp[-(\operatorname{Re}\lambda_j+c)t]$, $K(t)=\exp[-(\lambda_j+c)t]$ and $K_0=1+|\lambda_j+c|$, for each $j=1,2,\cdots,L$. The case $n=R[\tilde{u}]-R[\tilde{\tilde{u}}]$ is more complicated. According to (42) and our integrability conditions (55)-(58), we can write

$$\begin{aligned} R[\tilde{u}]-R[\tilde{\tilde{u}}]=&\sum_{k=2}^{n-1}(p_k-q_k)u^{(n-k-1)}+\sum_{k=2}^{n-1}q_k u^{(n-k-1)}\\ &+p_1u^{(n-2)}+\sum_{k=0}^{n-1}a_k g_{n-k}[\tilde{u},\tilde{\tilde{u}}]+p_1g_{n-1}[\tilde{u},\tilde{\tilde{u}}]\\ &+\sum_{k=2}^{n-1}(p_k-q_k)g_{n-k}[\tilde{u},\tilde{\tilde{u}}]+\sum_{k=2}^{n-1}q_k g_{n-k}[\tilde{u},\tilde{\tilde{u}}], \end{aligned} \tag{60}$$

where $u=\tilde{u}-\tilde{\tilde{u}}$ and $g_k[\tilde{u},\tilde{\tilde{u}}]=g_k[\tilde{u}]-g_k[\tilde{\tilde{u}}]$. To estimate the integrals in (59), for each member h of the right side of (60), we distinguish seven cases (i)-(vii). Lemma 4 applies in all of them except (iv), when Lemma 3 does. In (ii)-(v) and (vii), the magnitude of the integrand h is estimated, before using Lemmas 3 and 4.

(i) $h=(p_k-q_k)u^{(n-k-1)}$, $p(t)=(p_k(t)-q_k(t))\,e^{ct}$, $\psi_1(t)=e^{ct}$, $\psi_2(t)=\exp[-(\operatorname{Re}\lambda_j+c)t]\varphi(t)$,

$$K(t)=\exp[-(\lambda_j+c)t]u^{(n-k-1)},\quad K_0=\|u\|(1+|\lambda_j+c|),\quad 2\leqq k\leqq n-1,\quad 1\leqq j\leqq L.$$

(ii) $h=q_k u^{(n-k-1)}$, $|h|\leqq\|u\|\varphi|q_k|$, $p(t)=|q_k(t)|\,e^{ct}\varphi(t)$, $\psi_1(t)=e^{ct}\varphi(t)$, $\psi_2(t)=\exp[-(\operatorname{Re}\lambda_j+c)t]$, $K=\|u\|\psi_2$, $K_0=\|u\|\max(1,|\operatorname{Re}\lambda_j+c|)$, $2\leqq k\leqq n=1$, $1\leqq j\leqq L$.

(iii) $h=p_1u^{(n-2)}$, $|h|\leqq\|u\|\varphi|p_1|$, $p(t)=|p_1(t)|\,e^{ct}\varphi(t)$, ψ_1, ψ_2, K and K_0 as in (ii), $1\leqq j\leqq L$.

(iv) $h=g_{n-k}[\tilde{u},\tilde{\tilde{u}}]$, $|h|\leqq C\|u\|\varphi^2$, $\sigma=C\|u\|\varphi$,

$$\psi(t)=\exp[-\operatorname{Re}\lambda_j t]\varphi(t),\quad 0\leqq k\leqq n-1,\quad 1\leqq j\leqq L.$$

(v) $h=p_1g_{n-1}[\tilde{u},\tilde{\tilde{u}}]$, $|h|\leqq C\|u\|\varphi^2|p_1|$, p as in (iii), ψ_1, ψ_2, K and K_0 as in (ii), $1\leqq j\leqq L$.

(vi) $h=(p_k-q_k)g_{n-k}[\tilde{u},\tilde{\tilde{u}}]$, p, ψ_1 and ψ_2 as in (ii), $K(t)=\exp[-(\lambda_j+c)t]\times g_{n-k}[\tilde{u},\tilde{\tilde{u}}]$, $K_0=C\|u\|(1+|\lambda_j+c|)$, $2\leqq k\leqq n-1$, $1\leqq j\leqq L$.

(vii) $h=q_kg_{n-k}[\tilde{u},\tilde{\tilde{u}}]$, $|h|\leqq C\|u\|\varphi^2|q_k|$, p, ψ_1, ψ_2, K and K_0 as in (ii), $2\leqq k\leqq n-1$, $1\leqq j\leqq L$.

Finally note that the existence of $\mathscr{L}[\tilde{u}]$ follows from the preceding with $\tilde{\tilde{u}}=0$, because $\mathscr{L}[\tilde{\tilde{u}}]=0$. This completes the proof of Lemma 5.

Now it is easy to finish the proof of Theorem 1. From (47), (53) and (54) with $\tilde{u} = u$ and $\tilde{\tilde{u}} = 0$, we find that

$$|D^i \mathcal{T}[u](t)| \leqq 2\sigma(t_0, t)\varphi(t) \qquad (0 \leqq i \leqq n-2) \tag{61}$$

for any u in $\mathcal{S}(t_0)$. Moreover, if $\tilde{u}$, $\tilde{\tilde{u}}$ are in $\mathcal{S}(t_0)$, then

$$|D^i \mathcal{T}[\tilde{u}](t) - D^i \mathcal{T}[\tilde{\tilde{u}}](t)| \leqq \|\tilde{u} - \tilde{\tilde{u}}\| \sigma(t_0, t)\varphi(t) \qquad (0 \leqq i \leqq n-2). \tag{62}$$

Since $\sigma(t_0, t)$ is nonincreasing in t, (48), (49), (61) and (62) imply that $\|\mathcal{T}[u]\| \leqq 2\sigma(t_0, t_0)$ and $\|\mathcal{T}[\tilde{u}] - \mathcal{T}[\tilde{\tilde{u}}]\| \leqq \sigma(t_0, t_0)\|\tilde{u} - \tilde{\tilde{u}}\|$. Therefore, $\mathcal{T}$ is a contraction mapping of $\mathcal{S}(t_0)$ into itself if t_0 is so large that $\sigma(t_0, t_0) \leqq 1/2$, which we now assume (recall that $\sigma(t_0, t_0) \to 0$ as $t_0 \to \infty$). Consequently, $\mathcal{T}$ has a fixed point (function) u_0 which satisfies $u_0 = \mathcal{T}u_0$. Setting $u = u_0$ in (61), we conclude that

$$D^k u_0(t) = o(\varphi(t)) \qquad (0 \leqq K \leqq n-2), \tag{63}$$

because $\sigma(t_0, t) \to 0$ as $t \to \infty$. Moreover, (38) and (51) with $u = u_0$ and $\tilde{\tilde{u}} = 0$ imply that

$$g_k[u_0](t) = o(\varphi(t)) \qquad (1 \leqq k \leqq n). \tag{64}$$

Since u_0 is a solution of (46), the function

$$x_0(t) = \exp\left[\int_{t_0}^{t} u_0(s)\, ds\right]$$

satisfies (1) on $[t_0, \infty)$. From (40) with $x = x_0$ and $u = u_0$, (63) and (64), we conclude that x_0 is as in (6) with $\lambda_0 = 0$. This completes the proof of Theorem 1 in the case when (38) holds.

Our proof requires (38), because of part (iv) in the proof of Lemma 5, where $\sigma(t) = C\|u\|\varphi(t) = o(1)$ is assumed. Moreover, (38) is necessary for (51) to imply (64). From the statement of Theorem 1, it is clear that if (38) does not hold, then it may as well be assumed that $\varphi = 1$. This case was considered in [6], proivded that the integrals $\int^\infty |p_1(t)|\, dt$ and $\int^\infty p_k(t)\, dt$ $(2 \leqq k \leqq n)$ converge and that (4) has n roots with distinct real parts. Fortunately, it presents no difficulty to adapt the proof of [6] to that of Theorem 1 with $\varphi = 1$, and we omit it here.

4. Corollaries of Theorem 1. First we give two immediate consequences of Theorem 1.

COROLLARY 1. *Theorem* 1 *remains valid if* (11)-(13) *are replaced by*

$$p_k(t) = o(1) \quad (1 \leqq k \leqq n), \qquad f(t) = o(\varphi(t)). \tag{65}$$

Proof. Obviously, (65) implies (11)-(13).

COROLLARY 2. *Theorem* 1 *remains valid if* (11)-(13) *are replaced by the assumption that the integrals* $\int^\infty |p_1(t)|\varphi(t)\, dt$, $\int^\infty p_k(t)\, dt$ $(2 \leqq k \leqq n)$ *and* $\int^\infty f(t)\, dt$ *converge so that*

$$\int_t^\infty |p_1(s)|\varphi(s)\, ds = o(\varphi(t)), \qquad \int_t^\infty f(s)\, ds = o(\varphi(t)).$$

Proof. From Lemma 1 with $\gamma = 0$, the assumption in Corollary 2 implies (11)-(13).

Corollary 2 with $\varphi(t) = e^{-\rho t}t^{-q}$ (ρ and q are nonnegative constants) and the conclusion of Remark 2 in § 1 cover a part of the author's results [5] and [6]. Equation (1) was considered there under assumptions including the convergence of the integrals $\int^\infty p_k(t)\, e^{\rho t}t^q\, dt$, which is more restrictive than

$$\int_t^\infty p_k(s)\, ds = o(e^{-\rho t}t^{-q}).$$

Very recently, Trench [8] has given conditions like those of Corollary 2 which imply the behavior (18) in the difficult case when $\operatorname{Re}(\lambda_0-\lambda_j)=m_\varphi$, for some some roots λ_j of (4). (All these λ_j are assumed to be simple.) However, Trench's assumptions include either that

$$\int_t^\infty \varphi^2(s)\,ds = O(\varphi(t)),$$

or some additional smallness restrictions on p_k.

The last consequence of Theorem 1 concerns the equation

$$x^{(n)}+p_1(t)x^{(n-1)}+\cdots+p_n(t)x=0 \qquad (t\geqq 0,\ n\geqq 2) \tag{66}$$

with continuous coefficients p_k, regarded as a perturbation of $x^{(n)}=0$. Trench [7] has considered a solution x_0 of (66) satisfying

$$x_0^{(k)}(t)=[Q(t)t^d]^{(k)}+o(t^{d-k}\psi(t)) \qquad (0\leqq k\leqq n-1),$$

where ψ is positive and nonincreasing on $[T,\infty)$, d is an integer $(0\leqq d\leqq n-1)$ and Q is a polynomial of degree $\leqq n-d-1$. We restrict our attention to the case $Q=1$. If we introduce the notation

$$\begin{aligned} Q_k(\lambda)&=\prod_{j=0}^{k-1}(\lambda-j), \qquad Q_0=1,\\ g(t)&=\sum_{k=1}^{n} Q_{n-k}(d)p_k(t)t^{d-n+k}, \end{aligned} \tag{67}$$

then Trench's result may be stated as follows.

THEOREM 2. *Suppose ψ is continuous, positive and nonincreasing on $[T,\infty)$, d is a fixed integer $(0\leqq d\leqq n-1)$ and also, if $d\neq 0$, suppose $t^\gamma\psi(t)$ is nondecreasing on $[T,\infty)$, for some $\gamma<1$. Assume also that the integrals $\int^\infty p_k(t)\,dt$ $(2\leqq k\leqq n)$ and $\int^\infty t^{n-d-1}g(t)\,dt$ converge and satisfy*

$$-\int_t^\infty p_k(s)\,ds = 0(t^{1-k}) \qquad (2\leqq k\leqq n), \tag{68}$$

and

$$\int_t^\infty s^{n-d-1}g(s)\,ds = o(\psi(t)). \tag{69}$$

Finally, suppose that

$$\int^\infty |p_1(t)|\,dt<\infty, \tag{70}$$

and

$$\int_t^\infty s^{k-2}\psi(s)\left|\int_s^\infty p_k(r)\,dr\right| ds = o(\psi(t)) \qquad (2\leqq k\leqq n). \tag{71}$$

Then (66) has a solution x_0 satisfying

$$x_0^{(k)}(t)=[Q_k(d)+o(\psi(t))]t^{d-k} \quad (0\leqq k\leqq n-1).$$

Our following result implies that even (71) need not hold. Note first that, by Lemma 2, (68) is equivalent to

$$\sup_{s\geqq t}(1+\log(s/t))^{-1}\left|\int_t^s r^{k-1}p_k(r)\,dr\right|=o(1)\qquad(2\leqq k\leqq n),\tag{72}$$

while

$$\sup_{s\geqq t}(1+\log(s/t))^{-1}\left|\int_t^s r^{n-d-1}g(r)\,dr\right|=o(\psi(t)),\tag{73}$$

and

$$\sup_{s\geqq t}(1+\log(s/t))^{-1}\int_t^s |p_1(r)|\psi(r)\,dr=o(\psi(t))\tag{74}$$

are weaker than (69) and (70), respectively.

COROLLARY 3. *Let fixed ψ and d be as in the first sentence of Theorem* 2. *If* (72)–(74) *hold, then* (66) *has a solution x_0 satisfying*

$$\frac{x_0^{(k)}(t)}{x_0(t)}=[Q_k(d)+o(\psi(t))]t^{-k}\qquad(1\leqq k\leqq n-1).\tag{75}$$

Proof. We introduce the new variables y, τ by

$$\tau=\log t,\qquad x(t)=y(\tau).\tag{76}$$

Then

$$x^{(k)}(t)=e^{-k\tau}Q_k(D)y(\tau)\qquad\left(D=\frac{d}{d\tau},\,0\leqq k\leqq n\right)\tag{77}$$

and therefore, (66) is transformed into

$$Q_n(D)y+\sum_{k=1}^{n}\tilde{p}_k(\tau)D^{n-k}y=0,\tag{78}$$

where

$$\tilde{p}_k(\tau)=\frac{1}{(n-k)!}\sum_{j=1}^{k}Q_{n-j}^{(n-k)}(0)p_j(e^\tau)\,e^{j\tau}\qquad(1\leqq k\leqq n).\tag{79}$$

We now verify that (78) satisfies the assumptions of Theorem 1 with t replaced by τ, $\varphi(\tau)=\psi(e^\tau)$ and $\lambda_0=d$. Indeed, (4) now becomes $Q_n(\lambda)=0$, and hence has n distinct roots $\lambda_j=j-1$, $1\leqq j\leqq n$. If $d>0$, then $M_\varphi\leqq\gamma<1$, because $\varphi(\tau)\,e^{\gamma\tau}(=\psi(t)t^\gamma)$ is nondecreasing on $[\log\max(1,T),\infty]$. Thus (9) holds with $\lambda_0=d$, for any $\lambda_j\neq d$. Routine manipulations with (67) and (79) show that f in (14) now becomes $f(\tau)=g(e^\tau)\exp[(n-d)\tau]$. From this and (79), substituting $r=\log u$ yields

$$\int_\tau^s|\tilde{p}_1(r)|\varphi(r)\,dr=\int_{e^\tau}^{e^s}|p_1(u)|\psi(u)\,du,$$

$$\int_\tau^s f(r)\,dr=\int_{e^\tau}^{e^s}u^{n-d-1}g(u)\,du$$

and

$$\int_\tau^s(\tilde{p}_k(r)-c_1^k\tilde{p}_1(r))dr=\frac{1}{(n-k)!}\sum_{j=2}^{k}c_j^k\int_{e^\tau}^{e^s}u^{j-1}p_j(u)\,du\qquad(2\leqq k\leqq n),$$

where $c_j^k = Q_{n-j}^{(n-k)}(0)$. Consequently, (72)-(74) imply (11), (13), (15) and (16) with $p_k = \tilde{p}_k$ and $q_k = c_1^k \tilde{p}_1 (2 \leqq k \leqq n)$. Theorem 1 implies that (78) has a nontrivial solution y_0 satisfying

$$y_0^{(k)}(\tau) = [d^k + o(\varphi(\tau))] y_0(\tau) \qquad (1 \leqq k \leqq n-1)$$

as $\tau \to \infty$. Then (77) shows that the solution $x_0(t) = y_0(\log t)$ of (66) satisfies (75). This completes the proof of Corollary 3.

POLYNOMIALS RELATED TO EXPANSIONS OF CERTAIN RATIONAL FUNCTIONS IN TWO VARIABLES*

KARL DILCHER†

Abstract. A difference equation corresponding to a certain partial differential equation leads to a "Pascal type" triangle. The entries of a row of this triangle can be regarded as coefficients of a polynomial; the sequence of these polynomials is studied, together with its generating function and related polynomials. The entries of a more general class of number triangles are explicitly determined, as well as asymptotic expressions for the columns of the triangles. Chebyshev and Gegenhauer polynomials, as well as hypergeometric functions are used in the proofs.

Key words. sequences of polynomials, recursions, zeros of polynomials, Chebyshev polynomials, ultraspherical polynomials, hypergeometric functions, asymptotics, Darboux's method

AMS(MOS) subject classifications. 11B37, 33A30, 33A50, 41A60

1. Introduction.

Let $u = u(x, t)$ be a function in two variables, and consider the (hyperbolic) partial differential equation

$$\frac{\partial^2 u}{\partial x^2} = \frac{\partial^2 u}{\partial t^2} + \frac{\partial u}{\partial t}.$$

If we change this into a difference equation, we get

$$2u(x, t+1) = u(x-1, t) + u(x, t) + u(x+1, t) - u(x, t-1).$$

This suggests the "Pascal type" triangle (after normalizing)

(1.1)

$$\begin{array}{ccccccccccc}
 & & & & & 1 & & & & & \\
 & & & & 1 & 1 & 1 & & & & \\
 & & & 1 & 2 & 1 & 2 & 1 & & & \\
 & & 1 & 3 & 2 & 3 & 2 & 3 & 1 & & \\
 & 1 & 4 & 4 & 4 & 5 & 4 & 4 & 4 & 1 & \\
1 & 5 & 7 & 6 & 9 & 7 & 9 & 6 & 7 & 5 & 1 \\
 & & & & & \vdots & & & & &
\end{array}$$

where each element in the nth row is the sum of the three closest elements in the $(n-1)$th row, minus twice the closest element in the $(n-2)$th row.

Now we expand

$$G(z, t) := \frac{t}{1 - t(1+z+z^2) + 2z^2t^2} = \sum_{n=1}^{\infty} f_n(z) t^n;$$

it is clear that the $f_n(z)$ are polynomials of degree $2n$, and their coefficients are the rows of the triangle (1.1).

More generally, let $\nu > \frac{1}{2}$ and λ be real parameters. We expand

$$G^{\lambda,\nu}(z, t) := (1 - (1+z+z^2)t + \lambda z^2 t^2)^{-\nu} = \sum_{n=0}^{\infty} f_n^{\lambda,\nu}(z) t^n.$$

* Received by the editors January 13, 1986; accepted for publication February 9, 1987.

† Department of Mathematics, Statistics and Computing Science, Dalhousie University, Halifax, Nova Scotia, Canada B3H 3J5. The work of this author was supported by a Killam Postdoctoral Fellowship.

If we compare this with the generating function

$$(1-2zt+t^2)^{-\nu}=\sum_{n=0}^{\infty} C_n^{\nu}(z)t^n$$

for the ultraspherical (Gegenhauer) polynomials $C_n^{\nu}(z)$, we find

$$f_n^{\lambda,\nu}(z)=\lambda^{n/2}z^n C_n^{\nu}\left(\frac{1+z+z^2}{2\sqrt{\lambda}z}\right). \tag{1.2}$$

Using the recurrence relation for the ultraspherical polynomials (see, e.g., [1, p. 782]), we get $f_0^{\lambda,\nu}(z)=1$, $f_1^{\lambda,\nu}(z)=\nu(1+z+z^2)$, and

$$f_n^{\lambda,\nu}(z)=\left(1+\frac{\nu-1}{n}\right)(1+z+z^2)f_{n-1}^{\lambda,\nu}(z)-\left(1+2\frac{\nu-1}{n}\right)\lambda z^2 f_{n-2}^{\lambda,\nu}(z). \tag{1.3}$$

The polynomials $f_n^{\lambda,\nu}(z)$ are self-inverse, i.e., $f_n^{\lambda,\nu}(z)=z^{2n}f_n^{\lambda,\nu}(1/z)$. If we denote

$$f_n^{\lambda,\nu}(z)=C_{n,n}^{\lambda,\nu}+C_{n,n-1}^{\lambda,\nu}z+\cdots+C_{n,0}^{\lambda,\nu}z^n+C_{n,1}^{\lambda,\nu}z^{n+1}+\cdots+C_{n,n}^{\lambda,\nu}z^{2n}, \tag{1.4}$$

we get the triangle

$$\begin{array}{c} C_{0,0}^{\lambda,\nu} \\ C_{1,1}^{\lambda,\nu}\,C_{1,0}^{\lambda,\nu}\,C_{1,1}^{\lambda,\nu} \\ C_{2,2}^{\lambda,\nu}\,C_{2,1}^{\lambda,\nu}\,C_{2,0}^{\lambda,\nu}\,C_{2,1}^{\lambda,\nu}\,C_{2,2}^{\lambda,\nu} \\ \vdots \end{array} \tag{1.5}$$

where

$$C_{n,k}^{\lambda,\nu}=\left(1+\frac{\nu-1}{n}\right)(C_{n-1,k-1}^{\lambda,\nu}+C_{n-1,k}^{\lambda,\nu}+C_{n-1,k+1}^{\lambda,\nu})-\left(1+2\frac{\nu-1}{n}\right)\lambda C_{n-2,k}^{\lambda,\nu}, \tag{1.6}$$

with $C_{n,k}^{\lambda,\nu}=C_{n,-k}^{\lambda,\nu}$. For $\lambda=2$ and $\nu=1$, the triangle (1.5) has the form (1.1).

The main purpose of this paper is to study the coefficients $C_{n,k}^{\lambda,\nu}$. We derive the following explicit and asymptotic expressions.

THEOREM 1.

$$C_{n,k}^{\lambda,\nu}=\frac{1}{\Gamma(\nu)}\sum_{s=0}^{[(n-k)/2]}(-\lambda)^s\frac{\Gamma(\nu+n-s)}{s!(n-2s)!}\sum_{j=0}^{[(n-k-2s)/2]}\binom{2j+k}{j}\binom{n-2s}{2j+k}.$$

Here $[x]$ denotes, as usual, the greatest integer function.

THEOREM 2. *For fixed real $\nu>\frac{1}{2}$ and λ, and integer $k\geqq 0$, we have asymptotically as $n\to\infty$,*

(a) *if $\lambda<\frac{9}{4}$,*

$$C_{n,k}^{\lambda,\nu}\sim\frac{1}{2n\Gamma(\nu)\sqrt{\pi}}\left(\frac{n}{\sqrt{9-4\lambda}}\right)^{\nu-1/2}\left(\frac{3+\sqrt{9-4\lambda}}{2}\right)^{n+\nu};$$

(b) *if $\lambda>\frac{9}{4}$,*

$$C_{n,k}^{\lambda,\nu}\sim\frac{(\sqrt{\lambda})^{n+\nu}n^{\nu-3/2}}{\Gamma(\nu)\sqrt{\pi}}\left\{(\sqrt{4\lambda-1})^{1/2-\nu}\cos\left[(\alpha+\pi)n+\nu\alpha+\left(k+\frac{1}{4}-\frac{3\nu}{2}\right)\pi\right]\right.$$

$$\left.+(\sqrt{4\lambda-9})^{1/2-\nu}\cos\left[\beta n+\nu\beta+\left(\frac{1}{4}-\frac{\nu}{2}\right)\pi\right]\right\},$$

where

$$\alpha = \mathrm{Cos}^{-1}(1/2\sqrt{\lambda}), \qquad \beta = \mathrm{Cos}^{-1}(3/2\sqrt{\lambda});$$

(c) *if* $\lambda = \frac{9}{4}$,

$$C_{n,k}^{\lambda,\nu} \sim \frac{(3/2)^n}{\Gamma(\nu)}\left\{\frac{\sqrt{2/3}}{\Gamma(\nu)}\left(\frac{n}{2}\right)^{2\nu-2} + \frac{(\sqrt{8})^{1/2-\nu}}{\sqrt{\pi}}\left(\frac{3}{2}\right)^{\nu} n^{\nu-3/2}\cos\left[(\alpha+\pi)n + \nu\alpha + \left(k+\frac{1}{4}-\frac{3\nu}{2}\right)\pi\right]\right\},$$

where

$$\alpha = \mathrm{Cos}^{-1}(\tfrac{1}{3}).$$

Next we fix $\nu = 1$ and expand $G^{\lambda,1}(z, t)$ according to powers of z. If we set $t = 1 - \alpha^{-1}$, we get

$$G^{\lambda,1}(z, t) = \frac{\alpha}{1-(\alpha-1)z+\{(\lambda-1)\alpha+(1-2\lambda)+\lambda\alpha^{-1}\}z^2} = \alpha \sum_{n=0}^{\infty} g_n^{\lambda}(\alpha) z^n.$$

We have $g_0^{\lambda}(\alpha) = 1$, $g_1^{\lambda}(\alpha) = \alpha - 1$, and

$$g_{n+1}^{\lambda}(\alpha) = (\alpha-1)\{g_n^{\lambda}(\alpha) + (\lambda\alpha^{-1}+1-\lambda)g_{n-1}^{\lambda}(\alpha)\}. \tag{1.7}$$

In § 2 we find explicit expressions for the zeros of the $f_n^{\lambda,1}(z)$ and the $g_n^{\lambda,1}(\alpha)$ for all values of λ. In §§ 3-5, Theorems 1 and 2 are proved, and § 6 contains some further remarks and generalizations.

2. The zeros. The Chebyshev polynomials of the second kind $U_n(z)$ can be defined by the recursion $U_0(z) = 1$, $U_1(z) = 2z$, and

$$U_{n+1}(z) = 2zU_n(z) - U_{n-1}(z). \tag{2.1}$$

By taking $z = p(x)/2\sqrt{q(x)}$ we get the following lemma.

LEMMA 1. *Let* $p(x)$ *and* $q(x)$ *be arbitrary functions, and define the sequence* $V_n(x)$ *recursively by* $V_0(x) = 1$, $V_1(x) = p(x)$, *and*

$$V_{n+1}(x) = p(x)V_n(x) - q(x)V_{n-1}(x).$$

Then, if $q(x) \neq 0$,

$$V_n(x) = q(x)^{n/2} U_n(p(x)/2\sqrt{q(x)}).$$

To find the zeros of $g_n^{\lambda}(\alpha)$, we take $p(\alpha) := \alpha - 1$ and $q(\alpha) := -(\alpha-1)(\lambda\alpha^{-1}+1-\lambda)$. With (1.7) and Lemma 1 we find that

$$g_n^{\lambda}(\alpha) = \{(\alpha-1)(\lambda\alpha^{-1}+1-\lambda)\}^{n/2} U_n\left(\frac{i}{2}\left(\frac{\alpha-1}{\lambda\alpha^{-1}+1-\lambda}\right)^{1/2}\right).$$

Hence $g_n^{\lambda}(\alpha)$ has zeros when

$$\frac{\alpha-1}{\lambda\alpha^{-1}+1-\lambda} = -4\cos^2\frac{k\pi}{n+1},$$

i.e., the zeros are given by

$$\alpha = \frac{1}{2} - 2(1-\lambda)\cos^2\frac{k\pi}{n+1} \pm \left\{4(1-\lambda^2)\cos^4\left(\frac{k\pi}{n+1}\right) - 2(1+\lambda)\cos^2\left(\frac{k\pi}{n+1}\right) + \frac{1}{4}\right\}^{1/2}$$

$(k=1,2,\cdots,n)$. It is easy to see that these zeros are real unless

$$\frac{1+\lambda-2\sqrt{\lambda}}{4(\lambda-1)^2}<\sin^2\left(\frac{k\pi}{n+1}\right)<\frac{1+\lambda+2\sqrt{\lambda}}{4(\lambda-1)^2},$$

in which case they lie on the circle

$$y^2+\left(x-\frac{\lambda}{\lambda-1}\right)^2=\left(\frac{\sqrt{\lambda}}{\lambda-1}\right)^2 \qquad (\alpha=x+iy).$$

To find the zeros of $f_n^{\lambda,1}(z)$, we use the facts that $C_n^1(z)=U_n(z)$, and that the zeros of $U_n(z)$ are given by $\cos(k\pi/(n+1))$, $k=1,2,\cdots,n$. Hence with (1.2) we find that the $2n$ zeros of $f_n^{\lambda,1}(z)$ are

$$z=-\sqrt{\lambda}\cos\frac{k\pi}{n+1}-\frac{1}{2}\pm\left(\lambda\cos^2\frac{k\pi}{n+1}+\sqrt{\lambda}\cos\frac{k\pi}{n+1}-\frac{3}{4}\right)^{1/2}$$

for $k=1,2,\cdots,n$. We note that these zeros are real except when

$$\frac{-3}{2\sqrt{\lambda}}<\cos\frac{k\pi}{n+1}<\frac{1}{2\sqrt{\lambda}},$$

in which case they lie on the unit circle.

3. Proof of Theorem 1. Using the well-known explicit expression for the ultraspherical polynomials (see, e.g., [1, p. 775]) and (1.2), we get

$$f_n^{\lambda,\nu}(z)=\frac{1}{\Gamma(\nu)}\sum_{s=0}^{[n/2]}(-\lambda)^s\frac{\Gamma(\nu+n-s)}{s!(n-2s)!}z^{2s}(1+z+z^2)^{n-2s}. \tag{3.1}$$

If r is a positive integer, the binomial theorem, applied twice, gives

$$\begin{aligned}(1+z+z^2)^r&=\sum_{j=0}^{r}\sum_{i=0}^{j}\binom{r}{j}\binom{j}{i}z^{2j-i}\\&=\sum_{m=0}^{2r}z^m\sum_{j=0}^{[m/2]}\binom{r}{m-j}\binom{m-j}{m-2j},\end{aligned}$$

and with (3.1) we obtain

$$\begin{aligned}f_n^{\lambda,\nu}(z)&=\frac{1}{\Gamma(\nu)}\sum_{s=0}^{[n/2]}(-\lambda)^s\frac{\Gamma(\nu+n-s)}{s!(n-2s)!}z^{2s}\sum_{m=0}^{2n-4s}z^m\sum_{j=0}^{[m/2]}\binom{n-2s}{m-j}\binom{m-j}{m-2j}\\&=\frac{1}{\Gamma(\nu)}\sum_{k=-n}^{n}z^{n-k}\sum_{s=0}^{[(n-k)/2]}(-\lambda)^s\frac{\Gamma(\nu+n-s)}{s!(n-2s)!}\sum_{j=0}^{[(n-k-2s)/2]}\binom{n-2s}{n-k-j-2s}\\&\quad\cdot\binom{n-k-j-2s}{n-k-2j-2s}.\end{aligned}$$

The theorem now follows if we compare the last equation with (1.4) and note that the product of the two binomial coefficients in the last line is equal to that in Theorem 1.

4. Lemmas. We can rewrite Theorem 1 in the form

$$C_{n,k}^{\lambda,\nu}=\frac{1}{\Gamma(\nu)}\sum_{s=0}^{[(n-k)/2]}(-\lambda)^s\binom{n-k-s}{s}\frac{\Gamma(\nu+n-s)}{k!(n-k-s)!}B_k^{(n-k-2s)}, \tag{4.1}$$

where

$$B_k^{(m)} := \sum_{j=0}^{[m/2]} \binom{2j}{j}\binom{m}{2j}\Big/\binom{k+j}{j}.$$

LEMMA 2.

$$B_k^{(m)} = (-i\sqrt{3})^m \frac{m!(2k)!}{(m+2k)!} C_m^{k+1/2}\left(\frac{i}{\sqrt{3}}\right).$$

Proof. We have

$$\begin{aligned} B_k^{(m)} &= \sum_{j=0}^{[m/2]} \frac{(2j)!\,m!\,j!\,k!}{j!j!(m-2j)!(2j)!(k+j)!} \\ &= \sum_{j=0}^{[m/2]} \frac{(-m)_{2j}}{(k+1)_j j!} = \sum_{j=0}^{[m/2]} \frac{(-m/2)_j((1-m)/2)_j}{(k+1)_j} \frac{2^{2j}}{j!} \\ &= F\left(-\frac{m}{2}, \frac{1-m}{2}; k+1; 4\right), \end{aligned}$$

where $(a)_j$ is the Pochhammer symbol $(a)_j = a(a+1)\cdot\cdots\cdot(a+j-1)$ and $(a)_0 = 1$ and $F(a, b; c; x) = {}_2F_1(a, b; c; x)$ is the Gauss hypergeometric series (see, e.g., [1, p. 556]). The ultraspherical polynomials can be expressed as

$$C_m^{\nu}(x) = \frac{(2\nu)_m}{m!} x^m F\left(-\frac{m}{2}, \frac{1-m}{2}; \nu+\frac{1}{2}; 1-x^{-2}\right);$$

this gives the lemma, with $\nu = k+\frac{1}{2}$, $x = i/\sqrt{3}$.

If we combine (4.1) with Lemma 2, we get

LEMMA 3.

$$C_{n,k}^{\lambda,\nu} = \frac{(2k)!}{\Gamma(\nu)k!}(-i\sqrt{3})^{n-k} \sum_{s=0}^{[(n-k)/2]} \left(\frac{\lambda}{3}\right)^s \frac{\Gamma(\nu+n-s)}{s!(n+k-2s)!} C_{n-k-2s}^{k+1/2}\left(\frac{i}{\sqrt{3}}\right).$$

5. Proof of Theorem 2. First we determine the generating functions for the $C_{n,k}^{\lambda,\nu}$, where k, λ, and ν are fixed. To simplify notation, we write $C_n := C_{n,k}^{\lambda,\nu}$. We denote

$$d_n := \frac{\Gamma(\nu)k!}{\Gamma(k+\nu)}(\sqrt{\lambda})^{k-n} C_n \tag{5.1}$$

and

$$t_1 := \frac{-1}{2\sqrt{\lambda}}(1-\sqrt{1-4\lambda}), \qquad t_2 := \frac{-1}{2\sqrt{\lambda}}(1+\sqrt{1-4\lambda}),$$

$$t_3 := \frac{1}{2\sqrt{\lambda}}(3+\sqrt{9-4\lambda}), \qquad t_4 := \frac{1}{2\sqrt{\lambda}}(3-\sqrt{9-4\lambda});$$

note that $t_1 t_2 = 1 = t_3 t_4$.

LEMMA 4. *For real $\nu > 1/2$ and λ, and for $k = 0, 1, \cdots$, we have*

$$F_k(t) := t^k[(1+tt_1)(1+tt_2)]^{\nu-k-1}[(1-tt_1)(1-tt_2)(1-tt_3)(1-tt_4)]^{1/2-\nu}$$
$$\cdot F\left(\frac{k-\nu+2}{2}, \frac{k-\nu+1}{2}; k+1; \frac{4t^2/\lambda}{(t^2-(t/\sqrt{\lambda})+1)^2}\right) = \sum_{n=k}^{\infty} d_n t^n.$$

Proof. We use Lemma 3, change the order of summation, and apply the binomial theorem

$$\begin{aligned}
\sum_{n=k}^{\infty}\left(\frac{i}{\sqrt{3}}\right)^{n-k}\frac{\Gamma(\nu)k!}{(2k)!}C_n t^n &= \sum_{n=k}^{\infty}\left\{\sum_{s=0}^{[(n-k)/2]}\left(\frac{\lambda}{3}\right)^s\frac{\Gamma(\nu+n-s)}{s!(n+k-2s)!}C_{n-k-2s}^{k+1/2}\left(\frac{i}{\sqrt{3}}\right)\right\}t^n \\
&= \sum_{m=k}^{\infty}C_{m-k}^{k+1/2}\left(\frac{i}{\sqrt{3}}\right)t^m\sum_{s=0}^{\infty}\frac{\Gamma(\nu+m+s)}{s!(m+k)!}\left(\frac{\lambda}{3}t^2\right)^s \\
&= \sum_{m=k}^{\infty}C_{m-k}^{k+1/2}\left(\frac{i}{\sqrt{3}}\right)t^m\frac{\Gamma(\nu+m)}{(m+k)!}\sum_{s=0}^{\infty}\frac{\Gamma(\nu+m+s)}{s!\Gamma(\nu+m)}\left(\frac{\lambda}{3}t^2\right)^s \\
&= \sum_{m=k}^{\infty}C_{m-k}^{k+1/2}\left(\frac{i}{\sqrt{3}}\right)\frac{\Gamma(\nu+m)}{(m+k)!}t^m\left(1-\frac{\lambda}{3}t^2\right)^{-m-\nu} \\
&= \frac{t^k}{(1-(\lambda/3)t^2)^{k+\nu}}\frac{\Gamma(k+\nu)}{(2k)!}\sum_{m=0}^{\infty}C_m^{k+1/2}\left(\frac{i}{\sqrt{3}}\right) \\
&\quad\cdot\frac{(k+\nu)_m}{(2k+1)_m}\left(\frac{t}{1-(\lambda/3)t^2}\right)^m,
\end{aligned}$$

where we have used $(x)_n=\Gamma(x+n)/\Gamma(x)$. After changing the variable t to $-it\sqrt{3/\lambda}$, we get

$$\sum_{n=k}^{\infty}d_n t^n=\frac{t^k}{(1+t^2)^{k+\nu}}\sum_{m=0}^{\infty}C_m^{k+1/2}\left(\frac{i}{\sqrt{3}}\right)\frac{(k+\nu)_m}{(2k+1)_m}\left(\frac{-it\sqrt{3/\lambda}}{1+t^2}\right)^m. \tag{5.2}$$

Now we are going to use the following generating function for ultraspherical polynomials (see, e.g., [3, p. 279]),

$$\sum_{m=0}^{\infty}\frac{(\gamma)_m}{(2\alpha)_m}C_m^{\alpha}(x)z^m=(1-xz)^{-\gamma}F\left(\frac{\gamma}{2},\frac{\gamma+1}{2};\alpha+\frac{1}{2};\frac{z^2(x^2-1)}{(1-xz)^2}\right). \tag{5.3}$$

With $\gamma=k+\nu$, $\alpha=k+\frac{1}{2}$, $x=i\sqrt{3}$, and $z=-it\sqrt{3/\lambda}/(1+t^2)$, (5.2) becomes

$$\sum_{n=k}^{\infty}d_n t^n=\frac{t^k}{(t^2-(t/\sqrt{\lambda})+1)^{k+\nu}}F\left(\frac{k+\nu}{2},\frac{k+\nu+1}{2};k+1;y\right), \tag{5.4}$$

where

$$y=\frac{4t^2/\lambda}{(t^2-(t/\sqrt{\lambda})+1)^2}.$$

Using Euler's identity

$$F(a,b;c;y)=(1-y)^{c-a-b}F(c-a,c-b;c;y)$$

(for $|y|<1$; see [3, p. 60]), we get

$$F\left(\frac{k+\nu}{2},\frac{k+\nu+1}{2};k+1;y\right)=(1-y)^{1/2-\nu}F\left(\frac{k-\nu+2}{2},\frac{k-\nu+1}{2};k+1;y\right). \tag{5.5}$$

Now it is easy to verify that

$$1-y=[(1+tt_1)(1+tt_2)]^{-2}(1-tt_1)(1-tt_2)(1-tt_3)(1-tt_4);$$

the lemma now follows from (5.4) and (5.5).

Proof of Theorem 2. To find asymptotics for d_n, we apply Darboux's method (see, e.g., [2, p. 310]) on the generating function $F_k(t)$. Possible singularities of $F_k(t)$ are

at $t=t_j$, $j=1,\cdots,4$, and at $t=-t_1$, $t=-t_2$. To examine the behaviour of $F_k(t)$ in the neighbourhood of $-t_1$ and $-t_2$, we apply the identity (see, e.g., [1, p. 559])

$$F(a,b;c;z)=d_1(-z)^{-a}F\left(a,1-c+a;1-b+a;\frac{1}{z}\right)$$
$$+d_2(-z)^{-b}F\left(b,1-c+b;1-a+b;\frac{1}{z}\right),$$

where d_1 and d_2 are constants depending on a, b, c, to the right-hand side of (5.4). We find

$$F_k(t)=d_1\left(\frac{-\lambda}{4}\right)^{(k+\nu)/2}t^{-\nu}F\left(\frac{k+\nu}{2},\frac{-k+\nu}{2};\frac{1}{2};\frac{1}{y}\right)$$
$$+d_2\left(\frac{-\lambda}{4}\right)^{(k+\nu+1)/2}t^{-\nu-1}\left(t^2-\frac{t}{\sqrt{\lambda}}+1\right)F\left(\frac{k+\nu+1}{2},\frac{-k+\nu+1}{2};\frac{3}{2};\frac{1}{y}\right)$$

which shows that the singularities at $t=-t_1$ and $-t_2$ are removable.

Now we denote

$$F_k^{(j)}(t):=(1-tt_j)^{\nu-1/2}F_k(t)\qquad(j=1,\cdots,4)$$

and

$$F_k^{(5)}(t):=\{(1-tt_3)(1-tt_4)\}^{\nu-1/2}F_k(t).$$

Using the Gauss summation formula (see, e.g., [3, p. 49])

$$F\left(\frac{k-\nu+2}{2},\frac{k-\nu+1}{2};k+1;1\right)=\frac{\Gamma(k+1)\Gamma(\nu-1/2)}{\Gamma\left(\frac{k+\nu}{2}\right)\Gamma\left(\frac{k+\nu+1}{2}\right)}:=\Gamma,$$

which holds for $\nu>\frac{1}{2}$, we find

$$F_k^{(1)}(t_2)=\left(\frac{-1}{2}\right)^{k+\nu}(-\sqrt{1-4\lambda})^{1/2-\nu}(\sqrt{\lambda})^{k+\nu}\left(\frac{-1+\sqrt{1-4\lambda}}{2\sqrt{\lambda}}\right)^{\nu}\Gamma, \tag{5.6}$$

$$F_k^{(2)}(t_1)=\left(\frac{-1}{2}\right)^{k+\nu}(\sqrt{1-4\lambda})^{1/2-\nu}(\sqrt{\lambda})^{k+\nu}\left(\frac{-1-\sqrt{1-4\lambda}}{2\sqrt{\lambda}}\right)^{\nu}\Gamma, \tag{5.7}$$

$$F_k^{(3)}(t_4)=\left(\frac{1}{2}\right)^{k+\nu}(\sqrt{9-4\lambda})^{1/2-\nu}(\sqrt{\lambda})^{k+\nu}\left(\frac{3+\sqrt{9-4\lambda}}{2\sqrt{\lambda}}\right)^{\nu}\Gamma, \tag{5.8}$$

$$F_k^{(4)}(t_3)=\left(\frac{1}{2}\right)^{k+\nu}(-\sqrt{9-4\lambda})^{1/2-\nu}(\sqrt{\lambda})^{k+\nu}\left(\frac{3-\sqrt{9-4\lambda}}{2\sqrt{\lambda}}\right)^{\nu}\Gamma; \tag{5.9}$$

the arguments of these (in general multi-valued) expressions will be determined later.

We note that

(a) if $\lambda<\frac{9}{4}$, then $|t_4|<|t_j|$ for $j=1,2,3$;

(b) if $\lambda>\frac{9}{4}$, then $|t_j|=1$ $(j=1,\cdots,4)$ and no two t_j are equal;

(c) if $\lambda=\frac{9}{4}$, then $t_3=t_4=1$, $|t_1|=|t_2|=1$, $t_1\neq t_2$, $t_1\neq 1$, $t_2\neq 1$.

We prove Theorem 2 according to this distinction.

(a) Let $\lambda<\frac{9}{4}$. Then according to Darboux's method the coefficients in the MacLaurin expansion of

$$f(t):=F_k^{(3)}(t_4)(1-tt_3)^{1/2-\nu}$$

are asymptotics to the d_n, as $n\to\infty$. The binomial theorem gives

$$(1-tt_3)^{1/2-\nu}=\sum_{n=0}^{\infty}\frac{\Gamma(\nu-1/2+n)}{\Gamma(\nu-1/2)n!}\left(\frac{3+\sqrt{9-4\lambda}}{2\sqrt{\lambda}}\right)^{n}t^n, \tag{5.10}$$

and we obtain from (5.1), (5.8), and (5.10)

$$C_n \sim A2^{-k-\nu}(\sqrt{9-4\lambda})^{1/2-\nu}\left(\frac{3+\sqrt{9-4\lambda}}{2}\right)^{n+\nu}, \tag{5.11}$$

where all the gamma function and factorial terms from (5.1), (5.8) and (5.10) are collected in A. Using the duplication formula (see, e.g., [3, p. 24])

$$\frac{\Gamma(2z)}{\Gamma(z)\Gamma(z+\frac{1}{2})} = \frac{2^{2z-1}}{\sqrt{\pi}}, \tag{5.12}$$

we find

$$A = \frac{\Gamma(\nu-\frac{1}{2}+n)}{\Gamma(\nu)n!}\,\frac{2^{2k+\nu-1}}{\sqrt{\pi}}. \tag{5.13}$$

Stirling's formula now gives

$$\Gamma(\nu-\tfrac{1}{2}+n)/n! \sim n^{\nu-3/2} \qquad (\text{as } n\to\infty),$$

so finally we get with (5.11) and (5.13)

$$C_n \sim \frac{1}{\Gamma(\nu)\sqrt{\pi}}n^{\nu-3/2}(9-4\lambda)^{1/4-\nu/2}\left(\frac{3+\sqrt{9-4\lambda}}{2}\right)^{n+\nu},$$

which implies Theorem 2(a).

(b) Let $\lambda > \frac{9}{4}$. Asymptotics to the d_n (as $n\to\infty$) are given by the coefficients of the expansion of

$$g(t) := \sum_{j=1}^{4} F_k^{(j)}(t_j^{-1})(1-tt_j)^{1/2-\nu}.$$

We note that, in general, the values in (5.6)–(5.9) are not uniquely determined. However, the powers $(1-xz)^{-\gamma}$ and $(1-y)^{1/2-\nu}$ in (5.3), resp. (5.5) are to be taken with their principal values. With this in mind, we find that we have to take (5.6) and (5.7) with arguments

$$\varepsilon_1 := k\pi - \nu\alpha - \frac{\pi}{2}\left(\frac{1}{2}-\nu\right), \qquad \varepsilon_2 := k\pi + \nu\alpha + \frac{\pi}{2}\left(\frac{1}{2}-\nu\right),$$

respectively, where $\alpha := \arg\left((1+i\sqrt{4\lambda-1})/2\sqrt{\lambda}\right)$. Using the equivalent of (5.10) for t_1 and t_2, and with (5.1), (5.6), and (5.7), we find that the combined contribution from the first and second term of $g(t)$ is

$$\begin{aligned} &A2^{-k-\nu}(\sqrt{4\lambda-1})^{1/2-\nu}(\sqrt{\lambda})^{n+\nu}\left\{e^{i\varepsilon_1}\left(\frac{-1+i\sqrt{4\lambda-1}}{2\sqrt{\lambda}}\right)^n + e^{i\varepsilon_2}\left(\frac{-1-i\sqrt{4\lambda-1}}{2\sqrt{\lambda}}\right)^n\right\} \\ &\sim \frac{n^{\nu-3/2}}{\Gamma(\nu)\sqrt{\pi}}(\sqrt{4\lambda-1})^{1/2-\nu}(\sqrt{\lambda})^{n+\nu}\cos\left\{(\alpha+\pi)n+\nu\alpha+\left(k+\frac{1}{4}-\frac{3\nu}{2}\right)\pi\right\}. \end{aligned} \tag{5.14}$$

Similarly, we find that we have to take (5.8) and (5.9) with arguments

$$\varepsilon_3 := \nu\beta + \frac{\pi}{2}\left(\frac{1}{2}-\nu\right), \qquad \varepsilon_4 := -\nu\beta - \frac{\pi}{2}\left(\frac{1}{2}-\nu\right),$$

respectively, where $\beta := \arg((3+i\sqrt{4\lambda-9})/2\sqrt{\lambda})$. With (5.10) and its equivalent for t_4, and with (5.1), (5.8), and (5.9) we find the combined contribution from the third and fourth term of $g(t)$ to be

$$A2^{-k-\nu}(\sqrt{4\lambda-9})^{1/2-\nu}(\sqrt{\lambda})^{n+\nu}\left\{e^{i\varepsilon_3}\left(\frac{3+i\sqrt{4\lambda-9}}{2\sqrt{\lambda}}\right)^n + e^{i\varepsilon_4}\left(\frac{3-i\sqrt{4\lambda-9}}{2\sqrt{\lambda}}\right)^n\right\}$$

$$\sim \frac{n^{\nu-3/2}}{\Gamma(\nu)\sqrt{\pi}}(\sqrt{4\lambda-9})^{1/2-\nu}(\sqrt{\lambda})^{n+\nu}\cos\left\{\beta n+\nu\beta+\left(\frac{1}{4}-\frac{\nu}{2}\right)\pi\right\}.$$

This and (5.14) lead to Theorem 2(b).

(c) Let $\lambda = \frac{9}{4}$. Since $t_3 = t_4 = 1$, we have to find the coefficients of the expansion of

$$h(t) := F_k^{(1)}(t_2)(1-tt_1)^{1/2-\nu} + F_k^{(2)}(t_1)(1-tt_2)^{1/2-\nu} + F_k^{(5)}(1)(1-t)^{1-2\nu}.$$

The contribution from the first two terms of $h(t)$ is the same as in (5.14), with $\lambda = \frac{9}{4}$. Furthermore,

$$F_k^{(5)}(1) = \left(\frac{3}{4}\right)^{k-1/2} 2^{1/2-\nu}\Gamma \tag{5.15}$$

for $\lambda = \frac{9}{4}$, and the binomial theorem gives

$$(1-t)^{1-2\nu} = \sum_{n=0}^{\infty} \frac{\Gamma(2\nu-1+n)}{\Gamma(2\nu-1)n!}t^n. \tag{5.16}$$

Hence the contribution to the asymptotics of C_n from the third term of $h(t)$, with (5.16), (5.15), and (5.1) is

$$\frac{\Gamma(2\nu-1+n)}{n!\Gamma(2\nu-1)} \frac{\Gamma(k+\nu)\Gamma(\nu-1/2)}{\Gamma(\nu)\Gamma\left(\frac{k+\nu}{2}\right)\Gamma\left(\frac{k+\nu+1}{2}\right)}\left(\frac{3}{2}\right)^{n-1/2} 2^{1-k-\nu}. \tag{5.17}$$

By applying the duplication formula (5.12) twice, we get

$$\frac{\Gamma(k+\nu)\Gamma(\nu-1/2)}{\Gamma(2\nu-1)\Gamma\left(\frac{k+\nu}{2}\right)\Gamma\left(\frac{k+\nu+1}{2}\right)} = \frac{1}{\Gamma(\nu)}2^{1+k-\nu},$$

and Stirling's formula gives

$$\Gamma(2\nu-1+n)/n! \sim n^{2\nu-2} \qquad (\text{as } n\to\infty);$$

hence (5.17) is asymptotically equal to

$$\frac{1}{(\Gamma(\nu))^2}\left(\frac{n}{2}\right)^{2\nu-2}\left(\frac{3}{2}\right)^{n-1/2}.$$

This and (5.14) for $\lambda = \frac{9}{4}$ finally gives Theorem 2(c).

6. Further remarks. (1) Darboux's method can actually be used to find a complete asymptotic expansion for the $C_{n,k}^{\lambda,\nu}$; this would be a stronger result than Theorem 2. See, e.g., [5, Thm. 8.4].

(2) The sum of the elements of the nth row in the triangle (1.5) is easy to determine. Since the $C_{n,k}^{\lambda,\nu}$ are the coefficients of $f_n^{\lambda,\nu}(z)$, this sum is in fact $f_n^{\lambda,\nu}(1)$. Now (1.2) implies

$$f_n^{\lambda,\nu}(1) = (\sqrt{\lambda})^n C_n^{\nu}(3/2\sqrt{\lambda}).$$

More can be said in the case $\nu = 1$, since $C_n^1(x) = U_n(x)$. From (2.1) we get with a standard method (Binet's formula)

$$U_n(x) = \frac{1}{2\sqrt{x^2-1}}\{(x+\sqrt{x^2-1})^{n+1} - (x-\sqrt{x^2-1})^{n+1}\},$$

and therefore

$$f_n^{\lambda,1}(1) = \frac{(\sqrt{\lambda})^{n+1}}{\sqrt{9-4\lambda}}\left\{\left(\frac{3+\sqrt{9-4\lambda}}{2\sqrt{\lambda}}\right)^{n+1} - \left(\frac{3-\sqrt{9-4\lambda}}{2\sqrt{\lambda}}\right)^{n+1}\right\}. \tag{6.1}$$

As examples, we have

$$f_n^{0,1}(1) = 3^n,$$

$$f_n^{1,1}(1) = \frac{1}{\sqrt{5}}\left\{\left(\frac{3+\sqrt{5}}{2}\right)^{n+1} - \left(\frac{3-\sqrt{5}}{2}\right)^{n+1}\right\}$$

(the odd-index Fibonacci numbers 1, 3, 8, 21, $\cdots$);

$$f_n^{2,1}(1) = 2^{n+1} - 1$$

(see (1.1)), and

$$f_n^{9/4,1}(1) = (n+1)\left(\frac{3}{2}\right)^n.$$

If $\lambda > \frac{9}{4}$ then (6.1) can be rewritten as

$$f_n^{\lambda,1}(1) = 2(4\lambda-9)^{-1/2}(\sqrt{\lambda})^{n+1}\sin\{(n+1)\theta\} \tag{6.2}$$

where θ is such that $\exp(i\theta) = (3+i\sqrt{4\lambda-9})/2\sqrt{\lambda}$, or $\theta = \mathrm{Cos}^{-1}(3/2\sqrt{\lambda})$. (6.2) gives easy explicit formulas for $\lambda = 3 (\theta = \pi/6)$, $\lambda = \frac{9}{2}$ $(\theta = \pi/4)$, $\lambda = 9$ $(\theta = \pi/3)$.

(3) The generating function $G^{\lambda,1}(z,t)$ of § 1 can be generalized as follows. Let $p(z) := a_0 + a_1 z + \cdots + a_r z^r$ and $q(z) = b_0 + b_1 z + \cdots + b_s z^s$ and expand

$$G(z,t) := \frac{1}{1 - tp(z) + t^2 q(z)} = \sum_{n=0}^{\infty} Q_n(z)(z)t^n.$$

Then $Q_0(z) = 1$, $Q_1(z) = p(z)$, and

$$Q_{n+1}(z) = p(z)Q_n(z) - q(z)Q_{n-1}(z), \tag{6.3}$$

and we see that $Q_n(z)$ is a polynomial of degree $\leqq nr$. If we denote

$$Q_n(z) = C_0^{(n)} + C_1^{(n)} z + \cdots + C_{nr}^{(n)} z^{nr},$$

we have the recursion

$$C_k^{(n+1)} = \sum_{j=0}^{k} a_j C_{k-j}^{(n)} - \sum_{j=0}^{k} b_j C_{k-j}^{(n-1)} \tag{6.4}$$

where $a_j := 0$ for $j < 0, j > r$, and $b_j := 0$ for $j < 0, j > s$. We note the following special cases.

(a) $p(z) := 1 + z$, $q(z) := 0$ gives $Q_n(z) = (1-z)^n$, and the $C_k^{(n)}$ are the binomial coefficients.

(b) $p(z) := 1 + z + z^2$, $q(z) = \lambda z^2$; this is the case dealt with in this paper, with $\nu = 1$.

(c) To generalize (b), we set $p(z) := 1 + z + \cdots + z^{2m}$, $q(z) := \lambda z^{2m}$. After reindexing (so that $Q_n(z) = C_{nm}^{(n)} + C_{nm-1}^{(n)} z + \cdots + C_0^{(n)} z^{nm} + \cdots + C_{nm-1}^{(n)} z^{2nm-1} + C_{nm}^{(n)} z^{2nm}$) (6.4) becomes

$$C_k^{(n+1)} = C_{k-m}^{(n)} + \cdots + C_k^{(n)} + \cdots + C_{k+m}^{(n)} - \lambda C_k^{(n-1)}; \tag{6.5}$$

this is the analogue to (1.6). No attempt has been made to determine the $C_k^{(n)}$ explicitly or asymptotically. However, it is easy to derive the sums of the elements in the rows of the triangle generated by (6.5). In analogy to and as a generalization of (6.1) we obtain

$$Q_n(1) = \frac{(\sqrt{\lambda})^{n+1}}{\sqrt{(2m+1)^2-4\lambda}} \cdot \left\{ \left(\frac{2m+1+\sqrt{(2m+1)^2-4\lambda}}{2\sqrt{\lambda}} \right)^{n+1} - \left(\frac{2m+1-\sqrt{(2m+1)^2-4\lambda}}{2\sqrt{\lambda}} \right)^{n+1} \right\}.$$

For $\lambda \leqq (2m+1)^2/4$, $Q_n(1)$ is positive for all n, and for $\lambda > (2m+1)^2/4$ it is an alternating sequence.

(4) K. B. Stolarsky [4] recently studied the recurrence $p_0(x) = 1$, $p_1(x) = x$, and

$$p_n(x) = x^n p_{n-1}(x^{-1}) + p_{n-2}(x).$$

He showed that for $n \geqq 0$

$$p_{2n+1}(x) = x f_{2n+1}^{1,1}(x)$$

(in our notation), i.e., the $p_{2n+1}(x)$ are self-inverse polynomials, or in other words, the coefficients are "centrally symmetric." However, it is easy to see that the $p_{2n}(x)$ do not have this property; in fact, it is shown in [4] that the coefficients of $p_{2n}(x)$ are "strongly noncentrally symmetric."

Acknowledgments. I wish to thank Kenneth B. Stolarsky for suggesting the problem that led to this paper, and for useful discussions. I also thank the referee for suggesting various improvements.

A QUANTITATIVE DIRICHLET–JORDAN TYPE THEOREM FOR ORTHOGONAL POLYNOMIAL EXPANSIONS*

H. N. MHASKAR†

Abstract. In 1985, Bojanic estimated the rate at which the partial sums of the orthogonal expansion of a function of bounded variation converge to the function. We generalize and sharpen his estimates when the function being expanded is an iterated integral of a function of bounded variation. The class of orthogonal polynomials considered include the Jacobi polynomials orthogonal on $[-1, 1]$ with respect to $(1-x)^\alpha(1+x)^\beta$, $\alpha, \beta \geqq -\frac{1}{2}$. For the Jacobi series, our method gives an asymptotic expression for the difference between the function and its partial sums at points of discontinuity of a high order derivative of the function. In particular, discontinuities in an even order derivative are shown not to affect the rate of convergence.

Key words. orthogonal series, Jacobi polynomials, bounded variation

AMS(MOS) subject classifications. 41A25, 42C15, 33A65

The well-known Dirichlet-Jordan convergence criterion for Fourier series states that the trigonometric Fourier series of a 2π-periodic function f having bounded variation converges to $\frac{1}{2}[f(x+0)+f(x-0)]$ for every x and this convergence is uniform on every closed interval on which f is continuous [13, Thm. 2.8.1].

Many mathematicians have studied the generalizations and analogues of this criterion for series other than Fourier series, especially orthogonal polynomial series ([9], [12], [5], [11], [6], [10]). The most general theorem known to us about orthogonal polynomial series on $[-1, 1]$ is due to Freud [5].

To describe Freud's theorem, we develop some notation.

A function $w: [-1, 1] \to [0, \infty)$ is called a weight function if

$$\int_{-1}^{1} |t|^k w(t)\, dt < \infty, \qquad k = 0, 1, 2, \cdots. \tag{1}$$

The class of all polynomials of degree not exceeding n will be denoted by Π_n. When w is a weight function, there is a unique system $\{p_n\}$ of polynomials such that

$$p_n(w, x) := p_n(x) := \gamma_n x^n + \cdots \in \Pi_n, \qquad \gamma_n > 0 \tag{2}$$

and

$$\int_{-1}^{1} p_n(x) p_m(x) w(x)\, dx = \delta_{nm}. \tag{3}$$

If f is integrable on $[-1, 1]$, we put

$$c_k := c_k(w, f) := \int_{-1}^{1} f(t) p_k(t) w(t)\, dt, \qquad k = 0, 1, 2, \cdots, \tag{4a}$$

$$s_m(w, f, x) := s_m(f, x) := \sum_{k=0}^{m-1} c_k p_k(x), \qquad m = 1, 2, \cdots. \tag{4b}$$

Freud's theorem now states the following.

THEOREM 1 [5, Thm. V.7.5]. *Suppose w is a weight function satisfying*

$$0 < w(x) \leqq M(1-x^2)^{-1/2}, \qquad x \in (-1, 1). \tag{5}$$

* Received by the editors February 18, 1986; accepted for publication February 9, 1987.

† Department of Mathematics and Computer Science, California State University, Los Angeles, California 90032.

Further, let f be a function of bounded variation on $[-1, 1]$. Then $s_n(w, f, x)$ converges to $\frac{1}{2}(f(x+0)+f(x-0))$ for every $x \in (-1, 1)$ where w is continuous; the convergence is uniform in every $[a, b] \subset (-1, 1)$ on which f and w are continuous.

In particular, Freud's theorem applies to all the Jacobi polynomial expansions for $w(x) := (1-x)^{\alpha}(1+x)^{\beta}$ and $\alpha, \beta \geqq -\frac{1}{2}$. However, despite the applications of such theorems in numerical analysis and differential equations [8], only a few results are known about the rate at which the convergence takes place. In the case of classical Fourier series, one such theorem, unimprovable in some sense, was proved by Bojanic [1]. For orthogonal polynomial expansions, he proved the following.

THEOREM 2 ([2]). *Let w be a weight function and suppose that for $x \in (-1, 1)$ and $n = 1, 2, \cdots$*

$$0 < w(x) \leqq M(1-x^2)^{-A}, \tag{6}$$

$$|p_n(x)| \leqq M(1-x^2)^{-B}, \tag{7}$$

$$\left| \int_{-1}^{x} w(t)p_n(t)\, dt \right| \leqq \frac{C}{n}. \tag{8}$$

If f is a function of bounded variation on $[-1, 1]$ then

$$\begin{aligned} |s_n(w, f, x) - \tfrac{1}{2}(f(x+)+f(x-))| \leqq \frac{C(x)}{n} \sum_{k=1}^{n} V\left(\left[x - \frac{1+x}{k}, x + \frac{1-x}{k}\right], \bar{g}_x\right) \\ + \tfrac{1}{2}|f(x+)-f(x-)| \cdot |s_n(w, \psi_x, x)| \end{aligned} \tag{9}$$

where $\bar{g}_x$ is given by

$$\bar{g}_x(t) := \begin{cases} f(t)-f(x-), & -1 \leqq t < x, \\ 0, & t = x, \\ f(t)-f(x+), & x < t \leqq 1, \end{cases} \tag{10}$$

and

$$\psi_x(t) := \operatorname{sign}(t-x) := \begin{cases} \dfrac{t-x}{|t-x|}, & t \neq x, \\ 0, & t = x. \end{cases} \tag{11}$$

Moreover, $C(x) > 0$ for $x \in (-1, 1)$ and $V([a, b], g)$ is the total variation of g on $[a, b]$.

Under the conditions of Theorem 1, $\{S_n(\psi_x, x)\}$ tends to zero as $n \to \infty$. In the case of Jacobi expansions, it was noted in [2] that

$$|S_n(\psi_x, x)| \leqq \frac{M(x)}{n}. \tag{12}$$

We do not expect (12) to hold for a general weight function. It is possible to give an analogue where $1/n$ is replaced by a relatively complicated expression involving quantities related to w and x alone and we hope to obtain "easier" estimates on this expression in future.

While the techniques used in [2] are powerful enough to yield similar theorems in a more general setting than orthogonal polynomials, it is extremely difficult to extend them to study the case when the function has higher derivatives. Thus, for instance, the results in [3] which apply only to the special case of Legendre polynomial expansions are far more complicated than Theorem 2 and, in retrospect, require undue restrictions on the function to get a "good" rate.

In this paper, we study the case when the function has higher order derivatives and obtain a rate of convergence theorem under general conditions similar to those in Theorem 2. For the case of the Jacobi polynomial expansions, we get, in fact, an asymptotic expression for $s_n(w, f, x)$ when the high order derivative of f has a discontinuity at x. More precisely, we prove the following theorem in the general case.

THEOREM 3. *Suppose w is a weight function and*

$$|p_n(w, x)w(x)\sqrt{1-x^2}| \leqq M, \qquad x \in [-1, 1]. \tag{13}$$

Further suppose that $r \geqq 1$ is an integer, f is a $(r-1)$-times continuously differentiable function on $[-1, 1]$ and, for $x \in [-1, 1]$

$$f^{(r-1)}(x) = f^{(r-1)}(-1) + \int_{-1}^{x} \phi(t)\, dt \tag{14}$$

where ϕ is a function of bounded variation on $[-1, 1]$.

Then, for $x \in (-1, 1)$ and $n \geqq (1-x^2)^{-1}$,

$$\begin{aligned} &\left| s_n(w, f, x) - f(x) - \frac{1}{r!}[\phi(x+) - \phi(x-)] \cdot s_n(w, \Gamma_r(x, \cdot), x) \right| \\ &\leqq \frac{c_1}{(1-x^2)^{3/2} w(x)} \cdot \frac{1}{n^{r+1}} \sum_{k=1}^{n} V\left(\left[x - \frac{1+x}{n}, x + \frac{1-x}{n}\right], g_x\right) \end{aligned} \tag{15}$$

where

$$\Gamma_r(x, t) := \begin{cases} 0 & \text{if } t \leqq x, \quad -1 \leqq t \leqq x, \\ (t-x)^r & \text{if } t > x, \quad x < t \leqq 1, \end{cases} \tag{16}$$

and

$$g_x(t) := \begin{cases} \phi(t) - \phi(x-), & t < x, \\ 0, & t = x, \\ \phi(t) - \phi(x+), & t > x. \end{cases} \tag{17}$$

Here and in the sequel, $c, c_1, c_2, \cdots$, will denote constants whose value may be different in different occurrences of the symbol, even within a single formula. Constants which will retain their values will be denoted by capital letters.

In the case of the Jacobi weights $w(x) := w_{\alpha,\beta}(x) := (1-x)^{\alpha}(1+x)^{\beta}$, $\alpha, \beta \geqq -\frac{1}{2}$ we can explicitly compute $s_n(w_{\alpha,\beta}, \Gamma_r(x, \cdot), x)$ in terms of the Jacobi polynomials and hence, obtain asymptotics for the same. This is summarized in the following.

THEOREM 4. *We have, for $x \in (-1, 1)$,*

$$\left| s_n(w_{\alpha,\beta}, \Gamma_r(x, \cdot), x) - \frac{(1-x^2)^{r/2} \sin(r\pi/2)}{n^r \cdot \pi}(r-1)! \right| \leqq \frac{c_2(\alpha, \beta, x)}{n^{r+1}}.$$

The proof of Theorem 3, similar to the ones in [1]-[3], is based on a repeated integration by parts. However, we make a more effective use of the orthogonality of p_n's. In particular, instead of having to estimate the integrals involving the "Christoffel-Darboux kernel" as in [2], [3], we can apply the results of G. Freud on the one-sided L^1-approximation [7] of the functions Γ_r defined in (16).

To prove Theorem 3, we start with the formula

$$f(t) = f(x) + P(x, t) + \frac{1}{(r-1)!} \int_x (t-u)^{r-1} \phi(u)\, du$$

where $P(x, \cdot) \in \Pi_r$ and $P(x, x) = 0$. This formula can be easily verified using Taylor's theorem with the integral form for the remainder and (14). A simple computation now gives, for $t \neq x$,

$$f(t) = f(x) + P(x, t) + \frac{[\phi(x+) - \phi(x-)]}{r!}\Gamma_r(x, t) + F(x, t) \tag{18}$$

where

$$F(x, t) := \frac{1}{(r-1)!}\int_x^t (t-u)^{r-1} g_x(u)\, du = \frac{1}{r!}\int_x^t (t-u)^r\, dg_x(u). \tag{19}$$

Now,

$$s_n(w, P(x, \cdot), x) = P(x, x) = 0 \tag{20}$$

and hence,

$$\left| s_n(w, f, x) - f(x) - \frac{[\phi(x+) - \phi(x-)]}{r!} s_n(w, \Gamma_r(x, \cdot), x) \right| = |s_n(w, F(x, \cdot), x)|. \tag{21}$$

For simplicity of notation, we shall write in the sequel, g instead of g_x and $F(t)$ instead of $f(x, t)$. The following lemma summarizes certain technical estimates which will be needed, especially, to estimate the integrated terms when we use the integration by parts formula repeatedly.

LEMMA 5. *Put*

$$G(t) := \frac{(x-t)^{-1}}{r!}\int_x^t (t-u)^r\, dg(u) = (x-t)^{-1} F(t), \tag{22}$$

$$\Lambda_n(t) := \frac{1}{r!}\int_{-1}^t (t-u)^r p_n(u) w(u)\, du. \tag{23}$$

Then for integer k, $0 \leqq k \leqq r$,

$$|G^{(k)}(t)| \leqq c \cdot |x-t|^{r-k-1} \left| \int_x^t |dg(u)| \right|, \tag{24}$$

$$|\Lambda_n^{(k)}(t)| \leqq c \cdot n^{k-r-1}. \tag{25}$$

Proof. Estimate (24) follows easily when we compute $G^{(k)}(t)$ using Leibnitz's rule. Observe that

$$\Lambda_n^{(k)}(t) = \frac{1}{(r-k)!}\int_{-1}^t (t-u)^{r-k} p_n(u) w(u)\, du.$$

Thus,

$$\begin{aligned} \Lambda_n^{(k)}(t) &= \frac{1}{(r-k)!}\int_{-1}^1 \Gamma_{r-k}(u, t) p_n(u) w(u)\, du \\ &= \frac{1}{(r-k)!}\int_{-1}^1 [\Gamma_{r-k}(u, t) - P(u)] p_n(u) w(u)\, du \end{aligned} \tag{26}$$

for an arbitrary polynomial $P \in \Pi_{n-1}$. Hence, using (13),

$$|\Lambda_n^{(k)}(t)| \leqq c \cdot \inf_{P \in \Pi_{n-1}} \int_{-1}^1 |\Gamma_{r-k}(u, t) - P(u)| \frac{du}{\sqrt{1-u^2}}. \tag{27}$$

Estimate (25) now follows from formulas (15) and (18) of [7, pp. 15-16]. □

Proof of Theorem 3. In a view of (21), it is enough to estimate $|s_n(w, F, x)|$, when $n \geqq (1-x^2)^{-1}$.

It is well known [11, Thm. 3.2.2] that

$$s_n(w, F, x) = \int_{-1}^{1} K_n(x, t)F(t)w(t)\,dt \tag{28}$$

where, with the notation of (2),

$$K_n(x, t) := \frac{\gamma_{n-1}}{\gamma_n}\,\frac{P_n(x)p_{n-1}(t) - p_n(t)p_{n-1}(x)}{x - t}. \tag{29}$$

Let $\underline{x} := x - (1+x)/n$, $\bar{x} := x + (1-x)/n$. Then,

$$s_n(w, F, x) = A + B + C \tag{30}$$

where

$$A := \int_{-1}^{\underline{x}} K_n(x, t)F(t)w(t)\,dt, \tag{31a}$$

$$B := \int_{\underline{x}}^{\bar{x}} K_n(x, t)F(t)w(t)\,dt, \tag{31b}$$

$$C := \int_{\bar{x}}^{1} K_n(x, t)F(t)w(t)\,dt. \tag{31c}$$

In view of (13),

$$|K_n(x, t)| = \left|\sum_{k=0}^{n-1} p_k(x)p_k(t)\right| \leqq \frac{c}{w(x)\sqrt{1-x^2}} \cdot \frac{n}{w(t)\sqrt{1-t^2}}. \tag{32}$$

So

$$|B| \leqq c.n.[w(x)\sqrt{1-x^2}]^{-1} \cdot \int_{\underline{x}}^{\bar{x}} \left(\int_{x}^{t} (t-u)^r |dg(u)|\right) \cdot \frac{dt}{\sqrt{1-t^2}}. \tag{33}$$

$$\leqq c[w(x)\sqrt{1-x^2}]^{-1} n^{-r+1} V([\underline{x}, \bar{x}], g) \cdot \int_{\underline{x}}^{\bar{x}} \frac{dt}{\sqrt{1-t^2}}.$$

Since $n \geqq (1-x^2)^{-1}$, it is easy to see that

$$\int_{\underline{x}}^{\bar{x}} \frac{dt}{\sqrt{1-t^2}} \leqq \frac{c}{n\sqrt{1-x^2}}.$$

So,

$$|B| \leqq c \cdot [w(x)(1-x^2)]^{-1} \cdot n^{-r} V([\underline{x}, \bar{x}], g). \tag{34}$$

In view of (29), (22),

$$A = \int_{-1}^{\underline{x}} \frac{\gamma_{n-1}}{\gamma_n}[p_n(x)p_{n-1}(t) - p_{n-1}(x)p_n(t)]G(t)w(t)\,dt$$

$$= \frac{\gamma_{n-1}}{\gamma_n}\left\{p_n(x) \cdot \int_{-1}^{\underline{x}} \Lambda_{n-1}^{(r+1)}(t)G(t)\,dt - p_{n-1}(x) \int_{-1}^{\underline{x}} \Lambda_n^{(r+1)}(t)G(t)\,dt\right\}. \tag{35}$$

Thus, using (13), and the following estimate

$$\frac{\gamma_{n-1}}{\gamma_n} = \int_{-1}^{1} xp_{n-1}(u)p_n(u)w(u)\,du \leqq 1$$

(which can be seen easily using the Schwarz inequality), we get

$$|A| \leqq c[w(x)\sqrt{1-x^2}]^{-1}\{|A_1| + |A_2|\} \tag{36}$$

where

$$A_1 := \int_{-1}^{\underline{x}} \Lambda_{n-1}^{(r+1)}(t) G(t)\, dt, \tag{37a}$$

$$A_2 := \int_{-1}^{\underline{x}} \Lambda_{n}^{(r+1)}(t) G(t)\, dt. \tag{37b}$$

We estimate A_2, the estimate for A_1 being similar. Integrating by parts several times, we obtain

$$A_2 = \sum_{j=0}^{r} (-1)^j \Lambda_n^{(r-j)}(\underline{x}) G^{(j)}(\underline{x}) + (-1)^{r+1} \int_{-1}^{\underline{x}} \Lambda_n(t)\, dG^{(r)}(t). \tag{38}$$

Using Lemma 5 and then Leibnitz's rule, we obtain

$$\begin{aligned} |A_2| &\leqq \frac{c}{n^r} V([\underline{x}, x], g) + \frac{c}{n^{r+1}} \int_{-1}^{\underline{x}} |dG^{(r)}(t)| \\ &\leqq \frac{c}{n^r} V([\underline{x}, x], g) + \frac{c}{n^{r+1}} \int_{-1}^{\underline{x}} \frac{V(t)}{(x-t)^2}\, dt + \frac{c}{n^{r+1}} \int_{-1}^{\underline{x}} \frac{dV(t)}{x-t} \end{aligned} \tag{39}$$

where

$$V(t) := V([t, x], g).$$

Integrating by parts once more in the last integral, we obtain

$$\begin{aligned} |A_2| &\leqq \frac{c}{n^{r+1}} \cdot nV(\underline{x}) + \frac{c}{n^{r+1}} \int_{-1}^{\underline{x}} \frac{V(t)}{(x-t)^2}\, dt \\ &\leqq \frac{c}{n^{r+1}} \int_{-1}^{\underline{x}} \frac{V(t)}{(x-t)^2}\, dt. \end{aligned} \tag{40}$$

Similarly,

$$|A_1| \leqq \frac{c}{(n-1)^{r+1}} \int_{-1}^{\underline{x}} \frac{V(t)}{(x-t)^2}\, dt \leqq \frac{c}{n^{r+1}} \int_{-1}^{\underline{x}} \frac{V(t)}{(x-t)^2}\, dt. \tag{41}$$

Since $V(t)$ is decreasing, it follows from (40), (41), (36) that

$$\begin{aligned} |A| &\leqq c[w(x)\sqrt{1-x^2}]^{-1}(1+x)^{-1} \frac{1}{n^{r+1}} \sum_{k=1}^{n} V\left(\left[x - \frac{1+x}{k}, x\right], g\right) \\ &\leqq c[w(x)(1-x^2)^{3/2}]^{-1} \frac{1}{n^{r+1}} \sum_{k=1}^{n} V\left(\left[x - \frac{1+x}{k}, x\right], g\right). \end{aligned} \tag{42}$$

Similarly,

$$|C| \leqq c[w(x)(1-x^2)^{3/2}]^{-1} \frac{1}{n^{r+1}} \sum_{k=1}^{n} V\left(\left[x, x + \frac{1+x}{k}\right], g\right). \tag{43}$$

Substituting from (43), (42), (34) into (30), we see that

$$|s_n(w, F, x)| \leqq c \cdot [w(x)(1-x^2)^{3/2}]^{-1} \frac{1}{n^{r+1}} \sum_{k=1}^{n} V\left(\left[x - \frac{1+x}{k}, x + \frac{1-x}{k}\right], g\right). \tag{44}$$

In view of (21), this completes the proof of Theorem 3. □

Proof of Thoerem 4. The proof relies heavily on the special properties of the Jacobi polynomials. For the convenience of the reader, therefore, we use the standard notation as in [11] or [4]. Thus, with $w(x) := (1-x)^\alpha(1+x)^\beta$

$$P_n^{(\alpha,\beta)}(x) := \{h_n^{(\alpha,\beta)}\}^{1/2} p_n(w, x) \tag{45}$$

where

$$h_b^{(\alpha,\beta)} := \frac{2^{\alpha+\beta+1}}{2n+\alpha+\beta+1} \cdot \frac{\Gamma(n+\alpha+1)(n+\beta+1)}{\Gamma(n+1)\Gamma(n+\alpha+\beta+1)}. \tag{46}$$

Using Stirling's approximation, we see that

$$h_n^{(\alpha,\beta)} = \frac{2^{\alpha+\beta}}{n}\left(1+\mathcal{O}\left(\frac{1}{n}\right)\right). \tag{47}$$

Moreover, the Christoffel-Darboux kernel in (28), (29) is given by the equation 4.5.2 in [11]

$$K_n(x, t) = A_n \cdot \frac{P_n^{(\alpha,\beta)}(t)P_{n-1}^{(\alpha,\beta)}(x) - P_{n-1}^{(\alpha,\beta)}(t)P_n^{(\alpha,\beta)}(x)}{t-x} \tag{48a}$$

where

$$A_n := \frac{2^{-\alpha-\beta}}{2n+\alpha+\beta} \frac{\Gamma(n+1)\Gamma(n+\alpha+\beta+1)}{\Gamma(n+\alpha)\Gamma(n+\beta)} = 2^{-\alpha-\beta-1} n\left(1+\mathcal{O}\left(\frac{1}{n}\right)\right). \tag{48b}$$

Thus,

$$s_n(w, \Gamma_r(x, \cdot), x) = A_n\{P_{n-1}^{(\alpha,\beta)}(x)I_n(x) - P_n^{(\alpha,\beta)}(x)I_{n-1}(x)\} \tag{49}$$

where

$$I_n(x) := \int_x^1 (t-x)^{r-1} P_n^{(\alpha,\beta)}(t)(1-t)^\alpha(1+t)^\beta\, dt. \tag{50}$$

Now, the Rodrigues' formula [11, eq. (4.3.1)] implies (cf. [4, eq. 10.8(38)]) that

$$\int_x^1 P_n^{(\alpha,\beta)}(t)(1-t)^\alpha(1+t)^\beta\, dt = \frac{(1-x)^{\alpha+1}(1+x)^{\beta+1}P_{n-1}^{(\alpha+1,\beta+1)}(x)}{2n}. \tag{51}$$

Applying (51) repeatedly r times, we see that

$$I_n(x) = \frac{(r-1)!(n-r)!}{2^r n!}(1-x)^{\alpha+r}(1+x)^{\beta+r}P_{n-r}^{(\alpha+r,\beta+r)}(x). \tag{52}$$

Evaluating $I_{n-1}(x)$ in the same way and then substituting into (49), we get, after a little bit of simplification,

$$\begin{aligned} s_n(w, \Gamma_r(x, \cdot), x) = {} & \frac{(n-1-r)!}{2^r(n-1)!}A_n(1-x)^{\alpha+r}(1+x)^{\alpha+r}(1+x)^{\beta+r}(r-1)! \\ & \cdot \{P_{n-1}^{(\alpha,\beta)}(x)P_{n-r}^{(\alpha+r,\beta+r)}(x) - P_n^{(\alpha,\beta)}(x)P_{n-1-r}^{(\alpha+r,\beta+r)}(x)\} \\ & - \frac{(n-r-1)!r!}{2^r n!}A_n(1-x)^{\alpha+r}(1+x)^{\beta+r}P_{n-1}^{(\alpha,\beta)}(x)P_{n-r}^{(\alpha+r,\beta+r)}(x). \end{aligned} \tag{53}$$

Now, according to the Darboux formula, [11, Thm. 8.21.8], we have, with $x := \cos\theta$,

$$\begin{aligned} (1-x)^{\alpha/2}(1+x)^{\beta/2}P_n^{(\alpha,\beta)}(x) = {} & n^{-1/2}\pi^{-1/2}(1-x^2)^{-1/4}2^{(\alpha+\beta+1)/2} \\ & \cdot \cos\left[\left(n+\frac{\alpha+\beta+1}{2}\right)\theta - (\alpha+\tfrac{1}{2})\frac{\pi}{2}\right] + \mathcal{O}(n^{-3/2}) \quad \text{if } x \in (-1, 1). \end{aligned} \tag{54}$$

(Here, and in the sequel, the big $\mathcal{O}$ term may depend upon x.) In particular,

$$(1-x)^{\alpha/2}(1+x)^{\beta/2}P_n^{(\alpha,\beta)}(x)=\mathcal{O}(n^{-1/2}). \tag{55}$$

If we use (55) and (48b), a few simple computations reduce (53) to

$$\begin{aligned} s_n(w,\Gamma_r(x,\cdot),x)=&\frac{(r-1)!2^{-\alpha-\beta-1}}{2^r n^{r-1}}\\ &\cdot\{P_{n-1}^{(\alpha,\beta)}(x)P_{n-r}^{(\alpha+r,\beta+r)}(x)-P_n^{(\alpha,\beta)}(x)P_{n-r-1}^{(\alpha+r,\beta+r)}(x)\}\\ &\cdot(1-x)^{\alpha+r}(1+x)^{\beta+r}\left(1+\mathcal{O}\left(\frac{1}{n}\right)\right)+\mathcal{O}\left(\frac{1}{n^{r+1}}\right). \end{aligned} \tag{56}$$

Further, using (54), we get

$$\begin{aligned} &(1-x)^{\alpha+r}(1+x)^{\beta+r}P_{n-1}^{(\alpha,\beta)}(x)P_{n-r}^{(\alpha+r,\beta+r)}(x)\\ &=(1-x)^{\alpha/2}(1+x)^{\beta/2}P_{n-1}^{(\alpha,\beta)}(x)(1-x)^{(\alpha+r)/2}(1+x)^{(\beta+r)/2}P_{n-r}^{(\alpha+r,\beta+r)}(x)(1-x^2)^{r/2}\\ &=(1-x^2)^{r/2}n^{-1}\pi^{-1}(1-x^2)^{-1/2}2^{\alpha+\beta+1}2^r\\ &\quad\cdot\cos\left[\left(n-1+\frac{\alpha+\beta+1}{2}\right)\theta-\left(\alpha+\frac{1}{2}\right)\frac{\pi}{2}\right]\\ &\quad\cdot\cos\left[\left(n-r+\frac{\alpha+\beta+1+2r}{2}\right)\theta-\left(\alpha+r+\frac{1}{2}\right)\frac{\pi}{2}\right]+\mathcal{O}(n^{-2})\\ &=(1-x^2)^{r/2}n^{-1}\pi^{-1}(1-x^2)^{-1/2}2^{\alpha+\beta}2^r\\ &\quad\cdot\left\{\cos\left[(2n+\alpha+\beta)\theta-(2\alpha+r+1)\frac{\pi}{2}\right]+\cos\left(\theta-\frac{r\pi}{2}\right)\right\}+\mathcal{O}(n^{-2}). \end{aligned} \tag{57}$$

Similarly,

$$\begin{aligned} &(1-x)^{\alpha+r}(1+x)^{\beta+r}P_n^{(\alpha,\beta)}(x)P_{n-r-1}^{(\alpha+r,\beta+r)}(x)\\ &=(1-x^2)^{r/2}n^{-1}\pi^{-1}(1-x^2)^{-1/2}2^{\alpha+\beta}2^r\\ &\quad\cdot\left\{\cos\left[(2n+\alpha+\beta)\theta-(2\alpha+r+1)\frac{\pi}{2}\right]+\cos\left(\theta+\frac{r\pi}{2}\right)\right\}+\mathcal{O}(n^{-2}). \end{aligned} \tag{58}$$

Substituting from (57), (58) into (56), we get

$$\begin{aligned} s_n(w,\Gamma_r(x,\cdot),x)=&\frac{(r-1)!}{2^r n^{r-1}}2^{-\alpha-\beta-1}(1-x^2)^{r/2}n^{-1}\pi^{-1}(1-x^2)^{-1/2}2^{\alpha+\beta}2^r\\ &\cdot\left\{\cos\left(\theta-\frac{r\pi}{2}\right)-\cos\left(\theta+\frac{r\pi}{2}\right)\right\}+\mathcal{O}\left(\frac{1}{n^{r+1}}\right)\\ =&\frac{(r-1)!(1-x^2)^{r/2}}{\pi n^r}\sin\frac{r\pi}{2}\sin\theta(1-x^2)^{-1/2}+\mathcal{O}\left(\frac{1}{n^{r+1}}\right)\\ =&\frac{(r-1)!}{\pi n^r}\sin\frac{r\pi}{2}(1-x^2)^{r/2}+\mathcal{O}\left(\frac{1}{n^{r+1}}\right). \end{aligned} \tag{59}$$

□

In the general case, we do not yet have the analogue of Theorem 4, but using condition (13) and the one-sided approximation rsesults of Freud in [7], it is not hard to see that

$$|s_n(w, \Gamma_r(x, \cdot), x)| \leqq \frac{C(x)}{n^r}. \tag{60}$$

The ideas in the proof of Theorem 3 can be extended to obtain a similar rate of convergence for expansions in polynomials orthogonal on the whole real axis with respect to what is now known as the Freud weights. This, however, will be discussed in separate papers.

Acknowledgments. The author wishes to thank Professor Ranko Bojanic (Ohio State University, Columbus, Ohio) for his generous help in the research presented in this paper. The author is grateful to The Bowling Green State University, Bowling Green, Ohio for their support while this work was being done.

DETERMINANTS OF LAPLACIANS AND MULTIPLE GAMMA FUNCTIONS*

ILAN VARDI†

Abstract. In this paper we generalize the classical formula $\Gamma(\frac{1}{2})=\sqrt{\pi}$. We do this by recalling the Multiple Gamma Function first studied in the nineteenth century by Barnes and others. These functions at $\frac{1}{2}$ will be expressed in terms of the functional determinant of Laplacians of the n-sphere (thus these invariants of the n-sphere generalize π). Determinants of Laplacians have been a recent subject of research due to their relevance to Superstring Theory. While the determinant of the Laplacian has been computed for a flat torus using the Kronecker Limit Formula, our result gives the case of the n-sphere with the standard metric.

1. Introduction.

In this paper we generalize the classical formula

$$\Gamma(\tfrac{1}{2})=\sqrt{\pi}. \tag{1}$$

To do so we reinterpret (1) using the functional determinant of the Laplacian on a compact manifold.

Let Δ be the Laplacian of the compact manifold M. Then Δ has a discrete sequence of eigenvalues

$$0=\lambda_0<\lambda_1\leqq\lambda_2\leqq\cdots,$$

which, by the so-called Weyl Law have an asymptotic formula for λ_n as $n\to\infty$. Using this fact one can show that

$$F(s)=\sum_1^\infty \frac{1}{\lambda_n^s}$$

converges absolutely in a half plane $\operatorname{Re}(s)>\sigma$. Thus

$$F'(s)=-\sum_{n=1}^{\infty}\frac{\log\lambda_n}{\lambda_n^s},\qquad \operatorname{Re}(s)>\sigma.$$

One sees that *formally* $e^{-F'(0)}$ is the product of the eigenvalues of Δ. This product does not converge, but it can be shown that $F(s)$ can be continued analytically to $s=0$ and we define

$$\det\Delta=e^{-F'(0)}$$

to be the *Functional Determinant* of Δ. It is easily shown that for $M=S^1$, the unit circle, with standard Laplacian $\Delta_1=d^2/dx^2$

$$\det\Delta_1=4\pi^2. \tag{2}$$

Thus (1) can be rewritten as

$$\Gamma(\tfrac{1}{2})=(\det\Delta_1)^{1/4}2^{-1/2}. \tag{3}$$

* Received by the editors September 22, 1986; accepted for publication (in revised form) February 9, 1987.

† Department of Mathematics, Stanford University, Stanford, California 94305.

We generalize this formula to *Multiple Gamma Functions.* These are given by

(i) $\Gamma_0(x) = x^{-1}$,

(ii) $\Gamma_n(1) = 1$,

(iii) $\Gamma_{n+1}(x+1) = \Gamma_{n+1}(x)/\Gamma_n(x)$,

(iv) $\Gamma_n(x)^{-1}$ *is* C^∞ *on* $\mathbf{R}$,

(v) $(-1)^n(d^{n+1}/dx^{n+1}) \log \Gamma_n(x) \geqq 0$ for $x > 0$.

As in Vignéras [12] this defines $\Gamma_n(x)$ uniquely. For example

$$\Gamma_1(x) = \Gamma(x)$$

is the *Bohr-Mollerup Theorem* [1].

The Multiple Gamma Functions were first defined in a slightly different form by Barnes [2]. Our definition is due to Vignéras and seems more natural than that of Barnes.

$\Gamma_2(x)$ is the *Double Gamma Function,* which was originally studied in the latter half of the nineteenth century, notably by Barnes [3]. It has since been studied by Shintani in a similar form [10], while the function considered here was shown by Vignéras to occur naturally as the factor at infinity of the Selberg Zeta Function [12]. This has since been exploited by Sarnak [9].

Properties of the Double Gamma Function are:

(i) Weierstrass product:

$$\Gamma_2(x+1) = (2\pi)^{-x/2} \exp\left(\frac{x}{2} + \frac{\gamma+1}{2}x^2\right)\left(\prod_{k=1}^{\infty}\left(1+\frac{x}{k}\right)\exp\left(-x+\frac{x^2}{2k}\right)\right)^{-1}.$$

(ii) Stirling formula:

$$\log \Gamma_2(x+a+1) = -\frac{(x+a)}{2}\log 2\pi + \log A - \frac{1}{12} + \frac{3x^2}{4} + ax - \left(\frac{x^2}{2} - \frac{1}{12} + \frac{a^2}{2} + ax\right)\log x + \mathcal{O}\left(\frac{1}{x}\right)$$

where A is a constant of Kinkelin [5]

$$\log A = \lim_{k\to\infty}\left[\log(1^1 2^2 \cdots k^k) - \left(\frac{k^2}{2} + \frac{k}{2} + \frac{1}{2}\right)\log k + \frac{k^2}{4}\right].$$

In § 4 we will evaluate this as

$$\log A = \exp\left(\tfrac{1}{12} - \zeta'(-1)\right)$$

where $\zeta(s)$ is the Riemann ζ-function.

(iii) $\Gamma_2(n+2) = (1!2!\cdots n!)^{-1}$.

(iv) Multiplication formula:

$$\prod_{r=0}^{k-1}\prod_{s=0}^{k-1}\Gamma_2\left(x+\frac{r+s}{k}\right) = K(2\pi)^{-k(k-1)x/2}k^{(k^2x^2/2)-kx}\Gamma_2(kx)$$

where

$$K = A^{k^2-1}\, e^{(1-k^2)/12}(2\pi)^{(k-1)/2}k^{5/12}.$$

This formula, for the case $k = 2$, will be proved in § 2.

(v) Generalized Hilbert Determinant:

$$\begin{vmatrix} \frac{1}{1+1+b} & \frac{1}{1+2+b} & \cdots & \frac{1}{1+n+b} \\ \frac{1}{2+1+b} & \frac{1}{2+2+b} & \cdots & \frac{1}{2+n+b} \\ \vdots & \vdots & \cdots & \vdots \\ \frac{1}{n+1+b} & \frac{1}{n+2+b} & \cdots & \frac{1}{n+n+b} \end{vmatrix} = \frac{\Gamma_2(b+2)\Gamma_2(2n+b+2)}{\Gamma_2(n+b+2)^2\Gamma_2(n+1)^2}.$$

This follows from a result of Cauchy (see [8, Chap. 7, #3]) and is also noted by Gosper in [4].

(vi) $\Gamma_2(\frac{1}{2}) = A^{3/2}\pi^{1/4}e^{-1/8}2^{-1/24}$.

This is a first generalization of $\Gamma(\frac{1}{2}) = \sqrt{\pi}$; however, it lacks a geometric interpretation. We will find this interpretation by expressing $\Gamma_n(\frac{1}{2})$ in terms of $\det \Delta_m$ the determinant of the standard Laplacian of the m-sphere S^m.

Our result is Theorem 1.1.

THEOREM 1.1. *Let n be a positive integer, then there are computable rational numbers*

$$a_n, b_n, c_n, q_{n,1}, q_{n,2}, \cdots, q_{n,n} \quad \text{where } q_{n,n} = \frac{2^n - 1}{2^{n+1}}, \quad a_n \neq 0 \text{ s.t.},$$

$$\Gamma_n(\tfrac{1}{2}) = a_n^{b_n} e^{c_n} \prod_{m=1}^{n} (\det \Delta_m)^{q_{n,m}}. \tag{4}$$

In particular

$$\Gamma_2(\tfrac{1}{2}) = \det \Delta_2^{3/8} \det \Delta_1^{1/8}\, 2^{-7/24} e^{-3/16} = 1.2451432493632740351800384317993 18\cdots,$$

$$\Gamma_3(\tfrac{1}{2}) = \det \Delta_3^{7/16} \det \Delta_2^{31/64} \det \Delta_1^{-15/64} 2^{-11/48} e^{-31/128}.$$

It is seen that (4) can be written as

$$\begin{pmatrix} \log(\Gamma_1(\frac{1}{2}) a_1^{-b_1} e^{-c_1}) \\ \log(\Gamma_2(\frac{1}{2}) a_2^{-b_2} e^{-c_2}) \\ \vdots \\ \log(\Gamma_n(\frac{1}{2}) a_n^{-b_n} e^{-c_n}) \end{pmatrix} = \begin{pmatrix} \frac{1}{4} & 0 & \cdots & 0 \\ q_{2,1} & \frac{3}{8} & \cdots & 0 \\ \vdots & \vdots & \cdots & \vdots \\ q_{n,1} & q_{n,2} & \cdots & (2^n-1)/2^{n+1} \end{pmatrix} \begin{pmatrix} \log \det \Delta_1 \\ \log \det \Delta_2 \\ \vdots \\ \log \det \Delta_n \end{pmatrix}. \tag{5}$$

Thus (5) can be inverted to yield Theorem 1.2.

THEOREM 1.2. *For n be a positive integer there are computable rational numbers*

$$A_n, B_n, C_n, Q_{n,1}, Q_{n,2}, \cdots, Q_{n,n} \quad \text{where } Q_{n,n} = \frac{2^{n+1}}{2^n - 1}, \quad A_n \neq 0 \text{ s.t.},$$

$$\det \Delta_n = A_n^{B_n} e^{C_n} \prod_{m=1}^{n} \Gamma_m(\tfrac{1}{2})^{Q_{n,m}}.$$

In particular

$$\det \Delta_2 = \Gamma_2(\tfrac{1}{2})^{8/3} 2^{1/9} e^{1/2} = 3.19531148605918608395401893032062586902\cdots.$$

This has interest in light of a new result of Osgood, Phillips and Sarnak [7] (also Onofri [6]). They have shown that of all metrics on the 2-sphere of given constant area 4π, the metric of constant curvature 1 has the unique maximum value of $\det \Delta$. Theorem 1.2 computes this maximum value. As noted in [7], this result relates to recent progress in Superstring Theory in that it studies how $\det \Delta$ varies with the conformal structure.

The proof of Theorem 1.1 is in two parts. First, one expresses $\Gamma_n(\frac{1}{2})$ in terms of the Riemann ζ-function at negative integers, that is, as follows.

THEOREM 1.3. *There are rational numbers*

$$\alpha_n, \beta_n, \sigma_{n,0}, \sigma_{n,1}, \cdots, \sigma_{n,n-1} \quad \text{with } \sigma_{n,n-1} = -\frac{2^{n-1}-1}{2^{n-1}(n-1)!}$$

such that

$$\Gamma_n(\tfrac{1}{2}) = \alpha_n^{\beta_n} \prod_{m=0}^{n-1} e^{\sigma_{n,m}\zeta'(-m)}.$$

This will be proved in § 2. Second, one expresses $\det \Delta_m$ in terms of $\zeta'(s)$ at negative integers.

THEOREM 1.4. *There are rational numbers*

$$\gamma_n, \tau_{n,0}, \tau_{n,1}, \cdots, \tau_{n,n-1}, \quad \text{with } \tau_{n,n-1} = -\frac{4}{(n-1)!} \text{ s.t.},$$

$$\det \Delta_n = e^{\gamma_n} \prod_{m=0}^{n-1} e^{\tau_{n,m}\zeta'(-m)}.$$

Theorem 1.4 will be proved in § 3.

It is clear that the first part of Theorem 1.1 follows from Theorem 1.3 and Theorem 1.4. In § 4, the formulas of §§ 2 and 3 will be specialized to the cases $n = 2, 3$ and the second part of Theorem 1.1 will be proved.

2. Multiple Gamma Functions. The aim of this section is to give a proof of Theorem 1.2. The details of this, however, are quite technical. For clarity of exposition, we first prove the formula

$$\Gamma(\tfrac{1}{2}) = 2^{-1/2} e^{-\zeta'(0)}$$

using the same steps as in the theorem. The main proof will be a relatively straightforward generalization.

Remark. Since $\Gamma(\frac{1}{2}) = \sqrt{\pi}$ we will obtain a new proof of the classical result

$$\zeta'(0) = -\log \sqrt{2\pi}$$

which does not rely on other integral representations of $\zeta(s)$ (e.g. [13, p. 271]).

LEMMA 2.1. *Let* $\zeta(s, a) = \sum_{k=0}^{\infty} (k+a)^{-s}$, $0 < a < 1$, $\operatorname{Re}(s) > 1$ *be the Hurwitz* ζ*-function; then*

$$\Gamma(a) = \frac{e^{\zeta'(0,a)}}{R}, \qquad R \text{ constant}$$

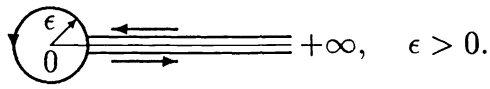
where

$$\zeta'(s, a) = \frac{\partial}{\partial s}\zeta(s, a).$$

Proof. First we note the integral formula [13]

$$\frac{i\Gamma(1-s)}{2\pi} \int_C (-z)^{s-1} e^{-qz}\, dz = q^{-s}, \qquad q > 0$$

where C is given by



Thus we have

$$\zeta(s, a) = \frac{i\Gamma(1-s)}{2\pi} \int_C \frac{e^{-az}(-z)^{s-1}}{1-e^{-z}}\, dz.$$

Therefore $\zeta(s, a)$ is analytically continued for all $s \neq 1$, $(a > 0)$. Now clearly:

$$\zeta(s, a+1) = \zeta(s, a) - a^{-s},$$

$$\zeta'(s, a+1) = \zeta(s, a) + a^{-s} \log a,$$

$$\zeta'(0, a+1) = \zeta'(0, a) + \log a.$$

Letting

$$G(a) = e^{\zeta'(0,a)}$$

we have

$$G(a+1) = aG(a)$$

and

$$\frac{d^2}{da^2} \log G(a) = \frac{d^2}{da^2} \frac{d}{ds} \zeta(s, a)\bigg|_{s=0} = \sum_{k=0}^{\infty} \frac{1}{(k+a)^2} > 0, \qquad a > 0.$$

And by the analytic continuation of $\zeta(s, a)$ one sees that $G(a)$ is C^∞ on $\mathbf{R}^+$. So, by the Bohr-Mollerup Theorem

$$G(a) = \Gamma(a)R, \qquad R \text{ constant.} \qquad \square$$

Note that $R = e^{\zeta'(0)}$ since $\zeta(s, 1) = \zeta(s)$ and so

$$R = G(1) = e^{\zeta'(0,1)}.$$

Next we prove the *Duplication Formula.*

LEMMA 2.2.

$$\Gamma(a)\Gamma(a+\tfrac{1}{2}) = 2^{(1/2)-2a}\, e^{-\zeta'(0)}\Gamma(2a).$$

Proof.

$$\zeta(s, a) + \zeta\left(s, a+\frac{1}{2}\right) = \sum_{k=0}^{\infty} \frac{2^s}{(2k+2a)^s} + \sum_{k=0}^{\infty} \frac{2^s}{(2k+1+2a)^s} = 2^s \zeta(s, 2a).$$

Thus, as in Lemma 2.1

$$G(a)G(a+\tfrac{1}{2}) = 2^{\zeta(0,2a)G(2a)}.$$

As is well known

$$\zeta(0, a) = -B_1(a)$$

where

$$B_1(a) = a - \tfrac{1}{2}$$

is the first Bernoulli polynomial, and the result follows. $\square$

On substituting $a=\frac{1}{2}$ in Lemma 2.1, we obtain

$$\Gamma(\tfrac{1}{2})=2^{-1/2}\,e^{-\zeta(0)}.$$

We now return to the proof of Theorem 1.2.

To study the Multiple Gamma Function we use the *Multiple Hurwitz Zeta Function* [2]

$$\begin{aligned}\zeta_n(s,a)&=\sum_{k_1,\cdots,k_n}(a+k_1+\cdots+k_n)^{-s}\\&=\sum_{k=0}^{\infty}\binom{k+n-1}{n-1}\Big/(k+a)^s,\qquad a>0,\quad \operatorname{Re}(s)>n.\end{aligned}$$

The first observation is Proposition 2.1.

PROPOSITION 2.1. *$\zeta_n(s,a)$ can be continued to a holomorphic function for $s\neq 1,2,\cdots,n$, $a>0$.*

Proof. By the integral formula above one has the integral representation

$$\zeta_n(s,a)=\frac{i\Gamma(1-s)}{2\pi}\int_C\frac{e^{-az}(-z)^{s-1}}{(1-e^{-z})^m}\,dz.$$

The integral is valid for $a>0$ and all s, so $\zeta(s,a)$ has possible poles only at the poles of $\Gamma(1-s)$, i.e., 1, 2, $\cdots$. But by the series definition $\zeta_n(s,a)$ is holomorphic for $\operatorname{Re}(s)>n$. □

Now define

$$G_n(a)=e^{\zeta_n'(0,a)}$$

where

$$\zeta_n'(s,a)=\frac{\partial}{\partial s}\zeta_n(s,a).$$

The basic properties of $G_n(a)$ are now given by the following proposition.

PROPOSITION 2.2. (a) $G_{n+1}(a+1)=(G_{n+1}(a))/G_n(a)$.

(b) *$G_n(a)$ can be continued to a meromorphic function on $\mathbf{C}$ with poles at the negative integers and a simple pole at zero.*

(c) *Let $R_n=\lim_{a\to 0}a\Gamma_n(a)$. Then $G_n(1)=R_n/R_{n-1}$, where $R_0=1$.*

Proof. (a) Follows from the identity

$$\zeta_{n+1}(s,a+1)=\zeta_{n+1}(s,a)-\zeta_n(s,a).$$

(b) Analytic continuation follows from the functional equation of (a). Further one has

$$G_{n+1}(a)=G_n(a)G_{n+1}(a+1),\quad\text{so}$$

$$\lim_{a\to 0}aG_{n+1}(a)=\Big(\lim_{a\to 0}aG_n(a)\Big)G_{n+1}(1). \tag{6}$$

Since $G_1(a)=\Gamma(a)/R$ by Lemma 2.1, the lemma follows by induction.

(c) This clearly follows from (6). □

PROPOSITION 2.3.

$$\Gamma_n(a)=\left[\prod_{m=1}^{n}R_{n-m+1}^{(-1)^m\binom{a}{m-1}}\right]G_n(a). \tag{7}$$

Proof. Denote by $g_n(a)$ the right side of (7). One shows that $g_n(a)$ satisfies the criteria of § 1:

(a) $g_n(1)=1$,

(b) $g_{n+1}(a+1)=g_{n+1}(a)/g_n(a)$,

(c) $g_n(a)^{-1}$ *is* $\mathbf{C}^\infty$ *on* $\mathbf{R}^+$,

(d) $(-1)^{n+1}(d^{n+1}/da^{n+1})\log g_n(a)\geqq 0$, $a>0$.

This is a straightforward verification as in Lemma 2.1. □

We now express the R_n in terms of the Riemann ζ-function. For this we write

$$\binom{x+n-1}{n-1}=\frac{(x+n-1)(x+n-2)\cdots(x+1)}{(n-1)!}=\sum_{m=0}^{n-1}S_{n,m}x^m$$

where $S_{n,m}$ are rational numbers related to *Stirling Numbers* [8].

Note. $S_{n,n-1}=1/(n-1)!$

PROPOSITION 2.4.

$$R_n=\exp\left(\sum_{r=1}^{n}\sum_{m=0}^{r-1}\zeta'(-m)\sum_{j=m}^{r-1}(-1)^{j-m}\binom{j}{m}S_{n,j}\right)$$

$$=\exp\left(\frac{\zeta'(-n+1)}{(n+1)!}+\sum_{r=0}^{n-2}\kappa_{n,r}\zeta'(-r)\right),$$

where $\kappa_{n,0},\cdots,\kappa_{n,n-2}$ *are rational numbers.*

Proof.

$$\zeta_r(s,a)=\sum_{k=0}^{\infty}\binom{k+r-1}{r-1}\Big/(a+k)^s$$

$$=\sum_{j=0}^{r-1}S_{r,j}\sum_{k=0}^{\infty}\frac{k^j}{(a+k)^s}$$

$$=\sum_{j=0}^{r-1}S_{r,j}\sum_{k=0}^{\infty}\frac{(k+a-a)^j}{(k+a)^s}$$

$$=\sum_{j=0}^{r-1}S_{r,j}\sum_{m=0}^{j}(-a)^{j-m}\binom{j}{m}\zeta(s-m,a).$$

Now $G_n(1)=R_n/R_{n-1}$, $R_0=1$ and so

$$\log R_n=\sum_{r=1}^{n}\log G_n(1)=\sum_{r=1}^{n}\zeta_r'(0,1).$$

The result follows. □

COROLLARY 2.1.

$$\zeta_n(0,a)=-\sum_{m=0}^{n-1}\frac{B_{m+1}(a)}{m+1}\sum_{j=m}^{n-1}(-1)^{j-m}\binom{j}{m}S_{n,j},$$

where $B_k(a)$ *is the kth Bernoulli Polynomial* (*recall that* $B_k(a)\in\mathbf{Q}[a]$).

Proof. It follows from the well-known formula [13]

$$\zeta(-m,a)=-\frac{B_{m+1}(a)}{m+1}.$$

□

Note. This implies $\zeta_n(0,a)\in\mathbf{Q}[a]$.

We prove the *Generalized Duplication Formula.*

PROPOSITION 2.5.

$$\prod_{(t_1,t_2,\cdots,t_n)} \Gamma_n\left(a+\frac{t_1+\cdots+t_n}{2}\right)$$

$$=\Gamma_n(2a)2^{\zeta_n(0,2a)}\exp\left(-\frac{2^n-1}{(n-1)!}\zeta'(-n+1)+\sum_{m=0}^{n-2} f_{n,m}(a)\zeta'(-n+1)\right)$$

where $(t_1,\cdots,t_n)$ *runs over all combinations* $t_j=0$ *or* $1, j=1,\cdots,n$ *and* $f_{n,m}(a)\in \mathbf{Q}[a]$, $m=1,\cdots,n-2$.

Proof. As in Lemma 2.2, we have

$$\sum_{(t_1,\cdots,t_n)} \zeta_n\left(s, a+\frac{t_1+\cdots+t_n}{2}\right)=2^s\zeta_n(s,2a)$$

so

$$\prod_{(t_1,\cdots,t_n)} G_n\left(a+\frac{t_1+\cdots+t_n}{2}\right)=2^{\zeta_n(0,2a)}G_n(2a).$$

Substituting

$$G_n(a)=\Gamma_n(a)\prod_{m=1}^{n} R_{n-m+1}^{(-1)^{m+1}\binom{a}{m-1}},$$

one has that these equal

$$R_n^{2^n}\prod_{m=2}^{n}\prod_{(t_1,\cdots,t_n)} R_{n-m+1}^{(-1)^{m+1}\binom{a+\frac{t_1+\cdots+t_n}{2}}{m-1}}$$

$$=2^{\zeta_n(0,2a)}R_n\prod_{m=2}^{n} R_{n-m+1}^{(-1)^{m+1}\binom{2a}{m-1}}\Gamma_n(2a)$$

and the result follows on substituting the values of R_m found in Proposition 2.4. □

At this point we can finish off the proof of Theorem 1.3.

Proof of Theorem 1.3. Let $a=\frac{1}{2}$ in Proposition 2.5. This gives:

$$\prod_{(t_1,\cdots,t_n)} \Gamma_n\left(\frac{1}{2}+\frac{t_1+\cdots+t_n}{2}\right)=2^{\zeta_n(0,1)}\exp\left(-\frac{2^n-1}{(n-1)!}\zeta'(-n+1)\right)$$

$$\cdot\exp\left(-\sum_{m=0}^{n-2} f_{n,m}\left(\frac{1}{2}\right)\zeta'(-m)\right)\Gamma_n(1).$$

Now

$$\prod_{(t_1,\cdots,t_n)} \Gamma_n\left(\frac{1}{2}+\frac{t_1+\cdots+t_n}{2}\right)$$

$$=\Gamma_n\left(\frac{1}{2}\right)\Gamma_n\left(\frac{3}{2}\right)^{\binom{n}{2}}\cdots\Gamma_n\left(\left[\frac{n}{2}\right]+\frac{1}{2}\right)^{\binom{n}{[n/2]}} \tag{8}$$

$$\cdot\Gamma_n(1)^{\binom{n}{1}}\Gamma_n(2)^{\binom{n}{3}}\cdots\Gamma_n\left(\frac{n}{2}+\frac{(1+(-1)^{n+1})}{4}\right)^{\binom{n}{n-(1+(-1)^n)/2}}.$$

It follows easily from the recursion formula that $\Gamma_n(m) \in \mathbf{Q}$ for m a positive integer. So the second line of (8) is a rational number q. As for the first line it can be reduced as follows.

Let k be a positive odd integer; then

$$\Gamma_n\left(\frac{k}{2}\right) = \frac{\Gamma_n((k-2)/2)}{\Gamma_{n-1}((k-2)/2)} = \cdots = \frac{\Gamma_n(\frac{1}{2})}{\Gamma_{n-1}((k-2)/2)\Gamma_{n-1}((k-4)/2)\cdots\Gamma_{n-1}(\frac{1}{2})}.$$

So by induction there are integers

$$C_{n,1}, C_{n,2}, \cdots, C_{n,n-1}$$

such that

$$\Gamma_n\left(\frac{n}{2}\right) = \Gamma_n\left(\frac{1}{2}\right) \prod_{m=1}^{n-1} \Gamma_m\left(\frac{1}{2}\right)^{C_{n,m}}.$$

The first line of (8) is thus

$$\Gamma_n\left(\frac{1}{2}\right)\Gamma_n\left(\frac{3}{2}\right)^{\binom{n}{2}} \cdots \Gamma_n\left(\left[\frac{n}{2}\right]+\frac{1}{2}\right)^{\binom{n}{2[n/2]}}$$

$$= \Gamma_n\left(\frac{1}{2}\right)^{1+\binom{n}{2}+\binom{n}{4}+\cdots+\binom{n}{2[n/2]}} \prod_{m=1}^{n-1} \Gamma_m\left(\frac{1}{2}\right)^{d_{n,m}} \quad \text{where } d_{n,m} \in \mathbf{Z}.$$

As can easily be shown

$$1+\binom{n}{2}+\binom{n}{4}+\binom{n}{2[n/2]} = 2^{n-1}.$$

So for each n one gets

$$\Gamma_n\left(\frac{1}{2}\right) = \prod_{m=1}^{n-1} \Gamma_m\left(\frac{1}{2}\right)^{d_m/2^{n-1}} q^{2^{1-n}} 2^{\zeta_n(0,1)/2^{n-1}}$$

$$\cdot \exp\left(-\frac{2^n-1}{2^{n-1}(n-1)!}\zeta'(-n+1)\right) \prod_{m=0}^{n-2} \exp\left(\frac{f_{n,m}(\frac{1}{2})}{2^{n-1}}\zeta'(-m)\right).$$

Theorem 1.3 follows on substituting values for $\Gamma_m(\frac{1}{2})$, $m = 1, 2, \cdots, n-1$ found in the above formula. □

3. Determinants of Laplacians. We will now evaluate $\det \Delta_n$ in terms of the Riemann ζ-function.

It is well known [10] that Δ_n has eigenvalues

$$k(n+k-1) \quad \text{with multiplicity } \binom{k+n}{n} - \binom{k+n-2}{n}.$$

This gives

$$F_n(s) = \sum_{k=1}^{\infty} \left[\binom{k+n}{n} - \binom{k+n-2}{n}\right] \Big/ k^s(n+k-1)^s.$$

Now write

$$\binom{x+n}{n} - \binom{x+n-2}{n} = \sum_{d=0}^{n-1} T_{n,d} x^n.$$

Note. $T_{n,d} = 2S_{n,d} - S_{n-1,d}$ where $S_{n,d}$ was defined in § 2.

We therefore have

$$F_n(s)=\sum_{d=0}^{n-1} T_{n,d} \sum_{k=1}^{\infty} \frac{k^d}{k^s(n+k-1)^s},$$

so it is natural to define

$$H_d(s)=\sum_{k=1}^{\infty} \frac{k^d}{k^s(k+n)^s}.$$

PROPOSITION 3.1.

$$H_d'(0)=\sum_{k=1}^{n}(k-n)^d \log k-\frac{1}{2}\frac{(-n)^{d+1}}{d+1}\sum_{j=1}^{d}\frac{1}{j}+\zeta'(-d)+(-n)^d\sum_{r=0}^{d}\binom{d}{r}\zeta'(-r)\Big/(-n)^r.$$

Proof.

$$H_d'(s)=\sum_{k=1}^{\infty}\frac{-k^d(\log k+\log(k+n))}{k^s(k+n)^s}$$

$$=-\sum_{k=1}^{n}\frac{\log k}{k^{s-d}(k+n)^s}-\sum_{k=n+1}^{\infty}\frac{\log k}{k^{2s-d}}\left(\left(1+\frac{n}{k}\right)^{-s}+\left(1-\frac{n}{k}\right)^{d-s}\right). \tag{9}$$

Now

$$\left(1+\frac{n}{k}\right)^{-s}+\left(1-\frac{n}{k}\right)^{d-s}=\sum_{k=0}^{\infty} b_m(s)\left(\frac{n}{k}\right)^m, \qquad k>n$$

where

$$b_m(s)=\binom{-s}{m}+(-1)^m\binom{-s+d}{m}.$$

So letting

$$A(s)=-\sum_{k=1}^{n}\frac{\log k}{k^{s-d}(k+n)^s}$$

be the first term of (9), we get

$$A(0)=-\sum_{k=1}^{n} k^d \log k.$$

So we examine the second term. First note that for $\varepsilon>0$

$$\sum_{k=n+1}^{\infty}\frac{\log k}{k^{\sigma}}\ll\sum_{k=n+1}^{\infty}k^{-\sigma+\varepsilon}$$

$$<\int_{n+1}^{\infty}\frac{du}{u^{\sigma+\varepsilon}}=\frac{1}{(\sigma-1+\varepsilon)(n+1)^{\sigma-1+\varepsilon}}.$$

Letting

$$B(s)=-\sum_{m=d+2}^{\infty} b_m(s)n^m\sum_{k=n+1}^{\infty}\frac{\log k}{k^{2s+m-d}}$$

one has as $s\to 0$

$$B(s)\ll\sum_{m=d+2}^{\infty}\frac{|b_m(s)|n^m}{(2\sigma+m-d-1+\varepsilon)(n+1)^{2\sigma+m-d-1+\varepsilon}}$$

$$\ll\sum_{m=d+2}^{\infty}|b_m(s)|\frac{n^m}{(n+1)^m}.$$

So for $m \geqq d+1$

$$b_m(s) = \frac{(-s)(-s-1)\cdots(-s-m+1)}{m!}$$

$$+(-1)^{m!}\frac{(-s+d)(-s+d-1)\cdots(-s)\cdots(-s+d-m+1)}{m!}$$

$$= sP_m(s)$$

where

$$P_m(0) = \frac{(-1)^m}{m} + (-1)^d \Big/ m\binom{m-1}{d} \to 0 \quad \text{as } m \to \infty.$$

Therefore we write

$$H_d'(s) = A(s) + B(s) + \sum_{m=0}^{d+1} b_m(s) n^m \sum_{k=0}^{n} \frac{\log k}{k^{2s+m-d}}$$

$$+ \sum_{m=0}^{d+1} b_m(s) n^m \zeta'(2s+m-d).$$

Letting

$$C(s) = \sum_{m=0}^{d+1} b_m(s) n^m \sum_{k=0}^{n} \frac{\log k}{k^{2s+m-d}},$$

we have

$$C(0) = \sum_{k=0}^{n} \log k(k-n)^d + \sum_{k=0}^{n} k^d \log k$$

and note that the second term cancels with $A(0)$. Turning to

$$D(s) = \sum_{m=0}^{d+1} b_m(s) n^m \zeta'(2s+m-d),$$

we distinguish 3 cases: $m=0$, $0 < m \leqq d$ and $m = d+1$.

Now

$$b_0(s) = \binom{-s}{0} + (-1)^0 \binom{-s+d}{0} \quad \text{so } b_0(0) = 2$$

and

$$b_m(0) = (-1)^m \binom{d}{m}, \qquad 0 < m \leqq d.$$

Thus

$$D(0) = 2\zeta'(-d) + \sum_{m=1}^{d} (-n)^m \binom{d}{m} \zeta'(m-d) + b_{d+1}(s) n^{d+1} \zeta'(2s+1)\big|_{s=0}.$$

Recall that

$$\zeta(s) = \frac{1}{s-1} + a_0 + a_1(s-1)\cdots,$$

so

$$\zeta'(2s+1)=\frac{-1}{4s^2}+2a_1s+\cdots.$$

While

$$b_{d+1}(s)=(-1)^{d+1}\frac{s(s+1)\cdots(s+d)}{(d+1)!}+\frac{s(s-1)\cdots(s-d)}{(d+1)!}$$
$$=\left[\frac{2(-1)^{d+1}}{d+1}\sum_{j=1}^{d}\frac{1}{j}\right]s^2+\mathcal{O}(s^3)\quad\text{as } s\to 0,$$

we have

$$\lim_{s\to 0} b_{d+1}n^{d+1}\zeta'(2s+1)=\frac{n^{d+1}}{2(d+1)}(-1)^d\sum_{j=1}^{d}\frac{1}{j}.$$ □

We can now prove Theorem 1.4, i.e., that there are rational numbers

$$\gamma_n,\ \tau_{n,0},\ \tau_{n,1},\ \cdots,\ \tau_{n,n-1},\quad\text{with } \tau_{n,n-1}=\frac{-4}{(n-1)!}\text{ s.t.,}$$

$$\det\Delta_n=e^{\gamma_n}\prod_{m=0}^{n-1}e^{\tau_{n,m}\zeta'(-m)}.$$

Proof. By the proposition

$$F_n'(0)=\sum_{d=0}^{n-1}T_{n,d}\sum_{k=1}^{n-1}(k-n+1)^d\log k-\frac{1}{2}\sum_{d=0}^{n-1}T_{n,d}\frac{(1-n)^{d+1}}{d+1}\sum_{j=1}^{d}\frac{1}{j}$$
$$+\sum_{r=0}^{n-1}\zeta'(-r)\left(T_{n,r}+\sum_{d=r}^{n-1}T_{n,r}(1-n)^{d-r}\binom{n-1}{r}\right).$$

Now $T_{n,d}=2S_{n,d}-S_{n-1,d}$; so

$$\sum_{d=0}^{n-1}(2S_{n,d}-S_{n-1,d})\sum_{k=1}^{n-1}(k-n+1)^d\log k$$
$$=\sum_{k=1}^{n-2}\log k\sum_{d=0}^{n-1}[2S_{n,d}(k-n+1)^d-S_{n-1,d}(k-n+1)^d]$$
$$=\sum_{k=1}^{n-2}\log k\left[2\binom{k-n+1+n-1}{n-1}-\binom{k-n+1+n-2}{n-2}\right]=0.$$

Furthermore

$$T_{n,n-1}=2S_{n,n-1}=\frac{2}{(n-1)!},$$

so

$$\sum_{r=0}^{n-1}\zeta'(-r)\left[T_{n,r}+\sum_{d=r}^{n-1}T_{n,r}(1-n)^{d-r}\binom{n-1}{r}\right]$$
$$=\frac{4}{(n-1)!}\zeta'(1-n)-\sum_{m=0}^{n-2}\tau_{n,m}\zeta'(-m),\ \tau_{n,m}\in\mathbf{Q}.$$

Letting

$$\tau_n = \frac{1}{2}\sum_{d=0}^{n-1} T_{n,d}\frac{(1-n)^{d+1}}{d+1}\sum_{j=1}^{d}\frac{1}{j} \in \mathbf{Q}$$

yields

$$\det \Delta_n = e^{-F_n'(0)} = \exp\left(\frac{-4}{(n-1)!}\zeta'(1-n) + \sum_{m=0}^{n-2}\tau_{n,m}\zeta'(-m)\right)e^{\tau_n}. \qquad \square$$

4. The cases $n=2, 3$. In this section we specialize the results of §§ 2 and 3 to the cases $n=2, 3$. Since these follow by substitution we omit the proofs.

PROPOSITION 4.1.

$$R_1 = e^{\zeta'(0)}, \qquad R_2 = e^{\zeta'(0)+\zeta(-1)}, \qquad R_3 = \exp\left(\zeta'(0)+\tfrac{3}{2}\zeta'(-1)+\tfrac{1}{2}\zeta'(-2)\right),$$

$$\zeta_1(0, a) = \tfrac{1}{2} - a, \qquad \zeta_2(0, a) = (1-a)\zeta(0, a) + \zeta(-1, a),$$

$$\zeta_3(0, a) = \frac{1}{2}\zeta(-2, a) + \left(\frac{3}{2} - a\right)\zeta(-1, a) + \left(\frac{a^2}{2} - \frac{3a}{2} + 1\right)\zeta(0, a)$$

and

$$\zeta(0, a) = \frac{1}{2} - a, \qquad \zeta(-1, a) = -\frac{a^2}{2} + \frac{a}{2} - \frac{1}{12},$$

$$\zeta(-2, a) = -\frac{a^3}{3} + \frac{a^2}{2} - \frac{a}{6}.$$

So

$$\zeta_1(0, 1) = \frac{-1}{12}, \qquad \zeta_2(0, 1) = \frac{-1}{12}, \qquad \zeta_3(0, 1) = \frac{-1}{24}.$$

The duplication formulas for $n=2, 3$ are given by the following proposition.

PROPOSITION 4.2.

$$\Gamma_2(a)\Gamma_2(a+\tfrac{1}{2})^2\Gamma_2(a+1) = 2^{\zeta_2(0,2a)}\exp\left(-3\zeta'(-1) + (2a-1)\zeta'(0)\right)\Gamma_2(2a),$$

$$\Gamma_3(a)\Gamma_3(a+\tfrac{1}{2})^3\Gamma_3(a+1)^3\Gamma_3(a+\tfrac{3}{2})$$

$$= 2^{\zeta_3(0,2a)}\exp\left(-\tfrac{7}{2}\zeta'(-2) + (6a-\tfrac{9}{2})\zeta'(-1) + (-2a^2+3a-1)\zeta'(0)\right)\Gamma_3(2a).$$

And so one gets Proposition 4.3.

PROPOSITION 4.3.

$$\Gamma_2(\tfrac{1}{2}) = 2^{-7/24}\exp\left(-\tfrac{3}{2}\zeta'(-1) - \tfrac{1}{2}\zeta'(0)\right),$$

$$\Gamma_3(\tfrac{1}{2}) = 2^{-11/48}\exp\left(-\tfrac{7}{8}\zeta'(-2) - \tfrac{3}{2}\zeta'(-1) - \tfrac{3}{8}\zeta'(0)\right).$$

On the other hand, one has the following proposition.

PROPOSITION 4.4.

$$F_1'(0) = 4\zeta'(0),$$

$$F_2'(0) = 4\zeta'(-1) - \tfrac{1}{2},$$

$$F_3'(0) = 2\zeta'(-2) - \zeta'(-1) + 3\zeta'(0).$$

So one gets Proposition 4.5.

PROPOSITION 4.5.

$$e^{\zeta'(0)} = (\det \Delta_1)^{-1/4},$$
$$e^{\zeta'(-1)} = (\det \Delta_2)^{-1/4}\, e^{1/8},$$
$$e^{\zeta'(-2)} = (\det \Delta_3)^{-1/2}(\det \Delta_2)^{-1/8}(\det \Delta_1)^{3/8}\, e^{1/16}.$$

The second part of Theorem 1.1 now follows from substituting Proposition 4.5 in Proposition 4.3.

This completes the proof of the main results of the paper. We conclude by proving the formula for Kinkelin's constant given in § 1.

PROPOSITION 4.6.

$$A = e^{1/12-\zeta'(-1)}.$$

Proof. Recall the Hurwitz ζ-function

$$\zeta(s, a) = \sum_{n=0}^{\infty} (n+a)^{-s}, \qquad s>1;$$

then

$$\sum_{k=1}^{n-1} k^s = \zeta(-s) - \zeta(-s, n).$$

Thus

$$\sum_{k=1}^{n-1} k \log k = -\zeta'(-1) + \zeta'(-s, n). \tag{10}$$

We have the representation

$$\zeta(s, a) = \frac{a^{1-s}}{s-1} + \frac{1}{2a^s} + \frac{sB_2}{2a^{s+1}} - \frac{s(s+1)(s+2)}{6} \int_0^{\infty} \frac{B_3(u-[u])}{(u+a)^{s+3}}\, du, \qquad \operatorname{Re}(s) > -2. \tag{11}$$

This is easily shown by expanding $B_3(u-[u])$ and collecting terms. This formula is an extension of the well-known representation for the Riemann ζ-function

$$\zeta(s) = \frac{s}{s-1} - s \int_0^{\infty} \frac{u-[u]}{u^{s+1}}\, du.$$

Differentiating (11) gives

$$\zeta'(s, a) = -\frac{a^{-s} \log a}{2} - \frac{a^{1-s}}{(1-s)^2} + \frac{a^{1-s} \log a}{1-s} + \frac{B_2 a^{-s-1}}{2} - \frac{B_2 a^{-s-1} \log a}{2} + \mathcal{O}\left(\frac{1}{a}\right)$$

and so

$$\zeta'(-1, n) = -\frac{n \log n}{2} + \frac{n^2 \log n}{2} + \frac{\log n}{12} - \frac{n^2}{4} + \frac{1}{12} + \mathcal{O}\left(\frac{1}{n}\right).$$

The result follows on substituting this in (10). □

Acknowledgments. I would like to thank Peter Sarnak for suggesting this problem to me and for his help on § 3, and Bill Gosper for his help with MACSYMA.

COMBUSTION IN A POROUS MEDIUM*

AVNER FRIEDMAN† AND ATHANASSIOS E. TZAVARAS‡

Abstract. A nonlinear time-dependent system of partial differential equations describing combustion in a porous medium is studied. Existence of a solution is established and its asymptotic behavior, as $t \to \infty$, is obtained.

Key words. combustion, porous medium, reaction rate

AMS(MOS) subject classifications. 80A20, 80A25, 35K60, 35K65

1. The physical problem. Porous medium combustion occurs in a number of situations including the burning of coal [7], the burning of cigarettes [1], the use of catalytic converters as exhaust filters [8] and the smouldering of polyurethane [6].

A model for combustion in a porous medium was developed by Lawson and Norbury [3], [4] and, more recently, by Norbury and Stuart [5]. Norbury and Stuart developed a three-dimensional model in a situation in which the chemical process is

$$\text{solid} + O_2 \to \text{heat} + CO_2 + \text{ash}.$$

Their model represents conservation of mass and energy for both the gas and solid species, while the fluid flow is governed by Darcy's law and the ideal gas law. Subsequently, in the case of one-space-dimensional combustion, they used a number of asymptotic considerations, including, most notably, large activation energy asymptotics (of Frank-Kamenetskii [2]) to arrive at a simplified model of the form

$$(1.1)\quad \frac{\partial \sigma}{\partial t} = -\lambda r, \quad \mu \frac{\partial w}{\partial x} = u - w, \quad \sigma \frac{\partial u}{\partial t} = \frac{\partial}{\partial x}\left((1+du^3)\frac{\partial u}{\partial x}\right) + w - u + r, \quad \frac{\partial g}{\partial x} = -\frac{a}{\mu} r,$$

where λ, μ, d, and a are positive constants, r is the reaction rate

$$(1.2)\qquad r = H(\sigma - \tau)H(u - u_c)H(g)\mu^{1/2} g f(w),$$

H is the Heaviside function,

$$f(w) = w^{\nu} \quad \text{where typically } \nu \sim 2.0$$

and τ, u_c are positive constants. Finally, the boundary conditions are

$$(1.3)\qquad u(\pm N, t) = u_a, \quad w(-N, t) = u_a, \quad g(-N, t) = g_a$$

where u_a, g_a are positive constants and N is a positive number or $+\infty$, and the initial conditions are

$$(1.4)\qquad \sigma(x, 0) = \sigma_0(x), \qquad u(x, 0) = u_0(x)$$

where $\sigma_0(x) > 0$, $u_0(x) > 0$.

In the above equations, up to scaling, u represents the temperature of the solid, w represents the temperature of the gas, σ is the heat capacity of the solid, and $g = u\alpha$ where α is the mass of the oxygen per unit volume. An interesting feature of the model, the mathematical ramifications of which we explore here, is the presence of a mechanism that switches off the reaction when either the temperature, or the heat capacity of the solid, or the mass of oxygen per unit volume drops below a certain level.

‡ Department of Mathematics, University of Wisconsin, Madison, Wisconsin 53706.

In this paper we shall establish the existence of a solution of (1.1)-(1.4) for all $t>0$; we shall also prove that the reaction rate r vanishes identically if t is sufficiently large. The occurrence of σ as a coefficient of $\partial u/\partial t$ in the parabolic equation for u in (1.1) turns out to be quite favorable for the proofs.

In §§ 2-5 we consider the case $N<\infty$ and in § 6 we consider the case $N=\infty$. In § 2 we formulate the mathematical problem more generally, and derive a priori lower bounds on u, w. In § 3 we derive various integral and pointwise bounds on the solution, assuming its existence. In § 4 we establish the existence of a solution, using the a priori estimates of §§ 2 and 3, and in § 5 we study the asymptotic behavior of the solution as $t\to\infty$.

2. Mathematical formulation; initial estimates. Let N be any positive number and let

$$\Omega=\{-N<x<N\},\qquad \Omega_t=\{(x,s),\ x\in\Omega,\ 0<s<t\}.$$

In studying (1.1)-(1.4) we assume for simplicity that $\lambda=1$, $\mu=1$, $a=1$ and $\tau=1$ (the proofs remain the same for general λ, μ, a, τ). We also replace $1+du^3$ by a general function $k(u)$ positive-valued for $u\geqq 0$ and take $f(w)$ to be a general positive-valued function for $w>0$. Thus the system has the form

$$\sigma_t=-r, \tag{2.1}$$

$$w_x=u-w, \tag{2.2}$$

$$\sigma u_t=(k(u)u_x)_x+w-u+r, \tag{2.3}$$

$$g_x=-r \tag{2.4}$$

where

$$r=r(x,t)=H(\sigma-1)H(u-u_c)H(g)gf(w) \tag{2.5}$$

with the initial conditions

$$\sigma(x,0)=\sigma_0(x), \tag{2.6}$$

$$u(x,0)=u_0(x) \tag{2.7}$$

and the boundary conditions

$$w(-N,t)=u_a, \tag{2.8}$$

$$u(\pm N,t)=u_a, \tag{2.9}$$

$$g(-N,t)=g_a. \tag{2.10}$$

Here

$$H(\xi)=0 \quad \text{if } \xi<0,\qquad H(\xi)=1 \quad \text{if } \xi>0.$$

We make the following assumptions:

$$g_a>0,\quad u_a>0,\quad u_0(\pm N)=u_a,$$

$$\sigma_0(x)>0,\quad u_0(x)>0 \quad \text{if } -N\leqq x\leqq N, \tag{2.11}$$

σ_0 is Holder continuous in $\{-N\leqq x\leqq N\}$, $\qquad u_0$ belongs to $W^{2,\infty}(-N,N)$,

$$k(u)\in C^{1+\alpha}(\mathbb{R}),\quad k(u)\geqq k_0>0 \quad (\text{for some } \alpha\in(0,1)), \tag{2.12}$$

$$f(w)\in C^{0,1}(\mathbb{R}),\qquad f(w)>0. \tag{2.13}$$

The function $H(u-u_c)$ is understood as a selection from the graph $H(u-u_c)$, and $H(\sigma-1)=0$ if $\sigma-1\leqq 0$, $H(g)=0$ if $g\leqq 0$. Since $\sigma(x,t)$ is decreasing in t, also $H(\sigma(x,t)-1)$ is decreasing in t. Similarly $H(g(x,t))$ is decreasing in x, and $H(g)g=g^+$.

In this section and in the following one we assume that a solution exists for all $0<t<T$ (for some $T>0$) and derive a priori estimates. These estimates will be used in § 4 to establish the existence of a solution. From (2.1), (2.6) we get

$$\begin{aligned}\sigma(x,t)&=1+\left[\sigma_0(x)-1-\int_0^t r(x,s)\,ds\right]^+ \quad \text{if } \sigma_0(x)>1\\ &=\sigma_0(x) \quad \text{if } \sigma(x)\leqq 1.\end{aligned}\tag{2.14}$$

Let

(2.15)

$$t_0(x)=\begin{cases}0 & \text{if } \sigma_0(x)\leqq 1,\\ \sup\left\{t;\int_0^t H(u(x,s)-u_c)g^+(x,s)f(w(x,s))\,ds\leqq\sigma_0(x)-1\right\} & \text{if } \sigma_0(x)>1.\end{cases}$$

From the choice of $H(\sigma-1)$ mentioned above we have

$$H(\sigma-1)H(u-u_c)g^+f(w)=\chi\{t\leqq t_0(x)\}H(u-u_c)g^+f(w)\equiv r.\tag{2.16}$$

Therefore

$$\int_0^t r(x,s)\,ds=\int_0^{t\wedge t_0(x)} H(u-u_c)g^+f(w)\,ds\leqq\sigma_0(x)\leqq C\tag{2.17}$$

where C is a positive constant independent of (x,t), and $t\wedge s=\min\{t,s\}$.

LEMMA 2.1. *There holds*

$$w(x,t)\geqq u_a\,e^{-2N},\tag{2.18}$$

$$u(x,t)\geqq u_a\,e^{-2N}\tag{2.19}$$

in Ω_T.

Proof. For some δ small enough $u\geqq 0$ in Ω_δ. From (2.2), (2.8) we then find that

$$w(x,t)\geqq u_a\,e^{-(x+N)}.\tag{2.20}$$

Then also

$$Lu\equiv\sigma(x,t)u_t-(k(u)u_x)_x+u=w+r\geqq u_a\,e^{-2N}\tag{2.21}$$

in Ω_δ. The constant $z\equiv u_a\,e^{-2N}$ satisfies

$$Lz=z\leqq Lu \quad \text{in } \Omega_\delta$$

and $z\leqq u$ on the parabolic boundary of Ω_δ. By comparison, it follows that

$$u\geqq z=u_a\,e^{-2N}\tag{2.22}$$

in Ω_δ. We can now continue to increase δ step-by-step and to establish (2.20), (2.22) in the corresponding domains Ω_δ; this completes the proof of the lemma.

3. A priori estimates. Set

$$\tilde{w} = w - u_a, \qquad \tilde{u} = u = u_a.$$

LEMMA 3.1. *There holds*

$$\begin{aligned} &\frac{1}{2}\int_{\Omega\times\{t\}} \sigma\tilde{u}^2\,dx + \frac{1}{4}\int\int_{\Omega_t} r\tilde{u}^2 + \int\int_{\Omega_t} k(u)u_x^2 \\ &\quad + \frac{1}{2}\int_0^t (\tilde{w}(N,t))^2\,dt + \int\int_{\Omega_t} (\tilde{w}-\tilde{u})^2 \leqq C \qquad (0<t<T) \end{aligned} \tag{3.1}$$

where C is a positive constant independent of T.

Proof. Multiplying (2.3) by $\tilde{u}$ and integrating over Ω_t, we get

$$\frac{1}{2}\int\int_{\Omega_t} \sigma(\tilde{u}^2)_t + \int\int_{\Omega_t} k(u)(\tilde{u}_x)^2 = \int\int_{\Omega_t} (\tilde{w}-\tilde{u})\tilde{u} + \int\int_{\Omega_t} r\tilde{u}. \tag{3.2}$$

The first term on the left-hand side is equal to

$$\frac{1}{2}\int_{\Omega\times\{t\}} \sigma(\tilde{u}^2) - \frac{1}{2}\int_{\Omega\times\{0\}} \sigma\tilde{u}^2 + \frac{1}{2}\int\int_{\Omega_t} r\tilde{u}^2 \qquad (\text{since } \sigma_t = -r).$$

The last term on the right-hand side of (3.2) is bounded above by

$$\int\int_{\Omega_t} r\left(\frac{1}{4}\tilde{u}^2 + 1\right) \leqq \frac{1}{4}\int\int_{\Omega_t} r\tilde{u}^2 + \int_\Omega \left(\int_0^t r\,dt\right) dx \leqq \frac{1}{4}\int\int_{\Omega_t} r\tilde{u}^2 + C,$$

by (2.17). We therefore obtain from (3.2)

$$\frac{1}{2}\int_{\Omega\times\{t\}} \sigma\tilde{u}^2\,dx + \frac{1}{4}\int\int_{\Omega_t} r\tilde{u}^2 + \int\int_{\Omega_t} k(u)u_x^2 \leqq \int\int_{\Omega_t} (\tilde{w}-\tilde{u})\tilde{u} + C \tag{3.3}$$

where C is a constant independent of T.

Next multiply (2.2) by $\tilde{w}$ and integrate over Ω_t

$$\frac{1}{2}\int\int_{\Omega_t} (\tilde{w}^2)_x = \int\int_{\Omega_t} (\tilde{u}-\tilde{w})\tilde{w}, \tag{3.4}$$

and the left-hand side is equal to

$$\frac{1}{2}\int_0^t \tilde{w}^2(N,t)\,dt.$$

When we add (3.4) to (3.3), the inequality (3.1) follows.

LEMMA 3.2. *There holds*

$$w \leqq C, \tag{3.5}$$

$$r \leqq C, \tag{3.6}$$

$$u \leqq C \tag{3.7}$$

in Ω_T, where C is a constant independent of T.

Proof. From Lemma 3.1 and (2.14),

$$\int_\Omega \tilde{u}^2(x,t)\,dx \leqq C. \tag{3.8}$$

Hence, solving for w from (2.2), (2.8) we easily obtain the estimate (3.5).

From (2.4), (2.10) we conclude that

$$0 \leqq g \leqq g_a. \tag{3.9}$$

When we combine this with (3.5), the estimate (3.6) follows.

From (3.5), (3.6) we deduce that

$$Lu \leqq 2C$$

where L is the parabolic operator defined in (2.21). If z is a constant larger than $2C$ and larger than u on the parabolic boundary of Ω_T then, since $Lz > 2C$, we get by comparison that $u < z$ in Ω_T. This yields the estimate (3.7).

LEMMA 3.3. *There holds*

$$\iint_{\Omega_T} u_t^2 + \int_{\Omega} u_x^2(x, t)\, dx \leqq C \quad \text{for } 0 < t < T \tag{3.10}$$

where C is a constant independent of T.

Proof. Multiplying (2.3) by $k(u)u_t$ and integrating over Ω_t, we get

$$\int_{\Omega_t} \sigma k(u) u_t^2 + \frac{1}{2} \int_{\Omega \times \{t\}} k^2(u) u_x^2\, dx = \iint_{\Omega_t} (\tilde{w} - \tilde{u} + r) k(u)_t + \frac{1}{2} \int_{\Omega} k^2(u_0) u_{0,x}^2\, dx. \tag{3.11}$$

Since $k(u)$ is bounded (by Lemma 3.2), the first integrate on the right-hand side of (3.11) can be estimated by

$$\left| \iint_{\Omega_t} (\tilde{w} - \tilde{u} + r) k(u) u_t \right| \leqq \frac{1}{2} \iint_{\Omega_t} \sigma k(u) u_t^2 + C \iint_{\Omega_t} (\tilde{w} - \tilde{u} + r)^2. \tag{3.12}$$

When we use the estimates

$$\iint_{\Omega_t} (\tilde{w} - \tilde{u})^2 \leqq C \qquad \text{(by Lemma 3.1)},$$

$$\iint_{\Omega_t} r^2 \leqq C \iint_{\Omega_t} r \leqq C \quad \text{(by (3.6), (2.17))}$$

on the right-hand side of (3.12) and then substitute (3.12) into (3.11), the assertion (3.10) follows.

From Lemma 3.3 and standard interpolation we get the following lemma.

LEMMA 3.4. *There exists $0 < \alpha < 1$ and $C > 0$ independent of T such that*

$$|u|_{C^{\alpha}(\Omega_T)} \leqq C. \tag{3.13}$$

Set

$$K(u) = \int_0^u k(v)\, dv. \tag{3.14}$$

Then

$$\frac{\sigma}{k(u)} K(u)_t = K(u)_{xx} + h \tag{3.15}$$

where $h = w - u + r$ satisfies

$$|h|_{L^{\infty}(\Omega_T)} \leqq C, \quad C \text{ independent of } T.$$

Applying L^p-theory we get the following lemma.

LEMMA 3.5. *For any $p>1$ there exists a constant C depending on p, T such that*

$$|u_x|_{L^p(\Omega_T)}+|u_t|_{L^p(\Omega_T)}+|u_{xx}|_{L^p(\Omega_T)}\leqq C. \tag{3.16}$$

4. Global existence. For any $\varepsilon>0$ set

$$H_\varepsilon(\xi)=\begin{cases}1 & \text{if } \xi\geqq\varepsilon,\\ \xi/\varepsilon & \text{if } 0<\xi<\varepsilon,\\ 0 & \text{if } \xi\leqq 0.\end{cases} \tag{4.1}$$

DEFINITION 4.1. We shall refer to the system (2.1)-(2.10) as problem (P); if we replace (in (2.1)-(2.5)) $H(\sigma-1)$, $H(u-u_c)$, $H(g)$ by $H_\varepsilon(\sigma-1)$, $H_\varepsilon(u-u_c)$, $H_\varepsilon(g)$, then we refer to the new system as problem (P_ε).

Remark 4.1. All the estimates derived in §§ 2 and 3 for solutions of problem (P) are valid, with the same proofs and the same constants, also for solutions of problem (P_ε).

LEMMA 4.1. *For any $T>0$, $\varepsilon>0$ there exists at most one solution of problem (P_ε) in Ω_T with $\partial u/\partial t$, $\partial u/\partial x$ in $L^\infty(\Omega_T)$.*

Proof. Suppose $(\sigma_i, w_i, u_i, g_i)$ are solutions of problem (P_ε) for $i=1,2$. Since $H_\varepsilon(\xi)$ is Lipschitz continuous, the function h in (3.15) is actually Holder continuous (for the case of problem (P_ε)) and the solutions $(\sigma_i, w_i, u_i, g_i)$ satisfy the differential equations and the initial-boundary conditions in the classical sense.

Take the difference of the equations (2.1) for σ_1 and σ_2, multiply by $\sigma_1-\sigma_2$ and integrate over Ω_t. We then easily obtain, after applying the Cauchy-Schwarz inequality,

$$\int_{\Omega\times\{t\}}(\sigma_1-\sigma_2)^2\leqq C\int\int_{\Omega_t}[(u_1-u_2)^2+(w_1-w_2)^2+(g_1-g_2)^2]. \tag{4.2}$$

Similarly we get from the equations for w_i,

$$\int\int_{\Omega_t}(w_1-w_2)^2\leqq C\int\int_{\Omega_t}(u_1-u_2)^2. \tag{4.3}$$

Next, using (2.3), we obtain for u_1-u_2,

$$\begin{aligned}\frac{1}{2}\int_{\Omega\times\{t\}}&\sigma_1(u_1-u_2)^2+\int\int_{\Omega_t}k(u_1)(u_{1,x}-u_{2,x})^2\\ &\leqq\int\int_{\Omega_t}|\sigma_1-\sigma_2|\left|\frac{\partial u_2}{\partial t}\right||u_1-u_2|+\int\int_{\Omega_t}|k(u_1)-k(u_2)||u_{2,x}||u_{1,x}-u_{2,x}|\\ &\quad+C\int\int_{\Omega_t}[(u_1-u_2)^2+(w_1-w_2)^2+(g_1-g_2)^2+(\sigma_1-\sigma_2)^2]\end{aligned}$$

whence, because of (2.12), Schwarz's inequality and the boundedness of $\partial u_2/\partial t$ and $\partial u_2/\partial x$,

$$\frac{1}{2}\int_{\Omega\times\{t\}}\sigma_1(u_1-u_2)^2\leqq C\int\int_{\Omega_t}[(u_1-u_2)^2+(w_1-w_2)^2+(g_1-g_2)^2+(\sigma_1-\sigma_2)^2]. \tag{4.4}$$

Finally, from (2.4),

$$\int\int_{\Omega_t}(g_1-g_2)^2\leqq C\int\int_{\Omega_t}[(u_1-u_2)^2+(w_1-w_2)^2+(\sigma_1-\sigma_2)^2]. \tag{4.5}$$

We now substitute $\iint (g_1-g_2)^2$ from (4.5) into (4.2), (4.4) and substitute $\iint (w_1-w_2)^2$ from (4.3) into (4.2), (4.4). Then, combining (4.2) and (4.4), we obtain the inequality

$$\int_{\Omega\times\{t\}} [(\sigma_1-\sigma_2)^2+(u_1-u_2)^2] \leqq C \int\int_{\Omega_t} [(\sigma_1-\sigma_2)^2+(u_1-u_2)^2].$$

This immediately implies that $\sigma_1-\sigma_2\equiv 0$, $u_1-u_2\equiv 0$ and then also $w_1-w_2\equiv 0$, $g_1-g_2\equiv 0$.

We shall now prove one of the main results of this paper.

THEOREM 4.2. *There exists a global solution of* (2.1)-(2.10) *satisfying* (3.16) *for any* $1<p<\infty$, $T>0$.

Proof. We first consider problem (P_ε) and establish the existence of a global solution. Choose a small $\delta>0$ and introduce the set

$$K=\{(\sigma, w, u, g)\in C(\bar{\Omega}_\delta),\ \|\sigma\|\leqq 1+\sup \sigma_0(x),\ \|w\|\leqq C_1,\ \|u\|\leqq 1+u_a + \sup u_0(x),\ \|g\|\leqq C_2\}$$

where $\|\cdot\|$ means the sup-norm in $\bar{\Omega}_\delta$ and C_1, C_2 are to be determined later on. Given any (σ, w, u, g) in K we define its image $(\bar{\sigma}, \bar{w}, \bar{u}, \bar{g})=W(\sigma, w, u, g)$ by solving

$$\bar{\sigma}_t=-H_\varepsilon(\sigma-1)H_\varepsilon(u-u_c)H_\varepsilon(g)gf(w),$$

$$\bar{w}_x=u-\bar{w},$$

$$\sigma\bar{u}_t=\frac{\partial}{\partial x}(k(u)\bar{u}_x)+\bar{w}-\bar{u}+H_\varepsilon(\sigma-1)H_\varepsilon(u-u_c)H_\varepsilon(g)gf(w),$$

$$\bar{g}_x=-H_\varepsilon(\sigma-1)H_\varepsilon(u-u_c)H_\varepsilon(g)gf(w)$$

in Ω_δ subject to the initial and boundary conditions (2.6)-(2.10).

For appropriately large C_1 and C_2 (C_2 depends on C_1) we can easily estimate

$$\|\bar{\sigma}\|\leqq 1+\sup \sigma_0(x),\quad \|\bar{w}\|\leqq C_1,\quad \|\bar{g}\|\leqq C_2.$$

While for C_1, C_2 as above and δ sufficiently small,

$$\|\bar{u}\|\leqq 1+u_a+\sup u_0(x).$$

By parabolic estimates we also have, for some $\alpha\in(0,1)$

$$|\bar{u}|_{C^\alpha(\bar{\Omega}_\delta)}\leqq C;$$

here C is a general constant which may depend on δ. Since $\sigma_0(x)$ is Hölder continuous, we then also deduce that

$$|\bar{\sigma}|_{C^\alpha(\bar{\Omega}_\delta)}\leqq C$$

with another α and C_1 and then, finally, also

$$|\bar{g}|_{C^\alpha(\bar{\Omega}_\delta)}\leqq C.$$

Hence W maps K into a compact subset. Since $(\bar{\sigma}, \bar{w}, \bar{u}, \bar{g})$ is uniquely determined by (σ, w, u, g), we can easily verify that W is a continuous mapping. Appealing to the Schauder fixed-point theorem we conclude that W has a fixed point. Thus problem (P_ε) has a solution in Ω_δ. We note that the size of δ depends only on the upper bounds on

$$|u_0|_{C^\beta(\Omega)},\qquad |\sigma_0|_{C^\beta(\Omega)} \tag{4.6}$$

for some fixed $\beta\in(0,1)$.

We now wish to extend the solution to $\delta < t < 2\delta$. We choose any initial time $t = \delta - \eta$ (η arbitrarily small) and repeat the previous step. We obtain a new solution for $\delta - \eta < t < (\delta - \eta) + \delta_1$ for some $\delta_1 > 0$, δ_1 independent of η. Since the solution constructed in Ω_δ is a classical solution with $\partial u/\partial t$, $\partial u/\partial x$ bounded (or even Holder continuous) in $\Omega_\delta \backslash \Omega_{\delta-\eta}$ (since $H_\varepsilon(\xi)$ is Lipschitz continuous) we can apply the uniqueness result of Lemma 4.1 in $\Omega_\delta \backslash \Omega_{\delta-\eta}$ and thus deduce that the new solution is an extension to $\Omega_{\delta-\eta+\delta_1}$ of the solution constructed in the first step in Ω_δ. Thus we obtain a solution of problem (P_ε) in Ω_{δ_2} where δ_2 in any number $< \delta + \delta_1$.

We can proceed in this manner step-by-step, and it only remains to show that in these steps the lengths of the t-intervals δ_i do not shrink to zero. For this it suffices to show that the quantities in (4.6) corresponding to any initial time $t = \tau$ remain uniformly bounded if $\tau \leqq T$, where T is any given positive number. But this clearly follows from Remark 4.1.

Having constructed a global solution to problem (P_ε), we denote it by $(\sigma_\varepsilon, w_\varepsilon, u_\varepsilon, g_\varepsilon)$. (Notice that we have not proved boundedness of $\partial u_\varepsilon/\partial t$, $\partial u_\varepsilon/\partial x$ at $t = 0$ and thus we cannot apply Lemma 4.1 to deduce that this solution is unique.) By Remark 4.1, the estimates of §§ 2 and 3 are valid for this solution. Hence a subsequence is convergent to a global solution of (2.1)-(2.10).

5. Asymptotic behavior.

THEOREM 5.1. *As* $t \to \infty$

$$u(x, t) \to u_a, \tag{5.1}$$

$$w(x, t) \to u_a \tag{5.2}$$

uniformly with respect to $x \in \Omega$.

Proof. From (3.1) and Poincaré's inequality we deduce that

$$\iint_{\Omega_\infty} \tilde{u}^2 < \infty \tag{5.3}$$

and from (3.10) we deduce that

$$|\tilde{u}(x, t) - \tilde{u}(x^1, t)| \leqq C|x - x^1|^{1/2} \tag{5.4}$$

for all x, x^1 in Ω, $t > 0$.

Suppose (5.1) is not true. Then there exist a sequence (x_n, t_n) in Ω_∞ with $t_n \to \infty$ and $c_0 > 0$, such that

$$|\tilde{u}(x_n, t_n)| \geqq c_0 > 0 \qquad (\tilde{u} = u - u_a).$$

By (5.4) it then follows that

$$\int_\Omega \tilde{u}^2(x, t_n)\, dx \geqq c > 0. \tag{5.5}$$

Let $t \in (t_n, t_n + 1)$. Then

$$|\tilde{u}(x, t) - \tilde{u}(x, t_n)| \leqq \int_{t_n}^{t} |u_\tau(x, \tau)|\, d\tau \leqq \left[\int_{t_n}^{t} u_t^2(x, \tau)\, d\tau\right]^{1/2}.$$

Hence

$$\int_\Omega |\tilde{u}(x, t) - \tilde{u}(x, t_n)|^2\, dx \leqq \int_{t_n}^{t_n+1} \int_\Omega u_t^2(x, t)\, dt \equiv \varepsilon_n \to 0 \tag{5.6}$$

if $n \to \infty$, by (3.10).

By the triangle inequality

$$\int_\Omega \tilde{u}^2(x, t_n)\, dx \leqq 2\int_\Omega \tilde{u}^2(x, t)\, dx + 2\int_\Omega |\tilde{u}(x, t) - \tilde{u}(x, t_n)|^2\, dx.$$

Recalling (5.5), (5.6) we then get

$$\int_\Omega \tilde{u}^2(x, t) \geqq \frac{c}{2} - 2\varepsilon_n \geqq \frac{c}{4} \qquad (t_n \leqq t \leqq t_n + 1),$$

if n is sufficiently large. Hence

$$\int_{t_n}^{t_n+1}\int_\Omega \tilde{u}^2(x, t)\, dx\, dt \geqq \frac{c}{4},$$

which is a contradiction to (5.3).

Having proved (5.1), the assertion (5.2) follows by solving

$$\tilde{w}_x + \tilde{w} = \tilde{u} \quad \text{with } \tilde{w}(-N, t) = 0$$

and using (5.1).

COROLLARY 5.2. *If $u_a < u_c$, then there exists a $T_0 > 0$ such that $r = 0$ if $t > T_0$.*

Indeed, by Theorem 5.1, $|u - u_a| < u_c - u_a$ if t is large enough, say $t > T_0$; this implies that $H(u - u_c) = 0$ and thus also $r = 0$ if $t > T_0$.

Corollary 5.2 means that the combustion has died out after a finite time T_0.

6. The Cauchy problem. In this section we extend the results of §§ 4 and 5 to the Cauchy problem, i.e., to the case $N = \infty$. We assume that

(6.1) $\sigma_0(x)$, $u_0(x)$ are positive-valued Holder continuous functions in $\mathbb{R}^1$,

(6.2) $$0 < \sigma_* \leqq \sigma_0(x) < 1 \quad \text{if } |x| > R_0 \text{ for some } R_0 > 0,$$

(6.3) $$u_0(x) \to u_a \quad \text{if } |x| \to \infty,$$

(6.4) $$\int_{\mathbb{R}} \sigma_0(x)(u_0(x) - u_a)^2\, dx < \infty,$$

and

(6.5) $$\int_{\mathbb{R}} k^2(u_0)(u_{0,x}(x))^2\, dx < \infty.$$

THEOREM 6.1. *Assume that* (2.12), (2.13), *and* (6.1)-(6.5) *hold. Then there exists a solution (σ, w, u, g) of* (2.1)-(2.7) *in $\mathbb{R}^1 \times (0, \infty)$ satisfying*

(6.6) $$w(x, t) \to u_a \quad \text{if } x \to -\infty, \quad t > 0,$$

(6.7) $$u(x, t) \to u_a \quad \text{if } |x| \to \infty, \quad t > 0,$$

(6.8) $$g(x, t) = g_a \quad \text{if } x > -R_0, \quad t > 0.$$

Proof. We modify the definition of $u_0(x)$ for $|x| > N - 1$ so that the new function $u_{0,N}(x)$ satisfies

(6.9) $$u_{0,N}(\pm N) = u_a, \qquad u_{0,N}(x) \geqq u_* > 0,$$

it is Holder continuous, and

(6.10) $$\int_{|x|<N} \sigma_0(x)(u_{0,N}(x) - u_a)^2\, dx \leqq C,$$

(6.11) $$\int_{|x|<N} k^2(u_{0,N})\left(\frac{\partial}{\partial x} u_{0,N}(x)\right)^2 dx \leqq C$$

where C is a positive constant independent of N.

Denote by $(\sigma_N, w_N, u_N, g_N)$ the solution (2.1)-(2.10) established in Theorem 4.2 for $\Omega = \Omega_N \equiv \{x; -N < x < N\}$ and $u_0 = u_{0,N}$. From (6.2) we have

$$r_N(x, t) = 0 \quad \text{if } |x| > R_0 \tag{6.12}$$

where r_N is the reaction rate r corresponding to the parameter N. Next, by comparison (since $w_N + r_N \geqq 0$), we obtain, for $\alpha > 1/(\sup \sigma_0(x))$,

$$u_N(x, t) \geqq u_* e^{-\alpha t}. \tag{6.13}$$

Also, from (2.2) by integration,

$$w_N(x, t) \geqq u_a e^{-x-N} + u_* e^{-\alpha t} \int_{-N}^{x} e^{-x+y}\, dy$$

so that

$$w_N(x, t) \geqq u_* e^{-\alpha t}. \tag{6.14}$$

Observe now that the proof of Lemma 3.1 is valid with C independent of N, since

$$\int_{\Omega_N} \int_0^t r_N\, dt\, dx \leqq C_1$$

where C_1 is independent of N (by (6.12)), and since (6.10) holds.

Next,

$$\begin{aligned} |\tilde{w}_N(x, t)| &= \int_{-N}^{x} e^{-x+y} |\tilde{u}_N(y, t)|\, dy \leqq \left[\int_{-N}^{x} e^{-2x+2y}\, dy\right]^{1/2} \left[\int_{-N}^{x} \tilde{u}_N^2(y, t)\, dy\right]^{1/2} \\ &\leqq \left[\int_{-N}^{x} \tilde{u}_N^2(y, t)\right]^{1/2} \leqq C \quad \text{by (3.1)} \end{aligned} \tag{6.15}$$

with C independent of N. This yields (3.5) and thus also (3.6), with C independent of N. The proof of (3.7) (with C independent of N) then follows as before.

Using (6.11), the proof of Lemma 3.3 follows as before with C independent of N.

Having established all the estimates of Lemmas 3.1-3.3 with C independent of N, we also obtain the estimates of Lemmas 3.4 and 3.5; thus

$$\int_0^T \int_D \left[\left|\frac{\partial}{\partial x} u_N\right|^p + \left|\frac{\partial^2}{\partial x^2} u_N\right|^p\right] dx\, dt \leqq C$$

for any bounded domain D in $\mathbb{R}^1$ where C is a constant depending on D and T but independent of N.

We can now take a subsequence of solutions $(\sigma_N, w_N, u_N, g_N)$ which converge uniformly on compact sets to a solution (σ, w, u, g) of (2.1)-(2.7). The assertion (6.8) follows from (6.12) and (2.4), (2.10). From (6.15) we get

$$|\tilde{w}(x, t)| \leqq \int_{-\infty}^{x} (\tilde{u}(y, t))^2\, dy \to 0 \quad \text{if } x \to -\infty,$$

and from

$$\int [\tilde{u}^2(x, t) + (\tilde{u}_x(x, t))^2]\, dx < \infty \quad \forall t > 0$$

we deduce (as in the proof of (5.1)) that

$$\tilde{u}(x, t) \to 0 \quad \text{if } |x| \to \infty \quad \forall t > 0.$$

Thus the proof of Theorem 6.1 is complete.

Remark 6.1. The solution constructed in Theorem 6.1 satisfies the integral estimates of Lemmas 3.1 and 3.3 (with $\Omega = \mathbb{R}^1$) and u_x, u_t, u_{xx} belong to $L^p_{\text{loc}}(\mathbb{R}^1 \times (0, \infty))$ for any $1 < p < \infty$.

Remark 6.2. We do not expect Theorem 5.1 to extend to the present case (of $\Omega = \mathbb{R}^1$) since, in general, a solution of

$$w_t - w_{xx} = f(x, t) \qquad \left(\int_0^\infty \int_{\mathbb{R}} f^2(x, t)\, dx\, dt < \infty \right),$$

$$w(x, 0) \to 0 \quad \text{if } |x| \to \infty, \qquad \int_{\mathbb{R}} w^2(x, 0)\, dx < \infty,$$

does not converge to zero as $t \to \infty$, x bounded. Indeed, a simple example is given by

$$w(x, t) = \exp\left\{ -\frac{x^2}{4(t+1)} \right\}.$$

GLOBAL EXISTENCE FOR A MODEL OF ELECTROPHORETIC SEPARATION*

JOEL D. AVRIN†

Abstract. We examine the modeling equations for a particular electrophoretic separation technique known as isotachophoresis. These equations form a system of advection-diffusion type and describe the time evolution of a number of charged chemical species. The transport mechanism arises from an electric field E where E_x is a superposition of the species concentrations; thus the equations are nonlinear. The spatial domain is the real line and the concentrations satisfy Dirichlet boundary conditions at $\pm\infty$. We show that these equations have global strong solutions that are unique in an appropriate sense.

Key words. global existence, isotachophoresis, advection-diffusion equation

AMS(MOS) subject classification. 35K

1. Introduction. The theory of electrophoretic separation describes the movement of charged particles in solution exposed to an electric field. Applications include the development of techniques for separating protein and other biological materials [2].

The strength of the electric field depends on the levels of concentrations of the species of charged particles present in the solution. Thus the modeling equations for the concentration levels and the field are nonlinear. Noting that the chemical reactions of the species occur on much shorter time scales than that of the diffusion or field-induced transport mechanisms, it is usually assumed that these reactions are in equilibrium; moreover, the experimental setup often admits the assumption that spatial variation is essentially one-dimensional. Under these hypotheses, the equations of electrophoresis, as developed in [6], are

$$(u_i)_t = [z_i\Omega_i E u_i + d_i(u_i)_x]_x, \qquad i = 1, \cdots, m, \tag{1.1a}$$

$$\varepsilon E_x = -e \sum_{k=1}^{m} z_k u_k. \tag{1.1b}$$

Here, for $u = u(x, t)$, u_x denotes $\partial u/\partial x$ and u_t denotes $\partial u/\partial t$. The unknowns in (1.1) are the species concentrations $u_i = u_i(x, t)$ and the electric field $E = E(x, t)$. The other parameters are known constants: Ω_i are the ionic mobilities and d_i are the diffusivities corresponding to each species, while $z_i = +1$ or -1 depending, respectively, on whether the u_i represent concentrations of positive or negative ions. In (1.1b) e is the molar charge and ε is the permittivity of the solvent.

In this paper we will establish the existence and uniqueness of global strong solutions of (1.1) with boundary conditions appropriate for a particular extensively used separation technique known as isotachophoresis, or ITP. In the usual set-up for ITP, the reaction column is long and is connected at both ends to large electrolyte reservoirs that negate the influence of reactions occurring at the electrodes. This makes the concentrations constant at the column ends, and effectively renders the system infinitely long [3], [6]. Thus x varies over the entire real line in (1.1), and the concentrations satisfy fixed Dirichlet boundary conditions:

$$u_i(-\infty) = \alpha_i, \qquad u_i(+\infty) = \beta_i. \tag{1.1c}$$

The boundary conditions for the electric field E can be deduced from (1.1c) and the fact that the electric current I through the medium is constant.

Setting

$$f_i = z_i\Omega_i E u_i + d_i(u_i)_x, \tag{1.2}$$

we have, as noted in [3], that

$$I = e\sum_{i=1}^{m} z_i(f_i)(-\infty) = e\sum_{i=1}^{m} z_i(f_i)(+\infty). \tag{1.3}$$

Since u_i must also satisfy

$$(u_i)_x(-\infty, t) = (u_i)_x(+\infty, t) = 0 \tag{1.4}$$

(see e.g. [3]) we have, from (1.1c) and (1.4) that (1.3) reduces to

$$I = e\sum_{i=1}^{m} \Omega_i\alpha_i E(-\infty, t) = e\sum_{i=1}^{m} \Omega_i\beta_i E(+\infty, t). \tag{1.5}$$

Since I is a constant, we must have from (1.5) that $E(\pm\infty, t) = E_{\pm}$ where E_+ and E_- are constants. We will see in § 2 that E can be determined in a completely satisfactory way by (1.1a)-(1.1c), (1.5), and the initial conditions

$$u_i(x, 0) = u_i^0. \tag{1.6}$$

Finally, as in [3], we assume that

$$\sum_{i=1}^{m} z_i\alpha_i = \sum_{i=1}^{m} z_i\beta_i = 0. \tag{1.7}$$

Condition (1.7) is a natural condition to impose in the applications in light of the separation mechanism and it will play an important role in what follows.

In § 2 below, we make some preliminary observations which will allow us to recast problem (1.1a)-(1.1c) together with the conditions (1.4)-(1.7) as a system of m equations of advection-diffusion type. Section 2 will conclude with the statement of our main local existence theorem. In § 3 we will prove this theorem, and in § 4 we will show that our solutions are global in time.

We note that the global existence result of this paper can be viewed as a companion result to the development in [3], in which traveling wave solutions were found for (1.1a)-(1.1c) with the conditions (1.4), (1.5), (1.7).

2. Some preliminary observations. We first define auxiliary functions $w_i = w_i(x)$ as follows:

$$w_i(x) = \begin{cases} \alpha_i, & x \leqq -1, \\ e_i(x), & -1 \leqq x \leqq 1, \\ \beta_i, & x \geqq 1, \end{cases} \tag{2.1}$$

where e_i are smooth functions that join the horizontal portions of w_i in a C^∞ manner, such that $\alpha_i \leqq e_i(x) \leqq \beta_i$ and such that

$$(w_i)_x \in C_0^\infty \tag{2.2}$$

where C_0^∞ denotes $C_0^\infty(\mathbb{R})$. Note from (1.7) that we also have

$$\sum_{i=1}^{m} z_i w_i \in C_0^\infty. \tag{2.3}$$

We can assume that the solutions u_i of (1.1) have the form

$$u_i = v_i + w_i. \tag{2.4}$$

where for each t $v_i(\cdot, t) \in W^{2,1} = W^{2,1}(\mathbb{R})$; the suitability of (2.4) proceeds from the smooth asymptotic behavior of u_i demonstrated in [3]. Note also that $v_i \in W^{2,1}$ implies that u_i and $(u_i)_x$ are in C_0, so that the right-hand side of (2.4) satisfies (1.1c) and (1.4). Eventually we will plug the right-hand side of (2.4) into (1.1) to obtain a system of equations in v_i. We first determine the form of E using (1.4)-(1.7). Assuming (2.4) we note that

$$U(x, t) \equiv \sum_{k=1}^{m} z_k u_k \in L^1 = L^1(\mathbb{R}) \tag{2.5}$$

where we have used (2.3). It is thus appropriate to set

$$E = -(e/\varepsilon) \int_{-\infty}^{x} U(y, t)\, dy + C(t) \tag{2.6}$$

and then solve for $C(t)$ using the boundary conditions. From (1.5) it is easy to see that

$$C(t) = \left[\sum_{k=1}^{m} \Omega_k \beta_k (-e/\varepsilon) \int_{-\infty}^{\infty} U(y, t)\, dy \right] \Big/ \left[\sum_{k=1}^{m} \Omega_k (\alpha_k - \beta_k) \right], \tag{2.7}$$

which is obtained simply by setting the two expressions on the right-hand side of (1.5) equal to each other. We now want to show that $C(t)$ is a *constant* which we will denote by E_-. Note from (1.1) that from superposition U satisfies

$$U_t = \left[\sum_{k=1}^{m} z_k f_k \right]_x \tag{2.8}$$

and thus

$$\frac{d}{dt} \int_{-\infty}^{\infty} U(y, t)\, dy = \sum_{k=1}^{m} z_k f_k(+\infty) - \sum_{k=1}^{m} z_k f_k(-\infty) = 0. \tag{2.9}$$

Hence

$$E(x, t) = -(e/\varepsilon) \int_{-\infty}^{x} U(y, t)\, dy + E_- \tag{2.10}$$

where E_- is the right-hand side of (2.7) with $U(y, t)$ replaced by

$$U(y, 0) = \sum_{k=1}^{m} z_k (u_k^0). \tag{2.11}$$

With E thus determined in terms of u_i and u_i^0, we are now ready to formulate our problem in terms of the u_i; setting $c_i = z_i \Omega_i$ and plugging $v_i + w_i$ into (1.1a) and (1.1b) in place of u_i, we obtain the following system of initial-value problems:

$$(v_i)_t = d_i (v_i)_{xx} + (c_i E)(v_i)_x + (c_i E_x) v_i + (c_i E)(w_i)_x + (c_i E_x) w_i + d_i (w_i)_{xx}, \tag{2.12a}$$

where E is given by (2.10) with

$$v_i(x, 0) = v_i^0 = u_i^0 - w_i(x), \tag{2.12b}$$

$$U(y, t) = \sum_{k=1}^{m} z_k (v_k + w_k). \tag{2.13}$$

Note that by (2.10) the system (2.12) is an integrodifferential equation. We will see in the next section that (2.12) can be treated using methods involving semigroups and variation-of-parameters formulas. Thus in the next section we will prove the following.

THEOREM 2.1. *The system* (2.12) *has a unique local strong solution* $v=(v_1, \cdots, v_m)$ *where each* $v_i \in C^1([0, T]; W^{2,1})$ *for some* $T>0$.

3. Proof of Theorem 2.1. We will let $\|\cdot\|_1$, $\|\cdot\|_{m,1}$ and $\|\cdot\|_\infty$ denote the norms on L^1, $W^{m,1}$, and C_0, respectively, where m is a positive integer. Let $M>0$ and $T>0$, with T to be determined. Let A_i be defined by $A_i f = d_i f_{xx}$ and let $W_i(t)$ denote the analytic semigroup generated by A_i. Let

$$Q=\Bigg\{u=(u_1, u_2, \cdots, u_m): u_i \in C([0, T]; W^{2,1}) \text{ and } \sup_i \sup_{0\le t\le T} \Bigg\| u_i(t) - W_i(t)u_i^0 - \int_0^t W_i(t-s)(w_i)_{xx}\, ds \Bigg\|_{2,1} \le M\Bigg\}. \tag{3.1}$$

If for each $u, v \in Q$ we set

$$\rho(u, v) = \sup_i \sup_{0\le t\le T} \| u_i(t) - v_i(t) \|_{2,1} \tag{3.2}$$

then (Q, ρ) is a complete metric space. For each i set

$$\begin{aligned}(S_i v_i)(t) &= W_i(t)v_i^0 + \int_0^t W_i(t-s)(w_i)_{xx}\, ds \\ &\quad + \int_0^t W_i(t-s)[c_i E(v(s))(v_i(s)+w_i)]_x\, ds\end{aligned} \tag{3.3}$$

where $E(v(s))$ is defined by (2.10) with $U(y, s)=\sum z_k(v_k+w_k)$. If we now let $Sv = (S_1v_1, S_2v_2, \cdots, S_mv_m)$, then we want to select T so that S is a contraction on E.

We first note that there exists a constant c such that

$$\| (W(t)f)_x \|_1 \le ct^{-1/2}\|f\|_1 \tag{3.4}$$

for all $f \in L^1$ and $t>0$, and a constant K_1 such that

$$\|f\|_\infty \le K_1 \|f\|_{1,1} \tag{3.5}$$

for all $f \in W^{1,1}$. Meanwhile, if $v \in E$ then

$$\begin{aligned}\| c_i E(v(s)) \|_\infty &\le |E_-| + \sup_x |c_i|\,|e/\varepsilon| \sum_{k=1}^m \int_{-\infty}^x (|v_k(y, s)| + |w_k(y)|)\, dy \\ &\le |E_-| + m\|\textstyle\sum w_k\|_1 \sup_i |c_i|\,|e/\varepsilon| \sup_k \|v_k(s)\|_1 \\ &\le |E_-| + m\|\textstyle\sum w_k\|_1 \sup_i |c_i|\,|e/\varepsilon| M \equiv K_2\end{aligned} \tag{3.6}$$

and

$$\begin{aligned}\| c_i[E(v(s))]_x \|_1 &\le |c_i|\,|e/\varepsilon| \Bigg(\sum_{k=1}^m \|v_k(s)\|_1 + \|\textstyle\sum w_k\|_1 \Bigg) \\ &\le \sup_i |c_i|\,|e/\varepsilon|\, \|\textstyle\sum w_k\|_1 mM \equiv K_3.\end{aligned} \tag{3.7}$$

If we set

$$G_i(t) = W_i(t)v_i^0 + \int_0^t W_i(t-s)(w_i)_{xx}\,ds \tag{3.8}$$

then from (3.3)-(3.8) we have

$$\begin{aligned}
&\|[(S_iv_i)(t) - G_i(t)]_x\|_1 \\
&\quad \leqq \int_0^t c(t-s)^{-1/2}\|[c_iE(v(s))(v_i(s)+w_i)]_x\|_1\,ds \\
&\quad \leqq \int_0^t c(t-s)^{-1/2}[\|c_iE(v(s))\|_\infty\|(v_i)_x(s)\|_1 \\
&\qquad + \|c_i[E(v(s))]_x\|_1\|v_i(s)\|_\infty + \|c_iE(v(s))\|_\infty\|(w_i)_x\|_1 \\
&\qquad + \|c_i[E(v(s))]_x\|_1\|w_i\|_\infty]\,ds \\
&\quad \leqq cT^{1/2}[(K_2+K_1K_3)M + K_2\|(w_i)_x\|_1 + K_3\|(w_i)\|_\infty].
\end{aligned} \tag{3.9}$$

In a similar fashion we can estimate

$$\|[(S_iv_i)(t) - G_i(t)]\|_1 \tag{3.10}$$

and

$$\|[(S_iv_i)(t) - G_i(t)]_{xx}\|_1. \tag{3.11}$$

We note that (3.10) will be bounded by the last line of (3.9) except that $cT^{1/2}$ is replaced by T. Meanwhile (3.11) is bounded by

$$\int_0^t c(t,s)^{-1/2}\|[c_iE(v(s))(v_i(s)+w_i)]_{xx}\|_1\,ds \tag{3.12}$$

which we can estimate by computing:

$$\begin{aligned}
&[c_iE(v(s))(v_i(s)+w_i)]_{xx} \\
&\quad = 2c_i[E(v(s))]_x(v_i(s)+w_i)_x + c_iE(v(s))(v_i(s)+w_i)_{xx} \\
&\qquad + c_i[E(v(s))]_{xx}(v_i(s)+w_i).
\end{aligned} \tag{3.13}$$

We now can proceed as in (3.9) once we observe that

$$\begin{aligned}
\|c_i[E(v(s))]_{xx}\|_1 &\leqq \sup_i|c_i|\,|e/\varepsilon|\sum_{k=1}[\|(v_i)_x(s)\|_1 + \|(w_k)_x\|_1] \\
&\leqq \sup_i|c_i|\,|e/\varepsilon|[mM + \textstyle\sum\|(w_k)_x\|_1].
\end{aligned} \tag{3.14}$$

From these remarks and the development in (3.19) we see that T can be selected so that S maps Q to Q.

To show that we can select T smaller, if necessary, so that for $u, v \in Q$

$$\rho(Su, Sv) \leqq K(T)\rho(u, v) \tag{3.15}$$

with $0 < K(T) < 1$ now requires more tedious calculations but no deeper than those made above. The main points of the development come from replacing $E(v(s))$ by $E(u(s)) - E(v(s))$ and $v_i(s)$ by $v_i(s) - u_i(s)$ in (3.6), (3.7), and (3.14).

These observations demonstrate that we have solutions $v_i(t)$ of the appropriate integral equations. To see that each v_i is a strong solution now proceeds in a standard fashion. We already have that $v_i(t)$ is in the domain of A_i for each t; we now differentiate under the integral sign in the usual manner (see,e.g.,[5]) using the dominated convergence theorem. This completes the proof of Theorem 2.1.

4. Global existence. Let $[0, T)$ be the maximal interval of existence for the solutions found in § 3. We first show that the L^1-norm of the v_i stays bounded on $[0, T)$, if T is finite. Consider, for $0 \leqq t < T$ and for each i, the *linear* equation

$$z_t = d_i z_{xx} + [c_i E z]_x, \tag{4.1a}$$

$$z(x, 0) = z_0, \tag{4.1b}$$

where z_0 is in $W^{2,1}$ and satisfies $z_0(x) \geqq 0$ for all x, while $E = E(v(t))$ with v as in § 3. It is clear that (4.1) has a solution $z(x, t)$ throughout $[0, T)$ with $z \in W^{2,1}$ for each t; in fact, the methods of § 3 apply; also note that $E \in C([0, T); C_B(\mathbb{R}))$. Therefore there exists a fundamental solution $U(t, \tau)$ such that $z(t) = U(t, 0)z_0$. It is clear, by applying the Trotter product formula for fixed τ, that $U(t, \tau)$ is positivity preserving. Moreover, since $z(t) \in W^{2,1}$,

$$\frac{d}{dt}\int_{-\infty}^{\infty} z(x, t)\, dx = \int_{-\infty}^{\infty} [c_i E z]_x\, ds = 0; \tag{4.2}$$

hence $U(t, \tau)$ preserves the L^1-norm for nonnegative initial data. For arbitrary initial data $z_0 \in W^{2,1}$, set $z_0^+ = \max\{z_0, 0\}$ and $z_0^- = \max\{-z_0, 0\}$, then

$$\begin{aligned} \| U(t, \tau) z_0 \|_1 &\leqq \| U(t, \tau) z_0^+ \|_1 + \| U(t, \tau) z_0^- \|_1 \\ &= \| z_0^+ \|_1 + \| z_0^- \|_1 = \| z_0 \|_1; \end{aligned} \tag{4.3}$$

thus $U(t, \tau)$ is a *contraction* on L^1 for each $0 \leqq \tau \leqq t < T$.

By variation-of-parameters our solutions v_i evidently satisfy

$$\begin{aligned} v_i(t) = U(t, 0)v_i^0 &+ \int_0^t U(t, s)(c_i E)(w_i)_x\, ds \\ &+ \int_0^t U(t, s)(c_i E_x)(w_i)\, ds \\ &+ \int_0^t U(t, s)\, d_i (w_i)_{xx}\, ds; \end{aligned} \tag{4.4}$$

hence for $0 \leqq t \leqq T$

$$\begin{aligned} \| v_i(t) \|_1 &\leqq \| v_i^0 \|_1 + \int_0^t \| c_i E \|_\infty \| (w_i)_x \|_1\, ds \\ &\quad + \int_0^t \| c_i E_x \|_1 \| w_i \|_\infty\, ds + d_i T \| (w_i)_{xx} \|_1 \\ &\leqq \| v_i \|_1 + d_i T \| (w_i)_{xx} \|_1 \\ &\quad + [|E_-| + \sup_i |c_i|\,|e/\varepsilon|][\| (w_i)_x \|_1 + \| w_i \|_\infty] T \| \textstyle\sum w_k \|_1 \\ &\quad + [|E_-| + \sup_i |c_i|\,|e/\varepsilon|][\| (w_i)_x \|_1 + \| w_i \|_\infty] \\ &\quad \cdot \int_0^t \sum_{k=1}^m \| v_k(s) \|_1\, ds \end{aligned} \tag{4.5}$$

where we have used (3.6) and (3.7). If we now sum up (4.5) for each i, we see that by Gronwall's inequality

$$\sum_{i=1} \| v_i(t) \|_1 \leqq K_6 \exp(K_7 T) \equiv N \tag{4.6}$$

for all $t \in [0, t)$, where K_6 and K_7 are constant on $[0, T)$.

We now use (4.6) to estimate $\| v_i \|_{1,1}$ on $[0, T)$. From the integral equation representation we have, for each $0 \leqq t < T$,

$$\begin{aligned}
\| v_i(t) \|_{1,1} &\leqq N + \| (v_i)_x(t) \|_1 \\
&\leqq N + \| (v_i^0)_x \|_1 + \int_0^t c(t-s)^{-1/2} \| (w_i)_{xx} \|_1 \, ds \\
&\quad + \int_0^t c(t-s)^{-1/2} [\| c_i E \|_\infty \| (v_i)_x \|_1 + \| c_i E_x \|_1 \| v_i \|_\infty \\
&\qquad + \| c_i E \|_\infty \| (w_i)_x \|_1 + \| c_i E_x \|_1 \| w_i \|_\infty] \, ds \qquad (4.7) \\
&\leqq N + cT^{1/2} \| (w_i)_{xx} \|_1 + \| (v_i^0)_x \|_1 + K_8 T (\| (w_i)_x \|_1 + \| w_i \|_\infty) \\
&\quad + K_8 \int_0^t c(t-s)^{-1/2} (1 + K_1) \| v_i(s) \|_{1,1} \, ds
\end{aligned}$$

where

$$K_8 = |E_-| + \sup_i |c_i| \, |e/\varepsilon| (N + \| \textstyle\sum w_k \|_1) \tag{4.8}$$

so again by Gronwall's inequality $\| v_i(t) \|_{1,1}$ stays bounded on $[0, T)$. Note that we have used (3.6), (3.7), and (4.6) to obtain (4.7). We can now use the uniform bound on $\| v_i(t) \|_{1,1}$ to show that $\| v_i(t) \|_{2,1}$ stays bounded on $[0, T)$; the development is similar to that used in (4.7), but now we also use (3.14).

Thus, if $T < +\infty$, standard arguments now obtain a contradiction in the usual fashion (see, e.g., [4], [5]). Hence we have demonstrated the following.

THEOREM 4.1. *The solutions found in* § 3 *are* <u>*global*</u> *solutions, i.e.,* $v_i \in C([0, +\infty); W^{2,1}) \cap C^1([0, +\infty); L^1)$ *for each* i.

5. Remarks. We have shown that (2.12) has global strong solutions in $W^{2,1}$ for each t. Using standard bootstrap techniques, however, we can show that our solutions lie in $\cap_n W^{n,1}$ for each $t > 0$; in particular each $v_i(t)$ is C^∞ for positive t. Our techniques of the last section to pass from bounds on the $W^{1,1}$ norm to bounds on the $W^{2,1}$ norm using (3.14) can be applied inductively to obtain this expected parabolic regularity.

Finally, there is an additional a priori estimate that can be derived for the solutions v_i. Rewriting (2.12a) as

$$(v_i)_t = [c_i E (v_i + w_i) + d_i (v_i)_x]_x \tag{5.1}$$

we integrate both sides of (5.1) to see that

$$\frac{d}{dt} \int_{-\infty}^{\infty} v_i(y, t) \, dy = [c_i E w_i]_{-\infty}^{\infty}, \tag{5.2}$$

so there exists a constant B_i, depending only on α_i, β_i, and $E_\pm$ such that

$$\int_{-\infty}^{\infty} v_i(y, t) \, dy = B_i t + \int_{-\infty}^{\infty} v_i^0(y) \, dy. \tag{5.3}$$

Since v_i is not necessarily nonnegative, it is not clear what the usefulness of (5.3) is, but perhaps it may prove to have some physical significance.

Acknowledgment. I would like to thank Professor Paul Fife of the University of Arizona for suggesting this problem to me and for many useful discussions.

REGULARITY AND STRONG CONVERGENCE OF A VARIATIONAL APPROXIMATION TO A NONHOMOGENEOUS DIRICHLET HYPERBOLIC BOUNDARY VALUE PROBLEM*

IRENA LASIECKA† AND JAN SOKOLOWSKI‡

Abstract. Variational approximations of the second order scalar hyperbolic equations with nonhomogeneous Dirichlet boundary data are considered. Strong convergence of the approximate solutions to the original ones is established.

Key words. variational approximations, hyperbolic equations, Dirichlet boundary conditions, regularity of solutions

AMS(MOS) subject classification. 35L20

1. Introduction. Let Ω be an open bounded domain in R^n with a smooth boundary Γ. Consider the following second order scalar hyperbolic equation:

$$\begin{aligned} &\ddot{u}(t,x)=\Delta u(t,x)+f(t,x), \qquad t,x\in(0,T]\times\Omega\equiv Q,\\ &u(0,x)=\dot{u}(0,x)=0 \quad \text{in } \Omega,\\ &u(t,x)|_{\Gamma}=g(t,x) \quad \text{in } (0,T)\times\Gamma\equiv\Sigma. \end{aligned} \tag{1.1}$$

Optimal regularity properties of the solution u, which improve upon previous literature, e.g., [LM], are established in [L1], [LT1], [LLT]; in particular, the following estimate holds:

$$|u|_{C[0T;L_2(\Omega)]}\leqq C[|g|_{L_2(\Sigma)}+|f|_{L_1[0,T;[H_0^1(\Omega)]']}].$$

The following question may be asked: how do we construct a numerical algorithm in order to compute effectively u from the boundary data g? It is well known that the "best" numerical approximations of various partial differential equation problems are based on a certain variational formulation of the original equation. The problem in our case is, however, that due to the Dirichlet nature of the nonhomogeneous boundary condition problem (1.1) does not admit a natural variational formulation (in contrast, a natural variational formulation is standard in the case of Neumann or Robin boundary conditions). In this context, the idea of Lions [L1] is to "approximate" the solution $u(t)$ of (1.1) by a sequence of functions $u_\varepsilon(t)$ which are determined as solutions of the following problems:

$$\begin{cases} \ddot{u}_\varepsilon(t,x)=\Delta u_\varepsilon(t,x)+f(t,x) & \text{in } Q,\\ u_\varepsilon(0,x)=\dot{u}_\varepsilon(0,x)=0 & \text{in } \Omega,\\ \varepsilon\dfrac{\partial u_\varepsilon}{\partial\eta}+\beta u_\varepsilon=\beta g & \text{in } \Sigma \end{cases} \tag{1.2}$$

where β is a self-adjoint second order elliptic operator defined on the variety Γ.[1] For example, one can take $\beta\equiv-\Delta_\Gamma+1$ where Δ_Γ is the Laplace's Beltrami operator corresponding to the Riemann metric on Γ induced by R^n.

[1] This in particular implies that $\beta: H^{s+2}(\Gamma)\to H^s(\Gamma)$ is an isomorphism.

The advantage of introducing (1.2) is, of course, that (1.2) admits a natural variational formulation

$$(1.3)\qquad \begin{cases} (\ddot{u}_\varepsilon, \phi)_\Omega + (\nabla u_\varepsilon, \nabla \phi)_\Omega + \dfrac{1}{\varepsilon}\langle \beta u_\varepsilon, \phi\rangle_\Gamma = \dfrac{1}{\varepsilon}\langle \beta g, \phi\rangle_\Gamma + (f, \phi)_\Omega, & \phi \in C^2(\bar{\Omega}), \\ u_\varepsilon(0) = \dot{u}_\varepsilon(0) = 0. \end{cases}$$

In [L1] it was shown that $u_\varepsilon(t)$ approximates $u(t)$ in the following sense: for any $g \in L_2(\Sigma)$ and $f \in L_1[0, T; L_2(\Omega)]$

$$(1.4)\qquad u_\varepsilon \to u \text{ in } L^\infty[0, T; L_2(\Omega)] \text{ weak star, when } \varepsilon \to 0.$$

In view of the above, we can think of (1.1) as a limit problem for (1.2). Therefore, in order to find an effective numerical approximation of (1.1), the natural idea to pursue is to look for numerical algorithms (Ritz-Galerkin, finite element, etc.) of the variational equality (1.3). However, in order to establish the convergence or even more—the rates of the convergence—of these approximations, a necessary prerequisite is to know more about the regularity properties of the solutions to (1.2) as well as their convergence to $u(t)$. Thus, the main purpose of the present paper is to study regularity (more precisely uniform differentiability) properties of the solutions $u_\varepsilon(t)$ along with the convergence of $u_\varepsilon(t)$ to $u(t)$. In particular, we will prove that the convergence in (1.4) is, in fact, strong. We shall also establish a number of regularity results for $u_\varepsilon(t)$, which are reminiscent of those valid for the limit solution $u(t)$. These results, besides being of interest in their own right, are of fundamental importance in the study of numerical schemes approximating (1.2). In fact, they are used crucially in [LS], where finite element techniques are developed to approximate $u_\varepsilon(t)$ and hence $u(t)$.

The outline of the paper is as follows. In § 2 we provide some background material on the properties of the solution $u(t)$ and we state our main results, Theorems 2.3 and 2.4. In § 3 we discuss the regularity and convergence of the steady state solutions to (1.2). These results are needed for § 5 where the proof of our main result, Theorem 2.4, on the uniform differentiability of the solution $u_\varepsilon(t)$ is provided. Section 4, instead, is devoted to the proof of Theorem 2.3 which states convergence of $u_\varepsilon(t)$ to $u(t)$.

Notation.

$(\,,\,)$ and $\|\ \|$ stand for inner product and the norm in $L_2(\Omega)$.

$\langle\,,\rangle$ and $|\ |$ stand for inner product and the norm in $L_2(\Gamma)$.

$H^r(\Omega)$, $H^{r,s}(Q)$ (respectively, $H^r(\Gamma)$, $H^{r,s}(\Sigma)$) denote the usual Sobolev space defined as in [LM].

$H^{-r,-s}(Q) \equiv (H^{r,s}(Q))'$.

$H^{-r}(\Omega) = (H^r(\Omega))'$; $H^{-r}(\Gamma) = H^r(\Gamma)'$.

$H_0^{-r}(\Omega) \equiv (H_0^r(\Omega))'$.

$\mathscr{L}(X \to Y)$ is the space of linear, bounded transformations from Banach space X to another Banach space Y.

$\dot{u} = (d/dt)u$; $\ddot{u} = d^2/dt^2$.

2. Preliminaries and the statements of the main results. Let us begin by collecting regularity results available for the original problem (1.1).

THEOREM 2.1 ([LT1], [LT2], [LLT], [L2], [S1]). *Let u be the solution to* (1.1) *with $g \in L_2(\Sigma)$ and $f = 0$. Then*

$$(2.1)\qquad |u|_{C[0T;L_2(\Omega)]} + |\dot{u}|_{C[0T;(H_0^1(\Omega))']} + \left|\frac{\partial u}{\partial \eta}\right|_{H^{-1,-1}(\Sigma)} \leqq C^2 |g|_{L_2(\Sigma)}.$$

[2] C will stand for a generic constant.

If in addition we assume that $g \in H^{1,1}(\Sigma)$, $g(0)=0$ *and we take* $f \in L_1[0T; L_2(\Omega)]$ *then*

$$|u|_{C[0T;H^1(\Omega)]}+|\dot{u}|_{C[0T;L_2(\Omega)]}+\left|\frac{\partial u}{\partial \eta}\right|_{L_2(\Sigma)} \leqq C[|g|_{H^{1,1}(\Sigma)}+|f|_{L_1[0T;L_2(\Omega)]}]. \tag{2.2}$$

More generally with $g \in H^{s,s}(\Sigma)$, $s \geqq 1$ *where* g *satisfies the appropriate compatibility conditions and with* $f=0$ *we have*

$$|u|_{C[0T;H^s(\Omega)]}+|\dot{u}|_{C[0T;H^{s-1}(\Omega)]}+\left|\frac{\partial u}{\partial \eta}\right|_{H^{s-1,s-1}(\Sigma)} \leqq C|g|_{H^{s,s}(\Sigma)}. \tag{2.3}$$

Remark 2.1. Notice that the regularity of the solution on the boundary does not follow from the interior regularity. In fact, the regularity of the normal derivative of the solution on the boundary is higher than the Trace Theorem combined with interior regularity would imply.

Next, let u_ε stand for the solution to (1.2). The following results were proved in [L1].

THEOREM 2.2 [L1]. *Let* u (*respectively,* u_ε) *be the solution to* (1.1) (*respectively,* (1.2)) *with* $g=0$ *and* $f \in L_1[0T; L_2(\Omega)]$. *Then*

$$|u_\varepsilon|_{C[0T;H^1(\Omega)]}+|\dot{u}_\varepsilon|_{C[0T;L_2(\Omega)]}+\left|\frac{\partial y_\varepsilon}{\partial \eta}\right|_{L_2(\Sigma)}+|\dot{u}_\varepsilon|_{L_2(\Sigma)} \leqq C|f|_{L_1[0T;L_2(\Omega)]}, \tag{2.4}$$

$$|u_\varepsilon|_{C[0T;H^1(\Gamma)]} \leqq C\sqrt{\varepsilon}|f|_{L_1[0T;L_2(\Omega)]}. \tag{2.5}$$

(2.6) (i) $u_\varepsilon \to u$ *in* $L^\infty[0T; H^1(\Omega)]$ *weak star,*

(ii) $\dot{u}_\varepsilon \to \dot{u}$ *in* $L^\infty[0T; L_2(\Omega)]$ *weak star,*

(iii) $u_\varepsilon \to 0$ *in* $C[0T; H^1(\Gamma)]$,

(iv) $\dfrac{\partial u_\varepsilon}{\partial \eta} \to \dfrac{\partial u}{\partial \eta}$ *in* $L^2(\Sigma)$ *weakly.*

With $g \in L_2(\Sigma)$ *in* (1.1) (*respectively,* (1.2)) *and* $f \in L_1[0T; L_2(\Omega)]$ *we have*

$$|u_\varepsilon|_{C[0T;L_2(\Omega)]} \leqq C[|g|_{L_2(\Sigma)}+|f|_{L_1[0T;L_2(\Omega)]}], \tag{2.7}$$

$$u_\varepsilon \to u \quad \text{in } L^\infty[0T; L_2(\Omega)] \text{ weak star}, \tag{2.8}$$

where C *stand for a generic constant* <u>*independent*</u> *of* $\varepsilon > 0$.

The main goals of this paper are (i) to prove the uniform (with respect to ε) differentiability of the solutions u_ε with nonhomogeneous, smooth boundary data g, and (ii) to improve the convergence results of (2.6) and (2.8).

Our results are as follows.

THEOREM 2.3 (Differentiability). (i) *Let* u (*respectively,* u_ε) *be the solution to* (1.1) (*respectively,* (1.2)) *with* $g \in H^{1,1}(\Sigma)$; $g(0)=0$ *and* $f \equiv 0$. *Then*

$$|u_\varepsilon|_{C[0T;H^1(\Omega)]}+|\dot{u}_\varepsilon|_{C[0T;L_2(\Omega)]} \leqq C|g|_{H^{1,1}(\Sigma)}, \tag{2.9}$$

$$\left|\frac{\partial u_\varepsilon}{\partial \eta}\right|_{L_2(\Sigma)}+|\dot{u}_\varepsilon|_{L_2(\Sigma)}+|u_\varepsilon|_{L_2[0T;H^1(\Gamma)]} \leqq C|g|_{H^{1,1}(\Sigma)}, \tag{2.10}$$

$$|u_\varepsilon - g|_{L_2[0T;H^2(\Gamma)]} \leqq C\varepsilon|g|_{H^{1,1}(\Sigma)}. \tag{2.11}$$

(ii) *If in addition we assume that* $g \in H^{s,s}(\Sigma)$, $s \geqq 1$ *and* g *satisfies the appropriate compatibility conditions then*

$$|u_\varepsilon|_{C[0T;H^s(\Omega)]}+|\dot{u}_\varepsilon|_{C[0T;H^{s-1}(\Omega)]} \leqq C|g|_{H^{s,s}(\Sigma)}, \tag{2.12}$$

$$\left|\frac{\partial u_\varepsilon}{\partial \eta}\right|_{H^{s-1,s-1}(\Sigma)}+|\dot{u}_\varepsilon|_{H^{s-1,s-1}(\Sigma)}+|u_\varepsilon|_{L_2[0T;H^s(\Gamma)]} \leqq C|g|_{H^{s,s}(\Sigma)}, \tag{2.13}$$

$$|u_\varepsilon - g|_{L_2[0T;H^{s+1}(\Gamma)]} \leqq C\varepsilon|g|_{H^{s,s}(\Sigma)}. \tag{2.14}$$

THEOREM 2.4 (Convergence). (i) *Let u (respectively, u_ε) be the solution to* (1.1) (*respectively*, (1.2)) *with $f \in L_1[0T; L_2(\Omega)]$ and $g = 0$. Then*

$$(2.15)\quad \text{(i)}\quad |u_\varepsilon|_{L_2[0T;H^2(\Gamma)]} \leqq C\varepsilon |f|_{L_1[0T;L_2(\Omega)]},$$

$$\text{(ii)}\quad |u_\varepsilon - u|_{L_\infty[0T;L_2(\Omega)]} \leqq C\varepsilon |f|_{L_1[0T;L_2(\Omega)]},$$

$$(2.16)\quad \text{(i)}\quad u_\varepsilon \to u \quad \text{in } C[0T;H^1(\Omega)],$$

$$\text{(ii)}\quad \dot{u}_\varepsilon \to \dot{u} \quad \text{in } C[0T;L_2(\Omega)],$$

$$(2.17)\quad \text{(i)}\quad \dot{u}_\varepsilon|_\Gamma \to 0 \quad \text{in } L_2(\Sigma),$$

$$\text{(ii)}\quad \frac{\partial u_\varepsilon}{\partial \eta} \to \frac{\partial u}{\partial \eta} \quad \text{in } L_2(\Sigma).$$

(ii) *Let u (respectively, u_ε) be the solution to* (1.1) (*respectively*, (1.2)) *with $f = 0$. Then*

$$(2.18)\qquad |u_\varepsilon - u|_{C[0T;L_2(\Omega)]} \leqq C\varepsilon |g|_{H^{1,1}(\Sigma)},$$

$$(2.19)\qquad u_\varepsilon \to u \quad \text{in } C[0T; L_2(\Omega)] \quad \text{for any } g \in L_2(\Sigma).$$

Remark 2.2. Notice that the regularity results of u_ε stated in Theorem 2.3 are reminiscent of those in Theorem 2.1. In fact, (2.9), (2.10) reconstruct the regularity of the original solution $u(t)$ given by (2.1) and (2.2).

3. Convergence of the steady state solutions.

3.1. Statement of results. In order to prove our regularity and convergence results for the problem (1.2), we first need to establish similar results for the corresponding elliptic problem. More precisely, consider the following elliptic problems:

$$(3.1)\qquad \Delta v = f \quad \text{in } \Omega, \qquad v|_\Gamma = 0 \quad \text{in } \Gamma$$

and

$$(3.2)\qquad \Delta v_\varepsilon = f \quad \text{in } \Omega, \qquad \varepsilon \frac{\partial v_\varepsilon}{\partial \eta} + \beta v_\varepsilon = 0 \quad \text{in } \Gamma.$$

If we define the operators $A: L_2(\Omega) \to L_2(\Omega)$ and $A_\varepsilon : L_2(\Omega) \to L_2(\Omega)$ by

$$Av \equiv \Delta v, \qquad v \in \mathscr{D}(A) \equiv H^2(\Omega) \cap H_0^1(\Omega), \quad \text{and}$$

$$A_\varepsilon v_\varepsilon \equiv \Delta v_\varepsilon \qquad v_\varepsilon \in \mathscr{D}(A_\varepsilon) = \left\{ u \in L_2(\Omega);\ \Delta u \in L_2(\Omega);\ \varepsilon \frac{\partial u}{\partial \eta} + \beta u = 0 \right\},$$

then (3.1) and (3.2) are equivalent to

$$(3.1')\qquad Av = f, \quad \text{and}$$

$$(3.2')\qquad A_\varepsilon v_\varepsilon = f.$$

Below we shall state a number of regularity and convergence results established for the problems (3.1) and (3.2). The proofs of these results are relegated to § 3.2.

LEMMA 3.1.

$$(3.3)\qquad |A_\varepsilon^{-1} f|_{H^1(\Omega)} + \frac{1}{\sqrt{\varepsilon}} |A_\varepsilon^{-1} f|_{H^1(\Gamma)} \leqq C |f|_{H^{-1}(\Omega)},$$

$$(3.4)\qquad |A_\varepsilon^{-1} f|_{H^2(\Omega)} + \frac{1}{\varepsilon} |A_\varepsilon^{-1} f|_{H^2(\Gamma)} \leqq C \|f\|,$$

$$(3.5)\qquad |A_\varepsilon^{-1} f - A^{-1} f|_{H^2(\Omega)} \leqq C\varepsilon |f|_{H^{-1}(\Omega)}.$$

Next, let us define the so-called Dirichlet map $D: L_2(\Gamma) \to L_2(\Omega)$ *by*

$$\Delta Dg = 0 \quad \text{in } \Omega, \qquad Dg|_\Gamma = g \quad \text{in } \Gamma. \tag{3.6}$$

It is well known [LM] *that*

$$D \in \mathscr{L}(H^s(\Gamma) \to H^{s+1/2}(\Omega)) \quad \text{for all real } s > 0. \tag{3.7}$$

Similarly we define a "variational approximation" of (3.6) *by introducing the map* $N_\varepsilon: L_2(\Gamma) \to L_2(\Omega)$ *where*

$$\Delta N_\varepsilon g = 0 \quad \text{in} \quad \Omega, \qquad \varepsilon \frac{\partial N_\varepsilon}{\partial \eta} g + \beta N_\varepsilon g = \beta g \quad \text{in } \Gamma. \tag{3.8}$$

We shall prove the following lemma.

LEMMA 3.2.

$$|N_\varepsilon g|_{H^{3/2}(\Omega)} + \left| \frac{\partial}{\partial \eta} N_\varepsilon g \right| \leqq C|g|_{H^1(\Gamma)}, \tag{3.9}$$

$$|N_\varepsilon g|_{H^{1/2}(\Omega)} + \left| \frac{\partial}{\partial \eta} N_\varepsilon g \right|_{H^{-1}(\Gamma)} \leqq C|g|, \tag{3.10}$$

$$|N_\varepsilon g|_{H^2(\Omega)} \leqq C|g|_{H^{3/2}(\Gamma)}, \tag{3.11}$$

$$|N_\varepsilon g - Dg|_{H^{3/2}(\Omega)} \leqq C\varepsilon|g|, \tag{3.12}$$

$$|N_\varepsilon g - Dg|_{H^{5/2}(\Omega)} \leqq C\varepsilon|g|_{H^1(\Gamma)}. \tag{3.13}$$

Remark 3.1. Notice that the regularity properties (3.3)-(3.4), and (3.9)-(3.11), reconstruct (uniformly in the parameter $\varepsilon > 0$) the well-known regularity properties of the elliptic Dirichlet problems.

Remark 3.2. The results of Lemma 3.2 can be easily generalized to obtain $N_\varepsilon \in \mathscr{L}(H^s(\Gamma) \to H^{s+1/2}(\Omega))$ for all real $s > 0$ with the norm uniform in $\varepsilon > 0$.

3.2. Proofs of Lemma 3.1 and Lemma 3.2.

Proof of Lemma 3.1. With A_ε introduced as in § 3.1 we associate the bilinear form $a_\varepsilon(u, v)$ defined by

$$a_\varepsilon(u, v) \equiv -(A_\varepsilon u, v) = (\nabla u, \nabla v) + \frac{1}{\varepsilon}\langle \beta u, v \rangle$$

for all $u, v \in \mathscr{D}(A_\varepsilon^{1/2}) \equiv \{u \in H^1(\Omega), (1/\sqrt{\varepsilon})u|_\Gamma \in H^1(\Gamma)\}$.

It follows by standard arguments that $A_\varepsilon = A_\varepsilon^*$ and

$$\begin{aligned} &\text{(a)} \quad |a_\varepsilon(u, v)| \leqq C\left[|u|_{H^1(\Omega)}|v|_{H^1(\Omega)} + \frac{1}{\varepsilon}|u|_{H^1(\Gamma)}|v|_{H^1(\Gamma)} \right], \\ &\text{(b)} \quad |a_\varepsilon(u, u)| \geqq c\left[|u|^2_{H^1(\Omega)} + \frac{1}{\varepsilon}|u|^2_{H^1(\Gamma)} \right], \qquad c, C > 0. \end{aligned} \tag{3.14}$$

With the above notation, solving (3.2′) is equivalent to finding v_ε such that

$$a_\varepsilon(v_\varepsilon, \phi) = (f, \phi) \quad \text{for all } \phi \in \mathscr{D}(A_\varepsilon^{1/2}). \tag{3.15}$$

Property (3.3) now follows immediately from (3.14) after setting $\phi = v_\varepsilon$ in (3.15). As for (3.4) we first notice that

$$|v_\varepsilon|_{H^1(\Gamma)} \leqq C\sqrt{\varepsilon}|f|_{H^{-1}(\Omega)}$$

together with

$$\Delta v_\varepsilon = f \in L_2(\Omega) \tag{3.16}$$

imply via standard results from elliptic theory (see for example [B1])

$$|v_\varepsilon|_{H^{3/2}(\Omega)} + \left|\frac{\partial v_\varepsilon}{\partial \eta}\right|_{L_2(\Gamma)} \leqq C[\sqrt{\varepsilon}|f|_{H^{-1}(\Omega)} + |f|_{H^{-1/2}(\Omega)}]. \tag{3.17}$$

Thus (3.17) and $\varepsilon(\partial v_\varepsilon/\partial \eta) + \beta v_\varepsilon = 0$ yield

$$|v_\varepsilon|_{H^2(\Gamma)} \leqq C|\beta v_\varepsilon| \leqq C\varepsilon\left|\frac{\partial v_\varepsilon}{\partial \eta}\right| \leqq C\varepsilon[\sqrt{\varepsilon}|f|_{H^{-1}(\Omega)} + |f|_{H^{-1/2}(\Omega)}]. \tag{3.18}$$

Using (3.18), (3.16) and well-known energy estimates for the Dirichlet problem [LM], we obtain

$$|v_\varepsilon|_{H^2(\Omega)} \leqq C[|v_\varepsilon|_{H^{3/2}(\Gamma)} + \|f\|] \leqq C\|f\|. \tag{3.19}$$

Formulae (3.18) and (3.19) yield (3.4).

As for (3.5), we notice first that by using regularity results from elliptic theory applied to (3.1′) we obtain

$$\left|\frac{\partial v}{\partial \eta}\right|_{H^{-1/2}(\Gamma)} \leqq C|f|_{H^{-1}(\Omega)}.$$

Consequently,

$$\left|\beta^{-1}\frac{\partial v}{\partial \eta}\right|_{H^{3/2}(\Gamma)} \leqq C\left|\frac{\partial v}{\partial \eta}\right|_{H^{-1/2}(\Gamma)} \leqq C|f|_{H^{-1}(\Omega)}. \tag{3.20}$$

Next we define

$$z_\varepsilon \equiv A_\varepsilon^{-1}f - A^{-1}f = v_\varepsilon - v.$$

We have

$$\Delta z_\varepsilon = 0, \qquad z_\varepsilon|_\Gamma = -\varepsilon\beta^{-1}\frac{\partial v}{\partial \eta} = -\varepsilon\beta^{-1}\frac{\partial}{\partial \eta}A^{-1}f.$$

Since $z_\varepsilon = -\varepsilon D\beta^{-1}\partial v/\partial \eta$, (3.20) together with (3.7) gives

$$|z_\varepsilon|_{H^2(\Omega)} \leqq C\varepsilon\left|\beta^{-1}\frac{\partial v}{\partial \eta}\right|_{H^{3/2}(\Gamma)} \leqq C\varepsilon|f|_{H^{-1}(\Omega)}$$

which completes the proof of the Lemma 3.1. □

Proof of Lemma 3.2. Let $v_\varepsilon \equiv N_\varepsilon g$. We have

$$a_\varepsilon(v_\varepsilon, \phi) = \frac{1}{\varepsilon}\langle \beta g, \phi\rangle, \qquad \phi \in \mathscr{D}(A_\varepsilon^{1/2}).$$

Setting $\phi \equiv v_\varepsilon$ and using (3.14) yields

$$|v_\varepsilon|^2_{H^1(\Omega)} + \frac{1}{\varepsilon}|v_\varepsilon|^2_{H^1(\Gamma)} \leqq \frac{c}{\varepsilon}|g|^2_{H^1(\Gamma)}. \tag{3.21}$$

Hence in particular

$$|v_\varepsilon|_{H^1(\Gamma)} \leqq C|g|_{H^1(\Gamma)} \quad \text{where } \Delta v_\varepsilon = 0. \tag{3.22}$$

The standard estimates for the Dirichlet problem applied to (3.22) now yield (3.9). To prove (3.10) we use transposition. Notice first that $N_\varepsilon \in \mathscr{L}(L_2(\Gamma) \to H^{1/2}(\Omega))$ is equivalent to

$$N_\varepsilon^* \in \mathscr{L}(H^{-1/2}(\Omega) \to L_2(\Gamma)) \tag{3.23}$$

(with the norm independent on $\varepsilon > 0$). On the other hand, it can be easily verified that

$$N_\varepsilon^* A_\varepsilon u = \frac{\partial}{\partial \eta} u, \qquad u \in \mathcal{D}(A_\varepsilon). \tag{3.24}$$

Indeed, for $u \in \mathcal{D}(A_\varepsilon)$ we have

$$\langle N_\varepsilon^* A_\varepsilon u, g\rangle = (A_\varepsilon u, N_\varepsilon g) = (\Delta u, N_\varepsilon g) = \left\langle \frac{\partial u}{\partial \eta}, N_\varepsilon g \right\rangle - \left\langle u, \frac{\partial}{\partial \eta} N_\varepsilon g \right\rangle$$

$$= \left\langle \frac{\partial u}{\partial \eta}, N_\varepsilon g \right\rangle + \left\langle \frac{\partial u}{\partial \eta}, g - N_\varepsilon g \right\rangle = \left\langle \frac{\partial u}{\partial \eta}, g \right\rangle$$

which proves (3.24).

In view of (3.24), (3.23) will be proved as soon as we show that for any $v \in H^{-1/2}(\Omega)$

$$\left| \frac{\partial u}{\partial \eta} \right| \leqq C |v|_{H^{-1/2}(\Omega)} \quad \text{where } u = A_\varepsilon^{-1} v. \tag{3.25}$$

On the other hand, from (3.3) we have

$$|u|_{H^1(\Gamma)} \leqq C\sqrt{\varepsilon}\, |v|_{H^{-1}(\Omega)} \leqq C\sqrt{\varepsilon}\, |v|_{H^{-1/2}(\Omega)}. \tag{3.26}$$

Formula (3.26) combined with $\Delta u = v \in H^{-1/2}(\Omega)$ and the standard Dirichlet estimates yield

$$|u|_{H^{3/2}(\Omega)} + \left| \frac{\partial u}{\partial \eta} \right| \leqq C[|v|_{H^{-1/2}(\Omega)} + |u|_{H^1(\Gamma)}] \leqq C|v|_{H^{-1/2}(\Omega)},$$

which in particular implies (3.25); hence we have (3.23) and consequently

$$|N_\varepsilon g|_{H^{1/2}(\Omega)} \leqq c|g|.$$

To complete the proof of (3.10) we need to show that

$$\left| \frac{\partial}{\partial \eta} N_\varepsilon g \right|_{H^{-1}(\Gamma)} \leqq C|g|. \tag{3.27}$$

We first prove that for any $0 < \rho < 1$

$$\left| \frac{\partial}{\partial \eta} N_\varepsilon g \right|_{H^{-1-\rho}(\Gamma)} \leqq C|g|. \tag{3.28}$$

To see this, we apply the Green identity to $(N_\varepsilon g, \Delta\phi)$ with $\phi \in C^\infty(\Omega)$. This yields

$$\left\langle \frac{\partial}{\partial \eta} N_\varepsilon g, \phi \right\rangle = \left\langle N_\varepsilon g, \frac{\partial}{\partial \eta} \phi \right\rangle + (N_\varepsilon g, \Delta\phi), \qquad \phi \in C^\infty(\Omega).$$

The surjectivity of the trace operator (see [LM]) implies that for any $\tilde{\phi} \in H^{1+\rho}(\Gamma)$ we can select $\phi \in H^{3/2+\rho}(\Omega)$ such that

$$\frac{\partial}{\partial \eta} \phi|_\Gamma = 0 \quad \text{and} \quad \tilde{\phi}|_\Gamma = \phi_\Gamma.$$

Therefore

$$\left\langle \frac{\partial}{\partial \eta} N_\varepsilon g, \tilde{\phi} \right\rangle = (N_\varepsilon g, \Delta\phi) \quad \text{for any } \tilde{\phi} \in H^{1+\rho}(\Gamma) \text{ where } \phi \in H^{3/2+\rho}(\Omega). \tag{3.29}$$

Since $N_\varepsilon \in \mathscr{L}(L_2(\Gamma) \to H^{1/2}(\Omega))$ (by (3.23)) and $\Delta\phi \in H^{-1/2}(\Omega)$ for any $g \in L_2(\Gamma)$, $(\partial/\partial\eta)N_\varepsilon g$ defines a linear bounded functional on $H^{1+\rho}(\Gamma)$. Formula (3.28) now follows from (3.29). To prove (3.27) we write

$$\Delta N_\varepsilon g = 0, \qquad N_\varepsilon g|_\Gamma = g - \varepsilon\beta^{-1}\frac{\partial N_\varepsilon}{\partial\eta}g. \tag{3.30}$$

Since by the virtue of (3.28)

$$\left|\beta^{-1}\frac{\partial N_\varepsilon}{\partial\eta}g\right| \leqq C\left|\frac{\partial N_\varepsilon}{\partial\eta}g\right|_{H^{-2}(\Gamma)} \leqq C\left|\frac{\partial N_\varepsilon}{\partial\eta}g\right|_{H^{-1-\rho}(\Gamma)} \leqq C|g|,$$

the standard Dirichlet estimates applied to (3.30) yield

$$|N_\varepsilon g|_{H^{1/2}(\Omega)} + \left|\frac{\partial}{\partial\eta}N_\varepsilon g\right|_{H^{-1}(\Gamma)} \leqq C\left[|g| + \varepsilon\left|\beta^{-1}\frac{\partial N_\varepsilon}{\partial\eta}g\right|\right] \leqq C|g|,$$

which proves (3.10).

In order to establish (3.11) we return to (3.30). From (3.9) we have

$$\left|\frac{\partial}{\partial\eta}N_\varepsilon g\right| \leqq C|g|_{H^1(\Gamma)} \leqq C|g|_{H^{3/2}(\Gamma)}.$$

Thus

$$\left|\beta^{-1}\frac{\partial}{\partial\eta}N_\varepsilon g\right|_{H^{3/2}(\Gamma)} \leqq C\left|\frac{\partial}{\partial\eta}N_\varepsilon g\right| \leqq C|g|_{H^{3/2}(\Gamma)}.$$

Since $N_\varepsilon g|_\Gamma = g - \varepsilon\beta^{-1}(\partial/\partial\eta)N_\varepsilon g$,

$$|N_\varepsilon g|_{H^{3/2}(\Gamma)} \leqq C|g|_{H^{3/2}(\Gamma)}. \tag{3.31}$$

Formula (3.31) combined with $\Delta N_\varepsilon g = 0$ and standard Dirichlet estimates give (3.11). As for (3.12) we set

$$z \equiv (N_\varepsilon - D)g.$$

Then

$$\Delta z = 0, \qquad \varepsilon\frac{\partial}{\partial\eta}z + \beta z = \varepsilon\beta\beta^{-1}\frac{\partial}{\partial\eta}Dg. \tag{3.32}$$

Since

$$\left|\beta^{-1}\frac{\partial}{\partial\eta}Dg\right|_{H^1(\Gamma)} \leqq C\left|\frac{\partial}{\partial\eta}Dg\right|_{H^{-1}(\Gamma)} \leqq C|g| \tag{3.33}$$

and $z = \varepsilon N_\varepsilon(\beta^{-1}(\partial/\partial\eta)Dg)$, (3.12) immediately follows from (3.33) and (3.9). Finally, to prove (3.13) we notice that

$$z|_\Gamma = [N_\varepsilon g - Dg]|_\Gamma = -\varepsilon\beta^{-1}\frac{\partial N_\varepsilon}{\partial\eta}g.$$

Hence by (3.9)

$$|z|_{H^2(\Gamma)} \leqq C\varepsilon\left|\frac{\partial N_\varepsilon}{\partial\eta}g\right| \leqq C\varepsilon|g|_{H^1(\Gamma)}. \tag{3.34}$$

Formula (3.34) combined with $\Delta z = 0$ and the standard results for the Dirichlet problems yield (3.13), hence completing the proof of the Lemma 3.2. □

4. Differentiability of the solution to nonhomogeneous boundary problems—Proof of Theorem 2.3. Let u_ε be the solution to (1.2) with $f \equiv 0$, $g \in H^{1,1}(\Sigma)$, such that $g(0) = 0$. We first multiply (1.2) by $\dot{u}_\varepsilon$, integrate over Q and use the boundary conditions $u|_\Gamma = g - \varepsilon\beta^{-1}(\partial u/\partial\eta)$.

This leads to

$$\begin{aligned}(4.1)\qquad &\|\dot{u}_\varepsilon(T)\|^2 + \|\nabla u_\varepsilon(T)\|^2 + \varepsilon\left|\beta^{-1/2}\frac{\partial u_\varepsilon}{\partial\eta}(T)\right|^2 + 2\int_0^T \left\langle \frac{\partial u_\varepsilon}{\partial\eta}, g\right\rangle dt \\ &\leqq 2\rho\left|\frac{\partial u_\varepsilon}{\partial\eta}\right|^2_{L_2(\Sigma)} + \frac{1}{2\rho}|g|^2_{L_2(\Sigma)} \quad \text{for } \rho > 0.\end{aligned}$$

Let $\mathbf{h}(x) \subset C^1(\bar{\Omega})$ be such that $\mathbf{h}|_\Gamma = \mathbf{n}(x)$ where $\mathbf{n}$ is a normal vector on the boundary. We multiply (1.2) by $\nabla u\ \mathbf{h}$ and integrate over Q. This gives

$$\begin{aligned}&(\dot{u}_\varepsilon(T), h\nabla u_\varepsilon(T)) - \frac{1}{2}|\dot{u}_\varepsilon|^2_{L_2(\Sigma)} + \frac{1}{2}\int_Q ((u_\varepsilon)^2 - |\nabla u_\varepsilon|^2)\operatorname{div}\mathbf{h}\, dQ \\ &\quad = \left|\frac{\partial u_\varepsilon}{\partial\eta}\right|^2_{L_2(\Sigma)} - \frac{1}{2}\int_\Sigma |\nabla u_\varepsilon|^2 \mathbf{h}\mathbf{n}\, d\Sigma - \sum_{ij=1}^n \int_Q \frac{\partial u_\varepsilon}{\partial x_j}\frac{\partial h_i}{\partial x_j}\frac{\partial u_\varepsilon}{\partial x_i}\, dQ.\end{aligned}$$

Writing $\nabla u_\varepsilon|_\Gamma = \partial u_\varepsilon/\partial\eta + \nabla_\Gamma u_\varepsilon$ where

$$|\nabla_\Gamma u| \leqq C|u|_{H^1(\Gamma)},$$

we obtain

$$\left|\frac{\partial u_\varepsilon}{\partial\eta}\right|^2_{L_2(\Sigma)} + |\dot{u}_\varepsilon|^2_{L_2(\Sigma)} \leqq C[|\dot{u}_\varepsilon|^2_{L_\infty[0T;L_2(\Omega)]} + |u_\varepsilon|^2_{L_\infty[0T;H^1(\Omega)]} + |u_\varepsilon|^2_{L_2[0T;H^1(\Gamma)]}].$$

On the other hand, from

$$\beta^{1/2}u_\varepsilon = \beta^{1/2}g - \varepsilon\beta^{-1/2}\frac{\partial u_\varepsilon}{\partial\eta}$$

we have

$$(4.2)\qquad |u_\varepsilon|_{H^1(\Gamma)} \leqq C\left[|g|_{H^1(\Gamma)} + \varepsilon\left|\beta^{-1/2}\frac{\partial u_\varepsilon}{\partial\eta}\right|\right].$$

Consequently,

$$\begin{aligned}(4.3)\qquad &\left|\frac{\partial u_\varepsilon}{\partial\eta}\right|^2_{L_2(\Sigma)} + |\dot{u}_\varepsilon|^2_{L_2(\Sigma)} \\ &\leqq C\left[|\dot{u}_\varepsilon|^2_{L_\infty[0T;L_2(\Omega)]} + |u_\varepsilon|^2_{L_\infty[0T;H^1(\Omega)]} + |g|^2_{L_2[0T;H^1(\Gamma)]} + \varepsilon^2\left|\beta^{-1/2}\frac{\partial u_\varepsilon}{\partial\eta}\right|^2_{L_2(\Sigma)}\right].\end{aligned}$$

After combining the estimates in (4.1) and (4.3) and noticing that $|u_\varepsilon|_{H^1(\Omega)} \leqq C\|\nabla u_\varepsilon\|$, we obtain

$$\begin{aligned}(4.4)\qquad &|\dot{u}_\varepsilon|^2_{L_\infty[0T;L_2(\Omega)]} + |u_\varepsilon|^2_{L_\infty[0T;H^1(\Omega)]} + \varepsilon\left|\beta^{-1/2}\frac{\partial u_\varepsilon}{\partial\eta}\right|^2_{L_\infty[0T;L_2(\Gamma)]} \\ &\leqq 2\rho c\Big[|\dot{u}_\varepsilon|^2_{L_\infty[0T;L_2(\Omega)]} + |u_\varepsilon|^2_{L_\infty[0T;H^1(\Omega)]} + |g|^2_{L_2[0T;H^1(\Gamma)]} \\ &\qquad + \varepsilon^2\left|\beta^{-1/2}\frac{\partial u_\varepsilon}{\partial\eta}\right|^2_{L_2(\Sigma)}\Big] + \frac{C}{\rho}|g|_{L_2(\Sigma)}\end{aligned}$$

where the constant C does not depend on either ρ or $\varepsilon > 0$. Formula (2.9) now follows after taking in (4.4) ρ small enough (such that $2\rho C < 1$ and $2\rho C\varepsilon < 1$). As for (2.10), we first notice that (4.4) also implies that

$$\sqrt{\varepsilon}\left|\beta^{-1/2}\frac{\partial u}{\partial \eta}\right|_{L_\infty[0T;L_2(\Gamma)]} \leqq C|g|_{H^{1,1}(\Sigma)}. \tag{4.5}$$

Combining (2.9), (4.5), and (4.3) yields

$$\left|\frac{\partial u_\varepsilon}{\partial \eta}\right|_{L_2(\Sigma)} + |u_\varepsilon|_{L_2(\Sigma)} \leqq C|g|_{H^{1,1}(\Sigma)}. \tag{4.6}$$

Going back to (4.2) and making use of (4.6) provides us with the estimate

$$|u_\varepsilon|_{L_2[0T;H^1(\Gamma)]} \leqq C\left[|g|_{L_2[0T;H^1(\Gamma)]} + \left|\frac{\partial u_\varepsilon}{\partial \eta}\right|_{L_2(\Sigma)}\right] \leqq C|g|_{H^{1,1}(\Sigma)}. \tag{4.7}$$

Formulae (4.6) and (4.7) yield the desired result stated in (2.10).

Finally we shall prove (2.11). Indeed, since $\beta[u_\varepsilon - g]|_\Gamma = \varepsilon(\partial u\varepsilon/\partial \eta)$, (2.11) follows from

$$|u_\varepsilon - g|_{L_2[0T;H^2(\Gamma)]} \leqq C|\beta(u_\varepsilon - g)|_{L_2(\Sigma)} \leqq C\varepsilon\left|\frac{\partial u_\varepsilon}{\partial \eta}\right|_{L_2(\Sigma)} \leqq C\varepsilon|g|_{H^{1,1}(\Sigma)},$$

where in the last inequality again we have used (4.6).

Next we prove part (ii) of the theorem for $s = 2$. Set $p \equiv \dot{u}_\varepsilon$ where u_ε satisfies (1.2) with $g \in H^{2,2}(\Sigma)$. Then

$$\ddot{p} = \Delta p, \quad p(0) = \dot{p}(0) = 0, \quad \varepsilon\frac{\partial p}{\partial \eta} + \beta p = \beta \dot{g}. \tag{4.8}$$

Formulae (2.9), (2.10) applied to (4.8) yield

$$|\dot{u}_\varepsilon|_{C[0T;H^1(\Omega)]} + |\ddot{u}_\varepsilon|_{C[0T;L_2(\Omega)]} + |\dot{u}_\varepsilon|_{H^{1,1}(\Sigma)} + \left|\frac{\partial \dot{u}_\varepsilon}{\partial \eta}\right|_{L_2(\Sigma)} \leqq C|g|_{H^{2,2}(\Sigma)}. \tag{4.9}$$

Therefore we have a situation where

$$\Delta u_\varepsilon = \ddot{u}_\varepsilon \in C[0T;\, L_2(\Omega)], \qquad \varepsilon\frac{\partial u_\varepsilon}{\partial \eta} + \beta u_\varepsilon = \beta g, \quad g \in H^{2,2}(\Sigma).$$

We write

$$u_\varepsilon = A_\varepsilon^{-1}(\ddot{u}_\varepsilon) + N_\varepsilon g. \tag{4.10}$$

By the virtue of (3.4) and (3.11) applied to (4.10) we obtain

$$|u_\varepsilon|_{L_\infty[0T;H^2(\Omega)]} \leqq C[|\ddot{u}_\varepsilon|_{L_\infty[0T;L_2(\Omega)]} + |g|_{L_\infty[0T;H^{3/2}(\Gamma)]}]. \tag{4.11}$$

On the other hand, we have

$$|g|_{L_\infty[0T;H^{3/2}(\Gamma)]} \leqq C|g|_{H^{2,2}(\Sigma)} \quad \text{(see [LM, Thm. 3.1, p. 19])}. \tag{4.12}$$

Combining (4.9), (4.11), and (4.12) yields

$$|u_\varepsilon|_{L_\infty[0T;H^2(\Omega)]} \leqq C|g|_{H^{2,2}(\Sigma)}, \tag{4.13}$$

which together with (4.9) completes the proof of (2.12) with $s = 2$.

To show (2.13), in view of (4.9), it is enough to establish the following estimate:

$$\left|\frac{\partial u_\varepsilon}{\partial \eta}\right|_{L_2[0T;H^1(\Omega)]} + |u_\varepsilon|_{L_2[0T;H^2(\Gamma)]} \leqq C|g|_{H^{2,2}(\Sigma)}. \tag{4.14}$$

To accomplish this, let us introduce the operator $T=\sum_{ij=1}^{n} t_i(x)(\partial/\partial x_i)$ where the coefficients $t_i(x)$ are smooth on $\bar{\Omega}$ and T is tangential to the boundary Γ (i.e., $\sum_{i=1}^{n} t_i(x)n_i(x)=0$ $x\in\Gamma$). Proving (4.14) is equivalent to showing that

$$\left|\frac{\partial}{\partial\eta}Tu_\varepsilon\right|_{L_2(\Sigma)}+|Tu_\varepsilon|_{L_2[0T;H^1(\Gamma)]}\leqq C|g|_{H^{1,1}(\Sigma)}. \tag{4.15}$$

Setting $p\equiv Tu_\varepsilon$ gives

$$\begin{aligned}&\text{(i)}\quad \ddot{p}=\Delta p+[\Delta, T]u_\varepsilon,\\ &\text{(ii)}\quad p(0)=\dot{p}(0)=0,\\ &\text{(iii)}\quad \varepsilon\frac{\partial p}{\partial\eta}+\beta p=\beta\beta^{-1}\left[[T,\beta]u_\varepsilon+\varepsilon\left[T,\frac{\partial}{\partial\eta}\right]u_\varepsilon+T\beta g\right]\end{aligned} \tag{4.16}$$

where $[A, B]$ stands for the commutator between operators A and B. Since T is a first order differential operator, we have

$$|[\Delta, T]u_\varepsilon|_{L_1[0T;L_2(\Omega)]}\leqq C|u_\varepsilon|_{L_1[0T;H^2(\Omega)]}\leqq C|g|_{H^{2,2}(\Sigma)} \tag{4.17}$$

where in the last inequality we have used (4.13).

Next we shall estimate all three terms on the right-hand side of (4.16)(iii).

$$\begin{aligned}|\beta^{-1}[T,\beta]u_\varepsilon|_{H^{1,1}(\Sigma)}&\leqq C[|[T,\beta]u_\varepsilon|_{L_2[0T;H^{-1}(\Gamma)]}+|[T,\beta]u_\varepsilon|_{L_2[0T;H^{-2}(\Gamma)]}]\\ &\leqq C[|u_\varepsilon|_{L_2[0T;H^1(\Gamma)]}+|u_\varepsilon|_{L_2(\Sigma)}]\\ &\leqq C|g|_{H^{1,1}(\Sigma)}\end{aligned} \tag{4.18}$$

where in the last inequality we have used (2.10)

$$\begin{aligned}\left|\beta^{-1}\left[T,\frac{\partial}{\partial\eta}\right]u_\varepsilon\right|_{H^{1,1}(\Sigma)}&\leqq C\left|\left[T,\frac{\partial}{\partial\eta}\right]u_\varepsilon\right|_{L_2[0T;H^{-1}(\Gamma)]}+\left|\left[T,\frac{\partial}{\partial\eta}\right]u_\varepsilon\right|_{L_2[0T;H^2(\Gamma)]}\\ &\leqq C\left[\left|\frac{\partial}{\partial\eta}u_\varepsilon\right|_{L_2(\Sigma)}+|u_\varepsilon|_{L_2(\Sigma)}+\left|\frac{\partial}{\partial\eta}u_\varepsilon\right|_{L_2(\Sigma)}+|u_\varepsilon|_{L_2(\Sigma)}\right]\\ &\leqq C|g|_{H^{2,2}(\Sigma)}.\end{aligned} \tag{4.19}$$

$$|\beta^{-1}T\beta g|_{H^{1,1}(\Sigma)}\leqq C|\beta^{1/2}g|_{H^{1,1}(\Sigma)}\leqq C|g|_{H^{2,2}(\Sigma)}. \tag{4.20}$$

Formula (4.16) can now be rewritten as

$$\ddot{p}=\Delta p+F,\quad p(0)=\dot{p}(0)=0,\quad \varepsilon\frac{\partial p}{\partial\eta}+\beta p=\beta G \tag{4.21}$$

where by (4.17)-(4.20) we have

$$|F|_{L_1[0T;L_2(\Omega)]}\leqq C|g|_{H^{2,2}(\Sigma)},\qquad |G|_{H^{1,1}(\Sigma)}\leqq C|g|_{H^{2,2}(\Sigma)}.$$

Thus we are in a position to apply the estimates (2.10), (2.4),and (2.5) to (4.21). This yields

$$\left|\frac{\partial p}{\partial\eta}\right|_{L_2(\Sigma)}+|p|_{L_2[0T;H^1(\Gamma)]}\leqq C|g|_{H^{2,2}(\Sigma)}$$

which is precisely (4.15). Thus the proof of (2.13) is completed. As for (2.14), we simply write

$$u_\varepsilon-g=\varepsilon\beta^{-1}\frac{\partial u}{\partial\eta}.$$

Formula (2.14) now follows from (2.13). Thus we have proved (2.12)-(2.14) for $s=2$. The proof of these statements for all integer values of s greater than two follows along the same line as for $s=2$. The results for $s \geqq 1$, s-real, can be easily obtained via interpolation. □

5. Proof of Theorem 2.4. Let u_ε be the solution to (1.2) with $g=0$. From (2.4) in particular we have

$$\left|\frac{\partial u_\varepsilon}{\partial \eta}\right|_{L_2(\Sigma)} \leqq C|f|_{L_1[0T;L_2(\Omega)]}.$$

Formula (2.15)(i) now follows after noticing that $u_\varepsilon|_\Gamma = -\varepsilon\beta^{-1}(\partial u/\partial\eta)$ and

$$|\beta^{-1}u|_{H^2(\Gamma)} \leqq C|u|.$$

As for (2.15)(ii), we set

$$z \equiv u_\varepsilon - u \text{ where } u \text{ satisfies (1.1) with } g=0.$$

Then

$$\ddot{z} = \Delta z, \quad z(0)=\dot{z}(0)=0, \quad \varepsilon\frac{\partial z}{\partial\eta}+\beta z = -\varepsilon\frac{\partial u}{\partial\eta}. \tag{5.1}$$

Formula (2.7) applied to (5.1) yields

$$|z|_{C[0T;L_2(\Omega)]} \leqq C\varepsilon\left|\frac{\partial u}{\partial\eta}\right|_{L_2(\Sigma)} \leqq C\varepsilon|f|_{L_1[0T;L_2(\Omega)]}$$

where in the last inequality we have used (2.2).

To establish (2.16) we shall need the following lemma.

LEMMA 5.1. *Let u_ε be the solution to* (1.2) *with $g\equiv 0$. Then for any $f\in L_1[0T;\ L_2(\Omega)]$ we have $\dot{u}_\varepsilon|_\Gamma \to 0$ in $L_2(\Sigma)$.*

Proof. To prove the lemma, in view of (2.4), it is enough to show that for f in some dense set $\mathcal{F}\in L_1[0T;\ L_2(\Omega)]$ we have

$$\dot{u}_\varepsilon \to 0 \quad \text{in } L_2(\Sigma). \tag{5.2}$$

To this end let $\mathcal{F}\equiv\{f\in H^1[0T;\ L_2(\Omega)],\ f(0)=0\}$, dense set in $L_1[0T;\ L_2(\Omega)]$.

If u_ε satisfies (1.2) with $g\equiv 0$ and the right-hand side of the equation is equal to f, then $p=\dot{u}_\varepsilon$ and $\tilde{f}\equiv\dot{f}$ satisfy

$$\ddot{p} = \Delta p + \tilde{f}, \quad p(0)=\dot{p}(0)=0, \quad \varepsilon\frac{\partial p}{\partial\eta}+\beta p = 0. \tag{5.3}$$

Energy estimate (2.5) applied to (5.3) yields

$$|p|_{C[0T;H^1(\Gamma)]} \leqq C\sqrt{\varepsilon}|\tilde{f}|_{L_1[0T;L_2(\Omega)]} \leqq C\sqrt{\varepsilon}|f|_{H^1[0T;L_2(\Omega)]}.$$

This proves that for $f\in\mathcal{F}$, $\dot{u}_\varepsilon\to 0$ in $C[0T;\ H^1(\Gamma)]$, hence in particular (5.2). □

To continue with the proof of Theorem 2.4 let us define $z\equiv u_\varepsilon - u$ where u_ε (respectively, u) satisfy (1.2) (respectively, (1.1)) with $g\equiv 0$. Then

$$\ddot{z} = \Delta z, \quad z(0)=z(0)=0, \quad \varepsilon\frac{\partial}{\partial\eta}z+\beta z = -\varepsilon\frac{\partial u}{\partial\eta}. \tag{5.4}$$

Multiplying (5.4) by $\dot{z}$ and integrating over Q leads to

$$\begin{aligned} &|\dot{z}|^2_{L_\infty[0T;L_2(\Omega)]}+|z|^2_{L_\infty[0T;H^1(\Omega)]}+\frac{1}{\varepsilon}|z|^2_{L_\infty[0T;H^1(\Gamma)]} \\ &\leqq 2\left|\frac{\partial u}{\partial\eta}\right|_{L_2(\Sigma)}|\dot{z}|_{L_2(\Sigma)} = 2\left|\frac{\partial u}{\partial\eta}\right|_{L_2(\Sigma)}|\dot{u}_\varepsilon|_{L_2(\Sigma)}. \end{aligned} \tag{5.5}$$

Application of Lemma 5.1 to (5.5), combined with the usual density argument, leads to the conclusion (2.16).

Statement (2.17) (i) is the same as that of Lemma 5.1. To prove (2.17)(ii) we argue as in the step (ii) of the proof of Theorem 2.3. In fact, multiplying (5.4) by $\Delta z\,\mathbf{h}$, integrating over Q and using the same arguments as step (ii) of Theorem 2.3 leads to

$$\left|\frac{\partial z}{\partial \eta}\right|^2_{L_2(\Sigma)} + |z|^2_{L_2(\Sigma)} \leqq C[|z|^2_{L_\infty[0T;H^1(\Omega)]} + |\dot z|^2_{L_\infty[0T;L_2(\Omega)]} + |z|^2_{L_2[0T;H^1(\Gamma)]}]. \tag{5.6}$$

Formula (2.17)(ii) now follows from (2.16) and (2.15)(i) applied to (5.6) (since $z|\Gamma = u^\varepsilon|\Gamma$). To complete the proof of the theorem we need to establish (2.18) and (2.19).

Proof of (2.18). Let $z \equiv u_\varepsilon - u$ where u_ε (respectively, u) satisfies (1.2) (respectively, (1.1)) with $f = 0$ and $g \in H^{1,1}(\Sigma)$. Then

$$\ddot z = \Delta z, \quad z(0) = \dot z(0) = 0, \quad \varepsilon\frac{\partial z}{\partial \eta} + \beta z = -\varepsilon\frac{\partial u}{\partial \eta} = -\varepsilon\beta\beta^{-1}\frac{\partial u}{\partial \eta}. \tag{5.7}$$

Since by (2.2)

$$\left|\beta^{-1}\frac{\partial u}{\partial \eta}\right|_{L_2(\Sigma)} \leqq C\left|\frac{\partial u}{\partial \eta}\right|_{L_2(\Sigma)} \leqq C|g|_{H^{1,1}(\Sigma)},$$

the application of formula (2.7) of Theorem 2.2 gives

$$|z|_{C[0T;L_2(\Omega)]} \leqq C\varepsilon\left|\beta^{-1}\frac{\partial u}{\partial \eta}\right|_{L_2(\Sigma)} \leqq C\varepsilon|g|_{H^{1,1}(\Sigma)}$$

which is precisely the statement (2.18). Formula (2.19) can be deduced from (2.18) and (2.7) followed by the standard density argument. The proof of Theorem 2.4 is thus completed. □

THE SOLUTION OF THE RIEMANN PROBLEM FOR A HYPERBOLIC SYSTEM OF CONSERVATION LAWS MODELING POLYMER FLOODING*

THORMOD JOHANSEN† AND RAGNAR WINTHER‡

Abstract. The global Riemann problem for a nonstrictly hyperbolic system of conservation laws modeling polymer flooding is solved. In particular, the system contains a term that models adsorption effects.

Key words. Riemann problem, polymer flooding, adsorption

AMS(MOS) subject classifications. 35L65, 76S05

1. Introduction. In this paper we solve the global Riemann problem for the mathematical model

$$\begin{aligned} &s_t + f(s, c)_x = 0, \\ &[sc + a(c)]_t + [f(s, c)c]_x = 0, \end{aligned} \tag{1.1}$$

where $t \in \mathbf{R}^+$, $x \in \mathbf{R}$, the state vector $(s, c) \in I \times I$ and $f: I \times I \to \mathbf{R}$ and $a: I \to \mathbf{R}$ are smooth functions. Here I denotes the unit interval $I = [0, 1]$. More precise assumptions on the functions f and a will be given in § 2.

Our results generalize the results of Isaacson [6], where the Riemann problem for (1.1) is solved with the term $a(c)$ neglected. In this simplified case the solution of the Riemann problem can also be derived from the analysis given by Keyfitz and Kranzer [7].

We note that when c is constant, (1.1) reduces to the single equation

$$s_t + f(s)_x = 0, \tag{1.2}$$

which in the petroleum literature is known as the Buckley–Leverett equation.

The model (1.1) arises in connection with enhanced oil recovery, for example when oil is displaced in a porous rock by water containing dissolved polymer. The variable s is the saturation of the mixture of water and polymer, which we call the aqueous phase. The variable c is the concentration of polymer in the aqueous phase. Furthermore, f describes the fractional flow of the aqueous phase, which is assumed to be immiscible with oil. The function $a(c)$ models adsorption of the polymer on rock.

Some other processes governed by (1.1) are discussed by Pope in [9], where detailed physical assumptions for the model are also discussed.

The derivation of (1.1) is based on material balance considerations. We assume that the fluids and the rock are incompressible, and that volumes do not change when polymer is dissolved in water. Assuming one-dimensional flow in a homogeneous medium, the mass conservation of water, oil, and polymer, respectively, can be formulated as follows:

$$\phi s_t + v_x = 0, \tag{1.3a}$$

$$\phi s_t^0 + v_x^0 = 0, \tag{1.3b}$$

$$\phi[sc + a(c)]_t + [vc]_x = 0, \tag{1.3c}$$

where ϕ is the rock porosity, s^0 is the oil saturation and v and v^0 denote the volumetric flow rates of the aqueous phase and oil, respectively. Neglecting gravity, capillarity and dispersion, we get v and v^0 by Darcy's law as follows:

$$v = -\lambda p_x, \qquad \lambda = -\frac{Kk}{\mu}, \tag{1.4a}$$

$$v^0 = -\lambda^0 p_x, \qquad \lambda^0 = -\frac{Kk^0}{\mu^0}. \tag{1.4b}$$

Here, p is the fluid pressure, K is the absolute permeability of the rock, $k = k(s, c)$ and $k^0 = k^0(s)$ are the relative permeabilities of the aqueous phase and oil, respectively, and μ, μ^0 are the corresponding viscosities.

Since $s^0 + s \equiv 1$, summation of (1.3a) and (1.3b) gives

$$v^T \equiv v^0 + v = \text{constant} \tag{1.5}$$

where the value of total volumetric flow rate v^T is determined from the boundary conditions. By elimination of the pressure p using (1.4a), (1.4b), and (1.5), the equations (1.3a) and (1.3b) can be rewritten in the form

$$\phi s_t + v^T f_x = 0, \tag{1.6a}$$

$$\phi[sc + a(c)]_t + v^T[fc]_x = 0, \tag{1.6b}$$

which together with (1.5) constitutes the model. Here $f = f(s, c)$ denotes the fractional flow function given by

$$f = \frac{\lambda}{\lambda + \lambda^0}. \tag{1.7}$$

The dependence on s is inherited from the relative permeability functions k and k^0 while the dependence on c is primarily introduced through the viscosity $\mu = \mu(c)$ of the aqueous phase.

If L denotes the length of the medium, a simple coordinate transformation

$$x' = \frac{x}{L} \quad \text{and} \quad t' = \frac{v^T t}{\phi L}$$

results in (1.1), when the primes on x', t' are dropped.

The model (1.1) is an example of a system of hyperbolic conservation laws. The main result of this paper is the construction of a unique global solution of the Riemann problem for the system (1.1); i.e., we construct a weak solution of the pure initial value problem for (1.1) with initial condition

$$(s, c)(x, 0) = \begin{cases} (s^L, c^L) & \text{if } x < 0, \\ (s^R, c^R) & \text{if } x > 0, \end{cases} \tag{1.8}$$

where the left and right states (s^L, c^L) and (s^R, c^R) in $I \times I$ are arbitrary. In order to distinguish the physically meaningful weak solutions we will also require that the solution satisfies an "entropy condition." This condition will be derived by demanding that the solution is evolutionary; i.e., any discontinuity of the solution is a limit of smooth solutions of associated "viscosity systems." The solution of the Riemann problem in general depends only on the ratio x/t and it will be constructed by connecting constant states, smooth solutions (or rarefaction waves) and discontinuous solutions (or shock waves).

In addition to being analytical solutions of the system, solutions of the Riemann problem can also be used as building blocks for the construction of numerical methods for (1.1). Examples of this are the Random Choice Method [1], [2], [4], and Godunov's method [5]. Unfortunately, for many hyperbolic systems no global solution of the Riemann problem has yet been found. A general theory for local existence and uniqueness of solution is described in [4], [8], or [11] under the condition of strict hyperbolicity of the system. However, this condition will not be satisfied in the analysis of (1.1) given below.

In the case of the single Buckley–Leverett equation (1.2) (i.e., when c is constant) the solution of the Riemann problem is well known (cf. [3], [8] and § 4 below for a precise formulation of the entropy condition in this case). Assume for example that $s^L < s^R$ and let $g(s) = (d/ds)f_L(s)$, where f_L is the lower convex envelope of f with respect to the interval $[s^L, s^R]$. The unique solution of the Riemann problem is then given by

$$s(x,t) = \begin{cases} s^L & \text{if } x/t < g(s^L), \\ s & \text{if } x/t = g(s), \\ s^R & \text{if } x/t > g(s^R), \end{cases} \tag{1.9}$$

where we adopt the convention that if $g(s) = \sigma$ on a maximal interval (s^1, s^2), with $s^1 < s^2$, then this corresponds to a discontinuity at $x = \sigma t$ with $s(\sigma t-, t) = s^1$ and $s(\sigma t+, t) = s^2$. Similarly, if $s^R < s^L$ the unique solution of the Riemann problem is again given by (1.9), where in this case $g(s) = (d/ds)f_U(s)$ is the derivative of the upper concave envelope f_U of f with respect to $[s^R, s^L]$. The solution of the Riemann problem for (1.2) given above will be a fundamental part of the solution of the Riemann problem for the system (1.1) constructed in this paper.

The main difference between the present paper and [6] is that the adsorption term $a(c)$ has been included in the model here. The effect of this term is that the linearly degenerate characteristic field appearing in the analysis in [6] (and [7]) is replaced by a nondegenerate field. The contact discontinuities in the Riemann solution given in [6] will therefore be replaced by either proper rarefaction waves or proper shock waves. As a consequence, both the state space solution and the x, t-space solution of the Riemann problem are unique. This is in contrast to [6], where the solution is unique in x, t-space, but not in state space. Also, in [6] the Lax entropy inequalities were used as the entropy condition for the system. In this paper we derive entropy conditions from traveling wave analysis and we conclude that, in general, the Lax inequalities are not the correct entropy condition for the system. In particular, we derive an admissible shock wave where both characteristics on both sides of the shock enter the shock. Such shock waves are referred to as overcompressive shocks by Schaeffer and Shearer [10]. However, this wave cannot be joined to any other wave in a Riemann solution.

The construction of the solution of the Riemann problem for the model (1.1) given below shows that if the solution is considered pointwise, it is discontinuous with respect to the left and right states for certain critical values of the left and right states. However, the solution is continuous in L^1 norm (cf. Example 8.2). This property is similar to properties of Riemann solutions of the nonstrictly hyperbolic systems studied in, e.g., [6], [7], and [10].

The precise assumptions on the system (1.1) are stated in § 2. The simple rarefaction waves are derived in § 3, while § 4 is devoted to shock waves and entropy conditions. In § 5 we formulate the general Riemann problem in terms of rarefaction waves and shock waves and state the main result of the paper. The proof is given in §§ 6 and 7.

In § 8 we present some numerical experiments. One of the purposes of these experiments is to show that the behavior of the exact solution of the Riemann problem is not easily detected from calculations done by standard finite difference schemes.

2. A precise formulation of the model. We recall that our model for the polymer process is the following 2×2 system of conservation laws:

$$\begin{aligned} &s_t + f(s, c)_x = 0, \\ &(sc + a(c))_t + (cf(s, c))_x = 0, \end{aligned} \tag{2.1}$$

where the unknown functions are $s = s(x, t)$ and $c = c(x, t)$. Throughout the paper we will assume that the real-valued function $f = f(s, c)$ is a smooth function for $(s, c) \in I \times I$, where $I = [0, 1]$, with the following properties (cf. Fig. 2.1):

(i) $f(0, c) \equiv 0$, $f(1, c) \equiv 1$;

(ii) $f_s(s, c) > 0$ for $0 < s < 1$, $0 \leqq c \leqq 1$;

(iii) $f_c(s, c) < 0$ for $0 < s < 1$, $0 \leqq c \leqq 1$;

(iv) For each $c \in I$, $f(\cdot, c)$ has a unique point of inflection, $s^I = s^I(c) \in (0, 1)$, such that $f_{ss}(s, c) > 0$ for $0 < s < s^I$ and $f_{ss}(s, c) < 0$ for $s^I < s < 1$.

The function $a = a(c)$, which models the adsorption effects of the process, is assumed to be a smooth function of $c \in I$ such that (cf. Fig. 2.2):

(i) $a(0) = 0$;

(ii) $h(c) = (da/dc)(c) > 0$ for $0 < c < 1$;

(iii) $(dh/dc)(c) = (d^2a/dc^2)(c) < 0$ for $0 < c < 1$.

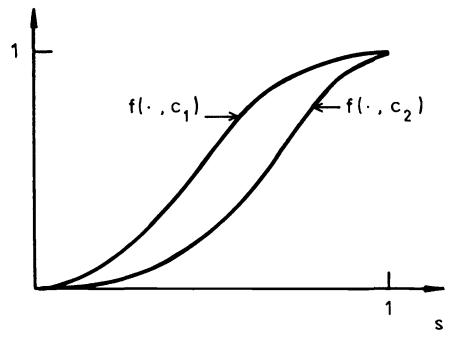

FIG. 2.1. $c_1 < c_2$.

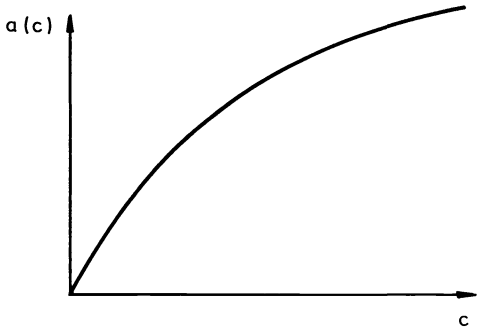

FIG. 2.2

Let u denote the state vector $u=(s, c)$. The system (2.1) may be reformulated in the form

$$u_t + A(u)u_x = 0,$$

where $A(u)=A(s, c)$ is the upper triangular 2×2 matrix

$$A(s, c)=\begin{bmatrix} f_s(s, c) & f_c(s, c) \\ 0 & \dfrac{f(s, c)}{s+h(c)} \end{bmatrix}. \tag{2.2}$$

The eigenvalues of A are $\lambda^s = f_s$ and $\lambda^c = f/(s+h)$, with corresponding eigenvectors $e^s=(1, 0)$, $e^c=(f_c, \lambda^c-\lambda^s)$ if $0<s<1$ and $e^c=(0, 1)$ if $s=0, 1$.

We observe (cf. Figs. 2.3, 2.4) that for each $c\in I$ there is at most one $s^T=s^T(c)\in I$ such that

$$\lambda^c(s^T, c)=\lambda^s(s^T, c). \tag{2.3}$$

Throughout the paper we will assume that there exists a unique $c^T\in I$ such that (2.3) has a unique solution $s^T(c)$ for $0\leqq c\leqq c^T$ and that (2.3) has no solution for $c^T<c\leqq 1$ (cf. Figs. 2.5, 2.6). We let T denote the transition curve

$$T=\{(s, c)\,|\,0\leqq c\leqq c^T,\ s=s^T(c)\}$$

and $\mathscr{L}$ and $\mathscr{R}$ the regions

$$\mathscr{L}=\{(s, c)\in I\times I\,|\,\lambda^s>\lambda^c\},\qquad \mathscr{R}=\{(s, c)\in I\times I\,|\,\lambda^c>\lambda^s\}.$$

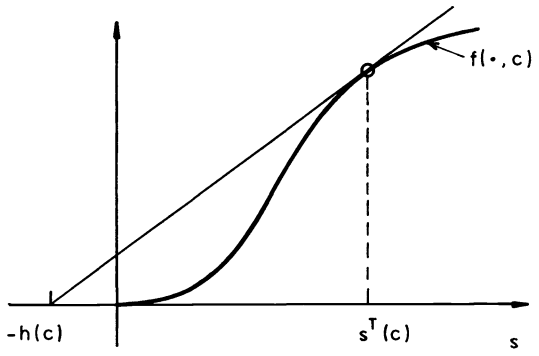

FIG. 2.3. $s^T(c)$ *exists.*

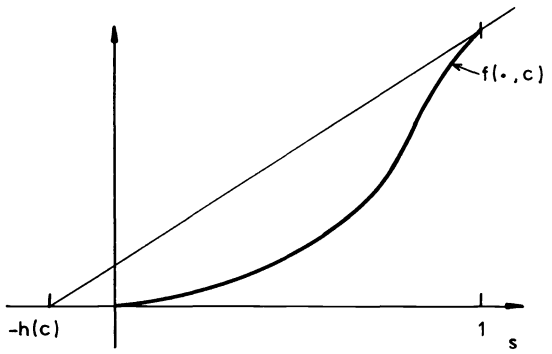

FIG. 2.4. *No* $s^T(c)$.

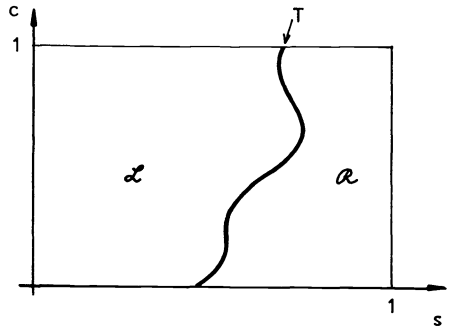

FIG. 2.5. $c^T = 1$.

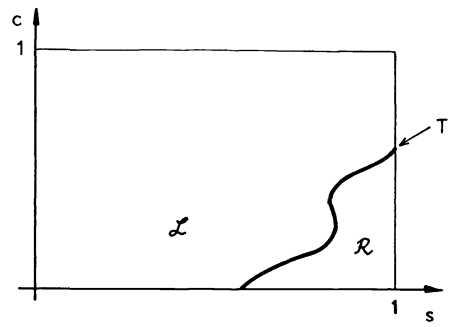

FIG. 2.6. $c^T < 1$.

We observe that if $(s, c) \in T$ and $0 < s < 1$, then $\lambda^s = \lambda^c$ and the two eigenvectors e^s and e^c become linearly dependent. Hence, in this case the matrix A given by (2.2) is not diagonalizable.

3. Rarefaction waves. The purpose of this section is to determine the simple rarefaction waves of the system (1.1). Hence, for two given states $u^L = (s^L, c^L)$ and $u^R = (s^R, c^R)$ we derive possible continuous solutions of the pure initial value problem for (1.1) with initial data

$$u(x, 0) = \begin{cases} u^L & \text{if } x < 0, \\ u^R & \text{if } x > 0. \end{cases} \tag{3.1}$$

Let λ be an eigenvalue of the matrix A given by (2.2) with corresponding eigenvector e. The simple rarefaction waves are continuous solutions of (1.1) and (3.1) of the form

$$u(x, t) = v(x/t),$$

where v corresponds to an integral curve of the vector field e. More precisely,

$$u(x, t) = \begin{cases} u^L & \text{if } x/t < \lambda(u^L), \\ v & \text{if } x/t = \lambda(v), \\ u^R & \text{if } x/t > \lambda(u^R), \end{cases} \tag{3.2}$$

where v is an integral curve of the vector field e connecting the states u^L and u^R with the additional property that the eigenvalue λ is increasing from u^L to u^R. Since the

matrix A has two eigenvalues, λ^s and λ^c, there are two possible rarefaction curves through any given state u^L.

s-rarefaction waves. If $\lambda = \lambda^s$ and $e = e^s = (1, 0)$ the integral curves of e are the curves where c is constant. Hence, a simple rarefaction wave of the form (3.2) exists if $c^L = c^R$ and if $\lambda^s = f_s(s, c^L)$ is increasing from s^L to s^R. This, of course, corresponds to a simple rarefaction wave of the Buckley–Leverett equation (1.2) with $f(s) = f(s, c^L)$. Such rarefaction waves will be referred to as s-rarefaction waves.

c-rarefaction waves. Next we consider the case when $\lambda = \lambda^c$. First assume that $0 < s < 1$. In this case $f_c < 0$, the eigenvector e^c can be taken to be $(f_c, \lambda^c - \lambda^s)$, and the rarefaction curves are determined by the differential equation

$$f_c \frac{dc}{ds} = \lambda^c - \lambda^s, \tag{3.3}$$

where $c = c(s)$. Hence, $dc/ds > 0$ in region $\mathscr{L}$, $dc/ds < 0$ in $\mathscr{R}$ and $dc/ds = 0$ on the transition curve T. Furthermore, by differentiating (3.3) with respect to s we also obtain

$$f_c \frac{d^2c}{ds^2} = -f_{ss}$$

when $(s, c(s)) \in T$. Hence, $d^2c/ds^2 < 0$ on T. As a consequence, any rarefaction curve can at most intersect the transition curve T in one point (cf. Fig. 3.1).

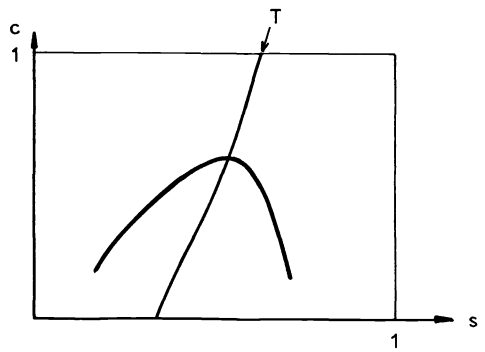

FIG. 3.1. *Rarefaction curve.*

Next consider $g(s) = \lambda^c(s, c(s))$, where $c(s)$ satisfies (3.3). A straightforward differentiation shows that

$$\frac{dg}{ds} = \frac{(f_s + f_c(dc/ds))(s+h) - f(1 + (dh/dc)(dc/ds))}{(s+h)^2}$$

or

$$\frac{dg}{ds}(s) = -\frac{(dh/dc)(c(s))(dc/ds)(s)}{(s + h(c(s)))^2} f(s, c(s)).$$

Since $(dh/dc)(c) < 0$ the eigenvalue $\lambda^c(s, c(s))$ is an increasing function of s in $\mathscr{L}$ and decreasing in $\mathscr{R}$. Hence, a simple rarefaction wave of the form (3.2) exists if and only if there is an integral curve of (3.3) connecting u^L and u^R with the additional property that c is increasing all the way from u^L and u^R (cf. Fig. 3.2). In particular this implies that such a simple c-rarefaction wave never exists when u^L and u^R are located on opposite sides of the transition curve T.

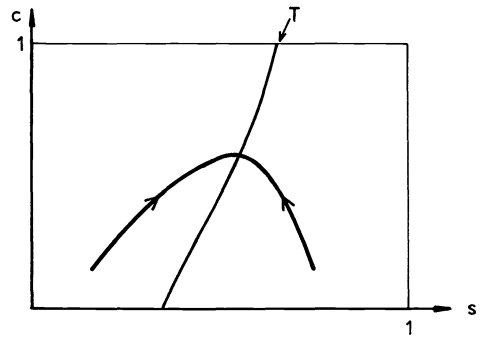

FIG. 3.2. *Rarefaction waves for* $0 < s < 1$.

Finally, consider the case when $s = 0$ or $s = 1$. Then $f_c = 0$ and the eigenvector e^c can be taken to be $(0, 1)$. Hence, the rarefaction curves are given by $s \equiv 0$ or $s \equiv 1$. If $s \equiv 1$ the eigenvalue λ^c is given by

$$\lambda^c(1, c) = \frac{1}{1+h(c)},$$

which is a strictly increasing function of c. Therefore, if $c^L < c^R$ this corresponds to a simple rarefaction wave. Particularly, if $c^T < 1$ (cf. § 2), such a c-rarefaction curve can connect states that are located on opposite sides of the transition curve T. If $s \equiv 0$ the eigenvalue $\lambda^c \equiv 0$. Hence, these "rarefaction curves" correspond to contact discontinuities with speed zero. In order to solve the general Riemann-problem for arbitrary states in $I \times I$ we will allow such discontinuities for arbitrary c^L and c^R in I. We remark however that these solutions are in some sense nonphysical, since states with $s = 0$ and $c > 0$ have no physical interpretation. We will refer to these discontinuities as c-rarefaction waves if $c^L < c^R$ and as c-shock waves if $c^L > c^R$ (cf. § 4).

4. Shock waves and entropy conditions. The purpose of this section is to determine the shock waves of the system (1.1); i.e., for given states $u^L = (s^L, c^L)$ and $u^R = (s^R, c^R)$ we derive possible discontinuous weak solutions of the system (1.1) of the form

$$u(x, t) = \begin{cases} u^L & \text{if } x/t < \sigma, \\ u^R & \text{if } x/t > \sigma. \end{cases} \tag{4.1}$$

Here σ denotes the shock speed. In order to distinguish the physically meaningful weak solutions of (1.1) we will also require that u satisfies an "entropy condition." This condition will be derived by requiring the shock waves to be evolutionary; i.e., any shock wave must be a limit of traveling wave solutions of associated "viscosity systems."

Any weak solution of (1.1) of the form (4.1) has to satisfy the Rankine-Hugoniot condition given by

$$\begin{aligned} &f(s^R, c^R) - f(s^L, c^L) = \sigma(s^R - s^L), \\ &c^R f(s^R, c^R) - c^L f(s^L, c^L) = \sigma(s^R c^R + a(c^R) - s^L c^L - a(c^L)). \end{aligned} \tag{4.2}$$

Let us first observe that if $c^R = c^L$ then the two equations of (4.2) are identical. Hence, in this case (4.2) reduces to

$$f(s^R, c^L) - f(s^L, c^L) = \sigma(s^R - s^L), \tag{4.3}$$

which is the Rankine-Hugoniot condition for the Buckley-Leverett equation (1.2) with $f(s)=f(s, c^L)$. From the theory for this equation (cf. [11] and § 1) shock waves of the form (4.1), with $c^L=c^R$ and with s^L and s^R satisfying (4.3), are said to satisfy an entropy condition if and only if

$$[f(s)-f(s^L)-\sigma(s-s^L)]\,\text{sign}\,(s^R-s^L)\geqq 0 \tag{4.4}$$

for any s between s^L and s^R. These shock waves will be referred to as *s-shock waves* for the system (1.1). (We remark that the entropy condition (4.4) can be derived, in the same way as below, by requiring the shock wave to be evolutionary.)

The entropy condition (4.4) implies that

$$\lambda^s(u^L)>\sigma>\lambda^s(u^R),$$

and from the definition of λ^c it follows that either

$$\lambda^c(u^L),\ \lambda^c(u^R)\geqq\sigma$$

or

$$\lambda^c(u^L),\ \lambda^c(u^R)\leqq\sigma.$$

Hence, since exactly one characteristic enters the shock on both sides, the s-shock waves satisfy the celebrated Lax entropy condition (cf. [8] and [11]).

In the rest of this section we shall determine the shock waves with $c^L\neq c^R$. These shock waves will be referred to as *c-shock waves.*

By applying the first equation of (4.2), the second equation of (4.2) can be written in the form

$$(c^R-c^L)f(s^L, c^L)=\sigma(c^R-c^L)s^L+\sigma(a(c^R)-a(c^L)). \tag{4.5}$$

By introducing the quantity

$$h_L(c)=\begin{cases}\dfrac{a(c)-a(c^L)}{c-c^L} & \text{if } c\neq c_L,\\ h(c) & \text{if } c=c_L,\end{cases} \tag{4.6}$$

(4.5) can again be written as

$$\sigma=\frac{f(s^L, c^L)}{s^L+h_L(c_R)}.$$

By applying this final equality in the first equation of (4.2) we also obtain that

$$\sigma(s^R+h_L(c^R))=\sigma(s^L+h_L(c^R))+f(s^R, c^R)-f(s^L, c^L)=f(s^R, c^R).$$

Hence, when $c^L\neq c^R$ the Rankine-Hugoniot condition (4.2) can be written in the form

$$\frac{f(s^R, c^R)}{s^R+h_L(c^R)}=\frac{f(s^L, c^L)}{s^L+h_L(c^R)}=\sigma. \tag{4.7}$$

If $s^L=s^R=0$ this condition is satisfied with $\sigma=0$. As we have already seen in § 3 this corresponds to a contact discontinuity with speed zero. In the rest of the discussion we shall therefore assume that $\sigma>0$.

We observe that the value $h_L(c^R)$ is determined from values of c^L and c^R and that, if s^L, c^L and c^R are given, there are at most two values of s^R that satisfy the Rankine-Hugoniot condition (4.7) (cf. Fig. 4.1).

In order to distinguish the physically meaningful weak solutions of (1.1) we shall require that a shock wave be evolutionary. Hence, for any $\varepsilon>0$ we consider the perturbed system

$$\begin{aligned} &s_t+f(s, c)_x=\varepsilon s_{xx},\\ &(sc+a(c))_t+(cf(s, c))_x=\varepsilon(sc+a(c))_{xx}.\end{aligned} \tag{4.8}$$

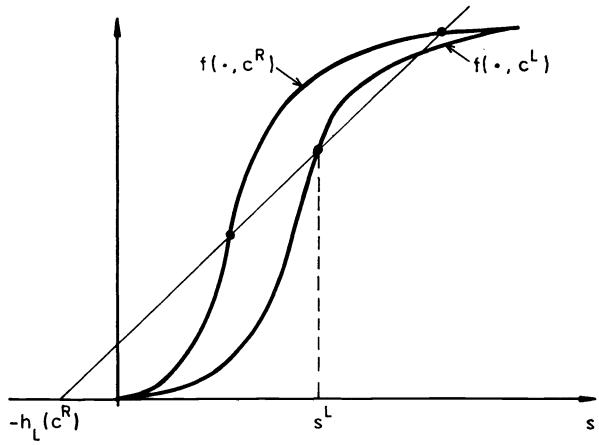

FIG. 4.1. $c^L > c^R$.

The entropy condition consists of requiring the shock wave to be a pointwise limit of traveling wave solutions of (4.8). In the same way as was done in, e.g., [7] or [11, Chap. 24], we obtain that two states $u^L = (s^L, c^L)$ and $u^R = (s^R, c^R)$, which satisfy the Rankine-Hugoniot condition (4.7) with shock speed σ, correspond to an evolutionary shock wave if and only if the 2×2 system

$$
\begin{aligned}
&\frac{ds}{d\xi} = f(s, c) - \sigma s - (f(s^L, c^L) - \sigma s^L), \\
&\frac{d}{d\xi}(sc + a(c)) = cf(s, c) - \sigma(sc + a(c)) - (c^L f(s^L, c^L) - \sigma(s^L c^L + a(c^L)))
\end{aligned} \tag{4.9}
$$

has a solution $(s(\xi), c(\xi))$ with $(s(-\infty), c(-\infty)) = u^L$ and $(s(+\infty), c(+\infty)) = u^R$. By applying (4.7) and by performing the differentiation in the second equation of (4.9) we rewrite the system in the form

$$
\begin{aligned}
&\frac{ds}{d\xi} = f(s, c) - \sigma(s + h_L(c^R)), \\
&(s + h(c))\frac{dc}{d\xi} = \sigma(c - c^L)(h_L(c^R) - h_L(c)),
\end{aligned} \tag{4.10}
$$

where $h_L(c)$ is defined by (4.6).

We observe that the Rankine-Hugoniot condition (4.7) implies that $u^L = (s^L, c^L)$ and $u^R = (s^R, c^R)$ are equilibrium points of (4.10). Since $\sigma > 0$ the second equation of (4.10) implies, in particular, that $dc/d\xi < 0$ for any value of c strictly between c^L and c^R. Therefore $c^L > c^R$. For the rest of this discussion we therefore assume that $c^L > c^R$.

Let us first assume that u^R is a state such that

$$\lambda^s(u^R) < \sigma.$$

Then there are at most two possible values of s^L, s^L_- and s^L_+ such that the Rankine-Hugoniot condition (4.7) holds where

$$\lambda^s(s^L_-, c^L) \geqq \sigma \quad \text{and} \quad \lambda^s(s^L_+, c^L) \leqq \sigma$$

(cf. Fig. 4.2).

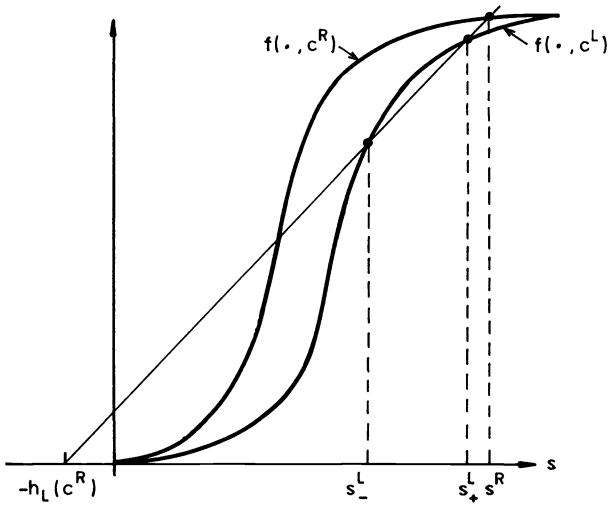

FIG. 4.2

Similarly, for any $c \in [c^R, c^L)$ let $s_-(c)$ and $s_+(c)$ be the two values determined by

$$\frac{f(s_-(c), c)}{s_-(c) + h_L(c^R)} = \sigma = \frac{f(s_+(c), c)}{s_+(c) + h_L(c^R)}$$

and

$$\lambda^s(s_-(c), c) > \sigma > \lambda^s(s_+(c), c).$$

Then $ds/d\xi < 0$ for $0 \leqq s < s_-(c)$ and $s_+(c) < s \leqq 1$, while $ds/d\xi > 0$ for $s_-(c) < s < s_+(c)$ (cf. Fig. 4.3).

It is now easy to see that any trajectory that passes through a point $(s_-(c), c)$, for some $c \in (c^R, c^L)$ has the properties

$$(s(-\infty), c(-\infty)) = (s_-^L, c^L) \quad \text{and} \quad (s(+\infty), c(+\infty)) = (s^R, c^R).$$

Furthermore, any trajectory through $(s_+(c), c)$, for some $c \in (c^R, c^L)$, is such that

$$(s(-\infty), c(-\infty)) = (+\infty, c^L) \quad \text{and} \quad (s(+\infty), c(+\infty)) = (s^R, c^R).$$

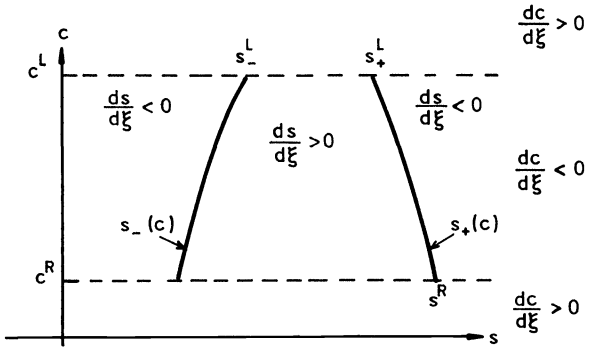

FIG. 4.3

Hence, by continuity, there must be at least one trajectory that separates the two classes and such a trajectory passes from (s_+^L, c^L) to u^R. Therefore we have seen that there exist trajectories from both the points (s_-^L, c^L) and (s_+^L, c^L) to u^R when $\lambda^s(u^R) < \sigma$.

Next consider the case when u^R satisfies

$$\lambda^s(u^R) > \sigma$$

(i.e., $s^R = s_-(c^R)$). By an argument similar to the one above we obtain the existence of a trajectory from (s_-^L, c^L) to u^R. However, if $u^L = (s_+^L, c^L)$ (i.e., $\lambda^s(u^L) < \sigma$) there exists no trajectory from u^L to u^R.

As a conclusion we obtain that two states $u^L = (s^L, c^L)$ and $u^R = (s^R, c^R)$, with $c^L \neq c^R$, correspond to a c-shock wave of speed σ if they satisfy the Rankine–Hugoniot condition (4.7) and if they satisfy the entropy conditions

$$c^L > c^R \tag{4.11}$$

and

$$\lambda^s(u^R) < \sigma \quad \text{or} \quad \lambda^s(u^L), \lambda^s(u^R) \geqq \sigma. \tag{4.12}$$

Since the function $h(c)$ is strictly decreasing, condition (4.7) implies that (4.11) is equivalent to the eigenvalue/shock speed relation

$$\lambda^c(u^L) > \sigma > \lambda^c(u^R).$$

Therefore, if

$$\lambda^s(u^L), \lambda^c(u^L) > \sigma > \lambda^s(u^R), \lambda^c(u^R),$$

we allow a shock wave where both characteristics on both sides of the shock enter the shock. This shock, which corresponds to $s^L = s_-^L$ and $s^R = s_+(c^R)$, is therefore a shock wave which does not satisfy the Lax entropy condition. We recall, that in the terminology of [10], this is an example of an overcompressive shock. In § 7 below we will discover that this shock cannot be joined by any other wave in a Riemann solution.

5. The Riemann problem. The purpose of the rest of this paper is to construct a unique global solution of the Riemann problem for the system (1.1); i.e., for arbitrary states $u^L, u^R \in I \times I$ we derive a solution of the pure initial value problem for (1.1) with initial condition

$$u(x, 0) = \begin{cases} u^L & \text{if } x < 0, \\ u^R & \text{if } x > 0, \end{cases} \tag{5.1}$$

which consists of a composition of a finite number of simple rarefaction waves and shock waves as described above.

If a left state u^1 can be connected to a right state u^2 by a simple rarefaction wave then the *initial speed* of the wave is $\lambda(u^1)$ and the *final speed* of the wave is $\lambda(u^2)$, where λ is the eigenvalue corresponding to the wave. The initial speed and the final speed of a simple shock wave is defined to be the shock speed σ.

By a *c-wave* we mean a simple c-rarefaction wave or a c-shock wave, while an *s-wave* is any composition of simple s-rarefaction waves and s-shock waves that corresponds to a solution of the Buckley–Leverett equation (1.2) with $f(s) = f(s, c)$ for some $c \in I$. We recall that for any left state $u^1 = (s^1, c)$ and right state $u^2 = (s^2, c)$, where $c \in I$, there is a unique s-wave that connects the two states (cf. the discussion in § 1).

Following [6] we will adopt the notation that $u^1 \xrightarrow{c} u^2$ means that the left state u^1 can be connected to the right state u^2 by a c-wave and we refer to this Riemann solution as $u^1 \xrightarrow{c} u^2$. The notation $u^1 \xrightarrow{s} u^2$ has the analogous meaning for s-waves.

Consider two waves $u^1 \xrightarrow{a} u^2$ and $u^2 \xrightarrow{b} u^3$. Let v_f^a denote the final wave speed of the a-wave and v_i^b the initial wave speed of the b-wave. The two waves are said to be *compatible* if they can be composed to solve the Riemann problem with left state u^1 and right state u^3. Hence the two waves are compatible if and only if

$$v_f^a \leqq v_i^b, \tag{5.2}$$

where we require a strict inequality if both v_f^a and v_i^b are shock speeds. Any solution of the Riemann problem will consist of a sequence of compatible s-waves and c-waves that connects the given left state u^L with the given right state u^R.

The main purpose of this paper is to give a constructive proof of the following existence/uniqueness theorem.

THEOREM 5.1. *For arbitrary states u^L, $u^R \in I \times I$ there exists a unique finite sequence of compatible s-waves and c-waves that generates a solution of the Riemann problem with left state u^L and right state u^R.*

The rest of this paper is devoted to the proof of Theorem 5.1. The following lemma will guarantee that the solution of the Riemann problem is monotone with respect to c; i.e., the solution $u = (s, c)$ of the Riemann problem has the property that the function $c(x, t)$ is a monotone function of x for any $t \geqq 0$.

LEMMA 5.1. *Assume that the three waves*

$$u^L \xrightarrow{c_1} u^1 \xrightarrow{s} u^2 \xrightarrow{c_2} u^R$$

are compatible. Then both the c-waves are rarefaction waves.

Proof. Since the three waves are all compatible we obtain from (5.2) that

$$v_f^1 \leqq v_i^s \leqq v_f^s \leqq v_i^2, \tag{5.3}$$

where v_i^s and v_f^s denote the initial and final speed of the s-wave, respectively, v_f^1 is the final speed of the c_1-wave and v_i^2 is the initial speed of the c_2-wave.

Let $u^1 = (s^1, c)$ and $u^2 = (s^2, c)$ for a suitable $c \in I$ and define

$$\alpha = \frac{f(s^1, c) - f(s^2, c)}{s^1 - s^2}.$$

From the structure of the s-waves (cf. § 1) it follows that

$$v_i^s \leqq \alpha \leqq v_f^s.$$

Therefore, (5.3) implies that

$$v_f^1 \leqq \alpha \leqq v_i^2. \tag{5.4}$$

From §§ 3 and 4 we recall that v_f^1 and v_i^2 are of the form

$$v_f^1 = \frac{f(s^1, c)}{s^1 + h_1} \quad \text{and} \quad v_i^2 = \frac{f(s^2, c)}{s^2 + h_2},$$

where $h_1, h_2 > 0$.

By applying this in (5.4) the inequality can be rewritten in the form

$$h_2 \leqq \frac{f(s^1, c)}{\alpha} - s^1 \leqq h_1. \tag{5.5}$$

However, from (5.5) we immediately obtain the desired result. Assume for example that the c_1-wave is a shock wave and that the c_2-wave is a rarefaction wave. If $s^1 = 0$ (i.e., the c_1-wave is a contact discontinuity), $h_2 = h(c) > 0$ while (5.5) implies that $h_2 \leqq 0$. We can therefore assume that $s^1 > 0$. In this case

$$h_1 = h_L(c) = \frac{a(c) - a(c^L)}{c - c^L} \quad \text{and} \quad h_2 = h(c),$$

which implies that $h_1 < h_2$ since $c < c^L$ and h is strictly decreasing. But this contradicts (5.5). Similar arguments also show that the compositions where the c_1-wave is a rarefaction wave and the c_2-wave is a shock wave or where both c-waves are shock-waves are incompatible. Hence, the only possibility is that both the c-waves are rarefaction waves. In this case $h_1 = h_2 = h(c)$. □

Let $u^L = (s^L, c^L)$ and $u^R = (s^R, c^R)$ denote the left and right state, respectively, of the Riemann problem. The lemma above immediately implies that if $c^L < c^R$, any solution of the Riemann problem will be composed of s-waves and c-rarefaction waves and, if $c^L > c^R$, any solution will be composed of s-waves and a single c-shock wave. Furthermore, if $c^L = c^R$, any solution will consist of a single s-wave. Hence from the theory of the Buckley-Leverett equation (1.2) (cf. § 1) there is a unique solution of the Riemann problem for the system (1.1) when $c^L = c^R$. It is therefore enough to prove Theorem 5.1 when $c^L \neq c^R$.

In § 6 below we treat the case where $c^L < c^R$, while the case $c^L > c^R$ is covered in § 7.

6. The case $c^L < c^R$. Throughout this section we shall consider the Riemann problem for (1.1) with $c^L < c^R$. In this case the purpose is to prove Theorem 5.1.

For any state $u = (s, c) \in \mathscr{R} \cup T$ define the critical value $s^K = s^K(u)$ to be the unique value of s^K such that $(s^K, c) \in \mathscr{L} \cup T$ with the property (cf. Fig. 6.1)

$$\lambda^c(s^K, c) = \lambda^c(u). \tag{6.1}$$

Similarly, if $u = (s, c) \in \mathscr{L}$ let $s^K = s^K(u)$ be the unique s^K such that either $(s^K, c) \in \mathscr{R}$ and that (6.1) holds or, if no such s^K exists, $s^K = \infty$.

As we have already observed above, any solution of the Riemann problem is composed of s-waves and c-rarefaction waves. We first determine the compatible pairs of waves.

LEMMA 6.1. *Assume that $c^L < c^R$.*

(i) *The two waves*

$$u^L \xrightarrow{c} u^M \xrightarrow{s} u^R$$

are compatible if and only if $u^M \in \mathscr{L} \cup T$ and $0 \leqq s^R \leqq s^K(u^M)$.

(ii) *The two waves*

$$u^L \xrightarrow{s} u^M \xrightarrow{c} u^R$$

are compatible if and only if $u^M \in \mathscr{R} \cup T$ and $s^K(u^M) \leqq s^L \leqq 1$.

Proof. Consider part (i) above. The two waves are compatible if and only if

$$\lambda^c(u^M) \leqq v_i^s,$$

where v_i^s is the initial speed of the s-wave. Since $v_i^s \leqq \lambda^s(u^M)$ we therefore derive that $u^M \in \mathscr{L} \cup T$. Furthermore, from the structure of the s-waves it follows that $v_i^s \geqq \lambda^c(u^M)$ if and only if $0 \leqq s^R \leqq s^K(u^M)$.

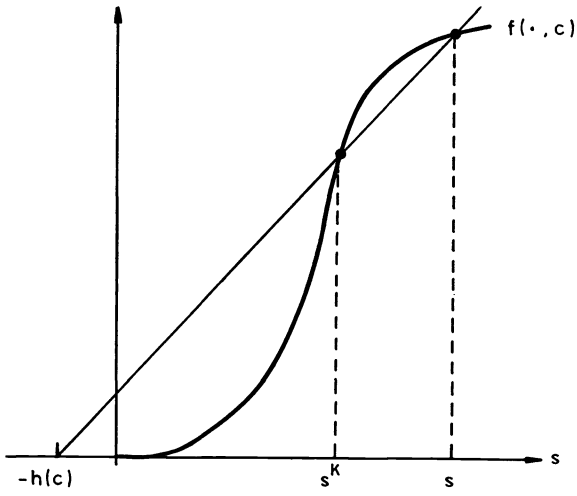

FIG. 6.1

Part (ii) follows by similar arguments. □

The above lemma implies that the three waves

$$u^L \xrightarrow{c_1} u^1 \xrightarrow{s} u^2 \xrightarrow{c_2} u^R \tag{6.2}$$

are compatible if and only if $u^1 \in \mathscr{L}$ and $u^2 \in \mathscr{R}$ with $s^K(u^1) = s^2$ (and $s^K(u^2) = s^1$). Hence, any solution of the Riemann problem will be composed of at most two c-rarefaction waves.

We are now in a position to construct the solution of the Riemann problem for arbitrary states u^L and u^R in $I \times I$. First we consider the case when $u^L \in \mathscr{R} \cup T$.

LEMMA 6.2. *Assume that $c^L < c^R$ and $u^L \in \mathscr{R} \cup T$. Then there exists a unique solution of the Riemann problem consisting of at most four states separated by s-waves and c-rarefaction waves.*

Proof. If $u^R \in \mathscr{R} \cup T$ the solution has the form

$$u^L \xrightarrow{s} u^1 \xrightarrow{c} u^R,$$

where $u^1 = (s^1, c^L) \in \mathscr{R}$ is determined by the c-rarefaction curve which connects u^R to the line $c = c^L$ (cf. Fig. 6.2). (Here and below it might, of course, occur that the s-wave is empty.)

This composition is compatible by part (ii) of Lemma 6.1.

Alternatively, consider the case when $u^R \in \mathscr{L}$. If $s^T(c^R)$ does not exist (cf. § 2), then a compatible composition is given by

$$u^L \xrightarrow{s} (1, c^L) \xrightarrow{c} (1, c^R) \xrightarrow{s} u^R.$$

Otherwise, the composition

$$u^L \to u^T \xrightarrow{s} u^R$$

where $u^T = (s^T(c^R), c^R)$ and $u^L \to u^T$ denotes the solution with left state u^L and right state u^T, is compatible (cf. Fig. 6.3).

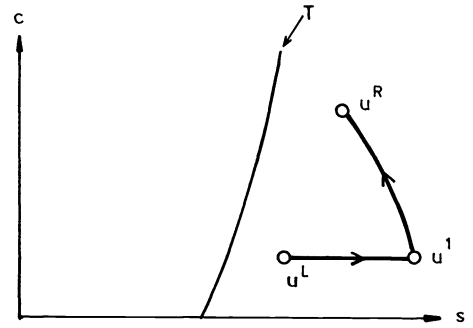

FIG. 6.2

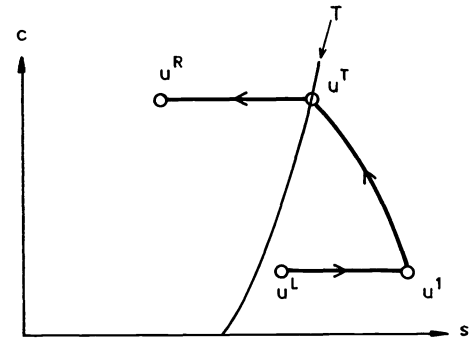

FIG. 6.3

Hence, the existence result of the lemma is established. Verification of the fact that all solutions are unique is straightforward from Lemma 6.1. □

When $u^L \in \mathscr{L}$ the situation is a little more complicated.

LEMMA 6.3. *Assume that $c^L < c^R$ and $u^L \in \mathscr{L}$. Then there exists a unique solution of the Riemann problem consisting of at most five states separated by s-waves and c-rarefaction waves.*

Proof. Let $\Gamma_R \in \mathscr{L} \cup T$ denote the c-rarefaction curve through u^L and let $u^* = (s^*, c^*) \in T$ be the state where Γ_R intersects T. (If no such u^* exists, let $u^* = (s^*, 1)$ be the state where Γ_R intersects the line $c = 1$.) Furthermore, let $\Gamma_K \subset \mathscr{R} \cup T$ be the associated critical curve defined by (cf. Fig. 6.4)

$$\Gamma_K = \{(s^K, c) \in \mathscr{R} \cup T \mid s^K = s^K(s, c) \text{ for } (s, c) \in \Gamma_R\}.$$

From (3.3), defining the c-rarefaction curves, and the definition of $s^K(u)$ it follows that, when $s^K(u) < \infty$,

$$(\lambda^c - \lambda^s)\frac{ds^K}{dc} = f_c + g, \tag{6.3}$$

where $g = g(c) = \lambda^c(s^K, c)(dh/dc)(c)((s^K - s)/(s + h(c)))$, $(s, c) \in \Gamma_R$ and the functions λ^c, λ^s and f_c are all evaluated at (s^K, c). Since $dh/dc < 0$, it follows that $g(c) < 0$ for any $c \in [c^L, c^*)$. By comparing (6.3) with (3.3) we therefore obtain that any c-rarefaction

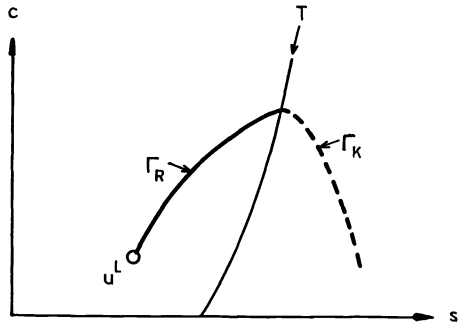

FIG. 6.4. Γ_R *and* Γ_K.

curve in $\mathcal{R}$ can, at most, intersect the critical curve Γ_K once, and that $ds^K/dc < ds/dc$, where $s(c)$ is a c-rarefaction curve (cf. Fig. 6.5).

After this introductory discussion we now construct the solution of the Riemann problem. Assume first that $u^R \in R_1$, where R_1 is the closed region in $I \times I$ bounded by the curves $c = c^L$, $c = c^*$ and Γ_K. In this case Lemma 6.1 implies that the composition

$$u^L \xrightarrow{c} u^1 \xrightarrow{s} u^R,$$

where $u^1 = (s^1, c^R) \in \Gamma_R$ is compatible (cf. Fig. 6.6)

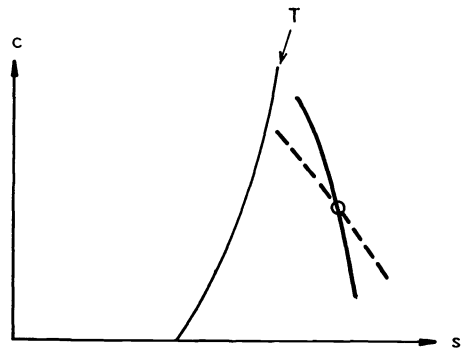

FIG. 6.5. ——— *c-rarefaction curve*; ------ Γ_K.

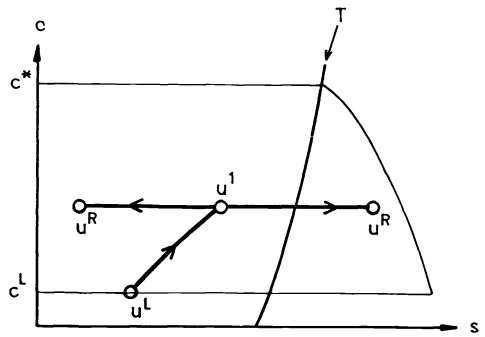

FIG. 6.6

Next assume that $u^R \in R_2$, where R_2 consists of all states in $\mathscr{R} \cup T$ that are not in R_1. Let $u^2 \in \mathscr{R}$ be the state where the c-rarefaction curve through u^R intersects the curve $\Gamma_K \cup \{c = c^L\}$.

If $c^2 = c^L$, Lemma 6.1 implies that the composition

$$u^L \xrightarrow{s} u^2 \xrightarrow{c} u^R$$

is compatible. If $c^2 > c^L$ the composition

$$u^L \xrightarrow{c_1} u^1 \xrightarrow{s} u^2 \xrightarrow{c_2} u^R,$$

where $u^1 = (s^1, c^2) \in \Gamma_R$, corresponds exactly to a compatible composition of the form (6.2). Hence we have constructed a solution for all $u^R \in R_2$ (cf. Fig. 6.7).

Finally, consider the case where

$$u^R \in R_3 = \{u = (s, c) \in \mathscr{L} \mid c > c^*\}.$$

If $s^T(c^R)$ exists the composition

$$u^L \to u^T \xrightarrow{s} u^R,$$

where $u^T = (s^T(c^R), c^R)$ and $u^L \to u^T$ denotes the solution with left state u^L and right state u^T, is compatible (cf. Fig. 6.8).

Otherwise, if $s^T(c^R)$ does not exist, a compatible composition is given by

$$u^L \to (1, c^T) \xrightarrow{c} (1, c^R) \xrightarrow{s} u^R$$

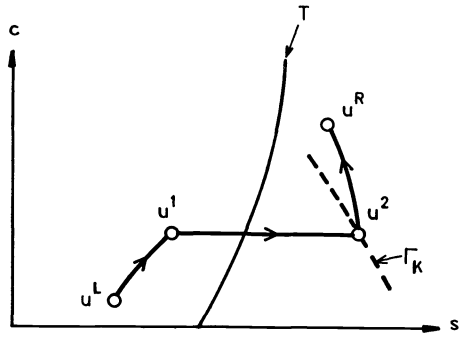

FIG. 6.7

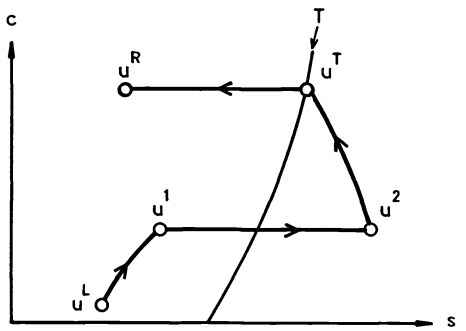

FIG. 6.8

where c^T is the unique value such that $(1, c^T) \in T$ (cf. § 2) and $u^L \to (1, c^T)$ is a solution of a Riemann problem. Hence, the desired existence result is established. Again uniqueness can be verified by applying Lemma 6.1. □

Lemmas 6.2 and 6.3 complete the proof of Theorem 5.1 in the case when $c^L < c^R$.

7. The case $c^L > c^R$. In this section we will complete the proof of Theorem 5.1 by constructing a unique solution of the Riemann problem when $c^L > c^R$. Throughout this section we shall therefore assume that the values of c^L and c^R are *fixed* with $c^L > c^R$.

For any state $u = (s, c) \in I \times I$ we define the "associated shock speed" $\sigma(u)$ by

$$\sigma(u) = \frac{f(s, c)}{s + h_L(c^R)}.$$

Hence, the Rankine-Hugoniot condition (4.7) can be written in the form

$$\sigma(u^L) = \sigma(u^R). \tag{7.1}$$

Similar to the definition given in § 6, for any state $u = (s, c) \in I \times I$, with $\lambda^s(u) \leqq \sigma(u)$, the critical value $s^K = s^K(u)$ is defined to be the unique value of s^K such that $\lambda^s(s^K, c) > \sigma(u)$ and such that (cf. Fig. 7.1)

$$\sigma(s^K, c) = \sigma(u). \tag{7.2}$$

If $\lambda^s(u) > \sigma(u)$, then $s^K(u)$ is either defined to be the unique value s^K such that $\lambda^s(s^K, c) < \sigma(u)$ and such that (7.2) holds or, if no such s^K exists, $s^K = \infty$.

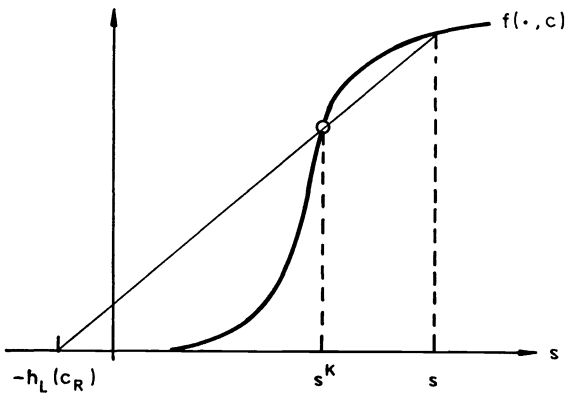

FIG. 7.1

As we have already observed in § 5, any solution of the Riemann problem will be composed of s-waves and one c-shock wave. We first characterize the compatible pairs of waves in the present case.

LEMMA 7.1. *Assume that* $c^L > c^R$.

(i) *The two waves*

$$u^L \xrightarrow{c} u^M \xrightarrow{s} u^R$$

are compatible if and only if $\lambda^s(u^M) \geqq \sigma(u^M)$ *and* $0 \leqq s^R < s^K(u^M)$.

(ii) *The two waves*

$$u^L \xrightarrow{s} u^M \xrightarrow{c} u^R$$

are compatible if and only if $\lambda^s(u^M) \leqq \sigma(u^M)$ *and* $s^K(u^M) < s^R \leqq 1$.

Proof. Consider part (i) above. The two waves are compatible if and only if

$$\sigma \leqq v_s^i, \tag{7.3}$$

where σ is the speed of the c-shock wave, v_s^i is the initial speed of the s-wave and where strict inequality is required if the s-wave starts with a shock wave. But since $\sigma = \sigma(u^M)$ and $v_s^i \leqq \lambda^s(u^M)$ it follows that $\lambda^s(u^M) \geqq \sigma(u^M)$. Furthermore, from the structure of the s-waves it follows that (7.3) holds if and only if $0 \leqq s^R < s^K(u^M)$. Part (ii) follows by similar arguments. □

As a consequence of the lemma above (and Lemma 5.1) we derive in particular that the admissible overcompressive shock discussed in § 4, where

$$\lambda^s(u^L), \lambda^c(u^L) > \sigma > \lambda^s(u^R), \lambda^c(u^R)$$

can never be joined by any other wave in a Riemann solution.

By applying the result of Lemma 7.1 we can now proceed to construct the solution of the Riemann problem.

LEMMA 7.2. *Assume that $c^L > c^R$. Then there exists a unique solution of the Riemann problem consisting of at most four states separated by s-waves and c-shock waves.*

Proof. Consider first the case when $\lambda^s(u^L) \geqq \sigma(u^L)$. Let $u^1 = (s^1, c^R)$ be the unique state such that (cf. Fig. 7.2)

$$\lambda^s(u^1) > \sigma(u^1) = \sigma(u^L).$$

Hence, from the Rankine-Hugoniot condition (7.1) and from the entropy conditions (4.10) and (4.11), the pair (u^L, u^1) corresponds to a c-shock wave with left state u^L, right state u^1 and shock speed $\sigma = \sigma(u^L)$. Furthermore, by part (i) of Lemma 7.1 the composition

$$u^L \xrightarrow{c} u^1 \xrightarrow{s} u^R$$

is compatible if $0 \leqq s^R < s^K(u^1)$. Alternatively, if $s^R > s^K(u^1)$ the composition

$$u^L \xrightarrow{s} u^2 \xrightarrow{c} u^R$$

is compatible, where $u^2 = (s^2, c^L)$ is the state such that

$$\lambda^s(u^2) \leqq \sigma(u^2) = \sigma(u^R).$$

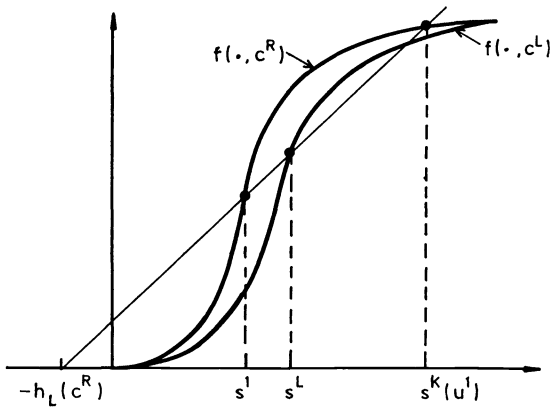

FIG. 7.2

Finally, if $s^R = s^K(u^1)$, the pair (u^L, u^R) corresponds to an admissible overcompressive c-shock (cf. § 4), where $\sigma = \sigma(u^L) = \sigma(u^R)$. Hence, we have constructed the solution of the Riemann problem in all cases when $\lambda^s(u^L) \geqq \sigma(u^L)$ (cf. Fig. 7.3).

Consider next the case when $\lambda^s(u^L) < \sigma(u^L)$ and let $u^* = (s^*, c^L)$ be the unique state such that

$$\sigma(u^*) = \lambda^s(u^*).$$

Furthermore, let $u^1 = (s^1, c^R)$ be determined by

$$\lambda^s(u^1) > \sigma(u^1) = \sigma(u^*)$$

and let $s^K = s^K(u^1)$ (cf. Fig. 7.4).

If $s^R \geqq s^K$ a solution of the Riemann problem is given by the composition

$$u^L \xrightarrow{s} u^2 \xrightarrow{c} u^R$$

where $u^2 = (s^2, c^L)$ is the unique state such that $\lambda^s(u^2) \leqq \sigma(u^2)$ and such that the pair (u^2, u^R) corresponds to a c-shock wave (cf. Fig. 7.5).

If $s^R < s^K$ a solution is given by the composition

$$u^L \xrightarrow{s} u^* \xrightarrow{c} u^1 \to u^R,$$

which is compatible by Lemma 7.1 (cf. Fig. 7.6).

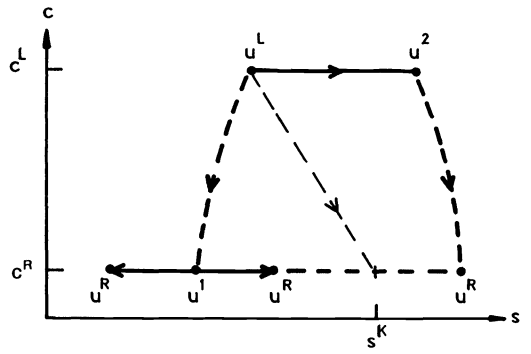

FIG. 7.3

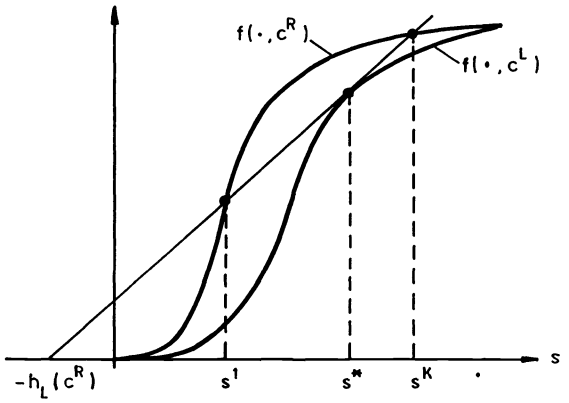

FIG. 7.4

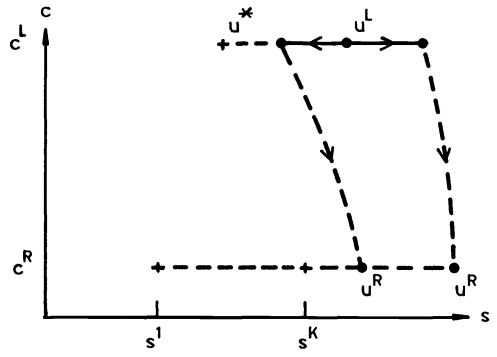

FIG. 7.5

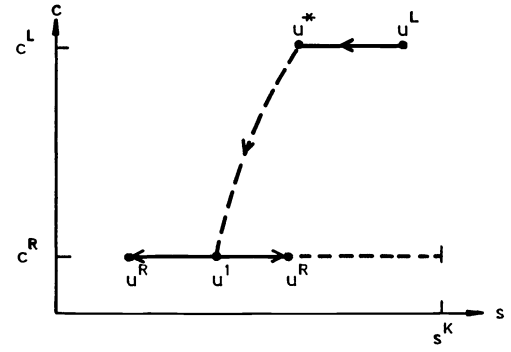

FIG. 7.6

Hence the desired existence result is established, and uniqueness can easily be verified by applying Lemma 7.1. □

As a consequence of the three Lemmas 6.2, 6.3, and 7.2 the proof of Theorem 5.1 is now completed. We observe that the existence proof is constructive; i.e., we have constructed an algorithm for the solution of the global Riemann problem for the system (1.1).

8. Numerical experiments. Based on the constructive proof of Theorem 5.1 a computer program is developed that solves the global Riemann problem for the model (1.1). In order to solve nonlinear equations obtained from the Rankine-Hugoniot condition (4.7) and the ordinary differential equations involved in the determination of the rarefaction waves, standard numerical methods are used.

The purpose of the numerical experiments presented below is to illustrate some typical behavior in the exact solution of the Riemann problem and to show that sometimes this behavior is not easily detected by means of finite difference schemes. In the examples presented below we have used the algebraic expressions

$$f(s, c) = \frac{s^2}{s^2 + (0.5 + 100c)(1-s)^2} \tag{8.1}$$

and

$$a(c) = \frac{0.2c}{1+100c}. \tag{8.2}$$

The function f is graphed in Fig. 8.1 for different values of c uniformly distributed between 0.00 and 0.01.

Example 8.1. In this example we calculate the solution of the Riemann problem with $u^L = (s^L, c^L) = (1.0, 0.01)$ and $u^R = (s^R, c^R) = (0.0, 0.0)$. This models a situation where the porous medium is initially 100 percent saturated with oil. Then water containing polymer is injected in order to displace the oil.

The structure of the solution of the Riemann problem in this case is illustrated by Fig. 7.6. The exact solution is shown on Fig. 8.2.

We observe that a bank of polymer-free water separates the polymer from the region with 100 percent oil. We remark that this bank forms as a consequence of the adsorption term $a(c)$ in the system (1.1).

One of the purposes of polymer injection is to increase the viscosity of the aqueous phase in order to reduce viscous fingering. The bank of pure water observed above might therefore decrease the desired efficiency of the displacement process.

Example 8.2. Throughout this example we consider the Riemann problem with $u^L = (s^L, c^L) = (0.9, 0.007)$ and $c^R = 0.003$ fixed and where s^R is close to the critical value s^K. These cases are illustrated in Fig. 7.5 ($s^R \geqq s^K$) and Fig. 7.6 ($s^R < s^K$). Examples of the s-component of the solution is shown in Fig. 8.3 and Fig. 8.4 below. Since the values s^* and s^1 are independent of s^R for $s^R < s^K$, this shows that, if the solution of the Riemann problem is considered pointwise, it is discontinuous with respect to s^R close to s^K. However, since the width of the constant solution s^1 is

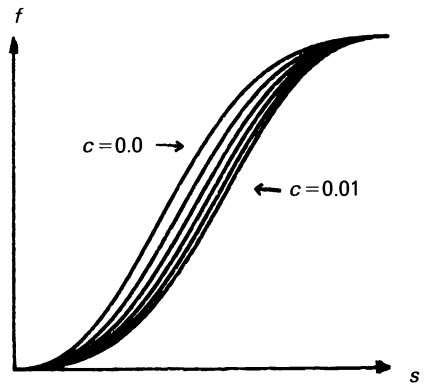

FIG. 8.1

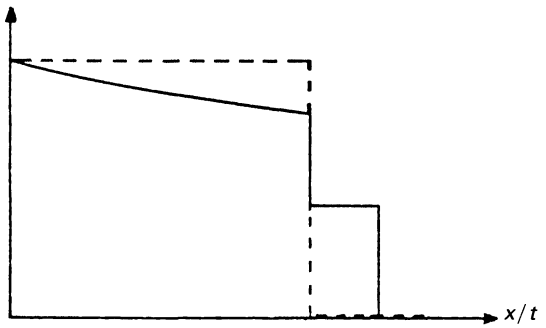

FIG. 8.2. ——— s; ------ $c \times 100$.

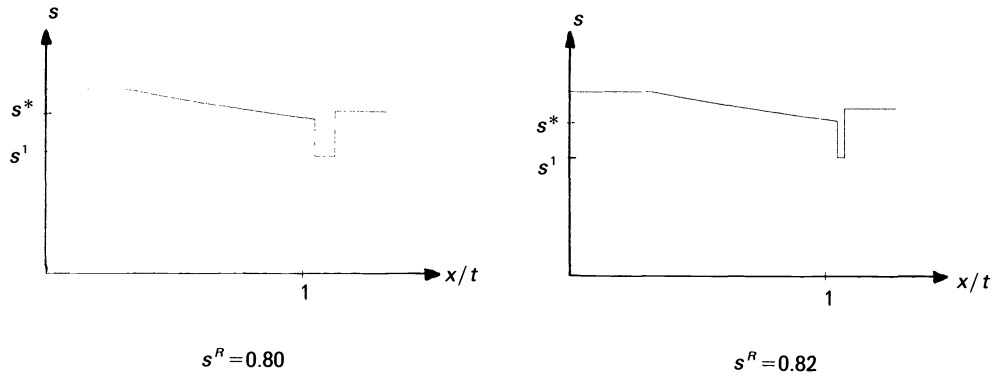

$s^R = 0.80$ $s^R = 0.82$

FIG. 8.3. $s^R < s^K$.

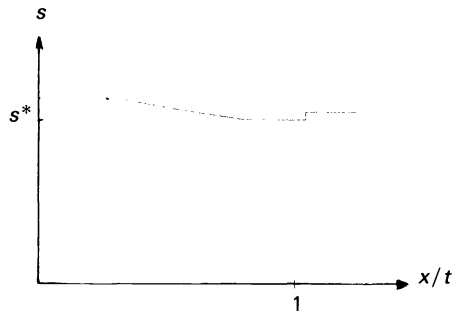

FIG. 8.4. $s^R = 0.84 > s^K$.

vanishing as s^R tends to s^K from below, the solution is continuous with respect to s^R in L^1 norm.

Example 8.3. Consider next the Riemann problem with $u^L = (s^L, c^L) = (0.45, 0.0)$ and $u^R = (s^R, c^R) = (0.20, 0.01)$. This corresponds to the case illustrated in Fig. 6.8 where the maximum number of intermediate states is present in the Riemann solution. The exact solution is shown in Fig. 8.5.

In order to test the efficiency of a standard difference method we have calculated the solution of this Riemann problem with the standard 1 order upwind scheme using a uniform grid. We have used $\Delta t/\Delta x = 12/25$ which satisfies the CFL stability condition.

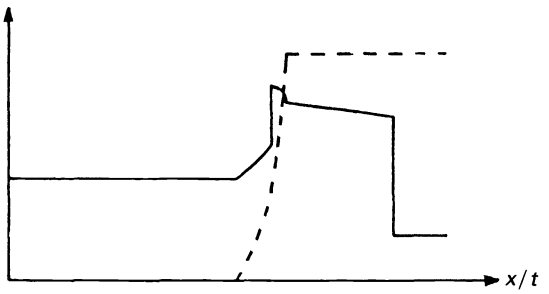

FIG. 8.5. ——— s; ------ $c \times 100$.

An approximation of the solution at $t = 1$ is calculated with $\Delta t = 0.04$ and the approximate saturation is compared with the exact saturation in Fig. 8.6.

As we observe the numerical method seems to neglect certain effects reflected in the exact solution. In order to investigate these phenomena further, similar numerical solutions, with decreasing time steps, have been calculated. In Fig. 8.7 we have plotted the different numerical paths in (s, c)-space together with the exact path. We have used $\Delta t = 0.04$, 0.016, 0.008, 0.004, 0.0016.

The results seem indeed to indicate that the solutions obtained by the upwind scheme converge to the exact solution. However, it might be difficult to give an accurate physical interpretation of the process from the numerical results.

A comparison between the numerical solution of s with $\Delta t = 0.0016$ and the exact solution (cf. Fig. 8.4) is shown in Fig. 8.8.

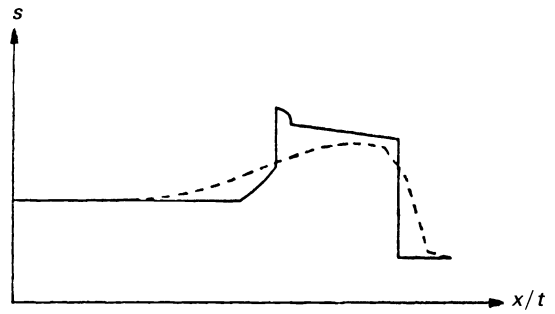

FIG. 8.6. ——— *exact solution of s*; ------ *numerical solution of s.* $\Delta t = 0.04$.

DISCONTINUOUS SOLUTIONS OF THE LINEARIZED, STEADY STATE, COMPRESSIBLE, VISCOUS, NAVIER–STOKES EQUATIONS*

R. BRUCE KELLOGG†

Abstract. The compressible steady state viscous Navier–Stokes equations in two space dimensions are considered. The equations are linearized around a given ambient flow field. It is shown that the linearized equations are not, in general, elliptic. Jump conditions across a possible curve of discontinuities of a solution of the linearized system are derived. In a particular case, a discontinuous solution of the linearized system is constructed.

Key words. compressible flow, Navier–Stokes equations, discontinuous solutions

AMS(MOS) subject classifications. 76N10, 35Q10

1. Introduction. A complete mathematical understanding of the equations of fluid dynamics has not yet been achieved. Some insight concerning these equations may be obtained from the linearized equations. In this paper we consider the system of equations obtained by linearizing the two-dimensional, compressible steady state viscous Navier–Stokes equations around a smooth, nonzero ambient flow field. This linearized system is not, in general, elliptic in the sense of Agmon, Douglis, and Nirenberg (ADN). (In the case of incompressible flow, the linearized equations are ADN elliptic.) It is therefore possible that the linearized equation have solutions with interior discontinuities. The main goal of the paper is to exhibit a discontinuous solution of these equations in the particular case when the ambient flow field is a constant nonzero flow. The discontinuous solution is constructed with the help of the Fourier transform. In addition, we derive jump conditions that a weak solution of the equations must satisfy if the weak solution has a curve Γ of discontinuities. The jump conditions permit a jump in the normal stress across Γ which is compensated by a jump in the pressure across Γ. Also, the jump conditions require that the temperature and its first derivatives be continuous across Γ. Finally, we consider the uniqueness of the discontinuous solution. The existence of discontinuous solutions may raise the issue of whether some further physical principle is required to specify the solution, analogous to the entropy condition in the nonlinear inviscid case. We investigate this in the particular case when the ambient flow field is constant. We show that an appropriate set of boundary conditions determines the solution uniquely. The boundary conditions, which are also used in [3], require the specification of velocity and temperature on the boundary of the region, and the specification of pressure on that part of the boundary for which the ambient flow enters the region.

The interior discontinuity in the solution that we construct arises from a jump in the specified pressure on the boundary of the region. The jump in the boundary pressure propagates to a jump in the pressure across the streamline of the ambient flow field that emanates from the boundary discontinuity. The strength of the discontinuity increases with smaller viscosity, but decays as one moves along the streamline away from the boundary. The rate of decay of the strength of the discontinuity is given by

the dimensionless quantity $x\rho_0/\mu U_0(\partial\rho/\partial P)$, where x is the distance along the ambient streamline, μ is the coefficient of viscosity, ρ_0 and U_0 are the (constant) density and velocity of the ambient flow, and the derivative of density with respect to pressure is evaluated at constant temperature. In the incompressible case, $\partial\rho/\partial P = 0$, and the rate of decay of the strength of the discontinuity is infinite.

Our work is related to a recent paper of Geymonat and Leyland [3], in which the time-dependent linearized compressible Navier-Stokes equations are discussed. The paper [3] provides an appropriate set of boundary conditions for the problem, gives the existence of a solution in a functional analytic setting, and has suggested some of the arguments used here. Our results may also be contrasted with those in a forthcoming paper of Hoff and Liu [4]. Reference [4] treats the full nonlinear time-dependent equations in one space variable. It is shown that if there is a discontinuity in the initial conditions, the discontinuity persists for all time, but the strength of the discontinuity decays exponentially with time. In the result of [4], the boundary conditions are continuous. Thus, these results are not inconsistent with our finding that, in the linear case, a discontinuity in the boundary conditions produces a discontinuity in the solution of the steady state problem.

In § 2 we derive the linearized equations, discuss the lack of ellipticity of the system, and derive the jump conditions across a putative curve of discontinuity. In § 3 we consider the case of uniform ambient flow. Using an energy argument, we derive an existence and uniqueness theorem for an appropriate boundary value problem associated with the linearized equations. Finally, we give the construction of a discontinuous solution. In § 4 we give some conclusions.

2. The linearized equations. We first write the two-dimensional compressible Navier-Stokes equations. We take the primary unknowns to be the velocity vector $(U(x, y), V(x, y))$, the pressure $P(x, y)$ and the temperature $\Theta(x, y)$, and we let

$$\rho(P, \Theta) = \text{density},$$

$$\varepsilon(P, \Theta) = \text{internal energy},$$

$$Q = \tfrac{1}{2}(U^2 + V^2), \qquad e = \rho\varepsilon + \rho Q,$$

$$\sigma_{11} = 2\mu U_x + \lambda(U_x + V_y),$$

$$\sigma_{12} = \sigma_{21} = \mu(U_y + V_x),$$

$$\sigma_{22} = 2\mu V_y + \lambda(U_x + V_y).$$

The viscosity coefficients λ, μ, and the thermal conductivity, κ, are assumed to be constant, and the Latin subscripts denote partial derivatives. With this notation, the compressible flow equations may be written, in divergence form, as

$$-\sigma_{11,x} - \sigma_{12,y} + (\rho U^2)_x + (\rho UV)_y + P_x = 0,$$

$$-\sigma_{12,x} - \sigma_{22,y} + (\rho UV)_x + (\rho V^2)_y + P_y = 0,$$

$$(\rho U)_x + (\rho V)_y = 0,$$

$$-\kappa\Delta\Theta - (U\sigma_{11})_x - (V\sigma_{12})_x - (U\sigma_{12})_y - (V\sigma_{22})_y,$$

$$+(Ue + UP)_x + (Ve + VP)_y = 0.$$

In the usual manner, after substituting the continuity equation into the momentum equations, and the momentum equations into the energy equation, we obtain

$$(2.1a) \qquad -\sigma_{11,x}-\sigma_{12,y}+\rho UU_x+\rho VU_y+P_x=0,$$

$$(2.1b) \qquad -\sigma_{12,x}-\sigma_{22,y}+\rho UV_x+\rho VV_y+P_y=0,$$

$$(2.1c) \qquad (\rho U)_x+(\rho V)_y=0,$$

$$(2.1d) \qquad -\kappa\Delta\Theta-U_x\sigma_{11}-(V_x+U_y)\sigma_{12}-V_y\sigma_{22}+\rho(U\varepsilon_x+V\varepsilon_y)+PU_x+PV_y=0.$$

We take the system (2.1) as our starting point. Suppose $U(x, y)$, $V(x, y)$, $P(x, y)$, $\Theta(x, y)$ are a solution to (2.1). We shall study the linearized system, linearizing around the "ambient" flow field U, V, P, Θ. Denote the linearized variables by u, v, p, θ, let $q=[u, v, p, \theta]^T$ be the vector of unknowns, and set $\rho_1=\partial\rho(P, \Theta)/\partial P$, $\rho_2=\partial\rho(P, \Theta)/\partial\Theta$, with similar notation for ε_1 and ε_2. The linearized equations are

$$(2.2a) \qquad L_1q\equiv-(2\mu+\lambda)u_{xx}-\mu u_{yy}-(\mu+\lambda)v_{xy}+\rho Uu_x+\rho Vu_y+p_x+A=0,$$

$$(2.2b) \qquad L_2q\equiv-\mu v_{xx}-(2\mu+\lambda)v_{yy}-(\mu+\lambda)u_{xy}+\rho Uv_x+\rho Vv_y+p_y+B=0,$$

$$(2.2c) \qquad L_3q\equiv\rho u_x+\rho v_y+\rho_1(Up_x+Vp_y)+\rho_2(U\theta_x+V\theta_y)+C=0,$$

$$(2.2d) \qquad \begin{aligned} L_4q\equiv&-\kappa\Delta\theta-\sigma_{11}u_x-\sigma_{12}(v_x+u_y)-\sigma_{22}v_y\\ &-U_x[2\mu u_x+\lambda(u_x+v_y)]-\mu(U_y+V_x)(u_y+v_x)\\ &-V_y[2\mu v_y+\lambda(u_x+v_y)]\\ &+\rho\varepsilon_1(Up_x+Vp_y)+\rho\varepsilon_2(U\theta_x+V\theta_y)+P(u_x+v_y)+D=0. \end{aligned}$$

In these equations, A, B, C, and D contain only undifferentiated terms in the linearized variables. Each term in A, B, C, or D contains derivatives of the ambient variables. Thus, in the particular case that the ambient field has uniform flow, these lowest order terms vanish. This fact will be used in the following section.

We first consider the ellipticity of the system (2.2).

LEMMA 1. *The system defined by the operators L_j in* (2.2) *is not, in general, elliptic in the sense of ADN.*

Proof. We use the Volevich criterion, as described in [1]. For this, we replace the derivatives in (2.2) by symbolic multipliers, ξ and η and their powers, and we consider the determinant

$$G=\begin{bmatrix} -(2\mu+\lambda)\xi^2-\mu\eta^2+\alpha_1^1 & -(\mu+\lambda)\xi\eta+\alpha_2^1 & \xi+\alpha_3^0 & \alpha_4^0 \\ -(\mu+\lambda)\xi\eta+\beta_1^1 & -\mu\xi^2-(2\mu+\lambda)\eta^2+\beta_2^1 & \eta+\beta_3^0 & \beta_4^0 \\ \rho\xi+\gamma_1^0 & \rho\eta+\gamma_2^0 & \rho_1(U\xi+V\eta)+\gamma_3^0 & \gamma_4^1 \\ \delta_1^1 & \delta_2^1 & \delta_3^1 & -\kappa(\xi^2+\eta^2)+\delta_4^1 \end{bmatrix}.$$

The α, β, γ, δ are polynomials in ξ and η, which may be determined from (2.2), but whose exact form is not important for the proof. The maximum degree in each of these polynomials is given by the superscript; thus, α_1^1 is a linear polynomial in ξ and η, α_3^0 is independent of ξ and η, etc. When the determinant G is written out as a sum of terms, each term is a polynomial in ξ and η. The degree of each term is $\leqq 7$, since each term in row 3 has degree $\leqq 1$. If $\rho_1\neq 0$, the product of the diagonal entries has degree 7. Hence the leading terms in G cannot be nonzero for not-zero (ξ, η), so the Volevich criterion is not satisfied and the system is not elliptic.

We remark that if the expansion of G is examined further, the terms of order 7 are found to be

$$-\rho_1\kappa\mu(2\mu+\lambda)(\xi^2+\eta^2)^3(U\xi+V\eta).$$

Thus, the streamline of the ambient flow field seems to play the role of a characteristic direction for this system. On the other hand, if $\rho_1=0$, we must examine terms of order 6 to determine the ellipticity of the system.

Since the system (2.2) is not elliptic, it is of interest to ask whether a solution of this system can be discontinuous. For this, we must define the notion of a weak solution of (2.2). Let $\Omega \subset R^2$ be an open set. We say that $q=[u, v, p, \theta]$ is a weak solution of (2.2) in Ω if u, v, p, and θ are integrable, and if for any $\phi \in C_0^\infty(\Omega)$, we have

$$\iint_\Omega \{u[-(2\mu+\lambda)\phi_{xx}-\mu\phi_{yy}-(\rho U\phi)_x-(\rho V\phi)_y]-(\mu+\lambda)v\phi_{xy}-p\phi_x$$

$$+A\phi\}\,dx\,dy=0, \tag{2.3a}$$

$$\iint_\Omega \{v[-\mu\phi_{xx}-(2\mu+\lambda)\phi_{yy}-(\rho U\phi)_x-(\rho V\phi)_y]-(\mu+\lambda)u\phi_{xy}-p\phi_y$$

$$+B\phi\}\,dx\,dy=0, \tag{2.3b}$$

$$\iint_\Omega \{-(\rho\phi)_x u-(\rho\phi)_y v-p[(\rho_1 U\phi)_x+(\rho_1 V\phi)_y]-\theta[(\rho_2 U\phi)_x+(\rho_2 V\phi)_y]$$

$$+C\phi\}\,dx\,dy=0, \tag{2.3c}$$

$$\begin{aligned}\iint_\Omega \{&\theta[-\kappa\Delta\phi-(\rho\varepsilon_2 U)_x-(\rho\varepsilon_2 V)_y]+u[(\sigma_{11}\phi)_x+(\sigma_{12}\phi)_y\\ &+2\mu(U_x\phi)_x+\lambda(U_x\phi)_x+\mu((U_y+V_x)\phi)_y+\lambda(V_y\phi)_x-(P\phi)_x]\\ &+v[(\sigma_{12}\phi)_x+(\sigma_{22}\phi)_y+\lambda(U_x\phi)_y+\mu((U_y+V_x)\phi)_x\\ &+2\mu(V_y\phi)_y+\lambda(V_y\phi)_y-(P\phi)_y]\\ &-p[(\rho\varepsilon_1 U\phi)_x+(\rho\varepsilon_1 V\phi)_y]+D\phi\}\,dx\,dy=0.\end{aligned} \tag{2.3d}$$

Suppose we are given a smooth curve $\Gamma=(x(s), y(s))$ in Ω which divides Ω into 2 pieces, Ω_1 and Ω_2. Suppose that the parameter s is arc length, so that $\underline{n}(s)=[\dot{y}(s), -\dot{x}(s)]^T$ is the unit normal vector along Γ. Suppose $\underline{n}(s)$ points into the region Ω_2, so $\underline{n}(s)$ is an outward pointing normal from the region Ω_1. Let $q=[u, v, p, \theta]$ be a weak solution of (2.2) such that the functions u, v, p, θ are smooth in each of the regions Ω_1, Ω_2 but u, v, p, θ and their derivatives may have jumps across Γ. Let u_1, u_2, u_{x1}, u_{x2}, etc. denote the one-sided limits of u, u_x, etc., on Γ, and let $\delta u=u_2-u_1$, $\delta u_x=u_{x2}-u_{x1}$ denote the jumps in these quantities. Also, let $u_t=\dot{x}u_x+\dot{y}u_y$, $u_n=\dot{y}u_x-\dot{x}u_y$, denote the normal and tangential derivatives of u on Γ, with a similar meaning for v_t, v_n, etc. With these assumptions and notation, we can state the jump conditions for our solution on Γ. The proof is a standard integration by parts argument, as is found, for example, in [2, V.1.3].

THEOREM 1. *Let the domain Ω be separated into subdomains Ω_1, Ω_2, by a smooth curve Γ. Let $q=[u, v, p, \theta]$ be a weak solution of* (2.1). *Suppose q is smooth in each subdomain Ω_i, with smooth one-sided limits on Γ. Suppose q is discontinuous on Γ. Then Γ is a steamline of the ambient flow field, and q satisfies on Γ the jump conditions*

$$\delta u=\delta v=\delta u_t=\delta v_t=0, \tag{2.4a}$$

$$\delta\theta=\delta\theta_x=\delta\theta_y=0, \tag{2.4b}$$

$$[\mu+(\mu+\lambda)\dot{y}^2]\delta u_n-\dot{x}\dot{y}(\mu+\lambda)\delta v_n=\dot{y}\delta p, \tag{2.4c}$$

$$[\mu+(\mu+\lambda)\dot{x}^2]\delta v_n-\dot{x}\dot{y}(\mu+\lambda)\delta u_n=-\dot{x}\delta p. \tag{2.4d}$$

Proof. Pick ϕ to have support in Ω_1. Then since u, v and p are smooth in Ω_1, (2.3a) may be integrated by parts twice to obtain $\iint \phi L_1 q\,dx\,dy=0$. Since this holds

for all such ϕ, $L_1 q = 0$ in Ω_1. A similar argument applies to Ω_2, and to the other equations of (2.2). Next, pick ϕ to have support including a portion of Γ. Writing the integral in (2.3a) as the sum of integrals over Ω_1 and Ω_2, and integrating each of these by parts, we obtain

$$\int_\Gamma \{-(2\mu+\lambda)\dot{y}[\phi_x \delta u - \phi \delta u_x] + \mu \dot{x}[\phi_y \delta u - \phi \delta u_y] + (\mu+\lambda)[\dot{x}\phi_x \delta v + \dot{y}\phi \delta v_y] - \rho\phi\delta u(U\dot{y} - V\dot{x}) - \dot{y}\phi\delta p\}\, ds = 0. \tag{2.5a}$$

We use the relations

$$\phi_x = \dot{x}\phi_t + \dot{y}\phi_n, \qquad \phi_y = \dot{y}\phi_t - \dot{x}\phi_n \tag{2.6}$$

in (2.5a). Since ϕ_n may be chosen independent of ϕ and ϕ_t on Γ, and since (2.5a) must hold for all test functions ϕ, we may set the coefficient of ϕ_n equal to zero. This gives, after some algebra,

$$[(2\mu+\lambda)\dot{y}^2 + \mu\dot{x}^2]\delta u - (\mu+\lambda)\dot{x}\dot{y}\delta v = 0. \tag{2.7a}$$

Writing the integral in (2.3b) as a sum of integrals over Ω_1 and Ω_2, and integrating each of these by parts, we obtain

$$\int_\Gamma \{-\mu\dot{y}[\phi_x \delta v - \phi \delta v_x] + (2\mu+\lambda)\dot{x}[\phi_y \delta v - \phi \delta v_y] + (\mu+\lambda)[\dot{x}\phi_x \delta u + \dot{y}\phi \delta u_y] - \rho\phi\delta v(U\dot{y} - V\dot{x}) + \dot{x}\phi\delta p\}\, ds = 0. \tag{2.5b}$$

Using (2.6) in (2.5b) we derive, in a manner similar to the derivation of (2.7a),

$$-\dot{x}\dot{y}(\mu+\lambda)\delta u + [\mu\dot{y}^2 + (2\mu+\lambda)\dot{x}^2]\delta v = 0. \tag{2.7b}$$

The system (2.7a), (2.7b) forms a system of two homogeneous linear equations in the two unknowns δu, δv. The determinant of this system is $\mu(2\mu+\lambda) \neq 0$. Hence $\delta u = \delta v = 0$ on Γ. From this it follows that $\delta u_t = \delta v_t = 0$, so (2.4a) has been verified. Using (2.4a) in (2.5a), we obtain

$$\int_\Gamma \phi\{(2\mu+\lambda)\dot{y}\delta u_x - \mu\dot{x}\delta u_y + (\mu+\lambda)\dot{y}\delta v_y - \dot{y}\delta p\}\, ds = 0.$$

Since this holds for all test functions ϕ, the quantity in braces must vanish. Using (2.4a) again, we find that $\delta u_x = \dot{y}\delta u_n$, $\delta u_y = -\dot{x}\delta u_n$, $\delta v_y = -\dot{x}\delta v_n$, and we conclude that (2.4c) holds. In a similar manner, (2.4d) is derived from (2.5b). We next consider the jump conditions coming from the energy equation. Writing the integral in (2.3d) as a sum of integrals over Ω_1 and Ω_2, integrating each of these by parts, and using the fact that $\delta u = \delta v = 0$, we obtain

$$\int_\Gamma \{-\kappa[\phi_n \delta\theta - \phi\delta\theta_n] - \rho\varepsilon_2[\dot{y}U\delta\theta - \dot{x}V\delta\theta] - \rho\varepsilon_1\phi\delta p[U\dot{y} - V\dot{x}]\}\, ds = 0.$$

Since ϕ_n may be chosen independently of ϕ, we obtain $\delta\theta = 0$ and

$$\kappa\delta\theta_n - \rho\varepsilon_1[U\dot{y} - V\dot{x}]\delta p = 0. \tag{2.8}$$

Finally, we consider the jump condition coming from the continuity equation. Writing the integral in (2.3c) as a sum of integrals over Ω_1 and Ω_2, integrating each of these

by parts, and using the fact that $\delta u = \delta v = \delta\theta = 0$, we obtain

$$\int_\Gamma \rho_1 \phi [U\dot{y} - V\dot{x}]\delta p \, ds = 0,$$

so we get

$$\rho_1[U\dot{y} - V\dot{x}]\delta p = 0. \tag{2.9}$$

If $U\dot{y} - V\dot{x} \neq 0$, then $\delta p = 0$. So, from (2.8), $\delta\theta_n = 0$, and from (2.4c), (2.4d), $\delta u_n = \delta v_n = 0$. In this case, there is no jump. If $U\dot{y} - V\dot{x} = 0$ so that Γ lies on a streamline of the ambient flow, from (2.8) we get $\delta\theta_n = 0$. Since $\delta\theta_t = 0$, we have $\delta\theta_x = \delta\theta_y = 0$. This establishes (2.4b) and completes the proof of the theorem.

3. Discontinuous solutions. We have seen that a generalized solution of (2.2) must satisfy (2.4) across a curve $(x(s), y(s))$ of discontinuity. The jump conditions (2.4) are analogous to the Rankine-Hugoniot condition for the discontinuous solution of a nonlinear conservation law. It may be asked if (2.4) suffices to specify the solution across the jump, or if there are further "entropy conditions" that must be satisfied. To answer this, we shall consider (2.2) in a special case, when the ambient field is constant. We define an appropriate boundary value problem for the system, and we show that there exists a unique generalized solution of the boundary value problem. As a consequence, a solution that is smooth in the subregions Ω_1 and Ω_2, and satisfies (2.4), is uniquely determined by its boundary conditions. So, there is no further "entropy condition" that must be satisfied. Finally, we establish the existence of solutions with a jump discontinuity on a given streamline Γ of the ambient field. Thus, discontinuous solutions really do occur.

We consider the particular case of (2.1) for which the ambient flow field satisfies $U(x, y) \equiv U_0 \neq 0$, $V(x, y) \equiv 0$, $P(x, y) \equiv P_0$, $\Theta(x, y) \equiv \Theta_0$. We let $\rho = \rho_0$, $\rho_1 = \rho_{10}$, $\rho_2 = \rho_{20}$, $\varepsilon_1 = \varepsilon_{10}$, $\varepsilon_2 = \varepsilon_{20}$, when evaluated at $P = P_0$, $\Theta = \Theta_0$. In this case, the lower order terms in (2.2) vanish, and (2.2) becomes

$$L_1 q \equiv -(2\mu + \lambda)u_{xx} - \mu u_{yy} - (\mu + \lambda)v_{xy} + \rho_0 U_0 u_x + p_x = 0, \tag{3.1a}$$

$$L_2 q \equiv -(\mu + \lambda)u_{xy} - \mu v_{xx} - (2\mu + \lambda)v_{yy} + \rho_0 U_0 v_x + p_y = 0, \tag{3.1b}$$

$$L_3 q \equiv \rho_0 u_x + \rho_0 v_y + \rho_{10} U_0 p_x + \rho_{20} U_{20}\theta_x = 0, \tag{3.1c}$$

$$L_4 q \equiv P_0 u_x + P_0 v_y + \rho_0 \varepsilon_{10} U_0 p_x - \kappa\Delta\theta + \rho_0 \varepsilon_{20} U_0 \theta_x = 0. \tag{3.1d}$$

For this problem, the possible curves of discontinuity are the lines $y = \text{constant}$. If $y = y^*$ is a line of discontinuity of the solution, the jump conditions (2.4) give

$$\delta u_y(x, y^*) = 0, \qquad (2\mu + \lambda)\delta v_y(x, y^*) = -\delta p(x, y^*).$$

Equation (2.4a) gives $\delta u_x(x, y^*) = 0$. Hence the second jump condition gives $\delta\sigma_{22} = \delta[\lambda u_x + (2\mu + \lambda)v_y] = -\delta p$, so the total normal stress is continuous across Γ.

It is important to clarify a potential misunderstanding concerning the system (3.1). The ambient field is a state of uniform motion, and thus may be obtained from the state of zero flow by a simple change of dependent variable. Nevertheless, the linearized system (3.1) is not related in a simple way to the corresponding system that is obtained by linearizing about a state of zero flow. An intuitive explanation of this arises from the fact that the linearized equations are satisfied by a small perturbation in the flow field. The effect of a nonconstant perturbation on a state of uniform motion is not related in a simple way to the effect of a nonconstant perturbation on the state of zero

motion. Some differences in the two linearized systems may also be seen from the results of the preceding section. As is suggested by the proof of Lemma 1, the system (2.2) is, in fact, elliptic at stagnant points of the ambient flow. Also, the curve Γ of possible discontinuities provided by Theorem 1 is meaningful only at nonstagnant points of the ambient field.

We shall consider the system (3.1) in the rectangle Ω defined by $0<x<1$, $-1<y<1$, with boundary $\partial\Omega$. In [3] it is shown that, for a time-dependent problem, it is appropriate to specify u, v and θ on $\partial\Omega$, and to specify p on the "incoming" portion of the boundary, that is, on the line $x=0$, $-1<y<1$. Thus, our boundary value problem consists of (3.1) with the boundary conditions

$$\begin{aligned} &u,\ v,\ \theta \quad \text{specified on } \partial\Omega, \\ &p(0,y) \quad \text{specified}, \qquad -1<y<1. \end{aligned} \tag{3.2}$$

We shall show that the problem (3.1), (3.2) has a unique solution. Since the numerical values of ρ_0, U_0, P_0, ρ_{10}, ρ_{20}, ε_{10}, and ε_{20} do not affect this analysis, we shall, for ease of notation, take all these values to be 1. It is convenient, for the analysis, to cast the problem into a different form. Subtracting (3.1d) from (3.1c), we obtain

$$-\kappa\Delta\theta=0. \tag{3.1e}$$

We solve this equation with the boundary conditions given by (3.2) to obtain $\theta(x,y)$. We next select functions $\bar{u}(x,y)$, $\bar{v}(x,y)$ which take on the same boundary values as u, v, and we define $\bar{p}(x,y)$ by $\bar{p}_x=-\bar{u}_x-\bar{v}_y-\theta_x$, $\bar{p}(0,y)=p(0,y)$. Considering as unknowns the functions $u-\bar{u}$, $v-\bar{v}$ and $p-\bar{p}$, and renaming these unknowns u, v, p, we are led to the problem

$$-(2\mu+\lambda)u_{xx}-\mu u_{yy}-(\mu+\lambda)v_{xy}+u_x+p_x=f, \tag{3.4a}$$

$$-(\mu+\lambda)u_{xy}-\mu v_{xx}-(2\mu+\lambda)v_{yy}+v_x+p_y=g, \tag{3.4b}$$

$$u_x+v_y+p_x=0 \tag{3.4c}$$

with boundary conditions

$$\begin{aligned} &u,\ v=0 \qquad \text{on } \partial\Omega, \\ &p(0,y)=0, \qquad -1<y<1. \end{aligned} \tag{3.5}$$

To analyze the problem (3.4), (3.5), we shall introduce some Hilbert spaces, define an appropriate bilinear form, and use the Lax-Milgram lemma—techniques that are familiar in the analysis of linear problems. We shall use the Hilbert space $L_2=L_2(\Omega)$, of square integrable functions, the space $H_0^1=H_0^1(\Omega)$ of functions $z(x,y)$ which vanish on $\partial\Omega$ and for which $\|z\|_1^2=\iint\{|\nabla z|^2+z^2\}\,dx\,dy<\infty$, and the dual space $H^{-1}=H^{-1}(\Omega)$. H^{-1} is defined as the set of distributions ϕ such that for some constant c and for $z\in C_0^\infty(\Omega)$, $|\phi(x)|\leqq c\|z\|_1$. The smallest such constant c is the norm $\|\phi\|_{-1}$. Equipped with this norm, and with a corresponding inner product, H^{-1} is a Hilbert space and may be regarded as the space of linear functionals on H_0^1. These spaces satisfy the inclusions $C_0^\infty(\Omega)\subset H_0^1\subset L_2\subset H^{-1}$, and $C_0^\infty(\Omega)$ is dense in each of these spaces in the appropriate norm. We shall also need the spaces $\underline{H}=L_2\times L_2$ and $\underline{V}=H_0^1\times H_0^1$ of pairs of functions on Ω.

Let $\xi=(u,v)\in\underline{V}$ be a pair of functions. Then u_x, $v_y\in L_2$. We define $S\xi=-u_x-v_y$, so $S:\underline{V}\to L_2$ is a bounded map. With ξ given, define $p(x,y)$ by

$$p(x,y)=\int_0^x (S\xi)(s,y)\,ds.$$

Then $p \in L_2$, so $p_y \in H^{-1}$. We define $T\xi = p_y$, so $T: \underline{V} \to H^{-1}$ is a bounded map. We then replace (3.4), (3.5) with the problem: given $(f, g) \in \underline{H}$, find $\xi = (u, v) \in \underline{V}$ so that

$$-(2\mu+\lambda)u_{xx} - \mu u_{yy} - (\mu+\lambda)v_{xy} + u_x + S\xi = f, \tag{3.6a}$$

$$-(\mu+\lambda)u_{xy} - \mu v_{xx} - (2\mu+\lambda)v_{yy} + v_x + T\xi = g. \tag{3.6b}$$

The following theorem establishes the unique solvability of (3.6).

THEOREM 2. *Suppose $\mu > 0$, $3\mu + 2\lambda > 0$. Then there is a constant $c > 0$ such that, given $(f, g) \in \underline{H}$, there exists a unique $\xi = (u, v) \in \underline{V}$ such that ξ solves* (3.6). *Also,*

$$\|\xi\|_{\underline{V}} \leqq c\|(f, g)\|_{\underline{H}}.$$

Proof. Let $\xi = (u, v) \in \underline{V}$, $\eta = (w, z) \in \underline{V}$, and define the bilinear form

$$a(\xi, \eta) = \iint \{(2\mu+\lambda)(u_x w_x + v_y z_y) + \mu(u_y w_y + v_x z_x) + (\mu+\lambda)v_y w_x + (\mu+\lambda)u_x z_y + w u_x + z v_x + w S\xi + z T\xi\}\, dx\, dy.$$

It is easily seen that $a(\xi, \eta)$ is well defined, and that a is a bounded bilinear form on $\underline{V} \times \underline{V}$. Furthermore, $\xi \in \underline{V}$ solves (3.6) if and only if

$$a(\xi, \eta) = \iint [fw + gz]\, dx\, dy, \qquad \eta \in \underline{V}.$$

Next we set $\eta = \xi$. The leading set of terms in $a(\xi, \xi)$ comprise a quadratic form in u_x, u_y, v_x, v_y. A computation shows that this quadratic form is positive definite provided that $\mu(3\mu + 2\lambda) > 0$. Since u and v vanish on $\partial\Omega$, $\iint u u_x\, dx\, dy = \iint v v_y\, dx\, dy = 0$. Set $S\xi = p_x$, $T\xi = p_y$. If u and v lie in $C_0^\infty(\Omega)$, then p is a smooth function, so

$$\iint u S\xi\, dx\, dy = \iint u p_x\, dx\, dy = -\iint u_x p\, dx\, dy.$$

Similarly,

$$\iint v T\xi\, dx\, dy = -\iint v_y p\, dx\, dy.$$

Hence

$$\begin{aligned}\iint [uS\xi + vT\xi]\, dx\, dy &= -\iint (u_x + v_y)p\, dx\, dy \\ &= \iint p p_x\, dx\, dy \\ &= \frac{1}{2}\int_{-1}^{1} p(1, y)^2\, dy \geqq 0,\end{aligned}$$

where the last equality holds because p vanishes on $x = 0$. Hence, using the density of C_0^∞ in $\underline{V}$, for any $\xi \in V$,

$$\iint [uS\xi + vT\xi]\, dx\, dy \geqq 0.$$

Using these facts, we find that

$$a(\xi, \xi) \geqq c \iint [|\nabla u|^2 + |\nabla v|^2]\, dx\, dy,$$

so there is a constant $\alpha > 0$ such that

$$\alpha\|\xi\|_V^2 \leqq a(\xi, \xi), \qquad \xi \in \underline{V}. \tag{3.7}$$

From the Lax-Milgram lemma (see, e.g., [6, III.7]) given $(f, g) \in \underline{H}$, there is a unique $\xi \in \underline{V}$ such that, for any $\eta \in \underline{V}$,

$$a(\xi, \eta) = \int\int [fw + gz]\, dx\, dy.$$

The asserted inequality is a direct consequence of (3.7), and the proof is complete.

We now construct a generalized solution to the equations (3.1) which is not smooth on the line $y = 0$. For simplicity, we shall carry out the construction in the case $\lambda = -\mu$. To carry out the construction, we shall consider the equations in the half plane $x > 0$ instead of in Ω, and we shall seek a solution with $\theta \equiv 0$. We formally take the Fourier transform of the system (3.1a), (3.1b), (3.1c) with respect to y. Setting

$$\tilde{u}(x, t) = \int u(x, y) \exp(-iyt)\, dy,$$

and similarly for $\tilde{v}, \tilde{p}$, we are led to the system

$$-\mu\tilde{u}_{xx} + \mu t^2\tilde{u} + \rho_0 U_0 \tilde{u}_x + \tilde{p}_x = 0, \tag{3.8a}$$

$$-\mu\tilde{v}_{xx} + \mu t^2\tilde{v} + \rho_0 U_0 \tilde{v}_x + it\tilde{p} = 0, \tag{3.8b}$$

$$a\tilde{u}_x + ita\tilde{v} + \tilde{p}_x = 0, \tag{3.8c}$$

where we have set $a = \rho_0/\rho_{10} U_0$.

To solve this system, we define

$$\tilde{V}(x, t) = \int_0^x \tilde{v}(s, t)\, ds.$$

Upon integrating (3.8c), we obtain

$$\tilde{p}(x, t) = -a\tilde{u}(x, t) - ita\tilde{V}(x, t) + \tilde{g}(t), \tag{3.9}$$

where we have set $\tilde{g}(t) = \tilde{p}(0, t) + a\tilde{u}(0, t)$. Using (3.9) to eliminate $\tilde{p}$ from (3.8a), (3.8b), we obtain

$$-\mu\tilde{u}_{xx} + b\tilde{u}_x + \mu t^2\tilde{u} - ita\tilde{V}_x = 0, \tag{3.10a}$$

$$-\mu\tilde{V}_{xxx} + (a + b)\tilde{V}_{xx} + \mu t^2\tilde{V}_x + at^2\tilde{V} - iat\tilde{u} = -it\tilde{g}(t), \tag{3.10b}$$

where we have set $b = \rho_0 U_0 - a$.

To solve (3.10), we consider the homogeneous linear system

$$[-\mu r^2 + br + \mu t^2]\alpha - iatr\beta = 0, \tag{3.11a}$$

$$-iat\alpha + [-\mu r^3 + (a + b)r^2 + \mu t^2 r + at^2]\beta = 0. \tag{3.11b}$$

The determinant of the system (3.11a), (3.11b) is a polynomial $q(r, t)$ which is of degree 5 in r. The roots $r(t)$ of this polynomial are important in our analysis. As $|t| \to \infty$, four of the roots tend to $\pm\infty$, whereas the fifth root tends to $-1/k$, where

$$k = \mu U_0 \rho_{10}/\rho_0.$$

The quantity k, which has the dimensions of length, plays an important role in the propagation of the discontinuities. As we will see, the dimensionless quantity x/k gives the rate of decay of the strength of the discontinuity along the streamline of the ambient flow. The following lemma gives the basic facts concerning the system (3.11) and the quantity k.

LEMMA 2. *There is a constant $d>0$, and piecewise continuous, complex-valued functions $\alpha(t)$, $\beta(t)$, $r(t)$, defined for all real t, such that for each real t, $\beta(t)\neq 0$ and* (3.11a), (3.11b) *is satisfied. As $|t|\to+\infty$, $\lim r(t)=-1/k$ and for $|t|\geqq 1$,*

$$|\alpha(t)|\leqq d/t, \quad 1\leqq d|\beta(t)|, \quad |r(t)+k^{-1}|\leqq d/t. \tag{3.12a}$$

For $|t|\leqq 1$,

$$|\alpha(t)|\leqq d, \quad 1\leqq d|\beta(t)|, \quad |r(t)|\leqq d. \tag{3.12b}$$

Proof. The determinant of the system (3.11a), (3.11b) is the quintic polynomial

$$\begin{aligned} q(r,t) &= \mu^2 r^5-\mu(a+2b)r^4-(2\mu^2t^2-ab-b^2)r^3+2b\mu t^2r^2 \\ &\quad + t^2(a^2+ab+\mu^2t^2)r+a\mu t^4 \\ &= (\mu r^2-(a+b)r-\mu t^2)(\mu r^3-br^2-\mu t^2r-at^2). \end{aligned}$$

We have $q(r,0)=\mu^2r^5-\mu(a+2b)r^4+(ab+b^2)r^3$. Hence $q(r,0)=0$ has roots $r=0$, with multiplicity at least three, and two other roots, $r=(a+b)/\mu$ and $r=b/\mu$. Since $a+b=\rho_0U_0\neq 0$, the root $r=\rho_0U_0/\mu$ of $q(r,0)$ is nonzero. Set $\varepsilon=1/t$. Then for ε near 0,

$$\varepsilon^4 q(r,t)=\mu^2 r+a\mu+O(\varepsilon),$$

so for $|t|$ large, $q(r,t)=0$ has a real root r that is close to $-a/\mu=-1/k$, and satisfies, for some $a>0$,

$$|r+1/k|\leqq d/|t|, \qquad |t|\geqq 1.$$

Also, setting $\chi=\varepsilon r$,

$$\varepsilon^5 q(r,t)=\mu^2\chi(\chi-1)^2(\chi+1)^2-\varepsilon\mu(\chi^2-1)((a+2b)\chi^2+a)+\varepsilon^2(a+b)\chi(b\chi^2+a),$$

so for $|t|$ large, $q(r,t)$ has four roots, λ, such that $\lambda\approx t,\ t,\ -t,\ -t$.

We now pick a piecewise continuous family of roots $r(t)$ of $q(r,t)$ so that $r(t)\to -1/k$ as $|t|\to+\infty$ and $r(t)\to\rho_0U_0/\mu$ as $t\to 0$. Having chosen $r(t)$, we define $[\alpha(t),\ \beta(t)]$ to be a piecewise continuous solution of (3.1) with $|\alpha(t)|^2+|\beta(t)|^2=1$. Then $|\alpha(t)|\leqq 1$, $|\beta(t)|\leqq 1$ for all t. Multiplying the first equation of (3.11) by ε^2 and taking the limit as $|t|\to+\infty$, we obtain $\lim\alpha(t)=0$. A perturbation argument shows that $|\alpha(t)|\leqq c/|t|$ for $|r|>1$. Since $\lim|\beta(t)|=1$, this proves (3.12a). Finally, we show that $\beta(t)\neq 0$ for all t. Suppose, to the contrary, that $\beta(t^*)=0$ for some real t^*. Then $|\alpha(t^*)|=1$, so from (3.11b), $t^*=0$. From (3.11a), either $r(0)=0$ or $r(0)=b/\mu$. This contradicts our choice of $r(t)$ for t near 0, and the proof is complete.

Using the functions $\alpha(t)$, $\beta(t)$, $r(t)$, we define functions $\tilde u(x,t)$, $\tilde v(x,t)$, $\tilde p(x,t)$ by

$$\tilde u(x,t)=\frac{i\tilde g(t)\alpha(t)}{at\beta(t)}\,e^{r(t)x}, \tag{3.13a}$$

$$\tilde v(x,t)=\frac{i\tilde g(t)r(t)}{at}\,e^{r(t)x}, \tag{3.13b}$$

$$\tilde p(x,t)=\tilde g(t)e^{r(t)x}-\frac{i\alpha(t)\tilde g(t)}{t\beta(t)}\,e^{r(t)x}. \tag{3.13c}$$

It may be verified by inspection that $\tilde u$, $\tilde v$, $\tilde p$ satisfy (3.8). Define the function $\tilde g(t)$ by $\tilde g=\tilde g_1-\tilde g_2$, where

$$\tilde g_1(t)=\frac{-1}{t+i},$$

and where $\tilde{g}_2(t)$ is a smooth function of compact support, chosen so that $\tilde{g}_1(0) = \tilde{g}_2(0)$. Then $\tilde{g}(t) = O(t)$ for t near 0, so since $\beta(t)$ is bounded away from 0, the formulas (3.13) have meaning for all real t. We note some properties of $\tilde{g}(t)$.

LEMMA 3. *The function $\tilde{g} \in L_2(R^1)$ and satisfies $|\tilde{g}(t)| \leqq c|t|^{-1}$ for $|t| \geqq 1$. The inverse Fourier transform $g(y) \in L_2(R^1)$ and g is continuous in $(-\infty, 0)$ and $(0, \infty)$ and satisfies $g(+0) - g(-0) = 1$.*

Proof. The inverse Fourier transform of $\tilde{g}_1$ is

$$g_1(y) = \begin{cases} e^{-y}, & y > 0, \\ 0, & y < 0, \end{cases}$$

and the inverse Fourier transform of $\tilde{g}_2$ is a C^∞ function that is rapidly decreasing at ∞. The lemma follows from these facts.

THEOREM 3. *The functions $\tilde{u}$, $\tilde{v}$ and $\tilde{p}$ are, for fixed x, in $H^1(R^1)$, $H^1(R^1)$, $L_2(R^1)$, respectively. The inverse Fourier transforms, u, v, p, are well defined, and $u, v \in H^1(S)$, $p \in L_2(S)$, on each strip $S = \{(x, y): 0 < x < x^*\}$. The functions u, v, p are a weak solution of (3.1). The function $p(x, y)$ is, for fixed x, continuous in y for $y \neq 0$, and has a jump discontinuity at $y = 0$.*

Proof. Using (3.12b) and the construction of $\tilde{g}$, we see that $|\tilde{u}|, |\tilde{v}|$ and $|\tilde{p}|$ are bounded for $|t| \leqq 1$. For $t \geqq 1$, $|\tilde{g}(t)| \leqq c/|t|$ and $|r(t)| \leqq c$, so from (3.12a) and Lemma 2, we have for all t,

$$|\tilde{u}(x, t)| \leqq c/(1+|t|)^3, \qquad |\tilde{u}_x(x, t)| \leqq c/(1+|t|)^3,$$
$$|\tilde{v}(x, t)| \leqq c/(1+|t|)^2, \qquad |\tilde{v}_x(x, t)| \leqq c/(1+|t|)^2,$$
$$|\tilde{p}(x, t)| \leqq c/(1+|t|).$$

Hence for each x,

$$(3.14) \quad \int_{-\infty}^{\infty} [(1+|t|^2)(|\tilde{u}(x, t)|^2 + |\tilde{v}(x, t)|^2) + |\tilde{u}_x(x, t)|^2 + |\tilde{v}_x(x, t)|^2 + |\tilde{p}(x, t)|^2]\, dt \leqq c$$

where the constant c is independent of x if x is bounded. It follows that the inverse transforms are well defined and $u, v \in H^1(S)$, $p \in L_2(S)$, as asserted. To show that u, v, p are weak solutions of (3.1), let $\phi \in C_0^\infty(S)$, and let $\tilde{\phi}(x, t)$ denote the transform of ϕ. Then

$$\iint_S [\mu u_x \phi_x + \mu u_y \phi_y + u_x \phi + p_x \phi)\, dx\, dy = 2\pi \iint_S [\mu \tilde{u} \tilde{\phi}_x + \mu t^2 \tilde{u} \tilde{\phi} + \tilde{u}_x \tilde{\phi} + \tilde{p}_x \tilde{\phi}]\, dx\, dt$$
$$= 0,$$

where the first equality follows from Parseval's formula and the second equality follows from (3.8a). Hence (3.1a) is satisfied in a generalized sense. The other two equations are verified in the same way. It remains to establish the continuity properties of p. From (3.14), for fixed x, $u(x, \cdot) \in H^1(R^1)$. Hence $u(x, y)$ is continuous in y for fixed x. Setting $\tilde{f}(x, t) = \tilde{g}(t) \exp(r(t)x)$, we find from (3.13) that $\tilde{p} = \tilde{f} - a\tilde{u}$, so it suffices to study the continuity properties of the inverse Fourier transform $f(x, y)$ of $\tilde{f}(x, t)$. Define

$$\tilde{f}_1(x, t) = \tilde{g}_1(t) \exp(-x/k),$$
$$\tilde{f}_2(x, t) = \tilde{g}_1(t)[\exp(r(t)x) - \exp(-x/k)],$$
$$\tilde{f}_3(x, t) = \tilde{g}_2(t) \exp(r(t)x).$$

For $|t| \geqq 1$ we use (3.12) to obtain

$$\begin{aligned} |\tilde{f}_2(x, t)| &\leqq |\tilde{g}_1(t)| \cdot |e^{r(t)x} - e^{-x/k}| \\ &\leqq c|t|^{-1}|r(t)x + x/k| \\ &\leqq cxt^{-2}. \end{aligned}$$

Hence, for x in a bounded interval and $-\infty < t < \infty$,

$$|\tilde{f}_2(x, t)| \leqq c(1+|t|)^{-2}.$$

Since $\tilde{g}_2(t)$ has compact support, $\tilde{f}_3(x, t)$ satisfies an even better inequality. Hence, for fixed x the inverse transforms, $f_2(x, y)$ and $f_3(x, y)$ belong to $H^1(R^1)$. Hence, for fixed x, f_2 and f_3 are continuous in y. Since the inverse transform $f_1(x, y) = g_1(y) \exp(-x/k)$, we find that $f_1(x, y)$ is continuous for $y \neq 0$, and $f_1(x, y)$ has a jump discontinuity as $y \to \pm 0$. Hence p has the same properties and the proof is complete.

From the construction of the solution, we see that

$$p(x, y) = g_1(y)\, e^{-x/k} + p_1(x, k), \tag{3.15}$$

where $p_1(x, y)$ is a continuous function. The function $g_1(y)$ has a jump discontinuity at $y = 0$, with a jump of magnitude one. The formula (3.15) shows that the jump is propagated into the region of the flow along the streamline of the ambient flow field that emanates from the point of the discontinuity on the boundary. The factor $\exp(-x/k)$ in (3.15) shows that the magnitude of the jump decays as we move to the interior, and the rate of the decay is measured by the dimensionless quantity x/k. As we move a distance k along the streamline, the magnitude of the jump decreases by a factor of e.

It would be of interest to know if the *nonlinear* system of equations representing steady state viscous barotropic flow has weak solutions with discontinuous pressures. It would also be of interest to know if these discontinuities have been observed experimentally.

4. Conclusions. We have found that the linearized steady state compressible Navier-Stokes equations in two dimensions admit discontinuous solutions. A curve Γ of discontinuities must lie on a streamline of the ambient flow field. The jump conditions for the discontinuity require that the total normal stress to the curve Γ be continuous across Γ, but permit the individual terms that make up this normal stress to be discontinuous. In particular, the pressure may be discontinuous across Γ, but this discontinuity in pressure is balanced by a discontinuity in the normal viscous stress σ_{22} across Γ. The temperature and its first derivatives are continuous across Γ.

In the case when the ambient flow is uniform flow with constant pressure and temperature, a specific discontinuous solution to the linearized system is constructed. The curve of discontinuities in this example emanates from a jump in the pressure on the boundary. The strength of the discontinuity decays as we move into the interior; the jump in pressure is given by the formula

$$\delta p = (\delta\rho)_0 \exp(-x\rho_0/\mu U_0(\partial\rho/\partial P)).$$

Here $(\delta p)_0$ is the jump in pressure at the boundary $x = 0$, and the derivative $\partial\rho/\partial P$ is taken at constant temperature. If the fluid is incompressible, $\partial\rho/\partial P = 0$, and there is no pressure discontinuity in the interior. In the case of an ideal polytropic gas, the dimensionless quantity $x/k = x\rho/\mu U_0(\partial\rho_0/\partial P)$ may be interpreted in terms of the Reynolds number and the Mach number. Setting $\rho = P/R\Theta$, we have $\partial\rho/\partial P = 1/R\Theta = \gamma c^{-2}$, where c is the sound speed and γ is the adiabatic exponent.

Hence in this case,

$$x/k = \frac{x\rho_0 c^2}{\gamma\mu U_0} = \gamma^{-1}M^{-2}\frac{xU_0\rho_0}{\mu} = \gamma^{-1}M^{-2}\,\mathrm{Re},$$

where we have set $M = U_0/c$ = the Mach number of the ambient flow and $\mathrm{Re} = xU_0\rho_0/\mu$ = the Reynolds number. If we consider air at room temperature and atmospheric pressure, the values $c \approx 1100$ ft/sec, $\rho_0 \approx 0.075$ $\mathrm{lb}_m/\mathrm{ft}^3$, $\mu = 1.22\times 10^{-5}$ $\mathrm{lb}_m/\mathrm{ft}$ sec may be found in Whitaker [5]. Hence, retaining $U_0/c = M$, the Mach number, we find that

$$k = \frac{x}{M}\cdot\frac{\rho_0 c}{\gamma\mu} \approx \frac{x}{M}\cdot 4.8\times 10^6,$$

where the distance x is measured in feet. For example, if the ambient flow is at the speed of sound, $M = 1$, the jump in pressure is reduced by a factor of $\exp(-4.8\times 10^6)$ at a distance of one foot from the boundary of the region. This may explain why these discontinuities do not seem to have been discussed in the literature. The pressure jump would decay more slowly with large viscosity.

Acknowledgments. We thank Professors A. Faller, H. Glaz, and T.-P. Liu and Dr. T.-F. Zien for some interesting conversations on this paper.

ON UNIQUENESS OF AXISYMMETRIC DEFORMATIONS OF ELASTIC PLATES AND SHELLS*

HUBERTUS J. WEINITSCHKE†

Abstract. Finite axisymmetric deformations of thin shells of revolution are considered for problems where the radial membrane stress is nonnegative. It is rigorously proved that the solutions of the relevant boundary value problems for both closed and open (doubly connected) shallow shells subjected to arbitrary normal surface load and various edge conditions are unique. This result is shown to hold also for a restricted class of boundary value problems for nonshallow shells.

Key words. geometrically nonlinear deformation of elastic plates and shells, uniqueness of tensile solution in shells, axisymmetric deformation in shells of revolution

AMS(MOS) subject classifications. 73C15, 73C50, 73K10, 73K15, 73L99

1. Introduction. We consider axisymmetric finite deformations of thin elastic shells of revolution. The most frequently encountered geometries in the applications are: a closed shell with no other boundary than the two outer surfaces, a shell closed at the apex, also called a regular dome having a circular boundary with some kind of edge support, or a (doubly connected) ring shell with an additional boundary which may be described as a central opening around the apex. When loads are applied to the surface and to the edges, we generally expect, on intuitive grounds and experience, *uniqueness* of solutions when the stresses throughout the shell are predominantly tensile, for instance if a closed shell is subjected to internal pressure. But shells may of course buckle under suitable loads, usually caused by compressive stresses, and in this case uniqueness can be expected only for sufficiently small loads.

The purpose of this paper is to prove some general uniqueness theorems by elementary methods of classical analysis. These theorems will confirm the intuitive conclusions indicated above. Basically, we assume that the meridional stress resultant N_s is positive throughout the shell, except at the edges (where $N_s = 0$ is permitted), but no assumptions are made on the sign of the circumferential stress resultant N_θ and on the stresses due to the bending moments M_s and M_θ. It turns out that $N_s \geqq 0$ alone implies uniqueness of axisymmetric solutions for a large class of shell problems. More precisely, this type of uniqueness holds for arbitrary shallow shells of revolution, open or closed at the apex, within the framework of small finite deflection theory. Here, N_s is essentially given by the radial stress resultant N_r. In the case of nonshallow shells, we prove uniqueness for a restricted class of boundary value problems in the sense that the boundary conditions for the relevant dependent variables are assumed to be linear. We suspect that uniqueness of axisymmetric solutions with $N_s \geqq 0$ holds true also in the general finite deflection theory for shells of revolution [11], that is, under any given surface load and a general class of physically meaningful edge conditions (linear or nonlinear) there cannot be more than one solution with N_s nonnegative. On the other hand, it is well known that $N_s \geqq 0$ does not imply global uniqueness, as shells of revolution may buckle asymmetrically when N_θ is compressive.

This work was done while the author was visiting at the Institute of Applied Mathematics, University of British Columbia, Vancouver, Canada. This work was supported in part by Natural Sciences and Engineering Research Council of Canada grant A-5201.

The problem of the *existence* of solutions for shallow spherical shells, closed at the apex, subjected to normal pressure and various edge conditions, has been resolved by Wagner [15], using methods of the calculus of variations. A different proof for the special case of a circular plate was later given by Dickey [2]. The results obtained in [15] imply a uniqueness proof for circular plate boundary value problems as shown by Reiss [10]. Here we give an elementary uniqueness proof for arbitrary shallow shells without using Wagner's result. In the special case of circular plates, our results specialize to those in [10]. Furthermore, we obtain new uniqueness results for ring shells, including annular plates as a special case. Apparently, the von Kármán equations for annular plates have not been analyzed in previous work with regard to the mathematical questions of existence and uniqueness of solutions. For annular flat membrane problems, these questions have recently been treated by the author and Grabmüller [19], [5] (see also recent work by Grabmüller and Novak [3], [4]).

2. Basic equations, shallow shells. Our starting point is the basic equations of shallow shell theory in the form given by E. Reissner [11], [12]. Restricting ourselves to axisymmetric stresses and displacements in shells of revolution, the equations can be written in terms of dimensionless variables as follows [17]:

$$Lf = -Z(x)g + fg + 2\gamma R(x, \varepsilon), \quad Lg = Z(x)f - \tfrac{1}{2}f^2, \quad \varepsilon < x < 1 \tag{2.1}$$

where

$$L = \frac{d^2}{dx^2} + \frac{3}{x}\frac{d}{dx}, \qquad R(x, \varepsilon) = \frac{2}{x^2}\int_{\varepsilon}^{x} \xi \bar{p}(\xi)\, d\xi.$$

f relates to an angular deflection, g to the radial stress σ_r, $Z(x)$ to the geometry of the undeformed middle surface, and $x = r/a$, $\varepsilon = r_i/a$, where a is the base radius of the outer edge and r_i is the radius of the central opening, called the inner edge. The polarly symmetric pressure $p(r)$ is scaled to $\bar{p} = p/p_0$, where $p_0 = \max |p(r)|$. Hence, γ is a measure of the intensity of the applied load, $\gamma \sim p_0$, and γ is positive for external pressure. In the special case of a spherical shell we have $Z(x) = \mu^2$, where $\mu^2 = 2m_0 H_0/t$, H_0 being the height of the apex above the base plane through $r = a$, t the shell thickness and $m_0^2 = 12(1-\nu^2)$, ν = Poisson's ratio.

At the outer edge $r = a$ we prescribe

$$g(1) = S \quad \text{or} \quad g'(1) + (1-\nu)g(1) = H \tag{2.2}$$

where S is a given dimensionless radial traction and H is a dimensionless radial displacement. For a clamped or a moment-supported outer edge we have, in addition to (2.2),

$$f(1) = 0 \quad \text{or} \quad f'(1) + (1+\nu)f(1) = M, \tag{2.3}$$

respectively, where M is a prescribed dimensionless radial edge moment.

If the shell is closed at the apex $r = 0$, we formally set $\varepsilon = 0$ in (2.1) and assume the usual regularity conditions

$$f'(0) = 0, \qquad g'(0) = 0. \tag{2.4}$$

Equations (2.1)-(2.4) then constitute the boundary value problem (BVP) for a closed (dome) shell, denoted as Problem I. Selecting one boundary condition from (2.2) and (2.3) we obtain the four different BVP's (C, S), (M, S), (C, H), and (M, H), with obvious notation and C referring to the clamped edge condition $f(1) = 0$, although it may be replaced by $f(1) = C$ if the angle of rotation is prescribed.

When the shell has a circular opening at the apex, we replace (2.4) by similar boundary conditions at the inner edge $r = r_i$, expressed in terms of f and g by

$$f(\varepsilon) = c \quad \text{or} \quad \varepsilon f'(\varepsilon) + (1+\nu) f(\varepsilon) = m \tag{2.5}$$

and

$$g(\varepsilon) = s \quad \text{or} \quad \varepsilon g'(\varepsilon) + (1-\nu) g(\varepsilon) = h. \tag{2.6}$$

The physical significance is analogous to that of conditions (2.2) and (2.3). In particular, the case of a "free edge" $g(\varepsilon) = \varepsilon f'(\varepsilon) + (1+\nu) f(\varepsilon) = 0$ is contained in (2.5), (2.6). Equations (2.1)-(2.3), (2.5), and (2.6) for $\varepsilon > 0$ define the boundary value problem for shells with a central hole, which will henceforth be denoted as Problem II. The special case of a uniform pressure is given by $R(x, \varepsilon) = 1 - (\varepsilon/x)^2$. Selecting one boundary condition from each of the sets (2.2), (2.3), (2.5), and (2.6) we obtain a total of 16 BVP's denoted by 4-tuples such as $(c, s; M, H)$, in obvious generalization of the notation for Problem I.

3. Uniqueness of tensile solutions of Problem I. Let (f_1, g_1) and (f_2, g_2) be two solutions of Problem I or II, then we have from (2.1), setting $v = f_1 - f_2$, $w = g_1 - g_2$,

$$\begin{aligned} Lv &= -Zw + f_1 g_1 - f_2 g_2 = -Zw + g_1 v + f_2 w, \\ Lw &= Zv - \tfrac{1}{2}(f_1^2 - f_2^2) = -\tfrac{1}{2}(f_1 + f_2 - 2Z) v, \end{aligned}$$

with homogeneous boundary conditions corresponding to (2.2)-(2.6) for v and w. Now we integrate $vLv + wLw$ after multiplying by x^3

$$\begin{aligned} \int_\varepsilon^1 (vLv + wLw) x^3 \, dx &= \int_\varepsilon^1 [v(x^3 v')' + w(x^3 w')'] \, dx \\ &= \int_\varepsilon^1 \left[-Zvw + g_1 v^2 - f_2 vw - \frac{1}{2} vw(f_1 + f_2 - 2Z) \right] x^3 \, dx. \end{aligned} \tag{3.1}$$

Integrating by parts and simplifying the second line of (3.1), we obtain

$$-\int_\varepsilon^1 x^3 (v'^2 + w'^2) \, dx + B_\varepsilon + B_1 = \frac{1}{2} \int_\varepsilon^1 x^3 v^2 (g_1 + g_2) \, dx. \tag{3.2}$$

In Problem I, $\varepsilon = 0$ and $B_0 = 0$ by (2.4), while $B_1 = v(1)v'(1) + w(1)w'(1)$, which is therefore given by

$$B_1 = -\alpha(1+\nu) v^2(1) - \beta(1-\nu) w^2(1) \leqq 0, \tag{3.3}$$

where α and β take on the values 0 or 1, depending on which combination of boundary conditions from (2.2) and (2.3) is selected. Hence, the left-hand side of (3.2) is always nonpositive, while the right-hand side is nonnegative, provided $g_i(x) \geqq 0$, $i = 1, 2$.

DEFINITION 1. A solution (f, g) of Problem I or II is called *tensile*, if $g(x) \geqq 0$, which is equivalent to $\sigma_r \geqq 0$.

Note that no conditions (other than smoothness) are imposed on the remaining stress components or bending moments for a solution to be tensile in our terminology.

THEOREM 3.1. *Tensile solutions* $(f(x), g(x))$ *of Problem* I *are unique.*

Proof. Since (3.2) implies $v' = w' \equiv 0$, we have $v(x) = v_0 = \text{const.}$ and $w(x) = w_0 = \text{const.}$ For $\alpha = \beta = 1$, that is BVP (M, H), (3.3) shows that $B_1 < 0$ unless $v(1) = v_0 = w(1) = w_0 = 0$; hence $v = w \equiv 0$. In BVP (M, S), $\beta = 0$, $\alpha = 1$, we conclude $v_0 = 0$ from (3.3), implying $v \equiv 0$, and since $g_1(1) = g_2(1) = S$, we also have $w_0 = 0$; hence $w \equiv 0$. A similar argument shows $v = w \equiv 0$ in BVP (C, H), where $\alpha = 0$, $\beta = 1$. Finally, $v(1) = w(1) = 0$ in BVP (C, S), which completes the proof.

In the case of a circular plate $Z=0$; hence the second equation of (2.1) implies

$$x^3 g'(x) = -\frac{1}{2}\int_0^x t^3 f^2(t)\,dt \leqq 0. \tag{3.4}$$

If $g(1)=S\geqq 0$, this yields $g(x)\geqq S$, as g is monotone nonincreasing. If $g'(1)+(1-\nu)g(1)=H$, with $H\geqq 0$ (to exclude buckling), $g'(1)\leqq 0$ from (3.4) implies $g(1)\geqq 0$, whence $g(x)\geqq g(1)$. Thus the solutions (f, g) are tensile and we conclude the following.

THEOREM 3.2. *The solutions of the circular plate BVP's* (C, S), (M, S), (C, H), *and* (M, H) *are unique, provided* $S\geqq 0$ *or* $H\geqq 0$.

The same result can be expected to hold for sufficiently small $Z(x)$. On the other hand, axisymmetric buckling of circular plates is known to occur in the range $S<0$ or $H<0$. A slightly less general version of Theorem 3.2 was proved in a different way by Reiss [10], on the basis of results of Wagner [15].

4. Uniqueness ot tensile solutions of Problem II. It is seen that the method of proving Theorem 3.1 carries over to Problem II only if $B_\varepsilon = -\varepsilon^3(vv'+ww')$ is zero, that is, if the boundary conditions are $f(\varepsilon)=c$ *and* $g(\varepsilon)=s\geqq 0$. If all other cases we have

$$B_\varepsilon = \varepsilon^2[\alpha(1+\nu)v^2(\varepsilon)+\beta(1-\nu)w^2(\varepsilon)]\geqq 0,$$

with $\alpha=1$ or $\beta=1$ or $\alpha=\beta=1$. Hence, we cannot conclude that the left-hand side of (3.2) is nonpositive.

In order to get the proper sign for B_ε, a transformation due to Schwerin [13] was used in earlier work on annular membranes [5]. This transformation can be adapted to our Problem II in several ways. For instance, let

$$z=\frac{x^2-\varepsilon^2}{1-\varepsilon^2},\quad f(x)=\frac{1}{x^2}\bar{f}(z),\quad g(x)=\bar{g}(z). \tag{4.1}$$

The interval $[\varepsilon, 1]$ is mapped onto $[0, 1]$, and any regular tensile solution (f, g) is transformed into such a solution $(\bar{f}, \bar{g})$ and vice versa. The differential equations for Problem II in terms of z, $\bar{f}$ and $\bar{g}$ are

$$\begin{aligned} k_\varepsilon^2\ddot{\bar{f}} &= -Z\bar{g}+2\gamma R+x^{-2}\bar{f}\bar{g}, \\ k_\varepsilon^2 x^2\ddot{\bar{g}}+4k_\varepsilon\dot{\bar{g}} &= Zx^{-2}\bar{f}-\tfrac{1}{2}x^{-4}\bar{f}^2, \end{aligned} \qquad 0<z<1 \tag{4.2}$$

where a dot denotes differentiation with respect to z and $x^2=\varepsilon^2+z(1-\varepsilon^2)$. The boundary conditions at $x=\varepsilon$ become

$$\bar{f}(0)=c\varepsilon^2 \quad \text{or} \quad \dot{\bar{f}}(0)-k_{-\nu}\bar{f}(0)=\bar{m}, \tag{4.3}$$

$$\bar{g}(0)=s \quad \text{or} \quad \dot{\bar{g}}(0)+k_{-\nu}\bar{g}(0)=\bar{h}\varepsilon^{-2} \tag{4.4}$$

and the boundary conditions at $x=1$ are

$$\bar{f}(1)=C \quad \text{or} \quad \dot{\bar{f}}(1)-\varepsilon^2 k_{-\nu}\bar{f}(1)=\bar{M}, \tag{4.5}$$

$$\bar{g}(1)=S \quad \text{or} \quad \dot{\bar{g}}(1)+\varepsilon^2 k_{-\nu}\bar{g}(1)=\bar{H}. \tag{4.6}$$

The constants in (4.2)–(4.6) are defined by

$$k_\varepsilon=\frac{2}{1-\varepsilon^2},\quad k_{\pm\nu}=\frac{1-\varepsilon^2}{2\varepsilon^2}(1\pm\nu),\quad (\bar{m}, \bar{h}, \bar{M}, \bar{H})=k_\varepsilon^{-1}(m, h, M, H). \tag{4.7}$$

Now let $(\bar f_i, \bar g_i)$ $i=1,2$ be two tensile solutions of (4.2)-(4.6), set $v=\bar f_1-\bar f_2$, $w=\bar g_1-\bar g_2$, $Q(z):=[\varepsilon^2+z(1-\varepsilon^2)]^2$ and carry out essentially the same steps which in § 3 led to the identity (3.2). Making use of the relation $x^4\ddot{\bar g}+(4x^2/k_\varepsilon)\dot{\bar g}=(Q\dot{\bar g})^{\cdot}$, the result is

$$-\int_0^1 (Q\dot w^2+\dot v^2)\,dz+B_0+B_1=\frac{1}{8}(1-\varepsilon^2)^2\int_0^1 Q^{-1/2}v^2(\bar g_1+\bar g_2)\,dz \tag{4.8}$$

where

$$B_0:=-v(0)\dot v(0)-\varepsilon^4 w(0)\dot w(0),\qquad B_1:=v(1)\dot v(1)+w(1)\dot w(1). \tag{4.9}$$

It is seen from (4.3) and (4.6) that the signs are such that we can conclude $B_0+B_1\leqq 0$ upon substituting $\dot v(0)$ into (4.9) and taking $w(0)=v(1)=w(1)=0$ or substituting $\dot v(0)$ and $\dot w(1)$ into (4.9) and taking $w(0)=v(1)=0$. Hence, uniqueness for the BVP's $(m, s; C, S)$ and $(m, s; C, H)$ follows as in the proof of Theorem 3.1.

A similar conclusion holds in the dual case where (4.1) is replaced by

$$z=\frac{x^2-\varepsilon^2}{1-\varepsilon^2},\quad f(x)=\bar f(z),\quad g(x)=\frac{1}{x^2}\bar g(z). \tag{4.10}$$

The boundary conditions now transform into

$$\bar f(0)=c \quad\text{or}\quad \dot{\bar f}(0)+k_{+\nu}\bar f(0)=\bar m\varepsilon^{-2}, \tag{4.11}$$

$$\bar g(0)=s\varepsilon^2 \quad\text{or}\quad \dot{\bar g}(0)-k_{+\nu}\bar g(0)=\bar h, \tag{4.12}$$

$$\bar f(1)=C \quad\text{or}\quad \dot{\bar f}(1)+\varepsilon^2 k_{+\nu}\bar f(1)=\bar M, \tag{4.13}$$

$$\bar g(1)=S \quad\text{or}\quad \dot{\bar g}(1)-\varepsilon^2 k_{+\nu}\bar g(1)=\bar H. \tag{4.14}$$

The identity corresponding to (4.8) is easily computed. We obtain

$$-\int_0^1 (Q\dot v^2+\dot w^2)\,dz+B_0+B_1=\frac{1}{8}(1-\varepsilon^2)^2\int_0^1 v^2(\bar g_1+\bar g_2)\,dz, \tag{4.15}$$

where $B_0:=-\varepsilon^2 v(0)\dot v(0)-w(0)\dot w(0)$ and B_1 is defined as in (4.9). Now the signs in (4.12) and (4.13) allow us to conclude $B_0+B_1\leqq 0$ for the BVP's $(c, h; C, S)$ and $(c, h; M, S)$, which implies uniqueness. Since the cases $(c, s; \cdot, \cdot)$ have already been resolved at the beginning of this section, we may summarize the results in the following.

THEOREM 4.1. *Tensile solutions* $(f(x), g(x))$ *of Problem* II *are unique for the following BVP's*:

$$\begin{aligned}&(c, s; C, S),\quad (c, s; M, S),\quad (c, s; C, H),\quad (c, s; M, H),\\ &(m, s; C, S),\quad (m, s; C, H),\quad (c, h; C, S),\quad (c, h; M, S).\end{aligned} \tag{4.16}$$

Obviously, one more case may be settled with the help of the transformation

$$z=\frac{x^2-\varepsilon^2}{1-\varepsilon^2},\quad f(x)=\frac{1}{x^2}\bar f(z),\quad g(x)=\frac{1}{x^2}\bar g(z). \tag{4.17}$$

In that case the boundary conditions are given by (4.3), (4.12), (4.5), and (4.14). Hence, $B_0\leqq 0$ but $B_1\geqq 0$, in the identity corresponding to (4.15), except in the single case $(m, h; C, S)$, where $B_1\leqq 0$. The above method has been discussed here as it may be useful in a variety of other BVP's. However, its scope is limited by the fact that transformations such as (4.1) and (4.10) change the sign in boundary conditions involving first derivatives at both ends of the interval, for example in (4.3) and (4.5), or in (4.12) and (4.14). In Problem II, this means that BVP's of type $(\cdot, h; \cdot, H)$ or $(m, \cdot; M, \cdot)$ cannot be handled by the above technique.

We next present a more flexible approach, in order to resolve the remaining eight cases not covered by (4.16) in Theorem 4.1. Again this method may be useful for a variety of other BVP's. Although its scope is limited in a different way, the method turns out to be general enough to yield uniqueness in all 16 BVP's for Problem II, including the ones settled by Theorem 4.1. However, this is due to the particular structure of both differential equations and boundary conditions of the present problem.

The variables x, f, g are transformed in accordance with (4.17). Let (f_i, g_i), $i=1, 2$ be two tensile solutions of Problem II and consider the weighted differences

$$v(z)=\frac{\bar f_1(z)-\bar f_2(z)}{p(z)}, \quad w(z)=\frac{\bar g_1(z)-\bar g_2(z)}{q(z)}, \quad p, q>0.$$

Subtracting the transformed differential equations we first get

$$k_\varepsilon^2(vp)^{\cdot\cdot}=-x^{-2}Zwq+x^{-4}(\bar f_1\bar g_1-\bar f_2\bar g_2),$$
$$k_\varepsilon^2(wq)^{\cdot\cdot}=x^{-2}Zvp-\tfrac{1}{2}x^{-4}(\bar f_1^2-\bar f_2^2).$$

Multiplying the first equation by pv, the second by qw, adding the resulting equations and integrating, we obtain, after simplifying the right-hand term in the same way as in § 3,

$$k_\varepsilon^2\int_0^1[vp(vp)^{\cdot\cdot}+wq(wq)^{\cdot\cdot}]\,dz=\int_0^1\frac{p^2v^2}{2Q(z)}(\bar g_1+\bar g_2)\,dz$$

where k_ε and $Q(z)$ have been defined before. The choice

$$p=Az+B, \quad q=Dz+E, \quad A, B, D, E=\text{positive constants}$$

implies $p(vp)^{\cdot\cdot}=(p^2\dot v)^{\cdot}$, and integration by parts yields

$$-\int_0^1(p^2\dot v^2+q^2\dot w^2)\,dz+\bar B_0+\bar B_1=\int_0^1\left(\frac{pv}{k_\varepsilon}\right)^2\frac{\bar g_1+\bar g_2}{2Q}\,dz \tag{4.18}$$

where

$$\bar B_0=-p^2v\dot v-q^2w\dot w|_{z=0}, \qquad \bar B_1=p^2v\dot v+q^2w\dot w|_{z=1}.$$

The boundary conditions for $\bar f$ and $\bar g$ are given by (4.3), (4.5), (4.12), and (4.14). Note that $\dot v$, $\dot w$ are now given by

$$\dot v=\frac{1}{p}(\bar f_1-\bar f_2)^{\cdot}-\frac{\dot p}{p^2}(\bar f_1-\bar f_2), \qquad \dot w=\frac{1}{q}(\bar g_1-\bar g_2)^{\cdot}-\frac{\dot q}{q^2}(\bar g_1-\bar g_2).$$

Evaluating the term $p^2v\dot v$ at $z=1$, we find

$$p^2v\dot v=p^2v^2\left[-\frac{\dot p}{p}+\frac{1-\varepsilon^2}{2}(1-\nu)\right]=p^2v^2\left[-\frac{A}{A+B}+\frac{1-\varepsilon^2}{2}(1-\nu)\right].$$

Setting $A=K_1B$, we can choose $K_1>0$ such that

$$\frac{K_1}{1+K_1}>\frac{1-\varepsilon^2}{2}(1-\nu), \tag{4.19a}$$

which makes $p^2(1)v(1)\dot v(1)\leqq 0$. Similarly, with $D=K_2E$ we can choose $K_2>0$ such that

$$\frac{K_2}{1+K_2}>\frac{1-\varepsilon^2}{2}(1+\nu) \tag{4.19b}$$

in order to have $q^2(1)w(1)\dot{w}(1)\leqq 0$. By the same device, we can achieve that $-p^2v\dot{v}$ and/or $-q^2w\dot{w}$ at $z=0$ are negative, that is, $\bar{B}_0\leqq 0$. From (4.3) we find, at $z=0$,

$$p^2v\dot{v}=p^2v^2\left(k_{-\nu}-\frac{\dot{p}}{p}\right)=p^2v^2\left[\frac{1-\varepsilon^2}{2\varepsilon^2}(1-\nu)-\frac{A}{B}\right]$$

and a similar expression for $q^2w\dot{w}$. Clearly the choice

$$\text{(4.20a, b)}\qquad 0<\frac{A}{B}=K_1<\frac{1-\varepsilon^2}{2\varepsilon^2}(1-\nu),\qquad 0<\frac{D}{E}=K_2<\frac{1-\varepsilon^2}{2\varepsilon^2}(1+\nu)$$

will make $\bar{B}_0\leqq 0$. Hence $p(z)>0$ and $q(z)>0$ can be found such that $\bar{B}_0+\bar{B}_1\leqq 0$ in the seven BVP's described by

$$\text{(4.21a, b)}\qquad (c, s; \cdot, \cdot),\qquad (\cdot, \cdot; C, S)$$

and in the two BVP's

$$\text{(4.22a, b)}\qquad (c, h; M, S),\qquad (m, s; C, H).$$

In the cases (4.21a), K_1 or K_2 or both must satisfy (4.19), in the cases (4.21b), they must satisfy (4.20). The BVP's (4.22) require that K_1 and K_2 must satisfy (4.19a) and (4.20b), or (4.19b) and (4.20a), respectively. Incidentally, the BVP's (4.21) and (4.22) are precisely those covered by Theorem 4.1 and the remark following it.

It remains to show that p and q can be chosen such that the cases where both h and H and/or m and M are involved, that is,

$$\text{(4.23)}\qquad (\cdot, h; \cdot, H)\quad \text{and/or}\quad (m, \cdot; M, \cdot),$$

can be resolved. In order to make both $-p^2(0)v(0)\dot{v}(0)$ and $p^2(1)v(1)\dot{v}(1)$ nonpositive, K_1 must satisfy the two inequalities

$$\text{(4.24a, b)}\qquad \frac{K_1}{1+K_1}\geqq\frac{1-\varepsilon^2}{2}(1-\nu)=\varepsilon^2k_{-\nu}\quad\text{and}\quad K_1<\frac{1-\varepsilon^2}{2\varepsilon^2}(1-\nu)=k_{-\nu}.$$

Taking equality in (4.24a), we get $K_1=\varepsilon^2k_{-\nu}/(1-\varepsilon^2k_{-\nu})$, which indeed satisfies (4.24b), because the function

$$\phi_-(\varepsilon)=\frac{\varepsilon^2}{1-\varepsilon^2k_{-\nu}}=\frac{2\varepsilon^2}{1+\nu+(1-\nu)\varepsilon^2}$$

satisfies $0<\phi_-(\varepsilon)<1$ for all ε, ν with $0<\varepsilon<1$, $\nu>-1$. Finally, in order to make both $-q^2(0)w(0)\dot{w}(0)$ and $q^2(1)w(1)\dot{w}(1)$ nonpositive, K_2 is chosen such that it satisfies inequalities obtained from (4.24) by replacing K_1 and $k_{-\nu}$ by K_2 and $k_{+\nu}$, respectively. This can be done since $0<\phi_+(\varepsilon)<1$, with $\phi_+(\varepsilon)=\varepsilon^2/(1-\varepsilon^2k_{+\nu})$. With these values of K_1 and K_2, uniqueness for the seven BVP's (4.23), which include $(m, h; M, H)$, is proved. In summary, we have obtained the analogue of Theorem 3.1, that is, the following.

THEOREM 4.2. *Tensile solutions* $(f(x), g(x))$ *of Problem* II *are unique.*

We remark that it is important that at least one of two inequalities (4.24) is not an equality, because we must show from $v'=w'\equiv 0$ that in all combinations of boundary conditions we actually have $v=w\equiv 0$, as was done in the proof of Theorem 3.1. Obviously, the same type of arguments carry over to Problem II.

5. An application to annular plates. In this section we prove that the solutions of all annular plate BVP's are tensile provided the edge stresses s and S are nonnegative and that any prescribed radial displacements h and H satisfy certain inequalities so

as to exclude buckling. But we shall not insist on the rather strong conditions $h \leqq 0$, $H \geqq 0$. Applying Theorem 4.2, we then get an extension of Theorem 3.2 to annular plate problems.

We transform the second equation of (2.1), with $Z = 0$, according to (4.10), and restate the resulting boundary conditions for $\bar{g}(z)$

$$k_\varepsilon^2 \ddot{\bar{g}}(z) = -\frac{1}{2}\bar{f}(z)^2 \qquad \begin{cases} \bar{g}(0) = s\varepsilon^2 & \text{or} \quad \bar{g}(0) - k_{+\nu}\bar{g}(0) = \bar{h}, \\ \bar{g}(1) = S & \text{or} \quad \dot{\bar{g}}(1) - \varepsilon^2 k_{+\nu}\bar{g}(1) = \bar{H}. \end{cases} \tag{5.1}$$

In the cases $(s, \cdot\,; S, \cdot)$ it follows that $\bar{g}(z)$ satisfies the equation

$$\bar{g}(z) = Az + B + \frac{1}{2k_\varepsilon^2}\int_0^1 G(z, \xi)\bar{f}(\xi)^2\, d\xi, \tag{5.2}$$

where

$$A = S - s\varepsilon^2, \qquad B = s\varepsilon^2, \qquad G(z, \xi) = \begin{cases} (1-\xi)z, & 0 \leqq z \leqq \xi, \\ (1-z)\xi, & \xi \leqq z \leqq 1. \end{cases}$$

G is simply Green's function for $-\ddot{g}$ and the selected boundary conditions. Clearly, for s, S nonnegative we have $\bar{g}(z) \geqq 0$.

The remaining three cases are handled in the same way. Again $\bar{g}(z)$ satisfies (5.2); the quantities A, B and G are summarized in Table 1, where $k = k_{+\nu}$, $k_0 = \varepsilon^2 k/(1-\varepsilon^2 k)$ and G for $\xi \leqq z \leqq 1$ is obtained from $G(z, \xi) = G(\xi, z)$. Obviously, we have $G \geqq 0$. The conditions $A + B \geqq 0$ and $B \geqq 0$ then imply $\bar{g}(z) \leqq 0$. Evaluation of these conditions yields

$$\begin{aligned} &(s, \cdot\,; S, \cdot) && S \geqq 0, \quad s \geqq 0, \\ &(s, \cdot\,; H, \cdot) && H(1-\varepsilon^2) + 2s\varepsilon^2 \geqq 0, \quad s \geqq 0, \\ &(h, \cdot\,; S, \cdot) && S \geqq 0, \quad h(1-\varepsilon^2) \leqq 2S, \\ &(h, \cdot\,; H, \cdot) && H \geqq h\left[1 - \frac{1-\varepsilon^2}{2}(1+\nu)\right], \quad \left[1 + \frac{1-\varepsilon^2}{2\varepsilon^2}(1+\nu)\right]H \geqq h, \end{aligned} \tag{5.3}$$

where (4.7) has been used. We note that the inequalities in (5.3) are identical with those in [5], where they delineate the range of values of s, S, h and H, for which existence and uniqueness of the corresponding annular membrane BVP's was proved. The above results may be summarized in the following.

THEOREM 5.1. *The solutions of all annular plate BVP's are unique, provided that s, S, h and H satisfy the inequalities given in* (5.3), *for the four types of Problem* II, *with no restrictions on the values of c, C, m and M, to be inserted into the slots of the symbols* $(s, \cdot\,; S, \cdot)$, *etc.*

TABLE 1

Case	A	B	$G(z, \xi)$, $\quad 0 \leqq z \leqq \xi$
$(s, \cdot\,; H, \cdot)$	$\dfrac{\bar{H} + \varepsilon^4 sk}{1-\varepsilon^2 k}$	$s\varepsilon^2$	$(1 + k_0\xi)z$
$(h, \cdot\,; S, \cdot)$	$\dfrac{\bar{h} + kS}{1+k}$	$\dfrac{S - \bar{h}}{1+k}$	$(1-\xi)\dfrac{1+kz}{1+k}$
$(h, \cdot\,; H, \cdot)$	$\dfrac{\bar{H} - \varepsilon^2\bar{h}}{1-\varepsilon^2(1+k)}$	$\dfrac{\bar{H} - \bar{h}(1-\varepsilon^2 k)}{k[1-\varepsilon^2(1+k)]}$	$(1 + k_0\xi)\dfrac{1+kz}{k-k_0}$

The conditions contained in (5.3) are satisfied if $H \geqq 0$ and $h \leqq 0$. However, $H < 0$ and $h > 0$ are not excluded. For example, $H < 0$ is admitted in BVP's of the type $(s, \cdot\,; H, \cdot)$ and $h > 0$ is admitted in BVP's of type $(h, \cdot\,; S, \cdot)$. It would be interesting to see how close the bounds in (5.3) are to the critical values where $\bar{g}$ ceases to be nonnegative.

6. Tensile solutions of BVP's for nonshallow shells of revolution. A system of equations governing the axisymmetric deformation of thin elastic shells of revolution undergoing small strains but arbitrarily large rotations was first derived by E. Reissner [11], and later simplified in [12]. This system reduces to a coupled pair of second-order differential equations for the meridional angle of deformation β and stress function ψ (defined below), which generalizes (2.1) to nonshallow shells. Existence of solutions of Reissner's equations for a limited class of shell problems, including ring shells with boundary conditions $\beta = \psi = 0$ at the inner edge, but excluding dome type shells, has been proved via the Leray–Schauder fixed point theorem by Srubshchik [14]. It is well known that these methods cannot be used for answering questions about the uniqueness of solutions.

As Koiter remarked, the nonlinear equations for shells of revolution "have always been (slightly) disfigured by the occurrence of (small) terms with Poisson's ratio ν as a factor" [7]. It has been observed by several authors, including Reissner and Koiter, that these terms never affect the solution significantly within the basic accuracy of first-approximation shell theory. Furthermore, it was shown in [7] and [9] that the terms in question do not appear at all, if the basic equations are derived from the well-founded general intrinsic equations of nonlinear shell theory. In view of these insights and the remarks in [12], we may simplify the basic equations (III) and (IV) in [11] by dropping the small terms multiplied by ν and some terms Reissner himself recognized as negligibly small in [11], in particular the terms containing the vertical stress resultant P_v on the right of equation (IV). The resulting equations (6.1) are given below. In many studies of axisymmetric buckling of hemispherical and complete spherical shells, the simplified equations (6.1) have been used, for example in [8]. Similar equations were used in [1] and [6]. Hence, we may take (6.1) as a realistic model for nonshallow shells of revolution.

Let the shell mid-surface be given in cylindrical coordinates by $r = r(s)$, $z = z(s)$, and let primes denote differentiation with respect to the meridional parameter s, $0 \leqq s_0 \leqq s \leqq s_1$ (for dome shells $s_0 = 0$). We introduce the angle ϕ by $r' = \alpha \cos \phi$ and $z' = \alpha \sin \phi$ where

$$\alpha(s) = [r'(s)^2 + z'(s)^2]^{1/2}.$$

The basic equations in [11], with the simplifications described above, can be written as

$$\beta'' + \frac{(r/\alpha)'}{r/\alpha}\beta' - \left(\frac{r'}{r}\right)^2 \beta = -\frac{\alpha^2}{rD}[\psi \sin \phi - rP_v \cos \phi - \beta(\psi \cos \phi + rP_v \sin \phi)],$$

$$\psi'' + \frac{(r/\alpha)'}{r/\alpha}\psi' - \left(\frac{r'}{r}\right)^2 \psi = \frac{\alpha^2 C}{r}(\beta \sin \phi - \tfrac{1}{2}\beta^2 \cos \phi) + A_1(s) rP_v + A_2(s)(rP_v)' + A_3(s) r^2 p_r + A_4(s)(r^2 p_r)' \tag{6.1}$$

where

$$\psi = rN_r, \qquad rP_v = -\int_{s_0}^{s} rp_v \alpha d\xi,$$

(6.2) N_r, P_v = radial (=horizontal) and vertical stress resultants,
p_r, p_v = radial (=horizontal) and vertical surface load intensities,
$C = Et$ = (constant) stretching stiffness,
$D = Et^3/12(1-\nu^2)$ = (constant) bending stiffness.

The functions $A_i(s)$ are given in terms of r, z, r' and z' [11], but as they disappear when forming $\psi_1 - \psi_2$, their explicit form is irrelevant for deriving uniqueness results. We have retained only quadratic nonlinear terms involving β and ψ, that is, we consider small finite displacements, as in the preceding sections. The fully nonlinear system for arbitrary finite displacements (see equations (I), (II) in [11]) involve terms like $\sin(\beta+\phi)$ and $\cos(\beta+\phi)$ instead of β and β^2 on the right of (6.1). In the shallow shell approximation, $\phi(s)$ is treated as a small quantity, resulting in the approximations $r \sim a_0 s$, where a_0 is a constant, $r'/r \sim 1/s$, $r/\alpha \sim s$, and $\alpha^2 \cos\phi(s) \sim \alpha_0^2 =$ constant, the geometry being given by $\alpha^2 \sin\phi(s)$. Setting $\beta = a_1 sf$, $\psi = a_2 sg$, with suitable constants a_i, observing $|\beta \sin\phi| \ll 1$, and neglecting the small terms $A_i(s)$, (6.1) transforms into (2.1), for $x = s/s_1$.

We now consider two solutions (β_1, ψ_1) and (β_2, ψ_2) of (6.1) and appropriate boundary conditions in terms of β and ψ, which will be discussed later. Setting $v = \beta_1 - \beta_2$, $w = \psi_1 - \psi_2$, multiplying (6.1) by r/α and subtracting, we find

$$D\left(\frac{r}{\alpha}v'\right)' = D\frac{r}{\alpha}\left(\frac{r'}{r}\right)^2 v - \alpha w \sin\phi + \alpha r P_v v \sin\phi + \alpha(\beta_1\psi_1 - \beta_2\psi_2)\cos\phi, \tag{6.3}$$

$$\frac{1}{C}\left(\frac{r}{\alpha}w'\right)' = \frac{r}{C\alpha}\left(\frac{r'}{r}\right)^2 w + \alpha v \sin\phi - \frac{1}{2}\alpha(\beta_1^2 - \beta_2^2)\cos\phi. \tag{6.4}$$

Multiplying (6.3) by v and (6.4) by w and integrating as before, we get

$$\begin{aligned} &-\int_{s_0}^{s_1} \frac{r}{\alpha}\left[D(v')^2 + \frac{1}{C}(w')^2\right] ds + \left(D\frac{r}{\alpha}vv' + \frac{r}{C\alpha}ww'\right)\Big|_{s_0}^{s_1} \\ &\quad = \int_{s_0}^{s_1} \frac{r}{\alpha}\left(\frac{r'}{r}\right)^2\left(Dv^2 + \frac{1}{C}w^2\right) ds + \int_{s_0}^{s_1}\left[v^2 r z' P_v + \frac{1}{2}v^2 r'(\psi_1+\psi_2)\right] ds. \end{aligned} \tag{6.5}$$

The term $(\psi_1+\psi_2)v^2/2$ is obtained exactly as in § 3 due to the same structure of the nonlinearity in (2.1) and (6.1). The integral on the left and the first integral on the right-hand side of the identity (6.5) are nonnegative since $r/\alpha \geqq 0$. Note that in the remaining integral we may have $r' < 0$ and/or $z' < 0$, depending on the given shell geometry. For unrestricted rotations, the stress resultants N_s, N_r, and P_v are related by [11]

$$N_s = N_r \cos(\phi+\beta) + P_v \sin(\phi+\beta).$$

In the approximation represented by (6.1), β is small in the sense that terms of higher than second degree are ignored. Hence we have, in small rotation theory,

$$\begin{aligned} \alpha r N_s &= \alpha r(N_r \cos\phi + P_v \sin\phi) + \alpha r\beta(-N_r \sin\phi + P_v \cos\phi) \\ &= r'\psi + rz'P_v + [-z'\phi\beta + rr'P_v\beta]. \end{aligned} \tag{6.6}$$

Insofar as cubic terms have been neglected in (6.1), there should be no quartic terms in the integrals of (6.5). Hence it is consistent within small finite displacement theory to approximate the second integral on the right-hand side by

$$\int_{s_0}^{s_1} v^2 \alpha r \frac{1}{2}(N_{s1}+N_{s2})\,ds, \tag{6.7}$$

neglecting quartic terms such as $v^2\beta_i\psi_i$ arising from the bracketed term in (6.6). A reasonable concept of tensile solution is stated in the following.

DEFINITION 2. A solution $(\beta(s), \psi(s))$ of (6.1) is called *tensile* if the meridional stress resultant N_s is nonnegative.

The relation (6.6) shows that for shallow shells this concept of a tensile solution is the same as the one introduced in Definition 1, § 3. As the integral (6.7) is nonnegative for tensile solutions, the proof of the uniqueness of solutions (β, ψ), $N_s \geqq 0$, is complete for all boundary conditions that make the term $(\cdots)\big|_{s_0}^{s_1}$ on the left-hand side of (6.5) nonpositive.

Suppose first that β and ψ satisfy the same type of linear boundary conditions as f and g, respectively. Setting $x = s/s_1$ and $\varepsilon = s_0/s_1$, they are given in the form (2.2)-(2.6) with f, g replaced by β, ψ. The BVP's for shells closed at the apex are again denoted as Problem I. In this case we have the symmetry condition $\beta(0)=0$, and $\psi(0)=0$ due to $r(0)=0$, $N_r(0)$ finite. As in § 3, we conclude that the boundary term in (6.5) reduces to

$$\frac{r}{\alpha}\left[Dv(s_1)v'(s_1)+\frac{1}{C}w(s_1)w'(s_1)\right] \leqq 0.$$

Clearly the method of weighted differences given in § 4 can also be applied to the present problem in order to transform the boundary terms in (6.5) such that they become nonpositive for all 16 cases of BVP's for open shells, denoted as Problem II. We pause to summarize these conclusions and state the main result of this section.

THEOREM 6.1. *Tensile solutions* $(\beta(s), \psi(s))$ *in the sense of Definition* 2 *of both Problem* I *and Problem* II *for nonshallow shells are unique if the boundary conditions for* β *and* ψ *at both edges of the shell are of the form*

$$a_1\beta' + a_2\beta = c_1, \qquad a_3\psi' + a_4\psi = c_2 \tag{6.8}$$

where the constants a_i *satisfy* $a_1^2+a_2^2>0$ *and* $a_3^2+a_4^2>0$.

The restrictions notwithstanding, this theorem covers some physically significant BVP's. When β and N_r are prescribed at the boundary, (6.8) is satisfied with $a_1 = a_3 = 0$, which corresponds to the case denoted by $(c, s; C, S)$ in § 4. Furthermore, it will be seen from relations (6.9)-(6.11) that boundary conditions where the meridional bending moment M_s and/or the radial displacement u are prescribed at one or at both edges are linear if $\nu = 0$. Hence, these cases are fully covered by Theorem 6.1.

Next we consider conditions where M_s and/or u is prescribed and $\nu \neq 0$. The meridional bending moment consistent with (6.1) is given by [11]

$$M_s = D\left[\frac{\beta'}{\alpha}+\frac{\nu}{r}\left(\beta\cos\phi+\frac{1}{2}\beta^2\sin\phi\right)\right], \tag{6.9}$$

which leads to a boundary term

$$vv' = -\frac{1}{r}\nu v^2\left[r'+\frac{1}{2}z'(\beta_1+\beta_2)\right]. \tag{6.10}$$

Although our model implies that $z'(\beta_1+\beta_2)$ is in general small compared to r', so long as $r'>0$ and $\cos\phi>(1/2)\sin\phi$, the sign of the term within the brackets of (6.10) cannot be determined a priori. Hence, Theorem 6.1 is rigorously applicable to BVP's with prescribed edge moment only if $z'=0$ and $r'\geqq 0$ at that edge.

We run into a similar difficulty if the displacement is prescribed at the edge. For instance, the radial displacement is given by

$$u=\frac{r}{Eh}(N_\theta-\nu N_s), \qquad N_\theta=\frac{1}{\alpha}\psi'+rp_r. \tag{6.11}$$

This leads to boundary terms $(\beta_1\psi_1-\beta_2\psi_2)z'$ and $rP_v vw$ in (6.5), whose signs cannot be determined except in the special case $z'=P_v=0$ at the edge. The boundary condition $N_s=S$ is also nonlinear and cannot be treated by the present method. Hence, apart from the special cases just mentioned, it remains an open problem to extend Theorem 6.1 to a general class of BVP's, with nonlinear boundary conditions not excluded.

7. Concluding remarks. We have considered axisymmetric deformations under the assumption that the meridional membrane stress is tensile. In the cases we have studied here, we have shown that there cannot be two different tensile solutions. The physical interpretation is that there cannot be symmetric snap buckling, characterized by the occurrence of a limit point, say $\gamma=\gamma_c$, along a load deflection path, unless the radial membrane stress is compressive in the unbuckled or buckled state at $\gamma=\gamma_c$, at least in some part of the shell. It is interesting to note that it has been a general experience in shell design that the bending stresses are unimportant for stability considerations, even when they are not confined to narrow edge layers, as in the case of shallow shells. This observation is confirmed by the results of this paper.

In problems involving finite deformations, tensile membrane stresses cannot, in general, be predicted a priori under a given load. An exception is the circular and the annular plate, where uniqueness of axisymmetric solutions can be proved for arbitrary load without assuming that the solution is tensile (Theorems 3.2 and 5.1). This result can be expected to hold also for very shallow shells, but we have not attempted to prove it. However, a priori uniqueness of solutions can be proved for small loads, provided the shell is sufficiently shallow. This was done by different methods in [18] for arbitrary shallow shells; the results can be adapted to axisymmetric deformations of shells of revolution.

Finally, we remark that it should be possible to include large rotations in the analysis. In particular, we expect uniqueness of axisymmetric solutions for problems of circular and annular plates under arbitrary vertical load. The finite rotation equations for plates [12] are stated here, to indicate that this extension is apparently not straightforward

$$r^2\beta''+r\beta'-\sin\beta\cos\beta=\frac{r}{D}(\psi\sin\beta-P_v\cos\beta),$$

$$r^2\psi''+r\psi'-\psi=\frac{r}{A}(\cos\beta-1)$$

with $r=s$ and primes denoting differentiation with respect to r. In addition to the different structure of the nonlinearity, we have nonlinear boundary conditions in most cases of physical interest, except when $\nu=0$. The above equations can be reduced to a single second order equation in the limit case of circular and annular membranes ($D=0$). Grabmüller and Pirner [21] have recently succeeded in proving the uniqueness of positive solutions for these problems under all physically relevant (linear and

nonlinear) boundary conditions with ν in the range $-1 < \nu \leqq \frac{1}{2}$. For circular membranes with linear boundary conditions, this result was obtained in [20].

Acknowledgments. The authors wishes to thank L. A. Mysak for his warm hospitality during the author's stay in Vancouver.

A MATHEMATICAL MODEL OF CONTRACTING MUSCLE WITH VISCOELASTIC ELEMENTS*

V. COMINCIOLI† AND A. TORELLI†

Abstract. A three-element model of contracting muscle is studied. This model incorporates a contractile element based on a two-state cross-bridge mechanism and two viscoelastic elements placed in series and in parallel to the contractile element. The existence, uniqueness, and asymptotic behavior of the mathematical solution is proved and the numerical approach is discussed.

Key words. cross-bridge mechanism, muscle contraction, nonlinear nonlocal partial differential equations

AMS(MOS) subject classifications. 92A09, 35F25

1. Introduction. According to the classic view of Hill [15] the muscle's mechanical properties can be separated into three elements: an active force generating contractile element (CE) representing the processes in response to a stimulation and two passive elastic elements: a series elastic element (SE) in series with the (CE), which represents the structures on which (CE) exerts its force during contraction (tendons in skeletal muscles and inactive or less active regions in cardiac muscle) and a parallel elastic component (PE), which determines the mechanical behavior of muscle at rest (sarcolemma of muscle cells and extracellular structures).

On this rheological framework many mathematical models have been introduced that differentiate for the different description of (CE) element. We quote some recent papers in our research group from which more convenient literature can also be found [5], [7], [6], [10], [11], [12], [4].

In these models the (PE) and (SE) elements are described as *elastic* springs following usually an exponential law. There is however a wealth of evidence that such elements exhibit a viscoelastic behavior (see, e.g., [14] and related literature, [2], [18], [3], [19]).

This requires an extension of the traditional Hill model by replacing the series and parallel elastic elements with *viscoelastic* elements. Along this direction we find the model proposed by Glantz [14] in which the (CE) element is described macroscopically on the basis of a *force-velocity curve.*

Our aim in this paper is to introduce in the Glantz's model a more structural description of the (CE) element by making use of the *sliding filament theory.*

According to this theory the generation of muscular force results from interactions between the myosin and actin filaments. Under the influence of the intracellular calcium concentration $[Ca^{2+}]$, which in turn depends on the time course of the action potential, we have the formation of links (cross-bridges) which act like springs.

From the original model proposed by A. F. Huxley in 1957 [16] a number of models have been proposed to account for new experimental findings (for an overview, also see [7], [21], [20], [24], [25]).

However, since in the present paper we want mainly to explore the *mathematical* implications of the replying elastic elements with nonlinear viscoelastic elements, we

* Received by the editors March 3, 1986; accepted for publication (in revised form) March 24, 1987. This work was supported by Ministero Pubblica Istruzione (fondi per la ricerca scientifica) and by Istituto Analisi Numerica del Consiglio Nazionale delle Ricerche, Pavia, Italy.

† Dipartimento di Matematica, Universitá di Pavia, Strada Nuova 65, 27100 Pavia, Italy.

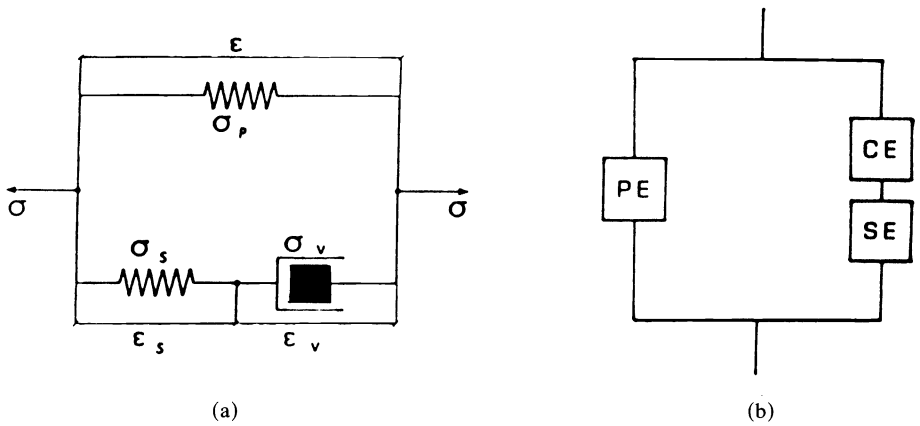
shall consider, for simplicity, the Huxley original model. For the same reason we shall study only the *isometric* contraction, corresponding to the experimental situation in which the muscle's length is kept constant and the force generated is observed. In this case the force of (PE) is constant and we have only to consider the contribution of the force of (SE). In [8], however, we report some numerical results corresponding to more general situations: *isotonic* (the force is assigned and muscle length is computed) and *isometric-isotonic.*

The present paper represents a *first* contribution in the validation process of the proposed model; indeed we prove that it is *mathematically* consistent, that is *there exists a unique solution* for admissible physical data, which agrees qualitatively with observed phenomena. We are now *identifying* the model parameters using experimental data collected in the muscle physiology laboratory at the Institute of Human Physiology, Pavia, Italy. The comparison with the results obtained by means of models containing only elastic passive elements ([5], [7], [6], [20], [23]) will be useful to estimate in quantitative ways the contribution of the viscosity in passive elements.

2. The model. The muscle, supposed homogeneous, is represented (Fig. 1(b)) by a three-element model consisting of a contractile element (CE) and two passive viscoelastic elements (SE), (PE), like those represented in Fig. 1(a) (Kelvin model, slightly different from that used in [14]).

Each of these elements is described by the following equation:

$$
\begin{aligned}
&\sigma_v = \eta \varepsilon_v' (\text{dashpot}), \qquad \varepsilon' = \frac{d\varepsilon}{dt}, \\
&\sigma_p = a(\exp(b(\varepsilon - \varepsilon_0)) - 1), \qquad \sigma_s = a(\exp(b(\varepsilon_s - \varepsilon_{s0})) - 1), \\
&\sigma_v = \sigma_s, \qquad \sigma_p + \sigma_v = \sigma, \\
&\varepsilon_v + \varepsilon_s = \varepsilon
\end{aligned}
\tag{2.1}
$$



(a) (b)

FIG. 1. (a) *Arrangement of pure elastic and viscous elements.* (b) *Classical three-element model consisting of a contractile element and two viscoelastic passive elements.*

where σ = force, ε = length, ε_0, ε_{s0} rest length. For simplicity we have supposed that the constants a, b are the same for both forces σ_p, σ_s.

From (2.1), eliminating the "internal" variables σ_v, ε_v, ε_s, σ_s, we have the following *constitutive* equation for a viscous element:

$$\sigma' = \varepsilon'(2ab + b\sigma) - \frac{b}{\eta}(\sigma - \sigma_p)(a + \sigma - \sigma_p). \tag{2.2}$$

We note that for $\eta = 0$ and for $\eta \to +\infty$ we have again two (different) only elastic situations.

We consider now the contractile element (CE). As already said it is described, for simplicity, on the basis of Huxley's theory [16] (see also for more details [5]). This element is identified with the half-sarcomere, which is the repeating unit of muscle structure and consists of an array of the thick (myosin) and the thin (actin) filaments. The links (cross-bridges) between these filaments are characterized by the distance x between the equilibrium position of the myosin head and reactive site (Fig. 2).

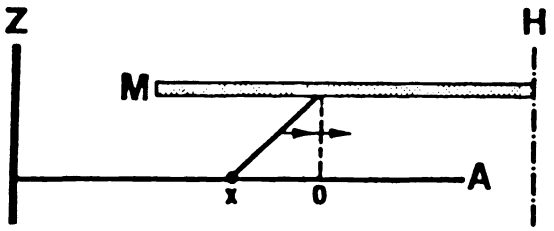


FIG. 2. *Schematic organization of a sarcomere*: A, *actin*; M, *myosin*; Z–*line*.

Let $n(x, t)$ denote the relative cross-bridge density at time t (fraction of the attached cross-bridges per unit of cross-bridge length in one half-sarcomere).

Supposing the cross-bridges to behave as linear elastic bonds with stiffness k and $n(x, t) = 0$ for x great enough, the force developed at time t by the half-sarcomere is given by

$$FCE(t) = k \int_{-\infty}^{+\infty} n(\xi, t)\xi \, d\xi. \tag{2.3}$$

The dynamics of the cross-bridges population $n(x, t)$ results from the balance of the formation and breakage, that is,

$$\frac{dn(x, t)}{dt} = f(x)\gamma(t)(1 - n(x, t)) - g(x)n(x, t) \tag{2.4}$$

where $\gamma(t)$ is the activation function, $f(x)$, $g(x)$ are the attachment rate functions and d/dt denotes the material derivative, i.e., the derivative with respect to a frame moving with the cross-bridges distribution.

Then we have

$$\frac{d}{dt} = \frac{\partial}{\partial t} + v\frac{\partial}{\partial x}, \qquad v = \frac{dx}{dt};$$

v is the half-sarcomere *velocity shortening*, that is,

$$v = \frac{dLCE}{dt}. \tag{2.5}$$

Since the sarcomere shortening follows the formation of cross-bridges, we have that v is a function of n. We want now to specify this dependence. From the rheological model we have at any time t verified these conditions:

$$\begin{aligned} &LCE(t)+LSE(t)=L(t),\\ &FCE(t)=FSE(t),\\ &P(t)=FCE(t)+FPE(t) \end{aligned} \tag{2.6}$$

where LCE, LSE, L represent the lengths of each element and FCE, FPE, P the forces.

In the following we shall consider the *isometric* situation: $L(t)=\text{const}$ and $P(t)$ is the output model. We have

$$\frac{dLCE}{dt}=-\frac{dLSE}{dt}. \tag{2.7}$$

From (2.1), noting that $\sigma=FSE$, $\varepsilon=LSE$, we have Problem 2.1.

PROBLEM 2.1. *$n(x,t)$ is the solution for $t>0$ and $x\in\mathbf{R}$ of the following equation*:

$$\frac{\partial n}{\partial t}+v\frac{\partial n}{\partial x}=f(x)\gamma(t)(1-n)-g(x)n \tag{2.8}$$

where $v(t)=-\varepsilon'(t)$ with $\varepsilon(t)$ solution of the differential equation

$$\sigma'=\varepsilon'(2ab+b\sigma)-\frac{b}{\eta}(\sigma-\sigma_p)(a+\sigma-\sigma_p) \tag{2.9}$$

where

$$\sigma(t)=k\int_{-\infty}^{+\infty} n(\xi,t)\xi\,d\xi. \tag{2.10}$$

Assuming at $t=0$ a resting situation, we have the initial conditions

$$n(x,0)=0, \qquad \varepsilon(0)=\varepsilon_0.$$

We shall prove in the following that Problem 2.1 has a unique solution under general assumptions on data $\gamma(t)$, $f(x)$, $g(x)$ and we shall study the behavior of the solution for $\eta\to 0$ and $\eta\to+\infty$.

To simplify the notation, but without loss of generality, we set the constants a, b, k equal to one for the following. Then we indicate by $u(x,t)$ the unknown function $n(x,t)$ and by $z(t)$ the function: $-(\varepsilon(t)-\varepsilon_0)$, that is the variation of the LCE length.

3. Mathematical formulation of the problem. We assume that

$$f, g\in C^1(\mathbf{R}), \qquad \gamma\in C^1([0,+\infty[), \tag{3.1}$$

$$f(x), g(x)\geqq 0, \qquad x\in\mathbf{R}, \tag{3.2}$$

$$\gamma(t)\geqq 0, \qquad t\in[0,+\infty[, \tag{3.3}$$

(3.4) The support of f is a compact set of $\mathbf{R}$.

Let also T be a fixed nonnegative number. According to § 2, we introduce the following.

PROBLEM 3.1. *Given $\eta\in[0,+\infty]$, we look for a couple $\{u,z\}$ verifying*

$$u\in C^1(\mathbf{R}\times[0,T]), \qquad z\in C^1([0,T]), \tag{3.5}$$

$$u(x,0)=0, \quad x\in\mathbf{R}; \qquad z(0)=0, \tag{3.6}$$

(3.7) *for all* $t \in [0, T]$, *the support of* $u(\cdot, t)$ *is a compact set of* $\mathbf{R}$,

$$u_t + z' u_x = \gamma f(1-u) - gu; \tag{3.8}$$

moreover, if we put

$$\sigma(t) = \int_{\mathbf{R}} xu(x, t)\, dx, \tag{3.9}$$

the following relations must also be fulfilled:

(i) *If* $\eta \in]0, +\infty[$, *then*

$$\sigma + 2 - \exp(-z) > 0, \tag{3.10}$$

$$\frac{[\sigma+1-\exp(-z)][\sigma+2-\exp(-z)]}{\sigma+2} = -\eta\left(z' + \frac{\sigma'}{\sigma+2}\right). \tag{3.11}$$

(ii) *If* $\eta = 0$, *then*

$$\sigma + 1 - \exp(-z) = 0. \tag{3.12}$$

(iii) *If* $\eta = +\infty$, *then*

$$\sigma + 2 - 2\exp(-z) = 0. \tag{3.13}$$

Remark 3.1. To simplify the notation we have omitted the dependence on η.

To study Problem 3.1 the idea is to introduce an *equivalent* problem (see next Problem 4.2) in terms of an *integral equation* for the function z; then this equation is studied by a fixed point argument.

4. Preliminary considerations. (a) If $\{u, z\}$ is a solution of Problem 3.1, we put

$$p(t) = [\sigma(t) + 2 - \exp(-z)]^{-1}, \tag{4.1}$$

and we have the following:

(i) If $\eta = 0$, then

$$p(t) \equiv 1. \tag{4.2}$$

(ii) If $\eta = +\infty$, then

$$p(t) = \exp(z(t)). \tag{4.3}$$

(iii) If $\eta \in]0, +\infty[$, then

$$p(0) = 1, \tag{4.4}$$

$$p(t) > 0, \qquad t \in [0, T], \tag{4.5}$$

$$p' = pz' + \frac{1}{\eta}(1-p). \tag{4.6}$$

(b) We now introduce the following nonlinear operator:

$$S: [0, +\infty] \times C^0([0, T]) \to C^0([0, T]) \tag{4.7}$$

for $r \in C^0([0, T])$ defined as follows:

$$S[0, r] \equiv 1, \tag{4.8}$$

$$S[+\infty, r] = \exp(r), \tag{4.9}$$

and, if $\eta \in]0, +\infty[$,

$$S[\eta, r](t) = \exp\left(r(t) - \frac{1}{\eta}t\right) + \frac{1}{\eta}\int_0^t \exp\left(r(t) - r(s) + \frac{s-t}{\eta}\right) ds. \tag{4.10}$$

It is easy to prove.

PROPOSITION 4.1. *For every $\eta \in [0, +\infty]$ and $r \in C^0([0, T])$ we have that*

$$S[\eta, r](t) > 0 \quad \forall t \in [0, T]. \tag{4.11}$$

PROPOSITION 4.2. *For every $\eta \in]0, +\infty[$ and $r \in C^1([0, T])$, $r(0) = 0$, the function $p = S[\eta, r]$ is the unique solution of problem* (4.4) *and* (4.6), *with z replaced by r.*

(c) We can now give a new formulation of Problem 3.1.

PROBLEM 4.1. *Given $\eta \in [0, +\infty]$, we look for a couple $\{u, z\}$ verifying* (3.5)-(3.8) *and*

$$S[\eta, z] = \left[2 - \exp(-z) + \int_{\mathbf{R}} xu(x, t)\, dx\right]^{-1}. \tag{4.12}$$

Problems 3.1 and 4.1 are equivalent as stated by the following proposition (the proof of which is immediate).

PROPOSITION 4.3. *Let $\eta \in [0, +\infty]$. We have that $\{u, z\}$ is a solution of Problem* 3.1 *if and only if it is a solution of Problem* 4.1.

(d) Now let

$$H(x, t) = \gamma(t)f(x) + g(x). \tag{4.13}$$

Following [5], we introduce the following operator (where $r \in C^0([0, T])$):

$$\begin{aligned}(Ur)(x, t) = &\int_0^t \gamma(s) f(r(s) - r(t) + x) \\ &\cdot \exp\left[-\int_s^t H(r(\tau) - r(t) + x, \tau)\, d\tau\right] ds.\end{aligned} \tag{4.14}$$

Given $r \in C^0([0, T])$, we put

$$[r](t) = \max\{|r(s) - r(0)|, s \in [0, t]\}. \tag{4.15}$$

If $v \in C^0(\mathbf{R} \times [0, T])$, we put

$$\operatorname{supp}_t(v) = \overline{\{x \in \mathbf{R}: v(x, t) \neq 0\}}, \tag{4.16}$$

that is, $\operatorname{supp}_t(v)$ is the support of v, with respect to x, at the time t.

Thanks to (3.4), we can find $N_-, N_+ \in \mathbf{R}$ such that

$$\operatorname{supp}(f) \subset [-N_-, N_+], \qquad N_-, N_+ > 0. \tag{4.17}$$

The following result can be proved by the method of [5].

PROPOSITION 4.4. (i) *Let $r \in C^0([0, T])$. Then we have*

$$0 \leqq (Ur)(x, t) \leqq 1, \qquad (x, t) \in \mathbf{R} \times [0, T], \tag{4.18}$$

$$\operatorname{supp}_t(Ur) \subset [-N_- - 2[r](t), N_+ + 2[r](t)]. \tag{4.19}$$

(ii) *If $r \in C^1([0, T])$, then $v = Ur$ is the unique solution of the problem*

$$v_t + r'v_x = \gamma f - Hv, \qquad v(x, 0) = 0. \tag{4.20}$$

(e) If $r \in C^0([0, T])$, we define

$$(Ar)(t) = \int_{\mathbf{R}} x[\gamma f - H(Ur)]\, dx. \tag{4.21}$$

The operator A has a meaning by (3.4) and by Proposition 4.4. Also let

$$F: [0, +\infty] \times C^0([0, T]) \to C^0([0, T]), \tag{4.22}$$

defined by

$$F[0, r] = \frac{-Ar}{\exp(-r) + \int_{\mathbf{R}} (Ur)(x, t)\, dx}, \tag{4.23}$$

$$F[+\infty, r] = \frac{-Ar}{2\exp(-r) + \int_{\mathbf{R}} Ur(x, t)\, dx} \tag{4.24}$$

and for every $\eta \in]0, +\infty[$

$$F[\eta, r] = -\frac{Ar + (1/\eta)((1 - S[\eta, r])/(S[\eta, r])^2)}{(S[\eta, r])^{-1} + \exp(-r) + \int_{\mathbf{R}} (Ur)(x, t)\, dx}. \tag{4.25}$$

The operator F has a meaning by Propositions 4.1 and 4.4. For every $\eta \in [0, +\infty]$ and $r \in C^0([0, T])$, we define

$$W[\eta, r](t) = \int_0^t F[\eta, r](s)\, ds. \tag{4.26}$$

We can now state the following problem.

PROBLEM 4.2. *Given $\eta \in [0, +\infty]$, we look for a function z verifying*

$$z \in C^1([0, T]), \tag{4.27}$$

$$z = W[\eta, z]. \tag{4.28}$$

Problems 4.1 and 4.2 are equivalent as stated by Proposition 4.5.

PROPOSITION 4.5. *Let $\eta \in [0, +\infty]$. Then*

(i) *If $\{u, z\}$ is a solution of Problem* 4.1, *then z is a solution of Problem* 4.2.

(ii) *If z is a solution of Problem* 4.2, *then the couple $\{Uz, z\}$ is a solution of Problem* 4.1.

Proof. (i) Let $\{u, z\}$ be a solution of Problem 4.1. By (3.8) and by Proposition 4.4, it follows that $u = Uz$. Multiplying (3.8) by x and integrating on $\mathbf{R}$, we have

$$\sigma' - z' \int_{\mathbf{R}} (Uz)(x, t)\, dx = Az, \tag{4.29}$$

where σ is defined in (3.9) and Az is defined in (4.21). Now put

$$p = [\sigma + 2 - \exp(-z)]^{-1}. \tag{4.30}$$

By (4.12), we obtain

$$p = S[\eta, z]; \tag{4.31}$$

hence (by Proposition 4.2),

$$p' = pz' + \frac{1}{\eta}(1 - p), \qquad \eta \in]0, +\infty[. \tag{4.32}$$

Recalling (4.29) and (4.30), we have

$$z'\left[\exp(-z)+\int_{\mathbf{R}}(Uz)(x,t)\,dx\right]=-\frac{p'}{p^2}-Az. \tag{4.33}$$

Using (4.8) and (4.9), we immediately obtain ($\eta=0,+\infty$), respectively,

$$z'=F[0,z],\qquad z'=F[+\infty,z]. \tag{4.34}$$

Let now $\eta\in\,]0,+\infty[$. It follows from (4.25), (4.32), and (4.33) that

$$z'=F[\eta,z],\qquad \eta\in\,]0,+\infty[. \tag{4.35}$$

Relations (4.34) and (4.35) imply (4.28).

(ii) Let z be a solution of Problem 4.2. Setting $u=Uz$, we must prove that $\{u,z\}$ verifies (3.5)-(3.8) and (4.12). The relations (4.14) and (4.26) imply (3.5) and (3.6). The relations (3.7) and (3.8) are a consequence of Proposition 4.4. It remains to prove (4.12). Assume $\eta\in\,]0,+\infty[$. Let

$$p=S[\eta,z]. \tag{4.36}$$

By Proposition 4.2 and (4.28), we have

$$z'\left[\exp(-z)+\int_{\mathbf{R}}u(x,t)\,dx\right]=-Az-\frac{p'}{p^2}. \tag{4.37}$$

By (3.8) (already proved), after multiplication by x and integration on $\mathbf{R}$, we have

$$\left(\int_{\mathbf{R}}xu(x,t)\,dx\right)'-z'\int_{\mathbf{R}}u(x,t)\,dx=Az. \tag{4.38}$$

Adding (4.37) and (4.38), recalling the initial data given by (3.6) and using Proposition 4.2, it follows that

$$-\exp(-z)+\int_{\mathbf{R}}xu(x,t)\,dx=\frac{1}{p}-2, \tag{4.39}$$

that is (4.12), in the special case $\eta\in\,]0,+\infty[$. If $\eta\in\{0,+\infty\}$ the proof is similar.

5. Existence and uniqueness of the solution. (a) Now set $r\in C^0([0,T])$,

$$\bar{r}(t)=\max\{r(s),\,s\in[0,t]\}, \tag{5.1}$$

$$\underline{r}(t)=\min\{r(s),\,s\in[0,t]\}, \tag{5.2}$$

$$E_r^+=\{t\in[0,T]:r(t)=\bar{r}(t)\}, \tag{5.3}$$

$$E_r^-=\{t\in[0,T]:r(t)=\underline{r}(t)\}. \tag{5.4}$$

LEMMA 5.1. *If* $\eta\in\,]0,+\infty[$ *and* $r\in C^0([0,T])$, *it follows that*

$$\begin{aligned}\exp(-\bar{r}(t))\left[1-\exp\left(\frac{-t}{\eta}\right)\right]+\exp\left(\frac{-t}{\eta}\right)&\leqq\frac{S[\eta,r](t)}{\exp(r(t))}\\&\leqq\exp(-\underline{r}(t))\left[1-\exp\left(\frac{-t}{\eta}\right)\right]+\exp\left(\frac{-t}{\eta}\right).\end{aligned} \tag{5.5}$$

Proof. Recalling (4.10), we have

$$S[\eta, r](t) \leqq \exp\left(r(t)-\frac{t}{\eta}\right)\left[1+\frac{1}{\eta}\exp\left(-\underline{r}(t)\right)\int_0^t \exp\frac{s}{\eta}\,ds\right]$$

$$= \exp\left(r(t)-\frac{t}{\eta}\right)\left[1+\exp\left(-\underline{r}(t)\right)\left(\exp\frac{t}{\eta}-1\right)\right].$$

The opposite inequality can be proved in a similar way.

COROLLARY 5.1. *Let* $\eta \in [0, +\infty]$ *and* $r \in C^0([0, T])$, *with* $r(0) = 0$. *Then we have*

(5.6) *if* $t \in E_r^+$, *then* $S[\eta, r](t) \geqq 1$,

(5.7) *if* $t \in E_r^-$, *then* $S[\eta, r](t) \leqq 1$.

Proof. The cases $\eta = 0$ and $\eta = +\infty$ are obvious. Let now $\eta \in]0, +\infty[$ and $t \in E_r^+$. We have that $r(t) = \bar{r}(t)$. Hence (by Lemma 5.1),

$$S[\eta, r](t) \geqq 1 - \exp\left(\frac{-t}{\eta}\right) + \exp\left(\bar{r}(t)-\frac{t}{\eta}\right).$$

Recalling that $r(0) = 1$, it follows that $\bar{r}(t) \geqq 0$. We have so obtained (5.6). The proof of (5.7) is similar.

(b) Now put

$$\Gamma(t) = \int_0^t \gamma(s)\,ds. \tag{5.8}$$

We can now prove the following lemma.

LEMMA 5.2. *Let* $\eta \in [0, +\infty]$ *and* z *is a solution of Problem* 4.2. *Then we have* ($t \in [0, T]$)

$$z(t) \geqq -\log\left[1 + N_+\Gamma(t)\int_0^{+\infty} f(x)\,dx\right], \tag{5.9}$$

where N_+ *is defined in* (4.17).

Proof. Let $\bar{t} \in E_z^-$. Put

$$I(\bar{t}) = \int_{-\infty}^{+\infty} x(Uz)(x, \bar{t})\,dx. \tag{5.10}$$

Recalling (3.2), (3.3), (4.13), and (4.14), it follows that

$$I(\bar{t}) \leqq \int_0^{+\infty} x \int_0^{\bar{t}} \gamma(s) f(z(s) - z(\bar{t}) + x)\,ds\,dx.$$

Changing the order of the integration and setting $y = z(s) - z(\bar{t}) + x$, we have

$$I(\bar{t}) \leqq \int_0^{\bar{t}} \gamma(s) \int_{\alpha(s)}^{+\infty} (y - \alpha(s)) f(y)\,dy\,ds,$$

where $\alpha(s) = z(s) - z(\bar{t})$. Since $\bar{t} \in E_z^-$, it follows that $\alpha(s) \geqq 0$ ($s \in [0, \bar{t}]$). Hence,

$$I(\bar{t}) \leqq \int_0^{\bar{t}} \gamma(s) \int_0^{+\infty} y f(y)\,dy\,ds \leqq N_+\Gamma(\bar{t}) \int_0^{+\infty} f(x)\,dx.$$

Recalling now the equivalence between Problems 4.1 and 4.2 (see Proposition 4.5), it follows that

$$(S[\eta, z](\bar{t}))^{-1}+\exp(-z(\bar{t}))-2 \leqq N_+\Gamma(\bar{t}) \int_0^{+\infty} f(y)\, dy.$$

Since $\bar{t} \in E_z^-$, by Corollary 5.1, we have that $S[\eta, z](\bar{t}) \leqq 1$. Hence,

$$\exp(-z(\bar{t})) \leqq 1+N_+\Gamma(\bar{t}) \int_0^{+\infty} f(y)\, dy.$$

This proves Lemma 5.2 in the case $t \in E_z^-$. If $t \in [0, T]$, then there exists $\bar{t} \in E_z^-$, such that

$$0 \leqq \bar{t} \leqq t, \qquad z(\bar{t}) \leqq z(t).$$

It follows that $\Gamma(t) \geqq \Gamma(\bar{t})$, and

$$z(t) \geqq z(\bar{t}) \geqq -\log\left(1+N_+\Gamma(t) \int_0^{+\infty} f(y)\, dy\right),$$

as we needed to show.

(c) Now let

$$K \in \mathbf{N}, \qquad K \geqq N_+\Gamma(T) \int_{-\infty}^0 f(x)\, dx+\frac{1}{1-\exp(-N_-)}, \tag{5.11}$$

where N_+ and N_- are defined in (4.17). Then we have Lemma 5.3.

LEMMA 5.3. *Let $\eta \in [0, +\infty]$. If z is a solution of Problem* 4.2, *then*

$$z(t) \leqq KN_-. \tag{5.12}$$

Proof. By contradiction, we can put $(k = 0, 1, \cdots, K)$

$$t_k = \min\{t \in [0, T]: z(t) = kN_-\}. \tag{5.13}$$

Then we have

$$0 = t_0 < t_1 < \cdots < t_K, \tag{5.14}$$

$$z(t_k) = kN_-, \qquad t_k \in E_z^+. \tag{5.15}$$

Now put

$$I_k = \int_{-\infty}^{+\infty} x(Uz)(x, t_k)\, dx. \tag{5.16}$$

If $k \geqq 1$, it follows that

$$I_k \geqq J_1+J_2, \tag{5.17}$$

where

$$J_1 = \int_{-\infty}^0 x \int_0^{t_{k-1}} \gamma(s) f(z(s)-kN_-+x)\, ds\, dx,$$

$$J_2 = \int_{-\infty}^0 x \int_{t_{k-1}}^{t_k} \gamma(s) f(z(s)-kN_-+x)\, ds\, dx.$$

We have that

$$J_1 = 0. \tag{5.18}$$

Indeed if $s \in [0, t_{k-1}]$, it follows that $z(s) \leqq (k-1)N_-$; hence, if $x \leqq 0$,

$$z(s)-kN_-+x \leqq -N_-.$$

Recalling (4.17), we obtain (5.18). Setting $y = z(s) - kN_- + x$, we have

$$J_2 = \int_{t_{k-1}}^{t_k} \gamma(s) \int_{-N_-}^{\beta(s)} [y - \beta(s)] f(y)\, dy\, ds,$$

where $\beta(s) = z(s) - kN_-$. Since $s \in [t_{k-1}, t_k]$, it follows that $\beta(s) \leqq 0$. Then we have

$$J_2 \geqq \int_{t_{k-1}}^{t_k} \gamma(s) \int_{-N_-}^{0} y f(y)\, dy\, ds;$$

hence

$$J_2 \geqq -N_-[\Gamma(t_k) - \Gamma(t_{k-1})] \int_{-\infty}^{0} f(x)\, dx. \tag{5.19}$$

By (5.16)-(5.19), it follows that

$$\int_{-\infty}^{+\infty} x(Uz)(x, t_k)\, dx \geqq -N_-[\Gamma(t_k) - \Gamma(t_{k-1})] \int_{-\infty}^{0} f(y)\, dy. \tag{5.20}$$

Using the equivalence between Problems 4.1 and 4.2 and recalling Corollary 5.1 (since $t_k \in E_z^+$), we obtain that

$$1 \leqq \exp(-kN_-) + N_-[(\Gamma(t_k) - \Gamma(t_{k-1}))] \int_{-\infty}^{0} f(y)\, dy.$$

Adding with respect to k $(k = 1, \cdots, K)$, we have

$$K \leqq \exp(-N_-) \frac{1 - \exp(-KN_-)}{1 - \exp(-N_-)} + N_-\Gamma(T) \int_{-\infty}^{0} f(y)\, dy,$$

hence

$$K < \frac{1}{1 - \exp(-N_-)} + N_-\Gamma(T) \int_{-\infty}^{0} f(y)\, dy,$$

which contradicts the (5.11).

(d) Notice that the estimates of Lemmas 5.2 and 5.3 are independent of $\eta \in [0, +\infty]$. Recalling also Lemma 5.1 we obtain immediately the following.

LEMMA 5.4. *If z is a solution of Problem* 4.2, *then there exists a constant $c_1 > 0$ (independent of $\eta \in [0, +\infty]$), such that*

$$|z(t)| < c_1, \qquad t \in [0, T], \tag{5.21}$$

$$\exp(-2c_1) \leqq S[\eta, z](t) \leqq \exp(2c_1), \qquad t \in [0, T]. \tag{5.22}$$

(e) It is easy to prove Lemma 5.5.

LEMMA 5.5. *There exists a constant $c_2 > 0$ such that for $r \in C^0([0, T])$, with*

$$|r(t)| \leqq c_1, \qquad t \in [0, T], \tag{5.23}$$

we have that

$$|(Ar)(t)| \leqq c_2, \qquad t \in [0, T], \tag{5.24}$$

where Ar is defined in (4.21) *and c_1 is the constant appearing in Lemma* 5.4.

Proof. It is a consequence of (3.1)-(3.4) and of Proposition 4.4.

(f) Looking at the formulation of Problem 4.2 and recalling Proposition 4.4 and Lemma 5.1, it is easy to find $c_3(\eta) > 0$ such that

$$\left| \frac{d}{dt} W[\eta, r](t) \right| \leqq c_3(\eta), \tag{5.25}$$

for all $r \in C^0([0, T])$ verifying

$$|r(t)| \leqq c_1, \qquad t \in [0, T]. \tag{5.26}$$

For more details, see [5]. Always following [5] (see also [7]), we can now apply the theorem of Browder [1] or (equivalently) the degree theory to obtain the following existence and uniqueness result.

THEOREM 5.1. *Let* $\eta \in [0, +\infty]$. *Then there exists one and only one solution of Problem* 4.2.

Remark 5.1. Thanks to (5.25) we can find a bound for z' depending on $\eta \in [0, +\infty]$. Having in mind to prove a theorem on the asymptotic behavior of the solution for $\eta \downarrow 0$ and for $\eta \to +\infty$, we need a stronger estimate. We shall do this in the next section.

6. Asymptotic behavior. (a) From now on we specify the dependence on η, writing z_η for a solution of Problem 4.2 with $\eta \in [0, +\infty]$. Also put

$$u_\eta = Uz_\eta, \tag{6.1}$$

$$p_\eta = S[\eta, z_\eta]. \tag{6.2}$$

With the new notation, Problem 4.2 can be written in the following way:

$$z_0' = -\frac{Az_0}{\exp(-z_0) + \int_{\mathbf{R}} u_0(x, t)\, dx}, \tag{6.3}$$

$$z_\infty' = -\frac{Az_\infty}{2\exp(-z_\infty) + \int_{\mathbf{R}} u_\infty(x, t)\, dx}, \tag{6.4}$$

$$z_\eta' = -\frac{Az_\eta + 1/\eta((1-p_\eta)/p_\eta^2)}{p_\eta^{-1} + \exp(-z_\eta) + \int_{\mathbf{R}} u_\eta(x, t)\, dx}, \qquad \eta \in]0, +\infty[\tag{6.5}$$

with the initial condition

$$z_\eta(0) = 0, \qquad \eta \in [0, +\infty]. \tag{6.6}$$

Since p_η is defined by (6.2), it follows that

$$p_\eta' = p_\eta z_\eta' + \frac{1}{\eta}(1 - p_\eta), \qquad p(0) = 1, \qquad \eta \in]0, +\infty[, \tag{6.7}$$

$$p_0 \equiv 1, \qquad p_\infty = \exp(z_\infty). \tag{6.8}$$

Later the following relation will be useful:

$$z_\eta' = -\frac{Az_\eta + p_\eta^{-2} p_\eta'}{\exp(-z_\eta) + \int_{\mathbf{R}} u_\eta(x, t)\, dx}, \qquad \eta \in]0, +\infty[\tag{6.9}$$

obtained by (6.5) and (6.7).

Now let

$$\mu_\eta = \exp(-z_\eta). \tag{6.10}$$

Relation (6.5) can be written as

$$\mu_\eta' = \mu_\eta \frac{Az_\eta + (1/\eta)((1-p_\eta)/p_\eta^2)}{p_\eta^{-1} + \mu_\eta + \int_{\mathbf{R}} u_\eta(x, t)\, dx}, \qquad \eta \in]0, +\infty[. \tag{6.11}$$

Recalling (4.10) and (6.2), we have

$$p_\eta(t) = \frac{1}{\mu_\eta(t)} \exp\left(\frac{-t}{\eta}\right) + \frac{1}{\eta} \int_0^t \left(\frac{\mu_\eta(s)}{\mu_\eta(t)} \exp\frac{s-t}{\eta}\right) ds. \tag{6.12}$$

Integrating by parts, it follows that

$$p_\eta(t)-1=-\int_0^t \frac{\mu'_\eta(s)}{\mu_\eta(t)}\exp\frac{s-t}{\eta}\,ds, \qquad \eta\in\,]0,+\infty[. \tag{6.13}$$

Recalling (6.11), we have

$$\mu'_\eta=\mu_\eta\frac{Az_\eta+(1/\eta)p_\eta^{-2}\mu_\eta^{-1}\int_0^t \mu'_\eta(s)\exp\left((s-t)/\eta\right)ds}{p_\eta^{-1}+\mu_\eta+\int_{\mathbf{R}} u_\eta(x,t)\,dx}. \tag{6.14}$$

(b) We begin the study of the asymptotic behavior of the solution with the following lemma.

LEMMA 6.1. *We have that*

$$\lim_{\eta\downarrow 0}\frac{1}{p_\eta}=1 \quad \textit{weakly in } L^2(]0,T[), \tag{6.15}$$

$$\lim_{\eta\to+\infty} p_\eta\exp(-z_\eta)=1 \quad \textit{uniformly in } [0,T]. \tag{6.16}$$

Proof. If $\eta\in\,]0,+\infty[$, we have that

$$p'_\eta=p_\eta z'_\eta+\frac{1}{\eta}(1-p_\eta). \tag{6.17}$$

Hence

$$\log p_\eta(t)-z_\eta(t)=\frac{1}{\eta}\int_0^t\left(\frac{1}{p_\eta(s)}-1\right)ds. \tag{6.18}$$

Recalling Lemma 5.4, it follows that $(\eta\downarrow 0)$

$$\int_0^t\left(\frac{1}{p_\eta(s)}-1\right)ds\to 0, \qquad t\in[0,T]. \tag{6.19}$$

Hence

$$\frac{1}{p_\eta}\to 1 \quad \text{in } \mathscr{D}'(]0,T[). \tag{6.20}$$

Let now η_n be a sequence such that $\eta_n\downarrow 0$. By Lemma 5.4, the sequence $1/p_{\eta_n}$ is bounded in $L^2(]0,T[)$. Then there exists a subsequence $1/p_{\eta_{n_k}}$ which converges to $l\in L^2(]0,T[)$ (weakly). But, thanks to (6.20), we obtain that $l=1$. Hence

$$\lim_{\eta\downarrow 0}\frac{1}{p_\eta}=1 \quad \text{weakly in } L^2(]0,T[),$$

that is,

$$\lim_{\eta\downarrow 0}\int_0^T\left(\frac{1}{p_\eta}(s)-1\right)\phi(s)\,ds=0 \quad \forall\phi\in L^2(]0,T[).$$

This proves (6.15). Let us now prove (6.16). Recalling Lemmas 5.1 and 5.4, it follows that

$$p_\eta(t)\exp(-z_\eta(t))-1\leqq\left[1-\exp\left(-\frac{t}{\eta}\right)\right][\exp c_1-1];$$

hence

$$p_\eta(t)\exp(-z_\eta(t))-1\leqq\frac{t}{\eta}\,[\exp c_1-1]. \tag{6.21}$$

In a similar way, we have

$$p_\eta(t)\exp(-z_\eta(t))-1\geqq\frac{t}{\eta}[\exp(-c_1)-1]. \tag{6.22}$$

This proves (6.16).

Now we prove an estimate on z'_η, for η not too small.

LEMMA 6.2. *For every $c_3>0$, there exists $c_4>0$ (independent of η), such that*

$$|z'_\eta(t)|\leqq c_4 \quad \forall t\in[0,T] \quad \forall \eta\in\,]c_3,+\infty]. \tag{6.23}$$

Proof. It is an easy consequence of Proposition 4.4 and Lemmas 5.4 and 5.5.

(c) It will be more difficult to prove the estimate on z'_η for η small. We begin by proving Lemma 6.3.

LEMMA 6.3. *There exists a constant $c_5>0$ (independent of $\eta\in[0,+\infty]$) such that*

$$z'_\eta(t)\leqq c_5 \quad \forall t\in[0,T]. \tag{6.24}$$

Proof. The relation (6.24) is obvious for $\eta=0,+\infty$. Now we assume that $\eta\in\,]0,+\infty[$. Thanks to (6.10) and Lemma 5.4, it is sufficient to prove that

$$\mu'_\eta(t)\geqq c_6 \quad \forall t\in[0,T], \tag{6.25}$$

where c_6 is independent of η. Let us fix now $\eta\in\,]0,+\infty[$ and put ($\bar t$ may depend on η)

$$\bar t\in[0,T]:\mu'_\eta(\bar t)\leqq\mu'_\eta(t), \quad t\in[0,T]. \tag{6.26}$$

We can obviously assume that $\mu'_\eta(\bar t)\leqq 0$.

We now distinguish two cases.

Case 1. We assume that $p_\eta(\bar t)\leqq 1$. In this case, using (6.11), we have

$$\mu'_\eta(\bar t)\geqq\mu_\eta(\bar t)\frac{(Az_\eta)(\bar t)}{p_\eta^{-1}(\bar t)+\mu_\eta(\bar t)+\int_{\mathbf{R}}u_\eta(x,\bar t)\,dx}. \tag{6.27}$$

Thanks to Proposition 4.4 and to Lemmas 5.4 and 5.5, this means that there exists c'_6 (independent of η) such that

$$\text{if } p_\eta(\bar t)\leqq 1, \text{ then } \mu'(\bar t)\geqq c'_6. \tag{6.28}$$

Case 2. We assume that $p_\eta(\bar t)>1$. Recalling Proposition 4.4 and the relation (6.14), it follows that there exists a constant C (independent of η) such that

$$\mu'_\eta(\bar t)\geqq C+\frac{1}{\eta}\frac{\int_0^{\bar t}\mu'_\eta(s)\exp((s-t)/\eta)\,ds}{p_\eta(\bar t)+p_\eta^2(\bar t)\mu_\eta(\bar t)}. \tag{6.29}$$

Recalling (6.26) and the assumption $p_\eta(\bar t)>1$, we obtain

$$\mu'_\eta(\bar t)\geqq C+\frac{1}{1+\mu_\eta(\bar t)}\mu'_\eta(\bar t). \tag{6.30}$$

Using Lemma 5.4, it follows that if $p_\eta(\bar t)>1$,

$$\mu'_\eta(\bar t)\geqq C\frac{\exp(-c_1)}{1+\exp(-c_1)}. \tag{6.31}$$

Recalling (6.28), we obtain (6.25), as needed.

(d) We can now prove Lemma 6.4.

LEMMA 6.4. *There exist two constants c_6, $c_7>0$ (independent of $\eta\in\,]0,+\infty[$) such that*

$$p'_\eta(t)\geqq -c_6, \qquad t\in[0,T], \tag{6.32}$$

$$\frac{1-p_\eta(t)}{\eta}\geqq -c_7, \qquad t\in\,]0,T[. \tag{6.33}$$

Proof. Recalling the relation (6.9) and using the estimates already proved, we readily obtain the relation (6.32). The proof of (6.33) is similar, but starting from the relation (6.5).

LEMMA 6.5. *We have that*

$$p_\eta \to 1 \quad \textit{uniformly in } [0, T]. \tag{6.34}$$

Proof. Let

$$q_\eta(t) = \begin{cases} p_\eta(t) - 1 + c_6 t, & t \in [0, T], \\ \dfrac{\exp 2c_1 - p_\eta(T)}{T}(t - T) + p_\eta(T) - 1 + c_6 T, & t \in [T, 2T] \end{cases} \tag{6.35}$$

where c_1 and c_6 are the constants appearing in (5.21) and (6.32). Thanks to Lemmas 5.4 and 6.4, $\{q_\eta\}$ is an equicontinuous family of nondecreasing functions defined in $[0, 2T]$, which verify

$$q_\eta(0) = 0, \qquad q_\eta(2T) = \exp 2c_1 - 1 + c_6 T. \tag{6.36}$$

Looking at the graph of q_η with respect to a new couple of coordinate axes rotated by $\pi/4$ (in the positive sense), we obtain a new family of functions $\{\lambda_\eta\}$ that verify (ρ independent of η)

$$\lambda_\eta : [0, \rho] \to \mathbf{R}, \tag{6.37}$$

$$\{\lambda_\eta\} \text{ are uniformly bounded,} \tag{6.38}$$

$$\lambda_\eta \text{ are equi-Lipschitz (with Lipschitz constant } \leqq 1). \tag{6.39}$$

By the Ascoli Theorem, for every sequence λ_{η_n} ($\eta_n \downarrow 0$) there exists a subsequence $\lambda_{\eta_{n_k}}$, such that

$$\lambda_{\eta_{n_k}} \to \bar{\lambda} \quad \text{uniformly in } [0, \rho], \tag{6.40}$$

where $\bar{\lambda}$ is a bounded and Lipschitz function (with Lipschitz constant $\leqq 1$). Going back to the original axes, the function $\bar{\lambda}$ becomes a bounded (not necessarily continuous) nondecreasing function λ. Moreover we have that

$$q_{\eta_{n_k}}(t) \to \lambda(t) \tag{6.41}$$

for each $t \in [0, 2T]$ where λ is continuous. Since λ is a monotone function, it follows that

$$q_{\eta_{n_k}} \to \lambda \quad \text{a.e. in } [0, 2T]. \tag{6.42}$$

Recalling the definition (6.35) of q_η, we obtain

$$p_{\eta_{n_k}} \to \lambda + 1 - c_6 t \quad \text{a.e. in } [0, T]. \tag{6.43}$$

By Lemma 5.4, we have that $\lambda(t) + 1 - c_6 t > 0$ (almost everywhere in $[0, T]$). Hence,

$$\frac{1}{p_{\eta_{n_k}}(t)} \to \frac{1}{\lambda(t) + 1 - c_6 t} \quad \text{a.e. in } [0, T]. \tag{6.44}$$

Comparing with (6.15), it follows that

$$p_\eta \to 1 \quad \text{a.e. in } [0, T]. \tag{6.45}$$

Since the limit function is continuous we obtain easily that the convergence is uniform in $[0, T]$.

(e) Lemma 6.4 allows us to prove the following estimate:

LEMMA 6.6. *There exist two constants c_8, $c_9 > 0$ (independent of η) such that*

$$z'_\eta(t) \geqq -c_8, \quad t \in [0, T], \quad \eta \in [0, c_9]. \tag{6.46}$$

Proof. If $\eta = 0$ the proof is obvious. As in the proof of Lemma 6.3, we can equivalently prove that

$$\mu'_\eta(t) \leqq c'_8, \qquad t \in [0, T], \tag{6.47}$$

where $\mu_\eta = \exp(-z_\eta)$. Given $\eta \in]0, +\infty[$, let $\bar{t} \in [0, T]$, verifying

$$\mu'_\eta(\bar{t}) \geqq \mu'_\eta(t), \qquad t \in [0, T]. \tag{6.48}$$

The value $\bar{t}$ may depend on η. Obviously we can assume that $\mu'_\eta(\bar{t}) \geqq 0$. Recalling (6.14), we have

$$\mu'_\eta(\bar{t}) \leqq C + \frac{1}{p_\eta(\bar{t}) + p_\eta^2(\bar{t})\mu_\eta(\bar{t})}\mu'_\eta(\bar{t}). \tag{6.49}$$

Hence, by Lemma 5.4,

$$\mu'_\eta(\bar{t}) \leqq C + \frac{1}{p_\eta(\bar{t}) + p_\eta^2(\bar{t})\exp(-c_1)}\mu'(\bar{t}). \tag{6.50}$$

That is

$$\mu'_\eta(\bar{t})B_\eta \leqq C, \tag{6.51}$$

where

$$B_\eta = 1 - \frac{1}{p_\eta(\bar{t}) + p_\eta^2(\bar{t})\exp(-c_1)}. \tag{6.52}$$

By Lemma 6.5

$$\lim_{\eta \downarrow 0} B_\eta = \frac{\exp(-c_1)}{1 + \exp(-c_1)}. \tag{6.53}$$

Hence there exists $c_9 > 0$, such that

$$B_\eta \geqq \frac{1}{2}\frac{\exp(-c_1)}{1+\exp(-c_1)}, \qquad \eta \in]0, c_9[, \tag{6.54}$$

that is,

$$\mu'_\eta(\bar{t}) \leqq 2C\frac{1+\exp(-c_1)}{\exp(-c_1)}. \tag{6.55}$$

(f) The following result can now be obtained.

LEMMA 6.7. *There exists a constant* $c > 0$ (*independent of* $\eta \in]0, +\infty[$) *such that* (*for all* $t \in [0, T]$)

$$|z'_\eta(t)| \leqq c, \tag{6.56}$$

$$|p'_\eta(t)| \leqq c, \tag{6.57}$$

$$\frac{1}{\eta}|1 - p_\eta(t)| \leqq c. \tag{6.58}$$

Proof. The relation (6.56) is a consequence of Lemmas 6.2, 6.3, and 6.6. The relations (6.57) and (6.58) are implied by (6.56) and the relations (6.9) and (6.5).

(g) At last we are now able to prove a result on the asymptotic behavior of the solution for $\eta \to +\infty$ and for $\eta \downarrow 0$.

THEOREM 6.1. *We have that*

$$\lim_{\eta \downarrow 0} z_\eta = z_0 \quad \textit{uniformly on } [0, T], \tag{6.59}$$

$$\lim_{\eta \to +\infty} z_\eta = z_\infty \quad \textit{uniformly on } [0, T], \tag{6.60}$$

where z_0 (*respectively*, z_η, z_∞), *is the solution of Problem* 4.2 *for* $\eta = 0$ (*respectively*, $\eta \in]0, +\infty[$, $\eta = +\infty$).

Proof. We begin proving (6.59). Let η_n be a sequence such that $\eta_n \downarrow 0$. By Lemmas 6.5 and 6.7, there exist a subsequence η_{n_k} and $\underline{z} \in C^0([0, T])$ such that

$$\lim_{k \to +\infty} p_{\eta_{n_k}} = 1 \quad \text{uniformly in } [0, T], \tag{6.61}$$

$$\lim_{k \to +\infty} z_{\eta_{n_k}} = \underline{z} \quad \text{uniformly in } [0, T], \tag{6.62}$$

$$\lim_{k \to +\infty} p'_{\eta_{n_k}} = 0 \quad \text{weakly in } L^2(]0, T[), \tag{6.63}$$

$$\lim_{k \to +\infty} z'_{\eta_{n_k}} = \underline{z}' \quad \text{weakly in } L^2(]0, T[). \tag{6.64}$$

Now let ($\eta \in [0, +\infty]$)

$$\alpha_\eta(t) = \frac{1}{p_\eta^2(t)[\exp(-z_\eta(t)) + \int_{\mathbf{R}} (Uz_\eta)(x, t)\, dx}. \tag{6.65}$$

By (6.61) and (6.62) we can prove easily that

$$\lim_{k \to +\infty} \alpha_{\eta_k} = \frac{1}{\exp(-\underline{z}) + \int_{\mathbf{R}} U\underline{z}\, dx} \quad \text{uniformly in } [0, T]; \tag{6.66}$$

hence,

$$\lim_{k \to +\infty} p'_{\eta_{n_k}} \alpha_{\eta_{n_k}} = 0 \tag{6.67}$$

in $\mathcal{D}'(]0, T[)$ (for instance).

Passing to the limit (as $k \to +\infty$) in the relation (6.9), it follows that

$$\underline{z}' = -\frac{A\underline{z}}{\exp(-\underline{z}) + \int_{\mathbf{R}} (U\underline{z})(x, t)\, dx}, \tag{6.68}$$

which implies that $\underline{z} \in C^1([0, T])$. This means that $\underline{z} = z_0$, where z_0 is the unique solution of Problem 4.2 with $\eta = 0$. Since the limit function $\underline{z}$ is independent of the sequence η_n, the relation (6.59) follows. We conclude by proving (6.60). Let η_n be a sequence such that $\eta_n \to +\infty$. By Lemmas 6.1 and 6.7, there exists a subsequence η_{n_k} and $\bar{z} \in C^0([0, T])$ such that

$$\lim_{k \to +\infty} z_{\eta_{n_k}} = \bar{z} \quad \text{uniformly in } [0, T], \tag{6.69}$$

$$\lim_{k \to +\infty} p_{\eta_{n_k}} = \exp(\bar{z}) \quad \text{uniformly in } [0, T], \tag{6.70}$$

$$\lim_{k \to +\infty} z'_{\eta_{n_k}} = \bar{z}' \quad \text{weakly in } L^2(]0, T[). \tag{6.71}$$

Recalling Lemma 5.4 and passing to the limit in the relation (6.5), we have

$$\bar{z}' = -\frac{A\bar{z}}{2\exp(-\bar{z}) + \int_{\mathbf{R}} (U\bar{z})(x, t)\, dx}. \tag{6.72}$$

As in the case $\eta \downarrow 0$, we can now obtain (6.60).

7. Numerical approximation. The equivalent formulation of Problem 2.1 in Problem 4.2 suggests a first way to approximate the solution. It comes down to numerically solve an integrodifferential equation along a characteristic line. This is a rather classical task.

Another approach, which we have used to obtain numerical simulations in [8], consists in solving Problem 2.1 directly in an implicit way at each time level. The underlying idea is like the one introduced in [17] and next adapted in [5], [7], [9], [13] for solving models with elastic passive elements. After a discretization of the time t with step Δt, we suppose to know the approximated values $\bar{n}(x, t)$ for $x \in \mathbf{R}$ and we want to compute $\bar{n}(x, t+\Delta t)$. This is achieved in two successive steps.

Step 1. Neglecting the interfilament notion, we solve the equation

$$\frac{dn(x, t)}{dt} = f(x)\gamma(t)(1 - n(x, t)) - g(x)n(x, t) \quad \text{from } t \text{ to } t+\Delta t. \tag{7.1}$$

We denote $\bar{n}_*(x, t+\Delta t)$ the solution, which is, therefore, the result in $(t, t+\Delta t)$ only of the chemical processes of association and dissociation of bridges.

We denote by $\overline{FCE}_*(t+\Delta t)$ the corresponding contractile element force, that is,

$$\overline{FCE}_*(t+\Delta t) = k \int_{-\infty}^{+\infty} \bar{n}_*(\xi, t+\Delta t)\xi\, d\xi. \tag{7.2}$$

Now, in order to restore the equilibrium of the contractile and series forces we must suitably translate $\bar{n}_*(x, t+dt)$ (interfilament motion).

Step 2. We set

$$\bar{n}(x, t+\Delta t) = \bar{n}_*(x+\delta, t+\Delta t), \qquad x \in \mathbf{R}.$$

The shift number δ is computed from (2.9) in the following way. We denote, for the sake of brevity, by $\bar{\sigma}_\delta(t+\Delta t)$ the contractile force related to the translated function $\bar{n}_*(x+\delta, t+\Delta t)$, that is,

$$\bar{\sigma}_\delta(t+\Delta t) = \int_{-\infty}^{+\infty} \bar{n}_*(\xi+\delta, t+\Delta t)\xi\, d\xi. \tag{7.3}$$

Note that as $\bar{n}_*$ vanishes for $|x| \to +\infty$ we have

$$\bar{\sigma}_\delta(t+\Delta t) = \sigma_0(t+\Delta t) - \delta KCE_* \tag{7.4}$$

where

$$KCE_* = \int_{-\infty}^{+\infty} \bar{n}_*(\xi, t+\Delta t)\, d\xi, \qquad \sigma_0 = \overline{FCE}_*(t+\Delta t).$$

We discretize now (2.9) by means of an implicit scheme by setting

$$\frac{d\sigma(t+\Delta t)}{dt} \simeq \frac{(\bar{\sigma}_\delta(t+\Delta t) - \bar{\sigma}(t))}{\Delta t},$$

$$\frac{d\varepsilon(t+\Delta t)}{dt} \simeq \frac{(\varepsilon(t+\Delta t) - \varepsilon(t))}{\Delta t}.$$

Note that $\varepsilon(t+\Delta t)=\varepsilon(t)+\delta$. The shift parameter δ is then the solution of the following nonlinear equation:

$$\frac{\bar{\sigma}_\delta(t+\Delta t)-\bar{\sigma}(t)}{\Delta t}=\frac{\delta}{\Delta t}(2ab+b\bar{\sigma}_\delta(t+\Delta t))$$

$$-\frac{b}{\eta}(\bar{\sigma}_\delta(t+\Delta t)-a(\exp(b(\varepsilon(t)+\delta-\varepsilon_0))-1)) \tag{7.5}$$

$$\cdot(a+\bar{\sigma}_\delta(t+\Delta t)-a(\exp(b(\varepsilon(t)+\delta-\varepsilon_0))-1)).$$

There exist two solutions of (7.5) one of which is spurious because of the term $(a+\sigma-\sigma_p)$; this one could be eliminated by computing the last term in t instead of $t+\Delta t$ (semi-implicit method). The good solution is that which in the limit case $\eta=0$ gives: $\sigma(t+\Delta t)=\sigma_p(t+\Delta t)$, the equilibrium between contractile and series forces. This value can be in practice easily computed by means of Newton method.

Adapting the analysis developed in [9] and [13] for the elastic passive elements models, it is possible to prove that for $\Delta t\to 0$ we have the convergence of $\bar{n}(x, t)$ to $n(x, t)$ in particular the uniform convergence of $\overline{FCE}(t)$ to FCE in $[0, T]$, $T>0$ fixed.

BOUNDARY INTEGRAL OPERATORS ON LIPSCHITZ DOMAINS: ELEMENTARY RESULTS*

MARTIN COSTABEL†

Abstract. The simple and double layer potentials for second order linear strongly elliptic differential operators on Lipschitz domains are studied and it is shown that in a certain range of Sobolev spaces, results on continuity and regularity can be obtained without using either Calderón's theorem on the L_2-continuity of the Cauchy integral on Lipschitz curves [J. L. Journé, "Calderón-Zygmuno operators, pseudo-differential operators and the Cauchy integral of Calderón," in *Lecture Notes in Math.* 994, Springer-Verlag, Berlin, 1983] or Dahlberg's estimates of harmonic measures ["On the Poisson integral for Lipschitz and C^1 domains," *Studia Math.*, 66 (1979), pp. 7-24]. The operator of the simple layer potential and of the normal derivative of the double layer potential are shown to be strongly elliptic in the sense that they satisfy Gårding inequalities in the respective energy norms. As an application, error estimates for Galerkin approximation schemes for integral equations of the first kind are derived.

Key words. Lipschitz domains, layer potentials, trace lemma, jump relations, Green's formula, Galerkin approximation, Gårding's inequality

1. Introduction.

Boundary value problems on Lipschitz domains and the method of layer potentials for their solution have attracted some attention in recent years both in the theoretical and the applied mathematical literature.

On one hand, the final proof by Coifman, McIntosh, and Meyer [5] of Calderón's Theorem on the L_2-continuity of the Cauchy integral on Lipschitz curves and Dahlberg's estimates [10] of the Poisson kernel paved the way for investigations of the Dirichlet and Neumann problems for the Laplace equation by means of boundary integral equations [12], [21], [27]. This method was also applied to some boundary value problems for the equations of linear elasticity theory [20].

On the other hand, in the applied sciences, the so-called boundary element methods are frequently used for domains with corners and edges without mathematical analysis being available. As long as there exists no elementary proof of Calderón's theorem and its consequences, it seems justified to study the range of possible results obtainable without this deep and, for the nonspecialist, not easily accessible result.

We use throughout the weak (distributional) definition of boundary values and show that the operators of the simple layer, the double layer, the normal derivative of the simple layer, and the normal derivative of the double layer define bounded operators in those Sobolev spaces on the boundary that correspond to the "energy norm," i.e., to the variational formulation of the boundary value problem. The simple layer and the normal derivative of the double layer define strongly elliptic operators. This implies stability of corresponding Galerkin approximation schemes.

In order to show continuity of the operators in a certain range of Sobolev spaces, we prove a generalization of Gagliardo's Trace Lemma (Lemma 3.6) and use regularity results for the Dirichlet and Neumann problems by Nečas [23]. Nečas obtained these results by elementary means, applying an identity of Rellich that had been used for similar purposes by Payne and Weinberger [24] and recently by Jerison and Kenig [16], [17] and Verchota [21], [27]. The same tools yield regularity results for the solutions of the integral equations and also invertibility under some hypotheses on the

† Mathematisches Institut, Technische Hochschule Darmstadt, D-6100 Darmstadt, Federal Republic of Germany.

differential operator and its fundamental solution satisfied for instance in the case of the Laplace operator unless the domain is a subset of $\mathbb{R}^2$ with analytic capacity equal to one.

This work is part of the author's habilitation thesis [7]. Further results concerning strong ellipticity of boundary integral operators for higher order differential equations on smooth domains have been published [9]. That paper also contains an extensive list of references on the Calderón-Seeley-Hörmander method of boundary integral equations for elliptic boundary value problems and on the history of strong ellipticity for boundary integral operators. Let us mention here only two references from each of these two fields: The books by Chazarain and Piriou [4] and by Dieudonné [11] describe the method of the Calderón projector of elliptic equations of any order on smooth domains. The lecture notes by Nedelec [22] and the paper by Hsiao and Wendland [15] contain, for the example of the Laplace operator on smooth domains, the idea of transforming the strong ellipticity of the differential operator via Green's formula into the strong ellipticity of certain operators on the boundary (see the proof of Theorem 2 below).

2. Main results. In this section we state the main results of this paper. Proofs are given in § 4.

Let $\Omega \subset \mathbb{R}^n$ be a bounded Lipschitz domain. This means that its boundary Γ is locally the graph of a Lipschitz function. For properties of Lipschitz domains we refer to Nečas [23] and Grisvard [14]. Because of the invariance of the Sobolev spaces $H^s = W^{s,2}$ under Lipschitz coordinate transformations for $|s| \leqq 1$, we can define the spaces $H^s(\Gamma)(|s| \leqq 1)$ in the usual way using local coordinate representations of the Lipschitz manifold Γ. The same reason implies Gagliardo's Trace Lemma:

$$\gamma_0 \colon u \mapsto \gamma_0 u := u|_\Gamma \colon H^s_{\mathrm{loc}}(\mathbb{R}^n) \to H^{s-1/2}(\Gamma) \text{ is continuous}$$

(2.1) and has a continuous right inverse

$$\gamma_0^- \colon H^{s-1/2}(\Gamma) \to H^s_{\mathrm{loc}}(\mathbb{R}^n) \quad \text{for all } s \in (\tfrac{1}{2}, 1].$$

Here traces are understood in the distributional sense, i.e., the mapping γ_0 is well defined for smooth (say continuous) functions, and for arbitrary $u \in H^s_{\mathrm{loc}}(\mathbb{R}^n)$ it is defined by approximating u by smooth functions.

Let

$$P = -\sum_{j,k=1}^{n} \partial_j a_{jk}\, \partial_k + \sum_{j=1}^{n} b_j\, \partial_j + c \tag{2.2}$$

be a differential operator with $C^\infty(\mathbb{R}^n; \mathbb{C})$-coefficients a_{jk}, b_j and c. Here $\partial_j = \partial/\partial x_j$.

We emphasize that all results will also be valid in the case of systems, i.e., for matrix valued coefficients a_{jk}, b_j and c. It is only for notational convenience that we stick to the scalar case.

We assume that P is strongly elliptic which implies that for the bilinear form

$$\Phi_\Omega(u, v) := \int_\Omega \left(\sum_{j,k=1}^{n} a_{jk}\, \partial_k u\, \overline{\partial_j v} + \sum_{j=1}^{n} b_j\, \partial_j u \bar{v} + c u \bar{v} \right) dx \tag{2.3}$$

there holds a Gårding inequality on all of $H^1(\Omega)$

$$\operatorname{Re} \Phi_\Omega(u, u) \geqq \lambda \|u\|^2_{H^1(\Omega)} - C \|u\|^2_{L_2(\Omega)} \quad \text{for all } u \in H^1(\Omega) \tag{2.4}$$

with some $\lambda > 0$. (In the case of systems we have to require (2.4) explicitly. It holds, for example, for the equations of linear elasticity theory by virtue of Korn's inequality [23, p. 194].)

Furthermore we assume that P has a fundamental solution G that is a two-sided inverse of P on the space of compactly supported distributions on $\mathbb{R}^n$. Then G has a weakly singular kernel that we also denote by G, and the function $(x, y) \mapsto G(x, y)$ is C^∞ outside the diagonal of $\mathbb{R}^n \times \mathbb{R}^n$.

For a locally integrable function v on Γ we then can define the simple layer potential

$$K_0 v(x) := \int_\Gamma G(x, y) v(y)\, ds(y) \qquad (x \in \mathbb{R}^n \backslash \Gamma) \tag{2.5}$$

where ds is the surface measure on Γ, and the double layer potential

$$K_1 v(x) := \int_\Gamma \partial_{\nu(y)} G(x, y) v(y)\, ds(y). \tag{2.6}$$

Here ∂_ν is the conormal derivative

$$\partial_\nu := \sum_{j,k=1}^{n} n_j a_{jk}\, \partial_k, \tag{2.7}$$

where n_j are the components of the almost everywhere defined outward pointing normal vector.

The boundary integral operators are defined by taking the boundary data of K_0 and K_1 (in the distributional sense; see (2.1) and Lemma 3.2 below)

$$\begin{aligned} Av &:= \gamma_0 K_0 v, & Bv &:= \gamma_1 (K_0 v|_\Omega), \\ Cv &:= \gamma_0 (K_1 v|_\Omega), & Dv &:= -\tilde{\gamma}_1 (K_1 v|_\Omega). \end{aligned} \tag{2.8}$$

Here $\gamma_1 u := \partial_\nu u|_\Gamma$ and $\tilde{\gamma}_1 u := \partial_\nu u|_\Gamma - \sum_{j=1}^n n_j b_j u|_\Gamma$.

Under these assumptions, we have the following continuity result.

THEOREM 1. *For all $\sigma \in (-\frac{1}{2}, \frac{1}{2})$ the following operators are continuous*:

(i) $K_0 : H^{-1/2+\sigma}(\Gamma) \to H^{1+\sigma}_{\mathrm{loc}}(\mathbb{R}^n)$;
(ii) $K_1 : H^{1/2+\sigma}(\Gamma) \to H^{1+\sigma}(\Omega)$;
(iii) $A : H^{-1/2+\sigma}(\Gamma) \to H^{1/2+\sigma}(\Gamma)$;
(iv) $B : H^{-1/2+\sigma}(\Gamma) \to H^{-1/2+\sigma}(\Gamma)$;
(v) $C : H^{1/2+\sigma}(\Gamma) \to H^{1/2+\sigma}(\Gamma)$;
(vi) $D : H^{1/2+\sigma}(\Gamma) \to H^{-1/2+\sigma}(\Gamma)$.

Remark. As shown by Verchota [27] and Jerison and Kenig [16], [17], the Calderón and Dahlberg theorems give the above results for the endpoint $\sigma = \frac{1}{2}$. An argument using duality and interpolation then allows to cover the whole range $\sigma \in [-\frac{1}{2}, \frac{1}{2}]$, which is optimal in the sense that, for Lipschitz boundaries, Sobolev spaces $H^s(\Gamma)$ with $|\sigma| > 1$ cannot be defined in a unique invariant way.

The operators A and D are strongly elliptic.

THEOREM 2. *There exist compact operators*

$$T_A : H^{-1/2}(\Gamma) \to H^{1/2}(\Gamma), \qquad T_D : H^{1/2}(\Gamma) \to H^{-1/2}(\Gamma)$$

and constants $\lambda_A, \lambda_D > 0$ such that

$$\mathrm{Re}\langle (A + T_A) v, \bar{v} \rangle \geqq \lambda_A \|v\|^2_{H^{-1/2}(\Gamma)} \quad \textit{for all } v \in H^{-1/2}(\Gamma), \tag{2.9}$$

$$\mathrm{Re}\langle (D + T_D) v, \bar{v} \rangle \geqq \lambda_D \|v\|^2_{H^{1/2}(\Gamma)} \quad \textit{for all } v \in H^{1/2}(\Gamma). \tag{2.10}$$

Here the brackets $\langle \cdot, \cdot \rangle$ denote the natural duality between a Sobolev space $H^s(\Gamma)$ and its dual $H^{-s}(\Gamma)$.

The following regularity result holds.

THEOREM 3. *Let $\sigma \in [0, \frac{1}{2}]$ and let $\psi \in H^{-1/2}(\Gamma)$ and $v \in H^{1/2}(\Gamma)$ satisfy*

$$A\psi \in H^{1/2+\sigma}(\Gamma) \quad \textit{or} \quad B\psi \in H^{-1/2+\sigma}(\Gamma)$$

and

$$Cv \in H^{1/2+\sigma}(\Gamma) \quad \text{or} \quad Dv \in H^{-1/2+\sigma}(\Gamma).$$

Then $\psi \in H^{-1/2+\sigma}(\Gamma)$ *and* $v \in H^{1/2+\sigma}(\Gamma)$, *and there hold the a priori estimates*

$$\|\psi\|_{H^{-1/2+\sigma}(\Gamma)} \leqq C(\|A\psi\|_{H^{1/2+\sigma}(\Gamma)} + \|\psi\|_{H^{-1/2}(\Gamma)}), \tag{2.11}$$

$$\|\psi\|_{H^{-1/2+\sigma}(\Gamma)} \leqq C(\|B\psi\|_{H^{-1/2+\sigma}(\Gamma)} + \|\psi\|_{H^{-1/2}(\Gamma)}), \tag{2.12}$$

$$\|v\|_{H^{1/2+\sigma}(\Gamma)} \leqq C(\|Cv\|_{H^{1/2+\sigma}(\Gamma)} + \|v\|_{H^{1/2}(\Gamma)}), \tag{2.13}$$

$$\|v\|_{H^{1/2+\sigma}(\Gamma)} \leqq C(\|Dv\|_{H^{-1/2+\sigma}(\Gamma)} + \|v\|_{H^{1/2}(\Gamma)}). \tag{2.14}$$

Now let $(S^h)_{h>0}$ be a family of subspaces of $H^{-1/2}(\Gamma)$ with the property that the orthogonal projection operators onto S^h tend strongly to the identity in $H^{-1/2}(\Gamma)$ for $h \to 0$.

For the equation

$$Av = g \quad \text{with } g \in H^{1/2}(\Gamma) \tag{2.15}$$

we consider the Galerkin scheme

$$\text{Find } v_h \in S^h \text{ such that } \langle Av_h, w\rangle = \langle g, w\rangle \text{ for all } w \in S^h. \tag{2.16}$$

From Theorem 2 then follows stability and convergence in $H^{-1/2}(\Gamma)$. Note that Theorem 2 implies that the operators A and D are Fredholm operators of index zero.

THEOREM 4. *If the operator* $A: H^{-1/2}(\Gamma) \to H^{1/2}(\Gamma)$ *is injective then for any* $g \in H^{1/2}(\Gamma)$ *there is a* $h_0 > 0$ *such that for all* $0 < h < h_0$ *the Galerkin scheme* (2.16) *has a unique solution* $v_h \in S^h$. *For* $h \to 0$, v_h *converges to the unique solution* $v \in H^{-1/2}(\Gamma)$ *of* (2.15) *quasioptimally, i.e., there exists a constant* C *such that for all* $0 < h < h_0$

$$\|v - v_h\|_{H^{-1/2}(\Gamma)} \leqq C \inf_{w \in S^h} \|v - w\|_{H^{-1/2}(\Gamma)}. \tag{2.17}$$

Of course, a corresponding result holds for the operator D.

From Theorem 3 we can deduce asymptotic error estimates using (2.17). We assume for instance that S^h are regular finite element spaces, in the simplest case, e.g., consisting of functions piecewise constant on Γ that are constant on the faces of a triangulation of Γ quasiuniform with respect to h where h is the meshsize. Then there holds the following theorem.

THEOREM 5. *Let* A *be injective as above and* $g \in H^1(\Gamma)$. *Then there is a constant* C *such that for all* $0 < h < h_0$

$$\|v - v_h\|_{H^{-1/2}(\Gamma)} \leqq Ch^{1/2}\|g\|_{H^1(\Gamma)}. \tag{2.18}$$

3. The tools. In this section we collect some results, some new but most of them known, and adapt them to the present situation.

We need some further notation.

$H^s_{\text{comp}}(\mathbb{R}^n)$ is the space of distributions in H^s with compact support. It is thus in a natural way the dual space of $H^{-s}_{\text{loc}}(\mathbb{R}^n)$.

$$H^s_P(\Omega) := \{u \in H^s(\Omega) \mid Pu \in L_2(\Omega)\}, \qquad \|u\|^2_{H^s_P(\Omega)} := \|u\|^2_{H^s} + \|Pu\|^2_{L_2},$$

$$P' := -\sum_{j,k=1}^{n} \partial_j a_{jk} \partial_k - \sum_{j=1}^{n} \partial_j b_j + c \quad \text{is the formal transpose of } P.$$

We may assume $a_{jk} = a_{kj}$ without restriction.

By P^0 we denote any operator with the same principal part as P and positive on $H^1(\Omega)$. We may take, e.g.,

$$-\sum_{j,k=1}^{n} \partial_j a_{jk} \partial_k + \lambda \quad \text{with } \lambda > 0.$$

Thus there holds with some $\lambda > 0$

$$\text{Re}(P^0 u, u)_{L_2(\Omega)} \geqq \lambda \|u\|^2_{H^1(\Omega)} \quad \text{for all } u \in C^2(\bar{\Omega}). \tag{3.1}$$

It follows with the trace lemma (2.1) that for P^0 the Dirichlet problem is uniquely solvable in the weak sense.

LEMMA 3.1. *The Dirichlet problem*

$$P^0 u = 0 \quad \text{in } \Omega, \qquad \gamma_0 u = v$$

has for $v \in H^{1/2}(\Gamma)$ *a unique solution* $u := Tv \in H^1(\Omega)$. *The solution operator* $T: H^{1/2}(\Gamma) \to H^1_P(\Omega)$ *is continuous.*

From the partial integration formula

$$\int_\Omega (\partial_j u v + u\, \partial_j v)\, dx = \int_\Gamma u v n_j\, ds \quad \text{for } u, v \in H^1(\Omega)$$

follow [23] the *first Green formula*

$$\int_\Omega \bar{v} P u\, dx = \Phi_\Omega(u, v) - \int_\Gamma \partial_\nu u \bar{v}\, ds \quad \text{for } v \in H^1(\Omega), \quad u \in H^2(\Omega) \tag{3.2}$$

and the *second Green formula*

$$\int_\Omega (uP'v - vPu)\, dx = \int_\Gamma (v\, \partial_{\tilde{\nu}} u - u\, \partial_{\tilde{\nu}} v)\, ds \quad \text{for } u, v \in H^2(\Omega) \tag{3.3}$$

where we defined

$$\partial_{\tilde{\nu}} u := \partial_\nu u - \sum_{j=1}^{n} n_j b_j u.$$

Now let u be a function defined on $\mathbb{R}^n$ such that

$$u_1 := u|_\Omega \in C^\infty(\bar{\Omega}) \quad \text{and} \quad u_2 := u|_{\Omega^c} \in C^\infty_{\text{comp}}(\bar{\Omega}^c),$$

where $\Omega^c := \mathbb{R}^n \backslash \bar{\Omega}$ is the exterior domain. Let $f := Pu|_{\mathbb{R}^n \backslash \Gamma}$ and let

$$[u] := \gamma_0 u_2 - \gamma_0 u_1 \quad \text{denote the jump of } u \text{ across } \Gamma.$$

Then there holds the *representation formula* (for $x \in \mathbb{R}^n \backslash \Gamma$)

$$u(x) = Gf(x) + \int_\Gamma (\partial_{\nu(y)} G(x, y)[u(y)] - G(x, y)[\partial_{\tilde{\nu}(y)} u(y)])\, ds(y). \tag{3.4}$$

We shall need equations (3.2)–(3.4) for more general functions. To this purpose, we first define the conormal derivative in the weak sense by using the first Green formula (3.2). Recall γ_0^- from (2.1).

LEMMA 3.2. *Let* $u \in H^1_P(\Omega)$. *Then the mapping*

$$\varphi \mapsto \langle \gamma_1 u, \varphi \rangle := \Phi_\Omega(u, \gamma_0^- \varphi) - \int_\Omega Pu \cdot \gamma_0^- \varphi\, dx$$

is a continuous linear functional $\gamma_1 u$ *on* $H^{1/2}(\Gamma)$ *that coincides for* $u \in H^2(\Omega)$ *with the functional defined by* $\partial_\nu u|_\Gamma \in L_2(\Gamma) \subset H^{-1/2}(\Gamma)$.

(3.5) *The mapping* $\gamma_1 : H^1_P(\Omega) \mapsto H^{-1/2}(\Gamma)$ *is continuous.*

The following lemma was shown by Grisvard [14] for the case $P = -\Delta$. The proof works verbatim for the present case.

LEMMA 3.3. $C^\infty(\bar{\Omega})$ *is dense in the Hilbert space* $H^1_P(\Omega)$.

Thus we can extend (3.2)-(3.4) by continuity.

LEMMA 3.4. (i) *The first Green formula in the form*

$$\int_\Omega \bar{v} P u \, dx = \Phi_\Omega(u, v) - \langle \gamma_1 u, \overline{\gamma_0 v} \rangle \tag{3.6}$$

holds for all $u \in H^1_P(\Omega)$, $v \in H^1(\Omega)$.

(ii) *The second Green formula in the form*

$$\int_\Omega (uP'v - vPu) \, dx = \langle \widetilde{\gamma_1} u, \gamma_0 v \rangle - \langle \gamma_1 v, \gamma_0 u \rangle \tag{3.7}$$

holds for all $u, v \in H^1_P(\Omega)$. *Here we define, corresponding to the definition of* $\partial_{\tilde{P}}$:

$$\widetilde{\gamma_1} u := \gamma_1 u - \sum_{j=1}^{n} n_j b_j \gamma_0 u.$$

(iii) *The representation formula in the form*

$$u(x) = Gf(x) + \langle \gamma_1 G(x, \cdot), [\gamma_0 u] \rangle - \langle [\widetilde{\gamma_1} u], G(x, \cdot) \rangle \qquad (x \in \mathbb{R}^n \setminus \Gamma) \tag{3.8}$$

holds for all $u \in L_2(\mathbb{R}^n)$ *with* $u|_\Omega \in H^1(\Omega)$, $u|_{\Omega^c} \in H^1_{\text{comp}}(\Omega^c)$, *and* $f = Pu|_{\mathbb{R}^n \setminus \Gamma} \in L_2(\mathbb{R}^n)$.

The proof is immediate if we keep in mind that $H^1_{P'} = H^1_P(\Omega)$ and that γ_1 remains the same, whether defined from P or from P'. For (3.8) we need only (3.7) and the representation formula (3.4) for a smooth domain, let us say a small ball enclosing the point x.

The following result will be needed in the proof of the jump relations (Lemma 4.1).

LEMMA 3.5. *The trace map*

$$(\gamma_0, \gamma_1) : \varphi \mapsto (\gamma_0 \varphi, \gamma_1 \varphi)$$

maps $C^\infty_{\text{comp}}(\mathbb{R}^n)$ *onto a dense subspace of* $H^{1/2}(\Gamma) \times H^{-1/2}(\Gamma)$.

Proof. Assume that for some $(\chi, \psi) \in H^{1/2}(\Gamma) \times H^{-1/2}(\Gamma)$ there holds

$$\langle \chi, \gamma_1 \varphi \rangle = \langle \psi, \gamma_0 \varphi \rangle \quad \text{for all } \varphi \in C^\infty_{\text{comp}}(\mathbb{R}^n). \tag{3.9}$$

We have to show that $\chi = \psi = 0$.

Let $T\chi \in H^1_P(\Omega)$ be the solution of the Dirichlet problem (see Lemma 3.1)

$$P^0 T\chi = 0 \quad \text{in } \Omega, \qquad \gamma_0 T\chi = \chi.$$

For arbitrary $f \in L_2(\Omega)$ let $Sf \in H^1_P(\Omega)$ be the unique weak solution of the Dirichlet problem

$$P^0 Sf = f \quad \text{in } \Omega, \qquad \gamma_0 Sf = 0.$$

The second Green formula (3.7) for the operator $P^0 = P^{0'}$ gives

$$\begin{aligned} \langle \gamma_1 Sf, \chi \rangle &= \langle \gamma_1 Sf, \gamma_0 T\chi \rangle - \langle \gamma_1 T\chi, \gamma_0 Sf \rangle \\ &= \int_\Omega (Sf \cdot P^0 T\chi - P^0 Sf \cdot T\chi) \, dx = -\int_\Omega f T\chi \, dx. \end{aligned} \tag{3.10}$$

Now (3.9) holds for all $\varphi \in H^1_P(\Omega)$ due to Lemma 3.3, in particular for $\varphi = Sf$; hence

$$\langle \gamma_1 Sf, \chi \rangle = \langle \psi, \gamma_0 Sf \rangle = 0.$$

This gives from (3.10)

$$\int_\Omega f T\chi \, dx = 0 \quad \text{for all } f \in L_2(\Omega).$$

Thus $T\chi = 0$ whence $\chi = \gamma_0 T\chi = 0$. From (3.9) now follows

$$\langle \psi, \gamma_0 \varphi \rangle = 0 \quad \text{for all } \varphi \in H^1(\Omega)$$

which implies $\psi = 0$ because of the surjectivity of

$$\gamma_0 : H^1(\Omega) \to H^{1/2}(\Gamma). \qquad \square$$

The continuity of the simple layer potential operator, Theorem 1(i) and (iii), will follow from an extension of Gagliardo's Trace Lemma, which seems to be new.

LEMMA 3.6. *For* $s \in (\frac{1}{2}, \frac{3}{2})$ *the trace map*

$$\gamma_0 : u \mapsto \gamma_0 u = u|_\Gamma : H^s_{\text{loc}}(\mathbb{R}^n) \to H^{s-1/2}(\Gamma) \quad \textit{is continuous.}$$

This result for $s = \frac{3}{2}$, from which the whole range $s \in (\frac{1}{2}, \frac{3}{2}]$ would follow by interpolation, is claimed by Jerison and Kenig [18]. However, there seems to be no proof available. The proof of Lemma 3.6 is given at the end of § 4.

The last tool we need is Nečas' result on the boundary regularity for the Dirichlet and Neumann problems.

LEMMA 3.7. *For* $\sigma \in [-\frac{1}{2}, \frac{1}{2}]$, *the mapping* $\gamma_1 T : H^{1/2+\sigma}(\Gamma) \to H^{-1/2+\sigma}(\Gamma)$ *is continuous, and* $\gamma_1 Tv \in H^{-1/2+\sigma}(\Gamma)$ *implies* $v \in H^{1/2+\sigma}(\Gamma)$.

Remarks. (i) Here the result for $\sigma < 0$ means, as above, the existence of a continuous extension of the map defined for $\sigma = 0$.

(ii) Nečas [23] showed that solutions of the Dirichlet problem with Dirichlet data in $H^1(\Gamma)$ have their Neumann data (i.e., conormal derivatives)in $L_2(\Gamma)$ and conversely. This is proved by applying an identity of Rellich, generalized to arbitrary second order equations by Payne and Weinberger. Thus it uses only partial integration and is completely elementary. The same argument has been used by Jerison and Kenig [16], [17] and Verchota [27], [21]. Having thus proved the result for $\sigma = \frac{1}{2}$, Nečas deduces the result for $\sigma = -\frac{1}{2}$ from a duality argument. The whole range $\sigma \in [-\frac{1}{2}, \frac{1}{2}]$ then clearly follows by interpolation.

4. The proofs.

Proof of Theorem 1 (i) *and* (iii). By definition (2.5) we can write the simple layer potential as

$$K_0 = G \circ \gamma_0', \tag{4.1}$$

where γ_0' is the adjoint of the trace map γ_0. By Lemma 3.6 we find that $\gamma_0 : H^{-s+1/2}(\Gamma) \to H^{-s}_{\text{comp}}(\mathbb{R}^n)$ is continuous for $s \in (\frac{1}{2}, \frac{3}{2})$. The operator G is a pseudodifferential operator of order -2 on $\mathbb{R}^n$, mapping $H^{-s}_{\text{comp}}(\mathbb{R}^n) \to H^{-s+2}_{\text{loc}}(\mathbb{R}^n)$ continuously for any $s \in \mathbb{R}$. Thus Theorem 1(i) follows. The continuity of the operator $A = \gamma_0 K_0$ then follows by a second application of Lemma 3.6. $\square$

Remark. If instead of Lemma 3.6, we use only the classical result (2.1), we find for theorem 1(i) only a range $\sigma \in [0, \frac{1}{2})$, and for (iii) only $\sigma = 0$ remains.

Next we use the representation formula (3.8) in order to write the double layer potential in terms of the simple layer potential. Writing (3.8) for a solution of the

Dirichlet problem $u = Tv \in H^1_P(\Omega)$ for $v \in H^{1/2}(\Gamma)$, we obtain $Tv = -K_1 v + K_0 \tilde{\gamma}_1 Tv$; hence

$$K_1 = (-1 + K_0 \widetilde{\gamma_1}) T. \tag{4.2}$$

This immediately implies that

$$K_1 : H^{1/2}(\Gamma) \to H^1(\Omega) \quad \text{is continuous.} \tag{4.3}$$

Thus, using (2.1) and Lemma 3.2, we obtain all statements of Theorem 1 for $\sigma = 0$ (i.e., in the "energy norm").

This will suffice to prove Theorem 2. The remaining cases of Theorem 1 will be shown together with Theorem 3.

Now we prove *jump relations* for the layer potentials. We use the notation introduced above

$$[\gamma_j u] := \gamma_j(u|_{\Omega^c}) - \gamma_j(u|_\Omega) \quad \text{for } j = 0, 1.$$

LEMMA 4.1.

$$[\gamma_0 K_0 \psi] = 0, \qquad [\gamma_1 K_0 \psi] = -\psi \quad \textit{for } \psi \in H^{-1/2}(\Gamma),$$

$$[\gamma_0 K_1 v] = v, \qquad [\tilde{\gamma}_1 K_1 v] = 0 \quad \textit{for } v \in H^{1/2}(\Gamma).$$

Proof. Let $\psi \in H^{-1/2}(\Gamma)$ and $u = K_0 \psi \in H^1_{\text{loc}}(\mathbb{R}^n)$. The equality $\gamma_0(u|_\Omega) = \gamma_0(u|_{\Omega^c})$ follows from the definition of γ_0. From (4.1) we obtain $Pu = \gamma_0' \psi$, if we apply P in the distributional sense to u. For any test function $\varphi \in C^\infty_{\text{comp}}(\mathbb{R}^n)$ we thus obtain

$$\int_{\mathbb{R}^n} uP'\varphi \, dx = \langle Pu, \varphi \rangle = \langle \gamma_0' \psi, \varphi \rangle = \langle \psi, \gamma_0 \varphi \rangle. \tag{4.4}$$

On the other hand, the second Green formula (3.7) gives

$$\int_\Omega uP'\varphi \, dx = \langle \widetilde{\gamma_1}(u|_\Omega), \gamma_0 \varphi \rangle - \langle \gamma_1 \varphi, \gamma_0 u \rangle.$$

The corresponding formula for Ω^c is

$$\int_{\Omega^c} uP'\varphi \, dx = -\langle \widetilde{\gamma_1}(u|_{\Omega^c}), \gamma_0 \varphi \rangle + \langle \gamma_1 \varphi, \gamma_0 u \rangle.$$

Adding both, we obtain with $[\gamma_0 u] = [\gamma_0 \varphi] = [\widetilde{\gamma_1} \varphi] = 0$

$$\int_{\mathbb{R}^n} uP'\varphi \, dx = -\langle [\widetilde{\gamma_1} u], \gamma_0 \varphi \rangle. \tag{4.5}$$

Comparison of (4.4) and (4.5) gives $[\gamma_1 u] = -\psi$, and from $[\gamma_0 u] = 0$ follows $[\gamma_1 u] = [\widetilde{\gamma_1} u] = -\psi$.

In order to show the jump relations for the double layer potential, we choose $v \in H^{1/2}(\Gamma)$ and $\varphi \in C^\infty_{\text{comp}}(\mathbb{R}^n)$ and define $u = K_1 v$. Then again the second Green formula gives

$$\int_{\mathbb{R}^n} uP'\varphi \, dx = -\langle [\widetilde{\gamma_1} u], \gamma_0 \varphi \rangle + \langle [\gamma_0 u], \gamma_1 \varphi \rangle. \tag{4.6}$$

On the other hand, the definition of K_1 gives $u = K_1 v = G(\gamma_1' v)$, where the compactly supported distribution on $\mathbb{R}^n$, $\gamma_1' v$ is defined by

$$\langle \gamma_1' v, \chi \rangle = \int_\Gamma v\, \partial_\nu \chi\, ds = \langle v, \gamma_1 \chi \rangle \quad \text{for all } \chi \in C^\infty_{\text{comp}}(\mathbb{R}^n).$$

Thus $Pu = \gamma_1' v$, implying

$$\int_{\mathbb{R}^n} uP'\varphi\, dx = \langle Pu, \varphi \rangle = \langle v, \gamma_1 \varphi \rangle. \tag{4.7}$$

Comparison of (4.6) and (4.7) gives

$$\langle v - [\gamma_0 u], \gamma_1 \varphi \rangle = \langle -[\tilde{\gamma}_1 u], \gamma_0 \varphi \rangle \quad \text{for all } \varphi \in C^\infty_{\text{comp}}(\mathbb{R}^n). \tag{4.8}$$

Finally we apply Lemma 3.5 which allows us to infer from (4.8):

$$v - [\gamma_0 u] = 0 = [\tilde{\gamma}_1 u]. \qquad \square$$

Proof of Theorem 2. Choose $v \in H^{-1/2}(\Gamma)$ and define $u = -K_0 v$. Then according to Lemma 4.1, we have the jump relations

$$[\gamma_0 u] = 0; \text{ hence } \gamma_0(u|_\Omega) = -Av = \gamma_0(u|_{\Omega^c}), \text{ and } [\gamma_1 u] = v. \tag{4.9}$$

Next we choose $\chi \in C^\infty_{\text{comp}}(\mathbb{R}^n)$ with $\chi = 1$ on a neighborhood of $\bar{\Omega}$ and define $u_1 := u|_\Omega$, $u_2 := \chi u|_{\Omega^c}$.

Next we add the first Green formula (3.6) for $u = v = u_1$ and its counterpart for Ω^c for $u = v = u_2$ and obtain using (4.9)

$$\Phi_\Omega(u_1, u_1) + \Phi_{\Omega^c}(u_2, u_2) - \int_{\Omega^c} \overline{u_2} P u_2\, dx = -\langle [\gamma_1 u], \overline{\gamma_0 u} \rangle = \langle v, \overline{Av} \rangle. \tag{4.10}$$

Here Φ_{Ω^c} is defined in accordance with (2.3).

Equation (4.10) now allows us to transfer the Gårding inequality for the operator P, which we assumed to hold, to the Gårding inequality on the boundary for the operator A.

The term $\int_{\Omega^c} \overline{u_2} P u_2\, dx$ gives rise to a compact bilinear form in $v \in H^{-1/2}(\Gamma)$ because Pu_2 has compact support in Ω^c and the mapping $v \mapsto u_2$ is continuous from $H^{-1/2}(\Gamma)$ to $C^\infty(\Omega^c)$. From the continuity of the trace mapping γ_1 (Lemma 3.2) we obtain an estimate

$$\begin{aligned} \|v\|^2_{H^{-1/2}(\Gamma)} &= \|\gamma_1 u_2 - \gamma_1 u_1\|^2_{H^{-1/2}(\Gamma)} \\ &\leqq C(\|u_1\|^2_{H^1(\Omega)} + \|u_2\|^2_{H^1(\Omega^c)} + \|Pu_1\|^2_{L_2(\Omega)} + \|Pu_2\|^2_{L_2(\Omega^c)}). \end{aligned} \tag{4.11}$$

Here on the right-hand side, Pu_1 vanishes and $\|Pu_2\|^2_{L_2(\Omega^c)}$ is a compact term.

Finally, the principal part of the right-hand side of (4.11) can be estimated from above up to compact terms by the left-hand side of (4.10) due to Gårding's inequality (2.4) which we assumed to hold. Thus (2.9) is proved.

In order to prove the strong ellipticity of the operator D, i.e., estimate (2.10), we proceed analogously.

For $v \in H^{-1/2}(\Gamma)$ we define $u = K_1 v$. Then we find the jump relations

$$[\gamma_0 u] = v \text{ and } [\overline{\gamma_1} u] = 0; \text{ hence } \overline{\gamma_1} u_1 = \overline{\gamma_1} u_2 = -Dv, \tag{4.12}$$

where u_1 and u_2 are defined from u as above. Then again the first Green formula gives

$$\Phi_\Omega(u_1, u_1) + \Phi_{\Omega^c}(u_2, u_2) - \int_{\Omega^c} \overline{u_2} P u_2\, dx = \langle Dv, \bar{v} \rangle. \tag{4.13}$$

This time the trace lemma (2.1) implies

$$\|v\|^2_{H^{1/2}(\Gamma)} = \|\gamma_0 u_2 - \gamma_0 u_1\|^2_{H^{1/2}(\Gamma)} \leqq C(\|u_1\|^2_{H^1(\Omega)} + \|u_2\|^2_{H^1(\Omega^c)}), \tag{4.14}$$

and again, (2.10) follows from (4.13) and (4.14) together with Gårding's inequality (2.4). □

The derivation of convergence and stability for Galerkin approximation schemes from strong ellipticity is standard by now [13], [26], as are the approximation properties of the finite element function spaces [1], [2]; thus proofs of Theorems 4 and 5 need not be given here.

Next we show regularity in the domain for the Dirichlet problem

LEMMA 4.2. *For $\sigma \in (-\frac{1}{2}, \frac{1}{2})$ the mapping $T: H^{1/2+\sigma}(\Gamma) \to H^{1+\sigma}_P(\Omega)$ is continuous.*

Proof. We choose a domain B containing $\bar{\Omega}$ in its interior, e.g., a large enough ball. Let $\Omega_2 := B \backslash \bar{\Omega}$ and $T_2: v \mapsto u = T_2 v$ be the solution operator of the Dirichlet problem

$$P^0 u = 0 \quad \text{in } \Omega_2, \quad \gamma_0 u = v, \quad u|_{\partial B} = 0.$$

Now choose $v \in H^1(\Gamma)$ and define

$$u = Tv \quad \text{in } \Omega, \qquad u = T_2 v \quad \text{in } \Omega_2.$$

Then the representation formula (3.8) applies and gives with $f = 0$ and $[\gamma_0 u] = 0$

$$u = -K_0[\widetilde{\gamma_1} u] + \int_{\partial B} \partial_\nu u(y) G(\cdot, y)\, ds(y) \quad \text{in } \Omega \cup \Omega_2. \tag{4.15}$$

Now we know from the boundary regularity result for the Dirichlet problem (Lemma 3.7) that there are estimates

$$\|\partial_\nu u|_{\partial B}\|_{H^{-1/2+\sigma}(\partial B)} + \|\widetilde{\gamma_1} Tv\|_{H^{-1/2+\sigma}(\Gamma)} + \|\widetilde{\gamma_1} T_2 v\|_{H^{-1/2+\sigma}(\Gamma)} \leqq C\|v\|_{H^{1/2+\sigma}(\Gamma)}$$

even for $\sigma \in [-\frac{1}{2}, \frac{1}{2}]$. Hence the continuity of the simple layer potential operator, Theorem 1(i) gives with (4.15) the desired estimate

$$\|u\|_{H^{1+\sigma}(\Omega)} \leqq C\|v\|_{H^{1/2+\sigma}(\Gamma)}. \qquad \square$$

Remark. The endpoint result $\sigma = \frac{1}{2}$ was shown by Jerison and Kenig [16] using Dahlberg's estimates for the Poisson kernel [10].

LEMMA 4.3. *For $s \in (\frac{1}{2}, \frac{3}{2})$ the trace map $\gamma_1: H^s_P(\Omega) \to H^{s-3/2}(\Gamma)$ is continuous.*

Proof. For $u \in H^1_P(\Omega)$ and arbitrary $\varphi \in H^{1/2}(\Gamma)$, $v := T\varphi$, we can apply the second Green formula (3.7) for the operator P^0 to obtain

$$\langle \gamma_1 u, \varphi \rangle = \langle \gamma_0 u, \gamma_1 T\varphi \rangle - \int_\Omega P^0 u T\varphi \, dx.$$

This can be written as

$$\gamma_1 = (\gamma_1 T)' \gamma_0 - T' P^0. \tag{4.16}$$

The first member on the right-hand side is continuous from $H^s(\Omega)$ to $H^{s-3/2}(\Gamma)$ due to Lemmas 3.6 and 3.7. The second member is continuous from $H^s(\Omega)$ to $H^t(\Gamma)$ for all s and $t < 0$ due to Lemma 4.2. □

As a corollary, Theorem 1(iv) follows from Theorem 1(i).

Proof of Theorem 1(ii), (v), and (vi). It suffices to show (ii). If we apply (4.2), this follows from Lemmas 4.2, 4.3, and Theorem 1(i). The proof of Theorem 1 is complete. □

Proof of Theorem 3. Let $\psi \in H^{-1/2}(\Gamma)$ and $A\psi \in H^{1/2+\sigma}(\Gamma)$. We show $\psi \in H^{-1/2+\sigma}(\Gamma)$. The a priori estimate (2.11) then follows from the closed graph theorem.

Define $u = K_0\psi$. Then we have $A\psi = \gamma_0 u$ and $\psi = -[\gamma_1 u]$ by Lemma 4.1. Thus u solves in Ω and Ω^c the Dirichlet problem with Dirichlet data $A\psi \in H^{1/2+\sigma}(\Gamma)$. According to Lemma 3.7, the Neumann data, and hence ψ, are in $H^{-1/2+\sigma}(\Gamma)$.

Now if $B\psi \in H^{-1/2+\sigma}(\Gamma)$, then $\gamma_1(u|_\Omega) = B\psi \in H^{-1/2+\sigma}(\Gamma)$, so that also $A\psi = \gamma_0(u|_\Omega) \in H^{1/2+\sigma}(\Gamma)$ holds.

The remaining statements follow in a similar way using the double layer potential and again Lemmas 3.7 and 4.1. □

Proof of Lemma 3.6. The statement is local, so we may assume that the boundary Γ is of the form

$$\Gamma = \{(x', x_n) \in \mathbb{R}^n \mid x' \in \mathbb{R}^{n-1};\ x_n = \psi(x')\}$$

with a function $\psi : \mathbb{R}^{n-1} \to \mathbb{R}$ that is uniformly Lipschitz, i.e., $\|\operatorname{grad} \psi\|_{L_\infty(\mathbb{R}^{n-1})} < \infty$.

For functions $f \in C^\infty_{\text{comp}}(\mathbb{R}^n)$ define

$$f_\psi(x', x_n) := f(x', x_n + \psi(x')).$$

We then have to show an estimate for $1 < s < \frac{3}{2}$

$$\|f_\psi(\cdot, 0)\|_{H^{s-1/2}(\mathbb{R}^{n-1})} \leqq C\|f\|_{H^s(\mathbb{R}^n)} \quad \text{for all } f \in C^\infty_{\text{comp}}(\mathbb{R}^n). \tag{4.17}$$

The problem is that in general for $s > 1$, $f_\psi \notin H^s(\mathbb{R}^n)$ and therefore the usual trace lemma cannot be applied to f_ψ. We show first that the mapping $f \mapsto f_\psi$ leaves a certain anisotropic Sobolev space X^s invariant, and then that in X^s there holds the trace estimate

$$\|f(\cdot, 0)\|_{H^{s-1/2}(\mathbb{R}^{n-1})} \leqq C\|f\|_{X^s} \quad \text{for all } f \in C^\infty_{\text{comp}}(\mathbb{R}^n). \tag{4.18}$$

For the definition of X^s we identify a function $f \in C^\infty_{\text{comp}}(\mathbb{R}^n)$ with the $C^\infty(\mathbb{R}^{n-1})$-valued function on $\mathbb{R}$,

$$x_n \mapsto f(\cdot, x_n).$$

Thus $H^s(\mathbb{R}^n) = H^s(\mathbb{R}; L_2(\mathbb{R}^{n-1})) \cap L_2(\mathbb{R}; H^s(\mathbb{R}^{n-1}))$. We define

$$X^s := H^s(\mathbb{R}; L_2(\mathbb{R}^{n-1})) \cap H^{s-1}(\mathbb{R}; H^1(\mathbb{R}^{n-1})).$$

If $\hat{f}$ is the Fourier transform of f, we define the norm in X^s by

$$\|f\|^2_{X^s} := \int_{-\infty}^{\infty} \int_{\mathbb{R}^{n-1}} \{(1+|\xi_n|)^{2s} + (1+|\xi_n|)^{2(s-1)} \cdot (1+|\xi'|)^2\} |\hat{f}(\xi', \xi_n)|^2 \, d\xi' \, d\xi_n.$$

Thus

$$\|f\|_{X^s} \leqq C\|f\|_{H^s(\mathbb{R}^n)}. \tag{4.19}$$

If we denote by $\tilde{f}(x', \xi_n)$ the Fourier transform of f with respect to the last variable, we have

$$\|f\|^2_{H^t(\mathbb{R};\, H^\tau(\mathbb{R}^{n-1}))} = \int_{-\infty}^{\infty} (1+|\xi_n|)^{2t} \|\tilde{f}(\cdot, \xi_n)\|^2_{H^\tau(\mathbb{R}^{n-1})} \, d\xi_n.$$

Now we have

$$\widetilde{(f_\psi)}(x', \xi_n) = e^{i\psi(x')\xi_n} \tilde{f}(x', \xi_n).$$

Hence

$$\|f_\psi\|_{H^t(\mathbb{R};\, L_2(\mathbb{R}^{n-1}))} = \|f\|_{H^t(\mathbb{R};\, L_2(\mathbb{R}^{n-1}))} \quad \text{for all } t \in \mathbb{R}. \tag{4.20}$$

For $k=1,\cdots,n-1$ we have

$$\widetilde{(\partial_k f_\psi)}(x',\xi_n)=e^{i\psi(x')\xi_n}\widetilde{(\partial_k f)}(x',\xi_n)+i\xi_n(\partial_k\psi)(x')\,e^{i\psi(x')\xi_n}\tilde f(x',\xi_n).$$

This implies that

$$\|\widetilde{(\partial_k f_\psi)}(\cdot,\xi_n)\|^2_{L_2(\mathbb{R}^{n-1})}\leqq\|\widetilde{(\partial_k f)}(\cdot,\xi_n)\|^2_{L_2(\mathbb{R}^{n-1})}+\xi_n^2\|\operatorname{grad}\psi\|^2_{L_\infty(\mathbb{R}^{n-1})}\|\tilde f(\cdot,\xi_n)\|^2_{L_2(\mathbb{R}^{n-1})}.$$

Hence

$$\|f_\psi\|^2_{H^t(\mathbb{R};\,H^1(\mathbb{R}^{n-1}))}\leqq\|f\|^2_{H^t(\mathbb{R};\,H^1(\mathbb{R}^{n-1}))}+C\|f\|^2_{H^{t+1}(\mathbb{R};\,L_2(\mathbb{R}^{n-1}))}\tag{4.21}$$

for all $t\in\mathbb{R}$.

Formulae (4.20) and (4.21) together imply the estimate

$$\|f_\psi\|_{X^s}\leqq\|f\|_{X^s}\quad\text{for all } s\in\mathbb{R}.\tag{4.22}$$

Next we show (4.18). We use the fact that with

$$m(\xi',\xi_n):=(1+|\xi_n|)^{2s}+(1+|\xi_n|)^{2s-2}\cdot(1+|\xi'|)^2$$

we have

$$\int_{-\infty}^{\infty}m(\xi',\xi_n)^{-1}\,d\xi_n=C_s(1+|\xi'|)^{1+2s}<\infty\quad\text{for } 1\leqq s<\tfrac{3}{2}.$$

Hence using the Cauchy-Schwarz inequality we have

$$\begin{aligned}\|f_\psi(\cdot,0)\|^2_{H^{s-1/2}(\mathbb{R}^{n-1})}&\int_{\mathbb{R}^{n-1}}(1+|\xi'|)^{2s-1}\left|\int_{-\infty}^{\infty}\hat f_\psi(\xi',\xi_n)\,d\xi_n\right|^2 d\xi'\\&\leqq\int_{\mathbb{R}^{n-1}}(1+|\xi'|)^{2s-1}\left(\int_{-\infty}^{\infty}m(\xi',\xi_n)^{-1}\,d\xi_n\right)\\&\quad\times\left(\int_{-\infty}^{\infty}m(\xi',\xi_n)|\hat f_\psi(\xi',\xi_n)|^2\,d\xi_n\right)d\xi'\\&=C\int_{\mathbb{R}^n}m(\xi',\xi_n)|\hat f_\psi(\xi',\xi_n)|^2\,d\xi_n\,d\xi'=C\|f_\psi\|^2_{X^s}.\end{aligned}$$

This together with the estimates (4.22) and (4.19) gives the desired estimate (4.17). □

5. Concluding remarks. (i) Along the same lines as presented here it is also possible to easily deduce invertibility results for integral equations involving the operators A, B, C, and D. Note that, for instance, by Theorem 2 the operators A and D are Fredholm operators of index 0 in the energy norm spaces. Thus if we assume injectivity, which in turn can be inferred from positivity of the bilinear form Φ_Ω, we obtain bijectivity. For the operator A this holds for the case of the Laplace equation and the standard fundamental solution in dimension $n\geqq 3$ and for $n=2$ if the analytic capacity of Γ is different from one. By Theorem 3 and duality arguments, bijectivity holds for the whole range of Sobolev spaces given in Theorem 1(ii). In this way we get results about the *solvability* of the boundary value problems by means of the boundary integral equations. Theorems 4 and 5 then are really statements about the numerical solution of boundary value problems by means of the so-called boundary element method [28]. In practice, this method is frequently used to solve (also mixed) boundary value problems of three-dimensional linear elasticity on domains with corners

and edges [25], [3]. For these problems, the present paper yields convergence proofs and asymptotic error estimates for Galerkin methods.

(ii) If the domain is more regular than merely Lipschitz, e.g., a smooth image of a polyhedron, then higher regularity results should be possible and they should improve with higher dimension. For the Dirichlet problem this is well known, but for the boundary integral equations higher regularity has been studied, to the best of the author's knowledge, only in the case of plane domains (see [6], [8], and the literature quoted therein).

ON THE SHARPNESS OF WEYL'S ESTIMATES FOR EIGENVALUES OF SMOOTH KERNELS, II*

J. B. READE†

Abstract. The estimate $\lambda_n = o(1/n)$ obtained by H. Weyl (1912) for the nth largest in modulus eigenvalue λ_n of any symmetric Fredholm operator on $L^2[0, 1]^2$ with kernel in $C^1[0, 1]^4$ is shown to be best possible in the sense that for any increasing sequence $\alpha_n \to \infty$ there exist such operators whose nth eigenvalue is not $o(1/n\alpha_n)$. The construction of the counterexample makes use of Rudin-Shapiro polynomials. The corresponding result for positive definite operators is proved with a simpler counterexample. The methods generalise to the case $L^2[0, 1]^m (m \geqq 3)$ without further difficulty.

Key words. eigenvalue, operator, kernel, asymptotics

AMS(MOS) subject classification. 45C

1. Introduction.

If $K(x, t) = \overline{K(t, x)} \in L^2[a, b]^2$ then

$$(Tf)(x) = \int_a^b K(x, t) f(t)\, dt$$

defines a compact symmetric operator T on the Hilbert space $L^2[a, b]$. Such an operator T has a real null sequence $(\lambda_n)_{n \geqq 1}$ of eigenvalues which we can assume has been enumerated so that

$$|\lambda_1| \geqq |\lambda_2| \geqq \cdots \geqq |\lambda_n| \geqq \cdots .$$

H. Weyl showed in [4] that if $K(x, t) \in C^1[a, b]^2$, i.e., $K(x, t)$ has continuous partial derivatives, then $\lambda_n = o(1/n^{3/2})$. We showed in [1] that if $K(x, t) \in PDC^1[a, b]^2$, i.e., $K(x, t)$ is positive definite and $\in C^1[a, b]^2$, then $\lambda_n = o(1/n^2)$.

Similar results are true for operators of the form

$$(Tf)(x, y) = \int_a^b \int_a^b K(x, y, t, u) f(t, u)\, dt\, du$$

where $K(x, y, t, u) = \overline{K(t, u, x, y)} \in L^2[a, b]^4$ and $f(t, u) \in L^2[a, b]^2$. The estimates are $\lambda_n = o(1/n)$ for $K(x, y, t, u) \in C^1[a, b]^4$ and $\lambda_n = o(1/n^{3/2})$ for $K(x, y, t, u) \in PDC^1[a, b]^4$. The proofs are similar to those for kernels in two variables.

In [2] we considered the sharpness of the estimates for two variable kernels. Here we consider four variable kernels.

2. Double Fourier series.

Any $k(t, u) \in L^2[0, 1]^2$ has a double Fourier series

$$\sum_{m=-\infty}^{\infty} \sum_{n=-\infty}^{\infty} c_{mn}\, e^{2\pi i(mt+nu)}$$

where

$$c_{mn} = \int_0^1 \int_0^1 k(t, u)\, e^{-2\pi i(mt+nu)}\, dt\, du$$

* Received by the editors February 25, 1986; accepted for publication (in revised form) May 12, 1987.
† Department of Mathematics, The University of Manchester, Manchester, United Kingdom M13 9PL.

for all integers m, n. The series is unconditionally convergent to $k(t, u)$ in mean square, so in particular

$$k(t, u) = \lim_{N\to\infty} \sum_{m=-N}^{N} \sum_{n=-N}^{N} c_{mn}\, e^{2\pi i(mt+nu)}$$

(in mean square).

LEMMA 1. *If $k(t, u) \in L^2[0, 1]^2$ has double Fourier series*

$$k(t, u) = \sum_{m=-\infty}^{\infty} \sum_{n=-\infty}^{\infty} c_{mn}\, e^{2\pi i(mt+nu)}$$

then $K(x, y, t, u) = k(x-t, y-u)$ has eigenvalues c_{mn} and eigenfunctions $e^{2\pi i(mt+nu)}$ (m, n integers).

Proof. For any integers p, q

$$\begin{aligned}
&\int_0^1 \int_0^1 K(x, y, t, u)\, e^{2\pi i(pt+qu)}\, dt\, du \\
&\quad = \lim_{N\to\infty} \int_0^1 \int_0^1 \sum_{m=-N}^{N} \sum_{n=-N}^{N} c_{mn}\, e^{2\pi im(x-t)}\, e^{2\pi in(y-u)}\, e^{2\pi i(pt+qu)}\, dt\, du \\
&\quad = c_{pq}\, e^{2\pi i(px+qy)}.
\end{aligned}$$

Observe that $K(x, y, t, u)$ is symmetric if $k(t, u) = \overline{k(-t, -u)}$, equivalently if c_{mn} is real for all m, n.

3. The Rudin–Shapiro signs. These are $\varepsilon_n = \pm 1 (n \geqq 0)$ with the property that

$$\sum_{n=0}^{N} \varepsilon_n\, e^{2\pi int} = O(N^{1/2})$$

uniformly in t. They occur as the coefficients of successive polynomials $P_n(z)$ defined inductively with $Q_n(z)$ by saying

$$\begin{aligned}
&P_0(z) = Q_o(z) = 1, \\
&P_{n+1}(z) = P_n(z) + z^{2^n} Q_n(z), \\
&Q_{n+1}(z) = P_n(z) - z^{2^n} Q_n(z) \qquad (n \geqq 1).
\end{aligned}$$

(See [3] for details.)

LEMMA 2. *If a_{mn} is the m, nth entry of the matrix*

$$\begin{pmatrix}
1 & 1/2^\alpha & 1/3^\alpha & \cdots & 1/n^\alpha & \cdots \\
1/2^\alpha & 1/2^\alpha & 1/3^\alpha & & 1/n^\alpha & \\
1/3^\alpha & 1/3^\alpha & 1/3^\alpha & & 1/n^\alpha & \\
\vdots & & & & \vdots & \\
1/n^\alpha & 1/n^\alpha & 1/n^\alpha & \cdots & 1/n^\alpha & \cdots \\
\vdots & & & & \vdots &
\end{pmatrix}$$

then the double Fourier series

$$\sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \varepsilon_m \varepsilon_n a_{mn}\, e^{2\pi i(mt+nu)}$$

is uniformly convergent in t, u for all $\alpha > 1$.

Proof. Let

$$A_N(t, u) = \sum_{m=1}^{N} \sum_{n=1}^{N} \varepsilon_m \varepsilon_n a_{mn}\, e^{2\pi i(mt+nu)}$$

for each $N \geqq 1$. Then if we write

$$s_N(t) = \sum_{n=1}^{N} \varepsilon_n\, e^{2\pi int}$$

we have

$$A_N(t, u) - A_M(t, u) = \sum_{n=M+1}^{N} \frac{s_n(t)s_n(u) - s_{n-1}(t)s_{n-1}(u)}{n^\alpha}$$

$$= -\frac{s_M(t)s_M(u)}{(M+1)^\alpha} + \sum_{n=M+1}^{N-1} \left(\frac{1}{n^\alpha} - \frac{1}{(n+1)^\alpha}\right) s_n(t)s_n(u) + \frac{s_N(t)s_N(u)}{N^\alpha}.$$

The first and third terms are $O(1/M^{\alpha-1})$, $O(1/N^{\alpha-1})$, respectively, and the middle term is the difference between the $(N-1)$th and Mth partial sums of a series whose nth term is $O(1/n^\alpha)$, all uniformly in t, u.

COROLLARY. *The function*

$$k(t, u) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \varepsilon_m \varepsilon_n a_{mn}\, e^{2\pi i(mt+nu)},$$

where a_{mn} is as in Lemma 2, is continuous if $\alpha > 1$.

LEMMA 3. *The derivative*

$$s'_N(t) = \sum_{n=1}^{N} 2\pi in\varepsilon_n\, e^{2\pi int} = O(N^{3/2})$$

uniformly in t.

Proof. We have

$$s'_N(t) = \sum_{1}^{N} 2\pi in(s_n(t) - s_{n-1}(t))$$

$$= -2\pi i \left(\sum_{1}^{N} s_n(t)\right) + 2\pi iNs_N(t)$$

$$= \left(\sum_{1}^{N} O(n^{1/2})\right) + NO(N^{1/2})$$

$$= O(N^{3/2}).$$

COROLLARY. *The function*

$$k(t, u) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \varepsilon_m \varepsilon_n a_{mn}\, e^{2\pi i(mt+nu)},$$

where a_{mn} is as in Lemma 2, is C^1 if $\alpha > 2$.

Proof. If

$$B_N(t, u) = \sum_{m=1}^{N} \sum_{n=1}^{N} 2\pi im\varepsilon_m \varepsilon_n a_{mn}\, e^{2\pi i(mt+nu)}$$

is the Nth partial sum of the series obtained by formally differentiating the double Fourier series of $k(x, t)$ partially with respect to t, then we have

$$B_N(t, u) - B_M(t, u) = \sum_{n=M+1}^{N} \frac{s_n'(t)s_n(u) - s_{n-1}'(t)s_{n-1}(u)}{n^\alpha}$$

$$\to 0$$

as $M, N \to \infty$ uniformly in t, u by the same argument as that used in the proof of Lemma 2. It follows that

$$\frac{\partial k}{\partial t}(t, u) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} 2\pi i m \varepsilon_m \varepsilon_n a_{mn} e^{2\pi i(mt+nu)}$$

is continuous, and similarly so is the other partial derivative.

LEMMA 4. *For any given $\alpha > 1$ there exist C^1 kernels $K(x, y, t, u)$ whose eigenvalues are not $o(1/n^\alpha)$.*

Proof. If $\alpha > 2$ and

$$k(t, u) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \varepsilon_m \varepsilon_n a_{mn} e^{2\pi i(mt+nu)},$$

where a_{mn} is as in Lemma 2, then $K(x, y, t, u) = k(x-t, y-u)$ is C^1 and has eigenvalues $\varepsilon_m \varepsilon_n a_{mn} (m, n \geqq 1)$. Arranging these eigenvalues in descending order of modulus and denoting them by

$$|\lambda_1| \geqq |\lambda_2| \geqq \cdots \geqq |\lambda_n| \geqq \cdots$$

we have $|\lambda_{n^2}| = 1/n^\alpha$ and so λ_n is not $o(1/n^{\alpha/2})$.

4. Positive definite kernels.

LEMMA 5. *If b_{mn} is the m, nth entry of the matrix*

$$\begin{pmatrix} 1 & 1/2^\alpha & 1/3^\alpha & \cdots & 1/n^\alpha & \cdots \\ 1/2^\alpha & 1/3^\alpha & & & & \\ 1/3^\alpha & & & & & \\ \vdots & & & & & \\ 1/n^\alpha & & & & & \\ \vdots & & & & & \end{pmatrix}$$

then the double Fourier series

$$\sum_{m=1}^{\infty} \sum_{n=1}^{\infty} b_{mn} e^{2\pi i(mt+nu)}$$

is uniformly absolutely convergent in t, u for all $\alpha > 2$.

Proof. The sum of the entries b_{mn} on the nth cross-diagonal of the matrix is $n/n^\alpha = 1/n^{\alpha-1}$ and $\sum_1^\infty 1/n^{\alpha-1} < \infty$ if $\alpha > 2$.

COROLLARY. *The function*

$$k(t, u) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} b_{mn} e^{2\pi i(mt+nu)},$$

where b_{mn} is as in Lemma 5, is continuous if $\alpha > 2$.

LEMMA 6. *The function*

$$k(t, u) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} b_{mn}\, e^{2\pi i(mt+nu)},$$

where b_{mn} is as in Lemma 5, is C^1 if $\alpha > 3$.

Proof. Formally we have

$$\frac{\partial k}{\partial t}(t, u) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} 2\pi i m b_{mn}\, e^{2\pi i(mt+nu)}$$

and the sum of the entries on the nth cross-diagonal is now

$$2\pi i \frac{1+2+\cdots+n}{n^{\alpha}} = O(1/n^{\alpha-2})$$

and $\sum_1^{\infty} 1/n^{\alpha-2} < \infty$ if $\alpha > 3$.

LEMMA 7. *For any given $\alpha > 3/2$ there exist PDC^1 kernels $K(x, y, t, u)$ whose eigenvalues are not $o(1/n^{\alpha})$.*

Proof. If $\alpha > 3$ and

$$k(t, u) = \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} b_{mn}\, e^{2\pi i(mt+nu)},$$

where b_{mn} is as in Lemma 5, then $K(x, y, t, u) = k(x-t, y-u)$ is PDC^1 and has eigenvalues $b_{mn}(m, n \geqq 1)$. Arranging in descending order and denoting by

$$\lambda_1 \geqq \lambda_2 \geqq \cdots \geqq \lambda_n \geqq \cdots$$

we have $\lambda_{n(n+1)/2} = 1/n^{\alpha}$ and so λ_n is not $o(1/n^{\alpha/2})$.

5. Sharper results.

LEMMA 8. *For any given real sequence $(\alpha_n)_{n\geqq 1}$ which increases and diverges to infinity there exist C^1 kernels $K(x, y, t, u)$ whose eigenvalues are not $o(1/n\alpha_n)$.*

Proof (see [2]). Choose $n_k\ (k \geqq 1)$ such that $\alpha_{n_k} > k^2$ and let $\beta_n = 1/n_k^2 \alpha_{n_k} (n_{k-1} < n \leqq n_k)$. If we replace every entry in the nth L-shaped section of the matrix (a_{mn}) of Lemma 2 by β_n, then the corresponding kernel $K(x, y, t, u)$ constructed as in Lemma 4 has the required properties.

LEMMA 9. *For any given increasing divergent real sequence $(\alpha_n)_{n\geqq 1}$ there exist PDC^1 kernels $K(x, y, t, u)$ whose eigenvalues are not $o(1/n^{3/2}\alpha_n)$.*

Proof. Choose $n_k (k \geqq 1)$ as in the proof of Lemma 8, but now let $\beta_n = 1/n_k^3 \alpha_{n_k} (n_{k-1} < n \leqq n_k)$ and replace every entry in the nth cross-diagonal of the matrix (b_{mn}) of Lemma 5 by β_n.

ON OPTIMAL ALGORITHMS IN AN ASYMPTOTIC MODEL WITH GAUSSIAN MEASURE*

G. W. WASILKOWSKI† AND H. WOŹNIAKOWSKI‡

Abstract. We study the approximate solution of linear problems in separable Hilbert spaces equipped with a Gaussian measure. We find information and algorithms with the best possible rate of convergence. Although adaptive information and nonlinear algorithms are permitted, we prove that *nonadaptive* information and *linear* algorithms are optimal. An algorithm is optimal if it converges with a rate of convergence that is no worse than the rate of any other algorithm except on sets of measure zero. We prove that algorithms and information that minimize the average errors lead to the best possible rate of convergence. This exhibits a close relation between the asymptotic and average case models.

Key words. asymptotic model, linear problems, Gaussian measures

AMS(MOS) subject classifications. 65J05, 41A65

1. Introduction. Many papers deal with optimal algorithms for problems that are approximately solved. In these papers an optimal algorithm is usually defined as one having minimal error. In a *worse case model* the error of an algorithm is defined by its worst performance whereas in an *average case model* the error of an algorithm is defined by its average performance (see [7]-[11]).

To make clear what we mean by worst and average case models we consider a simple integration example.

Example 1.1. Suppose we want to approximate $Sf = \int_0^1 f(t)\,dt$ where $f:[0,1] \to \mathbf{R}$ is a function belonging to a given class F, where F is a subset of a Hilbert space F_1. We assume that we sample f at n given points $t_1, t_2, \cdots, t_n$. Thus we know that $N_n(f) = [f(t_1), f(t_2), \cdots, f(t_n)]$. Based on $N_n(f)$ and the fact that $f \in F$, we approximate $S(f)$ by an algorithm φ_n. By an algorithm we mean a mapping from $N_n(F)$ into $\mathbf{R}$. Thus, $\varphi_n(N_n(f)) = \sum_{i=1}^n a_i f(t_i)$ is an example of an algorithm. In the worst case model, the error of φ_n is defined as:

$$e^w(\varphi_n, N_n) = \sup\{|Sf - \varphi_n(N_n(f))| : f \in F\}.$$

In the average case model, the error of φ_n is usually defined as:

$$e^{\text{avg}}(\varphi_n, N_n) = \sqrt{\int_F |Sf - \varphi_n(N_n(f))|^2 \mu(df)}$$

where μ is a given probability measure on F.

In this paper we study optimal algorithms in the asymptotic model. To explain what we mean by optimality in the asymptotic model, we shall use the integration example.

We first stress the main difference between the asymptotic and worst (or average) case models. In the worst (or average) case model fixed information N_n is applied for all functions f from F. This may be contrasted with the asymptotic model, where a

sequence of information N_n, with n tending to infinity, is applied for each f. That is, knowing $N_n(f)$ for all n, we want to find a sequence of approximations $\varphi_n(N_n(f))$ to Sf with good convergence properties. Here φ_n is an algorithm that uses N_n. Let $\bar{\varphi} = \{\varphi_n\}$ be a sequence of such algorithms. For brevity, $\bar{\varphi}$ is also called an algorithm.

Asymptotically convergent algorithms are widely used in practice. Examples include quadrature formulas for the integration problem, and algorithms for the solution of ordinary or partial differential equations with meshsize tending to zero. This approach, commonly used in numerical analysis, motivates our study. Our interest is to find an asymptotically optimal algorithm.

What is the optimal algorithm in the asymptotic model? We motivate our definition by the following discussion. Let $\bar{\varphi} = \{\varphi_n\}$ and $\bar{\varphi}^* = \{\varphi_n^*\}$ be two algorithms for approximating Sf. Let $A(\bar{\varphi}, \bar{\varphi}^*)$ denote the set of functions f for which the algorithm $\bar{\varphi}$ converges to Sf with a better rate of convergence than the algorithm $\bar{\varphi}^*$. That is, $f \in A(\bar{\varphi}, \bar{\varphi}^*)$ if and only if

$$\lim_n |Sf - \varphi_n(N_n(f))| / |Sf - \varphi_n^*(N_n(f))| = 0.$$

One might want to define $\bar{\varphi}^*$ as optimal if $\bar{\varphi}^*$ *never* "loses" to $\bar{\varphi}$. That is, $\bar{\varphi}^*$ is optimal if $A(\bar{\varphi}, \bar{\varphi}^*) = \varnothing$, for all $\bar{\varphi}$. We show that such an algorithm $\bar{\varphi}^*$ does *not* exist. Another attempt would be to define $\bar{\varphi}^*$ as optimal by requiring that $A(\bar{\varphi}, \bar{\varphi}^*)$ be finite or perhaps countable for all $\bar{\varphi}$. Unfortunately this also does not work. (This is proven in the Appendix.) Thus, optimality of $\bar{\varphi}^*$ must be defined differently.

One approach that does work is due to Trojan [8]. He defines $\bar{\varphi}^*$ to be optimal if the set $A(\bar{\varphi}, \bar{\varphi}^*)$ has empty interior for any $\bar{\varphi}$. We define optimality differently than Trojan. We assume that the space of elements f is equipped with a probability measure μ. Optimality of $\bar{\varphi}^*$ is then defined by zero measure of the set $A(\bar{\varphi}, \bar{\varphi}^*)$ for any algorithm $\bar{\varphi}$. Thus, $\bar{\varphi}^*$ is optimal if it "loses" to any algorithm $\bar{\varphi}$ only on a set of measure zero.

The integration example discussed above is a particular case of problems studied in this paper. The general formulation is as follows. For two separable Hilbert spaces F_1 and F_2, we consider a linear continuous operator S, $S: F_1 \to F_2$. We wish to approximate Sf for any element f from F_1. We assume that the element f is not known. Instead one can compute n linear continuous functionals $N_n(f)$. The choice of the ith functional may depend on the values of $(i-1)$ previously computed functionals. Then the sequence $\bar{N} = \{N_n\}$ is called *adaptive* information. For given adaptive information $\bar{N}$ we wish to find a sequence $\bar{\varphi} = \{\varphi_n\}$ such that $\varphi_n(N_n(f))$ goes to Sf with the best possible rate of convergence. The sequence $\bar{\varphi}$ is called an *algorithm*. We are looking for an *optimal* algorithm $\bar{\varphi}^* = \{\varphi_n^*\}$. As we already mentioned, optimality of $\bar{\varphi}^*$ means that an arbitrary algorithm $\bar{\varphi}$ approximates Sf with a better rate of convergence than the algorithm $\bar{\varphi}^*$ only on a set of measure zero. More precisely, we assume that the space F_1 is equipped with a Gaussian measure μ. Then $\bar{\varphi}^*$ is (asymptotically) *optimal* if and only if

$$\mu(\{f \in F_1 : \lim_n \|Sf - \varphi_n(N_n(f))\| / \|Sf - \varphi_n^*(N_n(f))\| = 0\}) = 0 \tag{1.1}$$

for any algorithm $\bar{\varphi} = \{\varphi_n\}$. Here we adopt the convention $0/0 = 1$.

Obviously, an optimal algorithm is *not* uniquely defined by (1.1). However, the difference between optimal algorithms is insignificant. Indeed, let $h_n = \varphi_{1,n} - \varphi_{2,n}$ be the difference between two optimal algorithms $\bar{\varphi}_1 = \{\varphi_{1,n}\}$ and $\bar{\varphi}_2 = \{\varphi_{2,n}\}$. Then $\|h_n(N_n(f))\| \leqq \|Sf - \varphi_{1,n}(N_n(f))\| + \|Sf - \varphi_{2,n}(N_n(f))\|$ goes to zero at least as fast as the errors of optimal algorithms.

The first problem studied in this paper is to find an optimal algorithm in the sense of (1.1). We solve this problem by showing a relation between optimality in the average case and asymptotic models. More precisely, let φ_n^* be an optimal algorithm in the average case model. The form of φ_n^* is known (see [10], [11]). In fact, $\varphi_n^*(N_n(f)) = S\sigma_n(N_n(f))$ where $\sigma_n(N_n(f))$ is a μ-spline element. If information N_n is nonadaptive, then φ_n^* is a linear mapping.

Let $\bar{\varphi}^* = \{\varphi_n^*\}$. That is, the algorithm $\bar{\varphi}^*$ consists of algorithms φ_n^* that minimize the average case errors for each n. The algorithm $\bar{\varphi}^*$ is called a μ-spline algorithm since it is based on μ-spline elements. We prove that $\bar{\varphi}^*$ is optimal. This is very desirable from a practical point of view. The μ-spline algorithm that has the best possible rate of convergence also has the minimal average case error at each step.

The second problem studied in this paper is to characterize the rate of convergence of the μ-spline algorithm. Once more, we solve this problem by showing a relation to the average case model. This relation is exhibited in terms of local average radii which play a key role in the average case analysis. We show that the sequence of local average radii fully characterizes the rate of convergence of the μ-spline algorithm.

The third problem is to find information $\bar{N}^* = \{N_n^*\}$ for which the rate of convergence of local radii is best possible, or equivalently, for which the rate of convergence of the optimal algorithm is best possible. It turns out that N_n^* is given by just that *nonadaptive* information that is optimal in the average case model.

Thus, although we permit adaptive information and nonlinear algorithms, the optimal information is *nonadaptive* and the optimal algorithm is *linear.*

Our results exhibit a close relation between the average case model and the asymptotic model for linear problems defined in Hilbert spaces with a Gaussian measure. Trojan [8] shows a similar relation between the worst case and the asymptotic models for linear problems defined on a Banach space that is *not* equipped with a measure. As we already mentioned, in his paper asymptotic optimality is defined by the condition that the sets $A(\bar{\varphi}, \bar{\varphi}^*)$ have empty interior. These relations are desirable from a practical point of view. Algorithms and information that minimize the worst or average case error also yield the best rate of convergence.

Our results hold for linear problems defined in Hilbert spaces with a Gaussian measure. We shall indicate which of them hold for more general measures, which are called elliptically contoured (see [1]). Recent research seems to indicate that the results of the paper also hold if F_1 is a Banach space.

The contents of this paper are summarized as follows. In § 2 we formulate the three problems studied in this paper. In the successive sections we present solutions to these problems. In § 3 we prove optimality of the μ-spline algorithm. In § 4 we show that the local average radii fully characterize the rate of convergence of the μ-spline algorithm. In § 5 we exhibit optimal information. Finally, the Appendix contains a proof that shows that the set $A(\bar{\varphi}, \bar{\varphi}^*)$ is uncountable.

2. Formulation of the problem. In this section we define the basic concepts and formulate the three problems that will be studied in this paper.

Let F_1 and F_2 be separable Hilbert spaces over the real field. Let μ be a Gaussian measure defined on Borel sets of F_1, $\mu(F_1) = 1$. We assume that the mean element of μ is zero and the self-adjoint covariance operator S_μ of μ is positive definite (see [3], [6]).

Consider a continuous linear operator S such that

$$S: F_1 \to F_2. \tag{2.1}$$

Our problem is to approximate Sf for all f from F_1. We assume that the element f is

not known but we can compute arbitrarily many functionals of f. That is, we define an *information operator* $\bar{N}$ of the form

$$\bar{N}(f) = [(f, g_1), (f, g_2(y_1)), \cdots, (f, g_n(y_1, \cdots, y_{n-1})), \cdots] \tag{2.2}$$

where $y_1 = (f, g_1)$, $y_i = (f, g_i(y_1, \cdots, y_{i-1}))$ for $i = 2, 3, \cdots$. Here $(\cdot, \cdot)$ denotes the inner product in F_1 and $g_i: \mathbf{R}^{i-1} \to F_1$ is a measurable mapping, i.e., $g_i^{-1}(B)$ is a Borel set of $\mathbf{R}^{i-1}$ whenever B is a Borel set of F_1. Without loss of generality (see [10], [11]) we assume that

$$(S_\mu g_i(y_1, \cdots, y_{i-1}), g_j(y_1, \cdots, y_{j-1})) = \delta_{i,j} \tag{2.3}$$

for $i, j = 1, 2, \cdots$, and all $y_1, y_2, \cdots$.

The essence of (2.2) is that the choice of $g_i(y_1, \ldots, y_{i-1})$ may depend on the $i-1$ previously computed inner products. Such an information operator $\bar{N}$ is therefore called *adaptive*. To stress the adaptive character of $\bar{N}$ we shall sometimes write $\bar{N} = \bar{N}^a$. On the other hand, if each $g_i(y_1, \cdots, y_{i-1})$ does not depend on $y_1, \cdots, y_{i-1}$, i.e., $g_i(y_1, \cdots, y_{i-1}) \equiv g_i^*$ for some g_i^* from F_1, then $\bar{N}$ is called *nonadaptive* and sometimes denoted by $\bar{N} = \bar{N}^{\text{non}}$. Thus the information operator $\bar{N}$ consists of a sequence of inner products chosen adaptively or nonadaptively. In either case, let

$$N_n(f) = [(f, g_1), (f, g_2(y_1)), \cdots, (f, g_n(y_1, \cdots, y_{n-1}))] \quad \forall f = F_1, \tag{2.4}$$

denote the first n inner products in $\bar{N}$. Knowing $N_n(f)$ for all n, we approximate Sf by an algorithm $\bar{\varphi}$. By the *algorithm* $\bar{\varphi} = \{\varphi_n\}$ that uses $\bar{N} = \{N_n\}$ we mean a sequence of mappings

$$\varphi_n: N_n(F_1) \subset \mathbf{R}^n \to F_2. \tag{2.5}$$

We assume that φ_n is measurable, i.e., $\varphi_n^{-1}(B)$ is a Borel set of $\mathbf{R}^n$ whenever B is a Borel set of F_2.

We approximate Sf by $\varphi_n(N_n(f))$. We want to find $\bar{N}$ and $\bar{\varphi}$ such that $\varphi_n(N_n(f))$ tends to Sf as fast as possible. More precisely, we shall study the following three problems:

(i) For a given information operator $\bar{N} = \{N_n\}$ find an *optimal algorithm* $\bar{\varphi}^* = \{\varphi_n^*\}$ using $\bar{N} = \{N_n\}$. That is, an algorithm $\bar{\varphi}^*$ such that

$$\mu\left(\left\{f \in F_1: \lim_n \frac{\|Sf - \varphi_n(N_n(f))\|}{\|Sf - \varphi_n^*(N_n(f))\|} = 0\right\}\right) = 0 \tag{2.6}$$

for any algorithm $\bar{\varphi} = \{\varphi_n\}$ using $\bar{N}$. Throughout this paper we adopt the convention $0/0 = 1$.

(ii) Let $\bar{\varphi}^*$ satisfy (2.6). Characterize the rate of convergence of φ^* in terms of the Gaussian measure μ, the operator S and the information operator $\bar{N}$.

(iii) Find an *optimal* information operator $\bar{N}^*$, i.e., $\bar{N}^*$ of the form (2.2) for which the rate of convergence of an optimal algorithm $\bar{\varphi}^*$ using $\bar{N}^*$ is best possible. This means, we want to determine the best elements $g_1^*, g_2^*(y_1), \cdots, g_n^*(y_1, \cdots, y_{n-1}), \cdots$, in (2.2). Are the best elements $g_i^*(y_1, \cdots, y_{i-1})$ independent of $y_1, \cdots, y_{i-1}$? (Equivalently, is the optimal information nonadaptive?)

3. Optimal algorithm. In this section we deal with problem (i) of § 2. We describe the μ-spline algorithm $\bar{\varphi}^s = \{\varphi_n^s\}$ using given information $\bar{N} = \{N_n\}$ (see [10], [11]) and show its optimality.

Let $\bar{N}$ be given by (2.2) and (2.3). For given n and $y = N_n(f)$ define

$$\sigma_n = \sigma_n(y) = \sum_{i=1}^{n} (f, g_i(y)) S_\mu g_i(y) = \sum_{i=1}^{n} y_i S_\mu g_i(y) \tag{3.1}$$

where $g_i(y) = g_i(y_1, \cdots, y_{i-1})$. The element σ_n is the unique solution of the problem

$$\begin{aligned} &N_n(\sigma_n) = N_n(f), \\ &\|S_\mu^{-1/2}\sigma_n\| = \inf\{\|S_\mu^{-1/2}g\|\colon g \in S_\mu^{1/2}(F_1),\ N_n(g) = N_n(f)\}. \end{aligned} \tag{3.2}$$

An element σ_n that is the solution of (3.2) is often called a $S_\mu^{-1/2}$-spline. To stress the dependence on the measure μ, we shall call σ_n a *μ-spline*. The algorithm $\bar{\varphi}^s = \{\varphi_n^s\}$, where

$$\varphi_n^s(N_n f) = S\sigma_n(N_n f) = \sum_{i=1}^{n} (f, g_i(y))SS_\mu g_i(y), \tag{3.3}$$

is called a *μ-spline algorithm.*

It is known (see [10], [11]) that the μ-spline algorithm φ_n^s is a unique algorithm that minimizes the average error $\int_{F_1} \|Sf - \varphi_n(N_n(f))\|^2 \mu(df)$ over all measurable mappings $\varphi_n\colon \mathbf{R}^n \to F_2$. We are ready to prove the optimality of $\bar{\varphi}^s$ in the sense of (2.6).

THEOREM 3.1. *The μ-spline algorithm $\bar{\varphi}^s$ is optimal. That is, for any algorithm $\bar{\varphi} = \{\varphi_n\}$ that uses $\bar{N} = \{N_n\}$ we have*

$$\mu\left(\left\{f \in F_1\colon \lim_n \frac{\|Sf - \varphi_n(N_n(f))\|}{\|Sf - \varphi_n^s(N_n(f))\|} = 0\right\}\right) = 0. \tag{3.4}$$

Proof. Given such an algorithm $\bar{\varphi}$, let $A = \{f \in F_1\colon \lim_n \|Sf - \varphi_n(N_n(f))\| / \|Sf - \varphi_n^s(N_n(f))\| = 0\}$. Take a number $q \in (0, 1)$ and define

$$A_n = \{f \in F_1\colon \|Sf - \varphi_n(N_n(f))\| < q\|Sf - \varphi_n^s(N_n(f))\|\}.$$

Then $A \subset \bigcup_{i=1}^{\infty} \bigcap_{n=i}^{\infty} A_n$. Note that A and A_n are measurable and

$$\mu(A) \leqq \lim_i \mu\left(\bigcap_{n=i}^{\infty} A_n\right) \leqq \overline{\lim_n}\, \mu(A_n). \tag{3.5}$$

We estimate $\mu(A_n)$. Define the probability measure

$$\mu_1(B) = \mu(N_n^{-1}B) = \mu(\{f \in F_1\colon N_n(f) \in B\})$$

where B is a Borel set of $\mathbf{R}^n$. (Although it is not needed here, we remark that μ_1 is a Gaussian measure with mean element zero and the identity covariance operator; see [9, Thm. 3.1(i)].)

From Theorem 8.1 of [5, p. 147] we know that there exists a unique (modulo a set of μ_1-measure zero) family of probability measures $\mu_2(\cdot|y)$ defined on Borel sets of F_1 such that

$$\begin{aligned} &\mu_2(N_n^{-1}(y)|y) = 1 \quad \forall y \in \mathbf{R}^n \text{ a.e.}, \\ &\mu_2(B|\cdot) \text{ is } \mu_1\text{-measurable}, \\ &\mu(B) = \int_{\mathbf{R}^n} \mu_2(B|y)\mu_1(df) \end{aligned} \tag{3.6}$$

for any Borel set B of F_1. Thus we have

$$\mu(A_n) = \int_{\mathbf{R}^n} \mu_2(A_n|y)\mu_1(dy). \tag{3.7}$$

It is shown in Theorem 3.1(ii) of [9], that $\mu_2(\cdot|y)$ is a Gaussian measure with mean element $\sigma_n(y)$ and the correlation operator

$$S_y = (I - \sigma_{n,y})S_\mu(I - \sigma_{n,y}^*),$$

where $\sigma_{n,y}: F_1 \to F_1$ is a linear operator such that

$$\sigma_{n,y}(h) = \sum_{i=1}^{n} (h, g_i(y)) S_\mu g_i(y) \quad \forall h \in F_1.$$

For $y = N_n(f)$, let $g_n(y) = \varphi_n(y) - \varphi_n^s(y)$. Then

$$N_n^{-1}(y) \cap A_n = N_n^{-1}(y) \cap B_n(y) + \sigma_n(y)$$

where $B_n(y) = \{h \in F_1: \|Sh - g_n(y)\| < q\|Sh\|\}$. Due to (3.6) and the fact that $\sigma_n(y)$ is the mean element of $\mu_2(\cdot|y)$ we have

$$\mu_2(A_n|y) = \mu_2(N_n^{-1}(y) \cap A_n|y) = \nu_y(B_n(y)) \tag{3.8}$$

where ν_y is a Gaussian measure with mean element zero and covariance operator S_y.

Observe that $S^* g_n(y) = 0$ implies that $B_n(y) = \varnothing$. Assume therefore that $S^* g_n(y) \neq 0$. Let $e_1 = g_n(y)/\|g_n(y)\|$. Every element $z \in F_2$ can be decomposed as $z = (z, e_1)e_1 + z_2$ where $(z_2, e_1) = 0$. Then for $h \in B_n(y)$ we have

$$(Sh - g_n(y), e_1)^2 + \|(Sh)_2\|^2 < q^2 (Sh, e_1)^2 + q^2 \|(Sh)_2\|^2.$$

This yields

$$(1-q^2)(h, S^* e_1)^2 - 2(h, S^* e_1)\|g_n(y)\| + \|g_n(y)\|^2 < 0,$$

and consequently

$$\frac{\|g_n(y)\|}{1+q} < (h, S^* e_1) < \frac{\|g_n(y)\|}{1-q}. \tag{3.9}$$

Since ν_y is a Gaussian measure, (3.9) yields

$$\nu_y(B_n(y)) \leqq \nu_y(\{h: (h, S^* e_1)/\|g_n(y)\| \in ((1+q)^{-1}, (1-q)^{-1})\})$$
$$= \begin{cases} 0 & \text{if } S_y S^* e_1 = 0, \\ \dfrac{1}{\sqrt{2\pi}} \displaystyle\int_{a_n}^{b_n} e^{-t^2/2}\, dt & \text{if } S_y S^* e_1 \neq 0, \end{cases}$$

where $a_n = \|g_n(y)\|/((1+q)\sqrt{(S_y S^* e_1, S^* e_1)})$ and $b_n = \|g_n(y)\|/((1-q)\times \sqrt{(S_y S^* e_1, S^* e_1)})$. If $S_y S^* e_1 \neq 0$, we estimate $e^{-t^2/2}$ by its value at a_n. Then we get

$$\nu_y(B_n(y)) \leqq \frac{1}{\sqrt{2\pi}} e^{-a_n^2/2}(b_n - a_n) = \sqrt{\frac{2}{\pi}} \frac{q}{1-q} a_n e^{-a_n^2/2}.$$

Since $x e^{-x^2/2} \leqq 1/\sqrt{e}$ we finally get

$$\nu_y(B_n(y)) \leqq cq/(1-q) \tag{3.10}$$

where $c = \sqrt{2/(\pi e)}$. From (3.7), (3.8) and (3.10) we have $\mu(A_n) \leqq cq/(1-q)$. Then (3.5) yields

$$\mu(A) \leqq cq/(1-q). \tag{3.11}$$

Since q can be arbitrarily small, $\mu(A) = 0$ as claimed. □

Remark 3.1. Theorem 3.1 remains true for more general measures μ. Namely, assume that μ is *elliptically contoured* with mean element zero and covariance operator S_μ (see Crawford [1]). That is, μ is of the form

$$\mu(B) = \int_0^\infty \mu_G\left(\frac{1}{\sqrt{t}} B\right) \alpha(dt) \qquad \forall B\text{-Borel set of } F_1, \tag{3.12}$$

where α is a measure defined on Borel sets of $(0, +\infty)$ such that

$$\int_0^\infty \alpha(dt) = \int_0^\infty t\alpha(dt) = 1. \tag{3.13}$$

Here μ_G denotes the Gaussian measure with mean element zero and covariance operator S_μ. Note that $\nu(B) = \mu_G(1/\sqrt{t}\, B)$ is a Gaussian measure with mean element zero and covariance operator tS_μ. Since (3.11) holds for any Gaussian measure with mean zero, then

$$\mu_G\left(\frac{1}{\sqrt{t}} A\right) \leqq \frac{cq}{1-q}, \qquad c = \sqrt{2/(\pi e)},$$

and consequently (3.12) and (3.13) yield

$$\mu(A) = \int_0^\infty \mu_G\left(\frac{1}{\sqrt{t}} A\right)\alpha(dt) \leqq \frac{cq}{1-q}.$$

This implies that $\mu(A) = 0$ as claimed.

Remark 3.2. The proof of Theorem 3.1 supplies a slightly stronger result than (3.4). Namely, for $q \in (0, 1)$ let

$$B = \left\{ f \in F_1 : \overline{\lim_n} \frac{\|Sf - \varphi_n(N_n(f))\|}{\|Sf - \varphi_n^s(N_n(f))\|} < q \right\}.$$

Then repeating the proof of Theorem 3.1 for the set B instead of the set A, we can obtain

$$\mu(B) \leqq \min\left\{\frac{1}{2}, \sqrt{\frac{2}{\pi e}} \frac{q}{1-q}\right\}. \tag{3.14}$$

Thus for small q, the measure of B is also small. We do not know whether the estimate (3.14) is sharp. Due to Remark 3.1, (3.14) also holds for an elliptically contoured measure.

4. Rate of convergence. In this section we deal with problem (ii) of § 2. We characterize the rate of convergence of the μ-spline algorithm $\bar{\varphi}^s = \{\varphi_n^s\}$ that uses given information $\bar{N} = \{N_n\}$. Observe that

$$\int_{F_1} \|Sf - \varphi_n^s(N_n(f))\|^2 \mu(df) = \int_{\mathbf{R}^n} \int_{F_1} \|Sf - \varphi_n^s(y)\|^2 \mu_2(df|y)\mu_1(dy) \tag{4.1}$$

where μ_1 and $\mu_2(\cdot|y)$ are defined as in § 3. As in [9], we define the local (average) radius rad (N_n, y) of information N_n by

$$\begin{aligned} \text{rad}\,(N_n, y) &= \inf_{g \in F_2} \left\{ \int_{F_1} \|Sf - g\|^2 \mu_2(df|y) \right\}^{1/2} \\ &= \left\{ \int_{F_1} \|Sf - \varphi_n^s(y)\|^2 \mu_2(df|y) \right\}^{1/2} \\ &= \left\{ \int_{F_1} \|Sf\|^2 \nu_y(df) \right\}^{1/2}, \end{aligned} \tag{4.2}$$

where ν_y is a Gaussian measure with mean element zero and covariance operator S_y,

$$S_y h = S_\mu h - \sum_{i=1}^n (h, S_\mu g_i) S_\mu g_i \quad \forall h \in F_1. \tag{4.3}$$

Here $g_i = g_i(y)$, $i = 1, 2, \cdots, n$.

We shall prove that the sequence of local radii rad $(N_n, N_n(f))$ characterizes the rate of convergence of the μ-spline algorithm. Before proving this, we obtain a more explicit form of rad (N_n, y). Let

$$\eta_i = \eta_i(y) = S_\mu^{1/2} g_i(y), \qquad i = 1, 2, \cdots, n. \tag{4.4}$$

Then (2.3) yields $(\eta_i, \eta_j) = \delta_{i,j}$. Define the operator

$$K = S_\mu^{1/2} S^* S S_\mu^{1/2} : F_1 \to F_1. \tag{4.5}$$

Note that $K = K^* \geqq 0$. Furthermore K has finite trace. Indeed, let $\{f_j\}$ be the orthonormal basis of F_1 such that $S_\mu f_j = \lambda_j f_j$. Then

$$\begin{aligned} \text{trace}\,(K) &= \sum_{j=1}^{\infty} (Kf_j, f_j) = \sum_{j=1}^{\infty} \lambda_j \|Sf_j\|^2 \\ &\leqq \|S\|^2 \,\text{trace}\,(S_\mu) < +\infty. \end{aligned} \tag{4.6}$$

Observe also that

$$\text{trace}\,(K) = \int_{F_1} \|Sf\|^2 \mu(df).$$

Indeed, $\|Sf\|^2 = \sum_{i,j=1}^{\infty} (f, f_i)(f, f_j)(Sf_i, Sf_j)$ and

$$\begin{aligned} \int_{F_1} \|Sf\|^2 \mu(df) &= \sum_{i,j=1}^{\infty} (S_\mu f_i, f_j)(Sf_i, Sf_j) \\ &= \sum_{j=1}^{\infty} \lambda_j (S^* S f_j, f_j) = \sum_{j=1}^{\infty} (S^* S S_\mu^{1/2} f_j, S_\mu^{1/2} f_j) \\ &= \sum_{j=1}^{\infty} (Kf_j, f_j) \end{aligned}$$

as claimed.

LEMMA 4.1.

$$\begin{aligned} \text{rad}\,(N_n, y) &= \sqrt{\text{trace}\,(S S_y S^*)} \\ &= \sqrt{\text{trace}\,(K) - \textstyle\sum_{i=1}^{n} (K\eta_i(y), \eta_i(y))}. \end{aligned} \tag{4.7}$$

Proof. Let $\beta_y = \nu_y S^{-1}$ be a measure defined on Borel sets of F_2. Note that β_y is a Gaussian measure defined on Borel sets of F_2 with mean element zero and covariance operator $S_{\beta_y} = S S_y S^*$. Change variables in (4.2) by setting $g = Sf$. Then

$$\begin{aligned} \text{rad}^2\,(N_n, y) &= \int_{F_1} \|Sf\|^2 \nu_y(df) = \int_{F_2} \|g\|^2 \beta_y(dg) \\ &= \text{trace}\,(S_{\beta_y}) = \text{trace}\,(S S_y S^*), \end{aligned}$$

which proves the first equality in (4.7).

To prove the second equality in (4.7), take any orthonormal basis $\{h_j\}$ of F_2. Then (4.3) yields

$$\begin{aligned} \text{trace}\,(S S_y S^*) &= \sum_{j=1}^{\infty} (S S_y S^* h_j, h_j) \\ &= \sum_{j=1}^{\infty} (S S_\mu S^* h_j, h_j) - \sum_{i=1}^{n} \sum_{j=1}^{\infty} (S S_\mu g_i, h_j)^2 \\ &= \text{trace}\,(S S_\mu S^*) - \sum_{i=1}^{n} \|S S_\mu^{1/2} \eta_i\|^2 \\ &= \text{trace}\,(S S_\mu S^*) - \sum_{i=1}^{n} (K\eta_i, \eta_i). \end{aligned}$$

Thus, it is enough to show that trace $(K) = \text{trace}\,(SS_\mu S^*)$. To do this observe that $S^*h_i = \sum_{j=1}^{\infty} (S^*h_i, f_j) f_j$ where $S_\mu f_j = \lambda_j f_j$. Then

$$\begin{aligned}\text{trace}\,(SS_\mu S^*) &= \sum_{i=1}^{\infty} (SS_\mu S^* h_i, h_i) \\ &= \sum_{j=1}^{\infty} \lambda_j \sum_{i=1}^{\infty} (h_i, Sf_j)^2 \\ &= \sum_{j=1}^{\infty} \lambda_j \|Sf_j\|^2 \\ &= \text{trace}\,(K)\end{aligned}$$

due to (4.6). This completes the proof. □

We need an estimate of a Gaussian measure ν of the ball $B_r = \{g \in F_2 : \|g\| \leqq r\}$. We assume that the Gaussian measure ν defined on Borel sets of F_2 has mean element zero and its covariance operator S_ν is nonzero.

THEOREM 4.1 (Kwapień [4]).

$$\nu(B_r) \leqq \tfrac{4}{3}\, \psi(2r/\sqrt{\text{trace}\,(S_\nu)}), \tag{4.8}$$

where

$$\psi(x) = \sqrt{\frac{2}{\pi}} \int_0^x e^{-\tau^2/2}\, d\tau.$$

Proof. Assume first that $S_\nu > 0$. Let $\{\zeta_i\}$ be the orthonormal basis of F_2 such that $S_\nu \zeta_i = \lambda_i \zeta_i$, where $\lambda_i > 0$ and $\text{trace}\,(S_\nu) = \sum_{i=1}^{\infty} \lambda_i$. Define the random variables $\xi_i(g) = (g, \zeta_i)/\sqrt{\lambda_i}$, $i = 1, 2, \cdots$. Then $\{\xi_i\}$ is a sequence of independent random variables each of them with Gaussian distribution with mean zero and variance one. Note that

$$\nu(B_r) = \nu\left(\left\{g \in F_2 : \sum_{i=1}^{\infty} \lambda_i \xi_i^2(g) \leqq r^2\right\}\right).$$

Let λ denote the Lebesgue measure on $[0, 1]$. Let $\{r_i\}$ be the Radamacher system on $[0, 1]$, i.e., $r_i : [0, 1] \to \mathbf{R}$, and $\{r_i\}$ is a sequence of independent random variables each of them with distribution $\lambda(\{t : r_i(t) = +1\}) = \lambda(\{t : r_i(t) = -1\}) = \frac{1}{2}$. For $g \in B_r$ and $c > 0$ we have

$$\lambda\left(\left\{t : \left|\sum_{i=1}^{\infty} \sqrt{\lambda_i}\, \xi_i(g) r_i(t)\right| \leqq c\right\}\right) \geqq R\left(\frac{c}{r}\right), \tag{4.9}$$

where

$$R(x) = \inf_{\sum_{i=1}^{\infty} c_i^2 \leqq 1} \lambda\left(\left\{t : \left|\sum_{i=1}^{\infty} c_i r_i(t)\right| \leqq x\right\}\right). \tag{4.10}$$

Due to Fubini's theorem, we get from (4.9)

$$\begin{aligned}&\nu \otimes \lambda\left(\left\{(g, t) : \left|\sum_{i=1}^{\infty} \sqrt{\lambda_i}\, \xi_i(g) r_i(t)\right| \leqq c\right\}\right) \\ &\quad \geqq \int_{B_r} \lambda\left(\left\{t : \left|\sum_{i=1}^{\infty} \sqrt{\lambda_i}\, \xi_i(g) r_i(t)\right| \leqq c\right\}\right) \nu(dg) \\ &\quad \geqq R\left(\frac{c}{r}\right) \nu(B_r),\end{aligned} \tag{4.11}$$

where $\nu \otimes \lambda$ denotes the usual product measure. On the other hand, let $\zeta_i(g, t) = \xi_i(g) r_i(t)$ for $g \in F_2$ and $t \in [0, 1]$. Then $\{\zeta_i\}$ is a sequence of independent random variables each with Gaussian distribution with mean zero and variance one. Therefore $\Sigma_{i=1}^{\infty} \sqrt{\lambda_i}\, \zeta_i$ has Gaussian distribution with mean zero and variance $\sigma = \sum_{i=1}^{\infty} \lambda_i =$ trace (S_ν). Hence the left-hand side of (4.11) is equal to

$$\frac{1}{\sqrt{2\pi\sigma}} \int_{-c}^{+c} e^{-\tau^2/(2\sigma)}\, d\tau = \sqrt{\frac{2}{\pi}} \int_0^{c/\sqrt{\sigma}} e^{-\tau^2/2}\, d\tau = \psi\left(\frac{c}{\sqrt{\sigma}}\right).$$

Thus we get

$$\nu(B_r) \leqq \psi\left(\frac{c}{\sqrt{\sigma}}\right) \Big/ R\left(\frac{c}{r}\right). \tag{4.12}$$

Let $c = 2r$. To estimate $R(2)$ we use Chebyshev's inequality, which states that

$$\lambda\left(\left\{t: \left|\sum_{i=1}^{\infty} c_i r_i(t)\right| > 2\right\}\right) \leqq \frac{1}{4} \int_0^1 \left(\sum_{i=1}^{\infty} c_i r_i(t)\right)^2 dt.$$

Since r_i are independent with mean zero, then

$$\int_0^1 \left(\sum_{i=1}^{\infty} c_i r_i(t)\right)^2 dt = \sum_{i=1}^{\infty} c_i^2 \leqq 1.$$

Hence $R(2) \geqq 1 - \frac{1}{4} = \frac{3}{4}$ and (4.12) yields (4.8) in the nonsingular case.

Assume now that S_ν is singular and let $X = \ker S_\nu$. Decompose F_2 as the direct sum $X \oplus X^\perp$ where $X^\perp$ is the orthonormal complement of X. Then for every g from F_2, we have $g = g_1 + g_2$, $g_1 \in X$ and $g_2 \in X^\perp$. We get

$$\nu(B_r) = \bar{\nu}(\{h \in X^\perp: \|h\| \leqq r\})$$

where $\bar{\nu}$ is the Gaussian measure on $X^\perp$ with mean element zero and covariance operator $S_\nu|_{X^\perp} > 0$. Applying (4.8) to $\bar{\nu}$, we get the desired estimate on $\nu(B_r)$. Hence the proof is complete. □

We are ready to characterize the rate of convergence of the μ-spline algorithm.

THEOREM 4.2.

$$\mu\left(\left\{f \in F_1: \lim_n \frac{\|Sf - \varphi_n^s(N_n(f))\|}{\operatorname{rad}(N_n, N_n(f))} = 0\right\}\right) = 0. \tag{4.13}$$

Proof. Let $A = \{f \in F_1: \lim_n \|Sf - \varphi_n^s(N_n(f))\| / \operatorname{rad}(N_n, N_n(f)) = 0\}$. Take a number $q \in (0, 1)$ and define

$$A_n = \{f \in F_1: \|Sf - \varphi_n^s(N_n(f))\| < q \operatorname{rad}(N_n, N_n(f))\}.$$

Then $A \subset \bigcup_{i=1}^{\infty} \bigcap_{n=i}^{\infty} A_n$ and $\mu(A) \leqq \overline{\lim_n}\, \mu(A_n)$. We estimate $\mu(A_n)$. From (3.7) we have

$$\begin{aligned} \mu(A_n) &= \int_{\mathbf{R}^n} \mu_2(\{f: \|Sf - \varphi_n^s(y)\| < q \operatorname{rad}(N_n, y)\} | y) \mu_1(dy) \\ &= \int_{\mathbf{R}^n} \nu_y(\{f: \|Sf\| < q \operatorname{rad}(N_n, y)\}) \mu_1(dy), \end{aligned} \tag{4.14}$$

where ν_y is the Gaussian measure with mean zero and covariance operator S_y given by (4.3). As in the proof of Lemma 4.1, let $\beta_y = \nu_y S^{-1}$ be the Gaussian measure with

mean element zero and covariance operator $S_{\beta_y} = SS_yS^*$. Let $r = q \operatorname{rad}(N_n, y)$ and $B_r = \{g \in F_2 : \|g\| \leq r\}$. Then

$$\beta_y(B_r) = \nu_y(\{f \in F_1 : \|Sf\| < r\}).$$

Due to Lemma 4.1 we have $r = q\sqrt{\operatorname{trace}(S_{\beta_y})}$. From (4.14) we get

$$\mu(A_n) = \int_{\mathbf{R}^n} \beta_y(\{g \in F_2 : \|g\| < q\sqrt{\operatorname{trace}(S_{\beta_y})}\})\mu_1(dy). \tag{4.15}$$

From Theorem 4.1 we have the following estimate:

$$\mu(A_n) \leq \frac{4}{3}\int_{\mathbf{R}^n} \psi(2q)\mu_1(dy) = \frac{4}{3}\psi(2g),$$

and consequently

$$\mu(A) \leq \tfrac{4}{3}\psi(2q).$$

Since q can be arbitrarily small and $\psi(2q)$ tends to zero with q, we conclude $\mu(A) = 0$, as claimed. □

Remark 4.1. It is also true that (4.13) of Theorem 4.2 holds for any algorithm $\bar{\varphi} = \{\varphi_n\}$ using $\bar{N} = \{N_n\}$. That is,

$$\mu\left(\left\{f \in F_1 : \lim_n \frac{\|Sf - \varphi_n(N_n(f))\|}{\operatorname{rad}(N_n, N_n(f))} = 0\right\}\right) = 0.$$

Indeed, repeating the proof of Theorem 4.2 we get for $B = \{f \in F_1 : \lim_n \|Sf - \varphi_n(N_n(f))\|/\operatorname{rad}(N_n, N_n(f)) = 0\}$

$$\mu(B) \leq \overline{\lim_n} \int_{\mathbf{R}^n} \beta_y(\{g \in F_2 : \|g - a\| < q\sqrt{\operatorname{trace}(S_{\beta_y})}\})\mu_1(dy),$$

where $a = a(y) = \varphi_n(y) - \varphi_n^s(y)$. It is known (see for instance [9]) that a Gaussian measure of the ball $B_r(a)$ of radius r and center a is maximal for $a = 0$. Thus

$$\begin{aligned}\beta_y(\{g \in F_2 : \|g - a\| < q\sqrt{\operatorname{trace}(S_{\beta_y})}\}) &\leq \beta_y(\{g \in F_2 : \|g\| < q\sqrt{\operatorname{trace}(S_{\beta_y})}\}) \\ &\leq \tfrac{4}{3}\psi(2q),\end{aligned}$$

due to Theorem 4.1. Therefore $\mu(B) \leq \frac{4}{3}\psi(2q)$, and since q can be arbitrarily small, $\mu(B) = 0$, as claimed.

Remark 4.2. Theorem 4.2 remains true for more general measures μ. Namely, assume as in Remark 3.1 that μ is elliptically contoured. Then for

$$A = \left\{f \in F_1 : \lim_n \frac{\|Sf - \varphi_n^s(N_n(f))\|}{\sqrt{\operatorname{trace}(SS_{N_n(f)}S^*)}} = 0\right\},$$

we have

$$\mu(A) = 0.$$

To prove this let A_n be defined as in the proof of Theorem 4.2. Then

$$\mu(A) \leq \mu(A_n) = \int_0^\infty \mu_G\left(\frac{1}{\sqrt{t}} A_n\right)\alpha(dt).$$

For every fixed t, $\mu_G(1/\sqrt{t}\,\cdot)$ is a Gaussian measure with mean element zero and covariance operator tS_μ. Repeating the proof of Theorem 4.2, we therefore obtain that

$$\mu(A_n) \leqq \frac{4}{3}\int_0^\infty \int_{\mathbf{R}^n} \psi(2q/\sqrt{t})\mu_1(dy)\alpha(dt) = \frac{4}{3}\int_0^\infty \psi(2g/\sqrt{t})\alpha(dt).$$

From the definition of ψ we have

$$\begin{aligned}\int_0^\infty \psi(2q/\sqrt{t})\alpha(dt) &= \sqrt{\frac{2}{\pi}}\int_0^\infty \int_0^{2q/\sqrt{t}} e^{-\tau^2/2}d\tau\,\alpha(dt)\\ &= \sqrt{\frac{2}{\pi}}\int_0^q \int_0^{2q/\sqrt{t}} e^{-\tau^2/2}\,d\tau\alpha(dt) + \sqrt{\frac{2}{\pi}}\int_q^\infty \int_0^{2q/\sqrt{t}} e^{-\tau^2/2}\,d\tau\,\alpha(dt)\\ &\leqq \int_0^q \left\{\sqrt{\frac{2}{\pi}}\int_0^\infty e^{-\tau^2/2}\,d\tau\right\}\alpha(dt) + \sqrt{\frac{2}{\pi}}\int_q^\infty \int_0^{2\sqrt{q}} e^{-\tau^2/2}\,d\tau\,\alpha(dt)\\ &= \alpha((0,q]) + \sqrt{\frac{2}{\pi}}\int_0^{2\sqrt{q}} e^{-\tau^2/2}d\tau \overset{df}{=} a(q).\end{aligned}$$

Since $0 = \alpha(\varnothing) = \lim_{q\to 0^+}\alpha((0,q])$, we see that $\alpha((0,q])$ and $\sqrt{2/\pi}\int_0^{2\sqrt{q}} e^{-\tau^2/2}d\tau$ tend to zero with q. Hence $\lim_{q\to 0} a(q) = 0$. Since $\mu(A) \leqq \mu(A_n) \leqq a(q)$ and q can be arbitrarily small, $\mu(A) = 0$, as claimed.

Theorem 4.2 states that modulo a set of measure zero the μ-spline algorithm does not converge *faster* than the sequence of local radii. We now show that the μ-spline algorithm does not converge more *slowly* than the sequence of local radii.

THEOREM 4.3.

$$\mu\left(\left\{f \in F_1 : \lim_n \frac{\operatorname{rad}(N_n, N_n(f))}{\|Sf - \varphi_n^s(N_n(f))\|} = 0\right\}\right) = 0. \tag{4.16}$$

Proof. Let $A = \{f \in F_1 : \lim_n \operatorname{rad}(N_n, N_n(f))/\|Sf - \varphi_n^s(N_n f)\| = 0\}$. Take a number $q \in (0,1)$ and define

$$A_n = \left\{f \in F_1 : \|Sf - \varphi_n^s(N_n(f))\| \geqq \frac{1}{q}\operatorname{rad}(N_n, N_n(f))\right\}.$$

Then $A \subset \bigcup_{i=1}^\infty \bigcap_{n=i}^\infty A_n$ and $\mu(A) \leqq \overline{\lim}_n \mu(A_n)$. As in the proof of Theorem 4.2, we conclude that

$$\mu(A_n) = 1 - \int_{\mathbf{R}^n} \beta_y\left(\left\{g \in F_2 : \|g\| < \frac{1}{q}\sqrt{\operatorname{trace}(S_{\beta_y})}\right\}\right)\mu_1(dy). \tag{4.17}$$

For any probability measure ν with covariance operator S_ν and for any ball $B_r = \{g \in F_2 : \|g\| < r\}$, we have

$$\begin{aligned}\operatorname{trace}(S_\nu) &= \int_{F_2} \|g\|^2 \nu(dg) \geqq \int_{F_2 - B_r} \|g\|^2 \nu(dg) \geqq r^2 \nu(F_2 - B_r)\\ &= r^2(1 - \nu(B_r)).\end{aligned}$$

Thus

$$\nu(B_r) \geqq 1 - \frac{\operatorname{trace}(S_\nu)}{r^2}.$$

In particular,

$$\beta_y\left(\left\{g \in F_2 : \|g\| < \frac{1}{q}\sqrt{\operatorname{trace}(S_{\beta_y})}\right\}\right) \geqq 1 - q^2.$$

From (4.17) we get $\mu(A_n) \leqq q^2$, and consequently $\mu(A) \leqq q^2$. Since q can be arbitrarily small, $\mu(A) = 0$, as claimed. □

Remark 4.3. The proof of Theorem 4.3 supplies a slightly stronger result than (4.12). Namely for $q \in (0, 1)$ let

$$B = \left\{ f \in F_1 : \overline{\lim_n} \frac{\operatorname{rad}(N_n, N_n(f))}{\|Sf - \varphi_n^s(N_n(f))\|} \leqq q \right\}.$$

Then repeating the proof of Theorem 4.3, we get

$$\mu(B) \leqq q^2. \tag{4.18}$$

Thus for small q, $\mu(B)$ is close to zero. We do not know whether the estimate (4.18) is sharp.

5. Optimal information. In this section we deal with problem (iii) of § 2. We find optimal information $\bar{N}^* = \{N_n^*\}$ of the form (2.2) for which the rate of convergence of the μ-spline algorithm $\bar{\varphi}^s = \{\varphi_n^s\}$ using $\bar{N}^*$ is best possible. Due to the result of § 4 this is equivalent to finding information $\bar{N}^*$ for which the sequence of local radii $\operatorname{rad}(N_n^*, N_n^*(f))$ goes to zero as fast as possible.

As in § 4, let

$$K = S_\mu^{1/2} S^* S S_\mu^{1/2} : F_1 \to F_1. \tag{5.1}$$

We know that $K = K^* \geqq 0$ and K has finite trace. Let m denote the total number of positive eigenvalues of K. Observe that m can be infinite. Let $\{\eta_i^*\}$, $i < m+1$, be the orthonormal eigenelements of K,

$$K\eta_i^* = \lambda_i^* \eta_i^*, \qquad \lambda_1^* \geqq \lambda_2^* \geqq \cdots > 0. \tag{5.2}$$

For $i < m+1$ define $g_i^* = S_\mu^{-1/2} \eta_i^*$. Then $(S_\mu g_i^*, g_j^*) = (\eta_i^*, \eta_j^*) = \delta_{i,j}$. For $n < m+1$ define

$$N_n^*(f) = [(f, g_1^*), (f, g_2^*), \cdots, (f, g_n^*)]. \tag{5.3}$$

Note that N_n^* is nonadaptive. Its local radius $\operatorname{rad}(N_n^*, y)$ given by (4.7) and (4.4) is independent of y and equal to

$$\operatorname{rad}(N_n^*) = \operatorname{rad}(N_n^*, y) = \sqrt{\sum_{i=n+1}^{m} \lambda_i^*}. \tag{5.4}$$

If m is finite then $\operatorname{rad}(N_m^*) = 0$ and $Sf = \varphi_m^s(N_m^*(f))$, for all $f \in F_1$. This means that we approximate Sf exactly for any f using m inner products. Therefore without loss of generality we assume from now on that $m = +\infty$. Define the information

$$\bar{N}^* = \{N_n^*\} \tag{5.5}$$

where N_n^* is given by (5.3). We stress that $\bar{N}^*$ is *nonadaptive* and the μ-spline algorithm $\bar{\varphi}^s = \{\varphi_n^s\}$ that uses $\bar{N}^*$ has the form

$$\varphi_n^s(N_n^*(f)) = \sum_{i=1}^{n} (f, \eta_i^*) S\eta_i^*.$$

Hence $\bar{\varphi}^s$ is *linear.*

Theorem 4.3 states that the μ-spline algorithm $\bar{\varphi}^s$ converges at least as fast as the sequence of the radii $\{\operatorname{rad}(N_n^*)\}$, i.e.,

$$\mu\left(\left\{ f \in F_1 : \lim_n \frac{\operatorname{rad}(N_n^*)}{\|Sf - \varphi_n^s(N_n^*(f))\|} = 0 \right\} \right) = 0.$$

We are ready to prove the optimality of $\bar{N}^*$.

THEOREM 5.1. *The nonadaptive information operator $\bar{N}^*$ is optimal in the class of adaptive information operators of the form* (2.2), *i.e., for any adaptive information operator $\bar{N}=\{N_n\}$ and any algorithm $\bar{\varphi}=\{\varphi_n\}$ using $\bar{N}$ we have*

$$\mu\left(\left\{f\in F_1\colon \lim_n \frac{\|Sf-\varphi_n(N_n(f))\|}{\operatorname{rad}(N_n^*)}=0\right\}\right)=0. \tag{5.6}$$

Proof. Let $A=\{f\in F_1\colon \lim_n \|Sf-\varphi_n(N_n(f))\|/\operatorname{rad}(N_n^*)=0\}$ and $B=\{f\in F_1\colon \lim_n \|Sf-\varphi_n(N_n(f))\|/\operatorname{rad}(N_n, N_n(f))=0\}$. It is known (see [10], [11]) that

$$\operatorname{rad}(N_n^*)\leqq \operatorname{rad}(N_n, N_n(f)) \quad \forall f\in F_1.$$

Therefore $A\subset B$ and $\mu(A)\leqq\mu(B)$. Due to Remark 4.1, $\mu(B)=0$. Thus $\mu(A)=0$ as claimed. □

Theorem 5.1 states that adaption does not help for approximation of linear operators in the asymptotic setting of this paper. This agrees with the similar result in a worst case, an average case (see [7], [2], [11]), respectively, and with the results of [8].

The best possible rate of convergence is obtained by the μ-spline algorithm using the information $\bar{N}^*$. This rate of convergence is given by $\operatorname{rad}(N_n^*)=\sqrt{\sum_{i=n+1}^{\infty}\lambda_i^*}$. Thus it depends on how fast the truncated series of the trace of K goes to zero. For instance, if $\lambda_i^*=i^{-r}$ for some $r>1$, then

$$\operatorname{rad}(N_n^*)\cong\frac{1}{r-1}\,\frac{1}{(n+1)^{(r-1)/2}}.$$

If $\lambda_i^*=q^i$ for $q\in(0,1)$, then

$$\operatorname{rad}(N_n^*)=\sqrt{\frac{q^{n+1}}{1-q}}.$$

Appendix. Here we prove the result mentioned in the Introduction. In fact, we will show a slightly stronger result. Namely, we relax the assumptions on the spaces F_1 and F_2 and the solution operator S. In this Appendix we assume that F_1 is an infinite-dimensional Banach space, F_2 is a normed linear space and that S is a one-to-one operator (not necessarily linear).

Let $\bar{\varphi}=\{\varphi_n\}$ be an algorithm using information $\bar{N}=\{N_n\}$. Here we assume that

$$N_n(f)=[L_1(f), L_2(f; y_1), \cdots, L_n(f; y_1, \cdots, y_{n-1})]$$

where $y_1=L_1(f)$, $y_i=L_i(f; y_1, y_2, \cdots, y_{i-1})$ and $L_i(\cdot; y_1, \cdots, y_{i-1})$ is a continuous linear functional. We also assume that $L_1\not\equiv 0$. Define

$$A(\bar{\varphi})=\{f\in F_1\colon \varphi_n(N_n(f))=Sf, \forall n\geqq k(f)\}$$

as the set of elements for which the algorithm $\bar{\varphi}$ solves the problem exactly for sufficiently large n.

LEMMA A.1. *The set $A(\bar{\varphi})$ has empty interior for every algorithm $\bar{\varphi}$.*

Proof. Assume on the contrary that $A(\bar{\varphi})$ contains a ball $B(f_1, r)=\{f\in F_1\colon \|f-f_1\|\leqq r\}$ for $r>0$. We construct a sequence $\{f_j\}$ from the ball $B(f_1, r)$. Suppose inductively that f_j is defined. Since $f_j\in B(f_1, r)\supset A(\bar{\varphi})$, then there exists $k_j=k(f_j)$ such that $\varphi_n(N_n(f_j))=Sf_j$ for $n\geqq k_j$. Take $h_j\in F_1$ such that $L_1(h_j)=L_2(h_j, y_1)=\cdots=L_{k_j}(h_j; y_1, \cdots, y_{k_j-1})=0$ and $\|h_j\|=r/3^j$. Here $y_i=L_i(f_j; y_1, \cdots, y_{i-1})$. Observe that such an element h_j exists since $\dim F_1=+\infty$. Define $f_{j+1}=f_j+h_j$. Then $f_{j+1}=f_1+\sum_{i=1}^{j}h_i$ and $\|f_{j+1}-f_1\|\leqq r\sum_{i=1}^{j}3^{-i}<r/2$. Thus $f_{j+1}\in B(f_1, r)$ and $N_{k_j}(f_{j+1})=N_{k_j}(f_j)$. Hence $\varphi_{k_j}(N_{k_j}(f_{j+1}))=\varphi_{k_j}(N_{k_j}(f_j))=Sf_j\neq Sf_{j+1}$ since $f_{j+1}\neq f_j$ and S is one to one. Thus $k_{j+1}=k(f_{j+1})\geqq k_j+1$.

Define $f = \lim_j f_j = f_1 + \sum_{j=1}^{\infty} h_j$. The element f exists since $\{f_j\}$ is a Cauchy sequence and F_1 is a Banach space. Note that $f \in B(f_1, r)$ and

$$\|f - f_j\| = \left\| \sum_{i=j}^{\infty} h_i \right\| \geq \|h_j\| - \sum_{i=j+1}^{\infty} \|h_i\| = \frac{1}{2} r/3^j > 0.$$

Thus $f \neq f_j$, for all j. The continuity of functionals that form $\bar{N}$ yields

$$N_{k_j}(f) = N_{k_j}\left(f_1 + \sum_{i=1}^{j-1} h_i\right) = N_{k_j}(f_j) \quad \forall j.$$

Thus we have

$$\varphi_{k_j}(N_{k_j}(f)) = \varphi_{k_j}(N_{k_j}(f_j)) = Sf_j \neq Sf.$$

Since k_j goes to infinity with j, this proves that $f \notin A(\bar{\varphi})$. This is a contradiction which completes the proof. □

Remark A.1. In fact, the proof of Lemma A.1 supplies a slightly stronger result. Namely, the proof yields that for every $f \in A(\bar{\varphi})$ and for every $r > 0$, there exists an element h such that $\|h\| \leq r$, $f + h \notin A(\bar{\varphi})$ and additionally $L_1(h) = 0$.

Based on Lemma A.1 and Remark A.1 we prove the result mentioned in the Introduction. Let $\bar{\varphi} = \{\varphi_n\}$ and $\bar{\varphi}^* = \{\varphi_n^*\}$ be two algorithms using information $\bar{N} = \{N_n\}$. Let $a_n(f) = \|Sf - \varphi_n(N_n(f))\|$ and $b_n(f) = \|Sf - \varphi_n^*(N_n(f))\|$. Then

$$A(\bar{\varphi}, \bar{\varphi}^*) = \{f \in F_1 : \lim_n a_n(f)/b_n(f) = 0\}.$$

We need to consider the case $a_n(f) = 0$, for all $n \geq n_0$, for some n_0. Then, if $b_n(f) = 0$, for all $n \geq n_1$, for some n_1, the two algorithms $\bar{\varphi}$ and $\bar{\varphi}^*$ solve the problem exactly and none of them are superior. It is therefore reasonable to set in this case $\lim_n a_n(f)/b_n(f) = 1$. On the other hand, if $\{b_n(f)\}$ contains a nonzero subsequence, then the algorithm $\bar{\varphi}$ is superior to the algorithm $\bar{\varphi}^*$ and it is reasonable to set in this case $\lim_n a_n(f)/b_n(f) = 0$. Having this convention in mind we are ready to prove the following theorem.

THEOREM A.1. *For every algorithm $\bar{\varphi}^*$ there exists an algorithm $\bar{\varphi}$ such that the set $A(\bar{\varphi}, \bar{\varphi}^*)$ is uncountable.*

Proof. Choose an element $f_1 \in F_1$ such that $L_1(f_1) = 1$. For $y \in \mathbf{R}$, define

$$g_y = \begin{cases} yf_1 & \text{if } yf_1 \notin A(\bar{\varphi}^*), \\ yf_1 + h & \text{if } yf_1 \in A(\bar{\varphi}^*). \end{cases}$$

Here h is chosen such that $L_1(h) = 0$ and $yf_1 + h \notin A(\bar{\varphi}^*)$. Such an element h exists due to Remark A.1.

We now define the algorithm $\bar{\varphi} = \{\varphi_n\}$ as

$$\varphi_n(N_n(f)) = Sg_{N_1(f)}.$$

Note that $\varphi_n(N_n(g_y)) = Sg_y$, for all $n \geq 1$ and $y \in \mathbf{R}$. Since $g_y \notin A(\bar{\varphi}^*)$, there exists a subsequence $\{n_i\}$ such that

$$\varphi_{n_i}^*(N_{n_i}(g_y)) \neq Sg_y.$$

This means that $g_y \in A(\bar{\varphi}, \bar{\varphi}^*)$, for all $g \in \mathbf{R}$. Note that g_y varies with y which means that $A(\bar{\varphi}, \bar{\varphi}^*)$ contains at least as many elements as $\mathbf{R}$. This completes the proof. □

Acknowledgments. We are pleased to thank S. Kwapień for providing the proof of Theorem 4.1 and useful remarks concerning measure theory.

We also thank J. F. Traub, K. Sikorski, and A. G. Werschulz for stimulating discussions and help during the preparation of this paper.

ENTRAINMENT OF A LIMIT-CYCLE OSCILLATOR WITH SHEAR BY LARGE AMPLITUDE FORCING*

MICHAEL ST. VINCENT†

Abstract. The entrainment of a circularly symmetric limit-cycle oscillator due to large amplitude periodic forcing is investigated. The unforced oscillator contains parameters controlling the local strength of attraction of the limit cycle and the amount of radial variation of angular velocity, or shear, near the limit cycle. It is shown that entrainment (1:1 phase locking) will occur for sufficiently large amplitude forcing whenever the local strength of attraction to the limit cycle is great enough. Furthermore, if the amount of shear is allowed to increase with the strength of attraction to the limit cycle, then increasing the ratio of shear to strength of attraction can have the effect of increasing the sensitivity of the oscillator to forcing.

Key words. entrainment, limit cycle, oscillator, phase locking

AMS(MOS) subject classifications. 34C15, 34C25

1. Introduction. This paper is concerned with the periodically forced nonlinear oscillator

$$\begin{pmatrix}\dot{x}\\ \dot{y}\end{pmatrix}=\begin{pmatrix}\lambda & -\omega\\ \omega & \lambda\end{pmatrix}\begin{pmatrix}x\\ y\end{pmatrix}+b_0\begin{pmatrix}u\\ v\end{pmatrix}p(\sigma t) \tag{1.1}$$

defined in a neighborhood of the unit circle, on which it is assumed to have a stable limit cycle. Here "$\cdot$" $= d/dt$, $\lambda=\lambda(r,\varepsilon)$, $\omega=\omega(r,\beta)$, $(r=\sqrt{x^2+y^2})$, $\lambda(1,\varepsilon)=0$, $\omega(1,\beta)=1$, and $p(s)$ is an odd 2π-periodic continuous function satisfying $p(s+\pi)=-p(s)$. All quantities are real, with ε, β, σ and b_0 positive, and $u^2+v^2=1$ (u, v constants).

The unforced oscillator ($b_0=0$) is a circularly symmetric limit-cycle oscillator of "$\lambda-\omega$" form. Oscillators of this form (though not always with a limit cycle on the unit circle) have been used to model a variety of nonlinear phenomena, including those of chemical kinetics and biology, and periodically forced Hopf bifurcations (e.g., [1]-[3]). When written in polar coordinates ($x=r\cos\theta$, $y=r\sin\theta$), it is given by

$$\dot{r}=r\lambda(r,\varepsilon),\qquad \dot{\theta}=\omega(r,\beta).$$

From this we see that λ determines the rate of approach of nearby solutions to the limit cycle, ω determines their angular velocity, and the limit-cycle solutions have constant angular speed 1.

The parameters ε and β are intended to control properties of the oscillator near the limit cycle. More specifically, the dependence on these parameters is meant to be such that the local strength of attraction of the limit cycle becomes infinite as $\varepsilon\to 0$, while the local rate of radial variation in angular velocity, or *shear*, becomes infinite as $\beta\to 0$. To this end, it is assumed that $\lambda_r(1,\varepsilon)\to-\infty$ as $\varepsilon\to 0$ and $|\omega_r(1,\beta)|\to\infty$ as $\beta\to 0$. (Additional assumptions are contained in § 2.)

The main results obtained in this paper concern large amplitude forcing, in contrast with many papers on nonlinear oscillations that consider only small amplitude forcing. In particular, it will be shown that if the forcing amplitude b_0 is sufficiently large, then (1.1) will be entrained, or 1:1 phase locked, whenever the strength of attraction to the

† Department of Mathematics and Computer Science, Clark University, Worcester, Massachusetts 01610.

limit cycle is great enough (i.e., ε is small enough), depending on b_0. In saying that (1.1) is entrained, it is meant that it has a stable periodic solution, of the same period as the forcing, that undergoes one oscillation in each period. It will also be shown that 1:1 phase locking does not occur for small amplitude forcing, except in the resonant case $\sigma = 1$.

A related result for large amplitude forcing of the van der Pol oscillator was obtained by Lloyd [4], and explained heuristically by Levi [5, p. 25]. In that case, both the shear and the strength of attraction to the limit cycle became infinite as a single parameter became small. This will also be considered in (1.1) by allowing β to depend on ε. However, an additional conclusion will be reached here, due to the fact that we can specify the relative magnitudes of the shear and strength of attraction to the limit cycle. In particular, it will be shown that the presence of large shear can reduce the amplitude of forcing required for entrainment. This will be done by showing that if β is made to depend on ε in such a way that $\omega_r(1, \beta)/\lambda_r(1, \varepsilon) \to c$ as $\varepsilon \to 0$, then the size of $b_0\sqrt{1+c^2}$, not just b_0, determines if entrainment will occur for small ε. Consequently, entrainment could be made to occur for any given forcing amplitude by making $|c|$ large enough. In addition, it will be seen how a nonzero value of c affects the location of the periodic solutions in the entrained state.

It is interesting to note that shear, which is shown by this paper to affect entrainment, is also important for the existence of "shock structure" solutions of reaction-diffusion equations [13].

The remainder of this paper is organized as follows: In § 2, (1.1) is simplified by a rotation of coordinates and a change of parameters. It is then shown that there is a family of nested attracting annuli A_ε, each of which is of width $O(\varepsilon)$ and contains the unit circle in its interior. All subsequent analysis of (1.1) concerns the behavior of solutions in A_ε for ε small. In § 3, a further change of variable is made in order to deal with the presence of large shear, and estimates are given for approximating the solutions in A_ε. In particular, it will be shown that the angular component of solutions in A_ε can be approximated by solutions of an equation of the form $\dot{\psi} = 1 - bp(\sigma t)\sin\psi$, which is analyzed in § 4. This phase approximation will be seen to be valid for large amplitude forcing, in addition to the more usual small amplitude case. The results of the previous sections are then used in § 5 to derive the results concerning entrainment. It is shown there that the period map will have exactly two fixed points in A_ε, one a sink and the other a saddle, when entrainment occurs. The paper then concludes with a brief discussion of the effects of large shear.

2. Existence of attracting annuli A_ε. We begin by stating some additional assumptions and simplifying (1.1). Let $I \subset (0, \infty)$ be an open interval containing 1, and let ε_M, β_M and k be positive constants. Then we assume that $\lambda(r, \varepsilon)$ is defined and continuous on $I \times (0, \varepsilon_M)$, $\omega(r, \beta)$ is defined and continuous on $I \times (0, \beta_M)$ and that they are twice continuously differentiable with respect to r. Furthermore, we assume that λ, ω and p satisfy the following:

($\lambda 1$) $\lambda_r(1, \varepsilon)$ is strictly monotonic, and $\lambda_r(1, \varepsilon) \to -\infty$ as $\varepsilon \to 0$;

($\lambda 2$) $|\lambda_{rr}| \leqq k|\lambda_r(1, \varepsilon)|$;

($\omega 1$) $\omega_r(1, \beta)$ is strictly monotonic, and $|\omega_r(1, \beta)| \to \infty$ as $\beta \to 0$;

($\omega 2$) $|\omega_{rr}| \leqq k|\omega_r(1, \beta)|$;

($p1$) $p(s) > 0$ for $s \in (0, \pi)$;

($p2$) $\max |p(s)| = 1$.

An example of functions satisfying these assumptions is provided by $\lambda = (1-r)/\varepsilon$, $\omega = 1+(r-1)/\beta$ and $p = \sin(s)$.

As is clear from the above, (1.1) is defined for all (x, y, t) for which (x, y) is in the annulus $A = \{(x, y) \mid x^2+y^2 = r^2, r \in I\}$. In addition, some simplifications can be made: since λ and ω are unchanged by a rotation of coordinates, rotation through an angle ϕ for which $\cos\phi = u$ and $\sin\phi = v$ allows us to assume that $u = 1$ and $v = 0$. Furthermore, if we let $\bar{\varepsilon} = -1/\lambda_r(1, \varepsilon)$ and $\bar{\beta} = 1/\omega_r(1, \beta)$, then assumptions $(\lambda 1)$ and $(\omega 1)$ allow us to invert these to get continuous functions $\varepsilon(\bar{\varepsilon})$ and $\beta(\bar{\beta})$. As a result, reparametrizing λ and ω by $\bar{\varepsilon}$ and $\bar{\beta}$ shows that we may also assume that $\lambda_r(1, \varepsilon) = -1/\varepsilon$ and $\omega_r(1, \beta) = 1/\beta$. Now, however, it is only assumed that β is of constant sign, with $|\beta| < \beta_M$, since no assumption was made concerning the sign of $\omega_r(1, \beta)$. Thus, from now on we only consider (1.1) in the case

$$\dot{x} = \lambda x - \omega y + b_0 p(\sigma t), \qquad \dot{y} = \omega x + \lambda y, \tag{2.1}$$

with conditions $(\lambda 1-2)$ and $(\omega 1-2)$ replaced by

$$\lambda_r(1, \varepsilon) = -1/\varepsilon, \tag{$\lambda 1'$}$$

$$|\lambda_{rr}| \leqq k/\varepsilon, \tag{$\lambda 2'$}$$

$$\omega_r(1, \beta) = 1/\beta, \tag{$\omega 1'$}$$

$$|\omega_{rr}| \leqq k/|\beta|. \tag{$\omega 2'$}$$

These conditions will now be used to conclude that there is a family of attracting annuli $A_\varepsilon \subset A$ of width $O(\varepsilon)$, each of which contains the unit circle. To begin, use $(\lambda 1')$ and $(\omega 1')$ to write

$$\lambda(r, \varepsilon) = -\frac{1}{\varepsilon}(r-1) + \lambda_1(r, \varepsilon), \qquad \omega(r, \beta) = 1 + \frac{1}{\beta}(r-1) + \omega_1(r, \beta)$$

where

$$\lambda_1 = \int_1^r (r-s)\lambda_{rr}(s, \varepsilon)\, ds \quad \text{and} \quad \omega_1 = \int_1^r (r-s)\omega_{rr}(s, \beta)\, ds.$$

Together with conditions $(\lambda 2')$ and $(\omega 2')$, this immediately yields the following lemma.

LEMMA 2.1. *The following hold on the domains of λ and ω:*

(i) $|\lambda_1(r, \varepsilon)| \leqq k|r-1|^2/\varepsilon$;

(ii) $|\lambda_{1r}(r, \varepsilon)| \leqq k|r-1|/\varepsilon$;

(iii) $|\omega_1(r, \beta)| \leqq k|r-1|^2/|\beta|$;

(iv) $|\omega_{1r}(r, \beta)| \leqq k|r-1|/|\beta|$. □

Now let $I_\varepsilon = [1-2\varepsilon b_0, 1+2\varepsilon b_0]$ and define the annulus A_ε by

$$A_\varepsilon = \{(x, y) \mid x^2+y^2 = r^2, r \in I_\varepsilon\}.$$

For any given b_0, we clearly have $I_\varepsilon \subset I$, and so also $A_\varepsilon \subset A$, whenever ε is small enough. To see that A_ε is attracting for small ε, write (2.1) in polar coordinates $(x = r\cos\eta, y = r\sin\eta)$ to get

$$\dot{r} = r\lambda + b_0 p(\sigma t)\cos\eta, \qquad \dot{\eta} = \omega - (b_0/r)p(\sigma t)\sin\eta. \tag{2.2}$$

Since $|p(\sigma t)| \leqq 1$ from assumption ($p2$), this shows that the vector field will be pointing in on the boundary of A_ε if $r\lambda < -b_0$ for $r = 1+2\varepsilon b_0$ and $r\lambda > b_0$ for $r = 1-2\varepsilon b_0$. We can now prove the following.

THEOREM 2.2. *The annulus $A_\varepsilon \subset A$ will be attracting if $\varepsilon < (1+k-\sqrt{k^2+1})/(4b_0k)$.*

Proof. Let ε be as above, and recall that $\lambda = (-1/\varepsilon)(r-1)+\lambda_1$. From (i) of Lemma 2.1, it follows that $|\lambda_1|/b_0 \leqq 4kb_0\varepsilon < 1+k-\sqrt{k^2+1} < 1$ for $r = 1 \pm 2\varepsilon b_0$. Consequently, on

(1) $r = 1+2\varepsilon b_0$, we have $r\lambda = -b_0(2-\lambda_1/b_0)(1+2\varepsilon b_0)$, so $r\lambda < -b_0$ since $|\lambda_1|/b_0 < 1$ and $2\varepsilon b_0 > 0$. This shows that the vector field points in on the outer boundary of A_ε.

(2) $r = 1-2\varepsilon b_0$, we have $r\lambda = b_0(2+\lambda_1/b_0)(1-2\varepsilon b_0)$. But $2+\lambda_1/b_0 \geqq 2-|\lambda_1|/b_0$, so the bounds for $|\lambda_1|/b_0$ and ε show that $2+\lambda_1/b_0 > 1-k+\sqrt{k^2+1}$ and $1-2\varepsilon b_0 > (k-1+\sqrt{k^2+1})/(2k)$. Thus, $r\lambda > b_0[\sqrt{k^2+1}-(k-1)]\cdot[\sqrt{k^2+1}+(k-1)]/(2k) = b_0$, so the vector field also points in on the inner boundary of A_ε. □

From now on, we only consider values of ε that are small enough to ensure that A_ε is contained in A and is attracting.

3. The estimates in A_ε. In this section, basic estimates are proved for the solutions of (2.2) in A_ε. In particular, it will be shown that the angular component can be approximated by the solution of an equation of the form $\dot{\psi} = 1 - bp(\sigma t)\sin\psi$, which will be analyzed in the next section. As will be seen in § 5, shear has a significant effect on entrainment when it is of the same order of magnitude as the strength of attraction of the limit cycle. In order to allow for this, it will from now on be assumed that β depends on ε in such a way that $\varepsilon/\beta \to c$ as $\varepsilon \to 0$, where c can be any real number.

We begin by rewriting (2.2) as

$$\begin{aligned} \dot{r} &= -\frac{1}{\varepsilon}(r-1)r + r\lambda_1 + b_0 p(\sigma t)\cos\eta, \\ \dot{\eta} &= 1 + \frac{1}{\beta}(r-1) + \omega_1 - (b_0/r)p(\sigma t)\sin\eta. \end{aligned} \tag{3.1}$$

The terms $r\lambda_1$ and ω_1 are $O(\varepsilon)$ in A_ε. Indeed, since $|r-1| \leqq 2b_0\varepsilon$ in A_ε, an immediate consequence of Lemma 2.1 is the following.

LEMMA 3.1. *The following hold in A_ε:*

(i) $|\lambda_1(r,\varepsilon)| \leqq 4b_0^2 k\varepsilon$;

(ii) $|\lambda_{1r}(r,\varepsilon)| \leqq 2b_0 k$;

(iii) $|\omega_1(r,\beta)| \leqq 4b_0^2 k|\gamma|\varepsilon$;

(iv) $|\omega_{1r}(r,\beta)| \leqq 2b_0 k|\gamma|$,

where $\gamma(\varepsilon) = \varepsilon/\beta \to c$ as $\varepsilon \to 0$. □

When $c = 0$, the term $(r-1)/\beta \to 0$ as $\varepsilon \to 0$. In that case, the equation for η can be approximated by $\dot{\eta} = 1 - b_0 p(\sigma t)\sin\eta$. However, when $c \neq 0$, $(r-1)/\beta$ is only bounded, so such an approximation would not be justified. In order to handle this case as well, let $\gamma(\varepsilon)$ be as in Lemma 3.1, let $b(\varepsilon) = b_0\sqrt{1+\gamma^2}$, $d(\varepsilon) = \tan^{-1}\gamma$ and make the change of variable $\theta = \eta + \gamma \ln r - d$ to get

$$\dot{r} = -\frac{1}{\varepsilon}(r-1)r + r\lambda_1 + b_0 p(\sigma t)\cos(\theta - \gamma\ln r + d), \tag{3.2a}$$

$$\dot{\theta} = 1 + \omega_1 + \gamma\lambda_1 - \left(\frac{b}{r}\right)p(\sigma t)\sin(\theta - \gamma\ln r), \tag{3.2b}$$

eliminating the $(r-1)/\beta$ term.

Now let $\psi(t; \psi_0)$ denote the general solution of

$$\dot{\psi} = 1 - b_1 p(\sigma t) \sin \psi, \qquad \psi(0; \psi_0) = \psi_0, \tag{3.3}$$

where $b_1 = \lim_{\varepsilon \to 0} b(\varepsilon) = b_0\sqrt{1+c^2}$, and let $r(t; r_0, \theta_0)$ and $\theta(t; r_0, \theta_0)$ denote the general solution of (3.2), with $r(0; r_0, \theta_0) = r_0$ and $\theta(0; r_0, \theta_0) = \theta_0$.

Standard theorems ensure that these solutions exist for all $t \geqq 0$ when $r_0 \in I_\varepsilon$, and have continuous first partial derivatives with respect to their arguments [6]. Let Ψ, R_i, Θ_i $(i = 1, 2)$ be given by

$$\Psi = \frac{\partial}{\partial \psi_0} \psi(t; \psi_0),$$

$$R_1 = \frac{\partial}{\partial r_0} r(t; r_0, \theta_0), \qquad R_2 = \frac{\partial}{\partial \theta_0} r(t; r_0, \theta_0),$$

$$\Theta_1 = \frac{\partial}{\partial r_0} \theta(t; r_0, \theta_0), \qquad \Theta_2 = \frac{\partial}{\partial \theta_0} \theta(t; r_0, \theta_0).$$

Observe that the periodicity of (3.2) in θ and (3.3) in ψ implies that r, Θ_i, and R_i are 2π-periodic in θ_0, and Ψ is 2π-periodic in ψ_0, with $\theta(t; r_0, \theta_0 + 2\pi) = \theta(t; r_0, \theta_0) + 2\pi$ and $\psi(t; \psi_0 + 2\pi) = \psi(t; \psi_0) + 2\pi$.

In the following lemma and theorem, which are the main results of this section, T is a positive number and $S_{T,\varepsilon}$ denotes the set $[0, T] \times I_\varepsilon \times \mathbb{R}$.

LEMMA 3.2. *There are positive constants $\varepsilon_1(b_0, T)$, $k_1(b_0, T)$, and $k_2(b_0, T)$ such that*

(i) $|R_1(t; r_0, \theta_0)| < e^{-t/2\varepsilon} + \varepsilon$,

(ii) $|\Theta_1(t; r_0, \theta_0)| < \varepsilon k_1$,

(iii) $|R_2(t; r_0, \theta_0)| < 2\varepsilon b_0 k_2$, *and*

(iv) $|\Theta_2(t; r_0, \theta_0)| < k_2$

for all $(t, r_0, \theta_0) \in S_{T,\varepsilon}$ whenever $\varepsilon < \varepsilon_1$.

THEOREM 3.3. *For every $\delta > 0$ there is an $\varepsilon_2(b_0, T) > 0$ such that*

(i) $|\theta(t; r_0, \theta_0) - \psi(t; \theta_0)| < \delta$, *and*

(ii) $|\Theta_2(t; r_0, \theta_0) - \Psi(t; \theta_0)| < \delta$

for all $(t, r_0, \theta_0) \in S_{T,\varepsilon}$ whenever $\varepsilon < \varepsilon_2$.

In addition to the explicit dependence on b_0 and T, these estimates also depend on c, k and the functions λ, ω and $\beta(\varepsilon)$ generally. On the other hand, it will be seen that they are independent of σ since $|p(\sigma t)| \leqq 1$.

Since the variational equations for (3.2) and (3.3) will be used in the proof of Lemma 3.2 and Theorem 3.3, we begin by observing that the functions R_i, Θ_i and Ψ satisfy

$$\dot{\Psi} = -(b_1 p(\sigma t) \cos \psi)\Psi, \tag{3.4}$$

$$\dot{R}_i = B_1 R_i + B_2 \Theta_i, \tag{3.5a}$$

$$\dot{\Theta}_i = B_3 R_i + B_4 \Theta_i, \tag{3.5b}$$

with $R_1(0)=\Theta_2(0)=\Psi(0)=1$ and $R_2(0)=\Theta_1(0)=0$, where the coefficients of (3.5) are given by

$$B_1=-\frac{1}{\varepsilon}(2r-1)+\lambda_1+r\lambda_{1r}+\left(\frac{\gamma b_0}{r}\right)p(\sigma t)\sin(\theta-\gamma\ln r+d),$$

$$B_2=-b_0p(\sigma t)\sin(\theta-\gamma\ln r+d),$$

$$B_3=\omega_{1r}+\gamma\lambda_{1r}+\left(\frac{b}{r^2}\right)p(\sigma t)[\sin(\theta-\gamma\ln r)+\gamma\cos(\theta-\gamma\ln r)],$$

$$B_4=-\left(\frac{b}{r}\right)p(\sigma t)\cos(\theta-\gamma\ln r).$$

Estimates for these coefficients follow easily from Lemma 3.1, together with the fact that $r\to 1$, $\gamma\to c$ and $b\to b_1$ as $\varepsilon\to 0$, yielding the following lemma.

LEMMA 3.4. *There is an* $M(b_0, c, k)>0$ *such that*

(i) $B_1\leqq -\dfrac{1}{2\varepsilon}$,

(ii) $|B_2|\leqq b_0$,

(iii) $|B_3|\leqq M$,

(iv) $|B_4|\leqq 2b_1$,

for $r\in I_\varepsilon$ *whenever* ε *is small enough.* □

In addition to Lemma 3.4, the following two lemmas will be needed. Lemma 3.5 plays the same role as the Gronwall lemma, but seems more convenient here. The proofs are omitted, since Lemma 3.5 is a special case of a lemma of Kelley [7] and the proof of Lemma 3.6 is elementary.

LEMMA 3.5. *Let* T, a, b *be positive constants, and let* v *be defined and continuous on* $[0, T]$, *smooth on* $(0, T)$, *with* $v(0)=0$ *and* $|\dot v|<a|v|+b$ *for* $t\in(0, T)$. *Then* $|v|<(b/a)(e^{at}-1)$ *for* $t\in(0, T]$. □

LEMMA 3.6. *Let* $T>0$ *be given, and let* f, g, h, i, u, v *be real valued and continuous on* $[0, T]$, u, v *smooth on* $(0, T)$, *with* $\dot v=f(t)+g(t)v$, $\dot u=h(t)+i(t)u$ *and* $u(0)\geqq|v(0)|$. *If* $h(t)>|f(t)|$ *and* $i(t)\geqq g(t)$ *for* $t\in(0, T)$, *then* $|v(t)|<u(t)$ *for* $t\in(0, T]$. □

We can now prove Lemma 3.2 and Theorem 3.3. In doing so, the fact that $r(t; r_0, \theta_0)$ is in I_ε for all $t\geqq 0$ if $r_0\in I_\varepsilon$ will be used without explicit mention.

Proof of Lemma 3.2. Let M be as in Lemma 3.4, and let

$$k_1=M\left(2+\frac{1}{2b_0}\right)e^{2b_1T},\qquad k_2=2e^{2b_1T}.$$

(i) and (ii). Consider only $\varepsilon<1/(2b_0k_1)$, and assume one of these is false. Then since they hold for $t=0$, there is a $\tau\in(0, T]$ such that they hold on $[0, \tau)$ but at least one of them fails at $t=\tau$. Then from (3.5a) and Lemma 3.4 we see that

$$\dot R_1=f_1(t)+g_1(t)R_1,\qquad R_1(0)=1,$$

where $|f_1(t)|<\frac{1}{2}$ and $g_1(t)\leqq -1/2\varepsilon$ on $(0, \tau)$. Lemma 3.6 shows that $|R_1|<u_1(t)$ on $(0, \tau]$, where

$$\dot u_1=\frac{1}{2}-\frac{1}{2\varepsilon}u_1,\qquad u_1(0)=1.$$

But $u_1 = (1-\varepsilon)e^{-t/2\varepsilon} + \varepsilon$, so $|R_1| < e^{-t/2\varepsilon} + \varepsilon$ on $[0, \tau]$, showing that (i) cannot have failed. Together with (3.5b) and Lemma 3.4, this shows that

$$\dot{\Theta}_1 = f_2(t) + g_2(t)\Theta_1, \qquad \Theta_1(0) = 0,$$

where $|f_2(t)| < M(e^{-t/2\varepsilon} + \varepsilon)$ and $g_2(t) \leqq 2b_1$ on $(0, \tau)$. Now Lemma 3.6 yields $|\Theta_1| < u_2(t)$ on $(0, \tau]$, where

$$\dot{u}_2 = M(e^{-t/2\varepsilon} + \varepsilon) + 2b_1 u_2, \qquad u_2(0) = 0.$$

But

$$u_2 = \varepsilon M\left[\left(\frac{2}{1+4\varepsilon b_1} + \frac{1}{2b_1}\right) e^{2b_1 t} - \left(\frac{2}{1+4\varepsilon b_1} e^{-t/2\varepsilon} + \frac{1}{2b_1}\right)\right],$$

so we get

$$|\Theta_1| < \varepsilon M\left(\frac{2}{1+4\varepsilon b_1} + \frac{1}{2b_1}\right) e^{2b_1 t} < \varepsilon M\left(2 + \frac{1}{2b_0}\right) e^{2b_1 T} = \varepsilon k_1$$

on $[0, \tau]$, having used $b_1 \geqq b_0 > 0$. But then (ii) cannot have failed at $t = \tau$ either, a contradiction. This establishes (i) and (ii).

(iii) and (iv). Now consider only $\varepsilon < 1/(Mk_2)$, and assume one of these is false. The proof in this case proceeds exactly as above, except now we have $|f_1(t)| < b_0 k_2$,

$$|f_2(t)| < 2\varepsilon b_0 k_2 M, \quad u_1(0) = 0, \quad u_2(0) = 1,$$

yielding

$$u_1 = 2\varepsilon b_0 k_2 (1 - e^{-t/2\varepsilon}), \qquad u_2 = e^{2b_1 t} + \varepsilon k_2 M \frac{b_0}{b_1}(e^{2b_1 t} - 1),$$

so then $|R_2| < 2\varepsilon b_0 k_2$ and

$$|\Theta_2| < (1 + \varepsilon k_2 M)\, e^{2b_1 t} < 2e^{2b_1 T} = k_2 \quad \text{on } [0, \tau]. \qquad \square$$

Proof of Theorem 3.3. (i) From (3.2b) and (3.3), it follows that

$$|\dot{\theta}(t; r_0, \theta_0) - \dot{\psi}(t; \theta_0)| = |b_1 p(\sigma t)(\sin \psi - \sin \theta) + \Delta|,$$

where $\Delta = \omega_1 + \gamma\lambda_1 + p(\sigma t)[b_1 \sin \theta - (b/r) \sin(\theta - \gamma \ln r)]$. Since $|p(\sigma t)| \leqq 1$, this shows that

$$|\dot{\theta} - \dot{\psi}| \leqq b_1 |\theta - \psi| + |\Delta|.$$

Now (i) and (ii) of Lemma 3.1, together with the fact that $\gamma \to c$, $b \to b_1$ and $r \to 1$ as $\varepsilon \to 0$, shows that $|\Delta|$ can be made less than any $\delta_1 > 0$ by taking ε small enough (depending on b_0 and the functions λ, ω and $\beta(\varepsilon)$). Consequently, Lemma 3.5 allows us to conclude that

$$|\theta(t; r_0, \theta_0) - \psi(t; \theta_0)| < \frac{\delta_1}{b_1}(e^{b_1 T} - 1)$$

for $(t, r_0, \theta_0) \in S_{T,\varepsilon}$.

(ii) From (3.4) and (3.5b) we get

$$|\dot{\Theta}_2 - \dot{\Psi}| \leqq |(b_1 \cos \psi)\Psi - (b/r)\Theta_2 \cos(\theta - \gamma \ln r)| + |B_3 R_2|,$$

where $\psi = \psi(t; \theta_0)$ and we have used $|p(\sigma t)| \leqq 1$. Adding and subtracting $\Theta_2 \cos \psi$ in the first term on the right, and using Lemmas 3.2 and 3.4, we find that

$$|\dot{\Theta}_2 - \dot{\Psi}| < b_1 |\Theta_2 - \Psi| + k_2(|b_1 \cos \psi - (b/r) \cos(\theta - \gamma \ln r)| + 2\varepsilon b_0 M)$$

on $S_{T,\varepsilon}$. Then (i) above, together with the fact that $r \to 1$, $b \to b_1$, and $\gamma \to c$ as $\varepsilon \to 0$, shows that

$$|\dot{\Theta}_2 - \dot{\Psi}| < b_1 |\Theta_2 - \Psi| + \delta_1$$

on $S_{T,\varepsilon}$ for any $\delta_1 > 0$ whenever ε is small enough. Since $(\Theta_2 - \Psi)(0) = 0$, Lemma 3.5 yields

$$|\Theta_2 - \Psi| \leqq \frac{\delta_1}{b_1}(e^{b_1 t} - 1) \leqq \frac{\delta_1}{b_1}(e^{b_1 T} - 1) \quad \text{on } S_{T,\varepsilon}. \qquad \square$$

4. The phase approximation. The solution ψ of (3.3) is analyzed in this section, with the intention of discovering when there are values of u for which $\psi(t; u)$ is periodic (mod 2π). The main result that will be obtained asserts that whenever b_1 is large enough (depending on p and σ) there will be exactly two values of u in $[-\pi, \pi)$ for which $\psi(t + 2\pi/\sigma; u) = \psi(t; u) + 2\pi$, with one corresponding to a sink and the other to a source, and all other values in $[-\pi, \pi)$ corresponding to solutions that approach the sink (mod 2π). Together with the results of § 3, this will be used in the next section to obtain results concerning entrainment in (2.1).

4.1. Analysis of $\psi(t; u)$. We begin by writing (3.3) as

$$\dot{\psi} = 1 - bp(\sigma t) \sin \psi, \tag{4.1}$$

where for this section only we write b for b_1. Thus, b here represents a constant, and not the function $b(\varepsilon)$ that it denotes in the rest of the paper. As is easily seen, any periodic solution of (4.1) must have an integer multiple of $2\pi/\sigma$ as its fundamental period. A useful tool in discussing such solutions is the rotation number ρ, given here by

$$\rho = \frac{1}{\sigma} \lim_{t \to \infty} \frac{\psi(t; u)}{t}.$$

As is well known, ρ exists independently of u, depends continuously on parameters, and is such that (4.1) will have a periodic solution of fundamental period $2N\pi/\sigma$ for which $\psi(t + 2N\pi/\sigma) = \psi(t) + 2M\pi$ if and only if ρ is rational, with $\rho = M/N$ in lowest terms [8]. An easy result is that $\rho > 0$ for (4.1), ruling out solutions that are periodic in the ordinary sense. To see this, let $f(t) = (\psi(t) - \psi(-t))/2$, where ψ is any solution of (4.1), and observe that $\dot{f} = 1$ whenever $f = 0$. Thus, $t = 0$ is the only zero of f and $f > 0$ for $t > 0$. Since (iv) of Lemma 4.1 (below) shows that ψ can be replaced by f in the expression for ρ, this shows that $\rho \geqq 0$. But $\rho = 0$ cannot occur, since if ψ was periodic f would have infinitely many zeros.

We now prove two lemmas that will provide the basic results needed to analyze the Poincaré map $u: \mapsto \psi(2\pi/\sigma; u)$ (mod 2π). From the symmetry properties of $p(\sigma t)$ and $\sin \psi$, we get

LEMMA 4.1. *The following hold for all real values of t and u:*

(i) $\psi(t; u) + 2\pi = \psi(t; u + 2\pi)$;

(ii) $\psi\left(t + \frac{2\pi}{\sigma}; u\right) = \psi\left(t; \psi\left(\frac{2\pi}{\sigma}; u\right)\right)$;

(iii) $\psi\left(t + \frac{\pi}{\sigma}; u\right) - \pi = \psi\left(t; \psi\left(\frac{\pi}{\sigma}; u\right) - \pi\right)$;

(iv) $-\psi(-t; u) = \psi(t; -u)$.

Proof. In each case, the function on the left is a solution of (4.1), so the result follows from uniqueness. □

One consequence of this lemma is that we need only consider $t \in [0, \pi/\sigma]$. The next lemma provides estimates for $\psi(t; 0)$ and $\psi(t; \pi)$ on this interval. In order to state it, we first define positive numbers $m(a_1, a_2)$ and $\bar{b}(\sigma, \delta)$ for $[a_1, a_2] \subset (0, \pi)$ and $0 < \delta \leqq \min(\pi/2, \pi/2\sigma)$ by

$$m(a_1, a_2) = \min_{s \in [a_1, a_2]} p(s),$$

$$\bar{b}(\sigma, \delta) = \max\,(1/[m(\sigma\delta, \pi - \sigma\delta) \sin \delta], (2\pi - 4\delta)/[\delta m(\sigma\delta/2, \sigma\delta) \sin (\delta/2)]).$$

Then we have the following lemma.

LEMMA 4.2. *If* $0 < \delta \leqq \min(\pi, \pi/\sigma)$, *then*

(i) $\psi(t; 0) < \delta$ *for* $t \in [0, \delta]$;

(ii) $\psi(t; -\pi) > -\pi + \delta$ *for* $t \in \left[\delta, \dfrac{\pi}{\sigma}\right]$.

If, in addition, $\delta \leqq \min(\pi/2, \pi/2\sigma)$ *and* $b > \bar{b}(\sigma, \delta)$, *then*

(iii) $\psi(t; 0) < \delta$ *for* $t \in \left[0, \dfrac{\pi}{\sigma} - \delta\right]$, *with*

$\psi(t; 0) < 2\delta$ *for* $t \in \left(\dfrac{\pi}{\sigma} - \delta, \dfrac{\pi}{\sigma}\right]$;

(iv) $\psi(t; -\pi) > -\delta$ *for* $t \in [\delta, 2\delta)$, *with*

$\psi(t; -\pi) > 0$ *for* $t \in \left[2\delta, \dfrac{\pi}{\sigma}\right]$.

Proof. (i) Since $\dot{\psi} < 1$ for $(t, \psi) \in (0, \delta] \times (0, \delta]$ it follows immediately that $\psi(t; 0) < \delta$ for $t \in [0, \delta]$ since $\psi(0; 0) = 0$.

(ii) Similarly, $\dot{\psi} > 1$ for $(t, \psi) \in (0, \delta] \times (-\pi, -\pi + \delta]$, so $\psi(\delta; -\pi) > -\pi + \delta$ since $\psi(0; -\pi) = -\pi$. But $\dot{\psi} \geqq 1$ at $\psi = -\pi + \delta$ for $t \in [0, \pi/\sigma]$ so $\psi(t; -\pi)$ cannot return to $-\pi + \delta$ until after $t = \pi/\sigma$.

(iii) We have $\psi(t; 0) < \delta$ for $t \in [0, \delta]$ by (i). But $b > \bar{b}$ implies that $\dot{\psi} < 0$ at $\psi = \delta$ for $t \in [\delta, \pi/\sigma - \delta]$, since then $\dot{\psi} = 1 - bp(\sigma t) \sin \delta$ is less than $1 - p(\sigma t)/m(\sigma\delta, \pi - \sigma\delta) \leqq 0$. Thus $\psi(t; 0) < \delta$ for $t \in [0, \pi/\sigma - \delta]$. To prove the rest, observe that $\dot{\psi} \leqq 1$ for $(t, \psi) \in [\pi/\sigma - \delta, \pi/\sigma] \times [\delta, \pi]$ and that $\pi - \delta \geqq \delta$ since $\delta \leqq \pi/2$. Together with $\psi(\pi/\sigma - \delta; 0) < \delta$, this shows that $\psi(t; 0) < 2\delta$ for $t \in [\pi/\sigma - \delta, \pi/\sigma]$.

(iv) Since $\dot{\psi} = 1$ at $\psi = 0$ for all t, and since $\dot{\psi} > 1$ for $(t, \psi) \in (0, 2\delta] \times [-\delta, 0)$, all that is needed is to show that $\psi(t; -\pi)$ reaches $-\delta$ before $t = \delta$. From (ii) we get $\psi(\delta/2; -\pi) > -\pi + \delta/2$. Thus it is sufficient to show that $(\delta/2)\dot{\psi} > \pi - 3\delta/2$ for $b > \bar{b}$ and $(t, \psi) \in [\delta/2, \delta] \times [-\pi + \delta/2, -\delta]$. But for such t, ψ and b we have $-bp(\sigma t) \sin \psi > (2\pi - 4\delta)/\delta$ yielding

$$\frac{\delta}{2}\dot{\psi} > \frac{\delta}{2}\left[1 + \frac{2\pi - 4\delta}{\delta}\right] = \pi - \frac{3\delta}{2}.$$ □

4.2. The Poincaré map and its square root. In order to discuss periodic solutions of (4.1), we now introduce the Poincaré map $h(u) = \psi(2\pi/\sigma; u) - 2\pi$ and the related function $g(u) = \psi(\pi/\sigma; u) - \pi$. Both of these functions are increasing diffeomorphisms of $\mathbb{R}$. Furthermore, since the n-fold composition $h^n(u)$ equals $\psi(2n\pi/\sigma; u) - 2n\pi$ by

(ii) of Lemma 4.1, $\psi(t; u)$ will be a $(2n\pi/\sigma)$-periodic solution of (4.1) if and only if $h^n(u) = u \pmod{2\pi}$. In particular, fixed points of h correspond to $(2\pi/\sigma)$-periodic solutions with $\rho = 1$. From Lemma 4.1 we get the following.

LEMMA 4.3. *g and h have the following properties*:

(i) $g(u+2\pi) = g(u)+2\pi, \qquad h(u+2\pi) = h(u)+2\pi;$

(ii) $h = g \circ g;$

(iii) $g^{-1}(u) = -g(-u).$

Proof. (i) follows immediately from (i) of Lemma 4.1. Similarly, (ii) follows from (iii) of Lemma 4.1 with $t = \pi/\sigma$. To prove (iii), we have

$$g(-g(-u)) = \psi\left(\frac{\pi}{\sigma}; -\psi\left(\frac{\pi}{\sigma}; -u\right) + \pi\right) - \pi,$$

which equals

$$-\psi\left(-\frac{\pi}{\sigma}; \psi\left(\frac{\pi}{\sigma}; -u\right) - \pi\right) - \pi$$

by (iv) of Lemma 4.1. Now (iii) of Lemma 4.1 shows that $g(-g(-u)) = -\psi(0; -u) = u$. □

As a result of (ii) above, h can be analyzed in terms of its "square root" g. This simplifies the analysis, since $p(\sigma t)$ is of constant sign on $[0, \pi/\sigma]$ and because it allows easy use of Lemma 4.2. The next result provides a sufficient condition for $\rho = 1$.

LEMMA 4.4. *Let* $0 < \delta \leqq \min(\pi/2, \pi/2\sigma)$. *If* $b > \bar{b}(\sigma, \delta)$, *then* $g([-\pi, 0]) \subset (-\pi, -\pi+2\delta)$ *and* $g^{-1}([0, \pi]) \subset (\pi-2\delta, \pi)$. *If* $\sigma = 1$, *then* $g([-\pi, 0]) \subset (-\pi, 0)$ *and* $g^{-1}([0, \pi]) \subset (0, \pi)$ *for all* $b > 0$.

Proof. The result for g^{-1} follows from the one for g by (iii) of Lemma 4.3. To prove the result for g, it is sufficient to prove that

(A) $$\psi\left(\frac{\pi}{\sigma}; 0\right) < \pi \quad \text{and} \quad \psi\left(\frac{\pi}{\sigma}; -\pi\right) > 0 \quad \text{for } \sigma = 1, \quad \text{and}$$

(B) $$\psi\left(\frac{\pi}{\sigma}; 0\right) < 2\delta \quad \text{and} \quad \psi\left(\frac{\pi}{\sigma}; -\pi\right) > 0 \quad \text{for } b > \bar{b}(\sigma, \delta).$$

But (A) follows from (i) and (ii) of Lemma 4.2 with $\delta = \pi$ and $t = \pi/\sigma$, while (B) follows from (iii) and (iv) of Lemma 4.2 with $t = \pi/\sigma$. □

Since $(-\pi, -\pi+2\delta) \subset (-\pi, 0)$ for δ as above, g clearly has fixed points when the conclusions of the lemma hold. Furthermore, fixed points of g are also fixed points of h since $h = g \circ g$, so Lemma 4.4 provides sufficient conditions for (4.1) to have rotation number 1. In particular, observe that $\rho = 1$ for all $b > 0$ when $\sigma = 1$. This cannot happen for any other value of σ since $\rho \to 1/\sigma$ as $b \to 0$, ruling out $\rho = 1$ for b small when $\sigma \neq 1$.

We now consider the questions of the number of fixed points in $[-\pi, \pi)$ and their stability. These questions can be answered by examining g', with a fixed point u of g being stable if $g'(u) < 1$ and unstable if $g'(u) > 1$. To begin, since $g'(u) = \Psi(\pi/\sigma; u)$ we can solve (3.4) to get

(4.2) $$g'(u) = \exp\left(-b \int_0^{\pi/\sigma} p(\sigma t) \cos \psi(t; u)\, dt\right).$$

Since $p(s)$ has maximum value 1 on $(0, \pi)$, there are numbers $0 < a_1 < a_2 < \pi$ for which $p(s) \geqq 1/\sqrt{2}$ on $[a_1, a_2]$. Now let the positive numbers δ and ν be given by

$$\nu = \frac{a_2 - a_1}{4}, \qquad \delta = \min\left(\frac{\pi}{4}, \frac{\pi}{2\sigma}, \frac{a_1}{\sigma}, \frac{\pi - a_2}{\sigma}, \frac{\nu}{\sigma}\right).$$

We can now prove the following.

THEOREM 4.5. *Let ν and δ be as above. Then*

(i) *If $b > \bar{b}(\sigma, \delta)$, then g is a contraction mapping on $[-\pi, 0]$, with $g' < \exp(-b\nu/\sigma)$ there.*

(ii) *If $\sigma = 1$, then there is an interval $J \subset (-\pi, 0)$ (depending on p) such that for all sufficiently small b, g is a contraction mapping on J, with $g' < \exp(-b\nu_2)$ there, and all points of $[-\pi, 0]$ not in J enter it under iteration of g. Here ν_2 is a positive constant determined by p.*

Furthermore, the corresponding assertions hold for g^{-1} on $[0, \pi]$ and $-J = \{x \mid -x \in J\}$.

Proof. Since $g^{-1}(u) = -g(-u)$ (Lemma 4.3), the assertions for g^{-1} follow from those for g. The proofs for g are as follows.

(i) For $b > \bar{b}(\sigma, \delta)$, we have $g([-\pi, 0]) \subset (-\pi, 0)$ by Lemma 4.4. To get the rest, we only need to show that the integral in (4.2) will be greater than ν/σ for $u \in [-\pi, 0]$. But for such u, it follows from (iii) and (iv) of Lemma 4.2 that $\psi(t; u) \in (-\delta, 2\delta)$ for $t \in [\delta, \pi/\sigma]$, with $\psi(t; u) \in (-\delta, \delta)$ for $t \in [\delta, \pi/\sigma - \delta]$. Furthermore, we have $(-\delta, 2\delta) \subset (-\pi/4, \pi/2)$, $(-\delta, \delta) \subset (-\pi/4, \pi/4)$, and $p(\sigma t) \geqq 1/\sqrt{2}$ for $t \in [a_1/\sigma, a_2/\sigma] \subset [\delta, \pi/\sigma - \delta]$. Thus, the negative contribution to the integral must be greater than $-\delta$, with $p(\sigma t) \cos \psi(t; u) > \frac{1}{2}$ for $t \in [a_1/\sigma, a_2/\sigma]$, so

$$\int_0^{\pi/\sigma} p(\sigma t) \cos \psi(t; u)\, dt > \frac{a_2 - a_1}{2\sigma} - \delta \geqq \frac{a_2 - a_1}{2\sigma} - \frac{\nu}{\sigma} = \frac{\nu}{\sigma}.$$

(ii) Now let $\sigma = 1$. Expanding $g(u)$ and $\cos \psi(t; u)$ in powers of b and making use of (4.1) and (4.2), we get expansions that can be written in the form

$$(*) \qquad g(u) = u - bA \sin(u + \xi) + O(b^2),$$

$$(**) \qquad g'(u) = \exp(-bA \cos(u + \xi) + O(b^2))$$

as $b \to 0$, uniformly in (t, u) for $t \in [0, \pi]$. Here $A = (\alpha^2 + \beta^2)^{1/2}$ and $\xi = \operatorname{arc\,cot}(\beta/\alpha)$, where

$$\alpha = \int_0^{\pi} p(t) \sin t\, dt \quad \text{and} \quad \beta = \int_0^{\pi} p(t) \cos t\, dt.$$

Since $\xi \in (0, \pi)$, there is a closed interval $J \subset (-\pi, 0)$, containing $-\xi$ in its interior, on which $\cos(u + \xi) > \frac{3}{4}$. Clearly $\sin(u + \xi)$ is bounded away from 0 on $[-\pi, 0] - J$, where it is positive to the right of J, and negative to the left. Together with (*), this shows that $g(J) \subset J$ and that points in $[-\pi, 0] - J$ enter J under iteration of g, whenever b is small enough.

To show that g is a contraction on J, we need only establish the estimate for g'. To this end, let $\nu_2 = A/2$. Since $\cos(u + \xi) > \frac{3}{4}$ on J, it follows from (**) that $g'(u) < \exp(-b\nu_2)$ there whenever b is small enough. □

When the conclusions of Theorem 4.5 hold, g (and so also h) has exactly two fixed points in $[-\pi, \pi)$: a sink $u_0 \in (-\pi, 0)$ and a source $-u_0 \in (0, \pi)$. Furthermore, if u is any other point of $[-\pi, \pi)$, then u approaches u_0 under iteration of g if $u < -u_0$ and approaches $u_0 + 2\pi$ if $u > -u_0$. The behavior of the corresponding map $\tilde{g}: S^1 \to S^1$ is sketched in Fig. 1.

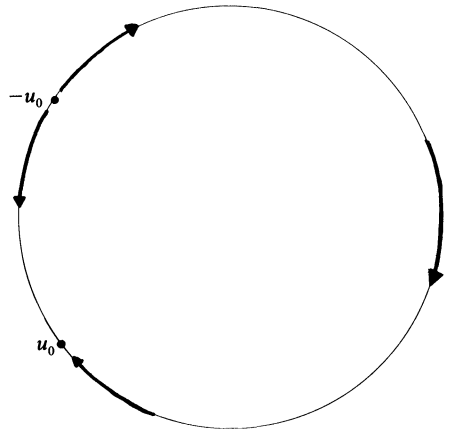

FIG. 1. *Behavior of $\tilde{g}$ when b is large and also for small b when $\sigma = 1$.*

Remark 1. In addition to their existence, we can obtain information about the location of the fixed points when b is large. In particular, $g([-\pi, 0]) \subset (-\pi, -\pi + 2\delta)$ for $b > \bar{b}(\sigma, \delta)$ by Lemma 4.4, which shows that $u_0 \to -\pi$ as $b \to \infty$.

Remark 2. It should be pointed out that it was not obviously to be expected that (4.1) would have rotation number 1 for large b. To see this, consider the equation

$$\dot{\psi} = 1 - bp(\sigma t)(1 + \sin \psi), \tag{4.3}$$

which appears similar to (4.1). If we let $\tau = \sigma t - \pi$ and introduce $v(\tau)$ by

$$\frac{v_\tau}{v} = \frac{-1}{2\sigma} \tan\left(\frac{\psi}{2} - \frac{\pi}{4}\right),$$

then (4.3) is transformed into

$$v_{\tau\tau} + (\alpha + \beta p(\tau))v = 0 \qquad \left(\alpha = \frac{1}{4\sigma^2},\ \beta = \frac{1}{2\sigma^2}\right) \tag{4.4}$$

which is Hill's equation. Using an argument given by Ermentrout [9] for the case $p(\tau) = \sin(\tau)$, and presented more fully by Ermentrout and Kopell [10] in the general case, it can be shown that (4.3) has rotation number k when (α, β) is in the kth *instability* zone of (4.4) ($k = 1, 2, 3, \cdots$).

When $p(\tau) = \sin(\tau)$, (4.4) is Mathieu's equation, for which the well-known stability diagram shows clearly that as b increases it passes in succession through an infinite sequence of intervals $(b_k, \tilde{b}_k)$, with $b_k < \tilde{b}_k < b_{k+1}$ and $b_k \to \infty$ as $k \to \infty$, on which (4.3) has rotation number k, which is in striking contrast to the behavior of (4.1). This can also be shown to occur when $p(\tau)$ is the square wave with $p = 1$ on $[0, \pi)$ and $p = -1$ on $[\pi, 2\pi)$, in which case explicit conditions for the boundaries of the instability zones can be obtained [10], [11]. Finally, work done by Weinstein and Keller [12] suggests that the relevant aspects of the instability zones in these two cases occur also for a large class of functions p.

5. Entrainment of (2.1). The results of the previous sections will now be used to obtain information concerning the behavior of the solutions of (2.1) in A_ε when ε is small. In particular, the fact that the θ-component of the solutions of (3.2) can be approximated by solutions of (4.1) will allow us to conclude that (2.1) will be 1:1 phase-locked for small ε whenever the conclusions of Theorem 4.5 hold. The main

result, which is contained in Theorem 5.4, asserts that if b_1 and σ satisfy the hypotheses of Theorem 4.5, then for all sufficiently small ε the period map of (2.1) will have exactly two fixed points in A_ε, a sink and saddle corresponding to the sink u_0 and source $-u_0$ of g, and that every point of A_ε that is not on the stable manifold of the saddle will be in the basin of attraction of the sink. This will follow naturally from the fact that $(r(\pi/\sigma; r_0, \theta_0), \theta(\pi/\sigma; r_0, \theta_0))$ can be C^1-approximated in $I_\varepsilon \times \mathbb{R}$ by $(1, g(\theta_0))$, as shown by Lemma 3.2 and Theorem 3.3. That (2.1) will then be 1:1 phase-locked is a consequence of the fact that (4.1) has rotation number 1 whenever g has fixed points.

To begin, let $x(t; x_0, y_0)$ and $y(t; x_0, y_0)$ denote the general solution of (2.1) with $x(0; x_0, y_0) = x_0$ and $y(0; x_0, y_0) = y_0$, and let X_t denote the t-advance map

$$X_t: \begin{pmatrix} x_0 \\ y_0 \end{pmatrix} \mapsto \begin{pmatrix} x(t; x_0, y_0) \\ y(t; x_0, y_0) \end{pmatrix}.$$

X_t is defined on A_ε for all $t \geqq 0$ since A_ε is compact and attracting and standard theorems ensure that X_t maps A_ε diffeomorphically onto its image. Furthermore, as shown in the next lemma, X_t has periodicity and symmetry properties similar to those of $\psi(t; u)$.

LEMMA 5.1. *The following hold for all* $t \geqq 0$:

(i) $X_{t+2\pi/\sigma} = X_t \circ X_{2\pi/\sigma}$;

(ii) $-X_{t+\pi/\sigma} = X_t \circ (-X_{\pi/\sigma})$.

Proof. In each case, when the function on the left is evaluated at an arbitrary initial point a solution of (2.1) is obtained. The result then follows from uniqueness. □

From (i) it follows that $X_{2n\pi/\sigma} = X^n_{2\pi/\sigma}$ (n a positive integer), while (ii) shows that $X_{2\pi/\sigma} = (-X_{\pi/\sigma}) \circ (-X_{\pi/\sigma})$. Thus, all information concerning periodic solutions must be contained in $-X_{\pi/\sigma}$ and we can once again restrict our analysis to a half period.

Corresponding to the maps X_t are the maps Φ_t given by

$$\Phi_t: \begin{pmatrix} r_0 \\ \theta_0 \end{pmatrix} \mapsto \begin{pmatrix} r(t; r_0, \theta_0) \\ \theta(t; r_0, \theta_0) \end{pmatrix},$$

where (r, θ) is the general solution of (3.2). Let $F = F_\varepsilon$ be the map connecting the coordinates (r, θ) and (x, y),

$$F_\varepsilon: \begin{pmatrix} r \\ \theta \end{pmatrix} \mapsto \begin{pmatrix} r\cos(\theta - \gamma \ln r + d) \\ r\sin(\theta - \gamma \ln r + d) \end{pmatrix}.$$

Then X_t and Φ_t are connected by

$$X_t \circ F = F \circ \Phi_t. \tag{5.1}$$

Observe that

$$D\Phi_t = \begin{pmatrix} R_1 & R_2 \\ \Theta_1 & \Theta_2 \end{pmatrix}, \tag{5.2}$$

which shows that

$$\frac{d}{dt} D\Phi_t = B(t) D\Phi_t, \qquad D\Phi_0 = I \tag{5.3}$$

where

$$B = \begin{pmatrix} B_1 & B_2 \\ B_3 & B_4 \end{pmatrix}$$

is the coefficient matrix of (3.5) and I is the 2×2 identity matrix. We can now prove the next lemma, which shows that Φ_t contracts areas in $I_\varepsilon \times \mathbb{R}$ for $t>0$ if ε is small enough.

LEMMA 5.2. *If ε is small enough, then*

$$0 < \det D\Phi_t \begin{pmatrix} r_0 \\ \theta_0 \end{pmatrix} \leqq e^{(2b_1 - 1/2\varepsilon)t}$$

for all $(r_0, \theta_0) \in I_\varepsilon \times \mathbb{R}$ and all $t>0$.

Proof. From (5.3) it follows that

$$\det D\Phi_t = \exp\left(\int_0^t \operatorname{tr} B(s)\, ds\right).$$

But $\operatorname{tr} B(s) = B_1(s) + B_4(s)$, so Lemma 3.4 shows that $\operatorname{tr} B(s) \leqq 2b_1 - 1/2\varepsilon$ for $r_0 \in I_\varepsilon$ whenever ε is small enough. □

Now consider the map

$$G: \quad \begin{pmatrix} r_0 \\ \theta_0 \end{pmatrix} \mapsto \Phi_{\pi/\sigma} \begin{pmatrix} r_0 \\ \theta_0 \end{pmatrix} - \begin{pmatrix} 0 \\ \pi \end{pmatrix}.$$

From (5.1) it follows that

$$(-X_{\pi/\sigma}) \circ F = F \circ G. \tag{5.4}$$

Clearly

$$\begin{pmatrix} x_0 \\ y_0 \end{pmatrix} = F \begin{pmatrix} r_0 \\ \theta_0 \end{pmatrix}$$

will be a fixed point of $-X_{\pi/\sigma}$ if $\binom{r_0}{\theta_0}$ is a fixed point of G. Moreover, if $\binom{r_0}{\theta_0}$ is a hyperbolic fixed point of G for which $r_0 \neq 0$, then $\binom{x_0}{y_0}$ will be a fixed point of the same type (sink, saddle or source) for $-X_{\pi/\sigma}$. To see this, observe that $\det DF\binom{r_0}{\theta_0} = r_0$ and that differentiation of (5.4) yields

$$D(-X_{\pi/\sigma}) \begin{pmatrix} x_0 \\ y_0 \end{pmatrix} DF \begin{pmatrix} r_0 \\ \theta_0 \end{pmatrix} = DF \begin{pmatrix} r_0 \\ \theta_0 \end{pmatrix} DG \begin{pmatrix} r_0 \\ \theta_0 \end{pmatrix}$$

when $\binom{r_0}{\theta_0}$ is a fixed point of G. Thus, $D(-X_{\pi/\sigma})\binom{x_0}{y_0}$ and $DG\binom{r_0}{\theta_0}$ are similar, and so must have the same eigenvalues, when $\binom{r_0}{\theta_0}$ is a fixed point with $r_0 \neq 0$.

The results of the previous section can easily be used to obtain information about G. This is because Lemma 3.2 and Theorem 3.3 show that G and DG can be made as close as desired to

$$\begin{pmatrix} 1 \\ g \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 0 & 0 \\ 0 & g' \end{pmatrix}$$

for $(r_0, \theta_0) \in I_\varepsilon \times \mathbb{R}$ by making ε small enough (depending on b_1, etc.). In particular, part of the proof of Theorem 5.4 will involve showing that G will be a contraction near $\binom{1}{u_0}$ for ε small. In this regard, observe that a smooth map from a compact convex set to itself will be a contraction if at each point the eigenvalues of its linear part are real, distinct and less than one in absolute value, and the corresponding eigenvectors are mutually orthogonal. The next lemma shows that the orthogonality condition can be relaxed.

LEMMA 5.3. *Let D be a compact convex subset of an open set $U \subset \mathbb{R}^n$ $(n \geqq 2)$, and let $f: U \to \mathbb{R}^n$ be a C^1 function that maps D into itself whose linear part $Df(x)$ has distinct real eigenvalues $\lambda_1(x), \cdots, \lambda_n(x)$ in D. Let $\lambda_M = \max |\lambda_i(x)| (x \in D, i = 1, \cdots, n)$, and let $\mathbf{v}_1(x), \cdots, \mathbf{v}_n(x)$ be unit eigenvectors corresponding to $\lambda_1(x), \cdots, \lambda_n(x)$. Then f will be a contraction mapping on D if $\lambda_M < 1$ and*

$$|\mathbf{v}_i \cdot \mathbf{v}_k| < \frac{1}{n-1} \frac{1-\lambda_M^2}{1+\lambda_M^2} \qquad (i \neq k)$$

for all $x \in D$.

Proof. Since $|\mathbf{v}_i(x) \cdot \mathbf{v}_k(x)|$ is continuous and D is compact, there is a $\lambda \in (\lambda_M, 1)$ such that

$$(*) \qquad |\mathbf{v}_i \cdot \mathbf{v}_k| < \frac{1}{n-1} \frac{\lambda^2 - \lambda_M^2}{\lambda^2 + \lambda_M^2}$$

on D. We now show that $\|Df(x)\mathbf{w}\| \leqq \lambda \|\mathbf{w}\|$ on D for all $\mathbf{w} \in \mathbb{R}^n$, where $\| \cdot \|$ denotes the Euclidean norm. To this end, let $x \in D$ and $\mathbf{w} \in \mathbb{R}^n$ be arbitrary, and let $A = Df(x)$, $B = \operatorname{diag}(\lambda_1(x), \cdots, \lambda_n(x))$, $M = \operatorname{col}(\mathbf{v}_1(x), \cdots, \mathbf{v}_n(x))$ and $N = M^T M - I$, where I is the $n \times n$ identity matrix. M is invertible since $\lambda_1, \cdots, \lambda_n$ are distinct, so we can also let $\mathbf{u} = M^{-1}\mathbf{w}$. We want to show that $\lambda^2\|\mathbf{w}\|^2 - \|A\mathbf{w}\|^2 \geqq 0$. But

$$\lambda^2\|\mathbf{w}\|^2 - \|A\mathbf{w}\|^2 = \mathbf{u}^T(\lambda^2 I - B^2)\mathbf{u} + \mathbf{u}^T(\lambda^2 N - BNB)\mathbf{u}.$$

Clearly $\mathbf{u}^T(\lambda^2 I - B^2)\mathbf{u} \geqq (\lambda^2 - \lambda_M^2)\mathbf{u}^T\mathbf{u}$, and $\lambda^2 N - BNB$ is a symmetric matrix whose diagonal elements are 0 and whose other elements are bounded in absolute value by $(\lambda^2 - \lambda_M^2)/(n-1)$ as follows from (*). As a result we see that

$$\lambda^2\|\mathbf{w}\|^2 - \|A\mathbf{w}\|^2 \geqq \frac{\lambda^2 - \lambda_M^2}{n-1} \mathbf{u}_+^T C \mathbf{u}_+,$$

where $\mathbf{u}_+$ is the vector whose components are the absolute value of the corresponding components of $\mathbf{u}$, and the matrix C has its diagonal elements equal to $n-1$ and its remaining elements equal to -1. Thus, it is sufficient to show that C is a nonnegative matrix. But this follows immediately from the fact that $C = (1/n)C^T C$.

Now let x and y be any two points in D. Since D is convex, the segment joining x and y lies in D and we have

$$\begin{aligned} \|f(y) - f(x)\| &= \left\| \int_0^1 Df(x + t(y-x))(y-x)\, dt \right\| \\ &\leqq \int_0^1 \|Df(x + t(y-x))(y-x)\| dt \\ &\leqq \int_0^1 \lambda \|y - x\| dt = \lambda \|y - x\|. \end{aligned}$$

Thus, f is a contraction on D with contraction constant λ. □

Let δ be as in Theorem 4.5. We can now prove the following.

THEOREM 5.4. *If $b_1 > \bar{b}(\sigma, \delta)$, or if $\sigma = 1$ and b_1 is small enough, then $X_{2\pi/\sigma}$ will have exactly two fixed points in A_ε, one a sink and the other a saddle, whenever ε is small enough (depending on b_1 and σ). Furthermore, all points of A_ε not on the stable manifold of the saddle are in the basin of attraction of the sink.*

The following proof uses the notions of horizontal curve and horizontal strip. Briefly, a smooth horizontal curve in this context is a curve whose tangent vectors have

a θ-component that is larger than its r-component. A horizontal strip is a strip whose upper and lower boundaries are nonintersecting horizontal curves. The width of a horizontal strip is the maximum vertical distance between corresponding points on the upper and lower boundaries. For details, see [14].

Proof. If $b_1 > \bar{b}(\sigma, \delta)$, or if $\sigma = 1$ and b_1 is small enough, then it follows from Theorem 4.5 that there are closed intervals $J_1 \subset (-\pi, 0)$ and $J_2 \subset (0, \pi)$, with $u_0 \in \text{Int}(J_1)$ and $-u_0 \in \text{Int}(J_2)$ (where the sink u_0 is the unique fixed point of g in $(-\pi, 0)$ and the source $-u_0$ is the unique fixed point of g in $(0, \pi)$), such that g' is bounded below 1 on J_1 and bounded above 1 on J_2. Let $D_1 = I_\varepsilon \times J_1$ and $D_2 = I_\varepsilon \times J_2$. Since $X_{2\pi/\sigma} = (-X_{\pi/\sigma}) \circ (-X_{\pi/\sigma})$, it follows from (5.4) that it is sufficient to prove that the following hold whenever ε is small enough.

(A) Points of $I_\varepsilon \times [-\pi, \pi)$ not in $D_1 \cup D_2$ enter $D_1 (\text{mod } 2\pi \text{ in } \theta)$ under iteration of G.

(B) G is a contraction mapping on D_1.

(C) G has a unique saddle point in D_2, and any point of D_2 not on its stable manifold leaves D_2 under iteration of G.

Proof of (A), (B), *and* (C).

(A) and (B). Theorems 4.5 and 3.3 show that there must be a $d > 0$ such that those points $\binom{r}{\theta}$ of $I_\varepsilon \times [-\pi, \pi)$ not in $D_1 \cup D_2$ for which $\theta \in [-\pi, -u_0)$ must move at least a distance d toward D_1 under G, while those with $\theta \in (-u_0, \pi)$ must move at least distance d toward the copy $\{\binom{r}{\theta} | \binom{r}{\theta} - \binom{0}{2\pi} \in D_1\}$ of D_1. This proves (A), and shows that $G(D_1) \subset D_1$. It could now be shown directly that G is a contraction on D_1, but instead we observe that G must satisfy the hypotheses of Lemma 5.3 in D_1 for small ε, since g' is bounded below 1 on J_1 while Lemma 3.2 and Theorem 3.3 show that $DG\binom{r}{\theta}$ can be made as close as desired to

$$\begin{pmatrix} 0 & 0 \\ 0 & g'(\theta) \end{pmatrix}$$

uniformly for $(r, \theta) \in I_\varepsilon \times \mathbb{R}$ by taking ε small enough.

(C). The fact that g' is bounded above 1 on J_2, together with the approximation of DG given above, shows that whenever ε is small enough G will map smooth horizontal curves in D_2 to smooth horizontal curves and DG will have eigenvalues λ_1, λ_2 that satisfy $0 < |\lambda_1| < 1 < |\lambda_2|$ at each point of D_2. Clearly any fixed point of G in D_2 will then be a saddle.

Now let $S_0 = D_2$ and define

$$S_k = D_2 \cap G(S_{k-1}) \qquad (k = 1, 2, 3, \cdots).$$

Since G maps smooth horizontal curves in D_2 to smooth horizontal curves, and since points on the ends of D_2 move at least a distance d away from D_2 under G, it follows that the S_k form a nested family of horizontal strips, each of which connects the ends of D_2. Furthermore, area of S_{k+1} is less than $\frac{1}{2}$ area of S_k whenever ε is small enough, since $\det(DG) < \frac{1}{2}$ for small ε by Lemma 5.2. As a result, the width of $S_k \to 0$ as $k \to \infty$, due to the fact that the upper and lower boundaries of S_k are horizontal curves of length not less than the length of J_2. Thus

$$S_\infty = \bigcap_{k=0}^{\infty} S_k$$

is a horizontal curve [14, p. 70] connecting the ends of D_2 (see Fig. 2).

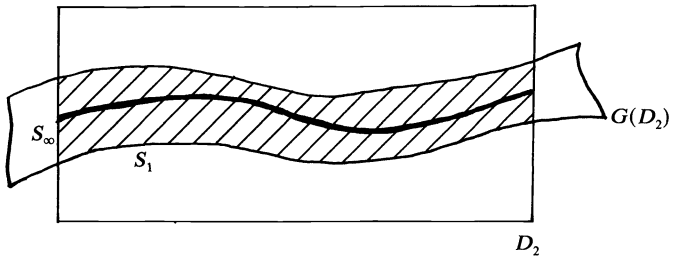

FIG. 2

Now let W^u be the unstable manifold of a fixed point in D_2. Since $D_2 \cap G(D_2 \cap W^u) = D_2 \cap W^u$, it follows that $D_2 \cap W^u \subset S_\infty$. Thus, there can be at most one fixed point in D_2 since otherwise the segment of S_∞ connecting any two fixed points would have to lie on the unstable manifold of each. On the other hand, there must be at least one fixed point in D_2, since $D_2 \cap G(S_\infty) = S_\infty$ shows that $G^{-1}(S_\infty) \subset S_\infty$. We must now conclude that $S_\infty = W^u \cap D_2$. That any points of D_2 not on the stable manifold of the saddle must leave D_2 under iteration of G is a consequence of the fact that such a point must otherwise approach W^u. □

The behavior of $X_{2\pi/\sigma}$ in A_ε when the conclusion of the theorem holds is sketched in Fig. 3. It should be observed that the sink and saddle mentioned in the theorem must approach

$$\begin{pmatrix} \cos(u_0 + d_0) \\ \sin(u_0 + d_0) \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} \cos(-u_0 + d_0) \\ \sin(-u_0 + d_0) \end{pmatrix}$$

as $\varepsilon \to 0$, where $d_0 = \tan^{-1} c$. This follows from the form of F, together with the fact that the intervals J_1 and J_2 used in the proof can be chosen as small as desired provided that $u_0 \in \text{Int}(J_1)$ and $-u_0 \in \text{Int}(J_2)$.

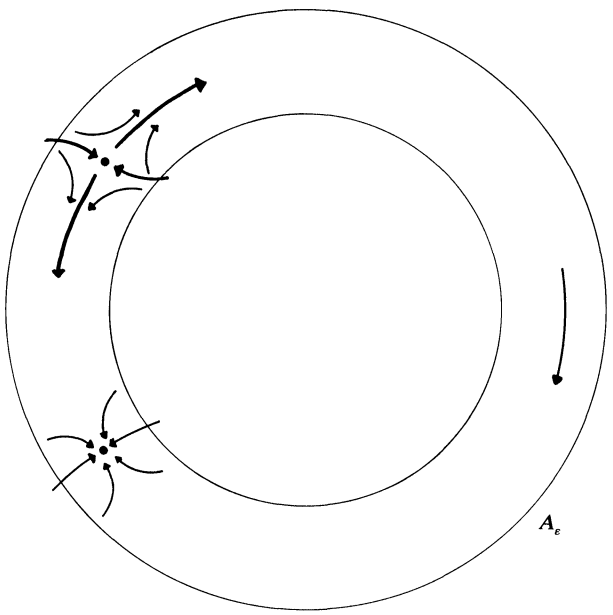

FIG. 3. *Behavior of $X_{2\pi/\sigma}$ in A_ε for small ε when b_1 is large and also for small b_1 when $\sigma = 1$. The width of A_ε has been exaggerated for purposes of illustration.*

Furthermore, since the proof involved approximating the θ-component of solutions of (2.1) by solutions of (4.1) with rotation number 1, it follows that the periodic solutions corresponding to the fixed points of $X_{2\pi/\sigma}$ go once around A_ε in each period, which shows that (2.1) is then 1:1 phase locked. Thus, (2.1) is 1:1 phase locked for small ε when $b_1 > \bar{b}(\sigma, \delta)$, and for b_1 small enough when $\sigma = 1$. That this cannot occur for b_1 small when $\sigma \neq 1$ follows easily from the fact that (4.1) cannot then have rotation number 1. However, this does not rule out the possibility that other types of phase locking (e.g., 2:1) might occur.

Remark. As previously noted, the shear, or radial variation in angular velocity near the limit cycle, is a property of the unforced oscillator. In our analysis of (2.1) it was assumed that β, which determines the amount of shear present in the unforced oscillator, depended on ε in such a way that $\varepsilon/\beta \to c$ as $\varepsilon \to 0$. As follows from Lemma 3.1, when $c = 0$ the angular velocity ω of solutions of the unforced oscillator is essentially constant in A_ε for ε small, since A_ε is of width $O(\varepsilon)$. On the other hand, when $c \neq 0$, ω will have an $O(1)$ variation across A_ε as $\varepsilon \to 0$. Thus, we say there is a large shear when $c \neq 0$.

The presence of large shear was accommodated in the analysis of (2.1) by making the change of variable

$$\theta = \eta + \gamma \ln r - \tan^{-1} \gamma$$

in the polar coordinate form (3.1) of (2.1). Since $r \to 1$ in A_ε and $\gamma \to c$ as $\varepsilon \to 0$, it follows that

$$\theta \to \eta - \tan^{-1} c$$

in A_ε as $\varepsilon \to 0$. Thus, we see that one effect of large shear is to appear to rotate coordinates in A_ε. In particular, the angular position of the fixed points mentioned in Theorem 5.4 will differ from that which would result from the same value of b_1 when $c = 0$ by an amount close to $\tan^{-1} c$.

The fact that $b_1 = b_0\sqrt{1+c^2}$ occurs in Theorem 5.4 instead of b_0 demonstrates that the presence of large shear can also increase the sensitivity of the oscillator to forcing. Specifically, we see that the amount of forcing required to bring about entrainment is reduced when $|c|$ is increased. Furthermore, Theorem 3.3 shows that the θ-component of the solutions of (3.2) can be approximated in the presence of large shear by a solution of (4.1) that would result from a larger forcing amplitude when $|c|$ is smaller. Since $r = 1 + O(\varepsilon)$ in A_ε, the θ-component determines the gross behavior of solutions there. Thus, not only does an increase in shear increase the sensitivity of the oscillator to forcing, but the solutions in A_ε appear to behave much as if the forcing had been increased instead of the shear.

Acknowledgment. The present paper grew out of the author's thesis. It is with pleasure that I thank my advisor Nancy Kopell, whose guidance and encouragement were essential to both this and the earlier work. I also thank G. Bard Ermentrout for helpful comments and suggestions.

SECOND ORDER NONLINEAR FORCED OSCILLATIONS*

JAMES S. W. WONG†

Abstract. We study the oscillatory behaviour of solutions of second order nonlinear differential equation $x''+a(t)f(x)=g(t)$ on the half line $[0,\infty)$. Conditions on $a(t)$, $f(x)$ and $g(t)$ are given so that all solutions are oscillatory. These results represent further improvements on those given by Kartsatos, Kusano and Onose and Foster.

Key words. second order, nonlinear, differential equations, oscillation

1. Introduction. We are concerned here with second order nonlinear differential equation on the half line $[0,\infty)$

$$x''+a(t)f(x)=g(t), \qquad t\in[0,\infty), \tag{1}$$

where $a(t)$, $g(t)$ are real-valued piecewise continuous functions on $[0,\infty)$ and $f(x)$ is a continuous and nondecreasing function of $x\in(-\infty,\infty)$. We shall assume that functions $a(t)$, $g(t)$ and $f(x)$ are sufficiently smooth so that equation (1) always has solutions that are continuable throughout $[0,\infty)$. Such a solution is said to be *oscillatory* if it has arbitrarily large zeros, i.e., for any $T>0$ there exists a $t\geqq T$ such that $x(t)=0$. Otherwise, the solution is said to be *nonoscillatory*, i.e., it is eventually positive or negative. Equation (1) is said to be *oscillatory* if all continuable solutions are oscillatory. Our interest is to find conditions on $a(t)$, $f(x)$ and $g(t)$ so that (1) is oscillatory.

In an earlier paper [29], we posed the problem of whether (1) remains oscillatory subject to a periodic forcing term $g(t)$, i.e., $g(t+P)=g(t)$ for all t and some positive constant P, provided that its unforced equation

$$u''+a(t)f(u)=0, \qquad t\in[0,\infty), \tag{2}$$

is oscillatory, where $f(x)$ satisfies, in addition,

$$xf(x)>0, \qquad x\neq 0. \tag{3}$$

Subsequently, Kartsatos [12] and Teufel [28] proved results showing that certain well-known oscillation criteria for the unforced equation (2) remain valid for (1) when $g(t)$ is periodic.

Kartsatos' technique introduced in [11], [12] is to assume the existence of a function $h(t)$ such that $h''(t)=g(t)$ and to reduce (1) to a second order homogeneous equation like (2). His technique has since been extended to higher order functional differential equations by Kartsatos and Manougian [14], Kartsatos and Onose [15], Kartsatos and Toro [16], Kusano and Onose [19], Onose [21], Staikos and Sficas [26], [27], and Foster [7], [8]. On the other hand, there are also a number of papers concerned with the more special linear equation, and the oscillatory nature of its solutions (see, e.g., Keener [17], Skidmore and Leighton [24], Skidmore and Bowers [25], Rankin [22], and Howard [9]). Other related results on forced oscillation for (1) may be found in Komkov [18] and Rankin [23].

The basic assumptions in Kartsatos' results [11], [12] are that $h(t)$ is either small for large values of t or it is periodic in t. It is useful to note that Atkinson [2] showed that if $g(t)$ is the second derivative of a periodic function, then a periodic second primitive $h(t)$ exists such that $h''(t)=g(t)$. Howard's results for the linear equation apply however to the more general oscillatory functions such as $g(t)=t^{\delta}\sin t$, δ being any real number.

More specifically, we consider the following specific Emden-Fowler equation:

$$x''+t^{\alpha}|x|^{\gamma}\operatorname{sgn} x=t^{\delta}\sin t, \qquad \gamma>0, \tag{4}$$

on $[0,\infty)$ where δ is any real number. Using Kartsatos' theorems [11], [12], we can conclude that (4) is oscillatory if $\alpha\geqq -1$ and $\delta\leqq 0$. Howard's theorem [9], when applied to a special case of (4), i.e.,

$$x''+x=t^{\delta}\sin t, \quad \delta \text{ real},$$

does yield oscillation for all values of δ. The results given below represent a further improvement in this direction and will show among other things that (4) is oscillatory for all values of δ provided that $\alpha+\gamma\delta>-1$. In the special cases when $\gamma>1$ and $0<\gamma<1$, sharper conditions are also available. Applications of our results to specific examples may be found in § 4.

2. Throughout this paper, we assume that $f(x)$ is continuous and nondecreasing in x satisfying condition (3), and that $a(t)$ is nonnegative but not eventually zero on $[0,\infty)$. Furthermore, we assume the following hypothesis on the forcing term:

(H_1) There exists an $h(t)\in C^2[0,\infty)$ such that $h''(t)=g(t)$ and that $h(t)$ is oscillatory, i.e., it has unbounded zeros.

Let $x(t)=y(t)+h(t)$, then (1) can be rewritten as a homogeneous equation

$$y''+a(t)f(y+h)=0. \tag{5}$$

To prove (1) is oscillatory, it is sufficient to assume the existence of an eventually positive solution $x(t)$ and deduce a contradiction by applying the various hypothesis to (5). Suppose that $x(t)>0$ on $[t_0,\infty)$. Since $a(t)\geqq 0$, from (5) we note that $y''(t)\leqq 0$ on $[t_0,\infty)$. In our first step, we show that $y'(t)\geqq 0$ on $[t_1,\infty)$ for some $t_1\geqq t_0$. If not, say $y'(t_2)<0$ for some $t_2\geqq t_0$. Since $y''(t)\leqq 0$, $y'(t)\leqq y'(t_2)<0$ for all $t\geqq t_2$; hence $y(t)\to-\infty$ as $t\to\infty$, but this together with $h(t)$ being oscillatory contradicts the assumption that $x(t)>0$. In fact, given that $y''(t)\leqq 0$, $y'(t)\geqq 0$, we must have $y'(t)$ eventually positive, i.e., $y'(t)>0$ for $t\geqq t_3\geqq t_0$. Suppose that $y'(t_3)=0$ for some $t_3\geqq t_0$. By $y''\leqq 0$, $y'\geqq 0$, this means that $y'(t)\equiv 0$ for all $t\geqq t_3$, and $y''(t)\equiv 0$. Returning to (5), this would imply $a(t)\equiv 0$ on $[t_3,\infty)$, contradicting the assumption stated at the beginning of this section.

Next, we show that $y(t)$ is eventually positive. Since $x(t)>0$ and $h(t)$ is oscillatory, so $y(t)=x(t)+h(t)$ certainly cannnot be eventually negative, nor can it be identically zero. On the other hand, if $y'(t)\geqq 0$ on $[t_1,\infty)$, then $y(t)$ certainly cannot be oscillatory. Hence, we must have that $y(t)>0$, $t\in[t_4,\infty)$, for $t_4\geqq t_1$. Thus, for simplicity, we conclude that $y(t)>0$, $y'(t)>0$ and $y''(t)\leqq 0$ eventually hold on $[0,\infty)$. We shall repeatedly avail to this conclusion in proving the various results in this paper.

THEOREM 1. *Assume that* (H_1) *holds and that* $h(t)$ *satisfies, in addition,*

$$\liminf_{t\to\infty} t^{-1}h(t)=-\infty \quad \textit{and} \quad \limsup_{t\to\infty} t^{-1}h(t)=+\infty. \tag{H_2}$$

Then (1) *is oscillatory.*

Proof. Under the given hypothesis, we have that $y(t)>0$, $y'(t)>0$ and $y''(t)\leqq 0$, $t\in[t_0,\infty)$ for some $t_0\geqq 0$. This implies that there exists a constant $M>0$ such that $0<y(t)\leqq Mt$ for large t, or

$$\limsup_{t\to\infty} t^{-1}y(t)\leqq M. \tag{6}$$

On the other hand, we have that $y(t)+h(t)=x(t)>0$ for large t, or $y(t)>-h(t)$. Dividing t and taking lim sup on both sides of $y>-h$, we immediately obtain a contradiction by invoking (H_2) to the inequality (6). Here we note that

$$\limsup_{t\to\infty} -t^{-1}h(t)=-\liminf_{t\to\infty} t^{-1}h(t)=+\infty. \tag{7}$$

The other part of hypothesis (H_2) is required when we assume the nonoscillatory solution $x(t)$ to be eventually negative and use a similar equation to (7) in that case.

THEOREM 2. *Assume that* (H_1) *holds and, in addition, that* $h(t)$ *satisfies*

$$\int_0^\infty a(t)f(h_+(t))\,dt=\int_0^\infty a(t)f(h_-(t))\,dt=+\infty \tag{H_3}$$

where $h_+(t)=\max\{h(t),0\}$ *and* $h_-(t)=\min\{h(t),0\}$. *Then* (1) *is oscillatory.*

Proof. As before, we may assume that $y(t)>0$, $y'(t)>0$ and $y''(t)\leqq 0$ on $[t_0,\infty)$. Integrating (5), we obtain

$$y'(t)-y'(t_0)+\int_{t_0}^t a(s)f(y(s)+h(s))\,ds=0. \tag{8}$$

Since $y''\leqq 0$, $\lim_{t\to\infty} y'(t)$ exists and is finite; hence the integral in (8) converges as $t\to\infty$.

We note that for all $t\geqq t_0$, $y(t)+h(t)>h_+(t)$. To see this, we write $y+h=y+h_+-h_-$ and observe that

(i) for $h_+=0$, $y+h=y-h_-=x>0=h_+$, and

(ii) for $h_-=0$, $y+h=y+h_+>h_+$ (since $y>0$).

Since f is nondecreasing, we have that $f(y+h)\geqq f(h_+)$. With $a(t)\geqq 0$, we can estimate as follows:

$$\int_{t_0}^t a(s)f(h_+(s))\,ds\leqq\int_{t_0}^t a(s)f(y+h)\,ds<\infty. \tag{9}$$

By applying (H_3) to (9), we obtain the desired contradiction.

THEOREM 3. *Assume that* (H_1) *holds and, in addition, that* $a(t)\geqq 0$ *with* $\int_0^\infty a(t)\,dt=\infty$, *and* $h(t)$ *satisfies*:

$$|h(t)|\leqq M, \text{ and } \lim_{t\to\infty} h(t) \text{ does not exist.} \tag{H_4}$$

Then the derivative of every solution of (1) *is oscillatory. Furthermore, all unbounded solutions are oscillatory.*

Proof. Let $x(t)$ be a nonoscillatory solution of (1), say $x(t)>0$ on $[t_0,\infty)$. We first show that if $x(t)$ is unbounded, then it must be oscillatory. Following the same argument as before, we may assume that $y(t)>0$, $y'(t)>0$, and $y''(t)\leqq 0$ on $[t_0,\infty)$. By (H_4), $|h(t)|\leqq M$. Suppose that $x(t)$ is unbounded, then $y(t)$ must also be unbounded. Otherwise $x(t)=y(t)-h(t)$ becomes bounded. Let $t_1\geqq t_0$ be such that $y(t_1)=2M$; then $y(t)\geqq 2M$ for all $t\geqq t_1$. Now, $y(t)+h(t)\geqq 2M-h_-(t)\geqq M$, hence $f(y+h)\geqq f(M)$ which, upon substituting in (8) and using $\int_0^\infty a=\infty$, we obtain the desired contradiction.

We now suppose that $x(t)$ is bounded and show that $x'(t)$ must be oscillatory. Since $h(t)$ is bounded, so is $y(t)$. Note that $y'' \leqq 0$ implies that $y'(t) \to 0$ and $y(t) \to c$ as $t \to \infty$, where c is some positive constant. If $x'(t)$ is eventually of one sign, it cannot be $x'(t) < 0$ because $y'(t) + h'(t) < 0$ would contradict $y' > 0$ when we set t equal to any zero of $h'(t)$. On the other hand, if $x'(t) > 0$, then $\lim_{t\to\infty} x(t) = b$ for some positive constant. Hence, $h(t) = x(t) - y(t)$ tends to $b - c$ as $t \to \infty$. This clearly contradicts (H_4). The proof is now complete.

THEOREM 4. *Assume that* (H_1) *holds and* $a(t) \geqq 0$ *with* $\int_0^\infty a = \infty$. *Suppose, in addition, that* $h(t)$ *satisfies*:

(H_5) *There exist sequence* $\{s_n\}, \{\bar{s}_n\}$ *such that* $\lim_{n\to\infty} s_n = \lim_{n\to\infty} \bar{s}_n = \infty$ *as* $n \to \infty$, *and* $h(s_n) = \inf\{h(t): t \geqq s_n\}$ $h(\bar{s}_n) = \sup\{h(t): t \geqq \bar{s}_n\}$.

Then (1) *is oscillatory.*

Proof. Once again we begin with $y(t) > 0$ and $y'(t) > 0$ on $[t_0, \infty)$. Note that there exists n_0 such that $s_{n_0} \geqq t_0$ and for $t \geqq s_{n_0} \geqq t_0$,

$$y(t) + h(t) \geqq y(s_{n_0}) + h(s_{n_0}) = x(s_{n_0}) > 0. \tag{10}$$

Substituting (10) into (8) and using the fact that f is nondecreasing and $\int_0^\infty a = \infty$, we find that $y'(t) \to -\infty$ as $t \to \infty$ which clearly contradicts $y'(t) > 0$ on $[t_0, \infty)$.

COROLLARY 1. *Suppose that* (H_1) *holds,* $a(t) \geqq 0$ *with* $\int_0^\infty a = \infty$, *and* $h(t)$ *satisfies the condition that* $\lim_{t\to\infty} h(t) = 0$ *or* $h(t)$ *is periodic in* t. *Then* (1) *is oscillatory.*

If $h(t) \to 0$ as $t \to \infty$ or $h(t)$ is periodic, then it is easy to see that (H_5) is satisfied; hence Corollary 1 follows from Theorem 4.

3. In this section, we shall consider the so-called superlinear and sublinear equations. In the case of the Emden-Fowler equation (4), this corresponds to $\gamma > 1$ and $0 < \gamma < 1$, respectively. For the more general equations (1) and (2), we said it is *superlinear* if

$$\int_\varepsilon^\infty \frac{dx}{f(x)} < \infty, \quad \int_{-\varepsilon}^{-\infty} \frac{dx}{f(x)} < \infty \quad \text{for any } \varepsilon > 0, \tag{11}$$

and it is *sublinear* if

$$\int_0^\varepsilon \frac{dx}{f(x)} < \infty, \quad \int_0^{-\varepsilon} \frac{dx}{f(x)} < \infty \quad \text{for any } \varepsilon > 0. \tag{12}$$

For the unforced equation (2), in the superlinear case Macki and Wong [20] have extended a well-known result of Atkinson [1] by proving the condition that $a(t) \geqq 0$ and

$$\lim_{T\to\infty} \int_0^T t a(t)\, dt = \infty \tag{13}$$

is necessary and sufficient for the oscillation of (2). Kamenev [10] shows that condition (13) alone suffices for oscillation, if we drop the assumption that $a(t) \geqq 0$. We now show that Theorem 4 can be improved in the superlinear case by relaxing the assumption that $\int_0^\infty a = \infty$ to (13).

THEOREM 5. *Assume that* $h(t)$ *satisfies* (H_1) *and* (H_5), *and* $a(t) \geqq 0$ *satisfying* (13). *Suppose, in addition, that* $f(x)$ *satisfies* (11). *Then* (1) *is oscillatory.*

Proof. We begin with $x(t) > 0$, $y(t) > 0$, $y'(t) > 0$ and $y''(t) \leqq 0$ on $[t_0, \infty)$. By (H_5), there exists n_0 such that for $t \geqq s_{n_0} \geqq t_0$ we have that

$$y(t) + h(t) \geqq y(t) + h(s_{n_0}) = z(t), \tag{14}$$

when $z(t)$ is defined by (14). Since $h(s_{n_0})$ is constant, from (5) we derive

$$z''+a(t)f(z)\leqq y''+a(t)f(y+h)=0 \tag{15}$$

because $z'=y'$ and $z''=y''$. Moreover, for $t\geqq s_{n_0}$,

$$z(t)=y(t)+h(s_{n_0})\geqq y(s_{n_0})+h(s_{n_0})=x(s_{n_0})>0. \tag{16}$$

Thus, we can now reduce the proof to the second order differential inequality (15) and apply the original method of proof for (2) as given in [20] to arrive at a desired contradiction. For the sake of completeness, we adopt a somewhat simpler argument developed in later papers (see, e.g., [19], [30]). By (16), we can divide (15) by $(f(z))^{-1}$ and then multiply through by t to arrive at

$$\frac{tz''}{f(z)}+ta(t)=0. \tag{17}$$

Now, integrate (17) from some $t_1\geqq s_{n_0}$ to t and obtain

$$\int_{t_1}^{t}\frac{sz''}{f(z)}ds+\int_{t_1}^{t}sa(s)\,ds=0. \tag{18}$$

Carrying out the first integral in (18), we have that

$$\int_{t_1}^{t}\frac{sz''}{f(z)}=\frac{tz'(t)}{f(z(t))}-\frac{t_1z'(t_1)}{f(z(t_1))}+\int_{t_1}^{t}\frac{sz'^2f'(z)}{f^2(z)}-\int_{t_1}^{t}\frac{z'}{f(z)}. \tag{19}$$

Since the second integral on (19) above is nonnegative, and we also have that $z'(t)>0$, we can estimate (18) by dropping these two terms as follows:

$$\int_{t_1}^{t}sa(s)\,ds\leqq\frac{t_1z'(t_1)}{f(z(t_1))}+\int_{z(t_1)}^{z(t)}\frac{d\xi}{f(\xi)}. \tag{20}$$

The last integral is finite by (11) and the fact that $z'>0$, so (13) produces the desired contradiction in (20) upon letting t tend to ∞. We remark that in (19) we have loosely used the term $f'(z)$, although differentiability of f has not been assumed. However, since f is nondecreasing we can make the integration by parts into a rigorous proof by approximations. Another approach is to use Lebesgue-Stieltjes integrals.

Next we turn our attention to the sublinear equation and refer to the corresponding results of Belohorec. In the special case of $f(x)=|x|^{\gamma}\operatorname{sgn}x$, $0<\gamma<1$, Belohorec [4] proved the analogue of Atkinson's theorem: the condition that $a(t)\geqq 0$ and

$$\lim_{T\to\infty}\int_0^T t^{\gamma}a(t)\,dt=\infty, \tag{21}$$

is necessary and sufficient for the oscillation of (2). Subsequently, Belohorec [5] also showed that condition (21) also remains sufficient for oscillation without $a(t)\geqq 0$. However, extension to (2) in its more general form, i.e., f satisfying (12), remains elusive. An attempt was made by Coles [6]; however, the additional assumption required on f, which states that there exists a positive constant c such that for all x

$$f'(x)\int_0^x\frac{d\xi}{f(\xi)}\geqq c>0, \tag{22}$$

seems somewhat artificial. On the other hand, Coles indicates at the end of his paper [6] that the natural extension of divergence condition (21) should perhaps be

$$\lim_{T\to\infty}\int_0^T f(t)a(t)\,dt=\infty. \tag{23}$$

In our next result we give an analogue of Theorem 5 in the sublinear case, except that ours is subject to additional conditions on f that f is even, $f(-x)=-f(x)$ and also

$$f(uv)\geqq f(u)f(v) \quad \text{for all } u>0, \text{ and } v \text{ large.} \tag{24}$$

Condition (24) may be referred to as supermultiplicativeness. Aside from rather restricted nature of this assumption, which is clearly satisfied by $f(x)=|x|^{\gamma}\sin x$, $0<\gamma<1$, our result does extend Belohorec's original result [4] when applied to (1) with $g(t)\equiv 0$.

THEOREM 6. *Assume that $h(t)$ satisfies (H_1) and (H_5), and $a(t)\geqq 0$ satisfying (23). Suppose, in addition, that $f(x)$ satisfies (12) and (24). Then (1) is oscillatory.*

Proof. We follow the argument in Theorem 5 up to the second order differential inequality

$$z''(t)+a(t)f(z(t))\leqq 0, \qquad t\geqq t_0, \tag{15}$$

with $z(t)>0$, $z'(t)>0$ and $z''(t)\leqq 0$ on $[t_0,\infty)$. Since $z''\leqq 0$, we have for some $0<\lambda<1$,

$$z(t)-z(t_0)=\int_{t_0}^{t} z'(s)\,ds\geqq z'(t)(t-t_0)\geqq \lambda z'(t)t. \tag{25}$$

Using (25) in (15) above, we obtain

$$z''(t)+a(t)f(\lambda z'(t)t)\leqq 0, \qquad t\geqq t_0$$

which by the supermultiplicative property (24) of f may be further reduced to

$$z''(t)+a(t)f(t)f(\lambda z'(t))\leqq 0. \tag{26}$$

Dividing the above through by $f(\lambda z'(t))$ and integrating, we first note that

$$\int_{t_0}^{t}\frac{z''(s)\,ds}{f(\lambda z'(s))}=\frac{1}{\lambda}\int_{\lambda z'(t_0)}^{\lambda z'(t)}\frac{d\xi}{f(\xi)},$$

from which we can estimate (26) as follows:

$$\int_{t_0}^{t} a(s)f(s)\,ds\leqq\frac{1}{\lambda}\int_{\lambda z'(t)}^{\lambda z'(t_0)}\frac{d\xi}{f(\xi)}<\infty. \tag{27}$$

The last integral in (27) is finite in view of (12) and the fact that z' is nonincreasing. The desired contradiction thus follows by applying (23) to (27).

4. In this section, we first apply the results given in the previous two sections to the specific example:

$$x''+t^{\alpha}|x|^{\gamma}\operatorname{sgn} x=t^{\delta}\sin t \qquad \gamma>0. \tag{4}$$

In (4), $g(t)=t^{\delta}\sin t$. A convenient second primitive $h(t)$ can be chosen with the following asymptotic behaviour:

$$h(t)=t^{\delta}\sin t+O(t^{\delta-1}), \qquad t\to\infty. \tag{28}$$

Applying Theorem 1 to (4), we deduce from (28) that (4) is oscillatory for all $\delta>1$ and for all values of α. Next, we apply Theorem 2 to (4), and again by using (29) in (H_4), we conclude that (4) is oscillatory if $\alpha+\gamma\delta>-1$. So if $\alpha\geqq -1$, $\delta>0$, then hypothesis (H_3) is satisfied and we have oscillation.

Last, we consider Theorem 4 for this specific example and note that for $\delta\leqq 0$, $h(t)=t^{\delta}\sin t$ satisfies (H_5), so we have oscillation of (4) if $\alpha\geqq -1$ and $\delta\leqq 0$. This conclusion is complementary to that determined by Theorem 2 and can be obtained

also by applying the original results of Kartsatos [11], [12]. For the superlinear case, $\gamma > 1$, we can use Theorem 5 to improve the condition on α and conclude oscillation for $\alpha \geqq -2$ and $\delta \leqq 0$. Likewise in the sublinear case, with $0 < \gamma < 1$, we use Theorem 6 to deduce oscillation (4) for $\alpha \geqq -(1+\gamma)$ and $\delta \leqq 0$.

Next, consider the following example:

$$x'' + t^{\alpha} x\, e^{|x|^2} = e^{-t} \sin t, \tag{29}$$

which arises from a certain radial solution of the Klein-Gordon equation in physics (see Atkinson and Peletier [3] and also Wong [31]). This example is also discussed in detail by Rankin [23], but the conditions required on $g(t)$ seem almost artificial. In any case, Rankin's result, when applied to (29), yields oscillation for $\alpha \geqq -1$. Here, $h(t) = \frac{1}{2}e^{-t} \cos t$, which tends to zero as $t \to \infty$. An application of Theorem 5 will result in oscillation of (29) for all $\alpha \geqq -2$ in this superlinear case.

As a third example, we consider the following sublinear equation, with $0 < \gamma < 1$,

$$x'' + t^{\alpha}(1+\sin t)|x|^{\gamma} \operatorname{sgn} x = \sin t\left(1 + \frac{1}{t} - \frac{2}{t^3}\right) + \frac{2\cos t}{t^2}. \tag{30}$$

First note that $h(t) = -1 + (1/t)\sin t$, which satisfies (H_5) (here $h(t)$ is neither periodic nor does it tend to zero), and then apply Theorem 6 to conclude oscillation of (30) for $\alpha \geqq -(1+\gamma)$.

For concluding remarks, we first note that Kartsatos [11], [12] and others stated their results for the more general nth order equations. Kusano and Onose [19] and others extended further to include delay differential equations. Some of our results admit ready extensions to higher order equations and others may not. We hope to return to such a discussion at a later data. Second, our results are based mainly on known techniques for nonlinear oscillations with nonnegative "potential" $a(t)$, and little is known concerning what occurs when $a(t)$ is allowed to change signs even in the linear case. Howard [9] made an extensive investigation using techniques for the linear equation without explicitly requiring $a(t)$ to be nonnegative. Unfortunately, his results do not apply to the many interesting examples when $a(t)$ does change sign. In particular, we are unable to determine whether the following simple linear is oscillatory:

$$x'' + (1 + 2\cos t)x = \sin t.$$

The solution to such a question will represent a major step forward in the study of forced oscillations. Third, we remark that our results depend heavily on the assumption that $f(x)$ is nondecreasing. It will be useful to prove results which do not require $f(x)$ to be monotone.

Returning to Theorem 6, we claimed that in the special case when $g(t) \equiv 0$ (which obviously satisfies (H_5)) it is an extension of Belohorec's result [4] originally proved for $f(x) = |x|^{\gamma} \operatorname{sgn} x$, $0 < \gamma < 1$. However, the supermultiplicative assumption (24) is rather restrictive and seems no better than Coles' condition (22). We believe that such an extension remains valid without the additional assumption (24), and in any case, one should expect it to be replaced by some less restrictive conditions. Finally, we began this paper by referring to a problem posed nearly twenty years ago, on the oscillation of (1) subject to a periodic forcing term. The original question stated in [29] was in fact (1) with $g(t) = \sin t$, i.e., a periodic function with zero mean value. The same question can now be extended by requiring $g(t)$ to be only an almost periodic function with mean value zero.

In closing, we refer the reader to the survey article by Kartsatos [13] and two others by the author [30], [32], where additional references and other open problems may be found.

RECURSIVELY GENERATED POLYNOMIALS AND GERONIMUS' VERSION OF ORTHOGONALITY ON A CONTOUR*

JOHN W. JAYNE†

Abstract. Let $\{p_n\}$ be a sequence of polynomials generated by the three-term recurrence $p_0=1$, $p_1=z+b_0$, $p_{n+1}=(z+b_n)p_n-c_np_{n-1}$, $n\geqq 1$. Using only the hypothesis that $\{b_n\}$ and $\{c_n\}$ are bounded complex sequences (with $c_n\neq 0$), we show by constructing a weight function as a convergent Laurent series—with coefficients given explicitly in terms of b_n and c_n—that the p_n are orthogonal on a contour in the sense that Geronimus describes (and that the Bessel polynomials exemplify). We thus obtain an elementary approach to this kind of orthogonality and provide a construction of the weight function which is an alternative to the continued fraction representation discussed by Askey and Ismail.

Key words. orthogonal polynomials, three-term recurrence relation, orthogonality on a contour

AMS(MOS) subject classifications. 33A65, 30E05

1. Introduction. In order to establish a frame of reference for this paper we review several points concerning orthogonal polynomials. Let Ψ be a real-valued, nondecreasing function on $(-\infty,\infty)$, all of whose moments $\int_{-\infty}^{\infty}x^n\,d\Psi$ exist. A sequence of polynomials $\{p_n\}$—assumed without loss of generality to be monic—is orthogonal (on the real line) with respect to Ψ if

$$\int_{-\infty}^{\infty}p_n(x)p_m(x)\,d\Psi(x)=\begin{cases}0, & m\neq n,\\ h_n>0, & m=n\geqq 0.\end{cases}\tag{1}$$

It has long been known that a sequence orthogonal in this sense satisfies a three-term recurrence relation

$$\begin{aligned}&p_0=1,\\ &p_1=x+b_0,\\ &p_{n+1}=(x+b_n)p_n-c_np_{n-1},\qquad n\geqq 1,\end{aligned}\tag{2}$$

where b_n is real and $c_n>0$. An early version of a converse to this statement is usually attributed to Favard. In its present form, which is due to the development of certain representation theorems for moment functionals, it runs as follows: if $\{p_n\}$ is generated by (2) where $\{b_n\}$ and $\{c_n\}$ are arbitrary *complex* sequences with $c_n\neq 0$, then there exists a function Ψ of bounded variation on $(-\infty,\infty)$ such that (1) holds, with $h_n\neq 0$. Furthermore Ψ can be chosen to be real-valued if and only if $\{b_n\}$ and $\{c_n\}$ are real sequences; Ψ is nondecreasing with infinite spectrum if and only if b_n is real, $c_n>0$. For a complete discussion see Chihara [2].

The concept of orthogonality in (1) is of course not the only one possible. Another for which (2) also holds (with complex coefficients and $c_n\neq 0$) is that of orthogonality on a simple closed curve C, as discussed by Geronimus [3]: instead of the distribution Ψ there is assumed to be a weight function w having one or more singularities inside C and such that

$$(1/2\pi i)\int_C p_n(z)p_m(z)w(z)\,dz=\begin{cases}0, & m\neq n,\\ h_n\neq 0, & m=n\geqq 0.\end{cases}\tag{3}$$

Perhaps the best known example is the sequence of Bessel polynomials, for which w has an essential singularity at the origin [4]. However, the Bessel polynomials are not

* Received by the editors March 7, 1986; accepted for publication May 18, 1987.
† Department of Mathematics, University of Tennessee, Chattanooga, Tennessee 37403.

unique in having this type of orthogonality: Geronimus showed that a sequence of polynomials which is orthogonal in the sense of (1) on a finite interval is also orthogonal in the sense of (3).

A problem to which a great deal of research has been devoted is that of recovering the distribution function Ψ from the recurrence (2). In [1] Askey and Ismail treat this problem by showing that under certain conditions w exists as a continued fraction obtainable from (2), and then they derive a fundamental relation between w and Ψ from which Ψ may be determined once w is found. Motivated by the example of the Bessel polynomials we show in this paper that w can be obtained directly from (2) as a convergent Laurent series, with coefficients given by explicit formulas in terms of b_n and c_n. Our only hypothesis is that $\{b_n\}$ and $\{c_n\}$ are bounded complex sequences with $c_n \neq 0$—we do not make any use of the theory of continued fractions (nor refer to orthogonality on the real line). Whether this approach would be helpful in recovering Ψ remains to be seen; it does provide an elementary proof that many families of recursively generated polynomials are orthogonal in the sense of (3), itself a fact of considerable interest.

2. Preliminaries: formal construction of the weight function. We start with the recurrence (2), in which b_n and c_n are taken to be complex, with $c_n \neq 0$. We assume for the present that (3) holds and furthermore that w has the representation

$$w(z) = \sum_{j=1}^{\infty} w_j z^{-j}, \qquad w_1 = 1 \tag{4}$$

for all z outside some circle $|z| = R$ lying interior to C. Our immediate task is to calculate the coefficients w_j in (4). One way to approach this problem is the following. Let the coefficient of z^k in p_n be denoted by $a(n, k)$ for $n \geqq 0$, $0 \leqq k \leqq n$ (note that $a(n, n) = 1$ since the polynomials are monic) and set $a(n, k) = 0$ if $k > n$. Since $p_0 = 1$ it follows from (3) that

$$(1/2\pi i) \int_C p_n(z) w(z)\, dz = \begin{cases} 0, & n \geqq 1, \\ h_0 \neq 0, & n = 0. \end{cases} \tag{5}$$

Inserting (4) and the representation

$$p_n(z) = \sum_{k=0}^{n} a(n, k) z^k$$

into (5) and integrating term by term yields

$$\begin{aligned} w_1 &= h_0 = 1 \\ w_2 &= -a(1, 0) w_1 \\ w_3 &= -a(2, 0) w_1 - a(2, 1) w_2 \\ &\vdots \\ w_{n+1} &= -\sum_{k=1}^{n} a(n, k-1) w_k, \qquad n \geqq 1. \end{aligned} \tag{6}$$

We can thus compute all the coefficients w_j from (6). Recall that the moment μ_n of the weight function w is given by

$$\mu_n = (1/2\pi i) \int_C z^n w(z)\, dz,$$

so if w has the representation (4) then

$$\mu_n = (1/2\pi i)\int_C \sum_{j=1}^{\infty} w_j z^{n-j}\,dz = w_{n+1}, \qquad n \geqq 0.$$

But we can write z^n as a linear combination of the polynomials $p_0, p_1, \cdots, p_n$ generated by (2)

$$z^n = \sum_{k=0}^{n} \gamma(k, n)p_k(z) \tag{7}$$

so that we also have

$$\begin{aligned} w_{n+1} = \mu_n &= (1/2\pi i)\int_C z^n w(z)\,dz \\ &= (1/2\pi i)\int_C \sum_{k=0}^{n} \gamma(k, n)p_k(z)w(z)\,dz \\ &= \gamma(0, n), \qquad n \geqq 0. \end{aligned} \tag{8}$$

It is this representation, rather than (6), that will be used to derive our results, and in doing so we shall find a way to calculate *all* the $\gamma(k, n)$ (cf. [5, pp. 45ff] for related calculations).

So far, by assuming the orthogonality expressed in (3) and the existence of a weight function w given by (4), we have shown that the coefficients w_j are given by (6) or (8). If we now take (8) as our starting point and formally construct the series (4) by letting $w_{n+1} = \gamma(0, n)$ for $n \geqq 0$ we of course have no a priori guarantee that it will converge (the convergence question being our main concern), but when it does the following theorem applies (cf. the proof of Favard's Theorem [2, pp. 21-22]).

THEOREM 1. *Let* $\{p_n\}$ *be generated by* (2) *and suppose the series* (4) *is constructed by setting* $w_{n+1} = \gamma(0, n)$ *for* $n \geqq 0$. *If this series converges for all* z *outside some circle* $|z| = R$ *and* C *is any simple closed curve having* $|z| = R$ *in its interior, then*

$$(1/2\pi i)\int_C p_n(z)p_m(z)w(z)\,dz = \begin{cases} 0, & m \neq n, \\ 1, & m = n = 0, \\ \prod_{j=1}^{n} c_j, & m = n \geqq 1. \end{cases} \tag{9}$$

Proof. The case $m = n = 0$ is clear, so assume $n \geqq 1$. Then it suffices to show that

$$(1/2\pi i)\int_C z^m p_n(z)w(z)\,dz = \begin{cases} 0, & 0 \leqq m < n, \\ \prod_{j=1}^{n} c_j, & m = n \geqq 1. \end{cases}$$

If $m = 0$ the result follows from the way w was constructed; if $m = 1$ then, since (2) implies

$$zp_n(z) = p_{n+1}(z) - b_n p_n(z) + c_n p_{n-1}(z),$$

we have

$$(1/2\pi i)\int_C zp_n(z)w(z)\,dz = (c_n/2\pi i)\int_C p_{n-1}(z)w(z)\,dz = \begin{cases} 0, & n > 1, \\ c_1, & n = 1. \end{cases}$$

The conclusion follows by induction.

In view of Theorem 1 it is clear that, given a sequence $\{p_n\}$ generated by (2), we can establish orthogonality in the sense of (3) *and* simultaneously exhibit the weight function by simply constructing the series (4) and proving it converges outside some circle $|z| = R$. Since we intend to establish this convergence by assuming that $\{b_n\}$ and $\{c_n\}$ are bounded complex sequences, we need a formula for w_j explicitly in terms of b_n and c_n, and we shall obtain it from (8) with the aid of the following lemma.

LEMMA 1. *Let* $\{p_n\}$ *be generated by* (2), *and consider the representation* (7)

$$z^n = \sum_{k=0}^{n} \gamma(k, n) p_k(z).$$

With the understanding that $\gamma(i, j) = 0$ *if* $i > j$ *or* $i < 0$, *we have*

$$\gamma(k, n+1) = \gamma(k-1, n) - b_k \gamma(k, n) + c_{k+1} \gamma(k+1, n), \tag{10}$$

valid for $0 \leqq k \leqq n+1$, $n \geqq 0$. *In particular,*

$$\gamma(n, n) = 1,$$

$$\gamma(0, n+1) = -b_0 \gamma(0, n) + c_1 \gamma(1, n),$$

$$\gamma(n, n+1) = \gamma(n-1, n) - b_n, \qquad n \geqq 0.$$

Proof. Because of (7) we have

$$\begin{aligned}
z^{n+1} &= \sum_{k=0}^{n} \gamma(k, n) z p_k(z) \\
&= \sum_{k=1}^{n} \gamma(k, n)[p_{k+1}(z) - b_k p_k(z) + c_k p_{k-1}(z)] + \gamma(0, n)[p_1(z) - b_0] \\
&= \sum_{j=2}^{n+1} \gamma(j-1, n) p_j(z) - \sum_{j=1}^{n} b_j \gamma(j, n) p_j(z) + \sum_{j=0}^{n-1} c_{j+1} \gamma(j+1, n) p_j(z) \\
&\quad + \gamma(0, n) p_1(z) - \gamma(0, n) b_0 p_0(z) \\
&= \gamma(n, n) p_{n+1}(z) + [\gamma(n-1, n) - b_n \gamma(n, n)] p_n(z) \\
&\quad + \sum_{j=1}^{n-1} [\gamma(j-1, n) - b_j \gamma(j, n) + c_{j+1} \gamma(j+1, n)] p_j(z) \\
&\quad + [-b_0 \gamma(0, n) + c_1 \gamma(1, n)] p_0(z).
\end{aligned}$$

But z^{n+1} also is given by

$$z^{n+1} = \sum_{j=0}^{n+1} \gamma(j, n+1) p_j(z),$$

so the conclusion follows by equating the coefficients of $p_j(z)$ in these two expressions for z^{n+1}.

Through (8) and repeated use of Lemma 1 (i.e., by solving the difference equation (10)) we can now determine the w_j in terms of b_n and c_n. Initially the results appear very involved, but after displaying the first few $\gamma(k, n)$ and introducing suitable notation, we shall be able to guess a formula for $\gamma(k, n)$, prove its validity, and then use it to prove convergence of the series $\sum w_j z^{-j}$.

We begin by making a few calculations using (10):

$$w_1=\gamma(0,0)=1, \qquad \gamma(1,1)=1,$$
$$w_2=\gamma(0,1)=-b_0, \qquad \gamma(1,2)=-b_0-b_1, \qquad \gamma(2,2)=1,$$
$$w_3=\gamma(0,2)=b_0^2+c_1, \qquad \gamma(1,3)=b_0^2+b_0b_1+b_1^2+c_1+c_2,$$
$$w_4=\gamma(0,3)=-b_0^3-2b_0c_1-b_1c_1, \qquad \gamma(2,3)=-b_0-b_1-b_2, \qquad \gamma(3,3)=1,$$

etc. Rewriting these as iterated sums, cumbersome though it may seem at first, we take a step toward recognizing the general pattern:

$$\begin{aligned}
&w_2=\gamma(0,1)=-\sum_{j_1=0}^{0} b_{j_1},\\
&w_3=\gamma(0,2)=\sum_{j_1=0}^{0}\sum_{j_2=0}^{j_1} b_{j_1}b_{j_2}+\sum_{j_1=1}^{1} c_{j_1}, \qquad \gamma(1,2)=-\sum_{j_1=0}^{1} b_{j_1},\\
&w_4=\gamma(0,3)=-\sum_{j_1=0}^{0}\sum_{j_2=0}^{j_1}\sum_{j_3=0}^{j_2} b_{j_1}b_{j_2}b_{j_3}-\sum_{j_1=1}^{1}\sum_{j_2=0}^{j_1} c_{j_1}b_{j_2}-\sum_{j_1=0}^{0}\sum_{j_2=1}^{j_1+1} b_{j_1}c_{j_2},\\
&\gamma(1,3)=\sum_{j_1=0}^{1}\sum_{j_2=0}^{j_1} b_{j_1}b_{j_2}+\sum_{j_1=1}^{2} c_{j_1}, \qquad \gamma(2,3)=-\sum_{j_1=0}^{2} b_{j_1}.
\end{aligned} \tag{11}$$

We add one more for good measure:

$$\begin{aligned}
w_5=\gamma(0,4)=&\sum_{j_1=0}^{0}\sum_{j_2=0}^{j_1}\sum_{j_3=0}^{j_2}\sum_{j_4=0}^{j_3} b_{j_1}b_{j_2}b_{j_3}b_{j_4}+\sum_{j_1=1}^{1}\sum_{j_2=0}^{j_1}\sum_{j_3=0}^{j_2} c_{j_1}b_{j_2}b_{j_3}\\
&+\sum_{j_1=0}^{0}\sum_{j_2=1}^{j_1+1}\sum_{j_3=0}^{j_2} b_{j_1}c_{j_2}b_{j_3}+\sum_{j_1=0}^{0}\sum_{j_2=0}^{j_1}\sum_{j_3=1}^{j_2+1} b_{j_1}b_{j_2}c_{j_3}+\sum_{j_1=1}^{1}\sum_{j_2=1}^{j_1+1} c_{j_1}c_{j_2}.
\end{aligned}$$

The pattern developing here can be brought out more clearly by introducing the following notation. Let $I(k,q)$ denote the set of all possible ordered k-tuples $\mathbf{p}_k=(p_1,p_2,\cdots,p_k)$ consisting of q ones and $k-q$ zeros, where $k\geqq 1$ and $0\leqq q\leqq k$ (e.g., $I(3,1)=\{(1,0,0),(0,1,0),(0,0,1)\}$). For fixed integers $N\geqq 0$, $k\geqq 1$ and fixed $\mathbf{p}_k\in I(k,q)$, let $S(N,\mathbf{p}_k)$ denote the sum

$$S(N,\mathbf{p}_k)=\sum_{j_1=p_1}^{N+p_1}\sum_{j_2=p_2}^{j_1+p_2}\sum_{j_3=p_3}^{j_2+p_3}\cdots\sum_{j_k=p_k}^{j_{k-1}+p_k}\left(\prod_{i=1}^{k} c_{j_i}^{p_i}b_{j_i}^{1-p_i}\right) \tag{12}$$

and let $S(N,\mathbf{p}_0)=1$. Furthermore, for fixed N, k and q (with $0\leqq q\leqq k$) let $\sum_{\mathbf{p}_k\in I(k,q)} S(N,\mathbf{p}_k)$ denote the sum of all the $S(N,\mathbf{p}_k)$ having $\mathbf{p}_k$ in the index set $I(k,q)$; set $\sum_{\mathbf{p}_k\in I(k,q)} S(N,\mathbf{p}_k)=0$ if $q>k$ or $N<0$. We also agree to set $\sum_{\mathbf{p}_k\in I(k,q)} S(N,\mathbf{p}_k)=1$ if $k=0$.

By way of examples we note that

$$\sum_{\mathbf{p}_2\in I(2,1)} S(N,\mathbf{p}_2)=\sum_{j_1=0}^{N}\sum_{j_2=1}^{j_1+1} b_{j_1}c_{j_2}+\sum_{j_1=1}^{N+1}\sum_{j_2=0}^{j_1} c_{j_1}b_{j_2}$$

(since $I(2,1)=\{(0,1),(1,0)\}$), and that sums over the index sets $I(k,0)$, $I(k,k)$ actually involve only one iterated sum each

$$\sum_{\mathbf{p}_k\in I(k,0)} S(N,\mathbf{p}_k)=\sum_{j_1=0}^{N}\sum_{j_2=0}^{j_1}\sum_{j_3=0}^{j_2}\cdots\sum_{j_k=0}^{j_{k-1}} b_{j_1}b_{j_2}b_{j_3}\cdots b_{j_k},$$
$$\sum_{\mathbf{p}_k\in I(k,k)} S(N,\mathbf{p}_k)=\sum_{j_1=1}^{N+1}\sum_{j_2=1}^{j_1+1}\sum_{j_3=1}^{j_2+1}\cdots\sum_{j_k=1}^{j_{k-1}+1} c_{j_1}c_{j_2}c_{j_3}\cdots c_{j_k}.$$

Every sum appearing in the representations in (11) for $\gamma(0,1)$, $\gamma(0,2)$, $\gamma(1,2)$, $\gamma(0,3)$, $\gamma(1,3)$, $\gamma(2,3)$, and $\gamma(0,4)$ has the form (12), and consequently we can now

write these as

$$w_2 = \gamma(0,1) = -\sum_{k=1}^{1} \sum_{\mathbf{p}_k \in I(k,1-k)} S(0,\mathbf{p}_k),$$

$$w_3 = \gamma(0,2) = \sum_{\mathbf{p}_2 \in I(2,0)} S(0,\mathbf{p}_2) + \sum_{\mathbf{p}_1 \in I(1,1)} S(0,\mathbf{p}_1) = \sum_{k=1}^{2} \sum_{\mathbf{p}_k \in I(k,2-k)} S(0,\mathbf{p}_k),$$

$$\gamma(1,2) = -\sum_{k=1}^{1} \sum_{\mathbf{p}_k \in I(k,1-k)} S(1,\mathbf{p}_k),$$

$$w_4 = \gamma(0,3) = -\sum_{\mathbf{p}_3 \in I(3,0)} S(0,\mathbf{p}_3) - \sum_{\mathbf{p}_2 \in I(2,1)} S(0,\mathbf{p}_2) = -\sum_{k=2}^{3} \sum_{\mathbf{p}_k \in I(k,3-k)} S(0,\mathbf{p}_k), \tag{13}$$

$$\gamma(1,3) = \sum_{\mathbf{p}_2 \in I(2,0)} S(0,\mathbf{p}_2) + \sum_{\mathbf{p}_1 \in I(1,1)} S(0,\mathbf{p}_1) = \sum_{k=1}^{2} \sum_{\mathbf{p}_k \in I(k,2-k)} S(1,\mathbf{p}_k),$$

$$\gamma(2,3) = -\sum_{k=1}^{1} \sum_{\mathbf{p}_k \in I(k,1-k)} S(2,\mathbf{p}_k),$$

$$w_5 = \gamma(0,4) = \sum_{\mathbf{p}_4 \in I(4,0)} S(0,\mathbf{p}_4) + \sum_{\mathbf{p}_3 \in I(3,1)} S(0,\mathbf{p}_3) + \sum_{\mathbf{p}_2 \in I(2,2)} S(0,\mathbf{p}_2)$$

$$= \sum_{k=2}^{4} \sum_{\mathbf{p}_k \in I(k,4-k)} S(0,\mathbf{p}_k).$$

These representations (and additional ones which fit the developing pattern here but which we omit) form the basis for conjecturing that

$$\gamma(j,M) = (-1)^{j+M} \sum_{k=M-j-[(M-j)/2]}^{M-j} \sum_{\mathbf{p}_k \in I(k,M-j-k)} S(j,\mathbf{p}_k),$$

where $[(M-j)/2]$ is the greatest integer less than or equal to $(M-j)/2$. This will be a key result (Theorem 2), but in order to prove it we need to investigate $S(N,\mathbf{p}_k)$ in more detail. As already noted above, for convenience we set

$$\sum_{\mathbf{p}_k \in I(k,q)} S(N,\mathbf{p}_k) = \begin{cases} 1 & \text{if } k=q=0, \quad N \geqq 0 \\ 0 & \text{if either } N<0, \text{ or } q>k, \text{ or } q<0. \end{cases} \tag{14}$$

The property of the sum $\sum_{\mathbf{p}_k \in I(k,q)} S(N,\mathbf{p}_k)$ which will be needed most is furnished in the following lemma.

LEMMA 2. *For all integers* $N \geqq 0$, $k \geqq 1$, $m \geqq 1$,

$$\sum_{\mathbf{p}_m \in I(m,k-m)} S(N,\mathbf{p}_m) = \sum_{\mathbf{p}_m \in I(m,k-m)} S(N-1,\mathbf{p}_m) + b_N \sum_{\mathbf{p}_{m-1} \in I(m-1,k-m)} S(N,\mathbf{p}_{m-1}) + c_{N+1} \sum_{\mathbf{p}_{m-1} \in I(m-1,k-m-1)} S(N+1,\mathbf{p}_{m-1}). \tag{15}$$

Proof. In view of (14) it is clear that (15) is trivially true whenever $k<m$ or $k>2m$, so suppose from the start that $k \leqq 2m \leqq 2k$. It then follows from (12) that for $N \geqq 1$

$$\begin{aligned} S(N,\mathbf{p}_m) &= \sum_{j_1=p_1}^{N+p_1} \sum_{j_2=p_2}^{j_1+p_2} \sum_{j_3=p_3}^{j_2+p_3} \cdots \sum_{j_m=p_m}^{j_{m-1}+p_m} \left(\prod_{i=1}^{m} c_{j_i}^{p_i} b_{j_i}^{1-p_i} \right) \\ &= \sum_{j_1=p_1}^{N+p_1-1} \sum_{j_2=p_2}^{j_1+p_2} \sum_{j_3=p_3}^{j_2+p_3} \cdots \sum_{j_m=p_m}^{j_{m-1}+p_m} \left(\prod_{i=1}^{m} c_{j_i}^{p_i} b_{j_i}^{1-p_i} \right) \\ &\quad + [(c_{N+p_1})^{p_1} (b_{N+p_1})^{1-p_1}] \sum_{j_2=p_2}^{N+p_1+p_2} \sum_{j_3=p_3}^{j_2+p_3} \cdots \sum_{j_m=p_m}^{j_{m-1}+p_m} \left(\prod_{i=2}^{m} c_{j_i}^{p_i} b_{j_i}^{1-p_i} \right) \\ &= S(N-1,\mathbf{p}_m) + [(c_{N+p_1})^{p_1} (b_{N+p_1})^{1-p_1}] S(N+p_1,\mathbf{p}_{m-1}) \end{aligned} \tag{16}$$

(where $\mathbf{p}_{m-1}=(p_2, p_3, \cdots, p_m)$), and thus summing over the index set $I(m, k-m)$ yields

$$(17)\qquad \sum_{\mathbf{p}_m\in I(m,k-m)} S(N,\mathbf{p}_m)=\sum_{\mathbf{p}_m\in I(m,k-m)} S(N-1,\mathbf{p}_m) + \sum_{\mathbf{p}_m\in I(m,k-m)} [(c_{N+p_1})^{p_1}(b_{N+p_1})^{1-p_1}]S(N+p_1,\mathbf{p}_{m-1}).$$

Now $\mathbf{p}_m=(p_1, p_2, \cdots, p_m)=(p_1, \mathbf{p}_{m-1})$ is an ordered m-tuple having $k-m$ ones and $m-(k-m)=2m-k$ zeros. Among the $\binom{m}{k-m}$ possible m-tuples of this type $\binom{m-1}{k-m-1}$ will have $p_1=1$; i.e., $\mathbf{p}_{m-1}$ is an ordered $(m-1)$-tuple having $k-m-1$ ones and $2m-k$ zeros, and consequently $\mathbf{p}_{m-1}\in I(m-1, k-m-1)$. The remaining $\binom{m-1}{k-m}$ ordered m-tuples will have $p_1=0$; and for these remaining ones $\mathbf{p}_{m-1}$ is an ordered $(m-1)$-tuple having $k-m$ ones and $2m-k-1$ zeros, so that $\mathbf{p}_{m-1}\in I(m-1, k-m)$. We may thus rewrite the second sum on the right of (17) as

$$(18)\qquad \sum_{\mathbf{p}_m\in I(m,k-m)} [(c_{N+p_1})^{p_1}(b_{N+p_1})^{1-p_1}]S(N+p_1,\mathbf{p}_{m-1}) = \sum_{\mathbf{p}_{m-1}\in I(m-1,k-m)} b_N S(N,\mathbf{p}_{m-1}) + \sum_{\mathbf{p}_{m-1}\in I(m-1,k-m-1)} c_{N+1}S(N+1,\mathbf{p}_{m-1})$$

which completes the proof for $N\geqq 1$. If $N=0$, the equality in (16) takes the form

$$S(0,\mathbf{p}_m)=[(c_{0+p_1})^{p_1}(b_{0+p_1})^{1-p_1}]S(0+p_1,\mathbf{p}_{m-1})$$

and the conclusion still holds, since $\sum_{\mathbf{p}_m\in I(m,k-m)} S(-1,\mathbf{p}_m)=0$, by (14).

In the recurrence relation (2) the case with constant coefficients

$$(19)\qquad b_n=b\geqq 0,\quad n\geqq 0,\quad c_1=2c>0,\quad c_n=c>0,\quad n\geqq 2$$

turns out to be especially important because it will provide a very nice bound for w_j, leading to convergence for $\sum w_j z^{-j}$. The polynomials generated by this special case are just the monic Chebyshev polynomials of the first kind, orthogonal on the interval $(-b-2\sqrt{c}, -b+2\sqrt{c})$. For these Chebyshev polynomials the sum $\sum_{\mathbf{p}_k\in I(k,q)} S(N,\mathbf{p}_k)$ takes on the following form.

LEMMA 3. *Let b_n, c_n in the recurrence relation* (2) *be the constants prescribed in* (19). *Then for all integers $M\geqq 0$ and all integers j, m satisfying $0\leqq j\leqq M$, $M-j-[(M-j)/2]\leqq m\leqq M-j$,*

$$(20)\qquad \sum_{\mathbf{p}_m\in I(m,M-j-m)} S(j,\mathbf{p}_m)=\binom{M}{2M-j-2m}\binom{2M-j-2m}{M-m} b^{-M+j+2m}c^{M-j-m}.$$

Proof. The proof is by induction on M, using (15) in Lemma 2 (the result (20) was initially guessed by doing an inordinate amount of elementary algebra). It is easy to check that (20) holds for $M=0$, $M=1$. Assume then that it holds for some integer $K>0$, with j, m satisfying $0\leqq j\leqq K$ and $K-j-[(K-j)/2]\leqq m\leqq K-j$. Then by Lemma 2

$$\sum_{\mathbf{p}_m\in I(m,K+1-j-m)} S(j,\mathbf{p}_m)=\sum_{\mathbf{p}_m\in I(m,K+1-j-m)} S(j-1,\mathbf{p}_m) + b\sum_{\mathbf{p}_{m-1}\in I(m-1,K+1-j-m)} S(j,\mathbf{p}_{m-1}) + c\sum_{\mathbf{p}_{m-1}\in I(m-1,K-j-m)} S(j+1,\mathbf{p}_{m-1}).$$

By the induction hypothesis the three sums on the right are, respectively,

$$\sum_{\mathbf{p}_m\in I(m,K+1-j-m)} S(j-1,\mathbf{p}_m)=\sum_{\mathbf{p}_m\in I(m,K-(j-1)-m)} S(j-1,\mathbf{p}_m) = \binom{K}{2K-(j-1)-2m}\binom{2K-(j-1)-2m}{K-m} b^{-K+(j-1)+2m}c^{K-(j-1)-m},$$

$$b \sum_{\mathbf{p}_{m-1} \in I(m-1,\, K+1-j-m)} S(j, \mathbf{p}_{m-1}) = b \sum_{\mathbf{p}_{m-1} \in I(m-1,\, K-j-(m-1))} S(j, \mathbf{p}_{m-1})$$

$$= b \binom{K}{2K-j-2(m-1)} \binom{2K-j-2(m-1)}{K-(m-1)} b^{-K+j+2(m-1)} c^{K-j-(m-1)},$$

$$c \sum_{\mathbf{p}_{m-1} \in I(m-1,\, K-j-m)} S(j+1, \mathbf{p}_{m-1}) = c \sum_{\mathbf{p}_{m-1} \in I(m-1,\, K-(j+1)-(m-1))} S(j+1, \mathbf{p}_{m-1})$$

$$= c \binom{K}{2K-(j+1)-2(m-1)}$$

$$\cdot \binom{2K-(j+1)-2(m-1)}{K-(m-1)} b^{-K+(j+1)+2(m-1)} c^{K-(j+1)-(m-1)},$$

and thus

$$\sum_{\mathbf{p}_m \in I(m,\, K+1-j-m)} S(j, \mathbf{p}_m)$$

$$= \left[\binom{K}{2K+1-j-2m} \binom{2K+1-j-2m}{K-m} + \binom{K}{2K+2-j-2m} \binom{2K+2-j-2m}{K+1-m} \right.$$

$$\left. + \binom{K}{2K+1-j-2m} \binom{2K+1-j-2m}{K+1-m} \right] b^{-(K+1)+j+2m} c^{(K+1)-j-m}.$$

But the first and third terms in the square brackets yield

$$\binom{K}{2K+1-j-2m} \binom{2K+1-j-2m}{K-m} + \binom{K}{2K+1-j-2m} \binom{2K+1-j-2m}{K+1-m}$$

$$= \binom{K}{2K+1-j-2m} \binom{2K+2-j-2m}{K+1-m}$$

and

$$\binom{K}{2K+1-j-2m} \binom{2K+2-j-2m}{K+1-m} + \binom{K}{2K+2-j-2m} \binom{2K+2-j-2m}{K+1-m}$$

$$= \binom{K+1}{2K+2-j-2m} \binom{2K+2-j-2m}{K+1-m},$$

and consequently (20) holds for $M = K+1$.

We are now in position to prove the validity of our conjecture about $\gamma(j, M)$ and then to prove a convergence theorem for $\sum w_j z^{-j}$.

THEOREM 2. *For each integer $M \geqq 0$ and all integers j satisfying $0 \leqq j \leqq M$*

$$\gamma(j, M) = (-1)^{j+M} \sum_{k=M-j-[(M-j)/2]}^{M-j} \sum_{\mathbf{p}_k \in I(k,\, M-j-k)} S(j, \mathbf{p}_k). \tag{21}$$

Proof. We have already seen in (13) that the formula is valid for $\gamma(0, 0), \cdots, \gamma(1, 2)$ and $\gamma(2, 2)$. So assume as induction hypothesis that for some $K > 0$ and all j satisfying $0 \leqq j \leqq K$, (21) is valid for $\gamma(j, K)$ and consider $\gamma(j, K+1)$. From (10) in Lemma 1 and the induction hypothesis we have

$$\begin{aligned}\gamma(j, K+1) &= \gamma(j-1, K) - b_j\gamma(j, K) + c_{j+1}\gamma(j+1, K)\\ &= (-1)^{j-1+K} \sum_{k=K-(j-1)-[(K-(j-1))/2]}^{K-(j-1)} \sum_{\mathbf{p}_k \in I(k, K-(j-1)-k)} S(j-1, \mathbf{p}_k)\\ &\quad - b_j(-1)^{j+K} \sum_{k=K-j-[(K-j)/2]}^{K-j} \sum_{\mathbf{p}_k \in I(k, K-j-k)} S(j, \mathbf{p}_k)\\ &\quad + c_{j+1}(-1)^{j+1+K} \sum_{k=K-(j+1)-[(K-(j+1))/2]}^{K-(j+1)} \sum_{\mathbf{p}_k \in I(k, K-(j+1)-k)} S(j+1, \mathbf{p}_k).\end{aligned} \tag{22}$$

A change of index in the first double sum on the right of (22) converts it to

$$\sum_{k=K-j-[(K-(j-1))/2]}^{K-j} \sum_{\mathbf{p}_{k+1} \in I(k+1, K-j-k)} S(j-1, \mathbf{p}_{k+1}).$$

By using (14) and the fact that the definition of greatest integer function implies

$$K-j-[(K-(j-1))/2] = K-(j+1)-[(K-(j+1))/2] \leqq K-j-[(K-j)/2]$$

we can start all three double sums on the right of (22) at $k = K-j-[(K-(j-1))/2]$, and end all three at $k = K-j$, so that (22) becomes

$$\begin{aligned}\gamma(j, K+1) = (-1)^{j+K+1} \sum_{k=K-j-[(K-(j-1))/2]}^{K-j} \Bigg[&\sum_{\mathbf{p}_{k+1} \in I(k+1, K-j-k)} S(j-1, \mathbf{p}_{k+1})\\ &+ b_j \sum_{\mathbf{p}_k \in I(k, K-j-k)} S(j, \mathbf{p}_k)\\ &+ c_{j+1} \sum_{\mathbf{p}_k \in I(k, K-(j+1)-k)} S(j+1, \mathbf{p}_k) \Bigg].\end{aligned} \tag{23}$$

But this result, by Lemma 2, is

$$\gamma(j, K+1) = (-1)^{j+K+1} \sum_{k=K-j-[(K-(j-1))/2]}^{K-j} \sum_{\mathbf{p}_{k+1} \in I(k+1, K-j-k)} S(j, \mathbf{p}_{k+1}),$$

or, letting $k = i-1$,

$$\gamma(j, K+1) = (-1)^{j+K+1} \sum_{i=K-j+1-[(K-j+1)/2]}^{K-j} \sum_{\mathbf{p}_i \in I(i, K+1-j-i)} S(j, \mathbf{p}_i),$$

valid for $0 \leqq j \leqq K$. The case $j = K+1$ obviously yields $\gamma(K+1, K+1) = 1$, and thus (21) holds for $K+1$ whenever it holds for K.

The sought-for formula for w_{n+1} in terms of b_n and c_n is now available from (21).

COROLLARY 1. *The coefficient w_{n+1} for the Laurent series* (4) *is given by*

$$w_{n+1} = \gamma(0, n) = (-1)^n \sum_{k=n-[n/2]}^{n} \sum_{\mathbf{p}_k \in I(k, n-k)} S(0, \mathbf{p}_k), \qquad n \geqq 0. \tag{24}$$

Applying Lemma 3 to (24) yields the following.

COROLLARY 2. *If b_n and c_n have the constant form* (19), (*i.e., the polynomials are the Chebyshev polynomials of the first kind*) *then denoting the coefficient in this special case by $\gamma_T(0, n)$ we have*

$$\gamma_T(0, n) = (-1)^n \sum_{k=n-[n/2]}^{n} \binom{n}{2n-2k} \binom{2n-2k}{n-k} b^{-n+2k} c^{n-k}. \tag{25}$$

3. Convergence of the Laurent series for $w(z)$.

THEOREM 3. *Let the sequence $\{w_j\}$ be generated by* (8), *and suppose that there exist constants $b \geqq 0$, $c > 0$ such that in* (2) $|b_k| \leqq b$ *for* $k \geqq 0$; $|c_1| \leqq 2c$, $|c_k| \leqq c$ *for* $k \geqq 2$.

Then

$$|w_{n+1}| \leqq |\gamma_T(0, n)| = \sum_{j=0}^{[n/2]} \binom{n}{2j}\binom{2j}{j} b^{n-2j} c^j. \tag{26}$$

Proof. With these bounds on b_k and c_k it is clear from the definition of $S(N, \mathbf{p}_k)$ in (12) and the conclusion (20) in Lemma 3 that

$$\sum_{\mathbf{p}_k \in I(k, n-j-k)} |S(j, \mathbf{p}_j)| \leqq \binom{n}{2n-j-2k}\binom{2n-j-2k}{n-k} b^{-n+j+2k} c^{n-j-k}.$$

Thus (24) and (25) imply $|w_{n+1}| \leqq |\gamma_T(0, n)|$. The change of index $j = n - k$ in (25) yields the sum on the right of (26).

THEOREM 4. *Let the sequence $\{w_j\}$ be generated by* (8), *and suppose that there exist constants $b \geqq 0$, $c > 0$ such that in* (2) $|b_k| \leqq b$ *for* $k \geqq 0$; $|c_1| \leqq 2c$, $|c_k| \leqq c$ *for* $k \geqq 2$. *Furthermore without loss of generality suppose* $b \leqq 2\sqrt{c}$. *Then for all* $n \geqq 0$

$$|w_{n+1}| \leqq \binom{2n}{n}(\sqrt{c})^n, \qquad n \geqq 0. \tag{27}$$

Proof. The hypotheses imply that (26) holds and that $b^{n-2j}c^j \leqq 2^{n-2j}(\sqrt{c})^n$, so from (26) and a combinatorial identity [6, p. 72] there follows

$$|w_{n+1}| \leqq (\sqrt{c})^n \sum_{j=0}^{[n/2]} \binom{n}{2j}\binom{2j}{j} 2^{n-2j} = (\sqrt{c})^n \binom{2n}{n}. \tag{28}$$

Remark. Polynomials generated by the recursion formula (2) when $b_n = 0$ for all $n \geqq 0$ are called symmetric polynomials. In this special case it is clear from (26) that

$$|w_{2n+1}| \leqq \binom{2n}{n} c^n, \qquad w_{2n+2} = 0, \quad n \geqq 0, \tag{29}$$

assuming the boundedness condition stated there for $\{c_n\}$.

We come finally to our main result.

THEOREM 5. *Let $\{p_n\}$ be a sequence of monic polynomials generated by the recurrence relation*

$$p_0 = 1,$$
$$p_1 = z + b_0,$$
$$p_{n+1} = (z + b_n)p_n - c_n p_{n-1}, \qquad n \geqq 1,$$

having complex coefficients b_n, c_n, with $c_n \neq 0$. Suppose there is a constant $c > 0$ such that $|b_n| \leqq 2\sqrt{c}$ for all $n \geqq 0$; $|c_1| \leqq 2c$, $|c_n| \leqq c$ for $n \geqq 2$. Then the series

$$w(z) = \sum_{j=1}^{\infty} w_j z^{-j}$$

with coefficients given by (8) (*or equivalently by* (24)) *converges for all z outside the circle $|z| = 4\sqrt{c}$. Furthermore, on any simple closed contour C having $|z| = 4\sqrt{c}$ in its interior,*

$$(1/2\pi i)\int_C p_n(z)p_m(z)w(z)\,dz = \begin{cases} 0, & m \neq n, \\ 1, & m = n = 0, \\ \prod_{i=1}^{n} c_i, & m = n \geqq 1. \end{cases}$$

Proof. Because of (28) the series $\sum w_j z^{-j}$ converges at least for $|z| > 4\sqrt{c}$ (in the symmetric case it follows from (29) that the convergence holds at least for $|z| > 2\sqrt{c}$). The orthogonality property now follows from Theorem 1.

Remark. A number of examples were helpful in gaining some insight about the kind of conditions to impose on $\{b_n\}$ and $\{c_n\}$ in order to guarantee convergence of the series $\sum w_j z^{-j}$. In addition to the already mentioned monic Chebyshev polynomials, which suggested bounds for the $\{b_n\}$ and $\{c_n\}$, the monic Laguerre polynomials with parameter $\alpha = 0$ show what can happen without a boundedness condition. In this case $b_n = -2n - 1$ for $n \geqq 0$, $c_n = n^2$, $n \geqq 1$. Here the hypotheses of Theorem 5 are clearly not satisfied; in fact we find that $w_j = j!$ for $j \geqq 1$, so $\sum w_j z^{-j}$ diverges for all z.

Acknowledgment. It is appropriate to express here sincere appreciation to Marvin B. Sledd, who first interested me in orthogonal polynomials.

THE LINEARIZATION OF THE PRODUCT OF TWO ZONAL POLYNOMIALS*

HOWARD B. KUSHNER†

Abstract. The linearization coefficients $g_{\mu\rho}^{\tau}$ are defined by

$$C_{\mu}(V)C_{\rho}(V)=\sum_{\tau} g_{\mu\rho}^{\tau}C_{\tau}(V)$$

where $C_{\tau}(V)$ is the zonal polynomial corresponding to the partition τ and V is a positive definite matrix. A formula for $g_{(m)\rho}^{\tau}$ is proved, and the partitions τ for which $g_{(m)\rho}^{\tau}\neq 0$ are characterized. An alternative computation of $C_{\tau}(I_k)$ is presented.

Key words. zonal polynomials, linearization of products, partitions

AMS(MOS) subject classifications. 33A75, 62H99

1. Introduction and notation.

Introduction. Zonal polynomials are polynomials of a real, symmetric $k\times k$ matrix V. In the general theory of harmonic analysis, the polynomials are called zonal spherical polynomials of the homogeneous space $\mathrm{GL}(k)/O(k)$, where $\mathrm{GL}(k)$ is the general linear group of invertible real $k\times k$ matrices and $O(k)$ is the orthogonal group of $k\times k$ matrices. They were introduced into multivariate statistical theory by A. T. James, in order to represent certain probability density functions in series form. For example, when V is distributed according to the Wishart distribution, $W_k(N,\Sigma)$—the distribution of $V=X'X$ where the rows of the $N\times k$ matrix X are independently and identically distributed according to the multivariate normal law, $N(0,\Sigma)$—an important problem is to determine the density function of the eigenvalues of V. By introducing the zonal polynomials $\{C_{\tau}(V)\}$—the subscript τ is a partition of t—James (1960) elegantly expressed this density using a bilinear sum of zonal polynomials.

The problem of expressing the product of two zonal polynomials as a linear combination of other zonal polynomials

$$C_{\mu}(V)C_{\rho}(V)=\sum_{\tau} g_{\mu\rho}^{\tau}C_{\tau}(V) \tag{1.1}$$

arose in related statistical problems considered by Constantine (1966), Hayakawa (1967), and Khatri and Pillai (1968), who required the coefficients $g_{\mu\rho}^{\tau}$ in order to compute integrals of products of zonal polynomials. The computation of $g_{\mu\rho}^{\tau}$ is the subject of this paper. Tables for these coefficients were computed by the above authors, but a general formula for them is still unknown. The case $\mu=(1)$ was solved in Kushner (1985). In this paper, the case $\mu=(m)$,

$$C_{(m)}(V)C_{\rho}(V)=\sum_{\tau} g_{(m)\rho}^{\tau}C_{\tau}(V) \tag{1.2}$$

is solved; a simple formula for the coefficients $g_{(m)\rho}^{\tau}$ is given and the partitions τ appearing in (1.2) are characterized. Also, the value of $C_{\tau}(I_k)$ is computed. It appears that the only other way of computing this value is that of James (1961) and Constantine (1963). Kikuchi (1981) has noted that it is not included in Farrell's (1976) treatment of zonal polynomials nor is it in the more recent treatments of Saw (1977), Kates (1981), or Takemura (1984). The present computation is in the spirit of Kushner, Lebow, and Meisner (1981) and thus supplies a missing link in that treatment of zonal polynomials.

In the mathematical literature, (1.1) is called the linearization of the product of two zonal polynomials; the "g-coefficients" are called the linearization coefficients. Problems of this sort, involving polynomials of one variable, are described in Askey (1975). Hylleraas (1962), for example, formulated a linearization problem in order to compute the integral of a product of Jacobi polynomials. Thus, analytic problems—the computation of integrals—have motivated linearization problems involving zonal polynomials and polynomials of one variable. Nevertheless, more directly related to our problem (1.1) is the better known algebraic problem of linearizing the product of two Schur polynomials (MacDonald (1979)),

$$s_\mu s_\rho = \sum_\tau c_{\mu\rho}^\tau s_\tau. \tag{1.3}$$

The linearization coefficients $c_{\mu\rho}^\tau$ arising in this problem are found by the Littlewood–Richardson rule—a combinatorial algorithm rather than an analytic formula—and are nonnegative integers which give the multiplicity of the representation $\langle\tau\rangle$ of the general linear group in the direct product $\langle\mu\rangle\times\langle\rho\rangle$, as well as the multiplicity of the representation $[\tau]$ of the symmetric group in the direct product $[\mu]\times[\rho]$ (Robinson (1961)). By applying the method of this paper to the case $\mu=(m)$ of linearization problem (1.3),

$$s_{(m)} s_\rho = \sum_\tau c_{(m)\rho}^\tau s_\tau \tag{1.4}$$

one can prove that the partitions τ appearing in (1.4) are precisely those that appear in (1.2) and that $c_{(m)\rho}^\tau = 1$ if τ appears in (1.4). Stanley (1986) has recently found a combinatorial formula for the linearization coefficients (for the case $\mu=(m)$) for a wide class of polynomials, which includes the zonal and Schur polynomials.

Notation.

(A) Partitions.

(A.1) A partition $\tau=(t_1, t_2, \cdots)$ is a finite sequence of nonnegative integers t_i satisfying $t_i \geqq t_{i+1}$. The partition τ is denoted by $\tau=(t_i)$ or by $\tau=[n_i]$, where $t_i - t_{i+1} = n_i$. If $t_i \neq 0$, t_i is called a part of τ. $p=l(\tau)$, the length of τ, is equal to the number of parts of τ. $t_p \neq 0$, but $t_{p+1}=0$. $t=\Sigma t_i$, the norm of τ.

(A.2) $\tau[j]$ is equal to the truncated partition of at most j parts given by $\tau[j]=[n_1, n_2, \cdots, n_j]=(t_1-t_{j+1}, t_2-t_{j+1}, \cdots, t_j-t_{j+1})$.

(A.3) If $\tau=(t_1, t_2, \cdots, t_j)=[n_1, n_2, \cdots, n_j]$ is a partition, the symbol $\tau-l$ is defined by the sequence $\tau-l=(t_1-l, t_2-l, \cdots, t_j-l)=[n_1, n_2, \cdots, n_j-l]$ and therefore the symbol $\tau[j]-l$ by $\tau[j]-l=(t_1-t_{j+1}-l, t_2-t_{j+1}-l, \cdots, t_j-t_{j+1}-l)=[n_1, n_2, \cdots, n_j-l]$. If $t_j \geqq l$, then $\tau-l$ is also a partition. If $t_j < l$, any expression such as $a_{\tau-l}$ will, in this paper, equal zero.

Note that the definition of $\tau-l$ distinguishes between partitions that differ by a string of zeros at the end, e.g., if $\tau_1=(4,2)$ and $\tau_2=(4,2,0)$, then

$$\tau_1-1=(3,1), \qquad \text{a partition}$$

but

$$\tau_2-1=(3,1,-1), \quad \text{a sequence.}$$

(B) Matrices.

(B.1) V is a symmetric $k\times k$ matrix. Usually $V>0$, i.e., V is positive definite. X is a $k\times k$ matrix.

(B.2) V_i is the upper left $i\times i$ matrix of V; $V_k=V$; X_i is the upper left $i\times i$ matrix of X; $X_k=X$. Sometimes (B.2) will not be in effect: X_1, X_2 will denote matrices of a type specified.

(B.3) An upper (right) triangular matrix $T=(t_{ij})$ is one that satisfies $t_{ij}=0$, $i>j$. A lower (left) triangular matrix $S=(s_{ij})$ satisfies $s_{ij}=0$, $i<j$. Upper triangular (respectively, lower triangular) always means upper right triangular (respectively, lower left triangular).

(C) Operators.

(C.1) $D_V=|((1+\delta_{ij})(\partial/\partial v_{ij}))|$ is an operator formed from the determinant of a symmetric $k\times k$ matrix of partial differential operators.

(C.2) $D_X=|(\partial/\partial x_{ij})|$ is an operator formed from the determinant of a $k\times k$ matrix of partial differential operators.

(C.3) D_i is the upper left $i\times i$ determinant of D_V; $D_k=D_V$.

(C.4) If f is a function of V and L is an operator on f, $[Lf](V=0)$ means the evaluation of Lf at the matrix $V=0$. Sometimes this will be written as $L[f](V=0)$. Similarly, if g is a function of X and L is an operator on g, then $[Lg](X)$ means the evaluation of Lg at the matrix X.

(C.5) $L_\tau=\prod_{i=1}^k D_i^{n_i}$, where $\tau=[n_i]$. If $P(V)=\sum_\tau A_\tau C_\tau(V)$, then $2^t t!A_\tau=[L_\tau P](V=0)$ (Kushner and Meisner (1984)).

(D) Eigenfunctions and eigenvalues.

(D.1) If $\tau=(t_i)=[n_i]$ and X is a $k\times k$ matrix, $\Phi_\tau(X)=\prod_{i=1}^k |X_i|^{n_i}$. When $X=V$, a symmetric matrix, $\Phi_\tau(V)=\prod_{i=1}^k |V_i|^{n_i}$ was called a "prototype" polynomial in Kushner, Lebow, and Meisner (1981) and the "power function" in Terras (1985).

$$|V_m|D_m\Phi_\tau=\sigma_m(\tau)\Phi_\tau \quad \text{if } l(\tau)\leqq m,$$

where

$$\sigma_m(\tau)=\prod_{i=1}^m (m-i+2t_i) \quad \text{(Maass (1971, p. 83))}.$$

(D.2) The expectation operator E_n in the Wishart distribution $W_k(n,\Sigma)$ is defined by

$$[E_n f](\Sigma)=C_n|\Sigma|^{-k/2}\int_{V>0} f(V)|V|^{(n-k-1)/2}\exp\left(-\left(\frac{1}{2}\right)\operatorname{tr} V\Sigma^{-1}\right)dV$$

where $C_n^{-1}=2^{(kn)/2}\pi^{k(k-1)/4}\prod_{i=1}^k \Gamma((n-i+1)/2)$. The prototype polynomial, Φ_τ, is an eigenfunction of all the expectation operators:

$$E_n\Phi_\tau=2^t(n/2)_\tau\Phi_\tau$$

where $(a)_\tau=(a)_{t_1}(a-\frac{1}{2})_{t_2}\cdots(a-(k-1)/2)_{t_k}$ is Constantine's generalized hypergeometric symbol (James (1964)).

(E) Miscellaneous.

(E.1) $O(k)$ is the group of orthogonal $k\times k$ matrices. dH is the normalized Haar measure on $O(k)$. All integrals, $\int f(H)\,dH$, are over the full orthogonal group. $f(V)$ is called orthogonally invariant if $f(H'VH)=f(V)$, $H\in O(k)$.

In integrals of the form $\int f(X)\,dX$, where X ranges over the space of $l\times q$ matrices, dX is Lebesgue measure normalized so that

$$\int \exp\left(-\left(\frac{1}{2}\right)\operatorname{tr} X'X\right)dX=(2\pi)^{lq/2}.$$

(E.2) If $a-b\geqq -1$ is an integer, the factorial symbol $[a,b]$ is defined by

$$[a,b]=a(a-1)\cdots b \quad \text{if } a\geqq b,$$

$$[a,b]=1 \quad \text{if } a-b=-1,$$

$$\text{i.e.,}\quad [a,b]=\Gamma(a+1)/\Gamma(b) \quad \text{if } b\neq 0,-1,-2,\cdots.$$

If $a-b \geqq -2$ is an even integer, the factorial symbol $[a, b]_2$ is defined by

$$[a, b]_2 = a(a-2)\cdots b \qquad \text{if } a \geqq b,$$

$$[a, b]_2 = 1 \qquad \text{if } a-b=-2,$$

$$\text{i.e.,} \quad [a, b]_2 = 2^{(a-b+2)/2}\Gamma\left(\frac{a}{2}+1\right)\Big/\Gamma\left(\frac{b}{2}\right) \quad \text{if } b \neq 0, -2, -4, \cdots.$$

(E.3) If (a_i), $1 \leqq i \leqq l$ are vectors in E_n, n-dimensional Euclidean space, then $\{a_i\}$, $1 \leqq i \leqq l$ denotes the vector subspace of E_n spanned by (a_i), $1 \leqq i \leqq n$ (E_n is also used for the expectation operator (D.2), but its meaning will be clear from the context).

2. The product of two zonal polynomials. Let ρ and μ be two partitions of r and m, respectively, whose lengths satisfy $l(\rho) \leqq k$ and $l(\mu) \leqq k$. Then from Kushner and Meisner (1984)

$$C_\mu(V) = a_\mu \int \Phi_\mu(X_1' V X_1)\, e^{-(1/2)\operatorname{tr} X_1' X_1}\, dX_1, \qquad V>0, \tag{2.1a}$$

$$C_\rho(V) = a_\rho \int \Phi_\rho(X_2' V X_2)\, e^{-(1/2)\operatorname{tr} X_2' X_2}\, dX_2, \qquad V>0, \tag{2.1b}$$

where X_1 is a $k \times q_1$ matrix ($q_1 \geqq l(\mu)$), X_2 is a $k \times q_2$ matrix ($q_2 \geqq l(\rho)$), $a_\mu = C_\mu(I_k)/((2\pi)^{q_1 k/2} 2^m (k/2)_\mu)$ and $a_\rho = C_\rho(I_k)/((2\pi)^{q_2 k/2} 2^r (k/2)_\rho)$. It follows that

$$C_\mu(V)C_\rho(V) = a_\mu a_\rho \int \Phi_\mu(X_1' V X_1)\Phi_\rho(X_2' V X_2)\, e^{-(1/2)\operatorname{tr}(X_1' X_1 + X_2' X_2)}\, dX_1\, dX_2. \tag{2.2}$$

Suppose that $l(\rho)+l(\mu) \leqq k$. Choose q_1 and q_2 so that $q_1+q_2=k$. Define a $k \times k$ matrix $X=[X_1; X_2]$ formed by adjoining the matrix X_2 to the matrix X_1. Further, define

$$\bar{V} = (v_{ij}), \qquad q_1+1 \leqq i, j \leqq k, \tag{2.3}$$

$$\bar{\Phi}_\rho(V) = \Phi_\rho(\bar{V}), \tag{2.4}$$

$$G(V) = \Phi_\mu(V)\bar{\Phi}_\rho(V). \tag{2.5}$$

Then (2.2) can be written as

$$C_\mu(V)C_\rho(V) = a_\mu a_\rho \int G(X'VX)\, e^{-(1/2)\operatorname{tr} X'X}\, dX \tag{2.6}$$

where the integration is over the space of $k \times k$ matrices X. Suppose now that $\mu=(m)$, a partition having at most one part, so that $l(\mu) \leqq 1$. Also, suppose $l(\rho) \leqq k-1$. Choose $q_1=1$ and $q_2=k-1$. Define

$$f_m(V) = (1/(2^m m!))\Phi_{(m)}(V) \tag{2.7}$$

and

$$F(V) = f_m(V)\bar{\Phi}_\rho(V). \tag{2.8}$$

Finally, define a function of V by

$$\{m, l, \rho, h\}(V) = |V|^l \int f_m(X_1' V X_1)\bar{\Phi}_\rho(X_2' V X_2) h(X)\, dX \tag{2.9a}$$

$$= |V|^l \int F(X'VX) h(X)\, dX. \tag{2.9b}$$

In (2.9), l is any nonnegative integer and $h(X)$ is a suitable function of X—we will only use rapidly decreasing functions of the form $h(X) = \text{polynomial}\ (X)\ e^{-(1/2)\,\mathrm{tr}\,X'X}$

From (2.6) with $\mu = (m)$ and (2.9) we have that

$$C_{(m)}(V)C_\rho(V) = a_{(m)}a_\rho 2^m m!\{m, 0, \rho, h\}(V) \tag{2.10}$$

where $h(X) \equiv e^{-(1/2)\,\mathrm{tr}\,X'X}$.

In the sequel, $\tau = (t_1, \cdots, t_k) = [n_1, \cdots, n_k]$ denotes an arbitrary partition of t of at most k parts and $\rho = (r_1, \cdots, r_{k-1}) = [m_1, \cdots, m_{k-1}]$ denotes a fixed partition of r at most $k-1$ parts.

3. The L_τ operator. According to Kushner and Meisner (1984) (see (C.5), § 1) the coefficient $g^\tau_{\mu\rho}$ is given by

$$2^t t!\, g^\tau_{\mu\rho} = L_\tau[C_\mu(V)C_\rho(V)](V=0), \qquad l(\tau) \leqq k. \tag{3.1}$$

The goal of this paper is the explicit evaluation of the right side of (3.1), when $\mu = (m)$. In this case, (3.1) can be written as

$$2^t t!\, g^\tau_{(m)\rho} = a_{(m)}a_\rho 2^m m![L_\tau\{m, 0, \rho, h\}](V=0), \qquad l(\tau) \leqq k, \tag{3.2}$$

where the function $\{m, 0, \rho, h\}$ and a_τ are defined in § 2, and L_τ is the operator defined in § 1. In the evaluation of the right side of (3.2), which occupies §§ 5–10, we will utilize two lemmas concerning the operator L_τ. Lemma 1 uses the notation $\tau - i$, $[a, b]$ and $[a, b]_2$ defined in § 1.

LEMMA 1. *If $p(V)$ is an orthogonally invariant polynomial, then*

$$L_\tau[|V|^i p(V)](V=0) = b^i_k(\tau)[L_{\tau-i}p](V=0), \qquad \tau = (t_1, t_2, \cdots, t_k),$$

where

$$b^i_k(\tau) = 2^{ki} \prod_{l=1}^{k} \left[\frac{1}{2}(T_l + k), \frac{1}{2}(T_l + k - 2i + 2)\right], \qquad T_l = 2t_l - l. \tag{3.3}$$

Proof. The zonal polynomials span the orthogonally invariant polynomials (Takemura (1984)). Consequently, $p(V)$ can be expanded into a sum of zonal polynomials

$$p(V) = \sum_\tau A_\tau C_\tau(V) \tag{3.4}$$

where the coefficients A_τ(see (C.5)) are given by

$$2^t t!\, A_\tau = [L_\tau p](V=0). \tag{3.5}$$

Since $|V|^i C_\tau(V) = (C_\tau(I_k)/C_{\tau+i}(I_k))C_{\tau+i}(V)$, we also have

$$\begin{aligned} |V|^i p(V) &= \sum_\tau A_\tau \frac{C_\tau(I_k)}{C_{\tau+i}(I_k)} C_{\tau+i}(V) \\ &= \sum_\tau A_{\tau-i} \frac{C_{\tau-i}(I_k)}{C_\tau(I_k)} C_\tau(V). \end{aligned}$$

Applying (3.5) to the above expansion of the polynomial $|V|^i p(V)$ into a sum of zonal polynomials gives

$$L_\tau[|V|^i p(V)](V=0) = 2^t t!\, A_{\tau-i} \frac{C_{\tau-i}(I_k)}{C_\tau(I_k)}. \tag{3.6}$$

Again using (3.5), but with the partition $\tau - i$ instead of τ, gives

$$2^{t-ki}(t-ki)!\,A_{\tau-i} = [L_{\tau-i}p](V=0). \tag{3.7}$$

Combining (3.6) and (3.7), we obtain

$$L_\tau[|V|^i p(V)](V=0) = \frac{2^t t!}{2^{t-ki}(t-ki)!}\,\frac{C_{\tau-i}(I_k)}{C_\tau(I_k)}[L_{\tau-i}p](V=0). \tag{3.8}$$

We now evaluate the ratio $C_{\tau-i}(I_k)/C_\tau(I_k)$. From James (1964) we have that

$$\frac{2^{2t}t!}{2^{2(t-ki)}(t-ki)!}\,\frac{C_{\tau-i}(I_k)}{C_\tau(I_k)} = \frac{(k/2)_{\tau-i}\prod_{l=1}^k (2t_l-l+k)!}{(k/2)_\tau \prod_{l=1}^k (2t_l-l+k-2i)!}. \tag{3.9}$$

Now

$$\begin{aligned}\frac{(k/2)_\tau}{(k/2)_{\tau-i}} &= \frac{\prod_{l=1}^k ((k-l+1)/2)_{t_l}}{\prod_{l=1}^k ((k-l+1)/2)_{t_l-i}} \\ &= \prod_{l=1}^k \left[\frac{k-l-1}{2}+t_l, \frac{k-l+1}{2}+t_l-i\right] \\ &= \prod_{l=1}^k 2^{-i}[2t_l-l+k-1, 2t_l-l+k-2i+1]_2 \\ &= 2^{-ki}\prod_{l=1}^k [T_l+k-1,\ T_l+k-2i+1]_2.\end{aligned} \tag{3.10}$$

Also,

$$\begin{aligned}\prod_{l=1}^k \frac{(2t_l+k-l)!}{(2t_l-2i+k-l)!} &= \prod_{l=1}^k [2t_l-l+k, 2t_l-l+k-2i+1] \\ &= \prod_{l=1}^k [T_l+k,\ T_l+k-2i+1].\end{aligned} \tag{3.11}$$

Dividing (3.11) by (3.10) evaluates the right side of (3.9) as

$$2^{ki}\prod_{l=1}^k [T_l+k,\ T_l+k-2i+2]_2 = 2^{2ki}\prod_{l=1}^k \left[\frac{1}{2}(T_l+k), \frac{1}{2}(T_l+k-2i+2)\right]$$

and so (3.9) may be written as

$$\frac{2^t t!\,C_{\tau-i}(I_k)}{2^{(t-ki)}(t-ki)!\,C_\tau(I_k)} = 2^{ki}\prod_{l=1}^k \left[\frac{1}{2}(T_l+k), \frac{1}{2}(T_l+k-2i+2)\right]$$

which, by (3.8), is the assertion of the lemma.

LEMMA 2. *If g is a function of the symmetric $k\times k$ matrix V, then*

$$[L_\tau g](V=0) = [L_{\tau[k-1]}G](V_{k-1}=0)$$

where G, a function of the matrix V_{k-1}, is defined by

$$G(V_{k-1}) = [D_k^{n_k} g]\left(V = \begin{pmatrix} V_{k-1} & 0 \\ 0 & 0 \end{pmatrix}\right).$$

Proof. $L_\tau = L_{\tau[k-1]}D_k^{n_k}$ and only D_k involves differentiation with respect to the variables v_{ki}, $1 \leqq i \leqq k$.

4. Matrix factorization; subspace basis. In the sequel, we need to know that, under certain conditions, a square matrix can be factored into various kinds of triangular

matrices and also that a subspace has a "trapezoidal basis." Here, we prove these results. In this section X_i, S_i, T_i denote the $i \times i$ upper left matrix of X, S, T, respectively (see (B) of § 1). Lemma 3, below, is immediately applied in § 5; the other results in this section are not used until § 8.

LEMMA 3. *If the upper left $i \times i$ determinants of the $k \times k$ matrix X satisfy*

$$|X_i| \neq 0, \qquad 1 \leqq i \leqq k,$$

then there exist an upper triangular $k \times k$ matrix, T, and a lower triangular $k \times k$ matrix S, such that

$$X = ST. \tag{4.1}$$

S can be uniquely chosen so that its diagonal entries are all equal to 1.

Proof. The decomposition (4.1) is the well-known Gauss decomposition (Naimark and Stern (1982, p. 249)).

To formulate the next lemma, call an $l \times n$ matrix $A = (a_{ij})$ a "trapezoidal matrix" if, for $1 \leqq i \leqq l$, $a_{ij} = 0$, $n - l + i + 1 \leqq j \leqq n$. (If $l = n$, the matrix A is a lower left triangular matrix.) If $C = \{a_i\}$, $1 \leqq i \leqq l$, where a_i are the row vectors of A, then (a_i) will be called a trapezoidal basis for the vector space C. Related to Lemma 3, but without any of its exceptional cases, is the following result.

LEMMA 4. *Let C be a subspace of E_n, Euclidean n-dimensional space. Suppose that* dim $C = l$. *Then there exists a trapezoidal basis for C.*

Proof. Let G be the $l \times n$ matrix whose row vectors are any basis of C. We must show that there exists an invertible $l \times l$ matrix F such that FG is trapezoidal. If FG is trapezoidal, then

$$f_i \in \{g_{n-l+1+i}, g_{n-l+2+i}, \cdots, g_n\}_\perp = G_i, \qquad 1 \leqq i \leqq l-1$$

where f_i, $1 \leqq i \leqq l$, is the ith row vector of F, g_j, $n - l + 2 \leqq j \leqq n$, is the jth column vector of G, and G_i is the orthogonal complement of the indicated subspace. Vectors f_i and g_i and the subspace G_i all are contained in E_l. G_i is the orthogonal complement of a space having at most $l - i$ independent vectors; hence, dim $G_i \geqq i$. The subspaces G_i satisfy $G_1 \subset G_2 \subset \cdots \subset G_{l-1} \subset G_l = E_l$.

Construct a basis of E_l as follows. Since dim $G_1 \geqq 1$, select $f_1 \neq 0$ from G_1; since dim $G_2 \geqq 2$, select f_2, linearly independent of f_1, from G_2; and so on, until we arrive at a basis, $\{f_i\}$, $1 \leqq i \leqq l$, of E_l with the property: $f_i \in G_i$, $1 \leqq i \leqq l$. The required invertible matrix F is constructed by taking f_i, $1 \leqq i \leqq l$ as its row vectors. (A similar construction was used in Lang (1966, p. 183).)

LEMMA 5. *Any $k \times k$ upper triangular matrix T, all of whose $(i, 1)$-minors are not zero, can be decomposed into $T = AT_1$ where*

$$A = \begin{bmatrix} a_1 & a_1 & 0 & \cdots & & 0 \\ 0 & a_2 & a_2 & \cdots & & 0 \\ 0 & 0 & a_3 & a_3 & \cdots & 0 \\ \vdots & \vdots & & & & \vdots \\ 0 & 0 & & & a_{k-1} & a_{k-1} \\ 0 & 0 & \cdots & & 0 & a_k \end{bmatrix}, \quad a_i \neq 0, \quad 1 \leqq i \leqq k,$$

and

$$T_1 = \begin{bmatrix} t_{11} & 0 & \cdots & 0 \\ 0 & & & \\ \vdots & & T_0 & \\ 0 & & & \end{bmatrix}.$$

Here T_0 is a $(k-1)\times(k-1)$ upper triangular matrix, and A can be uniquely chosen so that $a_k = 1$.

Proof. Let u_i denote the ith row vector of T_1. Then the ith row vector of AT_1 is

$$a_i(u_i + u_{i+1}) \qquad (u_{k+1} = 0).$$

If t_i denotes the ith row vector of T, define

$$u_l = (-)^k \sum_{i=l}^{k} (-)^i \frac{t_i}{a_i}, \qquad 1 \leqq l \leqq k, \tag{4.2}$$

where the nonzero numbers a_i are to be determined by setting the jth component ($j \geqq 2$) of u_1 equal to zero

$$0 = \sum_{i=1}^{k} (-)^i \frac{t_{ij}}{a_i}, \qquad 2 \leqq j \leqq k.$$

The system

$$0 = \sum_{i=1}^{k} t_{ij} y_i, \qquad 2 \leqq j \leqq k, \tag{4.3}$$

is a system of $k-1$ equations in k unknowns. Let c_i be the co-factor of t_{i1} in the matrix T, i.e.,

$$c_i = (-)^{i+1} C_i,$$

where C_i, the $(i, 1)$-minor of T, is the subdeterminant of T obtained by striking out row i and column 1 from T. Under the conditions of the lemma,

$$y_i = \alpha c_i, \qquad 1 \leqq i \leqq k,$$

α a scalar, exhausts all the solutions of (4.3). Define then $a_i = C_i^{-1}$, and the row vectors of T_1 by (4.2), to obtain the assertion of the lemma.

If R is a $k \times k$ matrix, let $R(j)$ denote the submatrix of R formed from rows 1 to j and columns 2 to $j+1$.

LEMMA 6. *If $|X(j)| \neq 0$, $1 \leqq j \leqq k-1$, and if $|X_l| \neq 0$, $1 \leqq l \leqq k$, then there exist a lower triangular matrix S, matrices A and T_1 of the form given in Lemma 5, such that $X = SAT_1$. The a_i may be chosen so that $a_i = 1$, $1 \leqq i \leqq k$.*

Proof. By Lemma 3,

$$X = ST \tag{4.4}$$

where S and T are lower and upper triangular, respectively, and $s_{ii} = 1$, $i \leqq k$. The plan of the proof is to apply Lemma 5 to the T in (4.4). T is invertible since $|S||T| = |X| \neq 0$. The $(i, 1)$-minors of T are equal to $\pm|T|b_i$, where b_i, $1 \leqq i \leqq k$, are the components of the first row vector of T^{-1}. Let $\bar{b}_l = (b_1, \cdots, b_l)$, an l-dimensional vector. Then from

$$\bar{b}_l T_l' = (1, 0, \cdots, 0)$$

we find

$$b_l = \frac{|T(l-1)|}{|T_l|}. \tag{4.5}$$

The matrices $X(l-1)$ and $T(l-1)$ are related by

$$X(l-1) = S_{l-1} T(l-1)$$

which follows from (4.4). Since $|S_{l-1}| = 1$, we obtain

$$|X(l-1)| = |T(l-1)|.$$

From (4.5), we then find that the $(l, 1)$-minor of T is given by

$$(-)^{l+1}|T|b_l = (-)^{l+1}\left(\prod_{j=l+1}^{k} t_{jj}\right)|X(l-1)|.$$

Certainly no t_{jj} is zero, since $\prod_{j=1}^{k} t_{jj} = |X| \neq 0$. We conclude that none of the $(i, 1)$-minors of T are equal to zero. Lemma 5 then permits us to write

$$T = AT_1.$$

Substituting the above representation of T in (4.4) gives the first assertion of the lemma. Replacing S by SD^{-1} where $D = \text{diag}\,(a_1, a_2, \cdots, a_k)$ gives the second assertion.

5. Operators bi-invariant with respect to matrix multiplication: eigenfunctions, eigenvalues, and an integral. An operator L is bi-invariant with respect to left and right matrix multiplication if it satisfies the chain rule property

$$[LF](X) = [Lf](T_1XT_2). \tag{5.1}$$

In (5.1), f is a polynomial of the $k \times k$ matrix X and F is the polynomial of X defined, for any two fixed matrices T_1 and T_2, by

$$F(X) = f(T_1XT_2).$$

The operator $L = |X|D_X$ is bi-invariant with respect to right and left matrix multiplication. Let T_1 and T_2 be two upper triangular matrices. The polynomial (§ 1) $\Phi_\tau(X)$ satisfies

$$\Phi_\tau(T_1'XT_2) = \Phi_\tau(X)\Phi_\tau(T_1'T_2). \tag{5.2}$$

This property is a generalization of the well-known property

$$\Phi_\tau(T'VT) = \Phi_\tau(V)\Phi_\tau(T'T), \quad T \text{ upper triangular},$$

of the "prototype" polynomials $\Phi_\tau(V)$. We will now use (5.2) to show that $\Phi_\tau(X)$ is an eigenfunction of every bi-invariant operator. The following proof of this assertion is modeled on the proof of the analogous statement in Selberg (1956) or Maass (1971).

THEOREM 1. *The polynomial $\Phi_\tau(X)$ is an eigenfunction of every bi-invariant operator.*

Proof. Let the bi-invariant operator L operate on both sides of (5.2), obtaining, for any two upper triangular matrices,

$$[L\Phi_\tau](T_1'XT_2) = \Phi_\tau(T_1'T_2)[L\Phi_\tau](X).$$

Setting $X = I$, the $k \times k$ identity, in the above equation yields

$$[L\Phi_\tau](T_1'T_2) = \lambda\Phi_\tau(T_1'T_2)$$

where $\lambda = [L\Phi_\tau](I)$. According to Lemma 3, every $k \times k$ matrix X satisfying $|X_i| \neq 0$, $1 \leqq i \leqq k$, can be represented in the form $X = T_1'T_2$, where T_1 and T_2 are upper triangular. Therefore, the eigenfunction property

$$[L\Phi_\tau](X) = \lambda\Phi_\tau(X) \tag{5.3}$$

holds, except possibly at matrices X for which one or more of the determinants $|X_i|$ vanish. It follows that (5.3) also holds at any matrix X for which both sides of the above equation are continuous, proving the theorem.

LEMMA 7. *Suppose $f(X) \geqq 0$ is an eigenfunction of $|X|D_X$ and that f satisfies either*

(5.4a) (a) $$f(XT) = \Phi_\mu(T'T)f(X)$$

where T is upper triangular, or

(5.4b) (b) $$f(SX) = \Phi_\mu(S'S)f(X)$$

where S is lower triangular. Then

(5.5) $$|X|D_X f = \sigma_k(\mu)f$$

where $\sigma_k(\mu)$ (given in § 1) is the eigenvalue in

(5.6) $$|V|D_V\Phi_\mu = \sigma_k(\mu)\Phi_\mu.$$

Proof. We confine ourselves to (a), the upper triangular version of the lemma. Define a function g of the symmetric matrix $V = X'X$ by

$$g(X'X) = \int f(HX)\, dH.$$

Setting $X = T$, an upper triangular matrix, in the above equation and using (5.4a) gives

$$g(T'T) = c\Phi_\mu(T'T)$$

where $c = \int f(H)\, dH$. If $X'X$ is positive definite, an upper triangular T can be found such that $X'X = T'T$. Therefore

$$g(X'X) = c\Phi_\mu(X'X)$$

and

(5.7) $$c\Phi_\mu(X'X) = \int f(HX)\, dH$$

whenever X is invertible. If $c = 0$ in (5.7), then f vanishes identically. For, $\int f(HX)\, dH = 0$ and $f(HX) \geqq 0$ imply that $f(HX) = 0$ for every $H \in O(k)$; in particular, $f(X) = 0$. Assume then that $c \neq 0$.

The operators $|X|D_X$ and $|V|D_V$ act identically on functions of the variable $X'X$. If $F(X) = G(X'X)$, then

(5.8) $$|X|D_X F = |V|D_V G, \qquad V = X'X.$$

Also, by assumption,

(5.9) $$|X|D_X f = \beta f.$$

Operate with the invariant operator $|X|D_X$ on both sides of (5.7), using (5.8) and (5.9). We obtain

$$c\sigma_k(\mu)\Phi_\mu(X'X) = \beta \int f(HX)\, dX = c\beta\Phi_\mu(X'X)$$

from which follows the equality

$$\beta = \sigma_k(\mu),$$

that is,

$$|X|D_X f = \sigma_k(\mu)f.$$

According to Theorem 1, the polynomial $\Phi_\tau(X)$ is an eigenfunction of $|X|D_X$. We now compute its eigenvalue.

THEOREM 2.

$$|X|D_X\Phi_\tau = \sigma_k(\tau/2)\Phi_\tau. \tag{5.10}$$

Proof. Setting $T_1 = I$ in (5.2) shows that $\Phi_\tau(X)$ satisfies the functional equation

$$\begin{aligned}\Phi_\tau(XT) &= \Phi_\tau(T)\Phi_\tau(X)\\ &= \Phi_{\tau/2}(T'T)\Phi_\tau(X), \quad T \text{ upper triangular.}\end{aligned}$$

Now assume that the parts of τ are even integers. Then $\Phi_\tau(X) \geqq 0$. The three conditions of Lemma 7 are now satisfied by the polynomial Φ_τ, so the assertion of the theorem is established for this case. Next, for any partition τ, consider the equation, obtained by evaluating (5.10) at $X = I$

$$[|X|D_X\Phi_\tau](I) = \sigma_k(\tau/2). \tag{5.11}$$

Equation (5.11) has just been proved in the case when the parts of τ are all even. Both sides of (5.11) have an obvious meaning even when t_i, the "parts" of τ are arbitrary real numbers. Indeed, both sides of (5.11) are polynomials in t_i, $1 \leqq i \leqq k$, and, since both sides of (5.11) are equal when all the t_i are even integers, we may deduce the truth of (5.11) for all real t_i. In particular, (5.11) is true for any partition τ. Theorem 2 now follows from Theorem 1 and (5.11).

The remainder of this section is devoted to the evaluation of the integrals (5.14), (5.16), (5.17), below. The evaluation repeatedly uses "integration by parts," unlike the evaluation of the analogous integral, $\int_{V>0} \Phi_\tau(V)\, e^{-(1/2)\operatorname{tr} V}\, dV$, which is directly accomplished by a change of variables, as in Selberg (1956), Constantine (1963), or Maass (1971). The integration by parts formula to be used is

$$fD_Xg - (-)^k gD_Xf = \operatorname{div} B. \tag{5.12}$$

In (5.12), f and g are functions of X, B is a vector of functions of X, and div is the divergence operator. Equation (5.12) follows from a more general result in Maass (1971); a different derivation of (5.12) is in Kushner (1980). If f and g are suitable functions, then

$$\int fD_Xg\, dX = (-)^k \int gD_Xf\, dX \tag{5.13}$$

follows from (5.12). In particular, we may use (5.13) when f is a polynomial in X and g is a polynomial in X times the function $e^{-(1/2)\operatorname{tr} X'X}$.

THEOREM 3. *Define c_τ by the integral*

$$c_\tau = (2\pi)^{-k^2/2} \int \Phi_\tau(X)\, e^{-(1/2)\operatorname{tr} X'X}\, dX. \tag{5.14}$$

Then

$$\begin{aligned}&c_{2\tau} = \prod_{l \leqq i}^{p} [T_l - T_{i+1} - 2,\ T_l - T_i + 1]_2, \qquad p = l(\tau), \quad T_i = 2t_i - i,\\ &c_\tau = 0 \quad \textit{if the } t_i \textit{ are not all even.}\end{aligned} \tag{5.15}$$

Also,

$$\text{(a)} \qquad 2^{r/2}(k/2)_{\tau/2} \int \Phi_\tau(H)\, dH = c_\tau \tag{5.16}$$

where $(a)_\mu$ *is Constantine's generalized hypergeometric symbol defined in* (D.2) *and*

$$(5.17)\qquad (b)\quad (2\pi)^{-k^2/2}\int \Phi_\tau(X)\, e^{-(1/2)\,\mathrm{tr}\, A^{-1}X'X}\, dX = \Phi_{\tau/2}(A)|A|^{k/2}c_\tau, \qquad A>0.$$

Proof. (a) By the substitution $X = HT$, $H \in O(k)$, T an upper triangular matrix with nonnegative diagonal entries, we have

$$dX = 2^k g_k \prod_{i=1}^{k} t_{ii}^{k-i}\, dH\, dT,$$

$$g_k = \pi^{k(k+1)/4} \Big/ \prod_{i=1}^{k} \Gamma(i/2),$$

$$\Phi_\tau(HT) = \Phi_\tau(H)\Phi_\tau(T),$$

so c_τ, as defined in (5.14), is given by

$$(5.18)\qquad c_\tau = (2\pi)^{-k^2/2}2^k g_k \int \Phi_\tau(T)\, e^{-(1/2)\,\mathrm{tr}\, T'T} \prod_{i=1}^{k} t_{ii}^{k-i}\, dT \int \Phi_\tau(H)\, dH.$$

But $\Phi_\tau(T) = \Phi_{\tau/2}(T'T)$, and if the change of variables, $V = T'T$, with $dV = 2^k \prod_{i=1}^{k} t_{ii}^{k+1-i}\, dT$ is used in (5.18), we obtain

$$\begin{aligned} c_\tau &= (2\pi)^{-k^2/2} g_k \int_{V>0} \Phi_{\tau/2}(V)\, e^{-(1/2)\,\mathrm{tr}\, V} \frac{dV}{|V|^{1/2}} \int \Phi_\tau(H)\, dH \\ &= [E_k \Phi_{\tau/2}](I_k) \int \Phi_\tau(H)\, dH \end{aligned} \qquad (5.19)$$

where E_k is the expectation operator in the Wishart $W_k(k, \Sigma)$ distribution. By $\tau/2$ we mean the partition $\tau/2 = (t_i/2)$, $1 \leqq i \leqq k$, and by $\Phi_{\tau/2}(V)$ we of course mean the function

$$\Phi_{\tau/2}(V) = \prod_{i=1}^{k} |V_i|^{t_i/2},$$

which is, in the terminology of Kushner, Lebow, and Meisner (1981), an *EP* function, satisfying $E_k\Phi_{\tau/2} = 2^{t/2}(k/2)_{\tau/2}\Phi_{\tau/2}$ by Constantine (1963). In particular,

$$(5.20)\qquad [E_k\Phi_{\tau/2}](I_k) = 2^{t/2}(k/2)_{\tau/2}.$$

Substituting (5.20) in (5.19) gives

$$c_\tau = 2^{t/2}(k/2)_{\tau/2} \int \Phi_\tau(H)\, dH.$$

(b) Write $A^{-1} = TT'$, T an upper triangular matrix. By the substitution $Y = XT$, we have

$$dY = |T|^k\, dX, \qquad \Phi_\tau(YT^{-1}) = \Phi_\tau(Y)\Phi_\tau(T^{-1})$$

so the integral (5.17) is given by

$$\begin{aligned} &(2\pi)^{-k^2/2} \int \Phi_\tau(X)\, e^{-(1/2)\,\mathrm{tr}\, A^{-1}X'X}\, dX \\ &\quad = \Phi_\tau(T^{-1})|T|^{-k} \int \Phi_\tau(Y)\, e^{-(1/2)\,\mathrm{tr}\, Y'Y}\, dY \\ &\quad = \Phi_{\tau/2}((T^{-1})'T^{-1})|TT'|^{-k/2} \int \Phi_\tau(Y)\, e^{-(1/2)\,\mathrm{tr}\, Y'Y}\, dY \\ &\quad = \Phi_{\tau/2}(A)|A|^{k/2} \int \Phi_\tau(Y)\, e^{-(1/2)\,\mathrm{tr}\, Y'Y}\, dY \\ &\quad = \Phi_{\tau/2}(A)|A|^{k/2}c_\tau. \end{aligned}$$

Next, we prove that if the t_i are not all even, then the integral (5.16) is zero. Let $K = \operatorname{diag}(1, 1, \cdots, -1, 1, \cdots, 1)$ with the -1 lying in the lth place. Then $K \in O(k)$ is upper triangular and $\Phi_\tau(HK) = \Phi_\tau(H)\Phi_\tau(K) = (-)^{t_l}\Phi_\tau(H)$. Using the substitution $H \to HK$ in (5.16), we obtain

$$c_\tau = (-)^{t_l} c_\tau \tag{5.21}$$

or $c_\tau = 0$ if any t_l is odd.

Finally, we now evaluate the integral (5.14) when t_i are all even. Let $h(X) = e^{-(1/2)\operatorname{tr} X'X}$, and note that $D_X h = (-)^k |X| h$. Then with $\tau = (t_1, t_2, \cdots, t_k)$,

$$\begin{aligned} \int \Phi_\tau(X) h(X)\, dX &= (-)^k \int \Phi_{\tau-1}(X) D_X h\, dX \\ &= \int [D_X \Phi_{\tau-1}](X) h(X)\, dX \\ &= \sigma_k((\tau-1)/2) \int \Phi_{\tau-2}(X) h(X)\, dX; \end{aligned} \tag{5.22}$$

the last two steps follow from (5.13) and (5.10).

Doing this $n_k/2$ times we obtain

$$\int \Phi_\tau(X) h(X)\, dX = \prod_{j=1}^{n_k/2} \sigma_k((\tau-(2j-1))/2) \int \Phi_{\tau[k-1]}(X) h(X)\, dX \tag{5.23}$$

$$\begin{aligned} &= (2\pi)^{(2k-1)/2} \prod_{j=1}^{n_k/2} \sigma_k((\tau-(2j-1))/2) \\ &\quad \cdot \int \Phi_{\tau[k-1]}(X_{k-1}) h(X_{k-1})\, dX_{k-1} \end{aligned} \tag{5.24}$$

where $(\tau-(2j-1))/2$ is the "partition" whose ith part is $(t_i-(2j-1))/2$ and X_{k-1} is the $(k-1)\times(k-1)$ upper left submatrix of X. If $n_k = 0$, the empty product $\prod_1^0$ may be omitted from (5.24). Again repeating this process, we obtain

$$\int \Phi_\tau(X) h(X)\, dX = (2\pi)^{k^2/2} \prod_{i=1}^{p} \prod_{j=i}^{n_i/2} \sigma_i((\tau[i]-(2j-1))/2), \qquad p = l(\tau). \tag{5.25}$$

Now the lth part of the "partition" $(\tau[i]-(2j-1))/2$ is $(t_l - t_{i+1}-(2j-1))/2$, $1 \leqq l \leqq i$. By (D.1) of § 1, $\sigma_i((\tau[i]-(2j-1)/2)) = \prod_{l=1}^{i}(i-l+t_l-t_{i+1}-(2j-1))$, and (5.25) becomes

$$\begin{aligned} \int \Phi_\tau(X) h(X)\, dX &= (2\pi)^{k^2/2} \prod_{i=1}^{p} \prod_{j=1}^{n_i/2} \prod_{l=1}^{i} (i-l+t_l-t_{i+1}-(2j-1)) \\ &= (2\pi)^{k^2/2} \prod_{i=1}^{p} \prod_{\text{odd } j=1}^{t_i-t_{i+1}} \prod_{l=1}^{i} (i-l+t_l-t_{i+1}-j) \qquad (t_{p+1}=0). \end{aligned} \tag{5.26}$$

Writing 2τ for τ in (5.26) and noting that

$$\prod_{\text{odd } j=1}^{2(t_i-t_{i+1})} (i-l+2t_l-2t_{i+1}-j) = [T_l - T_{i+1} - 2,\ T_l - T_i + 1]_2,$$

allows (5.26) to be written as

$$\int \Phi_{2\tau}(X) h(X)\, dX = (2\pi)^{k^2/2} \prod_{l \leqq i}^{p} [T_l - T_{i+1} - 2,\ T_l - T_i + 1]_2$$

which is formula (5.15).

6. Invariant operators; computation of $C_\tau(I_k)$; lengths of partitions. An operator L invariant with respect to congruence transformations, $V \to T'VT$, is one that obeys the simple chain rule law

$$[Lf_T](V) = [Lf](T'VT), \quad T \text{ any real matrix},$$

where f is a polynomial of the positive definite matrix V and $f_T(V) = f(T'VT)$. More generally, if

$$g(V) = \int F(X'VX)h(X)\,dX, \quad F(V) \text{ a polynomial}, \tag{6.1}$$

then it can be shown that

$$[Lg](V) = \int [LF](X'VX)h(X)\,dX. \tag{6.2}$$

Let $D = D_V$. With $L = |V|^n D^n$, an invariant operator with respect to congruence transformations, (6.2) becomes

$$|V|^n[D^n g](V) = |V|^n \int [D^n F](X'VX)|X|^{2n}h(X)\,dX$$

from which we obtain

$$[D^n g](V) = \int [D^n F](X'VX)|X|^{2n}h(X)\,dX. \tag{6.3}$$

As a first application of (6.3), we now compute the value of $C_\tau(I_k)$. As mentioned in § 1, it appears that the only other computation of $C_\tau(I_k)$ is that of James (1961) and Constantine (1963).

From Kates (1981) or Kushner and Meisner (1984),

$$(2\pi)^{k^2/2}2^t(k/2)_\tau C_\tau(V) = C_\tau(I_k)\int \Phi_\tau(X'VX)\,e^{-(1/2)\,\mathrm{tr}\,X'X}\,dX. \tag{6.4}$$

But from Kushner and Meisner (1984) (see (C.5)),

$$[L_\tau C_\tau](V=0) = 2^t t!. \tag{6.5}$$

Operating with L_τ on (6.4) and using (6.5) yields

$$(2\pi)^{k^2/2}2^{2t}t!(k/2)_\tau = C_\tau(I_k)\left[L_\tau \int \Phi_\tau(X'VX)\,e^{-(1/2)\,\mathrm{tr}\,X'X}\,dX\right](V=0). \tag{6.6}$$

By evaluating the right side of (6.6), we will obtain a formula for $C_\tau(I_k)$. The procedure is to repeatedly apply Lemma 2, Theorem 2, and (6.3).

Using (6.1) and (6.3) with $F(V) = \Phi_\tau(V)$ and $h(X) = e^{-(1/2)\,\mathrm{tr}\,X'X}$, the right side of (6.6) is, by Lemma 2 and Theorem 2,

$$C_\tau(I_k)\sigma_k^{n_k}(\tau)\left[L_{\tau[k-1]}\int \Phi_{\tau[k-1]}(X'_{k-1}V_{k-1}X_{k-1})|X|^{2n_k}\,e^{-(1/2)\,\mathrm{tr}\,X'X}\,dX\right](V_{k-1}=0) \tag{6.7}$$

where

$$\sigma_k^n(\tau) = \prod_{j=0}^{n-1}\sigma_k(\tau - j) \quad \text{if } n \geqq 1 \quad (\tau = (t_1, t_2, \cdots, t_k)),$$

$$\sigma_k^0(\tau) = 1$$

and

$$L_{\tau[k-1]} = \prod_{i=1}^{k-1} D_i^{n_i}. \tag{6.8}$$

Continuing in this fashion enables us to evaluate the right side of (6.6) and so to obtain the equation

$$\begin{aligned}(2\pi)^{k^2/2} 2^{2t} (k/2)_\tau t! = C_\tau(I_k) \prod_{i=1}^{p} \prod_{j=0}^{n_i-1} \sigma_i(\tau[i]-j) \\ \cdot \int \Phi_{2\tau}(X)\, e^{-(1/2)\operatorname{tr} X'X}\, dX, \qquad p = l(\tau).\end{aligned} \tag{6.9}$$

The product in (6.9) is evaluated as was the product in (5.25). We obtain

$$\begin{aligned}\prod_{i=1}^{p} \prod_{j=0}^{n_i-1} \sigma_i(\tau[i]-j) &= \prod_{i=1}^{p} \prod_{j=0}^{n_i-1} \prod_{l=1}^{i} (i-l+2(t_l-t_{i+1})-2j) \\ &= \prod_{i=1}^{p} \prod_{\text{even } j=0}^{2(t_i-t_{i+1})-2} \prod_{l=1}^{i} (i-l+2(t_l-t_{i+1})-j) \\ &= \prod_{l \leqq i}^{p} [T_l - T_{i+1} - 1,\ T_l - T_i + 2]_2.\end{aligned} \tag{6.10}$$

Finally, we use (5.15) and (6.10) to evaluate the right side of (6.9), obtaining

$$\begin{aligned}2^{2t}(k/2)_\tau t! &= C_\tau(I_k) \prod_{l \leqq i}^{p} [T_l - T_{i+1} - 1,\ T_l - T_i + 2]_2 \\ &\quad \cdot [T_l - T_{i+1} - 2,\ T_l - T_i + 1]_2\end{aligned} \tag{6.11}$$

$$= C_\tau(I_k) \prod_{l \leqq i}^{p} [T_l - T_{i+1} - 1,\ T_l - T_i + 1]. \tag{6.12}$$

We now show that the formula (6.12) for $C_\tau(I_k)$ is equivalent to that of James and Constantine. In (6.12), when $T_l - T_{i+1} - 1 < T_l - T_i + 1$, the symbol $[T_l - T_{i+1} - 1,\ T_l - T_i + 1] \equiv 1$. This happens when $2 > T_i - T_{i+1} = 2(t_i - t_{i+1}) + 1$, implying that $t_i = t_{i+1}$. Even in this case, when $i \geqq l$,

$$[T_l - T_{i+1} - 1,\ T_l - T_i + 1] = \frac{(T_l - T_{i+1} - 1)!}{(T_l - T_i)!}. \tag{6.13}$$

Noting that $T_l - T_i > 0$ for $i > l$, it follows from (6.13) that

$$\begin{aligned}\prod_{i=l}^{p} [T_l - T_{i+1} - 1,\ T_l - T_i + 1] &= \prod_{i=l}^{p} \frac{(T_l - T_{i+1} - 1)!}{(T_l - T_i)!} \\ &= (T_l - T_{l+1} - 1)! \prod_{i>l}^{p} \frac{(T_l - T_{i+1} - 1)!}{(T_l - T_i)!} \\ &= (T_l - T_{l+1} - 1)! \prod_{i>l}^{p} \frac{(T_l - T_{i+1} - 1)!}{(T_l - T_i)(T_l - T_i - 1)!} \\ &= (T_l - T_{l+1} - 1)! \frac{(T_l - T_{p+1} - 1)!}{(T_l - T_{l+1} - 1)!} \left[\prod_{i>l}^{p} (T_l - T_i) \right]^{-1} \\ &= \frac{(T_l + p)!}{\prod_{i>l}^{p} (T_l - T_i)} \quad \text{(fixed } l\text{)},\end{aligned} \tag{6.14}$$

which, with (6.12), gives the James-Constantine formula for $C_\tau(I_k)$ (James (1964)),

$$2^{2t}(k/2)_\tau t! = C_\tau(I_k)\frac{\prod_{l=1}^{p}(T_l+p)!}{\prod_{i>l}^{p}(T_l-T_i)}.$$

As a second application of (6.3), we now prove that the lengths of the partitions τ appearing in (1.1) satisfy

$$\max(l(\mu), l(\rho)) \leqq l(\tau) \leqq l(\mu)+l(\rho). \tag{6.15}$$

Let $G(V) \equiv \Phi_\mu(V)\Phi_\rho(\bar{V})$ as in (2.5). Then G is a function of the variables in V_j where $j = l(\mu)+l(\rho)$, implying $D_iG \equiv 0$, if $i > j$. Hence, by (6.3) and (2.6) (thinking of the k in (2.6) as i), $D_iC_\mu(V)C_\rho(V) \equiv 0$, if $i > l(\mu)+l(\rho)$. Consequently, if $l(\tau) > l(\mu)+l(\rho)$, then $0 = [L_\tau C_\mu(V)C_\rho(V)](V=0) = 2^t t! g^\tau_{\mu\rho}$, from (3.1). This proves the right side of (6.15). To prove the left side note that if $i < l(\mu)$, then $C_\mu(V_i) = 0$, which implies that

$$C_\mu(V_i)C_\rho(V_i) = \sum_\tau g^\tau_{\mu\rho}C_\tau(V_i) \equiv 0$$

or

$$g^\tau_{\mu\rho} = 0 \quad \text{if } l(\tau) \leqq i < l(\mu).$$

In calculating linearization coefficients via (3.1), it therefore suffices to take any $k \geqq l(\mu)+l(\rho)$.

7. *g*-coefficients: characterization of partitions; integral representation. In this section, we characterize the partitions τ appearing in (1.2) whose g-coefficient is not zero. Also, an integral formula for these g-coefficients is derived. The positivity of the coefficients is an immediate consequence of the integral formula, which is finally evaluated in § 10.

THEOREM 4. *Suppose* $\tau = (t_j)$, $1 \leqq j \leqq p+1$, $\rho = (r_j)$, $1 \leqq j \leqq p$ *and* $r_{p+1} = 0$. *If*

$$t_j \geqq r_j \geqq t_{j+1}, \qquad 1 \leqq j \leqq p \tag{7.1a}$$

and

$$t = r + m, \tag{7.1b}$$

then

$$2^t t! g^\tau_{(m)\rho} = C \int \Phi_\mu(X)\Phi_\nu(X^*)\, e^{-(1/2)\operatorname{tr} X'X}\, dX \tag{7.2a}$$

where

$$\mu = 2[t_j - r_j], \qquad 1 \leqq j \leqq p+1, \tag{7.2b}$$

$$\nu = 2[r_j - t_{j+1}], \quad 1 \leqq j \leqq p, \quad p = l(\rho), \tag{7.2c}$$

$$C = m! a_{(m)}a_\rho 2^t \prod_{l \leqq j}^{p} \left[\frac{1}{2}(R_l - R_{j+1} - 1), \frac{1}{2}(R_l - T_{j+1} + 1)\right] \cdot \left[\frac{1}{2}(T_l - T_{j+1} - 1), \frac{1}{2}(T_l - R_j + 2)\right], \tag{7.2d}$$

$$X = (x_{ij}), \qquad 1 \leqq i, j \leqq p+1, \tag{7.2e}$$

$$X^* = (x_{ij}), \quad 1 \leqq i \leqq p, \quad 2 \leqq j \leqq p+1, \quad \textit{the upper right } p \times p \textit{ part of } X. \tag{7.2f}$$

In (7.2d), $T_l = 2t_l - l$, $R_l = 2r_l - l$. a_τ *is defined in* § 2.

If τ does not satisfy (7.1), *then* $g^{\tau}_{(m)\rho} = 0$.

Proof. The proof starts with the expression for $g^{\tau}_{(m)\rho}$ given in (3.2). Let $k = p+1$. From (6.15), $l(\tau) \leqq k$. The first goal is to calculate the effect of D^n_k on the function $\{m, 0, \rho, h\}$. The procedure is similar to, but more complicated than, that used in § 6.

With $F(V)$ defined by (2.8), the function g defined in (6.1) is just $g(V) \equiv \{m, 0, \rho, h\}$. From (6.3), we therefore have

$$D^n_k\{m, 0, \rho, h\} = \int [D^n_k F](X'VX)|X|^{2n} h(X)\, dX. \tag{7.3}$$

We now calculate $D^n_k F$. By the Laplace expansion of a determinant, we can write the operator D_k as

$$D_k = \left(2\frac{\partial}{\partial v_{11}}\right)\bar{D}_{k-1} + \text{other terms}$$

where $\bar{D}_{k-1}$ is the $(k-1)\times(k-1)$ minor of $2(\partial/\partial v_{11})$ in D_k. The "other terms" all contain a $\partial/\partial v_{1i}$, $2 \leqq i \leqq k$. Therefore, $D_k F = D_k[f_m(V)\bar{\Phi}_\rho(V)] = (2(\partial/\partial v_{11}))f_m \bar{D}_{k-1}\bar{\Phi}_\rho$. For any n,

$$D^n_k F = \left(2\frac{\partial}{\partial v_{11}}\right)^n f_m \bar{D}^n_{k-1}\bar{\Phi}_\rho. \tag{7.4}$$

We now simplify the right side of (7.4). First, note that $(2(\partial/\partial v_{11}))f_m = f_{m-1}$. For any n,

$$\left(2\frac{\partial}{\partial v_{11}}\right)^n f_m = f_{m-n}, \qquad f_i \equiv 0 \quad \text{if } i < 0. \tag{7.5}$$

Second, from § 1, we have that $|V_{k-1}|D_{k-1}\Phi_\rho = \sigma_{k-1}(\rho)\Phi_\rho$ or $D_{k-1}\Phi_\rho = \sigma_{k-1}(\rho)\Phi_{\rho-1}$. With $\rho = (r_i) = [m_i]$, the symbol $\rho - 1 = (r_j - 1)$, $1 \leqq j \leqq k-1$. Similarly, for any n,

$$|V_{k-1}|^n D^n_{k-1}\Phi_\rho = \sigma^n_{k-1}(\rho)\Phi_\rho$$

or

$$D^n_{k-1}\Phi_\rho = \sigma^n_{k-1}(\rho)\Phi_{\rho-n}, \qquad \Phi_{\rho-n} \equiv 0 \quad \text{if } m_{k-1} < n, \tag{7.6}$$

and

$$\bar{D}^n_{k-1}\bar{\Phi}_\rho = \sigma^n_{k-1}(\rho)\bar{\Phi}_{\rho-n}, \qquad \bar{\Phi}_{\rho-n} \equiv 0 \quad \text{if } m_{k-1} < n, \tag{7.7}$$

where $\rho - n = (r_i - n)$, $1 \leqq i \leqq k-1$. $\rho - n$ is a partition only if $m_{k-1} > n$.

The eigenvalue $\sigma^n_{k-1}(\rho)$ may be computed via

$$\sigma^n_{k-1}(\rho) = \prod_{j=0}^{n-1} \sigma_{k-1}(\rho - j) \tag{7.8}$$

and is zero if $m_{k-1} < n$. Evaluating the right side of (7.4) by (7.5) and (7.7) gives

$$[D^n_k F](V) = \sigma^n_{k-1}(\rho) f_{m-n}(V)\bar{\Phi}_{\rho-n}(V). \tag{7.9}$$

Substituting (7.9) in (7.3), we obtain

$$D^n_k\{m, 0, \rho, h\} = \sigma^n_{k-1}(\rho) \int f_{m-n}(X'VX)\bar{\Phi}_{\rho-n}(X'VX)|X|^{2n} h(X)\, dX. \tag{7.10}$$

The first goal of the proof is accomplished in (7.10).

The second part of the proof is controlled by Lemma 2, since we need to calculate $L_\tau\{m, 0, \rho, h\}$ only at the matrix $V=0$. To do this, we use (7.10) to first evaluate $D_k^n\{m, 0, \rho, h\}$ at the matrix $V=\begin{pmatrix} V_{k-1} & 0 \\ 0 & 0 \end{pmatrix}$. Now

$$f_{m-n}\left(X'\begin{pmatrix} V_{k-1} & 0 \\ 0 & 0 \end{pmatrix}X\right)=f_{m-n}(X'_{k-1}V_{k-1}X_{k-1}) \tag{7.11a}$$

and

$$\bar{\Phi}_{\rho-n}\left(X'\begin{pmatrix} V_{k-1} & 0 \\ 0 & 0 \end{pmatrix}X\right)=\bar{\Phi}_{\rho[k-2]}(X'_{k-1}V_{k-1}X_{k-1})|X^*|^{2(m_{k-1}-n)}|V_{k-1}|^{m_{k-1}-n}, \tag{7.11b}$$

where X^* is defined in (7.2f). From (7.10) and (7.11a), (7.11b), we obtain

$$\begin{aligned}&[D_k^n\{m, 0, \rho, h_k\}]\left(V=\begin{pmatrix} V_{k-1} & 0 \\ 0 & 0 \end{pmatrix}\right)\\ &=\sigma_{k-1}^n(\rho)|V_{k-1}|^{m_{k-1}-n}\int f_{m-n}(X'_{k-1}V_{k-1}X_{k-1})\\ &\quad\cdot\bar{\Phi}_{\rho[k-2]}(X'_{k-1}V_{k-1}X_{k-1})h_{k-1}(X)\,dX\\ &=\sigma_{k-1}^n(\rho)\{m-n, m_{k-1}-n, \rho[k-2], h_{k-1}\}\end{aligned} \tag{7.12}$$

where

$$h_{k-1}(X)=|X^*|^{2(m_{k-1}-n)}|X|^{2n}h_k(X) \tag{7.13}$$

and $h_k(X)\equiv h(X)$. Note that the $\{\ \}$ function in (7.12) is now a function of the $(k-1)\times(k-1)$ matrix V_{k-1}. The second part of the proof is accomplished in (7.12).

In the third part of the proof, an expression is obtained for the effect of L_τ on the function $\{m, l, \rho, h\}$ at $V=0$. From Lemmas 1 and 2, with $\tau=(t_i)=[n_i]$, $1\leqq i\leqq k$,

$$\begin{aligned}[L_\tau\{m, l, \rho, h_k\}](V=0)&=b_k^l(\tau)[L_{\tau-l}\{m, 0, \rho, h_k\}](V=0)\\ &=b_k^l(\tau)[L_{\tau[k-1]}G](V_{k-1}=0)\end{aligned} \tag{7.14}$$

where

$$G(V_{k-1})=[D_k^{n_k-l}\{m, 0, \rho, h_k\}]\left(V=\begin{pmatrix} V_{k-1} & 0 \\ 0 & 0 \end{pmatrix}\right). \tag{7.15}$$

Evaluating (7.15) via (7.12), with $n=n_k-l$, allows (7.14) to be written as
