$$\begin{aligned}[L_\tau\{m, l, \rho, h_k\}](V_k=0)&=b_k^l(\tau)\sigma_{k-1}^{n_k-l}(\rho)\\ &\quad\cdot[L_{\tau[k-1]}\{m-n_k+l, m_{k-1}-n_k+l, \rho[k-2], h_{k-1}\}](V_{k-1}=0).\end{aligned} \tag{7.16}$$

The third part of the proof is accomplished in (7.16).

The left side of (7.16) involves the $k\times k$ matrix V_k, and partitions τ and ρ. The right side of (7.16) involves, except for the constants $b_k^l(\tau)$ and $\sigma_{k-1}^{n_k-l}(\rho)$, the $(k-1)\times(k-1)$ matrix V_{k-1} and the truncated partitions $\tau[k-1]$ and $\rho[k-2]$. This enables us to proceed inductively into the fourth part of the proof. Indeed, repeating $k-i$ times the procedure which results in (7.16), we obtain:

$$[L_\tau\{m, l, \rho, h_k\}](V_k=0)=C_i[L_{\tau[i]}\{M_i, l_i, \rho[i-1], h_i\}](V_i=0) \tag{7.17}$$

where

$$M_i = m - \sum_{j=i+1}^{k} (j-i)n_j + \sum_{j=i+1}^{k-1} (j-i)m_j + (k-i)l, \tag{7.18}$$

$$l_i = \sum_{j=i}^{k-1} m_j - \sum_{j=i+1}^{k} n_j + l, \tag{7.19}$$

$$h_i(X) = h_k(X) \prod_{j=i+1}^{k} |X_{j-1}^*|^{2(m_{j-1}-n_j+l_j)} |X_j|^{2(n_j-l_j)}, \tag{7.20}$$

and

$$C_i = \prod_{j=i+1}^{k} b_j^l(\tau[j]) \sigma_{j-1}^{n_j-l_j}(\rho[j-1]). \tag{7.21}$$

In terms of the parts of the partitions τ and ρ, (7.18)-(7.21) are

$$M_i = m - \sum_{j=i+1}^{k} t_j + \sum_{j=i+1}^{k-1} r_i + (k-i)l, \tag{7.22}$$

$$l_i = r_i - t_{i+1} + l, \tag{7.23}$$

$$h_i(X) = h_k(X) \prod_{j=i+1}^{k} |X_{j-1}^*|^{2(r_{j-1}-t_j+l)} |X_j|^{2(t_j-r_j-l)}, \tag{7.24}$$

$$C_i = \prod_{j=i+1}^{k} b_j^{r_j-t_{j+1}+l}(\tau[j]) \sigma_{j-1}^{t_j-r_j-l}(\rho[j-1]). \tag{7.25}$$

When $i = k$, (7.17) is identically true, since $M_k = m$, $l_k = l$, $C_k = 1$. When $i = k-1$, (7.17) yields (7.16) since $M_{k-1} = m - n_k + l = m - t_k + l$, $l_{k-1} = m_{k-1} - n_k + l = r_{k-1} - t_k + l$, $C_{k-1} = b_k^l(\tau)\sigma_{k-1}^{n_k-l}(\rho) = b_k^l(\tau)\sigma_{k-1}^{t_k-l}(\rho)$.

Set $l = 0$ and $i = 0$ in (7.24) and (7.25). The exponents of $|X_{j-1}^*|$ and of $|X_j|$ must be nonnegative integers, yielding (7.1a). The conditions (7.1a) also ensure that M_i and l_i are nonnegative integers and that $C_i \neq 0$. The symbol $[L_{\tau[0]}\{M_0, l_0, \rho[-1], h_0\}] \equiv h_0$, where, from (7.24),

$$\begin{aligned} h_0(X) &= e^{-(1/2)\operatorname{tr} X'X} \prod_{j=1}^{k} |X_{j-1}^*|^{2(r_{j-1}-t_j)} |X_j|^{2(t_j-r_j)} \\ &= e^{-(1/2)\operatorname{tr} X'X} \prod_{j=1}^{k-1} |X_j^*|^{2(r_j-t_{j+1})} \prod_{j=1}^{k} |X_j|^{2(t_j-r_j)} \\ &= e^{-(1/2)\operatorname{tr} X'X} \Phi_\nu(X^*) \Phi_\mu(X), \end{aligned} \tag{7.26}$$

the integrand in (7.2a). The constant C_0 is given by

$$\begin{aligned} C_0 &= \prod_{j=1}^{k} b_j^{r_j-t_{j+1}}(\tau[j]) \sigma_{j-1}^{t_j-r_j}(\rho[j-1]) \\ &= \prod_{j=1}^{k-1} b_j^{r_j-t_{j+1}}(\tau[j]) \prod_{j=1}^{k-1} \sigma_j^{t_{j+1}-r_j+1}(\rho[j]) \end{aligned} \tag{7.27}$$

an expression which we now simplify.

The "σ-symbols" in (7.27) are evaluated as in (5.25)

$$\begin{aligned} \sigma_j(\rho[j]-i) &= \prod_{l=1}^{j} (j-l+2r_l-2r_{j+1}-2i) \\ &= \prod_{l=1}^{j} (R_l - R_{j+1} - 2i - 1). \end{aligned}$$

It follows that

$$\sigma_j^{t_{j+1}-r_{j+1}}(\rho[j]) = \prod_{i=0}^{t_{j+1}-r_{j+1}-1} \sigma_j(\rho[j]-i)$$

$$= \prod_{l=1}^{j} \prod_{i=0}^{t_{j+1}-r_{j+1}-1} (R_l - R_{j+1} - 2i - 1)$$

$$= 2^{j(t_{j+1}-r_{j+1})} \prod_{l=1}^{j} \left[\frac{1}{2}(R_l - R_{j+1} - 1), \frac{1}{2}(R_l - T_{j+1} + 1)\right]$$

and

$$\prod_{j=1}^{k-1} \sigma_j^{t_{j+1}-r_{j+1}}(\rho[j]) = 2^a \prod_{l \leqq j}^{k-1} \left[\frac{1}{2}(R_l - R_{j+1} - 1), \frac{1}{2}(R_l - T_{j+1} + 1)\right] \tag{7.28}$$

where $a = \sum_{j=1}^{k} j(t_{j+1} - r_{j+1})$.

The "b-symbols" in (7.27) are evaluated using (3.3) with $i = r_j - t_{j+1}$, $k = j$, and the partition $\tau[j]$ in place of τ. The lth part of $\tau[j]$ is $t_l - t_{j+1}$. To evaluate $b_j^{r_j - t_{j+1}}(\tau[j])$, the $T_l + k$ in (3.3) is replaced by $2(t_l - t_{j+1}) - l + j = T_l - T_{j+1} - 1$; the $T_l + k - 2i + 2$ in (3.3) is replaced by $T_l - T_{j+1} - 1 - 2r_j + 2t_{j+1} + 2 = T_l - R_j + 2$. We obtain

$$b_j^{r_j - t_{j+1}}(\tau[j]) = 2^{j(r_j - t_{j+1})} \prod_{l=1}^{j} \left[\frac{1}{2}(T_l - T_{j+1} - 1), \frac{1}{2}(T_l - R_j + 2)\right] \tag{7.29}$$

or

$$\prod_{j=1}^{k-1} b_j^{r_j - t_{j+1}}(\tau[j]) = 2^b \prod_{l \leqq j}^{k-1} \left[\frac{1}{2}(T_l - T_{j+1} - 1), \frac{1}{2}(T_l - R_j + 2)\right] \tag{7.30}$$

where $b = \sum_{j=1}^{k-1} j(r_j - t_{j+1})$. Note that $a + b = r$.

Multiplying (7.28) and (7.30) together, with $p = l(\rho)$, $k = p + 1$ (or any $k \geqq p + 1$) evaluates the C_0 in (7.27). Using this expression for C_0 and (7.26), the case $i = 0$, $l = 0$ of (7.17) is

$$[L_\tau\{m, 0, \rho, h\}](V_k = 0) = C_0 \int \Phi_\mu(X)\Phi_\nu(X^*)\, e^{-(1/2)\operatorname{tr} X'X}\, dX$$

which, with (3.2), yields (7.2a).

8. More eigenfunctions. Theorem 4 expresses the g-coefficients by integrals of the form

$$c_{\mu\nu} = (2\pi)^{-k^2/2} \int \Phi_\mu(X)\Phi_\nu(X^*)\, e^{-(1/2)\operatorname{tr} X'X}\, dX \tag{8.1}$$

where

$$\Phi_\mu(X) = \prod_{i=1}^{k} |X_i|^{e_i}, \qquad \mu = [e_1, e_2, \cdots, e_k]$$

and

$$\Phi_\nu(X^*) = \prod_{i=1}^{k-1} |X_i^*|^{f_i}, \quad \nu = [f_1, f_2, \cdots, f_{k-1}].$$

Here, X is a $k \times k$ matrix and X^* is the upper right $(k-1) \times (k-1)$ submatrix of X. When $f_i = 0$, $1 \leqq i \leqq k-1$, the integral (8.1) was evaluated in § 5. The procedure for the evaluation of (8.1) is similar, but more complicated. It uses two eigenfunction properties of the integrand in (8.1).

THEOREM 5. *Let* $f(X)=\Phi_\mu(X)\Phi_\nu(X^*)$. *Then* $f(X)$ *is an eigenfunction of all the bi-invariant operators.*

Proof. The function $\Phi_\mu(X)$ satisfies the functional equation (5.2). For any upper right triangular T_2, and T_1 of the form given in Lemma 5, the function $g(X)=\Phi_\nu(X^*)$ satisfies

$$g(T_2'XT_1)=w_1(T_1)w_2(T_2)g(X)$$

where w_i are functions of the matrices T_i, $1\leqq i\leqq 2$. Consequently, for two such upper right triangular matrices, $f(X)$ satisfies

$$f(T_2'XT_1)=w(T_1,T_2)f(X) \tag{8.2}$$

where w is a function of the matrices T_1 and T_2.

Let A be a matrix in the form given in Lemma 5. Since $a_i\neq 0$, $1\leqq i\leqq k$, $f(A)\neq 0$, because

$$\Phi_\mu(A)=a_1^{e_1}(a_1a_2)^{e_2}\cdots(a_1\cdots a_k)^{e_k}\neq 0$$

and

$$\Phi_\nu(A^*)=a_1^{f_1}(a_1a_2)^{f_2}\cdots(a_1\cdots a_{k-1})^{f_{k-1}}\neq 0.$$

Let $X=A$ in (8.2); we then obtain

$$f(T_2'AT_1)=w(T_1,T_2)f(A). \tag{8.3}$$

Using (8.3) to eliminate the w function from (8.2), we obtain for $f(X)$ the functional equation

$$f(T_2'XT_1)=f(T_2'AT_1)f(X)/f(A). \tag{8.4}$$

In (8.4), T_2 is any upper right triangular matrix; T_1 and A are matrices of the form given in Lemma 5. Operating on both sides of (8.4) with a bi-invariant operator L gives

$$[Lf](T_2'XT_1)=f(T_2'AT_1)[Lf](X)/f(A). \tag{8.5}$$

Setting $X=A$ in (8.5) yields

$$[Lf](T_2'AT_1)=\lambda f(T_2'AT_1)$$

where $\lambda=[Lf](A)/f(A)$. By Lemma 6, any matrix X, certain of whose subdeterminants do not vanish, can be represented in the form $T_2'AT_1$, where A is a constant matrix. Therefore, the eigenfunction property

$$[Lf](X)=\lambda f(X) \tag{8.6}$$

holds, except possibly at matrices X for which one or more of the subdeterminants vanish. As in Theorem 1, it follows that (8.6) also holds at any matrix X for which both sides of (8.6) are continuous, proving the theorem.

When $e_k=0$ and the first column vector of X is fixed, the function f defined in Theorem 5 may be viewed as a function of X^*. The second eigenfunction property relates to this function.

THEOREM 6. *Suppose that the first column vector of* X *is fixed and define*

$$F(X^*)=\prod_{i=1}^{k-1}|X_i|^{e_i}\prod_{i=1}^{k-1}|X_i^*|^{f_i}$$

viewed as a function of the variables in X^*, *the* $(k-1)\times(k-1)$ *upper right part of* X. *Then* F *is an eigenfunction of all the bi-invariant operators* (*acting on functions of* X^*).

Proof. We begin by proving that, if $x_{11} \neq 0$, there is a lower left invertible $(k-1)\times(k-1)$ triangular matrix S such that, if $Y^{\#}$ denotes the $(k-2)\times(k-2)$ lower left part of a $(k-1)\times(k-1)$ matrix Y, then

$$|X_{i+1}| = |[(SX^*)^{\#}]_i|, \qquad 1 \leqq i \leqq k-2. \tag{8.7}$$

In (8.7), the matrix S depends only on the entries, $\{x_{i1}\}$, $1 \leqq i \leqq k-1$ in the first column of X. Now Cauchy's composition law (Karlin (1968)), states that

$$|AB|_{\rho\kappa} = \sum_{\tau} |A|_{\rho\tau}|B|_{\tau\kappa}. \tag{8.8}$$

In (8.8), $\rho = (r_1, r_2, \cdots, r_i)$ and $\kappa = (k_1, k_2, \cdots, k_i)$ are two fixed partitions, each having i parts; τ runs over all partitions having i parts; $|C|_{\rho\kappa}$ is the $i \times i$ subdeterminant of the matrix C formed from rows $\{r_l\}$ and columns $\{k_l\}$; and A and B are any two square matrices of the same order. Define partitions ρ and $\langle j\rangle$, both of length i, by

$$\rho = (i+1, \cdots, 3, 2), \tag{8.9a}$$

$$\langle j\rangle = (i+1, \cdots, \hat{j}, \cdots, 2, 1). \tag{8.9b}$$

$\hat{j}$ indicates that j does not appear in the partition $\langle j\rangle$. If S is a lower left $(k-1)\times(k-1)$ triangular matrix, and $i \leqq k-2$, then

$$|S|_{\rho\tau} = 0, \quad \text{unless } \tau = \langle j\rangle, \qquad 1 \leqq j \leqq i+1. \tag{8.10}$$

Let $\kappa = (i, \cdots, 2, 1)$. Note that

$$|SX^*|_{\rho\kappa} = |[(SX^*)^{\#}]_i|. \tag{8.11}$$

In (8.8), set $A = S$ and $B = X^*$. Together with (8.10) and (8.11) we then obtain

$$|[(SX^*)^{\#}]_i| = \sum_{j=0}^{i+1} |S|_{\rho\langle j\rangle}|X^*|_{\langle j\rangle\kappa}. \tag{8.12}$$

If a $(k-1)\times(k-1)$ lower triangular matrix S can be found satisfying

$$|S|_{\rho\langle j\rangle} = (-)^{j+1}x_{j1}, \qquad 1 \leqq j \leqq i+1 \leqq k, \tag{8.13}$$

where ρ and $\langle j\rangle$—which depend on i—are given in (8.9a), (8.9b), then the right side of (8.12) is equal to $|X_{i+1}|$, which is the assertion (8.7). We now demonstrate the existence of such a matrix.

Let $C = \{a\}_\perp$, where $a = (x_{i1})$, $1 \leqq i \leqq k-1$. Since $a \neq 0$, C is a $(k-2)$-dimensional subspace of E_{k-1}, Euclidean $(k-1)$-dimensional space. From Lemma 4, with $l = k-2$, $n = k-1$, C has a trapezoidal basis: $C = \{a\}_\perp = \{s_j\}$, $2 \leqq j \leqq k-1$, where the final $k-1-j$ components of s_j are zero. Define the vector s_1 by $s_1 = (1, 0, 0, \cdots, 0) \in E_{k-1}$ and let S be the $(k-1)\times(k-1)$ matrix whose row vectors are s_j, $1 \leqq j \leqq k-1$. S is a triangular matrix. If $s_1 \notin C$, i.e., if $x_{11} \neq 0$, then S is invertible. For fixed $1 \leqq i \leqq k-1$ and any vector $y = (y_1, y_2, \cdots, y_{k-1}) \in E_{k-1}$, let $\bar{y} = (y_1, y_2, \cdots, y_i) \in E_i$. Then

$$\{\bar{a}_i\}_\perp = \{\bar{s}_j\}, \qquad 2 \leqq j \leqq i. \tag{8.14}$$

For, $\bar{a}_i \neq 0$, hence $\dim\{\bar{a}_i\}_\perp = i-1$, and certainly the $i-1$ independent vectors $\bar{s}_j$, $2 \leqq j \leqq i$, are orthogonal to $\bar{a}_i$. Equating the Grassmann coordinates of the subspaces appearing in (8.14) gives, for scalars $\lambda_i \neq 0$,

$$|S|_{\rho\langle j\rangle} = \lambda_i(-)^{j+1}x_{j1}, \qquad 1 \leqq j \leqq i+1 \leqq k,$$

and renormalizing the vectors s_i results in a invertible triangular matrix S satisfying (8.13). This concludes the proof of (8.7).

We now use (8.7) to obtain the assertion of the theorem. Let $Y = X^*$. Then (8.7) together with $|(SY)_i| = |S_i||Y_i|$, $1 \leqq i \leqq k-1$ implies that the polynomial F defined in Theorem 6 can be written as

$$F(Y) = x_{11}^{e_1} w(S) H(SY) \tag{8.15}$$

where

$$H(Y) = \prod_{i=2}^{k-1} |Y_i^{\#}|^{e_i} \prod_{i=1}^{k-1} |Y_i|^{f_i} \tag{8.16}$$

and

$$w(S) = \prod_{i=1}^{k-1} |S_i|^{-f_i}.$$

But the polynomial $H(Y)$ is the analogue of the polynomial $f(X)$ in Theorem 5. Therefore, H is an eigenfunction of all the bi-invariant operators (acting on functions of $Y = X^*$) and also so is the left-translate of H and, by (8.15), the function $F(Y) = F(X^*)$.

9. More eigenvalues. In this section, we compute the eigenvalues of the functions $f(X)$ and $F(X^*)$ defined in the previous section.

The sum of two partitions is defined by component-wise addition. (This definition holds for both representations of partitions (§ 1).) Thus α, the sum of the two partitions μ and ν defined in the previous section, is

$$\alpha = \mu + \nu = [e_1 + f_1, e_2 + f_2, \cdots, e_{k-1} + f_{k-1}, e_k], \qquad k \geqq 2. \tag{9.1}$$

If $k = 1$, ν is defined to be a "null partition," i.e., a partition without any parts. In this case, $\alpha = \mu = [e_1]$. If $k \geqq 3$, define also the partition μ^* by

$$\mu^* = [e_2, \cdots, e_{k-1}]. \tag{9.2}$$

β, the sum of μ^* and ν, is

$$\beta = \mu^* + \nu = [e_2 + f_1, e_3 + f_2, \cdots, e_{k-1} + f_{k-2}, f_{k-1}], \qquad k \geqq 3. \tag{9.3}$$

If $k \leqq 2$, μ^* is the null partition. In this case, if $k = 2$, $\beta = \nu = [f_1]$; if $k = 1$, β itself is the null partition.

Using the above notation and that of the previous section, the next theorem gives the eigenvalues of the functions $f(X)$ and $F(X^*)$, defined as in Theorems 5 and 6, respectively.

THEOREM 7.

$$|X| D_X f = \sigma_k(\tfrac{1}{2}\alpha) f, \qquad \alpha = \mu + \nu. \tag{9.4}$$ (a)

$$|X^*| D_{X^*} F = \sigma_{k-1}(\tfrac{1}{2}\beta) F, \qquad \beta = \mu^* + \nu. \tag{9.5}$$ (b)

Proof. (a) In (8.4), let $T_1 = I$. Also, call A_1 the matrix obtained by setting $a_i = 1$, $1 \leqq i \leqq k$, in the matrix A. We obtain a functional equation for f

$$f(SX) = f(SA_1) f(X), \quad S = (s_{ij}) \text{ lower triangular.} \tag{9.6}$$

But

$$\begin{aligned} \Phi_\mu(SA_1) &= s_{11}^{e_1} (s_{11} s_{22})^{e_2} \cdots (s_{11} s_{22} \cdots s_{kk})^{e_k} \\ &= \Phi_{\mu/2}(SS') \end{aligned}$$

and

$$\Phi_\nu((SA_1)^*) = s_{11}^{f_1}(s_{11}s_{22})^{f_2}\cdots(s_{11}s_{22}\cdots s_{k-1,k-1})^{f_{k-1}}$$
$$= \Phi_{\nu/2}(SS')$$

implying $f(SA_1) = \Phi_\mu(SA_1)\Phi_\nu((SA_1)^*) = \Phi_{(\mu+\nu)/2}(SS')$. Therefore (9.6) can be written as

$$f(SX) = \Phi_{(\mu+\nu)/2}(SS')f(X), \quad S \text{ lower left triangular}, \tag{9.7}$$

which is condition (5.4b) of Lemma 7. By Theorem 5, $f(X)$ is an eigenfunction of $|X|D_X$. Now assume that the e_i and f_i are even integers, in which case $f(X) \geqq 0$. The assertion of part (a) then follows, in this case, from Lemma 7. To prove (9.4) in the general case, when the e_i and f_i are any integers, one can argue as in the proof of Theorem 2.

(b) Let $X^{**} = (x_{ij})$, $2 \leqq i, j \leqq k$, a submatrix of X^*. If $Y = X^*$, then $Y^{\#} = X^{**}$. It was shown in the proof of Theorem 6 that $F(X^*)$ is a multiple of a left-translate of a function H defined in (8.16), which in the present notation can be written as

$$H(X^*) = \Phi_\nu(X^*)\Phi_{\mu^*}(X^{**}). \tag{9.8}$$

The eigenvalue of $F(X^*)$ is the same as the eigenvalue of $H(X^*)$. Since $H(X^*)$ is the analogue of the function $f(X)$, part (a) of this theorem can be applied to obtain part (b).

10. Evaluation of integrals and g-coefficients. In this section, after evaluating integrals of the form (10.1a) below, we prove a simple formula for the g-coefficients $g^{\tau}_{(m)\rho}$.

THEOREM 8. *Let $\mu = [e_1, e_2, \cdots, e_k]$ and $\nu = [f_1, f_2, \cdots, f_{k-1}]$ be two partitions whose parts are even. The integral*

$$c_{\mu\nu} = (2\pi)^{-k^2/2}\int \Phi_\mu(X)\Phi_\nu(X^*)\, e^{-(1/2)\operatorname{tr} X'X}\, dX \tag{10.1a}$$

is given by

$$c_{\mu\nu} = 2^t \prod_{l\leqq j}^{q}\left[\frac{1}{2}(T_l - R_j - 1), \frac{1}{2}(T_l - T_j + 1)\right]$$
$$\cdot\left[\frac{1}{2}(R_l - T_{j+1} - 2), \frac{1}{2}(R_l - R_j + 1)\right], \qquad q = l(\mu), \tag{10.1b}$$

where

$$2\tau = \mu + \nu, \quad \tau = (t_j), \quad t = \sum_{j=1}^{q} t_j, \tag{10.2a}$$

$$2\rho = \mu^* + \nu, \qquad \rho = (r_j), \tag{10.2b}$$

$T_j = 2t_j - j$, $R_j = 2r_j - j$, *and* $\mu^* = [e_2, e_3, \cdots, e_{q-1}]$.

Proof. The function $g(X) = e^{-(1/2)\operatorname{tr} X'X}$ satisfies $D_X g = (-)^k|X|g$. Using (5.13) we express $c_{\mu\nu} = c_{\mu\nu}(k)$ by

$$c_{\mu\nu}(k) = (2\pi)^{-k^2/2}(-)^k\int \Phi_{\mu-1}(X)\Phi_\nu(X^*)D_X g\, dX$$
$$= (2\pi)^{-k^2/2}\int D_X[\Phi_{\mu-1}(X)\Phi_\nu(X^*)]g(X)\, dX \tag{10.3}$$
$$= (2\pi)^{-k^2/2}\int |X|^{-1}|X|D_X[\Phi_{\mu-1}(X)\Phi_\nu(X^*)]g(X)\, dX.$$

From Theorem 7, part (a), and (10.3), we obtain

$$c_{\mu\nu}(k) = (2\pi)^{-k^2/2}\sigma_k\left(\frac{\mu+\nu-1}{2}\right)\int \Phi_{\mu-2}(X)\Phi_\nu(X^*)g(X)\,dX.$$

Repeating this process $e_k/2$ times, we get

$$c_{\mu\nu}(k) = (2\pi)^{-k^2/2}\prod_{i=1}^{e_k/2}\sigma_k\left(\frac{\mu+\nu-2i+1}{2}\right)\int \Phi_{\mu[k-1]}(X)\Phi_\nu(X^*)g(X)\,dX. \tag{10.4}$$

The variables in the kth row of X do not appear in $\Phi_{\mu[k-1]}(X)\Phi_\nu(X^*)$. Fix the variables in the first column of X and integrate with respect to the remaining variables (those of X^*). By (5.13), with X^* in place of X, and Theorem 7, part (b), we further reduce the integral in (10.4), obtaining

$$c_{\mu\nu}(k) = (2\pi)^{-k^2/2}\left[\prod_{i=1}^{e_k/2}\sigma_k\left(\frac{\mu+\nu-2i+1}{2}\right)\right]\sigma_{k-1}\left(\frac{\mu^*+\nu-1}{2}\right)$$
$$\cdot\int \Phi_{\mu[k-1]}(X)\Phi_{\nu-2}(X^*)g(X)\,dX.$$

Again repeating the process $f_{k-1}/2$ times, we obtain

$$c_{\mu\nu}(k) = (2\pi)^{-k^2/2}\prod_{i=1}^{e_k/2}\sigma_k\left(\frac{\mu+\nu-2i+1}{2}\right)\prod_{i=1}^{f_{k-1}/2}\sigma_{k-1}\left(\frac{\mu^*+\nu-2i+1}{2}\right)$$
$$\cdot\int \Phi_{\mu[k-1]}(X)\Phi_{\nu[k-2]}(X^*)g(X)\,dX. \tag{10.5}$$

The variables in the kth row and column of X do not appear in $\Phi_{\mu[k-1]}(X)\Phi_{\nu[k-2]}(X^*)$. Integrating these $2k-1$ variables in integral (10.5) yields a recursion relation for $c_{\mu\nu}$

$$c_{\mu\nu}(k) = \prod_{i=1}^{e_k/2}\sigma_k\left(\frac{\mu+\nu-2i+1}{2}\right)$$
$$\cdot\prod_{i=1}^{f_{k-1}/2}\sigma_{k-1}\left(\frac{\mu^*+\nu-2i+1}{2}\right)c_{\mu[k-1],\nu[k-1]}(k-1). \tag{10.6}$$

Note that in (10.6), μ, ν, and μ^* are partitions of at most k, $k-1$, and $k-2$ parts, respectively.

The recursion relation (10.6) immediately yields a product formula for $c_{\mu\nu}$

$$c_{\mu\nu} = \prod_{j=1}^{q}\prod_{i=1}^{e_j/2}\sigma_j\left(\frac{\mu[j]+\nu[j-1]-2i+1}{2}\right)$$
$$\cdot\prod_{j=1}^{q-1}\prod_{i=1}^{f_j/2}\sigma_j\left(\frac{\mu^*[j-1]+\nu[j]-2i+1}{2}\right). \tag{10.7}$$

In (10.7), $\mu^*[j-1]=[e_2, e_3, \cdots, e_j]$, a partition of at most $j-1$ parts. (As usual, all the empty products, those with $e_j=0$, and $f_j=0$, do not appear in (10.7).)

We now simplify (10.7) by writing μ and ν as

$$\mu = 2[t_j - r_j], \tag{10.8a}$$

$$\nu = 2[r_j - t_{j+1}] \tag{10.8b}$$

which are the inverse forms of (10.2a), (10.2b). From (10.8a) we have $\mu[j]+\nu[j-1]=2[t_1-t_2, t_2-t_3, \cdots, t_{j-1}-t_j, t_j-r_j]$. By the same technique already used to evaluate σ-symbols

$$\prod_{j=1}^{q}\prod_{i=1}^{e_j/2}\sigma_j((\mu[j]+\nu[j-1]-2i+1)/2)=\prod_{j=1}^{q}\prod_{l=1}^{j}\prod_{i=1}^{t_j-r_j}(j-l+2(t_l-r_j)-2i+1)$$
$$=2^c\prod_{l\leqq j}^{q}\left[\frac{1}{2}(T_l-R_j-1),\frac{1}{2}(T_l-T_j+1)\right] \tag{10.9}$$

where $c=\sum_{j=1}^{q}j(t_j-r_j)$. Again, from (10.8b) we have $\mu^*[j-1]+\nu[j]=2[r_1-r_2, r_2-r_3, \cdots, r_{j-1}-r_j, r_j-t_{j+1}]$. Therefore,

$$\prod_{j=1}^{q}\prod_{i=1}^{f_j/2}\sigma_j((\mu^*[j-1]+\nu[j]-2i+1)/2)$$
$$=\prod_{j=1}^{q}\prod_{l=1}^{j}\prod_{i=1}^{r_j-t_{j+1}}(j-l+2(r_l-t_{j+1})-2i+1) \tag{10.10}$$
$$=2^b\prod_{l\leqq j}^{q}\left[\frac{1}{2}(R_l-T_{j+1}-2),\frac{1}{2}(R_l-R_j+1)\right]$$

where $b=\sum_{j=1}^{q}j(r_j-t_{j+1})$. Note that $c+b=t$. From (10.7), after multiplying (10.9) and (10.10) together, we get the assertion of the theorem.

THEOREM 9. *Suppose that $\tau=(t_i)$, and $\rho=(r_i)$, are partitions of t and r, respectively. If*

$$t_i\geqq r_i\geqq t_{i+1},\qquad 1\leqq i\leqq p=l(\rho) \tag{10.11a}$$

and

$$t=m+r, \tag{10.11b}$$

then the g-coefficient $g^{\tau}_{(m)\rho}$ defined in (1.2) *is given by*

$$\binom{t}{m}g^{\tau}_{(m)\rho}=\frac{m!}{(2m)!}\prod_{l=1}^{p+1}\frac{[2\delta_l-1,1]_2}{\delta_l!}\prod_{l<j}^{p+1}(R_l-R_j)$$
$$\cdot\prod_{l<j}^{p+2}[T_l-R_j-1, R_l-T_j+1]_2\Big/\prod_{l<j}^{p+1}[T_l-R_j, R_l-T_j]_2 \tag{10.12}$$

where $\delta_l=t_l-r_l$, $R_l=2r_l-l$, $T_l=2t_l-l$. The factorial symbol $[b, c]_2$ is defined by

$$[b, c]_2=b(b-2)(b-4)\cdots c \quad \text{if } b-c=2n\geqq 0,$$
$$[b, c]_2=1 \quad \text{if } b-c=-2.$$

If τ and ρ do not satisfy (10.11a), (10.11b), *then $g^{\tau}_{(m)\rho}=0$. If $g^{\tau}_{(m)\rho}\neq 0$, then*

$$l(\rho)\leqq l(\tau)\leqq l(\rho)+1. \tag{10.13}$$

Proof. From Theorem 4 and Theorem 8 (with $q=p+1$)

$$2^t t!\,g^{\tau}_{(m)\rho}=m!\,a_{(m)}a_{\rho}2^{2t}(2\pi)^{k^2/2}$$
$$\cdot\prod_{l\leqq j}^{p}\frac{\Gamma(\frac{1}{2}(R_l-R_{j+1}+1))}{\Gamma(\frac{1}{2}(R_l-T_{j+1}+1))}\frac{\Gamma(\frac{1}{2}(T_l-T_{j+1}+1))}{\Gamma(\frac{1}{2}(T_l-R_j+2))}$$
$$\cdot\prod_{l\leqq j}^{p+1}\frac{\Gamma(\frac{1}{2}(T_l-R_j+1))}{\Gamma(\frac{1}{2}(T_l-T_j+1))}\frac{\Gamma(\frac{1}{2}(R_l-T_{j+1}))}{\Gamma(\frac{1}{2}(R_l-R_j+1))}$$

which simplifies to

$$
\begin{aligned}
t!\,g^{\tau}_{(m)\rho} &= m!\,a_{(m)}a_{\rho}2^{t}(2\pi)^{(p+1)^2/2}\pi^{-(p+1)(p+2)/2} \\
&\quad\cdot\prod_{l=1}^{p+1}\Gamma\left(\frac{1}{2}(T_l-R_l+1)\right)\Gamma\left(\frac{1}{2}(R_l+p+2)\right) \\
&\quad\cdot\prod_{l\leqq j}^{p}\frac{\Gamma(\frac{1}{2}(T_l-R_{j+1}+1))}{\Gamma(\frac{1}{2}(R_l-T_{j+1}+1))}\,\frac{\Gamma(\frac{1}{2}(R_l-T_{j+1}))}{\Gamma(\frac{1}{2}(T_l-R_j+2))} \\
&= m!\,a_{(m)}a_{\rho}2^{t}(2\pi)^{(p+1)^2/2}\pi^{-(p+1)(p+2)/2} \\
&\quad\cdot\prod_{l=1}^{p+1}\Gamma\left(\frac{1}{2}(T_l-R_l+1)\right)\Gamma\left(\frac{1}{2}(R_l+p+2)\right) \\
&\quad\cdot\prod_{l<j}^{p+1}\frac{\Gamma(\frac{1}{2}(T_l-R_j+1))}{\Gamma(\frac{1}{2}(R_l-T_j+1))}\,\frac{\Gamma(\frac{1}{2}(R_l-T_j))}{\Gamma(\frac{1}{2}(T_l-R_j+2))} \\
&\quad\cdot\prod_{l\leqq j}^{p}\frac{\Gamma(\frac{1}{2}(T_l-R_{j+1}+2))}{\Gamma(\frac{1}{2}(T_l-R_j+2))} \qquad (10.14) \\
&= m!\,a_{(m)}a_{\rho}2^{t}(2\pi)^{(p+1)^2/2}\pi^{-(p+1)(p+2)/2} \\
&\quad\cdot\prod_{l=1}^{p+1}\frac{\Gamma(\frac{1}{2}(T_l-R_l+1))}{\Gamma(\frac{1}{2}(T_l-R_l+2))}\Gamma\left(\frac{1}{2}(T_l+p+3)\right)\Gamma\left(\frac{1}{2}(R_l+p+2)\right) \\
&\quad\cdot\prod_{l<j}^{p+1}\frac{\Gamma(\frac{1}{2}(T_l-R_j+1))}{\Gamma(\frac{1}{2}(R_l-T_j+1))}\,\frac{\Gamma(\frac{1}{2}(R_l-T_j))}{\Gamma(\frac{1}{2}(T_l-R_j+2))} \\
&= m!\,a_{(m)}a_{\rho}2^{t}(2\pi)^{(p+1)^2/2}\pi^{-(p+1)(p+2)/2} \\
&\quad\cdot\prod_{l=1}^{p+1}\frac{\Gamma(\frac{1}{2}(T_l-R_l+1))}{\Gamma(\frac{1}{2}(T_l-R_l+2))}\Gamma\left(\frac{1}{2}(R_l+p+3)\right)\Gamma\left(\frac{1}{2}(R_l+p+2)\right) \\
&\quad\cdot\prod_{l<j}^{p+2}\frac{\Gamma(\frac{1}{2}(T_l-R_j+1))}{\Gamma(\frac{1}{2}(R_l-T_j+1))}\prod_{l<j}^{p+1}\frac{\Gamma(\frac{1}{2}(R_l-T_j))}{\Gamma(\frac{1}{2}(T_l-R_j+2))}.
\end{aligned}
$$

When $m=0$, $\tau=\rho$, $t=r$ and $g^{\rho}_{(0)\rho}=1$. In this case, (10.14) is

$$
\begin{aligned}
r! &= a_{(0)}a_{\rho}2^{r}(2\pi)^{(p+1)^2/2}\pi^{-(p+1)(p+2)/2}\pi^{(p+1)(p+2)/4} \\
&\quad\cdot\prod_{l=1}^{p+1}\Gamma\left(\frac{1}{2}(R_l+p+3)\right)\Gamma\left(\frac{1}{2}(R_l+p+2)\right) \qquad (10.15) \\
&\quad\cdot\prod_{l<j}^{p+1}(2/(R_l-R_j)).
\end{aligned}
$$

Dividing (10.14) by (10.15) eliminates a_{ρ} and other terms from (10.13), giving

$$
\begin{aligned}
a_{(0)}t!\,g^{\tau}_{(m)\rho} &= r!\,m!\,a_{(m)}2^{m}\pi^{-(p+1)(p+2)/4}\prod_{l=1}^{p+1}\frac{\Gamma(\frac{1}{2}(T_l-R_l+1))}{\Gamma(\frac{1}{2}(T_l-R_l+2))} \\
&\quad\cdot\prod_{l<j}^{p+2}\frac{\Gamma(\frac{1}{2}(T_l-R_j+1))}{\Gamma(\frac{1}{2}(R_l-T_j+1))}\prod_{l<j}^{p+1}\frac{(R_l-R_j)\Gamma(\frac{1}{2}(R_l-T_j))}{2\Gamma(\frac{1}{2}(T_l-R_j+2))}. \qquad (10.16)
\end{aligned}
$$

Now if $b-c=2n\geqq -2$, then $[b,c]_2=2^{(b-c+2)/2}\Gamma(1+b/2)/\Gamma(c/2)$ $(c\neq 0,-2,-4,\cdots)$. Also, $\Gamma(\frac{1}{2}(T_l-R_l+1))=\Gamma(\frac{1}{2})2^{r_l-t_l}[2\delta_l-1,1]_2$ and $\Gamma(\frac{1}{2}(T_l-R_l+2))=\delta_l!$ Hence, (10.16) can be written as

$$
\begin{aligned}
a_{(0)}t!\,g^{\tau}_{(m)\rho}=r!\,m!\,a_{(m)}\prod_{l=1}^{p+1}\frac{[2\delta_l-1,1]_2}{\delta_l!}\\
\cdot\frac{\prod_{l<j}^{p+2}[T_l-R_j-1,R_l-T_j+1]_2}{\prod_{l<j}^{p+1}(R_l-R_j)[T_l-R_j,R_j-T_j]_2}.
\end{aligned}
\tag{10.17}
$$

Finally, $a_{(m)}$ is given in § 2 (with $q_1=1$ and $k=p+1$) by

$$a_{(m)}=C_{(m)}(I_{p+1})/((2\pi)^{(p+1)/2}2^m((p+1)/2)_m)=2^m m!/((2m)!(2\pi)^{k/2}),$$

so

$$a_{(m)}/a_{(0)}=2^m m!/(2m)!. \tag{10.18}$$

Substituting (10.18) in (10.17) gives the formula (10.12) of the theorem.

The interlacing condition (10.11a) is from Theorem 4. The inequality (10.13) is the case $l(m)=1$ of (6.15).

As an example of the theorem, let $m=2$, $\rho=(3,1,1)=(r_1,r_2,r_3)$, with $r=5$ and $p=3$. With $r_4=0$, the only partitions of $7=t=m+r$ satisfying (10.11a),

$$t_1\geqq 3\geqq t_2\geqq 1\geqq t_3\geqq 1\geqq t_4\geqq 0\geqq t_5,\qquad t_1+t_2+t_3+t_4=7,$$

are (5, 1, 1), (4, 2, 1), (4, 1, 1, 1), (3, 3, 1), and (3, 2, 1, 1).

The above five partitions τ are the only ones for which the coefficient $g^{\tau}_{(2)\rho}\neq 0$, as is also seen from Khatri and Pillai's (1968) table. Let $\tau=(4,2,1)$. Then from

	1	2	3	4	5
R_i	5	0	−1	−4	−5
T_i	7	2	−1	−4	−5
δ_i	1	1	0	0	0

we calculate

$$\prod_{l<j}^{4}(R_l-R_j)=5\cdot 6\cdot 9\cdot 1\cdot 4\cdot 3=a,$$

$$\prod_{l=1}^{4}[2\delta_l-1,1]_2=[1,1]_2\cdot[1,1]_2\cdot[-1,1]_2\cdot[-1,1]_2=1=b,$$

$$\prod_{l=1}^{4}\delta_l!=1\cdot 1\cdot 1\cdot 1=1=c,$$

	1,2	1,3	1,4	1,5	2,3	2,4	2,5	3,4	3,5	4,5
T_l-R_j	7	8	11	12	3	6	7	3	4	1
R_l-T_j	3	6	9	10	1	4	5	3	4	1

$$\prod_{l<j}^{5}[T_l-R_j-1, R_l-T_j+1]_2$$

$$=[6,4]_2[7,7]_2[10,10]_2[11,11]_2[2,2]_2[5,5]_2[6,6]_2[2,4]_2[3,5]_2[0,2]_2$$

$$=6\cdot 4\cdot 7\cdot 10\cdot 11\cdot 2\cdot 5\cdot 6=d,$$

$$\prod_{l<j}^{4}[T_l-R_j, R_l-T_j]=[7,3]_2[8,6]_2[11,9]_2[3,1]_2[6,4]_2[3,3]_2$$

$$=7\cdot 5\cdot 3\cdot 8\cdot 6\cdot 11\cdot 9\cdot 3\cdot 6\cdot 4\cdot 3=e,$$

$$m!\Big/(2m)!\binom{t}{m}=2!\Big/4!\binom{7}{2}=\frac{2\cdot 2}{4\cdot 3\cdot 2\cdot 7\cdot 6}=f.$$

According to (10.12),

$$g^{\tau}_{(m)\rho}=\frac{f\times b\times a\times d}{c\times e}$$

$$=\frac{2\cdot 2\cdot 5\cdot 6\cdot 9\cdot 4\cdot 3\cdot 6\cdot 4\cdot 7\cdot 10\cdot 11\cdot 2\cdot 5\cdot 6}{4\cdot 3\cdot 2\cdot 7\cdot 6\cdot 7\cdot 5\cdot 3\cdot 8\cdot 6\cdot 11\cdot\ 9\cdot 3\cdot 6\cdot 4}$$

$$=\frac{25}{189},$$

as given in Khatri and Pillai's (1968) table.

11. Special cases and applications.

(a) The linearization of tr $VC_\rho(V)$.

This is the case $m=1$ of Theorem 9, solved in Kushner (1985). Here (10.11a), (10.11b) imply that $g^{\tau}_{(1)\rho}\neq 0$ if and only if, for some $1\leqq i\leqq l(\rho)+1$, $\tau=\rho_i=(r_1, r_2, \cdots, r_{i-1}, r_i+1, r_{i+1}, \cdots)$ or $t_l=r_l+\delta^i_l$ (Kronecker delta). It follows that $T_l=R_l+2\delta^i_l$ and $\delta_l=\delta^i_l$. Also,

$$[T_l-R_j, R_l-T_j]_2=[R_l-R_j+2\delta^i_l, R_l-R_j-2\delta^i_l]_2$$

and

$$[T_l-R_j-1, R_l-T_j+1]_2=[R_l-R_j-1+2\delta^l_i, R_l-R_j-2\delta^l_i]_2.$$

Evaluating the product (10.12) leads to

$$(1+r)g^{\rho_i}_{(1)\rho}=\prod_{j=1}^{p+2}(R_i-R_j+1)\Big/\prod_{j=1}^{p+1}(R_i-R_j+2) \tag{11.1}$$

where $p=l(\rho)$ and ρ is a partition of r. Equation (11.1) is an equivalent, though more compact, form of the formula given in Theorem 1 of Kushner (1985).

(b) The linearization of the product of polynomials in one variable. Variations of the method of this paper—but by no means the full machinery—result in formulas for the linearization coefficients for some of the problems described in Askey (1975).

(c) An integral. A special case of the integral

$$c_{2\tau,\nu}=(2\pi)^{-k^2/2}\int \Phi_{2\tau}(X)|\det X|^{\nu}\, e^{-(1/2)\operatorname{tr} X'X}\, dX, \qquad \nu=n-k-1 \tag{11.2}$$

occurs in Schwager and Margolin (1982, p. 950). In (11.2), $|\det X|$ denotes the absolute value of $\det X$. When $\nu = 2e$ is an even integer, the integral (11.2) is given by Theorem 3 since

$$\Phi_{2\tau}(X)|\det X|^{\nu} = \Phi_{2(\tau+e)}(X),$$

implies

$$c_{2\tau,\nu} = c_{2(\tau+e)}, \qquad \nu = 2e. \tag{11.3}$$

The partition $(l_i) = \lambda = \tau + e$, having k parts, is given by

$$(l_i) = \lambda = \tau + e = (t_1 + e, t_2 + e, \cdots, t_p + e, e, e, \cdots, e)$$

from which we obtain

$$L_i = T_i + 2e, \qquad 1 \leqq i \leqq k,$$

$$L_{k+1} = T_{k+1} = -(k+1)$$

where $L_i = 2l_i - i$, $T_i = 2t_i - i$ (and $t_i = 0$, $p < i \leqq k+1$). Hence, $L_l - L_i = T_l - T_i$ if $1 \leqq i \leqq k$. Theorem 3 gives

$$\begin{aligned} c_{2(\tau+e)} = c_{2\lambda} &= \prod_{l \leqq i}^{k-1} [T_l - T_{i+1} - 2, T_l - T_i + 1]_2 \prod_{l=1}^{k} [T_l + 2e - T_{k+1} - 2, T_l - T_k + 1]_2 \\ &= \prod_{l \leqq i}^{k} [T_l - T_{i+1} - 2, T_l - T_i + 1]_2 \prod_{l=1}^{k} [T_l + 2e - T_{k+1} - 2, T_l - T_{k+1}]_2 \\ &= \prod_{l \leqq i}^{p} [T_l - T_{i+1} - 2, T_l - T_i + 1]_2 \prod_{l=1}^{k} [T_l + \nu + k - 1, T_l + k + 1]_2 \\ &= c_{2\tau} \prod_{l=1}^{k} [T_l + \nu + k - 1, T_l + k + 1]_2. \end{aligned} \tag{11.4}$$

In general, $c_{2\tau,\nu}$ can be computed using the substitution $X = HT$, as in Theorem 3. We obtain

$$c_{2\tau,\nu} = (2\pi)^{-k^2/2} 2^k g_k \int \Phi_{2\tau}(T)|T|^{\nu} e^{-(1/2)\operatorname{tr} T'T} \prod_{i=1}^{k} t_{ii}^{k-i}\, dT \int \Phi_{2\tau}(H)\, dH. \tag{11.5}$$

In (11.5), $|T|$ is, as usual, the determinant of T. In the same way that (5.18) followed from (5.17), we write the T-integral in (11.5) as an integral over the $k \times k$ positive definite matrices, and (11.5) becomes

$$\begin{aligned} c_{2\tau,\nu} &= (2\pi)^{-k^2/2} g_k \int \Phi_{\tau}(V)|V|^{(n-k-2)/2} e^{-(1/2)\operatorname{tr} V}\, dV \int \Phi_{2\tau}(H)\, dH \\ &= 2^{k(n-1-k)/2} \left[\prod_{i=1}^{k} \Gamma((n-k-1+k-i+1)/2)/\Gamma(i/2) \right] \\ &\quad \cdot [E_{n-1}\Phi_{\tau}](I_k) \int \Phi_{2\tau}(H)\, dH \end{aligned} \tag{11.6}$$

$$= 2^{k\nu/2} \left[\prod_{i=1}^{k} \Gamma((\nu+i)/2)\Gamma(i/2) \right] 2^t((n-1)/2)_{\tau} [c_{2\tau}/2^t(k/2)_{\tau}] \tag{11.7}$$

$$= 2^{k\nu/2} c_{2\tau} \left[\prod_{i=1}^{k} \Gamma((\nu+i)/2)/\Gamma(i/2) \right] ((n-1)/2)_{\tau}/(k/2)_{\tau}. \tag{11.8}$$

In (11.6), E_{n-1} is the expectation operator in the Wishart distribution, $W_k(n-1, \Sigma)$. Equation (11.7) follows from (11.8) from (D.2) of § 1 and Theorem 3. For any integral ν, $c_{2\tau,\nu}$ is given by (11.8). If ν is an even integer, after simplification, (11.8) reduces to (11.4). The case considered by Schwager and Margolin (1982) was $\tau = (4)$.

Acknowledgments. I would like to thank Donald Richards for suggesting application (c) and the referee for suggesting a shortening of the proof of (5.21).

THE TRIDIAGONAL APPROACH TO SZEGÖ'S ORTHOGONAL POLYNOMIALS, TOEPLITZ LINEAR SYSTEMS, AND RELATED INTERPOLATION PROBLEMS*

P. DELSARTE† AND Y. GENIN†

Abstract. The basic topics of the paper are the three-term recurrence relation $x_{k+1}(z) = (\alpha_k + \bar{\alpha}_k z)x_k(z) - zx_{k-1}(z)$ and the associated tridiagonal matrix. This relation, which underlies the Bistritz stability test, can be used as a starting point for a novel approach to the trigonometric moment problem and its relatives. In particular, the "tridiagonal approach" is shown to provide a new solution method for the classical Carathéodory–Fejér and Nevanlinna–Pick interpolation problems. The results include some Levinson-type and Schur-type algorithms, of reduced complexity, for computing reflection coefficients associated with nonnegative definite Hermitian Toeplitz matrices.

Key words. three-term recurrence, Szegö polynomials, Toeplitz matrices, interpolation problems

AMS (MOS) subject classifications. 30E05, 42A70, 30D50

1. Introduction. The Schur–Cohn test to check polynomial stability [18], [23] and the Levinson algorithm to solve Toeplitz linear systems [14], [21] are intimately related topics which have found various applications in the areas of discrete systems analysis, digital signal processing and linear least-squares estimation [19], [20], [22], [24], among others. These methods are quite efficient from the points of view of computational complexity and numerical accuracy. From a theoretical viewpoint, they owe a significant part of their popularity to the fact that they are direct implementations of two standard results of the Szegö theory of orthogonal polynomials on the unit circle [2], [12], [15], [26].

The Bistritz stability test [3], [4], [8] and the split Levinson algorithm [5], [6] have been proposed recently as substitutes for the Schur–Cohn test and the Levinson algorithm. These two methods are based on a remarkable three-term recurrence relation (with two very different interpretations). Their computational complexity and memory requirement are smaller than those of the corresponding standard algorithms; the number of multiplications and the storage space are reduced approximately by a factor 2. Although the recurrence relation just mentioned is not classical in the framework of Szegö's theory, it can actually be derived from the well-known recurrence relation for orthogonal polynomials on the unit circle [5].

This paper contains a thorough study of a suitable mathematical environment of the three-term recurrence relation or, equivalently, the associated tridiagonal matrix, underlying the Bistritz test and the split Levinson algorithm, in the general case of complex data. Our approach is of a function-theoretic nature essentially, in the sense that it brings out a new mathematical framework for some important aspects of the theory of Carathéodory functions (C-functions). In particular, the celebrated Carathéodory–Fejér (CF) and Nevanlinna–Pick (NP) interpolation problems [2], [25], which have interesting applications in systems, circuit and signal theory (see [7], [10], [11], [16], [17], for example), can be treated successfully in this framework. The "tridiagonal approach" yields not only new solvability criteria but also new efficient recursive "Schur-type" and "Nevanlinna-type" algorithms for the CF and NP problems. It is interesting to note that, in contrast with the classical Schur and Nevanlinna

algorithms that essentially involve Schur functions [2], the proposed new methods are specifically tailored to deal with Carathéodory functions. Furthermore, while establishing these results, we obtain a simple extension of the split Levinson algorithm to the complex case, as well as a straightforward derivation of a generalized version of the Bistritz stability test.

The technical contents of the paper can be summarized as follows. The tridiagonal polynomial matrix $J_n(z)$ associated with the three-term recurrence relation $x_{k+1}(z) = (\alpha_k + \bar{\alpha}_k z)x_k(z) - zx_{k-1}(z)$, with $k = 0, 1, \cdots, n$, is introduced and examined in § 2. Two independent solution polynomials $x_k(z)$, denoted by $p_k(z)$ and $q_k(z)$, are identified in terms of certain subdeterminants of $J_n(z)$; they are characterized by their symmetry and antisymmetry properties; they are called first-kind and second-kind polynomials. In particular, all polynomials $q_k(z)$ vanish at the point $z = 1$. The theory is essentially restricted to the case where the tridiagonal matrix $J_n(1)$ is nonnegative definite.

In § 3, the sequences of such polynomials $p_k(z)$ and $q_k(z)$ are shown to be in one-to-one correspondence with well-defined sequences of first-kind and second-kind Szegö orthogonal polynomials. In that context, $p_k(z)$ and $q_k(z)$ can be identified as "singular Szegö polynomials." The explicit relation between the recurrence parameters α_k and the Schur–Cohn parameters (or reflection coefficients) of the associated Szegö polynomials is explained in detail.

The quasi-orthogonality properties of the polynomials $p_k(z)$ with respect to any positive measure underlying Szegö's theory are examined in § 4. The Gram matrix of these polynomials is shown to coincide with the tridiagonal matrix $J_n(1)$, which yields an explicit congruence relation between $J_n(1)$ and the Toeplitz matrix relative to the Szegö polynomials. A Levinson-type algorithm to compute prediction filters and reflection coefficients for nonnegative definite Hermitian Toeplitz matrices is obtained in that context.

The properties of the zeros of the polynomials $p_k(z)$ and $q_k(z)$ are discussed in § 5. It is shown that these zeros are located on the unit circle $|z| = 1$. Moreover, the zeros of $p_k(z)$ alternate with those of $q_k(z)$ and with those of $(1-z)p_{k-1}(z)$. On this occasion one gives an explanation of the Bistritz stability test for complex polynomials which has the remarkable feature of revealing the close connection between this test and the Schur–Cohn test in a transparent manner.

In § 6, the classical "coefficient problems" for C-functions are revisited in the light of the tridiagonal approach. First, a new decomposition principle for an arbitrary C-function $f(z)$ is obtained; it is based on the extraction of a lossless rational function of degree one from $f(z)$, having its pole in $z = 1$ and assuming the same value as $f(z)$ in $z = 0$. It is then shown that the CF interpolation problem with $n+1$ constraints can be solved by n iterations (at most) of this decomposition method. The new algorithm generates a sequence of complex numbers α_k from the data. With the exception of some pathological situations, the nonnegative definiteness of the associated tridiagonal matrix $J_n(1)$ turns out to be a solvability criterion for the problem. Furthermore, the general solution can be parametrized in terms of an "almost arbitrary" C-function by means of a simple homographic transformation involving the first-kind and second-kind polynomials $p_n(z)$, $p_{n+1}(z)$ and $q_n(z)$, $q_{n+1}(z)$. A suitable implementation of this solution method provides an efficient Schur-type algorithm to compute the reflection coefficients for a given nonnegative definite Toeplitz matrix; it generalizes the split Schur algorithm [6] to the complex case. It involves about twice less multiplications than the classical Schur algorithm and the same number of additions. (Thus the gain in complexity is roughly equal to that of the Levinson-type algorithm of § 5 with respect to the classical Levinson algorithm.)

The Nevanlinna-Pick interpolation problem is considered in § 7. It is shown that the methods and results of the preceding section can be carried over to this problem via suitable iterative transformations of the unit disk, mapping the given interpolation points to the origin. This gives rise to a new solvability criterion for the NP problem, together with a new explicit description of the solution space and a new Nevanlinna-type algorithm for its actual computation. As an application, a generalization of the Bistritz stability test is proposed; it involves the values assumed by the given polynomial at m points arbitrarily selected in the unit disk, where m is the polynomial degree.

2. Tridiagonal matrices and associated polynomials. Let there be given a sequence of $n+1$ complex numbers $\alpha_0, \alpha_1, \cdots, \alpha_n$. For an integer k, with $0 \leqq k \leqq n$, define the tridiagonal matrix, or Jacobi matrix,

$$J_k(z) = \begin{bmatrix} \alpha_0 + \bar{\alpha}_0 z & z & & & & \\ 1 & \alpha_1 + \bar{\alpha}_1 z & z & & & \\ & 1 & & \cdots & & \\ & & \cdots & & z & \\ & & & 1 & \alpha_k + \bar{\alpha}_k z & \end{bmatrix}, \tag{2.1}$$

where z is a complex variable and the bar denotes the conjugate. Note that (2.1) can be written in the form $J_k(z) = A_k + z\tilde{A}_k$ where A_k is the lower-triangular matrix having $\alpha_0, \alpha_1, \cdots, \alpha_k$ on the diagonal, 1 just below it and 0 elsewhere, and the tilde denotes the conjugate transpose. With $J_{k-1}(z)$ let us associate the polynomial $p_k(z)$, of formal degree k, defined by

$$p_k(z) = \det J_{k-1}(z), \tag{2.2}$$

for $k = 0, 1, \cdots, n+1$, with the convention $p_0(z) = 1$. Since $J_k(z)$ equals $z\tilde{J}_k(1/\bar{z})$ it is clear that $J_k(z)$ enjoys the *symmetry property*

$$\hat{p}_k(z) = p_k(z), \tag{2.3}$$

with the notation $\hat{x}_k(z) = z^k \bar{x}_k(1/\bar{z})$. Furthermore, computing the determinant of $J_k(z)$ by Laplace's rule, we obtain the *three-term recurrence relation*

$$p_{k+1}(z) = (\alpha_k + \bar{\alpha}_k z)p_k(z) - zp_{k-1}(z), \tag{2.4}$$

with the initial conditions $p_{-1}(z) = 0$ and $p_0(z) = 1$. As a straightforward consequence of (2.4) we have

$$p_{k+1}(0) = \alpha_k p_k(0). \tag{2.5}$$

It is worth mentioning that (2.4) can be viewed as a special case of the Frobenius relation occurring in Padé approximation (see [13] in that respect). However, the main applications of (2.4) treated in this paper are quite different from those considered in classical Padé theory. Let us incidentally point out that the complex symmetric polynomial $p_k(z)$ yields the real trigonometric polynomial

$$\psi_k(\theta) = e^{-ik\theta} p_k(e^{2i\theta}), \tag{2.6}$$

which is a linear combination of the functions $\cos l\theta$ and $\sin l\theta$ with $l \leqq k$ and $l \equiv k \pmod 2$. The recurrence relation (2.4) assumes the nice form

$$\psi_{k+1}(\theta) = (x_k \cos\theta + y_k \sin\theta)\psi_k(\theta) - \psi_{k-1}(\theta), \tag{2.7}$$

with $x_k = 2 \operatorname{Re} \alpha_k$ and $y_k = 2 \operatorname{Im} \alpha_k$. The "real case" $y_k = 0$ (for all k) is closely related to the theory of orthogonal polynomials on the interval $[-1, +1]$. (See [26], and especially [5] in the context of this paper.)

In the sequel we exclusively consider the situation where the real symmetric matrix $J_n(1)$ *is nonnegative definite.* (Equivalently, the matrix iA_n is dissipative.) In view of the tridiagonal structure (2.1), this implies that $J_{n-1}(1)$ is positive definite. In particular, the real part of each α_k has to be positive. Our assumption can be expressed in terms of the polynomials (2.2) by the conditions $p_{n+1}(1) \geqq 0$ and $p_k(1) > 0$ for $k = 1, 2, \cdots, n$. In this context it is quite natural to introduce the *Jacobi parameters*

$$\lambda_k = p_k(1)/p_{k-1}(1), \tag{2.8}$$

for $k = 0, 1, \cdots, n+1$, with the convention $\lambda_0 = \infty$. (It is interesting to compare (2.8) with the expression $\alpha_{k-1} = p_k(0)/p_{k-1}(0)$.) The *positivity constraints* above can then be written in the form

$$\lambda_k > 0 \quad \text{for } 1 \leqq k \leqq n \quad \text{and } \lambda_{n+1} \geqq 0. \tag{2.9}$$

The Jacobi parameters λ_k can be determined from the data by means of a simple continued fraction. Indeed, (2.4) yields the recurrence relation

$$\lambda_{k+1} = 2 \operatorname{Re} \alpha_k - \lambda_k^{-1} \quad \text{for } 0 \leqq k \leqq n. \tag{2.10}$$

Without going into any detail let us mention that the general situation where $J_n(1)$ has an arbitrary inertia could presumably be treated with the help of the theory of pseudo-Carathéodory functions developed in [9].

For certain applications it is useful to consider a dual family of solutions of the recurrence relation (2.4). The *second-kind polynomials* $q_k(z)$ are defined by

$$q_k(z) = (1 - z) \det J_{k-1}^0(z), \tag{2.11}$$

where $J_k^0(z)$ is the submatrix of $J_k(z)$ obtained by deleting its first row and column. It is clear that we actually have

$$q_{k+1}(z) = (\alpha_k + \bar{\alpha}_k z) q_k(z) - z q_{k-1}(z), \tag{2.12}$$

for $k = 1, 2, \cdots, n$, with the initial conditions $q_0(z) = 0$ and $q_1(z) = 1 - z$. The main difference with the first-kind polynomials $p_k(z)$ lies in the fact that $q_k(z)$ enjoys the *antisymmetry property*

$$\hat{q}_k(z) = -q_k(z), \tag{2.13}$$

instead of (2.3). Furthermore, all polynomials $q_k(z)$ vanish at the point $z = 1$. As a consequence of the assumption (2.9) we can show that the derivative of $q_k(z)$ is negative at $z = 1$, for $1 \leqq k \leqq n+1$. Applying the classical Jacobi theorem [1] to the corner entries of $J_k(z)$ we obtain the interesting relation

$$p_k(z) q_{k+1}(z) - q_k(z) p_{k+1}(z) = (1 - z) z^k, \tag{2.14}$$

by use of (2.2) and (2.11). Equivalently, (2.14) can be deduced from (2.4) and (2.12), by induction. Note that we have $q_k(0) = \alpha_0^{-1} p_k(0)$ for $k \geqq 1$.

Let us add a short comment on the role played by the point $z = 1$ in the whole theory (see (2.8) and (2.11), for example). In our approach it is quite important that the second-kind polynomials $q_k(z)$ all vanish for *some* fixed point ζ of unit modulus and that the first-kind polynomials satisfy the inequality $\zeta^{-k/2} p_k(\zeta) \geqq 0$, with possible equality when $k = n+1$ only. The polynomials in question have the general form $p_k(z) = \det J_{k-1}(z)$ and $q_k(z) = (\zeta^{1/2} - \zeta^{-1/2} z) \det J_{k-1}^0(z)$, with $J_k(z)$ as in (2.1). In this paper we make the choice $\zeta = 1$ for the sake of definiteness and simplicity, which entails no loss of generality. Indeed, for an arbitrary ζ with $|\zeta| = 1$, we can construct "normalized polynomials" $p_k'(z) = \zeta^{-k/2} p_k(\zeta z)$ and $q_k'(z) = \zeta^{-k/2} q_k(\zeta z)$ having the

required properties (with $\zeta' = 1$); the corresponding parameters of the tridiagonal matrix (2.1) are deduced from the original parameters by the formula $\alpha'_k = \alpha_k \zeta^{-k/2}$.

3. Connections with the Szegö polynomials. From the symmetric polynomials $p_{k+1}(z)$ and $p_k(z)$ let us construct the *comonic polynomial* $a_k(z)$ of formal degree k via the identity

$$p_{k+1}(0)(1-z)a_k(z) = p_{k+1}(z) - \lambda_{k+1} z p_k(z), \tag{3.1}$$

where λ_k is the Jacobi parameter (2.8). Let $\rho_k = a_{k,k}$ denote the coefficient of z^k in $a_k(z)$. By definition, $\bar{p}_{k+1}(0) + \rho_k p_{k+1}(0) = \lambda_{k+1}\bar{p}_k(0)$. Using (2.5) and (2.10) we deduce

$$\rho_k = \left(1 - \frac{1}{\lambda_k \alpha_k}\right) \frac{\bar{p}_k(0)}{p_k(0)}, \tag{3.2}$$

which yields the remarkable identity

$$|\alpha_k|^2 (1 - |\rho_k|^2) = \lambda_k^{-1} \lambda_{k+1}. \tag{3.3}$$

Therefore, the positivity conditions (2.9) can be expressed by $|\rho_k| < 1$ for $1 \leqq k \leqq n-1$ and $|\rho_n| \leqq 1$.

Let $\hat{a}_k(z) = z^k \bar{a}_k(1/\bar{z})$ denote the reciprocal of $a_k(z)$. As explained below, the monic polynomials $\hat{a}_k(z)$ constitute a family of *Szegö polynomials*. To discover the intrinsic meaning of the parameter ρ_k let us compute the polynomial $a_{k-1}(z) + \rho_k \hat{z} a_{k-1}(z)$ by using (3.1) with k replaced by $k-1$. Applying (2.4), (2.10), and (3.2) we readily obtain the recurrence relation

$$a_k(z) = a_{k-1}(z) + \rho_k z \hat{a}_{k-1}(z). \tag{3.4}$$

Therefore, the numbers ρ_k constitute the sequence of *Schur-Cohn parameters* [18], [23] of the polynomial $a_n(z)$.

Some "second-kind Szegö polynomials" can be obtained from the antisymmetric polynomials (2.11) by a relation similar to (3.1). Define the polynomial $r_k(z)$, of formal degree k, via the identity

$$p_{k+1}(0)(1-z)r_k(z) = q_{k+1}(z) - \lambda_{k+1} z q_k(z), \tag{3.5}$$

for $k = 0, 1, \cdots, n$. Note that we have $r_k(0) = \alpha_0^{-1}$ and $r_{k,k} = -\bar{\alpha}_0^{-1}\rho_k$ for all k. By a similar argument as above we can prove the recurrence relation

$$r_k(z) = r_{k-1}(z) - \rho_k z \hat{r}_{k-1}(z). \tag{3.6}$$

This shows that the polynomials $\hat{r}_k(z) = z^k \bar{r}_k(1/\bar{z})$ defined from (3.5) constitute the family of second-kind Szegö polynomials associated with the first-kind Szegö polynomials $\hat{a}_k(z)$ (see [12]).

Next, let us explain how the polynomials $p_k(z)$ and $q_k(z)$ can be recovered from the Szegö polynomials $\hat{a}_k(z)$ and $\hat{r}_k(z)$. Using (3.1) and (3.5) we readily derive the relations

$$\begin{aligned} \lambda_{k+1} p_k(z) &= p_{k+1}(0) a_k(z) + \bar{p}_{k+1}(0) \hat{a}_k(z), \\ \lambda_{k+1} q_k(z) &= p_{k+1}(0) r_k(z) - \bar{p}_{k+1}(0) \hat{r}_k(z), \end{aligned} \tag{3.7}$$

for $k = 0, 1, \cdots, n$. Alternative relations, involving a_{k-1} and r_{k-1} instead of a_k and r_k, can be obtained by substituting (3.4) and (3.6) into (3.7). The results are

$$\begin{aligned} p_k(z) &= p_k(0) a_{k-1}(z) + \bar{p}_k(0) z \hat{a}_{k-1}(z), \\ q_k(z) &= p_k(0) r_{k-1}(z) - \bar{p}_k(0) z \hat{r}_{k-1}(z), \end{aligned} \tag{3.8}$$

for $k=1, 2, \cdots, n+1$. Thus, within a constant factor, $p_k(z)$ and $q_k(z)$ coincide with the "singular polynomials" (3.4) and (3.6) obtained by substituting the number

$$\varepsilon_k = \bar{p}_k(0)/p_k(0), \tag{3.9}$$

of unit modulus, for the Schur-Cohn parameter ρ_k. Since $q_k(1)$ vanishes, the second relation (3.8) yields the useful result

$$\varepsilon_k = r_{k-1}(1)/\bar{r}_{k-1}(1). \tag{3.10}$$

This allows us to determine the sequence of numbers ε_k from the parameters ρ_k. Indeed, (3.6) yields the recurrence relation

$$\varepsilon_{k+1} = (\varepsilon_k - \rho_k)/(1 - \varepsilon_k\bar{\rho}_k). \tag{3.11}$$

The initial value is $\varepsilon_1 = \bar{\alpha}_0/\alpha_0$. Equivalently, (3.11) can be written in the form of the factorization

$$1 - |\rho_k|^2 = (1 - \varepsilon_k\bar{\rho}_k)(1 + \varepsilon_{k+1}\bar{\rho}_k). \tag{3.12}$$

(Note that the theory is significantly simpler in the case of real data, which yields $\varepsilon_k = 1$ for all k.)

It remains to find out an expression for the values $p_k(0)$ or, equivalently, the numbers α_k, in terms of the Schur-Cohn parameters ρ_k. From (3.2), (3.3), and (3.12) we deduce both identities $\alpha_k(1 - \bar{\varepsilon}_k\rho_k) = \lambda_k^{-1}$ and $\alpha_k(1 + \varepsilon_{k+1}\bar{\rho}_k) = \lambda_{k+1}$, whence

$$\alpha_{k-1}\alpha_k = (1 + \varepsilon_k\bar{\rho}_{k-1})^{-1}(1 - \bar{\varepsilon}_k\rho_k)^{-1}. \tag{3.13}$$

For a given value of α_0, this allows us to determine the α_k's from the ρ_k's, with the convention $\rho_0 = 1$. In summary, the sequence of symmetric polynomials $p_k(z)$ can be computed from the Szegö polynomials $\hat{a}_k(z)$ by means of the first formula (3.8), with the help of (3.13) and (2.5). Furthermore, the recurrence relation (2.4), with the appropriate numbers α_k, can be deduced from the Szegö relation (3.4). A verification of the latter property is left to the reader. There are completely similar results concerning the associated antisymmetric polynomials $q_k(z)$. This subject will be examined in further detail in the next section, from the viewpoint of Toeplitz systems of linear equations.

In the case where $J_n(1)$ is singular we have $\lambda_{n+1} = 0$ (i.e., $\rho_n = \varepsilon_{n+1}$), which yields the identities $p_{n+1}(z) = p_{n+1}(0)(1-z)a_n(z)$ and $q_{n+1}(z) = p_{n+1}(0)(1-z)r_n(z)$ via (3.1) and (3.5). Since $q_{n+1}(z)$ has a simple zero at $z=1$, the value of $r_n(1)$ cannot vanish; this is the only restriction that our approach (with the choice $\zeta = 1$) places on the Szegö theory.

Let us finally comment on the environment of the formulas (3.8). The two-variable *Christoffel-Darboux polynomial* of the second kind can be defined by

$$Q_k(\zeta, z) = \zeta\hat{r}_{k-1}(\zeta)r_{k-1}(z) - r_{k-1}(\zeta)z\hat{r}_{k-1}(z) \tag{3.14}$$

(see [26]). In view of (3.10) we have $q_k(z) = \beta_k Q_k(1, z)$ for a real constant β_k. There is a similar interpretation for $p_k(z)$ in terms of a suitable two-variable "Green polynomial" $P_k(\zeta, z)$.

4. Orthogonality relations and Levinson-type algorithm. A family of monic polynomials $\hat{a}_k(z)$ satisfying the recurrence relation (3.4) with the constraints $|\rho_k| < 1$ for $1 \leqq k \leqq n-1$ and $|\rho_n| \leqq 1$ is known to be a Szegö family, in the sense that the $\hat{a}_k(z)$ are pairwise orthogonal on the unit circle with respect to a certain positive measure $d\omega(\theta)$.

Let us explain this property in precise terms (see [2], [12], [26]). The inner product $\langle x, y\rangle$ of any two pseudopolynomials $x(z)$ and $y(z)$ with respect to $d\omega(\theta)$ is defined by

$$\langle x, y\rangle = \int_0^{2\pi} \bar{x}(e^{i\theta}) y(e^{i\theta})\, d\omega(\theta). \tag{4.1}$$

For an appropriate choice of the measure, the polynomials $\hat{a}_k(z)$ satisfy the *orthogonality relations*

$$\langle \hat{a}_k, \hat{a}_l\rangle = \sigma_k \delta_{k,l}, \tag{4.2}$$

for $0 \leqq k, l \leqq n$, where δ is the Kronecker symbol and σ_k is a nonnegative real number. More precisely, we have $\sigma_k > 0$ for $0 \leqq k \leqq n-1$ and $\sigma_n \geqq 0$, with $\sigma_n = 0$ if and only if $|\rho_n| = 1$. In fact, the *squared norms* σ_k obey the recurrence relation $\sigma_k = (1-|\rho_k|^2)\sigma_{k-1}$. For the sake of normalization it proves convenient to set

$$\sigma_0 = c_0 = \mathrm{Re}\,(\alpha_0^{-1}). \tag{4.3}$$

From (3.3) and (2.5) we deduce the useful identity

$$\lambda_k = 2\sigma_{k-1}|p_k(0)|^2. \tag{4.4}$$

Except in the *singular case* $|\rho_n| = 1$ (i.e., $\lambda_{n+1} = 0$), the measure $d\omega(\theta)$ is not unique. However its first $2n+1$ trigonometric moments

$$c_s = \int_0^{2\pi} e^{-is\theta}\, d\omega(\theta), \qquad -n \leqq s \leqq n, \tag{4.5}$$

are uniquely determined from $a_n(z)$ or, equivalently, from the parameters $\rho_1, \cdots, \rho_n$. (Here c_0 is supposed to be given. Note the property $c_{-s} = \bar{c}_s$.) Conversely, the polynomials $a_k(z)$ can be computed from the moments (4.5) as follows. Construct the *Hermitian Toeplitz matrix*

$$C_k = [c_{s-t} : 0 \leqq s, t \leqq k], \tag{4.6}$$

which is the Gram matrix of the monomials $1, z, \cdots, z^k$ with respect to the inner product (4.1). It is positive definite for $0 \leqq k \leqq n-1$ and nonnegative definite for $k = n$. The orthogonality relations (4.2) can be expressed by the fact that the coefficient vector $a_k = [a_{k,t} : 0 \leqq t \leqq k]^T$ of the comonic polynomial $a_k(z) = \sum_{t=0}^{k} a_{k,t} z^t$ is the solution of the system of linear equations

$$C_k a_k = [\sigma_k, 0, \cdots, 0]^T. \tag{4.7}$$

Note that we have $\sigma_k = \det C_k / \det C_{k-1}$ for $k = 1, 2, \cdots, n$.

In view of (3.7), the coefficient vector $p_k = [p_{k,t} : 0 \leqq t \leqq k]^T$ of the symmetric polynomial $p_k(z) = \sum_{t=0}^{k} p_{k,t} z^t$ satisfies the linear system

$$C_k p_k = [\bar{\tau}_k, 0, \cdots, 0, \tau_k]^T, \tag{4.8}$$

for $k \geqq 1$, where $\tau_k = \sigma_k \bar{p}_{k+1}(0)/\lambda_{k+1} = (2p_{k+1}(0))^{-1}$, by (4.4). Applying (2.5) we obtain the important formula

$$\alpha_k = \tau_{k-1}/\tau_k, \tag{4.9}$$

with the convention $\tau_0 = (2\alpha_0)^{-1}$. From (4.8) we then deduce the set of relations

$$\begin{aligned} \langle p_k, p_k\rangle &= \mathrm{Re}\,(\alpha_k^{-1}), \\ \langle p_k, p_l\rangle &= (2\alpha_l \alpha_{l+1} \cdots \alpha_k)^{-1} \quad \text{for } k > l, \\ \langle p_k, z^t p_l\rangle &= 0 \quad \text{for } k - l > t > 0, \end{aligned} \tag{4.10}$$

for $0 \leqq k \leqq n$. Let us then introduce the pseudopolynomials $v_k(z)$ by normalizing and

shifting the polynomials $p_k(z)$ as follows:

$$\begin{aligned} v_{2t}(z) &= \sqrt{2}\alpha_{2t} z^{-t} p_{2t}(z), \\ v_{2t+1}(z) &= \sqrt{2}\,\bar{\alpha}_{2t+1}\, z^{-t} p_{2t+1}(z). \end{aligned} \tag{4.11}$$

It is easily seen that the relations (4.10) assume the simple form

$$\begin{aligned} \langle v_k, v_k \rangle &= 2\,\mathrm{Re}\,(\alpha_k), \\ \langle v_k, v_{k-t} \rangle &= \delta_{t,1} \quad \text{for } t \geqq 1. \end{aligned} \tag{4.12}$$

This shows that the tridiagonal matrix $J_n(1) = A_n + \tilde{A}_n$ can be interpreted as the Gram matrix of the pseudopolynomials $v_0(z), v_1(z), \cdots, v_n(z)$ with respect to the inner product (4.1). There is a close connection between (4.11) and (2.6). It appears that $\psi_k(\theta/2)$ and $\psi_l(\theta/2)$ are orthogonal when k and l have the same parity. This is generally not true for opposite parities, except in the case of real data (see [5]).

It is interesting to note that (4.12) can be interpreted as a congruence relation between the Toeplitz matrix C_n and the Jacobi matrix $J_n(1)$. Indeed, we have

$$J_n(1) = \tilde{V}_n C_n V_n, \tag{4.13}$$

where V_n is the square matrix of order $n+1$ whose columns are the coefficient vectors of the pseudo-polynomials $v_k(z)$. By definition, V_n is a triangular matrix within permutation of its rows. The result (4.13), or simply (4.4), yields an interesting *positivity test* for a given Hermitian Toeplitz matrix C_n of order $n+1$. Indeed, it shows that the conditions (2.9) on the Jacobi parameters λ_k characterize precisely the fact that C_n is nonnegative definite and C_{n-1} positive definite. The λ_k's can be obtained from the entries of C_n as by-products of the Levinson-type algorithm described below.

Given a nonnegative definite Toeplitz matrix C_n of nullity 0 or 1, the polynomial $a_n(z)$ defined from (4.7) yields the optimal *prediction filter* of length n for a stationary stochastic process having C_n as its autocorrelation matrix [20], [22]. The *Levinson algorithm* [14], [21] is a recursive method to compute the predictors $a_k(z)$ together with the Schur-Cohn parameters ρ_k (called reflection coefficients in this context). Let us now explain how the "singular predictors" $p_k(z)$ can be determined from C_n by a recursive method essentially different from but formally analogous to the Levinson algorithm. The outcome will be an efficient procedure to compute the desired predictor $a_n(z)$, together with the reflection coefficients ρ_k and the Jacobi parameters λ_k. The special case of a real Toeplitz matrix C_n has been recently treated in detail by the authors, who proposed the name "split Levinson algorithm" for their new method [5].

Recall that the coefficient vector of $p_k(z)$ is the solution of the Toeplitz system (4.8). Assuming $p_{k-1}(z)$, $p_k(z)$ and τ_{k-1} to be available at the kth step of the algorithm, let us indicate how to compute $p_{k+1}(z)$ and τ_k. In view of (4.8) we simply have

$$\tau_k = \sum_{i=0}^{k} c_{k-i}\, p_{k,i}. \tag{4.14}$$

Then the parameter α_k is given by (4.9) and the updated polynomial $p_{k+1}(z)$ results from the recurrence relation (2.4). The initial conditions are $p_{-1}(z) = 0$, $p_0(z) = 1$ and $\tau_0 = (2\alpha_0)^{-1}$. (Thus, $\mathrm{Re}\,\tau_0 = c_0/2$.) The numbers of real additions and multiplications in the kth step of the algorithm are found to be $8k+15$ and $4k+14$, respectively. The corresponding numbers for the Levinson algorithm are $8k-6$ and $8k-4$. The gain in computational complexity stems from the symmetry property $p_{k,k-t} = \bar{p}_{k,t}$ of the coefficients of $p_k(z)$, which allows one to significantly economize on arithmetic operations. Furthermore, the same property leads to a reduction of the memory space by a factor 2 (roughly speaking).

The predictor $a_n(z)$ can be computed at the end of the algorithm by means of (2.8) and (3.1) with $k=n$. The successive Jacobi parameters λ_k can be determined from the numbers α_k with the help of the recurrence relation (2.10). Then the reflection coefficients ρ_k are obtainable from (3.2). Note that $\varepsilon_k = \tau_{k-1}/\bar{\tau}_{k-1}$.

To conclude this section let us indicate how the entries $c_0, c_1, \cdots, c_n$ of the Hermitian Toeplitz matrix C_n can be computed from the numbers $\alpha_0, \alpha_1, \cdots, \alpha_n$ in a direct manner. As shown in § 6, we have the remarkable interpolation property

$$\frac{q_{n+1}(z)}{p_{n+1}(z)} = \alpha_0^{-1} + 2\sum_{t=1}^{n} c_t z^t + O(z^{n+1}), \tag{4.15}$$

where $p_{n+1}(z)$ and $q_{n+1}(z)$ are obtained from the recurrence relations (2.4) and (2.12) with the initializations indicated above. The significance of (4.15) will become clear in the sequel.

5. Zero location and Bistritz stability test. It is well known that the "predictor polynomial" $a_k(z)$ is devoid of zeros in the closed unit disk $|z| \leqq 1$ if and only if the associated Hermitian Toeplitz matrix C_k is positive definite (in case $c_0 > 0$). In view of (3.4), this can be interpreted as the *Schur-Cohn stability test* $|\rho_t| < 1$ for $< 1 \leqq t \leqq k$ (see [18], [23]). Furthermore, if C_n is nonnegative definite and has rank n then $a_n(z)$ has n distinct zeros on the unit circle $|z| = 1$ (see [15]). The same statements can be made concerning the polynomials $r_k(z)$.

Next, let us examine the properties of the zeros of the polynomials $p_k(z)$ and $q_k(z)$. Consider first the "nonsingular case" where $J_n(1)$ is strictly positive definite. It follows from (3.7) or (3.8) that $p_k(z)$ has k distinct zeros on the unit circle (for $1 \leqq k \leqq n+1$) and $q_k(z)$ has the same property. In fact, the zeros of $p_k(z)$ *separate* those of $q_k(z)$ on the unit circle. This follows from the fact that the quotient function $g_k(z) = q_k(z)/p_k(z)$ has degree k and is a Carathéodory function of *lossless* type, in the sense that it satisfies the inequality $\operatorname{Re} g_k(z) \geqq 0$ in the unit disk $|z| < 1$ and the equality $\operatorname{Re} g_k(z) = 0$ almost everywhere on the unit circle $|z| = 1$. Furthermore, it can be shown that the zeros of $p_k(z)$ separate those of $(1-z)p_{k-1}(z)$, because the quotient of these polynomials is a lossless function of degree k. The proof of the former result is elementary; the proof of the latter is contained in the derivation of the Bistritz test given below.

In the "singular case" where $\det J_n(1)$ vanishes and $J_{n-1}(1)$ is positive definite, the properties mentioned above have to be slightly modified (when $k = n+1$). Recall that $p_{n+1}(z)$ and $q_{n+1}(z)$ are proportional to $(1-z)a_n(z)$ and $(1-z)r_n(z)$, respectively. It turns out that the zeros of $a_n(z)$ separate those of $r_n(z)$, on the one hand, and those of $p_n(z)$, on the other hand.

The remaining part of this section is devoted to explaining how the *Bistritz stability criterion* fits nicely into the general framework of the paper. The Bistritz test is an interesting new method to check whether a given complex polynomial $x_n(z)$ of degree n is *stable*, in the sense that it does not vanish in the closed unit disk $|z| \leqq 1$ (see [3], [4], [8]); this method has a lower computational complexity than the classical Schur-Cohn stability test. Without loss of generality we assume that $x_n(1)$ is real. The main part of the Bistritz algorithm consists in computing the descending sequence of symmetric polynomials $p_k(z)$, for $k = n, n-1, \cdots, 1, 0$, from the recurrence relation (2.4) with the initialization

$$p_n(z) = x_n(z) + \hat{x}_n(z), \qquad (1-z)p_{n-1}(z) = x_n(z) - \hat{x}_n(z). \tag{5.1}$$

(Note that $p_0(z)$ is generally not equal to unity as in § 2. In the present context, the normalization is not given a priori.) The Bistritz criterion says that $x_n(z)$ is stable if

and only if the parameters $\lambda_k = p_k(1)/p_{k-1}(1)$ exist and are positive for $k = n, n-1, \cdots, 1$, which means that the tridiagonal matrix $J_{n-1}(1)$ built from the complex numbers $\alpha_k = p_{k+1}(0)/p_k(0)$ is positive definite. The following argument contains a simple proof of this result.

Using (3.7), (3.8), and (5.1) we derive the identity

$$\frac{x_n(z)+\hat{x}_n(z)}{x_n(z)-\hat{x}_n(z)} = \frac{\lambda_n}{2}\left[\frac{1+z}{1-z} + \frac{a_{n-1}(z)-\varepsilon_n \hat{a}_{n-1}(z)}{a_{n-1}(z)+\varepsilon_n \hat{a}_{n-1}(z)}\right], \tag{5.2}$$

by straightforward computation. If $J_{n-1}(1)$ is positive definite, then so is the Toeplitz matrix C_{n-1}, which implies that $a_{n-1}(z)$ is stable. Therefore, both terms in the right-hand side of (5.2) are lossless functions, which implies that $x_n(z)$ is stable. Conversely, if $x_n(z)$ is stable, then the left-hand side of (5.2) is a lossless function, having a pole at $z = 1$ with positive mass λ_n. The second term in (5.2) is precisely obtained by extraction of this pole; hence it is a lossless function, which implies that $a_{n-1}(z)$ is stable. It then follows from (3.3), via the Schur-Cohn criterion, that all parameters λ_k are positive.

6. Carathéodory–Fejér interpolation problem. This section contains a new approach to the trigonometric moment problem or, equivalently, the coefficient problem for Carathéodory functions. In fact, we are mainly interested in the partial trigonometric moment problem, which is equivalent to the Carathéodory-Fejér interpolation problem [2], [25]. Recall that a function $f(z)$ of the complex variable z belongs to the class C of *Carathéodory functions* if it is analytic and satisfies $\operatorname{Re} f(z) \geqq 0$ in the unit disk $|z| < 1$. Consider the Maclaurin expansion $f(z) = \gamma_0 + 2\sum_{t=1}^{\infty} c_t z^t$. The well-known *Carathéodory-Toeplitz theorem* says that $f(z)$ is a C-function if and only if the Hermitian Toeplitz matrix C_k built from the coefficients c_t, with $c_0 = \operatorname{Re} \gamma_0$ and $c_{-t} = \bar{c}_t$, is nonnegative definite for all k.

The Schur criterion provides a very interesting alternative solution to the same problem. Recall that a function $\phi(z)$ belongs to the class S of *Schur functions* if it is analytic and satisfies $|\phi(z)| \leqq 1$ in the unit disk. From a given function $\phi(z)$ let us construct a sequence of functions $\phi_k(z)$ by means of the Schur recurrence relation

$$\phi_{k+1}(z) = \frac{\phi_k(z) - \phi_k(0)}{z(1 - \bar{\phi}_k(0)\phi_k(z))}, \tag{6.1}$$

for $k = 0, 1$, etc., with the initialization $\phi_0(z) = \phi(z)$. The *Schur criterion* says that $\phi(z)$ is an S-function if and only if we have $|\phi_k(0)| \leqq 1$ for all k. (In case $|\phi_n(0)| = 1$ for a certain n, the criterion says that $\phi_n(z)$ has to be a constant; this characterizes the Blaschke products $\phi(z)$ of degree n.) Since the bilinear transform $\phi(z) = (1 - f(z))/(1 + f(z))$ establishes a bijection between the class S and the class C (supplemented with the "function" $f(z) = \infty$), the Schur criterion can be used to solve the Carathéodory coefficient problem. Note the identity $\phi_k(0) = \rho_k$, for $k \geqq 1$, where the ρ_k's are the reflection coefficients defined as in §§ 3 and 4.

Let there be given $n+1$ complex numbers $\gamma_0, c_1, \cdots, c_n$. The *Carathéodory-Fejér* (CF) *interpolation problem* requires to determine the set of C-functions $f(z)$ satisfying

$$f(z) = \gamma_0 + 2\sum_{t=1}^{n} c_t z^t + O(z^{n+1}). \tag{6.2}$$

This problem can be completely solved with the help of the Schur relation (6.1). When the Toeplitz matrix $C_n = [c_{s-t} : 0 \leqq s, t \leqq n]$, with $c_0 = \operatorname{Re} \gamma_0$ and $c_{-t} = \bar{c}_t$, is positive definite, there is an infinite number of solutions $f(z)$, given by

$$f(z) = \frac{r_n(z) - z\phi(z)\hat{r}_n(z)}{a_n(z) + z\phi(z)\hat{a}_n(z)}, \tag{6.3}$$

where $\phi(z)$ is an arbitrary S-function. (Here $a_n(z)$ and $r_n(z)$ denote the reciprocals of the first-kind and second-kind Szegö polynomials associated with C_n. The parameter α_0 is set equal to γ_0^{-1}.) When C_n is nonnegative definite but singular, there is a unique candidate solution, namely the rational lossless function $f(z) = r_m(z)/a_m(z)$ where m is the rank of C_n. In the remaining case, there is no solution. These results are quite classical (see especially [2]), except perhaps the explicit representation (6.3), for which a detailed proof can be found in [10].

In the sequel it is explained how the symmetric and antisymmetric polynomials $p_k(z)$ and $q_k(z)$ or, equivalently, their recurrence parameters α_k, yield alternative solution methods for the problems mentioned above. Roughly speaking, these data replace the classical polynomials $a_k(z)$ and $r_k(z)$, and the reflection coefficients ρ_k.

Given a C-function $g(z)$ let us denote by $\mu(g)$ the *inverse of the mass of* $g(z)$ *at the point* $z = 1$. More precisely,

$$\mu(g) = [\lim_{z \uparrow 1} (1-z)g(z)]^{-1}. \tag{6.4}$$

Thus we have $\mu(g) = \infty$ when $g(z)$ has no quasi-pole at $z = 1$. By convention, we set $\mu(g) = 0$ for the trivial "function" $g(z) = \infty$. In the remaining cases, $\mu(g)$ is a positive real number. The following lemma plays a crucial role in our approach; it could be viewed as a substitute for the Schwarz lemma underlying the Schur criterion.

LEMMA 1. *Let* $f_k(z)$ *be a* C*-function and define* $f_{k+1}(z)$ *by means of the relation*

$$f_k(z) = \frac{\alpha_k + \bar{\alpha}_k z}{1-z} + \frac{1}{(1-z)(1-z^{-1})f_{k+1}(z)}, \tag{6.5}$$

where $\alpha_k = f_k(0)$. *Then* $f_{k+1}(z)$ *is a* C*-function satisfying*

$$0 \leqq \mu(f_{k+1}) \leqq 2 \operatorname{Re} \alpha_k, \tag{6.6}$$

with the possibility $f_{k+1}(z) = \infty$. *Conversely, let* α_k *be a complex number and let* $f_{k+1}(z)$ *be a* C*-function, subject to the constraint* (6.6). *Then the right-hand side of* (6.5) *is a* C*-function satisfying* $f_k(0) = \alpha_k$.

Proof. Set $\psi_k(z) = (f_k(z) - \alpha_k)/z(f_k(z) + \bar{\alpha}_k)$. We readily verify that (6.5) can be written in the form

$$f_{k+1}(z) = \frac{1}{4 \operatorname{Re} \alpha_k} \left[\frac{1+z}{1-z} + \frac{1+\psi_k(z)}{1-\psi_k(z)} \right]. \tag{6.7}$$

Assume first $f_k(z)$ to be a C-function, with $f_k(0) = \alpha_k$. It follows from the Schwarz lemma that $\psi_k(z)$ is an S-function. Hence, (6.7) shows that $f_{k+1}(z)$ is a C-function (since it is the sum of two C-functions). Furthermore, (6.5) yields the identity

$$\mu^{-1}(f_k) + \mu(f_{k+1}) = 2 \operatorname{Re} \alpha_k, \tag{6.8}$$

which proves the bound (6.6).

Next, consider a C-function $f_{k+1}(z)$ satisfying (6.6), for a given number α_k. The interpolation property $f_k(0) = \alpha_k$ is a straightforward consequence of (6.5). Furthermore, the constraint (6.6) exactly says that the mass of the first summand of (6.7) at $z = 1$ does not exceed that of $f_{k+1}(z)$. Therefore, the second summand is a C-function, which means that $\psi_k(z)$ is an S-function, implying that $f_k(z)$ is a C-function. □

It is worth mentioning that Lemma 1 can be deduced immediately from the theory of pseudo-Carathéodory functions [9]. The first summand of (6.5), denoted here by $u_k(z)$, is the lossless function of degree 1, with its pole in $z = 1$, satisfying $u_k(0) = f_k(0)$. Then the second summand has the form of the canonical factorization of the residual

pseudo-Carathéodory function $f_k(z)-u_k(z)$; indeed, the inverses of the functions $(1-z)(1-z^{-1})$ and $f_{k+1}(z)$ are the density factor and the Carathéodory factor of $f_k(z)-u_k(z)$ (see [9]).

The recurrence relation (6.5) can be used to solve the CF interpolation problem (6.2) by an iterative procedure formally similar to the Schur method based on (6.1). Indeed, the expression (6.5) with $k=0$ provides a parametrization of all C-functions satisfying the interpolation constraint $f_0(0)=\alpha_0$ in terms of a C-function $f_1(z)$ subject to the only restriction $0\leqq\mu(f_1)\leqq 2\ \mathrm{Re}\ \alpha_0$. The remaining interpolation constraints can be transferred to the function $f_1(z)$ and the method above can be iterated in an obvious way. Thus it is seen that the problem admits a solution if and only if the inequalities (6.6) are satisfied at each step of the algorithm. Furthermore, it is intuitively clear that there is an infinite number of solutions unless one of the bounds (6.6) is tight.

Let us now examine the method in some detail. The recurrence relation (6.5) is used to solve the problem (6.2) with the initialization $f_0(z)=f^{-1}(z)$. From a computational viewpoint it is interesting to express (6.5) in terms of the functions $w_k(z)$ defined from the identity

$$f_k(z)=w_{k-1}(z)/(1-z)w_k(z), \tag{6.9}$$

with $w_{-1}(z)=1-z$ and $w_0(z)=f(z)$. Thus we have

$$w_k(z)=[(1-z)^k f_0(z)f_1(z)\cdots f_k(z)]^{-1}. \tag{6.10}$$

Using (6.9) we can write (6.5) in the form

$$zw_{k+1}(z)=(\alpha_k+\bar{\alpha}_k z)w_k(z)-w_{k-1}(z). \tag{6.11}$$

It is easily seen that, except in some "pathological situations," the interpolation constraints (6.2) determine the $n+1$ parameters $\alpha_0,\alpha_1,\cdots,\alpha_n$ (and conversely). Indeed, from (6.9) and (6.11) we deduce the identities

$$\alpha_k=w_{k-1,0}/w_{k,0}, \tag{6.12}$$

$$w_{k+1,t}=\alpha_k w_{k,t+1}+\bar{\alpha}_k w_{k,t}-w_{k-1,t+1}, \tag{6.13}$$

with $w_k(z)=\sum_{t=0}^{\infty}w_{k,t}z^t$. In general, these have to be used for $0\leqq k\leqq n$ and $0\leqq t\leqq n-k-1$, with the initial conditions $w_{-1,0}=1$, $w_{-1,1}=-1$, $w_{-1,t}=0$ for $t\geqq 2$, and $w_{0,0}=\gamma_0$, $w_{0,t}=2c_t$ for $t\geqq 1$. But the algorithm is bound to stop when it meets the situation $w_{l,0}=0$ for a certain l with $0\leqq l\leqq n$. If $w_{l,t}=0$ for $t=0,1,\cdots,n-l-1$, then the interpolation constraints are satisfied by the choice $w_l(z)=0$, i.e., $f_l(z)=\infty$; this will be referred to as the *degenerate case*. If $w_{l,t}\neq 0$ for some t, then it is clear that the CF problem admits no solution. The case where $w_{k,0}\neq 0$ for $0\leqq k\leqq n$ will be called *nondegenerate*; it will be appropriately characterized by the convention $l=n+1$ (which does not refer to the properties of $w_{n+1}(z)$).

From the parameters $\alpha_0,\alpha_1,\cdots,\alpha_{l-1}$ thus obtained let us construct the tridiagonal matrices $J_k(z)$, as in (2.1), and the corresponding polynomials $p_k(z)$ and $q_k(z)$. We are now in a position to describe the complete solution of the CF problem in terms of these data. (Henceforth we rule out the case where $w_{l,0}=0$ and $w_{l,t}\neq 0$ for some $t\geqq 1$.)

THEOREM 2. *A necessary and sufficient condition for the* CF *interpolation problem to be solvable is that the matrix $J_{l-1}(1)$ be nonnegative definite. In the degenerate case ($l\leqq n$) there is a unique solution, given by $f(z)=q_l(z)/p_l(z)$; it is lossless and its degree equals l or $l-1$ according as $J_{l-1}(1)$ is positive definite or singular. In the nondegenerate case ($l=n+1$), if $J_n(1)$ is singular then there is a unique solution, namely the rational*

lossless function $f(z)=q_{n+1}(z)/p_{n+1}(z)$, *which has degree* n; *if* $J_n(1)$ *is positive definite then there is an infinite number of solutions* $f(z)$, *given by*

$$f(z)=\frac{zq_n(z)-(1-z)g(z)q_{n+1}(z)}{zp_n(z)-(1-z)g(z)p_{n+1}(z)}, \tag{6.14}$$

where $g(z)$ *is a C-function subject to the only constraint*

$$0\leqq\mu(g)\leqq\lambda_{n+1}. \tag{6.15}$$

Proof. Let us write the recurrence relation (6.11) in the form

$$J_k(z)[w_0(z),-w_1(z),\cdots,(-1)^k w_k(z)]^T=[w_{-1}(z),0,\cdots,0,(-1)^k z w_{k+1}(z)]^T, \tag{6.16}$$

for $k\leqq l-1$. The four corner entries of $J_k^{-1}(z)$ can be explicitly determined with the help of (2.2) and (2.11). Solving (6.16) for $w_0(z)$ and $w_k(z)$ we then obtain

$$f(z)p_{k+1}(z)=q_{k+1}(z)+z^{k+1}w_{k+1}(z), \tag{6.17}$$

$$w_k(z)p_{k+1}(z)=1-z+zw_{k+1}(z)p_k(z), \tag{6.18}$$

by use of $w_{-1}(z)=1-z$ and $w_0(z)=f(z)$. Note that (6.17) can be used to define $q_{k+1}(z)$ and $w_{k+1}(z)$ from $f(z)$ and $p_{k+1}(z)$. Furthermore, note that (6.18) can be deduced from (6.17) and (2.14). Dividing (6.18) by $1-z$, using (6.10) and (6.4), we deduce the identity

$$\mu(f_0)\mu(f_1)\cdots\mu(f_k)[p_{k+1}(1)-\mu(f_{k+1})p_k(1)]=1. \tag{6.19}$$

Alternatively, this can be derived from (6.8) and (2.10).

Assume first the CF problem to admit a solution $f(z)$. In view of Lemma 1 we have $0<\mu(f_0)\leqq\infty$, $0<\mu(f_k)<\infty$ for $k=1,\cdots,l-1$, and $0\leqq\mu(f_l)<\infty$, with $\mu(f_l)=0$ in the degenerate case. Hence (6.19) yields $\lambda_{k+1}\geqq\mu(f_{k+1})\geqq 0$, which implies that $J_{l-1}(1)$ is nonnegative definite. Note incidentally that we have $\mu(f_k)=\lambda_k$ for all k if and only if $\mu(f_0)=\infty$, which means that $f(z)$ has no quasizero at $z=1$.

Conversely, assume $J_{l-1}(1)$ to be nonnegative definite, which implies $\lambda_k>0$ for $1\leqq k\leqq l-1$ and $\lambda_l\geqq 0$. Let us choose any C-function $f_l(z)$ satisfying $0\leqq\mu(f_l)\leqq\lambda_l$. We have to show that the function $f_0(z)$ obtained by repeated use of (6.5) belongs to class C. (Then $f(z)=f_0^{-1}(z)$ is a solution to the CF problem.) In view of Lemma 1 it suffices to prove that the constraint (6.6) is satisfied for $k=l-1,l-2,\cdots,0$. To that end let us make use of the descending recurrence relation

$$\mu^{-1}(f_k)-\lambda_k^{-1}=\lambda_{k+1}-\mu(f_{k+1}), \tag{6.20}$$

deduced from (6.19), or directly from (6.8) and (2.10). By induction, (6.20) yields $0\leqq\mu(f_k)\leqq\lambda_k$ whence the desired property $0\leqq\mu(f_k)\leqq 2\,\mathrm{Re}\,\alpha_{k-1}$ for $1\leqq k\leqq l$.

It remains to describe the set of solutions. In the nondegenerate case ($l=n+1$) we obtain the expression (6.14), with $g(z)=f_{n+1}(z)$, by elimination of $w_{n+1}(z)$ and $w_n(z)$ between (6.9) and two versions of (6.17). When $J_n(1)$ is singular, the only possibility is $g(z)=\infty$, which yields $f(z)=q_{n+1}(z)/p_{n+1}(z)$. Similarly, in the degenerate case ($l\leqq n$) we must have $f_l(z)=\infty$, whence $f(z)=q_l(z)/p_l(z)$. These rational functions $f(z)$ are clearly lossless. Their degree properties are described in § 5. □

It is very interesting to compare the formulas (6.3) and (6.14), which must be equivalent. Expressing $p_n(z)$, $q_n(z)$ and $p_{n+1}(z)$, $q_{n+1}(z)$ in terms of $a_n(z)$, $r_n(z)$ by means of (3.7) and (3.8) we obtain a simple relation between the "parameter functions" $\phi(z)$ and $g(z)$ occurring in (6.3) and (6.14), namely

$$g(z)=\frac{1}{2\lambda_{n+1}}\left[\frac{1+z}{1-z}+\frac{1+\bar{\varepsilon}_{n+1}\phi(z)}{1-\bar{\varepsilon}_{n+1}\phi(z)}\right]. \tag{6.21}$$

This establishes a bijection between the S-functions $\phi(z)$ and the C-functions $g(z)$ satisfying (6.15), in perfect agreement with Theorem 2.

Using Lemma 1 in the opposite direction we can obtain an interesting new criterion to check whether a certain function $f(z)$, given by its Maclaurin expansion, belongs to class C. This criterion is expressed in terms of the sequence of complex numbers $\alpha_k = f_k(0)$, with $k = 0, 1$, etc., deduced from the recurrence relation (6.5) applied to the initial function $f_0(z) = f^{-1}(z)$. An important distinction has to be made between the *regular case*, where the sequence of α_k is infinite, and the *singular case*, where the sequence has finite length $n+1$ (ending with α_n) because the algorithm yields $f_{n+1}(z) = \infty$.

THEOREM 3. *The given function $f(z)$ belongs to class C if and only if the tridiagonal matrix $J_k(1)$ built from the parameters $\alpha_t = f_t(0)$ is positive definite, for all k, in the regular case, and is nonnegative definite for $k = n$ in the singular case.*

Proof. The "only if" part follows directly from Theorem 2. The "if" part can be deduced from the Carathéodory-Toeplitz theorem with the help of the congruence relation (4.13). □

It should be noted that the singular case corresponds exactly to the case of a rational lossless function $f(z)$, whose degree equals the rank of $J_n(1)$. As an interpretation of Theorem 3 one can say that a C-function $f(z)$ admits a formal continued fraction expansion

$$f(z) = \frac{1|}{|u_0(z)} + \frac{1|}{|u_1(z)} + \frac{1|}{|u_2(z)} + \cdots, \tag{6.22}$$

with $u_t(z) = (\alpha_t + \bar{\alpha}_t z)/(1-z)$ for even t and $u_t(z) = (1-z^{-1})(\alpha_t + \bar{\alpha}_t z)$ for odd t, yielding nonnegative definite matrices $J_k(1)$. This fraction contains a finite number of terms if and only if $f(z)$ is a rational lossless function. More precisely, if (6.22) contains $n+1$ terms then $f(z)$ has degree n or $n+1$ according as $J_n(1)$ is singular or not.

To conclude this section let us explain how the basic relations (6.12) and (6.13) of our approach to the CF problem give rise to a new efficient "Schur-type algorithm" computing the reflection coefficients ρ_k for a given nonnegative definite Toeplitz matrix C_n (of rank n or $n+1$). In the case of real data, the method described below reduces to the split Schur algorithm recently proposed by the authors [6]. The formulas (6.12) and (6.13) allow us to determine the sequence of parameters $\alpha_0, \alpha_1, \cdots, \alpha_n$ from the data $w_{0,0} = \gamma_0$ (with $\operatorname{Re}\gamma_0 = c_0$) and $w_{0,t} = 2c_t$ for $1 \leqq t \leqq n$. Then the reflection coefficients $\rho_1, \rho_2, \cdots, \rho_n$ can be recursively computed with the help of (3.13). In explicit form, we have

$$\rho_k = \varepsilon_k - [\alpha_k \alpha_{k-1}(\bar{\varepsilon}_k + \bar{\rho}_{k-1})]^{-1}, \tag{6.23}$$

for $k = 1, 2, \cdots, n$, with the initialization $\rho_0 = 1$. The number ε_k appearing in (6.23) can be determined by

$$\varepsilon_k = w_{k-1,0} / \bar{w}_{k-1,0}. \tag{6.24}$$

Indeed, we have $w_k(0) p_{k+1}(0) = 1$ by (6.18), so that (6.24) results from the definition (3.9). It can be verified that the number of multiplications required by this method (based on (6.12), (6.13), (6.23), and (6.24)) is approximately reduced by a factor 2 with respect to the classical Schur algorithm, while the number of additions remains unchanged. These conclusions are very similar to those concerning the Levinson-type algorithm of § 3.

7. Nevanlinna–Pick interpolation problem. Given $n+1$ distinct points $z_0, z_1, \cdots, z_n$ in the unit disk $|z| < 1$ and $n+1$ complex numbers $u_0, u_1, \cdots, u_n$, the

Nevanlinna-Pick (NP) *interpolation problem* requires to determine the set of C-functions $f(z)$ satisfying

$$f(z_k) = u_k \quad \text{for } k = 0, 1, \cdots, n. \tag{7.1}$$

This appears as a natural analogue of the CF problem. It is classically solved by means of the Nevanlinna algorithm [2], which is an extension of the Schur algorithm. Let us now explain how the NP problem can alternatively be approached by a suitable modification of the "tradiagonal method" used in § 6. From the given point z_k define the binomial

$$y_k(z) = \beta_k \frac{z - z_k}{1 - z_k} \quad \text{with } \beta_k = \frac{|1 - z_k|^2}{1 - |z_k|^2}. \tag{7.2}$$

The Blaschke function $y_k(z)/\hat{y}_k(z)$ acts as a transformation that preserves the unit disk, fixes the point $z = 1$ and maps the point $z = z_k$ to the origin $z = 0$. Therefore, the following key result is obtained from Lemma 1 by a simple change of variables.

LEMMA 4. *Let $f_k(z)$ be a C-function and define $f_{k+1}(z)$ by means of the relation*

$$f_k(z) = \frac{\alpha_k \hat{y}_k(z) + \bar{\alpha}_k y_k(z)}{1 - z} - \frac{y_k(z)\hat{y}_k(z)}{(1 - z)^2 f_{k+1}(z)}, \tag{7.3}$$

where $\alpha_k = f_k(z_k)$ and $\hat{y}_k(z) = z\bar{y}_k(1/\bar{z})$. Then $f_{k+1}(z)$ is a C-function satisfying

$$0 \leqq \mu(f_{k+1}) \leqq 2\beta_k^{-1} \operatorname{Re} \alpha_k, \tag{7.4}$$

with the possibility $f_{k+1}(z) = \infty$. Conversely, let α_k be a complex number and let $f_{k+1}(z)$ be a C-function, subject to the constraint (7.4). *Then the right-hand side of* (7.3) *is a C-function satisfying $f_k(z_k) = \alpha_k$.*

It is easily seen that Lemma 4 yields an iterative solution method for the NP problem, like Lemma 1 for the CF problem. Let us briefly describe the method in question. Define the functions $w_k(z)$ exactly as in (6.9), (6.10). Then (7.3) can be written in the form of the recurrence relation

$$y_k(z)\hat{y}_k(z)w_{k+1}(z) = (\alpha_k \hat{y}_k(z) + \bar{\alpha}_k y_k(z))w_k(z) - w_{k-1}(z), \tag{7.5}$$

for $k = 0, 1, \cdots, n$. The initial conditions are given by $w_{-1}(z) = 1 - z$ and $w_0(z) = f(z)$, yielding $f_0(z) = f^{-1}(z)$, where $f(z)$ is supposed to be a solution of the NP problem (7.1).

Thus, except in some "pathological situations," the interpolation constraints (7.1) determine the $n+1$ parameters $\alpha_0, \alpha_1, \cdots, \alpha_n$ via the identities

$$\alpha_k = w_{k-1}(z_k)/(1 - z_k)w_k(z_k), \tag{7.6}$$

$$w_{k+1}(z_j) = [(\alpha_k \hat{y}_k(z_j) + \bar{\alpha}_k y_k(z_j))w_k(z_j) - w_{k-1}(z_j)]/y_k(z_j)\hat{y}_k(z_j). \tag{7.7}$$

In principle, they have to be used for $0 \leqq k \leqq n$ and $k+1 \leqq j \leqq n$, with the initial conditions $w_{-1}(z_j) = 1 - z_j$ and $w_0(z_j) = u_j$. But the algorithm has to stop if it meets the situation $w_l(z_l) = 0$. Then it is clear that the NP problem can have a solution only if $w_l(z_j) = 0$ for $j = l, l+1, \cdots, n$; this will be called the *degenerate case*. The normal situation where $w_k(z_k) \neq 0$ for all k will be called the *nondegenerate case* and is conveniently characterized by $l = n+1$.

As explained below, the complete solution of the NP problem can be expressed in terms of an appropriate tridiagonal matrix $J_k(z)$ built from the data z_j and α_j. The

definition is

$$J_k(z)=\begin{bmatrix} \alpha_0\hat{y}_0(z)+\bar{\alpha}_0 y_0(z) & y_0(z) & & \\ \hat{y}_0(z) & & \ddots & \\ & \ddots & & y_{k-1}(z) \\ & & \hat{y}_{k-1}(z) & \alpha_k\hat{y}_k(z)+\bar{\alpha}_k y_k(z) \end{bmatrix}, \tag{7.8}$$

for $k=0,1,\cdots,l-1$. Note that $y_k(1)=\hat{y}_k(1)=\beta_k$; hence $J_k(1)$ is a real symmetric matrix. From $J_k(z)$ define the polynomials $p_k(z)=\det J_{k-1}(z)$ and $q_k(z)=(1-z)\det J^0_{k-1}(z)$, exactly as in (2.2) and (2.11). They enjoy the symmetry and antisymmetry properties (2.3) and (2.13). Furthermore, they obey the recurrence relations

$$p_{k+1}(z)=(\alpha_k\hat{y}_k(z)+\bar{\alpha}_k y_k(z))p_k(z)-y_{k-1}(z)\hat{y}_{k-1}(z)p_{k-1}(z), \tag{7.9}$$

$$q_{k+1}(z)=(\alpha_k\hat{y}_k(z)+\bar{\alpha}_k y_k(z))q_k(z)-y_{k-1}(z)\hat{y}_{k-1}(z)q_{k-1}(z), \tag{7.10}$$

with the initial conditions $p_{-1}(z)=0$, $p_0(z)=1$ and $q_0(z)=0$, $q_1(z)=1-z$. As a generalization of (2.14), we have the identity

$$p_k(z)q_{k+1}(z)-q_k(z)p_{k+1}(z)=(1-z)\prod_{i=0}^{k-1} y_i(z)\hat{y}_i(z). \tag{7.11}$$

Define the *Jacobi parameters* $\lambda_k=p_k(1)/p_{k-1}(1)$ as in (2.8). It is clear that the matrix $J_n(1)$ is nonnegative definite if and only if the positivity constraints (2.9) are satisfied. (In this case, $J_{n-1}(1)$ is positive definite.) The Jacobi parameters can be recursively computed from the data α_k and β_k by the formula

$$\lambda_{k+1}=2\beta_k \operatorname{Re}\alpha_k-\beta_{k-1}^2\lambda_k^{-1}, \tag{7.12}$$

which directly follows from (7.9). It is a generalization of (2.10). The initialization is given by $\lambda_0=\infty$.

The solution of the Nevanlinna-Pick interpolation problem can be expressed in terms of these ingredients in essentially the same way as in Theorem 2. The only difference lies in the expression of the general solution in the nondegenerate case; it is given by

$$f(z)=\frac{y_n(z)\hat{y}_n(z)q_n(z)-(1-z)g(z)q_{n+1}(z)}{y_n(z)\hat{y}_n(z)p_n(z)-(1-z)g(z)p_{n+1}(z)}, \tag{7.13}$$

where $g(z)$ is a C-function subject to the only constraint

$$0\leqq\mu(g)\leqq\beta_n^{-2}\lambda_{n+1}. \tag{7.14}$$

In particular, if $J_n(1)$ is singular then (7.14) forces $g(z)=\infty$; this yields the unique solution $f(z)=q_{n+1}(z)/p_{n+1}(z)$, which is lossless and has degree n.

The proof will not be repeated here, since it is basically the same as that of Theorem 2. Let us only indicate the appropriate substitutes of the identities (6.8) and (6.17), which are required to derive (7.13). From (7.3) we immediately deduce

$$\beta_k^2\mu(f_{k+1})=2\beta_k \operatorname{Re}\alpha_k-\mu^{-1}(f_k). \tag{7.15}$$

By comparison with (7.12) this allows us to show that the property $\beta_k^2\mu(f_{k+1})\leqq\lambda_{k+1}$ holds for all k if and only if it holds for $k=n$ (under the positivity assumption). Hence, if the condition (7.14) is satisfied, with $g(z)=f_{n+1}(z)$, then so are all conditions (7.4). The representation (7.13) can be obtained with the help of the identity

$$f(z)p_{k+1}(z)=q_{k+1}(z)+\left(\prod_{i=0}^{k} y_i(z)\hat{y}_i(z)\right)w_{k+1}(z), \tag{7.16}$$

which results from a similar computation as in § 6. In fact, we deduce formula (7.13), with $g(z)=f_{n+1}(z)$, by equating the ratio $w_n(z)/w_{n+1}(z)$ derived from (7.16) to the function $(1-z)g(z)$, in agreement with (6.9). It is interesting to mention the analogue of (6.18), which is

$$w_k(z)p_{k+1}(z)=1-z+y_k(z)\hat{y}_k(z)w_{k+1}(z)p_k(z). \tag{7.17}$$

As an illustration of the theory let us finally indicate a generalization of the Bistritz stability test. Consider a complex polynomial $x_m(z)$ of degree m, having the property that $x_m(1)$ is real. Construct both symmetric polynomials

$$b_m(z)=x_m(z)+\hat{x}_m(z), \qquad b_{m-1}(z)=\frac{x_m(z)-\hat{x}_m(z)}{1-z}. \tag{7.18}$$

Choosing m distinct points $z_0, z_1, \cdots, z_{m-1}$ in the unit disk, define complex numbers α_k and symmetric polynomials $b_{m-k-2}(z)$, for $k=0, 1, \cdots, m-1$, from the relations

$$\alpha_k=b_{m-k}(z_k)/(1-z_k)b_{m-k-1}(z_k), \tag{7.19}$$

$$y_k(z)\hat{y}_k(z)b_{m-k-2}(z)=(\alpha_k\hat{y}_k(z)+\bar{\alpha}_k y_k(z))b_{m-k-1}(z)-b_{m-k}(z), \tag{7.20}$$

with the initialization (7.18). By construction, $b_t(z)$ is a polynomial of formal degree t (for $t\geqq 0$), and $b_{-1}(z)$ vanishes. It is interesting to note that $b_{m-k}(z)$ can be written in the form

$$b_{m-k}(z)=b_0 \det J_{m-1}^{k-1}(z), \tag{7.21}$$

for a real constant b_0, where $J_{m-1}^{k-1}(z)$ is the submatrix of $J_{m-1}(z)$ obtained by suppression of its first k rows and columns. The Bistritz stability criterion can be generalized as follows.

THEOREM 5. *The polynomial $x_m(z)$ is stable (i.e., devoid of zeros in the closed unit disk $|z|\leqq 1$) if and only if the tridiagonal matrix $J_{m-1}(1)$ built from the data z_k and α_k exists and is positive definite.*

Proof. Set $f(z)=(1-z)b_{m-1}(z)/b_m(z)$. It is well known that $x_m(z)$ is stable if and only if $f(z)$ is a lossless function of exact degree m. In this case, $f(z)$ can be viewed as a solution to the NP problem (7.1), with $u_k=(1-z_k)b_{m-1}(z_k)/b_m(z_k)$ and $n=m-1$. Let us construct rational functions $f_k(z)$ and complex numbers $\alpha_k=f_k(z_k)$, for $k=0, 1, \cdots, m-1$, by use of the recurrence relation (7.3) with the initialization $f_0(z)=f^{-1}(z)$. By comparison between (7.5) and (7.20) it is seen that the functions (6.10) are related to the polynomials $b_t(z)$ by the simple identity

$$w_k(z)=(1-z)b_{m-k-1}(z)/b_m(z), \tag{7.22}$$

for $-1\leqq k\leqq m$. The desired result is obtained by straightforward application of the generalized version of Theorem 2; the present situation corresponds to the nondegenerate case and the choice $g(z)=\infty$ in (7.13), yielding $f(z)=q_m(z)/p_m(z)$. □

When comparing the method above to that indicated in § 5 (in the "confluent case" $z_j=0$ for all j) one should note that the parameters α_k are numbered in the reverse order, which is a simple matter of notation. Of course, the positive definiteness of $J_{m-1}(1)$ amounts to the property $\lambda_k>0$ for $k=1, 2, \cdots, m$, where the parameters λ_k are determined by use of the recurrence relation (7.12), with $\lambda_0=\infty$. An equivalent version of the criterion of Theorem 5 says that $x_m(z)$ is stable if and only if the values assumed by the polynomials $b_t(z)$ at the point $z=1$ are nonzero and have constant sign for $0\leqq t\leqq m$. This is a straightforward consequence of the identity (7.21).

ON COMPLETE SYMMETRIC FUNCTIONS*

EDWARD NEUMAN†

Abstract. This paper is devoted to the study of some properties of the complete symmetric functions. These functions play an important role in the theory of partitions and in the combinatorics as well. Among other things, the representation formulas as well as the recurrence formulas and inequalities involving functions under discussion are given. Some applications are also included.

Key words. complete symmetric functions, divided differences, B-splines, q-binomial coefficients, r-Stirling numbers of the second kind

AMS(MOS) subject classification. primary 26C05

1. Introduction. Let $(x_0, \cdots, x_n) \in \mathbb{R}^{n+1}$ $(n \geqq 0)$. The rth complete symmetric function h_r $(r = 0, 1, \cdots)$ in the variables $x_0, \cdots, x_n$ is defined by

$$h_r \equiv h_r(x_0, \cdots, x_n) = \sum_{i_0+\cdots+i_n=r} x_0^{i_0} \cdots x_n^{i_n}, \tag{1.1}$$

where $i_0, \cdots, i_n \in \{0, 1, \cdots, r\}$ (see, e.g., [6]). The sum (1.1) involves $\binom{n+r}{r}$ terms. Without loss of generality we may assume $x_0 \leqq x_1 \leqq \cdots \leqq x_n$. Setting $x_i = q$ $(0 \leqq i \leqq n)$, we obtain $h_r = \binom{n+r}{r} q^r$. In what follows we will assume $x_0 < x_n$.

The functions h_r play an important role in the theory of partitions (see [1] for more details). Also they are useful in combinatorics. Letting $x_i = q^i$ $(0 \leqq i \leqq n)$, where q is an indeterminate, we obtain

$$h_r = \begin{bmatrix} n+r \\ r \end{bmatrix},$$

where as usual

$$\begin{bmatrix} m \\ k \end{bmatrix} = \frac{(q^m-1)(q^m-q) \cdot \cdots \cdot (q^m-q^{k-1})}{(q^k-1)(q^k-q) \cdot \cdots \cdot (q^k-q^{k-1})}$$

denotes the q-binomial coefficient or Gaussian polynomial (see, e.g., [1]). Another choice for x_i, namely $x_i = r+i$ $(0 \leqq i \leqq n;\ r = 0, 1, \cdots)$ leads to

$$h_m(r, r+1, \cdots, r+n) = S_r(m+n+r, n+r) \qquad (m, n, r \in \mathbb{N}_0) \tag{1.2}$$

(see § 7 for the proof of (1.2)). Here $S_r(\cdot, \cdot)$ stands for the r-Stirling number of the second kind. The number $S_r(k, n)$ $(0 \leqq r \leqq n \leqq k)$ is defined combinatorially as the number of partitions of the set $\{1, 2, \cdots, k\}$ into n nonempty disjoint subsets, such that the numbers $1, 2, \cdots, r$ are in distinct subsets (cf. [3]). The classical Stirling numbers of the second kind $S(k, n)$ coincide with $S_r(k, n)$ when $r = 0$ or $r = 1$.

In our proofs the B-splines of Curry and Schoenberg [5] play an important role. Some elementary properties of these functions are given in § 2. The representation formulas for h_r are discussed in § 3. In § 4 we deal with the generating functions for h_r. Some new recurrence formulas for h_r are given in § 5. Inequalities involving the functions under discussion are given in § 6. Section 7 is devoted to applications.

2. Preliminaries. Throughout this paper we will denote by $\mathbb{R}$, $\mathbb{Z}$, $\mathbb{N}_0$, and $\mathbb{N}$ the sets of all reals, integers, nonnegative integers and positive integers, respectively.

* Received by the editors September 2, 1986; accepted for publication June 4, 1987.
† Department of Mathematics, Southern Illinois University, Carbondale, Illinois 62901.

For our further aims we introduce the B-splines of Curry and Schoenberg [5]. Let $\cdots \leqq t_{-1} \leqq t_0 \leqq t_1 \leqq \cdots$ be a bi-infinite partition of $\mathbb{R}$ with at most n ($n \in \mathbb{N}$) values of the t's equal to each other, i.e., $t_i < t_{i+n}$ for all $i \in \mathbb{Z}$. The function

$$M_{i,n}(t) = n[t_i, \cdots, t_{i+n}](\cdot - t)_+^{n-1}$$

is the B-spline of degree $n-1$ (order n) with knots at $t_i, \cdots, t_{i+n}$. As usual $[t_i, \cdots, t_{i+n}]g$ denotes the divided difference of order n for the function g at the points t_{i+l} ($0 \leqq l \leqq n$) and

$$(x-t)_+^{n-1} = (\text{Max}\,\{0, x-t\})^{n-1}$$

denotes the truncation power function. For the reader's convenience we list below some well-known properties of the B-splines:

(i) $M_{i,n}(t) > 0$ for $t \in (t_1, t_{i+n})$ and $M_{i,n}(t) = 0$ otherwise. Thus supp $M_{i,n} = [t_i, t_{i+n}]$.

(ii) In each interval $[t_{i+j}, t_{i+j+1}]$ ($t_{i+j} < t_{i+j+1}$; $j = 0, 1, \cdots, n-1$) $M_{i,n}$ coincides with an algebraic polynomial of degree $n-1$ or less.

(iii) Let t_{i+j} be a knot of multiplicity k, i.e., let $t_{i+j-1} < t_{i+j} = \cdots = t_{i+j+k-1} < t_{i+j+k}$, then $M_{i,n}$ is exactly $n-1-k$ times continuously differentiable on (t_{i+j-1}, t_{i+j+k}).

(iv) If $f \in C^n[t_i, t_{i+n}]$, then

$$[t_i, \cdots, t_{i+n}]f = \frac{1}{n!} \int_{t_i}^{t_{i+n}} M_{i,n}(t) f^{(n)}(t)\, dt.$$

(v) The following recurrence formula

$$\frac{n-1}{n} M_{i,n}(t) = \frac{t-t_i}{t_{i+n}-t_i} M_{i,n-1}(t) + \frac{t_{i+n}-t}{t_{i+n}-t_i} M_{i+1,n-1}(t)$$

$$(i \in \mathbb{Z},\ n \geqq 2,\ t \in \mathbb{R})$$

holds true (see, e.g., [14]).

3. Representation formulas for the complete symmetric functions. The formula (1.1) seems to be rather inconvenient for our further purposes. In this section we offer several equivalent formulas for h_r. First of all we need more notation. Let $x_0 \leqq x_1 \leqq \cdots \leqq x_n$. In order to describe exactly where the equalities hold, we suppose that

$$x_0 \leqq x_1 \leqq \cdots \leqq x_n = \underbrace{\tau_0, \cdots, \tau_0}_{l_0}, \cdots, \underbrace{\tau_d, \cdots, \tau_d}_{l_d}, \tag{3.1}$$

where each τ_i is repeated exactly l_i times with $\sum_{i=0}^{d} l_i = n+1$. Then given any sufficiently differentiable functions $u_0, \cdots, u_n$, we define a matrix

$$\begin{bmatrix} x_0, \cdots, x_n \\ u_0, \cdots, u_n \end{bmatrix} := [D^{d_i} u_j(x_i)]_{i,j=0}^{n} \tag{3.2}$$

with $d_i = \text{Max}\,\{j\colon x_i = \cdots = x_{i+j}\}$, $i = 0, 1, \cdots, n$, where, as usual, D^m denotes the operator of differentiation. Further let

$$S^n = \left\{ (\lambda_1, \cdots, \lambda_n) \in \mathbb{R}^n \colon \lambda_i \geqq 0, \text{ for all } i, \sum_{i=1}^{n} \lambda_i \leqq 1 \right\}$$

denote the n-simplex.

Also let C denote a simple closed contour enclosing a simply connected region of the complex variable z in which are situated the points $\tau_0, \cdots, \tau_d$.

We are ready to state and prove the main result of this section.

THEOREM 3.1. *Let* $r \in \mathbb{N}_0$. *Then*

$$h_r = [x_0, \cdots, x_n]t^{n+r}, \tag{3.3}$$

and also

$$h_r = \binom{n+r}{r} \int_{x_0}^{x_n} M_{0,n}(t)t^r \, dt, \tag{3.4}$$

where $M_{0,n}$ *denotes the B-spline of order n with knots at* $x_0, \cdots, x_n$. *Also*

$$h_r = (n+r) \cdots (r+1) \int_{S^n} \left[\sum_{i=0}^{n} \lambda_i x_i \right]^r d\lambda, \tag{3.5}$$

where $\lambda_0 = 1 - \lambda_1 - \cdots - \lambda_n$ *and* $d\lambda = d\lambda_1 \cdots d\lambda_n$. *Moreover, if* τ_i *and* l_i *are the same as in* (3.1), *then*

$$h_r = \frac{1}{2\pi i} \int_C \frac{z^{n+r} \, dz}{(z-\tau_0)^{l_0} \cdots (z-\tau_d)^{l_d}}, \tag{3.6}$$

and also the following formula:

$$h_r = \det \begin{bmatrix} x_0 & x_1, \cdots, x_{n-1}, x_n \\ 1 & t, \cdots, t^{n-1}, t^{n+r} \end{bmatrix} \Big/ \det \begin{bmatrix} x_0, \cdots, x_n \\ 1, \cdots, t^n \end{bmatrix} \tag{3.7}$$

holds true.

Proof. The formula (3.3) has been established in [8]. In order to prove (3.4) we set $t_{i+j} = x_j$ $(j = 0, 1, \cdots, n)$, next $i = 0$ and $f(t) = t^{n+r}$ into (iv). Hence and from (3.3) the desired result follows. For the proof of (3.5) we apply the Hermite-Genocchi formula for divided differences

$$[x_0, \cdots, x_n]f = \int_{S^n} f^{(n)} \left[\sum_{i=0}^{n} \lambda_i x_i \right] d\lambda \qquad (f \in \mathbb{C}^n[x_0, x_n]) \tag{3.8}$$

(cf. [2]). Setting above $f(t) = t^{n+r}$, then making use of (3.3), we obtain (3.5). Direct applications of (3) in [8, p. 14] to (3.3) gives the assertion (3.6). Equation (3.7) follows immediately from (2.86) in [14] and from (3.3). This completes the proof. □

COROLLARY 3.1 [13]. *Let* $x_j = -\cos(\pi j/n)$ $(j = 0, 1, \cdots, n)$ *be the Chebyshev points. Then*

$$h_r = \begin{cases} 2^{-2m} \sum_{i=0}^{[m/n]} \binom{n+2m}{m-in} & \text{if } r = 2m \\ 0 & \text{if } r = 2m+1 \end{cases} \qquad (m = 0, 1, \cdots), \tag{3.9}$$

where, as usual, $[x]$ *denotes the largest integer not bigger than x.*

Proof. First we will establish the first formula of (3.9). Let g be an integrable function on $[-1, 1]$ and let

$$a_j[g] = \frac{2}{\pi} \int_{-1}^{1} \frac{g(t)T_j(t)}{\sqrt{1-t^2}} \, dt$$

denote the jth Fourier-Chebyshev coefficient of g with T_j—the jth Chebyshev polynomial of the first kind. We will use the following result due to S. Bernstein:

$$[x_0, \cdots, x_n]g = 2^{n-1} \sum_{i=0}^{\infty} a_{(2i+1)n}[g] \tag{3.10}$$

(see, e.g., [12]). Also it is known that

$$t^{n+2m} = 2^{-n-2m+1} \sum_{j=0}^{[n/2]+m\,\circ} \binom{n+2m}{j} T_{n+2m-2j}(t) \tag{3.11}$$

where

$$\sum_{j=l}^{m\,\circ} a_j T_{k_j} := \sum_{j=l}^{m} \left[\frac{1}{2} a_j \text{ if } k_j = 0,\ a_j \text{ if } k_j \neq 0\right] T_{k_j}$$

(cf. [12, (2.40)]). Hence we obtain

$$a_{(2i+1)n}[t^{n+2m}] = 2^{-n-2m+1}\binom{n+2m}{m-in}. \tag{3.12}$$

Combining (3.3), (3.10), and (3.12) yields

$$h_{2m} = [x_0, \cdots, x_n]t^{n+2m} = 2^{-2m} \sum_{i=0}^{[m/n]} \binom{n+2m}{m-in}.$$

The second formula of (3.9) follows immediately from (3.4) and from the fact that the B-spline $M_{0,n}$ is an even function in the case under consideration. The proof is completed. □

COROLLARY 3.2 [13]. *Let* $x_j = -\cos \alpha_j$, *where* $\alpha_j = (2j+1)\pi/(2n+2)$ $(j = 0, 1, \cdots, n)$ *be the zeros of* T_{n+1}. *Then*

$$h_r = \begin{cases} 2^{-2m}(-1)^n \left\{ \sum_{q=0}^{[m/(n+1)]} \binom{n+2m}{m-q(n+1)} \right. \\ \qquad \left. - \sum_{q=0}^{[(m-1)/(n+1)]} \binom{n+2m}{m-1-q(n+1)} \right\} & \text{if } r = 2m, \\ 0 \quad \text{if } r = 2m+1 \end{cases} \tag{3.13}$$

$(m = 0, 1, \cdots,).$

Proof. It is a well-known fact that

$$[x_0, \cdots, x_n]g = (-1)^{n+1} \frac{2^n}{n+1} \sum_{j=0}^{n} (-1)^j \sin \alpha_j g(x_j).$$

In order to prove the first formula of (3.13) we set above $g(t) = t^{n+2m}$. Hence and by virtue of (3.3) we get

$$h_{2m} = [x_0, \cdots, x_n]t^{n+2m} = \frac{-2^n}{n+1} \sum_{j=0}^{n} (-1)^j \sin \alpha_j \cos^{n+2m} \alpha_j.$$

The last sum depends upon the numbers $\mathscr{D}_{nk}$, where

$$\mathscr{D}_{nk} := \sum_{j=0}^{n} (-)^j \sin \alpha_j \cos kj \quad (k\text{-integer}).$$

It is easy to verify that

$$\mathscr{D}_{nk} = \frac{1}{2}(E_{n,k+1} - E_{n,k-1}), \tag{3.14}$$

where

$$E_{nk} := \sum_{j=0}^{n} (-1)^j \sin k\alpha_j.$$

Hence, we obtain

$$\left[\cos\frac{k\pi}{2n+2}\right]E_{nk}=\sum_{j=0}^{n}(-1)^j\sin\frac{(2j+1)k\pi}{2n+2}\cos\frac{k\pi}{2n+2}$$
$$=\frac{1}{2}\sum_{j=0}^{n}(-1)^j\left\{\sin\frac{(j+1)k\pi}{n+1}+\sin\frac{jk\pi}{n+1}\right\}$$
$$=\frac{1}{2}(-1)^n\sin\frac{(n+1)k\pi}{n+1}=0.$$

Therefore if $k\pi/(2n+2)\neq(p+\frac{1}{2})\pi$ (p-integer), i.e., if $k\neq(2p+1)(n+1)$, then $E_{nk}=0$. Assume now $k=(2p+1)(n+1)$. Then

$$E_{nk}=\sum_{j=0}^{n}(-1)^j\sin\frac{(2j+1)(2p+1)(n+1)\pi}{2n+2}=(-1)^p(n+1).$$

Hence and from (3.14) we conclude that

$$\mathscr{D}_{nk}=\begin{cases}\frac{1}{2}(-1)^{k+1}(n+1) & \text{if } \frac{k+1}{n+1}\text{ is odd},\\ -\frac{1}{2}(-1)^{k-1}(n+1) & \text{if } \frac{k-1}{n+1}\text{ is odd},\\ 0 & \text{otherwise.}\end{cases}\tag{3.15}$$

Setting $t=\cos\rho$ in (3.11), we obtain

$$\cos^{n+2m}\alpha_j=2^{-n-2m+1}\sum_{i=0}^{[n/2]+m}{}^{\circ}\binom{n+2m}{i}\cos(n+2m-2i)\alpha_j.$$

Therefore

$$h_{2m}=\frac{-2^n}{n+1}2^{-n-2m+1}\sum_{i=0}^{[n/2]+m}{}^{\circ}\binom{n+2m}{i}\mathscr{D}_{n,n+2m-2i}.\tag{3.16}$$

In the last sum the only nonzero terms are those for which

$$\frac{n+2m-2i+1}{n+1}\text{ is odd}\quad\text{or}\quad\frac{n+2m-2i-1}{n+1}\text{ is odd},$$

i.e., if $m-i=q(n+1)$ (q-integer) or $m-i-1=q(n+1)$, respectively. Hence one gets $i=m-q(n+1)$ or $i=m-1-q(n+1)$. Simultaneously $0\leqq i\leqq[n/2]+m$. Therefore $0\leqq q\leqq[m/(n+1)]$ or $0\leqq q\leqq[(m-1)/(n+1)]$. Hence and from (3.16) and (3.15) the assertion follows. For the proof that $h_r=0$ if r is odd we apply the same arguments like those in the proof of Corollary 3.1. This completes the proof. □

The functions h_r are well defined when $r\in\mathbb{N}_0$. In many places they are defined to be zero when $r=-1,-2,\cdots$ (see, e.g., [6]). Assuming that (3.3)–(3.7) are the defining formulas for h_r with $r\in\mathbb{Z}$ we get $h_r=0$ for $r=-1,-2,\cdots,-n$. If $r=-n-1,-n-2,\cdots$, then h_r is not necessarily equal to zero. This confirms the following.

COROLLARY 3.3. *Let $x_j\neq 0$ for all j. Then for $l=1,2,\cdots$, we have*

$$h_{-n-l}=\frac{(-1)^n}{\prod_{j=0}^{n}x_j^l}\det\begin{bmatrix}[x_0,x_1]t^l & [x_1]t^l & \cdots & 0\\ \vdots & \vdots & \cdots & \vdots\\ [x_0,\cdots,x_{n-1}]t^l & [x_1,\cdots,x_{n-1}]t^l & \cdots & [x_{n-1}]t^l\\ [x_0,\cdots,x_n]t^l & [x_1,\cdots,x_n]t^l & \cdots & [x_{n-1},x_n]t^l\end{bmatrix}.\tag{3.17}$$

Hence in particular

$$h_{-n-1}=(-1)^n\Big/\prod_{j=0}^{n}x_j \tag{3.18}$$

and

$$h_{-n-2}=(-1)^n\left\{\sum_{j=0}^{n}\prod_{\substack{l=0\\ l\neq j}}^{n}x_l\right\}\Big/\prod_{j=0}^{n}x_j^2. \tag{3.19}$$

Proof. In order to prove the identity (3.17) we apply the following formula:

$$[x_0,\cdots,x_n]\frac{1}{f(x)}=\frac{(-1)^n}{\prod_{j=0}^{n}f(x_j)}\det\begin{bmatrix}[x_0,x_1]f & [x_1]f & 0 & \cdots & 0\\ \vdots & \vdots & & \cdots & \vdots\\ [x_0,\cdots,x_n]f & [x_1,\cdots,x_n]f & & \cdots & [x_{n-1},x_n]f\end{bmatrix}$$

which holds true provided $f(x_j)\neq 0$ for all j (see [11, Ex. 2.4.19]). Setting above $f(t)=t^l$ and next making use of (3.3), we arrive at (3.17). The identities (3.18) and (3.19) follow immediately from (3.17). The proof is completed. □

Combining (3.5) and (3.18) yields

$$\int_{S^n}\left[\sum_{i=0}^{n}\lambda_i x_i\right]^{-n-1}d\lambda=1/n!\prod_{j=0}^{n}x_j\qquad(x_j\neq 0).$$

The last identity is due to R. Feynman.

We close the section with a differentiation formula for h_r.

COROLLARY 3.4. *Let x_j be of the multiplicity l_j $(0\leqq j\leqq n;\ 1\leqq l_j\leqq n)$. Then*

$$\frac{\partial^l}{\partial x_j^l}h_r(x_0,\cdots,x_{j-1},\underbrace{x_j,\cdots,x_j}_{l_j},x_{j+1},\cdots,x_n)$$

$$=l_j(l_j+1)\cdots(l_j+l-1)h_r(x_0,\cdots,x_{j-1},\underbrace{x_j,\cdots,x_j}_{l_j+l},x_{j+1},\cdots,x_n).$$

Proof. The last result follows immediately from (3.3) and from the well-known formula for the divided differences (see [11]). □

4. Generating functions. Let H denote a generating function for the complete symmetric functions, i.e., let

$$H(t)=\sum_{r=0}^{\infty}h_r t^r.$$

Then

$$H(t)=\prod_{i=0}^{n}(1-x_i t)^{-1}$$

(see, e.g., [6]). In this section we give simple formulas for the exponential generating function E, where

$$E(t)=\sum_{r=0}^{\infty}h_r\frac{t^{n+r}}{(n+r)!}\qquad(n\in\mathbb{N}).$$

We have the following.

THEOREM 4.1. *Let* $n \in \mathbb{N}$. *Then*

$$E(t) = [x_0, \cdots, x_n]_{(x)}\, e^{xt}, \tag{4.1}$$

where the subscript (x) *denotes that the divided difference operator acts on the variable* x. *Also*

$$E(t) = \frac{t^n}{n!} \int_{x_0}^{x_n} M_{0,n}(x)\, e^{xt}\, dx, \tag{4.2}$$

where $M_{0,n}$ *denotes the B-spline of order* n *with knots at* $x_0, \cdots, x_n$. *Moreover, if* $x_i \neq x_j$ *for* $i \neq j$, *then*

$$E(t) = \sum_{j=0}^{n} e^{x_j t}/w_j \tag{4.3}$$

with

$$w_j = \prod_{\substack{i=0 \\ i \neq j}}^{n} (x_j - x_i) \qquad (0 \leqq j \leqq n).$$

Proof. First we will show that the following identity

$$[x_0, \cdots, x_n]f = \sum_{r=0}^{\infty} h_r \frac{f^{(n+r)}(0)}{(n+r)!} \tag{4.4}$$

holds true provided f is sufficiently smooth. We have

$$f(x) = \sum_{r=0}^{\infty} f^{(r)}(0) \frac{x^r}{r!} = \sum_{r=-n}^{\infty} f^{(n+r)}(0) \frac{x^{n+r}}{(n+r)!}.$$

Hence

$$[x_0, \cdots, x_n]f = \sum_{r=-n}^{\infty} ([x_0, \cdots, x_n]x^{n+r}) \frac{f^{(n+r)}(0)}{(n+r)!}.$$

Taking into account (3.3) one obtains the assertion (4.4). In order to prove (4.1) we insert $f(x) = e^{xt}$ into (4.4). The identity (4.2) follows immediately from (4.1) and (iv). For the proof of (4.3) it is enough to apply the well-known formula for the divided differences with distinct knots

$$[x_0, \cdots, x_n]g = \sum_{j=0}^{n} g(x_j)/w_j.$$

Hence and from (4.1) the desired result follows. This completes the proof. □

COROLLARY 4.1. *Let* $x_j = a + jh$ $(0 \leqq j \leqq n)$. *Then*

$$E(t) = \frac{e^{at}}{n!} \left[\frac{e^{ht} - 1}{h}\right]^n.$$

Proof. In this case we have

$$w_j = (-1)^{n-j} h^n j!(n-j)!.$$

Direct application of (4.3) yields the desired result. □

5. The recurrence formulas for h_r. For the sake of notation we write often $h_r(i, j)$ instead of $h_r(x_i, x_{i+1}, \cdots, x_j)$ $(0 \leqq i \leqq j \leqq n)$. We are ready to state and prove the main result of this section.

THEOREM 5.1. *For any $r \in \mathbb{N}_0$ and $n \in \mathbb{N}$ the complete symmetric functions satisfy the following recurrence relations*:

$$h_r(0, n) = h_r(0, n-1) + x_n h_{r-1}(0, n) \qquad (r \in \mathbb{N}), \tag{5.1}$$

$$h_r(0, n) = \sum_{j=0}^{n} \frac{(-1)^{n-j}}{x_j \cdots x_n} h_{n-j+r+1}(0, j), \tag{5.2}$$

$$h_r(0, n) = \frac{1}{x_n - x_0} \{h_{r+1}(1, n) - h_{r+1}(0, n-1)\}, \tag{5.3}$$

$$h_r(0, n) = \frac{1}{x_n - x_0} \{x_n h_r(1, n) - x_0 h_r(0, n-1)\}, \tag{5.4}$$

$$h_r(x_0 + \gamma, \cdots, x_n + \gamma) = \sum_{l=0}^{r} \binom{n+r}{l} \gamma^l h_{r-l}(x_0, \cdots, x_n) \qquad (\gamma \in \mathbb{R}). \tag{5.5}$$

Proof. The recurrence relation (5.1) has been established by Menon [7]. Below we will present another proof. We need Leibniz' formula for divided differences

$$[x_0, \cdots, x_n](f \cdot g) = \sum_{j=0}^{n} ([x_0, \cdots, x_j]f)([x_j, \cdots, x_n]g), \tag{5.6}$$

where f and g are real-valued functions defined on $[x_0, x_n]$. Making use of (3.3) and (5.6) we obtain

$$\begin{aligned} h_r(0, n) &= [x_0, \cdots, x_n](t^{n+r-1} \cdot t) \\ &= ([x_n]t)([x_0, \cdots, x_n]t^{n+r-1}) + ([x_{n-1}, x_n]t)([x_0, \cdots, x_{n-1}]t^{n+r-1}) \\ &= x_n h_{r-1}(0, n) + h_r(0, n-1). \end{aligned}$$

In a similar fashion we can establish (5.2). For our purposes we need the following identity:

$$[x_0, \cdots, x_j]\frac{1}{t} = (-1)^j \Big/ \prod_{l=0}^{j} x_l \qquad (x_l \neq 0, \text{ all } l), \tag{5.7}$$

which follows immediately from (3.18) and (3.3). From (5.6) and (3.3), we obtain

$$\begin{aligned} h_r(0, n) &= [x_0, \cdots, x_n]\left(\frac{1}{t} \cdot t^{n+r+1}\right) \\ &= \left([x_n]\frac{1}{t}\right)([x_0, \cdots, x_n]t^{n+r+1}) \\ &\quad + \left([x_{n-1}x_n]\frac{1}{t}\right)([x_0, \cdots, x_{n-1}]t^{n+r+1}) + \cdots \\ &\quad + \left([x_0, \cdots, x_n]\frac{1}{t}\right)([x_0]t^{n+r+1}). \end{aligned}$$

Hence and from (3.3) and (5.7) the desired result follows. In order to prove the formula (5.3) we apply the well-known recurrence for the divided differences

$$[x_0, \cdots x_n]t^{n+r} = \frac{1}{x_n - x_0} \{[x_1, \cdots, x_n]t^{n+r} - [x_0, \cdots, x_{n-1}]t^{n+r}\}.$$

Hence, by virtue of (3.3), the assertion (5.3) follows. For the proof of (5.4) we employ the recursion (v) setting $i=0$ and $t_{i+j}=x_j$ $(0\leqq j\leqq n)$. Further, multiplying both sides by t^r and performing integration over $[x_0, x_n]$, we obtain, in view of (3.4),

$$\frac{n-1}{n+r}h_r(0,n)=\frac{1}{x_n-x_0}\{x_nh_r(1,n)-x_0h_r(0,n-1)\}$$
$$-\frac{r+1}{n+r}\frac{1}{x_n-x_0}\{h_{r+1}(1,n)-h_{r+1}(0,n-1)\}.$$

Hence and from (5.3) we get the desired result (5.4) provided $n\geqq 2$. Direct calculations show that (5.4) holds true if $n=1$. We prove now the last statement of our theorem. For $r=0$ the assertion is a trivial one. Assume $r\in\mathbb{N}$. Let $M_{0,n}(\cdot\,|x_0,\cdots,x_n)\equiv M_{0,n}(\cdot)$. It is well known that the following identity

$$M_{0,n}(\cdot\,|x_0+\gamma,\cdots,x_n+\gamma)=M_{0,n}(\cdot-\gamma\,|x_0,\cdots,x_n)$$

holds true for any $\gamma\in\mathbb{R}$. According to (3.4) we obtain

$$h_r(x_0+\gamma,\cdots,x_n+\gamma)=\binom{n+r}{r}\int_{x_0+\gamma}^{x_n+\gamma}M_{0,n}(t|x_0+\gamma,\cdots,x_n+\gamma)t^r\,dt$$
$$=\binom{n+r}{r}\int_{x_0+\gamma}^{x_n+\gamma}M_{0,n}(t-\gamma|x_0,\cdots,x_n)t^r\,dt$$
$$=\binom{n+r}{r}\int_{x_0}^{x_n}M_{0,n}(z|x_0,\cdots,x_n)(z+\gamma)^r\,dz,$$

where $z=t-\gamma$. Hence and from (3.4) the assertion follows. The proof is completed. □

6. Inequalities involving h_r. In this section we assume $x_j\geqq 0$, all j. Thus $0\leqq x_0\leqq\cdots\leqq x_n$ with $x_0<x_n$. In [7] it is proved that

(6.1) $$h_{p-m}h_{q+m}\geqq h_{p-m-1}h_{q+m+1} \qquad (p\leqq q, 0\leqq m<p),$$

(6.2) $$h_{r-1}h_{r+1}\leqq h_r^2 \qquad (r\in\mathbb{N}),$$

(6.3) $$h_r^{1/r}\geqq h_s^{1/s} \qquad (1\leqq r\leqq s).$$

These inequalities are strict unless all but one of the variables are zero. The inequality (6.2) tells us that the sequence $\{h_r\}_0^\infty$ is logarithmically concave. The companion inequality to (6.2) is provided by the following.

THEOREM 6.1. *Let $p, q, r>0$ and let $1/p+1/q=1/r$. Then the following inequality*

(6.4)
$$\left[\binom{n+r(l+m)}{n}^{-1}h_{r(l+m)}\right]^{1/r}\leqq\left[\binom{n+pl}{n}^{-1}h_{pl}\right]^{1/p}\cdot\left[\binom{n+qm}{n}^{-1}h_{qm}\right]^{1/q}$$

holds true provided that $r(l+m)$, pl, $qm\in\mathbb{N}_0$. Hence, in particular

(6.5)
$$\left[\binom{n+l+m}{n}^{-1}h_{l+m}\right]^2\leqq\left[\binom{n+2l}{n}^{-1}h_{2l}\right]\cdot\left[\binom{n+2m}{n}^{-1}h_{2m}\right] \qquad (l+m, 2l, 2m\in\mathbb{N}_0),$$

and

(6.6) $$h_r^2\leqq\frac{(n+r)(r+1)}{(n+r+1)r}h_{r-1}h_{r+1} \qquad (r\in\mathbb{N}).$$

Proof. Let $L_p \equiv L_p(S, \Sigma, \mu)$, $-\infty < p < \infty$, be the space of all pth power nonnegative integrable functions over a given finite measure space (S, Σ, μ). If $f \in L_p$ and if

$$\|f\|_p = \left[\int_S f^p \, d\mu\right]^{1/p},$$

then for any $f_1 \in L_p$ and any $f_2 \in L_q$ with $1/p + 1/q = 1/r$ $(p, q, r > 0)$

$$\|f_1 \cdot f_2\|_r \leqq \|f_1\|_p \|f_2\|_q$$

(see [16]). In order to prove the inequality (6.4) we set $d\mu = dt$, $f_1(t) = M_{0,n}(t)^{1/p} t^l$, $f_2(t) = M_{0,n}(t)^{1/q} \cdot t^m$. Taking into account the above result and (3.4), we arrive at (6.4). The inequality (6.5) follows immediately from (6.4) by letting $p = q = 2$. Setting $l = (r+1)/2$, $m = (r-1)/2$ into (6.5) we obtain (6.6). This completes the proof. □

Let

$$A_r = \left[\frac{1}{n+1} \sum_{i=0}^{n} x_i^r\right]^{1/r} \qquad (r \in \mathbb{R};\ r \neq 0)$$

denote the rth mean in variables $x_0, \cdots, x_n$. It is well known that $A_1 \leqq A_r (r \geqq 1)$. We are in a position to prove the following.

THEOREM 6.2. *For any* $r \in \mathbb{N}$

$$A_1 \leqq \left[\binom{n+r}{r}^{-1} h_r\right]^{1/r} \leqq A_r. \tag{6.7}$$

Proof. In order to prove the inequality (6.7) we will apply the following result:

$$f(A_1) \leqq \int_{x_0}^{x_n} M_{0,n}(t) f(t)\, dt \leqq \frac{1}{n+1} \sum_{j=0}^{n} f(x_j),$$

where f is a convex function on (x_0, x_n). The inequalities are strict unless f is a polynomial of degree one or less (see [10]). Setting above $f(t) = t^r$ $(r \in \mathbb{N})$ and next making use of (3.4) we arrive at (6.7). The proof is completed. □

Our next result reads as follows.

THEOREM 6.3. *Let* $m, r \in \mathbb{N}_0$ *and let*

$$\alpha \in \begin{cases} [x_n, \infty) & \text{if } m \text{ is odd,} \\ (-\infty, \infty) & \text{if } m \text{ is even.} \end{cases}$$

Then

$$\sum_{j=0}^{m} (-1)^{m-j} \binom{m}{j} \binom{n+m+r-j}{n}^{-1} \alpha^j h_{m+r-j} \geqq 0. \tag{6.8}$$

Proof. There is nothing to prove when $m = 0$. Assume $m > 0$. The inequality (6.8) follows immediately from the obvious inequality

$$\int_{x_0}^{x_n} t^r (\alpha - t)^m M_{0,n}(t)\, dt \geqq 0$$

and from (3.4). This completes the proof. □

Imposing some restrictions on the distribution of the x's we can prove more inequalities involving h_r.

THEOREM 6.4. *Let* $1/(n+1)\sum_{j=0}^{n} x_j \geqq 1$. *Then for any* r *and* s *with* $0 \leqq r \leqq s$ *the following inequalities*

$$h_r \leqq \frac{(r+1)(r+2)\cdot\cdots\cdot s}{(n+r+1)(n+r+2)\cdot\cdots\cdot(n+s)} h_s, \tag{6.9}$$

and

$$h_r \leqq h_s \tag{6.10}$$

hold true. Moreover, if $0 \leqq x_0 \leqq \cdots \leqq x_n \leqq 1$ *with* $x_0 < x_n$, *then*

$$h_r \geqq \frac{(r+1)(r+2)\cdot\cdots\cdot s}{(n+r+1)(n+r+2)\cdot\cdots\cdot(n+s)} h_s. \tag{6.11}$$

Proof. Let $H_r := \binom{n+r}{r}^{-1} h_r$ $(r \in \mathbb{N}_0)$. Hence in particular $H_0 = 1$, $H_1 = 1/(n+1)\sum_{j=0}^{n} x_j$. It has been shown in [9] that the sequence $\{h_r\}_0^\infty$ is logarithmically convex, i.e.,

$$H_r^2 \leqq H_{r-1} H_{r+1} \qquad (r \in \mathbb{N}). \tag{6.12}$$

We already know that the sequence $\{h_r\}_0^\infty$ is logarithmically concave. In order to prove the inequality (6.9) let us observe that if for some $r \in \mathbb{N}$, $H_{r-1} \leqq H_r$, then also $H_r \leqq H_{r+1}$. This follows from (6.12). The inequality $H_r \leqq H_{r+1} (r \in \mathbb{N}_0)$ implies

$$h_r \leqq \frac{r+1}{n+r+1} h_{r+1}.$$

Hence (6.9) follows. Inequality (6.10) is an obvious consequence of the previous inequality. For the proof of (6.11) we apply Theorem 6.3 with $m = \alpha = 1$. The proof is completed. □

We close this section with the following theorem.

THEOREM 6.5. *Let*

$$0 \leqq x_0 \leqq \cdots \leqq x_{i-1} < x_i = \cdots = x_n$$

for some i $(1 \leqq i \leqq n)$. *Then*

$$h_{n+r-i}(x_0, \cdots, x_i) \leqq \frac{x_n^{n+r}}{(x_n - x_0)\cdot\cdots\cdot(x_n - x_{i-1})}. \tag{6.13}$$

In particular if $0 \leqq x_0 \leqq \cdots \leqq x_{n-1} < x_n$, *then*

$$h_r(x_0, \cdots, x_n) \leqq \frac{x_n^{n+r}}{(x_n - x_0)\cdot\cdots\cdot(x_n - x_{n-1})}. \tag{6.14}$$

Proof. Let f be a real-valued and sufficiently smooth function defined on $[x_0, x_n]$. Then Newton's theorem provides

$$f(t) = \sum_{j=0}^{n+r} ([x_0, \cdots, x_j]f) \prod_{l=0}^{j-1} (t - x_l) + R(f),$$

where $R(f) = 0$ if and only if f is a polynomial of degree $n+r$ or less. Setting above $f(t) = t^{n+r}$ and next using (3.3), we obtain

$$t^{n+r} = \sum_{j=0}^{n+r} h_{n+r-j}(0, j) \prod_{l=0}^{j-1} (t - x_l).$$

Putting $t = x_n$, we get

$$x_n^{n+r} = \sum_{j=0}^{n+r} h_{n+r-j}(0, j) \prod_{l=0}^{j-1} (x_n - x_l).$$

If for some i $(1 \leqq i \leqq n)$, $x_i = \cdots = x_n$, then the above identity reduces to

$$x_n^{n+r} = h_{n+r-i}(0, i) \prod_{l=0}^{i-1} (x_n - x_l) + \sum_{j=0}^{i-1} h_{n+r-j}(0, j) \prod_{l=0}^{j-1} (x_n - x_l).$$

Since the last sum is nonnegative, the assertion (6.13) follows. Setting $i = n$ in (6.13), we obtain (6.14). This completes the proof. □

7. Applications. In this section we give some two-fold applications of our previous results. In §§ 7.1 and 7.2 we deal with the q-binomial coefficients and the r-Stirling numbers of the second kind, respectively.

7.1. Assume $x_i = q^i$ $(i = 0, 1, \cdots, n;\ q > 0,\ q \neq 1)$. We already know that $h_r = \begin{bmatrix} n+r \\ r \end{bmatrix}$ $(r \in \mathbb{N}_0;\ n \in \mathbb{N})$. Hence and from (5.1) we rediscover the well-known recurrence formula for the q-binomial coefficients

$$\begin{bmatrix} m \\ r \end{bmatrix} = \begin{bmatrix} m-1 \\ r \end{bmatrix} + q^{m-r} \begin{bmatrix} m-1 \\ r-1 \end{bmatrix} \qquad (1 \leqq r \leqq m)$$

(see, e.g., [1]). From (5.2), we obtain in a similar manner

$$\begin{bmatrix} m \\ r \end{bmatrix} = \sum_{j=0}^{m-r} \frac{(-1)^{m-r-j}}{q^j \cdots q^{m-r}} \begin{bmatrix} m+1 \\ j \end{bmatrix}.$$

From (6.4), we obtain the following inequality involving the q-binomial coefficients:

$$\left\{ \binom{n+r(l+m)}{n}^{-1} \begin{bmatrix} n+r(l+m) \\ n \end{bmatrix} \right\}^{1/r}$$
$$\leqq \left\{ \binom{n+pl}{n}^{-1} \begin{bmatrix} n+pl \\ n \end{bmatrix} \right\}^{1/p} \left\{ \binom{n+qm}{n}^{-1} \begin{bmatrix} n+qm \\ n \end{bmatrix} \right\}^{1/q}$$
$$(p, q, r > 0;\ 1/p + 1/q = 1/r;\ (l+m)r, pl, qm \in \mathbb{N}_0).$$

Combining (6.2) and (6.6) we get

$$\begin{bmatrix} m-1 \\ r-1 \end{bmatrix} \begin{bmatrix} m+1 \\ r+1 \end{bmatrix} \leqq \begin{bmatrix} m \\ r \end{bmatrix}^2 \leqq \frac{m(r+1)}{(m+1)r} \begin{bmatrix} m-1 \\ r-1 \end{bmatrix} \begin{bmatrix} m+1 \\ r+1 \end{bmatrix} \qquad (r, m \in \mathbb{N};\ r \leqq m).$$

The inequality (6.3) gives us

$$\begin{bmatrix} n+r \\ r \end{bmatrix}^{1/r} \geqq \begin{bmatrix} n+s \\ s \end{bmatrix}^{1/s} \qquad (1 \leqq r \leqq s;\ n \in \mathbb{N}_0).$$

The inequality (6.7) implies the following inequality:

$$\frac{q^{n+1}-1}{(n+1)(q-1)} \leqq \left\{ \binom{n+r}{r}^{-1} \begin{bmatrix} n+r \\ r \end{bmatrix} \right\}^{1/r} \leqq \left\{ \frac{q^{r(n+1)}-1}{(n+1)(q-1)} \right\}^{1/r}$$
$$(r \in \mathbb{N};\ n \in \mathbb{N}_0).$$

From (6.9), we obtain

$$\begin{bmatrix} n+r \\ r \end{bmatrix} \leqq \frac{(r+1)(r+2) \cdot \cdots \cdot s}{(n+r+1)(n+r+2) \cdot \cdots \cdot (n+s)} \begin{bmatrix} n+s \\ s \end{bmatrix} \qquad (0 \leqq r \leqq s)$$

provided that $q > 1$. This inequality is reversed if $0 < q < 1$. Finally, (6.14) implies the following two inequalities:

$$\begin{bmatrix} n+r \\ r \end{bmatrix} \leqq \frac{1}{(1-q^n) \cdot \cdots \cdot (1-q)}$$

when $0<q<1$ and

$$\begin{bmatrix} n+r \\ r \end{bmatrix} \leqq \frac{q^{n(n+r)}}{(q^n-1)\cdot\cdots\cdot(q^n-q^{n-1})}$$

when $q>1$.

7.2. Assume now $x_i = r+i$ with $r\in\mathbb{N}_0$ and $i=0, 1, \cdots, n$. First we will show that the identity (1.2) holds true. It is proved that

$$S_r(k+r, n+r) = [r, r+1, \cdots, r+n]t^k$$

($r\in\mathbb{N}_0$, $k\geqq n\geqq 0$) (cf. [3]). According to (3.3) we can rewrite the last identity as

$$S_r(k+r, n+r) = h_{k-n}(r, r+1, \cdots, r+n).$$

Hence (1.2) follows. Applying (1.2) to (5.1), we obtain

$$S_r(k, n) = S_r(k, n-1) + nS_r(k-1, n) \qquad (0\leqq r\leqq k;\ k\geqq n-1)$$

(see [3]). Equation (5.2) leads to the following recurrence relation for the r-Stirling numbers of the second kind

$$S_r(k+r, n+r) = \sum_{j=0}^{n} \frac{(-1)^{n-j}}{(r+j)\cdot\cdots\cdot(r+n)} S_r(k+r+1, j+r) \qquad (0\leqq r\leqq k;\ n\in\mathbb{N}_0).$$

Setting $\gamma = r$, $x_i = i$ $(0\leqq i\leqq n)$ into (5.5), we obtain

$$S_r(n+k, n+r) = \sum_{m=n}^{k} \binom{k}{m} S(m, n) r^{k-m} \qquad (0\leqq n\leqq k;\ r\in\mathbb{N}_0),$$

where, as usual, $S(\cdot, \cdot)$ denotes the Stirling number of the second kind. The polynomial (in r) that appears on the right-hand side is commonly referred to as the Stirling polynomial of the second kind (see [4]). We will close this section giving three inequalities involving the numbers $S_r(\cdot, \cdot)$. Combining (6.2) and (6.6) gives us

$$S_r(l-1, k)S_r(l+1, k) \leqq S_r(l, k)^2$$

$$\leqq \frac{(l-r)(l-k+1)}{(l-r+1)(l-k)} S_r(l-1, k)\cdot S_r(l+1, k) \qquad (0\leqq r\leqq k<l).$$

The left inequality tells us that the sequence $\{S_r(\cdot, k)\}$ is logarithmically concave. Our second inequality reads as follows:

$$\frac{(r+n)^k - n(r+n-1)^k}{n!} \leqq S_r(k+r, n+r) \leqq \frac{(r+n)^k}{n!} \qquad (r\in\mathbb{N}_0;\ 0\leqq n\leqq k).$$

There is nothing to prove when $n=0$. Assume $n>0$. In this case the right inequality follows from (6.10) and (1.2). For the proof of the left inequality it is enough to apply the following one:

$$[r, r+1, \cdots, r+n]t^k \geqq (r+n)^k/n! - (r+n-1)^k/(n-1)!$$

(cf. [17]). Next, taking into account that

$$[r, r+1, \cdots, r+n]t^k = S_r(k+r, n+r) \qquad (r\in\mathbb{N}_0;\ k\geqq n\geqq 0)$$

we obtain the desired result. Our last inequality reduces to that given by Wegner [17] (see also [15]) when $r=0$.

Before the presentation of our last result we introduce more notation. Let $0 \leqq \mu \leqq \nu$ (μ, ν-integers) and let

$$x(t) = \sum_{m=\mu}^{\nu} a_m t^m \qquad (a_m, t \in \mathbb{R}).$$

Further, let

$$a = \min\{x(t): r \leqq t \leqq r+n\},$$
$$b = \max\{x(t): r \leqq t \leqq r+n\},$$

with $r \in \mathbb{N}_0$, $n = \mathbb{N}$. If f is a convex function on (a, b), then the following inequality

$$f\left[\sum_{m=\mu}^{\nu} a_m \binom{m+n}{n}^{-1} S_r(m+n+r, n+r)\right] \leqq \left[J_n \int_r^{r+n} f(x(t))^2\, dt\right]^{1/2}$$

holds true, where

$$J_n = 2n \sum_{j=1}^{n} (-1)^{n-j} \frac{j^{2n-1}}{(n-j)!(n+j)!} \qquad (n \in \mathbb{N}).$$

Our inequality is a special case of the following one:

$$g\left[\sum_{m=\mu}^{\nu} a_m \binom{m+n}{n}^{-1} h_m(x_0, \cdots, x_n)\right] \leqq \left[J_n \int_{x_0}^{x_n} g(x(t))^2\, dt\right]^{1/2}$$

with g convex on (a, b), where now

$$a = \min\{x(t): x_0 \leqq t \leqq x_n\},$$
$$b = \max\{x(t): x_0 \leqq t \leqq x_n\}$$

(see [9] for the details). Setting $x_j = j + r$, all j, we obtain the desired result.

Let us notice that $J_1 = 1$, $J_2 = 2/3$, $J_3 = 11/20$, $J_4 = 151/315$, $J_5 = 15619/36288$.

Acknowledgments. The author thanks Professor Stefan Paszkowski for his proofs of Corollaries 3.1 and 3.2. Thanks are due to Professor Philip Feinsilver for drawing my attention to the Feynman identity and for useful conversations. I would also like to thank Mrs. Linda Macak for her excellent typing.

OSCILLATION PROPERTIES FOR SOME POLYNOMIAL ANALOGUES OF THE PROLATE SPHEROIDAL WAVE FUNCTIONS*

MARCI A. PERLSTADT†

Abstract. Slepian, Landau, and Pollak found that a certain finite integral operator commutes with a much simpler second-order differential operator. The eigenfunctions that these operators share are prolate spheroidal wave functions and the study of these eigenfunctions has led to applications in several areas. Grünbaum displayed analogues of this commutativity for certain integral operators involving orthogonal polynomials. We discuss some implications of this commutativity for these eigenfunctions.

Key words. orthogonal polynomials, prolate spheroidal wave functions, oscillation

AMS(MOS) subject classifications. primary 33A65; secondary 42A16

1. Introduction. Let f be a square integrable function with Fourier transform $\hat{f} = Ff$. For $\mathscr{A}$ and $\mathscr{B}$ subsets of $\mathbb{R}$, we let A be the operator that restricts f (timelimits f) to $\mathscr{A}$ and let B be the operator that restricts $\hat{f}$ (bandlimits f) to $\mathscr{B}$, i.e.,

$$Af = f \cdot \chi_{\mathscr{A}} \quad \text{and} \quad B\hat{f} = \hat{f} \cdot \chi_{\mathscr{B}}.$$

In a series of papers [1], [2], [3], Slepian, Landau, and Pollak studied the integral operator that timelimits then bandlimits and then again timelimits a function, $AF^{-1}BFA$ (here F^{-1} denotes the inverse Fourier transform). The eigenvalues and eigenfunctions of this operator proved critical to an understanding of the "space" of "nearly" time and bandlimited functions. The realization that the operator $AF^{-1}BFA$ commuted with a relatively simple Sturm–Liouville type second-order differential equation with simple spectrum [1] was crucial in determining many properties of the eigenfunctions, including the fact that the eigenfunctions were prolate spheroidal wave functions.

In recent years the problem has been looked at for more general Fourier situations [4], [5]. In particular, we will be interested in the case of expansions in terms of orthogonal polynomials $\{p_i(x)\}$ where the orthogonality is with respect to a nonnegative continuous weight $w(x)$ on $\mathscr{C}$. Assuming polynomials are complete for the space of functions square integrable with respect to the inner product

$$\langle f, g\rangle_{w(x),\mathscr{C}} = \int_{\mathscr{C}} f(x)g(x)w(x)\,dx,$$

we have for such functions that

$$f(x) = \sum_{i=0}^{\infty} \hat{f}(i)p_i(x) \quad \text{where } F(f) = \hat{f}(i) = \langle f(x), p_i(x)\rangle_{w(x),\mathscr{C}}.$$

Here and throughout the remainder of this paper we assume the $p_i(x)$'s are orthonormal.

If now A is the operator that restricts f to $\mathscr{A} \subset \mathscr{C}$, i.e.,

$$Af = f \cdot \chi_{\mathscr{A}}$$

and B is the operator that restricts $\hat{f}(i)$ via

$$B\hat{f}(i) = \begin{cases} \hat{f}(i), & i = 0, 1, \cdots, L, \\ 0, & i > L, \end{cases}$$

* Received by the editors October 29, 1986; accepted for publication (in revised form) May 18, 1987.
† Department of Mathematics, Drexel University, Philadelphia, Pennsylvania 19104.

we can again study $AF^{-1}BFA$. In this case (see [6])

$$(1.1)\quad AF^{-1}BFAf(x)=\int_{A} K_L(x,y)f(y)w(y)\,dy, \qquad K_L(x,y)=\sum_{i=0}^{L} p_i(x)p_i(y).$$

We can also study the band-time-bandlimiting operator $BFAF^{-1}B$ which can be represented as an $(L+1)\times(L+1)$ matrix G [6] with

$$(1.2)\quad (G)_{ij}=\int_{\mathscr{A}} p_i(x)p_j(x)w(x)\,dx, \qquad i,j=0,1,\cdots,L.$$

In [5] it is shown that for the classical orthogonal polynomials, $AF^{-1}BFA$ has a commuting second-order differential operator and G has a commuting tridiagonal matrix provided $\mathscr{A}$ is chosen properly. We will use this commutativity to establish a number of properties of the eigenfunctions for these operators. Most of these properties are analogous to those found in [1] for the case of the standard Fourier transform and these eigenfunctions can be viewed as polynomial analogues of the prolate spheroidal wave functions.

2. Background. We begin by noting the following lemma whose proof can be found in [6].

LEMMA 2.1. *Let $\{p_i(x)\}$ be a complete orthonormal family of polynomials ($i=0,1,2,\cdots$, degree of $p_i(x)=i$) with respect to the continuous nonnegative weight function $w(x)$ on $\mathscr{C}$. Let $\mathscr{A}\subset\mathscr{C}$ be such that*

$$0<\int_{\mathscr{A}} w(x)\,dx<\int_{\mathscr{C}} w(x)\,dx.$$

Then

(i) *$AF^{-1}BFA$ and $BFAF^{-1}B$ have $L+1$ positive eigenvalues,*

$$1>\lambda_0\geqq\lambda_1\geqq\cdots\geqq\lambda_L>0.$$

(ii) *If $\phi_0(x),\phi_1(x),\cdots,\phi_L(x)$ are eigenfunctions of $AF^{-1}BFA$ corresponding to eigenvalues $\lambda_0,\lambda_1,\cdots,\lambda_L$, respectively, then $BF\phi_i$ is an eigenvector of $BFAF^{-1}B$ corresponding to λ_i for $i=0,1,\cdots,L$.*

(iii) *If $\vec{c}^{(0)},\vec{c}^{(1)},\cdots,\vec{c}^{(L)}$ are eigenvectors of $BFAF^{-1}B$ corresponding to $\lambda_0,\lambda_1,\cdots,\lambda_L$, respectively, then $AF^{-1}\vec{c}^{(i)}$ is an eigenfunction of $AF^{-1}BFA$ corresponding to λ_i.*

(iv) *The $\phi_i(x)$'s are polynomials of degree less than or equal to L and can be normalized so that*

(a) $\lambda_i\phi_i(x)=\int_{\mathscr{A}} K_L(x,y)\phi_i(y)w(y)\,dy$,

(b) $\langle\phi_i(x),\phi_j(x)\rangle_{w(x),\mathscr{C}}=\delta_{ij}$, *and*

(c) $\langle\phi_i(x),\phi_j(x)\rangle_{w(x),\mathscr{A}}=\lambda_i\delta_{ij}$.

(v) *If we let $\sim\mathscr{A}=\mathscr{C}-\mathscr{A}$ and $\sim Af=f\cdot\chi_{\sim\mathscr{A}}$ we have*

(a) $\sim AF^{-1}BF\sim A\phi_i(x)=(1-\lambda_i)\phi_i(x)$, *and*

(b) $\langle\sim A\phi_i,\sim A\phi_i\rangle_{w(x),\mathscr{C}}=\langle\phi_i,\phi_i\rangle_{w(x),\sim\mathscr{A}}=1-\lambda_i$.

We now turn our attention to the problem Grünbaum investigated in [5], namely that of determining for which orthogonal polynomial families the operator $AF^{-1}BFA$ commutes with a second-order differential operator and the matrix G of (1.2) commutes with a tridiagonal matrix. He found the following.

THEOREM 2.2. *For the classical orthogonal polynomials (Jacobi, Hermite, Laguerre, and Bessel), orthogonal on (δ,ε) with respect to $w(x)$, if we choose $A=(\sigma,\varepsilon)$ where*

$\delta < \sigma < \varepsilon$, then there exists a second-order differential operator D commuting with $AF^{-1}BFA$ and a tridiagonal matrix T commuting with G.

The differential operators D are explicitly constructed in [5]. If we apply D to $p_n(x)$ and use a number of properties peculiar to the classical orthogonal polynomials, we find that there are constants T_{ij} such that

$$Dp_n(x) = T_{nn-1}p_{n-1}(x) + T_{nn}p_n(x) + T_{nn+1}p_{n+1}(x).$$

Thus taking

$$\phi_i(x) = \sum_{n=0}^{L} c_n^{(i)} p_n(x) \tag{2.3}$$

and applying D to (2.3), we obtain a three-term recurrence for the $c_n^{(i)}$:

$$T_{nn-1}c_{n-1}^{(i)} + T_{nn}c_n^{(i)} + T_{nn+1}c_{n+1}^{(i)} = \mu_i c_n^{(i)}$$

where $D\phi_i(x) = \mu_i\phi_i(x)$. Thus we may take the T_{ij}'s as the entries of the matrix T that commutes with G. An example of this sort is carried out in [4].

Our efforts will be limited to the Jacobi, Hermite, and Laguerre polynomials. Since we will make use of D and T, we will give them explicitly below.

The orthonormalized polynomials $\{p_i(x)\}$ all satisfy [9] recurrences of the form

$$b(n)xp_n(x)\sqrt{h_n} = a(n)\sqrt{h_{n+1}}\,p_{n+1}(x) + c(n)\sqrt{h_n}\,p_n(x) + d(n)\sqrt{h_{n-1}}\,p_{n-1}(x),$$

second-order differential equations of the form

$$\frac{1}{w(x)}\frac{d}{dx}\left[W(x)\frac{d}{dx}p_n(x)\right] = \mu_n p_n(x),$$

and first-order equations of the form

$$\frac{W(x)}{w(x)}\frac{d}{dx}p_n(x) = \alpha_n p_n(x) + x\beta_n p_n(x) + \sqrt{\frac{h_{n-1}}{h_n}}\,\gamma_{n-1}p_{n-1}(x).$$

Here we have (following the notation in [9]) that for the

(a) Jacobi polynomials on $(-1, 1)$:

$w(x) = (1-x)^\alpha(1+x)^\beta \quad (\alpha, \beta > -1)$, $\qquad W(x) = (1-x^2)w(x)$,

$\mu_n = -n(n+\alpha+\beta+1)$, $\qquad h_n = \dfrac{2^{\alpha+\beta+1}}{\alpha+\beta+2n+1} \cdot \dfrac{\Gamma(\alpha+n+1)\Gamma(\beta+n+1)}{n!\Gamma(\alpha+\beta+n+1)}$,

$a(n) = 2(n+1)(\alpha+\beta+n+1)(\alpha+\beta+2n)$, $\qquad b(n) = (\alpha+\beta+2n)(\alpha+\beta+2n+1) \cdot (\alpha+\beta+2n+2)$,

$c(n) = (\alpha+\beta+2n+1)(\beta^2-\alpha^2)$, $\qquad d(n) = 2(\alpha+n)(\beta+n) \cdot (\alpha+\beta+2n+2)$,

$\alpha(n) = \dfrac{n(\alpha-\beta)}{\alpha+\beta+2n}$, $\qquad \beta(n) = -n$,

$\gamma(n-1) = \dfrac{2(n+\alpha)(n+\beta)}{\alpha+\beta+2n}$;

(b) Laguerre polynomials on $(0, \infty)$:

$$w(x) = e^{-x}x^{\alpha} \quad (\alpha > -1), \qquad W(x) = e^{-x}x^{\alpha+1},$$

$$\mu_n = -n, \qquad h_n = \Gamma(1+\alpha)\binom{n+\alpha}{n},$$

$$a(n) = -(n+1), \qquad b(n) = 1,$$

$$c(n) = (2n+\alpha+1), \qquad d(n) = -(n+\alpha),$$

$$\alpha(n) = n, \qquad \beta(n) = 0,$$

$$\gamma(n-1) = -(n+\alpha);$$

(c) Hermite polynomials on $(-\infty, \infty)$:

$$w(x) = e^{-x^2}, \qquad W(x) = e^{-x^2},$$

$$\mu_n = -2n, \qquad h_n = \pi^{1/2}2^n n!,$$

$$a(n) = 1, \qquad b(n) = 2,$$

$$c(n) = 0, \qquad d(n) = 2n,$$

$$\alpha(n) = 0, \qquad \beta(n) = 0,$$

$$\gamma(n-1) = 2n.$$

The commuting operators D, given in [5], have the form

$$D = \frac{1}{w(x)}\frac{d}{dx}\left[(x-\sigma)W(x)\frac{d}{dx}\right] + Ax$$

where for the Jacobi polynomials, $A = L(L+\alpha+\beta+2)$; Laguerre polynomials, $A = L$; Hermite polynomials, $A = 2L$.

The matrices T are given by

$$T_{i+1,i} = T_{i,i+1} = (A + \mu_i + \beta_i)\frac{a(i)}{b(i)}\sqrt{\frac{h_{i+1}}{h_i}}, \qquad i = 0, 1, \cdots, L-1,$$

$$T_{i,i} = (A + \mu_i + \beta_i)\frac{c(i)}{b(i)} + \alpha_i - \sigma\mu_i, \qquad i = 0, 1, \cdots, L.$$

Note that since all of the super- and subdiagonal elements of the matrices T are nonzero, we are guaranteed that T has simple spectrum [10, p. 300]. Thus the eigenvectors of T are also eigenvectors of G.

3. Statement of the main result. Our goal here is to show that in the special cases where commuting operators D and T exist, we know a great deal more about the eigenfunctions ϕ_i and eigenvectors $\vec{c}^{(i)}$ than what was stated in Lemma 2.1. We have, in fact, the following.

THEOREM 3.1. *For the Jacobi, Hermite, and Laguerre polynomials with $A = (\sigma, \varepsilon)$ as described above we have*

(a) *$AF^{-1}BFA$ and $BFAF^{-1}B$ have simple spectrum (away from 0), i.e., $1 > \lambda_0 > \cdots > \lambda_L > 0$.*

(b) *If the eigenvalues of the commuting matrices T are ordered so that $\mu_0 > \mu_1 > \cdots > \mu_L$ with corresponding eigenfunctions $\phi_{i_0}\phi_{i_1}, \cdots, \phi_{i_L}$ then, in fact, $i_0 = 0, i_1 = 1, \cdots, i_L = L$.*

(c) *$\phi_0, \phi_1, \cdots, \phi_L$ each have L simple zeros on $\mathscr{C} = (\delta, \varepsilon)$ and ϕ_i has exactly i zeros on $A = (\sigma, \varepsilon)$. Furthermore the zeros of ϕ_i separate those of ϕ_{i+1}.*

(d) *For a vector $\vec{x} = (x_0, \cdots, x_L)$, let $S^-(\vec{x})$ be the number of sign changes in the sequence $x_0, x_1, \cdots, x_L$ with zero terms discarded. Let $S^+(\vec{x})$ be the maximum number of sign changes in the sequence $x_0, x_1, \cdots, x_L$ where zero terms are arbitrarily assigned values of $+1$ or -1. Then $S^-(\vec{c}^{(i)}) = S^+(\vec{c}^{(i)}) = i$, for $i = 0, 1, \cdots, L$, for the case of Jacobi and Hermite polynomials. For the Laguerre polynomials $S^-(\vec{c}^{(i)}) = S^+(\vec{c}^{(i)}) = L - i$.*

Before beginning the proof of Theorem 3.1 we note that in many applications we are primarily interested in the $\phi_i(\vec{c}^{(i)})$ as eigenfunctions (eigenvectors) of $AF^{-1}BFA$ ($BFAF^{-1}B$) as opposed to as eigenfunctions (eigenvectors) of $D(T)$. Theorem 3.1(b) allows us to extend properties of the ϕ_i and $\vec{c}^{(i)}$ that are readily derived from D and T to the operators $AF^{-1}BFA$ and $BFAF^{-1}B$.

Proof. We begin by showing that if (a) and (b) are established then (c) and (d) follow readily.

If we write

$$\text{(3.1(e))} \qquad \frac{d}{dx}\left((x-\sigma)W(x)\frac{d}{dx}\phi_n(x)\right) + Aw(x)x\phi_n(x) = \mu_n w(x)\phi_n(x),$$

then we can apply the argument in [7, pp. 719–721] to show that if $\mu_i > \mu_j$, then ϕ_j has at least one more zero than ϕ_i on (σ, ε). For completeness we sketch the argument here.

Suppose that $\mu_i > \mu_j$. Multiplying equation (3.1(e)) for ϕ_i by ϕ_j and equation (3.1(e)) for ϕ_j by ϕ_i and subtracting yields

$$\text{(3.1(f))} \qquad \begin{aligned} &\frac{d}{dx}\left((x-\sigma)W(x)\left(\phi_j(x)\frac{d}{dx}\phi_i(x) - \phi_i(x)\frac{d}{dx}\phi_j(x)\right)\right) \\ &\qquad = (\mu_i - \mu_j)w(x)\phi_i(x)\phi_j(x). \end{aligned}$$

If we integrate this equation from σ to $\tilde{x}$ ($\tilde{x} < \varepsilon$), we get

$$\text{(3.1(g))} \qquad (\tilde{x}-\sigma)W(\tilde{x})(\phi_j(\tilde{x})\phi_i'(\tilde{x}) - \phi_i(\tilde{x})\phi_j'(\tilde{x})) = (\mu_i - \mu_j)\int_\sigma^{\tilde{x}} \phi_i(x)\phi_j(x)w(x)\,dx.$$

Suppose $\tilde{x}$ is chosen so that $\phi_i(\tilde{x}) = 0$ and $\phi_i(x) \neq 0$, $x \in (\sigma, \tilde{x})$. Without loss of generality we may assume $\phi_i(x) > 0$ on $(\sigma, \tilde{x})$ and thus that $\phi_i'(\tilde{x}) < 0$. Suppose now that $\phi_j(x)$ has no zeros in $(\sigma, \tilde{x})$ and without loss of generality we take $\phi_j(x) > 0$ on $(\sigma, \tilde{x})$. Then (3.1(g)) becomes

$$\text{(3.1(h))} \qquad (\tilde{x}-\sigma)W(\tilde{x})\phi_j(\tilde{x})\phi_i'(\tilde{x}) = (\mu_i - \mu_j)\int_\sigma^{\tilde{x}} \phi_i(x)\phi_j(x)w(x)\,dx.$$

But in all cases being studied $(\tilde{x}-\sigma)W(\tilde{x}) > 0$ and $\mu_i > \mu_j$, thus forcing the left-hand side of (3.1(h)) to be negative and the right-hand side of (3.1(h)) to be positive. This contradicts the assumption that $\phi_j(x)$ has no zeros on $(\sigma, \tilde{x})$.

We can now repeat this argument on $(\tilde{x}, \tilde{y})$ where $\tilde{y}$ is the next zero of $\phi_i(x)$. A similar argument integrating (3.1(f)) from $\tilde{x}$ to $\tilde{y}$ will show that $\phi_j(x)$ has a zero between $\tilde{x}$ and $\tilde{y}$. This argument can be repeated to show that there is a zero of $\phi_j(x)$ between any two consecutive zeros of $\phi_i(x)$.

In a similar fashion we see that if $\tilde{z}$ is the largest zero of $\phi_i(x)$ on (σ, ε), then $\phi_j(x)$ has a zero in $(\tilde{z}, \varepsilon)$. Thus ϕ_j has at least one more zero than ϕ_i $(j > i)$.

Noting that the ϕ_j's are polynomials of degree $\leqq L$ and thus have at most L zeros, we conclude that ϕ_j has at most j zeros. Furthermore we can show that since ϕ_0 has

no zeros, applying the argument above to the interval (σ, ε) (i.e., integrating (3.1(f)) from σ to ε) with $i=0$ and $j=1$ enables us to conclude that $\phi_1(x)$ has exactly one zero and that $\phi_j(x)$ has exactly j zeros.

We can now repeat the argument above on the interval (δ, σ) (see Lemma 2.1(v)), i.e., integrate (3.1(f)) from $\tilde{x}$ to σ $(\tilde{x}<\sigma)$, to show that if $\mu_i<\mu_j$, then ϕ_j has at least one more zero than ϕ_i on (δ, σ). Thus ϕ_j has $L-j$ zeros on (δ, σ).

The interlacing property of the zeros is immediate thus proving (c).

Part (d) follows from consideration of the matrix T. If T is oscillatory [8] then (d) follows immediately. A tridiagonal matrix is oscillatory if its super- and subdiagonal elements are positive and its successive principal minors are all positive [8]. Clearly in the Jacobi and Hermite cases the matrices T all have positive elements along the super- and subdiagonals but it need not be that the successive principal minors are all positive. Note, however, that if $TG=GT$, then also $(T+\lambda l)G=G(T+\lambda l)$ and $T+\lambda l$ has the same eigenvectors as T does, but has eigenvalues $\mu_0+\lambda>\mu_1+\lambda>\cdots>\mu_L+\lambda$. Since there are a finite number of principal minors of $T+\lambda l$, all of which are polynomials in λ with leading coefficient 1, we can choose λ sufficiently large so as to guarantee that the principal minors of $T+\lambda l$ are positive and so $T+\lambda l$ is oscillating. This assures (d) in these two cases.

In the Laguerre case the elements along the super- and subdiagonals of T are negative. We can replace T by $-T$ and carry out the same argument, only now the eigenvalues are $-\mu_L>-\mu_{L-1}>\cdots>-\mu_0$, and thus this reordering leads to $S^-(\vec{c}^{(i)})=L-i$.

We now consider (a). Note that $p(x)$ is an eigenfunction of $AF^{-1}BFA$ corresponding to $\lambda\neq 0$ if and only if

$$\int (\chi_{\mathscr{A}}-\lambda\chi_{\mathscr{C}})p(x)f(x)w(x)\,dx=0 \tag{3.2}$$

for all polynomials $f(x)$ of degree $\leqq L$. For if $p(x)$ is an eigenfunction of $AF^{-1}BFA$, then

$$\int_{\mathscr{A}} K_L(x,y)p(y)w(y)\,dy=\lambda p(x)=\lambda\int_{\mathscr{C}} K_L(x,y)p(y)w(y)\,dy.$$

The last equality is due to the fact that $p(y)$ is a polynomial of degree $\leqq L$ and $K_L(x,y)$ is a reproducing kernel for such polynomials. From this we see that

$$\int (\chi_{\mathscr{A}}-\lambda\chi_{\mathscr{C}})K_L(x,y)p(y)w(y)\,dy=0, \quad \text{or}$$

$$\sum_{i=0}^{L}\left(\int(\chi_{\mathscr{A}}-\lambda\chi_{\mathscr{C}})p_i(y)p(y)w(y)\,dy\right)p_i(x)=0$$

and so the coefficients of $p_0(x), p_1(x), \cdots, p_L(x)$ in the above sum must each be 0. Thus for any polynomial $f(x)$ of degree $\leqq L$ we have (3.2). Conversely if (3.2) holds for all polynomials of degree $\leqq L$, then we have

$$\begin{aligned}\int_{\mathscr{A}} K_L(x,y)p(y)w(y)\,dy&=\sum_{i=0}^{L}p_i(x)\left(\int_{\mathscr{A}}p_i(y)p(y)w(y)\,dy\right)\\&=\lambda\sum_{i=0}^{L}p_i(x)\int_{\mathscr{C}}p_i(y)p(y)w(y)\,dy\\&=\lambda\int_{\mathscr{C}}K_L(x,y)p(y)w(y)\,dy=\lambda p(x)\end{aligned}$$

and thus $p(x)$ is an eigenfunction.

Suppose now that $AF^{-1}BFA$ does not have simple spectrum. Then there exist eigenfunctions $f(x)$ and $g(x)$, linearly independent polynomials of degree $\leqq L$, corresponding to eigenvalue λ. Without loss of generality, we may assume one of these, say $g(x)$, has degree strictly less than L. Since $g(x)(\sigma - x)$ has degree $\leqq L$, by (3.2) we have

$$\int (\chi_{\mathscr{A}} - \lambda\chi_{\mathscr{C}})g^2(x)(\sigma - x)w(x)\,dx = 0. \tag{3.3}$$

But the left-hand side of (3.3) is in fact equal to

$$(1-\lambda)\int_{\mathscr{A}} g^2(x)(\sigma - x)w(x)\,dx - \lambda\int_{\sim\mathscr{A}} (\sigma - x)g^2(x)w(x)\,dx$$

and this is clearly less than 0, contradicting (3.3). Thus $AF^{-1}BFA$ has simple spectrum proving (a).

To prove (b), we claim that it suffices to show that the ordering in (b) holds for just one value of σ. For suppose that L is fixed and that we write $G(\sigma)$ for the matrix G of (1.2) in order to denote its dependence on σ. Since the elements of $G(\sigma)$ are analytic functions of σ and the eigenvalues $\lambda_j(\sigma)$ of $G(\sigma)$ are distinct, we know that the functions $\lambda_j(\sigma)$ are analytic functions of σ [12]. Now if the ordering in (b) holds for some particular σ and for some σ' the ordering does not hold, i.e., $\lambda_j(\sigma') > \lambda_{j-1}(\sigma')$, for some j, then by continuity considerations for some σ'' between σ and σ', $\lambda_{j-1}(\sigma'') = \lambda_j(\sigma'')$, contradicting (a). This shows the claim.

Before continuing the proof of (b), we make note of the following ideas from the theory of total positivity [13], [14], [15]. A kernel $K(x, y)$ is said to be totally positive on (α, β) [14] provided the Fredholm determinants

$$K\begin{pmatrix} x_0, \cdots, x_n \\ y_0, \cdots, y_n \end{pmatrix} = \det\,(K(x_i, y_j))_{i,j=0}^{n} \geqq 0 \tag{3.4}$$

for all $\alpha \leqq x_0 < x_1 < \cdots < x_n \leqq \beta$ and $\alpha \leqq y_0 < y_1 < \cdots < y_n \leqq \beta$ and $n = 0, 1, 2, \cdots$.

Gantmacher and Krein prove the following theorem [13, pp. 207–217].

THEOREM. *Let $K(x, y)$ be a totally positive continuous symmetric kernel on (α, β), and suppose that*

$$K\begin{pmatrix} x_0, \cdots, x_n \\ x_0, \cdots, x_n \end{pmatrix} > 0 \quad \textit{for all } \alpha < x_0 < x_1 < \cdots < x_n < \beta \textit{ and } n = 0, 1, 2, \cdots. \tag{3.5}$$

Then the integral equation

$$\int_{\alpha}^{\beta} K(x, y)f(y)w(y)\,dy = \lambda f(x)$$

has positive simple eigenvalues $\lambda_0 > \lambda_1 > \cdots > 0$. The corresponding eigenfunctions $\phi_0(x)$, $\phi_1(x), \cdots$ are such that ϕ_i has exactly i (simple) zeros in (α, β).

If we could show that for some σ, $K_L(x, y)$ satisfies the conditions of the theorem on (σ, ε) then we could conclude that, by the proof of (c), the ordering in (b) holds. In fact, a σ can be found so that $K_L(x, y)$ satisfies (3.4) and (3.5), but only for $n = 0, 1, \cdots, L$. With only minor modifications of the proof in [13], however, we see that if (3.5) holds only for $n = 0, 1, \cdots, L$ then the eigenfunctions $\phi_i(x)$ have exactly i zeros in (σ, ε) for $i = 0, 1, \cdots, L$.

In order to show that $K_L(x, y)$ satisfies (3.4) and (3.5) for $n = 0, 1, \cdots, L$ and some σ, we will make use of Karlin's notion of extended total positivity [11]. We call the kernel $K(x, y)$ extended totally positive of order r on (α, β) if

$$\tilde{K}^{(n)}(x, y) = \det\left(\frac{\partial^{i+j} K(x, y)}{\partial x^i \, \partial y^j}\right)_{i,j=0}^{n} > 0 \tag{3.6}$$

for $n = 0, 1, \cdots, r$ and for all $x, y \in (\alpha, \beta)$. A theorem of Karlin [11] states that if (3.6) holds then (3.4) holds with strict inequality for $n = 0, 1, \cdots, r$. Thus it suffices to show that there exists σ so that $\tilde{K}_L^{(n)}(x, y) > 0$ for $n = 0, 1, \cdots, L$ and $x, y \in (\sigma, \varepsilon)$.

Let

$$A^{(n)}(z) = \begin{bmatrix} p_0(z) & p_1(z) & \cdots & p_L(z) \\ p_0'(z) & p_1'(z) & \cdots & p_L'(z) \\ \vdots & \vdots & & \vdots \\ p_0^{(n)}(z) & p_1^{(n)}(z) & \cdots & p_L^{(n)}(z) \end{bmatrix}$$

$$= \begin{bmatrix} p_0(z) & p_1(z) & \cdots & p_n(z) & \cdots & p_L(z) \\ 0 & p_1'(z) & \cdots & p_n'(z) & \cdots & p_L'(z) \\ \vdots & \vdots & & \vdots & & \vdots \\ 0 & 0 & \cdots & p_n^{(n)}(z) & \cdots & p_L^{(n)}(z) \end{bmatrix}.$$

Then $\tilde{K}_L^{(n)}(x, y) = \det\left(A^{(n)}(y)(A^{(n)}(x))^T\right)$. We consider the cases of Jacobi, Hermite, and Laguerre polynomials separately.

(i) Jacobi polynomials. Noting that $A^{(L)}(z)$ is a square upper triangular matrix whose diagonal terms are nonzero constants, we have at once that

$$\tilde{K}_L^{(L)}(x, y) = \det\left(A^{(L)}(y)\right) \det\left(A^{(L)}(x)\right)^T = \left(\det\left(A^{(L)}(y)\right)\right)^2 > 0.$$

If we fix x then $\tilde{K}_L^{(n)}(x, x)$ is the determinant of the nonnegative definite matrix $A^{(n)}(x)(A^{(n)}(x)^T)$. For $n = L$ this matrix is positive definite ($\tilde{K}_L^{(L)}(x, x) > 0$) and thus the eigenvalues of this matrix are positive numbers

$$0 < \tau_0 \leqq \tau_1 \leqq \tau_2 \leqq \cdots \leqq \tau_L.$$

By the separation theorem for the eigenvalues of a symmetric matrix [10], the eigenvalues $\tau_0' \leqq \tau_1' \leqq \cdots \leqq \tau_{L-1}'$ of $A^{(L-1)}(x)(A^{(L-1)}(x))^T$ interlace with the τ_i's, and thus

$$0 < \tau_0 \leqq \tau_0' \leqq \tau_1 \leqq \tau_1' \cdots \leqq \tau_{L-1} \leqq \tau_{L-1}' \leqq \tau_L$$

and $\tilde{K}_L^{(L-1)}(x, x) = \tau_0' \cdots \tau_{L-1}' > 0$. Continuing in this fashion we see that $\tilde{K}_L^{(n)}(x, x) > 0$ for $n = 0, 1, \cdots, L$.

Since $\tilde{K}_L^{(n)}(x, y)$ is a continuous function of x and y for each n and since $\tilde{K}_L^{(n)}(1, 1) > 0$, we have that $\tilde{K}_L^{(n)}(x, y) > 0$ in a neighborhood of $(1, 1)$. In particular, if σ is sufficiently close to 1, $\tilde{K}_L^{(n)}(x, y) > 0$ for all $x, y \in (\sigma, 1)$ and $n = 0, 1, \cdots, L$.

(ii) Laguerre polynomials. Here we can basically repeat the argument for Jacobi polynomials, only this time on the set $\sim A = (0, \sigma)$, i.e., we consider the operator $\sim AF^{-1}BF \sim A$ of Lemma 2.1(v). The eigenvalues in this case are $1 > 1 - \lambda_L > 1 - \lambda_{L-1} > \cdots > 1 - \lambda_0 > 0$ with corresponding eigenvectors $\phi_L, \phi_{L-1}, \cdots, \phi_0$. The same D and T of Theorem 2.2 commute with $\sim AF^{-1}BF \sim A$ and $BF \sim AF^{-1}B$, respectively. By taking σ sufficiently close to 0 we can conclude that $\tilde{K}_L^{(n)}(x, y) > 0$ for all $x, y \in (0, \sigma)$, $n = 0, 1, \cdots, L$. Thus ϕ_i has $L - i$ zeros in $(0, \sigma)$ and thus i zeros in (σ, ∞), completing (b) of Theorem 3.1.

(iii) Hermite polynomials. In this case we will use the Cauchy-Binet formula [14]. This gives us that

$$\tilde{K}_L^{(n)}(x,y)=\sum_{1\leqq i_1<i_2<\cdots<i_n\leqq L} A^{(n)}(y)\begin{pmatrix}1&2&\cdots&n\\ i_1&i_2&\cdots&i_n\end{pmatrix}\cdot(A^{(n)}(x))^T\begin{pmatrix}i_1&i_2&\cdots&i_n\\ 1&2&\cdots&n\end{pmatrix} \tag{3.7}$$

where

$$B\begin{pmatrix}j_1&j_2&\cdots&j_n\\ i_1&i_2&\cdots&i_n\end{pmatrix}$$

is the determinant of the $n\times n$ matrix obtained by omitting all rows from B except $j_1,\cdots,j_n$ and all columns from B except $i_1,\cdots i_n$. Note that $A^{(n)}(y)\left(\begin{smallmatrix}1&2&\cdots&n\\ i_1&i_2&\cdots&i_n\end{smallmatrix}\right)$ is a polynomial in y. We will show that the leading coefficient of the polynomial is always positive. Thus if σ is sufficiently large, $A^{(n)}(y)\left(\begin{smallmatrix}1&2&\cdots&n\\ i_1&i_2&\cdots&i_n\end{smallmatrix}\right)>0$ for all $y>\sigma$ and all choices of $i_1<i_2<\cdots<i_n$ and $n=0,1,\cdots,L$. This in turn would enable us to conclude that every term in the sum (3.7) is positive for $x,y\in(\sigma,\infty)$ and thus that $\tilde{K}_L^{(n)}(x,y)>0$ on (σ,∞).

It remains only to show that the leading coefficient of

$$A^{(n)}(x)\begin{pmatrix}1&2&\cdots&n\\ i_1&i_2&\cdots&i_n\end{pmatrix}=\det\begin{bmatrix}p_{i_1}(x)&p_{i_2}(x)&\cdots&p_{i_n}(x)\\ p'_{i_1}(x)&p'_{i_2}(x)&\cdots&p'_{i_n}(x)\\ \vdots&\vdots&&\vdots\\ p_{i_1}^{(n)}(x)&p_2^{(n)}(x)&\cdots&p_{i_n}^{(n)}(x)\end{bmatrix}$$

is positive.

The $p_i(x)$'s are the orthonormalized Hermite polynomials and, since their leading coefficients are all positive, we may renormalize them to have leading coefficient 1 without affecting the sign of $A^{(n)}(x)\left(\begin{smallmatrix}1&\cdots&n\\ i_1&\cdots&i_n\end{smallmatrix}\right)$. Thus $A^{(n)}(x)\left(\begin{smallmatrix}1&2&\cdots&n\\ i_1&i_2&\cdots&i_n\end{smallmatrix}\right)$ is the determinant of

$$\begin{bmatrix}x^{i_1}+\cdots&x^{i_2}+\cdots&\cdots&x^{i_n}+\cdots\\ i_1x^{i_1-1}+\cdots&i_2x^{i_2-1}+\cdots&\cdots&i_nx^{i_n-1}+\cdots\\ 2!\binom{i_1}{2}x^{i_1-2}+\cdots&2!\binom{i_2}{2}x^{i_2-2}+\cdots&\cdots&2!\binom{i_n}{2}x^{i_n-2}+\cdots\\ \vdots&\vdots&&\vdots\\ (n-1)!\binom{i_1}{n-1}x^{i_1-(n-1)}&(n-1)!\binom{i_2}{n-1}x^{i_2-(n-1)}&\cdots&(n-1)!\binom{i_n}{n-1}x^{i_n-(n-1)}\end{bmatrix}$$

(here $\binom{i}{j}=0$ if $j>i$) and this determinant has x degree at most $i_1+i_2+\cdots+i_n-\binom{n}{2}$. Thus the coefficient of $x^{i_1+\cdots+i_n-\binom{n}{2}}$ is $(n-1)!(n-2)!\cdots 2!$ times the determinant of

$$\begin{bmatrix}1&1&1\\ \binom{i_1}{1}&\binom{i_2}{1}&\binom{i_n}{1}\\ \binom{i_1}{2}&\binom{i_2}{2}&\binom{i_n}{2}\\ \vdots&\vdots&\vdots\\ \binom{i_1}{n-1}&\binom{i_2}{n-1}&\binom{i_n}{n-1}\end{bmatrix}. \tag{3.8}$$

That determinants of matrices of the form (3.8) are greater than or equal to 0 follows immediately from the fact that these determinants are minors of the transpose of the matrix $(B)_{ij} = \binom{i}{j}$, $i, j = 0, \cdots, N$, and all minors of B are known to be greater than or equal to 0 [15, p. 50]. Suppose now that the determinant of (3.8) is 0. Then the n rows of the matrix (3.8) must be linearly dependent and thus there exist constants $c_0, c_1, \cdots, c_{n-1}$, not all 0, so that

$$c_0 + c_1 x + c_2 \frac{(x)(x-1)}{2!} + \cdots + c_{n-1} \frac{(x)(x-1)\cdots(x-(n-2))}{(n-1)!} \tag{3.9}$$

has n distinct roots, $i_1, i_2, \cdots, i_n$. But the polynomial in (3.9) has degree $n-1$, a contradiction. Thus the determinant of (3.8) is always positive. This completes (b) of Theorem 3.1.

4. Comments. In [16] Gilbert and Slepian looked at the operator $AF^{-1}BFA$ for Legendre polynomials with $\mathcal{A} = (-\sigma, \sigma)$, where $0 < \sigma < 1$. They sought a commuting differential operator. The results in this case were more complex and simplicity of spectrum did not follow. The general techniques they employed in studying this problem, however, form the basis of the argument in the proof of Theorem 3.1(a). We further note that this argument applies quite generally to show that $AF^{-1}BFA$ has simple spectrum away from 0 (regardless of whether or not the underlying polynomials are classical ones) as long as $\mathcal{A} = (\sigma, \varepsilon)$.

The fact that the matrix T is oscillating as noted in the proof of Theorem 3.1(d) means that much stronger results can be stated about the eigenvectors $\vec{c}^{(i)}$. See, for example, [8] and [15].

In the case of the standard Fourier transform discussed in [1], applications have arisen based on the oscillation properties of the eigenfunctions [17]. Some related applications for the polynomial cases will be discussed elsewhere.

REGULARITY THROUGH APPROXIMATION FOR SCALAR CONSERVATION LAWS*

BRADLEY J. LUCIER†

Abstract. In this paper it is shown that recent approximation results for scalar conservation laws in one space dimension imply that solutions of these equations with smooth, convex fluxes have more regularity than previously believed. Regularity is measured in spaces determined by quasinorms related to the solution's approximation properties in $L^1(\mathbf{R})$ by discontinuous, piecewise linear functions. Using a previous characterization of these approximation spaces in terms of Besov spaces, it is shown that there is a one-parameter family of Besov spaces that are invariant under the differential equation. An intriguing feature of this investigation is that regularity is measured quite naturally in smoothness classes that are not locally convex—they are similar to L^p spaces for $0 < p < 1$. Extensions to Hamilton-Jacobi equations are mentioned.

Key words. regularity, approximation, Besov spaces, conservation laws

1. Introduction.

It is well known that discontinuities may form in the solution $u(x,t)$ of the hyperbolic conservation law

$$\text{(C)} \qquad \begin{aligned} &u_t + f(u)_x = 0, \qquad x \in \mathbf{R}, \quad t > 0, \\ &u(x,0) = u_0(x), \qquad x \in \mathbf{R}, \end{aligned}$$

even if the flux f and the initial data u_0 are smooth. (In gas dynamics these discontinuities represent shocks.) Hence, classical solutions of (C) do not generally exist. Weak solutions of (C) are not unique, but both existence and uniqueness of weak solutions that satisfy an auxiliary "entropy" condition were shown by Vol'pert [22] and Kružkov [15]. The regularity of these weak solutions is the topic of this paper.

There have been two different approaches to studying the regularity of solutions of hyperbolic conservation laws of one or more independent variables. Both approaches are "structural" in that they describe properties of the solution without quantifying a norm, seminorm, or quasinorm that says, for example, that one function is twice as smooth as another. The first approach is to show that "generic" solutions of the scalar equation (C) with C^∞ initial data are piecewise C^∞. This approach has been followed, for example, by Schaeffer [21], Guckenheimer [13], and Dafermos [5], [6]. A typical result is that except for a set of first Baire category in the Schwartz class $\mathcal{S}$, initial data in $\mathcal{S}$ results in piecewise C^∞ solutions $u(x,t)$. (Various assumptions are made on the flux f, typically that it is convex or has isolated points of inflection.)

The second, more measure-theoretic, approach is to show that the set of singularities of a solution $u(x,t)$ is more restricted than those of an arbitrary function of bounded variation in $\mathbf{R} \times \mathbf{R}^+$. Consider the following definitions. If $u(x,t) \in \mathrm{BV}(\mathbf{R}^2)$, then it is known [11], [22] that for every point (x,t) outside of a set of one-dimensional Hausdorff measure zero (called the set of singular points), there exist numbers u^+ and

u^- and a direction $\nu \in \mathbb{R}^2$ such that

$$\lim_{r\to 0} \frac{1}{r^2} \iint_{\{(y,\tau)\cdot(\pm\nu)\geq 0\}\cap B((x,t),r)} |u(y,\tau) - u^{\pm}|\, dy\, d\tau = 0.$$

If $u^+ = u^-$, then (x,t) is a point of approximate continuity; if $u^+ \neq u^-$, then (x,t) is a point of approximate discontinuity (a jump point). Furthermore, the set of regular points consisting of the jump points is at most a countable union of rectifiable sets of dimension $n-1$. DiPerna [9], [10] showed for genuinely nonlinear systems of two equations that the singular set of any solution u constructed by the random choice method of Glimm [12] is in fact at most countable, and that at each regular point of u, u has true one-sided limits that satisfy the Rankine-Hugoniot conditions. Furthermore, the shock set of u has "nice" structure.

In a similar vein, Oleinik [18] has shown that if f is convex, then u is continuous except on the union of a countable set of Lipschitz continuous curves (shocks). Dafermos [6] and Liu [16] establish similar results.

Rather than considering structural properties of solutions, either of the solution values (e.g., smoothness) or solution singularities (e.g., shocks), I consider smoothness in certain approximation spaces that are closely related to Besov spaces. I show that if u_0 is in one of these approximation spaces, then $u(\cdot\,,t)$ is in the same space for all later time if f is convex and smooth enough. (Of course, the results in this paper also hold if f is concave.) These function spaces are not Banach spaces, and are not even locally convex topological vector spaces, but they are composed of functions that are, in some sense, smoother than arbitrary functions in BV, or even arbitrary piecewise C^∞ functions (see §6). In §2 I rationalize this approach by arguing that $\mathrm{BV}(\mathbb{R})$ is the wrong space in which to measure smoothness, precisely because it is a locally convex topological vector space. The convexity of the "unit ball" of $\mathrm{BV}(\mathbb{R})$ allows only coarse measurement of the smoothness of functions that are discontinuous.

In this paper I consider a function smooth if it can be approximated well in L^1 by possibly discontinuous, piecewise linear functions with free knots—the better the approximation, the better the smoothness. This notion is developed in §3, in which I recount certain results of DeVore and Popov [7], [8], based on work by Petrushev [19], [20], that characterize the approximation spaces used here.

In §4, results from [17] are used to show that solutions of (C) that are initially in $\mathrm{BV}(\mathbb{R})$ preserve whatever smoothness is obtained by the initial data in the sense given in §3. In particular, it is shown that there is a one-parameter family of Besov spaces that are invariant under the action of (C) provided the initial data is of bounded variation. In §5, I point out that this is indeed a new result, because $\mathrm{BV}(\mathbb{R})$ is not contained in the approximation spaces when the order of smoothness is greater than one.

In §6, I show that there is, in general, no smoothing by the solution operator of (C) in the approximation spaces considered here. This result follows from the partial reversibility in time of the equation (C). The question arises because it is known that if f is uniformly convex, then initial data in $L^1(\mathbb{R})$ generate solutions that have locally bounded variation for all positive time, so there is some smoothing action from $L^1(\mathbb{R})$ to $\mathrm{BV}(\mathbb{R})$.

These ideas also have applications to regularity of solutions of Hamilton-Jacobi equations based on approximation properties in L^∞; this will be explored in a later paper. However, in §7 I present one result that follows immediately from the results in §4.

2. Why nonconvex spaces are natural. I begin with a specific example. Let u_0 be the characteristic function of $[0,1]$ and let $f(u) = u$. Then the solution $u(\cdot, t)$ of (C) is the characteristic function of $[t, 1+t]$. Except for the two jumps at the points t and $1+t$, $u(\cdot, t)$ is a very smooth function of x for every t. If the space that one uses to measure regularity allows any jumps at all (which it must, because solutions of (C) can develop jumps even for smooth data when f is nonlinear), then $u(\cdot, t)$ must be a relatively smooth function in that space.

Consider the inclusion of the functions $u(\cdot, t)$ in $\mathrm{BV}(\mathbb{R})$, or in fact in any normed or seminormed space whose unit ball is convex, and define the smoothness of $u(\cdot, t)$ to be its norm in this space. The solution $u(\cdot, t)$, being a translation of u_0, must have the same smoothness as u_0. (Of course, I am assuming that the norm or seminorm is translation invariant.) This implies that any convex linear combination of $u(\cdot, t)$ (for $0 \le t \le 1$, say) will also have the same smoothness, because the unit ball of $\mathrm{BV}(\mathbb{R})$ is convex.

It is easily seen that convex linear combinations of $u(\cdot, t)$ can approximate arbitrarily well in $L^1([0,1])$ any monotone function that takes the values 0 at 0 and 1 at 1. But, as is shown in §5 in a particular technical sense, an arbitrary monotone function is very rough, in that one can say very little, a priori, about the size and distribution of discontinuities in the interval $[0,1]$, for example, except that the sum of the jumps is bounded.

Thus, the convex hull of the solutions $u(\cdot, t)$ of (C) for our chosen u_0 contains functions that are quite rough. It is shown in §4 that *these rough functions cannot arise as solutions to* (C) *if* u_0 *and* f *are smooth enough.* It is in this sense that one discards information when one concludes that the solution of (C) at any particular time t has exactly the same smoothness as all functions in the convex hull of $u(\cdot, t)$ for $t > 0$. I conclude that it is better to measure the smoothness of solutions of (C) in spaces whose "unit balls" are not convex.

3. Approximation spaces and Besov spaces. Smoothness will be defined by how well a function can be approximated by piecewise polynomials with free knots. This section summarizes results in [7] and [8], which are given as general references for this section.

Consider the approximation of functions in $L^p(I)$ for $0 < p < \infty$ and a finite interval $I \subset \mathbb{R}$. For any $f \in L^p(I)$ and any positive integers r and N, let

$$E_N^r(f, L^p(I)) = \inf \|f - \phi\|_{L^p(I)},$$

where the infimum is taken over all discontinuous, piecewise polynomial functions ϕ defined on I of degree less than r with $N-1$ free interior knots. In other words, for each function f and number N one picks the best set of knots to minimize $\|f - \phi\|_{L^p(I)}$.

For each positive number α choose an integer $r > \alpha$. For any $q \in (0, \infty]$, define $\mathcal{A}_q^\alpha(L^p(I))$ to be the set of functions for which

$$\|f\|_{\mathcal{A}_q^\alpha(L^p(I))} = \|f\|_{L^p(I)} + \left(\sum_{N=1}^{\infty} [N^\alpha E_N^r(f, L^p(I))]^q N^{-1} \right)^{1/q} < \infty.$$

(In this and all later cases, make the usual modification when $q = \infty$.) It can be shown that all values of r greater than α specify the same space. Note that α is the primary determinant of smoothness: If $\alpha_1 > \alpha_2$, then no matter the value of

q_1 and q_2, $\mathcal{A}_{q_1}^{\alpha_1}(L^p(I)) \subset \mathcal{A}_{q_2}^{\alpha_2}(L^p(I))$. However, if $\alpha_1 = \alpha_2 = \alpha$ and $q_1 > q_2$, then $\mathcal{A}_{q_1}^{\alpha}(L^p(I)) \supset \mathcal{A}_{q_2}^{\alpha}(L^p(I))$.

The spaces $\mathcal{A}_q^\alpha(L^p(I))$ are not as strange as they might seem. If one denotes by $\mathcal{A}_q^\alpha(L^p(I), \text{free})$ the spaces described above, and by $\mathcal{A}_q^\alpha(L^p(I), \text{uniform})$ the similar spaces defined by considering approximation using only uniform knot sequences, then the space $\mathcal{A}_q^\alpha(L^p(I), \text{uniform})$ is the Besov space $B_q^\alpha(L^p(I))$ given below (cf. [7]). Also, if α is not an integer and $1 \le p < \infty$, then $\mathcal{A}_p^\alpha(L^p(I), \text{uniform})$ is the Sobolev space $W^{\alpha,p}(I)$ (cf. [1, p. 223]). Thus, there is a strong connection between approximation spaces and more classical function spaces.

$\mathcal{A}_q^\alpha(L^p(I))$ can be characterized as the interpolation space of $L^p(I)$ and certain Besov spaces using the real method of interpolation. For $\alpha \in (0, \infty)$ and $q \in (0, \infty]$, define the Besov space $B_q^\alpha(L^p(I))$ as follows. Pick any integer $r > \alpha$; let $\Delta^r(f,h)(x)$ be the rth forward difference of f at x with interval h;[1] and let $I_h = \{x \in I \mid x + rh \in I\}$. Define

$$w_r(f,t)_{L^p(I)} = \sup_{|h|<t} \|\Delta^r(f,h)\|_{L^p(I_h)}.$$

The Besov space $B_q^\alpha(L^p(I))$ is defined to be the set of functions f for which

$$|f|_{B_q^\alpha(L^p(I))} \equiv \left(\int_0^\infty [t^{-\alpha} w_r(f,t)_{L^p(I)}]^q \, dt/t \right)^{1/q}$$

is finite. Set $\|f\|_{B_q^\alpha(L^p(I))} = \|f\|_{L^p(I)} + |f|_{B_q^\alpha(L^p(I))}$. I specifically require the case when p and q are less than one.

The real method of interpolation using K-functionals can be described as follows. For any two spaces X_0 and X_1 contained in some larger space X, define the following functional for all f in $X_0 + X_1$:

$$K(f,t,X_0,X_1) = \inf_{f=f_0+f_1} \{\|f_0\|_{X_0} + t\|f_1\|_{X_1}\},$$

where $f_0 \in X_0$ and $f_1 \in X_1$. The new space $X_{\theta,q} = (X_0, X_1)_{\theta,q}$ $(0 < \theta < 1$, $0 < q \le \infty)$ consists of functions f for which

$$\|f\|_{X_{\theta,q}} = \|f\|_{X_0+X_1} + \left(\int_0^\infty [t^{-\theta} K(f,t,X_0,X_1)]^q \, dt/t \right)^{1/q} < \infty,$$

where $\|f\|_{X_0+X_1} = K(f,1,X_0,X_1)$. Using results of Petrushev [19], [20], the following theorem is proved in [8].

THEOREM 3.1 (DeVore and Popov). *When $0 < p < \infty$, $0 < q \le \infty$, and $0 < \alpha < \beta$, define $\sigma = 1/(\beta + 1/p)$. Then*

$$\mathcal{A}_q^\alpha(L^p(I)) = (L^p(I), B_\sigma^\beta(L^\sigma(I)))_{\alpha/\beta,q},$$

and if $q = 1/(\alpha + 1/p)$,

$$\mathcal{A}_q^\alpha(L^p(I)) = B_q^\alpha(L^q(I)).$$

Thus, there is a two-parameter family of spaces $\mathcal{A}_q^\alpha(L^p(I))$ that are Besov spaces, albeit with q possibly less than 1.

[1] Set $\Delta^0(f,h)(x) = f(x)$ and $\Delta^r(f,h)(x) = \Delta^{r-1}(f,h)(x+h) - \Delta^{r-1}(f,h)(x)$.

Although there is not now an exact characterization of all the spaces $\mathcal{A}_q^\alpha(L^p(I))$ in terms of Besov or other spaces, the above theorem allows one to make rather precise statements about inclusions of these spaces in Besov spaces. For example, if $0 < q < 1/(\alpha + 1/p)$, $\beta > \alpha$, $\tilde{\beta} = 1/(\beta + 1/p)$, and $\tilde{\alpha} = 1/(\alpha + 1/p)$, then

$$B_{\tilde{\beta}}^{\beta}(L^{\tilde{\beta}}(I)) = \mathcal{A}_{\tilde{\beta}}^{\beta}(L^p(I)) \subset \mathcal{A}_q^\alpha(L^p(I)) \subset \mathcal{A}_{\tilde{\alpha}}^{\alpha}(L^p(I)) = B_{\tilde{\alpha}}^{\alpha}(L^{\tilde{\alpha}}(I)).$$

There is an atomic decomposition for functions in $B_q^\alpha(L^p(I))$; see [7] for details.

4. Regularity for scalar conservation laws. I modify several results in [17] to prove Theorem 4.2, which is the major result of this paper. The definitions from §3 will be used, assuming always now that $L^p = L^1$. First, I prove the following lemma.

LEMMA 4.1. *There is a constant C_1 such that for all u_0 in $\mathrm{BV}(\mathbb{R})$ with support in $[0,1]$ and for any N, the best $L^1([0,1])$, discontinuous, piecewise linear approximation with $N-1$ free interior knots v_0 to u_0 satisfies $|v_0|_{\mathrm{BV}(\mathbb{R})} \le C_1 |u_0|_{\mathrm{BV}(\mathbb{R})}$.*

Proof. Let $\{\tau_i\}_{i=0}^N$, with $\tau_0 = 0$ and $\tau_N = 1$, be the ordered set of knots of v_0. Consider now only one interval $I_i = (\tau_i, \tau_{i+1})$; let $\Delta\tau = \tau_{i+1} - \tau_i$, and let $\overline{u} = \sup_{x \in I_i} u_0(x)$, $\underline{u} = \inf_{x \in I_i} u_0(x)$, and $\Delta u = \overline{u} - \underline{u}$. Let s be the slope of v_0 in I_i.

If $|s|\Delta\tau > \Delta u$, then it is easily calculated that the $L^1(I_i)$ difference between u_0 and v_0 is at least

$$\frac{|s|}{4}\left(\Delta\tau - \frac{\Delta u}{s}\right)^2,$$

which is simply the area of the set of points that are greater than $\overline{u}$ but less than v_0 plus those points that are less than $\underline{u}$ but greater than v_0. If $|s| > 2(1+\sqrt{3})\Delta u/\Delta\tau$, then this error is greater than the error of the constant approximation $v_0 \equiv (\overline{u} + \underline{u})/2 = \tilde{u}$, so one must conclude that $|s| \le 2(1+\sqrt{3})\Delta u/\Delta\tau$. Thus

$$\begin{aligned}\mathrm{Var}_{I_i} v_0 &= |s|\Delta\tau \\ &\le 2(1+\sqrt{3})\Delta u \\ &\le 2(1+\sqrt{3})\mathrm{Var}_{I_i} u_0.\end{aligned}$$

So $\sum_i \mathrm{Var}_{I_i} v_0 \le 2(1+\sqrt{3})|u_0|_{\mathrm{BV}(\mathbb{R})}$.

Consider now the jump $|v_0(\tau_i^+) - v_0(\tau_i^-)|$. Subscript the quantities s, $\overline{u}$, $\underline{u}$, $\tilde{u}$, $\Delta\tau$, and Δu to indicate the interval I_i to which they pertain. Without loss of generality, assume that $s_{i-1} > 0$ and $s_i > 0$. Then $v_0(\tau_i^-) \le \tilde{u}_{i-1} + (1+\sqrt{3})\Delta u_{i-1}$ and $v_0(\tau_i^+) \ge \tilde{u}_i - (1+\sqrt{3})\Delta u_i$. So

$$\begin{aligned}|v_0(\tau_i^+) - v_0(\tau_i^-)| &\le |\tilde{u}_{i-1} - \tilde{u}_i| + (1+\sqrt{3})(|\Delta u_i| + |\Delta u_i|) \\ &\le \mathrm{Var}_{I_{i-1}\cup I_i} u_0 + (1+\sqrt{3})\mathrm{Var}_{I_{i-1}\cup I_i} u_0 \\ &\le (2+\sqrt{3})\mathrm{Var}_{I_{i-1}\cup I_i} u_0.\end{aligned}$$

So, $\sum_i |v_0(\tau_i^+) - v_0(\tau_i^-)| \le (4+2\sqrt{3})|u_0|_{\mathrm{BV}(\mathbb{R})}$. Adding these two constants will give the required value of C_1. □

The previous argument can be extended to show that the ranges of u_0 and all best piecewise linear approximations v_0 are uniformly bounded and contained in some interval, here denoted by Ω.

THEOREM 4.1 (Approximation). *Let $u_0 \in \mathrm{BV}(\mathbb{R})$ have support in the interval $I = [0,1]$. Assume that $f'' \geq 0$ and that f' and f''' are bounded on Ω. Then $u(\cdot,t)$ has support in $I_t = [\inf_{\xi\in\Omega} f'(\xi)t, 1 + \sup_{\xi\in\Omega} f'(\xi)t]$, $|u(\cdot,t)|_{\mathrm{BV}(\mathbb{R})} \leq |u_0|_{\mathrm{BV}(\mathbb{R})}$, and for any $N \geq 1$,*

$$E^2_{F(N)}(u(\cdot,t), L^1(I_t)) \leq E^2_N(u_0, L^1(I)) + \frac{t}{4N^2}|u_0|_{\mathrm{BV}(\mathbb{R})}\|f'''\|_{L^\infty}, \tag{4.1}$$

where $F(N) = \lfloor (C_1|u_0|_{\mathrm{BV}(\mathbb{R})} + 4)N + 4 \rfloor$ and C_1 is given in Lemma 4.1.

Proof. I will not discuss the first two conclusions of the theorem, which are classical. The proof of the third part models very closely the proofs of Theorems 3 and 4 in [17]. However, for the sake of completeness, I will recall the major parts of that paper.

Let v_0 be the best $L^1(I)$, discontinuous, piecewise linear approximation with $N-1$ free knots to u_0. Then, as shown in Lemma 4.1, $|v_0|_{\mathrm{BV}(\mathbb{R})} \leq C_1|u_0|_{\mathrm{BV}(\mathbb{R})}$. Consider the C^1, piecewise quadratic function g with knots at the points j/N, $j \in \mathbb{Z}$, that is defined by: $g'(j/N) = f'(j/N)$ and $g(0) = f(0)$. In [17] I constructed an explicit solution to the perturbed problem

$$\text{(P)} \qquad \begin{aligned} &v_t + g(v)_x = 0, && x \in \mathbb{R}, \quad t > 0, \\ &v(x,0) = v_0(x), && x \in \mathbb{R}, \end{aligned}$$

provided that one augments the knots of v_0 by putting a new knot at each isolated point x for which $v_0(x) = j/N$ for some j. (If v_0 is discontinuous at x, and there are k values of j such that $\min(v_0(x^-), v_0(x^+)) < j/N < \max(v_0(x^-), v_0(x^+))$, then add k knots at the point x.) Although these knots are not needed for the definition of v_0, the solution $v(\cdot,t)$ of (P) may develop discontinuities in its first derivative ("kinks") at these new knots for positive times.

The new knots number no more than $(2 + |v_0|_{\mathrm{BV}(\mathbb{R})})N + 1$, by the following argument. Let the original knots of v_0 be $\tau_0 = 0 < \tau_1 < \cdots < \tau_N = 1$, let $\sigma_{2i} = \sigma_{2i+1} = \tau_i$ for $i = 0, \ldots, N$, and consider the B-spline basis for v_0 with the knots $\{\sigma_i\}$. (See de Boor [2, Chap. 9] for this construction.) For each i, let k_i denote the number of original intervals (σ_j, σ_{j+1}) that had i new knots added. The value of $\sum_i ik_i$ is to be bounded. Now, $\sum_i k_i = 2N + 1$. But if i points are added in an original interval (σ_j, σ_{j+1}), the variation of v_0 in that interval must be at least $(i-1)/N$, so $\sum_i (i-1)k_i/N \leq |v_0|_{\mathrm{BV}(\mathbb{R})}$, or $\sum_i (i-1)k_i \leq N|v_0|_{\mathrm{BV}(\mathbb{R})}$. Adding these two known inequalities shows that $\sum_i ik_i \leq (2 + |v_0|_{\mathrm{BV}(\mathbb{R})})N + 1$, as claimed. Thus, the total number of knots in v_0 (counting the points σ_i and the new points, all of which may travel along different characteristics for t positive) is bounded by $(4 + C_1|u_0|_{\mathrm{BV}(\mathbb{R})})N + 3$.

It is shown in [17] that $v(\cdot,t)$ is piecewise linear for all time and that the number of knots decreases monotonically, because f'' is nonnegative. Theorem 3 of [17] shows that

$$\|u(\cdot,t) - v(\cdot,t)\|_{L^1(\mathbb{R})} \leq \|u_0 - v_0\|_{L^1(\mathbb{R})} + t\|f' - g'\|_{L^\infty}|u_0|_{\mathrm{BV}(\mathbb{R})}.$$

Because of the way g is constructed, $\|f' - g'\|_{L^\infty} \leq \|f'''\|_{L^\infty}/(4N^2)$, so (4.1) follows immediately. □

The proof can be easily modified to cover the case where $f \in C^1$ and is piecewise C^3 on intervals I_j with $\inf |I_j|$ positive.

Theorem 4.1 can be used to prove the following main result of this paper.

THEOREM 4.2 (Regularity). *Assume that there is an* $\alpha \in (0,2)$ *and a* $q \in (0,\infty]$ *such that* u_0 *has support in* $[0,1]$ *and* $u_0 \in \mathrm{BV}(\mathbb{R}) \cap \mathcal{A}_q^\alpha(L^1([0,1]))$. *Assume that* $f'' \geq 0$ *and that* f' *and* f''' *are bounded on* Ω. *Then* $u(\cdot,t)$ *has support in* $I_t = [\inf_{\xi\in\Omega} f'(\xi)t, 1 + \sup_{\xi\in\Omega} f'(\xi)t]$ *and* $u(\cdot,t) \in \mathrm{BV}(\mathbb{R}) \cap \mathcal{A}_q^\alpha(L^1(I_t))$.

Proof. Inequality (4.1) shows that the error in approximation (by piecewise linear functions) of $u(\cdot,t)$ is no more than the error in approximation of u_0 plus something of $O(N^{-2})$, and that the number of knots remains $O(N)$ for all later times. This is sufficient to show that $u(\cdot,t) \in \mathcal{A}_q^\alpha(L^1(I_t))$ if $\alpha < 2$. □

By combining Theorem 4.2 and the characterization of the spaces $\mathcal{A}_q^\alpha(L^1(I_t))$ in terms of Besov spaces, the following corollary is obtained.

COROLLARY 4.1. *Let* $0 < \alpha < 2$, *and set* $q = 1/(\alpha+1)$. *If* u_0 *has support in* $I = [0,1]$ *and* $u_0 \in \mathrm{BV}(\mathbb{R}) \cap B_q^\alpha(L^q(I))$, $f'' \geq 0$ *and* f' *and* f''' *are bounded on* Ω, *then* $u(\cdot,t)$ *has support in* $I_t = [\inf_{\xi\in\Omega} f'(\xi)t, 1 + \sup_{\xi\in\Omega} f'(\xi)t]$ *and* $u(\cdot,t) \in \mathrm{BV}(\mathbb{R}) \cap B_q^\alpha(L^q(I_t))$.

Thus, there is a one-parameter family of Besov spaces that are invariant under the action of the semigroup S_t that takes u_0 to $u(\cdot,t)$.

Theorem 4.2 and Corollary 4.1 are of interest only when α is greater than one, because any function in $\mathrm{BV}([0,1])$ can be approximated to within $O(N^{-1})$ in $L^1([0,1])$ by piecewise constant functions with $N-1$ uniformly spaced knots, so $\mathrm{BV}([0,1]) \subset \mathcal{A}_q^\alpha(L^1([0,1]))$ when $0 < \alpha < 1$, or when $\alpha = 1$ and $q = \infty$.

5. Approximation spaces and BV. In this section I give examples of the known fact that $\mathcal{A} \equiv \mathcal{A}_q^\alpha(L^1([0,1])) \not\subseteq \mathrm{BV}([0,1])$ and, if α is greater than one, $\mathrm{BV}([0,1]) \not\subseteq \mathcal{A}$.

First, I present an increasing function ϕ in $\mathrm{BV}([0,1])$ but not in $\mathcal{A}$ for any α greater than one. The function ϕ will take the value 0 to the left of 0 and will take the value $\pi^2/6$ to the right of 1. Its definition is as follows.

The jumps of ϕ will be at the points $p/2^k$ for p an odd integer between 1 and $2^k - 1$ with k a positive integer. For each k, the size of the jump at the point $p/2^k$ will be $1/(k^2 2^{k-1})$. Between the jumps, ϕ will be constant, so that if one arbitrarily defines ϕ to be right continuous, ϕ is given by the formula

$$\phi(x) = \sum_{\substack{p/2^k < x \\ k>0,\ 0<p<2^k,\ p \text{ odd}}} \frac{1}{k^2 2^{k-1}}.$$

Because for each k there are 2^{k-1} odd integers p between 0 and 2^k, $\phi(1)$, which is the sum of the jumps, is indeed $\pi^2/6$. Figure 1 is a graph of $\phi(x)/\phi(1)$.

Now consider the approximation of this function ϕ by possibly discontinuous linear functions with $2^M - 1$ interior knots for some positive M. Because ϕ behaves in exactly the same way on each interval $(j/2^M, (j+1)/2^M)$, it can be shown that the optimal placement of knots will be at the points $j/2^M$ for $0 < j < 2^M$. Because there is a jump of height $1/((M+1)^2 2^M)$ in the center of each interval $(j/2^M, (j+1)/2^M)$ and the width of the interval is $1/2^M$, the best linear approximation on this interval will have error greater than $C/((M+1)^2 2^{2M})$. Summing these errors over the 2^M intervals gives a global error of greater than $C/((M+1)^2 2^M)$, or, if one sets $N = 2^M$, $C/(\log^2(N)N)$. This quantity is asymptotically greater than C/N^α for any α greater than one, so ϕ is not in $\mathcal{A}$. Thus, one can conclude that if the conditions of Theorem

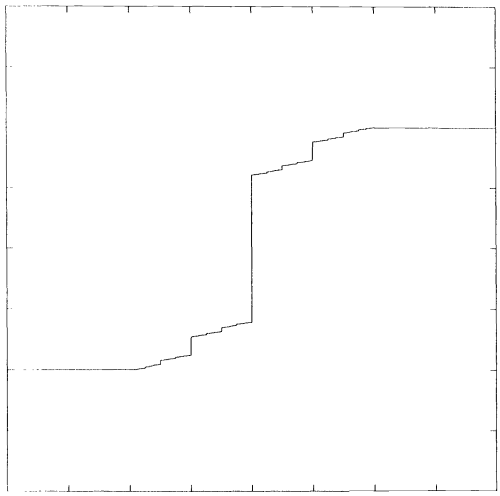

FIG. 1. *A function in* $\mathrm{BV}([0,1])$ *but not in* $\mathcal{A}_q^\alpha(L^1([0,1]))$ *for any* $\alpha > 1$.

4.2 hold with $\alpha > 1$, then this function ϕ cannot be the solution $u(\cdot, t)$ of (C) for any positive time t.

It is perhaps simpler to construct a function ϕ in $\mathcal{A}$ that is not of bounded variation. For x between 0 and 1, define

$$\phi(x) = \begin{cases} 0 & \text{for } 2^{-N} \le x < 1.5 \cdot 2^{-N},\ N > 0, \\ 1 & \text{for } 1.5 \cdot 2^{-N} \le x < 2^{-N+1},\ N > 0, \end{cases}$$

with $\phi(x) = 0$ for other values of x. (See Fig. 2.) It is clear that $\phi(x)$ can be approximated exactly by a piecewise *constant* function ψ with $2N$ knots for $2^{-N} < x < 1$. By setting $\psi(x) = 0$ for x greater than 0 and less than 2^{-N}, one obtains a global error in $L^1(\mathbb{R})$ of less than 2^{-N} with $O(N)$ knots. In other words, this ϕ can be approximated exponentially well by piecewise constant functions, and hence is in $\mathcal{A}$ for any values of α and q, yet ϕ is not of bounded variation.

Thus, the class $\mathcal{A}$ says little about the size of the jumps by themselves, but more about the combination of the size and *distribution* of the jumps in the functions. The example of a function of bounded variation but not in $\mathcal{A}$ had its jumps distributed uniformly in the interval $[0,1]$, thereby inhibiting good approximation by piecewise linear functions. In contrast, the example of a function in $\mathcal{A}$ but not of bounded variation had its jumps concentrated in a very small region. One may conclude intuitively that solutions of (C) that satisfy the hypotheses of Theorem 4.2 may be rough, but they are rough only in very small regions. This intuition is quantified in the atomic decomposition formula given in [7] for functions in Besov spaces.

6. Lack of smoothing. There is, in general, no smoothing in the spaces $\mathcal{A}_q^\alpha(L^1(I_t))$ for solutions of (C) as t progresses, even if the flux f is uniformly convex. This follows because of the partial reversibility of (C), as described below.

Define initial data u_0 as follows: Let $u_0(x)$ be zero for x less than 0 and greater than R, and constant between 1 and R, where R is a large parameter to be chosen

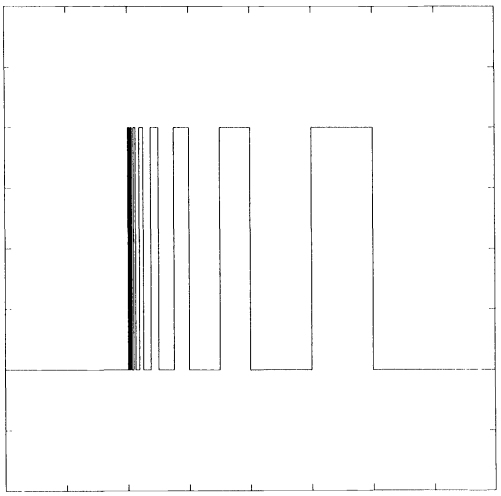

FIG. 2. *A function in* $\mathcal{A}_q^\alpha(L^1([0,1]))$ *for all* $\alpha > 1$ *but not in* $\mathrm{BV}([0,1])$.

later. Between 0 and 1 define $u_0(x)$ by

$$u_0(x) = \sum_{\substack{p/2^k < x \\ k>0,\ 0<p<2^k,\ p \text{ odd}}} \frac{1}{k^r 2^{\beta k}}, \qquad r > 0, \quad \beta > 1.$$

Then it can be shown that u_0 is in any space $\mathcal{A}_q^\alpha(L^1([0,1]))$ containing $\mathcal{A}_{1/r}^\beta(L^1([0,1]))$. Therefore, $u(\cdot,t) \in \mathcal{A}_q^\alpha(L^1([0,R]))$ for the same values of α and q.

Consider the solution $u(\cdot,t)$ of (C) for t between 0 and T for some T when $f(u) = u^2$. The increasing part of u_0 between 0 and 1 spreads out into a series of expansion waves, and there is a shock emanating from the point $(R,0)$ in (x,t) space. For a fixed T, if R is big enough then these waves will not interact. Consider now the solution of

$$\begin{aligned} v_t + g(v)_x &= 0, \qquad x \in \mathbb{R}, \quad t > 0, \\ v(x,0) &= u(x,T), \qquad x \in \mathbb{R}, \end{aligned}$$

with $g(u) = -u^2$. It is easily seen that $v(x,T) = u_0(x)$ for x between 0 and 1, while the rest of $v(x,T)$ consists of constant states and a linear function representing a rarefaction wave. It follows that $v(x,0) = u(x,T)$ cannot have more smoothness than u_0 in the sense of these approximation spaces.

It is interesting to note that $u(\cdot,t)$ is piecewise C^∞ for all positive t and is in the Sobolev space $W^{1,\infty}([0,R])$, yet it is not in the spaces $\mathcal{A}_q^\alpha([0,R])$ if α is large enough.

7. Hamilton-Jacobi equations. A special Hamilton-Jacobi equation in one space dimension is given by

$$\text{(H-J)} \qquad \begin{aligned} w_t + f(w_x) &= 0, \qquad x \in \mathbb{R}, \quad t > 0, \\ w(x,0) &= w_0(x), \qquad x \in \mathbb{R}. \end{aligned}$$

Problems of existence and uniqueness of solutions of (H-J) were solved in papers by M. G. Crandall and P. L. Lions [3], [4], in which they showed that the notion of "viscosity

solution" of (H-J) led to well-posedness. Certain "structural" regularity results are known for solutions of (H-J); see, for example, [14].

The problem (C) can be derived formally from (H-J) by setting $u = w_x$ and differentiating (H-J) with respect to x. This association is more than formal, however, because Crandall and Lions showed that the viscosity solution of (H-J) is the limit as ϵ tends to zero of the solution of (H-J) with the right-hand side replaced by ϵw_{xx} (hence the name "viscosity solution"). The entropy solution of (C) is also the limit as ϵ tends to zero of the equation with the right-hand side replaced with ϵu_{xx} (see, e.g., [15]), so if w_0' is in L^1, then the formal calculations are in fact valid. Thus one can immediately derive the following theorem from the results in §4.

THEOREM 7.1. *Let w_0 have support in $[0,1]$, and assume that there is an $\alpha \in (0,2)$ and a $q \in (0,\infty]$ such that $w_0' \in \mathrm{BV}(\mathbb{R}) \cap \mathcal{A}_q^\alpha(L^1([0,1]))$. Assume also that $f'' \geq 0$, $f(0) = 0$, and that f' and f''' are bounded on Ω (see the comment following Lemma 4.1). Then $w(\cdot,t)$ has support in $I_t = [\inf_{\xi\in\Omega} f'(\xi)t, 1 + \sup_{\xi\in\Omega} f'(\xi)t]$ and $w_x(\cdot,t) \in \mathrm{BV}(\mathbb{R}) \cap \mathcal{A}_q^\alpha(L^1(I_t))$. In particular, when $q = 1/(\alpha+1)$ and $w_0' \in \mathrm{BV}(\mathbb{R}) \cap B_q^\alpha(L^q(I))$, then $w_x(\cdot,t) \in \mathrm{BV}(\mathbb{R}) \cap B_q^\alpha(L^q(I_t))$.*

INVARIANT REGIONS AND GLOBAL ASYMPTOTIC STABILITY IN AN ISOTHERMAL CATALYST*

JOSÉ M. VEGA†

Abstract. A well-known model for the evolution of the (space-dependent) concentration and (lumped) temperature in a porous catalyst is considered. A sequence of invariant regions of the phase space is given, which converges to a globally asymptotically stable region B. Quantitative sufficient conditions are obtained for (the region B to consist of only one point and) the problem to have a (unique) globally asymptotically stable steady state.

Key words. global stability, invariant regions, porous catalysts, isothermal catalysts

AMS(MOS) subject classifications. 35B35, 35B40, 35K57, 80A32

1. Introduction. This paper is concerned with a well-known model (Aris [1]) for the evolution of a single reactant concentration u and of the uniform temperature v in an isothermal catalyst

$$\partial u/\partial t = \Delta u - \phi^2 f(u, v) \quad \text{in } \Omega, \qquad \partial u/\partial n = \sigma(1-u) \qquad \text{on } \partial\Omega, \tag{1.1}$$

$$dv/dt = \lambda\mu(1-v) + \lambda\phi^2 \int_\Omega f(u, v)\, dx. \tag{1.2}$$

Here, Δ is the Laplacian operator and n is the outward unit normal to the boundary of the bounded domain $\Omega \subset \mathbf{R}^p$ ($p = 1, 2,$ or 3). The parameters ϕ^2, σ, λ, and μ are strictly positive.

As it has been frequently pointed out in the literature ([1] and references given therein), the isothermal model (1.1), (1.2) is not unrealistic because temperature is often lumped in practice, due to the high conductivity of the solid catalyst. In fact, such a model is a first approximation, as $\beta \to 0$ and $\nu \to 0$, of the nonisothermal model, in which temperature is spatially distributed, and given by

$$L^{-1}\partial v/\partial t = \Delta v + \beta\phi^2 f(u, v) \quad \text{in } \Omega, \qquad \partial v/\partial n = \nu(1-v) \quad \text{on } \partial\Omega. \tag{1.3}$$

In this limit, the parameters λ and μ of (1.2) are $\lambda = \beta L/V_\Omega$ and $\mu = \nu/S_\Omega\beta$, where V_Ω and S_Ω are the volume and the external area of the domain Ω (see [2]).

The following basic assumptions will be made:

(**H.1**) The domain $\Omega \subset \mathbf{R}^p$ is bounded and (if $p > 1$) it is uniformly of class $C^{2+\alpha}$, for some $0 < \alpha < 1$. Then, it satisfies uniformly *the interior and exterior sphere properties*: there are two constants, $\rho_1 > 0$ and $\rho_2 > 0$, such that, for every point q of $\partial\Omega$, two hyperspheres, S_1 and S_2, of radius ρ_1 and ρ_2, are tangent to $\partial\Omega$ at q and satisfy: $S_1 \subset \Omega$, $\bar{S}_2 \cap \bar{\Omega} = \{q\}$.

(**H.2**) The function $f : [0, \infty[\times [0, \infty[\to \mathbf{R}$ is of class C^1 and there is a continuous function $F : [0, \infty[\to \mathbf{R}$ such that: (i) $f(0, v) = 0$ for all $v \in [0, \infty[$; (ii) $0 < f(u, v) \leqq F(u)$, $|f_u(u, v)| \leqq F(u)$, $0 < f_v(u, v)$ for all $(u, v) \in]0, \infty[\times]0, \infty[$.

Assumption (H.1) is made for some existence and comparison theorems to be applicable. Assumption (H.2) is satisfied by

$$f_1(u, v) = u^m \exp(\gamma - \gamma/v), \quad m \geqq 1, \quad \gamma \geqq 0, \tag{1.4}$$

$$f_2(u, v) = u^m (k+u)^{-r} \exp(\gamma - \gamma/v), \quad m \geqq 1, \quad \gamma \geqq 0, \quad k > 0, \tag{1.5}$$

$$f_3(u, v) = u^m [k \exp(\gamma_a - \gamma_a/v) + u]^{-r} \exp(\gamma - \gamma/v), \tag{1.6}$$

$$m \geqq 1, \quad \gamma \geqq r\gamma_a \geqq 0, \quad k > 0.$$

The Arrhenius reaction rate function f_1 is most frequently used to model thermal effects on the reaction rate (see [1]). The Langmuir-Hinshelwood functions f_2 and f_3 have received a considerable attention in the literature. Function f_2 was first proposed to model carbon monoxide oxidation over platinum catalysts, which is the main reaction in automotive pollution-abatement devices. Further experimental evidence showed that several hydrocarbons, such as ethylene and propylene, follow similar rate laws when oxidized over noble metal catalysts (see [3]).

In this paper, some global asymptotic stability properties of the steady state of (1.1), (1.2) will be obtained. Of course, results in the literature for model (1.1), (1.3) (see [4]–[6]) apply to (1.1), (1.2) after small changes; unfortunately they are rather mild: the steady state of (1.1), (1.3) is globally asymptotically stable (and hence, it is unique) if the parameter ϕ^2 is small enough. A slightly stronger result was proven in [5], but it requires the function f to satisfy $f(u, 0) > 0$ for $u > 0$, and this property does not hold if f is given by (1.4)–(1.6). The results of [4] were obtained by means of a generalized Gronwall inequality. The results of [5], [6] were established by constructing sub- and supersolutions converging to the steady state; the same idea has been used also in the analysis of related reaction-diffusion problems (see, e.g., [7]–[10]).

Our approach is somewhat different, although it is also based on comparison theorems. We shall construct a sequence $\{B_m\}$ of invariant, stable regions of the phase space of (1.1), (1.2), such that every region B_m traps the transient state of the system in a finite time for arbitrary initial conditions. If the sequence $\{B_m\}$ converges to a region of the phase space B in an appropriate uniform sense, then such region is globally asymptotically stable for (1.1), (1.2). Therefore, B contains the nonwandering set of (1.1), (1.2) (i.e., the set of points (u, v) of the phase space of (1.1), (1.2) such that, for every neighborhood of (u, v), $U \subset C(\bar{\Omega}) \times \mathbf{R}$, and every $T > 0$, there are a constant $t > T$ and a point $(u_0, v_0) \in U$ that are such that the solution of (1.1), (1.2), with initial conditions $(u(0), v(0)) = (u_0, v_0)$, satisfies $(u(t), v(t)) \in U$ (see Hirsch [11])). In particular, B contains every (stable or unstable) steady state, periodic, or quasiperiodic solution, $\cdots$, of (1.1), (1.2). If B consists of only one point, then such point is a globally asymptotically stable (and hence, a unique) steady state of (1.1), (1.2). This method of finding globally asymptotically stable invariant regions for nonmonotone flows is similar to that used by Leung [12] in his study of some prey-predator problems; in some sense, the ideas are in the spirit of the work by Keller [13] and Sattinger [14] on semilinear elliptic problems.

In § 2 we shall prove some basic results and state some definitions. In § 3, a sequence of invariant regions of the phase space of (1.1), (1.2), of the type described above, will be obtained. The results of § 3 will be applied in § 4, to obtain some quantitative sufficient conditions for the steady state of (1.1), (1.2) to be globally asymptotically stable for a function f of a rather general type: $f(u, v) = g(u) \exp(\gamma - \gamma/v)$, which includes the particular instances of (1.4) and (1.5). In particular, we shall obtain global asymptotic stability of the steady state if ϕ^2 is

sufficiently small or large, or if the function g is increasing and γ is sufficiently small. As a corollary, some sufficient conditions for the steady state of (1.1), (1.2) to be unique will be obtained. For results on existence and uniqueness of the steady state of (1.1), (1.3), see [4], [6], [15], [16]. It should be pointed out that to prove uniqueness for large ϕ^2 is not an easy task (see [16]).

The following notation will be widely used in the sequel. If Ω is defined as above, and if $u_1, u_2 \in C(\bar{\Omega})$, then $u_1 \leqq u_2$ will mean that $u_1(x) \leqq u_2(x)$ for all $x \in \bar{\Omega}$, and $u_1 < u_2$ will mean that $u_1 \leqq u_2$ and $u_1 \neq u_2$. If $u_1(x) < u_2(x)$ for all $x \in \bar{\Omega}$, then we shall write $u_1 \ll u_2$.

2. Preliminary results and definitions. Let us first consider some basic results concerning the evolution problem (1.1), (1.2), with initial conditions

$$u(x, 0) = \tilde{u}(x) \geqslant 0 \quad \text{for all } x \in \bar{\Omega}, \quad v(0) = \tilde{v} \geqq 0, \tag{2.1}$$

where $\tilde{u} \in C^2(\bar{\Omega})$ and satisfies the boundary condition (1.1). By a (classical) *regular solution* of (1.1), (1.2), (2.1) we shall mean a couple of functions

$$u \in C^{1,0}(\bar{\Omega} \times [0, \infty[) \cap C^{2,1}(\bar{\Omega} \times]0, \infty[), \qquad v \in C^1([0, \infty[),$$

which satisfy (1.1), (1.2), (2.1) pointwise, and are such that $u(\cdot, t) \geqq 0$, $v(t) \geqq 0$ for all $t > 0$. Here, $u \in C^{1,0}$ means that the functions $(x, t) \to u$ and $(x, t) \to Du$ are continuous. $u \in C^{2,1}$ means that $u \in C^{1,0}$ and the functions $(x, t) \to D^2u$ and $(x, t) \to \partial u/\partial t$ are continuous, where Du and D^2u are the matrices of first- and second-order x-derivatives of u. Observe that negative concentrations and temperatures are not allowed since they do not make sense from the physical point of view.

The following consequence of maximum principles will be widely used in the sequel.

LEMMA 2.1. *Let Ω be as in assumption* (H.1), *and let W be a function of $C^{1,0}(\bar{\Omega} \times [0, \infty[) \cap C^{2,1}(\bar{\Omega} \times]0, \infty[)$, such that*

(a) $W(x, 0) \geqq 0$ *for all* $x \in \bar{\Omega}$.

(b) $\partial W/\partial t > \Delta W$ *for all* $(x, t) \in \Omega \times]0, \infty[$ *such that* $W(x, t) < 0$.

(c) $\partial W/\partial n > 0$ *for all* $(x, t) \in \partial\Omega \times]0, \infty[$ *such that* $W(x, t) < 0$.

Then $W(x, t) \geqq 0$ *for all* $(x, t) \in \bar{\Omega} \times [0, \infty[$.

Proof. The result follows by standard arguments, using maximum principles (Protter and Weinberger [17]).

Global existence and uniqueness of solution of (1.1), (1.2), (2.1) will be a consequence of the following a priori bound.

LEMMA 2.2. *Under assumptions* (H.1) *and* (H.2), *let $u = u(x, t)$, $v = v(t)$, be a regular solution of* (1.1), (1.2), (2.1). *Then, there is a constant $\alpha > 0$ and a function $\psi \in C^2(\bar{\Omega})$, such that*

$$u(x, t) \leqq 1 + \psi(x) \exp(-\alpha t) \quad \textit{for all } (x, t) \in \bar{\Omega} \times [0, \infty[.$$

Proof. As is well known, the problem

$$\Delta\psi + \alpha\psi = 0 \quad \text{in } \Omega, \qquad \partial\psi/\partial n + \sigma\psi = 0 \quad \text{on } \partial\Omega, \tag{2.2}$$

has a smallest eigenvalue $\alpha > 0$, and eigenfunctions ψ such that $\psi \gg 0$. Hence, ψ may be chosen to be such that $\psi \geqq 2(\tilde{u} - 1)$, $\psi \gg 0$ and the function $W = W(x, t) = 1 - u(x, t) + [2 \exp(-\alpha t) - \exp(-2\alpha t)]\psi(x)/2$ satisfies $W(\cdot, t) \geqq 0$ for all $t \geqq 0$, as it comes out when Lemma 2.1 is applied.

THEOREM 2.3. *Under assumptions* (H.1) *and* (H.2), *the problem* (1.1), (1.2), (2.1) *has a unique regular solution if* $\tilde{u} \in C^2(\bar{\Omega})$ *and* $\tilde{u}$ *satisfies the boundary condition.*

Proof. For given $\tilde{u}$ and $\tilde{v}$, let ψ be as in Lemma 2.2 and let $k = 1 + \max\{\psi(x): x \in \bar{\Omega}\}$. Then, no regular solution of (1.1), (1.2), (2.1) is affected when f is replaced, in (1.1), (1.2), by another function, $\tilde{f}: \mathbf{R}^2 \to \mathbf{R}$, that is defined by: $\tilde{f}(u, v) = 0$ for $u < 0$, $\tilde{f}(u, v) = f(u, |v|)$ for $0 \leqq u \leqq k$, $\tilde{f}(u, v) = f(k, |v|)$ for $u > k$. Any solution of (1.1), (1.2), (2.1), with f modified as above, is a regular solution of the original problem (the converse is trivially satisfied). That is, if $u \in C^{1,0}(\bar{\Omega} \times [0, \infty[) \cap C^{2,1}(\bar{\Omega},]0, \infty[)$, $v \in C^1([0, \infty[)$ is a solution of the modified problem, then $u(\cdot, t) \geqq 0$ and $v(t) \geqq 0$ for all $t > 0$. Since $\tilde{f}(u, v) \geqq 0$ for all $(u, v) \in \mathbf{R}^2$, (1.2) yields $dv/dt \geqq \lambda\mu(1 - v)$ and $v(t) \geqq 0$ for all $t > 0$; also, $u(\cdot, t) \geqq 0$ for all $t > 0$, as it comes out when Lemma 2.1 is applied to $W = u \exp(-t)$, and it is taken into account that $\tilde{f}(u, v) = 0$ for $u < 0$. Then, we only need to prove the conclusion of the theorem when f is replaced by $\tilde{f}$, and this comes out from standard theory on semilinear equations (e.g., from [18, Cor. 3.3.5] and [19, Lemma 4.2]), when taking into account that $\tilde{f}$ is locally Lipschitz and globally bounded.

The following $\varepsilon - \delta$ stability definitions of the Lyapunov type will be used in the sequel. They are given in terms of the distance d, associated with the norm

$$\|(u, v)\| = \max\{|u(x)|: x \in \bar{\Omega}\} + |v| \quad \text{for } (u, v) \in C(\bar{\Omega}) \times \mathbf{R}.$$

The distance between $(u, v) \in C(\bar{\Omega}) \times \mathbf{R}$ and $B \subset C(\bar{\Omega}) \times \mathbf{R}$ is defined as usually $d[(u, v), B] = \inf\{\|(u - u', v - v')\|: (u', v') \in B\}$. Observe that $C(\bar{\Omega}) \times \mathbf{R}$ includes the phase space of (1.1), (1.2), (2.1).

DEFINITION 2.4. Let $B \subset C(\bar{\Omega}) \times \mathbf{R}$. B is said to be an *invariant region* for the problem (1.1), (1.2), (2.1) if, for any regular solution of the problem, $(u(\cdot, 0), v(0)) \in B$ implies $(u(\cdot, t), v(t)) \in B$ for all $t > 0$. An invariant region B is said to be *stable* if, for every $\varepsilon > 0$, there is a $\delta > 0$ such that for every regular solution of the problem $d[(u(\cdot, 0), v(0)), B] < \delta$ implies $d[(u(\cdot, t), v(t)), B] < \varepsilon$ for all $t > 0$. A region B is said to be *globally asymptotically attracting* if every regular solution of the problem satisfies $d[(u(\cdot, t), v(t)), B] \to 0$ as $t \to \infty$. An invariant region B is said to be *globally asymptotically stable* if it is stable and globally asymptotically attracting. A region B is said to be *globally finitely attracting* if, for every regular solution of the problem, there is a constant $T < \infty$ such that $(u(\cdot, t), v(t)) \in B$ for all $t \geqq T$.

The concept of globally finitely attracting region and the following lemma will be used in § 3.

LEMMA 2.5. *Let the sequence of regions* $\{B_m\}$ *and the region* $B = \cap\{B_m: m \in \mathbf{N}\}$, *of* $C(\bar{\Omega}) \times \mathbf{R}$, *be such that*

(a) *Every* B_m *is invariant, and globally finitely attracting for* (1.1), (1.2), (2.1);

(b) *For every* $m \in \mathbf{N}$, *there are two constants,* $\varepsilon_m > 0$ *and* $\delta_m > 0$, *such that* $N(B, \delta_m) \subset B_m \subset N(B, \varepsilon_m)$, *where*

$$N(B, \delta) = \{(u, v) \in C(\bar{\Omega}) \times \mathbf{R}: d[(u, v), B] < \delta\};$$

(c) $\varepsilon_m \to 0$ *as* $m \to \infty$.

Then the region B is invariant and globally asymptotically stable for the problem.

Proof. Since $B = \cap\{B_m: m \in \mathbf{N}\}$, the region B is clearly invariant. B is stable since for every $\varepsilon > 0$ there is an $m \in \mathbf{N}$ such that $\varepsilon_m < \varepsilon$; then the definition of stable region is satisfied with $\delta = \delta_m$. Finally, B is globally asymptotically attracting since for every $\varepsilon > 0$ there is a constant T such that $d[(u(\cdot, t), v(t)), B] < \varepsilon$ for all $t \geqq T$. To see that, take m such that $\varepsilon_m < \varepsilon$ and take into account that B_m is globally finitely attracting and $B_m \subset N(B, \varepsilon_m) \subset N(B, \varepsilon)$.

3. Invariant regions. In this section, we obtain a sequence of regions satisfying the hypothesis of Lemma 2.5, which leads to a globally asymptotically stable region of the phase space of (1.1), (1.2), (2.1).

Let $\{\alpha^m\}$ be a strictly decreasing sequence of real numbers, such that $\alpha^m \to 1$ as $m \to \infty$ and $\alpha^0(\alpha^1 - 1) \leqq M^{-1}\alpha^1 f(\alpha^0, 1/\alpha^0)$, where the constant $M > 0$ is defined below. Let the sequence $\{\alpha_m\}$ be defined by $\alpha_m = 1/\alpha^m$ for all $m \in \mathbf{N}$. From assumption (H.2) (see Introduction), it turns out that there is a constant $M > 0$ and a function $h : [0, \alpha^0] \times [\alpha_0, \infty[\to \mathbf{R}$, of class C^1 and bounded, such that $h \geqq 0$, $\partial h/\partial u \geqq 0$, $\partial h/\partial v \geqq 0$, $-\partial h/\partial u \leqq \partial f/\partial u < M$ for all $(u, v) \in [0, \alpha^0] \times [\alpha_0, \infty[$.

We consider the sequence of regions $\{B_m\} \subset C(\bar{\Omega}) \times \mathbf{R}$, defined by

$$(3.1)\quad B_m = \left\{(u, v) \in C(\bar{\Omega}) \times \mathbf{R}:\ u_m \leqq u \leqq u^m,\ G_m \leqq v + \lambda \int_\Omega u\, dx \leqq G^m,\ v_m \leqq v \leqq v^m\right\},$$

where u_0, u^0, G_0, G^0, v_0, and v^0 are

$$(3.2)\quad u_0 = 0, \quad G_0 = \alpha_0 - \mu^{-1}\sigma S_\Omega(\alpha^0 - 1), \quad v_0 = \alpha_0, \quad u^0 = \alpha^0,$$

$$(3.3)\quad \begin{aligned} G^0 &= \alpha^0(1 + \lambda V_\Omega) + \mu^{-1}\sigma S_\Omega, \\ v^0 &= \alpha^0 + \mu^{-1}\phi^2 V_\Omega \sup\{f(\alpha^0, v) + h(\alpha^0, v):\ v \geqq \alpha_0\} \end{aligned}$$

(V_Ω and S_Ω are the volume of Ω and the area of $\partial\Omega$, respectively), and where u_m, u^m, G_m, G^m, v_m, and v^m ($m \geqq 1$) are defined, inductively, by

$$(3.4)\quad \begin{aligned} \Delta u_m - \phi^2 M u_m &= \alpha_m \phi^2 [f(u_{m-1}, v^{m-1}) - M u_{m-1}] \quad \text{in } \Omega, \\ \partial u_m/\partial n &= \sigma(\alpha_m - u_m) \quad \text{on } \partial\Omega, \end{aligned}$$

$$(3.5)\quad \begin{aligned} \Delta u^m - \phi^2 M u^m &= \alpha^m \phi^2 [f(u^{m-1}, v_{m-1}) - M u^{m-1}] \quad \text{in } \Omega, \\ \partial u^m/\partial n &= \sigma(\alpha^m - u^m) \quad \text{on } \partial\Omega, \end{aligned}$$

$$(3.6)\quad \begin{aligned} G_m &= \alpha_m + \lambda \int_\Omega u_m\, dx + \mu^{-1}\sigma \int_{\partial\Omega} (1 - u^m)\, ds, \\ G^m &= \alpha^m + \lambda \int_\Omega u^m\, dx + \mu^{-1}\sigma \int_{\partial\Omega} (1 - u_m)\, ds, \end{aligned}$$

$$(3.7)\quad v_m = \max\left\{\alpha_m, G_m - \lambda \int_\Omega u^m\, dx, w_m\right\}, \qquad v^m = \min\left\{G^m - \lambda \int_\Omega u_m\, dx, w^m\right\}$$

with

$$(3.8)\quad w_m = \alpha_m + \mu^{-1}\phi^2 \int_\Omega [f(u_m, v_{m-1}) + h(u_m, v_{m-1}) - h(u^m, v^{m-1})]\, dx,$$

$$(3.9)\quad w^m = \alpha^m + \mu^{-1}\phi^2 \int_\Omega [f(u^m, v^{m-1}) + h(u^m, v^{m-1}) - h(u_m, v_{m-1})]\, dx.$$

LEMMA 3.1. *Let $m \geqq 0$ be an integer. If a regular solution of* (1.1), (1.2), (2.1) *satisfies, for all $t \geqq 0$,*

$$(3.10)\quad u_0 \leqq u(\cdot, t) \leqq u^0, \qquad \alpha_0 \leqq v(t) \quad \text{if } m = 0, \quad \text{or}$$

$$(3.11)\quad u_m \leqq u(\cdot, t) \leqq u^m, \qquad v_{m-1} \leqq v(t) \leqq v^{m-1} \quad \text{if } m \geqq 1,$$

then there is a constant T such that for all $t \geqq T$,

$$G_m \leqq v(t) + \lambda \int_\Omega u(x, t)\, dx \leqq G^m, \qquad v_m \leqq v(t) \leqq v^m. \tag{3.12}$$

If, in addition, the inequalities (3.12) *hold for $t = 0$, then they also hold for all $t > 0$.*

Proof. By using (3.10) or (3.11), the time derivative of $G(t) = v(t) + \lambda \int_\Omega u(x, t)\, dx$,

$$dG/dt = \lambda\mu(1 - G) + \lambda^2\mu \int_\Omega u\, dx + \lambda\sigma \int_{\partial\Omega} (1 - u)\, ds,$$

and dv/dt are easily seen to satisfy, for all $t \geqq 0$,

$$\lambda\mu(G_m - G + 1 - \alpha_m) \leqq dG/dt \leqq \lambda\mu(G^m - G + 1 - \alpha^m) \quad \text{for } m \geqq 0,$$

$$\lambda\mu(1 - v) \leqq dv/dt \leqq \lambda\mu(v^0 - v + 1 - \alpha^0),$$

$$\lambda\mu(w_m - v + 1 - \alpha_m) \leqq dv/dt \leqq \lambda\mu(w^m - v + 1 - \alpha^m) \quad \text{for } m \geqq 1.$$

From these inequalities, the conclusion of the lemma readily follows.

LEMMA 3.2. *The sequences defined by* (3.1)-(3.7) *satisfy, for all $m \in \mathbf{N}$:*

A. $u_m \ll u_{m+1} \ll u^{m+1} \ll u^m$, $G_m < G_{m+1} < G^{m+1} < G^m$, $v_m < v_{m+1} < v^{m+1} < v^m$.

B. *B_m is an invariant region for the problem* (1.1), (1.2), (2.1).

C. *B_m is a globally, finitely attracting region for* (1.1), (1.2), (2.1).

Proof. An induction argument will be used in the three cases. It will be proved that the required property holds for $m = 0$ and that it is satisfied for $m = p$ if it holds for $m = p - 1$.

A. Both steps of the induction argument are easily accomplished by means of maximum principles.

B. To prove that B_0 is invariant, observe that if a regular solution of (1.1), (1.2), (2.1) is such that $(u(\cdot, 0), v(0)) \in B_0$, then it satisfies, for all $t \geqq 0$: (i) $u(\cdot, t) \geqq u_0 = 0$ (definition of regular solution); (ii) $v(t) \geqq v_0 = \alpha_0$ (use the inequality $dv/dt \geqq \lambda\mu(1 - v)$); (iii) $u(\cdot, t) \leqq u^0 = \alpha^0$ (apply Lemma 2.1 with $W = \alpha^0 - u$); and (iv) $G_0 \leqq v(t) + \lambda \int_\Omega u(x, t)\, dx \leqq G^0$, $v(t) \leqq v^0$ (Lemma 3.1). In the same way, if B_{p-1} is invariant and if $(u(\cdot, 0), v(0)) \in B_p \subset B_{p-1}$, then for all $t \geqq 0$, $(u(\cdot, t), v(t)) \subset B_{p-1}$ and (i) $u_p \leqq u(\cdot, t) \leqq u^p$ (apply Lemma 2.1 with $W = u - u_p$ and with $W = u^p - u$), and (ii) $G_p \leqq v(t) + \lambda \int_\Omega u(x, t)\, dx \leqq G^p$, $v_p \leqq v(t) \leqq v^p$ (Lemma 3.1).

C. To prove that B_0 is globally finitely attracting, observe that any regular solution of (1.1), (1.2), (2.1) satisfies, for some finite constants, T_1, T_2, and T_3 (i) $0 = u_0 \leqq u(\cdot, t) \leqq u^0 = \alpha^0$ for all $t \geqq T_1$ (Lemma 2.2); (ii) $v(t) \geqq v_0 = \alpha_0$ for all $t \geqq T_2$ (use the inequality $dv/dt \geqq \lambda\mu(1 - v)$); and (iii) $G_0 \leqq v(t) + \lambda \int_\Omega u(x, t)\, dx \leqq G^0$, $v_0 \leqq v(t) \leqq v^0$ for all $t \geqq T_3$ (take the time variable $t = t - \max\{T_1, T_2\}$ and apply Lemma 3.1).

Now, we assume that B_{p-1} satisfies property C and prove that B_p also satisfies it. Let (u, v) be a regular solution of (1.1), (1.2), (2.1). By taking an appropriate origin of the time scale, we may assume that $u_{p-1} \leqq u(\cdot, t) \leqq u^{p-1}$ and $v_{p-1} \leqq v(t) \leqq v^{p-1}$ for all $t \geqq 0$. Then there are finite constants, T_1 and T_2, such that (i) $u_p \leqq u(\cdot, t) \leqq u^p$ for all $t \geqq T_1$ (apply Lemma 2.1 with $W = u + \psi_p \exp(-\alpha t) - \alpha^p u_p$ and with $W = \alpha_p u^p + \psi^p \exp(-\alpha t) - u$, where $\alpha > 0$ is the smallest eigenvalue of (2.2), and $\psi_p \geqq 0$ and $\psi^p \geqq 0$ are eigenfunctions such that $\psi_p \geqq \alpha^p u_p - u(\cdot, 0)$ and $\psi^p \geqq u(\cdot, 0) - \alpha_p u^p$); (ii) $G_p \leqq v(t) + \lambda \int_\Omega u(x, t)\, dx \leqq G^p$, $v_p \leqq v(t) \leqq v^p$ for all $t \geqq T_2$ (take the time variable $t = t - T_1$ and apply Lemma 3.1).

THEOREM 3.3. A. *The sequences defined by* (3.2)-(3.7) *satisfy* $u_m \to u_*$, $u^m \to u^*$, *uniformly in* $\bar{\Omega}$; $G_m \to G_*$, $G^m \to G^*$, $v_m \to v_*$, $v^m \to v^*$, *as* $m \to \infty$, *where* $u_*, u^* \in C^2(\bar{\Omega})$, G_*, G^*, v_*, *and* v^* *satisfy*

$$\Delta u_* = \phi^2 f(u_*, v^*) \quad \text{in } \Omega, \qquad \partial u_*/\partial n = \sigma(1-u_*) \quad \text{on } \partial\Omega, \tag{3.13}$$

$$\Delta u^* = \phi^2 f(u^*, v_*) \quad \text{in } \Omega, \qquad \partial u^*/\partial n = \sigma(1-u^*) \quad \text{on } \partial\Omega, \tag{3.14}$$

$$\begin{aligned} G_* &= 1+\lambda \int_\Omega u_*\, dx + \mu^{-1}\sigma \int_{\partial\Omega} (1-u^*)\, ds, \\ G^* &= 1+\lambda \int_\Omega u^*\, dx + \mu^{-1}\sigma \int_{\partial\Omega} (1-u_*)\, ds, \end{aligned} \tag{3.15}$$

$$v_* = \max\left\{1,\ G_* - \lambda \int_\Omega u^*\, dx,\ 1+\mu^{-1}\phi^2 \int_\Omega [f(u_*, v_*)+h(u_*, v_*)-h(u^*, v^*)]\, dx\right\}, \tag{3.16}$$

$$v^* = \min\left\{G^* - \lambda \int_\Omega u_*\, dx,\ 1+\mu^{-1}\phi^2 \int_\Omega [f(u^*, v^*)+h(u^*, v^*)-h(u_*, v_*)]\, dx\right\}, \tag{3.17}$$

$$0 \ll u_* \leqq u^* \ll 1, \quad 1 \leqq G_* \leqq G^* < \infty, \quad 1 \leqq v_* \leqq v^* < \infty. \tag{3.18}$$

B. *The region*

$$B = \left\{(u, v) \in C(\bar{\Omega}) \times \mathbf{R}:\ u_* \leqq u \leqq u^*,\ G_* \leqq v + \lambda \int_\Omega u\, dx \leqq G^*,\ v_* \leqq v \leqq v^*\right\}$$

is invariant, and globally asymptotically stable for the problem (1.1), (1.2), (2.1).

Proof. A. The monotone, bounded sequences $\{G_m\}$, $\{G^m\}$, $\{v_m\}$, and $\{v^m\}$ are convergent, and their limits satisfy (3.18) (Lemma 3.2A). In the same way, the monotone, bounded sequences $\{u_m\}$ and $\{u^m\}$ are pointwise-convergent to some functions u_* and u^* satisfying $0 \ll u_* \leqq u^*$. By means of elliptic estimates, it may be seen that u_* and u^* are twice continuously differentiable and satisfy (3.13), (3.14), and that the convergence is uniform in $\bar{\Omega}$ (only slight modifications are necessary in the proof of Theorem 2.1 of [14], or in the proof of Theorem 10.3 of [20]). Then (3.15)-(3.17) are obtained as limits of (3.6), (3.7). The inequality $u^* \ll 1$ is easily obtained when maximum principles are applied to (3.14).

B. The sequence $\{B_m\}$ satisfies the hypothesis (a) of Lemma 2.5 (Lemma 3.2). Hypothesis (c) is also satisfied if δ_m and ε_m are

$$\begin{aligned} (1+\lambda V_\Omega)\delta_m = \min\{&\min\{u_* - u_m:\ x \in \bar{\Omega}\},\ \min\{u^m - u^*:\ x \in \bar{\Omega}\}, \\ &G_* - G_m,\ G^m - G^*,\ v_* - v_m,\ v^m - v^*\}, \\ \varepsilon_m = 3(1+\lambda V_\Omega)\max\{&\max\{u_* - u_m:\ x \in \bar{\Omega}\},\ \max\{u^m - u^*:\ x \in \bar{\Omega}\}, \\ &G_* - G_m,\ G^m - G^*,\ v_* - v_m,\ v^m - v^*\}. \end{aligned}$$

Observe that $\delta_m > 0$ for $m = 0, 1, \cdots$, as it comes out from the inequalities $u_m \ll u_* \leqq u^* \ll u^m$, $G_m < G_* \leqq G^* < G^m$, $v_m < v_* \leqq v^* < v^m$ (for $m = 0, 1, \cdots$), which are easily obtained from Lemma 3.2A.

Then, we only need to prove that hypothesis (b) is also satisfied. To this end, observe that.

(i) If $(u, v) \in N(B, \delta_m)$, then there is $(u', v') \in B$ such that

$$d[(u, v), (u', v')] = \max \{|u - u'|: x \in \bar{\Omega}\} + |v - v'| < \delta_m.$$

Hence, $u_* \leqq u' \leqq u^*$, $G_* \leqq v' + \lambda \int_\Omega u'\, dx \leqq G^*$, $v_* \leqq v' \leqq v^*$ and

$$u^m - u \geqq (u^m - u^*) + (u^* - u') - |u - u'| \geqq (1 + \lambda V_\Omega)\delta_m + 0 - \delta_m \geqq 0,$$

$$G^m - v - \lambda \int_\Omega u\, dx \geqq (G^m - G^*) + \left(G^* - v' - \lambda \int_\Omega u'\, dx\right) - \left(|v - v'| + \lambda \int_\Omega |u - u'|\, dx\right)$$

$$\geqq (1 + \lambda V_\Omega)\delta_m + 0 - (1 + \lambda V_\Omega)\delta_m \geqq 0,$$

$$v^m - v \geqq (v^m - v^*) + (v^* - v') - |v - v'| \geqq (1 + \lambda V_\Omega)\delta_m + 0 - \delta_m \geqq 0.$$

Similarly, it is easily seen that $u - u_m \geqq 0$, $v + \lambda \int_\Omega u\, dx - G_m \geqq 0$ and $v - v_m \geqq 0$. Hence, $(u, v) \in B_m$.

(ii) If $(u, v) \in B_m$ and if $(u', v') \in C(\bar{\Omega}) \times \mathbf{R}$ is given by

$$u'(x) = \max \{u_*(x), \min \{u(x), u^*(x)\}\} \quad \text{for } x \in \bar{\Omega},$$

$$v' = \max \left\{ v_*, G_* - \lambda \int_\Omega u'\, dx, \min \left\{ v, v^*, G^* - \lambda \int_\Omega u'\, dx \right\} \right\},$$

then $(u', v') \in B$ and $d[(u, v), (u', v')] \leqq 2\varepsilon_m/3 < \varepsilon_m$, as is easily seen. Therefore, $(u, v) \in N(B, \varepsilon_m)$.

Remark 3.4. Some remarks about the results above are in order.

A. It is easily seen, by means of an induction argument, that for every solution of (3.13)-(3.18), $(u_*, u^*, G_*, G^*, v_*, v^*)$, the sequence defined by (3.2)-(3.7) satisfies

$$u_m \ll u_* \leqq u^* \ll u^m, \qquad G_m < G_* \leqq G^* < G^m, \qquad v_m < v_* \leqq v^* < v^m, \tag{3.19}$$

for all $m \in \mathbf{N}$. Therefore, the solution of (3.13)-(3.18) that is approached as $m \to \infty$ by the sequence (3.2)-(3.7), $(\tilde{u}_*, \tilde{u}^*, \tilde{G}_*, \tilde{G}^*, \tilde{v}_*, \tilde{v}^*)$, is maximal in the following sense: any other solution of (3.13)-(3.18) is such that $\tilde{u}_* \leqq u_* \leqq u^* \leqq \tilde{u}^*$, $\tilde{G}_* \leqq G_* \leqq G^* \leqq \tilde{G}^*$, $\tilde{v}_* \leqq v_* \leqq v^* \leqq \tilde{v}^*$. Since such maximal solution of (3.13)-(3.18) is necessarily unique, the region B of Theorem 3.3 is independent of the choice of the sequence $\{\alpha^m\}$ and of the constant M. Furthermore, if one takes $\alpha_m = \alpha^m = 1$ for all $m \in \mathbf{N}$ in (3.1)-(3.9), the following sequence of regions is obtained

$$B_m = \left\{ (u, v) \in C(\bar{\Omega}) \times \mathbf{R}: u_m \leqq u \leqq u^m, G_m \leqq v + \lambda \int_\Omega u\, dx \leqq G^m, v_m \leqq v \leqq v^m \right\}, \tag{3.20}$$

where u_0, u^0, G_0, G^0, v_0, and v^0 are

$$u_0 = 0, \qquad G_0 = v_0 = 1, \qquad u^0 = 1, \qquad G^0 = 1 + \lambda V_\Omega + \mu^{-1}\sigma S_\Omega, \tag{3.21}$$

$$v^0 = 1 + \mu^{-1}\phi^2 V_\Omega \sup \{f(1, v) + h(1, v): v \geqq 1\}, \tag{3.22}$$

and where u_m, u^m, G_m, G^m, v_m, and v^m $(m \geqq 1)$ are defined inductively by

$$\begin{aligned} \Delta u_m - \phi^2 M u_m &= \phi^2[f(u_{m-1}, v^{m-1}) - M u_{m-1}] \quad \text{in } \Omega, \\ \partial u_m/\partial n &= \sigma(1-u_m) \quad \text{on } \partial\Omega, \end{aligned} \tag{3.23}$$

$$\begin{aligned} \Delta u^m - \phi^2 M u^m &= \phi^2[f(u^{m-1}, v_{m-1}) - M u^{m-1}] \quad \text{in } \Omega, \\ \partial u^m/\partial n &= \sigma(1-u^m) \quad \text{on } \partial\Omega, \end{aligned} \tag{3.24}$$

$$\begin{aligned} G_m &= 1 + \lambda \int_\Omega u_m \, dx + \mu^{-1}\sigma \int_{\partial\Omega} (1-u^m) \, ds, \\ G^m &= 1 + \int_\Omega u^m \, dx + \mu^{-1}\sigma \int_{\partial\Omega} (1-u_m) \, ds, \end{aligned} \tag{3.25}$$

$$\begin{aligned} v_m = \max \Big\{ & 1, \; G_m - \lambda \int_\Omega u^m \, dx, \\ & 1 + \mu^{-1}\phi^2 \int_\Omega [f(u_m, v_{m-1}) + h(u_m, v_{m-1}) - h(u^m, v^{m-1})] \, dx \Big\}, \end{aligned} \tag{3.26}$$

$$\begin{aligned} v^m = \min \Big\{ & G^m - \lambda \int_\Omega u_m \, dx, \\ & 1 + \mu^{-1}\phi^2 \int_\Omega [f(u^m, v^{m-1}) + h(u^m, v^{m-1}) - h(u_m, v_{m-1})] \, dx \Big\}. \end{aligned} \tag{3.27}$$

The sequence defined by (3.21)-(3.27) is such that (i) it approaches a solution of (3.13)-(3.18) as $m \to \infty$ (since it is seen to satisfy Lemma 3.2A and Theorem 3.3A), and (ii) it satisfies (3.19) for all $m \in \mathbf{N}$ and for every solution of (3.13)-(3.18) (to prove it, use an induction argument, as above). Hence such sequence also approaches the maximal solution of (3.13)-(3.18) as $m \to \infty$, and the region B of Theorem 3.3 may be obtained as the limit of the sequence of regions defined by (3.20), which may be easily computed (numerically in general) from the linear problems (3.23)-(3.27).

B. As it was mentioned in § 1, since the region B of Theorem 3.3 is globally asymptotically stable, it contains the nonwandering set of (1.1), (1.2), (2.1), and the same is true for any of the regions B_m defined by (3.20)-(3.27) (since $B \subset B_m$ for all $m \in \mathbf{N}$, as it was seen in remark A above). In particular every (stable or unstable) steady state of (1.1), (1.2) is included in B.

C. If every solution of (3.13)-(3.18) satisfies $u_* = u^*$ and $v_* = v^*$, then the region B of Theorem 3.3 is a singleton, $B = \{(u_s, v_s)\}$, and (u_s, v_s) is a globally asymptotically stable steady state of (1.1), (1.2); in addition, (u_s, v_s) is the unique steady state of (1.1), (1.2), as it comes out from remark B above. Observe also that (3.13)-(3.18) has a unique solution in this case. This result will be used in the next section to obtain quantitative, sufficient conditions for global asymptotic stability and uniqueness of the steady state of (1.1), (1.2).

4. Global asymptotic stability of the steady state. In this section, we shall obtain sufficient conditions for global asymptotic stability of the steady state of (1.1), (1.2), (2.1), when the function f is given by

$$f(u, v) = g(u) \exp(\gamma - \gamma/v), \tag{4.1}$$

where $g : [0, \infty[\to \mathbf{R}$ is a C^1-function satisfying

$$g(0) = 0, \qquad g(u) > 0 \quad \text{for all } u > 0. \tag{4.2}$$

Particular instances of such form of f are those in (1.4), (1.5). Some additional assumptions about the function g will be considered below, when needed.

In order to avoid too many involved expressions, we shall obtain only reasonably good sufficient conditions for global stability (and not the best ones that can be obtained from the results of § 3).

The role of the parameters ϕ^2, λ, and σ deserves some attention. The Damköhler number ϕ^2 is the basic parameter; the steady-state solutions of (1.1), (1.2), for example, are usually represented by the curve $\eta - \phi^2$, where η is a significant functional of the steady state, i.e.,

$$\eta = \int_\Omega f(u_s(x), v_s)\, dx / V_\Omega f(1, 1),$$

which is called the effectiveness factor (see [1]). Below, we shall prove that the steady state is globally asymptotically stable (i) if ϕ^2 is sufficiently small or large, for fixed values of the remaining parameters; and (ii) for arbitrary values of ϕ^2 if the parameter γ is sufficiently small and the function g is increasing. The parameter λ is a Lewis number; increasing values of λ are expected to make any steady state of (1.1), (1.2) more and more linearly unstable (i.e., to increase the growth rate of the linear stability analysis). This has been shown to be true for lumped chemically reacting systems (see [21]), and for some distributed systems (such as (1.1), (1.2) if $f(u, v) = u \exp(\gamma - \gamma/v)$; see [2]). Observe that the steady-state solutions of (1.1), (1.2) do not depend on λ. Some of the results below will be independent of λ (they will be valid for $0 < \lambda < \infty$), and some others (depending on λ) will be quite useful for small values of λ. The Sherwood number σ is usually fairly large (see [1]). Some emphasis will be put on obtaining results that are significant as $\sigma \to \infty$ (see, e.g., Theorems 4.4 and 4.5).

Let us assume that the domain Ω satisfies assumption (H.1) (see Introduction). If the function f is as defined by (4.1), then Theorem 3.3 applies. The system (3.13)–(3.18) may be written as

$$\Delta u_* = \phi^2 g(u_*) \exp(\gamma - \gamma/v^*) \quad \text{in } \Omega, \qquad \partial u_*/\partial n = \sigma(1 - u_*) \quad \text{on } \partial\Omega, \tag{4.3}$$

$$\Delta u^* = \phi^2 g(u^*) \exp(\gamma - \gamma/v_*) \quad \text{in } \Omega, \qquad \partial u^*/\partial n = \sigma(1 - u^*) \quad \text{on } \partial\Omega, \tag{4.4}$$

$$\begin{aligned} v_* = 1 + \max\Big\{ 0, -\lambda \int_\Omega (u^* - u_*)\, dx + \mu^{-1}\sigma \int_{\partial\Omega} (1 - u^*)\, ds, \\ \mu^{-1}\phi^2 \Big[\exp(\gamma - \gamma/v_*) \int_\Omega (g(u_*) + h(u_*))\, dx \\ - \exp(\gamma - \gamma/v^*) \int_\Omega h(u^*)\, dx \Big] \Big\}, \end{aligned} \tag{4.5}$$

$$\begin{aligned} v^* = 1 + \min\Big\{ \lambda \int_\Omega (u^* - u_*)\, dx + \mu^{-1}\sigma \int_{\partial\Omega} (1 - u_*)\, ds, \\ \mu^{-1}\phi^2 \Big[\exp(\gamma - \gamma/v^*) \int_\Omega (g(u^*) + h(u^*))\, dx \\ - \exp(\gamma - \gamma/v_*) \int_\Omega h(u_*)\, dx \Big] \Big\}, \end{aligned} \tag{4.6}$$

$$0 \ll u_* \leqq u^* \ll 1, \qquad 1 \leqq v_* \leqq v^* < \infty, \tag{4.7}$$

where $h = [0, 1] \to \mathbf{R}$ is a C^1-function satisfying

$$h'(u) \geqq 0, \; g'(u) + h'(u) \geqq 0 \quad \text{for all } 0 \leqq u \leqq 1. \tag{4.8}$$

The function h may be chosen to be such that

$$k_1 = \max\{0, \max\{-g'(u): 0 \leqq u \leqq 1\}\} = \max\{h'(u): 0 \leqq u \leqq 1\}. \tag{4.9}$$

The main idea to be used in the sequel is the following. According to Remark 3.4C, if every solution of (4.3)-(4.7) satisfies

$$u_* = u^*, \qquad v_* = v^*, \tag{4.10}$$

then (1.1), (1.2), (2.1) possess a unique steady state, which is globally asymptotically stable.

THEOREM 4.1 (*Global asymptotic stability for small* ϕ^2). *Under the assumptions above,* (1.1), (1.2), (2.1) *has a unique steady state, which is globally asymptotically stable if* ϕ^2 *satisfies*

$$\phi^2 \exp\gamma < \alpha/k_1, \tag{4.11}$$

and one of the following inequalities:

$$\gamma V_\Omega\{k_2(2k_1+k_5)[k_3+k_1k_4\phi^2\exp\gamma/(\alpha-k_1\phi^2\exp\gamma)]\phi^2 \cdot \exp\gamma + k_2 + 2k_6\}\phi^2\exp\gamma \leqq \mu, \tag{4.12}$$

$$\gamma k_2(2\lambda\mu V_\Omega + \sigma S_\Omega)[k_3+k_1k_4\phi^2\exp\gamma/(\alpha-k_1\phi^2\exp\gamma)]\phi^2\exp\gamma \leqq \mu, \tag{4.13}$$

$$\gamma k_2 V_\Omega\{1+(2\lambda\mu+k_5\phi^2\exp\gamma)[k_3+k_1k_4\phi^2\exp\gamma/(\alpha-k_1\phi^2\exp\gamma)]\phi^2 \cdot \exp\gamma \leqq \mu, \tag{4.14}$$

where α, k_1, k_2, k_3, *and* k_4 *are as in Lemma* A.1 (*see Appendix*), *and*

$$k_5 = \max\{g'(u): 0 \leqq u \leqq 1\}, \qquad k_6 = \max\{h(u): 0 \leqq u \leqq 1\}.$$

Proof. We shall prove that if (4.11) and one of the inequalities (4.12)-(4.14) hold, then every solution of (4.3)-(4.7) satisfies (4.10). To this end, observe that if (4.11) holds, then u_* and u^* satisfy (Lemma A.1)

$$u^* - u_* \leqq k_2[k_3+k_1k_4\phi^2\exp\gamma/(\alpha-k_1\phi^2\exp\gamma)]\phi^2\exp\gamma[1-\exp(-\gamma\xi)], \tag{4.15}$$

where

$$\xi = 1/v_* - 1/v^* \tag{4.16}$$

is such that

$$0 \leqq \xi \leqq 1, \quad \xi/(1-\xi) \leqq v_*^2\xi/(1-v_*\xi) = v^* - v_*, \tag{4.17}$$

as it comes out from (4.7). Subtraction of (4.5) from (4.6) yields

$$v^* - v_* \leqq \mu^{-1}\phi^2\Big[\exp(\gamma-\gamma/v^*)\int_\Omega (g(u^*)+2h(u^*))\,dx - \exp(\gamma-\gamma/v_*)\int_\Omega (g(u_*)+2h(u_*))\,dx\Big], \tag{4.18}$$

$$v^* - v_* \leqq 2\lambda\int_\Omega (u^*-u_*)\,dx + \mu^{-1}\sigma\int_{\partial\Omega}(u^*-u_*)\,ds. \tag{4.19}$$

Integration over Ω in (4.3) and (4.4) and application of Green's identity yield

$$\sigma\int_{\partial\Omega}(1-u_*)\,ds = \phi^2\exp(\gamma-\gamma/v^*)\int_\Omega g(u_*)\,dx, \tag{4.20}$$

$$\sigma\int_{\partial\Omega}(1-u^*)\,ds = \phi^2\exp(\gamma-\gamma/v_*)\int_\Omega g(u^*)\,dx. \tag{4.21}$$

Substraction of (4.21) from (4.20) and substitution in (4.19) lead to

$$v^* - v_* \leqq 2\lambda \int_\Omega (u^* - u_*) + \mu^{-1}\phi^2 \Big[\exp(\gamma - \gamma/v^*) \int_\Omega g(u_*)\, dx - \exp(\gamma - \gamma/v_*) \int_\Omega g(u^*)\, dx \Big]. \tag{4.22}$$

Finally, after substitution of (4.15)-(4.17) in (4.18), (4.19), and (4.22), the following inequalities are obtained:

$$\xi/(1-\xi) \leqq A_i[1 - \exp(-\gamma\xi)] \quad \text{for } i = 1, 2, \text{ and } 3, \tag{4.23}$$

where $\gamma\mu A_1$, $\gamma\mu A_2$, and $\gamma\mu A_3$ are the first members of (4.12), (4.13), and (4.14). If one of the inequalities (4.12)-(4.14) is satisfied, then $\xi = 0$ (i.e., $v_* = v^*$), as it comes out from (4.23), $u_* = u^*$ (Lemma A.1) and the conclusion of the theorems follows.

Remark. Condition (4.12) does not depend on λ, and it is more stringent than (4.14) if $k_1 \neq 0$ and λ is sufficiently small. If σ is sufficiently small, condition (4.14) is more stringent than (4.13).

THEOREM 4.2 (*Global asymptotic stability for all* $\phi^2 > 0$). *If, in addition to the assumptions of Theorem* 4.1, *the function g satisfies condition* (A.6) *of Lemma* A.2 (*see Appendix*), *then, for all* $\phi^2 > 0$, (1.1), (1.2), (2.1) *have a unique steady state, which is globally asymptotically stable, provided that* γ *satisfies one of the following inequalities* (*see Fig.* 1):

$$k_7\gamma\sigma S_\Omega/\mu \leqq 1/(1 + 2\lambda\mu V_\Omega/\sigma S_\Omega), \tag{4.24}$$

$$\gamma\sigma S_\Omega/\mu \leqq 1/(1 + k_7\lambda\mu V_\Omega/\sigma S_\Omega), \tag{4.25}$$

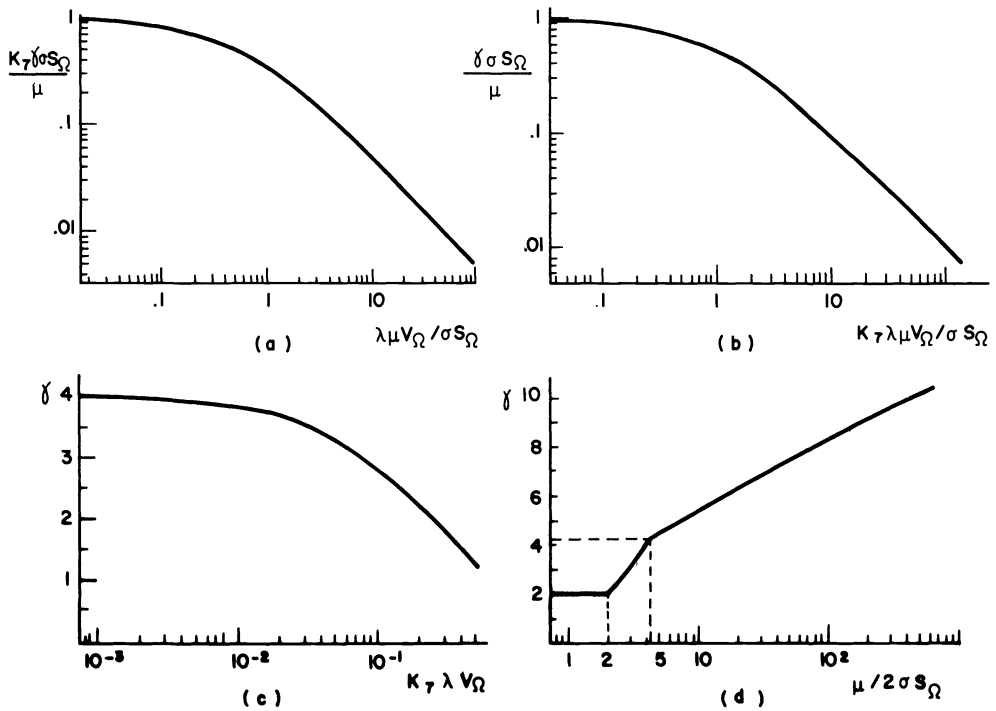

FIG. 1. *Global asymptotic stability for all* $\phi^2 > 0$. *Plots* (a)-(d) *correspond to conditions* (4.24)-(4.27).

$$\gamma \leqq 4/(1+4k_7\lambda V_\Omega), \tag{4.26}$$

$$\gamma \leqq H_1(\mu/2\sigma S_\Omega). \tag{4.27}$$

Here, k_7 is as defined in Lemma A.2, *and the positive, nondecreasing function $H_1:[0,\infty[\to$ $\mathbf{R}$ is defined by $H_1(y)=2$ for $0\leqq y\leqq 2$, $H_1(y)=y$ for $2<y\leqq y_1$, and $H_1(y)=h_2[h_1^{-1}(y)]$ for $y_1<y<\infty$, where* (i) $y_1=h_1(z_1)=4.2488\cdots$ *and $z_1=2.6761\cdots$ is the unique positive solution of the equation $z^2=\sinh z\tanh z$, and* (ii) *the strictly increasing functions, h_1, $h_2:[z_1,\infty[\to[y_1,\infty[$ are given by*

$$h_1(z)=\sinh z\tanh z/(z-\tanh z), \qquad h_2(z)=z^2/(z-\tanh z).$$

Proof. If Lemma A.2 is applied to (4.3), (4.4), one obtains

$$0\leqq u^*-u_*<1-\exp(-k_7\gamma\xi), \tag{4.28}$$

where ξ is given by (4.16) and satisfies (4.17) and

$$\begin{gathered} 1/v_*v^*\leqq 1-\xi, \quad (v_*-1)/v_*v^*<(1-\xi)^2/4, \\ (v^*-1)/(v_*-1)\geqq(1+\xi)^2/(1-\xi)^2, \end{gathered} \tag{4.29}$$

as is easily seen when taking into account (4.7).

When using (4.20), (4.21), the following inequalities are obtained from (4.5), (4.6), upon subtraction or division,

$$v^*-v_*\leqq 2\lambda\int_\Omega (u^*-u_*)\,dx+\mu^{-1}\sigma\int_{\partial\Omega}(u^*-u_*)\,ds, \tag{4.30}$$

$$v^*-v_*\leqq \lambda\int_\Omega (u^*-u_*)\,dx+\mu^{-1}\sigma[1-\exp(-\gamma\xi)]\int_{\partial\Omega}(1-u_*)\,ds, \tag{4.31}$$

$$v^*-v_*\leqq(\sigma/\mu)\left[\exp(\gamma\xi)\int_{\partial\Omega}(1-u^*)\,ds-\exp(-\gamma\xi)\int_{\partial\Omega}(1-u_*)\,ds\right], \tag{4.32}$$

$$(v^*-1)/(v_*-1)\leqq\exp(2\gamma\xi)\left[\int_{\partial\Omega}(1-u^*)\,ds\right]\Big/\left[\int_{\partial\Omega}(1-u_*)\,ds\right]. \tag{4.33}$$

(Recall that the function h identically vanishes since $g'(u)>0$ for all $0<u\leqq 1$, according to condition (A.6) of Lemma A.2.) A further substitution of (4.5), (4.20) into (4.31) yields

$$v^*-v_*\leqq\lambda\int_\Omega (u^*-u_*)\,dx+(v_*-1)[\exp(\gamma\xi)-1]. \tag{4.34}$$

When taking into account (4.7), (4.16), (4.28), (4.29), the following inequalities are obtained from (4.30)-(4.34):

$$\xi/(1-\xi)\leqq(2\lambda V_\Omega+\sigma S_\Omega/\mu)[1-\exp(-k_7\gamma\xi)], \tag{4.35}$$

$$\xi/(1-\xi)\leqq\lambda V_\Omega[1-\exp(-k_7\gamma\xi)]+(\sigma S_\Omega/\mu)[1-\exp(-\gamma\xi)], \tag{4.36}$$

$$\xi/(1-\xi)<(2\sigma S_\Omega/\mu)\sinh(\gamma\xi), \qquad (1+\xi)/(1-\xi)<\exp(\gamma\xi) \quad \text{if } \xi>0, \tag{4.37}$$

$$\xi/(1-\xi)\leqq\lambda V_\Omega[1-\exp(-\gamma k_7\xi)]+(1-\xi)[\exp(\gamma\xi)-1]/4. \tag{4.38}$$

If inequality (4.24) ((4.25) or (4.26), respectively) holds, then (4.35) ((4.36) or (4.38), respectively) yields $\xi=0$ (i.e., $v_*=v^*$); then $u_*=u^*$ (apply Lemma A.1 and take into account that $k_1=0$) and the conclusion of the theorem follows. If (4.27) holds, then $\xi=0$ and the conclusion of the theorem follows again. Use the second inequality (4.37)

if $\gamma \leqq 2$ to prove it, and observe that if $\gamma > 2$ and $\xi > 0$, then (4.27) and the first inequality (4.37) yield

$$H_1^{-1}(\gamma) < (1/\xi - 1)\sinh(\gamma\xi);$$

but this inequality cannot be satisfied for any $\xi > 0$ since the maximum of its second member, in $0 \leqq \xi \leqq 1$, is $H_1^{-1}(\gamma)$.

THEOREM 4.3 (*Global asymptotic stability for large ϕ^2*). *In addition to the assumptions of Theorem* 4.1, *let the function g satisfy conditions* (A.7) *and* (A.8) *of Lemma* A.3. *Then,* (1.1), (1.2), (2.1) *have a unique steady state, which is globally asymptotically stable for*

$$\phi^2 \geqq \phi_c^2 = \sigma(\sigma + p/\rho_1)/G(\delta), \tag{4.39}$$

if δ is such that $0 < \delta \leqq a$ and satisfies one of the following inequalities:

$$\gamma \leqq \gamma_c = (1-\delta)H_2(a_1(1-\delta)/2 + 1/2a_1(1-\delta)), \tag{4.40}$$

$$\delta \leqq \max\{(1+1/a_1)/[1+\gamma k_8(1+2a_2)],\ 2a_3/[a_4+\sqrt{a_4^2-4a_3}]\}, \tag{4.41}$$

where (i) *the strictly increasing function G and the constants ρ_1, a, and k_8 are as in Lemma* A.3; (ii) *the strictly increasing function $H_2 : [1, \infty[\to [2, \infty[$ (see Fig.* 2) *is given by $H_2(y) = 1 + y$ for $1 \leqq y \leqq 2$, $H_2(y) = h_3[h_4^{-1}(y)]$ for $2 < y < \infty$*; (iii) *the strictly increasing functions $h_3 : [0, \infty[\to [3, \infty[$ and $h_4 : [0, \infty[\to [2, \infty[$ are defined by*

$$h_3(z) = z^2 \sinh z/(z\cosh z - \sinh z), \qquad h_4(z) = (\sinh z \cosh z - z)/(z\cosh z - \sinh z);$$

and (iv) *the parameters a_1, a_2, a_3, and a_4 are*

$$a_1 = \sigma S_\Omega/\mu, \quad a_2 = \lambda\mu V_\Omega/\sigma S_\Omega, \quad a_3 = (1+1/a_1^2)/(1+a_2),$$

$$a_4 = [(1+a_1)(2+a_2) + \gamma k_8(1+2a_2)]/a_1(1+a_2).$$

Proof. If (4.39) holds and $0 < \delta \leqq a$, then (Lemma A.3)

$$0 \ll u_* \leqq u^* < \delta \leqq a, \qquad 0 \leqq u^* - u_* \leqq \delta[1 - \exp(-\gamma k_8 \xi)], \tag{4.42}$$

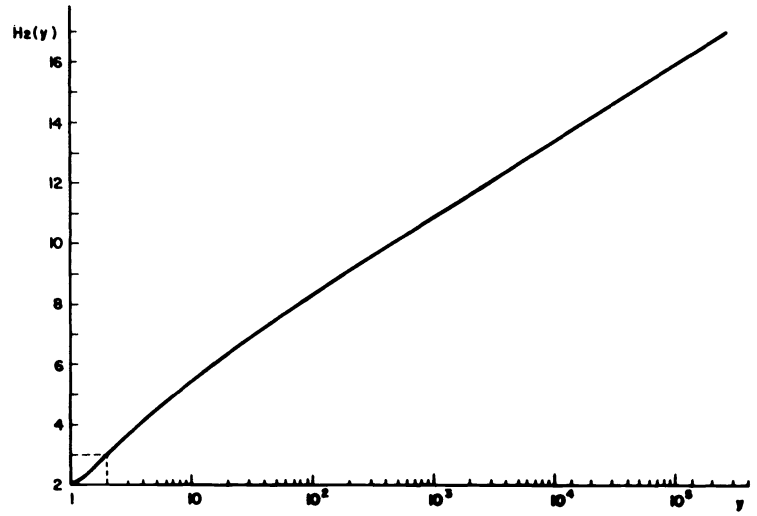

FIG. 2. *The function H_2 of Theorems* 4.3 *and* 4.4.

where $\xi = 1/v_* - 1/v^* \leqq 1$. Then if the function h is chosen to be such that $h(u) = 0$ for $0 \leqq u \leqq a$ (this may be done, with h satisfying (4.8), (4.9), since the function g satisfies (A.7)),

$$h(u_*(x)) = h(u^*(x)) = 0 \quad \text{for all } x \in \bar{\Omega}. \tag{4.43}$$

Let us first assume that ϕ^2 and δ satisfy (4.39), (4.40) and prove that $\xi = 0$. To this end, we define

$$\begin{aligned} A_* &= 1 + \mu^{-1}\sigma \exp(-\gamma\xi) \int_{\partial\Omega} (1 - u_*)\, ds, \\ A^* &= 1 + \mu^{-1}\sigma \exp(\gamma\xi) \int_{\partial\Omega} (1 - u^*)\, ds. \end{aligned} \tag{4.44}$$

$A_* \leqq v_*$ and $A^* \geqq v^*$, as it comes out from (4.5), (4.6), (4.20), (4.21), (4.43). Hence, if ξ were different from zero, it would satisfy

$$\begin{aligned} \xi = 1/v_* - 1/v^* &\leqq (A^* - A_*)/A_* A^* \\ &< 2a_1 \sinh(\gamma\xi)/[1 + a_1(1-\delta)\exp(-\gamma\xi)][1 + a_1(1-\delta)\exp(\gamma\xi)], \end{aligned} \tag{4.45}$$

or

$$1 > (1-\delta)\xi[a_1(1-\delta)/2 + 1/2a_1(1-\delta) + \cosh\gamma\xi]/\sinh\gamma\xi,$$

as obtained from (4.42), (4.44). But this inequality cannot hold for any $\xi > 0$ since the minimum of its second member, in $0 \leqq \xi < \infty$, is $(1-\delta)H_2(a_1(1-\delta)/2 + 1/2a_1(1-\delta))/\gamma$, and γ satisfies (4.40). Then, $\xi = 0$ (i.e., $v_* = v^*$), $u_* = u^*$ (Lemma A.3) and the conclusion of the theorem follows.

If ϕ^2 and δ satisfy (4.39) and (4.41), then

$$v_* \geqq \max\{1, 1 + a_1(1 - \delta - a_2\delta)\}, \qquad v^* > 1 + a_1(1-\delta), \tag{4.46}$$

as it comes out from (4.5), (4.6), (4.21), (4.42). If ξ were different from zero, (4.30), (4.42), (4.46) would yield

$$1 < a_1(1 + 2a_2)\delta[1 - \exp(-k_8\gamma\xi)]/\xi[1 + a_1(1-\delta)]\max\{1, 1 + a_1(1 - \delta - a_2\delta)\}.$$

But this inequality cannot hold for any $\xi > 0$ if δ satisfies (4.41), as is easily seen. Therefore, $\xi = 0$ and the conclusion of the theorem follows again.

Remarks. If ϕ_c^2 is calculated by means of (4.39), (4.40), then it does not depend on λ, while if it is obtained from (4.39), (4.41), then $\phi_c^2 \to \infty$ as $\lambda \to \infty$.

It is easily seen that, for fixed values of the remaining parameters, the functions $\delta \to \phi_c^2(\delta)$ and $\delta \to \gamma_c(\delta)$ are strictly decreasing in $0 < \delta < 1$. Therefore, if

$$\gamma < H_2(a_1/2 + 1/2a_1), \tag{4.47}$$

then the maximum value of δ satisfying (4.40), δ_M, is the unique solution of the equation $\gamma = \gamma_c(\delta)$. Then, the best value of ϕ_c^2 provided by (4.39), (4.40) is $\sigma(\sigma + p/\rho_1)/G(\delta)$, with $\delta = \min\{a, \delta_M\}$. If (4.47) does not hold, then (4.40) is not satisfied for any $\delta > 0$, and Theorem 4.3 does not provide a value of ϕ_c^2 uniformly valid in $0 < \lambda < \infty$. Although Theorem 4.3 provides only sufficient conditions for global asymptotic stability of the steady state, it may be seen, as a converse of Theorem 4.3 in a certain sense, that for first-order Arrhenius kinetics (i.e., for $g(u) \equiv u$) and large values of σ (see [2]), the upper linear instability bound (i.e., the supremum of the set of values of ϕ^2 such that the steady state of (1.1), (1.2), (2.1) is linearly unstable), ϕ_u^2, satisfies $\phi_u^2 \to \phi_{u0}^2 < \infty$ if $\gamma < (1 + a_1)^2/a_1$ and $\phi_u^2 \to \infty$ otherwise as $\lambda \to \infty$.

Any ϕ_c^2 provided by (4.39), (4.40), or by (4.39), (4.41), is such that $\phi_c^2 \to \infty$ as $\sigma \to \infty$. In order to calculate a value of ϕ_c^2 uniformly valid in $0 < \sigma < \infty$, which is expected to exist under mild assumptions on the function g, one would need the following result, which is stronger than that in Lemma A.3 and seemingly true (under mild assumptions on the function g): there are two constants, $\bar{\Lambda}$ and k, such that, for every $\sigma > 0$, (i) the problem (A.1) of the Appendix has a unique solution if $\Lambda \geqq \bar{\Lambda}$, and (ii) if $\bar{\Lambda} \leqq \Lambda_2 < \Lambda_1 < \infty$, then the solutions of (A.1) for $\Lambda = \Lambda_1$ and $\Lambda = \Lambda_2$, u_1 and u_2, satisfy $|u_2(x) - u_1(x)| \leqq k(\Lambda_1 - \Lambda_2)$, for all $x \in \bar{\Omega}$. Property (i) may be proved if one is able to obtain an upper multiplicity bound $\bar{\Lambda}$ when the Robin boundary data in (A.1) is replaced by Dirichlet data: $u = 1$ on $\partial\Omega$; if Ω is the unit ball of $\mathbf{R}^p$, this comes out from results by Dancer [23] that were obtained by means of topological degree theory; unfortunately, even if the results of [23] are extended to arbitrary bounded domains of $\mathbf{R}^p$, they do not seem to provide the constant k of part (ii) of the required result above. Related results in the literature, such as those in [24], [25], do not apply to our case.

Theorems 4.4 and 4.5 below provide a uniform value of ϕ_c^2 in $0 < \sigma < \infty$ but they require the function g to be strictly increasing.

THEOREM 4.4 (*Global asymptotic stability for large* ϕ^2). *In addition to the assumptions of Theorem* 4.1, *let us assume that* g *is such that* $g'(u) > 0$ *for all* $0 < u \leqq 1$, *and that*

$$2 < \gamma \leqq H_2(a_1/2 + 1/2a_1), \tag{4.48}$$

where the constant a_1 *and the function* H_2 (*see Fig.* 2) *are as defined in Theorem* 4.3. *Then,* (1.1), (1.2), (2.1) *have a unique steady state, which is globally asymptotically stable if*

$$\phi^2 \geqq 2(\mu/S_\Omega)^2 K[pS_\Omega/\mu\rho_1 + 2^{-1/p}K]/G(\delta_1), \tag{4.49}$$

where the constants δ, δ_1, *and* K *are the unique solutions of the equations*

$$\gamma = (1-\delta)H_2[a_1(1-\delta)/2 + 1/2a_1(1-\delta)], \qquad 0 < \delta < 1, \tag{4.50}$$

$$(1-\delta_1)/\sqrt{2G(\delta_1)} = (1 + D/2\rho_2)^{p-1}\sqrt{(1 + p/\sigma\rho_1)/G(\delta)}, \qquad 0 < \delta_1 < 1, \tag{4.51}$$

$$H_2(K/2 + 2/K) = \gamma a_5, \qquad K \geqq 1, \tag{4.52}$$

the constants ρ_1, ρ_2, *and* D *are as defined in Lemma* A.4, *and*

$$a_5 = (1 + D/2\rho_2)^{p-1}[p/\rho_1 + \sqrt{(p/\rho_1)^2 + 2^{1-1/p}a_6}]\sqrt{2G(1)/a_6 G(\delta_1)},$$

$$a_6 = 2(\mu/S_\Omega)^2[pS_\Omega/\mu\rho_1 + 2^{-1/p}].$$

Remarks. If $\gamma \leqq 2$, then the conclusion of the theorem is true for all $\phi^2 > 0$, according to Theorem 4.2. Equation (4.50) has a unique solution if γ satisfies (4.48), as was seen in a remark above. For a given value of δ, (4.51) has a unique solution δ_1 (which is such that $\delta_1 < \delta$), since the first member of (4.51) is a strictly decreasing function of δ_1, and it approaches 0 and ∞ as $\delta_1 \to 1$ and as $\delta_1 \to 0$, respectively. Since the second member of (4.52) is larger than 2 ($a_5 > 1$ and $\gamma > 2$), (4.52) has a unique solution (recall that $H_2(1) = 2$, H_2 is strictly increasing and $H_2(y) \to \infty$ as $y \to \infty$).

Proof of Theorem 4.4. If $\phi^2 G(\delta) \exp(\gamma - \gamma/v_*) \geqq \sigma(\sigma + p/\rho_1)$, then $u_* \leqq u^* \leqq \delta$ (Lemma A.3) and, as in the proof of Theorem 4.3, $\xi = 1/v_* - 1/v^*$ is seen to satisfy (4.45), which implies $\xi = 0$ (i.e., $v_* = v^*$). Then $u_* = u^*$ (Lemma A.1), and the conclusion of the theorem follows.

If $\phi^2 G(\delta) \exp(\gamma - \gamma/v_*) < \sigma(\sigma + p/\rho_1)$, then $u_m^* = \min\{u^*(x): x \in \partial\Omega\}$ satisfy (Lemma A.4)

$$(1 - u_m^*)/\sqrt{2G(u_m^*)} < (1 + D/2\rho_2)^{p-1}\sqrt{(1 + p/\sigma\rho_1)/G(\delta)}. \tag{4.53}$$

Since the first member of (4.53) is a strictly decreasing function of u_m^* and δ_1 satisfies (4.51), $\delta_1 \leqq u_m^*$ and

$$\delta_1 < u^*(x) \quad \text{for all } x \in \partial\Omega. \tag{4.54}$$

Then, u_m^* and $u_M^* = \max\{u^*(x): x \in \partial\Omega\} = \max\{u^*(x): x \in \bar{\Omega}\}$ satisfy (Lemma A.4)

$$\sigma(1-u_m^*) < (1+D/2\rho_2)^{p-1}\sqrt{2\Lambda_* G(1)}, \tag{4.55}$$

$$\sigma(1-u_M^*) > \Lambda_* G(\delta_1)/[p/\rho_1 + \sqrt{(p/\rho_1)^2 + 2^{1-1/p}\Lambda_* G(\delta_1)}] = \mu K_*/S_\Omega \tag{4.56}$$

where

$$\Lambda_* = \phi^2 \exp(\gamma - \gamma/v_*). \tag{4.57}$$

Since $K \geqq 1$ and ϕ^2 satisfies (4.49), we have $\Lambda_* G(\delta_1) \geqq \phi^2 G(\delta_1) \geqq a_6$, and

$$(1+D/2\rho_2)^{p-1}\sqrt{2\Lambda_* G(1)}\, S_\Omega/\mu K_* \leqq a_5. \tag{4.58}$$

Furthermore, (4.49), (4.56), (4.57) yield

$$K \leqq K_*. \tag{4.59}$$

Then, if A_* and A^* are as defined by (4.44), $\xi = 1/v_* - 1/v^* \leqq (A^* - A_*)/A_* A^*$ must vanish because otherwise it would satisfy

$$\xi < a_5 \sinh(\gamma\xi)/(K/2 + 1/2K + \cosh\gamma\xi),$$

as it comes out from (4.44), (4.55), (4.56), (4.58), (4.59), or

$$a_5 > (K/2 + 1/2K + \cosh\gamma\xi)/\sinh\gamma\xi,$$

and this inequality cannot hold for any $\xi > 0$ since the minimum of its second member in $0 \leqq \xi < \infty$ is $H_2(K/2 + 1/2K)/\gamma$, and K satisfies (4.52). Therefore, $\xi = 0$ (i.e., $v_* = v^*$), $u_* = u^*$ (Lemma A.1) and the conclusion of the theorem follows.

Observe that the second member of (4.49) does not depend on λ. The following theorem provides a better result if λ is sufficiently small. It also applies for arbitrarily large values of σ.

THEOREM 4.5 (*Global asymptotic stability for large* ϕ^2). *In addition to the hypothesis of Theorem* 4.1, *let us assume that the function g satisfies condition* (A.6) *of Lemma* A.2, *and that*

$$\gamma > 2, \quad \delta = \max\{(1+1/a_1)/[1+\gamma k_7(1+2a_2)],\ 2a_3/[a_7 + \sqrt{a_7^2 - 4a_3}]\} < 1, \tag{4.60}$$

where the constants a_1, a_2, *and* a_3 *are as in Theorem* 4.3, k_7 *is as defined in Lemma* A.2, *and*

$$a_7 = [(1+a_1)(2+a_2) + \gamma k_7(1+2a_2)]/a_1(1+a_2).$$

Then, (1.1), (1.2), (2.1) *possess a unique solution, which is globally asymptotically stable if*

$$\phi^2 \geqq 2(\mu/S_\Omega)^2 K[pS_\Omega/\mu\rho_1 + 2^{-1/p}K]/G(\delta_1),$$

where δ_1 *is the unique solution of*

$$(1-\delta_1)/\sqrt{2G(\delta_1)} = (1+D/2\rho_2)^{p-1}\sqrt{(1+p/\sigma\rho_1)/G(\delta)}, \qquad 0 < \delta_1 < 1,$$

the constants ρ_1, ρ_2, *and* D *are as in Lemma* A.4, *and*

$$K = [\gamma - 2 + \lambda V_\Omega + \sqrt{(\gamma + \lambda V_\Omega)^2 + 4\gamma\lambda k_7 V_\Omega}]/2. \tag{4.61}$$

Remark. If $\gamma \leqq 2$ or if $\delta \geqq 1$, then the conclusion of the theorem is true for all $\phi^2 > 0$, according to Theorem 4.2.

Proof. If $\phi^2 G(\delta)\exp(\gamma-\gamma/v_*)\geqq\sigma(\sigma+p/\rho_1)$, then $u_*\leqq u^*\leqq\delta$ (Lemma A.3) and, as in the proof of Theorem 4.3, $\xi=1/v_*-1/v^*$ is seen to satisfy

$$\xi\leqq a_1(1+2a_2)\delta[1-\exp(-k_7\gamma\xi)]/[1+a_1(1-\delta)]\max\{1,1+a_1(1-\delta-a_2\delta)\}.$$

This inequality cannot hold for any $\xi>0$ if δ is given by (4.60). Therefore, $\xi=0$ (i.e., $v_*=v^*$), $u_*=u^*$ (Lemma A.1) and the conclusion of the theorem follows.

If $\phi^2 G(\delta)\exp(\gamma-\gamma/v_*)<\sigma(\sigma+p/\rho_1)$, then $u_m^*=\min\{u^*(x): x\in\partial\Omega\}$ satisfies (4.53) (Lemma A.4). As in the proof of Theorem 4.4, this implies that u^* satisfies (4.54). Then u_m^* and $u_M^*=\max\{u^*(x): x\in\partial\Omega\}$ are seen to satisfy (4.55), (4.56), where Λ_* is given again by (4.57), and K satisfies (4.59) again. In addition, u_* and u^* satisfy (4.28) (Lemma A.2). Then B_* and B^*, which are defined by

$$B_*=1-\lambda\int_\Omega(u^*-u_*)\,dx+\mu^{-1}\sigma\int_{\partial\Omega}(1-u^*)\,ds,$$

$$B^*=1+\mu^{-1}\sigma\exp(\gamma\xi)\int_{\partial\Omega}(1-u^*)\,ds,$$

satisfy

$$0\leqq B^*-B_*\leqq\lambda\int_\Omega(u^*-u_*)\,dx+(B^*-1)[1-\exp(-\gamma\xi)],$$
$$B_*\geqq 1+K-\lambda V_\Omega,\quad B^*\geqq 1+K, \tag{4.62}$$

as it comes out from (4.56), (4.59). Also, $B_*\leqq v_*$ and $B^*\geqq v^*$ (see (4.5), (4.6), (4.21)). Hence, $\xi=1/v_*-1/v^*\leqq(B^*-B_*)/B_*B^*$ satisfies

$$\xi\leqq[1-\exp(-\gamma\xi)]/(1+K-\lambda V_\Omega)+\lambda V_\Omega[1-\exp(-k_7\gamma\xi)]/(1+K)(1+K-\lambda V_\Omega),$$

as obtained from (4.28), (4.62). But this inequality cannot hold for any $\xi>0$ if K is given by (4.61), as it is easily seen. Therefore $\xi=0$ and the conclusion of the theorem follows.

Finally, since the steady-state solutions of (1.1), (1.2) do not depend on the parameter λ, the following corollary is true.

COROLLARY 4.6. *If, for some $\lambda>0$, the hypothesis of one of the Theorems* 4.1-4.5 *hold, then* (1.1), (1.2) *has a unique steady state.*

5. Concluding remarks. A sequence of nested, globally finitely attracting, invariant regions of the phase space of (1.1), (1.2), (2.1), converging to an invariant, globally asymptotically stable region, has been obtained in § 3. In § 4, some quantitative sufficient conditions (ϕ^2 sufficiently large or small, or g increasing and γ sufficiently small) for global asymptotic stability of the steady state have been obtained, for a kinetic function f of the type $f(u,v)=g(u)\exp(\gamma-\gamma/v)$. Some of the results, which were not uniformly valid in $0<\lambda<\infty$ if γ is too large, have been explained by comparison with linear stability results that were obtained in [2]. Of course, similar results to those of § 4 may be obtained for any kinetic function satisfying assumption (H.2), such as that in (1.6).

The results of § 3 remain valid when the Robin type of boundary data is replaced by Dirichlet boundary data ($u=1$ on $\partial\Omega$), and $\sigma\int_{\partial\Omega}(1-u)\,ds$ is replaced by $\int_{\partial\Omega}(\partial u/\partial n)\,ds$ everywhere. To see that, a unit order (see, e.g., Amann [26]) must be used to replace the definition of the order relation $\ll$ at the end of § 1 by $u_1\ll u_2$ means that there is a positive constant c such that $u_1(x)+ce(x)\leqq u_2(x)$ for all $x\in\Omega$, where the unit e is defined by $\Delta e+1=0$ in Ω, $e=0$ on $\partial\Omega$. Such order definition could have been used in § 3 to obtain results for both Robin and Dirichlet problems at the same time, although it has not been done for the sake of clarity.

Growth restrictions on the function f are not necessary for the ideas of § 3 to apply. The assumption $f_v(u, v) > 0$ has been imposed because it is satisfied by the most commonly used kinetic functions (i.e., by those in (1.4)-(1.6)), but it could be removed; then the definition of the sequence (3.1)-(3.7) should be changed somewhat.

The ideas of this paper are naturally extended if: (a) the Laplacian operator Δ is replaced by a uniformly strongly elliptic operator; (b) the function f and/or the boundary data depend on the space variable x; or (c) the linear boundary conditions in (1.1) are replaced by appropriate nonlinear ones. They apply also to some more general reaction-diffusion problems, such as the nonisothermal model (1.1), (1.3) (this point is currently under research). Nevertheless, (1.1), (1.2) has been considered first because such isothermal model (a) has practical interest in itself (not only as a limit of (1.1), (1.3)), as was explained in the Introduction, and (b) it retains the main intrinsic difficulty of (1.1), (1.3), namely, the flow defined by (1.1), (1.2) is not monotone. Also, global stability results for (1.1)-(1.2) may be (and have been) compared with local stability results, which were obtained in [2] for the slab geometry and first-order Arrhenius kinetics.

Appendix. Let us consider the elliptic semilinear problem

$$\Delta u = \Lambda g(u) \quad \text{in } \Omega, \qquad \partial u/\partial n = \sigma(1-u) \quad \text{on } \partial\Omega, \tag{A.1}$$

where $\Lambda \geqq 0$, $\sigma > 0$, $\Omega \subset \mathbf{R}^p$ ($p = 1$, 2, or 3) satisfies assumption (H.1) and the C^1-function g satisfies (4.2).

LEMMA A.1. *Under the assumptions above*:

A. *The problem* (A.1) *possesses a minimal and a maximal solution,* $\underline{u}$, $\tilde{u} \in C^2(\bar{\Omega})$ *such that*

$$0 \ll \underline{u} \leqq \tilde{u} \ll 1. \tag{A.2}$$

B. *The solution of* (A.1) *is unique if* $0 \leqq \Lambda < \alpha/k_1 \leqq \infty$, *where* $\alpha > 0$ *is the smallest eigenvalue of* (2.2), *and* k_1 *is given by* (4.9). *Furthermore, if* u_1 *and* u_2 *are the solutions of* (A.1) *for* $\Lambda = \Lambda_1$ *and for* $\Lambda = \Lambda_2$ *with* $0 \leqq \Lambda_2 < \Lambda_1 < \alpha/k_1 \leqq \infty$, *then*

$$0 \ll u_2 - u_1 \leqq k_2[k_3 + k_4\Lambda_1 k_1/(\alpha - \Lambda_1 k_1)](\Lambda_1 - \Lambda_2), \tag{A.3}$$

where

$$k_2 = \max\{g(u): 0 \leqq u \leqq 1\}, \quad k_3 = \max\{\psi_1(x): x \in \bar{\Omega}\}, \quad k_4 = \max\{\psi_2(x): x \in \bar{\Omega}\},$$

$\psi_1 \gg 0$ *is the unique solution of*

$$\Delta\psi_1 + 1 = 0 \quad \text{in } \Omega, \qquad \partial\psi_1/\partial n + \sigma\psi_1 = 0 \quad \text{on } \partial\Omega,$$

and ψ_2 *is any eigenfunction of* (2.2) *such that* $\psi_2 \geqq \psi_1$.

Proof. A. For the existence of the minimal and maximal solutions of (A.1) see, e.g., [13], [14], or [20]. Inequalities (A.2) follow by standard arguments, using maximum principles.

B. Since the function $u \to g(u) + k_1 u$ is nondecreasing in $0 \leqq u \leqq 1$, $U = \tilde{u} - \underline{u}$ satisfies

$$\Delta U + \Lambda k_1 U \geqq 0 \quad \text{in } \Omega, \qquad \partial U/\partial n + \sigma U = 0 \quad \text{on } \partial\Omega. \tag{A.4}$$

Then, if $\Lambda k_1 < \alpha$, the generalized maximum principle (see [17]) shows that $U \leqq 0$. Therefore, $\underline{u} = \tilde{u}$ and the solution of (A.1) is unique.

Since the smallest eigenvalue of (2.2) depends continuously on the parameter σ (see, e.g., [22]), one may choose $\varepsilon > 0$ sufficiently small for the smallest eigenvalue of

$$\Delta\psi + \alpha_1\psi = 0 \quad \text{in } \Omega, \qquad \partial\psi/\partial n + (\sigma - \varepsilon)\psi = 0 \quad \text{on } \partial\Omega, \tag{A.5}$$

α_1, to be such that $k_1\Lambda_1 \leqq \alpha_1$. Then if $\psi \gg 0$ is an eigenfunction of (A.5), $U = (u_2 - u_1)/\psi$ satisfies

$$\psi \Delta U + 2\nabla\psi \cdot \nabla U \leqq \Lambda_1[g(u_2) - g(u_1)] + \alpha_1(u_2 - u_1) \quad \text{in } \Omega, \qquad \partial U/\partial n + \varepsilon U = 0 \quad \text{on } \partial\Omega.$$

Then, standard maximum principles show that $U \gg 0$, i.e., that $u_2 \gg u_1$.

Finally, $U = u_2 - u_1 - (\Lambda_1 - \Lambda_2)k_2[\psi_1 + \Lambda_1 k_1 \psi_2/(\alpha - \Lambda_1 k_1)]$ is easily seen to satisfy (A.4) with $\Lambda = \Lambda_1$. Therefore, $U \leqq 0$ and the second inequality (A.3) readily follows.

Remark. If $g'(u) \geqq 0$ for all $u \in [0, 1]$, then $k_1 = 0$, the solution of (A.1) is unique for all $\Lambda \geqq 0$ and inequalities (A.3) become $0 \ll u_2 - u_1 \leqq k_2 k_3(\Lambda_1 - \Lambda_2)$. Under an additional mild assumption on the function g, the following lemma provides another upper bound to $u_2 - u_1$, which is stronger than that above when Λ_2 is large.

LEMMA A.2. *In addition to the assumptions of Lemma* A.1, *let us assume that*

$$k_7 = \sup\{g(u)/ug'(u) : 0 < u \leqq 1\} < \infty. \tag{A.6}$$

Let u_1 and u_2 be the solutions of (A.1) *for $\Lambda = \Lambda_1$ and $\Lambda = \Lambda_2$ with $0 \leqq \Lambda_2 < \Lambda_1 < \infty$. Then*

$$0 \ll u_2 - u_1 \leqq [1 - (\Lambda_2/\Lambda_1)^{k_7}] \max\{u_2(x) : x \in \bar{\Omega}\}.$$

Remark. Assumption (A.6) implies that $g'(u) > 0$ for all $0 < u \leqq 1$. Although the converse is not true in general, it is true if, for example, the function $u \to g'(u)$ is nondecreasing in a neighborhood of $u = 0$, as is the case for most commonly used kinetic functions (e.g., for those given in (1.4), (1.5)).

Proof. $U = u_2 - u_1 \gg 0$ satisfies

$$\Delta U = \Lambda_2 g(u_2) - \Lambda_1 g(u_1) \quad \text{in } \Omega, \qquad \partial U/\partial n + \sigma U = 0 \quad \text{on } \partial\Omega.$$

Let x_0 be a point (not necessarily unique) where the maximum of U is attained. Since $\sigma > 0$ and $U(x_0) > 0$, x_0 cannot be a point of $\partial\Omega$. Then, $\Delta U \leqq 0$ at $x = x_0$ and

$$\Lambda_2/\Lambda_1 \leqq g(u_1(x_0))/g(u_2(x_0)) \leqq [u_1(x_0)/u_2(x_0)]^{1/k_7},$$

where the second inequality is easily obtained when using (A.6) (the function $u \to g(u)/u^{1/k_7}$ is nondecreasing). Then the conclusion of the lemma readily follows.

Let us assume now that the function g is such that there exists a constant a, $0 < a \leqq 1$, satisfying

$$g'(u) > 0 \quad \text{for all } 0 < u \leqq a, \qquad g(a) < g(u) \quad \text{for all } a < u \leqq 1, \tag{A.7}$$

$$k_8 = \sup\{g(u)/ug'(u) : 0 < u \leqq a\} < \infty. \tag{A.8}$$

Then, we have the following.

LEMMA A.3. *Let us assume that, in addition to the hypothesis of Lemma* A.1, (A.7) *holds. If*

$$\Lambda G(a) \geqq \sigma(\sigma + p/\rho_1) \tag{A.9}$$

then (A.1) *has a unique solution, $u = u(x)$, which satisfies*

$$\Lambda G(u(x)) \leqq \sigma(\sigma + p/\rho_1) \quad \textit{for all } x \in \bar{\Omega}, \tag{A.10}$$

where ρ_1 is defined in the interior sphere property (*assumption* (H.1); *see Introduction*), *and $G : [0, 1] \to \mathbf{R}$ is the strictly increasing function*

$$G(u) = \int_0^u g(z)\, dz. \tag{A.11}$$

If, in addition, (A.8) *holds and if* u_1 *and* u_2 *are the solutions of* (A.1) *for* $\Lambda=\Lambda_1$ *and* $\Lambda=\Lambda_2$, *where* Λ_1 *and* Λ_2 *satisfy* (A.9) *and* $\Lambda_2<\Lambda_1<\infty$, *then*

$$0 \ll u_2-u_1 \leqq [1-(\Lambda_2/\Lambda_1)^{k_8}] \max\{u_2(x): x\in\bar{\Omega}\}. \tag{A.12}$$

Proof. Let $u=u(x)$ be a solution of (A.1) and let x_0 be a point (not necessarily unique) of $\bar{\Omega}$ where the maximum of u, $u_M=\max\{u(x): x\in\bar{\Omega}\}$, is attained. $x_0\in\partial\Omega$ because otherwise $\Delta u(x_0)>0$. Let $S_1\subset\Omega$ be the hypersphere, of radius ρ_1, that is tangent to $\partial\Omega$ at x_0. We consider the problem

$$\Delta w=\Lambda g_1(w) \quad \text{in } S_1, \qquad w=u_M \quad \text{on } \partial S_1, \tag{A.13}$$

where the C^1-function $g_1:[0,1]\to\mathbf{R}$ is such that $g_1(u)=g(u)$ for $0\leqq u\leqq a$, $g_1'(u)>0$ for $a<u\leqq 1$. Problem (A.13) has a unique solution (Lemma A.1), which is spherically symmetric (Gidas et al. [27]), and given by

$$r^{1-p}\,d[r^{p-1}\,dw/dr]/dr\equiv d^2w/dr^2+(p-1)r^{-1}\,dw/dr=\Lambda g_1(w) \quad \text{in } 0<r<\rho_1, \tag{A.14}$$

$$dw/dr=0 \quad \text{at } r=0, \qquad w=u_M \quad \text{at } r=\rho_1, \tag{A.15}$$

where $r=\overline{x_1x}$ and x_1 is the center of S_1. Furthermore, the solution of (A.13) satisfies $w(x)\geqq u(x)$ for all $x\in S_1$, as it is easily seen by means of maximum principles. Hence

$$\sigma(1-u_M)=(\partial u/\partial n)_{x=x_0}\geqq(dw/dr)_{r=\rho_1}. \tag{A.16}$$

On the other hand, integration of (A.14), (A.15) yields

$$r^{p-1}\,dw/dr=\Lambda\int_0^r z^{p-1}g_1(w(z))\,dz. \tag{A.17}$$

Therefore, the function $r\to w(r)$ is strictly increasing and (A.17) yields $p\,dw/dr<\Lambda r g_1(w(r))$ for all $0<r\leqq\rho_1$. Hence, (A.14) implies that the function $r\to dw/dr$ is also strictly increasing, and (A.17) leads to

$$\begin{aligned}\rho_1^{p-1}(dw/dr)^2_{r=\rho_1} &> \Lambda\int_{\varepsilon\rho_1}^{\rho_1} z^{p-1}g_1(w(z))(dw/dz)\,dz\\ &> \Lambda(\varepsilon\rho_1)^{p-1}[G_1(u_M)-G_1(w(\varepsilon\rho_1))],\end{aligned} \tag{A.18}$$

for any real constant ε such that $0<\varepsilon<1$, where

$$G_1(u)=\int_0^u g_1(z)\,dz. \tag{A.19}$$

But, as it is seen from (A.17), (A.19),

$$\rho_1^{p-1}(dw/dr)_{r=\rho_1}>\Lambda g_1(w(\varepsilon\rho_1))\int_{\varepsilon\rho_1}^{\rho_1} z^{p-1}\,dz=\Lambda g_1(w(\varepsilon\rho_1))\rho_1^p(1-\varepsilon^p)/p, \tag{A.20}$$

$$G_1(w(\varepsilon\rho_1))<w(\varepsilon\rho_1)g_1(w(\varepsilon\rho_1))<u_M g_1(w(\varepsilon\rho_1)). \tag{A.21}$$

Equations (A.16), (A.18), (A.20)-(A.21) lead to the inequality

$$\Lambda G_1(u_M)<\sigma(1-u_M)[\varepsilon^{1-p}\sigma(1-u_M)+pu_M/\rho_1(1-\varepsilon^p)],$$

which is valid for $0<\varepsilon<1$. Then, when replacing ε^p by $1-u_M$, we obtain (recall that $0<u_M<1$)

$$\Lambda G_1(u_M)<\sigma(\sigma+p/\rho_1). \tag{A.22}$$

Since the function G_1 is strictly increasing and $G_1(u)=G(u)$ for $0\leqq u\leqq a$, if Λ satisfies (A.9), then (A.22) yields $u_M<a$, i.e., any solution of (A.1) satisfies

$$u(x)<a \quad \text{for all } x\in\bar{\Omega}. \tag{A.23}$$

Then, (A.1) has a unique solution, as it comes out when Lemma A.1 and maximum principles are applied and (A.7) and (A.23) are taken into account. Inequality (A.10) is readily obtained from (A.22).

Finally, (A.12) is obtained by the argument of the proof of Lemma A.2, when taking into account that u_1 and u_2 satisfy (A.23).

LEMMA A.4. *In addition to the assumptions of Lemma* A.1, *let us assume that* $g'(u)>0$ *for all* $0<u\leqq 1$, *and let* $u=u(x)$ *be the (unique) solution of* (A.1) *for a given value of* $\Lambda>0$. *Then,* $u_M=\max\{u(x): x\in\partial\Omega\}=\max\{u(x): x\in\bar{\Omega}\}$, and $u_m=\min\{u(x): x\in\partial\Omega\}$ *satisfy*

$$\sigma(1-u_M)>\Lambda G(u_M)/[p/\rho_1+\sqrt{(p/\rho_1)^2+2^{1-1/p}\Lambda G(u_M)}], \tag{A.24}$$

$$\sigma(1-u_m)<(1+D/2\rho_2)^{p-1}\sqrt{2\Lambda G(u_m)}, \tag{A.25}$$

where ρ_1 *and* ρ_2 *are defined in the interior and exterior sphere properties (assumption* (H.1); *see Introduction), D is the diameter of* Ω *and the strictly increasing function* $G:[0,1]\to\mathbf{R}$ *is defined by* (A.11).

Proof. The argument that led to (A.21) in the proof of Lemma A.3 shows that u_M satisfies

$$\Lambda G(u_M)<\sigma(1-u_M)[\varepsilon^{1-p}\sigma(1-u_M)+pu_M/\rho_1(1-\varepsilon^p)]$$

for all $0<\varepsilon<1$. Then, if $\varepsilon^p=\frac{1}{2}$ (A.24) is readily obtained.

Let $x_0\in\partial\Omega$ be a point (not necessarily unique) where u_m is attained. Let S_2 be the hypersphere of radius ρ_2, tangent to $\partial\Omega$ at x_0 to which the exterior sphere property refers. Let x_2 be the center of S_2 and let S be the hypersphere of center at x_2 radius ρ_2+D. Then $\Omega\subset S-\bar{S}_2$. Let $w:\bar{S}-S_2\to\mathbf{R}$ be defined by

$$\Delta w=\Lambda g(w) \quad \text{in } S-\bar{S}_2, \qquad w=u_m \quad \text{on } \partial(S-\bar{S}_2). \tag{A.26}$$

Problem (A.26) possesses a unique solution, which is spherically symmetric, and given by

$$\begin{aligned} r^{1-p}\,d[r^{p-1}\,dw/dr]/dr&=\Lambda g(w) \quad \text{in } \rho_2<r<\rho_2+D,\\ w&=u_m \quad \text{at } r=\rho_2 \text{ and } r=\rho_2+D \end{aligned} \tag{A.27}$$

where $r=\overline{x_2x}$. To see this, observe that (A.27) has (at least) a solution (see, e.g., Keller [13]), and that (A.26) has (at most) one solution (Lemma A.1).

The (unique) solution of (A.26) satisfies (apply maximum principles)

$$0<w(x)<u_m \quad \text{for all } x\in S-\bar{S}_2, \qquad w(x)\leqq u(x) \quad \text{for all } x\in\bar{\Omega}.$$

Hence

$$-(dw/dr)_{r=\rho_2}\geqq(\partial u/\partial n)_{x=x_0}=\sigma(1-u_m). \tag{A.28}$$

On the other hand, let $r_1>\rho_2$ be the smallest value of r where $dw/dr=0$. Since $r_1\leqq\rho_2+D/2$ (see Gidas et al. [27]), when (A.27) is multiplied by $r^{2p-2}\,dw/dr$ and the resulting equation is integrated between ρ_2 and r_1, we obtain

$$\begin{aligned} [\rho_2^{p-1}(dw/dr)_{r=\rho_2}]^2&=-2\Lambda\int_{\rho_2}^{r_1}r^{2p-2}g(w(r))(dw/dr)\,dr\\ &\leqq 2\Lambda r_1^{2p-2}\int_{w_1}^{u_m}g(w)\,dw<2\Lambda(\rho_2+D/2)^{2p-2}G(u_m) \end{aligned} \tag{A.29}$$

where $w_1=w(r_1)>0$. Then (A.25) readily follows from (A.28), (A.29), taking into account that $(dw/dr)_{r=\rho_2}<0$.

TRANSPORT EQUATIONS WITH SECOND-ORDER DIFFERENTIAL COLLISION OPERATORS*

CHRIS COSNER†, SUZANNE M. LENHART‡, AND VLADIMIR PROTOPOPESCU§

Abstract. This paper discusses existence, uniqueness, and a priori estimates for time-dependent and time-independent transport equations with unbounded collision operators. These collision operators are described by second-order differential operators resulting from diffusion in the velocity space. The transport equations are degenerate parabolic-elliptic partial differential equations, that are treated by modifications of the Fichera–Oleinik–Radkevic Theory of second-order equations with nonnegative characteristic form. We consider weak solutions in spaces that are extensions of L^p to include traces on certain parts of the boundary. This extension is necessary due to the nonclassical boundary conditions imposed by the transport problem, which requires a specific analysis of the behavior of our weak solutions.

Key words. transport equations, electron scattering, degenerate parabolic-elliptic PDE, traces

AMS(MOS) subject classifications. 35K65, 82A70

1. Introduction. Recently, an abstract theory of the time-dependent transport equations has been given [4], covering a fairly large number of possible applications. The transport equations in [4] are first-order partial differential equations, with general time-dependent phase spaces, boundary conditions, and transport operators (irrespective of dimensionality), and they are analyzed largely by the method of characteristics. In the present article, we consider transport equations with unbounded collision operators, that are described by second-order differential operators resulting from diffusion in the velocity space. Clearly the method of characteristics does not work for these equations which are of degenerate parabolic-elliptic type. Instead we use the theory of second-order equations with nonnegative characteristic form developed by Fichera and Oleinik and Radkevic [10]. Our analysis extends that of [10] by giving a more careful discussion of boundary values of weak solutions. This extension is necessary due to the nonclassical boundary conditions imposed by the transport problem.

The results of [4] are quite general. The major limitation of the theory presented in [4] is related to the collision part of the transport operator. Namely, (i) the collision operator is assumed to be separable into a sum of two operators describing the "in" and "out" scattering, respectively, and (ii) the "out" operator is required to be a bounded operator. The second assumption allows them to consider the transport operators as a bounded perturbation of a first-order differential operator derived from a real vector field. Accordingly, the strategy to obtain the existence and uniqueness results in [4] was to use the method of characteristics for the vector field and a perturbative approach for the full transport operator. Obviously, this strategy fails when the collision operator is not bounded with respect to the vector field. This happens to be the case in several important physical problems such as Brownian motion [6]

and electron scattering [5], in which collisions are characterized by very small deflection angles. Mathematically, these collisions are described by second-order differential operators accounting for diffusion in the velocity space. Since the collision operator acts only on the velocity variable, this leads to a special type of partial differential equation known as degenerate parabolic-elliptic or ultraparabolic [9].

For one-dimensional systems in the absence of external forces, the Hilbert space theory of the stationary transport equations with second-order differential collision operators has been recently developed to a quite satisfactory general level [1], [2]. Under certain regularity assumptions, the existence and uniqueness results for one-dimensional time-dependent problems follow immediately from the corresponding stationary theory (see [3], [7]). Since the results of [3] are based on (half-range) eigenfunction expansions, they appear to be limited to one-dimensional geometries, which allow for the separation of spatial and velocity variables in the streaming term of the transport equation.

The aim of this paper is to extend the existence and uniqueness theory for transport equations with second-order differential collision operators to a more general setting than considered previously. In § 2, we shall consider the existence of weak solutions, under boundary conditions of classical type, in L^P spaces, $1<p<\infty$. Time will not be singled out as in ordinary evolution problems, but rather treated together with position and velocity, which will allow inclusion of noncylindrical phase spaces and time-dependent transport operators.

In this paper, only bounded phase spaces have been considered, which leaves out the Fokker–Planck equation but includes the electron scattering equation. Existence theory in the spirit of Theorem 2.4 is probably feasible, even for unbounded domains, at the expense of extra technicalities. Much of the existence theory proceeds by duality arguments which single out L^1 as a distinct case. At this stage, it is not clear how to include it in the analysis.

Section 3 is devoted to the uniqueness issue. Since our definition of solution is rather weak, uniqueness is not always guaranteed. To recapture this feature, we have to strengthen the requirements on the solution. Some of these aspects of the uniqueness question are discussed in §§ 3 and 5. Section 4 extends the existence and uniqueness to include the case of general boundary conditions, encountered in transport problems.

In § 5, we construct a solution in a Hilbert space setting which provides uniqueness. A different Hilbert space setting also providing uniqueness is discussed in connection with recent results of Degond and Mas-Gallic [7] for the one-dimensional electron scattering problem.

2. Existence. In this section we shall discuss existence and a priori estimates for solutions of boundary value problems of classical type for transport equations with data in L^p. To be specific, we shall consider the operators

$$Lu \equiv \nabla_\xi \cdot \mu(\xi, x, t)\nabla_\xi u - \xi \cdot \nabla_x u + \xi \cdot \nabla_\xi u - \lambda u - \frac{\partial u}{\partial t} \tag{2.1}$$

and

$$L_0 u \equiv \nabla_\xi \cdot \mu_0(\xi, x)\nabla_\xi u - \xi \cdot \nabla_x u + \xi \cdot \nabla_\xi u - \lambda u \tag{2.2}$$

where $x \in \mathbb{R}^N$, $\xi \in \mathbb{R}^N$, $t \in \mathbb{R}$; ∇_ξ and ∇_x denote gradients taken with respect to ξ and x; μ and μ_0 are smooth, positive functions, and $\lambda > 0$ is a convenient positive constant. Due to the nature of the applications, we only consider first-order terms of the form shown in (2.1) and (2.2) (see the remarks at the end of this section for elaboration).

The problems we consider have the form $Lu = f$ in Ω with u specified on an appropriate subset of $\partial\Omega$ and similarly, $L_0 u = f$ on Ω_0 where Ω and Ω_0 are smooth, bounded domains in $\mathbb{R}^N \times \mathbb{R}^N \times \mathbb{R}$ and $\mathbb{R}^N \times \mathbb{R}^N$, respectively. Observe that we can change λ in (2.1) by replacing u with $\tilde{u} = e^{-\alpha t} u$ for any constant α; since we shall study L_0 as the operator obtained by taking a given L and omitting the $\partial/\partial t$ term, we also have no essential loss of generality by taking a convenient choice of λ in L_0.

To describe the appropriate parts of the boundary of Ω or Ω_0 on which to specify boundary data, we shall use some ideas from the theory of second-order partial differential equations with nonnegative characteristic form. The ideas we use are modifications of those that were developed by G. Fichera and which are discussed in detail in the book of Oleinik and Radkevic [10]. Our modifications consist primarily of more detailed and, in some cases, more delicate analyses of the behavior of weak solutions on the boundary of domain. The extra information about the boundary values of our weak solutions will be used in § 4 to treat certain boundary conditions occurring from transport problems which are nontypical for second-order equations. Since our methods are the same for L and L_0, we give a detailed analysis only for L.

The notation used in [10] is somewhat different from that sometimes used in discussions of transport problems, such as [4]. The differences in notation reflect an interest focussed on different aspects of the operators L and L_0 and their physical interpretation. We shall give a brief discussion of how they are related and then state most of our results in the notation of [4], which emphasizes the *transport* character of L and L_0.

Suppose that $\Omega \subseteq \mathbb{R}^N \times \mathbb{R}^N \times \mathbb{R}$ is a bounded domain with $\partial\Omega$ of class $C^{2,\alpha}$. We shall denote points of $\bar{\Omega}$ by (x, ξ, t). If $(x, \xi, t) \in \partial\Omega$, let $n(x, \xi, t) \in \mathbb{R}^N \times \mathbb{R}^N \times \mathbb{R}$ denote the *inner* normal to $\partial\Omega$ at (x, ξ, t). It will be convenient to write $n = (n_x, n_\xi, n_t)$ with $n_x \in \mathbb{R}^N$, $n_\xi \in \mathbb{R}^N$, and $n_t \in \mathbb{R}$. Following Fichera as presented in [10], we divide $\partial\Omega$ into four subsets. Let $\Sigma_3 = \{(x, \xi, t) \in \partial\Omega\colon n_\xi(x, \xi, t) \neq 0\}$. The set Σ_3 is the noncharacteristic part of $\partial\Omega$. Applying the definition given in [10] for general second-order operators to the specific operator L, let $b(x, \xi, t) = -\xi \cdot n_x + \xi \cdot n_\xi - n_t$ denote the Fichera function for L. Let

$$\Sigma_0 = \{(x, \xi, t) \in \partial\Omega \backslash \Sigma_3\colon b(x, \xi, t) = 0\},$$
$$\Sigma_1 = \{(x, \xi, t) \in \partial\Omega \backslash \Sigma_3\colon b(x, \xi, t) > 0\},$$
$$\Sigma_2 = \{(x, \xi, t) \in \partial\Omega \backslash \Sigma_3\colon b(x, \xi, t) < 0\}.$$

It can be shown that Σ_0, Σ_1, Σ_2, and Σ_3 are invariant under smooth nondegenerate changes of coordinates. If L^* denotes the formal adjoint of L, then the noncharacteristic part of $\partial\Omega$ for L^* is the same as for L; that is, $\Sigma_3(L^*) = \Sigma_3(L)$. On $\partial\Omega \backslash \Sigma_3$, applying the definition of [10] to L^* gives $b^* = -b$ where b^* is the Fichera function for L^*.

We now give the correspondence between some of the transport theory notation used in [4] and the notation of [10]. Let $D^+ = \Sigma_1$, $D^- = \Sigma_2$; let $d\nu^+$ denote the positive measure on D^+ given by $d\nu^+ = b\,d\sigma$ where $d\sigma$ the surface measure on $\partial\Omega$, and let $d\nu^- = -b\,d\sigma$ on D^-.

Our definition of weak solutions to boundary value problems for L and L_0 and our a priori estimates on these solutions are based on the following form of Green's identity: let $u, v \in C^2(\bar{\Omega})$; then

$$\int_\Omega (vLu - uL^*v)\,dx\,d\xi\,dt = -\int_{\Sigma_3} [vn_\xi \cdot \nabla_\xi u - un_\xi \cdot \nabla_\xi v]\mu\,d\sigma - \int_{\partial\Omega} buv\,d\sigma. \tag{2.3}$$

This is essentially formula (1.1.14) of [10]. If we require $u = v = 0$ on Σ_3 and use the notation of [4] we have the following lemma.

LEMMA 2.1. *Suppose* $u, v \in C^2(\bar{\Omega})$ *with* $u = v = 0$ *on* Σ_3. *Then*

$$\int_\Omega (vLu - uL^*v)\, dx\, d\xi\, dt = \int_{D^-} uv\, d\nu^- - \int_{D^+} uv\, d\nu^+. \tag{2.4}$$

Lemma 2.1 follows immediately from formula (1.1.14) of [10]. Formula (2.4) is closely related to formula (2.20) of [4]. (Note that in [4], $Y \simeq -L$ and formally $-Y^* = Y$; this accounts for the apparent sign difference between the two formulas.)

We can now state the basic problem considered in this section and give an appropriate weak formulation of the problem. We wish to solve

$$\begin{aligned} Lu &= f \quad \text{in } \Omega, \\ u &= 0 \quad \text{on } \Sigma_3, \\ u &= g \quad \text{on } D^- \end{aligned} \tag{2.5}$$

where we shall require $f \in L^p(\Omega)$, $g \in L^p(D^-, d\nu^-)$. Observe that if u is a classical solution of (2.5) then for any $v \in C^2(\bar{\Omega})$ with $v = 0$ on Σ_3 we have via (2.4) that

$$\int_\Omega (uL^*v)\, dx\, d\xi\, dt - \int_{D^+} uv\, d\nu^+ = \int_\Omega vf\, dx\, d\xi\, dt - \int_{D^-} vg\, d\nu^-. \tag{2.6}$$

To give a precise definition for the types of boundary data and weak solutions that we consider, we must first define certain spaces. Let

$$\begin{aligned} E^p &= L^p(\Omega, dx\, d\xi\, dt) \times L^p(D^+, d\nu^+) \times L^p(D^-, d\nu^-), \\ E_1^p &= L^p(\Omega, dx\, d\xi\, dt) \times L^p(D^+, d\nu^+) \times \{0\}, \\ E_2^p &= L^p(\Omega, dx\, d\xi\, dt) \times \{0\} \times L^p(D^-, d\nu^-), \end{aligned}$$

with norms

$$\|(u, u^+, u^-)\|_{E^p} = (\|u\|^p_{L^p(\Omega)} + \|u^+\|^p_{L^p(D^+, d\nu^+)} + \|u^-\|^p_{L^p(D^-, d\nu^-)})^{1/p}$$

and $\| \ \|_{E_1^p}$, $\| \ \|_{E_2^p}$ defined similarly. It is easy to see via the Riesz Representation Theorem (or its proof) that if $1 < p < \infty$ and $1/p + 1/q = 1$ then the dual spaces for E^p, E_1^p, and E_2^p are $E^{p*} = E^q$, $E_1^{p*} = E_1^q$, and $E_2^{p*} = E_2^q$.

Suppose $f \in L^p(\Omega)$ and $g \in L^p(D^-, d\nu^-)$.

DEFINITION. A weak solution of (2.5) in E^p is a triple $(u, u^+, u^-) \in E^p$ with $u^- = g$ such that

$$\int_\Omega uL^*v\, dx\, d\xi\, dt - \int_{D^+} u^+v^+\, d\nu^+ = \int_\Omega vf\, dx\, d\xi\, dt - \int_{D^-} v^-g\, d\nu^- \tag{2.7}$$

for all $v \in C^2(\bar{\Omega})$ with $v = 0$ on Σ_3, where $v^\pm = v|_{D^\pm}$.

Our objective in the remainder of this section will be to show that such weak solutions exist and satisfy certain a priori bounds. Specifically, it is crucial for the applications we consider to be able to control the L^p norm or u^+; our arguments are similar to those of [10] but are modified to allow us that control.

LEMMA 2.2. *Suppose that* $u \in C^2(\bar{\Omega})$ *with* $u = 0$ *on* Σ_3, *and* $1 < p < \infty$. *Then for* $\lambda > 0$

$$p\lambda \int_\Omega |u|^p\, dx\, d\xi\, dt + \int_{D^+} |u|^p\, d\nu^+ \leqq -p \int_\Omega |u|^{p-1} (\operatorname{sgn} u) Lu\, dx\, d\xi\, dt + \int_{D^-} |u|^p\, d\nu^- \tag{2.8}$$

and if we denote $u^+ = u|_{D^+}$ *and* $u^- = u|_{D^-}$, *then*

$$\lambda \|u\|^p_{L^p(\Omega)} + \|u^+\|^p_{L^p(D^+, d\nu^+)} \leqq \lambda^{1-p} \|Lu\|^p_{L^p(\Omega)} + \|u^-\|^p_{L^p(D^-, d\nu^-)}. \tag{2.9}$$

Proof. We follow the proof of Lemma 1.21 of [10], but do not require $u = 0^-$ on D^-. Applying (2.3) to the pair of functions $\{(u^2+\delta)^{p/2}, -1\}$ yields

$$\begin{aligned}\int_\Omega \lambda(u^2+\delta)^{p/2}\,dx\,d\xi\,dt + \int_\Omega L(u^2+\delta)^{p/2}\,dx\,d\xi\,dt \\ = -\int_{\Sigma_3} b(u^2+\delta)^{p/2}\,d\sigma + \int_{D^-}(u^2+\delta)^{p/2}\,d\nu^- - \int_{D^+}(u^2+\delta)^{p/2}\,d\nu^+.\end{aligned} \tag{2.10}$$

(Observe that since $u = 0$ on Σ_3, we have

$$\nabla_\xi (u^2+\delta)^{p/2} = (p/2)(u^2+\delta)^{(p/2-1)}(2u\nabla_\xi u) = 0 \quad \text{on } \Sigma_3;$$

since $v = -1$ is constant the first integral on the right side of (2.3) is zero.) A calculation yields

$$\begin{aligned}L(u^2+\delta)^{p/2} = p(u^2+\delta)^{p/2-1}uLu - \lambda(u^2+\delta)^{p/2-1}[(1-p)u^2+\delta] \\ + \mu(\xi, x, t)(\nabla_\xi u \cdot \nabla_\xi u)p(u^2+\delta)^{p/2-2}[(p-1)u^2+\delta];\end{aligned}$$

since the last term on the right is nonnegative and since $u = 0$ on Σ_3, we obtain from (2.10) the inequality

$$\begin{aligned}\int_\Omega \{\lambda(u^2+\delta)^{p/2} - \lambda(u^2+\delta)^{p/2-1}[(1-p)u^2+\delta]\}\,dx\,d\xi\,dt \\ + \int_\Omega p(u^2+\delta)^{p/2-1}uLu\,dx\,d\xi\,dt \leqq \delta^{p/2}\int_{\Sigma_3}|b|\,d\sigma + \int_{D^-}(u^2+\delta)^{p/2}\,d\nu^- \\ - \int_{D^+}(u^2+\delta)^{p/2}\,d\nu^+.\end{aligned}$$

Letting $\delta \to 0$ yields

$$p\lambda\int_\Omega |u|^p\,dx\,d\xi\,dt + p\int_\Omega |u|^{p-2}\,uLu\,dx\,d\xi\,dt \leqq \int_{D^-}|u|^p\,d\nu^- - \int_{D^+}|u|^p\,d\nu^+,$$

which is equivalent to (2.8). To obtain (2.9) from (2.8) we use Young's inequality, as in the proof of Proposition 4 in [4, § 3]: if $a, b > 0$ and $1 < p < \infty$, $1/p + 1/q = 1$, we have $ab \leqq a^p/p + b^q/q$. Applying the inequality with $a = \lambda^{-1/q}|Lu|$, $b = \lambda^{1/q}|u|^{p-1}$ and integrating over Ω yields

$$\begin{aligned}p\int_\Omega |u|^{p-1}|Lu|\,dx\,d\xi\,dt \leqq p\int_\Omega (\lambda^{-p/q}|Lu|^p/p)\,dx\,d\xi\,dt \\ + p\int_\Omega (\lambda^{q/q}|u|^{(p-1)q}/q)\,dx\,d\xi\,dt \\ = \lambda^{1-p}\|Lu\|^p_{L^p(\Omega)} + \lambda(p-1)\|u\|^p_{L^p(\Omega)}.\end{aligned}$$

Using the last inequality to estimate the first term on the right side in (2.8) and combining like terms yields (2.9). □

The same type of analysis may be applied to L^*. Noting that the sign of b changes and thus the role of D^+ and D^- are reversed for L^*, we have Lemma 2.3.

LEMMA 2.3. *Suppose that* $v \in C^2(\bar{\Omega})$ *with* $v = 0$ *on* Σ_3, *and* $1 < q < \infty$. *Then for* $\lambda > 0$,

$$q\lambda \int_\Omega |v|^q \, dx \, d\xi \, dt + \int_{D^-} |v|^q \, d\nu^- \leqq -q \int_\Omega |v|^{q-1} (\operatorname{sgn} v) L^* v \, dx \, d\xi \, dt + \int_{D^+} |v|^q \, d\nu^+ \tag{2.11}$$

and if $v^+ = v|_{D^+}$, $v^- = v|_{D^-}$, *then*

$$\lambda \|v\|^q_{L^q(\Omega)} + \|v^-\|^q_{L^q(D^-, d\nu^-)} \leqq \lambda^{1-q} \|L^* v\|^q_{L^q(\Omega)} + \|v^+\|^q_{L^q(D^+, d\nu^+)}. \tag{2.12}$$

We now turn to the question of existence of solutions to (2.5) in the sense of (2.7).

THEOREM 2.4. *Suppose that* $\lambda \geqq 1$, $1 < p < \infty$, $f \in L^p(\Omega)$, *and* $g \in L^p(D^-, d\nu^-)$. *Then* (2.5) *has a solution* $(u, u^+, u^-) \in E^p$ *in the sense of* (2.7) *with* $u^- = g$, *and that solution satisfies the estimate*

$$\inf_{(y,z,0) \in Z} [\|u + y\|^p_{L^p(\Omega)} + \|u^+ - z\|^p_{L^p(D^+, d\nu^+)}] \leqq \|f\|^p_{L^p(\Omega)} + \|g\|^p_{L^p(D^-, d\nu^-)} \tag{2.13}$$

where

$$Z = \left\{ (y, z, 0) \in E_1^p : \int_\Omega y L^* v \, dx \, d\xi \, dt + \int_{D^+} z v^+ \, d\nu^+ = 0 \right.$$
$$\left. \text{for all } v \in C^2(\bar{\Omega}) \text{ with } v = 0 \text{ on } \Sigma_3 \text{ and } v^+ = v|_{D^+} \right\}.$$

Remark. If $Z = \{0\}$, then (2.13) becomes

$$\|u\|^p_{L^p(\Omega)} + \|u^+\|^p_{L^p(D^+, d\nu^+)} \leqq \|f\|^p_{L^p(\Omega)} + \|g\|^p_{L^p(D^-, d\nu^-)}. \tag{2.14}$$

Conditions implying $Z = \{0\}$ are given in the next section. The dimension or "size" of the subspace Z measures the nonuniqueness of solutions in our sense in a given L^p class. That Z need not always be $\{0\}$ is illustrated in the next section via a counter example adapted from [10].

Proof. Let q be such that $1/p + 1/q = 1$. Since $\lambda \geqq 1$ it follows from (2.12) of Lemma 2.3 that for $v \in C^2(\bar{\Omega})$ with $v = 0$ on Σ_3 we have

$$\|(v, 0, v^-)\|^q_{E^q} \leqq \|(L^* v, v^+, 0)\|^q_{E^q} \quad \text{where } v^\pm = v|_{D^\pm}. \tag{2.15}$$

Let $\tilde{E}_1^q$ be the completion in E_1^q of the subspace $\{(L^* v, v^+, 0) : v \in C^2(\bar{\Omega}), v = 0 \text{ on } \Sigma_3\}$. If $(\varphi, \psi_1, 0) \in \tilde{E}_1^q$ then there must exist a sequence $v_n \in C^2(\bar{\Omega})$ with $v_n = 0$ on Σ_3 such that $(L^* v_n, v_n^+, 0) \to (\varphi, \psi_1, 0)$ in E_1^q (where $v_n^+ = v_n|_{D^+}$), so the sequence $\{(v_n, 0, v_n^-)\}$ with $v_n^- = v_n|_{D^-}$ is Cauchy in E_2^q by (2.15), and we obtain a uniquely defined limit $(\theta, 0, \psi_2) \in E_2^q$ satisfying

$$\|(\theta, 0, \psi_2)\|_{E_2^q} \leqq \|(\varphi, \psi_1, 0)\|_{E_1^q}. \tag{2.16}$$

Thus, the map $(L^* v, v^+, 0) \mapsto (v, 0, v^-)$ extends to a bounded linear map $G : \tilde{E}_1^q \to E_2^q$ with $\|G\| \leqq 1$. Suppose $(\varphi, \psi_1, 0) \in \tilde{E}_1^q$ with $G(\varphi, \psi_1, 0) = (\theta, 0, \psi_2)$. Define a linear functional F on $\tilde{E}_1^q$ as follows:

$$F(\varphi, \psi_1, 0) = \int_\Omega \theta f \, dx \, d\xi \, dt - \int_{D^-} \psi_2 g \, d\nu^-. \tag{2.17}$$

By Hölder's inequality, we have

$$\begin{aligned}|F(\varphi,\psi_1,0)| &\leqq \|\theta\|_{L^q(\Omega)}\|f\|_{L^p(\Omega)}+\|\psi_2\|_{L^q(D^-,d\nu^-)}\|g\|_{L^p(D^-,d\nu^-)}\\ &\leqq [\|\theta\|^q_{L^q(\Omega)}+\|\psi_2\|^q_{L^q(D^-,d\nu^-)}]^{1/q}[\|f\|^p_{L^p(\Omega)}+\|g\|^p_{L^p(D^-,d\nu^-)}]^{1/p}\\ &= \|(\theta,0,\psi_2)\|_{E_2^q}\|(f,0,g)\|_{E_2^p}\\ &= \|G(\varphi,\psi_1,0)\|_{E_2^q}\|(f,0,g)\|_{E_2^p}\\ &\leqq \|(\varphi,\psi_1,0)\|_{E_1^q}\|(f,0,g)\|_{E_2^p}.\end{aligned}$$

Thus, F is a bounded linear functional on $\tilde{E}_1^q$ with $\|F\|\leqq\|(f,0,g)\|_{E_2^p}$. Since $\tilde{E}_1^q$ is a closed subspace of E_1^q, it follows from the Hahn–Banach theorem that we may extend F to a functional $\hat{F}$ on all of E_1^q with $\|\hat{F}\|\leqq\|(f,0,g)\|_{E_2^p}$. In general, the extension $\hat{F}$ of F and the element of $E_1^p\cong E_1^{q*}$ associated with $\hat{F}$ are not unique. In fact, $\tilde{E}_1^{q*}$ can be identified with the factor space E_1^p/Z where

$$Z=\left\{(y,z,0)\in E_1^p\colon \int_\Omega y\varphi\,dx\,d\xi\,dt+\int_{D^+} z\psi_1 d\nu^+=0 \text{ for all } (\varphi,\psi_1,0)\in\tilde{E}_1^q\right\}.$$

Since $\tilde{E}_1^q$ is the closure of $\{(L^*v,v^+,0)\colon v\in C^2(\bar{\Omega}),\ v=0 \text{ on } \Sigma_3\}$, we may characterize Z as

$$Z=\left\{(y,z,0)\in E_1^p\colon \int_\Omega yL^*v\,dx\,d\xi\,dt+\int_{D^+} zv^+\,d\nu^+=0 \quad \text{for all } v\in C^2(\bar{\Omega}) \text{ with } v=0 \text{ on } \Sigma_3\right\}.$$

From the identification of $\tilde{E}_1^{q*}$ with E_1^p/Z it follows that F can be represented by a coset $[(u,w,0)+Z]\in E_1^p/Z$; that is, for $(\varphi,\psi_1,0)\in\tilde{E}_1^q$ and $(\theta,0,\psi_2)=G(\varphi,\psi_1,0)$ we have

$$\int_\Omega \theta f\,dx\,d\xi\,dt-\int_{D^-}\psi_2 g\,d\nu^-=F(\varphi,\psi_1,0)=\int_\Omega u\varphi\,dx\,d\xi\,dt+\int_{D^+} w\psi_1\,d\nu^+. \tag{2.18}$$

If $(\varphi,\psi_1,0)=(L^*v,v^+,0)$ for some $v\in C^2(\bar{\Omega})$ with $v=0$ on Σ_3, (2.18) becomes (taking $v^\pm=v|_{D^\pm}$)

$$\int_\Omega vf\,dx\,d\xi\,dt-\int_{D^-} v^-g\,d\nu^-=\int_\Omega uL^*v\,dx\,d\xi\,dt+\int_{D^+} wv^+\,d\nu^+. \tag{2.19}$$

If we let $u^+=-w$ and $u^-=g$, then (2.19) is equivalent to (2.7). Also, $\|F\|_{\tilde{E}_1^{q*}}\leqq\|(f,0,g)\|_{E_2^p}$, and since we may identify E_1^{q*} with the factor space E_1^p/Z it follows from the definition of the norm for a coset that

$$\inf_{(y,z,0)\in Z}\|(u,w,0)+(y,z,0)\|_{E_1^p}=\|F\|\leqq\|(f,0,g)\|_{E_2^p}. \tag{2.20}$$

By the definition of the norms on E_1^p and E_2^p, and using $u^+=-w$, (2.20) is equivalent to (2.13). □

The analysis for L_0 is essentially the same as that for L, so we shall only state the corresponding results. Suppose that $\Omega_0\subseteq\mathbb{R}^N\times\mathbb{R}^N$ is bounded with $\partial\Omega_0$ of class $C^{2,\alpha}$. Let $n(x,\xi)=(n_x,n_\xi)\in\mathbb{R}^N\times\mathbb{R}^N$ denote the inner unit normal at (x,ξ). Let

$$\Sigma_3^0=\{(x,\xi)\in\partial\Omega\colon n_\xi(x,\xi)\neq 0\} \quad \text{let } b_0=-\xi\cdot n_x+\xi\cdot n_\xi,$$

$$D_0^+=\{(x,\xi)\in\partial\Omega\backslash\Sigma_3^0\colon b_0(x,\xi)>0\},$$

$$D_0^-=\{(x,\xi)\in\partial\Omega\backslash\Sigma_3^0;\ b_0(x,\xi)<0\} \quad \text{and} \quad d\nu_0^\pm=\pm b_0\,d\sigma \quad \text{on } D_0^\pm.$$

Define the spaces

$$E_0^p = L^p(\Omega_0) \times L^p(D_0^+, d\nu_0^+) \times L^p(D_0^-, d\nu_0^-),$$
$$E_{01}^p = L^p(\Omega_0) \times L^p(D_0^+, d\nu_0^+) \times \{0\},$$
$$E_{02}^p = L^p(\Omega_0) \times \{0\} \times L^p(D_0^-, d\nu_0^-),$$

with norms as for E^p, E_1^p, and E_2^p. We are interested in solutions in E_0^p of

$$\begin{aligned} L_0 u &= f \quad \text{in } \Omega_0, \\ u &= 0 \quad \text{on } \Sigma_3^0, \\ u &= g \quad \text{on } D_0^- \end{aligned} \tag{2.21}$$

with $(f, 0, g) \in E_{02}^p$. Such solutions are defined as for (2.5); that is, $(u, u^+, u^-) \in E_0^p$ is a solution of (2.21) if $u^- = g$ and for every $v \in C^2(\bar{\Omega}_0)$ with $v = 0$ on Σ_3^0 we have

$$\int_{\Omega_0} u L_0^* v \, dx \, d\xi - \int_{D_0^+} u^+ v^+ \, d\nu_0^+ = \int_{\Omega_0} v f \, dx \, d\xi - \int_{D_0^-} v^- g \, d\nu_0^- \tag{2.22}$$

where $v^\pm = v|_{D_0^\pm}$.

Corresponding to our results for (2.5) we have the following lemma.

LEMMA 2.5. *Suppose that $u \in C^2(\bar{\Omega}_0)$ with $u = 0$ on Σ_3^0 and $1 < p < \infty$. Then for $\lambda > 0$,*

$$p\lambda \int_{\Omega_0} |u|^p \, dx \, d\xi + \int_{D_0^+} |u|^p \, d\nu_0^+ \leqq -p \int_{\Omega_0} |u|^{p-1} \operatorname{sgn}(u) L_0 u \, dx \, d\xi + \int_{D_0^-} |u|^p \, d\nu_0^-, \tag{2.23}$$

$$p\lambda \int_{\Omega_0} |u|^p \, dx \, d\xi + \int_{D_0^-} |u|^p \, d\nu_0^- \leqq -p \int_{\Omega_0} |u|^{p-1} \operatorname{sgn}(u) L_0^* u \, dx \, d\xi + \int_{D_0^+} |u|^p \, d\nu_0^+. \tag{2.24}$$

Moreover if we denote $u^\pm = u|_{D_0^\pm}$, then

$$\lambda \|u\|_{L^p(\Omega_0)}^p + \|u^+\|_{L^p(D_0^+, d\nu_0^+)}^p \leqq \lambda^{1-p} \|L_0 u\|_{L^p(\Omega_0)}^p + \|u^-\|_{L^p(D_0^-, d\nu_0^-)}^p \tag{2.25}$$

and

$$\lambda \|u\|_{L^p(\Omega_0)}^p + \|u^-\|_{L^p(D_0^-, d\nu_0^-)}^p \leqq \lambda^{1-p} \|L_0^* u\|_{L^p(\Omega_0)}^p + \|u^+\|_{L^p(D_0^+, d\nu_0^+)}^p. \tag{2.26}$$

Using the estimates of Lemma 2.5 yields the following existence result via essentially the same proof as that of Theorem 2.4.

THEOREM 2.6. *Suppose that $\lambda \geqq 1$, $1 < p < \infty$, $f \in L^p(\Omega_0)$, and $g \in L^p(D_0^-, d\nu_0^-)$. Then (2.21) has a solution $(u, u^+, u^-) \in E_0^p$ in the sense of (2.22) with $u^- = g$ and that solution satisfies the estimate*

$$\inf_{(y,z,0) \in Z_0} [\|u + y\|_{L^p(\Omega_0)}^p + \|u^+ - z\|_{L^p(D_0^+, d\nu_0^+)}^p] \leqq \|f\|_{L^p(\Omega_0)}^p + \|g\|_{L^p(D_0^-, d\nu_0^-)}^p \tag{2.27}$$

where

$$Z_0 = \left\{ (y, z, 0) \in E_{01}^p : \int_{\Omega_0} y L^* v \, dx \, d\xi + \int_{D_0^+} z v^+ \, d\nu^+ = 0 \right.$$
$$\left. \text{for all } v \in C^2(\bar{\Omega}) \text{ with } v = 0 \text{ on } \Sigma_3^0 \text{ and } v^+ = v|_{D_0^+} \right\}.$$

Remark. Again, if $Z_0 = \{0\}$, (2.27) becomes

$$\|u\|_{L^p(\Omega_0)}^p + \|u^+\|_{L^p(D_0^+, d\nu_0^+)}^p \leqq \|f\|_{L^p(\Omega_0)}^p + \|g\|_{L^p(D_0^-, d\nu_0^-)}^p. \tag{2.28}$$

As noted in the remarks following Theorem 2.4, Z_0 provides a measure of the nonuniqueness of our weak solutions.

In general, estimates of the type given in (2.14) or (2.28) are not quite strong enough to permit a free application of semigroup theory. A more careful analysis can provide somewhat sharper estimates in terms of λ when $g=0$, but those are not quite sufficient. To obtain a weak solution satisfying strong enough estimates we must return to the original formulation of weak solutions on L^p given in [10], and thereby relinquish some control over the boundary behavior of our solutions.

In the case $g=0$, if we return to the analysis following (2.17) we have

$$|F(\varphi,\psi_1,0)|\leqq\|\theta\|_{L^q(\Omega)}\|f\|_{L^p(\Omega)}\leqq[\lambda\|\theta\|^q_{L^q(\Omega)}]^{1/q}\lambda^{-1/q}\|f\|_{L^p(\Omega)}. \tag{2.29}$$

Since there exist $v_n\in C^2(\bar{\Omega})$ with $v_n=0$ on Σ_3 such that $(L^*v_n, v_n^+, 0)\to(\varphi,\psi_1,0)$ in E_1^q and $(v_n, 0, v_n^-)\to(\theta,0,\psi_2)$ in E_2^q, and since each v_n satisfies (2.12), we have

$$\lambda\|\theta\|^q_{L^q(\Omega)}+\|\psi_2\|^q_{L^q(D^-,d\nu^-)}\leqq\lambda^{1-q}\|\varphi\|^q_{L^q(\Omega)}+\|\psi_1\|^q_{L^q(D^+,d\nu^+)}$$

so that for $\lambda\geqq1$ (2.29) yields

$$\begin{aligned}|F(\varphi,\psi_1,0)|&\leqq[\lambda^{1-q}\|\varphi\|^q_{L^q(\Omega)}+\|\psi_1\|^q_{L^q(D^+,d\nu^+)}]^{1/q}\lambda^{-1/q}\|f\|_{L^p(\Omega)}\\&\leqq[\|\varphi\|^q_{L^q(\Omega)}+\|\psi_1\|^q_{L^q(D^+,d\nu^+)}]^{1/q}\lambda^{-1/q}\|f\|_{L^p(\Omega)}\end{aligned}$$

so that

$$|F(\varphi,\psi_1,0)|\leqq\|(\varphi,\psi_1,0)\|_{E_1^q}\lambda^{-1/q}\|f\|_{L^p(\Omega)}$$

and thus

$$\|F\|\leqq\lambda^{-1/q}\|f\|_{L^p(\Omega)}. \tag{2.30}$$

Using the bound (2.30) in the remainder of the proof of Theorem 2.4 allows us to replace (2.14) with the estimate

$$\|u\|^p_{L^p(\Omega)}+\|u^+\|^p_{L^p(D^+,d\nu^+)}\leqq\lambda^{-p/q}\|f\|^p_{L^p(\Omega)} \tag{2.31}$$

provided $\lambda\geqq1$, $g=0$, and $Z=\{0\}$. Similarly, if $\lambda\geqq1$, $Z_0=\{0\}$ and $g=0$ in Theorem 2.6, we may replace (2.28) with

$$\|u\|^p_{L^p(\Omega_0)}+\|u^+\|^p_{L^p(D_0^+,d\nu_0^+)}\leqq\lambda^{-p/q}\|f\|^p_{L^p(\Omega_0)}. \tag{2.32}$$

To apply semigroup theory to L_0 we would really want an estimate on $\|(u,u^+,0)\|_{E_{01}^p}$ of order $\lambda^{-1}\|f\|_{L^p(\Omega_0)}$. We can obtain an estimate on $\|u\|_{L^p(\Omega_0)}$ for certain weak solutions from the theory of [10], but only at the price of losing essentially all information about u^+, which largely defeats the purpose of the present article. Specifically, in [10] the L^p weak solutions for

$$\begin{aligned}&L_0u=f \quad \text{in } \Omega_0,\\&u=0 \quad \text{on } \Sigma_3^0,\\&u=0 \quad \text{on } D_0^+\end{aligned} \tag{2.33}$$

are required to satisfy

$$\int_{\Omega_0}uL_0^*v\,dx\,d\xi=\int_{\Omega_0}vf\,dx\,d\xi \tag{2.34}$$

for all $v\in C^2(\bar{\Omega})$ with $v=0$ on $\Sigma_3^0\cup D_0^+$. The following is essentially Theorem 1.3.1 of [10] specialized to L_0.

THEOREM 2.7. *Suppose that* $\lambda \geqq 1$, $1<p<\infty$, *and* $f \in L^p(\Omega_0)$. *Then* (2.33) *has a solution* $u \in L^p(\Omega_0)$ *in the sense of* (2.34) *and the solution satisfies the estimate*

$$\inf_{y \in \tilde{Z}_0} \|u+y\|_{L^p(\Omega_0)} \leqq \lambda^{-1} \|f\|_{L^p(\Omega_0)} \tag{2.35}$$

where

$$\tilde{Z}_0 = \left\{ y \in L^p(\Omega_0) : \int_{\Omega_0} y L_0^* v \, dx \, d\xi = 0 \text{ for all } v \in C^2(\bar{\Omega}) \text{ with } v = 0 \text{ on } \Sigma_0^3 \cup D_0^+ \right\}.$$

Remarks. In the situation where $\tilde{Z}_0 = \{0\}$ we have, from (2.35),

$$\|u\|_{L^p(\Omega_0)} \leqq \lambda^{-1} \|f\|_{L^p(\Omega_0)}. \tag{2.36}$$

Other types of possible weak solutions and conditions under which these solutions coincide are discussed at the end of the next section. Note however that since the test functions v in (2.34) are required to be zero on D_0^+, that formulation of a weak solution gives no information about the existence or properties of a trace u^+ for u on D_0^+.

We could replace the coefficients of the first-order terms in (2.1) by general (sufficiently smooth) functions. This replacement is necessary if one wishes to include the effects of external forces, via a term of the form $\nu(x, \xi, t) \nabla_\xi u$. The replacement of the other coefficients of the first-order terms is possible, but academic, as far as *transport* problems are concerned, since their significance is related to the vector field part of the transport equation. Either replacement changes only the actual form of the characteristic parts of the boundary and the corresponding results follow similarly.

3. Uniqueness. We now consider the question of uniqueness for the solutions obtained in Theorems 2.4 and 2.6. Clearly, the solutions obtained are unique if and only if $Z = \{0\}$ and $Z_0 = \{0\}$; and in that case the estimates (2.14) and (2.28) hold. To conclude uniqueness we must impose certain additional conditions on f, g, and Ω or Ω_0; that some type of additional hypotheses are needed is illustrated by a counterexample at the end of this section.

Suppose that $\partial\Omega$ is given locally by the equation $h(x, \xi, t) = 0$ with $(\nabla_x h, \nabla_\xi h, \partial h/\partial t) \neq 0$ and $h > 0$ inside Ω. Define $\beta^* \equiv L^* h$. At points of $\partial\Omega$ which lie in the interior of $\partial\Omega \backslash \Sigma_3$ (or at limits of sequences of such points) the sign of β^* agrees with that of $b^* = -b$, the Fichera function for L^* (see [10, p. 31]). Let Γ denote the boundary in $\partial\Omega$ of the set $D^- \cup \Sigma_0$. We have the following uniqueness result, which is a special case of Theorem 1.6.1 of [10].

LEMMA 3.1. *Suppose that* $\lambda > 0$ *and that* $\beta^* < 0$ *at points of* D^+. *Suppose that in some neighborhood of each of its points* Γ *lies on the intersection of the surface* $h(x, \xi, t) = 0$ *defining* $\partial\Omega$ *and a surface* $\Psi(x, \xi, t) = 0$ *with* h *and* Ψ *of class* C^2 *such that the normal* h *to* $\partial\Omega$ *is not orthogonal to the surface* $\Psi(x, \xi, t) = 0$. *If* $u \in L^p(\Omega)$ *for* $p \geqq 3$ *and*

$$\int_\Omega u L^* v \, dx \, d\xi \, dt = 0 \tag{3.1}$$

for every $v \in C^2(\bar{\Omega})$ *with* $v = 0$ *on* $\Sigma_3 \cup D^+$, *then* $u = 0$ *almost everywhere in* Ω.

Remark. If $\partial\Omega \backslash \Sigma_3$ consists entirely of its own interior points in $\partial\Omega$ and their limits, then as noted before the statement of Lemma 3.1 the condition $\beta^* < 0$ on D^+ is satisfied automatically since $b < 0$ on D^+.

Lemma 3.1 yields the following uniqueness result.

THEOREM 3.2. *Suppose that* Ω *satisfies the conditions of Lemma* 3.1, $\lambda \geqq 1$, *and* $3 \leqq p < \infty$. *Then if* Z *is the set defined in Theorem* 2.4, *we have* $Z = \{0\}$, *so* (2.5) *has a unique weak solution* $(u, u^+, u^-) \in E^p$ *and the weak solution satisfies* (2.14).

Proof. Suppose $(y, z, 0) \in Z$. Then by definition

$$\int_\Omega yL^*v\, dx\, d\xi\, dt + \int_{D^+} zv^+\, d\nu^+ = 0$$

for any $v \in C^2(\bar{\Omega})$ with $v = 0$ on Σ_3. If $v = 0$ on D^+ then $v^+ = 0$ so for $v \in C^2(\bar{\Omega})$ with $v = 0$ on $\Sigma_3 \cup D^+$ we have

$$\int_\Omega yL^*v\, dx\, d\xi\, dt = 0.$$

Since $(y, z, 0) \in Z \subseteq E^p$, $p \geqq 3$ and Ω satisfies the hypotheses of Lemma 3.1, it follows from that lemma that $y = 0$ almost everywhere in Ω. Hence, we have

$$\int_{D^+} v^+ z\, d\nu^+ = 0$$

for all $v^+ = v|_{D^+}$ with $v \in C^2(\bar{\Omega})$ and $v = 0$ on Σ_3. Since $C_0^\infty(D^+)$ is dense in $L^q(D^+, d\nu^+)$ for any q, we have $z = 0$ almost everywhere on D^+. Thus we see that $Z = \{0\}$. If (u_1, u_1^+, u_1^-) and (u_2, u_2^+, u_2^-) are solutions of (2.5) in E^p then $u_1^- = u_2^- = g$ and $(u_1 - u_2, u_1^+ - u_2^+, 0) \in Z$, so $Z = \{0\}$ implies $u_1 = u_2$ almost everywhere in Ω and $u_1^+ = u_2^+$ almost everywhere $(d\nu^+)$ in D^+. Hence $(u_1, u_1^+, u_1^-) = (u_2, u_2^+, u_2^-)$ in E^p, establishing the uniqueness of the weak solution. Finally, (2.14) immediately follows from (2.13) once we know that $Z = \{0\}$. □

If the boundary of Ω_0 is given locally by $h_0(x, \xi) = 0$, then we can define $\beta_0^* = L_0^* h_0$, and define Γ_0 to be the boundary in $\partial\Omega_0$ of $D_0^+ \cup \{(x, \xi) \in \partial\Omega_0 \backslash \Sigma_3^0 \colon b_0(x, \xi) = 0\}$. Applying the results of [10] to L_0 in the same way we applied them to L, we obtain Theorem 3.3.

THEOREM 3.3. *Suppose that $\lambda \geqq 1$ and $\beta_0^* < 0$ at points of D_0^+. Suppose that in some neighborhood of each of its points Γ_0 lies on the intersection of the surface $h_0(x, \xi) = 0$ defining $\partial\Omega_0$ and a surface $\Psi_0(x, \xi) = 0$ with h_0 and Ψ of class C^2 such that the normal to $\partial\Omega$ is not orthogonal to $\Psi(x, \xi) = 0$. Then for $3 \leqq p < \infty$ we have $Z_0 = \{0\}$, where Z_0 is the set defined in Theorem* 2.6, *and hence problem* (2.21) *has a unique weak solution $(u, u^+, u^-) \in E_0^p$, and that solution satisfies* (2.28).

We now present an example showing that the condition $p \geqq 3$ in Theorem 3.3 as well as in Theorem 3.2 is sharp. In other words the solution may not be unique in E^p. As a particular realization of (2.1), we consider the equation

$$u_{yy} + yu_y - u_s = 0$$

in a bounded domain in the (y, s) plane with $s > 0$. By making the change of coordinates $y = \xi/\sqrt{2t}$, $s = (\ln t)/2$ (equivalently $t = e^{2s}$, $\xi = \sqrt{2}e^s y$) we obtain the heat equation

$$u_{\xi\xi} - u_t = 0. \tag{3.2}$$

Following [10], we consider this last equation in a bounded domain Ω in the plane (ξ, t) such that the boundary of Ω is a closed smooth curve Σ which in the neighborhood of $(0, 0)$ behaves like $t = |\xi|^{2+\varepsilon}$, $\varepsilon > 0$, and which has no tangents parallel to the ξ-axis except at $(0, 0)$ and $(0, 1)$. Then the points $(0, 0)$, $(0, 1)$ belong to D^- and D^+, respectively, and the rest of the boundary belongs to Σ_3. The function $w = t^{-1/2} e^{-\xi^2/4t}$ is a solution of (3.2) in Ω. On Σ, w determines a continuous function which in a neighborhood of $(0, 0)$ behaves like

$$|\xi|^{-(1+\varepsilon/2)} e^{-1/4|\xi|^{-\varepsilon}}.$$

We now consider the problem

$$u_{\xi\xi} = u_t = 0, \qquad u|_\Sigma = w|_\Sigma. \tag{3.3}$$

Since the boundary Σ is smooth, there exists a solution $W(\xi, t)$ of problem (3.3), continuous together with its derivatives W_t, W_ξ, $W_{\xi\xi}$, everywhere in $\Omega \cup \Sigma$ except maybe at $(0,0)$ and $(0,1)$ [8, Thms. 5, 6, p. 64].

The function $u := W - w$ satisfies the homogeneous equation

$$L(u) = 0, \qquad u|_\Sigma = 0, \tag{3.4}$$

but is different from zero on a set of positive measure, since W is continuous on $\Omega \cup \Sigma$ while $w \to \infty$ for $\xi = 0$ and $t \to 0$. Moreover, $u \in L^p(\Omega)$ if $p < 3$. Indeed, since W is bounded, we have

$$\begin{aligned}\int_\Omega |u|^p \, d\xi \, dt &\simeq \int_\Omega |w|^p \, d\xi \, dt \sim \int t^{-p/2} \, e^{-p\xi^2/4t} \, d\xi \, dt \\ &\leqq \int_0^{t_0} \left(t^{-p/2} \int_{-t^{1/(2+\varepsilon)}}^{t^{1/(2+\varepsilon)}} d\xi \right) dt + C_1 \\ &= 2 \int_0^{t_0} t^{-p/2+1/(2+\varepsilon)} \, dt + C_1 < C_2\end{aligned}$$

if $-p/2 + 1/(2+\varepsilon) > -1$, i.e., if $p < 3$.

Following [10] it is not difficult to check that u also satisfies Green's identity; therefore, it is a solution of (3.4) different from the one that is identically zero.

The lack of uniqueness comes from our rather general definition of a solution. Extra regularity requirements can restore this property. For instance, when $p \geqq 3$ our formulation already imposes enough regularity to ensure uniqueness. A different formulation that imposes more regularity is given in § 5, and yields a uniqueness result for data in L^2. When we have uniqueness we may assert that weak solutions obtained by different methods must coincide. That observation is useful because certain properties of the solution may be easier to obtain by some methods than by others.

Our approach was chosen to yield information about u^+ and u^- and their relation to u and f. Another approach, used in [10], can be adapted to yield more precise information about the sign of solutions. The alternative method is to approximate f and g with sequences with smooth functions f_n and g_n such that $f_n \to f$ in $L^p(\Omega)$, $g_n \to g$ in $L^p(D^-, d\nu^-)$, and then to solve the problem

$$\begin{aligned} &\varepsilon \Delta u + Lu = f_n && \text{in } \Omega, \\ &u = g_n && \text{on } D^-, \\ &u = 0 && \text{on } \partial\Omega \setminus D^- \end{aligned} \tag{3.5}$$

where $\Delta u = \nabla_\xi \cdot \nabla_\xi u + \nabla_x \cdot \nabla_x u + u_{tt}$. Standard elliptic theory asserts the evidence of a classical solution to (3.5) for each ε and n, and it can be shown as in [10, § 1.5], that if the solution to (3.5) is denoted by $u_{\varepsilon,n}$ then there are subsequences $\varepsilon_k \to 0$ and $n_k \to \infty$ such that u_{ξ_k, n_k} converges weakly to $\tilde{u} \in L^p(\Omega)$, with $\tilde{u}$ satisfying

$$\int_\Omega \tilde{u} L^* v \, dx \, d\xi \, dt = \int_\Omega v f \, dx \, d\xi \, dt - \int_{D^-} v g \, d\nu^- \tag{3.6}$$

for all $v \in C^2(\bar{\Omega})$ with $v = 0$ on $\Sigma_3 \cup D^+$. (It seems to be difficult to adapt this approach to the formulation given in (2.7) where v need not vanish on D^+. Since we are interested in transport phenomena where the relation between the characteristic boundary values u^- and u^+ is essential, our main line of analysis uses the alternative approach discussed in § 2.) The advantage of the above method is that if $f \leqq 0$ and $g \geqq 0$ almost everywhere,

then we can construct f_n and g_n by mollification so that $f_n \leqq 0$ and $g_n \geqq 0$ for each ε and n, so that $\tilde{u} \geqq 0$ almost everywhere in Ω. Under the hypotheses of Theorem 3.2, the weak solution $\tilde{u}$ in the sense of (3.6) is unique. However, our weak solution u in the sense of (2.7) is also unique, and satisfies (3.6). Hence, under the hypotheses of Theorem 3.2, $u = \tilde{u} \geqq 0$ almost everywhere.

Another approach to solving (2.5) in a domain of the form $\Omega_0 \times (0, T]$ with $g = 0$ on $D_0^- \times (0, T]$ would be to assume $\mu = \mu(x, \xi)$, use the estimate (2.36) and the Hille-Yosida Theorem to assert that for $p \geqq 3$, L_0 generates a C_0-semigroup of contractions on $L^p(\Omega_0)$, and then to use the semigroup in a variation of parameters formula to solve (2.5). However, the analysis of §§ 2 and 3 can with care be extended to cylindrical domains; most of the technicalities are contained in [10], and since we need $p \geqq 3$ and a uniqueness result analogous to Theorem 3.3 to obtain (2.36), there seems to be little advantage to us in the semigroup method. (The semigroup solution would satisfy (3.6), and hence coincide with $\tilde{u}$, so we would obtain the same solution by that approach. If we decompose L_0 into a sum of a first-order operator and the second-order operator generated by $\nabla\xi \cdot \mu(x, \xi)\nabla\xi$, we could recover the positivity of the semigroup by noting that each operator separately generates a positivity preserving semigroup and apply the Trotter product formula.)

In summary, we see that there are various possible formulations of L^p weak solutions to (2.5) and various ways of producing them. Our choice of approach is based on our interest in keeping as much information as possible about boundary behavior of our solution. Under sufficiently strong hypotheses, the various forms of weak solution all agree; however, without some added hypotheses uniqueness may fail.

4. General boundary conditions. In this section, we shall extend the existence and uniqueness theory developed in §§ 2 and 3 so as to include more general boundary conditions encountered in transport problems. The very nature of the *transport* problem implies that such a boundary condition relates distributions defined only on the characteristic parts of the boundary (in our case, D^+ and D^-):

$$u^- = Ku^+ + g \quad \text{on } D^-,$$

where K is a bounded operator,

$$K : L^p(D^+, d\nu^+) \to L^p(D^-, d\nu^-),$$

and, as before, g accounts for the autonomous boundary source. The distribution on the noncharacteristic part, Σ_3, is set to zero as in (2.5). Our main result is summarized in Theorem 4.1.

THEOREM 4.1. *Consider the following problem*:

$$\begin{aligned} Lu &= f && \text{in } \Omega, \\ u &= 0 && \text{on } \Sigma_3, \\ u^- &= Ku^+ + g && \text{on } D^- \end{aligned} \tag{4.1}$$

where Ω *satisfies the hypotheses of Lemma* 3.1, $f \in L^p(\Omega)$, $g \in L^p(D^-, d\nu^-)$, $3 \leqq p < \infty$, $\lambda \geqq 1$, *and* $\|K\| < 1$. *Then there exists a unique solution of* (4.1) *in* E_p *in the sense of* (2.7).

Proof. When $K = 0$ we may apply Theorems 2.4 and 3.2 and obtain a unique weak solution $(u, u^+, u^-) \in E_p$ with $u^- = g$ which satisfies (2.14), that is,

$$\|u\|^p_{L^p(\Omega)} + \|u^+\|_{L^p(D^+, d\nu^+)} \leqq \|f\|^p_{L^p(\Omega)} + \|g\|^p_{L^p(D^-, d\nu^-)}.$$

Let us call this solution $(u, u^+, u^-) := (T_\lambda(f, g), T_\lambda(f, g)^+, T_\lambda(f, g)^-)$. Observe that T_λ, T_λ^+, and T_λ^- are linear in f and g and $T_\lambda(f, g)^- \equiv g$. Using the linearity of T_λ and T_λ^+ and the estimate (2.14) we have

$$
\begin{aligned}
&\| T_\lambda(f, 0)\|_{L^p(\Omega)} \leqq \|f\|_{L^p(\Omega)},\\
&\| T_\lambda(f, 0)^+\|_{L^p(D^+, d\nu^+)} \leqq \|f\|_{L^p(\Omega)},\\
&\| T_\lambda(0, g)\|_{L^p(\Omega)} \leqq \|g\|_{L^p(D^-, d\nu^-)},\\
&\| T_\lambda(0, g)^+\|_{L^p(D^+, d\nu^+)} \leqq \|g\|_{L^p(D^-, d\nu^-)}.
\end{aligned} \tag{4.2}
$$

Following [4], we seek a solution of (4.1) in the form

$$(u, u^+, u^-) = (T_\lambda(f, g^*), T_\lambda(f, g^*)^+, T_\lambda(f, g^*)^-) \tag{4.3}$$

where we must have g^* satisfying the fixed point equation

$$g^* \equiv T_\lambda(f, g^*)^- = KT_\lambda(f, g^*)^+ + g. \tag{4.4}$$

(Recall that $g^* = T_\lambda(f, g)^-$ by definition.) We may rewrite (4.4) as

$$g^* = KT_\lambda(f, 0)^+ + KT_\lambda(0, g^*)^+ + g$$

or

$$(1 - M_\lambda)g^* = g + KT_\lambda(f, 0)^+ \tag{4.5}$$

where

$$M_\lambda g^* := KT_\lambda(0, g^*)^+.$$

Observe that $M_\lambda : L^p(D^-, d\nu^-) \to L^p(D^-, d\nu^-)$. Equation (4.5) has a unique solution which may be expressed by expanding $(I - M_\lambda)^{-1}$ in a Neumann series $\sum_{k=0}^{\infty} M_\lambda^k$ provided $\|M_\lambda\| < 1$. But (4.2) implies

$$
\begin{aligned}
\|M_\lambda g^*\|_{L^p(D^-, d\nu^-)} &\leqq \|K\| \, \|T_\lambda(0, g^*)^+\|_{L^p(D^+, d\nu^+)}\\
&\leqq \|K\| \, \|g^*\|_{L^p(D^-, d\nu^-)}
\end{aligned}
$$

so that $\|M_\lambda\| \leqq \|K\| < 1$. Then (4.5) has a unique solution g^*, and hence (4.1) has the unique solution

$$(u, u^+, u^-) = (T_\lambda(f, g^*), T_\lambda(f, g^*)^+, g^*).$$

This argument is equivalent to using the contraction mapping theorem or the Picard iteration method. □

Remark. In fact, we could use the more refined estimate (2.32) to assert

$$\| T_\lambda(f, 0)\|_{L^p(\Omega)} \leqq \lambda^{-1/q} \|f\|_{L^p(\Omega)}$$

and

$$\| T_\lambda(f, 0)^+\|_{L^p(D^+, d\nu^+)} \leqq \lambda^{-1/q} \|f\|_{L^p(\Omega)}$$

where $1/p + 1/q = 1$; however, that estimate is not required for our analysis.

5. Hilbert space solutions. Seeing the difficulties with uniqueness in weak solutions in E^p, $1 < p < 3$, we turn our attention to a stronger notion of solution in a "Sobolev type" Hilbert space. This approach will give uniqueness in its class and enables us to compare our results with recent results of Degond and Mas-Gallic [7].

We construct a Hilbert space that reflects the degeneracy in our equation. This construction is similar to the construction in Oleinik and Radkevic [10, § 1.4]. Define a class of test functions

$$\mathcal{W}=\{v\in C^1(\bar{\Omega}_0)\colon v=0 \text{ on } \Sigma_3^0\}.$$

For $(u, v)\in\mathcal{W}$, define an inner product

$$(u, v)_{\mathcal{H}}=\int_{\Omega_0}\left(\sum_{i=1}^{N} u_{\xi_i}v_{\xi_i}+uv\right)dx\,d\xi+\int_{D_0^+} u^+v^+\,d\nu_0^+ +\int_{D_0^-} u^-v^-\,d\nu_0^-$$

and define the Hilbert space $\mathcal{H}$ to be the closure of $\mathcal{W}$ with respect to the norm from the above inner product,

$$\|u\|_{\mathcal{H}}^2=(u, u)_{\mathcal{H}} \quad \text{for } u\in\mathcal{W}.$$

Define the bilinear form, for $u, v\in\mathcal{W}$,

$$B(u, v)=\int_{\Omega_0}\left[-\sum_{i=1}^{N} v_{\xi_i}u_{\xi_i}+u\left(-\sum_{i=1}^{N}\xi_i v_{\xi_i}+\sum_{i=1}^{N}\xi_i v_{x_i}\right)-(\lambda+1)uv\right]dx\,d\xi$$
$$-\int_{D_0^+} u^+v^+\,d\nu^+.$$

The definition of $B(u, v)$ may be extended to all functions $u\in\mathcal{H}$, $v\in\mathcal{W}$, and

$$|B(u, v)|\leqq C\left[\int_{\Omega_0}\left[\sum_{i=1}^{N}(v_{\xi_i}^2+v_{x_i}^2)+v^2\right]dx\,d\xi+\int_{D_0^+}(v^+)^2\,d\nu_0^+\right]^{1/2}\|u\|_{\mathcal{H}}$$

where C depends on the coefficients of the operator L_0. For fixed $v\in\mathcal{W}$, $B(u, v)$ is a bounded linear functional on $\mathcal{H}$.

DEFINITION. For $f\in L^2(\Omega_0)$, $g\in L^2(D_0^-, d\nu_0^-)$, a function u in $\mathcal{H}$ is a *weak solution in* $\mathcal{H}$ of

$$\begin{aligned} &L_0u=f \quad \text{in } \Omega_0,\\ &u^-=g \quad \text{on } D_0^-,\\ &u=0 \quad \text{on } \Sigma_3^0 \end{aligned} \tag{5.1}$$

if for all $v\in\mathcal{W}$,

$$B(u, v)=\int_{\Omega_0} fv\,dx\,d\xi-\int_{D_0^-} v^-g\,d\nu_0^-.$$

THEOREM 5.1. *Suppose* $\lambda>-\frac{1}{2}$, $f\in L^2(\Omega_0)$, $g\in L^2(D_0^-, d\nu_0^-)$; *then there exists a unique weak solution in* $\mathcal{H}$ *of* (5.1).

Proof. By the Riesz Theorem on the representation of linear functionals in Hilbert space, there exists a linear operator T on $\mathcal{W}$ with range in $\mathcal{H}$ such that

$$B(u, v)=(u, T(v))_{\mathcal{H}}.$$

Since $\lambda>-\frac{1}{2}$, $B(v, v)$ is strongly coercive,

$$|B(v, v)|=\int_{\Omega_0}\left[\sum_{i=1}^{N} v_{\xi_i}^2+\left(\lambda+\frac{1}{2}\right)v^2\right]dx\,d\xi+\frac{1}{2}\int_{D_0^+}(v^+)^2\,d\nu_0^+ +\frac{1}{2}\int_{D_0^-}(v^-)^2\,d\nu_0^-$$
$$\geqq\alpha\|v\|_{\mathcal{H}}^2, \qquad \alpha>0 \quad \text{for } v\in\mathcal{W}.$$

This coercivity implies

$$\|v\|_{\mathcal{H}}\leqq 1/\alpha\,\|T(v)\|_{\mathcal{H}}$$

and T is a one-to-one map. Denote by $\mathcal{H}_1$ the closure of the range of T in the norm of $\mathcal{H}$. Then

$$\int_{\Omega_0} vf\,dx\,d\xi - \int_{D_0^-} v^- g\,dv_0^-$$

is a continuous linear functional on $\mathcal{H}_1$. By the Riesz Theorem, there exists u in $\mathcal{H}_1$ such that

$$\int_{\Omega_0} vf\,dx\,d\xi - \int_{D_0^-} v^- g\,dv_0^- = (u, T(v))_{\mathcal{H}} = B(u, v) \quad \text{for all } v \in \mathcal{W}.$$

Thus u is a weak solution in $\mathcal{H}$.

By approximating u by a sequence $\{u_n\}$ in $\mathcal{W}$ with

$$\|u_n - u\|_{\mathcal{H}} \to 0 \quad \text{and} \quad B(u_n, v) \to B(u, v) \quad \text{for all } v \in \mathcal{W},$$

and integrating by parts on $B(u_n, v)$, we obtain

$$\int_{\Omega_0} (L_0^* v) u\,dx\,d\xi - \int_{D_0^+} v^+ u^+\,dv_0^+ = \int_{\Omega_0} vf\,dx\,d\xi + \int_{D_0^-} v^- g\,dv_0^- \tag{5.2}$$

$$\text{for all } v \in C^2(\bar{\Omega}), \quad v = 0 \text{ on } \Sigma_3^0.$$

We can use (5.2) to show the uniqueness of our weak solution in $\mathcal{H}$. Suppose u, $\tilde{u}$ are two weak solutions in $\mathcal{H}$, then

$$\int_{\Omega_0} (L_0^* v)(u - \tilde{u})\,dx\,d\xi = 0 \quad \text{for all } v \in C^2(\bar{\Omega}_0), \tag{5.3}$$

$$v = 0 \quad \text{on } \Sigma_3^0 \cup D_0^+.$$

By a result of Phillips and Sarason [10, Thm. 1.6.7], condition (5.3) implies $u = \tilde{u}$ almost everywhere. □

Remark. If $f \in L^p(\Omega_0)$, $g \in L^p(D_0^-, dv_0^-)$, $p \geqq 2$, and if $u \in \mathcal{H} \cap E_0^p$, condition (5.2) would imply that u would be a weak solution in E_0^p. But u is not necessarily in E_0^p. We can conclude that if $g = 0$ on D_0^-, $u \in L^p(\Omega_0)$, and then u is a weak solution in L^p sense, without the E_0^p requirement of L^p traces.

We now discuss another Hilbert space solution analyzed in a recent paper of Degond and Mas-Gallic [7]. They consider a one-dimensional electron scattering equation of the following form:

$$\sigma \frac{\partial}{\partial \xi}\left((1-\xi^2)\frac{\partial u}{\partial \xi}\right) - \xi \frac{\partial u}{\partial x} - \lambda u = f(x, \xi) \quad \text{for } (x, \xi) \in [0, L] \times [-1, 1],$$

$$u(0, \xi) = u_0(\xi) \quad \text{for } \xi \geqq 0, \tag{5.4}$$

$$u(L, \xi) = u_L(\xi) \quad \text{for } \xi \geqq 0, \quad \lambda > 0.$$

This particular solution Hilbert space Y is defined by

$$V = \left\{ \varphi \in L^2(-1, 1) : \sqrt{1-\xi^2}\,\frac{\partial \varphi}{\partial \xi} \in L^2(-1, 1) \right\},$$

$$\|\varphi\|_V = \int_{-1}^{1} \varphi^2(\xi)\,d\xi + \int_{-1}^{1} (1-\xi^2)\left(\frac{d\varphi}{d\xi}\right)^2 d\xi,$$

$$X = L^2([0, L], V) \qquad Y = \left\{ u \in X : \xi \frac{\partial u}{\partial x} \in X^* \right\}$$

where X^* is the dual space of X. Degond and Mas-Gallic obtain an existence and uniqueness result in Y. Their assumptions,

$$u \in L^2 \quad \text{and} \quad \xi \frac{\partial u}{\partial x} \in L^2,$$

provide L^2 traces on $D_0^+ \cup D_0^-$ by first-order methods. (See, for instance, [4].) Notice that the sides, $\xi = \pm 1$, are Σ_0 in our notation, and traces are not needed there. The combination of operator and domain is such that a priori estimates derived from (5.5) are all that are necessary; their a priori estimates can be obtained by only taking into account the first-order terms.

The weighted first derivative regularity in Degond and Mas-Gallic's paper is stronger than the regularity required in our case. This additional regularity yields also a strongly continuous semigroup of contractions on L^2 associated with the operator in (5.4).

Notice their second-order coefficient

$$\mu(\xi) = 1 - \xi^2,$$

becomes zero on the side boundaries, $\xi = \pm 1$. In § 2, we considered only strictly positive functions μ. The theory of equations with nonnegative characteristic forms in Oleinik and Radkevic [10] covers the case of such nonnegative coefficients μ. But including such coefficients involves redefining the characteristic parts of the boundary, which did not suit our goal here.

Acknowledgments. At an earlier stage of the preparation of the paper, Suzanne Lenhart and Vladimir Protopopescu benefitted from helpful comments from Professor R. Beals.

ON EXISTENCE OF SOLUTIONS FOR SEVERAL CLASSES OF FREE BOUNDARY PROBLEMS*

PHILIP KORMAN†

Dedicated to Ken Meyer on the occasion of his 50th birthday.

Abstract. Some general techniques are developed for treating nonstandard nonlinear elliptic problems arising when a so-called domain perturbation method is applied to free boundary problems. Our results are applied to two model problems from fluid mechanics.

Key words. free boundary problems, domain perturbation method, existence and uniqueness of solutions

AMS(MOS) subject classification. 35J60

1. Introduction. Our goal is to explore a general approach to free boundary problems, based on the so-called domain perturbation method. Using this method we get a solution, which is a perturbation of a known one, by mapping (nonconformally) the unknown fluid domain back to the known domain for an unperturbed solution. The linear equations of motion then get transformed to a fully nonlinear system, but since nonlinearities are small, it can usually be treated by the contractive mapping argument. The earliest reference that we know for the domain perturbation method is Joseph [6]. It was then used by Shinbrot [10] to prove the existence of double-periodic water waves in three dimensions. Our work was motivated by that paper.

Rather than present our results in general form, we prefer to consider two model problems, whose treatment illustrates how one should approach various possibilities, and which are of considerable independent interest.

The nonlinear elliptic problems obtained by the domain perturbation method can be either coercive or noncoercive (here "coercive" means that the problem satisfies the Lopatinski–Schapiro condition at all points of the boundary). For the coercive problems we outline an approach using the Schauder-type estimates of Agmon, Douglis, and Nirenberg [1], and present it for the model Problem I. For noncoercive problems there are no Schauder's estimates. Estimates in the Sobolev spaces (which are available for Problems I and II) cannot be used, because of loss of smoothness when taking traces. For the model Problem II we present the second approach based on Λ^m spaces, which are defined and studied below. Similar spaces were used by Shinbrot [10]; however, ours have several advantages: it is easier to establish their properties, the proofs of the estimates for $m>2$ are more transparent, and finally they seem to be more natural. Problem II leads to a coercive problem, so that the first approach based on Schauder's estimates can be used as well. In § 6 we present an example of a physically significant problem, leading to a noncoercive problem which can be solved only by the second approach. We proceed to describe our model problems.

Problem I. Let $x \in R^n$. Given a 2π periodic in each variable x_i function $B(x)$ (bottom), find the functions $u(x, y)$, $H(x)$, 2π periodic in each x_i, such that

$$\begin{aligned} &u=0, \quad \frac{\partial u}{\partial n}=-1, \quad y=H(x), \\ &\Delta u=0, \qquad B(x)<y<H(x), \\ &u=1, \qquad y=B(x), \end{aligned} \tag{1.1}$$

* Received by the editors December 22, 1986; accepted for publication (in revised form) June 8, 1987.
† Department of Mathematical Sciences, University of Cincinnati, Cincinnati, Ohio 45221.

where $\partial/\partial n$ is the outward normal derivative.

Problem II. Let $r = B(\theta)$ be a closed curve in the plane. Find another closed curve $r = H(\theta)$ outside of $B(\theta)$, and a function u on the closed region between $B(\theta)$ and $H(\theta)$ with

$$\begin{aligned} &u = 0, \quad \frac{\partial u}{\partial n} = -1, \quad r = H(\theta), \\ &\Delta u = 0, \qquad B(\theta) < r < H(\theta), \\ &u = 1, \qquad r = B(\theta). \end{aligned} \tag{1.2}$$

For Problem I we start with flat bottom $B = 0$, and the corresponding solution $H = 1$ and $u = 1 - y$. Then for small bottoms $B = \varepsilon b(x)$ we are looking for the solution in the form

$$H = 1 + \varepsilon h(x), \qquad u = 1 - y + \varepsilon v(x, y), \tag{1.3}$$

and show existence if ε is sufficiently small. We use the change of variables $(x, y) \to (x, y')$, $y' = (y - \varepsilon b)/(1 + \varepsilon h - \varepsilon b)$, to transform the unknown domain onto a fixed one, $0 \leqq y' \leqq 1$.

For Problem II notice that if $B(\theta) = 1$ then the solution is $H(r) = h_0$, $u = -h_0 \log r + 1$, where $h_0 \simeq 1.76$ is defined by $h_0 \log h_0 = 1$, and (r, θ) are the polar coordinates. Then we assume that $B = 1 + \varepsilon b(\theta)$, and look for the solution in the form

$$H = h_0 + \varepsilon h(\theta), \qquad u = -h_0 \log r + 1 + \varepsilon v(r, \theta). \tag{1.4}$$

We show the existence of such a solution for ε sufficiently small.

Problem II was considered by Hamilton [5] (and also earlier by Schaeffer [9] and Acker [11]). Hamilton proved that for every smooth convex curve B there exists a unique solution to Problem II (the curve $H(\theta)$ is also smooth and convex, and u is smooth). His result is strictly two-dimensional, since conformal mappings were used to derive a priori estimates. Our existence result complements Hamilton's in that we do not require the curve $r = B(\theta)$ to be convex. In three dimensions we were unable so far to carry out a similar approach, because of the singularities in the Laplace operator in spherical coordinates.

We wish to stress the generality of our approach. It can be used to attack problems with boundary conditions of arbitrary order and variable coefficients, and with nonlinear equations of motion. In contrast, a more common variational approach (see, e.g., [2, Chap. 3]) is rather restricted (but it is a global method).

Finally, we mention that Problems I and II have an interesting physical interpretation. For Problem II it is described in [5, p. 215], so that we present a similar interpretation for Problem I (with similar deficiency as mentioned in [5]). We consider fluid occupying the half space $y > 0$, $x \in R^n$, and assume there is a stream flowing over the periodic bottom $y = B(x)$. The fluid is assumed to be perfect with unit density, and at rest outside a free surface boundary, so that there is a velocity jump at the free surface. Let u be the stream potential. By choosing units of length and time we can make the velocity on free surface $y = H(x)$ and circulation equal to one. This leads us to Problem I.

2. Preliminary results. Let $x = (x_1, \cdots, x_n)$, $j = (j_1, \cdots, j_n)$, $n \geqq 1$. Let the function $u = u(x, y)$ be 2π periodic in each variable x_i, $i = 1, \cdots, n$, $0 \leqq y \leqq 1$; $u(x, y) = \sum_{j=-\infty}^{\infty} u_j(y)\, e^{ij \cdot x}$. Define the norms $\|u(x, y)\|_0 = \sum_{j=-\infty}^{\infty} \max_{0 \leqq y \leqq 1} |u_j(y)|$, $\|u\|_m = \sum_{|\alpha| \leqq m} \|D^\alpha u\|_0$, where D^α is a mixed partial in x and y, m = integer $\geqq 1$. Denote

$D=[0,2\pi]^n$, $V=D\times[0,1]$. Let $\Lambda^m(V)$ be the closure of trigonometric polynomials of the form $\sum u_j(y)\,e^{ij\cdot x}$, $u_j(y)\in C^\infty[0,1]$, with respect to the norm $\|\cdot\|_m$. Clearly $\Lambda^m(V)$ are Banach spaces with $\|u\|_m\leqq\|u\|_n$ if $m\leqq n$. The space $\Lambda^m(D)$ is defined in the same way for functions independent of y. The norm on $\Lambda^m(D)$ is denoted by $|||\cdot|||_m$. If we are given a function of polar coordinates in the plane, $u=u(r,\theta)=\sum_{n=-\infty}^{\infty}u_n(r)\,e^{in\theta}$ on an annulus $1\leqq r\leqq h_0$, $h_0=$ constant, then as before $\|u\|_0=\sum_{n=-\infty}^{\infty}\max_{1\leqq r\leqq h_0}|u_n(r)|$, and $\|u\|_m=\sum_{|\alpha|\leqq m}\|D^\alpha u\|_0$ where D^α is a mixed partial in r and θ. This time domain V is defined by $1\leqq r\leqq h_0$, $0\leqq\theta\leqq 2\pi$ domain D by $r=h_0$, $0\leqq\theta\leqq 2\pi$.

We write c for all positive constants independent of unknown functions. We write $f=f(D^2v)$ when f depends on the function v and all its partial derivatives or orders one and two.

LEMMA 2.1. *Let* $u,v\in\Lambda^m$. *Then* $uv\in\Lambda^m$, *and* $\|uv\|_m\leqq c_m\|u\|_m\|v\|_m$, $c_m=$ const $(c_0=1)$.

Proof. Let $u=\sum_{j=-\infty}^{\infty}u_j\,e^{ij\cdot x}$, $v=\sum_{k=-\infty}^{\infty}v_k\,e^{ik\cdot x}$. Then

$$\|uv\|_0=\sum_\gamma\max_y\left|\sum_\delta u_{\gamma-\delta}v_\delta\right|\leqq\sum_\delta\max_y|v_\delta|\sum_\gamma\max_y|u_{\gamma-\delta}|$$
$$=\|u\|_0\|v\|_0.$$

For $m\geqq 1$ we get

$$\|uv\|_m=\sum_{|\alpha|\leqq m}\|D^\alpha uv\|=\sum_{|\alpha|\leqq m}\sum_{0\leqq\beta\leqq\alpha}c_\beta\|D^\beta u\|_0\|D^{\alpha-\beta}v\|_0$$
$$\leqq c_m\|u\|_m\|v\|_m.$$

COROLLARIES. (i) $\|g_1\cdots g_p\|_m\leqq c_m^{p-1}\|g_1\|_m\cdots\|g_p\|_m$.

(ii) $\|g^p\|_m\leqq c_m^{p-1}\|g\|_m^p$.

LEMMA 2.2. *Let* B *be a ball in* R^p *centered at the origin,* $f(x_1,\cdots,x_p)$: $B\to R^1$ *be a real analytic function. Let* g *be a vector function on* V, $g=(g_1,\cdots,g_p)$, $\|g\|_m\equiv\sum_{i=1}^p\|g_i\|_m=r$. *Assume that* r *is sufficiently small. Then* $f(g_1,\cdots,g_p)\in\Lambda^m$, *and*

$$\|f(g)\|_m\leqq c_0+c_1(r),$$

where $c_0=\text{const}>0$, c_1 *is analytic function of* r, *depending only on* f *and* r, *and* $c_1(0)=0$.

Proof. Let $f=\sum_{|\alpha|\geqq 0}f_\alpha x^\alpha$ for $x=(x_1,\cdots,x_p)\in B$, $f(g)=\sum_{|\alpha|\geqq 0}f_\alpha g_\alpha$. Then by Lemma 2.1

$$\|f(g)\|_m\leqq\sum_{|\alpha|\geqq 0}|f_\alpha|\,\|g^\alpha\|_m\leqq\sum_{|\alpha|\geqq 0}|f_\alpha|c_m^{|\alpha|-1}r^{|\alpha|},$$

which is easily seen to be a convergent series for r sufficiently small.

LEMMA 2.3. $\Lambda^m(V)(\Lambda^m(D))$ *is boundedly imbedded in* $C^m(V)(C^m(D))$.

Proof. Since for any multi-index α, $|\alpha|=m$, $\max_{x,y}|D^\alpha u|\leqq\|u\|_m$ the proof follows.

By $|\cdot|_{m+\alpha}$ we denote the norm in the space $C^{m+\alpha}(V)$, $m=\text{integer}\geqq 0$, $0<\alpha<1$ (see, e.g., [1] for the definition).

3. Transformation to a fixed domain. For Problem I we suppose that $B(x)=\varepsilon b(x)$, and look for solution in the form (1.3). Notice that on $y=H(x)=1+\varepsilon h(x)$

$$\frac{\partial u}{\partial n}=\nabla u\cdot n=\frac{-\varepsilon\sum_{i=1}^n u_ih_i+u_y}{\sqrt{1+\varepsilon^2|\nabla h|^2}}.$$

Substituting this and (1.3) into (1.1) we get

$$v(x,y)=h(x),\qquad\frac{-\varepsilon^2\sum_{i=1}^n v_ih_i-1+\varepsilon v_y}{\sqrt{1+\varepsilon^2|\nabla h|^2}}=-1,\qquad y=1+\varepsilon h,$$

$$\Delta v=0,\qquad\varepsilon b(x)<y<1+\varepsilon h(x),\tag{3.1}$$
$$v=b(x),\qquad y=\varepsilon b(x).$$

The change of variables $(x, y) \to (x', y')$ defined by

$$x_i' = x_i, \qquad i = 1, \cdots, n,$$

$$y' = \frac{y - \varepsilon b}{1 + \varepsilon(h - b)} \equiv y d(x) + e(x),$$

$$\left(d(x) = \frac{1}{1 + \varepsilon(h - b)}, \; e(x) = -\frac{\varepsilon b}{1 + \varepsilon(h - b)} \right)$$

will transform the unknown fluid domain onto $0 \leqq y' \leqq 1$.

By a straightforward calculation, the problem (3.1) will transform as follows (we drop primes for the independent variables)

$$\begin{aligned} & v(x, 1) = h(x), \\ & v_y = \varepsilon g(\varepsilon, Dv, Dh, Db), && y = 1, \\ & \Delta v = \varepsilon f(\varepsilon, D^2 v, D^2 h, D^2 b), && 0 < y < 1, \\ & v = b(x), && y = 0. \end{aligned} \tag{3.2}$$

Here

$$\varepsilon g = \frac{1 - \sqrt{1 + \varepsilon^2 |Dh|^2} + \varepsilon^2 \sum_{i=1}^{n} [v_{x_i} + v_y (Y d_{x_i} + e_{x_i})] h_{x_i}}{\varepsilon d(x)}, \tag{3.3}$$

where $Y = y(1 + \varepsilon h - \varepsilon b) + \varepsilon b$, and

$$\begin{aligned} -\varepsilon f = (d^2 - 1) v_{yy} + \sum_{i=1}^{n} & [2 v_{x_i y} (Y d_{x_i} + e_{x_i}) + v_{yy} (Y d_{x_i} + e_{x_i})^2 \\ & + v_y (Y d_{x_i x_i} + e_{x_i x_i})]. \end{aligned} \tag{3.4}$$

We easily see that the functions f and g are analytic in their arguments for small ε.

For Problem II we suppose that $B = 1 + \varepsilon b(\theta)$, and look for a solution in the form (1.4). By an elementary computation on $r = H(\theta) = h_0 + \varepsilon h(\theta)$ we have

$$\frac{\partial u}{\partial n} = \frac{r}{\sqrt{r^2 + \varepsilon^2 h'^2}} u_r - \frac{\varepsilon h'}{r \sqrt{r^2 + \varepsilon^2 h'^2}} u_\theta. \tag{3.5}$$

Using this formula and (1.4) in (1.2) we get

$$\begin{aligned} & v = \frac{-1 + h_0 \log r}{\varepsilon}, && r = h_0 + \varepsilon h, \\ & \frac{r}{\sqrt{r^2 + \varepsilon^2 h'^2}} \left(-\frac{h_0}{r} + \varepsilon v_r \right) - \frac{\varepsilon^2 h'}{r \sqrt{r^2 + \varepsilon^2 h'^2}} v_\theta = -1, && r = h_0 + \varepsilon h, \\ & \Delta v = 0, && 1 + \varepsilon b(\theta) < r < h_0 + \varepsilon h(\theta), \\ & v = \frac{h_0 \log r}{\varepsilon}, && r = 1 + \varepsilon b(\theta). \end{aligned} \tag{3.6}$$

The change of variables $(r, \theta) \to (r', \theta')$

$$r' = (h_0 - 1) \frac{r - 1 - \varepsilon b}{\varepsilon(h - b) + h_0 - 1} + 1, \qquad \theta' = \theta$$

maps the fluid domain $1+\varepsilon b \leqq r \leqq h_0+\varepsilon h$ onto the annulus $1 \leqq r' \leqq h_0$. The problem (3.5) will transform as follows (dropping the primes)

$$
\begin{aligned}
&v = h + \varepsilon r(\varepsilon, h), && r = h_0,\\
&v_r = -\frac{h}{h_0} + \varepsilon g(\varepsilon, Dv, Dh, Db), && r = h_0,\\
&\Delta v = \varepsilon f(\varepsilon, D^2 v, D^2 h, D^2 b), && 1 < r < h_0,\\
&v = h_0 b + \varepsilon q(\varepsilon, b), && r = 1.
\end{aligned} \tag{3.7}
$$

Here

$$
\varepsilon r = \frac{h_0 \log (h_0+\varepsilon h) - 1}{\varepsilon} - h,
$$

$$
\varepsilon g = \frac{\varepsilon}{(h_0+\varepsilon h)^2 p}\left[v_\theta h' + v_r(Rp_\theta + q_\theta)h' - h^2 - (h_0+\varepsilon h)^2 r_1\right] + \frac{1}{\varepsilon}\left(\frac{h}{h_0} - \frac{h_0 h}{r^2 p}\right)
$$

with

$$
p = \frac{h_0 - 1}{\varepsilon(h-b)+h_0-1}, \qquad q = -\frac{(h_0-1)(1+\varepsilon b)}{\varepsilon(h-b)+h_0+1} + 1,
$$

$$
R = \frac{r-q}{p}, \qquad r_1 = \frac{1}{\varepsilon^2}\left(\sqrt{1+\varepsilon^2\frac{h'^2}{R^2}} - 1\right),
$$

$$
-\varepsilon f = (p^2-1)v_{rr} + \left(\frac{p}{R} - \frac{1}{r}\right)v_r + \left(\frac{1}{R^2} - \frac{1}{r^2}\right)v_{\theta\theta}
$$

$$
+ \frac{1}{R^2}\left[2v_{\theta r}(Rp_\theta + q_\theta) + v_{rr}(Rp_\theta + q_\theta)^2 + v_r(Rp_{\theta\theta} + q_{\theta\theta})\right],
$$

$$
\varepsilon q = \frac{h_0}{\varepsilon}(\log(1+\varepsilon b) - \varepsilon b).
$$

We verify that the functions r, g, f, q are analytic in their arguments for small ε.

4. A priori estimates for the linear problem. Consider the problem ($x \in R^n$)

$$
\begin{aligned}
&u_y = g(x), && y = 1,\\
&\Delta u = f(x, y), && 0 < y < 1,\\
&u = b(x), && y = 0,
\end{aligned} \tag{4.1}
$$

where f, g, and b are given functions, 2π periodic in each variable x_i, $i = 1, \cdots, n$.

LEMMA 4.1. *Assume that $f \in C^\alpha(V)$, $g \in C^{1+\alpha}(D)$. Then* (4.1) *has a unique 2π periodic in each x_i solution, and*

$$
|u|_{2+\alpha} \leqq c(|f|_\alpha + |g|_{1+\alpha} + |b|_{2+\alpha}). \tag{4.2}
$$

Proof. Existence of solutions follows by elementary Fourier analysis, uniqueness from the estimate

$$
|u|_0 \leqq c(|f|_0 + |g|_0 + |b|_0), \tag{4.3}
$$

which easily follows by the maximum principle. It remains to show how one adapts Schauder's estimates for our problem (4.1). Redefine f, g, b as functions of compact

support outside $0 \leqq x_i \leqq 2\pi$, $i = 1, \cdots, n$, and call the extensions $\bar{f}$, $\bar{g}$, $\bar{b}$, respectively. Clearly, this can be done with say $|\bar{f}|_\alpha \leqq 2|f|_\alpha$, $|\bar{g}|_\alpha \leqq 2|g|_\alpha$, $|\bar{b}|_\alpha \leqq 2|b|_\alpha$. Let $\xi_1(y)$, $\xi_2(y)$ be C^∞ functions on $[0, 1]$, such that $\xi_1 \equiv 1$ near $y = 1$ and $\xi_1 \equiv 0$ near $y = 0$, and $\xi_2 = 1 - \xi_1$. Write $u = \xi_1 u + \xi_2 u \equiv u_1 + u_2$. Multiplying (4.1) by ξ_1 and ξ_2, we easily get

$$
\begin{aligned}
& u_{1y} = \bar{g}, && y = 1, \\
& \Delta u_1 = \xi_1'' u + 2\xi_1' u_y + \xi_1 \bar{f}, && -\infty < y < 1,
\end{aligned} \tag{4.4}
$$

$$
\begin{aligned}
& \Delta u_2 = \xi_2'' u + 2\xi_2' u_y + \xi_2 \bar{f}, && 0 < y < \infty, \\
& u_2 = \bar{b}(x), && y = 0.
\end{aligned} \tag{4.5}
$$

Using usual Schauder's estimates (see [1, Thm. 7.3]), we get (for arbitrary small ε)

$$
\begin{aligned}
|u|_{2+\alpha} &\leqq c\left(\sum_{i=1}^{2} |\xi_i'' u + 2\xi_i' u_y + \xi_i \bar{f}|_\alpha + |\bar{g}|_{1+\alpha} + |\bar{b}|_{2+\alpha} \right) \\
&\leqq c(\varepsilon |u|_{2+\alpha} + c_\varepsilon |u|_0 + |f|_\alpha + |g|_{1+\alpha} + |b|_{2+\alpha}),
\end{aligned}
$$

and by (4.3) the lemma follows.

Next, in the plane (r, θ) consider the problem ($h_0 \log h_0 = 1$)

$$
\begin{aligned}
& u_r + \sigma u = g(\theta), && r = h_0 \quad (\sigma = \text{const} \geqq 0), \\
& \Delta u = f(r, \theta), && 1 < r < h_0, \\
& u = b(\theta), && r = 1.
\end{aligned} \tag{4.6}
$$

Here, g, f, b are given functions 2π periodic in θ.

LEMMA 4.2. *Assume* $b \in \Lambda^{m+2}$, $f \in \Lambda^m$, $g \in \Lambda^{m+1}$, $m \geqq 0$. *Then* (4.6) *has a unique solution and*

$$
\|u\|_{m+2} + \overline{\|u\|}_{m+2} \leqq c(\|f\|_m + \|g\|_{m+1} + \|b\|_{m+2}). \tag{4.7}
$$

Proof. Express $f = \sum_{n=-\infty}^{\infty} f_n(r)\, e^{in\theta}$, $g = \sum_{n=-\infty}^{\infty} g_n\, e^{in\theta}$, $b = \sum_{n=-\infty}^{\infty} b_n\, e^{in\theta}$, $u = \sum_{n=-\infty}^{\infty} u_n(r)\, e^{in\theta}$. Substituting these into (4.6) and suppressing the subscript n (i.e., writing f for f_n, g for g_n, etc.) and letting $r = e^x$, we get

$$
u_{xx} - n^2 u = e^{2x} f(e^x), \quad u(0) = b, \quad \frac{1}{h_0} u_x(h_1) + \sigma u(h_1) = g, \tag{4.8}
$$

where $h_1 = \log h_0 \simeq 0.57$. Set $F(t) = e^{2t} f(e^t)$. The solution of (4.8) is

$$
u(x) = \gamma \sinh nx + b \cosh nx + \frac{1}{n} \int_0^x F(t) \sinh n(x - t)\, dt, \tag{4.9}
$$

where the constant γ is determined from

$$
\begin{aligned}
& \gamma A + b\left(\frac{n \sinh nh_1}{h_0} + \sigma \cosh nh_1 \right) \\
& \quad + \int_0^{h_1} F(t) \left[\frac{1}{h_0} \cosh n(h_1 - t) + \frac{\sigma}{n} \sinh n(h_1 - t) \right] dt = g.
\end{aligned} \tag{4.10}
$$

Here we denoted

$$
A = \frac{n \cosh nh_1}{h_0} + \sigma \sinh nh_1 \geqq cn\, e^{nh_1}. \tag{4.11}
$$

Multiplying (4.9) by A, using (4.10) and the standard identities for hyperbolic functions, we easily derive

$$
\begin{aligned}
Au(x) &= g \sinh nx + b\left(\frac{n}{h_0}\cosh n(h_1-x) + \sigma \sinh n(h_1-x)\right) \\
&\quad - \int_x^{h_1} F(t)\left[\frac{1}{h_0}\cosh n(h_1-t)\sinh nx + \frac{\sigma}{n}\sinh n(h_1-t)\sinh nx\right] dt \qquad (4.12)\\
&\quad - \int_0^{x} F(t)\left[\frac{1}{h_0}\sinh nt \cosh n(h_1-x) + \frac{\sigma}{n}\sinh nt \sinh n(h_1-x)\right] dt.
\end{aligned}
$$

Then in view of (4.11) we easily estimate

$$
\begin{aligned}
|u(r)| &\leqq c\left[\frac{|g|}{n} + |b| + \frac{1}{n}\int_x^{h_1} |F(t)|\, e^{n(x-t)}\, dt + \frac{1}{n}\int_0^{x} |F(t)|\, e^{n(t-x)}\, dt\right] \\
&\leqq c\left[\frac{|g|}{n} + |b| + \frac{1}{n}\sup_{1\leqq r\leqq h_0} |f(r)|\left(\frac{2}{n} - \frac{e^{n(x-h_1)}}{n} - \frac{e^{-nx}}{n}\right)\right] \qquad (4.13)\\
&\leqq c\left[\frac{|g|}{n} + |b| + \frac{1}{n^2}\max_{1\leqq r\leqq h_0} |f(r)|\right].
\end{aligned}
$$

Differentiating (4.9) and going through the same steps, we estimate

$$
|u'(r)| \leqq c\left[|g| + n|b| + \frac{1}{n}\max_{1\leqq r\leqq h_0} |f(r)|\right]. \qquad (4.14)
$$

Combining (4.13) with (4.14), and estimating $|u''(r)|$ from the equation, we conclude the estimate (4.7) with $m = 0$. The higher estimates are easily proved by induction.

An a priori estimate for (4.1) is given by the following lemma whose proof is similar to the above.

LEMMA 4.3. *Assume* $f \in \Lambda^m$, $g \in \Lambda^{m+1}$, $b \in \Lambda^{m+2}$, $m = \text{integer} \geqq 0$. *Then* (4.1) *has a unique* 2π *periodic in each* x_i *solution, and*

$$
\|u\|_{m+2} + \overline{\|u\|}_{m+2} \leqq c(\|f\|_m + \|g\|_{m+1} + \|b\|_{m+2}).
$$

5. Existence and uniqueness of solutions for Problems I and II.

THEOREM 5.1. *For* (3.2) *assume that* $b(x) \in C^{m+\alpha}(D)$, *and* $\varepsilon|b|_{m+\alpha}$ *is sufficiently small,* $m = \text{integer} \geqq 2$, $0 < \alpha < 1$. *Then there exists a pair of functions* $(v, h) \in C^{m+\alpha}(V) \times C^{m+\alpha}(D)$ *satisfying* (3.2).

Proof. Define a map T: $(w, k) \to (v, h)$ from $C^{m+\alpha}(V) \times C^{m+\alpha}(D)$ to itself by solving

$$
\begin{aligned}
v_y &= \varepsilon g(\varepsilon, Dw, Dk, Db), && y = 1,\\
\Delta v &= \varepsilon f(\varepsilon, D^2 w, D^2 k, D^2 b), && 0 < y < 1,\\
v &= b(x), && y = 0,
\end{aligned}
$$

and then computing $h(x) = v(x, 1)$. By Lemma 4.1 we easily conclude that the map T is well defined, takes a ball $|w|_{m+\alpha} + |k|_{m+\alpha} \leqq R$, with say $R = 2|b|_{m+\alpha}$, into itself, and is a contraction for $\varepsilon|b|_{m+\alpha}$ sufficiently small.

A similar proof could be given for Problem II. Instead, we give an existence proof in Λ^m spaces based on Lemma 4.2, which provides a more general approach, as will be seen in § 6.

THEOREM 5.2. *For the problem* (3.7) *assume that* $b(\theta) \in \Lambda^m$, *and* $\varepsilon \|b\|_m$ *is sufficiently small,* $m = \text{integer} \geqq 2$. *Then there exists a pair of functions* $(v, h) \in \Lambda^m(V) \times \Lambda^m(D)$ *satisfying* (3.6).

Proof. Substituting the first equation in (3.7) into the second we get

$$v_r + \frac{1}{h_0} v = \frac{\varepsilon}{h_0} r(\varepsilon, h) + \varepsilon g \equiv \varepsilon \bar{g}(\varepsilon, Dv, Dh, Db).$$

Next, we define a map $T: (w, k) \to (v, h)$ from $\Lambda^m(V) \times \Lambda^m(D)$ to itself by solving

$$\begin{aligned} &v_r + \frac{1}{h_0} v = \varepsilon \bar{g}(\varepsilon, Dw, Dk, Db), && r = h_0, \\ &\Delta v = \varepsilon f(\varepsilon, D^2 w, D^2 k, D^2 b), && 1 < r < h_0, \\ &v = h_0 b + \varepsilon q(\varepsilon, b), && r = 1, \end{aligned} \tag{5.1}$$

and then solving for $h(\theta)$ from

$$v(h_0, \theta) = h + \varepsilon r(\varepsilon, h) \left(h = \frac{h_0}{\varepsilon} (e^{\varepsilon v / h_0} - 1) \right). \tag{5.2}$$

Notice that the map T is well defined, i.e., it takes $\Lambda^m(V) \times \Lambda^m(D)$ into itself, provided $\varepsilon \|b\|_m$ is sufficiently small. Indeed, in view of the estimate (4.7) of Lemma 4.2, it suffices to show that $\bar{g} \in \Lambda^{m-1}(D)$, $f \in \Lambda^{m-2}(V)$. For this we use the special structure of f and $\bar{g}$. Indeed, consider $\bar{g}$. By Lemma 2.3, $\log(h_0 + \varepsilon h)$, p_θ, q_θ, $1/(h_0 + \varepsilon h)^2 \in \Lambda^{m-1}(D)$ for ε small (if smallness of $\varepsilon \|b\|_m$ comes from $\|b\|_m$, then work in small balls), and then by Lemma 2.2, $\bar{g} \in \Lambda^{m-1}(D)$. Similarly, $f \in \Lambda^{m-2}$ by Lemma 2.2.

Then one easily sees that map T takes the ball $\|w\|_m + \|k\|_m \leqq 2\|b\|_m$ into itself, and is a contraction.

Remark. A similar argument is valid for Problem I.

Next we prove uniqueness results, using techniques similar to [3] and [4].

THEOREM 5.3. *Problem* I *can have at most one solution* (*in the class of free surfaces satisfying interior sphere condition*).

Proof. Assume that this is not true, i.e., there are two solutions $(u(x, y), h(x))$ and $(\bar{u}(x, y), \bar{h}(x))$. By the maximum principle we conclude that $0 \leqq u \leqq 1$ for $b \leqq y \leqq h$, and $0 < u < 1$ for $b < y < h$, and also that h and $\bar{h}$ are different. Consider first the special case, when one free surface is above the other, touching at some point, say, $h(x) \geqq \bar{h}(x)$, $h(x_0) = \bar{h}(x_0)$. Consider $w = u - \bar{u}$ in the domain $b \leqq y \leqq \bar{h}$. Then $\Delta w = 0$, $w = 0$ for $y = b(x)$, $w \geqq 0$ for $y = \bar{h}(x)$ with $w(x_0) = 0$. Hence x_0 is a point of minimum for w. Since h and $\bar{h}$ have the same normal at x_0, by Hopf's lemma we have

$$0 > \frac{\partial w}{\partial n}(x_0) = \frac{\partial u}{\partial n}(x_0) - \frac{\partial \bar{u}}{\partial n}(x_0) = 0,$$

a contradiction.

Turning to the general case, we introduce translation of solution (u, h) downward, by considering

$$u_\tau(x, y) = u(x, y + \tau), \quad h_\tau(x) = h(x) - \tau, \quad \tau \geqq 0.$$

Clearly $\Delta u_\tau = 0$ for $b - \tau < y < h - \tau$. Choose $\tau = \tau_0$ so that $h_{\tau_0} \leqq \bar{h}$, and $h_{\tau_0}(x_0) = \bar{h}(x_0)$ for some x_0. (If h and $\bar{h}$ intersect, we translate either of two solutions, if $h > \bar{h}$ then translate (u, h).) Let $\bar{D} = \{x \mid x_0 \in D \text{ and } h_{\tau_0}(x) > b(x)\}$. By periodicity either $\bar{D} = (-\infty, \infty)$ or D is a bounded interval. In the first case consider $w = \bar{u} - u_{\tau_0}$ with $\bar{u}$, u_{τ_0}

restricted to $b(x) \leqq y \leqq h_{\tau_0}(x)$. Then $w > 0$ on $y = b(x)$, $w \geqq 0$ on $y = h_{\tau_0}(x)$, $w(x_0) = 0$, and as before we get contradiction at the point x_0. In the second case we consider the same w, with $\bar{u}$, u_{τ_0} restricted to $(x, y) = \{x \in \bar{D}, b(x) \leqq y \leqq h_{\tau_0}(x)\}$. Again we get the same contradiction at x_0.

THEOREM 5.4. *Problem* II *can have at most one solution* (*assuming* $h(\theta)$ *satisfying interior sphere condition*).

Proof. This time we introduce contraction of the solution by considering $u_a = u(ar, \theta) = u(ax, ay)$, $h_a = h/a$, $a > 1$. Clearly, $\Delta u_a = 0$. By contracting one of the free surfaces, until it is inside the other touching it at some point x_0, we get the same contradiction at x_0 as in the previous theorem. (Again, if the surfaces intersect, contract either one; if one is outside the other, contract the outside one. Also, notice that $\partial u_a / \partial n|_{h=h_a} = -a < -1$, as is clear from (3.5).)

6. General noncoercive problems. We discuss the problem ($x \in R^n$, $0 \leqq y \leqq 1$)

$$
\begin{aligned}
& u_y + \sum_{|\alpha| \leqq k} a_\alpha D^\alpha u = \varepsilon g(\varepsilon, D^k u, D^k h, D^k b), && y = 1, \\
& \Delta u = \varepsilon f(\varepsilon, D^2 u, D^2 h, D^2 b), && 0 < y < 1, \\
& u_y + \sum_{|\alpha| \leqq l} b_\alpha D^\alpha u = b(x), && y = 0.
\end{aligned} \tag{6.1}
$$

Here $h = u(x, 1)$, g, f, and b are given functions, 2π periodic in each variable x_i, $i = 1, \cdots, n$; $\alpha = (\alpha_1, \cdots, \alpha_n, 0)$, ε, a_α, b_α are constants, and k, l are integers whose magnitudes are not restricted. We are looking for 2π periodic in each x_i solution $u(x, y)$, assuming ε is small.

Solving a problem of type (6.1) was the key ingredient in solving Problems I and II, as well as in Shinbrot's proof of existence of water waves in three dimensions. If the boundary condition at $y = 1$ is coercive, i.e., satisfies the Lopatinski-Schapiro condition, then one should be able to prove existence based on Schauder's estimates, as we did for Problem I. In particular, in Shinbrot's paper one has the boundary operators (with $u = u(x, y, z)$) $u_y - \tau(u_{yxx} + u_{yzz}) + F u_{xx}$ at $y = 1$, and u_y at $y = 0$, which are both coercive. Hence, it appears that Schauder's estimates can be used, considerably simplifying the proof.

Using Λ^m spaces one can treat more general problems, including noncoercive ones. In particular, we have the following theorem, whose proof is similar to that of Theorem 5.2.

THEOREM 6.1. *Assume the following estimate for the problem* (6.1) (*with* $g = g(x)$, $f = f(x, y)$)

$$
\|u\|_m + \overline{\|u\|}_m \leqq c(\|f\|_{m-2} + \|g\|_{m-k} + \|b\|_m),
$$

with integer $m \geqq \max(2, k)$. *Assume that the functions* g *and* f *are analytic in their arguments and small if either* ε *or* $\|b\|_m$, $\|u\|_m$, $\|h\|_m$ *are sufficiently small. Then for* $\varepsilon \|b\|_m$ *sufficiently small the problem* (6.1) *has a solution.*

Example. In Shinbrot's water wave model assume that the surface tension $\tau = 0$, and the gravity is pointing up, i.e., g and $F = U^2/g$ are negative numbers, say $F = -f$, $f \geqq 0$. Assuming for simplicity $u = 0$ at $y = 0$, we consider the problem (different from the one in [10])

$$
\begin{aligned}
& u_y - f u_{xx} = \varepsilon g(\varepsilon, Du, Dh, Db), && y = 1, \\
& \Delta u = \varepsilon f(\varepsilon, D^2 u, D^2 h, D^2 b), && 0 < y < 1, \\
& u = 0, && y = 0.
\end{aligned} \tag{6.2}
$$

Here $u = u(x, y, z)$, $h = u(x, 1, z)$. The boundary condition at $y = 1$ is noncoercive (see [7]); hence Schauder's estimates are not valid for (6.2). However, by an argument similar to that of Lemma 4.2 we can estimate (with $g = g(x, z)$, $f = f(x, y, z)$)

$$\|u\|_{m+2} + \overline{\|u\|}_{m+2} \leq c(\|f\|_m + \|g\|_{m+1}),$$

and Theorem 6.1 applies, giving existence for (6.2). (We do not know any other way to prove existence for (6.2).)

Acknowledgments. I wish to thank A. Friedman, P. L. Lions, and S. Stojanovic for useful comments.

GLOBAL BIFURCATION AND CONTINUATION IN THE PRESENCE OF SYMMETRY WITH AN APPLICATION TO SOLID MECHANICS*

TIMOTHY J. HEALEY†

Abstract. A group-theoretic approach to global bifurcation and continuation for one-parameter problems with symmetry is presented. The basic theme is the construction of a reduced problem, having solutions with specified symmetries, that can be analyzed by global or local techniques. A global analysis of a general class of reduced problems via well-established continuation techniques shows that symmetry is preserved on global continua of solutions. The approach is illustrated in the analysis of large post-buckling solutions of a nonlinearly elastic ring with $O(2)$ symmetry under uniform hydrostatic pressure, and yields several new results. Specific symmetries of global bifurcating solution branches are enumerated, which enables a detailed qualitative analysis.

Key words. symmetry, bifurcation, global, groups, solid mechanics, structures, post-buckling

AMS(MOS) subject classifications. 34, 58, 73

1. Introduction. Let B be a real Banach space, let Ω be an open, connected subset of $B\times\mathbb{R}$, and let $f:\Omega\to B$ be $(m\geqq 1)$-times continuously Fréchet differentiable. Consider a steady or static bifurcation problem of the form

$$f(x,\lambda)=0. \tag{1.1}$$

The goal is to determine the *solution set*

$$\Sigma\equiv\{(x,\lambda)\in\Omega: f(x,\lambda)=0\}. \tag{1.2}$$

Bifurcation problems often arise in the physical sciences for systems with symmetry. Suppose that (1.1) models such a system, characterized by a symmetry group $\mathcal{G}$. In such a case, (1.1) is usually *equivariant* under a specific representation (cf. Robert [1983]) T of $\mathcal{G}$ on B

$$f(T_g x,\lambda)=T_g f(x,\lambda)\quad\forall g\in\mathcal{G}, \tag{1.3}$$

where it is presumed henceforth that $T_g(\Omega)\subseteq\Omega$ for all $g\in\mathcal{G}$.

It is well known that (1.3) can be used to simplify what is often an intractable analysis of local bifurcation (cf. Sattinger [1979], Vanderbauwhede [1982], Golubitsky and Schaeffer [1985]). The purpose of this paper is to demonstrate that equivariance can also be exploited to considerable advantage in global bifurcation problems. The general approach is presented in § 2, where it is shown that a reduced problem for (1.1) can be constructed in a straightforward manner. The analysis of a reduced problem via well-known continuation theorems (cf. Rabinowitz [1973], Alexander and Yorke [1976]) then shows that symmetry properties are preserved on global continua of solutions. The procedure is illustrated in § 3 in the analysis of a nonlinearly elastic ring with $O(2)$ symmetry, and yields several new results. Symmetries of global post-buckling solution branches are enumerated, which enables a detailed qualitative analysis. In particular, it is shown that all global (primary) bifurcating branches with distinct symmetries are mutually nonintersecting.

2. Reduction and continuation. Let $\mathscr{H} \subseteq \mathscr{G}$ be a subgroup (not necessarily proper) and define

$$B_{\mathscr{H}} \equiv \{u \in B: T_g u = u \ \forall g \in \mathscr{H}\}, \tag{2.1}$$

which is called the *$\mathscr{H}$-fixed-point set.* It is straightforward to show that $B_{\mathscr{H}} \subseteq B$ is a linear subspace. Suppose that $B_{\mathscr{H}}$ is complemented in B, viz.,

$$B = B_{\mathscr{H}} \oplus A_{\mathscr{H}}. \tag{2.2}$$

It can be shown that (2.2) holds if and only if there exists a continuous projection $P_{\mathscr{H}}: B \to B$ with $\mathscr{R}(P_{\mathscr{H}}) = B_{\mathscr{H}}$ (cf. Rudin [1973, § 5.16]). If $\mathscr{H}$ is a compact group, then $P_{\mathscr{H}}$ is given explicitly by

$$P_{\mathscr{H}} x \equiv \int_{\mathscr{H}} T_g x \, d\mu(g) \quad \forall x \in B, \tag{2.3}$$

where μ is the Haar measure of $\mathscr{H}$. In the sequel, the decomposition (2.2) is assumed to hold.

By virtue of (1.3) and (2.1), it follows that

$$T_g f(u, \lambda) = f(u, \lambda) \quad \forall (u, \lambda) \in \Omega_{\mathscr{H}}, \quad g \in \mathscr{H}. \tag{2.4}$$

Thus, $f(u, \lambda) \in B_{\mathscr{H}}$ for all $(u, \lambda) \in \Omega_{\mathscr{H}}$ and $f: \Omega_{\mathscr{H}} \to B_{\mathscr{H}}$, where $\Omega_{\mathscr{H}} \equiv \Omega \cap (B_{\mathscr{H}} \times \mathbb{R})$. This leads to the following conclusion.

THEOREM 2.1. *Define $f_{\mathscr{H}} \equiv P_{\mathscr{H}} \circ f | \Omega_{\mathscr{H}}$. A point $(u_0, \lambda_0) \in \Omega_{\mathscr{H}}$ is a solution of* (1.1) *if and only if it is a solution of the $\mathscr{H}$-reduced problem*

$$f_{\mathscr{H}}(u, \lambda) = 0. \tag{2.5}$$

The solution set of (2.5), *denoted by $\Sigma_{\mathscr{H}}$, is called the $\mathscr{H}$-solution set.*

Henceforth, if $B_{\mathscr{H}}$ is finite-dimensional, then all such $(m \geqq 1)$-times continuously differentiable maps $f_{\mathscr{H}}: \Omega_{\mathscr{H}} \to B_{\mathscr{H}}$ are considered. If $B_{\mathscr{H}}$ is infinite-dimensional, then $f_{\mathscr{H}}$ is assumed to be of the form

$$f_{\mathscr{H}}(u, \lambda) \equiv u - c_{\mathscr{H}}(u, \lambda), \tag{2.6}$$

where $c_{\mathscr{H}}: \Omega_{\mathscr{H}} \to B_{\mathscr{H}}$ is completely continuous.

Recall that a *regular* solution point $(x_0, \lambda_0) \in \Sigma$ of (1.1) is one at which the Fréchet derivative $D_1 f^0 \equiv D_1 f(x_0, \lambda_0): B \to B$ is invertible. If $D_1 f^0$ is not invertible, then (x_0, λ_0) is called a *singular* point. Regular and singular points of the $\mathscr{H}$-reduced problem are defined analogously and are henceforth referred to as $\mathscr{H}$-regular and $\mathscr{H}$-singular points, respectively.

It often happens in applications that at least one solution point of (1.1), say, $(u_0, \lambda_0) \in \Sigma$, is known a priori. Suppose that $u_0 \in \Omega_{\mathscr{H}}$, for a particular subgroup $\mathscr{H} \subseteq \mathscr{G}$. Then $(u_0, \lambda_0) \in \Sigma_{\mathscr{H}}$ by Theorem 2.1. If (u_0, λ_0) is $\mathscr{H}$-regular, then the implicit function theorem guarantees the existence of a unique, local branch of solutions of (2.5) through (u_0, λ_0). By Theorem 2.1, that branch is a local, $\mathscr{H}$-symmetric solution path of (1.1). Let Σ^0 denote the connected component of Σ containing (u_0, λ_0). The following extension of the implicit function theorem shows that $\mathscr{H}$ symmetry is preserved globally.

EQUIVARIANT CONTINUATION THEOREM 2.2. *Let $(u_0, \lambda_0) \in \Sigma_{\mathscr{H}}$ be $\mathscr{H}$-regular. Then there exists a global, $\mathscr{H}$-symmetric solution branch of* (1.1) *through (u_0, λ_0). That is, there exists a connected subset $\Sigma^0_{\mathscr{H}} \subseteq \Sigma_{\mathscr{H}} \cap \Sigma^0$ containing (u_0, λ_0) that is characterized by at least one of the following alternatives:*

(i) *$\Sigma^0_{\mathscr{H}}$ is unbounded in $B \times \mathbb{R}$.*

(ii) *$\overline{\Sigma^0_{\mathscr{H}}} \cap \partial\Omega \neq \varnothing$.*

(iii) *$\Sigma^0_{\mathscr{H}} - \{(u_0, \lambda_0)\}$ is connected in $B \times \mathbb{R}$.*

Proof. In the context of the $\mathcal{H}$-reduced problem (2.5), this is precisely a theorem due to Alexander and Yorke [1976]. The claims hold for (1.1) by virtue of Theorem 2.1. □

Remark 2.1. This simple but profound result implies that the symmetry of an $\mathcal{H}$-regular point cannot completely "die out" somewhere along Σ^0. This has important applications in the construction of efficient numerical algorithms for global bifurcation problems (cf. Healey [1988a]). On the other hand, $\Sigma^0_{\mathcal{H}}$ need not coincide with Σ^0. Rather $\Sigma^0_{\mathcal{H}} \subseteq \Sigma^0$, and $\Sigma^0 \backslash \Sigma^0_{\mathcal{H}}$ (if it is nonempty) is the $\mathcal{H}$-symmetry-breaking component of Σ^0, which branches from $\Sigma^0_{\mathcal{H}}$. Indeed, an $\mathcal{H}$-regular point need not be a regular point of (1.1), i.e., (u_0, λ_0) may be an $\mathcal{H}$-symmetry-breaking bifurcation point. The $\mathcal{H}$ regularity of such a point can be exploited to enable its accurate computation in a numerical setting (cf. Werner and Spence [1984], Healey [1988a]).

Consider next the problem of bifurcation from a trivial branch of solutions of (1.1). Assume that

$$f(0, \lambda) = 0 \quad \forall (0, \lambda) \in \Omega. \tag{2.7}$$

The set $\Sigma^0_t \equiv (\{0\} \times \mathbb{R}) \cap \Omega \subset \Sigma_{\mathcal{G}}$ is called the trivial solution branch of (1.1), and is assumed to be homeomorphic to $\{0\} \times \mathbb{R}$. A solution pair $(0, \lambda_0) \in \Sigma^0_t$ is said to be a *bifurcation point* of (1.1) if every neighborhood of $(0, \lambda_0)$ contains solution pairs $(u_*, \lambda_*) \in \Sigma$ with $u_* \neq 0$. Let Σ^0 denote the connected component of Σ that contains $(0, \lambda_0)$. Define $L(\lambda) \equiv D_1 f(0, \lambda)$ and assume that $L(\lambda_0): B \to B$ is singular, which is necessary for $(0, \lambda_0)$ to be a bifurcation point.

It often happens in applications that some, but not all, of the $\mathcal{G}$ symmetry is broken on a bifurcating branch. Accordingly, suppose that $\mathcal{N}(L(\lambda_0)) \not\subset B_{\mathcal{G}}$. When $\mathcal{G}$ characterizes highly redundant symmetry (e.g., $\mathcal{G} = O(3)$), then $\dim \mathcal{N}(L(\lambda_0))$ is often quite large (cf. for example, Knightly and Sather [1980], Ihrig and Golubitsky [1984]). Thus, the analysis of local bifurcation at $(0, \lambda_0)$ can become intractable ($\dim \mathcal{N}(L(\lambda_0)) \geqq 3$ is enough (cf. Iooss and Joseph [1980])). This motivates seeking a reduced problem that simplifies the analysis of (1.1) near $(0, \lambda_0)$.

For any subgroup $\mathcal{H} \subseteq \mathcal{G}$, it follows from (2.5) and (2.7) that

$$f_{\mathcal{H}}(0, \lambda) = 0 \quad \forall (0, \lambda) \in \Omega_{\mathcal{H}}, \tag{2.8}$$

i.e., Σ^0_t is also the trivial solution branch of (2.5). The goal is to determine a subgroup (or subgroups) that yields a problem having nontrivial solutions in common with those of (1.1) near $(0, \lambda_0)$. A well-known procedure (in local bifurcation theory) for finding $\mathcal{H}$ is to seek a null vector, $y \in \mathcal{N}(L(\lambda_0))$, such that the *isotropy subgroup* of $\mathcal{G}$ at y,

$$\mathcal{H} \equiv \{g \in G \mid T_g y = y\}, \tag{2.9}$$

is proper. It then follows from Theorem 2.1 that $L_{\mathcal{H}}(\lambda_0) \equiv D_1 f_{\mathcal{H}}(0, \lambda_0) = [L(\lambda_0) \mid B_{\mathcal{H}}]: B_{\mathcal{H}} \to B_{\mathcal{H}}$ is singular. This suggests the following theorem.

EQUIVARIANT BIFURCATION THEOREM 2.3. *Suppose that f is C^2 and there exists a null vector $y \in \mathcal{N}(A(\lambda_0))$ that defines a proper isotropy subgroup $\mathcal{H}$ (cf.* (2.9)*). Assume the following*:

(EB1) $\dim \mathcal{N}(L_{\mathcal{H}}(\lambda_0))$ *is odd.*

(EB2) $[L'_{\mathcal{H}}(\lambda_0)]v \notin \mathcal{R}(L_{\mathcal{H}}(\lambda_0)) \quad \forall v \in \mathcal{N}(L_{\mathcal{H}}(\lambda_0))$.

Then $(0, \lambda_0)$ *is a bifurcation point of* (1.1) *such that in every sufficiently small neighborhood*

of $(0, \lambda_0)$, *there are nontrivial solutions* $(u_*, \lambda_*) \in \Sigma_{\mathscr{H}}$. *In particular, if* $\dim \mathscr{N}(L_{\mathscr{H}}(\lambda_0)) = 1$, *then there exists a unique, local, bifurcating branch of solutions of the form* $s \mapsto (\hat{u}(s), \hat{\lambda}(s)) \in \Sigma_{\mathscr{H}}$. *Moreover, there exists a connected subset* $\zeta^0_{\mathscr{H}} \subseteq \Sigma_{\mathscr{H}} \cap \Sigma^0 \backslash \Sigma^0_t$ *containing* $(0, \lambda_0)$ *that is characterized by at least one of the following properties*:

(i) $\zeta^0_{\mathscr{H}}$ *is unbounded in* $B \times \mathbb{R}$.

(ii) $\zeta^0_{\mathscr{H}} \cap \partial\Omega \neq \varnothing$.

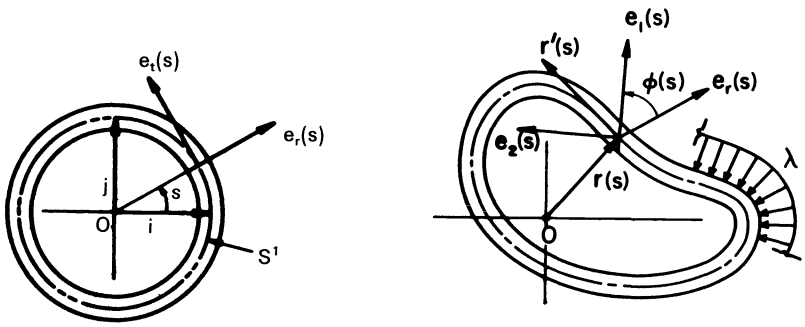
(iii) *There exists a pair* $(0, \lambda_*) \in \zeta^0_{\mathscr{H}} \cap \Sigma^0_t$ *with* $\lambda_* \neq \lambda_0$.

The subset $\zeta^0_{\mathscr{H}}$ *is called a global,* $\mathscr{H}$*-symmetric, bifurcating branch of* (1.1) *through* $(0, \lambda_0)$.

Proof. In the context of the $\mathscr{H}$-reduced problem (2.5), the first claim is Krasnosel'skii's theorem [1965], the second statement holds by a theorem of Crandall and Rabinowitz [1971], and the third result is due to Rabinowitz [1973]. Conditions (EB1) and (EB2) insure that the Leray-Schauder degree of $u \mapsto f_{\mathscr{H}}(u, \lambda)$ (which is well defined because of (3.1); cf., for example, Cronin [1964]) changes sign as λ passes through λ_0 along $u = 0$ (cf. Alexander and Fitzpatrick [1980]). That all claims hold for the full problem (1.1) is a direct consequence of Theorem 2.1. □

Remark 2.2. The claims of Theorem 2.3 pertaining to local bifurcation are well known and have appeared in various different forms (cf. Cicogna [1981], Vanderbauwhede [1982], Sattinger [1983], and Golubitsky [1983]). However, in those treatments the Lyapunov-Schmidt technique (cf., for example, Golubitsky and Schaeffer [1985]) is employed before the use of group-theoretic reasoning, thus obviating global conclusions.

3. Large post-buckling of a nonlinearly elastic ring with $O(2)$ symmetry. The analysis of a planar, nonlinearly elastic, circular ring under hydrostatic pressure (cf. Fig. 1) is presented in this section as an application of Theorem 2.3. The techniques of § 2 enable a detailed qualitative analysis of global post-buckling solution branches. The ring is modeled as a nonlinearly elastic rod that is capable of suffering geometrically exact stretching, shearing and bending. The formulation is due to Antman [1973]. In that work, global existence theorems were established, and some symmetry properties of solutions were obtained by phase-plane techniques. Similar results for an unshearable ring have been obtained by Antman [1970a], [1970b], where the latter work also includes a local bifurcation analysis from a radially symmetric state. A global bifurcation analysis of a circular arch (which leads to a two-point boundary-value problem involving the same differential equations as the ring in Antman [1973]) is presented in Antman and Dunn [1980].



undeformed configuration deformed configuration

FIG. 1. *Planar configurations of a ring.*

Let $\{\mathbf{i}, \mathbf{j}, \mathbf{k}\}$ be a fixed orthonormal basis for E^3, Euclidean 3-space. The curve of centroids of the cross sections of the undeformed ring is taken to coincide with the unit circle $S^1 \subset \text{span}\{\mathbf{i}, \mathbf{j}\}$, along which points are identified by arclength $s \in \mathbb{R}_{2\pi} \equiv \mathbb{R}(\text{mod } 2\pi)$ (cf. Fig. 1). Define the unit vectors

$$\mathbf{e}_r(s) \equiv \cos(s)\mathbf{i} + \sin(s)\mathbf{j} \quad \text{and} \quad \mathbf{e}_t(s) \equiv -\sin(s)\mathbf{i} + \cos(s)\mathbf{j}. \tag{3.1}$$

Then $\{\mathbf{e}_r, \mathbf{e}_t, \mathbf{k}\}$ is an orthonormal frame field for E^3 on S^1.

A planar configuration of the ring is described by a mapping

$$\mathbb{R}_{2\pi} \ni s \mapsto (\mathbf{r}(s), \phi(s)) \in \text{span}\{\mathbf{i}, \mathbf{j}\} \times \mathbb{R}, \tag{3.2}$$

where $s \in \mathbb{R}_{2\pi}$ emphasizes the 2π-periodicity of $\mathbf{r}$ and ϕ. The vector $\mathbf{r}(s)$ is the position (measured from the center 0 of the ring) of the material point on the deformed centroidal curve that has position vector $\mathbf{e}_r(s)$ on the undeformed centroidal curve. The unit vector

$$\mathbf{e}_1[\phi(s), s] \equiv \cos[\phi(s)]\mathbf{e}_r(s) + \sin[\phi(s)]\mathbf{e}_t(s) \tag{3.3}$$

characterizes the deformed orientation of the cross section at s that has undeformed orientation coincident with $\mathbf{e}_r(s)$. Thus, $\phi(s)$ is a measure of rotation between the deformed and undeformed cross section at s. Defining

$$\mathbf{e}_2[\phi(s), s] \equiv -\sin[\phi(s)]\mathbf{e}_r(s) + \cos[\phi(s)]\mathbf{e}_t(s), \tag{3.4}$$

it follows that $\{\mathbf{e}_1, \mathbf{e}_2, \mathbf{k}\}$ is also an orthonormal frame field for E^3 on S^1.

The strain field of the rod is defined by

$$(\mathbf{r}', \phi') \quad \text{on } \mathbb{R}_{2\pi}, \tag{3.5}$$

where $(\,)'$ denotes differentiation with respect to argument on $\mathbb{R}_{2\pi}$. It is convenient to express $\mathbf{r}$ and $\mathbf{r}'$ as

$$\mathbf{r} = r_1\mathbf{e}_1 + r_2\mathbf{e}_2 \quad \text{and} \quad \mathbf{r}' = \xi_1\mathbf{e}_1 + \xi_2\mathbf{e}_2 \quad \text{on } \mathbb{R}_{2\pi}, \tag{3.6}$$

and to define

$$\xi_3 \equiv \phi' \quad \text{on } \mathbb{R}_{2\pi}. \tag{3.7}$$

Then by (3.1), (3.6), and (3.7), the strain-displacement relations for the ring are

$$r_1' - (1 + \xi_3)r_2 - \xi_1 = 0, \tag{3.8a}$$

$$r_2' + (1 + \xi_3)r_1 - \xi_2 = 0, \tag{3.8b}$$

$$\phi' - \xi_3 = 0 \qquad \text{on } \mathbb{R}_{2\pi}. \tag{3.8c}$$

The condition

$$\mathbf{r}' \cdot \mathbf{e}_2 = \xi_2 > 0 \quad \text{on } \mathbb{R}_{2\pi} \tag{3.9}$$

is imposed to insure that the local ratio of deformed length to undeformed length of centroidal curve does not vanish, and that $\mathbf{e}_1$ is not tangent to the deformed centroidal curve.

The undeformed ring is subjected to a uniform, hydrostatic pressure of intensity $\lambda > 0$ per unit (deformed) length of centroidal curve. Let $\mathbf{n}(s) \in \text{span}\{\mathbf{i}, \mathbf{j}\}$ denote the resultant force and $m(s)\mathbf{k}$ the resultant couple acting across the deformed cross section at s. The well-known equilibrium equations for the ring are

$$\mathbf{n}' + m'\mathbf{k} + \lambda\mathbf{k} \times \mathbf{r}' + \mathbf{r}' \times \mathbf{n} = \mathbf{0} \quad \text{on } \mathbb{R}_{2\pi}, \tag{3.10}$$

where "$\times$" denotes the usual right-handed cross product on E^3.

The ring is assumed to be homogeneous and nonlinearly elastic by requiring the existence of smooth constitutive functions

$$\mathbb{R}\times(0,\infty)\times\mathbb{R}\ni(\xi_1,\xi_2,\xi_3)\mapsto\hat{t}_i(\xi_1,\xi_2,\xi_3)\in\mathbb{R},\qquad i=1,2,3,$$

such that

$$\begin{aligned}\mathbf{n}(s)&=\sum_{i=1}^{2}\hat{t}_i(\xi_1(s),\xi_2(s),\xi_3(s))\mathbf{e}_i[\phi(s),s],\\ m(s)&=\hat{t}_3(\xi_1(s),\xi_2(s),\xi_3(s)).\end{aligned}\tag{3.11}$$

The constitutive functions are assumed to satisfy the following physically reasonable conditions (cf. Antman and Dunn [1980]):

The 3×3 Jacobian matrix

$$\left[\frac{\partial\hat{t}_i}{\partial\xi_j}\right]\text{ is positive-definite on }\mathbb{R}\times(0,\infty)\times\mathbb{R},\tag{3.12}$$

$$\hat{t}_1(0,\xi_2,\xi_3)=0\quad\forall\xi_2\in(0,\infty),\quad\xi_3\in\mathbb{R},\tag{3.13a}$$

$$\hat{t}_2(\xi_1,1,\xi_3)=0\quad\forall\xi_1,\quad\xi_3\in\mathbb{R},\tag{3.13b}$$

$$\hat{t}_3(\xi_1,\xi_2,0)=0\quad\forall\xi_1\in\mathbb{R},\quad\xi_2\in(0,\infty),\tag{3.13c}$$

$$\frac{\partial\hat{t}_2}{\partial\xi_1}(0,\xi_2,0)=\frac{\partial\hat{t}_2}{\partial\xi_3}(0,\xi_2,0)=0\quad\forall\xi_2\in(0,\infty),\tag{3.14}$$

$$\lim_{\xi_2\searrow0}\hat{t}_2(0,\xi_2,0)=-\infty.\tag{3.15}$$

Substitution of (3.11) into (3.10) leads to the following componential form of the equilibrium equations with respect to $\{\mathbf{e}_1,\mathbf{e}_2,\mathbf{k}\}$:

$$[\hat{t}_1(\xi_1,\xi_2,\xi_3)]'-(1+\xi_3)\hat{t}_2(\xi_1,\xi_2,\xi_3)-\lambda\xi_2=0,\tag{3.16a}$$

$$[\hat{t}_2(\xi_1,\xi_2,\xi_3)]'+(1+\xi_3)\hat{t}_1(\xi_1,\xi_2,\xi_3)+\lambda\xi_1=0,\tag{3.16b}$$

$$[\hat{t}_3(\xi_1,\xi_2,\xi_3)]'+\xi_1\hat{t}_2(\xi_1,\xi_2,\xi_3)-\xi_2\hat{t}_1(\xi_1,\xi_2,\xi_3)=0\quad\text{on }\mathbb{R}_{2\pi}.\tag{3.16c}$$

The systems (3.8) and (3.16) together with the constraint (3.9) constitute the field equations for the ring, where r_1, r_2, ϕ, ξ_i, $i=1,2,3$, are each 2π-periodic.

It is convenient to express the governing equations in a more compact form. Define the six-tuple

$$\mathcal{y}\equiv(r_1,r_2,\phi,\xi_1,\xi_2,\xi_3)\in\mathbb{R}^6.\tag{3.17}$$

Let $C^0_{2\pi}$ denote the Banach space of all continuous, 2π-periodic functions from $\mathbb{R}_{2\pi}$ into $\mathbb{R}^6$ with norm

$$|\mathcal{y}|=\max_{s\in\mathbb{R}_{2\pi}}\|\mathcal{y}(s)\|,$$

where $\|\ell\|$ denotes the Euclidean norm of $\ell\in\mathbb{R}^6$. Let $C^1_{2\pi}\subset C^0_{2\pi}$ denote the Banach space of all such mappings that are also continuously differentiable with norm

$$|\mathcal{y}|_1=|\mathcal{y}|+|\mathcal{y}'|.$$

Define the subset

$$\mathcal{O}\equiv\{\mathcal{y}\in C^1_{2\pi}:\xi_2>0\text{ on }\mathbb{R}_{2\pi}\}\times(0,\infty).\tag{3.18}$$

Consider a mapping $\mathcal{k}: \mathcal{O} \to C^0_{2\pi}$ defined by identifying the real-valued component functions h_1, h_2, and h_3 with the left sides of (3.16a), (3.16b), and (3.16c), respectively, and h_4, h_5, and h_6 with the left sides of (3.8a), (3.8b), and (3.8c), respectively. Then the field equations are equivalent to

$$\mathcal{k}(\mathcal{y}, \lambda) = 0. \tag{3.19}$$

Since the ring is homogeneous, it follows that the proper orthogonal group $SO(2)$ is a symmetry group of the ring. However, the material properties of the ring are assumed to concur with the complete geometric symmetry group $O(2)$. That is, the ring posesses through-thickness properties that are taken to be invariant under reflections as well as rotations in the plane. This places the following further restrictions on the constitutive functions:

$$\begin{aligned} &\hat{t}_1(-\xi_1, \xi_2, \xi_3) = -\hat{t}_1(\xi_1, \xi_2, \xi_3), \\ &\hat{t}_i(-\xi_1, \xi_2, \xi_3) = \hat{t}_i(\xi_1, \xi_2, \xi_3), \qquad i = 2, 3, \\ &\qquad\qquad \forall (\xi_1, \xi_2, \xi_3) \in \mathbb{R} \times (0, \infty) \times \mathbb{R}. \end{aligned} \tag{3.20}$$

Remark 3.1. The restrictions (3.20) can be justified by viewing the rod as a constrained, two-dimensional, homogeneous, isotropic elastic body, with the constitutive functions $\hat{t}_i$, $i = 1, 2, 3$, defined by appropriate resultants over the cross section (cf., for example, Antman and Carbone [1977, § 8]).

The appropriate representation of $O(2)$ is defined as follows. Let $T_g: C^m_{2\pi} \to C^m_{2\pi}$ $(m = 0, 1)$ be given by

$$[T_g \mathcal{y}](s) \equiv \begin{cases} \mathcal{y}(s+g) & \forall g \in \mathbb{R}_{2\pi} \cong SO(2), \\ E\mathcal{y}(g-s) & \forall g \in \mathbb{R}_{2\pi} \cong O(2) \backslash SO(2), \end{cases} \tag{3.21}$$

where $E: \mathbb{R}^6 \to \mathbb{R}^6$ is defined by $E\mathcal{y} \equiv (r_1, -r_2, -\phi, -\xi_1, \xi_2, \xi_3)$. It is straightforward to show that $g \mapsto T_g$ is a representation of $O(2)$ on $C^m_{2\pi}$. By (3.18) and (3.21), it is readily demonstrated that $T_g(\mathcal{O}) \subseteq \mathcal{O}$ for all $g \in \mathcal{G}$.

THEOREM 3.1. *The mapping in* (3.19) *is equivariant under T, i.e.,*

$$h(T_g \mathcal{y}, \lambda) = T_g h(\mathcal{y}, \lambda) \quad \forall g \in O(2).$$

Proof. Since the system (3.8), (3.16) is autonomous, the claim is immediate for all $g \in SO(2)$. If $g \in O(2) \backslash SO(2)$, it follows from (3.21) that

$$[T_g \mathcal{y}](s) = (r_1, -r_2, -\phi, -\xi_1, \xi_2, \xi_3)(g - s),$$

and

$$\frac{d}{ds}[T_g \mathcal{y}](s) = (-r_1', r_2', \phi', \xi_1', -\xi_2', -\xi_3')(g - s).$$

Substitution of these expressions into (3.8) and (3.16), while making use of (3.20), then yields the desired result. □

Intuitively, it is natural to seek a "trivial" radially symmetric solution (the existence of which is well known). Nonetheless, it is of interest to demonstrate that Theorem 2.1 leads to the same result by constructing the $O(2)$-reduced problem. By (2.3) and (3.21), the projection onto the $O(2)$-fixed-point set is given by

$$P\mathcal{y} = \frac{1}{2}\left[\frac{1}{2\pi}\int_0^{2\pi} \mathcal{y}(s+g)\, dg + \frac{1}{2\pi}\int_0^{2\pi} E\mathcal{y}(g-s)\, dg\right]. \tag{3.22}$$

By (3.17), (3.21), and the 2π-periodicity of y, it follows that

$$\frac{1}{2\pi}\int_0^{2\pi} y(s+g)\,dg = (\bar{r}_1, \bar{r}_2, \bar{\phi}, \bar{\xi}_1, \bar{\xi}_2, \bar{\xi}_3) \in \mathbb{R}_6,$$

and

$$\frac{1}{2\pi}\int_0^{2\pi} Ey(g-s)\,dg = (\bar{r}_1, -\bar{r}_2, -\bar{\phi}, -\bar{\xi}_1, \bar{\xi}_2, \bar{\xi}_3) \in \mathbb{R}_6,$$

where $\bar{r}_1$ denotes the average value of r_1 on $\mathbb{R}_{2\pi}$, etc. Thus, (3.22) becomes

$$Py = (\bar{r}_1, 0, 0, 0, \bar{\xi}_2, \bar{\xi}_3) \quad \text{on } \mathbb{R}_{2\pi}. \tag{3.23}$$

Note that (3.23) includes a reduction in both independent and dependent variables. By Theorem 2.1, the substitution of (3.23) into (3.19) identically satisfies (3.16b), (3.16c), and (3.8a), which is easily verified, and (3.8c) reduces to $\bar{\xi}_3 = 0$. The remaining nonzero algebraic equations are

$$\hat{t}_2(0, \bar{\xi}_2, 0) + \lambda\bar{\xi}_2 = 0, \qquad \bar{r}_1 = \bar{\xi}_2. \tag{3.24}$$

By (3.12) and (3.15), it follows that (3.24) has a unique solution $\bar{r}_1 = \bar{\xi}_2 = \psi(\lambda)$ for all $\lambda \geqq 0$, where $\psi : [0, \infty) \to (0, 1]$ is monotonically decreasing.

To investigate bifurcation from the $O(2)$-symmetric solution, it is convenient to bring (3.19) into the form of (2.7). Define

$$\bar{y}(\lambda) = (\psi(\lambda), 0, 0, 0, \psi(\lambda), 0) \quad \text{on } \mathbb{R}_{2\pi}, \tag{3.25}$$

and let $y = \bar{y}(\lambda) + x$, where

$$x = (x_1, x_2, x_3, x_4, x_5, x_6) \in C^1_{2\pi}. \tag{3.26}$$

Then set

$$f(x, \lambda) \equiv h(\bar{y}(\lambda) + x, \lambda) = 0. \tag{3.27}$$

In view of (3.18), $f : \Omega \to C^1_{2\pi}$, where

$$\Omega \equiv \{x \in C^1_{2\pi} : x_5 > -\psi(\lambda) \text{ on } \mathbb{R}_{2\pi}\} \times (0, \infty). \tag{3.28}$$

Clearly, (3.27) possesses the trivial solution $\{0\} \times (0, \infty)$. By (3.21) and (3.25), $T_g\bar{y}(\lambda) = \bar{y}(\lambda)$ for all $g \in O(2)$. Then by Theorem 3.1, the mapping in (3.27) is also equivariant

$$f(T_g x, \lambda) = T_g f(x, \lambda) \quad \forall g \in O(2). \tag{3.29}$$

The linearization of (3.27) about the trivial solution $x = 0$ is given by

$$L(\lambda)x = 0, \tag{3.30}$$

where $L(\lambda) \equiv D_1 f(0, \lambda) = D_1 h(\bar{y}(\lambda), \lambda) : C^1_{2\pi} \to C^0_{2\pi}$. By (3.8), (3.13), (3.14), (3.16), (3.19), and (3.24), the system (3.30) is given explicitly by

$$\hat{t}^0_{1,1}(\lambda)x_4' - [\hat{t}^0_{2,2}(\lambda) + \lambda]x_5 + \lambda\psi(\lambda)x_6 = 0, \tag{3.31a}$$

$$\hat{t}^0_{2,2}(\lambda)x_5' + [\hat{t}^0_{1,1}(\lambda) + \lambda]x_4 = 0, \tag{3.31b}$$

$$\hat{t}^0_{3,3}(\lambda)x_6' - \psi(\lambda)[\hat{t}^0_{1,1}(\lambda) + \lambda]x_4 = 0, \tag{3.31c}$$

$$x_1' - x_2 - x_4 = 0, \tag{3.31d}$$

$$x_2' + x_1 - x_5 + \psi(\lambda)x_6 = 0, \tag{3.31e}$$

$$x_3' - x_6 = 0 \quad \text{on } \mathbb{R}_{2\pi}, \tag{3.31f}$$

where

$$\hat{t}^0_{i,i}(\lambda) \equiv \frac{\partial \hat{t}_i}{\partial \xi_i}(0, \psi(\lambda), 0), \qquad i = 1, 2, 3.$$

A straightforward computation shows that (3.31) has three linearly independent null solutions for *any* value of λ, viz.,

$$\begin{aligned} &\Phi_1(s) \equiv (\cos(s), -\sin(s), 0, 0, 0, 0), \\ &\Phi_2(s) \equiv (\sin(s), \cos(s), 0, 0, 0, 0), \\ &\Phi_3(s) \equiv (0, 0, 1, 0, 0, 0,). \end{aligned} \tag{3.32}$$

Moreover, it is easy to demonstrate that whenever (x_0, λ_0) is a solution pair of (3.27), then so is $(x_0 + \sum_{i=1}^{3} c_i \Phi_i, \lambda_0)$, for arbitrary constants c_i, $i = 1, 2, 3$. This is quite reasonable from a physical point of view, since the ring is free to translate and rotate rigidly in the plane spanned by **i** and **j**. It can be shown that any rigid displacement of the ring has the form $\sum_{i=1}^{3} c_i \Phi_i$.

The system (3.31) also possesses nontrivial solution pairs $(x, \lambda) = (v_1^n, \lambda_n), (v_2^n, \lambda_n)$ whenever λ_n satisfies the characteristic equation

$$q(\lambda) = \left[1 + \frac{\lambda}{\hat{t}^0_{1,1}(\lambda)}\right]\left[1 + \frac{\lambda}{\hat{t}^0_{2,2}(\lambda)} + \frac{\lambda[\psi(\lambda)]^2}{\hat{t}^0_{3,3}(\lambda)}\right] = n^2, \tag{3.33}$$

where $n \geqq 2$ is an integer. By (3.12), $q(0) = 1$ (cf. Remark 3.2) and q is a strictly positive function on $\lambda > 0$. As discussed by Antman and Dunn [1980], (3.33) may have no roots, one root, or many roots, for a given integer n, depending on the behavior of the function q. Henceforth, it is assumed that q is monotonically increasing on the interval $(0, a]$, where $2 < a < \infty$. Thus, (3.33) has at least one root λ_n for each integer $n \in [2, \sqrt{q(a)}]$. There are two linearly independent null vectors associated with each root λ_n:

$$\begin{aligned} v_1^n(s) \equiv (&\alpha_1^n \cos(ns), \alpha_2^n \sin(ns), \alpha_3^n \sin(ns), \alpha_4^n \sin(ns), \alpha_5^n \cos(ns), \\ &n\alpha_3^n \cos(ns)), \\ v_2^n(s) \equiv (&-\alpha_1^n \sin(ns), \alpha_2^n \cos(ns), \alpha_3^n \cos(ns), \alpha_4^n \cos(ns), -\alpha_5^n \sin(ns), \\ &-n\alpha_3^n \sin(ns)), \end{aligned} \tag{3.34}$$

where

$$\begin{aligned} &\alpha_1^n = -\frac{1}{n}(\alpha_2^n + \alpha_4^n), \\ &\alpha_2^n = \frac{1}{n^2 - 1}[-n^2 \psi(\lambda_n)\alpha_3^n + \alpha_4^n + n\alpha_5^n], \\ &\alpha_3^n = \frac{-\psi(\lambda_n)}{n^2 \hat{t}^0_{3,3}(\lambda_n)}[\hat{t}^0_{1,1}(\lambda_n) + \lambda_n]\alpha_4^n, \\ &\alpha_4^n \neq 0, \\ &\alpha_5^n = \frac{[\hat{t}^0_{1,1}(\lambda_n) + \lambda_n]}{n\hat{t}^0_{2,2}(\lambda_n)}\alpha_4^n. \end{aligned}$$

Remark 3.2. It is interesting to note that if λ_1 is a root of (3.33) for $n = 1$ ($\lambda = 0$ is always such a root), then the 2π-periodicity conditions dictate that (3.31) evaluated

at $\lambda = \lambda_1$ admits only the trivial solution and the rigid-body solutions (3.32). This contrasts with results from several previous works on circular rings where strain formulations were employed without accounting for displacements (cf. Antman [1973], Tadjbakhsh and Odeh [1967]). Such an analysis is equivalent to considering only (3.31a), (3.31b), and (3.31c), which admit nontrivial solutions at $\lambda = \lambda_1$ similar to (3.34) for (x_4, x_5, x_6). This in turn, ostensibly implies the existence of bifurcating solutions (x_4, x_5, x_6) of least period 2π to the full nonlinear problem. In the above-cited works, subtle techniques were required to demonstrate the inadmissibility of such solutions. In this formulation, the existence of such solutions (bifurcating from the trivial solution) never arises.

The analysis of bifurcation is complicated for two reasons. The linearized operator in (3.30) has a three-dimensional kernel for all $\lambda \in (0, \infty)$, and it admits two additional null vectors for all values of λ satisfying (3.33). The latter condition is common in problems with $O(2)$ symmetry (cf., for example, Vanderbauwhede [1982]). Following (2.9), consider the null vector v_1^n and note that

$$v_1^n(s + 2\pi j/n) = v_1^n(s),$$
$$Ev_1^n(2\pi j/n - s) = v_1^n(s), \qquad j = 1, 2, \cdots, n.$$

By (3.21), it follows that the isotropy subgroup of $O(2)$ at v_1^n is

$$D_n \cong \{g \in O(2): T_g v_1^n = v_1^n\},$$

where D_n denotes the dihedral group of order $2n$. The "mode shapes" associated with v_1^n for $n = 2, 3, 4, 5$ are shown schematically in Fig. 2. This motivates constructing the D_n-reduced problem.

Remark 3.3. It is easy to show that any linear combination of the modes $v_1^n(s)$ and $v_2^n(s)$ (suitably scaled) is equivalent to a change of phase; $v_1^n(s+g) = [T_g v_1^n](s)$

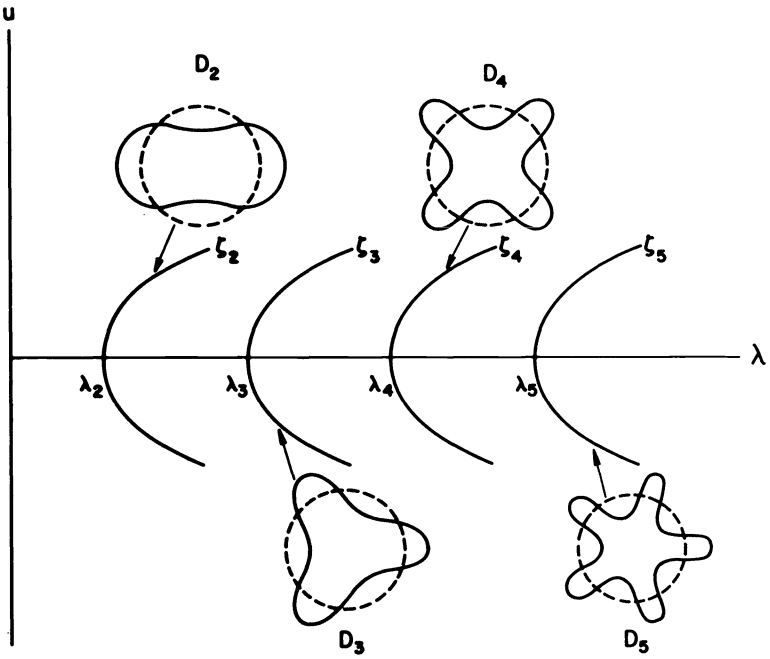


FIG. 2. *Schematic bifurcation diagram for* $\mu_{2n} > 0$, $n = 2, 3, 4, 5$.

for some $g \in SO(2)$. The isotropy subgroup of $O(2)$ at $T_g v_1^n$ is $gD_ng^{-1} \equiv \{ghg^{-1}: h \in D_n\}$, which is conjugate to D_n. It is shown later in this section that the solutions of a gD_ng^{-1}-reduced problem can be generated from the solutions of the D_n-reduced problem.

By Theorem 2.1, the D_n-reduced problem for (3.27) consists of the same mapping $\mathscr{f}$ restricted to the D_n-fixed-point set. By (2.3), the projection onto that subspace is given by

$$P_n x = \frac{1}{2n} \sum_{j=1}^{n} [x(s + 2\pi j/n) + Ex(2\pi j/n - s)]. \tag{3.35}$$

THEOREM 3.2. *Let $C^m_{2\pi/n}$ denote the space of all m-times continuously differentiable functions from $\mathbb{R}_{2\pi}$ into $\mathbb{R}^6$ that are $2\pi/n$-periodic. Let $B^m_{2\pi/n}$ denote the D_n-fixed-point set of $C^m_{2\pi}$. Then $B^m_{2\pi/n}$ is the subspace of all $u = (u_1, u_2, u_3, u_4, u_5, u_6) \in C^m_{2\pi/n}$ such that the component functions $u_i(s)$ are even for $i = 1, 5, 6$ and odd for $i = 2, 3, 4$, i.e.,*

$$B^m_{2\pi/n} = \{u \in C^m_{2\pi/n}: u_i(-s) = u_i(s),\ u_j(-s) = -u_j(s),\ i = 1, 5, 6,\ j = 2, 3, 4\}. \tag{3.36}$$

Proof. For $x \in C^m_{2\pi/n}$, consider the ith component function of $P_n x(s) \equiv (u_1(s), u_2(s), \cdots, u_6(s)) \in B^m_{2\pi/n}$. By (3.21) and (3.35),

$$u_i(s) = \begin{cases} \dfrac{1}{2n} \displaystyle\sum_{j=1}^{n} [x_i(s + 2\pi j/n) + x_i(2\pi j/n - s)] & \text{for } i = 1, 5, 6, \\ \dfrac{1}{2n} \displaystyle\sum_{j=1}^{n} [x_i(s + 2\pi j/n) - x_i(2\pi j/n - s)] & \text{for } i = 2, 3, 4. \end{cases}$$

Clearly, $u_i(-s) = u_i(s)$ for $i = 1, 5, 6$, and $u_i(-s) = -u_i(s)$, $i = 2, 3, 4$. Moreover, the $2\pi/n$-periodicity of u_i follows from the 2π-periodicity of x_j, $j = 1, 2, \cdots, 6$, on $\mathbb{R}_{2\pi}$.

On the other hand, if $u \in B^m_{2\pi/n}$ as defined by (3.36), then it is straightforward to verify that

$$u(s + 2\pi j/n) = u(s),$$

and

$$Eu(2\pi j/n - s) = u(s), \qquad j = 1, 2, \cdots, n,$$

i.e., $T_g u = u$ for all $g \in D_n$, by virtue of (3.21). □

The D_n-reduced problem for (3.27) is given by

$$\mathscr{f}_n(u, \lambda) \equiv h(\bar{y}(\lambda) + u, \lambda) = 0, \tag{3.37}$$

where $\mathscr{f}_n: \Omega_n \to B^0_{2\pi/n}$, and where

$$\Omega_n \equiv \{u \in B^1_{2\pi/n}: u_5 > -\psi(\lambda) \text{ on } \mathbb{R}_{2\pi}\} \times (0, \infty). \tag{3.38}$$

The linearization of (3.37) about $u = 0$, denoted

$$L_n(\lambda) u = 0, \tag{3.39}$$

where $L_n(\lambda) \equiv D_1 \mathscr{f}_n(0, \lambda): B^1_{2\pi/n} \to B^0_{2\pi/n}$, is again defined by (3.31). However, the $2\pi/n$-periodicity of $u \in B^1_{2\pi/n}$, $n \geqq 2$, shows that Φ_1 and Φ_2 (cf. (3.32)) are not solutions of (3.39). Also, Φ_3 is not a solution, since u_3 is odd. Finally, the evenness and oddness of the various components of u imply that the only nontrivial solution of (3.39) at a root λ_n of (3.33) is v_1^n. That is, $\dim \mathscr{N}(L_n(\lambda_n)) = 1$, and condition (EB1) of Theorem 2.3 is satisfied.

Define the formal adjoint operator $L_n^*(\lambda)$ of $L_n(\lambda)$ with respect to the inner product

$$\langle y, x \rangle \equiv \frac{n}{2\pi} \int_0^{2\pi/n} y(s)^t x(s)\, ds, \tag{3.40}$$

where $\mathscr{y}^t x \equiv \sum_{i=1}^n y_i x_i$. A straightforward computation shows that $L_n^*(\lambda)\mathscr{y} = 0$ is given explicitly by

$$
\begin{aligned}
&y_4' - y_5 = 0, \qquad y_5' + y_4 = 0, \qquad y_6' = 0,\\
&\hat{t}^0_{1,1}(\lambda) y_1' - [\hat{t}^0_{1,1}(\lambda) + \lambda] y_2 + \psi(\lambda)[\hat{t}^0_{1,1}(\lambda) + \lambda] y_3 + y_4 = 0,\\
&\hat{t}^0_{2,2}(\lambda) y_2' + [\hat{t}^0_{2,2}(\lambda) + \lambda] y_1 + y_5 = 0,\\
&\hat{t}^0_{3,3}(\lambda) y_3' - \lambda\psi(\lambda) y_1 - \psi(\lambda) y_5 + y_6 = 0 \quad \text{on } \mathbb{R}_{2\pi/n}.
\end{aligned} \tag{3.41}
$$

For each root λ_n, $n \geqq 2$, of (3.33), the system (3.41) admits nontrivial solutions

$$
\begin{aligned}
v_1^{n^*}(s) &\equiv (\beta_1^n \cos(ns), -\beta_2^n \sin(ns), \beta_3^n \sin(ns), 0, 0, 0),\\
v_2^{n^*}(s) &\equiv (\beta_1^n \sin(ns), \beta_2^n \cos(ns), -\beta_3^n \cos(ns), 0, 0, 0),
\end{aligned} \tag{3.42}
$$

where

$$
\begin{aligned}
&\beta_1^n \neq 0,\\
&\beta_2^n = \frac{1}{n}\left[1 + \frac{\lambda_n}{\hat{t}^0_{2,2}(\lambda_n)}\right]\beta_1^n,\\
&\beta_3^n = \frac{\lambda_n \psi(\lambda_n)}{n\hat{t}^0_{3,3}(\lambda_n)}\beta_1^n,
\end{aligned}
$$

such that $\langle v_i^{n^*}, v_j^n \rangle = \delta_{ij}$. However, it is easily demonstrated that $\langle v_2^{n^*}, u \rangle = 0$ for all $u \in B^0_{2\pi/n} \Rightarrow v_2^{n^*} \notin B^{0^*}_{2\pi/n}$, the dual space of $B^0_{2\pi/n}$. In particular, $v_2^{n^*} \notin \mathcal{N}(L_n^*(\lambda_n)) \subset B^{0^*}_{2\pi/n}$. Thus, $L_n^*(\lambda_n)$ has only $v_1^{n^*}(s)$ as a null vector, and $L_n(\lambda_n)$ has a simple zero eigenvalue. By the alternative theorem (cf., for example, Stakgold [1979]), the transversality condition (EB2) of Theorem 2.3 then reduces to

$$
\langle v_1^{n^*}, [L_n'(\lambda_n)] v_1^n \rangle \neq 0. \tag{3.43}
$$

A lengthy but straightforward computation employing (3.13), (3.24), (3.31), and (3.33) yields

$$
\begin{aligned}
\langle v_1^{n^*}, [L_n'(\lambda_n)] v_1^n \rangle = -K_n \Bigg\{ &1 + \frac{\lambda_n}{\hat{t}^0_{2,2}(\lambda_n)} + n^2 \frac{\hat{t}^0_{1,1}(\lambda_n)[\hat{t}^0_{2,2}(\lambda_n) + \lambda_n]}{[\hat{t}^0_{1,1}(\lambda_n) + \lambda_n]^2}\\
&+ \frac{\lambda_n \psi(\lambda_n)}{[\hat{t}^0_{2,2}(\lambda_n)]^2}\hat{t}^0_{2,22}(\lambda_n) + \frac{[\psi(\lambda_n)]^2}{\hat{t}^0_{3,3}(\lambda_n)}[\hat{t}^0_{2,2}(\lambda_n) - \lambda_n]\Bigg\},
\end{aligned} \tag{3.44}
$$

where $K_n > 0$ is a constant and $\hat{t}^0_{2,22}(\lambda) \equiv (\partial^2 \hat{t}_2 / \partial \xi_2^2)(0, \psi(\lambda), 0)$. By (3.12), it follows that the first three terms inside the brackets on the right side of (3.44) are strictly positive. However, the last two terms can each be positive, zero, or negative, depending upon the behavior of the function $\xi_2 \mapsto \hat{t}_2(0, \xi_2, 0)$. There are no (known) natural hypotheses for the second derivative $\hat{t}^0_{2,22}(\lambda)$. Thus, the right side of (3.44) could conceivably vanish at a given root λ_n. In such case, a more refined local analysis is required (cf. Rabier [1985]), which is beyond the scope of this work. At any rate, if (3.43) is satisfied, then Theorem 2.3 leads to the following result.

THEOREM 3.3. *If* (3.43) *holds, then there exists a unique, local, nontrivial,* D_n*-symmetric branch of solutions of* (3.27) *of the form* $(x, \lambda) = (\hat{u}_n(t), \hat{\lambda}_n(t)) \in \Omega_n$ *for all* $|t| < \varepsilon$ *with* $(\hat{u}_n(0), \hat{\lambda}_n(0)) = (0, \lambda_n)$. *Moreover,* $\hat{u}_n(t) = tv_1^n + o(t)$ *as* $t \to 0$.

If $\mathscr{f}_n$ is sufficiently smooth, then a local analysis of (3.37) at $(0, \lambda_n)$ shows that the bifurcation diagram is a "pitchfork," i.e., $\hat{\lambda}_n(t) = \lambda_n + \mu_{2n}t^2 + o(t)$ as $t \to 0$. That is, the coefficient of the first-order term vanishes, viz., $\mu_{1n} \equiv \langle v_1^{n^*}, D_1^2\mathscr{f}_n(0, \lambda_n)[v_1^n, v_1^n]\rangle = 0$, where $D_1^2\mathscr{f}_n(0, \lambda_n): B^1_{2\pi/n} \times B^1_{2\pi/n} \to B_{2\pi/n}$ is the second (Fréchet) derivative of $\mathscr{f}_n$ with respect to its first argument evaluated at $(u, \lambda) = (0, \lambda_n)$. To see this, note that (3.21), (3.34), and (3.42) lead to

$$
\begin{aligned}
&[T_{\pi/n}v_1^n](s) = -v_1^n(s),\\
&[T_{\pi/n}v_1^{n^*}](s) = -v_1^{n^*}(s) \quad \text{for } \frac{\pi}{n} \in SO(2).
\end{aligned} \tag{3.45}
$$

Successive differentiation of (3.29) with respect to x leads to

$$
D_1^2\mathscr{f}(0, \lambda_n)[T_g v, T_g w] = T_g D_1^2\mathscr{f}(0, \lambda_n)[v, w], \tag{3.46}
$$

for all $g \in O(2)$, $v, w \in C^1_{2\pi/n}$. Evaluating (3.46) at $g = \pi/n \in SO(2)$ and $v = w = v_1^n$, and then taking its inner product with $T_{\pi/n}v_1^{n^*}$ yields

$$
\begin{aligned}
\langle T_{\pi/n}v_1^{n^*}, D_1^2\mathscr{f}(0, \lambda_n)[T_{\pi/n}v_1^{n^*}, T_{\pi/n}v_1^n]\rangle &= \langle T_{\pi/n}v_1^{n^*}, T_{\pi/n}D_1^2\mathscr{f}(0, \lambda_n)[v_1^n, v_1^n]\rangle\\
&= \langle v_1^{n^*}, D_1^2\mathscr{f}(0, \lambda_n)[v_1^n, v_1^n]\rangle,
\end{aligned} \tag{3.47}
$$

where $(3.47)_2$ follows from (3.21), (3.40), and (3.42). By virtue of Theorem 2.1, it follows that $D_1^2\mathscr{f}_n(0, \lambda_n)[v, w] \equiv D_1^2\mathscr{f}(0, \lambda_n)[v, w]$ for all $v, w \in B^1_{2\pi/n}$. Hence, (3.45) and (3.47) lead to

$$
-\langle v_1^{n^*}, D_1^2\mathscr{f}_n(0, \lambda_n)[v_1^n, v_1^n]\rangle = \langle v_1^{n^*}, D_1^2\mathscr{f}_n(0, \lambda_n)[v_1^n, v_1^n]\rangle \Rightarrow \mu_{1n} = 0.
$$

It can be shown that μ_{2n} is the quotient of $-\langle v_1^{n^*}, D_1^3\mathscr{f}_n(0, \lambda_n)[v_1^n, v_1^n, v_1^n]\rangle$ and the right side of (3.44), (cf., for example, Golubitsky and Schaeffer [1985]). A schematic bifurcation diagram for $\mu_{2n} > 0$, $n = 2, 3, 4, 5$, is presented in Fig. 2.

To make the conclusions of Theorem 3.3 global via Theorem 2.3, it is sufficient to demonstrate that (3.37) can be recast into the form (2.6). Referring back to (3.8), (3.16), (3.19), and (3.27), it follows that (3.37) can be expressed as

$$
[M_n(u, \lambda)]u' - \mathscr{h}_n(u, \lambda) = 0, \tag{3.48}
$$

where $\mathscr{h}_n: \mathbb{R}^6 \times (0, \infty) \to \mathbb{R}^6$ is smooth and M_n is a smooth, (6×6)-matrix-valued function on $\mathbb{R}^6 \times (0, \infty)$. M_n is given explicitly by

$$
M(u, \lambda) = \left[\begin{array}{c|c} [0] & [\partial \hat{t}_i/\partial \xi_j](\bar{\mathscr{y}}(\lambda) + u) \\ \hline [I] & [0] \end{array}\right],
$$

where $[0]$ is the 3×3 zero matrix, $[I]$ is the 3×3 identity matrix and $[\partial \hat{t}_i/\partial \xi_j](\bar{\mathscr{y}}(\lambda) + u)$ is the 3×3 Jacobian of the constitutive functions (cf. (3.11)) evaluated at $(\xi_1, \xi_2, \xi_3) = (u_4, \psi(\lambda) + u_5, u_6)$. By (3.12), $M_n(u, \lambda)$ is invertible for all $(u, \lambda) \in \Omega_n$. Thus, (3.48) leads to

$$
u' = [M_n(u, \lambda)]^{-1}\mathscr{h}_n(u, \lambda), \tag{3.49}
$$

where

$$
[M_n(u, \lambda)]^{-1} = \left[\begin{array}{c|c} [0] & [I] \\ \hline [\partial \hat{t}_i/\partial \xi_j]^{-1}(\bar{\mathscr{y}}(\lambda) + u) & [0] \end{array}\right].
$$

Equation (3.49) is equivalent to the integral equation (cf. Krasnosel'skii and Zabreiko [1984, § 28])

$$u(s) = u(2\pi/n) + \int_0^s [M_n(u(\tau), \lambda)]^{-1} \not{p}_n(u(\tau), \lambda)\, d\tau. \tag{3.50}$$

The right side of (3.50) defines a mapping $c_n : \Omega_n \to B^1_{2\pi/n}$. Moreover, c_n is readily shown to be completely continuous by virtue of the continuity of the integrand and the Arzelà-Ascoli Theorem. Thus, (3.50) is of the form (2.6).

Let Σ_n denote the solution set of (3.37), and denote the trivial solution by $\Sigma_t = \{0\} \times (0, \infty)$. The following theorem is a consequence of the final part of Theorem 2.3.

THEOREM 3.4. *Let the hypothesis of Theorem* 3.3 *hold. Then the D_n-symmetric bifurcating branch of* (3.27) *from* $(0, \lambda_n)$ *is global. That is, there exists a connected set* $\zeta_n \subset \overline{\Sigma_n \backslash \Sigma_t} \subset \Omega_n$ *containing* $(0, \lambda_n)$ *that is characterized by at least one of the following properties*:

(i) *ζ_n is unbounded in* $C^1_{2\pi}(0, \infty)$.

(ii) $\zeta_n \cap \partial\Omega \neq \varnothing$.

(iii) *There exists a pair* $(0, \lambda_*) \in \zeta_n \cap \Sigma_t$ *with* $\lambda_* \neq \lambda_n$.

The D_n symmetry of each global branch ζ_n, $n \in N \cap [2, \sqrt{q(a)}]$, does not directly imply which properties (i)-(iii) of Theorem 3.4 actually characterize ζ_n. Indeed, by (2.1), $D_n \subset D_{pn} \Rightarrow \Sigma_{pn} \subseteq \Sigma_n$ for all $n, p \in N$, $n \geqq 2$. In particular, this does not preclude the possibility that $\zeta_{pn} \cap \zeta_n \neq \varnothing$. However, a further analysis of the reduced problem (3.50) or equivalently (3.37) shows that this cannot occur.

For any $u \in B^1_{2\pi/n}$, $n \geqq 2$, it follows from the continuity, oddness, and $2\pi/n$-periodicity of the component function u_4 (which represents the shear strain) that $u_4(j\pi/n) = 0, j = 1, 2, \cdots, 2n$. Let $S^1_{2\pi/n}$ denote the open set of all $u \in B^1_{2\pi/n}$ such that u_4 has exactly $2n$ simple zeros at $s = j\pi/n, j = 1, 2, \cdots, 2n$, on $\mathbb{R}_{2\pi}$. An analysis similar to that of Rabinowitz [1973, Lemma 2.7], based on the fact that $v^1_n \in S^1_{2\pi/n}$, shows that $u \in S^1_{2\pi/n}$ for all $(u, \lambda) \in \mathcal{N}_n \cap \zeta_n$, where $\mathcal{N}_n \subset \Omega_n$ is some sufficiently small neighborhood of $(0, \lambda_n)$. That is, u_4 inherits the nodal properties of the corresponding eigenfunction locally along ζ_n.

Now the nodal behavior of u_4 can change only if u is in the closure of $S^1_{2\pi/n}$ somewhere along $\zeta_n \Rightarrow \exists$ at least one number $\tau \in \mathbb{R}_{2\pi}$ such that $u_4(\tau) = u_4'(\tau) = 0$, i.e., u_4 has a double zero at $s = \tau$ (cf. Rabinowitz [1973]). Consider the degenerate initial-value problem (3.37) subject to $u_4(\tau) = u_4'(\tau) = 0$. By (3.19), (3.25), and (3.27), this is equivalent to finding a solution of (3.8) and (3.16) of the form $(r_1, r_2, \phi, \xi_1, \xi_2, \xi_3) = (\psi(\lambda) + u_1, u_2, u_3, u_4, \psi(\lambda) + u_5, u_6)$, where $u \in \Omega_n$, subject to the same degenerate initial conditions. The evaluation of (3.16) and (3.8) at $s = \tau$, while making use of (3.13a), leads to

$$(1 + u_6(\tau))\tilde{t}_2(\lambda, \tau) + \lambda[\psi(\lambda) + u_5(\tau)] = 0, \tag{3.16a)''}$$

$$\tilde{t}_{2,2}(\lambda, \tau)u_5'(\tau) + \tilde{t}_{2,3}(\lambda, \tau)u_6'(\tau) = 0, \tag{3.16b)''}$$

$$\tilde{t}_{3,2}(\lambda, \tau)u_5'(\tau) + \tilde{t}_{3,3}(\lambda, \tau)u_6'(\tau) = 0, \tag{3.16c)''}$$

$$u_1'(\tau) = [1 + u_6(\tau)]u_2(\tau), \tag{3.8a)''}$$

$$u_2'(\tau) = -[1 + u_6(\tau)]u_1(\tau) + u_5(\tau) - \psi(\lambda)u_6(\tau), \tag{3.8b)''}$$

$$u_3'(\tau) = u_6(\tau), \tag{3.8c)''}$$

where

$$\tilde{f}_2(\lambda, \tau) \equiv \hat{f}_2(0, \psi(\lambda) + u_5(\tau), u_6(\tau)),$$

$$\tilde{f}_{i,j}(\lambda, \tau) \equiv \frac{\partial \hat{f}_i}{\partial \xi_j}(0, \psi(\lambda) + u_5(\tau), u_6(\tau)).$$

From (3.12), it follows that (3.16b)″ and (3.16c)″ have the unique solution $u_5'(\tau) = u_6'(\tau) = 0$. By (3.8c)″, $u_6(\tau) = \prime \Rightarrow u_3^0(\tau) = 0$, in which case (3,16a)″ has the unique solution $u_5(\tau) = 0$, by virtue of (3.24). Thus $(r_1, r_2, \xi_1, \xi_2, \xi_3) = (\psi(\lambda), 0, u_3(\tau), 0, \psi(\lambda), 0)$ is a critical point of the system (3.8) and (3.16)$\Rightarrow u = (0, 0, u_3(\tau), 0, 0, 0)$ is a critical point of (3.37). Moreover, $u \in B^1_{2\pi/n} \Rightarrow u_3$ is odd $\Rightarrow u_3(\tau) = 0$. Thus, $u \equiv 0$ is the unique solution of (3.37) subject to the degenerate initial conditions. However, this implies that u_4 can change its nodal properties along ζ_n only at the trivial solution branch, i.e., branches with distinct symmetries do not intersect. This leads to the following strengthened version of Theorem 3.4.

THEOREM 3.5. *Let the hypothesis of Theorem* 3.3 *hold. Then in addition to the claims of Theorem* 3.4, *it follows that* $\zeta_n - \{(0, \lambda_n)\} \subset S^1_{2\pi/n} \times (0, \infty)$. *In particular,* $S^1_{2\pi/n} \cap S^1_{2\pi/m} = \varnothing$ *for* $m \neq n \Rightarrow \zeta_n \cap \zeta_m = \varnothing$. *Thus,* ζ_n *is characterized by property* (iii) *of Theorem* 3.4 *only if* λ_* *and* λ_n *are two distinct roots of* (3.33) *corresponding to the same integer* $n \geqq 2$.

A particular case of interest is when $q: (0, \infty) \to (0, \infty)$ (cf. (3.33)) is monotonically increasing with $q \to \infty$ as $\lambda \to \infty$, in which case (3.33) has exactly one root λ_n for each integer $n \geqq 2$. Then by Theorem 3.5, ζ_n is either unbounded or $\zeta_n \cap \partial\Omega \neq \varnothing$. By (3.28), the latter condition is characterized by the existence of a solution point $(u^0, \lambda^0) \in \zeta_n$ such that $\xi_2^0 \equiv u_5^0 + \psi(\lambda) = 0$ somewhere on $\mathbb{R}_{2\pi}$ and/or $\lambda^0 = 0$. With appropriate growth conditions on the constitutive functions (for which there is little or no physical basis), the possibility of violating the unilateral constraint (3.9) can be eliminated by the existence theorems of Antman [1973].

To conclude the analysis of the ring, note that if (x_0, λ_0) is a solution point of (3.27), then so is $(T_g x_0, \lambda_0)$ for all $g \in O(2)$, by virtue of (3.29). In particular, if $(0, \lambda_n) \neq (u_0, \lambda_0) \in \zeta_n$, then $\{(T_g u_0, \lambda_0): 0 \leqq g < 2\pi/n,\ g \in SO(2)\}$ is a one-parameter family or an orbit of *distinct* solutions of (3.27). By (3.21), $[T_g u_0](s) = u_0(s + g)$ for all $g \in SO(2)$, which has the physical interpretation of a clockwise rotation of the buckled shape corresponding to $u_0 \in \zeta_n$ (cf. Fig. 2) through the angle g. That is, u_0 and $T_g u_0$ differ by only a change of phase. Now $T_g u_0$ is an element of the $(gD_n g^{-1})$-fixed-point set (cf. Remark 3.3), i.e., $T_h[T_g u_0] = T_g u_0$ for all $h \in gD_n g^{-1}$. Consequently,

$$\Gamma_n \equiv \{(T_g u, \lambda): (u, \lambda) \in \zeta_n, 0 \leqq g < 2\pi/n, g \in SO(2)\}$$

is a global, connected "sheet" of bifurcating solutions from $(0, \lambda_n)$, with each "slice" $T_g\zeta_n \equiv \{(T_g u, \lambda): (u, \lambda) \in \zeta_n\} \subset \Gamma_n$ being a global bifurcating branch of solutions of the $(gD_n g^{-1})$-reduced problem. Finally, it follows from (3.21) and (3.28) that $|u|_1 = |T_g u|_1$ and $(u, \lambda) \in \partial\Omega \Rightarrow (T_g u, \lambda) \in \partial\Omega$, for all $g \in O(2)$, $u \in C^1_{2\pi/n}$. Thus, if ζ_n is unbounded and/or $\zeta_n \cap \partial\Omega \neq \varnothing$, then $T_g\zeta_n$ is unbounded and/or $T_g\zeta_n \cap \partial\Omega \neq \varnothing$, respectively.

4. Concluding remarks. The analysis of the ring problem is noteworthy for several reasons. First, many results are new and complement the general existence theorems of Antman [1973]. In that work symmetry properties of solutions that agree with those obtained here were deduced by clever phase-plane arguments. However, the results of this work are sharper. Symmetries of specific global solution branches are enumerated, and it is shown that primary bifurcating branches with distinct symmetries are mutually disjoint. Further, in contrast to phase-plane methods, the systematic techniques of § 2 are applicable to a broad class of equivariant operators.

The ring problem demonstrates other advantages in analyzing a reduced problem that are not apparent in the abstract development of § 2. The D_n-reduced problem is designed to eliminate the troublesome analysis of bifurcation that is associated with a two-dimensional null space in the presence of $O(2)$ symmetry (cf. (3.34)). However, the D_n-reduced problem also eliminates the rigid-body solutions (cf. (3.32)), thus yielding a standard bifurcation problem with a one-dimensional kernel.

Of more importance is the fact that the D_n-reduced problem admits a detailed qualitative analysis. The technique of identifying nodal properties of a solution along global bifurcating branches was devised by Crandall and Rabinowitz [1970] for nonlinear Sturm–Liouville problems. Since that time, there have been numerous applications of the method, mostly due to Antman and his co-workers, to more general two-point boundary-value problems. The application of such techniques to the full ring equations and to problems with $O(2)$ symmetry, in general, is not clear. However, the D_n-reduced problem fixes the indeterminate phase and admits only solutions with shear strains (in particular) that are odd with period $2\pi/n$. Consequently, it was possible to show that the nodal properties of the shear strain on $\mathbb{R}_{2\pi}$ are inherited from the corresponding eigenfunction of the linearized problem and are preserved on global bifurcating branches. That the shear strain plays a crucial role is hardly surprising in view of the work of Antman and Dunn [1980] on circular arches.

It is interesting to note that if the symmetry group of a ring is $SO(2)$, but not $O(2)$, then the subgroups are the cyclic groups C_n. It can be shown that the state variable of the C_n-reduced problem is an element of $C^1_{2\pi/n}$. In particular, the various component functions do not possess the evenness and oddness that play a crucial role in the detailed qualitative analysis of an $O(2)$-symmetric ring.

Finally, it should be pointed out that the construction of a reduced problem presented in § 2 also holds for multi-parameter problems. Moreover, it can be easily extended to more general classes of operator equations (cf. Healey [1988b]). Thus, it is clear that the analysis of reduced problems by other global continuation theorems, e.g., Alexander and Antman [1981], [1983] and Fitzpatrick and Pejsachowicz [1986], leads to obvious generalizations of Theorems 2.2 and 2.3.

ASYMPTOTIC PROPERTIES FOR INHOMOGENEOUS ITERATIONS OF NONLINEAR OPERATORS*

TAKAO FUJIMOTO† AND ULRICH KRAUSE‡

Abstract. The theorems on weak and strong ergodicity for inhomogeneous products of nonnegative matrices are extended to inhomogeneous iterations of nonlinear positive operators on Euclidean space. In particular some concave version of the Coale-Lopez theorem is presented and applied to a density-dependent Leslie model. The results are obtained, via Hilbert's projective pseudometric, from general theorems on inhomogeneous iterations of operators mapping a metric space into itself.

Key words. discrete dynamical systems, weak and strong ergodicity, Hilbert's projective metric, nonlinear Leslie model

AMS(MOS) subject classifications. 47H05, 47H10, 54H20, 92A15

1. Introduction. Consider a discrete dynamical system given by an operator f mapping the state space into itself. For the dynamical behaviour of the system of particular interest are asymptotic properties of the iterates f^n if $n \to \infty$. If, however, the system itself changes in the course of time with f_t as "law of motion" at, say, time t, then one will become interested in asymptotic properties of the inhomogeneous iterations $f_n \cdot f_{n-1} \cdot \cdots \cdot f_1$ if $n \to \infty$. This kind of problem arises in mathematical biology and mathematical economics where, e.g., the principle governing the growth of a population or the choice of a technology itself depends on time (cf. [4], [7], [8], [13], [14]). For the case of linear operators in finite dimensions, inhomogeneous iterations become inhomogeneous products $A_nA_{n-1} \cdots A_1$ of matrices, the asymptotic properties of which have been investigated for a long time in the theory of Markov chains and the theory of nonnegative matrices, respectively (cf. [14]). Since absolute magnitudes tend thereby to grow exponentially, one considers relative magnitudes as exemplified by $x_n = A_nA_{n-1} \cdots A_1x / \|A_nA_{n-1} \cdots A_1x\|$, x being a starting vector and $\|\cdot\|$ some vector space norm. There are two major stability results here, one on so-called strong ergodicity, meaning convergence of x_n for arbitrary starting vectors to the same limit and the other one on so-called weak ergodicity, meaning convergence of $x_n - y_n$ to 0 for any two starting vectors x, y, and y_n starting with y. These results have important applications, in particular to population dynamics, where the second result is known also as the Coale-Lopez theorem (cf. [4], [8], [13], [14]).

As in other fields too, linearity is a strong idealization concerning applications and on behalf of the latter results on nonlinear operators, e.g., concave ones, are requested. We present in § 3 as the main results of this paper theorems on weak and strong ergodicity for positive nonlinear operators in finite dimensions that contain the well-known theorems on nonnegative matrices as special cases. In particular, a concave version of the Coale-Lopez theorem is presented. Section 4 provides some concrete classes of nonlinear examples for these results by developing a density- and time-dependent version of the Leslie model of population dynamics.

To prove the theorems of § 3 we translate the order-theoretic framework of positive operators into a metric framework and prove in § 2 the corresponding theorems. The metric used is Hilbert's projective pseudometric which was first introduced by

Birkhoff [1], [2] into functional analysis. He used it to extend Jentzsch's theorem on linear integral operators to abstract linear operators by applying Banach's contraction mapping principle with respect to this metric (cf. also [10], [11]). Hilbert's metric is applied to inhomogeneous products of matrices in [8] and in [14, 2nd ed.] (cf. also [4]). In extending Birkhoff's theorem to nonlinear operators, Hilbert's metric is used in [11] within an infinite-dimensional nonlinear context (cf. also [12] for the finite-dimensional case). The present paper applies Hilbert's metric to inhomogeneous iterations of nonlinear operators in finite dimensions. (A direct approach to inhomogeneous iterations in finite dimensions that does not involve Hilbert's metric, but that is by no means more simple, can be found for matrices in [14, 1st ed.] and for nonlinear operators in [6].) In the case of homogeneous iterations usually one of the many variations of the contraction mapping principle is applied with respect to Hilbert's metric. To treat inhomogeneous iterations, however, something different is needed. Although there is an enormous literature on the contraction mapping principle, as surveyed, e.g., in [3], [5], and [10], there seems to be none handling the composition of several different contractions. Hence in § 2 we give a systematic account of inhomogeneous iterations within the metric framework. Although in the present paper the material of § 2 is used in § 3 only for the finite-dimensional case, it may also be applied to infinite dimensions.

2. Inhomogeneous iterations of operators mapping a metric space into itself. An operator $f: X \to X$ on a metric space X with metric d is said to be *nonexpansive* if $d(f(x), f(y)) \leqq d(x, y)$ for all $x, y \in X$; it is said *contractive on* Y, for $Y \subseteq X$, if

$$d(f(x), f(y)) < d(x, y) \quad \text{for all } x, y \in Y \text{ with } x \neq y.$$

We call a sequence $(f_n)_n$ of operators $f_n: X \to X$ an (asymptotically) *contractive sequence on* Y for $Y \subseteq X$, if there exists a continuous mapping $c: Y \times Y \to \mathbb{R}$ such that the following two conditions are satisfied:

(i) $c(x, y) < d(x, y)$ for all $x, y \in Y$ with $x \neq y$;

(ii) To every $\varepsilon > 0$ there exists a $N(\varepsilon) \in \mathbb{N}$ such that $d(f_n(x), f_n(y)) \leqq c(x, y) + \varepsilon$ for all $n \geqq N(\varepsilon)$, all $x, y \in Y$.

For a given $r \geqq 1$ and a given sequence $(f_n)_n$ of operators on X we will consider also the sequence of *lumped operators* $(F_m)_m$ defined by

$$F_m = f_{m+r-1} \cdot \cdots \cdot f_{m+1} \cdot f_m$$

(where $\cdot$ stands for the composition of mappings).

In what follows we are concerned with the asymptotic behaviour of inhomogeneous iterations, which means the behaviour of $f_n \cdot \cdots \cdot f_2 \cdot f_1(x)$ for $n \to \infty$ where $x \in X$ and $(f_n)_n$ is a sequence of operators on X. In the special case of (homogeneous) iteration the underlying sequence is simply $(f, f, \cdots)$ for some operator f on X. This is a contractive sequence precisely when f is a contractive operator, and the sequence of lumped operators in this case is $(f^r, f^r, \cdots)$.

The following theorem provides conditions under which inhomogeneous iterations come close together irrespective of the starting point. This does not necessarily mean that the iterations itself do converge. (In the next section we will see that the former is related to so-called weak ergodicity and the latter to strong ergodicity.)

THEOREM 1. *Let $(f_n)_n$ be a sequence of nonexpansive operators on the metric space (X, d) such that for some $r \geqq 1$ the sequence $(F_m)_m$ of lumped operators is contractive on Y and satisfies $F_m(X) \subseteq Y$ for some compact subset Y of X and almost all m. Then $\lim_{n\to\infty} d(x_n, y_n) = 0$ for any two sequences defined by $x_{n+1} = f_n(x_n)$ and $y_{n+1} = f_n(y_n)$ with arbitrary starting points $x_1, y_1 \in X$.*

Proof. (1) Consider first a sequence $(g_m)_m$ of nonexpansive operators, contractive on Y and satisfying $g_m(X) \subseteq Y$ for some compact $Y \subseteq X$ and almost all m. Let $x_{m+1} = g_m(x_m)$, $y_{m+1} = g_m(y_m)$ for $m \in \mathbb{N}$ and $x_1, y_1 \in X$ arbitrary. Since eventually $(x_m, y_m) \in Y \times Y$ and Y is compact, there exists a subsequence $(x_{k(m)}, y_{k(m)})_m$ converging to some $(x^*, y^*) \in Y \times Y$. By the nonexpansiveness of g_m

$$d(x_{m+1}, y_{m+1}) = d(g_m(x_m), g_m(y_m)) \leqq d(x_m, y_m),$$

and hence $\lim_{m\to\infty} d(x_m, y_m) = d(x^*, y^*)$.

The sequence $(g_{k(m)})_m$ is also contractive and according to the definition there exists a function c and to every $\varepsilon > 0$ an $M(\varepsilon)$ such that

$$d(x_{k(m)+1}, y_{k(m)+1}) = d(g_{k(m)}(x_{k(m)}), g_{k(m)}(y_{k(m)})) \leqq c(x_{k(m)}, y_{k(m)}) + \varepsilon$$

for all $m \geqq M(\varepsilon)$. Letting $m \to \infty$ from this we obtain $d(x^*, y^*) \leqq c(x^*, y^*) + \varepsilon$ because of $d(x^*, y^*) \leqq d(x_m, y_m)$ and the continuity of c. Since $\varepsilon > 0$ was arbitrary $d(x^*, y^*) \leqq c(x^*, y^*)$ which together with $c(x, y) < d(x, y)$ for $x \neq y$ and $x, y \in Y$ yields $x^* = y^*$. Thus finally $\lim_{m\to\infty} d(x_m, y_m) = 0$.

(2) Suppose now $(f_n)_n$ is a sequence as in the theorem and put $g_m = F_{(m-1)r+1}$. Being a composition of nonexpansive mappings, g_m is nonexpansive. Step (1) therefore yields $\lim_{m\to\infty} d(\bar{x}_m, \bar{y}_m) = 0$ for sequences defined by $\bar{x}_{m+1} = g_m(\bar{x}_m)$, $\bar{y}_{m+1} = g_m(\bar{y}_m)$, $\bar{x}_1 = x_1$, $\bar{y}_1 = y_1$. By the definition of lumped operators

$$g_m \cdot g_{m-1} \cdot \cdots \cdot g_2 \cdot g_1 = f_{mr} \cdot f_{mr-1} \cdot \cdots \cdot f_2 \cdot f_1,$$

and hence $\bar{x}_{m+1} = x_{mr+1}$, $\bar{y}_{m+1} = y_{mr+1}$. For any natural number n there exist nonnegative integers $m(n)$ and i such that $n = m(n)r + i$ with $0 \leqq i < r$. Since $x_{n+1} = f_n \cdot f_{n-1} \cdot \cdots \cdot f_{n-i+1}(x_{n-i+1})$ and the f_n's are nonexpansive it follows that

$$d(x_{n+1}, y_{n+1}) \leqq d(x_{m(n)r+1}, y_{m(n)r+1}) = d(\bar{x}_{m(n)+1}, \bar{y}_{m(n)+1}).$$

Thus $\lim_{n\to\infty} d(x_n, y_n) = 0$. □

Remark. The above proof shows that Theorem 1's conclusion remains valid if instead of the F_m's the operators $g_m = F_{(m-1)r+1}$ are considered with $g_m(X) \subseteq Y$ for some compact $Y \subseteq X$ and almost all m and such that the sequence $(g_m)_m$ contains a contractive subsequence on Y.

Now we are looking for conditions ensuring the convergence of the inhomogeneous iterations itself to a common limit for arbitrary starting points. Obviously this is stronger than the convergence statement made in Theorem 1 and therefore we have to add some assumptions.

THEOREM 2. *Let $(f_n)_n$ and $(F_m)_m$ be sequences of operators as in Theorem 1. Suppose in addition for the lumped operators F_m uniform convergence on the metric space to some operator F. This assumption is particularly fulfilled in case the operators f_n converge uniformly to some f. Then for arbitrary starting points $x_1 \in X$ the sequence defined by $x_{n+1} = f_n(x_n)$ converges to the unique fixed point of F, or f, respectively.*

Proof. (1) Consider first a sequence $(g_m)_m$ of nonexpansive operators, contractive on Y and satisfying $g_m(X) \subseteq Y$ for some compact $Y \subseteq X$ and almost all m. Assume g_m converges uniformly on (X, d) to some operator g, i.e., to $\varepsilon > 0$ there exists $N_1(\varepsilon)$ such that $d(g_m(x), g(x)) \leqq \varepsilon$ for all $m \geqq N_1(\varepsilon)$ and all $x \in X$. Since $(g_m)_m$ is contractive on Y there exists a function c and to $\varepsilon > 0$ there exists $N_2(\varepsilon)$ such that

$$d(g_m(x), g_m(y)) \leqq c(x, y) + \varepsilon \quad \text{for all } m \geqq N_2(\varepsilon) \text{ and all } x, y \in Y.$$

Therefore

$$\begin{aligned} d(g(x), g(y)) &\leqq d(g(x), g_m(x)) + d(g_m(x), g_m(y)) + d(g_m(y), g(y)) \\ &\leqq c(x, y) + 3\varepsilon \quad \text{for } m \geqq N_1(\varepsilon), m \geqq N_2(\varepsilon). \end{aligned}$$

This yields $d(g(x), g(y)) \leqq c(x, y) < d(x, y)$ for $x \neq y$, $x, y \in Y$, i.e., g is contractive on Y.

Let now $x_1 \in X$ be an arbitrary starting point, fixed in what follows. We want to show that the set A of all limit points of the set $\{x_m\}$, where $x_{m+1} = g_m(x_m)$, consists precisely of the unique fixed point of g. Since $(x_m)_m$ is eventually contained in the compact set Y, $A \subseteq Y$ and $A \neq \emptyset$. Pick some $x \in A$. Then there is a subsequence $(x_{j(n)})_n$ of $(x_n)_n$ converging to x and we may assume that $x_{j(n)-1} \in Y$ for all n. $(x_{j(n)-1})_n$ contains a subsequence $(x_{k(n)-1})_n$ converging to some $y \in Y$. Obviously

$$d(x, g(y)) \leqq d(x, x_{k(n)}) + d(g_{k(n)-1}(x_{k(n)-1}), g(x_{k(n)-1})) + d(g(x_{k(n)-1}), g(y))$$

and taking into account that $(x_{k(n)})_n$ converges to x, $(g_m)_m$ converges uniformly to g and that g is contractive on Y we obtain $d(x, g(y)) = 0$, i.e., $x = g(y)$. Because of $y \in A$ by the same argument we can find $y_2 \in A$ such that $y = g(y_2)$. By iteration we obtain to every $n \in \mathbb{N}$ a $y_n \in A$ such that $x = g^n(y_n)$. Since $y_n \in A \subseteq Y$, $(y_n)_n$ contains a subsequence $(y_{h(n)})_n$ converging to some $y^* \in Y$. Because of $g(Y) \subseteq Y$, g is contractive also on the metric space (Y, d) and hence by a well-known version of Banach's contraction mapping principle $(g^n(y^*))_n$ converges to the unique fixed point x^* of g. From $d(x, x^*) \leqq d(g^{h(n)}(y_{h(n)}), g^{h(n)}(y^*)) + d(g^{h(n)}(y^*, x^*)$ we therefore obtain $d(x, x^*) = 0$, i.e., $x = x^*$. This proves $A = \{x^*\}$, i.e., the convergence of the sequence $(x_m)_m$, defined by $x_{m+1} = g_m(x_m)$ with arbitrary starting point, to the unique fixed point of g.

(2) Let for arbitrary $x_1 \in X$ $(x_n)_n$ be defined by $x_{n+1} = f_n(x_n)$. We fix i with $0 \leqq i < r$ and define $g_m = F_{(m-1)r+i+1}$. By the assumptions made on the lumped operators F_m we may apply step (1) to the sequence $(g_m)_m$. Therefore the sequence defined by $\bar{x}_{m+1} = g_m(\bar{x}_m)$, $\bar{x}_1 = x_{i+1}$ converges to the unique fixed point x^* of $g = F$.

By the definition of lumped operators

$$g_m \cdot g_{m-1} \cdot \cdots \cdot g_1 = f_{mr+i} \cdot f_{mr+i-1} \cdot \cdots \cdot f_{i+1},$$

and hence $\bar{x}_{m+1} = x_{mr+i+1}$. Therefore for any fixed $0 \leqq i < r$ $(x_{mr+i+1})_m$ converges to the unique fixed point x^* of F. Since any natural n can be written as $n = mr + i$ with $0 \leqq i < r$ it follows that $(x_n)_n$ converges to x^*. This proves the theorem in case the lumped operators converge uniformly to some F.

(3) Let $(f_n)_n$ be an arbitrary sequence of operators on a metric space X converging uniformly on X to some uniformly continuous operator f. We first show that to every $\varepsilon > 0$ and to every natural k there exists an $N(\varepsilon, k)$ such that

$$(*) \qquad d(f^k(x), f_{n_1} \cdot f_{n_2} \cdot \cdots \cdot f_{n_k}(x)) \leqq \varepsilon \quad \text{for } n_i \geqq N(\varepsilon, k) \text{ and all } x \in X.$$

By assumption, for $\varepsilon > 0$ given there exist $\delta(\varepsilon) > 0$ and $N(\varepsilon)$ such that

$$d(f(x), f_n(y)) \leqq d(f(x), f(y)) + d(f(y), f_n(y)) \leqq \varepsilon/2 + \varepsilon/2 \leqq \varepsilon,$$

provided $d(x, y) \leqq \delta(\varepsilon)$ and $n \geqq N(\varepsilon)$.

Hence, $(*)$ holds for $k = 1$ with $N(\varepsilon, 1) = N(\varepsilon)$. Suppose, $(*)$ holds for some $k \geqq 1$. Then

$$d(f^k(x), f_{n_2} \cdot \cdots \cdot f_{n_{k+1}}(x)) \leqq \delta(\varepsilon) \quad \text{for all } n_2, \cdots, n_{k+1} \geqq N(\delta(\varepsilon), k).$$

Putting $N(\varepsilon, k+1) = \max\{N(\varepsilon), N(\delta(\varepsilon), k)\}$, we obtain

$$d(f^{k+1}(x), f_{n_1} \cdot f_{n_2} \cdot \cdots \cdot f_{n_{k+1}}(x)) = d(f(f^k(x)), f_{n_1}(f_{n_2} \cdot \cdots \cdot f_{n_{k+1}}(x))) \leqq \varepsilon$$

for $n_1, n_2, \cdots, n_{k+1} \geqq N(\varepsilon, k+1)$. This proves $(*)$ to hold for all k.

Now, let $(f_n)_n$ as in Theorem 2 and Theorem 1, respectively, and suppose uniform convergence to some operator f. Since every f_n is nonexpansive, f must be uniformly continuous. Thus (*) applies and yields for $\varepsilon > 0$ given $d(f^r(x), F_m(x)) \leqq \varepsilon$ for all $m \geqq N(\varepsilon)$ and all $x \in X$. Therefore $(F_m)_m$ converges uniformly on X to $F = f^r$. Step (2) then yields convergence of the sequence defined by $x_{n+1} = f_n(x_n)$, $x_i \in X$, to the unique fixed point x^* of F. By nonexpansiveness of f_n and uniform convergence to f, from

$$d(f(x^*), x^*) \leqq d(f(x^*), f(x_n)) + d(f(x_n), f_n(x_n)) + d(x_{n+1}, x^*)$$

it follows that $f(x^*) = x^*$. □

Remark. Theorem 2 remains valid, if instead of the whole sequence $(F_m)_m$ only some subsequence is required to be contractive on Y. The beginning of step (1) in the proof, when applied to this subsequence yields that F is contractive on Y. But then $(F_m)_m$ is contractive on Y too. For, it is true in general that a sequence of operators h_m converging uniformly to some contractive h must be contractive (with $c(x, y) = d(h(x), h(y))$).

From Theorem 2 we may derive the following criterion which is cast more directly in terms of the given operators.

THEOREM 3. *For any sequence $(f_n)_n$ of nonexpansive operators on the metric space X the sequence defined by $x_{n+1} = f_n(x_n)$ converges for arbitrary $x_1 \in X$ to the same limit point, provided the following condition is satisfied: For some $r \geqq 1$ the sequence $(F_m)_m$ of lumped operators converges uniformly on X to some operator F for which there exists an open and relatively compact subset U of X such that $F(X) \subseteq U$ and F is contractive on the closure $\bar{U}$.*

This condition is particularly satisfied if $(f_n)_n$ converges uniformly on X to some f for which $f^r(X) \subseteq U$ and f^r is contractive on $\bar{U}$ for some $r \geqq 1$, U being an open and relatively compact subset of X.

Proof. To derive the above criterion from Theorem 2 we only have to show that $(F_m)_m$ is contractive on Y and for almost all m $F_m(X) \subseteq Y$ for some compact subset Y of X. Putting $Y = \bar{U}$ F is contractive on Y and hence (cf. the remark following the proof of Theorem 2) the sequence $(F_m)_m$ is contractive on Y. It remains to show that $F_m(X) \subseteq Y$ for almost all m. To every $x \in X$ there exists some $\varepsilon(x) > 0$ such that $B(F(x), \varepsilon(x)) \subseteq U$, $B(F(x), \varepsilon(x))$ being the open ball with center $F(x)$ and radius $\varepsilon(x)$. Obviously the closure $\overline{F(X)}$ is contained in $\bigcup_{x \in X} B(F(x), \frac{1}{2}\varepsilon(x))$ and there is a finite cover, $\overline{F(X)} \subseteq \bigcup_{x \in \tilde{X}} B(F(x), \frac{1}{2}\varepsilon(x))$ for some finite set $\tilde{X} \subseteq X$, because $\overline{F(X)}$ is contained in the compact set $\bar{U}$. Let ε be the smallest of the numbers $\frac{1}{2}\varepsilon(x)$, $x \in \tilde{X}$. By uniform convergence of the lumped operators there exists $N(\varepsilon)$ such that $d(F_m(x), F(x)) \leqq \varepsilon$ for all $m \geqq N(\varepsilon)$ and all $x \in X$. For $x \in X$ there exists some $\tilde{x} \in \tilde{X}$ such that $F(x) \in B(F(\tilde{x}), \frac{1}{2}\varepsilon(\tilde{x}))$ and therefore

$$d(F_m(x), F(\tilde{x})) \leqq d(F_m(x), F(x)) + d(F(x), F(\tilde{x})) \leqq \tfrac{1}{2}\varepsilon(\tilde{x}) + \tfrac{1}{2}\varepsilon(\tilde{x}) = \varepsilon(\tilde{x})$$

for all $m \geqq N(\varepsilon)$. Hence $F_m(x) \in B(F(\tilde{x}), \varepsilon(\tilde{x})) \subseteq U$ for all $x \in X$, all $m \geqq N(\varepsilon)$. Thus $F_m(X) \subseteq Y$ for almost all m. □

Remark. In the situation of Theorem 3 the meaning of being contractive for the sequence of lumped operators is that some iterate of the limit function of the original sequence is contractive. More precisely, let $(f_n)_n$ be a sequence of nonexpansive operators converging uniformly on a metric space to some operator f. Then for any $r \geqq 1$, the sequence $(F_m)_m$ of lumped operators is contractive if and only if f^r is contractive. This is immediate by parts (1) and (3) in the proof of Theorem 2 and the remark thereafter.

3. Inhomogeneous iterations of nonlinear positive operators on Euclidean space. The results of the previous section we shall now apply to obtain the theorems of weak and strong ergodicity for inhomogeneous iterations of nonlinear positive operators on Euclidean space. As in the case of linear operators, these theorems have applications in mathematical biology. We shall obtain a concave version of the Coale-Lopez theorem of population dynamics as a corollary, which then is applied in the next section to a density-dependent Leslie model.

Let E denote the k-dimensional Euclidean space with typical element $x = (x_1, \cdot, \cdot, \cdot, x_k)$, $x_i \in \mathbb{R}$. For $x, y \in E$ we write $x \leqq y$ if $x_i \leqq y_i$ for all i; we write $x < y$ if $x_i < y_i$ for all i. E_+ denotes the positive cone $E_+ = \{x \in E \mid x \geqq 0\}$. By a *scale* we mean a continuous functional $p: E_+ \to \mathbb{R}_+$ with $p(x) = 0$ only for $x = 0$ and such that p is positively homogeneous, i.e., $p(\lambda x) = \lambda p(x)$ for $x \in E_+$, $\lambda \in \mathbb{R}_+$, and p is monotonic, i.e., $p(x) \leqq p(y)$ for $0 \leqq x \leqq y$. Obviously every monotonic norm is a scale, but there are others, e.g., maxima or minima of these norms. In what follows we fix on E_+ an arbitrary scale p and we denote its unit level set by X, $X = \{x \in E_+ \mid p(x) = 1\}$. This set X when equipped with a metric defined below will serve as the metric space underlying the previous section. As for the operators we shall employ various properties in the sequel. An operator $T: E_+ \to E_+$ is

proper if $Tx = 0$ is equivalent to $x = 0$;

subhomogeneous if for $x, y \in X$, $0 \leqq \lambda \leqq 1$, $\lambda x \leqq y$ implies $\lambda Tx \leqq Ty$;

ray-preserving if for every $x \in X$ and $\lambda > 0$ there exists some $\lambda' > 0$ such that $T(\lambda x) = \lambda' Tx$;

ascending (for p; cf. [11]) if there exists a continuous mapping φ of the unit interval $[0, 1]$ into itself with $\lambda < \varphi(\lambda)$ for $0 < \lambda < 1$ and such that for any $\lambda \in [0, 1]$ and any $x, y \in X$, $\lambda x \leqq y$ implies $\varphi(\lambda) Tx \leqq Ty$;

pointwise bounded (for p) if for every $x \in X$ there exist $u(x)$, $v(x) \in E_+$, $u(x) > 0$, such that $u(x) \leqq Tx \leqq v(x)$.

A sequence $(T_n)_n$ of operators $T_n: E_+ \to E_+$ is *uniformly ascending*, if all operators are ascending with the same φ, i.e., $\lambda x \leqq y$ implies $\varphi(\lambda) T_n x \leqq T_n y$ for all n. Similarly a sequence is *uniformly pointwise bounded* if $u(x) \leqq T_n x \leqq v(x)$ for all n.

On the unit level set X of the scale we now consider Hilbert's projective pseudometric, or *Hilbert's metric* for short (cf. [1], [2], [4], [8], [10], [11], [12], [14]). For $x, y \in E_+ \backslash \{0\}$ let $\lambda(x, y) = \sup\{\lambda \in \mathbb{R}_+ \mid \lambda x \leqq y\}$ and let $\mu(x, y) = -\log[\lambda(x, y) \cdot \lambda(y, x)]$. It is easily verified that μ is a metric on X except that μ may take on the value $+\infty$. The following lemma translates properties of positive operators into properties of operators acting on the metric space (X, μ).

LEMMA 1. *For an operator $T: E_+ \to E_+$ which is proper let $\tilde{T}: X \to X$, $\tilde{T}x = Tx/p(Tx)$ for $x \in X$.*

(i) *T subhomogeneous $\Rightarrow$ $\tilde{T}$ nonexpansive (on (X, μ)).*

(ii) *S proper and ray-preserving $\Rightarrow \widetilde{S \cdot T} = \tilde{S} \cdot \tilde{T}$.*

(iii) *T ascending $\Rightarrow \mu(\tilde{T}x, \tilde{T}y) \leqq c(x, y)$ for all $x, y \in X$. Thereby $c(x, y) = -\log[\varphi(\lambda(x, y)) \cdot \varphi(\lambda(y, x))]$ (φ as in the definition of "ascending") is continuous on $\{(x, y) \in X \times X \mid x > 0, y > 0\}$ with respect to Euclidean topology. Furthermore, $c(x, y) \leqq \mu(x, y)$ for all $x, y \in X$ and $c(x, y) < \mu(x, y)$ if $x \neq y$ and $\mu(x, y) < +\infty$.*

(iv) *T pointwise bounded and subhomogeneous $\Rightarrow$ There exists $a, b \in X$, $a \leqq \tilde{T}x \leqq b$ for all $x \in X$. If $(T_n)_n$ is uniformly pointwise bounded, then the bounds a, b are independent of n.*

Proof. (i) Since T is subhomogeneous it follows that $\lambda(\tilde{T}x, \tilde{T}y) \geqq (p(Tx)/p(Ty))\lambda(x, y)$ for all $x, y \in X$. Hence by the definition of Hilbert's metric $\mu(\tilde{T}x, \tilde{T}y) \leqq \mu(x, y)$, i.e., $\tilde{T}$ is nonexpansive on (X, μ).

(ii) With S, T proper, $S \cdot T$ is proper too. Since S is ray-preserving, for a given $x \in X$ there exists $\lambda' > 0$ such that $S(Tx/p(Tx)) = \lambda' S(Tx)$. Hence

$$\tilde{S}(\tilde{T}x) = \frac{S(\tilde{T}x)}{p(S(\tilde{T}x))} = \frac{\lambda' S \cdot T(x)}{p(\lambda' S \cdot T(x))} = \frac{S \cdot T(x)}{p(S \cdot T(x))} = \widetilde{S \cdot T}(x).$$

(iii) Applying p to $\lambda x \leqq y$ it follows that $\lambda(x, y) \in [0, 1]$ for $x, y \in X$. Since T is ascending it follows that $\varphi(\lambda(x, y))Tx \leqq Ty$, and hence $\lambda(\tilde{T}x, \tilde{T}y) \geqq (p(Tx)/p(Ty))\varphi(\lambda(x, y))$.

Interchanging the roles of x and y the definition of μ yields $\mu(\tilde{T}x, \tilde{T}y) \leqq c(x, y)$ with $c(x, y)$ as stated in the assertion. Suppose $x, y \in X$, $x \neq y$, and $\mu(x, y) < +\infty$. Because of the latter, $0 < \lambda(x, y)$ and $0 < \lambda(y, x)$. $\lambda(x, y) \leqq 1$ and $\lambda(y, x) \leqq 1$, because of $x, y \in X$, and equality in both cases would imply $x \leqq y$ and $y \leqq x$, i.e., $x = y$. Without restriction we may assume $\lambda(x, y) < 1$. Therefore by the properties of φ $\lambda(x, y) \cdot \lambda(y, x) < \varphi(\lambda(x, y)) \cdot \varphi(\lambda(y, x))$, implying $c(x, y) < \mu(x, y)$. From this $c(x, y) \leqq \mu(x, y)$ for $x, y \in X$. Finally, $c(x, y)$ depends continuously on $x > 0$, $y > 0$ since by an easy calculation $\lambda(x, y) = \min\{y_i/x_i \mid i \in \{1, \cdots, k\}\}$.

(iv) We shall show $u \leqq Tx \leqq v$ with $u, v \in E_+$, $u > 0$. Then $p(u) \leqq p(Tx) \leqq p(v)$, and (iv) follows by setting $a = u/p(v)$, $b = v/p(u)$. Let T be subhomogeneous and $u(x) \leqq Tx \leqq v(x)$ for $x \in X$, $u(x), v(x) \in E_+$, $u(x) > 0$. Denote by e_i, $i = 1, \cdots, k$, the vector in $E = \mathbb{R}^k$ having 1 in component i and 0's otherwise and let $e = e_1 + \cdots + e_k$. Define $u = (\min_i p(e_i)/p(e)) \min_i u(e_i/p(e_i))$, where $\min_i u(e_i/p(e_i))$ is a vector the jth component of which is obtained by taking the minimum over i of the jth component of $u(e_i/p(e_i))$. Define $v = (p(e)/\min_i p(e_i))v(e/p(e))$. Obviously, $u, v \in E_+$ and $u > 0$. To see $u \leqq Tx \leqq v$, let $x \in X$. If x_i denotes the ith component of x, then $x_i e_i \leqq x \leqq (\max_i x_i)e$ and by applying p $x_i p(e_i) \leqq p(x) = 1 \leqq (\max_i x_i)p(e)$ and hence $1/p(e) \leqq \max_i x_i \leqq 1/\min_i p(e_i)$. Since T is subhomogeneous, from $(\min_i p(e_i)/p(e))x \leqq e/p(e)$ it follows that $(\min_i p(e_i)/p(e))Tx \leqq T(e/p(e)) \leqq v(e/p(e))$. According to the definition of v, therefore, $Tx \leqq v$. Furthermore, from $x_i p(e_i)(e_i/p(e_i)) \leqq x$ subhomogeneity of T yields $x_i p(e_i) T(e_i/p(e_i)) \leqq Tx$. From the definition of u it follows that

$$p(e)x_i u \leqq x_i p(e_i) u\left(\frac{e_i}{p(e_i)}\right) \leqq x_i p(e_i) T\left(\frac{e_i}{p(e_i)}\right) \leqq Tx.$$

Hence $(\max_i x_i)p(e)u \leqq Tx$ and $u \leqq Tx$ because of $(\max_i x_i)p(e) \geqq 1$. Finally, the independence statement holds by construction of a and b. □

To apply the results of the previous section, we need the following comparison of Hilbert's metric and the maximum metric $|x - y| = \max_i |x_i - y_i|$ as defined on $\mathbb{R}^k$. (x_i the ith component of x.)

LEMMA 2. *For any $x, y \in X$*

$$(\min_i x_i)[1 - \exp(-\tfrac{1}{2}\mu(x, y))] \leqq |x - y| \leqq \max_i \{x_i, y_i\}(1 - \exp(-\mu(x, y))).$$

Proof. To see the first inequality, let $r = \min_i x_i$. If $r \leqq |x - y|$, then the first inequality holds trivially. Suppose $r > |x - y|$. Obviously $r(x - y) \leqq |x - y|x$, and hence $(1 - (|x - y|/r))x \leqq y$. Thus $\lambda(x, y) \geqq 1 - (|x - y|/r)$ and $\lambda(x, y) \cdot \lambda(y, x) \geqq (1 - (|x - y|/r))^2$. Because of $\lambda(x, y) \cdot \lambda(y, x) = \exp(-\mu(x, y))$ this proves the first inequality. For the second inequality observe that $x - y \leqq (1 - \lambda(x, y))x \leqq (1 - \lambda(x, y)\lambda(y, x))x$ and therefore $x_i - y_i \leqq (1 - \lambda(x, y)\lambda(y, x))x_i$. By interchanging the roles of x and y and taking the maximum over i the second inequality is obtained. □

Remark. The proof shows that the first inequality is true for any $x, y \in E_+ \setminus \{0\}$.

Our first application is concerned with weak ergodicity, a concept which originally stems from the theory of Markov chains (cf. [4], [8], [13], [14]). More generally, there

holds *weak ergodicity* (relative to some fixed scale p) for a sequence $(T_n)_n$ of operators on $\mathbb{R}_+^k$, $T_n:\mathbb{R}_+^k\to\mathbb{R}_+^k$, whenever for arbitrary nonzero starting points $x_1, y_1\in\mathbb{R}_+^k$ and x_n, y_n defined by $x_n = T_{n-1}\cdot\cdots\cdot T_2\cdot T_1(x_1)/p(T_{n-1}\cdot\cdots\cdot T_2T_1(x_1))$, y_n analogously with y_1 instead of x_1, the sequence $x_n - y_n$ tends to 0 for $n\to\infty$ in the Euclidean topology.

THEOREM 4 (*Weak ergodicity for nonlinear operators*). *Let $(T_n)_n$ be a sequence of operators on $\mathbb{R}_+^k$ that are proper, subhomogeneous, and ray-preserving. Suppose there is some $r\geqq 1$ such that the sequence of lumped operators $(S_m)_m$ defined by $S_m = T_{m+r-1}\cdot\cdots\cdot T_{m+1}\cdot T_m$ is uniformly ascending and uniformly pointwise bounded. Then there holds weak ergodicity for the sequence $(T_n)_n$.*

Proof. The theorem will be a consequence of Theorem 1. Let $X=\{x\in\mathbb{R}_+^k \mid p(x)=1\}$ and put $f_n=\tilde{T}_n$. By Lemma 1(ii) $\tilde{S}_m=\tilde{T}_{m+r-1}\cdot\cdots\cdot\tilde{T}_{m+1}\cdot\tilde{T}_m=f_{m+r-1}\cdot\cdots\cdot f_{m+1}\cdot f_m=F_m$, F_m being a lumped operator for $(f_n)_n$. Since $(S_m)_m$ is assumed to be uniformly ascending, each S_m has to be subhomogeneous. Hence by the assumption of uniform pointwise boundedness from Lemma 1(iv) the existence of $a, b\in\mathbb{R}_+^k$ $a>0$ follows such that $F_m(X)\subseteq Y$ for $Y=\{x\in X \mid a\leqq x\leqq b\}$. Because of $a>0$, the first inequality of Lemma 2 yields $s=\sup\{\mu(x,y)\mid x,y\in Y\}<+\infty$. Truncating μ as $d(x,y)=\min(\mu(x,y), s)$ for $x, y\in X$ we obtain the metric space (X, d). Since Y is compact in the Euclidean topology (p was assumed to be continuous) according to Lemma 2, Y is compact also in (X, d). f_n is nonexpansive on (X, d) because of Lemma 1(i). Furthermore, by Lemma 1(iii) $\mu(F_m(x), F_m(y))\leqq c(x,y)$ for all $x, y\in X$ and $c(x,y)<d(x,y)$ for all $x\neq y$ with $\mu(x,y)<+\infty$ where $c(x,y)=-\log[\varphi(\lambda(x,y))\cdot\varphi(\lambda(y,x))]$. Thus we obtain for all $x, y\in Y$ $d(F_m(x), F_m(y))\leqq c(x,y)$ and $c(x,y)<d(x,y)$ provided $x\neq y$. That is, $(F_m)_m$ is contractive on Y and we may apply Theorem 1. By this theorem together with Lemma 2 $x_n-y_n\to 0$ in the Euclidean topology, whereby

$$x_n = f_{n-1}\cdot\cdots\cdot f_2\cdot f_1(x_1)=\frac{T_{n-1}\cdot\cdots\cdot T_2\cdot T_1(x_1)}{p(T_{n-1}\cdot\cdots\cdot T_2\cdot T_1(x_1))},$$

and y_n analogously. The starting points x_1, y_1 are arbitrary in X, but since the T_i are ray-preserving we may allow for arbitrary nonzero starting points in all of $\mathbb{R}_+^k$. □

An interesting special case of the theorem is obtained if concave operators are considered. An operator $T:\mathbb{R}_+^k\to\mathbb{R}_+^k$ is *concave* whenever $T(\lambda x+(1-\lambda)y)\geqq\lambda Tx+(1-\lambda)Ty$ for any $x, y\in\mathbb{R}_+^k$ and any $\lambda\in[0,1]$.

COROLLARY (*Concave version of the Coale-Lopez theorem*). *Consider a scale induced on $\mathbb{R}_+^k$ by a vector space norm. There holds weak ergodicity for every sequence $(T_n)_n$ of proper, ray-preserving and concave operators on $\mathbb{R}_+^k$ provided some sequence of lumped operators $S_m = T_{m+r-1}\cdot\cdots\cdot T_{m+1}\cdot T_m$ is uniformly pointwise bounded.*

Proof. To obtain the corollary from Theorem 4 we show that T_n is subhomogeneous and that $(S_m)_m$ is ascending. Consider a concave operator T on $\mathbb{R}_+^k$ and let $\lambda x\leqq y$ for $x, y\in X$ and $0\leqq\lambda<1$. For $z=y-\lambda x$, $z\geqq 0$ and $y=\lambda x+(1-\lambda)(z/(1-\lambda))$. Concavity implies $Ty\geqq\lambda Tx+(1-\lambda)T(z/(1-\lambda))$. In particular $Ty\geqq\lambda Tx$ which by approximation is seen to be true also for $\lambda=1$. Hence each T_n is subhomogeneous. Suppose now for all $x\in X$ and some $u, v\in\mathbb{R}_+^k$, $u>0$, $u\leqq Tx\leqq v$. By subhomogeneity of T

$$T\left(\frac{z}{1-\lambda}\right)=T\left(\frac{p(z)}{1-\lambda}\,\frac{z}{p(z)}\right)\geqq\frac{p(z)}{1-\lambda}\,T\left(\frac{z}{p(z)}\right)$$

and therefore $Ty\geqq\lambda Tx+p(z)T(z/p(z))$. Since p is induced by a norm, $p(y)=p(\lambda x+z)\leqq\lambda p(x)+p(z)$ and hence $p(z)\geqq 1-\lambda$. Furthermore, there is a real number $0<s\leqq 1$ such that $sv\leqq u$ and therefore $sTx\leqq sv\leqq u\leqq T(z/p(z))$. Thus we obtain $Ty\geqq\lambda Tx+(1-\lambda)sTx=\varphi(\lambda)Tx$, with $\varphi(\lambda)=\lambda+(1-\lambda)s$. This formula is true by approximation also for $\lambda=1$. Being a composite of concave operators S_m is concave

too and by the uniform pointwise b undedness there exist $u, v \in \mathbb{R}_+^k$, $u > 0$, such that $u \leqq S_m x \leqq v$ for all $x \in X$ and all m. Putting $T = S_m$ we conclude that $\lambda x \leqq y$ for $x, y \in X$ and $\lambda \in [0, 1]$ implies $\varphi(\lambda) S_m x \leqq S_m(y)$ for all m, whereby $\varphi(\lambda) = \lambda + (1-\lambda)s$. This shows that $(S_m)_m$ is ascending. □

The weak ergodicity theorem or Coale-Lopez theorem referred to in the literature (cf. [4], [8], [13], [14]) is contained in the above corollary as the special case of linear operators T_n. In that special case weak ergodicity holds provided the T_n are proper and $(S_m)_m$ is uniformly pointwise bounded. For example, this is guaranteed if all S_m are strictly positive (for some $r \geqq 1$) and all the possible entries (all the possible nonzero entries) of the matrices T_n for $n = 1, 2, \cdots$, are bounded from above (bounded from below by some positive constant) (cf. [8], [14]; in [8] weak ergodicity is not with respect to the Euclidean topology but with respect to the topology belonging to Hilbert's metric).

The concept of strong ergodicity also stems from the theory of Markov chains. Generalizing, we say there holds *strong ergodicity* (relative to some fixed scale p) for a sequence $(T_n)_n$ of operators on $\mathbb{R}_+^k$, when for arbitrary nonzero starting points $x_1 \in \mathbb{R}_+^k$ the sequence defined by

$$x_n = \frac{T_{n-1} \cdot \cdots \cdot T_2 \cdot T_1(x_1)}{p(T_{n-1} \cdot \cdots \cdot T_2 \cdot T_1(x_1))}$$

converges in the Euclidean topology to the same limit point x^*.

THEOREM 5 (*Strong ergodicity for nonlinear operators*). *Let $(T_n)_n$ and $(S_m)_m$ be sequences of operators on $\mathbb{R}_+^k$ as in Theorem 4. Suppose in addition for the lumped operators S_m uniform convergence on $X = \{x \in \mathbb{R}_+^k \mid p(x) = 1\}$ equipped with the Euclidean metric to some operator S on $\mathbb{R}_+^k$. Then there holds strong ergodicity for the sequence $(T_n)_n$ and the limit point x^* is the unique eigenvector of S in X.*

Proof. Putting $f_n = \tilde{T}_n$, $F_m = \tilde{S}_m$ the assumptions of Theorem 1 are satisfied according to the proof of Theorem 4. To apply Theorem 2 we show uniform convergence of F_m to $F = \tilde{S}$ on the metric space (X, d) with $d(x, y) = \min(\mu(x, y), s)$ being the truncated Hilbert metric (as in the proof of Theorem 4). Since by assumption $(S_m)_m$ is uniformly pointwise bounded it follows that $S_m x \geqq u > 0$ for all m, all $x \in X$ (as in the proof of part (iv) of Lemma 1). In particular $Sx \geqq u > 0$ for all $x \in X$ and $F = \tilde{S}$ is well defined on X. Because of Lemma 2 (and the remark thereafter) and because of $\mu(S_m x, Sx) = \mu(F_m(x), F(x))$ for $x \in X$ the uniform convergence of S_m to S for the Euclidean metric implies uniform convergence of F_m to F for the metric d. Theorem 2 yields convergence with respect to d of

$$x_n = f_{n-1} \cdot \cdots \cdot f_2 \cdot f_1(x_1) = \frac{T_{n-1} \cdot \cdots \cdot T_2 \cdot T_1(x_1)}{p(T_{n-1} \cdot \cdots \cdot T_2 \cdot T_1(x_1))}, \qquad x_1 \in X,$$

to the unique fixed point x^* of F in X. By Lemma 2 convergence is also with respect to Euclidean topology. Obviously fixed points of F in X correspond in a unique manner to eigenvectors of S in X. Because the T_n are ray-preserving, $x_1 \in X$ may be replaced by any nonzero $x_1 \in \mathbb{R}_+^k$. This proves strong ergodicity of $(T_n)_n$. □

As for weak ergodicity we may specialize to concave operators.

COROLLARY (*Strong ergodicity for concave operators*). *Consider a scale induced on $\mathbb{R}_+^k$ by a vector space norm. There holds strong ergodicity for every sequence $(T_n)_n$ of proper, ray-preserving, and concave operators on $\mathbb{R}_+^k$ provided some sequence of lumped operators $(S_m)_m$ is uniformly pointwise bounded and converges uniformly on $X = \{x \in \mathbb{R}_+^k \mid p(x) = 1\}$ equipped with the Euclidean metric to some operator S on $\mathbb{R}_+^k$.*

Proof. $(T_n)_n$, $(S_m)_m$ satisfy the assumptions of Theorem 4, according to the proof of the corollary following Theorem 4. Hence the above corollary is implied by Theorem 5. □

Using Theorem 3 of the previous section, we may obtain sufficient conditions for strong ergodicity without referring to lumped operators. For this from matrix theory we borrow the following notion. An operator $T:\mathbb{R}_+^k \to \mathbb{R}_+^k$ is *primitive* (for p), if there exists $r \geqq 1$ such that for any

$$x, y \in X = \{x \in \mathbb{R}_+^k \mid p(x) = 1\} \quad \text{and} \quad \lambda \in \mathbb{R}_+ \quad \lambda x \leqq y, \lambda x \neq y \quad \text{implies that } \lambda T^r x < T^r y.$$

THEOREM 6. *Let $T_n:\mathbb{R}_+^k \to \mathbb{R}_+^k$, $n = 1, 2, \cdots$, be proper, subhomogeneous, and ray-preserving operators that converge, uniformly on the intersection with the unit sphere of some monotonic norm $\|\cdot\|$, to an operator T on $\mathbb{R}_+^k$. Suppose the operator T is proper ray-preserving, continuous, and primitive (for $\|\cdot\|$). Then there holds strong ergodicity for $(T_n)_n$ with scale $\|\cdot\|$ and the limit point x^* is the unique normalized eigenvector of T.*

Proof. $X = \{x \in \mathbb{R}_+^k \mid \|x\| = 1\}$ equipped with $e(x, y) = \|x - y\|$ is a compact metric space on which $(T_n)_n$ converges uniformly to an operator T which must be uniformly continuous. Formula $(*)$ of step (3) in the proof of Theorem 2 then yields that on (X, e) the sequence of lumped operators $S_m = T_{m+r-1} \cdot \cdots \cdot T_{m+1} \cdot T_m$ converges uniformly to T^r (r as in the definition of primitivity). Take $\|\cdot\|$ as scale and put $f_n = \tilde{T}_n$, $f = \tilde{T}$. From Lemma 1 for the lumped operators F_m to $(f_n)_n$ $F_m = \tilde{S}_m$ and $F = \tilde{T}^r = \tilde{T}^r = f^r$. Since T is primitive, T^r is in particular pointwise bounded and subhomogeneous (using continuity of T). Hence by Lemma 1(iv) there exist $a, b \in X = \{x \in \mathbb{R}_+^k \mid \|x\| = 1\}$, $a > 0$ such that $a \leqq f^r(x) \leqq b$. From Lemma 2 (and the remark thereafter) it follows that on X F_m converges uniformly to F with respect to Hilbert's metric μ. We shall apply Theorem 3 for $U = \{y \in X \mid \frac{1}{2}a < y < 2b\}$. Obviously, U is relatively open in X for the Euclidean topology and the closure $\bar{U} = \{y \in X \mid \frac{1}{2}a \leqq y \leqq 2b\}$ is compact. For $d(x, y) = \min(\mu(x, y), s)$, $s = \sup\{\mu(x, y) \mid x, y \in \bar{U}\} < +\infty$ from Lemma 2 it follows that U is open in (X, d), the closure of U in this space equals $\bar{U}$ and $\bar{U}$ is compact in (X, d). Furthermore $F(X) \subseteq U$. Finally, from the primitivity of T it follows (as for part (iii) of Lemma 1) that $\mu(F(x), F(y)) < \mu(x, y)$ for $x, y \in \bar{U}$. Hence F is contractive on $\bar{U}$ for d.

Thus Theorem 3 yields the convergence relative to d of the sequence defined by $x_{n+1} = f_n(x_n)$, $x_1 \in X$, to some $x^* \in X$. Also, x^* is the unique fixed point of F in X. Primitivity of T implies $x^* = T^r x^* / \|T^r x^*\| > 0$. By Lemma 2 $(x_n)_n$ converges to x^* in the Euclidean topology. Since the T_n are ray-preserving, any nonzero $x_1 \in \mathbb{R}_+^k$ is allowed to be a starting point. Thus $(T_n)_n$ is strongly ergodic. Concerning the assertion on x^* in the theorem, it suffices to show x^* to be an eigenvector of T. Since $x^* > 0$, there exists $0 < \lambda$ sufficiently small with $\lambda T^{r-1} x^* / \|T^{r-1} x^*\| \leqq x^*$. Being the limit of subhomogeneous operators, T is subhomogeneous and therefore $\lambda T(T^{r-1} x^* / \|T^{r-1} x^*\|) \leqq Tx^*$. Since T is ray-preserving it follows that $\mu T^r x^* \leqq Tx^*$ for some $\mu > 0$ and hence $Tx^* > 0$. Because of $T_n x_n \to Tx^*$ in the Euclidean topology by Lemma 2 it follows that $f_n(x_n) \to f(x^*)$ for d. But $f_n(x_n) = x_{n+1} \to x^*$, and hence $f(x^*) = x^*$, i.e., x^* is an eigenvector of T. □

As a simple special case the theorem on strong ergodicity for nonnegative matrices (cf. [14]) follows directly from Theorem 6. For T_n linear the only assumptions placed on T_n by Theorem 6 are properness (e.g., fulfilled if there is no column of zeros) and pointwise convergence of T_n to an operator T some power of which is strictly increasing.

4. Example: A density- and time-dependent Leslie model. Consider a population of female individuals at discrete points of time. The growth of the population is

dependent upon birth and death which are, among others, age-specific. Hence the population is divided into a finite number of age groups, say $1, 2, \cdots, k$. Denote by $X_i(t)$ *the number of individuals in age group* $i \in \{1, \cdots, k\}$ *at time* $t \in \{1, 2, \cdots\}$ and let $X(t) = (X_1(t), \cdots, X_k(t))$ be the *population vector at time t.* The *total population at time t* is given by $\|X(t)\|$, where $\|\cdot\|$ is the norm on $\mathbb{R}^k$ defined by $\|x\| = \Sigma|x_i|$. The vector $x(t) = X(t)/\|X(t)\|$ is called the *age structure at time t.* The *birth rate in age group i* is denoted by $b_i(t, X(t))$ and may depend on time and the population vector. The *survival rate in age group i,* denoted by $s_i(t, X(t))$, specifies the proportion of $X_i(t)$ surviving to be in age group $i+1$ at time $t+1$. The survival rate $s_k(\cdot, \cdot)$ for the oldest group therefore is 0. It is assumed that all the other survival rates and the birth rates are strictly positive. Thus we arrive at the following *model*:

$$X_1(t+1) = \sum_{i=1}^{k} b_i(t, X(t))X_i(t),$$

$$X_{i+1}(t+1) = s_i(t, X(t))X_i(t) \quad \text{for } i = 1, \cdots, k-1.$$

Or, equivalently,

$$X(t+1) = T(t)X(t) \quad \text{where } T(t): \mathbb{R}_+^k \to \mathbb{R}_+^k$$

is given by

$$T(t)x = L(t, x)x = \begin{bmatrix} b_1(t, x) & \cdots & b_k(t, x) \\ s_1(t, x) & 0 & 0 \\ 0 & & \vdots \\ \vdots & \ddots & \\ 0 & s_{k-1}(t, x) & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ \vdots \\ x_k \end{bmatrix} \begin{bmatrix} x_1 \\ \vdots \\ x_k \end{bmatrix}.$$

This is a *generalized Leslie model* where birth rates and survival rates are allowed to depend on time and on density $X(t)$. In the original *Leslie model* (cf. [4], [8], [13], [14]) birth rates and survival rates are assumed to be constant, and hence the *Leslie matrix* $L(t, x)$ is constant, $L(t, x) = L$ for all t and x. Since L turns out to be a primitive matrix this case is already covered by a theorem on matrices due to Perron which implies that the age structure $x(t)$ converges to an equilibrium x^* (cf. [12], [14]).

The case that $L(t, x)$ is time-dependent only, $L(t, x) = L(t)$, is covered by the (linear) Coale-Lopez theorem which yields weak ergodicity of the age structure $x(t)$ (cf. [4], [8], [13], [14]). However, if $L(t, x)$ also depends on x and therefore $T(t)$ becomes a nonlinear operator, a lot of things may happen. So it is shown in [9] for the very simple model given by $k = 2$, $b_i(t, x) = b_i \exp[-a(x_1 + x_2)]$, $s_1(t, x) = \text{constant}$, that chaotic dynamics occurs for certain choices of the parameters b_1, b_2, a.

Being interested in weak ergodicity also for the nonlinear case we therefore have to make some assumptions which constitute our concave Leslie model.

The concave Leslie model is based on the following assumptions.

(1) The functions $x \to b_i(t, x)x_i$, $x \to s_i(t, x)x_i$ are concave on $\mathbb{R}_+^k$ for all i, t.

(2) $b_i(t, \lambda x)/b_i(t, x) = s_j(t, \lambda x)/s_j(t, x)$ for all $\lambda > 0$ and all i, j, x.

(3) There exist functions $c(\cdot)$, $d(\cdot): \mathbb{R}_+^k \backslash \{0\} \to \mathbb{R}_+ \backslash \{0\}$ with $c(\cdot)$ not increasing, $d(\cdot)$ not decreasing with respect to "$\leqq$" such that

$$c(x) \leqq b_i(t, x), s_i(t, x) \quad \text{and} \quad b_i(t, x)x_i, s_i(t, x)x_i \leqq d(x)$$

for all i, t and x.

We show that the concave Leslie model satisfies the assumptions of the concave version of the Coale-Lopez theorem presented in the last section. Assumption (1)

obviously implies that all the operators $T(t)=L(t,x)x$ are concave. The assumption itself means that the number of births or survivals contributed by a particular age group decreases by "population pressure" with the density in that group. Assumption (2) implies $L(t,\lambda x)=\mu L(t,x)$ for some μ, which may depend on λ, t, x and hence every $T(t)$ is ray-preserving. By this assumption a certain "homogeneity" of the vitality rates with respect to changes in total population is required. The assumption is met, e.g., if all vitality rates are homogeneous of the same degree with respect to total population. The assumption (3) requiring uniform upper and lower bounds for the vitality rates implies obviously that the $T(t)$ are proper and yields the existence of a uniformly pointwise bounded sequence of inhomogeneous iterates as shown by the following lemma.

LEMMA 3. *By assumption* (3) *there exist for every* $x\in\mathbb{R}^k_+\backslash\{0\}$ $u(x)$, $v(x)\in\mathbb{R}^k_+$ *where* $u(x)>0$ *such that*

$$u(x)\leqq T(m+k-1)\cdot\cdots\cdot T(m+1)\cdot T(m)x\leqq v(x)\quad \textit{for all } m\in\mathbb{N}.$$

Proof. By (3) $T(t)x\leqq w(x)$ for all t, where $w(x)=(kd(x),d(x),\cdots,d(x))$ and $w(\cdot)$ is not decreasing with respect to "$\leqq$." Hence $T(t)T(s)x\leqq w(T(s)x)\leqq w\cdot w(x)$. By iteration, if $S(m)=T(m+k-1)\cdot\cdots\cdot T(m+1)\cdot T(m)$, $S(m)x\leqq w\cdot\cdots\cdot w(x)$. Choose $v(x)=w^k(x)=w\cdot\cdots\cdot w(x)$. Furthermore by (3) $L(t,x)\geqq c(x)L$, where

$$L=\begin{bmatrix}1&1&\cdots&1\\1&0&\cdots&0\\0&&&\vdots\\\vdots&&\ddots&\vdots\\0&0&1&0\end{bmatrix}.$$

Hence $T(t)x=L(t,x)x\geqq c(x)Lx$ for all t. It follows, by using $T(s)x\leqq w(x)$, that

$$T(t)T(s)x\geqq c(T(s)x)LT(s)x\geqq c(T(s)x)c(x)L^2x\geqq c(w(x))c(x)L^2x.$$

Therefore by iteration for $S(k)$ defined above

$$S(m)x\geqq c(w^{k-1}(x))\cdot c(w^{k-2}(x))\cdots c(w(x))c(x)L^kx.$$

Choose as $u(x)$ the right-hand side of this inequality. It is easily checked that the matrix L^k is strictly positive. Hence $u(x)>0$. □

Due to the lemma we can apply the concave version of the Coale–Lopez theorem (corollary to Theorem 4) which yields that weak ergodicity holds in the above concave Leslie model. A simple example of a concave Leslie model is the following one that contains the linear time-dependent Leslie model as a special case. Let for k arbitrary and $i\in\{1,\cdots,k\}$, $t\in\{1,2,\cdots\}$,

$$b_i(t,x)=b_i(t)x_i^{\alpha-1},\qquad s_i(t,x)=s_i(t)x_i^{\alpha-1},$$

where $0<\alpha\leqq 1$ and $c_1\leqq b_i(t)$, $s_i(t)\leqq c_2$ for all i, all t with certain positive constants c_i. Assumptions (1) and (2) for a concave Leslie model are obviously satisfied. Assumption (3) is fulfilled by choosing the following functions:

$$c(x)=c_1\min_i x_i^{\alpha-1},\qquad d(x)=c_2\sum_i x_i^{\alpha}\quad\text{for } x\in\mathbb{R}^k_+\backslash\{0\}.$$

The linear Leslie model is obviously contained for $\alpha=1$. For $\alpha<1$, e.g., $\alpha=\frac{1}{2}$, the operator $T(t)$ is neither positive homogeneous nor additive. Nevertheless, as for the linear case, weak ergodicity holds for this simple nonlinear example.

The example may serve also to illustrate the general Theorem 6 on strong ergodicity. For this suppose that for all i, $b_i(t)$ and $s_i(t)$ tend to $b_i > 0$ and $s_i > 0$, respectively, as $t \to \infty$. If

$$L(t) = \begin{bmatrix} b_1(t) & \cdots & b_k(t) \\ s_1(t) & & 0 \\ 0 & & \vdots \\ \vdots & & \\ 0 \quad \cdots & s_{k-1}(t) & 0 \end{bmatrix}, \qquad L = \begin{bmatrix} b_1 & \cdots & b_k \\ s_1 & & 0 \\ 0 & & \vdots \\ \vdots & & \\ 0 \quad \cdots & s_{k-1} & 0 \end{bmatrix},$$

$$x^\alpha = \begin{bmatrix} x_1^\alpha \\ x_2^\alpha \\ \vdots \\ x_k^\alpha \end{bmatrix},$$

then $T(t)x = L(t)x^\alpha$ and $T(t)$ converges uniformly on $X = \{x \in \mathbb{R}_+^k \mid \|x\| = 1\}$ to the operator T given by $Tx = Lx^\alpha$. Obviously, $T(t)$ and T are proper and T is continuous on X. $T(t)$ is also ray-preserving and subhomogeneous because of

$$T(t)(\lambda x) = L(t)(\lambda x)^\alpha = \lambda^\alpha L(t)x^\alpha = \lambda^\alpha T(t)x.$$

The same applies to T. To see primitivity let $\lambda x \leqq y$, $\lambda x \neq y$ for $x, y \in X$. Successive application of L yields, using the monotonicity of $x \mapsto x^\alpha$, that $T^k(\lambda x) < T^k y$. Hence $\lambda T^k x \leqq \lambda^{\alpha^k} T^k x = T^k(\lambda x) < T^k y$, and T is primitive. Thus Theorem 6 supplies strong ergodicity for this little nonlinear example, a result that still contains the corresponding result for the linear case.

ANALYSIS OF LARGE DEFORMATION OF A HEAVY CANTILEVER*

SZE-BI HSU† AND SHIN-FENG HWANG‡

Abstract. In this paper a mathematical model is discussed describing the deformation of a cantilever by its own weight. We assume that a cantilever of uniform cross-section and density is held fixed at an angle α at one end and is free at the other end. The shape of the cantilever depends heavily on α and a nondimensional parameter K which represents the relative importance of density and length to that of flexural rigidity. We analyze the bifurcation phenomena for the vertical case, $\alpha = \pi$. Several numerical results are presented and discussed.

Key words. bifurcation, Sturm comparison, nonlinear eigenvalue problem, nonlinear oscillation

AMS(MOS) subject classifications. 73K05, 34B15, 34C10, 34C15

1. Introduction. The deformation of a cantilever by its own weight is of interest both practically due to its engineering significance and theoretically due to its inherent nonlinearity. We assume that a cantilever of uniform cross-section and density is held fixed at an angle α at one end and is free at the other end. If the cantilever is thin enough then its deformed shape can be described by the elastica theory. Using this approximation and small deflections, Euler first investigated the stability of a vertical cantilever (column) under its own weight [3]. Euler's stability problem was later corrected by Greenhill [4] who obtained the minimum unstable height for a column of given density and rigidity. The large deformation of a heavy elastica was first numerically integrated by Bickeley [1] who found only one of the solutions of the originally horizontal cantilever. Later, Wang [8] used the perturbation method on the elastica equations for a small and large parameter K, where K is a nondimensional parameter which represents the relative importance of density and length to that of flexural rigidity. In [8] Wang also studied the bifurcation phenomena numerically as the parameters K, α change.

In this paper we first give the uniqueness results for the solutions of the elastica equation. We then give the complete bifurcation results for the vertical case, $\alpha = \pi$, in the spirit of [6], [7]. From these analytic results we improve the numerical results in [8] and give the reliable numerical computation results.

2. Formulation. We assume a cantilever of uniform density ρ and total length L, is held fixed at an angle α at one end, say, the origin, and is free at the other end. Let us consider a small segment of the cantilever. A moment balance gives (see Fig. 1)

$$m - \rho(L - s') \sin\theta \, ds' = m + dm, \tag{2.1}$$

where $m = m(s')$ is the local moment, s' is the arc length from the origin, and $\theta = \theta(s')$ is the local angle of inclination. According to Euler, the local moment is proportional to the curvature $d\theta/ds'$, i.e.,

$$m = -\mathrm{EI}\frac{d\theta}{ds'}, \tag{2.2}$$

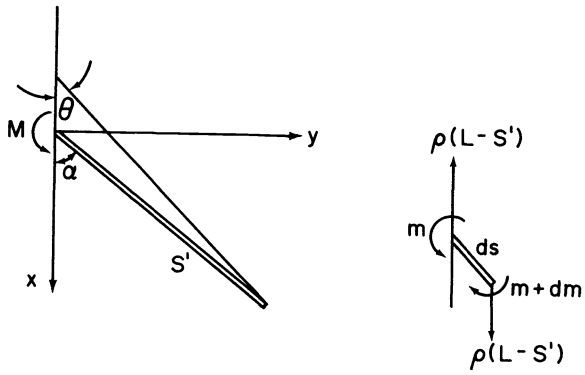

FIG. 1

where EI is the flexural rigidity of the material. From (2.1), (2.2), we obtain

$$\text{EI}\frac{d^2\theta}{ds'^2}=\rho(L-s')\sin\theta, \tag{2.3}$$

and the boundary conditions are

$$\theta(0)=\alpha, \qquad \frac{d\theta}{ds'}(L)=0. \tag{2.4}$$

Let $s=s'/L$ and then (2.3), (2.4) become

$$\begin{aligned}&\frac{d^2\theta}{ds^2}=K^3(1-s)\sin\theta, \quad K>0, \quad 0\leqq s\leqq 1,\\ &\theta(0)=\alpha, \quad \theta'(1)=0, \quad -\pi<\alpha<\pi.\end{aligned} \tag{2.5}$$

The important parameter $K=(\rho L^3/\text{EI})^{1/3}$ represents the relative importance of density and length to that of flexural rigidity.

The main concern of this paper is to determine the multiplicities of solutions of (2.5) provided that $K>0$, $-\pi\leqq\alpha\leqq\pi$ are given.

First of all, we shall reformulate our problem (2.5). Let

$$\psi(s)=\theta(1-s), \qquad 0\leqq s\leqq 1.$$

Then (2.5) becomes

$$\begin{aligned}&\frac{d^2\psi}{ds^2}=K^3 s\sin\psi, \quad 0<s<1, \quad K>0,\\ &\psi'(0)=0, \quad \psi(1)=\alpha, \quad -\pi\leqq\alpha\leqq\pi.\end{aligned} \tag{P}_\alpha$$

Since $\psi(s)$, $0\leqq s\leqq 1$, is a solution of $(\text{P})_\alpha$ if and only if $-\psi(s)$ is a solution of $(\text{P})_{-\alpha}$. Hence we only consider the problem with $0\leqq\alpha\leqq\pi$. We may also reduce the problem $(\text{P})_\alpha$, $0\leqq\alpha\leqq\pi$, by the following scaling:

$$\Psi(s)=\psi(s/K).$$

Then $\Psi(s)$ satisfies

$$\begin{aligned}&\frac{d^2\Psi}{ds^2}=s\sin\Psi(s), \qquad 0\leqq s\leqq K,\\ &\Psi'(0)=0, \quad \Psi(K)=\alpha, \quad 0<\alpha<\pi.\end{aligned} \tag{2.6}$$

3. Uniqueness of solutions of $(P)_\alpha$, $0 \leqq \alpha \leqq \pi$. In this section, we present some results concerning the uniqueness of solutions of boundary value problem

$$(P)_\alpha \qquad \frac{d^2\psi}{ds^2} = K^3 s \sin\psi, \quad 0 \leqq s \leqq 1, \quad K > 0,$$
$$\psi'(0) = 0, \quad \psi(1) = \alpha, \quad 0 \leqq \alpha \leqq \pi.$$

LEMMA 3.1. *The problem* $(P)_0$ *has a unique solution, namely,*

$$\psi(s) \equiv 0, \quad 0 \leqq s \leqq 1 \quad \textit{for any } K > 0.$$

Proof. Obviously $\psi(s) \equiv 0$ is a solution of $(P)_0$. Multiplying the equation in $(P)_0$ by $d\psi/ds$ and integrating the resulting equation from 0 to 1, we obtain

$$\frac{1}{2}(\psi'(1))^2 = K^3\left[\int_0^1 \cos\psi(s)\, ds - 1\right] \geqq 0.$$

However,

$$\int_0^1 \cos\psi(s)\, ds - 1 \leqq 0.$$

Hence we have $\psi'(1) = 0$. Since $\psi(1) = 0$, $\psi'(1) = 0$, the conclusion $\psi(s) \equiv 0$ follows directly from the uniqueness of solutions of ordinary differential equations. □

The existence of solution of problem $(P)_\alpha$ follows directly from the results in [2] since the right-hand side of $(P)_\alpha$, $K^3 s \sin\psi$, is a bounded function for $0 \leqq s \leqq 1$.

We now present a result concerning the uniqueness of solution of $(P)_\alpha$.

LEMMA 3.2. *If* $K^3 < \sqrt{45}$, *then* $(P)_\alpha$ *has a unique solution for every* $\alpha \in [0, \pi]$.

Proof. Let $\psi(s)$ be a solution of $(P)_\alpha$; then

$$\psi(s) = \alpha - \int_0^1 K^3 \xi \sin\psi(\xi) G(s, \xi)\, d\xi,$$

where

$$G(s, \xi) = 1 - \max(s, \xi).$$

Let $\psi_1(s)$, $\psi_2(s)$ be solutions of $(P)_\alpha$. Then

$$|\psi_1(s) - \psi_2(s)| \leqq \int_0^1 G(s, \xi)\xi |\psi_1(\xi) - \psi_2(\xi)|\, d\xi$$
$$\leqq K^3\left[\int_0^1 G^2(s, \xi)\xi^2\, d\xi\right]^{1/2} \|\psi_1 - \psi_2\|_2,$$

or

$$\|\psi_1 - \psi_2\|_2^2 = \int_0^1 |\psi_1(s) - \psi_2(s)|^2\, ds$$
$$\leqq K^6\left(\int_0^1 \int_0^1 G^2(s, \xi)\xi^2\, d\xi\right)\|\psi_1 - \psi_2\|_2^2$$

since

$$\int_0^1 \int_0^1 G^2(s, \xi)\xi^2\, d\xi\, ds = \frac{1}{45}.$$

If $K^6/45 < 1$ or $K^3 < \sqrt{45}$ then we must have

$$\psi_1 \equiv \psi_2. \qquad \square$$

4. The multiplicities of the solutions of $(P)_\alpha$ for $\alpha = \pi$. In this section we shall present the analytic results for the vertical case, $\alpha = \pi$. The analytic results for this special case will help us to understand the bifurcation phenomena for the general problem $(P)_\alpha$. In the rest of this section, we shall restrict our attention to the vertical case, $\alpha = \pi$:

$$\frac{d^2\psi}{ds^2} = K^3 s \sin\psi, \quad \psi'(0) = 0, \quad \psi(1) = \pi. \tag{4.1}$$

Let $s = x$, $v(x) = \psi(x/K) - \pi$. Then (4.1) takes the form

$$\begin{aligned} &v''(x) + x \sin v = 0, \qquad ' = d/dx, \\ &v'(0) = 0, \qquad v(K) = 0. \end{aligned} \tag{4.2}$$

We shall study the boundary value problem (4.2) by the shooting method and consider the following initial value problem

$$\begin{aligned} &v''(x) + x \sin v = 0, \\ &v'(0) = 0, \\ &v(0) = a, \qquad a \in \mathbb{R}. \end{aligned} \tag{4.3}$$

We denote the solution of (4.3) by $v(x, a)$. From the uniqueness of solutions of ordinary differential equations, it follows that

$$\begin{aligned} &v(x, 2\pi + a) = 2\pi + v(x, a), \\ &v(x, 2\pi - a) = 2\pi - v(x, a), \\ &v(x, a) = -v(x, -a), \\ &v(x, 0) \equiv 0, \qquad v(x, \pi) \equiv \pi. \end{aligned} \tag{4.4}$$

From (4.4), we shall consider $v(x, a)$ only for $0 < a < \pi$.

LEMMA 4.1. *Let $0 < a < \pi$. Then*

(i) $-\pi/2 < v(x, a) < \pi/2$ *for* $0 < a < \pi/2$, $x \geqq 0$.

(ii) $-\pi < v(x, a) < \pi$ *for* $\pi/2 \leqq a < \pi$, $x \geqq 0$.

(iii) $v(x, a)$ *is oscillatory over* $[0, \infty)$ *for all* $0 < a < \pi$.

Proof. Multiplying (4.3) by $v'(x)$ and integrating the resulting equation from 0 to x, we obtain

$$\frac{1}{2}(v'(x))^2 = x \cos v(x) - \int_0^x \cos v(\xi)\, d\xi \geqq 0. \tag{4.5}$$

If $0 < a < \pi/2$, then $\cos a = \cos v(0) > 0$. We claim that $\cos v(x) > 0$ for all $x \geqq 0$. If not, then there exists $x_0 > 0$ such that $\cos v(x) > 0$ for all $0 \leqq x < x_0$ and $\cos v(x_0) = 0$. Then this contradicts (4.5) with $x = x_0$ and we complete the proof for (i).

If $\pi/2 \leqq a < \pi$, then $\cos a = \cos v(0) \in (-1, 0]$. We claim that $\cos v(x) \neq -1$ for all $x \geqq 0$. If not, then there exists $x_0 > 0$ such that $\cos v(x_0) = -1$ and $\cos v(x) > 1$ for $0 \leqq x < x_0$. Again from (4.5) we obtain a contradiction. Hence $-\pi < v(x, a) < \pi$ for all $x \geqq 0$ and we established (ii).

We next show that $v(x, a)$ is oscillatory over $[0, \infty)$ for any $0 < a < \pi$. Let

$$V(x) = (1 - \cos v(x)) + \frac{1}{2}\frac{(v'(x))^2}{x}.$$

It is easy to verify that

$$V'(x) = -\frac{1}{2}\left(\frac{v'(x)}{x}\right)^2 \leqq 0.$$

Then we have

$$1 - \cos v(x) \leqq V(x) \leqq V(0) = 1 - \cos a.$$

Since $-\pi < v(x) < \pi$, we then have $|v(x)| \leqq a$ for all $x \geqq 0$. We rewrite the equation in (4.3) as

$$v''(x) + x\left(\frac{\sin v(x)}{v(x)}\right) v(x) = 0. \tag{4.6}$$

Let $0 < \delta < \min_{0 \leqq v \leqq a} (\sin v / v)$. Using Sturm's comparison theorem [5], we compare (4.6) with

$$v'' + \delta v = 0, \tag{4.7}$$

which is oscillatory over $[0, \infty)$. Thus we complete the proof for (iii). □

Next we introduce the following notation:

$$\Delta(x, a) = \frac{dv}{da}(x, a), \qquad \phi(x) = \Delta(x, 0).$$

Differentiating (4.3) with respect to a yields

$$\Delta''(x) + x(\cos v(x, a))\Delta(x) = 0, \quad \Delta(0) = 1, \quad \Delta'(0) = 0. \tag{4.8}$$

Setting $a = 0$ in (4.8) yields

$$\phi''(x) + x\phi(x) = 0, \quad \phi(0) = 1, \quad \phi'(0) = 0. \tag{4.9}$$

The equation in (4.9) is the well-known Airy equation which is oscillatory over $[0, \infty)$. Let λ_n, γ_n be the nth zero of $\phi(x)$ and $\phi'(x)$, respectively, for $n = 1, 2, \cdots$. We note that

$$\begin{aligned} &\lambda_1 \approx 1.98635, \quad \lambda_2 \approx 3.82557, \quad \lambda_3 \approx 5.29566, \\ &\lambda_4 \approx 6.58432, \text{ etc. (See Fig. 2.)} \end{aligned} \tag{4.10}$$

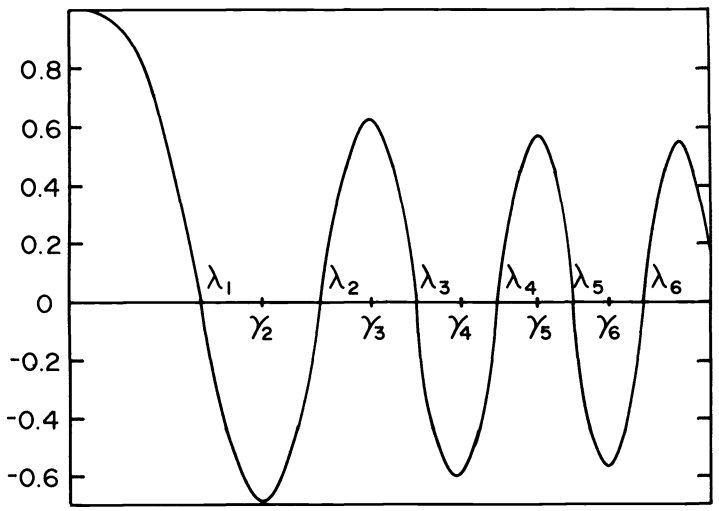

FIG. 2

From Lemma 4.1(iii), $v(x, a)$ is oscillatory over $[0, \infty)$ for any $0 < a < \pi$. Let $y_n(a)$, $z_n(a)$ be the nth zero of $v(x, a)$ and $v'(x, a)$, respectively, for $n = 1, 2, \cdots$, $0 < a < \pi$. (See Fig. 3.)

LEMMA 4.2.

(i) $\lim_{a \to 0^+} y_n(a) = \lambda_n$, $\lim_{a \to 0^+} z_n(a) = \gamma_n$ *for* $n = 1, 2, \cdots$,

(ii) $\lim_{a \to \pi^-} y_n(a) = +\infty$ *for* $n = 1, 2, \cdots$.

Proof. The proof of (i) follows directly from the following identities [6]:

$$\lim_{a \to 0^+} \frac{v(x, a)}{a} = \lim_{a \to 0^+} \frac{v(x, a) - v(x, 0)}{a}$$

$$= \lim_{a \to 0^+} \frac{dv}{da}(x, \delta_a), \qquad 0 < \delta_a < a$$

$$= \frac{dv}{da}(x, 0) = \phi(x),$$

and

$$\lim_{a \to 0^+} \frac{v'(x, a)}{a} = \lim_{a \to 0^+} \frac{v'(x, a) - v'(x, 0)}{a}$$

$$= \lim_{a \to 0^+} \frac{d}{da}(v'(x, \delta_a)) \qquad 0 < \delta_a < a$$

$$= \frac{d}{dx}\left(\frac{d}{da} v(x, 0)\right) = \phi'(x)$$

since $v(x, \pi) \equiv \pi$ and $v(x, a)$ are oscillatory over $[0, \infty)$ for $0 < a < \pi$. From continuous dependence on initial values, we obtain $\lim_{a \to \pi^-} y_1(a) = +\infty$ and hence $\lim_{a \to \pi^-} y_n(a) = +\infty$ for $n = 1, 2, \cdots$. Thus we complete the proof for (ii). □

In addition to the properties (i), (ii) in Lemma 4.2., we shall show that $y_n(a)$ satisfies

$$\frac{dy_n}{da} > 0 \quad \text{for all } n = 1, 2, \cdots \text{ and } 0 < a < \pi. \tag{4.11}$$

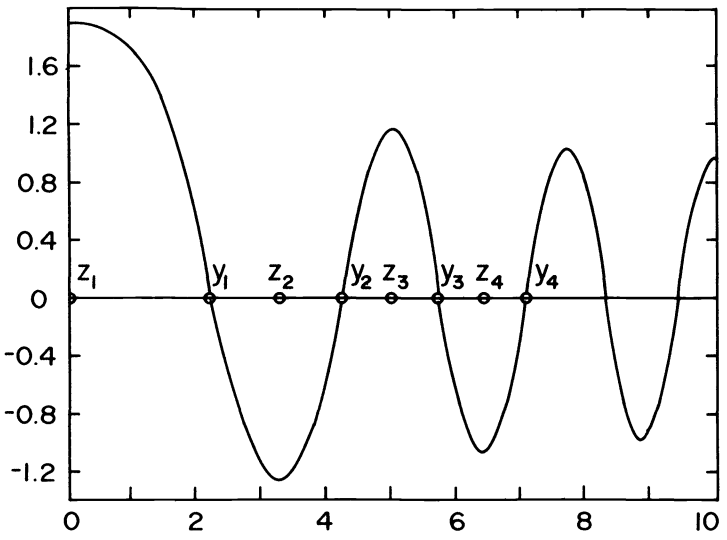

FIG. 3

Assume that (4.11) holds; then we may plot the following graphs for $y_n(a)$, $n = 1,2,\cdots$. (See Fig. 4.) Then we conclude from (4.2) and (4.4) that

If $0 < K < \lambda_1$ then (4.2) has the unique solution $v(x) \equiv 0$.

If $\lambda_1 < K < \lambda_2$ then (4.2) has three distinct solutions.

If $\lambda_n < K < \lambda_{n+1}$ then (4.2) has $2n+1$ distinct solutions.

Since

$$v(y_n(a), a) = 0, \qquad 0 < a < \pi, \tag{4.12}$$

differentiating (4.12) with respect to a yields

$$v'(y_n(a), a)\frac{dy_n}{da} + \frac{dv}{da}(y_n(a), a) = 0,$$

or

$$\frac{dy_n}{da} = -\frac{\Delta(y_n(a), a)}{y'(y_n(a), a)}. \tag{4.13}$$

We now state our main result.

THEOREM 1. *Let* $0 < a < \pi$.

(i) *The solution* $v(x, a)$ *of* (4.3) *has an infinite number of isolated zeros* $y_n(a)$, $y_1 < y_2 < \cdots < y_n$ *and* $y_n \to \infty$ *as* $n \to \infty$; *likewise* $v'(x, a)$ *has an infinite number of isolated zeros,* $z_n(a)$, $0 = z_1 < z_2 < \cdots < z_n$, *interlacing the* y_n; *furthermore*

$$\lim_{a \to 0^+} y_n(a) = \lambda_n, \qquad \lim_{a \to 0^+} z_n(a) = \gamma_n,$$

and

$$\lim_{a \to \pi^-} y_n(a) = \infty \qquad \text{for } n = 1, 2, \cdots.$$

(ii) $y_n(a)$ *is a differentiable function of* a *and*

$$\frac{dy_n}{da} > 0 \quad \text{for } n = 1, 2, \cdots.$$

We have shown part (i) in the above lemmas. The proof of (ii) follows directly from (4.13) and Lemma 4.3 below.

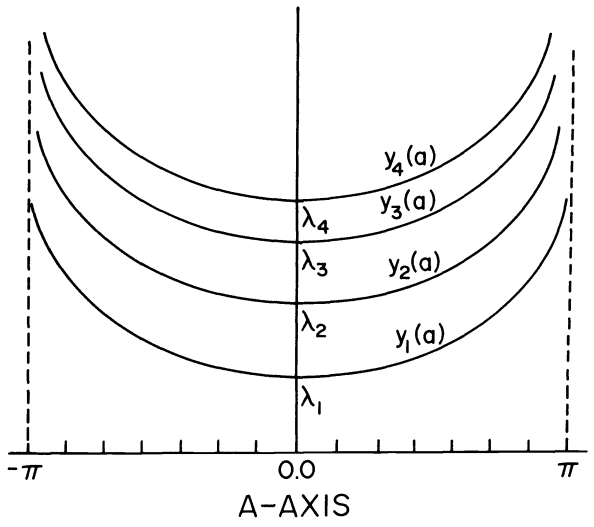

FIG. 4

LEMMA 4.3. *Let* $0<a<\pi$. *Then* $\Delta(x, a)$ *has an infinite number of isolated zeros* $\alpha_n(a)$, $0<\alpha_1<\cdots<\alpha_n$. $\Delta'(x, a)$ *satisfies the following*:

(i) *If* $0<a<\pi/2$, *then* $\Delta'(x, a)$ *has an infinite number of isolated zeros* $\beta_n(a)$, $0=\beta_1<\beta_2<\cdots<\beta_n$. *Furthermore* $\beta_1=z_1=0<y_1<\alpha_1<z_2<\beta_2<y_2<\alpha_2<\cdots<y_n<\alpha_n<z_{n+1}<\beta_{n+1}<y_{n+1}$. (See Fig. 5.)

(ii) *If* $\pi/2\leqq a<\pi$ *then* $\Delta'(x, a)$ *has an infinite number of isolated zeros* $\beta_n(a)$, $0=\beta_0<\beta_1<\cdots<\beta_n$. *Furthermore* $\beta_0=z_1=0<\beta_1<y_1<\alpha_1<z_2<\beta_2<y_2<\cdots<y_n<\alpha_n<z_{n+1}<\beta_{n+1}<y_{n+1}$. (See Fig. 6.)

Before we prove Lemma 4.3 we consider (4.3) and (4.8). Let

(A) $$v''+x\sin v=0,\quad v(0)=a,\quad v'(0)=0,$$

(B) $$\Delta''+x(\cos v)\Delta=0,\quad \Delta(0)=1,\quad \Delta'(0)=0.$$

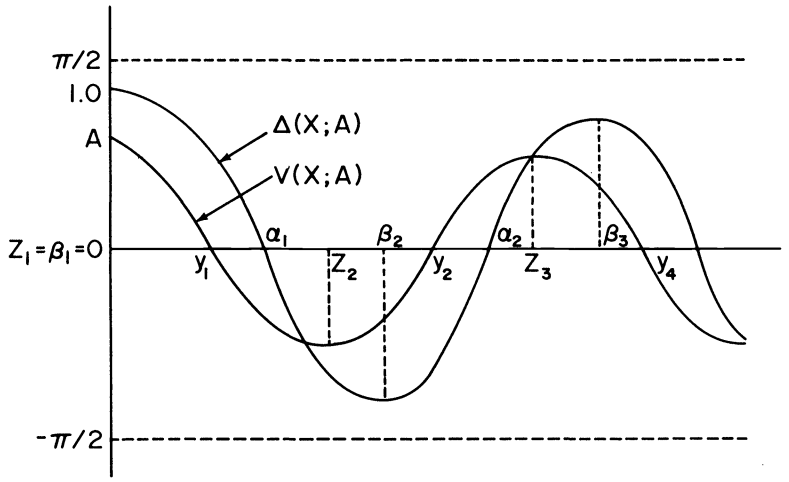

FIG. 5

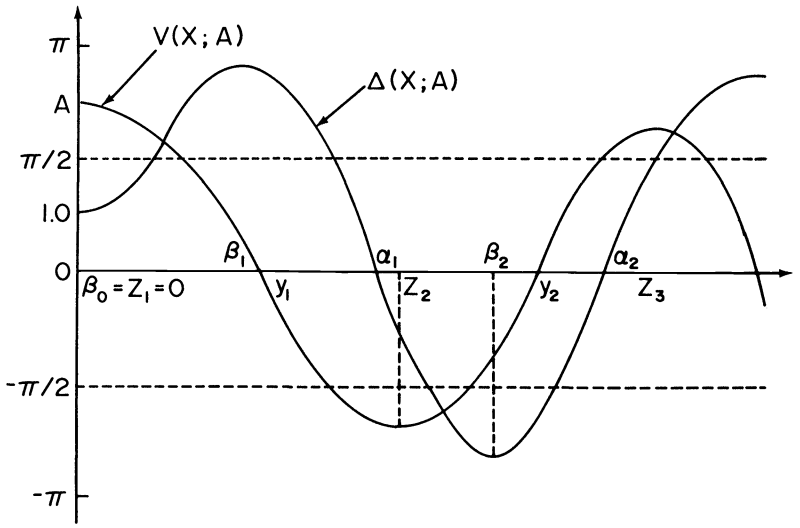

FIG. 6

In addition to (A) and (B), we form the following equations satisfied by Δ' and $\hat{v} = (x - 3y_n)v'$, respectively:

(C) $$(\Delta')'' + x \cos v\Delta' = \Delta(xv' \sin v - \cos v),$$

(D) $$\hat{v}'' + x \cos v\hat{v} = -3(x - y_n) \sin v.$$

Multiplying (A) by Δ and multiplying (B) by v, subtracting the resulting equations from each other and integrating the final expression from α to β, we obtain

(a) $$(v'\Delta - v\Delta')\Big|_\alpha^\beta = \int_\alpha^\beta x\Delta v\left(\cos v - \frac{\sin v}{v}\right) dx.$$

Multiplying (A) by Δ' and multiplying (C) by v, subtracting the resulting equations from each other and integrating the final expression from α to β, we obtain

(b) $$(v'\Delta' - v\Delta'')\Big|_\alpha^\beta = \int_\alpha^\beta \{-x\Delta' \sin v + x\Delta' v \cos v + \Delta v(\cos v - xv' \sin v)\}\, dx.$$

Multiplying (D) by Δ and multiplying (B) by $\hat{v}$, subtracting the resulting equation from each other and integrating the final expression from α to β, we obtain

(c) $$(\hat{v}'\Delta - \hat{v}\Delta')\Big|_\beta^\alpha = -\int_\beta^\alpha 3(x - y_n)\Delta \sin v\, dx.$$

Finally we observe that, since $v'(0) = 0$, $v(0) = a$, $\Delta(0) = 1$, $\Delta'(0) = 0$, $0 < a < \pi$,

$$\operatorname{sg} v = (-1)^n \quad \text{for } y_n < x < y_{n+1},$$
$$\operatorname{sg} v' = (-1)^n \quad \text{for } z_n < x < z_{n+1},$$
$$\operatorname{sg} \Delta = (-1)^n \quad \text{for } \alpha_n < x < \alpha_{n+1},$$
$$\operatorname{sg} \Delta' = (-1)^n \quad \text{for } \beta_n < x < \beta_{n+1}.$$

Proof of Lemma 4.3. We shall prove the lemma by induction. We assume the truth of the statement up to α_m, for $m = 1$.

If $\pi/2 \leqq a < \pi$, then we claim that $\beta_1 < y_1$. If not, $\beta_1 \geqq y_1$, then $\Delta'(x) > 0$ for all $0 \leqq x \leqq y_1$. We specialize (α, β) in (b) to $(0, y_1)$. Then we obtain

$$\begin{aligned} v'\Delta' - v\Delta''\Big|_0^{y_1} &= \int_0^{y_1} (v\Delta' x \cos v - x\Delta' \sin v + \Delta v \cos v)\, dx \\ &\quad + \int_0^{y_1} x\Delta v(-v' \sin v)\, dx. \end{aligned} \tag{4.14}$$

Since

$$\int_0^{y_1} x\Delta v(-v' \sin v)\, dx = x\Delta v \cos v\Big|_0^{y_1} - \int_0^{y_1} \cos v(x\Delta' v + x\Delta v' + \Delta v)\, dx$$

and $v'(0) = 0$, $\Delta''(0) = 0$, $v(y_1) = 0$. Then (4.14) becomes

$$\begin{aligned} v'(y_1)\Delta'(y_1) &= \int_0^{y_1} -x\Delta' \sin v\, dx - \int_0^{y_1} x\Delta v' \cos v\, dx \\ &= \int_0^{y_1} \Delta \sin v\, dx. \end{aligned} \tag{4.15}$$

This is a desired contradiction for $v'(y_1) < 0$, $\Delta'(y_1) > 0$ and $\Delta(x) > 0$, $\sin v(x) > 0$ for $0 \leqq x < y_1$.

We shall now show that $\alpha_1 > y_1$ for $0 < a < \pi$. If not, then there exists $\alpha^* \in (0, y_1)$ such that $\Delta(\alpha^*) = 0$, $\Delta'(\alpha^*) < 0$ and $\Delta(x) > 0$ for $0 \leqq x < \alpha^*$. We specialize (α, β) in (a) to $(0, \alpha^*)$. Then we have

$$-v(\alpha^*)\Delta'(\alpha^*) = \int_0^{\alpha^*} x\Delta v\left(\cos v - \frac{\sin v}{v}\right) dx. \tag{4.16}$$

Since $\cos v \leqq \sin v/v$ for $-\pi < v < \pi$ and $\Delta(x) > 0$, $v(x) > 0$ for $0 \leqq x < \alpha^*$, it follows that the right-hand side of (4.16) is negative. However, the left-hand side of (4.16) is positive. This leads to a contradiction.

We now want to complete the induction. For $0 < a < \pi$, we want to show the following:

(i) $y_m < \alpha_m < z_{m+1}$. By induction hypothesis $y_m < \alpha_m$. We want to show that $\alpha_m < z_{m+1}$. For $a = 0$, it is obvious that $\alpha_m(0) = \lambda_m$. From Lemma 4.2, we have

$$\lim_{a \to 0^+} z_{m+1}(a) = \gamma_{m+1} > \lambda_m.$$

By continuous dependence on parameter a, we have that $\alpha_m(a) < z_{m+1}(a)$ for $a > 0$ sufficiently small. We claim that $\alpha_m(a) < z_{m+1}(a)$ for all $0 < a < \pi$. If not, there exists $a^* \in (0, \pi)$ such that $\alpha_m(a^*) = z_{m+1}(a^*)$. We now specialize (α, β) in (c) to $(z_m(a^*), z_{m+1}(a^*))$ and $n = m$. Then we obtain

$$\hat{v}'\Delta - \hat{v}\Delta'\Big|_{z_m}^{z_{m+1}} = \int_{z_m}^{z_{m+1}} 3(x - y_m)(-\sin v(x))\Delta(x)\, dx \tag{4.17}$$

since $\hat{v}(z_{m+1}) = \hat{v}(z_m) = 0$, $z_{m+1} = \alpha_m$, $\hat{v}'(z_m) = (z_m - 3y_m)v''(z_m)$. Then (4.17) becomes

$$0 = (z_m - 3y_m)v''(z_m)\Delta(z_m) + \int_{z_m}^{z_{m+1}} 3(x - y_m)(-\sin v(x))\Delta(x)\, dx. \tag{4.18}$$

It is easy to verify that the right-hand side of (4.18) is positive. Then this is a desired contradiction. Hence, we have $\alpha_m(a) < z_{m+1}(a)$ for all $0 < a < \pi$.

(ii) $z_{m+1} < \beta_{m+1} < y_{m+1} < \alpha_{m+1}$. First we show that $z_{m+1} < \beta_{m+1}$. If not, then $\alpha_m < \beta_{m+1} \leqq z_{m+1}$. We specialize (α, β) in (a) to (α_m, β_{m+1}). Then we obtain

$$v'(\beta_{m+1})\Delta(\beta_{m+1}) + v(\alpha_m)\Delta'(\alpha_m) = \int_{\alpha_m}^{\beta_{m+1}} x\Delta v\left(\cos v - \frac{\sin v}{v}\right) dx. \tag{4.19}$$

It is easy to verify that the left-hand side of (4.19) is positive while the right-hand side is negative. This is a contradiction.

Next we show that $\beta_{m+1} < y_{m+1}$. If not, then $\beta_{m+1} \geqq y_{m+1}$. We specialize (α, β) in (b) to (z_{m+1}, y_{m+1}). Following similar arguments in the case $\beta_1 < y_1$, we deduce that

$$v'(y_{m+1})\Delta'(y_{m+1}) = z_{m+1}\Delta(z_{m+1}) \sin v(z_{m+1}) + \int_{z_{m+1}}^{y_{m+1}} \Delta \sin v\, dx.$$

It is easy to verify $v'(y_{m+1})\Delta'(y_{m+1}) \leqq 0$, $z_{m+1}\Delta(z_{m+1}) \sin v(z_{m+1}) > 0$, and $\int_{z_{m+1}}^{y_{m+1}} \Delta \sin v\, dx > 0$. Thus we obtain a contradiction.

Finally, we want to show that $y_{m+1} < \alpha_{m+1}$. If not, then $y_{m+1} \geqq \alpha_{m+1}$. We specialize (α, β) in (a) to $(\beta_{m+1}, \alpha_{m+1})$. Then we have

$$-[v'(\beta_{m+1})\Delta(\beta_{m+1}) + v(\alpha_{m+1})\Delta'(\alpha_{m+1})] = \int_{\beta_{m+1}}^{\alpha_{m+1}} x\Delta v\left(\cos v - \frac{\sin v}{v}\right) dx. \tag{4.20}$$

It is easy to verify that the left-hand side of (4.20) is positive while the right-hand side is negative. This is a contradiction. □

5. Numerical studies for $\alpha \neq \pi$ and discussions. In this section, we present our numerical studies for the multiplicities of the solutions of the problem $(P)_\alpha$, $0 < \alpha < \pi$. The analytic results in § 4 shall confirm that our numerical results are reliable.

Consider our bifurcation problem

$$(P)_\alpha \qquad \frac{d^2\psi}{ds^2} = K^2 s \sin\psi, \qquad K > 0,$$
$$\psi'(0) = 0, \quad \psi(1) = \alpha, \quad 0 < \alpha < \pi$$

and its scaled form

$$\frac{d^2\Psi}{ds^2} = s \sin\Psi, \quad \Psi'(0) = 0, \quad \Psi(K) = \alpha. \tag{2.6}$$

Let $\Psi(s, a)$ be the solution of the following initial value problem:

$$\frac{d^2\Psi}{ds^2} = s \sin\Psi, \quad \Psi'(0) = 0, \quad \Psi(0) = a. \tag{5.1}$$

It is easy to verify the following relations:

$$\Psi(s, a + 2\pi) = \Psi(s, a) + 2\pi, \tag{5.2}$$

$$\Psi(s, 2\pi - a) = 2\pi - \Psi(s, a). \tag{5.3}$$

For any $K > 0$, we consider the map

$$a \to \Psi(K, a), \qquad 0 \leqq a \leqq 2\pi.$$

Since $0 < \alpha < \pi$, from (5.3) we only need to compute numerically for $0 < a < \pi$. In the following, we used the ODE Solver DGEAR of the IMSL Library to compute the function $\alpha = \Psi(K, \alpha)$, $0 < a < \pi$, for various K.

In Fig. 7, the parameter K satisfies $0 < K = 1.0 < \lambda_1 \approx 1.98635$ and the graph $\alpha = \Psi(K, a)$ intersects $\alpha = \pi$ at only one point. *We conjecture that for* $0 < K < \lambda_1$ *the problem* $(P)_\alpha$ *has a unique solution for every* $\alpha \in (0, \pi)$. In Fig. 8, the parameter K satisfies

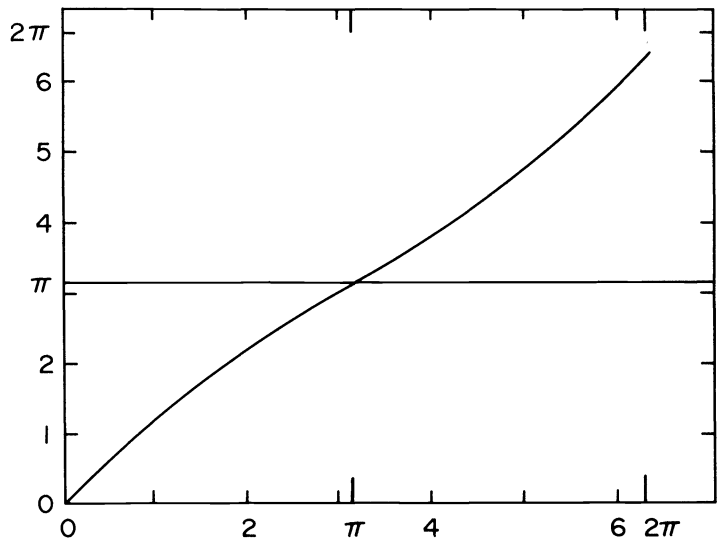

FIG. 7

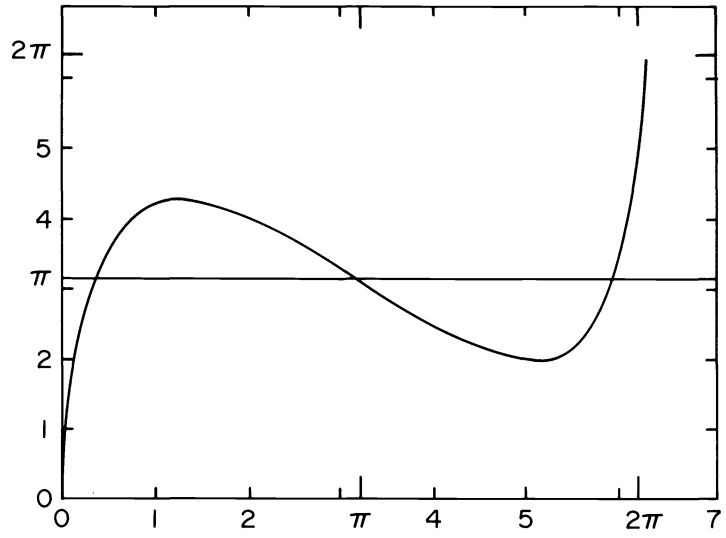

FIG. 8

$\lambda_1 < K = 3.0 < \lambda_2 \approx 3.82557$ and the graph $\alpha = \Psi(K, a)$ intersects $\alpha = \pi$ at three distinct points. It shows that if $\lambda_1 < K < \lambda_2$, then the problem $(P)_\alpha$ has at most three distinct solutions. In Fig. 9, the parameter K satisfies $\lambda_2 < K = 4.5 < \lambda_3 \approx 5.29566$ and the graph $\alpha = \Psi(K, a)$ intersects $\alpha = \pi$ at five distinct points. It shows that if $\lambda_2 < K < \lambda_3$, then the problem $(P)_\alpha$ has at most five distinct solutions. *We conjecture that for* $\lambda_n < K < \lambda_{n+1}$ *the problem* $(P)_\alpha$ *has* $1, 3, \cdots, 2n+1$ *solutions for various* α.

Acknowledgments. We thank Professor C. Y. Wang of Michigan State University for suggesting this problem to us and for stimulating discussions. The authors also thank a referee for his comments.

ON THE UNIQUENESS OF A LIMIT CYCLE FOR A PREDATOR-PREY SYSTEM*

LII-PERNG LIOU† AND KUO-SHUNG CHENG‡

Abstract. The uniqueness of a limit cycle for a predator-prey system is proved in this paper. The method used is an improvement of the method used earlier by Cheng.

Key words. limit cycle, preditor-prey system

AMS(MOS) subject classifications. primary 34D05; secondary 34C15

1. Introduction. Stability analysis for a nontrivial periodic solution of ordinary differential equations is very rare and difficult to obtain even in a two-dimensional system. One well-known example is the Lienard equation, in particular, the Van der Pol equation. See Hartman [6] and Hirsch and Smale [7] for details. For biological predator-prey systems, Hsu, Hubbell, and Waltman [8], [9] considered the following competing-predators system:

$$
\begin{aligned}
&\dot{S}(t) = rS(t)\left(1-\frac{S(t)}{K}\right)-\left(\frac{m_1}{y_1}\right)\left(\frac{X_1(t)S(t)}{a_1+S(t)}\right)-\left(\frac{m_2}{y_2}\right)\left(\frac{X_2(t)S(t)}{a_2+S(t)}\right),\\
&\dot{X}_1(t) = X_1(t)\left(\frac{m_1S(t)}{a_1+S(t)}-D_1\right), \qquad (1)\\
&\dot{X}_2(t) = X_2(t)\left(\frac{m_2S(t)}{a_2+S(t)}-D_2\right),\\
&S(0)=S_0>0, \quad X_i(0)=X_{i0}>0, \quad i=1,2,
\end{aligned}
$$

where $X_i(t)$ is the population of the ith predator at time t; $S(t)$ is the population of the prey at time t; m_i is the maximum growth rate of the ith predator; D_i is the death rate of the ith predator; y_i is the yield factor of the ith predator feeding on the prey; and a_i is the half-saturation constant of the ith predator, which is the prey density at which the functional response of the predator is half maximal. The parameters r and K are the intrinsic rate of increase and the carrying capacity for the prey population, respectively. Hsu, Hubbell, and Waltman analyzed solutions of this system and found that the behavior of solutions depends mainly on the two-dimensional system:

$$
\begin{aligned}
&\dot{S}(t) = rS(t)\left(1-\frac{S(t)}{K}\right)-\left(\frac{m}{y}\right)\left(\frac{x(t)S(t)}{a+S(t)}\right),\\
&\dot{x}(t) = x(t)\left(\frac{mS(t)}{a+S(t)}-D_0\right), \qquad (2)\\
&S(0)=S_0>0, \qquad x(0)=x_0>0,
\end{aligned}
$$

where r, K, m, y, a, and D_0 are positive constants. They analyzed system (2) and found that if $\lambda < (K-a)/2$, where $\lambda = a/(b-1)$ and $b = m/D_0$, then the unique interior equilibrium point (λ, x^*) is unstable. They conjectured that the system (2) has a unique stable limit cycle in this case. This conjecture was answered affirmatively by Cheng in [2]. In these examples, symmetric properties are an important ingredient of the proof. The Van der Pol equations are

$$\begin{aligned} \dot{x} &= y - (x^3 - x), \\ \dot{y} &= -x. \end{aligned} \tag{3}$$

The isocline $\dot{x} = 0$, i.e., the curve $y = x^3 - x$, is symmetric with respect to the origin. This fact is important in the analysis of (3). For the system (2), the isocline $\dot{S} = 0$ is the curve

$$x = r(y/m)(1 - S/K)(a + S). \tag{4}$$

This curve is part of a parabola and hence is also symmetric with respect to the line $S = (K-a)/2$. The proof of Cheng [2] uses this symmetry property in an essential way. From the point of view of perturbation theory, there is no reason to believe that some symmetry properties are indispensable for a stable limit cycle. In this respect, if we can devise a proof that is valid for a more general "nonsymmetric" system, even if it is only a slight generalization, we will feel comfortable with it.

The purpose of this paper is to improve our method used in [2] to prove the uniqueness of a limit cycle for a more general predator-prey system without the symmetry properties of the isocline. At the end of our proof, we also close a gap in the original proof given in [2].

2. The equations and statements of the main result. We will consider the following predator-prey system:

$$\begin{aligned} &\dot{x} = x(f(x) - y), \\ &\dot{y} = y(g(x) - \lambda), \\ &x(0) = x_0 > 0, \qquad y(0) = y_0 > 0, \qquad \lambda > 0. \end{aligned} \tag{5}$$

Note that if $g(x) = x$ and $f(x) = (1 - x/K)(a + x)$, then the system (5) is essentially equivalent to the system (2) up to some irrelevant constants. Our general assumptions about $f(x)$ and $g(x)$ are:

(i) $g \in C^1([0, \infty))$, $g(0) = 0$, $g'(x) > 0$ for all $x \geqq 0$.

(ii) $f \in C^2([0, \infty))$, $f(0) \geqq 0$, and there exists $K > 0$ such that $f(K) = 0$ and $(x - K)f(x) < 0$ for $x \neq K$. There exists an a, $0 < a < K$, such that $f'(x) > 0$ for $0 < x < a$, $f'(a) = 0$ and $f'(x) < 0$ for $a < x$.

(iii) $g(x^*) = \lambda$, $y^* = f(x^*)$, and $0 < x^* < a$.

(iv) $(d/dx)(xf'(x))/(g(x) - \lambda)) < 0$ for $x < x^*$ and $x > \bar{x}^*$, where $\bar{x}^* = f_2^{-1} \circ f_1(x^*)$ and $f_1 = f|_{(0,a)}$, $f_2 = f|_{(a,K)}$.

The phase plane of (5) under assumptions (i)-(iv) is roughly as shown in Fig. 1. We consider only the case $x^* < a$. In the case $a < x^* < K$, the equilibrium point (x^*, y^*) is locally asymptotically stable. We refer to Cheng, Hsu, and Lin [3] for global stability analysis.

Note that if

$$\begin{aligned} g(x) &= x, \\ f(x) &= F(x) + \varepsilon H(x), \end{aligned}$$

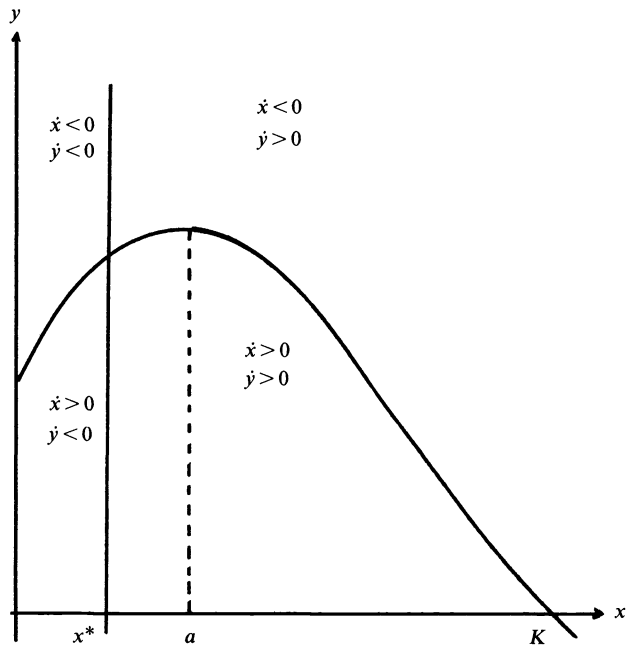

FIG. 1

then g and f satisfy assumptions (i)-(iv) if $\varepsilon > 0$ is sufficiently small where

$$F(x) = (1-x)(b+x)$$

and $H(x)$ is a C^2 function satisfying

$$H'(x) \geqq 0 \quad \text{for } 0 < x < a,$$

$$H'(x) \leqq 0 \quad \text{for } a < x,\ a = \frac{1-b}{2}.$$

In fact,

$$\frac{d}{dx}\left(\frac{xf'(x)}{x-\lambda}\right) = \frac{-1}{(x-\lambda)^2}\{[2(x-\lambda)^2 + 2\lambda(a-\lambda)] - \varepsilon[(x-\lambda)xH''(x) - \lambda H'(x)]\}.$$

Thus if $(a-\lambda)$ is reasonably large, we can allow ε to be reasonably large and the isocline

$$y = F(x) + \varepsilon H(x)$$

can be quite unsymmetric with respect to the line $x = a$.

Our main result follows.

THEOREM 1. *Under the assumptions* (i)-(iv), (5) *posseses a unique limit cycle which is globally stable.*

3. Proof of Theorem 1. We need some lemmas.

LEMMA 1. *The solutions* $x(t)$, $y(t)$ *of* (5) *are positive and bounded.*

LEMMA 2. *The unique interior equilibrium point* (x^*, y^*) *of* (5) *is a source.*

LEMMA 3. *Let* Γ *be a nontrivial closed orbit of* (2). *Then*

$$\Gamma \subset \{(x, y): 0 < x < K, 0 < y\}.$$

Let L, R, H, and J be the leftmost, rightmost, highest, and lowest points of Γ, *respectively. Then*

$$L \in \{(x, y): 0 < x < x^*, y = f(x)\},$$

$$R \in \{(x, y): x^* < x < K, y = f(x)\},$$

$$H \in \{(x, y): x = x^*, y > y^*\},$$

$$J \in \{(x, y): x = x^*, 0 < y < y^*\}.$$

The proof of Lemma 1 is given in Albrecht et al. [1]. Lemma 2 follows from a straightforward calculation and Lemma 3 is easy enough. Hence we omit all the proofs of these lemmas.

Before we state and prove our next lemma, we define a transformation T from $(0, a) \times (0, \infty)$ to $(a, K) \times (0, \infty)$,

$$\begin{aligned} T(x, y) &\equiv (T_1(x, y), T_2(x, y)) \\ &\equiv (f_2^{-1} \circ f_1(x), y), \end{aligned} \tag{6}$$

where f_1 and f_2 are the restriction of f on $(0, a)$ and (a, K), respectively. From assumption (ii), it is easy to see that T is a one-to-one transformation.

Now, we can state our main lemmas.

LEMMA 4. *Let* Γ *be a nontrivial closed orbit of* (5). Γ *meets the vertical line* $x = a$ *at points A and B with y-coordinates* $y_B > y_A$. (*See Fig.* 2.) *Let the image of* arc $\widehat{BHLJA}$ *of* Γ *under the transformation T be* $\widehat{BH'L'J'A}$. *Then* arc $\widehat{H'L'J'}$ *intersects* arc $\widehat{BRA}$ *of* Γ *at exactly two points* $P = (x_1, y_1)$ *and* $Q = (x_2, y_2)$ *with* $y_1 > f(x_1)$ *and* $y_2 < f(x_2)$.

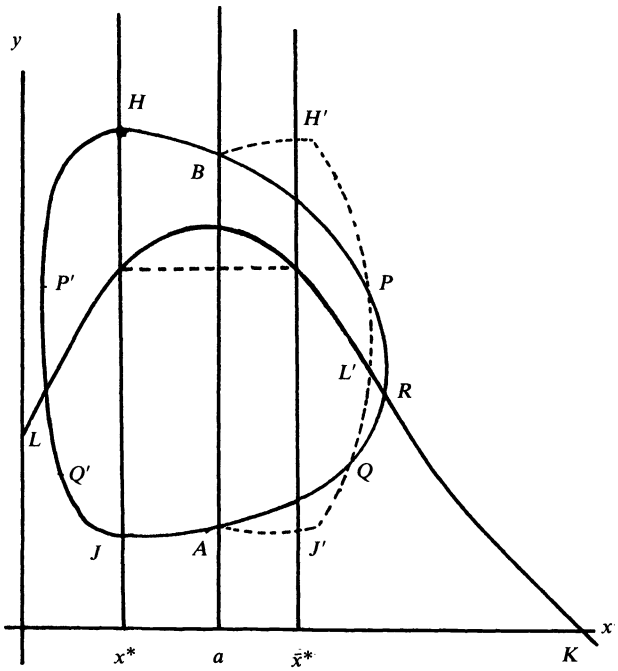

FIG. 2

Furthermore, let $P' = (x_1', y_1') = T^{-1}(P)$ *and* $Q' = (x_2', y_2') = T^{-1}(Q)$. *Then*

$$0 > \frac{x_1' f_1'(x_1')}{g(x_1') - \lambda} \geqq \frac{x_1 f_2'(x_1)}{g(x_1) - \lambda}, \tag{7}$$

$$0 > \frac{x_2' f_1'(x_2')}{g(x_2') - \lambda} \geqq \frac{x_2 f_2'(x_2)}{g(x_2) - \lambda}. \tag{8}$$

Proof. Consider the function

$$V(x, y) = \int_{x^*}^{x} \frac{g(\xi) - \lambda}{\xi}\, d\xi. \tag{9}$$

Then

$$\frac{dV(x(t), y(t))}{dt} = [g(x(t)) - \lambda][f(x(t)) - y(t)]. \tag{10}$$

Let the period of Γ be τ. We have

$$\int_0^{\tau} \frac{dV(x(t), y(t))}{dt}\, dt = 0. \tag{11}$$

On the other hand, we have

$$\begin{aligned} \int_0^{\tau} \frac{dV(x(t), y(t))}{dt}\, dt &= \int_0^{\tau} [g(x(t)) - \lambda][f(x(t)) - y(t)]\, dt \\ &= \oint_{\Gamma} (f(x) - y)\frac{dy}{y}. \end{aligned} \tag{12}$$

Let Ω_1 be the interior of the domain bounded by arc $\widehat{BHLJA}$ and line $x = a$ and Ω_2 be the interior of the domain bounded by arc $\widehat{BRA}$ and the line $x = a$. Also, let $\Omega = \Omega_1 \cup \Omega_2$ and $\Omega_1' = T(\Omega_1)$. From the definition of T it is easy to see arc $\widehat{BH'}$ lies above Γ and arc $\widehat{J'A}$ lies below Γ. Hence either

$$\widehat{BH'L'J'A} \cap \Omega_2 = \varnothing(\text{empty}) \quad \text{and} \quad \Omega_2 \subset \Omega_1' \tag{13}$$

or

$$S \equiv \widehat{BH'L'J'A} \cap \Omega_2 \neq \varnothing.$$

We now show that the assumption $\Omega_2 \subset \Omega_1'$ leads to a contradiction. From (11) and (12), we have

$$\begin{aligned} 0 &= \int_0^{\tau} \frac{dV(x(t), y(t))}{dt}\, dt \\ &= \oint_{\Gamma} \frac{1}{y}[f(x) - y]\, dy \\ &= \iint_{\Omega} \frac{f'(x)}{y}\, dx\, dy \quad \text{(Green's theorem)} \\ &= \iint_{\Omega_1} \frac{f'(x)}{y}\, dx\, dy + \iint_{\Omega_2} \frac{f'(x)}{y}\, dx\, dy \\ &= \iint_{\Omega_1} \frac{f_1'(x)}{y}\, dx\, dy + \iint_{\Omega_2} \frac{f_2'(x)}{y}\, dx\, dy. \end{aligned} \tag{14}$$

Now let $T: \Omega_1 \to \Omega_1'$ be the transformation defined in (6). Let

$$T(x, y) = (u, v).$$

Then

$$\begin{aligned} u &= f_2^{-1} \circ f_1(x), \\ v &= y. \end{aligned}$$

Hence $(x, y) = T^{-1}(u, v)$ and

$$\begin{aligned} x &= f_1^{-1} \circ f_2(u), \\ y &= v. \end{aligned} \tag{15}$$

The Jacobian of T^{-1} is

$$\begin{aligned} \frac{\partial(x, y)}{\partial(u, v)} &= \begin{vmatrix} (f_1^{-1})'(f_2(u)) \cdot f_2'(u) & 0 \\ 0 & 1 \end{vmatrix} \\ &= (f_1^{-1})'(f_2(u)) \cdot f_2'(u). \end{aligned} \tag{16}$$

But since $f_2'(u) < 0$ and $(f_1^{-1})'(f_2(u)) > 0$, we have

$$\left| \frac{\partial(x, y)}{\partial(u, v)} \right| = -(f_1^{-1})'(f_2(u)) \cdot f_2'(u). \tag{17}$$

Hence, we have from (17)

$$\begin{aligned} \iint_{\Omega_1} \frac{f_1'(x)}{y}\, dx\, dy &= \iint_{\Omega_1'} \frac{f_1'(f_1^{-1} \circ f_2(u))}{v} \cdot [-(f_1^{-1})'(f_2(u)) \cdot f_2'(u)\, du\, dv \\ &= -\iint_{\Omega_1'} \frac{f_1'(f_1^{-1} \circ f_2(u)) \cdot (f_1^{-1})'(f_2(u)) \cdot f_2'(u)}{v}\, du\, dv. \end{aligned} \tag{18}$$

But

$$\begin{aligned} f_1'(f_1^{-1} \circ f_2(u)) \cdot (f_1^{-1})'(f_2(u)) &= \frac{d}{dz}(f_1 \circ f_1^{-1}(z))\Big|_{z = f_2(u)} \\ &= 1. \end{aligned} \tag{19}$$

From (18) and (19), we obtain

$$\begin{aligned} \iint_{\Omega_1} \frac{f_1'(x)}{y}\, dx\, dy &= -\iint_{\Omega_1'} \frac{f_2'(u)}{v}\, du\, dv \\ &= -\iint_{\Omega_1'} \frac{f_2'(x)}{y}\, dx\, dy \quad \text{(identify } u = x, v = y\text{)}. \end{aligned} \tag{20}$$

Combining (13), (14), and (20), finally we have

$$\begin{aligned} 0 &= \int_0^{\tau} \frac{dV(x(t), y(t))}{dt}\, dt \\ &= \iint_{\Omega_1} \frac{f_1'(x)}{y}\, dx\, dy + \iint_{\Omega_2} \frac{f_2'(x)}{y}\, dx\, dy \\ &= -\iint_{\Omega_1'} \frac{f_2'(x)}{y}\, dx\, dy + \iint_{\Omega_2} \frac{f_2'(x)}{y}\, dx\, dy \\ &= -\iint_{\Omega_1' - \Omega_2} \frac{f_2'(x)}{y}\, dx\, dy \\ &> 0 \quad \text{(recall that } f_2'(x) < 0\text{)}. \end{aligned} \tag{21}$$

This is a contradiction. Hence $S = \widehat{BH'L'J'A} \cap \Omega_2 \neq \varnothing$.

Let $\bar{S}$ denote the closure of S and let $P=(x_1, y_1)$ and $Q=(x_2, y_2)$ be the "highest" and "lowest" points of $\bar{S}$, respectively. Then, P is the highest point and Q is the lowest point where arc $\widehat{BH'L'J'A}$ enters the region Ω_2 from the outside of Ω_2. It is easy to see that $y_1 > y_2$. First we assume that $y_1 > f(x_1)$. Let $(dy/dx)'_P$ and $(dy/dx)_P$ be the slopes of arcs $\widehat{BH'L'J'A}$ and $\widehat{BRA}$ at point P, respectively. Since arc $\widehat{BH'L'J'A}$ enters Ω_2 from the outside of Ω_2 at point P, we have

$$0 > \left(\frac{dy}{dx}\right)_P \geqq \left(\frac{dy}{dx}\right)'_P. \tag{22}$$

But we have

$$\begin{aligned}\left(\frac{dy}{dx}\right)_P &= \frac{y_1(g(x_1)-\lambda)}{x_1(f(x_1)-y_1)} \\ &= \frac{y_1(g(x_1)-\lambda)}{x_1(f_2(x_1)-y_1)},\end{aligned} \tag{23}$$

and

$$\begin{aligned}\left(\frac{dy}{dx}\right)'_P &= \left(\frac{dv}{du}\right)_{(u,v)=(x_1,y_1)} \\ &= \left(\frac{dy}{d(f_2^{-1}\circ f_1(x))}\right)_{(x,y)=(x'_1,y'_1)=T^{-1}(x_1,y_1)} \\ &= \frac{y'_1(g(x'_1)-\lambda)}{(f_2^{-1})'(f_1(x'_1))\cdot f'_1(x'_1)\cdot x'_1\cdot(f_1(x'_1)-y'_1)}.\end{aligned} \tag{24}$$

Since

$$f_1(x'_1) = f_1(f_1^{-1}\circ f_2(x_1)) = f_2(x_1), \tag{25}$$

$$y'_1 = y_1, \tag{26}$$

and

$$\begin{aligned}(f_2^{-1})'(f_1(x'_1))\cdot f'_2(f_2^{-1}\circ f_1(x'_1)) &= (f_2^{-1})'(f_1(x'_1))\cdot f'_2(x_1) \\ &= 1.\end{aligned} \tag{27}$$

We have from (24), (25), (26), and (27)

$$\left(\frac{dy}{dx}\right)'_P = \frac{y'_1(g(x'_1)-\lambda)}{x'_1(f_2(x_1)-y_1)\cdot(1/f'_2(x_1))\cdot f'_1(x'_1)}. \tag{28}$$

Thus from (22), (23), and (29) we obtain

$$0 > \frac{y_1(g(x_1)-\lambda)}{x_1(f_2(x_1)-y_1)} \geqq \frac{y_1(g(x'_1)-\lambda)}{x'_1\cdot f'_1(x'_1)\cdot(f_2(x_1)-y_1)\cdot(1/f'_2(x_1))}. \tag{29}$$

Finally we get

$$0 > \frac{x'_1 f'_1(x'_1)}{g(x'_1)-\lambda} \geqq \frac{x_1 f'_2(x_1)}{g(x_1)-\lambda}. \tag{30}$$

Now the arc $\widehat{PR}$ satisfies the following differential equations:

$$\left(\frac{dy}{dx}\right)_{\widehat{PR}} = \frac{y(g(x)-\lambda)}{x(f_2(x)-y)} \tag{31}$$

and the arc $\widehat{PL'}$ satisfies

$$\begin{aligned}\left(\frac{dy}{dx}\right)_{\widehat{PL'}} &= \left(\frac{dv}{du}\right)_{(u,v)=(x,y)} \\ &= \frac{y'(g(x')-\lambda)}{(f_2^{-1})'(f_1(x'))\cdot f_1'(x')\cdot x'\cdot(f_1(x')-y')} \\ &= \frac{y(g(x')-\lambda)}{x'(f_2(x)-y)\cdot(1/f_2'(x))\cdot f_1'(x')}\end{aligned} \tag{32}$$

as in (24)-(28).

From (31) and (32) we have

$$\left(\frac{dy}{dx}\right)_{\widehat{PR}} = \frac{g(x)-\lambda}{xf_2'(x)}\cdot\frac{yf_2'(x)}{f_2(x)-y}, \tag{33}$$

$$\left(\frac{dy}{dx}\right)_{\widehat{PL'}} = \frac{g(x')-\lambda}{x'f_1'(x')}\cdot\frac{yf_2'(x)}{f_2(x)-y}. \tag{34}$$

From the assumption (iv) and (30), we have

$$\frac{g(x')-\lambda}{x'f_1'(x')} < \frac{g(x_1')-\lambda}{x_1'f_1'(x_1')} \leqq \frac{g(x_1)-\lambda}{x_1f_2'(x_1)} < \frac{g(x)-\lambda}{xf_2'(x)} \tag{35}$$

for all $x_1 < x$ (hence $x' < x_1'$).

Hence we have

$$0 > \frac{g(x)-\lambda}{xf_2'(x)}\cdot\frac{yf_2'(x)}{f_2(x)-y} > \frac{g(x')-\lambda}{x'f_1'(x')}\cdot\frac{yf_2'(x)}{f_2(x)-y}$$

for all $x_1 < x$.

From a well-known comparison theorem we get

$$y(x)_{\widehat{PR}} > y(x)_{\widehat{PL'}} \quad \text{for } x_1 < x < x_{L'}, \tag{36}$$

where $x_{L'}$ is the x-coordinate of L'.

This proves that if $y_1 > f(x_1)$, then the arc $\widehat{BH'L'}$ intersects the arc $\widehat{BR}$ only at the point P.

Now assume that $y_2 < f(x_2)$. Let $(dy/dx)_Q'$ and $(dy/dx)_Q$ be the slopes of arcs $\widehat{BH'L'J'A}$ and $\widehat{BRA}$ at the point $Q = (x_2, y_2)$, respectively. Then since $y_2 < f(x_2)$, it is obvious that

$$0 < \left(\frac{dy}{dx}\right)_Q \leqq \left(\frac{dy}{dx}\right)_Q'. \tag{37}$$

By arguments similar to those in (23)-(28), we have

$$\begin{aligned}\left(\frac{dy}{dx}\right)_Q &= \frac{y_2(g(x_2)-\lambda)}{x_2(f_2(x_2)-y_2)} \\ &= \frac{g(x_2)-\lambda}{x_2f_2'(x_2)}\cdot\frac{y_2f_2'(x_2)}{f_2(x_2)-y_2},\end{aligned} \tag{38}$$

$$\left(\frac{dy}{dx}\right)_Q' = \frac{g(x_2')-\lambda}{x_2'f_1'(x_2')}\cdot\frac{y_2f_2'(x_2)}{f_2(x_2)-y_2}. \tag{39}$$

Hence from (37), (38), and (39) we obtain

$$0>\frac{x_2' f_1'(x_2')}{g(x_2')-\lambda}\geqq\frac{x_2 f_2'(x_2)}{g(x_2)-\lambda}. \tag{40}$$

By arguments similar to those in (31)-(36), we can prove that if $y_2<f(x_2)$, then the arc $\widehat{L'J'A}$ intersects the arc $\widehat{RA}$ only at the point Q. From the above conclusion, P cannot be one of the intersection points of arcs $\widehat{L'J'A}$ and $\widehat{RA}$. Hence we conclude that

$$y_1>f(x_1), \qquad y_2<f(x_2) \tag{41}$$

and P and Q are the only intersection points of arcs $\widehat{BH'L'J'A}$ and $\widehat{BRA}$. Hence (30) and (40) hold. This completes the proof of the lemma. □

LEMMA 5. *Let* Γ *be a nontrivial closed orbit of* (5) *as described in Lemma* 4. *Define*

$$h(x, y)=x(f(x)-y), \qquad k(x, y)=y(g(x)-\lambda).$$

Then

$$\oint_\Gamma \operatorname{Div}(h, k)\, dt\equiv\oint_\Gamma\left(\frac{\partial h(x, y)}{\partial x}+\frac{\partial k(x, y)}{\partial y}\right) dt<0. \tag{42}$$

Proof. From the definitions of h and k, we have

$$\frac{\partial h(x, y)}{\partial x}+\frac{\partial k(x, y)}{\partial y}=(f(x)-y)+(g(x)-\lambda)+xf'(x). \tag{43}$$

But since Γ is a closed orbit, we have

$$\oint_\Gamma [f(x)-y]\, dt=\oint_\Gamma \frac{\dot{x}}{x}\, dt=0$$

and

$$\oint_\Gamma [g(x)-\lambda]\, dt=\oint_\Gamma \frac{\dot{y}}{y}\, dt=0.$$

Thus

$$\oint_\Gamma \operatorname{Div}(h, k)\, dt=\oint_\Gamma xf'(x)\, dt. \tag{44}$$

We divide the integration along Γ into integration along several arcs, that is, we let

$$\oint_\Gamma=\int_{\widehat{AQ}}+\int_{\widehat{QRP}}+\int_{\widehat{PB}}+\int_{\widehat{BP'}}+\int_{\widehat{P'LQ'}}+\int_{\widehat{Q'A}}. \tag{45}$$

Consider the integration along $\widehat{Q'A}$ first. The arc $\widehat{Q'A}$ of Γ can be parametrized by $(x, y_1(x))$, where $x_2'\leqq x\leqq a$. Hence

$$\begin{aligned}\int_{\widehat{Q'A}} x(t)f'(x(t))\, dt&=\int_{x_2'}^{a}\frac{f'(x)}{f(x)-y_1(x)}\, dx\\&=\int_{x_2'}^{a}\frac{f_1'(x)}{f_1(x)-y_1(x)}\, dx.\end{aligned} \tag{46}$$

Now let

$$u=f_2^{-1}\circ f_1(x), \qquad x\in[x_2', a]$$

or

$$x = f_1^{-1} \circ f_2(u), \qquad u \in [a, x_2].$$

Then

$$\begin{aligned}\int_{x_2'}^{a} \frac{f_1'(x)}{f_1(x) - y_1(x)}\,dx &= \int_{x_2}^{a} \frac{f_1'(f_1^{-1} \circ f_2(u)) \cdot (f_1^{-1})'(f_2(u)) \cdot f_2'(u)}{f_1(f_1^{-1} \circ f_2(u)) - y_1(f_1^{-1} \circ f_2(u))}\,du \\ &= \int_{x_2}^{a} \frac{f_2'(u)}{f_2(u) - y_1(f_1^{-1} \circ f_2(u))}\,du \\ &= -\int_{a}^{x_2} \frac{f_2'(x)}{f_2(x) - y_1(f_1^{-1} \circ f_2(x))}\,dx. \end{aligned} \tag{47}$$

We parametrize the arc $\overset{\frown}{AQ}$ of Γ by $(x, y_2(x))$, where $x \in [a, x_2]$. Then

$$\begin{aligned}\int_{\overset{\frown}{AQ}} x(t) f'(x(t))\,dt &= \int_{a}^{x_2} \frac{f'(x)}{f(x) - y_2(x)}\,dx \\ &= \int_{a}^{x_2} \frac{f_2'(x)}{f_2(x) - y_2(x)}\,dx. \end{aligned} \tag{48}$$

Combining (47) and (48), we obtain

$$\begin{aligned}&\left(\int_{\overset{\frown}{Q'A}} + \int_{\overset{\frown}{AQ}}\right)(x(t) f'(x(t)))\,dt \\ &\quad = \int_{a}^{x_2} \frac{f_2'(x)[y_2(x) - y_1(f_1^{-1} \circ f_2(x))]\,dx}{[f_2(x) - y_2(x)][f_2(x) - y_1(f_1^{-1} \circ f_2(x))]}.\end{aligned}$$

But for $x \in (a, x_2)$, we have

$$\begin{aligned}&f_2'(x) < 0, \qquad y_2(x) - y_1(f_1^{-1} \circ f_2(x)) > 0, \\ &f_2(x) - y_2(x) > 0, \qquad f_2(x) - y_1(f_1^{-1} \circ f_2(x)) > 0.\end{aligned}$$

Hence

$$\left(\int_{\overset{\frown}{Q'A}} + \int_{\overset{\frown}{AQ}}\right)(x(t) f'(x(t)))\,dt < 0. \tag{49}$$

Next we parametrize arc $\overset{\frown}{BP'}$ of Γ by $(x, y_3(x))$ and arc $\overset{\frown}{PB}$ by $(x, y_4(x))$. Then

$$\begin{aligned}\int_{\overset{\frown}{BP'}} (x(t) f'(x(t)))\,dt &= \int_{a}^{x_1} \frac{f'(x)}{f(x) - y_3(x)}\,dx \\ &= \int_{a}^{x_1'} \frac{f_1'(x)}{f_1(x) - y_3(x)}\,dx. \end{aligned} \tag{50}$$

Let $x = f_1^{-1} \circ f_2(u)$ or $u = f_2^{-1} \circ f_1(x)$. Then from (50)

$$\begin{aligned}&\int_{\overset{\frown}{BP'}} (x(t) f'(x(t)))\,dt \\ &\quad = \int_{a}^{x_1} \frac{f_1'(f_1^{-1} \circ f_2(u)) \cdot (f_1^{-1})'(f_2(u)) f_2'(u)}{f_1(f_1^{-1} \circ f_2(u)) - y_3(f_1^{-1} \circ f_2(u))}\,du \\ &\quad = \int_{a}^{x_1} \frac{f_2'(u)}{f_2(u) - y_3(f_1^{-1} \circ f_2(u))}\,du \\ &\quad = \int_{a}^{x_1} \frac{f_2'(x)}{f_2(x) - y_3(f_1^{-1} \circ f_2(x))}\,dx.\end{aligned} \tag{51}$$

Now from the parametrization of arc $\widehat{PB}$, we have

$$\begin{aligned}\int_{\widehat{PB}}(x(t)f'(x(t)))\,dt &= \int_{x_1}^{a}\frac{f'(x)}{f(x)-y_4(x)}\,dx \\ &= -\int_{a}^{x_1}\frac{f_2'(x)}{f_2(x)-y_4(x)}\,dx.\end{aligned} \tag{52}$$

Combining (51) and (52) we obtain

$$\begin{aligned}&\left(\int_{\widehat{PB}}+\int_{\widehat{BP'}}\right)(x(t)f'(x(t)))\,dt \\ &\quad=\int_{a}^{x_1}\frac{f_2'(x)[y_3(f_1^{-1}\circ f_2(x))-y_4(x)]}{[f_2(x)-y_4(x)][f_2(x)-y_3(f_1^{-1}\circ f_2(x))]}\,dx \\ &\quad<0.\end{aligned} \tag{53}$$

Now let us assume that $x_1'\geqq x_2'$, i.e., $x_2\geqq x_1$. (The case $x_1'<x_2'$ can be treated in the same manner.) Let

$$L_1=\{(x,y)\colon x=x_1',\ y_2'\leqq y\leqq y_1'\},$$
$$L_2=\{(x,y)\colon y=y_2',\ x_2'\leqq x\leqq x_1'\}.$$

We parametrize the arc $\widehat{P'LQ'}$ by $(h_1(y),y)$ and let the domain bounded by the arc $\widehat{P'LQ'}$, L_2 and L_1 be denoted by D_1. Then we have

$$\begin{aligned}&\int_{\widehat{P'LQ}}(x(t)f'(x(t)))\,dt \\ &\quad=\int_{\widehat{P'LQ'}}\frac{xf'(x)}{y[g(x)-\lambda]}\bigg|_{x=h_1(y)}dy \\ &\quad=\left(\int_{\widehat{P'LQ'}}+\int_{L_2}+\int_{L_1}\right)\left(\frac{xf'(x)}{y[g(x)-\lambda]}\right)dy \\ &\qquad-\left(\int_{L_2}+\int_{L_1}\right)\left(\frac{xf'(x)}{y[g(x)-\lambda]}\right)dy \\ &\quad=\int\int_{D_1}\frac{1}{y}\frac{d}{dx}\left(\frac{xf'(x)}{g(x)-\lambda}\right)dx\,dy-\int_{y_2'}^{y_1'}\frac{x_1'f_1'(x_1')}{y[g(x_1')-\lambda]}\,dy \\ &\quad<-\int_{y_2}^{y_1}\frac{x_1'f_1'(x_1')}{y[g(x_1')-\lambda]}\,dy\quad\text{(by assumption (iv)).}\end{aligned} \tag{54}$$

Now we can consider the integration along the arc $\widehat{QRP}$. Let $L_1'=TL_1$, $L_2'=TL_2$ and let D_2 be the domain bounded by the arc $\widehat{QRP}$ of Γ, L_1', and L_2'. Then

$$\begin{aligned}\int_{\widehat{QRP}}xf'(x)\,dt&=\left(\int_{QRP}+\int_{-L_1'}+\int_{-L_2'}\right)\frac{xf'(x)}{y[g(x)-\lambda]}\,dy \\ &\qquad-\left(\int_{-L_1'}+\int_{-L_2'}\right)\frac{xf'(x)}{y[g(x)-\lambda]}\,dy \\ &=\int\int_{D_2}\frac{1}{y}\frac{d}{dx}\left(\frac{xf'(x)}{g(x)-\lambda}\right)dx\,dy+\int_{y_2}^{y_1}\frac{x_1f_2'(x_1)}{y[g(x_1)-\lambda]}\,dy \\ &<\int_{y_2}^{y_1}\frac{x_1f_2'(x_1)}{y[g(x_1)-\lambda]}\,dy.\end{aligned} \tag{55}$$

Combining (54) and (55), we have

$$\left(\int_{\widehat{P'LQ'}} + \int_{\widehat{QRP}}\right)(xf'(x))\,dt < \int_{y_2}^{y_1}\left[\frac{x_1 f_2'(x_1)}{g(x_1)-\lambda} - \frac{x_1' f_1'(x_1')}{g(x_1')-\lambda}\right]\frac{dy}{y} \tag{56}$$
$$< 0 \quad \text{(by (7))}.$$

Combining (49), (53), and (56), we have

$$\oint_\Gamma \operatorname{Div}(h, k)\,dt = \oint_\Gamma xf'(x)\,dt < 0. \tag{57}$$

This completes the proof of this lemma. □

Now we are in a position to prove Theorem 1.

Proof of Theorem 1. From Lemma 1, the solutions are positive and bounded. From Lemma 2, the equilibrium point (x^*, y^*) is a source. Hence there exists a closed orbit. But from Lemmas 3, 4, and 5, each closed orbit must be stable. But two adjacent periodic orbits cannot be positively stable on the sides facing each other (Coddington and Levinson [4, Thm. 3.4, p. 397]). Hence the closed orbit is a unique limit cycle. It is easy to see that this limit cycle is also globally stable, that is, nonequilibrium solutions will tend to this cycle eventually. This completes the proof of Theorem 1. □

Remark. In the proof of Lemma 5, we introduce the line segments L_1 and L_2. In the original proof of Cheng [2], we use the line segment $\overline{P'Q'}$ instead. Hadeler pointed out to us that $\overline{P'Q'}$ may intersect the orbit Γ [5]. This is the gap (in [2]) mentioned in the Introduction.

Acknowledgments. K.-S. Cheng thanks K. P. Hadeler for pointing out the gap referred to in the above remark. Both authors express thanks to Paul Waltman and Sze-Bi Hsu for their constant interest in this problem and their kind encouragement.

A DIRECT LYAPUNOV APPROACH TO VOLTERRA INTEGRODIFFERENTIAL EQUATIONS*

OLOF J. STAFFANS†

Abstract. We propose a different approach to the Lyapunov theory for Volterra integrodifferential equations. Instead of using Lyapunov functionals we use Lyapunov functions, which typically are the norm of the solution raised to some power. Our Lyapunov functions are not decreasing along solutions, so we use separate estimates to bound them from above. Our approach is direct and straightforward, and it appears to be applicable to most of the results that have been proved earlier by means of Lyapunov functionals.

Key words. Lyapunov, Volterra equation

AMS(MOS) subject classifications. 45D05, 45A05, 45M10

1. Introduction. An important ingredient in the stability theory for ordinary differential equations (ODEs) is Lyapunov's method. Theoretically this method is very appealing, and there are applications where it is natural to use it.

For the convenience of the reader, let us give a short description of Lyapunov's method for the autonomous ordinary differential equation

$$x'(t)=f(x(t)), \quad t\geqq 0, \quad x(0)=x_0. \tag{1.1}$$

We denote the solution of (1.1) with initial condition $x(0)=\xi$ by $x(t,\xi)$ (assuming that a unique solution exists for each ξ), and define

$$\dot{V}(\xi)=\limsup_{h\to 0+}\frac{1}{h}[V(x(h,\xi))-V(\xi)].$$

Clearly, under sufficient differentiability assumptions, we have $\dot{V}(\xi)=\langle V'(\xi),f(\xi)\rangle$, where V' represents the gradient of V.

The following result is found in [28, Thm. 1.1, p. 293].

PROPOSITION 1.1. *If there is a positive definite function V on Ω with $\dot{V}\leqq 0$, then the solution $x=0$ of (1.1) is stable. If, in addition, $-\dot{V}$ is positive definite on Ω, then the solution $x=0$ is asymptotically stable.*

The function V above is called a *Lyapunov function* for (1.1) on Ω.

A companion result also exists, which says that if $\dot{V}$ is positive definite, then the zero solution is unstable (to prove this it suffices to observe that by Proposition 1.1, the equation is asymptotically stable in the backwards time direction). Actually, it is possible to prove instability under somewhat weaker assumptions; see [28, Thm. 1.2, p. 294].

Numerous attempts have veen made to obtain similar results for integral and functional equations. The formal theory presents no difficulties. However, it is a quite difficult task to find a Lyapunov function for a given ordinary differential equation, and it is virtually impossible to find a Lyapunov function or functional for a Volterra integral or a functional equation. There are some simple exceptions to this general rule, and we shall discuss these exceptions below.

The key requirement in Proposition 1.1 is that V is nonincreasing along solutions. In practice this requirement is so difficult to satisfy that to many ordinary differential

* Received by the editors February 5, 1987; accepted for publication June 4, 1987.
† Institute of Mathematics, Helsinki University of Technology, SF-02150 Espoo 15, Finland.

equations we cannot apply Lyapunov theory unless we know in advance that the zero solution is asymptotically stable. Of course, if we know in advance that the zero solution is asymptotically stable, then there is no need to apply Lyapunov theory.

The situation becomes even worse when we replace the ordinary differential equation with an integral equation. If we want to have a Lyapunov function V which is nonincreasing along the solutions of the equation, then, due to the way in which solutions of integral equations behave, we are forced to let V depend not only on the present value $x(t)$ of x, but also on past values $x(s)$ with $s \leqq t$. In other words, we use Lyapunov functionals instead of Lyapunov functions. This makes it more difficult to specify what we mean by the second requirement in Proposition 1.1, i.e., the requirement that V should be positive definite.

During the last eight years, Burton, Huang, and Mahfoud have developed a Lyapunov theory, which primarily seems to apply to Volterra integrodifferential equations that have a dominant ODE part, or more generally, equations that can be transformed into equations with a dominant ODE part (see [2]–[17]). They use Lyapunov functionals, which are (most of the time) nonincreasing or strictly decreasing along solutions. The purpose of this work is to show that we can obtain the same results by using Lyapunov functions, which are allowed to increase as well as decrease, but stay bounded from above and below. Our approach applies to the same general class of equations, and it has two advantages:

(1) It is easy to construct the Lyapunov function. More specifically, we use the same Lyapunov function for the integrodifferential equation as we do for the corresponding unperturbed ordinary differential equation.

(2) The estimates that we need to compensate for the fact that our Lyapunov function is allowed to increase as well as decrease are simple, most of the time completely trivial (one uses the variation of constants formula, or a comparison theorem, or integration by parts).

The reader may object to the fact that most of the examples that we discuss below are fairly simple, and that they may be regarded as small perturbations of ordinary differential equations. This is true. However, apart from a number of well-known results for equations with kernels of positive type, these are the only ones that fall within the scope of this note, because they are the only ones that we know about to which the Lyapunov theory has been successfully applied. In addition, as several examples given in [16] and [17] show, this class of equations is larger than what we, at first sight, might expect.

The technique that we use is a variant of the so-called *energy technique.* This means that we obtain most of our basic estimates (i.e., those that we call L^1-estimates and L^2-estimates) by taking the inner product of the equation and some function, and integrating.

To keep this paper at a reasonable length, we restrict ourselves to linear Volterra integrodifferential equations, but the argument that we present can be applied to more general equations as well, e.g., to some nonlinear Volterra equations, and to nonlinear functional differential equations. For the same reason we, moreover, restrict ourselves to the case where we want to prove stability. However, it should not be too difficult for readers to convince themselves that the same type of argument can be applied when they want to prove instability.

2. The reduction to the scalar case. Below we show how one may reduce a system of equations to a scalar integrodifferential equation or inequality, or equivalently, how to construct Lyapunov functions for a system of integrodifferential equations. (The

Lyapunov function that we use is a natural Lyapunov function for the ordinary differential equation, which is the dominant part of the integrodifferential equation.)

Let us look at the equation

$$x'(t)+Ax(t)=\int_{t_0}^{t} C(t,s)x(s)\,ds+f(t), \quad t\geqq t_0, \quad x(t_0)=x_0. \tag{2.1}$$

Here x and f take their values in $\mathbf{R}^n$, A is an $n\times n$ matrix with real entries, $C(t,s)$ is a matrix-valued function, and t_0 is a real number.

The basic assumption in this equation is that the ordinary differential equation

$$x'(t)+Ax(t)=f(t), \quad t\geqq t_0, \quad x(t_0)=x_0, \tag{2.2}$$

is asymptotically stable. This means that it is possible to find a unique symmetric, positive definite matrix B such that

$$A^TB+BA=I$$

(see [10, Thm. 5.11, p. 124]). Let α be the smallest eigenvalue and β the largest eigenvalue of this matrix (an equivalent definition is $\beta=\|B\|$ and $\alpha=\|B^{-1}\|^{-1}$, where $\|\cdot\|$ is the matrix norm corresponding to the Euclidean norm in $\mathbf{R}^n$). Then $0<\alpha\leqq\beta$, and for all $x\in\mathbf{R}^n$,

$$\alpha\langle x,x\rangle\leqq\langle x,Bx\rangle\leqq\beta\langle x,x\rangle; \qquad \langle Bx,Bx\rangle\leqq\beta\langle x,Bx\rangle,$$

where $\langle\cdot,\cdot\rangle$ is the Euclidean inner product.

In the sequel we denote the Euclidean norm in $\mathbf{R}^n$ by $|\cdot|$, and denote the corresponding matrix norm by $\|\cdot\|$. We let $|\cdot|_B$ be the norm induced by the inner product $\langle x,y\rangle_B=\langle x,By\rangle$, i.e., $|x|_B=|\sqrt{B}\,x|$. The corresponding matrix norm is denoted by $\|\cdot\|_B$. These norms satisfy

$$\sqrt{\alpha}\,|\cdot|\leqq|\cdot|_B\leqq\sqrt{\beta}\,|\cdot|, \qquad \sqrt{\alpha/\beta}\,\|\cdot\|\leqq\|\cdot\|_B\leqq\sqrt{\beta/\alpha}\,\|\cdot\|.$$

In our L^1 and L^∞ estimates we use the Lyapunov function

$$z(t)=|x(t)|_B, \qquad t\in[t_0,\infty).$$

This function is locally absolutely continuous, and its derivative $z'(t)$ satisfies (for almost all $t\geqq t_0$)

$$z'(t)=\frac{1}{|x(t)|_B}\left(-\frac{1}{2}|x(t)|^2+\int_{t_0}^{t}\langle x(t),BC(t,s)x(s)\rangle\,ds+\langle x(t),Bf(t)\rangle\right). \tag{2.3}$$

It is natural to do one of two things: Either replace the only remaining $|x(t)|$ by $|x(t)|_B$, or replace $|x(t)|_B$ by $|x(t)|$. The first alternative leads to the inequality

$$z'(t)+\frac{1}{2\beta}z(t)\leqq\int_{t_0}^{t}\|C(t,s)\|_Bz(s)\,ds+|f(t)|_B, \qquad t\geqq t_0, \tag{2.4}$$

and the second alternative leads to the inequality

$$z'(t)+\frac{1}{2\sqrt{\beta}}|x(t)|\leqq\int_{t_0}^{t}\|\sqrt{B}\,C(t,s)\|\,|x(s)|\,ds+|f(t)|_B, \qquad t\geqq t_0. \tag{2.5}$$

The first of these two equations has the advantage that it contains only one function $z(t)$ as opposed to the two functions $z(t)$ and $|x(t)|$ in (2.5), but as we shall see below, also the latter equation can be exploited. Note, in particular, that the smallest eigenvalue α of B does not enter in the expressions above (unless we estimate $\|C(t,s)\|_B$ by $\sqrt{\beta/\alpha}\|C(t,s)\|$).

Equation (2.1) is a perturbation of a time-independent ordinary differential equation. In a similar way we can perturb a time-dependent differential equation to get

$$x'(t)+A(t)x(t)=\int_{t_0}^{t} C(t,s)x(s)\,ds+f(t),\quad t\geqq t_0,\quad x(t_0)=x_0. \tag{2.6}$$

The setting is the same as before, except that we let $A\in L^1_{\mathrm{loc}}([t_0,\infty);\mathbf{R}^{n\times n})$. We suppose that it is possible to find a positive definite matrix B such that the matrix

$$R(t)=A^T(t)B+BA(t)$$

is positive definite for almost all $t\geqq t_0$. Define α and β as before, and define

$$p(t)=\beta\inf_{x\in\mathbf{R}^n}\frac{\langle x,R(t)x\rangle}{|x|_B^2},\qquad q(t)=\sqrt{\beta}\inf_{x\in\mathbf{R}^n}\frac{\langle x,R(t)x\rangle}{|x|_B|x|}$$

(here β and $\sqrt{\beta}$ are scaling factors which make $p(t)=q(t)=1$ if $R(t)=I$). (The constant $p(t)$ could also have been defined as the smallest eigenvalue of the matrix $\beta\sqrt{B}\,R(t)(\sqrt{B})^{-1}$.) It is not difficult to check that

$$p(t)\geqq q(t)\geqq\sqrt{\alpha/\beta}\,p(t).$$

In this case (2.3) becomes

$$z'(t)=\frac{1}{|x(t)|_B}\left(-\frac{1}{2}\langle x(t),R(t)x(t)\rangle+\int_{t_0}^{t}\langle x(t)C(t,s),Bx(s)\rangle\,ds+\langle x(t),Bf(t)\rangle\right), \tag{2.7}$$

and the inequalities (2.4) and (2.5) become

$$z'(t)+\frac{p(t)}{2\beta}z(t)\leqq\int_{t_0}^{t}\|C(t,s)\|_B z(s)\,ds+|f(t)|_B,\qquad t\geqq t_0, \tag{2.8}$$

and

$$z'(t)+\frac{q(t)}{2\sqrt{\beta}}|x(t)|\leqq\int_{t_0}^{t}\|\sqrt{B}\,C(t,s)\|\,|x(s)|\,ds+|f(t)|_B,\qquad t\geqq t_0. \tag{2.9}$$

Observe that there is nothing that prevents us from choosing $B=I$. Likewise, there is nothing that prevents us from applying this approach to the time-independent case. If we in the time-independent case choose $B=I$, then $R=A^T+A$, $\alpha=\beta=1$, and $p(t)=q(t)$ is the smallest eigenvalue of A^T+A (which is required to be positive, if we are to choose B this way).

It is possible to use a time-dependent transformation matrix $B(t)$ as well. In this case the Lyapunov function z is

$$z(t)=\langle x(t),B(t)x(t)\rangle^{1/2},$$

and we redefine R to be

$$R(t)=A^T(t)B(t)+B(t)A(t)-B'(t).$$

We leave the details to the reader (cf. [35, §§ 6.5, 6.6, pp. 114–127]).

In the scalar case we throughout choose $B=I$, $\alpha=\beta=1$ and $p(t)=q(t)=2A(t)$.

3. Some L^1-estimates. Let us first develop the most elementary estimate for (2.8) and (2.9) (the same estimate is of course valid for (2.4) and (2.5) if one replaces $p(t)$

and $q(t)$ by one). To get this estimate we integrate (2.8) and (2.9) over $[t_0, T]$, and change the order of integration. This leads to the inequalities

$$z(T)+\int_{t_0}^{T}\left(\frac{p(s)}{2\beta}-\int_s^T \|C(t,s)\|_B\,dt\right)z(s)\,ds \leqq z(t_0)+\int_{t_0}^{T}|f(t)|_B\,dt, \qquad T\geqq t_0, \tag{3.1}$$

and

$$\begin{aligned} &z(T)+\int_{t_0}^{T}\left(\frac{q(s)}{2\sqrt{\beta}}-\int_s^T \|\sqrt{B}\,C(t,s)\|\,dt\right)|x(s)|\,ds \\ &\qquad \leqq z(t_0)+\int_{t_0}^{T}|f(t)|_B\,dt, \qquad T\geqq t_0. \end{aligned} \tag{3.2}$$

From these inequalities we get by direct inspection the first part of the following theorem.

THEOREM 3.1. (i) *If $f\in L^1([t_0,\infty);\mathbf{R}^n)$, and $\int_s^\infty \|C(t,s)\|_B\,dt\leqq p(s)/2\beta$ for almost all $s\geqq t_0$, or $\int_s^\infty \|\sqrt{B}\,C(t,s)\|\,dt\leqq q(s)/2\sqrt{\beta}$ for almost all $s\geqq t_0$, then the solution x of* (2.6) *is bounded. More precisely, $|x(t)|_B\leqq |x_0|_B+\int_{t_0}^t |f(s)|_B\,ds$ for all $t\geqq t_0$.*

(ii) *Let $f\in L^1([t_0,\infty);\mathbf{R}^n)$, and assume that for some constant $\varepsilon\in(0,1/2\beta)$, $\int_s^\infty \|C(t,s)\|_B\,dt\leqq (p(s)/2\beta)-\varepsilon(1+p(s))$ for almost all $s\geqq t_0$, or $\int_s^\infty \|\sqrt{B}\,C(t,s)\|\,dt\leqq (q(s)/2\sqrt{\beta})-\varepsilon(1+p(s))$ for almost all $s\geqq t_0$. Then the function $z(\cdot)=|x(\cdot)|_B$ satisfies $\int_{t_0}^\infty ((1+p(t))z(t)+|z'(t)|)\,dt<\infty$. In particular, $x(t)\to 0$ as $t\to\infty$.*

(iii) *In addition to* (ii), *suppose that $\|A(s)\|\leqq M(1+p(s))$ for some constant M and almost all $s\geqq t_0$. Then $x'\in L^1([t_0,\infty);\mathbf{R}^n)$.*

Note, in particular, that in the case where A is unbounded we do not have to assume that $\operatorname{ess\,sup}_{s\geqq t_0}\int_s^\infty \|C(t,s)\|\,dt<\infty$. In this respect Theorem 3.1 and some of the other theorems below seem to be new.

The second and third conclusions can be simplified slightly in the autonomous case (2.1). Then the additional assumption in (iii) is automatically satisfied, and the conditions $\int_s^\infty \|C(t,s)\|_B\,dt\leqq (p(s)/2\beta)-\varepsilon(1+p(s))$ and $\int_s^\infty \|\sqrt{B}\,C(t,s)\|\,dt\leqq (q(s)/2\sqrt{\beta})-\varepsilon(1+p(s))$ can be written as $\int_s^\infty \|C(t,s)\|_B\,dt\leqq (1/2\beta)-\varepsilon$ and $\int_s^\infty \|\sqrt{B}\,C(t,s)\|\,dt\leqq (1/2\sqrt{\beta})-\varepsilon$.

The additional assumption in (iii) is automatically satisfied in the scalar time-dependent case as well.

Proof. As we already observed above, the first of the two claims follows from a direct inspection of (3.1) and (3.2). Likewise, it is a direct consequence of (3.1) and (3.2) that under the extra assumption we have $\int_{t_0}^\infty (1+p(t))z(t)\,dt<\infty$. This implies that the last two terms on the right-hand side of (2.7) are integrable (estimate these terms in the same say as in (2.8)). Since z is bounded (from below), and the first term on the right-hand side of (2.7) is nonpositive, also this term must be integrable. This proves that z' is integrable. That x' itself is integrable under the additional assumption made in (iii) follows directly from (2.6). □

Some scalar nonlinear convolution versions of this result are given in [33, Thm. 1, p. 458] and [34, Thm. 1, p. 340], and some nonlinear nonconvolution versions are given in [19]–[21].

Theorem 3.1 contains and extends the claims about stability and asymptotic stability made in [2, Thm. 1, p. 102], [2, Thm. 2, p. 104], [3, Thm. 1, p. 42], and [3, Thm. 2, p. 43]. (We shall return below to the question of uniform stability and uniform asymptotic stability.)

There is another equally obvious estimate which can be applied to (2.8) and (2.9). Instead of just integrating (2.8) we introduce a scalar function η (which need not be

positive), and add and subtract the term $\eta(t)z(t)$ from (2.8). Then we multiply the equation by $\exp\left(\int_{t_0}^{t}\eta(v)\,dv\right)$, integrate over $[t_0, T]$, and finally divide by $\exp\left(\int_{t_0}^{T}\eta(v)\,dv\right)$. This leads to the inequality

$$z(T)+\int_{t_0}^{T}\left(\frac{p(s)}{2\beta}-\eta(s)-\int_{s}^{T}\exp\left(\int_{s}^{t}\eta(v)\,dv\right)\|C(t,s)\|_B\,dt\right)$$

$$\times\exp\left(-\int_{s}^{T}\eta(v)\,dv\right)z(s)\,ds \tag{3.3}$$

$$\leqq z(t_0)\exp\left(-\int_{t_0}^{T}\eta(v)\,dv\right)+\int_{t_0}^{T}\exp\left(-\int_{t}^{T}\eta(v)\,dv\right)|f(t)|_B\,dt, \qquad T\geqq t_0.$$

The same manipulations applied to (2.9), with $\eta\geqq 0$, lead to the inequality

$$z(T)+\int_{t_0}^{T}\left(\frac{q(s)}{2\sqrt{\beta}}-\sqrt{\beta}\,\eta(s)-\int_{s}^{T}\exp\left(\int_{s}^{t}\eta(v)\,dv\right)\|\sqrt{B}\,C(t,s)\|\,dt\right)$$

$$\times\exp\left(-\int_{s}^{T}\eta(v)\,dv\right)|x(s)|\,ds \tag{3.4}$$

$$\leqq z(t_0)\exp\left(-\int_{t_0}^{T}\eta(v)\,dv\right)+\int_{t_0}^{T}\exp\left(-\int_{t}^{T}\eta(v)\,dv\right)|f(t)|_B\,dt, \qquad T\geqq t_0.$$

This very last estimate gives us the following theorem.

THEOREM 3.2. *If*

$$\int_{s}^{\infty}\exp\left(\int_{s}^{t}\eta(v)\,dv\right)\|\sqrt{B}\,C(t,s)\|\,dt\leqq\frac{q(s)}{2\sqrt{\beta}}-\sqrt{\beta}\,\eta(s)$$

for some function $\eta\geqq 0$ and almost all $s\geqq t_0$, then the solution x of (2.6) *satisfies*

$$|x(t)|_B\leqq|x_0|_B\exp\left(-\int_{t_0}^{t}\eta(v)\,dv\right)+\int_{t_0}^{t}\exp\left(-\int_{s}^{t}\eta(v)\,dv\right)|f(s)|_B\,ds$$

for all $t\geqq t_0$. In particular, if the right-hand side of this inequality is bounded, then so is x, and if it tends to zero as $t\to\infty$, then so does x.

The proof is obvious.

A scalar nonlinear version of this result is given in [20, Cor. 2.4, pp. 328-329].

Theorem 3.2 extends [2, Thm. 3, p. 106], [3, Thm. 4, p. 45], [6, Cor. 1.3, p. 173], [6, Thm. 3, p. 180], and [8, Thm. 3, p. 278]. In these theorems Burton uses various conditions, some of which do not directly seem to be related to the assumption of Theorem 3.2. However, they are all special cases of Theorem 3.2. For example, in formula (2.5.21) of [10, p. 44], it is assumed that

$$\|C(t,s)\|\geqq\lambda(t)\int_{t}^{\infty}\|C(u,s)\|\,du, \tag{3.5}$$

where λ is nonnegative. If we choose $\eta(t)=\varepsilon\lambda(t)$ for some small positive ε, then it is easy to show (integrate by parts) that

$$\int_{s}^{\infty}\exp\left(\int_{s}^{t}\eta(v)\,dv\right)\|C(t,s)\|\,dt\leqq\frac{1}{1-\varepsilon}\int_{s}^{\infty}\|C(t,s)\|\,dt.$$

Clearly, this means that if, in addition to (3.5), one has $\int_{s}^{\infty}\|C(t,s)\|dt\leqq(1-\varepsilon)(q(s)/2\beta-\varepsilon\lambda(s))$ for almost all $s\geqq t_0$, then Theorem 3.2 applies (recall that $\|\sqrt{B}\,C(t,s)\|\leqq\|\sqrt{B}\|\,\|C(t,s)\|\leqq\sqrt{B}\|C(t,s)\|$).

A result similar to Theorem 3.2 is true for the inequality (3.3) as well, but we leave the formulation of that result to the reader.

Another possible use of (3.3) is the following: Let us introduce the notation

$$|z|_- = \max[0, -z], \qquad z \in \mathbf{R},$$

and, let us define λ by

$$\lambda \overset{\text{def}}{=} \sup_{T \geqq t_0} \int_{t_0}^{T} \left| \frac{p(s)}{2\beta} - \eta(s) - \int_s^T \exp\left(\int_s^t \eta(v)\, dv\right) \|C(t,s)\|_B\, dt \right|_- \times \exp\left(-\int_s^T \eta(v)\, dv\right) ds. \tag{3.6}$$

If we suppose that $z(T) = \max_{s \in [t_0, T]} z(s)$, then clearly (3.3) implies that

$$(1-\lambda) z(T) \leqq z(t_0) \exp\left(-\int_{t_0}^T \eta(v)\, dv\right) + \int_{t_0}^T \exp\left(-\int_t^T \eta(v)\, dv\right) |f(t)|_B\, dt.$$

This proves the following theorem.

THEOREM 3.3. *Suppose that the constant λ defined in* (3.6) *satisfies $\lambda < 1$, that*

$$\inf_{t \geqq t_0} \int_{t_0}^t \eta(v)\, dv > -\infty,$$

and that

$$\sup_{t \geqq t_0} \int_{t_0}^t \exp\left(-\int_s^t \eta(v)\, dv\right) |f(s)|_B\, ds < \infty.$$

Then the solution x of (2.6) *is bounded.*

This theorem extends [11, Prop., p. 247].

One particular case where Theorem 3.3 can be applied is the following. We integrate by parts to get

$$\int_s^T \exp\left(\int_s^t \eta(v)\, dv\right) \|C(t,s)\|_B\, dt = \int_s^T \|C(t,s)\|_B\, dt + \int_s^T \eta(t) \exp\left(\int_s^t \eta(v)\, dv\right) \int_t^T \|C(u,s)\|_B\, du\, dt.$$

Thus, if we assume that $\int_s^\infty \|C(t,s)\|_B\, dt \leqq (p(s)/2\beta) - \eta(s)$, and that $\eta \geqq 0$, then we can estimate the constant λ in (3.6) by

$$\begin{aligned}
\lambda &\leqq \int_{t_0}^T \int_s^T \eta(t) \exp\left(-\int_t^T \eta(v)\, dv\right) \int_t^T \|C(u,s)\|_B\, du\, dt\, ds \\
&= \int_{t_0}^T \eta(t) \exp\left(-\int_t^T \eta(v)\, dv\right) \int_{t_0}^t \int_t^T \|C(u,s)\|_B\, du\, ds\, dt \\
&\leqq \int_{t_0}^T \eta(t) \exp\left(-\int_t^T \eta(v)\, dv\right) dt \sup_{t \geqq t_0} \int_{t_0}^t \int_t^\infty \|C(u,s)\|_B\, du\, ds \\
&\leqq \sup_{t \geqq t_0} \int_{t_0}^t \int_t^\infty \|C(u,s)\|_B\, du\, ds.
\end{aligned}$$

Thus, if we define ρ by

$$\rho = \sup_{t \geqq t_0} \int_{t_0}^t \int_t^\infty \|C(u,s)\|_B\, du\, ds, \tag{3.7}$$

then $\lambda \leqq \rho$.

The argument above, combined with Theorem 3.3, proves the following theorem.

THEOREM 3.4. *Suppose that* $\int_s^\infty \|C(t,s)\|_B\,dt \leqq p(s)/2\beta - \eta(s)$ *for some function* $\eta \geqq 0$ *and almost all* $s \geqq t_0$. *In addition, suppose that the constant* ρ *defined in* (3.7) *satisfies* $\rho < 1$, *and that* $\sup_{t \geqq t_0} \int_{t_0}^t \exp\left(-\int_s^t \eta(v)\,dv\right)|f(s)|_B\,ds < \infty$. *Then the solution* x *of* (2.6) *is bounded.*

Theorem 3.4 extends [3, Thm. 3, p. 44], [6, Cor. 1.1, p. 171], [6, Cor. 1.2, p. 172], [7, Prop. 2, p. 64], and [7, Prop. 3, p. 66]. (In these results, $\eta(t)$ is a small constant.)

4. Some L^∞-estimates. Our L^∞-estimates are based on the following lemma.

LEMMA 4.1. *Let* z *be real-valued and locally absolutely continuous, and define the set* E *by* $E = \{t \in [t_0, \infty) \mid z(t) = \max_{s \in [t_0, t]}\}$. *Then the function* $t \mapsto \sup_{s \in [t_0,t]} z(s)$ *is locally absolutely continuous, and its derivative is almost everywhere equal to* $\chi_E(t)z'(t)$. *In particular, if* $z'(t) \leqq f(t)$ *for almost all* $t \in E$, *then* $z(t) \leqq z(t_0) + \int_{t_0}^t \chi_E(s)f(s)\,ds$ *for all* $t \geqq t_0$.

The easy proof of this lemma is left to the reader.

When we apply Lemma 4.1 to the inequality (2.8) we get the following result.

THEOREM 4.2. (i) *If* $f \in L^1([t_0, \infty); \mathbf{R}^n)$, *and* $\int_{t_0}^t \|C(t,s)\|_B\,ds \leqq p(t)/2\beta$ *for almost all* $t \geqq t_0$, *then the solution* x *of* (2.6) *is bounded. More precisely,* $|x(t)|_B \leqq |x_0|_B + \int_{t_0}^t |f(s)|_B\,ds$ *for all* $t \geqq t_0$.

(ii) *If* $\operatorname{ess\,sup}_{s \geqq t_0} (1+p(s))^{-1}|f(s)|_B < \infty$, *and* $\int_{t_0}^t \|C(t,s)\|_B\,ds \leqq p(t)/2\beta - \varepsilon(1+p(t))$ *for some constant* $\varepsilon \in (0, 1/2\beta)$ *and almost all* $t \geqq t_0$, *then the function* $z(\cdot) = |x(\cdot)|_B$ *satisfies* $z(t) \leqq \max\{|x_0|_B, (1/\varepsilon) \operatorname{ess\,sup}_{s \in [t_0,t]} (1+p(s))^{-1}|f(s)|_B\}$ *for all* $t \geqq t_0$, *and* $\operatorname{ess\,sup}_{t \geqq t_0} (1+p(t))^{-1}|z'(t)| < \infty$.

(iii) *In addition to* (ii), *suppose that* $\|A(s)\| \leqq M(1+p(s))$ *for some constant* M *and almost all* $s \geqq t_0$. *Then* $\operatorname{ess\,sup}_{t \geqq t_0} (1+p(t))^{-1}|x'(t)| < \infty$.

The proof is left to the reader (note that in (ii) the derivative will be nonpositive on E as soon as z has exceeded the given bound).

Theorem 4.2 generalizes [22, Thm. 4, p. 149].

By applying Lemma 4.1 to the function $\exp\left(\int_{t_0}^t \eta(v)\,dv\right)z(t)$ rather than to z itself we get the following analogue of Theorem 3.2.

THEOREM 4.3. *If*

$$\int_{t_0}^t \exp\left(\int_s^t \eta(v)\,dv\right)\|C(t,s)\|_B\,ds \leqq \frac{p(t)}{2\beta} - \eta(t)$$

for almost all $t \geqq t_0$, *then the solution* x *of* (2.6) *satisfies*

$$|x(t)|_B \leqq |x_0|_B \exp\left(-\int_{t_0}^t \eta(v)\,dv\right) + \int_s^t \exp\left(-\int_s^t \eta(v)\,dv\right)|f(s)|_B\,ds$$

for all $t \geqq t_0$. *In particular, if the right-hand side of this inequality is bounded, then so is* x, *and if it tends to zero as* $t \to \infty$, *then so does* x.

The easy proof is left to the reader.

Theorem 4.3 is closely related to [27, Thm. 3.1, p. 1398].

Extensive work has been done on the question of whether the function x in Theorem 4.2 tends to a limit at infinity. See [1, Thm. 4.2, p. 242], [25, Thm. 5.3, p. 264], [26, Cor. 1, p. 100], and [26, Thm. 3.1, p. 108].

5. L^2-estimates and kernels of positive type. To get an L^2-estimate rather than an L^1-estimate or an L^∞-estimate we use the Lyapunov function $w(t) = \frac{1}{2}z^2(t)$ instead of the function $z(t)$. From (2.7) we get

$$(5.1)\quad z(t)z'(t) = -\frac{1}{2}\langle x(t), R(t)x(t)\rangle + \int_{t_0}^t \langle x(t), BC(t,s)x(s)\rangle\,ds + \langle x(t), B(f(t)\rangle,$$

and (3.1) and (3.2) are replaced by

$$\begin{aligned}(5.2)\qquad &\frac{1}{2}z^2(T)+\int_{t_0}^{T}\frac{p(t)}{2\beta}z^2(t)\,dt-\int_{t_0}^{T}\int_{t_0}^{t}z(t)\|C(t,s)\|_B z(s)\,ds\,dt\\ &\leqq\frac{1}{2}z^2(t_0)+\int_{t_0}^{T}z(t)|f(t)|_B\,dt,\qquad T\geqq t_0,\end{aligned}$$

and

$$\begin{aligned}(5.3)\qquad &\frac{1}{2}z^2(T)+\int_{t_0}^{T}\frac{r(t)}{2}|x(t)|^2\,dt-\int_{t_0}^{T}\int_{t_0}^{t}|x(t)|\,\|BC(t,s)\|\,|x(s)|ds\,dt\\ &\leqq\frac{1}{2}z^2(t_0)+\int_{t_0}^{T}z(t)|f(t)|_B\,dt,\qquad T\geqq t_0,\end{aligned}$$

where

$$r(t)=\inf_{x\in\mathbf{R}^n}\frac{\langle x,R(t)x\rangle}{|x|^2}$$

is the smallest eigenvalue of the matrix $R(t)$. The double integral in (5.2) can be estimated in the following way: As the geometric mean is no larger than the arithmetic mean, we get for all $\kappa>0$,

$$\begin{aligned}(5.4)\qquad \int_{t_0}^{T}\int_{t_0}^{t}z(t)\|C(t,s)\|_B z(s)\,ds\,dt&\leqq\int_{t_0}^{T}\int_{t_0}^{t}\|C(t,s)\|_B\left(\frac{\kappa}{2}z^2(t)+\frac{1}{2\kappa}z^2(s)\right)ds\,dt\\ &=\int_{t_0}^{T}\left(\frac{\kappa}{2}\int_{t_0}^{t}\|C(t,u)\|_B\,du\right.\\ &\qquad\left.+\frac{1}{2\kappa}\int_{t}^{T}\|C(v,t)\|_B\,dv\right)z^2(t)\,dt.\end{aligned}$$

This is the key estimate in the remainder of this section.

Applying (5.4) to (5.2) and (5.3) we get the following result.

THEOREM 5.1. (i) *If $f\in L^1([t_0,\infty);\mathbf{R}^n)$, and there is some $\kappa>0$ such that*

$$\frac{\kappa}{2}\int_{t_0}^{t}\|C(t,u)\|_B\,du+\frac{1}{2\kappa}\int_{t}^{\infty}\|C(v,t)\|_B\,dv\leqq\frac{p(t)}{2\beta}$$

for almost $t>t_0$, or

$$\frac{\kappa}{2}\int_{t_0}^{t}\|BC(t,u)\|\,du+\frac{1}{2\kappa}\int_{t}^{\infty}\|BC(v,t)\|\,dv\leqq\frac{r(t)}{2}$$

for almost all $t>t_0$, then the solution x of (2.6) is bounded. More precisely, $|x(t)|_B\leqq|x_0|_B+\int_{t_0}^{t}|f(s)|_B\,ds$ for all $t\geqq t_0$.

(ii) *If $\int_{t_0}^{\infty}(1+p(t))^{-1}|f(t)|_B^2\,dt<\infty$, and there are constants $\kappa>0$ and $\varepsilon\in(0,1/2\beta)$ such that*

$$\frac{\kappa}{2}\int_{t_0}^{t}\|C(t,u)\|_B\,du+\frac{1}{2\kappa}\int_{t}^{\infty}\|C(v,t)\|_B\,dv\leqq\frac{p(t)}{2\beta}-\varepsilon(1+p(t))$$

for almost all $t>t_0$, or

$$\frac{\kappa}{2}\int_{t_0}^{t}\|BC(t,u)\|\,du+\frac{1}{2\kappa}\int_{t}^{\infty}\|BC(v,t)\|\,dv\leqq\frac{r(t)}{2}-\varepsilon(1+p(t))$$

for almost all $t>t_0$, then the function $w(\cdot)=|x(\cdot)|_B^2$ satisfies $\int_{t_0}^{\infty}((1+p(t))w(t)+|w'(t)|)\,dt<\infty$. In particular, $x(t)\to0$ as $t\to\infty$.

(iii) *In addition to* (ii), *suppose that* $\|A(s)\| \leqq M(1+p(s))$ *for some constant* M *and almost all* $s \geqq t_0$. *Then* $\int_{t_0}^{\infty} (1+p(t))^{-1}|x'(t)|^2\,dt < \infty$.

Proof. It follows from (5.2), (5.3), and (5.4) (and from the analogue of (5.4) for (5.3)) that in part (i) of the theorem,

$$\frac{1}{2}z^2(T) \leqq \frac{1}{2}z^2(t_0) + \int_{t_0}^{T} z(t)|f(t)|_B\,dt, \qquad T \geqq t_0. \tag{5.5}$$

Using, e.g., [36, Thm. 6.1, p. 121] we find that z is dominated by the solution y of the equation

$$\frac{1}{2}y^2(T) = \frac{1}{2}z^2(t_0) + \int_{t_0}^{T} y(t)|f(t)|_B\,dt, \qquad T \geqq t_0.$$

However, this is an ordinary differential equation, which can be solved explicitly to give the estimate in part (i).

In part (ii) of the theorem, instead of (5.5), we get from the same formulas as before (if necessary, decrease the value of ε, and replace $|x(t)|$ by $z(t)$)

$$\frac{1}{2}z^2(T) + \varepsilon\int_{t_0}^{T} (1+p(t))z^2(t)\,dt \leqq \frac{1}{2}z^2(t_0) + \int_{t_0}^{T} z(t)|f(t)|_B\,dt, \qquad T \geqq t_0.$$

This together with Hölder's inequality gives the conclusion that $\int_{t_0}^{\infty}(1+p(t))z^2(t)\,dt < \infty$. To prove the claim about the derivative one argues in the same way as in the proof of Theorem 3.1.

To prove (iii) one uses (2.6), observes that for some constant $M > 0$,

$$\operatorname*{ess\,sup}_{t \geqq t_0} (1+p(t))^{-1}\int_{t_0}^{t} \|C(t,s)\|_B\,ds \leqq M,$$

$$\operatorname*{ess\,sup}_{s \geqq t_0} (1+p(s))^{-1}\int_{s}^{\infty} \|C(t,s)\|_B\,dt \leqq M,$$

and uses Hölder's inequality and a change of the order of integration to get

$$\begin{aligned}
&\int_{t_0}^{T} (1+p(t))^{-1}\left[\int_{t_0}^{t} \|C(t,s)\|_B z(s)\,ds\right]^2 dt \\
&\quad \leqq \int_{t_0}^{T} (1+p(t))^{-1}\int_{t_0}^{t} \|C(t,s)\|_B\,ds \int_{t_0}^{t} \|C(t,s)\|_B z^2(s)\,ds\,dt \\
&\quad \leqq M\int_{t_0}^{T}\int_{s}^{T} \|C(t,s)\|_B\,dt\,z^2(s)\,ds \\
&\quad \leqq M^2\int_{t_0}^{T} (1+p(s))z^2(s)\,ds.
\end{aligned}$$

□

Theorem 5.1 contains the linear versions of the stability claims in [5, Thm. 1, p. 92], [5, Thm. 5, p. 100], [16, Thm. 3, p. 148], [16, Cor. 1, p. 149], and [16, Thm. 8, p. 156]. (The nonlinear versions given in [5] can be proved in a similar way.)

It is customary to make the following definition.

DEFINITION 5.2. A linear mapping F which takes the $\mathbf{R}^n$-valued function x into the $\mathbf{R}^n$-valued function $F(x)(t)$ is of positive type with respect to the inner product $\langle\cdot,\cdot\rangle_B$ on the interval $[t_0, \infty)$ if it is true for all continuous x and all $T > t_0$ that

$$\int_{t_0}^{T} \langle x(t), F(x)(t)\rangle_B \geqq 0.$$

Clearly, Theorem 5.1 is a special case of the following result (the proof remains the same).

THEOREM 5.3. (i) *If* $f \in L^1([t_0, \infty); \mathbf{R}^n)$, *and if the mapping which takes* x *into the function* $A(t)x(t) - \int_{t_0}^t C(t, s)x(s)\,ds$ *is of positive type with respect to the inner product* $\langle \cdot, \cdot \rangle_B$ *on* $[t_0, \infty)$, *then the solution* x *of* (2.6) *is bounded. More precisely,* $|x(t)|_B \leqq |x_0|_B + \int_{t_0}^t |f(s)|_B\,ds$ *for all* $t \geqq t_0$.

(ii) *If* $\int_{t_0}^\infty (1+p(t))^{-1}|f(t)|_B^2\,dt < \infty$, *and there is a constant* $\varepsilon \in (0, 1/2\beta)$ *such that the mapping that takes* x *into the function* $A(t)x(t) - \int_{t_0}^t C(t, s)x(s)\,ds - \varepsilon(1+p(t))x(t)$ *is of positive type with respect to the inner product* $\langle \cdot, \cdot \rangle_B$ *on* $[t_0, \infty)$, *then the solution* x *of* (2.6) *is bounded and satisfies* $\int_{t_0}^\infty (1+p(t))|x(t)|_B^2\,dt < \infty$. *If, in addition,* $\int_{t_0}^t \|C(t, u)\|_B\,du + \int_t^\infty \|C(v, t)\|_B\,dv \leqq M(1+p(t))$ *for some constant* $M > 0$ *and almost all* $t \geqq t_0$, *then the derivative of the function* $\|x(t)\|_B^2$ *is integrable. In particular, in this case* $x(t) \to 0$ *as* $t \to \infty$.

(iii) *In addition to* (ii), *suppose that* $\|A(s)\| \leqq M(1+p(s))$ *for some constant* M *and almost all* $s \geqq t_0$. *Then* $\int_{t_0}^\infty (1+p(t))^{-1}|x'(t)|^2\,dt < \infty$.

Scalar convolution versions of this result are given in [41, p. 83] and [43, Cor. 3.2, p. 132]. Some other results which fall within the scope of this theorem are [4, Thm. 3, p. 397], [5, Thm. 3, p. 97], and [5, Thm. 7, p. 103].

(Two of the theorems in [5], i.e., Theorem 2 on p. 94 and Theorem 6 on p. 102, can be proved with standard energy technique for second-order ordinary differential equations. It is easy to show that, under the assumptions in [5], the equations discussed in these two theorems are integrated versions of the damped nonlinear oscillator equation

$$x''(t) - \lambda(t)x'(t) + C(t, t)E(x(t)) = 0,$$

with initial condition $x'(0) = 0$.)

For additional results on scalar nonconvolution kernels of positive type, see [23] and the references mentioned there.

By adding and subtracting a term $\eta(t)z^2(t)$ from (5.1), multiplying the equation by $\exp(2\int_{t_0}^t \eta(v)\,dv)$, and finally integrating, we can prove the following analogue of Theorems 3.2 and 4.3.

THEOREM 5.4. *If the mapping that takes* x *into the function*

$$A(t)x(t) - \int_{t_0}^t \exp\left(\int_s^t \eta(v)\,dv\right) C(t, s)x(s)\,ds$$

is of positive type with respect to the inner product $\langle \cdot, \cdot \rangle_B$ *on* $[t_0, \infty)$, *then the solution* x *of* (2.6) *satisfies*

$$|x(t)|_B \leqq |x_0|_B \exp\left(-\int_{t_0}^t \eta(v)\,dv\right) + \int_{t_0}^t \exp\left(-\int_s^t \eta(v)\,dv\right)|f(s)|_B\,ds$$

for all $t \geqq t_0$. *In particular, if the right-hand side of this inequality is bounded, then so is* x, *and if it tends to zero as* $t \to \infty$, *then so does* x.

This result seems to be new.

Note, in particular, that if the size hypothesis on C in part (i) of Theorem 5.1 holds with $C(t, s)$ replaced by $\exp(\int_s^t \eta(v)\,dv)C(t, s)$, then Theorem 5.4 applies.

6. Perturbations of the derivative. So far, in our study of perturbed versions of the ordinary differential equation

$$x'(t) + A(t)x(t) = f(t), \qquad t \geqq t_0, \tag{6.1}$$

we have only permitted perturbations that can be dominated by the term $A(t)x(t)$ (Theorems 3.3 and 3.4 were exceptions; there we needed the term $x'(t)$ as well). Next we want to allow perturbations that are dominated by the term $x'(t)$. More precisely,

we study equations of the type

$$\frac{d}{dt}\left(x(t)+\int_{t_0}^{t} G(t,s)x(s)\,ds+g(t)\right)+A(t)x(t)=\int_{t_0}^{t} C(t,s)x(s)\,ds+f(t),$$
$$t\geqq t_0,\quad x(t_0)=x_0. \tag{6.2}$$

If G and g are sufficiently differentiable, then one can carry out the differentiations to get an equation which is of the form (2.6), with $A(t)$ replaced by $A(t)+G(t,t)$, $C(t,s)$ replaced by $C(t,s)-(\partial/\partial t)G(t,s)$ and $f(t)$ replaced by $f(t)-g'(t)$. In particular, if $A(t)+G(t,t)=0$, then the equation which one gets in this way has no leading ODE term. Therefore, we should not regard (6.2) as a perturbation of the equation

$$x'(t)+(A(t)+G(t,t))x(t)=f(t),\qquad t\geqq t_0. \tag{6.3}$$

Instead, it should be regarded as a perturbation of (6.1).

References [16] and [17] contain several nice examples on equations of the type (2.6), which can be rewritten in the form (6.2) in such a way that (6.2) becomes a small perturbation of (6.1).

Equations of the type (6.2) are a special subclass of the so-called neutral functional differential equations, and the operator which maps x into the function $t\mapsto x(t)+\int_{t_0}^{t} G(t,s)x(s)\,ds+g(t)$ is usually called the D-operator. Under the assumptions which we use below, both the D-operator and the unperturbed equation (6.1) will be asymptotically stable. (For a further discussion on a neutral functional differential equation with a stable D-operator, see [44].)

There are at least two different ways to approach (6.2). One possibility is to first use the variation of constants formula for (6.1), and then apply the contraction mapping principle. We shall return to this approach in the next section. The other possibility, the one we present now, is to use L^2-estimates in the spirit of the preceding section.

Earlier, when we developed our L^2-estimates for (2.6), we simply took the B-inner product of the equation with $x(t)$, and integrated. This time, the natural thing to do is to take the B-inner product of (6.2) with $x(t)+\int_{t_0}^{t} G(t,s)x(s)\,ds+g(t)$, and integrate. This leads to the identity (we have collected all the quadratic terms in x to the left-hand side and all the affine terms to the right-hand side, and $R(t)$ has the same meaning as before)

$$\begin{aligned}
&\frac{1}{2}\left|x(T)+\int_{t_0}^{T} G(T,s)x(s)\,ds+g(T)\right|_B^2+\frac{1}{2}\int_{t_0}^{T}\langle x(t),R(t)x(t)\rangle\,dt\\
&\quad+\int_{t_0}^{T}\int_{t_0}^{t}\langle x(t),(A^T(t)BG(t,s)-BC(t,s))x(s)\rangle\,ds\,dt\\
&\quad-\int_{t_0}^{T}\int_{t_0}^{t}\int_{t_0}^{t}\langle G(t,s)x(s),BC(t,v)x(v)\rangle\,dv\,ds\,dt\\
&=\frac{1}{2}|x_0+g(t_0)|_B^2+\int_{t_0}^{T}\langle f(t),Bg(t)\rangle\,dt\\
&\quad+\int_{t_0}^{T}\langle Bf(t)-A^T(t)Bg(t),x(t)\rangle\,dt\\
&\quad+\int_{t_0}^{T}\int_{t_0}^{t}\langle f(t),BG(t,s)x(s)\rangle\,ds\,dt\\
&\quad+\int_{t_0}^{T}\int_{t_0}^{t}\langle g(t),BC(t,s)x(s)\rangle\,ds\,dt.
\end{aligned} \tag{6.4}$$

Generally speaking, in this formula we can use the first two terms to dominate all the

rest. Most of the remaining perturbation terms are of a familiar nature; the only exception is the last term on the left-hand side (which can easily be estimated with Hölder's inequality).

We shall make no attempt to prove a general result based on (6.4), with all the terms present. There are simply too many different possible estimates. For example, in the last two terms, we may allow G and C to be "large" at infinity, if we instead require f and g to be "small," and vice versa (these terms can be estimated in a way similar to the one that we used at the end of the proof of Theorem 5.1). To prove [17, Thm. 1, p. 492] and [17, Thm. 5, p. 503] we drop the two functions f and g (after which the right-hand side of (6.4) is a constant), and estimate the last term on the left-hand side in the same way as Burton and Mahfoud do on the bottom of p. 491 in [17]. Here we shall only prove a result that applies to the equation which one gets by dropping the functions C and f on the right-hand side of (6.2), i.e., we look at the equation

$$\frac{d}{dt}\left(x(t)+\int_{t_0}^{t} G(t,s)x(s)\,ds+g(t)\right)+A(t)x(t)=0,\quad t\geqq t_0,\quad x(t_0)=x_0. \tag{6.5}$$

If we drop the corresponding terms in (6.4), and make the standard estimates, then we get

$$\begin{aligned}&\frac{1}{2}\left|x(T)+\int_{t_0}^{T} G(T,s)x(s)\,ds+g(T)\right|_B^2+\int_{t_0}^{T}\frac{p(t)}{2\beta}z^2(t)\,dt\\&\quad-\int_{t_0}^{T}\int_{t_0}^{t} z(t)\|B^{-1}A^T(t)BG(t,s)\|_B z(s)\,ds\,dt\\&\quad\leqq\frac{1}{2}|x_0+g(t_0)|_B^2+\int_{t_0}^{T}|A^T(t)Bg(t)||x(t)|\,dt,\qquad T\geqq t_0,\end{aligned} \tag{6.6}$$

and

$$\begin{aligned}&\frac{1}{2}\left|x(T)+\int_{t_0}^{T} G(T,s)x(s)\,ds+g(T)\right|_B^2+\int_{t_0}^{T}\frac{r(t)}{2}|x(t)|^2\,dt\\&\quad-\int_{t_0}^{T}\int_{t_0}^{t}|x(t)|\,\|A^T(t)BG(t,s)\|\,|x(s)|\,ds\,dt\\&\quad\leqq\frac{1}{2}|x_0+g(t_0)|_B^2+\int_{t_0}^{T}|A^T(t)Bg(t)||x(t)|\,dt,\qquad T\geqq t_0.\end{aligned} \tag{6.7}$$

These estimates combined with (5.4) gives us the following theorem.

THEOREM 6.1. (i) *If* $\int_{t_0}^{\infty}(1+p(t))^{-1}|A^T(t)Bg(t)|^2\,dt<\infty$, *and there are constants* $\kappa>0$ *and* $\varepsilon\in(0,1/2\beta)$ *such that*

$$\begin{aligned}&\frac{\kappa}{2}\int_{t_0}^{t}\|B^{-1}A^T(t)BG(t,u)\|_B\,du+\frac{1}{2\kappa}\int_{t}^{\infty}\|B^{-1}A^T(v)BG(v,t)\|_B\,dv\\&\quad\leqq\frac{p(t)}{2\beta}-\varepsilon(1+p(t))\end{aligned}$$

for almost all $t>t_0$, *or*

$$\begin{aligned}&\frac{\kappa}{2}\int_{t_0}^{t}\|A^T(t)BG(t,u)\|\,du+\frac{1}{2\kappa}\int_{t}^{\infty}\|A^T(v)BG(v,t)\|\,dv\\&\quad\leqq\frac{r(t)}{2}-\varepsilon(1+p(t))\end{aligned}$$

for almost all $t>t_0$, *then the solution* x *of* (6.5) *satisfies* $\int_{t_0}^{\infty}(1+p(t))|x(t)|^2\,dt<\infty$.

(ii) *In addition to* (i), *suppose that* $\int_{t_0}^{\infty}(1+p(t))^{-1}|g'(t)|^2\,dt<\infty$, *and that for some constant* M *and almost all* $t\geqq t_0$ *and* $s\geqq t_0$,

$$\|A(t)+G(t,t)\|\leqq M(1+p(t)),$$
$$\int_{t_0}^{t}\left\|\frac{\partial}{\partial t}G(t,s)\right\|ds\leqq M(1+p(t)),$$
$$\int_{s}^{\infty}\left\|\frac{\partial}{\partial t}G(t,s)\right\|dt\leqq M(1+p(s)).$$

Then $\int_{t_0}^{\infty}(|w'(t)|+(1+p(t))^{-1}|x'(t)|^2\,dt<\infty$, *where* $w(\cdot)=|x(\cdot)|_B^2$. *In particular,* $x(t)\to 0$ *as* $t\to\infty$.

The proof is essentially the same as the proof of parts (ii) and (iii) of Theorem 5.1.

Theorem 6.1 contains the linear versions of the stability claims in [16, Thm. 4, p. 150], [16, Thm. 14, p. 164], [16, Thm. 15, p. 166], and [16, Thm. 16, p. 167]. (The nonlinear versions are proved in an analogous way.)

7. The variation of constants formula. It is not possible to discuss equations (2.1), (2.6), and (6.2) without mentioning the most obvious approach to a stability theory for these equations, namely the use of the variation of constants formula. If we let $Z(t,s)$ denote the fundamental matrix solution of the equation $x'(t)+A(t)x(t)=0$, i.e., the solution of the equations

$$\frac{\partial}{\partial t}Z(t,s)+A(t)Z(t,s)=0,\qquad t_0\leqq s\leqq t<\infty,$$
$$\frac{\partial}{\partial s}Z(t,s)-Z(t,s)A(s)=0,\qquad t_0\leqq s\leqq t<\infty,$$
$$Z(t,t)=I,\qquad t\geqq t_0;$$

then we can multiply the equation

$$\frac{d}{dt}\left(x(t)+\int_0^t G(t,s)x(s)\,ds+g(t)\right)+A(t)x(t)=\int_{t_0}^{t}C(t,s)x(s)\,ds+f(t),\qquad t\geqq t_0,\quad x(t_0)=x_0,\tag{6.2}$$

by $Z(T,t)$, integrate over $[t_0,T]$, and finally integrate the term with the derivative on the left-hand side by parts to get the variation of constants formula

$$\begin{aligned}x(T)=(x_0+g(t_0))Z(T,t_0)-g(T)+\int_{t_0}^{T}Z(T,t)(f(t)+A(t)g(t))\,dt\\ -\int_{t_0}^{T}G(T,s)x(s)\,ds\\ +\int_{t_0}^{T}Z(T,t)\int_{t_0}^{t}(C(t,s)+A(t)G(t,s))x(s)\,ds\,dt.\end{aligned}$$

For notational convenience, let $\mathcal{B}$ denote one of the spaces $L^p([t_0,\infty);\mathbf{R}^n)$, $1\leqq p\leqq\infty$, $BUC([t_0,\infty);\mathbf{R}^n)$ (the space of bounded uniformly continuous functions on $[t_0,\infty)$), or $BC_0([t_0,\infty);\mathbf{R}^n)$ (the space of continuous functions tending to zero at infinity). Clearly, if all the operators $\mathcal{X}(x)(t)=\int_{t_0}^{t}Z(t,s)x(s)\,ds$, $\mathcal{G}(x)(t)=\int_{t_0}^{t}G(t,s)x(s)\,ds$, and $\mathcal{H}(x)(t)=\int_{t_0}^{t}(C(t,s)+A(t)G(t,s))x(s)\,ds$ are continuous from $\mathcal{B}$ into itself, if f and g belong to $\mathcal{B}$, and if the norm of the operators $\mathcal{G}$ and $\mathcal{H}$ are small enough, then we can use the contraction mapping principle to show that the solution of (6.2) belongs

to $\mathcal{B}$. It is even possible to let $\mathcal{G}$, $\mathcal{H}$, g, and f depend on x, as long as the dependence is so weak that the contraction mapping principle is applicable.

The approach described above is a minor modification of the approach used in [4]. Arguing as above one can remove the assumption in [4] that $A(t)$ commutes with $Z(t, s)$.

The following result is useful when one wants to show that the operators $\mathcal{L}$, $\mathcal{G}$, and $\mathcal{H}$ map some L^p-space into itself.

LEMMA 7.1. *Let $R \in L^1_{\text{loc}}([t_0, \infty) \times [t_0, \infty); \mathbf{R}^{n\times n})$, and denote the operator which maps x into the function $t \mapsto \int_{t_0}^t R(t, s)x(s)\, ds$ by $\mathcal{R}$. Then the following claims are true:*

(i) *$\mathcal{R}$ maps $L^\infty([t_0, \infty); \mathbf{R}^n)$ continuously into itself if and only if* $\operatorname{ess\,sup}_{t\geqq t_0} \int_{t_0}^t \|R(t, s)\|\, ds < \infty$.

(ii) *$\mathcal{R}$ maps $L^1([t_0, \infty); \mathbf{R}^n)$ continuously into itself if and only if* $\operatorname{ess\,sup}_{s\geqq t_0} \int_s^\infty \|R(t, s)\|\, dt \leqq \infty$.

(iii) *If $\mathcal{R}$ maps both $L^1([t_0, \infty); \mathbf{R}^n)$ and $L^\infty([t_0, \infty); \mathbf{R}^n)$ continuously into themselves, then $\mathcal{R}$ maps all intermediate spaces $L^p([t_0, \infty); \mathbf{R}^n)$, $1 < p < \infty$, continuously into themselves.*

All of these results are well known. No necessary and sufficient condition is known in the intermediate cases $1 < p < \infty$ (except for convolution kernels in the space L^2, which are continuous if and only if their distribution Fourier transforms are bounded). Additional admissibility results of this type are discussed in [18].

In particular, if there is some function $\gamma \in L^1([t_0, \infty), \mathbf{R})$ such that $\|R(t, s)\| \leqq \gamma(t-s)$, i.e., if R is dominated by a scalar L^1 convolution kernel, the $\mathcal{R}$ maps all the the spaces $L^p([t_0, \infty); \mathbf{R}^n)$, $1 \leqq p \leqq \infty$, continuously into themselves.

Instead of using the variation of constants formula for the equation $x'(t) + A(t)x(t) = 0$ one can use the variation of constants formula for (2.6). We let $R(t, s)$ be the differential resolvent of (2.6), i.e., the solution of the equations

$$
\begin{aligned}
&\frac{\partial}{\partial t} R(t, s) + A(t)R(t, s) = \int_s^t C(t, u)R(u, s)\, du \qquad t_0 \leqq s \leqq t < \infty,\\
&\frac{\partial}{\partial s} R(t, s) - R(t, s)A(s) = -\int_s^t R(t, u)C(u, s)\, du, \qquad t_0 \leqq s \leqq t < \infty,\\
&R(t, t) = I, \qquad t \geqq t_0,
\end{aligned} \tag{7.1}
$$

If we multiply (6.2) by $R(T, t)$, integrate over $[t_0, T]$, and finally integrate the term with the derivative on the left-hand side by parts, then we get

$$
\begin{aligned}
x(T) &= (x_0 + g(t_0))R(T, t_0) - g(T)\\
&\quad + \int_{t_0}^T R(T, t)(f(t) + A(t)g(t))\, dt - \int_{t_0}^T R(T, t) \int_{t_0}^t C(t, s)g(s)\, ds\, dt\\
&\quad - \int_{t_0}^T G(T, s)x(s)\, ds + \int_{t_0}^T R(T, t)A(t) \int_{t_0}^t G(t, s)x(s)\, ds\, dt\\
&\quad - \int_{t_0}^T R(T, t) \int_{t_0}^t C(t, u) \int_{t_0}^u G(u, s)x(s)\, ds\, du\, dt.
\end{aligned} \tag{7.2}
$$

This equation has a form that makes it possible to apply the contraction mapping principle under suitable smallness assumptions on G. In addition, one may let g, f and G depend on f (cf. [24]). We leave the exact formulation to the reader.

One point that ought to be made is that Theorems 3.1, 3.2, 3.3, 3.4, 4.2, 4.3, 5.1, 5.3, and 5.4 give sufficient conditions under which the differential resolvent maps

various spaces $\mathcal{B}$ continuously into themselves (to see this, take $x_0 = g = G = 0$ in (7.2)). Thus, they enable us to use the contraction mapping principle to study perturbations.

In the case where A is periodic with period T, and C satisfies $C(t+T, s+T) = C(t, s)$ for almost all s and t, then $R(t, s)$ can be defined for $-\infty < s \leqq t < \infty$, and, because of the fact that (under very weak conditions) the solution of (7.1) is unique, R automatically satisfies $R(t+T, s+T) = R(t, s)$ for almost all s and t. If, in addition, $\operatorname{ess\,sup}_{0 \leqq t \leqq T} \int_{-\infty}^{t} (\|C(t, s)\| + \|R(t, s)\|)\, ds < \infty$, or equivalently, $\operatorname{ess\,sup}_{t \geqq 0} \int_{0}^{t} (\|C(t, s)\| + \|R(t, s)\|)\, ds < \infty$, then it is not difficult to show (use Fubini's theorem and the resolvent equations (7.1)) that for each bounded periodic function f the equation

$$x'(t) + A(t) = \int_{-\infty}^{t} C(t, s)x(s)\, ds + f(t), \qquad -\infty < t < \infty, \tag{7.3}$$

has a unique bounded periodic solution, namely

$$x(t) = \int_{-\infty}^{t} R(t, s)f(s)\, ds, \qquad -\infty < t < \infty.$$

This means that under periodicity assumptions on A and C, if we can show that the solutions of (2.6) are bounded for bounded f, then we automatically get a periodicity result for (7.3). In the convolution case we may alternatively show that for each integrable f the solution of (2.6) is integrable, because this together with Lemma 7.1 will imply that solutions are bounded for bounded f (cf. the discussion of convolution equations given below).

8. Uniform stability and uniform asymptotic stability. When we formulate a stability result for a time dependent ordinary differential equation of the type

$$x'(t) + A(t)x(t) = 0, \quad t \geqq t_0, \quad x(t_0) = x_0, \tag{8.1}$$

we distinguish between the notions of stability, asymptotic stability, uniform stability, and uniform asymptotic stability. Stability at a point t_0 means that there is a constant $K(t_0)$, such that $|x(t)| \leqq K(t_0)|x(t_0)|$ for $t \geqq t_0$. The stability is uniform in an interval $J = [\beta, \infty)$, or in the interval $J = (-\infty, \infty)$, if the constant $K(t_0)$ can be made independent of $t_0 \in J$. The equation is asymptotically stable at t_0, if there is a bounded function γ_{t_0}, defined on $\mathbf{R}^+$ and tending to zero at infinity, such that $|x(t)| \leqq \gamma_{t_0}(t - t_0)|x(t_0)|$ for $t \geqq t_0$. Finally, it is uniformly asymptotically stable on an interval J if the function γ_{t_0} can be made independent of $t_0 \in J$.

In the special case where $C \equiv 0$ and $f \equiv 0$ in (2.6), it is obvious that the estimates that we have given above imply, under appropriate assumptions on the functions p and q, that (8.1) is stable, uniformly stable, or asymptotically stable on $\mathbf{R}$. A slightly less obvious fact is that they also can be used to prove uniform asymptotic stability on $\mathbf{R}$. For example, from Theorem 3.1(ii) it is easy to get a bound of the form $\|x\|_{L^1(t_0,\infty)} \leqq M|x(t_0)|$, for some constant M. Suppose that we have already proved that the equation is uniformly stable, i.e., suppose that $|x(t)| \leqq K|x(t_0)|$ for some K and all $t \geqq t_0$. Fix some $\varepsilon > 0$, and define $T(\varepsilon) = KM/\varepsilon$. Then, because of the upper bound that we have on $\|x\|_{L^1(t_0,\infty)}$, there must be at least one point t_1 in the interval $[t_0, t_0 + T(\varepsilon)]$ where $|x(t_1)| \leqq \varepsilon|x(t_0)|/K$. But this, together with the uniform stability, implies that $|x(t)| \leqq \varepsilon|x(t_0)|$ for $t \geqq t_1$. In particular, $|x(t)| \leqq \varepsilon|x(t_0)|$ for $t \geqq t_0 + T(\varepsilon)$. As $T(\varepsilon)$ is independent of t_0, this proves that the equation is uniformly asymptotically stable.

Maybe the main reason for why the property of being uniformly asymptotically stable is such an attractive one for an ordinary differential equation is the fact that uniform asymptotic stability implies exponential asymptotic stability, i.e., the function γ which we used above in the definition of uniform asymptotic stability can always be chosen so that it decays exponentially. (To see this, observe that if $\gamma(T) \leqq \frac{1}{2}$ for some T, then we can replace $\gamma(t)$ by $\frac{1}{2}\gamma(t-T)$ for $t \in [T, 2T]$, by $\frac{1}{4}\gamma(t-2T)$ for $t \in [2T, 3T]$, etc.) This means that the fundamental solution Z of (8.1) satisfies $\|Z(t, s)\| \leqq Me^{-\varepsilon(t-s)}$ for some positive constants M and ε. Therefore, the operator $\mathscr{L}$ defined in § 7 maps all L^p-spaces, $1 \leqq p \leqq \infty$, into themselves. As we saw in § 7, this property is extremely useful when one wants to prove perturbation results.

When we discuss the integral equation (2.6), we may very well interpret the notions of stability and asymptotic stability to mean exactly the type of results which we have given above. The notions of "uniform stability" and "uniform asymptotic stability" are much less clear. One interpretation of uniform stability would be to simply require the bounds that we get on x to be uniform in t_0. Clearly, such bounds follow immediately from our theorems.

Burton's interpretation of the notions uniform stability and uniform asymptotic stability is the following: He takes $f \equiv 0$, replaces the lower bound t_0 in the integral in (2.6) by zero, and specifies a bounded initial function φ on the interval $[0, t_0]$. The equation is supposed to hold for $t \geqq t_0$, and the solution is required to have the same type of uniform behavior as in the ODE case with $J = [t_0, \infty)$, but $|x(t_0)|$ is replaced by $\sup_{0 \leqq s \leqq t_0} |\varphi(s)|$.

To achieve a slightly greater generality, let us replace the interval $[0, t_0]$ by the interval $(-\infty, t_0]$, and specify an initial function on this interval. In other words, let us look at the initial value problem

$$\begin{aligned} &x'(t) + A(t)x(t) = \int_{-\infty}^{t} C(t, s)x(s)\, ds, \qquad t \geqq t_0, \\ &x(t) = \varphi(t), \qquad t \leqq t_0. \end{aligned} \tag{8.2}$$

(Clearly, we can consider (6.2) in a similar setting, but we leave this to the reader.) Let us follow Burton, and specify a bounded initial function (as opposed to an initial function in some L^p-space or weighted L^p-space). This equation is of the type (2.6), with f replaced by

$$f_{t_0,\varphi}(t) = \int_{-\infty}^{t_0} C(t, s)\varphi(s)\, ds, \tag{8.3}$$

and x_0 replaced by $\varphi(t_0)$. As

$$|f_{t_0,\varphi}(t)| \leqq \left(\int_{-\infty}^{t_0} \|C(t, s)\|\, ds \right) \sup_{s \leqq t_0} |\varphi(s)|, \tag{8.4}$$

and as the bounds that we have obtained on $\sup_{t \geqq t_0} |x(t)|$ throughout can be written as a constant times the maximum of $|x_0|$ and the appropriate L^p-norm of f, this means that it is very easy to get results on uniform stability in Burton's sense. The only thing that we have to do is to impose conditions on C that imply that the function $t \mapsto \int_{-\infty}^{t_0} \|C(t, s)\|\, ds$ has a uniformly bounded L^p-norm in the right L^p-space, so that the appropriate theorem applies. In particular, if we want to apply one of the results where $f \in L^1([t_0, \infty); \mathbf{R}^n)$, then it suffices to require that

$$\sup_{t_0 \in \mathbf{R}} \int_{t_0}^{\infty} \int_{-\infty}^{t_0} \|C(t, s)\|\, ds\, dt < \infty. \tag{8.5}$$

This is a very common condition (with the lower bound $-\infty$ replaced by 0) for uniform stability in [2]-[16]. The analogous condition for Theorem 5.1(ii) is

$$\sup_{t_0\in\mathbf{R}}\int_{t_0}^{\infty}(1+p(t))^{-1}\left[\int_{-\infty}^{t_0}\|C(t,s)\|\,ds\right]^2 dt<\infty. \tag{8.6}$$

For Theorem 4.2(ii) no special new condition is needed, because

$$(1+p(t))^{-1}\int_{-\infty}^{t_0}\|C(t,s)\|\,ds\leqq(1+p(t))^{-1}\int_{-\infty}^{t}\|C(t,s)\|\,ds$$

for $t\geqq t_0$.

The comments made above, together with Theorems 3.1(i), 4.2(i), 4.2(ii), 5.1(i), and 5.1(ii) prove the following theorem on uniform asymptotic stability in Burton's sense.

THEOREM 8.1. *Each of the following conditions imply that* (8.2) *is uniformly stable*:

(i) *Condition* (8.5) *holds, and* $\int_s^{\infty}\|C(t,s)\|_B\,dt\leqq p(s)/2\beta$ *for almost all* $s\in\mathbf{R}$, *or* $\int_s^{\infty}\|\sqrt{B}\,C(t,s)\|\,dt\leqq q(s)/2\sqrt{\beta}$ *for almost all* $s\in\mathbf{R}$.

(ii) *Condition* (8.5) *holds, and there is some* $\kappa>0$ *such that*

$$\frac{\kappa}{2}\int_{-\infty}^{t}\|C(t,u)\|_B\,du+\frac{1}{2\kappa}\int_{t}^{\infty}\|C(v,t)\|_B\,dv\leqq\frac{p(t)}{2\beta}$$

for almost all $t\in\mathbf{R}$, *or*

$$\frac{\kappa}{2}\int_{-\infty}^{t}\|BC(t,u)\|\,du+\frac{1}{2\kappa}\int_{t}^{\infty}\|BC(v,t)\|\,dv\leqq\frac{r(t)}{2}$$

for almost all $t\in\mathbf{R}$.

(iii) *Condition* (8.5) *holds, and* $\int_{-\infty}^{t}\|C(t,s)\|_B\,ds\leqq p(t)/2\beta$ *for almost all* $t\in\mathbf{R}$.

(iv) *Condition* (8.6) *holds, and there are constants* $\kappa>0$ *and* $\varepsilon\in(0,1/2\beta)$ *such that*

$$\frac{\kappa}{2}\int_{-\infty}^{t}\|C(t,u)_B\,du+\frac{1}{2\kappa}\int_{t}^{\infty}\|C(v,t)\|_B\,dv\leqq\frac{p(t)}{2\beta}-\varepsilon(1+p(t))$$

for almost all $t\in\mathbf{R}$, *or*

$$\frac{\kappa}{2}\int_{-\infty}^{t}\|BC(t,u)\|\,du+\frac{1}{2\kappa}\int_{t}^{\infty}\|BC(v,t)\|\,dv\leqq\frac{r(t)}{2}-\varepsilon(1+p(t))$$

for almost all $t\in\mathbf{R}$.

(v) $\int_{-\infty}^{t}\|C(t,s)\|_B\,ds\leqq p(t)/2\beta-\varepsilon(1+p(t))$ *for some constant* $\varepsilon\in(0,1/2\beta)$ *and almost all* $t\in\mathbf{R}$.

We leave it to the reader to formulate similar results based on the remaining theorems in §§ 3-6.

The question of uniform asymptotic stability is more delicate, and concrete results on uniform asymptotic stability are scarce in [2]-[17] (here the word "concrete" refers to results that have been applied to (2.6) or (6.2)). Moreover, it is not clear to what extent this property implies that the operator $\mathcal{R}$ induced by the resolvent R (cf. § 7) maps various spaces of functions into themselves, as it does for ordinary differential equations. The convolution case in an exception; see § 8.

The main result in [10] on the uniform asymptotic stability of (2.6) (in the case when (2.6) is not a convolution equation) seems to be [10, Thm. 2.5.1(d), p. 39]. That theorem is closely related to our Theorem 3.1, so it is to be expected that one should be able to prove a version of Theorem 3.1 where one has a uniform rate of convergence to zero. This is indeed the case.

First, let us prove an auxiliary lemma.

LEMMA 8.2. *Let* $x \in L^1([t_0, \infty); \mathbf{R}^n)$, *and* $x' \in L^1([t_0, \infty); \mathbf{R}^n)$. *For each* $\varepsilon > 0$, *define* $S(\varepsilon) = 2\|x\|_{L^1(t_0,\infty)}/\varepsilon$ *and* $N(\varepsilon) = 2\|x'\|_{L^1(t_0,\infty)}/\varepsilon + 1$. *Then, for every* $T \geqq S(\varepsilon)$, *the interval* $[t_0, t_0 + N(\varepsilon)T]$ *contains at least one subinterval of length* T *on which* $|x(t)| \leqq \varepsilon$.

The proof given below has been adopted from [10, pp. 40–41].

Proof. Clearly, each interval of length T contains at least one point t_1 where $|x(t_1)| \leqq \frac{1}{2}\varepsilon$ (otherwise the L^1-norm of x over this interval is too big). If it also contains a point t_2 where $|x(t_2)| \geqq \varepsilon$, then the integral of $|x'|$ over this interval is at least $\frac{1}{2}\varepsilon$. Because of the bound that we have on the L^1-norm of x', there can be at most $2/\varepsilon\|x'\|_{L^1(t,\infty)}$ (rounded upwards to the nearest integer) intervals of this type, containing points of both the types t_1 and t_2. From this the conclusion follows. □

Suppose that (8.5) holds, and that the assumption on C in Theorem 3.1(ii) is satisfied, with a constant ε independent of t_0. Let x be the solution of (8.2). Then, from Theorem 3.1(ii) we get a bound of the form

$$\sup_{t \geqq t_0} |x(t)| + \|x\|_{L^1(t_0,\infty)} + \|x'\|_{L^1(t_0,\infty)} \leqq M(|\varphi(t_0)| + \|f_{t_0,\varphi}\|_{L^1(t_0,\infty)}), \tag{8.7}$$

where the constant M is independent of t_0 and φ. But (8.4) and (8.5) imply that

$$\|f_{t_0,\varphi}\|_{L^1(t_0,\infty)} \leqq K \sup_{s \leqq t_0} |\varphi(s)|, \tag{8.8}$$

where K is the supremum on the left-hand side of (8.5). Therefore,

$$\sup_{t \geqq t_0} |x(t)| + \|x\|_{L^1(t_0,\infty)} + \|x'\|_{L^1(t_0,\infty)} \leqq M(1+K) \sup_{s \leqq t_0} |\varphi(s)|. \tag{8.9}$$

By (8.9) and Lemma 8.2 (with ε replaced by $\varepsilon M(1+K)\sup_{s\leqq t_0}|\varphi(s)|$), for every $\varepsilon > 0$ and every $T \geqq 2/\varepsilon$, we can within the interval $[t_0, t_0 + (2/\varepsilon + 1)T]$ find a subinterval of length T on which $|x(t)| \leqq \varepsilon M(1+K)\sup_{s\leqq t_0}|\varphi(s)|$. If we want this fact to imply that (8.2) is uniformly asymptotically stable, then we need the following property of the function $f_{t_0,\varphi}$:

(8.10) There exists a constant K and a function $V(\varepsilon)$ such that for all $\varepsilon > 0$, all $t_0 \in \mathbf{R}$, and all bounded φ, it is true that $\|f_{t_0,\varphi}\|_{L^1(t_0,\infty)} \leqq K(\sup_{t_0 - V(\varepsilon) \leqq s \leqq t_0} |\varphi(s)| + \varepsilon \sup_{s \leqq t_0 - V(\varepsilon)} |\varphi(s)|)$.

When this property is satisfied, we get uniform asymptotic stability by the following argument: Fix some $\varepsilon > 0$. Define $T = \max\{2/\varepsilon, V(\varepsilon)\}$. Let t_1 be the right end point of the interval referred to above where $|x(t)| \leqq \varepsilon M(1+K)\sup_{s\leqq t_0}|\varphi(s)|$. Then $t_1 - t_0 \leqq (2/\varepsilon + 1)T$ (so we get an upper bound on $t_1 - t_0$ that depends on ε, but is independent of t_0 and φ). For $t \in [t_0, t_1]$, define $\varphi(t) = x(t)$. Then $\sup_{s\leqq t_1 - V(\varepsilon)}|\varphi(s)\| \leqq M(1+K)\sup_{s\leqq t_0}|\varphi(s)|$ and $\sup_{t_1 - V(\varepsilon) \leqq s \leqq t_1}|\varphi(s)| \leqq \varepsilon M(1+K)\sup_{s\leqq t_0}|\varphi(s)|$. Therefore, by (8.10), we have $\|f_{t,\varphi}\|_{L^1(t_1,\infty)} \leqq 2\varepsilon MK(1+K)\sup_{s\leqq t_0}|\varphi(s)|$. However, by (8.7), this means that for $t \geqq t_1$, we have $|x(t)| \leqq \varepsilon M^2(1+K)(2+K)\sup_{s\leqq t_0}|\varphi(s)|$. Thus, the solution tends to zero with a convergence rate that is independent of t_0. (The reader who prefers to end up with a clean result should divide ε by $M^2(1+K)(2+K)$ at the beginning.)

It only remains to transfer (8.10) into an assumption on C. By (8.3),

$$|f_{t_0,\varphi}| \leqq \left(\int_{-\infty}^{t_0 - V(\varepsilon)} \|C(t,s)\|\, ds\right) \sup_{s \leqq t_0 - V(\varepsilon)} |\varphi(s)| + \left(\int_{t_0 - V(\varepsilon)}^{t_0} \|C(t,s)\|\, ds\right) \sup_{t_0 - V(\varepsilon) \leqq s \leqq t_0} |\varphi(s)|$$

and therefore, it suffices to assume, in addition to (8.5), that

$$\lim_{T\to\infty}\sup_{t_0\in\mathbf{R}}\int_{t_0}^{\infty}\int_{-\infty}^{t_0-T}\|C(t,s)\|\,ds\,dt=0. \tag{8.11}$$

(This is the same condition which Burton uses in [10, Thm. 2.5.1(d)]. It says that the kernel "forgets" old values of the function φ with a uniform rate in a certain sense.)

The argument above proves the following theorem.

THEOREM 8.3. *Let* (8.5) *and* (8.11) *hold. In addition, suppose that for some constant* $\varepsilon\in(0,1/2\beta)$, *it is true that* $\int_s^{\infty}\|C(t,s)\|_B\,dt\leqq p(s)/2\beta-\varepsilon(1+p(s))$ *for almost all* $s\in\mathbf{R}$, *or that* $\int_s^{\infty}\|\sqrt{B}\,C(t,s)\|\,dt\leqq q(s)/2\sqrt{\beta}-\varepsilon(1+p(s))$ *for almost all* $s\in\mathbf{R}$. *Then* (8.2) *is uniformly asymptotically stable on* $\mathbf{R}$.

The same argument, but with Theorem 3.1(ii) replaced by Theorem 5.1(ii), gives the following result.

THEOREM 8.4. *Suppose that there are constants* $\kappa>0$ *and* $\varepsilon\in(0,1/2\beta)$ *such that*

$$\frac{\kappa}{2}\int_{-\infty}^{t}\|C(t,u)\|_B\,du+\frac{1}{2\kappa}\int_{t}^{\infty}\|C(v,t)\|_B\,dv\leqq\frac{p(t)}{2\beta}-\varepsilon(1+p(t))$$

for almost all $t\in\mathbf{R}$, *or*

$$\frac{\kappa}{2}\int_{-\infty}^{t}\|BC(t,u)\|\,du+\frac{1}{2\kappa}\int_{t}^{\infty}\|BC(v,t)\|\,dv\leqq\frac{r(t)}{2}-\varepsilon(1+p(t))$$

for almost all $t\in\mathbf{R}$. *In addition, suppose that* (8.6) *holds, and that*

$$\lim_{T\to\infty}\sup_{t_0\in\mathbf{R}}\int_{t_0}^{\infty}(1+p(t))^{-1}\left[\int_{-\infty}^{t_0-T}\|C(t,s)\|\,ds\right]^2dt=0. \tag{8.12}$$

Then (8.2) *is uniformly asymptotically stable on* $\mathbf{R}$.

(To prove this theorem, argue as in the proof of Theorem 8.3, but apply Lemma 8.2 to the function $|x|^2$ instead of to the function x.)

This result seems to be new.

The analogue of (8.11) and (8.12) for Theorem 4.2(ii) would be

$$\lim_{T\to\infty}\sup_{t_0\in\mathbf{R}}\operatorname*{ess\,sup}_{t\geqq t_0}(1+p(t))^{-1}\int_{-\infty}^{t_0-T}\|C(t,s)\|\,ds=0.$$

However, this condition is not enough for uniform asymptotic stability, because Lemma 8.2 no longer applies. It is an interesting open problem, under what conditions one gets uniform asymptotic stability in Theorem 4.2.

9. Convolution equations. In our preceding discussions we have ignored all the available Lyapunov results for convolution equations. The convolution versions of (2.6) and (7.1) are

$$x'(t)+Ax(t)=\int_0^t C(t-s)x(s)\,ds+f(t),\quad t\geqq 0,\quad x(0)=x_0 \tag{9.1}$$

and

$$\begin{aligned}&R'(t)+A(t)R(t)=\int_0^t C(t-s)R(s)\,du, && t\geqq 0,\\ &R'(t)+R(t)A(t)=\int_0^t R(t-s)C(s)\,du, && t\geqq 0,\\ &R(0)=I.\end{aligned} \tag{9.2}$$

For linear convolution equations all significant stability properties can be related to one of the three conditions:

(1) The differential resolvent R is bounded;

(2) The differential resolvent R tend to zero at infinity;

(3) The differential resolvent R is integrable.

Especially the third condition is of fundamental importance; it is equivalent both to uniform stability and to uniform asymptotic stability. A necessary and sufficient condition is known for R to be integrable in the case where $C \in L^1(\mathbf{R}^+; \mathbf{R}^{n\times n})$: The Laplace transform $\hat{C}$ of C must satsify $\det(zI + A - \hat{C}(z)) \neq 0$ for $\Re z \geqq 0$ (see [24, Thm. 3.5, p. 558] for the scalar case). The same Laplace transform condition is necessary and sufficient for the integrability of the differential resolvent also, e.g., in the cases where $\hat{C}(0) = \lim_{t\to\infty} \int_0^t C(s)\,ds$ exists, and $\int_0^\infty \| \int_0^t C(s)\,ds - \hat{C}(0)\|\,dt < \infty$, and where C is of bounded variation and $C(\infty)$ is invertible (this follows from [30, Prop. 2.3, p. 755]). A similar result is true for the convolution version of (6.2), namely

$$\frac{d}{dt}\left(x(t) + \int_0^t G(t-s)x(s)\,ds + g(t)\right) + Ax(t) = \int_0^t C(t-s)x(s)\,ds + f(t), \tag{9.3}$$
$$t \geqq 0, \quad x(0) = x_0.$$

These results are quite powerful, and they supersede the Lyapunov theory for these classes of equations in the sense that in all the cases where one has used Lyapunov methods to prove uniform stability or uniform asymptotic stability, it is possible to check that the Laplace transform condition is satisfied. This applies, in particular, to [4, Cor., p. 396], [8, Thm. 6, p. 284], [11, Prop., p. 242], [16, Thm. 1, p. 145], [16, Thm. 2, p. 146], [16, Thm. 3′, p. 152], [16, Thm. 4′, p. 152], [16, Thm. 5, p. 153], [16, Cor. 3, p. 158], [16, Thm. 10, p. 159], [16, Thm. 11, p. 161], [16, Thm. 12, p. 162], [17, Thm. 4, p. 498], and [17, Thm. 9, p. 511].

(To show that the Laplace transform condition is satisfied in the convolution versions of Theorems 3.1(ii), 4.2(ii), 5.1(ii), and 5.3(ii), we can use the following simple observation: Define $\Delta(z) = zI + A - \hat{C}(z)$. If $\det \Delta(z_0) = 0$ for some z_0 with $\Re z_0 \geqq 0$, then there is some nonzero $w \in \mathbf{C}^n$ for which $\Delta(z_0)w = 0$; hence $\langle w, B\Delta(z_0)w\rangle = 0$. Thus, to prove that $\det \Delta(z) \neq 0$ for $\Re z \geqq 0$, it certainly suffices to show that for all nonzero $w \in \mathbf{R}^n$, we have $\Re\langle w, B\Delta(z)w\rangle > 0$ for $\Re z \geqq 0$. If we denote $A^TB + BA$ by R, then this is equivalent to showing that $|w|_B^2 \Re z + \frac{1}{2}\langle w, Rw\rangle > \Re\langle w, B\hat{C}(z)w\rangle$ for all nonzero $w \in \mathbf{C}^n$ and all $z \in \mathbf{C}$ with $\Re z \geqq 0$. In particular, it suffices to show that $|w|_B^2 \Re z + \frac{1}{2}\langle w, Rw\rangle > \int_0^\infty |\langle w, BC(t)w\rangle|\,dt$, because $\Re\langle w, B\hat{C}(z)w\rangle \leqq |\langle w, B\hat{C}(z)w\rangle| \leqq \int_0^\infty |\langle w, BC(t)w\rangle|\,dt$ for such w and z.)

Results on specific decay rates of linear convolution equations are available through Laplace transform methods as well, see e.g. [30] and [37, Thm. 3, p. 318] (some special cases of this theorem were proved independently in [14, Thm. 4, p. 660] and [14, Thm. 5, p. 661]).

Another class of equations which we have ignored above is the class of nonlinear equations of the type

$$x'(t) + AG(x(t)) = \int_0^t C(t-s)G(x(s))\,ds + f(t), \quad t \geqq 0, \quad x(0) = x_0, \tag{9.4}$$

with a kernel of positive type. The traditional approach is to study these equations by means of Lyapunov methods (see Levin's classical papers [31] and [32]), but for this

class of equations the Lyapunov method has been superseded by the energy method (see, e.g., [38], [39], and [40]).

The question of specific decay rates for solutions of a scalar version of (9.4) have been studied in [42]. The proofs given there are based on an L^2-technique. Similar results are proved in [14] with a Lyapunov technique.

RIEMANN FUNCTION OF HARMONIC EQUATION AND APPELL'S F_4*

KATSUNORI IWASAKI†

Abstract. In this paper we calculate the Riemann function of Darboux's Harmonic equation (H). The Riemann function of (H) admits an action of a certain finite group, which permits us to reduce (H) to the system of Appell's F_4. Then, by using Takano's integral representation for F_4, we solve a connection problem to find a representation of R in terms of the Appell's hypergeometric function. We also discuss the symmetry algebras for classical and typical hyperbolic partial differential equations.

Key words. Riemann function, Harmonic equation, Euler-Poisson-Darboux equation, Appell's F_4, symmetry algebra, integral representation, connection problem

1. Introduction. In general, the solution space of a linear partial differential equation is not finite-dimensional. However, it can have a "fundamental solution" represented in terms of a solution of an ordinary differential equation or a system of partial differential equations with finite-dimensional solution space. In a sense, such a partial differential equation may be considered as one of good nature.

A few examples are the Euler-Poisson-Darboux (EPD), Confluent Euler-Poisson-Darboux (CEPD) and Telegraphic (TEL) equations:

$$\text{(EPD)} \qquad \{(x-y)(\partial^2/\partial x\partial y)+a(\partial/\partial x)-b(\partial/\partial y)\}u=0,$$

$$\text{(CEPD)} \qquad \{x(\partial^2/\partial x\partial y)+(\partial/\partial x)-b(\partial/\partial y)\}u=0,$$

$$\text{(TEL)} \qquad \{(\partial^2/\partial x\partial y)-1\}u=0,$$

where a and b are complex numbers. In a special case where $a=b=0$, (EPD) reduces to the Wave equation (W). Equation (CEPD) is obtained from (EPD) by a confluent procedure, and (TEL) from (CEPD). It is known as Appell's theorem (Darboux [2], Miller [7]) that the Lie group $SL_2(\mathbb{C})$ acts on the solution space of (EPD) by

$$u(x,y)\mapsto(\gamma x+\delta)^a(\gamma y+\delta)^b u\left(\frac{\alpha x+\beta}{\gamma x+\delta},\frac{\alpha y+\beta}{\gamma y+\delta}\right), \qquad \begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix}\in SL(2,\mathbb{C}).$$

By using this fact, we can show that a fundamental solution (the Riemann function) of (EPD) can be represented in terms of the Gauss' hypergeometric function (see Darboux [2], and, in a special case where $a=b$, see Iwanami Sûgaku Ziten [4]). Then, by a confluence, the Riemann functions of (CEPD) and (TEL) turn out to be represented in terms of the confluent hypergeometric function and the Bessel function, respectively. We note that (CEPD) and (TEL) also admit actions of certain Lie groups, which are alternatively used for a determination of their Riemann functions. These examples show that a situation in which a Lie group (or a Lie algebra) acts on the solution space of a differential equation is very important.

We consider a partial differential equation of the form

$$(1) \qquad Du=\{a(\partial^2/\partial x\partial y)+b(\partial/\partial x)+c(\partial/\partial y)+d\}u=0,$$

a, b, c, d: functions of x and y,

which contains the above examples as special cases. For the reason mentioned above, the symmetry algebra of (1) (see Miller [6], [7]) may give us some information about its Riemann function. If (1) contains parameters, then the parameter changing symmetry algebra (Miller [7]) may also be useful. In fact, we will prove (Theorem 1) that, if the dimension of the *reduced* symmetry algebra (see § 2 for definition) is bigger than one, then (1) is essentially equivalent to either (EPD), (CEPD), or (TEL). Hence the former algebra is useless for all equations except for the above three examples.

In this paper, we shall consider another example

$$\text{(H)} \qquad L_{(x,y)}u = \left\{\frac{\partial^2}{\partial x \partial y} + \frac{a(a-1)}{(x-y)^2} - \frac{b(b-1)}{(x+y)^2}\right\}u = 0, \qquad a, b \in \mathbb{C},$$

which is called *équations harmoniques* by Darboux [2]. The symmetry algebra of (H) is trivial and not very useful, but its parameter changing symmetry algebra becomes $sl_4(\mathbb{C})$, (§ 2), which will reveal a relation between the Riemann function of (H) and Appell's F_4. In this paper, however, we take another approach. We find that a finite group isomorphic to $\mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_2$ acting on its Riemann function permits us to reduce (H) to Appell's system (F_4) (§§ 4–6). Then, by using an integral representation for F_4 obtained by Takano [10], we solve a connection problem to find a representation of the Riemann function in terms of Appell's hypergeometric function F_4 (§§ 7–10). A final result is given in Theorem 20 (§ 11).

We note that (H) arises from the complex wave equation $v_{tt} - \Delta_3 v = 0$ in four-dimensional space time, which has $sl_4(\mathbb{C})$-symmetry, by separating two angular coordinates. The parameters a and b of (H) are simply separation constants. Hence we can also examine (H) from the point of view of Kalnins and Miller [8].

Recall that the Riemann function $R(x, y; \xi, \eta)$ of (H) is a function of four variables satisfying the condition

$$LR = 0 \qquad \text{(as a function of } x \text{ and } y\text{)}, \tag{2}$$

$$(x-\xi)(y-\eta) = 0 \text{ implies } R = 1. \tag{3}$$

In this paper, we use the notation $\partial_x = \partial/\partial x$, $\delta_x = x(\partial/\partial x)$, etc.

2. Symmetry algebra. Following Miller [6], we define the *symmetry algebra* $\mathcal{S}$ of (1) by a Lie algebra of operators S of the form

$$S = \varphi \partial_x + \phi \partial_y + \psi, \qquad \varphi, \phi, \psi: \text{ functions of } x \text{ and } y,$$

$$[D, S] \equiv 0 \pmod{D}.$$

The Lie algebra $\mathcal{S}$ contains a trivial ideal $\mathbb{C}$. We call the quotient algebra $\mathcal{S}/\mathbb{C}$ the *reduced symmetry algebra* and denote it by $\hat{\mathcal{S}}$. If (1) has polynomial coefficients, then, from a practical point of view, it is convenient to restrict symmetry operators S to those for which φ, ϕ and ψ are polynomials. Thus we define the (reduced) polynomial symmetry algebra $\mathcal{S}_{pol}$ ($\hat{\mathcal{S}}_{pol}$) in a similar manner. For the above examples, the symmetry algebras are given, respectively, by (Miller [7], Okamoto [9])

$$\hat{\mathcal{S}}_{pol} = \{H, X, Y, 1\} \quad \text{(generators)},$$

where

$$\text{(EPD)} \qquad \begin{array}{lll} H = -2\delta_x - 2\delta_y - a - b, & [X, Y] = H, & \\ X = -\delta_x - \delta_y, & [H, X] = 2X, & \mathcal{S}_{pol} = sl_2(\mathbb{C}) \oplus \mathbb{C}, \\ Y = x\delta_x + y\delta_y + bx + ay, & [H, Y] = -2Y, & \hat{\mathcal{S}}_{pol} = sl_2(\mathbb{C}), \end{array}$$

$$\text{(CEPD)}\quad \begin{aligned} &H=-2\delta_x-2\delta_y, && [X,Y]=-1, && \mathcal{S}_{pol}=T_3\vec{\oplus}\mathbb{C},\\ &X=\partial_y, && [H,X]=2X, && \hat{\mathcal{S}}_{pol}=T_3,\\ &Y=x\delta_x-bx-y, && [H,Y]=-2Y, \end{aligned}$$

$$\text{(TEL)}\quad \begin{aligned} &H=-2\delta_x+2\delta_y, && [X,Y]=0, && \mathcal{S}_{pol}=T_3\oplus\mathbb{C},\\ &X=\partial_x, && [H,X]=2X, && \hat{\mathcal{S}}_{pol}=T_3,\\ &Y=\partial_y, && [H,Y]=-2Y, \end{aligned}$$

$$\text{(W)}\qquad \mathcal{S}=\mathcal{W}_x\oplus\mathcal{W}_y\oplus\mathbb{C},\qquad \hat{\mathcal{S}}=\mathcal{W}_x\oplus\mathcal{W}_y,$$

where $\oplus$ denotes the direct sum of Lie algebras, and $T_3\vec{\oplus}\mathbb{C}$ stands for a nontrivial central extension of T_3 by $\mathbb{C}$. Moreover, $\mathcal{W}_x$ is the Lie algebra of all functions in one variable x with Lie bracket $[f,g]=f(\partial_x g)-(\partial_x f)g$, the Wronskian of f and $g\in\mathcal{W}$.

THEOREM 1. *If the dimension of the reduced symmetry algebra $\hat{\mathcal{S}}$ is bigger than one, then* (1) *is equivalent to one of* (EPD), (CEPD), *or* (TEL) *up to transformations of independent variables $(x,y)\mapsto(X,Y)$ and those of dependent variable $u\mapsto U$ of the form*:

$$X=f(x),\quad Y=g(y),\quad U=h(x,y)u,$$

f, g, h: functions of x, y and (x,y), respectively.

We omit a proof of this theorem. Okamoto [9] independently showed a similar result in a different situation. Only we point out that there is an injective homomorphism from $\hat{\mathcal{S}}$ to $\mathcal{W}_x\oplus\mathcal{W}_y$

$$\hat{\mathcal{S}}\ni S\ (\mathrm{mod}\ \mathbb{C})\mapsto(\varphi,\phi)\in\mathcal{W}_x\oplus\mathcal{W}_y,$$

and that (1) admits an infinite-dimensional symmetry algebra only if (1) = (W). Therefore, in view of Lemma 2 below, nontrivial symmetry algebras that can act on (1) are very restricted, where we say "nontrivial" if $\dim\hat{\mathcal{S}}>1$ and "trivial" if $\dim\hat{\mathcal{S}}\leqq 1$.

LEMMA 2. *Finite-dimensional subalgebra of $\mathcal{W}$ is one-, two-, or three-dimensional and, in the latter two cases, it is noncommutative. Hence there are just three cases up to isomorphisms of Lie algebra.*

A proof of this lemma will be given in the Appendix (§ 12).

From now on, we consider the (polynomial) symmetry algebra $\mathcal{S}_{pol}$ for $D=(x-y)^2(x+y)^2L$, which we call the symmetry algebra of (H). We separate (H) to a *special case* and a *generic case* according to whether $a(a-1)$ is equal to $b(b-1)$ or not. Compared with those of (EPD), (CEPD), and (TEL), the symmetry algebra of (H) is trivial in a generic case. In a special case it is of some interest, but then (H) is essentially reduced to (EPD).

PROPOSITION 3. (i) *In a generic case, $\mathcal{S}_{pol}$ has a single generator $\delta_x+\delta_y$.*

(ii) *In a special case, $\mathcal{S}_{pol}$ is generated by $\delta_x+\delta_y$ and $x^2\delta_x+y^2\delta_y$.*

In fact, in a generic case, we can show that $\mathcal{S}=\mathcal{S}_{pol}$. In view of Theorem 1 and Proposition 3 (ii), in a special case (H) can be reduced to one of (EPD), (CEPD), or (TEL). Indeed, we have the following.

PROPOSITION 4. *In a special case, the substitution $X=x^2$, $Y=y^2$ converts* (H) *to*

$$\text{(SEPD)}\qquad \{(\partial^2/\partial X\partial Y)+a(a-1)/(X-Y)^2\}u=0\quad (\textit{special}\ \text{EPD}).$$

Moreover, the substitution $u=(X-Y)^a v$ reduces (SEPD) *to* (EPD) *with $a=b$. The fractional linear (Möbius) transformation group* Möb *acts on* (SEPD) *by*

$$u(X,Y)\mapsto u(AX,AY),\qquad A\in\text{Möb}. \tag{4}$$

We shall here refer to the parameter changing symmetry algebra $\mathcal{T}$ of (H). It is a Lie algebra of operators T of the form

$$T = \varphi\partial_x + \phi\partial_y + \xi\partial_s + \eta\partial_t + \psi, \qquad [L', T] \equiv 0 \pmod{L'},$$

where L' is an operator defined by

$$L' = (x+y)^2(x-y)^2\partial_x\partial_y + (x+y)^2\delta_s(\delta_s - 1) - (x-y)^2\delta_t(\delta_t - 1).$$

Miller [7] found that the parameter changing symmetry algebra of (EPD) becomes $sl_4(\mathbb{C})$. In a similar manner, we find that $\mathcal{T} \simeq sl_4(\mathbb{C})$. In fact, (H) arises from the complex wave equation

$$(\partial_t^2 - \partial_x^2 - \partial_y^2 - \partial_z^2)v = 0 \tag{4W}$$

in four-dimensional space time, by separating off two angular coordinates. Equation (EPD) also arises from this equation by another separation of variables. The symmetry algebra of (4W) is $o_6(\mathbb{C}) \simeq sl_4(\mathbb{C})$ (Miller [6]), which leads to the parameter changing symmetry algebras of (EPD) and (H). The algebra $\mathcal{T}$ will reveal a relationship between the Riemann function of (H) and Appell's F_4. In this paper, however, we shall not investigate this problem further.

3. Riemann function in a special case. Denote the Riemann function of (SEPD) (or equally of (EPD) with $a = b$) by $\hat{R}(X, Y; \Xi, \mathrm{H})$; then $R(x, y; \xi, \eta) = \hat{R}(x^2, y^2; \xi^2, \eta^2)$. Although $\hat{R}$ is already known ([2], [4]), we now give another simple calculation. We have a fibration

$$\begin{array}{ccc} \text{Möb} & \longrightarrow & \mathbb{C}^4 \\ & & \Big\downarrow \pi\text{: cross-ratio}, \qquad \dim \text{Möb} = 3, \\ & & \mathbb{C}^1 \end{array}$$

where the action of $A \in$ Möb on $\mathbb{C}^4$ is defined by $(X, Y, \Xi, \mathrm{H}) \mapsto (AX, AY, A\Xi, A\mathrm{H})$ and π is a cross-ratio

$$\pi(X, Y, \Xi, \mathrm{H}) = (X - \Xi)(Y - \mathrm{H})/(X - Y)(\Xi - \mathrm{H}).$$

On the other hand, (2), (3), and (4) show that

$$\hat{R}(X, Y; \Xi, \mathrm{H}) = \hat{R}(AX, AY; A\Xi, A\mathrm{H}), \qquad A \in \ddot{\text{Mob}},$$

so that the fibration implies that $\hat{R}$ is only a function of $s = \pi(X, Y, \Xi, \mathrm{H})$. Rewriting (SEPD) as an ordinary differential equation of an independent variable s, we find that $\hat{R}$ satisfies

$$\{s(1-s)\partial_s^2 + (\gamma - (1 + \alpha + \beta)s)\partial_s - \alpha\beta\}\hat{R} = 0, \tag{HG}$$

with $\alpha = a$, $\beta = 1 - a$, $\gamma = 1$. With this specialization of parameters, (HG) is transformed to the Legendre equation of an independent variable $t = 2s + 1$. It is interesting that (SEPD) is related to the Bessel equation on one hand and to the Legendre equation on the other hand. The condition (3) is now restated that $s = 0$ implies $\hat{R} = 1$. Hence we have the following.

THEOREM 5. *In a special case, the Riemann function of* (H) *is given by*

$$R(x, y; \xi, \eta) = F(a, 1 - a, 1; (x^2 - \xi^2)(y^2 - \eta^2)/(x^2 - y^2)(\xi^2 - \eta^2)),$$

where $F(\alpha, \beta, \gamma; s)$ *is the Gauss hypergeometric function.*

4. Group acting on the Riemann function. We turn to a generic case. The following transformations of independent variables act on the solution space of (H):

(A) $(x, y)\mapsto(\lambda x, \lambda y)$, $\lambda\in\mathbb{C}^\times$,

(B) $(x, y)\mapsto(1/x, 1/y)$,

(C) $(x, y)\mapsto(y, x)$.

(A) is a transformation corresponding to an infinitesimal one $\delta_x+\delta_y$.

The Riemann function R is invariant under the transformations of the independent variables (x, y, ξ, η) of the form

(a) $(x, y, \xi, \eta)\mapsto(\lambda x, \lambda y, \lambda\xi, \lambda\eta)$, $\lambda\in\mathbb{C}^\times$,

(b) $(x, y, \xi, \eta)\mapsto(1/x, 1/y, 1/\xi, 1/\eta)$,

(c) $(x, y, \xi, \eta)\mapsto(y, x, \eta, \xi)$,

(d) $(x, y, \xi, \eta)\mapsto(\xi, \eta, x, y)$.

Among these, (a), (b), and (c) are obtained by applying (A), (B), and (C) to (2)-(3) respectively, and (d) follows from formal self-adjointness of the operator L. By putting

$$X=x/\eta,\quad Y=y/\eta,\quad Z=\xi/\eta,$$

we can regard R as a function of X, Y, and Z because of its invariance by (a). Thus the transformations of (X, Y, Z) induced by (b), (c), and (d) are given, respectively, by

$$(X, Y, Z)\mapsto(1/X, 1/Y, 1/Z),$$

$$(X, Y, Z)\mapsto(Y/Z, X/Z, 1/Z),$$

$$(X, Y, Z)\mapsto(Z/Y, 1/Y, X/Y).$$

The group G generated by these transformations has more symmetrical generators

$$X^*:\quad (X, Y, Z)\mapsto(X, X/Z, X/Y),$$

$$Y^*:\quad (X, Y, Z)\mapsto(Y/Z, Y, Y/X),$$

$$Z^*:\quad (X, Y, Z)\mapsto(Z/Y, Z/X, Z).$$

As is easily seen, X^*, Y^*, and Z^* are involutions and commutative with each other. Hence the group $G=\langle X^*, Y^*, Z^*\rangle$ is

$$G\simeq\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2,\qquad |G|=8.$$

PROPOSITION 6. *The Riemann function R is a function of (X, Y, Z) and invariant under the action of G. Equations* (2)-(3) *are rewritten as*

$$L_{(X,Y)}R=0 \tag{5}$$

$$(X-Z)(Y-1)=0\quad \textit{implies } R=1. \tag{6}$$

5. Extension of a field. Consider an extension of a field $\mathbf{K}/\mathbf{k}$

$$\mathbf{K}=\mathbb{C}(X, Y, Z),$$

$$\mathbf{k}=\{f\in\mathbf{K};\ f \text{ is } G\text{-invariant}\},$$

where the action of G on $\mathbf{K}$ is one induced by the action of G on the independent variables. Then the degree of extension is given by

$$[\mathbf{K}:\mathbf{k}]=|G|=8. \tag{7}$$

With this fact in mind, we seek generators of $\mathbf{k}$ over $\mathbb{C}$. For a systematization, we denote

$$X_1=X,\quad X_2=Y,\quad X_3=Z.$$

Consider the following expressions:

$$\begin{aligned} p_i &= X_i + 1/X_i + X_k/X_j + X_j/X_k, \\ q_i &= X_i/(X_jX_k) + (X_jX_k)/X_i + 2, \end{aligned} \qquad (i = 1, 2, 3) \tag{8}$$

where (i, j, k) runs over all permutations of $(1, 2, 3)$. As is easily seen,

$$p_i, q_i \in \mathbf{k} \qquad (i = 1, 2, 3). \tag{9}$$

THEOREM 7. *For any permutation* (i, j, k) *of* $(1, 2, 3)$,

$$\mathbf{k} = \mathbb{C}(p_i, p_j, q_k).$$

Proof. Denote $\mathbf{k}' = \mathbb{C}(p_i, p_j, q_k)$. Then (9) implies $\mathbf{k}' \subset \mathbf{k}$. Hence, by (7), it suffices to show that $[\mathbf{K}:\mathbf{k}'] \leqq 8$. Putting $\theta = X_k/(X_iX_j)$, we obtain from (8),

$$\theta^2 + (2 - q_k)\theta + 1 = 0,$$

$$(1+\theta)\theta X_\nu^2 - (\theta p_\nu)X_\nu + (\theta + 1) = 0 \qquad (\nu = i, j).$$

Therefore θ, X_i and X_j are at most of degree two over $\mathbf{k}'$, $\mathbf{k}'(\theta)$ and $\mathbf{k}'(\theta, X_i)$, respectively. Hence $\mathbf{k}'(\theta, X_i, X_j) = \mathbf{k}'(X_i, X_j, X_k) = \mathbf{K}$ is at most of degree eight over $\mathbf{k}'$, namely, $[\mathbf{K}:\mathbf{k}'] \leqq 8$. □

In addition to p_i and q_i $(i = 1, 2, 3)$ defined in (8), we consider the following elements of $\mathbf{K}$:

$$\begin{aligned} r_{ij} &= X_i - 1/X_i + X_k/X_j - X_j/X_k, \\ s_i &= X_i + 1/X_i - X_k/X_j - X_j/X_k, \\ t_i &= -X_i/(X_jX_k) + (X_jX_k)/X_i. \end{aligned} \tag{10}$$

Again (i, j, k) runs over all permutations of $(1, 2, 3)$. We define an unordered triple $\langle \nu_1 1, \nu_2 2, \nu_3 3\rangle$ $(\nu_j = \pm)$ by a linear subspace of $\mathbf{K}$ over $\mathbf{k}$ of the form

$$\langle \nu_1 1, \nu_2 2, \nu_3 3\rangle = \{f \in \mathbf{K};\ X_j^*(f) = \nu_j f,\ j = 1, 2, 3\}.$$

LEMMA 8. *Let* (i, j, k) *be a permutation of* $(1, 2, 3)$. *Then*

(i) $p_i, q_i \in \mathbf{k} = \langle 1, 2, 3\rangle$, $\quad r_{ij} \in \langle i, -j, k\rangle$
$s_i \in \langle i, -j, -k\rangle$, $\quad t_i \in \langle -i, j, k\rangle$.

(ii) $p_ip_j = p_kq_k$, $\quad r_{ij}t_j = p_i(q_j - 4)$,
$r_{ij}r_{jk} = p_ip_j - 4p_k$, $\quad r_{ij}^2 = p_i^2 - 4q_k$, $\quad r_{ij}r_{ji} = q_ks_k$,
$t_i^2 = q_i(q_i - 4)$, $\quad s_i^2 = p_i^2 - 4(q_j + q_k) + 16$.

(iii) $2\delta_{X_i} = (r_{ij} + r_{ji})\partial_{p_i} + (r_{jk} - r_{ji})\partial_{p_j} + 2t_k\partial_{q_k}$,
$\delta_{X_j}(r_{ij} + r_{ji}) = \delta_{X_j}(r_{jk} - r_{ji}) = 0$, $\quad \delta_{X_j}t_k = q_k - 2$.

6. Reduction to Appell's F_4. We introduce new variables

$$r = p_1/q_3, \quad s = p_2/q_3, \quad t = q_3.$$

Since $\mathbf{k} = \mathbb{C}(p_1, p_2, q_3) = \mathbb{C}(r, s, t)$, R is regarded as a function of (r, s, t). Using Lemma 8, we can rewrite (5) as follows:

$$s_3M_1R + rstM_1R + 2M_2R + 2M_3R = 0, \tag{11}$$

where M_1, M_2, and M_3 are differential operators defined by

$$M_1 = L_{(r,s)} = \partial_r\partial_s + a(a-1)/(r-s)^2 - b(b-1)/(r+s)^2,$$

$$\begin{aligned} M_2 = {} & (1-r^2)\partial_r^2 + (1-s^2)\partial_s^2 - 2rs\partial_r\partial_s - 2r\partial_r - 2s\partial_s \\ & - 2a(a-1)/(r-s)^2 - 2b(b-1)^2/(r+s)^2, \end{aligned}$$

$$M_3 = t\{(t-4)\partial_t(\delta_t - \delta_r - \delta_s - 1) + 2\partial_t\}.$$

Since M_1R and $rstM_1R+2M_2R+2M_3R$ are G-invariant and s_3 is not an element of $\mathbf{k}$, (11) splits into two parts:

$$M_1R = M_2R + M_3R = 0. \tag{12}$$

Condition (6) is now rewritten as

$$s = 1 \text{ implies } R = 1. \tag{13}$$

In view of the explicit forms of M_j $(j = 1, 2, 3)$, if $f(r, s, t)$ is a solution of (12)-(13) (suppose f makes sense at $t = 0$), then $f(r, s, 0)$ is also a solution of (12)-(13). Hence it is reasonable to expect that R is a function depending only on (r, s), and to consider a system of partial differential equations

$$M_1u = M_2u = 0, \tag{14}$$

to which (12) reduces, if our expectation is correct. Note that if (14) has a solution satisfying the condition

$$s = 1 \text{ implies } u = 1 \quad \text{(see (13))}, \tag{13'}$$

then our expectation is actually correct, and R is given by this solution. This will be true in the rest of this section and in the next section.

We find that the substitutions

$$\begin{aligned} p &= \{(r-s)/2\}^2 = \{(x-y)(\xi-\eta)/2(xy+\xi\eta)\}^2, \\ q &= \{(r+s)/2\}^2 = \{(x+y)(\xi+\eta)/2(xy+\xi\eta)\}^2, \\ u &= p^{a/2}q^{b/2}v \end{aligned} \tag{15}$$

transform (14) to a system of partial differential equations associated with Appell's generalized hypergeometric function $F_4(\alpha, \beta, \gamma, \gamma'; p, q)$ with a specialization of parameters α, β, γ, and γ'.

Recall (see Appell and Kampé de Fériet [1], Kimura [5]) that the function F_4 is defined by a double power series

$$F_4(\alpha, \beta, \gamma, \gamma'; p, q) = \sum_{m,n=0}^{\infty} \frac{(\alpha, m+n)(\beta, m+n)}{(\gamma, m)(\gamma', n)(1, m)(1, n)} p^m q^n,$$

where (a, k) denotes a factorial function $(a, k) = a(a+1)\cdots(a+k-1)$. This power series converges in a domain

$$(p, q) \in \mathbb{C}^2, \qquad |p|^{1/2} + |q|^{1/2} < 1.$$

The function F_4 satisfies a system of partial differential equations

$$\begin{aligned} N_1v &= \{\delta_p(\delta_p+\gamma-1) - p(\delta_p+\delta_q+\alpha)(\delta_p+\delta_q+\beta)\}v = 0, \\ N_2v &= \{\delta_q(\delta_q+\gamma'-1) - q(\delta_p+\delta_q+\alpha)(\delta_p+\delta_q+\beta)\}v = 0. \end{aligned} \tag{F_4}$$

The system (F_4) can be rewritten as an integrable Pfaffian equation of rank four, so that the family of all solutions of (F_4) forms a four-dimensional vector space. Solutions of (F_4) are multivalued holomorphic functions in $\mathbb{C}^2 \backslash S$, where

$$S = \{(p, q) \in \mathbb{C}^2;\ pqD(p, q) = 0\},$$

and $D(p, q)$ is a polynomial defined by

$$D(p, q) = (p-q+1)^2 - 4p = (q-p+1)^2 - 4q. \tag{16}$$

LEMMA 9. *The substitution* (15) *transforms* (14) *to* (F_4) *with the following specialization of parameters*:

$$\alpha=(a+b)/2,\qquad \beta=(a+b+1)/2,\qquad \gamma=a+\tfrac{1}{2},\qquad \gamma'=b+\tfrac{1}{2}. \tag{17}$$

If the independent variables are real, then the condition (13′) *becomes*

$$(p, q)\in\Gamma \text{ implies } v=p^{-a/2}q^{-b/2}, \tag{18}$$

where Γ *is a part of a parabola*:

$$\Gamma=\{(p, q)\in\mathbb{R}^2;\ 0<p, q<1,\ D(p, q)=0\}.$$

We note that (14) is equivalent to the pull-back of (F_4) by a covering map

$$\mathbb{C}^2=\{(r, s)\}\to\mathbb{C}^2=\{(p, q)\},\qquad (r, s)\mapsto((r-s)^2/4,\ (r+s)^2/4),$$

which removes an apparent singularity $p+q=1$ of the Pfaffian equation associated with (F_4).

7. Integral representation. Takano [10] computed the monodoromy group of the system (F_4) on the basis of an integral representation.

THEOREM 10 (Takano [10]). *Suppose* $f(s)$ *is a solution of Gauss' hypergeometric equation*

$$\{s(1-s)\partial_s^2+[(\gamma+\gamma'-1)-(\alpha+\beta+1)s]\partial_s-\alpha\beta\}f=0, \tag{HG′}$$

and C *is a curve satisfying certain conditions*; *then an integral*

$$v(p, q)=(2\pi i)^{-1}\int_C t^{-\gamma}(1-t)^{-\gamma'}f(p/t+q/(1-t))\,dt \tag{19}$$

gives a solution of (F_4).

Hereafter we assume (17) throughout the rest of this paper. In this section, we shall observe that, under an appropriate choice of a function $f(s)$ and a curve C, a function v defined by (19) satisfies (F_4)-(18), i.e., $u=p^{a/2}q^{b/2}v$ gives a solution of (13′)-(14).

In what follows, we assume that (p, q) moves in a real domain

$$\Omega=\{(p, q)\in\mathbb{R}^2;\ 0<p, q<1,\ D(p, q)>0\}.$$

We explain how we should take a function $f(s)$ and a curve C. Under (17), (HG′) has the following characteristic exponents at each singular point:

$$s=0:\ 0,\ 1-a-b;\qquad s=1:\ 0,\ -\tfrac{1}{2};\qquad s=\infty:\ (a+b)/2,\ (a+b+1)/2.$$

Choice of $f(s)$. Let $f(s)$ be a solution of (HG′) having an exponent $-\frac{1}{2}$ at $s=1$ and normalized so that

$$f(s)=(s-1)^{-1/2}g(s),\qquad g(s)\text{: holomorphic at } s=1,\qquad g(1)=1.$$

Explicitly, $g(s)$ is given by

$$g(s)=F((a+b)/2,\ (a+b-1)/2,\ \tfrac{1}{2};\ 1-s). \tag{20}$$

If we introduce the notation

$$s=s(t)=s(t; p, q)=p/t+q/(1-t),$$
$$z_m=z_m(p, q)=\tfrac{1}{2}\{p-q+1+(-)^{m+1}\sqrt{D(p, q)}\}\quad (m=0, 1),$$
$$z_2=z_2(p, q)=p/(p-q),$$

where the square root is chosen so that $D^{1/2}>0$, then we observe

(i) $t=0$ and $t=1$ correspond to $s=\infty$,

(ii) $t=z_0$ and $t=z_1$ correspond to $s=1$,

(iii) $t=z_2$ and $t=\infty$ correspond to $s=0$.

The three points $z_m(m=0,1,2)$ are located in a following manner:

(I) $0<z_0<z_1<1$, $z_2<0$ or $z_2>1$ or $z_2=\infty$,

(II) z_0 and z_1 degenerate into a single point as $\Omega\ni(p,q)\to\Gamma$.

Choice of C. Let C be a closed Jordan curve that encircles the points z_0 and z_1 once anticlockwisely and leaves the points 0, 1, and z_2 outside.

LEMMA 11. *Let $g(s)$ and C be as above, then a function*

$$v(p,q)=(2\pi i)^{-1}\int_C t^{-a}(1-t)^{-b}(t-z_0)^{-1/2}(t-z_1)^{-1/2}g(s(t))\,dt \tag{21}$$

is a solution of (F_4)-(18).

Proof. The expression (21) is only a rewriting of (19). Since z_0 and z_1 are branch points of degree one of the integrand of (21), the curve C is a closed curve on a Riemann surface of the integrand. Hence, C satisfies a condition needed in Theorem 10, and (21) gives a solution to (F_4). We show that (21) satisfies the condition (18). In a limiting process as $(p,q)\to\Gamma$, the branch points z_0 and z_1 degenerate into a single point in an interval (0, 1), which becomes a pole of order one of the integrand. Thus, by the residue theorem, we have

$$v(p,q)=z_0^{-a}(1-z_0)^{-b}g(s(z_0)),\qquad (p,q)\in\Gamma.$$

On the other hand, if $(p,q)\in\Gamma$, (16) and (ii) show that

$$z_0=(p-q+1)/2=p^{1/2},\qquad 1-z_0=(q-p+1)/2=q^{1/2},\qquad s(z_0)=1,$$

then we obtain $v(p,q)=p^{-a/2}q^{-b/2}$, condition (18). □

We change the path of integration C into C' in a way indicated in Fig. 1. Since z_1 is a branch point of degree one of the integrand and we have an estimate

$$|\text{the integrand of (21)}|\leqq \text{const.}\,|t-z_0|^{1/2}|t-z_1|^{1/2}$$

in a neighbourhood of $[z_0,z_1]$, we obtain the following theorem.

THEOREM 12. *Let $g(s)$ be defined by* (20); *then a function*

$$v(p,q)=\pi^{-1}\int_{z_0}^{z_1} t^{-a}(1-t)^{-b}(t-z_0)^{-1/2}(z_1-t)^{-1/2}g(s(t))\,dt \tag{22}$$

is a solution of (F_4)-(18), *where the integration is taken over the interval $z_0<t<z_1$.*

As pointed out in the previous section, this theorem ensures that $R=p^{a/2}q^{b/2}v$ gives the Riemann function of (H).

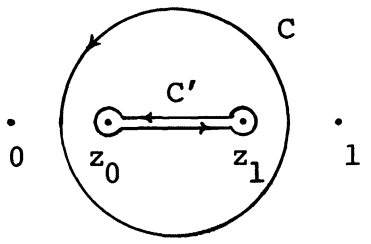

FIG. 1

8. Connection coefficients. Equation (F_4) has a fundamental set of solutions $v_j(p, q) = v_j(p, q; a, b)$ $(j = 0\text{-}3)$ in a domain $|p|^{1/2} + |q|^{1/2} < 1$ (see [1], [5]), where, in the present case,

$$
\begin{aligned}
&v_0(p, q) = F_4((a+b)/2, (a+b+1)/2, a+\tfrac{1}{2}, b+\tfrac{1}{2}; p, q),\\
&v_1(p, q) = p^{1/2-a} F_4((b-a+1)/2, 1+(b-a)/2, \tfrac{3}{2}-a, b+\tfrac{1}{2}; p, q),\\
&v_2(p, q) = q^{1/2-b} F_4((a-b+1)/2, 1+(a-b)/2, a+\tfrac{1}{2}, \tfrac{3}{2}-b; p, q),\\
&v_3(p, q) = p^{1/2-a} q^{1/2-b} F_4(1-(a+b)/2, (3-a-b)/2, \tfrac{3}{2}-a, \tfrac{3}{2}-b; p, q).
\end{aligned} \tag{23}
$$

Let $v(p, q) = v(p, q; a, b)$ be a function defined by (22). Then it can be expressed as a linear combination of v_j $(j = 0\text{-}3)$

$$
v(p, q; a, b) = \sum_{j=0}^{3} C_j(a, b) v_j(p, q; a, b). \tag{24}
$$

LEMMA 13. *The connection coefficients* C_j $(j = 0\text{-}3)$ *are meromorphic functions of* $(a, b) \in \mathbb{C}^2$ *with poles only in* $\mathcal{P}$, *where*

$$
\mathcal{P} = \{(a, b) \in \mathbb{C}^2;\ a \text{ or } b \in \tfrac{1}{2} + \mathbb{Z}\}.
$$

Proof. For a function $f(p, q)$, we define

$$
\mathbf{f} = {}^t(f^{(0)}, f^{(1)}, f^{(2)}, f^{(3)}),
$$

where

$$
f^{(0)} = f, \qquad f^{(1)} = \partial_p f, \qquad f^{(2)} = \partial_q f, \qquad f^{(3)} = \partial_p \partial_q f.
$$

For a fixed (p, q), $F_4^{(i)}(\alpha, \beta, \gamma, \gamma'; p, q)$ $(i = 0\text{-}3)$ are meromorphic functions of $(\alpha, \beta, \gamma, \gamma')$ whose poles are points for which γ or γ' is a nonpositive integer; hence (23) shows that $v_j^{(i)}$ $(i, j = 0\text{-}3)$ are meromorphic functions with poles only in $\mathcal{P}$. Since (F_4) for a function f is rewritten as an integrable Pfaffian equation for a vector $\mathbf{f}$ (see [1], [5]), a Wronskian matrix $W = (\mathbf{v}_0, \cdots, \mathbf{v}_3)$ is a nonsingular meromorphic function of (a, b) with poles only in $\mathcal{P}$. On the other hand, for a fixed (p, q), the vector $\mathbf{v}$ is an entire function of (a, b), since the Riemann function of (H) satisfies a Volterra integral equation depending entirely on the parameters (a, b). Hence the relation ${}^t(C_0, \cdots, C_3) = W^{-1}\mathbf{v}$, which follows from (24), establishes the lemma. □

In the rest of this paper, we determine the coefficients C_j. In view of Lemma 13, it suffices to determine these coefficients in some subdomains of $\mathbb{C}^2 = \{(a, b)\}$, and then continue them to whole domain by analyticity. It follows from (23) and (24) that

(1°) if $\operatorname{Re}(a) + \operatorname{Re}(b) \leqq 1$, $\operatorname{Re}(a) > \frac{1}{2}$, then

$$
v(p, p) = p^{1/2-a}\{C_1(a, b) + o(1)\} \quad \text{as } p \to 0,
$$

(2°) if $\operatorname{Re}(a) + \operatorname{Re}(b) \leqq 1$, $\operatorname{Re}(b) > \frac{1}{2}$, then

$$
v(p, p) = q^{1/2-b}\{C_2(a, b) + o(1)\} \quad \text{as } p \to 0,
$$

(3°) if $\operatorname{Re}(a) < \frac{1}{2}$, $\operatorname{Re}(b) < \frac{1}{2}$, then

$$
v(p, p) = C_0(a, b) + o(1) \quad \text{as } p \to 0,
$$

(4°) if $\operatorname{Re}(a) > \frac{1}{2}$, $\operatorname{Re}(b) > \frac{1}{2}$, then

$$
v(p, p) = p^{1-a-b}\{C_3(a, b) + o(1)\} \quad \text{as } p \to 0.
$$

This observation tells us that we have to investigate behaviours of $v(p, p)$ for small values of p in the respective cases where (a, b) lies in the four subdomains of $\mathbb{C}^2$ indicated above.

In the rest of this paper, we assume that (p, q) lies in a set

$$\Delta = \{(p, q) \in \mathbb{R}^2;\ 0 < p = q < \tfrac{3}{16}\} \subset \Omega.$$

Then $s(t)$ and z_m $(m = 0, 1, 2)$, defined before, take the forms

$$s = s(t) = s(t; p) = p/t(1-t),$$
$$z_m = z_m(p) = \tfrac{1}{2}\{1 + (-)^{m+1}\sqrt{1-4p}\} \quad (m = 0, 1),$$
$$z_2 = \infty.$$

From these, we observe that

$$\begin{aligned} &s(t) = s(1-t), \qquad 4p \leqq s(t) < 1, \qquad (z_0 < t < z_1), \\ &s(t): \quad \text{decreasing in } z_0 < t \leqq \tfrac{1}{2}, \text{ increasing in } \tfrac{1}{2} \leqq t < z_1. \end{aligned} \tag{25}$$

For $0 < p \leqq \frac{3}{16}$, z_0 and z_1 are located in the following manner:

(I′) $0 < z_0 < \frac{1}{4}$, $\frac{3}{4} < z_1 < 1$, $z_0 + z_1 = 1$, $z_0 z_1 = p$,

(II′) $z_0/p \to 1$, $(1 - z_1)/p \to 1$ as $p \to 0$.

Let (HG″) be the hypergeometric equation satisfied by $g(s)$. Then the characteristic exponents of (HG″) at the singular points $s = 0$ and 1 are

$$0 \text{ and } 1 - a - b \text{ at } s = 0; \qquad 0 \text{ and } \tfrac{1}{2} \text{ at } s = 1. \tag{26}$$

9. Determination of C_1 and C_2. An integral

$$E(a, b) = \pi^{-1} \int_0^1 s^{a-3/2}(1-s)^{-1/2} g(s)\, ds$$

is a holomorphic function of a and b in $\mathrm{Re}\,(a) + \mathrm{Re}\,(b) < 0$, $\mathrm{Re}\,(a) > \frac{1}{2}$, since (26) shows that this integral is absolutely convergent for those values of a and b.

PROPOSITION 14.

$$C_1(a, b) = E(a, b) \text{ for } \mathrm{Re}\,(a) + \mathrm{Re}\,(b) \leqq 1, \qquad \mathrm{Re}\,(a) > \tfrac{1}{2},$$
$$C_2(a, b) = E(b, a) \text{ for } \mathrm{Re}\,(a) + \mathrm{Re}\,(b) \leqq 1, \qquad \mathrm{Re}\,(b) > \tfrac{1}{2}.$$

Proof. We prove the first formula of the proposition. We assume $\mathrm{Re}\,(a) + \mathrm{Re}\,(b) \leqq 1$ and $\mathrm{Re}\,(a) > \frac{1}{2}$. Then it follows that $\mathrm{Re}\,(b) < \frac{1}{2}$. Since $\mathrm{Re}\,(1 - a - b) \geqq 0$, (26) shows that

$$|g(s)| \leqq \text{constant} \quad (0 \leqq s \leqq 1). \tag{27}$$

We divide the integral (22) into two parts whose intervals of integration are $z_0 < t < \frac{1}{2}$ and $\frac{1}{2} < t < z_1$. We denote them by $I_0(p)$ and $I_1(p)$, respectively. Namely,

$$v(p, p) = I_0(p) + I_1(p),$$

where, for $\nu = 0$ and 1,

$$I_\nu(p) = (-)^m \pi^{-1} \int_{z_\nu}^{1/2} t^{-a}(1-t)^{-b}(t - z_0)^{-1/2}(z_1 - t)^{-1/2} g(s(t))\, dt.$$

We first investigate $I_0(p)$. Substituting $t = z_0/u$, we obtain

$$I_0(p) = z_0^{1/2-a} I_2(p),$$

where $I_2(p)$ is given by

$$I_2(p) = \pi^{-1} \int_0^1 \chi(u; z_0) u^{a-3/2}(1-u)^{-1/2}(1 - z_0/u)^{-b}(z_1 - z_0/u)^{-1/2} g(s(z_0/u))\, du,$$

and $\chi(u; z_0)$ is a function having value one in $2z_0 < u < 1$ and zero outside. From (I') and (27), we have an estimate

$$|\text{the integrand of } I_2| \leqq \text{const } u^{\mathrm{Re}(a)-3/2}(1-u)^{-1/2} \quad (0 \leqq u \leqq 1),$$

the right-hand side being integrable in $0 \leqq u \leqq 1$. Formula (II') shows that

$$\text{the integrand} \to u^{a-3/2}(1-u)^{-1/2}g(u) \quad \text{as } p \to 0.$$

Hence, by Lebesgue's convergence theorem, we find that $I_2(a, b) \to E(a, b)$ as $p \to 0$. Therefore, taking the fact $z_0/p \to 1$ into account, we obtain

$$I_0(p) = p^{1/2-a}\{E(a, b) + o(1)\} \quad \text{as } p \to 0.$$

Next we consider the integral $I_1(p)$. From (27), we obtain

$$\begin{aligned} |I_1(p)| &\leqq \text{const} \int_{1/2}^{z_1} (1-t)^{-\mathrm{Re}(b)}(z_1-t)^{-1/2}\,dt \\ &= \text{const } z_1^{1/2} \int_{1/2z_1}^{1} (1-z_1t)^{-\mathrm{Re}(b)}(1-t)^{-1/2}\,dt \\ &\leqq \text{const} \int_0^1 \{1+(1-t)^{-\mathrm{Re}(b)}\}(1-t)^{-1/2}\,dt. \end{aligned}$$

Since $\mathrm{Re}\,(b) < \frac{1}{2}$, the right-hand side is finite, so that $I_1(p)$ is bounded in $0 < p < \frac{3}{16}$. Comparing the asymptotic behaviours of $I_0(p)$ and $I_1(p)$, we obtain

$$I(p) = p^{1/2-a}\{E(a, b) + o(1)\} \quad \text{as } p \to 0.$$

We combine this formula with (1°) to establish the first formula of the proposition. The second formula can be proved similarly by exchanging the role of a and b. □

LEMMA 15. $E(a, b) = \pi^{-1}2^{a-b-1}\Gamma(a-\frac{1}{2})\Gamma(\frac{1}{2}-b)/\Gamma(a-b)$.

Proof. Suppose that $\mathrm{Re}\,(a) + \mathrm{Re}\,(b) \leqq 0$, $\mathrm{Re}\,(a) > 1$, $|p| \leqq 1$, and we consider an integral

$$E(p; a, b) = \pi^{-1} \int_0^1 t^{-1/2}(1-t)^{a-3/2}g(pt)\,dt.$$

This integral converges for those (p, a, b) mentioned above, and

$$\begin{aligned} &E(1; a, b) = E(a, b), \\ &E(0; a, b) = \pi^{-1}B(\tfrac{1}{2}, a-\tfrac{1}{2}) = \pi^{-1/2}\Gamma(a-\tfrac{1}{2})/\Gamma(a). \end{aligned}$$

We observe that $E(p; a, b)$ satisfies the hypergeometric equation

$$p(1-p)E'' + \{a-(a+b+\tfrac{1}{2})p\}E - \tfrac{1}{4}(a+b)(a+b-1)E = 0.$$

Since the characteristic exponents at $p = 0$ are 0 and $1-a$ $(\mathrm{Re}\,(1-a) < 0)$,

$$E(p; a, b) = \pi^{-1/2}\Gamma(a-\tfrac{1}{2})\Gamma(a)^{-1}F((a+b)/2, (a+b-1)/2, a; p).$$

By the connection formula in Lemma 16 below, we have

$$\begin{aligned} E(p; a, b) = \hat{E}(a, b)&F((a+b)/2, (a+b-1)/2, b+\tfrac{1}{2}; 1-p) \\ &+ (1-p)^{1/2-b} \times (\text{a holomorphic function at } p = 1), \end{aligned}$$

where $\hat{E}(a, b)$ is a constant given by the right-hand side of Lemma 15. Hence, by the assumption $\mathrm{Re}\,(\frac{1}{2}-b) > 0$, we obtain $E(a, b) = E(1; a, b) = \hat{E}(a, b)$. This proves the lemma. □

A connection formula for the Gauss hypergeometric function is well known.

LEMMA 16 (*see, e.g.*, [3], [5]).

$$F(\alpha, \beta, \gamma; p) = \frac{\Gamma(\gamma)\Gamma(\gamma-\alpha-\beta)}{\Gamma(\gamma-\alpha)\Gamma(\gamma-\beta)} F(\alpha, \beta, \alpha+\beta-\gamma+1; 1-p)$$
$$+ \frac{\Gamma(\gamma)\Gamma(\alpha+\beta-\gamma)}{\Gamma(\alpha)\Gamma(\beta)} (1-p)^{\gamma-\alpha-\beta} F(\gamma-\alpha, \gamma-\beta, \gamma-\alpha-\beta+1; 1-p).$$

10. Determination of C_0 and C_3. Recall that $g(s)$ is a solution to (HG″) holomorphic in a neighbourhood of $s=1$. In the present situation, Lemma 16 is restated as follows.

LEMMA 17. *Let $h(s; a, b)$ and $A(a, b)$ be defined by*

$$h(s; a, b) = F((a+b)/2, (a+b-1)/2, a+b; s),$$
$$A(a, b) = 2^{-(a+b)}\pi^{-1}.$$

Then $g(s)$ can be represented as follows:

$$g(s) = \pi A(a, b)h(s; a, b) + \pi A(1-a, 1-b)s^{1-a-b}h(s; 1-a, 1-b). \tag{28}$$

The function $h(s: a, b)$ is not only holomorphic at $s=0$, by definition, but also bounded near $s=1$ by (26). Hence we have

$$|h(s; a, b)| \leqq \text{constant} \quad (0 \leqq s \leqq 1). \tag{29}$$

Substituting (28) into (22), we obtain

$$v(p, p) = A(a, b)J(p; a, b) + A(1-a, 1-b)J(p; 1-a, 1-b), \tag{30}$$

where $J(p; a, b)$ is given by

$$J(p; a, b) = \int_{z_0}^{z_1} t^{-a}(1-t)^{-b}(t-z_0)^{-1/2}(z_1-t)^{-1/2}h(s(t); a, b)\, dt.$$

LEMMA 18. (i) *If* $\operatorname{Re}(a) < \frac{1}{2}$ *and* $\operatorname{Re}(b) < \frac{1}{2}$, *then*

$$J(p; a, b) \to \Gamma(\tfrac{1}{2}-a)\Gamma(\tfrac{1}{2}-b)/\Gamma(1-a-b) \quad \text{as } p \to 0.$$

(ii) *If* $\operatorname{Re}(a) > \frac{1}{2}$ *and* $\operatorname{Re}(b) > \frac{1}{2}$, *then*

$$|J(p; a, b)| \leqq \text{const}\, p^{1/2-\max(\operatorname{Re}(a), \operatorname{Re}(b))} \quad (0 < p < \tfrac{3}{16}).$$

Proof. (i) Let $t = z_1 u + z_0(1-u)$, then $J(p; a, b)$ is rewritten as

$$J(p; a, b) = \int_0^1 (uz_1 + (1-u)z_0)^{-a}(uz_0 + (1-u)z_1)^{-b}$$
$$\times u^{-1/2}(1-u)^{-1/2}h(s(uz_1 + (1-u)z_0); a, b)\, du.$$

Hence (I′) and (29) shows that the integrand satisfies

$$|\text{the integrand}| \leqq \text{const}\ (1+(u/2))^{-\operatorname{Re}(a)}(1+(u/2))^{-\operatorname{Re}(b)}u^{-1/2}(1-u)^{-1/2}.$$

Since $\operatorname{Re}(a) < \frac{1}{2}$ and $\operatorname{Re}(b) < \frac{1}{2}$, the right-hand side is integrable in $0 < u < 1$. Moreover, $z_0 \to 0$, $z_1 \to 1$ and $s(uz_1 + (1-u)z_0) \to 0$ as $p \to 0$, so that we have

$$\text{the integrand} \to u^{-a-1/2}(1-u)^{-b-1/2} \quad \text{as } p \to 0.$$

Hence, by Lebesgue's convergence theorem, we obtain

$$J(p; a, b) \to B(\tfrac{1}{2}-a, \tfrac{1}{2}-b) = \Gamma(\tfrac{1}{2}-a)\Gamma(\tfrac{1}{2}-b)/\Gamma(1-a-b),$$

where $B(\cdot, \cdot)$ is the beta function. This proves assertion (i).

(ii) If $\mathrm{Re}\,(a)$, $\mathrm{Re}\,(b)>\frac{1}{2}$, then $J(p; a, b)$ is estimated as follows:

$$\begin{aligned}|J(p; a, b)| &\leqq \text{const} \int_{z_0}^{1/2} t^{-\mathrm{Re}(a)}(t-z_0)^{-1/2}\,dt \\ &\quad + \text{const} \int_{1/2}^{z_1} (1-t)^{-\mathrm{Re}(b)}(z_1-t)^{-1/2}\,dt \\ &\leqq \text{const} \int_{z_0}^{1/2} \{t^{-\mathrm{Re}(a)}+t^{-\mathrm{Re}(b)}\}(t-z_0)^{-1/2}\,dt \\ &\leqq \text{const}\, z_0^{1/2-\max(\mathrm{Re}(a),\mathrm{Re}(b))} \int_1^{\infty} u^{-\min(\mathrm{Re}(a),\mathrm{Re}(b))}(u-1)^{-1/2}\,du \\ &\leqq \text{const}\, p^{1/2-\max(\mathrm{Re}(a),\mathrm{Re}(b))}.\end{aligned}$$

Here we note that the third inequality follows from the substitution $t=z_0u$ in the second line, and the integral in the third line is finite, since $\mathrm{Re}\,(a)$, $\mathrm{Re}\,(b)>\frac{1}{2}$. Hence the assertion (ii) is proved. □

PROPOSITION 19.

$$C_0(a, b)=\pi^{-1}2^{-(a+b)}\Gamma(\tfrac{1}{2}-a)\Gamma(\tfrac{1}{2}-b)/\Gamma(1-a-b),$$
$$C_3(a, b)=\pi^{-1}2^{a+b-2}\Gamma(a-\tfrac{1}{2})\Gamma(b-\tfrac{1}{2})/\Gamma(a+b-1).$$

Proof. We prove the first formula. Suppose $\mathrm{Re}\,(a)<1/2$ and $\mathrm{Re}\,(b)<1/2$. Applying Lemma 18 (ii) with a and b replaced by $1-a$ and $1-b$, respectively, we obtain an estimate

$$|p^{1-a-b}J(p; a, b)| \leqq \text{const}\, p^{1/2-\max(\mathrm{Re}(a),\mathrm{Re}(b))} = o(1) \quad \text{as } p\to 0.$$

Hence (30) and Lemma 18(i) shows that

$$v(p, p)=A(a, b)\Gamma(\tfrac{1}{2}-a)\Gamma(\tfrac{1}{2}-b)/\Gamma(1-a-b) \quad \text{as } p\to 0.$$

Comparing this formula with (3°), we obtain the first formula of the proposition in a domain $\mathrm{Re}\,(a)$, $\mathrm{Re}\,(b)<\frac{1}{2}$, and then in a whole domain by analyticity (see Lemma 13). Next we prove the second formula. Suppose that $\mathrm{Re}\,(a)$, $\mathrm{Re}\,(b)>\frac{1}{2}$. Applying Lemma 18(ii), we obtain

$$J(p; a, b)=o(|p^{1-a-b}|) \quad \text{as } p\to 0.$$

Hence (30) and Lemma 18(i) with a and b replaced by $1-a$ and $1-b$ shows that

$$v(p, p)=p^{1-a-b}\{A(a, b)\Gamma(a-\tfrac{1}{2})\Gamma(b-\tfrac{1}{2})/\Gamma(a+b-1)+o(1)\},$$

Comparing this formula with (4°), we obtain the second formula. □

11. Conclusion. We have proved the following theorem.

THEOREM 20. *The Riemann function of* (H) *is given by*

$$R(x, y; \xi, \eta)=\sum_{j=0}^{3} C_j(a, b)u_j(p, q; a, b),$$

where

$$p=\left\{\frac{(x-y)(\xi-\eta)}{2(xy+\xi\eta)}\right\}^2, \qquad q=\left\{\frac{(x+y)(\xi+\eta)}{2(xy+\xi\nu)}\right\}^2,$$

$$u_0=u(p, q; a, b), \qquad C_0=C(a, b),$$
$$u_1=u(p, q; 1-a, b), \qquad C_1=C(1-a, b),$$
$$u_2=u(p, q; a, 1-b), \qquad C_2=C(a, 1-b),$$
$$u_3=u(p, q; 1-a, 1-b), \qquad C_3=C(1-a, 1-b),$$

and

$$u(p, q; a, b) = p^{a/2}q^{b/2}F_4((a+b)/2, (a+b+1)/2, a+\tfrac{1}{2}, b+\tfrac{1}{2}; p, q),$$
$$C(a, b) = \pi^{-1}2^{-a-b}\Gamma(\tfrac{1}{2}-a)\Gamma(\tfrac{1}{2}-b)/\Gamma(1-a-b).$$

Remark 21. We look back upon this note and give some comments.

(i) Arguments in § 4 and in a part of § 6 are rather formal and heuristic, but they are justified later. See a comment following Theorem 12.

(ii) Theorem 20 shows that the Riemann function of (H) is represented in a very symmetric manner. But the determination of the connection coefficients C_1 and C_2 (§ 9) and that of C_0 and C_3 (§ 10) are not so symmetric. It is because a reduction to (F_4)-(18) and an integral representation of its solution break down a symmetry.

12. Appendix. We give a proof of Lemma 2. Such a statement was not in print, as far as we are aware.

The most important property of the Lie algebra $\mathcal{W}$ is as follows:

(*) *If $f, g \in \mathcal{W}$ and $[f, g] = 0$, then f and g are linearly dependent.*

Let $\mathfrak{g} \neq \{0\}$ be a finite-dimensional subalgebra of $\mathcal{W}$. Then the following two cases occur.

Case 1. For every $f \in \mathfrak{g}$, $ad(f) = [f, \cdot] \in \mathrm{End}(\mathfrak{g})$ is nilpotent.

Case 2. For some $f \in \mathfrak{g}$, $ad(f)$ is not nilpotent.

In Case 2, by considering a constant multiple of f, if necessary, we may assume that $ad(f)$ has an eigenvalue 1. Let e be an eigenvector of $ad(f)$ corresponding to the eigenvalue 1. Note that the following commutation relation holds:

(**) $$ad(e)ad(f) = (ad(f) - 1)ad(e).$$

Case 1. $\dim \mathfrak{g} = 1$.

Proof. For any $f \in \mathfrak{g}$, there exists an $m \geqq 1$ such that $ad(f)^m g = [f, ad(f)^{m-1}g] = 0$ for every $g \in \mathfrak{g}$. Hence, (*) implies that $ad(f)^{m-1}g = cf$ for some constant c. If $m \geqq 2$, then this shows that $ad(f')f = cf$, where $f' = -ad(f)^{m-2}g$. By the nilpotency of $ad(f')$, we have $c = 0$. Hence, $ad(f)^{m-1}g = 0$ for every $g \in \mathfrak{g}$. By repeating this argument, we have $ad(f)g = 0$ $(g \in \mathfrak{g})$. Hence (*) implies that $\mathfrak{g} = \mathbb{C}f$, which proves the assertion. □

Case 2. Let f and $e \in \mathfrak{g}$ be as above.

CLAIM 1. *Eigenvalues of $ad(f) \in \mathrm{End}(\mathfrak{g})$ are at most 0 and ± 1.*

Proof. Let λ be an eigenvalue other than 0 and 1 (if it exists). If $m + \lambda \neq 1$ held for every $m \in \mathbb{N}$, then infinitely many numbers $m + \lambda$ $(m \in \mathbb{N})$ would become eigenvalues of $ad(f)$. (Indeed, this assertion is apparently true for $m = 0$. If it is true for $m = n$, and let e_n be an eigenvector corresponding to $n + \lambda$ $(\neq 1)$, then e and e_n are linearly independent. Here we recall that e is an eigenvector of $ad(f)$ corresponding to 1. Hence (*) implies that $e_{n+1} := [e, e_n] \neq 0$ and $ad(f)e_{n+1} = (n + 1 + \lambda)e_{n+1}$, which shows that the assertion is also true for $m = n + 1$.) This contradicts the finite-dimensionality of $\mathfrak{g}$. Hence, there exists an $m \in \mathbb{N}$ such that $m + \lambda = 1$. Similarly by exchanging the role of 1 and λ, we see that there exists an $n \in \mathbb{N}$ such that $1 + n\lambda = \lambda$. Thus we have $\lambda = 1 - m = (1 - n)^{-1}$, which can happen only when $m = n = 2$ and $\lambda = -1$. This establishes the claim. □

CLAIM 2. *The generalized eigenspace of $ad(f)$ corresponding to a nonzero eigenvalue is one-dimensional.*

Proof. We show this claim for the eigenvalue 1. Similarly, we can prove it for -1, if it is an eigenvalue. If g is any generalized eigenvector corresponding to 1, then there exists an $m \in \mathbb{N}$ such that $(ad(f) - 1)^m g = 0$. Operating $ad(e)$ on this equality and using

(**), we have $(ad(f)-2)^m[e, g]=0$. By Claim 1, 2 is not an eigenvalue of $ad(f)$, so that $[e, g]=0$, which, combined with (*), shows that $g \in \mathbb{C}e$. This establishes the claim. □

CLAIM 3. *The generalized eigenspace of $ad(f)$ corresponding to the eigenvalue 0 is also one-dimensional.*

Proof. Let g be any generalized eigenvector corresponding to 0. Note that $[e, g] \neq 0$. There exists an $m \in \mathbb{N}$ such that $ad(f)^m g=0$. Operating $ad(e)$ on this equality and using (**), we have $(ad(f)-1)^m[e, g]=0$. This shows that $[e, g]$ is a generalized eigenvector of $ad(f)$ corresponding to the eigenvalue 1. Hence, by Claim 2, there exists a constant c such that $[g, e]=ce$. Taking $ad(f)e=e$ into account, we obtain $[g-cf, e]=0$. Hence, by (*), $g-cf=c'e$ for some constant c'. However, $g-cf$ is a generalized eigenvector corresponding to 0, and $c'e$ is a one corresponding to 1, so that $c'=0$ and $g=cf$. This establishes the claim. □

By using these claims, we can easily show that, in Case 2, the subalgebra $\mathfrak{g}$ must be noncommutative Lie algebra of dimension 2 or 3. Conversely, the examples $\mathfrak{g}=\mathbb{C} \oplus \mathbb{C}x$ and $\mathfrak{g}=\mathbb{C} \oplus \mathbb{C}x \oplus \mathbb{C}x^2$ ensure the actual existence of such subalgebras, where $\oplus$ denotes the direct sum as a linear space. This proof is due to a discussion with M. Furuta.

Acknowledgment. The author wishes to thank Professor W. Miller, Jr. for several helpful suggestions about the symmetries of the differential equations examined in this paper.

UNIFORMLY VALID COMPOSITE EXPANSIONS FOR LAPLACE INTEGRALS*

LINDSAY A. SKINNER†

Abstract. A uniformly valid asymptotic expansion for integrals of the form

$$F(t,\nu)=e^{\nu h(t)}\int_t^\infty e^{-\nu h(x)}g(x)x^{\alpha-1}\,dx,$$

where $0<\alpha\leqq 1$ and $h(x)$ has a zero of order $r\geqq 1$ at $x=0$, is established. The result, which generalizes a well-known one for $h(x)=x$, also confirms the formal matched asymptotic expansion solution of the equivalent singular perturbation problem $-y'+\nu h'(t)y=g(t)t^{\alpha-1}$, $y(\infty)=0$. Comparable matched expansion results are derived for related integrals, including one from Bessel function theory, which do not satisfy differential equations.

Key words. matched asymptotic expansions, coalescing critical points

AMS(MOS) subject classification. 41A60

1. Introduction. The first part of this paper is concerned with the asymptotic evaluation of integrals of the form

$$F(t,\nu)=e^{\nu h(t)}\int_t^\infty e^{-\nu h(x)}g(x)x^{\alpha-1}\,dx. \tag{1.1}$$

It is assumed that $0<\alpha\leqq 1$ and $g(x)$, $h(x)\in C^\infty[0,\infty)$. Also, $h'(x)>0$ for $x>0$, but $h(x)$ has a zero of order $r\geqq 1$ at $x=0$. In addition, $g^{(n)}(x)$, $k^{(n)}(x)=O(1)$ as $x\to\infty$, where $k(x)=1/h'(x)$. Thus, in the integral, $h(x)$ has its minimum at the endpoint $x=t$, and this point coalesces with the singular point $x=0$ as $t\to 0^+$. Also, $h'(x)=x^{r-1}a(x)$ where $a(x)>0$ for $x\geqq 0$.

Our initial objective is to establish an asymptotic expansion for $F(t,\nu)$ that is uniformly valid for $0\leqq t<\infty$ as $\nu\to\infty$. The result is a generalization of a well-known one [1], [4], [8], [9] for $h(x)=x$. Following this we take up variations of (1.1) in which the integrand may depend on t. As an example, for

$$A(t,\nu)=e^{\nu(\tanh t-t)}\int_0^\infty e^{-\nu(\sinh x\,\operatorname{sech} t-x)}x^{\alpha-1}\,dx, \tag{1.2}$$

which is related to the Anger function [5], we establish

$$\begin{aligned}A(t,\nu)=\nu^{-\alpha/3}Z_0(\nu^{1/3}t)+(2\pi\nu)^{-1/2}t^{\alpha-1}[(\tanh t)^{-1/2}-t^{-1/2}]\\ +\tfrac{1}{6}\nu^{-(2+\alpha)/3}V(\nu^{1/3}t)+O(\nu^{-(4+\alpha)/3})\end{aligned} \tag{1.3}$$

uniformly for $0\leqq t<\infty$. In this formula

$$V(T)=\tfrac{1}{4}TZ_4(T)-T^3Z_2(T)-(2\pi)^{1/2}T^{\alpha+1/2} \tag{1.4}$$

and

$$Z_k(T)=\int_{-T}^\infty X^k e^{-(X^3+3TX^2)/6}(X+T)^{\alpha-1}\,dX. \tag{1.5}$$

* Received by the editors November 3, 1986; accepted for publication (in revised form) July 21, 1987.

Like (1.1), the integral for $A(t, \nu)$ involves coalescing critical points. There are saddle points at $x = \pm t$, and the algebraic singularity at $x = 0$. A uniform approximation asymptotically equivalent to (1.3) could be obtained by the method of Chester, Friedman, and Ursell [3] and Bleistein [2]. The result would not be so simple, however, nor would the proof of its validity. Details, which involve the change of variable defined by $\frac{1}{3}z^3 + \zeta(t)z = \sinh x \operatorname{sech} t - x$, where $\zeta(t) = [\frac{3}{2}(t - \tanh t)]^{2/3}$, are given in [5] for the case $\alpha = 1$. A comparable expansion can be obtained for $F(t, \nu)$ by introducing $z = [h(x)]^{1/r}$ and expanding the resulting coefficient of $z^{\alpha-1}\exp(-\nu z^r)$ about $z = [h(t)]^{1/r}$.

The proof of (1.3), and analogous expansions for other integrals, including $F(t, \nu)$, is accomplished in two steps. In the first step we prove the existence of a preliminary expansion comparable to the type of expansion established for Laplace integrals in [6]. In the second step we show that Theorem 2, given in the next section, can be applied to the individual terms of the preliminary expansion, and that this yields the final result. As a bonus we learn in the end that actual computations can be done directly, without a preliminary stage, using the method of matched asymptotic expansions.

2. Basic results. To begin our analysis, it is appropriate, but not essential, to observe that $F(t, \nu)$ is the solution of the singular perturbation problem

$$-y' + \nu h'(t)y = g(t)t^{\alpha-1}, \qquad y(\infty) = 0. \tag{2.1}$$

From here the desired uniform expansion can be readily determined formally by matching inner and outer expansions. Bearing in mind that $h'(t) = t^{r-1}a(t)$, if we write the N-term outer expansion as

$$O_N F(t, \nu) = \nu^{-1/r} \sum_{n=0}^{N-1} \nu^{-n/r} y_n(t); \tag{2.2}$$

then, obviously,

$$y_{r-1}(t) = t^{\alpha-1}g(t)/h'(t), \tag{2.3}$$

$$y_{kr-1}(t) = y'_{kr-r-1}(t)/h'(t), \qquad k \geqq 2, \tag{2.4}$$

and $y_n(t) = 0$ if $n \neq kr - 1$. The corresponding formal N-term inner expansion has the form

$$I_N F(t, \nu) = \nu^{-\alpha/r} \sum_{m=0}^{N-1} \nu^{-m/r} Y_m(\nu^{1/r}t), \tag{2.5}$$

and it is easy to see

$$Y_0(T) = g(0)Q_0(T), \tag{2.6}$$

$$Y_1(T) = g'(0)Q_1(T) - \frac{1}{r+1}g(0)a'(0)[Q_{r+1}(T) - T^{r+1}Q_0(T)], \tag{2.7}$$

where

$$Q_k(T) = e^{[a(0)/r]T^r} \int_T^\infty e^{-[a(0)/r]X^r} X^{\alpha-1+k}\, dX. \tag{2.8}$$

Additional terms of (2.5) can be obtained by the method developed in § 4.

The coefficients in (2.2) have asymptotic expansions of the form

$$y_n(t) \sim t^{\alpha-n-1} \sum_{m=0}^{\infty} c_{mn} t^m, \qquad t \to 0^+. \tag{2.9}$$

Presumably, therefore,

$$Y_m(T) \sim T^{\alpha+m-1} \sum_{n=0}^{\infty} c_{mn} T^{-n}, \qquad T \to \infty, \tag{2.10}$$

so that $O_N I_N F(t, \nu)$ is the same as

$$I_N O_N F(t, \nu) = \nu^{-\alpha/r} \sum_{m=0}^{N-1} \nu^{-m/r} \sum_{n=0}^{N-1} c_{mn} (\nu^{1/r} t)^{\alpha+m-n-1}. \tag{2.11}$$

Then the composite $C_N F(t, \nu)$, where $C_N = O_N + I_N - O_N I_N$, has the same N-term inner and outer expansions as $F(t, \nu)$. Thus we come to the following theorem.

THEOREM 1. *Under the assumptions stated in the three sentences just below* (1.1), $F(t, \nu) = C_N F(t, \nu) + O(\nu^{-(N+\alpha)/r})$ *uniformly for* $0 \leqq t < \infty$, *as* $\nu \to \infty$. *In other words,*

$$F(t, \nu) = \nu^{-\alpha/r} \sum_{n=0}^{N-1} \nu^{-n/r} [q_n(\nu^{1/r} t) + \nu^{-(1-\alpha)/r} p_n(t)] + O(\nu^{-(N+\alpha)/r}), \tag{2.12}$$

where

$$p_n(t) = y_n(t) - t^{\alpha-n-1} \sum_{m=0}^{n} c_{mn} t^m, \tag{2.13}$$

$$q_m(T) = Y_m(T) - T^{\alpha+m-1} \sum_{n=0}^{m-1} c_{mn} T^{-n}, \tag{2.14}$$

for any $N \geqq 1$.

For $r = 1$, and $N = 1$, (2.12) says

$$F(t, \nu) = \lambda^{-\alpha} g(0)\, e^{-\lambda t} \Gamma(\alpha, \lambda t) + \nu^{-1} [G(t) - G(0)] + O(\nu^{-\alpha-1}), \tag{2.15}$$

where $\lambda = a(0)\nu$, $G(t) = g(t)/a(t)$ and $\Gamma(\alpha, T)$ is the complementary incomplete gamma function [5]. Note also that for any $r > 1$, $p_n(t) = 0$ and $q_n(T) = Y_n(T)$ for $n \leqq r - 1$.

To prove Theorem 1 we need a generalization of the composite expansion theory given in [6] and [7]. We will use the same notation. Thus

$$\phi^{[m,-n]}(t, T) = \frac{1}{(m!)(n!)} \left(\frac{\partial}{\partial t}\right)^m \left(-T^2 \frac{\partial}{\partial T}\right)^n \phi(t, T) \tag{2.16}$$

and $\phi(t, T) \in C^\infty([0, b] \times [1, \infty])$ means $\tilde{\phi}(t, T) \in C^\infty([0, b] \times [0, 1])$, where $\tilde{\phi}(t, T) = \phi(t, 1/T)$. Also, $f^{[n]}(x, X, t) = f^{[n,0,0]}(x, X, t)$, and $f(x, X, t) = o(X^{-\infty})$ means $f(x, X, t) = o(X^{-n})$ for any n. The corollary following Theorem 2 is essentially Corollary 1 in [6].

THEOREM 2. *Let* $f(t, T) = T^{\alpha-1} \phi(t, T)$ *where* $0 < \alpha \leqq 1$. *If* $f(t, T) \in C^\infty([0, b] \times [0, 1])$ *and* $\phi(t, T) \in C^\infty([0, b] \times [1, \infty])$, *then*

$$f(t, \mu t) = \sum_{n=0}^{N-1} \mu^{-n} [v_n(\mu t) + \mu^{\alpha-1} u_n(t)] + O(\mu^{-N}) \tag{2.17}$$

uniformly for $0 \leqq t \leqq b$, *as* $\mu \to \infty$, *where*

$$u_n(t) = t^{\alpha-n-1} \left[\phi^{[0,-n]}(t, \infty) - \sum_{m=0}^{n} \phi^{[m,-n]}(0, \infty) t^m \right], \tag{2.18}$$

$$v_m(T) = T^{\alpha+m-1} \left[\phi^{[m,0]}(0, T) - \sum_{n=0}^{m-1} \phi^{[m,-n]}(0, \infty) T^{-n} \right]. \tag{2.19}$$

Proof. From $\phi(t, T) \in C^\infty([0, b]\times[1, \infty])$, by Taylor's theorem,

$$\phi(t, T) = \sum_{n=0}^{N-1} T^{-n}\phi^{[0,-n]}(t, \infty) + O(T^{-N}) \tag{2.20}$$

uniformly for $0 \leqq t \leqq b$ as $T \to \infty$. Therefore

$$f(t, T) = T^{\alpha-1} \sum_{n=0}^{N-1} T^{-n}\phi^{[0,-n]}(t, \infty) + O(T^{-N}) \tag{2.21}$$

uniformly for $0 \leqq t \leqq b$ as $T \to \infty$. Similarly, $\phi(t, T) \in C^\infty([0, b]\times[1, \infty])$ implies

$$f(t, T) = T^{\alpha-1} \sum_{n=0}^{N-1} t^m\phi^{[m,0]}(0, T) + O(t^N) \tag{2.22}$$

uniformly for $1 \leqq T \leqq \infty$, as $t \to 0^+$. In fact, (2.22) holds uniformly for $0 \leqq T \leqq \infty$, since, in addition, $f(t, T) \in C^\infty([0, b]\times[0, 1])$. The remainder of the proof of this theorem parallels the proof of Theorem 1 in [6], which is the current theorem with $\alpha = 1$, and therefore is omitted.

COROLLARY 1. *If* $f(x, X, t) \in C^\infty([0, b]\times[0, \infty]\times[0, c])$ *and if* $f(x, X, t)$ *is uniformly* $o(X^{-\infty})$ *as* $X \to \infty$, *then*

$$f(x, \mu x, t) = \sum_{k=0}^{N-1} \mu^{-k}[(\mu x)^k f^{[k]}(0, \mu x, t)] + O(\mu^{-N}) \tag{2.23}$$

uniformly for all $(x, t) \in [0, b]\times[0, c]$ *as* $\mu \to \infty$.

3. Proof of Theorem 1. For the first step in proving Theorem 1 observe that straightforward integration by parts shows

$$F(t, \nu) = \nu^{-1/r} \sum_{n=0}^{N-1} \nu^{-n/r} y_n(t) + O(\nu^{-(N+1)/r}) \tag{3.1}$$

uniformly for $c \leqq t < \infty$, for any $c > 0$. The coefficients here are the same as in (2.2). Next,

$$e^{\nu h(t)} \int_{b+t}^{\infty} e^{-\nu h(x)} g(x) x^{\alpha-1}\, dx = e^{-\nu[h(b+t)-h(t)]} F(b+t, \nu) \tag{3.2}$$

and hence, for any $b > 0$,

$$F(t, \nu) = I(t, \nu) + o(\nu^{-\infty}) \tag{3.3}$$

uniformly for $0 \leqq t \leqq b$, where

$$I(t, \nu) = \int_0^b e^{-\nu[h(x+t)-h(t)]} g(x+t)(x+t)^{\alpha-1}\, dx. \tag{3.4}$$

Let $\psi(x, t) = x^{-r}[h(x+t) - h(t) - \kappa(x, t)]$, where

$$\kappa(x, t) = \sum_{k=1}^{r-1} x^k h^{[k]}(t). \tag{3.5}$$

Then $\psi(0, 0) = a(0)r! > 0$, so, for $b > 0$ sufficiently small, $\psi(x, t) > 0$ on $[0, b]\times[0, b]$. Therefore

$$f(x, X, t) = g(x+t) \exp[-X^r \psi(x, t)] \tag{3.6}$$

is in $C^\infty([0, b]\times[0, \infty]\times[0, b])$ and we can apply Corollary 1 to expand $f(x, \nu^{1/r}x, t)$. Upon substituting into

$$I(t, \nu) = \int_0^b f(x, \nu^{1/r}x, t)\, e^{-\nu\kappa(x,t)}(x+t)^{\alpha-1}\, dx, \tag{3.7}$$

and returning to (3.3), we find

$$F(t, \nu) = \nu^{-\alpha/r} \sum_{k=0}^{N-1} \nu^{-k/r} Q_k(t, \nu^{1/r}t) + O(\nu^{-(N+\alpha)/r}) \tag{3.8}$$

uniformly for $0 \leqq t \leqq b$, where

$$Q_k(t, T) = \int_0^\infty X^n\, e^{-\sigma(X,T,t)} q_n(X, t)(X+T)^{\alpha-1}\, dX. \tag{3.9}$$

Here we have introduced

$$\sigma(X, T, t) = \sum_{k=1}^{r} X^k T^{r-k} a_k(t) \tag{3.10}$$

where $a_k(t) = t^{k-r}h^{[k]}(t)$. Also

$$q_0(X, t) = g(t), \qquad q_1(X, t) = g'(t) - g(t)a_r(t)X^r, \tag{3.11}$$

and in general

$$q_n(X, t) = f^{[n]}(0, X, t) \exp[a_r(t)X^r] \tag{3.12}$$

is a polynomial of degree n in X^r.

Expansion (3.8) is to be expected from our work in [6]. In general it is not uniformly valid for $0 \leqq t < \infty$. Nevertheless, from (3.8) we will now derive (2.12), which is uniformly valid for $0 \leqq t < \infty$.

To get from (3.7) to (3.8) we had to have $Q_n(t, T) = O(1)$ on $[0, b]\times[0, \infty)$. To see that this holds, it suffices to check that

$$f(t, T) = \int_T^\infty X^k\, e^{-\sigma(X,T,t)}(X+T)^{\alpha-1}\, dX \tag{3.13}$$

is uniformly $O(1)$ in t as $T \to \infty$ for any $k \geqq 1$. If we substitute TX for X in (3.13), we get

$$f(t, T) = T^{k+\alpha} \int_0^\infty X^k\, e^{-T^r\rho(X,t)}(X+1)^{\alpha-1}\, dX \tag{3.14}$$

where $\rho(X, t) = \sigma(X, 1, t)$. Also, since

$$a_k(0) = \binom{r}{k} h^{[r]}(0) > 0, \tag{3.15}$$

we may presume $a_k(t) > 0$ on $[0, b]$, and thus $\rho^{[1]}(X, t) > 0$ on $[0, \infty)\times[0, b]$. Therefore, $f(t, T)$ has a uniformly valid expansion of the form

$$f(t, T) \sim T^{\alpha-1} \sum_{n=0}^{\infty} c_n(t) T^{-n}, \qquad T \to \infty, \tag{3.16}$$

and each $c_n(t) \in C^\infty[0, b]$. But this says more than just $f(t, T) = O(1)$ as $T \to \infty$. It shows that $f(t, T)$, and therefore each $Q_k(t, T)$, satisfies the hypotheses of Theorem 2. Hence,

$$Q_k(t, \mu t) = \sum_{n=0}^{N-1} \mu^{-n}[v_{kn}(\mu t) + \mu^{\alpha-1}u_{kn}(t)] + O(\mu^{-N}) \tag{3.17}$$

uniformly for $0 \leqq t \leqq b$, where $u_{kn}(t)$, $v_{kn}(T)$ are defined, for each k, by (2.18), (2.19). Upon substituting (3.17) into (3.8), we have

$$F(t, \nu) = \nu^{-\alpha/r} \sum_{k=0}^{N-1} \nu^{-k/r} [q_k(\nu^{1/r} t) + \nu^{-(1-\alpha)r} p_k(t)] + O(\nu^{-(N+\alpha)/r}) \tag{3.18}$$

for $0 \leqq t \leqq b$, where

$$q_k(T) = \sum_{n=0}^{k} v_{n,k-n}(T), \qquad p_k(t) = \sum_{n=0}^{k} u_{n,k-n}(t). \tag{3.19}$$

It remains to see, in view of (3.1), and (2.19), that (3.18) actually holds for $0 \leqq t < \infty$, and, furthermore, that the functions $p_k(t)$ and $q_k(T)$ defined above are the same as the ones defined by (2.13) and (2.14). But these are fairly routine items, and we shall omit the details. This completes the proof of Theorem 1.

4. Related integrals. It is a straightforward matter to modify the proof of Theorem 1 to cover integrals of the more general form

$$\phi(t, \nu) = e^{\nu h(t,t)} \int_t^\infty e^{-\nu h(x,t)} g(x, t) x^{\alpha-1} \, dx. \tag{4.1}$$

Assume $g(x, t)$, $h(x, t) \in C^\infty([0, \infty) \times [0, \infty))$, $h^{[1]}(x, t) = x^{r-1} a(x, t)$ with $a(x, t) > 0$, and $g^{[n]}(x, t)$, $k^{[n]}(x, t) = O(1)$ uniformly in t as $x \to \infty$, where $k(x, t) = 1/h^{[1]}(x, t)$. The same integration by parts process that led to (3.1) now yields

$$\phi(t, \nu) = \nu^{-1/r} \sum_{n=0}^{N-1} \nu^{-n/r} y_n(t, t) + O(\nu^{-(N+1)/r}) \tag{4.2}$$

for $t \geqq c > 0$, where, in analogy with (2.3) and (2.4),

$$y_{r-1}(x, t) = x^{\alpha-1} g(x, t)/h^{[1]}(x, t), \tag{4.3}$$

$$y_{kr-1}(x, t) = y^{[1]}_{kr-r-1}(x, t)/h^{[1]}(x, t), \qquad k \geqq 2 \tag{4.4}$$

and $y_n(x, t) = 0$ for $n \neq kr - 1$. Similarly, for $0 \leqq t \leqq b$ we again get (3.8), except now $a_k(t) = t^{k-r} h^{[k]}(t, t)$. Also $g^{[k]}(t, t)$ replaces $g^{[k]}(t)$ in the formulas for $q_k(X, t)$. Finally, we still have $a_k(0) > 0$, so we can still apply Theorem 2 to the (modified) terms of (3.8). The resulting expansion has the same form as (3.18), and like (3.18) it is uniformly valid for $0 \leqq t < \infty$.

Unlike (1.1), in the case of (4.1) we do not, in general, have an equivalent differential equation problem. From the above discussion, however, it is clear that, nevertheless, $\phi(t, \nu)$ does have matching inner and outer expansions. Furthermore, we can calculate these expansions directly. Indeed, the outer expansion for $\phi(t, \nu)$ is the integration by parts formula (4.2), just as (3.1) is the outer expansions for $F(t, \nu)$. In particular,

$$O_r \phi(t, \nu) = \nu^{-1} g(t, t)/h^{[1]}(t, t). \tag{4.5}$$

In addition, we have

$$\phi(\varepsilon T, \nu) = \varepsilon^\alpha e^{T^r \eta(\varepsilon T, \varepsilon T)} \int_T^\infty e^{-X^r \eta(\varepsilon X, \varepsilon T)} g(\varepsilon X, \varepsilon T) X^{\alpha-1} \, dX, \tag{4.6}$$

where $\eta(x, t) = x^{-r} h(x, t)$ and $\varepsilon = \nu^{-1/r}$. The inner expansion for $\phi(t, \nu)$ is obtained directly from here if we just expand in powers of ε, as if X and T were fixed, and then integrate term by term.

A simple example will show how this goes. Let $h(x, t) = x^3(1+t+3x^2)$, $g(x, t) = 1$ and $\alpha = 1$. Substitution into (4.5) yields $O_3\phi(t, \nu) = \nu^{-1}[3t^2(1+t+5t^2)]^{-1}$. It follows that $[O_3 - I_3O_3]\phi(t, \nu) = \nu^{-1}U(t)$, where

$$U(t) = (3t+\tfrac{20}{3}t^2)/(1+t+5t^2). \tag{4.7}$$

In addition, with $\eta(x, t) = 1+t+3x^2$ in (4.6) we can readily calculate $I_3\phi(t, \nu)$. Indeed, for fixed $T \neq \infty$,

$$\int_T^\infty e^{-X^3\eta(\varepsilon X, \varepsilon T)}\, dX = \int_T^\infty [1 - \varepsilon TX^3 - \tfrac{1}{2}\varepsilon^2(6X^5 - T^2X^6)]\, e^{-X^3}\, dX + O(\varepsilon^3), \tag{4.8}$$

and thus, for this example,

$$\phi(t, \nu) = \nu^{-1/3}V_0(\nu^{1/3}t) + \nu^{-2/3}V_1(\nu^{1/3}t) + \nu^{-1}[U(t) + V_2(\nu^{1/3}t)] + O(\nu^{-4/3}) \tag{4.9}$$

uniformly for $0 \leqq t < \infty$, where

$$V_0(T) = e^{T^3}\int_T^\infty e^{-X^3}\, dX, \tag{4.10}$$

$$V_1(T) = (T^4 - \tfrac{1}{3}T)V_0(T) - \tfrac{1}{3}T^2, \tag{4.11}$$

$$V_2(T) = (\tfrac{2}{9}T^2 + \tfrac{8}{3}T^5 + \tfrac{1}{2}T^8)V_0(T) - (1 + \tfrac{7}{9}T^3 + \tfrac{1}{6}T^6). \tag{4.12}$$

Our methods are applicable also to integrals of the form

$$\psi(t, \nu) = e^{\nu h(t,t)}\int_0^\infty e^{-\nu h(x,t)}g(x, t)x^{\alpha-1}\, dx. \tag{4.13}$$

To illustrate, we shall take $h(x, t) = \sinh x \operatorname{sech} t - x$ and $g(x, t) = 1$. Thus $\psi(t, \nu) = A(t, \nu)$, where $A(t, \nu)$ is given by (1.2). The idea here is that the exponent $h(x, t)$ has its minimum at $x = t$, as in (1.1) and (4.1), but now $h^{[1]}(t, t) = 0$. Instead of $h^{[1]}(t, t) > 0$ for $t > 0$, now we have $h^{[2]}(t, t) = \frac{1}{2}\tanh t > 0$ for $t > 0$, but $h^{[2]}(0, 0) = 0$.

Let $c(t) = 6t^{-1}h^{[2]}(t, t)$. By means of Corollary 1, since $c(0) > 6h^{[3]}(0, 0) = 1$, we can show (by dividing the integral into two parts, $0 \leqq x \leqq t$ and $x \geqq t$) there exists $b > 0$ such that

$$A(t, \nu) = \nu^{-\alpha/3}\sum_{k=0}^{N-1}\nu^{-k/3}Q_k(t, \nu^{1/3}t) + O(\nu^{-(N+1)/3}) \tag{4.14}$$

uniformly for $0 \leqq t \leqq b$, where

$$Q_k(t, T) = \int_{-T}^\infty X^k q_k(X, t)\, e^{-(X^3 + c(t)TX^2)/6}(X+T)^{\alpha-1}\, dX, \tag{4.15}$$

and $q_k(X, t)$ is a polynomial of degree k in X^3. Also,

$$Q_k(t, T) \sim T^{\alpha-3/2}\sum_{n=0}^\infty c_{kn}(t)T^{-3n/2}, \qquad T \to \infty, \tag{4.16}$$

in analogy with (3.16), and thus we can apply Theorem 2 to $f(s, S) = Q_k(s^2, S^2)$. Therefore $A(t, \nu)$ has matching inner and outer expansions, and a uniformly valid composite expansion.

The leading term of the outer expansion for $A(t, \nu)$ can be determined directly by the standard Laplace method. Indeed,

$$A(t, \nu) = \nu^{-1/2}y_0(t) + O(\nu^{-3/2}), \qquad t \neq 0, \tag{4.17}$$

where, $y_0(t) = t^{\alpha-1}(2\pi/\tanh t)^{1/2}$. To get the inner expansion observe that

$$A(\varepsilon T, \nu) = \varepsilon^{\alpha} \int_{-T}^{\infty} e^{-\nu\psi(\varepsilon X, \varepsilon T)}(X+T)^{\alpha-1}\, dX \tag{4.18}$$

where $\psi(x, t) = \sinh(x+t)\operatorname{sech} t - x - \tanh t$ and $\varepsilon = \nu^{-1/3}$. Since

$$\psi(x, t) = \tfrac{1}{6}(x^3+3tx^2) + \tfrac{1}{24}(tx^4 - 4t^3x^2) + O((x^2+t^2)^{7/2}), \tag{4.19}$$

it follows that

$$A(\nu^{-1/3}T, \nu) = \nu^{-\alpha/3}[Y_0(T) + \nu^{-2/3}Y_1(Y) + O(\nu^{-4/3})] \tag{4.20}$$

for $T \neq \infty$, where

$$Y_0(T) = \int_{-T}^{\infty} e^{-(X^3+3TX^2)/6}(X+T)^{\alpha-1}\, dX, \tag{4.21}$$

$$Y_1(T) = \frac{1}{24}\int_{-T}^{\infty} e^{-(X^3+3TX^2)/6}(TX^4 - 4T^3X^2)(X+T)^{\alpha-1}\, dX. \tag{4.22}$$

In addition,

$$\nu^{-1/2}y_0(\varepsilon T) = (2\pi)^{1/2}\nu^{-\alpha/3}T^{\alpha-3/2}[1 + \tfrac{1}{6}\nu^{-2/3}T^2 + O(\nu^{-4/3})]; \tag{4.23}$$

thus, combining (4.17), (4.20), and (4.23), we obtain the uniformly valid composite formula (1.3).

A DEFINITE INTEGRAL OF A PRODUCT OF TWO POLYLOGARITHMS*

V. S. ADAMCHIK† AND K. S. KÖLBIG‡

Abstract. Using the product theorem for the Mellin transform, a definite integral depending on several parameters and containing a product of two polylogarithm functions (or two logarithms in the degenerate case) is replaced by a Mellin-Barnes integral, which in turn is evaluated by residue techniques. The results are given in terms of infinite series of hypergeometric type. Some special cases for which the infinite series can be expressed in closed form are also considered.

Key words. polylogarithms, logarithmic integrals, Mellin-Barnes integral, hypergeometric series

AMS(MOS) subject classifications. primary 33A70; secondary 33A35, 44A15

1. Introduction.

It is the purpose of this paper to evaluate the integral

$$I_{n,m}(\alpha, \sigma, \omega, r) = \int_0^\infty x^{\alpha-1} Li_n(-\sigma x) Li_m(-\omega x^r)\, dx \tag{1.1}$$

for positive integers n, m, complex α, σ, ω, and real $r \neq 0$ such that the integral exists. $Li_k(z)$ is the polylogarithm function defined for $|z| \leqq 1$ and $k \geqq 2$ by the power series [9, p. 189]

$$Li_k(z) = \sum_{j=1}^{\infty} \frac{z^j}{j^k} \qquad (|z| \leqq 1) \tag{1.2}$$

and for $|z| > 1$ by [9, p. 192], [8]

$$\begin{aligned} Li_k(z) = (-1)^{k+1} Li_k\left(\frac{1}{z}\right) - \frac{1}{k!} \ln^k(-z) \\ - \sum_{j=0}^{k-2} \frac{1}{j!} (1+(-1)^{k-j})(1-2^{1-k+j}) \zeta(k-j) \ln^j(-z), \end{aligned} \tag{1.3}$$

where $\zeta(q)$ is the Riemann zeta function and where the logarithm is defined on its principal sheet. For $k = 1$ we obtain from (1.2)

$$Li_1(z) = -\ln(1-z) \tag{1.4}$$

as a degenerate case. Interest in polylogarithms, which have been investigated in the past by many mathematicians, has revived in recent years because of their applications in quantum electrodynamics, group theory, and geometry. For example, Berndt and Joshi [2] have analysed Ramanujan's work on these functions, Maier and Kiesewetter [10] have investigated systematically some of their functional relations, and Böhm and Hertel [3] have made use of them in the theory of n-dimensional polyhedrals. Gastmans and Troost [5] and Devoto and Duke [4] present tables of integrals leading to or containing polylogarithms which are useful in quantum electrodynamics.

An integral representation of $Li_k(z)$ given recently by Marichev [12, p. 105], namely

$$Li_k(-z) = \frac{1}{2\pi i} \int_{a-i\infty}^{a+i\infty} \frac{\Gamma(s)\Gamma(-s)}{(-s)^{k-1}} z^{-s}\, ds \qquad (-1 < a < 0, |\arg z| < \pi, k = 0, 1, 2, \cdots) \tag{1.5}$$

* Received by the editors October 8, 1986; accepted for publication (in revised form) June 18, 1987.
† Belorussian State University, Minsk, U.S.S.R.
‡ European Organization for Nuclear Research (CERN), CH-1211 Geneva 23, Switzerland.

allows us to evaluate the integral (1.1) by using the product theorem of the Mellin transform, and by applying the residue theorem.

From (1.3), we find that

$$Li_k(-z) = -\frac{1}{k!}\ln^k z + O(\ln^{k-2} z) \qquad (z \to \infty) \tag{1.6}$$

which can be used, together with (1.2), to show that the integral (1.1) converges under the conditions

$$\begin{aligned} &-1-r<\operatorname{Re}\alpha<0 \quad \text{if } r>0, \\ &-1<\operatorname{Re}\alpha<-r \quad \text{if } r<0, \end{aligned} \tag{1.7}$$

and $|\arg\sigma|<\pi$, $|\arg\omega|<\pi$.

We may add here that, by making the substitution $x=\xi^{1/r}$, we obtain from (1.1) the "symmetry" relation

$$I_{n,m}(\alpha,\sigma,\omega,r) = \frac{1}{|r|} I_{m,n}\left(\frac{\alpha}{r}, \omega, \sigma, \frac{1}{r}\right). \tag{1.8}$$

2. An alternative integral for $I_{n,m}(\alpha,\sigma,\omega,r)$. In this section, we derive a Mellin-Barnes integral for $I_{n,m}$. By introducing (1.5) into (1.1), we find with the (allowed) substitution $rs=-s'$,

$$\begin{aligned} I_{n,m} = \frac{1}{\sigma^\alpha |r|}\int_0^\infty \frac{du}{u}\left(u^\alpha \frac{1}{2\pi i}\int_{a-i\infty}^{a+i\infty} \frac{\Gamma(s)\Gamma(-s)}{(-s)^{n-1}} u^{-s}\,ds\right) \\ \cdot\left(\frac{1}{2\pi i}\int_{a'-i\infty}^{a'+i\infty} \frac{\Gamma(s/r)\Gamma(-s/r)}{(s/r)^{m-1}}\left(\frac{\zeta}{u}\right)^{-s} ds\right) \end{aligned}$$

where $\zeta=\sigma\omega^{-1/r}$. Applying well-known theorems for the Mellin transform (see, e.g., Sneddon [17, pp. 262-297]), in particular the product theorem

$$\int_0^\infty f\left(\frac{\zeta}{u}\right) g(u)\frac{du}{u} = \frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty} f^*(s)g^*(s)\zeta^{-s}\,ds,$$

we see that

$$\begin{aligned} g^*(s) &= (-1)^{n+1}\Gamma(s+\alpha)\Gamma(-s-\alpha)(s+\alpha)^{1-n}, \\ f^*(s) &= \Gamma\left(\frac{s}{r}\right)\Gamma\left(-\frac{s}{r}\right)\left(\frac{s}{r}\right)^{1-m}, \end{aligned}$$

and therefore that

$$I_{n,m}(\alpha,\sigma,\omega,r) = \frac{(-1)^{n+1}}{\sigma^\alpha|r|}\frac{1}{2\pi i}\int_{\gamma-i\infty}^{\gamma+i\infty} \frac{\Gamma(s+\alpha)\Gamma(-s-\alpha)\Gamma(s/r)\Gamma(-s/r)}{(s+\alpha)^{n-1}(s/r)^{m-1}}\zeta^{-s}\,ds, \tag{2.1}$$

where

$$\begin{aligned} &\max(0,-1-\operatorname{Re}\alpha)<\gamma=\operatorname{Re}s<\min(r,-\operatorname{Re}\alpha) \qquad (r>0), \\ &\max(r,-1-\operatorname{Re}\alpha)<\gamma=\operatorname{Re}s<\min(0,-\operatorname{Re}\alpha) \qquad (r<0). \end{aligned} \tag{2.2}$$

Using [6, No. 8.3343]

$$\Gamma(z)\Gamma(-z) = -\frac{\pi}{z}\csc\pi z,$$

the integral (2.1) can be written as

$$I_{n,m}(\alpha, \sigma, \omega, r) = \frac{(-1)^{n+1}\pi^2}{\sigma^{\alpha}|r|}\frac{1}{2\pi i}\int_{\gamma-i\infty}^{\gamma+i\infty} \csc[\pi(s+\alpha)]\csc\left(\pi\frac{s}{r}\right)(s+\alpha)^{-n}\left(\frac{s}{r}\right)^{-m}\zeta^{-s}\,ds. \tag{2.3}$$

Formula (2.3) is more suitable than (2.1) for evaluation by the residue theorem.

We may note here that $I_{n,m}$ is a special case of Fox's H-function (see Mathai and Saxena [14, p. 2]), namely

$$I_{n,m}(\alpha, \sigma, \omega, r) = \frac{1}{\sigma^{\alpha}|r|}H^{m+1,n+1}_{m+n,m+n} \times\left[\frac{\sigma}{\omega^{1/r}}\middle|\begin{matrix}(1+\alpha,1),\cdots,(1+\alpha,1),(1,1/r),\cdots,(1,1/r)\\ (0,1/r),\cdots,(0,1/r),(\alpha,1),\cdots,(\alpha,1)\end{matrix}\right] \tag{2.4}$$

with n repetitions of the brackets $(1+\alpha, 1)$, $(\alpha, 1)$ and m repetitions of $(1, 1/r)$, $(0, 1/r)$.

For rational $r = \pm p/q$, $(p, q \in \mathbb{N})$ it is possible to express the integral (2.1) as a special case of Meijer's G-function in the logarithmic case [13, p. 176]. Substituting $s' = s/p$ in (2.1), and applying the product theorem [6, No. 8.335] of the gamma function we obtain

$$I_{n,m}\left(\alpha, \sigma, \omega, \pm\frac{p}{q}\right) = (-1)^{n+1}(\pm 1)^{m+1}\frac{(2\pi)^{2-p-q}}{\sigma^{\alpha}p^{n}q^{m-1}}G^{m',n'}_{p',p'}\left(\frac{\sigma^{p}}{\omega^{\pm q}}\middle|\begin{matrix}a_j\\ b_j\end{matrix}\right), \tag{2.5}$$

where

$$\begin{aligned} m' &= n+m+p+q-2,\\ n' &= p+q,\\ p' &= n+m+p+q-2, \end{aligned} \tag{2.6}$$

and

$$a_j = \begin{cases} 1+(1+\alpha-j)/p, & j=1,\cdots,p,\\ 1+(1-j)/q, & j=p+1,\cdots,p+q,\\ 1+\alpha/p, & j=p+q+1,\cdots,p+q+n-1,\\ 1, & j=p+q+n,\cdots,p+q+n+m-2, \end{cases}$$

$$b_j = \begin{cases} \alpha/p, & j=1,\cdots,n-1,\\ 0, & j=n,\cdots,n+m-2,\\ (\alpha+j-1)/p, & j=n+m-1,\cdots,n+m+p-2,\\ (j-1)/q, & j=n+m+p-1,\cdots,n+m+p+q-2. \end{cases} \tag{2.7}$$

According to the theory of the G-function [15], we know that $G^{m',n'}_{p',p'}(z)$ is analytic and continuous in the whole sector $|\arg z| < \pi(m'+n'-p')$, provided that $m'+n'-p' > 1$. From (2.6), we have that $m'+n'-p' = p+q > 1$, which further implies [15] that the point $(-1)^{m'+n'-p'}$ is not a singular point. It follows that, for rational r, the function (2.1) is analytic and continuous in the whole sector $|\arg \zeta| < \pi(1+q/p)$. Using the analyticity of the integral (2.1) with respect to r, it follows that this property holds for any real r. We shall use this continuity property of (2.1) when considering the examples in § 4.

3. The evaluation of the integral. Using techniques developed by Marichev [11], [12] and, for the logarithmic case of integrals (2.1), by Adamchik and Marichev [1] and Mathai and Saxena [13, p. 157], [14, p. 70], it is possible to evaluate the integral (1.1) in terms of infinite (hypergeometric type) series. We thus obtain the following theorem.

THEOREM. *Let $r \neq 0$ be real, α, σ, ω be complex with $|\arg \sigma| < \pi$, $|\arg \omega| < \pi$, and let $\zeta = \sigma\omega^{-1/r}$. Further, with $\mathbb{N} = \{1, 2, 3, \cdots\}$, let $\mathbb{N}_0 = \{0, \mathbb{N}\}$,*

$$h(x) = \begin{cases} 1 & \text{if } x \in \mathbb{N}, \\ 0 & \text{otherwise,} \end{cases} \qquad \bar{h}(x) = 1 - h(x);$$

$$H(x) = \begin{cases} 1 & \text{if } x > 0, \\ 0 & \text{if } x < 0, \end{cases}$$

and let k, l, $K \in \mathbb{N}$.

Then, for $|\zeta| \neq 1$ and

$$-1 - r < \operatorname{Re} \alpha < 0 \quad \text{if } r > 0,$$

$$-1 < \operatorname{Re} \alpha < -r \quad \text{if } r < 0,$$

the integral (1.1) *can, for $\alpha \neq 0$, be expressed in the form*

(3.1)

$$\begin{aligned}
&\int_0^\infty x^{\alpha-1} Li_n(-\sigma x) Li_m(-\omega x^r)\, dx \\
&\quad = (-1)^n (\pm \operatorname{sgn} r)^{m+1} \pi \sigma^{-\alpha} \sum_{|r|k \pm \alpha \notin \mathbb{N}_0} (-1)^k \csc[\pi(\alpha \pm |r|k)] (\alpha \pm |r|k)^{-n} k^{-m} \zeta^{\mp |r| k} \\
&\qquad \mp (\pm 1)^n (-1)^{m+n} \frac{\pi}{|r|} \omega^{-\alpha/r} \sum_{(l \mp \alpha)/|r| \notin \mathbb{N}_0} (-1)^l \csc\left(\pi \frac{\alpha \mp l}{r}\right) \left(\frac{\alpha \mp l}{r}\right)^{-m} l^{-n} \zeta^{\mp l} \\
&\qquad + (-1)^{n+1} (\pm \operatorname{sgn} r)^{m+1} \sigma^{-\alpha} \sum_{|r|K \pm \alpha \in \mathbb{N}} (-1)^{K + |r|K \pm \alpha} (\alpha \pm |r|K)^{-n} K^{-m} \zeta^{\mp |r| K} \\
&\qquad \cdot \left(\pm \frac{m}{|r|K} + \frac{n}{\alpha \pm |r|K} + \ln \zeta \right) + H(\mp r)(-1)^{n+1} \sigma^{-\alpha} \pi^{m+1} r^m \alpha^{-n} \\
&\qquad \cdot \Bigg\{ h(\pm\alpha)(-1)^\alpha \sum_{m_1=0}^{m+1} \frac{1}{m_1!} \left(-\frac{1}{\pi} \ln \zeta \right)^{m_1} \\
&\qquad\quad \cdot \sum_{m_2=0}^{m+1-m_1} \binom{m_2 + n - 1}{n-1} (-\pi\alpha)^{-m_2} \sum_{m_3=0}^{m+1-m_1-m_2} r^{-m_3} B^*_{m_3} B^*_{m+1-m_1-m_2-m_3} \\
&\qquad\quad + \bar{h}(\pm\alpha) \sum_{m_1=0}^{m} \frac{1}{m_1!} \left(-\frac{1}{\pi} \ln \zeta \right)^{m_1} \\
&\qquad\quad \cdot \sum_{m_2=0}^{m-m_1} \binom{m_2 + n - 1}{n-1} (-\pi\alpha)^{-m_2} \sum_{m_3=0}^{m-m_1-m_2} r^{-m_3} B^*_{m_3} C_{m-m_1-m_2-m_3}(\pi\alpha) \Bigg\} \\
&\qquad + H(\pm 1)(-1)^m (\operatorname{sgn} r) \omega^{-\alpha/r} \pi^{n+1} r^m \alpha^{-m} \\
&\qquad \cdot \Bigg\{ h\left(-\frac{\alpha}{|r|}\right)(-1)^{n+\alpha/r} \sum_{n_1=0}^{n+1} \frac{1}{n_1!} \left(-\frac{1}{\pi} \ln \zeta \right)^{n_1} \\
&\qquad\quad \cdot \sum_{n_2=0}^{n+1-n_1} \binom{n_2 + m - 1}{m-1} (\pi\alpha)^{-n_2} \sum_{n_3=0}^{n+1-n_1-n_2} r^{-n_3} B^*_{n_3} B^*_{n+1-n_1-n_2-n_3}
\end{aligned}$$

$$-\bar{h}\left(-\frac{\alpha}{|r|}\right)r^{-n-1}\sum_{n_1=0}^{n}\frac{1}{n_1!}\left(\frac{r}{\pi}\ln\zeta\right)^{n_1}$$
$$\cdot\sum_{n_2=0}^{n-n_1}(-1)^{n_2}\binom{n_2+m-1}{m-1}\left(\pi\frac{\alpha}{r}\right)^{-n_2}\sum_{n_3=0}^{n-n_1-n_2}(-r)^{n_3}B_{n_3}^{*}C_{n-n_1-n_2-n_3}\left(\pi\frac{\alpha}{r}\right)\Bigg\},$$

and for $\alpha=0$ *(which implies* $r<0$*), in the form*

$$\int_0^\infty Li_n(-\sigma x)Li_m(-\omega x^r)\frac{dx}{x}$$
$$=-(\mp1)^{m+n}\Bigg\{|r|^{-n}\pi\sum_{|r|k\notin\mathbb{N}}(-1)^k\csc(\pi|r|k)k^{-(m+n)}\zeta^{\mp|r|k}$$
$$+|r|^{m-1}\pi\sum_{l/|r|\notin\mathbb{N}}(-1)^l\csc\left(\pi\frac{l}{|r|}\right)l^{-(m+n)}\zeta^{\mp l}$$
(3.2)
$$-|r|^{-n}\sum_{|r|K\in\mathbb{N}}(-1)^{K(1+r)}K^{-(m+n)}\zeta^{\mp|r|K}\left(\frac{m+n}{|r|K}\pm\ln\zeta\right)\Bigg\}$$
$$+H(\pm1)(-1)^{n+1}\pi^{m+n+1}r^m$$
$$\cdot\sum_{m_1=0}^{m+n+1}\frac{1}{m_1!}\left(-\frac{1}{\pi}\ln\zeta\right)^{m_1}\sum_{m_2=0}^{m+n+1-m_1}r^{-m_2}B_{m_2}^{*}B_{m+n+1-m_1-m_2}^{*},$$

where

$$B_j^{*}=\frac{|2^j-2|}{j!}|B_j|, \tag{3.3}$$

B_j *are the Bernoulli numbers, where*

$$C_j(x)=\frac{1}{j!}\frac{d^j}{ds^j}\csc(s+x)|_{s=0}, \tag{3.4}$$

and where the logarithm is defined on its principal sheet.

In all the expressions above, the upper sign corresponds to $|\zeta|>1$, the lower sign to $|\zeta|<1$.

Proof. Using the theory of the H-function [14], we find that the poles of the integrand in (2.3), i.e., of

$$\varphi_{n,m}(s;\alpha,r)=\csc[\pi(s+\alpha)]\csc\left(\pi\frac{s}{r}\right)(s+\alpha)^{-n}\left(\frac{s}{r}\right)^{-m}, \tag{3.5}$$

which need to be taken into account when evaluating the integral (1.1), are those which, for $|\zeta|>1$ lie on the right, and for $|\zeta|<1$ on the left, of the line $\operatorname{Re} s=\gamma$. In the first case the values of the corresponding residues must be multiplied by a factor -1. The relevant poles are:

$|\zeta|>1$.

(i) At $s=0$ if $r<0$. Pole of order $m+2$ if $\alpha\in\mathbb{N}$, of order $m+n+2$ if $\alpha=0$, of order $m+1$ if $\alpha\notin\mathbb{N}_0$.

(ii) At $s=-\alpha$. If $r<0$: pole of order $n+2$ if $\alpha/r\in\mathbb{N}$, of order $n+1$ if $\alpha/r\notin\mathbb{N}_0$. If $r>0$: pole of order $n+2$ if $-\alpha/r\in\mathbb{N}$, of order $n+1$ if $-\alpha/r\notin\mathbb{N}$.

(iii) At $s=|r|k$ and at $s=-\alpha+l$, for $k,l\in\mathbb{N}$. Both poles of order 1 if $|r|k\neq-\alpha+l$, single pole of order 2 if $|r|k=-\alpha+l$.

$|\zeta|<1$.

(i) At $s=0$ if $r>0$. Pole of order $m+2$ if $-\alpha\in\mathbb{N}$, of order $m+1$ if $-\alpha\notin\mathbb{N}$.

(ii) At $s=-|r|k$ and at $s=-\alpha-l$ for $k,l\in\mathbb{N}$. Both poles of order 1 if $|r|k\neq\alpha+l$, single pole of order 2 if $|r|k=\alpha+l$.

The residues corresponding to these poles can be evaluated by standard methods, making use of the Leibniz formula for the mth derivative of a product of k functions of one variable, together with elementary properties of the cosecant and cotangent functions, and the power series expansion [6, No. 1.41111]

$$\pi x \csc \pi x = \sum_{j=0}^{\infty} \frac{|2^j - 2|}{j!} |B_j| (\pi x)^j \qquad (|x| < 1). \tag{3.6}$$

By collecting the computed residues appropriately we obtain formulae (3.1) and (3.2) of the theorem.

We here list, for convenience, the first six functions $C_j(x)$ defined by (3.4):

$$C_j(x) = \frac{1}{j!} \frac{d^j}{ds^j} \csc(s+x)\Big|_{s=0} = \frac{1}{j!} \csc^{j+1} x \tilde{C}_j(x) \tag{3.7}$$

where

$$\tilde{C}_0(x) = 1,$$
$$\tilde{C}_1(x) = -\cos x,$$
$$\tilde{C}_2(x) = 2 - \sin^2 x,$$
$$\tilde{C}_3(x) = \cos x(\sin^2 x - 6),$$
$$\tilde{C}_4(x) = \sin^4 x - 20 \sin^2 x + 24,$$
$$\tilde{C}_5(x) = \cos x(-\sin^4 x + 60 \sin^2 x - 120).$$

We may add here that it is not difficult to evaluate the finite sums in (3.1) and (3.2) by a symbolic algebra system such as REDUCE [7].

4. Special cases. In this section, we consider some special cases of (3.1) and (3.2). For notational purposes, we make use of the Lerch function [6, No. 9.550]

$$\Phi(z, u, v) = \sum_{k=0}^{\infty} \frac{z^k}{(k+v)^u} \qquad (|z| < 1, -v \notin \mathbb{N}_0), \tag{4.1}$$

which is a generalization of the polylogarithm function (1.2). In particular, for $u = 2$, $v = \frac{1}{2}$, we have

$$\Phi\left(-z, 2, \frac{1}{2}\right) = \frac{4}{\sqrt{z}} \sum_{k=0}^{\infty} \frac{(-1)^k (\sqrt{z})^{2k+1}}{(2k+1)^2} = \frac{4}{\sqrt{z}} Ti_2(\sqrt{z}) \tag{4.2}$$

where

$$Ti_2(z) = \int_0^z t^{-1} \arctan t \, dt$$

is the arctangent integral.

We shall also make use of the following lemma.

LEMMA. *Let E_j be the Euler numbers* [6, No. 9.72], *let*

$$E_j^* = \begin{cases} 0, & j \in \{-2, -1\}, \\ |E_j|/j!, & j \in \mathbb{N}_0, \end{cases}$$

and let B_j^* be defined by (3.3). *Then*

$$S_k \equiv \sum_{j=0}^{k} (\pm 2)^{k-j} B_j^* B_{k-j}^* = E_{k-2}^* - (k-1) B_k^* \qquad (k \in \mathbb{N}_0). \tag{4.3}$$

Proof. We start from the identity

$$(x \csc x)(2x \csc 2x) = x^2\left(\sec x - \frac{d}{dx}\csc x\right)$$

and replace the trigonometric functions by their power series (3.6) and [6, No. 1.4119]

$$\sec x = \sum_{j=0}^{\infty} \frac{|E_j|}{j!} x^j \qquad \left(|x| < \frac{1}{2}\pi\right),$$

respectively. Multiplying together the two power series on the left-hand side of the identity and equating coefficients yields the lemma.

4.1. $r=-2$, $\alpha=0$. In this case the summation conditions for the infinite series become

$$2k \notin \mathbb{N}, \quad \tfrac{1}{2}l \notin \mathbb{N}, \quad 2K \in \mathbb{N},$$

which exclude all $k \in \mathbb{N}$ but permit all odd values of $l \in \mathbb{N}$, and all $K \in \mathbb{N}$. Thus, from (3.2) with $\zeta = \sigma\sqrt{\omega}$, using (1.2) and (4.3),

(4.4)

$$\begin{aligned}
&\int_0^\infty Li_n(-\sigma x) Li_m(-\omega x^{-2}) \frac{dx}{x} \\
&\quad = (\mp)^{m+n}\left\{2^{-(n+1)}\pi\zeta^{\mp 1}\Phi\left(-\zeta^{\mp 2}, m+n, \frac{1}{2}\right)\right. \\
&\qquad\qquad \left. + 2^{-(n+1)}(m+n) Li_{m+n+1}(-\zeta^{\mp 2}) \pm 2^{-n} \ln\zeta\, Li_{m+n}(-\zeta^{\mp 2})\right\} \\
&\quad + H(\pm 1)(-\pi)^{m+n+1} 2^{-n-1} \sum_{j=0}^{m+n+1} \frac{1}{j!}\left(-\frac{2}{\pi}\ln\zeta\right)^j S_{m+n+1-j} \\
&\qquad\qquad (|\zeta| \gtrless 1,\ m, n \in \mathbb{N},\ |\arg\sigma| < \pi,\ |\arg\omega| < \pi).
\end{aligned}$$

In particular, for $n = m = 1$, using (1.4) and (4.2):

$$\begin{aligned}
\int_0^\infty \ln(1+\sigma x)\ln(1+\omega x^{-2})\frac{dx}{x} &= \pi Ti_2(\zeta^{\mp 1}) + \frac{1}{2} Li_3(-\zeta^{\mp 2}) \pm \frac{1}{2}\ln\zeta Li_2(-\zeta^{\mp 2}) \\
&\quad + \begin{cases} \frac{1}{3}\ln^3\zeta + \frac{5}{12}\pi^2\ln\zeta & (|\zeta| > 1), \\ 0 & (|\zeta| < 1). \end{cases}
\end{aligned} \tag{4.5}$$

For $n = 1$, $m = 2$:

$$\begin{aligned}
\int_0^\infty \ln(1+\sigma x) Li_2(-\omega x^{-2})\frac{dx}{x} &= \pm\frac{1}{4}\pi\zeta^{\mp 1}\Phi\left(-\zeta^{\mp 2}, 3, \frac{1}{2}\right) \pm \frac{3}{4} Li_4(-\zeta^{\mp 2}) \\
&\quad + \frac{1}{2}\ln\zeta\, Li_3(-\zeta^{\mp 2}) \\
&\quad - \begin{cases} \frac{1}{6}\ln^4\zeta + \frac{5}{12}\pi^2\ln^2\zeta + \frac{53}{480}\pi^4 & (|\zeta| > 1), \\ 0 & (|\zeta| < 1). \end{cases}
\end{aligned} \tag{4.6}$$

For $n=2$, $m=1$:

$$\int_0^\infty Li_2(-\sigma x)\ln(1+\omega x^{-2})\frac{dx}{x}=\frac{1}{2}\int_0^\infty \ln(1+\sigma x)Li_2(-\omega x^{-2})\frac{dx}{x}. \tag{4.7}$$

For $n=m=2$:

$$\int_0^\infty Li_2(-\sigma x)Li_2(-\omega x^{-2})\frac{dx}{x}=\frac{1}{8}\pi\zeta^{\mp1}\Phi\left(-\zeta^{\mp2},4,\frac{1}{2}\right)+\frac{1}{2}Li_5(-\zeta^{\mp2})\pm\frac{1}{4}\ln\zeta Li_4(-\zeta^{\mp2})$$

$$-\begin{cases}\dfrac{1}{30}\ln^5\zeta+\dfrac{5}{36}\pi^2\ln^3\zeta+\dfrac{53}{480}\pi^4\ln\zeta & (|\zeta|>1),\\ 0 & (|\zeta|<1).\end{cases} \tag{4.8}$$

Using the fact that the integral is continuous for $|\arg\sigma\sqrt{\omega}|<\pi/2$, we can set $\sigma=\omega=1$ and obtain from (4.4):

$$\int_0^\infty Li_n(-x)Li_m(-x^{-2})\frac{dx}{x}=2^{-(n+1)}\left\{\pi\Phi\left(-1,n+m,\frac{1}{2}\right)+(n+m)Li_{n+m+1}(-1)\right\}$$

$$=2^{-(n+1)}\left\{\pi 2^{n+m}\sum_{k=0}^{\infty}\frac{(-1)^k}{(2k+1)^{n+m}}-(n+m)\sum_{k=1}^{\infty}\frac{(-1)^k}{k^{n+m+1}}\right\}. \tag{4.9}$$

In the case of $n+m$ odd, these series are well known (e.g., [16, No. 5.1.3.3, 5.1.4.2]). Thus we obtain

$$\int_0^\infty Li_n(-x)Li_m(-x^{-2})\frac{dx}{x}=2^{-(n+2)}\frac{\pi^{n+m+1}}{(n+m-1)!}\left\{|E_{n+m-1}|-\frac{2^{n+m+1}-2}{n+m+1}|B_{n+m+1}|\right\} \tag{4.10}$$

$(n, m\in\mathbb{N}, n+m \text{ odd}).$

This formula is remarkable insofar as it contains both the Bernoulli and Euler numbers. For $n=m=1$, formula (4.9) reduces to

$$\int_0^\infty \ln(1+x)\ln(1+x^{-2})\frac{dx}{x}=\pi G-\frac{3}{8}\zeta(3), \tag{4.11}$$

where G is Catalan's constant.

4.2. $r=2$, $\alpha=-2$. In this case the summation conditions for the infinite series become

$$2k\mp2\notin\mathbb{N}_0,\quad \tfrac{1}{2}l\pm1\notin\mathbb{N}_0,\quad 2K\mp2\in\mathbb{N},$$

which exclude all $k\in\mathbb{N}$, but permit all odd values of $l\in\mathbb{N}$, all $K\in\mathbb{N}\setminus\{1\}$ if $|\zeta|>1$, and all $K\in\mathbb{N}$ if $|\zeta|<1$. Thus, from (3.1) with $\zeta=\sigma/\sqrt{\omega}$, using (4.3),

$$\int_0^\infty x^{-3}Li_n(-\sigma x)Li_m(-\omega x^2)dx$$

$$=(-1)^n\left\{2^{m-1}\pi\frac{\omega^{3/2}}{\sigma}\sum_{l=0}^{\infty}\frac{(-\zeta^{-2})^l}{(2l+1)^n(2l+3)^m}\right.$$

$$+2^{n-1}\omega\left[m\sum_{k=1}^{\infty}\frac{(-\zeta^{-2})^k}{k^n(k+1)^{m+1}}+n\sum_{k=1}^{\infty}\frac{(-\zeta^{-2})^k}{k^{n+1}(k+1)^m}+2\ln\zeta\sum_{k=1}^{\infty}\frac{(-\zeta^{-2})^k}{k^n(k+1)^m}\right] \tag{4.12a}$$

$$\left.-\left(\frac{\pi}{2}\right)^{n+1}\omega\sum_{n_1=0}^{n+1}\frac{1}{n_1!}\left(-\frac{2}{\pi}\ln\zeta\right)^{n_1}\sum_{n_2=0}^{n+1-n_1}\binom{n_2+m-1}{m-1}(-\pi)^{-n_2}S_{n+1-n_1-n_2}\right\}$$

$(|\zeta|>1, m, n\in\mathbb{N}, |\arg\sigma|<\pi, |\arg\omega|<\pi),$

(4.12b)

$$\int_0^\infty x^{-3} Li_n(-\sigma x) Li_m(-\omega x^2)\, dx$$

$$= (-1)^m \left\{ 2^{m-1} \pi \sigma \sqrt{\omega} \sum_{l=0}^{\infty} \frac{(-\zeta^2)^l}{(2l+1)^n (2l-1)^m} - 2^{-n-1} \sigma^2 \right.$$

$$\left. \times \left[m \sum_{k=1}^{\infty} \frac{(-\zeta^2)^k}{k^{m+1}(k+1)^n} + n \sum_{k=1}^{\infty} \frac{(-\zeta^2)^k}{k^m (k+1)^{n+1}} - 2 \ln \zeta \sum_{k=1}^{\infty} \frac{(-\zeta^2)^k}{k^m (k+1)^n} \right] \right\}$$

$$- \pi^{m+1} 2^{-n-1} \sigma^2 \sum_{m_1=0}^{m+1} \frac{1}{m_1!} \left(-\frac{2}{\pi} \ln \zeta \right)^{m_1} \sum_{m_2=0}^{m+1-m_1} \binom{m_2 - n - 1}{n-1} \pi^{-m_2} S_{m+1-m_1-m_2}$$

$$(|\zeta| < 1,\ m, n \in \mathbb{N},\ |\arg \sigma| < \pi,\ |\arg \omega| < \pi).$$

Using the relations [16, Nos. 5.2.5.5,15, 5.2.6.1,2]

$$\sum_{l=0}^{\infty} \frac{(-1)^l x^{2l+3}}{(2l+1)(2l+3)} = \frac{1}{2}(1+x^2) \arctan x - \frac{1}{2} x,$$

$$\sum_{k=1}^{\infty} \frac{x^{k+1}}{k(k+1)^2} = 2x + (1-x) \ln (1-x) - Li_2(x),$$

(4.13)

$$\sum_{k=1}^{\infty} \frac{x^{k+1}}{k^2(k+1)} = (x-1) \ln (1-x) + x(Li_2(x) - 1),$$

$$\sum_{k=1}^{\infty} \frac{x^{k+1}}{k(k+1)} = x + (1-x) \ln (1-x),$$

we find for $n = m = 1$, after some calculation,

(4.14)

$$\int_0^\infty x^{-3} \ln (1+\sigma x) \ln (1+\omega x^2)\, dx$$

$$= \frac{1}{2} \left\{ (\sigma^2 + \omega) \left[\ln \left(\frac{\sigma}{\sqrt{\omega}} \right) \ln \left(1 + \frac{\omega}{\sigma^2} \right) - \frac{1}{2} Li_2 \left(-\frac{\omega}{\sigma^2} \right) - \pi \arctan \left(\frac{\sqrt{\omega}}{\sigma} \right) \right] \right.$$

$$\left. + \omega \left[\pi \frac{\sigma}{\sqrt{\omega}} + \ln^2 \left(\frac{\sigma}{\sqrt{\omega}} \right) + \frac{5}{12} \pi^2 \right] \right\} \qquad (|\sigma/\sqrt{\omega}| > 1),$$

$$= \frac{1}{2} \left\{ (\sigma^2 + \omega) \left[\ln \left(\frac{\sigma}{\sqrt{\omega}} \right) \ln \left(1 + \frac{\sigma^2}{\omega} \right) + \frac{1}{2} Li_2 \left(-\frac{\sigma^2}{\omega} \right) + \pi \arctan \left(\frac{\sigma}{\sqrt{\omega}} \right) \right] \right.$$

$$\left. + \sigma^2 \left[\pi \frac{\sqrt{\omega}}{\sigma} - \ln^2 \left(\frac{\sigma}{\sqrt{\omega}} \right) - \frac{5}{12} \pi^2 \right] \right\} \qquad (|\sigma/\sqrt{\omega}| < 1).$$

For $\sigma \to \sqrt{\omega}$, we obtain in the limit, using $Li_2(-1) = -\pi^2/12$,

(4.15)
$$\int_0^\infty x^{-3} \ln (1+x) \ln (1+x^2)\, dx = \frac{\pi}{2}.$$

Using the fact that the integral is continuous at $\sigma=\omega=1$, we obtain

(4.16)

$$\int_0^\infty x^{-3}Li_n(-x)Li_m(-x^2)\,dx$$
$$=(-1)^n\Bigg\{2^{m-1}\pi\sum_{l=0}^{\infty}\frac{(-1)^l}{(2l+1)^n(2l+3)^m}$$
$$+2^{-n-1}\Bigg[m\sum_{k=1}^{\infty}\frac{(-1)^k}{k^n(k+1)^{m+1}}+n\sum_{k=1}^{\infty}\frac{(-1)^k}{k^{n+1}(k+1)^m}\Bigg]$$
$$-\left(\frac{\pi}{2}\right)^{n+1}\sum_{j=0}^{n+1}\binom{j+m-1}{m-1}(-\pi)^{-j}S_{n+1-j}\Bigg\}.$$

From [16, No. 5.1.24.14] we see that the first sum can in general be expressed only in terms of generalized zeta functions $\zeta(j,\frac{1}{2})$ and $\zeta(j,\frac{1}{4})$. For $n=m$, however, using the relations [16, Nos. 5.1.24.10, 5.1.24.15][1,2]

(4.17)

$$\sum_{k=1}^{\infty}\frac{(-1)^{k+1}}{k^m(k+1)^n}=(-1)^{m-1}\sum_{k=0}^{n-2}\binom{m+k-1}{k}(1-2^{1-n+k})\zeta(n-k)$$
$$+\sum_{k=0}^{m-2}(-1)^k\binom{n+k-1}{k}(1-2^{1-m+k})\zeta(m-k)$$
$$+(-1)^m\binom{m+n-1}{n-1}+(-1)^{m-1}\binom{m+n-2}{m-1}2\ln 2 \qquad (m,n\in\mathbb{N})$$

and

(4.18)

$$\sum_{l=0}^{\infty}\frac{(-1)^l}{(2l+1)^n(2l+3)^n}$$
$$=(-1)^n\left\{\frac{1}{2}-\frac{\pi}{2^{2n}(n-1)!}\sum_{k=0}^{[(n-1)/2]}\frac{(2n-2k-2)!}{(n-2k-1)!(2k)!}\pi^{2k}|E_{2k}|\right\} \qquad (n\in\mathbb{N})$$

where E_{2k} are the Euler numbers, we find that

(4.19)

$$\int_0^\infty x^{-3}Li_n(-x)Li_n(-x^2)\,dx$$
$$=2^{n-2}\pi-\frac{2^{-n-1}}{(n-1)!}\Bigg\{\sum_{k=0}^{n-1}\frac{(2n-k-2)!}{(n-k-1)!k!}\pi^{k+2}|E_k|$$
$$+\Bigg[\sum_{k=0}^{n-1}[1-(-1)^{n+k}]$$

[1] Note the misprint in [16, No. 5.1.24.10], where the factor $(-1)^m$ reads $(-1)^n$.

[2] Note that [16, No. 5.1.24.15] is erroneous: $|E_{2k}|$ there reads E_{2k} and $(2n-2k-2)!/(n-2k-1)!$ reads $(2n-k-2)!/(n-k-1)!$.

$$\times(k-n)\frac{(n+k-1)!}{k!}(1-2^{k-n})\zeta(n-k+1)$$
$$+\sum_{k=0}^{n}(-1)^{k+n}\frac{(k+n-1)!}{k!}\pi^{n-k+1}S_{n-k+1}\Bigg]\Bigg\}.$$

Because of the fact that only even integers occur as arguments for the zeta function, expression (4.19) represents a polynomial in π with rational coefficients. However, using (4.3) and the relation [6, No. 9.5421]

$$\zeta(2j)=2^{2j-1}\pi^{2j}\frac{|B_{2j}|}{(2j)!} \tag{4.20}$$

it is not difficult to show that the coefficients of all but the first power vanish, and therefore that

$$\int_0^\infty x^{-3}Li_n(-x)Li_n(-x^2)\,dx=2^{n-2}\pi \qquad (n\in\mathbb{N}). \tag{4.21}$$

We note that, for $n=1$, (4.21) agrees with (4.15).

4.3. $r=1$, $\alpha=-1/2$. In this case, the summation conditions for the infinite series become

$$k\mp\tfrac{1}{2}\notin\mathbb{N}_0,\quad l\pm\tfrac{1}{2}\notin\mathbb{N}_0,\quad K\mp\tfrac{1}{2}\in\mathbb{N}$$

which permit all k, $l\in\mathbb{N}$ and exclude all $K\in\mathbb{N}$. Thus from (3.1) with $\zeta=\sigma/\omega$

(4.22)

$$\int_0^\infty x^{-3/2}Li_n(-\sigma x)Li_m(-\omega x)\,dx$$
$$=-(\pm1)^{m+1}2^n\pi\sqrt{\sigma}\sum_{k=1}^{\infty}\frac{\zeta^{\mp k}}{k^m(1\mp2k)^n}\pm(\mp1)^n2^m\pi\sqrt{\omega}\sum_{l=1}^{\infty}\frac{\zeta^{\mp l}}{(1\pm2l)^m l^n}$$
$$-H(\mp1)2^n\pi^{m+1}\sqrt{\sigma}\sum_{m_1=0}^{m}\frac{1}{m_1!}\left(-\frac{1}{\pi}\ln\zeta\right)^{m_1}$$
$$\cdot\sum_{m_2=0}^{m-m_1}\binom{m_2+n-1}{n-1}\left(\frac{2}{\pi}\right)^{m_2}\sum_{m_3=0}^{m-m_1-m_2}B^*_{m_3}C_{m-m_1-m_2-m_3}\left(-\frac{\pi}{2}\right)$$
$$-H(\pm1)2^m\pi^{n+1}\sqrt{\omega}\sum_{n_1=0}^{n}\frac{1}{n_1!}\left(-\frac{1}{\pi}\ln\zeta\right)^{n_1}$$
$$\cdot\sum_{n_2=0}^{n-n_1}\binom{m_2+n-1}{n-1}\left(\frac{2}{\pi}\right)^{n_2}\sum_{n_3=0}^{n-n_1-n_2}(-1)^{n_3}B^*_{n_3}C_{n-n_1-n_2-n_3}\left(-\frac{\pi}{2}\right)$$
$$(|\zeta|\gtrless1,\ m,\ n\in\mathbb{N},\ |\arg\sigma|<\pi,\ |\arg\omega|<\pi).$$

Using the relations

(4.23)

$$\sum_{k=1}^{\infty}\frac{x^{2k}}{k(2k+1)}=2-\frac{2}{x}\operatorname{Arth}x-\ln(1-x^2),$$
$$\sum_{k=1}^{\infty}\frac{x^{2k}}{k(2k-1)}=2x\operatorname{Arth}x+\ln(1-x^2),$$

$$\sum_{k=1}^{\infty} \frac{x^{2k}}{k(2k+1)^2} = -\ln(1-x^2) - \frac{2}{x}\operatorname{Arth} x - \frac{1}{x}[Li_2(x) - Li_2(-x)] + 4,$$

$$\sum_{k=1}^{\infty} \frac{x^{2k}}{k(2k-1)^2} = -\ln(1-x^2) - 2x \operatorname{Arth} x + x[Li_2(x) - Li_2(-x)],$$

$$\sum_{k=1}^{\infty} \frac{x^{2k}}{k^2(2k+1)} = Li_2(x^2) + 2\ln(1-x^2) + \frac{4}{x}\operatorname{Arth} x - 4,$$

$$\sum_{k=1}^{\infty} \frac{x^{2k}}{k^2(2k-1)} = -Li_2(x^2) + 2\ln(1-x^2) + 4x \operatorname{Arth} x,$$

$$\sum_{k=1}^{\infty} \frac{x^{2k}}{k^2(2k+1)^2} = Li_2(x^2) + 4\ln(1-x^2) + \frac{8}{x}\operatorname{Arth} x + \frac{2}{x}[Li_2(x) - Li_2(-x)] - 12,$$

$$\sum_{k=1}^{\infty} \frac{x^{2k}}{k^2(2k-1)^2} = Li_2(x^2) - 4\ln(1-x^2) - 8x \operatorname{Arth} x + 2x[Li_2(x) - Li_2(-x)],$$

and [9, p. 6]

$$Li_2(x^2) = 2[Li_2(x) + Li_2(-x)], \tag{4.24}$$

we can express (4.21) in closed form for $n = 1, 2$ and $m = 1, 2$. After some calculation with REDUCE we obtain for $n = m = 1$:

$$\begin{aligned} &\int_0^{\infty} x^{-3/2} \ln(1+\sigma x) \ln(1+\omega x)\, dx \\ &\quad = 4\pi\left\{\sqrt{\sigma} \ln\left(1+\sqrt{\frac{\omega}{\sigma}}\right) + \sqrt{\omega}\left[\ln\left(1+\sqrt{\frac{\omega}{\sigma}}\right) - \ln\sqrt{\frac{\omega}{\sigma}}\right]\right\}, \end{aligned} \tag{4.25}$$

where, because of the symmetry of the integral with respect to σ and ω, we can assume $|\sigma/\omega| > 1$.

For $n = 1$, $m = 2$, formula (4.21) reduces to

(4.26)

$$\begin{aligned} &\int_0^{\infty} x^{-3/2} \ln(1+\sigma x) Li_2(-\omega x)\, dx \\ &\quad = 4\pi\left\{2\sqrt{\sigma}\left[Li_2\left(-\sqrt{\frac{\omega}{\sigma}}\right) - \ln\left(1+\sqrt{\frac{\omega}{\sigma}}\right)\right] - \sqrt{\omega}\left[2\ln\left(1+\sqrt{\frac{\omega}{\sigma}}\right) - \ln\frac{\omega}{\sigma}\right]\right\} \\ &\qquad (|\sigma/\omega| > 1), \\ &\quad = -\pi\left\{8\sqrt{\omega}\ln\left(1+\sqrt{\frac{\sigma}{\omega}}\right)\right. \\ &\qquad \left. + \sqrt{\sigma}\left[8\ln\left(1+\sqrt{\frac{\sigma}{\omega}}\right) + \ln^2\frac{\sigma}{\omega} - 4\ln\frac{\sigma}{\omega} + 8Li_2\left(-\sqrt{\frac{\sigma}{\omega}}\right) + \frac{4}{3}\pi^2\right]\right\} \\ &\qquad (|\sigma/\omega| < 1). \end{aligned}$$

The same expression, with σ and ω interchanged, holds for $n = 2$, $m = 1$.

For $n = m = 2$, we obtain from (4.21)

$$\int_0^\infty x^{-3/2} Li_2(-\sigma x) Li_2(-\omega x)\, dx$$

$$= 2\pi \left\{ 8\sqrt{\sigma} \left[2 \ln\left(1+\sqrt{\frac{\omega}{\sigma}}\right) - Li_2\left(-\sqrt{\frac{\omega}{\sigma}}\right) \right] \right. \tag{4.27}$$

$$\left. + \sqrt{\omega} \left[16 \ln\left(1+\sqrt{\frac{\omega}{\sigma}}\right) + \ln^2 \frac{\omega}{\sigma} - 8 \ln \frac{\omega}{\sigma} + 8 Li_2\left(-\sqrt{\frac{\omega}{\sigma}}\right) + \frac{4}{3}\pi^2 \right] \right\},$$

where, as for (4.25), we can assume $|\sigma/\omega| > 1$.

For $\sigma = \omega = 1$, the above results lead to

$$\int_0^\infty x^{-3/2} \ln^2(1+x)\, dx = 8\pi \ln 2,$$

$$\int_0^\infty x^{-3/2} \ln(1+x) Li_2(-x)\, dx = -\frac{2}{3}\pi(\pi^2 + 24 \ln 2), \tag{4.28}$$

$$\int_0^\infty x^{-3/2} [Li_2(-x)]^2\, dx = \frac{8}{3}\pi(\pi^2 + 24 \ln 2).$$

Acknowledgment. K. S. Kölbig would like to thank H. Lipps of CERN for a helpful discussion.

SPECTRAL MEASURES, ORTHOGONAL POLYNOMIALS, AND ABSOLUTE CONTINUITY*

JOANNE DOMBROWSKI†

Abstract. This paper studies the spectral measure of an unbounded tridiagonal matrix operator for which the matrix entries satisfy a certain growth condition, and presents a sufficient condition for the existence of an absolutely continuous part. The results are related to a class of orthogonal polynomials with exponential weights.

Key words. absolute continuity, commutators, orthogonal polynomials

AMS(MOS) subject classification. primary 47B15

1. Introduction. The purpose of this paper is to continue the study of unbounded tridiagonal matrix operators, measures and systems of orthogonal polynomials begun in [2]. A brief review of some known results in the bounded case will introduce the unbounded problem to be considered.

A bounded cyclic self-adjoint operator C, with cyclic vector ϕ, defined on a separable Hilbert space $\mathcal{H}$, can be represented as a tridiagonal matrix with respect to the basis obtained by orthonormalizing $\{C^n\phi\}_{n=0}^{\infty}$. The positive subdiagonal sequence $\{a_n\}$ and diagonal sequence $\{b_n\}$ in this matrix can be used to obtain information about the Borel measure $\mu(\beta)=\|E(\beta)\phi_1\|^2$, obtained from the spectral resolution $C=\int \lambda\, dE_\lambda$. It is shown in [1] and [4], for example, that if $\lim a_n = a$, $a\neq 0$, $\lim b_n = 0$, $\sum |a_n - a_{n-1}|<\infty$ and $\sum |b_n - b_{n-1}|<\infty$ then μ restricted to $(-2a, 2a)$ is absolutely continuous with respect to Lebesgue measure. This result was motivated by and is applicable to the study of orthogonal polynomials. For the spectral measure μ is also the measure of orthogonality for the sequence of polynomials $\{P_n\}$ recursively defined as follows:

$$P_1(\lambda)=1, \qquad P_2(\lambda)=\frac{\lambda-b_1}{a_1},$$
$$P_n(\lambda)=\frac{(\lambda-b_n)P_{n-1}(\lambda)-a_{n-2}P_{n-2}(\lambda)}{a_{n-1}}. \tag{1.1}$$

In fact, the polynomials $\{P_n\}$ form an orthonormal basis for $L^2(\mu)$ and C is unitarily equivalent to the multiplication operator on $L^2(\mu)$ defined by $Mf(\lambda)=\lambda f(\lambda)$. Such systems of polynomials have been studied extensively in the literature. One item of interest, among many, has been the relationship between the recurrence coefficients and the nature of the measure of orthogonality.

Recently there has been considerable interest in the study of systems of the form (1.1) with $a_n>0$, b_n real, for which the support of the measure of orthogonality is an unbounded set. In this case the sequence $\{a_n\}$ is unbounded. As discussed in [2], the corresponding tridiagonal matrix $C=[c_{ij}]$ with $c_{ii}=b_i$ and $c_{i,i+1}=c_{i+1,i}=a_i$ defines an unbounded operator on l^2 with domain consisting of those elements in l^2 for which matrix multiplication yields a vector in l^2. If $\sum (1/a_n)=\infty$ then C is self-adjoint and hence has a spectral decomposition $C=\int \lambda\, dE\lambda$. If $\{\phi_n\}$ is the standard basis for l^2, then ϕ_1 is a cyclic vector for C and $\mu(\beta)=\|E(\beta)\phi_1\|^2$ is the measure of orthogonality for the polynomials in (1.1). The purpose of this paper is to present a sufficient condition

* Received by the editors May 12, 1986; accepted for publication June 8, 1987.
† Department of Mathematics and Statistics, Wright State University, Dayton, Ohio 45435.

in terms of the sequences $\{a_n\}$ and $\{b_n\}$ for the existence of a nontrivial absolutely continuous part for the measure μ. The condition to be presented seems to be the natural generalization to the unbounded case of the condition given above for the bounded case. Whereas in the bounded case it is sufficient that limits exist and differences are absolutely summable, in the unbounded case it is sufficient that limits exist and differences of differences are absolutely summable. This will be made more precise below. The main result will be illustrated with a class of orthogonal polynomials introduced by G. Freud.

2. Main results. Henceforth C will denote an infinite matrix of the form

$$C=\begin{bmatrix} 0 & a_1 & 0 & 0 & \cdots \\ a_1 & 0 & a_2 & 0 & \cdots \\ 0 & a_2 & 0 & a_3 & \cdots \\ 0 & 0 & a_3 & 0 & \cdots \\ \cdot & \cdot & \cdot & \cdot & \end{bmatrix} \tag{2.1}$$

with $a_n>0$ and $\lim a_n=\infty$. It will further be assumed that $\sum(1/a_n)=\infty$ (so that C is self-adjoint), that $\sum_{n=2}^{\infty}[a_n^2-a_{n-1}^2]^-<\infty$ and that $\sum|d_n-d_{n-1}|<\infty$, where $d_n=|a_n-a_{n-1}|$. The domain of C will consist of those vectors in l^2 for which matrix multiplication yields a vector in l^2. As shown below, such operators have no eigenvalues. Therefore the spectrum coincides with the essential spectrum and remains fixed if a finite number of terms in the sequence $\{a_n\}$ are changed. This is needed for the main result.

To establish the results on eigenvalues and the existence of an absolutely continuous part the following notation is needed. If $\{\phi_n\}$ is the standard basis for l^2 then $C\phi_n=\frac{1}{2}(T+T^*)\phi_n$ where $T\phi_n=2a_n\phi_{n+1}$. Let $J\phi_n=(1/2i)(T-T^*)\phi_n$ and obtain the bounded operator J_N from J by substituting a_N for a_n when $n\geqq N$. It follows that $CJ_N-J_NC=-2iK_N$ where $K_N=[k_{ij}]$ is a bounded operator with $k_{ii}=a_i^2-a_{i-1}^2$ for $i=1,\cdots,N$, $k_{ii}=a_N(a_i-a_{i-1})$ for $i>N$, $k_{i,i+2}=k_{i+2,i}=\frac{1}{2}a_N(a_{i+1}-a_i)$ for $i\geqq N$ and all other entries equal to zero. This commutator equation, which holds only on a dense subset of H, is fundamental to the arguments to be presented.

The following result essentially appears in [2]. The proof is summarized to indicate the modifications needed for the general setting of this paper. Note that $d_n=|a_n-a_{n-1}|$. Recall from [1] that an induction argument can be used to show that the polynomials defined in (1.1) satisfy the equation

$$a_1^2P_1^2(\lambda)+\sum_{n=2}^{N}(a_n^2-a_{n-1}^2)P_n^2(\lambda)=\left[a_{N-1}P_{N-1}(\lambda)-\frac{\lambda}{2}P_N(\lambda)\right]^2+\left(a_N^2-\frac{\lambda^2}{4}\right)P_N^2(\lambda).$$

THEOREM 1. *If* $\sum[a_n-a_{n-1}]^-<\infty$ *and* $\sum|d_n-d_{n-1}|<\infty$ *then* C *has no eigenvalues.*

Proof. Assume λ is an eigenvalue. One corresponding eigenvector must be $x=\{P_n(\lambda)\}$. Choose N_0 such that for $n\geqq N_0$, $\sum_n^{\infty}[a_i-a_{i-1}]^-<\frac{1}{8}(a_n-|\lambda|/2)$, $d_n<\frac{1}{4}(a_n-|\lambda|/2)$ and $\sum_n^{\infty}|d_i-d_{i-1}|<\frac{1}{4}(a_n-|\lambda|/2)$. Let N be defined by $P_N^2(\lambda)=\max_{n\geqq N_0}P_n^2(\lambda)$. It then follows that

$$\begin{aligned}\langle K_Nx,x\rangle &\geqq\left[a_{N-1}P_{N-1}(\lambda)-\frac{\lambda}{2}P_N(\lambda)\right]^2+\left(a_N^2-\frac{\lambda^2}{4}\right)P_N^2(\lambda)+a_N\sum_{N+1}^{\infty}d_iP_i^2(\lambda)\\ &\quad-2a_N\sum_{N+1}^{\infty}[a_i-a_{i-1}]^-P_i^2(\lambda)-\frac{1}{2}a_N\sum_{N+1}^{\infty}d_i[P_{i+1}^2(\lambda)+P_{i-1}^2(\lambda)]\\ &\geqq\left[a_{N-1}P_{N-1}(\lambda)-\frac{\lambda}{2}P_N(\lambda)\right]^2+\frac{1}{4}\left(a_N^2-\frac{\lambda^2}{4}\right)P_N^2(\lambda).\end{aligned}$$

But this contradicts the fact, established in [2], that if $\{d_n\}$ is bounded and $Cx = \lambda x$ then $\langle K_N x, x\rangle = 0$. □

If C given by (2.1) is self-adjoint with spectral resolution $C = \int \lambda\, dE_\lambda$ then the polynomials defined in (1.1) are orthonormal with respect to the measure $\mu(\beta) = \|E(\beta)\phi_1\|^2$. The following technical lemma about these polynomials is needed for the result on absolute continuity. Note that the lemma has content when a_1^2 is large relative to the sum $\sum_{n=2}^{\infty}[a_n^2 - a_{n-1}^2]^-$. Obviously, for example, the lemma provides information when $\{a_n\}$ is monotone increasing.

LEMMA 1. *Suppose there exists a subinterval* Δ *of* $[-2a_1, 2a_1]$ *and a* $\delta > 0$ *such that* $\lambda \in \Delta$ *implies that* $4a_1^2 - \lambda^2 \geqq \delta$ *and* $\sum_{n=2}^{\infty}[a_n^2 - a_{n-1}^2]^- < \delta/8$. *Then for* $n > 1$, $\int_\Delta P_n^2\, d\mu \leqq 8a_1^2\mu(\Delta)/\delta$.

Proof. Fix $n > 1$. Choose $N < n$ such that $\int_\Delta P_N^2\, d\mu = \max_{1<i\leqq n}\int_\Delta P_i^2\, d\mu$. Then

$$a_1^2\int_\Delta P_1\, d\mu = a_1^2\int_\Delta P_1\, d\mu + \sum_{i=2}^{N}(a_i^2 - a_{i+1}^2)\int_\Delta P_i^2\, d\mu - \sum_{i=2}^{N}(a_i^2 - a_{i-1}^2)\int_\Delta P_i^2\, d\mu$$

$$\geqq \int_\Delta \left(a_N^2 - \frac{\lambda^2}{4}\right)P_N^2\, d\mu - \sum_{i=2}^{N}(a_i^2 - a_{i-1}^2)^+\int_\Delta P_i^2\, d\mu.$$

Since $a_N^2 - a_1^2 = \sum_{i=1}^{N}[a_i^2 - a_{i-1}^2]^+ - \sum_{i=2}^{N}[a_i^2 - a_{i-1}^2]^-$ it follows that

$$a_1^2\int_\Delta P_1\, d\mu \geqq \int_\Delta \left(a_1^2 - \frac{\lambda^2}{4}\right)P_N^2\, d\mu - \frac{\delta}{8}\int_\Delta P_N^2\, d\mu.$$

Hence $(8a_1^2/\delta)\mu(\Delta) \geqq \int_\Delta P_N^2\, d\mu \geqq \int_\Delta P_n^2\, d\mu$ as was to be shown. □

This lemma will now be used to present the main result of this paper. The notation sp (C) will be used for the spectrum of C.

THEOREM 2. *If* $\sum_{n=2}^{\infty}[a_n^2 - a_{n-1}^2]^- < \infty$ *and* $\sum_{n=2}^{\infty}|d_n - d_{n-1}| < \infty$ *then* μ *has an absolutely continuous part with support* sp (C).

Proof. Fix $R \geqq 1$. By the Kato-Rosenblum Theorem [3], [7] it is enough to show that the spectral measure of the trace class perturbation of C obtained by changing a finite number of weights in $\{a_n\}$ is absolutely continuous on $[-R, R]$. Observe that since there are no eigenvalues, all such perturbations of C will have the same spectrum. Now choose N such that $2a_N - R \geqq 8\sum_{n=N}^{\infty}|d_n - d_{n-1}|$, $2a_N - R \geqq 32\sum_{n=N}^{\infty}[a_n^2 - a_{n-1}^2]^-$ and such that for $n \geqq N$, $a_n \geqq R$ and $a_n \geqq \frac{1}{2}a_N$. Note that if N is so chosen, then for $n \geqq N$, $\Delta \subset [-R_1 R]$ and $\lambda \in \Delta$, it follows that $4a_n^2 - \lambda^2 \geqq 4a_n^2 - R^2 \geqq 16a_n\sum_N^{\infty}|d_n - d_{n-1}|$. Similarly, $4a_n^2 - \lambda^2 \geqq 64a_n\sum_N^{\infty}[a_n^2 - a_{n-1}^2]^-$. Assume, for now, that $a_1 = a_2 = \cdots = a_N$ (i.e., consider a trace class perturbation of the given operator). If Δ is a subinterval of $[-R, R]$, then $E(\Delta)\phi_1 = \sum_{i=1}^{\infty}\langle E(\Delta)\phi_1, \phi_i\rangle\phi_i$ where $\langle E(\Delta)\phi_1, \phi_i\rangle = \int_\Delta P_i\, d\mu$. The commutator equation $CJ_N - J_N C = -2iK_N$ is used in [2] to show that $|\langle K_N E(\Delta)\phi_1, E(\Delta)\phi_1\rangle| \leqq \frac{1}{2}\|J_N\|\,|\Delta|\,\|E(\Delta)\phi_1\|^2$. On the other hand,

$$\langle K_N E(\Delta)\phi_1, E(\Delta)\phi_1\rangle = \sum_1^N (a_i^2 - a_{i-1}^2)\left|\int_\Delta P_i\, d\mu\right|^2 + \sum_{N+1}^{\infty} a_N(a_i - a_{i-1})\left|\int_\Delta P_i\, d\mu\right|^2$$

$$+ \sum_{N+1}^{\infty} a_N(a_i - a_{i-1})\int_\Delta P_{i+1}\, d\mu\int_\Delta P_i\, d\mu$$

$$\geqq a_1^2\left|\int P_1\, d\mu\right|^2 + \sum_{N+1}^{\infty} a_N(a_i - a_{i-1})\left|\int_\Delta P_i\, d\mu\right|^2$$

$$-\frac{1}{2}\sum_{N+1}^{\infty} a_N d_i\left[\left|\int_\Delta P_{i+1}\, d\mu\right|^2 + \left|\int_\Delta P_{i-1}\, d\mu\right|^2\right]$$

$$\geqq a_1^2\left|\int_\Delta P_1\,d\mu\right|^2+a_N\left[(a_{N+1}-a_N)-\frac{1}{2}d_{N+1}\right]\left|\int_\Delta P_{N+1}\,d\mu\right|^2$$

$$+\sum_{N+2}^{\infty}a_N[(a_i-a_{i-1})-d_i]\left|\int_\Delta P_i\,d\mu\right|^2$$

$$-\sum_{N}^{\infty}a_N|d_i-d_{i-1}|\left|\int_\Delta P_i\,d\mu\right|^2$$

$$\geqq a_1^2\left|\int_\Delta P_1\,d\mu\right|^2-2\sum_{N+1}^{\infty}a_N[a_i-a_{i-1}]^-\left|\int_\Delta P_i\,d\mu\right|^2$$

$$-\sum_{N}^{\infty}a_N|d_i-d_{i-1}|\left|\int_\Delta P_i\,d\mu\right|^2$$

$$\geqq a_1^2\left|\int_\Delta P_1\,d\mu\right|^2-2\sum_{N+1}^{\infty}(a_i^2-a_{i-1}^2)^-\left|\int_\Delta P_i d\mu\right|^2$$

$$-\sum_{N}^{\infty}a_N|d_i-d_{i-1}|\left|\int_\Delta P_i\,d\mu\right|^2.$$

Now apply Lemma 1 with $\delta=4a_N^2-R^2$. Recall that $\Delta\subset[-R,R]$. It follows that

$$\langle K_N E(\Delta)\phi_1, E(\Delta)\phi_1\rangle\geqq\frac{a_N^2}{8}|\mu(\Delta)|^2.$$

Combining this result with the inequality obtained from the commutator equation implies that $|\mu(\Delta)|\leqq 4a_N^2\|J_N\||\Delta|$. Let β be a Borel subset of $[-R,R]$ of Lebesgue measure zero. Then for any $\varepsilon>0$ there exists a pairwise disjoint sequence of intervals $\{\Delta_j\}$ such that $\beta\subset\cup\,\Delta_j$ and $\sum|\Delta_j|<\varepsilon$. Since $\mu(\beta)\leqq\sum\mu(\Delta_j)\leqq 4a_N^2\|J_N\|\sum|\Delta_j|$ it follows that $\mu(\beta)=0$. Hence it has been shown that the spectral measure of a trace class perturbation of C is absolutely continuous with respect to Lebesgue measure on $[-R,R]$. The theorem follows from an application of the Kato-Rosenblum Theorem.

3. Examples. In this section examples will be presented to illustrate the above results. The asymptotic expansions needed for these examples are developed in [5]. See also the references cited therein.

The simplest example of practical interest is obtained by letting $a_n=\sqrt{n/2}$. It is easily checked that the conditions of the above theorems are satisfied. The corresponding polynomials $\{P_n\}$ are the Hermite polynomials and it is well known that $\mu(\beta)=\int_\beta e^{-x^2}\,dx$.

For a related class of examples choose α to be an even positive integer and let $\{P_n(\lambda)\}$ be the sequence of polynomials obtained by orthonormalizing the sequence $\{\lambda^n\}_{n=0}^{\infty}$ with respect to the measure $\mu(\beta)=\int_\beta e^{-x^\alpha/\alpha}\,dx$. These polynomials satisfy a recursion formula of the form (1.1) with $b_n=0$ and, as shown in [5],

$$a_n=n^{1/\alpha}\left[c_0+\frac{c_2}{n^2}+O\left(\frac{1}{n^4}\right)\right].$$

Since

$$a_n-a_{n-1}=c_0[n^{1/\alpha}-(n-1)^{1/\alpha}]+c_2[n^{-2+(1/\alpha)}-(n-1)^{-2+(1/\alpha)}]+n^{1/\alpha}t_n-(n-1)^{1/\alpha}t_{n-1}$$

with $|t_n| \leqq M/n^4$ for all n, the Mean Value Theorem applied to $f(x) = x^{1/\alpha}$ shows that for large n, $a_n \geqq a_{n-1}$. That is, the term $c_0[n^{1/\alpha} - (n-1)^{1/\alpha}]$ is positive and, for large n, dominates the remaining terms of the sum. For large n, write $d_n = a_n - a_{n-1} = x_n + y_n$ with $x_n = c_0[n^{1/\alpha} - (n-1)^{1/\alpha}]$. Note that $\{x_n\}$ is decreasing and $\sum |y_n| < \infty$. It follows that $\sum |d_n - d_{n-1}| \leqq \sum |x_n - x_{n-1}| + \sum |y_n - y_{n-1}| < \infty$. Therefore the hypotheses of the above theorems are satisfied.

4. Final comments. The main theorem of this paper presents a sufficient condition for the existence of an absolutely continuous part for the measure μ. It does not, in contrast to the results presented in [2], claim that μ is absolutely continuous. This is, however, true for the examples cited above. It would be interesting to know if the hypotheses of the main theorem are sufficient to conclude that μ is indeed absolutely continuous.

A PROOF OF SOME q-ANALOGUES OF SELBERG'S INTEGRAL FOR $k=1$*

KEVIN W. J. KADELL†

Abstract. Selberg has given an important multiple beta type integral. We conjecture that for all $k \geqq 0$, there exists a family $\{s^k_{n,\lambda}(\mathbf{t})\}$ of homogeneous symmetric polynomials with the following property. If the integrand in Selberg's integral is multiplied by $s^k_{n,\lambda}(\mathbf{t})$, then the integral still has a simple closed form. For all $k \geqq 0$, this family should include the elementary symmetric functions.

For $k=1$, our symmetric functions are the Schur functions. We prove some q-analogues of this and some related results.

Key words. Selberg's integral, Schur functions, Selberg polynomials, q-beta integral

AMS(MOS) subject classification. 33A15

1. Introduction and summary. Selberg [27] has given an important multiple beta type integral. It is the case $m=l=0$ of Conjecture 1.

Conjecture 1.

$$I_{n,m,l}(x,y,k)=\int_0^1\cdots\int_0^1\prod_{i=1}^n t_i^{(x-1)+\chi(i\leqq m)}(1-t_i)^{(y-1)+\chi(n-i+1\leqq l)}\Delta_n^{2k}(\mathbf{t})\,dt_1\cdots dt_n$$

$$=\prod_{i=1}^n\frac{\Gamma(x+(n-i)k+\chi(i\leqq m))\Gamma(y+(n-i)k+\chi(i\leqq l))\Gamma(1+ik)}{\Gamma(x+y+(2n-i-1)k+\chi(i\leqq m+l))\Gamma(1+k)}, \tag{1.1}$$

where $\chi(A)$ is 1 or 0 according to whether A is true or false,

$$\Delta_n(t_1,\cdots,t_n)=\Delta_n(\mathbf{t})=\prod_{1\leqq i<j\leqq n}(t_i-t_j), \tag{1.2}$$

and, as holds throughout, $\operatorname{Re}(x)>0$, $\operatorname{Re}(y)>0$ and n, m, l, and k are nonnegative integers satisfying $m+l\leqq n$. We omit l when $l=0$. The substitution $t_i\to(1-t_{n-i+1})$, $1\leqq i\leqq n$, gives the symmetry

$$I_{n,m,l}(x,y,k)=I_{n,l,m}(y,x,k). \tag{1.3}$$

We can probably extend Selberg's proof to treat Conjecture 1 using (1.3).

Bombieri and Selberg recently observed that Selberg's integral includes a conjecture of Mehta [22, p. 42] as a limiting case. Macdonald [20] and Morris [24] used it to establish the case $q=1$ of some constant term conjectures associated with certain root systems. See Evans [11] for character sum analogues of these results. Askey [6] gives a number of conjectured q-analogues of Selberg's integral and relates them to the case $a_1=a_2=\cdots=a_n$ of Andrews' q-Dyson conjecture [1]. Zeilberger and Bressoud [29] have recently proven this conjecture.

We have the following conjecture.

Conjecture 2. Let λ denote a partition $\lambda_1\geqq\lambda_2\geqq\cdots\geqq\lambda_n\geqq 0$ with at most n parts. For all $k\geqq 0$ there exists a homogeneous symmetric polynomial $s^k_{n,\lambda}(\mathbf{t})$ with leading

term $\prod_{i=1}^{n} t_i^{\lambda_i}$ such that

$$
\begin{aligned}
I_{n,\lambda}(x, y, k) &= \int_0^1 \cdots \int_0^1 \prod_{i=1}^{n} t_i^{(x-1)}(1-t_i)^{(y-1)} s_{n,\lambda}^{k}(\mathbf{t}) \Delta_n^{2k}(\mathbf{t})\, dt_1 \cdots dt_n \\
&= n!\, f_{n,\lambda}^{k} \prod_{i=1}^{n} \frac{\Gamma(x+(n-i)k+\lambda_i)\Gamma(y+(n-i)k)}{\Gamma(x+y+(2n-i-1)k+\lambda_i)},
\end{aligned} \tag{1.4}
$$

where

$$
f_{n,\lambda}^{k} = \prod_{1 \le i < j \le n} \prod_{u=0}^{k-1} (k(j-i)+\lambda_i-\lambda_j+u). \tag{1.5}
$$

We call these the Selberg polynomials. Mena [23] and Richards [26] obtained a similar set of polynomials. They used a different basis which retains the symmetry in x and y.

Clearly $s_{n,\lambda}^{0}(\mathbf{t})$ are the monomial symmetric functions. We shall show that

$$
s_{n,\lambda}^{1}(\mathbf{t}) = \frac{\det |t_j^{n-i+\lambda_i}|_{n\times n}}{\det |t_j^{n-i}|_{n\times n}} \tag{1.6}
$$

are the Schur symmetric functions. Conjecture 1 is motivated by the fact that the elementary symmetric functions are both monomial and Schur functions. Equation (1.6) includes the case $l=0$ of Conjecture 1 when $k=1$. The restriction on l is easily removed. We prove q-analogues of all of these results for $k=1$.

Fix q with $0<q<1$ and set

$$
\begin{aligned}
&(x)_0 = (x; q)_0 = 1, \\
&(x)_n = (x; q)_n = \prod_{i=0}^{n-1} (1-xq^i), \qquad n \ge 1, \\
&(x)_\infty = (x; q)_\infty = \lim_{n\to\infty} (x)_n = \prod_{i=0}^{\infty} (1-xq^i).
\end{aligned} \tag{1.7}
$$

We usually omit the base q. Following Jackson [13] we set

$$
\int_0^1 f(t)\, d_q t = (1-q) \sum_{n=0}^{\infty} q^n f(q^n) \tag{1.8}
$$

and

$$
\Gamma_q(x) = (1-q)^{(1-x)} \frac{(q)_\infty}{(q^x)_\infty}. \tag{1.9}
$$

Askey's first conjectured q-analogue [6] of Selberg's integral is based upon the q-analogue

$$
\int_0^1 t^{(x-1)} \frac{(tq)_\infty}{(tq^y)_\infty}\, d_q t = \frac{\Gamma_q(x)\Gamma_q(y)}{\Gamma_q(x+y)} \tag{1.10}
$$

of the beta integral. See Askey [5]. It is

$$
\begin{aligned}
&\int_0^1 \cdots \int_0^1 \prod_{i=1}^{n} t_i^{(x-1)} \frac{(t_i q)_\infty}{(t_i q^y)_\infty} \prod_{1\le i<j\le n} t_i^{2k} \left(\frac{t_j q^{1-k}}{t_i}\right)_{2k} d_q t_1 \cdots d_q t_n \\
&\quad = q^{[kx\binom{n}{2}+2k^2\binom{n}{3}]} \prod_{i=1}^{n} \frac{\Gamma_q(x+(n-i)k)\Gamma_q(y+(n-i)k)\Gamma_q(1+ik)}{\Gamma_q(x+y+(2n-i-1)k)\Gamma_q(1+k)}.
\end{aligned} \tag{1.11}
$$

Selberg's proof could not be used directly on (1.11), since the exponent of q is not symmetric in x and y. Macdonald [19] has proven (1.11) when $k=1$ by using a basic property [18, Chap. I, (5.11)] of the skew Schur symmetric functions.

In § 2, we give a recurrence relation for $I_{n,m}(x, y, k)$ which holds for all $k \geqq 0$. In § 3, we prove Conjecture 1 for $k=1$ and treat (1.6). This gives our basic proof of the case $k=1$.

In § 4, we give some preliminary results which we require for the q-case. We reformulate (1.11) with an integrand that is symmetric in $t_1, t_2, \cdots, t_n$ and generalize the Vandermonde determinant.

In § 5, we insert the parameters m and l into Askey's conjecture (1.11). We establish the case $n=2$, $l=0$. This result holds for all $k \geqq 0$. We obtain the sum of a nearly poised ${}_3\phi_2$ which is a companion to Carlitz's q-analogue [9] of Dixon's theorem (Bailey [8, § 3.1, (1)]).

In § 6, we prove our q-analogue of Conjecture 1 for $k=1$, $l=0$. In § 7, we prove a q-analogue of Conjecture 2 for $k=1$. In § 8, we extend the analysis to treat $l>0$ for any $k \geqq 0$. In § 9, we obtain further results by using different q-analogues of the beta integral. Surprisingly, each of these cases leads to the same determinant, which can be evaluated by Lemma 5 of § 4.

2. A recurrence relation. We obtain a recurrence relation which holds for all $k \geqq 0$. Observe that

$$I_{n,m}(x, y, k) = m \int_0^1 t_1^x (1-t_1)^{(y-1)} \left[\int_{t_1}^1 \cdots \int_{t_1}^1 \prod_{i=2}^{n} t_i^{(x-1)+\chi(i \leqq m)} (1-t_i)^{(y-1)} \cdot \Delta_n^{2k}(\mathbf{t})\, dt_2 \cdots dt_n \right] dt_1 \tag{2.1a}$$

$$+ (n-m) \int_0^1 t_n^{(x-1)} (1-t_n)^{(y-1)} \left[\int_{t_n}^1 \cdots \int_{t_n}^1 \prod_{i=1}^{n-1} t_i^{(x-1)+\chi(i \leqq m)} (1-t_i)^{(y-1)} \cdot \Delta_n^{2k}(\mathbf{t})\, dt_1 \cdots dt_{n-1} \right] dt_n. \tag{2.1b}$$

Equation (2.1a) gives the contribution to the integral for $1 \leqq i \leqq m$ where $t_i = \min(t_1, t_2, \cdots, t_n)$ and (2.1b) gives the contribution for $m < i \leqq n$. Let $\operatorname{Re}(y) > 1$. Then

$$\lim_{x \to 0} x \int_0^1 t_1^x (1-t_1)^{(y-1)} \left[\int_{t_1}^1 \cdots \int_{t_1}^1 \prod_{i=2}^{n} t_i^{(x-1)+\chi(i \leqq m)} (1-t_i)^{(y-1)} \cdot \Delta_n^{2k}(\mathbf{t})\, dt_2 \cdots dt_n \right] dt_1$$

$$\leqq \lim_{x \to 0} x \int_0^1 t^x \left[\int_t^1 s^{(x-1)}\, ds \right]^{(n-1)} dt \tag{2.2}$$

$$= \lim_{x \to 0} x^{(2-n)} \int_0^1 t^x (1-t^x)^{(n-1)}\, dt$$

$$= \lim_{x \to 0} x^{(1-n)} \int_0^1 u^{(1/x)} (1-u)^{(n-1)}\, du$$

$$= \lim_{x \to 0} \frac{x\Gamma(n)}{(1+x) \cdots (1+nx)} = 0.$$

Although the restriction $\operatorname{Re}(y) > 1$ can be removed by a careful treatment of the contribution near $t_i = 1$, $1 \leqq i \leqq n$, we prefer to remove it later. We have the following lemma.

LEMMA 3. *Let*

$$f(x, t)=f(x, 0)+O(t) \tag{2.3}$$

with a constant independent of x for some neighborhood of $x=0$ and let $f(x, 0)$ be continuous at $x=0$. Then

$$\lim_{x\to 0} x\int_0^1 t^{(x-1)}(1-t)^{(y-1)}f(x, t)\,dt=f(0, 0). \tag{2.4}$$

Proof. Substituting (2.3) into (2.4), we obtain

$$\begin{aligned}&\lim_{x\to 0} x\int_0^1 t^{(x-1)}(1-t)^{(y-1)}f(x, t)\,dt\\ &\quad=\lim_{x\to 0} x\int_0^1 t^{(x-1)}(1-t)^{(y-1)}(f(x, 0)+O(t))\,dt\\ &\quad=\lim_{x\to 0} x\frac{\Gamma(x)\Gamma(y)}{\Gamma(x+y)}f(x, 0)+O\left(\lim_{x\to 0} x\frac{\Gamma(x+1)\Gamma(y)}{\Gamma(x+y+1)}\right)\\ &\quad=f(0, 0),\end{aligned} \tag{2.5}$$

as required. □

Observe that

$$f(x, t_n)=\int_{t_n}^1\cdots\int_{t_n}^1\prod_{i=1}^{n-1} t_i^{(x-1)+\chi(i\leqq m)}(1-t_i)^{(y-1)}\Delta_n^{2k}(\mathbf{t})\,dt_1\cdots dt_{n-1} \tag{2.6}$$

satisfies our hypotheses. Since

$$\Delta_n^{2k}(\mathbf{t})=\prod_{i=1}^{n-1}(t_i-t_n)^{2k}\Delta_{n-1}^{2k}(\mathbf{t}), \tag{2.7}$$

we have

$$f(0, 0)=I_{n-1,m}(2k, y, k). \tag{2.8}$$

When $m=n$, we must use the convention

$$I_{n-1,n}(x, y, k)=I_{n-1,n-1}(x, y, k). \tag{2.9}$$

Using (2.1a) and (2.1b), we obtain the recurrence relation

$$\lim_{x\to 0} xI_{n,m}(x, y, k)=(n-m)I_{n-1,m}(2k, y, k). \tag{2.10}$$

By (2.2), the contribution of (2.1a) to the limit in (2.10) is 0. The result follows by applying Lemma 3 to (2.1b). This idea is due to Askey.

Let $P_n(\mathbf{t})$ be a symmetric polynomial. Then

$$\begin{aligned}&\lim_{x\to 0} x\int_0^1\cdots\int_0^1\prod_{i=1}^{n} t_i^{(x-1)}(1-t_i)^{(y-1)}P_n(\mathbf{t})\Delta_n^{2k}(\mathbf{t})\,dt_1\cdots dt_n\\ &\quad=n\int_0^1\cdots\int_0^1\prod_{i=1}^{n-1} t_i^{(2k-1)}(1-t_i)^{(y-1)}P_n(t_1, t_2, \cdots, t_{n-1}, 0)\\ &\qquad\cdot\Delta_{n-1}^{2k}(\mathbf{t})\,dt_1\cdots dt_{n-1}.\end{aligned} \tag{2.11}$$

Since $P_n(\mathbf{t})$ is a symmetric function, the integral on the left side of (2.11) is n times the integral taken over the region $t_n=\min(t_1, t_2, \cdots, t_n)$. As in (2.2), we find that any

term ω of $P_n(\mathbf{t})$ which contains t_n to a positive power contributes 0 to the limit in (2.11). Setting $t_n = 0$ we delete these terms from $P_n(\mathbf{t})$. Applying Lemma 3 gives (2.11).

We conjecture that

$$s^k_{n,\lambda}(\mathbf{t}) = \left(\prod_{i=1}^{n} t_i\right)^{\lambda_n} s^k_{n,(\lambda_1-\lambda_n,\cdots,\lambda_{n-1}-\lambda_n,0)}(\mathbf{t}) \tag{2.12}$$

and

$$s^k_{n,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1},0)}(t_1, t_2, \cdots, t_{n-1}, 0) = s^k_{n-1,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1})}(\mathbf{t}). \tag{2.13}$$

These are easy to see for the Schur functions.

Equation (2.12) gives

$$I_{n,\lambda}(x, y, k) = I_{n,(\lambda_1-\lambda_n,\cdots,\lambda_{n-1}-\lambda_n,0)}(x+\lambda_n, y, k). \tag{2.14}$$

Since $f^k_{n,\lambda}$ is a function of the differences $\lambda_i - \lambda_j$, $1 \leqq i < j \leqq n$, the product on the right side of (1.4) also satisfies (2.14). Thus the parameter λ_n in Conjecture 2 is subsumed by x. Using (2.11), we obtain

$$\lim_{x\to 0} xI_{n,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1},0)}(x, y, k) = nI_{n-1,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1})}(2k, y, k). \tag{2.15}$$

If $\lambda_n > 0$, then $\lim_{x\to 0} xI_{n,\lambda}(x, y, k)$ is 0.

3. A proof of the case $k = 1$. We have the Vandermonde determinant

$$\begin{aligned}\Delta_n(\mathbf{t}) &= \prod_{1\leqq i<j\leqq n} (t_i - t_j) = \det |t_j^{n-i}|_{n\times n} \\ &= \sum_{\pi\in S_n} \operatorname{sgn}(\pi) \prod_{i=1}^{n} t_i^{(n-\pi(i))}\end{aligned} \tag{3.1}$$

and the expansion

$$\begin{aligned}\Delta_n(\mathbf{t}) &= \prod_{1\leqq i<j\leqq n} [(1-t_j)-(1-t_i)] \\ &= \sum_{\pi\in S_n} \operatorname{sgn}(\pi) \prod_{i=1}^{n} (1-t_i)^{(\pi(i)-1)}\end{aligned} \tag{3.2}$$

about $t_i = 1$, $1 \leqq i \leqq n$.

Let

$$S_{n,m} = \{\pi \in S_n \mid \pi(i) \leqq m \text{ whenever } 1 \leqq i \leqq m\}. \tag{3.3}$$

Clearly $S_{n,0} = S_{n,n} = S_n$. Expanding one of the $2k$ Vandermondes $\Delta_n(\mathbf{t})$ by (3.1), we obtain

$$\begin{aligned}I_{n,m}(x, y, k) = \sum_{\pi\in S_n} \operatorname{sgn}(\pi) \int_0^1 \cdots \int_0^1 \prod_{i=1}^{n} t_i^{(x-1)+\chi(i\leqq m)+n-\pi(i)}(1-t_i)^{(y-1)} \\ \cdot \Delta_n^{(2k-1)}(\mathbf{t})\, dt_1 \cdots dt_n.\end{aligned} \tag{3.4}$$

For $\pi \notin S_{n,m}$, it is easy to see that at least two of the exponents

$$(x-1)+n-\pi(i)+\chi(i\leqq m), \qquad 1 \leqq i \leqq n, \tag{3.5}$$

must be equal. Since $\Delta_n^{(2k-1)}(\mathbf{t})$ is an antisymmetric function, the contribution to (3.4) must be 0. Hence, the sum in (3.4) may be restricted to $S_{n,m}$. The Jacobian of the

transformation $t_i \to t_{\pi(i)}$, $1 \leqq i \leqq n$, is sgn (π). Since $\Delta_n^{(2k-1)}(\mathbf{t})$ is an antisymmetric function, each $\pi \in S_{n,m}$ gives the same contribution to the sum in (3.4). Hence

$$I_{n,m}(x, y, k) = m!(n-m)! \int_0^1 \cdots \int_0^1 \prod_{i=1}^{n} t_i^{(x-1)+\chi(i\leqq m)+(n-i)}(1-t_i)^{(y-1)} \cdot \Delta_n^{(2k-1)}(\mathbf{t})\, dt_1 \cdots dt_n. \tag{3.6}$$

Let (1^m) denote the partition in which the part 1 occurs m times. The elementary symmetric function is given by

$$e_{n,m}(\mathbf{t}) = \sum_{\substack{M\subset\{1,\cdots,n\} \\ |M|=m}} \prod_{i\in M} t_i. \tag{3.7}$$

Our argument shows that

$$\Delta_n(\mathbf{t}) e_{n,m}(\mathbf{t}) = \det |t_j^{(n-i)+\chi(i\leqq m)}|_{n\times n}. \tag{3.8}$$

Hence, by (1.6)

$$s^1_{n,(1^m)}(\mathbf{t}) = e_{n,m}(\mathbf{t}). \tag{3.9}$$

For $k=1$, we expand the Vandermonde in (3.6) using (3.2). This yields

$$\begin{aligned} I_{n,m}(x, y, 1) &= m!(n-m)! \sum_{\pi\in S_n} \operatorname{sgn}(\pi) \int_0^1 \cdots \int_0^1 \prod_{i=1}^{n} t_i^{(x-1)+\chi(i\leqq m)+(n-i)} \\ &\quad \cdot (1-t_i)^{(y-1)+(\pi(i)-1)}\, dt_1 \cdots dt_n \\ &= m!(n-m)! \sum_{\pi\in S_n} \operatorname{sgn}(\pi) \prod_{i=1}^{n} \frac{\Gamma(x+n-i+\chi(i\leqq m))\Gamma(y+\pi(i)-1)}{\Gamma(x+y+n-i+\pi(i)-1+\chi(i\leqq m))} \\ &= m!(n-m)! \prod_{i=1}^{n} \Gamma(x+n-i+\chi(i\leqq m))\Gamma(y+n-i)\, U_{n,m}(x, y, 1), \end{aligned} \tag{3.10}$$

where

$$U_{n,m}(x, y, 1) = \sum_{\pi\in S_n} \operatorname{sgn}(\pi) \prod_{i=1}^{n} \frac{1}{\Gamma(x+y+n-i+\pi(i)-1+\chi(i\leqq m))}. \tag{3.11}$$

We wish to prove that Conjecture 1 holds for $l=0$, $k=1$. This is

$$I_{n,m}(x, y, 1) = \prod_{i=1}^{n} \frac{\Gamma(x+n-i+\chi(i\leqq m))\Gamma(y+n-i)}{\Gamma(x+y+2n-i-1+\chi(i\leqq m))}\Gamma(1+i). \tag{3.12}$$

We have explicitly obtained part of this result. Selberg's proof [29] extracts a different set of factors. Observe that in agreement with (3.12), $U_{n,m}(x, y, 1)$ is a function of $x+y$ rather than of x and y. Thus

$$U_{n,m}(x, y, 1) = U_{n,m}(0, x+y, 1). \tag{3.13}$$

To evaluate $U_{n,m}(x, y, 1)$, we proceed by induction on n. Let $0 \leqq m < n$. Since $\Gamma(x)$ occurs as a factor on the right side of (3.10), we obtain

$$\begin{aligned} &\lim_{x\to 0} xI_{n,m}(x, y, 1) \\ &\quad = m!(n-m)!\Gamma(y) \prod_{i=1}^{n-1} \Gamma(n-i+\chi(i\leqq m))\Gamma(y+n-i)\, U_{n,m}(0, y, 1). \end{aligned} \tag{3.14}$$

However, our recurrence relation (2.10) and our induction hypothesis give

$$\lim_{x\to 0} xI_{n,m}(x, y, 1) = (n-m)I_{n-1,m}(2, y, 1)$$

$$= (n-m)\prod_{i=1}^{n-1} \frac{\Gamma(n-i+1+\chi(i\leqq m))\Gamma(y+n-i-1)}{\Gamma(y+2n-i-1+\chi(i\leqq m))}\Gamma(1+i). \tag{3.15}$$

Solving (3.14) and (3.15) for $U_{n,m}(0, y, 1)$, we obtain

$$U_{n,m}(0, y, 1) = \frac{1}{m!(n-m)!}\frac{(n-m)}{\Gamma(y)}\prod_{i=1}^{n-1}\frac{(n-i+\chi(i\leqq m))}{(y+n-i-1)}\frac{\Gamma(1+i)}{\Gamma(y+2n-i-1+\chi(i\leqq m))}$$

$$= \frac{1}{m!(n-m)!}\frac{n!}{\Gamma(y+n-1)}\prod_{i=1}^{n-1}\frac{\Gamma(1+i)}{\Gamma(y+2n-i-1+\chi(i\leqq m))} \tag{3.16}$$

$$= \frac{1}{m!(n-m)!}\prod_{i=1}^{n}\frac{\Gamma(1+i)}{\Gamma(y+2n-i-1+\chi(i\leqq m))}.$$

Replacing y by $x+y$ in (3.16) and using (3.13) yields

$$U_{n,m}(x, y, 1) = \frac{1}{m!(n-m)!}\prod_{i=1}^{n}\frac{\Gamma(1+i)}{\Gamma(x+y+2n-i-1+\chi(i\leqq m))}. \tag{3.17}$$

Substituting (3.17) into (3.10), we get the required result (3.12). The case $m=n$ is equivalent to the case $m=0$ with x replaced by $x+1$. This completes our induction subject to the condition $\mathrm{Re}\,(y)>1$ imposed for (2.2). We may analytically continue both sides of (3.12) to $\mathrm{Re}\,(y)>0$.

Since

$$1 = (1-t_{m+1}) + t_{m+1}, \tag{3.18}$$

we obtain

$$I_{n,m,l}(x, y, k) = I_{n,m,l+1}(x, y, k) + I_{n,m+1,l}(x, y, k). \tag{3.19}$$

Equation (3.12) gives Conjecture 1 for $l=0$, $k=1$. Conjecture 1 follows for $k=1$ by induction on l using (3.19).

We turn to the case $k=1$ of Conjecture 2. This is

$$I_{n,\lambda}(x, y, 1) = \int_0^1\cdots\int_0^1 \prod_{i=1}^{n} t_i^{(x-1)}(1-t_i)^{(y-1)}s^1_{n,\lambda}(\mathbf{t})\Delta_n^2(\mathbf{t})\,dt_1\cdots dt_n$$

$$= n!\prod_{1\leqq i<j\leqq n}(j-i+\lambda_i-\lambda_j)\prod_{i=1}^{n}\frac{\Gamma(x+n-i+\lambda_i)\Gamma(y+n-i)}{\Gamma(x+y+2n-i-1+\lambda_i)}, \tag{3.20}$$

where $s^1_{n,\lambda}(\mathbf{t})$ is the Schur function given by (1.6). Multiplying (1.6) by $\Delta_n(\mathbf{t})$ gives

$$s^1_{n,\lambda}(\mathbf{t})\Delta_n(\mathbf{t}) = \det|t_j^{n-i+\lambda_i}|_{n\times n}. \tag{3.21}$$

Substituting (3.21) into (3.20) yields

$$I_{n,\lambda}(x, y, 1) = \sum_{\pi\in S_n}\mathrm{sgn}\,(\pi)\int_0^1\cdots\int_0^1\prod_{i=1}^{n} t_i^{(x-1)+(n-\pi(i)+\lambda_{\pi(i)})}(1-t_i)^{(y-1)}\Delta_n(\mathbf{t})\,dt_1\cdots dt_n$$

$$= n!\int_0^1\cdots\int_0^1\prod_{i=1}^{n} t_i^{(x-1)+(n-i+\lambda_i)}(1-t_i)^{(y-1)}\Delta_n(\mathbf{t})\,dt_1\cdots dt_n. \tag{3.22}$$

Using (3.2) to expand the Vandermonde in (3.22) yields

$$
\begin{aligned}
I_{n,\lambda}(x,y,1) &= n!\sum_{\pi\in S_n}\operatorname{sgn}(\pi)\int_0^1\cdots\int_0^1\prod_{i=1}^n t_i^{(x-1)+(n-i+\lambda_i)}\\
&\quad\cdot(1-t_i)^{(y-1)+(\pi(i)-1)}\,dt_1\cdots dt_n\\
&= n!\sum_{\pi\in S_n}\operatorname{sgn}(\pi)\prod_{i=1}^n\frac{\Gamma(x+n-i+\lambda_i)\Gamma(y+\pi(i)-1)}{\Gamma(x+y+n-i+\lambda_i+\pi(i)-1)}\\
&= n!\prod_{i=1}^n\Gamma(x+n-i+\lambda_i)\Gamma(y+n-i)\,U_{n,\lambda}(x,y,1),
\end{aligned}
\tag{3.23}
$$

where

$$
U_{n,\lambda}(x,y,1)=\sum_{\pi\in S_n}\operatorname{sgn}(\pi)\prod_{i=1}^n\frac{1}{\Gamma(x+y+n-i+\lambda_i+\pi(i)-1)}.
\tag{3.24}
$$

Observe that

$$
U_{n,\lambda}(x,y,1)=U_{n,(\lambda_1-\lambda_n,\cdots,\lambda_{n-1}-\lambda_n,0)}(0,x+y+\lambda_n,1).
\tag{3.25}
$$

We proceed by induction on n. We treat first the case $\lambda_n=0$. By (3.23) we have

$$
\begin{aligned}
&\lim_{x\to 0} xI_{n,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1},0)}(x,y,1)\\
&\quad= n!\Gamma(y)\prod_{i=1}^{n-1}\Gamma(n-i+\lambda_i)\Gamma(y+n-i)\,U_{n,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1},0)}(0,y,1).
\end{aligned}
\tag{3.26}
$$

Our recurrence relation (2.15) and our induction hypothesis give

$$
\begin{aligned}
&\lim_{x\to 0} xI_{n,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1},0)}(x,y,1)\\
&\quad= n(n-1)!f^1_{n-1,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1})}\prod_{i=1}^{n-1}\frac{\Gamma(n-i+1+\lambda_i)\Gamma(y+n-i-1)}{\Gamma(y+2n-i-1+\lambda_i)}\\
&\quad= n!\prod_{1\le i<j\le n-1}(j-i+\lambda_i-\lambda_j)\prod_{i=1}^{n-1}\frac{\Gamma(n-i+1+\lambda_i)\Gamma(y+n-i-1)}{\Gamma(y+2n-i-1+\lambda_i)}.
\end{aligned}
\tag{3.27}
$$

Solving (3.26) and (3.27) for $U_{n,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1},0)}(0,y,1)$ yields

$$
\begin{aligned}
&U_{n,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1},0)}(0,y,1)\\
&\quad=\prod_{1\le i<j\le n-1}(j-i+\lambda_i-\lambda_j)\prod_{i=1}^{n-1}(n-i+\lambda_i)\prod_{i=1}^{n}\frac{1}{\Gamma(y+2n-i-1+\lambda_i)}.
\end{aligned}
\tag{3.28}
$$

Replacing y by $x+y+\lambda_n$ and λ_i, $1\le i\le n-1$, by $\lambda_i-\lambda_n$, $1\le i\le n-1$, in (3.28) and using (3.25) yields

$$
U_{n,\lambda}(x,y,1)=\prod_{1\le i<j\le n}(j-i+\lambda_i-\lambda_j)\prod_{i=1}^{n}\frac{1}{\Gamma(x+y+2n-i-1+\lambda_i)}.
\tag{3.29}
$$

Substituting (3.29) into (3.23), we get the required result (3.20).

4. Preliminaries. Let $\mathbf{Q}=(Q_{i,j})_{n\times n}$ be an upper triangular matrix. Expanding the $\mathbf{Q}$-Vandermonde

$$
{}_{\mathbf{Q}}\Delta_n(\mathbf{t})=\prod_{1\le i<j\le n}(t_i-Q_{i,j}t_j)
\tag{4.1}
$$

in powers of $t_1, t_2, \cdots, t_n$ yields

$$(4.2)\qquad {}_{\mathbf{Q}}\Delta_n(\mathbf{t}) = \sum_{\pi\in S_n} \operatorname{sgn}(\pi)\left(\prod_{\substack{1\leqq i<j\leqq n\\ \pi(i)>\pi(j)}} Q_{i,j}\right)\prod_{i=1}^{n} t_i^{(n-\pi(i))} + {}_{\mathbf{Q}}\Sigma_n^{**}(\mathbf{t}),$$

where ${}_{\mathbf{Q}}\Sigma_n^{**}(\mathbf{t})$ is the sum of all of the terms in the expansion of ${}_{\mathbf{Q}}\Delta_n(\mathbf{t})$ in which at least two of the variables $t_1, t_2, \cdots, t_n$ occur to the same power. ${}_{\mathbf{Q}}\Sigma_n^{**}(\mathbf{t})$ expresses the extent to which ${}_{\mathbf{Q}}\Delta_n(\mathbf{t})$ fails to be an antisymmetric function like $\Delta_n(\mathbf{t})$. We define the antisymmetrization of $f_n(\mathbf{t})$ by

$$(4.3)\qquad \begin{aligned} &\Xi_n(f_n(\mathbf{t})) = \sum_{\pi\in S_n} \operatorname{sgn}(\pi) f_n(\pi(\mathbf{t})),\\ &\pi(\mathbf{t}) = (t_{\pi(1)}, t_{\pi(2)}, \cdots, t_{\pi(n)}). \end{aligned}$$

We have the following lemma.

LEMMA 4.

$$(4.4)\qquad \Xi_n\left(\prod_{i=1}^{m} t_i\, {}_{\mathbf{Q}}\Delta_n(\mathbf{t})\right) = \left[\sum_{\pi\in S_{n,m}} \prod_{\substack{1\leqq i<j\leqq n\\ \pi(i)>\pi(j)}} Q_{i,j}\right] e_{n,m}(\mathbf{t})\Delta_n(\mathbf{t}).$$

Proof. Let ω be a term of ${}_{\mathbf{Q}}\Delta_n(\mathbf{t})$. If t_i and t_j where $1\leqq i<j\leqq n$ occur to the same power in $\omega\prod_{i=1}^{m} t_i$, then, since the left side of (4.4) is an antisymmetric function, we see that the contribution of ω to (4.4) is 0. Assume that all of the exponents in $\omega\prod_{i=1}^{m} t_i$ are distinct. We claim that

$$(4.5)\qquad \omega\prod_{i=1}^{m} t_i = \operatorname{sgn}(\pi)\left(\prod_{\substack{1\leqq i<j\leqq n\\ \pi(i)>\pi(j)}} Q_{i,j}\right)\prod_{i=1}^{n} t_i^{(n-\pi(i))+\chi(i\leqq m)},$$

where

$$(4.6)\qquad \pi\in S_{n,m}.$$

This is clear for $m=0$. Assume that $m>0$. Since the maximum exponent in $\omega\prod_{i=1}^{m} t_i$ is n and they are distinct, there is a single possibility which fails to occur. The total of all of the exponents of $\omega\prod_{i=1}^{m} t_i$ is $m+\binom{n}{2}$, so the missing exponent is $n-m$. Since $m>0$, there exists k, $1\leqq k\leqq n$, such that t_k occurs to the power n in $\omega\prod_{i=1}^{m} t_i$. The exponent of t_k in ω is at most $n-1$. Hence $1\leqq k\leqq m$ and t_k is chosen from each possible factor of ${}_{\mathbf{Q}}\Delta_n(\mathbf{t})$. We may take $\pi(k)=1$ and our claim (4.6) follows by induction with n, m, replaced by $n-1$, $m-1$.

For $\pi\in S_{n,m}$, we obtain

$$(4.7)\qquad \Xi_n\left(\operatorname{sgn}(\pi)\prod_{i=1}^{n} t_i^{(n-\pi(i))+\chi(i\leqq m)}\right) = \det\left|t_j^{(n-i)+\chi(i\leqq m)}\right|_{n\times n}.$$

The result follows by using (4.7) and (3.8) to evaluate the contributions (4.5) to the left side of (4.4). □

Let $d_\mu(\mathbf{t})$ be an n-dimensional antisymmetric measure. That is, for all $\pi\in S_n$

$$(4.8)\qquad d_\mu(\pi(\mathbf{t})) = \operatorname{sgn}(\pi)\, d_\mu(\mathbf{t}).$$

Multiply both sides of (4.4) by $d_\mu(\mathbf{t})$ and integrate. The Jacobian of the transformation

$t_i \to t_{\pi(i)}$, $1 \leqq i \leqq n$, is sgn (π). Using (3.8), we obtain

$$\begin{aligned}(4.9)\qquad &\int \cdots \int \prod_{i=1}^{m} t_i \, {}_Q\Delta_n(\mathbf{t})\, d_\mu(\mathbf{t}) \\ &= \left[\sum_{\pi \in S_{n,m}} \prod_{\substack{1 \leqq i<j \leqq n \\ \pi(i)>\pi(j)}} Q_{i,j}\right] \int \cdots \int \prod_{i=1}^{n} t_i^{(n-i)+\chi(i \leqq m)}\, d_\mu(\mathbf{t}).\end{aligned}$$

When $Q_{i,j}=1$, $1 \leqq i<j \leqq n$, (4.9) becomes

$$(4.10)\qquad \int \cdots \int \prod_{i=1}^{m} t_i \Delta_n(\mathbf{t})\, d_\mu(\mathbf{t}) = m!(n-m)! \int \cdots \int \prod_{i=1}^{n} t_i^{(n-i)+\chi(i \leqq m)}\, d_\mu(\mathbf{t}).$$

Comparing (4.9) and (4.10), we obtain

$$\begin{aligned}(4.11)\qquad &\int \cdots \int \prod_{i=1}^{m} t_i \, {}_Q\Delta_n(\mathbf{t})\, d_\mu(\mathbf{t}) \\ &= \frac{1}{m!(n-m)!}\left[\sum_{\pi \in S_{n,m}} \prod_{\substack{1 \leqq i<j \leqq n \\ \pi(i)>\pi(j)}} Q_{i,j}\right] \int \cdots \int \prod_{i=1}^{m} t_i \Delta_n(\mathbf{t})\, d_\mu(\mathbf{t}).\end{aligned}$$

It is well known (see MacMahon [21]) that

$$(4.12)\qquad \sum_{\pi \in S_n} \prod_{\substack{1 \leqq i<j \leqq n \\ \pi(i)>\pi(j)}} Q = \prod_{i=1}^{n} \frac{(1-Q^i)}{(1-Q)}.$$

For $m=0$, (4.4) becomes

$$(4.13)\qquad \Xi_n\left(\prod_{1 \leqq i<j \leqq n} (t_i - Qt_j)\right) = \prod_{i=1}^{n} \frac{(1-Q^i)}{(1-Q)} \Delta_n(\mathbf{t}).$$

This is a result of Macdonald [17] for the root system A_{n-1}. See Carter [10, Thms. 10.2.1, 10.2.3] and Kadell [16].

Using the simple identity

$$(4.14)\qquad (\alpha)_n = (-\alpha)^n q^{\binom{n}{2}} \left(\frac{1}{\alpha q^{n-1}}\right)_n,$$

we find that

$$(4.15)\qquad t_i^{(2k-1)} \left(\frac{t_j q^{1-k}}{t_i}\right)_{2k-1} = -t_j^{(2k-1)} \left(\frac{t_i q^{1-k}}{t_j}\right)_{2k-1}.$$

Thus

$$(4.16)\qquad {}_q\Delta_n^{(2k-1)}(\mathbf{t}) = \prod_{1 \leqq i<j \leqq n} t_i^{(2k-1)} \left(\frac{t_j q^{1-k}}{t_i}\right)_{2k-1}$$

is an antisymmetric function and

$$(4.17)\qquad {}_q\Delta_n^{2k}(\mathbf{t}) = \Delta_n(\mathbf{t})\, {}_q\Delta_n^{(2k-1)}(\mathbf{t})$$

is a symmetric function.

Let $m=0$, $Q_{i,j}=q^k$, $1\leqq i<j\leqq n$, and choose $d_\mu(\mathbf{t})$ so that the left side of (4.11) is Askey's integral in (1.11). Using (4.11) and (4.12), we obtain

$$\begin{aligned}\int_0^1\cdots\int_0^1\prod_{i=1}^n t_i^{(x-1)}\frac{(t_iq)_\infty}{(t_iq^y)_\infty}\,{}_q\Delta_n^{2k}(\mathbf{t})\,d_qt_1\cdots d_qt_n\\ =n!\,q^{[kx\binom{n}{2}+2k^2\binom{n}{3}]}\prod_{i=1}^n\frac{\Gamma_q(x+(n-i)k)\Gamma_q(y+(n-i)k)\Gamma_q(ik)}{\Gamma_q(x+y+(2n-i-1)k)\Gamma_q(k)},\end{aligned}\tag{4.18}$$

which is the symmetric version of Askey's conjecture (1.11). Observe that the integrand in (4.18) is a symmetric function. This is the first step in Macdonald's proof [19] of (1.11) for $k=1$.

While we offer only the Laurent expansion (4.2) of ${}_Q\Delta_n(\mathbf{t})$, the ordinary Vandermonde $\Delta_n(\mathbf{t})$ is capable of many expansions. We have the following lemma.

LEMMA 5. *Let $B_0=\{p_1(t),p_2(t),\cdots,p_n(t)\}$ be a basis for the space of polynomials in t of degree at most $n-1$. Then there is a constant c such that*

$$\det|p_i(t_j)|_{n\times n}=c\Delta_n(\mathbf{t}).\tag{4.19}$$

Proof. We proceed by induction on s to show that

$$B_s=\{t^{n-1},\cdots,t^{n-s},p_{s+1}(t),\cdots,p_n(t)\}\tag{4.20}$$

is a basis for all s with $0\leqq s\leqq n$, provided the basis B_0 is properly ordered. This holds for $s=0$ by assumption. Let $0\leqq s\leqq n-1$ and write t^{n-s-1} in terms of the basis B_s. This gives

$$t^{n-s-1}=\sum_{r=1}^{s}c_{s,r}t^{n-r}+\sum_{r=s+1}^{n}c_{s,r}p_r(t).\tag{4.21}$$

Since $t^{n-s-1}\notin\operatorname{span}(t^{n-1},\cdots,t^{n-s})$, $c_{s,r}$ cannot be 0 for all r with $s+1\leqq r\leqq n$. We assume that B_0 is ordered so that

$$c_{s,s+1}\neq 0.\tag{4.22}$$

Solving (4.21) for $p_{s+1}(t)$, we see that $p_{s+1}(t)\in\operatorname{span}(B_{s+1})$ and hence B_{s+1} is a basis. For $0\leqq s\leqq n$, we set

$$D_s=\begin{vmatrix} t_1^{n-1} & t_2^{n-1} & \cdots & t_n^{n-1}\\ \vdots & \vdots & \cdots & \vdots\\ t_1^{n-s} & t_2^{n-s} & \cdots & t_n^{n-s}\\ p_{s+1}(t_1) & p_{s+1}(t_2) & \cdots & p_{s+1}(t_n)\\ \vdots & \vdots & \cdots & \vdots\\ p_n(t_1) & p_n(t_2) & \cdots & p_n(t_n)\end{vmatrix}.\tag{4.23}$$

Let $0\leqq s\leqq n-1$. Multiply row $s+1$ of D_s by $c_{s,s+1}$ and for each r with $1\leqq r\leqq n$, $r\neq s+1$, add $c_{s,r}$ times row r to row $s+1$. We obtain

$$\det(D_{s+1})=c_{s,s+1}\det(D_s),\qquad 0\leqq s\leqq n-1,\tag{4.24}$$

provided the basis B_0 has been properly ordered. The left side of (4.19) is $\det(D_0)$ and $\det(D_n)=\Delta_n(\mathbf{t})$. Thus (4.24) yields

$$\det|p_i(t_j)|_{n\times n}=\prod_{s=0}^{n-1}\frac{1}{c_{s,s+1}}\Delta_n(\mathbf{t}),\tag{4.25}$$

as required. □

Kadell [15, Lemma 7] gives a weaker version of Lemma 5. See Gordon and Houten [12a], [12b] for an interesting special case which is related to plane partitions. We require the special cases

$$\det|(At_j)_{(i-1)}|_{n\times n} = q^{\binom{n}{3}}A^{\binom{n}{2}}\Delta_n(\mathbf{t}), \tag{4.26}$$

$$\det|t_j^{n-i}(At_j)_{(i-1)}|_{n\times n} = \Delta_n(\mathbf{t}), \tag{4.27}$$

and

$$\det|(Aq^{n-i}t_j)_{(i-1)}|_{n\times n} = q^{2\binom{n}{3}}A^{\binom{n}{2}}\Delta_n(\mathbf{t}). \tag{4.28}$$

5. The case $n=2$, $l=0$. Let $L\subset\{1,\cdots,n\}$ and set

$$\begin{aligned} {}_Q\Delta_{n,L}(\mathbf{t}) &= \Delta_n(Q^{\chi(1\in L)}t_1,\cdots,Q^{\chi(n\in L)}t_n)\\ &= \prod_{1\leqq i<j\leqq n}(Q^{\chi(i\in L)}t_i - Q^{\chi(j\in L)}t_j)\\ &= Q^{[\sum_{i\in L}n-i]}\prod_{1\leqq i<j\leqq n}(t_i - Q^{\chi(j\in L)-\chi(i\in L)}t_j) \end{aligned} \tag{5.1}$$

and

$$\begin{aligned} {}_Q\Delta_{n,m,l}(\mathbf{t}) &= {}_Q\Delta_{n,\{1,\cdots,m\}\cup\{n-l+1,\cdots,n\}}(\mathbf{t})\\ &= \Delta_n(Qt_1,\cdots,Qt_m,t_{m+1},\cdots,t_{n-l},Qt_{n-l+1},\cdots,Qt_n). \end{aligned} \tag{5.2}$$

The support of the measure d_qt has an accumulation point at $t=0$, but not at $t=1$. We cannot make the substitution $t_i\to(1-t_{n-i+1})$, $1\leqq i\leqq n$, as we did for (1.3). This accounts for the asymmetry of the exponent of q in (1.11). Set

$$\begin{aligned} {}_qI_{n,m,l}(x,y,k) = \int_0^1\cdots\int_0^1\prod_{i=1}^n t_i^{(x-1)+\chi(i\leqq m)}\frac{(t_iq)_\infty}{(t_iq^{y+\chi(n-i+1\leqq l)})_\infty}\\ \cdot{}_{(q^k)}\Delta_{n,0,l}(\mathbf{t})\,{}_q\Delta_n^{(2k-1)}(\mathbf{t})\,d_qt_1\cdots d_qt_n. \end{aligned} \tag{5.3}$$

The q-multinomial coefficient is given by

$$\begin{bmatrix} A \\ a_1,\cdots,a_n \end{bmatrix}_q = \frac{(q)_A}{(q)_{a_1}\cdots(q)_{a_n}(q)_{(A-a_1-\cdots-a_n)}}. \tag{5.4}$$

In particular,

$$\begin{bmatrix} n \\ m \end{bmatrix}_q = \frac{(q^{n-m+1})_m}{(q)_m}, \qquad \begin{bmatrix} n \\ m,l \end{bmatrix}_q = \frac{(q^{n-m-l+1})_{m+l}}{(q)_m(q)_l}. \tag{5.5}$$

We have the following conjecture.

Conjecture 6.

$$\begin{aligned} {}_qI_{n,m,l}(x,y,k) = n!\frac{\begin{bmatrix} n \\ m,l \end{bmatrix}_{(q^k)}}{\binom{n}{m,l}}q^{[kx\binom{n}{2}+k\binom{m}{2}+k\binom{l}{2}+2k^2\binom{n}{3}]}\\ \cdot\prod_{i=1}^n\frac{\Gamma_q(x+(n-i)k+\chi(i\leqq m))\Gamma_q(y+(n-i)k+\chi(i\leqq l))\Gamma_q(ik)}{\Gamma_q(x+y+(2n-i-1)k+\chi(i\leqq m+l))\Gamma_q(k)}. \end{aligned} \tag{5.6}$$

When $m=l=0$ or $m=n$, $l=0$, or $m=0$, $l=n$, (5.6) reduces to (4.18) which is equivalent to Askey's conjecture (1.11).

Observe that the right side of (5.6) satisfies

$$q^{[ky\binom{n}{2}]}\,{}_qI_{n,m,l}(x,y,k)=q^{[kx\binom{n}{2}]}\,{}_qI_{n,l,m}(y,x,k). \tag{5.7}$$

We should be able to prove Conjecture 6 if we could establish the symmetry (5.7). We have the following theorem.

THEOREM 7. *Conjecture 6 holds when $n=2$ and $l=0$.*

Proof. Askey [6] has shown that (1.11) holds when $n=2$. Thus (4.18) holds when $n=2$ and (5.6) holds when $n=2$, $m=l=0$, and when $n=m=2$, $l=0$. We must treat the case $n=2$, $m=1$, $l=0$. Observe that

$$\frac{(t_iq)_\infty}{(t_iq^{y+1})_\infty}=\frac{(t_iq)_\infty}{(t_iq^y)_\infty}(1-t_iq^y) \tag{5.8}$$

and

$$(1-t_1q^y)(1-t_2q^y)=1-q^y(t_1+t_2)+q^{2y}t_1t_2. \tag{5.9}$$

Since ${}_{(q^k)}\Delta_{n,0,0}(\mathbf{t})\,{}_q\Delta_n^{(2k-1)}(\mathbf{t})={}_q\Delta_n^{2k}(\mathbf{t})$ is a symmetric function, we obtain

$${}_qI_{2,0}(x,y+1,k)={}_qI_{2,0}(x,y,k)-2q^y\,{}_qI_{2,1}(x,y,k)+q^{2y}\,{}_qI_{2,2}(x,y,k). \tag{5.10}$$

The result follows by solving (5.10) for ${}_qI_{2,1}(x,y,k)$. □

The case $n=2$, $m=1$, $l=0$, provides an interesting summation formula for a nearly well-poised ${}_3\phi_2$. We have the well-known q-binomial theorem (see Andrews [2, (2.2.1)])

$${}_1\phi_0\left[\begin{matrix}a\\ \end{matrix}\middle|\, q,t\right]=\frac{(at)_\infty}{(t)_\infty},\qquad |t|<1, \tag{5.11}$$

where the basic hypergeometric series is given by

$${}_{s+1}\phi_s\left[\begin{matrix}a_1,a_2,\cdots,a_{s+1}\\ b_1,b_2,\cdots,b_s\end{matrix}\middle|\, q,x\right]=\sum_{n=0}^{\infty}\frac{(a_1)_n\cdots(a_{s+1})_n}{(b_1)_n\cdots(b_s)_n}\frac{x^n}{(q)_n}. \tag{5.12}$$

Using the special case

$$t_1^{2k}\left(\frac{t_2q^{1-k}}{t_1}\right)_{2k}=\sum_{i=0}^{2k}\frac{(q^{-2k})_i}{(q)_i}q^{(1+k)i}t_1^{(2k-i)}t_2^i \tag{5.13}$$

of (5.11) and (1.10), we obtain

$$\begin{aligned}
{}_qI_{2,1}(x,y,k)&=\int_0^1\cdots\int_0^1 t_1^xt_2^{x-1}\frac{(t_1q)_\infty}{(t_1q^y)_\infty}\frac{(t_2q)_\infty}{(t_2q^y)_\infty}t_1^{2k}\left(\frac{t_2q^{1-k}}{t_1}\right)_{2k}d_qt_1\,d_qt_2\\
&=\sum_{i=0}^{2k}\frac{(q^{-2k})_i}{(q)_i}q^{(1+k)i}\int_0^1 t_1^{x+2k-i}\frac{(t_1q)_\infty}{(t_1q^y)_\infty}d_qt_1\\
&\quad\cdot\int_0^1 t_2^{x+2k-i}\frac{(t_2q)_\infty}{(t_2q^y)_\infty}d_qt_2\\
&=\sum_{i=0}^{2k}\frac{(q^{-2k})_i}{(q)_i}q^{(1+k)i}\frac{\Gamma_q(x+2k-i+1)\Gamma_q(y)}{\Gamma_q(x+y+2k-i+1)}\frac{\Gamma_q(x+i)\Gamma_q(y)}{\Gamma_q(x+y+i)}\\
&=\frac{\Gamma_q(x)\Gamma_q(x+2k+1)\Gamma_q(y)\Gamma_q(y)}{\Gamma_q(x+y)\Gamma_q(x+y+2k+1)}\,{}_3\phi_2\left[\begin{matrix}q^{-2k},q^{-2k-x-y},q^x\\ q^{-2k-x},q^{x+y}\end{matrix}\middle|\, q^{y+k+1}\right].
\end{aligned} \tag{5.14}$$

The first equality in (5.14) holds since we have added an antisymmetric function to the integrand. By Theorem 7, we have

$$(5.15)\qquad {}_qI_{2,1}(x,y,k)=q^{kx}(1+q^k)\frac{\Gamma_q(x)\Gamma_q(x+k+1)\Gamma_q(y)\Gamma_q(y+k)\Gamma_q(2k)}{\Gamma_q(x+y+k)\Gamma_q(x+y+2k+1)\Gamma_q(k)}.$$

Equating (5.14) and (5.15) and solving for the ${}_3\phi_2$ yields

$$(5.16)\qquad \begin{aligned}&{}_3\phi_2\left[\begin{matrix}q^{-2k},\,q^{-2k-x-y},\,q^{x}\\ q^{-2k-x},\,q^{x+y}\end{matrix}\,\middle|\,q^{y+k+1}\right]\\ &\quad=q^{kx}(1+q^k)\frac{\Gamma_q(x+k+1)\Gamma_q(y+k)\Gamma_q(x+y)\Gamma_q(2k)}{\Gamma_q(x+2k+1)\Gamma_q(y)\Gamma_q(x+y+k)\Gamma_q(k)}.\end{aligned}$$

This may be written as

$$(5.17)\qquad {}_3\phi_2\left[\begin{matrix}q^{-2k},\,a,\,b\\ q^{-2k}/a,\,q^{-2k}/b\end{matrix}\,\middle|\,q,\,q^{1-k}/ab\right]=\frac{(q^{k+1})_k(abq^{k+1})_k}{(aq^{k+1})_k(bq^{k+1})_k}.$$

Compare this with

$$(5.18)\qquad {}_3\phi_2\left[\begin{matrix}q^{-2k},\,a,\,b\\ q^{1-2k}/a,\,q^{1-2k}/b\end{matrix}\,\middle|\,q,\,q^{2-k}/ab\right]=\frac{(q^{k+1})_k(abq^{k})_k}{(aq^{k})_k(bq^{k})_k},$$

which is due to Jackson [14]. Carlitz [9] gives another proof of (5.18) using some q-analogues of quadratic transformations.

6. A proof of Conjecture 6 for $k=1$, $l=0$. Although our q-integral is a discrete sum, the integrand vanishes if any two of the variables $t_1, t_2, \cdots, t_n$ are equal. As with (2.1), we obtain

$$(6.1a)\qquad \begin{aligned}{}_qI_{n,m}(x,y,k)=m\int_0^1 t_1^x\frac{(t_1q)_\infty}{(t_1q^y)_\infty}\Bigg[\int_{t_1}^1\cdots\int_{t_1}^1\prod_{i=2}^{n}t_i^{(x-1)+\chi(i\leqq m)}\frac{(t_iq)_\infty}{(t_iq^y)_\infty}\\ \cdot{}_q\Delta_n^{2k}(\mathbf{t})\,d_qt_2\cdots d_qt_n\Bigg]\,d_qt_1,\end{aligned}$$

$$(6.1b)\qquad \begin{aligned}+(n-m)\int_0^1 t_n^{(x-1)}\frac{(t_nq)_\infty}{(t_nq^y)_\infty}\Bigg[\int_{t_n}^1\cdots\int_{t_n}^1\prod_{i=1}^{n-1}t_i^{(x-1)+\chi(i\leqq m)}\frac{(t_iq)_\infty}{(t_iq^y)_\infty}\\ \cdot{}_q\Delta_n^{2k}(\mathbf{t})\,d_qt_1\cdots d_qt_{n-1}\Bigg]\,d_qt_n.\end{aligned}$$

It is easy to use the q-beta integral (1.10) to obtain a recurrence relation as we did in § 2. Equation (1.9) gives

$$(6.2)\qquad \lim_{x\to0}\frac{(1-q^x)}{(1-q)}\Gamma_q(x)=\lim_{x\to0}\Gamma_q(x+1)=1.$$

Under the hypotheses of Lemma 3, we obtain

$$(6.3)\qquad \lim_{x\to0}\frac{(1-q^x)}{(1-q)}\int_0^1 t^{x-1}\frac{(tq)_\infty}{(tq^y)_\infty}f(x,t)\,d_qt=f(0,0).$$

In replacing (2.2), we must change d_qt to $d_{(q^x)}u$. This shows that (6.1a) contributes 0 to the limit in (6.4) below. Taking $f(x,t)$ to be an $(n-1)$-dimensional q-integral as in (2.6), we obtain

$$(6.4)\qquad \lim_{x\to0}\frac{(1-q^x)}{(1-q)}{}_qI_{n,m}(x,y,k)=(n-m)\,{}_qI_{n-1,m}(2k,y,k).$$

This is valid for all m, $0 \leqq m \leqq n$, using the convention

$$ {}_qI_{n-1,n}(x, y, k) = {}_qI_{n-1,n-1}(x, y, k). \tag{6.5} $$

The cancellation argument for (3.6) gives

$$ \begin{aligned} {}_qI_{n,m}(x, y, k) = m!(n-m)! \int_0^1 \cdots \int_0^1 \prod_{i=1}^{n} t_i^{(x-1)+\chi(i\leqq m)+(n-i)} \frac{(t_iq)_\infty}{(t_iq^y)_\infty} \\ \cdot {}_q\Delta_n^{(2k-1)}(\mathbf{t})\, d_qt_1 \cdots d_qt_n. \end{aligned} \tag{6.6} $$

Setting $A = q^y$ in (4.26) and solving for $\Delta_n(\mathbf{t})$, we obtain

$$ \Delta_n(\mathbf{t}) = q^{-[y\binom{n}{2}+\binom{n}{3}]} \sum_{\pi\in S_n} \operatorname{sgn}(\pi) \prod_{i=1}^{n} (t_iq^y)_{(\pi(i)-1)}. \tag{6.7} $$

For $k = 1$, we expand the Vandermonde in (6.6) using (6.7). This yields

$$ \begin{aligned} {}_qI_{n,m}(x, y, 1) = m!(n-m)!\, q^{-[y\binom{n}{2}+\binom{n}{3}]} \\ \cdot \prod_{i=1}^{n} \Gamma_q(x+n-i+\chi(i\leqq m))\Gamma_q(y+n-i)\ {}_qU_{n,m}(x, y, 1), \end{aligned} \tag{6.8} $$

where

$$ {}_qU_{n,m}(x, y, 1) = \sum_{\pi\in S_n} \operatorname{sgn}(\pi) \prod_{i=1}^{n} \frac{1}{\Gamma_q(x+y+n-i+\pi(i)-1+\chi(i\leqq m))}. \tag{6.9} $$

Since ${}_qU_{n,m}(x, y, 1)$ is a function of $x+y$ rather than of x and y, we have

$$ {}_qU_{n,m}(x, y, 1) = {}_qU_{n,m}(0, x+y, 1). \tag{6.10} $$

We evaluate ${}_qU_{n,m}(x, y, 1)$ using the argument of § 3. We proceed by induction on n and let $0 \leqq m < n$. By (6.8) we obtain

$$ \begin{aligned} \lim_{x\to 0} \frac{(1-q^x)}{(1-q)}\, {}_qI_{n,m}(x, y, 1) = m!(n-m)!\, q^{-[y\binom{n}{2}+\binom{n}{3}]} \\ \cdot \Gamma_q(y) \prod_{i=1}^{n-1} \Gamma_q(n-i+\chi(i\leqq m))\Gamma_q(y+n-i)\ {}_qU_{n,m}(0, y, 1). \end{aligned} \tag{6.11} $$

The recurrence relation (6.4) and our induction hypothesis give

$$ \begin{aligned} &\lim_{x\to 0} \frac{(1-q^x)}{(1-q)}\, {}_qI_{n,m}(x, y, 1) \\ &\quad = (n-m)\ {}_qI_{n-1,m}(2, y, 1) \\ &\quad = (n-m)(n-1)! \frac{\begin{bmatrix} n-1 \\ m \end{bmatrix}_q}{\binom{n-1}{m}} q^{[\binom{m}{2}+2\binom{n}{3}]} \\ &\qquad \cdot \prod_{i=1}^{n-1} \frac{\Gamma_q(n-i+1+\chi(i\leqq m))\Gamma_q(y+n-i-1)}{\Gamma_q(y+2n-i-1+\chi(i\leqq m))} \Gamma_q(i). \end{aligned} \tag{6.12} $$

Solving (6.11) and (6.12) for ${}_qU_{n,m}(0, y, 1)$, we obtain

$$
\begin{aligned}
{}_qU_{n,m}(0,y,1) &= \begin{bmatrix} n-1 \\ m \end{bmatrix}_q q^{[y\binom{n}{2}+\binom{m}{2}+3\binom{n}{3}]} \frac{1}{\Gamma_q(y)} \\
&\quad \cdot \prod_{i=1}^{n-1} \frac{(1-q^{n-i+\chi(i\leqq m)})}{(1-q^{y+n-i-1})} \frac{\Gamma_q(i)}{\Gamma_q(y+2n-i-1+\chi(i\leqq m))} \\
&= \begin{bmatrix} n \\ m \end{bmatrix}_q q^{[y\binom{n}{2}+\binom{m}{2}+3\binom{n}{3}]} \frac{1}{\Gamma_q(y)} \frac{(1-q^{n-m})}{(1-q^n)} \\
&\quad \cdot \prod_{i=1}^{n-1} \frac{(1-q^{n-i+\chi(i\leqq m)})}{(1-q^{y+n-i-1})} \frac{\Gamma_q(i)}{\Gamma_q(y+2n-i-1+\chi(i\leqq m))} \\
&= \begin{bmatrix} n \\ m \end{bmatrix}_q q^{[y\binom{n}{2}+\binom{m}{2}+3\binom{n}{3}]} \prod_{i=1}^{n} \frac{\Gamma_q(i)}{\Gamma_q(y+2n-i-1+\chi(i\leqq m))}.
\end{aligned} \tag{6.13}
$$

Replacing y by $x+y$ in (6.13) and using (6.10) yields

$$
{}_qU_{n,m}(x,y,1) = \begin{bmatrix} n \\ m \end{bmatrix}_q q^{[x\binom{n}{2}+y\binom{n}{2}+\binom{m}{2}+3\binom{n}{3}]} \prod_{i=1}^{n} \frac{\Gamma_q(i)}{\Gamma_q(x+y+2n-i-1+\chi(i\leqq m))}. \tag{6.14}
$$

Substituting (6.14) into (6.8) gives

$$
\begin{aligned}
{}_qI_{n,m}(x,y,1) &= n! \frac{\begin{bmatrix} n \\ m \end{bmatrix}_q}{\binom{n}{m}} q^{[x\binom{n}{2}+\binom{m}{2}+2\binom{n}{3}]} \\
&\quad \cdot \prod_{i=1}^{n} \frac{\Gamma_q(x+n-i+\chi(i\leqq m))\Gamma_q(y+n-i)}{\Gamma_q(x+y+2n-i-1+\chi(i\leqq m))} \Gamma_q(i),
\end{aligned} \tag{6.15}
$$

in agreement with Conjecture 6 for $k=1$, $l=0$.

7. A proof of a q-analogue of Conjecture 2 for $k=1$. A q-analogue of Conjecture 2 is given by the following conjecture.

Conjecture 8. Let $\boldsymbol{\lambda}$ denote a partition $\lambda_1 \geqq \lambda_2 \geqq \cdots \geqq \lambda_n \geqq 0$ with at most n parts. For all $k \geqq 0$ there exists a homogeneous symmetric polynomial ${}_qs^k_{n,\boldsymbol{\lambda}}(\mathbf{t})$ with leading term $\prod_{i=1}^n t_i^{\lambda_i}$ such that

$$
\begin{aligned}
{}_qI_{n,\boldsymbol{\lambda}}(x,y,k) &= \int_0^1 \cdots \int_0^1 \prod_{i=1}^{n} t_i^{(x-1)} \frac{(t_iq)_\infty}{(t_iq^y)_\infty} {}_qs^k_{n,\boldsymbol{\lambda}}(\mathbf{t})\, {}_q\Delta_n^{2k}(\mathbf{t})\, d_qt_1 \cdots d_qt_n \\
&= n!\, q^{[k(\sum_{i=1}^n (i-1)\lambda_i)+kx\binom{n}{2}+2k^2\binom{n}{3}]} {}_qf^k_{n,\boldsymbol{\lambda}} \\
&\quad \cdot \prod_{i=1}^{n} \frac{\Gamma_q(x+(n-i)k+\lambda_i)\Gamma_q(y+(n-i)k)}{\Gamma_q(x+y+(2n-i-1)k+\lambda_i)},
\end{aligned} \tag{7.1}
$$

where

$$
{}_qf^k_{n,\boldsymbol{\lambda}} = \prod_{1\leqq i<j\leqq n} \frac{(q^{k(j-i)+\lambda_i-\lambda_j})_k}{(1-q)^k}. \tag{7.2}
$$

We now show that Conjecture 8 holds for $k=1$ with

$$
{}_qs^1_{n,\boldsymbol{\lambda}}(\mathbf{t}) = s^1_{n,\boldsymbol{\lambda}}(\mathbf{t}). \tag{7.3}
$$

Since the integrand is a symmetric function and contains $\Delta_n(\mathbf{t})$ as a factor, the argument for (2.15) and (6.3) yields

$$\lim_{x\to 0}\frac{(1-q^x)}{(1-q)}\,{}_qI_{n,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1},0)}(x,y,1)=n\,{}_qI_{n-1,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1})}(2,y,1). \tag{7.4}$$

Substituting (3.21) into (7.1) gives

$${}_qI_{n,\boldsymbol{\lambda}}(x,y,1)=n!\int_0^1\cdots\int_0^1\prod_{i=1}^n t_i^{(x-1)+(n-i+\lambda_i)}\frac{(t_iq)_\infty}{(t_iq^y)_\infty}\Delta_n(\mathbf{t})\,d_qt_1\cdots d_qt_n. \tag{7.5}$$

Using (6.7) to expand the Vandermonde in (7.5) yields

$${}_qI_{n,\boldsymbol{\lambda}}(x,y,1)=n!\,q^{-[y\binom{n}{2}+\binom{n}{3}]}\prod_{i=1}^n\Gamma_q(x+n-i+\lambda_i)\Gamma_q(y+n-i)\,{}_qU_{n,\boldsymbol{\lambda}}(x,y,1), \tag{7.6}$$

where

$${}_qU_{n,\boldsymbol{\lambda}}(x,y,1)=\sum_{\pi\in S_n}\operatorname{sgn}(\pi)\prod_{i=1}^n\frac{1}{\Gamma_q(x+y+n-i+\lambda_i+\pi(i)-1)}. \tag{7.7}$$

We have

$${}_qU_{n,\boldsymbol{\lambda}}(x,y,1)={}_qU_{n,(\lambda_1-\lambda_n,\cdots,\lambda_{n-1}-\lambda_n,0)}(0,x+y+\lambda_n,1). \tag{7.8}$$

We proceed by induction on n. We treat first the case $\lambda_n=0$. By (7.6) we have

$$\begin{aligned}&\lim_{x\to 0}\frac{(1-q^x)}{(1-q)}\,{}_qI_{n,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1},0)}(x,y,1)\\&\quad=n!\,q^{-[y\binom{n}{2}+\binom{n}{3}]}\Gamma_q(y)\prod_{i=1}^{n-1}\Gamma_q(n-i+\lambda_i)\Gamma_q(y+n-i)\\&\qquad\cdot{}_qU_{n,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1},0)}(0,y,1).\end{aligned} \tag{7.9}$$

Our recurrence relation (7.4) and our induction hypothesis give

$$\begin{aligned}&\lim_{x\to 0}\frac{(1-q^x)}{(1-q)}\,{}_qI_{n,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1},0)}(x,y,1)\\&\quad=n(n-1)!\,q^{[\sum_{i=1}^{n-1}(i-1)\lambda_i+2\binom{n-1}{2}+2\binom{n-1}{3}]}\,{}_qf^1_{n-1,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1})}\\&\qquad\cdot\prod_{i=1}^{n-1}\frac{\Gamma_q(n-i+1+\lambda_i)\Gamma_q(y+n-i-1)}{\Gamma_q(y+2n-i-1+\lambda_i)}\\&\quad=n!\,q^{[\sum_{i=1}^{n-1}(i-1)\lambda_i+2\binom{n}{3}]}\prod_{1\le i<j\le n-1}\frac{(1-q^{j-i+\lambda_i-\lambda_j})}{(1-q)}\\&\qquad\cdot\prod_{i=1}^{n-1}\frac{\Gamma_q(n-i+1+\lambda_i)\Gamma_q(y+n-i-1)}{\Gamma_q(y+2n-i-1+\lambda_i)}.\end{aligned} \tag{7.10}$$

Solving (7.9) and (7.10) for ${}_qU_{n,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1},0)}(0,y,1)$ yields

$$\begin{aligned}&{}_qU_{n,(\lambda_1,\lambda_2,\cdots,\lambda_{n-1},0)}(0,y,1)\\&\quad=q^{[\sum_{i=1}^{n-1}(i-1)\lambda_i+y\binom{n}{2}+3\binom{n}{3}]}\prod_{1\le i<j\le n-1}\frac{(1-q^{j-i+\lambda_i-\lambda_j})}{(1-q)}\\&\qquad\cdot\prod_{i=1}^{n-1}\frac{(1-q^{n-i+\lambda_i})}{(1-q)}\prod_{i=1}^n\frac{1}{\Gamma_q(y+2n-i-1+\lambda_i)}.\end{aligned} \tag{7.11}$$

Replacing y by $x+y+\lambda_n$ and λ_i, $1\leqq i\leqq n-1$, by $\lambda_i-\lambda_n$, $1\leqq i\leqq n-1$, in (7.11) and using (7.8) yields

$$
\begin{aligned}
{}_qU_{n,\boldsymbol{\lambda}}(x,y,1) &= q^{[\sum_{i=1}^n (i-1)\lambda_i + x\binom{n}{2} + y\binom{n}{2} + 3\binom{n}{3}]} \\
&\quad \cdot \prod_{1\leqq i<j\leqq n} \frac{(1-q^{j-i+\lambda_i-\lambda_j})}{(1-q)} \prod_{i=1}^n \frac{1}{\Gamma_q(x+y+2n-i-1+\lambda_i)}.
\end{aligned} \tag{7.12}
$$

Substituting (7.12) into (7.6), we get the required result (7.1).

8. The case $l>0$. The following special case of Lemma 4 is important enough to be labeled a theorem.

THEOREM 9.

$$
\sum_{\substack{M\subset\{1,\cdots,n\},|M|=m \\ L\subset\{1,\cdots,n\}-M,|L|=l \\ J\subset L,|J|=j}} \prod_{i\in M\cup J} t_i\, {}_Q\Delta_{n,L}(\mathbf{t}) = {}_Qc_{n,m,l,j}\, e_{n,m+j}(\mathbf{t})\Delta_n(\mathbf{t}), \tag{8.1}
$$

where

$$
{}_Qc_{n,m,l,j} = Q^{[(n-ml)j+\binom{l}{2}]} \begin{bmatrix} m+j \\ j \end{bmatrix}_Q \begin{bmatrix} n-m-j \\ l-j \end{bmatrix}_Q. \tag{8.2}
$$

Proof. It is easy to see that since $\Delta_n(\mathbf{t})$ is an antisymmetric function, so is the left side of (8.1). Explicitly, $m!(n-m-l)!j!(l-j)!$ times the left side of (8.1) equals

$$
\Xi_n\left(\prod_{i=1}^{m+j} t_i\, {}_Q\Delta_{n,\{m+1,\cdots,m+l\}}(\mathbf{t})\right). \tag{8.3}
$$

Thus (8.1) holds for some constant ${}_Qc_{n,m,l,j}$, which can be evaluated using (5.1) and (4.4). Alternatively, we set

$$
t_i = Q^i, \qquad 1\leqq i\leqq n. \tag{8.4}
$$

The left side of (8.1) vanishes unless $L=\{n-l+1,\cdots,n\}$. Thus

$$
\begin{aligned}
&\left(\sum_{\substack{M\subset\{1,\cdots,n-l\} \\ |M|=m}} Q^{[\sum_{i\in M} i]}\right)\left(\sum_{\substack{J\subset\{n-l+1,\cdots,n\} \\ |J|=j}} Q^{[\sum_{i\in J} i]}\right)\Delta_n(Q,\cdots,Q^{n-l},Q^{n-l+2},\cdots,Q^{n+1}) \\
&\qquad = {}_Qc_{n,m,l,j}\left(\sum_{\substack{S\subset\{1,\cdots,n\} \\ |S|=m+j}} Q^{[\sum_{i\in S} i]}\right)\Delta_n(Q,\cdots,Q^n).
\end{aligned} \tag{8.5}
$$

The case $a=q^{-N}$, $t=q^{N+s}x$, of the q-binomial theorem (5.11) is

$$
(q^s x)_N = \sum_{n=0}^N q^{[sn+\binom{n}{2}]} \begin{bmatrix} N \\ n \end{bmatrix}_q (-x)^n. \tag{8.6}
$$

Replacing q by Q and equating coefficients of x^n yields

$$
\sum_{\substack{A\subset\{s,\cdots,s+N-1\} \\ |A|=n}} Q^{[\sum_{i\in S} i]} = Q^{[sn+\binom{n}{2}]} \begin{bmatrix} N \\ n \end{bmatrix}_Q. \tag{8.7}
$$

Using (8.7) to evaluate the three sums in (8.5) and solving for ${}_Qc_{n,m,l,j}$, we obtain (8.2), as required. □

The parameter $l\geqq 0$ introduces the factor

$$
\prod_{i=n-l+1}^n (1-At_i) = \sum_{j=0}^l (-A)^j e_{l,j}(t_{n-l+1},\cdots,t_n) \tag{8.8}
$$

with $A = q^y$ into the integrand in (5.3) and replaces the Vandermonde $\Delta_n(\mathbf{t})$ by ${}_{(q^k)}\Delta_{n,0,l}(\mathbf{t})$ (recall (5.2)). Let $d_\mu(\mathbf{t})$ be an n-dimensional antisymmetric measure. We have

$$\begin{aligned}&\int\cdots\int \prod_{i=1}^{m} t_i \prod_{i=n-l+1}^{n} (1-At_i)\ {}_Q\Delta_{n,0,l}(\mathbf{t})\ d_\mu(\mathbf{t})\\ &\quad=\sum_{j=0}^{l}(-A)^j\binom{l}{j}\int\cdots\int \prod_{i=1}^{m} t_i \prod_{i=n-j+1}^{n} t_i\ {}_Q\Delta_{n,0,l}(\mathbf{t})\ d_\mu(\mathbf{t}),\end{aligned}\tag{8.9}$$

since each of the $\binom{l}{j}$ terms in the expansion (3.7) of the elementary symmetric function in (8.8) gives the same contribution to the integral. Multiply both sides of (8.1) by $d_\mu(\mathbf{t})$ and integrate. The $\binom{n}{m,l}\binom{l}{j}$ terms on the left side of (8.1) give the same contribution to the integral as do the $\binom{n}{m+j}$ terms that arise when the elementary symmetric function on the right side is expanded. We obtain

$$\begin{aligned}&\binom{n}{m,l}\binom{l}{j}\int\cdots\int \prod_{i=1}^{m} t_i\ {}_Q\Delta_{n,0,l}(\mathbf{t})\ d_\mu(\mathbf{t})\\ &\quad={}_Qc_{n,m,l,j}\binom{n}{m+j}\int\cdots\int \prod_{i=1}^{m+j} t_i\ \Delta_n(\mathbf{t})\ d_\mu(\mathbf{t}).\end{aligned}\tag{8.10}$$

Solving (8.10) for the integral on the left side and substituting into (8.9) yields

$$\begin{aligned}&\int\cdots\int \prod_{i=1}^{m} t_i \prod_{i=n-l+1}^{n} (1-At_i)\ {}_Q\Delta_{n,0,l}(\mathbf{t})\ d_\mu(\mathbf{t})\\ &\quad=\frac{1}{\binom{n}{m,l}}\sum_{j=0}^{l}(-A)^j\,{}_Qc_{n,m,l,j}\binom{n}{m+j}\int\cdots\int \prod_{i=1}^{m+j} t_i\,\Delta_n(\mathbf{t})\ d_\mu(\mathbf{t}).\end{aligned}\tag{8.11}$$

Setting $Q = q^k$, $A = q^y$, and taking the appropriate choice of $d_\mu(\mathbf{t})$, (8.11) becomes

$${}_qI_{n,m,l}(x,y,k)=\frac{1}{\binom{n}{m,l}}\sum_{j=0}^{l}(-q^y)^j\,{}_{(q^k)}c_{n,m,l,j}\binom{n}{m+j}\,{}_qI_{n,m+j}(x,y,k).\tag{8.12}$$

We have the following theorem.

THEOREM 10. *Fix $n \geqq 2$, x, y and $k \geqq 0$. Conjecture* 6 (5.6) *holds for all $m \geqq 0$, $l \geqq 0$, $m+l \leqq n$, if and only if it holds for all m, $0 \leqq m \leqq n$, when $l = 0$.*

Proof. We must show that (8.12) holds when we substitute (5.6). Dividing by

$$\frac{1}{\binom{n}{m,l}}\,{}_{(q^k)}c_{n,m,l,0}\binom{n}{m}\,{}_qI_{n,m}(x,y,k),$$

this is

$$\frac{(q^{y+(n-l)k};q^k)_l}{(q^{x+y+(2n-m-l-1)k};q^k)_l}=\sum_{j=0}^{l}\frac{(q^{-kl};q^k)_j(q^{-x-(n-m-1)k};q^k)_j}{(q^k;q^k)_j(q^{-x-y-(2n-m-2)k};q^k)_j}\,q^{kj}.\tag{8.13}$$

This is equivalent to the special case (Slater [28, (3.3.2.7)])

$$\frac{(d/b)_n}{(d)_n}\,b^n=\sum_{i=0}^{n}\frac{(q^{-n})_i(b)_i}{(q)_i(d)_i}\,q^i\tag{8.14}$$

of the well-known q-analogue (Slater [28, (3.3.2.2)]) of Saalschütz's theorem. □

We have thus proved Conjecture 6 when $n=2$ and when $k=1$.

An alternative special case of the q-analogue of Saalschütz's theorem is the q-analogue (Andrews [2, Cor. 2.4]) of Gauss' theorem. We require only the terminating case (Slater [28, (3.3.2.6)])

$$\frac{(d/b)_n}{(d)_n}=\sum_{i=0}^{n}\frac{(q^{-n})_i(b)_i}{(q)_i(d)_i}\left(q^n\frac{d}{b}\right)^i. \tag{8.15}$$

Set

$$\begin{aligned}{}_qJ_{n,m,l}(x,y,k)=&\int_0^1\cdots\int_0^1\prod_{i=1}^{n}t_i^{(x-1)+\chi(i\leqq m)}\frac{(t_iq^{\chi(i\leqq n-l)})_\infty}{(t_iq^y)_\infty}\\&\cdot{}_{(q^{-k})}\Delta_{n,m,l}(\mathbf{t})\,{}_q\Delta_n^{(2k-1)}(\mathbf{t})\,d_qt_1\cdots d_qt_n.\end{aligned} \tag{8.16}$$

We have the following conjecture.

Conjecture 11.

$$\begin{aligned}{}_qJ_{n,m,l}(x,y,k)=&\,n!\frac{\begin{bmatrix}n\\m,\,l\end{bmatrix}_{(q^k)}}{\binom{n}{m,\,l}}q^{[kx\binom{n}{2}+xl+k\binom{m}{2}+k\binom{l}{2}+2k^2\binom{n}{3}]}\\&\cdot\prod_{i=1}^{n}\frac{\Gamma_q(x+(n-i)k+\chi(i\leqq m))\Gamma_q(y+(n-i)k+\chi(i\leqq l))}{\Gamma_q(x+y+(2n-i-1)k+\chi(i\leqq m+l))}\frac{\Gamma_q(ik)}{\Gamma_q(k)}.\end{aligned} \tag{8.17}$$

We may take $Q=q^{-k}$, $A=1$, in (8.11). Substituting into (8.17), we obtain an identity which is equivalent to (8.15) with base q^k. This proves the following theorem.

THEOREM 12. *Fix $n\geqq 2$, x, y and $k\geqq 0$. Conjecture* 11 (8.17) *holds for all $m\geqq 0$, $l\geqq 0$, $m+l\leqq n$ if and only if it holds for all m, $0\leqq m\leqq n$, when $l=0$.*

Since our formulas (5.6) and (8.17) for ${}_qI_n$ and ${}_qJ_n$ agree when $l=0$, they are equivalent by Theorems 10 and 12.

9. Further extensions of Selberg's integral. Following Askey [6], we may give q-analogues of Selberg's integral using a number of known q-analogues of the beta integral. Let

$$\int_0^\infty f(t)\,d_qt=(1-q)\sum_{n=-\infty}^{\infty}q^nf(q^n). \tag{9.1}$$

We may use

$$\int_0^\infty t^{(x-1)}\frac{(-cq^{x+y}t)_\infty}{(-ct)_\infty}\,d_qt=\frac{(-cq^x)_\infty}{(-c)_\infty}\frac{(-c^{-1}q^{1-x})_\infty}{(-c^{-1}q)_\infty}\frac{\Gamma_q(x)\Gamma_q(y)}{\Gamma_q(x+y)}, \tag{9.2}$$

where there are no zero factors in the denominator of the integrand. This is given by Askey [5]. Set

$$\begin{aligned}{}_q^cF_{n,m,l}(x,y,k)=&\int_0^\infty\cdots\int_0^\infty\prod_{i=1}^{n}t_i^{(x-1)+\chi(i\leqq m)}\frac{(-cq^{x+y+2(n-1)k+\chi(i\leqq m)+\chi(n-i+1\leqq l)}t_i)_\infty}{(-ct_i)_\infty}\\&\cdot{}_{(q^k)}\Delta_{n,m,l}(\mathbf{t})\,{}_q\Delta_n^{(2k-1)}(\mathbf{t})\,d_qt_1\cdots d_qt_n\end{aligned} \tag{9.3}$$

and

$$\begin{aligned}{}_q^cG_{n,m,l}(x,y,k)=&\int_0^\infty\cdots\int_0^\infty\prod_{i=1}^{n}t_i^{(x-1)+\chi(i\leqq m)}\frac{(-cq^{x+y+2(n-1)k}t_i)_\infty}{(-cq^{-1+\chi(m<i\leqq n-l)}t_i)_\infty}\\&\cdot{}_{(q^{-k})}\Delta_{n,m,l}(\mathbf{t})\,{}_q\Delta_n^{(2k-1)}(\mathbf{t})\,d_qt_1\cdots d_qt_n.\end{aligned} \tag{9.4}$$

Since $k \geqq 0$ is a nonnegative integer, all of our q-analogues of $\Delta_n^{2k}(\mathbf{t})$ are polynomials. Thus, ${}_qF_n$ and ${}_qG_n$ divided by the nth power of (9.2) are rational functions in q, q^x, q^y and c. Similar remarks apply to ${}_qI_n$ and ${}_qJ_n$. For any integer μ, we have

$$
\begin{aligned}
&{}_{-q^{(\mu-x-y-2(n-1)k)}}F_{n,m,l}(x, y, k) \\
&\quad = q^{-[\mu(nx+m)+(2\mu-1)k\binom{n}{2}]}\, {}_qJ_{n,m,n-m-l}(x, -x-y-2(n-1)k, k)
\end{aligned} \tag{9.5}
$$

and

$$
\begin{aligned}
&{}_{-q^{(\mu-x-y-2(n-1)k)}}G_{n,m,l}(x, y, k) \\
&\quad = q^{-[(\mu-1)(nx+m)+(2\mu-1)k\binom{n}{2}]}\, {}_qI_{n,m,n-m-l}(x, -x-y-2(n-1)k, k).
\end{aligned} \tag{9.6}
$$

Since a rational function is determined by finitely many values, we see that Conjecture 6 (5.6) and Conjecture 11 (8.17) are equivalent to

$$
\begin{aligned}
{}_q^cF_{n,m,l}(x, y, k) &= n! \frac{\begin{bmatrix} n \\ m, l \end{bmatrix}_{(q^k)}}{\binom{n}{m, l}} q^{[km(n-1)-k\binom{m}{2}-k\binom{l}{2}]} \\
&\quad \cdot \prod_{i=1}^{n} \frac{(-cq^{x+2(n-i)k+\chi(i\leqq m)})_\infty}{(-c)_\infty} \frac{(-c^{-1}q^{1-x-2(n-i)k-\chi(i\leqq m)})_\infty}{(-c^{-1}q)_\infty} \\
&\quad \cdot \prod_{i=1}^{n} \frac{\Gamma_q(x+(n-i)k+\chi(i\leqq m))\Gamma_q(y+(n-i)k+\chi(i\leqq l))}{\Gamma_q(x+y+(2n-i-1)k+\chi(i\leqq m+l))} \frac{\Gamma_q(ik)}{\Gamma_q(k)}
\end{aligned} \tag{9.7}
$$

and

$$
\begin{aligned}
{}_q^cG_{n,m,l}(x, y, k) &= n! \frac{\begin{bmatrix} n \\ m, l \end{bmatrix}_{(q^k)}}{\binom{n}{m, l}} q^{[m(x+1)+xl+km(n-1)-k\binom{m}{2}-k\binom{l}{2}]} \\
&\quad \cdot \prod_{i=1}^{n} \frac{(-cq^{x+2(n-i)k+\chi(i\leqq m)})_\infty}{(-c)_\infty} \frac{(-c^{-1}q^{1-x-2(n-i)k-\chi(i\leqq m)})_\infty}{(-c^{-1}q)_\infty} \\
&\quad \cdot \prod_{i=1}^{n} \frac{\Gamma_q(x+(n-i)k+\chi(i\leqq m))\Gamma_q(y+(n-i)k+\chi(i\leqq l))}{\Gamma_q(x+y+(2n-i-1)k+\chi(i\leqq m+l))} \frac{\Gamma_q(ik)}{\Gamma_q(k)},
\end{aligned} \tag{9.8}
$$

respectively, with l replaced by $n-m-l$. This establishes the equivalence of our formulas (5.6), (8.17), (9.7), and (9.8) for ${}_qI_n$, ${}_qJ_n$, ${}_qF_n$, and ${}_qG_n$, respectively.

Our entire analysis goes through as before with the cases $l=0$ and $m+l=n$ interchanged. Carlitz's q-analogue (5.18) of Dixon's theorem and its companion (5.17) also arise in the case $n=2$. Rather than give a direct proof, we may use (9.5) and (9.6) to "transport" Theorems 10 and 12 to apply to ${}_qF_n$ and ${}_qG_n$. For $k=1$, we may take $m+l=n$ and use (3.1) and (4.26) with $A=-c$.

Askey's last conjecture in [6] is based upon

$$
\int_{-c}^{d} \frac{(-tc^{-1}q)_\infty (td^{-1}q)_\infty}{(-tc^{-1}q^x)_\infty (td^{-1}q^y)_\infty} d_qt = \frac{cd}{(c+d)} \frac{(-cd^{-1})_\infty (-dc^{-1})_\infty}{(-q^ycd^{-1})_\infty (-q^xdc^{-1})_\infty} \frac{\Gamma_q(x)\Gamma_q(y)}{\Gamma_q(x+y)}, \tag{9.9}
$$

where there are no zero factors in the denominator of the integrand and

$$
\int_{-c}^{d} f(t)d_qt = c(1-q)\sum_{n=0}^{\infty} q^n f(-cq^n) + d(1-q)\sum_{n=0}^{\infty} q^n f(dq^n). \tag{9.10}
$$

This is given by Andrews and Askey [3]. We set

$$
{}_q^{c,d}H_{n,m,l}(x,y,k)=\int_{-c}^{d}\cdots\int_{-c}^{d}\prod_{i=1}^{n}\frac{(-t_ic^{-1}q)_\infty}{(-t_ic^{-1}q^{x+\chi(i\leqq m)})_\infty}\frac{(t_id^{-1}q)_\infty}{(t_id^{-1}q^{y+\chi(n-i+1\leqq l)})_\infty}
$$

$$
\cdot {}_{(q^k)}\Delta_{n,m,l}(\mathbf{t})\ {}_q\Delta_n^{(2k-1)}(\mathbf{t})\ d_qt_1\cdots d_qt_n \tag{9.11}
$$

and

$$
{}_q^{c,d}K_{n,m,l}(x,y,k)=\int_{-c}^{d}\cdots\int_{-c}^{d}\prod_{i=1}^{n}\frac{(-t_ic^{-1}q^{\chi(i>m)})_\infty}{(-t_ic^{-1}q^{x})_\infty}\frac{(t_id^{-1}q^{\chi(i\leqq n-l)})_\infty}{(t_id^{-1}q^{y})_\infty}
$$

$$
\cdot {}_{(q^{-k})}\Delta_{n,m,l}(\mathbf{t})\ {}_q\Delta_n^{(2k-1)}(\mathbf{t})\ d_qt_1\cdots d_qt_n. \tag{9.12}
$$

We shall work with ${}_qH_n$. We have the following conjecture.

Conjecture 13.

$$
\begin{aligned}
{}_q^{c,d}H_{n,m,l}(x,y,k)=n!&\frac{\begin{bmatrix}n\\m,\,l\end{bmatrix}_{(q^k)}}{\binom{n}{m,\,l}}q^{[k\binom{m}{2}+k\binom{l}{2}-\binom{k}{2}\binom{n}{2}+k^2\binom{n}{3}]}\\
&\cdot\prod_{i=1}^{n}\frac{(cd)^{1+(n-i)k}}{(c+d)}\frac{(-cd^{-1})_\infty}{(-q^{y+(n-i)k+\chi(i\leqq l)}cd^{-1})_\infty}\\
&\cdot\frac{(-dc^{-1})_\infty}{(-q^{x+(n-i)k+\chi(i\leqq m)}dc^{-1})_\infty}\\
&\cdot\prod_{i=1}^{n}\frac{\Gamma_q(x+(n-i)k+\chi(i\leqq m))\Gamma_q(y+(n-i)k+\chi(i\leqq l))}{\Gamma_q(x+y+(2n-i-1)k+\chi(i\leqq m+l))}\frac{\Gamma_q(ik)}{\Gamma_q(k)}.
\end{aligned} \tag{9.13}
$$

The substitution $t_i\to -t_{n-i+1}$, $1\leqq i\leqq n$, gives the q-analogue

$$
{}_q^{c,d}H_{n,m,l}(x,y,k)={}_q^{d,c}H_{n,l,m}(y,x,k) \tag{9.14}
$$

of the symmetry (1.3). We cannot use this substitution for ${}_qI_n$, ${}_qJ_n$, ${}_qF_n$, or ${}_qG_n$ since the lower limit of integration is 0. The substitution $t_i\to t_{n-i+1}^{-1}$, $1\leqq i\leqq n$, only gives again the equivalence of our formulas (9.7) and (9.8) for ${}_qF_n$ and ${}_qG_n$. Unfortunately, (9.14) does not imply the symmetry law (5.7) of ${}_qI_n$. If we could establish (5.7) (or an equivalent symmetry of ${}_qJ_n$, ${}_qF_n$, or ${}_qG_n$), then we should be able to extend Selberg's proof [27] by expanding our q-analogue of $\Delta_n^{2k}(\mathbf{t})$ in powers of t_i, $1\leqq i\leqq n$. We cannot make use of the symmetry (9.14) since we must expand in terms of $(-tc^{-1}q^x)_m$, $1\leqq i\leqq n$, and $(td^{-1}q^y)_m$, $1\leqq i\leqq n$. We can do this for $k=1$ using Lemma 5. Our proof of the case $k=1$ works because our key results (6.9) and (7.7) show that ${}_qU_{n,m}(x,y,1)$ and ${}_qU_{n,\lambda}(x,y,1)$ are symmetric in x and y. This gives the case $k=1$, $m=l=0$, of (5.7).

The usual argument for obtaining a recurrence relation gives

$$
\begin{aligned}
&\lim_{x\to 0}\frac{(1-q^x)}{(1-q)}\,{}_q^{c,d}H_{n,m}(x,y,k)\\
&\quad=(n-m)\frac{cd}{(c+d)}\frac{(-cd^{-1})_\infty}{(-q^ycd^{-1})_\infty}q^{km}c^{(n-m-1)}\\
&\qquad\cdot\int_{-c}^{d}\cdots\int_{-c}^{d}\prod_{i=1}^{n-1}t_i^{(2k-1)+\chi(i\leqq m)}\left(\frac{-cq^{1-k-\chi(i\leqq m)}}{t_i}\right)_{(2k-1)+\chi(i\leqq m)}\\
&\qquad\cdot\prod_{i=1}^{n-1}\frac{(t_id^{-1}q)_\infty}{(t_id^{-1}q^y)_\infty}\,{}_{(q^k)}\Delta_{n-1,m}(\mathbf{t})\ {}_q\Delta_{n-1}^{(2k-1)}(\mathbf{t})\ d_qt_1\cdots d_qt_{n-1}.
\end{aligned} \tag{9.15}
$$

Since

$$t_i^{(2k-1)+\chi(i\leqq m)}\left(\frac{-cq^{1-k-\chi(i\leqq m)}}{t_i}\right)_{(2k-1)+\chi(i\leqq m)} = c^{(2k-1)}(cq^{-k})^{\chi(i\leqq m)}(-t_iq^{1-k}c^{-1})_{(2k-1)+\chi(i\leqq m)}, \tag{9.16}$$

we obtain

$$\lim_{x\to 0}\frac{(1-q^x)}{(1-q)}\,{}_q^{c,d}H_{n,m}(x,y,k) = (n-m)\frac{cd}{(c+d)}\frac{(-cd^{-1})_\infty}{(-q^ycd^{-1})_\infty}c^{2k(n-1)}\,{}_q^{cq^k,d}H_{n-1,m}(2k,y,k). \tag{9.17}$$

To treat the case $k=1$, set $A=-q^xc^{-1}$ and $A=q^yd^{-1}$ in (4.26). In short order we have

$$\begin{aligned}{}_q^{c,d}H_{n,m}(x,y,1) &= m!(n-m)!q^{-[x\binom{n}{2}+y\binom{n}{2}+2\binom{n}{3}]}\\ &\cdot\prod_{i=1}^{n}\frac{(cd)^{1+n-i}}{(c+d)}\frac{(-cd^{-1})_\infty}{(-q^{y+n-i}cd^{-1})_\infty}\frac{(-dc^{-1})_\infty}{(-q^{x+n-i+\chi(i\leqq m)}dc^{-1})_\infty}\\ &\cdot\prod_{i=1}^{n}\Gamma_q(x+n-i+\chi(i\leqq m))\Gamma_q(y+n-i)\\ &\cdot\sum_{\pi\in S_n}\operatorname{sgn}(\pi)\prod_{i=1}^{n}\frac{1}{\Gamma_q(x+y+n-i+\pi(i)-1+\chi(i\leqq m))}.\end{aligned} \tag{9.18}$$

Observe that the sum on the right side of (9.18) equals ${}_qU_{n,m}(x,y,1)$ (6.9), which we have already (6.14) evaluated. Equation (9.13) follows for $k=1$, $l=0$.

Since (6.14) also arises in connection with orthogonal polynomials and plane partitions, it is an important sum. As with all of our q-analogues of Selberg's integral, it is really a polynomial identity. Set $z=x+y$ and multiply both sides of (6.14) by

$$(q-1)^{\binom{n}{2}}\prod_{i=1}^{n}\Gamma_q(z+2n-i-1+\chi(i\leqq m)). \tag{9.19}$$

Equation (6.14) then becomes

$$\begin{aligned}&\sum_{\pi\in S_n}\operatorname{sgn}(\pi)\prod_{i=1}^{n}(q^{z+2n-i-\pi(i)+\chi(i\leqq m)})_{(\pi(i)-1)}\\ &\quad=q^{[z\binom{n}{2}+2\binom{n}{2}+5\binom{n}{3}]}\prod_{1\leqq i<j\leqq n}(q^{-i+\chi(i\leqq m)}-q^{-j+\chi(j\leqq m)}),\end{aligned} \tag{9.20}$$

which is equivalent to the case (4.28) of Lemma 5 with $A=q^{z+n}$ and $t_j=q^{j-\chi(j\leqq m)}$, $1\leqq j\leqq n$.

We may give the same type of results for ${}_q^{c,d}K_{n,m,l}$. The formula is

$${}_q^{c,d}K_{n,m,l}(x,y,k) = q^{[xl+ym]}\,{}_q^{c,d}H_{n,m,l}(x,y,k). \tag{9.21}$$

An important generalization of the Schur function is given by

$${}_q^{A}S_{n,\lambda}(\mathbf{t}) = \frac{\det|(At_j)_{n-i+\lambda_i}|_{n\times n}}{\det|t_j^{n-i}|_{n\times n}}. \tag{9.22}$$

Set $A=-q^x c^{-1}$ in (9.22) and $A=q^y d^{-1}$ in (4.26). Using our evaluation (7.12) of ${}_qU_{n,\lambda}(x, y, 1)$, we obtain

$$
\begin{aligned}
{}_q^{c,d}I_{n,\lambda}(x, y, 1) &= \int_{-c}^{d} \cdots \int_{-c}^{d} \prod_{i=1}^{n} \frac{(-t_i c^{-1} q)_\infty}{(-t_i c^{-1} q^x)_\infty} \frac{(t_i d^{-1} q)_\infty}{(t_i d^{-1} q^y)_\infty} \\
&\quad \cdot {}^{(-q^x c^{-1})}_{q}S_{n,\lambda}(\mathbf{t})\, \Delta_n^2(\mathbf{t})\, d_q t_1 \cdots d_q t_n \\
&= n!\, q^{[\sum_{i=1}^{n}(i-1)\lambda_i + x\binom{n}{2} + 2\binom{n}{3}]} d^{\binom{n}{2}} \prod_{1 \le i < j \le n} \frac{(1-q^{j-i+\lambda_i-\lambda_j})}{(1-q)} \\
&\quad \cdot \prod_{i=1}^{n} \frac{cd}{(c+d)} \frac{(-cd^{-1})_\infty}{(-q^{y+n-i}cd^{-1})_\infty} \frac{(-dc^{-1})_\infty}{(-q^{x+n-i+\lambda_i}dc^{-1})_\infty} \\
&\quad \cdot \prod_{i=1}^{n} \frac{\Gamma_q(x+n-i+\lambda_i)\Gamma_q(y+n-i)}{\Gamma_q(x+y+2n-i-1+\lambda_i)}.
\end{aligned} \tag{9.23}
$$

Askey and Wilson [7] give the orthogonal polynomials for an important q-analogue of the beta distribution. Rahman [25] conjectures a q-analogue of Selberg's integral using this measure. It would be interesting to apply our methods in this case.

Note added in proof. Aomoto [A] has proven Conjecture 1 for $l=0$. The conjecture follows by (3.18) and (3.19). Kadell [K] extends Aomoto's proof to treat (1.11) and Conjectures 6 and 11.

A PROOF OF ASKEY'S CONJECTURED q-ANALOGUE OF SELBERG'S INTEGRAL AND A CONJECTURE OF MORRIS*

KEVIN W. J. KADELL†

Abstract. Aomoto has recently given an extension of Selberg's integral. We extend his proof to the q-case and establish a conjecture of Askey. Our result is equivalent to a constant term identity for the root system A_n. This extends a conjecture of Morris.

Key words. Selberg's integral, Aomoto's extension, q-beta integral, Morris' theorem, Cauchy-Selberg labeling for A_n

AMS(MOS) subject classification. 33A15

1. Introduction and summary. In 1944, Selberg [15] gave an elegant evaluation of an important multivariable beta type integral. Macdonald [12] obtained the case $q=1$ of his constant term conjectures for B_n, C_n, D_n and BC_n. Recently, Aomoto [4] proved an extension of Selberg's integral to which we may add the parameter l. This is the following.

THEOREM 1 (Aomoto [4]).

$$I_{n,m,l}(x,y,k)=\int_0^1\cdots\int_0^1\prod_{i=1}^{n}t_i^{(x-1)+\chi(i\leqq m)}(1-t_i)^{(y-1)+\chi(n-i+1\leqq l)}\Delta_n^{2k}(\mathbf{t})\,dt_1\cdots dt_n$$

$$=\prod_{i=1}^{n}\frac{\Gamma(x+(n-i)k+\chi(i\leqq m))\Gamma(y+(n-i)k+\chi(i\leqq l))\Gamma(1+ik)}{\Gamma(x+y+(2n-i-1)k+\chi(i\leqq m+l))\Gamma(1+k)}, \tag{1.1}$$

where $\chi(A)$ is 1 or 0 according to whether A is true or false,

$$\Delta_n(t_1,\cdots,t_n)=\Delta_n(\mathbf{t})=\prod_{1\leqq i<j\leqq n}(t_i-t_j), \tag{1.2}$$

and, as holds throughout, $\operatorname{Re}(x)>0$, $\operatorname{Re}(y)>0$, *and n, m, l, and k are nonnegative integers satisfying $m+l\leqq n$. We omit l when $l=0$.*

The substitution $t_i\to(1-t_{n-i+1})$, $1\leqq i\leqq n$, gives the symmetry

$$I_{n,m,l}(x,y,k)=I_{n,l,m}(y,x,k). \tag{1.3}$$

This is essential to Selberg's proof [15] of the case $m=l=0$ of (1.1). See Andrews [3] for a readily accessible version of this argument. This proof did not work in the q-case since we could not give an appropriate symmetry for Askey's Conjecture 1 of [6]. Where the symmetry was restored [6, Conjecture 8], the argument failed for other reasons.

Aomoto's proof [4] of the case $l=0$ of Theorem 1 relies on a difference equation involving the extra parameter m. We extend this argument to treat a q-analogue of (1.1). Our result is Theorem 2.

THEOREM 2.

$$
\begin{aligned}
{}_qS_{n,m,l}(x,y,k) &= \int_0^1 \cdots \int_0^1 \prod_{i=1}^{n} t_i^{(x-1)+\chi(i\leqq m)} \frac{(qt_i)_\infty}{(q^{y+\chi(n-i+1\leqq l)}t_i)_\infty} \\
&\quad \cdot \prod_{1\leqq i<j\leqq n} t_i^{2k}\left(q^{1-k}\frac{t_j}{t_i}\right)_{2k} d_qt_1\cdots d_qt_n \qquad (1.4)\\
&= q^{[kx\binom{n}{2}+k\binom{m}{2}+2k^2\binom{n}{3}]} \\
&\quad \cdot \prod_{i=1}^{n} \frac{\Gamma_q(x+(n-i)k+\chi(i\leqq m))\Gamma_q(y+(n-i)k+\chi(i\leqq l))\Gamma_q(1+ik)}{\Gamma_q(x+y+(2n-i-1)k+\chi(i\leqq m+l))\Gamma_q(1+k)},
\end{aligned}
$$

where q is fixed with $0<q<1$,

$$
\begin{aligned}
(x)_0 &= (x;q)_0 = 1, \\
(x)_n &= (x;q)_n = \prod_{i=0}^{n-1}(1-xq^i), \qquad n\geqq 1, \qquad (1.5)\\
(x)_\infty &= (x;q)_\infty = \lim_{n\to\infty}(x)_n = \prod_{i=0}^{\infty}(1-xq^i),
\end{aligned}
$$

and, following Jackson [8],

$$
\int_0^a f(t)\,d_qt = a(1-q)\sum_{n=0}^{\infty} q^n f(aq^n), \qquad (1.6)
$$

$$
\Gamma_q(x) = (1-q)^{(1-x)}\frac{(q)_\infty}{(q^x)_\infty}. \qquad (1.7)
$$

The key to Aomoto's proof [4] is the observation that if

$$
F(0,t_2,\cdots,t_n) = F(1,t_2,\cdots,t_n) = 0 \qquad (1.8)
$$

and F satisfies some simple conditions, then

$$
\int_0^1 \cdots \int_0^1 \frac{\partial}{\partial t_1} F(\mathbf{t})\,dt_1\cdots dt_n = 0. \qquad (1.9)
$$

Aomoto sets $l=0$ and takes F to be t_1^δ times the integrand in (1.1), where δ equals 0 or 1. Two simple lemmas allow us to eliminate the results of (1.9) for $\delta=0$ and $\delta=1$. This gives

$$
I_{n,m}(x,y,k) = \frac{(x+(n-m)k)}{(x+y+(2n-m-1)k)} I_{n,m-1}(x,y,k), \qquad m\geqq 1. \qquad (1.10)
$$

The case $l=0$ follows using a recurrence relation given by Selberg [15]. See also Kadell [10]. Since $1=t_i+(1-t_i)$, we have

$$
I_{n,m,l}(x,y,k) = I_{n,m+1,l}(x,y,k) + I_{n,m,l+1}(x,y,k). \qquad (1.11)
$$

Theorem 1 now follows by induction on l.

In § 2, we introduce the q-derivative corresponding to the q-integral (1.6). A simple telescoping sum provides a q-analogue of the fundamental theorem of calculus. We extend (1.9), thus taking the first step in the proof of Theorem 2.

In § 3, we give two lemmas that extend the basic steps of Aomoto's proof [4] to the q-case. Unfortunately, we cannot eliminate from our equations as easily as we can when $q=1$. This is because the integrand of (1.4) with $m=l=0$ is not symmetric in $t_1, t_2, \cdots, t_n$. In § 4, we recall Lemma 4 of Kadell [10] and give a useful alternative formulation. This allows us to treat all of the difficulties arising from the asymmetry. We also recall a recurrence relation [10, (6.4)] and obtain a recurrence relation for ${}_qS_{n,m}(x, y, k)$.

In § 5, we use simple manipulations of our results to obtain a q-analogue of (1.10). We then establish the case $l=0$ of Theorem 2.

By Lemma 4 of [10], this gives the case $l=0$ of Conjectures 6 and 11 of [10]. These conjectures now follow by Theorems 10 and 12 of [10]. In § 6, we use the same approach to prove Theorem 2.

In § 7, we show that Theorem 2 is equivalent to a constant term identity for the root system A_n. Set

$$
\begin{aligned}
{}_qcs_{n,m,l}(a, b, k; \mathbf{t}) = \prod_{i=1}^{n} (q^{\chi(i>m)}t_i)_{a+\chi(i\leqq m)+\chi(n-i+1\leqq l)}\left(\frac{q^{\chi(i\leqq m)}}{t_i}\right)_{b-\chi(i\leqq m)} \\
\cdot \prod_{1\leqq i<j\leqq n}\left(q\frac{t_j}{t_i}\right)_k\left(\frac{t_i}{t_j}\right)_k,
\end{aligned} \tag{1.12}
$$

where a and b are nonnegative integers. Let

$$
{}_qCS_{n,m,l}(a, b, k) = \text{C.T. } {}_qcs_{n,m,l}(a, b, k; \mathbf{t}), \tag{1.13}
$$

where C.T.$f(\mathbf{t})$ is the constant term in the Laurent expansion of $f(\mathbf{t})$ in powers of $t_1, t_2, \cdots, t_n$. Our result is

THEOREM 3.

$$
{}_qCS_{n,m,l}(a, b, k) = \prod_{i=1}^{n} \frac{(q)_{a+b+(n-i)k+\chi(i\leqq l)}(q)_{ik}}{(q)_{a+(n-i)k+\chi(i\leqq m+l)}(q)_{b+(i-1)k-\chi(i\leqq m)}(q)_k}. \tag{1.14}
$$

The case $m=l=0$ was conjectured by Morris [14, (4.12)]. He proved [14, § 6] the case $m=l=0$, $q=1$, by using a version of Selberg's integral which extends Cauchy's form of the beta integral.

2. q-derivatives. Set

$$
\frac{d_q}{d_qt}F(t) = \frac{F(t)-F(qt)}{t(1-q)}. \tag{2.1}
$$

A q-analogue of the fundamental theorem of calculus is given by

$$
\begin{aligned}
\int_0^a \frac{d_q}{d_qt}F(t)\, d_qt &= (1-q)\sum_{n=0}^{\infty} aq^n \frac{F(aq^n)-F(aq^{n+1})}{aq^n(1-q)} \\
&= \sum_{n=0}^{\infty} F(aq^n)-F(aq^{n+1}) = F(a)-\lim_{n\to\infty} F(aq^n).
\end{aligned} \tag{2.2}
$$

Let

$${}_qW_n(x, y, k) = \prod_{i=1}^{n} t_i^{(x-1)}\frac{(qt_i)_\infty}{(q^yt_i)_\infty}\prod_{1\leqq i<j\leqq n} t_i^{2k}\left(q^{1-k}\frac{t_j}{t_i}\right)_{2k} \tag{2.3}$$

denote the integrand in (1.4) when $m=l=0$. For $1\leqq i<j\leqq n$, the function

$${}_q\Delta_n^{(2k-1)}(\mathbf{t}) = \prod_{1\leqq i<j\leqq n} t_i^{(2k-1)}\left(q^{1-k}\frac{t_j}{t_i}\right)_{(2k-1)} \tag{2.4}$$

vanishes when $t_i = t_j$ and on $k-1$ lines on one side of this line and $k-1$ lines symmetrically located on the other side. Thus (see Kadell [10, (4.15)])

$$
\begin{aligned}
&{}_q\Delta_n^{(2k-1)}(\pi(\mathbf{t})) = \operatorname{sgn}(\pi)\, {}_q\Delta_n^{(2k-1)}(\mathbf{t}), \\
&\pi(\mathbf{t}) = (t_{\pi(1)}, t_{\pi(2)}, \cdots, t_{\pi(n)}),
\end{aligned} \tag{2.5}
$$

where $\pi \in S_n$. To obtain a q-analogue of $\Delta_n^{2k}(\mathbf{t})$, we may multiply ${}_q\Delta_n^{(2k-1)}(\mathbf{t})$ by $\prod_{1\leqq i<j\leqq n}(t_i - q^k t_j)$ (as in ${}_qW_n(x, y, k)$) or by $\prod_{1\leqq i<j\leqq n}(t_i - q^{-k}t_j)$. Thus ${}_qW_n(x, y, k)$ is not symmetric in $t_1, t_2, \cdots, t_n$ even though ${}_q\Delta_n^{(2k-1)}(\mathbf{t})$ is antisymmetric (2.5). The reader should carefully observe the role played by this last factor throughout the proof of Theorem 2.

We now assume that

$$
1 \leqq m \leqq n, \quad \operatorname{Re}(x) > 0, \quad \operatorname{Re}(y) > 1 \quad \text{and} \quad \delta \text{ is a nonnegative integer.} \tag{2.6}
$$

This assures that ${}_qW_n(x, y, k)$ is 0 if $t_i = 1/q$ for some i, $1 \leqq i \leqq n$. Hence, we may extend the range of each integration in (1.4) to $1/q$. We adopt the obvious notation for partial q-derivatives. Since $m \geqq 1$, we see that $\prod_{i=1}^m t_i$ vanishes when $t_1 = 0$. Using (2.2), we obtain

$$
0 = \int_0^{1/q} \cdots \int_0^{1/q} \frac{\partial_q}{\partial_q t_1}\left(t_1^{\delta} \prod_{i=1}^{m} t_i\, {}_qW_n(x, y, k)\right) d_q t_1 \cdots d_q t_n. \tag{2.7}
$$

In order to compute the partial q-derivative above, we require a product rule for q-derivatives. It is

$$
\begin{aligned}
\frac{d_q}{d_q t} \prod_{v=1}^{u} F_v(t) &= \frac{1}{t(1-q)}\left(\prod_{v=1}^{u} F_v(t) - \prod_{v=1}^{u} F_v(qt)\right) \\
&= \frac{1}{t(1-q)} \sum_{v=1}^{u} \prod_{i=1}^{v-1} F_i(qt)\left(F_v(t) - F_v(qt)\right) \prod_{j=v+1}^{u} F_j(t) \\
&= \sum_{v=1}^{u} \prod_{i=1}^{v-1} F_i(qt) \frac{d_q}{d_q t} F_v(t) \prod_{j=v+1}^{u} F_j(t).
\end{aligned} \tag{2.8}
$$

A few simple computations give

$$
\begin{aligned}
\frac{\partial_q}{\partial_q s}\left(s^{2k}\left(q^{1-k}\frac{t}{s}\right)_{2k}\right) &= \frac{(1-q^{2k})}{(1-q)} s^{(2k-1)}\left(q^{1-k}\frac{t}{s}\right)_{(2k-1)} \\
&= \frac{(1-q^{2k})}{(1-q)} \frac{1}{(s-q^k t)} s^{2k}\left(q^{1-k}\frac{t}{s}\right)_{2k},
\end{aligned} \tag{2.9}
$$

$$
\frac{d_q}{d_q t} t^x = \frac{(1-q^x)}{(1-q)} t^{(x-1)}, \tag{2.10}
$$

$$
\frac{d_q}{d_q t} \frac{(qt)_\infty}{(q^y t)_\infty} = -q\frac{(1-q^{(y-1)})}{(1-q)} \frac{1}{(1-qt)} \frac{(qt)_\infty}{(q^y t)_\infty}. \tag{2.11}
$$

Let v run from 2 to n and take $s = t_1$, $t = t_v$, in (2.4). Using our product rule (2.8) and

$$
(qs)^{2k}\left(q^{1-k}\frac{t}{qs}\right)_{2k} = q^{2k}\frac{(s-q^{-k}t)}{(s-q^k t)} s^{2k}\left(q^{1-k}\frac{t}{s}\right)_{2k}, \tag{2.12}
$$

we obtain

$$\frac{\partial_q}{\partial_q t_1}\left(\prod_{1\leqq i<j\leqq n} t_i^{2k}\left(q^{1-k}\frac{t_j}{t_i}\right)_{2k}\right)=\frac{(1-q^{2k})}{(1-q)}\sum_{v=2}^{n} q^{2k(v-2)}\prod_{j=2}^{v-1}\frac{(t_1-q^{-k}t_j)}{(t_1-q^k t_j)} \cdot\frac{1}{(t_1-q^k t_v)}\prod_{1\leqq i<j\leqq n} t_i^{2k}\left(q^{1-k}\frac{t_j}{t_i}\right)_{2k}. \tag{2.13}$$

Continuing with our product rule (2.8), we use (2.10) followed by (2.11) to compute the partial q-derivative in (2.7). We obtain

$$0=\frac{(1-q^{2k})}{(1-q)}\sum_{v=2}^{n} q^{2k(v-2)}\,{}_q^{\delta}A_{n,m}^{v}(x,y,k)+q^{2k(n-1)}\frac{(1-q^{x+\delta})}{(1-q)}\,{}_q^{\delta}K_{n,m}(x,y,k) -q^{2k(n-1)+x+\delta+1}\frac{(1-q^{(y-1)})}{(1-q)}\,{}_q^{\delta}E_{n,m}(x,y,k), \tag{2.14}$$

where

$${}_q^{\delta}A_{n,m}^{v}(x,y,k)=\int_0^{1/q}\cdots\int_0^{1/q}\prod_{j=2}^{v-1}\frac{(t_1-q^{-k}t_j)}{(t_1-q^k t_j)}\frac{1}{(t_1-q^k t_v)} \cdot t_1^{\delta}\prod_{i=1}^{m} t_i\,{}_qW_n(x,y,k)\,d_qt_1\cdots d_qt_n, \tag{2.15}$$

$${}_q^{\delta}K_{n,m}(x,y,k)=\int_0^{1/q}\cdots\int_0^{1/q}\prod_{j=2}^{n}\frac{(t_1-q^{-k}t_j)}{(t_1-q^k t_j)} \cdot t_1^{\delta}\prod_{i=2}^{m} t_i\,{}_qW_n(x,y,k)\,d_qt_1\cdots d_qt_n, \tag{2.16}$$

$${}_q^{\delta}E_{n,m}(x,y,k)=\int_0^{1/q}\cdots\int_0^{1/q}\prod_{j=2}^{n}\frac{(t_1-q^{-k}t_j)}{(t_1-q^k t_j)}\frac{1}{(1-qt_1)} \cdot t_1^{\delta}\prod_{i=1}^{m} t_i\,{}_qW_n(x,y,k)\,d_qt_1\cdots d_qt_n. \tag{2.17}$$

3. Two lemmas. The effect of the factor $(t_1-q^{-k}t_j)/(t_1-q^k t_j)$ in (2.15), (2.16),and (2.17) is to replace the factor $(t_1-q^k t_j)$ of ${}_qW_n(x,y,k)$ (which "glues onto" one end of ${}_q\Delta_n^{(2k-1)}(\mathbf{t})$) by $(t_1-q^{-k}t_j)$ (which "glues onto" the other end). Observe that

$$\prod_{j=2}^{v-1}\frac{(t_1-q^{-k}t_j)}{(t_1-q^k t_j)}\frac{1}{(t_1-q^k t_v)}\,{}_qW_n(x,y,k)=\prod_{i=1}^{n} t_i^{(x-1)}\frac{(qt_i)_\infty}{(q^y t_i)_\infty}\,{}_q\Delta_n^{(2k-1)}(\mathbf{t}) \cdot\prod_{\substack{2\leqq i<j\leqq n\\ i\neq v\neq j}}(t_i-q^k t_j)\prod_{j=v+1}^{n}(t_1-q^k t_j)(t_v-q^k t_j) \cdot\prod_{j=2}^{v-1}(t_1-q^{-k}t_j)\prod_{i=2}^{v-1}(t_i-q^k t_v). \tag{3.1}$$

Since

$$(t_1-q^{-k}t_j)=-q^{-k}(t_j-q^k t_1), \tag{3.2}$$

the function (3.1) is antisymmetric in t_1 and t_v. We have Lemma 4.

LEMMA 4. *Let a be a nonnegative integer and* Sym (t) *be symmetric in t_1 and t_v where $2 \leqq v \leqq n$. Then*

$$\int_0^{1/q} \cdots \int_0^{1/q} t_1^a \operatorname{Sym}(\mathbf{t}) \prod_{j=2}^{v-1} \frac{(t_1 - q^{-k}t_j)}{(t_1 - q^k t_j)} \frac{1}{(t_1 - q^k t_v)} {}_qW_n(x, y, k)\, d_q t_1 \cdots d_q t_n$$

$$= \frac{1}{(1+q^{ak})} \int_0^{1/q} \cdots \int_0^{1/q} \left(\sum_{i=0}^{a-1} t_1^i (q^k t_v)^{(a-1-i)} \right) \operatorname{Sym}(\mathbf{t}) \tag{3.3}$$

$$\cdot \prod_{j=2}^{v-1} \frac{(t_1 - q^{-k}t_j)}{(t_1 - q^k t_j)} {}_qW_n(x, y, k)\, d_q t_1 \cdots d_q t_n.$$

Proof. Let X denote the integral in (3.3). Interchanging t_1 and t_v gives

$$X = -\int_0^{1/q} \cdots \int_0^{1/q} t_v^a \operatorname{Sym}(\mathbf{t}) \prod_{j=2}^{v-1} \frac{(t_1 - q^{-k}t_j)}{(t_1 - q^k t_j)} \frac{1}{(t_1 - q^k t_v)} {}_qW_n(x, y, k)\, d_q t_1 \cdots d_q t_n, \tag{3.4}$$

since Sym (t) and (3.1) are symmetric and antisymmetric, respectively, in t_1 and t_v. Observe for $a = 0$ that $X = -X$ and hence $X = 0$. We have

$$\frac{(t_1^a - q^{ak} t_v^a)}{(t_1 - q^k t_v)} = \sum_{i=0}^{a-1} t_1^i (q^k t_v)^{(a-1-i)}. \tag{3.5}$$

The result (3.3) now follows by adding q^{ak} times (3.4) to X (3.3), simplifying the integrand by (3.5), and dividing by $(1+q^{ak})$. □

We now apply this lemma to ${}^{\delta}_{q}A^{v}_{n,m}(x, y, k)$ where δ equals 0 or 1. For $2 \leqq v \leqq m$, we may take $a = \delta$, Sym (t) $= \prod_{i=1}^{m} t_i$. This gives

$${}^{0}_{q}A^{v}_{n,m}(x, y, k) = 0, \qquad 2 \leqq v \leqq m, \tag{3.6}$$

$${}^{1}_{q}A^{v}_{n,m}(x, y, k) = \frac{1}{(1+q^k)} \int_0^{1/q} \cdots \int_0^{1/q} \prod_{i=1}^{m} t_i \prod_{j=2}^{v-1} \frac{(t_1 - q^{-k}t_j)}{(t_1 - q^k t_j)}$$

$$\cdot {}_qW_n(x, y, k)\, d_q t_1 \cdots d_q t_n, \qquad 2 \leqq v \leqq m. \tag{3.7}$$

For $m < v \leqq n$, we may take $a = \delta + 1$, Sym (t) $= \prod_{i=2}^{m} t_i$. We obtain

$${}^{0}_{q}A^{v}_{n,m}(x, y, k) = \frac{1}{(1+q^k)} \int_0^{1/q} \cdots \int_0^{1/q} \prod_{i=2}^{m} t_i \prod_{j=2}^{v-1} \frac{(t_1 - q^{-k}t_j)}{(t_1 - q^k t_j)}$$

$$\cdot {}_qW_n(x, y, k)\, d_q t_1 \cdots d_q t_n, \qquad m < v \leqq n, \tag{3.8}$$

$${}^{1}_{q}A^{v}_{n,m}(x, y, k) = \frac{1}{(1+q^{2k})} \int_0^{1/q} \cdots \int_0^{1/q} \prod_{i=2}^{m} t_i (t_1 + q^k t_v) \prod_{j=2}^{v-1} \frac{(t_1 - q^{-k}t_j)}{(t_1 - q^k t_j)}$$

$$\cdot {}_qW_n(x, y, k)\, d_q t_1 \cdots d_q t_n, \qquad m < v \leqq n. \tag{3.9}$$

We have a simple lemma.

LEMMA 5.

$${}^{\delta}_{q}E_{n,m}(x, y, k) = {}^{\delta+1}_{q}K_{n,m}(x, y, k) + q\, {}^{\delta+1}_{q}E_{n,m}(x, y, k). \tag{3.10}$$

Proof. The integrand (2.17) of ${}^{\delta}_{q}E_{n,m}(x, y, k)$ equals

$$\frac{t_1}{(1 - qt_1)} = t_1 + \frac{qt_1^2}{(1 - qt_1)} \tag{3.11}$$

times the integrand (2.16) of ${}^{\delta}_{q}K_{n,m}(x, y, k)$. The result (3.10) follows directly by using (3.11) to expand the integrand (2.17) of ${}^{\delta}_{q}E_{n,m}(x, y, k)$. □

4. A basic lemma. Lemma 4 of Kadell [10] enables us to treat factors of the form $(t_1-q^{-k}t_j)/(t_1-q^k t_j)$. We require the integral formulation [10, (4.9)]. This is

$$\int\cdots\int \prod_{i=1}^{m} t_i \prod_{1\leqq i<j\leqq n}(t_i-Q_{i,j}t_j)\,d_\mu(\mathbf{t}) = \left[\sum_{\pi\in S_{n,m}} \prod_{\substack{1\leqq i<j\leqq n\\ \pi(i)>\pi(j)}} Q_{i,j}\right] \cdot \int\cdots\int \prod_{i=1}^{n} t_i^{(n-i)+\chi(i\leqq m)}\,d_\mu(\mathbf{t}), \tag{4.1}$$

where $d_\mu(\mathbf{t})$ is an n-dimensional antisymmetric measure and

$$S_{n,m}=\{\pi\in S_n \mid \pi(i)\leqq m \text{ iff } i\leqq m\}. \tag{4.2}$$

For any choice of $Q_{i,j}$, $1\leqq i<j\leqq n$, we need only be concerned with the sum in brackets on the right side of (4.1). Since

$$(t_i-Q_{i,j}t_j)=-Q_{i,j}(t_j-Q_{i,j}^{-1}t_i), \tag{4.3}$$

we may permute the t_i, $1\leqq i\leqq n$, thus changing $\prod_{i=1}^m t_i$ to the product of any m of the t_i, $1\leqq i\leqq n$. This is precisely what we require and, fortunately, there is an easy way to do the computation.

In the proof of Lemma 4 of [10], we showed the following. The terms in the expansion of $\prod_{i=1}^m t_i \prod_{1\leqq i<j\leqq n}(t_i-Q_{i,j}t_j)$ in which no two of the variables t_i, $1\leqq i\leqq n$, occur to the same power are of the form

$$\prod_{i=1}^{m} t_i \prod_{\substack{1\leqq i<j\leqq n\\ \pi(i)<\pi(j)}} t_i \prod_{\substack{1\leqq i<j\leqq n\\ \pi(i)>\pi(j)}}(-Q_{i,j}t_j)=\operatorname{sgn}(\pi) \prod_{\substack{1\leqq i<j\leqq n\\ \pi(i)>\pi(j)}} Q_{i,j} \prod_{i=1}^{n} t_i^{(n-\pi(i))+\chi(i\leqq m)}, \tag{4.4}$$

where $\pi\in S_{n,m}$. Since $d_\mu(\mathbf{t})$ is antisymmetric (2.5), the other terms contribute 0 to the integral (4.1). The substitution $t_i\to t_{\pi(i)}$, $1\leqq i\leqq n$, gives $\prod_{1\leqq i<j\leqq n,\pi(i)>\pi(j)} Q_{i,j}$ times the integral on the right side of (4.1).

Let $[s,t]=\{i\in Z \mid s\leqq i\leqq t\}$ and let $M\subset[1,n]$ with $|M|=m$. The terms in the expansion of $\prod_{i\in M} t_i \prod_{1\leqq i<j\leqq n}(t_i-Q_{i,j}t_j)$ with distinct exponents are of the form

$$\prod_{i\in M} t_i \prod_{\substack{1\leqq i<j\leqq n\\ \pi(i)<\pi(j)}} t_i \prod_{\substack{1\leqq i<j\leqq n\\ \pi(i)>\pi(j)}}(-Q_{i,j}t_j)=\operatorname{sgn}(\pi) \prod_{\substack{1\leqq i<j\leqq n\\ \pi(i)>\pi(j)}} Q_{i,j} \prod_{i=1}^{n} t_i^{(n-\pi(i))+\chi(i\in M)}, \tag{4.5}$$

where π is in

$$S_{n,M}=\{\pi\in S_n \mid \pi(i)\leqq m \text{ iff } i\in M\}. \tag{4.6}$$

We obtain

$$\int\cdots\int \prod_{i\in M} t_i \prod_{1\leqq i<j\leqq n}(t_i-Q_{i,j}t_j)\,d_\mu(\mathbf{t}) = \left[\sum_{\pi\in S_{n,M}} \prod_{\substack{1\leqq i<j\leqq n\\ \pi(i)>\pi(j)}} Q_{i,j}\right] \cdot \int\cdots\int \prod_{i=1}^{n} t_i^{(n-i)+\chi(i\leqq m)}\,d_\mu(\mathbf{t}). \tag{4.7}$$

It is well known (see MacMahon [13]) that

$$\sum_{\pi\in S_n} \prod_{\substack{1\leqq i<j\leqq n\\ \pi(i)>\pi(j)}} Q=\frac{(Q;Q)_n}{(1-Q)^n}. \tag{4.8}$$

Q marks the inversions $1\leqq i<j\leqq n$, $\pi(i)>\pi(j)$, of π. We may view π as a word $\pi(i)$, $1\leqq i\leqq n$, and let the letters be any set of n distinct numbers.

Let $\pi \in S_{n,M}$ and consider i, j with $1 \leqq i < j \leqq n$. If $i \in M$, $j \notin M$, then $\pi(i) \leqq m < \pi(j)$. If $i \notin M$, $j \in M$, then $\pi(i) > m \geqq \pi(j)$. This gives

$$e(M) = \sum_{\substack{1 \leqq i < j \leqq n \\ i \notin M, j \in M}} 1 \tag{4.9}$$

inversions of π. The remaining inversions have either $i, j \in M$ or $i, j \notin M$. These arise independently from the subwords $\pi(i)$, $i \in M$ and $\pi(i)$, $i \in [1, n] - M$, respectively. See Kendall and Stuart [11, pp. 496-512] and Goulden and Jackson [7, pp. 96-99] for the multinomial version of this argument. We obtain

$$\sum_{\pi \in S_{n,M}} \prod_{\substack{1 \leqq i < j \leqq n \\ \pi(i) > \pi(j)}} Q = Q^{e(M)} \frac{(Q; Q)_m (Q; Q)_{n-m}}{(1-Q)^n}. \tag{4.10}$$

Equation (4.7) then becomes

$$\begin{aligned} \int \cdots \int \prod_{i \in M} t_i \prod_{1 \leqq i < j \leqq n} (t_i - Qt_j)\, d_\mu(\mathbf{t}) &= Q^{e(M)} \frac{(Q; Q)_m (Q; Q)_{n-m}}{(1-Q)^n} \\ &\quad \cdot \int \cdots \int \prod_{i=1}^{n} t_i^{(n-i)+\chi(i \leqq m)}\, d_\mu(\mathbf{t}). \end{aligned} \tag{4.11}$$

Observe that the integral on the right side of (4.11) is independent of Q and M. We have

$$e([1, m]) = 0, \qquad \operatorname{card}(S_{n,M}) = m!(n-m)!. \tag{4.12}$$

Set $M = [1, m]$ and compare (4.11) and the case $Q = 1$. This yields

$$\begin{aligned} \int \cdots \int \prod_{i=1}^{m} t_i \prod_{1 \leqq i < j \leqq n} (t_i - Qt_j)\, d_\mu(\mathbf{t}) &= \frac{(Q; Q)_m (Q; Q)_{n-m}}{(1-Q)^n} \frac{1}{m!(n-m)!} \\ &\quad \cdot \int \cdots \int \prod_{i=1}^{m} t_i \prod_{1 \leqq i < j \leqq n} (t_i - t_j)\, d_\mu(\mathbf{t}). \end{aligned} \tag{4.13}$$

Comparing (4.11) and the case $M = [1, m]$, we obtain

$$\begin{aligned} &\int \cdots \int \prod_{i \in M} t_i \prod_{1 \leqq i < j \leqq n} (t_i - Qt_j)\, d_\mu(\mathbf{t}) \\ &\quad = Q^{e(M)} \int \cdots \int \prod_{i=1}^{m} t_i \prod_{1 \leqq i < j \leqq n} (t_i - Qt_j)\, d_\mu(\mathbf{t}). \end{aligned} \tag{4.14}$$

By (2.5), the measure

$$d_\mu(\mathbf{t}) = \prod_{i=1}^{n} t_i^{(x-1)} \frac{(qt_i)_\infty}{(q^y t_i)_\infty}\, {}_q\Delta_n^{(2k-1)}(\mathbf{t})\, d_q t_1 \cdots d_q t_n \tag{4.15}$$

is antisymmetric. For $l = 0$, the integrand (1.4) of ${}_qS_{n,m}(x, y, k)$ is

$$\prod_{i=1}^{m} t_i\, {}_qW_n(x, y, k)\, d_q t_1 \cdots d_q t_n = \prod_{i=1}^{m} t_i \prod_{1 \leqq i < j \leqq n} (t_i - q^k t_j)\, d_\mu(\mathbf{t}). \tag{4.16}$$

In [10], we studied

$$\begin{aligned} {}_qI_{n,m,l}(x, y, k) &= \int_0^1 \cdots \int_0^1 \prod_{i=1}^{n} t_i^{(x-1)+\chi(i \leqq m)} \frac{(qt_i)_\infty}{(q^{y+\chi(n-i+1 \leqq l)} t_i)_\infty} \\ &\quad \cdot \Delta_n(t_1, \cdots, t_{n-l}, q^k t_{n-l+1}, \cdots, q^k t_n) \\ &\quad \cdot {}_q\Delta_n^{(2k-1)}(\mathbf{t})\, d_q t_1 \cdots d_q t_n. \end{aligned} \tag{4.17}$$

For $l=0$, the integrand is

$$\prod_{i=1}^{m} t_i \prod_{1\leqq i<j\leqq n} (t_i - t_j)\, d_\mu(\mathbf{t}). \tag{4.18}$$

For $Q=q^k$, (4.13) becomes

$$ {}_qS_{n,m}(x, y, k) = \frac{(q^k; q^k)_m (q^k; q^k)_{n-m}}{(1-q^k)^n} \frac{1}{m!(n-m)!}\, {}_qI_{n,m}(x, y, k). \tag{4.19}$$

We have the recurrence relation [10, (6.4)]

$$\lim_{x\to 0} \frac{(1-q^x)}{(1-q)}\, {}_qI_{n,m}(x, y, k) = (n-m)\, {}_qI_{n-1,m}(2k, y, k). \tag{4.20}$$

Using (4.19) or the same analysis, we obtain

$$\lim_{x\to 0} \frac{(1-q^x)}{(1-q)}\, {}_qS_{n,m}(x, y, k) = \frac{(1-q^{k(n-m)})}{(1-q^k)}\, {}_qS_{n-1,m}(2k, y, k). \tag{4.21}$$

Let $1\leqq s\leqq n$. The permutations

$$\begin{aligned} \pi_s(\mathbf{t}) &= (t_s, t_1, \cdots, t_{s-1}, t_{s+1}, \cdots, t_n), \\ \sigma_s(\mathbf{t}) &= (t_2, \cdots, t_s, t_1, t_{s+1}, \cdots, t_n), \end{aligned} \tag{4.22}$$

are inverses and

$$\operatorname{sgn}(\pi_s) = \operatorname{sgn}(\sigma_s) = (-1)^{(s-1)}. \tag{4.23}$$

Observe that

$$\begin{aligned} \prod_{j=2}^{s} \frac{(t_1 - Q^{-1}t_j)}{(t_1 - Qt_j)} \prod_{1\leqq i<j\leqq n} (t_i - Qt_j) &= \prod_{2\leqq i<j\leqq n} (t_i - Qt_j) \prod_{j=2}^{s} (t_1 - Q^{-1}t_j) \prod_{j=s+1}^{n} (t_1 - Qt_j) \\ &= (-Q^{-1})^{(s-1)} \prod_{2\leqq i<j\leqq n} (t_i - Qt_j) \prod_{j=2}^{s} (t_j - Qt_1) \\ &\quad \cdot \prod_{j=s+1}^{n} (t_1 - Qt_j) \\ &= (-Q^{-1})^{(s-1)} \prod_{1\leqq i<j\leqq n} (t_{\sigma_s(i)} - Qt_{\sigma_s(j)}). \end{aligned} \tag{4.24}$$

The substitution

$$t_i \to t_{\pi_s(i)}, \qquad 1\leqq i\leqq n, \tag{4.25}$$

gives

$$\begin{aligned} &\int \cdots \int f(\mathbf{t}) \prod_{j=2}^{s} \frac{(t_1 - Q^{-1}t_j)}{(t_1 - Qt_j)} \prod_{1\leqq i<j\leqq n} (t_i - Qt_j)\, d_\mu(\mathbf{t}) \\ &\quad = Q^{-(s-1)} \int \cdots \int f(\pi_s(\mathbf{t})) \prod_{1\leqq i<j\leqq n} (t_i - Qt_j)\, d_\mu(\mathbf{t}). \end{aligned} \tag{4.26}$$

We again assume that (2.6) holds. Setting $s=v-1$, $Q=q^k$, in (4.26), our results (3.7), (3.8), and (3.9) become

$$\begin{aligned} {}_q^1A_{n,m}^v(x, y, k) &= \frac{q^{-k(v-2)}}{(1+q^k)} \int_0^{1/q} \cdots \int_0^{1/q} \prod_{i=1}^{m} t_i\, {}_qW_n(x, y, k)\, d_qt_1 \cdots d_qt_n \\ &= \frac{q^{-k(v-2)}}{(1+q^k)}\, {}_qS_{n,m}(x, y, k), \qquad 2\leqq v\leqq m, \end{aligned} \tag{4.27}$$

$$
\begin{aligned}
{}_q^0A_{n,m}^v(x,y,k) &= \frac{q^{-k(v-2)}}{(1+q^k)}\int_0^{1/q}\cdots\int_0^{1/q}\prod_{i=1}^{m-1} t_i\,{}_qW_n(x,y,k)\,d_qt_1\cdots d_qt_n \\
&= \frac{q^{-k(v-2)}}{(1+q^k)}\,{}_qS_{n,m-1}(x,y,k), \qquad m<v\leqq n,
\end{aligned} \tag{4.28}
$$

$$
\begin{aligned}
{}_q^1A_{n,m}^v(x,y,k) &= \frac{q^{-k(v-2)}}{(1+q^{2k})}\int_0^{1/q}\cdots\int_0^{1/q}\prod_{i=1}^{m-1} t_i(t_{v-1}+q^kt_v) \\
&\quad\cdot\,{}_qW_n(x,y,k)\,d_qt_1\cdots d_qt_n, \qquad m<v\leqq n.
\end{aligned} \tag{4.29}
$$

We have

$$
\begin{aligned}
e([1,m-1]\cup\{v-1\}) &= v-m-1, \\
e([1,m-1]\cup\{v\}) &= v-m.
\end{aligned} \tag{4.30}
$$

Setting $Q=q^k$ in (4.14) and using (4.30), (4.29) becomes

$$
\begin{aligned}
{}_q^1A_{n,m}^v(x,y,k) &= \frac{q^{-k(v-2)}}{(1+q^{2k})}(q^{k(v-m-1)}+q^{k(v-m+1)})\,{}_qS_{n,m}(x,y,k) \\
&= q^{k(1-m)}\,{}_qS_{n,m}(x,y,k), \qquad m<v\leqq n.
\end{aligned} \tag{4.31}
$$

Set $s=n$, $Q=q^k$, in (4.26). Recalling (2.16), we obtain

$$
{}_q^\delta K_{n,m}(x,y,k) = q^{-k(n-1)}\int_0^{1/q}\cdots\int_0^{1/q} t_n^\delta\prod_{i=1}^{m-1} t_i\,{}_qW_n(x,y,k)\,d_qt_1\cdots d_qt_n. \tag{4.32}
$$

We have

$$
{}_q^0K_{n,m}(x,y,k) = q^{-k(n-1)}\,{}_qS_{n,m-1}(x,y,k). \tag{4.33}
$$

Since

$$
e([1,m-1]\cup\{n\}) = n-m, \tag{4.34}
$$

(4.14) gives

$$
{}_q^1K_{n,m}(x,y,k) = q^{k(1-m)}\,{}_qS_{n,m}(x,y,k). \tag{4.35}
$$

5. A proof of Theorem 2 for $l=0$. We must first give a q-analogue of (1.10) Assume that (2.6) holds. Set $\delta=0$ in (2.14) and use (3.6), (4.28) and (4.33). We obtair

$$
\begin{aligned}
0 &= \frac{(1-q^{2k})}{(1-q)}\sum_{v=m+1}^{n}\frac{q^{k(v-2)}}{(1+q^k)}\,{}_qS_{n,m-1}(x,y,k) \\
&\quad + q^{k(n-1)}\frac{(1-q^x)}{(1-q)}\,{}_qS_{n,m-1}(x,y,k) \\
&\quad - q^{2k(n-1)+x+1}\frac{(1-q^{(y-1)})}{(1-q)}\,{}_q^0E_{n,m}(x,y,k).
\end{aligned} \tag{5.1}
$$

Multiply by $(1-q)$ and move the term with ${}_q^0E_{n,m}(x,y,k)$ to the left side. This gives

$$
\begin{aligned}
&q^{2k(n-1)+x+1}(1-q^{(y-1)})\,{}_q^0E_{n,m}(x,y,k) \\
&= \left[(1-q^k)\sum_{v=m+1}^{n} q^{k(v-2)}+q^{k(n-1)}(1-q^x)\right]{}_qS_{n,m-1}(x,y,k) \\
&= [(q^{k(m-1)}-q^{k(n-1)})+q^{k(n-1)}(1-q^x)]\,{}_qS_{n,m-1}(x,y,k) \\
&= q^{k(m-1)}(1-q^{x+k(n-m)})\,{}_qS_{n,m-1}(x,y,k).
\end{aligned} \tag{5.2}
$$

Set $\delta = 0$ in (3.10), solve for $q\,{}_q^1E_{n,m}(x, y, k)$, and use (4.35). This gives

$$\begin{aligned} q\,{}_q^1E_{n,m}(x, y, k) &= -{}_q^1K_{n,m}(x, y, k) + {}_q^0E_{n,m}(x, y, k) \\ &= -q^{k(1-m)}\,{}_qS_{n,m}(x, y, k) + {}_q^0E_{n,m}(x, y, k). \end{aligned} \tag{5.3}$$

Set $\delta = 1$ in (2.14) and use (4.27), (4.31), (4.35), and (5.3). We obtain

$$\begin{aligned} 0 = {} & \frac{(1-q^{2k})}{(1-q)} \sum_{v=2}^{m} \frac{q^{k(v-2)}}{(1+q^k)}\,{}_qS_{n,m}(x, y, k) \\ & + \frac{(1-q^{2k})}{(1-q)} \sum_{v=m+1}^{n} q^{k(2v-m-3)}\,{}_qS_{n,m}(x, y, k) \\ & + q^{k(2n-m-1)} \frac{(1-q^{x+1})}{(1-q)}\,{}_qS_{n,m}(x, y, k) \\ & + q^{k(2n-m-1)+x+1} \frac{(1-q^{(y-1)})}{(1-q)}\,{}_qS_{n,m}(x, y, k) \\ & - q^{2k(n-1)+x+1} \frac{(1-q^{(y-1)})}{(1-q)}\,{}_q^0E_{n,m}(x, y, k). \end{aligned} \tag{5.4}$$

Multiply by $(1-q)$ and move the term with ${}_q^0E_{n,m}(x, y, k)$ to the left side. This yields

$$\begin{aligned} & q^{2k(n-1)+x+1}(1-q^{(y-1)})\,{}_q^0E_{n,m}(x, y, k) \\ & = \Bigg[(1-q^k) \sum_{v=2}^{m} q^{k(v-2)} + (1-q^{2k}) \sum_{v=m+1}^{n} q^{k(2v-m-3)} \\ & \quad + q^{k(2n-m-1)}(1-q^{x+1}) + q^{k(2n-m-1)+x+1}(1-q^{(y-1)}) \Bigg]\,{}_qS_{n,m}(x, y, k) \\ & = [(1-q^{k(m-1)}) + (q^{k(m-1)} - q^{k(2n-m-1)}) \\ & \quad + (q^{k(2n-m-1)} - q^{k(2n-m-1)+x+y})]\,{}_qS_{n,m}(x, y, k) \\ & = (1-q^{x+y+k(2n-m-1)})\,{}_qS_{n,m}(x, y, k). \end{aligned} \tag{5.5}$$

Comparing (5.2) and (5.5), we have

$$q^{k(m-1)}(1-q^{x+k(n-m)})\,{}_qS_{n,m-1}(x, y, k) = (1-q^{x+y+k(2n-m-1)})\,{}_qS_{n,m}(x, y, k) \tag{5.6}$$

or

$${}_qS_{n,m}(x, y, k) = q^{k(m-1)} \frac{(1-q^{x+k(n-m)})}{(1-q^{x+y+k(2n-m-1)})}\,{}_qS_{n,m-1}(x, y, k), \tag{5.7}$$

provided (2.6) holds. It is easy to see that

$${}_qpr_{n,m}(x, y, k) = q^{[kx\binom{n}{2}+k\binom{m}{2}]} \prod_{i=1}^{n} \frac{\Gamma_q(x+(n-i)k+\chi(i \leqq m))}{\Gamma_q(x+y+(2n-i-1)k+\chi(i \leqq m))} \tag{5.8}$$

satisfies (5.7) since, by (1.7),

$$\Gamma_q(x+1) = \frac{(1-q^x)}{(1-q)}\Gamma_q(x). \tag{5.9}$$

Clearly

$${}_qS_{n,n}(x, y, k) = {}_qS_{n,0}(x+1, y, k) \tag{5.10}$$

and ${}_qpr_{n,m}(x, y, k)$ also satisfies (5.10). Hence

$$ {}_qQ_{n,m}(x, y, k) = \frac{{}_qS_{n,m}(x, y, k)}{{}_qpr_{n,m}(x, y, k)} \tag{5.11} $$

satisfies

$$ \begin{aligned} {}_qQ_{n,m}(x, y, k) &= {}_qQ_{n,m-1}(x, y, k), \\ {}_qQ_{n,n}(x, y, k) &= {}_qQ_{n,0}(x+1, y, k). \end{aligned} \tag{5.12} $$

We easily obtain

$$ {}_qQ_{n,m}(x, y, k) = {}_qQ_{n,m}(x+1, y, k) \tag{5.13} $$

for all m, $0 \leqq m \leqq n$. Thus ${}_qQ_{n,m}(x, y, k)$ is independent of m and periodic in x with period 1. We extend ${}_qQ_{n,m}(x, y, k)$ to all x.

In order to prove Theorem 2 for $l = 0$, we must show that

$$ {}_qQ_{n,m}(x, y, k) = q^{2k^2\binom{n}{3}} \prod_{i=1}^{n} \Gamma_q(y+(n-i)k) \frac{\Gamma_q(1+ik)}{\Gamma_q(1+k)}. \tag{5.14} $$

By (5.12), it suffices to treat the case $m = 0$. We proceed by induction on n. For $n = 1$, (1.4) is the q-analogue

$$ \int_0^1 t^{(x-1)} \frac{(qt)_\infty}{(q^y t)_\infty} \, d_q t = \frac{\Gamma_q(x)\Gamma_q(y)}{\Gamma_q(x+y)} \tag{5.15} $$

of the beta integral. See Askey [5].

It is clear from (5.9) that

$$ \lim_{x \to 0} \frac{(1-q^x)}{(1-q)} \Gamma_q(x) = \Gamma_q(1) = 1 \tag{5.16} $$

and from (5.11) that

$$ {}_qS_{n,m}(x, y, k) = {}_qpr_{n,m}(x, y, k) \; {}_qQ_{n,m}(x, y, k). \tag{5.17} $$

Observe that ${}_qpr_{n,0}(x, y, k)$ has $\Gamma_q(x)$ as a factor. A simple computation gives

$$ \begin{aligned} \lim_{x \to 0} \frac{(1-q^x)}{(1-q)} {}_qS_{n,0}(x, y, k) &= \lim_{x \to 0} \frac{(1-q^x)}{(1-q)} {}_qpr_{n,0}(x, y, k) \; {}_qQ_{n,0}(x, y, k) \\ &= \frac{1}{\Gamma_q(y+(n-1)k)} \prod_{i=1}^{n-1} \frac{\Gamma_q((n-i)k)}{\Gamma_q(y+(2n-i-1)k)} \, {}_qQ_{n,0}(0, y, k). \end{aligned} \tag{5.18} $$

However, the recurrence relation (4.21) and our induction hypothesis give

$$ \begin{aligned} \lim_{x \to 0} \frac{(1-q^x)}{(1-q)} {}_qS_{n,0}(x, y, k) &= \frac{(1-q^{kn})}{(1-q^k)} {}_qS_{n-1,0}(2k, y, k) \\ &= \frac{(1-q^{kn})}{(1-q^k)} q^{[2k^2\binom{n-1}{2}+2k^2\binom{n-1}{3}]} \\ &\quad \cdot \prod_{i=1}^{n-1} \frac{\Gamma_q(2k+(n-1-i)k)\Gamma_q(y+(n-1-i)k)\Gamma_q(1+ik)}{\Gamma_q(2k+y+(2(n-1)-i-1)k)\Gamma_q(1+k)}. \end{aligned} \tag{5.19} $$

Equating these two results and solving for ${}_qQ_{n,0}(0, y, k)$, we obtain

$$
\begin{aligned}
{}_qQ_{n,0}(0,y,k) &= \frac{(1-q^{kn})}{(1-q^k)} q^{[2k^2\binom{n-1}{2}+2k^2\binom{n-1}{3}]} \Gamma_q(y+(n-1)k) \prod_{i=1}^{n-1} \Gamma_q(y+(n-1-i)k) \\
&\quad \cdot \prod_{i=1}^{n-1} \frac{\Gamma_q((n+1-i)k)}{\Gamma_q((n-i)k)} \frac{\Gamma_q(1+ik)}{\Gamma_q(1+k)} \\
&= q^{2k^2\binom{n}{3}} \prod_{i=1}^{n} \Gamma_q(y+(n-i)k) \frac{(1-q^{kn})}{(1-q^k)} \frac{\Gamma_q(nk)}{\Gamma_q(k)} \prod_{i=1}^{n-1} \frac{\Gamma_q(1+ik)}{\Gamma_q(1+k)} \\
&= q^{2k^2\binom{n}{3}} \prod_{i=1}^{n} \Gamma_q(y+(n-i)k) \frac{\Gamma_q(1+ik)}{\Gamma_q(1+k)}.
\end{aligned} \tag{5.20}
$$

By (5.13), this establishes (5.14) when x is an integer. To treat all x, we may use Liouville's theorem: a bounded entire function is constant. See Ahlfors [1, Chap. 4]. Let $a, b \in R$. Since $0<q<1$, we have

$$
|q^{a+ib}| = q^a, \qquad |(1-q)^{a+ib}| = (1-q)^a, \tag{5.21}
$$

and

$$
(q^a)_\infty \leqq |(q^{a+ib})_\infty| \leqq (-q^a)_\infty, \qquad a>0. \tag{5.22}
$$

This gives

$$
|{}_qS_{n,0}(x,y,k)| \leqq {}_qS_{n,0}(\mathrm{Re}\,(x), \mathrm{Re}\,(y), k). \tag{5.23}
$$

Recalling (1.7), we have

$$
(1-q)^{(1-a)} \frac{(q)_\infty}{(-q^a)_\infty} \leqq |\Gamma_q(a+ib)| \leqq (1-q)^{(1-a)} \frac{(q)_\infty}{(q^a)_\infty} = \Gamma_q(a), \qquad a>0. \tag{5.24}
$$

This shows that the modulus of each factor of ${}_qpr_{n,0}(x, y, k)$ (5.8) is bounded above and below by a continuous function of $\mathrm{Re}\,(x)$. Using (5.11) and (5.23), we see that $|{}_qQ_{n,0}(x, y, k)|$ is bounded by a continuous function of $\mathrm{Re}\,(x)$. Since a continuous function assumes its maximum on a closed set, $|{}_qQ_{n,0}(x, y, k)|$ is bounded for all x in the strip

$$
S = \{x \mid 1 \leqq \mathrm{Re}\,(x) \leqq 2\}. \tag{5.25}
$$

By (5.13), it is bounded for all x. The result (5.14) now follows by Liouville's theorem. The restriction $\mathrm{Re}\,(y)>1$ (2.6) is easily removed by analytic continuation. This completes the proof of the case $l=0$ of Theorem 2.

6. A proof of Theorem 2. By (4.19), the case $l=0$ of Theorem 2 (1.4) gives the case $l=0$ of Conjectures 6 and 11 of [10]. These conjectures now follow by Theorems 10 and 12 of [10]. A similar analysis establishes Theorem 2.

We have

$$
\begin{aligned}
{}_qS_{n,m,l}(x,y,k) &= \int_0^1 \cdots \int_0^1 \prod_{i=1}^{m} t_i \prod_{i=n-l+1}^{n} (1-q^y t_i)\, {}_qW_n(x,y,k)\, d_qt_1 \cdots d_q t_n \\
&= \sum_{j=0}^{l} (-q^y)^j \sum_{\substack{A\subset[n-l+1,n] \\ |A|=j}} \\
&\quad \cdot \int_0^1 \cdots \int_0^1 \prod_{i=1}^{m} t_i \prod_{i\in A} t_i\, {}_qW_n(x,y,k)\, d_qt_1 \cdots d_qt_n.
\end{aligned} \tag{6.1}
$$

Observe that

$$e([1, m] \cup A) = \sum_{i \in A} i - (m+1)|A| - \binom{|A|}{2}. \tag{6.2}$$

Setting $Q = q^k$ in (4.14) and using (6.2), (6.1) becomes

$$ {}_qS_{n,m,l}(x, y, k) = \sum_{j=0}^{l} (-q^y)^j \sum_{\substack{A \subset [n-l+1,n] \\ |A|=j}} q^{[k(\sum_{i \in A} i-(m+1)j-\binom{j}{2})]}\, {}_qS_{n,m+j}(x, y, k). \tag{6.3}$$

We can perform the inner sum by using the well-known (see Andrews [2, (2.2.1)]) q-binomial theorem

$$\frac{(at)_\infty}{(t)_\infty} = \sum_{j=0}^{\infty} \frac{(a)_j}{(q)_j} t^j, \qquad |t| < 1. \tag{6.4}$$

For $a = q^{-l}$, $t = xq^{n+1}$, this gives

$$(xq^{n-l+1})_l = \sum_{j=0}^{l} \frac{(q^{-l})_j}{(q)_j} (xq^{n+1})^j. \tag{6.5}$$

Equating coefficients yields

$$\sum_{\substack{A \subset [n-l+1,n] \\ |A|=j}} q^{\sum_{i \in A} i} = (-1)^j \frac{(q^{-l})_j}{(q)_j} q^{(n+1)j}. \tag{6.6}$$

Replacing q by q^k in (6.6) and substituting into (6.3), we obtain

$$ {}_qS_{n,m,l}(x, y, k) = \sum_{j=0}^{l} q^{(yj+k(n-m)j-k\binom{j}{2})} \frac{(q^{-lk}; q^k)_j}{(q^k; q^k)_j}\, {}_qS_{n,m+j}(x, y, k). \tag{6.7}$$

Since we have evaluated each of the integrals on the right side of (6.7), we can evaluate ${}_qS_{n,m,l}(x, y, k)$. By (5.9) and (1.4), we have

$$\begin{aligned} \frac{{}_qS_{n,m+j}(x, y, k)}{{}_qS_{n,m}(x, y, k)} &= q^{(kmj+k\binom{j}{2})} \prod_{i=m+1}^{m+j} \frac{(1-q^{x+(n-i)k})}{(1-q^{x+y+(2n-i-1)k})} \\ &= q^{(-yj+k(m-n+1)j+k\binom{j}{2})} \frac{(q^{-x-(n-m-1)k}; q^k)_j}{(q^{-x-y-(2n-m-2)k}; q^k)_j}. \end{aligned} \tag{6.8}$$

Equation (6.7) now gives

$$ {}_qS_{n,m,l}(x, y, k) = {}_qS_{n,m}(x, y, k) \sum_{j=0}^{l} \frac{(q^{-lk}; q^k)_j (q^{-x-(n-m-1)k}; q^k)_j}{(q^k; q^k)_j (q^{-x-y-(2n-m-2)k}; q^k)_j} q^{kj}. \tag{6.9}$$

This is the same series that arose [10, (8.13)] in our analysis of ${}_qI_{n,m,l}(x, y, k)$. It can be summed by the special case (see Slater [16, (3.3.2.7)])

$$b^n \frac{(d/b)_n}{(d)_n} = \sum_{i=0}^{n} \frac{(q^{-n})_i (b)_i}{(q)_i (d)_i} q^i \tag{6.10}$$

of the well-known q-analogue [16, (3.3.2.2)] of Saalschütz's theorem. Taking base q^k in (6.10), we obtain

$$ {}_qS_{n,m,l}(x, y, k) = {}_qS_{n,m}(x, y, k) \frac{(q^{y+(n-l)k}; q^k)_l}{(q^{x+y+(2n-m-l-1)k}; q^k)_l}. \tag{6.11}$$

Theorem 2 (1.4) now follows easily using (5.9).

7. A proof of Theorem 3. Since k is a nonnegative integer, we have the finite sum

$$\prod_{1\leqq i<j\leqq n} t_i^{2k}\left(q^{1-k}\frac{t_j}{t_i}\right)_{2k} = \sum_{\alpha} {}_qc_n^k(\alpha) \prod_{i=1}^{n} t_i^{\alpha_i}, \tag{7.1}$$

where $\alpha_i \geqq 0$, $1 \leqq i \leqq n$,

$$\sum_{i=1}^{n} \alpha_i = 2k\binom{n}{2}, \tag{7.2}$$

and each ${}_qc_n^k(\alpha)$ is a polynomial in q. Substitute (7.1) into (1.4) and use (5.15) and (5.9). This yields

$$\begin{aligned} {}_qS_{n,m,l}(x, y, k) &= \int_0^1 \cdots \int_0^1 \prod_{i=1}^{n} t_i^{(x-1)+\chi(i\leqq m)} \frac{(qt_i)_\infty}{(q^{y+\chi(n-i+1\leqq l)}t_i)_\infty} \\ &\quad \cdot \left(\sum_{\alpha} {}_qc_n^k(\alpha) \prod_{i=1}^{n} t_i^{\alpha_i}\right) d_qt_1 \cdots d_qt_n \\ &= \sum_{\alpha} {}_qc_n^k(\alpha) \prod_{i=1}^{n} \frac{\Gamma_q(x+\chi(i\leqq m)+\alpha_i)\Gamma_q(y+\chi(n-i+1\leqq l))}{\Gamma_q(x+y+\chi(i\leqq m)+\chi(n-i+1\leqq l)+\alpha_i)} \\ &= \prod_{i=1}^{n} \frac{\Gamma_q(x+\chi(i\leqq m))\Gamma_q(y+\chi(n-i+1\leqq l))}{\Gamma_q(x+y+\chi(i\leqq m)+\chi(n-i+1\leqq l))} \\ &\quad \cdot \sum_{\alpha} {}_qc_n^k(\alpha) \prod_{i=1}^{n} \frac{(q^{x+\chi(i\leqq m)})_{\alpha_i}}{(q^{x+y+\chi(i\leqq m)+\chi(n-i+1\leqq l)})_{\alpha_i}}. \end{aligned} \tag{7.3}$$

Equate (7.3) and Theorem 2 (1.4) and solve for the last $\sum_\alpha$. Using (5.9), we obtain

$$\begin{aligned} \sum_{\alpha} {}_qc_n^k(\alpha) \prod_{i=1}^{n} \frac{(q^{x+\chi(i\leqq m)})_{\alpha_i}}{(q^{x+y+\chi(i\leqq m)+\chi(n-i+1\leqq l)})_{\alpha_i}} &= q^{[kx\binom{n}{2}+k\binom{m}{2}+2k^2\binom{n}{3}]} \\ \cdot \prod_{i=1}^{n} \frac{(q^{x+\chi(i\leqq m)})_{(n-i)k}(q^{y+\chi(i\leqq l)})_{(n-i)k}(q)_{ik}}{(q^{x+y+\chi(i\leqq m+l)})_{(2n-i-1)k}(q)_k}. \end{aligned} \tag{7.4}$$

Since the left side of (7.4) is a finite sum, both sides are rational functions of q, q^x, and q^y. Thus (7.4) holds for all x and y. Observe that we do not need to use Liouville's theorem or analytic continuation to prove Theorem 2.

By reversing the order of the factors, we have

$$(x)_n = (-x)^n q^{\binom{n}{2}}\left(\frac{q^{1-n}}{x}\right)_n. \tag{7.5}$$

Applying this to $(t_i/t_j)_k$ gives

$$\left(q\frac{t_j}{t_i}\right)_k\left(\frac{t_i}{t_j}\right)_k = \left(-\frac{1}{t_it_j}\right)^k q^{\binom{k}{2}} t_i^{2k}\left(q^{1-k}\frac{t_j}{t_i}\right)_{2k}. \tag{7.6}$$

Multiplying these equations for $1 \leqq i < j \leqq n$ and using (7.1), we obtain

$$\begin{aligned} \prod_{1\leqq i<j\leqq n}\left(q\frac{t_j}{t_i}\right)_k\left(\frac{t_i}{t_j}\right)_k &= (-1)^{k\binom{n}{2}} q^{\binom{k}{2}\binom{n}{2}} \prod_{i=1}^{n} t_i^{-(n-1)k} \prod_{1\leqq i<j\leqq n} t_i^{2k}\left(q^{1-k}\frac{t_j}{t_i}\right)_{2k} \\ &= (-1)^{k\binom{n}{2}} q^{\binom{k}{2}\binom{n}{2}} \sum_{\alpha} {}_qc_n^k(\alpha) \prod_{i=1}^{n} t_i^{(\alpha_i-(n-1)k)}. \end{aligned} \tag{7.7}$$

Recall (Kadell [9, (3.31)]) that

$$(qt)_a\left(\frac{1}{t}\right)_b = \sum_{j=-b}^{a} (-t)^j q^{\binom{j+1}{2}} \frac{(q)_{a+b}}{(q)_{a-j}(q)_{b+j}} \tag{7.8}$$

is equivalent to the special case (6.5) of the q-binomial theorem. Replacing t by t/q gives

$$(t)_a\left(\frac{q}{t}\right)_b = \sum_{j=-b}^{a} (-t)^j q^{\binom{j}{2}} \frac{(q)_{a+b}}{(q)_{a-j}(q)_{b+j}}. \tag{7.9}$$

Substitute (7.7) into (1.12) and extract the constant term using (7.8) and (7.9). This yields

$$\begin{aligned} {}_qCS_{n,m,l}(a,b,k) &= (-1)^{k\binom{n}{2}} q^{\binom{k}{2}\binom{n}{2}} \\ &\cdot \sum_{\boldsymbol{\alpha}} {}_qc_n^k(\boldsymbol{\alpha}) \prod_{i=1}^{n} (-1)^{(\alpha_i-(n-1)k)} q^{(\chi(i>m)-\frac{\alpha_i}{2}+(n-1)k)} \\ &\cdot \prod_{i=1}^{n} \frac{(q)_{a+b+\chi(n-i+1\leqq l)}}{(q)_{a+\chi(i\leqq m)+\chi(n-i+1\leqq l)-(n-1)k+\alpha_i}(q)_{b-\chi(i\leqq m)+(n-1)k-\alpha_i}}. \end{aligned} \tag{7.10}$$

By (7.2), we have

$$\prod_{i=1}^{n} (-1)^{(\alpha_i-(n-1)k)} = \prod_{i=1}^{n} (-1)^{\alpha_i} = 1. \tag{7.11}$$

Equation (7.5) gives

$$\begin{aligned} \frac{1}{(q)_{b-\chi(i\leqq m)+(n-1)k-\alpha_i}} &= \frac{(q^{b+1-\chi(i\leqq m)+(n-1)k-\alpha_i})_{\alpha_i}}{(q)_{b-\chi(i\leqq m)+(n-1)k}} \\ &= (-1)^{\alpha_i} q^{\alpha_i(b+1-\chi(i\leqq m)+(n-1)k-\alpha_i)+\binom{\alpha_i}{2}} \\ &\cdot \frac{(q^{-b+\chi(i\leqq m)-(n-1)k})_{\alpha_i}}{(q)_{b-\chi(i\leqq m)+(n-1)k}}. \end{aligned} \tag{7.12}$$

Using

$$\binom{A}{2} = -A + \binom{1+A}{2}, \tag{7.13}$$

$$\binom{A+B}{2} = \binom{A}{2} + AB + \binom{B}{2}, \tag{7.14}$$

$$\binom{1-A}{2} = \binom{A}{2}, \tag{7.15}$$

and (7.2), we obtain

$$\prod_{i=1}^{n} q^{(\chi(i>m)-\frac{\alpha_i}{2}+(n-1)k)+\alpha_i(b+1-\chi(i\leqq m)+(n-1)k-\alpha_i)+\binom{\alpha_i}{2}} = q^{(n-m)(n-1)k+2bk\binom{n}{2}+n\binom{(n-1)k}{2}} \tag{7.16}$$

Equation (7.10) now becomes

$$\begin{aligned} {}_qCS_{n,m,l}(a,b,k) &= (-1)^{k\binom{n}{2}} q^{\binom{k}{2}\binom{n}{2}+(n-m)(n-1)k+2bk\binom{n}{2}+n\binom{(n-1)k}{2}} \\ &\cdot \prod_{i=1}^{n} \frac{(q)_{a+b+\chi(i\leqq l)}}{(q)_{a+\chi(i\leqq m+l)-(n-1)k}(q)_{b-\chi(i\leqq m)+(n-1)k}} \\ &\cdot \sum_{\boldsymbol{\alpha}} {}_qc_n^k(\boldsymbol{\alpha}) \prod_{i=1}^{n} \frac{(q^{-b+\chi(i\leqq m)-(n-1)k})_{\alpha_i}}{(q^{a+1+\chi(i\leqq m)+\chi(n-i+1\leqq l)-(n-1)k})_{\alpha_i}}. \end{aligned} \tag{7.17}$$

We can evaluate the last $\sum_{\alpha}$ by taking

$$x=-b-(n-1)k, \qquad y=a+b+1, \tag{7.18}$$

in (7.4). This gives

$$\begin{aligned}\sum_{\alpha} {}_qc_n^k(\alpha) \prod_{i=1}^{n} \frac{(q^{-b+\chi(i\leqq m)-(n-1)k})_{\alpha_i}}{(q^{a+1+\chi(i\leqq m)+\chi(n-i+1\leqq l)-(n-1)k})_{\alpha_i}} \\ = q^{-k(b+(n-1)k)\binom{n}{2}+k\binom{m}{2}+2k^2\binom{n}{3}} \\ \cdot \prod_{i=1}^{n} \frac{(q^{-b+\chi(i\leqq m)-(n-1)k})_{(n-i)k}(q^{a+b+1+\chi(i\leqq l)})_{(n-i)k}(q)_{ik}}{(q^{a+1-(n-1)k+\chi(i\leqq m+l)})_{(2n-i-1)k}(q)_k}.\end{aligned} \tag{7.19}$$

By (7.5), we have

$$\begin{aligned}(q^{-b+\chi(i\leqq m)-(n-1)k})_{(n-i)k} = (-1)^{(n-i)k} q^{(-b+\chi(i\leqq m)-(n-1)k)(n-i)k+\binom{(n-i)k}{2}} \\ \cdot (q^{b+1-\chi(i\leqq m)+(i-1)k})_{(n-i)k}.\end{aligned} \tag{7.20}$$

Clearly, for fixed j,

$$\sum_{i=1}^{n} \binom{n-i}{j-1} = \binom{n}{j}. \tag{7.21}$$

Substituting (7.19) into (7.17) and simplifying by (7.20) and (7.21), we obtain

$${}_qCS_{n,m,l}(a,b,k) = q^{\mathrm{EXP}} \prod_{i=1}^{n} \frac{(q)_{a+b+(n-i)k+\chi(i\leqq l)}(q)_{ik}}{(q)_{a+(n-i)k+\chi(i\leqq m+l)}(q)_{b+(i-1)k-\chi(i\leqq m)}(q)_k}, \tag{7.22}$$

where

$$\begin{aligned}\mathrm{EXP} = \binom{k}{2}\binom{n}{2} + (n-m)(n-1)k + n\binom{(n-1)k}{2} - 2k^2(n-1)\binom{n}{2} \\ + k\binom{m}{2} + 2k^2\binom{n}{3} + \sum_{i=1}^{m}(n-i)k + \sum_{i=1}^{n}\binom{(n-i)k}{2}.\end{aligned} \tag{7.23}$$

It is easy to see that EXP is independent of m. Thus

$$\begin{aligned}\mathrm{EXP} = \binom{k}{2}\binom{n}{2} + 2k\binom{n}{2} + n\binom{(n-1)k}{2} - 2k^2(n-1)\binom{n}{2} + 2k^2\binom{n}{3} \\ + \sum_{i=1}^{n}\binom{(n-i)k}{2}.\end{aligned} \tag{7.24}$$

Observe that

$$\binom{AB}{2} = A^2\binom{B}{2} + \binom{A}{2}B. \tag{7.25}$$

Take $A=k$, $B=n-i$, in (7.25) and $j=2,3$, in (7.21). This gives

$$\sum_{i=1}^{n}\binom{(n-i)k}{2} = \sum_{i=1}^{n} k^2\binom{n-i}{2} + \binom{k}{2}(n-i) = k^2\binom{n}{3} + \binom{k}{2}\binom{n}{2}. \tag{7.26}$$

We obtain

$$\text{EXP} = 2\binom{k}{2}\binom{n}{2} + 2k\binom{n}{2} + n\left(k^2\binom{n-1}{2} + \binom{k}{2}(n-1)\right) - 2k^2(n-1)\binom{n}{2} + 3k^2\binom{n}{3}$$

$$= k\binom{n}{2}[(k-1)+2+k(n-2)+(k-1)-2k(n-1)+k(n-2)] \tag{7.27}$$

$$= 0.$$

This proves Theorem 3 since (7.22) now agrees with (1.14).

A similar argument shows that Theorem 2 follows from Theorem 3. Indeed, Theorems 2 and 3 are equivalent to the summation formula (7.4). Observe that x in (7.18) is negative. Thus, (7.4) provides a common analytic continuation of Theorem 2 (1.4) and Theorem 3 (1.14).

A UNIFIED APPROACH TO MACDONALD'S ROOT-SYSTEM CONJECTURES*

DORON ZEILBERGER†

Dedicated to Dennis Stanton and John Stembridge for reminding me that antisymmetry is even more powerful than symmetry.

"*Yes, of course. It works with herring, but will it work with ferrous metals?*"
(*Woody Allen* [Al]).

Abstract. Using ideas of Stembridge and Stanton a method is presented that should settle the Macdonald (and the more refined Macdonald-Morris) root-system conjectures for any *specific* root system, provided there is sufficient computer time, memory space, and (for now) some luck. The method consists of an algorithm that reduces Macdonald's conjecture for a given root system to a finite, albeit long, algebraic calculation, which is then performed using computer algebra. The method is illustrated by proving the so far open G_2^{ν} case of the Macdonald-Morris conjectures. The question that remains is: will it work with E_8 (and F_4, E_6, E_7)?

Key words. Macdonald's root-system conjectures, constant term, q-analogue, computer algebra

AMS(MOS) subject classifications. 05A15, 05A17, 33A15, 33A75

Introduction. This paper is about Macdonald's *root-system* conjectures. In order to understand it, it is necessary to know a little bit about root systems and their Weyl groups. While it seems obvious that before one can talk about *root-system* conjectures one has to know about root systems, this is not the case for many of the papers on this subject. By the classification theorem for root systems, it is possible to spell out what the conjectures say for each of the four infinite families and the five exceptional root systems, and then treat each case separately [Mo]. Although only one root-system is treated at a time in this paper, its method is cast in the general root-system mold.

Historically root systems first came up in the deep and sophisticated theory of Lie algebras. This noble birth gave them a fancy aura that scared away many a plebeian mathematician. However, root systems are really very simple-minded, combinatorial-geometrical structures and it is possible, perhaps even preferable, to study root systems without knowing anything about Lie algebras.

A root system is a finite collection of vectors, called roots, in regular (Euclidean) space such that if you place a mirror perpendicular to any of them, the image of the visible part that is reflected in the mirror coincides exactly with the invisible part behind the mirror. Furthermore, the vector difference between any root and its image under any such mirror is an *integer* multiple of the root corresponding to the mirror (i.e., the root that is perpendicular to the mirror). These two conditions are very strong and it turns out (the classification theorem) that all irreducible root systems fall into five infinite families and five exceptionals. If you add the condition that these vectors can only be parallel to their negatives (reduced root systems) then one infinite family (BC_n) drops out.

An excellent treatment of root systems and Weyl groups is given in Chapters 2 and 10 of Carter's book [C]. These two chapters are completely independent of the rest of the book and are entirely elementary. This paper can be understood by any one who has read the first two sections of Chapter 2 and the first two sections of Chapter 10 of [C]. A comprehensive and (surprisingly) quite readable account is given in [Bo], but for the present paper [C] is more than enough.

Notation. The Macdonald conjectures are about certain multivariable Laurent polynomials. A Laurent polynomial is a linear combination of monomials that may have negative integer exponents as well as positive integer exponents. For example $x+1+x^{-1}$ is a Laurent polynomial in one variable and $x+y+x^{-1}y^2$ is one in two variables. Usually x denotes a vector of variables, $x=(x_1,\cdots,x_l)$ and α a vector of integers, $\alpha=(\alpha_1,\cdots,\alpha_l)$. Also

$$x^{\alpha}=x_1^{\alpha_1}\cdots x_l^{\alpha_l}.$$

For example $x^{(1,-2,5)}=x_1x_2^{-2}x_3^5$.

For the roots α of a root system, x^{α}, are often called "formal exponentials." But since all root systems can be made to have all their roots with integer components, these exponentials can be easily defrocked of their formality. The root lattice of a root system consists of all integer linear combination of roots, and all our Laurent polynomials will be linear combinations of monomials x^{γ} for γ in the root lattice. The Weyl group W of a root system [C, Chap. 2] acts on the roots, and by linearity on the root lattice. The elements w of the Weyl group W are made to act on monomials by

$$w(x^{\gamma})=x^{w(\gamma)}$$

and by linearity on all Laurent polynomials. For example, if $w(\alpha_1,\alpha_2)=(-\alpha_2,\alpha_1)$, then

$$w(x^{-1}y^2+3+x^5y^{-2})=x^{-2}y^{-1}+3+x^2y^5.$$

A Laurent polynomial G is *symmetric* with respect to the Weyl group W if $w(G)=G$ for every w in W. The *sign* of an element w of W, written $\operatorname{sgn}(w)$, may be defined as [C, p. 18] $(-1)^{n(w)}$, where $n(w)$ is the number of positive roots that w turns into negative roots, i.e., the number of elements in the set $w(R^+)\cap R^-$. A Laurent polynomial G is *antisymmetric* if for any w in the Weyl group W, $w(G)=\operatorname{sgn}(w)G$.

C.T. stands for "the constant term of" (in $x=(x_1,\cdots,x_l)$), and $|A|$ denotes the number of elements of the finite set A. The letter l usually denotes the rank of R, and $d_1,\cdots,d_l$, are the "fundamental invariants" [C, p. 155] of R.

The $(\ )_a$ q-notation will be used extensively. $(y;Q)_a$, the q-analogue of $(1-y)^a$ to base Q, is defined by

$$(y;Q)_a=(1-y)(1-Qy)(1-Q^2y)\cdots(1-Q^{a-1}y),$$

and whenever the "base" Q happens to be q we will omit it: $(y)_a=(y;q)_a$. The standard base of Euclidean space is denoted by $\{e_i\}$, $e_i=(0,0,\cdots,0,1,0,0,\cdots,0)$, where all the components are zero except the i component that is 1. Of course $x^{e_i}=x_i$.

1. Conjectures. In 1962, in his study of the statistical theory of complex systems, Dyson [D1] conjectured

$$\text{(D)}\qquad \text{constant term of } \prod_{1\le i\ne j\le n}\left(1-\frac{x_i}{x_j}\right)^a=\frac{(na)!}{a!^n}.$$

His conjecture was soon proved by Gunson [Gu] and Wilson [W] and Good [Goo] gave a beautiful proof some years later.

When Macdonald saw Dyson's conjecture (D) he saw the root system A_{n-1}. Indeed, since

$$A_{n-1}=\{e_i-e_j;\ 1\leqq i\neq j\leqq n\} \quad \text{and} \quad x^{e_i-e_j}=\frac{x_i}{x_j},$$

(D) can be written as

$$\text{constant term of } \prod_{\alpha\in A_{n-1}}(1-x^{\alpha})^{a}=\frac{(na)!}{a!^{n}}.$$

He then wondered what happens if A_{n-1} is replaced by other root systems.

The case $a=1$ of Dyson's conjecture (D) is an almost immediate consequence of the Vandermonde determinant identity and the constant term then is $n!=n(n-1)\cdots(2)$. Now the Vandermonde determinant identity has a celebrated root-system analogue: Weyl's denominator identity (e.g., [C, p. 149]), and imitating the argument that proved (D) for $a=1$ yields, for any root-system R with Weyl group W,

$$\text{C.T.} \prod_{\alpha\in R}(1-x^{\alpha})=|W|.$$

For $R=A_{n-1}$, $W=S_n$ and since $|W|=|S_n|=n!$, this agrees with the $a=1$ case of (D).

So the $a=1$ case of (D) has a nice root-system analogue. What about general a? It is well known that $|W|$ factorizes nicely [C, 9.3.4(i), p. 133]:

$$|W|=d_1d_2\cdots d_l,$$

where $d_1,\cdots,d_l$ are the "fundamental invariants" of the Weyl group W (these fundamental invariants are, among other things, the degrees of the generators of the algebra of polynomials invariant under W). For A_{n-1} these invariants are $2,3,\cdots,n$ (the degrees of the elementary symmetric functions!). Rewriting the right-hand side of (D) as

$$\binom{2a}{a}\cdots\binom{na}{a},$$

Macdonald [Ma3] conjectured that

$$\text{(M)} \qquad \text{constant term of } \prod_{\alpha\in R}(1-x^{\alpha})^{a}=\binom{d_1a}{a}\cdots\binom{d_la}{a}.$$

Macdonald was also able to prove the special case $a=2$, and by using Selberg's integral [Se] he proved the B_n, C_n, and D_n cases. Recently Habsieger [Hab1] and Zeilberger [Z2] proved the G_2 case. For $R=F_4$, E_6, E_7, and E_8, (M) is still open, as far as I know.

Next Macdonald went on to formulate a "q-analogue" of (M). Andrews ([An1]; see also [An2]) already formulated a q-analogue of (D) in 1975. Actually Andrews conjectured a q-analogue of a more general conjecture of Dyson, and his conjecture specializes to the following q-analogue of (D):

$$\text{(qD)} \qquad \text{C.T.} \prod_{1\leqq i<j\leqq n}\binom{x_i}{x_j}_k\binom{qx_j}{x_i}_k=\frac{[nk]!}{[k]!^{n}}\left(=\begin{bmatrix}2k\\k\end{bmatrix}\cdots\begin{bmatrix}nk\\k\end{bmatrix}\right).$$

The general Andrews conjecture was proved in [Z-B].

Motivated by this and (M) Macdonald [Ma3] conjectured

$$\text{(qM)} \qquad \text{C.T.} \prod_{\alpha\in R^{+}}(x^{\alpha})_k(qx^{-\alpha})_k=\begin{bmatrix}d_1k\\k\end{bmatrix}\cdots\begin{bmatrix}d_lk\\k\end{bmatrix}.$$

Macdonald [Ma3] was able to prove (qM) for $k=1, 2$ and $k=\infty$. For $k=\infty$ (qM) is a consequence of his own famous Macdonald Weyl identities [Ma2] (many special cases of which were known to Dyson [D2], but Dyson "missed the opportunity" to see the connection to root systems). For general k (qM) is only known to date for $R=A_n$ [Z-B] and G_2 ([Hab1], [Z2]). Hanlon [Han1] did the limiting case $n=\infty$ of B_n, C_n, and D_n.

One of the greatest delights of mathematics is the interplay between the abstract and the concrete, the general and the special. Whenever one has a general result or conjecture, it is very instructive to see what it says in special cases, and studying these special cases often sheds new light on the general case. Morris [Mo] took Macdonald's conjectures and made them explicit for all the root systems. Then by studying the G_2 case and playing with MACSYMA he was able to come up with a more general G_2-Macdonald conjecture, involving two parameters a and b instead of the single parameter k:

$$\text{C.T.} \prod_{\alpha \in \text{short } G_2} (1-x^{\alpha})^{a} \prod_{\alpha \in \text{long } G_2} (1-x^{\alpha})^{b} = \frac{(3a+3b)!(3b)!(2a)!(2b)!}{(2a+3b)!(a+2b)!(a+b)!a!b!b!}.$$

This was encouraging because it always helps to have more parameters (recall Polya's dictum: "the more general the easier"). Indeed Good's ([Goo]; see also [An2], [As3]) elegant proof of Dyson's conjecture (D) proceeds by proving the more general formula (also conjectured by Dyson [D1]):

$$\text{(D')} \qquad \text{C.T.} \prod_{1 \leq i \neq j \leq n} \left(1-\frac{x_i}{x_j}\right)^{a_i} = \frac{(a_1+\cdots+a_n)!}{a_1!\cdots a_n!},$$

and the extra elbow room provided by the n parameters $a_1, \cdots, a_n$ is crucial.

Morris sent his G_2 conjecture to Macdonald and, once again, Macdonald saw the right root-system generalization ([Ma3], [Mo]). Now there is a parameter associated with each root length. (Since A_l, D_l, E_6, E_7, E_8 have only one root length the generalization is void for them. For B_l, C_l, G_2, F_4 we have two parameters and BC_l has three parameters.)

Macdonald soon found a q-analogue [Ma3, 3.1]: if k_α are nonnegative integers such that $k_\alpha = k_\beta$ if α and β have the same length, then

$$\text{(qM-M1)} \qquad \text{C.T.} \prod_{\alpha \in R^+} (x^{\alpha})_{k_\alpha} (qx^{-\alpha})_{k_\alpha} = \text{a certain explicit product.}$$

I already mentioned that the case $k=\infty$ of (qM) is a consequence of Macdonald's Weyl identitities [Ma1]. These identities are the analogue of the Weyl denominator formula for affine root systems. (Incidentally these were "the tip of the iceberg" that motivated the representation theory of Kac-Moody algebras [Kac, p. xiii], but that's another story.) It turned out that the Macdonald-Morris conjectures (qM-M1) can be viewed as the "truncated form" of Macdonald's identities for the so-called $S(R)$ affine root systems ([Ma3, p. 999]; see [Ma1] and [Mo] for definitions of affine root systems). The classification theory of affine root systems [Ma1] says that the irreducible ones are either of the form $S(R)$ or $S(R)^{\vee}$. It was thus natural for Macdonald to formulate his conjectures as the truncated form of his identities and that led to the ultimate generalization ([Ma3, Conjecture 3.3], [Mo, pp. 25, 26]): Let k_α be as before and let u_α be certain *constant* integers (depending on the affine root system) that satisfy $u_\alpha = u_\beta$ whenever α and β have the same length (see [Ma1] or [Mo] for their values, for example for $S(G_2)^{\vee}$, $u_{\text{short}}=1$ and $u_{\text{long}}=3$). Let R be the underlying finite root system;

then,

(qM-M2) C.T. $\prod_{\alpha\in R^+}(x^\alpha; q^{u_\alpha})_{k_\alpha}(q^{u_\alpha}x^{-\alpha}; q^{u_\alpha})_{k_\alpha}$ = a certain explicit product.

The Macdonald conjectures, like most interesting mathematics, lie on the crossroads of several subjects, and so appeal to a wide spectrum of mathematicians. Lie algebraists suspect that, like the Macdonald identities, they are the tip of a deep algebraic iceberg [Han1]–[Han3], [Stanl1], [Stanl2]. Analysts [Mo], [As1]–[As3] see many interesting examples of multivariate hypergeometric series identities, "a topic about which little is currently known" [Mo, p. 4]. Geometers wonder whether there are things about root systems that they do not know, and combinatorialists [Z–B], [Br1], [Br2], [C-H], [B-G] are challenged to develop a combinatorial theory of Weyl groups that will emulate the rich theory of the symmetric group.

But regardless of our parochial interests and prejudices, we are all awed by the simplicity of these conjectures. The statement of the Macdonald conjectures, for any specific root system, can be explained to a high school student, but the proofs elude us.

2. Approaches. I will now give a very brief survey of the various approaches that have been used to tackle the Macdonald conjectures.

Selberg's integral. This fascinating generalization of Euler's beta integral was discovered by Selberg [Se] in 1944 but lay dormant for about 35 years, partially because it was ahead of its time, partially because it was written in Norwegian and partially because Selberg wrote it before he got *really* famous. This sleeping beauty awoke from its deep slumber when Enrico Bombieri consulted Selberg about a certain conjectured definite integral of Mehta [Me], [As3], [Ma3] and Selberg dug his old paper out of his files. It turned out that Mehta's conjecture (that has been open for about 15 years) is an easy consequence, via a limiting process, of Selberg's integral.

Mehta's conjecture [Me], which can be thought of as an integral analogue of Dyson's conjecture (D), also received root-system analogues by Macdonald [Ma3, § 5]. Beckner and Regev (see [Ma3, § 5]) showed how Selberg's integral can be used to get these root-system-Mehta conjectures for the classical root systems.

Macdonald [Ma3] showed, by a clever change of variable, that Selberg's integral is equivalent to the BC_n, $q=1$, case of (qM-M), which implies (M) for B_n, C_n, and D_n. Using a corollary of Selberg's integral, due to Morris [Mo, p. 94], Zeilberger [Z2], and Habsieger [Hab1] proved the G_2 case of (M). Aomoto [Ao] has recently found a very ingenious proof of Selberg's integral by using integration by parts, recurrences, and symmetry; see [As3] for a nice account.

By employing Jackson's q-analogue of integration, Askey [As1] formulated an elegant q-analogue of Selberg's integral that has recently been proved by Kadell [Kad1] and by Habsieger [Hab2]. Kadell q-analogized Aomoto's proof and Habsieger used Selberg's original method coupled with some brilliant ideas of his own. Kadell and Habsieger also showed that their Askey- q-Selberg identity implies the q-analogue of Morris' identity mentioned above. This q-analogue, conjecture by Morris himself [Mo], enabled Habsieger [Hab1] and Zeilberger [Z2] to prove the G_2 case of (qM-M1). Incidentally, Kadell and Habsieger's q-Morris identity contains, as a special case, the A_n case of (qM-M) (first proved in [Z-B]).

Counting tournaments. I already mentioned that the case $a=1$ of (D) follows from the Vandermonde determinant identity. The case $n=3$ is also classical, being equivalent to Dixon's identity [An1]. Both these classical identities received beautiful combinatorial proofs. Gessel [Ge] (see also [An2, 4.4]) gave an elegant graph-theoretical proof of Vandermonde's determinant identity by counting tournaments, and

Foata [F], [C-F] gave a gorgeous proof of Dixon's identity by using multitournaments on three players.

Combining these two pretty proofs, Zeilberger [Z1] managed to give a purely combinatorial proof of Dyson's conjecture (D′) (and thus of (D)). In that paper Zeilberger wrote: "We believe that our proof has a good chance of being generalized, because most combinatorial proofs involving binomial coefficients have q-analogues. However, another idea is still needed since the obvious q-generalization fails." The "obvious generalization" was to q-count words by using either the number of inversions or the major index as the "statistics" because both yield the q-multinomial coefficients. But neither of these worked. The new idea that was needed was to introduce a brand-new statistic, the z-index, and to prove that it, too, yields the q-multinomial coefficients. This was done in [Z-B], which contains a proof of Andrews' conjecture (and hence of the A_{n-1} case of (qM)).

Motivated by the success of the combinatorial method, there were attempts to extend it to general root systems [Br1], [Br2], [C-H]. Although these papers contain some very promising ideas, they failed, so far, even to prove the G_2 case. I should also mention [B-G], that, using the methods of [Z-B], contains interesting extensions of Andrews' conjecture, and [Gr], that gives an elegant MacMahon-style combinatorial proof for the above-mentioned fact that the z-statistics yield the q-multinomial coefficients.

Lie algebra cohomology. Hanlon [Han2], [Han3] found an interesting formulation and refinement of Macdonald's conjectures in the context of the cyclic homology of the exterior product of a Lie algebra with $\mathbb{C}[t, t^{-1}]$. Besides the considerable intrinsic merit of this approach, it also serves to make the conjectures accessible and appetitizing to all those sophisticates who are unwilling or unable to think in terms of the simple formulation of the original conjectures.

Hypergeometric $SU(N)$. Milne [Mi] found an elegant elementary proof of the $A_l^{(1)}$ case of Macdonald's identities. It is very possible that Milne's deep generalized hypergeometric theory will, one day, contain the Macdonald conjectures as a very special case.

Schur functions. Stanley [Stanl1], [Stanl2] found an interesting connection between the A_n cases and Schur functions. This connection was further explored by Stembridge [Ste1], [Ste2] and Goulden [Gou]. While these works do not try to prove the Macdonald conjecture per se, they Schur do give lots of insight. Indeed, it was exactly this study that led Stembridge [Ste3] to his elegant proof discussed below. It is not unlikely that a similar study of characters of general simple Lie algebras will lead us in the right direction.

I should also mention the interesting character sums analogues of Evans [E] and the fascinating connection between Mehta type integrals, PI rings and the representation of the symmetric group found by Regev [R1], [R2], and further explored by Cohen and Regev [C-R].

In April 1986, Dennis Stanton told me that John Stembridge had a short and elementary proof of the A_{n-1} case of (qM) (or equivalently, the equal parameter case of Andrews' q-Dyson conjecture). At first I was only mildly interested, since Kadell and Habsieger had just then completed, independently, the proof of Askey's conjectured q-Selberg integral ([Hab2], [Kad1], mentioned above) and also showed that it implies the q-Morris conjecture, that in turn implies the A_{n-1} case of (qM). In fact, I saw [Z3] how to use the Aomoto-Kadell method to get the q-Morris directly, without q-Selberg.

I wrote to John Stembridge anyway, requesting an account of the proof, and received from him a barely legible xerox copy of a three-page handwritten sketch that

Dennis Stanton had prepared. When I finally understood the proof I got excited. At long last a proof that has a "root-systemy" flavor! Although the proof was only of the A_{n-1} case, it had some universal root-system elements in it, and it used properties of the symmetric group that pass verbatim to any Weyl group, that I was sure that it should extend to the general case.

This was, of course, also realized by John Stembridge himself as he pointed out later when he finally got around to writing the paper [Ste3]. However, his proof took advantage of a certain "miracle" that seemed to occur only for A_{n-1}. Surely what was needed was to get rid of the dependence on the miracle, possibly by sacrificing elegance. I thought about that all through the summer (while taking care of my newborn daughter Tamar) and the result is this paper. (The fall was spent programming the algorithm and debugging the programs. If nothing else, this project made me a fairly competent *C* programmer.)

As John Stembridge told me himself, his proof, as well as parts of his impressive thesis [Ste1], were largely motivated and inspired by Dennis Stanton's ingenious proof of Macdonald's Weyl denominator identity for the classical root-systems [Stant1], [Stant2].

Using these beautiful ideas of Stembridge and Stanton, I will present a method that systematically handles the Macdonald conjectures for any given, fixed, root system, provided there are sufficient computer resources, and, for the time being, some luck. What I do know for sure is that it works for the (already known) A_2 and G_2 cases and for the (so far open) G_2^ν case (§ 9). Besides, I am almost sure that the element of luck can be disposed of and that the method can be proved to constitute an effective algorithm for settling the Macdonald and the Macdonald-Morris conjectures for any given root system. Of course, that by itself would not constitute a proof, or even an effective algorithm for the general conjecture, because there are an infinite number of root systems.

On the other hand, it is very possible that the A-D cases of the Macdonald and Macdonald-Morris conjectures will soon be settled by either using the Askey q-Selberg integral [Kad1], [Hab2] directly, or by using similar methods of proof. In that case we will only be left with the seven exceptional cases (G_2 and its dual, F_4 and its dual, and E_6, E_7, and E_8, but since the first two are already known this leaves us with five cases). These should succumb to the method of this paper (at least in principle, and barring very bad luck). But even if that would turn out to be the case, it would certainly not be the proof from *the book*. The ultimate proof should be "classification-free" and take care of all root systems at once.

To give a very apt analogy, the Weyl denominator formula [C, p. 149] can be proved case by case. A_{n-1} is just the Vandermonde determinant identity, which is an elementary exercise in determinants. The cases B_n, C_n, and D_n also specialize to simple algebraic identities that can be easily proved by induction. The remaining exceptional cases, G_2-E_8, give rise to finite polynomial identities that can be checked by computer (although I have to admit that, for E_8, even the CRAY will take "a while" to handle the 2^{120} terms). However, there is a beautiful "classification-free" proof of Weyl's identity that can be found in Carter's book ([C, § 10.1]).

I believe that besides the instant gratification that the present method brings, it is also an important step toward the ultimate proof. Unlike any previous approach, it makes use of the general root-system-Weyl group framework, and thus may pave the way to the final proof. In addition, it also provides a "laboratory" for computing other coefficients, besides the constant term, for any specific root system (see below). This may lead us to formulate a yet more general conjecture, and this more general conjecture

may very well turn out to be much easier to prove.

3. Antisymmetry.

No two fermions can exist in identical quantum states.
(*Wolfgang Pauli*)

Let R be a root system and let us define

$$F'_k(x)=\prod_{\alpha\in R^+}(x^\alpha)_k(qx^{-\alpha})_k, \qquad H'_k=\text{C.T. } F'_k(x). \tag{3.1}$$

Macdonald's conjecture (qM) asserts that H'_k has a nice explicit form (namely, the right-hand side of (qM)). In any case, whether (qM) is true or false, our goal will be to compute H'_k. It turns out (and this observation is due to Macdonald, although Stembridge was the one to realize its full significance) that one can consider instead

$$F_k(x)=\prod_{\alpha\in R^+}(x^\alpha)_k(qx^{-\alpha})_{k-1} \tag{3.2}$$

and

$$H_k=\text{C.T. } F_k(x).$$

This is so because of the fact, soon to proved, that H_k and H'_k are related by a simple formula

$$H'_k=H_k\prod_{i=1}^{l}\left(\frac{1-q^{kd_i}}{1-q^k}\right). \tag{3.3}$$

The reason why it is better to consider the constant term of F_k rather than that of F'_k is that F_k is a much nicer Laurent polynomial: it is almost antisymmetric.

Indeed, by peeling off the first layer out of the $(x^\alpha)_k$ in (3.1) we get (since $(y)_k=(1-y)(qy)_{k-1}$)

$$\begin{aligned}F_k(x)&=\prod_{\alpha\in R^+}(1-x^\alpha)\prod_{\alpha\in R^+}(qx^\alpha)_{k-1}(qx^{-\alpha})_{k-1}\\ &=\prod_{\alpha\in R^+}x^{\alpha/2}(x^{-\alpha/2}-x^{\alpha/2})\prod_{\alpha\in R}(qx^\alpha)_{k-1}\\ &=x^\delta\prod_{\alpha\in R^+}(x^{-\alpha/2}-x^{\alpha/2})\prod_{\alpha\in R}(qx^\alpha)_{k-1}\end{aligned} \tag{3.4}$$

(δ is one half the sum of all the positive roots). Let

$$G_k(x)=x^{-\delta}F_k(x). \tag{3.5}$$

Then, because of (3.4)

$$G_k(x)=\prod_{\alpha\in R^+}(x^{-\alpha/2}-x^{\alpha/2})\prod_{\alpha\in R}(qx^\alpha)_{k-1}. \tag{3.6}$$

We claim that $G_k(x)$ is antisymmetric. Indeed, the second product is symmetric because any element $w\in W$ sends R to itself [C, p. 13, line 4] and the first product is antisymmetric for the same reason, only now we get a minus sign whenever a positive root α is sent to a negative root (i.e., whenever $w(\alpha)\in R^-$). Thus the effect of applying $w\in W$ on the first product of (3.6) is to multiply it by $(-1)^{n(w)}$ where $n(w)=|w(R^+)\cap R^-|$ and this is equal to the sign of w [C, p. 18]. It thus follows that $G_k(x)$ itself is antisymmetric.

From now on, we will forget all about F_k (and certainly about F'_k) and work solely with G_k, noting that the quantity of interest, H_k, is given in terms of G_k by

$$H_k = \text{C.T.}\,(x^{\delta} G_k) C_{x^{-\delta}} G_k. \tag{3.7}$$

Our goal, to be pursued in the next two sections, is to find H_k. But we must show now, following Stembridge [Ste3], that H_k is indeed related to H'_k as promised by (3.3).

Indeed, since $(y)_k = (y)_{k-1}(1-q^k y)$, we have (by (3.1) and (3.2))

$$\begin{aligned} H'_k &= \text{C.T.} \prod_{\alpha \in R^+} (1-q^k x^{-\alpha}) F_k = \text{C.T.} \left[\prod_{\alpha \in R^+} (1-q^k x^{-\alpha}) \right] x^{\delta} G_k \\ &= \text{C.T.} \prod_{\alpha \in R^+} [(1-q^k x^{-\alpha}) x^{\alpha/2}] G_k = \text{C.T.} \prod_{\alpha \in R^+} (x^{\alpha/2} - q^k x^{-\alpha/2}) G_k. \end{aligned} \tag{3.8}$$

When the product on the extreme right is expanded we get $2^{|R^+|}$ terms, since each term in the product corresponds to a pair of opposite roots, and each term in the resulting huge sum corresponds to choosing, for every α in R^+, whether to take it or its negative. This prompts us to define a *choice set* Ω, as a subset of R such that for each $\alpha \in R^+$ either $\alpha \in \Omega$ or $-\alpha \in \Omega$.

We can now write the right-hand side of (3.8) as (set $t = q^k$),

$$\text{C.T.} \sum_{\Omega \text{ choice set}} (-t)^{|\Omega \cap R^-|} (x^{\text{sum}(\Omega)/2} G_k). \tag{3.9}$$

Here sum (Ω) denotes the (vector) sum of all the elements in Ω.

Now let us call a choice set a *bad guy*, if sum (Ω) lies on a reflecting hyperplane, i.e., there exists a root β such that $(\text{sum}\,(\Omega), \beta) = 0$. Otherwise let us call it a *good guy*. The sum in (3.9) can, of course, be written as

$$\text{C.T.} \sum_{\Omega \text{ good guy}} (-t)^{|\Omega \cap R^-|} (x^{\text{sum}(\Omega)/2} G_k) + \text{C.T.} \sum_{\Omega \text{ bad guy}} (-t)^{|\Omega \cap R^-|} (x^{\text{sum}(\Omega)/2} G_k). \tag{3.10}$$

The proof of (3.3) will continue *right after this.*

CRUCIAL LEMMA. *Let $G(x)$ be antisymmetric with respect to the Weyl group W and let γ be any vector of integers.*

(i) $\text{C.T.}\,(x^{w(\gamma)} G) = \text{sgn}\,(w)\ \text{C.T.}\,(x^{\gamma} G)$, *for each element w in the Weyl group W.*

(ii) *If γ lies on a reflecting hyperplane, i.e., there exists an $\alpha \in R$ such that $(\gamma, \alpha) = 0$, then* $\text{C.T.}\,(x^{\gamma} G) = 0$.

Proof of the Crucial Lemma.

Proof of (i).

$$\begin{aligned} \text{C.T.}\,(x^{w(\gamma)} G) &= \text{C.T.}\ w(x^{\gamma} w^{-1}(G)) \\ &= \text{C.T.}\, x^{\gamma} w^{-1}(G) = \text{C.T.}\, x^{\gamma}\ \text{sgn}\,(w^{-1}) G \\ &= \text{sgn}\,(w)\ \text{C.T.}\, x^{\gamma} G. \end{aligned}$$

In this chain of equalities we have used, in that order: (a) the definition of the action of w on a Laurent polynomial; (b) the fact that applying w on a Laurent polynomial never changes the consant term (because w is, among other things, a linear transformation, so $w(0) = 0$ and $w(x^0) = x^{w(0)} = x^0$); (c) the antisymmetry of G; (d) $\text{sgn}\,(w^{-1}) = \text{sgn}\,(w)$, and you can always take a constant out of C.T.

Proof of (ii). Let w_α be the Weyl reflection corresponding to the root α [C, p. 12]; then $w_\alpha(\gamma) = \gamma$ (since γ lies on the mirror that is perpendicular to α) and since $\text{sgn}\,(w_\alpha) = -1$, we have, by part (i),

$$\text{C.T.}\,(x^{\gamma} G) = \text{C.T.}\,(x^{w_\alpha(\gamma)} G) = (\text{sgn}\,(w_\alpha))\ \text{C.T.}\,(x^{\gamma} G) = -\text{C.T.}\,(x^{\gamma} G).$$

Thus $\text{C.T.}\,(x^{\gamma} G)$ is equal to its negative and must be zero. □

We now return to the proof of (3.3).

Because of part (ii) of the Crucial Lemma and the definition of a bad guy, the second sum in (3.10) vanishes. Now from Lemma 10.1.6. and its proof of [C, p. 147], or from Lemma 2.13 of [Ma2], it follows that if Ω is a good guy then there exists a w in the Weyl group W such that sum $(\Omega)/2 = w(\delta)$ and $\Omega = w(R^+)$. So a good choice set Ω uniquely determines $w \in W$ and vice versa. It is thus possible to write (3.9) as (note that $|w(R^+) \cap R^-| = n(w)$)

$$H'_k = \sum_{w \in W} (-1)^{n(w)} t^{n(w)} \text{ C.T. } (x^{w(\delta)} G_k).$$

But because of part (i) of the Crucial Lemma,

$$\text{C.T. } (x^{w(\delta)} G_k) = \text{sgn } (w) \text{ C.T. } (x^{\delta} G_k)$$

and since sgn $(w) = (-1)^{n(w)}$, we have that H'_k is equal to

$$H'_k = \left(\sum_{w \in W} t^{n(w)} \right) H_k,$$

and (3.3) follows because of the following beautiful identity due to Bott, Solomon, and Macdonald [Ma2] (see [C, p. 135 ff, p. 155])

$$\sum_{w \in W} t^{n(w)} = \prod_{i=1}^{l} \frac{1 - t^{d_i}}{1 - t}. \tag{3.11}$$

We should remark, though, that if one is only interested in one root system at a time (as we are in the present method), then we really do not need (3.11), since the left-hand side is just a specific polynomial that can be explicitly computed and, if desired, factorized.

4. Induction. This section constitutes my own twist on the Stembridge approach. Stembridge's [Ste3] inductive scheme, for A_n, was to creep along the coefficients of G_k (keeping k fixed) until one gets to a high enough coefficient whose value is equal to the H_k for A_{n-1}. So his induction was with respect to n, and his k stayed fixed. Our induction is with respect to k and the root system stays fixed.

Using $(y)_{k+1} = (1 - q^k y)(y)_k$, $(qy)_k = (1 - q^k y)(qy)_{k-1}$, (3.2) and (3.5), we have

$$H_{k+1} = \text{C.T. } (x^{\delta} G_{k+1}) = \text{C.T. } \left(x^{\delta} \prod_{\alpha \in R} (1 - q^k x^{\alpha}) G_k \right). \tag{4.1}$$

Now put $t = q^k$ and expand the product

$$x^{\delta} \prod_{\alpha \in R} (1 - t x^{\alpha}) = \sum_{\rho' \in S'} a_{\rho'}(t) x^{\rho'} \tag{4.2}$$

where S' is a certain *finite* set of vectors in the lattice generated by the roots and $a_{\rho'}(t)$ are polynomials in t. Now, each $\rho' \in S'$ is either on a reflecting hyperplane (a bad guy) or [C, Prop. 2.3.4, p. 22] there is a $w \in W$ and ρ in the fundamental chamber such that $\rho' = w(\rho)$. Thus defining S to be the set of all the W images of S' that lie in the fundamental chamber, the right-hand side of (4.2) can be written as

$$\sum_{\rho' bad} a_{\rho'}(t) x^{\rho'} + \sum_{\rho \in S} \sum_{w \in W} a_{\rho, w}(t) x^{w(\rho)} \tag{4.3}$$

where $a_{\rho, w}(t)$ are certain (easily computable) polynomials in t (some of which may be zero).

Substituting this into the right-hand side of (4.1) we get that the contribution from the first sum in (4.3) is zero (Crucial Lemma (ii)), and it follows from part (i) of the Crucial Lemma that

$$H_{k+1} = \sum_{\rho \in S} \sum_{w \in W} a_{\rho,w}(t)\ \text{C.T.}\ (x^{w(\rho)} G_k) = \sum_{\rho \in S} \left(\sum_{w \in W} a_{\rho,w}(t)\ \text{sgn}\ (w) \right) \text{C.T.}\ (x^{\rho} G_k). \tag{4.4}$$

Now for each $\rho \in S$, let

$$A_\rho(t) = \sum_{w \in W} a_{\rho,w}(t)\ \text{sgn}\ (w). \tag{4.5}$$

$A_\rho(t)$ is a certain explicitly computable polynomial in t. Going back to (4.4) we have

$$H_{k+1} = \sum_{\rho \in S} A_\rho(t)\ \text{C.T.}\ (x^{\rho} G_k). \tag{4.6}$$

One of the summands here is $\rho = \delta$, so we have expressed H_{k+1} in terms of C.T. $(x^{\delta} G_k) = H_k$ and a certain *finite* number of "neighboring coefficients." We have thus encountered the notorious "problem of uninvited guests" that crops up so often when trying to prove something by induction. One way out of this, the polite way, is to put up with these undesirable terms and conjecture that they too, have a certain explicit form, and then redo (4.6) to account for these as well (and cross our fingers that they will not bring in more undesirable terms). I do not see how to do it (at least not yet). The other way is the rude way. Get rid of these undesirable terms by expressing all of them in terms of the only term that we really care about: the one and only H_k.

5. Equations. This section will describe Stembridge's variation on an old trick in q-series, adapted to our needs. This trick converts a q-product in one variable $f(x)$ into a sum by computing $f(qx)/f(x)$. If this turns out to be a rational function, then cross-multiplying yields a functional equation relating $f(x)$ and $f(qx)$. By expanding $f(x)$ in a power series, this translates into a linear recurrence in the coefficients, that sometimes can be solved explicitly. However, attempting to use this method for multivariate products always produces a mess, unless we have antisymmetry on our side, and even then one has to be very careful.

So let us go to business. Using the definitions (3.2) and (3.5), we have

$$G_k(x) = x^{-\delta} \prod_{\alpha \in R^+} (x^{\alpha})_k (qx^{-\alpha})_{k-1}. \tag{5.1}$$

Recall that $x = (x_1, \cdots, x_l)$, $\alpha = (\alpha_1, \cdots, \alpha_l)$ and $x^{\alpha} = x_1^{\alpha_1} \cdots x_l^{\alpha_l}$. Define

$$f_\alpha(x) = (x^{\alpha})_k (qx^{-\alpha})_{k-1};$$

then if $\alpha_1 = 0$, $f_\alpha(x_1 \leftarrow qx_1) = f_\alpha(x)$, and in general (we assume, without loss of generality (see Introduction) that α has integer coordinates)

$$\frac{f_\alpha(x_1 \leftarrow qx_1)}{f_\alpha(x)} = \frac{(q^{\alpha_1} x^{\alpha})_k (q^{1-\alpha_1} x^{-\alpha})_{k-1}}{(x^{\alpha})_k (qx^{-\alpha})_{k-1}}. \tag{5.2}$$

Now by making all the $(\ )_k$ explicit and using telescoping, we easily obtain

$$\frac{f_\alpha(x_1 \leftarrow qx_1)}{f_\alpha(x_1)} = \frac{p_\alpha(x)}{q_\alpha(x)} \tag{5.3}$$

where, if $\alpha_1 > 0$,

$$\begin{aligned} p_\alpha(x) &= (1 - q^k x^{\alpha}) \cdots (1 - q^{k+\alpha_1 - 1} x^{\alpha}), \\ q_\alpha &= (q^{k-1} - x^{\alpha}) \cdots (q^{k-1} - q^{\alpha_1 - 1} x^{\alpha}), \end{aligned} \tag{5.4a}$$

and if $\alpha_1 < 0$,

$$\begin{aligned} p_\alpha(x) &= (q^{k-1} - q^{-1}x^\alpha) \cdots (q^{k-1} - q^{\alpha_1}x^\alpha), \\ q_\alpha(x) &= (1 - q^{k-1}x^\alpha) \cdots (1 - q^{k+\alpha_1}x^\alpha). \end{aligned} \tag{5.4b}$$

Since for all root-systems [C, pp. 47-49] $-2 \leqq \alpha_1 \leqq 2$, p_α, q_α, are at worst quadratic in x^α.

It follows from (5.3) and the definition (5.1) that

$$\frac{G_k(x_1 \leftarrow qx_1)}{G_k(x_1)} = q^{-\delta_1} \prod_{\alpha \in R^+} \frac{p_\alpha(x)}{q_\alpha(x)} = \frac{P(x, q^k, q)}{Q(x, q^k, q)}, \tag{5.5}$$

say, where P and Q are certain, explicitly computable, polynomials in $x = (x_1, \cdots, x_l)$, q^k and q.

Now, by cross-multiplying (5.5), we get the functional equation

$$Q(x)G_k(x_1 \leftarrow qx_1) = P(x)G_k(x). \tag{5.6}$$

Out of this functional equation we can get many linear equations relating various coefficients of G_k. For any vector β in the lattice generated by R, we will get a linear equation E_β, involving coefficients C.T. $(x^\gamma G_k)$ for γ in a certain set of vector exponents $Ex(\beta)$, that is contained in the fundamental chamber.

The way to do this is to first multiply both sides of (5.6) by x^β and then apply the functional C.T.

$$\text{C.T.}\,[x^\beta Q(x)G_k(x_1 \leftarrow qx_1)] = \text{C.T.}\,[x^\beta P(x)G_k(x)]. \tag{5.7}$$

We now plug into (5.7) the expanded form of P and Q (remember that P and Q are certain explicit polynomials that we have to compute in order to perform the algorithm). Then we use the linearity of C.T. and get on the right-hand side a linear combination of creatures of the form C.T. $[x^\gamma G_k]$. On the left-hand side we get a linear combination of entities of the form C.T. $[x^\gamma G_k(x_1 \leftarrow qx_1)]$. These should be converted to the previous form using the obvious relation

$$\text{C.T.}\,[x^\gamma G_k(x_1 \leftarrow qx_1)] = q^{-\gamma_1}\,\text{C.T.}\,[x^\gamma G_k]. \tag{5.8}$$

We now use the Crucial Lemma, discarding all the "bad" γ, i.e., those that are orthogonal to a root, and for any good γ' that is not in the fundamental chamber we find the unique $w \in W$ and γ in the fundamental chamber such that $\gamma' = w(\gamma)$ and rewrite C.T. $[x^{\gamma'} G_k]$ as sgn (w) C.T. $[x^\gamma G_k(x)]$. Then we collect all the terms and bring them to the left-hand side and get a certain linear equation

$$E_\beta\colon \quad \sum a_\gamma(q^k, q)\,\text{C.T.}\,(x^\gamma G_k) = 0 \tag{5.9}$$

where the sum is over a *finite* set $Ex(\beta)$ of exponents γ that lie in the fundamental chamber.

By a judicious choice of β we would hopefully obtain equations that only involve those $\rho \in S$ that feature in (4.6). Hopefully there would be $|S| - 1$ such independent equations. (Of course it would also be all right if we could say the same thing about some set that contains S.) By a proper choice of β it is always possible to get an equation that involves C.T. $(x^\delta G_k) = H_k$.

Solving this system of $|S| - 1$ homogeneous equations, at least one of which involves H_k, we should be able to express all the unknowns as H_k times some rational function in q^k and q. This is so since the coefficients in the system are polynomials in q^k and q. We have thus found explicit expressions for all the terms that feature in (4.6) in

terms of H_k, and plugging them in we will get H_{k+1}/H_k, a certain rational function in q^k and q. Calling the conjectured value of H_k by the name of R_k (R_k is the right-hand side of (qM) divided by (3.11)), we can then compare H_{k+1}/H_k with R_{k+1}/R_k. Since obviously $H_1 = R_1$, the fate of (qM) will be determined by whether or not H_{k+1}/H_k is equal to R_{k+1}/R_k.

6. Implementation. This can be, and has been, implemented on a computer. The input is the root system R, and it is necessary to know the Weyl group W (this is given in the *planches* of [Bo]). It is very easy to write a routine to check whether a given vector is a *bad guy* (just do-loop the inner product along R^+). Then you need to write a Weyl-sorting routine that given any good vector in the root-lattice finds its image in the fundamental chamber and the sign of the element w in W that sends it there. Of course you also need a polynomial multiplication routine (which you can easily jot down yourself, no need for MACSYMA). This is enough to produce (4.6) and the $P(x)$ and $Q(x)$ of (5.5).

Now comes the creative part, experimenting with various β's that will give an equation E_β that involves the relevant coefficients that feature in (4.6). For those root systems for which $-1 \leqq \alpha_1 \leqq 1$ (most of them) the choice $\beta = -\delta$ will produce a tautology: $0 = 0$, because the only survivor, after applying part (ii) of the Crucial Lemma, is C.T. $[x^\delta G_k] = H_k$. It is thus likely that for β near $-\delta$ we will get relatively few terms.

Once you have $|S| - 1$ independent equations you solve them and plug the solutions into (4.6). You will never have to see (or print out) the solutions of the system (5.9), because it can all be done internally (in MACSYMA this amounts to finishing your lines with dollar signs rather than with semicolons). You will not even have to see or print out the resulting rational function H_{k+1}/H_k obtained by plugging in the solutions of the system (5.9) into (4.6).

All you have to do is enter the rational function R_{k+1}/R_k (you can even write a routine for that) and ask the computer to output the difference between these two rational functions. If you get ZERO then you have proved (qM) for your particular root system. If you get something else then you have *disproved* (qM). Either that or (more likely), you have made an error somewhere.

7. A_2. The new method will now be illustrated on the simplest nontrivial case, the root system A_2. Of course this case is already well known, even classical (it is equivalent to Jackson's q-Dixon identity [An1]), and the proof that we present here is perhaps the longest and ugliest ever. But in order to learn how to use machine guns to kill elephants one should first practise on flies. Another reason for doing the A_2 case is that its results will be needed in § 9, when we do G_2^ν, and this will make the paper self-contained. The present example is simple enough that it can be done by hand, and the reader is encouraged to check all the steps and to supply all the details.

Equation (qM) says, in its equivalent formulation derived in § 3, that if

$$F_k = \left(\frac{x_1}{x_2}\right)_k \left(\frac{x_1}{x_3}\right)_k \left(\frac{x_2}{x_3}\right)_k \left(q\frac{x_2}{x_1}\right)_{k-1} \left(q\frac{x_3}{x_1}\right)_{k-1} \left(q\frac{x_3}{x_2}\right)_{k-1},$$

$$H_k = \text{C.T. } F_k$$

and

$$R_k = \frac{(q)_{3k-1}}{(q)_{k-1}^2 (q)_k (1-q^{2k})},$$

then $H_k = R_k$.

To get R_k from $R'_k=(q)_{3k}/(q)_k^3$ we used (3.3) with the fundamental invariants 2, 3 of A_2. A list of the fundamental invariants for all finite irreducible root systems can be found for example in the excellent appendices of [Bo], as well as in [C, p. 155].

Now a routine calculation shows that ($t=q^k$),

$$\frac{R_{k+1}}{R_k}=\frac{(1+t+t^2)(1-qt^3)(1-q^2t^3)(1+t)}{(1-qt)(1-q^2t^2)}. \tag{7.1}$$

Now it is easily checked that $R_1=1$ and $H_1=1$, so all we have to do is verify that H_{k+1}/H_k is equal to R_{k+1}/R_k. So let us compute H_{k+1}/H_k.

For A_2 we have (e.g., [Bo, p. 250] or [C, p. 46])

$$A_2^+=\{(1,-1,0);(1,0,-1);(0,1,-1)\}.$$

$\delta=(1,0,-1)$, and the Weyl group W is S_3, the symmetric group on three elements that acts by permuting the coordinates of $(\gamma_1,\gamma_2,\gamma_3)$ for γ in the root lattice. The bad guys are those vectors that have two of their coordinates equal.

Now we do (4.2), namely we expand

$$\frac{x_1}{x_3}\left(1-t\frac{x_1}{x_2}\right)\left(1-t\frac{x_2}{x_1}\right)\left(1-t\frac{x_1}{x_3}\right)\left(1-t\frac{x_3}{x_1}\right)\left(1-t\frac{x_2}{x_3}\right)\left(1-t\frac{x_3}{x_2}\right).$$

Discarding the bad guys, grouping the good guys into orbits under S_3, as in (4.3), plugging into (4.1) and using the Crucial Lemma yields, like in (4.4)-(4.6) (set $A(\rho)=\text{C.T.}[x^\rho G_k]$),

$$\begin{aligned}H_{k+1}=&(1+2t+3t^2+3t^3+3t^4+2t^5+t^6)A(1,0,-1)\\&-(t+t^2+2t^3+t^4+t^5)A(2,0,-2)\\&+(t^2+t^3+t^4)A(2,1,-3)+(t^2+t^3+t^4)A(3,-1,-2)-t^3A(3,0,-3).\end{aligned} \tag{7.2}$$

Thus, $S=\{(1,0,-1),(2,0,-2),(2,1,-3),(3,-1,-2),(3,0,-3)\}$, and we need to find four independent equations relating $\{A(\rho);\rho\in S\}$.

Now (5.3) becomes

$$\frac{f_{1-10}(qx_1,x_2,x_3)}{f_{1-10}(x_1,x_2,x_3)}=\frac{\left(1-q^k\frac{x_1}{x_2}\right)}{\left(q^{k-1}-\frac{x_1}{x_2}\right)},\qquad \frac{f_{10-1}(qx_1,x_2,x_3)}{f_{10-1}(x_1,x_2,x_3)}=\frac{\left(1-q^k\frac{x_1}{x_3}\right)}{\left(q^{k-1}-\frac{x_1}{x_3}\right)},$$

and (5.5) becomes ($\delta_1=1$),

$$\frac{G_k(qx_1,x_2,x_3)}{G_k(x_1,x_2,x_3)}=q^{-1}\frac{\left(1-q^k\frac{x_1}{x_2}\right)\left(1-q^k\frac{x_1}{x_3}\right)}{\left(q^{k-1}-\frac{x_1}{x_2}\right)\left(q^{k-1}-\frac{x_1}{x_3}\right)},$$

and (5.6) becomes

$$q\left(q^{k-1}-\frac{x_1}{x_2}\right)\left(q^{k-1}-\frac{x_1}{x_3}\right)G_k(qx_1,x_2,x_3)=\left(1-q^k\frac{x_1}{x_2}\right)\left(1-q^k\frac{x_1}{x_3}\right)G_k(x_1,x_2,x_3)$$

and multiplying out yields

$$\begin{aligned}&\left(q^{2k-1}-q^k\frac{x_1}{x_2}-q^k\frac{x_1}{x_3}+q\frac{x_1^2}{x_2x_3}\right)G_k(qx_1,x_2,x_3)\\&\quad=\left(1-q^k\frac{x_1}{x_2}-q^k\frac{x_1}{x_3}+q^{2k}\frac{x_1^2}{x_2x_3}\right)G_k(x_1,x_2,x_3).\end{aligned} \tag{7.3}$$

Experimenting with various β yields that $(0,1,-1)$, $(1,0,-1)$, $(0,2,-2)$, and $(1,1,-2)$ produce the desired equations (of course there are many other choices of β that will do). For each of these β, multiplying both sides of (7.3) by x^{β}, using (5.8) and the Crucial Lemma yields the equations:

$$E_{(0,1,-1)}\colon (1-q^{2k-1}-q^{k-1}+q^{k})A(1,0,-1)+(q^{-1}-q^{2k})A(2,0,-2)=0,$$

$$E_{(1,0,-1)}\colon (1-q^{2k-2})A(1,0,-1)+(q^{k-2}-q^{k})A(2,0,-2)+(q^{2k}-q^{-2})A(3,-1,-2)=0,$$

$$E_{(0,2,-2)}\colon (1-q^{2k-1})A(2,0,-2)+(q^{-1}+q^{k-1}-q^{k}-q^{2k})A(2,1,-3)=0,$$

$$E_{(1,1,-2)}\colon (q^{k-2}-q^{k})A(2,0,-2)+(q^{k-2}-q^{k})A(2,1,-3)+(q^{2k}-q^{-2})A(3,0,-3)=0.$$

Solving this system we get $(t=q^{k})$ (recall that $A(1,0,-1)=H_k$),

$$A(2,0,-2)=\frac{(t-q)(1-t^2)}{(1-t)(1-qt^2)}H_k,$$

$$A(3,-1,-2)=A(2,1,-3)=\frac{(q-t)(q-t^2)}{(1-qt)(1-qt^2)}H_k, \tag{7.4}$$

$$A(3,0,-3)=\frac{-t(1-q^2)(q-t)(1-q)(1-t^3)}{(1-qt)(1-qt^2)(1-q^2t^2)(1-t)}H_k.$$

This much was done by hand. Now using MACSYMA we can plug it all into (7.2) and get H_{k+1}/H_k. Then we subtract it from R_{k+1}/R_k given in (7.1). The answer is indeed zero and we have just proved (qM) for A_2.

Now that we know that H_k is indeed equal to what it is supposed to be, namely to R_k, we can plug that expression into (7.4) and get as a lagnappe explicit expressions for $A(2,0,-2)=A_k(2,0,-2)=\text{C.T.}[x_1^2x_3^{-2}G_k]=\text{C.T.}[x_1x_3^{-1}F_k]$, etc. This will be needed in § 9.

8. Modifications. Our method can be easily adapted to the more refined Macdonald–Morris conjectures (qM-M1) and (qM-M2). In fact, because of the added parameter it is even computationally faster. We will only treat (qM-M2), since (qM-M1) is just a special case of (qM-M2) ((qM-M1) corresponds to the $S(R)$ cases for which it is well known [Ma1], [Mo] that $u_\alpha\equiv 1$). It is also well known (for example from the classification theorem for finite root systems [Bo], [C] that all the irreducible reduced finite root systems have either just one root length (A_n, D_n, E_6, E_7, and E_8) or two root lengths (B_n, C_n, G_2, and F_4). The only nonreduced irreducible finite root systems, BC_n, have three different root lengths. Since (qM-M2) reduces to (qM) for all the single-length root systems, we will assume that the root systems have two root lengths, short and long, and leave it to the reader to do the appropriate obvious modifications for BC_n.

So let us rewrite (qM-M2) for two-lengths root systems. Denoting k_{short} by a, k_{long} by b, u_{short} by u_s, and u_{long} by u_l, we have

$$\text{(qM-M2')}\quad \text{C.T.}\left\{\prod_{\alpha\in R^+_{\text{short}}}(x^{\alpha};q^{u_s})_a(q^{u_s}x^{-\alpha};q^{u_s})_a\prod_{\alpha\in R^+_{\text{long}}}(x^{\alpha};q^{u_l})_b(q^{u_l}x^{-\alpha};q^{u_l})_b\right\}$$

$$=\text{a certain explicit product.}$$

The right-hand side can be looked up in [Ma3] or [Mo, pp. 25–26]. Its exact form is irrelevant for the purposes of the present method whose modest aim is to prove (qM-M2) for one root-system *at a time*, and as such does not care to look at the general pattern. Besides, the method should be able to compute the constant term in question *from scratch* and it is dishonest to "peek at the answer." In any case, for any specific root-system, it is possible to look up the explicit conjectured right-hand side from [Mo].

So let us call the polynomial inside the braces of (qM-M2′) $F'_{a,b}(x)$. We are interested in evaluating

$$H'_{a,b} = \text{C.T. } F'_{a,b}(x). \tag{8.1}$$

In analogy with § 3, we will consider instead

$$F_{a,b}(x) = \prod_{\alpha \in R^+_{\text{short}}} (x^\alpha; q^{u_s})_a (q^{u_s} x^{-\alpha}; q^{u_s})_{a-1} \prod_{\alpha \in R^+_{\text{long}}} (x^\alpha; q^{u_l})_b (q^{u_l} x^{-\alpha}; q^{u_l})_{b-1},$$

$$H_{a,b} = \text{C.T. } F_{a,b}(x).$$

Since the Weyl group W acts separately on the long roots and the short roots (as is obvious from the fact that the elements of W are isometries), the calculation of (3.3) can be carried verbatim to show that

$$G_{a,b}(x) =: x^{-\delta} F_{a,b}(x) \tag{8.2}$$

is antisymmetric.

For w in the Weyl group W let $n_s(w) = |w(R^+_{\text{short}}) \cap R^-|$ and $n_l(w) = |w(R^+_{\text{long}}) \cap R^-|$ (so $n(w) = n_s(w) + n_l(w)$). Define

$$W(t, s) = \sum_{w \in W} t^{n_s(w)} s^{n_l(w)}, \tag{8.3}$$

which for a fixed root system (and therefore a fixed Weyl group) is a specific polynomial. Macdonald [Ma2] has a wonderful formula for $W(t, s)$ as a product that is indexed over the positive roots (for $t = s$ it reduces to (3.11)), but it is not really needed for our present narrow-minded purposes.

A completely analogous argument to that of § 3 (only now we keep track of the short and long roots separately, with their respective parameters t and s) yields

$$H'_{a,b} = H_{a,b} W(q^{au_s}, q^{bu_l}). \tag{8.4}$$

We now want to evaluate

$$H_{a,b} = \text{C.T. } [x^\delta G_{a,b}].$$

The difference now is that we have two parameters a and b rather than the single parameter k. The induction step is similar to that described in § 4 only now we induct with respect to either a *or* b (I prefer a). Unlike the previous case where the base case was trivial, now $a = 1$ is no longer trivial but is essentially the (qM) conjecture for the subroot system consisting of the long roots

$$H_{1,b} = \text{C.T. } F_{1,b}(x)$$

where

$$F_{1,b}(x) = \prod_{\alpha \in R^+_{\text{short}}} (1 - x^\alpha) \prod_{\alpha \in R^+_{\text{long}}} (x^\alpha; q^{u_l})_b (q^{u_l} x^{-\alpha}; q^{u_l})_{b-1}. \tag{8.5}$$

Expanding

$$\prod_{\alpha\in R^+_{\text{short}}}(1-x^\alpha),$$

we can express $H_{1,b}$ as a certain linear combination of various coefficients of

$$\hat{F}_b(x):=\prod_{\alpha\in R^+_{\text{long}}}(x^\alpha;q^{u_l})_b(q^{u_l}x^{-\alpha};q^{u_l})_{b-1}.$$

Thus before we can embark on (qM-M2) for R we must do first (qM) for the subroot system R_{long} and find not only the constant term of $\hat{F}_b(x)$ but also some neighboring coefficients. It can be easily shown that these coefficients are among those "lagnappes" that we got anyway in system (5.9). For example, the long roots of G_2 constitute the root system A_2, and when we do G_2^ν in the next section we will use the A_2 information obtained in § 7. Similarly, before we can do F_4 we must do D_4, etc.

Having established the base case $a=1$, § 4 passes almost verbatim: (4.1) becomes

$$H_{a+1,b}=\text{C.T.}\,[x^\delta G_{a+1,b}(x)]=\text{C.T.}\left[x^\delta\prod_{\alpha\in R_{\text{short}}}(1-q^{au_s}x^\alpha)G_{a,b}\right] \tag{8.6}$$

and (4.6) becomes ($t=q^{au_s}$)

$$H_{a+1,b}=\sum_{\rho\in S}A_\rho(t)\,\text{C.T.}\,[x^\rho G_{a,b}]. \tag{8.7}$$

Now comes the analogue of § 5. We have to be a little careful because $G_{a,b}(x_1\leftarrow qx_1)/G_{a,b}(x)$ may not be a rational function. Instead we look for vectors of integers $z=(z_1,\cdots,z_n)$ such that

$$\frac{G_k(q^{z_1}x_1,\cdots,q^{z_n}x_n)}{G_k(x_1,\cdots,x_n)} \tag{8.8}$$

is a rational function. This can be achieved if u_s divides (α,z) for every short root α, and u_l divides (α,z) for every long α. Of course we will try to choose z in such a way that the rational function (8.8) is as simple as possible (in the next section $z=(2,1,0)$).

In analogy with § 5 we define

$$f_\alpha(x)=(x^\alpha;q^{u_\alpha})_{k_\alpha}(q^{u_\alpha}x^{-\alpha};q^{u_\alpha})_{k_\alpha-1}$$

where $k_\alpha=a$, $u_\alpha=u_s$ if α is short and $k_\alpha=b$ and $u_\alpha=u_l$ if α is long.

In analogy with (5.2) we have

$$\frac{f_\alpha(q^{z_1}x_1,\cdots,q^{z_n}x_n)}{f_\alpha(x_1,\cdots,x_n)}=\frac{(q^{(z,\alpha)}x^\alpha;q^{u_\alpha})_{k_\alpha}(q^{u_\alpha-(z,\alpha)}x^{-\alpha};q^{u_\alpha})_{k_\alpha-1}}{(x^\alpha;q^{u_\alpha})_{k_\alpha}(q^{u_\alpha}x^{-\alpha};q^{u_\alpha})_{k_\alpha-1}}.$$

So if we replace

$$q\leftarrow q^{u_\alpha},\qquad \alpha_1\leftarrow(z,\alpha)/u_\alpha,\qquad k\leftarrow k_\alpha$$

then (5.3) and (5.4) are still true. Equation (5.5) now becomes

$$\frac{G_{a,b}(q^{z_1}x_1,\cdots,q^{z_n}x_n)}{G_{a,b}(x_1,\cdots,x_n)}=q^{-(\delta,z)}\prod_{\alpha\in R^+}\frac{p_\alpha(x)}{q_\alpha(x)}=\frac{P}{Q} \tag{8.9}$$

where P and Q are explicitly computable polynomials in x, q, t, and s where $t=q^{au_s}$; $s=q^{bu_l}$.

Equations (5.6) and (5.7) are still true but with $G_k(x_1 \leftarrow qx_1)$ replaced by $G_k(q^{z_1}x_1, \cdots, q^{z_n}x_n)$ and instead of (5.8) we need

$$\text{C.T.}[x^\gamma G_{a,b}(q^{z_1}x_1, \cdots, q^{z_n}x_n)] = q^{-(\gamma,z)}\,\text{C.T.}[x^\gamma G_{a,b}]. \tag{8.10}$$

This follows from

$$\text{C.T.}[x^\gamma G_{a,b}(q^{z_1}x_1, \cdots, q^{z_n}x_n)]$$
$$= q^{-(\gamma,z)}\,\text{C.T.}[(q^{z_1}x_1)^{\gamma_1}\cdots(q^{z_n}x_n)^{\gamma_n}\cdots G_{a,b}(q^{z_1}x_1, \cdots, q^{z_n}x_n)]$$

and the fact that C.T. is unaffected by scaling.

Everything is as before; the only difference is that in (5.9) the coefficients a_γ depend on (t, s, q) where $t = q^{au_s}$ and $s = q^{bu_l}$, i.e.,

$$E_\beta\colon \quad \sum a_\gamma(t, s, q)\,\text{C.T.}[x^\gamma G_{a,b}] = 0. \tag{8.11}$$

Everything else translates smoothly. Solving the system we will express all the coefficients that feature in (8.7) as certain rational functions in (q, t, s) times $\text{C.T.}[x^\gamma G_{a,b}] = H_{a,b}$. Substituting the solutions thus obtained into (8.7) will give us the rational function $H_{a+1,b}/H_{a,b}$. Since we already have a formula for $H_{1,b}$ this easily yields a formula for $H_{a,b}$. Alternatively, if we believe that the conjectured value for $H_{a,b}$, let us call it $R_{a,b}$, has a good chance of being correct then all we have to do is look up $R'_{a,b}$ (the conjectured right-hand side of (qM-M2)) in [Mo] and then compute $R_{a,b}$ by dividing $R'_{a,b}$ by $W(q^{au_s}, q^{bu_l})$ of (8.3). We then compute $R_{a+1,b}/R_{a,b}$ (a rational function in (q, t, s)). Assuming that we have already checked that $H_{1,b} = R_{1,b}$, the status of the conjecture (qM-M2) for the particular root-system in question is determined by whether or not $H_{a+1,b}/H_{a,b} - R_{a+1,b}/R_{a,b}$ is zero or not.

9. G_2^ν.

THEOREM (G_2^ν case of (qM-M2)). *The constant term of*

$$F'_{a,b}(x, y, z) := \left(\frac{x}{y}; q\right)_a \left(\frac{z}{y}; q\right)_a \left(\frac{z}{x}; q\right)_a \left(\frac{z^2}{xy}; q^3\right)_b \left(\frac{xz}{y^2}; q^3\right)_b \left(\frac{yz}{x^2}; q^3\right)_b$$
$$\cdot \left(q\frac{y}{x}; q\right)_a \left(q\frac{y}{z}; q\right)_a \left(q\frac{x}{z}; q\right)_a \left(q^3\frac{xy}{z^2}; q^3\right)_b \left(q^3\frac{y^2}{xz}; q^3\right)_b \left(q^3\frac{x^2}{yz}; q^3\right)_b$$

is equal to

$$R'_{a,b} := \frac{(q;q)_{3a+3b}(q;q)_{3b}(q;q)_{2a}(q^3;q^3)_{a+3b}(q^3;q^3)_{2b}(q^3;q^3)_a}{(q;q)_{2a+3b}(q;q)_{a+3b}(q;q)_a^2(q^3;q^3)_{a+2b}(q^3;q^3)_{a+b}(q^3;q^3)_b^2}.$$

In this explict form the conjecture appears in Morris' thesis [Mo, p. 139]. It is alluded to in [As3, § 5, fifth sentence] and is mentioned explicitly in [As4].

From [Bo, pp. 274–275] or [Mo] or [C], $G_2^+ = \{(1, -1, 0), (0, -1, 1), (-1, 0, 1), (-1, -1, 2), (1, -2, 1), (-2, 1, 1)\}$; $\delta = (-1, -2, 3)$, and the Weyl group is the dihedral group of order 12, that is the direct product of S_3 with $\{I, -I\}$, where I denotes the identity mapping and $-I(\alpha, \beta, \gamma) = (-\alpha, -\beta, -\gamma)$. (It is a very instructive exericise for you to obtain the Weyl group yourself.) The bad guys are the vectors of integers $(\alpha_1, \alpha_2, \alpha_3)$ in which two coordinates are equal (those that are orthogonal to one of the short roots) and those vectors of integers in which one component is zero (those orthogonal to one of the long roots; recall that for all vectors in the root-lattice the sum of the components is zero).

A direct calculation shows that $W(t, s)$ of (8.3) is given by

$$W(t, s) = 1 + t + s + 2ts + ts^2 + t^2s + 2t^2s^2 + t^3s^2 + t^2s^3 + t^3s^3. \tag{9.1}$$

(For example -231 sends $(1,-1,0)$ to $(1,0,-1)$, a negative root; $(0,-1,1)$ goes to $(1,-1,0)$, a positive root; $(-1,0,1)$ goes to $(0,-1,1)$ a positive root; so $n_s(-231) = |(-231)(R^+) \cap R^-| = |\{(1,0,-1)\}| = 1$. Similarly, $n_l(-231) = 1$ and so -231 gives a contribution of ts to the sum of (8.3).)

$W(t, s)$ factorizes nicely, namely

$$W(t,s) = (1+t)(1+s)(1+ts+t^2s^2) \tag{9.2}$$

(compare [Ma2, p. 168]).

So with the notation of § 8 it follows from (8.4) that ($u_s = 1$, $u_l = 3$, $t = q^a$, $s = q^{3b}$)

$$H_{a,b} = \frac{H'_{a,b}}{(1+q^a)(1+q^{3b})(1+q^{a+3b}+q^{2a+6b})}$$

and the theorem will be proved if we can show that $H_{a,b} = R_{a,b}$ where $R_{a,b} = R'_{a,b}/W(q^a, q^{3b})$.

A simple calculation gives that

$$R_{a,b} = \frac{(q;q)_{3a+3b}(q;q)_{3b}(q;q)_{2a-1}(q^3;q^3)_{a+3b-1}(q^3;q^3)_{2b-1}(q^3;q^3)_a}{(q;q)_{2a+3b}(q;q)_{a+3b-1}(q;q)_a(q;q)_{a-1}} \cdot (q^3;q^3)_{a+2b}(q^3;q^3)_{a+b}(q^3;q^3)_b(q^3;q^3)_{b-1}. \tag{9.3}$$

A routine calculation gives ($t = q^a$, $s = q^{3b}$)

$$R_{a+1,b}/R_{a,b} = \frac{(1-qt^3s)(1-q^2t^3s)(1-t^2)(1-qt^2)(1-t^3s^3)(1-q^3t^3)}{(1-qt^2s)(1-q^2t^2s)(1-ts)(1-qt)(1-t)(1-q^3t^3s^2)}. \tag{9.4}$$

So let

$$\begin{aligned} F_{a,b}(x) = &\left(\frac{x}{y};q\right)_a \left(\frac{z}{y};q\right)_a \left(\frac{z}{x};q\right)_a \left(\frac{z^2}{xy};q^3\right)_b \left(\frac{xz}{y^2};q^3\right)_b \left(\frac{yz}{x^2};q^3\right)_b \\ &\cdot \left(q\frac{y}{x};q\right)_{a-1} \left(q\frac{y}{z};q\right)_{a-1} \left(q\frac{x}{z};q\right)_{a-1} \\ &\cdot \left(q^3\frac{xy}{z^2};q^3\right)_{b-1} \left(q^3\frac{y^2}{xz}q^3\right)_{b-1} \left(q^3\frac{x^2}{yz};q^3\right)_{b-1}, \end{aligned} \tag{9.5}$$

$$H_{a,b} = \text{C.T. } F_{a,b}.$$

We must show that $H_{a,b} = R_{a,b}$. This will be done by induction on a. First we must prove the base case $H_{1,b} = R_{1,b}$.

Proof of the base case $a = 1$. Substituting $a = 1$ in $R_{a,b}$ given in (9.3) and setting $Q = q^3$ gives

$$R_{1,b} = \frac{(Q)_{3b}}{(Q)_b^3} \frac{(1-Q^b)(1-Q)}{(1-Q^{2b})(1-Q^{2b+1})}. \tag{9.6}$$

We will need the A_2 results proved in § 7. For our present purposes it is convenient to rewrite it in the "fundamental roots" form (sometimes used by Morris [Mo]) obtained by setting $u_1 = x_1/x_2$ and $u_2 = x_2/x_3$. Also let us replace q by Q (so everything is to base Q: $(u_1)_b = (u_1;Q)_b$, etc).

Let $\hat{F}_b$ be defined by

$$\hat{F}_b = (u_1)_b(u_2)_b(u_1u_2)_b(Q/u_1)_{b-1}(Q/u_2)_{b-1}(Q/u_1u_2)_{b-1}. \tag{9.7}$$

Then the results from § 7 that we need here are

$$\text{C.T. } \hat{F}_b = \frac{(Q)_{3b-1}}{(Q)_{b-1}^2 (Q)_b (1-Q^{2b})} \tag{9.8a}$$

and from (7.4) ($A(2, 0, -2)$)

$$\text{C.T. } (u_1 u_2 \hat{F}_b) = \frac{(Q^b - Q)(1+Q^b)}{(1-Q^{2b+1})} (\text{C.T. } \hat{F}_b). \tag{9.8b}$$

Now we want $H_{1,b} = \text{C.T. } F_{1,b}$, where (plug in $a=1$ in (9.5)),

$$F_{1,b} = (1-x/y)(1-z/y)(1-z/x) \cdot \left(\frac{z^2}{xy}; q^3\right)_b \left(\frac{xz}{y^2}; q^3\right)_b \left(\frac{yz}{x^2}; q^3\right)_b \left(q^3 \frac{xy}{z^2}; q^3\right)_{b-1} \left(q^3 \frac{y^2}{xz}; q^3\right)_{b-1} \left(q^3 \frac{x^2}{yz}; q^3\right)_{b-1}.$$

Now let $u_1 = xz/y^2$, $u_2 = yz/x^2$. Then

$$\frac{x}{y} = u_1^{1/3} u_2^{-1/3}, \qquad \frac{z}{y} = u_1^{2/3} u_2^{1/3}, \qquad \frac{z}{x} = u_1^{1/3} u_2^{2/3},$$

and then if we take $Q = q^3$,

$$F_{1,b} = (1 - u_1^{1/3} u_2^{-1/3})(1 - u_1^{2/3} u_2^{1/3})(1 - u_1^{1/3} u_2^{2/3}) \hat{F}_b.$$

So

$$H_{1,b} = \text{C.T. } [1 - u_1^{1/3} u_2^{-1/3} - u_1^{1/3} u_2^{2/3} + u_1 + u_1 u_2 - u_1^{4/3} u_2^{2/3}] \hat{F}_b = \text{C.T. } [(1+u_1 u_2) \hat{F}_b].$$

(u_1 corresponds to the vector $(1, -1, 0) + \delta = (1, -1, 0) + (1, 0, -1) = (2, -1, -1)$, a bad guy (for A_2), and all other terms are even worse: they are fractional. Their contribution is of course zero since $\hat{F}_b$ does not have any terms with fractional exponents, being a Laurent *polynomial.*)

Using (9.8a) and (9.8b) we get

$$H_{1,b} = \left[1 + \frac{(Q^b - Q)(1+Q^b)}{(1-Q^{2b+1})}\right] \frac{(Q)_{3b-1}}{(Q)_{b-1}^2 (Q)_b (1-Q^{2b})}, \tag{9.9}$$

which after a routine calculation turns out to be equal to $R_{1,b}$ in (9.6) (end of proof of the base case $a=1$). □

Proof of the inductive step. Now that we know that $H_{a,b} = R_{a,b}$ for $a=1$ we go next to the inductive step.

For the root system G_2, δ, one-half the sum of the positive roots, is equal to $(-1, -2, 3)$, and (8.6) becomes (recall $t = q^a$)

$$\begin{aligned} H_{a+1,b} &= \text{C.T. } [x^{-1} y^{-2} z^3 G_{a+1,b}] \\ &= \text{C.T. } [x^{-1} y^{-2} z^3 (1-tx/y)(1-tz/y)(1-tz/x) \\ &\qquad \cdot (1-ty/x)(1-ty/z)(1-tx/z) G_{a,b}]. \end{aligned} \tag{9.10}$$

We now expand

$$x^{-1} y^{-2} z^3 (1-tx/y)(1-tz/y)(1-tz/x)(1-ty/x)(1-ty/z)(1-tx/z),$$

discard all the bad guys and collect all the good guys into orbits under W. We then substitute everything back into (9.10) and use the Crucial Lemma, and then finally we

collect terms. (I highly recommend that the reader check this either by hand or by machine, there are only $2^6 = 64$ terms in the expansion.)

We get for (8.7)

$$\begin{aligned} H_{a+1,b} &= (1+t+t^2+t^4+t^5+t^6)\ \text{C.T.}\,[x^{-1}y^{-2}z^3 G_{a,b}] \\ &\quad -(t+t^3+t^5)\ \text{C.T.}\,[x^{-1}y^{-3}z^4 G_{a,b}] \\ &\quad +(t^2+t^3+t^4)\ \text{C.T.}\,[x^{-2}y^{-3}z^5 G_{a,b}] - t^3\ \text{C.T.}\,[x^{-1}y^{-4}z^5 G_{a,b}]. \end{aligned} \tag{9.11}$$

In preparation for the MACSYMA *input file* given below let us put

$$\begin{aligned} x0 &= \text{C.T.}\,[x^{-1}y^{-2}z^3 G_{a,b}]/H_{a,b} \equiv 1 \quad \text{(by definition)}, \\ x1 &= \text{C.T.}\,[x^{-1}y^{-3}z^4 G_{a,b}]/H_{a,b}, \\ x2 &= \text{C.T.}\,[x^{-2}y^{-3}z^5 G_{a,b}]/H_{a,b}, \\ x3 &= \text{C.T.}\,[x^{-1}y^{-4}z^5 G_{a,b}]/H_{a,b}. \end{aligned}$$

With $p0$, $p1$, $p2$, $p3$ as defined in the *input file* below, (9.11) becomes

$$H_{a+1,b}/H_{a,b} = p0*x0 + p1*x1 + p2*x2 + p3*x3 \tag{9.12}$$

and we will call this "sum" in the *input file* below.

Finally we need linear equations relating $x0$, $x1$, $x2$, and $x3$. The simplest vector $z = (z_1, z_2, z_3)$ that makes (8.8) a rational function is $(2, 1, 0)$. Now (8.9) becomes

$$\frac{G_{a,b}(q^2x, qy, z)}{G_{a,b}(x, y, z)} = \frac{P}{Q}$$

where P and Q are computed using (5.3) and (5.4) as modified in § 8 before (8.9). Proceeding as described in § 6 (I used a computer but it is possible to do it by hand) we get the following results. ($a00, \cdots, a23$ are given in the MACSYMA *input file* below.) The choice $\beta = (2, 2, -4)$ yields

$$E_{(2,2,-4)}: \quad a00*x0 + a01*x1 = 0;$$

$\beta = (0, 3, -3)$ yields

$$E_{(0,3,-3)}: \quad a10*x0 + a11*x1 + a12*x2 = 0;$$

and $\beta = (4, 0, -4)$ yields

$$E_{(4,0,-4)}: \quad a20*x0 + a21*x1 + a22*x2 + a23*x3 = 0.$$

(A copy of the *C* program that implements the algorithm of § 5, modified as in § 8, by which I obtained the above equations, is available upon request (either a printout by U.S. mail or by electronic mail; sorry, no disks). However it is highly recommended that the readers write their own programs. It is much easier to write your own code than to try to understand somebody else's computer scratch.)

```

In the *input file* we solve for $x1, x2, x3$ successively. Then we ask MACSYMA to compute "sum" $= H_{a+1,b}/H_{a,b}$. We enter $R_{a+1,b}/R_{a,b}$ given in (9.4) and call it "rhs." So far every line has been terminated with a dollar sign so that the partial steps are not going to be printed out. The second line from the bottom is

$$sum: sum - rhs\$$$

that defines the new "sum" to be the difference between the conjectured right-hand side and the real right-hand side. This should be zero if the conjecture is true. The last line asks MACSYMA to simplify this difference: *ratsimp*(*sum*); and now, finally, there is a semicolon, because now we *do* want to see the answer.

On December 22, 1986, 3:30 p.m., after two previous unsuccessful attempts (due to typing errors that were presently detected), I typed on my terminal:

$$macsyma < inputfile$$

After a few minutes came the output: 27 blank double lines (due to the dollar signs) and

$(c28)$
$(d28)$ 0

YEA!!!

□

10. Prospects. The next in line is F_4. But before we can do F_4, we must do D_4, the short part of F_4. A preliminary calculation done by Dave Robbins shows that for D_4, (4.6) involves more than one hundred terms. So we will have to find and solve a system of more than one hundred linear equations with rather complicated coefficients. While this is still within the reach of current computers, it is hard to justify that kind of expense before all other means have been exhausted.

As I have already mentioned, the reason why the Macdonald-Morris conjectures (qM-M2) are easier than the original Macdonald conjectures (qM), is that the two parameters let us break the problem into two subproblems. In a way we are first doing the long roots and only then the short roots. But nowhere in § 8 have we ever used the "physical appearance" of the short and long roots, that is the fact that the roots of R_{long} are "longer" than those of R_{short}. All we used was the fact that the partition $R = R_{\text{short}} \cup R_{\text{long}}$ partitions the root-system R into two subsets both of which are invariant under the action of the Weyl group W.

Is it possible to find such a partition for those root systems that have only one root length (A_n, D_n, E_6, E_7, E_8)? The answer is: not quite, but almost. Instead of the Weyl group W itself, we have to settle for invariance under a certain subgroup of W. It turns out that it is possible to find such a partition of R which is invariant under a very large subgroup of W, so we only have to sacrifice a little bit of symmetry. Still, we have to put up with some vectors that were previously denounced as bad guys. In return, however, the corresponding polynomial that appears in (4.1) is much smaller and the trade-off is well in our favor, since the resulting set S in (4.6) turns out to be much smaller.

For example, A_{n-1} can be partitioned into

$$A_{n-1} = \{\pm(e_1 - e_i);\ 2 \leqq i \leqq n\} \cup \{\pm(e_i - e_j);\ 2 \leqq i < j \leqq n\}.$$

The second set is the subroot system A_{n-2} in the last $n-1$ coordinates and its Weyl group S_{n-1} (that acts by permuting the last $n-1$ coordinates) is the subgroup that leaves both subsets invariant.

In fact, the first subset above can be further partitoned into its positive and negative roots and so A_{n-1} can be partitioned into *three* subsets, each of which is invariant under the above-mentioned S_{n-1}. Indeed, we have

$$A_{n-1} = \{e_1 - e_i;\ 2 \leqq i \leqq n\} \cup \{-e_1 + e_i;\ 2 \leqq i \leqq n\} \cup \{\pm(e_i - e_j;\ 2 \leqq i < j \leqq n)\}.$$

We should thus expect a three parameter "pseudo"-Macdonald-Morris conjecture

$$\text{(10.1)}\quad \text{C.T.} \prod_{i=2}^{n} (x_1/x_i)_a \prod_{i=2}^{n} (qx_i/x_1)_b \prod_{2 \leqq i < j \leqq n} (x_i/x_j)_c (qx_j/x_i)_{c-1} = \text{something explicit.}$$

Such an identity indeed exists and was conjectured by Morris [Mo] (Morris proved the $q=1$ case). It was recently proved by Kadell [Kad1] and Habsieger [Hab2], who deduced it from their Askey q-Selberg integral. However it is possible to get a Stembridge-style proof by using the method of § 8 [Z4]. The $a=0$ case is easily seen to be equivalent to the $a=b=0$ case. Then one inducts on a and gets a recurrence in a. The analogue of (4.6) contains only n terms and it is easy to find $n-1$ independent equations satisfied by them. The base case $a=b=0$ is just the A_{n-1} case while the $a=b=c$ is the A_n case. This provides the necessary induction.

For D_n the situation is not quite as rosy, but it is still very promising. While it is not possible to partition D_n into *three* subsets invariant under a large subgroup of W, it is possible to do it with *two* subsets.

Indeed,

$$D_n = \{\pm e_1 \pm e_i;\ 2 \leqq i \leqq n\} \cup \{\pm e_i + e_j;\ 2 \leqq i < j \leqq n\}. \tag{10.2}$$

The second set is just the root-system D_{n-1} on the last $n-1$ coordinates. The Weyl group of this D_{n-1} consists of all signed permutations with an even number of signs that act on the last $n-1$ coordinates [Bo, p. 257, (X)]. It leaves both subsets of (10.2) invariant. I conjecture that if

$$\begin{aligned} H_{a,b} =: \text{C.T.} \prod_{i=2}^{n} (x_1/x_i)_a (qx_i/x_1)_{a-1} (x_1 x_i)_a (q/x_1 x_i)_{a-1} \\ \cdot \prod_{2 \leqq i < j \leqq n} (x_i/x_j)_b (qx_j/x_i)_{b-1} (x_i x_j)_b (q/x_i x_j)_{b-1}, \end{aligned} \tag{10.3}$$

then $H_{a,b}$ has an explicit and perhaps nice expression. In any case the method described in § 8 should produce $H_{a,b+1}/H_{a,b}$, a certain rational function, and whether it is nice or not it should give us a formula for $H_{a,b}$ that we know should be nice when $a = b$. In any case the analogue of (4.6) is much simpler now, and the number of equations needed is considerably reduced. The base case $a = 1$ is essentially D_{n-1}, and once we obtain the recurrence in a, and thus the expression for $H_{a,b}$, then $H_{b,b}$ will give the D_n case of (qM). Once we will have D_n, the remaining classical families B_n and C_n should be relatively easy. D_n is the "hard core" of both B_n and C_n, and it hopefully would be relatively easy to add the rest. Similarly, it should be possible to find more refined conjectures for F_4 and the E's that will enable us to break the proof into manageable parts.

Another possibility is to find the "trivializing generalization": a much more general statement than the Macdonald conjectures that would be trivial (or at least easy, or in any case possible) to prove. Except for some coefficients in the A_{n-1} case [Ste3], the general coefficients of G_k and $G_{a,b}$ do not seem to have nice expressions. So we have to abandon the hope of finding a *nice* expression for the general coefficient of G_k. But perhaps it is possible to find certain *linear combinations* of these messy coefficients that are good-looking. Remember that in our method the desired coefficient, H_{k+1}, was obtained, via (4.6) as a certain linear combination of more or less ugly coefficients of the k case. Maybe it is possible to find a family of polynomials, a_λ, say, parametrized by partitions λ such that

$$\text{C.T.} \left[\prod_{\alpha \in R^+} (x^\alpha)_k (qx^{-\alpha})_{k-1} a_\lambda \right] \tag{10.4}$$

has a nice expression in k and λ. Now that we have a laboratory for producing not only the constant term, but also other coefficients of $F_k(F_{a,b})$, there is a vast hunting ground for formulating and testing such more general conjectures (see [Kad2] for a similar idea in the context of the Selberg integral).

A related idea, inspired by Aomoto's [Ao] proof of Selberg's integral, was suggested by Askey [As3]: Break the ascent from k to $k+1$ in (qM) by raising the subscripts on the roots one, or few, at a time. The present method also offers a convenient workbench for Askey's approach. In particular it is possible to verify his G_2 conjectures made at the end of § 4 of [As3].

Acknowledgments. I wish to thank all the people, machines, and institutions that helped me in this research. Among the first category I wish to thank: John Stembridge

and Dennis Stanton for the brilliant ideas that led to this paper; Richard Askey, Dominique Foata, and Dave Robbins for many stimulating discussions; Chip Morris for his extraordinary thesis [Mo] that enabled a mere mortal to understand the Macdonald conjectures; Dave Robbins (again) for independently verifying, using ALTRAN, the MACSYMA calculations in § 9; and, of course, I. G. Macdonald for his intriguing conjectures that have been keeping me busy all these years. I also wish to thank my wife, Jane, for convincing me that C is a better language than BASIC, and Marci Perlstadt and Ron Perline for initiating me to MACSYMA. Finally, the referee deserves thanks for many helpful remarks.

In the second category, I wish to thank the Drexel Electrical Engineering Department's VAX 780 for being such a faithful slave and for its hospitality toward the time-consuming MACSYMA.

Among the third category I wish to thank the Drexel Electrical Engineering Department for letting a poor cousin from the Mathematics Department use their computer.

Note added in proof. Kevin Kadell has meanwhile proved the BC_n cases of (qM-M1), and thus also the B_n, C_n, D_n cases. Frank Garvan (preprint) has used the method of this paper to prove the $q=1$ case of F_4. He also succeeded in proving the F_4, I_3 cases of the Macdonald-Mehta conjectures. Frank Garvan and Dennis Stanton have proved that the system (5.9) is always upper triangular, in the $q=1$ case.

STRONG INTERNAL RESONANCE, $Z_2 \oplus Z_2$ SYMMETRY, AND MULTIPLE PERIODIC SOLUTIONS*

THOMAS J. BRIDGES†

Abstract. Equal (strong internal resonance) or nearly equal natural frequencies in a Hamiltonian system are shown to lead to a higher multiplicity and secondary branching of periodic solutions. The role of $Z_2 \oplus Z_2$ symmetry is emphasized as a basis for the analysis. The Lyapunov-Schmidt method is used to generate a set of bifurcation equations. The higher order terms in the bifurcation equations are formally neglected, leading to the basic normal form for coupled equations with $Z_2 \oplus Z_2$ symmetry. Known results for this normal form are used to determine the nature of the periodic solutions in a neighborhood of a 1 : 1 resonance. A stability analysis is based on Floquet theory and the Lyapunov-Schmidt method. Regions of stability are established and particular singular points in parameter space are found where periodic solutions may not exist. The analysis is carried out on an example: the orthogonal planar pendulum.

Key words. Hamiltonian system, bifurcation, symmetry, singularity theory

1. Introduction. The circle group S^1 and the symmetry group Z_2 play a fundamental role in an analysis of the nature of periodic solutions of a Hamiltonian system near equilibrium. The action of the circle group represents the translation invariance in time. A development of this role with the use of the Lyapunov-Schmidt method has been given by Moser [23]. The role of Z_2 symmetry is more subtle and appears in the bifurcation equations *after* application of a Lyapunov-Schmidt splitting. The importance of Z_2 symmetry and its basic role in the analysis of periodic solutions has been emphasized by Golubitsky and Langford [10]. In Hamiltonian systems, where a Hopf bifurcation parameter is absent, it is usual to treat the period as a bifurcation parameter and then apply the Lyapunov-Schmidt method (Hale [13, Chap. 8]). For a nonresonant Hamiltonian in this setting it is generic that the bifurcation equations are Z_2 equivalent to the pitchfork. When a 1 : 1 resonance occurs we find that the symmetry group $Z_2 \oplus Z_2$ plays a central role. Similarly the symmetry group $Z_2 \oplus Z_2 \oplus Z_2$ can be shown to play a central role in an analysis of the $1:1:k$ $(k \geqq 1)$ resonance.

This is similar to the role played by $Z_2 \oplus Z_2$ symmetry when a double eigenvalue occurs in an equilibrium problem. In this context Bauer, Keller, and Reiss [1] first showed that splitting a double eigenvalue results in secondary bifurcation. Golubitsky and Schaeffer [11] subsequently showed that this was a result of the unfolding of the normal form for equations with $Z_2 \oplus Z_2$ symmetry. This principle of splitting a double eigenvalue to find secondary branches has since been observed in a number of interesting applications. Golubitsky and Schaeffer [12] have analyzed the buckling of rectangular plates, Buzano [5] has analyzed the buckling of thin rods, and Kriegsmann and Reiss [17] have analyzed magneto-hydrodynamic equilibria. Margolis and Matkowsky [20] first applied this concept to the secondary branching of periodic solutions, and Bridges [3], [4] subsequently applied this theory to find secondary branches of periodic surface waves in an enclosed basin.

From a strictly Hamiltonian point of view, periodic solutions near a resonant equilibrium have been well studied in the celestial mechanics literature. Hénon and Heiles [14], Braun [2], and Kummer [18], for example, have used numerical methods and the Gustavson normal form to determine the multiplicity and stability of periodic

solutions *at* a 1:1 resonance. An up-to-date review of generic bifurcations in Hamiltonian systems is given by Meyer [21].

In this paper the Lyapunov-Schmidt method is used to reduce the analysis of Hamiltonian systems at 1:1 resonance to a set of bifurcation equations. Known properties of the normal form for $Z_2 \oplus Z_2$ symmetry are then used to analyze the nature and multiplicity of the periodic solutions. Stability is determined using Floquet theory. The number of degrees of freedom may be arbitrary as long as the other degrees of freedom are nonresonant. Clearly it is sufficient to consider a system with two degrees of freedom,

$$H(\theta_1, \dot\theta_1, \theta_2, \dot\theta_2) = \tfrac{1}{2}\omega_1(\theta_1^2 + \dot\theta_1^2) + \tfrac{1}{2}\omega_2(\theta_2^2 + \dot\theta_2^2) + H_3$$

where H_3 is a convergent power series that begins with a third-order term.

However, for added insight, we will develop the ideas by considering a physical problem with two degrees of freedom, which is sufficiently general and contains some interesting properties besides. The system is a compound orthogonal pendulum.

Consider a right-handed coordinate system with the z-axis directed upwards and the x-axis directed to the right with a pendulum of mass m_1 and length l_1 suspended from the origin with its motion restricted to the x-z-plane. Suspended from the mass m_1 is a second pendulum of mass m_2 and length l_2 *whose motion is restricted to the y-z-plane.* In addition the base of the pendulum (the origin) undergoes a horizontal planar harmonic excitation, say

$$\begin{pmatrix} x_0 \\ y_0 \end{pmatrix} = \begin{pmatrix} \mu_1 l_1 2\sqrt{2} \cos(\omega t + \zeta) \\ \mu_2 l_2 2\sqrt{2} \cos \omega t \end{pmatrix} \tag{1.1}$$

where $\mu = (\mu_1, \mu_2)$ is a measure of the excitation amplitude and ζ corresponds to the phase between the two components of the excitation.

The Lagrangian for such a system is easily shown to be

$$\begin{aligned} \mathbf{L} = {} & \tfrac{1}{2}(m_1 + m_2)[\dot x_0^2 + \dot y_0^2 + 2 l_1 \dot x_0 \dot\theta_1] + m_2 l_2 \dot y_2 \dot\theta_2 \cos\theta_1 \cos\theta_2 \\ & + \tfrac{1}{2}(m_1 + m_2) l_1^2 \dot\theta_1^2 + \tfrac{1}{2} m_2 l_2^2 \dot\theta_2^2 + m_2 l_1 l_2 \dot\theta_1 \dot\theta_2 \sin\theta_1 \sin\theta_2 \\ & + (m_1 + m_2) g l_1 (\cos\theta_1 - 1) + m_2 g l_2 (\cos\theta_2 - 1). \end{aligned} \tag{1.2}$$

The interval of time $[0, 2\pi/\omega]$ is mapped to $[0, 2\pi]$ and we define the parameters $\lambda = g/\omega^2 l_1$, $l_1/l_2 = 1 - \sigma$ and $m = m_2/(m_1 + m_2)$. Then application of the Euler-Lagrange operator to (1.2) generates the nonlinearly coupled pair of second-order ordinary differential equations

$$\begin{aligned} & \frac{d^2\theta_1}{dt^2} + \lambda \sin\theta_1 - \mu_1 2\sqrt{2} \cos(t + \zeta) \cos\theta_1 \\ & \qquad + \frac{m}{1 - \sigma} \sin\theta_1 [\ddot\theta_2 \sin\theta_2 + \dot\theta_2^2 \cos\theta_2] = 0, \end{aligned} \tag{1.3a}$$

$$\begin{aligned} & \frac{d^2\theta_2}{dt^2} + \lambda(1 - \sigma) \sin\theta_2 - \mu_2 2\sqrt{2} \cos t \cos\theta_2 \\ & \qquad + (1 - \sigma) \sin\theta_2 [\ddot\theta_1 \sin\theta_1 + \dot\theta_1^2 \cos\theta_1] = 0 \end{aligned} \tag{1.3b}$$

where λ will play the role of a bifurcation parameter, σ is a parameter that is used to unfold the 1:1 resonance, and $\mu \in R^2$ will be an unfolding parameter that breaks the symmetry. We are interested in periodic solutions of the set of equations (1.3) when the two linear natural frequencies are equal or nearly equal, that is, in the neighborhood of $\sigma = 0$. Physically this is when the lengths of the two pendulums are very nearly equal.

Although the results herein are for the 1:1 resonance they are not so limited. The $1:k$ resonance, although referred to as a higher order resonance when $k \geqq 1$, behaves much like a 1:1 resonance. It can be shown that the $1:k$ resonance may have a normal form similar to that of the 1:1 resonance and in addition the $1:1:k$ resonance can be analyzed using the normal form for a $Z_2 \oplus Z_2 \oplus Z_2$ symmetric problem.

The results herein for secondary branching of periodic solutions may also hold for the 1:1 resonance in nondegenerate Hopf bifurcation when two parameters are present. The analogous situation is given by the following evolution equation with $u \in R^4$:

$$\omega \frac{du}{dt} + \mathbf{A}(\sigma)u + \mathbf{B}(h)u = \mathbf{F}(h, \sigma, u)$$

where $h, \sigma \in R$, $\mathbf{F}(h, \sigma, 0) = 0$ and $\mathbf{F}$ is nonlinear in u, $\mathbf{A}, \mathbf{B} \in R^{4\times 4}$ with $\mathbf{B}(0) = 0$ and $\mathbf{A}(\sigma)$ has eigenvalues $\lambda_1^-(\sigma), \lambda_1^+(\sigma), \lambda_2^-(\sigma), \lambda_2^+(\sigma)$ with $\lambda_1^-(0) = -i$, $\lambda_1^+(0) = i$, $\lambda_2^-(0) = -i$, and $\lambda_2^+(0) = i$. If varying σ away from zero splits the 1:1 resonance with h fixed, then we expect analogous secondary branching of periodic or quasi-periodic solutions. Related results for the Hopf bifurcation theorem at resonance have been obtained by Kielhöfer [15], Caprino, Maffei, and Negrini [6], and Chow, Mallet-Paret, and Yorke [7].

2. Symmetry and the branching equation. It is usual to convert (1.3) to a set of four first-order equations and set the problem in a Banach space with a graph norm. With a second-order derivative in the nonlinearity, however, some simplification is found by working from an integral equation point of view. Consider the integral operators

$$\mathbf{K}\phi = \int_0^{2\pi} k(t, \tau)\phi(\tau)\, d\tau, \tag{2.1a}$$

$$\mathbf{K}_t\phi = \int_0^{2\pi} k_t(t, \tau)\phi(\tau)\, d\tau \tag{2.1b}$$

where

$$k(t, \tau) = \sum_{n=1}^{\infty} \frac{\psi_n(t)\psi_n^*(\tau) + \psi_n^*(t)\psi_n(\tau)}{n^2} \tag{2.1c}$$

and $\psi_n(t) = e^{int}/\sqrt{2\pi}$, $i = \sqrt{-1}$; the * denotes complex conjugation and $k_t(t, \tau) = \partial k/\partial t$. Expressed using the above operators, terms in the equations (1.3) become $\ddot{\theta}_j = \phi_j$, $\theta_j = -\mathbf{K}\phi_j$ and $\dot{\theta}_j = -\mathbf{K}_t\phi_j$ for $j = 1, 2$.

The governing equations may then be written as the abstract operation

$$\Phi(\phi, \lambda, \sigma, \mu) = 0$$

for fixed m with $\Phi = (\Phi_1, \Phi_2)$ and $\phi = (\phi_1, \phi_2)$ and the operators Φ_j are given explicitly by

$$\begin{aligned}\Phi_1(\phi, \lambda, \sigma, \mu) &= \phi_1 - \lambda \sin \mathbf{K}\phi_1 - 2\sqrt{2}\mu_1 \cos(t+\zeta) \cos \mathbf{K}\phi_1 \\ &\quad + \frac{m}{1-\sigma} \sin \mathbf{K}\phi_1 [\phi_2 \sin \mathbf{K}\phi_2 - (\mathbf{K}_t\phi_2)^2 \cos \mathbf{K}\phi_2],\end{aligned} \tag{2.2a}$$

$$\begin{aligned}\Phi_2(\phi, \lambda, \sigma, \mu) &= \phi_2 - \lambda(1-\sigma) \sin \mathbf{K}\phi_2 - 2\sqrt{2}\mu_2 \cos t \cos \mathbf{K}\phi_2 \\ &\quad + (1-\sigma) \sin \mathbf{K}\phi_2 [\phi_1 \sin \mathbf{K}\phi_1 - (\mathbf{K}_t\phi_1)^2 \cos \mathbf{K}\phi_1].\end{aligned} \tag{2.2b}$$

Φ is now a compact mapping $\Phi: \chi \times R \times R \times R^2 \to \chi$ where χ is a Banach space of pairs of continuous functions, $\chi = \chi_0 \times \chi_0$ where χ_0 is the Banach space $\chi_0 = \{f: f(t+2\pi) = f(t), f: \mathbf{R} \to \mathbf{C}$ is continuous, *and* $\int_0^{2\pi} f(\tau)\, d\tau = 0\}$ and for any $f \in \chi_0$ the $\|f\| = \sup_t |f(t)|$ and for any $\phi \in \chi$ we have $\|\phi\|_\chi = \max\{\|\phi_1\|, \|\phi_2\|\}$.

When $\mu = 0$ the mapping Φ satisfies two sets of symmetry conditions. Due to the translation invariance in time Φ_1 and Φ_2 commute with the action of the circle group $\Gamma_\theta = S^1$. Associating angles θ in S^1 with numbers in $[0, 2\pi)$,

$$\Gamma_\theta f(t) = f(t-\theta)$$

for $\theta \in \Gamma_\theta$, $f \in \chi_0$. On χ we consider the diagonal action of Γ_θ on $\chi_0 \times \chi_0$. In addition we note that (2.2a) is odd in ϕ_1 and even in ϕ_2 whereas (2.2b) is even in ϕ_1 and odd in ϕ_2. In other words Φ commutes with the action of the symmetry group $\Gamma_2 = Z_2 \oplus Z_2$ [12, Chap. X], where Γ_2 is a four element group that may be represented by the set of four diagonal operators $\Gamma_2 = \text{diag}[\pm 1, \pm 1]$. In summary we have Proposition 2.1.

PROPOSITION 2.1. *When $\mu = 0$, Φ commutes with the action of Γ_θ and Γ_2.*

Proof. The proof comes from the fact that $\Gamma_2 \Phi(\phi, \lambda, \sigma, 0) = \Phi(\Gamma_2 \phi, \lambda, \sigma, 0)$ which follows from substitution of $\Gamma_2 = \text{diag}[\pm 1, \pm 1]$ and noting that Φ_1 is odd in ϕ_1 and even in ϕ_2 and Φ_2 is even in ϕ_1 and odd in ϕ_2. The fact that $\Phi(\phi, \lambda, \sigma, 0)$ commutes with the diagonal action of Γ_θ on $\chi_0 \times \chi_0$ follows if Γ_θ commutes with $\mathbf{K}$. Consider

$$\begin{aligned}
\Gamma_\theta \mathbf{K} \phi_j &= \int_0^{2\pi} k(t-\theta, \tau) \phi_j(\tau)\, d\tau \\
&= \int_0^{2\pi} k(t, \tau+\theta)\, \phi_j(\tau)\, d\tau \\
&= \int_\theta^{\theta+2\pi} k(t, s) \phi_j(s-\theta)\, ds \\
&= \mathbf{K} \Gamma_\theta \phi_j. \qquad \square
\end{aligned}$$

Whether or not Φ commutes with the action of Γ_2 is not a necessary component of the analysis. The important point is that the bifurcation equations commute with action of Γ_2. An example from celestial mechanics is the well-studied Hamiltonian at 1:1 resonance of Hénon and Heiles [14], [2], [18], [19],

$$H = \tfrac{1}{2}(\theta_1^2 + \dot\theta_1^2) + \tfrac{1}{2}(\theta_2 + \dot\theta_2^2) + c\theta_1^2\theta_2 + d\theta_2^3 \tag{2.3}$$

that corresponds to the differential equations

$$\frac{d^2\theta_1}{dt^2} + \theta_1 + 2c\theta_1\theta_2 = 0, \tag{2.4a}$$

$$\frac{d^2\theta_2}{dt^2} + \theta_2 + c\theta_1^2 + 3\, d\theta_2^2 = 0. \tag{2.4b}$$

This pair considered as a mapping does not commute with the action of Γ_2. However the bifurcation equations do. Additional properties of this equation are considered in § 6.

When $\mu \neq 0$ both the Γ_2 and Γ_θ symmetry properties are lost. However for a more general analysis μ will be included in the Lyapunov-Schmidt reduction and when appropriate the symmetry properties are reintroduced in the analysis of the bifurcation equations for the special case $\mu = 0$. For the Lyapunov-Schmidt reduction we need Proposition 2.2.

PROPOSITION 2.2. *$\Phi(\phi, \lambda, \sigma, \mu)$ is continuously Fréchet differentiable with respect to ϕ and the Fréchet derivative of Φ at $\phi = 0$, $\lambda = 1$, and $\sigma = \mu = 0$ is a symmetric Fredholm operator with index zero and four-dimensional nullspace.*

Proof. First define an identity operator on χ by $\mathbf{I} = \operatorname{diag}[1, 1]$. Then the Fréchet derivative Φ_ϕ of Φ at $\phi = 0$, $\lambda = 1$, $\sigma = 0$ acting on a vector $u = (u_1, u_2)$ is

$$\Phi_\phi(0, 1, 0, 0)\begin{pmatrix} u_1 \\ u_2 \end{pmatrix} = [\mathbf{I} - \Lambda\mathbf{K}]\begin{pmatrix} u_1 \\ u_2 \end{pmatrix}$$

where in this case Λ is a diagonal operator $\Lambda = \operatorname{diag}[1, 1]$ and $\mathbf{K}$ is as defined in (2.1a). $\mathbf{K}$ is a completely continuous operator with symmetric kernel $k(t, \tau) = k(\tau, t)$. Therefore the dim $N(\mathbf{I} - \Lambda\mathbf{K}) = \operatorname{codim} R(\mathbf{I} - \Lambda\mathbf{K})$. The operator $[\mathbf{I} - \Lambda\mathbf{K}]$ is a diagonal operator acting on $\chi_0 \times \chi_0$ with a two-dimensional nullspace corresponding to each χ_0 spanned by $\{\psi_1, \psi_1^*\}$. Therefore taken together on χ dim $N(\mathbf{I} - \Lambda\mathbf{K}) = 4$. □

With Proposition 2.2 we may decompose the space χ as $\chi = N(\mathbf{I} - \Lambda\mathbf{K}) \oplus R(\mathbf{I} - \Lambda\mathbf{K})$ and we define a projection operator $\mathbf{P} = \operatorname{diag}[\mathbf{P}_1, \mathbf{P}_1]$ where

$$\mathbf{P}_1 f = \psi_1(t)\langle \psi_1, f\rangle + \psi_1^*(t)\langle \psi_1^*, f\rangle.$$

$\langle \cdot, \cdot \rangle$ is a functional pairing on χ_0

$$\langle f, g\rangle = \int_0^{2\pi} f^*(\tau) g(\tau)\, d\tau.$$

It follows that $R(\mathbf{I} - \Lambda\mathbf{K}) = \{f \in \chi : \mathbf{P}f = 0\}$. Now the function ϕ is split into two parts

$$\begin{pmatrix} \phi_1 \\ \phi_2 \end{pmatrix} = \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} + \begin{pmatrix} v_1 \\ v_2 \end{pmatrix}$$

where $u = \mathbf{P}\phi$ and $v = [\mathbf{I} - \mathbf{P}]\phi$ and we define the mapping from $N(\mathbf{I} - \Lambda\mathbf{K}) \to \mathrm{C}$ by

$$\alpha_j = \langle \psi_1, \phi_j \rangle \quad \text{for } j = 1, 2. \tag{2.5}$$

The equations may now be decomposed in Lemma 2.3.

LEMMA 2.3. *The function $\phi = u + v$ is a 2π periodic solution of $\Phi = 0$ if and only if*

$$[\mathbf{I} - \Lambda\mathbf{K} + \mathbf{P}]\begin{pmatrix} v_1 \\ v_2 \end{pmatrix} = \begin{pmatrix} h_1(u_1 + v_1, u_2 + v_2, t) \\ h_2(u_1 + v_1, u_2 + v_2, t) \end{pmatrix} \tag{2.6}$$

and

$$\mathbf{P}\begin{pmatrix} h_1(u_1 + v_1, u_2 + v_2, t) \\ h_2(u_1 + v_1, u_2 + v_2, t) \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \tag{2.7}$$

where

$$\begin{aligned} h_1(\phi_1, \phi_2, t) = {} & (\lambda - 1)\mathbf{K}\phi_1 + \lambda(\sin \mathbf{K}\phi_1 - \mathbf{K}\phi_1) + 2\sqrt{2}\mu_1 \cos(t + \zeta) \cos \mathbf{K}\phi_1 \\ & - \frac{m}{1 - \sigma} \sin \mathbf{K}\phi_1 [\phi_2 \sin \mathbf{K}\phi_2 - (\mathbf{K}_t\phi_2)^2 \cos \mathbf{K}\phi_2], \end{aligned} \tag{2.8a}$$

$$\begin{aligned} h_2(\phi_1, \phi_2, t) = {} & (\lambda - 1 - \sigma)\mathbf{K}\phi_2 + \lambda(1 - \sigma)(\sin \mathbf{K}\phi_2 - \mathbf{K}\phi_2) + 2\sqrt{2}\mu_2 \cos t \cos \mathbf{K}\phi_2 \\ & - (\lambda - 1)\sigma\mathbf{K}\phi_2 - (1 - \sigma) \sin \mathbf{K}\phi_2 [\phi_1 \sin \mathbf{K}\phi_1 - (\mathbf{K}_t\phi_1)^2 \cos \mathbf{K}\phi_1] \end{aligned} \tag{2.8b}$$

and $[\mathbf{I} - \Lambda\mathbf{K} + \mathbf{P}]$ is an isomorphism from $N(\mathbf{I} - \Lambda\mathbf{K})^\perp \to R(\mathbf{I} - \Lambda\mathbf{K})$.

Proof. The pair of equations (2.2) has simply been rearranged into a linear and a nonlinear part $h : \chi \to \chi$ that satisfies $D_\phi h(0, 0, t) = 0$ where D_ϕ is the Fréchet derivative. By the Fredholm alternative the equation $[\mathbf{I} - \Lambda\mathbf{K}] = h$ has a solution only if

$h \in R(\mathbf{I}-\Lambda\mathbf{K})$ or equally $h \in N(\mathbf{I}-\Lambda\mathbf{K})^{\perp}$. This yields (2.7). Equation (2.6) is found by projecting (2.2) along $N(\mathbf{I}-\Lambda\mathbf{K})$ onto its complement. The restriction of $[\mathbf{I}-\Lambda\mathbf{K}]$ to $N(\mathbf{I}-\Lambda\mathbf{K})^{\perp}$ is then an isomorphism $[\mathbf{I}-\Lambda\mathbf{K}+\mathbf{P}]: N(\mathbf{I}-\Lambda\mathbf{K})^{\perp} \to R(\mathbf{I}-\Lambda\mathbf{K})$. □

Properties of (2.6) are established in Lemma 2.4.

LEMMA 2.4. *There exists a solution* $v(t; \alpha, \lambda-1, \sigma, \mu)$ *of* (2.6) *satisfying* (a) $v(t; 0, 0, 0, 0) = 0$, *and* (b) for $|\alpha|, |\lambda-1|, |\sigma|$ *bounded away from zero the solution* v *of* (2.6) *is also bounded away from zero but tends to zero with its last four arguments.*

The mapping $h: \chi \to \chi$ *defined in* (2.8) *satisfies the following inequalities*:

$$\|h\|_{\chi} = \max\{\|h_1\|, \|h_2\|\} \leqq c_1(\alpha, \lambda-1, \sigma, \mu) \tag{2.9}$$

and

$$\max_{t=1,2}\left\{\sum_{j=1}^{2} \|(Dh_i)_{v_j}\|\right\} \leqq c_2(\alpha, \lambda-1, \sigma, \mu) \tag{2.10}$$

where c_1, c_2 *are positive bounded functions that tend to zero with their arguments.*

Proof. When $\alpha = \lambda - 1 = \sigma = \mu = 0$ v satisfies

$$[\mathbf{I}-\Lambda\mathbf{K}+\mathbf{P}]\begin{pmatrix} v_1 \\ v_2 \end{pmatrix} = \begin{pmatrix} \sin \mathbf{K}v_1 - \mathbf{K}v_1 - m \sin \mathbf{K}v_1[v_2 \sin \mathbf{K}v_2 - (\mathbf{K}_t v_2)^2 \cos \mathbf{K}v_2] \\ \sin \mathbf{K}v_2 - \mathbf{K}v_2 - \sin \mathbf{K}v_2[v_1 \sin \mathbf{K}v_1 - (\mathbf{K}_t v_1)^2 \cos \mathbf{K}v_1] \end{pmatrix}. \tag{2.11}$$

The Fréchet derivative of (2.11) is $[\mathbf{I}-\Lambda\mathbf{K}+\mathbf{P}]$ which was established in Lemma 2.3 to be an isomorphism from $N(\mathbf{I}-\Lambda\mathbf{K})^{\perp} \to R(\mathbf{I}-\Lambda\mathbf{K})$. By the implicit function theorem there exists a unique $v \in \chi$ in a neighborhood of the origin. But note that $v = 0$ satisfies (2.11). It follows that $v = 0$ is the only solution *connected* to the origin and (a) follows.

When $\alpha, \lambda-1, \sigma, \mu$ are nonzero $v = 0$ is clearly *not* a solution of (2.6). It follows that $v \neq 0$ when $\alpha, \lambda-1, \sigma, \mu$ are nonzero but by (a) v must tend to zero with its last four arguments.

The inequalities will now be proved. From (2.8) we have that

$$\begin{aligned} \|h_1\| \leqq |\lambda-1|\,\|\mathbf{K}\|\,\|u_1+v_1\| + 2\sqrt{2}|\mu_1| + |\lambda|\,\|\sin \mathbf{K}(u_1+v_1) - \mathbf{K}(u_1+v_1)\| \\ + \left|\frac{m}{1-\sigma}\right|[\|u_2+v_2\| + \|\mathbf{K}_t\|^2\|u_2+v_2\|^2] \end{aligned} \tag{2.12}$$

and $\|h_2\|$ has a similar expression. Now $\|u_j\| \leqq 2|\alpha_j|$ for $j = 1, 2$, $\|\mathbf{K}\|$ is bounded and by the first part of this lemma $\|v\|_{\chi}$ tends to zero with its arguments. Therefore $\|h_1\|, \|h_2\|$ are bounded by functions of $\alpha, \lambda-1, \sigma, \mu$ which tend to zero with their arguments. Choosing the maximum of these we have c_1 in (2.9).

The Fréchet derivative of h_1 with respect to v_1 is

$$(Dh_1)_{v_1} = \left[(\lambda-1) + \lambda[\cos \mathbf{K}\phi_1 - \mathbf{I}] - 2\sqrt{2}\mu_1 \cos(t+\zeta) \sin \mathbf{K}\phi_1 - \frac{m}{1-\sigma} \cos \mathbf{K}\phi_1[\phi_2 \sin \mathbf{K}\phi_2 - (\mathbf{K}_t\phi_2)^2 \cos \mathbf{K}\phi_2]\right]\mathbf{K}.$$

Therefore

$$\|(Dh_1)_{v_1}\| \leqq \|\mathbf{K}\|\left[|\lambda-1| + |\lambda|\,\|\cos \mathbf{K}\phi_1 - \mathbf{I}\| + 2\sqrt{2}|\mu_1| + \frac{m}{1-\sigma}[\|\phi_2\| + \|\mathbf{K}_t\|^2\|\phi_2\|^2]\right]. \tag{2.13}$$

However, by part (a) we know that $\|\phi\|_\chi \to 0$ with $\alpha, \lambda - 1, \sigma, \mu$. Therefore the right-hand side of (2.13) is less than some number dependent on $\alpha, \lambda - 1, \sigma, \mu$ and going to zero with $\alpha, \lambda - 1, \sigma, \mu$. Repeating this argument for each of the other Fréchet derivatives of h_i and choosing the maximum of the bounds as c_2 we have (2.10). □

With Lemmas 2.3 and 2.4 the bifurcation equations are constructed in Theorem 1.

THEOREM 1. *There are positive constants $\varepsilon_0 > 0$, $\lambda_0 > 0$, $\sigma_0 > 0$, $\mu_0 > 0$ with $\|u\|_\chi \leqq \varepsilon_0$, $|\lambda - 1| \leqq \lambda_0$, $|\sigma| \leqq \sigma_0$, and $|\mu| \leqq \mu_0$ such that there exists a unique $\hat{v} \in \chi$ with $v = \hat{v}(t; \alpha, \lambda - 1, \sigma, \mu)$ which satisfies* (2.6). *$\hat{v}$ has a continuous first derivative with respect to its arguments and $\hat{v}(t; 0, 0, 0, 0) = 0$. Substitution of this unique v into* (2.7) *generates the bifurcation equations*

$$(\lambda - 1)\alpha_1 - \frac{1}{4\pi}|\alpha_1|^2\alpha_1 + 2\sqrt{\pi}\mu_1 e^{i\zeta} + \frac{1}{\pi}m\alpha_2^2\alpha_1^* + r_1(\alpha, \alpha^*, \lambda - 1, \sigma, \mu) = 0,$$

$$(\lambda - 1 - \sigma)\alpha_2 - \frac{1}{4\pi}|\alpha_2|^2\alpha_2 + 2\sqrt{\pi}\mu_2 - \frac{1}{\pi}\alpha_1^2\alpha_2^* + r_2(\alpha, \alpha^*, \lambda - 1, \sigma, \mu) = 0$$

and

$$\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix} = \begin{pmatrix}\alpha_1\\ \alpha_2\end{pmatrix}\psi_1(t) + \begin{pmatrix}\alpha_1^*\\ \alpha_2^*\end{pmatrix}\psi_1^*(t) + \begin{pmatrix}\hat{v}(t; \alpha, \lambda - 1, \sigma, \mu)\\ \hat{v}(t; \alpha, \lambda - 1, \sigma, \mu)\end{pmatrix}$$

is a 2π periodic solution of (2.2) *if and only if the bifurcation equations are nondegenerate. The remainder term $r = (r_1, r_2)$ satisfies*

$$\|r\|_\chi = 0\{(|\alpha_1| + |\alpha_2|)^2|\mu_1| + (|\lambda - 1| + |\sigma|)(|\alpha_1| + |\alpha_2|) + (|\alpha_1| + |\alpha_2|)^3\}$$

as $(|\alpha_1|, |\alpha_2|, |\lambda - 1|, |\sigma|, |\mu|) \to 0$.

Proof. $v = [\mathbf{I} - \Lambda\mathbf{K} + \mathbf{P}]^{-1}h$ is a mapping from the ball $\|v\|_\chi \leqq v_0$ to itself when $c_1 \leqq 3v_0/7$. In addition $v = [\mathbf{I} - \Lambda\mathbf{K} + \mathbf{P}]^{-1}h$ is a uniform contraction when $c_2 < 3/7$. As c_1, c_2 may be made arbitrarily small by proper choice of λ_0, ε_0, σ_0, and μ_0 the existence, and properties, of $\phi = u + \hat{v}$ are a consequence of the uniform contraction mapping theorem. The function $\hat{v}$ may be obtained as the limit of the sequence $\{v_n\}$ with $v_{n+1} = [\mathbf{I} - \Lambda\mathbf{K} + \mathbf{P}]^{-1}h(v_n, t)$ for $n = 0, 1, \cdots$ with $v_0 = 0$. Using the first approximation we arrive at the bifurcation equations with the given error bounds. □

As the bifurcation equations are nonanalytic they will be analyzed by decomposing the amplitudes into $\alpha_j = \rho_j e^{i\xi_j}$ for $j = 1, 2$. This yields

$$(\lambda - 1)\rho_1 - \frac{1}{4\pi}\rho_1^3 - \frac{m}{\pi}\rho_2^2\rho_1 \cos 2(\xi_2 - \xi_1) + 2\sqrt{\pi}\mu_1 \cos(\xi_1 - \zeta) + \operatorname{Re}[r_1 e^{-i\xi_1}] = 0, \tag{2.14a}$$

$$(\lambda - 1 - \sigma)\rho_2 - \frac{1}{4\pi}\rho_2^3 - \frac{1}{\pi}\rho_1^2\rho_2 \cos 2(\xi_2 - \xi_1) + 2\sqrt{\pi}\mu_2 \cos \xi_2 + \operatorname{Re}[r_2 e^{-i\xi_2}] = 0, \tag{2.14b}$$

$$-\frac{m}{\pi}\rho_1\rho_2^2 \sin 2(\xi_2 - \xi_1) - 2\sqrt{\pi}\mu_1 \sin(\xi_1 - \zeta) + \operatorname{Im}[r_1 e^{-i\xi_1}] = 0, \tag{2.15a}$$

$$\frac{1}{\pi}\rho_1^2\rho_2 \sin 2(\xi_2 - \xi_1) - 2\sqrt{\pi}\mu_2 \sin \xi_2 + \operatorname{Im}[r_2 e^{-i\xi_2}] = 0. \tag{2.15b}$$

These equations are the basis of the qualitative behavior of the nondegenerate periodic solutions for the orthogonal planar pendulum. It provides a family of initial conditions and relative phases that result in periodic orbits. It is these equations that will be analyzed in the next two sections.

3. Autonomous oscillations and $Z_2 \oplus Z_2$ symmetry. Treating the phase difference $\xi_2 - \xi_1$ as a parameter the four bifurcation equations may be thought of as functions of $\rho = (\rho_1, \rho_2)$ and $\kappa = (\lambda, \xi_2 - \xi_1, \sigma, \mu)$, with $\mu = 0$,

$$f_1(\rho; \kappa) = \rho_1\left[\lambda - 1 - \frac{1}{4\pi}\rho_1^2 - \frac{m}{\pi}\cos 2(\xi_2 - \xi_1)\rho_2^2\right] + 0_5, \tag{3.1a}$$

$$f_2(\rho; \kappa) = \rho_2\left[\lambda - 1 - \sigma - \frac{1}{4\pi}\rho_2^2 - \frac{1}{\pi}\cos 2(\xi_2 - \xi_1)\rho_1^2\right] + 0_5, \tag{3.1b}$$

$$g_1(\rho; \kappa) = -\frac{m}{\pi}\rho_1\rho_2^2 \sin 2(\xi_2 - \xi_1) + 0_5, \tag{3.2a}$$

$$g_2(\rho; \kappa) = -\frac{1}{\pi}\rho_1^2\rho_2 \sin 2(\xi_2 - \xi_1) + 0_5 \tag{3.2b}$$

where 0_5 contains terms of fifth order and higher. Equations (3.1) are analogous to the normal form for the double cusp with symmetry [11, p. 219]. In the absence of (3.2) the function f when nondegenerate is $Z_2 \oplus Z_2$ equivalent to

$$f_1(x, y; \kappa) = x[x^2 + 4m\varepsilon_3 y^2 - (\lambda - 1)] = 0, \tag{3.3a}$$

$$f_2(x, y; \kappa) = y[4\varepsilon_3 x^2 + y^2 - (\lambda - 1 - \sigma)] = 0 \tag{3.3b}$$

where $\varepsilon_3 = \cos 2(\xi_2 - \xi_1)$. However, the presence of g and its coupling to f through the phase make the equivalence formal only. We have no rigorous basis for neglecting 0_5 in all four equations and therefore proceed on a formal basis by neglecting 0_5. This implies that $\sin 2(\xi_2 - \xi_1) = 0$ when $\rho_1\rho_2 \neq 0$; therefore we study solutions of (3.3) with $\varepsilon_3 = \pm 1$. The set (3.3) is the basic normal form for problems with $Z_2 \oplus Z_2$ symmetry and has been studied in much detail by Golubitsky and Schaeffer [12, Chap. X], from which we have the following proposition.

PROPOSITION 3.1. *The bifurcation problem f in* (3.3) *is degenerate when $m = \frac{1}{4}$ and $\varepsilon_3 = 1$ or whem $m = \frac{1}{16}$ and $\varepsilon_3 = \pm 1$.*

Proof. The equations become dependent at these values of ε_3 and m. The complete proof is given in [12, p. 423].

The implication is that the system has families of periodic solutions at admissible values of m and ε_3 other than these critical values. The points of degeneracy point towards more complex solutions. In § 6 some examples will be given to suggest what might occur in the system at these points of degeneracy.

For values of m and ε_3 other than the degenerate points, the periodic solutions corresponding to (3.3) are

$$\text{I:} \quad x = \sqrt{\lambda - 1}; \qquad y = 0,$$

$$\text{II:} \quad x = 0; \qquad y = \sqrt{\lambda - 1 - \sigma},$$

$$\text{III:} \quad x^2 = \frac{1 - 4m\varepsilon_3}{1 - 16m}\left[\lambda - 1 + \frac{4m\varepsilon_3}{1 - 4m\varepsilon_3}\sigma\right],$$

$$y^2 = \frac{1 - 4\varepsilon_3}{1 - 16m}\left[\lambda - 1 - \frac{\sigma}{1 - 4\varepsilon_3}\right]$$

and only nonnegative values of x, y are admissible. Solution sets I and II are pure mode pitchforks and correspond to the Lyapunov families emitted by the bifurcation points $\lambda = 1$ and $\lambda = 1 + \sigma$. The mixed mode solutions are divided into five sets separated by the points of degeneracy. For $\varepsilon_3 = +1$; $0 < m < \frac{1}{16}$, $\frac{1}{16} < m < \frac{1}{4}$, and $\frac{1}{4} < m < 1$ and for

$\varepsilon_3 = -1$; $0 < m < \frac{1}{16}$ and $\frac{1}{16} < m < 1$. Solution types for each of these regions have been classified by Golubitsky and Schaeffer [12, Chap. X]. The parameter σ which perturbs the 1:1 resonance plays the role of the universal unfolding for this normal form. The unfolding results in a secondary branching of the periodic solutions.

Although there is a translation invariance with respect to time, the requirement that $\sin 2(\xi_2 - \xi_1) = 0$ restricts the phase between the two pendulums. $\varepsilon_3 = 1$ corresponds to in phase motions and $\varepsilon_3 = -1$ corresponds to a phase difference of $\pm\pi/2$ between the two pendulums.

Figures 1-4 show examples of the multiplicity and nature of the autonomous periodic solutions in a neighborhood of the 1:1 resonance. Figure 1 contains in-phase and out-of-phase solutions at 1:1 resonance with $m = \frac{1}{2}$, and Fig. 2 is an unfolding of Fig. 1 with $\sigma = \frac{1}{2}$. Figure 3 shows a neighborhood of the 1:1 resonance for $m = \frac{1}{7}$ and $\sigma = -\frac{3}{5}$ with both in-phase and out-of-phase solutions. Note that there is a global connection between the two Lyapunov families. Figure 4 is similar with parameters $m = \frac{1}{20}$ and $\sigma = -\frac{3}{5}$ with in-phase and out-of-phase solutions. In Figs. 1-4 the in-phase coupled solutions are indicated by +1 and the out-of-phase coupled solutions are indicated by −1.

These figures are not bifurcation diagrams in the usual sense, although the terminology applies well, due to the fact that λ corresponds to the period of the oscillations. The figures are essentially maps of initial displacements and relative phase between the two modes such that periodic solutions result. A stability analysis of the solutions is carried out in § 5 using Floquet theory. That analysis shows that the in-phase motions, $\varepsilon_3 = +1$, are stable for all m such that $m > \frac{1}{7}$ while the out-of-phase coupled motions, $\varepsilon_3 = -1$, are stable for all m (the degenerate points excepted). The stability of the solutions implies that there is no exchange of energy between the two degrees of freedom during the motion.

4. Symmetry breaking due to forced oscillations. When the parameter μ is included in the analysis the bifurcation equations for ρ_1, ρ_2 no longer commute with the action of $\mathbf{Z}_2 \oplus \mathbf{Z}_2$. The symmetry is broken and μ provides an unfolding of the normal form. Although the Γ-codimension (the dimension of the unfolding that preserves the $Z_2 \oplus Z_2$ symmetry) is three (two modal parameters (m, ε_3) and σ) the *contact* codimension which allows for the dissolution of the $Z_2 \oplus Z_2$ symmetry is 16 [11, p. 219]. Consequently the addition of the parameters μ_1 and μ_2 is by no means a universal unfolding but the parameters have been introduced naturally and correspond to a measure of the forcing of the dynamical system. The addition of more parameters and further study is necessary before a complete picture of the forced oscillations may be formed. After neglecting terms of fifth order and higher, and performing a smooth change of variables, the bifurcation equations are

$$x(x^2 + 4m\varepsilon_3 y^2 - (\lambda - 1)) - \mu_1 \cos(\xi_1 - \zeta) = 0, \tag{4.1a}$$

$$y(4\varepsilon_3 x^2 + y^2 - (\lambda - 1 - \sigma)) - \mu_2 \cos \xi_2 = 0 \tag{4.1b}$$

with the constraints,

$$\mu_1 \sin(\xi_1 - \zeta) + 4mxy^2 \sin 2(\xi_2 - \xi_1) = 0, \tag{4.2a}$$

$$\mu_2 \sin \xi_2 - 4x^2 y \sin 2(\xi_2 - \xi_1) = 0. \tag{4.2b}$$

Equations (4.2) clearly include the special case

$$\sin(\xi_1 - \zeta) = \sin \xi_2 = 0. \tag{4.3}$$

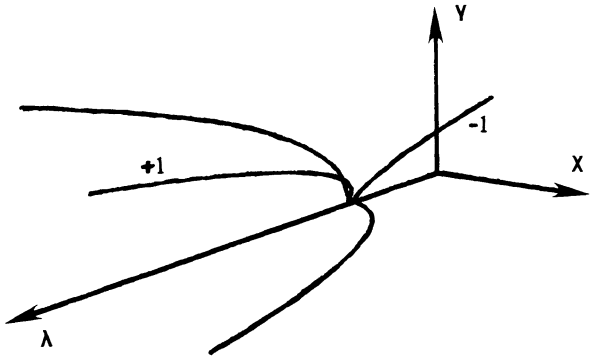

FIG. 1. *Bifurcation diagram for autonomous periodic solutions at* 1:1 *resonance with* $m=\frac{1}{2}$ *and* $\sigma=0$. $+1$ *corresponds to an in-phase mixed mode and* -1 *corresponds to an out-of-phase mixed mode.*

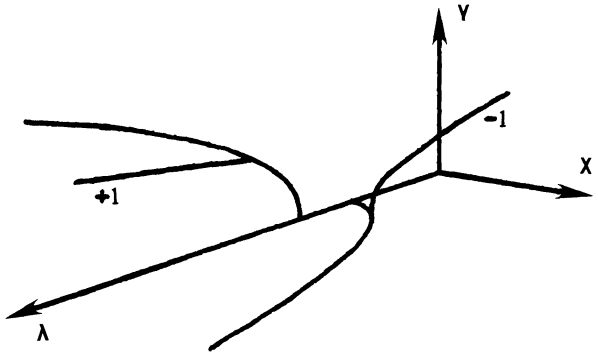

FIG. 2. *Same parameters as Fig.* 1 *but with* $\sigma=\frac{1}{2}$.

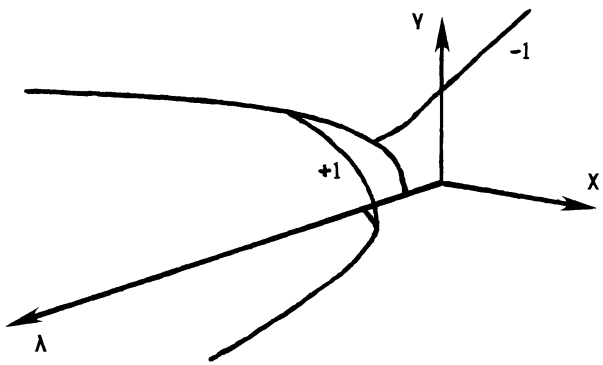

FIG. 3. *Bifurcation diagram for autonomous periodic solutions with* $m=\frac{1}{7}$ *and* $\sigma=-\frac{3}{5}$.

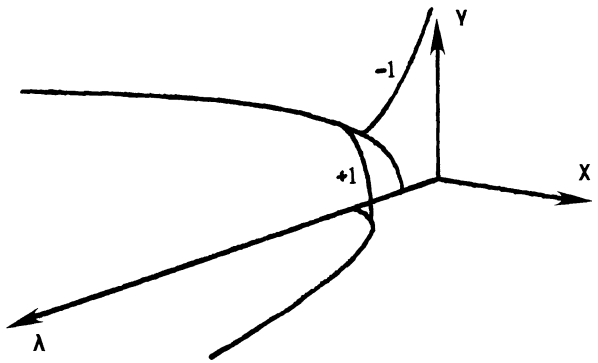

FIG. 4. *Bifurcation diagram for autonomous periodic solutions with* $m=\frac{1}{20}$ *and* $\sigma=-\frac{3}{5}$.

From this subclass of solutions some examples will be shown. We note however that there may be other families of periodic solutions with $\sin(\xi_1-\zeta)\neq 0$ and $\sin\xi_2\neq 0$. With the restriction (4.3) we have

$$f_1(x, y; \kappa) = x[x^2+4m\varepsilon_3 y^2-(\lambda-1)]-\mu_1\varepsilon_1 = 0, \tag{4.4a}$$

$$f_2(x, y; \kappa) = y[4\varepsilon_3 x^2+y^2-(\lambda-1-\sigma)]-\mu_2\varepsilon_3 = 0, \tag{4.4b}$$

with $\kappa=(\lambda, m, \sigma, \mu, \varepsilon)$ and $\varepsilon=(\varepsilon_1, \varepsilon_2, \varepsilon_3)$ where

$$\varepsilon_1 = \cos(\xi_1-\zeta) = \pm 1,$$

$$\varepsilon_2 = \cos\xi_2 = \pm 1,$$

$$\varepsilon_3 = \cos 2(\xi_2-\xi_1) = \pm 1.$$

Particular solution sets for (4.4) are illustrated in Figs. 5-9.

In Fig. 5 $\mu_1=0$, $\zeta=0$, $m=\frac{1}{2}$, $\sigma=0$, and $\zeta=0$ forces $\varepsilon_3=+1$. This is an unfolding of Fig. 1. There are two branches with $x=0$. At $x=0$, $y=(\mu_2/2)^{1/3}$, $\lambda=1+3(\mu_2/2)^{2/3}$ there is a bifurcation point for a branch with $x\neq 0$. In addition there is an isolated branch with $x\neq 0$. Solid lines correspond to a stable branch and dashed lines correspond to an unstable branch. There is no qualitative difference when σ is nonzero here as indicated in Fig. 6. Figure 6 has the same parameters as Fig. 5 but with $\sigma>0$.

In Fig. 7 $\mu_1\neq 0$ but $\mu_2=\sqrt{3}\mu_1$, $\xi=0$, $m=\frac{1}{2}$, $\sigma=0$, and $\zeta=0$ requires that $\varepsilon_3=+1$. Here there are two branches satisfying $y=\sqrt{3}x$. On the lower of these there is a limit point at $x=(\mu_1/14)^{1/3}$, $\lambda=1+21(\mu_1/14)^{2/3}$. The bifurcation point, at $x=(\mu_1/6)^{1/3}$, $\lambda=1+(\mu_1/6)^{2/3}$, on the upper symmetric branch is a pitchfork bifurcation and emits two *unstable* branches with $y\neq\sqrt{3}x$. The stability properties are indicated by dashed and solid lines. Figure 8 is similar to Fig. 7 but a phase is introduced in the forcing function; $\zeta=\pi/2$, and $\mu_2=\sqrt{5/3}\mu_1$. This generates two branches with $y=\sqrt{5/3}x$. On the lower of these there is a limit point at $x=(3\mu_1/14)^{1/3}$, $\lambda=1+\frac{23}{20}(4\mu_2/3)^{2/3}$. The bifurcation point at $x=(\mu_1/10)^{1/3}$, $\lambda=1+\frac{23}{3}(\mu_1/10)^{2/3}$ is a pitchfork bifurcation and it emits one locally stable and one locally unstable branch with $y\neq\sqrt{5/3}x$.

Figure 9 is a σ-unfolding of Fig. 7. The parameters are the same as those of Fig. 7 but with $\sigma=.005$. In this situation σ splits the bifurcation point on the upper symmetric branch producing a limit point. The results in Figs. 5-9 correspond to $m=\frac{1}{2}$ (the two masses are equal). μ-unfoldings for $\frac{1}{16}<m<\frac{1}{4}$ and $0<m<\frac{1}{16}$ should also provide interesting results.

5. Stability analysis of the periodic solutions. The stability of the periodic solutions found in the previous sections will be determined using Floquet theory. As the periodic orbits themselves are only known locally the stability properties will be determined locally using the Lyapunov-Schmidt method to determine the sign of the Floquet exponents in the neighborhood of a bifurcation point.

The Fréchet derivative of the coupled ordinary differential equations governing the motion of the orthogonal planar pendulum results in the linear system

$$[\mathbf{I}+\mathbf{A}_1(t)]\frac{d^2\theta'}{dt^2}+\mathbf{A}_2(t)\frac{d\theta'}{dt}+[\mathbf{I}+\mathbf{A}_3(t)]\theta' = 0 \tag{5.1}$$

where the 2×2 matrices $\mathbf{A}_j(t)$ for $j=1, 2, 3$ satisfy $\mathbf{A}_j(t+2\pi)=\mathbf{A}_j(t)$ and expressions for each of them are given in the Appendix.

From Floquet theory we know that (5.1) has a solution $\theta'(t)=\theta''(t)\,e^{\eta t}$ with the stipulation that $\theta''(t+2\pi)=\theta''(t)$ and η is the Floquet exponent that determines the stability of the periodic orbits. Sign $[\mathrm{Re}(\eta)]<0$ implies stability and sign $[\mathrm{Re}(\eta)]>0$ implies instability.

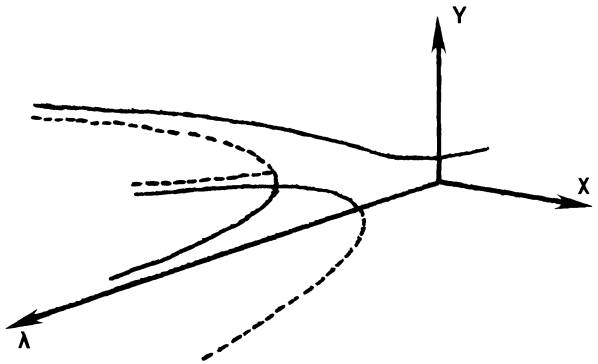

FIG. 5. *Bifurcation diagram for forced periodic solutions with one component forcing.* $m=\frac{1}{2}$, $\mu_1=0$, $\mu_2=\frac{1}{4}$, $\zeta=0$, *and* $\sigma=0$. *Stable branches are solid and unstable branches are dashed.*

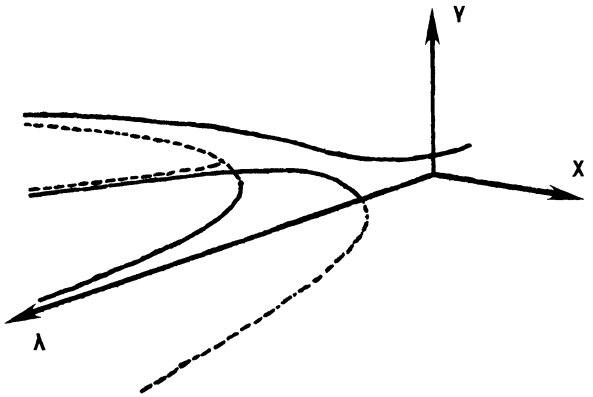

FIG. 6. *Same parameters as Fig. 5 but with* $\sigma=\frac{3}{10}$.

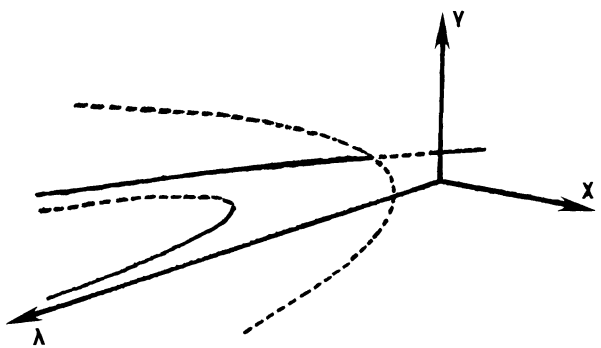

FIG. 7. *Bifurcation diagram for forced periodic solutions with two component forcing.* $m=\frac{1}{2}$, $\mu_1=\frac{1}{4}$, $\mu_2=\sqrt{3}\mu_1$, $\zeta=0$, *and* $\sigma=0$.

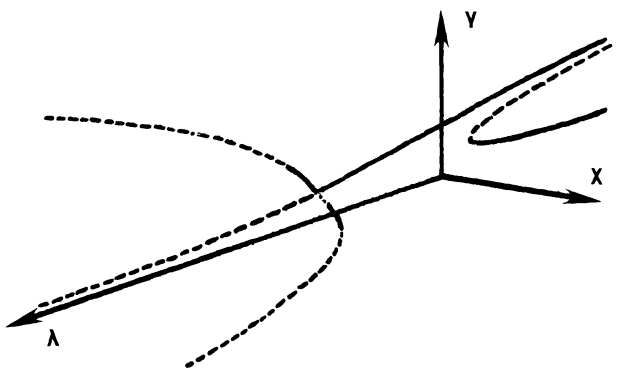

FIG. 8. *Bifurcation diagram for forced periodic solutions with nonzero* ζ. $m=\frac{1}{2}$, $\mu_1=\frac{1}{4}$, $\mu_2=\sqrt{\frac{5}{3}}\mu_1$, $\zeta=\pi/2$, *and* $\sigma=0$.

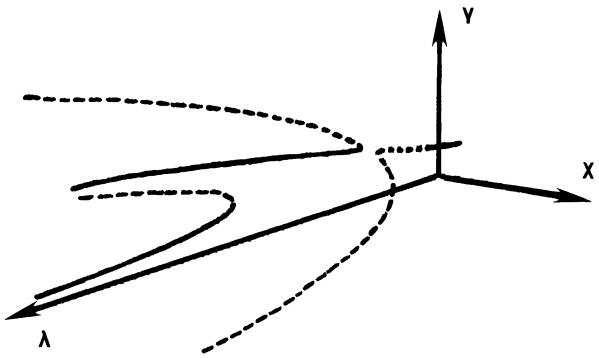

FIG. 9. *Effect of σ on two component forced oscillations. Same parameters as Fig. 7 but with $\sigma = .005$.*

The Lyapunov-Schmidt method will be used to estimate η near the origin. To simplify the analysis (5.1) is converted to an integral equation for $\zeta(t) = -\mathbf{K}\theta''$ where $\zeta = (\zeta_1, \zeta_2)$ and $\zeta(t) = \theta''$. After some manipulation the equation for ζ is

$$[\mathbf{I} - \Lambda\mathbf{K}]_\zeta = [-\mathbf{A}_1 + (2\eta(\mathbf{I} + \mathbf{A}_1) + \mathbf{A}_2)\mathbf{K}_t + (\eta^2(\mathbf{I} + \mathbf{A}_1) + \eta\mathbf{A}_2 + \mathbf{A}_3)\mathbf{K}]\zeta, \tag{5.2}$$

which is a mapping from $\chi \to \chi$ and terms are as previously defined. For (5.2) we have the following lemma.

LEMMA 5.1. *Equation* (5.2) *has a* 2π *periodic solution only if* $\zeta = a\cos t + b\sin t + \zeta'$, *where* $a, b \in R^2$, *satisfies the system of equations*

$$[\mathbf{I} - \Lambda\mathbf{K} + \mathbf{P}]\zeta' = h(\zeta', t; a, b) \tag{5.3}$$

and

$$\mathbf{P}h = 0 \tag{5.4}$$

where h is given by the right-hand side of (5.2).

Proof. It was previously established that $[\mathbf{I} - \Lambda\mathbf{K}]$ is a Fredholm operator and $\chi = N(\mathbf{I} - \Lambda\mathbf{K}) \oplus R(\mathbf{I} - \Lambda\mathbf{K})$ and the Fredholm alternative applies. This requires that $h \in R(\mathbf{I} - \Lambda\mathbf{K})$ resulting in (5.4). The operator $[\mathbf{I} - \Lambda\mathbf{K} + \mathbf{P}]$ is a restriction of $[\mathbf{I} - \Lambda\mathbf{K}]$ to $N(\mathbf{I} - \Lambda\mathbf{K})^\perp$. □

Is is now straightforward to apply the implicit function theorem to (5.3) resulting in a unique ζ' in a neighborhood of the origin. Substitution of this solution into (5.4) will then result in the "bifurcation-stability" equations,

$$(\lambda - 1)A_1 + 2i\eta A_1 - \frac{2m}{\pi}\overline{\alpha_1}\alpha_2 A_2 - \frac{1}{4\pi}\alpha_1^2\overline{A_1} - \frac{1}{2\pi}|\alpha_1|^2 A_1 - \frac{m}{\pi}\alpha_2^2\overline{A_1} + r_1 = 0, \tag{5.5a}$$

$$\begin{aligned}(\lambda - 1 - \sigma)A_2 + 2i\eta A_2 - \frac{2}{\pi}\alpha_1\overline{\alpha_2}A_1 - \frac{1}{\pi}\alpha_1^2\overline{A_2} \\ - \frac{1}{4\pi}[\alpha_2^2\overline{A_2} + 2|\alpha_2|^2 A_2] + r_2 = 0\end{aligned} \tag{5.5b}$$

where r_1 and r_2 are higher order terms which satisfy

$$\|r\| = O\{(|\alpha_1| + |\alpha_2|)^2(|\lambda - 1| + |\sigma| + (|\alpha_1| + |\alpha_2|)^2) + |\sigma|\,|\lambda - 1| + |\eta|^2\}$$

and $A_1=(a_1-ib_1)/\sqrt{2}$ and $A_2=(a_2-ib_2)/\sqrt{2}$. If we formally neglect the higher order terms and expand the set (5.5) into four real homogeneous equations, then a solution exists only if the determinant of the coefficient matrix is zero. This yields a fourth-order algebraic equation for the Floquet exponents,

$$\Delta(\eta)=\eta^4-2b\eta^2+|J_1|\cdot|J_2|=0$$

where

$$b=-\frac{\mu_1}{2}\varepsilon_1[2x+\mu_1\varepsilon_1/x^2-8my^2\varepsilon_3/x]-\frac{\mu_2}{2}\varepsilon_2[2y+\mu_2\varepsilon_2/y^2-8x^2\varepsilon_3/y]$$
$$-8x^2y^2[(8-\varepsilon_3)m-\varepsilon_3]$$

and

$$J_1=\begin{pmatrix}2x+\mu_1\varepsilon_1/x^2 & 8my\varepsilon_3\\ 8x\varepsilon_3 & 2y+\mu_2\varepsilon_2/y^2\end{pmatrix},$$
$$J_2=\begin{pmatrix}-\mu_1\varepsilon_1+8mxy^2\varepsilon_3 & -8mxy^2\varepsilon_3\\ -8x^2y\varepsilon_3 & -\mu_2\varepsilon_2+8x^2y\varepsilon_3\end{pmatrix}.$$

When $\mu=0$, $|J_1|\cdot|J_2|=0$ and stability is assured if $b<0$, that is when $(8-\varepsilon_3)m-\varepsilon_3>0$. This yields the result stated in § 3 for stability of autonomous oscillations. Out of phase oscillations ($\varepsilon_3=-1$) are stable for all m and in phase oscillations ($\varepsilon_3=+1$) are stable for $m>\frac{1}{7}$.

When $\mu\neq 0$, the important points are those where $|J_1|\cdot|J_2|=0$. These correspond to points where there is an exchange of stability. Rather than a complete analysis, stability properties corresponding to Figs. 5-9 will be given. For Figs. 5 and 6 $\mu_1=0$ and $|J_1|=4x[(1-16m)y+\mu_2\varepsilon_3/2y^2]$. If $x\neq 0$, then $|J_1|=0$ if

$$y=\left(\frac{\mu_2\varepsilon_2}{2(16m-1)}\right)^{1/3}.$$

In Fig. 5 this corresponds to the limit point for the $x\neq 0$ branch. With $\mu_1=0$ $|J_2|=-8mxy^2\mu_2$, which provides no additional information. When $x=0$ a stability exchange occurs when $b=0$. This occurs when $y^3=(-\mu_2\varepsilon_2/2)$. This is the limit point on the lower $x=0$ branch. A similar result holds for $\sigma\neq 0$ with the location of the critical points perturbed. The results are indicated in Figs. 5 and 6.

For Figs. 7 and 8 a general analysis is more difficult but the following information may be obtained. Along the symmetric branches, where $y=kx$, $|J_1|=0$ when

$$x=\left[\frac{\mu_1}{28}\left(\frac{k^2-1}{k^2}\right)\left[\sqrt{1+\frac{28k^2}{(k^2+1)^2}}+\varepsilon_1\right]\right]^{1/3} \tag{5.6}$$

where $k^2=3$ for Fig. 7 and $k^2=5/3$ for Fig. 8, and $|J_2|=0$ when

$$x=\left(\frac{\mu_1\varepsilon_1}{4\varepsilon_3(2+k^2)}\right)^{1/3}. \tag{5.7}$$

First, for Fig. 7, (5.6) results in a bifurcation point at $x=(\mu_1/6)^{1/3}$, $\lambda=1+(\mu_1/6)^{2/3}$ on the upper symmetric branch and a limit point at $x=(\mu_1/14)^{1/3}$, $\lambda=1+21(\mu_1/14)^{2/3}$ on the lower symmetric branch. $|J_2|=0$ when $x=(\mu_1/20)^{1/3}$, $\lambda=1-14(\mu_1/20)^{2/3}$. Therefore we have that the solutions along the upper symmetric branch are stable for $0<\lambda<1-14(\mu_1/20)^{2/3}$, unstable for $1-14(\mu_1/20)^{2/3}<\lambda<1+(\mu_1/6)^{2/3}$, and stable for $\lambda>1+(\mu_1/6)^{2/3}$. The unsymmetric branches emitted by the bifurcation point are

unstable. The anomaly here is that there are no *stable* periodic solutions for $1-14(\mu_1/20)^{2/3}<\lambda<1+(\mu_1/6)^{2/3}$. This is a small neighborhood of the linear resonance $\lambda=1$.

A similar analysis for Fig. 8 shows that the upper symmetric branch is stable for $\lambda>\lambda_b$ where λ_b is the bifurcation point, and there is an exchange of stability at the limit point on the lower symmetric branch. For the unsymmetric branch the stability properties are anomalous. For the $+x$ branch there is a small region of stable solutions, separated from the bifurcation point by a region of unstable solutions, and for the $-x$ branch the solutions are stable for a small distance and then they become unstable. A blow-up of the region around the bifurcation point is shown in Fig. 10. The reason for these stability regions is not clear.

6. Remarks. The basis of §§ 3 and 4 is that the bifurcation equations *when nondegenerate* correspond to periodic solutions. When the bifurcation equations are degenerate we expect other solutions to occur or more complex families of periodic solutions. To illustrate what may occur at degenerate points we consider the Hamiltonian of Hénon and Heiles [14] given in (2.3)-(2.4). Following the analysis in this paper the bifurcation equations for the Hénon-Heiles problem are:

$$x[x^2+py^2-(\lambda-1)]=0, \tag{6.1a}$$

$$y[qx^2+y^2-(\lambda-1)]=0 \tag{6.1b}$$

with

$$p=\frac{2}{5r}(1-\varepsilon_3/6), \tag{6.2a}$$

$$q=\tfrac{1}{5}(4+18r+3(2-r)\varepsilon_3) \tag{6.2b}$$

with $\varepsilon_3=\pm1$ and $r=d/c$. When $p\neq1$, $q\neq1$, and $pq\neq1$ the equations are nondegenerate and periodic solutions occur. This has been proved from a different point of view by Braun [2] and Kummer [18]. When $r=-\frac{1}{3}$ and $\varepsilon_3=1$ the normal form is degenerate; $q=1$. (This is analogous to the degeneracy $m=\frac{1}{4}$, $\varepsilon_3=1$ for the O-P pendulum.) The critical value $r=-\frac{1}{3}$ is precisely the Hamiltonian studied by Hénon and Heiles [14] and Lichtenberg and Lieberman [19]. Lichtenberg and Lieberman [19, pp. 46-50] show that regions of stochasticity occur in the phase space for this particular set of parameters.

This normal form is also similar to the normal form for the spherical pendulum studied by Miles [22]. Using the approach in this paper we find that the normal form

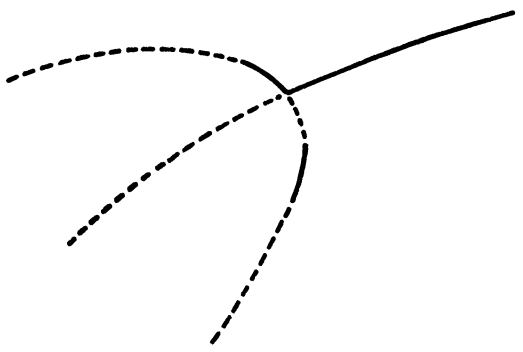

FIG. 10. *Blow-up of the neighborhood of the bifurcation point in Fig. 8 showing the regions of stability.*

for the spherical pendulum without forcing or damping is

$$x[x^2+(3\varepsilon_3-2)y^2-(\lambda-1)]=0,$$
$$y[(3\varepsilon_3-1)x^2+y^2-(\lambda-1)]=0,$$

which is clearly degenerate when $\varepsilon_3=1$. At this value the form is similar to the form for the O-P pendulum when $m=\frac{1}{4}$, $\varepsilon_3=1$, and the Hénon-Heiles form with $r=-\frac{1}{3}$. Miles [22] has shown that the spherical pendulum has quasi-periodic as well as chaotic solutions when damping and forcing are present.

The degeneracy corresponding to $m=\frac{1}{16}$ in the O-P pendulum is more severe. The equations are completely degenerate. However this is precisely the type of degeneracy studied by Erneux and Reiss [8] in their study of equilibrium solutions, and Erneux and Matkowsky [9]. Erneux and Matkowsky showed that a bifurcation from periodic solutions into quasi-periodic solutions may occur in the neighborhood of a degeneracy of this type in the context of the Hopf bifurcation.

Knobloch [16] has begun a systematic classification of degenerate normal forms for $O(2)$ symmetric Hopf bifurcation. The $O(2)$ symmetric normal form is a special case of the $Z_2\oplus Z_2$ symmetric normal form, therefore those results may also be applicable to the degenerate 1:1 resonance in Hamiltonian systems. His approach is to include the appropriate higher order terms and this leads to interesting new classes of periodic solutions.

Appendix. The matrices $\mathbf{A}_1(t)$, $\mathbf{A}_2(t)$, $\mathbf{A}_3(t)$ introduced in (5.1) are defined here.

$$\mathbf{A}_1(t)=\begin{pmatrix} 0 & \dfrac{m}{1-\sigma}\sin \mathbf{K}\phi_1 \sin \mathbf{K}\phi_2 \\ (1-\sigma)\sin \mathbf{K}\phi_1 \sin \mathbf{K}\phi_2 & 0 \end{pmatrix},$$

$$\mathbf{A}_2(t)=\begin{pmatrix} 0 & 2\dfrac{m}{1-\sigma}(\mathbf{K}_t\phi_2)\sin \mathbf{K}\phi_1 \cos \mathbf{K}\phi_2 \\ 2(1-\sigma)(\mathbf{K}_t\phi_1)\cos \mathbf{K}\phi_1 \sin \mathbf{K}\phi_2 & 0 \end{pmatrix},$$

$$\mathbf{A}_3(t)=\begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}$$

and

$$a_{11}=(\lambda-1)\cos \mathbf{K}\phi_1+[\cos \mathbf{K}\phi_1-1]-2\sqrt{2}\mu_1 \cos t \sin \mathbf{K}\phi_1$$
$$-\frac{m}{1-\sigma}\cos \mathbf{K}\phi_1[\phi_2 \sin \mathbf{K}\phi_2+(\mathbf{K}_t\phi_2)^2 \cos \mathbf{K}\phi_2],$$
$$a_{12}=-\frac{m}{1-\sigma}\sin \mathbf{K}\phi_1[\phi_2 \cos \mathbf{K}\phi_2+(\mathbf{K}_t\phi_2)^2 \sin \mathbf{K}\phi_2],$$
$$a_{21}=-(1-\sigma)\sin \mathbf{K}\phi_2[\phi_1 \cos \mathbf{K}\phi_1+(\mathbf{K}_t\phi_1)^2 \sin \mathbf{K}\phi_1],$$
$$a_{22}=[\lambda(1-\sigma)-1]\cos \mathbf{K}\phi_2+[\cos \mathbf{K}\sigma_2-1]-2\sqrt{2}\mu_2 \cos t \sin \mathbf{K}\phi_2$$
$$=-(1-\sigma)\cos \mathbf{K}\phi_2[\phi_1 \sin \mathbf{K}\phi_1-(\mathbf{K}_t\phi_1)^2 \cos \mathbf{K}\phi_1].$$

STUDY OF A DOUBLY NONLINEAR HEAT EQUATION WITH NO GROWTH ASSUMPTIONS ON THE PARABOLIC TERM*

DOMINIQUE BLANCHARD† AND GILLES A. FRANCFORT†

Abstract. A doubly nonlinear equation with no growth assumptions on the parabolic term or on the heat flux is studied. Two existence and comparison results are established under different assumptions on the data. The technique uses truncation-penalization of the energy and energy estimates through convex conjugate functions.

Key words. heat equation, fast growing energy, nonlinear flux, energy estimates, convexity

AMS(MOS) subject classification. 35K55

Introduction. Doubly nonlinear evolution equations of the form

$$\frac{\partial b(u)}{\partial t} - \operatorname{div} A(\nabla u) = f \quad \text{on } \Omega \times (0, T),$$

$$u = 0 \quad \text{on } \partial\Omega \times (0, T),$$

$$b(u)|_{t=0} = b(u_0),$$

Ω bounded domain of $\mathbb{R}^N$

were first studied, to our knowledge, by Lions [8], Raviart [10], and Bamberger [2] in the case where

$$b(u) = |u|^{\alpha-2}u, \qquad A(w) = |w|^{p-2}w.$$

Grange and Mignot [7] address this problem in an abstract setting, namely

$$\frac{d}{dt}(Bu) + Au = f, \qquad Bu|_{t=0} = Bu_0,$$

where A and B denote the subdifferentials of the convex functions Φ and Ψ. The analysis developed in [7] is based on the essential restriction that Φ must be continuous on a Banach space V_1, and Ψ on a Banach space V_2, where V_1 is *densely and compactly embedded* in V_2. Power type nonlinearities are then restricted to satisfy

$$\frac{1}{\alpha} > \frac{1}{p} - \frac{1}{N}.$$

Furthermore A and B are assumed to be bounded on the bounded sets of V_1 and V_2 and Φ is assumed to be coercive.

Similar equations are also investigated with the help of semigroup techniques in L_1 (cf., e.g., Benilan [3]).

In this paper existence of a solution of semi-abstract equations of the form

$$\frac{\partial}{\partial t} b(u) - \operatorname{div} D\Phi(\nabla u) = f \quad \text{in } \Omega \times (0, T),$$

* Received by the editors March 19, 1987; accepted for publication (in revised form) January 25, 1988.

$$u = 0 \quad \text{on } \partial\Omega \times (0, T),$$

$$b(u)|_{t=0} = b(u_0),$$

is established in the following framework:

—Φ is a C^1 convex functional on $[L_q(\Omega)]^N$, $q > 1$, with $\Phi(w) \geqq \beta(\int_\Omega |w|^q\, dx)^{r/q}$, $r > 1$, $2N/(N+2) < q$.

—b is a locally Lipschitz monotone real-valued function.

Loosely speaking, there need not exist a Banach space V_2 on which b is the subdifferential of a convex *continuous* function Ψ, and, if it exists, V_1 need not be embedded in V_2. We are, for instance, in a position to solve the doubly nonlinear evolution equation with power type nonlinearities for any values of α and p (greater than one). Furthermore the function b may grow faster than any power function at infinity ($b(u) = e^{e^u}$, for example). In contrast, it need not be strictly increasing on any part of $\mathbb{R}$. Thus the evolution equation may become stationary in subdomain of $\Omega \times (0, T)$.

Similar results are given by Alt and Luckhaus [1] in a setting that includes equations of the form

$$\frac{db(u)}{\partial t} - \operatorname{div} A(\nabla u) = f,$$

where A is a monotone strongly elliptic operator on $\mathbb{R}^N$, i.e.,

$$(A(z) - A(z'), z - z')_{\mathbb{R}^N} \geqq \alpha |z - z'|^p.$$

Note that in the case when $A(w) = |w|^{p-2}w$, p is then restricted to be greater than or equal to two.

In Alt and Luckhaus [1], as well as in Grange and Mignot [7], the proof of the existence of a solution is based on a backward time difference scheme. Our method uses penalization through addition of a term of the form $\varepsilon(\partial u/\partial t)$ together with a truncation of the function b.

The detailed hypotheses on b, Φ, the initial condition $b(u_0)$, and the forcing term f are given in § 1, together with the existence results. The first result (Theorem 1) is concerned with forcing terms f in $W^{1,1}(0, T; L_2(\Omega))$ and initial conditions $b(u_0)$ in $L_2(\Omega)$ with u_0 in $W_0^{1,q}(\Omega)$. It states the existence of a solution u that also satisfies a maximum principle if f has a distinguished sign. The second result (Theorem 2) addresses the case of a forcing term f in $W^{1,1}(0, T; W^{-1,q'}(\Omega))(1/q + 1/q' = 1)$ and an initial condition $b(u_0)$ in $L_1^{\text{loc}}(\Omega) \cap W^{-1,q'}(\Omega)$ with u_0 in $W_0^{1,q}(\Omega)$.

Section 2 is devoted to the proof of Theorem 1 while § 3 addresses the proof of Theorem 2. The details of the different steps are briefly described at the end of § 1. It should be noted however that our proof of Theorem 2 (§ 3) is inspired by the Lemmas 1.8 and 1.9 of Alt and Luckhaus [1].

Throughout the paper, the notation $\|u\|_{m,s}$ denotes the usual Sobolev norm of u on $W^{m,s}(\Omega)$, where $W^{m,s}(\Omega)$ is the space of all $L_s(\Omega)$-functions with derivatives up to order m in $L_s(\Omega)$. Unless otherwise specified, the product $\langle\, , \rangle$ stands for the duality product between $W_0^{1,q}(\Omega)$ and $W^{-1,q'}(\Omega)$.

1. Assumptions and statement of the existence results. Let Ω be a bounded domain of $\mathbb{R}^N$ ($N \geqq 1$) with Lipschitz boundary $\partial\Omega$. Let q, r, α, and T be four real numbers

satisfying

$$1<q<+\infty,$$

$$q>\frac{2N}{N+2}, \qquad r>1, \tag{1}$$

$$\alpha>0, \qquad T>0.$$

Inequalities (1) result in the following *compact* imbeddings:

$$W_0^{1,q}(\Omega)\hookrightarrow L_2(\Omega)\hookrightarrow W^{-1,q'}(\Omega). \tag{2}$$

In (2) the space $W_0^{1,q}(\Omega)$ is the subspace of all $W^{1,q}(\Omega)$-functions with null traces, whereas q' is the conjugate of q, i.e., $1/q+1/q'=1$.

Let b be defined as a real-valued function of the real variable with the following properties:

$$b \text{ is locally Lipschitz,}$$

$$b \text{ is monotone increasing,} \tag{3}$$

$$b(0)=0.$$

Remark 1. The function b is *not* restricted by any growth assumption at infinity, *nor* is it assumed to be strictly increasing.

If Ψ denotes the primitive of b, i.e.,

$$\Psi(t)=\int_0^t b(s)\,ds,$$

Ψ is a positive C^1 convex function, and its convex conjugate function Ψ^*, defined as

$$\Psi^*(t)=\sup_{s\in\mathbb{R}}\{ts-\Psi(s)\},$$

satisfies, for every t of $\mathbb{R}$,

$$\Psi^*(t)\geqq 0, \qquad \Psi^*(b(t))=b(t)t-\Psi(t). \tag{4}$$

Let Φ be defined as a real-valued functional on $[L_q(\Omega)]^N$ with the following properties:

$$\Phi \text{ is } C^1,$$

$$\Phi \text{ is convex,}$$

$$D\Phi \text{ is bounded on the bounded sets of } [L_q(\Omega)]^N, \tag{5}$$

$$\Phi(0)=0,$$

$$\Phi(w)\geqq \alpha\|w\|_{0,q}^r \quad \text{for any } w \text{ in } [L_q(\Omega)]^N.$$

The remainder of this paper is devoted to the proof of the following theorems.

THEOREM 1. *Under the assumptions* (1), (3), *and* (5), *and if*

$$u_0\in W_0^{1,q}(\Omega), \qquad b(u_0)\in L_2(\Omega), \tag{6}$$

$$f\in W^{1,1}(0,T;L_2(\Omega)), \tag{7}$$

the problem

$$\begin{aligned} &\frac{\partial b(u)}{\partial t} - \operatorname{div} D\Phi(\nabla u) = f \quad \text{in } \Omega \times (0, T), \\ &u = 0 \quad \text{on } \partial\Omega \times (0, T), \\ &b(u)|_{t=0} = b(u_0), \end{aligned} \tag{8}$$

admits a solution u such that

$$u \in L_\infty(0, T; W_0^{1,q}(\Omega)), \tag{9}$$

$$b(u) \in L_\infty(0, T; L_2(\Omega)) \cap W^{1,\infty}(0, T; W^{-1,q'}(\Omega)). \tag{10}$$

The norm u in $L_\infty(0, T; W_0^{1,q}(\Omega))$ *is bounded above by a continuous function of* $\Phi(\nabla u_0)$ *and of the norm* $|||f|||$ *of f in* $W^{1,1}(0, T; W^{-1,q'}(\Omega))$.

Furthermore, if u_{01} *and* u_{02} *satisfy* (6); *while* f_1 *and* f_2 *satisfy* (7), *and if* $b(u_{01}) - b(u_{02})$ *is almost everywhere positive on* Ω *while* $f_1 - f_2$ *is almost everywhere positive on* $\Omega \times (0, T)$, *there exist a solution* u_1 *associated to* u_{01}, f_1 *and a solution* u_2 *associated to* u_{02}, f_2 *such that* $b(u_1) - b(u_2)$ *is almost everywhere positive on* $\Omega \times (0, T)$. □

THEOREM 2. *Under the assumption* (1), (3), *and* (5), *and if*

$$u_0 \in W_0^{1,q}(\Omega), \qquad b(u_0) \in L_1^{\text{loc}}(\Omega) \cap W^{-1,q'}(\Omega), \tag{11}$$

$$f \in W^{1,1}(0, T; W^{-1,q'}(\Omega)), \tag{12}$$

the problem

$$\begin{aligned} &\frac{\partial b(u)}{\partial t} - \operatorname{div} D\Phi(\nabla u) = f \quad \text{in } \Omega \times (0, T), \\ &u = 0 \quad \text{on } \partial\Omega \times (0, T), \\ &b(u)|_{t=0} = b(u_0), \end{aligned} \tag{13}$$

admits a solution u such that

$$u \in L_\infty(0, T; W_0^{1,q}(\Omega)), \tag{14}$$

$$b(u) \in \mathscr{C}^0(0, T; L_1(\Omega)) \cap W^{1,\infty}(0, T; W^{-1,q'}(\Omega)). \tag{15}$$

Furthermore, if u_{01} *and* u_{02} *satisfy* (11) *while* f_1 *and* f_2 *satisfy* (12) *and if* $b(u_{01}) - b(u_{02})$ *is almost everywhere positive on* Ω, *while* $\langle (f_1 - f_2)(t), \varphi \rangle$ *is almost everywhere positive on* $(0, T)$ *for any* φ *in* $W_0^{1,q}(\Omega)$, *there exist a solution* u_1 *associated to* u_{01}, f_1 *and a solution* u_2 *associated to* u_{02}, f_2 *such that* $b(u_1) - b(u_2)$ *is almost everywhere positive on* $\Omega \times (0, T)$. □

Remark 2. In the settings of both theorems,

$$b(u_0)u_0 \in L_1(\Omega), \qquad b(u(t))u(t) \in L_\infty(0, T; L_1(\Omega)).$$

This property is trivially checked in the case of Theorem 1. It results from a theorem of Brézis and Browder [5, Thm. 1] in the case of Theorem 2. The positivity of Ψ and Ψ^* then implies that

$$\Psi(u_0), \Psi^*(b(u_0)) \in L_1(\Omega) \quad \text{and} \quad \Psi(u), \Psi^*(b(u)) \in L_\infty(0, T; L_1(\Omega)).$$

Furthermore in the setting of Theorem 2 the initial condition $b(u_0)$ will be shown in Remark 10 to lie in $L_1(\Omega)$, which is consistent with the continuity property of $b(u)$ with respect to time.

Remark 3. Theorem 2 provides an existence result for a class of nonlinear parabolic homogenization problems. A family A^ε of symmetric bounded measurable matrices is considered. It satisfies, for almost every x of $\mathbb{R}^N$,

$$\alpha|\xi|^2 \leqq (A^\varepsilon(x)\xi, \xi)_{\mathbb{R}^N} \leqq \beta|\xi|^2,$$

where α and β are two strictly positive real numbers.

If u_0^ε is an element of $H_0^1(\Omega)$ such that

$$b(u_0^\varepsilon) \in L_1^{\text{loc}}(\Omega) \cap H^{-1}(\Omega)$$

and if f is an arbitrary element of $W^{1,1}(0, T; H^{-1}(\Omega))$, the problem

$$\frac{\partial b(u^\varepsilon)}{\partial t} - \operatorname{div} A^\varepsilon \nabla u^\varepsilon = f \quad \text{in } \Omega,$$

$$b(u^\varepsilon)|_{t=0} = b(u_0^\varepsilon),$$

$$u^\varepsilon = 0 \quad \text{on } \partial\Omega$$

admits a solution u^ε in $L_\infty(0, T; H_0^1(\Omega))$ with $b(u^\varepsilon)$ in $L_\infty(0, T; L_1(\Omega)) \cap W^{1,\infty}(0, T; H^{-1}(\Omega))$. We assume that, as ε tends to zero,

$$u_0^\varepsilon \text{ converges weakly to } u_0^0 \text{ in } H_0^1(\Omega),$$

$$\langle b(u_0^\varepsilon), u_0^\varepsilon \rangle \text{ remains bounded independently of } \varepsilon.$$

The theory of H-convergence (Tartar [13]) ensures the existence of a subsequence $A^{\varepsilon'}$ of A^ε and of a symmetric bounded measurable matrix A^0 with

$$\alpha|\xi|^2 \leqq (A^0(x)\xi, \xi)_{\mathbb{R}^N} \leqq \beta|\xi|^2,$$

almost everywhere in $\mathbb{R}^N$, such that, as ε tends to zero,

$$A^{\varepsilon'} \text{ } H\text{-converges to } A^0.$$

It is then fairly straightforward to prove the following homogenization result: there exists a subsequence $u^{\varepsilon''}$ of u^ε such that, as ε'' tends to zero,

$$u^{\varepsilon''} \rightharpoonup u^0 \quad \text{weakly in } H_0^1(\Omega),$$

$$A^{\varepsilon''}\nabla u^{\varepsilon''} \rightharpoonup A^0 \nabla u^0 \quad \text{weakly in } [L_2(\Omega)]^N,$$

where u^0 is a solution of

$$\frac{\partial b(u^0)}{\partial t} - \operatorname{div} A^0 \nabla u^0 = f \quad \text{in } \Omega \times (0, T),$$

$$b(u^0)|_{t=0} = b(u_0^0),$$

$$u^0 = 0 \quad \text{on } \partial\Omega \times (0, T).$$

The proof of this result will not be presented here for the sake of brevity.

The proof of Theorem 1 is presented in § 2. It is divided into five steps to which correspond five sections. Section 2.1 is devoted to the formulation of a Galerkin approximation. To this effect, the function b is truncated and a small linear perturbation is added; $b(t)$ becomes $b^\eta(t) + \varepsilon t$, where b^η is the function resulting from the truncation of b at height $1/\eta$. In § 2.2 the limit process is performed in the Galerkin approximation. In § 2.3 the truncation height $1/\eta$ is increased to infinity. The coercivity parameter ε tends to zero in § 2.4. Finally the comparison result is derived in § 2.5.

The proof of Theorem 2 is presented in § 3. The initial condition u_0 is truncated at the height n while f is approximated by a sequence f^n in $W^{1,1}(0, T; L_2(\Omega))$. Theorem 1 is applied with the truncated u_0 as initial condition and with f^n as forcing term. The parameter n is then increased to infinity.

2. Proof of Theorem 1.

2.1. The Galerkin approximation. As previously mentioned, we introduce $b^\eta(t)$, $\Psi^\eta(t)$ to be

$$b^\eta(t) = \begin{cases} b(t) & \text{if } |b(t)| \leqq \dfrac{1}{\eta}, \\ \dfrac{1}{\eta}\operatorname{sg}(t) & \text{if } |b(t)| > \dfrac{1}{\eta}, \end{cases}$$

$$\Psi^\eta(t) = \int_0^t b^\eta(s)\, ds.$$

The function Ψ^η is C^1 convex and the function b^η is monotone. We propose to solve

$$\begin{aligned} &\frac{\partial}{\partial t}(b^\eta(u_\varepsilon^\eta) + \varepsilon u_\varepsilon^\eta) - \operatorname{div} D\Phi(\nabla u_\varepsilon^\eta) = f \quad \text{in } \Omega \times (0, T), \\ &u_\varepsilon^\eta = 0 \quad \text{on } \partial\Omega \times (0, T), \\ &b^\eta(u_\varepsilon^\eta)|_{t=0} = b^\eta(u_0), \end{aligned} \tag{16}$$

using a Galerkin approximation.

Let $\varphi_1, \cdots, \varphi_m, \cdots$ be a basis of $W_0^{1,q}(\Omega)$ consisting of $\mathscr{C}_0^\infty(\Omega)$-functions. If v is an arbitrary element of $W_0^{1,q}(\Omega)$, there exists a sequence V_1^m of $\mathbb{R}$ such that

$$\sum_{i=1}^m V_i^m \varphi_i \xrightarrow{m \to +\infty} v \quad \text{strongly in } W_0^{1,q}(\Omega).$$

Let m be an arbitrary but fixed integer. To any element V^m of $\mathbb{R}^m$ corresponds the element v^m of $\mathscr{C}_0^\infty(\Omega)$ defined as

$$v^m = \sum_{i=1}^m V_i^m \varphi_i.$$

The mapping is one-to-one since the φ_i are a basis of $W_0^{1,q}(\Omega)$.

Let G^m be the mapping from $\mathbb{R}^m$ into itself whose ith component is

$$[G^m(V^m)]_i = \int_\Omega (b^\eta(v^m) + \varepsilon v^m)\varphi_i\, dx.$$

If V^m and W^m are two arbitrary elements of $\mathbb{R}^m$,

$$\begin{aligned} (G^m(V^m) - G^m(W^m),\, V^m - W^m)_{\mathbb{R}^m} &= \int_\Omega (b^\eta(v^m) - b^\eta(w^m))(v^m - w^m)\, dx \\ &\quad + \varepsilon \int_\Omega |v^m - w^m|^2\, dx \geqq \varepsilon \mathscr{C}_m |V^m - W^m|_{\mathbb{R}^m}^2, \end{aligned} \tag{17}$$

where $\mathscr{C}_m$ is a constant such that for any V^m in $\mathbb{R}^m$

$$\mathscr{C}_m |V^m|_{\mathbb{R}^m}^2 \leqq \int_\Omega |v^m|^2\, dx.$$

Hence G^m is monotone coercive; it is also clearly continuous. We thus conclude with the help of Brouwer's fixed point theorem that G^m is onto (cf., for example, [8, Lemma 4.3, p. 53]). In view of (17),

$$(G^m)^{-1} \text{ is Lipschitz with Lipschitz ratio } 1/\varepsilon. \tag{18}$$

Let Φ^m be the mapping from $\mathbb{R}^m$ into itself whose ith component is

$$[\Phi^m(V^m)]_i = \int_\Omega (D\Phi(\nabla v^m), \nabla \varphi_i)_{\mathbb{R}^N}\, dx.$$

Since $D\Phi$ is continuous on $[L_q(\Omega)]^m$, Φ^m is continuous.

Finally define $F^m(t)$ to be the vector of $\mathbb{R}^m$ whose ith component is

$$[F^m(t)]_i = \int_\Omega f(t)\varphi_i\, dx.$$

By virtue of (7), $F^m(t)$ is a continuous function of t.

The continuity properties of $(G^m)^{-1}$, Φ^m, and F^m imply that the ordinary differential equation

$$\frac{dW^m}{dt}(t) + \Phi^m((G^m)^{-1}(W^m))(t) = F^m(t), \qquad W^m(0) = W_0^m, \tag{19}$$

where W_0^m is an arbitrary element of $\mathbb{R}^m$, has a local C^1 solution $W^m(t)$ on a time interval $[0, T(W_0^m))$; $T(W_0^m)$ is a strictly positive real number which depends on W_0^m.

The existence of a global solution on $[0, T]$ is ensured if $|W^m(t)|$ is proved not to blow up whenever t tends to $T(W_0^m)$ with $T(W_0^m) \leqq T$. In view of the continuity properties of G^m, it suffices to show that $V^m(t)$, defined as

$$V^m(t) = (G^m)^{-1}(W^m(t)),$$

has a bounded norm as t tends to $T(W_0^m)$.

If we set

$$V_0^m = (G^m)^{-1}(W_0^m),$$

the system (19) reads as follows:

$$\frac{d}{dt} G^m(V^m(t)) + \Phi^m(V^m(t)) = F^m(t), \qquad V^m(0) = V_0^m. \tag{20}$$

Multiplication of the first equality of (20) by $V^m(t)$ and integration over the time interval $(0, t)$ of the resulting expression leads to

$$\int_0^t \int_\Omega \left(\frac{\partial b^\eta(v^m)}{\partial t} v^m + \varepsilon \frac{\partial v^m}{\partial t} v^m \right)(s)\, dx\, ds + \int_0^t \int_\Omega (D\Phi(\nabla v^m(s)), \nabla v^m(s))_{\mathbb{R}^N}\, dx\, ds$$
$$= \int_0^t \int_\Omega f(s) v^m(s)\, dx\, ds. \tag{21}$$

We now appeal to the following result first established by Alt and Luckhaus [1, Lemma 1.5, p. 315].

LEMMA 1. *Let Ω be a bounded domain of $\mathbb{R}^n$. Let $\tilde{\Psi}$ be a C^1 convex function on $\mathbb{R}$, with $\tilde{b}$ as derivative ($\tilde{\Psi}(0) = 0$). Let $\tilde{\Psi}^*$ be its convex conjugate. Assume that*

$$\begin{aligned} &u \in L_\infty(0, T; W_0^{1,s}(\Omega)), \qquad 1 < s < +\infty, \\ &\tilde{b}(u) \in L_\infty(0, T; L_1(\Omega)), \\ &\frac{\partial}{\partial t}\tilde{b}(u) \in L_\infty(0, T; W^{-1,s'}(\Omega)), \qquad \frac{1}{s} + \frac{1}{s'} = 1. \end{aligned} \tag{22}$$

Assume further that there exists an element u_0 *in* $W_0^{1,s}(\Omega)$ *such that*

$$\tilde{b}(u)|_{t=0} = \tilde{b}(u_0), \tag{23}$$

and that

$$\tilde{b}(u_0) \in L_1^{\mathrm{loc}}(\Omega) \cap W^{-1,s'}(\Omega). \tag{24}$$

Then

$$\tilde{\Psi}^*(\tilde{b}(u)) \in L^\infty(0, T; L_1(\Omega)), \qquad \tilde{\Psi}^*(\tilde{b}(u_0)) \in L_1(\Omega) \tag{25}$$

and, for almost any t *in* $(0, T)$,

$$\int_\Omega \tilde{\Psi}^*(b(u(t)))\, dx - \int_\Omega \tilde{\Psi}^*(\tilde{b}(u_0))\, dx = \int_0^t \left\langle \frac{\partial \tilde{b}(u(s))}{\partial t}, u(s) \right\rangle ds, \tag{26}$$

where $\langle\, , \rangle$ *stands for the duality bracket between* $W_0^{1,s}(\Omega)$ *and* $W^{-1,s'}(\Omega)$. □

Lemma 1 is applied in our context with $s = q$, $\tilde{\Psi}(t) = \Psi^\eta(t) + \varepsilon(t^2/2)$, $T = t < T(W_0^m)$, $u_0 = v_0^m$ and it yields

$$\begin{aligned} &\int_0^t \int_\Omega \frac{\partial}{\partial t}(b^\eta(v^m(s)) + \varepsilon v^m(s)) v^m(s)\, dx\, ds \\ &\quad = \int_\Omega (\Psi^\eta)^*(b^\eta(v^m(t)))\, dx + \frac{\varepsilon}{2}\|v^m(t)\|_{0,2}^2 - \frac{\varepsilon}{2}\|v_0^m\|_0^2 - \int_\Omega (\psi^\eta)^*(b^\eta(v_0^m))\, dx. \end{aligned} \tag{27}$$

Remark 4. In view of the regularity of the function v^m relation (27) can be established independently of Lemma 1. At a later stage of this study however, Lemma 1 will become an essential ingredient and it will be repeatedly applied with $s = q$.

Inserting (27) into (21) leads to

$$\begin{aligned} &\int_\Omega (\Psi^\eta)^*(b^\eta(v^m(t)))\, dx + \frac{\varepsilon}{2}\|v^m(t)\|_{0,2}^2 + \int_0^t \int_\Omega (D\Phi(\nabla v^m(s)), \nabla v^m(s))_{\mathbb{R}^N}\, dx\, ds \\ &\quad \leqq \int_\Omega (\Psi^\eta)^*(b^\eta(v_0^m))\, dx + \frac{\varepsilon}{2}\|v_0^m\|_{0,2}^2 + |||f||| \int_0^t \|v^m(s)\|_{1,q}\, ds, \end{aligned} \tag{28}$$

where from now on $|||f|||$ stands for the norm of f in $W^{1,1}(0, T; W^{-1,q'}(\Omega))$.

Since

$$\Phi(0) = 0,$$

the coercivity property of Φ (cf. (5)) together with Poincaré's inequality imply that

$$\int_0^t \int_\Omega (D\Phi(\nabla v^m(s)), \nabla v^m(s))_{\mathbb{R}^N}\, dx\, ds \geqq \int_0^t \Phi(\nabla v^m(s))\, ds \geqq \alpha \int_0^t \|v^m(s)\|_{1,q}^r\, ds. \tag{29}$$

Because $(\Psi^\eta)^*$ is always positive, insertion of (25) and (29) into (28) yields

$$\frac{\varepsilon}{2}\|v^m(t)\|_{0,2}^2 + \alpha \int_0^t \|v^m(s)\|_{1,q}^r\, ds \leqq \mathscr{C} + |||f||| \int_0^t \|v^m(s)\|_{1,q}\, ds, \tag{30}$$

where $\mathscr{C}$ denotes a generic constant.

Since r is strictly greater than one, (30) implies that $\|v^m(t)\|_{0,2}$ remains bounded on $[0, T(W_0^m))$ and thus that $|V^m(t)|$ remains bounded as t tends to $T(W_0^m)$, which was the result sought.

Recalling (6), we denote by U_0^m the vector of $\mathbb{R}^m$ associated with the projection u_0^m of u_0 on the span of $\varphi_1, \cdots, \varphi_m$, i.e.,

$$u_0^m = \sum_{i=1}^{m} U_{01}^m \varphi_i \xrightarrow{m \to +\infty} u_0 \quad \text{strongly in } W_0^{1,q}(\Omega).$$

According to the previous analysis, the equation

$$\frac{d}{dt} G^m(U^m(t)) + \Phi^m(U^m(t)) = F^m(t), \qquad U^m(0) = U_0^m, \tag{31}$$

admits a global Lipschitz solution on $[0, T]$.

A priori estimates. Multiplication of the first equality of (31) by dU^m/dt and integration over the time interval $(0, t)$ of the resulting expression leads to

$$\begin{aligned} &\int_0^t \int_\Omega \frac{\partial b^\eta(u^m(s))}{\partial t} \frac{\partial u^m(s)}{\partial t}\, dx\, ds + \varepsilon \int_0^t \int_\Omega \left|\frac{\partial u^m(s)}{\partial t}\right|^2 dx\, ds + \Phi(\nabla u^m(t)) \\ &\quad = \Phi(\nabla u_0^m) + \int_0^t \int_\Omega f(s) \frac{\partial u^m(s)}{\partial t}\, dx\, ds, \end{aligned} \tag{32}$$

where

$$u^m(t) = \sum_{i=1}^{m} U_i^m(t) \varphi_i.$$

The function b^η is Lipschitz and u^m is in $\mathrm{Lip}\,(\Omega \times (0, T))$; thus, by virtue of the monotonicity of b^η,

$$\int_0^t \int_\Omega \frac{\partial b^\eta(u^m(s))}{\partial t} \frac{\partial u^m(s)}{\partial t}\, dx\, ds = \int_0^t \int_\Omega (b^\eta)'(u^m(s)) \left(\frac{\partial u^m(s)}{\partial t}\right)^2 dx\, ds \geqq 0. \tag{33}$$

The coercivity property of Φ (cf. (5)), (in)equalities (32), (33), and Poincaré's inequality imply that

$$\int_0^t \left\| \sqrt{\varepsilon} \frac{\partial u^m}{\partial t} \right\|_{0,2}^2 ds + \alpha \|u^m(t)\|_{1,q}^r \leqq \Phi(\nabla u_0^m) + \int_0^t \int_\Omega f(s) \frac{\partial u^m(s)}{\partial t}\, dx\, ds. \tag{34}$$

The last term of the right-hand side of inequality (34) is integrated by parts with the help of (7). We obtain

$$\int_0^t \left\| \sqrt{\varepsilon} \frac{\partial u^m}{\partial t} \right\|_{0,2}^2 ds + \alpha \|u^m(t)\|_{1,q}^r \leqq \Phi(\nabla u_0^m) + 3 |||f||| \sup_{s \in [0,t]} \|u^m(s)\|_{1,q}. \tag{35}$$

The time t can be chosen arbitrarily in $[0, T]$; thus,

$$\begin{aligned} &\int_0^T \left\| \sqrt{\varepsilon} \frac{\partial u^m(s)}{\partial t} \right\|_{0,2}^2 ds + \alpha \sup_{t \in [0,T]} \|u^m(t)\|_{1,q}^r \\ &\quad \leqq \Phi(\nabla u_0^m) + 3 |||f||| \sup_{t \in [0,T]} \|u^m(t)\|_{1,q}. \end{aligned} \tag{36}$$

Finally ∇u_0^m converges to ∇u_0 in $[L_q(\Omega)]^N$ as m goes to infinity. The continuity of Φ on $[L_q(\Omega)]^N$ implies that

$$\Phi(\nabla u_0^m) \xrightarrow{m \to +\infty} \Phi(\nabla u^0).$$

If m is taken to be large enough, (36) reads as follows:

$$\int_0^T \left\| \sqrt{\varepsilon} \frac{\partial u^m}{\partial t} \right\|_{0,2}^2 ds + \alpha \sup_{t\in[0,T]} \|u^m(t)\|_{1,q}^r \leqq \Phi(\nabla u_0) + 1 + 3|||f||| \sup_{t\in[0,T]} \|u^m(t)\|_{1,q}. \tag{37}$$

The function $\|u^m(t)\|_{1,q}$ is continuous on $[0, T]$; it reaches its supremum on $[0, T]$. It is then easily deduced from (37) that

(38) $\sqrt{\varepsilon}\, \partial u^m/\partial t$ is bounded in $L_2(0, T; L_2(\Omega))$ independently of m, η, or ε,

(39) $u^m(t)$ is bounded in $L_\infty(0, T; W_0^{1,q}(\Omega))$ independently of m, η, or ε.

Because $D\Phi$ is bounded on the bounded sets of $[L_q(\Omega)]^N$, (39) implies that, if $1/q' + 1/q = 1$,

(40) $D\Phi(\nabla u^m)$ is bounded in $L_\infty(0, T; [L_{q'}, (\Omega)]^N)$ independently of m, η, or ε.

Remark 5. The bounds in (38)–(40) continuously depend on $\Phi(\nabla u_0)$ and $|||f|||$ only (recall that $|||f|||$ is the $W^{1,1}(0, T; W^{-1,q'}(\Omega))$-norm of f).

Finally, since b^η is bounded on $\mathbb{R}$,

(41) $b^\eta(u^m)$ is bounded in $L_\infty((0, T)\times\Omega)$,

but the bound depends on η.

With the help of (38)–(41) we conclude that there exists a suitably extracted subsequence of u^m (still denoted u^m) such that, as m tends to infinity,

$$\begin{aligned} &u^m \rightharpoonup u_\varepsilon^\eta \quad \text{weak-* in } L_\infty(0, T; W_0^{1,q}(\Omega)), \\ &\sqrt{\varepsilon}\frac{\partial u^m}{\partial t} \rightharpoonup \sqrt{\varepsilon}\frac{\partial u_\varepsilon^\eta}{\partial t} \quad \text{weakly in } L_2(0, T; L_2(\Omega)), \\ &D\Phi(\nabla u^m) \rightharpoonup Y_\varepsilon^\eta \quad \text{weak-* in } L_\infty(0, T; [L_{q'}(\Omega)]^N), \\ &b^\eta(u^m) \rightharpoonup \chi_\varepsilon^\eta \quad \text{weak-* in } L_\infty((0, T)\times\Omega). \end{aligned} \tag{42}$$

In the following section we propose to use (42) to pass to the limit in (31) as m tends to infinity, and to identify the quantities Y_ε^η and χ_ε^η.

2.2. Passing to the limit in the Galerkin approximation. Let ζ be an arbitrary element of $\mathscr{C}_0^\infty((0, T))$. Equation (31) together with the convergence (42) imply that, for any integer i,

$$\left\langle\!\!\left\langle \frac{\partial \chi_\varepsilon^\eta}{\partial t} + \varepsilon \frac{\partial u_\varepsilon^\eta}{\partial t} - \operatorname{div} Y_\varepsilon^\eta - f, \varphi_i \zeta \right\rangle\!\!\right\rangle = 0,$$

where the duality bracket refers to the duality between $\mathscr{C}_0^\infty((0, T)\times\Omega)$ and $\mathscr{D}'((0, T)\times\Omega)$ (the basis vectors φ_i lie in $\mathscr{C}_0^\infty(\Omega)$).

The sequence $\{\varphi_i\}$ is a basis of $W_0^{1,q}(\Omega)$ which contains $\mathscr{C}_0^\infty(\Omega)$. Thus, if φ is an arbitrary element of $\mathscr{C}_0^\infty(\Omega)$,

$$\left\langle\!\!\left\langle \frac{\partial \chi_\varepsilon^\eta}{\partial t} + \varepsilon \frac{\partial u_\varepsilon^\eta}{\partial t} - \operatorname{div} Y_\varepsilon^\eta - f, \varphi \zeta \right\rangle\!\!\right\rangle = 0,$$

and, by the density of $\mathscr{C}_0^\infty((0, T))\times\mathscr{C}_0^\infty(\Omega)$ in $\mathscr{C}_0^\infty((0, T)\times\Omega)$,

$$\frac{\partial \chi_\varepsilon^\eta}{\partial t} + \varepsilon \frac{\partial u_\varepsilon^\eta}{\partial t} - \operatorname{div} Y_\varepsilon^\eta - f = 0. \tag{43}$$

In view of (43), χ_ε^η has a trace in $W^{-1,q'}(\Omega)$. A proper choice of ζ in $\mathscr{C}_0^\infty([0, T))$ and convergence (42) lead to

$$\langle\langle \chi_\varepsilon^\eta(0) + \varepsilon u_\varepsilon^\eta(0)\varphi_i\zeta(0)\rangle\rangle = \lim_{m\to+\infty} \int_\Omega (b^\eta(u_0^m) + \varepsilon u_0^m)\varphi_i\zeta(0).$$

But $\{\varphi_i\}$ is a basis of $W_0^{1,q}(\Omega)$ and u_0^m converges strongly to u_0 in $W_0^{1,q}(\Omega)$; thus

$$\chi_\varepsilon^\eta(0) + \varepsilon u_\varepsilon^\eta(0) = b^\eta(u_0) + \varepsilon u_0. \tag{44}$$

Because of the estimates on u^m and $\partial u^m/\partial t$ (cf. (42))

$$u^m(0) \rightharpoonup u_\varepsilon^\eta(0) \quad \text{weakly in } L_2(\Omega)$$

as m tends to infinity; thus

$$u_\varepsilon^\eta(0) = u_0, \tag{45}$$

and (44) yields

$$\chi_\varepsilon^\eta(0) = b^\eta(u_0). \tag{46}$$

We now seek to identify the quantities χ_ε^η and Y_ε^η. The identification of χ_ε^η is very simple. A straightforward application of Aubin's lemma (cf., e.g., [12, Cor. 4]) to u^m implies that

$$u^m \to u_\varepsilon^\eta \quad \text{strongly in } \mathscr{C}^0([0, T]; L_2(\Omega))$$

as m tends to infinity. Since b^η is Lipschitz and bounded, it follows that for any finite s

$$b^\eta(u^m) \to b^\eta(u_\varepsilon^\eta) \quad \text{strongly in } \mathscr{C}^0([0, T]; L_s(\Omega))$$

as m tends to infinity and, in view of (42), that

$$\chi_\varepsilon^\eta = b^\eta(u_\varepsilon^\eta), \qquad b^\eta(u_\varepsilon^\eta) \in \mathscr{C}^0([0, T]; L_s(\Omega)), \qquad 1 \leqq s < +\infty. \tag{47}$$

The identification of Y_ε^η is performed with the help of the following simple lemma.

LEMMA 2. *Assume that* Φ *satisfies* (5) *and that* w_m *is a sequence of* $L_\infty(0, T; [L_q(\Omega)]^N)$ *such that*

$$\begin{aligned} &w_m \rightharpoonup w \quad \textit{weak-* in } L_\infty(0, T; [L_q(\Omega)]^N), \\ &D\Phi(w_m) \rightharpoonup Y \quad \textit{weak-* in } L_\infty(0, T; [L_{q'}(\Omega)]^N), \end{aligned} \tag{48}$$

as m *tends to infinity (or zero). If*

$$\int_0^T \int_0^t \int_\Omega (Y(s), w(s))_{\mathbb{R}^N}\, dx\, ds\, dt \geqq \overline{\lim} \int_0^T \int_0^t \int_\Omega (D\Phi(w_m(s), w_m(s)))\, dx\, ds\, dt, \tag{49}$$

then

$$Y = D\Phi(w). \tag{50}$$

The proof of this lemma is a straightforward adaptation of a classical result of Minty (cf., e.g., [8, Remark 2.1, p. 173 and Prop. 2.5, p. 179]). It will not be reproduced here.

In our setting w_m, w, and Y are to be identified with ∇u^m, $\nabla u_\varepsilon^\eta$, and Y_ε^η, respectively. In view of (42), (48) is satisfied. To show that

$$Y_\varepsilon^\eta = D\Phi(\nabla u_\varepsilon^\eta) \tag{51}$$

we only need to prove that

$$\int_0^T \int_0^t \int_\Omega (Y_\varepsilon^\eta(s), \nabla u_\varepsilon^\eta(s))_{\mathbb{R}^N} \, dx \, ds \, dt \tag{52}$$
$$\geqq \overline{\lim_{m \to +\infty}} \int_0^T \int_0^t \int_\Omega (D\Phi(\nabla u^m(s)), \nabla u^m(s))_{\mathbb{R}^N} \, dx \, ds \, dt.$$

According to (21) and (27) (applied to u^m in place of v^m), we have

$$\int_0^T \int_0^t \int_\Omega (D\Phi(\nabla u^m(s)), \nabla u^m(s))_{\mathbb{R}^N} \, dx \, ds \, dt$$
$$= \int_0^T \int_0^t \int_\Omega f(s) u^m(s) \, dx \, ds \, dt + T \left[\int_\Omega (\Psi^\eta)^*(b^\eta(u_0^m)) \, dx + \frac{\varepsilon}{2} \|u_0^m\|_{0,2}^2 \right] \tag{53}$$
$$- \int_0^T \left[\int_\Omega (\Psi^\eta)^*(b^\eta(u^m(t))) \, dx + \frac{\varepsilon}{2} \|u^m(t)\|_{0,2}^2 \right] dt.$$

Note that Ψ^η is Lipschitz and that (4) holds for b^η, Ψ^η, and $(\Psi^\eta)^*$ in place of b, Ψ, and Ψ^*, respectively. Since u^m converges weak-* to u_ε^η in $L_\infty(0, T; W_0^{1,q}(\Omega))$ and u_0^m converges strongly in $W_0^{1,q}(\Omega)$ to u_0, the two first terms of the right-hand side of equality (53) are easily seen to converge to

$$\int_0^T \int_0^t \int_\Omega f(s) u_\varepsilon^\eta(s) \, dx \, ds \, dt + T \left[\int_\Omega (\Psi^\eta)^*(b^\eta(u_0)) \, dx + \frac{\varepsilon}{2} \|u_0\|_{0,2}^2 \right]$$

as m goes to infinity.

The strong convergences of the sequences $b^\eta(u^m)$ and u^m in $\mathscr{C}^0([0, T]; L_2(\Omega))$ imply that

$$\lim_{m \to +\infty} - \int_0^T \int_\Omega (\Psi^\eta)^*(b^\eta(u^m(t))) \, dx \, dt = - \int_0^T \int_\Omega (\Psi^\eta)^*(b^\eta(u_\varepsilon^\eta(t))) \, dx \, dt$$

and

$$\lim_{m \to +\infty} \int_0^T \|u^m(t)\|_{0,2}^2 \, dt = \int_0^T \|u_\varepsilon^\eta(t)\|_{0,2}^2 \, dt.$$

We are now in a position to pass to the limit in (53). We obtain the following:

$$\lim_{m \to +\infty} \int_0^T \int_0^t \int_\Omega (D\Phi(\nabla u^m(s)), \nabla u^m(s))_{\mathbb{R}^N} \, dx \, ds \, dt$$
$$= \int_0^T \int_0^t \int_\Omega f(s) u_\varepsilon^\eta(s) \, dx \, ds \, dt + T \left[\int_\Omega (\Psi^\eta)^*(b^\eta(u_0)) \, dx + \frac{\varepsilon}{2} \|u_0\|_{0,2}^2 \right] \tag{54}$$
$$- \int_0^T \left[\int_\Omega (\Psi^\eta)^*(b^\eta(u_\varepsilon^\eta(t))) \, dx + \frac{\varepsilon}{2} \|u_\varepsilon^\eta(t)\|_{0,2}^2 \right] dt.$$

Multiplication of (43) by u_ε^η and integration of the resulting expression over $(0, t) \times \Omega$, then over $(0, T)$ yields, with the help of (47),

$$\int_0^T \int_0^t \int_\Omega (Y_\varepsilon^\eta(s), \nabla u_\varepsilon^\eta(s))_{\mathbb{R}^N} \, dx \, ds \, dt$$
$$= \int_0^T \int_0^t \int_\Omega f(s) u_\varepsilon^\eta(s) \, dx \, ds \, dt \tag{55}$$
$$- \int_0^T \int_0^t \left\langle \frac{\partial}{\partial t} (b^\eta(u_\varepsilon^\eta(s)) + \varepsilon u_\varepsilon^\eta(s)), u_\varepsilon^\eta(s) \right\rangle ds \, dt.$$

The last term in the right-hand side of equality (55) is evaluated with the help of Lemma 1 (cf. Remark 4). We obtain the following:

$$\begin{aligned}&\int_0^T \int_0^t \left\langle \frac{\partial}{\partial t}(b^\eta(u_\varepsilon^\eta(s)) + \varepsilon u_\varepsilon^\eta(s)),\, u_\varepsilon^\eta(s) \right\rangle ds\, dt \\ &\quad = \int_0^T \int_\Omega (\Psi^\eta)^*(b^\eta(u_\varepsilon^\eta(t)))\, dx\, dt \\ &\quad\quad + \frac{\varepsilon}{2}\int_0^T \|u_\varepsilon^\eta(t)\|_{0,2}^2\, dt - T\frac{\varepsilon}{2}\|u_0\|_{0,2}^2 - T\int_\Omega (\Psi^\eta)^*(b^\eta(u_0))\, dx.\end{aligned} \tag{56}$$

Inserting (56) into (55) and comparing the resulting expression with the right-hand side of inequality (54) yields (52), which in turn proves (51).

At this stage of the proof we have constructed a sequence u_ε^η with the following properties:

$$u_\varepsilon^\eta \in L_\infty(0, T; W_0^{1,q}(\Omega)), \qquad b^\eta(u_\varepsilon^\eta) \in L_\infty((0, T)\times\Omega),$$

$$\frac{\partial b^\eta(u_\varepsilon^\eta)}{\partial t} + \varepsilon\frac{\partial u_\varepsilon^\eta}{\partial t} - \operatorname{div} D\Phi(\nabla u_\varepsilon^\eta) = f, \tag{57}$$

$$u_\varepsilon^\eta(0) = u_0, \tag{58}$$

$$b^\eta(u_\varepsilon^\eta)|_{t=0} = b^\eta(u_0). \tag{59}$$

Furthermore the weak lower semicontinuity properties of the L_2, $L_{q'}$, and L_q norms imply, by virtue of (38)–(40) and (42), that

(60) $\sqrt{\varepsilon}\,\partial u_\varepsilon^\eta/\partial t$ is bounded in $L_2(0, T; L_2(\Omega))$ independently of ε and η,

(61) u_ε^η is bounded in $L_\infty(0, T; W_0^{1,q}(\Omega))$ independently of ε and η,

(62) $D\Phi(\nabla u_\varepsilon^\eta)$ is bounded in $L_\infty(0, T; [L_{q'}(\Omega)]^N)$ independently of ε and η.

With the help of (60)–(62) we conclude that there exists a suitably extracted subsequence (still denoted u_ε^η) such that, for fixed ε,

$$\begin{aligned}&u_\varepsilon^\eta \rightharpoonup u_\varepsilon \quad \text{weak-* in } L_\infty(0, T; W_0^{1,q}(\Omega)), \\ &\sqrt{\varepsilon}\frac{\partial u_\varepsilon^\eta}{\partial t} \rightharpoonup \sqrt{\varepsilon}\frac{\partial u_\varepsilon}{\partial t} \quad \text{weakly in } L_2(0, T; L_2(\Omega)), \\ &D\Phi(\nabla u_\varepsilon^\eta) \rightharpoonup Y_\varepsilon \quad \text{weak-* in } L_\infty(0, T; [L_{q'}(\Omega)]^N),\end{aligned} \tag{63}$$

as η goes to zero.

In the following section we propose to use (63) to pass to the limit in (57)–(59) as η tends to zero, and to identify the quantity Y_ε. To this effect we need to derive an estimate on $b^\eta(u_\varepsilon^\eta)$ independent of η (and ε) and to identify its weak limit.

2.3. Passing to the limit in the truncation. The quantities $\Psi^\eta(u_\varepsilon^\eta)$, $b^\eta(u_\varepsilon^\eta)$ lie in $L_\infty(0, T; W_0^{1,q}(\Omega)) \cap W^{1,2}(0, T; L_2(\Omega))$ because Ψ^η and b^η are Lipschitz. Thus, $b^\eta(u_\varepsilon^\eta)$ is an admissible test function in (57). Upon integration over the time interval $(0, t)$ of the result of the multiplication of (57) by $b^\eta(u_\varepsilon^\eta)$, we obtain

$$\begin{aligned}&\frac{1}{2}\|b^\eta(u_\varepsilon^\eta(t))\|_{0,2}^2 + \varepsilon\int_\Omega \Psi^\eta(u_\varepsilon^\eta(t))\, dx \\ &\quad + \int_0^t \int_\Omega (b^\eta)'(u_\varepsilon^\eta(s))(D\Phi(\nabla u_\varepsilon^\eta(s)), \nabla u_\varepsilon^\eta(s))_{\mathbb{R}^N}\, dx\, ds \\ &\quad = \frac{1}{2}\|b^\eta(u_0)\|_{0,2}^2 + \varepsilon\int_\Omega \Psi^\eta(u_0)\, dx + \int_0^t \int_\Omega f(s) b^\eta(u_\varepsilon^\eta(s))\, dx\, ds.\end{aligned} \tag{64}$$

The derivation formula for the composition of a $W^{1,q}$ function by a Lipschitz function is implicitly used in (64). It is classical if the Lipschitz function is piecewise C^1. For a proof in the case of an arbitrary Lipschitz function see, for example, [9, Cor. 1.3, p. 353] or [4, Thm. 4.3].

Since b^η is monotone and Ψ^η is positive, (64) yields

$$\begin{aligned}\frac{1}{2}\|b^\eta(u_\varepsilon^\eta(t))\|_{0,2}^2 \leqq \frac{1}{2}\|b^\eta(u_0)\|_{0,2}^2 + \varepsilon \int_\Omega \Psi^\eta(u_0)\,dx \\ + T \sup_{t\in[0,T]} \|f(t)\|_{0,2} \sup_{t\in[0,T]} \|b^\eta(u_\varepsilon^\eta(t))\|_{0,2}.\end{aligned} \tag{65}$$

Remark 6. The L_2 space regularity of f is required in estimate (65), and it motivates the regularity hypothesis (7) on f.

As η tends to zero, $b^\eta(u_0)$ and $\Psi^\eta(u_0)$ converge almost everywhere to $b(u_0)$ and $\Psi(u_0)$, respectively, while

$$|b^\eta(u_0(x))| \leqq |b(u_0(x))|, \qquad \Psi^\eta(u_0(x)) \leqq \Psi(u_0(x)),$$

for almost every x of Ω. By hypothesis, $b(u_0)$ belongs to $L_2(\Omega)$ (see (6)). In view of (4) and the positivity of Ψ,

$$0 \leqq \Psi(u_0(x)) \leqq b(u_0(x))u_0(x)$$

for almost every x of Ω, and thus $\Psi(u_0)$ belongs to $L_1(\Omega)$.

The dominated convergence theorem permits us to conclude that

$$\begin{aligned} b^\eta(u_0) &\to b(u_0) \qquad \text{strongly in } L_2(\Omega), \\ \Psi^\eta(u_0) &\to \Psi(u_0) \qquad \text{strongly in } L_1(\Omega), \end{aligned} \tag{66}$$

and thus to give an upper bound for the right-hand side of (65). We obtain, for η small enough,

$$\begin{aligned}\frac{1}{2}\|b^\eta(u_\varepsilon^\eta(t))\|_{0,2}^2 \leqq \frac{1}{2}\|b(u_0)\|_{0,2}^2 + \varepsilon \int_\Omega \Psi(u_0)\,dx + 1 \\ + T \sup_{t\in[0,T]} \|f(t)\|_{0,2} \sup_{t\in[0,T]} \|b^\eta(u_\varepsilon^\eta(t))\|_{0,2}.\end{aligned} \tag{67}$$

Since $\|b^\eta(u_\varepsilon^\eta(t))\|_{0,2}$ is continuous on $[0, T]$ (cf. (47)), an argument similar to the one that led to (38), (39), would show that

$$b^\eta(u_\varepsilon^\eta) \text{ is bounded in } L_\infty(0, T, L_2(\Omega)) \text{ independently of } \varepsilon \text{ and } \eta. \tag{68}$$

At the possible expense of extracting one more subsequence, we are thus at liberty to assume that the sequence u_ε^η is also such that

$$b^\eta(u_\varepsilon^\eta) \rightharpoonup \chi_\varepsilon \quad \text{weak-*} \text{ in } L_\infty(0, T; L_2(\Omega)) \tag{69}$$

as η tends to zero.

Passing to the limit in (57)-(59) is now an immediate task if we remark that, in view of (57), (60), and (62),

$$\partial b^\eta(u_\varepsilon^\eta)/\partial t \text{ is bounded in } L_2(0, T; W^{-1,q'}(\Omega)). \tag{70}$$

We obtain the following:

$$\frac{\partial \chi_\varepsilon}{\partial t} + \varepsilon \frac{\partial u_\varepsilon}{\partial t} - \operatorname{div} Y_\varepsilon = f, \tag{71}$$

and, with the help of (60), (61), (68), and (70),

$$u_\varepsilon(0) = u_0, \tag{72}$$

$$\chi_\varepsilon|_{t=0} = b(u_0). \tag{73}$$

It now remains to identify χ_ε and Y_ε. Once again, the identification of χ_ε directly results from Aubin's lemma. In view of (63),

$$u_\varepsilon^\eta \to u_\varepsilon \quad \text{strongly in } \mathscr{C}^0([0, T]; L_2(\Omega))$$

as η tends to zero. Since b^η converges pointwise to b on $\mathbb{R}$ as η tends to zero, a subsequence of $b^\eta(u_\varepsilon^\eta)$ (still denoted $b^\eta(u_\varepsilon^\eta)$) satisfies

$$b^\eta(u_\varepsilon^\eta(x, t)) \to b(u_\varepsilon(x, t)) \text{ for almost every } (x, t) \text{ of } \Omega \times (0, T)$$

as η tends to zero. Recalling (69) then implies that

$$\chi_\varepsilon = b(u_\varepsilon), \qquad b(u_\varepsilon) \in L_\infty(0, T; L_2(\Omega)). \tag{74}$$

The identification of Y_ε relies on Lemma 2. The quantities w_m, w, and Y are identified with $\nabla u_\varepsilon^\eta$, ∇u_ε, and Y_ε, respectively. In view of (63), (48) is satisfied. To show that

$$Y_\varepsilon = D\Phi(\nabla u_\varepsilon), \tag{75}$$

we only need to prove that

$$\begin{aligned} &\int_0^T \int_0^t \int_\Omega (Y_\varepsilon(s), \nabla u_\varepsilon(s))_{\mathbb{R}^N} \, dx \, ds \, dt \\ &\qquad \geqq \overline{\lim_{\eta \to 0}} \int_0^T \int_0^t \int_\Omega (D\Phi(\nabla u_\varepsilon^\eta(s)), \nabla u_\varepsilon^\eta(s))_{\mathbb{R}^N} \, dx \, ds \, dt. \end{aligned} \tag{76}$$

The proof of (76) is essentially the same as that of (52). It consists in passing to the limit in (55), (56) as η tends to zero (with Y_ε^η replaced by $D\Phi(\nabla u_\varepsilon^\eta)$). We obtain the following:

$$\begin{aligned} &\overline{\lim_{\eta \to 0}} \int_0^T \int_0^t \int_\Omega (D\Phi(\nabla u_\varepsilon^\eta(s)), \nabla u_\varepsilon^\eta(s))_{\mathbb{R}^N} \, dx \, ds \, dt \\ &\qquad \leqq \int_0^T \int_0^t \int_\Omega f(s) u_\varepsilon(s) \, dx \, ds \, dt + T\frac{\varepsilon}{2} \|u_0\|_{0,2}^2 - \frac{\varepsilon}{2} \int_0^T \|u_\varepsilon(t)\|_{0,2}^2 \, dt \\ &\qquad - \underline{\lim_{\eta \to 0}} \int_0^T \int_\Omega (\Psi^\eta)^*(b^\eta(u_\varepsilon^\eta(t))) \, dx \, dt + T \lim_{\eta \to 0} \int_\Omega (\Psi^\eta)^*(b^\eta(u_0)) \, dx. \end{aligned} \tag{77}$$

Since

$$(\Psi^\eta)^*(b^\eta(u_0)) = u_0 b^\eta(u_0) - \Psi^\eta(u_0),$$

convergences (66) imply that

$$\lim_{\eta \to 0} \int_\Omega (\Psi^\eta)^*(b^\eta(u_0)) \, dx = \int_\Omega (u_0 b(u_0) - \Psi(u_0)) \, dx = \int_\Omega \Psi^*(b(u_0)) \, dx. \tag{78}$$

Similarly, since u_ε^η and $b^\eta(u_\varepsilon^\eta)$ converge almost everywhere to u_ε and $b(u_\varepsilon)$, respectively,

$$(\Psi^\eta)^*(b^\eta(u_\varepsilon^\eta(x, t))) \to \Psi^*(b(u_\varepsilon(x, t)))$$

for almost any (x, t) in $\Omega \times (0, T)$ as η tends to zero. The positivity of $(\Psi^\eta)^*$ together with Fatou's lemma yield

$$\varliminf_{\eta \to 0} \int_0^T \int_\Omega (\Psi^\eta)^*(b^\eta(u_\varepsilon^\eta(t)))\, dx\, dt \geqq \int_0^T \int_\Omega \Psi^*(b(u_\varepsilon(t)))\, dx\, dt. \tag{79}$$

Insertion of (78) and (79) into (77) leads to

$$\begin{aligned} &\varlimsup_{\eta \to 0} \int_0^T \int_0^t \int_\Omega (D\Phi(\nabla u_\varepsilon^\eta(s)), \nabla u_\varepsilon^\eta(s))_{\mathbb{R}^N}\, dx\, ds\, dt \\ &\leqq \int_0^T \int_0^t \int_\Omega f(s) u_\varepsilon(s)\, dx\, ds\, dt + T\left[\int_\Omega \Psi^*(b(u_0))\, dx + \frac{\varepsilon}{2}\|u_0\|_{0,2}^2\right] \\ &\quad - \int_0^T \left[\int_\Omega \Psi^\eta(b(u_\varepsilon(t)))\, dx + \frac{\varepsilon}{2}\|u_\varepsilon(t)\|_{0,2}^2\right] dt. \end{aligned} \tag{80}$$

Multiplication of (71) by u_ε, integration of the resulting expression over $(0, t) \times \Omega$ then over $(0, T)$, and application of Lemma 1 readily shows that the right-hand side of inequality (80) is precisely $\int_0^T \int_0^t \int_\Omega (Y_\varepsilon(s), \nabla u_\varepsilon(s))_{\mathbb{R}^N}\, dx\, ds\, dt$, which proves (76) and thus (75).

We have constructed a sequence u_ε with the following properties:

$$u_\varepsilon \in L_\infty(0, T; W_0^{1,q}(\Omega)), \qquad b(u_\varepsilon) \in L_\infty(0, T; L_2(\Omega)),$$

$$\frac{\partial b(u_\varepsilon)}{\partial t} + \varepsilon \frac{\partial u_\varepsilon}{\partial t} - \operatorname{div} D\Phi(\nabla u_\varepsilon) = f, \tag{81}$$

$$u_\varepsilon(0) = u_0, \tag{82}$$

$$b(u_\varepsilon)|_{t=0} = b(u_0). \tag{83}$$

Once again, the weak lower semicontinuity properties of the L_2, $L_{q'}$, and L_q norms imply, by virtue of (60)–(63), (68), (69), (74), and (75) that

(84) $\sqrt{\varepsilon}\, \partial u_\varepsilon / \partial t$ is bounded in $L_2(0, T; L_2(\Omega))$ independently of ε,

(85) u_ε is bounded in $L_\infty(0, T; W_0^{1,q}(\Omega))$ independently of ε,

(86) $\Phi(\nabla u_\varepsilon)$ is bounded in $L_\infty(0, T; [L_{q'}(\Omega)]^N)$ independently of ε,

(87) $b(u_\varepsilon)$ is bounded in $L_\infty(0, T; L_2(\Omega))$ independently of ε.

With the help of (84)–(87), we conclude that there exists a suitably extracted subsequence (still denoted u_ε) such that

$$\begin{aligned} &u_\varepsilon \rightharpoonup u \quad \text{weak-* in } L_\infty(0, T; W_0^{1,q}(\Omega)), \\ &\sqrt{\varepsilon}\, \frac{\partial u_\varepsilon}{\partial t} \rightharpoonup 0 \quad \text{weakly in } L_2(0, T; L_2(\Omega)), \\ &D\Phi(\nabla u_\varepsilon) \rightharpoonup Y \quad \text{weak-* in } L_\infty(0, T; [L_{q'}(\Omega)]^N), \\ &b(u_\varepsilon) \rightharpoonup \chi \quad \text{weak-* in } L_\infty(0, T; L_2(\Omega)) \end{aligned} \tag{88}$$

as ε tends to zero.

In the following section, (88) is used to pass to the limit in (81)–(83) as ε tends to zero, and the quantities χ and Y are identified.

2.4. Passing to the limit in the coercivity parameter. By virtue of (81), (84), and (86)

$$\frac{\partial b(u_\varepsilon)}{\partial t} \text{ is bounded in } L_2(0, T; W^{-1,q'}(\Omega)). \tag{89}$$

In view of (88) and (89), the limit of (81) as ε tends to zero is

$$\frac{\partial \chi}{\partial t} - \operatorname{div} Y = f, \tag{90}$$

while that of (83) is

$$\chi|_{t=0} = b(u_0). \tag{91}$$

Remark 7. The initial value of u_ε, i.e., u_0, is lost in the limiting process because of the absence of estimates on $\partial u_\varepsilon/\partial t$ that are independent of ε.

The absence of an estimate on $\partial u_\varepsilon/\partial t$ precludes the application of Aubin's lemma to u_ε. However, that lemma can be applied to $b(u_\varepsilon)$ because of (87) and (89); it implies that, as ε tends to zero,

$$b(u_\varepsilon) \to \chi \quad \text{strongly in } \mathscr{C}^0([0, T]; W^{-1,q'}(\Omega)).$$

Since u_ε converges weak-* to u in $L_\infty(0, T; W_0^{1,q}(\Omega))$ we conclude that

$$\int_0^T \int_\Omega b(u_\varepsilon(t)) u_\varepsilon(t)\, dx\, dt \to \int_0^T \int_\Omega \chi(t) u(t)\, dx\, dt \tag{92}$$

as ε tends to zero.

We introduce the functional J defined on $L_2(\Omega \times (0, T))$ as

$$J(v) = \begin{cases} \displaystyle\int_0^T \int_\Omega \Psi(v(t))\, dx\, dt & \text{if } \Psi(v) \text{ belongs to } L_1(\Omega \times (0, T)), \\ +\infty & \text{otherwise.} \end{cases}$$

In view of the properties of Ψ (cf. § 2.1), J is positive, convex, and lower semicontinuous. It is also proper, since $\Psi(0) = 0$.

A classical result of convex analysis [11, Thm. 2, p. 532] allows us to identify the subdifferential $\partial J(v)$ of J at any point v of $L_2(\Omega \times (0, T))$ as

$$\begin{aligned} \partial J(v) = \{ w \in L_2(\Omega \times (0, T)) \,|\, & w(x, t) = b(v(x, t)) \\ & \text{almost everywhere in } \Omega \times (0, T) \}. \end{aligned} \tag{93}$$

Since both u^ε and $b(u^\varepsilon)$ lie, in particular, in $L_2(\Omega \times (0, T))$, $b(u^\varepsilon)$ belongs to $\partial J(u^\varepsilon)$. Thus,

$$\int_0^T \int_\Omega b(u_\varepsilon(t)) u_\varepsilon(t)\, dx\, dt + J(w) \geqq J(u_\varepsilon) + \int_0^T \int_\Omega b(u_\varepsilon(t)) w(t)\, dx\, dt, \tag{94}$$

for any w in $L_2(\Omega \times (0, T))$. Because of (88), (92), and the weak lower semicontinuity of J, we are in a position to compute the limit of each term in inequality (94). We obtain that, for any w in $L_2(\Omega \times (0, T))$,

$$\int_0^T \int_\Omega \chi(t) u(t)\, dx\, dt + J(w) \geqq J(u) + \int_0^T \int_\Omega \chi(t) w(t)\, dx\, dt. \tag{95}$$

Inequality (95) implies that u belongs to the domain of J and that

$$\chi \in \partial J(u), \tag{96}$$

and the characterization (93) of ∂J enables us to conclude that

$$\chi = b(u). \tag{97}$$

Once again the identification of Y relies on Lemma 2. The quantities w_m, w, and Y are identified with ∇u_ε, ∇u, and Y, respectively, and (48) is satisfied with the help of the convergences (88). To show that

$$Y = D\Phi(\nabla u) \tag{98}$$

reduces to proving that

$$\begin{aligned} &\int_0^T \int_0^t \int_\Omega (Y(s), \nabla u(s))_{\mathbb{R}^N} \, dx \, ds \, dt \\ &\geqq \overline{\lim_{\varepsilon \to 0}} \int_0^T \int_0^t \int_\Omega (D\Phi(\nabla u_\varepsilon(s)), \nabla u_\varepsilon(s))_{\mathbb{R}^N} \, dx \, ds \, dt. \end{aligned} \tag{99}$$

As seen earlier, the right-hand side of (99) is the lim-sup of the right-hand side of (80) as ε tends to zero. We obtain the following:

$$\begin{aligned} &\overline{\lim_{\varepsilon \to 0}} \int_0^T \int_0^t \int_\Omega (D\Phi(\nabla u_\varepsilon(s)), \nabla u_\varepsilon(s))_{\mathbb{R}^N} \, dx \, ds \, dt \\ &\quad \leqq \int_0^T \int_0^t \int_\Omega f(s) u(s) \, dx \, ds \, dt + T \int_\Omega \Psi^*(b(u_0)) \, dx \\ &\quad - \underline{\lim_{\varepsilon \to 0}} \int_0^T \int_\Omega \Psi^*(b(u_\varepsilon(t))) \, dx \, dt. \end{aligned}$$

But Ψ^* is positive lower semicontinuous and convex on $\mathbb{R}$; thus, with the help of (97),

$$0 \leqq \int_0^T \int_\Omega \Psi^*(b(u(t))) \, dx \, dt \leqq \underline{\lim_{\varepsilon \to 0}} \int_0^T \int_\Omega \Psi^*(b(u_\varepsilon(t))) \, dx \, dt,$$

which leads to

$$\begin{aligned} &\overline{\lim_{\varepsilon \to 0}} \int_0^T \int_0^t \int_\Omega (D\Phi(\nabla u_\varepsilon(s)), \nabla u_\varepsilon(s)) \, dx \, ds \, dt \\ &\quad \leqq \int_0^T \int_0^t \int_\Omega f(s) u(s) \, dx \, ds \, dt + T \int_\Omega \Psi^*(b(u_0)) \, dx \\ &\quad - \int_0^T \int_\Omega \Psi^*(b(u(t))) \, dx. \end{aligned} \tag{100}$$

The right-hand side of inequality (100) is easily seen to coincide with $\int_0^T \int_0^t \int_\Omega (Y(s), \nabla u(s))_{\mathbb{R}^N} \, dx \, ds \, dt$ after multiplication of (90) by u, integration of the resulting expression over $(0, t) \times \Omega$ then over $(0, T)$, and application of Lemma 1. Inequality (99) is proved and equality (98) is established.

Recalling (88), (90), (91), (97), and (98) we conclude that there exists an element u of $L_\infty(0, T; W_0^{1,q}(\Omega))$ which satisfies (8)-(10). The proof of the existence part of Theorem 1 is now complete.

The bound on the norm of u in $L_\infty(0, T; W_0^{1,q}(\Omega))$ is a direct consequence of Remark 5 and of the weak lower semicontinuity property of the L_q norm.

2.5. Comparison result. It is now assumed that u_{01}, u_{02}, f_1, f_2 satisfy the hypotheses of Theorem 1 and that

$$b(u_{01}) \geqq b(u_{02}) \quad \text{almost everywhere on } \Omega,$$

$$f_1 \geqq f_2 \quad \text{almost everywhere on } \Omega \times (0, T).$$

Let u_1 and u_2 denote the associated solutions of (8)-(10) whose existence was established in the previous sections.

Let $\mathrm{sg}_\alpha^-(t)$ and $\mathrm{sg}_0(t)$ denote the following real-valued functions of the real variable:

$$\mathrm{sg}_\alpha^-(t) = \begin{cases} 0 & \text{if } t \geqq 0, \\ \dfrac{1}{\alpha} t & \text{if } -\alpha \leqq t \leqq 0, \\ -1 & \text{if } t \leqq -\alpha, \end{cases}$$

$$\mathrm{sg}_0(t) = \begin{cases} 0 & \text{if } t \geqq 0, \\ -1 & \text{if } t < 0. \end{cases}$$

In view of (60) and (61), the quantity $\mathrm{sg}_\alpha^-(u_{1\varepsilon}^\eta - u_{2\varepsilon}^\eta)$ is an element of $L_\infty(0, T; W_0^{1,q}(\Omega)) \cap W^{1,2}(0, T; L_2(\Omega))$ (and $b^\eta(u_\varepsilon^\eta)$ as well). Thus it is an admissible test function in (57) (with u_ε^η, f replaced by $u_{1\varepsilon}^\eta, f_1$ or $u_{2\varepsilon}^\eta, f_2$). Upon integration over the time interval $(0, t)$ of the result of the multiplication of (57) by $\mathrm{sg}_\alpha^-(u_{1\varepsilon}^\eta - u_{2\varepsilon}^\eta)$, we obtain by difference

$$\begin{aligned} &\int_0^t \int_\Omega \frac{\partial}{\partial t}[(b^\eta(u_{1\varepsilon}^\eta) + \varepsilon u_{1\varepsilon}^\eta) - (b^\eta(u_{2\varepsilon}^\eta) + \varepsilon u_{2\varepsilon}^\eta)](s)\, \mathrm{sg}_\alpha^-(u_{1\varepsilon}^\eta - u_{2\varepsilon}^\eta)(s)\, dx\, ds \\ &\quad + \int_0^t \int_\Omega (\mathrm{sg}_\alpha^-)'(u_{1\varepsilon}^\eta - u_{2\varepsilon}^\eta)(s)(D\Phi(\nabla u_{1\varepsilon}^\eta(s)) \\ &\qquad - D\Phi(\nabla u_{2\varepsilon}^\eta(s)), (\nabla u_{1\varepsilon}^\eta - \nabla u_{2\varepsilon}^\eta)(s))_{\mathbb{R}^N}\, dx\, ds \\ &= \int_0^t \int_\Omega (f_1 - f_2)(s)\, \mathrm{sg}_\alpha^-(u_{1\varepsilon}^\eta - u_{2\varepsilon}^\eta)(s)\, dx\, ds. \end{aligned} \tag{101}$$

Once again the derivation formula for the composition of a $W_0^{1,q}$ function by a Lipschitz function is implicitly used in (101). By virtue of the monotonicity of sg_α^- and $D\Phi$ and the positivity of $f_1 - f_2$, (101) yields

$$\int_0^t \int_\Omega \frac{\partial}{\partial t}[(b^\eta(u_{1\varepsilon}^\eta) + \varepsilon u_{1\varepsilon}^\eta) - (b^\eta(u_{2\varepsilon}^\eta) + \varepsilon u_{2\varepsilon}^\eta)](s)\, \mathrm{sg}_\alpha^-(u_{1\varepsilon}^\eta - u_{2\varepsilon}^\eta)(s)\, dx\, ds \leqq 0. \tag{102}$$

As α tends to zero, $\mathrm{sg}_\alpha^-(u_{1\varepsilon}^\eta - u_{2\varepsilon}^\eta)$ converges weak-* in $L_\infty(\Omega \times (0, T))$ to $\mathrm{sg}_0^-(u_{1\varepsilon}^\eta - u_{2\varepsilon}^\eta)$ and (102) becomes

$$\int_0^t \int_\Omega \frac{\partial}{\partial t}[(b^\eta(u_{1\varepsilon}^\eta) + \varepsilon u_{1\varepsilon}^\eta) - (b^\eta(u_{2\varepsilon}^\eta) + \varepsilon u_{2\varepsilon}^\eta)](s)\, \mathrm{sg}_0^-(u_{1\varepsilon}^\eta - u_{2\varepsilon}^\eta)(s)\, dx\, ds \leqq 0.$$

Since $b^\eta(t) + \varepsilon t$ is monotone and takes the value zero for t equal to zero,

$$\mathrm{sg}_0^-(u_{1\varepsilon}^\eta - u_{2\varepsilon}^\eta) = \mathrm{sg}_0^-[(b^\eta(u_{1\varepsilon}^\eta) + \varepsilon u_{1\varepsilon}^\eta) - (b^\eta(u_{2\varepsilon}^\eta) + \varepsilon u_{2\varepsilon}^\eta)]$$

almost everywhere in $\Omega\times(0, T)$. The function $b^\eta(u_{i\varepsilon}^\eta)+\varepsilon u_{i\varepsilon}^\eta$ $(i=1,2)$ lies in $W^{1,2}(0, T; L_2(\Omega))$. Consequently the last inequality reads as

$$\begin{aligned}&\int_\Omega [(b^\eta(u_{1\varepsilon}^\eta)+\varepsilon u_{1\varepsilon}^\eta)-(b^\eta(u_{2\varepsilon}^\eta)+\varepsilon u_{2\varepsilon}^\eta)]^-(t)\,dx\\ &\leqq \int_\Omega [(b^\eta(u_{01})+\varepsilon u_{01})-(b^\eta(u_{02})+\varepsilon u_{02})]^-\,dx,\end{aligned}\tag{103}$$

for any t in $[0, T]$. In (103), $[\cdot]^-$ denotes the convex Lipschitz function $-\inf(\cdot, 0)$.

Since $[\ ]^-$ is convex and continuous, the convergences (63), (66), (69), and (88) together with relations (74) and (97), easily allow passing to the limit in the result of the integration of inequality (103) over the time interval $(0, T)$ as η and ε successively tend to zero. We finally conclude that

$$\int_0^T\int_\Omega [b(u_1)-b(u_2)]^-(t)\,dx\,dt \leqq T\int_\Omega [b(u_{01})-b(u_{02})]^-\,dx.\tag{104}$$

The function $[b(u_{01})-b(u_{02})]^-$ is by assumption equal to zero, which implies that for almost every (x, t) in $\Omega\times(0, T)$,

$$(b(u_1)-b(u_2))(x, t)\leqq 0.$$

The proof of Theorem 1 is now complete.

Remark 8. Note that the hypothesis on $b(u_{01})-b(u_{02})$ has not been used in the derivation of inequality (104) which thus holds true only under the assumption that f_1-f_2 is almost everywhere positive on $\Omega\times(0, T)$.

3. Proof of Theorem 2. The proof of Theorem 2 is based on the existence result given by Theorem 1. Specifically we introduce

$$u_0^n = T_n(u_0),$$

where, for any positive r, T_r is the Lipschitz function defined as

$$T_r(t)=\begin{cases} t & \text{if } |t|\leqq r,\\ r\,\mathrm{sg}\,(t) & \text{if } |t|>r.\end{cases}$$

Since T_n is a piecewise C^1 Lipschitz function and u_0 is in $W_0^{1,q}(\Omega)$, u_0^n is in $W_0^{1,q}(\Omega)$, and the derivation formula applies, from which it is easily deduced that

$$u_0^n \rightharpoonup u_0 \quad \text{weakly in } W_0^{1,q}(\Omega),\tag{105}$$

as n tends to infinity.

We also introduce a sequence f^n in $W^{1,1}(0, T; L_2(\Omega))$ such that

$$f^n \to f \quad \text{strongly in } W^{1,1}(0, T; W^{-1,q'}(\Omega))\tag{106}$$

as n tends to infinity, and we propose to study the behavior of u^n, the solution of

$$\begin{aligned}&\frac{\partial b(u^n)}{\partial t}-\operatorname{div} D\Phi(\nabla u^n)=f^n \quad \text{in } \Omega\times(0, T),\\ &u^n=0 \quad \text{on } \partial\Omega\times(0, T),\\ &b(u^n)\big|_{t=0}=b(u_0^n),\end{aligned}\tag{107}$$

as n tends to infinity. Theorem 1 ensures the existence of such a u^n in $L_\infty(0, T; W_0^{1,q}(\Omega))$ with $b(u^n)$ in $L_\infty(0, T; L_2(\Omega))\cap W^{1,\infty}(0, T; W^{-1,q'}(\Omega))$.

Furthermore the norm of u^n in $L_\infty(0, T; W_0^{1,q}(\Omega))$ is bounded by a continuous function of $\Phi(\nabla u_0^n)$ and of the norm $|||f^n|||$ of f^n in $W^{1,1}(0, T; W^{-1,q'}(\Omega))$ (cf. Theorem 1). It is then immediately deduced from (105), (106), and the properties (5) of Φ that

(108) u^n is bounded in $L_\infty(0, T; W_0^{1,q}(\Omega))$ independently of n.

Once again the boundedness of $D\Phi$ on the bounded sets of $L_q(\Omega)$ implies that

(109) $D\Phi(\nabla u^n)$ is bounded in $L_\infty(0, T; [L_{q'}(\Omega)]^N)$.

With the help of (108) and (109) we conclude that there exists a suitably extracted subsequence (still denoted u^n) such that

$$\begin{aligned} &u^n \rightharpoonup u \quad \text{weak-* in } L_\infty(0, T; W_0^{1,q}(\Omega)), \\ &D\Phi(\nabla u^n) \rightharpoonup Y \quad \text{weak-* in } L_\infty(0, T; [L_{q'}(\Omega)]^N) \end{aligned} \tag{110}$$

as n tends to infinity. Furthermore, by virtue of (106)-(109),

(111) $\dfrac{\partial b(u^n)}{\partial t}$ is bounded in $L_\infty(0, T; W^{-1,q'}(\Omega))$ independently of n.

We need to derive an estimate on $b(u^n)$ so as to be in a position to pass to the limit in (107). The function u^n is an admissible test function in the first equation of (107). Upon integration over $\Omega \times (0, t)$ of the result of the multiplication of the first equation of (107) by u^n we obtain the following estimate:

$$\int_\Omega \Psi^*(b(u^n(t)))\, dx \leqq \int_\Omega \Psi^*(b(u_0^n))\, dx + |||f^n||| \int_0^t \|u^n(s)\|_{1,q}\, ds, \tag{112}$$

where $|||f^n|||$ denotes the norm of f^n in $W^{1,1}(0, T; W^{-1,q'}(\Omega))$. Lemma 1 and the coercivity properties of Φ are implicitly used in establishing (112) (refer to (21), (27)-(29) for an identical argument).

A subsequence of $\Psi^*(b(u_0^n))$, still denoted $\Psi^*(b(u_0^n))$, converges almost everywhere to $\Psi^*(b(u_0))$. Furthermore, in view of (4) and the positivity of Ψ,

$$0 \leqq \Psi^*(b(u_0^n(x))) \leqq b(u_0^n(x))u_0^n(x) \leqq b(u_0(x))u_0(x),$$

for almost every x of Ω. Recalling Remark 2 we conclude that, as n tends to infinity

$$\int_\Omega \Psi^*(b(u_0^n))\, dx \to \int_\Omega \Psi^*(b(u_0))\, dx, \tag{113}$$

and, with the help of (112), that

(114) $\Psi^*(b(u^n))$ is bounded in $L_\infty(0, T; L_1(\Omega))$ independently of n.

In (114) we have identified $\Psi^*(b(u^n))$ with one of its subsequences.

We now make use of the following remark (cf. [1, Remark 1.2, p. 314]).

Remark 9. Let δ be an arbitrary strictly positive real number. Then

$$|b(t)| \leqq \delta \Psi^*(b(t)) + \sup_{|\sigma| \leqq 1/\delta} |b(\sigma)|$$

for every t in $\mathbb{R}$.

Remark 10. Note that Remarks 2 and 9 immediately imply that $b(u_0)$ is in fact an element of $L_1(\Omega)$.

Thus, for any strictly positive δ and almost any (x, t) in $\Omega \times (0, T)$,

(115) $$|b(u^n(x, t))| \leqq \delta \Psi^*(b(u^n(x, t))) + \sup_{|\sigma| \leqq 1/\delta} |b(\sigma)|.$$

Integration of (115) over any measurable subset Q of Ω implies, in view of (114), that, for almost any t in $(0, T)$,

$$\int_Q |b(u^n(t))|\,dx \leqq \delta\mathscr{C} + \text{mes}\,(Q) \sup_{|\sigma|\leqq 1/\delta} |b(\sigma)|, \tag{116}$$

where $\mathscr{C}$ is a generic constant independent of n.

Thus,

$$\begin{aligned} &b(u^n) \text{ is bounded in } L_\infty(0, T; L_1(\Omega)) \text{ independently of } n, \\ &b(u^n) \text{ is uniformly equi-integrable in } L_1(\Omega). \end{aligned} \tag{117}$$

We are now in a position to prove the following lemma.

LEMMA 3. *The sequence $b(u_n(t))$ lies in $\mathscr{C}^0([0, T]; L_1(\Omega))$ and as n tends to infinity*

$$b(u_n(t)) \to \chi \quad \textit{strongly in } \mathscr{C}^0([0, T]; L_1(\Omega)), \tag{118}$$

where χ is also an element of $\mathscr{C}^0([0, T]; L_1(\Omega))$.

Proof of Lemma 3. By virtue of (108) and since the embedding of $W_0^{1,q}(\Omega)$ into $L_1(\Omega)$ is compact, we conclude that there exists a measurable set Z in $(0, T)$ of zero measure such that

$$F = \{u_n(t);\ n \in \mathbb{N},\ t \in (0, T) - Z\} \text{ is relatively compact in } L_1(\Omega). \tag{119}$$

Through application of the Dunford-Pettis Theorem (see, e.g., [6, Cor. 11, p. 294]), (117) implies that

$$b(F) = \{b(u_n(t));\ n \in N,\ t \in (0, T) - Z\} \text{ is sequentially weakly relatively compact in } L_1(\Omega). \tag{120}$$

The compactness properties (119) and (120) of the sets F and $b(F)$ ensure that

$$b(F) \text{ is relatively compact in } L_1(\Omega). \tag{121}$$

Indeed, if h_n is an arbitrary sequence of $b(F)$, there exists a subsequence of h_n (still denoted by h_n) and a sequence w_n of F such that, as n tends to infinity,

$$w_n \to w \quad \text{in } L_1(\Omega) \text{ and almost everywhere in } \Omega, \tag{122}$$

$$b_n = b(w_n) \rightharpoonup h \quad \text{weakly in } L_1(\Omega). \tag{123}$$

Since b is a continuous function (122) implies the almost pointwise convergence of $b(w_n)$ to $b(w)$. The weak convergence (123) then implies the strong convergence in $L_1(\Omega)$ of the sequence $b(w_n)$ to $b(w)$ (see [6, Thm. 12, p. 295], which proves (121).

By virtue of (121), there exists a compact set K in $L_1(\Omega)$ such that

$$b(u_n(t)) - b(u_n(t')) \in K \text{ for any } n \text{ and for almost every } t \text{ and } t' \text{ in } (0, T). \tag{124}$$

In view of (111) a proper choice of s (s small enough) guarantees that

$$L^1(\Omega) \hookrightarrow W^{-1,s}(\Omega), \tag{125}$$

and

$$\frac{\partial b(u_n)}{\partial t} \text{ is bounded in } L^\infty(0, T; W^{-1,s}(\Omega)). \tag{126}$$

We now appeal to a straightforward adaptation of a classical lemma of Lions (see [8, Lemma 5.1, p. 58]), which may be proved exactly as in [12, Lemma 8, p. 84].

LEMMA 4. *Let B and Y be two Banach spaces with continuous embedding of B into Y. Let X be a compact subset of B. Then, for any strictly positive number ε, there exists a strictly positive constant C_ε such that*

$$|f|_B \leqq \varepsilon + C_\varepsilon |f|_Y \quad \textit{for any } f \textit{ in } X. \qquad \square$$

Lemma 4 is applied in our context with $B = L_1(\Omega)$, $Y = W^{-1,s}(\Omega)$, and $X = K$. Thus, with the help of (124) and (125), for any strictly positive number ε, there exists a strictly positive constant C_ε such that

$$\|b(u_n(t)) - b(u_n(t'))\|_{0,1} \leqq \varepsilon + C_\varepsilon \|b(u_n(t)) - b(u_n(t'))\|_{-1,s} \tag{127}$$

for any n and for almost every t and t' in $(0, T)$.

Estimate (126) implies that

$$\|b(u_n(t)) - b(u_n(t'))\|_{-1,s} \leqq \int_t^{t'} \left\| \frac{\partial b(u_n)(\sigma)}{\partial t} \right\|_{-1,s} d\sigma \leqq \mathscr{C}|t - t'|, \tag{128}$$

where $\mathscr{C}$ is a generic constant independent of n.

Inserting (128) into (127) leads to

$$\|b(u_n(t)) - b(u_n(t'))\|_{0,1} \leqq \varepsilon + C_\varepsilon |t - t'| \text{ for any } n \text{ and for almost every } t \text{ and } t' \text{ in } (0, T). \tag{129}$$

Estimate (129) readily yields the existence of a sequence of continuous representatives of $b(u_n(t))$ (still denoted by $b(u_n(t))$) such that for any positive number ε, there exists a strictly positive constant C_ε with

$$\|b(u_n(t)) - b(u_n(t'))\|_{0,1} \leqq \varepsilon + C_\varepsilon |t - t'| \text{ for any } n \text{ and every } t \text{ and } t' \text{ in } [0, T]. \tag{130}$$

The continuity of $b(u_n(t))$ and (121) imply that $b(u_n(t))$ is continuous on $[0, T]$ with value in a compact set of $L_1(\Omega)$ (which is independent of n). The uniform equicontinuity (130) of the sequence $b(u_n(t))$ permits the application of Ascoli's theorem, which completes the proof of Lemma 3.

It remains to prove that $\chi = b(u)$. Let ω be an arbitrary function in $L_1(\Omega \times (0, T))$. The function $T_R(b(u^n) - b(\omega))$ converges almost everywhere in $\Omega \times (0, T)$ to $T_R(\chi - b(\omega))$ and its L_∞-norm is bounded above by R. Hence

$$T_R(b(u^n) - b(\omega)) \to T_R(\chi - b(\omega)) \quad \text{strongly in } L_s(\Omega \times (0, T)), \qquad 1 \leqq s < +\infty, \tag{131}$$

as n tends to infinity. If φ denotes an arbitrary positive element of $\mathscr{C}_0^\infty(\Omega \times (0, T))$ we conclude, with the help of (110) and (131), that

$$\begin{aligned} &\lim_{n \to +\infty} \int_0^T \int_\Omega \varphi(t) T_R(b(u^n(t)) - b(\omega(t)))(u^n(t) - \omega(t))\, dx\, dt \\ &\quad = \int_0^T \int_\Omega \varphi(t) T_R(\chi(t) - b(\omega(t)))(u(t) - \omega(t))\, dx\, dt. \end{aligned} \tag{132}$$

The integrand in the left-hand side of equality (132) is always positive because b is monotone. Thus the limit is positive and we conclude that, for almost every (x, t) in $\Omega \times (0, T)$,

$$T_R(\chi(x, t) - b(\omega(x, t)))(u(x, t) - \omega(x, t)) \geqq 0. \tag{133}$$

Since R is arbitrary, (133) implies that, for almost any (x, t) in $\Omega \times (0, T)$,

$$(\chi(x, t) - b(\omega(x, t)))(u(x, t) - \omega(x, t)) \geqq 0. \tag{134}$$

A proper choice of ω in (134) then shows that

$$\chi = b(u) \quad \text{almost everywhere in } \Omega \times (0, T). \tag{135}$$

Passing to the limit in (107) is now an immediate task in view of (106), (110), (111), (118), and (135). We obtain the following:

$$\frac{\partial b(u)}{\partial t} - \operatorname{div} Y = f \quad \text{in } \Omega \times (0, T). \tag{136}$$

Since a subsequence of $b(u_0^n)$ (still denoted $b(u_0^n)$) converges almost everywhere and monotonically to $b(u_0)$, and with the help of Remark 10,

$$b(u_0^n) \to b(u_0) \quad \text{strongly in } L_1(\Omega), \tag{137}$$

as n tends to infinity. By virtue of (111), (118), and (135)

$$b(u)|_{t=0} = b(u_0). \tag{138}$$

It now remains to identify Y. The identification relies once again on Lemma 2. The quantities w_m, w, and Y are identified with ∇u^n, ∇u, and Y, respectively, and (48) is satisfied with the help of estimates (110). To show that

$$Y = D\Phi(\nabla u) \tag{139}$$

we only need to prove that

$$\begin{aligned} &\int_0^T \int_0^t \int_\Omega (Y(s), \nabla u(s))_{\mathbb{R}^N} \, dx \, ds \, dt \\ &\qquad \geqq \overline{\lim} \int_0^T \int_0^t \int_\Omega (D\Phi(\nabla u^n(s)), \nabla u^n(s))_{\mathbb{R}^N} \, dx \, ds \, dt. \end{aligned} \tag{140}$$

As was seen earlier (cf. § 2.4) the right-hand side of (140) is the limit superior of the right-hand side of inequality (100) with f, u_0, and u, respectively, replaced by f^n, u_0^n, and u^n.

We obtain, in view of (106), (110), and (113),

$$\begin{aligned} &\overline{\lim_{\varepsilon \to 0}} \int_0^T \int_0^t \int_\Omega (D\Phi(\nabla u^n(s)), \nabla u^n(s))_{\mathbb{R}^N} \, dx \, ds \, dt \\ &\qquad \leqq \int_0^T \int_0^t \int_\Omega f(s) u(s) \, dx \, ds \, dt + T \int_\Omega \Psi^*(b(u_0)) \, dx \\ &\qquad\quad - \underline{\lim_{n \to +\infty}} \int_0^T \int_\Omega \Psi^*(b(u^n(t))) \, dx \, dt. \end{aligned}$$

But Ψ^* is positive and lower semicontinuous on $\mathbb{R}$; thus, with the help of (118), (135), and Fatou's lemma,

$$0 \leqq \int_0^T \int_\Omega \Psi^*(b(u(t))) \, dx \, dt \leqq \underline{\lim_{m \to +\infty}} \int_0^T \int_\Omega \Psi^*(b(u^n(t))) \, dx \, dt,$$

which leads to

$$\begin{aligned} &\overline{\lim_{\varepsilon \to 0}} \int_0^T \int_0^t \int_\Omega (D\Phi(\nabla u^n(s)), \nabla u^n(s))_{\mathbb{R}^N} \, dx \, ds \, dt \\ &\qquad \leqq \int_0^T \int_0^t \int_\Omega f(s) u(s) \, dx \, ds \, dt + T \int_\Omega \Psi^*(b(u_0)) \, dx \\ &\qquad\quad - \int_0^T \int_\Omega \Psi^*(b(u(t))) \, dx \, dt. \end{aligned} \tag{141}$$

The right-hand side of inequality (141) is easily seen to coincide with $\int_0^T \int_0^t \int_\Omega (Y(s), \nabla u(s))_{\mathbb{R}^N} dx\, ds\, dt$ after multiplication of (136) by u, integration of the resulting expression over $(0, t)\times\Omega$ then over $(0, T)$, and application of Lemma 1. Inequality (140) is proved and equality (139) follows.

Recalling (110), (118), and (135)-(139), we conclude that there exists an element u of $L_\infty(0, T; W_0^{1,q}(\Omega))$ which satisfies (13)-(15). The proof of the existence part of Theorem 2 is complete.

If f_1 and f_2 satisfy (12), and $f_1 - f_2$ is positive in the sense of Theorem 2, the sequences f_1^n, f_2^n introduced in (106) can be chosen such that $f_1^n - f_2^n$ is positive almost everywhere on $\Omega\times(0, T)$. According to Remark 8, inequality (104) applies to u_1^n and u_2^n. We obtain the following:

$$\int_0^T \int_\Omega [b(u_1^n) - b(u_2^n)]^-(t)\, dx\, dt \leqq T \int_\Omega [b(u_{01}^n) - b(u_{02}^n)]^-\, dx, \tag{142}$$

where u_{01}^n and u_{02}^n are the sequences associated to u_{01} and u_{02} through (105). In view of (118), (135), and (138), inequality (142) is easily seen to yield

$$\int_0^T \int_\Omega [b(u_1) - b(u_2)]^-(t)\, dx\, dt \leqq T \int_\Omega [b(u_{01}) - b(u_{02})]^-\, dx,$$

as n tends to infinity and the hypothesis on $b(u_{01}) - b(u_{02})$ permits us to conclude.

Acknowledgments. The authors thank the referee for his numerous remarks and A. Damlamian for his advice in improving the original manuscript.

TRAVELING WAVE SOLUTIONS ARISING FROM A TWO-STEP COMBUSTION MODEL*

DAVID TERMAN†

Abstract. The combustion process $A \to B \to C$ may give rise to many traveling wave solutions, each traveling with a different velocity. The first reaction, $A \to B$, may produce a flame F1 with speed θ_1, while the second reaction may produce a second flame F12 with speed θ_2. If $\theta_1 < \theta_2$, then the rear flame F12 will approach the forward one, F1. One may expect that what eventually evolves is a single configuration moving with constant velocity. This corresponds to a third traveling wave solution. In this paper it is shown that if $\theta_1 < \theta_2$, then such a third wave does indeed exist.

Key words. reaction-diffusion equation, Conley index, traveling wave solution

AMS(MOS) subject classification. 35K57

1. Introduction. This paper is concerned with proving the existence of traveling wave solutions of a reaction-diffusion system which arises in the theory of combustion. The equations take the form

$$U_t = DU_{xx} + F(U) \tag{1.1}$$

where $U = (T, Y_1, \cdots, Y_{n-1}) \in \mathbb{R}^n$ and D is a positive, diagonal matrix. The traveling wave represents a combustion front in a premixed reactive gas. The components of U specify the dimensionless temperature and the mass fractions of the reactants. For a background of the physical motivation of these equations, see [2] and [13].

By a traveling wave solution of (1.1) we mean a nonconstant, bounded solution of the form $U(x, t) = U(z)$, $z = x + \theta t$. Note that a traveling wave solution satisfies the system of ordinary differential equations

$$DU'' - \theta U' + F(U) = 0.$$

We are primarily concerned with the two-step reaction process $A \to B \to C$. However, in order to motivate our results, we make a few remarks concerning the simple reaction $A \to B$. If we assume that the reaction rate is of mass action-Arrhenius form, T is the dimensionless temperature, and Y is the mass fraction of A, then (T, Y) satisfies the system

$$T_t = d_1 T_{xx} + QBY e^{-E/T}, \qquad Y_t = d_2 Y_{xx} - BY e^{-E/T}, \tag{1.2}$$

where d_1, d_2, Q, B, and E are all positive constants. We assume that (T, Y) satisfy boundary conditions of the form

$$(T(-\infty), Y(-\infty)) = (T_-, Y_-) \quad \text{and} \quad (T(\infty), Y(\infty)) = (T_+, 0). \tag{1.3}$$

A traveling wave solution then satisfies the system

$$d_1 T'' - \theta T' = -QBY e^{-E/T}, \qquad d_2 Y'' - \theta Y' = BY e^{-E/T} \tag{1.4}$$

along with the boundary conditions (1.3). To prove the existence of a traveling wave solution we must show that there exists a θ for which there exists a solution of (1.3), (1.4). Because the right-hand side (1.4) is zero only when $T = 0$ or $Y = 0$, there cannot

* Received by the editors February 25, 1986; accepted for publication (in revised form) January 6, 1987. This work was supported in part by the National Science Foundation under grant 8401719.

† Department of Mathematics, Ohio State University, Columbus, Ohio 43210.

exist any traveling wave solutions unless $T_- = 0$, which is physically not reasonable. This is often referred to as the "cold boundary difficulty" (see [13]); because the formulation (1.2) requires that the mixture react all the way in from $x = -\infty$, by the time finite x is reached the combustion would be complete. To overcome this difficulty, it is necessary to avoid reactions at a finite rate over an infinite time. A common way to do this is to introduce an ignition temperature. We replace (1.2) by

$$T_t = d_1 T_{xx} + QBYf(T), \qquad Y_t = d_2 Y_{xx} - BYf(T), \tag{1.5}$$

where $f(T)$ is continuous and satisfies the following:

(a) There exists $T_1 > 0$ such that $f(T) = 0$ for $T < T_1$;

(b) $f(T) > 0$ for $T > T_1$.

Berestycki, Nicolaenko, and Scheurer [1] prove that there does indeed exist a traveling wave solution of (1.5) which satisfies (1.3). They show that on such a solution $T(z)$ is monotone increasing, $Y(z)$ is monotone decreasing, and

$$T_+ = T_- + QY_-. \tag{1.6}$$

Note that (1.6) is easily obtained by integrating the equations in (1.4) for $-\infty < z < \infty$.

In this paper we consider the existence of traveling wave solutions arising from the reactions

$$A \xrightarrow{\text{(i)}} B \xrightarrow{\text{(ii)}} C. \tag{1.7}$$

If T is the dimensionless temperature, Y_1 the mass fraction of A, and Y_2, the mass fraction of B, then the traveling wave equations corresponding to this reaction network are

$$\begin{aligned} &d_0 T'' - \theta T' = -Q_1 Y_1 f_1(T) - Q_2 Y_2 f_2(T), \\ &d_1 Y_1'' - \theta Y_1' = Y_1 f_1(T), \\ &d_2 Y_2'' - \theta Y_2' = -Y_1 f_1(T) + Y_2 f_2(T) \end{aligned} \tag{1.8}$$

where $f_1(T) = B_1 e^{-E_1/T}$ and $f_2(T) = B_2 e^{-E_2/T}$. The constants d_0, d_1, d_2, Q_1, Q_2, B_1, B_2, E_1, and E_2 are all assumed to be positive. As before, because of the cold boundary difficulty we introduce ignition temperatures. We assume that $f_1(T)$ and $f_2(T)$ are continuous functions, and there exist positive constants T_1 and T_2 such that for $i = 1$ or 2, $f_i(T) = 0$ for $T < T_i$, and $f_i(T) > 0$ for $T > T_i$.

We assume that the unburned state

$$U_- = (T_-, Y_{1-}, Y_{2-})$$

is prescribed. Let us now imagine (1.7) as taking place in two steps, and thus producing two flames. The first reaction, $A \to B$, in (1.7) will convert the given unburned state to a partially burned state. This will produce a flame, F1, with speed say θ^1. The second reaction, $B \to C$, will then act on the product of F1 and convert the partially burned state to a completely burned state. We denote this second flame by F12 and its velocity by θ^{12}.

The above flames will proceed at different velocities. For example, if the speed of F12, which is built on the products of F1, is slower than F1 itself, then we can imagine two flames both existing, but the distance between them would be ever increasing. Now suppose that F12 is faster than F1. In this case the rear flame approaches the forward one. As it does, its effect is to heat up the forward one. We may then expect that what eventually evolves is a single configuration moving with constant velocity. This corresponds to a traveling wave solution of (1.8). In this paper we prove that if $\theta^1 < \theta^{12}$, then such a wave does indeed exist.

In order to formally state our first result we assume, for now, that $T_1 < T_2$. For convenience, we assume, without loss of generality, that the unburned state is given by

$$U_- = (T_-, Y_{1-}, Y_{2-}) = (0, 1, 1). \tag{1.9}$$

For our first result we assume that

$$0 < T_1 < Q_1 < T_2 < Q_1 + 2Q_2. \tag{1.10}$$

This condition will be needed to guarantee the existence of the simple flames, which we now define.

Suppose that $T < T_2$. Then $f_2(T) = 0$, and (T, Y_1) satisfies the reduced system

$$d_0 T'' - \theta T' = -Q_1 Y_1 f_1(T), \qquad d_1 Y_1'' - \theta Y_1' = Y_1 f_1(T). \tag{1.11}$$

This is the traveling wave system corresponding to the single reaction $A \to B$. From [1] we conclude that there exists a solution of (1.11) which satisfies

$$(T(-\infty), Y_1(-\infty)) = (0, 1) \quad \text{and} \quad (T(\infty), Y_1(\infty)) = (Q_1, 0). \tag{1.12}$$

Here we used (1.6). This wave corresponds to the flame F1. If (1.10) is satisfied, then on this solution $T(z) < Q_1 < T_2$ for all z. Hence, the solution of (1.11), (1.12) satisfies (1.8) for all z. Note that because $T(z) < T_2$, $Y_2(z)$ satisfies

$$d_2 Y_2'' - \theta Y_2' = -Y_1 f_1(T).$$

Integrating this last equation and the second equation in (1.11) for $-\infty < z < \infty$, we find that

$$-\theta(Y_2(\infty) - 1) = -\int_{-\infty}^{\infty} Y_1 f_1(T)\, dz = -\theta,$$

or $Y_2(\infty) = 2$.

We do not know that the solution of (1.11), (1.12) is unique. Let

$$\theta^1 = \sup\{\theta\text{: there exists a solution of (1.11), (1.12) with speed } \theta\}.$$

That is, θ^1 is the maximum speed of F1.

We now consider the flame F12. Along F12, $Y_1(z) = 0$. Hence, (T, Y_2) satisfies

$$d_0 T'' - \theta T' = -Q_2 Y_2 f_2(T), \qquad d_2 Y_2'' - \theta Y_2' = Y_2 f_2(T), \tag{1.13}$$

$$(T(-\infty), Y_2(-\infty)) = (Q_1, 2), \qquad (T(\infty), Y_2(\infty)) = (T_+, 0). \tag{1.14}$$

These are the traveling wave equations corresponding to the single reaction $B \to C$. From (1.6) we conclude that $T_+ = Q_1 + 2Q_2$. From [1] we conclude that there exists a solution of (1.13), (1.14). Let

$$\theta^{12} = \inf\{\theta\text{: there exists a solution of (1.13), (1.14) with speed } \theta\}.$$

In this paper we are interested in the case $\theta^1 < \theta^{12}$. We prove the following theorem.

THEOREM 1. *Assume $T_1 < T_2$, (1.10), and $\theta^1 < \theta^{12}$. Then there exists a solution of (1.8), for some speed θ, which satisfies*

$$(T, Y_1, Y_2)(-\infty) = (0, 1, 1) \quad \textit{and} \quad (T, Y_1, Y_2)(+\infty) = (Q_1 + 2Q_2, 0, 0). \tag{1.15}$$

Moreover, T, Y_1, and Y_2 are positive for all z, $T(z)$ is monotone increasing, and $Y_1(z)$ is monotone decreasing.

In this paper we only prove this theorem for the case $d_0 = d_1 = d_2 = 1$. The proof for the case of unequal diffusion constants can be found in [11]. We outline the proof in § 5 of this paper.

We now state other theorems which we can prove in a manner similar to the proof of Theorem 1. The proofs of these other results will appear in a future paper.

Assume that $T_2 < T_1$, and

$$0 < T_2 < Q_2 < T_1 < Q_1 + 2Q_2. \tag{1.16}$$

If $T < T_1$, then (T, Y_2) satisfies

$$d_0 T'' - \theta T' = -Q_2 Y_2 f_2(T), \qquad d_2 Y_2'' - \theta Y_2' = Y_2 f_2(T). \tag{1.17}$$

From [1] we conclude that there exists a solution of (1.17) which satisfies

$$(T(-\infty), Y_2(-\infty)) = (0, 1) \quad \text{and} \quad (T(\infty), Y_2(\infty)) = (Q_2, 0). \tag{1.18}$$

Let us denote this flame by F2. Because the solution of (1.17), (1.18) may not be unique we let

$$\theta^2 = \sup\{\theta: \text{there exists a solution of (1.17), (1.18) with speed } \theta\}.$$

There will be a second flame, which we denote by F21, which acts on the product of F2. We can think of this flame as converting A to B by reaction (i) in (1.7) and B thereupon being almost immediately converted to C by the faster reaction (ii). Unlike before, F21 does not correspond to the solution of a reduced system. Instead it is a solution of (1.8) together with the boundary conditions

$$(T, Y_1, Y_2)(-\infty) = (Q_2, 1, 0) \quad \text{and} \quad (T, Y_1, Y_2)(+\infty) = (Q_1 + 2Q_2, 0, 0). \tag{1.19}$$

We can then prove Theorem 2.

THEOREM 2. *Assume that* $T_2 < T_1$ *and* (1.16). *Then there exists a solution of* (1.8), (1.19) *for some* $\theta > 0$. *Moreover* T, Y_1, *and* Y_2 *are positive for all* z, T *is monotone increasing, and* $Y_1(z)$ *is monotone decreasing.*

Let

$$\theta^{21} = \inf\{\theta: \text{there exists a solution of (1.8), (1.19) with speed } \theta\}.$$

We then have Theorem 3.

THEOREM 3. *Assume that* $T_2 < T_1$, (1.16), *and* $\theta^2 < \theta^{21}$. *Then there exists a solution of* (1.8), *for some speed* θ, *which satisfies*

$$(T, Y_1, Y_2)(-\infty) = (0, 1, 1) \quad \textit{and} \quad (T, Y_1, Y_2)(+\infty) = (Q_1 + 2Q_2, 0, 0).$$

Moreover, T, Y_1, *and* Y_2 *are positive for all* z, $T(z)$ *is monotone increasing, and* $Y_1(z)$ *is monotone decreasing.*

It remains to consider the cases when (1.10) and (1.16) are not satisfied. We then have Theorem 4.

THEOREM 4. *Assume that* (1.10) *and* (1.16) *are not satisfied. Then there exists a solution of* (1.8), *for some speed* θ, *which satisfies*

$$(T, Y_1, Y_2)(-\infty) = (0, 1, 1) \quad \textit{and} \quad (T, Y_1, Y_2)(+\infty) = (Q_1 + 2Q_2, 0, 0).$$

Moreover, T, Y_1, *and* Y_2 *are positive for all* z, $T(z)$ *is monotone increasing, and* $Y_1(z)$ *is monotone decreasing.*

In the next section we outline the proof of Theorem 1. The proof is quite geometrical, and the purpose of the next section is to introduce the basic geometrical features of the proof. The proof of the theorems consists of three basic steps. The first step is to obtain a priori bounds for the solutions. These estimates are derived in § 3. The next step in the proof is to prove the theorem for the special case $d_0 = d_1 = d_2 = 1$. The proof for this case is based on the Conley index and is carried out in § 4. The last step of the proof is to continue the solution from the case $d_0 = d_1 = d_2 = 1$. As we mentioned earlier, this continuation is carried out in [11].

An essential feature in the proof of the theorem is the Conley index. Other authors have used index arguments to prove the existence of traveling wave solutions. In particular, Gardner [9] also considered a combustion problem. In that paper he introduced the method of perturbing the ignition temperature kinetics so that Conley's methods can be applied. This method is used here (see § 4B). Another important step in this paper is to attach to the traveling wave equation a flow in the θ-direction. This idea was used by Conley and Smoller [5] who considered the existence of traveling wave solutions for systems of the form $U_t = U_{xx} + \nabla F(U)$.

2. A brief outline of the proof of Theorem 1. We now briefly outline the proof of Theorem 1. We assume throughout this section that $T_1 < T_2$ and (1.10) is satisfied. The proof of Theorem 1 is quite geometrical. The purpose of this section is to introduce the basic geometric features of the proof.

The first step is to reduce (1.8) to a first order system. Let $q = T'$, $p_1 = Y_1'$, and $p_2 = Y_2'$. Then (1.8) is equivalent to the system

$$\begin{aligned} &T' = q, \\ &d_0 q' = \theta q - Q_1 Y_1 f_1(T) - Q_2 Y_2 f_2(T), \\ &Y_1' = p_1, \\ &d_1 p_1' = \theta p_1 + Y_1 f_1(T), \\ &Y_2' = p_2, \\ &d_2 p_2' = \theta p_2 - Y_1 f_1(T) + Y_2 f_2(T). \end{aligned} \tag{2.1}$$

Let $\gamma(z) = (T(z), q(z), Y_1(z), p_1(z), Y_2(z), p_2(z))$, and

$$A = (0, 0, 1, 0, 1, 0), \qquad B = (Q_1, 0, 0, 0, 2, 0), \qquad C = (Q_1 + 2Q_2, 0, 0, 0, 0, 0).$$

The flame F1 corresponds to a solution, $\gamma_1(z)$, of (2.1) which satisfies

$$\lim_{z \to -\infty} \gamma_1(z) = A \quad \text{and} \quad \lim_{z \to +\infty} \gamma_1(z) = B. \tag{2.2a}$$

The flame F12 corresponds to a solution $\gamma_{12}(z)$ of (2.1) which satisfies

$$\lim_{z \to -\infty} \gamma_{12}(z) = B \quad \text{and} \quad \lim_{z \to \infty} \gamma_{12}(z) = C. \tag{2.2b}$$

We assume, in this section, that these simple waves are unique. In particular, the wave speeds θ^1 and θ^{12} are uniquely determined. We wish to prove that if $\theta^1 < \theta^{12}$, then there exists a solution $\gamma_0(z)$ of (2.1) which satisfies

$$\lim_{z \to -\infty} \gamma_0(z) = A \quad \text{and} \quad \lim_{z \to \infty} \gamma_0(z) = 0. \tag{2.2c}$$

In each case the traveling wave solution corresponds to a trajectory in phase space which connects two critical points.

One of the key ideas in the proof of the theorems is to attach to (2.1) the equation

$$\theta' = \varepsilon(\theta - \theta_0)(\theta - \theta_1) \tag{2.3}$$

where $\theta_1 \leqq \theta_0$ and $0 \leqq \varepsilon \ll 1$. Let

$$\begin{aligned} &A_1 = (A, \theta_0), \quad B_1 = (B, \theta_0), \quad C_1 = (C, \theta_0), \\ &A_2 = (A, \theta_1), \quad B_2 = (B, \theta_1), \quad C_2 = (C, \theta_1), \\ &l_A = \{(\gamma, \theta): \gamma = A, \theta_1 \leqq \theta \leqq \theta_0\}, \\ &l_B = \{(\gamma, \theta): \gamma = B, \theta_1 \leqq \theta \leqq \theta_0\}, \\ &l_C = \{(\gamma, \theta): \gamma = C, \theta_1 \leqq \theta \leqq \theta_0\}. \end{aligned}$$

First consider the case $\varepsilon = 0$. Then l_A, l_B, and l_C correspond to lines of critical points, and $(\gamma_1(z), \theta^1)$ and $(\gamma_{12}(z), \theta^{12})$ trace out curves in phase space which "connect" these lines. This is illustrated in Fig. 1. Figure 1(a) depicts the case $\theta^1 < \theta^{12}$, and Fig. 1(b) depicts the case $\theta^1 < \theta^{12}$.

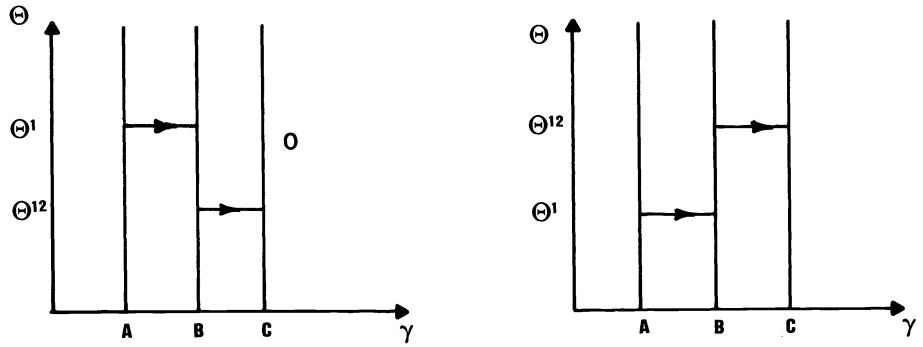
Now suppose that $\varepsilon > 0$. The lines l_A, l_B, and l_C now correspond to solutions which connect the critical points A_1 to A_2, B_1 to B_2, and C_1 to C_2, respectively. Crucial to the proof of Theorem 1 is the following result.

PROPOSITION 2.1. *For each $\varepsilon > 0$, there exists a solution $(\gamma^\varepsilon(z), \theta^\varepsilon(z))$ of (2.1), (2.3) which satisfies*

$$\lim_{z \to -\infty} (\gamma^\varepsilon(z), \theta^\varepsilon(z)) = A_1 \quad \text{and} \quad \lim_{z \to +\infty} (\gamma^\varepsilon(z), \theta^\varepsilon(z)) = C_2. \tag{2.4}$$

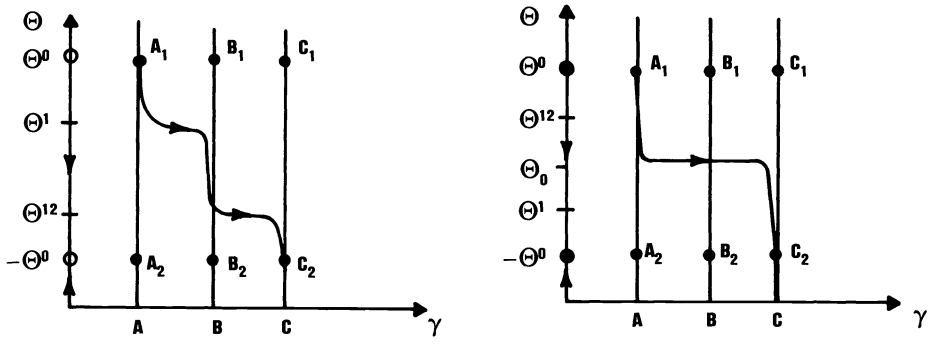
Remark. This proposition is true in both cases, $\theta^1 < \theta^{12}$ and $\theta^1 > \theta^{12}$. This result is proved later in the paper. We comment on the proof shortly. First we discuss what happens to $(\gamma^\varepsilon(z), \theta^\varepsilon(z))$ as $\varepsilon \to 0$. We shall have a priori bounds so it will be clear that at least some subsequence of $\{(\gamma^\varepsilon(z), \theta^\varepsilon(z))\}$ converges to something.

Let us, for the moment, consider the case $\theta^1 > \theta^{12}$. It is possible that for $0 < \varepsilon \ll 1$, $(\gamma^\varepsilon(z), \theta^\varepsilon(z))$ is as shown in Fig. 2(a). That is, $(\gamma^\varepsilon(z), \theta^\varepsilon(z))$ lies close to l_A for



(a) (b)

FIG. 1



(a) (b)

FIG. 2

$\theta^1 \leqq \theta \leqq \theta_0$, then lies close to $(\gamma_1(z), \theta^1)$, then lies close to l_B for $\theta^{12} \leqq \theta \leqq \theta^1$, then lies close to $(\gamma_{12}(z), \theta^{12})$, and finally lies close to l_C for $\theta_1 \leqq \theta \leqq \theta^{12}$. In the limit $\varepsilon \to 0$, the curves $(\gamma^\varepsilon(z), \theta^\varepsilon(z))$ converge to the union of the curves l_A for $\theta^1 \leqq \theta \leqq \theta_0$, $(\gamma_1(z), \theta^1)$, l_B for $\theta^{12} \leqq \theta \leqq \theta^1$, $(\gamma_{12}(z), \theta^{12})$, and l_C for $\theta_1 \leqq \theta \leqq \theta^{12}$. Hence, $(\gamma^\varepsilon(z), \theta^\varepsilon(z))$ does not converge to a traveling wave solution.

In the above paragraph we strongly used the assumption that $\theta^1 > \theta^{12}$. Since $\theta' < 0$ for $\varepsilon > 0$, it follows that if $\theta^1 < \theta^{12}$, then $(\gamma^\varepsilon(z), \theta^\varepsilon(z))$ cannot converge to a curve which is the union of $(\gamma_1(z), \theta^1)$, $(\gamma_{12}(z), \theta^{12})$ and pieces of l_A, l_B, and l_C. We prove later that the only other possibility is that there exists $\theta^0 \in (\theta_1, \theta_0)$, and a sequence $\{\varepsilon_n\}$ such that as $n \to \infty$, $\varepsilon_n \to 0$ and $\{(\gamma^{\varepsilon_n}(z), \theta^{\varepsilon_n}(z))\}$ converges to a curve which consists of three pieces. These are the following:

(a) l_A for $\theta^0 < \theta < \theta_0$;

(b) A trajectory $(\gamma_0(z), \theta^0)$ which satisfies (2.1), (2.3) for all z with $\varepsilon = 0$, $\lim_{z \to -\infty} \gamma_0(z) = A$ and $\lim_{z \to +\infty} \gamma_0(z) = C$;

(c) l_C for $\theta_1 < \theta < \theta^0$.

Then $\gamma_0(z)$ is the desired solution.

The proof of Proposition 2.1 is based on Conley's Morse Theory (see [3], [6], and [10]). First we prove the proposition for the case $d_0 = d_1 = d_2 = 1$. For general diffusion coefficients, we continue the solution. This last step is outlined in § 5.

3. A priori bounds. We now derive some a priori bounds which establish the positivity and monotonicity properties of the dependent variables. We will also find an upper bound on the speed θ of a solution. Let $\Phi(z) = (T, q, Y_1, p_1, Y_2, p_2, \theta)(z)$ be a solution of (2.1), (2.3) together with the boundary conditions

$$\lim_{z \to -\infty} \Phi(z) = A_1 \quad \text{and} \quad \lim_{z \to +\infty} \Phi(z) = C_2. \tag{3.1}$$

We assume that $\varepsilon \geqq 0$, and $\theta_0 > 0$. The motivation for considering such a solution was given in the previous section.

LEMMA 3.1. $Y_1(z) > 0$ *for all* z.

Proof. We first show that $Y_1(z) \geqq 0$ for each z. If not, there exists z_0 such that

$$Y_1(z_0) < 0 \quad \text{and} \quad Y_1'(z_0) > 0. \tag{3.2}$$

Let $\alpha = \sup\{z < z_0 \colon Y_1'(z_0) = 0\}$. Certainly α is well defined. Then $Y_1'(\alpha) = 0$, $Y_1'(z) > 0$ for $z \in (\alpha, z_0)$, and $Y_1(z) < 0$ on (α, z_0). Then

$$d_1 Y_1'' - \theta Y_1' = Y_1 f_1(T) \leqq 0 \quad \text{on } [\alpha, z_0].$$

On the other hand,

$$d_1 Y_1'' - \theta Y_1' \geqq d_1 Y_1'' - \theta_0 Y_1' \quad \text{on } [\alpha, z_0].$$

Therefore, $d_1 Y_1'' - \theta_0 Y_1' \leqq 0$ on $[\alpha, z_0]$, and $(e^{-\theta_0/d_1 Z} Y_1')' \leqq 0$ on $[\alpha, z_0]$. Integrate this last equation from α to z_0 to obtain $Y_1'(z_0) \leqq 0$. This, however, contradicts (3.2).

If $Y_1(z_0) = 0$ for some z_0, then we must have $Y_1'(z_0) = 0$. This implies that $Y_1'(z) = 0$ for all z. Since $Y_1(-\infty) = 1$, this gives a contradiction.

LEMMA 3.2. $Y_2(z) > 0$ *for all* z.

Proof. We first prove that $Y_2(z) \geqq 0$ for all z. If not, there exists z_0 such that

$$Y_2(z_0) < 0 \quad \text{and} \quad Y_2'(z_0) > 0. \tag{3.3}$$

Let $\alpha = \sup\{z < z_0;\ Y_2'(z) = 0\}$. Then $Y_2'(\alpha) = 0$, $Y_2'(z) > 0$ on (α, z_0), and $Y_2(z) < 0$ on $[\alpha, z_0]$. Therefore,

$$d_2 Y_2'' - \theta Y_2' = -Y_1 f_1(T) + Y_2 f_2(T) \leqq 0 \quad \text{on } [\alpha, z_0].$$

Therefore, $d_2 Y_2'' - \theta_0 Y_2' \leqq 0$ on $[\alpha, z_0]$, or

$$(e^{-\theta_0/d_2 z} Y_2')' \leqq 0 \quad \text{on } [\alpha, z_0].$$

Integrate this last equation from α to z_0 to obtain $Y_2'(z_0) \leqq 0$. This, however, contradicts (3.3).

If $Y_2(z_0) = 0$ for some z_0, then $Y_2'(z_0) = 0$ and $Y_2''(z_0) \geqq 0$. If $T(z_0) \leqq T_1$, then $Y_2(z) = 0$ for all z, which is impossible. If $T(z_0) > T_1$, then $d_2 Y_2'' = -Y_1 f_1(T) < 0$, which again gives a contradiction.

In a similar manner we have Lemma 3.3.

LEMMA 3.3. *$T(z) > 0$ for all z.*

Proof. The proof of this result is similar to the two just given, so we do not give the details.

LEMMA 3.4. *$Y_1'(z) \leq 0$ for all z.*

Proof. If not, then there exists z_0 such that $Y_1'(z_0) = 0$ and $Y_1''(z_0) \leqq 0$. If $T(z_0) \leqq T_1$, then $d_1 Y_1'' - \theta Y_1' = 0$. Hence, $Y_1(z) = Y_1(z_0)$ for all z, which is impossible. If $T(z_0) > T_1$, then $Y_1''(z_0) = Y_1 f_1(T) > 0$ which gives a contradiction.

LEMMA 3.5. *If $0 < T(z) < Q_1 + 2Q_2$, then $T'(z) \geqq 0$.*

Proof. If not, then because $T(+\infty) = Q_1 + 2Q_2$, there exists z_0 such that $T'(z_0) = 0$ and $T''(z_0) \geqq 0$. If $T(z_0) < T_1$, then $T(z) = T(z_0)$ for all z, which is impossible. If $T(z_0) > T_1$, then $T''(z_0) = -Q_1 Y_1 f_1(T) - Q_2 Y_2 f_2(T) < 0$, which again gives a contradiction.

Remark. The proof of this last result shows that if $T(z_0) > Q_1 + 2Q_2$ for some z_0, then there exists z_1 such that $T'(z) \geqq 0$ for $z < z_1$, and $T'(z) \leqq 0$ for $z \geqq z_1$. If this were not true then there must exist z_2 such that $T'(z_2) = 0$ and $T''(z_2) \geqq 0$. We then proceed as before.

LEMMA 3.6. *If $\varepsilon = 0$, then $T'(z) \geqq 0$ for all z.*

Proof. Consider the equation $T'' - \theta T' = -Q_1 Y_1 f_1(T) - Q_2 Y_2 f_2(T) \leqq 0$. Multiply this equation by $e^{-\theta z}$ to obtain $(e^{-\theta z} T'(z))' \leqq 0$. If we integrate this last equation from z to ∞, then we obtain the desired result.

LEMMA 3.7. *If $\varepsilon = 0$, then $0 < Y_2(z) \leqq 2$.*

Proof. If $\varepsilon = 0$, then $\theta'(z) = 0$ for all z. Suppose that $\theta(z) = \theta$. Let $u = d_1 Y_1' - \theta Y_1$, $v = d_2 Y_2' - \theta Y_2$, and $w = u + v$. Then

$$u_1'(z) = d_1 Y_1''(z) - \theta Y_1'(z) = Y_1 f_1(T) \geqq 0.$$

Hence, $u(z)$ is an increasing function. Since $u(-\infty) = \theta$ and $u(\infty) = 0$, it follows that $-\theta \leqq u(z) \leqq 0$ for all z. Moreover, $w'(z) = Y_2 f_2(T) \geqq 0$, and $w(z)$ is an increasing function. Since $w(-\infty) = -2\theta$ and $w(\infty) = 0$, it follows that $-2\theta \leqq w(z) \leqq 0$. Because $v = w - u$, it follows that $-2\theta \leqq v(z) \leqq \theta$. Hence, $d_2 Y_2' - \theta Y_2 = v \geqq -2\theta$. Multiply the left and right sides of this equation by $e^{-\theta/d_2 z}$ and integrate from z to $-\infty$ to obtain the desired result.

We conclude this section by obtaining a priori bounds on the speed θ for which there exists a solution of (2.1) which satisfies certain boundary conditions. If $\gamma(z)$ is a solution of (2.1) which satisfies either (2.2a) or (2.2c), then $\gamma(z)$ lies in $W_A^u(\theta)$, the unstable manifold of A for a particular value of θ. To obtain an upper bound on θ, we prove that if θ is sufficiently large, then each nontrivial trajectory in $W_A^u(\theta)$ becomes unbounded.

Choose L so that for $i = 1, 2$, $f_i(T) < LT$ for $0 < T < Q_1 + 3Q_2$. Let

$$\theta_0 = 2 + 2L(Q_1 + 2Q_2 + 1) + Q_1. \tag{3.4}$$

PROPOSITION 3.8. *If $\theta > \theta_0$, then each nontrivial trajectory in $W_A^u(\theta)$ is unbounded.*

Proof. Suppose that $\Phi(z) = (T, q, Y_1 p_1, Y_2, p_2)(z)$ is a solution of (2.1) with $\theta > \theta_0$ such that $\lim_{z\to-\infty} \Phi(z) = A$. Let

$$S = \{(T, q, Y_1, p_1, Y_2, p_2)\colon 0 \leqq T \leqq q \text{ or } q \leqq T \leqq 0\}.$$

First we prove that $\Phi(z) \in S$ for each z. Note that if $T < T_1$, then $f_1(T) = f_2(T) = 0$. Hence, (T, q) satisfies $T' = q$, $q' = \theta q$. This implies that $(\theta T - q)' = 0$. Because $T(-\infty) = q(-\infty) = 0$, it follows that $q = \theta T$ for all z such that $T(z) < T_1$. Since $\theta > \theta_0$, this implies that $\Phi(z) \in S$ as long as $T(z) < T_1$. In particular, there exists z_0 such that $\Phi(z) \in S$ for $z < z_0$.

We now prove that $\Phi(z) \in S$ for all $z > z_0$. If this is not true, let $z_1 = \inf\{z > z_0\colon \Phi(z) \notin S\}$. Then $\Phi(z_1) \in \partial S$. We assume that $T(z_1) > 0$. The other case is similar. Let $n = (1, -1)$. Because $\Phi(z)$ is leaving S at $z = z_1$,

$$n \cdot (T'(z_1), q'(z_1)) \geqq 0.$$

We shall prove that this is impossible. Note that $q(z_1) = T(z_1)$. Moreover, from Lemmas 3.4 and 3.7, $0 < Y_1(z) \leqq 1$ and $0 < Y_2(z) \leqq 2$. Therefore,

$$\begin{aligned} n \cdot (T'(z_1), q'(z_1)) &= q(z_1) - \theta q(z_1) + Q_1 Y_1 f_1(T) + Q_2 Y_2 f_2(T) \\ &= q(z_1)\left[1 - \theta + \frac{Q_1 Y_1 f_1(T) + Q_2 Y_2 f_2(T)}{q(z_1)}\right] \\ &= q(z_1)\left[1 - \theta + \frac{Q_1 Y_1 f_1(T) + Q_2 Y_2 f_2(T)}{T(z_1)}\right] \\ &\leqq q(z_1)[1 - \theta_0 + L(Q_1 + 2Q_2)] \\ &< 0, \end{aligned}$$

and we have the desired contradiction.

We have now shown that $\Phi(z) \in S$ for all z. Because $q(z) = T'(z)$, this implies that $T'(z) > T(z)$ for all z. Hence, $T(z) > K e^z$ for some K and the result follows.

4. The case $d_0 = d_1 = d_2 = 1$.

4A. Reduction of order. Our goal is to prove Proposition 2.1 for the case $d_0 = d_1 = d_2 = 1$, which we assume to be true throughout this section. If we multiply the second equation in (1.8) by $Q_1 + Q_2$, the third by Q_2, add the resulting equations to the first, and let

$$Z = T + (Q_1 + Q_2) Y_1 + Q_2 Y_2,$$

we find that $Z'' - \theta Z' = 0$. Since $Z'(-\infty) = Z'(\infty) = 0$, it follows that Z is constant. By assumption $Z(-\infty) = Q_1 + 2Q_2$. This implies that

$$Y_2 = \frac{1}{Q_2}[Q_1 + 2Q_2 - T - (Q_1 + Q_2) Y_1]. \tag{4A.1}$$

Plugging (4A.1) into (1.8) we obtain

$$\begin{aligned} T'' - \theta T' &= -Q_1 Y_1 f_1(T) - [Q_1 + 2Q_2 - T - (Q_1 + Q_2) Y_1] f_2(T), \\ Y_1'' - \theta Y_1' &= Y_1 f_1(T). \end{aligned} \tag{4A.2}$$

The boundary conditions (1.15) reduce to

$$(T, Y_1)(-\infty) = (0, 1), \qquad (T, Y_1)(\infty) = (Q_1 + 2Q_2, 0). \tag{4A.3}$$

4B. Perturbation of the equations. Let $P=\{(T, Y_1): T\geqq 0, Y_1\geqq 0\}$. Of course, we are only interested in values of $(T, Y_1)\in P$. The rest points of (4A.2) in P are

$$\{(T, Y_1): 0\leqq T\leqq T_1, Y_1\geqq 0\}\cup\{(T, Y_1): Y_1=0, 0\leqq T\leqq T_2\}\cup\{(Q_1+2Q_2), 0)\}.$$

This set is too large to work with. Recalling the discussion in § 2, we eventually want to reduce the problem to one in which there are only three critical points. This is done in a number of steps. We begin by perturbing (4A.2) so that the resulting system has five critical points. Let

$$F(T, Y_1)=Q_1Y_1f_1(T)+[Q_1+2Q_2-T-(Q_1+Q_2)Y_1]f_2(T).$$

Then (4A.2) can be written as

$$T''-\theta T'=F(T, Y_1), \qquad Y_1''-\theta Y_1'=Y_1f_1(T).$$

Let

$$g_1(T)=\begin{cases} T(T-T_1) & \text{if } T<Q_1,\\ 0 & \text{if } T>Q_1\end{cases}$$

and

$$g_2(T, Y_1)=-g_1(T)+Y_1\left(\frac{1}{Q_1}(Q_1-T)-Y_1\right).$$

We shall consider the perturbed system for $\varepsilon_1>0$:

(4B.1) $$T''-\theta T'=-F(T, Y_1)-\varepsilon_1 g_1(T), \qquad Y_1''-\theta Y_1'=Y_1f_1(T)-\varepsilon_1 g_2(T, Y_1).$$

Note that the rest points of (4B.1) are at the following values of (T, Y_1): $(0, 0)$, $(T_1, 0)$, $(Q_1+2Q_2, 0)$, $(0, 1)$, and $(T_1, (1/Q_1)(Q_1-T_1))$.

In what follows we consider the traveling wave system:

(4B.2)
$$\begin{aligned} T'&=q,\\ q'&=\theta q-F(T, Y_1)-\varepsilon_1 g_1(T),\\ Y_1'&=p_1,\\ p_1'&=\theta p_1+Y_1f_1(T)-\varepsilon_1 g_2(T, Y_1)\end{aligned}$$

for ε_1 small. After proving the existence of the desired connecting orbit, we let ε_1 approach zero.

4C. An isolating neighborhood. A compact set N in phase space is an isolating neighborhood if each trajectory on the boundary of N leaves N in forward or backward time. Isolating neighborhoods are important because we can assign an index (the Conley index) to the maximal invariant set inside them. Moreover, isolating neighborhoods remain isolating neighborhoods upon perturbations of the equations. In this section we construct an isolating neighborhood which contains all the trajectories of interest.

To begin with, fix δ and δ_1 positive, and let D be the set shown in Fig. 3. That is,

$$D=\left\{(T, Y_1): -\delta\leqq T\leqq -Q_1Y+2Q_2+\delta,\ Y_1\geqq\frac{1}{Q_1}(T+2\delta)\right\}$$

$$\cup\left\{(T, Y_1): -Q_1Y_1+T_1+\delta\leqq T\leqq -Q_1Y_1+Q_1+2Q_2+\delta, 0\leqq Y_1\leqq\frac{1}{Q_1}(T_1+2\delta)\right\}$$

$$\cup\{(T, Y_1): -Q_1Y_1+T_1+\delta\leqq T\leqq Q_1+2Q_2+\delta, -\delta_1\leqq Y_1\leqq 0\}.$$

Let σ_1, σ_2, σ_3, σ_4, σ_5 be the (closed) sides of D as shown in Fig. 3.

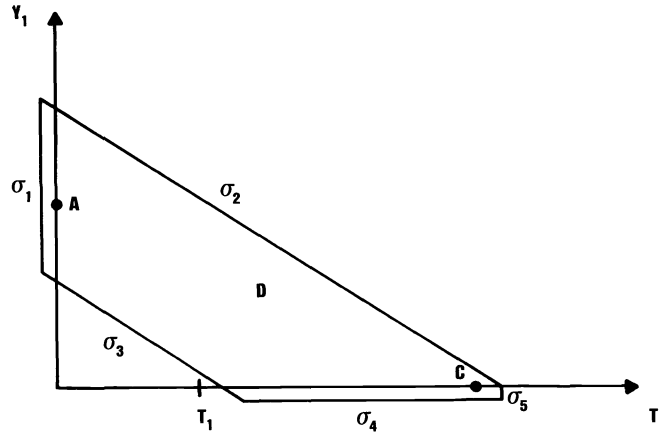


FIG. 3

LEMMA 4C.1. *There exist* δ, δ_1, *and* ε^* *such that if* $0<\varepsilon_1<\varepsilon^*$, *then* D *is positively invariant for the reaction equations*

$$\begin{aligned} T' &= F(T, Y_1)+\varepsilon_1 Q_1 g_1(T)\equiv h_1(T, Y_1),\\ Y_1' &= -Y_1 f_1(T)+\varepsilon_1 g_2(T, Y_1)\equiv h_2(T, Y_1). \end{aligned} \tag{4C.1}$$

Remark. To say that D is positively invariant means that any solution of (4C.1) which lies in D for some z_0 remains in D for all $z>z_0$.

Proof. Let

$$\begin{aligned} &\delta=\tfrac{1}{2}\min\{T_1, Q_1-T_1, 1\}\\ &M_1=\inf\{f_1(T):\ T_1+\delta<T<Q_1+2Q_2+\delta\},\\ &\hat{M}_2=T(T-T_1)\quad \text{for } T=Q_1+2Q_2+\delta,\\ &M_2=\sup\{1, \hat{M}_2\},\\ &M_3=\inf\left\{\frac{1}{2}, \frac{T_2-T_1}{2M_2^{1/2}}, Q_1\frac{M_2^{1/2}}{Q_1-T_1}, \delta Q_1 M_2^{-1/2}\right\},\\ &\varepsilon^*=\min\left\{\frac{M_1M_3}{2M_2^{1/2}}, 1\right\}\quad\text{and}\quad \delta_1=M_3M_2^{1/2}. \end{aligned}$$

Assume that $0<\varepsilon_1<\varepsilon^*$. We show that the vector field defined by the right side of (4C.1) points into D. We treat the five sides of D separately.

(a) On σ_1, $T'=\varepsilon_1 Q_1 T(T-T_1)>0$.

(b) Suppose that $(T, Y_1)\in\sigma_2$. Let $n=(1, Q_1)$ be a normal to σ_2 pointing out of D. We wish to prove that on σ_2, $n\cdot(T', Y_1')<0$ where (T', Y_1') is given by (4C.1). If $T<Q_1$, then $F_2(T)=0$. Hence, on σ_2,

$$\begin{aligned} n\cdot(T', Y_1') &= Q_1Y_1f_1(T)+\varepsilon_1Q_1T(T-T_1)-Q_1Y_1f_1(T)\\ &\quad -\varepsilon_1Q_1T(T-T_1)+\varepsilon_1Q_1Y_1\left(\frac{1}{Q_1}(Q_1-T)-Y_1\right)\\ &= -\varepsilon_1Y_1(2Q_2+\delta)<0. \end{aligned}$$

If $T\geqq Q_1$, then on σ_2,

$$\begin{aligned} n\cdot(T', Y_1') &= Q_1Y_1f_1(T)+[Q_1+2Q_2-T-(Q_1+Q_2)Y_1]f_2(T)\\ &\quad -Q_1Y_1f_1(T)+\varepsilon_1Q_1Y_1\left(\frac{1}{Q_1}(Q_1-T)-Y_1\right)\\ &= -(\delta+Q_2Y_1)f_2(T)-\varepsilon_1Y_1(\delta+2Q_2)<0. \end{aligned}$$

(c) On σ_3, $n=(-1,-Q_1)$ is an outward normal. On σ_3, $T<T_1+\delta<Q<T_2$. If $Y_1>0$, then on σ_3,

$$n\cdot(T',Y_1')=-Q_1Y_1f_1(T)-\varepsilon_1Q_1T(T-T_1)+Q_1Y_1f_1(T)-\varepsilon_1Q_1Y_1\left(\frac{1}{Q_1}(Q_1-T)-Y_1\right)$$
$$=-\varepsilon_1Q_1T(T-T_1)-\varepsilon_1Y_1(Q_1-(T+\delta))<0.$$

If $Y_1<0$, then on σ_3, $T<T_1+\delta$ and $Y_1>\delta_1$. Hence,

$$n\cdot(T',Y_1')=-\varepsilon_1Q_1T(T-T_1)-\varepsilon_1Y_1(Q_1-(T+\delta))$$
$$<-\varepsilon_1Q_1M_1+\varepsilon_1\delta_1(Q_1-T)<0.$$

(d) On σ_4, $Y_1=-\delta_1$ and $T_1+\delta<T<Q_1+2Q_2+\delta$. If $T\leqq Q_1$, then on σ_4,

$$Y_1'=-Y_1f_1(T)-\varepsilon_1T(T-T_1)+\varepsilon_1Y_1\left(\frac{1}{Q_1}(Q_1-T)-Y_1\right)$$
$$\geqq\delta_1M_1-\varepsilon_1M_2-\varepsilon_1\delta_1(1+\delta_1)$$
$$\geqq\delta_1M_1-2M_2\varepsilon^*>0.$$

If $T>Q_1$, then

$$Y_1'=-Y_1f_1(T)+\varepsilon_1Y_1\left(\frac{1}{Q_1}(Q_1-T)-Y_1\right)$$
$$\geqq\delta_1M_1-\varepsilon^*\delta_1^2>0.$$

(e) Finally, assume that $(T,Y_1)\in\sigma_5$. Then

$$T'=Q_1Y_1f_1(T)+[Q_1+2Q_2-T-(Q_1+Q_2)Y_1]f_2(T)$$
$$\leqq Q_1Y_1f_1(T)-[\delta+Q_1Y_1]f_2(T)$$
$$\leqq-[\delta-Q_1\delta_1]f_2(T)<0.$$

We now construct an isolating neighborhood for the four-dimensional flow defined by (4B.2). For $V>0$, let

$$D_1=\{(T,q,Y_1,p_1):(T,Y_1)\in D,|q|\leqq V,|p_1|\leqq V\}.$$

LEMMA 4C.2. *V can be chosen so that D_1 is an isolating neighborhood for each θ.*

Proof. Assume that $\gamma(z_0)=(T,q,Y_1,p_1)(z_0)\in\partial D_1$. We must show that $\gamma(z)$ leaves D in either backward or forward time. First assume that $|q(z_0)|<V$ and $|p_1(z_0)|<V$. Let n be an outward normal to ∂D at $(T(z_0),Y_1(z_0))$. If $\gamma(z)$ is not tangent to ∂D_1, then the result follows immediately. If $\gamma(z)$ is tangent to ∂D_1 at z_0, then $(T(z),Y_1(z))$ must be tangent to ∂D at z_0. Hence, $n\cdot(q(z_0),p_1(z_0))=0$. This implies that at $z=z_0$,

$$n\cdot(q'(z),p_1'(z))=\theta n\cdot(q(z),p(z))-n\cdot(F(T,Y_1)+\varepsilon_1g_1(T),Y_1f_1(T)-\varepsilon_1g_2(T_1,Y_1))$$
$$=-n\cdot(F(T,Y_1)+\varepsilon_1g_1(T),Y_1f_1(T)-\varepsilon_1g_2(T,Y_1))>0$$

by Lemma 4C.2. Hence, $(T(z),Y_1(z))$ is outwardly normal to ∂D at z_0. This implies the desired result.

It remains to consider the cases $|q(z_0)|=V$ and $|p(z_0)|=L$. We assume that $q(z_0)=V$. The other cases are similar. For convenience, we assume that $z_0=0$. Choose K such that

$$|F(T,Y_1)+\varepsilon_1g_1(T)|+|Y_1f_1(T)-\varepsilon_1g_2(T,Y_1)|<K\quad\text{in } D.$$

Then, if $\theta\geqq0$,

$$q'=\theta q+F(T,Y_1)+\varepsilon_1g_1(T)>-K$$

as long as $q(z)>0$. Hence, $q(z)>q(0)-Kz>V-Kz>V/2$ as long as $0<z<1$ and $V>2K$. Therefore, if $0\leqq z\leqq 1$, then $T'=q\geqq V/2$. This implies that

$$T'(1)>T(0)+\frac{V}{2}>Q_1+2Q_2+\delta$$

if V is sufficiently large. In particular, $(T(1),\ Y_1(1))\notin D$ and $\gamma(1)\notin D_1$.

Now suppose that $q(z_0)=V$ and $\theta<0$. Then

$$q'=\theta q+F(T,\ Y_1)+\varepsilon_1 g_1(T)<K$$

as long as $q(z)>0$. Hence, if $-1\leqq z\leqq 0$, then

$$q(z)>q(0)+Kz=V+Kz>\frac{V}{2}$$

as long as $-1<z<0$ and $V>2K$. Therefore, if $-1\leqq z\leqq 0$, then $T'=q>V/2$. This implies that

$$T(-1)<T(0)-\frac{V}{2}<Q_1+2Q_2+\delta-\frac{V}{2}<-\delta$$

if V is sufficiently large. In particular, $(T(1),\ Y_1(1))\notin D$ and $\gamma(1)\notin D_1$.

4D. A Morse decomposition. Let θ_0 be as in (3.4) and fix $\varepsilon>0$. Attach to (4B.2) the equation

$$\theta'=\varepsilon(\theta^2-\theta_0^2). \tag{4D.1}$$

The reason for doing this was motivated in § 2. Let

$$N=\{(\gamma,\theta):\ \gamma\in D_1,\ |\theta|\leqq\theta_0+1\}.$$

There are six critical points of (4B.2), (4D.1) in N. These are at the following values of $(T,\ q,\ Y_1,\ p_1,\ \theta)$:

$$\alpha_1=(0,0,1,0,\theta_0),\qquad \alpha_2=(0,0,1,0,-\theta_0),$$

$$\beta_1=\left(T_1,0,\frac{1}{Q_1}(T-Q_1),0,\theta_0\right),\qquad \beta_2=\left(T_1,0,\frac{1}{Q_1}(T-Q_1),0,-\theta_0\right),$$

$$\gamma_1=(Q_1+2Q_2,0,0,0,\theta_0),\qquad \gamma_2=(Q_1+2Q_2,0,0,0,-\theta_0).$$

Our immediate goal is to prove that for each $\varepsilon>0$ there exists a solution of (4B.2), (4D.1) which satisfies

$$\lim_{z\to-\infty}(\gamma(z),\theta(z))=\alpha_1\quad\text{and}\quad\lim_{z\to+\infty}(\gamma(z),\theta(z))=\gamma_2. \tag{4D.2}$$

The proof will involve the Conley index. We begin by constructing a Morse decomposition of the maximal invariant set in N.

DEFINITION (Morse decomposition). Assume that S is a compact, invariant subset of phase space. A Morse decomposition of S is a finite collection $\{M_\pi\}_{\pi\subset P}$ of subsets $M_\pi\subset S$ which are disjoint, compact, and invariant and can be ordered $\{M_1,\cdots,M_n\}$ so that for every $\gamma\in S\backslash\cup_{1\leqq j\leqq n}M_j$, there exist indices $i<j$ such that $\omega(\gamma)\in M_j$ and $\omega^*(\gamma)\in M_i$. By $\omega(\gamma)$ and $\omega^*(\gamma)$ we mean the ω-limit and ω^*-limit sets of γ, respectively.

The construction of the Morse decomposition requires a number of steps. First we define certain neighborhoods of

$$\alpha_0=(0,0,1,0)\quad\text{and}\quad\gamma_0=(Q_1+2Q_2,0,0,0).$$

Here we have given the (T, q, Y_1, p_1) coordinates of α_0 and γ_0. Let δ be as in the definition of D. Let

$$G_1 = \{(T, q): -\delta \leqq T \leqq q + \delta, 0 \leqq q \leqq V\}$$
$$\cup \{(T, q): q - \delta \leqq T \leqq \delta, -V \leqq q \leqq 0\},$$
$$G_2 = \{(Y_1, p_1): 1 - \delta \leqq Y_1 \leqq p_1 + 1 + \delta, 0 \leqq p_1 \leqq V\}$$
$$\cup \{(Y_1, p_1): p_1 + 1 - \delta \leqq Y_1 \leqq 1 + \delta, -V \leqq p_1 \leqq 0\},$$
$$G'_\alpha = \{(T, q, Y_1, p_1): (T, q) \in G_1, (Y_1, p_1) \in G_2, \text{ and } (T, Y_1) \in D\}.$$

LEMMA 4D.1. *If $\theta \geqq \theta_0 - 1$, then solutions of* (4B.2) *can only leave G'_α through the sides $|q| = V$ or $|p_1| = V$.*

Proof. We prove that on $\partial G'_\alpha \cap \{|q| < V$ and $|p_1| < V\}$ the vector field given by (4B.2) points into G'_α. If $(T, q, Y_1, p_1) \in \partial G'_\alpha$, then either $(T, q) \in \partial G_1$ or $(Y_1, p_1) \in \partial G_2$. We assume that $(T, q) \in \partial G_1 \cap \{|q| < V\}$. That proof for G_2 is similar. We treat each side of G_1 separately.

(a) Assume that $T = -\delta$ and $q > 0$. Then $T' = q > 0$.

(b) Assume that $T = \delta$ and $q < 0$. Then $T' = q < 0$.

(c) Assume that $T = q + \delta$ and $q > 0$. An outward normal to ∂G_1 is $n = (1, -1)$. If $T \leqq T_1$, then for $\theta > \theta_0 - 1$,

$$n \cdot (T', q') = q - \theta q + \varepsilon_1 T(T - T_1)$$
$$\leqq (2 - \theta_0) q < 0.$$

Here we used (3.4). If $T_1 < T \leqq Q_1$, then

$$n \cdot (T', q') = q - \theta q + Q_1 Y_1 f_1(T) + \varepsilon_1 T(T - T_1)$$
$$\leqq (2 - \theta_0) q + Q_1 Y_1 L T + \varepsilon_1 (Q_1 - T_1) T$$
$$\leqq [2 + Q_1 Y_1 L + Q_1 - Q_0] T$$
$$\leqq 0$$

where we use (3.4) and $Y_1 \leqq 1/Q_1[Q_1 + 2Q_2 + 1]$ in D.

(d) Assume that $T = q - \delta$ and $q < 0$. An outward normal to ∂G_1 at (T, q) is $n = (-1, 1)$. Moreover,

$$n \cdot (T', q') = -q + \theta q + \varepsilon_1 T(T - T_1)$$
$$< (2 - \theta_0) q < 0.$$

This completes the proof of the lemma.

In a similar fashion we construct a neighborhood of γ_0. Let

$$H_1 = \{(T, q): Q_1 + 2Q_2 - \delta \leqq T \leqq q + Q_1 + 2Q_2 + \delta, 0 \leqq q \leqq V\}$$
$$\cup \{(T, q): q + Q_1 + 2Q_2 - \delta \leqq T \leqq Q_1 + 2Q_2 + \delta, -V \leqq q \leqq 0\},$$
$$H_2 = \{(Y_1, p_1): -\delta \leqq Y_1 \leqq p_1 + \delta, 0 \leqq p_1 \leqq V\}$$
$$\cup \{(Y_1, p_1): p_1 - \delta \leqq Y_1 \leqq \delta, -V \leqq p_1 \leqq 0\},$$
$$H'_\gamma = \{(T, q, Y_1, p_1): (T, q) \in H_1 \text{ and } (Y_1, p_1) \in H_2\}.$$

As in Lemma 4D.1, we have Lemma 4D.2.

LEMMA 4D.2. *If* $\theta < -\theta_0 + 1$, *then a solution of* (4B.2) *can only enter* H'_γ *through the sides* $|q| = V$ *or* $|p_1| = V$.

We are now ready to define the Morse decomposition.

Let

$$G_\alpha = \{(T, q, Y_1, p_1, \theta): (T, q, Y_1, p_1) \in G'_\alpha, |\theta - \theta_0| \leqq 1\},$$

$$H_\gamma = \{(T, q, Y_1, p_1, \theta): (T, q, Y_1, p_1) \in G'_\alpha, |\theta + \theta_0| \leqq 1\},$$

$$N_1 = \text{cl}\,\{(\gamma, \theta): \gamma \in D_1 \backslash G'_\alpha, |\theta - \theta_0| \leqq 1\},$$

$$N_2 = G_\alpha \cup \{(\gamma, \theta): \gamma \in D_1, |\theta| \leqq \theta_0 - 1\} \cup H_\gamma,$$

$$N_3 = \text{cl}\,\{(\gamma, \theta): \gamma \in D_1 \backslash H'_\gamma, |\theta + \theta_0| \leqq 1\}.$$

By cl X we mean the topological closure of a set X. Let M_0 equal the maximal invariant set in N, and M_i, $i = 1, 2, 3$, equal the maximal invariant set in N_i. The picture we have in mind is shown in Fig. 4.

We claim that (M_1, M_2, M_3) defines a Morse decomposition of M_0.

LEMMA 4D.3. N *is an isolating neighborhood.*

Proof. Suppose that $(\gamma(x_0), \theta(z_0)) \in \partial N$. If $\theta(z_0) = \theta_0 + 1$, then $\theta'(z_0) > 0$. Therefore, $(\gamma(z), \theta(z))$ leaves N in forward time. If $\theta(z_0) = -\theta_0 - 1$, then $\theta'(z_0) > 0$. Therefore, $(\gamma(z), \theta(z))$ leaves N in backward time. If $\gamma(z) \in \partial D_1$, then because D_1 is an isolating neighborhood for each θ, it follows that $\gamma(z)$ must leave D_1 in either forward or backward time. Hence, $(\gamma(z), \theta(z))$ must leave N in forward or backward time.

LEMMA 4D.4. N_1, N_2, *and* N_3 *are all isolating neighborhoods.*

Proof. We prove the lemma for N_1; the proofs for N_2 and N_3 are similar. Suppose that $(\gamma(z_0), \theta_0(z_0)) \in \partial N_1$. If $\theta(z_0) = \theta_0 + 1$, then $\theta' > 0$ so $(\gamma(z), \theta(z))$ leaves N_1 in forward time. If $\theta = \theta_0 - 1$, then $\theta' < 0$ so, again, $(\gamma(z), \theta(z))$ leaves N_1 in forward time. If $(\gamma(z), \theta(z)) \in \partial N$, then, because N is an isolating neighborhood, $(\gamma(z), \theta(z))$ must leave N, and therefore N_1. Finally if $(\gamma(z_0), \theta(z_0)) \in \partial G_\alpha$, then by Lemma 4D.1, $(\gamma(z), \theta(z))$ must enter N_2, and therefore leave N_1, in forward time.

PROPOSITION 4D.5. (M_1, M_2, M_3) *defines a Morse decomposition for* M_0.

Proof. Trajectories that lie in N_2 cannot enter N_1 in forward time, and trajectories that lie in N_3 cannot enter N_2 in forward time. This is because on $\partial N_1 \cap \partial N_2$ the vector field points into N_2, while the vector field on $\partial N_2 \cap \partial N_3$ points into N_3.

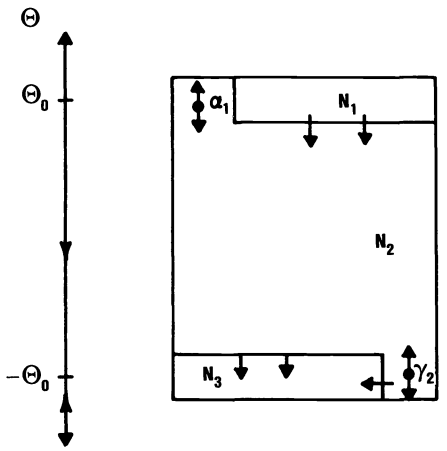

FIG. 4

Choose $\Gamma_0 \in M_0 \backslash (M_1 \cup M_2 \cup M_3)$, and let $\Gamma(z)$ be the solution of (4B.2), (4D.1) which satisfies $\Gamma(0) = \Gamma_0$. If $\Gamma_0 \in N_1$, then the above comments imply that $\Gamma(z) \notin N_2 \cup N_3$ for all $z < 0$. Hence $\omega^*(\Gamma_0) \in M_1$. Certainly $\omega(\Gamma_0) \notin M_1$, since this would imply that $\Gamma_0 \in M_1$ which we are assuming is not true. Hence, $\omega(\Gamma_0) \in M_2 \cup M_3$.

A similar argument shows that if $\Gamma_0 \in N_2$, then $\omega^*(\Gamma_0) \in M_1 \cup M_2$ and $\omega(\Gamma_0) \in M_2 \cup M_3$. If $\Gamma_0 \in N_3$, then $\omega^*(\Gamma_0) \in M_1 \cup M_2$ and $\omega(\Gamma_0) \in M_3$.

4E. Computation of the indices. We prove that $h(M_0) = h(M_1) = h(M_3) = \bar{0}$ where h is the Conley (homotopy) index and $\bar{0}$ is the Conley index of the empty set. This information will be used in the next section when we discuss $h(M_2)$ and then prove the existence of a connecting orbit.

LEMMA 4E.1. $h(M_0) = \bar{0}$.

Proof. We continue the flow (4B.2), (4D.1) to one in which the maximal invariant set in N is the empty set. Consider the following equations parametrized by λ:

$$\theta' = -\varepsilon(\theta_0^2 - \theta^2) + \lambda. \tag{4E.1λ}$$

Of course, if $\lambda = 0$ then (4E.1λ) is the same as (4D.1). The proof of Lemma 4D.3 shows that N is an isolating neighborhood for the equations (4B.2), (4E.1λ) for each $\lambda \geqq 0$. If λ_0 is sufficiently large, then $\theta' = -\varepsilon(\theta_{0\lambda}^2 - \theta^2) + \lambda_0 > 0$ for each θ. Hence (4B.2), (4E.1λ_0) does not have any bounded solutions. If I_λ is the maximal invariant set in N for the flow given by (4B.2), (4E.1λ), then $h(I_{\lambda_0}) = h(\phi) = \bar{0}$. Since $I_0 = M_0$ and I_{λ_0} are related by continuation (see [3]) it follows that $h(M_0) = \bar{0}$.

LEMMA 4E.2. $h(M_1) = \bar{0}$.

Proof. Clearly M_1 lies in the set $\{(\gamma, \theta)\colon \theta = \theta_0\}$. Let $h_1(M_1)$ equal the Conley index of M_1 considered as an isolated invariant set for the flow defined by (4B.2) with $\theta = \theta_0$. We prove that $h_1(M_1) = \bar{0}$. From elementary properties of Conley's theory, it then follows that $h(M_1) = h_1(M_1) \wedge \Sigma^1 = \bar{0}$. We shall need other properties of the Conley index.

Consider the equations (4C.1). Then $\alpha \equiv \{(T, Y_1) = (0, 1)\}$ is an attracting rest point for these equations. Choose H to be an open neighborhood of α such that $H \in D$, and on ∂H the vector field defined by (4C.1) points into H. Recall that D was defined in § 4C. It follows that $D \backslash H$ is an isolating neighborhood. Let P be the maximal invariant set in $D \backslash H$ for the equations (4C.1), and $h(P)$ equals the Conley index of P.

We wish to relate $h_1(M_1)$ with $h(P)$. To do this we need one more preliminary step. Recall the sets D_1 and G'_α. Note that $M_1 \subset N_1 \cap \{\theta = \theta_0\} = \text{cl}\,\{(\gamma, \theta)\colon \gamma \in D_1 \backslash G'_\alpha, \theta = \theta_0\}$. Let $S = \text{cl}\,(D_1 \backslash G'_\alpha)$. Lemma 4C.2 and Lemma 4D.1 imply that S is an isolating neighborhood for the flows given by (4B.2) for each $\theta \geqq \theta_0$. For $\theta \geqq \theta_0$, let $h(\theta)$ be equal to the Conley index for the maximal invariant set inside of S for the flow given by (4B.2). From the definitions, we have that $h(\theta_0) = h_1(M_1)$. From the basic Continuation Theorem [3] it follows that $h(\theta_0) = h(\theta)$ for all $\theta > \theta_0$. Hence, it remains to prove that $h(\theta) = \bar{0}$ for θ sufficiently large. From [12, Thm. I] we conclude that for θ sufficiently large, $h(\theta) = h(P)$. We now show that $h(P) = \bar{0}$.

We compute the index of P directly. Recall that P is maximal invariant set in $D \backslash H$. By Lemma 4C.1, trajectories enter $D \backslash H$ along its outer boundary. Moreover, trajectories leave $D \backslash H$ along ∂H. It is easy to imagine a vector field which enters $D \backslash H$ along its outer boundary, leaves $D \backslash H$ along ∂H, and has no invariant sets. Hence, $h(P) = h(\phi) = \bar{0}$. Of course, we could also compute $h(P)$ directly, using the isolating neighborhood $D \backslash H$.

LEMMA 4E.3. $h(M_3) = \bar{0}$.

Proof. The proof of this result is similar to the proof just given, so we do not give the details.

4F. A connecting orbit for $\varepsilon_1, \varepsilon_2 > 0$. In this section we prove the following proposition.

PROPOSITION 4F.1. *There exists a solution* $\Phi(z)$ *of* (4B.2), (4D.1) *which satisfies* $\lim_{z\to-\infty}\Phi(z)=\alpha_1$ *and* $\lim_{z\to\infty}\Phi(z)=\gamma_2$.

The first step in the proof of this result is to prove something about $h(M_2)$. Note that if S is any isolated covariant set, then $h(S)$ is the homotopy type of a certain topological space. Let $H(h(S))$ be the homology for $h(S)$ with coefficients in some fixed ring.

LEMMA 4F.2. $H(h(M_2))=0$.

Proof. Let $N_{12}=N_1\cup N_2$ and M_{12} be equal to the maximal variant set in N_{12}. Then (M_3, M_{12}) defines a Morse decomposition of M_0. It follows (see [6]) that this induces the exact sequence

$$\begin{aligned}(4F.1)\qquad &\to H^2(h(M_3))\to H^1(h(M_{12}))\to H^1(h(M_0))\to H^1(h(M_3))\\ &\to H^0(h(M_{12}))\to H^0(h(M_0))\to H^1(h(M_3))\to 0.\end{aligned}$$

Because $h(M_3)=h(M_0)=\bar{0}$, we conclude that $H(M_3)=H(M_0)=0$. From the exact sequence we conclude that $H(M_{12})=0$.

Now (M_2, M_1) defines a Morse decomposition of M_{12}. This induces another exact sequence relating $H(M_1)$, $H(M_2)$, and $H(M_{12})$. Because $H(M_1)=H(M_2)=0$, the result follows.

LEMMA 4F.3. $M_2\neq\alpha_1\cup\gamma_2$.

Proof. If this were not true, then (see [3]) we must have that $H(M_2)=H(\alpha_1)\oplus H(\gamma_2)$. Because $H(M_2)=0$, and α_1 and γ_2 are nondegenerate rest points, this is impossible.

We now return to the proof of Proposition 4F.1. Choose $\lambda_0\in M_2\backslash(\alpha_1\cup\gamma_2)$ and let $\Gamma(z)$ be the solution of (4B.2), (4D.1) which satisfies $\Gamma(0)=\lambda_0$. We prove that $\lim_{z\to-\infty}\Gamma(z)=\alpha_1$ and $\lim_{z\to\infty}\Gamma(z)=\gamma_2$. Assume that $\Gamma(z)=(\gamma(z), \theta(z))$. If $|\theta(z)|\neq\theta_0$, then $\theta'(z)<0$. It immediately follows that

$$\omega(\Gamma(z))\cup\omega^*(\Gamma(z))\subset M_2\cap\{(\gamma,\theta)\colon|\theta|=\theta_0\}.$$

To complete the proof of the proposition we show that

$$M_2\cap\{(\gamma,\theta)\colon\theta=\theta_0\}=\alpha_1\quad\text{and}\quad M_2\cap\{(\gamma,\theta)\colon\theta=-\theta_0\}=\gamma_2.$$

We only prove the first identity since the proof of the second is almost identical.

Recall the sets G_1, G_2, and G'_α defined in § 4D. Note that $M_2\subset N_2$ and

$$N_2\cap\{(\gamma,\theta)\colon\theta=\theta_0\}\subset\{(\gamma,\theta)\colon\gamma\in G'_\alpha,\ \theta=\theta_0\}\equiv G.$$

We prove that the only bounded solution in G is the rest point α_1. Suppose that $\beta_0\in G'_\alpha$, $(\beta_0,\theta_0)\neq\alpha_1$, and $(T, q, Y_1, p_1)(z)$ is the solution of (4B.2) which satisfies $(T, q, Y_1, p_1)(0)=\beta_0$. Then either $(T, q)(0)\neq(0,0)$ or $(Y_1, p_1)(0)\neq(1,0)$. Suppose that $(T, q)(0)\neq(0,0)$. The other case is similar. We prove that $(T, q)(z)$ leaves G_1 in either forward or backward time. This will imply that $(T, q, Y_1, p_1)(z)$ leaves G_1 in forward or backward time.

There are many cases to consider. For example, suppose that $T(0)>0$ and $q(0)>0$. As long as $q(z)>0$ we have that $T'(z)=q(z)>0$. We claim that as long as $(T, q)(z)\in G_1$, $q(z)>0$. If not, choose z_1 so that $q(z_1)=0$ and $q(z)>0$ for $0<z<z_1$. Then $T(z_1)>T(0)>0$, and, from the definition of G_1, if $(T, q)(z_1)\in G_1$, then $T(z_1)<T_1$.

This is due to the assumption that $\delta < \frac{1}{2}T_1$. It follows that $q'(z_1) = \theta q(z_1) - \varepsilon T(T - T_1) > 0$, which is impossible. We have now shown that as long as $(T, q)(z) \in G_1$, $T'(z) = q(z) > 0$. Because there are no rest points in G_1 for $T > 0$, we conclude that (T, q) must leave G_1.

There are other cases to consider, but their proofs are very similar to the one just given.

4G. The limit $\varepsilon_1 \to 0$. In this section we complete the proof of Proposition 2.1 if $\theta_1 = -\theta_0$ and $d_0 = d_1 = d_2 = 1$. So far we have proven that for each $\varepsilon > 0$, $0 < \varepsilon_1 < \varepsilon^*$, there exists a solution $\Phi(\varepsilon, \varepsilon_1)(z)$ of (4B.2), (4D.1) which satisfies

$$\lim_{z \to -\infty} \Phi(\varepsilon, \varepsilon_1)(z) = \alpha_1 \quad \text{and} \quad \lim_{z \to \infty} \Phi(\varepsilon, \varepsilon_1)(z) = \gamma_2.$$

Fix $\varepsilon > 0$ and let $\Phi^k(z) = \Phi(\varepsilon, 1/k\varepsilon^*)(z)$. Assume that

$$\Phi^k(z) = (T^k, q^k, Y_1^k, p_1^k, \theta^k)(z) = (\gamma^k(z), \theta^k(z)),$$

and choose the translation so that $\theta^k(0) = 0$. Since $\Phi^k(0) \in N$, a compact set, for each k it follows that some subsequence of $\{\Phi^k(0)\}$ converges to, say, Φ_0. For convenience, we assume that the entire sequence $\{\Phi^k(0)\}$ converges to Φ_0.

Let $\Phi(z)$ be the solution of (4B.2), (4D.1) with $\varepsilon_1 = 0$ which satisfies $\Phi(0) = \Phi_0$. We wish to prove that $\lim \Phi(z) = \alpha_1$ and $\lim \Phi(z) = \gamma_2$. If we then make the substitution (4A.1), this will complete the proof of Proposition 2.1 if $d_0 = d_1 = d_2 = 1$, and $\theta_1 = -\theta_0$.

Because $\varepsilon > 0$, on $\Phi(z)$, $\theta'(z) = \varepsilon(\theta^2 - \theta_0^2) < 0$. Moreover, $\Phi^k(z) \in N_2$ for all k and z. Hence,

$$\omega^*(\Phi(0)) \subset N_2 \cap \{\theta = \theta_0\} \quad \text{and} \quad \omega(\Phi(0)) \subset N_2 \cap \{\theta = -\theta_0\}.$$

We must now be more careful than in the preceding section because when $\varepsilon_1 = 0$, $N_2 \cap \{\theta = \theta_0\}$ contains uncountably many rest points. We must, therefore, understand in more detail the behavior of each $\Phi^k(z)$ near α_1 and γ_2. We use the fact that for each k, $\Phi^k(z)$ lies in both the unstable manifold at α_1 and the stable manifold at γ_2.

To prove that $\lim_{z \to -\infty} \Phi(z) = \alpha_1$, let

$$\Sigma = \{(T, q, Y_1, p_1, \theta): 0 \leqq T \leqq q \text{ or } q \leqq T \leqq 0\} \cap \{\theta \geqq \theta_0 - 1\}.$$

We prove the following lemma.

LEMMA 4G.1. *There exists z_0 such that $\Phi(z) \in \Sigma$ for $z < z_0$. This implies that $\lim_{z \to -\infty} \Phi(z) = \alpha$, because the only bounded solution in Σ is α_1.*

Proof of Lemma 4G.1. Because $\lim_{z \to -\infty} \Phi^k(z) = \alpha_1$ for each k, we may choose z_0, M so that if $k > M$ and $z < z_0$, then $\theta^k(z) > \theta_0 - 1$ and $T^k(z) < T_1$. We shall prove that if $k > M$ and $z < z_0$, then $\Phi^k(z) \in \Sigma$. This will imply the desired result.

Fix $k > M$. To complete the proof, first we show that there exists z_1 such that $\Phi_k(z) \in \Sigma$ for $z < z_1$. To prove this, note that as $z \to -\infty$, $\Phi^k(z)$ approaches α_1 tangent to the linear space spanned by the eigenvectors corresponding to the positive eigenvalues of the linearized equations at α_1. These linearized equations are the following:

$$T' = q, \qquad q' = \theta_0 q, \qquad Y_1' = p_1, \qquad p_1' = \theta_0 p_1, \qquad \theta' = 2\varepsilon\theta.$$

The positive eigenvalues are θ_0, θ_0, and 2ε, with eigenvectors $(1, \theta_0, 0, 0, 0)$, $(0, 0, 1, \theta_0, 0)$, and $(0, 0, 0, 0, 1)$, respectively. The linear subspace spanned by these eigenvectors lies in Σ as long as $\theta > \theta_0 - 1$. This proves that there exists z_1 such that $\Phi^k(z) \in \Sigma$ for $z < z_1$.

We now show that $\Phi^k(z) \in \Sigma$ for $z_1 \leqq z \leqq z_0$. If this is not true, let $z_2 = \inf\{z: \Phi^k(z) \notin \Sigma\}$. Then $\Phi^k(z)$ must be leaving Σ at z_2. We prove that this is impossible

by showing that if $\theta > \theta_0 - 1$ and $T < T_1$, then on $\partial\Sigma$ the vector field defined by (4B.2) points into Σ. We consider each side of $\partial\Sigma$ separately.

If $T(z_2) = 0$ and $q(z_2) > 0$, then $T'(z_2) = q(z_2) > 0$. If $T(z_2) = 0$ and $q(z_2) < 0$, then $T'(z_2) = q(z_2) < 0$. In both cases, the vector field points into Σ.

Suppose that $T(z_2) = q(z_2) > 0$. Let $n = (1, -1)$ be a vector outwardly normal to $\{(T, q): 0 \leqq T \leqq q\}$ at $(T(z_2), q(z_2))$. Then $n \cdot (T', q') = (1, -1) \cdot (q, \theta q) = q - \theta q < 0$ because $\theta > \theta_0 - 1 > 1$. A similar analysis holds if $T(z_2) = q(z_0) < 0$. In both cases, the vector field points into Σ. This completes the proof of the lemma.

The proof that $\lim \Phi(z) = \gamma_2$ is much easier because γ_2 is an isolated rest point. In fact, it is the only bounded solution in $N_2 \cap \{\theta = -\theta\}$.

4H. The limit $\varepsilon \to 0$. For $\varepsilon > 0$ let $\Phi_\varepsilon(z) = (T_\varepsilon, q_\varepsilon, Y_{1\varepsilon}, p_{1\varepsilon}, Y_{2\varepsilon}, p_{2\varepsilon}, \theta_\varepsilon)(z)$ be the solution of (2.1), (2.3) with $d_0 = d_1 = d_2 = 1$ which satisfies (2.4). We assume that $\theta_1 = -\theta_0$. We wish to let $\varepsilon \to 0$ and prove that if $\theta^1 < \theta^{12}$, then $\Phi_\varepsilon(z)$ converges, somehow, to the desired connecting orbit.

Choose the translation so that $T_\varepsilon(0) = \frac{1}{2}(Q_1 + 2Q_2 + T_2)$. By compactness, there exists a subsequence $\{\varepsilon_k\}$ such that $\varepsilon_k \to 0$ as $k \to \infty$, and $\Phi_{\varepsilon_k}(0)$ converges to, say, $\Phi^* = (T^*, q^*, Y_1^*, p_1^*, Y_2^*, p_2^*, \theta^*)$. Let $\Phi(z) = (T, q, Y_1, p_1, Y_2, p_2, \theta)(z)$ be the solution of (2.1), (2.3) with $\varepsilon = 0$ such that $\Phi(0) = \Phi^*$. Of course, $\theta(z) = \theta^*$ for each z.

LEMMA 4H.1. $\theta^* > 0$.

Proof. Lemma 3.5 and the remark following it imply that there exist rest points K_1 and K_2 of (2.1) such that $\lim_{z \to -\infty} \Phi(z) = (K_1, \theta^*)$ and $\lim_{z \to +\infty} \Phi(z) = (K_2, \theta^*)$. In particular, there exists τ_1, τ_2 such that $\lim_{z \to -\infty} T(z) = \tau_1$ and $\lim_{z \to +\infty} T(z) = \tau_2$. Because $T(0) = \frac{1}{2}(Q_1 + 2Q_2 + T_2)$, we conclude that

$$\tau_1 < \tfrac{1}{2}(Q_1 + 2Q_2 + T_2) < \tau_2.$$

There are no rest points of (2.1) with $T_2 < T < Q_1 + 2Q_2$ or $T > Q_1 + 2Q_2$. This implies that $\tau_1 \leqq T_2$ and $\tau_2 = Q_1 + 2Q_2$. Now $T(z)$ satisfies the following equations:

$$\text{(4H.1)} \qquad \begin{aligned} &\text{(a)} \quad T'' - \theta^* T' = -Q_1 Y_1 f_1(T) - Q_2 Y_2 f_2(T); \\ &\text{(b)} \quad T(-\infty) = \tau_1 < T_1, \text{ and } T(\infty) = Q_1 + 2Q_2. \end{aligned}$$

If $Y_1^* > 0$, then $Y_1(z) > 0$ for all z. In this case we integrate (4H.1)(a) for $-\infty < z < \infty$ to obtain

$$\theta^* > Q_1[Q_1 + 2Q_2 - \tau_1]^{-1} \int_{-\infty}^{\infty} Y_1 f_1(T)\, dz > 0.$$

If $Y_1^* = 0$, then $Y_1(z) = 0$ for all z. We again integrate (4H.1)(a) for $-\infty < z < \infty$, and use (4A.1), to obtain

$$\begin{aligned} \theta^* &= Q_2[Q_1 + 2Q_2 - \tau_1]^{-1} \int_{-\infty}^{\infty} Y_2 f_2(T)\, dz \\ &= [Q_1 + 2Q_2 - \tau_1]^{-1} \int_{-\infty}^{\infty} [Q_1 + 2Q_2 - T] f_2(T)\, dz \\ &> 0. \end{aligned}$$

Choose z_ε so that $T_\varepsilon(z_\varepsilon) = T_1$. By Lemma 3.5, $z_\varepsilon < 0$ for all $\varepsilon > 0$.

LEMMA 4H.2. *There exists δ such that if $\varepsilon < \delta$ and $z < z_\varepsilon$, then $q_\varepsilon(z) > \frac{1}{2}\theta^* T_\varepsilon(z)$, $|p_{1\varepsilon}(z)| > \frac{1}{2}\theta^* |Y_{1\varepsilon}(z) - 1|$, and $|p_{2\varepsilon}(z)| > \frac{1}{2}\theta^* |Y_{2\varepsilon} - 1|$.*

Proof. Choose δ so that if $\varepsilon<\delta$, then $|\theta_\varepsilon(0)-\theta^*|<\frac{1}{2}\theta^*$. It then follows that $\theta(z)>\frac{1}{2}\theta^*$ for $z<z_\varepsilon$. If $z<z_\varepsilon$, then $T(z)<T_1$. Hence, if $z<z_\varepsilon$, then $T'_\varepsilon=q_\varepsilon$ and $q'_\varepsilon=\theta_\varepsilon q_\varepsilon>\frac{1}{2}\theta^* q_\varepsilon$. This implies that $(\frac{1}{2}\theta^* T_\varepsilon-q_\varepsilon)'<0$. If we integrate this equation from $-\infty$ to z we find that $q_\varepsilon(z)>\frac{1}{2}\theta^* T_\varepsilon(z)$. The proofs of the other two inequalities are similar.

By compactness, there exists a subsequence $\{\varepsilon_j\}$ such that $\varepsilon_j\to 0$ as $j\to\infty$ and $\Phi_{\varepsilon j}(z_{\varepsilon j})$ converges to, say, $\Gamma^0=(T^0, q^0, Y_1^0, p_1^0, Y_2^0, p_2^0, \theta^0)$. Let $\Gamma(z)=(T, q, Y_1, p_1, Y_2, p_2, \theta)(z)$ now be the solution of (2.1), (2.3) with $\varepsilon=0$ which satisfies $\Gamma(0)=\Gamma^0$. Clearly, $\theta(z)=\theta^0$ for all z. Because $\theta'_\varepsilon(z)<0$ for each $\varepsilon>0$ and z, we conclude that $\theta^0\geqq\theta^*$. From Lemma 4H.2 we conclude the following lemma.

LEMMA 4H.3. *If* $z<0$, *then* $q(z)\geqq\frac{1}{2}\theta^* T(z)$, $|p_1(z)|\geqq\frac{1}{2}\theta^*|Y_1(z)-1|$, *and* $|p_2(z)|\geqq\frac{1}{2}\theta^*|Y_2(z)-1|$.

Corollary 4H.4 follows immediately.

COROLLARY 4H.4. $\lim_{z\to-\infty}(T, q, Y_1, p_1, Y_2, p_2)(z)=(0, 0, 1, 0, 1, 0)$.

From Lemmas 3.4 and 3.5 we have that $Y'_1(z)\leqq 0$ for all z and $T'(z)\geqq 0$ as long as $z<Q_1+2Q_2$. It follows that there must be a rest point $(T^+, q^+, Y_1^+, p_1^+, Y_2^+, p_2^+)$ such that

$$\lim_{z\to\infty}(T, q, Y_1, p_1, Y_2, p_2)(z)=(T^+, q^+, Y_1^+, p_1^+, Y_2^+, p_2^+).$$

Moreover, $T^+>T_1$. This last statement implies that $q^+=Y_1^+=p_1^+=p_2^+=0$.

LEMMA 4H.5. *Either* $(T^+, Y_2^+)=(Q_1, 2)$ *or* $(T^+, Y_2^+)=(Q_1+2Q_2, 0)$.

Proof. Suppose that $T(z)<T_2$ for all z. Then (T, Y_1) satisfies the equations

$$\text{(4H.2)}\qquad T''-\theta^0 T'+Q_1 Y_1 f_1(T)=0,\qquad Y_1''-\theta^0 Y_1'-Y_1 f_1(T)=0,$$
$$\lim_{z\to-\infty}(T, Y_1)(z)=(0, 1)\quad\text{and}\quad\lim_{z\to+\infty}(T, Y_1)(z)=(T^+, 0).$$

If we integrate the first equation in (4H.2) we find that

$$\text{(4H.3)}\qquad T^+\theta^0=Q_1\int_{-\infty}^{\infty}Y_1 f_1(T)\,dz.$$

If we integrate the second equation in (4H.2) we find that

$$\text{(4H.4)}\qquad \theta^0=\int_{-\infty}^{\infty}Y_1 f_1(T)\,dz.$$

It follows from (4H.3) and (4H.4) that $T^+=Q_1$.

Note that $Y_2''-\theta^0 Y_2'+Y_1 f_1(T)=0$. If we integrate this equation for $-\infty<z<\infty$, use (4H.4), and the fact that $Y_2(-\infty)=1$, we find that $Y_2(\infty)=2$.

Now suppose that $T(z)>T_2$ for some z. Then (T, Y_1, Y_2) satisfy the equations

$$\text{(4H.5)}\qquad \begin{gathered} T''-\theta^0 T'+Q_1 Y_1 f_1(T)+Q_2 Y_2 f_2(T)=0,\\ Y_1''-\theta^0 Y_1'-Y_1 f_1(T)=0,\\ Y_2''-\theta^0 Y_2'+Y_1 f_1(T)-Y_2 f_2(T)=0,\\ \lim_{z\to-\infty}(T, Y_1, Y_2)=(0, 1, 1),\qquad \lim_{z\to+\infty}(T, Y_1, Y_2)=(T^+, 0, 0).\end{gathered}$$

Integrate the second equation in (4H.5) for $-\infty<z<\infty$ to find that (4H.4) holds. Integrate the third equation in (4H.5) for $-\infty<z<\infty$ to obtain

$$\int_{-\infty}^{\infty}Y_2 f_2(T)\,dz=2\theta^0.$$

Finally, if we integrate the first equation in (4H.5) for $-\infty < z < \infty$ we find that $T^+ = Q_1 + 2Q_2$.

Note that if $T^+ = Q_1 + 2Q_2$, then the proof of Theorem 1 is complete for the case $d_0 = d_1 = d_2 = 1$. That is, $(T, Y_1, Y_2)(z)$ is a solution of (1.8) which satisfies (1.15). Therefore, we assume that $T^+ = Q_1$. We shall show that this implies that $\theta^1 > \theta^{12}$, thus completing the proof of Theorem 1.

Let $\{\varepsilon_j\}$ and $\{z_{\varepsilon j}\}$ be as before. That is, $\Phi_{\varepsilon J}(z_{\varepsilon J})$ converges to Γ^0 as $j \to \infty$. For each j, reparametrize the trajectories $\Phi_{\varepsilon j}(z)$ so that instead of $-\infty < z < \infty$ we have $0 < s < 1$. Call the new curves $\Lambda_j(s)$. As $j \to \infty$, the curves $\Lambda_j(s)$ will converge to a curve which we denote by

$$\Lambda(s) = (T(s), q(s), Y_1(s), p_1(s), Y_2(s), p_2(s), \theta(s)) = (\gamma(s), \theta(s)).$$

PROPOSITION 4H.6. *Suppose that* $T^+ = Q_1$. *Then there exists* $0 < s_1 < s_2 < s_3 < s_4 < 1$ *such that we have the following*:

(a) $\gamma(s) = A$ *for* $0 < s \leqq s_1$;
(b) $\theta(s) = \theta^0$ *for* $s_1 \leqq s \leqq s_2$;
(c) $\gamma(s) = B$ *for* $s_2 \leqq s \leqq s_3$;
(d) $\theta(s) = \theta^*$ *for* $s_3 \leqq s \leqq s_4$;
(e) $\gamma(s) = C$ *for* $s_4 \leqq s < 1$.

Proof. We have already shown that there exists $0 < s_1 < s_2$ such that $\gamma(s) = A$ for $0 < s \leqq s_1$, $\theta(s) = \theta^0$ for $s_1 \leqq s \leqq s_2$ and $\gamma(s_2) = B$. To determine the behavior of $\Lambda(s)$ for $s > s_2$ we must first study the local behavior of the flow (2.1), (2.3) near the points (B, θ) for $\theta^* \leqq \theta \leqq \theta_0$.

First assume that $\varepsilon = 0$ and $\theta \geqq \theta^*$. Then the linearized equation at (B, θ) has two positive eigenvalues, two negative eigenvalues, and a triple zero eigenvalue. The triple zero eigenvalue is because near (B, θ) there is a three-dimensional subset of rest points. This subset of rest points is of the form

$$\{(T, q, Y_1, p_1, Y_2, p_2, \theta): Y_1 = q_1 = p_1 = p_2 = 0\}.$$

Through (B, θ) there is a two-dimensional stable and a two-dimensional unstable manifold. We show that for j large, $\Lambda_j(s)$ approaches close to (B, θ^0) near the stable manifold at (B, θ^0) and leaves a small neighborhood of B close to the unstable manifold at (B, θ^*).

Choose new coordinates so that in the new coordinates, (2.1), (2.3) with $\varepsilon = 0$ become near (B, θ),

$$\begin{aligned} x_1' &= -\lambda_1 x_1 + g_1(\eta), & x_2' &= -\lambda_2 x_2 + g_2(\eta), \\ y_1' &= g_3(\eta), & y_2' &= g_4(\eta), \\ z_1' &= \lambda_3 z_1 + g_3(\eta), & z_2' &= \lambda_4 z_2 + g_6(\eta), \\ \theta' &= 0. \end{aligned} \tag{4H.6}$$

Here, $\eta = (x_1, x_z, y_1, y_2, z_1, z_2, \theta)$ and $g_i(\eta) = 0\|\eta\|$ for each i. Moreover, $\lambda_i > 0$ for each i, and if $\|\eta\|$ is sufficiently small and $\theta^* \leqq \theta < \theta_0$, then

$$\begin{aligned} &g_1(x_1, x_2, 0, 0, 0, 0, \theta) = g_2(x_1, x_2, 0, 0, 0, 0, \theta) = 0, \\ &g_3(0, 0, y_1, y_2, 0, 0, \theta) = g_4(0, 0, y_1, y_2, 0, 0, \theta) = 0, \\ &g_5(0, 0, 0, 0, z_1, z_2, \theta) = g_6(0, 0, 0, 0, z_1, z_2, \theta) = 0. \end{aligned} \tag{4H.7}$$

In the new coordinates $(B, \theta) = (0, 0, 0, 0, 0, 0, \theta)$. Choose $\delta_0 > 0$ so that (4H.6), (4H.7) hold for $\|\eta\| \leqq \delta_0$. For $\delta < \delta_0$, let

$$N_\delta = \{\eta: |x_1| \leqq \delta, |x_2| \leqq \delta, |z_1| \leqq \delta_0, |z_2| \leqq \delta_0, \|Y\|^2 \leqq \delta(\|z\|^2 + 1), \theta^* \leqq \theta_0\}.$$

Here, $\|Y\|^2 = y_1^2 + y_2^2$ and $\|z\|^2 = z_1^2 + z_2^2$.

We show that if δ_0 is sufficiently small, then for each $\delta < \delta_0$, trajectories can only leave N_δ through the sides $|z_1| = \delta_0$ or $|z_2| = \delta_0$. To prove this we show that on the other sides of N_δ the vector field given by (4H.6) points into N_δ.

If $x_1 = \delta$, then $x_1' = -\lambda_1 x_1 + g(\eta) < 0$ for δ_0 sufficiently small. If $x_1 = -\delta$, then $x_1' = -\lambda_1 x_1 + g_1(\eta) > 0$ for δ_0 sufficiently small. A similar analysis shows that if $|x_2| = \delta$, then the vector field given by (4H.6) points into N_δ.

Now supppose that $\|Y\|^2 = \delta(\|z\|^2 + 1)$. Let

$$n = (0, 0, 2y_1, 2y_2, -2\delta^2 z_1, -2\delta^2 z_2, 0)$$

be a vector outwardly normal to N_δ at η. If x is the vector field given by the right side of (4H.6), then

$$n \cdot x = 2y_1 g_3(\eta) + 2y_2 g_4(\eta) - 2\delta^2 \lambda_3 z_1^2 - 2\delta^2 \lambda_4 z_2^2 - 2\delta^2 z_1 g_5(\eta) - 2\delta^2 z_2 g_6(\eta) < 0$$

if δ_0 is sufficiently small. This is what we wished to prove.

For $\delta < \delta_0$, let $E_\delta = \{\eta: |z_1| = \delta_0 \text{ or } |z_2| = \delta_0\} = N_\delta$. We have shown that any solution of (2.1), (2.3) with $\varepsilon = 0$ can only leave N_δ through E_δ. By continuity of the solutions of an ordinary differential equation with respect to a parameter we conclude that for each $\delta < \delta_0$ there exists ε_δ such that if $0 < \varepsilon < \varepsilon_\delta$ and $\Phi(z)$ is a solution of (2.1), (2.3) which lies in N_δ for some z, then $\Phi(z)$ can only leave N_δ through E_δ.

We have shown that $\lim_{z \to \infty} \Gamma(z) = (B, \theta^0)$. Hence, for each $\delta, \Gamma(z) \in N_\delta$ for z sufficiently large. Another way to say this is that for each δ, $\Lambda(s) \in N_\delta$ for s sufficiently close to s_2. This implies that given δ, there exists K_δ such that if $k > K_\delta$, then $\Lambda_k(s) \in N_\delta$ for some s. Now $\Phi_\varepsilon(z) \to C_2$ as $z \to \infty$ for each $\varepsilon > 0$. Therefore, if $k > K_\delta$, then $\Lambda_k(s)$ must leave N_δ. Choosing K_δ larger, if necessary, we conclude that if $k > K_\delta$, then $\Lambda_k(s)$ leaves N_δ through E_δ. Let $\delta_k = 1/k\delta_0$. For $k > K_\delta$, choose s_k so that $\Lambda_k(s_k) \in E_{\delta_k}$. Then $\{\Lambda_k(s_k)\}$ will converge to a point $\Lambda_0 \in \bigcap_k E_{\delta_k}$. However, $\bigcap E\delta_k$ lies in $W^u_{(B,\theta)}$, the unstable manifold of (2.1), (2.3) with $\varepsilon = 0$ at the point (B, θ) for some $\theta \in (\theta^*, \theta_0)$. Let $s_3 = \sup\{s > s_2: \Lambda(s) = (B, \theta) \text{ for some } \theta\}$, and choose $\sigma_0 > s_3$ so that $\Lambda(\sigma_0) = \Lambda_0$. Note that $\sigma_0 = \lim_{k \to \infty} s_k$. Let $\theta_* = \theta(s_3)$. We have now shown that $\gamma(s) = B$ for $s_2 \leqq s \leqq s_3$ and $\Lambda(s) \in W^u_{(B,\theta_*)}$ for $s \in (s_3, \sigma_0)$.

We must now analyze what happens for $s > \sigma_0$. Let $\hat{\Gamma}(z)$ be the solution of (2.1), (2.3) with $\varepsilon = 0$ such that $\hat{\Gamma}(0) = \Lambda_0$. From Lemma 3.5 and the remark following it, there exists a critical point K_0 of (2.1), (2.3) with $\varepsilon = 0$ and $\theta = \theta_*$ such that $\lim_{z \to \infty} \hat{\Gamma}(z) = K_0$. We shall prove that $K_0 = (C, \theta_*)$. This will complete the proof of Proposition 4H.6. From the definitions it is clear that $\theta_* = \theta^*$.

We assume that $\hat{\Gamma}(z) = (T, q, Y_1, p_1, Y_2, p_2, \theta)(z)$. Because the Y_1 component of B is zero, and $Y_1(z)$ is nonincreasing (Lemma 3.4), it follows that $Y_1(z) = 0$ for all z. Hence, $(T(z), Y_2(z))$ satisfies the equations

$$\text{(4H.8)} \qquad T'' - \theta_* T' + Q_2 Y_2 f_2(T) = 0, \qquad Y_2'' - \theta_* Y_2' - Y_2 f_2(T) = 0,$$

$\lim_{z \to +\infty} (T(z), Y_2(z)) = (Q_1, 2)$, and $\lim_{z \to \infty} (T(z), Y_2(z)) = (r_1, r_2)$ for some r_1, r_2. Of course, we wish to prove that $(r_1, r_2) = (Q_1 + 2Q_2, 0)$.

For $Q_1 \leqq T < T_2$, $f_2(T) = 0$. Hence, while $Q_1 \leqq T(z) \leqq T_2$, $T(z)$ satisfies $T'' - \theta_* T' = 0$. Integrate this equation from $-\infty$ to z to find that $T' = \theta_*(T - Q_1) > 0$. Hence, $T(z)$ is strictly increasing while $Q_1 \leqq T(z) \leqq T_2$. This implies that $r_1 > T_2$. This, however, implies that $r_2 = 0$.

Integrate the second equation in (4H.8) for $-\infty < z < \infty$ to obtain

$$\theta_* = \frac{1}{2}\int_{-\infty}^{\infty} Y_2 f_2(T)\, dz.$$

Integrate the first equation in (4H.8) for $-\infty < z < \infty$ to obtain

$$-\theta_*(r_1 - Q_1) = -Q_2 \int_{-\infty}^{\infty} Y_2 f_2(T)\, dz = -2\theta_* Q_2,$$

or $r_1 = Q_1 + 2Q_2$. The proof of Proposition 4H.6 is now complete.

We are now ready to complete the proof of Theorem 1. From Lemma 4H.5, either $(T^+, Y_2^+) = (Q_1, 2)$ or $(T^+, Y_2^+) = (Q_1 + 2Q_2, 0)$. We have already seen that if $(T^+, Y_2^+) = (Q_1 + 2Q_2, 0)$, then the proof of Theorem 1 is complete. So assume that $(T^+, Y_2^+) = (Q_1, 2)$, and consider Proposition 4H.6. Note that $\gamma(s)$ for $s_1 \leqq s \leqq s_2$ corresponds to a solution of (1.11), (1.12) with $\theta = \theta^0$. From the definition of θ^1, we conclude that $\theta^1 > \theta^0$. On the other hand, $\gamma(s)$ for $s_3 \leqq s \leqq s_4$ corresponds to a solution of (1.13), (1.14) with speed θ^*. From the definition of θ^{12} we conclude that $\theta^* > \theta^{12}$. Because $\theta^0 > \theta^*$ we have that $\theta^1 > \theta^{12}$, and the proof of Theorem 1 is complete.

5. Distinct diffusion constants. We briefly describe how to prove Theorem 1 for the case of distinct diffusion constants. The major difference in the proof is the derivation of the a priori bounds. For the case of equal diffusion constants we constructed an isolating neighborhood N. This gave us the desired bounds because the solution had to lie in N. In [11] we derive the a priori bounds for the case of distinct diffusion constants.

Once we have the a priori bounds, the basic outline of the proof of Theorem 1 is the same. The key idea is the geometric construction described in § 2. Proposition 2.1 is proved by defining a homotopy between the equations with equal diffusion constants and those with distinct diffusion constants. There is some difficulty here because for the case of equal diffusion constants, we assume that $\theta_1 = -\theta_0$ in (2.3), while the a priori bounds for distinct diffusion constants only hold for $\theta > 0$. For this reason, the homotopy is carried out in two steps. First we assume that the diffusion constants are equal, and continue the solution of (2.1), (2.3), (2.4) with $\theta_1 < 0$ to a solution with $\theta_1 > 0$. We then fix θ_1 and then homotopy the diffusion constants. These continuations are quite technical, and are carried out in [11, §§ 5I and 6].

Acknowledgment. I thank R. Gardner for carefully reading the original manuscript of this paper. His many suggestions greatly helped to simplify and clarify the proofs.

SOME EXPLICIT FORMULAE FOR THE SINGULAR VALUES OF CERTAIN HANKEL OPERATORS WITH FACTORIZABLE SYMBOL*

CIPRIAN FOIAS†, ALLEN TANNENBAUM‡, AND GEORGE ZAMES§

Abstract. In this paper a determinantal formula is written that allows one to compute the singular values of Hankel operators, the L^∞-symbols of which are of the form $\bar{m}w$ for $w \in H^\infty$ rational and $m \in H^\infty$ inner. (All of the Hardy spaces are defined on the unit circle in the usual way.) This is related, moreover, to some problems from control and systems theory.

Key words. Hankel operator, compressed shift, discrete spectrum, singular values, H^∞-optimization

AMS(MOS) subject classifications. 47A20, 93B35

1. Introduction. In the past few years there has been a substantial literature devoted to the computation of the norm and, more generally, singular values of Hankel operators, the L^∞-symbol of which is of the form $\bar{m}w$ for $w \in H^\infty$ rational and $m \in H^\infty$ inner. (All of our Hardy spaces will be defined on the open unit disc D following the standard conventions of [9].) A partial reference list of this work can be found in the monograph [5].

A strong motivation for studying this problem comes from control engineering, e.g., from H^∞-optimal sensitivity theory, and from Hankel norm approximation problems in system design. (Once again we refer the interested reader to [5] for the relevant physical background.)

This paper is based on the authors' previous work [2]–[4] and [10]. We put these ideas together here, and write an elementary procedure for the computation of the singular values of the above operators based on a determinantal formula, which we derive in § 3 (see (3.8)).

More precisely, let us take our point of view from [8] and [9]. Given $m \in H^\infty$ inner and nonconstant let $H^2 \ominus mH^2$ denote the orthogonal complement of mH^2 in H^2, and let $P: H^2 \to H^2 \ominus mH^2 =: H$ denote the orthogonal projection. Given $w \in H^\infty$, $M_w: H^2 \to H^2$ denotes the operator induced by multiplication by w. We now set $w(T) := PM_w | H$. In particular, $T := PS | H$ for $S: H^2 \to H^2$, the unilateral right shift. (T is called the *compressed shift*.) Then it is completely standard to show [7] that in order to solve the aforementioned Hankel singular value problem, we can equivalently find the singular values of $w(T)$.

In point of fact, the more general problem we solve in this paper is the rather explicit computation of the discrete spectrum of operators of the form $w(T)w(T)^*$, where $T \in C_0(1)$ and $w \in H^\infty$ is rational. Recall from [9] that a contraction T on a Hilbert space H is of class $C_0(1)$ if $T^n \to 0$ and $T^{*n} \to 0$ strongly, and the operators (the squares of the "defect" operators) $I - TT^*$ and $I - T^*T$ have rank 1. Such operators appear in great abundance in mathematics and in a number of physical problems. See the recent treatise [6].

Although the methods we employ in this note are basically operator theoretic, there is an important algebraic constituent as well, which allows us via a determinantal formula (see (3.8) below) to explicitly determine certain invertible elements of the noncommutative ring of operators $\mathbf{C}[T, T^*]$. We believe this is the main mathematical contribution of this paper.

Hopefully, some other uses will be found for our methods, both from the theoretical and applied points of view. In particular, we believe it would be very interesting to digitally implement some of the formulae given in § 3.

2. Problem statement and preliminary results. As we noted in the Introduction, we are interested in determining the discrete spectrum of $w(T)w(T)^*$ for $w \in H^\infty$ rational, and T the compressed shift associated to the nonconstant inner function $m \in H^\infty$. Recall that the discrete spectrum of a bounded self-adjoint operator B, denoted by $\sigma_d(B)$, consists of the isolated points of the spectrum $\sigma(B)$, which are eigenvalues of finite multiplicity. For such an operator B, the essential spectrum (denoted by $\sigma_e(B)$) is the complement of $\sigma_d(B)$ in the spectrum $\sigma(B)$. (See, e.g., [6] for a more detailed discussion.) We should also mention that for the compressed shift T, we have that $\sigma_d(T) = \sigma(T) \cap D$ (the eigenvalues of finite multiplicity), while for the essential spectrum we have $\sigma_e(T) = \sigma(T) \cap \partial D$, where D denotes the open unit disc and ∂D the unit circle (see [6], [9]).

Now in order to avoid some (minor) technical difficulties we will assume throughout this paper that w is *not* a constant multiple of a Blaschke product. Indeed, in the event w is a constant times a (finite) Blaschke product, all of the "s-numbers" of the Hankel associated to $\bar{m}w$ will be equal to $\|w\|_\infty$ when $\deg m > \deg w$ (see [1], [6]). Thus the interesting case of irrational m is easily solved. Moreover, the case of $\deg m \leqq \deg w$ can be handled using classical Nevanlinna–Pick interpolation theory.

We now express $w = p/q$ as a ratio of relatively prime polynomials, and we set $n := \max\{\deg p, \deg q\}$. For $\rho \in \mathbf{R}$, let

$$P_\rho := q(T)\left(I - \frac{1}{\rho^2} w(T)w(T)^*\right)q(T)^* = q(T)q(T)^* - \frac{1}{\rho^2} p(T)p(T)^*.$$

We can clearly write

$$P_\rho = \sum_{k,j=0}^{n} C_{kj}^\rho T^k T^{*j}$$

for some constants C_{kj}^ρ with the property

$$C_{kj}^\rho = \bar{C}_{jk}^\rho. \tag{1}$$

For $z \in \mathbf{C}$, define

$$\phi_\rho(z, \bar{z}) := \sum_{k,j=0}^{n} C_{kj}^\rho z^k \bar{z}^j \tag{2}$$

and note that

$$\phi_\rho(T, T^*) = P_\rho.$$

Next $\rho^2 \in \sigma(w(T)w(T)^*)$ if and only if $0 \in \sigma(\phi_\rho(T, T^*))$. Further $\rho^2 \in \sigma_d(w(T)w(T)^*)$ if and only if $0 \in \sigma_d(\phi_\rho(T, T^*))$, and similarly for σ_e.

We now will prove some preliminary lemmas that we will need in order to make some reductions in our computation of $\sigma_d(w(T)w(T)^*)$. Our first result is Lemma 2.1.

LEMMA 2.1. *$T = V + F$ where V is unitary, and the rank of F is finite. Moreover $\sigma_e(V) = \sigma_e(T) = \sigma(T) \cap \partial D$.*

Proof. Set

$$V := T\left(I - \frac{1}{\|\mu\|^2}\mu \otimes \mu\right) + \frac{1}{\|\mu\|^2}\mu_* \otimes \mu$$

where

$$(a \otimes b)c := \langle c, b\rangle a$$

for $a, b, c \in H := H^2 \ominus mH^2$, $\mu(\zeta) := \bar{\zeta}(m(\zeta) - m(0))$, and $\mu_*(\zeta) := 1 - m(\zeta)\overline{m(0)}$. Then it is easy to check that V is unitary, rank $F \leqq 2$, and $\sigma_e(V) = \sigma_e(T) = \sigma(T) \cap \partial D$ (since V and T differ by a finite rank perturbation). □

Since we have assumed that w is not a constant times a Blaschke product, we see that

$$\phi_\rho | \partial D \not\equiv 0. \tag{3}$$

Set $\hat{\phi}_{0\rho}(\zeta) := \phi_\rho(\zeta, \bar{\zeta})$ for $\zeta \in \partial D$ (the unit circle). Then we have Corollary 2.2.

COROLLARY 2.2. *$0 \in \sigma_e(P_\rho)$ if and only if $\{\zeta \in \partial D: \hat{\phi}_{0\rho}(\zeta) = 0\} \cap \sigma(T) \neq \varnothing$.*

Proof. From (2.1) we get that $P_\rho = \phi_\rho(T, T^*) = \hat{\phi}_{0\rho}(V) + Q$, where Q is a finite rank operator. Thus from the fact that V is unitary and our above discussion, we see

$$\sigma_e(P_\rho) = \sigma_e(\hat{\phi}_{0\rho}(V)) = \hat{\phi}_{0\rho}(\sigma_e(V)) = \{\hat{\phi}_{0\rho}(\zeta): \zeta \in \sigma(T) \cap \partial D\},$$

which immediately implies our result. □

Remark 2.3. (i) Corollary 2.2 implies that in order to determine if $\rho^2 \in \sigma_d(w(T)w(T)^*)$ we can always assume that

$$\{\zeta \in \partial D: \hat{\phi}_{0\rho}(\zeta) = 0\} \cap \sigma(T) = \varnothing. \tag{4}$$

(ii) Let $\rho_{\text{ess}} := \rho_{\text{ess}}(w(T))$ denote the *essential norm* of $w(T)$ (i.e., the distance of $w(T)$ to the space of compact operators on H). Then we can show that [6], [9]

$$\begin{aligned}\rho_{\text{ess}}^2 &= \sup\{|w(\lambda)|^2: \lambda \in \sigma_e(T)\} \\ &= \sup\{|w(\lambda)|^2: \lambda \text{ is a singular point of } m \text{ on } \partial D\}.\end{aligned}$$

Notice that if $\rho > \rho_{\text{ess}}$, then automatically the assumption (4) given in (i) is satisfied. Moreover, the points in the set $\sigma(w(T)w(T)^*) \cap (\rho_{\text{ess}}^2, \infty)$ are precisely squares of the singular values of the operator $w(T)$. These points are part of the discrete spectrum of $w(T)w(T)^*$.

In summary, we have shown in this section that the computation of the discrete spectrum of $w(T)w(T)^*$ amounts to determining whether zero is an eigenvalue of finite multiplicity of the operator $\phi_\rho(T, T^*) \in \mathbf{C}[T, T^*]$ for given $\rho \in R$, where ϕ_ρ enjoys the properties (1)–(4). This is precisely the problem that we solve in the next section.

3. Main results. In this section we will formulate and prove our theorem on the computation of the discrete spectrum of operators of the form $w(T)w(T)^*$. From our discussion in § 2 we are reduced to the following kind of operator theoretic problem.

Let

$$\phi(z, \bar{z}) = \sum_{k,j=0}^{n} C_{kj} z^k \bar{z}^j \qquad (z \in \mathbf{C})$$

be a polynomial with the following properties:

(i) $\phi(z, \bar{z}) = \overline{\phi(z, \bar{z})}$, i.e., $C_{kj} = \bar{C}_{jk}$ $(0 \leqq j, k \leqq n)$.

(ii) $\phi | \partial D \not\equiv 0$. Set $\hat{\phi}_0(\zeta) := \phi(\zeta, \bar{\zeta})$, $\zeta \in \partial D$.

(iii) $\{\zeta \in \partial D: \hat{\phi}_0(\zeta) = 0\} \cap \sigma(T) = \varnothing$.

Now set

$$A := \phi(T, T^*) = \sum_{k,j=0}^{n} C_{kj} T^k T^{*j}.$$

From our arguments in § 2, we need to find a computable procedure for determining whether $0 \in \sigma_d(A)$. This will be done via a determinantal formula given in (3.6) and (3.8). For convenience, we now state the following reformulation of (2.2).

LEMMA 3.1. $0 \notin \sigma_e(A)$. *Equivalently* $0 \in \sigma_d(A)$ *if and only if* $0 \in \sigma(A)$.

Proof. This follows immediately from (2.2) and property (iii) above. □

Now in order to give our determinantal formula we will first have to compute the action of A on an element $g \in H := H^2 \ominus mH^2$. Accordingly, let

$$g = g_0 + g_1\zeta + \cdots \qquad (\zeta \in \partial D),$$
$$\bar{m}g = g_{-1}\bar{\zeta} + g_{-2}\bar{\zeta}^2 + \cdots.$$

Then

$$T^j g = P(\zeta^j g) = \zeta^j g - m(\zeta^{j-1} g_{-1} + \cdots + g_{-j}),$$
$$T^{*j} g = \bar{\zeta}^j g - (\bar{\zeta}^j g_0 + \cdots + \bar{\zeta} g_{j-1})$$

for $j \geqq 1$, and where $P: L^2 \to H$ denotes orthogonal projection.

Consequently,

$$\begin{aligned} Ag &= \sum_{k,j=0}^{n} C_{kj} P(\zeta^k T^{*j} g) \\ &= \sum_{k,j=0}^{n} C_{kj} P(\zeta^{k-j} g) - \sum_{j>0} C_{kj} \sum_{l=0}^{j-1} g_l P\zeta^{k-j+l} \\ &= \hat{\phi}_0(\zeta) g - \sum_{k>j} C_{kj} m \sum_{l=1}^{k-j} g_{-l} \zeta^{k-j-l} \\ &\quad - \sum_{k<j} C_{kj} \sum_{l=0}^{j-k-1} g_l \bar{\zeta}^{j-k-l} - \sum_{\substack{j>0 \\ k-j+l>0 \\ j>l}} C_{kj} g_l P\zeta^{k-j+l} \\ &= \hat{\phi}_0(\zeta) g - \sum_{l=1}^{n} g_{-l} m \sum_{k-j \geqq l} C_{kj} \zeta^{k-j-l} \\ &\quad - \sum_{l=0}^{n-1} g_l \sum_{j-k>l} C_{kj} \bar{\zeta}^{j-k-l} - \sum_{l=0}^{n-1} g_l \sum_{k+l \geqq j>l} C_{kj} P\zeta^{k+l-j}. \end{aligned}$$

Set

$$\phi_l^+(\zeta) := \sum_{k-j \geqq l} C_{kj} \zeta^{k-j-l} \qquad (1 \leqq l \leqq n), \tag{5}$$

$$\phi_l^-(\zeta) := \sum_{j-k>l} C_{kj} \bar{\zeta}^{j-k-l} \qquad (0 \leqq l \leqq n-1), \tag{6}$$

$$\begin{aligned} \phi_l(\zeta) &:= \sum_{k+l \geqq j>l} C_{kj} P\zeta^{k+l-j} \qquad (0 \leqq l \leqq n-1) \\ &= \sum_{k+l \geqq j>l} C_{kj} (P(\zeta^{k+l-j} P1))(\zeta) \qquad (7) \\ &= \sum_{k+l \geqq j>l} C_{kj} [\zeta^{k+l-j} \mu_*(\zeta) - m(\zeta^{k+l-j-1} \mu_{*,-1} + \cdots + \mu_{*,-(k+l)+j})] \end{aligned}$$

where

$$\mu_{*,-j} := \bar{m}_j \quad \text{for } j \geqq 1. \tag{8}$$

(We are setting $m(\zeta) = \sum_{j=0}^{\infty} m_j \zeta^j$.)

We can now summarize our above computation by Lemma 3.2.

LEMMA 3.2. *We have for $g \in H$ that*

$$Ag = \hat{\phi}_0 g - \sum_{l=1}^{n} g_{-l} m \phi_l^+ - \sum_{l=0}^{n-1} g_l \phi_l^- - \sum_{l=0}^{n-1} g_l \phi_l \tag{9}$$

where $\hat{\phi}_0$, ϕ_l^-, ϕ_l^+, and ϕ_l are explicitly given from (ii), (5), (6), (7), *respectively, above.*

Remark 3.3. Notice from (3.1) that $0 \in \sigma(A)$ if and only if there exists $g \in H$, $g \neq 0$ such that $Ag = 0$. From (3.2) we can compute the action of A on g. We assume from now on that $Ag = 0$. Then by (3.2) (for $Ag = 0$), we have that

$$\hat{\phi}_0 g = \sum_{l=1}^{n} g_{-l} m \phi_l^+ + \sum_{l=0}^{n-1} g_l (\phi_l^- + \phi_l). \tag{10}$$

Now define

$$\psi(z) := \sum_{k,j=0}^{n} C_{kj} z^{n+k-j} \qquad (z \in \mathbf{C}). \tag{11}$$

Then multiplying (10) by ζ^n, we can easily deduce that

$$\psi(z) g(z) = \sum_{l=1}^{n} g_{-l} m(z) \phi_l^+(z) z^n + \sum_{l=0}^{n-1} g_l (\psi_l^-(z) + z^n \phi_l(z)) \tag{12}$$

for $z = \zeta \in \partial D$, where

$$\psi_l^-(z) := \sum_{j-k>l} C_{kj} z^{n+l+k-j} \tag{13}$$

for $z \in \mathbf{C}$.

We now make a technical assumption in order to simplify our exposition. This assumption of genericity will be *removed* when we state our final result in (3.8).

Assumption 3.4. All the zeros of ψ are distinct and different from zero.

We now come to the following result.

LEMMA 3.5. *Under assumption* (3.4), *there exist* $z_1, z_2, \cdots, z_p \in D$, $\zeta_1, \zeta_2, \cdots, \zeta_q \in \partial D \backslash \sigma(T)$, $2p + q = 2n$, *such that* $\psi(z) = \alpha(z - z_1) \cdots (z - z_p)(z - 1/\bar{z}_1) \cdots (z - 1/\bar{z}_p)(z - \zeta_1) \cdots (z - \zeta_q)$ *for some* $\alpha \neq 0$.

Proof. From properties (i) and (ii) at the beginning of this section we have that

$$\begin{aligned} z^{2n} \overline{\psi(1/\bar{z})} &= z^{2n} \sum_{k,j=0}^{n} \overline{C_{kj} (1/\bar{z})^{n+k-j}} \\ &= \sum_{k,j=0}^{n} \bar{C}_{kj} z^{n-k+j} \\ &= \sum_{k,j=0}^{n} C_{jk} z^{n-k+j} = \psi(z). \end{aligned}$$

From (ii), $\psi \not\equiv 0$. Denote by $\zeta_1, \zeta_2, \cdots, \zeta_q$ the zeros of ψ on ∂D. From our above computation it follows that if $\psi(z_0) = 0$ for $z_0 \in D$ with $z_0 \neq 0$, then $\psi(1/\bar{z}_0) = 0$ also. This yields the representation of ψ. Finally $\zeta_j \notin \sigma(T)$ by (iii) for $j = 1, \cdots, q$. □

We are almost done! Indeed all the functions in (12) are analytic in a neighborhood of D except $\sigma(T)\cap\partial D$. This allows us to set $z=z_1, z_2, \cdots, z_p, \zeta_1, \cdots, \zeta_q$ in (12) obtaining

$$\sum_{l=1}^{n} g_{-l}m(z_r)\phi_l^+(z_r)z_r^n+\sum_{l=0}^{n-1} g_l(\psi_l^-(z_r)+z_r^n\phi_l(z_r))=0 \quad \text{for } 1\leqq r\leqq p, \tag{14}$$

$$\sum_{l=1}^{n} g_{-l}m(\zeta_s)\phi_l^+(\zeta_s)\zeta_s^n+\sum_{l=0}^{n-1} g_l(\psi_l^-(\zeta_s)+\zeta_s^n\phi_l(\zeta_s))=0 \quad \text{for } 1\leqq s\leqq q. \tag{15}$$

Now multiplying (10) by $\overline{\zeta^n m(\zeta)}$, we see

$$[\bar{z}^n\hat{\phi}_0](z)(\bar{m}g)(z)=\sum_{l=1}^{n} g_{-l}[\bar{z}^n\phi_l^+](z)+\sum_{l=0}^{n-1} g_l\{[\bar{z}^n\bar{m}\phi_l^-](z)+[\bar{z}^n\bar{m}\phi_l](z)\} \tag{16}$$

where $z=\zeta\in\partial D$ and all the functions are analytic in $\bar{z}$. Note that even though this equation has been derived on ∂D, it is valid on the complement of D if we replace $\bar{z}$ by $1/z$ for $|z|>1$.

Now set

$$\psi_l^+(z):=(\bar{z}^n\phi_l^+)(z)=\sum_{k-j\geqq l} C_{kj}\bar{z}^{n+j-k+l} \qquad (1\leqq l\leqq n) \tag{17}$$

and

$$\begin{aligned}\psi_l(z)&:=\bar{z}^n(\bar{m}\phi_l)(z) \qquad (0\leqq l\leqq n-1)\\ &=\sum_{k+l\geqq j>l} C_{kj}\bar{z}^{n+j-k-l}[(\overline{m(z)}-\overline{m(0)})-(\bar{z}^{n-k-l+j+1}\mu_{*,-1}\\ &\qquad +\cdots+\bar{z}^n\mu_{*,-(k+l)+j})]\end{aligned} \tag{18}$$

for $z=\zeta\in\partial D$. Once again $\psi_l^+(z)$, $\psi_l(z)$ admit analytic extensions to the complement of $\bar{D}$ if we replace $\bar{z}$ by $1/z$ for $|z|>1$.

Moreover for $1\leqq r\leqq p$,

$$\bar{z}_r^n\hat{\phi}_0\left(\frac{1}{\bar{z}_r}\right)=\bar{z}_r^{2n}\psi\left(\frac{1}{\bar{z}_r}\right)=0. \tag{19}$$

(Notice we are setting $\hat{\phi}_0(z):=\phi(z,1/z)$ for $z\in\mathbf{C}$.) Then from (16) we see that for $1\leqq r\leqq p$,

$$\sum_{l=1}^{n} g_{-l}\psi_l^+\left(\frac{1}{\bar{z}_r}\right)+\sum_{l=0}^{n-1} g_l\left\{z^{-n}\bar{m}\phi_l\left(\frac{1}{\bar{z}_r}\right)+\psi_l\left(\frac{1}{\bar{z}_r}\right)\right\}=0. \tag{20}$$

(We are setting $\bar{m}(z):=\overline{m(1/\bar{z})}$ for $|z|>1$.)

Finally we note that if $g_{-n}=\cdots=g_{n-1}=0$, then from (3.2) we have that $\phi_0 g=0$ (note we have taken g such that $Ag=0$), which by property (ii) above implies that $g=0$.

We now come to the final point in our computations. Namely the above argument shows that $0\in\sigma(A)$ if and only if the characteristic determinant of the $2n$ equations in the $2n$ "unknowns" $g_{-n}, \cdots, g_{n-1}$ is zero. We can write this determinant quite explicitly. Indeed in order to do this, let us introduce the notation

$$M(\theta_1, \cdots, \theta_R; \xi_1, \cdots, \xi_N)=\begin{bmatrix}\theta_1(\xi_1) & \cdots & \theta_R(\xi_1)\\ \vdots & & \vdots\\ \theta_1(\xi_N) & \cdots & \theta_R(\xi_N)\end{bmatrix} \tag{21}$$

for functions $\theta_1, \cdots, \theta_R$ well defined in a neighborhood of $\xi_1, \cdots, \xi_N$ with the ξ_i distinct for $i = 1, \cdots, N$.

Using this notation, our preceding arguments prove the following theorem.

THEOREM 3.6. *Under Assumption* 3.4, $0 \in \sigma(A)$ *if and only if*

$$\det \begin{bmatrix} M^- & M^+ \\ N^- & N^+ \\ M_*^- & M_*^+ \end{bmatrix} = 0 \tag{22}$$

where

$$M^- := M(z^n m\phi_n^+, \cdots, z^n m\phi_1^+; z_1, \cdots, z_p), \tag{23}$$

$$M^+ := M(\psi_0^- + z^n\phi_0, \cdots, \psi_{n-1}^- + z^n\phi_{n-1}; z_1, \cdots, z_p), \tag{24}$$

$$M_*^- := M(\psi_n^+, \cdots, \psi_1^+; 1/\bar{z}_1, \cdots, 1/\bar{z}_p), \tag{25}$$

$$M_*^+ := M(\psi_0 + z^{-n}\bar{m}\phi_0^-, \cdots, \psi_{n-1} + z^{-n}\bar{m}\phi_{n-1}^-; 1/\bar{z}_1, \cdots, 1/\bar{z}_p). \tag{26}$$

N^- *and* N^+ *are defined as in* (23) *and* (24) *by replacing* $z_1, \cdots, z_p$ *with* $\zeta_1, \cdots, \zeta_q$.

Proof. Write the characteristic determinant of the system of equations in (14), (15), (20)! □

Remark 3.7. We will now eliminate Assumption 3.4 in Theorem 3.6. Note that if the roots of ψ are not distinct perturbing ψ by ε, ε a suitable sufficiently small number, will assure that the corresponding ψ_ε does have distinct roots different from zero.

Before stating our result, we will need to extend the definition of M in (21) to the case where the ξ_i have multiplicities. Indeed, we set

$$M(\theta_1, \cdots, \theta_R; \xi_1, \cdots, \xi_1, \cdots, \xi_S, \cdots, \xi_S) := \begin{bmatrix} \theta_1(\xi_1) & \theta_2(\xi_1) & \cdots & \theta_R(\xi_1) \\ \theta_1'(\xi_1) & \theta_2'(\xi_1) & \cdots & \theta_R'(\xi_1) \\ \vdots & \vdots & & \vdots \\ \theta_1^{(N_1-1)}(\xi_1) & \theta_2^{(N_1-1)}(\xi_1) & \cdots & \theta_R^{(N_1-1)}(\xi_1) \\ \cdots\cdots & \cdots\cdots & \cdots & \cdots\cdots \\ \theta_1(\xi_S) & \theta_2(\xi_S) & \cdots & \theta_R(\xi_S) \\ \vdots & \vdots & & \vdots \\ \theta_1^{(N_S-1)}(\xi_S) & \theta_2^{(N_S-1)}(\xi_S) & \cdots & \theta_R^{(N_S-1)}(\xi_S) \end{bmatrix} \tag{27}$$

where ξ_i has multiplicity N_i for $i = 1, \cdots, S$ in M, and the functions $\theta_1, \cdots, \theta_R$ are analytic in a neighborhood of $\xi_1, \cdots, \xi_S$. (For θ analytic, $\theta^{(N)}$ denotes the derivative of order N.)

Then taking $\varepsilon \to 0$ in our above argument, we easily get the following corollary.

COROLLARY 3.8. *In complete generality* (*i.e., without Assumption* 3.4), *we have that* $0 \in \sigma(A)$ *if and only if the determinant* (22) *is zero where we use the definition* (27) *of* M *in* (23)–(26) *above, and each root of* $\psi(z)$ *is counted according to its multiplicity.*

Remark 3.9. (i) The determinantal formula (22) gives us an explicit expression for determining the invertibility of the operator $A \in \mathbf{C}[T, T^*]$. Moreover from our discussion in § 2, we can now also find $\sigma_d(w(T)w(T)^*)$. We will apply this to an example in § 4.

(ii) We should also note that the multiplicity of zero as a root of $\det M$ (in (22)) is its multiplicity as an eigenvalue of A. Moreover, from (10) we have a formula for the corresponding *eigenvectors.* Hence we have a general procedure for computing the multiplicity of the singular values of $w(T)$ and for the corresponding Schmidt vectors.

4. Example. In this section we illustrate via an example some of the computational issues involved in the determinantal scheme for computing the singular values of the operators $w(T)$ that we have discussed above. We are convinced that it will be possible in the near future to implement on a computer the formulae discussed in § 3, so that hopefully these ideas can become of practical use for some applied problems.

Let $w(z)=z^2+1$, and let $m\in H^\infty$ be a nonconstant inner function. We want to study the singular values of the corresponding operator $w(T)$. First note that $\|w\|_\infty=2$, and w attains its maximum at ± 1. If $\pm 1\in\sigma_e(T)$ (i.e., if m is singular at ± 1), then all of the s-numbers of $w(T)$ will be equal to two. Consequently, we will assume for now on that $\pm 1\notin\sigma_e(T)$, and $\rho_{\text{ess}}:=\rho_{\text{ess}}(w(T))<2$. We will study the invertibility of P_ρ (notation as § 2) for ρ contained in the interval $(\rho_{\text{ess}},2)$.

The computation of the determinantal formula for the singular values of $w(T)$ in $(\rho_{\text{ess}},2)$ is now quite elementary following the arguments of § 3. Indeed using the notation of § 2 (see (11)), we have that

$$\psi_\rho(z)=-\frac{1}{\rho^2}z^4-\left(\frac{2}{\rho^2}-1\right)z^2-\frac{1}{\rho^2}.$$

We can calculate that in the interval of interest all of the roots of $\psi_\rho(z)$ lie on ∂D and are distinct. The exact formulae for these roots are $\zeta_1=e^{i\theta/2}$, $\xi_2=-e^{i\theta/2}$, $\zeta_3=e^{-i\theta/2}$, $\zeta_4=-e^{-i\theta/2}$, where

$$\theta:=\arctan\frac{\rho\sqrt{1-\rho^2/4}}{(1-\rho^2/2)}\qquad(0<\theta<\pi/2).$$

(Notice that $\zeta_3=\bar{\zeta}_1$, $\zeta_4=\bar{\zeta}_2$.)

If we now follow the recipe of § 3, we see (the computations actually were quite easy!) that the singular values of $w(T)$ in the interval $(\rho_{\text{ess}},2)$ may be derived from the determinant of the following 4×4 matrix:

$$M=[N^-\quad N^+] \tag{28}$$

where

$$N^-:=\begin{bmatrix}-(1/\rho^2)\zeta_1^2m(\zeta_1) & -(1/\rho^2)\zeta_1^3m(\zeta_1)\\ \vdots & \vdots\\ -(1/\rho^2)\zeta_4^2m(\zeta_4) & -(1/\rho^2)\zeta_4^3m(\zeta_4)\end{bmatrix},$$

$$N^+=\begin{bmatrix}-(1/\rho^2)(1+\zeta_1^2\mu_*(\zeta_1)) & -(1/\rho^2)(\zeta_1+\zeta_1^2(\zeta_1\mu_*(\zeta_1)-m(\zeta_1)\bar{m}_1))\\ \vdots & \vdots\\ -(1/\rho^2)(1+\zeta_4^2\mu_*(\zeta_4)) & -(1/\rho^2)(\zeta_4+\zeta_4^2(\zeta_4\mu_*(\zeta_4)-m(\zeta_4)\bar{m}_1))\end{bmatrix}.$$

(Recall that $\mu_*(\zeta)=1-m(\zeta)\overline{m(0)}$, and $m_1:=dm/d\zeta|_{\zeta=0}$.)

Notice that in this formula m appears as a "parameter," and that, in general, the size and complexity of the matrix given in (22) above only depends on the "weighting" function w. We checked (28) for the trivial case of $m(z)=z$, and got (of course) the obvious answer that the unique root of $\det M$ in $(0,2)$ is 1.

In conclusion, the determinantal formula (22) offers a very general theoretical procedure for the computation of the discrete spectrum of operators of the form $w(T)w(T)^*$ for both rational and irrational inner functions $m\in H^\infty$. The writing of appropriate software for actually carrying this out should make a very interesting project.

A FUNDAMENTAL INTEGRAL RELATION OF SCATTERING THEORY*

MARGARET CHENEY†, JAMES H. ROSE‡, AND BRIAN DEFACIO§

Abstract. This paper concerns three-dimensional scattering and inverse scattering for a variety of time-reduced wave equations. The main result is an integral relation that relates the wavefield to the scattering data. A rigorous derivation of this integral relation is given for a specific class of linear, scalar wave equations. Three specific examples of wave equations to which these results apply are then considered: the Schrödinger equation with complex potential, the wave equation with variable speed, and the acoustic equation with variable density and speed. Finally, three consequences of the integral relation are considered. First, this equation is used to derive a generalized optical theorem for the above-mentioned class of wave equations. Second, the relation's implications for long wavelength scattering are discussed. Third, this equation is shown to lie at the heart of certain inverse scattering methods.

Key words. scattering theory, inverse problems, optical theorem, Marchenko equation

AMS(MOS) subject classification. 35P25

1. Introduction. In 1980, R. G. Newton published two exact three-dimensional inverse scattering methods for Schrödinger's equation [1]. Recently [2], one of these methods has been generalized to apply to scattering from an inhomogeneous medium. This may be an important step towards solving the multidimensional inverse problem for acoustic, elastic, and electromagnetic scattering.

The method mentioned above proceeds in two steps. First a linear integral equation is used to compute the wavefield everywhere from the scattering data. Then the properties of the scatterer are inferred from the reconstructed wavefield. The frequency domain version of the integral equation just mentioned is the subject of this paper.

These frequency domain integral relations relating the wavefield to the scattering data have been developed in a number of contexts. For obstacle scattering, such a relation was found by Lax and Phillips [3]. For quantum scattering, a similar relation appears in Schmidt [4] and in Newton [5]. A very similar integral relation was found by the authors [6] for scattering governed by a hyperbolic equation closely related to the Schrödinger equation. The authors found [2] that essentially the same integral relation holds for scattering of waves in inhomogeneous media.

The fact that all these integral relations are identical is rather surprising. It suggests that they reflect something common to scattering problems. Indeed, in a recent letter [7], the authors have derived this integral relation on physical grounds for a wide class of scattering experiments. Scattering experiments in this class were assumed to be governed by a variety of linear hyperbolic wave equations, but exact conditions on the equations were not stated.

In this paper, we give a careful mathematical derivation of the integral relation for a specific class of three-dimensional scattering experiments. This derivation has a number of advantages over the derivations of [4], [5], and [6]. First, the proofs of [4] and [5] are worked out only for the Schrödinger equation, whereas our proof holds

for a wide class of wave equations. It is especially hard to see how to generalize the argument of [5] to other equations because that argument depends heavily on the use of spectral theory. Many interesting equations cannot be considered as eigenvalue equations in a natural way. The earlier work of the authors [2] is applicable to a fairly wide class of equations, but the proof in [2] required smoothness assumptions on the scatterer. This is quite a drawback, because many of the applications of inverse scattering deal with imaging discontinuities (e.g., an object imbedded in a solid). The proof in this paper is valid for discontinuous scatterers.

The various proofs in this paper are carried out in the frequency domain. The Fourier transform of the integral relation to obtain a time-domain equation will be only briefly mentioned. Our use of the frequency domain underlines a continuing tension in the development of inverse scattering theory. The theory is most transparent in the time domain where causality appears naturally. However, the mathematical development is simpler in the frequency domain where considerably more is known.

The structure of this paper is as follows. In § 2, the problem is discussed and the physical picture is explained. Section 3 contains a derivation of the integral relation mentioned above. In § 4, several wave equations which arise from different classes of physical problems are discussed as examples. In § 5, the integral relation is used to obtain various results. First we show that it leads to a straightforward proof of a generalized optical theorem for these wave equations. Then we show that it leads to certain results in the long wavelength scattering limit. In particular, we show that the long wavelength phase for acoustic wave scattering satisfies certain symmetry conditions. Finally, § 6 contains applications of the integral relation to inverse scattering problems.

2. Physical picture and statement of results. We assume that the scattering is governed by the equation

$$(\nabla^2 + k^2)\psi = V\psi. \tag{2.1}$$

Here ∇^2 is the Laplacian on R^n, k is a real scalar, and V is a linear operator satisfying certain hypotheses below.

In defining scattering solutions of (2.1), it will be useful to consider the operator $(\nabla^2 + k^2)$. For the time being, we take its domain to be H^2, the space of functions with derivatives up to order two in L^2. Although we will ultimately be interested in real values of k, it is helpful to consider $\nabla^2 + k^2$ also for complex k. For nonreal k, $\nabla^2 + k^2$ maps H^2 onto L^2 and has a bounded inverse [8]. We denote the inverse by $G_0 = (\nabla^2 + k^2)^{-1}$. For real k, G_0 is no longer bounded as a map from L^2 to H^2. However, $\nabla^2 + k^2$ still has fundamental solutions or Green's functions. We denote by $G_0^+ (G_0^-)$ the fundamental solution which in a certain sense (to be specified later) is the limit of the kernel of G_0 as k approaches the real axis from the upper (lower) half-plane [9]. Specifically for $n = 3$ we have

$$G_0^{\pm}(k, r) = -(4\pi r)^{-1} \exp(\pm ikr) \tag{2.2}$$

where r is the length of $\vec{x}$ for $\vec{x}$ in R^3. We will use (2.2) to obtain an integral equation for solutions of (2.1).

We are especially interested in scattering solutions of (2.1); thus we are interested in solutions which for large $\vec{x}$ behave like plane waves $\exp(ik\hat{e} \cdot \vec{x})$ propagating in direction $\hat{e}$, where $\hat{e}$ is a unit vector in $\mathbb{R}^n$. We therefore define the scattering solutions $\psi^{\pm}$ by the integral equation

$$\psi^{\pm}(k, \hat{e}, \vec{x}) = \exp(ik\hat{e} \cdot \vec{x}) + \int G_0^{\pm}(k, |\vec{x} - \vec{y}|)(V\psi^{\pm})(k, \hat{e}, \vec{y})\, d\vec{y}. \tag{2.3$\pm$}$$

(The spaces in which the solutions $\psi^{\pm}$ lie will be discussed later.) In what follows we will also use the symbols $G_0^{\pm}V$ to mean the integral operator of (2.3±). Moreover, we will assume below (and, in fact show for a certain class of V's) that (2.3±) has a unique solution $\psi^{\pm}$. Physically, this means that the system responds in a well-defined way to the incident plane wave.

In many cases, expanding (2.3±) for large $|\vec{x}|$ shows that the interaction of the incident plane wave with the scatterer gives rise to a spherically spreading wave. For example, for $n=3$, ψ^{+} can be written asymptotically as

$$\psi^{+}(k, \hat{e}, \vec{x}) = \exp(ik\hat{e}\cdot\vec{x}) + \frac{A(k, \hat{x}, \hat{e})}{|\vec{x}|} e^{ik|\vec{x}|} + O(|x|^{-2}). \tag{2.4}$$

Here $\hat{e}$ and $\hat{x}$ denote the direction of incidence and scattering, respectively, and A denotes the scattering amplitude. For $n=3$, the scattering amplitude is given by the formula [5]

$$A(k, \hat{e}, \hat{e}') = -\frac{1}{4\pi}\int \exp(-ik\hat{e}\cdot\vec{y})(V\psi^{+})(k, \hat{e}', \vec{y})\, d\vec{y}. \tag{2.5}$$

Sections 3 and 4 require only definition (2.5) of the scattering amplitude. Its relation (2.4) to the physical picture is irrelevant to the mathematics in these two sections. The goal of this paper is to prove, for $n=3$, the following relation between ψ^{+}, ψ^{-}, and A:

$$\psi^{+}(k, \hat{e}, \vec{x}) = \psi^{-}(k, \hat{e}, \vec{x}) + \frac{ik}{2\pi}\int_{S^2} A(k, \hat{e}', \hat{e})\psi^{-}(k, \hat{e}', \vec{x})\, d\hat{e}', \tag{2.6}$$

where S^2 denotes the unit sphere in $\mathbb{R}^3$. After proving (2.6), we will consider some of the conclusions that can be drawn from this equation.

3. Proof of (2.6). In this section, we prove (2.6) for scattering governed by an operator V which satisfies conditions (H1) and (H2) (uniqueness and decay, see below) for $n=3$. Since (H1) and (H2) are rather abstract, the question then arises, for what operators V do (H1) and (H2) hold? Theorem 3.1 gives a specific class of operators for which (H1) and (H2) hold. As we will see in the examples, this class includes several physically interesting wave equations.

We define the weighted L^2 space on R^n

$$L^{2,s} = \{u: (1+|\vec{x}|^2)^{s/2}u \in L^2\}$$

and the weighted Sobolev space $H^{m,s}$, which is the space of functions with derivatives up to order m in $L^{2,s}$.

THEOREM 3.1. *Suppose V is given by*

$$V(f) = \sum_{j=1}^{n} a_j(k, \vec{x})\frac{\partial}{\partial x_j}f(\vec{x}) + b(k, \vec{x})f(\vec{x}), \tag{3.1}$$

where the coefficients satisfy the following conditions:

(a) *For almost all $\vec{x}$, the a_j and b are entire functions of k.*

(b) *For each complex k, there is some $\varepsilon > 0$ such that for some α with $0 < \alpha < 4$,*

$$\sup_{\vec{x}\in\mathbb{R}^n}\left[\int_{|\vec{y}-\vec{x}|<1}(1+|\vec{y}|^2)^{n+\varepsilon}|b(k, \vec{y})|^2|\vec{y}-\vec{x}|^{\alpha-n}\, d\vec{y}\right]$$

is finite and

$$\int_{|\vec{y}-\vec{x}|<1}(1+|\vec{x}|^2)^{n+\varepsilon}|b(k, \vec{x})|^2\, d\vec{x} \to 0 \quad \text{as } |\vec{y}|\to\infty.$$

(*This hypothesis will be satisfied if $b(k, \vec{x})$ is locally in L^2 and is $O(|\vec{x}|^{-n-2\varepsilon})$ as $|\vec{x}|\to\infty$.*)

(c) *For each* $j=1, 2, \cdots, n$ *and each complex* k, *there is some* β *with* $0<\beta<2$ *such that for the above* ε,

$$\sup_{\vec{x}\in\mathbb{R}^n} \int_{|\vec{y}-\vec{x}|<1} (1+|\vec{y}|^2)^{n+\varepsilon} |a_j(k, \vec{y})|^2 |\vec{y}-\vec{x}|^{\beta-n}\, d\vec{y}$$

is finite and

$$\int_{|\vec{y}-\vec{x}|<1} (1+|\vec{y}|^2)^{n+\varepsilon} |a_j(k, \vec{y})|^2\, d\vec{y} \to 0 \quad \text{as } |\vec{x}|\to\infty.$$

(*This hypothesis will be satisfied if* $a_j(k, \vec{x})$ *is bounded and is* $O(|\vec{x}|^{-n-2\varepsilon})$ *as* $|\vec{x}|\to\infty$.)

(d) *The operator* $\nabla^2 - V + k^2 : H^2 \to L^2$ *is invertible for some* k *in the set* $\{k: \operatorname{Im} k>0, k\notin[0,\infty)\}$.

Then for almost all real k, V *satisfies the following*:

(H1+) (*uniqueness*) $I - G_0^+ V$ *is invertible on* $H^{2,-s}$ *for* $s = n/2+\varepsilon/2$.

(H2) (*decay*) *For some* $\varepsilon>0$, V *maps* $H^{2,-s}$ *into* $L^{2,s}$ *for* $s = n/2+\varepsilon/2$.

A similar statement holds if $\operatorname{Im} k>0$ *in* (d) *is replaced by* $\operatorname{Im} k<0$; *the conclusion* (H1+) *is then replaced by*

(H1−) $I - G_0^- V$ *is invertible on* $H^{2,-s}$ *for* $s = n/2+\varepsilon/2$.

Remark. As we will see in the examples, it is often easy to show that hypothesis (d) is satisfied. It does not appear to be known whether hypotheses (b) and (c) always imply (d); there are examples of differential operators with no resolvent set (see [10]) but they are not of the form considered here.

Proof. We will show that the operator $G_0 V$ is compact on $H^{2,-s}$ for $s = n/2+\varepsilon/2$. This fact plus condition (a) allows us to apply the analytic Fredholm Theorem [10], [11] to $I - G_0 V$ in the upper-half k-plane. The analytic Fredholm Theorem implies that one of two things must be true about $I - G_0 V$; either

(i) $I - G_0 V$ is invertible nowhere in $\operatorname{Im} k \geqq 0$, or

(ii) $I - G_0 V$ is invertible in $\operatorname{Im} k \geqq 0$, except possibly on a discrete set in $\operatorname{Im} k>0$ whose limit points on the real axis are of Lebesgue measure zero. Thus $I - G_0^+ V$ is invertible for almost all real k.

We will use hypothesis (d) to rule out alternative (i).

We will prove compactness by the following argument. First, Agmon [9] has shown that for $\operatorname{Im} k \geqq 0$, G_0 is a bounded operator mapping $L^{2,s}$ into $H^{2,-s}$ for $s>\frac{1}{2}$. We need only show that $V: H^{2,-s} \to L^{2,s}$ is compact. Thus we will prove (H2) in the process of proving (H1+).

First we consider the last term of (3.1). Condition (b) is precisely the condition guaranteeing that the operator of multiplication by $(1+|x|^2)^{n+\varepsilon/2} b(k, x)$ is compact as a mapping from H^2 into L^2 [12]. In other words, b is compact as a mapping from H^2 to $L^{2,n+\varepsilon}$. Moreover, by the following argument, b is compact from $H^{2,s}$ to $L^{2,s+n+\varepsilon}$ for any s. The operator of multiplication by $(1+|x|^2)^{s/2}$ is bounded from $H^{2,r}$ to $H^{2,r-s}$ and from $L^{2,r}$ to $L^{2,r-s}$ for any r. Multiplication by b can thus be considered as the composition

$$H^{2,s} \xrightarrow[(1+|x|^2)^{s/2}]{} H^2 \underset{b}{\to} L^{2,n+\varepsilon} \xrightarrow[(1+|x|^2)^{-s/2}]{} L^{2,s+n+\varepsilon}.$$

Since the composition of bounded operators and compact operators is again compact, this shows that b is compact as a mapping from $H^{2,s}$ to $L^{2,s+n+\varepsilon}$. For $s = n/2+\varepsilon/2$, $b: H^{2,-s} \to L^{2,s}$ is compact.

A very similar argument works for the other terms in (3.1). We consider instead the composition

$$H^{2,s} \xrightarrow[\partial/\partial x_j]{} H^{1,s} \xrightarrow[(1+|x|^2)^{s/2}]{} H^1 \xrightarrow[a_j]{} L^{2,n+\varepsilon} \xrightarrow[(1+|x|^2)^{-s/2}]{} L^{2,s+n+\varepsilon}.$$

Again condition (c) is precisely the right condition to ensure that the map $a_j: H^1 \to L^{2,n+\varepsilon}$ is compact [12].

We have now shown that G_0V is compact on $H^{2,-s}$ for $s = n/2 + \varepsilon/2$. Now we must rule out alternative (i) of the analytic Fredholm Theorem. For this we use hypothesis (d). Note that (d) is a statement about invertibility on L^2, not on $H^{2,-s}$. We show now that for the k in hypothesis (d), $I - G_0V$ is invertible on $H^{2,-s}$. We do this by an argument similar to that in [9]. We will use the identity

$$(\nabla^2 + k^2)^{-1} = (\nabla^2 - V + k^2)^{-1} - (\nabla^2 + k^2)^{-1} V (\nabla^2 - V + k^2)^{-1}$$

which we rewrite using $G_0 = (\nabla^2 + k^2)^{-1}$ and $G = (\nabla^2 - V + k^2)^{-1}$ as $G_0 = G - G_0VG$ or

$$G_0 = (I - G_0V)G. \tag{3.2}$$

This identity is valid for values of k for which both $(\nabla^2 + k^2)$ and $\nabla^2 - V + k^2$ are invertible as maps from H^2 to L^2. In particular, hypothesis (d) asserts that there is at least one k for which (3.2) holds. At this k, the similar identity $G_0 = G - GVG_0$ or

$$G_0 = G(I - VG_0) \tag{3.3}$$

also holds. Since $I - VG_0$ maps L^2 into L^2 and since the range of G_0 is all of H^2, (3.3) shows that G maps L^2 onto H^2. Equation (3.2) then shows that $I - G_0V$ maps H^2 onto H^2. Therefore $(I - G_0V)H^{2,-s}$ must contain all of H^2. However, since G_0V is compact, the range of $I - G_0V$ in $H^{2,-s}$ is closed. Since H^2 is dense in the range of $I - G_0V$ (in the $H^{2,-s}$ norm), it must be true that the range of $I - G_0V$ is all of $H^{2,-s}$. $I - G_0V$ is therefore invertible on $H^{2,-s}$. □

The condition (H1±) is useful for working with (2.3±). In particular, condition (H1±) means that for f in $H^{2,-s}$, the integral equation

$$h = f + \int G_0^{\pm} Vh$$

has a unique solution h in $H^{2,-s}$. In particular, equations (2.3±) each have unique solutions in $H^{2,-s}$. The scattering solutions $\psi^{\pm}$ are therefore well defined. Since ψ^+ is used in the definition (2.5) of the scattering amplitude A, condition (H1+) should be satisfied whenever A is used.

We note that V is assumed to be independent of the boundary conditions of the problem in § 2; in particular it is independent of the variable $\hat{e}$.

LEMMA 3.2. *Suppose conditions* (H1+) *and* (H2) *hold for* $n = 3$. *Then* A *defined by* (2.5) *is bounded.*

Proof. Write the integrand of (2.5) as the product $\exp(-ik\hat{e}\cdot\vec{y})(1+|\vec{y}|^2)^{-s/2}$ times $(1+|\vec{y}|^2)^{s/2}(V\psi^+)(k, \hat{e}', \vec{y})$ for $s = 3/2 + \varepsilon/2$ and apply the Schwarz inequality. By condition (H2), $(1+|\vec{y}|^2)^{s/2}V\psi^+$ has finite L^2 norm. □

PROPOSITION 3.3. *Suppose conditions* (H1+) *and* (H2) *hold for* $n = 3$. *Then*

$$\int_{S^2} A(k, \hat{e}, \hat{e}') \exp(ik\hat{e}\cdot\vec{x})\, d\hat{e}$$
$$= \frac{2\pi}{ik}\left[\psi^+(k, \hat{e}', \vec{x}) - \exp(ik\hat{e}'\cdot\vec{x}) - \int G_0^-(k, |\vec{x}-\vec{y}|)(V\psi^+)(k, \hat{e}', \vec{y})\, d\vec{y}\right]. \tag{3.4}$$

Proof. We use (2.5) in the left side of (3.4). By Lemma 3.2, the iterated integrals converge absolutely, so we may interchange the order of integration. We compute the $\hat{e}$ integral as follows. We write $\int_{S^2} \exp(ik\hat{e}\cdot(\vec{x}-\vec{y}))\, d\hat{e}$ in polar coordinates with the polar angle measured from the direction $\vec{x}-\vec{y}$. We can then carry out the integration explicitly: the result is

$$\int_{S^2} \exp[ik\hat{e}\cdot(\vec{x}-\vec{y})]\, d\hat{e} = -\frac{8\pi^2}{ik}[G_0^+(k,|\vec{x}-\vec{y}|) - G_0^-(k,|\vec{x}-\vec{y}|)]. \tag{3.5}$$

Finally, we use (2.3+) to obtain (3.4). □

THEOREM 3.4. *Suppose conditions* (H1±) *and* (H2) *hold for* $n=3$. *Then*

$$\psi^+(k,\hat{e}',\vec{x}) = \psi^-(k,\hat{e}',\vec{x}) + \frac{ik}{2\pi}\int_{S^2} A(k,\hat{e},\hat{e}')\psi^-(k,\hat{e},\vec{x})\, d\hat{e}. \tag{3.6}$$

Proof. Our plan is to obtain an equation similar to (2.3±) but with the plane wave replaced by $\exp[ik\hat{e}'\cdot\vec{x}] + ik/2\pi \int A(k,\hat{e},\hat{e}')\exp(ik\hat{e}\cdot\vec{x})\, d\hat{e}$. We will compare this new equation with (3.4); from the uniqueness of the solution of equations such as (2.3±), we will conclude (3.6).

First we multiply (2.3−) by $(ik/2\pi)A(k,\hat{e},\hat{e}')$ and integrate with respect to $\hat{e}$

$$\begin{aligned}
&\frac{ik}{2\pi}\int_{S^2} A(k,\hat{e},\hat{e}')\psi^-(k,\hat{e},\vec{x})\, d\hat{e} \\
&= \frac{ik}{2\pi}\int_{S^2} A(k,\hat{e},\hat{e}')\exp(ik\hat{e}\cdot\vec{x})\, d\hat{e} \\
&\quad + \frac{ik}{2\pi}\int_{S^2} A(k,\hat{e},\hat{e}')\int G_0^-(k,|\vec{x}-\vec{y}|)(V\psi^-)(k,\hat{e},\vec{y})\, d\vec{y}\, d\hat{e}.
\end{aligned} \tag{3.7}$$

We next interchange the order of integration in the last term of (3.7). This is valid because the following estimate shows that the iterated integral converges absolutely; first we use Lemma 3.2 to obtain

$$\begin{aligned}
&\int\int_{S^2} |A(k,\hat{e},\hat{e}')||G_0^-(k,|\vec{x}-\vec{y}|)||(V\psi^-)(k,\hat{e},\vec{y})|\, d\hat{e}\, d\vec{y} \\
&\leqq 4\pi \max_{S^2\times S^2} A \int |\vec{x}-\vec{y}|^{-1}|(V\psi^-)(k,\hat{e},\vec{y})|\, d\vec{y}.
\end{aligned} \tag{3.8}$$

The right side of (3.8) can easily be shown to be finite by using condition (H2) as in the proof of Lemma 3.2.

Upon interchange of the order of integrals in (3.7), we obtain

$$\frac{ik}{2\pi}\int_{S^2} A\psi^- = \frac{ik}{2\pi}\int_{S^2} A\exp + \frac{ik}{2\pi}\int G_0^- \int_{S^2} A(V\psi^-). \tag{3.9}$$

Next we write (2.3−) with $\hat{e}'$ substituted for $\hat{e}$ and add (3.9) to the result. We obtain

$$\begin{aligned}
&\psi^-(k,\hat{e}',\vec{x}) + \frac{ik}{2\pi}\int_{S^2} A(k,\hat{e},\hat{e}')\psi^-(k,e,\vec{x})\, de \\
&= \exp(ik\hat{e}'\cdot\vec{x}) + \frac{ik}{2\pi}\int_{S^2} A(k,\hat{e},\hat{e}')\exp(ik\hat{e}\cdot\vec{x})\, d\hat{e} \\
&\quad + \int G_0^-(k,|\vec{x}-\vec{y}|)\left[(V\psi^-)(k,\hat{e}',\vec{y}) - \frac{ik}{2\pi}\int_{S^2} A(k,\hat{e},\hat{e}')(V\psi^-)(k,\hat{e},\vec{y})\, d\hat{e}\right] d\vec{y}.
\end{aligned} \tag{3.10}$$

Since V is linear and is independent of $\hat{e}$, we pull V outside the bracket in the last term of (3.10). We note that by Lemma 3.2, the inhomogeneous term $\exp(ik\hat{e}'\cdot\vec{x})+ik/2\pi\int_{S^2}A(k,\hat{e},\hat{e}')\exp(ik\hat{e}\cdot\vec{x})\,d\hat{e}$ is in $H^{2,-s}$. By hypothesis (H1−), the solution of (3.10) is unique; we obtain (3.6) by comparing (3.10) to (3.4). □

4. Examples. In this section, we show that (2.6) holds for three physically relevant equations.

Example 1. *The Schrödinger equation.* Here we consider the case in which V is the operator of multiplication by a complex-valued function

$$V(\vec{x})=U(\vec{x})+iW(\vec{x}),$$

where U and W are real-valued functions satisfying hypothesis (b) of Theorem 3.1. Equation (2.1) then becomes the Schrödinger equation

$$(\nabla^2+k^2)\psi=(U+iW)\psi. \tag{4.1}$$

Equation (4.1) with nonzero W is commonly used to model many-body systems in which there is attenuation. For example it is used in the optical model for scattering from nuclei [13].

In order to show that (3.6) holds for almost all real k, we must check hypothesis (d) of Theorem 3.1.

LEMMA 4.1. *Suppose V is in $L^2(\mathbb{R}^3)$. Then for* $\operatorname{Im}k>\|V\|^2_{L^2}(32\pi^2)^{-1}$, *$I-G_0V$ is invertible on L^2.*

Sketch of proof. The square of the Hilbert-Schmidt norm [10] of G_0V can be explicitly computed for $\operatorname{Im}k>0$. It turns out to be $\|V\|^2_{L^2}(32\pi^2\operatorname{Im}k)^{-1}$. Thus for $\operatorname{Im}k>\|V\|^2_{L^2}(32\pi^2)^{-1}$, the Hilbert-Schmidt norm of G_0V is less than one, so $(I-G_0V)^{-1}$ can be constructed by iteration [10]. □

COROLLARY 4.2. *Suppose V is in L^2 and satisfies condition* (b) *of Theorem* 3.1. *Then for* $\operatorname{Im}k>\|V\|^2_{L^2}(32\pi^2)^{-1}$, $(\nabla^2+k^2-V):H^2\to L^2$ *is invertible.*

Proof. We consider the operator $G=G_0(I-G_0V)^{-1}$. It is well known [8] that for $\operatorname{Im}k>0$, G_0 maps L^2 onto H^2. This fact and Lemma 4.1 imply that G maps L^2 into H^2. By arguments similar to the one above (3.2), it can be checked that G is the inverse of (∇^2+k^2-V). □

We have proved the following result.

THEOREM 4.3. *Suppose V is in L^2 and satisfies condition* (b) *of Theorem* 3.1. *Then* (2.6) *holds for almost all real k.*

In fact, if V is real-valued, then it is known [9] *that* (H1±) *holds for all nonzero real k, and consequently* (2.6) *holds for all nonzero real k.*

Example 2. *The wave equation with variable speed.* Here we consider the equation

$$[\nabla^2+k^2c^{-2}(\vec{x})]\psi(k,\vec{x})=0, \tag{4.2}$$

where $c^{-2}(\vec{x})-1$ satisfies hypothesis (b) of Theorem 3.1. In this case, V is the operator of multiplication by $k^2(c^{-2}(\vec{x})-1)$. In order to conclude that (2.6) holds for almost all k, we must check hypothesis (d) of Theorem 3.1.

We note that it is easy to show that for $c^{-2}(\cdot)-1$ in L^2, $I-G_0V$ is invertible on L^2 for small $|k|$. (The Hilbert-Schmidt norm of G_0V can be shown to be small, and $(I-G_0V)^{-1}$ can be constructed by iteration [10].) We then define the operator $G:L^2\to H^2$ by $G=G_0(I-G_0V)^{-1}$. If $(I-G_0V)^{-1}$ exists, then G exists and is the inverse of ∇^2-V+k^2. (See the argument above (3.2).) Hypothesis (d) of Theorem 3.1 is thus satisfied, and we can conclude that (2.6) holds. We have proved the following theorem.

THEOREM 4.4. *Suppose $c^{-2}(\cdot)-1$ is in $L^2(R^3)$ and satisfies hypothesis* (b) *of Theorem* 3.1. *Then for almost all real k,* (2.6) *holds, where $V=k^2(c^{-2}(\cdot)-1)$.*

We note that c^{-2} has not been assumed to be real-valued, positive, or smooth. However, if c^{-2} satisfies the conditions of Theorem 4.4 and, in addition, is strictly positive, it is known that conditions (H1±) actually hold for all real k [9], [14], so in fact (2.6) holds for all real k.

Example 3. *The acoustic equation.* The acoustic equation governs the propagation of pressure waves in a fluid [15]

$$[\nabla^2 - \rho^{-1}\nabla\rho\cdot\nabla + k^2c^{-2}]\psi(k,\vec{x}) = 0 \tag{4.3}$$

where $\psi(k,\vec{x})$ is the pressure at $\vec{x}$, $\rho(\vec{x})$ is the density, and $c(\vec{x})$ is the speed of propagation. We will assume that for some ρ_0, $\rho(\vec{x})-\rho_0$ and $c^{-2}(\vec{x})-1$ are functions of compact support with two continuous derivatives and that $\rho(\vec{x})$ and $c^2(\vec{x})$ are positive. Thus $c^{-2}(\vec{x})-1$ and $\nabla\rho/\rho$ automatically satisfy hypotheses (b) and (c) of Theorem 3.1. Again we must check that hypothesis (d) is satisfied.

We note that (4.3) can be written

$$[-c^2\rho\nabla\cdot\rho^{-1}\nabla - k^2]\psi(k,\vec{x}) = 0.$$

It is shown in [16] that the operator $-c^2\rho\nabla\cdot\rho^{-1}\nabla$ on H^2 is unitarily equivalent to a self-adjoint operator. Therefore the spectrum of $-c^2\rho\nabla\cdot\rho^{-1}\nabla$ is contained on the real axis; this shows that $-c^2\rho\nabla\cdot\rho^{-1}\nabla - k^2$ is invertible for all complex k except possibly k on the real and imaginary axes. Thus we have shown the following theorem.

THEOREM 4.5. *Suppose that for some* ρ_0, $\rho(\vec{x})-\rho_0$ *and* $c^{-2}(\vec{x})-1$ *are functions of compact support with two continuous derivatives and that* $\rho(\vec{x})$ *and* $c^2(\vec{x})$ *are positive. Then* (2.6) *holds for almost all real* k. (*Here* $V = -\rho^{-1}\nabla\rho\cdot\nabla + k^2(c^{-2}-1)$.)

We note that when ρ is constant, (4.3) reduces to (4.2). The argument of Example 3, however, requires stronger conditions on c^2.

5. Consequences of the integral relation (2.6). Some of the consequences of (2.6) are discussed in this section. First we show that if the linear operator V satisfies (H1±) and (H2) and also has compact support (in a sense described below), then a generalized optical theorem holds for the scattering amplitude.

Next, we discuss some simple consequences of the generalized optical theorem in the long wavelength limit. In particular, for certain scatterers such as those in Example 3, we assume the scattering amplitude can be expanded in a power series about $k=0$

$$A = A_2k^2 + iA_3k^3 + \cdots.$$

The generalized optical theorem implies certain symmetry relations for the A_j.

First we use (2.6) to derive a generalized optical theorem for scattering governed by (2.1). The derivation involves using (2.4) in (2.6) and letting $|\vec{x}|\to\infty$. To be sure that (2.4) holds, we assume that the operator V has compact support

(H3) There is some radius $R>0$ such that $\chi_R V = 0$, where $\chi_R(\vec{x}) = 1$ if $|\vec{x}| > R$ and zero otherwise.

We also need the analogue of (2.4) for ψ^-:

$$\psi^-(k,\hat{e},\vec{x}) = \exp(ik\hat{e}\cdot\vec{x}) + B(k,\hat{x},\hat{e})\exp(-ik|\vec{x}|)/|\vec{x}| + O(|\vec{x}|^{-2}) \tag{5.1}$$

where

$$B(k,\hat{e},\hat{e}') = -\frac{1}{4\pi}\int \exp(-ik\hat{e}\cdot\vec{y})(V\psi^-)(k,\hat{e}',\vec{y})\,d\vec{y}. \tag{5.2}$$

THEOREM 5.1. *Suppose V satisfies* (H1±), (H2), *and* (H3) (*for* $n=3$). *Then*

$$A(k,-\hat{e},\hat{e}')-B(k,\hat{e},\hat{e}')=\frac{ik}{2\pi}\int A(k,\hat{e}'',\hat{e}')B(k,\hat{e},\hat{e}'')\,de''. \tag{5.3}$$

Proof. We substitute (2.4) in (2.6), and multiply by $|x|$. This results in

$$\begin{aligned}A(k,\hat{x},\hat{e})\exp(ik|\vec{x}|)=B(k,\hat{x},\hat{e})\exp(-ik|x|)+\frac{ik|x|}{2\pi}\int A(k,\hat{e}',\hat{e})\exp(ik\hat{e}'\cdot\vec{x})\,d\hat{e}'\\ +\frac{ik}{2\pi}\int A(k,\hat{e}',\hat{e})B(k,\hat{x},\hat{e}')\,d\hat{e}'\exp(-ik|\vec{x}|)+O(|x|^{-1}),\end{aligned} \tag{5.4}$$

where we have used Lemma 3.2. Next we consider the second term on the right side of (5.4). This term we denote by I. We write the integral in polar coordinates with $e'=(\theta,\varphi)$

$$I=\frac{ik|x|}{2\pi}\int_0^{2\pi}\int_0^{\pi}A(k,(\theta,\varphi),\hat{e})\exp(ik|\vec{x}|\cos\theta)\sin\theta\,d\theta\,d\varphi. \tag{5.5}$$

In (5.5) we integrate by parts, obtaining

$$\begin{aligned}I=A(k,\hat{x},\hat{e})\exp(ik|\vec{x}|)-A(k,-\hat{x},\hat{e})\exp(-ik|\vec{x}|)\\ -\frac{1}{2\pi}\int_0^{2\pi}\int_0^{\pi}\frac{\partial}{\partial\theta}A(k,(\theta,\varphi),\hat{e})\exp(ik|\vec{x}|\cos\theta)\,d\theta\,d\varphi.\end{aligned} \tag{5.6}$$

We next apply the method of stationary phase [17] to the θ integral of (5.6); this shows that

$$I=A(k,\hat{x},\hat{e})\exp(ik|\vec{x}|)-A(k,-\hat{x},\hat{e})\exp(-ik|\vec{x}|)+O((k|\vec{x}|)^{-1/2}). \tag{5.7}$$

We use (5.7) in (5.4), divide by $\exp(-ik|\vec{x}|)$, and let $|\vec{x}|\to\infty$. A simple relabeling of variables gives (5.3). □

We note that (5.3) simplifies if $V(-k)=V(k)$. In this case, (2.3±) together with hypotheses (H1±) show that

$$\psi^+(-k,-\hat{e},\vec{x})=\psi^-(k,\hat{e},\vec{x}). \tag{5.8}$$

This, in turn, when used with (2.4) and (5.1), shows that

$$B(k,\hat{e},\hat{e}')=A(-k,\hat{e},-\hat{e}'). \tag{5.9}$$

Equation (5.3) then becomes

$$A(k,\hat{e},\hat{e}')-A(-k,-\hat{e},-\hat{e}')=\frac{ik}{2\pi}\int A(k,\hat{e}'',\hat{e}')A(-k,-\hat{e},-\hat{e}'')\,d\hat{e}'', \tag{5.10}$$

where $-\hat{e}$ has been relabeled $\hat{e}$.

We obtain even further simplification of (5.3) if both $V(-k)=V(k)$ and $\bar{V}=V$ hold. (Here the bar denotes complex conjugate.) However, first we note that when $\bar{V}=V$, (2.3±) plus hypothesis (H1±) show that

$$\psi^-(k,\hat{e},\vec{x})=\overline{\psi^+(k,-\hat{e},\vec{x})}. \tag{5.11}$$

Equations (5.8), (5.11), and (2.4) can then be used [5] to show that

$$\overline{A(k,\hat{e},\hat{e}')}=A(-k,\hat{e},\hat{e}'). \tag{5.12}$$

Finally, (2.3±) and (2.5) can be used [5] to derive the reciprocity relation

$$A(k,\hat{e},\hat{e}')=A(k,-\hat{e}',-\hat{e}). \tag{5.13}$$

When equations (5.12) and (5.13) are used in (5.10), the result is the generalized optical theorem which is well known for some wave equations (e.g., the Schrödinger equation and equations governing electromagnetic scattering [5]),

$$A(k, \hat{e}, \hat{e}') - \overline{A(k, \hat{e}', \hat{e})} = \frac{ik}{2\pi} \int A(k, \hat{e}'', \hat{e}') \overline{A(k, \hat{e}'', \hat{e})}\, d\hat{e}''. \tag{5.14}$$

Most derivations of the optical theorem rely on unitarity, but the derivations in this paper do not. In particular, note that (5.3) differs from the usual generalized optical theorem for dissipative systems.

Next we consider wave equations and scatterers (see Examples 2 and 3) such that at long wavelength the scattering amplitude may be expanded about $k = 0$ as

$$\begin{aligned} A(k, \hat{e}, \hat{e}') = {} & A_2(\hat{e}, \hat{e}')k^2 + iA_3(\hat{e}, \hat{e}')k^3 + A_4(\hat{e}, \hat{e}')k^4 \\ & + iA_5(\hat{e}, \hat{e}')k^5 + O(k^6) \end{aligned} \tag{5.15}$$

where $A_2, A_3, \cdots$ are real functions. Substituting (5.15) into (5.14) and equating orders of k leads to the following consistency requirements:

$$A_2(\hat{e}, \hat{e}') = A_2(-\hat{e}, -\hat{e}'), \tag{5.16}$$

$$A_3(\hat{e}, \hat{e}') = -A_3(-\hat{e}, -\hat{e}'), \tag{5.17}$$

$$A_4(\hat{e}, \hat{e}') = A_4(-\hat{e}, -\hat{e}'), \tag{5.18}$$

$$A_5(\hat{e}, \hat{e}') + A_5(-\hat{e}, -\hat{e}') = \frac{1}{2\pi} \int d^2\hat{e}'' A_2(\hat{e}'', \hat{e}) A_2(\hat{e}'', \hat{e}'). \tag{5.19}$$

Note that these relations do *not* follow solely from reciprocity. For a number of circumstances (5.17) implies that $A_3(\hat{e}, \hat{e}') = 0$. This is important in practical problems because it allows signals from different transducers to be matched together properly. This will be discussed in more detail in the next section.

6. Applications to inverse scattering. In this section we will discuss the applications of (2.6) and (5.15)–(5.17) to inverse scattering. First we will show that (5.17) can be used in an important phase retrieval problem. Then we will show how (2.6) can be used to find V from A. Finally, we conclude with a few remarks on other applications to inverse scattering.

The phase retrieval problem arises as follows. In applications of inverse scattering theory to experiments (e.g., various forms of imaging), the scattering amplitude is only known in a corrupted form. Generally it is necessary to solve various preliminary problems in order to obtain the scattering amplitude from measured data. Due to measurement error and difficulties in the precise mathematical modeling of the physical process, it often happens that the scattering amplitude can be found only up to a phase factor which depends on the directions of incidence and scattering. Proceeding without correcting for this unknown phase factor leads to "blurring" in the image produced by the inverse scattering algorithm. See [19] for a discussion of the physical difficulties.

Consequently the following problem, which is an idealization of the physical system just discussed, is of interest. Suppose we know the corrupted form A^c of the scattering amplitude A, where

$$A^c(k, \hat{e}, \hat{e}') = A(k, \hat{e}, \hat{e}') \exp[ik\tau(\hat{e}, \hat{e}')], \tag{6.1}$$

τ being a bounded, real function that is otherwise unknown. Then the problem is to recover A given A^c. In general this problem is impossible to solve, since both A and τ are unknown.

However, let us further suppose that the governing wave equation satisfies (5.15)–(5.17). In addition, let us suppose that the scatterer is known to be symmetric with respect to the origin. We show below that $A_3(\hat{e}, \hat{e}')$ vanishes, $A_2(\hat{e}, \hat{e}') = A_2^c(\hat{e}, \hat{e}')$ and

$$A(k, \hat{e}, \hat{e}') = A^c(k, \hat{e}, \hat{e}') \exp [-ikA_3^c(\hat{e}, \hat{e}')/A_2^c(\hat{e}, \hat{e}')]. \tag{6.2}$$

Here we have expanded the right-hand side of (6.1) as a power series in k, which implies that A^c can be expanded as

$$A^c(k, \hat{e}, \hat{e}') = k^2 A_2^c(\hat{e}, \hat{e}') + ik^3 A_3^c(\hat{e}, \hat{e}') + \mathcal{O}(k^4), \tag{6.3}$$

where the expansion coefficients are real.

We show (6.2) by noting that the inversion symmetry implies that $A(k, \hat{e}, \hat{e}') = A(k, -\hat{e}, -\hat{e}')$ and consequently that

$$A_3(\hat{e}, \hat{e}') = A_3(-\hat{e}, -\hat{e}'). \tag{6.4}$$

Comparison of (6.4) and (5.17) shows that $A_3 = 0$. Now expand both sides of (6.1) in a power series in k and equate coefficients of corresponding powers of k. We obtain $A_2 = A_2^c$ and $\tau = A_3^c/A_2^c$. Substitution of these results in (6.1) and rearrangement yield (6.2).

Equation (6.2) solves the phase retrieval problem: it shows how the true scattering amplitude can be recovered from the corrupted one.

Equation (2.6) can also be used to attack the inverse scattering problem. This problem is to determine V from $A(k, e, e')$. One difficulty in using (2.6) for this is that (2.6) contains two unknowns ψ^+ and ψ^-. In order to obtain an equation with only one unknown, it is generally necessary to Fourier transform and use domain of dependence results to separate ψ^+ and ψ^-. This procedure results in an integral equation for the wavefield in terms of the scattering data.

Specifically, the theory goes as follows in the Schrödinger equation case. We denote the Fourier transform of $\psi^\pm$ by

$$u^\pm(t, \hat{e}, \vec{x}) = (2\pi)^{-1} \int_{-\infty}^{\infty} \exp(-ikt)\psi^\pm(k, \hat{e}, \vec{x})\, dk \tag{6.5}$$

and the Fourier transform of $A(k, \hat{e}, \hat{e}')$ by

$$R(t, \hat{e}, \hat{e}') = (2\pi)^{-1} \int_{-\infty}^{\infty} \exp(-ikt)A(k, \hat{e}, \hat{e}')\, dk. \tag{6.6}$$

In this notation, the Fourier transform of (2.6) is

$$u^+(t, \hat{e}, \vec{x}) = u^-(t, \hat{e}, \vec{x}) - (2\pi)^{-1} \int_{-\infty}^{\infty} \int_{S^2} \dot{R}(t-\tau, \hat{e}', \hat{e}) u^-(\tau, \hat{e}', \vec{x})\, d\hat{e}'\, d\tau, \tag{6.7}$$

where the dot denotes differentiation with respect to t. We note that u^+ satisfies the hyperbolic equation

$$(\nabla^2 - \partial_{tt} - V)u^+ = 0 \tag{6.8}$$

together with the condition that for large negative times, $u^+(t, \hat{e}, \vec{x}) = \delta(t - \hat{e} \cdot \vec{x})$. By domain-of-dependence results for (6.8), when V is real, u^+ satisfies

$$u^+(t, \hat{e}, \vec{x}) = 0 \quad \text{for } t < \hat{e} \cdot \vec{x}. \tag{6.9}$$

In addition, by (5.8),

$$u^-(t, \hat{e}, \vec{x}) = u^+(-t, -\hat{e}, \vec{x}) \tag{6.10}$$

and therefore

$$u^-(t, \hat{e}, \vec{x}) = 0 \quad \text{for } t > \hat{e} \cdot \vec{x}. \tag{6.11}$$

Writing $u^{\pm} = \delta + u^{\pm}_{sc}$ and taking (6.10) and (6.11) into account, (6.7) for $t > \hat{e} \cdot \vec{x}$ becomes

$$\begin{aligned} u^+_{sc}(t, \hat{e}, \vec{x}) = &-(2\pi)^{-1} \int_{S^2} \dot{R}(t - \hat{e}' \cdot \vec{x}, \hat{e}', \hat{e})\, d\hat{e}' \\ &-(2\pi)^{-1} \int_{-\infty}^{\infty} \int_{S^2} \dot{R}(t + \tau, -\hat{e}', \hat{e}) u^+_{sc}(\tau, \hat{e}', \vec{x})\, d\hat{e}'\, d\tau. \end{aligned} \tag{6.12}$$

Newton has shown [1], [20] that (6.12) is a Fredholm equation that can always be solved. We thus obtain u^+_{sc}, and from it, V can be obtained via the formula [1], [21]

$$V(\vec{x}) = -2\hat{e} \cdot \nabla u^+_{sc}(\hat{e} \cdot \vec{x}, \hat{e}, \vec{x}). \tag{6.13}$$

For more details concerning this method of solving the inverse scattering problem for the Schrödinger equation, the reader is referred to [1], [6], and [20].

It is natural to try a similar procedure for solving the inverse scattering problem for the wave equation (Example 2). For this equation, the inverse problem is to recover $c(\vec{x})$ from $A(k, \hat{e}, \hat{e}')$. Again we start with (2.6) which is Fourier transformed [14] to obtain (6.7). The next step is to use causality; for the wave equation, (6.9) holds only when $c(\vec{x}) \leqq 1$ for all $\vec{x}$. Thus we obtain (6.12) only under the hypothesis that $c(\vec{x}) \leqq 1$.

Equation (6.12) is no longer a Fredholm equation, and little is known about it. Nevertheless, if it can be solved for u^+, then $c(\vec{x})$ can be recovered as follows. We know from geometrical optics that

$$u^+(t, \hat{e}, \vec{x}) = z(\hat{e}, \vec{x}) \delta(t - s(\hat{e}, \vec{x})) + (\text{less singular terms}). \tag{6.14}$$

If u^+ is known, then $s(\hat{e}, \vec{x})$ is known; $c(\vec{x})$ is related to s by

$$c^{-2}(\vec{x}) = |\nabla s(\hat{e}, \vec{x})|^2. \tag{6.15}$$

For more details concerning this method of solving the inverse scattering problem for the wave equation, the reader is referred to [2].

The wave equation inverse scattering problem can also be attacked with (2.6) directly. Equations (4.2) and (2.6), together with

$$V(\vec{x}) = \nabla^2[(\psi^+(k, \hat{e}, \vec{x}) - \exp(ik\hat{e} \cdot \vec{x}))/k^2]_{k=0}, \tag{6.16}$$

form a system of equations whose simultaneous solution solves the inverse scattering problem. This system of equations can be attacked by an iterative method; preliminary numerical results indicate that this method converges for some problems. More details about this can be found in [23] and [14].

Finally, relation (2.6) for the wave equation can also be used together with various approximations. For example, if $k^2 V$ is small, we expect to recover from (2.6) the Born approximation and inverse methods based on it. Similarly, if k is large but V is small, then we expect that geometrical optics should be useful and that the rays should be nearly straight. Some such approximate schemes have been worked out in [22].

A SINGULAR LIMIT PROBLEM FOR A VOLTERRA EQUATION*

RICHARD NOREN†

Abstract. Concerning the solution $u(t, c)$ of the equation

$$u'(t)+\int_0^t [a(t-s)+c]u(s)\,ds=0, \qquad u(0)=1$$

weaker sufficient conditions are found for $\int_0^\infty \sup_{0\leqq c\leqq 1}|u(t, c)|\,dt<\infty$ than were previously known. In particular the assumption $(-1)^k a^{(k)}(t)\geqq 0$, $t>0$, $k=0, 1, 2, \cdots$, is replaced by the assumption a is nonnegative, nonincreasing, convex and $-a'$ is convex for $t>0$.

Key words. Volterra equation, L^1, completely monotone, nonnegative, nonincreasing, convex

AMS(MOS) subject classification. 45

1. Introduction.

Concerning the solution $u=u(t)=u(t, c)$ of the equation

$$u'(t)+\int_0^t [a(t-s)+c]u(s)\,ds=0, \quad t\geqq 0, \quad u(0)=1, \quad \left(' =\frac{d}{dt}\right), \tag{1.1}$$

we prove the following theorem.

THEOREM 1. *Let $a(t)$ satisfy*

$$a\in L^1(0, 1) \text{ is nonnegative, nonincreasing, convex and } -a' \text{ is convex on } (0, \infty);\ 0=a(\infty)<a(0+)\leqq\infty, \tag{1.2}$$

and

$$\int_1^\infty \frac{\log u}{uA(u)}\,du<\infty, \tag{1.3}$$

where $A(u)\equiv\int_0^u a(s)\,ds$. Then

$$\int_0^\infty \sup_{0\leqq c\leqq 1}|u(t, c)|\,dt<\infty. \tag{1.4}$$

Define $\hat{a}(\tau)\equiv\int_0^\infty e^{-i\tau t}a(t)\,dt\equiv\phi(\tau)-i\tau\theta(\tau)$, where the integral exists for $\operatorname{Im}\tau<0$, *$\hat{a}$ is extended by continuity to* $(\operatorname{Im}\tau\leqq 0,\ \tau\neq 0)$ *and $\hat{a}\in C^1(0, \infty)$.*

In [7], (1.4) is proved for the completely monotonic function $a(t)=\int_0^\infty e^{-xt}\,d\alpha(x)$ where it is assumed that the nondecreasing function $\alpha(t)$ $(0\leqq t<\infty)$ also satisfies

$$\int_0^{x_0}\frac{dx}{x\alpha'(x)}<\infty \quad \text{for some } x_0>0. \tag{1.5}$$

The proof depends on the decomposition of u into a completely monotonic term plus an exponentially decaying term as given in [6] and on obtaining certain estimates uniformly in $0\leqq c\leqq 1$.

In our proof of Theorem 1 we use techniques similar to those used in [1] and the following inequalities. Assuming (1.2),

$$2^{-3/2}A(\tau^{-1}) \leqq |\hat{a}(\tau)| \leqq 4A(\tau^{-1}), \qquad \tau > 0, \tag{1.6}$$

$$\frac{1}{5}A_1(\tau^{-1}) \leqq \theta(\tau) \leqq 12A_1(\tau^{-1}), \qquad \tau > 0 \qquad \left(A_1(x) \equiv \int_0^x sa(s)\,ds\right), \tag{1.7}$$

$$|\hat{a}'(\tau)| \leqq 40A_1(\tau^{-1}), \qquad |\hat{a}''(\tau)| \leqq 6000\int_0^{1/\tau} r^2 a(r)\,dr, \qquad \tau > 0 \tag{1.8}$$

(see [1, (4.1), (4.3), (4.2), and (5.3)]),

$$|u(t, c)| \leqq 1, \qquad 0 \leqq t < \infty, \qquad 0 \leqq c \tag{1.9}$$

(see [3, Thm. 2] and [8]. The number $\sqrt{2}$ appears in [3] instead of 1 because of a typographical error). Note that (1.6)-(1.9) all hold without the assumption $-a'$ is convex except for the second inequality in (1.8).

In [1], [4], [5] the inequality analogous to (1.4),

$$\int_0^\infty \sup_{1 \leqq \lambda < \infty} |u_\lambda(t)|\,dt < \infty,$$

is obtained under the assumption (1.2) for the problem

$$u_\lambda'(t) + \lambda \int_0^t [a(t-s)+d]u_\lambda(s)\,ds = 0, \qquad u_\lambda(0) = 1,$$

with d fixed and nonnegative.

For (1.4) to hold it is necessary that $a(t) \notin L^1(0, \infty)$ (see [7, p. 200]) but not sufficient as the completely monotonic function $a(t) = (1-e^{-t})/t$ shows (see [7, § 4]). Clearly, (1.3) implies that $a \notin L^1(0, \infty)$.

The conditions (1.3) and (1.5) are similar. Thus if $\alpha'(x) = (-\log x)^q$ for $0 < x < x_0$, $q > 0$, then $a(t)$ behaves like $t^{-1}\log^q t$ as $t \to \infty$, as the following two calculations show. First, we have

$$t^{-1}\log^q t \int_0^1 e^{-x}\,dx < t^{-1}\int_0^1 e^{-x}\log^q(t/x)\,dx \leqq t^{-1}\int_0^{tx_0} e^{-x}\log^q(t/x)\,dx$$

$$= \int_0^{x_0} e^{-yt}(-\log y)^q\,dy \leqq a(t), \qquad x_0^{-1} < t.$$

Also for $0 < \varepsilon < x_0$, we have

$$\begin{aligned}
a(t) &= \int_0^{x_0} e^{-yt}(-\log y)^q\,dy + \int_{x_0}^\infty e^{-yt}\alpha'(y)\,dy \\
&\leqq t^{-1}\int_0^{tx_0} e^{-x}\log^q(t/x)\,dx + e^{-\varepsilon t}\int_{x_0}^\infty e^{-t(y-\varepsilon)}\alpha'(y)\,dy \\
&\leqq M_1\left[t^{-1}\int_0^{tx_0} e^{-x}(|\log^q t| + |\log^q x|)\,dx + e^{-\varepsilon t}\int_{x_0-\varepsilon}^\infty e^{-tx}\alpha'(x+\varepsilon)\,dx\right] \\
&\leqq M_2\left[t^{-1}\log^q t\int_0^\infty e^{-x}(1+|\log^q x|)\,dx + e^{-\varepsilon t}t\int_{(x_0-\varepsilon)t}^\infty e^{-u}\alpha(u/t+\varepsilon)\,du\right] \\
&\leqq M_3\left[t^{-1}\log^q t + e^{-\varepsilon t}t\int_{x_0-\varepsilon}^\infty e^{-u}\alpha(u+\varepsilon)\,du\right] \\
&\leqq M_4 t^{-1}\log^q t \quad \text{for } t > \max\left\{\frac{1}{x_0}, 1\right\} \qquad (M_1, M_2, M_3, M_4, \text{constant}),
\end{aligned}$$

where the first inequality uses $x = yt$, the second inequality uses $(x+y)^q \leqq 2^q(x^q+y^q)$ for $x, y, q > 0$ and $y = x+\varepsilon$, the third inequality uses integration by parts, the fourth inequality uses the fact α is positive and nondecreasing and $t > 1$, and the last inequality uses the fact that $a \in L^1(0,1)$ if and only if $\int_{x_0}^{\infty} \alpha(x)x^{-2}\,dx < \infty$, and therefore

$$\int_{x_0-\varepsilon}^{\infty} e^{-u}\alpha(u+\varepsilon)\,du = e^{\varepsilon}\int_{x_0}^{\infty} e^{-x}\alpha(x)\,dx < \infty.$$

In this case (1.3) and (1.5) both hold if and only if $q > 1$. Also, $a(t) = \Gamma(p)t^{-p}$ corresponds to $\alpha'(x) = x^{p-1}$, $p > 0$ and (1.3) and (1.5) both hold if and only if $0 < p < 1$. For completely monotonic a, condition (1.5) rules out purely jump functions α, whereas (1.3) does not.

2. Proof of Theorem 1. By [9, Thm. 2] we have $\int_0^{\infty} |u(t,c)|\,dt < \infty$ for $c \geqq 0$. We will prove that

$$\int_0^{\infty} \sup_{0 \leqq c \leqq 1} |u(t,c) - u(t,0)|\,dt < \infty,$$

which implies (1.4) by the triangle inequality. Let $D \equiv D(\tau) \equiv \hat{a}(\tau) + i\tau$, $D(\tau, c) \equiv D - ic\tau^{-1}$. By [1, (4.32)], we have the representation

$$\begin{aligned}
\pi u(t,c) - \pi u(t,0) &= \operatorname{Im}\left\{\frac{1}{t}\int_0^{\infty} e^{i\tau t}\left[\frac{D_\tau(\tau,c)}{D(\tau,c)^2} - \frac{D'}{D^2}\right]d\tau\right\} \\
&= \operatorname{Im}\left\{\frac{1}{t}\int_0^{\infty} e^{i\tau t}\left[\frac{ic\tau^{-2}}{D(\tau,c)^2} + \frac{2ic\tau^{-1}D'}{DD(\tau,c)^2} + \frac{c^2\tau^{-2}D'}{D^2D(\tau,c)^2}\right]d\tau\right\} \qquad (2.1) \\
&\equiv \operatorname{Im}\left\{\frac{1}{t}\left(\int_0^{1/t} + \int_{1/t}^{\varepsilon} + \int_{\varepsilon}^{K} + \int_K^{\infty}\right) e^{i\tau t}[I_1 + I_2 + I_3]\,d\tau\right\}, \qquad t > 0,
\end{aligned}$$

where ε and K are constants that will be defined in the next paragraph.

To estimate the right-hand side of (2.1) we need lower bounds for $|D(\tau,c)|$ (and for $|D| = |D(t,0)|$). We first note that (1.7) and $a \notin L^1(1,\infty)$ imply that, for some $\varepsilon > 0$,

$$2\tau \leqq \tau\theta(\tau), \qquad 0 < \tau \leqq \varepsilon, \qquad (2.2)$$

and then by (1.6) (for $0 < \tau \leqq \varepsilon$, $0 \leqq c \leqq 1$)

$$\begin{aligned}
|D(\tau,c)|^2 &= \phi^2(\tau) + (c\tau^{-1} + \tau\theta(\tau) - \tau)^2 \geqq \phi^2(\tau) + (c\tau^{-1} + \tau\theta(\tau)/2)^2 \\
&\geqq \max\{c^2\tau^{-2}, |\hat{a}(\tau)|^2/4\} \geqq \max\{c^2\tau^{-2}, A^2(\tau^{-1})/32\}.
\end{aligned}$$

That is

$$|D(\tau,c)| \geqq \max\{c\tau^{-1}, A(\tau^{-1})/\sqrt{32}\}, \qquad 0 < \tau \leqq \varepsilon, \quad 0 \leqq c \leqq 1. \qquad (2.3)$$

Also by (1.6) we see that there exists a constant $K > \max\{1, \varepsilon\}$ so that

$$|D(\tau,c)| \geqq \tau - 1, \qquad \tau \geqq K. \qquad (2.4)$$

We will use these estimates with (2.1) to prove that

$$\sup_{0 \leqq c \leqq 1} |u(t,c) - u(t,0)| \leqq f(t), \qquad t > 1/\varepsilon,$$

where $\int_{1/\varepsilon}^{\infty} f(t)\,dt < \infty$. This together with (1.9) will complete the proof. The function f that we use is defined by

$$f(t) \equiv M\left[\frac{1}{t^2} + \frac{1}{tA(t)} + \frac{1}{t}\int_t^{\infty} \frac{du}{uA(u)} + \frac{1}{t^2}\int_{1/\varepsilon}^{t} \frac{du}{A(u)}\right].$$

(Here and for the rest of the paper M denotes a constant whose exact value may change each time it appears.) A simple calculation that uses the Fubini Theorem and (1.3) shows that $\int_{1/\varepsilon}^{\infty} f(t)\,dt < \infty$.

Let $t > 1/\varepsilon$. By (2.3) and (1.8) we have

$$\left|\operatorname{Im}\left\{\frac{1}{t}\int_0^{1/t} e^{i\tau t}[I_1+I_2+I_3]\,d\tau\right\}\right| \leqq \frac{M}{t}\int_0^{1/t}\frac{\tau^{-1}}{A(\tau^{-1})}+\frac{A_1(\tau^{-1})}{A^2(\tau^{-1})}\,d\tau$$
$$\leqq \frac{M}{t}\int_0^{1/t}\frac{\tau^{-1}}{A(\tau^{-1})}\,d\tau$$
$$= \frac{M}{t}\int_t^{\infty}\frac{du}{uA(u)} \leqq f(t).$$

Now we integrate by parts and use (2.3) and (1.8) to obtain

$$\left|\operatorname{Im}\left\{\frac{1}{t}\left\{\int_{1/t}^{\varepsilon} e^{i\tau t}I_1\,d\tau\right\}\right\}\right| = \left|\frac{1}{t^2}\operatorname{Im}\left\{\frac{c\,e^{i\varepsilon t}\varepsilon^{-2}}{D(\varepsilon,c)^2}-\frac{e^{i}t^2c}{D(1/t,c)^2}\right.\right.$$
$$\left.\left.+2\int_{1/t}^{\varepsilon} e^{i\tau t}\left(\frac{\tau^{-3}c}{D(\tau,c)^2}+\frac{c\tau^{-2}D_\tau(\tau,c)}{D(\tau,c)^3}\right)d\tau\right\}\right|$$
$$\leqq \frac{M}{t^2}\left[1+\frac{t}{A(t)}+\int_{1/t}^{\varepsilon}\frac{\tau^{-2}}{A(\tau^{-1})}\,d\tau\right]$$
$$= M\left[\frac{1}{t^2}+\frac{1}{tA(t)}+\frac{1}{t^2}\int_{1/\varepsilon}^{t}\frac{du}{A(u)}\right] \leqq f(t).$$

The terms $-\operatorname{Im}\{1/t\int_{1/t}^{\varepsilon} e^{i\tau t}(I_2+I_3)\,d\tau\}$ are treated in exactly the same way.

Again we integrate by parts, then use $|D(\tau,c)| \geqq \phi(\tau) \geqq m > 0$ (m constant), $\varepsilon \leqq \tau \leqq K$, and (1.8) to obtain

$$\left|\operatorname{Im}\left\{\frac{1}{t}\int_{\varepsilon}^{K} e^{i\tau t}I_1\,d\tau\right\}\right| = \left|\frac{1}{t^2}\operatorname{Im}\left\{\frac{c\,e^{iKt}K^{-2}}{D(K,c)^2}-\frac{c\,e^{i\varepsilon t}\varepsilon^{-2}}{D(\varepsilon,c)^2}\right.\right.$$
$$\left.\left.+2\int_{\varepsilon}^{K} e^{i\tau t}\left(\frac{\tau^{-3}c}{D(\tau,c)^2}+\frac{c\tau^{-2}D_\tau(\tau,c)}{D(\tau,c)^3}\right)d\tau\right\}\right|$$
$$\leqq \frac{M}{t^2} \leqq f(t).$$

The terms $-\operatorname{Im}\{1/t\int_{\varepsilon}^{K} e^{i\tau t}(I_2+I_3)\,d\tau\}$ are also treated in this way.

Finally we integrate by parts and use (2.4) and (1.8) to obtain

$$\left|\frac{1}{t}\operatorname{Im}\left\{\int_K^{\infty} e^{i\tau t}I_1\,d\tau\right\}\right| \leqq \frac{M}{t^2}+\frac{M}{t^2}\int_K^{\infty}\frac{\tau^{-3}}{(\tau-1)^2}+\frac{\tau^{-2}}{(\tau-1)^3}\,d\tau$$
$$\leqq \frac{M}{t^2} \leqq f(t).$$

The terms $\operatorname{Im}\{1/t\int_K^{\infty} e^{i\tau t}(I_2+I_3)\,d\tau\}$ are treated in this way also. This completes the proof.

A LOTKA–McKENDRICK MODEL FOR A POPULATION STRUCTURED BY THE LEVEL OF PARASITIC INFECTION*

R. WALDSTÄTTER†, K. P. HADELER†, AND G. GREINER‡

Abstract. A population is subdivided into classes of noninfected and infected individuals. The latter is structured by a real variable measuring the level of infection. Birth, death, and immigration of parasites are modeled by a diffusion operator, birth of hosts by a Lotka–McKendrick birth law. The resulting evolution equation is treated by semigroup methods. The generator is interpreted as a self-adjoint operator with a one-dimensional unbounded perturbation.

Key words. epidemics, one parameter semigroups, self-adjoint operator

AMS(MOS) subject classifications. 92A15, 47A55, 47B25

1. Introduction. The classical epidemic model of Kermack–McKendrick and its extensions (SIR, SIS, etc.), formulated in terms of ordinary differential equations, describes the development of an epidemic disease under three important assumptions. (1) The individuals are classified as infected or noninfected; there is no subdivision of the infected population according to degree of illnesss, degree of infectivity, number of parasites. (2) The disease is transmitted by direct contact between individuals. (3) The parasite population is acquired at one instant.

For many infectious diseases these assumptions are quite appropriate. Many diseases caused by bacteria and viruses that are or at least have been widespread in human populations are transmitted by direct contact; the parasite population is acquired at one instant and is large and unstructured. On the other hand, in diseases caused by macroparasites, in particular helminthic diseases such as onchocerciasis, the parasite population within one host contains few individuals that are acquired at different times and die at different times. Typically in the life cycle of these parasites, there are states in intermediate hosts; these hosts may act as vectors for the larvae of the parasites or the larvae are acquired from the environment.

Anderson and May [1], [2] have designed and investigated models for such diseases with the assumption of a finite number of parasites per host. In [1], [2], and successive papers, a priori assumptions have been made about the distribution of parasites within hosts; moments of such distributions have been introduced into ordinary differential equations which then could be investigated by phase plane methods. In [3] and in subsequent papers, it is assumed that the parasite population within a host is governed by a birth and death process with the killing of the host. With a linearity assumption, this model leads to first-order partial differential equations for generating functions.

If the number of parasites per host is large but fluctuating according to birth, death, or immigration of individual parasites, it appears justified to introduce a continuous variable $x \geqq 0$ measuring the size of the parasite population within a host and to model the development of the host and parasite populations by a diffusion equation.

The typical diffusion approximations for birth and death processes on a half-line $x \geqq 0$ yield differential operators with a singularity at $x = 0$. Then the solutions of the evolution equation tend to infinity for $x \to 0$. In epidemiological terms: all individuals are infected, though many to a very low extent. Such models have at least two disadvantages. (i) There is no well-defined class of "susceptibles" or "noninfected." Such a class can be defined only by arbitrarily prescribing a level of infection below which the infection is considered negligible or tolerable. (ii) The offspring of individuals of any parasite load should be noninfected (so-called vertical transmission is excluded). This requirement is difficult to realize if there is no mass at $x = 0$.

For these reasons in the announcement [5] the following approach has been chosen. There is a class of definitely noninfected individuals and a class of infected individuals that are classified according to the level of infection $x \geqq 0$. In other words, we have introduced a distribution on the half-line $x \geqq 0$ together with a point mass at zero. Furthermore, we assume that the distribution of infected individuals is continuous on $x \geqq 0$.

We assume that, apart from stochastic birth and death of parasites, the hosts acquire parasites according to a conservation law

$$u_t = (\tilde{\phi}(x)u)_x$$

where $\tilde{\phi}$ is a function describing the presence of parasites in the environment and the reaction of the host.

It turns out that with these assumptions the structure of the model is essentially determined.

If we want to interpret the model as a diffusion approximation, the assumptions of a class of noninfected and of a distribution of infected continuous at $x = 0$ may lead to technical difficulties. It seems unavoidable in modeling a population structured by a continuous level x of infection that difficulties of interpretation arise near $x = 0$.

The nucleus of the model is a diffusion equation on a half-line associated with an ordinary differential equation. This situation is similar to diffusion in a long narrow tube connected to a reservoir. Such diffusion and heat conduction problems lead to self-adjoint operator equations in suitable spaces. Hence it is not surprising that methods from the theory of self-adjoint operators are useful for the present model.

A complete discussion of the model should comprise the proof of existence and uniqueness of the initial value problem, the characterization of stationary ("persistent") solutions and their stability, and, furthermore the quantitative behavior of the solutions for some realistic choices of the parameters.

Compared to these goals the results of the present paper are somewhat modest. We show that the linear part of the model, for a constant infection rate, has a solution in some suitable Hilbert space. The mathematical approach to this linear problem seems sufficiently novel and interesting to present here.

In [10] it has been proved that the evolution equations preserve positivity, i.e., nonnegative initial data give rise to nonnegative solutions for $t \geqq 0$.

2. Description of the model. In a first step we describe the variables and parameters of the model. Let t be the chronological time and x the individual parasite load or the level of infection of a host. Let $u(t, x)$ be the density of infected hosts at time t, i.e.,

$$\int_{x_1}^{x_2} u(t, x)\, dx$$

is the number of infected hosts at time t with a level of infection between x_1 and x_2.

Let $U(t)$ be the number of noninfected hosts at time t. Then

$$P(t) = U(t) + \int_0^\infty u(t, x)\, dx \tag{1}$$

is the total population size of hosts at time t. The model assumes a distinction between noninfected hosts and hosts with a very low ($x = 0$) level of infection. It would not be justified to require $U(t) = u(t, 0)$, since U is the size of a compartment and $u(t, 0)$ is one value of a density.

Let the functions $k(x)$ and $l(x)$ describe the stochastic birth and death within the parasite population, $k(x)$ is the diffusion rate, and $l(x)$ is the drift coefficient of the diffusion process governing the change of the level of infection within hosts. The function $k(x)$ is positive; the function $l(x)$ can assume either sign.

The function $\tilde{\varphi}(t, x)$ describes the rate at which new parasites are acquired by hosts with infection level x at time t. Of course $\tilde{\varphi}(t, x) \geqq 0$. We shall assume that $\tilde{\varphi}$ can be represented as $\tilde{\varphi}(t, x) = \varphi(t)\phi(x)$, where the function $\phi(x)$ describes the reaction of the host and the function $\varphi(t)$ depends on the presence of infected vectors. The latter quantity will in turn depend on the average parasite load of the population. Similarly the function $\tilde{\varphi}_0(t)$ is the rate at which noninfected hosts acquire parasites. For reasons of symmetry we write $\tilde{\varphi}_0(t) = \varphi(t) \cdot \phi_0$ with the same $\varphi(t)$ as before. Here $\phi_0 \geqq 0$ is a constant.

The parameter γ enters the boundary condition of the diffusion equation at $x = 0$. It is the rate at which infected hosts at low infection rates lose all their parasites and become noninfected.

So far the parameters mainly describe the changes of the parasite population within the hosts. The dynamics of the host population has yet to be specified. Let $\mu(x) > 0$ be the mortality of an infected host at a level of infection x, and $\mu_0 > 0$ the mortality of noninfected hosts. Let $b(x) \geqq 0$ be the fertility of infected hosts of level x, and $b_0 \geqq 0$ the fertility of noninfected hosts.

Finally, the acquisition (immigration) function φ is not prescribed a priori, but given implicitly as

$$\varphi = \beta f(w),$$

where f is a given function modeling the dynamics of vectors (e.g., insects transmitting the disease), β is a positive contact rate between hosts and vectors, and w is the average parasite load (w could be a more general functional of the population).

As described above, the population is governed by two equations of the form

$$u_t = (k(x)u_x)_x + (l(x)u)_x - \varphi(t)(\phi(x)u)_x - \mu(x)u, \tag{2a}$$

$$U_t = (b_0 - \mu_0)U - \varphi(t)\phi_0 U + \gamma u(t, 0) + \int_0^\infty b(x)u(t, x)\, dx. \tag{2b}$$

These two equations are coupled by the transition parameter γ in (2b) and by a boundary condition of the form

$$a_0 u(t, 0) + a_1 u_x(t, 0) + a_2 U(t) = 0. \tag{3}$$

The coefficients in the boundary condition are uniquely determined up to a common factor. If $\mu(x) \equiv 0$, $\mu_0 = 0$, $b(x) \equiv 0$, $b_0 = 0$ then a conservation law must hold:

$$\frac{d}{dt}\left(U(t) + \int_0^\infty u(t, x)\, dx \right) = 0. \tag{4}$$

If $u(t, x)$ converges sufficiently fast for $x \to \infty$ then (4) implies

$$
\begin{aligned}
&-\varphi(t)\phi_0 U + \gamma u(t,0) + \int_0^\infty [k(x)u_x + l(x)u - \varphi(t)\phi(x)u]_x \, dx \\
&\quad = -\varphi(t)\phi_0 U + \gamma u(t,0) - k(0)u_x - l(0)u + \varphi(t)\phi(0)u \equiv 0.
\end{aligned} \tag{5}
$$

Thus the desired boundary condition at $x = 0$ is

$$
k(0)u_x + l(0)u - \varphi(t)\phi(0)u - \gamma u = -\varphi(t)\phi_0 U. \tag{6}
$$

The most natural boundary condition at $x = \infty$ is

$$
u(t, \cdot) \in L^1(0, \infty). \tag{7}
$$

However the mathematical discussion of the initial value problem is simpler in an appropriate Hilbert space setting. This Hilbert space is specified later.

The initial condition reads

$$
u(0, x) = u_0(x) \quad \text{for } x \geqq 0, \qquad U(0) = U_0. \tag{8}
$$

The transmission law is given by $\varphi = \beta f(w)$, where

$$
w = \frac{\int_0^\infty x u(t, x)\, dx}{U(t) + \int_0^\infty u(t, x)\, dx}. \tag{9}
$$

As announced earlier, we shall restrict our attention to the linear part of the problem, i.e., we consider (2), (6) for a constant φ.

3. Transformation to normal form. For the following arguments we can neglect the biological interpretation of the coefficient functions and introduce a condensed notation by

$$
\begin{aligned}
&\tilde{l} = l - \varphi\phi, \\
&\tilde{b}_0 = b_0 - \mu_0 - \varphi\phi_0, \\
&\kappa = \varphi\phi_0 / k(0), \\
&\sigma = [\gamma - l(0) + \varphi\phi(0)]/k(0).
\end{aligned} \tag{10}
$$

Then the equations read

$$
u_t = (k(x)u_x)_x + (\tilde{l}(x)u)_x - \mu(x)u, \tag{11}
$$

$$
U_t = \tilde{b}_0 U + \int_0^\infty b(x)u(t, x)\, dx + \gamma u(t, 0),
$$

$$
u_x(t, 0) = \sigma u(t, 0) - \kappa U(t). \tag{12}
$$

This system describes an evolution equation in a product space $X = Y \times \mathbb{R}$, where Y is some function space on $\mathbb{R}_+$. The right-hand side describes diffusion on a set $P \cup [0, \infty)$, where P is a compartment. It also contains a Lotka birth law. The diffusion part can be interpreted as a self-adjoint operator in various ways, the Lotka part (as its finite-dimensional analogon, the Leslie matrix) is definitely nonself-adjoint and must be interpreted as a nonself-adjoint perturbation. This concept can be carried through in various ways depending on how the right-hand side is split into a main part and a perturbation. In the following we apply a Liouville transformation to achieve the normal form for the diffusion part.

The Liouville transformation is defined as follows. Define the function

$$
\beta(x) = \int_0^x k(s)^{-1/2}\, ds; \tag{13}
$$

then the new independent variable $y = \beta(x)$. Let $x = \alpha(y)$ be the inverse transformation. Then define the function $\rho = \rho(y)$ by

$$\rho(y) = \exp\left\{-\frac{1}{4}\int_0^x (k_x(s) + 2\tilde{l}(s))k(s)^{-1}\,ds\right\}. \tag{14}$$

Then the new dependent variables are introduced by

$$u(t, x) = \rho(y)w(t, y), \qquad U = \frac{\tilde{\sigma}}{\tilde{\kappa}}W.$$

The function w satisfies

$$w_t(t, y) = w_{yy}(t, y) - p(y)w(t, y), \tag{15}$$

where the function p is defined by

$$p(y) = \frac{1}{4}k_{xx}(x) - \frac{1}{16}\frac{k_x^2(x)}{k(x)} - \frac{1}{2}\tilde{l}_x(x) + \frac{1}{4}\frac{\tilde{l}^2(x)}{k(x)} + \mu(x). \tag{16}$$

Then functions w and u satisfy the equation

$$\int_0^\infty w^2(t, y)\,dy = \int_0^\infty m(x)u^2(t, x)\,dx, \tag{17}$$

with

$$m(x) = k(x)^{-1/2}\exp\left(\frac{1}{2}\int_0^x \frac{k_x(s) + 2\tilde{l}(s)}{k(s)}\,ds\right). \tag{18}$$

The proof is well known and will be reproduced only for the convenience of the reader. In

$$\begin{aligned} u_t &= (ku_x)_x + (\tilde{l}u)_x - \mu u \\ &= ku_{xx} + k_x u_x + \tilde{l}u_x + \tilde{l}_x u - \mu u \end{aligned}$$

insert

$$u_x = u_y\beta_x, \qquad u_{xx} = u_{yy}\beta_x^2 + u_y\beta_{xx}$$

to obtain

$$u_t = k\beta_x^2 u_{yy} + (k_x\beta_x + k\beta_{xx} + \tilde{l}\beta_x)u_y + (\tilde{l}_x - \mu)u,$$

and then

$$u = \rho w, \quad u_y = \rho w_y + \rho_y w, \quad u_{yy} = \rho w_{yy} + 2\rho_y w_y + \rho_{yy} w$$

which gives

$$\begin{aligned} w_t = k\beta_x^2 w_{yy} &+ \left(k\beta_x^2 2\frac{\rho_y}{\rho} + k_x\beta_x + k\beta_{xx} + \tilde{l}\beta_x\right)w_y \\ &+ \left(k\beta_x^2\frac{\rho_{yy}}{\rho} + k_x\beta_x\frac{\rho_y}{\rho} + k\beta_{xx}\frac{\rho_y}{\rho} + \tilde{l}\beta_x\frac{\rho_y}{\rho} + \tilde{l}_x - \mu\right)w. \end{aligned}$$

The special choice of β produces $\beta_x = k^{-1/2}$, $\beta_{xx} = -\frac{1}{2}k^{-3/2}k_x$, and thus

$$\begin{aligned} w_t = w_{yy} &+ \left(2\frac{\rho_y}{\rho} + \frac{1}{2}k^{-1/2}k_x + \tilde{l}k^{-1/2}\right)w_y \\ &+ \left(\frac{\rho_{yy}}{\rho} + \frac{1}{2}k^{-1/2}k_x\frac{\rho_y}{\rho} + \tilde{l}k^{-1/2}\frac{\rho_y}{\rho} + \tilde{l}_x - \mu\right)w. \end{aligned}$$

The special choice of ρ annihilates the coefficient of the first derivative and produces the potential p given in (16).

Define the new coefficients

$$\tilde{b}(y) = b(\alpha(y)\rho(y))\sqrt{k(\alpha(y))}, \tag{19}$$

$$\tilde{\sigma} = \sigma\sqrt{k(0)} + \frac{1}{4}\frac{k_x(0)}{\sqrt{k(0)}} + \frac{1}{2}\frac{\tilde{l}(0)}{\sqrt{k(0)}}, \tag{20}$$

$$\tilde{\kappa} = \kappa\sqrt{k(0)}. \tag{21}$$

We write again u instead of w. Then equations (2) and (6) assume the form

$$u_t = u_{yy} - p(y)u, \tag{22a}$$

$$\begin{aligned} U_t &= \tilde{b}_0 U + \frac{\tilde{\kappa}}{\tilde{\sigma}}\int_0^\infty \tilde{b}(y)u(t,y)\,dy + \frac{\tilde{\kappa}}{\tilde{\sigma}}\gamma u(t,0) \\ &= \tilde{\sigma}(u(t,0) - U(t)) + (\tilde{b}_0 + \tilde{\sigma})U(t) \\ &\quad + \frac{\tilde{\kappa}}{\tilde{\sigma}}\int_0^\infty \tilde{b}(y)u(t,y)\,dy + \left(\frac{\tilde{\kappa}}{\tilde{\sigma}}\gamma - \tilde{\sigma}\right)u(t,0), \end{aligned} \tag{22b}$$

$$u_y(t,0) = \tilde{\sigma}(u(t,0) - U(t)). \tag{23}$$

We have shown the following proposition.

PROPOSITION 1. *There is a one-to-one correspondence between the solutions of* (11), (12) *and* (22), (23). *If the solution of* (11), (12) *is in* $L^2_m(0,\infty)$, *then the solution of* (22), (23) *is in* $L^2(0,\infty)$.

4. Existence of solutions. Define the Hilbert space $X = L^2(0,\infty)\times\mathbb{C}$ with the inner product

$$\left\langle \begin{pmatrix} u \\ U \end{pmatrix}, \begin{pmatrix} v \\ V \end{pmatrix} \right\rangle = \int_0^\infty u\bar{v}\,dy + U\bar{V}. \tag{24}$$

In X define the operator L by

$$L\begin{pmatrix} u \\ U \end{pmatrix} = \begin{pmatrix} u'' - pu \\ \tilde{\sigma}u(0) - \tilde{\sigma}U \end{pmatrix} \tag{25}$$

with domain

$$D(L) = \left\{ \begin{pmatrix} u \\ U \end{pmatrix} \in X;\ u \in C_0^\infty(\mathbb{R}_+),\ u'(0) = \tilde{\sigma}(u(0) - U) \right\}. \tag{26}$$

Of course $D(L)$ is dense in X. We easily verify that L is symmetric and that the following identity holds:

$$\left\langle L\begin{pmatrix} u \\ U \end{pmatrix}, \begin{pmatrix} u \\ U \end{pmatrix} \right\rangle = -\tilde{\sigma}|u(0) - U|^2 - \int_0^\infty |u'|^2\,dy - \int_0^\infty p|u|^2\,dy. \tag{27}$$

Here is the appropriate place to introduce the qualitative properties that we require for the coefficients. We assume that there is a real constant c_0 such that

$$-k''(y) \leqq c_0, \quad k'^2(y)/k(y) \leqq c_0, \quad \tilde{l}'(y) \leqq c_0 \quad \text{for all } y \geqq 0. \tag{28}$$

Then there is a constant c such that

$$p(y) \geqq c \quad \text{for all } y \geqq 0. \tag{29}$$

We also assume that $\tilde{\sigma}$ is nonnegative, i.e.,

$$\tilde{\sigma}\sqrt{k(0)} = \gamma - \tfrac{1}{2}(l(0) - \varphi\phi(0)) + \tfrac{1}{4}k'(0) \geqq 0. \tag{30}$$

Hence the operator L is bounded above with constant c. Finally we assume $\tilde{b} \in L^2(0, \infty)$.

PROPOSITION 2. *The operator L is essentially self-adjoint.*

In the proof we use the following results ([9, II, 182, 184]).

THEOREM A. *Let H be a complex Hilbert space and A with $D(A)$ a symmetric operator that is strictly positive definite. Then the following are equivalent*:

(i) *A is essentially self-adjoint*;

(ii) $\operatorname{im}(A)$ *is dense*;

(iii) $\ker(A^*) = \{0\}$;

(iv) *A has exactly one self-adjoint extension bounded below.*

THEOREM B. *Let $u \in L^1(\mathbb{R}^n)_{\mathrm{loc}}$ such that $\Delta u \in L^1(\mathbb{R}^n)_{\mathrm{loc}}$ in the distributional sense. Define* $\operatorname{sgn} u \in L^\infty$ *by*

$$(\operatorname{sgn} u)(x) = \begin{cases} 0 & \text{if } u(x) = 0, \\ \overline{u(x)} \cdot |u(x)|^{-1} & \text{if } u(x) \neq 0. \end{cases}$$

Then, in the distributional sense,

$$\Delta|u| \geqq \operatorname{Re}[(\operatorname{sgn} u)\, \Delta u].$$

Proof of Proposition 2. The expressions φ, ϕ, l used in this proof have not the same meaning as in (2).

Define the functional l on $C_0^\infty(\mathbb{R}) \times \mathbb{C}$ by

$$l(\varphi, \phi) = \varphi'(0) - \tilde{\sigma}(\varphi(0) - \phi). \tag{31}$$

Define $\tilde{L} = L - (1-c)I$, $D(\tilde{L}) = D(L)$. Then $\tilde{L}$ is strictly negative. In view of Theorem A it is sufficient to show $\ker(\tilde{L}^*) = \{0\}$. Thus suppose $(u, U) \in X$ such that $\langle \tilde{L}(\varphi, \phi), (u, U)\rangle_{\mathbb{R}_+} = 0$ for all $(\varphi, \phi) \in D(\tilde{L})$.

Choose any fixed $(\varphi_1, \phi_1) \in C_0^\infty(\mathbb{R}) \times \mathbb{C}$ such that $l(\varphi_1, \phi_1) = 1$. For $(\varphi, \phi) \in C_0^\infty(\mathbb{R}) \times \mathbb{C}$ define

$$(\psi, \Psi) = (\varphi, \phi) - l(\varphi, \phi) \cdot (\varphi_1, \phi_1). \tag{32}$$

Then, trivially

$$(\varphi, \phi) = (\psi, \Psi) + l(\varphi, \phi) \cdot (\varphi_1, \phi_1),$$

and

$$(\psi, \Psi)|_{\mathbb{R}_+} \in D(\tilde{L}).$$

Hence

$$\langle \tilde{L}(\psi, \Psi)|_{\mathbb{R}_+}, (u, U)\rangle_{\mathbb{R}_+} = 0.$$

On the other hand,

$$\langle \tilde{L}(\psi, \Psi)_{\mathbb{R}_+}, (u, U)\rangle_{\mathbb{R}_+} = l(\varphi, \phi) \cdot \xi, \tag{33}$$

where

$$\xi = \langle \tilde{L}(\varphi_1, \phi_1)|_{\mathbb{R}_+}, (u, U)\rangle_{\mathbb{R}_+} \tag{34}$$

does not depend on (φ, ϕ).

Now extend the functions u and p to all of $\mathbb{R}$ by defining $u=0$ and $p=c-1$ for $x<0$. Then

$$\langle\varphi''-(p+1-c)\varphi, u\rangle_{\mathbb{R}}+\tilde{\sigma}\varphi(0)\bar{U}-(\tilde{\sigma}+1-c)\phi\bar{U}=(\varphi'(0)-\tilde{\sigma}\varphi(0)+\tilde{\sigma}\phi)\xi. \tag{35}$$

Now derivatives are taken in the sense of distributions. Then (35) can be written in the form

$$\langle\varphi, u''-(p+1-c)u+\tilde{\sigma}\bar{U}\delta_0+\xi\delta_0'+\tilde{\sigma}\xi\delta_0\rangle_{\mathbb{R}}=\phi((\tilde{\sigma}+1-c)\bar{U}+\tilde{\sigma}\xi) \tag{36}$$

where, as usual, $\delta_0\varphi=\varphi(0)$, $\delta_0'\varphi=-\varphi'(0)$.

Hence, in the sense of distributions, the following two equations hold:

$$u''-(p+1-c)u+\tilde{\sigma}U\delta_0+\xi\delta_0'+\tilde{\sigma}\xi\delta_0=0, \tag{37a}$$

$$(\tilde{\sigma}+1-c)\bar{U}+\tilde{\sigma}\xi=0, \tag{37b}$$

or, replacing $\bar{U}$ from the second equation,

$$u''-(p+1-c)u+\xi\delta_0'+\frac{\tilde{\sigma}(1-c)}{\tilde{\sigma}+1+c}\xi\delta_0=0. \tag{38}$$

Now define

$$\nu(x)=\max(x, 0) \tag{39}$$

and define its derivatives (in the sense of distributions) $H(x)=\nu'(x)$ (the Heaviside function), $H'(x)=\nu''(x)=\delta_0(x)$, and $H''(x)=\delta_0'(x)$.

Then (38) reads

$$u''-(p+1-c)u+\xi H''+\hat{\sigma}\xi\nu''=0, \tag{40}$$

where

$$\hat{\sigma}=\frac{\tilde{\sigma}(1-c)}{\tilde{\sigma}+1-c} \tag{41}$$

or

$$(u+h)''-(p+1-c)u=0, \tag{42}$$

where the function h is defined as

$$h(x)=\xi H(x)+\hat{\sigma}\xi\nu(x)-\xi(x\hat{\sigma}+1). \tag{43}$$

Then $h(x)=0$ for $x\geqq 0$.

Since the functions p and u are both in $L^2(\mathbb{R})_{\text{loc}}$, the function $\Delta(u+h)=(u+h)''$ is in $L^1(\mathbb{R})_{\text{loc}}$. Hence Kato's inequality (Theorem B) can be applied:

$$\begin{aligned}0&=\operatorname{sgn}(\overline{u+h})[(u+h)''-(p+1-c)u]\\&\leqq|u+h|''-\operatorname{sgn}(\overline{u+h})(p+1-c)(u+h)+\operatorname{sgn}(\overline{u+h})(p+1-c)h,\end{aligned}$$

since $h=0$ for $x\geqq 0$ and $p=c-1$ for $x\leqq 0$,

$$\begin{aligned}0&\leqq|u+h|''-(p+1-c)|u+h|\\&\leqq|u+h|''-|u+h|,\end{aligned}$$

i.e.,

$$(I-\Delta)|u+h|\leqq 0. \tag{44}$$

Since $u \in L^2(\mathbb{R})$ and h is of polynomial growth the function $|u+h|$ is a tempered distribution (i.e., a continuous linear functional on the Schwarz space $\mathcal{S}(\mathbb{R})$). The map $I-\Delta$ is a bijection on $\mathcal{S}(\mathbb{R})$ with inverse given by

$$(I-\Delta)^{-1}f(x)=\frac{1}{2}\int_{-\infty}^{\infty} e^{-|x-y|}f(y)\,dy \quad \text{for } f\in\mathcal{S}(\mathbb{R}).$$

It follows that $(I-\Delta)^{-1}$ is positive on $\mathcal{S}(\mathbb{R})'$; hence (44) implies $|u+h|\leqq 0$. Thus $u+h=0$. On the other hand, by definition, $h=0$ for $x\geqq 0$ and $u=0$ for $x<0$, and thus $u=0$, $h=0$. Consequently also $\xi=0$ and $U=0$. Thus $(u, U)=0$ as desired. Proposition 2 is proved.

By definition the closure $\bar{L}$ of L is a self-adjoint operator. Trivially also $\bar{L}$ has the upper bound zero. By the spectral mapping theory $\|(\mu I-\bar{L})^{-1}\|\leqq \mu^{-1}$ for $\mu>0$. In view of the Hille-Yosida Theorem the operator $\bar{L}$ is a generator of a contractive C_0-*semigroup* $T(t)$, $t\geqq 0$.

From [9, Thm. X. 52], it follows immediately that the semigroup is holomorphic of angle $\pi/2$.

Define the operator L_1 with $D(L_1)=D(L)$ and

$$L_1\begin{pmatrix} u \\ U \end{pmatrix}=\begin{pmatrix} 0 \\ (\tilde{b}_0+\tilde{\sigma})U+\frac{\tilde{\kappa}}{\tilde{\sigma}}\int_0^{\infty}\tilde{b}(y)u(y)\,dy+\left(\frac{\tilde{\kappa}}{\tilde{\sigma}}\gamma-\tilde{\sigma}\right)u(0) \end{pmatrix}. \tag{45}$$

PROPOSITION 3. *The operator L_1 is L-bounded with L-bound* 0.

Proof (cf. [6, IV., Ex. 1.8]). Let $u\in C^2(\mathbb{R}_+)$. Then for any x, $y\geqq 0$ and $r>0$ the following equality trivially holds:

$$u(x)=\frac{r+y-x}{r}u(y)+\frac{x-y}{r}u(y+r)+\frac{1}{r}\int_y^{y+r}\int_y^x\int_z^s u''(\tau)\,d\tau\,ds\,dz. \tag{46}$$

Choose a, b such that $b\geqq a\geqq 0$, $b-a=r>0$. Assume $a\leqq x$, $y\leqq b$. Then $|y-x|\leqq r$ and thus

$$\begin{aligned} |u(x)| &\leqq 2|u(y)|+|u(y+r)|+\frac{1}{r}\left|\int_y^{y+r}\int_y^x\int_z^s u''(\tau)\,d\tau\,ds\,dz\right| \\ &\leqq 2|u(y)|+|u(y+r)|+\frac{1}{r}\left|\int_y^{y+r}\int_y^x\int_z^s [u''(\tau)-p(\tau)u(\tau)]\,d\tau\,ds\,dz\right| \\ &\quad +\frac{1}{r}\left|\int_y^{y+r}\int_y^x\int_z^s p(\tau)u(\tau)\,d\tau\,ds\,dz\right|. \end{aligned} \tag{47}$$

Now integrate over y from a to b and apply the Cauchy-Schwarz inequality

$$r|u(x)|\leqq 3\sqrt{r}\|u\|+r^2\sqrt{2r}\|u''-pu\|+r^2\left(\int_a^{b+r}p^2(s)\,ds\right)^{1/2}\|u\|. \tag{48}$$

Hence

$$|u(x)|\leqq\left[\frac{3}{\sqrt{r}}+r\left(\int_a^{b+r}p^2(s)\,ds\right)^{1/2}\right]\|u\|+r\sqrt{2r}\|u''-pu\|.$$

In particular, for $x=0$

$$|u(0)|\leqq c_1\|u\|+c_2\|u''-pu\|, \tag{49}$$

where

$$c_1 = \frac{3}{\sqrt{r}} + r\left(\int_0^{2r} p^2(s)\,ds\right)^{1/2}, \qquad c_2 = r^2\sqrt{2r}. \tag{50}$$

Of course c_2 can be made arbitrarily small.

Since $\tilde{b} \in L^2(0,\infty)$, we have

$$\left|\int_0^{\infty} \tilde{b}(x)u(x)\,dx\right| \leqq \|\tilde{b}\| \cdot \|u\|. \tag{51}$$

Hence for the operator L_1 the following inequality holds:

$$\left\|L_1\begin{pmatrix} u \\ U \end{pmatrix}\right\| \leqq (\tilde{b}_0 + \tilde{\sigma})|U| + \left|\frac{\tilde{\kappa}}{\tilde{\sigma}}\gamma - \tilde{\sigma}\right|\{c_1\|u\| + c_2\|u'' - pu\|\} + \left|\frac{\tilde{\kappa}}{\tilde{\sigma}}\right| \cdot \|\tilde{b}\| \cdot \|u\|. \tag{52}$$

Define

$$\begin{aligned} \alpha &= 2\max\left\{b_0 + \tilde{\sigma}, \left|\frac{\tilde{\kappa}}{\tilde{\sigma}}\gamma - \tilde{\sigma}\right| c_1 + \left|\frac{\tilde{\kappa}}{\tilde{\sigma}}\right| \cdot \|\tilde{b}\|\right\}, \\ \beta &= 2\left|\frac{\tilde{\kappa}}{\tilde{\sigma}} - \tilde{\sigma}\right| c_2. \end{aligned} \tag{53}$$

Then

$$\left\|L_1\begin{pmatrix} u \\ U \end{pmatrix}\right\| \leqq \alpha\left\|\begin{pmatrix} u \\ U \end{pmatrix}\right\| + \beta\left\|L\begin{pmatrix} u \\ U \end{pmatrix}\right\|. \tag{54}$$

Since β can be made arbitrarily small, the operator L_1 is L-bounded with L-bound 0.

Now we can define the extension $\bar{L}_1$ of L_1 from $D(L)$ to $D(\bar{L})$. Assume $(u, U) \in D(\bar{L})$ and let $(u_n, U_n) \in D(L)$ be a sequence with $(u_n, U_n) \to (u, U)$. Then, in view of (54), the sequence $L_1(u_n, U_n)$ is a Cauchy sequence. Its limit is defined as $\bar{L}_1(u, U)$. Trivially this definition is independent of the choice of the sequence. Hence the operator $\bar{L}_1$ with domain $D(\bar{L})$ is defined. Finally define the operator A with $D(A) = D(\bar{L})$ by $A = \bar{L} + \bar{L}_1$.

For the last step of the existence proof we use the following two theorems ([6, p. 497 ff], [8, p. 8]; see also [7]).

THEOREM C. *Let $\bar{L}$ be the generator of a quasibounded holomorphic semigroup and let $\bar{L}_1$ be an $\bar{L}$-bounded operator with $\bar{L}$-bound 0. Then $\bar{L} + \bar{L}_1$ is the generator of a quasibounded holomorphic semigroup.*

THEOREM D. *Let A with domain $D(A)$ be the generator of a holomorphic semigroup $T(t)$ on a Banach space X. Then for every initial value $u_0 \in X$ the Cauchy problem*

$$\frac{d}{dt}u(t) = Au(t), \qquad u(0) = u_0$$

has a unique solution $u(t)$ which is continuous for $t \geqq 0$, continuously differentiable and $u(t) \in D(A)$ for $t > 0$. This solution is given by $u(t) = T(t)u_0$.

If $u_0 \in D(A)$ then $u \in C^1(\mathbb{R}_+, X)$.

The immediate consequence of these theorems and of Propositions 1, 2, 3 is the following theorem.

THEOREM 4. *The Cauchy problem* (22), (23) *has a unique solution for initial data in $L^2(0,\infty) \times \mathbb{C}$, and the Cauchy problem* (2), (3), *with φ constant, has a unique solution for initial data in $L^2_m(0,\infty) \times \mathbb{C}$, with weight function m given by* (18).

EXISTENCE OF SOLUTIONS OF THE SIMILARITY EQUATIONS FOR FLOATING RECTANGULAR CAVITIES AND DISKS*

CHUNQING LU†¶, NICHOLAS D. KAZARINOFF†,
J. BRYCE McLEOD‡, AND WILLIAM C. TROY§

Abstract. The differential equation $f'''+Q[Aff''-(f')^2]=\beta$ $(0\leqq A<\infty,\ Q>0,\ \beta$ real$)$ $(' = d/dx)$ for $0\leqq x\leqq 1$ with boundary conditions $f(0)=f(1)=0$, $f''(1)=f''(0)+1=0$ is considered. Existence of at least one solution of this two-point boundary-value problem is proved under various hypotheses, and some qualitative properties of this solution are established. The main tools used are shooting arguments and the Schauder fixed point theorem.

Key words. existence, similarity equations, nonlinear two-point boundary-value problem

AMS(MOS) subject classifications. 34B10, 34A, 76

1. Introduction.

We consider the differential equation

$$f'''+Q[Aff''-(f')^2]=\beta \qquad (0\leqq A<\infty,\ Q>0,\ \beta \text{ real}) \tag{1}$$

$(' = d/dx)$ for $0\leqq x\leqq 1$ subject to the boundary conditions

$$f(0)=f(1)=f''(1)=f''(0)+1=0. \tag{2}$$

In this paper we prove existence of at least one solution of the two-point boundary-value problem (TPBVP) (1)-(2) under various hypotheses, and we establish some qualitative properties of this solution. The results are as follows.

THEOREM 1. *For each given $\beta\in(0,1)$ and each $A\geqq 0$ there exists at least one $Q>0$ such that* (1) *subject to the boundary conditions* (2) *having at least one solution.*

THEOREM 2. *If $A=2$, then for each $Q>0$ there exists at least one real number β, with $1>\beta>1-\frac{1}{4}Q$, such that the problem* (1)-(2) *has a nonnegative, convex solution.*

THEOREM 3. *If $A=1$, then for each $Q>0$ there exists at least one real number β with $1>\beta>1-\frac{1}{4}Q$ such that the problem* (1)-(2) *has a nonnegative, convex solution.*

Remarks. If $Q=0$, then for any A (1)-(2) has the unique polynomial solution $x(x-1)(x-2)/6$ corresponding to $\beta=1$. The conclusion of Theorem 1 holds for any $A>0$, although for the model described below $A\geqq 1$.

The TPBVP (1)-(2) arises from a reduction by similarity of the boundary-layer formulation of the Navier-Stokes equations for the distributions of velocity in a low Prandtl number fluid zone in the shape of either a floating rectangular slot or a floating circular disk [2], [3]. Here "floating" means that two opposite surfaces of the rectangular cavity are free surfaces and that the two opposite surfaces of the disk are free. The flow in the low Prandtl number fluid (liquid metal or silicon) is contained by the lateral solid surfaces and surface tension. A temperature gradient caused by radiation heating is assumed to exist on the free surfaces. This gradient from the hot midline (center for the disk) to the cold solid walls (wall) drives the flow. The floating zones are assumed to be in a microgravity environment, as on the space shuttle, so that the force of gravity may be neglected. The physical coordinates (x, y) and velocities (u, v) for the slot are

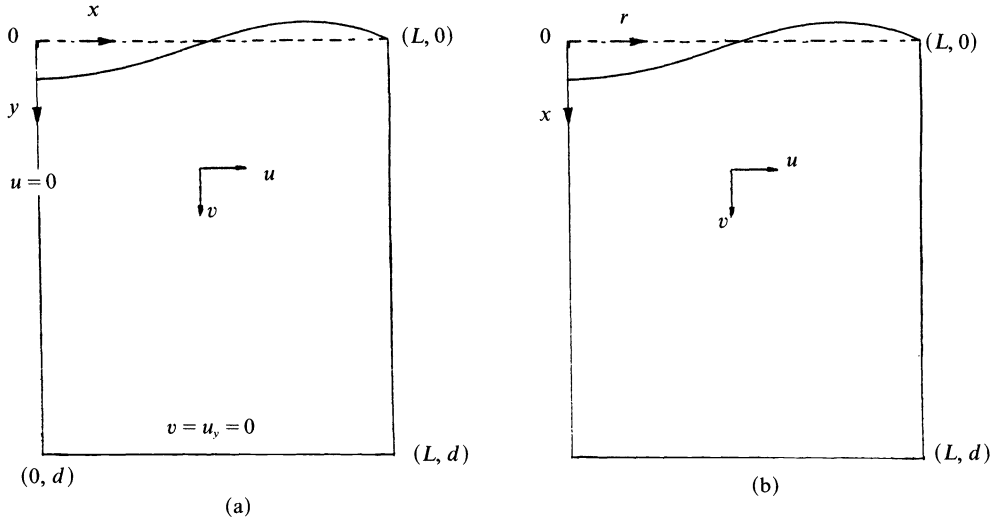

FIG. 1. (a) *The coordinates* (x, y) *and velocity components* (u, v) *for a floating slot. One quarter of a cross-section is shown.* (b) *The coordinates* (x, y) *and velocity components for a floating disk. One quarter of a section made by a bisecting plane is shown. The surface deflection is exaggerated in both figures.*

shown in Fig. 1(a). For the slot, if (a) the temperature distribution varies as $c_0 + g(\eta) \times (x/L)^m$ $(\frac{1}{2} < m < 2)$, (b) the similarity variable is chosen to be $\eta = y/\delta(x)$, and (c) $(u, v) = (c_1 x^{(2m-1)/3} f'(\eta),\ (-c_2 \eta f'(\eta) + c_3 f(\eta)) x^{(m-2)/3})$ (where the c_i are suitably chosen positive constants), then, provided $\delta(x) = \text{const.} \times (x/L)^{(2-m)/3}$, the x-acceleration equation leads to (1)-(2) with $A = (m+1)/(2m-1)$ and $Q = 2(d/L)^3 \operatorname{Re} m(2m-1)/3$. Here Re is the Reynolds number. For convenience we rename η by x in this paper. For the disk, if $\eta = x/d$ and $(u, v) = (-c_1 f, c_2 r f')$, where the c_i are positive constants, then f satisfies (1)-(2) with $A = 2$. The physical coordinates (x, y) and velocities (u, v) for the disk are illustrated in Fig. 1(b).

Numerical solution [2], [3] of the TPBVP (1)-(2) has led to the bifurcation diagrams shown in Figs. 2(a) and (b) for $A = 1$ and $A = 2$, respectively. The references to two-cell flow and three-cell flow in Figs. 2(a) and (b) are related to the number of zeros of $f'(x)$ on $(0, 1)$. If f' has but one zero, then the u-component of velocity in Figs. 1(a) and (b) changes sign once in each half-zone, which corresponds to a flow with one cell in each half-zone. But if f' changes sign twice on $(0, 1)$, then $u = 0$ twice in each half-zone, and there are three flow cells, half of the middle one lying in each zone. We have verified only a small portion of the information represented in these diagrams. For the solutions we have found, f' always has but one zero on $(0, 1)$.

We prove Theorem 1 using a topological method introduced by Hastings in [1]. We prove Theorems 2 and 3 using the Schauder Fixed Point Theorem [4]. The proof of Theorem 1 is given in § 2, and the proofs of Theorem 2 and 3 are given in § 3.

2. Proof of Theorem 1. We divide the proof of Theorem 1 into several lemmas. In the proof, for a given $\beta \in (0, 1)$, we let $f(x; Q, \alpha)$ be the solution of (1) satisfying

$$f(0; Q, \alpha) = f''(0; Q, \alpha) + 1 = 0, \qquad f'(0; Q, \alpha) = \alpha; \tag{3}$$

we define four subsets of points (Q, α) in $R_+^2 = (0, \infty) \times (0, \infty)$ as follows:

$$\begin{aligned} S_1 &= \{(Q, \alpha) \mid f(1; Q, \alpha) > 0\}, \qquad S_2 = \{(Q, \alpha) \mid f(1; Q, \alpha) < 0\} \\ S_3 &= \{(Q, \alpha) \mid f''(1; Q, \alpha) > 0\}, \qquad S_4 = \{(Q, \alpha) \mid f''(1; Q, \alpha) < 0\}. \end{aligned} \tag{4}$$

Our proof is based on Hasting's Lemma 3 in [1] and an additional argument in [1,

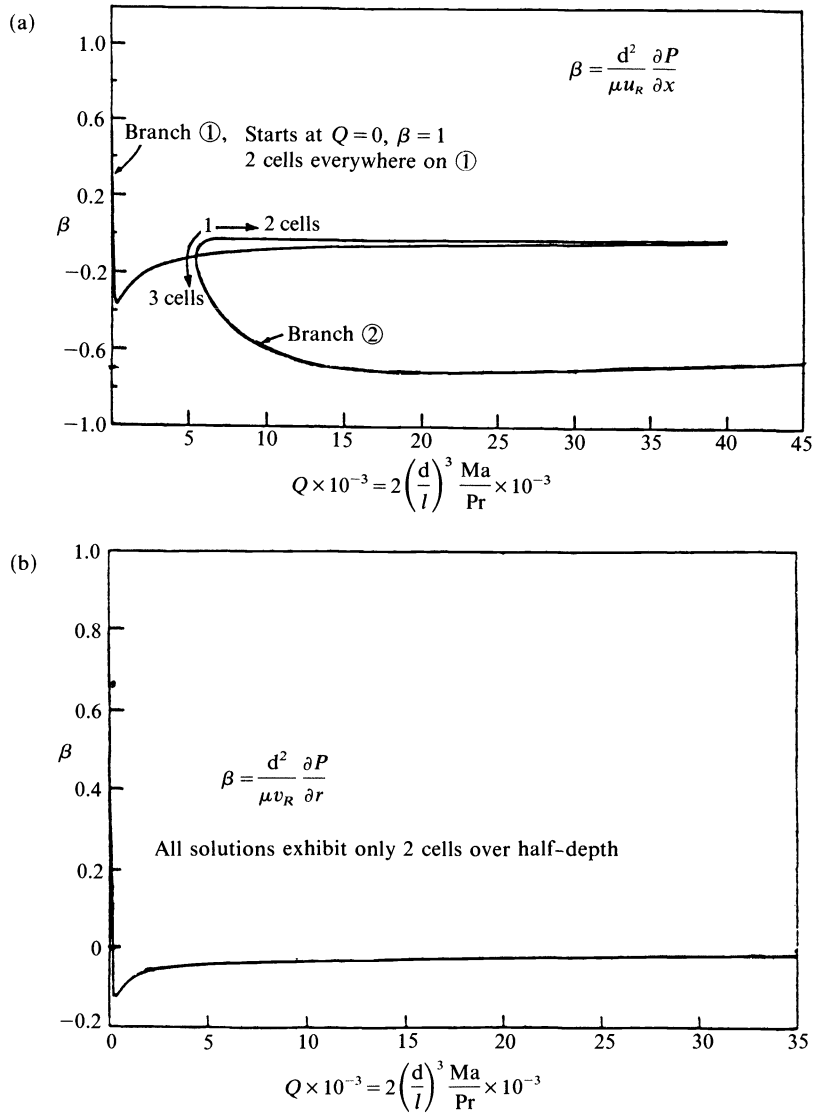

FIG 2. *Bifurcation diagrams for a floating slot (problem* (1)-(2) *with* $A = 1$*) and the floating disk (problem* (1)-(2) *with* $A = 2$*):* β *versus* $Q \times 10^{-3}$. (a) *The slot*; (b) *the disk.*

pp. 106-107]. His lemma is: Suppose S_i $(i = 1, \cdots, 4)$ are open sets of R_+^2 with $S_1 \cap S_2 = \varnothing$ and $S_3 \cap S_4 = \varnothing$. Further, suppose there are components $P_i \subset S_i$ such that $P_1 \cap P_4$, $P_1 \cap P_3$, $P_2 \cap P_3$, and $P_2 \cap P_4$ are not empty. Then $S = S_1 \cup S_2 \cup S_3 \cup S_4 \neq R_+^2$. If $P_2 \cap P_3$ is not empty, then Hastings' lemma applies. However, we are not able to determine whether or not $P_2 \cap P_3 = \varnothing$. If $P_2 \cap P_3 = \varnothing$, we follow Hastings [1, pp. 106-107] to construct and use a nonempty, unbounded, connected subset $W \subset S_2 \cup S_3$ to show that for each $\beta \in (0, 1)$ the complement of S in R_+^2 contains at least one point (Q_0, α_0) that corresponds to a solution of (1)-(2). We observe that several times in the sequel we use the same symbols P_i for a component of S_i and for a subset of that component. For brevity, we denote solutions of (1)-(3) simply by $f(x)$, suppressing their dependence on Q and α.

It is obvious that S_i $(i=1,\cdots,4)$ is open, $S_1 \cap S_2 = \varnothing$, and $S_3 \cap S_4 = \varnothing$. We first prove that S_1 is not empty and that, if $\alpha > 1$, then f is positive everywhere on $(0, 1)$.

LEMMA 1. *If $\alpha > 1$ and $0 < \beta < 1$, then for any $Q > 0$, $(Q, \alpha) \in S_1$ $(S_1 \neq \varnothing)$, $f'(x) \geqq 0$ on $[0, 1]$, and f is monotonic increasing on $(0, 1)$.*

Proof. Choose $\alpha > 1$ and $0 < \beta < 1$. Then $f(0)f''(0) \leqq 0$, and

$$f''' \geqq \beta + Q(f')^2 \geqq \beta > 0 \tag{5}$$

as long as $ff'' \leqq 0$. Integrating (5) twice and using (3), we find that

$$f'(x) \geqq \beta x^2/2 - x + \alpha > \beta x^2/2 + (-x+1) > 0. \tag{6}$$

Consequently, if $\alpha > 1$, then $f' > 0$ so long as $ff'' \leqq 0$. Thus $f'(x) \geqq 0$ for $0 \leqq x \leqq 1$. If not, $f'(x_1) < 0$ for some $x_1 \in (0, 1)$. Then there exists an x_0, the first zero of f' at which $f''(x_0) < 0$ and $f(x_0) > 0$. We claim that $ff'' \leqq 0$ on $(0, x_0)$. If not, since $f > 0$ on $(0, x_0)$ there is an $x_3 \in (0, x_0)$ with $f''(x_3) = 0$ and $f'''(x_3) < 0$, which is impossible. Hence, $ff'' \leqq 0$ on $(0, x_0)$ and $f'(x_0) = 0$, which contradicts (6). Thus, $f'(x) \geqq 0$ on $[0, 1]$, and since $f'(0) = \alpha > 1$, $f(1) > 0$. □

We next prove the following.

LEMMA 2. *Each of S_4, $S_1 \cap S_4$, and $S_2 \cap S_4$ is nonempty.*

Proof. If $Q = 0$, then $f''(1; 0, \alpha) = \beta - 1 < 0$. Let $\alpha^* = \frac{1}{2}(1 + \beta/3)$. Then, if $\alpha > \alpha^*$, $f(1; 0, \alpha) > 0$; and if $\alpha < \alpha^*$, $f(1; 0, \alpha) < 0$. By continuity of solutions of (1)-(3) in Q, the conclusions of Lemma 2 now follow.

Remark. What we have actually proved in Lemma 2 is that there exist components $P_i \subset S_i$ $(i=1,\cdots,4)$ such that $P_1 \cap P_4$ and $P_2 \cap P_4$ are not empty.

In order to show that the union of the four S_i is not all of R_+^2, we use two additional lemmas, Lemmas 3 and 4 below. Finally, as indicated in the Introduction, topological arguments (Hastings [1]) will be used to complete the proof of Theorem 1.

LEMMA 3. *The set $W_2 = \{(Q, \alpha) \mid Q > 0, \alpha > \max\{(6/Q)^{1/3}, (4/Q)^{1/2}\}\} \subset S_3$.*

Proof. By (5) and the hypothesis of the lemma,

$$f''' \geqq \beta + Q(f')^2 > \beta + Q\alpha^2/4$$

as long as $ff'' \leqq 0$ and $f'(x) > \alpha/2$. Then integrations give

$$f''(x) > (\beta + Q\alpha^2/4)x - 1 \tag{7}$$

and

$$f'(x) > \tfrac{1}{2}(\beta + Q\alpha^2/4)x - x + \alpha. \tag{8}$$

Since $\alpha > (6/Q)^{1/3}$, $\frac{1}{2}(\beta + Q\alpha^2/4)x - x + \alpha > 2\alpha/3$ for $x \in [0, 1]$. If $f(x) \geqq 0$ and $f''(x) \leqq 0$ for $x \in [0, 1]$, then $f'(x) > \alpha/2$ for $x \in [0, 1]$. Otherwise there must be an interval $[0, x^*)$ such that $f'(x) > \alpha/2$ on $[0, x^*)$ and $f'(x^*) = \alpha/2$, which is impossible since $\alpha > (6/Q)^{1/3}$, which implies $f'(x) \geqq 2\alpha/3$ on $[0, x^*)$. By (7), however, if $f(x) \geqq 0$ and $f''(x) \leqq 0$ for $x \in [0, 1]$, $f''(1) > (\beta + Q\alpha^2/4) - 1 > \beta > 0$ since $\alpha \geqq (4/Q)^{1/2} > 0$, which is a contradiction. Thus there must exist an $x_* \in (0, 1)$, such that $f''(x_*) > 0$, which implies that $f''(1) > 0$, because wherever $f''(x) = 0$, $f'''(x) > 0$. □

LEMMA 4. *The set $W_1 = \{(Q, \alpha)_i \mid Q > 0, 0 < \alpha < \beta/64\} \subset S_2 \cup S_3$.*

Proof. Let Q and α be given in W_1. If $f(1) < 0$, $(Q, \alpha) \in S_2$, and we are done. We shall therefore consider the following cases.

Case 1. $f(1) \geqq 0$ and there exists an $x^* \in (0, 1)$ such that $f(x^*) < 0$. Then it must be that $f''(1) > 0$. Otherwise, $f''(1) \leqq 0$ and $f(1) \geqq 0$ would imply that there would be an $x_1 \in (x^*, 1)$ such that $f''(x_1) = 0$ and $f'''(x_1) < 0$, which is a contradiction of the differential equation (1) at x_1. Therefore, $(Q, \alpha) \in S_3$.

Case 2. $f(1) \geqq 0$ and $f(x) \geqq 0$ on $[0, 1)$.

If $f''(1) \leqq 0$, then $f''(x) \leqq 0$ for all $x \in [0, 1]$; otherwise there is an x where $f''(x) = 0$ and $f'''(x) < 0$, which is a contradiction as above. Hence $f'''(x) \geqq Q[f'(x)]^2 + \beta \geqq \beta$ for all $x \in [0, 1]$. We consider two subcases.

(i) There is an $x_2 \in (0, \frac{1}{4})$ such that $f''(x_2) = -\frac{1}{4}\beta$. In this subcase,

$$\int_{x_2}^{x_2+1/2} f'''(x)\,dx = f''\left(x_2 + \frac{1}{2}\right) - f''(x_2) \geqq \frac{1}{2}\beta,$$

and hence $f''(x_2 + \frac{1}{2}) > \frac{1}{2}\beta + f''(x_2) = \frac{1}{4}\beta > 0$, which is a contradiction.

(ii) $f''(x) < -\frac{1}{4}\beta$ for all $x \in (0, \frac{1}{4}]$. In this subcase,

$$f'(x) \leqq -\tfrac{1}{4}\beta x + \alpha \qquad (x \in (0, \tfrac{1}{4}])$$

so that

$$f(x) \leqq -(\beta x^2/8) + \alpha x \leqq x(-\beta x/8 + \beta/64).$$

Hence $f(\frac{1}{4}) < 0$, which contradicts the main hypothesis that $f(x) \geqq 0$ on $[0, 1)$. Therefore $f''(1) > 0$, and $(Q, \alpha) \in S_3$.

Case 3. $f(1) < 0$. In this case $(Q, \alpha) \in S_2$. □

An important consequence of Lemma 3 is that S_3 has a nonempty component P_3. Moreover, there is a component P_1 of S_1 such that $P_1 \cap P_3 \neq \varnothing$. To see this, consider the quarter-plane

$$W_0 = \{(Q, \alpha) \mid Q > Q_0, \alpha > 1\}.$$

By Lemma 1, $W_0 \subset S_1$. But $S_1 \cap S_2 = \varnothing$. By Lemma 4, W_0 must contain points in a component P_3 of S_3, and $P_1 \cap P_3 \neq \varnothing$.

In like manner, by Lemma 4, we conclude that W_1 contains at least a subset of a component P_2 of S_2; hence by Lemma 2 $P_2 \cap P_4 \neq \varnothing$.

Using Lemmas 1–4 and the last paragraph, we can sketch portions of the four sets P_i as shown in Fig. 3. If we now define $W = W_1 \cup W_2$, an argument essentially identical to the one in [1, pp. 106–107] completes the proof of Theorem 1. (The reader

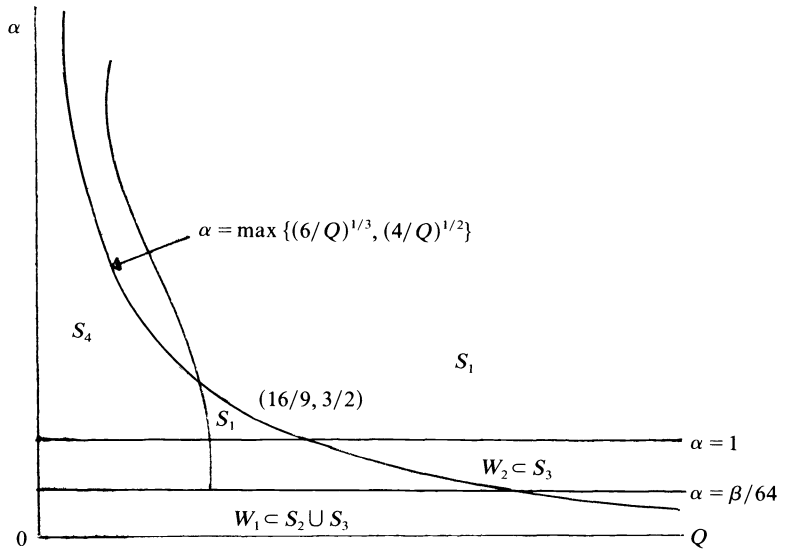

FIG 3. *The sets* S_1, S_3, S_4, *and* $S_2 \cup S_3$.

should identify our W, P_1, P_2, P_3, P_4, S_1, S_2, S_3, and S_4 with Hastings' W, R_1, Q_1, Q_2, R_2, T_1, S_1, S_2, and T_4, respectively.)

3. Proofs of Theorems 2 and 3. We begin with the proof of Theorem 2. Let $Q>0$ be given and fixed. It is sufficient to prove

$$f^{(4)}(x)+2Qff'''=0 \tag{9}$$

has a solution satisfying the boundary conditions (2). Let

$$D=\{f\,|\,f\in C^2[0,1], f(0)=f(1)=0, -1=f''(0)\leqq f''(x)\leqq f''(1)=0, \text{ and } 0\leqq f(x) \text{ on } [0,1]\},$$

where $C^2[0,1]$ is the Banach space containing all real-valued functions f twice continuously differentiable on $[0,1]$ with $\|f\|=\sup(|f|)+\sup(|f'|)+\sup(|f''|)$ over $[0,1]$. Then

(i) D is a closed, bounded, convex subset of $C^2[0,1]$. If we integrate the differential inequality for $f''(x)$ twice and use $f(1)=f(0)=0$, we find that $-1\leqq -x+\alpha\leqq f'(x)\leqq\alpha$ and $0\leqq f(x)\leqq\alpha x\leqq\frac{1}{2}$, where $0<\alpha=f'(0)\leqq\frac{1}{2}$ ($\alpha\geqq 0$ since if $\alpha=f'(0)<0$, $0\leqq f(x)<0$, which is a contradiction).

(ii) D contains nonzero elements; for example, $x(x-1)(x-2)/6\in D$.

We now define a mapping T with domain D as follows. For $f\in D$, $T(f)=f^*$, where f^* satisfies

$$f^{*(iv)}+2Qff^{*'''}=0, \qquad f^*(0)=f^*(1)=f^{*''}(0)+1=f^{*''}(0)=0.$$

We will show that T is well defined, maps D into D, and is compact. Then Schauder's Fixed Point Theorem [4] will apply to T; and, for each $Q>0$, the fixed point will be the desired solution of (1)-(2).

For any given $f\in D$, the unique solution and its derivatives are given by the formulas

$$f^{*'''}(x)=c\,e^{w(x)}, \tag{10}$$

$$f^{*''}(x)=c\int_0^x e^{w(s)}\,ds-1, \tag{11}$$

$$f^{*'}(x)=\int_0^x\left\{\int_0^v c\,e^{w(s)}\,ds-1\right\}dv+\alpha_f, \tag{12}$$

$$f^*(x)=\int_0^x\int_0^u\left\{\int_0^v c\,e^{w(s)}\,ds-1\right\}dv\,du+\alpha_f x, \tag{13}$$

where

$$w(x)=-2Q\int_0^x f(t)\,dt \tag{14}$$

and

$$1<c=f^{*'''}(0)=\left[\int_0^1 e^{w(s)}\,ds\right]^{-1}<\frac{Q}{1-e^{-Q}} \tag{15}$$

by (10) since $\frac{1}{2}\geqq f(x)$, and $\alpha_f=f^{*'}(0)$ is uniquely determined by the condition $f^*(1)=0$, namely

$$\alpha_f=\int_0^1\int_0^u\left\{1-\int_0^v c\,e^{w(s)}\,ds\right\}dv\,du. \tag{16}$$

The above formulas show that $f^* = Tf$ is well defined and continuous for $f \in D$. Since $\frac{1}{2} \geqq f(x) \geqq 0$, $Q/[1-e^{-Q}] \geqq c = f^{*'''}(0) \geqq f^{*'''}(x) \geqq f^{*'''}(1) > 0$ by (10), (14), and (15), and $f^{*'''}$ is decreasing for x increasing. Further, $-1 \leqq f^{*''}(x) \leqq 0$, and $f^{*''}$ is increasing for x increasing. From (16) it follows that $\alpha_f \leqq \frac{1}{2}$. Integrating the inequalities for $f^{*''}$ and using the boundary conditions satisfied by f^*, it follows that $\frac{1}{2} \geqq \alpha_f x \geqq f^*(x) \geqq 0$ and $-1 \leqq -x + \alpha_f \leqq f^{*'}(x) \leqq \alpha_f \leqq \frac{1}{2}$. Hence, $f^* \in D$.

We next show that T is compact, namely, that $\overline{T(K)}$, the closure of $T(K)$, is compact for every closed, bounded subset K of D. Let K be a closed, bounded subset of D, and let $\{f_i\}$ be a sequence of functions in K with images $\{f_i^*\}$ under T. Then $|f_i^{*'''}| \leqq Q/[1-e^{-Q}]$, $|f_i^{*''}| \leqq 1$, $|f_i^{*'}| \leqq 1$, and $|f_i^*| \leqq \frac{1}{2}$ on $[0, 1]$ for each i. Therefore, the f_i^*, $f_i^{*'}$, and $f_i^{*''}$ are equicontinuous on $[0, 1]$. Hence, by the Arzela-Ascoli Theorem, there exist a subsequence $\{f_{n(i)}^*\}$ of $\{f_i\}$ and a $g \in \overline{T(K)}$ such that $\|f_{n(i)}^* - g\| \to 0$ as $i \to \infty$. Thus $\overline{T(K)}$ is compact. Hence, by Schauder's Theorem [4], T is a compact operator from D into D, and there exists a fixed point f_0 of T, which by (10)-(16) is a solution of the TPBVP (1)-(2) for the given $Q > 0$, and for which $\beta = f'''(0) - Q[f_0'(0)]^2 = f'''(1) - Q[f_0'(1)]^2$. By (15), $1 < c$; and, since $\frac{1}{2} \geqq f(x) \geqq 0$, by (10), $f'''(1) \leqq 1$. Moreover $0 < f_0'(0) < \frac{1}{2}$. Therefore, $1 > \beta > 1 - Q/4$. This completes the proof of Theorem 2.

In the proof of Theorem 3, we again use the subset D of $C^2[0, 1]$, with the usual C^2-norm, used in the proof of Theorem 2. Recall that D is closed, bounded, convex, and nonempty, and that, integrating the inequalities for $f''(x)$ and using $f(1) = f(0) = 0$, we obtain the bounds $-1 \leqq f'(x) \leqq \frac{1}{2}$ and $0 \leqq f(x) \leqq \frac{1}{2}x \leqq \frac{1}{2}$. In the case considered $A = 1$ so that the differential equation (1) is: $f''' + Q[ff'' - (f')^2] = \beta$. The map T from D into $C^2[0, 1]$ now is the following: $Tf = f^*$, where f^* is a solution of the linear TPBVP

$$(17) \qquad f^{*(iv)} + Qff^{*'''} - Qf'f^{*''} = 0, \qquad f^*(0) = f^*(1) = f^{*''}(0) + 1 = f^{*''}(1) = 0.$$

Note that $f^{*(iv)}(1) = 0$ for a solution of (17) since $f(1) = f^{*''}(1) = 0$. To show that T is well defined we use a backward shooting method to solve the related second-order TPBVP

$$(18) \qquad H'' + QfH' - Qf'H = 0, \quad H(0) = -1, \quad H(1) = 0.$$

Then we shall set $f^{*''} = H$, and integrate $f^{*''}$ twice, using $f^*(0) = f^*(1) = 0$ to determine $f^{*'}(0)$ so that f^* will lie in D.

Let $H'(1) = \lambda$. We differentiate (18), multiply both sides by the integrating factor $\exp[w(s)]$, where

$$w(s) = -Q \int_s^1 f(t)\, dt,$$

and integrate both sides from one to x, using the boundary condition $H''(1) = 0$ ($f^{*(iv)}(1) = 0$ implies $H''(1) = 0$). The result is

$$(19) \qquad H''(x)\, e^{w(s)} = Q \int_1^x f''(s) H(s)\, e^{w(s)}\, ds.$$

Therefore if $\lambda < 0$, $H(x) > 0$ for x near one, and hence $H''(x) > 0$ near one. Indeed, by (19), $H''(x) > 0$ so long as $H(x) > 0$. Thus (19) and $\lambda < 0$ imply that $H(0) > 0$. Since we want $H(0) = -1$, we proceed further. If $\lambda = 0$, then $H \equiv 0$ (the solution of the backward linear initial value problem is unique). Consequently, we try $\lambda > 0$. Then since $H(1) = 0$, $H(x) < 0$; and, by (19), $H''(x) < 0$ for x close to one. Now we conclude from (19) that $H''(x) < 0$ so long as $H(x) < 0$. Thus $H(0) < 0$. Indeed, $H''(x) < 0$ on $(0, 1)$ implies $H'(x) \geqq \lambda$ on $[0, 1]$. Integrating this inequality from zero to one and

using $H(1)=0$, we obtain $H(0)\leqq -\lambda$. Thus for $\lambda=1$, $H(0)\leqq -1$. Since H is a solution of a linear initial value problem (going backward from one), H is continuous in λ. Therefore, since for $\lambda=0$, $H(0)=0$, and for $\lambda=1$, $H(0)\leqq -1$, there must be a λ_0 on $(0,1]$ such that $H(0)=-1$, as desired. Moreover, for $H'(1)=\lambda_0$, $H'(x)\geqq \lambda_0>0$, since $H''(x)<0$ on $(0,1)$. Thus $H''(x)$, $-H'(x)$, and $H(x)$ are negative on $(0,1)$. Therefore, $H(x)=f^{*''}(x)$ monotonically increases on $[0,1]$ and $-1\leqq H(x)=f^{*''}(x)\leqq 0$ for $x\in[0,1]$. By repeated integration of (19) from one to x, we can choose $f^*(1)=0$ and $f^{*'}(1)$ so that $f^*(0)=0$. Then, integrating $-1\leqq f^{*''}\leqq 0$, we obtain the bounds on $f^{*'}$ and f^* required for f^* to lie in D. Since the TPBVP (18) is linear, the function $H=f^{*''}$ satisfying (18) for $\lambda=\lambda_0$ is unique and depends continuously on f. It follows that $f^*=Tf$ is unique and depends continuously on f. Consequently, T is a continuous map from D into D. That T is compact would follow from uniform bounds on $f^{*'''}$, $f^{*''}$, $f^{*'}$, and f^*. We have established these bounds except for a uniform bound for $|f^{*'''}(x)|$. We have a lower bound for $H'=f^{*'''}$, namely $H'(1)=\lambda_0>0$.

The parameter $Q>0$ is given and fixed. Differentiating (18), we see that $H'''+QfH''-Qf''H=0$; and hence $H'''=Qf''H-QfH\geqq 0$. Therefore, $0\geqq H''(x)\geqq H''(0)$ on $[0,1]$. From (18) we conclude that $H''(0)=-Qf'(0)\geqq -Q/2$; hence $0\geqq H''\geqq -\frac{1}{2}Q$, and $-\frac{1}{2}Qx+c\leqq H'\leqq c$, where $c=H'(0)=f^{*'''}(0)$. Now, $H(0)=-1$ implies that $-\frac{1}{4}Qx^2+cx-1\leqq H\leqq cx-1$. Applying $H(1)=0$, we find that $-\frac{1}{4}Q+c-1\leqq 0$ or $1+c\leqq\frac{1}{4}Q$, and $c-1\geqq 0$. Thus, since $1\geqq\lambda_0>0$, $|H'|=|f^{*'''}|\leqq 1+\frac{1}{4}Q$.

We now can assert that T is compact as a map from D into D. Schauder's Theorem [4] thus applies to T, and there exists a fixed point $f_0\in D$ which satisfies the TPBVP (17). Integrating the differential equation of (17) from zero to x yields

$$f_0'''+Q[f_0f_0''-(f_0')^2]=\beta,$$

where $\beta=f_0'''(0)-Q[f_0'(0)]^2=f_0'''(1)-Q[f_0'(1)]^2$. Since this solution lies in D, $0<f_0'(0)\leqq\frac{1}{2}$. We also proved that $f_0'''(1)=f_0^{*'''}(1)\geqq 1$. Thus $1>\beta>1-\frac{1}{4}Q$. This completes the proof of Theorem 3.

Acknowledgments. We most sincerely thank Professor S. P. Hastings for his interest and suggestions and Professor W. N. Gill for leading us to these problems.

EQUATIONS SURQUADRATIQUES ET DISPARITION DES SAUTS*

FRANCINE DIENER†

Abstract. The following question is answered: Under which conditions on f can the solutions of $\varepsilon x'' = f(t, x, x')$, ε infinitesimal, have jumps, and under which conditions will they never have jumps? To do this a nonstandard approach is used called "la methode du plan d'observabilité," which was introduced in [SIAM J. Math. Anal., 17 (1986), pp. 533-559]. The results are applied to explain the vanishing of a limit cycle and also the disappearance of the solution for some boundary value problems.

Key words. saut, surquadratique, plan d'observabilité, couche limite

AMS(MOS) subject classifications. 34A34, 34E15, 03405

Nous nous interesserons ci-dessous aux solutions $x(t)$ d'une équation différentielle du second ordre singulièrement perturbée

$$\varepsilon x'' = f(t, x, x') \tag{1}$$

où $\varepsilon > 0$ est un nombre fixé infinitésimal et f une fonction interne définie dans $\mathbb{R}^3$ est suffisamment régulière pour que l'équation différentielle possède la propriété d'existence et d'unicité des solutions.

On sait que les solutions de cette équation adoptent alternativement l'un ou l'autre des deux comportements suivants:

—D'une part un comportement qu'on peut qualifier de *lent*, correspondant à des phases pendant lesquelles la vitesse reste limitée et donc au cours desquelles la solution $x(t)$ a une ombre continue $x_0(t)$. Dans ce cas, en tout point t où elle est dérivable, l'ombre satisfait l'équation réduite $f(t, x, x') = 0$, obtenue en remplaçant ε par 0 dans l'équation.

—D'autre part un comportement *quasi-discontinu* correspondant à des phases pendant lesquelles, la vitesse atteignant des valeurs non limitées, la solution "saute" brutalement d'une phase lente à une autre phase lente.

Dans un article récent [3], nous avons montré de quelle façon on peut étudier, pour la plupart des équations (1), les sauts des solutions, leur origine, leur extrémité, leur épaisseur. Dans le présent article, nous nous proposons de préciser quelles conditions doivent être vérifiées par f pour rendre possible la présence de sauts dans les solutions et de quelle façon, lorsque ces conditions ne sont pas remplies, ces sauts peuvent être amenés à disparaître totalement, les solutions ne pouvant plus avoir alors qu'un comportement lent.

Le problème de la disparition des sauts a été rencontré pour la première fois probablement en 1952 par Coddington et Levinson [1] dans l'étude du problème aux limites

$$\varepsilon x'' = -x' - x'^3,$$

$$x(0) = a, \qquad x(1) = b.$$

Ces auteurs observèrent que pour $a \neq b$ ce problème n'a pas de solution, si ε est choisi infinitésimal. Il est facile de voir qu'aucune solution gardant un comportement lent sur tout l'intervalle de temps $[0, 1]$, ne peut convenir (car pour une telle solution on

a $-x'(t)-x'^3(t)\simeq 0$, et donc $x'(t)\simeq 0$, c'est-à-dire $x(t)$ presque constante). L'absence de solution à ce problème aux limites était donc un signe de rareté des sauts pour les solutions de cette équation, ce qui a pu paraître étrange compte tenu des seuls cas bien connus à l'époque, à savoir les cas où f est indépendante de x' ou linéaire en x'.

Cette énigme trouva son explication quelques années plus tard (1960) dans un article de Višik et Liusternik [6] où il est montré que, lorsque f se comporte, en tant que fonction de x', comme une puissance x'^s, pour x' tendant vers l'infini, il est nécessaire que s soit inférieur ou égal à 2 pour que les solutions puissent présenter des sauts.

Nous nous proposons de retrouver ce résultat, et de l'étendre à une classe très générale d'équations (1) (où f ne se comporte pas nécessairement comme une puissance de x'), et surtout d'en donner une interprétation géométrique par l'intermédiaire de la méthode du plan d'observabilité [3]. Nous verrons également le parti qu'on peut tirer d'une bonne connaissance du processus de disparition des sauts dans l'étude de problèmes à un ou plusieurs paramètres.

1. Quelques définitions. Voici quelques définitions, introduites pour la plupart dans [3], qui nous serons utiles pour la suite:

DÉFINITION. Soit $v_0\geqq 0$ limité, et soit $F:[v_0, +\infty[\to\mathbb{R}^+$ une fonction interne, de classe S^0, continuement dérivable et nulle part infinitésimale. On dit que F est le *type de croissance de* f pour les v positifs s'il existe deux fonctions internes $a(t, x)$ et $r(t, x, v)$ continues et de classe S^0 telles que, pour tout t et x limités, on ait

$$f(t, x, v)=a(t, x)F(v)+r(t, x, v) \quad \text{pour tout } v\geqq v_0 \quad \text{et}$$

$$r(t, x, v)/F(v)\simeq 0 \quad \text{pour tout } v \text{ non limité.}$$

La fonction $a(t, x)$ est la *mantisse* de f pour les v positifs.

DÉFINITION. Soit $f(t, x, v)$ une fonction ayant le type de croissance $F(v)$ pour $v\geqq v_0$. On dit que f est *surquadratique* pour les v positifs si on a

$$\int_{v_0}^{+\infty} v\,dv/F(v)<+\infty.$$

Remarque. On définirait de la même façon les type de croissance et mantisse pour les v négatifs ainsi que le fait d'être surquadratique pour les v négatifs.

Exemples. Les équations (1) de la forme $\varepsilon x''=a(t, x)x'+b(t, x)$ (équations quasilinéaires) correspondent à une fonction f ayant pour type de croissance (positif et négatif) $F(v)=v$ (non surquadratique).

Les équations de la forme $\varepsilon x''=a(t, x)x'^2+b(t, x)x'+c(t, x)$ correspondent à une fonction f ayant pour type de croissance (positif et négatif) $F(v)=v^2$ (non surquadratique).

Cependant une fonction f ayant pour type de croissance $F(v)=v^2\log v$ n'est pas non plus surquadratique.

Par contre l'équation $\varepsilon x''=-x'-x'^3$ dont nous avons parlé cidessus, correspond à une fonction surquadratique puisque son type de croissance est $F(v)=v^3$.

Remarque. Dans la suite nous supposerons toujours que l'équation différentielle (1) est définie par une fonction f ayant un type de croissance pour les v positifs ainsi que pour les v négatifs (ces deux types de croissance seront presque toujours identiques dans les exemples). On se limitera également, sauf mention contraite, au cas des vitesses positives, celui des vitesses négatives s'en déduisant facilement.

DÉFINITION. Un instant standard t_0 sera dit *singulier* pour l'équation $\varepsilon x''=f(t, x, x')$ s'il existe un intervalle standard $[x_1, x_2]$, tel que pour tout $x\in[x_1, x_2]$, $a(t_0, x)\simeq 0$.

DÉFINITION. On dit qu'une solution $x(t): I \to \mathbb{R}$ (qu'on supposera toujours limitée) *présente un saut sur l'intervalle* $[t_1, t_2] \subset I$ si, sur cet intervalle, la vitesse $x'(t)$ est non limitée et si $x(t_1) \neq x(t_2)$. Si t_0 est la partie standard commune de t_1 et t_2, on dit aussi que $x(t)$ *présente un saut à l'instant* t_0. Enfin un saut à l'instant t_0 sera dit *singulier* si t_0 est un instant singulier pour l'équation et si l'intervalle standard $[x_1, x_2]$ sur lequel $a(t_0, x) \simeq 0$ rencontre l'intervalle $[x(t_1), x(t_2)]$. Sinon, le saut est dit *régulier.*

2. La géométrie des sauts: les plans d'observabilité. Pour étudier les sauts des solutions d'une équation (1), on pense généralement à un changement d'échelle de temps. En effet un saut étant un passage presque instantané ($t_1 \simeq t_2$) d'une position ($x(t_1)$) à une autre position ($x(t_2)$), il est naturel d'imaginer qu'un changement d'échelle de temps doit permettre, en "étalant" le saut dans le temps, d'en faciliter l'étude. C'est l'idée de départ de la plupart des études classiques [4], [5]. Malheureusement, si les changements de temps auxquels on pense aussitôt, tels que $T = t/\varepsilon$, ou $T = t/\sqrt{\varepsilon}$, se révèlent efficaces pour certains types d'équations (1), comme par exemple lorsque f est indépendante de x' ou linéaire en x', ils ne conviennent pas pour l'étude des sauts pour la plupart des autres équations.

La méthode du plan d'observabilité [2], [3], envisage l'étude des sauts d'un point de vue différent. Il consiste à remplacer l'équation (1) par le champ de vecteurs lent-rapide de $\mathbb{R}^3$

$$\mathcal{V}\begin{cases} t' = 1, \\ x' = v, \\ \varepsilon v' = f(t, x, v), \end{cases}$$

et à étudier les portions de trajectoires de ce champ qui correspondent aux sauts de l'équation initiale. Avec ce point de vue géométrique (Fig. 1) il apparaît aussitôt que pour étudier les sauts, qui n'ont pas d'ombre à l'échelle initiale puisqu'au cours du saut v est non limité, il est naturel de faire un changement d'échelle, de vitesse cette fois. On pose $v = h(V/\varepsilon)$ et on cherche à déterminer h en fonction de f de telle sorte

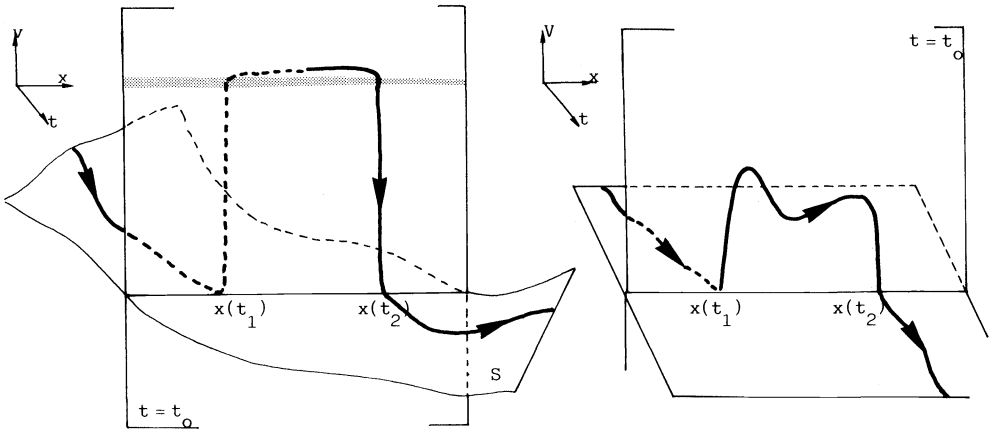

FIG. 1. *Le champ de vecteur* $\mathcal{V}$ *associé à l'équation* (1) *est presque vertical hors du halo de la surface lente S et aussi longtemps que l'ordonnée v reste limitée. On a représenté une trajectoire de* $\mathcal{V}$*: elle présente une portion lente contenue dans le halo de S, deux portions verticales et un saut contenus dans le halo du plan* $t = t_0$ *au cours desquels la trajectoire passe presque instantanément de la valeur* $x(t_1)$ *à la valeur* $x(t_2)$ *avec une vitesse non limitée.*

Après changement d'échelle de vitesse $v = h(V/\varepsilon)$*, le saut reste d'ordonnée limitée. Son ombre est contenue dans le plan d'observabilité* $t = t_0$ *et elle satisfait l'équation* (*).

que le champ obtenu à la nouvelle échelle soit, après division de ses composantes par la quantité $h(V/\varepsilon)$, un champ presque standard intégrable (voir ci-dessous la démonstration du théorème). On constate que si f a pour $v \geqq v_0$ le type de croissance $F(v)$, il suffit de prendre pour h la solution de l'équation différentielle $h' = F(h)/h$ telle que $h(0) = v_0$. A la nouvelle échelle, un saut à l'instant t_0 a pour ombre la courbe, contenue dans le plan $t = t_0$, d'équation

$$(*) \qquad V(x) = V(x_0) + \int_{x_0}^{x} a(t_0, \xi)\, d\xi$$

où $a(t, x)$ est la mantisse de f. Les plans $t = t_0$ dans lesquels viennent se "ranger" les ombres des sauts à l'échelle (x, V) sont les plans d'observabilité des sauts [2].

Notons encore que, pour les sauts singuliers, le plan d'observabilité n'est pas l'échelle adhéquate, puisque, $a(t, x)$ s'annulant pour $t = t_0$, les sauts ont tous pour ombre à cette échelle des droites horizontales $V(x) = V_0$ (Fig. 2). Donc si une trajectoire issue d'un point de coordonnées limitées à l'échelle initiale présente un saut singulier, $V(x)$ reste infinitésimal tout au long du saut. L'examen des trajectoires des plans d'observabilité ne permet donc pas, dans ce cas, de décrire les sauts (origine et extrémité, par exemple) ni même de prouver leur existence.

3. Disparition des sauts.

THÉORÈME. *Soit $f(t, x, v)$ une fonction ayant pour type de croissance pour $v > 0$ la fonction $F(v)$. Supposons $F(v)$ surquadratique et posons $V_0 = \varepsilon \int_0^{+\infty} v\, dv/F(v)$. Alors tout saut $x(t)$ de l'équation différentielle $\varepsilon x'' = f(t, x, x')$ doit satisfaire à la fois*:

(a) $V(x(t)) = V(x_0) + \int_{x_0}^{x(t)} a(t_0, \xi)\, d\xi$,

(b) $V(x(t)) \lesssim V_0$,

où $V(x(t))$ est défini par $x'(t) = h(V(x(t))/\varepsilon)$ avec $h' = F(h)/h$ et $h_0 = v_0$.

COROLLAIRE. *Aucune solution d'une équation différentielle* (1) *pour laquelle f est standard et de type de croissance surquadratique ne peut présenter de saut régulier.*

Preuve du théorème. La preuve s'appuie sur la remarque suivante: l'équation différentielle $h' = F(h)/h$, permettant de déterminer un changement d'échelle $h(w)$ convenable, a des solutions globales, c'est-à-dire définies pour toutes valeurs de la variables w, si et seulement si F n'est pas surquadratique. Au contraire, lorsque F est surquadratique, la solution $h(w)$ de cette équation telle que $h(0) = v_0$ est définie sur l'intervalle $[0, w_0[$ où $w_0 = \int_0^{+\infty} v\, dv/F(v)$ et elle tend vers $+\infty$ quand w tend vers $w_0 = V_0/\varepsilon$.

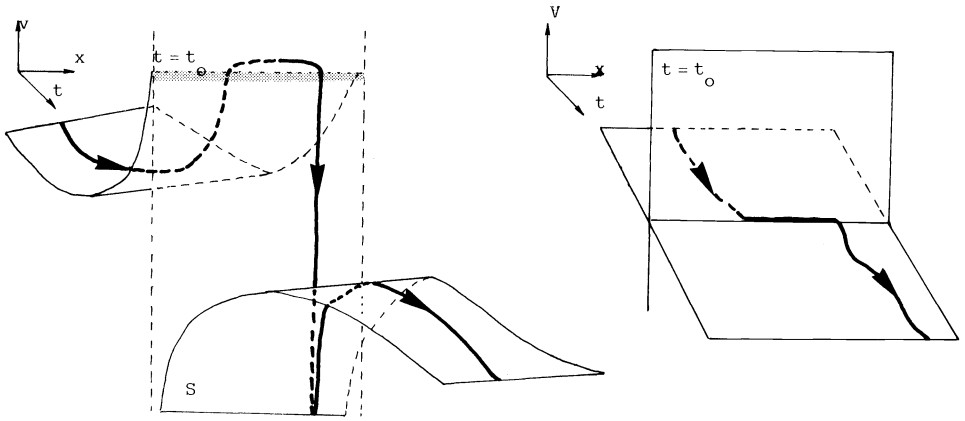

FIG. 2. *Dans le cas d'un saut singulier, la surface S est asymptote au plan $t = t_0$ entre $x(t_1)$ et $x(t_2)$. A l'échelle du plan d'observabilité, le saut a une ordonnée infinitésimale entre ces deux abscisses.*

Effectuons le changement d'échelle $v = h(V/\varepsilon)$. Le champ v se transforme en

$$\begin{cases} t' = 1, \\ x' = h(V/\varepsilon), \\ V' = f(t, x, h(V/\varepsilon))/h'(V/\varepsilon) \end{cases}$$

qui a mêmes trajectoires, lorsque $v(=h(V/\varepsilon))$ est non limité (et donc non nul) que le champ:

$$\tilde{\mathcal{V}} \begin{cases} t' = 1/h(V/\varepsilon), \\ x' = 1, \\ V' = f(t, x, h(V/\varepsilon))/h(V/\varepsilon)h'(V/\varepsilon) \end{cases}$$

qui est presque égal, lorsque v est non limité, au champ standard de composantes $(0, 1, a(t, x))$, en vertu des hypothèses sur f et h. On en déduit, comme dans le cas où f n'est pas surquadratique [3], que les ombres des trajectoires satisfont l'équation (a). De plus, comme h n'est, dans le cas surquadratique, définie que sur l'intervalle $[0, V_0/\varepsilon[$, seules les portions de trajectoires de $\tilde{\mathcal{V}}$ pour lesquelles V reste inférieur à V_0 sont les images de trajectoires du champ initial (Fig. 3). D'où l'inégalité (b).

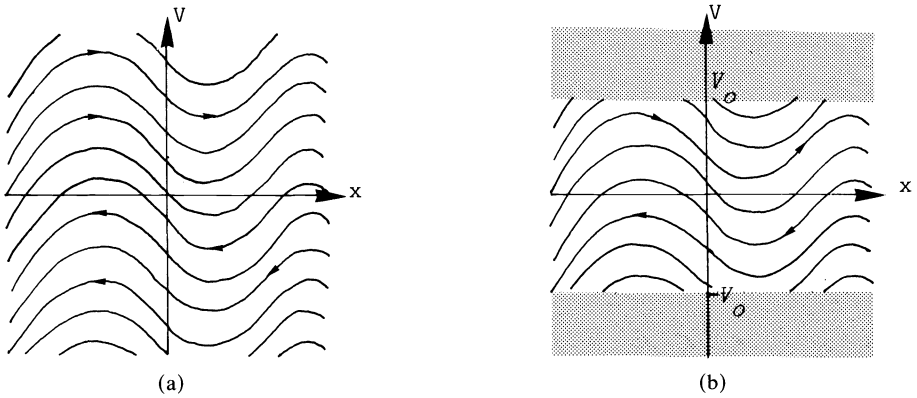

FIG. 3. *Ombres des sauts dans le plan d'observabilité.* (a) *Cas où f n'est pas surquadratique.* (b) *Cas où f est surquadratique* ($V_0 = \varepsilon \int_0^\infty v\, dv/F(v)$).

Preuve du corollaire. C'est une conséquence immédiate du théorème. En effet dans le cas où f est standard, $w_0 = \int_0^{+\infty} vdv/F(v)$ l'est également et donc $V_0 = \varepsilon w_0$ est infinitésimal. De l'inégalité (b) il résulte donc que, à la nouvelle échelle, on a $V(x(t)) \simeq 0$. Or si $x(t)$ est un saut régulier à l'instant t_0, $a(t_0, x)$ reste appréciable (i.e., non infinitésimal), ce qui est impossible compte tenu de l'égalité (a).

Commentaires. (1) Le corollaire ci-dessus pourrait être reformulé en termes plus géométriques de la façon suivante: lorsque f est standard et à type de croissance surquadratique, et si $a(t, x)$ ne s'annule identiquement pour aucune valeur de t, les trajectoires de $\mathcal{V}$ restent, à l'échelle initiale, équivalentes à leur ombre, pourvu que $a(t, x)$ ne s'annulle pas identiquement pour certaines valeurs de t. Ceci est faux si les trajectoires peuvent présenter des sauts car dans ce cas, même si leurs ombres sont verticales à l'échelle initiale, les trajectoires ne sont pas quasi verticales lorsque v est non limité. Dans le cas surquadratique cependant, le corollaire précédent montre que les trajectoires restent quasi verticales même pour des v non limités.

(2) Les résultats ci-dessus ne disent rien sur l'existence éventuelle de sauts singuliers lorsque f est surquadratique. En fait, de tels sauts peuvent fort bien exister, comme l'a montré Howes par exemple [4] aussi bien dans le cas surquadratique que dans le cas contraire. Leur étude complète reste à faire.

(3) Le corollaire ci-dessus est une nouvelle formulation, dans un cas un peu plus général, des résultats de Višik et Liusternik. Mais, comme ceux-ci, il donne de la disparition des sauts, lorsque le type de croissance devient surquadratique, l'impression d'un phénomène discontinu: si le type de croissance n'est pas surquadratique, toutes les trajectoires standard du champ de composantes $(0, 1, a(t, x))$ sont ombres de sauts, s'il le devient, aucune n'est plus l'ombre d'un saut de l'équation initiale. En réalité, la disparition des sauts lorsque f devient surquadratique, est progressive. Mais pour s'en rendre compte, il convient de prendre en considération également certaines équations non standard intermédiaires: plus précisément celles qui sont surquadratiques mais pour lesquelles $w_0 = \int_0^{+\infty} v/F(v)\, dv$ est non limité. L'étude de familles à un paramètre, proposée au paragraphe suivant, illustrera ce mécanisme de disparition progressive.

4. Exemples de bifurcations liés à la disparition des sauts. (a) Considérons la famille d'équations autonomes à un paramètre suivante

$$\varepsilon x'' + (x^2 - 1)x'^{[s]} + x = 0$$

où $x'^{[s]}$ désigne la fonction impaire de x' égale à x'^s quand $x' \geqq 0$ (étudiée dans [2], [3]). Les trajectoires du champ $\mathcal{V}$ associé se projettent, puisque l'équation ne dépend pas du temps, sur celles du champ de vecteurs du plan

$$x' = v,$$
$$\varepsilon v' = (1 - x^2)v^{[s]} - x.$$

Le type de croissance $F_s(x) = v^s$ est surquadratique si et seulement si $s > 2$. Lorsque $s = 1$ (équation de van der Pol) il existe un unique cycle limite vers lequel tendent toutes les trajectoires, à l'exception du point stationnaire $x = v = 0$. Au contraire lorsque s est standard et strictement supérieur à 2, les trajectoires restent, en vertu du commentaire (1) ci-dessus, équivalentes à leurs ombres à l'échelle initiale: il en résulte qu'il ne peut y avoir de cycle limite dans ce cas. Comment et pour quelle valeur du paramètre le cycle disparait-il?

Dans le plan d'observabilité (x, V), où V est défini par $v = h(V/\varepsilon)$ comme précédemment, les sauts, s'ils existent, ont nécessairement pour ombre les courbes d'équation

$$V(x) = V(x_0) + \int_{x_0}^{x} (1 - \xi^2)\, d\xi$$

ou bien encore

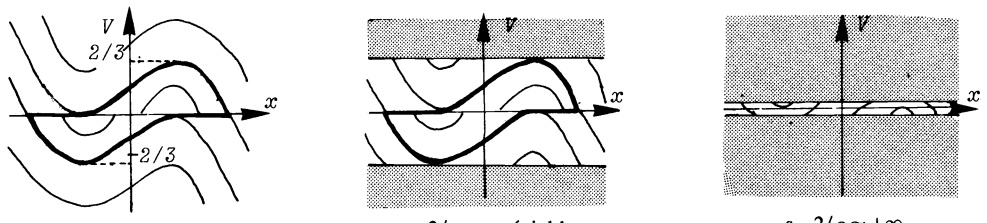
$$V(x) = x - x^3/3 + K, \quad K \text{ constante.}$$

D'autre part, dès que s est supérieur à 2, il convient de ne considérer que les portions de ces courbes dont l'ordonnée ne dépasse pas, en valeur absolue,

$$V_0 = \varepsilon w_0 = \varepsilon \int_{v_0}^{+\infty} v/v^s\, dv = \varepsilon v_0^{2-s}/(s-2).$$

On peut choisir $v_0 = 1$. Le cycle limite, qui doit nécessairement, s'il existe, atteindre la vitesse $V = 2/3$ (et $V = -2/3$) comme l'indique la Fig. 4, n'existe qu'à la condition que $\varepsilon/(s-2) \gg 2/3$; en d'autres termes, il disparaît, en "éclatant" à l'infini, pour une valeur s_0 telle que

$$s_0 \simeq 2 + 3\varepsilon/4.$$



$s-2/\varepsilon \simeq 0$ $s-2/\varepsilon$ appréciable $s-2/\varepsilon \simeq +\infty$

FIG. 4

Mais auparavant, alors que le cycle était un attracteur global (excepté pour le point stationnaire) pour $s \leqq 2$, il existe, dès que $s > 2$ certaines trajectoires qui ne tendent plus vers le cycle mais qui tendent vers l'infini. Le nombre de ces trajectoires augmente progressivement avec s jusqu'à la disparition du cycle.

(b) Le second exemple concerne non plus une bifurcation de portrait de phase mais la disparition de la solution d'un problème aux limites lorsque le type de croissance de l'équation devient surquadratique.

Considérons le problème aux limites suivant:

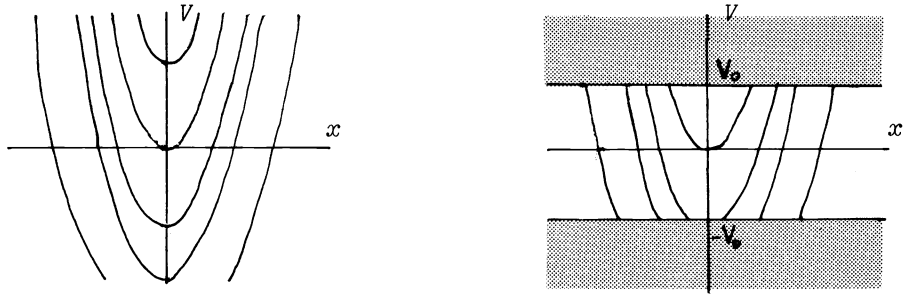
$$\varepsilon x'' = x x'^{[s]},$$
$$x(-1) = a,$$
$$x(1) = b.$$

Comme pour l'exemple historique évoqué en introduction, il est facile de voir qu'aucune solution de l'équation, lente sur tout l'intervalle $[-1, 1]$, ne peut satisfaire à la fois les deux conditions aux limites, sauf éventuellement si $a \simeq b$, car les solutions lentes sont presque constantes (x' nul). Donc lorsque s est standard et strictement supérieur à 2, ce problème ne peut avoir de solutions si $a \neq b$. Par ailleurs des études classiques [5], [4], ou l'examen des sauts dans leur plan d'observabilité, montrent qu'il existe une solution lorsque $s = 1$ et même plus généralement lorsque $0 < s \leqq 2$. Que peut-on dire du problème posé lorsque s est supérieur et équivalent à 2?

Dans le plan d'observabilité (x, V), où $V = h(v/\varepsilon)$ comme précédemment, les sauts, s'ils existent, ont nécessairement pour ombres les courbes d'équation

$$V(x) = V(x_0) + \int_{x_0}^{x} \xi \, d\xi$$

ou bien encore $V(x) = x^2/2 + K$, K constante (Fig. 5). D'autre part, dès que s est



$s \leqq 2$ $s > 2, 0 \ll (s-2)/\varepsilon \ll +\infty$.

FIG. 5

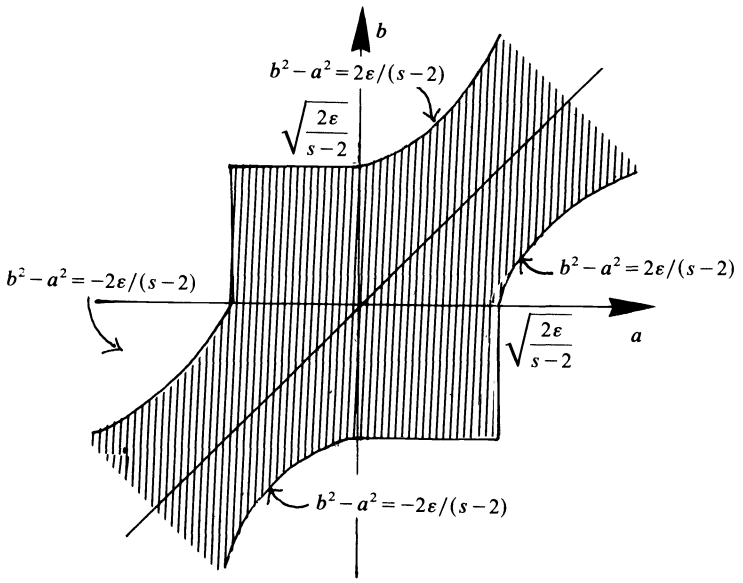


FIG. 6

supérieur à 2, il convient de ne considérer que les portions de courbes dont l'ordonnée ne dépasse pas, en valeur absolue,

$$V_0=\varepsilon w_0=\varepsilon\int_0^\infty v/v^s\,dv=\varepsilon v_0^{2-s}/(s-2)=\varepsilon/(s-2)\quad\text{pour } v_0=1.$$

Il est alors facile de voir à quelles conditions sur a et b il est possible ou non de joindre, en longeant une parabole d'équation $V=x^2/2+K$, un point d'abscisse a à un point d'abscisse b sans dépasser l'ordonnée $\varepsilon/(s-2)$. Plus précisément, pour s fixé, strictement supérieur à 2, le problème aux limites posé possède une solution si et seulement si a et b appartiennent à la région hachurée indiquée sur la Fig. 6. Cette région tend à recouvrir le plan tout entier lorsque s tend vers 2 et tend à se réduire à la diagonale $a=b$ lorsque s croît au-delà de 2.

SINGULAR SELF-ADJOINT STURM–LIOUVILLE PROBLEMS. II: INTERIOR SINGULAR POINTS*

ALLAN M. KRALL† AND ANTON ZETTL‡

Abstract. The second-order Sturm–Liouville operator

$$ly = [-(py')' + qy]/w$$

is considered over a region (a, b) on the real line, $-\infty \leqq a < b \leqq \infty$, on which the operator may have a finite number of singular points. By considering l over various subintervals on which singularities occur only at the ends, restrictions of the maximal operator generated by l in $L^2_w(a, b)$ may be found which are self-adjoint. In addition to direct sums of self-adjoint operators defined on the separate subintervals, there are other self-adjoint restrictions of the maximal operator which involve linking the various intervals together in interface-like style.

Key words. singular, Sturm–Liouville, boundary condition, operator adjoint

1. Introduction. This article is an extension of the work of Everitt and Zettl [2], which dealt with the problem of finding self-adjoint operators of the form

$$ly = [-(py')' + qy]/w$$

with one interior singular point, or possibly over two disjoint intervals, using singular Naimark boundary forms [8]. We use the *equivalent* concrete boundary representation discussed in [5] and consider finitely many singular points, or perhaps finitely many disjoint intervals.

The extension to many singular points or many disjoint intervals is done with relative ease because we use the explicit Fulton-type boundary forms exhibited in [3], [5], [6] for singular ends. By using these concrete forms, not only are direct sum self-adjoint operators easily exhibited, but also self-adjoint operators whose boundaries are linked together are explicitly described. We also bypass the abstract and rather difficult to use Naimark boundary forms found in [8].

We assume that the terminology of limit-point and limit-circle ends is familiar to the reader. Classic descriptions may be found in [1], [4], [9], as well as many other books on differential equations. Essentially limit-point means that the differential equation

$$-(py')' + qy = \lambda wy, \qquad \operatorname{Im} \lambda \neq 0$$

has only one independent solution that is square integrable in any local region containing the singular point. Limit-circle implies that all solutions are locally square integrable for *all* λ near the singular point.

Regular endpoints may be thought of as benign limit-circle points.

We can without loss of generality assume that the interval (a, b), $-\infty \leqq a < b \leqq \infty$, in question is decomposed into four sets of subintervals:

(1) $\{I_j\}_{j=1}^m$. Considered on I_j, l is limit-point at both ends.

(2) $\{J_j\}_{j=1}^n$. Considered on J_j, l is limit-point at the left end, limit-circle at the right end.

(3) $\{K_j\}_{j=1}^p$. Considered on K_j, l is limit-circle at the left end, limit-point at the right end.

(4) $\{L_j\}_{j=1}^q$. Considered on L_j, l is limit-circle at both ends.

DEFINITION 1.1. We denote by D_M the collection of those elements y satisfying the following:

(1) $y \in L_w^2(I_j)$, $j = 1, \cdots, m$, $y \in L_w^2(J_j)$, $j = 1, \cdots, n$, $y \in L_w^2(K_j)$, $j = 1, \cdots, p$, $y \in L_w^2(L_j)$, $j = 1, \cdots, q$.

(2) y is differentiable almost everywhere in each I_j, J_j, K_j, L_j. (py') is locally absolutely continuous in each I_j, J_j, K_j, L_j.

(3) ly exists in each I_j, J_j, K_j, L_j by 2, and $ly \in L_w^2(I_j)$, $j = 1, \cdots, m$, $ly \in L_w^2(J_j)$, $j = 1, \cdots, n$, $ly \in L_w^2(K_j)$, $j = 1, \cdots, p$, $ly \in L_w^2(L_j)$, $j = 1, \cdots, q$.

DEFINITION 1.2. We define the operator L_M by setting $L_M y = ly$ for all $y \in D_M$.

The underlying Hilbert space is, of course,

$$H = \sum_{j=1}^{m} L_w^2(I_j) \oplus \sum_{j=1}^{n} L_w^2(J_j) \oplus \sum_{j=1}^{p} L_w^2(K_j) \oplus \sum_{j=1}^{q} L_w^2(L_j).$$

2. Green's formulas. In order to properly look for restrictions of L_M, Green's formula for each of the regions I_j, J_j, K_j, L_j must be developed. It is by using the sum of these that the restrictions *through boundary conditions* can be developed.

Let us consider I_j, and let (α, β) be a subinterval of I_j with neither α nor β an end of I_j. It is an easy computation to show that if $y, z \in D_M$, then

$$\int_\alpha^\beta [\bar{z}(L_M y) - (\overline{L_M z})y]w\,dx = p[y\bar{z}' - y'\bar{z}]|_\alpha^\beta.$$

Likewise it is well known that as x approaches a limit-point end, $p[y\bar{z}' - y'\bar{z}]$ approaches zero. In this case, therefore,

$$\int_{I_j} [\bar{z}(L_M y) - (\overline{L_M z})y]w\,dx = 0, \qquad j = 1, \cdots, m.$$

Now replace I_j by J_j. If $J_j = (\alpha_j, \beta_j)$, then as α approaches α_j, $p[y\bar{z}' - y'\bar{z}]$ approaches zero; but as β approaches β_j, it does not necessarily approach zero. A closer look is required. Note that $p[y\bar{z}' - y'\bar{z}]$ can be written as

$$(\bar{z}, p\bar{z})\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} y \\ py' \end{pmatrix}.$$

Let θ, ϕ be solutions of $ly = 0$ satisfying $p(\theta\phi' - \theta'\phi) = 1$. Then

$$-\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} \theta & \phi \\ p\theta' & p\phi' \end{pmatrix}\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} \theta & p\theta' \\ \phi & p\phi' \end{pmatrix}\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

If this is inserted in the middle of the preceding product, the result is

$$(\overline{W(z, \theta)}, \overline{W(z, \phi)})\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} W(y, \theta) \\ W(y, \phi) \end{pmatrix}$$

where $W(f, g) = p(fg' - f'g)$.

Furthermore, since both θ and ϕ are square integrable near β_j, the terms W all have finite limits as β approaches β_j. (Use Green's formula, or see [7].) Hence Green's formula over J_j becomes

$$\int_{J_j} [\bar{z}(L_M y) - (\overline{L_M z})y]w\,dx = (\overline{Q_j(z,\theta)}, \overline{Q_j(z,\phi)})\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\begin{pmatrix}Q_j(y,\theta)\\ Q_j(y,\phi)\end{pmatrix},$$

where Q replaces W to indicate the limit has been taken as β approaches β_j.

If the interval is K_j, rather than J_j, then it is the lower limit as α approaches α_j that remains. With the limit-circle case holding at the lower end, therefore,

$$\int_{K_j} [\bar{z}(L_M y) - (\overline{L_M z})y]w\,dx = -(\overline{R_j(z,\theta)}, \overline{R_j(z,\phi)})\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\begin{pmatrix}R_j(y,\theta)\\ R_j(y,\phi)\end{pmatrix}$$

where R replaces W to indicate the limit has been taken as α approaches α_j.

Finally if the interval is L_j, limiting terms at both ends remain. If S indicates a limit at β, and T a limit at α, then

$$\int_{L_j} [\bar{z}(L_M y) - (\overline{L_M z})y]w\,dx = (\overline{S_j(z,\theta)}, \overline{S_j(z,\phi)})\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\begin{pmatrix}S_j(y,\theta)\\ S_j(y,\phi)\end{pmatrix}$$
$$-(\overline{T_j(z,\theta)}, \overline{T_j(z,\phi)})\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\begin{pmatrix}T_j(y,\theta)\\ T_j(y,\phi)\end{pmatrix}.$$

Green's formula over all of (a, b) is the sum of these. If we let $\langle\cdot,\cdot\rangle$ denote the inner product over H,

$$\langle f, g\rangle = \sum_{j=1}^{m}\int_{I_j} \bar{g}fw\,dx + \sum_{j=1}^{n}\int_{J_j} \bar{g}fw\,dx + \sum_{j=1}^{p}\int_{K_j} \bar{g}fw\,dx + \sum_{j=1}^{q}\int_{L_j} \bar{g}fw\,dx,$$

then summing the previous expressions, we get the following theorem.

THEOREM 2.1. *Let $y, z \in D_M$. Then,*

$$\langle L_M y, z\rangle - \langle y, L_M z\rangle = \sum_{j=1}^{n}(\overline{Q_j(z,\theta)}, \overline{Q_j(z,\phi)})\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\begin{pmatrix}Q_j(y,\theta)\\ Q_j(y,\phi)\end{pmatrix}$$
$$-\sum_{j=1}^{m}(\overline{R_j(z,\theta)}, \overline{R_j(z,\phi)})\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\begin{pmatrix}Q_j(y,\theta)\\ Q_j(y,\phi)\end{pmatrix}$$
$$+\sum_{j=1}^{q}(\overline{S_j(z,\theta)}, \overline{S_j(z,\phi)})\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\begin{pmatrix}S_j(y,\theta)\\ S_j(y,\phi)\end{pmatrix}$$
$$-\sum_{j=1}^{q}(\overline{T_j(z,\theta)}, \overline{T_j(z,\phi)})\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\begin{pmatrix}T_j(y,\theta)\\ T_j(y,\phi)\end{pmatrix}.$$

This is Green's formula over all of (a, b).

3. General boundary conditions. The sums involved in Green's formula may be more efficiently handled by the use of additional matrix notation. Let $B(y)$, $B(z)$, and $\mathbf{J}$ be defined as follows:

$$B(y) = (Q_1(y,\theta)\cdots Q_n(y,\theta), R_1(y,\theta)\cdots R_p(y,\phi), S_1(y,\theta)\cdots S_q(y,\phi),$$
$$T_1(y,\theta)\cdots T_q(y,\phi))^T,$$
$$B(z) = (Q_1(z,\theta)\cdots Q_n(z,\phi), R_1(z,\theta)\cdots R_p(z,\phi), S_1(z,\theta)\cdots S_q(z,\phi),$$
$$T_1(z,\theta)\cdots T_q(z,\phi))^T.$$

Here θ and ϕ terms alternate, giving first Q, then R, then S, then T terms.

$$\mathbf{J}=\begin{pmatrix}\mathbf{J}_1 & 0 & 0 & 0\\ 0 & \mathbf{J}_2 & 0 & 0\\ 0 & 0 & \mathbf{J}_3 & 0\\ 0 & 0 & 0 & \mathbf{J}_4\end{pmatrix},$$

where

$$\mathbf{J}_1=\begin{pmatrix}J & & \\ & \ddots & \\ & & J\end{pmatrix}$$

consists of n blocks of

$$J=\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}.$$

$$\mathbf{J}_2=\begin{pmatrix}-J & & \\ & \ddots & \\ & & -J\end{pmatrix}$$

consists of p blocks of $-J$. $\mathbf{J}_3$ is like $\mathbf{J}_1$, but consists of q blocks. $\mathbf{J}_4$ is like $\mathbf{J}_2$, but consists of q blocks.

THEOREM 3.1. *Green's formula for $y, z \in D_M$ is*

$$\langle L_M y, z\rangle - \langle y, L_M z\rangle = B(z)^*\mathbf{J}B(y).$$

General boundary conditions involve linear combinations of terms Q_j, R_j, S_j, T_j, or, more concisely, combinations of the entries in $B(y)$. These are introduced by matrix multiplication.

Let M be an $r\times(2n+2p+4q)$ matrix, rank $M=r$. Let N be a $(2n+2p+4q-r)\times(2n+2p+4q)$ matrix, rank $N=2n+2p+4q-r$. Let $\binom{M}{N}$ be nonsingular.

Likewise let P be an $r\times(2n+2p+4q)$ matrix, rank $P=r$. Let Q be a $(2n+2p+4q-r)\times(2n+2p+4q)$ matrix, rank $Q=2n+2p+4q-r$. Assume also that

$$(P^*, Q^*)\begin{pmatrix}M\\ N\end{pmatrix}=\mathbf{J}.$$

THEOREM 3.2. *Green's formula for $y, z \in D_M$ is*

$$\langle L_M y, z\rangle - \langle y, L_M z\rangle = [PB(z)]^*[MB(y)]+[QB(z)]^*[NB(y)].$$

The proof consists of substituting for $\mathbf{J}$, and carrying out the matrix multiplication.

4. Restrictions of L_M, self-adjointness. We are now in a position to restict L_M by the imposition of boundary conditions.

DEFINITION 4.1. We denote by D the collection of those elements y satisfying the following:

(1) $y\in D_M$;

(2) $MB(y)=0$.

DEFINITION 4.2. We define the operator L by setting $Ly=ly$ for all $y\in D$.

DEFINITION 4.3. We denote by D^* the collection of those elements z satisfying the following:

(1) $z\in D_M$;

(2) $QB(z)=0$.

DEFINITION 4.4. We define the operator L^* by setting $L^*z=lz$ for all z in D^*.

We have abused notation here because traditionally L^* denotes the adjoint operator in H. We clear this up immediately.

THEOREM 4.5. *The adjoint of L in H is L^*. Likewise the adjoint of L^* in H is L.*

Proof. It is well known that the form of the adjoint of L is l (see [6]). Green's formula shows that if $MB(y)=0$, while $NB(y)$ is arbitrary, then $QB(z)=0$.

Conversely, the operator with form lz and domain D^* is clearly contained in the adjoint of L. So the adjoint is L^*.

We show that $(L^*)^*$ is L in the same way.

There are parametric forms for the boundary conditions as well. In order to characterize self-adjointness, these forms are used here.

We have

$$\begin{pmatrix} M \\ N \end{pmatrix} B(y) = \begin{pmatrix} 0 \\ \Delta \end{pmatrix},$$

where Δ is arbitrary. If this is multiplied by $-\mathbf{J}(P^*, Q^*)$, then since $\mathbf{J}^2 = -I$,

$$B(y) = -\mathbf{J}(P^*, Q^*)\begin{pmatrix} 0 \\ \Delta \end{pmatrix},$$

or

$$B(y) = -\mathbf{J}Q^*\Delta.$$

This parametric boundary condition is equivalent to $MB(y)=0$.

Likewise, if

$$B(z)^*(P^*, Q^*) = (\Gamma^*, 0)$$

where Γ is arbitrary, then postmultiplying by $-\binom{M}{N}\mathbf{J}$ yields

$$B(z) = \mathbf{J}M^*\Gamma$$

as the adjoint parametric boundary conditions, equivalent to $QB(z)=0$.

THEOREM 4.6. *L is self-adjoint if and only if $r = n+p+2q$ and $M\mathbf{J}M^* = 0$.*

Proof. If L is self-adjoint, then the number of boundary conditions for L and L^* is the same. Hence $2n+2p+4q-r=r$. Furthermore, z must satisfy the D boundary condition, so

$$MB(z) = M\mathbf{J}M^*\Gamma = 0.$$

Since Γ is arbitrary, $M\mathbf{J}M^* = 0$.

Conversely, if $r = n+p+2q$ and $M\mathbf{J}M^* = 0$, then the number of boundary constraints is the same. Further, since

$$(P^*, Q^*)\begin{pmatrix} M \\ N \end{pmatrix} = \mathbf{J},$$

we have

$$-\mathbf{J}(P^*, Q^*)\begin{pmatrix} M \\ N \end{pmatrix} = \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix},$$

and reversing the order,

$$\begin{pmatrix} M \\ N \end{pmatrix}(-\mathbf{J}P^*, -\mathbf{J}Q^*) = \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix}.$$

This implies $-MJQ^* = 0$. This further implies that there is a nonsingular matrix C such that $Q^* = M^*C^*$ or $Q = CM$. Thus $QB(y) = 0$ and $MB(y) = 0$ are equivalent boundary conditions.

In view of the connection made in [5], the following statement can be made.

THEOREM 4.7. *Let M be an $(n+p+2q)\times(2n+2p+4q)$ matrix satisfying $MJM^* = 0$. Then L, defined by Definition 4.2, is self-adjoint. Conversely, if L is a self-adjoint differential operator which is a restriction of L_M, then there exists a matrix M, with the above-mentioned properties, such that the domain of L is restricted by $MB(y) = 0$ as in Definition 4.1.*

5. Examples. Let us assume that $m = 0$, $n = 2$, $p = 0$, $q = 0$. Suppose that (a, b) consists of $(0, 2)$ with an interior singularity at $x = 1$. Suppose further that l is limit-point at 0 and 1+, but limit-circle at 1− and 2. Thus $J_1 = (0, 1)$, $J_2 = (1, 2)$, and

$$B(y) = (Q_1(y, \theta), Q_1(y, \phi), Q_2(y, \theta), Q_2(y, \phi))^T.$$

Simple separated boundary conditions are given by $MB(y) = 0$, where

$$M = \begin{pmatrix} \alpha & \beta & 0 & 0 \\ 0 & 0 & \gamma & \delta \end{pmatrix}$$

where α, β, γ, δ are real, $\alpha^2+\beta^2 \neq 0$, $\gamma^2+\delta^2 \neq 0$. This problem is equivalent to the direct sum of two self-adjoint problems, one on $(0, 1-)$, one on $(1+, 2)$, joined together.

A new problem in which the intervals are mixed together would be generated by

$$M = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 1 & 0 & 1 & 2 \end{pmatrix}.$$

Here, the intervals cannot be separated.

As a second example let $m = 0$, $n = 1$, $p = 0$, $q = 1$. Suppose that (a, b) consists of $(0, 2)$ with an interior singular point at $x = 1$, l being limit-point at 0, limit-circle at $1-$, at $1+$ and at 2. Thus $J_1 = (0, 1)$, $L_1 = (1, 2)$. Then $B(y)$ is given by

$$B(y) = (Q_1(y, \theta), Q_1(y, \phi), S_1(y, \theta), S_2(y, \phi), T_1(y, \theta), T_1(y, \phi))^T.$$

A general set of self-adjoint, mixed boundary conditions is given by

$$M = \begin{pmatrix} 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 3 & 4 & 3 & 5 \\ 2 & 4 & 6 & 8 & 7 & 11 \end{pmatrix}.$$

We close with two classic examples. First consider the Legendre operator

$$ly = ((1-x^2)y')'.$$

$\pm\infty$ are limit-point, and no boundary conditions are required at those points. ± 1 from either side are limit-circle, however. Thus here, $m = 0$, $n = 1$, $p = 1$, $q = 1$, $J_1 = (-\infty, -1-)$, $K_1 = (1+, \infty)$, and $L_1 = (-1+, 1-)$.

$$H = L^2(-\infty, -1) \oplus L^2(1, \infty) \oplus L^2(-1, 1).$$

Boundary terms $B(y)$ are given by

$$B(y) = (Q_1(y, \theta), Q_1(y, \phi), R_1(y, \theta), R_1(y, \phi), S_1(y, \theta), S_1(y, \phi), T_1(y, \theta), T_1(y, \phi))^T,$$

where $\theta = 1$ in all intervals, $\phi = \frac{1}{2}\ln((x-1)/(x+1))$ on $(-\infty, -1)$ and $(1, \infty)$, but $\phi = \frac{1}{2}\ln((1+x)/(1-x))$ on $(-1, 1)$.

With $\mathbf{J} = \operatorname{diag}(J, -J, J, -J)$,

$$\langle L_M y, z\rangle - \langle y, L_M z\rangle = [PB(z)]^*[MB(y)] + [QB(z)]^*[NB(y)]$$

provided $(P^*, Q^*)\binom{M}{N} = \mathbf{J}$.

Self-adjointness occurs when $M\mathbf{J}M^* = 0$. The simplest case is that of separated conditions. Since M is 4×8, let $m_{11} = m_{23} = m_{35} = m_{47} = 1$, with $m_{ij} = 0$ otherwise. The four boundary terms produced are $Q_1(y, 1) = 0$, $R_1(y, 1) = 0$, $S_1(y, 1) = 0$, $T_1(y, 1) = 0$, which are satisfied by the Legendre polynomials. The projection onto the last component (in $L^2(-1, 1)$) generates the self-adjoint boundary value problem traditionally associated with the Legendre polynomials.

The Laguerre operator

$$ly = -e^x(x\,e^{-x}y')'$$

must be considered on $L^2(-\infty, 0; e^{-x}) \oplus L^2(0, \infty; e^{-x})$. It is limit-point at $\pm\infty$, limit-circle at $0\pm$. Hence $m = 0$, $n = 1$, $p = 1$, $q = 0$. $J_1 = (-\infty, 0)$, $K_1(0, \infty)$.

With $\lambda = 0$, we choose

$$\theta = 1, \quad \phi = \int_1^x (e^\xi/\xi)\,d\xi, \quad x > 0,$$

$$\theta = 1, \quad \phi = \int_{-1}^x (e^\xi/\xi)\,d\xi, \quad x < 0,$$

to define boundary conditions.

$$B(y) = (Q_1(y, \theta), Q_1(y, \phi), R_1(y, \theta), R_1(y, \phi))^T$$

and

$$\mathbf{J} = \begin{pmatrix} J & 0 \\ 0 & -J \end{pmatrix}.$$

Then if $(P^*, Q^*)\binom{M}{N} = \mathbf{J}$,

$$\langle L_M y, z\rangle - \langle y, L_M z\rangle = [PB(z)]^*[MB(y)] + [QB(z)]^*[NB(y)],$$

and self-adjointness occurs when $M\mathbf{J}M^* = 0$. For example,

$$M = \begin{pmatrix} 1 & -2 & 3 & 4 \\ 1 & 0 & 1 & 2 \end{pmatrix}$$

generates a mixed self-adjoint operator on $L^2(-\infty, 0; e^{-x}) \oplus L^2(0, \infty; e^{-x})$.

ASYMPTOTIC SOLUTIONS OF A HAMILTONIAN SYSTEM IN INTERVALS WITH SEVERAL TURNING POINTS*

HARRY GINGOLD† AND PO-FANG HSIEH‡

Abstract. The global asymptotic decomposition of a Hamiltonian system $i\varepsilon Y' = H(x)Y$, as $\varepsilon \to 0^+$, is studied. Here $H(x)$ is a Hermitian matrix analytic on $I = [a, b]$ where a could be $-\infty$ and b could be ∞. Furthermore, I may contain several turning points with various orders of this system. A complete decomposition for the asymptotic solutions is also given.

Key words. global complete asymptotic decomposition, Hamiltonian system, several turning points, asymptotic solutions

AMS(MOS) subject classifications. primary 34E20; secondary 34E15

1. Introduction. In the study of a given ordinary differential system, the process of reducing it to a simpler system by an analytic transformation is an important first step. This is also true for a system of linear equations depending on a parameter in a singular way, such as

$$\varepsilon Y' = A(x, \varepsilon)Y, \qquad ' = d/dx, \tag{1.1}$$

where ε is a small real parameter and Y and A are $n \times n$ matrices. If the eigenvalues of the leading coefficient $A(x, 0)$ coalesce on its domain of definition, the simplification process at the coalescing points, as $\varepsilon \to 0$, is usually valid only in a small neighborhood of each of such points. The points where the eigenvalues of $A(x, 0)$ coalesce are called "turning points" or "transition points" of the system (e.g., see Hsieh [7], Sibuya [14]-[16], and Wasow [19]-[21]). Thus, it is necessary to find the connection formulas if we want to study the global behavior of the system (e.g., see McHugh [9], Olver [11], [12], Sibuya [17], Turrittin [18], Wasow [20], [21], and references therein).

The purpose of this paper is to provide a *global* complete asymptotic decomposition, as $\varepsilon \to 0^+$, of the matrix Hamiltonian system

$$i\varepsilon Y' = H(x)Y, \qquad i = \sqrt{-1}, \tag{1.2}$$

where x is a real variable, ε is a parameter given in $G_{\varepsilon_0} = (0, \varepsilon_0)$, Y and $H(x)$ are $n \times n$ matrices; $H(x)$ is a Hermitian matrix analytic on $I = [a, b]$. Here a could be $-\infty$ and b could be ∞. Furthermore, the interval I may contain several (but finitely many) turning points with various (finite) orders. Such differential systems are relevant to problems in quantum mechanics. The methods presented here and in previous articles (Gingold [2] and Gingold and Hsieh [5], [6]) assisted in constructing a counterexample to the adiabatic approximation theorem in quantum mechanics (see Gingold [3]). This theorem can be found in textbooks on quantum mechanics, such as Liboff [8] and Messiah [10]. The *complete asymptotic decomposition* of solutions of (1.2) to be given here is instrumental in the proof of a modified so-called adiabatic hypothesis. Moreover, it sheds more light on the relation between transition and

degeneracy in time-dependent self-adjoint Hamiltonian systems (see Gingold [2]–[4] and Gingold and Hsieh [6]).

2. Main theorems. In order to formulate our theorems, let $\{\lambda_1(x), \lambda_2(x), \cdots, \lambda_\sigma(x)\}$ be eigenvalues of $H(x)$ with multiplicities $n_1, n_2, \cdots, n_\sigma$ $(n_1+n_2+\cdots+n_\sigma=n)$, respectively. Moreover,

$$\lambda_j(x) \not\equiv \lambda_k(x), \quad (j \neq k) \quad \text{for } x \text{ on } I. \tag{2.1}$$

The point $x=x_0$ on I such that $\lambda_j(x_0)=\lambda_k(x_0)$ for some indices j and k $(j\neq k)$ is called a "turning point," or a "transition point," of the system (1.2). The order of zero of $\lambda_j(x)-\lambda_k(x)$ at a turning point $x=x_0$ is called the order of that turning point with respect to the pair of eigenvalues (λ_j, λ_k). It is allowed that I may contain several turning points of (1.2) with various orders.

It is noteworthy that the eigenvalues $\{\lambda_1(x), \lambda_2(x), \cdots, \lambda_\sigma(x)\}$ of $H(x)$ are real and analytic on I. By a theorem of linear algebra due to Rellich [13] there exists a unitary matrix $U(x)$ nonsingular and analytic on I such that

$$U^{-1}(x)H(x)U(x)=\lambda_1(x)I_{n_1}\oplus\lambda_2(x)I_{n_2}\oplus\cdots\oplus\lambda_\sigma(x)I_{n_\sigma}, \tag{2.2}$$

I_j: j by j identity matrix.

Let

$$Y=U(x)V; \tag{2.3}$$

then V satisfies the following equation:

$$i\varepsilon V'=\{U^{-1}(x)H(x)U(x)-i\varepsilon U^{-1}(x)U'(x)\}V. \tag{2.4}$$

Before we state our theorems, let

$$U^{-1}(x)H(x)U(x)=\Lambda_1(x)\oplus\Lambda_2(x), \tag{2.5}$$

where

$$\Lambda_1(x)=\lambda_1(x)I_{n_1}, \qquad \Lambda_2(x)=\lambda_2(x)I_{n_2}\oplus\cdots\oplus\lambda_\sigma(x)I_{n_\sigma}. \tag{2.6}$$

Also denote the partition of the second part of the coefficient of (2.4) according to that of (2.5)

$$-iU^{-1}(x)U'(x)=\begin{bmatrix} R_{11}(x) & R_{12}(x) \\ R_{21}(x) & R_{22}(x) \end{bmatrix}. \tag{2.7}$$

Namely, R_{11} is $n_1\times n_1$, R_{12} is $n_1\times(n-n_1)$, R_{21} is $(n-n_1)\times n_1$, and R_{22} is $(n-n_1)\times(n-n_1)$. Also, let

$$R(x)=\begin{bmatrix} 0 & R_{12}(x) \\ R_{21}(x) & 0 \end{bmatrix} \tag{2.8}$$

and

$$B_1(x,\varepsilon)=\Lambda_1(x)+\varepsilon R_{11}(x), \qquad B_2(x,\varepsilon)=\Lambda_2(x)+\varepsilon R_{22}(x). \tag{2.9}$$

Thus, (2.4) can be rewritten as

$$i\varepsilon V'=\{[B_1(x,\varepsilon)\oplus B_2(x,\varepsilon)]+\varepsilon R(x)\}V. \tag{2.10}$$

We shall prove the following theorem.

THEOREM 1. *There exist a positive constant* ε_1 $(0<\varepsilon_1\leqq\varepsilon_0)$ *and an* $n\times n$ *matrix* $P(x,\varepsilon)$ *analytic on* $I\times G_{\varepsilon_1}$, *such that the transformation*

$$V=W[I_n+P(x,\varepsilon)] \tag{2.11}$$

reduces (2.10) *to*

$$i\varepsilon W'=\{B_1(x,\varepsilon)\oplus B_2(x,\varepsilon)\}W, \tag{2.12}$$

where $B_j(x,\varepsilon)$ *are the matrices given by* (2.9).

Furthermore, $P(x,\varepsilon)$ *satisfies*

$$\lim P(x,\varepsilon)=0 \quad \text{as } \varepsilon \text{ tends to } 0^+. \tag{2.13}$$

We shall prove this theorem in §§ 3–5.

Applying Theorem 1 $(\sigma-1)$ times, we can get the following theorem.

THEOREM 2. *There exist a positive constant* ε_2 $(0<\varepsilon_2\leqq\varepsilon_0)$ *and an* $n\times n$ *matrix* $\hat{P}(x,\varepsilon)$ *analytic on* $I\times G_{\varepsilon_2}$, *such that the transformation*

$$V=W[I_n+\hat{P}(x,\varepsilon)] \tag{2.14}$$

reduces (2.4) *to*

$$i\varepsilon W'=\{\hat{B}_1(x,\varepsilon)\oplus\hat{B}_2(x,\varepsilon)\oplus\cdots\oplus\hat{B}_\sigma(x,\varepsilon)\}W \tag{2.15}$$

where $\hat{B}_j(x,\varepsilon)$ *are* $n_j\times n_j$ *matrices* $(j=1,2,\cdots,\sigma)$, *analytic in* $I\times G_{\varepsilon_2}$, *satisfying*

$$\hat{B}_j(x,0)=\lambda_j(x)I_{n_j} \qquad (j=1,2,\cdots,\sigma). \tag{2.16}$$

Furthermore, $\hat{P}(x,\varepsilon)$ *satisfies*

$$\lim \hat{P}(x,\varepsilon)=0 \quad \text{as } \varepsilon \text{ tends to } 0^+. \tag{2.17}$$

By the result of Theorem 2, we can obtain the following theorem.

THEOREM 3. *Let* α *be a fixed point on I. The system* (1.2) *has a fundamental matrix*

$$Y(x,\alpha,\varepsilon)=U(x)E(x,\alpha,\varepsilon)\Psi(x,\alpha)[I_n+\hat{P}(x,\varepsilon)]C \tag{2.18}$$

where $U(x)$ *is the unitary matrix given in* (2.2),

$$E(x,\alpha,\varepsilon)=E_1(x,\alpha,\varepsilon)\oplus E_2(x,\alpha,\varepsilon)\oplus\cdots\oplus E_\sigma(x,\alpha,\varepsilon) \tag{2.19}$$

with

$$E_j(x,\alpha,\varepsilon)=\exp\left\{-i\varepsilon^{-1}\int_\alpha^x\lambda_j(s)\,ds\right\}I_{n_j}, \qquad j=1,2,\cdots,\sigma, \tag{2.20}$$

$$\Psi(x,\alpha)=\Psi_1(x,\alpha)\oplus\Psi_2(x,\alpha)\oplus\cdots\oplus\Psi_\sigma(x,\alpha); \tag{2.21}$$

$\Psi_j(x,\alpha)$ *is an* $n_j\times n_j$ *unitary analytic matrix function on* $I\times G_{\varepsilon_2}$, $(j=1,2,\cdots,\sigma)$ $\hat{P}(x,\varepsilon)$ *is the matrix given in Theorem* 2, *and* C *is a suitable* $n\times n$ *constant matrix.*

This is a theorem pointed out in Gingold [3]. Its proof will be given in § 6.

Remarks. (1) Unlike other decomposition methods (e.g. Sibuya [14]–[16] and Wasow [19]) where the coefficients of the simplified equation are computed in the process, we can tell the coefficients $B_1(x,\varepsilon)$ and $B_2(x,\varepsilon)$ of the simplified equation (2.12), i.e., those given by (2.9), from the original equation (2.4). Similarly, $\hat{B}_j(x,\varepsilon)$, $(j=1,2,\cdots,\sigma)$ in (2.15) are the corresponding block-diagonal entries of (2.4). As is to be seen in § 6, $E_j(x,\alpha,\varepsilon)$ and $\Psi_j(x,\alpha)$ $(j=1,2,\cdots,\sigma)$ can be obtained directly from solving the differential equations involving the corresponding block-diagonal entries of (2.4).

(2) Unlike $U(x)$, which is obtained by finite algorithms from the given system (1.2), $\Psi_j(x, \alpha)$ are obtained as solutions of certain differential equations, or as a set of infinite series.

3. Preliminary reduction. In order to prove Theorem 1, let $Z(x, \alpha, \varepsilon)$ denote the fundamental matrix of the simplified system (2.12) satisfying

$$i\varepsilon Z' = \{B_1(x, \varepsilon) \oplus B_2(x, \varepsilon)\} Z, \qquad Z(\alpha, \alpha, \varepsilon) = I_n, \tag{3.1}$$

where α is a fixed point on I.

From (2.10), (2.11), and (2.12), we know that $P(x, \varepsilon)$ should satisfy the differential equation

$$iP' = Z^{-1} R Z (I_n + P), \tag{3.2}$$

or, equivalently, the integral equation

$$P(x, \varepsilon) = -i \int_\alpha^x Z^{-1}(s, \alpha, \varepsilon) R(s) Z(s, \alpha, \varepsilon)[I_n + P(s, \varepsilon)]\, ds. \tag{3.3}$$

Define the integral operator

$$MP = -i \int_\alpha^x Z^{-1}(s, \alpha, \varepsilon) R(s) Z(s, \alpha, \varepsilon) P(s, \varepsilon)\, ds, \tag{3.4}$$

and let

$$P_0 = MI_n. \tag{3.5}$$

Then, the integral equation (3.3) can be rewritten as

$$P = P_0 + MP. \tag{3.6}$$

In order to have a better estimate of the kernel of this integral equation, we take the second iteration of (3.6), namely,

$$P = P_0 + M^2 I_n + M^2 P, \tag{3.7}$$

where

$$\begin{aligned} M^2 P = & \int_\alpha^x Z^{-1}(s, \alpha, \varepsilon) R(s) Z(s, \alpha, \varepsilon) \\ & \cdot \left\{ \int_\alpha^s Z^{-1}(t, \alpha, \varepsilon) R(t) Z(t, \alpha, \varepsilon) P(t, \varepsilon)\, dt \right\} ds, \end{aligned} \tag{3.8}$$

or, by the change of order of integration,

$$M^2 P = \int_\alpha^x \left\{ \int_t^x Z^{-1}(s, \alpha, \varepsilon) R(s) Z(s, \alpha, \varepsilon)\, ds \right\} Z^{-1}(t, \alpha, \varepsilon) R(t) Z(t, \alpha, \varepsilon) P(t, \varepsilon)\, dt. \tag{3.9}$$

Put

$$Z = \begin{bmatrix} Z_1 & 0 \\ 0 & Z_2 \end{bmatrix}, \qquad P = \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix}; \tag{3.10}$$

then

$$Z^{-1} R Z = \begin{bmatrix} 0 & Z_1^{-1} R_{12} Z_2 \\ Z_2^{-1} R_{21} Z_1 & 0 \end{bmatrix} \tag{3.11}$$

and

$$Z^{-1}RZP=\begin{bmatrix} Z_1^{-1}R_{12}Z_2P_{21} & Z_1^{-1}R_{12}Z_2P_{22} \\ Z_2^{-1}R_{21}Z_1P_{11} & Z_2^{-1}R_{21}Z_1P_{12}\end{bmatrix}. \tag{3.12}$$

Thus, by (3.7), (3.9), (3.11), and (3.12), we have the following decoupled equations for P_{jk}, $(j, k=1, 2)$:

$$\begin{aligned} P_{11}(x,\varepsilon)=&\int_\alpha^x\left\{\int_t^x Z_1^{-1}(s,\alpha,\varepsilon)R_{12}(s)Z_2(s,\alpha,\varepsilon)\,ds\right\}\\ &\cdot Z_2^{-1}(t,\alpha,\varepsilon)R_{21}(t)Z_1(t,\alpha,\varepsilon)\,dt\\ &+\int_\alpha^x\left\{\int_t^x Z_1^{-1}(s,\alpha,\varepsilon)R_{12}(s)Z_2(s,\alpha,\varepsilon)\,ds\right\}\\ &\cdot Z_2^{-1}(t,\alpha,\varepsilon)R_{21}(t)Z_1(t,\alpha,\varepsilon)P_{11}(t,\varepsilon)\,dt, \end{aligned} \tag{3.13}$$

$$\begin{aligned} P_{12}(x,\varepsilon)=&\int_\alpha^x Z_1^{-1}(s,\alpha,\varepsilon)R_{12}(s)Z_2(s,\alpha,\varepsilon)\,ds\\ &+\int_\alpha^x\left\{\int_t^x Z_1^{-1}(s,\alpha,\varepsilon)R_{12}(s)Z_2(s,\alpha,\varepsilon)\,ds\right\}\\ &\cdot Z_2^{-1}(t,\alpha,\varepsilon)R_{21}(t)Z_1(t,\alpha,\varepsilon)P_{12}(t,\varepsilon)\,dt, \end{aligned} \tag{3.14}$$

$$\begin{aligned} P_{21}(x,\varepsilon)=&\int_\alpha^x Z_2^{-1}(s,\alpha,\varepsilon)R_{21}(s)Z_1(s,\alpha,\varepsilon)\,ds\\ &+\int_\alpha^x\left\{\int_t^x Z_2^{-1}(s,\alpha,\varepsilon)R_{21}(s)Z_1(s,\alpha,\varepsilon)\,ds\right\}\\ &\cdot Z_1^{-1}(t,\alpha,\varepsilon)R_{12}(t)Z_2(t,\alpha,\varepsilon)P_{21}(t,\varepsilon)\,dt, \end{aligned} \tag{3.15}$$

$$\begin{aligned} P_{22}(x,\varepsilon)=&\int_\alpha^s\left\{\int_t^x Z_2^{-1}(s,\alpha,\varepsilon)R_{21}(s)Z_1(s,\alpha,\varepsilon)\,ds\right\}\\ &\cdot Z_1^{-1}(t,\alpha,\varepsilon)R_{12}(t)Z_2(t,\alpha,\varepsilon)\,dt\\ &+\int_\alpha^x\left\{\int_t^x Z_2^{-1}(s,\alpha,\varepsilon)R_{21}(s)Z_1(s,\alpha,\varepsilon)\,ds\right\}\\ &\cdot Z_1^{-1}(t,\alpha,\varepsilon)R_{12}(t)Z_2(t,\alpha,\varepsilon)P_{22}(t,\varepsilon)\,dt. \end{aligned} \tag{3.16}$$

We shall prove that there exist the solutions P_{jk} of (3.13)-(3.16), respectively, satisfying the required properties described in Theorem 1. It is noteworthy that these decoupled equations (3.13)-(3.16) are analogous to the scalar equations obtained for a two-dimensional system used in Gingold [2].

4. A fundamental lemma. In order to prove the existence of the solution P_{jk} of (3.13)-(3.16) we must have certain estimates of the magnitude of the kernels in their respective integrals. For this purpose, we must invoke a lemma of ours proved recently in [6].

LEMMA 1. *Let there be given an integral expression*

$$J(a,b)=\int_a^b r(s,\varepsilon)\exp\left\{i\varepsilon^{-1}\int_\alpha^s p(\eta)\,d\eta\right\}ds, \qquad a\leqq\alpha\leqq b, \tag{4.1}$$

where $r(x, \varepsilon)$ is in the class $C^1(I \times \bar{G}_{\varepsilon_0})$ and $p(x)$ is real analytic on $I \times \bar{G}_{\varepsilon_0}$. Furthermore, assume the following:

(i) *$p(x)$ may vanish at some points of I, but it is not identically zero in I.*

(ii) *$r(x, \varepsilon)$ is uniformly bounded on $I \times \bar{G}_{\varepsilon_0}$.*

(iii) *Both $r(x, \varepsilon)$ and $r'(x, \varepsilon)$ are absolutely integrable over I for ε in G_{ε_0}.*

Then, there exist positive constants $\hat{K}$, γ, and $\hat{\varepsilon}$ $(0 < \gamma < 1,\ 0 < \hat{\varepsilon} \leqq \varepsilon_0)$ such that

$$|J(a, b)| \leqq \hat{K}\varepsilon^{\gamma} \quad \text{for } \varepsilon \text{ in } G_{\hat{\varepsilon}}. \tag{4.2}$$

Remark. As defined in [6], the zero points of $p(x)$ on I are called the turning points of the integral expression $J(a, b)$.

To simplify the notation, let

$$\hat{n}_1 = n_1, \qquad \hat{n}_2 = n - n_1. \tag{4.3}$$

In the notation of (3.10) and (3.9), $Z_1(x, \alpha, \varepsilon)$ and $Z_2(x, \alpha, \varepsilon)$ satisfy the following initial value problem:

$$i\varepsilon Z_j' = [\Lambda_j(x) + \varepsilon R_{jj}(x)]Z_j, \quad Z_j(\alpha, \alpha, \varepsilon) = I_{\hat{n}_j}, \quad j = 1, 2. \tag{4.4}$$

Put

$$Z_j(x, \alpha, \varepsilon) = \Phi_{1j}(x, \alpha, \varepsilon)\Phi_{2j}(x, \alpha, \varepsilon), \qquad j = 1, 2, \tag{4.5}$$

where $\Phi_{1j}(x, \alpha, \varepsilon)$ satisfies the equation

$$i\varepsilon \Phi_{1j}' = \Lambda_j(x)\Phi_{1j}, \quad \Phi_{1j}(\alpha, \alpha, \varepsilon) = I_{\hat{n}_j}, \quad j = 1, 2. \tag{4.6}$$

Since $\Lambda_j(x)$, $(j = 1, 2)$ is diagonal in the form of (2.6), we have

$$\Phi_{1j}(x, \alpha, \varepsilon) = \exp\left\{-i\varepsilon^{-1}\int_{\alpha}^{x} \Lambda_j(s)\, ds\right\}, \qquad j = 1, 2. \tag{4.7}$$

Furthermore, $\Phi_{2j}(x, \alpha, \varepsilon)$ satisfies the conditions

$$i\Phi_{2j}' = [\Phi_{1j}^{-1}(x, \alpha, \varepsilon)R_{jj}(x)\Phi_{1j}(x, \alpha, \varepsilon)]\Phi_{2j}, \qquad \Phi_{2j}(\alpha, \alpha, \varepsilon) = I_{\hat{n}_j}. \tag{4.8}$$

By the assumptions of $\Lambda_j(x)$ and $R_{jj}(x)$, we know that $\Phi_{2j}(x, \alpha, \varepsilon)$ are in the class of C^1 on $I \times I \times G_{\varepsilon_0}$ (e.g., see Coddington and Levinson [1]). Thus, the entries of $\Phi_{2j}'(x, \alpha, \varepsilon)$ are also absolutely integrable $(j = 1, 2)$.

Now, by (4.5), let

$$\begin{aligned}(r_{(jk)\mu\nu}) &:= Z_j^{-1}R_{jk}Z_k = \Phi_{2j}^{-1}\Phi_{1j}^{-1}R_{jk}\Phi_{1k}\Phi_{2k}, \\ &\mu = 1, 2, \cdots, \hat{n}_j, \quad \nu = 1, 2, \cdots, \hat{n}_k \quad (j = 1, 2).\end{aligned} \tag{4.9}$$

Since Φ_{1j} are diagonal and are in the form of (4.7), we know that $r_{(jk)\mu\nu}$ are finite sums of the terms of the form

$$r_{(jk)\mu\nu} = \sum_{\rho=1}^{\hat{n}_j \times \hat{n}_k} \tilde{r}_{(jk)\mu\nu\rho}(x, \alpha, \varepsilon) \exp\left\{i\varepsilon^{-1}\int_{\alpha}^{x} p_{(jk)\mu\nu\rho}(s)\, ds\right\}, \tag{4.10}$$

where each of $p_{(jk)\mu\nu\rho}(x)$ is one of the difference of the diagonal elements of $\Lambda_1(x)$ and those of $\Lambda_2(x)$, or vice versa. $\tilde{r}_{(jk)\mu\nu\rho}(x, \alpha, \varepsilon)$ are products of the elements of Φ_{2j}^{-1}, R_{jk}, and Φ_{2k}. Thus $\tilde{r}_{(jk)\mu\nu\rho}(x, \alpha, \varepsilon)$ are analytic and bounded for $I \times G_{\varepsilon_0}$. Furthermore, $\tilde{r}_{(jk)\mu\nu\rho}(x, \alpha, \varepsilon)$ and their derivatives, with respect to x, are absolutely integrable on I. Therefore, every element of the matrix $Z_j^{-1}R_{jk}Z_k$ satisfies the assumptions of Lemma 1.

Now, let $\|\cdot\|$ denote a suitable norm of a matrix. By the use of Lemma 1 and the discussion above, we have the following lemma.

LEMMA 2. *For each pair* (j, k) $(j, k = 1, 2)$ *there exist positive constants* K_{jk}, d_{jk}, *and* ε_{jk} $(0 < d_{jk} < 1,\ 0 < \varepsilon_{jk} \leqq \varepsilon_0)$ *such that*

$$\left\| \int_\alpha^x Z_j^{-1}(s, \alpha, \varepsilon) R_{jk}(s) Z_k(s, \alpha, \varepsilon)\, ds \right\| < K_{jk} \varepsilon^{d_{jk}} \tag{4.11}$$

for all α *and* x *on* I, *and* $0 < \varepsilon < \varepsilon_{jk}$.

5. Completion of the proof of Theorem 1. By applying Lemma 2 to (3.13)-(3.16), we know that for each pair (j, k) $(j, k = 1, 2)$ there exist a positive constant $\tilde{K}_{jk}$ and a positive function $\varphi_{jk}(\varepsilon)$ such that

$$\lim \varphi_{jk}(\varepsilon) = 0 \quad \text{as } \varepsilon \text{ tends to } 0^+, \tag{5.1}$$

and

$$\|P_{jk}\| \leqq \varphi_{jk}(\varepsilon) + \tilde{K}_{jk} \varepsilon^{d_{jk}} \|P_{jk}\| \quad \text{for } x \text{ on } I \text{ and } 0 < \varepsilon < \varepsilon_{jk}. \tag{5.2}$$

Now, choose ε_1 sufficiently small such that

$$\varepsilon_1 \leqq \min \{\varepsilon_{jk} \,|\, j, k = 1, 2\} \tag{5.3}$$

and

$$\tilde{K}_{jk} \varepsilon_1^{d_{jk}} < 1 \qquad \text{for } j, k = 1, 2. \tag{5.4}$$

Thus, each of the equations (3.13)-(3.16) defines a contraction mapping for x on I and ε in G_{ε_1}. Therefore their solutions P_{jk} exist and, furthermore,

$$\|P_{jk}\| \leqq \varphi_{jk}(\varepsilon)/(1 - \tilde{K}_{jk} \varepsilon^{d_{jk}}), \qquad j, k = 1, 2. \tag{5.5}$$

Hence, each of P_{jk} satisfies the relation (2.13), and Theorem 1 is proved.

6. Proof of Theorem 3. In order to prove Theorem 3, let

$$-iU^{-1}(x) U'(x) = \begin{bmatrix} \hat{R}_{11}(x) & \hat{R}_{12}(x) & \cdots & \hat{R}_{1\sigma}(x) \\ \hat{R}_{21}(x) & \hat{R}_{22}(x) & \cdots & \hat{R}_{2\sigma}(x) \\ \vdots & \vdots & & \vdots \\ \hat{R}_{\sigma 1}(x) & \hat{R}_{\sigma 2}(x) & \cdots & \hat{R}_{\sigma\sigma}(x) \end{bmatrix} \tag{6.1}$$

where $\hat{R}_{jk}(x)$ are $n_j \times n_k$ matrices $(j, k = 1, 2, \cdots, \sigma)$. Then,

$$\hat{B}_j(x, \varepsilon) = \lambda_j(x) I_{n_j} + \varepsilon \hat{R}_{jj}(x). \tag{6.2}$$

Also, let $W_j(x, \alpha, \varepsilon)$ be the solution of

$$i\varepsilon W_j' = \hat{B}_j(x, \varepsilon) W_j, \qquad W_j(\alpha, \alpha, \varepsilon) = I_{n_j}. \tag{6.3}$$

Then the fundamental matrix (2.15) is given by

$$W(x, \alpha, \varepsilon) = \{W_1(x, \alpha, \varepsilon) \oplus W_2(x, \alpha, \varepsilon) \oplus \cdots \oplus W_\sigma(x, \alpha, \varepsilon)\} G, \tag{6.4}$$

where G is an $n \times n$ constant matrix. Similar to (4.5), let

$$W_j(x, \alpha, \varepsilon) = E_j(x, \alpha, \varepsilon) \Psi_j(x, \alpha), \tag{6.5}$$

where $E_j(x, \alpha, \varepsilon)$ is given by (2.20). Namely, it satisfies

$$i\varepsilon E_j' = \lambda_j(x) E_j, \qquad E_j(\alpha, \alpha, \varepsilon) = I_{n_j}. \tag{6.6}$$

Since $E_j(x, \alpha, \varepsilon)$ is in the form of (2.20), $\Psi_j(x, \alpha)$ satisfies the equation

$$i\Psi_j' = \hat{R}_{jj}(x) \Psi_j, \qquad \Psi_j(\alpha, \alpha) = I_{n_j}. \tag{6.7}$$

Observe first that, for an analytic unitary matrix $U(x)$, $U^{-1}(x)U'(x)$ is anti-Hermitian. By the facts that the independent variable x is real and the operations of differentiation and conjugate transposition are commutative, we have

$$\begin{aligned}[U^{-1}U']^* &= [U^{-1}\{-U(U^{-1})'U\}]^* = -[(U^{-1})'U]^* \\ &= -U^*[(U^{-1})']^* = -U^{-1}U'.\end{aligned} \tag{6.8}$$

Thus, by (6.1), $\hat{R}_{jj}(x)$ $(j=1,2,\cdots,\sigma)$ are Hermitian. Therefore, by (6.7), Ψ_j $(j=1,2,\cdots,\sigma)$ are unitary. Hence, Theorem 3 is proved.

7. Concluding remark. By repeating the iterations of (3.6), we have the infinite series expansion for the matrix

$$P=\sum_{\nu=0}^{\infty} M^{\nu}I_n. \tag{7.1}$$

As pointed out in [2], by a similar estimate as that given in Lemma 2, there exist two constants K and d $(0<d<1)$, such that

$$\|M^{\nu}I_n\| \leqq K^{\nu}\varepsilon^{\nu d}, \qquad \nu=1,2,3,\cdots \tag{7.2}$$

for all x on I. Thus the series (7.1) represents a generalized asymptotic expansion. Moreover, it is possible to extract from the series of (7.1), an asymptotic series in the sense of Poincaré wherever it exists (compare with [2]).

Note added in proof. By (2.4), (2.14), (2.15), (2.16), and (6.2), the matrix $I_n+\hat{P}(x,\varepsilon)$ satisfies a differential equation similar to (6.7). Thus, $I_n+\hat{P}(x,\varepsilon)$ is unitary.

EXTREMAL PROBLEMS FOR EIGENVALUE FUNCTIONALS II*

DAVID C. BARNES†

Abstract. This paper is actually the fourth in a series of works [*SIAM J. Math. Anal.*, 16(1985), pp. 341-357, 1284-1294; 18(1987), pp. 933-940] whose overall purpose is to develop some variational and approximation theory for eigenvalue functionals. These functionals are defined by the eigenvalues of differential operators, of the general form $\mathcal{L}(\cdot) = \lambda M(\cdot)$. We assume the operators $\mathcal{L}(\cdot)$ and $M(\cdot)$ have coefficients that depend on some real valued function (or functions) $\rho(x)$ taken from a class C. When subject to appropriate boundary conditions, the eigenvalues λ become real valued functionals of ρ. The functionals are defined on the class C, and are denoted by $\lambda_n(\rho)$. In this work we show a new way to apply the classical theory of variational calculus to the problem of maximizing or minimizing a function of two (or more) such eigenvalues $\Phi(\lambda_n(\rho), \mu_m(\rho))$. We then give an extensive application of the example $\Phi(u, v) = \min\{u, v\}$ to a three-dimensional version of the strongest column problem.

Key words. strongest column, eigenvalue, extremal problem

AMS(MOS) subject classifications. 35P15, 49A99

1. The general theory of extremals for functions of eigenvalues. Consider a vibrating string having density function $\rho(x)$ with fixed end points. Its characteristic frequencies of vibration are determined by the eigenvalues $\lambda = \lambda(\rho)$ of the system

$$y'' + \lambda\rho(x)y = 0, \qquad y(0) = y(l) = 0, \qquad 0 \le x \le l. \tag{1}$$

There will be an infinite sequence of eigenvalues $\lambda_1(\rho) \le \lambda_2(\rho) \le \lambda_3(\rho) \le \cdots$. Several works [21],[13],[9] have considered the problem of maximizing and minimizing the ratio $\lambda_1(\rho)/\lambda_2(\rho)$. Theorem 1 below, with $\Phi(u, v) = u/v$, can be used to easily reproduce the extremal conditions used in those works.

Suppose a number of such strings (and perhaps some rods as well) are all vibrating together and that they each have density function $\rho_i(x)$, length l_i and eigenvalues $\lambda_n(\rho_i)$. The fundamental frequencies of vibration Λ and the total mass M of the system are now determined by

$$\Lambda = \min_i\{\lambda_1(\rho_i)\}, \qquad M = \sum_i \int_0^{l_i} \rho_i(x)\,dx.$$

One might want to minimize Λ subject to a given mass constraint. In a similar way, consider a single large load, being supported by several columns of length l_i and total volume V. The critical buckling load of each column is determined by an eigenvalue problem similar to (1). To maximize the load-carrying capacity of the structure, one would want to maximize the sum of all of the first eigenvalues for each of the systems.

We will now give a general theory of the extremals for functions of eigenvalues $\Phi(\lambda_n, \mu_m)$. We will assume, whenever necessary, that the problem under study does actually have an extremal function, denoted by $\rho^*(x)$. Methods used by Barnes [6] or Holmåker [11] could, perhaps, be used to give proofs of that assumption.

1.1. The necessary conditions. Consider differential operators $\mathcal{L}(\cdot)$, $M(\cdot)$ of the general form

$$\mathcal{L}(\rho, y) = \sum_{i=0}^{m} (-1)^i \left(f_i(x,\rho) y^{(i)}\right)^{(i)}, \qquad M(\rho, y) = \sum_{j=0}^{m'} (-1)^j \left(g_j(\rho, x) y^{(j)}\right)^{(j)}.$$

The operators will be linear in y but may be nonlinear in ρ. Here, the function ρ ranges through some class C, and the coefficient functions f_i and g_j depend on x as well as the function $\rho(x)$. We shall use the abbreviated notation $f_i[\rho] = f_i(x, \rho(x))$ for the various coefficients that are assumed to satisfy appropriate smoothness conditions and so on. For more details, see [20],[4].

We will be concerned with generalized eigenvalue problems of the form

$$\mathcal{L}(\rho, y) = \lambda M(\rho, y), \qquad U_p(y, \rho, \lambda) = 0, \qquad p = 1, 2, \cdots, 2m. \tag{2}$$

We will assume that $m > m' \geq 0$. The boundary conditions U_p may also depend on the values of ρ at $x = 0$ or l, as well as the eigenvalue parameter λ.

Now, suppose that two distinct eigenvalue problems of the form (2) are given, so we have four operators, $\mathcal{L}_i(\cdot)$ and $M_i(\cdot)$, each with coefficients depending on $\rho \in C$. The two eigenvalue equations are

$$\mathcal{L}_1(\rho, y) = \lambda M_1(\rho, y), \qquad \mathcal{L}_2(\rho, z) = \mu M_2(\rho, z). \tag{3}$$

Suppose that $\Phi(u, v)$ is a given function of u, v. The major problem considered in this work is the following.

Problem 1. Let C be a given class of functions $\rho(x)$ and let $\lambda_n(\rho), \mu_m(\rho)$ be eigenvalues of (3). Find that function $\rho^*(x) \in C$ that maximizes (minimizes) the functional $\Phi(\lambda_n(\rho), \mu_m(\rho))$ for all functions $\rho \in C$.

The eigenvalues for these systems are functionals defined on the class C of functions $\rho(x)$. Let ρ^* be a fixed function in C and suppose that it is smoothly imbedded into a family of functions $\rho_\epsilon(x) \in C$ so that $\rho_0(x) = \rho^*(x)$. Using methods given by Barnes [5], we obtain the following theorem.

THEOREM 1. *Given functions ρ^*, $\rho_\epsilon \in C$, let y^* and y be eigenfunctions for* (2), *corresponding to eigenvalues $\lambda(\rho^*)$ and $\lambda(\rho_\epsilon)$. Define a functional $J(\rho)$ on the class C by*

$$J(\rho) = \int_0^l \left\{ \sum_{j=0}^{m'} g_j[\rho] \left(y^{*(j)}\right)^2 - \sum_{i=0}^{m} f_i[\rho] \left(y^{*(i)}\right)^2 \right\} dx.$$

Define boundary terms $BT1$, $BT2$, and $BT3$ by the following equations:

$$\begin{gathered} (\mathcal{L}(\rho^*, y), y^*) = BT1 + (y, \mathcal{L}(\rho^*, y^*)), \\ (M(\rho^*, y), y^*) = BT2 + (y, M(\rho^*, y^*)), \\ (\mathcal{L}(\rho, y^*), y^*) - \lambda^*(M(\rho, y^*), y^*) = BT3 - J(\rho). \end{gathered}$$

Suppose that y^* is normalized so that

$$(M(\rho^*, y^*), y^*) = 1, \qquad (\mathcal{L}(\rho^*, y^*), y^*) = \lambda^*.$$

Finally, define a functional $K(\rho)$ on C by

$$K(\rho) = \lambda^* + BT1 - \lambda^* BT2 + BT3 - J(\rho).$$

Then

$$\begin{aligned}\lambda(\rho_\epsilon) &= K(\rho_\epsilon) + O(\epsilon^2)\\ &= \lambda^* + BT1 - \lambda^* BT2 + BT3 - J(\rho_\epsilon) + O(\epsilon^2).\end{aligned}$$

Thus, the two functionals $K(\rho)$ *and* $\lambda(\rho)$ *are tangent to each other at* $\rho = \rho^*$. *That is,*

$$K(\rho^*) = \lambda(\rho^*), \quad \textit{and, at } \rho = \rho^*, \quad \delta K = \delta\lambda.$$

The term $O(\epsilon^2)$ *is given by*

$$O(\epsilon^2) = (\Delta\mathcal{L}(\Delta y) - \Delta\lambda M^*(\Delta y) - \Delta\lambda\Delta M(y^*) - \lambda\Delta M(\Delta y)\,,\, y^*)$$

where $\Delta(\cdot) = (\cdot) - (\cdot)^*$.

It frequently happens that the boundary terms can be calculated in a simple form that is independent of the eigenfunction y. If that is so, then Theorem 1 shows that ρ^* is an extremal of $\lambda(\rho)$ if and only if it is also an extremal of the functional $J(\rho)$. Now $J(\rho)$ is a classical functional defined on $\mathcal{C}$, and classical methods can be used to find its extremals. This was the essential idea used in the works [3],[4]. To apply these methods to Problem 1, we first use Theorem 1 to construct the two functionals $K_i(\rho)$ associated with the eigenvalue problems (3). The solution of Problem 1 can then be found using the following theorem.

THEOREM 2. *Suppose that* $\Phi(u, v)$ *satisfies the Lipschitz condition*

$$|\Phi(u_1, v_1) - \Phi(u_2, v_2)| \le L\{\,|u_1 - u_2| + |v_1 - v_2|\,\}$$

and that y^*, z^* *are eigenfunctions of* (3) *corresponding to* $\lambda(\rho^*)$ *and* $\mu(\rho^*)$. *Let* $K_1(\rho)$ *and* $K_2(\rho)$ *be the functionals corresponding to* (3) *defined by Theorem* 1. *Then the two functionals* $\Phi(\lambda(\rho), \mu(\rho))$ *and* $\Phi(K_1(\rho), K_2(\rho))$ *are tangent to each other at* $\rho = \rho^*$. *That is,*

$$\begin{gathered}\Phi(\lambda(\rho_\epsilon), \mu(\rho_\epsilon)) = \Phi(K_1(\rho_\epsilon), K_2(\rho_\epsilon)) + O(\epsilon^2),\\ \Phi(\lambda(\rho^*), \mu(\rho^*)) = \Phi(K_1(\rho^*), K_2(\rho^*)),\\ \delta\Phi(\lambda(\rho), \mu(\rho)) = \delta\Phi(K_1(\rho), K_2(\rho)) \textit{ at } \rho = \rho^*.\end{gathered}$$

The proof of this theorem follows immediately from Theorem 1 and the inequality

$$|\Phi(\lambda(\rho_\epsilon), \mu(\rho_\epsilon)) - \Phi(K_1(\rho_\epsilon), K_2(\rho_\epsilon))| \le L\{\,|\lambda(\rho_\epsilon) - K_1(\rho_\epsilon)| + |\mu(\rho_\epsilon) - K_2(\rho_\epsilon)|\,\} = O(\epsilon^2).$$

It follows that ρ^* is an extremal of $\Phi(\lambda(\rho), \mu(\rho))$ if and only if it is also an extremal of the classical functional $\Phi(K_1(\rho), K_2(\rho))$. We may now proceed to find ρ^* using well-known methods. Incidentally, this theory requires only that the function Φ satisfy a Lipschitz condition, not that it be differentiable as other treatments of the problem have assumed. This is especially critical for the example $\Phi(u, v) = \min\{u, v\}$ considered below.

2. The strongest column in three dimensions. An interesting problem, with a long history (see, for example, [16],[8],[12],[18],[14],[2]) is to design a column having a given length and volume, so that, when subject to an axial compressive load, the critical buckling load is as large as possible. We will now investigate this problem allowing certain kinds of three-dimensional variation in its cross-sectional shape, and allowing for three-dimensional supports of the end points. Suppose the column lies on the x axis, has length l, is perpendicular to the y-z plane and, at $x = 0$, is attached to

a crankshaft using a journal bearing. The crankshaft is the y axis. Thus, the column is pinned in the x-z plane but it is clamped in the x-y plane. Suppose that it is pinned in both planes at $x = l$.

Let $\mathcal{D}_x$ be a cross section of the column, taken by a plane parallel to the y-z plane at a distance x from it. We will need the two moments of inertia $I_y(\mathcal{D}_x)$ and $I_z(\mathcal{D}_x)$ of the cross section defined by

$$I_y(\mathcal{D}_x) = \iint_{\mathcal{D}_x} z^2\,dy\,dz, \qquad I_z(\mathcal{D}_x) = \iint_{\mathcal{D}_x} y^2\,dy\,dz.$$

The critical buckling load in the x-y plane is determined by the second eigenvalue λ_2, of the system [19],[2]

$$y'' + \frac{\lambda}{I_z(\mathcal{D}_x)}y = 0, \qquad y(0) + y'(0) = 0, \quad y(l) = 0,$$

while the critical buckling load in the x-z plane is determined by the first eigenvalue μ_1, of the system

$$z'' + \frac{\mu}{I_y(\mathcal{D}_x)}z = 0, \qquad z(0) = 0, \quad z(l) = 0.$$

For now, we will only consider buckling in these two planes. In §2.4 we will consider diagonal planes.

We will suppose that, at any given x, the shape of the cross section $\mathcal{D}_x$ is determined by using some given geometrical figure, call it $\widehat{\mathcal{D}}$, such as a circle or square, and applying to $\widehat{\mathcal{D}}$ a stretching factor, $a(x)$ in the y direction, and $b(x)$ in the z direction, to obtain the cross section $\mathcal{D}_x$. So, for example, if $\widehat{\mathcal{D}}$ is a circle, then $\mathcal{D}_x$ will be an ellipse; if $\widehat{\mathcal{D}}$ is a square, then $\mathcal{D}_x$ will be a rectangle. The quantities $a(x)$, $b(x)$ are nondimensional variables.

We will assume, for convenience and without loss of generality, that the two moments of inertia of $\widehat{\mathcal{D}}$ satisfy $I_y(\widehat{\mathcal{D}}) = I_z(\widehat{\mathcal{D}}) = 1$. Indeed, if this were not true, then we could first stretch $\widehat{\mathcal{D}}$ one way or another to make it true, and then simply multiply $a(x)$ and $b(x)$ by appropriate constants and still maintain the same size and shape for the column.

We will now map $\widehat{\mathcal{D}}$ onto $\mathcal{D}_x$ using the stretching transformation $y = a(x)\widehat{y}$, $z = b(x)\widehat{z}$. We see that

$$I_y(\mathcal{D}_x) = \iint_{\mathcal{D}_x} y^2\,dy\,dz = a^3(x)b(x)\iint_{\widehat{\mathcal{D}}} \widehat{y}^2\,d\widehat{y}\,d\widehat{z} = a^3(x)b(x).$$

Similarly, $I_z(\mathcal{D}_x) = a(x)b^3(x)$. Thus, we obtain the equations

$$y'' + \frac{\lambda}{a^3(x)b(x)}y = 0, \qquad y(0) + y'(0) = y(l) = 0, \tag{4}$$

$$z'' + \frac{\mu}{a(x)b^3(x)}z = 0, \qquad z(0) = z(l) = 0. \tag{5}$$

We use the following notation: $A(x)$ is the area of $\mathcal{D}_x$, $\widehat{A}$ is the area of $\widehat{\mathcal{D}}$, V is the volume of the column, and $\widehat{V} = V/\widehat{A}$. It follows that

$$A(x) = \iint_{\mathcal{D}_x} dy\,dz = a(x)b(x)\widehat{A}, \qquad \int_0^l a(x)b(x)\,dx = \widehat{V}. \tag{6}$$

In order to avoid certain difficulties with singular points [6], we will also assume that constants H_1, H_2, H_3, H_4 are given and that the functions $a(x)$, $b(x)$ are constrained by the conditions

$$(7)\quad 0 < H_1 \le a(x) \le H_2, \qquad 0 < H_3 \le b(x) \le H_4, \qquad lH_1H_3 < \widehat{V} < lH_2H_4.$$

We let $\mathcal{C}$ denote the class of all piecewise continuous function pairs $(a(x), b(x))$ satisfying (7). The eigenvalues of (4), (5) are real valued functionals of the pair $(a(x), b(x))$, and we denote them by $\lambda_n(a,b)$, $\mu_m(a,b)$. The critical buckling load in the x-y plane is determined by $\lambda_2(a,b)$ and in the x-z plane by $\mu_1(a,b)$. If we want the strongest column, then we need to maximize the minimum of the two.

Problem 2. Let $\lambda_2(a,b)$ be the second eigenvalue of (5), and let $\mu_1(a,b)$ be the first eigenvalue of (4). Find $(a^*(x), b^*(x)) \in \mathcal{C}$, that maximizes the functional

$$\min\{\lambda_2(a,b),\ \mu_1(a,b)\}$$

over all $(a,b) \in \mathcal{C}$.

We will assume that a solution $(a^*(x), b^*(x)) \in \mathcal{C}$ of Problem 2 exists.

2.1. The necessary conditions for the strongest column. Suppose that we are given extremals $(a^*(x), b^*(x))$ for Problem 2 and let y^*, z^* be the corresponding eigenfunctions of (4), (5). To obtain the necessary conditions, we first use Theorem 1 to calculate the functionals $K_i(a,b)$ finding,

$$(8)\quad \begin{aligned} K_1(a,b) &= 2\lambda_2^* - y^{*2}(0) - \int_0^l \frac{\lambda_2^*}{a^3(x)b(x)} y^{*2}\,dx, \\ K_2(a,b) &= 2\mu_1^* - \int_0^l \frac{\mu_1^*}{a(x)b^3(x)} z^{*2}\,dx. \end{aligned}$$

We now use Theorem 2, with $\Phi(u,v) = \min\{u,v\}$ to transform Problem 2 into the following more easily understood problem.

Problem 3. With K_1, K_2 defined by (8) find $(a^*(x), b^*(x)) \in \mathcal{C}$, that maximizes the functional

$$\min\{K_1(a,b),\ K_2(a,b)\}$$

over all $(a,b) \in \mathcal{C}$.

In most cases, the extremal (a^*, b^*) will be such that $\lambda_2^* = \mu_1^*$. If not, we could shave a little mass from one side of the column and paste it onto the other, thereby increasing its overall strength. The only time this is not possible is when the constraints H_i interfere with this possibility (if, for example, $a^*(x) = H_1$ for all x). Although it could be easily done, we will not give the details of the analysis in such degenerate cases since, with any reasonable choice of H_i, a little working space would be left over. It would require consideration of various cases, in which we take either $a(x) \equiv H_i$ or $b(x) \equiv H_i$ and, one by one, optimize over the other function. Such problems have been dealt with extensively before. Thus we will assume that $K_1(a^*, b^*) = K_2(a^*, b^*)$. This relationship can now be used to transform Problem 3 into the following form.

Problem 4. Find $(a^*(x), b^*(x)) \in \mathcal{C}$, that maximizes the functional $K_1(a,b)$ over all $(a(x), b(x)) \in \mathcal{C}$ satisfying the additional constraint $K_1(a,b) - K_2(a,b) = 0$. That is,

$$2\lambda_2^* - y^{*2}(0) - 2\mu_1^* + \int_0^l \left\{ \frac{\mu_1^*}{a(x)b^3(x)} z^{*2} - \frac{\lambda_2^*}{a^3(x)b(x)} y^{*2} \right\} dx = 0.$$

This is one example of a class of rather ordinary problems in calculus of variations. Generally, they are of the following form.

Problem 5. Find $\rho^*(x)$ so that $J(\rho) = \int_0^l F_0(x, \rho(x))\,dx$ is a maximum subject to the constraints,

$$\int_0^l F_i(x, \rho(x))\,dx = V_i \quad \text{for } i = 1, 2, 3, \cdots, N \text{ and } \quad h \le \rho(x) \le H.$$

The solution of such problems can be obtained using the method of Lagrange Multipliers. See, for example, the books by Hestenes [10] or Troutman [20] for the following theorem.

THEOREM 3. *Let $F_i(x, \rho)$ be continuous and let $\rho^*(x)$ be a solution of Problem* 5. *Then there exist constants $\gamma_0 \ge 0$ and $\gamma_1, \gamma_2, \cdots, \gamma_N$, not all zero, such that for all $x \in [0, l]$,*

$$\begin{aligned}(9)\qquad &\max_{h \le \rho \le H} \{\gamma_0 F_0(x, \rho) + \gamma_1 F_1(x, \rho) + \cdots + \gamma_N F_N(x, \rho))\} \\ &\qquad = \gamma_0 F_0(x, \rho^*(x)) + \gamma_1 F_1(x, \rho^*(x)) + \cdots + \gamma_N F_N(x, \rho^*(x)).\end{aligned}$$

Conversely, if a function $\rho^*(x)$ and constants $\gamma_0 > 0$, and $\gamma_1, \gamma_2, \cdots \gamma_N$ exist satisfying (9) *and if the conditions*

$$\int_0^l F_i(x, \rho^*(x))\,dx = V_i\,, \qquad h \le \rho^*(x) \le H$$

hold, then $\rho^*(x)$ solves Problem 5.

We will use the converse part of Theorem 3 and methods similar to those used in [3],[4] to solve Problem 4. Using $\rho = (a, b)$ and selecting convenient values for the Lagrange Multipliers γ_i we find, after a bit of manipulation, that the extremal condition for (a, b) as a function of y, z can be obtained as the solution of the following elementary minimum problem.

Problem 6. For any given $y, z \ge 0$, find the values of a, b that minimizes the function $r(a, b)$ defined by

$$r(a, b) = \frac{y^2}{a^3 b} + \frac{z^2}{a b^3} + ab,$$

over all (a, b) in the rectangle $H_1 \le a \le H_2, \quad H_3 \le b \le H_4$.

The minimizing point for r is uniquely defined and is a continuous function of y, z. Thus we can express the extremal condition for Problem 4 in the general form

$$(10)\qquad a = S_1(y, z), \qquad b = S_2(y, z).$$

More precisely, the values for $S_1(y, z)$ and $S_2(y, z)$ that minimize r are selected from the following five possibilities.

If the minimum is inside the rectangle, then solving $\partial r/\partial a = 0$ and $\partial r/\partial b = 0$ simultaneously gives

$$(11)\qquad a = \sqrt[3]{2y^2/z}, \qquad b = \sqrt[3]{2z^2/y}.$$

If the minimum is on the bottom or the top of the rectangle, then either $b = H_3$ or $b = H_4$ and solving $\partial r/\partial a = 0$ gives

$$(12)\qquad a = \max\left\{H_1,\ \min\left\{H_2,\ \sqrt{z^2 + \sqrt{z^4 + 12b^6y^2}}\Big/\sqrt{2b^2}\right\}\right\}.$$

If the minimum is on the left or right edge then either $a = H_1$ or $a = H_2$ and solving $\partial r/\partial b = 0$ gives

$$b = \max\left\{H_3,\ \min\left\{H_4,\ \sqrt{y^2 + \sqrt{y^4 + 12a^6z^2}}\Big/\sqrt{2}a^2\right\}\right\}. \tag{13}$$

Now (10) can now be inserted into (4), (5) to obtain a pair of nonlinear second-order differential equations for y, z which we write in the vector form

$$\vec{U}' = \vec{G}\left(x, \vec{U}\right), \qquad \text{where} \qquad \vec{U} = (y, yp, z, zp), \qquad y' = yp, \quad z' = zp. \tag{14}$$

The solution of this system will then give $a(x)$, $b(x)$, using (10).

2.2. The numerical solutions. The equations (14) are, for the most part, numerically well behaved. In order to begin the solution of (14) we need four boundary conditions at $x = 0$. We choose two parameters y_0 and z_0' and use the given boundary conditions (4), (5) to obtain the four initial conditions

$$\vec{U}\Big]_{x=0} = (y_0, -y_0, 0, z_0').$$

The three values y_0, z_0', and λ are then used as shooting parameters to satisfy the two boundary conditions at $x = l$ and the volume condition (6). This gives a system of three equations in three unknowns of the form $\vec{F}(\vec{\alpha}) = \vec{0}$ where

$$\vec{\alpha} = (y_0, z_0', \lambda), \qquad \vec{F}(\vec{\alpha}) = \left(y(l),\ z(l),\ \widehat{V} - \int_0^l a(x)b(x)\,dx\right).$$

The numerical solution of this problem was quite straightforward. Some canned subroutines from the standard computing package CMLIB were used. The initial value problem (14) was solved using DEBRKF and the subroutine SNSQE was used to solve the three simultaneous equations $\vec{F}(\vec{\alpha}) = \vec{0}$. A simple FORTRAN program was written, which defined the equations, called up the subroutines from CMLIB and output the results. Some computer-generated plots of the extremals are given in Fig. 1 where the curves are labeled as follows: 1 is b, 2 is ab, 3 is a, 4 is z, 5 is y, 6 is $1/(ab^3)$, and 7 is $1/(a^3b)$. An artist's visualization[1] of this three-dimensional shape is also given in the left-hand side of Fig. 2. The other two columns are the optimal shapes for other boundary conditions. The middle one is when both ends of the column are supported by journal bearings where the shafts are at right angles to each other. The one on the right is when both ends are supported by journal bearings having the two shafts parallel to each other.

The only real difficulty with the method was that a very good first guess (sometimes to within 30 percent or so) had to be used for $\vec{\alpha}$ in order to get convergence from SNSQE. Depending on the accuracy of the first guess (if it produced convergence), it would generally require less than 30 to 60 seconds of CPU time on a VAX-11/750 computer to get the solution when using 100 mesh points.

SNSQE works by simply minimizing the norm of $\vec{F}$. This sometimes gave erroneous solutions for which the norm was locally minimized but was not small. There were also invalid solutions having a very small norm, but either y or z had too many zeros in the interval. Occasional difficulties arose with the calculation of y^2/z and z^2/y near $x = l$ where both vanish. In this case, it was easy to simply recognize that we should have $a(x) = H_1$ and $b(x) = H_3$.

[1] Figure 2 was drawn by Jack Snowden.

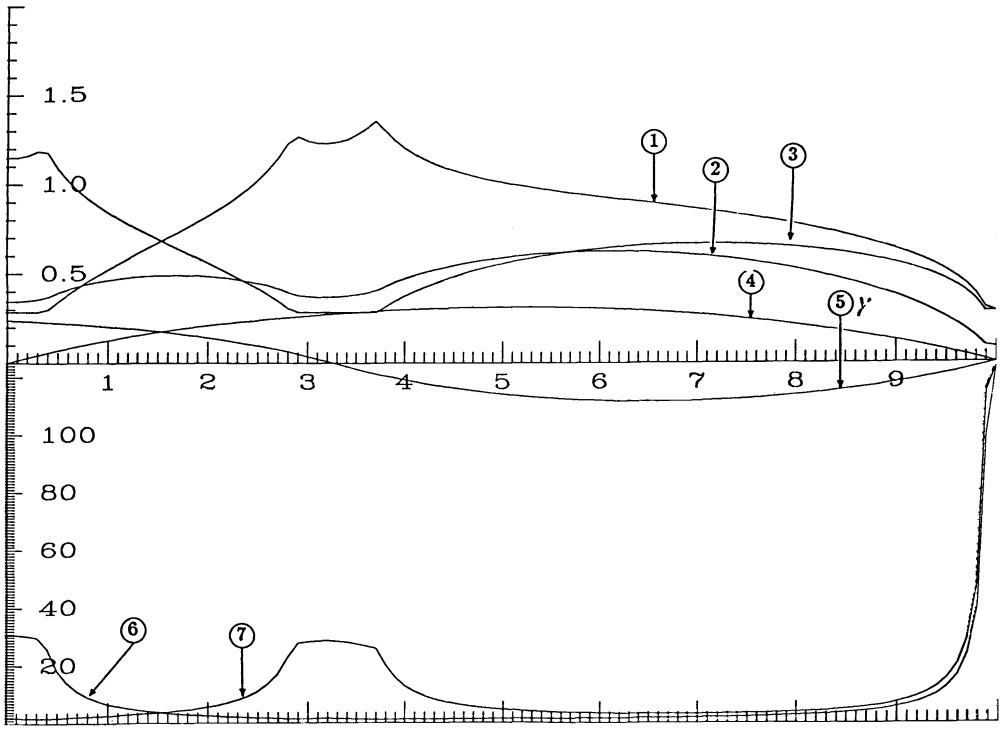

FIG. 1. *Graphs for the clamped-pinned-pinned-pinned column with* $H_1 = H_3 = .3$, $H_2 = H_4 = \infty$, $l = 1$, $y(0) = .2519$, $z'(0) = 1.596$, $\lambda = 5.023$, $\widehat{V} = .5$.

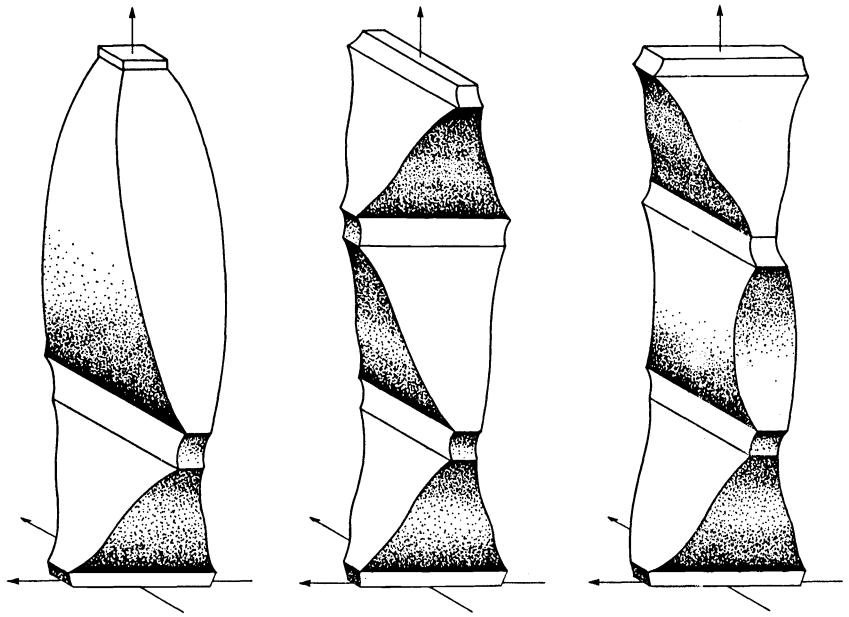

FIG. 2. *The shapes of some strongest columns using a square for* $\widehat{D}$.

2.3. Discussion of the solutions and generalizations. Many results in the literature (for example, [1],[2] and the references given there) use arguments involving rearrangements to prove certain kinds of symmetry relationships for the solution of some extremal eigenvalue problems. Although, the shape of this column (given in the left-hand side of Fig. 2) is not at all symmetric, it is interesting to note that, for most choices of H_i, the computed values for the eigenfunction z were observed to satisfy the relation $z(x) = z(l - x)$ to within a few percent. In a similar way, if x^* is the interior zero of the eigenfunction y then the symmetry relations $y(x^* - x) = -y(x^* + x)$ and $y(l - x) = y(x^* + x)$ are "almost" satisfied. Considering the strange and nonsymmetrical shape of the column on the left side of Fig. 2, it is, on the one hand, remarkable that the eigenfunctions displayed such a high degree of symmetry. On the other hand, this is the optimal shape, so a nearly symmetrical buckling mode is to be expected. In fact, it was observed that the solutions y, z became more and more symmetric as $H_1, H_3 \to 0$ and $H_2, H_4 \to \infty$. It also appeared that the graph of the cross-sectional area $a(x)b(x)$ was smooth at the points near $x = \frac{1}{3}$ where the other functions had corner points.

There are many different combinations of boundary conditions that could be imposed on the column besides those considered so far. It could be either clamped, pinned, or free in either the x-y plane or in the x-z plane at either $x = 0$ or $x = l$. The extremal condition (10) is the same in any case. The only difference occurs in the boundary conditions to be imposed on y and z. Figure 2 shows the optimal shapes for some other possible combinations of boundary conditions.

Suppose we consider the example where the column is pinned in all directions at both $x = 0$ and $x = l$. Let us also take $H_1 = H_3 = 0$ and $H_2 = H_4 = \infty$.[2] Because of the symmetric nature of the problem, the extremals will satisfy $a(x) = b(x)$ and $y = z$. The extremal condition (10) reduces to $a^3(x)b^3(x) = 4yz$, the singularities have canceled out, and, using $A(x) = \hat{A}a(x)b(x)$, we see that $A^3(x) = 4\hat{A}^3y^2$. When y is properly renormalized, this is the same extremal condition used by Keller [12].

It is interesting to note that if $H_1 > 0$ and $H_3 > 0$ are fixed, then H_2 and H_4 will not impinge on the extremal shapes if they are large enough. That is, the computed values for the extremal solution $a(x)$, $b(x)$ will automatically satisfy $a(x) < H_2$ and $b(x) < H_4$ for all x, so we can take $H_2 = H_4 = \infty$. Also, if H_2 and H_4 are fixed and if the eigenfunctions y, z do not have a common zero, then the lower bounds H_1 and H_2 will not impinge on the extremal shape if they are small enough. A proof of these statements can be based on (11)-(13). Another way to think about this is to hold all the bounds H_i fixed and change $\hat{V}$. If $\hat{V}$ is small enough, then H_2 and H_4 will not impinge. If, however, $\hat{V}$ is large enough and if, in addition, y, z do not have a common zero, then H_1 and H_3 will not impinge. If, however, y, z have a common zero, then H_1 and H_3 will always impinge. In any of these cases, at least one of the constraints will always impinge.

2.4. Buckling in other planes. We now propose to consider buckling in some plane other than the x-y or x-z planes. Suppose that $\hat{\mathcal{D}}$ is a very thin rectangle with its axis inclined at an angle of $\pi/4$ to the x-z plane. In this case the column will clearly not buckle first in either the x-y or x-z planes as expected. We must take care of this possibility by imposing some further restrictions on the geometry of $\hat{\mathcal{D}}$.

Let P_θ be a plane containing the x axis including an angle θ between P_θ and the x-z plane. Let $I(x, \theta)$ denote the moment of inertia of $\mathcal{D}_x$ about a line through its

[2] One must, however, be careful when using $H_1 = H_3 = 0$. There are unexpected problems associated with such things [6].

centroid and perpendicular to P_θ so that

$$I(x,\theta) = \iint_{D_x} r^2\,dy\,dz, \qquad r = |y\sin\theta - z\cos\theta|.$$

It follows that

$$I(x,\theta) = a^3(x)b(x)\sin^2\theta + a(x)b^3(x)\cos^2\theta - a^2(x)b^2(x)\sin 2\theta \iint_{\widehat{D}} \widehat{y}\widehat{z}\,d\widehat{y}\,d\widehat{z}.$$

In order to rule out the case of the inclined thin rectangle considered above, and others like it, we will simply assume that $\widehat{D}$ satisfies the condition, $\iint_{\widehat{D}} \widehat{y}\widehat{z}\,d\widehat{y}\,d\widehat{z} = 0$. This could be easily achieved by rotating $\widehat{D}$ in the y-z plane and then renormalizing it so that $I_y(\widehat{D}) = I_z(\widehat{D}) = 1$. It follows that the moment of $\widehat{D}$ is 1 with respect to any line and that $I(x,\theta) = a^3(x)b(x)\sin^2\theta + a(x)b^3(x)\cos^2\theta$. Now we see that if θ moves from 0 to $\pi/2$ then $I(x,\theta)$ is a monotonic function, moving between the two values $a^3(x)b(x)$ and $a(x)b^3(x)$.

Suppose the column buckles in the P_θ plane and let $w(x)$ be the displacement in the buckled state. At $x = 0$ the boundary conditions on w should be intermediate between being pinned and clamped. Such conditions are given by

$$w(0) = (1-\alpha)w''(0) + \alpha w'(0) = 0, \qquad w(l) = w''(l) = 0.$$

The number $\alpha \in [0,1]$ measures the "hardness" of the support for the column at $x = 0$ in the P_θ plane. It is a function of θ so that, $\alpha = \alpha(\theta)$. We now introduce the bending moment $v = I(x,\theta)w''$ and, using the equations given by Barnes [2], we obtain the boundary conditions and the eigenvalue problem for the determination of the buckling load in the P_θ plane

$$(15) \qquad v'' + \frac{\Lambda}{I(x,\theta)}v = 0, \qquad \alpha I(0,\theta)[v(0) + v'(0)] - \Lambda(1-\alpha)v(0) = v(l) = 0.$$

Note that the eigenvalue Λ occurs in both the boundary conditions and in the differential equation. In order to ensure that the solution of Problem 2 determined above really is maximal, we need to guarantee that the column will buckle first in the x-y and x-z planes and not in any P_θ plane. To do this we select a value for $\alpha = \alpha_0(\theta)$ so that the second eigenvalue Λ of (15) is equal to the optimal value λ^*, determined above. That is, we make the support as hard as is necessary. Then, $\alpha_0(\theta)$ will define the lower limit on α for which these solutions are really the optimal ones. It would be simple enough to calculate this value in any given example using (15).

These observations show one way to deal with buckling in the P_θ plane. Another way would be to optimize over each plane P_θ for any given support function $\alpha(\theta)$. We leave that problem for the interested reader to pursue.

CANONICAL FACTORIZATIONS OF DISCONJUGATE DIFFERENTIAL OPERATORS—PART II*

ANTONIO GRANATA†

Abstract. This paper, which completes the discussion in Part I [*SIAM J. Math. Anal.*, 11 (1980), pp. 160–172], provides the following: (1) some characterizations of those operators that are disconjugate on an open interval $\mathcal{T}$ and that admit only one Pólya–Mammana factorization on $\mathcal{T}$ (constant factors apart); (2) a sufficient condition for the existence, on a given interval of disconjugacy, of a double canonical factorization of type (II) together with some counterexamples showing that the given condition is likely to be necessary. A detailed nontrivial treatment of factorizations of second-order operators will guide and highlight the whole discussion.

Key words. disconjugacy, canonical factorizations

AMS(MOS) subject classifications. primary 34C10; secondary 34C99

Introduction. This paper is a continuation of a previous work [3] and solves some of the problems left open therein. The numbering of the sections and formulas follows that given in [3]. As in the first part, operators of type (*) are considered; see formula (1.1) and subsequent lines in [3]. The particular factorizations discussed are always of type (1.3)–(1.4); it is tacitly assumed that these factorizations are *global* on the specified interval: [3, p. 162, line 5]. Disconjugacy on a *closed* interval $[a, b]$, $-\infty \leqq a < b \leqq +\infty$ (closed in the topology of the extended real line), is meant in the sense given by Definition 3.5. Besides the symbol $D_n(a, b)$ (see Definition 2.1), we use the symbols $D_n[a, b)$, $D_n(a, b]$, and $D_n[a, b]$, all of whose meanings are obvious. It must be kept in mind that the three relationships $L \in D_n(a, b)$, $L \in D_n[a, b)$, and $L \in D_n(a, b]$ are equivalent to each other [6, Lemma 2.3]. On the other hand, $L \in D_n[a, b]$ is in general a stronger property than $L \in D_n(a, b)$; for example, the operator d^n/dt^n belongs to $D_n(-\infty, +\infty)$ but not to $D_n[-\infty, +\infty]$. The following definition can be useful.

DEFINITION. The symbol $\tilde{D}_n[a, b]$ denotes the set of all the operators $L \in D_n(a, b)$ such that L has the properties stated in Theorem 3.3.

The locutions "one" or "essentially unique" (in quotes) are used to mean "one apart from constant factors" when referring to a function, a set of functions, or the coefficients p_i of a factorization (1.3). C.F. is used instead of *canonical factorization* for the sake of brevity.

6. Factorizations of second-order operators. We discuss some nonobvious results concerning second-order operators that clarify the main results in the following sections.

A. A description of all the possible factorizations. Given a linear second-order operator

$$L_2 u \equiv u'' + a_1(t)u + a_0(t)u; \quad a_i \in L^1_{\text{loc}}(a, b) \quad (i = 1, 2), \tag{6.1}$$

we shall describe all its possible factorizations on (a, b) of type

$$L_2 u \equiv p_2[p_1(p_0 u)']' \quad \forall u \in AC^1(a, b) \tag{6.2}$$

for some suitable strictly positive functions $p_i(t)$, $i = 1, 2, 3$.

* Received by the editors December 8, 1986; accepted for publication (in revised form) October 10, 1987. This paper was written while the author was a member of the Italian Committee for Scientific Research C.N.R.-G.N.A.F.A.

† Dipartimento di Matematica, Università della Calabria, 87036 Rende (Cosenza), Italy.

THEOREM 6.1. *If $L_2 \in D_2(a, b)$, then for each solution u_0 to $L_2u = 0$ strictly positive on (a, b), there exists a "unique" factorization of type* (6.2) *such that $p_0(t) \equiv 1/u_0(t)$. The coefficient p_1 in this factorization is given by*

$$p_1(t) = \frac{1}{p_0^2(t)} \exp\left(\int_{t_0}^{t} a_1(\tau)\, d\tau\right) \quad \text{with } t_0 \text{ fixed in } (a, b), \tag{6.3}$$

while p_2 is obviously given by $p_2(t) = 1/p_0p_1$. In particular all the factorizations of the operator $u'' + q(t)u$, $q \in L^1_{\text{loc}}(a, b)$, are given by

$$u'' + q(t)u \equiv \frac{1}{u_0(t)}\left[u_0^2(t)\left(\frac{u}{u_0(t)}\right)'\right]', \qquad u_0(t) > 0 \quad \text{on } (a, b). \tag{6.4}$$

Proof. Our simple argument completes the standard one used to show the existence of a factorization (6.2) (cf. [1, p. 6] or [7, p. 316]). If (6.2) holds true, the function $u_0(t) \equiv 1/p_0(t)$ must be a solution strictly positive on (a, b), whence it follows that all the possible factorizations can be obtained by considering all the possible choices for p_0. When p_0 has been fixed, we infer from the identity (6.2) that

$$L_2u = 0 \Leftrightarrow p_2[p_1(p_0u)']' = 0$$

if and only if

$$p_1(t)[p_0(t)u(t)]' = \text{constant} \quad \forall u \text{ such that } L_2u = 0, \tag{6.5}$$

where the constant obviously depends on the choice of u. To derive p_1 from (6.5) let us suppose that u is any solution independent of $1/p_0$ (otherwise $u(t) \equiv c/p_0(t)$ and $(p_0(t)u(t))' \equiv 0$). In this case Liouville's formula gives

$$W\left(u(t), \frac{1}{p_0(t)}\right) = A \exp\left(-\int_{t_0}^{t} a_1(\tau)\, d\tau\right)$$

where $A = \text{constant} \neq 0$ and t, $t_0 \in (a, b)$. On the other hand, direct calculations give

$$W\left(u(t), \frac{1}{p_0(t)}\right) = -\frac{(p_0u)'}{p_0^2}$$

whence

$$(p_0u)' - Ap_0(t) \exp\left(-\int_{t_0}^{t} a_1(\tau)\, d\tau\right). \tag{6.6}$$

From (6.5), (6.6) it can be inferred that, up to a constant factor, p_1 is given by (6.3). □

B. Examples: Constant coefficient operators. In order to illustrate the theorem we consider the operator

$$L_2u \equiv u'' + Au' + Bu \quad \text{where } A, B \text{ are real constants.} \tag{6.7}$$

Let r_1 and r_2 be the complex roots of the characteristic equation $r^2 + Ar + B = 0$. When r_1 and r_2 are not real, then L_2 is only disconjugate on sufficiently small intervals of $\mathbb{R}$, while when both r_1 and r_2 are real then L_2 is disconjugate on $(-\infty, +\infty)$ and hence on any interval of $\mathbb{R}$. Let us limit our investigation to those cases where the roots are real.

First case. $A^2 - 4B = 0$. The operator is

$$L_2u \equiv u'' + Au' + \frac{A^2}{4}u. \tag{6.8}$$

(i) If we choose $(a, b) = (-\infty, +\infty)$, then L_2 has only "one" factorization, namely

$$L_2 u \equiv e^{-(A/2)t}[(e^{(A/2)t})']' \tag{6.9}$$

which, by Theorem 2.1, is necessarily a double C.F. of type (I).

(ii) If we choose $(a, b) \neq \mathbb{R}$ then, besides (6.9), L_2 admits of an infinite number of factorizations which are given by

$$L_2 u \equiv \frac{e^{-(A/2)t}}{\alpha + \beta t}\left[(\alpha + \beta t)^2\left(\frac{e^{(A/2)t}u}{\alpha + \beta t}\right)'\right]' \tag{6.10}$$

where α, β are such that $\alpha + \beta t > 0$ on (a, b). Hence it can be seen that on any fixed interval (a, b), L_2 has an infinite number of essentially different double C.F.s of type (II).

Second case. $A^2 - 4B > 0$. Assuming that $r_1 < r_2$, we have the following three types of factorizations:

$$L_2 u \equiv e^{r_1 t}[e^{(r_2 - r_1)t}(e^{-r_2 t}u)']' \quad \text{on } (-\infty, +\infty), \tag{6.11}$$

which is of type (I) at $-\infty$ and of type (II) at $+\infty$;

$$L_2 u \equiv e^{r_2 t}[e^{(r_1 - r_2)t}(e^{-r_1 t}u)']' \quad \text{on } (-\infty, +\infty), \tag{6.12}$$

which is of type (II) at $-\infty$ and of type (I) at $+\infty$;

$$L_2 u \equiv \frac{e^{(r_1+r_2)t}}{\alpha e^{r_1 t} + \beta e^{r_2 t}}\left[\frac{(\alpha e^{r_1 t} + \beta e^{r_2 t})^2}{e^{(r_1+r_2)t}}\left(\frac{u}{\alpha e^{r_1 t} + \beta e^{r_2 t}}\right)'\right]' \tag{6.13}$$

where α, β are such that $\alpha e^{r_1 t} + \beta e^{r_2 t} > 0$ on the chosen interval (a, b). Hence, corresponding to all the possible couples α, $\beta > 0$, we obtain an infinite number of factorizations valid on any interval (a, b), all of which are double C.F.s of type (II) on (a, b), including the case $(a, b) = (-\infty, +\infty)$.

C. Theoretical results. The above examples provide a good illustration of the following general results.

THEOREM 6.2. *Let* $L_2 \in D_2(a, b)$.

(I) *The following properties are equivalent*:

(i) $L_2 \in \tilde{D}_2[a, b]$;

(ii) $L_2 u = 0$ *has only "one" solution* u_0 *that is strictly positive on* (a, b);

(iii) L_2 *has only "one" factorization on* (a, b) *of type* (1.3)-(1.4), *which is necessarily a double* C.F. *of type* (I).

(II) L_2 *is disconjugate on* $[a, b]$ *if and only if it has infinitely many essentially different double* C.F.*s of type* (II).

In the case where $L_2 \in D_2[a, b]$, we can give a complete description of the various types of factorizations by relating them to a mixed hierarchical system of solutions.

THEOREM 6.3. *Let* $L_2 \in D_2[a, b]$ *and let* $(\bar{u}_1, \bar{u}_2)$ *be the mixed hierarchical system of solutions to* $L_2 u = 0$ *such that*

$$\begin{aligned} &\bar{u}_1 \ll \bar{u}_2, \qquad t \to a, \\ &\bar{u}_2 \ll \bar{u}_1, \qquad t \to b. \end{aligned} \tag{6.14}$$

Then:

(I) L_2 *has a* ("*unique*") *factorization on* (a, b) *of form*

$$L_2 u = p_2\left[p_1\left(\frac{u}{\bar{u}_1}\right)'\right]', \tag{6.15}$$

which is the C.F. *of type* (I) *at a.*

Similarly L_2 has a ("unique") factorization on (a, b) of form

$$L_2u \equiv q_2\left(q_1\left(\frac{u}{\bar{u}_2}\right)'\right]', \tag{6.16}$$

which is the C.F. *of type* (I) *at b.*

(II) *If $\bar{u}$ is any solution to $L_2u = 0$ of type*

$$\bar{u}(t) = \alpha\bar{u}_1(t) + \beta\bar{u}_2(t) \quad (\alpha, \beta = \textit{positive constants}), \tag{6.17}$$

then L_2 has a ("unique") factorization on (a, b)

$$L_2u \equiv r_2\left(r_1\left(\frac{u}{\bar{u}}\right)'\right]', \tag{6.18}$$

which is a double C.F. *of type* (II).

Proofs of Theorems 6.2 *and* 6.3. It is known that the operator L_2 is disconjugate on (a, b) if and only if $L_2u = 0$ has a solution u_0 that is strictly positive on (a, b). Two contingencies can arise: there exists only "one" strictly positive solution on (a, b) or there are two linearly independent such solutions (hence infinitely many, essentially different such solutions). Now the claims in Theorem 6.2 directly follow from Theorem 6.1 by considering that, for a second-order operator, each factorization is a C.F. at each separate endpoint. In order to prove Theorem 6.3, note that the two functions $\bar{u}_1$, $\bar{u}_2$ are strictly positive on (a, b) [3, Lemma 5.5]; hence, by Theorem 6.1, L_2 has "unique" factorizations on (a, b) of form (6.15), (6.16), and (6.18). Let us examine (6.15), which implies that $L_2u = 0$ has a solution $v(t) \equiv \bar{u}_1(t)\int_{t_0}^{t} 1/p_1$, with t_0 arbitrarily fixed on (a, b). As v and $\bar{u}_1$ are linearly independent, the first relation (6.14) implies that $\bar{u}_1 = o(v)$, $t \to a$. This in turn implies that

$$\lim_{t\to a}\left|\int_{t_0}^{t}\frac{1}{p_1}\right| = +\infty, \quad \text{i.e.,} \quad \int_a \frac{1}{p_1} = +\infty.$$

The claim about (6.16) is similarly proved. Factorization (6.18) implies that $L_2u = 0$ has a solution $w(t) \equiv \bar{u}(t)\int_{t_0}^{t} 1/r_1$. On the other hand, both (6.14) and (6.17) imply that $\bar{u}$ is a solution with maximal order of growth at both a and b; this means that for any solution u to $L_2u = 0$ both $\lim_{t\to a} u(t)/\bar{u}(t)$ and $\lim_{t\to b} u(t)/\bar{u}(t)$ exist as finite numbers ($=0$ or $\neq 0$). Hence we infer that both limits

$$\lim_{\substack{t\to a\\ [t\to b]}}\frac{w(t)}{\bar{u}(t)} \equiv \lim_{\substack{t\to a\\ [t\to b]}}\int_{t_0}^{t}\frac{1}{r_1}$$

exist in $\mathbb{R}$. This means that $\int_a^b 1/r_1 < +\infty$. □

In the subsequent sections we investigate to what extent the contingencies described in Theorems 6.2 and 6.3 hold for nth order operators. In § 7 we show that Theorem 6.2(I) directly extends to nth order operators. In § 8 a sufficient condition for the existence of a double C.F. of type (II) is given. Section 9 shows that the results in Theorem 6.3, when literally extended to the nth order case, are completely false. For the sake of completeness we now state a refinement of Theorem 6.2 which is interesting in the context of this section but admits of no extension to the nth order case.

PROPOSITION 6.4. *Let the operator L_2, defined by* (6.1), *be disconjugate on (a, b) and define*

$$A_1(t) \equiv \exp\left(\int_{t_0}^{t} a_1(\tau)\, d\tau\right) \tag{6.19}$$

for some fixed $t_0 \in (a, b)$, the particular choice of t_0 being immaterial. Then to the properties listed in Theorem 6.2(I), *the following can be added*:

(iv) $L_2u = 0$ *has a solution u_0 with no zeros both in a neighborhood of a and in a neighborhood of b and such that*

$$\int_a \frac{dt}{A_1(t)u_0^2(t)} = \int^b \frac{dt}{A_1(t)u_0^2(t)} = +\infty. \tag{6.20}$$

If this is the case then $L_2u = 0$ has a "unique" solution u_0 satisfying (6.20); *it coincides with "the" solution u_0 strictly positive on (a, b) and is such that*

$$u_0 \ll u_1, \qquad \begin{cases} t \to a, \\ t \to b, \end{cases} \tag{6.21}$$

for any solution u_1 linearly independent from u_0. The "only" global factorization of L_2 on (a, b) is

$$L_2u \equiv \frac{1}{A_1(t)u_0(t)}\left[A_1(t)u_0^2(t)\left(\frac{u}{u_0^2(t)}\right)'\right]' \quad \forall u \in AC^1(a, b). \tag{6.22}$$

The easy proof can be based on Theorems 3.3 and 6.2 and is left to the reader. Some explanations on the statement are needed. It is a classical fact that if L_2 is nonoscillatory at a $[b]$—which is the case if and only if it is disconjugate on a one-sided neighborhood of a $[b]$—then there is a "unique" solution u_a $[u_b] \neq 0$ in a neighborhood of a $[b]$ such that

$$\int_a \frac{dt}{A_1(t)u_a^2(t)} = +\infty, \qquad \left[\int^b \frac{dt}{A_1(t)u_b^2(t)} = +\infty\right] \tag{6.23}$$

(see Hartman [4_{bis}, p. 355]). If u_a and u_b both exist it can happen that $u_a \neq u_b$ even if $L_2 \in D_2(a, b)$. Proposition 6.4 provides some characterizations for the contingency $u_a = u_b$ to occur and completes the results in Hartman [4_{bis}, Thm. 6.4, p. 355].

7. Operators that admit of only "one" factorization. This section proves the following conjecture made in [3, § 3, p. 165]: the operators described in Theorem 3.3 are those that admit of only "one" global Pólya-Mammana factorization.

THEOREM 7.1. *If $L \in D_n(a, b)$ then to the properties listed in Theorem* 3.3 *the following can be added*:

$(2)_{\text{bis}}$. *L has only "one" factorization of type* (1.3)-(1.4) *on* (a, b).

$(4)_{\text{bis}}$. *If u, v are any two nontrivial solutions to $Lu = 0$ such that $u = o(v)$, $t \to a$, then the relation $u = o(v)$, $t \to b$, also holds true. By interchanging the roles of a and b a similar result is obtained.*

$(5)_{\text{bis}}$. *If u, v are any two nontrivial solutions to $Lu = 0$ such that $u \sim c_1v$, $t \to a$, (for a suitable constant $c_1 \neq 0$), then the relation $u \sim c_2v$, $t \to b$, also holds true (for another suitable constant $c_2 \neq 0$).*

The roles of a and b can be interchanged.

Proof. The inferences $(4)_{\text{bis}} \Rightarrow (4)$ and $(5)_{\text{bis}} \Rightarrow (5)$ are obvious.

$(4) \Rightarrow (4)_{\text{bis}}$. Let $(u_1, \cdots, u_n)$ be some fixed double hierarchical system to $Lu = 0$ on (a, b), i.e.,

$$u_1 \ll u_2 \ll \cdots \ll u_n \quad \text{both as } t \to a \text{ and as } t \to b. \tag{7.1}$$

The hypothesis on u, v implies that there exist two indices j, $k \in \{1, \cdots, n\}$, $j < k$, such that

$$\begin{aligned} u &\sim c_ju_j, \qquad t \to a, \\ v &\sim c_ku_k, \qquad t \to b, \end{aligned} \tag{7.2}$$

where c_j, c_k are suitable constants. From (7.1) and (7.2) we infer that $u \ll v$ both as $t \to a$ and as $t \to b$.

(5)$\Rightarrow$(5)$_{\text{bis}}$. Let $(u_1, \cdots, u_n)$ and $(v_1, \cdots, v_n)$ be two fixed double hierarchical systems; hence

$$\begin{aligned} u_i &\sim \alpha_i v_i, \qquad t \to a, \\ u_i &\sim \beta_i v_i, \qquad t \to b, \end{aligned} \tag{7.3}$$

where α_i, β_i are nonzero constants. On the other hand, for a suitable couple of indices j, $k \in \{1, \cdots, n\}$ we have the relations

$$u \sim \alpha u_j, \quad t \to a, \qquad v \sim \beta v_k, \quad t \to a \quad (\alpha, \beta \neq 0). \tag{7.4}$$

The hypothesis $u \sim c_1 v$, $t \to a$, implies that $j = k$, and from (7.3) and (7.4) we infer that $u \sim c_2 v$, $t \to b$.

(2)$_{\text{bis}}\Rightarrow$(2). It is obvious from Theorem 2.1.

(2)$\Rightarrow$(2)$_{\text{bis}}$. This is true for $n = 2$ (see Theorem 6.2). Assume that $n \geqq 3$ and that

$$Lu = p_n[p_{n-1}(\cdots(p_0 u)' \cdots)']' \tag{7.5}$$

is any global factorization of L on (a, b). We shall prove that (7.5) is necessarily a double C.F. of type (I) on (a, b). As a first step we show that the contingency cannot arise: $\int_a 1/p_1 < +\infty$. If it did arise the two solutions

$$u_0(t) = \frac{1}{p_0(t)} \quad \text{and} \quad u_1(t) = \frac{1}{p_0(t)} \int_a^t \frac{1}{p_1}$$

would verify the relation $u_1 \ll u_0$ as $t \to a$ and also as $t \to b$ (by property (4)$_{\text{bis}}$). But this is impossible since

$$\lim_{t \to b} \frac{u_1(t)}{u_0(t)} = \lim_{t \to b} \int_a^t \frac{1}{p_1} = \int_a^b \frac{1}{p_1} > 0 \quad (\text{possibly} = +\infty).$$

It thus follows that $\int_a 1/p_1 = +\infty$.

Now we want to show that $\int_a 1/p_i = +\infty$ $(i = 1, \cdots, n-1)$. If this were not the case, there would exist a number $k \in \{1, \cdots, n-2\}$ such that

$$\int_a \frac{1}{p_i} = +\infty, \quad i = 1, \cdots, k, \qquad \int_a \frac{1}{p_{k+1}} < +\infty. \tag{7.6}$$

Let us consider the $(k+2)$ solutions

$$u_0(t) = \frac{1}{p_0(t)}, \quad u_i(t) = \frac{1}{p_0(t)} \int_\alpha^t \frac{1}{p_1} \cdots \int_\alpha^{t_{k-1}} \frac{1}{p_k}, \quad i = 1, \cdots, k,$$

$$u_{k+1}(t) = \frac{1}{p_0(t)} \int_\alpha^t \frac{1}{p_1} \cdots \int_\alpha^{t_{k-1}} \frac{1}{p_k} \int_a^{t_k} \frac{1}{p_{k+1}}$$

for some fixed α, $a < \alpha < b$. From (7.6) we infer that

$$u_0 \ll u_1 \ll \cdots \ll u_k, \qquad t \to a \tag{7.7}$$

and also as $t \to b$, by property (4)$_{\text{bis}}$. From (7.7) we infer at once that

$$\int_\alpha^b \frac{1}{p_1} = \lim_{t \to b} \frac{u_1(t)}{u_0(t)} = +\infty.$$

Hence it is legitimate to use l'Hôpital's rule in evaluating the following limit:

$$\lim_{t\to b}\frac{u_2(t)}{u_1(t)}\equiv\lim_{t\to b}\int_\alpha^t\frac{1}{p_1}\int_\alpha^{t_1}\frac{1}{p_2}\Big/\int_\alpha^t\frac{1}{p_1}=\lim_{t\to b}\int_\alpha^t\frac{1}{p_2}.$$

As the limit on the left-hand side is $+\infty$, by (7.7), we derive $\int_\alpha^b 1/p_2=+\infty$.

By iterating the procedure we can show that

$$\int^b\frac{1}{p_i}=+\infty,\qquad i=1,\cdots,k. \tag{7.8}$$

As a conclusive step we investigate the asymptotic behavior, as $t\to b$, of the ratio u_{k+1}/u_k by two different methods giving rise to a contradiction.

First method. Relations (7.8) allow us to iterate l'Hôpital's rule in evaluating the following limit:

$$\begin{aligned}\lim_{t\to b}\frac{u_{k+1}(t)}{u_k(t)}&\equiv\lim_{t\to b}\int_\alpha^t\frac{1}{p_1}\cdots\int_\alpha^{t_{k-1}}\frac{1}{p_k}\int_a^{t_k}\frac{1}{p_{k+1}}\Big/\int_\alpha^t\frac{1}{p_1}\cdots\int_\alpha^{t_{k-1}}\frac{1}{p_k}\\ &=\lim_{t\to b}\int_\alpha^t\frac{1}{p_2}\cdots\int_\alpha^{t_{k-1}}\frac{1}{p_k}\int_a^{t_k}\frac{1}{p_{k+1}}\Big/\int_\alpha^t\frac{1}{p_2}\cdots\int_\alpha^{t_{k-1}}\frac{1}{p_k}\\ &=\cdots=\lim_{t\to b}\int_a^t\frac{1}{p_{k+1}}\equiv A>0\quad(\text{possibly } A=+\infty).\end{aligned} \tag{7.9}$$

Second method. By a similar procedure, using (7.6), we can show that

$$\lim_{t\to a}\frac{u_{k+1}(t)}{u_k(t)}=\lim_{t\to a}\int_a^t\frac{1}{p_{k+1}}=0,$$

and hence, by property $(4)_{\text{bis}}$, that $\lim_{t\to b}u_{k+1}(t)/u_k(t)=0$. This contradicts (7.9) and shows that the contingency (7.6) cannot arise; thus the proof is complete. □

Remarks. (1) Properties $(4)_{\text{bis}}$, $(5)_{\text{bis}}$ mean that the asymptotic behavior of a solution with respect to another solution is the same at both endpoints. (2) Property $(2)_{\text{bis}}$ has a certain historical interest. From some of the early work on factorizations, Frobenius [2], Ince [5, p. 125], and others, we get the distinct impression that these authors unconsciously believed that Pólya-Mammana factorizations were not only valid for any operator (which is false; see Theorem 1.1), but also "unique" (which is again false). This naive conviction led Ince to an inconclusive proof. We refer the interested reader to the introduction in [4], which provides a more detailed historical analysis.

Example. If L is the constant coefficient operator (4.1), considered on the whole real line, then $L\in\tilde{D}_n[-\infty,+\infty]$ if and only if its characteristic equation has a root of multiplicity n, say λ. If this is the case then the only "one" global factorization of L on $(-\infty,+\infty)$ is given by

$$Lu\equiv e^{\lambda t}(e^{-\lambda t}u)^{(n)}. \tag{7.10}$$

8. Double canonical factorizations of type (II). To extend the result in Theorem 6.2(II) to nth order operators the most natural approach would be to ascertain the existence of infinitely many double C.F.s of type (II) by proving the natural extension of Theorem 6.3 to nth order operators. But, as shown by the simple operator d^3/dt^3 (see § 9), all such natural extensions are completely false! Hence the legitimate suspicion arises that not every operator $L\in D_n[a,b]$, $n>2$, has double C.F.s of type (II). On the other hand, there exists one particular case when this contingency is trivially true:

this happens when L is disconjugate on a larger interval than $[a, b]$, say $(a-\varepsilon, b+\varepsilon)$, $\varepsilon > 0$. In this case each factorization of L of type (1.3)-(1.4) on $(a-\varepsilon, b+\varepsilon)$ is obviously a double C.F. of type (II) on (a, b) as the coefficients p_i are continuous and strictly positive on the compact interval $[a, b]$; hence $\int_a^b 1/p_i < +\infty$, $i = 0, 1, \cdots, n$. In this section we give a less trivial sufficient condition for the existence of at least one double C.F. of type (II) by imposing a restriction on the nature of one endpoint. We have as yet no counterexample for the general case and the question still arises whether any operator $L \in D_n[a, b]$, $n > 2$, has a double C.F. of type (II), or even an infinity of them.

A. Extension of disconjugate operators. We give some preliminary results concerning the extension of a disconjugate operator to a larger interval.

LEMMA 8.1. *Let L be an nth order operator of type (*) on an open interval $(a, b) \neq \mathbb{R}$. If L is disconjugate on an interval $[\alpha, \beta] \subsetneqq [a, b]$, then there exists a positive number ε such that L is disconjugate on $(\alpha-\varepsilon, \beta+\varepsilon) \subset (a, b)$. (Agreement: $\alpha-\varepsilon = \alpha$ if $\alpha = a$; $\beta+\varepsilon = b$ if $\beta = b$.)*

Proof. Coppel [1, Lemma 7, p. 93], outlines a proof when L has continuous coefficients. In its full generality Lemma 8.1 follows easily from nontrivial results by Levin [6, § 3]. First, let us suppose that $\beta < b$ and prove that there exists $\varepsilon_1 > 0$ such that $L \in D_n[\alpha, \beta+\varepsilon_1]$. Suppose, if possible, that $L \notin D_n[\alpha, \beta+\varepsilon]$ for each $\varepsilon > 0$; as $L \in D_n[\alpha, \beta]$ by assumption, it follows that $\bar{\alpha} = \beta$, where $\bar{\alpha}$ denotes the point conjugate to α on the right (see the definition in [6, p. 70]). Now Lemma 3.3 [6, p. 71] implies that $L \notin D_n[\alpha, \beta]$, which contradicts our assumption. Extensions to the left of the endpoint a and beyond both endpoints are similarly proved. □

DEFINITION 8.1. For a given operator L of type (*) on some interval (a, b) the endpoint a [b] is called a nonsingular endpoint if $a > -\infty$ [$b < +\infty$] and the coefficients $a_i(t)$, $i = 1, \cdots, n$, in the representation (1.1) are such that

$$a_i \in L^1(a, a+\varepsilon) \quad [a_i \in L^1(b-\varepsilon, b)] \tag{8.1}$$

for some $\varepsilon > 0$. Otherwise the endpoint is termed singular.

As an immediate corollary of Lemma 8.1 we obtain the following.

LEMMA 8.2. *Suppose that $L \in D_n(a, b)$ and that b is a nonsingular endpoint for L. Then, in whatever manner we extend the coefficients $a_i(t)$, $i = 1, \cdots, n$, of the representation (1.1) to the interval $(a, +\infty)$ by means of functions $\tilde{a}_i \in L^1_{\mathrm{loc}}(a, +\infty)$, there exists a number $\varepsilon > 0$ such that the operator $\tilde{L}$, defined by (1.1), where the coefficients a_i's are replaced by $\tilde{a}_i$'s, is disconjugate on $(a, a+\varepsilon)$. (The number ε will of course depend on the particular extension chosen.)*

Similar versions of Lemma 8.2 are to be found for cases where a is nonsingular or both a and b are nonsingular.

B. Double C.F.s of type (II). Where second-order operators are concerned the property of having infinitely many double C.F.s of type (II) has no relationship to the nature of the two endpoints. This property holds when both endpoints are nonsingular or when only one is nonsingular (see the factorizations of the operator d^2/dt^2 on any interval $\mathcal{I} \neq \mathbb{R}$ [3, p. 162]), or when both endpoints are singular as shown by

$$u'' + \frac{2}{t}u' \equiv \frac{1}{\alpha t^2 + \beta t}\left[(\alpha t+\beta)^2\left(\frac{u}{\alpha+\beta/t}\right)'\right]' \qquad (\alpha, \beta > 0) \tag{8.2}$$

on the interval $(0, +\infty)$.

For nth order operators, $n > 2$, we shall show the existence of a double C.F. of type (II) when the nature of the endpoints is restricted; the result has been stated without proof in [3, p. 164].

THEOREM 8.3. *If $L \in D_n(a, b)$ and if at least one endpoint is nonsingular then to the properties listed in Theorems* 3.1 *and* 3.2 *the following can be added*:

$$L \text{ has a double C.F. of type (II) on } (a, b). \tag{8.3}$$

Proof. Let us suppose for the sake of argument that b is a nonsingular endpoint. We have only to prove that if $L \in D_n[a, b]$ then (8.3) holds. By Lemma 8.2 there exists an extension of L, say $\tilde{L}$, which is disconjugate on some interval $(a, \tilde{b})$, $\tilde{b} > b$. Let t_0 be any number such that $b < t_0 < \tilde{b}$. As $L \in D_n[a, t_0]$, Theorem 3.1 implies that $\tilde{L}$ has a C.F. on (a, t_0) of type (II) at a. On the other hand, the coefficients of such a factorization are continuous and strictly positive on (a, t_0). Hence if we consider this factorization on the interval (a, b) only, we see that it is a double C.F. of L of type (II). □

9. Counterexamples. The following proposition shows that a direct literal extension of Theorem 6.3 to nth order operators fails to hold true.

PROPOSITION 9.1. *Let $L \in D_n[a, b]$ and let $(\bar{u}_1, \cdots, \bar{u}_n)$ be the mixed hierarchical system*

$$\begin{aligned} &\bar{u}_1 \ll \cdots \ll \bar{u}_n, && t \to a, \\ &\bar{u}_n \ll \cdots \ll \bar{u}_1, && t \to b. \end{aligned} \tag{9.1}$$

Then:

(1) *L admits of global factorizations in the following forms*:

$$Lu \equiv p_n\left[p_{n-1}\left(\cdots\left(p_1\left(\frac{u}{\bar{u}_1}\right)'\right)'\cdots\right)'\right]', \tag{9.2}$$

$$Lu \equiv q_n\left[q_{n-1}\left(\cdots\left(q_1\left(\frac{u}{\bar{u}_n}\right)'\right)'\cdots\right)'\right]'. \tag{9.3}$$

(2) *Factorizations of type* (9.2) *or* (9.3) *are in general not "unique" (they can even be infinitely many) and they are not necessarily all* C.F.*s at some endpoint.*

(3) *If $\bar{u}(t) \equiv \alpha\bar{u}_1(t) + \beta\bar{u}_n(t)$ $(\alpha, \beta > 0)$, then L admits of global factorizations in the form*

$$Lu \equiv r_n\left[r_{n-1}\left(\cdots\left(r_1\left(\frac{u}{\bar{u}}\right)'\right)'\cdots\right)'\right]'; \tag{9.4}$$

but it can happen that not even a single factorization (9.4) *is a* C.F. *at some endpoint.*

Proof. By Lemma 5.5 we may suppose that the functions $\bar{u}_1, \cdots, \bar{u}_n$ are strictly positive on (a, b). The second relation (9.1) then implies that the ordered n-tuple $(u_1, \cdots, u_n) \equiv (\bar{u}_n, \cdots, \bar{u}_1)$ satisfies condition (1.2) on (a, b); see [6, Thm. 2.1]. From this we infer that for some suitable choice of the constants $\varepsilon_i = \pm 1$, the ordered n-tuple $(v_1, \cdots, v_n) \equiv (\bar{u}_1, \varepsilon_2\bar{u}_2, \cdots, \varepsilon_n\bar{u}_n)$ also satisfies (1.2) on (a, b). This in turn implies that the ordered n-tuple $(w_1, \cdots, w_n) \equiv (\bar{u}_1, \varepsilon_2\bar{u}_2, \cdots, \varepsilon_{n-1}\bar{u}_{n-1}, \varepsilon_n\bar{u})$ also satisfies (1.2) on (a, b). Now the existence of factorizations of forms (9.2), (9.3), and (9.4) follows from Theorem 1.1. The other claims in the statement follow from an inspection of the factorizations of the operator d^3/dt^3 on $(0, +\infty)$; see the next proposition. □

PROPOSITION 9.2. *All the factorizations of the operator d^3/dt^3 are of the type*

$$u''' \equiv \frac{1}{A(t)}\left[\frac{A^2(t)}{B(t)}\left(\frac{B^2(t)}{A(t)}\left(\frac{u}{B(t)}\right)'\right)'\right]' \tag{9.5}$$

where $B(t)$ denotes, apart from a nonzero constant factor, a generic solution to $u'''=0$ strictly positive on the chosen open interval $\mathcal{T}$

$$B(t)=c_0+c_1t+c_2t^2 \quad (c_i=\text{constant}); \tag{9.6}$$

while $A(t)$ is defined by

$$A(t)=(\beta c_0-\alpha c_1)+2(\gamma c_0-\alpha c_2)t+(\gamma c_1-\beta c_2)t^2 \tag{9.7}$$

and depends on three arbitrary constants α, β, γ which, when $B(t)$ has been fixed, are subject to the restriction that $A(t)>0$ on $\mathcal{T}$.

In particular we explicitly mention the following factorizations on $(0,+\infty)$:

(1) *Apart from positive constant factors all the factorizations on $(0,+\infty)$ with $B(t)\equiv 1$ are*

$$u'''\equiv((u')')', \tag{9.8}$$

$$u'''\equiv(t+c)^{-1}[(t+c)^2((t+c)^{-1}u')']', \quad t>0 \quad (c=\text{constant}\geqq 0). \tag{9.9}$$

(2) *All the factorizations on $(0,+\infty)$ with $B(t)=t^2$ are (positive constant factors apart)*

$$u'''\equiv\frac{1}{t^2}\left[t^2\left(t^2\left(\frac{u}{t^2}\right)'\right)'\right]', \qquad t>0, \tag{9.10}$$

$$u'''\equiv\frac{1}{t}\left[\left(t^3\left(\frac{u}{t^2}\right)'\right)'\right]', \qquad t>0, \tag{9.11}$$

$$u'''\equiv\frac{1}{t(t+c)}\left\{(t+c)^2\left[\frac{t^3}{t+c}\left(\frac{u}{t^2}\right)'\right]'\right\}', \quad t>0 \quad (c=\text{constant}>0). \tag{9.12}$$

(3) *All the factorizations on $(0,+\infty)$ with $B(t)=t^2+c$ $(c>0)$ are (positive constant factors apart)*

$$u'''\equiv\frac{1}{t}\left\{\frac{t^2}{t^2+c}\left[\frac{(t^2+c)^2}{t}\left(\frac{u}{t^2+c}\right)'\right]'\right\}', \qquad t>0. \tag{9.13}$$

Remark. Factorizations (9.8)-(9.12) on $(0,+\infty)$ prove the claims in Proposition 9.1(2), while factorizations (9.13) prove the claim in Proposition 9.1(3).

Proof of Proposition 9.2. The proof is easy only if appropriate devices are employed. The object is to find all the possible factorizations

$$u'''\equiv p_3[p_2(p_1(p_0u)')'] \tag{9.14}$$

valid on some open interval $\mathcal{T}\subset\mathbb{R}$. If (9.14) holds on $\mathcal{T}$, then p_0 must be of the form

$$p_0(t)=\frac{1}{c_0+c_1t+c_2t^2}\equiv\frac{1}{B(t)} \tag{9.15}$$

where $B(t)>0$ on $\mathcal{T}$. Once p_0 has been chosen, p_1 must be such that the function $[1/p_0(t)]\int_{t_0}^{t}d\tau/p_1(\tau)$, with t_0 arbitrarily fixed on $\mathcal{T}$, is a solution to $u'''=0$. Hence

$$\frac{1}{p_0(t)}\int_{t_0}^{t}\frac{d\tau}{p_1(\tau)}=\alpha+\beta t+\gamma t^2$$

and

$$\begin{aligned}\frac{1}{p_1(t)}&=[(B(t))^{-1}(\alpha+\beta t+\gamma t^2)]'\\&=-(B(t))^{-2}B'(t)(\alpha+\beta t+\gamma t^2)+(B(t))^{-1}(\beta+2\gamma t)=(B(t))^{-2}A(t)\end{aligned}$$

whence

$$p_1(t)=\frac{B^2(t)}{A(t)}. \tag{9.16}$$

Once p_0 and p_1 have been chosen we shall show that p_2 is uniquely determined (up to constant factors). Let us first evaluate the differential expression

$$\begin{aligned}(p_1(p_0u)')'&=\left[\frac{B^2(t)}{A(t)}\left(\frac{u}{B(t)}\right)'\right]'\\ &=(A(t))^{-2}\{[A'(t)B'(t)-A(t)B''(t)]u-A'(t)B(t)u''\\ &\qquad +A(t)B(t)u''\}.\end{aligned} \tag{9.17}$$

On the other hand, by using the explicit expressions for $B(t)$ and $A(t)$, as given by (9.6) and (9.7), we get

$$A'(t)B'(t)-A(t)B''(t)=2(\gamma c_1-\beta c_2)B(t)$$

and, substituting into (9.17), we obtain

$$(p_1(p_0u)')'\equiv(A(t))^{-2}B(t)L(u) \tag{9.18}$$

where $L(u)$ is the differential operator defined as

$$L(u)\equiv A(t)u''-A'(t)u'+2(\gamma c_1-\beta c_2)u, \tag{9.19}$$

which satisfies the relation

$$\frac{d}{dt}L(u)=A(t)u'''. \tag{9.20}$$

By using (9.18) and (9.20) we now evaluate the differential expression

$$\begin{aligned}[p_2(p_1(p_0u)')']'&=[p_2(t)(A(t))^{-2}B(t)L(u)]'\\ &=[p_2(t)(A(t))^{-2}B(t)]'L(u)+p_2(t)(A(t))^{-2}B(t)\frac{d}{dt}L(u)\\ &=[p_2(t)(A(t))^{-2}B(t)]'L(u)+p_2(t)(A(t))^{-1}B(t)u'''.\end{aligned} \tag{9.21}$$

From this we immediately infer that identity (9.14) can hold on $\mathcal{T}$ if and only if

$$p_2(t)(A(t))^{-2}B(t)=\text{constant on } \mathcal{T},$$

whence (constant factors apart)

$$p_2(t)=\frac{A^2(t)}{B(t)}. \tag{9.22}$$

To complete the proof of Proposition 9.2 a few words concerning (3) must be added. When we choose $B(t)=t^2+c$ $(c>0)$ on some interval $\mathcal{T}$ then, constant factors apart, $A(t)$ must take either the form

$$A(t)=t^2+2\lambda t-c \quad (\lambda=\text{constant}), \quad \text{or} \tag{9.23}$$

$$A(t)=t. \tag{9.24}$$

As $c>0$ the polynomial (9.23) has a positive zero for any choice of λ; hence it can never be strictly positive on $(0,+\infty)$. Thus, if we are interested in factorizations valid on $(0,+\infty)$, the only admissible choice for $A(t)$ is (9.24). □

We draw the reader's attention to the fact that the operator d^3/dt^3, as ensured by Theorem 8.3, has double C.F.s of type (II) on $(0, +\infty)$. However these C.F.s are not of type (9.5) with $B(t) = t^2 + c$ $(c > 0)$; the admissible choices for the couple $(B(t), A(t))$ are in fact a little more involved.

ON THE CONVERGENCE OF INTERPOLATED ITERATION METHODS*

ERICH NOVAK†

Abstract. Convergence proofs are presented for the two iterations $f_{n+1}(x)=\alpha Af_n(x)+(1-\alpha)f_n(x)$, $0<\alpha\leqq 1$ and $f_{n+1}(x)=(Af_n(x))^{\beta}\cdot f_n(x)^{1-\beta}$, $0<\beta\leqq 1$. Here A are special integral operators arising in the nonlinear elastic deformation of circular membranes and plates.

Three problems are studied. In the first the fixed points $Af=f$ are identical with the solutions of the circular membrane problem for uniform lateral load and (dimensionless) radial edge tension S, where it is shown that both methods converge, with arbitrary choice of the starting function $f_0\geqq S$, provided α and β are suitably chosen.

The second problem concerns annular elastic membranes under the action of axisymmetric surface load and several types of edge boundary conditions. It is shown how the first iteration method can be used to obtain statements on the existence of positive solutions.

In the third problem, $Af=f$ represents the solutions of the circular plate bending problem for uniform lateral load. A conjecture concerning the first iteration method due to Keller and Reiss is proved.

Key words. approximation of fixed points, nonlinear integral equations, nonlinear elasticity

AMS(MOS) subject classifications. 45G10, 47H17, 73C50

1. Introduction. Consider the iteration method $x_{n+1}=f(x_n)$ for finding a fixed point of f. The condition $|f'(x)|\leqq R<1$ is sufficient for convergence of the iteration method. Ostrowski [8] showed that when $1>R\geqq f'(x)\geqq r$, then the interpolated iteration

$$x_{n+1}=\alpha f(x_n)+(1-\alpha)x_n \tag{I}$$

converges for the (optimal) choice $\alpha=2/(2-r-R)$ to the unique fixed point of f.

In their work on nonlinear bending of a circular elastic plate, Keller and Reiss [6] proposed the same iteration for solving a nonlinear integral equation $Af=f$ equivalent to the plate bending boundary value problem, that is,

$$f_{n+1}=\alpha Af_n+(1-\alpha)f_n. \tag{I'}$$

They argued heuristically that (I') can be expected to converge if the spectral radius of $\alpha A'f+(1-\alpha)I$ is less than 1, where I is the identity and $A'f$ is the Fréchet derivative of the operator A at the point f. Their conjecture that (I') always converges if α is suitably chosen was demonstrated numerically by extensive computations [6], but a rigorous proof has never been obtained. We remark, however, that the local convergence of (I') easily follows from the results of Kitchen [7]. The iteration (I') has also been applied successfully in [9] and [10] to the simpler problems of nonlinear deformation of circular and annular elastic membranes.

In a different context, Amann [1] considered the iteration (I'), where A is an operator that corresponds to certain Hammerstein type equations. Prior to Amann, the iteration (I') has been used by Zarantonello [11].

THEOREM 1 (Amann [1]). *Let H be a real Hilbert space, $F: H\to H$ Lipschitz continuous in each bounded set and monotone, i.e., $(Ff-Fg, f-g)\geqq 0$ for $f, g\in H$ and let $K: H\to H$ be linear, continuous, self-adjoint, and positive, i.e., $(Kf, f)\geqq 0$ for $f\in H$. Then the equation*

$$f+KFf=g \quad \text{or} \quad f=g-KFf:=Af, \tag{1}$$

* Received by the editors April 21, 1986; accepted for publication (in revised form) August 6, 1987.

† Universität Erlangen-Nürnberg, Mathematisches Institut, Bismarckstrasse 11/2, D-8520 Erlangen, Federal Republic of Germany.

with $g \in H$, has a unique solution $f^* \in H$. Furthermore, the iteration method

$$f_{n+1} = \alpha A f_n + (1-\alpha) f_n, \tag{I'}$$

$f_0 \in H$, converges to f^* for all $\alpha > 0$ with $0 < \alpha < \alpha_0$ provided α_0 is chosen sufficiently small.

2. The circular membrane under uniform load.

2.1. The convergence of the iteration (I'). Consider a circular elastic membrane subject to a uniform normal pressure and radial edge traction within the nonlinear Föppl-Hencky theory of small finite deflection. Then the radial stress is determined by the following boundary value problem:

$$y'' + 3y'/x + 2/y^2 = 0 \qquad (0 < x < 1) \tag{2}$$

and

$$y'(0) = 0, \qquad y(1) = S > 0.$$

These equations are equivalent to the integral equation

$$f(x) = S + \int_0^1 k(x, t)\varphi(t, f(t))\, dt \tag{3}$$

where $\varphi(t, u) = u^{-2}$ and

$$k(x, t) = \begin{cases} (x^{-2} - 1)t^3 & \text{for } t \leqq x, \\ (t^{-2} - 1)t^3 & \text{for } t > x. \end{cases}$$

For more details concerning these equations, see Dickey [3], Callegari and Reiss [2], and Weinitschke [10]. Clearly each solution f_S^* of (2) or (3) satisfies $f_S^* \geqq S$. Hence (3) is equivalent to

$$f + KFf = g \quad \text{or} \quad f = g - KFf := Af \tag{1}$$

where $g = S$, $Ff(t) = -\text{Max}\,(S, f(t))^{-2}$, and $Kh(x) = \int_0^1 k(x, t)h(t)\, dt$. Applying Theorem 1 to the Hilbert space H which is given by the weighted L_2-norm $\|h\| = (\int_0^1 h(x)^2 x^3\, dx)^{1/2}$, we obtain the following result.

THEOREM 2. *The boundary value problem* (2) *has a unique solution f_S^* and the iterative method*

$$f_{n+1} = \alpha A f_n + (1-\alpha) f_n, \tag{I'}$$

$f_0 \in H$, converges for all $\alpha > 0$ which are sufficiently small.

Next we propose to replace the iterative method (I') *by*

$$f_{n+1} = (Af_n)^\beta \cdot f_n^{1-\beta}, \qquad f_0 \geqq S, \tag{II}$$

where $\beta > 0$ is chosen sufficiently small.

We shall prove that this method also converges to the solution f_S^*. Numerical calculations of Weinitschke [10] show that (II) converges faster then (I'), especially for small values of $S > 0$.

2.2. Some preliminary lemmas.

LEMMA 1. *Let $S > 0$ and $M_S = \{f \in C[0, 1] \mid S \leqq f \leqq S + 1/4S^2$, f monotone decreasing$\}$. Then $A(M_S) \subseteq M_S$.*

Proof. This is an immediate consequence of the fact that A is an antitone operator in the sense that $Af \geqq Ag$ for any $f \leqq g$.

Next consider a sequence f_n in M_S, and set $g_n = \log f_n$. Then the following statements are equivalent:

(i) f_n is uniformly convergent, $\lim f_n = f$;

(ii) g_n is uniformly convergent, $\lim g_n = g = \log f$.

This implies that the iteration (II) is equivalent to $\log f_{n+1} = \beta \log Af_n + (1-\beta)\log f_n$, which can be written as

$$g_{n+1} = \beta \tilde{A} g_n + (1-\beta) g_n, \tag{II'}$$

where $\tilde{A}g = \log(A(\exp g))$. We find again that $\tilde{A}(\tilde{M}_S) \subseteq \tilde{M}_S$, if we define

$$\tilde{M}_S = \left\{ f \in C[0,1] \,|\, \log S \leqq f \leqq \log\left(S + \frac{1}{4S^2}\right), f \text{ monotone decreasing} \right\}.$$

Calculating the Fréchet derivative of $\tilde{A}$, we find

$$(\tilde{A}'g)h(x) = -2\frac{\int_0^1 k(x,t)\varphi(t, \exp g(t))h(t)\,dt}{S + \int_0^1 k(x,t)\varphi(t, \exp g(t))\,dt}.$$

LEMMA 2. *Let $g \in \tilde{M}_S$. Then we have the estimate*

$$\|\tilde{A}'g\| \leqq 2 \cdot (1+4S^3)^{-1},$$

where $\|\cdot\|$ is the operator norm with respect to the sup-norm in $C[0,1]$.

Proof. Calculating $\|\tilde{A}'g\|$, we find

$$\|\tilde{A}'g\| = \sup_{x\in[0,1]} \frac{2\int k(x,t)\varphi(t, \exp g(t))\,dt}{S + \int k(x,t)\varphi(t, \exp g(t))\,dt}$$

$$= \frac{2 \cdot \int (1-t^2) t (\exp g(t))^{-2}\,dt}{S + \int (1-t^2) t (\exp g(t))^{-2}\,dt}.$$

Since $\|\tilde{A}'g\|$ is maximal for $g = \log S$, we have $\|\tilde{A}'g\| \leqq \|\tilde{A}'(\log S)\| = 2 \cdot (1+4S^3)^{-1}$.

2.3. The convergence of $f_{n+1} = Af_n$. An immediate consequence of Lemma 2 is the following theorem.

THEOREM 3. *The iteration $f_{n+1} = Af_n$ converges for all S with $4S^3 > 1$, that is, $S > 0.63$.*

This result is a slight improvement of [3] mentioned earlier. However, it is known from [10] that the simple iteration $f_{n+1} = Af_n$ converges even for $S > 0.5609$. This improvement was achieved by replacing the sup-norm by a weighted sup-norm. Theorem 3 says that A is a contraction with respect to the metric

$$d(f,h) = \sup_{x\in[0,1]} |\log f(x) - \log h(x)|,$$

if $4S^3 > 1$. We may also improve the result of Theorem 3 by using a weighted norm for $\tilde{A}$

$$\|h\| := \sup_{x\in[0,1]} \left|\frac{h(x)}{w(x)}\right|, \qquad w(x) > 0,$$

which amounts to taking $\sup |(\log f(x) - \log h(x))/w(x)|$ as a metric for A. Computing the operator norm of $\tilde{A}'g$ with respect to the weighted norm we obtain with $\exp g = f \in M_S$, $g \in \tilde{M}_S$,

$$\|\tilde{A}'g\|_w = \sup_{x\in[0,1]} \int \frac{2k(x,t)\varphi(t,f(t))w(t)}{w(x)(S + \int k(x,t)\varphi(t,f(t))\,dt)}\,dt.$$

Since the function $af(t)^{-2}/(b+cf(t)^{-2})$, $a, b, c>0$ is increasing with decreasing f, we have

$$\|\tilde{A}'g\|_w \leqq \|\tilde{A}' \log S\|_w = \sup_{x\in[0,1]} \frac{8}{w(x)(4S^3+1-x^2)} \int_0^1 k(x,t)w(t)\,dt.$$

Similarly as in [10], we attempt to find an optimal weight w so as to make $\|\tilde{A}'(\log S)\|<1$ for $S>S_0>0$. Thus we wish to have

$$\int_0^1 k(x,t)w(t)\,dt = w(x)\left(\delta - \frac{1}{8}x^2\right), \qquad \delta := \frac{1}{8}(4S_0^3+1).$$

We omit the calculations which lead to the value $\delta = 0.1842$ and $\varepsilon_0 = 0.491$. Thus we arrive to the following result.

THEOREM 3A. *The simple iteration $f_{n+1} = Af_n$ converges for all $S > 0.491$.*

2.4. The convergence of the iteration (II). We consider operators of the form

$$Lf(x) = \int G(x,t)f(t)\,dt$$

where

$$G(x,t) = \begin{cases} b(x)c(t) & \text{for } x \leqq t, \\ b(t)c(x) & \text{for } x > t, \end{cases}$$

with the following assumptions: $b, c \in C^1[0,1]$ are nonnegative and $c(x) = g(x)b(x)$, with a nonincreasing function g. We need the following lemma.

LEMMA 3. *The operator L is positive-semidefinite, that is, $(Lh, h) \geqq 0$ for all $h \in L_2[0,1]$.*

Proof. Let h be a differentiable function and set $B(x) = \int_0^x b(t)h(t)\,dt$. It follows that

$$\int_0^1 \int_0^1 G(x,t)h(x)h(t)\,dt\,dx = 2\int_0^1 \int_0^x c(x)b(t)h(x)h(t)\,dt\,dx$$
$$= 2\int_0^1 g(x)b(x)h(x)B(x)\,dx,$$

and since $(\frac{1}{2}B^2)' = Bbh$, we obtain

$$(Lh, h) = g(1)B^2(1) - \int_0^1 g'(x)B^2(x)\,dx \geqq 0.$$

Now we consider a weighted L_2-norm

$$\|h\| = \left(\int_0^1 h(x)^2 p(x)\,dx\right)^{1/2},$$

where p is a positive weight. If the mapping $L = \tilde{A}'g$, $g \in \tilde{M}_S$ is given by $Lh(x) = \int G(x,t)h(t)\,dt$, then $L^*h(x) = \int G(t,x)p(t)\colon p(x)h(t)\,dt$ and $\|L\| = (\lambda_{\max}(LL^*))^{1/2} \leqq (\iint G(x,t)^2 p(x)\colon p(t)\,dt\,dx)^{1/2}$. The quadratic form that is related to L is given by

$$Lh \cdot h = \int_0^1 \int_0^1 G(x,t)h(t)h(x)p(x)\,dt\,dx.$$

If $\beta \in]0, 1]$ and $L_\beta = \beta L + (1-\beta)I$, then

$$\|L_\beta\| \leqq (\beta^2\|L\| + (1-\beta)^2 + 2\beta(1-\beta) \cdot C)^{1/2},$$

where

$$C = \sup_{h \neq 0} Lh \cdot h / h \cdot h.$$

If $C < 1$ then L_β is a contraction for all $\beta > 0$ that are sufficiently small. With $L = \tilde{A}'g$, $f(t) = (\exp g(t))^{-2}$ and $l(x) = (S + \int k(x, t)(\exp g(t))^{-2}\, dt)^{-1}$ we have

$$G(x, t) = \begin{cases} -2l(x)(1-t^2)tf(t), & x \leqq t, \\ -2(1-x^2) : x^2 l(x) f(t) t^3, & x > t. \end{cases}$$

The mapping $L = \tilde{A}'g$ has the form

$$\begin{aligned} Lh(x) &= -2\int_0^x b_2(t)c_2(x)h(t)\, dt - 2\int_x^1 b_1(x)c_1(t)h(t)\, dt \\ &= L_2h(x) + L_1h(x), \end{aligned}$$

where

$$\begin{aligned} b_2(t) &= f(t)t^3, & c_2(x) &= (1-x^2) : x^2 l(x), \\ b_1(x) &= l(x), & c_1(t) &= (1-t^2)tf(t). \end{aligned}$$

The related quadratic functional may be written as $Lh \cdot h = L_2h \cdot h + L_1h \cdot h$. Using Lemma 3 we see that $L_2h \cdot h$ is negative-semidefinite, if $b_2/(c_2p)$ is monotone increasing.

LEMMA 4. *In the case $p(x) = x^5$ the quadratic functional $Q(h) = L_2h \cdot h$ is negative-semidefinite for all $S > 0$ and $g \in M_S$.*

Proof. We have to show that $H(x) = b_2(x)/(c_2(x)p(x))$ is increasing

$$H(x) = \frac{f(x)x^5(S + \int k(x, t)f(t)\, dt)}{(1-x^2)x^5} = \frac{f(x)(S + \int k(x, t)f(t)\, dt)}{1-x^2}$$

yields

$$H'(x) = -2x^{-3}\int_0^x t^3 f(t)\, dt + \frac{2x}{(1-x^2)^2}\int_x^1 (1-t^2)tf(t)\, dt,$$

which is nonnegative if $f \geqq 0$ is increasing. As the function

$$N(x) = b_1(x)p(x)/c_1(x) = \frac{x^4}{f(x)(1-x^2)(S + \int k(x, t)f(t)\, dt)}$$

is not increasing we cannot conclude that $L_1h \cdot h$ is negative-semidefinite. We assume that $f(x) = (S + \int k(x, t)r(t)\, dt)^{-2}$ with a positive increasing function r. As in Lemma 4, it follows that $f(x) \cdot (1-x^2)^2$ is decreasing. Since $(S + \int k(x, t)f(t)\, dt)$ is decreasing too, the function N is increasing at least in those subintervals where $x^4(1-x^2)$ is increasing. Hence N is increasing in $[0, \sqrt{2/3}]$. Now we approximate L_1 by a mapping $\tilde{L}_1$ such that $\tilde{Q}(h) = \tilde{L}_1h \cdot h$ is negative-semidefinite. We define $\tilde{L}_1$ by

$$\tilde{L}_1h(x) = -2\int_x^1 \tilde{b}_1(x)c_1(t)h(t)\, dt,$$

where

$$\tilde{b}_1(x) = b_1(x)$$

for $x \in [0, \sqrt{2/3}]$ and

$$\tilde{b}_1(x) = c_1(x)\colon p(x) \cdot \left(\frac{b_1 p}{c_1}\left(\sqrt{\frac{2}{3}}\right)\right) \quad \text{for } x > \sqrt{\frac{2}{3}}.$$

Clearly $\tilde{b}_1 p / c_1$ is increasing on $[0, 1]$ and $\tilde{Q}$ is negative-semidefinite by Lemma 3. Furthermore, we have

$$c = \sup_{h \neq 0} \frac{Lh \cdot h}{h \cdot h} \leqq \| L_1 - \tilde{L}_1 \|.$$

Hence

$$c^2 \leqq 4 \cdot \int_{\sqrt{2/3}}^1 \int_x^1 (\tilde{b}_1(x) - b_1(x))^2 c_1(t)^2 p(x)\colon p(t)\, dt\, dx.$$

The integral is maximal for $f = \text{const}$ and $\varepsilon \to 0$, and we get

$$c^2 \leqq 4 \cdot \int_{\sqrt{2/3}}^1 \int_x^1 \left(\frac{4}{1-x^2} - \frac{16(1-x^2)}{x^4}\right)^2 (1-t^2)^2 t^2 x^5\colon t^5\, dt\, dx.$$

A computation of the integral yields about 0.6, and thus we have proved the following theorem.

THEOREM 4. *Assume that $\beta > 0$ is sufficiently small. Then the iteration method*

$$f_{n+1}(x) = (Af_n(x))^{\beta} \cdot f_n(x)^{(1-\beta)},$$

$S > 0$, $f_0 \geqq S$, converges to the unique fixed point f_S^* of A.

The convergence follows from the contraction lemma with the metric

$$d(f, g) = \left(\int_0^1 (\log f(x) - \log g(x))^2 x^5\, dx\right)^{1/2}.$$

3. Nonlinear boundary value problems for the annular membrane. We consider here an annular elastic membrane under the action of axisymmetric surface loads and uniform radial edge stresses or displacements, again within the Föppl-Hencky theory. This leads us to consider four different boundary value problems for the nonlinear differential equation

$$y'' + 3y'/x + 2R^2(x)/y^2 = 0, \qquad 0 < a < x < 1,$$

where R is nondecreasing with $R(a) = 0$. We refer to [4], [5], or [9] for a more complete description of this problem. By means of appropriate Green functions, these problems can be written as integral equations of the following form:

$$f(x) = g(x) - \int_0^1 k(x, t)\varphi(t, f(t))\, dt. \tag{4}$$

We are interested in positive solutions of (4) and observe that in all four cases the following conditions are fulfilled:

(i) $\varphi\colon [0, 1] \times [\varepsilon, \infty[\to \mathbb{R}$ is Lipschitz continuous for every $\varepsilon > 0$;

(ii) $\varphi(t, \cdot)\colon \mathbb{R}^+ \to \mathbb{R}$ is nondecreasing for each $t \in [0, 1]$;

(iii) The kernel k is continuous, symmetric, and positive semidefinite, i.e.,

$$\int_0^1 \int_0^1 k(x, t)h(x)h(t)\, dt\, dx \geqq 0 \quad \text{for all } h \in L_2[0, 1];$$

(iv) g is continuous.

Under these conditions, a positive solution of (4) does not always exist. Although in many cases it can be decided by means of a priori estimates whether a positive solution exists, such a decision is not always possible (see [5]). The following theorem shows that the positive solution of (4) (if it exists) is unique. For a different proof, see [4]. Moreover we give a method how to decide whether a positive solution exists and how to construct it. We always assume that the conditions (i)-(iv) are satisfied.

THEOREM 5. *Let* $\varepsilon > 0$ *and* $A_\varepsilon : L_2[0,1] \to L_2[0,1]$ *be defined by*

$$A_\varepsilon f(x) = g(x) - \int_0^1 k(x,t)\varphi(t, \operatorname{Max}(f(t), \varepsilon))\, dt.$$

Then

(i) A_ε *has a unique fixed point* f_ε (*which is continuous*);

(ii) f_ε *can be obtained by means of the iteration*

$$f_{n+1} = \alpha A_\varepsilon f_n + (1-\alpha) f_n, \tag{I'}$$

where f_0 *is arbitrary and* $\alpha > 0$ *is sufficiently small*;

(iii) *Equation* (4) *has a positive solution* f^* *with* $\inf f^* \geqq c$ *if and only if the fixed point* f_c *of* A_c *fulfills* $f_c \geqq c$. *In this case we have* $f^* = f_\varepsilon$ *for all* $\varepsilon \leqq c$;

(iv) *The positive solution* f^* *of* (4) *is unique* (*if it exists*).

Proof. Statements (i) and (ii) follow from Theorem 1 with $H = L_2[0,1]$ and $A = A_\varepsilon$. The continuity of f_ε follows from the fact that g and k are continuous. If f^* is a solution of (4) with $f^* \geqq c > 0$, then $A_\varepsilon f^* = f^*$ for all $\varepsilon \leqq c$. Hence we have $f^* = f_\varepsilon$ for $\varepsilon \leqq c$ and therefore $f_c \geqq c$. If, on the other hand, $c > 0$ and $f_c \geqq c$, then we have $A_\varepsilon f_c = f_c$ for all $\varepsilon \leqq c$ and $f_c = f_\varepsilon$ ($\varepsilon \leqq c$) is a positive solution of (4). Assume that f_1 and f_2 are positive solutions of (4). Then f_1 and f_2 are solutions of $A_\varepsilon f = f$ for $\varepsilon \leqq \operatorname{Min}(\inf f_1, \inf f_2)$, and hence $f_1 = f_2$.

4. Iterative solution for the nonlinear bending of circular plates. We study a thin circular elastic plate subjected to uniform lateral pressure within the nonlinear theory of von Kármán. According to Keller and Reiss [6], the resulting boundary value problems can be reduced to an equivalent integral equation of the form

$$f(x) = -\tfrac{1}{2} G_1(f \cdot G_2(f^2))(x) + g(x) := Af(x), \tag{5}$$

where

$$G_i f(x) = -\int_0^1 g_i(x,t) f(t)\, dt, \qquad i = 1, 2$$

with

$$g_i(x,t) = \begin{cases} \dfrac{-1}{2\mu_i}\left(\dfrac{\mu_i}{x} + x\right) t & \text{for } t \leqq x, \\ \dfrac{-1}{2\mu_i}\left(\dfrac{\mu_i}{t} + t\right) x & \text{for } t > x \end{cases}$$

and

$$g(x) = \gamma x(1 - x^2).$$

The constants μ_i and γ satisfy $\mu_1 = -1$, $\mu_2 > 0$, and $\gamma > 0$, where γ is proportional to the applied pressure.

The existence of a unique solution of (5) was proved in [6] for a restricted range of γ. More precisely, it was shown that the simple iteration $f_{n+1} = Af_n$ converges for $\gamma \leqq \gamma_0$ but diverges for $\gamma \geqq \gamma_1$, where numerical estimates for γ_0 and γ_1 were given. The following theorem proves the conjecture of Keller and Reiss [6], described in the Introduction, and at the same time yields the existence of a unique solution for *arbitrary* large positive values of γ.

THEOREM 6. *Equation* (5) *has a unique solution* f^* *and the iteration method*

$$f_{n+1} = \alpha A f_n + (1-\alpha) f_n, \tag{I'}$$

$f_0 \in H = L_2[0, 1]$, $\alpha > 0$ *sufficiently small, converges and* $\lim_{n\to\infty} f_n = f^*$.

Proof. We define $F: H \to H$ by $Ff(x) = f(x) \cdot G_2(f^2)(x)$. Let $f, h \in H = L_2[0, 1]$. We have

$$\begin{aligned} \|G_2(f^2) - G_2(h^2)\|_\infty &= \|G_2(f^2 - h^2)\|_\infty \leqq c \cdot \|f^2 - h^2\|_1 \\ &= c \cdot (|f-h|, |f+h|) \leqq c \cdot \|f-h\|_2 \cdot \|f+h\|_2 \end{aligned}$$

for some $c > 0$, and hence

$$\begin{aligned} \|Ff - Fh\|_2 &= \|fG_2(f^2) - hG_2(h^2)\|_2 \\ &\leqq \|fG_2(f^2) - fG_2(h^2)\|_2 + \|fG_2(h^2) - hG_2(h^2)\|_2 \\ &\leqq \|f\|_2 \cdot c\|f-h\|_2 \cdot \|f+h\|_2 + \|f-h\|_2 \cdot c \cdot \|h\|_2^2 \\ &= c \cdot \|f-h\|_2 \cdot (\|f\|_2 \cdot \|f+h\|_2 + \|h\|_2^2). \end{aligned}$$

Thus F is Lipschitz continuous on bounded sets of H. Because of

$$F'f(h)(x) = h(x)G_2(f^2)(x) + f(x)G_2(2fh)(x),$$

we get

$$(F'f(h), h) = \int_0^1 h^2(x)G_2(f^2)(x)\,dx + \int_0^1 f(x)h(x)G_2(2fh)(x)\,dx.$$

It follows from Lemma 3 that G_2 is positive, and hence $(F'f(h), h) \geqq 0$ and F is a monotone operator. Since G_1 is (again by Lemma 3) positive we can apply Theorem 1 and the proof is complete.

Acknowledgment. I would like to express my thanks to Professor H. J. Weinitschke for valuable comments concerning this paper. He initiated this work during my stay at the Institut für Angewandte Mathematik, Erlangen, and also helped with the final version of this paper.

RICCATI MATRIX DIFFERENCE EQUATIONS AND DISCONJUGACY OF DISCRETE LINEAR SYSTEMS*

CALVIN D. AHLBRANDT† AND JOHN W. HOOKER‡

Abstract. Disconjugacy criteria analogous to well-known results of W. T. Reid for linear differential systems are obtained here for the linear vector difference equation

$$-\Delta(C_{n-1}\Delta x_{n-1})+A_n x_n=0,$$

where A_n and C_n are real symmetric (or complex hermitian) matrices. The coefficients C_n are assumed to be nonsingular, but C_n and A_n are not assumed to be positive definite. Disconjugacy is defined in terms of the concept of conjugate intervals. A discrete Riccati matrix operator is defined, which plays a central role in the discussion of disconjugacy. This work extends and generalizes earlier work of the authors.

Key words. difference equation, linear system, disconjugacy, discrete Riccati matrix equation

AMS(MOS) subject classifications. 39A10, 39A12, 34C10

1. Introduction.

Consider a linear vector difference equation

$$l[x]_n=-\Delta(C_{n-1}\Delta x_{n-1})+A_n x_n=0, \qquad n=1,2,3,\cdots, \tag{1.1}$$

where $\{A_n\}$ and $\{C_n\}$ are given sequences of $r\times r$ real symmetric (or complex hermitian) matrices, x_n is an $r\times 1$ vector, and Δ is the forward difference operator $\Delta x_n=x_{n+1}-x_n$. Discrete-time linear systems and related discrete matrix Riccati equations arise in discrete linear optimal control and filtering problems (cf. Vaughan [24], Kalman [14], and Kwakernaak and Sivan [15]). This paper extends results obtained by the authors in [2] and [3] for the scalar case of (1.1) with real coefficients a_n and c_n, $c_n>0$. Some of the arguments used in [2] for the scalar case, which depend on the assumption $c_n>0$, do not generalize to the vector equation (1.1), so different techniques are used here, and we do *not* assume that C_n is positive definite. Principal solutions of (1.1) were discussed by the authors in [1] under the assumption that A_n and C_n are positive definite for all n.

We will make use of the related matrix difference equation

$$L[X]_n=-\Delta(C_{n-1}\Delta X_{n-1})+A_n X_n=0, \tag{1.2}$$

where X_n is an $r\times r$ matrix for each n.

Recent oscillation results concerning the vector or scalar case of (1.1) appear in [2], [3], [7], [9]–[13], [16], [17], [23], where (1.1) is sometimes given in the alternative three-term recurrence relation form

$$l[x]_n=-C_n x_{n+1}-C_{n-1}x_{n-1}+B_n x_n=0 \tag{1.3}$$

with $B_n=C_n+C_{n-1}+A_n$, $n=1, 2, 3,\cdots$. A general discussion of the scalar case of (1.3), including basic results on oscillation and boundary value problems, has been carried out by Atkinson [4] and Fort [6].

Similarly, (1.2) may be expressed as

$$L[X]_n=-C_n X_{n+1}-C_{n-1}X_{n-1}+B_n X_n=0. \tag{1.4}$$

For integers M and N, with $0<M<N$, a *solution* of (1.1) on the interval $[M, N]$ is a sequence $x=\{x_n\}$ of real or complex $r\times 1$ vectors, defined at least for $n=M-1, \cdots, N+1$, and satisfying (1.1) for $n=M, \cdots, N$.

In § 2 below, the concept of disconjugacy is defined for (1.1), along with the notions of self-conjoined solutions of (1.1) and prepared or isotropic solutions of (1.2).

In § 3 we then proceed to formulate and prove a discrete version of the well-known variational results of Reid [19], [20], which give several conditions equivalent to disconjugacy. Extensive use will be made of solutions of the related discrete Riccati equation

$$R[W]_n=0, \tag{1.5}$$

where $R[W]$ is the discrete matrix Riccati operator defined by

$$R[W]_n=-W_{n+1}+A_n+W_n(W_n+C_{n-1})^{-1}C_{n-1}.$$

This operator and the operator $L[X]$ defined by (1.2) will be seen to be related by the matrix identity (where $'$ denotes conjugate transpose)

$$X'_nL[X]_n=X'_nR[W]_nX_n$$

analogous to that which holds for differential systems (cf. Reid [19, p. 740], [20, p. 667]). For an extensive discussion of the relationship between Riccati matrix operators and associated linear systems in the continuous case, see Reid [22].

2. Definitions and preliminary results. We include here for ready reference the following elementary properties of the forward difference operator:

$$\Delta(a_nb_n)=a_n\Delta b_n+(\Delta a_n)b_{n+1}=a_{n+1}\Delta b_n+(\Delta a_n)b_n, \tag{2.1}$$

$$\sum_M^N \Delta a_n=a_{N+1}-a_M, \tag{2.2}$$

and the resulting "summation-by-parts" formula

$$\sum_M^N a_n\Delta b_n=a_Nb_{N+1}-a_{M-1}b_M-\sum_M^N(\Delta a_{n-1})b_n. \tag{2.3}$$

Given a sequence $C=\{C_n\}$ of hermitian matrices, we introduce a "bracket function" defined for complex vector or matrix sequences u and v as

$$\begin{aligned}\{u, v\}_n&=u'_nC_{n-1}\Delta v_{n-1}-(C_{n-1}\Delta u_{n-1})'v_n\\&=u'_{n-1}C_{n-1}v_n-u'_nC_{n-1}v_{n-1}.\end{aligned} \tag{2.4}$$

Note that the bracket function satisfies

$$\{u, v\}=-\{v, u\}' \tag{2.5}$$

as well as the following property.

LEMMA 2.1. *Let A and C be hermitian sequences. Then for any vector solutions u and v of* (1.1), $\{u, v\}_n$ *is constant, and for any matrix solutions U and V of* (1.2), $\{U, V\}_n$ *is constant.*

Proof. By use of the assumptions that A_n and C_n are hermitian, it is readily verified for solutions of (1.1) and (1.2) that $\Delta\{u, v\}_n\equiv 0$ and $\Delta\{U, V\}_n\equiv 0$, respectively.

DEFINITION. Vector sequences u and v are *conjoined* (Reid [19]) if $\{u, v\}_n\equiv 0$. A vector sequence u is *self-conjoined* if $\{u, u\}_n\equiv 0$, i.e., if

$$u'_{n-1}C_{n-1}u_n=u'_nC_{n-1}u_{n-1}, \qquad n=1, 2, \cdots. \tag{2.6}$$

Similarly, a matrix sequence X is called *prepared* (Hartman [8]), or *isotropic* (Coppel [5]) if $\{X, X\}_n \equiv 0$, or, equivalently, if $X'_{n-1}C_{n-1}X_n$ is hermitian for every n.

Note 2.1. If the coefficients A_n and C_n in (1.1) are real symmetric matrices, then $\{u, u\}_n$ is real for every real solution of (1.1). Thus every real vector solution is self-conjoined by (2.5) and, in particular, satisfies (2.6). The identity (2.6) is used in the proof of our main theorem. This is the main reason for restricting our attention below to real solutions and real coefficients. Otherwise we must consider self-conjoined vector solutions instead of real vector solutions and symmetric matrices must be replaced by hermitian matrices.

In order to formulate our main theorem, we need a discrete analogue of the concept of disconjugacy. While this has been introduced in various ways by different authors (cf. Hartman [7] and Peterson [18]), we will use here a notion of conjugate intervals. It is natural to speak of conjugate intervals, rather than conjugate points, for a solution u of a discrete equation, since the discrete analogue of a zero of a solution of a scalar differential equation may be either a value n such that $u_n = 0$ or a pair of values $(n, n+1)$ such that $u_n u_{n+1} < 0$.

DEFINITION 2.1. For positive integers M and N, with $M < N$, (1.1) is called *disconjugate* on $[M-1, N]$ if the real interval $[M-1, N]$ contains no pair of *conjugate intervals.* Distinct real intervals $[p, p+1]$ and $[q, q+1]$ (where p and q are integers in $[M-1, N-1]$) are called *conjugate intervals* if there exists a real vector solution x of (1.1) such that

$$x'_p C_p x_{p+1} \leqq 0 \quad \text{and} \quad x'_q C_q x_{q+1} \leqq 0, \tag{2.7}$$

with $x_{p+1} \neq 0$, $x_{q+1} \neq 0$, and x_n not identically zero for n in the interior of the smallest interval containing $[p, p+1]$ and $[q, q+1]$.

3. Disconjugacy criteria. We are now in a position to state discrete analogues of several of Reid's disconjugacy criteria [19, Thm. 2.1], [20, Thm. 5.2], [20, Thm. 5.1]. In order to simplify the details in the proof below, we restrict ourselves to real vector and matrix solutions of (1.1) and (1.2), and we assume the following condition:

$$A_n \text{ and } C_n \text{ are } r \times r \text{ real symmetric matrices for all } n. \tag{3.1}$$

Our theorem could equally well be stated for complex solutions, under assumption (3.1), or for complex coefficients, i.e., A_n and C_n complex hermitian matrices. The proof is the same in outline for these cases, and we will point out some of the modifications which would be needed.

We assume also the following nonsingularity condition:

$$C_n \text{ is nonsingular for } n = 0, 1, 2, \cdots. \tag{3.2}$$

THEOREM 3.1. *Assume conditions* (3.1)-(3.2). *Let M and N be positive integers with $M < N$. Then the following conditions are equivalent*:

(i) *If u is a real vector solution of* (1.1) *on $[M, N]$ with $u'_{M-1}C_{M-1}u_M \leqq 0$ and $u_M \neq 0$, then*

$$u'_n C_n u_{n+1} > 0 \quad \text{for } n = M, \cdots, N-1.$$

(ii) *If v is a real vector solution of* (1.1) *on $[M, N]$ with $v'_{N-1}C_{N-1}v_N \leqq 0$ and $v_{N-1} \neq 0$, then*

$$v'_n C_n v_{n+1} > 0 \quad \text{for } n = M-1, \cdots, N-2.$$

(iii) *Equation* (1.1) *is disconjugate on $[M-1, N]$.*

(iv) *There exists a prepared matrix solution X of* (1.2) *on* $[M, N]$ *with*

$$X'_{n-1}C_{n-1}X_n > 0 \quad \text{for } n = M, \cdots, N.$$

(v) *There exists a sequence W of symmetric matrices, defined for* $n = M, \cdots, N+1$, *with* $W_n + C_{n-1} > 0$ *for* $n = M, \cdots, N$, *satisfying the Riccati matrix equation*

$$W_{n+1} - A_n = W_n(W_n + C_{n-1})^{-1}C_{n-1}, \qquad n = M, \cdots, N. \tag{3.3}$$

(vi) *The quadratic form J_2 defined by*

$$J_2[\eta] = \sum_M^N (\Delta\eta_{n-1})'C_{n-1}\Delta\eta_{n-1} + \eta'_n A_n \eta_n \tag{3.4}$$

is positive definite on the class of real vector sequences η with

$$\eta_{M-1} = 0 = \eta_N.$$

We note that with modifications in the proof, conditions (iv) and (v) can be replaced by the following inequality conditions:

(iv′) There exists a prepared matrix solution X satisfying the inequality $X'_n L[X]_n \geqq 0$ for $n = M, \cdots, N$, with

$$X'_{n-1}C_{n-1}X_n > 0 \quad \text{for } n = M, \cdots, N.$$

(v′) There exists a sequence W of symmetric matrices with $W_n + C_{n-1} > 0$ for $n = M, \cdots, N$, satisfying the inequality

$$W_{n+1} - A_n \leqq W_n(W_n + C_{n-1})^{-1}C_{n-1}, \qquad n = M, \cdots, N.$$

As a corollary to the theorem we also have the following result.

COROLLARY 3.1. *Each of the conditions* (i)-(vi) *above implies the strengthened Legendre condition*

$$B_n = A_n + C_n + C_{n-1} > 0 \quad \text{for } n = M, \cdots, N-1.$$

This is most easily proved by assuming condition (iv). Then equation (1.2) written in the form (1.4) yields

$$X'_n C_n X_{n+1} + X'_n C_{n-1} X_{n-1} = X'_n B_n X_n.$$

Since X satisfies condition (iv), the corollary follows immediately.

The fact that $B_n > 0$ is indeed a discrete analogue of the strengthened Legendre condition of the calculus of variations is discussed in [3, p. 14] where it is shown that the quadratic form J_2 of (3.4) may be written as

$$J_2[n] = \sum_M^N (\eta'_n B_n \eta_n - \eta'_{n-1}C_{n-1}\eta_n - \eta'_n C_{n-1}\eta_{n-1}).$$

The matrix associated with this quadratic form is the block tridiagonal matrix

$$T = \begin{bmatrix} B_M & -C_M & & \\ -C_M & & \ddots & \\ & & & -C_{N-2} \\ & & -C_{N-2} & B_{N-1} \end{bmatrix}.$$

In view of condition (vi), we are led immediately to a second corollary.

COROLLARY 3.2. *If the nonsingularity condition* (3.2) *is satisfied and T is positive definite, then all of the conditions* (i)-(vi) *hold.*

For a Sturmian comparison result along the lines of Proposition 10 of Coppel [5], we need only compare tridiagonal matrices $\tilde{T}$ to the above matrix T in order for disconjugacy to be preserved.

COROLLARY 3.3. *Suppose $\tilde{T}$ is of the same form as T with B_n and C_n replaced by $\tilde{B}_n$ and $\tilde{C}_n$, where C_n and $\tilde{C}_n$ both satisfy the nonsingularity condition* (3.2). *If the system* (1.1) *is disconjugate on* $[M-1, N]$ *and* $\tilde{T} \geqq T$, *i.e.*, $\tilde{T}-T$ *is positive semidefinite, then* $\tilde{L}[x]=0$ *is disconjugate on* $[M-1, N]$. *In particular, if* $\tilde{C}_n = C_n$ *for* $n = M, \cdots, N-2$, *and* $\tilde{B}_n \geqq B_n$ *for* $n = M, \cdots, N-1$, *then disconjugacy of* (1.1) *implies disconjugacy of* $\tilde{L}[x]=0$.

Before proceeding to the proof of the theorem, we need three lemmas.

LEMMA 3.1. *Let X be a real matrix sequence, with X_n nonsingular for $n = M-1, \cdots, N$, and let W be defined by the Riccati transformation*

$$W_n = (C_{n-1}\Delta X_{n-1})X_{n-1}^{-1}, \qquad n = M, \cdots, N+1. \tag{3.5}$$

Then $W_n + C_{n-1}$ is nonsingular and W satisfies

$$X_n' L[X]_n = X_n' R[W]_n X_n \quad \text{for } n = M, \cdots, N, \tag{3.6}$$

where $R[W]$ is the Riccati difference operator defined by

$$R[W]_n = -W_{n+1} + W_n(W_n + C_{n-1})^{-1}C_{n-1} + A_n, \qquad n = M, \cdots, N. \tag{3.7}$$

Furthermore, if X is a prepared sequence, then W_n is symmetric for $n = M, \cdots, N+1$.

Proof. Given X and W as stated, we have

$$\begin{aligned} L[X]_n &= -\Delta(C_{n-1}\Delta X_{n-1}) + A_n X_n = -C_n \Delta X_n + C_{n-1}\Delta X_{n-1} + A_n X_n \\ &= -W_{n+1}X_n + W_n X_{n-1} + A_n X_n, \qquad n = M, \cdots, N. \end{aligned} \tag{3.8}$$

Thus, for $n = M, \cdots, N$,

$$X_n' L[X]_n = X_n'(-W_{n+1} + W_n X_{n-1} X_n^{-1} + A_n)X_n. \tag{3.9}$$

Now (3.5) may be written as

$$W_n + C_{n-1} = C_{n-1} X_n X_{n-1}^{-1}, \qquad n = M, \cdots, N+1, \tag{3.10}$$

so $W_n + C_{n-1}$ is nonsingular for $n = M, \cdots, N$. From (3.10) we obtain $X_{n-1}X_n^{-1} = (W_n + C_{n-1})^{-1}C_{n-1}$. Substituting this into (3.9) yields (3.6). Equation (3.10) may also be written as

$$W_n + C_{n-1} = (X_{n-1}')^{-1}(X_{n-1}' C_{n-1} X_n)X_{n-1}^{-1}, \tag{3.11}$$

so if X is prepared then $W_n + C_{n-1}$, and hence W_n also, is symmetric for $n = M, \cdots, N+1$.

LEMMA 3.2. *If y is a vector sequence defined for $n = p-1, \cdots, q+1$, then*

$$\sum_p^q [(\Delta y_{n-1})' C_{n-1}\Delta y_{n-1} + y_n' A_n y_n] = y_q' C_q \Delta y_q - y_{p-1}' C_{p-1}\Delta y_{p-1} + \sum_p^q y_n' l[y]_n.$$

Proof. Consider the summation-by-parts formula (2.3) written in the form

$$\sum_p^q (\Delta S_{n-1})T_n = S_q T_{q+1} - S_{p-1}T_p - \sum_p^q S_n \Delta T_n.$$

Application of this formula with $S_n = y'_n$, $T_n = C_{n-1}\Delta y_{n-1}$ yields

$$\sum_{p}^{q} [(\Delta y_{n-1})' C_{n-1} \Delta y_{n-1} + y'_n A_n y_n]$$

$$= y'_q C_q \Delta y_q - y'_{p-1} C_{p-1} \Delta y_{p-1} + \sum_{p}^{q} [-y'_n \Delta(C_{n-1}\Delta y_{n-1}) + y'_n A_n y_n].$$

Since $l[y]_n = -\Delta(C_{n-1}\Delta y_{n-1}) + A_n y_n$, this proves the lemma.

LEMMA 3.3. *Suppose u is a real (or self-conjoined) solution of* (1.1) *on* $[M, N]$, *and for integers p and q satisfying $M-1 \leqq p < q < N$, let*

$$\eta_n = \begin{cases} u_n, & p+1 \leqq n \leqq q, \\ 0, & \text{otherwise.} \end{cases}$$

Then $J_2[\eta]$ as defined by (3.4) *satisfies*

$$J_2[\eta] = u'_p C_p u_{p+1} + u'_q C_q u_{q+1}. \tag{3.12}$$

(Note. If u were not real (or self-conjoined), the expression $u'_p C_p u_{p+1}$ in (3.12) would be replaced by $u'_{p+1} C_p u_p$, as in (3.17) below.)

Proof. ($p+2 \leqq q$). From the definition of η, we have

$$\begin{aligned} J_2[\eta] &= \sum_{p+1}^{q+1} [(\Delta\eta_{n-1})' C_{n-1} \Delta\eta_{n-1} + \eta' A_n \eta_n] \\ &= (\Delta\eta_p)' C_p \Delta\eta_p + \eta'_{p+1} A_{p+1} \eta_{p+1} + (\Delta\eta_q)' C_q \Delta\eta_q \\ &\quad + \sum_{p+2}^{q} [(\Delta u_{n-1})' C_{n-1} \Delta u_{n-1} + u'_n A_n u_n]. \end{aligned} \tag{3.13}$$

Also, since u is a solution of (1.1), Lemma 3.2 implies

$$\sum_{p+1}^{q} [(\Delta u_{n-1})' C_{n-1} \Delta u_{n-1} + u'_n A_n u_n] = u'_q C_q \Delta u_q - u'_p C_p \Delta u_p.$$

We rewrite this as

$$\begin{aligned} &\sum_{p+2}^{q} [(\Delta u_{n-1})' C_{n-1} \Delta u_{n-1} + u'_n A_n u_n] + (\Delta u_p)' C_p \Delta u_p + u'_{p+1} A_{p+1} u_{p+1} \\ &\quad = u'_q C_q \Delta u_q - u'_p C_p \Delta u_p. \end{aligned} \tag{3.14}$$

Then substitution from (3.14) into (3.13) yields

$$\begin{aligned} J_2[\eta] &= (\Delta\eta_p)' C_p \Delta\eta_p + \eta'_{p+1} A_{p+1} \eta_{p+1} + (\Delta n_q)' C_q \Delta\eta_q \\ &\quad + u'_q C_q \Delta u_q - u'_p C_p \Delta u_p - (\Delta u_p)' C_p \Delta u_p - u'_{p+1} A_{p+1} u_{p+1}. \end{aligned} \tag{3.15}$$

Now

$$\eta_{p+1} = u_{p+1}, \quad \Delta\eta_q = \eta_{q+1} - \eta_q = -u_q, \quad \Delta\eta_p = \eta_{p+1} - \eta_p = u_{p+1}, \tag{3.16}$$

and use of these relations in (3.15) gives us

$$J_2[\eta] = u'_q C_q u_{q+1} + u'_{p+1} C_p u_p. \tag{3.17}$$

By Note 2.1, this yields the desired result, for $q \geqq p+2$.

For the case $q=p+1$, the sum from $p+2$ to q in (3.13) vanishes, and (3.13), (3.16), and (1.3) together then imply

$$\begin{aligned} J_2[\eta] &= u'_{p+1}C_p u_{p+1} + u'_{p+1}A_{p+1}u_{p+1} + u'_{p+1}C_{p+1}u_{p+1} \\ &= u'_q B_q u_q = u'_q C_q u_{q+1} + u'_{p+1}C_p u_p, \end{aligned}$$

which completes the proof.

We now proceed to prove Theorem 3.1, in the following order: (iv)$\Rightarrow$(v)$\Rightarrow$(vi)$\Rightarrow$(i)$\Leftrightarrow$(ii)$\Rightarrow$(iii)$\Rightarrow$(iv).

Proof of Theorem 3.1. (iv)$\Rightarrow$(v). Assume that X is a prepared matrix solution of (1.2) on $[M, N]$, with

$$X'_{n-1}C_{n-1}X_n > 0 \quad \text{for } n = M, \cdots, N.$$

Then X_n is nonsingular for $n = M-1, \cdots, N$, and by Lemma 3.1, W_n as defined by (3.5) satisfies

$$X'_n L[X]_n = X'_n R[W]_n X_n = 0, \qquad n = M, \cdots, N.$$

Therefore $R[W]_n = 0$ for $n = M, \cdots, N$, from which (3.3) follows. Furthermore, since $X'_{n-1}C_{n-1}X_n > 0$ for $n = M, \cdots, N$, it follows from (3.11) that $W_n + C_{n-1}$ is positive definite for $n = M, \cdots, N$, and W_n is symmetric for $n = M, \cdots, N+1$. Thus (iv) implies (v).

(v)$\Rightarrow$(vi). Let W be a matrix sequence satisfying (v), and let η be a vector sequence defined for $n = M-1, \cdots, N$, satisfying $\eta_{M-1} = 0 = \eta_N$. We substitute A_n from (3.3) into (3.4) to obtain

$$J_2[\eta] = \sum_M^N (\Delta\eta_{n-1})' C_{n-1}\Delta\eta_{n-1} + \sum_M^N \eta'_n[W_{n+1} - W_n(W_n + C_{n-1})^{-1}C_{n-1}]\eta_n. \tag{3.18}$$

Since $\eta_{M-1} = 0 = \eta_N$, we have

$$\sum_M^N \eta'_n W_{n+1}\eta_n = \sum_{M-1}^{N-1} \eta'_n W_{n+1}\eta_n = \sum_M^N \eta'_{n-1} W_n \eta_{n-1}, \tag{3.19}$$

so the second sum on the right in (3.18) may be rewritten as

$$\sum_M^N [\eta'_{n-1} W_n \eta_{n-1} - \eta'_n W_n (W_n + C_{n-1})^{-1} C_{n-1}\eta_n], \tag{3.20}$$

while the first sum on the right in (3.18) may be expanded as

$$\sum_M^N [\eta'_n C_{n-1}\eta_n - \eta'_n C_{n-1}\eta_{n-1} - \eta'_{n-1}C_{n-1}\eta_n + \eta'_{n-1}C_{n-1}\eta_{n-1}]. \tag{3.21}$$

Adding (3.20) and (3.21) we obtain

$$\begin{aligned} J_2[\eta] = \sum_M^N \{ &\eta'_n[C_{n-1} - W_n(W_n + C_{n-1})^{-1}C_{n-1}]\eta_n \\ &+ \eta'_{n-1}(W_n + C_{n-1})\eta_{n-1} - \eta'_n C_{n-1}\eta_{n-1} - \eta'_{n-1}C_{n-1}\eta_n\}. \end{aligned} \tag{3.22}$$

Now

$$\begin{aligned} C_{n-1} - W_n(W_n + C_{n-1})^{-1}C_{n-1} &= [I - W_n(W_n + C_{n-1})^{-1}]C_{n-1} \\ &= [(W_n + C_{n-1}) - W_n](W_n + C_{n-1})^{-1}C_{n-1} \\ &= C_{n-1}(W_n + C_{n-1})^{-1}C_{n-1}, \end{aligned}$$

so (3.22) becomes

$$J_2[\eta]=\sum_{M}^{N}\{\eta_n' C_{n-1}(W_n+C_{n-1})^{-1}C_{n-1}\eta_n+\eta_{n-1}'(W_n+C_{n-1})\eta_{n-1} - \eta_n' C_{n-1}\eta_{n-1}-\eta_{n-1}' C_{n-1}\eta_n\}. \tag{3.23}$$

By use of the symmetry of W_n+C_{n-1}, this may be written in "completed-square" form as

$$J_2[\eta]=\sum_{M}^{N}\phi_n'(W_n+C_{n-1})^{-1}\phi_n \tag{3.24}$$

where

$$\phi_n=C_{n-1}\eta_n-(W_n+C_{n-1})\eta_{n-1}.$$

Thus $J_2[\eta]\geqq 0$. Furthermore, if $J_2[\eta]=0$ for some sequence η with $\eta_{M-1}=0=\eta_N$, then $\phi_n=0$, $n=M,\cdots,N$, i.e.,

$$C_{n-1}\eta_n=(W_n+C_{n-1})\eta_{n-1},\qquad n=M,\cdots,N.$$

Since $\eta_{M-1}=0$ and C_{n-1} is nonsingular, this implies that $\eta_n=0$ for $n=M,\cdots,N$. Thus $J_2[\eta]$ is positive definite, as claimed.

(vi)$\Rightarrow$(i). Assume $J_2[\eta]$ is positive definite on the given class of sequences η, and let u be a real vector solution of $l[u]=0$ with

$$u_{M-1}'C_{M-1}u_M\leqq 0 \quad\text{and}\quad u_M\neq 0. \tag{3.25}$$

For $p=M-1$ and $M-1<q<N$, define η as in Lemma 3.3, i.e., $\eta_n=u_n$ for $p+1\leqq n\leqq q$ and $\eta_n=0$ otherwise. Then $\eta_M=u_M\neq 0$ and $\eta_{M-1}=0=\eta_N$. Thus $J_2[\eta]>0$ and by Lemma 3.3,

$$\begin{aligned}0<J_2[\eta]&=u_{M-1}'C_{M-1}u_M+u_q'C_qu_{q+1}\\&\leqq u_q'C_qu_{q+1}\quad\text{for } q=M,\cdots,N-1.\end{aligned} \tag{3.26}$$

Thus (vi) implies (i).

(i)$\Leftrightarrow$(ii). Assume that (i) holds. Let U be the real matrix solution of $L[U]=0$ satisfying

$$U_{M-1}=0,\qquad U_M=I.$$

By Lemma 2.1, U is prepared, since $\{U,U\}_M=0$. For every nonzero constant vector z, the solution u of $l[u]=0$ defined by $u_n=U_nz$ satisfies

$$u_{M-1}'C_{M-1}u_M=z'U_{M-1}'C_{M-1}U_Mz=0,$$

and $u_M=U_Mz=z\neq 0$. Hence, by (i), $u_n'C_nu_{n+1}>0$ for $n=M,\cdots,N-1$, so

$$U_n'C_nU_{n+1}>0\quad\text{for } n=M,\cdots,N-1,$$

i.e.,

$$U_{n-1}'C_{n-1}U_n>0\quad\text{for } n=M+1,\cdots,N.$$

Thus U satisfies condition (iv) on the interval $n=M+1,\cdots,N$. Since we have already proved that (iv) implies (vi), it follows that the quadratic form defined by

$$J_2^*[\eta]=\sum_{M+1}^{N}[(\Delta\eta_{n-1})'C_{n-1}\Delta\eta_{n-1}+\eta_n'A_n\eta_n] \tag{3.27}$$

is positive definite on the class of vector sequences η which satisfy $\eta_M=0=\eta_N$.

Now let v be a real vector sequence of (1.1) satisfying the hypothesis of condition (ii), i.e.,

$$v'_{N-1}C_{N-1}v_N \leqq 0 \quad \text{and} \quad v_{N-1} \neq 0.$$

Application of Lemma 3.3 with $M-1$ replaced by M gives

$$0 < J_2^*[\eta] = v'_{p+1}C_pv_p + v'_qC_qv_{q+1}, \qquad M \leqq p < q < N,$$

for η defined by

$$\eta_n = \begin{cases} v_n, & p+1 \leqq n \leqq q, \\ 0, & \text{otherwise.} \end{cases}$$

In particular, for $q = N-1$, we have

$$0 < v'_{p+1}C_pv_p + v'_{N-1}C_{N-1}v_N \leqq v'_{p+1}C_pv_p \tag{3.28}$$

for $M \leqq p < N-1$, i.e., for $p = M, \cdots, N-2$. By Note 2.1, $v'_{p+1}C_pv_p = v'_pC_pv_{p+1}$ for all p, so (3.28) gives us

$$0 < v'_pC_pv_{p+1}, \qquad p = M, \cdots, N-2. \tag{3.29}$$

Finally we must show that (3.29) also holds for $p = M-1$. But, if not, then v is a real solution of (1.1) with

$$v'_{M-1}C_{M-1}v_M \leqq 0$$

and, from (3.29), $v_M \neq 0$, so by condition (i), $v'_{N-1}C_{N-1}v_N > 0$, contrary to our assumptions about v. Hence (i) implies (ii).

The proof that (ii) implies (i) is the dual of the preceding argument. We omit the details.

(ii)$\Rightarrow$(iii). Assume (ii). Then (i) also holds, and we actually prove here that (i) implies (iii). We must show that the interval $[M-1, N]$ contains no pair of conjugate intervals. By (i), $[M-1, M)$ is not conjugate to any other interval $[q, q+1)$ in $[M-1, N]$.

Suppose that two intervals $[p, p+1)$ and $[q, q+1)$ are conjugate for some p and q with $M \leqq p < q \leqq N-1$. Then (1.1) has a real vector solution y satisfying

$$y'_pC_py_{p+1} \leqq 0 \quad \text{and} \quad y'_qC_qy_{q+1} \leqq 0, \tag{3.30}$$

with $y_n \not\equiv 0$ on $[p+1, q]$ (which may be a single point, if $p+1 = q$). Let

$$\eta_n = \begin{cases} y_n, & p+1 \leqq n \leqq q, \\ 0 & \text{otherwise.} \end{cases}$$

Then by Lemma 3.3 and condition (3.30), $J_2^*[\eta]$ as defined in (3.27) satisfies

$$J_2^*[\eta] = y'_pC_py_{p+1} + y'_qC_qy_{q+1} \leqq 0. \tag{3.31}$$

But, as in the preceding proof, $J_2^*[\eta] > 0$, a contradiction. Thus (i), and hence (ii), implies (iii).

(iii)$\Rightarrow$(iv). Let U be the matrix solution of (1.2) satisfying

$$U_{M-1} = 0, \qquad U_M = I. \tag{3.32}$$

Then, as in the proof that (i) implies (ii), U is a prepared solution, and for every nonzero constant vector z, the solution $u_n = U_nz$ of (1.1) satisfies

$$u'_{M-1}C_{M-1}u_M = 0, \qquad u_M \neq 0.$$

Hence, by assumption (iii), there is no interval $[p, p+1)$ in $[M, N]$ conjugate to the interval $[M-1, M)$, so

$$u_n' C_n u_{n+1} > 0, \qquad n = M, \cdots, N-1. \tag{3.33}$$

Since $u_n' C_n u_{n+1} = z' U_n' C_n U_{n+1} z$, it follows that

$$U_n' C_n U_{n+1} > 0, \qquad n = M, \cdots, N-1; \tag{3.34}$$

hence U_n is nonsingular for $n = M, \cdots, N$.

Let V be the solution of (1.2) with

$$V_N = 0, \qquad V_{N-1} = (U_N' C_{N-1})^{-1}. \tag{3.35}$$

Since disconjugacy on $[M-1, N]$ implies (i), and (i) implies (ii), then by an argument similar to that leading to (3.34) we obtain

$$V_n' C_n V_{n+1} > 0, \qquad n = M-1, \cdots, N-2. \tag{3.36}$$

Also,

$$\begin{aligned} \{U_n, V_n\} \equiv \{U_N, V_N\} &= U_{N-1}' C_{N-1} V_N - U_N' C_{N-1} V_{N-1} \\ &= -U_N' C_{N-1} (U_N' C_{N-1})^{-1} = -I; \end{aligned} \tag{3.37}$$

hence by (2.5), for all n for which U_n and V_n are defined,

$$\{V_n, U_n\} = -\{U_n, V_n\}' = I. \tag{3.38}$$

Now let X be the solution of (1.2) defined by $X_n = U_n + V_n$. Then X is a prepared solution, since

$$\begin{aligned} \{X_n, X_n\} &= \{U_n + V_n, U_n + V_n\} = \{U_n, U_n\} + \{U_n, V_n\} + \{V_n, U_n\} + \{V_n, V_n\} \\ &= 0 - I + I + 0 = 0. \end{aligned}$$

We must show that

$$X_{n-1}' C_{n-1} X_n > 0 \quad \text{for } n = M, \cdots, N. \tag{3.39}$$

First, for $n = M$, we note that

$$-I = \{U_M, V_M\} = U_{M-1}' C_{M-1} V_M - U_M' C_{M-1} V_{M-1} = -C_{M-1} V_{M-1}$$

so

$$C_{M-1} V_{M-1} = I. \tag{3.40}$$

Then

$$\begin{aligned} X_{M-1}' C_{M-1} X_M &= (U_{M-1}' + V_{M-1}') C_{M-1} (U_M + V_M) \\ &= V_{M-1}' C_{M-1} (U_M + V_M) = V_{M-1}' C_{M-1} + V_{M-1}' C_{M-1} V_M \\ &= I + V_{M-1}' C_{M-1} V_M > 0 \end{aligned}$$

by (3.36), so (3.39) holds for $n = M$.

For $n = N$, using (3.34) and (3.35) we obtain

$$\begin{aligned} X_{N-1}' C_{N-1} X_N &= (U_{N-1}' + V_{N-1}') C_{N-1} (U_N + V_N) \\ &= U_{N-1}' C_{N-1} U_N + V_{N-1}' C_{N-1} U_N \\ &= U_{N-1}' C_{N-1} U_N + (C_{N-1} U_N)^{-1} C_{N-1} U_N \\ &= U_{N-1}' C_{N-1} U_N + I > 0, \end{aligned}$$

so (3.39) holds for $n = N$.

Finally, suppose that $M<k<N$, and let α be an arbitrary unit vector. We must show that

$$\alpha' X'_{k-1} C_{k-1} X_k \alpha > 0. \tag{3.41}$$

Let

$$\eta_n = \begin{cases} U_n\alpha, & M-1 \leqq n \leqq k-1, \\ -V_n\alpha, & k \leqq n \leqq N+1. \end{cases} \tag{3.42}$$

Then by definition of U and V, η satisfies

$$\begin{aligned} &\eta_{M-1} = U_{M-1}\alpha = 0, \qquad \eta_N = -V_N\alpha = 0, \\ &\eta_M = U_M\alpha = \alpha \neq 0, \qquad \Delta\eta_{M-1} = \eta_M - \eta_{M-1} = \alpha. \end{aligned} \tag{3.43}$$

We will show that $J_2[\eta]$ as defined in (vi) satisfies

$$0 \leqq J_2[\eta] = \alpha' X'_{k-1} C_{k-1} X_k \alpha + \alpha'\{U, V\}\alpha = \alpha' X'_{k-1} C_{k-1} X_k \alpha - 1, \tag{3.44}$$

from which (3.41) follows.

Consider the prepared solution U of (1.2) determined by the initial conditions (3.32). This solution satisfies (3.34), which we rewrite as

$$U'_{n-1} C_{n-1} U_n > 0, \qquad n = M+1, \cdots, N. \tag{3.45}$$

Thus U satisfies condition (iv) on the interval $[M+1, N]$. Since (iv) implies (v) there exists a symmetric sequence W defined by

$$W_n = (C_{n-1}\Delta U_{n-1})U_{n-1}^{-1}, \qquad n = M+1, \cdots, N+1, \tag{3.46}$$

with $W_n + C_{n-1} > 0$ for $n = M+1, \cdots, N$, and

$$W_{n+1} - A_n = W_n(W_n + C_{n-1})^{-1} C_{n-1}, \qquad n = M+1, \cdots, N. \tag{3.47}$$

Since our sequence η defined by (3.42) fails to have $\eta_M = 0$, the argument used above in (v)$\Rightarrow$(vi) to show $J_2[\eta]$ positive definite does not hold here, and we must treat $J_2[\eta]$ somewhat differently in this case. Using (3.43) we obtain

$$J_2[\eta] = \alpha' C_{M-1}\alpha + \alpha' A_M \alpha + \sum_{M+1}^{N} [(\Delta\eta_{n-1})' C_{n-1} \Delta\eta_{n-1} + \eta'_n A_n \eta_n],$$

so, by substitution for A_n from (3.47),

$$\begin{aligned} J_2[\eta] = \alpha' C_{M-1}\alpha + \alpha' A_M \alpha &+ \sum_{M+1}^{N} (\Delta\eta_{n-1})' C_{n-1} \Delta\eta_{n-1} \\ &+ \sum_{M+1}^{N} [\eta'_n(W_{n+1} - W_n(W_n + C_{n-1})^{-1} C_{n-1})\eta_n]. \end{aligned} \tag{3.48}$$

Now

$$\sum_{M+1}^{N} \eta'_n W_{n+1} \eta_n = \sum_{M}^{N-1} \eta'_n W_{n+1} \eta_n + \eta'_N W_{N+1} \eta_N - \eta'_M W_{M+1} \eta_M.$$

By a shift of indices in the sum on the right, and use of $\eta_N = 0$, this becomes

$$\sum_{M+1}^{N} \eta'_n W_{n+1} \eta_n = \sum_{M+1}^{N} \eta'_{n-1} W_n \eta_{n-1} - \eta'_M W_{M+1} \eta_M.$$

From (3.43) and (3.46) this yields

$$\sum_{M+1}^{N} \eta'_n W_{n+1} \eta_n = \sum_{M+1}^{N} \eta'_{n-1} W_n \eta_{n-1} - \alpha'(C_M \Delta U_M) U_M^{-1} \alpha. \tag{3.49}$$

Using (3.49), we write the second sum on the right in (3.48) as

$$(3.50)\quad \sum_{M+1}^{N} (\eta'_{n-1} W_n \eta_{n-1} - \eta'_n W_n (W_n + C_{n-1})^{-1} C_{n-1} \eta_n) - \alpha'(C_M \Delta U_M) U_M^{-1} \alpha$$

while the first sum on the right in (3.48) can be expanded as

$$(3.51)\quad \sum_{M+1}^{N} (\eta'_n C_{n-1} \eta_n - \eta'_n C_{n-1} \eta_{n-1} - \eta'_{n-1} C_{n-1} \eta_n + \eta'_{n-1} C_{n-1} \eta_{n-1}).$$

Substituting (3.50) and (3.51) into (3.48) gives us

$$\begin{aligned} J_2[\eta] = {} & \alpha'[C_{M-1} + A_M - (C_M \Delta U_M) U_M^{-1}]\alpha \\ & + \sum_{M+1}^{N} \{\eta'_n [C_{n-1} - W_n (W_n + C_{n-1})^{-1} C_{n-1}]\eta_n \\ & \qquad + \eta'_{n-1}(W_n + C_{n-1})\eta_{n-1} - \eta'_n C_{n-1} \eta_{n-1} - \eta'_{n-1} C_{n-1} \eta_n\}. \end{aligned} \tag{3.52}$$

The same steps that led from (3.22) to (3.24) now yield

$$(3.53)\quad J_2[\eta] = \alpha'[C_{M-1} + A_M - (C_M \Delta U_M) U_M^{-1}]\alpha + \sum_{M+1}^{N} \phi'_n (W_n + C_{n-1})^{-1} \phi_n,$$

where

$$\phi_n = C_{n-1}\eta_n - (W_n + C_{n-1})\eta_{n-1}.$$

We will show that the first term on the right in (3.53) equals zero. Since $U_M = I$, we have

$$(3.54)\quad C_{M-1} + A_M - (C_M \Delta U_M) U_M^{-1} = C_{M-1} + A_M - (C_M U_{M+1} - C_M) = B_M - C_M U_{M+1},$$

where, as in (1.3) and (1.4),

$$B_M = C_M + C_{M-1} + A_M.$$

Now $L[U] = 0$, so from (1.4) we know

$$-C_M U_{M+1} - C_{M-1} U_{M-1} + B_M U_M = 0.$$

Since $U_{M-1} = 0$ and $U_M = I$, this becomes

$$-C_M U_{M+1} + B_M = 0.$$

Thus it follows from (3.54) that the first term on the right in (3.53) equals zero, so

$$J_2[\eta] = \sum_{M+1}^{N} \phi'_n (W_n + C_{n-1})^{-1} \phi_n \geqq 0.$$

If $J_2[\eta] = 0$, then $\phi_n = 0$, $n = M+1, \cdots, N$, i.e.,

$$(3.55)\quad C_{n-1}\eta_n = (W_n + C_{n-1})\eta_{n-1}, \qquad n = M+1, \cdots, N.$$

Since $\eta_N = 0$ and $W_n + C_{n-1}$ is nonsingular for $n = M+1, \cdots, N$, (3.55) implies $\eta_M = 0$, contrary to (3.43). Thus $J_2[\eta] > 0$. Let $u_n = U_n \alpha$ and $v_n = V_n \alpha$, $n = M-1, \cdots, N+1$,

so that (3.42) may be written as

$$\eta_n = \begin{cases} u_n, & M-1 \leqq n \leqq k-1, \\ -v_n, & k \leqq n \leqq N+1. \end{cases}$$

Thus

$$\Delta\eta_n = \begin{cases} \Delta u_n, & M-1 \leqq u \leqq k-2, \\ -v_k - u_{k-1}, & n = k-1, \\ -\Delta v_n, & k \leqq n \leqq N, \end{cases}$$

and $J_2[\eta]$ becomes

$$\begin{aligned} J_2[\eta] = &\sum_{M}^{k-1} [(\Delta u_{n-1})' C_{n-1} \Delta u_{n-1} + u_n' A_n u_n] + (-v_k' - u_{k-1}') C_{k-1}(-v_k - u_{k-1}) + v_k' A_k v_k \\ &+ \sum_{k+1}^{N} [(\Delta v_{n-1})' C_{n-1} \Delta v_{n-1} + v_n' A_n v_n]. \end{aligned} \tag{3.56}$$

Application of Lemma 3.2 to the two sums on the right in (3.56) yields

$$\begin{aligned} J_2[\eta] = &u_{k-1}' C_{k-1} \Delta u_{k-1} - u_{M-1}' C_{M-1} \Delta u_{M-1} + \sum_{M}^{k-1} u_n' l[u]_n \\ &+ (v_k' C_{k-1} v_k + v_k' C_{k-1} u_{k-1} + u_{k-1}' C_{k-1} v_k + u_{k-1}' C_{k-1} u_{k-1} + v_k' A_k v_k) \\ &+ v_N' C_N \Delta v_N - v_k' C_k \Delta v_k + \sum_{k+1}^{N} v_n' l[v]_n. \end{aligned} \tag{3.57}$$

But u and v satisfy $l[u] = 0$ and $l[v] = 0$, and also $u_{M-1} = 0 = v_N$, so (3.57) reduces to

$$\begin{aligned} J_2[\eta] &= u_{k-1}' C_{k-1}(u_k - u_{k-1}) + v_k' C_{k-1} v_k + v_k' C_{k-1} u_{k-1} \\ &\quad + u_{k-1}' C_{k-1} v_k + u_{k-1}' C_{k-1} u_{k-1} + v_k' A_k v_k - v_k' C_k (v_{k+1} - v_k) \\ &= u_{k-1}' C_{k-1} u_k + u_{k-1}' C_{k-1} v_k + v_k' (B_k v_k + C_{k-1} u_{k-1} - C_k v_{k+1}). \end{aligned} \tag{3.58}$$

Since v is a solution of (1.3), this becomes

$$J_2[\eta] = u_{k-1}' C_{k-1} u_k + u_{k-1}' C_{k-1} v_k + v_k' C_{k-1} u_{k-1} + v_k' C_{k-1} v_{k-1}. \tag{3.59}$$

The last term in (3.59) equals $v_{k-1}' C_{k-1} v_k$, by Note 2.1, and (3.59) may thus be rewritten as

$$J_2[\eta] = \alpha'(U_{k-1}' C_{k-1} U_k + U_{k-1}' C_{k-1} V_k + V_k' C_{k-1} U_{k-1} + V_{k-1}' C_{k-1} V_k)\alpha. \tag{3.60}$$

Now for the solution $X = U + V$ of (1.2), we have

$$X_{k-1}' C_{k-1} X_k = U_{k-1}' C_{k-1} U_k + U_{k-1}' C_{k-1} V_k + V_{k-1}' C_{k-1} U_k + V_{k-1}' C_{k-1} V_k. \tag{3.61}$$

Also, from (3.38),

$$\{V_k, U_k\} = V_{k-1}' C_{k-1} U_k - V_k' C_{k-1} U_{k-1} = I, \tag{3.62}$$

and combining (3.60), (3.61), and (3.62), we see that

$$\begin{aligned} J_2[\eta] &= \alpha'(X_{k-1}' C_{k-1} X_k - \{V_k, U_k\})\alpha \\ &= \alpha' X_{k-1}' C_{k-1} X_k \alpha - \alpha'\alpha \\ &= \alpha' X_{k-1}' C_{k-1} X_k \alpha - 1, \end{aligned}$$

since α was an arbitrary unit vector. Since $J_2[\eta]>0$, it follows that $X'_{k-1}C_{k-1}X_k$ is positive definite, which completes the proof of the theorem.

Note added in proof. A referee has raised the question of conditions equivalent to disconjugacy on $[M-1,\infty)$. The following result gives a set of related, but not equivalent, conditions.

COROLLARY 3.4. *Assume hypotheses* (3.1)-(3.2). *The following conditions are related by* $(\alpha)\Rightarrow(\beta)\Rightarrow(\gamma)\Rightarrow(\delta)$.

(α) *Equation* (1.1) *is disconjugate on* $[M-1,\infty)$.

(β) *The matrix solution* U_n *defined by* $U_{M-1}=0$, $U_M=I$ *has* $U'_nC_nU_{n+1}>0$, $n=M,\cdots$.

(γ) *There exists a sequence* W *of symmetric matrices with* $W_n+C_{n-1}>0$ *for* $n=M+1,\cdots$, *satisfying* (3.3) *for* $n=M+1,\cdots$.

SAMPLING BANDLIMITED FUNCTIONS OF POLYNOMIAL GROWTH*

GILBERT G. WALTER†

Abstract. Two new versions of the sampling theorem extended to functions whose Fourier transform is a generalized function are given. One involves a correction by means of an arbitrary polynomial and the other involves (C, α)-summability. The best approximation to nonbandlimited functions of polynomial growth by functions whose transform has compact support in the Sobolev norm is found.

Key words. sampling theorem, bandlimited signal, generalized functions, Sobolev spaces, best approximation

AMS(MOS) subject classifications. 41A05, 40G05

1. Introduction. The sampling theorem for bandlimited signals is the name usually given to the formula

$$f(t) = \sum_{n=-\infty}^{\infty} f(nT) \frac{\sin \sigma(t-nT)}{\sigma(t-nT)} \tag{1.1}$$

where $T = \pi/\sigma$ is the sampling period. "Bandlimited" means the Fourier transform $F(w)$ of $f(t)$ is zero for $|w| > \sigma$.

This theorem is well established for $F(w)$ which are L^2 functions, and goes back to Whittaker [8], but was developed and exploited by Shannon [7] much later. Subsequently it was generalized in a number of different directions [2], in particular to f such that $F(w)$ is a generalized function with compact support [1], [3]-[5]. In this work we shall extend it further in this direction.

Such functions f belong to L^2_r the space of functions on $\mathbb{R}^1$ square integrable with respect to the measure $dm_r = (1+t^2)^{-r}\,dt$, $r = 0, 1, \cdots$. Following [3], we denote by $B_r(\sigma)$ those $f \in L^2_r$ which are bandlimited to $[-\sigma, \sigma]$. These functions are also, by the Schwartz-Paley-Wiener Theorem, entire functions whose restriction to the real axis is of polynomial growth. Hence we shall refer to them as *bandlimited functions of polynomial growth.*

Several versions of the sampling theorem for bandlimited functions of polynomial growth have appeared. The first were due to Campbell [1] and to Pfaffelhuber [5]. The former deals with signals $f(t)$ whose Fourier transform $F(w)$ has compact support in the *interior* of the interval $(-\sigma, \sigma)$, where $S(t) = S_\varepsilon(t)$ is an appropriate smoothing function used to obtain convergence in (1.1).

Pfaffelhuber showed that the generalized sampling theorem can be extended to the case where $F(w)$ has support in the closed interval $[-\sigma, \sigma]$. He replaced (1.1) with the expression

$$f(t) = q_N(t)\cos \sigma t + \sum_{n=-\infty}^{\infty} (f(nT) - q_N(nT)(-1)^n)\left(\frac{t}{nT}\right)^N \frac{\sin \sigma(t-nT)}{\sigma(t-nT)}, \tag{1.2}$$

where N is the order of the generalized function $F(w)$ and $q_N(t)$ is an appropriate polynomial of degree $\leqq N-1$.

Lee [4] replaced the $\cos \sigma t$ by e^{iat}, $|a| \leqq \sigma$ in (1.2), and thus was able to replace $q_N(t)$ by the Taylor polynomial of $f(t)$ for $a = 0$.

* Received by the editors September 18, 1986; accepted for publication (in revised form) October 1, 1987. This research was supported in part by National Science Foundation grant DCR-8504620.

† Department of Mathematical Sciences, University of Wisconsin, Milwaukee, Wisconsin 53201.

Hoskins and De Sousa Pinto [3] generalized both results by replacing $\cos \sigma t$ and $e^{i\alpha t}$ by an arbitrary bandlimited function $\eta(t)$, $\eta(0) \neq 0$, whose Fourier transform is a measure with support in $[-\sigma, \sigma]$.

In this work we shall first generalize Lee's result in a different direction, to polynomials other than the Taylor polynomials. We then show that for certain such polynomials the sampling expansion converges in L_r^2 and obtain the best approximation to $f \in L_r^2$ by a function $g \in B_r(\sigma)$. Finally we give a version of the sampling theorem for bandlimited functions of polynomial growth having the same form as (1.1) except that convergence is replaced by (C, α)-summability.

2. Sampling expansions with polynomials correction. In this section we prove a sampling theorem for bandlimited functions of polynomial growth which involves an arbitrary polynomial of the same degree as the order of $F(w)$, the Fourier transform of f. We shall use the convention that F is of order r if $f \in L_r^2$, that is, that F is given by an rth order differential operator applied to an L^2 function. We shall consider polynomials of the form

$$P(t) = \prod_{j=1}^{k} (t - a_j)^{m_j}, \qquad \sum_{j=1}^{k} m_j = N, \tag{2.1}$$

a_j possibly complex.

LEMMA 2.1. *Let $f(t)$ be a signal in $B_N(\sigma)$ such that $f^{(i)}(a_j) = 0$, $i = 0, 1, \cdots, m_j - 1$, $j = 1, 2, \cdots, k$. Then, with P given in* (2.1),

$$f(t) = \sum_{n=-\infty}^{\infty} f(nT) \frac{P(t)}{P(nT)} \frac{\sin \sigma(t - nT)}{\sigma(t - nT)} \tag{2.2}$$

where the convergence is uniform on bounded subsets of the complex t-plane.

Proof. We first note that $B_N(\sigma)$ is closed under translation. Hence $f(t)/P(t)$ may be obtained by repeated division by t and translation. Accordingly let $\psi(t) \in B_K(\sigma)$, $1 \leqq K \leqq N$, $\psi(0) = 0$, and $\varphi(t) = \psi(t)/t$.

By the Schwartz-Paley-Wiener Theorem, ψ is an entire function of exponential type $\leqq \sigma$, and since $B_K(\sigma) \subset L_K^2$, $\psi(t)/(t^2+1)^{K/2} \in L^2(\mathbb{R}^1)$. Since the exponential type of an entire function depends only on its Taylor coefficients, it follows that $\varphi(t)$ is also entire of exponential type $\leqq \sigma$. Moreover, $\varphi(t)/(t^2+1)^{(K-1)/2} \in L^2(\mathbb{R}^1)$, and hence $\varphi(t) \in B_{K-1}(\sigma)$.

We return now to our original $f(t)$ and conclude that $f(t)/P(t) \in B_0(\sigma) \subset L^2(R^1)$. By applying the sampling theorem for L^2 functions to $h(t) = f(t)/P(t)$, we obtain (2.2).

Remark 2.1. Among the interesting cases for (2.1) are the following:

(i) $P(t) = (t - a)^N$;

(ii) All a_j distinct, $P(t) = \prod_{j=1}^{N} (t - a_j)$;

(iii) $P(t) = (t^2+1)^M$, $N = 2M$.

Each gives us a different application.

The first gives us Lee's result with Taylor's polynomial but at an arbitrary point instead of zero. Case (ii) is an interpolation result that is particularly useful when the values of f are known only at a discrete set. We state it as follows.

COROLLARY 2.2. *Let $P(t) = \prod_{j=1}^{N} (t - a_j)$ where all a_j are distinct, $f(t) \in B_N(\sigma)$; let $L_N(t)$ be the polynomial that interpolates f at the points $(a_1, \cdots, a_N)$. Then*

$$f(t) - L_N(t) = \sum_{n=-\infty}^{\infty} (f(nT) - L_N(nT)) \frac{P(t)}{P(nT)} \frac{\sin \sigma(t - nT)}{\sigma(t - nT)}.$$

Case (iii) is useful when we want to obtain convergence in the sense of L_r^2.

3. Convergence and approximation in L_r^2. In this section we deal with convergence in L_r^2 of the sampling expansion of bandlimited signals of polynomial growth. We use a form of $P(t)$, the polynomial in (2.2), which is particularly simple and which enables us to remove the restrictions on $f(t)$. Since $B_r(\sigma)$ is a proper subspace of L_r^2, we may consider best approximations in the former to an arbitrary element in L_r^2.

We should note that the Fourier transform maps L_r^2 into the Sobolev space H^{-r} isometrically. See Rudin [6] for details. This latter space is composed of distributions of the form $F=(1-D^2)^N G$ for $r=2N$ where $G\in L^2(\mathbb{R}^1)$.

PROPOSITION 3.1. *Let N be a positive integer and let $f\in B_{2N}(\sigma)$; then there exists a polynomial $P(t)$ of degree $2N-1$ such that*

$$f(t)-P(t)\sin\sigma t=\sum_{n=-\infty}^{\infty} f(nT)\left[\frac{t^2+1}{n^2T^2+1}\right]^N \frac{\sin\sigma(t-nT)}{\sigma(t-nT)} \tag{3.1}$$

where the series converges in the sense of L_{2N}^2 and uniformly on compact sets.

Proof. There is a polynomial $d(t)$ of degree $\leqq 2N-1$ such that $f(t)-d(t)$ has N-fold zeros at $t=\pm i$. Then by Lemma 2.1,

$$f(t)-d(t)=\sum_{n=-\infty}^{\infty}[f(nT)-d(nT)]\left[\frac{t^2+1}{n^2T^2+1}\right]^N \frac{\sin\sigma(t-nT)}{\sigma(t-nT)}. \tag{3.2}$$

This series is easily seen to converge in the sense of L_{2N}^2 since $s_n(t)=\sin\sigma(t-nT)/\sigma(t-nT)$ is an orthonormal sequence. The Fourier transform of $d(t)$ is of the form

$$D(w)=\sum_{j=0}^{2N-1} a_j\delta^{(j)}(w), \tag{3.3}$$

and hence has a Fourier series on $(-\sigma,\sigma)$

$$D(w)=\sum c_n e^{-iwnT}, \qquad |w|<\sigma, \tag{3.4}$$

with coefficients $c_n=d(nT)=O(n^{2N-1})$, which converges to the periodic extension $D^*(w)$ for real w. But $D^*(w)=(1-D_w^2)^N G^*(w)$ where D_w is the differentiation operator and

$$G^*(w)=\sum\frac{c_n}{(1+n^2T^2)^N}e^{-iwnT}\in L^2(-\sigma,\sigma). \tag{3.5}$$

Let $G(w)=G^*(w)\chi(w)$ where χ is the characteristic function of $[-\sigma,\sigma]$. Then G is in $L^2(\mathbb{R}^1)$ and its inverse Fourier transform $g(t)$ is given by

$$g(t)=\sum\frac{d(nT)}{(1+n^2T^2)^N}\frac{\sin\sigma(t-nT)}{\sigma(t-nT)}, \tag{3.6}$$

where $g\in L^2(R^1)$. Therefore $(1+t^2)^N g(t)\in L_{2N}^2$ and the series

$$\sum d(nT)\left(\frac{1+t^2}{1+n^2T^2}\right)^N\frac{\sin\sigma(t-nT)}{\sigma(T-nT)} \tag{3.7}$$

converges to $(1+t^2)^N g(t)$ in the sense of L_{2N}^2. Since $D^*(w)$ has support on 0, $\pm 2\sigma$, $\pm 4\sigma,\cdots$, it is locally equal to zero on open intervals excluding these points. Hence G^* is a classical solution to $(1-D^2)^N Y=0$ on $(\sigma/2,3\sigma/2)$ and on $(-3\sigma/2,-\sigma/2)$ and is locally a C^∞ function at $w=\pm\sigma$. Since it is also periodic, it follows by repeated integration by parts that

$$d(t)=\frac{1}{2\sigma}\int_{-\sigma}^{\sigma}(1-D^2)^N G(w)\,e^{iwt}\,dw=(1+t^2)^N g(t)+P(t)\sin\sigma t. \tag{3.8}$$

The result for best approximation in L^2_{2p} in the proper norm is somewhat more complex than in L^2.

PROPOSITION 3.2. *Let $f \in L^2_{2p}$, $g(t) = f(t)/(t^2+1)^p$; then the best approximation to f among $y \in B_{2p}(\sigma)$ is obtained for*

$$y_0 = (t^2+1)^p \left(g(t) * \frac{\sin \sigma t}{\sigma t} \right) + \sum_{j=0}^{p-1} a_j t^j e^{i\sigma t} + \sum_{j=0}^{p-1} b_j t^j e^{-i\sigma t} \tag{3.9}$$

where $a_0, \cdots, a_{p-1}, b_0, \cdots, b_{p-1}$ depend on f.

Proof. Let $F(w)$ and $G(w)$ be the Fourier transform of f and g, respectively. Then $F(w) = (1-D^2)^p G(w)$ and $G \in L^2(\mathbb{R}^1)$. We split up G into three mutually orthogonal functions as follows: first we let

$$G = G\chi + G(1-\chi)$$

where χ is the characteristic function of $[-\sigma, \sigma]$. We then take $G_1 = G\chi$ and G_2 to be the projection of $G(1-\chi)$ on to the subspace of $L^2(R^1)$ spanned by functions of the form

$$w^k e^{-w} H(w-\sigma), \quad w^k e^{w} H(-w-\sigma), \quad k = 0, 1, \cdots, p-1$$

where $H(w)$ is the Heaviside function. We take $G_3 = G(1-\chi) - G_2$ which is clearly orthogonal to G_2. Hence we have a decomposition

$$G = G_1 + G_2 + G_3$$

into mutually orthogonal functions.

We now let $y \in B_{2p}(\sigma)$. Its Fourier transform Y has a decomposition $Y = (1-D^2)^p(Z_1 + Z_2 + Z_3)$ and the norm of the difference is

$$\|f - y\|^2_{2p} = \|G_1 + G_2 + G_3 - Z_1 - Z_2 - Z_3\|^2. \tag{3.10}$$

But since $(1-D^2)^p(Z_2+Z_3) = 0$ on $(-\infty, -\sigma) \cup (\sigma, \infty)$, it follows that $Z_2 + Z_3$ is a polynomial of degree $\leqq p-1$ times e^{-w} on (σ, ∞), and hence $Z_3 = 0$ for $w > \sigma$. A similar result holds for $-\sigma > w$. Hence (3.10) is minimized by choosing $Z_1 = G_1$ and $Z_2 = G_2$, i.e., the inverse Fourier transform y_0 of

$$Y_0 = (1-D^2)^p (G_1 + G_2)$$

is the best approximation. It is

$$y_0(t) = (1+t^2)^p \mathcal{F}^{-1}(G\chi) + \mathcal{F}^{-1} \sum_{n=0}^{p-1} a_n \delta^{(n)}(w-\sigma) + \mathcal{F}^{-1} \sum_{n=0}^{p-1} b_n \delta^{(n)}(w+\sigma),$$

where the coefficients a_n and b_n involve the value of G_2 and its derivatives at $w = \pm\sigma$. This gives us the theorem.

4. (C, α)-summability. In this section we shall consider a version of (1.1) appropriate for bandlimited functions of polynomial growth which, however, involve (C, α) Cesaro summability instead of pointwise convergence. That is, we shall show that

$$f(t) = \lim_{N \to \infty} \sum_{n=-N}^{N} C^{\alpha}_{N,n} f(nT) \frac{\sin \sigma(t-nT)}{\sigma(t-nT)} \tag{4.1}$$

where

$$C^{\alpha}_{N,n} = A^{\alpha}_{N-|n|} / A^{\alpha}_{N}, \qquad A^{\alpha}_{k} = \binom{k+\alpha}{k}.$$

This is the same weight used in (C, α)-summability in Fourier series [10a, p. 77]. This result is closer to the original formulation than those considered in the previous sections.

We suppose that $f(t)$ is a bandlimited function of polynomial growth with $F(w)$ having support in $[-\sigma, \sigma]$. We shall need a characterization of such F in terms of piecewise continuous functions. It is similar to that in [3] and could be derived from it.

The space of generalized functions with compact support is denoted by $\mathscr{E}'$ $\mathscr{E}'$ is a subspace of S', the space of all tempered distributions, and thus each element is a finite order derivative of a continuous function of polynomial growth. We use this for our characterization.

LEMMA 4.1. *Let $F \in \mathscr{E}'$ with support in $[-\sigma, \sigma]$; then there exists a piecewise continuous function $G \in \mathscr{E}'$ with the same support as F, an integer p, and constants $c_0, \cdots, c_{p-1}$ such that*

$$F(w) = D^p G(w) + \sum_{i=0}^{p-1} c_i \delta^i(w). \tag{4.2}$$

Proof. We begin by observing that each $F \in S'$ has an antiderivative in S', $F^{(-1)}$. Since $F = 0$ on $(-\infty, -\sigma) \cup (\sigma, \infty)$, $F^{(-1)}$ is constant on these two intervals and we may assume without loss of generality that $F^{(-1)}(w) = 0$ on $(-\infty, -\sigma)$. Let $a_1 = F^{(-1)}(w)$ on (σ, ∞). Then

$$F^{(-1)}(w) - a_1 H(w),$$

where $H(w)$ is the unit step function, is zero on $(-\infty, -\sigma) \cup (\sigma, \infty)$ and hence belongs to $\mathscr{E}'$. We repeat this argument $(p-1)$ times to obtain an element

$$G(w) = F^{(-p)}(w) - a_1 \frac{w^{p-1}}{(p-1)!} H(w) - \frac{a_2 w^{p-2}}{(p-2)!} H(w) - \cdots - a_p H(w)$$

in $\mathscr{E}'$ with support in $[-\sigma, \sigma]$. But for p sufficiently large $F^{(-p)}$ is a continuous function, and hence $G(w)$ is continuous except at 0. The pth derivative of G is the expression given in (4.2).

We now turn to (C, α)-summability of the Fourier series of $F(w)$. We need the following.

LEMMA 4.2. *Let $\varphi_t(w) = e^{iwt} \chi_{[-\pi, \pi]}(w)$, $t \in \mathbb{R}^1$, and let φ_t^* be its periodic extension. Then the Fourier series of the pth derivative of φ_t^* is uniformly (C, α)-summable on closed subintervals of $(-\pi, \pi)$ for t on bounded sets when $\alpha > p$.*

Proof. The fact that $D^p \varphi_t^*(w)$ has a Fourier series which is (C, α)-summable at each $w \in (-\pi, \pi)$ follows from a classical theorem [10b, p. 59] since the pth derivative of φ_t^* exists at each such w. The same proof gives uniform convergence provided w is restricted to an interval $[-\pi + \varepsilon, \pi - \varepsilon]$ since the pth derivative of φ_t^* is uniformly continuous in this interval.

We now use these lemmas to obtain (C, α)-summability of the Fourier transform of $F \in \mathscr{E}'$.

THEOREM 4.3. *Let $F \in \mathscr{E}'$ with support in the interior of $(-\pi, \pi)$; let $f(t) = 1/2\pi \langle F, e^{-iwt} \rangle$ and $f_n^\alpha(t) = 1/2\pi \langle F, \sigma_{nt}^\alpha \rangle$ where $\sigma_{nt}^\alpha(w)$ is the (C, α) mean of the nth partial sum of the Fourier series of e^{iwt}. Then*

$$f_n^\alpha(t) \to f(t)$$

uniformly on bounded sets.

Proof. By Lemma 4.1, $F = D^p G + \sum_{i=0}^{p-1} c_i \delta^i$ where F has support in the same interval as G. By Lemma 4.2, we have

$$\langle D^p G, \sigma_{nt}^\alpha \rangle = \langle G, D^p \sigma_{nt}^\alpha \rangle (-1)^p \to \langle G, D^p e^{iwt} \rangle (-1)^p = \langle D^p G, e^{iwt} \rangle,$$

and, similarly for $\varphi_t(w) = e^{iwt}$,

$$\langle \delta^{(i)}, \sigma_{nt}^{\alpha} \rangle = \sigma_{nt}^{\alpha(i)}(0)(-1)^i \to \varphi_t^{(i)}(0)(-1)^i = \langle \delta^{(i)}, \varphi_t \rangle.$$

COROLLARY 4.4. *Let $f(t)$ be a bandlimited function of polynomial growth bandlimited to $[-\sigma', \sigma']$. Then for each $\sigma > \sigma'$*

$$f(t) = \sum_{n=-\infty}^{\infty} f(nT) \frac{\sin \sigma(t - nT)}{\sigma(t - nT)}$$

where convergence is in the sense of (C, α)-summability for some $\alpha > p$.

This is a restatement of the theorem with a change of scale from $[-\pi, \pi]$ to $[-\sigma, \sigma]$.

ASYMPTOTICS OF COMBINATORIAL SUMS AND THE CENTRAL LIMIT THEOREM*

PAULA S. COHEN† AND AMITAI REGEV‡

Abstract. The aim of this paper is to generalize the results of Regev [*Adv. in Math.*, 41 (1981), pp. 115–136] and to simplify the proofs by deducing them from the Central Limit Theorem of probability theory. The generalized results also yield a method for calculating certain multi-integrals, some of which seem highly nontrivial.

AMS(MOS) subject classifications. 60F05, 20C30

1. Introduction. Let $k>0$ be an integer and $\beta>0$ a real number. For integers $n\to\infty$, the asymptotic behavior of the sum

$$S_k^{(\beta)}(n)=\sum_{\lambda\in\Lambda_k(n)} d_\lambda^\beta,$$

where $\Lambda_k(n)=\{\lambda=(\lambda_1,\cdots,\lambda_k)\in\mathbb{Z}^k \mid \lambda_1\geqq\cdots\geqq\lambda_k\geqq 0,\ \lambda_1+\cdots+\lambda_k=n\}$ and d_λ is the number of standard Young tableaux of shape λ, was studied in [12].

This was essentially done as follows. We began with a family $\{\Lambda_k(n,\rho)\}_{\rho\in\mathbb{R}}$ (see § 5) of subsets of $\Lambda_k(n)$, chosen so that for each fixed ρ, and each λ in $\Lambda_k(n,\rho)$, the d_λ, and hence the d_λ^β, could be evaluated asymptotically as $n\to\infty$. The sums of d_λ^β over λ in $\Lambda_k(n,\rho)$, converging to $S_k^{(\beta)}(n)$ as $\rho\to\infty$, were then approximated by certain integrals from which we obtained the asymptotic values of the $S_k^{(\beta)}(n)$.

Examples of such sums, having their origin in combinatorics and in algebras that satisfy polynomial identities, are given in § 5 (see also [2]).

In this paper the set $\Lambda_k(n)$ is replaced by

$$A_k(n)=\{\alpha=(\alpha_1,\cdots,\alpha_k)\in\mathbb{Z}^k \mid \alpha_1\geqq 0,\cdots,\alpha_k\geqq 0;\ \alpha_1+\cdots+\alpha_k=n\}.$$

We denote

$$\binom{n}{\boldsymbol{\alpha}}=\frac{n!}{\prod_{j=1}^k \alpha_j!}$$

and we study the asymptotics of sums of the form

$$\sum_{\boldsymbol{\alpha}\in A_k(n)} f(\boldsymbol{\alpha})\binom{n}{\boldsymbol{\alpha}}^\beta$$

for certain functions $f:\bigcup_{n\geqq 0} A_k(n)\to\mathbb{R}$.

In § 5 we show that these latter sums generalize the sums $S_k^{(\beta)}(n)$.

In § 2 we state the main result for these generalized sums, the proof of which is given in §§ 3 and 4. In particular, in § 3 we reduce the proof for arbitrary $\beta>0$ to the case $\beta=1$, and this case we treat in § 4 using the Central Limit Theorem of probability theory.

The approach of this article is much simpler than that of [12] and it allows us to deduce a general theorem about the asymptotics of such sums. All asymptotics of related sums known to us are particular cases of that theorem. Our general results also yield a method for calculating certain multi-integrals, some of which seem highly nontrivial. In § 5 we give illustrative examples of such applications.

Recently, Macdonald found some very interesting identities that involve certain multi-integrals [7]. The evaluation of these integrals is done by the Selberg formula [15]. Some of the integrals evaluated in § 5 constitute partial generalizations of these "Macdonald" (or "Mehta") integrals but it seems that their evaluation cannot be obtained from the Selberg integral.

2. The main result. For positive integers k, n we write

$$A_k(n) = \{\boldsymbol{\alpha} = (\alpha_1, \cdots, \alpha_k) \in \mathbb{Z}^k \,|\, \alpha_1 \geqq 0, \cdots, \alpha_k \geqq 0;\ \alpha_1 + \cdots + \alpha_k = n\},$$

$$A_k = \bigcup_{n \geqq 0} A_k(n).$$

For $\boldsymbol{\alpha} = (\alpha_1, \cdots, \alpha_k)$ in $A_k(n)$, let

$$c_j = c_j(\boldsymbol{\alpha}) = \frac{1}{\sqrt{n}}\left(\alpha_j - \frac{n}{k}\right), \qquad j = 1, \cdots, k,$$

and $c(\boldsymbol{\alpha}) = (c_1, \cdots, c_k)$.

Given a real number $\rho > 0$ we write

$$C_k(\rho) = \{(c_1, \cdots, c_k) \in \mathbb{R}^k \,|\, |c_j| \leqq \rho, j = 1, \cdots, k\}$$

and

$$A_k(n, \rho) = \{\boldsymbol{\alpha} \in A_k(n) \,|\, c(\boldsymbol{\alpha}) \in C_k(\rho)\}.$$

DEFINITION. A function $h : A_k \to \mathbb{R}$ is defined to be permissible if

(i) There exists a polynomial $p(\mathbf{x}) = p(x_1, \cdots, x_k)$ such that for all n and all $\boldsymbol{\alpha}$ in $A_k(n)$

$$|h(\boldsymbol{\alpha})| \leqq |p(c(\boldsymbol{\alpha}))|.$$

(ii) Given $\rho > 0$,

$$\lim_{\substack{n \to \infty \\ \boldsymbol{\alpha} \in A_k(n,\rho)}} h(\boldsymbol{\alpha}) = 1.$$

By this we mean the following: given $\varepsilon > 0$, there exists an integer $N = N(\varepsilon, \rho)$ such that if $n \geqq N$ then

$$|h(\boldsymbol{\alpha}) - 1| < \varepsilon$$

for all $\boldsymbol{\alpha} \in A_k(n, p)$.

Throughout this article, for functions $f : A_k \to \mathbb{R}$, $g : \mathbb{R}^k \to \mathbb{R}$, and γ a real number the notation

$$f(\boldsymbol{\alpha}) \approx g(c(\boldsymbol{\alpha})) \cdot n^{\gamma}, \qquad \boldsymbol{\alpha} \text{ in } A_k(n),$$

means that there exists a permissible function $h : A_k \to \mathbb{R}$ and real numbers $\theta > 0$, $N_0 > 0$ such that for $n \geqq N_0$ and all $\boldsymbol{\alpha}$ in $A_k(n)$

$$|f(\boldsymbol{\alpha}) - h(\boldsymbol{\alpha}) g(c(\boldsymbol{\alpha})) \cdot n^{\gamma}| < n^{\gamma - \theta}.$$

For technical reasons we introduced the above relation $\approx$ rather than the conventional $\simeq$: recall $a_n \simeq b_n$ if $\lim_{n\to\infty}(a_n/b_n)=1$. The results of subsequent sections include the fact that if $f(\boldsymbol{\alpha}) \approx g(c(\boldsymbol{\alpha}))\cdot n^{\gamma}$, then

$$\sum_{\boldsymbol{\alpha}\in A_k(n)} f(\boldsymbol{\alpha})\binom{n}{\boldsymbol{\alpha}}^{\beta} \underset{n\to\infty}{\simeq} \sum_{\boldsymbol{\alpha}\in A_k(n)} g(c(\boldsymbol{\alpha}))\cdot n^{\gamma}\cdot\binom{n}{\boldsymbol{\alpha}}^{\beta}.$$

Remark. Let $p(x_1,\cdots,x_k)$ be a polynomial. By choosing ρ large enough, the integral

$$\int\cdots\int_{\mathbb{R}^k\setminus C_k(\rho)} |p(x_1,\cdots,x_k)|\cdot\exp\left(-\sum x_i^2\right) d^{(k)}x$$

can be made arbitrarily small. This is the only fact about $p(x)$ which will be used in the sequel (see § 4).

For this reason, one could weaken the condition that $p(x)$ is a polynomial, by requiring that $p(x)$ be a function which satisfies the above property.

The main result of the present article is as follows.

THEOREM 1. *Let γ be a real number and*

$$f: A_k \to \mathbb{R}, \qquad g: \mathbb{R}^k \to \mathbb{R}$$

be functions such that g is continuous almost everywhere and

$$f(\boldsymbol{\alpha}) \approx g(c(\boldsymbol{\alpha}))\cdot n^{\gamma}, \qquad \boldsymbol{\alpha} \text{ in } A_k(n).$$

Then for $\beta>0$ real

$$\lim_{n\to\infty}\sum_{\boldsymbol{\alpha}\in A_k(n)} f(\boldsymbol{\alpha})\binom{n}{\boldsymbol{\alpha}}^{\beta} n^{-\gamma+(1/2)(\beta-1)(k-1)}k^{-\beta n}$$
$$=\left(\frac{1}{2\pi}\right)^{(1/2)\beta(k-1)} k^{(1/2)\beta k}\int_{x_1+\cdots+x_k=0}\int_{\mathbb{R}^{k-1}} g(\mathbf{x})$$
$$\times\exp\left(-\tfrac{1}{2}\beta k(x_1^2+\cdots+x_k^2)\right) dx_1\cdots dx_{k-1}$$

whenever the integral on the right exists.

In § 3 we reduce the proof of Theorem 1 to the case $\beta=1$, which we in turn handle in § 4 using the Central Limit Theorem of probability theory.

We will also encounter the following easy variants of Theorem 1.

Variation 1. In the situation of Theorem 1, let D be a fixed domain in $\mathbb{R}^k$ and let

$$D(n)=\{\boldsymbol{\alpha}\in A_k(n)\,|\,c(\boldsymbol{\alpha})\in D\}.$$

A simple modification of the proof of Theorem 1 yields

$$\lim_{n\to\infty}\sum_{\boldsymbol{\alpha}\in A_k(n)\cap D(n)} f(\boldsymbol{\alpha})\binom{n}{\boldsymbol{\alpha}}^{\beta} n^{-\gamma+(1/2)(\beta-1)(k-1)}k^{-\beta n}$$
$$=\left(\frac{1}{2\pi}\right)^{(1/2)\beta(k-1)} k^{(1/2)\beta k}\int_{\substack{x_1+\cdots+x_k=0\\(x_1,\cdots,x_k)\in D}}\int_{\mathbb{R}^{k-1}} g(\mathbf{x})$$
$$\times\exp\left(-\tfrac{1}{2}\beta k(x_1^2+\cdots+x_k^2)\right) dx_1\cdots dx_{k-1}$$

whenever the integral on the right exists.

Variation 2. In the situation of Theorem 1 we assume further that the $g = g(x_1, \cdots, x_k)$ is a function of the differences $x_i - x_j$, $i, j = 1, \cdots, k$. We may argue as in Lemma 4.3 of [12] to obtain

$$\int_{x_1+\cdots+x_k=0} \int_{\mathbb{R}^{k-1}} g(\mathbf{x}) \exp\left(-\tfrac{1}{2}\beta k(x_1^2+\cdots+x_k^2)\right) dx_1 \cdots dx_{k-1}$$

$$= \sqrt{\frac{\beta}{2\pi}} \int \cdots \int_{\mathbb{R}^k} g(\mathbf{x}) \exp\left(-\tfrac{1}{2}\beta k(x_1^2+\cdots+x_k^2)\right) dx_1 \cdots dx_k.$$

Given the result of Theorem 1 we thereby have

$$\lim_{n\to\infty} \sum_{\boldsymbol{\alpha}\in A_k(n)} f(\boldsymbol{\alpha}) \binom{n}{\boldsymbol{\alpha}}^{\beta} n^{-\gamma+(1/2)(\beta-1)(k-1)} k^{-\beta n}$$

$$= \left(\frac{1}{2\pi}\right)^{(1/2)\beta(k-1)} k^{(1/2)\beta k} \sqrt{\frac{\beta}{2\pi}} \int \cdots \int_{\mathbb{R}^k} g(\mathbf{x})$$

$$\times \exp\left(-\tfrac{1}{2}\beta k(x_1^2+\cdots+x_k^2)\right) dx_1 \cdots dx_k$$

whenever the integral on the right exists.

We conclude this section with some illustrative examples of the types of functions we encounter in the proof of Theorem 1 and its applications.

We remark that a product of permissible functions is itself a permissible function.

Example 1. For $\boldsymbol{\alpha} = (\alpha_1, \cdots, \alpha_k)$ in $A_k(n)$ write $\alpha_j = (n/k)(1 + c_j k/\sqrt{n})$, $j = 1, \cdots, k$, as above and suppose $\alpha_j \geqq 1$, $j = 1, \cdots, k$. If n is large enough it is easy to verify that

$$(2 + c_j^2 k)^{-1} \leqq (1 + c_j k/\sqrt{n}) \leqq k.$$

It follows that the functions $h^{(j)}: A_k \to \mathbb{R}$ and $\bar{h}^{(j)}: A_k \to \mathbb{R}$ given by

$$h^{(j)}(\boldsymbol{\alpha}) = 1 + c_j k/\sqrt{n}, \qquad \boldsymbol{\alpha} \text{ in } A_k(n), \quad j = 1, \cdots, k,$$

$$\bar{h}^{(j)}(\boldsymbol{\alpha}) = (h^{(j)}(\boldsymbol{\alpha}))^{-1}, \qquad \boldsymbol{\alpha} \text{ in } A_k(n), \quad j = 1, \cdots, k,$$

are permissible.

Example 2. For b a real number, one form of Stirling's formula is given by

$$\Gamma(n + b + 1) \simeq \sqrt{2\pi}\, e^{-n} n^{n+b} \sqrt{n}, \qquad n \to \infty.$$

Write

$$\Gamma(n + b + 1) = h_b(n) \sqrt{2\pi}\, e^{-n} n^{n+b} \sqrt{n}$$

and

$$h_{j,b}^{\pm 1}(\boldsymbol{\alpha}) = h_b^{\pm 1}(\alpha_j), \qquad \boldsymbol{\alpha} = (\alpha_1, \cdots, \alpha_j) \quad \text{in } A_k, \quad j = 1, \cdots, k.$$

Clearly the $h_{j,b}^{\pm 1}$, $j = 1, \cdots, k$, are permissible functions.

Example 3. For $\boldsymbol{\alpha} \in A_k(n)$ and $c_j(\boldsymbol{\alpha})$ as before, $\alpha_i - \alpha_j = [c_i(\boldsymbol{\alpha}) - c_j(\boldsymbol{\alpha})]\sqrt{n}$, and $\alpha_i - \alpha_j + j - i \approx [c_i(\boldsymbol{\alpha}) - c_j(\boldsymbol{\alpha})]\sqrt{n}$: here $h(\boldsymbol{\alpha}) \equiv 1$, and $|[\alpha_i - \alpha_j + j - i] - [c_i(\boldsymbol{\alpha}) - c_j(\boldsymbol{\alpha})]\sqrt{n}| = |j - i| < n^{(1/2)-\theta}$ for any $0 < \theta < \frac{1}{2}$ and n large enough.

Moreover, let $r = \frac{1}{2}k(k-1)$ and choose an ordering $\{x_i - x_j \,|\, 1 \leqq i < j \leqq k\} = \{y_1, \cdots, y_r\}$. Let $M(x_i - x_j \,|\, i < j) = M(y_1, \cdots, y_r)$ be any monomial in the $x_i - x_j$'s of degree d. Clearly, $M(\alpha_i - \alpha_j \,|\, i < j) = [M(c_i(\boldsymbol{\alpha}) - c_j(\boldsymbol{\alpha}) \,|\, i < j)] \cdot n^{d/2}$, and it is easy to check that $M(\alpha_i - \alpha_j + j - i \,|\, i < j) \approx [M(c_i(\boldsymbol{\alpha}) - c_j(\boldsymbol{\alpha}) \,|\, i < j)] n^{d/2}$.

For example, $D_k(x_1, \cdots, x_k) = \prod_{i<j}(x_i - x_j)$ is of degree r; hence

$$D_k(\alpha_1 + k - 1, \alpha_2 + k - 2, \cdots, \alpha_k) \approx D_k(c(\boldsymbol{\alpha})) \cdot n^{r/2} = D_k(\alpha_1, \cdots, \alpha_k) \text{ (see § 5).}$$

3. Reduction to the case $\beta = 1$. In this section we show that the proof of Theorem 1 may be reduced to the case $\beta = 1$. By Carlson's theorem (see for example [3, p. 153, § 9.2]) it suffices to prove Theorem 1 for β a positive integer. To pass from this case to the case $\beta = 1$ we show, with notation as in § 2, the following proposition.

PROPOSITION. *Let β be a positive integer. For γ a real number and*

$$f: A_k \to \mathbb{R}, \qquad g: \mathbb{R}^k \to \mathbb{R},$$

functions such that g is continuous almost everywhere and

$$f(\boldsymbol{\alpha}) \approx g(c(\boldsymbol{\alpha})) \cdot n^{\gamma}, \qquad \boldsymbol{\alpha} \text{ in } A_k(n)$$

we have

$$\sum_{\boldsymbol{\alpha} \in A_k(n)} f(\boldsymbol{\alpha}) \binom{n}{\boldsymbol{\alpha}}^{\beta} n^{-\gamma + (1/2)(k-1)(\beta-1)} k^{-\beta n} \approx \delta^{(\beta)}(k) \sum_{\mathbf{a} \in A_k(\beta n)} f^*(\mathbf{a}) \binom{\beta n}{\mathbf{a}} n^{-\gamma} k^{-\beta n}$$

where

$$\delta^{(\beta)}(k) = \left(\frac{1}{\sqrt{2\pi}}\right)^{(k-1)(\beta-1)} \beta^{(k-1)/2} k^{(1/2)k(\beta-1)}$$

and

$$f^*: A_k \to \mathbb{R} \quad \textit{satisfies}$$

$$f^*(\mathbf{a}) \approx g\left(\frac{1}{\sqrt{\beta}} c(\mathbf{a})\right) \cdot n^{\gamma}, \qquad \mathbf{a} \text{ in } A_k(\beta n).$$

We divide the proof of the proposition into two lemmas.

For β a positive integer and $\boldsymbol{\alpha} = (\alpha_1, \cdots, \alpha_k)$ in $A_k(n)$ we denote by $\beta\boldsymbol{\alpha}$ the element $(\beta\alpha_1, \cdots, \beta\alpha_k)$ of $A_k(\beta n)$.

LEMMA 1. *Let β be a positive integer. For $\boldsymbol{\alpha} = (a_1, \cdots, \alpha_k)$ in A_k we have as $n \to \infty$,*

$$\left(\frac{n!}{\alpha_1! \cdots \alpha_k!}\right)^{\beta} \approx h_0^{(\beta)}(\boldsymbol{\alpha}) \delta_0^{(\beta)}(k) n^{-(1/2)(k-1)(\beta-1)} \left(\frac{(\beta n)!}{(\beta\alpha_1)! \cdots (\beta\alpha_k)!}\right)$$

where

$$\delta_0^{(\beta)}(k) = \left(\frac{1}{\sqrt{2\pi}}\right)^{(k-1)(\beta-1)} \beta^{(k-1)/2} k^{(1/2)k(\beta-1)}$$

and

$$h_0^{(\beta)}: A_k \to \mathbb{R}$$

is a permissible function.

Proof. In particular, for $\boldsymbol{\alpha} \in A_k(n)$, since $0! = 1! = 1$, we may assume that $\alpha_j \geqq 1$. Applying Stirling's formula as in Example 2 of § 2, respectively, to $(n!/\alpha_1! \cdots \alpha_k!)$ and $((n)!/(\beta\alpha_1)! \cdots (\beta\alpha_k)!)$ we deduce that as $n \to \infty$

$$\left(\frac{n!}{\alpha_1! \cdots \alpha_k!}\right) \approx h_1^{(\beta)}(\boldsymbol{\alpha}) \delta_1^{(\beta)}(k) n^{(\beta-1)/2} \left(\prod_{j=1}^{k} \alpha_j\right)^{-(\beta-1)/2} \left(\frac{(\beta n)!}{(\beta\alpha_1)! \cdots (\beta\alpha_k)!}\right)$$

where

$$\delta_1^{(\beta)}(k)=\left(\frac{1}{\sqrt{2\pi}}\right)^{(k-1)(\beta-1)}\beta^{(k-1)/2}$$

and $h_1^{(\beta)}$ is a permissible function.

To conclude the proof of the lemma, we apply Example 1 and the remark preceding it in § 2

$$\left(\prod_{j=1}^{k}\alpha_j\right)^{-(\beta-1)/2}\approx\left(\frac{n}{k}\right)^{-(k/2)(\beta-1)}.$$

We now note that to each $\mathbf{a}=(a_1,\cdots,a_k)$ in $A_k(\beta n)$ we may associate a unique $\boldsymbol{\alpha}=\boldsymbol{\alpha}(\mathbf{a})=(\alpha_1,\cdots,\alpha_k)$ in $A_k(n)$ satisfying

$$\beta\alpha_j\leqq a_j<\beta\alpha_j+\beta,\qquad j=1,\cdots,k-1,$$

$$\alpha_k=n-(\alpha_1+\cdots+\alpha_{k-1}).$$

Each $\boldsymbol{\alpha}$ in $A_k(n)$ is associated in this way to exactly β^{k-1} elements of $A_k(\beta n)$.

We can easily check that as $n\to\infty$

$$c_j(\mathbf{a})\approx\sqrt{\beta}\,c_j(\boldsymbol{\alpha}(\mathbf{a})),\qquad j=1,\cdots,k,$$

in the notation of § 2.

With the correspondence $\boldsymbol{\alpha}=\boldsymbol{\alpha}(\mathbf{a})$ above we show the following lemma.

LEMMA 2. *For all* $\mathbf{a}$ *in* $A_k(\beta n)$

$$\binom{\beta n}{\beta\boldsymbol{\alpha}}=h_2^{(\beta)}(\mathbf{a})\binom{\beta n}{\mathbf{a}}$$

where $\boldsymbol{\alpha}=\boldsymbol{\alpha}(\mathbf{a})$ *and* $h_2^{(\beta)}$ *is a permissible function.*

Proof. The lemma follows on applying Stirling's formula as in Example 2 of § 2 to both sides of the above equation, and from Example 1 of § 2 and the remark preceding it. The main point is that the distance between $\mathbf{a}$ and $\beta\boldsymbol{\alpha}$ is uniformly bounded for all $\mathbf{a}$ in $A_k(\beta n)$.

The proposition now follows after applying Lemmas 1 and 2, being careful to note the remarks preceding Lemma 2.

If Theorem 1 holds for $\beta=1$ we may apply it to the right-hand sum of the proposition to deduce the result of Theorem 1 for β a positive integer, and hence, by the remarks at the beginning of the section, for all real $\beta>0$.

4. Proof of the theorem in the case $\beta=1$. By the results of § 3 it suffices to consider the case $\beta=1$. This case is a straightforward application of the Central Limit Theorem of probability and its proof is due to Gideon Schechtman.

Let $\mathbf{e}_i$, $i=1,\cdots,k$, be the vector in $\mathbb{R}^k$ with ith coordinate 1 and zeros elsewhere. We introduce random variables $\mathbf{X}_1,\cdots,\mathbf{X}_n$ that take values in the set $\{e_1,\cdots,e_k\}$ with probability

$$P(\mathbf{X}_i=\mathbf{e}_j)=\frac{1}{k},\qquad i=1,\cdots,n,\quad j=1,\cdots,k.$$

For $\boldsymbol{\alpha}$ in $A_k(n)$ we have

$$P(\mathbf{X}_1+\cdots+\mathbf{X}_n=\boldsymbol{\alpha})=\binom{n}{\boldsymbol{\alpha}}k^{-n}.$$

In this setting, the sum

$$S_k(n) = n^{-\gamma} \sum_{\alpha \in A_k(n)} f(\alpha) \binom{n}{\alpha} k^{-n}$$

equals $n^{-\gamma} E(f(\mathbf{X}_1 + \cdots + \mathbf{X}_n))$ where E stands for expected value.

On the other hand, consider the expected value $E(g((1/\sqrt{n})(\mathbf{Y}_1 + \cdots + \mathbf{Y}_n)))$ where the

$$\mathbf{Y}_i = \mathbf{X}_i - \left(\frac{1}{k}, \cdots, \frac{1}{k}\right), \qquad i = 1, \cdots, n$$

are independent random variables with expected values zero. We remark that if, for $i = 1, \cdots, n$, we write $\mathbf{Y}_i = \mathbf{Y} = (y_1, \cdots, y_k)$ then $y_k = -(y_1 + \cdots + y_{k-1})$. We may therefore apply the Central Limit Theorem (see, for example, [4, Problem 6, p. 241]) in $k-1$ dimensions with expectation matrix $\Gamma = E(y_i y_j)$ $i, j = 1, \cdots, k-1$ to deduce that

$$\lim_{n \to \infty} E\left(g\left(\frac{1}{\sqrt{n}}(\mathbf{Y}_1 + \cdots + \mathbf{Y}_n)\right)\right)$$
$$= \left(\frac{1}{\sqrt{2\pi}}\right)^{k-1} \sqrt{\det{}^{-1} \Gamma} \int \cdots \int_{\mathbb{R}^{k-1}} g(\mathbf{x}(\mathbf{u})) \exp\left(-\tfrac{1}{2}\mathbf{u}\Gamma^{-1}\mathbf{u}^t\right) d\mathbf{u}$$

where $\mathbf{u} = (u_1, \cdots, u_{k-1})$

$$\mathbf{x} = \mathbf{x}(\mathbf{u}) = (x_1, \cdots, x_k) = (u_1, \cdots, u_{k-1}, -(u_1 + \cdots + u_{k-1})).$$

Now, if $i \neq j$, $1 \leqq i, j \leqq k$,

$$(y_i, y_j) = \begin{cases} (1 - 1/k, -1/k) & \text{with probability } 1/k, \\ (-1/k, 1 - 1/k) & \text{with probability } 1/k, \\ (-1/k, -1/k) & \text{with probability } 1 - 2/k. \end{cases}$$

Hence $E(y_i, y_j) = (2/k)(1 - 1/k)(-1/k) + (1 - 2/k)(1/k)^2 = -1/k^2$. Similarly $E(y_j^2) = (k-1)/k^2$. It therefore follows that

$$\Gamma = \frac{1}{k^2} \begin{pmatrix} k-1 & & -1 \\ & \ddots & \\ -1 & & k-1 \end{pmatrix}, \quad \det \Gamma = k^{-k}, \quad \Gamma^{-1} = k \begin{pmatrix} 2 & & 1 \\ & \ddots & \\ 1 & & 2 \end{pmatrix}$$

and $\mathbf{u}\Gamma^{-1}\mathbf{u}^t = k \sum_{j=1}^{k} x_j^2$. Therefore

$$\lim_{n \to \infty} E\left(g\left(\frac{1}{\sqrt{n}}(\mathbf{Y}_1 + \cdots + \mathbf{Y}_n)\right)\right)$$
$$= \left(\frac{1}{\sqrt{2\pi}}\right)^{k-1} k^{k/2} \int \cdots \int_{\mathbb{R}^{k-1}} g(\mathbf{x}) \exp\left(-\frac{k}{2} \sum_{i=1}^{k} x_i^2\right) dx_1 \cdots dx_{k-1},$$
$$x_k = -(x_1 + \cdots + x_{k-1}).$$

It is now straightforward to verify that as

$$f(\alpha) \approx g(c(\alpha)) \cdot n^{\gamma}, \qquad \alpha \quad \text{in } A_k(n),$$

we have

$$\lim_{n \to \infty} S_k(n) = \lim_{n \to \infty} E\left(g\left(\frac{1}{\sqrt{n}}(\mathbf{Y}_1 + \cdots + \mathbf{Y}_n)\right)\right)$$

so that Theorem 1 now follows immediately in the case $\beta = 1$.

5. Applications. The applications we give here require the following theorem, which follows from our main theorem and is almost equivalent to it ($\Lambda_k = \bigcup_{n\geqq 0} \Lambda_k(n)$; § 1).

THEOREM 2. *Assume* $f:\Lambda_k \to \mathbb{R}$ *satisfies* $f(\lambda) \approx g(c(\lambda)) \cdot n^{\gamma}$ *and* $g(x_1, \cdots, x_k)$ *is continuous almost everywhere. Then*

$$\sum_{\lambda\in\Lambda_k} f(\lambda)\, d_\lambda^\beta \simeq \left(\frac{1}{2\pi}\right)^{(1/2)\beta(k-1)} \cdot k^{(1/2)\beta k^2} \cdot n^{\gamma-(1/2)(\beta-1)(k-1)-(\beta/4)k(k-1)}$$

$$\cdot k^{\beta n} \cdot \int\cdots\int_{\substack{x_1+\cdots+x_k=0\\ x_1\geqq\cdots\geqq x_k}} g(x)\cdot D_k^\beta(x)\cdot \exp\left(-\frac{k\beta}{2}\cdot\sum_{j=1}^{k} x_j^2\right) d^{(k-1)}x.$$

Proof. It is well known that

$$d_\lambda = \binom{n}{\lambda}\cdot \prod_{m=1}^{k-1}\prod_{j=1}^{m}\left(\frac{\lambda_m-\lambda_{m+j}+j}{\lambda_m+j}\right).$$

As in Examples 1 and 2 of § 2 we have

$$\frac{1}{\lambda_m+j}\approx\frac{k}{n} \quad\text{and}\quad \lambda_m-\lambda_{m+j}+j\approx(c_m(\lambda)-c_{m+j}(\lambda))\sqrt{n},$$

so

$$\prod_{m=1}^{k-1}\prod_{j=1}^{n}\left(\frac{\lambda_m-\lambda_{m+j}+j}{\lambda_m+j}\right)^\beta \approx D_k^\beta(c(\lambda))\cdot n^{-(\beta/4)k(k-1)}\cdot k^{(\beta/2)k(k-1)}.$$

The proof is now a straightforward use of Theorem 1.

Remark. Theorem 2 clearly indicates that the maximum of the d_λ, $\lambda\in\Lambda_k(n)$, is obtained for $\lambda\in\Lambda_k(n,\rho)\overset{\text{def}}{=}\Lambda_k(n)\cap A_k(n,\rho)$, for some $\rho>0$ (§ 2).

We do have a rigorous algorithmic proof of this fact (see [16]). The corresponding λ can then be found as in [1].

For further applications, the following corollary is very useful.

COROLLARY. *Let* $f:\Lambda_k\to\mathbb{R}$ *and assume* $f(\lambda)\approx g(c(\lambda))\cdot n^{\gamma}$, *where* $g(x_1,\cdots,x_k)$ *is continuous almost everywhere. Let* $d_n=\sum_{\lambda\in\Lambda_k(n)} f(\lambda)d_\lambda$, $n=1,2,\cdots$, *and assume*

$$d_n \underset{n\to\infty}{\simeq} c\cdot n^p\cdot k^n \quad (c \text{ a constant}).$$

Then $p=\gamma-\frac{1}{4}k(k-1)$ *and*

$$\int\cdots\int_{\substack{x_1+\cdots+x_k=0\\ x_1\geqq\cdots\geqq x_k}} g(x)\cdot D_K(x)\cdot\exp\left(-\frac{k}{2}\left(\sum_j x_j^2\right)\right)d^{(k-1)}x=\left(\frac{1}{k}\right)^{k^2/2}\cdot(2\pi)^{(k-1)/2}\cdot c.$$

Proof. The proof follows by equating the asymptotics of d_n with that of $\sum_{\lambda\in\Lambda_K(n)} f(\lambda)d_\lambda$, which is given by the above theorem. □

To apply this corollary, one usually constructs a series $\{\chi_n\}$, χ_n is an S_n character, such that for a fixed k and for all n, $\chi_n=\sum_{\lambda\in\Lambda_k(n)} f(\lambda)\chi_\lambda$.

If f and $d_n=\deg\chi_n$ satisfy the above assumptions, then γ and the integral are determined.

Example 4. The sums $S_k^{(\beta)}(n) = \sum_{\lambda \in \Lambda_k(n)} d_\lambda^\beta$. Here $f(\lambda) = 1$ (constant), $r = 0$, $g(x) = 1$ and by Theorem 2 we have

$$S_k^{(\beta)}(n) \simeq \left(\frac{1}{2\pi}\right)^{(1/2)\beta(k-1)} \cdot k^{(1/2)\beta k^2} \cdot n^{-(\beta/4)k(k-1)-(1/2)(\beta-1)(k-1)} \cdot k^{\beta n}$$

$$\cdot \int_{\substack{x_1+\cdots+x_k=0 \\ x_1 \geqq \cdots \geqq x_k}} \cdots \int \left[D_K(x) \exp\left(-\frac{k}{2}\left(\sum_j x_j^2\right)\right)\right]^\beta d^{(k-1)}x.$$

This agrees with (F.2.10) of [12].

Example 5. Evaluate

$$\int_{\substack{x_1+\cdots+x_k=0 \\ x_1 \geqq \cdots \geqq x_k}} \cdots \int (D_k(x))^2 \, e^{-(k/2)\|x\|^2} d^{(k-1)}x = J_2(k) \qquad \left(\|x\| = \sum_{j=1}^k x_j^2\right).$$

As a special case of the corollary we now determine $J_2(k)$. (This is a special case of the Mehta integrals [8],

$$\int_{\substack{x_1+\cdots+x_k=0 \\ x_1 \geqq \cdots \geqq x_k}} \cdots \int (D_k(x))^{2z} \cdot e^{-(k/2)\|x\|^2} d^{(k-1)}x = J_{2z}(k).$$

These can be evaluated by the Selberg integral [7].)

Let $s_k(\lambda)$ denote the number of the k-semistandard tableaux. It is well known that

$$s_k(\lambda) = D_k(\boldsymbol{\alpha}(\lambda))/D_k(k, k-1, \cdots, 1) = [\Gamma(1) \cdots \Gamma(k)]^{-1} \cdot D_k(\boldsymbol{\alpha}(\lambda)).$$

The identity $k^n = \sum_{\lambda \in \Lambda_k(n)} s_k(\lambda) d_\lambda$ can be deduced from either the Knuth-Robinson-Schensted correspondence, or from the S_n-character $\chi_n = \sum_{\lambda \in \Lambda_k(n)} s_k(\lambda)\chi_\lambda$. It is known that χ_n is the character of the natural (permuting coordinates) action of S_n on $V^{\otimes n}$, $\dim V = k$; thus $\deg \chi_n = k^n$. It follows from the corollary that $J_2(k) = \Gamma(1) \cdots \Gamma(k) \cdot \sqrt{2\pi}^{\,k-1} \cdot (1/k)^{k^2/2}$. Thus by Variation 2

$$\int_{\mathbb{R}^k} (D_k(x))^2 \, e^{-(k/2)\|x\|^2} d^{(k)}x = \left(\prod_{j=1}^k j!\right) \cdot \sqrt{2\pi}^{\,k} \cdot \left(\frac{1}{k}\right)^{k^2/2}.$$

Example 6. Let $\varphi_n \odot \psi_n$ denote the inner (Kronecker) product of the S_n characters φ_n, ψ_n. Note that *no* formula (or a "rule") is (yet) known for calculations (decomposing) $\varphi_n \odot \psi_n$. Define

$$\chi_n = \left(\sum_{\lambda \in \Lambda_k(n+1)} \chi_\lambda \odot \chi_\lambda\right)\downarrow_{S_n} \quad \text{(restrict to } S_n\text{)}.$$

By [11],

$$\chi_n = \sum_{\mu \in \Lambda_{k_2}(n)} f(\mu)\chi_\mu,$$

where $f: \Lambda_{k^2} \to \mathbb{R}$ is some function which is unknown, except for the case $k = 2$. It would be very interesting to find whether or not $f(\mu)$ has the following.

Property. (a) There exists $\gamma \in \mathbb{R}$ such that $f(\mu) \approx g(\mathbf{c}(\mu)) \cdot n^\gamma$.

(b) $g(x_1, \cdots, x_{k^2})$ is continuous almost everywhere.

Note. When $k = 2$, f does satisfy that property. We discuss that case later.

Assuming now that f does satisfy that property, we obtain by Theorem 2 that

$$\deg \chi_n \approx I_{k^2} \cdot \left(\frac{1}{\sqrt{2\pi}}\right)^{k^2-1} \cdot \left(\frac{1}{k}\right)^{k^4} \cdot n^{\gamma-(1/4)k^2(k^2-1)} \cdot k^{2n},$$

where

$$I_{k^2}(g) = I_{k^2} = \int\cdots\int_{\substack{x_1+\cdots+x_{k_2}=0 \\ x_1\geqq\cdots\geqq x_{k_2}}} g(x_1,\cdots,x_{k^2}) \cdot D_{k^2}(x) \cdot \exp\left(-\frac{k^2}{2}(x_1^2+\cdots+x_{k^2}^2)\right) d^{(k^2-1)}x.$$

On the other hand, since $\deg \chi_n = \sum_{\lambda\in\Lambda_k(n+1)} d_\lambda^2$, hence

$$\deg \chi_n \simeq \tilde{J}_2(k) \cdot \left(\frac{1}{2\pi}\right)^{k-1} \cdot k^{k^2} \cdot n^{-(k^2-1)/2} \cdot k^{2(n+1)},$$

where $\tilde{J}_2(k) = (1/2\pi)^{k^2-1} \cdot J_2(k)$, $J_2(k)$ as in Example 5. Equating, we deduce the following.

General case. Let

$$\chi_n = \left(\sum_{\lambda\in\Lambda_k(n+1)} \chi_\lambda \odot \chi_\lambda\right)\downarrow_{S_n} = \sum_{\mu\in\Lambda_{k_2}(n)} f(\mu)\chi_\mu$$

and assume $f(\mu)$ satisfies the above property; then

$$I_{k^2} = J_2(k) \cdot \sqrt{2\pi}^{\,k^2-2k+1} \cdot k^{-k^2(k^2-1)+2}.$$

Also, we must have $\gamma = \gamma(k) = \frac{1}{4}(k^2-1)(k^2-2)$.

The case $k=2$. It follows from [9] and [6] that

$$f(\mu) \approx (c_1-c_2)(c_2-c_3)(c_3-c_4) \cdot \sqrt{n}^{\,3},$$

where $\mathbf{c} = \mathbf{c}(\mu)$. Thus

$$\int\cdots\int_{\substack{x_1+\cdots+x_4=0 \\ x_1\geqq\cdots\geqq x_4}} (x_1-x_2)(x_2-x_3)(x_3-x_4) \cdot \prod_{1\leqq i<j\leqq 4} (x_i-x_j) \cdot e^{-2(x_1^2+\cdots+x_4^2)}\, dx_1\, dx_2\, dx_3$$

$$= \tilde{J}_2(2) \cdot \sqrt{2\pi} \cdot \left(\frac{1}{2}\right)^{10} = \sqrt{2} \cdot \pi \cdot \left(\frac{1}{2}\right)^{13}.$$

Remarks. I_{k^2} determines the codimensions of the $k\times k$ matrices [14], [6] and $I_{2^2} = I_4$ was therefore calculated in [13, Appendix]. This was a long and complicated calculation by recursive methods, in which a computer was also used; a sketch of it occupies three pages in [13]. Later, William Beckner showed us a very elegant calculation of I_{2^2}, which could occupy about two printed pages. The above should be viewed as an "algebraic" (and almost effortless) calculation of I_{2^2}. For a higher number ($\geqq 3$), $f(\mu)$ and $g(\mathbf{c}(\mu))$ are unknown, but any conjecture about these can be tested by the above general case.

Example 7. Let $\psi_l(n) = \sum_{\lambda\in\Lambda_l(n)} Y_l(\lambda)\chi_\lambda$ as in [10].

The case $l=3$. By (4.2) of [10] $\deg \psi_3(n) \simeq (1/\sqrt{2\pi})^2 \cdot \sqrt{3}^{\,3} \cdot 1/n \cdot 3^n$, while $Y_3(\lambda) = \min\{\lambda_1-\lambda_2, \lambda_2-\lambda_3\}+1 \approx \min\{c_1(\lambda)-c_2(\lambda), c_2(\lambda)-c_3(\lambda)\} \cdot \sqrt{n}$.

Thus, by the corollary,

$$\iint\limits_{\substack{x_1+x_2+x_3=0\\ x_1\geqq x_2\geqq x_3}} \min\{x_1-x_2, x_2-x_3\}\cdot D_3(x)\cdot e^{-(3/2)(x_1^2+x_2^2+x_3^2)}\,dx_1\,dx_2$$
$$=\left(\frac{1}{\sqrt{3}}\right)^9\cdot(\sqrt{2\pi})^2\cdot(\sqrt{3})^3\cdot\left(\frac{1}{\sqrt{2\pi}}\right)^2=\frac{1}{27}.$$

The case $l=4$. Here $\deg\psi_4(n)\simeq(1/\sqrt{2p})^2\cdot 2^4\cdot(1/\sqrt{n})^3\cdot 4^n$.
Define

$$g(x_1,\cdots,x_4)=\begin{cases}\dfrac{1}{2}(x_1-x_2)(x_2-x_3)(x_3-x_4)-\dfrac{1}{8}[\min(x_1-x_2, x_3-x_4)]\\ \qquad\cdot(x_1-x_2-x_3+x_4)^3 \quad \text{if } x_2-x_3>\left|\dfrac{x_1-x_2-x_3+x_4}{2}\right|,\\ \dfrac{1}{2}(x_2-x_3)[\min(x_1-x_2, x_3-x_4)]\\ \qquad\cdot(x_2-x_3+[\min(x_1-x_2, x_3+x_4)]) \quad \text{if } x_2-x_3\leqq\left|\dfrac{x_1-x_2-x_3+x_4}{2}\right|,\end{cases}$$

By Theorem 5 of [5], we have $Y_4(\lambda)\approx g(c_1,\cdots,c_4)\cdot\sqrt{n}^3$, where $\mathbf{c}=\mathbf{c}(\lambda)$. Thus,

$$\iiint\limits_{\substack{x_1+\cdots+x_4=0\\ x_1\geqq\cdots\geqq x_4}} g(x_1,\cdots,x_4)D_4(x)\cdot e^{-2(x_1^2+\cdots+x_4^2)}\,d^{(3)}x$$
$$=\left(\frac{1}{\sqrt{4}}\right)^{16}\cdot(\sqrt{2\pi})^3\cdot\left(\frac{1}{\sqrt{2\pi}}\right)^3\cdot 2^4=\left(\frac{1}{2}\right)^{12}=\left(\frac{1}{4}\right)^6.$$

Example 8. Young's rule and the Littlewood-Richardson rule for the outer products of S_n-characters provide many "combinatorial" indentities; these yield quite interesting integrals. We demonstrate this below.

Let $n=m^2$, $\lambda=(n+\sqrt{n}, n-\sqrt{n})\vdash(2n)$ and *define* $\chi_{3n}=\chi_\lambda\hat{\otimes}\chi_{(n)}=\chi_{(n+\sqrt{n},n-\sqrt{n})}\hat{\otimes}\chi_{(n)}$ (outer products). By Young's rule,

$$\chi_{3n}=\sum_{\substack{\mu=(\mu_1,\mu_2,\mu_3)\vdash(3n)\\ \mu_1\geqq n+\sqrt{n}\geqq\mu_2\geqq n-\sqrt{n}\geqq\mu_3}},\qquad \chi_\mu=\sum_{\mu\in\Lambda_3(3n)} f(\mu)\chi_\mu.$$

Write $\mu_j=(3n/3)+c_j\sqrt{3n}$; then $\mu_1\geqq n+\sqrt{n}\geqq\mu_2\geqq n-\sqrt{n}\geqq\mu_3$ if and only if $c_1\geqq 1/\sqrt{3}\geqq c_2\geqq -1/\sqrt{3}\geqq c_3$. Thus

$$f(\mu)\approx g(\mathbf{c}(\mu))=\begin{cases}1, & c_1\geqq 1/\sqrt{3}\geqq c_2\geqq -1/\sqrt{3}\geqq c_3,\\ 0 & \text{otherwise.}\end{cases}$$

Clearly, $g(x_1,x_2,x_3)$ is continuous almost everywhere. Thus

$$\deg\chi_{3n}\simeq\iint\limits_{\substack{x_1+x_2+x_3=0\\ x_1\geqq 1/3\geqq x_2\geqq -1/3\geqq x_3}} D_3(x)\,e^{-(3/2)(x_1^2+x_2^2+x_3^2)}\,d^{(2)}x\cdot\left(\frac{1}{\sqrt{2\pi}}\right)^2\cdot\sqrt{3}^{3^2}\cdot n^{-3/2}\cdot 3^n.$$

Now,

$$\deg \chi_{3n} = \binom{3n}{2n} \cdot d_\lambda$$

where

$$d_\lambda = \frac{2n!}{(n+\sqrt{n})!(n-\sqrt{n})!} \frac{2\sqrt{n}+1}{n+\sqrt{n}+1}.$$

Apply Stirling's formula; since

$$\lim_{n\to\infty} \left(1+\frac{1}{\sqrt{n}}\right)^{n+\sqrt{n}} \cdot \left(1-\frac{1}{\sqrt{n}}\right)^{n-\sqrt{n}} = e,$$

we easily find that

$$\deg \chi_{3n} \simeq \frac{1}{e} \cdot \frac{\sqrt{3}}{\pi} \cdot \frac{1}{n\sqrt{n}} \cdot 3^{3n}.$$

By the corollary,

$$\iint\limits_{\substack{x_1+x_2+x_3=0 \\ x_1 \geqq 1/\sqrt{3} \geqq x_2 \geqq -1/\sqrt{3} \geqq x_3}} D_3(x)\, e^{+(3/2)(x_1^2+x_2^2+x_3^2)}\, d^{(2)}x = \left(\frac{1}{\sqrt{3}}\right)^{3^2} \cdot \sqrt{2\pi}^2 \cdot \frac{1}{e} \cdot \frac{\sqrt{3}}{\pi} = \frac{2}{3^4 e}.$$

This example can easily be generalized to higher integrals.

Acknowledgment. We are indebted to G. Schechtman for his considerable help with the probabilistic aspects of this paper.

q-SERIES AND ORTHOGONAL POLYNOMIALS ASSOCIATED WITH BARNES' FIRST LEMMA*

E.G. KALNINS† AND WILLARD MILLER, JR.‡

Abstract. We exploit symmetry (recurrence relation) techniques for the derivation of properties associated with families of basic hypergeometric functions. Similar methods have been used by Nikiforov, Suslov, and Uvarov. Here we apply these ideas to find new proofs of Barnes' First Lemma and some of its q-analogues. We show that these integrals correspond to the weight functions determining the orthogonality relations for Hahn, q-Hahn, and big q-Jacobi polynomials. As another example of our method we introduce a biorthogonal system of rational functions whose weight function corresponds to the q-analogue of Kummer's Theorem.

Key words. basic hypergeometric functions, orthogonal polynomials, Barnes' Lemma, biorthogonal functions

AMS(MOS) subject classifications. 33A65, 33A75, 39A10

1. Introduction.

In papers Agarwal et al. (1987), Kalnins and Miller (1987), Miller (1988), the authors have advocated the exploitation of symmetry (recurrence relation) techniques for the derivation of properties associated with families of basic hypergeometric functions, in analogy with the local Lie theory techniques for ordinary hypergeometric functions. In particular, we have used these ideas to give simple derivations of the orthogonality relations for the Askey-Wilson and Wilson polynomials (Askey and Wilson (1985), Wilson (1980)), and, in particular, simple evaluations of the weight function integrals that determine the normalizations of these polynomials. Similar techniques have been employed by Nikiforov, Suslov, and Uvarov (1985) and Nikiforov and Suslov (1986), but they have apparently not applied them to the computation of contour integrals and summation formulas.

In §2 we use recurrence relations obeyed by a family of q-Hahn polynomials to derive the complex orthogonality of these polynomials and several q-analogues of Barnes' First Lemma, including those of Watson (1910) and Askey and Roy (1987, eq. 2.8). These integrals correspond to the square of the norm of the constant polynomial 1. Expanding one of these contour integrals by residues we obtain the real orthogonality relations for the big q-Jacobi polynomials.

In §3 we carry out the corresponding computations for the limiting case $q \to 1-$ and obtain the classical Barnes' Lemma, which we now see is associated with the orthogonality of the Hahn polynomials.

In §4 we work out a simple but nontrivial example of the use of these ideas to derive biorthogonality relations for rational basic hypergeometric functions. The associated summation formula is the q-analogue of Kummer's Theorem, originally due to Andrews (1973).

This link between recurrence relations obeyed by families of special functions, orthogonality relations for the functions, associated contour integrals and summation formulas appears capable of extensive generalization.

Most of the computations in the following sections were checked with SMP.

2. q-analogues of Barnes' Lemma. We are concerned with the q-Hahn polynomials

$$\Phi_n^{a,b,c,d}(z) = {}_3\varphi_2\left(\begin{matrix} q^{-n}, & q^{n-1}abcd, & az \\ ac, & ad & \end{matrix}; q\right), \tag{2.1}$$

$$n = 0, 1, 2, \ldots$$

where the basic hypergeometric functions ${}_{p+1}\varphi_p$ are defined as usual by

$${}_{p+1}\varphi_p\left(\begin{matrix} a_1, \ldots & a_{p+1} \\ b_1, \ldots & b_p \end{matrix}; x\right) = \sum_{m=0}^{\infty} \frac{(a_1;q)_m \ldots (a_{p+1};q)_m x^m}{(b_1;q)_m \ldots (b_p;q)_m (q;q)_m}$$

and

$$(a;q)_0 = 1,$$
$$(a;q)_m = (1-a)(1-aq)\ldots(1-aq^{m-1}), \quad m \geq 1.$$

Initially we require $0 < |q| < 1$, $acd \neq 0$, and $|a|, |b|, |c|, |d| < 1$, but some of these conditions can be relaxed later. The polynomials obey the fundamental recurrence relations

$$\mu^{(a,b,c,d)}\Phi_n^{(a,b,c,d)} = \frac{q^{\frac{1}{2}}}{d}\left(1 - \frac{ad}{q}\right)\Phi_n^{(aq^{-\frac{1}{2}}, bq^{\frac{1}{2}}, cq^{\frac{1}{2}}, dq^{-\frac{1}{2}})}, \tag{2.2A}$$

$$\tau^{(a,b,c,d)}\Phi_n^{(a,b,c,d)} = \frac{a(1-q^{-n})(1-q^{n-1}abcd)}{q^{-\frac{1}{2}}(1-ad)(1-ac)}\Phi_{n-1}^{(aq^{\frac{1}{2}}, bq^{\frac{1}{2}}, cq^{\frac{1}{2}}, dq^{\frac{1}{2}})} \tag{2.2B}$$

where

$$\mu^{(a,b,c,d)} = \frac{1}{z}\left[(1 - azq^{-\frac{1}{2}})E_z^{\frac{1}{2}} - \left(1 - \frac{zq^{\frac{1}{2}}}{d}\right)E_z^{-\frac{1}{2}}\right],$$
$$\tau^{(a,b,c,d)} = \frac{1}{z}[E_z^{\frac{1}{2}} - E_z^{-\frac{1}{2}}]$$

and $E_z^{\alpha} f(z) = f(q^{\alpha} z)$. These relations follow from

$$\mu(za;q)_n = \frac{q^{\frac{1}{2}}}{d}(1 - adq^{n-1})(zaq^{\frac{1}{2}};q)_n,$$
$$\tau(za;q)_n = \frac{a}{q^{\frac{1}{2}}}(1 - q^n)(zaq^{-\frac{1}{2}};q)_{n-1}.$$

The existence of μ suggests the existence of a recurrence taking $\Phi_n^{(aq^{-\frac{1}{2}}, bq^{\frac{1}{2}}, cq^{\frac{1}{2}}, dq^{-\frac{1}{2}})}$ to $\Phi_n^{(a,b,c,d)}$. Indeed, the appropriate operator is

$$\mu^* = -\frac{q^{\frac{1}{2}}}{\rho}\mu^{(bq^{\frac{1}{2}}, aq^{-\frac{1}{2}}, dq^{-\frac{1}{2}}, cq^{\frac{1}{2}})},$$

$$\mu^*\Phi_n^{(aq^{-\frac{1}{2}}, bq^{\frac{1}{2}}, cq^{\frac{1}{2}}, dq^{-\frac{1}{2}})} \tag{2.2C}$$

$$= \frac{q^{\frac{1}{2}}}{\rho}\frac{(\frac{ad}{q} - q^{-n})(1 - bcq^n)}{c(1 - \frac{ad}{q})}\Phi_n^{(a,b,c,d)}, \quad \rho \neq 0,$$

which follows from

$$\frac{\rho}{q^{\frac{1}{2}}}\mu^*(azq^{-\frac{1}{2}};q)_n = (az;q)_n(bcq^n-1)\frac{q^{-n}}{c} + (az;q)_{n-1}(acq^{n-1}-1)(q^n-1)\frac{q^{-n}}{c}.$$

Let $w_{a,b,c,d}(z)$ be a (complex-valued) weight function and $S_{a,b,c,d}$ be the indefinite inner product space of polynomials $f(z)$ with respect to the inner product

$$(f_1,f_2)_{a,b,c,d} = \frac{1}{2\pi i}\oint_C f_1(z)f_2(z)w_{a,b,c,d}(z)\frac{dz}{z} \tag{2.3}$$

where C is a deformation of the unit circle $|z|=1$. Now consider $\mu = \mu^{(a,b,c,d)}$ and $\mu^* = -\frac{q^{\frac{1}{2}}}{\rho}\mu^{(bq^{\frac{1}{2}},aq^{-\frac{1}{2}},dq^{-\frac{1}{2}},cq^{-\frac{1}{2}})}$ as mappings

$$\begin{aligned}&\mu : S_{a,b,c,d} \to S_{aq^{-\frac{1}{2}},bq^{\frac{1}{2}},cq^{\frac{1}{2}},dq^{-\frac{1}{2}}},\\ &\mu^* : S_{aq^{-\frac{1}{2}},bq^{\frac{1}{2}},cq^{\frac{1}{2}},dq^{-\frac{1}{2}}} \to S_{a,b,c,d}\end{aligned} \tag{2.4}$$

and determine $w_{a,b,c,d}$ so that

$$(\mu f,g)_{aq^{-\frac{1}{2}},bq^{\frac{1}{2}},cq^{\frac{1}{2}},dq^{-\frac{1}{2}}} = (f,\mu^* g)_{a,b,c,d} \tag{2.5}$$

for all $f \in S_{a,b,c,d}$, $q \in S_{aq^{-\frac{1}{2}},bq^{\frac{1}{2}},cq^{\frac{1}{2}},dq^{-\frac{1}{2}}}$. Condition (2.5) yields a q-difference equation for $w_{a,b,c,d}$ with solution

$$w_{a,b,c,d}(z) = \frac{(\frac{\rho z}{d};q)_\infty(\frac{qd}{z\rho};q)_\infty(\frac{\rho c}{z};q)_\infty(\frac{qz}{c\rho};q)_\infty}{(az;q)_\infty(bz;q)_\infty(\frac{c}{z};q)_\infty(\frac{d}{z};q)_\infty} \tag{2.6}$$

where

$$(x;q)_\infty = \lim_{n\to\infty}(x;q)_n.$$

This result is a consequence of the invariance of the contour integral under the changes of variable $z \to q^{\pm\frac{1}{2}}z$, and the property $h(qz) = -h(z)/z$ where $h(z) = (z;q)_\infty(q/z;q)_\infty$.

It follows immediately that $\mu^*\mu$ is a self-adjoint operator

$$\mu^*\mu : S_{a,b,c,d} \to S_{a,b,c,d}$$

and from the recurrence relations (2.2) we have

$$\mu^*\mu\Phi_n^{(a,b,c,d)} = \lambda_n\Phi_n^{(a,b,c,d)}, \quad \lambda_n = \frac{q}{cd\rho}\left(\frac{ad}{q}-q^{-n}\right)(1-bcq^n). \tag{2.7}$$

Since eigenfunctions corresponding to distinct eigenvalues are orthogonal we have

$$(\Phi_n^{(a,b,c,d)},\Phi_m^{(a,b,c,d)})_{a,b,c,d} = 0 \quad \text{for } m \neq n. \tag{2.8}$$

Relation (2.5) for $f = g \equiv 1$ yields

$$\|1\|^2_{aq^{-\frac{1}{2}},bq^{\frac{1}{2}},cq^{\frac{1}{2}},dq^{-\frac{1}{2}}} = -\frac{d}{\rho c}\frac{1-bc}{(1-\frac{ad}{q})}\|1\|^2_{a,b,c,d} \tag{2.9}$$

where

$$\|1\|^2_{a,b,c,d} = (1,1)_{a,b,c,d}.$$

The symmetry of the weight function in (a,b) yields an additional relation of the form (2.9). Furthermore the obvious relation

$$(\Phi_1^{(a,b,c,d)},\Phi_0^{(a,b,c,d)})_{a,b,c,d} = 0,$$

the explicit expression (2.1), and the property $(1, p_n)_{a,b,c,d} = \|1\|^2_{aq^n,b,c,d}$ for $p_n(z) = (az;q)_n$, yield the relation

$$\|1\|^2_{aq,b,c,d} = \frac{(1-ad)(1-ac)}{(1-abcd)}\|1\|^2_{a,b,c,d}. \tag{2.10}$$

Again, the symmetry in (a,b) gives an additional relation. The solution of these q-difference equations is

$$\|1\|^2_{a,b,c,d} = \frac{(abcd;q)_\infty(\frac{c\rho}{d};q)_\infty(\frac{qd}{c\rho};q)_\infty}{(ad;q)_\infty(ac;q)_\infty(ac;q)_\infty(bc;q)_\infty(bd;q)_\infty}\mathscr{K}(\rho,q) \tag{2.11}$$

where $\mathscr{K}(\rho,q)$ is to be determined. In the special case $a = \rho/d$, $b = q/c\rho$ we can compute the (trivial) integral directly: $\|1\|^2_{\rho/d,q/c\rho,c,d} = 1$. Hence $\mathscr{K}(\rho,q) = (\rho;q)_\infty(q/\rho;q)_\infty/(q;q)_\infty$ and we have

$$\begin{aligned}\|1\|^2_{a,b,c,d} &= \frac{1}{2\pi}\int_{-\pi}^{\pi}\frac{(\frac{\rho}{d}e^{i\theta};q)_\infty(\frac{qd}{\rho}e^{-i\theta};q)_\infty(\rho ce^{i\theta};q)_\infty}{(ae^{i\theta};q)_\infty(be^{i\theta};q)_\infty(ce^{i\theta};q)_\infty}\\ &\quad\cdot\frac{(\frac{q}{c\rho}e^{i\theta};q)_\infty}{(de^{-i\theta};q)_\infty}d\theta\\ &= \frac{(abcd;q)_\infty(\frac{c\rho}{d};q)_\infty(\frac{qd}{c\rho};q)_\infty(\rho;q)_\infty(\frac{q}{\rho};q)_\infty}{(ad;q)_\infty(ac;q)_\infty(bc;q)_\infty(bd;q)_\infty(q;q)_\infty}\end{aligned} \tag{2.12}$$

in agreement with Askey and Roy (1986).

Now we consider the recurrence

$$\tau^{(a,b,c,d)} : S_{a,b,c,d} \to S_{aq^{\frac12},bq^{\frac12},cq^{\frac12},dq^{\frac12}},$$

(2.2B) and compute the adjoint $\tau^* \equiv \tau^{*(aq^{\frac12},bq^{\frac12},cq^{\frac12},dq^{\frac12})}$ such that

$$(\tau f, g)_{aq^{\frac12},bq^{\frac12},cq^{\frac12},dq^{\frac12}} = (f, \tau^* g)_{a,b,c,d} \tag{2.13}$$

for all $f \in S_{a,b,c,d}$, $g \in S_{aq^{\frac12},bq^{\frac12},cq^{\frac12},dq^{\frac12}}$. A straightforward computation yields

$$\tau^{*(aq^{\frac12},bq^{\frac12},cq^{\frac12},dq^{\frac12})} = \frac{1}{q^{\frac12}z}\left[-(1-az)(1-bz)E_z^{\frac12} + \left(1-\frac{z}{c}\right)\left(1-\frac{z}{d}\right)E_z^{-\frac12}\right]. \tag{2.14}$$

It follows that $\tau^*\tau : S_{a,b,c,d} \to S_{a,b,c,d}$ is self-adjoint. Moreover, the action of τ^* on the polynomial basis is

$$\tau^*\Phi_{n-1}^{(aq^{\frac12},bq^{\frac12},cq^{\frac12},dq^{\frac12})} = \frac{(1-ac)(1-ad)}{q^{\frac12}acd}\Phi_n^{(a,b,c,d)}. \tag{2.15}$$

This follows from

$$\tau^*(aq^{\frac12}z;q)_k = \frac{q^{-k-\frac12}}{acd}(1-acq^k)(1-adq^k)(az;q)_k - \frac{q^{-k-\frac12}}{acd}(1-abcdq^k)(az;q)_{k+1}.$$

Thus

$$\tau^*\tau\Phi_n^{(a,b,c,d)} = \frac{1}{cd}(1-q^{-n})(1-q^{n-1}abcd)\Phi_n^{(a,b,c,d)}. \tag{2.16}$$

Setting $f = \Phi_n^{(a,b,c,d)}$, $g = \Phi_{n-1}^{(aq^{\frac12},bq^{\frac12},cq^{\frac12},dq^{\frac12})}$ in (2.13) we obtain the recurrence

$$\|\Phi_n^{(a,b,c,d)}\|^2_{a,b,c,d} = \frac{qa^2cd(1-q^{-n})(1-q^{n-1}abcd)}{(1-ad)^2(1-ac)^2}\|\Phi_{n-1}^{(aq^{\frac12},\ldots,dq^{\frac12})}\|^2_{aq^{\frac12},\ldots,dq^{\frac12}}, \tag{2.17}$$

which permits us to compute the norms $\|\Phi_n^{(a,\dots,d)}\|^2_{a,\dots,d}$ recursively from $\|1\|^2_{a,\dots,d}$. Note that the norms are all nonzero. We have shown that the q–Hahn polynomials $\{\Phi_n^{(a,b,c,d)}\}$ are uniquely characterized by their orthogonality with respect to the complex weight function $w_{a,b,c,d}$.

Since the weight function is symmetric in $\{a,b\}$ the orthogonal polynomials satisfies the transformation rule

(2.18)
$$ {}_3\varphi_2\left(\begin{matrix} q^{-n}, & q^{n-1}abcd, & bz \\ bc, & dc & \end{matrix}; q\right) = \left(\frac{b}{a}\right)^n \frac{(ac;q)_n(ad;q)_n}{(bc;q)_n(bd;q)_n} {}_3\varphi_2\left(\begin{matrix} q^{-n}, & q^{n-1}abcd, & az \\ ac, & ad & \end{matrix}; q\right). $$

Also, the action of $\tau^{*(aq^{\frac12},\dots,dq^{\frac12})}$ determines a Rodrigues formula.

The complex orthogonality (2.8) for the q-Hahn polynomials leads to real discrete orthogonality for the big q-Jacobi polynomials (Andrews and Askey (1985)):

$$ {}_3\varphi_2\left(\begin{matrix} q^{-n}, & q^{n-1+\alpha+\beta+\gamma+\delta}, & q^{x+1} \\ q^{\alpha+\gamma}, & q^{\alpha+\delta} & \end{matrix}; q\right). \tag{2.19} $$

The polynomials (2.19) are orthogonal with respect to the discrete measure with mass points and corresponding weights (Ismail and Wilson (1982)):

$$ \begin{aligned} x &= \alpha+\delta+k-1 \qquad \frac{(q^{\delta-\gamma+k+1};q)_\infty (q^{k+1};q)_\infty}{(q^{\alpha+\delta+k};q)_\infty (q^{\beta+\delta+k};q)_\infty} q^k q^{\alpha+\delta-1}(1-q), \\ x &= \alpha+\gamma+k-1 \qquad \frac{(q^{\gamma-\delta+k+1};q)_\infty (q^{k+1};q)_\infty}{(q^{\alpha+\gamma+k};q)_\infty (q^{\beta+\gamma+k};q)_\infty} q^k q^{\alpha+\gamma-1}(1-q), \end{aligned} \tag{2.20} $$

$k = 0,1,2,\dots$. To obtain this result from (2.6), (2.8) we first set $a = q^\alpha, \dots, d = q^\delta$. If $\operatorname{Re}(\alpha,\beta,\gamma,\delta) > 0$ and there are no double poles we can expand the integral $(\Phi_n,\Phi_m)_{a,b,c,d}$ by residues, using the simple poles of $w_{a,b,c,d}(z)$, (2.6), at $z = q^{\gamma+k}$, $z = q^{\delta+k}$. The result of this expansion is (2.20) with $z = q^x$. In particular, the dependence on ρ cancels out.

Our approach relating orthogonal polynomials to integrals of weight functions can be used to evaluate other important integrals. One class of such integrals can be conveniently studied through the change of variables given in the preceding paragraph:

$$ a = q^\alpha, \quad b = q^\beta, \quad c = q^\gamma, \quad d = q^\delta, \quad z = q^x. \tag{2.21} $$

This change reduces q-difference equations for the weight function to ordinary difference equations. Indeed the operators (2.2) now take the form

$$ \begin{aligned} \mu^{(\alpha,\beta,\gamma,\delta)} &= q^{-x}[(1-q^{\alpha+x-\frac12})\mathscr{E}_x^{\frac12} - (1-q^{x-\delta+\frac12})\mathscr{E}_x^{-\frac12}], \\ \tau^{(\alpha,\beta,\gamma,\delta)} &= q^{-x}[\mathscr{E}_x^{\frac12} - \mathscr{E}_x^{-\frac12}], \\ \mu* &= -q^{-x}[(1-q^{\beta+x})\mathscr{E}_x^{\frac12} - (1-q^{x-\gamma})\mathscr{E}_x^{-\frac12}] \end{aligned} \tag{2.22} $$

where $\mathscr{E}_x^s g(x) = g(x+s)$.

The orthogonal functions are now polynomials in q^x. We require that the inner product take the form

$$ (f_1,f_2)_{\alpha,\beta,\gamma,\delta} = \frac{1}{2\pi i}\int_{-i\infty}^{i\infty} f_1(q^x) f_2(q^x) w_{\alpha,\beta,\gamma,\delta}(x)\,dx \tag{2.23} $$

where the contour in the complex x-plane will run from $-i\infty$ to $+i\infty$ so that decreasing sequences of poles for w lie on the left and increasing sequences of poles lie on the right. The condition that μ^* be the adjoint of μ now becomes

$$ (\mu f, g)_{\alpha-\frac12,\beta+\frac12,\gamma+\frac12,\delta-\frac12} = (f,\mu^* g)_{\alpha,\beta,\gamma,\delta} \tag{2.24} $$

with $f \in S_{\alpha,\beta,\gamma,\delta}$, $g \in S_{\alpha-\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta-\frac{1}{2}}$, where $S_{\alpha,\beta,\gamma,\delta}$ is the space of polynomials in q^x with inner product (2.23). The nonunique solution for w is

$$w_{\alpha,\beta,\gamma,\delta}(x) = \frac{(q^{x-\gamma+1};q)_\infty (q^{x-\delta+1};q)_\infty}{(q^{x+\alpha};q)_\infty (q^{x+\beta};q)_\infty} q^x H(\alpha,\beta,\gamma,\delta,x) \tag{2.25}$$

where H is an analytic function of its variables satisfying the periodicity properties

$$\begin{aligned} H(\alpha,\beta,\gamma,\delta,x) &= H(\alpha,\beta,\gamma,\delta,x+1), \\ H\left(\alpha-\frac{1}{2},\beta-\frac{1}{2},\gamma\pm\frac{1}{2},\delta\mp\frac{1}{2},x+\frac{1}{2}\right) &= H\left(\alpha-\frac{1}{2},\beta-\frac{1}{2},\gamma\pm\frac{1}{2},\delta\mp\frac{1}{2},x+\frac{1}{2}\right) \\ &= H\left(\alpha-\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta+\frac{1}{2},x+\frac{1}{2}\right). \end{aligned} \tag{2.26}$$

One solution of (2.26) is

$$H(\alpha,\beta,\gamma,\delta,x) = \frac{\sin\pi(\gamma-\delta)}{\sin\pi(\gamma-x)\sin\pi(\delta-x)}$$

so that the weight function becomes

$$w_{\alpha,\beta,\gamma,\delta}(x) = \frac{(q^{x-\gamma+1};q)_\infty (q^{x-\delta+1};q)_\infty q^x \sin\pi(\gamma-\delta)}{(q^{x+\alpha};q)_\infty (q^{x+\beta};q)_\infty \sin\pi(\gamma-x)\sin\pi(\delta-x)}. \tag{2.27}$$

Then the polynomials are

(2.28)

$$\Phi_n^{(\alpha,\beta,\gamma,\delta)}(q^x) = {}_3\varphi_2\left(\begin{matrix} q^{-n}, & q^{n+\alpha+\beta+\gamma+\delta-1}, & q^{\alpha+x} \\ q^{\alpha+\gamma}, & q^{\alpha+\delta} & \end{matrix}; q\right), \qquad n = 0,1,2,\ldots$$

and the eigenvalue equation is

$$\mu^*\mu\Phi_n^{\alpha,\beta,\gamma,\delta} = q^{\frac{1}{2}-\gamma-\delta}(q^{\alpha+\delta-1}-q^{-n})(1-q^{\beta+\gamma+n})\Phi_n^{(\alpha,\beta,\gamma,\delta)}.$$

We have immediately

$$(\Phi_n^{(\alpha,\ldots,\delta)}, \Phi_m^{(\alpha,\ldots,\delta)})_{\alpha,\ldots,\delta} = 0, \qquad m \neq n$$

and

$$\|1\|^2_{\alpha-\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta-\frac{1}{2}} = q^{-\frac{1}{2}+\delta-\gamma}\frac{(1-q^{\beta+\gamma})}{(1-q^{\alpha+\delta-1})}\|1\|^2_{\alpha,\beta,\gamma,\delta}. \tag{2.29}$$

The symmetry of w in (α,β) leads to a similar recurrence. Also, the skew-symmetry of w in γ,δ yields a new recurrence. Finally, the orthogonality

$$(\Phi_1^{(a,\ldots,\delta)}, \Phi_0^{(\alpha,\ldots,\delta)}) = 0$$

leads to the recurrences

$$\|1\|^2_{\alpha+1,\beta,\gamma,\delta} = \frac{(1-q^{\alpha+\gamma})(1-q^{\alpha+\delta})}{(1-q^{\alpha+\beta+\gamma+\delta})}\|1\|^2_{\alpha,\beta,\gamma,\delta}$$

and

$$\|1\|^2_{\alpha,\beta,\gamma+1,\delta} = -\frac{q^{\delta-\gamma}(1-q^{\alpha+\gamma})(1-q^{\beta+\gamma})}{(1-q^{\alpha+\beta+\gamma+\delta})}\|1\|^2_{\alpha,\beta,\gamma,\delta}$$

with the solution

$$\|1\|^2_{\alpha,\beta,\gamma,\delta} = \frac{(q^{\alpha+\beta+\gamma+\delta};q)_\infty (q^{\delta-\gamma};q)_\infty (q^{1+\gamma-\delta};q)_\infty q^\gamma}{(q^{\alpha+\delta};q)_\infty (q^{\alpha+\gamma};q)_\infty (q^{\beta+\gamma};q)_\infty (q^{\beta+\delta};q)_\infty} M(\alpha,\beta,\gamma,\delta) \tag{2.30}$$

where M is an analytic function of its arguments, symmetric in (α,β) and in (γ,δ), satisfying the periodicity relations

$$\begin{aligned} M(\alpha,\beta,\gamma,\delta) &= M(\alpha+1,\beta,\gamma,\delta) = M(\alpha,\beta,\gamma+1,\delta) \\ &= M\left(\alpha-\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta-\frac{1}{2}\right). \end{aligned} \tag{2.31}$$

To evaluate M we replace α by $\alpha+k$, k a positive integer, and rewrite the integral for $\|1\|^2_{\alpha+k,\beta,\gamma,\delta}$ in the form $(x=iy)$

$$\begin{aligned} &\frac{1}{2\pi}\int_{-\infty}^{\infty}\left[\frac{(q^{\alpha+k+\delta};q)_\infty (q^{\alpha+k+\delta};q)_\infty}{(q^{\alpha+\beta+\gamma+\delta+k};q)_\infty (q^{iy+\alpha+k};q)_\infty}\right]\frac{(q^{iy-\gamma+1};q)_\infty}{(q^{iy+\beta};q)_\infty} \\ &\qquad \cdot\frac{(q^{iy-\delta+1};q)_\infty q^{iy}dy}{\sin\pi(\gamma-iy)\sin\pi(\delta-iy)} \\ &= \frac{q^\gamma (q^{\delta-\gamma};q)_\infty (q^{1+\gamma-\delta};q)_\infty}{(q^{\beta+\gamma};q)_\infty (q^{\beta+\delta};q)_\infty} M(\alpha,\beta,\gamma,\delta). \end{aligned} \tag{2.32}$$

Notice that the right-hand side of (2.32) is independent of k and that the bracketed quantity on the left goes to 1 as $k\to+\infty$. From the Lebesgue dominated convergence theorem we conclude that

$$\begin{aligned} &\frac{1}{2\pi}\int_{-\infty}^{\infty}\frac{(q^{iy-\gamma+1};q)_\infty (q^{iy-\delta+1};q)_\infty q^{iy}}{(q^{iy+\beta};q)_\infty \sin\pi(\gamma-iy)\sin\pi(\delta-iy)} \\ &= \frac{q^\delta (q^{\delta-\gamma};q)_\infty (q^{1+\gamma-\delta};q)_\infty}{(q^{\beta+\gamma};q)_\infty (q^{\beta+\delta};q)_\infty} M(\alpha,\beta,\gamma,\delta). \end{aligned}$$

It follows immediately that M is independent of α and β. Now in (2.32) set $k=0$, $\alpha=1-\gamma$, $\beta=1-\delta$:

$$\frac{1}{2\pi}\int_{-\infty}^{\infty}\frac{q^{iy}\sin\pi(\gamma-\delta)dy}{\sin\pi(\gamma-iy)\sin\pi(\delta-iy)} = \frac{M(\gamma,\delta)q^\gamma(1-q^{\delta-\gamma})}{(1-q)(q;q)_\infty}. \tag{2.33}$$

The rather elementary integral on the left-hand side of (2.33) can be easily evaluated by residues and the resulting geometric series summed to yield $M(\gamma,\delta)=(q;q)_\infty/\pi$. Thus

$$\begin{aligned} &\frac{1}{2\pi}\int_{-\infty}^{\infty}\frac{(q^{iy-\gamma+1};q)_\infty (q^{iy-\delta+1};q)_\infty q^{iy}\sin\pi(\gamma-\delta)}{(q^{iy+\alpha};q)_\infty (q^{iy+\beta};q)_\infty \sin\pi(\gamma-iy)\sin\pi(\delta-iy)}dy \\ &= \frac{(q;q)_\infty q^\gamma (q^{\alpha+\beta+\gamma+\delta};q)_\infty (q^{\delta-\gamma};q)_\infty (q^{1+\gamma-\delta};q)_\infty}{\pi(q^{\alpha+\delta};q)_\infty (q^{\alpha+\gamma};q)_\infty (q^{\beta+\gamma};q)_\infty (q^{\beta+\delta};q)_\infty}, \end{aligned} \tag{2.34}$$

which is Watson's q-analogue of Barnes' First Lemma (Watson (1910)).

By choosing other solutions H of relations (2.26) we can evaluate other integrals in the form (2.30), (2.31). For example, if $H=\cos^{-2}\pi x$ then $M=(q;q)_\infty q^{\frac{1}{4}}(1-q^{\frac{1}{2}})/2\pi(q^\gamma-q^\delta)$. However, in general one cannot evaluate M by the simple method we used for (2.34).

3. The classical Barnes' Lemma. To see the relationship between our results and Barnes' Lemma we could, with care, let $q \to 1-$ in expression (2.12) (i.e., at the end of our construction). However, it is more instructive to take the limit $q \to 1-$ immediately and then proceed step-by-step through the argument of the preceding section. From this point of view the functions to be considered are the Hahn polynomials

$$\Phi_n^{(\alpha,\beta,\gamma,\delta)}(x) = {}_3F_2\left(\begin{matrix} -n, & n+\alpha+\beta+\gamma+\delta-1, & \alpha+x \\ \alpha+\gamma, & \alpha+\delta & \end{matrix}; 1\right) \tag{3.1}$$

$$n = 0, 1, 2, \ldots, \qquad \alpha, \beta, \gamma, \delta > 0$$

where ${}_3F_2$ is a generalized hypergeometric function:

$${}_{p+1}F_p\left(\begin{matrix} \alpha, \ldots, \alpha_{p+1} \\ \beta_1, \ldots, \beta_p \end{matrix}, z\right) = \sum_{m=0}^{\infty} \frac{(\alpha_1)_m \ldots (\alpha_{p+1})_m z^m}{(\beta_1)_m \ldots (\beta_p)_m m!},$$

$$(\alpha)_m = \begin{cases} 1 & \text{if } m = 0, \\ \alpha(\alpha+1)\ldots(\alpha+m-1) & \text{if } m \geq 1. \end{cases}$$

The recurrence relations are

$$\mu^{(\alpha,\beta,\gamma,\delta)}\Phi_n^{(\alpha,\beta,\gamma,\delta)} = (\alpha+\delta-1)\Phi_n^{(\alpha-\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta-\frac{1}{2})}, \tag{3.2A}$$

(3.2B)

$$\mu^{*(\alpha-\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta-\frac{1}{2})}\Phi_n^{(\alpha-\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta-\frac{1}{2})} = \frac{(n+\alpha+\delta-1)(n+\beta+\gamma)}{(\alpha+\delta-1)}\Phi_n^{(\alpha,\beta,\gamma,\delta)},$$

$$\tau^{(\alpha,\beta,\gamma,\delta)}\Phi_n^{(\alpha,\beta,\gamma,\delta)} = \frac{-n(n+\alpha+\beta+\gamma+\delta-1)}{(\alpha+\delta)(\alpha+\gamma)}\Phi_{n-1}^{(\alpha+\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta+\frac{1}{2})}, \tag{3.2C}$$

$$\tau^{*(\alpha+\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta+\frac{1}{2})}\Phi_{n-1}^{(\alpha+\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta+\frac{1}{2})} = (\alpha+\delta)(\alpha+\gamma)\Phi_n^{(\alpha,\beta,\gamma,\delta)}, \tag{3.2D}$$

where

$$\mu^{(\alpha,\beta,\gamma,\delta)} = \left(\alpha+x-\frac{1}{2}\right)\mathscr{E}_x^{\frac{1}{2}} + \left(\delta-x-\frac{1}{2}\right)\mathscr{E}_x^{-\frac{1}{2}},$$

$$\mu^{*(\alpha-\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta-\frac{1}{2})} = (\beta+x)\mathscr{E}_x^{\frac{1}{2}} + (\gamma-x)\mathscr{E}_x^{-\frac{1}{2}},$$

$$\tau^{(\alpha,\beta,\gamma,\delta)} = \mathscr{E}_x^{\frac{1}{2}} - \mathscr{E}_x^{-\frac{1}{2}},$$

$$\tau^{*(\alpha+\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta+\frac{1}{2})} = (\gamma-x)(\delta-x)\mathscr{E}_x^{-\frac{1}{2}} - (\alpha+x)(\beta+x)\mathscr{E}_x^{\frac{1}{2}},$$

and $\mathscr{E}_x^s g(x) = g(x+s)$.

We define a complex inner product by

$$(g_1, g_2)_{\alpha,\beta,\gamma,\delta} = \frac{1}{2\pi i}\int_{-i\infty}^{i\infty} g_1(x)g_2(x)w_{\alpha,\beta,\gamma,\delta}(x)dx \tag{3.3}$$

for polynomials g_1, g_2 where the integration path is the imaginary axis in the complex x-plane. Let $S_{\alpha,\beta,\gamma,\delta}$ be the space of polynomials with this inner product. We require that

$$(\mu f, g)_{\alpha-\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta-\frac{1}{2}} = (f, \mu^* g)_{\alpha,\beta,\gamma,\delta} \tag{3.4}$$

for all $f \in S_{\alpha,\beta,\gamma,\delta}$, $g \in S_{\alpha-\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta-\frac{1}{2}}$. In order that (3.4) hold, the weight function must satisfy a difference equation whose solution is (essentially)

$$w_{\alpha,\beta,\gamma,\delta}(x) = \Gamma(\alpha+x)\Gamma(\beta+x)\Gamma(\gamma-x)\Gamma(\delta-x) \tag{3.5}$$

where Γ is the gamma function (Whittaker and Watson (1958, Chap. XII)). Here we are using the fundamental recurrence for the gamma function

$$\Gamma(z+1) = z\Gamma(z).$$

It now follows that $\mu^*\mu : S_{\alpha,\beta,\gamma,\delta} \to S_{\alpha,\beta,\gamma,\delta}$ is self-adjoint with respect to this inner product and has eigenfunctions $\Phi_n^{\alpha,\beta,\gamma,\delta}$:

$$\mu^*\mu\Phi_n^{\alpha,\beta,\gamma,\delta} = (n+\alpha+\delta-1)(n+\beta+\gamma)\Phi_n^{\alpha,\beta,\gamma,\delta}. \tag{3.6}$$

Since eigenfunctions corresponding to distinct eigenvalues are orthogonal we have

$$(\Phi_n^{(\alpha,\beta,\gamma,\delta)}, \Phi_m^{(\alpha,\beta,\gamma,\delta)})_{\alpha,\beta,\gamma,\delta} = 0, \qquad n \neq m. \tag{3.7}$$

A similar computation gives

$$(\tau f, g)_{\alpha+\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta+\frac{1}{2}} = (f, \tau^* g)_{\alpha,\beta,\gamma,\delta} \tag{3.8}$$

for the same weight function and all

$$g \in S_{\alpha+\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta+\frac{1}{2}}, \qquad f \in S_{\alpha,\beta,\gamma,\delta}.$$

Thus $\tau^*\tau$ is self-adjoint on $S_{\alpha,\beta,\gamma,\delta}$ and

$$\tau^*\tau\Phi_n^{(\alpha,\beta,\gamma,\delta)} = -n(n+\alpha+\beta+\gamma+\delta-1)\Phi_n^{(\alpha,\beta,\gamma,\delta)}. \tag{3.9}$$

Setting $f = g = 1$ in (3.4) we find

$$\|1\|^2_{\alpha-\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta-\frac{1}{2}} = \frac{(\beta+\gamma)}{(\alpha+\delta-1)}\|1\|^2_{\alpha,\beta,\gamma,\delta}. \tag{3.10}$$

Symmetry of the weight function in (α,β) and in (γ,δ) gives three more such relations. Furthermore

$$(\Phi_1^{(\alpha,\beta,\gamma,\delta)}, \Phi_0^{(\alpha,\beta,\gamma,\delta)})_{\alpha,\beta,\gamma,\delta} = 0,$$

which, from (3.1) and (3.5), implies

$$\|1\|^2_{\alpha+1,\beta,\gamma,\delta} = \frac{(\alpha+\gamma)(\alpha+\delta)}{(\alpha+\beta+\gamma+\delta)}\|1\|^2_{\alpha,\beta,\gamma,\delta} \tag{3.11}$$

and also

$$\|1\|^2_{\alpha,\beta,\gamma+1,\delta} = \frac{(\gamma+\alpha)(\gamma+\beta)}{(\alpha+\beta+\gamma+\delta)}\|1\|^2_{\alpha,\beta,\gamma,\delta}. \tag{3.12}$$

The symmetry of the weight function in (α,β) and in (γ,δ) gives two more such relations. It follows that

$$\|1\|^2_{\alpha,\beta,\gamma,\delta} = \frac{\Gamma(\alpha+\gamma)\Gamma(\alpha+\delta)\Gamma(\beta+\gamma)\Gamma(\beta+\delta)}{\Gamma(\alpha+\beta+\gamma+\delta)}M(\alpha,\beta,\gamma,\delta) \tag{3.13}$$

where M is symmetric in (α,β) and in (γ,δ), and satisfies the periodicity properties

$$\begin{aligned} M(\alpha+1,\beta,\gamma,\delta) &= M\left(\alpha-\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta-\frac{1}{2}\right) \\ &= M(\alpha,\beta,\gamma+1,\delta) = M(\alpha,\beta,\gamma,\delta). \end{aligned} \tag{3.14}$$

To evaluate M we replace α by $\alpha + k$ and γ by $\gamma + k$, k a positive integer, and write the expression (3.13) in the form

$$\frac{1}{2\pi}\int_{-\infty}^{\infty}\left(\frac{\Gamma(\alpha+\beta+\gamma+\delta+2k)\Gamma(\alpha+k+iy)\Gamma(\gamma+k-iy)}{\Gamma(\alpha+\gamma+2k)\Gamma(\alpha+\delta+k)\Gamma(\beta+\gamma+k)}\right)$$
$$\cdot\,\Gamma(\beta+iy)\Gamma(\delta-iy)dy = \Gamma(\beta+\delta)M(\alpha,\beta,\gamma,\delta). \tag{3.15}$$

From Stirling's formula (Whittaker and Watson (1958, Chap. XII)), we have

$$\lim_{k\to+\infty}\frac{\Gamma(\alpha+\beta+\gamma+\delta+2k)\Gamma(\alpha+k+iy)\Gamma(\gamma+k-iy)}{\Gamma(\alpha+\gamma+2k)\Gamma(\alpha+\delta+k)\Gamma(\beta+\gamma+k)} = 2^{\beta+\delta}$$

and it follows easily that

$$\frac{1}{2\pi}\int_{-\infty}^{\infty}\Gamma(\beta+iy)\Gamma(\delta-iy)dy = 2^{-(\beta+\delta)}\Gamma(\beta+\delta)M.$$

Hence, M is a constant, independent of $\alpha,\beta,\gamma,\delta$. To evaluate the constant we set $\alpha = \beta+\gamma = \delta = \frac{1}{2}$ in (3.13) and use the reflection formula for gamma functions:

$$\|1\|^2_{\frac{1}{2},\frac{1}{2},\frac{1}{2},\frac{1}{2}} = M = 2\pi\int_0^{\infty}\frac{dy}{\cosh\pi y} = 1.$$

Thus,

$$\|1\|^2_{\alpha,\beta,\gamma,\delta} = \frac{1}{2\pi}\int_{-\infty}^{\infty}\Gamma(\alpha+iy)\Gamma(\beta+iy)\Gamma(\gamma-iy)\Gamma(\delta-iy)dy$$
$$= \frac{\Gamma(\alpha+\gamma)\Gamma(\alpha+\delta)\Gamma(\beta+\gamma)\Gamma(\beta+\delta)}{\Gamma(\alpha+\beta+\gamma+\delta)}. \tag{3.16}$$

This is Barnes' First Lemma (Bailey (1935, p.6), Slater (1966, p. 109)).

In relation (3.8) we set $f = \Phi_n^{(\alpha,\beta,\gamma,\delta)}$, $g = \Phi_{n-1}^{(\alpha+\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta+\frac{1}{2})}$ to obtain the recurrence

$$\|\Phi_n^{(\alpha,\beta,\gamma,\delta)}\|^2_{\alpha,\beta,\gamma,\delta} = \frac{-n(n+\alpha+\beta+\gamma+\delta-1)}{(\alpha+\gamma)^2(\alpha+\delta)^2}\cdot$$
$$\cdot\,\|\Phi_{n-1}^{(\alpha+\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta+\frac{1}{2})}\|^2_{\alpha+\frac{1}{2},\beta+\frac{1}{2},\gamma+\frac{1}{2},\delta+\frac{1}{2}}. \tag{3.17}$$

It follows that the norms of the orthogonal polynomials are nonzero and can be computed recursively from $\|1\|^2_{\alpha,\beta,\gamma,\delta}$. Thus these polynomials are defined uniquely by their orthogonality with respect to the weight function w.

The symmetry of the weight function in (α,β) implies the identity

$${}_3F_2\left(\begin{matrix}-n, & n+\alpha+\beta+\gamma+\delta-1, & x+\beta\\ \beta+\gamma, & \beta+\delta & \end{matrix};1\right)$$
$$= \frac{(\alpha+\gamma)_n(\alpha+\delta)_n}{(\beta+\gamma)_n(\beta+\delta)_n}{}_3F_2\left(\begin{matrix}-n, & n+\alpha+\beta+\gamma+\delta-1, & x+\alpha\\ \alpha+\gamma, & \alpha+\delta & \end{matrix};1\right).$$

Furthermore, the symmetry of the weight function with respect to the interchanges $x\leftrightarrow -x$, $\alpha\leftrightarrow\delta$, $\beta\leftrightarrow\gamma$ implies

$${}_3F_2\left(\begin{matrix}-n, & n+\alpha+\beta+\gamma+\delta-1, & -x+\alpha\\ \alpha+\gamma, & \alpha+\delta & \end{matrix};1\right)$$
$$= (-1)^n\frac{(\beta+\delta)_n}{(\alpha+\gamma)_n}{}_3F_2\left(\begin{matrix}-n, & n+\alpha+\beta+\gamma+\delta-1, & x+\delta\\ \alpha+\delta, & \beta+\delta & \end{matrix};1\right).$$

4. Biorthogonality relations. We will extend the ideas of the previous sections by considering rational functions rather than polynomials. Thus the basic object of study will be the rational function of z

$$p_n^{a,b}(z) = \frac{(az;q)_n}{(bz;q)_n} \tag{4.1}$$

rather than the polynomial $(az;q)_n$ of §2. Two fundamental recurrences are

$$\mu_1 p_{n-1}^{a,bq} = \frac{(a - \frac{b\rho}{a}q^{-n+1})}{a-b} p_{n-2}^{a,b} + \frac{b}{a}\frac{(-b+\rho q^{-n+1})}{a-b} p_n^{a,b}, \tag{4.2A}$$

$$\mu_2 p_n^{a,b} = (a-b)(1-q^n) p_{n-1}^{a,bq}, \tag{4.2B}$$

where

$$\mu_1 = \frac{(1 - \frac{b\rho z}{aq})}{(1 - \frac{az}{q})} E_z^{-1} + \frac{b}{a}\frac{1-\rho z}{1-bz} I_z,$$

$$\mu_2 = \frac{q}{z}(1 - bq^{-1}z)(1-bz)[I_z - E_z^{-1}],$$

and

$$E_z^s f(z) = f(q^s z), \quad I_z f(z) = f(z).$$

It is not difficult to verify that the eigenvalue equation

$$\mu_1 \mu_2 \Psi(z) = \lambda \Psi(z) \tag{4.3}$$

has the solutions

$$\Psi_\ell^{a,b,\rho}(z) = \sum_{k=0}^{\ell} \frac{(q^{-2\ell};q^2)_k (\frac{b}{\rho}q^{2\ell-1};q^2)_k}{(q^2;q^2)_k (\frac{a^2 q}{b\rho};q^2)_k} \frac{(az;q)_{2k}}{(bz;q)_{2k}} q^{2k} \tag{4.4}$$

corresponding to the eigenvalues

$$\lambda_\ell = \frac{b}{a}(1-q^{-2\ell})(bq^{2\ell} - \rho q), \quad \ell = 0,1,2,\ldots. \tag{4.5}$$

Let $S_e^{a,b,\rho}$ be the complex vector space of all finite linear combinations of the functions $\{\Psi_\ell^{a,b,\rho}\}$. Consider the bilinear form

$$< f, g >_{a,b,\rho}^e = \oint_C f(z) g(z) w_{a,b,\rho}^e(z) \frac{dz}{z} \tag{4.6}$$

where $g \in S_e^{a,b,\rho}$, w is a weight function, C is a positively oriented closed curve in the complex z-plane and $f \in \hat{S}_e^{a,b,\rho}$ (a space to be determined). We interpret $\mu_1\mu_2$ as the map

$$\mu_1\mu_2 : S_e^{a,b,\rho} \to S_e^{a,b,\rho}$$

and try to determine w, C, and $\hat{S}_e^{a,b,\rho}$ such that the adjoint eigenvalue equation

$$(\mu_1\mu_2)^* \hat{\Psi}_\ell^{a,b,\rho} = \lambda_\ell \hat{\Psi}_\ell^{a,b,\rho}, \quad \ell = 0,1,2,\ldots \tag{4.7}$$

has hypergeometric solutions $\hat{\Psi}_\ell^{a,b,\rho}$ where

$$(\mu_1\mu_2)^* : \hat{S}_e^{a,b,\rho} \to \hat{S}_e^{a,b,\rho}.$$

An evident solution is

$$\hat{\Psi}_\ell^{a,b,\rho}(z) = \Psi_\ell^{a,b,\rho}\left(\frac{q}{b\rho z}\right)$$

$$= \sum_{k=0}^{\ell} \frac{(q^{-2\ell};q^2)_k(\frac{b}{\rho}q^{2\ell-1};q^2)_k}{(q^2;q^2)_k(\frac{a^2q}{b\rho};q^2)_k}\frac{(\frac{aq}{b\rho z};q)_{2k}}{(\frac{q}{\rho z};q)_{2k}}q^{2k} \tag{4.8}$$

with $\hat{S}_e^{a,b,\rho}$ as the space of all finite linear combinations of the $\{\hat{\Psi}_\ell^{a,b,\rho}\}$. The weight function must satisfy the recurrence

$$\frac{w^e_{a,b,\rho}(qz)}{w^e_{a,b,\rho}(z)} = -\frac{(1-az)(1-\frac{1}{\rho z})}{(1-\frac{a}{b\rho z})(1-bz)}. \tag{4.9}$$

This recurrence has many solutions, depending on our choice of the zeros and the poles of w in the z-plane. One of the solutions with the simplest pole structure is

$$w^e_{a,b,\rho}(z) = \frac{(bz;q)_\infty(-\rho z;q)_\infty(-\frac{q}{\rho z};q)_\infty}{(az;q)_\infty(\frac{qa}{\rho bz};q)_\infty(\rho z;q)_\infty} \tag{4.10}$$

where we assume

$$|q| < |\rho| < 1, \qquad |qa| < |\rho b|. \tag{4.11}$$

For C we take the unit circle: $|z| = 1$. We will adopt solution (4.10) in the computations to follow.

Note that

$$\mu_2\Psi_\ell^{a,b,\rho} = \frac{q^2(a-b)(1-q^{-2\ell})(1-\frac{b}{\rho}q^{2\ell-1})}{(1-\frac{a^2q}{b\rho})}\Theta_{\ell-1}^{a,b,\rho} \tag{4.12}$$

where

$$\Theta_{-1}^{a,b,\rho} = 0,$$

$$\Theta_\ell^{a,b,\rho} = \sum_{k=0}^{\ell} \frac{(q^{-2\ell};q^2)_k(\frac{b}{\rho}q^{2\ell+3};q^2)_k}{(q^2;q^2)_k(\frac{a^2q^3}{b\rho};q^2)_k}\frac{(az;q)_{2k+1}q^{2k}}{(bzq;q)_{2k+1}}, \tag{4.13}$$

$$\ell = 0, 1, \ldots.$$

It follows from (4.3)-(4.5) that

$$\mu_1\Theta_{\ell-1}^{a,b,\rho} = \frac{(a^2q-\rho b)}{qa(a-b)}\Psi_\ell^{a,b,\rho}, \quad \ell = 1, 2, \ldots. \tag{4.14}$$

Let $S_o^{a,b,\rho}$ be the space of all finite linear combinations of the $\{\Theta_\ell^{a,b,\rho}\}$. We have the interpretation

$$\mu_1 : S_o^{a,b,\rho} \to S_e^{a,b,\rho}, \ \mu_2 : S_e^{a,b,\rho} \to S_o^{a,b,\rho}.$$

Furthermore, $(\mu_1\mu_2)^*$ factors as $(\mu_1\mu_2)^* = \mu_2^*\mu_1^*$ where

$$\mu_1^* = \frac{q^2}{\rho^2 z}(1-\rho z)\left(1-\frac{\rho z}{q}\right)(I_z - E_z^1),$$

$$\mu_2^* = \frac{b^2q^2}{qa^2}\frac{(1-az)}{(1-\frac{b\rho z}{a})}E_z^1 + \frac{b\rho^2}{qa}\frac{(1-\frac{bz}{q})}{(1-\frac{\rho z}{q})}I_z$$

and

$$\mu_1^*\hat{\Psi}_\ell^{a,b,\rho} = \frac{\frac{q^3}{\rho}(\frac{a}{b}-1)}{(1-\frac{a^2q}{b\rho})}(1-q^{-2\ell})\left(1-\frac{b}{\rho}q^{2\ell-1}\right)\hat{\Theta}_{\ell-1}^{a,b,\rho},$$

$$\mu_2^*\hat{\Theta}_{\ell-1}^{a,b,\rho} = -\frac{b^2\rho^2(1-\frac{a^2q}{b\rho})}{aq^2(a-b)}\hat{\Psi}_\ell^{a,b,\rho}, \tag{4.15}$$

with

$$\hat{\Theta}_{-1}^{a,b,\rho}(z) = 0,$$

$$\hat{\Theta}_\ell^{a,b,\rho}(z) = \sum_{k=0}^{\ell}\frac{(q^{-2\ell};q^2)_k(\frac{b}{\rho}q^{2\ell+3};q^2)_k}{(q^2;q^2)_k(\frac{a^2q^3}{b\rho};q^2)_k}\frac{(\frac{aq}{b\rho z};q)_{2k+1}}{(\frac{q^2}{\rho z};q)_{2k+1}}q^{2k}, \tag{4.16}$$

$$\ell = 0, 1, \ldots.$$

Let $\hat{S}_o^{a,b,\rho}$ be the space of all finite linear combinations of the functions $\{\hat{\Theta}_\ell^{a,b,\rho}\}$. Then we have the interpretations

$$\mu_1^* : \hat{S}_e^{a,b,\ell} \to \hat{S}_o^{a,b,\rho}, \quad \mu_2^* : \hat{S}_o^{a,b,\rho} \to \hat{S}_e^{a,b,\rho}.$$

We now try to determine a weight function $w_{a,b,\rho}^o(z)$ such that the adjoint relation

$$< \mu_1^* f, g >_{a,b,\rho}^o = < f, \mu_1 g >_{a,b,\rho}^e \tag{4.17}$$

holds for all $f \in \hat{S}_e^{a,b,\rho}$, $g \in S_o^{a,b,\rho}$, where

$$< g_1, g_2 >_{a,b,\rho}^o = \oint_C g_1(z)g_2(z)w_{a,b,\rho}^o(z)\frac{dz}{z}. \tag{4.18}$$

A straightforward computation yields

$$w_{a,b,\rho}^o(z) = \frac{\rho^2 bz w_{a,b,\rho}^e(z)}{aq^2(1-bz)(1-\frac{\rho z}{q})}$$

$$= \frac{\rho^2 bz(bqz;q)_\infty(-\rho z;q)_\infty(-\frac{q}{\rho z};q)_\infty}{aq^2(az;q)_\infty(\frac{qa}{\rho bz};q)_\infty(\frac{\rho z}{q};q)_\infty}. \tag{4.19}$$

We can similarly verify that the adjoint relation

$$< \mu_2^* g, f >_{a,b,\rho}^e = < g, \mu_2 f >_{a,b,\rho}^o \tag{4.20}$$

holds for all $f \in S_e^{a,b,\rho}$, $g \in \hat{S}_o^{a,b,\rho}$.

It follows immediately from these adjoint relations and the eigenvalue equations (4.3) and (4.7) that the biorthogonality relations

$$< \hat{\Psi}_\ell^{a,b,\rho}, \Psi_{\ell'}^{a,b,\rho} >_{a,b,\rho}^e = 0, \tag{4.21A}$$

$$< \hat{\Theta}_\ell^{a,b,\rho}, \Theta_{\ell'}^{a,b,\rho} >_{a,b,\rho}^o = 0, \tag{4.21B}$$

hold for all $\ell \neq \ell'$. Our remaining problem is to compute the left-hand sides of expressions (4.21A), (4.21B) for $\ell = \ell'$.

One appropriate operator for this problem is

$$\xi = \frac{q}{z}(1-bqz)\left(1-\frac{b^2\rho z}{a^2}\right)I_z - \frac{q}{z}\frac{(1-bz)(1-bqz)(1-\frac{b\rho z}{aq})}{(1-\frac{az}{q})}E_z^{-1} \tag{4.22}$$

which satisfies

$$\xi p_{2k+1}^{a,bq} = (a-bq)\frac{b\rho}{a^2}\left(1-\frac{q^{2k+1}a^2}{b\rho}\right)p_{2k}^{a,bq^2},$$

$$k = 0,1,2,\dots \tag{4.23}$$

where the basis functions $p_n^{a,b}$ are defined by (4.1). It follows that

$$\xi\Theta_\ell^{a,b,\rho} = -q(a-bq)\left(1-\frac{b\rho}{a^2q}\right)\Psi_\ell^{a,bq^2,\rho q^{-2}}, \tag{4.24}$$

$$\ell = 0,1,\dots$$

and that ξ has the interpretation

$$\xi : S_o^{a,b,\rho} \to S_e^{a,bq^2,\rho q^{-2}}.$$

We define the adjoint operator

$$\xi^* : \hat{S}_e^{a,bq^2,\rho q^{-2}} \to \hat{S}_o^{a,b,\rho}$$

by

$$< g, \xi f >_{a,bq^2,\rho q^{-2}}^{e} = < \xi^* g, f >_{a,b,\rho}^{o} \tag{4.25}$$

where $g \in \hat{S}_e^{a,bq^2,\rho q^{-2}}$, $f \in S_o^{a,b,\rho}$. A straightforward computation yields

$$\xi^* = qE_z^1 + \frac{a}{b}\frac{(1-\frac{b^2\rho z}{a^2})}{(1-\frac{\rho z}{q^2})}I_z \tag{4.26}$$

and

$$\frac{(a-bq)}{q}\xi^*\hat{\Psi}_\ell^{a,bq^2,\rho q^{-2}} = -\frac{q^2}{a}\frac{(1-\frac{a^2q^{2\ell+1}}{b\rho})}{(1-\frac{a^2q}{b\rho})}(b^2-a^2q^{-2\ell-2})\hat{\Theta}_\ell^{a,b,\rho}. \tag{4.27}$$

Set

$$\|\Psi_\ell^{a,b,\rho}\|_e^2 = < \hat{\Psi}_\ell^{a,b,\rho}, \Psi_\ell^{a,b,\rho} >_{a,b,\rho}^{e}, \quad \|\Theta_\ell^{a,b,\rho}\|_o^2 = < \hat{\Theta}_\ell^{a,b,\rho}, \Theta_\ell^{a,b,\rho} >_{a,b,\rho}^{o}, \tag{4.28}$$

$$\ell = 0,1,2,\dots.$$

From (4.14), (4.15), and (4.17) with $f = \hat{\Psi}_\ell^{a,b,\rho}$, $g = \Theta_{\ell-1}^{a,b,\rho}$ we have

$$\|\Psi_\ell^{a,b,\rho}\|_e^2 = -\frac{a\rho q^2(a-b)^2(1-q^{-2\ell})(1-\frac{b}{\rho}q^{2\ell-1})}{(b\rho-a^2q)^2}\|\Psi_{\ell-1}^{a,b,\rho}\|_o^2. \tag{4.29}$$

Relation (4.20) yields the same recurrence. Expressions (4.24), (4.25), and (4.27) with $f = \Theta_\ell^{a,b,\rho}$, $g = \hat{\Psi}_\ell^{a,bq^2,\rho q^{-2}}$ produce

$$\|\Psi_\ell^{a,bq^2,\rho q^{-2}}\|_e^2 = -\frac{a^2q^3(1-\frac{a^2q^{2\ell+1}}{b\rho})(b^2-a^2q^{-2\ell-2})}{b\rho(a-bq)^2(1-\frac{a^2q}{b\rho})^2}\|\Theta_\ell^{a,b,\rho}\|_o^2. \tag{4.30}$$

It follows from these results that if we know $\|1^{a,b,\rho}\|_e^2$ for all a, b, ρ then we can compute recursively expressions (4.28) for all ℓ. In general these norms will be nonzero.

Replacing ρz by z in (4.6), (4.10) we have

$$\|1^{a,b,\rho}\|_e^2 = G(u,v,q) = \frac{1}{2\pi}\oint_C \frac{(\frac{uz}{v};q)_\infty(-z;q)_\infty(-\frac{q}{z};q)_\infty}{(uz;q)_\infty(\frac{qv}{z};q)_\infty(z;q)_\infty}\frac{dz}{z} \tag{4.31}$$

where $u = a/\rho$, $v = a/b$. From the relation

$$< \hat{\Psi}_0^{a,b,\rho}, \Psi_1^{a,b,\rho} >_e = 0$$

it is straightforward to compute the recurrence

$$\|1^{aq^2,bq^2,\rho}\|_e^2 = \frac{(1 - \frac{a^2q}{b\rho})}{(1 - \frac{bq}{\rho})}\|1^{a,b,\rho}\|_e^2$$

or $G(q^2u, v, q) = (1 - uvq)G(u, v, q)/(1 - uq/v)$, which implies

$$G(u, v, q) = \frac{(\frac{uq}{v}; q^2)_\infty}{(uvq; q^2)_\infty}\mathscr{G}(v, q). \tag{4.32}$$

To finish the computation of (4.31) we utilize the recurrence operator

$$\eta = \frac{(aq - b)}{(1 - az)}\left[\left(1 - \frac{bz}{q}\right)E_z^{-1} + \frac{b}{aq}\left(1 - \frac{a^2qz}{b}\right)I_z\right]. \tag{4.33}$$

Here,

$$\eta p_n^{a,b} = aq(1 - q^{-n})p_{n-2}^{aq,b} + \frac{(-b^2 + a^2q^{2-n})}{aq}p_n^{aq,b},$$

hence

$$\eta\Psi_\ell^{a,b,\rho} = -\frac{q^{-2\ell}(b - \frac{a^2}{\rho}q^{2\ell+1})}{abq(1 - \frac{a^2q}{b\rho})}(-a^2q^2 + b^2q^{2\ell})\Psi_\ell^{aq,b,\rho}. \tag{4.34}$$

Interpreting $\eta : S_e^{a,b,\rho} \to S_e^{aq,b,\rho}$ we compute the adjoint $\eta^* : \hat{S}_e^{aq,b,\rho} \to \hat{S}_e^{a,b,\rho}$ with the result

$$\eta^* = (aq - b)\left[\frac{(1 - \rho z)}{\rho z}(1 - az)E_z^1 + \frac{b}{aq}\left(1 - \frac{qa}{\rho bz}\right)\left(1 - \frac{a^2qz}{b}\right)I_z\right]. \tag{4.35}$$

This leads to the recurrence

$$\eta^*\hat{\Psi}_\ell^{aq,b,\rho} = -\frac{(aq - b)^2}{aq}\left(1 - \frac{a^2q}{b\rho}\right)\hat{\Psi}_\ell^{a,b,\rho}. \tag{4.36}$$

Thus the relation

$$< \eta^*1, 1 >_{a,b,\rho}^e = < 1, \eta 1 >_{aq,b,\rho}^e$$

implies

$$\|1^{aq,b,\rho}\|_e^2 = \left(1 - \frac{a^2q}{bm}\right)\left(\frac{b - aq}{b + aq}\right)\|1^{a,b,\rho}\|_e^2$$

or $\mathscr{G}(qv, q) = (1-qv)\mathscr{G}(v, q)/(1+qv)$. We conclude $\mathscr{G}(v, q) = (-vq; q)_\infty\mathscr{K}(q)/(vq; q)_\infty$ where $\mathscr{K}(q)$ is to be determined. Setting $u = 0$, $v = 1$ in (4.31) we find $G(0, -1, q) = 1 = (q; q)_\infty\mathscr{K}(q)/(-q; q)_\infty$, so

$$\|1^{a,b,\rho}\|_e^2 = \frac{(-q; q)_\infty(\frac{bq}{\rho}; q^2)_\infty(-\frac{aq}{b}; q)_\infty}{(q; q)_\infty(\frac{a^2q}{b\rho}; q^2)_\infty(\frac{aq}{b}; q)_\infty}. \tag{4.37}$$

Expanding the original integral $\|1^{a,b,\rho}\|_e^2$ by residues inside the circle C, we see that our result is equivalent to the summation formula

$${}_2\varphi_1\left(\begin{matrix} vq, & uvq \\ uq & \end{matrix}; -\frac{1}{v}\right) = \frac{(-q; q)_\infty(\frac{uq}{v}; q^2)_\infty(uvq^2; q^2)_\infty}{(uq; q)_\infty(-\frac{1}{v}; q)_\infty}. \tag{4.38}$$

This is a q-analogue of Kummer's Theorem, first proved by Andrews (1973); see also Andrews (1977, p. 20).

Acknowledgments. Willard Miller wishes to thank Dick Askey and Dennis Stanton for consultation on this work. We also thank Dennis Stanton for pointing out the fact in (2.19).

Note added in proof. A referee points out that the system of biorthogonal functions in §4 is a special case of a system found by J.A. Wilson in 1977 but not yet published.

UNIFORM ASYMPTOTIC EXPANSIONS OF LAGUERRE POLYNOMIALS*

C. L. FRENZEN† AND R. WONG‡

Abstract. Two asymptotic expansions are obtained for the Laguerre polynomial $L_n^{(\alpha)}(x)$ for large n and fixed $\alpha > -1$. These expansions are uniformly valid in two overlapping intervals covering the entire x-axis. The leading terms of both agree with the two asymptotic formulas given by Erdélyi who used the theory of differential equations. Our approach is based on two integral representations for the Laguerre polynomials. The phase function of one of these integrals has two coalescing saddle points, and to this one the cubic transformation introduced by Chester, Friedman, and Ursell is applied. The phase function of the other integral also has two coalescing saddle points, but in addition it has a simple pole. Moreover, the saddle points coalesce onto this pole. In this case a rational transformation is used, which mimics the singular behavior of the phase function. In both cases explicit expressions are given for the remainders associated with the asymptotic expansions.

Key words. uniform asymptotic expansion, Laguerre polynomial, Airy function, Bessel function

1. Introduction.

Many special functions of mathematical physics have integral representations of the form

$$I(\lambda) = \int_C g(z)\, e^{\lambda f(z,t)}\, dz, \tag{1.1}$$

where C is a contour in the complex plane, λ is a large positive parameter, and $f(z, t)$ and $g(z)$ are analytic functions of their arguments. For fixed t the asymptotic expansion of $I(\lambda)$ can often be found by the method of steepest descents, which shows that the major contributions to $I(\lambda)$ come from the saddle points of $f(z, t)$, i.e., the points where $\partial f(z, t)/\partial z$ vanishes. In general, the saddle points depend on t. As t varies continuously, the saddle points may coalesce with each other, and the form of the asymptotic expansion may change. The problem at hand is to obtain an asymptotic expansion for large λ that is uniform with respect to t as t ranges over a given connected set that is not necessarily bounded. When $\partial f(z, t)/\partial z$ has exactly two simple zeros that coalesce into a double zero, Chester, Friedman, and Ursell suggested, in their innovative paper [2], the use of the cubic transformation

$$f(z, t) = \tfrac{1}{3} u^3 - \zeta(t) u + \eta(t), \tag{1.2}$$

where $\zeta(t)$ and $\eta(t)$ are determined explicitly from the requirement that the transformation (1.2) from z to u be analytic in a neighborhood containing the two saddle points. As a result, a uniform asymptotic expansion of the form

$$\exp\{-\lambda\eta(t)\}\left[\frac{\mathrm{Ai}\,(\lambda^{2/3}\zeta)}{\lambda^{1/3}} \sum_{s=0}^{\infty} \frac{A_s(\alpha)}{\lambda^s} + \frac{\mathrm{Ai}'\,(\lambda^{2/3}\zeta)}{\lambda^{2/3}} \sum_{s=0}^{\infty} \frac{B_s(\alpha)}{\lambda^s}\right] \tag{1.3}$$

was obtained, where Ai and Ai′ are the Airy function and its derivative, respectively. Airy function expansions of the form (1.3) were in fact first found by Langer [7] and

Olver [11] in their study of asymptotic solutions to the differential equation

$$\frac{d^2w}{dz^2}=\{u^2p(z)+q(z)\}w \tag{1.4}$$

for large values of u. When the function $p(z)$ has only a simple turning point, (1.4) can be transformed into one which is approximately the same as the equation satisfied by the Airy functions. For an elegant version of this theory, see the book by Olver [13, Chap. 11].

In this paper we shall study the behavior of the integral (1.1), when $f(z, t)$ is given by

$$f(z, t)=z-t\coth z. \tag{1.5}$$

Note that this function has two symmetrically located saddle points

$$z_{\pm}=\pm i\sin^{-1}\sqrt{t}$$

and, in addition, a simple pole at $z=0$. As t tends to zero, the saddle points coalesce with each other and also with the pole. The simplest function which also possesses these essential features is provided by the rational function $u-A^2(t)/u$. Thus, instead of (1.2), the appropriate transformation is

$$z-t\coth z=u-\frac{A^2(t)}{u}, \tag{1.6}$$

where $A(t)$ is to be determined. As a consequence of (1.6), we obtain a uniform asymptotic expansion of $I(\lambda)$ of the form

$$\frac{J_\alpha(2\lambda A)}{A^\alpha}\sum_{k=0}^{\infty}\frac{C_{2k}(t)}{\lambda^{2k}}-\frac{J_{\alpha+1}(2\lambda A)}{A^{\alpha+1}}\sum_{k=0}^{\infty}\frac{D_{2k+1}(t)}{\lambda^{2k+1}}, \tag{1.7}$$

where J_α is the Bessel function of the first kind. A transformation similar to (1.6) has been suggested by Temme [15, eq. (6.12)], but, as he points out, his argument is only formal (cf. [15, lines 6–8, p. 313]). It is of interest to observe that expansions of this form have also been given in the theory of differential equations. They represent the asymptotic solutions to (1.4), when the coefficient function $p(z)$ has a simple pole (see [12] and also [13, Chap. 12]).

The integral (1.1) with $f(z, t)$ given by (1.5) arises in the study of the asymptotic behavior of the Laguerre polynomial $L_n^{(\alpha)}(x)$. The best known result in this area is probably that of Erdélyi [4]. Erdélyi put $\nu=4N=4n+2\alpha+2$, and gave two uniform asymptotic formulas for $L_n^{(\alpha)}(\nu t)$, as $n\to\infty$, where α is fixed and nonnegative, and t is real. One formula holds uniformly for $t\leqq a$ and the other for $t\geqq b$, where a and b are two fixed numbers, $0<b<a<1$. Note that these two intervals overlap and between them cover the entire real axis. Erdélyi's formulas were considered important results by Szegö [14, p. 243], and their validity was extended from $\alpha\geqq 0$ to $\alpha>-1$ by Muckenhoupt [10] through the use of recurrence relations. It should be mentioned that since Laguerre polynomials can be expressed in terms of confluent hypergeometric functions [13, p. 259], it is possible to derive their infinite asymptotic expansions with error bounds directly from those for Whittaker functions given by Olver [13, pp. 412, 446–447]. However, so far, all of these results have only been obtained from the theory of differential equations.

The object of the present paper is to obtain the same kind of asymptotic expansions for the Laguerre polynomial from its definite integral representations. An attempt in this direction was made earlier by Wyman [18], but the range of validity of his result is much more restricted than that of Erdélyi. The method we shall use depends heavily on establishing that the transformation (1.6) has one branch $u = u(z, t)$ that is analytic in z and continuous in t, and that the correspondence $u \leftrightarrow z$ is one-to-one. This can be done in two ways. It can either be proved directly, as was done by Copson [3, Chap. 10] and Olver [13, Chap. 9, § 12], who both used the cubic transformation for Bessel and Anger functions, respectively, or it can be obtained as a consequence of a general theorem corresponding to the one given by Chester, Friedman, and Ursell [2, Thm. 1]. Although it is possible to establish such a general result like the one for the cubic transformation in [2], it will hold only locally and not globally. We therefore find it preferable to adopt the approach taken by Copson and Olver. Indeed, it will be shown that the mapping $z \leftrightarrow u$ in (1.6) is actually one-to-one and analytic along an infinite loop starting at $-\infty$, enclosing the origin, and ending at $-\infty$.

Here we wish to remark that although we consider only the case of Laguerre polynomials, the method presented in this paper is quite general. It can be applied to many other integrals whose phase function $f(z, t)$ has two symmetrically located saddle points and a simple pole. Since there are functions that are expressible in the form of an integral but do not satisfy any second-order linear differential equation, a complete theory of asymptotic analysis requires integral as well as differential equation methods for deriving uniform asymptotic expansions.

The present paper is arranged as follows. In § 2 we first show that the Laguerre polynomial $L_n^{(\alpha)}(\nu t)$ has an integral representation whose phase function is given by (1.5), and then we use the rational transformation (1.6) to reduce it to canonical form. For $-\infty < t \leqq a < 1$, the one-to-one nature of the transformation (1.6) is demonstrated in § 3. The derivation of the asymptotic expansion is given in § 4. In § 5, we study the case $0 < b \leqq t < \infty$, and obtain an Airy function expansion. A concluding remark is given in § 6.

2. Reduction to a canonical integral. We start with the integral representation [14, p. 384]

$$e^{-x/2}L_n^{(\alpha)}(x) = \frac{1}{2\pi i}\int_{-\infty}^{(0+)} \exp\left\{-\frac{x}{2}\frac{1+e^{-z}}{1-e^{-z}}\right\}(1-e^{-z})^{-\alpha-1}\, e^{nz}\, dz, \tag{2.1}$$

where the path of integration is the usual loop which begins and ends at $-\infty$ and encircles the origin in the positive direction. (Note that this is not the integral used by Wyman.) *Throughout this paper we shall assume that* $\alpha > -1$. Clearly (2.1) can be written as

$$\begin{aligned} e^{-x/2}L_n^{(\alpha)}(x) = \frac{1}{2\pi i}\int_{-\infty}^{(0+)} &\exp\left\{-\frac{x}{2}\coth\frac{z}{2} + Nz\right\} \\ &\cdot\left(\frac{\sinh z/2}{z/2}\right)^{-\alpha-1} z^{-\alpha-1}\, dz \end{aligned} \tag{2.2}$$

with $N = n + \frac{1}{2}(\alpha+1)$. If we replace z by $2z$ and let $\nu = 4N$ and $x = \nu t$, $-\infty < t < 1$, then (2.2) becomes

$$e^{-\nu t/2}L_n^{(\alpha)}(\nu t) = \frac{2^{-\alpha}}{2\pi i}\int_{-\infty}^{(0+)} \exp\left\{\frac{\nu}{2}f(z, t)\right\}\left(\frac{\sinh z}{z}\right)^{-\alpha-1} z^{-\alpha-1}\, dz, \tag{2.3}$$

where $f(z, t)$ is given in (1.5):

$$f(z, t) = z - t \coth z. \tag{2.4}$$

We shall represent $f(z, t)$ by the rational function

$$f(z, t) = u - \frac{A^2(t)}{u}. \tag{2.5}$$

For this to be an analytic transformation in the regions of interest, we must have $dz/du \neq 0$ or ∞. Now

$$f_z(z, t)\frac{dz}{du} = 1 + \frac{A^2(t)}{u^2} \tag{2.6}$$

and $f_z(z, t)$ vanishes at $z = z_+$ and z_- in $|\operatorname{Im} z| < \pi/2$, where

$$z_\pm = \begin{cases} \pm i \sin^{-1}\sqrt{t}, & 0 \leqq t < 1, \\ \mp \sinh^{-1}\sqrt{-t}, & t < 0. \end{cases}$$

Since the right-hand side of (2.6) vanishes at $u = \pm iA(t)$, we must make $z = z_+$ correspond to $u = +iA(t)$, and $z = z_-$ to $u = -iA(t)$. This gives

$$A(t) = \begin{cases} \frac{1}{2}[\sin^{-1}\sqrt{t} + \sqrt{t(1-t)}], & 0 \leqq t < 1, \\ \frac{i}{2}[\sinh^{-1}\sqrt{-t} + \sqrt{t(t-1)}], & t < 0. \end{cases} \tag{2.7}$$

Note that our $A(t)$ is exactly the same as Erdélyi's $\psi(t)$. In § 3, it will be shown that with this choice, the transformation (2.5) is one-to-one and analytic along the whole infinite loop given in (2.3). Thus, changing the variable to u, we obtain

$$e^{-\nu t/2} L_n^{(\alpha)}(\nu t) = \frac{2^{-\alpha}}{2\pi i} \int_{-\infty}^{(0+)} u^{-\alpha-1} h(u) \exp\left\{\frac{\nu}{2}\left(u - \frac{A^2(t)}{u}\right)\right\} du, \tag{2.8}$$

where

$$h(u) = \left(\frac{\sinh z(u)}{z(u)}\right)^{-\alpha-1} \left(\frac{z(u)}{u}\right)^{-\alpha-1} \frac{dz}{du}. \tag{2.9}$$

Here we have assumed that the mapping $z \leftrightarrow u$ preserves the loop nature of the path of integration. Note that the function h in (2.9) depends also on the variable t; thus, $h = h(u, t)$. However, for simplicity, we shall not indicate this dependence explicitly.

3. The transformation (1.6). The properties of the mapping between z and u are best seen by introducing an intermediate variable Z defined by

$$z - t \coth z = Z = u - \frac{A^2(t)}{u}. \tag{3.1}$$

For our purpose, it suffices to consider only the strip $|\operatorname{Im} z| \leqq \pi/2$. We first restrict ourselves to the case $0 < t < 1$. The half-strip $\{z: \operatorname{Re} z \leqq 0, 0 \leqq \operatorname{Im} z \leqq \pi/2\}$ is shown in Fig. 1. Its image in the Z-plane is depicted in Fig. 2. Note that as z traverses once along the indented boundary $ABCC'DEFA$ in Fig. 1, Z also traverses exactly once along the corresponding curve in Fig. 2. Here we treat the straight lines $C'D$ and DE in Fig. 2 as distinct parts of the boundary (see [17, p. 375, lines 22–25]). Hence, by

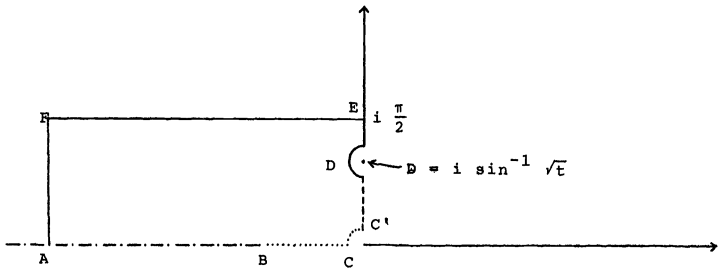

FIG. 1. *z-plane* $(0<t<1)$.

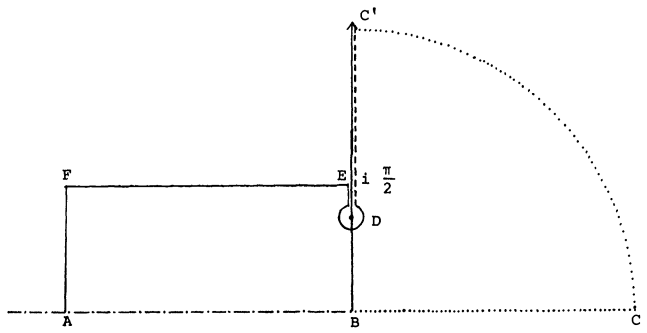

FIG. 2. *Z-plane.*

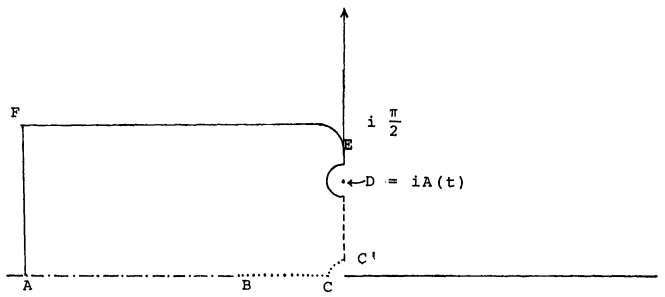

FIG. 3. *u-plane.*

Theorem 4.5 in [9, vol. 2, p. 118], $\phi = z - t\coth z$ is one-to-one in the interior of the region bounded by this curve (see also [16, §§ 6.45 and 6.46]).

We next consider the mapping $\psi: u \to Z$ defined by $\psi(u) = u - A^2(t)/u$. By the same argument as above, when u traverses once along the boundary of the region $ABCC'DEFA$ in Fig. 3, Z goes once around the corresponding curve in the Z-plane. Hence ψ is one-to-one in the interior of the region $ABCC'DEFA$ in Fig. 3. The equation of the boundary curve EF in Fig. 3 is given implicitly by

$$\frac{\pi}{2} = s + \frac{A^2(t)s}{r^2+s^2}, \qquad \operatorname{Re} Z = r - \frac{A^2(t)r}{r^2+s^2},$$

where $u = r + is$ and $r < 0$. Since $r \leqq 0$ and $\operatorname{Re} Z \leqq 0$, we have, from the second equation above, $A^2(t) \leqq r^2+s^2$. This together with the first equation implies that $s \geqq \pi/4$, i.e., the curve EF in Fig. 3 remains in the region $\operatorname{Im} u \geqq \pi/4$. Also, from (2.7), we have $A(0) = 0$, $A'(t) > 0$ for $0 < t < 1$ and $A(1^-) = \pi/4$. Hence, $0 < A(t) < \pi/4$ for $0 < t < 1$. Therefore, for $0 < t \leqq a < 1$, the point D in Fig. 3 is at a positive distance away from the curve EF.

The transformation $z \leftrightarrow u$ is obtained by composing $\phi^{-1}: Z \to z$ and $\psi: u \to Z$. Since the transformations $z \leftrightarrow Z$ and $u \leftrightarrow Z$ are one-to-one within the boundary $ABCC'DEFA$, so is $z \leftrightarrow u$. Let $z = x + iy$ and $u = r + is$. It can be shown by direct computation that the real parts of $z - t \coth z$ and $u - (1/u)A^2(t)$ are odd in x and r, respectively, and even in y and s, respectively. Similarly, the imaginary parts of these functions are odd in y and s, respectively, and even in x and r, respectively. Hence, the mapping of the rest of the strip $|\text{Im } z| \leqq \pi/2$ is deducible from Figs. 1 and 3 by reflection in the real and imaginary axes. This establishes the one-to-one and analytic nature of the function $u(z, t)$ in $|\text{Im } z| \leqq \pi/2$, except possibly at $z = z_{\pm}$ and $z = 0$. From the above argument (cf. Figs. 1 and 3), it is also evident that neighborhoods of these points are mapped into neighborhoods of their corresponding images. Consequently, $u(z, t)$ is bounded and analytic at these points. (Note also that near $z = 0$ and $t = 0$, we have $u \sim (1/t)A^2(t)z$ and $A^2(t) \sim t$, respectively.)

To emphasize what has been proved, we state again that the mapping $z \leftrightarrow u$, when $0 < t < 1$, is one-to-one and analytic from $|\text{Im } z| \leqq \pi/2$ to its image in the u-plane. The same properties, when $-\infty < t < 0$, can be established in a similar manner. In the latter case, the regions bounded by $ABCC'DEFA$ in the z-, Z-, and u-planes are shown in Figs. 1′, 2′, and 3′, respectively. Arguments similar to ours have been used earlier by Copson [3, § 49] and Olver [13, Chap. 9, § 12.3].

We have therefore proved (2.8) for the cases $0 < t < 1$ and $-\infty < t < 0$. The fact that (2.8) holds also at $t = 0$ follows from continuity. To show that $u(z, t)$ is continuous in t, we note that when $z = 0$, u is identically zero and hence is continuous in t. For $z \neq 0$, we have $u \neq 0$, as there is a one-to-one correspondence between z and u. Thus, for $z \neq 0$, (3.1) is equivalent to the quadratic equation $u^2 - (z - t \coth z)u - A^2(t) = 0$. Since $A^2(t)$ is continuous in t and the solutions of the quadratic equation depend continuously on its coefficients, u is continuous in t for $-\infty < t < 1$.

It may be of interest to note that, by using Hartogs' theorem [6, pp. 27-28] in the theory of several complex variables, we can actually prove that $u(z, t)$ is analytic in both variables in a neighborhood of $z = t = 0$. However, no use is made of this property in our later analysis.

4. Derivation of the expansion. We now return to the integral in (2.8) and deform the loop path of integration so that it consists of two straight lines along the negative real axis and a circle centered at the origin with radius ρ. The radius will be specified later, and depends on whether t is close to, or bounded away from, the origin. From (3.1) it can be shown that $z(u)$ is an odd function of u. Thus, (2.9) implies that $h(u)$ is an even function. Put $h_0(u) = h(u)$ and write

$$h_0(u) = \alpha_0 + \frac{\beta_0}{u} + \left(1 + \frac{A^2(t)}{u^2}\right) g_0(u), \tag{4.1}$$

where α_0, β_0, and $g_0(u)$ are to be determined. Since $h(u)$ is even, $h_0(iA) = h_0(-iA)$ and it follows that $\beta_0 = 0$, $\alpha_0 = h_0(iA)$. Thus

$$g_0(u) = u^2 \frac{h_0(u) - h_0(iA)}{u^2 - (iA)^2}. \tag{4.2}$$

Clearly, $g_0(u)$ is analytic for $u^2 \neq (iA)^2$ and has removable singularities at $u = \pm iA$. Near $u = \pm iA$,

$$g_0(u) = \frac{u^2}{u + (\pm iA)} \frac{h_0(u) - h_0(\pm iA)}{u - (\pm iA)},$$

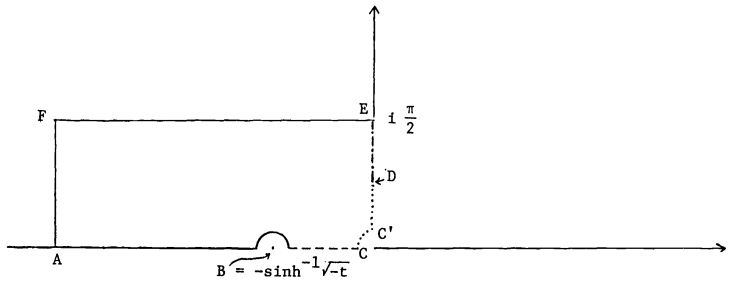

FIG. 1'. *z-plane* ($t<0$).

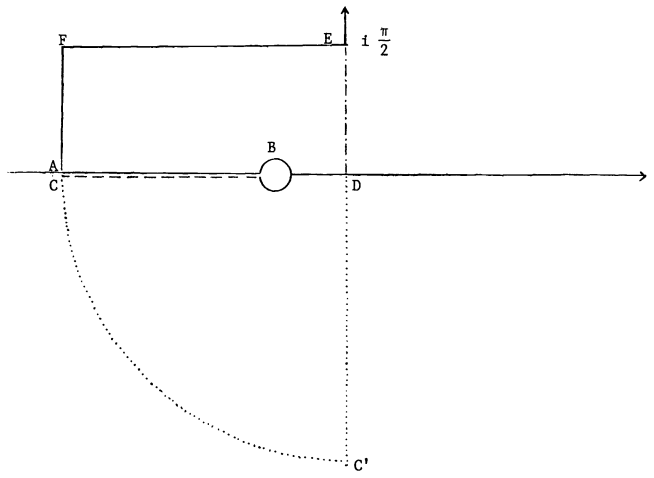

FIG. 2'. *Z-plane* ($t<0$).

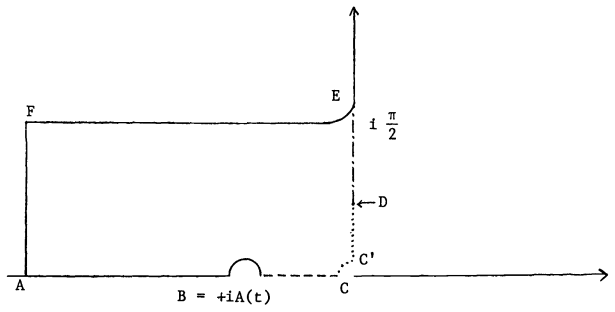

FIG. 3'. *u-plane* ($t<0$).

where either all "+" or all "−" signs are to be taken. From this, we conclude that $g_0(u)$ is analytic everywhere in the domain of $h_0(u)$. Now substitute (4.1) in (2.8), and express the first integral in terms of the Bessel function J_α. To the second integral, we apply an integration by parts. The integrated term vanishes, since $z(u)\sim u$ and $dz/du = O(1)$ as $u\to-\infty$, for fixed t. The final result is

$$2^\alpha e^{-\nu t/2}L_n^{(\alpha)}(\nu t)=\frac{\alpha_0}{A^\alpha}J_\alpha(\nu A)-\left(\frac{2}{\nu}\right)\frac{1}{2\pi i}\int_{-\infty}^{(0+)}u^{-\alpha-1}h_1(u)\cdot\exp\left\{\frac{\nu}{2}\left(u-\frac{A^2(t)}{u}\right)\right\}du, \tag{4.3}$$

where

$$h_1(u) = g_0'(u) - \frac{\alpha+1}{u} g_0(u).$$

A similar technique of integration by parts has been used by Temme [15, eq. (6.2)].

We now digress to briefly discuss the asymptotic behavior of $z^{(n)}(u)$, for fixed t, as $u \to -\infty$, $n = 0, 1, 2, \cdots$. From (1.6) (or (3.1)), it is easily seen that $z(u) \sim u$ as $u \to -\infty$. Differentiating (1.6) with respect to u, we obtain

$$(1 + t\ \mathrm{csch}^2 z) z'(u) = 1 + \frac{A^2(t)}{u^2}, \tag{4.4}$$

which in turn yields $z'(u) = O(1)$ as $u \to -\infty$. From (4.4), we also have, by Leibniz's rule,

$$\begin{aligned}(1 + t\ \mathrm{csch}^2 z) z^{(n+1)}(u) + \sum_{j=1}^{n} \binom{n}{j-1} (1 + t\ \mathrm{csch}^2 z(u))^{(n-j+1)} z^{(j)}(u) \\ = (-1)^n A^2(t) \frac{(n+1)!}{u^{n+2}}.\end{aligned} \tag{4.5}$$

Since every term in the above sum is exponentially decaying, (4.5) implies, by induction, that for fixed t,

$$\frac{d^{n+1} z}{du^{n+1}} = O\left(\frac{1}{u^{n+2}}\right), \qquad n \geqq 1, \quad \text{as } u \to -\infty. \tag{4.6}$$

To derive the form of the expansion given in (1.7), we repeat the procedures indicated in (4.1) and (4.3). Thus, we define recursively

$$\begin{aligned} h_0(u) &= h(u), \\ h_n(u) &= \alpha_n + \frac{\beta_n}{u} + \left(1 + \frac{A^2}{u^2}\right) g_n(u), \\ h_{n+1}(u) &= g_n'(u) - \frac{\alpha+1}{u} g_n(u). \end{aligned}$$

Using induction, we can show that $h_n(u) = O(1)$, as $u \to -\infty$, for fixed t and for all $n \geqq 0$. From this, it follows that we also have $g_n(u) = O(1)$, as $u \to -\infty$, for fixed t and for $n \geqq 0$. Furthermore, we can show that for $n \geqq 0$, $g_{2n}(u)$ and $h_{2n}(u)$ are even analytic functions, and that $g_{2n+1}(u)$ and $h_{2n+1}(u)$ are odd analytic functions. Consequently, we have

$$\alpha_{2n} = h_{2n}(iA), \qquad \alpha_{2n+1} = 0$$

and

$$\beta_{2n} = 0, \qquad \beta_{2n+1} = iA h_{2n+1}(iA).$$

Thus, for each n, both α_n and β_n are continuous in t for $-\infty < t < 1$. Repeated application of integration by parts then gives

$$\begin{aligned} 2^{\alpha} e^{-\nu t/2} L_n^{(\alpha)}(\nu t) = \frac{J_{\alpha}(\nu A)}{A^{\alpha}} \sum_{k=0}^{[(p-1)/2]} \alpha_{2k} \left(\frac{2}{\nu}\right)^{2k} \\ - \frac{J_{\alpha+1}(\nu A)}{A^{\alpha+1}} \sum_{k=0}^{[p/2]-1} \beta_{2k+1} \left(\frac{2}{\nu}\right)^{2k+1} + \varepsilon_p, \end{aligned} \tag{4.7}$$

where

$$\varepsilon_p = \left(-\frac{2}{\nu}\right)^p \cdot \frac{1}{2\pi i} \int_{-\infty}^{(0+)} u^{-\alpha-1} h_p(u) \exp\left\{\frac{\nu}{2}\left(u - \frac{A^2(t)}{u}\right)\right\} du. \tag{4.8}$$

To estimate ε_p, we recall the auxiliary function

$$\tilde{J}_\alpha(z) = \begin{cases} J_\alpha(z) & \text{if } z \text{ is imaginary or } 0 \leqq z \leqq \delta, \\ (|J_\alpha(z)|^2 + |Y_\alpha(z)|^2)^{1/2} & \text{if } z > \delta, \end{cases} \tag{4.9}$$

introduced by Erdélyi [4], where δ is chosen so that $J_\alpha(z) \neq 0$ when $0 < |z| \leqq \delta$ and $\delta > 0$. Furthermore, we define

$$\tilde{\beta}_p(t) = \begin{cases} 1 & \text{for } -\eta \leqq t \leqq a < 1, \\ |\beta_p| & \text{for } -\infty < t < -\eta, \end{cases} \tag{4.10}$$

and define $\tilde{\alpha}_p(t)$ in a similar manner, where α_p and β_p are the coefficients in the expansion (4.7), and η is a positive number to be chosen later. We shall now show that for $-\infty < t \leqq a < 1$,

$$\begin{aligned} |\varepsilon_p| &\leqq \frac{M_p}{\nu^p} \tilde{\beta}_p(t) \left|\frac{\tilde{J}_{\alpha+1}(\nu A(t))}{A(t)^{\alpha+1}}\right| \quad \text{if } p \text{ is odd}, \\ |\varepsilon_p| &\leqq \frac{N_p}{\nu^p} \tilde{\alpha}_p(t) \left|\frac{\tilde{J}_\alpha(\nu A(t))}{A(t)^\alpha}\right| \quad \text{if } p \text{ is even}, \end{aligned} \tag{4.11}$$

where M_p and N_p are constants depending only on p. Recall that $\nu A(t)$ in our case is either positive or imaginary. Since α_p and β_p are continuous at $t = 0$, the estimates in (4.11) show that the error term ε_p has the same behavior as the first neglected term in the expansion (4.7) near both $t = 0$ and $t = -\infty$.

An alternative bound for the remainder ε_p could be expressed also in terms of the auxiliary functions $E_\alpha(x)$ and $M_\alpha(x)$ given in [13, Chap. 12, § 1.3] for real argument or $\mathfrak{E}_\alpha(z)$ and $\mathfrak{M}_\alpha(z)$ given in [13, Chap. 12, § 8] for complex argument.

The proof of (4.11) is divided into separate cases: (i) $0 \leqq t \leqq a < 1$, and (ii) $-\infty < t < 0$. We first consider case (i). Here, $0 \leqq A(t) < \pi/4$. We shall subdivide this case into two subcases: (i)(a) $0 \leqq \nu A(t) \leqq \delta$, and (i)(b) $\nu A(t) > \delta > 0$. In subcase (i)(a), we make the change of variable $\nu u = w$ in (4.8). The result is

$$\varepsilon_p = \left(-\frac{2}{\nu}\right)^p \frac{\nu^\alpha}{2\pi i} \int_{-\infty}^{(0+)} w^{-\alpha-1} h_p\left(\frac{w}{\nu}\right) \exp\left\{\frac{1}{2}\left(w - \frac{\nu^2 A^2}{w}\right)\right\} dw. \tag{4.12}$$

Since the last integral is bounded uniformly with respect to ν and t, (4.12) gives

$$\varepsilon_p = O(\nu^{-p+\alpha}), \tag{4.13}$$

the O-symbol being independent of t and ν. The estimate (4.11) now follows, when we take into account the small-z behavior of $\tilde{J}_{\alpha+1}(z)$. In subcase (i)(b), we recall that the curve EF in Fig. 3 is bounded away from the point D (see the second paragraph in § 3). Thus, we may take the radius ρ of the circle in the loop path of integration in (4.8) to be equal to $|A(t)|$. Consequently, we can write (4.8) as

$$\begin{aligned} \varepsilon_p = \left(-\frac{2}{\nu}\right)^p A(t)^{-\alpha} \Bigg\{ &\frac{\sin \alpha\pi}{\pi} \int_1^\infty r^{-\alpha-1} h_p(-A(t)r) \exp\left[\frac{\nu A(t)}{2}\left(\frac{1}{r} - r\right)\right] dr \\ &- \frac{1}{2\pi} \int_{-\pi}^{\pi} \exp(i\nu A(t) \sin\theta) h_p(A(t)\, e^{i\theta})\, e^{-i\alpha\theta}\, d\theta \Bigg\}. \end{aligned} \tag{4.14}$$

By Laplace's method [13, Thm. 7.1, p. 81], the first integral is asymptotically equal to $h_p(-A(t))/\nu A(t)$; and by the method of stationary phase [13, Thm. 13.1, p. 101], the second integral is asymptotic to

$$-2i\sqrt{\frac{2\pi}{\nu A}}\, h_p(iA(t)) \sin\left(\nu A - \frac{\pi}{4} - \frac{\alpha\pi}{2}\right).$$

Therefore we conclude

$$\varepsilon_p = \left(\frac{2}{\nu}\right)^p A(t)^{-\alpha} h_p(iA(t)) O\left(\frac{1}{\sqrt{\nu A(t)}}\right). \tag{4.15}$$

(Note that the contribution from the first integral in (4.14) actually cancels with the endpoint contribution from the second integral there.) The result (4.11) now follows from (4.15), in view of the large-z behavior of $\tilde{J}_\alpha(z)$.

We next consider case (ii). Here $A(t)$ is purely imaginary and $iA(t)$ is negative. We shall also divide this case into two subcases: (ii)(a) $-\eta \leqq t < 0$, and (ii)(b) $-\infty < t < -\eta$, where $\eta > 0$ is chosen so that $|A(t)| < \pi/2$ for $-\eta \leqq t < 0$ (cf. (4.10)). Since the argument for case (ii)(a) is similar to that of case (i), it will be omitted. However, we point out that in this case $\nu A(t)$ is purely imaginary and positive, and hence the roles of Laplace's method and the method of stationary phase in case (i) must be reversed. In case (ii)(b), we choose the radius ρ of the circle in the loop integral (4.8) to be any fixed positive number less than $\pi/2$ and make the substitution $u = -iA(t)v$. The result is

(4.16)

$$\varepsilon_p = \left(-\frac{2}{\nu}\right)^p (-iA(t))^{-\alpha} \frac{1}{2\pi i} \int_{-\infty}^{(0+)} v^{-\alpha-1} h_p(-iA(t)v) \exp\left\{-\frac{i\nu A(t)}{2}\left(v + \frac{1}{v}\right)\right\} dv.$$

Observe that in our present case, $iA(t)$ is large and negative, and that the saddle points are at $v = \pm 1$. By using Cauchy's theorem, we may make the circular portion of the contour in (4.16) have radius 1. An argument similar to that leading to (4.14) and (4.15), or a straightforward application of the saddle-point method [3, § 36], then gives

$$\varepsilon_p \sim \left(-\frac{2}{\nu}\right)^p [-iA(t)]^{-\alpha} \frac{1}{2\pi i} h_p(-iA(t)) \exp\{-i\nu A(t)\} \sqrt{\frac{-2\pi}{i\nu A(t)}}. \tag{4.17}$$

Note that $h_p(-iA(t))$ can be expressed in terms of the coefficients α_{2k} and β_{2k+1}, depending on whether p is even or odd. In view of the large-z behavior of $\tilde{J}_\alpha(z)$, z being purely imaginary and positive, the result in (4.11) now follows immediately from (4.17). This completes our proof of (4.11).

The leading coefficient α_0 in (4.7) can be calculated as follows. Since $\alpha_0 = h_0(iA) = h(iA)$, from (2.9) we have

$$\alpha_0 = \left[\frac{\sinh z(u)}{u}\right]^{-\alpha-1} \left.\frac{dz}{du}\right|_{u=iA}.$$

Since $u = iA$ corresponds to $z = z_+$ and $\sinh^2 z_+ = -t$, differentiating (1.6) twice with respect to u, we obtain

$$\left(\frac{dz}{du}\right)^2\Bigg|_{u=iA} = \frac{i \sinh^3 z_+}{tA \cosh z_+}.$$

Thus

$$\alpha_0 = \left(\frac{A}{\sqrt{t}}\right)^{\alpha+1}\left(\frac{t}{1-t}\right)^{1/4} A^{-1/2} \quad \text{if } 0 \leqq t < 1$$
$$= \left(\frac{|A|}{\sqrt{-t}}\right)^{\alpha+1}\left(\frac{-t}{1-t}\right)^{1/4} |A|^{-1/2} \quad \text{if } t < 0. \tag{4.18}$$

The second coefficient β_1 in (4.7) can also be computed, but the work is overwhelming. After a great deal of computation, we find that for $0 \leqq t < 1$

$$\beta_1 = \frac{\alpha_0 A}{2}\left[\frac{1-4\alpha^2}{8} A^{-1} + \frac{\sqrt{1-t}}{\sqrt{t}}\left\{\frac{4\alpha^2-1}{8} + \frac{1}{4}\frac{t}{1-t} + \frac{5}{24}\left(\frac{t}{1-t}\right)^2\right\}\right] \tag{4.19}$$

and for $t < 0$

$$\beta_1 = \frac{\alpha_0 A}{2}\left[\frac{1-4\alpha^2}{8} A^{-1} - i\frac{\sqrt{1-t}}{\sqrt{-t}}\left\{\frac{4\alpha^2-1}{8} + \frac{1}{4}\frac{t}{1-t} + \frac{5}{24}\left(\frac{t}{1-t}\right)^2\right\}\right], \tag{4.20}$$

where A is given by (2.7). Note that (4.20) can be formally obtained from (4.19) by simply replacing $\sqrt{t}$ by $i\sqrt{-t}$.

By using a matching procedure, it is possible to obtain recursive formulas for the coefficients α_n and β_n. This procedure consists of re-expanding the Bessel functions in (4.7) and comparing the results with expansions obtained by using the ordinary steepest descent method for t bounded away from zero. For some illustrations of this procedure, see [13, Chap. 11, Ex. 7.4 and Chap. 12, Ex. 5.2].

5. Airy function expansion. We now consider the case $b \leqq t < \infty$, where $0 < b < 1$. Our starting point is the integral representation [5, p. 190]

$$e^{-x/2} L_n^{(\alpha)}(x) = \frac{(-1)^n}{2^\alpha} \cdot \frac{1}{2\pi i} \int^{(1+)} e^{-xz/2}\left(\frac{1+z}{1-z}\right)^{\nu/4} (1-z^2)^{(\alpha-1)/2}\, dz, \tag{5.1}$$

where, as in (2.3), $\nu = 4n + 2\alpha + 2$. The path of integration encircles $z = 1$ in the positive direction, and closes at $\operatorname{Re} z = +\infty$, $|\operatorname{Im} z| = \text{constant}$. With $x = \nu t$, (5.1) can be written as

$$e^{-\nu t/2} L_n^{(\alpha)}(\nu t) = \frac{(-1)^n}{2^\alpha} \cdot \frac{1}{2\pi i} \int^{(1+)} e^{\nu f(z,\, t)} (1-z^2)^{(\alpha-1)/2}\, dz, \tag{5.2}$$

where

$$f(z, t) = \frac{1}{4} \ln \frac{1+z}{1-z} - \frac{1}{2} zt. \tag{5.3}$$

The saddle points of $f(z, t)$ are located at

$$z_+ = \sqrt{1-1/t} \quad \text{and} \quad z_- = -\sqrt{1-1/t}$$

if $t > 1$, and at

$$z_+ = i\sqrt{1/t-1} \quad \text{and} \quad z_- = -i\sqrt{1/t-1}$$

if $0 < t \leqq 1$. As $t \to 1$, the saddle points z_+ and z_- coalesce at $z = 0$. This suggests the use of the cubic transformation (1.2). Since $f(z, t)$ in (5.3) is an odd function, we set

$$\frac{1}{4} \ln \frac{1+z}{1-z} - \frac{1}{2} zt = \frac{u^3}{3} - B^2(t) u. \tag{5.4}$$

The coefficient $B(t)$ is to be chosen so that $z(u)$ is an analytic function of u. Upon differentiating (5.4) with respect to u and making the correspondence $u=+B(t)$ with $z=z_+$ and $u=-B(t)$ with $z=z_-$, we find

$$\begin{aligned} B(t) &= i[3\beta(t)/2]^{1/3}, \qquad 0<t\leqq 1, \\ &= [3\gamma(t)/2]^{1/3}, \qquad t>1, \end{aligned} \tag{5.5}$$

where

$$\begin{aligned} \beta(t) &= \tfrac{1}{2}[\cos^{-1} t^{1/2} - \sqrt{t-t^2}], \\ \gamma(t) &= \tfrac{1}{2}[(t^2-t)^{1/2} - \cosh^{-1} t^{1/2}]. \end{aligned} \tag{5.6}$$

Note that our function $B(t)$ and Erdélyi's $\phi(t)$ are related via the identity $B^2(t)=-\phi(t)$.

The mapping between z and u is most easily constructed by introducing an intermediate variable Z, defined by

$$\frac{1}{4}\ln\frac{1+z}{1-z} - \frac{1}{2}zt = Z = \frac{u^3}{3} - B^2(t)u. \tag{5.7}$$

We first consider the case $t>1$. The first quadrant of the z-plane is depicted in Fig. 4. Its image in the Z-plane is shown in Fig. 5. When z describes the indented boundary $ABCC'DEFA$ once, the image point Z also describes the corresponding boundary once. Here we again consider the line segments AB and BC being distinct parts of the boundary. Hence, the function $\xi(z)=\frac{1}{4}\ln((1+z)/(1-z))-\frac{1}{2}zt$ is one-to-one in that region (see [16, § 6.45]). The function $\eta(u)=\frac{1}{3}u^3-B^2(t)u$ is one-to-one in the shaded region $BCC'DEB$ in Fig. 6. This function has also been studied by Copson [3, p. 110–113]. The parametric equation of the boundary curve BE in Fig. 6 is given by

$$s^2-3r^2+3B^2=0 \qquad (s>0,\ r>0), \tag{5.8}$$

where $s=\operatorname{Im} u$ and $r=\operatorname{Re} u$. The transformation $z\leftrightarrow u$ is obtained by composing $\xi^{-1}: Z\to z$ and $\eta: u\to Z$. Since $z\leftrightarrow Z$ and $u\leftrightarrow Z$ are both one-to-one in the region $BCC'DEB$, so is $z\leftrightarrow u$. The mapping of the fourth quadrant in the z-plane can be discussed in the same manner, and the final result is obvious by symmetry.

The mappings $z\leftrightarrow Z$ and $Z\leftrightarrow u$, when $0<t<1$, can be constructed in a similar manner; they are illustrated in Figs. 4′, 5′, and 6′.

We now return to the integral (5.2). With the transformation (5.4) this integral becomes

$$e^{-\nu t/2}L_n^{(\alpha)}(\nu t) = \frac{(-1)^n}{2^\alpha}\cdot\frac{1}{2\pi i}\int_{\mathfrak{L}} h(u)\exp\left\{\nu\left(\frac{u^3}{3}-B^2(t)u\right)\right\}du, \tag{5.9}$$

where

$$h(u) = [1-z^2(u)]^{(\alpha-1)/2}\frac{dz}{du} \tag{5.10}$$

and $\mathfrak{L}$ is the branch of the hyperbolic curve in the right half-plane, half of which is given by (5.8). Note that (5.9) is first established separately under the conditions $t>1$ and $0<t<1$, and then extended to $t=0$ by continuity.

To derive the asymptotic expansion of the integral in (5.9), we apply the integration-by-parts technique introduced by Bleistein [1]. First, we write

$$h(u) = h_0(u) = \alpha_0 + \beta_0 u + (u^2 - B^2(t))g_0(u), \tag{5.11}$$

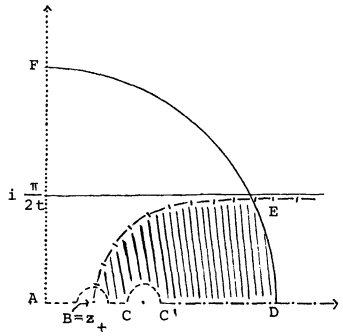

FIG. 4. *z-plane.*

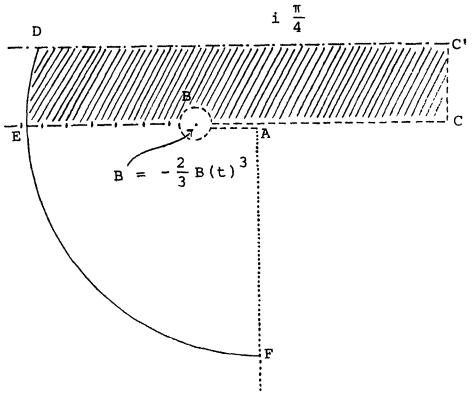

FIG. 5. *Z-plane.*

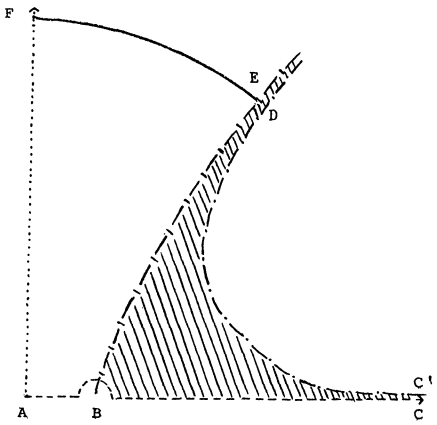

FIG. 6. *u-plane.*

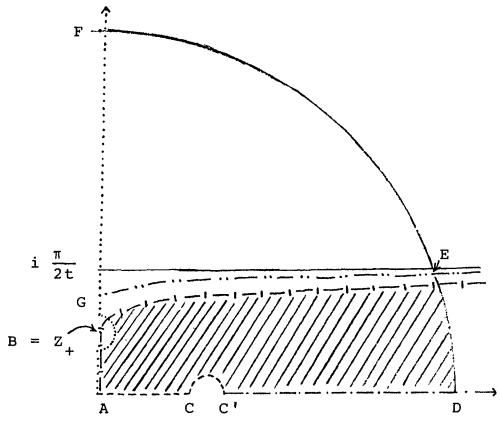

FIG. 4'. *z-plane* $(0<t<1)$.

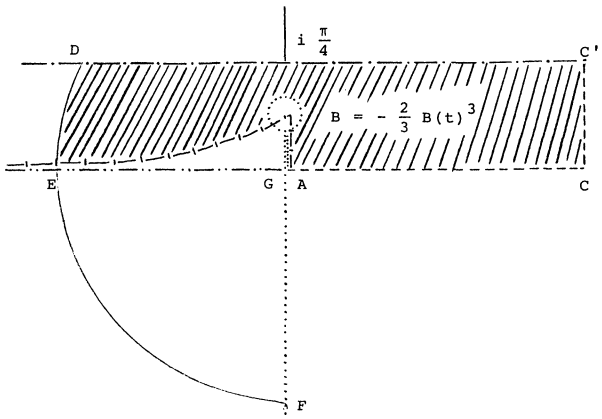

FIG. 5'. *Z-plane* $(0<t<1)$.

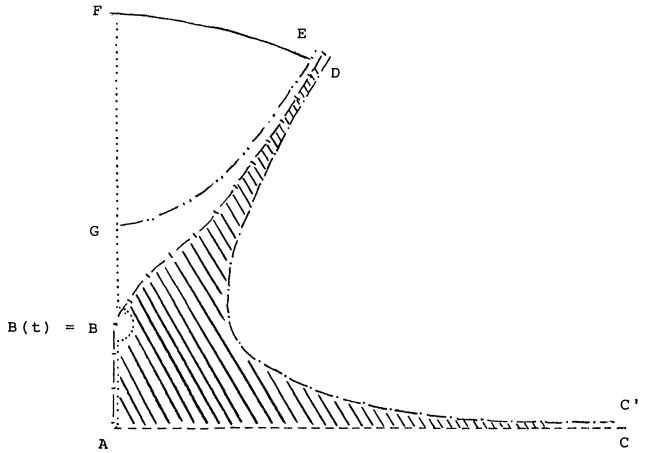

FIG. 6'. *u-plane* $(0<t<1)$.

where α_0, β_0, and $g_0(u)$ are to be determined. From (5.4), it is easily seen that $z(u)$ is an odd function of u. Hence, $h(u)$ is an even function of u, and $h(B)=h(-B)$. From this and (5.11), it follows that $\beta_0=0$, $\alpha_0=h_0(B)$, and

$$g_0(u)=\frac{h_0(u)-h_0(B)}{u^2-B^2}.$$

Thus, $g_0(u)$ is analytic in a neighborhood of $u=B$, and consequently analytic in the domain of $h_0(u)$. We now substitute (5.11) in (5.9), and express the first integral in terms of the Airy function. The second integral can be integrated by parts; the integrated term vanishes, since $g_0(u)$ has at most algebraic growth at infinity. The final result is

$$\begin{aligned}(-1)^n 2^\alpha e^{-\nu t/2} L_n^{(\alpha)}(\nu t) &= \mathrm{Ai}(\nu^{2/3}B^2)\frac{\alpha_0}{\nu^{1/3}} \\ &\quad -\left(\frac{1}{\nu}\right)\frac{1}{2\pi i}\int_{\mathfrak{L}} g_0'(u)\exp\left\{\nu\left(\frac{u^3}{3}-B^2u\right)\right\}du.\end{aligned} \tag{5.12}$$

The above procedure can be repeated, and proceeding in this manner we obtain

$$\begin{aligned}(-1)^n 2^\alpha e^{-\nu t/2} L_n^{(\alpha)}(\nu t) &= \mathrm{Ai}\,(\nu^{2/3}B^2)\sum_{k=0}^{[(p-1)/2]}\alpha_{2k}\nu^{-2k-1/3} \\ &\quad -\mathrm{Ai}'\,(\nu^{2/3}B^2)\sum_{k=0}^{[p/2]-1}\beta_{2k+1}\nu^{-2k-5/3}+\varepsilon_p,\end{aligned} \tag{5.13}$$

where we define inductively, for $m=0, 1, 2, \cdots$,

$$h_m(u)=\alpha_m+\beta_m u+(u^2-B^2)g_m(u), \qquad h_{m+1}(u)=g_m'(u). \tag{5.14}$$

It can be shown that for $n\geqq 0$, h_{2n} and g_{2n} are even analytic functions, and that h_{2n+1} and g_{2n+1} are odd analytic functions. Consequently,

$$\begin{aligned}&\alpha_{2n}=h_{2n}(B), \qquad \alpha_{2n+1}=0,\\ &\beta_{2n}=0, \qquad \beta_{2n+1}=h_{2n+1}(B)/B,\end{aligned} \tag{5.15}$$

and, for each n, both α_n and β_n are continuous in t for $0<t<\infty$. The remainder ε_p is explicitly given by

$$\varepsilon_p=\frac{1}{\nu^p}\cdot\frac{1}{2\pi i}\int_{\mathfrak{L}} h_p(u)\exp\left\{\nu\left(\frac{u^3}{3}-B^2u\right)\right\}du. \tag{5.16}$$

To estimate ε_p, we introduce the auxiliary functions

$$\tilde{\mathrm{Ai}}\,(z)=\begin{cases}\mathrm{Ai}\,(z) & \text{if } z\geqq 0,\\ [\mathrm{Ai}^2\,(z)+\mathrm{Bi}^2\,(z)]^{1/2} & \text{if } z<0,\end{cases} \tag{5.17}$$

and

$$\tilde{\mathrm{Ai}}'\,(z)=\begin{cases}\mathrm{Ai}'\,(z) & \text{if } z\geqq 0,\\ [\mathrm{Ai}'^2\,(z)+\mathrm{Bi}'^2\,(z)]^{1/2} & \text{if } z<0.\end{cases} \tag{5.18}$$

Furthermore, we define

$$\tilde{\alpha}_p(t)=\begin{cases}1 & \text{if } 0<t<\xi,\\ |\alpha_p| & \text{if } t>\xi,\end{cases}$$

and define $\tilde{\beta}_p(t)$ in a similar manner, where α_p and β_p are the coefficients in the expansion (5.13), and ξ is a positive number. The behavior of $\tilde{\mathrm{Ai}}\,(z)$ and $\tilde{\mathrm{Ai}}'\,(z)$ mimics

the behavior of $\mathrm{Ai}(z)$ and $\mathrm{Ai}'(z)$, respectively. Moreover, $\tilde{\alpha}_p$ and $\tilde{\beta}_p$ have the same behavior as α_p and β_p, respectively. For large values of ν and for $0<b\leqq t<\infty$, it can be shown that

$$|\varepsilon_p|\leqq\frac{N_p}{\nu^{p+2/3}}|\tilde{\beta}_p(t)||\tilde{\mathrm{A}}\mathrm{i}'(\nu^{2/3}B^2)| \quad \text{if } p \text{ is odd,} \tag{5.19}$$

and that

$$|\varepsilon_p|\leqq\frac{M_p}{\nu^{p+1/3}}|\tilde{\alpha}_p(t)||\tilde{\mathrm{A}}\mathrm{i}(\nu^{2/3}B^2)| \quad \text{if } p \text{ is even} \tag{5.20}$$

(for similar estimations, see [1] and [2]). Alternative estimates for ε_p could be expressed in terms of the auxiliary functions $E(x)$, $M(x)$, and $N(x)$ given in [13, Chap. 11, § 2] for a real argument or their analogues given in [13, Chap. 11, § 8] for a complex argument.

We conclude this paper with an evaluation of the leading coefficient α_0 in (5.13). From (5.15) and (5.10), it follows that

$$\alpha_0=[1-z^2(u)]^{(\alpha-1)/2}\left.\frac{dz}{du}\right|_{u=B}. \tag{5.21}$$

Since $u=B$ corresponds to $z=z_+$ and $1-z_+^2=1/t$, upon differentiating (5.4) twice, we obtain

$$\left.\left(\frac{dz}{du}\right)^2\right|_{u=B}=\frac{2B}{z_+t^2},$$

which in turn gives

$$\begin{aligned}\alpha_0&=t^{(1-\alpha)/2}\frac{\sqrt{2B}}{(t-1)^{1/4}t^{3/4}} \quad \text{if } t>1\\ &=t^{(1-\alpha)/2}\frac{\sqrt{2|B|}}{(1-t)^{1/4}t^{3/4}} \quad \text{if } 0<t<1.\end{aligned} \tag{5.22}$$

For completeness, we also record the formula

$$\beta_1=\frac{\alpha_0}{2B}\left[\frac{5}{24}B^{-3}-\frac{3}{4}\frac{\sqrt{t-1}}{\sqrt{t}}+\frac{1}{2}\frac{\sqrt{t}}{\sqrt{t-1}}-\frac{5}{12}\frac{t^{3/2}}{(t-1)^{3/2}}-(\alpha^2-1)\frac{\sqrt{t-1}}{\sqrt{t}}\right], \tag{5.23}$$

if $t>1$. A corresponding formula exists for the case $0<t<1$, and can be obtained formally from (5.23) by simply replacing $\sqrt{t-1}$ by $i\sqrt{1-t}$. To calculate the coefficients of higher terms, we can again use the matching procedure mentioned at the end of § 4.

6. Conclusion. In this paper two uniform asymptotic expansions are obtained for the Laguerre polynomial $L_n^{(\alpha)}(x)$. One is in terms of Bessel functions and holds for $-\infty<x\leqq a\nu$, while the other is in terms of Airy's integral and holds for $b\nu\leqq x<\infty$, where $0<b<a<1$ and $\nu=4n+2\alpha+2$. The leading terms of these expansions agree with the two asymptotic forms given by Erdélyi [4] using the theory of differential equations. Our method is based on two integral representations of the Laguerre polynomial.

From Olver's theory [13, Chaps. 11 and 12], it is evident that the two uniform asymptotic expansions for the Laguerre polynomial given in this paper can also be obtained from differential equation theory. However, there are functions which have relatively simple integral representations but do not satisfy any differential equations.

Thus it is desirable to have a method using integral representations as well as one using differential equation theory to derive uniform asymptotic expansions. The method presented in this paper is quite general, although we have considered only the case of Laguerre polynomials. We chose to do it this way, since in this case we could compare our results with those given by Erdélyi.

For both Bessel-function and Airy-function expansions, we have provided explicit expressions for the remainder terms. Despite this fact, only order estimates have been established for them. Our method does not seem to lend itself to the construction of numerical error bounds because of the complicated nature of the transformations involved. Therefore the integral-theoretic method is not as complete as the corresponding theory for differential equations [13, Chaps. 11 and 12], and error analysis for uniform asymptotic expansions of integrals obtained by the rational and the cubic transformations used in this paper remains a difficult problem yet to be resolved.

Acknowledgments. We are grateful to Professor F. W. J. Olver for making several helpful suggestions on an earlier version of the paper, and would also like to thank the referee for pointing out several shortcomings in the original version.

AN ANALYTIC CONTINUATION FORMULA FOR THE GENERALIZED HYPERGEOMETRIC FUNCTION*

WOLFGANG BÜHRING†

Abstract. For $p=1,2,3,\cdots$, the hypergeometric function ${}_{p+1}F_p(z)$ is expressed in terms of power series in the variable $1/(z-z_0)$ that converge for $|z-z_0|>\max(|z_0|,|z_0-1|)$ where z_0 is any complex number.

Key words. special functions, hypergeometric functions, hypergeometric series, continuation formulas, analytic continuation

AMS(MOS) subject classifications. 33A30, 30B40

1. Introduction. Some of the analogues to the well-known continuation formulas of the Gaussian hypergeometric function ${}_2F_1(z)$ are considerably more complicated or are not known at all for the generalized hypergeometric functions ${}_{p+1}F_p(z)$ with $p=2,3,\cdots$. The coefficients in the expansion of the ${}_3F_2(z)$ in powers of $z-1$, for instance, although now known in detail [3], cannot be generalized in a simple way, but become more and more complicated as p increases. In contrast to this behavior, the expansion of ${}_3F_2(z)$ in powers of $1/(z-1)$, or more generally $1/(z-z_0)$ with any complex number z_0, is of such a relatively simple type that it can easily be written down for any p. This will be shown in the present paper.

2. The continuation formula. Our starting point is the continuation formula [4], [5]

$$\left(\prod_{j=1}^{p}\Gamma(b_j)\right)^{-1}{}_{p+1}F_p\left(\begin{matrix}a_1,a_2,\cdots,a_{p+1}\\ b_1,b_2,\cdots,b_p\end{matrix}\,\middle|\,z\right)=\sum_{k=1}^{p+1}C_k y_k(z), \tag{1}$$

with known connecting constants C_k to be displayed below in (9) and

$$y_k(z)=(-z)^{-a_k}{}_{p+2}F_{p+1}\left(\begin{matrix}1,a_k,1+a_k-b_1,1+a_k-b_2,\cdots,1+a_k-b_p\\ 1+a_k-a_1,1+a_k-a_2,\cdots,1+a_k-a_{p+1}\end{matrix}\,\middle|\,\frac{1}{z}\right), \tag{2}$$

$$|\arg(-z)|<\pi.$$

Here the ${}_{p+2}F_{p+1}$ is really a ${}_{p+1}F_p$ since one of its denominator parameters is always equal to 1. As they stand, the formulas are valid provided that none of the differences between any two numerator parameters a_j is equal to an integer.

In a similar way as in [2], we now may observe that, when $|z|$ is sufficiently large, the series representation of (2) may be re-expanded in powers of $1/(z-z_0)$ for any fixed z_0 by means of

$$\begin{aligned}(-z)^{-a_k-n}&=\left\{(z_0-z)\left(1+\frac{z_0}{z-z_0}\right)\right\}^{-a_k-n}\\ &=(z_0-z)^{-a_k-n}\sum_{j=0}^{\infty}\frac{(a_k+n)_j}{j!}\left(\frac{-z_0}{z-z_0}\right)^j.\end{aligned} \tag{3}$$

* Received by the editors May 18, 1987; accepted for publication August 17, 1987.
† Physikalisches Institut, Universität Heidelberg, D-6900 Heidelberg, Federal Republic of Germany.

Collecting the terms with equal powers of $1/(z-z_0)$ we then obtain

$$y_k(z) = (z_0 - z)^{-a_k} \sum_{n=0}^{\infty} D_n(a_k, z_0)(z - z_0)^{-n} \tag{4}$$

where

$$D_n(a_k, z_0) = \sum_{j=0}^{n} \frac{(1)_j (a_k)_j \prod_{m=1}^{p} (1 + a_k - b_m)_j}{j! \prod_{m=1}^{p+1} (1 + a_k - a_m)_j} \frac{(a_k + j)_{n-j}}{(n-j)!} (-z_0)^{n-j} \tag{5}$$

or, in view of

$$\frac{(a_k + j)_{n-j}}{(n-j)!} = (-1)^j \frac{(a_k)_n (-n)_j}{(a_k)_j n!}, \tag{6}$$

$$D_n(a_k, z_0) = \frac{(a_k)_n}{n!} (-z_0)^n {}_{p+2}F_{p+1}\left(\begin{matrix} 1, -n, 1 + a_k - b_1, 1 + a_k - b_2, \cdots, 1 + a_k - b_p \\ 1 + a_k - a_1, 1 + a_k - a_2, \cdots, 1 + a_k - a_{p+1} \end{matrix} \middle| \frac{1}{z_0} \right). \tag{7}$$

Here again the ${}_{p+2}F_{p+1}$ is really a ${}_{p+1}F_p$ since one of its denominator parameters is always equal to 1. Turning the (finite) series around [1], we may obtain a different representation of (7) as displayed below in (10). The convergence domain of the series (4) is determined by the finite singular points 0 or 1 of the differential equation of which the ${}_{p+1}F_p(z)$ and the $y_k(z)$ are solutions. Thus we have proved the following theorem.

THEOREM 1. *If no two of the numerator parameters a_j differ by an integer, we have for $|\arg(z_0 - z)| < \pi$ the continuation formula*

$$\left\{ \prod_{j=1}^{p} \Gamma(b_j) \right\}^{-1} {}_{p+1}F_p\left(\begin{matrix} a_1, a_2, \cdots, a_{p+1} \\ b_1, b_2, \cdots, b_p \end{matrix} \middle| z \right) = \sum_{k=1}^{p+1} C_k (z_0 - z)^{-a_k} \sum_{n=0}^{\infty} D_n(a_k, z_0)(z - z_0)^{-n} \tag{8}$$

where the connecting constants are

$$C_k = \frac{\prod_{j=1, j \neq k}^{p+1} \Gamma(a_j - a_k)}{\left(\prod_{j=1, j \neq k}^{p+1} \Gamma(a_j)\right)\left(\prod_{j=1}^{p} \Gamma(b_j - a_k)\right)} \tag{9}$$

and the power series with the coefficients

$$D_n(a_k, z_0) = \frac{(a_k)_n \prod_{j=1}^{p} (1 + a_k - b_j)_n}{\prod_{j=1}^{p+1} (1 + a_k - a_j)_n} {}_{p+1}F_p\left(\begin{matrix} a_1 - a_k - n, a_2 - a_k - n, \cdots, a_{p+1} - a_k - n \\ b_1 - a_k - n, b_2 - a_k - n, \cdots, b_p - a_k - n \end{matrix} \middle| z_0 \right) \tag{10}$$

converge outside the circle $|z - z_0| = \max(|z_0|, |z_0 - 1|)$.

Since one of the numerator parameters of the ${}_{p+1}F_p$ in (10) is always equal to $-n$, this ${}_{p+1}F_p$ is a polynomial in z_0 of degree n, so that the continuation formula (8) is relatively simple. With the choice $z_0 = 1$ it gives the desired generalization of one of the well-known continuation formulas of the Gaussian hypergeometric function ${}_2F_1(z)$.

Also of interest is the choice $z_0 = \frac{1}{2}$ since in this case the convergence domain, $|z - \frac{1}{2}| > \frac{1}{2}$, of the series on the right of (8) is significantly larger than it would be with $z_0 = 0$ or $z_0 = 1$ and contains in its interior the two exceptional points $z = \frac{1}{2}(1 \pm i\sqrt{3}) = \exp(\pm i\pi/3)$, which before were not accessible by power series. From this point of view, the present paper generalizes some results of [2].

ADDENDUM: Oscillation Theorems for Nonlinear Second-Order Differential Equations with a Nonlinear Damping Term*

S. R. GRACE†, B. S. LALLI‡, AND C. C. YEH§

This is an addendum to our previous paper [1]. For related results, we refer to [2], [3]. Consider the following second-order nonlinear differential equation

$$(E) \qquad (a(t)\psi(x(t))\dot{x}(t))^{\cdot} + q(t)f(x(t)) = 0 \qquad \left(\cdot = \frac{d}{dt}\right)$$

where

(a) $a \in C^1[0, \infty)$ and $a(t) > 0$ for $t \geqq 0$;

(b) $\psi \in C(-\infty, \infty)$, $\psi(x) > 0$ for all $x \in R$;

(c) $f \in C(-\infty, \infty) \cap C^1(-\infty, 0) \cap C^1(0, \infty)$, $xf(x) > 0$ for $x \neq 0$, and there exists a positive constant k such that $f'(x) \geqq k\psi(x) > 0$ for $x \neq 0$;

(d) $q \in C[0, \infty)$.

The following generalizes a theorem of Kusano, Onose, and Tobe [2].

THEOREM. *Suppose that there exists a function $\rho \in C^2([0, \infty), (0, \infty))$ with $\dot{\rho}(t) \geqq 0$ such that*

$$(1) \qquad \int^{\infty} \rho(t)q(t)\, dt = \infty,$$

$$(2) \qquad \int^{\infty} \frac{dt}{\rho(t)a(t)} = \infty,$$

$$(3) \qquad \int^{\infty} \frac{a(t)(\dot{\rho}(t))^2}{\rho(t)}\, dt < \infty,$$

$$(4) \qquad \int_{\varepsilon}^{\infty} \frac{\psi(u)}{f(u)}\, du < \infty \quad \text{and} \quad \int_{-\varepsilon}^{-\infty} \frac{\psi(u)}{f(u)}\, du < \infty \quad \text{for every } \varepsilon > 0.$$

Then all solutions of (E) *are oscillatory.*

Proof. Let $x(t)$ be a nonoscillatory solution of (E), say $x(t) > 0$ for $t \geqq t_1 \geqq 0$. Let

$$w(t) := \frac{a(t)\psi(x(t))\dot{x}(t)}{f(x(t))}\rho(t).$$

Then $w(t)$ satisfies

$$\dot{w}(t) = -\rho(t)q(t) + \frac{a(t)\dot{\rho}(t)\psi(x(t))\dot{x}(t)}{f(x(t))} - \frac{a(t)\rho(t)\psi(x(t))f'(x(t))(\dot{x}(t))^2}{(f(x(t)))^2}.$$

* Received by the editors August 3, 1987; accepted for publication December 18, 1987. SIAM J. Math. Anal., 15 (1984), pp. 1082–1093.

§ Department of Mathematics, Central University, Chung-Li, Taiwan, Republic of China.

Thus

$$
\begin{aligned}
w(t) \leqq w(t_1) &- \int_{t_1}^{t} \rho(s)q(s)\,ds + \int_{t_1}^{t} \frac{a(s)\dot{\rho}(s)\psi(x(s))\dot{x}(s)}{f(x(s))}\,ds \\
&- \int_{t_1}^{t} a(s)\rho(s)f'(x(s))\psi(x(s))\left(\frac{\dot{x}(s)}{f(x(s))}\right)^2 ds.
\end{aligned} \tag{5}
$$

It follows from the Schwarz inequality that

$$
\begin{aligned}
&\left|\int_{t_1}^{t} \frac{a(s)\dot{\rho}(s)\psi(x(s))\dot{x}(s)}{f(x(s))}\,ds\right| \\
&\quad \leqq \left(\int_{t_1}^{t} \frac{a(s)(\dot{\rho}(s))^2}{\rho(s)}\right)^{1/2}\left(\int_{t_1}^{t} \frac{a(s)\rho(s)\psi^2(x(s))(\dot{x}(s))^2}{(f(x(s)))^2}\,ds\right)^{1/2} \\
&\quad \leqq K\left(\int_{t_1}^{t} \frac{a(s)\rho(s)\psi^2(x(s))(\dot{x}(s))^2}{(f(x(s)))^2}\,ds\right)^{1/2},
\end{aligned}
$$

where $K := (\int_{t_1}^{\infty} (a(t)(\dot{\rho}(t))^2/\rho(t))\,dt)^{1/2}$ is finite because condition (3) holds. Thus, by (c), we have

$$
\begin{aligned}
w(t) \leqq w(t_1) &- \int_{t_1}^{t} \rho(s)q(s)\,ds + K\left(\int_{t_1}^{t} \frac{a(s)\rho(s)\psi^2(x(s))(\dot{x}(s))^2}{(f(x(s)))^2}\,ds\right)^{1/2} \\
&- k\int_{t_1}^{t} a(s)\rho(s)\psi^2(x(s))\left(\frac{\dot{x}(s)}{f(x(s))}\right)^2 ds.
\end{aligned}
$$

Clearly, the sum of the last two integrals on the right-hand side of the above inequality remains bounded above as $t \to \infty$. Thus, by (1), we have

$$
\lim_{t\to\infty} \frac{\rho(t)a(t)\psi(x(t))\dot{x}(t)}{f(x(t))} = -\infty.
$$

This means that there exists a $t_2 \geqq t_1$ such that

$$
\dot{x}(t) < 0 \quad \text{for } t \geqq t_2.
$$

This and (5) imply that there exists a $t_3 \geqq t_2$ such that

$$
1 + \int_{t_3}^{t} a(s)\rho(s)f'(x(s))\psi(x(s))\left(\frac{\dot{x}(s)}{f(x(s))}\right)^2 ds \leqq \frac{a(t)\rho(t)\psi(x(t))(-\dot{x}(t))}{f(x(t))}.
$$

The rest of the proof is similar to that of Theorem 7 in [1], and is omitted.

Remark. From condition (4), we see that our theorem and some theorems in [2] are strictly nonlinear oscillatory results for equation (E) with $\psi(x) = 1$, that is, these theorems cannot apply to equation $(a(t)\dot{x}(t))^{\cdot} + q(t)x(t) = 0$.

ERRATA: Homoclinic Orbits in Slowly Varying Oscillators*

STEPHEN WIGGINS† AND PHILIP HOLMES‡

Equation (3.14) is incorrect. The reason for this is that the perturbed orbits through the points $q^s_\varepsilon(0,\theta)$, $q^u_\varepsilon(0,\theta)\in\Pi_o$ cannot be assumed to lie on the same z level at $\varepsilon=0$. Rather they may lie on z levels differing by $O(\varepsilon)$. Thus it is possible for $z^s_1(\infty,\theta)\neq z^u_1(-\infty,\theta)$ with $q^s_\varepsilon(\infty,\theta)=q^u_\varepsilon(-\infty,\theta)$; for more discussion of this point, see Wiggins [1988]. Therefore (3.16) for the Melnikov function should be

$$M(\theta)=\int_{-\infty}^{\infty}(\nabla H\cdot g)(q_0(t),t+\theta)\,dt-\frac{\partial H}{\partial z}(\gamma(z_0))\int_{-\infty}^{\infty}g_3(q_0(t),t+\theta)\,dt. \tag{1}$$

In Proposition 5.1, (1) should be omitted and (2) should be changed to

$$\lim_{\substack{m\to\infty\\ z\to z_0}} M^{m/1}=\frac{1}{\|f(q_0(-\theta))\|}\left[\int_{-\infty}^{\infty}(\nabla H\cdot g)(q_0(t),t+\theta)\,dt-\frac{\partial H}{\partial z}(\gamma(z_0))\int_{-\infty}^{\infty}g_3(q_0(t),t+\theta)\,dt\right]. \tag{2}$$

Concerning example (6.1), the orbits (6.9a) and (6.9b) should be on the level $z=(-\gamma/\alpha)\sqrt{1-(\gamma/\alpha)}$ and the corrected Melnikov functions in (6.13) and (6.14) are, respectively, given by

$$M=-4\delta\left[\frac{d}{3}+\frac{\gamma b}{\sqrt{2}\alpha}\left(\frac{\pi}{2}\pm\sin^{-1}\sqrt{\frac{2\alpha}{\gamma}}\,b\right)\right]+2\gamma\left[2d-2\sqrt{2}b\left(\frac{\pi}{2}\pm\sin^{-1}\sqrt{\frac{2\alpha}{\gamma}}\,b\right)\right]\mp 2\sqrt{2}\pi\beta\frac{\sinh\left[\frac{1}{d}\sin^{-1}\sqrt{\frac{\alpha}{\gamma}}\,d\right]}{\sinh\frac{\pi}{d}}\cos\theta, \tag{3}$$

$$M=-4\delta\left[\frac{d}{3}+\frac{\gamma b}{\sqrt{2}\alpha}\left(\frac{\pi}{2}\pm\sin^{-1}\sqrt{\frac{2\alpha}{\gamma}}\,b\right)\right]+2\gamma\left[2d-2\sqrt{2}b\left(\frac{\pi}{2}\pm\sin^{-1}\sqrt{\frac{2\alpha}{\gamma}}\,b\right)\right]\pm 2\sqrt{2}\pi\beta\frac{\sinh\left[\frac{1}{d}\sin^{-1}\sqrt{\frac{\alpha}{\gamma}}\,d\right]}{\sinh\frac{\pi}{d}}\cos\theta. \tag{4}$$

Figure 6 is qualitatively correct; however, the details are not right and the corrected version can be found in Wiggins [1988].

ERRATA: Restricted Quadratic Forms and Their Applications to Bifurcation and Stability in Constrained Variational Principles*

JOHN H. MADDOCKS†

The statement and proofs of Theorems 1 and 2 appearing in [1] are flawed. The blanket assumption that $\ker L$ is closed should be added to Hypotheses H1–H3, in which case $\mathscr{H} = \mathscr{R}(L) \oplus \ker L$, where $\mathscr{R}(L)$ denotes the range of L. Theorems 1 and 2 should then read:

THEOREM 1. *Let the subspaces $\mathscr{C}$, $L(\mathscr{C}^\perp)$, and $(\mathscr{C}^\perp \cap L^{-1}(\mathscr{C}))$ be closed, and let $\mathscr{C}^\perp \cap \mathscr{D}(L)$ be dense in $\mathscr{C}^\perp$. Then*

$$d^0(\mathscr{C}^\perp \cap \mathscr{D}) = \dim\{[\mathscr{C}^\perp \cap L^{-1}(\mathscr{C})] \backslash \ker L\}. \tag{2.3}$$

Remark. The hypotheses appear to be extremely restrictive, but they are valid in several important cases that arise in applications. In particular, $L(\mathscr{C}^\perp)$ is closed provided L is bounded away from zero on $(\ker L)^\perp = \mathscr{R}(L)$. Moreover, if L is bounded, $(\mathscr{C}^\perp \cap L^{-1}(\mathscr{C}))$ is closed whenever $\mathscr{C}$ is closed, and the condition involving $\mathscr{D}(L)$ is vacuous. When L is unbounded and only densely defined, the hypotheses are implied if $\mathscr{C}$ has finite dimension with $\mathscr{C} \subset \mathscr{D}(L)$.

Proof. Let $\mathscr{G}$ denote the subspace $(\mathscr{C}^\perp \cap L^{-1}(\mathscr{C})) \backslash \ker L$, and let $\mathfrak{M}$ be any maximal negative subspace of $\mathscr{C}^\perp \cap \mathscr{D}$. We shall prove that $\mathfrak{M} \oplus \mathscr{G}$ is a maximal nonpositive subspace of $\mathscr{C}^\perp \cap \mathscr{D}$. Equation (2.3) is a consequence of this fact because the sum of $\mathfrak{M}$ and $\mathfrak{G}$ is direct, and because

$$d^0(\mathscr{C}^\perp \cap \mathscr{D}) = \dim[\mathfrak{M} \oplus \mathscr{G}] - \dim \mathfrak{M}.$$

To see that the sum is direct note that any $x \in \mathscr{G}$ satisfies $x \in \mathscr{C}^\perp + \ker L$ and $Lx \in \mathscr{C}$. Consequently $Q(x)$ vanishes and therefore $x \notin \mathfrak{M}$. It is also clear that $\ker L \cap (\mathfrak{M} \oplus \mathscr{G}) = \{0\}$, and that $\mathfrak{M} \oplus \mathscr{G}$ is a nonpositive subspace.

It remains to prove that $\mathfrak{M} \oplus \mathscr{G}$ is maximal, that is, to demonstrate that

$$\text{If } x \in \mathscr{C}^\perp \cap \mathscr{D} \text{ is } L\text{-orthogonal to } \mathfrak{M} \oplus \mathscr{G}, \text{ and } x \notin \mathfrak{M} \oplus \mathscr{G} \oplus \ker L, \text{ then } \langle x, Lx \rangle > 0. \tag{2.4}$$

The maximality of $\mathfrak{M}$ as a negative subspace implies that any such x satisfies $\langle x, Lx \rangle \geqq 0$, so we obtain maximality of $\mathfrak{M} \oplus \mathscr{G}$ after reaching a contradiction on the assumption $\langle x, Lx \rangle = 0$. Because $(\mathscr{C}^\perp \cap L^{-1}(\mathscr{C}))$ is closed and is contained in $\mathscr{C}^\perp \cap \mathscr{D}$, any $x \in \mathscr{C}^\perp \cap \mathscr{D}$ can be decomposed as the sum

$$x = p + q, \quad \text{with } p \in \mathscr{C}^\perp \cap \mathscr{D} \cap [\mathscr{C}^\perp \cap L^{-1}(\mathscr{C})]^\perp \quad \text{and} \quad q \in [\mathscr{C}^\perp \cap L^{-1}(\mathscr{C})].$$

Moreover, $q \in \mathscr{G} \oplus \ker L$, so that

$$\text{if } x \notin \mathfrak{M} \oplus \mathscr{G} \oplus \ker L, \text{ then } p \notin \mathfrak{M} \oplus \mathscr{G} \oplus \ker L;$$

$$\text{if } x \text{ is } L\text{-orthogonal to } \mathfrak{M} \oplus \mathscr{G}, \text{ so is } p;$$

and, by choice of p and q,

$$\langle x, Lx \rangle = \langle p, Lp \rangle.$$

* Received by the editors January 6, 1988; accepted for publication January 11, 1988. SIAM J. Math. Anal., 16 (1985), pp. 47–68.

† Department of Mathematics, University of Maryland, College Park, Maryland 20742. The research of this author was supported by the Air Force Office of Scientific Research.

A contradiction on the assumption that there exists $p \neq 0 \in \mathscr{C}^{\perp} \cap \mathscr{D} \cap [\mathscr{C}^{\perp} \cap L^{-1}(\mathscr{C})]^{\perp}$ satisfying the hypotheses of (2.4) and $\langle p, Lp \rangle = 0$ is therefore sufficient to obtain the desired maximality.

The contradiction will be obtained from the construction of a vector that violates the maximality of the *negative* subspace $\mathfrak{M}$ of $\mathscr{C}^{\perp} \cap \mathscr{D}$. Because $\mathscr{C}^{\perp} \cap \mathscr{D}$ is dense in $\mathscr{C}^{\perp}$, a simple calculation shows that $L^{-1}(\mathscr{C}) = [L(\mathscr{C}^{\perp} \cap \mathscr{D})]^{\perp} \cap \mathscr{D}$. Consequently, because $\mathscr{C}$ and $L(\mathscr{C}^{\perp} \cap \mathscr{D})$ are closed,

$$(\mathscr{C}^{\perp} \cap L^{-1}(\mathscr{C}))^{\perp} = (\mathscr{C}^{\perp} \cap [L(\mathscr{C}^{\perp} \cap \mathscr{D})]^{\perp} \cap \mathscr{D})^{\perp} = (\mathscr{C}^{\perp} \cap [L(\mathscr{C}^{\perp} \cap \mathscr{D})]^{\perp})^{\perp}$$
$$= \mathscr{C} + L(\mathscr{C}^{\perp} \cap \mathscr{D}).$$

Thus, $p \in \mathscr{C}^{\perp} \cap \mathscr{D}$ can be represented as $p = u + Lv$ with $u \in \mathscr{C}$ and $v \in \mathscr{C}^{\perp} \cap \mathscr{D}$ with $Lv \neq 0$. Then a Gram-Schmidt procedure can be used to construct a vector $f = v - \sum_i \alpha_i u_i$ in $\mathscr{C}^{\perp} \cap \mathscr{D}$ that is L-orthogonal to $\mathfrak{M}$. Here $\{u_i, i = 1, \cdots, d^-(\mathscr{C}^{\perp} \cap \mathscr{D})\}$ is a mutually L-orthogonal basis of $\mathfrak{M}$ (the existence of which is guaranteed by Lemma 1), and $\alpha_i \in \mathfrak{R}$. Consequently, $\beta p + f \in \mathscr{C}^{\perp} \cap \mathscr{D}$ is L-orthogonal to $\mathfrak{M}$, for all $\beta \in \mathfrak{R}$. However, $Q(\beta p + f)$ can be expanded to obtain

$$\beta^2 \langle p, Lp \rangle + 2\beta \langle p, Lv \rangle - 2\beta \left\langle Lp, \sum_i \alpha_i u_i \right\rangle + \langle f, Lf \rangle. \tag{2.5}$$

By hypothesis, $\langle p, Lp \rangle = 0, \langle Lp, u_i \rangle = 0$, and, because $p \in \mathscr{C}^{\perp}$ with $u \in \mathscr{C}, \langle p, Ly \rangle = \langle p, u + Lv \rangle = \langle p, p \rangle$. Therefore (2.5) can be rewritten as $2\beta \langle p, p \rangle + \langle f, Lf \rangle$. Because $p \neq 0$, β can be chosen such that this last expression is negative, contradicting the maximality of $\mathfrak{M}$. □

The corrected statement of Theorem 2 is then:

THEOREM 2. *Under the hypotheses of Theorem* 1 *and the additional assumption that* $L^{-1}(\mathscr{C})$ *is closed,*

$$d^0(\mathscr{C}^{\perp} \cap \mathscr{D}) = \dim \{[\mathscr{C}^{\perp} \cap L^{-1}(\mathscr{C})] \backslash \ker L\} = d^0(L^{-1}(\mathscr{C})), \tag{2.6}$$

and

$$d^-(\mathscr{C}^{\perp} \cap \mathscr{D}) + d^-(L^{-1}(\mathscr{C})) + d^0(L^{-1}(\mathscr{C})) = \sigma^-. \tag{2.7}$$

Remark. If L is bounded, or $\mathscr{C}$ has finite dimension, $L^{-1}(\mathscr{C})$ is necessarily closed.

Proof. The proof requires only minor changes to that presented in [1]. First, the quantity $\cdots \cap (\ker L)^{\perp}$ should be replaced with $\cdots \backslash \ker L$ wherever it appears. Second, if $\mathscr{C} \not\subset \mathscr{R}(L)$, it is necessary to add elements of $\ker L$ to the vectors v constructed in (2.11) and (2.12) in order to guarantee that $v \in \mathscr{C}^{\perp}$. □

ITERATES OF MAPS WITH SYMMETRY*

PASCAL CHOSSAT† AND MARTIN GOLUBITSKY‡

Abstract. In this paper the elementary aspects of bifurcation of fixed points, period doubling, and Hopf bifurcation for iterates of equivariant mappings are discussed. The most interesting of these is an algebraic formulation of the hypotheses of Ruelle's theorem (D. Ruelle [1973], "Bifurcations in the presence of a symmetry group," *Arch. Rational Mech. Anal.*, 51, pp. 136–152) on Hopf bifurcation in the presence of symmetry.

In the last sections this result is used to show that Hopf bifurcation from standing waves in a system of ordinary differential equations with $O(2)$ symmetry can lead directly to motion on an invariant 3-torus; indeed, depending on the exact symmetry of the standing waves, one might expect to see three invariant 3-tori emanating from such a bifurcation. The unexpected third frequency comes from drift along the torus of standing waves whose existence is forced by the $O(2)$ symmetry.

Key words. symmetry, Hopf bifurcation, iterates of mappings

AMS (MOS) subject classifications. 58F14, 58F27, 34C35

Introduction. Symmetries change the types of bifurcation that may be expected in discrete dynamical systems. Typically, nonsymmetric systems generate unique branches of new solutions at points of bifurcation while symmetric systems generate multiple branches. Results of Vanderbauwhede [1980] and Golubitsky and Stewart [1985] on steady-state and Hopf bifurcation in continuous systems show that certain of these solution branches may be enumerated using only group theoretic techniques. The first task in this paper is the translation of these results to statements about bifurcation in the discrete dynamics of equivariant mappings. For further background, see Field [1980], [1986].

In § 1, we briefly describe the group theoretic results of Vanderbauwhede [1980] and Golubitsky and Stewart [1985]. In § 2, we apply Vanderbauwhede's result in a straightforward manner to enumerate certain branches of fixed points and branches of period two orbits for equivariant mappings. We also indicate how the simplest nontrivial symmetry ($\mathbb{Z}_2 = \{\pm 1\}$ acting on $\mathbb{R}$) may be expected to affect period doubling cascades and lead naturally to mergings of attractors. In § 3, we adapt the results of Golubitsky and Stewart [1985] to enumerate branches of invariant curves stemming from Hopf bifurcation of equivariant mappings. This adaptation leans heavily on nontrivial results of Ruelle [1973]. Our contribution is really only to observe that there is an algebraic formulation for Hopf bifurcation of equivariant maps that satisfies the hypotheses of Ruelle's theorem.

The second task in this paper is to enumerate the number and type of tori that are produced when a periodic solution to an equivariant system of ordinary differential equations (ODEs) loses stability by having Floquet multipliers cross the unit circle in the complex plane. For example, we show in § 4 that (under certain hypotheses) standing wave solutions to $O(2)$ symmetric systems generate (generically) three branches of 3-tori at such a bifurcation. The existence of this extra frequency comes

from the $O(2)$ symmetries and is based on observations of Iooss [1986] and Chossat [1986]. In § 5, we give a general setting for the example in § 4.

1. Background. Let $\Gamma \subset O(n)$ be a compact Lie group acting linearly on $\mathbb{R}^n$ and let $f:\mathbb{R}^n \to \mathbb{R}^n$ be a one-parameter family of smooth mapping commuting with Γ, i.e.,

$$f(\gamma x, \lambda) = \gamma f(x, \lambda). \tag{1.1}$$

The equivariant branching lemma of Vanderbauwhede [1980] and Cicogna [1981] gives a simple algebraic condition for determining the existence of branches of steady-state solutions to the system of ODEs

$$\dot{x} = f(x, \lambda).$$

We assume that Γ acts absolutely irreducibly on $\mathbb{R}^n$, that is, that the only linear maps on $\mathbb{R}^n$ that commute with Γ are scalar multiples of the identity. For a subgroup Σ, we define

$$\text{Fix}(\Sigma) = \{y \in \mathbb{R}^n : \sigma y = y \quad \forall \sigma \in \Sigma\}. \tag{1.2}$$

Applying the chain rule to (1.1) implies that

$$(df)_{0,\lambda}\gamma = \gamma(df)_{0,\lambda}.$$

Absolute irreducibility then implies that

$$(df)_{0,\lambda} = c(\lambda)I. \tag{1.3}$$

Also observe that

$$f: \text{Fix}(\Sigma) \times \mathbb{R} \to \text{Fix}(\Sigma) \tag{1.4}$$

since $\sigma f(y, \lambda) = f(\sigma y, \lambda) = f(y, \lambda)$ for all $\sigma \in \Sigma$, $y \in \text{Fix}(\Sigma)$. In particular, irreducibility implies $\text{Fix}(\Gamma) = \{0\}$, and hence by (1.4)

$$f(0, \lambda) = 0.$$

Thus, there is a "trivial" solution at $x = 0$.

EQUIVARIANT BRANCHING LEMMA. *Let $\Sigma \subset \Gamma$ be a subgroup. Assume that $c(0) = 0$, $c'(0) \neq 0$, and $\dim \text{Fix}(\Sigma) = 1$. Then there exists a unique (nontrivial) branch of small amplitude steady states for $f|(\text{Fix}(\Sigma) \times \mathbb{R}) = 0$.*

See Ihrig and Golubitsky [1984], Golubitsky, Swift, and Knobloch [1984], and Golubitsky, Stewart, and Schaeffer [1988] for applications of this result.

There is a similar result regarding Hopf bifurcation in symmetric systems. Here we assume that the system $\dot{x} = f(x, \lambda)$ is on the center manifold. In particular, we assume that $x \in \mathbb{R}^{2n}$ and that

$$L \equiv (df)_{0,0} = \begin{pmatrix} 0 & -\omega I_n \\ \omega I_n & 0 \end{pmatrix}.$$

There is the natural action of the circle group S^1 or $\mathbb{R}^{2n}$ given by

$$x \to \exp(tL)x. \tag{1.5}$$

We assume that the action of $\Gamma \times S^1$ on $\mathbb{R}^{2n}$ is irreducible. It then follows, as above, that $f(0, \lambda) \equiv 0$, i.e., that there is a "trivial" steady-state solution. It also follows that the eigenvalues of $(df)_{0,\lambda}$ are $\sigma(\lambda) \pm i\omega(\lambda)$, each of multiplicity n.

THEOREM 1.1. *Let* $\Sigma \subset \Gamma \times S^1$ *be a subgroup. Assume that* $\sigma(0)=0$, $\omega(0)\neq 0$, $\sigma'(0)\neq 0$, *and* $\dim \operatorname{Fix}(\Sigma)=2$. *Then there exists a unique (nontrivial) branch of small amplitude periodic trajectories with period near* $2\pi/\omega(0)$ *to* $\dot{x}=f(x,\lambda)$ *with symmetries* Σ.

Note $(\sigma,\theta)\in\Sigma\subset\Gamma\times S^1$ is a symmetry of a periodic solution $x(t)$ to $\dot{x}=f(x,\lambda)$ if

$$\gamma x(t)=x(t+\theta). \tag{1.6}$$

See Golubitsky and Stewart [1985], [1986b], Roberts, Swift, and Wagner [1986], and Golubitsky, Stewart, and Schaeffer [1988] for a proof and applications.

We remark that in certain instances it is possible to use invariant theory and group theory to compute the asymptotic stability of the steady-state and periodic solutions found using the results stated above. We refer to these references for examples of this process.

2. Fixed points and period doubling. Let $g:\mathbb{R}^n\times\mathbb{R}\to\mathbb{R}^n$ be a one-parameter family of Γ-equivariant mappings. We assume that Γ acts absolutely irreducibly on $\mathbb{R}^n$. It follows that $x=0$ is a "trivial" fixed point for g and that $(Dg)_{0,\lambda}=c(\lambda)I$. In this section, we briefly discuss the bifurcation of fixed points ($c(0)=+1$) and period doubling bifurcation ($c(0)=-1$).

LEMMA 2.1. *Let* $\Sigma\subset\Gamma$ *be a subgroup. Suppose that* $c(0)=1$, $c'(0)\neq 0$, *and* $\dim \operatorname{Fix}(\Sigma)=1$. *Then* $g(x,\lambda)$ *has a unique (nontrivial) branch of fixed points in* $\operatorname{Fix}(\Sigma)$.

Proof. Set $f(x,\lambda)=g(x,\lambda)-x$ and apply the Equivariant Branching Lemma. □

To eliminate trivialities, we assume that Σ is an isotropy subgroup, that is, there is an $x\in\mathbb{R}^n$ such that

$$\Sigma=\{\gamma\in\Gamma:\ \gamma x=x\}. \tag{2.1}$$

The largest subgroup of Γ that leaves $\operatorname{Fix}(\Sigma)$ invariant is $N(\Sigma)$, the normalizer of Σ in Γ (cf. Golubitsky [1983] or Golubitsky, Stewart, and Schaeffer [1988]). It follows that $g|\operatorname{Fix}(\Sigma)\times\mathbb{R}$ commutes with the action of $N(\Sigma)/\Sigma$. Now, if we assume that Σ is a maximal isotropy subgroup (a hypothesis that is satisfied when $\dim \operatorname{Fix}(\Sigma)=1$), then $N(\Sigma)/\Sigma$ acts fixed point free. It follows that when $\dim \operatorname{Fix}(\Sigma)=1$, either $N(\Sigma)=\Sigma$ or $N(\Sigma)/\Sigma\cong\mathbb{Z}_2$. In the latter case, the bifurcation of fixed points in Lemma 2.1 will be via a pitchfork bifurcation, with the two new bifurcating fixed points lying on the same group orbit (conjugacy being given by any $\gamma\in N(\Sigma)\sim\Sigma$). When $N(\Sigma)=\Sigma$, we expect each new fixed point to be on a distinct group orbit.

We now discuss the case of period doubling, i.e., $c(0)=-1$. As in the standard period doubling theorem (without symmetry), we observe that nonzero fixed points for the composite mapping g^2 correspond to period two points for g, since the implicit function theorem guarantees that there are no new fixed points for g. We apply Lemma 2.1 to g^2 to obtain the following lemma.

LEMMA 2.2. *Let* $\Sigma\subset\Gamma$ *be a subgroup. Suppose that* $c(0)=-1$, $c'(0)\neq 0$, *and* $\dim \operatorname{Fix}(\Sigma)=1$. *Then* $g(x,\lambda)$ *has a unique branch of period two points in* $\operatorname{Fix}(\Sigma)$.

Again, we have different interpretations for Lemma 2.2, depending on whether $N(\Sigma)=\Sigma$ or $N(\Sigma)/\Sigma\cong\mathbb{Z}_2$. In the first case, we expect a standard period doubling to occur, while in the second case, the equivariance of $g|(\operatorname{Fix}(\Sigma)\times\mathbb{R})$ with respect to $\mathbb{Z}_2$ implies that

$$g(x,\lambda)=-x. \tag{2.2}$$

To verify (2.2), note that $g(-x,\lambda)=-g(x,\lambda)$. Therefore, if x is a period two point for

g, then so is $-x$. Since x and $-x$ are in Fix (Σ) and the period two orbit obtained from Lemma 2.2 in Fix (Σ) is unique, it follows that $g(x, \lambda) = -x$.

Remark. Identity (2.2) states that this period two trajectory is a discrete analogue of a rotating wave; the same result is obtained by taking one timestep (iteration by g) or by acting by the group $(x \to -x)$.

We end this section with some speculations on period doubling sequences when $N(\Sigma)/\Sigma \cong \mathbb{Z}_2$. As a parameter is varied, we might expect the trivial fixed point to undergo a bifurcation to a nontrivial fixed point, as in Lemma 2.1. As we discussed above, when $N(\Sigma)/\Sigma \cong \mathbb{Z}_2$, this new fixed point is formed by a pitchfork bifurcation.

Suppose now that, as this parameter is varied, each of the nontrivial fixed points undergoes a period doubling sequence. The $\mathbb{Z}_2$ action forces the period doubling sequence to occur at the same parameter values for each nontrivial fixed point. The simplest such example is given by the cubic polynomial

$$g(x, \lambda) = \mu x - x^3, \qquad \mu > 0 \tag{2.3}$$

on Fix $(\Sigma) \times \mathbb{R}$. For $\mu > 0$, each of these period doubling sequences seems to behave like the simple logistic equation. This results in pairs of attractors (one for $x > 0$ and one for $x < 0$) consisting of single orbits filling up parts of the real line, say, for x in $[\alpha, \beta]$ and for x in $[-\beta, -\alpha]$.

As λ is increased, α decreases and eventually becomes negative (when $\lambda = 3\sqrt{3/2}$). This merging of attractors causes an interesting kind of chaotic behavior. Start with an initial point $x_0 > 0$ and form the iterated sequence $x_{n+1} = g(x_n, \lambda)$. Now form the symbol sequence of $+$'s and $-$'s where the nth element in the sequence is sgn (x_n). In effect, we see chaotic behavior on two time scales. There is the chaotic behavior on a fast time scale within each of the attractors ($[0, \beta]$ and $[-\beta, 0]$) and then there is the chaotic behavior on a slow time scale defined by the transitions between the remnants of the two attractors.

A detailed study of the related map

$$h(x, \lambda) = -(\mu x - x^3), \qquad \mu > 0$$

is given in Rogers and Whitley [1983]. There, however, the primary bifurcation of the fixed point $x = 0$ is a period doubling bifurcation, as discussed in Lemma 2.2.

3. Hopf bifurcation. In this section, we assume that the trivial fixed point for the Γ-equivariant mapping g loses stability by a pair of complex conjugate eigenvalues crossing the unit circle. Due to the presence of symmetry, the eigenvalues may have high multiplicity. We assume that $g: \mathbb{R}^{2n} \times \mathbb{R} \to \mathbb{R}^{2n}$ and that $(Dg)_{0,0}$ has eigenvalues $e^{\pm 2\pi i\theta}$, each with multiplicity n, where $\theta \neq 0, \frac{1}{2}$.

The standard Hopf bifurcation theorem for mappings ($n = 1$) states that if $\theta \neq \frac{1}{3}, \frac{1}{4}, \frac{2}{3}, \frac{3}{4}$ and if the eigenvalues cross the unit circle with nonzero speed, then there exists a family of invariant circles for $g(\cdot, \lambda)$ emanating from the trivial fixed point $x = 0$. This theorem is proved using near identity changes of coordinates to put the terms of g up to order four in normal form. This truncated normal form actually has S^1 symmetry, and, because of this symmetry, we can easily find invariant circles using polar coordinates. Then we use scaling and normal hyperbolicity arguments to show that the invariant circles that are present at order four persist independently of the higher order terms in g. When resonances exist ($\theta = \frac{1}{3}, \frac{1}{4}, \frac{2}{3}, \frac{3}{4}$), the normal form does not have this S^1-equivariance in the fourth-order truncated normal form (cf. Arnold [1977], [1983] and Iooss [1979]).

We obtain a simple generalization of the Hopf bifurcation theorem as follows: Let $\Sigma \subset \Gamma$ be a subgroup with dim Fix $(\Sigma) = 2$. Then there exists a branch of g-invariant

circles in Fix (Σ), as long as $\theta \neq \frac{1}{3}, \frac{1}{4}, \frac{2}{3}, \frac{3}{4}$. Just apply the standard Hopf theorem to $g|\text{Fix}(\Sigma)$; the eigenvalues of $D(g|\text{Fix}(\Sigma))$ are constrained by dimension to be simple.

Remark. Assume that Σ is an isotropy subgroup with dim Fix $(\Sigma) = 2$. The group $N(\Sigma)/\Sigma$ acts on Fix (Σ) by a fixed-point free action and $g|\text{Fix}(\Sigma)$ commutes with this action. (In fact, Σ is a maximal isotropy subgroup since the complex eigenvalues preclude the existence of one-dimensional fixed-point subspaces; cf. Golubitsky and Stewart [1985].) Fixed-point free actions on $\mathbb{R}^2$ exist only for the groups 1, $\mathbb{Z}_n$ $(n \geqq 2)$ or $SO(2)$. Observe that if $N(\Sigma)/\Sigma \cong \mathbb{Z}_n$ $(n \geqq 5)$ or $SO(2)$, then $g|\text{Fix}(\Sigma)$ automatically has a fourth-order truncated normal form with S^1 symmetry. In these cases, the assumption $\theta \neq \frac{1}{3}, \frac{1}{4}, \frac{2}{3}, \frac{3}{4}$ is *not* necessary, as the remainder of the proof of the standard Hopf theorem is still valid.

As in the case of Hopf bifurcation for systems of ODEs (Theorem 1.1), we can improve on this simple generalization by looking for subgroups of $\Gamma \times S^1$ with two-dimensional fixed-point subspaces. First, we define the action of S^1. Choose a matrix A with purely imaginary eigenvalues such that $e^A = (dg)_{0,0}$. The action of S^1 is then given by e^{tA}. Since $(dg)_{0,0}$ commutes with Γ, so does the action of S^1. In this way, we have defined an action of $\Gamma \times S^1$ on $\mathbb{R}^{2n}$.

THEOREM 3.1. *Let* $\Sigma \subset \Gamma \times S^1$ *be a subgroup such that* dim Fix $(\Sigma) = 2$. *Assume* $\theta \neq \frac{1}{3}, \frac{1}{4}, \frac{2}{3}, \frac{3}{4}$ *and that the eigenvalues cross the unit circle with nonzero speed. Then generically there exists a unique branch of g-invariant circles emanating from the trivial fixed point* $x = 0$ *and this branch is tangent to* Fix $(\Sigma) \subset \mathbb{R}^{2n} \times \mathbb{R}$ *at* $x = 0$.

Proof. The truncated normal form h of g has symmetry group $\Gamma \times S^1$. Therefore, $h: \text{Fix}(\Sigma) \times \mathbb{R} \to \text{Fix}(\Sigma)$, and we can find invariant circles for h, as above. At this point, however, we cannot conclude directly from the proof of the standard Hopf bifurcation theorem that there is a family of g-invariant circles. The difficulty is that g itself need not leave invariant Fix (Σ) since g does not necessarily commute with S^1. However, Ruelle [1973, Thm. 3.1] does prove a theorem sufficient to conclude that g has a family of invariant circles, at least when certain assumptions, which are valid generically, hold.

The needed assumptions are the following:

(a) The third-order terms in h determine the direction of branching of the invariant circles of h in Fix (Σ).

(b) The invariant circles for h are normally hyperbolic in the sense that the eigenvalues of dh on the invariant circles, which are not forced by the $\Gamma \times S^1$ action to be unity, in fact lie off the unit circle.

In order for (b) to hold, it is often necessary to have truncated the normal form at some high order. This order depends on both $\Gamma \times S^1$ and the subgroup Σ. Once the invariant circles of h are normally hyperbolic, Ruelle's Theorem 3.1 is sufficient to prove that the higher order terms of g (which are not in normal form) will neither destroy the invariant circles nor change their stability. □

Example 3.2. Consider $\Gamma = D_n$ $(n \geqq 3)$ acting absolutely irreducibly on $\mathbb{C}$ and by the diagonal action on $\mathbb{C}^2$. As was shown in Golubitsky and Stewart [1986b], there are three (conjugacy classes of) isotropy subgroups in $D_n \times S^1$ where the fixed-point subspaces are two-dimensional. Theorem 3.1 implies that for D_n-equivariant mappings, we may expect three families of g-invariant circles at such a Hopf bifurcation. We note that two of the isotropy subgroups are isomorphic to $\mathbb{Z}_2$ and one to $\mathbb{Z}_3$. The normal hyperbolicity of the $\mathbb{Z}_3$ circles are determined at third order, while the normal hyperbolicity of the $\mathbb{Z}_2$ branches are determined at order m where

$$m = \begin{cases} n, & n \text{ odd}, \\ (n+2)/2, & n \text{ even}. \end{cases}$$

4. Bifurcation of standing waves to 3-tori. For an $O(2)$ invariant system of ODEs, a symmetry-breaking Hopf bifurcation leads to two types of periodic solutions: rotating waves and standing waves (cf. Golubitsky and Stewart [1985]). We are interested here in the bifurcation of these periodic solutions to tori. Bifurcation from rotating waves has been considered by Rand [1982], Renardy [1982], and Iooss [1984]. By changing coordinates to a rotating frame, they show that rotating waves correspond to stationary solutions and that 2-tori may be found by standard Hopf bifurcation techniques for systems of ODEs. Moreover, the circular symmetry of the rotating waves forces the flow on the 2-torus to be linear. Standing waves, however, have no circular symmetry in their isotropy subgroup, and the technique of changing coordinates to a rotating frame does not apply. Using the techniques described in § 3 applied to a certain Poincaré map, we shall study here the bifurcation to tori from standing waves. In the next section, we give a unified discussion of these two techniques when $O(2)$ is replaced by a general group Γ.

Bifurcation to 2-tori from a branch of standing waves has been considered in the context of degenerate, symmetry-breaking, $O(2)$ Hopf bifurcations by a number of authors (Erneux and Matkowsky [1984], Knobloch [1986], and Golubitsky and Roberts [1987]). These authors decouple the normal form equations for $O(2)$ Hopf bifurcation (on $\mathbb{C}^2$) into phase-amplitude equations and find the 2-tori by steady-state bifurcation in the amplitude equations. Using the extra S^1 phase shift symmetry of normal form, it is easy to see that in normal form the flow on these 2-tori must also be linear. Chossat [1986] uses a Lyapunov–Schmidt reduction to prove that the flow on such 2-tori is linear even when the vector field is not assumed to be in normal form. His method is to assume that the flow on the 2-torus has the form $y(t) = R_{\eta t}x(t)$ where x is periodic, η is a real parameter, and R_θ denotes the action of θ in $SO(2)$. The original equation is then transformed by substitution of $y(t)$ and elimination of $R_{\eta t}$ to an equation for x. It is this equation to which the Lyapunov–Schmidt reduction is applied, and this idea we will use to analyze bifurcation to tori from standing waves. In § 5, we will show that, in principle, when considering bifurcation to tori from a branch of periodic solutions in a symmetric system, one of the two techniques described above always works. Which one will work depends on the symmetries of the periodic solution.

Consider the following system of ODEs:

$$\dot{y} = F(y, \lambda), \qquad F(0, \lambda) = 0 \tag{4.1}$$

where $y \in \mathbb{R}^N$ and $F: \mathbb{R}^N \times \mathbb{R} \to \mathbb{R}^N$ commutes with a linear action of $O(2)$ on $\mathbb{R}^N$. This action may not be faithful; we assume, however, that the kernel of the action is the cyclic group $\mathbb{Z}_n$, $n \geqq 1$.

Let $y(t)$ be a *standing wave* periodic solution to (4.1), that is, assume that the isotropy subgroup

$$\Sigma = \{\gamma \in O(2): \gamma y(t) = y(t)\} \tag{4.2}$$

is discrete and contains a reflection in $O(2)$. Thus $\Sigma = D_n$. Note that standing waves lie on the invariant 2-torus

$$M = \{\gamma y(t): \gamma \in O(2)\}$$

foliated by periodic trajectories.

We now consider bifurcation of standing waves to tori. This bifurcation is detected by having a complex conjugate pair of Floquet multipliers cross the unit disk at $e^{\pm 2\pi i\theta}$ where $\theta \neq 1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{2}{3}, \frac{3}{4}$. The eigenspaces corresponding to these Floquet multipliers are invariant under $\Sigma = D_n$, and generically we may assume that D_n acts irreducibly

on the eigenspaces. The irreducible representations of D_n are either one-dimensional or, if $n \geqq 3$, two-dimensional.

We prove the following theorem.

THEOREM 4.1. *Let $x_\lambda(t)$ be a family of standing wave periodic solutions to the $O(2)$ symmetric system* (4.1) *with isotropy subgroup D_n. Assume that the periodic solution loses stability by having a pair of complex conjugate Floquet multipliers cross the unit disk with nonzero speed and assume that D_n acts irreducibly on the corresponding eigenspaces.*

(a) *If the Floquet multipliers are simple, then there exists a branch of 3-tori emanating from this bifurcation.*

(b) *If the Floquet multipliers are double (which may happen generically when $n \geqq 3$), then there exist three branches of 3-tori emanating from the bifurcation.*

Our proof consists of constructing a D_n-equivariant Poincaré map to which we can apply the results of § 3.

Remarks. (a) Such bifurcations to 3-tori occur in the interaction of two symmetry-breaking $O(2)$ Hopf bifurcations (see Chossat, Golubitsky, and Keyfitz [1986]) and in the interaction of $O(2)$ symmetry-breaking steady-state and Hopf bifurcations (see Golubitsky and Stewart [1986a]).

(b) Normally we would expect the bifurcation of a periodic solution to tori to produce an invariant 2-torus. The extra frequency comes from the $O(2)$ symmetry. As noted above, each standing wave $x(t)$ lies on the 2-torus M defined by $\gamma x(t)$ for $\gamma \in O(2)$. When bifurcation to tori occurs, we get two independent frequencies from the "Poincaré map" and a third independent (slow) frequency from flow transverse to $\gamma x(t)$ in the group generated 2-torus M. It is here that we use the ideas of Iooss [1986] and Chossat [1986], described above.

(c) Suppose that the standing waves are generated by Hopf bifurcation with $O(2)$ symmetry from an invariant steady state in (4.1). Then the bifurcation to tori we describe in Theorem 4.1 cannot occur in a system of differential equations posed only on the four-dimensional center subspace. Since the hypotheses of the theorem presume the existence of four nontrivial Floquet multipliers and periodic solutions always have one trivial Floquet multiplier (equal to unity), such a system cannot live on a four-dimensional manifold. In effect, the question we discuss here is: suppose that a standing wave with D_n symmetry is formed from a symmetry-breaking $O(2)$ Hopf bifurcation and suppose that we track this solution to finite amplitude; then how should we expect this standing wave to lose stability?

(d) In models of the Couette–Taylor apparatus where periodic boundary conditions in the axial direction are assumed, the transition from wavy vortices to modulated wavy vortices is an example of the bifurcation considered in Theorem 4.1.

Proof of Theorem 4.1. Let $x_\lambda(t)$ be the one-parameter family of standing-wave solutions to (4.1) with periods $2\pi/\omega_\lambda$. Write the Floquet equation

$$\frac{dy}{dt} = L_\lambda(t) \cdot y \tag{4.3}$$

where

$$L_\lambda(t) = (D_x F)_{x_\lambda(t),\lambda}.$$

We assume that (4.3) has a Floquet multiplier $\alpha(\lambda)$ of multiplicity two where $\alpha(0) = e^{2\pi i\theta}$ and $\theta \neq 1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{2}{3}, \frac{3}{4}$. We also assume

$$\frac{d}{d\lambda}|\alpha(\lambda)|\Big|_{\lambda=0} \neq 0.$$

We know that $\dot{x}_\lambda(t)$ is always a solution to (4.3) yielding a Floquet multiplier equal to unity. Similarly, the $O(2)$ equivariance of F implies that $Jx_\lambda(t)$ is also a solution to (4.3) yielding another Floquet multiplier equal to unity where J is the infinitesimal generator of the $SO(2)$ action.

In order to eliminate this extra "trivial" Floquet multiplier, we look for solutions to (4.1) of the form

$$y(t) = R_{\eta t}x(t) \tag{4.4}$$

where R_ϕ denotes the action of $\phi \in SO(2)$ on $\mathbb{R}^N$, and η is a real parameter. As mentioned above, this trick is used in Chossat [1986] and, in a slightly different context, in Iooss [1986]. The system (4.1) now becomes

$$\dot{y} = F(y, \lambda) - \eta Jy. \tag{4.5}$$

Observe from (4.4) that periodic solutions of (4.5), $(y(t), \eta)$, correspond to quasiperiodic solutions of (4.1), $x(t)$.

Next we define our Poincaré map. Let $\phi_t(y_0, \lambda, \eta)$ denote the one-parameter group of solutions to (4.5) with initial condition y_0. Note that when $\eta = 0$, (4.5) is identical to (4.1). Recall that $x_0(t)$ is a $2\pi/\omega_0$-periodic solution to (4.1), and hence

$$x_0(0) = \phi_{2\pi/\omega_0}(x_0(0), 0, 0),$$

that is, $x_0(0)$ is a fixed point for the mapping $\phi_{2\pi/\omega_0}(\,\cdot\,, 0, 0)$.

Let $\zeta_1 = dx_0/dt(0)$ and $\zeta_2 = Jx_0(0)$. Since $x_0(t)$ is a nonconstant periodic solution to (4.1), we know that $x_0(0) \neq 0$ (since $F(0, \lambda) \equiv 0$). Thus, ζ_1 is tangent to the trajectory $x_0(t)$ and ζ_2 is tangent to the $O(2)$ group orbit through x_0. The hypothesis that $x_0(t)$ is a standing wave guarantees that ζ_1 and ζ_2 are linearly independent. Let $\langle\,,\rangle$ denote an inner product on $\mathbb{R}^N$ and let $W = \operatorname{span}\{\zeta_1, \zeta_2\}^\perp$.

We now define the first return map of trajectories to (4.5) starting in the plane $W_0 = \{x_0(0) + y_0 : y_0 \in W\}$ close to $x_0(0)$. In order for such a trajectory to return to W_0 at time τ, it must satisfy the equations

$$f_j(y_0, \lambda, \eta, \tau) \equiv \langle \zeta_j, \phi_\tau(x_0(0) + y_0, \lambda, \eta) - x_0(0)\rangle = 0. \tag{4.6}$$

Now recall that if we set $y(t) = x_0(t) + z(t)$ in (4.5) and $z(0) = y_0$ is close enough to zero, then the integral form of (4.5) is

$$z(t) = S(t)y_0 + \int_0^t S(t-s)\hat{F}(z(s), \lambda, \eta)\,ds \tag{4.7}$$

where $S(t)$ is the monodromy operator associated with (4.3) and

$$\hat{F}(z, \lambda, \eta) = F(x_0 + z, \lambda) - F(x_0, \lambda) - L_0(t)z - \eta J(z).$$

Since $\phi_\tau(x_0(0) + y_0, \lambda, \eta) = x_0(\tau) + z(\tau)$ it can be seen from (4.7) that

$$\begin{aligned} &\text{(a)} \quad f_1(y_0, \lambda, \eta, \tau) = \tau - 2\pi/\omega_0 + \cdots, \\ &\text{(b)} \quad f_2(y_0, \lambda, \eta, \tau) = \eta + \cdots, \end{aligned} \tag{4.8}$$

where $\cdots$ indicates terms of the form

$$o(|\tau - 2\pi/\omega_0| + |\eta| + O(|\lambda| + |y_0|)).$$

Using the implicit function theorem, we can solve equations (4.6) for $\tau = \tau(y_0, \lambda)$ and $\eta = \eta(y_0, \lambda)$ when $\tau(0, 0) = 2\pi/\omega_0$ and $\eta(0, 0) = 0$. Observe that generically η itself is nonzero. The Poincaré map is now defined by

$$G_\lambda(y_0) = \phi_{\tau(y_0, \lambda)}(x_0(0) + y_0, \lambda, \eta(y_0, \lambda)) - x_0(0). \tag{4.9}$$

Note that $G_0(0) = \phi_{2\pi/\omega_0}(x_0(0), 0, 0) - x_0(0) = 0$.

A consequence of this construction is that, if G_λ undergoes a Hopf bifurcation at $y_0 = 0$, then we find an invariant 2-torus in (4.5) that corresponds using (4.4) to an invariant 3-torus in (4.1). It follows from (4.4) that one of the independent frequencies is η, which is small, but typically nonzero.

A second important consequence of the construction (4.8) is that G_λ is D_n-equivariant. We claim that

$$\begin{aligned}
&\text{(a)} \quad \gamma\zeta_1 = \zeta_1 \qquad \forall \gamma \in D_n;\\
&\text{(b)} \quad \gamma\zeta_2 = \zeta_2 \qquad \forall \gamma \in \mathbb{Z}_n, \quad \text{and} \quad \phi_t(\gamma y_0, \lambda, \eta) = \gamma\phi_t(y_0, \lambda, \eta);\\
&\text{(c)} \quad S\zeta_2 = -\zeta_2 \qquad \forall S \in D_n \sim \mathbb{Z}_n, \quad \text{and} \quad \phi_t(Sy_0, \lambda, -\eta) = S\phi_t(y_0, \lambda, \eta).
\end{aligned} \tag{4.10}$$

Using the identities (4.10) in (4.6) and uniqueness of solutions to the implicit function theorem allows us to conclude that

$$\begin{aligned}
&\text{(a)} \quad \tau(\gamma y_0, \lambda) = \tau(y_0, \lambda) \qquad \forall \gamma \in D_n,\\
&\text{(b)} \quad \eta(\gamma y_0, \lambda) = \eta(y_0, \lambda) \qquad \forall \gamma \in \mathbb{Z}_n, \quad \text{and}\\
&\text{(c)} \quad \eta(Sy_0, \lambda) = -\eta(y_0, \lambda) \qquad \forall S \in D_n \sim \mathbb{Z}_n.
\end{aligned} \tag{4.11}$$

Using the definition of G_λ in (4.8), we now find it easy to check using (4.9) and (4.10) that G_λ commutes with D_n.

To verify (4.10)(a), recall that since $x_0(t)$ is a standing wave, we know that $\gamma x_0(t) = x_0(t)$ for all $\gamma \in D_n$. Now differentiate with respect to t. Next, observe that $\mathbb{Z}_n$ commutes with J while $SJ = -JS$ for all S in $D_n \sim \mathbb{Z}_n$. Now we prove (4.10)(b),(c) by invoking uniqueness of solutions to the initial value problems for systems of ODEs.

If the Floquet multipliers are simple, then this construction gives a unique invariant circle by the standard Hopf theorem for mappings. However, when the Floquet multipliers are double, we can invoke the discussion concerning Hopf bifurcation for D_n-equivariant mappings given at the end of § 3. We conclude that when G_λ undergoes a Hopf bifurcation, three families of invariant tori are produced from this bifurcation. Of course, the hypotheses of Theorem 4.1 imply that G_λ does undergo a Hopf bifurcation at $\lambda = 0$. This completes our proof. □

Remarks. (a) The stability of these 3-tori can, in principle, be computed from the results in Golubitsky and Stewart [1986b]. The simplest statement of these results is: suppose the standing waves are stable when $\lambda < 0$. Then generically, for any of the 3-tori to be stable, all those families must appear supercritically (for $\lambda > 0$). If all three families are supercritical, then precisely one family is asymptotically stable.

(b) The reader may check that these results explain the existence of the invariant 3-tori found in the interaction of two symmetry-breaking $O(2)$ Hopf bifurcations from a branch of standing-wave solutions. See Chossat, Golubitsky, and Keyfitz [1986].

5. Bifurcation from periodic solutions. In this section, we generalize the discussion of bifurcation from a periodic solution of $O(2)$ symmetric systems of ODEs to bifurcation in systems invariant under a general compact Lie group Γ. Our formulation here is mainly geometric and may be contrasted with the analytic nature of the remarks in § 4.

Let $x(t)$ be a T-periodic solution to

$$\dot{x} = f(x) \tag{5.1}$$

where $f: \mathbb{R}^n \to \mathbb{R}^n$ is Γ-equivariant, $\Gamma \subset O(n)$. Let $\phi_t: \mathbb{R}^n \to \mathbb{R}^n$ be the flow associated with (5.1) and note that ϕ_t is also Γ-equivariant. We now define a Poincaré map associated with $x(t)$.

Define a local action of $\Gamma \times \mathbb{R}$ on $\mathbb{R}^n$ by

$$(\gamma, t) \cdot x = \gamma \phi_t(x). \tag{5.2}$$

Since the actions of γ and t commute (ϕ_t is Γ-equivariant), we see that (5.2) actually defines an action of $\Gamma \times \mathbb{R}$. Let $x_0 = x(0)$. Since orbits of (smooth) Lie group actions are immersed submanifolds (cf. Bredon [1972]), we see that

$$M = (\Gamma \times \mathbb{R}) \cdot x_0 \tag{5.3}$$

is an immersed submanifold of $\mathbb{R}^n$. However, since $x(t)$ is periodic, it follows that M is compact, and hence a submanifold of $\mathbb{R}^n$. Moreover, M is foliated by the periodic solutions $\{\gamma x(t) : \gamma \in \Gamma\}$.

Remark. Let S^1 be identified with the interval $[0, T)$. Then we can define

$$\Sigma_{x_0} = \{(\gamma, \theta) \in \Gamma \times S^1 : (\gamma, \theta) x_0 = x_0\}. \tag{5.4}$$

Σ_{x_0} is the isotropy subgroup of $x(t)$ and M is diffeomorphic to $(\Gamma \times S^1)/\Sigma_{x_0}$.

Since M is compact and Γ-invariant, there exists an open Γ-invariant tubular neighborhood of M in $\mathbb{R}^n$. More precisely, there exists a vector bundle $N \overset{\pi}{\to} M$ and a smooth Γ-equivariant diffeomorphism $\sigma : N \to \mathbb{R}^n$ defined on an open neighborhood of M and N such that $\operatorname{Im} \sigma$ is an open neighborhood of M in $\mathbb{R}^n$ and $\sigma | M$ is the identity (see Bredon [1972, p. 306]). Via σ we can pull back the vector field f to N and discuss the bifurcation of the periodic orbit in N. The advantage of these coordinates is that Γ acts linearly on the fibers of N and these fibers are orthogonal to M.

Next we define the manifold

$$P_\gamma = \pi^{-1}(\{\gamma \cdot x(t)\}); \tag{5.5}$$

that is, P_γ is just that part of the vector bundle N that lies over the periodic trajectory $\gamma \cdot x(t)$ in M. It is possible to write (cf. Vanderbauwhede, Krupa, and Golubitsky [1988] or Krupa [1988])

$$f(y) = f_P(y) + f_T(y) \tag{5.6}$$

where $f_P(y)$ is tangent to P_γ for all $y \in P_\gamma$ and $f_T(y)$ is tangent to the group orbit Γy. Moreover, both f_P and f_T are Γ-equivariant.

Next, observe that Γ-equivariance implies that f_T is a linear vector field on Γy. Hence, the flow of f_T is given by $\exp(t\eta)$ for some $\eta \in L(\Gamma)$, the Lie algebra of Γ. (In fact, if we define

$$\Gamma_{x_0} = \{\gamma \in \Gamma : \gamma x_0 = x_0\} \tag{5.7}$$

and we choose a vector space complement U to $\mathcal{L}(\Gamma_{x_0})$ in $\mathcal{L}(\Gamma)$, then we can assume η is uniquely defined in U.) Note that $\mathcal{L}(O(2)) = \mathbb{R}$ and that the η defined in § 4 may be thought of as residing in the Lie algebra of $O(2)$. Also, in § 4, we solved implicitly for $\eta = \eta(y_0, \lambda)$. This discussion allows us to write explicitly the first-order terms of η. We have not set up such an explicit algorithm here. Nevertheless, we know that generically η is nonzero, which is all we need. Similarly, since f_P is Γ-equivariant, the dynamics of f_P are determined by the dynamics of $f_P | P_1$. We just transport the flow from P_1 to P_γ using multiplication by γ, which acts orthogonally.

It now follows that the flow of f may be understood as composing the flow of f_P on P_1 with linear flow on orbits Γy. In particular, if W is an invariant set under the flow of f_P, then

$$\hat{W} = \bigcup_{y \in W} \Gamma y \subset N$$

is invariant under f. Moreover, W is asymptotically stable under f_P if and only if the invariant set $\hat{W}$ is asymptotically stable under f. Since $f_T|M \equiv 0$, we may think of the flow of f on $\hat{W}$ as being the composition of the flow of f_P on W with a slow drift along the group orbits of Γ in $\hat{W}$. For the example $O(2)$, connected components of the group orbits are just circles (being diffeomorphic to $SO(2)$) and the flow for f_T along the group orbit is periodic. If, in addition, we assume that W is a 2-torus, then $\hat{W}$ will be a 3-torus with the flow along the group orbit having a small frequency.

Thus, bifurcation of the periodic orbit $x(t)$ for f is determined by bifurcation of the periodic orbit $x(t)$ for $F = f_P|P_1$. Note that, since f_P is Γ-equivariant, it follows that F is Γ_{x_0}-equivariant where Γ_{x_0} is the isotropy subgroup defined in (5.7). We assume henceforth that f, and hence F, depend on a real parameter λ.

Recall now the isotropy subgroup Σ_{x_0} of $x(t)$ in $\Gamma \times S^1$, which was defined in (5.4). We call $x(t)$ a *rotating wave* if there is a loop

$$(\gamma(\theta), \theta) \in \Sigma_{x_0}, \qquad \gamma(0) = 1 \tag{5.8}$$

and a *standing wave* otherwise. The bifurcation analysis for rotating waves proceeds along the lines of the Renardy-Rand approach. The assumption (5.8) implies that

$$x(t) = \gamma(t)^{-1} \cdot x(0).$$

Now transform the equation $\dot{y} = f_P(y)$ by looking for solutions of the form

$$y(t) = \gamma(t) z(t)$$

and obtain the system

$$\dot{z}(t) = f_P(z(t), \lambda) - \dot{\gamma}(0) z(t). \tag{5.9}$$

In this system, $x(t)$ corresponds to the steady-state solution $z(t) = x_0$ and bifurcation to tori for $x(t)$ is determined by a Hopf bifurcation in (5.9).

For standing waves, we use another approach, which is also valid for rotating waves. Let S be a cross section to $x(t)$ in the fiber of N over x_0. Since $x(t)$ is periodic, the flow of $F(\cdot, 0)$ returns to x_0 after time T. Thus, we can define the Poincaré map

$$\psi : S \times \mathbb{R} \to S$$

with $\psi(x_0, 0) = x_0$, and since F commutes with Γ_{x_0}, so does ψ. We can now study Hopf bifurcation of ψ with symmetry Γ_{x_0} using the techniques of § 3. Of course in the discussion of § 4, $\Gamma_{x_0} = D_n$ and that specific case represents an example of the general approach described here.

Acknowledgment. We are grateful to Andre Vanderbauwhede for making a number of helpful comments.

HETEROCLINIC ORBITS AND CHAOTIC DYNAMICS IN PLANAR FLUID FLOWS*

ANDREA LOUISE BERTOZZI†

Abstract. An extension of the planar Smale–Birkhoff homoclinic theorem to the case of a heteroclinic saddle connection containing a finite number of fixed points is presented. This extension is used to find chaotic dynamics present in certain time-periodic perturbations of planar fluid models. Specifically, the Kelvin–Stuart cat's eye flow is studied, a model for a vortex pattern found in shear layers. A flow on the two-torus with Hamiltonian $H_0 = (2\pi)^{-1} \sin(2\pi x_1) \cos(2\pi x_2)$ is studied, as well as the evolution equations for an elliptical vortex in a three-dimensional strain flow.

Key words. homoclinic orbits, Melnikov's method, Kelvin–Stuart cat's eyes, elliptical vortices

AMS(MOS) subject classifications. 34C35, 54H20, 58F08, 58F13, 70K99, 76C05

1. Introduction. Organized vortex structures in two-dimensional fluid flows can often be viewed as planar dynamical systems with multiple heteroclinic saddle connections. We wish to study how such saddle connections break up under small perturbations. In the homoclinic case, the Smale–Birkhoff Theorem and Melnikov's method are two useful tools for studying the onset of chaos and mixing in planar flows possessing a simple homoclinic orbit. We extend the planar homoclinic theorem to the case of a heteroclinic orbit connecting a finite number of saddle points, enabling us to analyze fluid models to which the original homoclinic theory does not apply.

We present three planar fluid models that exhibit heteroclinic saddle connections. The Kelvin–Stuart cat's eye flow is a well-known model for a pattern found in shear layers. This flow is a planar dynamical system possessing an infinite number of heteroclinic saddle connections involving two fixed points each. We also study a planar lattice flow in which we find groups of four saddle points linked by heteroclinic orbits. The lattice flow is an interesting model for certain convection patterns as well as for nonlinear Taylor vortex flow. In the unperturbed case, these flows are steady solutions to the inviscid Euler equations and thus have a direct Hamiltonian formulation. We apply the simplified Hamiltonian form of Melnikov's method to find chaotic motion and mixing occurring in time-periodic perturbations of these two planar flows.

The third application of Melnikov's method presented here is of a somewhat different nature from the first two. We examine the evolution equations for an elliptical vortex in an imposed strain. These equations have a Hamiltonian form based on a dimensionless time parameter. The most physically interesting perturbations are based on real time and so we are forced to study a non-Hamiltonian dynamical system with a homoclinic orbit. We apply the non-Hamiltonian version of Melnikov's method to find chaotic dynamics occurring in the case of periodic stretching of the straining flow in a third dimension.

2. Extension of the homoclinic theorem and Melnikov's method. The ideas for the homoclinic theorem were first laid out by Birkhoff [5] and were developed by Smale [26]. We consider a planar diffeomorphism φ possessing a hyperbolic saddle point p whose stable and unstable manifolds intersect transversely at a point q. A result of this theorem is that φ possesses a subsystem equivalent to a shift on two symbols. We extend this theorem to the case of N fixed points joined by transverse saddle connections

* Received by the editors October 1, 1987; accepted for publication January 21, 1988.

(see Fig. 2.3 for the case $N=3$). The homoclinic theorem is proved by constructing the horseshoe map and showing that it possesses the shift as a subsystem (Moser [19]). We must then show that φ possesses the horseshoe map as a subsystem. Keeping in mind Moser's proof of the homoclinic theorem, we construct the generalized horseshoe map, and present a sketch of the heteroclinic theorem. For the complete details the reader is referred to [4].

2.1. The horseshoe map and the shift on two symbols. We first define the horseshoe map used in the homoclinic case. The horseshoe map is a topological mapping of the unit square Q into the plane such that $\varphi(Q)\cap Q$ has two components U_1 and U_2. The pre-images of U_1 and U_2 are denoted by $V_i=\varphi^{-1}(U_i)$, $i=1,2$. V_1 and V_2 are vertical strips connecting the upper and lower edges of Q (see Fig. 2.1). The iterates φ^k of φ are not defined in all of Q, so we construct the invariant set

$$I=\bigcap_{k=-\infty}^{\infty}\varphi^{-k}(Q),$$

in which all iterates φ^k are defined. Associated with each point p of I is a bi-infinite sequence $(\cdots s_{-1}, s_0; s_1, s_2\cdots)$, $s_i\in\{1,2\}$ of ones and twos, where $\varphi^{-k}(p)\in V_{s_k}$ or

$$p\in\bigcap_{k=-\infty}^{\infty}\varphi^{k}(V_{s_k}).$$

On the set S of all such sequences, we define a map σ by $(\sigma s)_i=s_{i+1}$. Under the map σ, all the elements of s are shifted over by one. This provides a mapping $\tau: I\to S$ with $\tau\varphi|_I=\sigma\tau$ as long as τ is invertible. We introduce a topology on S as follows: Given $s^*=(\cdots, s^*_{-2}, s^*_{-1}, s^*_0; s^*_1, s^*_2, \cdots)\in S$ then $U_j=\{s\in S | s_k=s^*_k, (|k|<j)\}$ form a neighborhood basis for s^*. We see that the horseshoe map possesses periodic orbits of arbitrary period, as well as an orbit that comes arbitrarily close to all points of I. This last orbit is obtained by constructing a sequence that contains all possible finite strings of ones and twos.

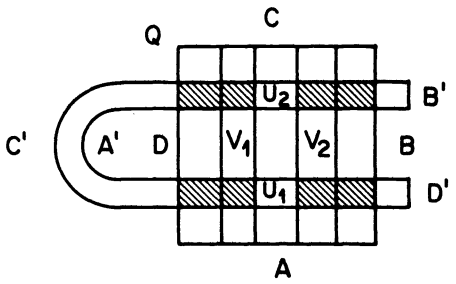

FIG. 2.1. *The horseshoe map.*

2.2. A generalization of the horseshoe map. Consider a set of N disjoint squares Q_i in the plane and a map $\varphi: \cup Q_i\to\mathbb{R}^2$ such that $\varphi(Q_i)\cap Q_i$ is a horizontal strip in Q_i and $\varphi(Q_i)\cap Q_{i+1(\text{mod } N)}$ is a horizontal strip in $Q_{i+1(\text{mod } N)}$. Here it is not important how each square Q_i is oriented with respect to the other squares, only that $\varphi(\cup_i Q_i)\cap Q_j$ are horizontal strips in Q_j (see Fig. 2.2). Our invariant set thus will be

$$I=\bigcap_{k=-\infty}^{\infty}\varphi^{-k}\left(\bigcup_i Q_i\right).$$

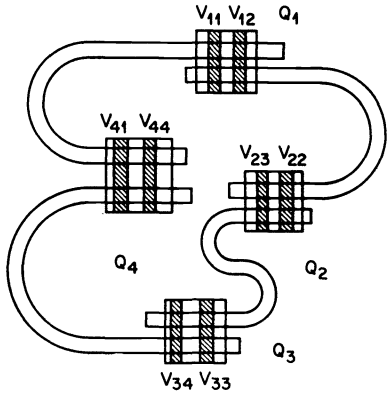

FIG. 2.2

We will associate with each point $p \in I$ a bi-infinite sequence $(\cdots, s_{-1}, s_0; s_1, s_2 \cdots) \in S'$ of N consecutive symbols where

$$S' = \{s | s_i \in \{1, \cdots, N\}, \quad s_{i+1} = s_i \quad \text{or} \quad s_{i+1} = s_i + 1 \pmod N\}$$

such that $\varphi^{-k}(p) \in Q_{s_k}$. Under the appropriate conditions there is a one-to-one correspondence between points of I and sequences $s \in S'$. For the precise details of the above construction as well as a proof of the fact that I and S' are topologically isomorphic, the reader is referred to [4].

2.3. A heteroclinic theorem.

THEOREM 2.3.1. *If a diffeomorphism $\varphi : \mathbb{R}^2 \to \mathbb{R}^2$ possesses N fixed points $p_1, p_2, \cdots, p_N$ that are nondegenerate hyperbolic saddle points, and there exist points q_i at which the unstable manifold $W^u(p_i)$ intersects the stable manifold $W^s(p_{i+1 (\mathrm{mod}\, N)})$ transversely for all i, then φ possesses an invariant set I on which some iteration φ^k is homeomorphic to the shift on S', the set of bi-infinite sequences of N consecutive symbols (as described in the preceding section).*

We provide an outline of the proof. For details, the reader is referred to [4]. We want to show that φ possesses a subsystem satisfying the requirements for the generalized horseshoe map of § 2.2. The stable and unstable manifolds are depicted in Fig. 2.3 (for the case $N = 3$).

CLAIM. We can choose an integer k and neighborhoods U_i of p_i such that the following conditions are satisfied (see Fig. 2.4):

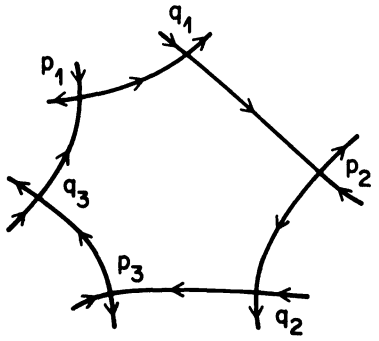

FIG. 2.3

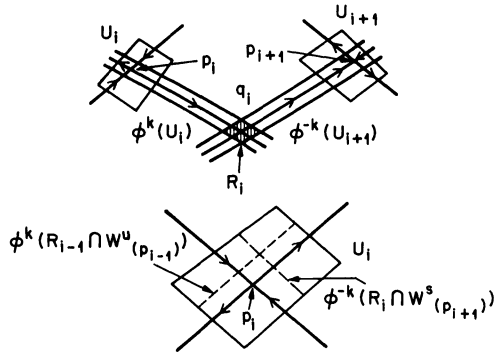

FIG. 2.4

(1) There exists a local coordinate system in U_i so that φ is linear, and U_i is the unit square.

(2) $q_i \in \varphi^k(U_i)$ and $q_i \in \varphi^{-k}(U_{i+1(\text{mod } N)})$ for all i.

(3) For $R_i = \varphi^k(U_i) \cap \varphi^{-k}(U_{i+1(\text{mod } N)})$, we have $\varphi^{-k}(R_i \cap W^s(p_{i+1(\text{mod } N)}))$ intersects $\varphi^k(R_{i-1(\text{mod } N)} \cap W^u(p_{i-1(\text{mod } N)}))$ transversely in exactly one point.

We choose U_i so that (1) is satisfied for all i. Note that if we shrink each U_i, (1) will still hold. Given any U_i satisfying (1), by the definition of stable and unstable manifolds, there exists a k such that (2) is satisfied. Note that k depends on the sizes of the U_i, which we will continue to shrink until all the above conditions are satisfied. By the λ-lemma of Palis [23], $\varphi^{-k}(R_i \cap W^s(p_{i+1(\text{mod } N)}))$ approaches $W^s(p_i)$ and $\varphi^k(R_{i-1(\text{mod } N)} \cap W^u(p_{i-1(\text{mod } N)}))$ approaches $W^u(p_i)$ as $k \to \infty$. Thus for k sufficiently large and the U_i sufficiently small, (3) is satisfied. Transversal intersection results because $W^s(p_i)$ and $W^u(p_i)$ intersect transversely at p_i. Once (3) is achieved, we can find U_i sufficiently small so that $\varphi^{-k}(R_i)$ is a vertical strip and $\varphi^k(R_{i-1(\text{mod } N)})$ is a horizontal strip in U_i. Thus, φ^{2k} possess a subsystem equivalent to the generalized horseshoe map, which in turn possesses a subsystem topologically equivalent to the shift on N consecutive symbols.

This last subsystem is termed "chaotic" because of the interesting properties it exhibits under iterations of φ^{2k}. We have orbits of arbitrary period greater than N as well as dense orbits. The bi-infinite sequence corresponding to a dense orbit is formed by concatenating all possible finite sequences of consecutive symbols. We further note the unpredictability of this subsystem. Any two orbits with sequences that agree for some finite length may have completely different sequences further on. Physically we will find these orbits near each other under a finite number of iterations of φ^{2k}, yet the orbits diverge as we proceed past the point where their sequences agree. Thus, knowing where a point will be for a fixed finite time in no way predicts where it will be at later times.

2.4. Melnikov's method. Melnikov [18] devised a method for finding the transverse intersection of stable and unstable manifolds given a time-periodic perturbation of a system with a saddle connection. We present the theorem without proof.

Consider the following planar dynamical system:

$$\text{(A)} \qquad \dot{x} = f(x) + \varepsilon g(x, t), \quad x \in \mathbb{R}^2, \quad g(x, t) = g(x, t+T), \quad 0 \leqq \varepsilon \ll 1,$$

where for $\varepsilon = 0$ we have a saddle connection Γ_0 between two nondegenerate hyperbolic saddle points p_1 and p_2 (see Fig. 2.5). The unstable manifold $W_0^u(p_1)$ of p_1 and the

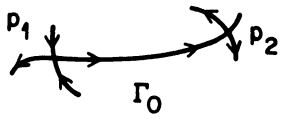

FIG. 2.5

stable manifold $W_0^s(p_2)$ of p_2 coincide. Here we include the homoclinic case where $p_1 = p_2$. Associated with (A) is the suspended system

(B) $$\dot{x} = f(x) + \varepsilon g(x, \theta), \quad (x, \theta) \in \mathbb{R}^2 \times S^1 \quad (S^1 = \mathbb{R}/T).$$

For ε sufficiently small, (B) possesses a Poincaré map: $P_\varepsilon^{t_0}: \Sigma_{t_0} \to \Sigma_{t_0}$ where $\Sigma_{t_0} = \{(x, \theta) \in \mathbb{R}^2 \times S^1 | \theta = t_0\}$ is a global cross-section of the flow. Let $F_t^\varepsilon(x_0, t_0)$ be the flow map of (B) on $\mathbb{R}^2 \times S^1$. $P_\varepsilon^{t_0}$ is obtained by a projection onto the first factor: $P_\varepsilon^{t_0}(x) = \pi(F_T^\varepsilon(x, t_0))$ where $\pi((x, \theta)) = x$. Here $P_\varepsilon^{t_0}$ is a map from $\mathbb{R}^2$ to $\mathbb{R}^2$.

Our assumptions imply that for $\varepsilon = 0$, $P_\varepsilon^{t_0}(x)$ has fixed points at p_1 and p_2 and so the suspended system has circular orbits $\gamma^1 = p_1 \times S^1$, $\gamma^2 = p_2 \times S^1$ with stable and unstable manifolds $W_0^u(\gamma^1)$ and $W_0^s(\gamma^2)$ coinciding to form a "cylinder" $\Gamma_0 \times S^1$. Such saddle connections are quite unstable and thus are expected to break under small perturbations.

We define the Melnikov function

$$M(t_0) = \int_{-\infty}^{\infty} d(q^0(t - t_0)) \wedge g(q^0(t - t_0), t) \exp\left(\int_0^{t - t_0} \operatorname{tr} Df(q^0(s))\, ds\right) dt,$$

where $q^0(t)$ is the solution to the unperturbed equation (A) starting at t_0 on the saddle connection Γ_0. We define the wedge product by $a \wedge b = a_1 b_2 - b_1 a_2$.

In the case where the unperturbed system is Hamiltonian, we have $\operatorname{tr} Df(q^0) = 0$ and the Melnikov function becomes

$$M(t_0) = \int_{-\infty}^{\infty} f(q^0(t - t_0)) \wedge g(q^0(t - t_0), t)\, dt.$$

The examples of §§ 3 and 4 are both Hamiltonian systems. Two useful forms for computation are

$$M(t_0) = \int_{-\infty}^{\infty} f(q^0(t)) \wedge g(q^0(t), t + t_0) \exp\left(\int_0^t \operatorname{tr} Df(q^0(s))\, ds\right) dt$$

in the non-Hamiltonian case and

$$M(t_0) = \int_{-\infty}^{\infty} f(q^0(t)) \wedge g(q^0(t), t + t_0)\, dt$$

in the Hamiltonian case. We note that $M(t_0)$ is itself a periodic function in t_0. Using the second form, we have that

$$\begin{aligned} M(t_0 + T) &= \int_{-\infty}^{\infty} f(q^0(t)) \wedge g(q^0(t), t + t_0 + T) \exp\left(\int_0^t \operatorname{tr} Df(q^0(s))\, ds\right) dt \\ &= \int_{-\infty}^{\infty} f(q^0(t)) \wedge g(q^0(t), t + t_0) \exp\left(\int_0^t \operatorname{tr} Df(q^0(s))\, ds\right) dt \\ &= M(t_0), \end{aligned}$$

since $g(x, t + T) = g(x, t)$.

MELNIKOV'S THEOREM. *Given the above conditions, and ε sufficiently small, if $M(t_0)$ has simple zeros, then $W^s_\varepsilon(p^2_\varepsilon)$ and $W^u_\varepsilon(p^1_\varepsilon)$ intersect transversely. If $M(t_0)$ has no zeros in $t_0 \in [0, T]$ then $W^s_\varepsilon(p^2_\varepsilon) \cap W^u_\varepsilon(p^1_\varepsilon) = \varnothing$.*

For a concise proof of the homoclinic case, the reader is directed to Guckenheimer and Holmes [8]. The heteroclinic proof is an obvious generalization. For details, the reader is referred to [4].

3. Kelvin–Stuart cat's eye flow. Consider the following flow in the plane:

$$\dot{x} = \frac{a \sinh y}{a \cosh y + \sqrt{a^2-1}\cos x},$$

$$\dot{y} = \frac{\sqrt{a^2-1}\sin x}{a \cosh y + \sqrt{a^2-1}\cos x}.$$

This is a Hamiltonian system with $H_0 = \log(a \cosh y + \sqrt{a^2-1}\cos x)$. It is a model for a pattern found in shear layer flow (see [27], [12]). The parameter a controls the shape of the cat's eye with a larger a corresponding to wider "eyes." Here we consider only $a > 1$. Streamlines are constants of H_0 (see Fig. 3.1).

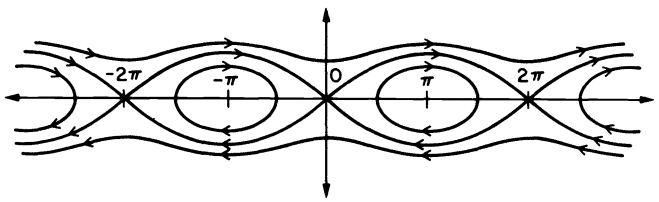

FIG. 3.1

We have fixed points at $(2\pi N, 0)$ that satisfy the conditions for Melnikov's method. Consider the upper trajectory $(x_0(t), y_0(t))$ from $(0, 0)$ to $(2\pi, 0)$. Along this trajectory we have x_0 satisfying the equation

$$\dot{x}_0 = a\sqrt{\left(\frac{a}{\sqrt{a^2-1}} + 1 - \cos x_0\right)^2 \left(\frac{a^2-1}{a^2}\right) - 1} \Big/ \left(a + \sqrt{a^2-1}\right).$$

This implicitly defines x_0 by

$$t = \int_\pi^{x_0} (a + \sqrt{a^2-1})\, dx \Big/ a\sqrt{\left(\frac{a^2-1}{a^2}\right)\left(\cos x - \frac{a}{\sqrt{a^2-1}} - 1\right)^2 - 1}.$$

By changing variables to $s = 1 - \cos x$, this integral becomes

$$\int_2^{1-\cos x_0} \left(\left(\frac{a}{\sqrt{a^2-1}} + 1\right) \Big/ s\sqrt{\left(s + \frac{2a}{\sqrt{a^2-1}}\right)(2-s)}\right) ds.$$

This can be solved exactly to yield

$$\cos x_0 = 1 - \left(\frac{8a}{a + \sqrt{a^2-1}}\right)\left(\frac{1}{e^{\gamma t} + \beta + e^{-\gamma t}}\right),$$

$$\gamma = \left(\frac{\sqrt{a^2-1}}{a + \sqrt{a^2-1}}\right)\sqrt{\frac{4a}{\sqrt{a^2-1}}}, \qquad \beta = 2\frac{a - \sqrt{a^2-1}}{a + \sqrt{a^2-1}}$$

along the upper saddle connection from $(0, 0)$ to $(2\pi, 0)$.

3.1. Periodic stretching of the cat's eye flow. Instead of examining a general perturbation $g(\vec{x}, t)$, consider a perturbation of the parameter a. If we take a to be a time-varying parameter of the form $a_0+\varepsilon b(t)$, where $b(t)$ is periodic with period T, we get a phase diagram where the "cat's eyes" are periodically stretched and compressed by an ε amount. This corresponds to a time-dependent solution to the Euler equation with external force.

To first order in ε, our perturbed equation is

$$\dot{x} = \frac{a_0 \sinh y}{a_0 \cosh y + \sqrt{a_0^2-1}\cos x} - \frac{\varepsilon b(t) \sinh y \cos x}{\sqrt{a_0^2-1}(a_0 \cosh y + \sqrt{a_0^2-1}\cos x)^2},$$

$$\dot{y} = \frac{\sqrt{a_0^2-1}\sin x}{a_0 \cosh y + \sqrt{a_0^2-1}\cos x} + \frac{\varepsilon b(t) \sin x \cosh y}{\sqrt{a_0^2-1}(a_0 \cosh y + \sqrt{a_0^2-1}\cos x)^2}.$$

Thus the driving force for our perturbation is

$$\vec{F}_\varepsilon = \frac{\varepsilon b'(t)}{\sqrt{a_0^2-1}} e^{-2H_0(x,y)} \begin{pmatrix} -\sinh y \cos x \\ \sin x \cosh y \end{pmatrix}.$$

The perturbed Hamiltonian for this system is

$$H = H_0 + \frac{\varepsilon b(t)}{\sqrt{a_0^2-1}} \left(\frac{\sqrt{a_0^2-1}\cosh y + a_0 \cos x}{a_0 \cosh y + \sqrt{a_0^2-1}\cos x} \right)$$
$$= H_0 + H_1.$$

Along all streamlines of the unperturbed flow,

$$H_1 \propto b(t)\left(\sqrt{a_0^2-1}\cosh y + a_0 \cos x\right).$$

Since the saddle connections are streamlines of the unperturbed flow, how they break up under a perturbation depends only on the perturbation at the points of the saddle connection. Thus, the Melnikov function for the above perturbation is identical to the one corresponding to the simpler perturbation

$$H_1 = \varepsilon b(t)\left(\sqrt{a^2-1}\cosh y + a \cos x\right).$$

If we let $b(t)$ have the form $\cos(kt)$, then this perturbation corresponds to the superposition of four waves:

$$\sqrt{a^2-1}\cosh y(e^{i(z-kt)} + e^{i(z+kt)}) + a(e^{i(x-kt)} + e^{i(x+kt)}).$$

Here z is the third coordinate and we take the cross-sectional flow in the plane $z=0$. The wavelength of the perturbation is exactly equal to the length of one of the cat's eyes. The wave speed is allowed to vary.

3.2. The Melnikov function for periodic stretching. Consider the upper trajectory $(x_0(t), y_0(t))$ from $(0, 0)$ to $(2\pi, 0)$ for the unperturbed system.

The Melnikov function for this trajectory is

$$M(t_0) = \int_{-\infty}^{\infty} C_1[(a_0 \sin x_0(t) \cosh y_0(t) \sinh y_0(t)$$
$$+\sqrt{a_0^2-1}\sinh y_0(t) \cos x_0(t) \sin x_0(t) b(t+t_0))]\, dt,$$

which can be reduced to

$$M(t_0) = \int_{-\infty}^{\infty} C_2(\sin x_0(t) \sinh y_0(t) b(t+t_0))\, dt$$

where

$$C_2 = \frac{1}{\sqrt{a_0^2-1}(a_0+\sqrt{a_0^2-1})^2}.$$

Here we have exploited the fact that

$$a_o \cosh y_0(t) + \sqrt{a_0^2-1} \cos x_0(t) = a_0 + \sqrt{a_0^2-1}.$$

We expand $b(t)$ into its Fourier series:

$$b(t) = \sum_{-\infty}^{\infty} (a_k \sin kt + b_k \cos kt).$$

The above Melnikov integral then becomes

$$\sum_{k=-\infty}^{\infty} \int_{-\infty}^{\infty} C_2 \sin x_0(t) \sinh y_0(t)(a_k \sin k(t+t_0) + b_k \cos k(t+t_0))\, dt$$

$$= \sum_{k=-\infty}^{\infty} \left((a_k \cos kt_0 - b_k \sin kt_0) \int_{-\infty}^{\infty} C_2 \sin x_0(t) \sinh y_0(t) \sin (kt)\, dt \right)$$

$$= \sum_{k=-\infty}^{\infty} ((a_k \cos (kt_0) - b_k \sin (kt_0)) M_0(k)),$$

where we define

$$M_0(k) = \int_{-\infty}^{\infty} C_3 \frac{d}{dt}[\cos x_0(t)] \sin (kt)\, dt,$$

$$C_3 = -(a_0+\sqrt{a_0^2-1})C_2.$$

We have used the fact that $\sin x_0(t) \sinh y_0(t)$ is an odd function in t. Thus,

$$M_0(k) = \int_{-\infty}^{\infty} C_4 \frac{e^{\gamma t} - e^{-\gamma t}}{(e^{\gamma t} + \beta_0 + e^{-\gamma t})^2} \sin (kt)\, dt,$$

$$C_4 = C_3\left(\gamma\left(\frac{8a_0}{a_0+\sqrt{a_0^2-1}}\right)\right).$$

Evaluation by residues (see Appendix A) yields, for $k \neq 0$,

$$\left(\frac{\gamma}{2\pi C_4}\right) M_0(k) = \left[\frac{m e^{-|m|\alpha}}{2 \sin \alpha} - \left(\frac{e^{-|m|2\pi}}{1-e^{-|m|2\pi}}\right)\left(\frac{m \sinh |m|\alpha}{\sin \alpha}\right)\right],$$

$$m = \frac{k}{\gamma}, \quad \alpha = \cos^{-1}\left(\frac{\beta_0}{2}\right), \quad 0 < \alpha < \pi/2.$$

Whether or not $M(t_0)$ has simple zeros depends on the values of a_k and b_k. For instance, if $b(t)$ is of the form $\cos kt$, then we see that $M(t_0)$ has simple zeros for almost all k. A similar analysis shows that the lower trajectory has a Melnikov function that is just the negative of the one for the upper trajectory. Since both trajectories break up under the same perturbation to yield the transverse intersection of stable and unstable manifolds, we have satisfied the requirements for the heteroclinic theorem (Theorem 2.3.1) with $N = 2$. Our perturbed system has a chaotic subsystem topologically equivalent to a shift on two symbols.

3.3. Mixing in the perturbed cat's eye flow. By exploiting the symmetry of this model, we see that this perturbing function breaks up all trajectories transversely. In fact, we can view both the perturbed and unperturbed cases as flows on the cylinder. Here we take $x \in \mathbb{R}/2\pi$, $y \in \mathbb{R}$. All of the saddle points are identified and we obtain two homoclinic orbits to a single saddle point. We can now use the standard homoclinic theorem to find a shift on two symbols.

Based on the proof of the theorem from the second section, we expect mixing to occur at least within the region around the fixed point. We know that there exists a neighborhood U of the fixed point $(0, 2\pi N)$ on which the Poincaré map for this system acts like a version of the horseshoe map (see Fig. 3.2).

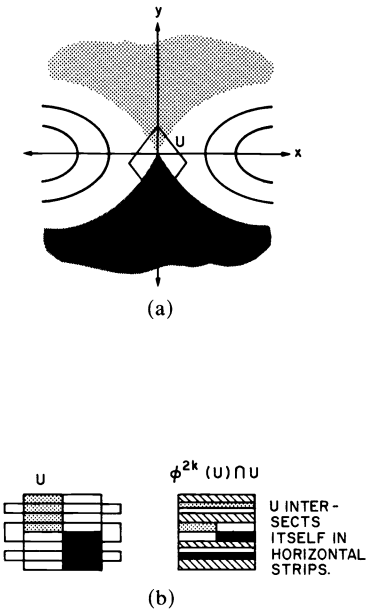

FIG. 3.2. (a) *The cat's eye flow on the cylinder.* (b) *Perturbed cat's eye flow. Here the top and bottom layers are mixed into the cat's eyes region and eventually into each other.*

Viewed as a flow on the plane, we see that the perturbed system has a geometric structure similar to that of Holmes's perturbed sine-Gordon equation [11, § 3]. We show that the perturbed cat's eye flow has a subsystem isomorphic to the shift on the symbols "+" and "−," where the "+" corresponds to traveling "downstream" along an upper trajectory and the "−" corresponds to traveling "upstream" along a lower trajectory (see Fig. 3.3). This provides a mechanism for fluid inside one cat's eye to travel both upstream and downstream. This mechanism does not exist for the unperturbed case, since flow within an "eye" will remain there for all time. In the perturbed system, all saddle connections are broken up to give us transversal intersection of stable and unstable manifolds. The heteroclinic theorem tells us that at each fixed point $p_n = (2\pi n, 0)$, there is a neighborhood U_n, a unit square in local coordinates, such that for some fixed time T^*, the flow φ_{T^*} maps U_i to intersect U_{i-1} and U_{i+1} in horizontal strips. A simplified model of the dynamics present is pictured in Fig. 3.4. Here each U_i is intersected by the horizontal strips $H_{i-1,i} = \varphi(U_{i-1}) \cap U_i$ and $H_{i+1,i} = \varphi(U_{i+1}) \cap U_i$.

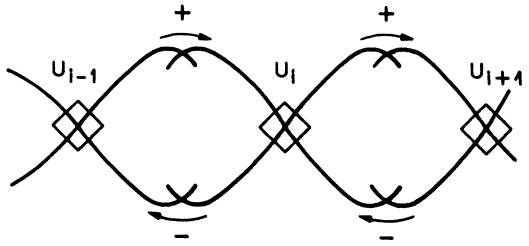

FIG. 3.3

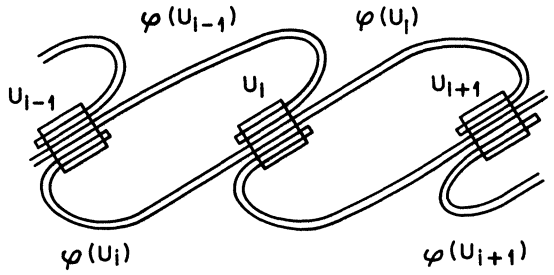

FIG. 3.4

By the symmetry of the flow and its perturbation, we can choose each U_i so that $U_i + 2\pi = U_{i+1}$ and $\varphi(U_i) + 2\pi = \varphi(U_{i+1})$. Our invariant set is

$$I = \bigcap_{k=-\infty}^{\infty} \varphi^{-k}\left(\bigcup_i (H_{i+1,i} \cup H_{i-1,i})\right).$$

I can be decomposed into disjoint sets $I_i = U_i \cap I$. For any given i, we have a one-to-one correspondence between I_i and $S^{\pm}$, the set of all bi-infinite sequences of "+" and "−":

$$\tau : I_i \to S^{\pm},$$
$$[\tau(x)]_l = \quad + \quad \text{if } \varphi^l(x) \in U_k \Rightarrow \varphi^{l+1}(x) \in U_{k+1},$$
$$= \quad - \quad \text{if } \varphi^l(x) \in U_k \Rightarrow \varphi^{l+1}(x) \in U_{k-1}.$$

Thus there is a set $S^{\pm}$ of sequences corresponding to each I_i. We see that there is a mechanism for pieces of fluid to move rather chaotically both upstream and downstream as well as for fluid within each "eye" to mix with fluid in other "eyes." This mixing and chaotic motion was not present in the unperturbed cat's eye flow. The fact that the perturbation cos kt leads to such chaos for almost all k indicates that such mixing may be rather common in the actual shear layers.

4. Planar lattice flow. We consider the following flow:

$$\dot{x}_1 = -\sin(2\pi x_1)\sin(2\pi x_2), \qquad \dot{x}_2 = -\cos(2\pi x_1)\cos(2\pi x_2)$$

a Hamiltonian system with $H_0 = (2\pi)^{-1}\sin(2\pi x_1)\cos(2\pi x_2)$ (see Fig. 4.1). This is a model for axisymmetric Taylor vortex flow as well as for many convective flows. If we take x_1 to be a moving coordinate, these equations model the Rossby waves of geophysical fluid dynamics (see [24, p. 84]). This flow is obviously doubly periodic, yielding a flow on the torus $T = \mathbb{R}^2/\Gamma$ where Γ is the lattice $\{(n_1, n_2);\ n_1, n_2 \in \mathbb{Z}\}$.

Viewed as a flow on the torus T, we obtain a system with heteroclinic orbits connecting four saddle points. Melnikov's theory can then be applied to perturbations of this flow.

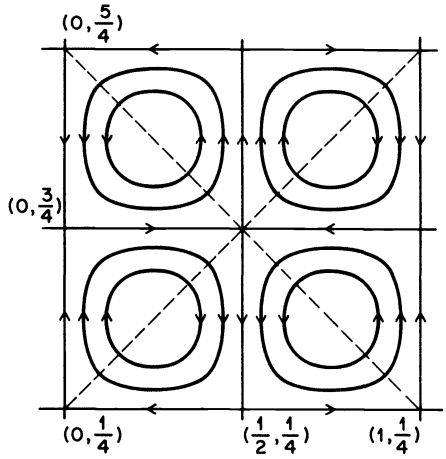

FIG. 4.1. Γ' *is represented by the dashed line.*

We can also map this flow onto a "smaller" torus $T' = \mathbb{R}^2/\Gamma'$ where $\Gamma' = \{(\frac{1}{2}(n_1 - n_2), \frac{1}{2}(n_1 + n_2))\}$ (see Fig. 4.1). Here we have exploited the periodicity in the variables $(x_1 - x_2)$, $(x_1 + x_2)$ as well as in x_1 and x_2. The flow on T' has only two heteroclinic saddle points. By examining perturbed flows on T', we can look for a subsystem that is a shift on two symbols. This horseshoe-like structure will result if all heteroclinic orbits are broken up so that stable and unstable manifolds intersect transversely.

4.1. Time- and space-dependent perturbations. We consider two types of perturbations, ones that are functions of time only and ones that have an added space dependence. In the purely time-dependent case, we have $\varepsilon \vec{f}(t)$ as a perturbation to the velocity field, with $\vec{f}(t) = \vec{f}(t+T)$. This corresponds to an external driving force $\vec{F}_\varepsilon = \varepsilon \vec{f}'(t)$ that is uniform in space at any given moment. This is physically reasonable as an approximation to an external force that is time-periodic and has an average space variation much larger than the periodic lattice structure of the flow. For the vertical saddle connections, the Melnikov function for this perturbation is

$$M_v(t_0) = \pm \int_{-\infty}^{\infty} \cos(2\pi x_2(t)) f_1(t + t_0)\, dt$$

since $\sin(2\pi x_1) = 0$ for these trajectories. Likewise for the horizontal orbits, $\cos(2\pi x_2) = 0$ and so

$$M_h(t_0) = \pm \int_{-\infty}^{\infty} \sin(2\pi x_1(t)) f_2(t + t_0)\, dt.$$

We see that the vertical and horizontal components of $\vec{f}$ are decoupled. We will show by symmetry properties that f_1 and f_2 must satisfy the same conditions in order for M_v and M_h to have simple zeros. For this space-independent perturbation, the Γ'-lattice symmetry is preserved and chaotic motion can be reduced to a subsystem isomorphic to the shift on two symbols. The following example presents a spatially dependent perturbation that breaks up the Γ' symmetry.

In general, a perturbing velocity of the form

$$\varepsilon \begin{pmatrix} v_1(x_2, t) \\ v_2(x_1, t) \end{pmatrix}$$

constitutes a solution to the two-dimensional Euler equation with external force

$$\vec{F}_\varepsilon = \varepsilon \begin{pmatrix} \partial v_1(x_2, t)/\partial t \\ \partial v_2(x_1, t)/\partial t \end{pmatrix}.$$

A particularly interesting perturbation of this form is

$$\varepsilon \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} = \varepsilon \begin{pmatrix} \cos(2\pi x_2)\cos kt \\ \sin(2\pi x_1)\cos kt \end{pmatrix}.$$

This has a stream function

$$\frac{\varepsilon}{2\pi}\cos kt[\sin(2\pi x_2) - \cos(2\pi x_1)],$$

which can be viewed as a superposition of linear waves traveling along coordinate axes:

$$-(e^{i(2\pi x_1 + kt)} + e^{i(2\pi x_1 - kt)}) - i(e^{i(2\pi x_2 + kt)} - e^{i(2\pi x_2 - kt)}).$$

This perturbation is geometrically interesting because it breaks up the Γ' symmetry and we are forced to consider heteroclinic orbits joining four points instead of two points. We shall show that for almost all k, the saddle connections break up to yield a subsystem topologically equivalent to the shift on four consecutive symbols.

4.2. Explicit calculation of the Melnikov functions. Along an unperturbed horizontal saddle connection, we have

$$\dot{x}_1 = \pm\sin(2\pi x_1), \qquad \dot{x}_2 = 0$$

and along a vertical connection

$$\dot{x}_2 = \pm\cos(2\pi x_2), \qquad \dot{x}_1 = 0.$$

In the case of the connection from $(\frac{1}{2}, \frac{1}{4})$ to $(0, \frac{1}{4})$, we have $\dot{x}_1 = -\sin(2\pi x_1)$. This has a solution $x_1 = (1/\pi)\tan^{-1}(e^{-2\pi t})$, which by symmetry properties of the flow yields

$$\sin(2\pi x_1) = \pm\frac{2e^{-2\pi t}}{1+e^{-4\pi t}}$$

along all horizontal connections and

$$\cos(2\pi x_2) = \pm\frac{2e^{-2\pi t}}{1+e^{-4\pi t}}$$

along all vertical ones.

For a spatially independent perturbation, the Melnikov function of § 4.1, for either saddle connection, is of the form

$$M_i(t_0) = \int_{-\infty}^{\infty} \frac{2e^{-2\pi t}}{1+e^{-4\pi t}} f_i(t+t_0)\, dt.$$

If we expand f_i into its Fourier series

$$f_i(t) = \sum_{k=-\infty}^{\infty} \left(A_k \cos\left(\frac{2\pi kt}{T}\right) + B_k \sin\left(\frac{2\pi kt}{T}\right)\right)$$

we find that

$$M_i(t_0) = \sum_{k=-\infty}^{\infty} \left[\left(A_k \cos\left(\frac{2\pi kt_0}{T}\right) + B_k \sin\left(\frac{2\pi kt_0}{T}\right)\right) \int_{-\infty}^{\infty} \frac{2e^{-2\pi t}}{1+e^{-4\pi t}} \cos\left(\frac{2\pi kt}{T}\right) dt \right].$$

Evaluation by residues reveals

$$M_i(t_0) = \sum_{k=-\infty}^{\infty} \left(A_k \cos\left(\frac{2\pi k t_0}{T}\right) + B_k \sin\left(\frac{2\pi k t_0}{T}\right)\right)\left(\frac{1}{e^{-\pi k/2T} + e^{\pi k/2T}}\right).$$

Whether or not $M_i(t_0)$ has simple zeros depends on the respective values of A_k and B_k. For example, if $f_i = A_0 + A_1 \cos(2\pi k t/T)$, we require

$$|A_0| < |A_1| \left[\frac{2}{e^{-\pi k/2T} + e^{\pi k/2T}}\right]$$

for $M_i(t_0)$ to have simple zeros. Now we see that the class of perturbing functions $\vec{f} = (A \cos(t), B \sin(t))$ yields $M_v(t_0)$ and $M_h(t_0)$ with simple zeros for all saddle connections. Applying the results of § 2, we obtain a shift on four symbols as a subsystem of the perturbed flow on T, and a shift on two symbols as a subsystem of the perturbed flow on T'.

For the spatially dependent perturbation

$$\varepsilon \begin{pmatrix} \cos(2\pi x_2) \cos kt \\ \sin(2\pi x_1) \cos kt \end{pmatrix}$$

we find that, up to a change of sign, the Melnikov function for either a vertical or horizontal saddle connection is

$$M(t_0) = 4 \cos(kt_0) \int_{-\infty}^{\infty} \frac{e^{-4\pi t}}{(1+e^{-4\pi t})^2} \cos kt \, dt$$

which we evaluate via residues (using the procedure outlined in Appendix A for the calculation of the integral in § 3) to be

$$\begin{aligned} M(t_0) &= \cos kt_0 \left(\frac{k}{4\pi \sinh(k/4)}\right) \\ &= \cos kt_0 M_0(k). \end{aligned}$$

$M_0(k)$ is nonzero for almost all k so that the Melnikov function will have simple zeros and we have a subsystem topologically equivalent to the shift on four consecutive symbols.

4.3. Mixing in the perturbed lattice flow. Under both perturbations, we expect some sort of mixing to occur that was not present in the unperturbed case. In the perturbed systems, all connections are broken up to yield transverse intersection of stable and unstable manifolds. As in the cat's eye model, at each fixed point $p_{n_1 n_2} = (\frac{1}{2}n_1, \frac{1}{2}n_2 + \frac{1}{4})$, $n_1, n_2 \in \mathbb{Z}$, we have neighborhoods $U_{n_1 n_2}$ that intersect each other in horizontal strips under some fixed time mapping of the flow (see Fig. 4.2). In the case of the first perturbation studied, we can exploit the T' symmetry to obtain a subsystem topologically equivalent to the shift on two symbols. The perturbed and unperturbed systems are both flows on the torus T'. Under this symmetry, we can identify all clockwise rotating cells with each other and likewise all counterclockwise rotating cells with each other (Fig. 4.3). In the unperturbed case, these patches of fluid do not mix. The perturbation satisfies the conditions of the heteroclinic theorem with two fixed points, yielding a subsystem of the flow topologically equivalent to the shift on two symbols. In the perturbed case we see mixing patterns similar to those present in the cat's eye flow.

In the case of the second perturbation, we do not have the T' symmetry. The cells break up into two different clockwise and counterclockwise rotations (see Fig. 4.3).

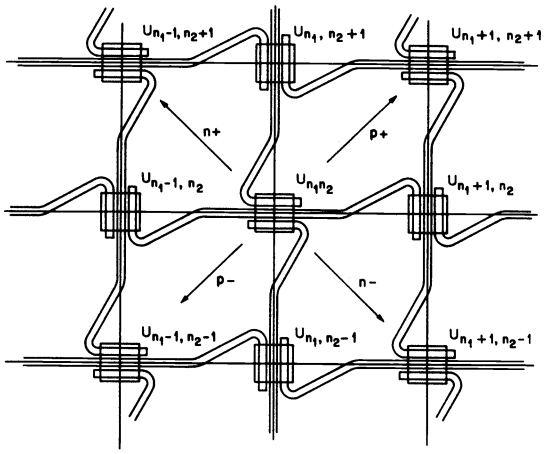

FIG. 4.2

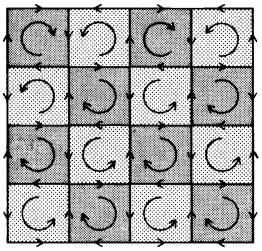
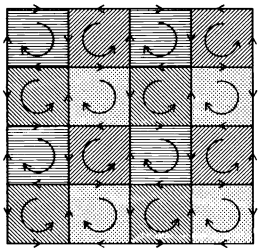


(a)



(b)

FIG. 4.3. (a) *Flow on T'. All clockwise rotating cells are identified, as are all counterclockwise rotating cells.* (b) *Flow on T. There are two types of clockwise rotations as well as two types of counterclockwise rotations.*

On the torus T we have four fixed points in the heteroclinic orbit and our system breaks up to yield a subsystem topologically equivalent to the shift on four consecutive symbols. In the previous case we have symbols 1 and 2 identified with 3 and 4, respectively. This is analogous to identifying the two clockwise rotations with each other and likewise the two counterclockwise rotations with each other. Again we expect similar mixing patterns to occur.

In the cat's eye flow, we found a mechanism for traveling up- and downstream randomly within the cat's eyes. This corresponded to a shift in the symbols "+" and "−." In the lattice flow, we find a mechanism for traveling all over the plane, along the Γ' lattice. We find that the perturbed lattice flow has a subsystem isomorphic to the shift on the four symbols "n_+," "n_-," "p_+," "p_-." Here, $n_\pm$ corresponds to a

translation by $\pm(-\frac{1}{2}, \frac{1}{2})$ along the lattice. Likewise $p_\pm$ corresponds to a translation by $\pm(\frac{1}{2}, \frac{1}{2})$ (see Fig. 4.2).

In the neighborhood $U_{n_1 n_2}$ of each fixed point $p_{n_1 n_2}$, we find that for some fixed time T^*, the flow φ_{T^*} maps $U_{n_1 n_2}$ to intersect U_{n_1-1,n_2} and U_{n_1+1,n_2} for n_1+n_2 odd, or U_{n_1,n_2-1} and U_{n_1,n_2+1} for n_1+n_2 even, in horizontal strips (see Fig. 4.2).

These strips are mapped to smaller strips in U_{n_1-1,n_2-1}, U_{n_1+1,n_2-1}, U_{n_1-1,n_2+1}, U_{n_1+1,n_2+1}, by a second iteration of φ_{T^*}. Thus φ_{2T^*} maps $U_{n_1 n_2}$ to intersect U_{n_1-1,n_2-1}, U_{n_1+1,n_2-1}, U_{n_1-1,n_2+1}, U_{n_1+1,n_2+1}, in horizontal strips.

For convenience, we now refer to φ_{2T^*} as φ. Thus our invariant set is

$$I = \bigcap_{k=-\infty}^{\infty} \varphi^{-k}\left(\bigcup_{n_1,n_2} (\varphi(U_{n_1 n_2}) \cap (U_{n_1-1,n_2-1} \cup U_{n_1+1,n_2-1} \cup U_{n_1-1,n_2+1} \cup U_{n_1+1,n_2+1}))\right),$$

where I can be decomposed into the disjoint sets $I_{n_1 n_2} = U_{n_1 n_2} \cap I$. For any given pair (n_1, n_2), there is a one-to-one correspondence between $I_{n_1 n_2}$ and the set of bi-infinite sequences on the symbols p_+, p_-, n_+, n_-:

$$\tau : I_{n_1 n_2} \to S$$

$$[\tau(x)]_l = p_+ \quad \text{if } \varphi^l(x) \in U_{n_1 n_2} \Rightarrow \varphi^{l+1}(x) \in U_{n_1+1,n_2+1},$$

$$[\tau(x)]_l = p_- \quad \text{if } \varphi^l(x) \in U_{n_1 n_2} \Rightarrow \varphi^{l+1}(x) \in U_{n_1-1,n_2-1},$$

$$[\tau(x)]_l = n_+ \quad \text{if } \varphi^l(x) \in U_{n_1 n_2} \Rightarrow \varphi^{l+1}(x) \in U_{n_1-1,n_2+1},$$

$$[\tau(x)]_l = n_- \quad \text{if } \varphi^l(x) \in U_{n_1 n_2} \Rightarrow \varphi^{l+1}(x) \in U_{n_1+1,n_2-1}.$$

Thus, fluid particles within one cell can travel randomly around the plane in the perturbed case. In the unperturbed case, this sort of mixing is not allowed since fluid within one cell will remain there for all time.

5. Motion of an elliptical vortex in a strain field. An important part of fluid mechanics is the study of vortices, their structure, and how they interact with one another. In §§ 3 and 4 we examined two well-known two-dimensional planar fluid models. Since organized vortex structures are observed frequently, we would like to find a simple model for a vortex affected by a field of neighboring vortices. As the examples of §§ 3 and 4 indicate, the presence of multiple vortices in stationary planar fluid flow often results in fixed points of the flow, between vortex structures, that can be modeled as hyperbolic saddle points in a planar dynamical system. In a neighborhood of such saddle points, the velocity field is roughly linear and can be locally approximated by a simple strain. Thus it is physically reasonable to model certain vortex interaction locally as a single vortex in a straining flow. Moore and Saffman [20], as well as Neu [21], describe vortex interaction that can be modeled in such a way.

We study the motion of an elliptical vortex in a three-dimensional imposed strain. We see that the evolution of such a vortex can be characterized as a planar dynamical system that has interesting Hamiltonian and non-Hamiltonian formulations involving the aspect ratio $\eta = a/b$ and the angle θ of rotation of the ellipse. Here a and b correspond to the major and minor axes of the ellipse. We apply Melnikov's method to the evolution equations of the vortex to show chaotic dynamics occurring in the presence of three-dimensional periodic stretching of the imposed strain. The actual analysis differs somewhat from what was done in the previous sections in that we study chaos occurring in the evolution equation of the shape and orientation of the ellipse as opposed to chaos occurring in the flow pattern of an actual fluid model.

5.1. Hamiltonian formulation of exact Euler solution. The Hamiltonian formulation presented below is due to Neu [22] and represents a three-dimensional generalization of the exact solutions of an elliptical vortex in a two-dimensional straining flow (described by Kida [14]). First consider a planar vortex region in the shape of an ellipse with constant vorticity in the interior. The points on the boundary of the region are solutions to the equation $x^2/a^2+y^2/b^2=\text{constant}$. Following a potential theory calculation described in Lamb [15], we see that the velocity field inside the ellipse is linear:

$$\begin{pmatrix}\dot{x}\\ \dot{y}\end{pmatrix}=\tilde{U}(a,b,\theta)\begin{pmatrix}x\\ y\end{pmatrix},$$

$$\tilde{U}(a,b,\theta)=-\frac{\omega}{a+b}R(\theta)\begin{pmatrix}0 & a\\ -b & 0\end{pmatrix}R(\theta).$$

Here a and b correspond, respectively, to the major and minor axes of this elliptical cross-section and θ is the angle of the major axis with respect to the x-axis. $R(\theta)$ is the rotation matrix

$$\begin{pmatrix}\cos\theta & -\sin\theta\\ \sin\theta & \cos\theta\end{pmatrix}.$$

In three dimensions we have a cylindrical vortex region whose cross-section in the xy-plane is the above velocity field. We add an irrotational straining field the velocity of which is given by $v=(\gamma' x,-\gamma y,\gamma'' z)$ where $\gamma'-\gamma+\gamma''=0$ is required for incompressibility. The combination of vortex and strain yields a fluid velocity that, in the xy-plane, has the form $U(a,b,\theta)(x,y)^T$ where

$$U(a,b,\theta)=-\frac{\omega}{a+b}R(\theta)\begin{pmatrix}0 & a\\ -b & 0\end{pmatrix}R(\theta)+\begin{pmatrix}\gamma' & 0\\ 0 & -\gamma\end{pmatrix}.$$

The velocity field inside the vortex is again linear and the path of a fluid particle on the boundary must satisfy the equation of an ellipse which we write in matrix form:

$$\begin{pmatrix}x\\ y\end{pmatrix}E(a,b,\theta)\begin{pmatrix}x & y\end{pmatrix}=\text{constant},$$

$$E(a,b,\theta)=R(\theta)\begin{pmatrix}a^{-2} & 0\\ 0 & b^{-2}\end{pmatrix}R(\theta).$$

Differentiating the ellipse equation, we obtain

$$\dot{X}^TEX+X^T\dot{E}X+X^TE\dot{X}=0$$

where X is the vector (x,y). Since $\dot{X}=U(a,b,\theta)X$, we have the matrix evolution equation

$$\dot{E}+U^TE+EU=0,$$

which we can write out explicitly in terms of a, b, and θ to give us the evolution equations for the elliptical vortex:

$$\dot{a}+(\gamma\sin^2\theta-\gamma'\cos^2\theta)a=0,$$

$$\dot{b}+(\gamma\cos^2\theta-\gamma'\sin^2\theta)b=0,$$

$$\dot{\theta}=\frac{\omega ab}{(a+b)^2}-\frac{1}{2}(\gamma+\gamma')\frac{a^2+b^2}{a^2-b^2}\sin 2\theta.$$

These evolution equations have the following Hamiltonian formulation: let $\eta=a/b$ be the aspect ratio and τ be a dimensionless time defined by $d\tau/dt=\omega\eta^2/(\eta^2-1)$.

Then the evolution equations become

$$\frac{d\eta}{d\tau} = -\frac{\partial H}{\partial \theta} = \frac{\gamma+\gamma'}{\omega}\left(\eta - \frac{1}{\eta}\right)\cos 2\theta,$$

$$\frac{d\theta}{d\tau} = \frac{\partial H}{\partial \eta} = \frac{\eta-1}{\eta(1+\eta)} - \frac{1}{2}\frac{\gamma+\gamma'}{\omega}\left(1+\frac{1}{\eta^2}\right)\sin 2\theta,$$

$$H = \log\frac{(1+\eta)^2}{\eta} - \frac{1}{2}\frac{\gamma+\gamma'}{\omega}\left(\eta - \frac{1}{\eta}\right)\sin 2\theta.$$

We consider γ, γ', and ω to be, in general, time-dependent parameters in this equation. The total circulation of the vortex is $\Gamma = \pi ab\omega$, which we know to be constant by the Kelvin Circulation Theorem (see [6, p. 28]). The evolution equations imply that

$$\frac{d(ab)}{dt} = (\gamma' - \gamma)ab$$

so that

$$ab = a_0 b_0 e^{(\gamma'-\gamma)t},$$

which in turn yields

$$\omega = \omega_0 e^{(\gamma-\gamma')t}.$$

Thus, when $\gamma'' = 0$, $\gamma' - \gamma + \gamma'' = 0$ implies that $\gamma = \gamma'$. Our Hamiltonian system is autonomous if and only if $\gamma'' = 0$, γ, γ' are both constant. We will consider the case where this autonomous Hamiltonian system is perturbed by a periodic stretching of the strain where we set $\gamma'' = \varepsilon g(t)$.

In the autonomous case, we have $\gamma = \gamma'$, and are interested in the dynamics indicated in the phase portrait for $0 < \gamma/\omega < 0.15$ (see Fig. 5.1). There are no heteroclinic

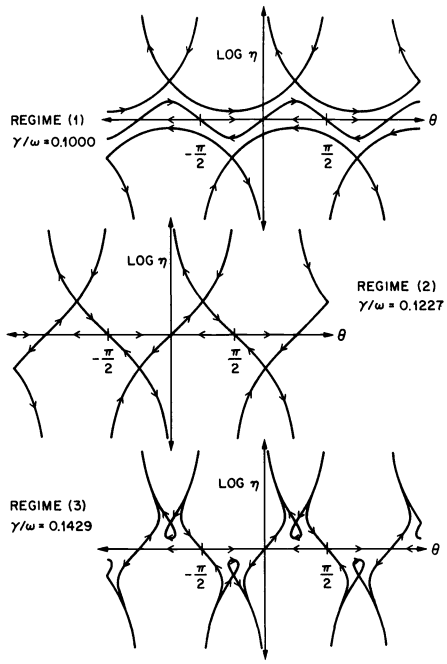


FIG. 5.1

orbits in the phase portrait for $\gamma/\omega > .15$. The three interesting regimes are depicted in Fig. 5.1:

(1) For $0 < \gamma/\omega < .1227$, there are oscillating regions (bubbles close to the $\log \eta = 0$ axis) as well as rotating regions between the bubbles and the outer saddle connections.

(2) At $\gamma/\omega = .1227$ we have a bifurcation where saddle connections between three fixed points exist for this value of γ/ω only.

(3) For γ/ω between .1227 and .15, we have homoclinic saddle connections, the interior of which represents an ellipse oscillating about the ray $\theta = \pi/4$.

The importance of the bifurcation is that in regimes (2) and (3) we no longer have the possibility of a rotating ellipse.

5.2. Real time formulation of evolution equations. In order to apply Melnikov's method to the above Hamiltonian system, we would need to consider time-periodic perturbations of the dimensionless time τ. This is not a reasonable physical model, since a periodic perturbation of the straining flow would be periodic in real time, and not in the dimensionless time τ. Note that the evolution equations written in terms of the orientation, aspect ratio and real time are

$$\frac{d\theta}{dt} = \frac{\omega\eta}{(\eta+1)^2} - \frac{1}{2}(\gamma+\gamma')\frac{\eta^2+1}{\eta^2-1}\sin 2\theta,$$

$$\frac{d\eta}{dt} = (\gamma+\gamma')\eta\cos 2\theta.$$

Since (η, θ) and $(\eta^{-1}, \theta+\pi/2)$ correspond to the same ellipse, we can parameterize the evolution equation in terms of $r = \log \eta$, $\varphi = 2\theta$, and yield a polar coordinates formulation for these equations in which there is a one-to-one correspondence between ellipses and points in the phase space (r, φ). The evolution equations become

$$\dot{r} = (\gamma+\gamma')\cos\varphi$$

$$\dot{\varphi} = \frac{2\omega e^r}{(e^r+1)^2} - (\gamma+\gamma')\frac{e^{2r}+1}{e^{2r}-1}\sin\varphi.$$

From the Hamiltonian formulation, we know that trajectories correspond to constants of

$$H = \log\left[\frac{(1+e^r)^2}{e^r}\right] - \frac{\gamma+\gamma'}{2\omega}(e^r - e^{-r})\sin\varphi.$$

This can be verified by calculating $dH/dt = 0$ for the real time t. These equations seem to blow up for $r = 0$. Fortunately, we see that this blow-up is due to the coordinates we are using and not the equations themselves. Polar coordinates are not well defined at $r = 0$ so we convert the equations to Cartesian form by $x = r\cos\varphi$, $y = r\sin\varphi$. The evolution equations become:

$$\dot{x} = (\gamma+\gamma')\frac{x^2}{x^2+y^2} - \frac{2\omega y e^{\sqrt{x^2+y^2}}}{(e^{\sqrt{x^2+y^2}}+1)^2} + (\gamma+\gamma')\frac{e^{2\sqrt{x^2+y^2}}+1}{e^{2\sqrt{x^2+y^2}}-1}\frac{y^2}{\sqrt{x^2+y^2}},$$

$$\dot{y} = (\gamma+\gamma')\frac{xy}{x^2+y^2} + \frac{2\omega x e^{\sqrt{x^2+y^2}}}{(e^{\sqrt{x^2+y^2}}+1)^2} - (\gamma+\gamma')\frac{e^{2\sqrt{x^2+y^2}}+1}{e^{2\sqrt{x^2+y^2}}-1}\frac{xy}{\sqrt{x^2+y^2}}.$$

We see that as $r \to 0$, the first and third terms in $\dot{x}$ appear to blow up. Using Taylor

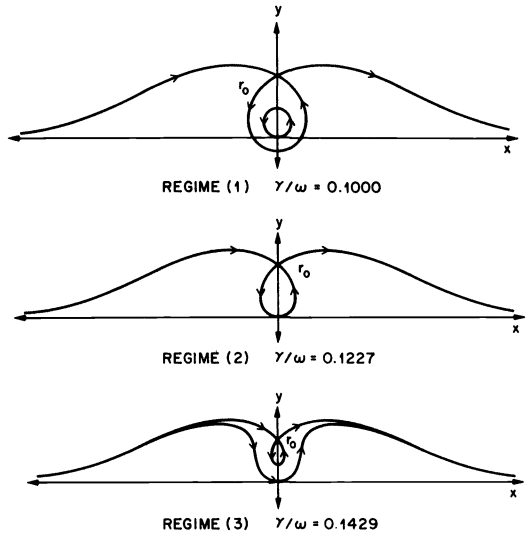

FIG. 5.2

expansion techniques, we see that the third term can be approximated by

$$(\gamma+\gamma')\frac{y^2}{x^2+y^2}(1+\mathcal{O}(r^2))$$

for r small. Thus, $\dot{x}\to\gamma+\gamma'$ as $r\to 0$. In a similar fashion, we see that $\dot{y}\to 0$ as $r\to 0$.

The phase portrait (Fig. 5.2) for the real time formulation has a much simpler form than that of the Hamiltonian one we first introduced (Fig. 5.1). We see that for $(\gamma+\gamma')/2\omega<.15$, there is a homoclinic loop with hyperbolic fixed point corresponding to the largest root of $e^r(e^r-1)=((\gamma+\gamma')/2\omega)(e^{2r}+1)(e^r+1)$. We see that the bifurcation at $\gamma/\omega=.1227$ is represented by the loop crossing the origin.

5.3. Periodic stretching of an elliptical vortex. In general, our perturbed system will have the form

$$\dot{r}=C_0\cos\varphi+\varepsilon g_1(r,\varphi,t),$$

$$\dot{\varphi}=\frac{2\omega_0 e^r}{(e^r+1)^2}-C_0\frac{e^{2r}+1}{e^{2r}-1}\sin\varphi+\varepsilon g_2(r,\varphi,t).$$

Here g_1 and g_2 are periodic in time, $C_0=(\gamma_0+\gamma_0')$.

For $0<C_0/\omega_0<0.15$, the unperturbed system has a hyperbolic fixed point p_0 at $\varphi=\pi/2$, $r=r_0$ where r_0 corresponds to the largest real root of the cubic $e^{3r}+e^{2r}(1-B)+e^r(1+B)+1=0$ where $B=(\frac{1}{2}C_0\omega_0)^{-1}$. This fixed point has a homoclinic saddle connection Γ_0 as depicted in Fig. 5.2. If we consider a perturbation involving a periodic stretching by an amount $\varepsilon\gamma''(t)$, then our perturbation has the form

$$g_1=C_1(t)\cos\varphi,$$

$$g_2=\frac{2C_2(t)e^r}{(e^r+1)^2}-C_1(t)\frac{e^{2r}+1}{e^{2r}-1}\sin\varphi.$$

Here C_1 and C_2 are periodic in time with period T. We consider the symmetric case where the oscillation of γ'' puts equal and opposite oscillations on γ' and γ while

maintaining the incompressibility condition $\gamma' - \gamma + \gamma'' = 0$. Thus, $\gamma + \gamma'$ stays constant even though $\gamma - \gamma'$ oscillates with γ''. This implies $C_1(t) = 0$ so that our perturbation has the simpler form

$$g_1 = 0, \qquad g_2 = \frac{2C_2(t)e^r}{(e^r+1)^2}.$$

If we parameterize Γ_0 by $(r(t), \varphi(t))$, the Melnikov function for the perturbed system can be calculated using the non-Hamiltonian form. There are two ways of doing the Melnikov function calculation. We can view Γ_0 as a trajectory in the (r, φ) coordinate system, which has the advantage of a simpler formulation. Since these coordinates break up at $r = 0$, we cannot treat the case where Γ_0 contains the point $r = 0$. This occurs only at the value $\gamma/\omega = .1227$. For any other value of γ/ω, we can find a C^∞ vector field $(f_1(r, \varphi), f_2(r, \varphi))$ so that

$$\dot{r} = f_1(r, \varphi), \qquad \dot{\varphi} = f_2(r, \varphi)$$

is a planar differentiable dynamical system in the coordinates (r, φ) with a saddle connection identical to Γ_0 in its real time parameterization. We have $f_1 = C_0 \cos \varphi$, $f_2 = 2\omega_0 e^r/(e^r+1)^2 - C_0 \sin \varphi (e^{2r}+1)/(e^{2r}-1)$ in a neighborhood of the curve Γ_0. This new dynamical system is suitable for Melnikov's method and in a neighborhood of Γ_0 has dynamics identical to that of the original system.

Alternatively, we can treat the evolution equation as a dynamical system in the (x, y) coordinates. This allows us to show that chaos will also occur in the degenerate case of $\gamma/\omega = .1227$. Both calculations are presented.

The Melnikov function in (r, φ) *coordinates.* For this we need to know $\exp\left(\int_0^t \operatorname{tr} Df(\Gamma_0(s))\, ds\right)$. We have

$$\operatorname{tr} Df = -C_0 \frac{e^{2r}+1}{e^{2r}-1} \cos \varphi = \frac{-\dot{r}(e^{2r}+1)}{e^{2r}-1}.$$

This gives us

$$\exp\left(\int_0^t \operatorname{tr} Df(\Gamma_0(s))\, ds\right) = \frac{e^{r(t)}(e^{r_0} - e^{-r_0})}{e^{2r(t)}-1}.$$

This yields a Melnikov function

$$M(t_0) = C_3 \int_{-\infty}^{\infty} \frac{e^{2r} \cos \varphi}{(e^r+1)^2(e^{2r}-1)} C_2(t+t_0)\, dt,$$
$$C_3 = C_0(e^{r_0} - e^{-r_0}).$$

Using the fact that the integral represents a convolution with an odd function, for $C_2 = \cos kt$, we have

$$M(t_0) = C_3 \sin kt_0 \int_{-\infty}^{\infty} \frac{e^{2r} \cos \varphi}{(e^r+1)^2(e^{2r}-1)} \sin kt\, dt$$
$$= \sin kt_0 M_0(k).$$

Since $\cos \varphi \propto \dot{r}(t)$, we can see that the above integral is the sine transform of an L^1 function.

$$\int_{-\infty}^{\infty} \left| \frac{e^{2r} \cos \varphi}{(e^r+1)^2(e^{2r}-1)} \right| dt = 2 \int_0^{\infty} \left| \frac{e^{2r} \cos \varphi}{(e^r+1)^2(e^{2r}-1)} \right| dt$$
$$\leqq \frac{C_3}{C_0} \int_{r(0)}^{r(\infty)} \frac{e^{2r}}{(e^r+1)^2(e^{2r}-1)}\, dr < \infty.$$

We know by the properties of the Fourier transform on $L^1(\mathbb{R})$ ([13, pp. 120–131]) that $M_0(k)$ is a uniformly continuous function of k that is not identically zero. Thus there exists some interval $k_1 \leqq k \leqq k_2$ such that $M_0(k)$ is nonzero. For these values of k, $M(t_0)$ has simple zeros.

The Melnikov function in (x, y) coordinates. We now consider the dynamical system

$$\dot{x} = (\gamma+\gamma')\cos^2\varphi - \frac{2\omega r \sin\varphi e^r}{(e^r+1)^2} + (\gamma+\gamma')\frac{e^{2r}+1}{e^{2r}-1} r\sin^2\varphi, \qquad r \neq 0,$$

$$\dot{y} = (\gamma+\gamma')\cos\varphi\sin\varphi + \frac{2\omega r\cos\varphi e^r}{(e^r+1)^2} - (\gamma+\gamma')\frac{e^{2r}+1}{e^{2r}-1} r\sin\varphi\cos\varphi, \qquad r \neq 0,$$

$$\dot{x} = \gamma+\gamma', \qquad \dot{y} = 0,$$

for $r = 0$. Here $r = \sqrt{x^2+y^2}$, $\varphi = \tan^{-1}(y/x)$. We have the time-periodic perturbation

$$\vec{g}(t, x, y) = \frac{\varepsilon C_2(t) r e^r}{(e^r+1)^2}\begin{pmatrix} -\sin\varphi \\ \cos\varphi \end{pmatrix}.$$

The following analysis is for the case $\gamma+\gamma' = .1227$; the nondegenerate case can be studied in a similar fashion. We have

$$f \wedge g = (\gamma+\gamma')\cos\varphi C_2(t_0)\left(\frac{re^r}{(e^r+1)^2}\right),$$

$$\operatorname{tr} Df = (\gamma+\gamma')\cos\varphi\left(\frac{1}{r} - \frac{e^{2r}+1}{e^{2r}-1}\right) \qquad r \neq 0,$$

$$= 0, \qquad r = 0,$$

$$e^{\int_0^t \operatorname{tr} Df ds} = \frac{2r(t)e^{r(t)}}{e^{2r(t)}-1}.$$

For $C_2(t) = \cos kt$, our Melnikov function is

$$M(t_0) = -\int_{-\infty}^{\infty} \sin kt_0 \dot{r}(t) \sin kt \frac{r^2 e^{2r}}{(e^{2r}-1)(e^r+1)^2}\, dt$$

$$= \sin kt_0 M_0(k).$$

Again we see that $M_0(k)$ is a sine transform of an L^1 function:

$$\int_{-\infty}^{\infty} \left|\frac{\dot{r}(t) r^2 e^{2r}}{(e^{2r}-1)(e^r+1)^2}\right| dt = \int_{r(0)}^{r(\infty)} \frac{r^2 e^{2r}}{(e^{2r}-1)(e^r+1)^2}\, dr$$

$$= \int_0^{r(\infty)} \frac{r^2 e^{2r}}{(e^{2r}-1)(e^r+1)^2}\, dr$$

$$< \infty.$$

This is because $r^2 e^{2r}/(e^{2r}-1)(e^r+1)^2$ is bounded on the interval $(0, r(\infty)]$. We see that $M_0(k)$ is again the sine transform of an odd L^1 function so that there exists an interval $k_1 \leqq k \leqq k_2$ so that $M_0(k)$ is nonzero, giving us a Melnikov function with simple zeros.

Under such a periodic stretching, we find chaotic dynamics occurring in the phase portrait of the evolution equations for the ellipse. This indicates a sort of randomness in the evolution of the vortex. The phase portrait includes a horseshoe as a subsystem that, as we know from § 2, indicates somewhat erratic behavior on an invariant set. Assuming the inability to make completely precise measurements, we can only predict what will happen to the vortex for a finite time; after this time we have no knowledge of how it will evolve.

Appendix A. We present the details of the calculation of the following integral from § 3 via residues:

$$M_0(K) = \int_{-\infty}^{\infty} \frac{e^{\gamma t} - e^{-\gamma t}}{(e^{\gamma t} + \beta + e^{-\gamma t})^2} \sin kt \, dt,$$

which by a change of variables $\tau = \gamma t$ becomes

$$M_0'(m) = \frac{1}{\gamma} \int_{-\infty}^{\infty} \frac{e^{\tau} - e^{-\tau}}{(e^{\tau} + \beta + e^{-\tau})^2} \sin m\tau \, d\tau,$$

where $m = k/\gamma$. Consider the meromorphic function

$$\frac{(e^{3z} - e^{z}) e^{imz}}{(e^{2z} - \beta e^{z} + 1)^2}.$$

The denominator has roots

$$e^{z} = \frac{\beta \pm \sqrt{\beta^2 - 4}}{2},$$

which we can write as

$$= e^{\pm i\alpha},$$

since we know that $0 < \beta < 2$. Here, $\alpha = \cos^{-1}(\beta/2)$, which gives us $0 < \alpha < \pi/2$. Thus, the function

$$\frac{(e^{3z} - e^{z}) e^{imz}}{(e^{z} - e^{i\alpha})^2 (e^{z} - e^{-i\alpha})^2}$$

has double poles at $z = \pm i\alpha + 2\pi i N$, $N \in \mathbb{Z}$. Let $r = z - (i\alpha + 2\pi i N)$. The integral is clearly odd in m. Thus we need only consider the case $m > 0$. We have that

$$\begin{aligned}
&\operatorname{Im} \frac{1}{\gamma} \int_{-\infty}^{\infty} \frac{e^{3\tau} - e^{\tau}}{(e^{2\tau} + \beta e^{\tau} + 1)^2} e^{im\tau} \, d\tau \\
&\quad = \lim_{N \to \infty} \operatorname{Im} \frac{1}{\gamma} \int_{-(2N+1)\pi}^{(2N+1)\pi} \frac{e^{3\tau} - e^{\tau}}{(e^{2\tau} + \beta e^{\tau} + 1)^2} e^{im\tau} \, d\tau \\
&\quad = \lim_{N \to \infty} \operatorname{Im} \frac{1}{\gamma} \left[\frac{1}{2\pi i} \sum_{0 < y < (2N+1)\pi} \operatorname{Res} \left(\frac{e^{3z} - e^{z}}{(e^{2z} + \beta e^{z} + 1)^2} e^{imz} \right) \right. \\
&\qquad \left. - \int_{|z| = (2N+1)\pi, y > 0} \frac{e^{3\tau} - e^{\tau}}{(e^{2\tau} + \beta e^{\tau} + 1)^2} e^{im\tau} \, d\tau \right].
\end{aligned}$$

The last integral goes to zero as $N \to \infty$ so that for $m > 0$, we wish to calculate

$$\operatorname{Im} \left[\frac{2\pi i}{\gamma} \sum_{y > 0} \operatorname{Res} \left(\frac{e^{3z} - e^{z}}{(e^{2z} + \beta e^{z} + 1)^2} e^{imz} \right) \right].$$

Thus we need to calculate the residues of the function in the upper half-plane. We can calculate the coefficients of the Laurent expansion of the function by first considering the expansion of its components in the neighborhood of $i\alpha+2\pi iN$. Writing $r=z-(i\alpha+2\pi iN)$, we have

$$e^{3z}=e^{3i\alpha}\left(1+3r+\frac{9}{2}r^2+\cdots\right),$$

$$e^{z}=e^{i\alpha}\left(1+r+\frac{1}{2}r^2+\cdots\right),$$

$$e^{imz}=e^{-m\alpha-2\pi mN}\left(1+imr-\frac{m^2}{2}r^2+\cdots\right),$$

$$(e^z-e^{i\alpha})^2=e^{2i\alpha}(r^2+r^3+\cdots),$$

$$(e^z-e^{-i\alpha})^2=-4\sin^2\alpha+4i\sin\alpha e^{i\alpha}r+\cdots.$$

We write the function in the form

$$\frac{1}{r^2}\left(\frac{a+br+\cdots}{c+dr+\cdots}\right),$$

which has the Laurent expansion

$$\frac{a}{c}r^{-2}+\left(\frac{b}{c}-\frac{da}{c^2}\right)r^{-1}+\cdots,$$

so that the residue at $r=0$ is $b/c-da/c^2$. Here

$$a=(e^{3i\alpha}-e^{i\alpha})e^{-m\alpha-2\pi mN},$$

$$b=e^{-m\alpha-2\pi mN}[im(e^{3i\alpha}-e^{i\alpha})+3e^{3i\alpha}-e^{i\alpha}],$$

$$c=e^{2i\alpha}(-4\sin^2\alpha),$$

$$d=e^{2i\alpha}(4ie^{i\alpha}\sin\alpha-4\sin^2\alpha).$$

Let R_x denote the residue at the point x. Then,

$$R_{i\alpha+2\pi iN}=\frac{me^{-m\alpha-2\pi mN}}{2\sin\alpha}.$$

Notice that $R_{i\alpha+2\pi iN}=R_{i\alpha}e^{-2\pi Nm}$. A similar calculation shows that

$$R_{-i\alpha+2\pi iN}=\frac{-me^{m\alpha-2\pi mN}}{2\sin\alpha}.$$

We add the residues in the upper half plane to obtain $M_0'(m)$ for $m>0$, and exploit the fact that $M_0'(m)$ is odd in m to obtain $M_0'(m)$ for $m<0$. Thus for $m\neq 0$, our integral becomes

$$M_0'(m)=\frac{2\pi}{\gamma}\left[\frac{me^{-|m|\alpha}}{2\sin\alpha}-\frac{m\sinh|m|\alpha}{\sin\alpha}\frac{e^{-2\pi|m|}}{1-e^{-2\pi|m|}}\right].$$

Acknowledgments. I would like to credit Prof. Andrew Majda of Princeton University for originally suggesting the idea of extending the Melnikov theory to study the onset of chaos in fluid flows with heteroclinic orbits. I would also like to thank him for the guidance he has given me on my A.B. thesis, from which this paper stems. I would like to thank AT&T Bell Laboratories at Murray Hill, New Jersey, where I spent the summers of 1987 and 1988, for supplying me with the diagrams.

BIFURCATIONS OF RELATIVE EQUILIBRIA IN THE N-BODY AND KIRCHHOFF PROBLEMS*

KENNETH R. MEYER† AND DIETER S. SCHMIDT‡

Abstract. The bifurcations of a one-parameter family of relative equilibria in the N-body problem are studied using normal form theory, Lie transforms, and an algebraic processor. The one-parameter family consists of $N-1$ bodies of mass 1 at the vertices of a regular polygon and one body of mass m at the centroid. As N increases there are more and more values of the mass parameter m where the relative equilibrium is degenerate. For $N \leqq 13$ each of these degenerates gives rise to a bifurcation and a new relative equilibrium. This is established using a computer-aided proof. A similar analysis is carried out for the N-vortex problem of Kirchhoff.

Key words. central configurations, relative equilibria, N-body, bifurcation

AMS(MOS) subject classification. 70F10

1. Introduction. The study of relative equilibria (r.e.) of the N-body problem has had a long history starting with the famous collinear configuration of the 3-body problem found by Euler (1767). Over the intervening years many different technologies have been applied to the study of r.e. In the older papers of Euler (1767), Lagrange (1772), Hoppe (1879), Lehmann-Filhes (1891), and Moulton (1910), special coordinates, symmetries, and analytic techniques were used. In their investigations, Dziobek (1900) used the theory of determinants; Smale (1970) used Morse theory; Palmore (1975) used homology theory; Simo (1977) used a computer; and Moeckel (1985) used real algebraic geometry. Thus, the study of r.e. has been a testing ground for many different methodologies of mathematics.

In Meyer and Schmidt (1987) the methods of bifurcation analysis and the use of the automated algebraic processor were brought to bear on this subject and the present paper continues the attack. Specifically we study the bifurcations of the relative equilibrium which consists of $N-1$ particles of mass 1 at the vertices of a regular polygon and one particle of mass m at the centroid. We call this the regular polygon relative equilibrium (r.p.r.e.). Our first paper considers the 4- and 5-body problems and uses the special coordinates of Dziobek (1900). These coordinates make the 4-body problem relatively easy to handle and the 5-body problem accessible, but beyond 5, Dziobek's coordinates become very cumbersome. The 4- and 5-body problems in these special coordinates are sufficiently simple that the general purpose algebraic processor MACSYMA could handle the tedious calculations. For larger N the special purpose algebraic processor POLYPAK written by the second author was needed because the computations increased rapidly with N. In the analysis of the 4- and 5-body problems the classical power series methods of bifurcation analysis handles the problems nicely, but for larger n a systematic use of Lie transforms by Deprit (1969) was mandated in order to bring the equations into a normal form. Thus this paper uses substantially different techniques than our previous paper.

The problem of finding an r.e. can be reduced to finding a critical point of the potential energy function on the manifold of constant moment of inertia. Thus the problem falls within the domain of catastrophe theory and so the general theory is well understood. However, this specific problem has a high degree of symmetry, many variables, and a constraint, so the computations must be performed with care. We consider this paper as a case study in bifurcation analysis in the face of these complexities.

Indeed we analyze the problem at three different computational levels. First, for small N, we perform the normalization to high order to determine the existence, uniqueness, and exact shape of the bifurcating equilibria. For medium ranges of N we exploit the symmetry so that fewer computations need be carried out in order to establish existence, but now the uniqueness is only within the class of symmetric equilibria. Last, for large N, we carry out some calculations to establish existence of bifurcations with no uniqueness information. We can see that for a fixed amount of computing power the precision of the information obtained decreases as N increases.

For the planar problem that we consider, a relative equilibrium is also a central configuration and vice versa, that is, a homothetic solution which begins or ends in total collapse or tends to infinity. Even though as solutions of the N-body problem r.e. are quite rare and rather special, they are of central importance in the analysis of the asymptotic behavior of the universe. In general, solutions which expand beyond bounds or collapse in a collision do so asymptotically to a central configuration. A survey and entrance to this literature can be found in Saari (1980).

Interestingly this problem in celestial mechanics is formally similar to the problem in fluid dynamics of describing the evolution of finitely many interacting point vortices in the plane. Kirchhoff (1897) shows that this problem is specified by a Hamiltonian which is similar to the Hamiltonian of an N-body problem with a logarithmic potential. The constants that correspond to the masses are now the circulations, which may be positive or negative, and so a richer store of bifurcations are to be expected. We develop the theory and evolution of the bifurcations of the problem in parallel with that of the N-body problem.

In Meyer and Schmidt (1987) we studied the 4- and 5-body problem and found that there was a unique value of the mass of the central particle where the potential was degenerate. This agrees with the findings in Palmore (1973). However, for larger N there are more and more values of this mass at which the potential is degenerate, which disagrees with Palmore (1976). In fact, for large N many bifurcations occur. We developed the general theory of the bifurcations for these two problems for all N and completely analyze the bifurcations for $4 \leqq N \leqq 13$. Figures 1 and 2 illustrate the bifurcations which occur at the unique critical mass when $N = 4, 5$ and Fig. 3 illustrates the multitude of bifurcations that occurs in the 13-body problem.

Also we found that the self-potential for the N-body problem with the central mass removed was not always a nondegenerate minimum. In fact it is a saddle for $N > 6$. This disagrees with one of the findings in Palmore (1975). There were other surprises in our investigations, which will be explained below when we have developed the necessary definitions and notation.

2. Relative equilibria for the N-body and Kirchhoff problems. The N-body problem is the system of differential equations that describes the motion of N particles moving under the influence of their mutual gravitational attraction. Let $q_j \in R^2$ be the position vector, $p_j \in R^2$ the momentum vector, and $m_j > 0$ the mass of the jth particle, $1 \leqq j \leqq N$;

then the equations of motion are

$$\begin{aligned} \dot{q}_j &= \frac{\partial H}{\partial p_j} = \frac{1}{m_j} p_j, \\ \dot{p}_j &= -\frac{\partial H}{\partial q_j} = \frac{\partial U}{\partial q_j}, \end{aligned} \qquad j = 1, \cdots, N \tag{2.1}$$

where H is the Hamiltonian

$$H = \sum_{j=1}^{N} \frac{\|p_j\|^2}{2m_j} - U(q) \tag{2.2}$$

and U is the (self) potential

$$U = \sum_{1 \leqq i < j \leqq N} \frac{m_i m_j}{\|q_i - q_j\|}. \tag{2.3}$$

These equations reduce to the Newtonian formulation

$$m_j \ddot{q}_j = \frac{\partial U}{\partial q_j}, \qquad j = 1, \cdots, N. \tag{2.4}$$

To change to rotating coordinates let $q_j = \exp(\nu J t) u_j$ where $\nu > 0$ is the frequency of the rotating frame and

$$J = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$$

so (2.4) becomes

$$m_j \{\ddot{u}_j + 2\nu J \dot{u}_j - \nu^2 u_j\} = \frac{\partial U}{\partial u_j}(u), \qquad j = 1, \cdots, N. \tag{2.5}$$

An equilibrium in these rotating coordinates is a solution of the system of algebraic equations

$$-\lambda m_j u_j = \frac{\partial U}{\partial u_j}, \qquad j = 1, \cdots, N \tag{2.6}$$

where $\lambda = \nu^2 > 0$.

The Kirchhoff problem is the system of differential equations describing the motion of N vortices moving in the plane under their mutual interaction. Let q_j be the position vector and $m_j \neq 0$ the circulation of the jth vortex for $j = 1, \cdots, N$. Then Kirchhoff (1897) gives the equations of motion as

$$m_j \dot{q}_j = J \frac{\partial U(q)}{\partial q_j}, \qquad j = 1, \cdots, N \tag{2.7}$$

where now U is the Hamiltonian

$$U = -\sum_{1 \leqq i < j \leqq N} m_i m_j \log \|q_i - q_j\|. \tag{2.8}$$

Introducing rotating coordinates as before by setting $q_j = \exp(\nu Jt)u_j$ transforms (7) to the system

$$m_j\{\dot{u}_j + \nu J u_j\} = J\frac{\partial U(u)}{\partial u_j}, \qquad j = 1, \cdots, N. \tag{2.9}$$

An equilibrium in these rotating coordinates is a solution of the system of algebraic equations

$$-\lambda m_j u_j = \frac{\partial U(u)}{\partial u_j}, \qquad j = 1, \cdots, N \tag{2.10}$$

where $\lambda = -\nu$.

It is classical and easy to verify that if $\bar{u} = (\bar{u}_1, \cdots, \bar{u}_N)$ and $\bar{\lambda}$ is a solution of (6) (or (10), respectively), then the center of mass of $\bar{u}$ is at the origin ($\sum m_j \bar{u}_j = 0$) and $\bar{\lambda} = U(\bar{u})/(1+\delta)I(\bar{u})$ (>0 for (6)) where I is the moment of inertia

$$I(u) = \tfrac{1}{2}\sum m_j \|u_j\|^2 \tag{2.11}$$

and $\delta = 0$ for the Kirchhoff problem or $\delta = 1$ for the N-body problem. For either problem we will set

$$\begin{aligned} M &= \{u \in R^{2N} : \textstyle\sum m_j u_j = 0\}, \\ \Delta &= \{u \in R^{2N} : u_i = u_j \text{ for some } i \neq j\}, \\ S &= \{u \in M : I(u) = 1\}. \end{aligned} \tag{2.12}$$

The variable λ can be considered a Lagrange multiplier and so an equivalent definition of a relative equilibrium is a critical point of U restricted to $S\backslash\Delta$. If u is an r.e. then so is $Au = (Au_1, \cdots, Au_N)$ where $A \in \mathrm{SO}(2, R)$ is a rotation matrix. We can define an equivalence relation by $u \sim Au$ when $A \in \mathrm{SO}(2, R)$, and since U, I, are constant on equivalence classes we can define the quotient spaces $\mathcal{S} = (S\backslash\Delta)/\sim$ and the function $\mathcal{U} : \mathcal{S} \to R$ by $\mathcal{U}([u]) = U(u)$, where [ ] denotes an equivalence class. $\mathcal{S}$ and $\mathcal{U}$ are smooth. Thus a similarity class of r.e. is a critical point of $\mathcal{U}$.

A relative equilibrium is called nondegenerate if its equivalence class is a nondegenerate critical point of $\mathcal{U}$ in the sense of Morse theory, i.e., the Hessian is nonsingular at the critical point. It follows from the implicit function theorem that bifurcations can occur only at degenerate critical points, so first we must find degenerate r.e.

3. Palmore coordinates. Our first step is to introduce the local coordinate system on the quotient space $\mathcal{S}$ which was given in Palmore (1976). Let $n = N-1$ and $\omega = \exp(i2\pi/n)$ be a primitive nth root of unity. Consider complex numbers as vectors in the plane, so ω^j, $0 \leqq j < n$ are the vertices of a regular polygon with n sides. By the regular polygon relative equilibrium (r.p.r.e.) we shall mean the r.e. which consists of n particles of unit mass, $m_j = 1$, situated at ω^j for $j = 0, \cdots, n-1$, and one particle of arbitrary mass, $m_n = m$, situated at the origin.

Let $q = (q_0, q_1, \cdots, q_n)^T$ be the position vector of the $N = n+1$ particles in the plane, $\Omega = (\omega^0, \omega^1, \omega^2, \cdots, \omega^{n-1}, 0)^T$ be the position vector of the r.p.r.e., and change coordinates by

$$q = \Omega + \mathcal{V}z \tag{3.1}$$

where $z=(z_0, z_1, \cdots, z_n)$ is the position vector in the new Palmore coordinates and $\mathcal{V}$ is the matrix

$$\mathcal{V}=\begin{pmatrix} 1 & 1 & 1 & \cdots & 1 & 1 \\ 1 & \omega^1 & \omega^2 & \cdots & \omega^{n-1} & 1 \\ 1 & \omega^2 & \omega^4 & \cdots & \omega^{2(n-1)} & 1 \\ \vdots & \vdots & \vdots & & \vdots & \vdots \\ 1 & \omega^{n-1} & \omega^{2(n-1)} & \cdots & \omega^{(n-1)^2} & 1 \\ 0 & 0 & 0 & \cdots & 0 & -n/m \end{pmatrix}. \tag{3.2}$$

In these coordinates the center of mass is

$$\sum_{j=0}^{n} m_j q_j = n z_0 \tag{3.3}$$

so setting $z_0=0$ fixes the center of mass at the origin. The moment of inertia is

$$\begin{aligned} I &= \frac{1}{2}\sum_{j=0}^{n-1} \|q_j\|^2 + \frac{m}{2}\|q_n\|^2 \\ &= \frac{1}{2}\left(n + z_1 + \bar{z}_1 + \sum_{j=1}^{n} z_j \bar{z}_j + \frac{n}{m}\|z_n\|^2 \right) \end{aligned} \tag{3.4}$$

so that the first approximation, the manifold $I = I_0 = n/2$, is given by $z_1 + \bar{z}_1 = 2 \operatorname{Re} z_1 = 0$. Requiring z_1 to be real, $\operatorname{Im} z_1 = 0$, we select a representative from the rotational equivalence class. Thus to the first approximation local coordinates on $\mathcal{S}$ near $[\Omega]$ are $z_0 = z_1 = 0$ and $z_2, z_3, \cdots, z_n$ arbitrary.

Henceforth, set $z_0=0$ and $\operatorname{Im} z_1 = 0$ and let $\operatorname{Re} z_1 = x_1$. From (3.4) we see that $\partial I/\partial x_1(\Omega) = 1 \neq 0$, so by the implicit function theorem we can solve $I = I_0$ for x_1, as a function of the remaining variables. Let $x_1 = \phi(z_2, z_3, \cdots, z_n)$ be this solution. Changing variables by $x_1' = x_1 - \phi(z_2, \cdots, z_n)$, $z_2' = z_2, \cdots, z_n' = z_n$ brings the manifold $I = I_0$ to the hyperplane $x_1 = 0$ locally. Thus $z_2', \cdots, z_n'$ are valid local coordinates on $\mathcal{S}$ near $[\Omega]$.

Computationally we effect this change of variables by using the method of Lie transforms as given by Deprit (1969). We construct the change of variables from the unprimed to the primed variables order by order using the standard normalization procedure. That is, we eliminate the x_1 dependence in I order by order. Henceforth, we will assume that this initial normalization has been carried out, we will ignore z_0 and z_1, and we will drop the primes on the variables.

The next step is to look at the Hessian of the function $\mathcal{U}$ at $[\Omega]$. We can consider (1) as a change to the $(z, \bar{z})$ coordinates or follow Palmore and use the real and imaginary parts of z. We choose the latter for exposition purposes.

Let $z_j = x_j + iy_j$, $\xi = (x_2, \cdots, x_n)^T$, $\eta = (y_2, \cdots, y_n)^T$, $u = (x_2, \cdots, y_n)^T$, and $A = \partial^2 \mathcal{U}/\partial u^2[\Omega]$. Palmore (1976) shows that the Hessian, A, has the relatively simple form

$$A = \begin{pmatrix} B+C & 0 \\ 0 & B-C \end{pmatrix} \tag{3.5}$$

where B and C are $(n-1)\times(n-1)$ matrices, B is a standard diagonal matrix, and C has nonzero entries only on the cross diagonal running northeast. These nonzero entries are given in Appendix A for reference. In Appendix A we give the general formulas for all potentials which vary inversely with the distance of the δ power, so the N-body problem is when $\delta = 1$, and the Kirchhoff problem is the limiting case when $\delta = 0$.

Let $D(n, k)$ (respectively, $D^-(n, k)$), $2 \leqq k \leqq n/2$ be the 2×2 submatrix of $B+C$ (respectively, $B-C$) formed by taking the (k, k), $(k, n+2-k)$, $(n+2-k, k)$, and $(n+2-k, n+2-k)$ entries. In the case that n is even the two diagonals B and C cross in a single entry at the $(n/2+1, n/2+1)$ position; let $D(n, n/2+1)$ (respectively, $D^-(n, n/2+1)$) be the corresponding 1×1 matrix or number. This is a special case, which requires special treatment, and we will typically discuss this case last.

The r.p.r.e. is degenerate when A is singular, which happens when one of the submatrices $D(n, k)$ is singular. Except for the last row of $B \pm C$ all the nonzero entries of $B \pm C$ are linear in m and in fact the determinants of the $D(n, k)$, $2 < k \leqq n/2+1$, are linear in m also. Referring to Appendix A shows that the last row is slightly more complicated, the determinant $D(n, 2)$ has an extraneous factor of $(m+n)$ and another linear factor in m. Thus, there is a unique $m = m(n, k)$, which makes the submatrices $D(n, k)$ and $D^-(n, k)$ singular. In the special case when n is even and $k = n/2+1$ the 1×1 matrix or number $D^-(n, k)$ does not contain m, and so when $m = m(n, k)$ we have $D(n, k) = 0$ but $D^-(n, k) \neq 0$. In this special case the dimension of the kernel of A is one. Let $d(n, k) = \det D(n, k)$ for $m = 0$, $2 < k \leqq n/2+1$. Appendix A also contains the general formulas for $m(n, k)$ and Appendix B contains a table of $m(n, k)$ and $d(n, k)$ for all $3 \leqq n \leqq 12$ for both the N-body problem and the Kirchhoff problem. Recall that $d(n, 2)$ is not defined. The tables in Appendix B are easily generated from the formulas in Appendix A.

Palmore (1973) considered this one-parameter family of r.e. for the $N = n-1$ body problem for $n = 3$, 4 and showed that there was a unique positive value of the mass that makes this r.e. degenerate. In Meyer and Schmidt (1987), we verify this fact and show that additional families of r.e. bifurcate from the original family. Palmore (1976) makes a similar statement about the existence of a unique positive critical mass for all n. From the table in Appendix B, we see that $m(6, 2) \simeq 20.91$ and $m(6, 4) \simeq .00598$, and so this is not the case for $n = 6$. We computed this table all the way up to $n = 20$ and found that as n increases, more and more positive critical masses appear. Moreover, the critical mass of Palmore is $m(n, 2)$ in our notation, and it becomes negative at $n = 7$ and remains negative up to $n = 20$. Later we will show that these positive critical masses give rise to new families of r.e. which bifurcate from the r.p.r.e.

Palmore (1982) also states that there is a unique positive circulation which makes the Kirchhoff potential degenerate for all $n \geqq 3$. Appendix B shows that the uniqueness is false for $8 \leqq n \leqq 12$ and we extended the table to $n = 20$ to find more and more positive critical circulations as n increases. For the Kirchhoff problem the exact formula for the critical circulation $m(n, k)$ takes on a simple form as shown in Appendix A. From this we see that $m(7, 4) \equiv 0$, so one critical circulation is zero. Negative values of the circulation are meaningful and so we investigate these bifurcations in the next section also.

There are several other errors in Palmore (1976), (1982). He also states that the r.e. when $m = 0$ is a nondegenerate maximum of the potential for both problems and for all n. Since we work with the self-potential or the negative of the potential, this would mean that the matrices obtain by deleting the first and last rows and columns of $B \pm C$ are positive definite and in particular the $d(n, k) > 0$ for $2 < k \leqq n/2+1$. This is false when $6 \leqq n \leqq 12$, which can be seen easily by looking at determinants $d(n, k)$ given in Appendix B—in particular $d(6, 4) \simeq -0.036 < 0$. Again we extended this all the way to $n = 20$. We give a simple analytic argument in Appendix D which shows that the potential does not have a minimum at this r.e. when $n = 6$. As noted above the Kirchhoff problem is degenerate when $n = 7$ since $m(7, 4) \equiv 0$. The source of all these errors seems to be in the analysis of the 2×2 submatrices $D(n, k)$.

4. The splitting lemma, reflections, and Hopf's method. There is a simple argument due to Hopf (1942) that establishes a bifurcation without a knowledge of higher-order terms. The analysis of the Hessian given in the previous section along with the symmetry of the potential function is enough to adapt Hopf's argument to the present situation. We present this argument before the discussion of the full normalization to emphasize how little computation is necessary to establish some information about the nature of the bifurcation.

Fix n and k, let $\mu = m - m(n, k)$ and $h = 2n-2$. The special case when n is even and $k = n/2+1$ will be treated at the end, so for now assume we are not in this case. By the analysis of the previous section and the splitting lemma as found in Poston and Stewart (1978) there is a coordinate system η near $[\Omega]$ so that

$$\mathcal{U} = \pm\eta_3^2 \pm \eta_4^2 \pm \cdots \pm \eta_h^2 + G(\eta_1, \eta_2, \mu). \tag{4.1}$$

In catastrophe theory the Lyapunov-Schmidt method is called the splitting lemma. In the next section we discuss in detail how the quadratic terms are brought into the above form and how the function G is computed order by order using Deprit's method of Lie transforms and the second author's algebraic processor POLYPAK.

From the form of the Hessian A in (3.5) and the fact that the submatrices $D(n, k)$ and $D^-(n, k)$ have the same determinant which is linear in the mass m, we see that the quadratic terms of G have the form $\alpha\mu(\eta_1^2+\eta_2^2)/2$ where α is a nonzero constant.

Also $\mathcal{U}$ is invariant under a reflection $\mathcal{R}$ which leaves the regular polygon relative equilibrium fixed. In the original coordinates the reflection is

$$\mathcal{R}: q_j \to \bar{q}_{n-j}, \quad 0 \leqq j < n, \qquad q_n \to \bar{q}_n. \tag{4.2}$$

At one of the critical masses a perturbation in the direction of the kernel of the Hessian is of the form

$$\begin{aligned} q_j &= \omega^j + \omega^{jk} z_k + \omega^{jl} z_l, \qquad k+l = n+2, \\ q_j &= \omega^j + \omega^{jk} z, \qquad k = l = n/2+1. \end{aligned} \tag{4.3}$$

In the first case the z_k and z_l are not independent but are linearly related (essentially conjugates), so one can be used as a coordinate of the perturbation. In the second case the z is arbitrary. Thus we can use z_k or z as a coordinate in the kernel of the Hessian. The action of $\mathcal{R}$ on this subspace is

$$\begin{aligned} &\mathcal{R}: \omega^j + \omega^{jk} z_k + \omega^{jl} z_l \to \omega^j + \omega^{jk} \bar{z}_k + \omega^{jl} \bar{z}_l, \qquad k \neq l, \\ &\mathcal{R}: \omega^j + \omega^{jk} z \to \omega^j + \omega^{jk} \bar{z}, \qquad k = l = n/2+1. \end{aligned} \tag{4.4}$$

Thus in coordinates $\mathcal{R}: z_k \to \bar{z}_k$ or $\mathcal{R}: z \to \bar{z}$, so $\mathcal{R}$ is a reflection on this subspace also. Therefore, we can choose the coordinates η_1 and η_2 so that

$$G(\eta_1, \eta_2, \mu) \equiv G(\eta_1, -\eta_2, \mu). \tag{4.5}$$

This is essentially the same as Lyapunov-Schmidt reduction in the presence of symmetry discussed in Proposition 3.3 of Golubitsky and Schaeffer (1985).

Thus, if $\partial G/\partial\eta_1(\bar{\eta}_1, 0, 0) = 0$, then $\eta = (\bar{\eta}_1, 0, \cdots, 0)$ is a critical point of $\mathcal{U}$. Since $\partial G/\partial\eta_1(0, 0, \mu) = 0$, η_1 is a factor of $\partial G/\partial\eta_1(\eta_1, 0, \mu)$, and so we must solve

$$\begin{aligned} \frac{\partial G}{\partial \eta_1}(\eta_1, 0, \mu) &= \mu\alpha\eta_1 + \eta_1 g(\eta_1, \mu) \\ &= \eta_1(\alpha\mu + g(\eta_1, \mu)) \end{aligned} \tag{4.6}$$

or

$$\alpha\mu + g(\eta_1, \mu) = 0 \tag{4.7}$$

where $g(0, \mu) \equiv 0$. Since $\alpha \neq 0$, the implicit function theorem gives a solution of (3) of the form $\mu = v(\eta_1)$ and so $\eta = (\eta_1, 0, \cdots, 0)$ is a critical point of $\mathcal{U}$ when $\mu = v(\eta_1)$. So we have shown that locally the critical point set of $\mathcal{U}$ in $R^h \times R^1$ consists of two intersecting curves namely $(\eta, \mu) \equiv (0, \mu)$ and $(\eta, \mu) = ((\eta_1, 0, \cdots, 0), v(\eta_1))$. These solutions are symmetric with respect to the reflection $\mathcal{R}$ and are unique in this class. Of course there may be more nonsymmetric solutions.

Hopf's argument just given depends only on the analysis of the Hessian and the symmetry of the system and so is quite easy to apply. The values of $m(n, k)$ and the corresponding α's are easy to compute from the formulas in Appendix A for both the N-body problem and the Kirchhoff problem. Appendix B contains a table of $m(n, k)$ and Appendix C a table of α for $3 \leqq n \leqq 12$. Since the computed values of the α's are nonzero the above result holds in all these cases.

However, this result is rather weak. First of all G could be identically equal to zero, in which case the function $v(\eta_1)$ would be identically zero also. Most people would not call this a bifurcation. The result does not tell how many r.e. are found since the method only looks for symmetric solutions. To overcome the first weakness only a little more computation needs to be carried out.

The full normalization of $\mathcal{U}$ was carried out by the method of Lie transforms using the second author's algebraic processor POLYPAK in almost all cases. The size of the problem grows rapidly with n since (1) the number of variables increases, (2) the number of critical masses increases, and (3) the order to which we must carry out the normalization increases. The first two cause linear growth in complexity whereas the third causes exponential growth in complexity. The full normalization is discussed in the next section.

If we are content to seek only solutions that are symmetric with respect to the x-axis we need only compute the first nonzero term in $G(\eta_1, 0, 0)$ to determine the general nature of the bifurcation. Thus the quest for symmetric solutions grows like a polynomial in n in the generic case.

Using the previous notation as found in (6) assume that

$$g(\eta_1, 0) = -\beta\eta_1^\rho + \cdots \tag{4.8}$$

where $\beta \neq 0$. Then the solution $\mu = v(\eta_1)$ is a solution of

$$\alpha\mu = g(\eta_1, \mu) = \alpha\mu - \beta\eta_1^\rho + \cdots = 0, \tag{4.9}$$

$$\mu = v(\eta_1) = \frac{\beta}{\alpha}\eta_1^\rho + \cdots. \tag{4.10}$$

Now we can decide how many symmetric relative equilibria bifurcate from the regular polygon relative equilibria as μ varies, since we can solve (4.6) for η_1 to find

$$\eta_1 = \sqrt[\rho]{\alpha\mu/\beta + \cdots}. \tag{4.11}$$

Here we use the standard convention about the ρth roots. In particular, if ρ is even, there are two r.e. that bifurcate from the r.p.r.e. for $\mu > 0$ when $\alpha\beta > 0$ or for $\mu < 0$ when $\alpha\beta < 0$. If ρ is odd one r.e. bifurcates from the r.p.r.e. for $\mu < 0$ and one for $\mu > 0$.

In the special case when n is even and $k = n/2 + 1$ the kernel of A has dimension 1 and so the splitting lemma says there are coordinates such that

$$\mathcal{U} = \pm\eta_2^2 \pm \eta_3^2 \pm \cdots \pm \eta_h^2 + G(\eta_1, \mu). \tag{4.12}$$

In the previous case we used the symmetry $\mathcal{R}$ to reduce the problem to that of solving (4.6). In this case we need only look at $\partial G/\partial \eta_1(\eta_1, \mu) = 0$ and proceed exactly as above.

Generically we would expect $\rho = 1$ unless the problem had a further symmetry in which case we would expect $\rho = 2$. We explain this difference in the next section. Thus in the generic case we do not have to compute the function G to high order. Appendix C contains a table of α, β, and ρ for both the N-body and the Kirchhoff problems for $3 \leqq n \leqq 12$, $2 \leqq k \leqq n/2+1$. Note that several entries are missing from the table for the N-body problem since these correspond to negative mass. The N-body problem behaves in a generic manner with ρ being 1 or 2, but the Kirchhoff problem is somewhat unpredictable. Note in Appendix C, when $n = 11$, $k = 6$ that $\rho = 2$ for the N-body problem whereas $\rho = 4$ for the Kirchhoff problem. The Kirchhoff problem is even more degenerate when $n = 4$, $k = 3$. In this case $\rho = 1$ and with it $g(\eta_1, \mu) = 8\mu(\eta_1 + \eta_1^3 + \cdots)$. All the terms have a factor μ and therefore the r.e. exists for $\mu = 0$ with η_1 arbitrary. We will come back to this case in the next section.

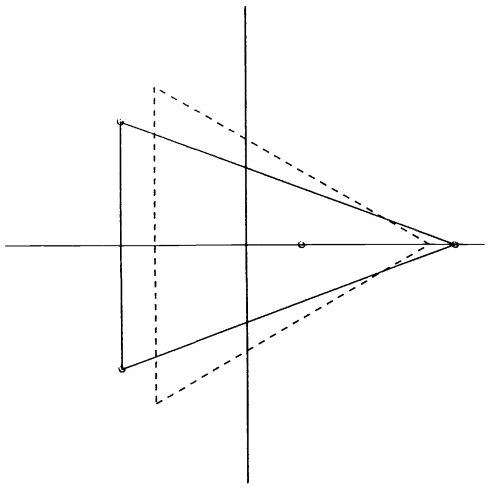

FIG. 1(a). $n = 3$, $k = 2$.

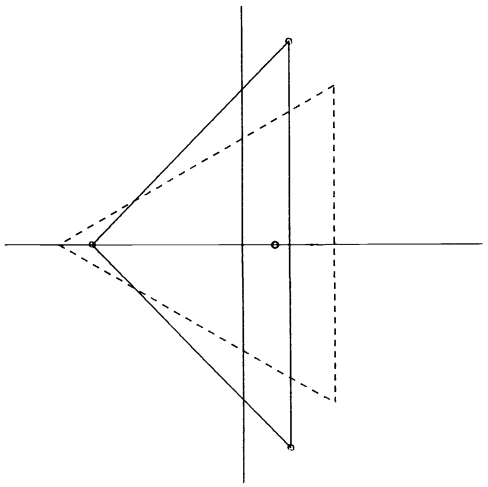

FIG. 1(b). $n = 3$, $k = 2$.

Figure 1 shows the r.e. which bifurcate from the equilateral triangle family. This is the case when $n = 3$, $k = 2$, and $\rho = 1$, so the two isosceles triangle r.e. exist on either side of the critical mass $m(3, 2) \simeq 0.77$ for the 4-body problem or $m(3, 2) = 1$ for the Kirchhoff problem. The acute triangle exists for $m < m(3, 2)$ and the obtuse for $m > m(3, 2)$. Figure 2 shows the r.e. which bifurcate from the square family when $n = 4$, $k = 3$, and $\rho = 2$. Only the kite r.e. shown in Figure 2(a) is symmetric with respect to the x-axis and is established by the above argument. It exists for $m > m(4, 3)$. Figure 3 shows all the r.e. that bifurcate from the duodecigon family when $n = 12$ and for various k and ρ. Only those shown in Figs. 3(a), 3(c), 3(e), 3(g), 3(i), 3(k) (every other one) are symmetric with respect to the x-axis or with respect to $\mathcal{R}$. Figure 3 shows the special case when n is even and $k = n/2+1$. These are the ones established by this argument. Note that all of the r.e. in Fig. 3 have an axis of symmetry even though in some cases it is difficult to see at first glance. We will discuss these figures more in the next section.

5. Symmetries and higher-order normalization. In the special case when n is even and $k = n/2+1$ the Hessian A does not have a two-dimensional kernel, and so the

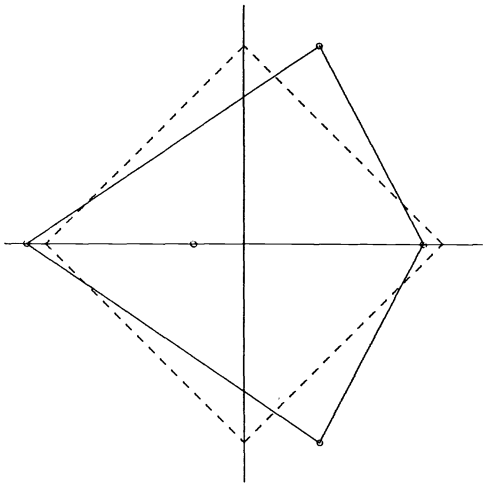

FIG. 2(a). $n=4$, $k=2$.

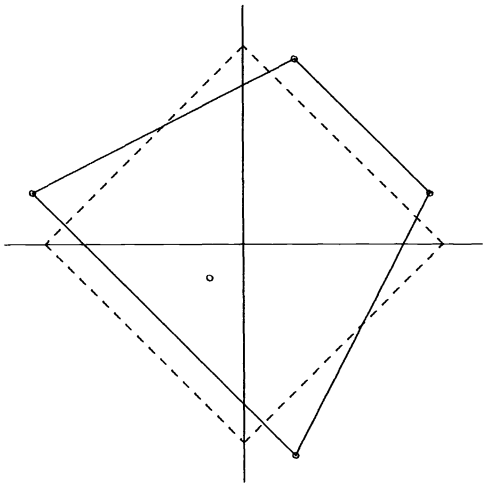

FIG. 2(b). $n=4$, $k=2$.

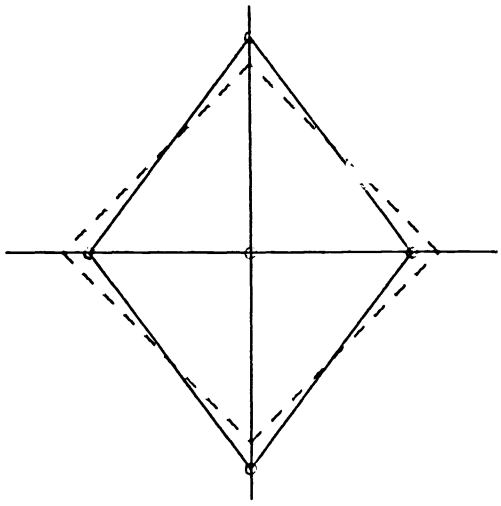

FIG. 2(c). $n=4$, $k=3$.

discussion of the previous section is complete for this case. Thus we will assume that $k \neq n/2+1$ throughout this section.

Let $\xi=(\xi_1, \cdots, \xi_h)^T=(x_2, \cdots, x_n, y_2, \cdots, y_n)^T$, where $h=2n-2$, are the Palmore coordinates discussed in § 2. As before fix n and k and let $\mu=m-m(n,k)$. Obviously $\mathcal{U}$ is invariant under the symmetries of the regular polygon with n sides; that is, there is a subgroup D_n of the orthogonal group $O(h, R)$ which is isomorphic to the dihedral group such that

$$\mathcal{U}(D\xi, \mu)=\mathcal{U}(\xi, \mu) \tag{5.1}$$

for all $D \in D_n$ and all small ξ and μ.

When $\mu=0$, the Hessian A of $\mathcal{U}$ at $\xi=0$ has a two-dimensional kernel and therefore there is an orthogonal matrix O, such that $O^TAO=\operatorname{diag}(0, 0, \lambda_3, \cdots, \lambda_h)$ where $\lambda_i \neq 0$ for $3 \leqq i \leqq h$. Let $O_2=\operatorname{diag}(1, 1, 1/\sqrt{|\lambda_3|}, \cdots, 1/\sqrt{|\lambda_h|})$ so $B=O^TAO=$

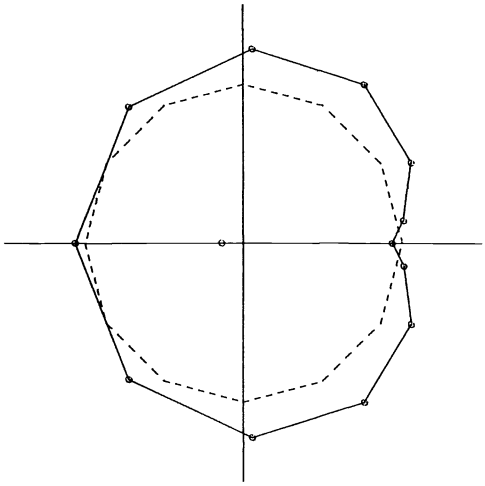

FIG. 3(a). $n = 12$, $k = 2$.

diag $(0, 0, \pm 1, \cdots, \pm 1)$ where $O = O_1 O_2$. If we change coordinates by $\xi = O\zeta$ then the Hessian of $\mathcal{U}$ in these coordinates is B or the quadratic part of $\mathcal{U}$ is as in (4.1). Usually, we use the same symbol for a function in different coordinates, but for the moment let $\mathcal{U}'(\zeta, \mu) = \mathcal{U}(O\zeta, \mu)$ so

$$\begin{aligned} &\mathcal{U}(D\xi, \mu) = \mathcal{U}(\xi, \mu), \\ &\mathcal{U}(OO^{-1}DO\zeta, \mu) = \mathcal{U}(O\zeta, \mu), \\ &\mathcal{U}'(O^{-1}DO\zeta, \mu) = \mathcal{U}'(\zeta, \mu), \end{aligned} \tag{5.2}$$

or

$$\mathcal{U}'(D'\zeta, \mu) = \mathcal{U}'(\zeta, \mu) \tag{5.3}$$

where $D' \in \mathcal{D}_n' = O^{-1}\mathcal{D}_n O$. From (5.3) D' leaves the Hessian of $\mathcal{U}'$ invariant and so $D'^T B D' = B$. This and the special form of O implies D' is of the form

$$D' = \begin{pmatrix} E & 0 \\ 0 & F \end{pmatrix} \tag{5.4}$$

where E is a 2×2 orthogonal matrix and F is some nonsingular $(h-2) \times (h-2)$ matrix. The set of such E's form a subgroup $\mathcal{E}$ of $O(2, R)$ which is clearly isomorphic to the subgroup of $\mathcal{D}_n'$ obtained by letting F be the identity matrix in (5.4). Since $\mathcal{E}$ is isomorphic to a subgroup of a dihedral group and as we saw in the last section contains a reflection, it must be isomorphic to a dihedral group whose order divides $2n$. The order of this group depends on n and k, and the precise dependence will be given at the end of this section along with the discussion of the specific findings.

Let ε be a formal parameter and consider

$$\mathcal{U}_*(\zeta, \mu, \varepsilon) = \sum_{i=0}^{\infty} \left(\frac{\varepsilon^i}{i!}\right) \mathcal{U}_i^0(\zeta, \mu) \tag{5.5}$$

where $\mathcal{U}_*(\zeta, \mu, 1) = \mathcal{U}(\zeta, \mu)$ and $\mathcal{U}_i^0$ is a homogeneous polynomial in ζ of degree $i+2$. The method of Lie transform given by Deprit (1969) constructs a near identity change of variables

$$\zeta = \zeta(\eta, \mu, \varepsilon) = \eta + \cdots$$

where ζ is the general solution of the differential equation

$$\frac{d\zeta}{d\varepsilon} = W(\zeta, \mu, \varepsilon), \qquad \zeta|_{\varepsilon=0} = \eta. \tag{5.6}$$

If the function W has the formal expansion

$$W(\zeta, \mu, \varepsilon) = \sum_{l=0}^{\infty} \left(\frac{\varepsilon^l}{l!}\right) W_{l+1}(\zeta, \mu) \tag{5.7}$$

then in the new coordinates

$$\begin{aligned} \mathcal{U}^*(\eta, \mu, \varepsilon) &= \mathcal{U}_*(\zeta(\eta, \mu, \varepsilon), \mu, \varepsilon) \\ &= \sum_{j=0}^{\infty} \left(\frac{\varepsilon^j}{j!}\right) \mathcal{U}_0^j(\zeta, \mu). \end{aligned} \tag{5.8}$$

The functions $\mathcal{U}_*$ and $\mathcal{U}^*$ are related by the double index array $\{\mathcal{U}_i^j\}$, which agrees with the previous definitions when either i or j is zero and are related by the recursive

relation

$$\mathcal{U}_i^j = \mathcal{U}_{i-1}^{j+1} + \sum_{k=0}^{i} \binom{i}{k} [\mathcal{U}_{i-k}^{j-1}, W_{k+1}], \tag{5.9}$$

where [,] is the Lie derivative operator on functions given by

$$[\mathcal{U}, W] = \frac{\partial \mathcal{U}}{\partial \zeta} W. \tag{5.10}$$

Let $\mathcal{P}_k$ be the space of homogeneous polynomials of degree $k+2$ in $\zeta_1, \cdots, \zeta_h$ with coefficients which are smooth in μ. Let $\mathcal{K}_k$ be the subspace of $\mathcal{P}_k$ of homogeneous polynomials in ζ_1 and ζ_2 only and $\mathcal{R}_k = \zeta_3 \mathcal{P}_{k-1} + \cdots + \zeta_h \mathcal{P}_{k-1}$ so that $\mathcal{P}_k = \mathcal{K}_k \oplus \mathcal{R}_k$. Since $\mathcal{U}_0^0 = \frac{1}{2}\zeta^T B \zeta$ the operator $L: W \to [\mathcal{U}_0^0, W]$ defines a self-map of $\mathcal{P}_k$ with kernel $\mathcal{K}_k$ and range $\mathcal{R}_k$. By a standard argument in normal form theory, we can find a formal series for W so that $\mathcal{U}^*$ is in normal form, i.e., $\mathcal{U}_0^k \in K_k$ for all $k \geqq 1$. That is, the higher-order terms in $\mathcal{U}^*$ depend only on η_1 and η_2. This argument is found in Meyer and Schmidt (1977), for example. This is the formal version of the splitting lemma.

Moreover, the normalizing generating function W satisfies $W_k \in \mathcal{R}_k$ so that the function W is zero on $\Xi = \{\xi: \xi_3 = \cdots = \xi_h = 0\}$. Thus Ξ is an invariant surface for (7) or the change of variables (6) fixes Ξ or $\Xi = \{\eta: \eta_3 = \cdots = \eta_h = 0\}$. This means that the new function $\mathcal{U}^*$ is invariant under the linear action defined by the matrices of the form (5.4) with $F = I$, the identity matrix.

We see that the normal form for $\mathcal{U}$ is the same as given by the splitting lemma in formula (4.1). Moreover, if the normalization is carried out as outlined above, the higher-order terms (i.e., G in 4.1) are invariant under the standard action of $\mathcal{E}$ on the plane.

Let $\mathcal{E}$ have order $2d$ where d divides n. Appendix C has a table giving d for various n and k. Consider the η_1, η_2 plane as the complex plane by setting $w = \eta_1 + i\eta_2$ and let $\phi = \exp(2\pi i/d)$ be a primitive dth root of unity. By the above, we are reduced to studying the critical points of

$$\Gamma(w, \bar{w}, \mu) = G(\eta_1, \eta_2, \mu) \tag{5.11}$$

where Γ is invariant under the action of $\mathcal{E}$ or

$$\Gamma(\phi w, \overline{\phi w}, \mu) = \Gamma(w, \bar{w}, \mu), \qquad \Gamma(w, \bar{w}, \mu) = \Gamma(\bar{w}, w, \mu). \tag{5.12}$$

The only terms in a Taylor expansion which satisfy the conditions in (5.12) are of the form

$$(w\bar{w})^i w^{dj} \quad \text{or} \quad (w\bar{w})^i \bar{w}^{dj} \tag{5.13}$$

where i and j are integers. Thus a typical expansion of Γ would look like this:

$$\Gamma(w, \bar{w}, \mu) = p_1(w\bar{w}) + p_2(w\bar{w})^2 + \cdots + (1/d) q_1(w^d + \bar{w}^d) + \cdots. \tag{5.14}$$

The p's and q's are real functions of μ. By the analysis of the Hessian given in § 3, $p_1(\mu) = a\mu + \cdots$ where a is a nonzero constant. Assume we are in the generic case so that $q_1(0) \neq 0$ and in addition $p_2(0) \neq 0$ when $d > 4$ and $p_2(0) \neq q_1(0)$ when $d = 4$.

Case 1. $d = 3$. Let $q_1(0) = b$, so we must solve

$$\begin{aligned} &\frac{\partial \Gamma}{\partial w} = a\mu\bar{w} + bw^2 + \cdots = 0, \\ &a\mu(w\bar{w}) + bw^3 + \cdots = 0, \\ &a\mu r^2 + br^3 \exp(i3\theta) + \cdots = 0 \end{aligned} \tag{5.15}$$

where $w = r\exp(i\theta)$. Thus, by the implicit function theorem Γ has critical points at $r = \mp a\mu/b + \cdots$ when $\exp(i3\theta) = \pm 1$. That is, three critical points move linearly away from the origin (or the r.p.r.e.) as μ varies from zero. This case occurs when $n = 3$, $k = 2$ (Fig. 1(a) shows a solution where $\exp(i3\theta) = +1$ and Fig. 1(b) where $\exp(i3\theta) = -1$.); when $n = 9$, $k = 4$; $n = 12$, $k = 5$ (Fig. 3(g) shows a solution where $\exp(i3\theta) = +1$ and Fig. 3(h) where $\exp(i3\theta) = -1$) for both problems, and when $n = 6$, $k = 3$ for the Kirchhoff problem. See Appendix C. In the notation of the previous section $\alpha = a$, $\beta = b$, and $\rho = 1$.

Case 2. $d \geqq 5$. Let $p_2(0) = b \neq 0$ and $q_1(0) = c \neq 0$, so we must solve

$$\begin{aligned} \frac{\partial \Gamma}{\partial w} &= a\mu\bar{w} + b(w\bar{w})^2 + \cdots + cw^{d-1} + \cdots = 0, \\ a\mu r^2 + br^4 + \cdots + cr^d \exp(id\theta) + \cdots &= 0. \end{aligned} \tag{5.16}$$

By the implicit function theorem Γ has critical points at

$$r = \sqrt{-a\mu/b + \cdots}, \qquad \exp(id\theta) = \pm 1. \tag{5.17}$$

That is, Γ has $2d$ nonzero critical points for $\mu > 0$ and none for $\mu < 0$ when $ab < 0$ and vice versa when $ab > 0$. These solutions fall into two families of d each depending on the sign of $\exp(id\theta)$. The families move away from the origin like the square root of μ. For most n and k, we have $d \geqq 5$ (see Appendix C). For $n = 12$, Figs. 3(a), 3(i) show the solutions where $\exp(i12\theta) = +1$ and Figs. 3(b), 3(j) show the solutions where $\exp(i12\theta) = -1$. In the notation of the previous section $\alpha = a$, $\beta = b$, and $\rho = 2$.

Case 3. $d = 4$. Using the above notation, we must solve

$$a\mu r^2 + (b + c\exp(i4\theta))r^4 + \cdots = 0 \tag{5.18}$$

and so there are solutions of the form

$$r = \sqrt{-a\mu/(b \pm c) + \cdots}, \qquad \exp(i4\theta) = \pm 1. \tag{5.19}$$

If $b \pm c$ are of one sign then there are eight solutions for μ on one side of zero as in Case 2. This happens when $n = 12$, $k = 4$. Figure 3(e) shows a solution when $\exp(i4\theta) = +1$ and Fig. 3(f) shows a solution where $\exp(i4\theta) = -1$. If $b \pm c$ have two signs then there are four solutions when μ is negative and when μ is positive as in Case 1. This happens when $n = 4$, $k = 2$. Figure 2(a) shows a solution when $\exp(i4\theta) = +1$ and Fig. 2(b) shows a solution when $\exp(i4\theta) = -1$.

To understand the relationship between n, k, and the order d of the rotational subgroup which acts on the two-dimensional subspace, we proceed as we did in the previous section when we discussed the reflection symmetry. $\mathcal{U}$ is invariant also under a rotation $\mathcal{C}$ which leaves the regular polygon relative equilibrium fixed. In the original coordinates the rotation is

$$\mathcal{C}: q_j \to \omega q_{j-1}, \quad 0 \leqq j < n, \qquad \mathcal{C}: q_n \to q_n. \tag{5.20}$$

This rotation $\mathcal{C}$ with the reflection $\mathcal{R}$ generates the symmetry group of $\mathcal{U}$ which also fixes the r.p.r.e. Ω. At one of the critical masses a perturbation in the direction of the kernel of the Hessian is of the form

$$\begin{aligned} q_j &= \omega^j + \omega^{jk} z_k + \omega^{jl} z_l, \qquad k + l = n + 2, \\ q_j &= \omega^j + \omega^{jk} z, \qquad k = l = n/2 + 1. \end{aligned} \tag{5.21}$$

In the first case the z_k and z_l are not independent but are linearly related (essentially conjugates), so one can be used as a coordinate of the perturbation. In the second case the z is arbitrary. Thus we can use z_k or z as a coordinate in the kernel of the Hessian. The action of $\mathcal{O}$ on this subspace is

$$\begin{aligned} &\mathcal{O}: \omega^j + \omega^{jk} z_k + \omega^{jl} z_l \to \omega^j + \omega^{jk}(\omega^{1-k}) z_k + \omega^{jl}(\omega^{l-1}) z_l, \qquad k \neq l, \\ &\mathcal{O}: \omega^j + \omega^{jk} z \to \omega^j + \omega^{jk}(\omega^{1-k}) z, \qquad k = l = n/2 + 1. \end{aligned} \tag{5.22}$$

Thus in coordinates $\mathcal{O}: z_k \to (\omega^{1-k}) z_k$ or $\mathcal{O}: z \to (\omega^{1-k}) z$, so $\mathcal{O}$ is a rotation on this subspace also; but it does not necessarily generate the full symmetry group. The order of the rotation group generated by $\mathcal{O}$ on this subspace is d where $(k-1)d \equiv 0 \bmod n$. Appendix C lists n, k, and d for all cases $3 \leqq n \leqq 12$.

Consider Figs. 3(e) and 3(f) for example where $n = 12$, $k = 4$, and $d = 4$. By rotating these figures by $l2\pi/12$ for $l = 0, 1, \cdots, 11$ we obtain $d = 4$ distinct r.e. which have symmetry given by the dihedral group D_3, because $k - 1 = 3$. Contrast that with Figs. 3(a) and 3(b) where $n = 12$, $k = 2$, $d = 12$. When we rotate these figures by $l2\pi/12$, $l = 0, \cdots, 11$ we obtain $d = 12$ distinct r.e., which have the symmetries of the dihedral group D_1 (generated by a single reflection), since $k - 1 = 1$. The other figures follow the same pattern.

Finally we will consider the degeneracy in the Kirchhoff problem when $n = 4$, $k = 3$. In this case the symmetry with respect to both axes is preserved. Since the moment of inertia has to remain constant, r.e. can only be formed by a rhombus with the fifth vortex at the center. The coordinates of the five vortices are

$$\begin{aligned} q_0 &= -q_2 = 1 + x_0, \\ q_1 &= q_3 = i\sqrt{1 - 2x_0 - x_0^2}, \\ q_4 &= 0. \end{aligned}$$

Let m be the value of the vorticity at the origin, then the potential function (2.8) turns out to be

$$-\tfrac{7}{8}\log 2 - (1+2m)\{\log(1+x_0) + \tfrac{1}{2}\log(1 - 2x_0 - x_0^2)\}.$$

For $m \neq -\frac{1}{2}$ the potential function has extrema at $x_0 = 0$ and $x_0 = -\frac{1}{2}$. For $m = -\frac{1}{2}$ the potential function is independent of x_0 and therefore any rhombus can serve as a r.e. for the Kirchhoff problem. See Fig. 2(c).

Appendix A. Entries in the Hessian.

$$B = \begin{pmatrix} b_2 & & & \\ & b_3 & & \\ & & \ddots & \\ & & & b_n \end{pmatrix}, \qquad C = C^T = \begin{pmatrix} & & & c_n \\ & & \iddots & \\ & c_3 & & \\ c_2 & & & \end{pmatrix},$$

$$b_k = \frac{n}{2}(-R_k - \gamma m), \qquad k = 2, 3, \cdots, n-1,$$

$$b_n = \frac{n}{2}\frac{m+n}{m}(-\gamma m - \delta n - S),$$

$$c_k = \frac{n}{2}(T_k - \gamma m), \qquad k = 3, 4, \cdots, n-1,$$

$$c_k = -\frac{n}{2}(m+n)\gamma, \qquad k = 2, n$$

where $\gamma = \delta + 2$ and

$$S = \frac{1}{2^\delta} \sum_{r=1}^{n-1} \frac{1}{\sin^\delta (\pi r/n)},$$

$$R_k = \frac{\delta}{2^{\delta+1}} \sum_{r=1}^{n-1} \frac{\sin^2 (\pi rk/n)}{\sin^\gamma (\pi r/n)} + S,$$

$$T_k = \frac{\gamma}{2^{\delta+1}} \sum_{r=1}^{n-1} \frac{\sin (\pi rk/n) \sin (\pi r(k-2)/n)}{\sin^\gamma (\pi r/n)},$$

$$m(n, 2) = \frac{R_k(\delta n + S)}{\gamma(2n - R_2 - S)},$$

$$m(n, k) = \frac{T_k^2 - R_k R_l}{\gamma(R_k + R_l + 2T_k)}, \qquad k + l = n + 2, \quad k \neq l,$$

$$m(n, k) = \frac{T_k - R_k}{2\gamma}, \qquad 2k = n + 2.$$

In the Kirchhoff problem, $\delta = 0$, the formulas for m simplify to

$$m(n, 2) = \tfrac{1}{4}(n-1)^2,$$

$$m(n, k) = \tfrac{1}{4}\{(k-2)(n-k) - n + 1\}, \qquad k = 3, 4, \cdots, (n+2)/2.$$

Appendix D. The potential of the hexagon configuration. Consider the one-parameter perturbation of the hexagon configuration (with no particle at the centroid) in the n-body problem given by

$$q_0=(1+\varepsilon)(2,0), \qquad q_1=\sqrt{(1-2\varepsilon-\varepsilon^2)}(1,\sqrt{3}),$$
$$q_2=(1+\varepsilon)(-1,\sqrt{3}), \qquad q_3=\sqrt{(1-2\varepsilon-\varepsilon^2)}(-2,0),$$
$$q_4=(1+\varepsilon)(-1,-\sqrt{3}), \qquad q_5=\sqrt{(1-2\varepsilon-\varepsilon^2)}(1,-\sqrt{3}).$$

This perturbation has been chosen to keep the moment of inertia, I, fixed. From the symmetry,

$$\begin{aligned} U &= \frac{6}{\|q_0-q_1\|}+\frac{3}{\|q_0-q_2\|}+\frac{3}{\|q_1-q_3\|}+\frac{3}{\|q_0-q_3\|} \\ &= 3\{1-\varepsilon^2+\cdots\}+\frac{\sqrt{3}}{2}\{1-\varepsilon+\varepsilon^2+\cdots\}+\frac{\sqrt{3}}{2}\{1+\varepsilon+2\varepsilon^2+\cdots\}+\frac{3}{4}\left\{1+\frac{1}{2}\varepsilon^2+\cdots\right\} \\ &= \left(\frac{15}{4}+\sqrt{3}\right)-\frac{3}{8}(7-4\sqrt{3})\varepsilon^2+\cdots \\ &\simeq 5.48-0.0269\varepsilon^2+\cdots. \end{aligned}$$

Thus U initially decreases along this family and so the hexagon configuration is not a minimum of the (self-) potential.

AN EXISTENCE RESULT FOR THE ELECTROPAINTING PROBLEM*

PIERLUIGI COLLI† AND LUC OSWALD‡

Abstract. A time-dependent family of harmonic problems with boundary condition $h(\partial\varphi/\partial\nu)=\varphi$, where h is a function dependent on the history of φ, models an electropaint process. It is proven that the problem has a weak solution $\{\varphi(x,t), h(x,t)\}$ and $\lim_{t\to\infty}\varphi(x,t)$ exists and coincides with the solution of an appropriate Signorini problem.

Key words. electropainting process, time-dependent family of harmonic problems

AMS (MOS) subject classifications. 35D05, 35J65, 35R35

Introduction. In this paper we are interested in an electropaint process model, which was introduced by Aitchison, Lacey, and Shillor [ALS] as an approximation of the physical problem. Electropainting is a commonly used method for painting metal surfaces: a workpiece is immersed in an electrolyte solution and a potential difference is applied between the workpiece and the outside boundary of the bath. This induces a deposition of ions on the surface of the metal, which is subsequently painted (for more details, see [ALS]).

Let us describe the mathematical problem. We denote by Γ the surface of the workpiece and by S the boundary of the bath: Ω will be the region occupied by the electrolyte solution. Then $\partial\Omega=S\cup\Gamma$ and Ω is a domain in $\mathbb{R}^N$, $N\geqq 2$. Let φ be the electric potential in Ω and h the thickness of the paint layer on Γ. The problem is to find $\varphi(x,t)$, $h(x,t)$ such that

$$\Delta\varphi=0 \quad \text{in } \Omega, \qquad t>0, \tag{0.1}$$

$$\varphi=1 \quad \text{on } S, \qquad t>0, \tag{0.2}$$

$$h\frac{\partial\varphi}{\partial\nu}=\varphi \quad \text{on } \Gamma, \qquad t>0, \tag{0.3}$$

$$\frac{\partial h}{\partial t}=\frac{\partial\varphi}{\partial\nu}-\varepsilon \quad \text{if } x\in\Gamma, \qquad h(x,t)>0, \tag{0.4}$$

$$\frac{\partial h}{\partial t}=\left(\frac{\partial\varphi}{\partial\nu}-\varepsilon\right)^{+} \quad \text{if } x\in\Gamma, \qquad h(x,t)=0, \tag{0.5}$$

$$h(x,0)=0 \quad \text{on } \Gamma, \tag{0.6}$$

where $\varepsilon>0$ is the dissolution current constant; $\partial/\partial\nu$ denotes the inward normal derivative. Let ψ be the solution of (0.1), (0.2), and

$$\psi=0 \quad \text{on } \Gamma. \tag{0.7}$$

Obviously, if $\partial\psi/\partial\nu\leqq\varepsilon$ on Γ, then $(\psi,0)$ is a trivial solution of (0.1)-(0.6). In order to exclude this case, we will always assume in the sequel that

$$\operatorname{meas}\left(\left\{x\in\Gamma:\frac{\partial\psi}{\partial\nu}>\varepsilon\right\}\right)>0. \tag{0.8}$$

* Received by the editors October 1, 1986; accepted for publication (in revised form) December 20, 1987.

Under this assumption, Caffarelli and Friedman showed in [CF] that a smooth solution of (0.1)-(0.6) satisfies

$$\frac{\partial h}{\partial t}=\left(\frac{\partial \varphi}{\partial \nu}-\varepsilon\right)^{+} \quad \text{on } \Gamma, \tag{0.9}$$

i.e., there is no paint dissolution in the process; moreover, they introduced a time-discretized version of the above problem with (0.9) instead of (0.4), (0.5) and they proved existence and uniqueness of the discretized solution and its convergence to the steady state Signorini problem.

The study of the electropainting problem has been taken up by Marquez and Shillor in [MS], where they introduced an overpotential $\sigma(x)\geqq\sigma_*>0$ for the paint thickness h. Namely they considered the following conditions:

$$\frac{\partial h}{\partial t}=\frac{\partial \varphi}{\partial \nu}-\varepsilon \quad \text{if } x\in\Gamma, \qquad h(x,t)>\sigma(x), \tag{0.10}$$

$$\frac{\partial h}{\partial t}=\left(\frac{\partial \varphi}{\partial \nu}-\varepsilon\right)^{+} \quad \text{if } x\in\Gamma, \qquad h(x,t)=\sigma(x), \tag{0.11}$$

$$h(x,0)=\sigma(x) \quad \text{if } x\in\Gamma, \tag{0.12}$$

instead of (0.4)-(0.6).

Note that this is an approximation that regularizes the original problem because it avoids degeneracy in the Neuman condition (0.3). Thus they are able to show that a smooth solution of (0.1)-(0.3), (0.10)-(0.12) satisfies (0.9) and, moreover, that $\partial h/\partial t\not\equiv 0$ on Γ is impossible. The work of Marquez and Shillor also contains an existence and uniqueness result for the smooth solution of (0.1)-(0.3), (0.9), (0.12). Furthermore an $L^3(\Gamma)$ estimate of $\partial\varphi/\partial\nu$ is proved in [MS, Lemma 6.3] under the following geometrical assumption: Ω is the difference between a convex set with boundary Γ, and a subset of it with boundary S; thus Γ and S are inverted.

The novelty in this paper is the extension of this $L^3(\Gamma)$ estimate to Ω with a general geometry; such a generalization is obtained via a harmonic supersolution technique.

Then, letting $\sigma\to 0$, we are able to obtain a weak solution of the problem (0.1)-(0.3), (0.9), (0.6) as a monotone limit of the solutions $(\varphi_\sigma, h_\sigma)$ given in [MS] for $\sigma(x)=\sigma>0$. Furthermore, showing that in fact $(\varphi_\sigma, h_\sigma)$ is a solution of (0.1)-(0.3), (0.10)-(0.12), we prove that the obtained weak solution satisfies (0.4), (0.5), i.e., it is a solution of the electropainting problem. Finally, following the argument given in [CF], it can be shown that the process converges asymptotically to a unique steady state.

1. An existence result. Let Ω_1 and Ω_2 be connected bounded open sets in $\mathbb{R}^N$ ($N\geqq 2$) with $C^{1,1}$ boundaries Γ and S, respectively. We assume that $\bar{\Omega}_1\subset\Omega_2$ and set $\Omega:=\Omega_2\backslash\bar{\Omega}_1$. In the physical situation Ω_1 is the workpiece and Ω_2 is the bath.

We consider the following problem:

(P_0) Given $T>0$, find a couple $\{\varphi, h\}$, $\varphi:\Omega\times[0,T]\to\mathbb{R}$, $h:\Gamma\times[0,T]\to\mathbb{R}$ satisfying

$$\Delta\varphi=0 \quad \text{in } \Omega, \qquad 0\leqq t\leqq T, \tag{1.1}$$

$$\varphi=1 \quad \text{on } S, \qquad 0\leqq t\leqq T, \tag{1.2}$$

$$h\frac{\partial \varphi}{\partial \nu}=\varphi \quad \text{on } \Gamma, \qquad 0\leqq t\leqq T, \tag{1.3}$$

$$h=\int_0^t\left(\frac{\partial \varphi}{\partial \nu}-\varepsilon\right)^{+} d\tau \quad \text{on } \Gamma, \qquad 0\leqq t\leqq T, \tag{1.4}$$

where $\partial\varphi/\partial\nu$ is the inward normal derivative of φ on Γ and $\varepsilon > 0$ is a given real number.

First we define a weak solution of (P_0).

DEFINITION 1.1. A weak solution of (P_0) is a couple of functions $\{\varphi, h\}$ such that

$$\varphi \in L^\infty(0, T; H^{3/2}(\Omega)), \tag{1.5}$$

$$h \in L^\infty(\Gamma \times (0, T)), \qquad h_t \in L^\infty(0, T; L^2(\Gamma)), \tag{1.6}$$

where h_t is the derivative of h with respect to t;

$$\varphi \text{ and } h \text{ satisfy (1.1)-(1.4).} \tag{1.7}$$

Note that the equalities (1.3), (1.4) make sense; indeed from (1.5) and (1.1) it follows that $\partial\varphi/\partial\nu \in L^\infty(0, T; L^2(\Gamma))$ (cf., e.g., [LM, Chap. 2, Thm. 7.3]).

Our aim is to prove the existence of a weak solution of (P_0). To this end, we recall a result of Marquez and Shillor [MS] on the existence and uniqueness of a smooth solution of the following problem:

(P_σ) Find $(\varphi_\sigma, h_\sigma)$ satisfying (1.1)-(1.3) and

$$h_\sigma = \sigma + \int_0^t \left(\frac{\partial\varphi_\sigma}{\partial\nu} - \varepsilon\right)^+ d\tau \quad \text{on } \Gamma, \qquad 0 \leqq t \leqq T, \tag{1.8}$$

where $\sigma > 0$ is a constant.

THEOREM 1.1. *There exists one and only one solution φ_σ, h_σ of (P_0) such that*

$$\varphi_\sigma \in W^{1,\infty}(0, T; H^{3/2}(\Omega)) \cup C^{0,\alpha}(\bar{\Omega} \times [0, T]), \tag{1.9}$$

$$\nabla\varphi_\sigma \in C^0(\bar{\Omega} \times [0, T]), \tag{1.10}$$

$$(\varphi_\sigma)_t \in C^\alpha(\bar{\Omega} \times [0, T]), \tag{1.11}$$

$$\varphi_\sigma, (\varphi_\sigma)_t \in C^{1,\alpha}(\bar{\Omega}), \qquad 0 \leqq t \leqq T, \tag{1.12}$$

$$\frac{\partial\varphi_\sigma}{\partial\nu}, \left(\frac{\partial\varphi_\sigma}{\partial\nu}\right)_t \in C^\alpha(\Gamma \times [0, T]), \tag{1.13}$$

$$h_\sigma, (h_\sigma)_t \in C^\alpha(\Gamma \times [0, T]), \tag{1.14}$$

for any $\alpha \in (0, 1)$.

Proof. See Theorems 4.2 and 4.4 of [MS].

We will use these results to prove the next theorem.

THEOREM 1.2. *There exists at least one weak solution of (P_0).*

Before giving the proof, we state some preliminary results. The next lemma generalizes an idea of [MS] for a particular geometry of Ω.

LEMMA 1.1. *Let W be the solution of*

$$\begin{aligned} &\Delta W = 0 && \text{in } \Omega, \\ &W = 1 && \text{on } S, \\ &\sigma\frac{\partial W}{\partial\nu} = W && \text{on } \Gamma. \end{aligned} \tag{1.15}$$

Then there is a constant $\theta > 0$ independent of $\sigma > 0$ such that

$$0 \leqq \frac{\partial W}{\partial\nu} \leqq \theta. \tag{1.16}$$

Proof. As Γ is $C^{1,1}$, Ω_1 has the uniform interior sphere property, i.e., there exists $r_0>0$ such that for every $x\in\Gamma$ there exists a sphere of radius r_0 contained in Ω_1 and tangent to Γ at the point x.

Denote by x_0 the point of Γ where the maximum of W on Γ is achieved. Then the maximum of $\partial W/\partial\nu$ on Γ is also achieved at x_0 (cf. (1.15)). We want to find a supersolution U such that $(\partial U/\partial\nu)(x_0)\geqq(\partial W/\partial\nu)(x_0)$; then, in order to prove the lemma, it will be sufficient to bound $(\partial U/\partial\nu)(x_0)$.

Let y be the center of the ball of radius r_0 contained in Ω_1 and tangent to Γ in x_0. Set

$$r=|x-y|,\qquad d_0=d(S,\Gamma),$$
$$\text{if}\quad N\geqq 3\quad U(x)=C_1-C_2/r^{N-2},$$
$$\text{if}\quad N=2\quad U(x)=C_1-C_2\log r,$$

where C_1 and C_2 are given by

$$\begin{aligned} &C_1-C_2/r_0^{N-2}=W(x_0)\\ &C_1-C_2/(r_0+d_0)^{N-2}=1 \end{aligned}\qquad \text{if}\quad N\geqq 3, \tag{1.17}$$

and, respectively,

$$\begin{aligned} &C_1-C_2\log r_0=W(x_0)\\ &C_1-C_2\log(r_0+d_0)=1 \end{aligned}\qquad \text{if}\quad N=2. \tag{1.18}$$

Note that U satisfies

$$\begin{aligned} &\Delta U=0 && \text{in } \Omega,\\ &U\geqq 1 && \text{on } S,\\ &U\geqq W && \text{on } \Gamma. \end{aligned} \tag{1.19}$$

By the comparison principle, from (1.15) and (1.19) it follows that $U\geqq W$ on $\bar\Omega$. Moreover $U(x_0)=W(x_0)$; therefore by the strong maximum principle we infer that $(\partial U/\partial\nu)(x_0)\geqq(\partial W/\partial\nu)(x_0)$.

It is easy to check that C_2 is bounded independently of σ and x_0 (note that $0<W(x)<1$ for $x\in\Omega\cup\Gamma$) and this gives the desired estimate for $(\partial U/\partial\nu)(x_0)$.

LEMMA 1.2. *Let $(\varphi_\sigma, h_\sigma)$ be the solution of (P_σ) given by Theorem* 1.1. *Then there exists a constant $C>0$ independent of σ, T such that*

$$\int_\Gamma\left|\frac{\partial\varphi_\sigma}{\partial\nu}\right|^3\leqq C \quad \textit{for any } \sigma>0,\ t\in[0,T]. \tag{1.20}$$

Proof. See Lemma 6.3 of [MS]. However, since their lemma is the crucial step needed in passing to the limit with $\sigma\to 0$, we briefly outline their proof.

By assumption, $(\varphi_\sigma, h_\sigma)$ satisfies

$$h_\sigma\frac{\partial\varphi_\sigma}{\partial\nu}=\varphi_\sigma \quad \text{on } \Gamma,\ 0\leqq t\leqq T. \tag{1.3}$$

Differentiating (1.3) with respect to time, then multiplying it by $(\partial\varphi_\sigma/\partial\nu)_t$, integrating over Γ and noting that

$$\int_\Gamma(\varphi_\sigma)_t\left(\frac{\partial\varphi_\sigma}{\partial\nu}\right)_t=-\int_\Omega|\nabla(\varphi_\sigma)_t|^2\leqq 0,$$

and that if $\partial\varphi_\sigma/\partial\nu \leqq \varepsilon$ then $(\partial\varphi_\sigma/\partial\nu)_t > 0$, we obtain

$$\int_\Gamma \left(\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon\right)\frac{\partial\varphi_\sigma}{\partial\nu}\left(\frac{\partial\varphi_\sigma}{\partial\nu}\right)_t \leqq \int_\Gamma \left(\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon\right)^+\frac{\partial\varphi_\sigma}{\partial\nu}\left(\frac{\partial\varphi_\sigma}{\partial\nu}\right)_t$$

$$\leqq \int_\Gamma (\varphi_\sigma)_t\left(\frac{\partial\varphi_\sigma}{\partial\nu}\right)_t \leqq 0,$$

which can be rewritten as

$$\int_\Gamma \left(\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon\right)^2\left(\frac{\partial\varphi_\sigma}{\partial\nu}\right)_t + \varepsilon\int_\Gamma \left(\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon\right)\left(\frac{\partial\varphi_\sigma}{\partial\nu}\right)_t \leqq 0;$$

i.e.,

$$\frac{d}{dt}\int_\Gamma \left\{\frac{1}{3}\left(\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon\right)^3+\frac{\varepsilon}{2}\left(\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon\right)^2\right\} \leqq 0.$$

The estimate follows by integration over $(0, t)$ and from the uniform estimate of $(\partial\varphi_\sigma/\partial\nu)\ (x, 0)$ given by Lemma 1.1.

Now we collect some results proved in [MS], namely Lemmas 6.4, 4.3, and 6.5.

LEMMA 1.3. *There exists $C > 0$ independent of σ and T such that*

$$\|\varphi_\sigma\|_{H^1(\Omega)} \leqq C, \qquad 0 \leqq t \leqq T. \tag{1.21}$$

Moreover for every $\sigma < 1/\varepsilon$

$$0 \leqq h_\sigma \leqq 1+\frac{1}{\varepsilon} \quad \text{on } \Gamma\times[0, T]. \tag{1.22}$$

Finally if $0 < \sigma_1 < \sigma_2$ and $(\varphi_{\sigma_1}, h_{\sigma_1})$, $(\varphi_{\sigma_2}, h_{\sigma_2})$ are, respectively, the solutions of (P_{σ_1}) and (P_{σ_2}) given by Theorem 1.1, then

$$\varphi_{\sigma_1} \leqq \varphi_{\sigma_2} \quad \text{on } (\Omega\cup\Gamma)\times[0, T], \tag{1.23}$$

$$h_{\sigma_1} \leqq h_{\sigma_2} \quad \text{on } \Gamma\times[0, T]. \tag{1.24}$$

Proof of Theorem 1.2. Let us denote by φ, h the monotone limits of the sequences φ_σ, h_σ as $\sigma \to 0$ (cf. (1.23), (1.24)). From (1.21), (1.22) it follows that

$$\varphi_\sigma \searrow \varphi \quad \text{weakly in } H^1(\Omega), \quad 0 < t < T, \quad \text{a.e. in } \Omega, \tag{1.25}$$

$$h_\sigma \searrow h \quad \text{weakly * in } L^\infty(\Gamma\times(0, T)), \quad \text{a.e. in } \Gamma. \tag{1.26}$$

From (1.20), (1.21), and (1.1) for φ_σ it follows that $\{\varphi_\sigma\}$ actually is bounded in $L^\infty(0, T; H^{3/2}(\Omega))$ (see, e.g., [LM, Chap. 2, (7.28)]); thus $\varphi_\sigma \to \varphi$ weakly * in this space, which yields $\partial\varphi_\sigma/\partial\nu \to \partial\varphi/\partial\nu$ weakly * in $L^\infty(0, T; L^2(\Gamma))$ (see for instance [LM, Chap. 2, Thm. 7.3]); by (1.20) normal derivatives actually converge in $L^\infty(0, T; L^3(\Gamma))$. Note that all this is true in principle for a subsequence, but the monotonicity of $\{\varphi_\sigma\}$ implies a unique limit and thus the "whole" sequences converge.

Due to Lebesgue's theorem, we have that $h_\sigma \to h$ strongly in $L^p(\Gamma)$ for any $1 < p < +\infty$, $0 \leqq t \leqq T$. Then, taking the limit in

$$h_\sigma\frac{\partial\varphi_\sigma}{\partial\nu} = \varphi_\sigma,$$

we obtain (1.3). Note that h is a nondecreasing function with respect to t, as it is the limit of nondecreasing functions. It remains to prove (1.4); therefore it suffices to show that

$$\left(\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon\right)^+ \xrightarrow[\sigma\to 0]{} \left(\frac{\partial\varphi}{\partial\nu}-\varepsilon\right)^+ \quad \text{in } L^1(\Gamma\times(0,T)). \tag{1.27}$$

Indeed (1.27) will allow us to take the limit in (1.8) to obtain (1.4).

Set the following:

$$\begin{aligned} &Q_0=\{(x,t)\in\Gamma\times(0,T): h(x,t)=0\},\\ &Q_+=(\Gamma\times(0,T))\setminus Q_0, \end{aligned} \tag{1.28}$$

$$\begin{aligned} &\Gamma_0(t)=\{x\in\Gamma: h(x,t)=0\},\\ &\Gamma_+(t)=\Gamma\setminus\Gamma_0(t). \end{aligned} \tag{1.29}$$

As h is monotone nondecreasing with respect to t, $\Gamma_0(t)\times[0,t]\subset Q_0$ for any $t\in[0,T]$. Now, integrating (1.8) on $\Gamma_0(t)$ and taking the limit as $\sigma\to 0$, we get

$$\left(\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon\right)^+\to 0 \quad \text{in } L^1(\Gamma_0(t)\times[0,t]), \qquad 0\leqq t\leqq T. \tag{1.30}$$

As $\partial\varphi_\sigma/\partial\nu\to\partial\varphi/\partial\nu$ weakly * in $L^\infty(0,T;L^3(\Gamma))$, thus weakly in $L^1(\Gamma_0(t)\times[0,T])$ for any $t\in[0,T]$, from the equality

$$\left(\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon\right)=\left(\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon\right)^+-\left(\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon\right)^- \tag{1.31}$$

and (1.30) it follows that the weak limit $\xi:=\lim((\partial\varphi_\sigma/\partial\nu)-\varepsilon)^-$ exists in $L^1(\Gamma_0(t)\times[0,T])$ and that $(\partial\varphi/\partial\nu)-\varepsilon=0-\xi\leqq 0$; that is,

$$\left(\frac{\partial\varphi}{\partial\nu}-\varepsilon\right)^+=0 \quad \text{on } \Gamma_0(t)\times[0,t],\ 0\leqq t\leqq T. \tag{1.32}$$

Now, because of the monotonicity of the set $\Gamma_0(t)$, it is possible to find a sequence $t_m\in(0,T)$ such that

$$\text{meas}\,(Q_0-E_n)\to 0 \quad \text{as } n\to\infty, \tag{1.33}$$

where $E_n=U_{m\leqq n}\Gamma_0(t_m)\times(0,t_m)$. Note that (1.30) and (1.32) are still true in $L^1(E_n)$.

Applying the Schwarz-Hölder inequality and (1.20), we have

$$\begin{aligned} \int_{Q_0}\left|\left(\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon\right)^+-\left(\frac{\partial\varphi}{\partial\nu}-\varepsilon\right)^+\right| &= \int_{Q_0\setminus E_n}\left|\left(\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon\right)^+-\left(\frac{\partial\varphi}{\partial\nu}-\varepsilon\right)^+\right|+\int_{E_n}\left|\left(\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon\right)^+\right|\\ &\leqq C\{\text{meas}\,(Q_0-E_n)\}^{2/3}+\int_{E_n}\left|\left(\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon\right)^+\right|, \end{aligned} \tag{1.34}$$

where C is independent of σ. Taking the lim sup as $\sigma\to 0$ in (1.34), we obtain by (1.30)

$$\limsup_{\sigma\to 0}\int_{Q_0}\left|\left(\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon\right)^+-\left(\frac{\partial\varphi}{\partial\nu}-\varepsilon\right)^+\right|\leqq C\{\text{meas}\,(Q_0-E_n)\}^{2/3}. \tag{1.35}$$

From (1.33), (1.35) it follows that (1.27) is satisfied on Q_0.

In addition, by the definition of Q_+, (1.25), (1.26), and (1.3), we have

$$\frac{\partial \varphi_\sigma}{\partial \nu} = \frac{\varphi_\sigma}{h_\sigma} \xrightarrow[\sigma \to 0]{} \frac{\varphi}{h} = \frac{\partial \varphi}{\partial \nu} \quad \text{a.e. on } Q_+. \tag{1.36}$$

Now Egorov's theorem asserts that for every $\delta > 0$ there exists a subset $A_\delta \subset Q_+$ such that $\partial \varphi_\sigma / \partial \nu \longrightarrow_{\sigma \to 0} \partial \varphi / \partial \nu$ uniformly on A_δ and meas $(Q_+ \setminus A_\delta) < \delta$. Then, using the Schwarz-Hölder inequality, we derive from (1.20)

$$\int_{Q_+} \left| \frac{\partial \varphi_\sigma}{\partial \nu} - \frac{\partial \varphi}{\partial \nu} \right| \leqq C\delta^{2/3} + \int_{A_\delta} \left| \frac{\partial \varphi_\sigma}{\partial \nu} - \frac{\partial \varphi}{\partial \nu} \right|, \tag{1.37}$$

where C is independent of σ. Thus (1.27) is also satisfied on Q_+. This concludes the proof of Theorem 1.2. □

Remark 1.1. Note that, by Theorem 1.2, problem (P_0) has a solution for every $T > 0$, i.e., on $[0, +\infty)$.

2. A solution of the electropainting problem. In [MS], Marquez and Shillor, following Caffarelli and Friedman [CF], show a smooth solution (in the sense of Theorem 1.1) of the following problem:

(EP_σ) Find $(\varphi_\sigma, h_\sigma)$ satisfying (1.1)-(1.3) and

$$(h_\sigma)_t = \left(\frac{\partial \varphi_\sigma}{\partial \nu} - \varepsilon \right)^+ \quad \text{on } \Gamma \cap \{h_\sigma = \sigma\}, \qquad t \geqq 0, \tag{2.1}$$

$$(h_\sigma)_t = \left(\frac{\partial \varphi_\sigma}{\partial \nu} - \varepsilon \right) \quad \text{on } \Gamma \cap \{h_\sigma > \sigma\}, \qquad t \geqq 0, \tag{2.2}$$

$$h_\sigma(x, 0) = \sigma \quad \text{on } \Gamma, \tag{2.3}$$

where $\sigma > 0$ is a smooth solution of (P_σ).

Our aim is to prove that the converse is also true, by means of an argument suggested by Theorem 2.1 of [CF]. This result will allow us to take the limit in (2.1)-(2.3) as $\sigma \to 0$ in order to obtain a solution of the following problem:

(EP_0) Find (φ, h) satisfying (1.1)-(1.3) and

$$h_t = \left(\frac{\partial \varphi}{\partial \nu} - \varepsilon \right)^+ \quad \text{on } \Gamma \cap \{h = 0\}, \qquad t \geqq 0, \tag{2.4}$$

$$h_t = \left(\frac{\partial \varphi}{\partial \nu} - \varepsilon \right) \quad \text{on } \Gamma \cap \{h > 0\}, \qquad t \geqq 0, \tag{2.5}$$

$$h(x, 0) = 0 \quad \text{on } \Gamma. \tag{2.6}$$

THEOREM 2.1. *There exists a unique solution* $(\varphi_\sigma, h_\sigma)$ *of* (EP_σ) *satisfying* (1.9)-(1.14).

Proof. Let $(\varphi_\sigma, h_\sigma)$ be the solution of (P_σ) given by Theorem 1.1. In order to prove that $(\varphi_\sigma, h_\sigma)$ is a solution of (EP_σ), it suffices to show that h_σ verifies (2.2). By contradiction, we assume that there exists $x_0 \in \Gamma$ and $c > \sigma$ such that

$$h_\sigma(x_0, t) = c \tag{2.7}$$

for any t belonging to an open interval $I \subset (0, +\infty)$. Let $(t_0, \bar{t})$ be the maximal interval where (2.7) is satisfied. Note that, by (2.3), $t_0 > 0$.

Step 1. $(\varphi_\sigma)_t \geqq 0$. Since h_σ is monotone increasing, the claim follows from the following property (see [CF, Lemma 2.2]): if φ^1, φ^2 are the solutions of

$$\begin{aligned} &\Delta\varphi^i = 0 && \text{in } \Omega, \\ &\varphi^i = 1 && \text{on } S, \\ &h_i \frac{\partial \varphi_i}{\partial \nu} = \varphi_i && \text{on } \Gamma, \quad i = 1, 2, \end{aligned} \tag{2.8}$$

corresponding, respectively, to h_1, h_2, and if $h_1 \geqq h_2$ on Γ, then $\varphi_1 \geqq \varphi_2$ in Ω.

Step 2. $(\partial\varphi_\sigma/\partial\nu)_t(x_0, t_0) \leqq 0$, $(h_\sigma)_t(x_0, t_0) = 0$. Since $(t_0, \bar{t})$ is the maximal interval where (2.7) is satisfied, by (1.8) there exists $t_i \nearrow t_0$ such that $(\partial\varphi_\sigma/\partial\nu)(x_0, t_i) > \varepsilon$. On the other hand, $\partial\varphi_\sigma/\partial\nu(x_0, t_0) \leqq \varepsilon$. Then $(\partial\varphi_\sigma/\partial\nu)_t(x_0, t_0) \leqq 0$. $(h_\sigma)_t(x_0, t_0) = 0$ follows from (2.7).

Step 3. $(\varphi_\sigma)_t(x, t_0) = 0$ for $x \in \Omega$, $(h_\sigma)_t(x, t_0) = 0$ for $x \in \Gamma$. The expression $(\varphi_\sigma)_t$ is a solution of the following:

$$\Delta(\varphi_\sigma)_t = 0 \quad \text{in } \Omega, \tag{2.9}$$

$$(\varphi_\sigma)_t = 0 \quad \text{on } S, \tag{2.10}$$

$$(h_\sigma)_t \frac{\partial \varphi_\sigma}{\partial \nu} + h_\sigma \frac{\partial}{\partial \nu}(\varphi_\sigma)_t = (\varphi_\sigma)_t \quad \text{on } \Gamma. \tag{2.11}$$

From (2.7), Step 1, Step 2, and (2.11) we find

$$(\varphi_\sigma)_t(x_0, t_0) = \frac{\partial}{\partial \nu}(\varphi_\sigma)_t(x_0, t_0) = 0. \tag{2.12}$$

Then, by the strong maximum principle, $(\varphi_\sigma)_t(x, t_0) = 0$ for every $x \in \Omega$; therefore, $(\partial/\partial\nu)(\varphi_\sigma)_t(x, t_0) = 0$ for $x \in \Gamma$ and (2.11) becomes

$$(h_\sigma)_t \frac{\partial \varphi_\sigma}{\partial \nu} = 0 \quad \text{on } \Gamma.$$

It follows that $(h_\sigma)_t(x, t_0) = 0$ for $x \in \Gamma$ ($(\partial\varphi_\sigma/\partial\nu) > 0$, by the strong maximum principle applied to (1.1)-(1.3)).

Step 4. Definition of τ. For any $x \in \Gamma$ set

$$A(x) = \bigcup_{\alpha \in \mathcal{A}} I_\alpha(x), \tag{2.13}$$

where $I_\alpha(x)$ is an open interval of $(0, +\infty)$ such that

$$h(x, t) = C_\alpha > \sigma \quad \text{for every} \quad t \in I_\alpha, \tag{2.14}$$

where C_α is a constant and $\mathcal{A}$ indexes all the intervals satisfying (2.14). Set

$$t_0(x) = \begin{cases} \inf A(x) & \text{if } A(x) \neq \varnothing, \\ +\infty & \text{if } A(x) = \varnothing. \end{cases} \tag{2.15}$$

Now, let τ be defined by

$$\tau = \inf_{x \in \Gamma} t_0(x). \tag{2.16}$$

Note that $\tau < +\infty$ by our contradiction assumption.

Step 3 implies $(h_\sigma)_t(x, t_0(y)) = 0$ for every $x, y \in \Gamma$ with $t_0(y) < +\infty$, and consequently $(h_\sigma)_t(x, \tau) = 0$ for $x \in \Gamma$. Hence $\tau > 0$, if not, we would have a contradiction with (0.8).

Step 5. End of the proof. By the definition of τ, we have that for $t<\tau$ the solution of (P_σ) is a solution of (EP_σ). Therefore we can apply the final argument of the proof of Theorem 2.3 in [MS] to obtain a contradiction.

The uniqueness of the solution is obvious for the equivalence between (P_σ) and (EP_σ) and the uniqueness of the solution of (P_σ).

THEOREM 2.2. *There exists a weak solution (in the sense of Definition* 1.1*) of problem* (EP_0).

Proof. Let (φ, h) be the solution of (P_0) obtained in § 1 as the limit of $(\varphi_\sigma, h_\sigma)$. We want to show that in fact (φ, h) is a solution of (EP_0). The only thing to prove is (2.5).

We fix $T>0$. Due to the monotonicity of the set $\Gamma_+(t)$, it is possible to find a sequence $t_m \in (0, T)$ such that, if $A_n = \bigcup_{m\leqq n} \Gamma_+(t_m)\times(t_m, T)$, then

$$\text{meas}\,(Q_+ \setminus A_n)\to 0 \quad \text{as} \quad n\to+\infty. \tag{2.17}$$

Set

$$B_n = \bigcup_{\substack{m\leqq n\\ l\leqq n}} \left\{(x,t): h(x,t)>\frac{1}{m},\ t_l\leqq t\leqq T\right\}. \tag{2.18}$$

Note that A_n and B_n are two monotone set sequences and

$$\bigcup_{n\in\mathbb{N}} B_n = \bigcup_{n\in\mathbb{N}} A_n \tag{2.19}$$

so that

$$\text{meas}\left(Q_+ \setminus \left(\bigcup_{n\in\mathbb{N}} B_n\right)\right)=0. \tag{2.20}$$

Using (1.24) and (1.26) we have

$$h_\sigma(x,t)\geqq h(x,t)>\frac{1}{n}>\sigma \quad \text{for } (x,t)\in B_n,\ \ \sigma<\frac{1}{n}. \tag{2.21}$$

From Theorem 2.1 it follows that

$$(h_\sigma)_t=\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon=\left(\frac{\partial\varphi_\sigma}{\partial\nu}-\varepsilon\right)^+ \quad \text{on } B_n. \tag{2.22}$$

As $\partial\varphi_\sigma/\partial\nu\to\partial\varphi/\partial\nu$ weakly in $L^3(\Gamma)$ for every $t\in[0,T]$ and $((\partial\varphi_\sigma/\partial\nu)-\varepsilon)^+\to((\partial\varphi/\partial\nu)-\varepsilon)^+$ in $L^1(\Gamma\times[0,T])$ as $\sigma\to 0$ (cf. (1.20) and (1.27)), we can deduce from (2.22)

$$\frac{\partial\varphi}{\partial\nu}-\varepsilon=\left(\frac{\partial\varphi}{\partial\nu}-\varepsilon\right)^+ \quad \text{on } B_n. \tag{2.23}$$

Finally from (2.20) it follows that

$$\frac{\partial\varphi}{\partial\nu}-\varepsilon=\left(\frac{\partial\varphi}{\partial\nu}-\varepsilon\right)^+ \quad \text{on } Q_+. \tag{2.24}$$

Since T is arbitrary, (2.5) is proved.

Remark 2.1. Concerning the asymptotic behaviour of the solution (φ, h) of the electropainting problem (EP_0), we recall that φ and h increase in t and are bounded in $H^1(\Omega)$ and $L^\infty(\Gamma)$, respectively. We can thus define

$$w:=\lim_{t\to\infty}\varphi(\cdot,t) \quad \text{weakly in } H^1(\Omega), \tag{2.25}$$

$$\bar{h}:=\lim_{t\to\infty} h(\cdot,t) \quad \text{weakly * in } L^\infty(\Gamma). \tag{2.26}$$

We are able to prove that w is the unique solution to the following variational inequality:

$$
\begin{aligned}
&w \in K, \quad \int_{\Omega} \nabla w \nabla(\eta - w) + \varepsilon \int_{\Gamma} (\eta - w) \geqq 0 \quad \forall \eta \in K, \\
&K = \{\eta \in H^1(\Omega): \quad \eta = 1 \quad \text{on } S, \quad \eta \geqq 0 \quad \text{on } \Gamma\}.
\end{aligned} \tag{2.27}
$$

For the proof, it is sufficient to follow the arguments of [CF, § 5]. Then the electropainting process stabilizes as $t \to \infty$ and tends asymptotically to a unique steady state; in fact w is a $C^{1,\alpha}$-function (cf. [F]) and

$$
\bar{h}(x) = \begin{cases} w(x) \Big/ \dfrac{\partial w}{\partial \nu}(x) & \text{if} \quad w(x) > 0, \\ 0 & \text{if} \quad w(x) = 0. \end{cases} \tag{2.28}
$$

EXACT ESTIMATES FOR POTENTIALS*

MARTIN SCHECHTER†

Abstract. For $\lambda \geqq 0$ it is determined precisely which functions $V(x) \geqq 0$ on $\mathbf{R}^n$ satisfy an inequality of the form

$$(Vu, u) \leqq C_\lambda(V)(\|\nabla u\|^2 + \lambda^2 \|u\|^2), \qquad u \in C_0^\infty$$

for some constant $C_\lambda(V)$. The value of the smallest such constant is found. Inequalities of this type are important in the study of the Schrödinger equation. An application is given.

Key words. Bessel potentials, Schrödinger operators, spectral theory

AMS(MOS) subject classifications. primary 26D10, 45P05, 47G05; secondary 26O15, 35P15, 35J10

1. Introduction.

Let

$$(u, v) = \int_{\mathbf{R}^n} u(x)v(x)^* \, dx, \qquad \|u\| = (u, u)^{1/2}$$

denote the scalar product and norm in $L^2 = L^2(\mathbf{R}^n)$, and let $V(x) \geqq 0$ be a measurable function on $\mathbf{R}^n$. For $\lambda \geqq 0$ define

$$C_\lambda(V) = \sup_{u \in C_0^\infty} \frac{(Vu, u)}{\|\nabla u\|^2 + \lambda^2 \|u\|^2} \tag{1}$$

where C_0^∞ denotes the set of all infinitely differentiable functions on $\mathbf{R}^n$ with compact supports. Our first result is Theorem 1.

THEOREM 1.

$$C_\lambda(V) = \inf_{\rho > 0} \sup_y \frac{1}{\rho(y)} \int V(x)\rho(x)G_\lambda(x-y) \, dx \tag{2}$$

where

$$G_\lambda(x) = \frac{|x|^{2-n}}{4\pi^{n/2}} \int_0^\infty e^{-(\lambda^2|x|^2/4t)-t} t^{n/2-2} \, dt \tag{3}$$

(*if* $n \leqq 2$, *assume* $\lambda \neq 0$).

As a consequence we have Corollary 2.

COROLLARY 2. *If* $n > 2$, *then*

$$C_0(V) = \frac{\Gamma(n/2-1)}{4\pi^{n/2}} \inf_{\rho > 0} \sup_y \frac{1}{\rho(y)} \int V(x)\rho(x)|x-y|^{2-n} \, dx. \tag{4}$$

Thus there is a constant C *such that*

$$(Vu, u) \leqq C\|\nabla u\|^2, \qquad u \in C_0^\infty \tag{5}$$

if and only if for each $\varepsilon > 0$ *there is a* $\rho(x) > 0$ *such that*

$$\int V(x)\rho(x)|x-y|^{2-n} \, dx \leqq \frac{4\pi^{n/2}}{\Gamma(\frac{1}{2}n-1)} (C+\varepsilon)\rho(y). \tag{6}$$

2. Integral operators. Our proof of Theorem 1 will be based on Theorem 3.

THEOREM 3. *Let $K(x, y) \geqq 0$ be a measurable function on $\mathbf{R}^{2n}$, and define*

$$Tu(x) = \int K(x, y)u(y)\, dy. \tag{7}$$

Then T is a bounded operator on $L^2(\mathbf{R}^n)$ if and only if there are a function $\phi(x) \geqq 0$ on $\mathbf{R}^n$ and a constant C such that

(a) $K(x, y) = 0$ *a.e. when* $\psi(x) = 0$ *and* $\phi(y) = 0$

and

(b) $\int K(x, y)\psi(x)\, dx \leqq C\phi(y)$ *a.e.*

where

$$\psi(x) = \int K(x, y)\phi(y)\, dy. \tag{8}$$

Moreover, $\|T\|^2 \leqq C$. If

$$C_0 = \inf_{\phi} \sup_{y} \frac{1}{\phi(y)} \int K(x, y)K(x, z)\phi(z)\, dz\, dx \tag{9}$$

where the infimum is taken over all $\phi(x) \geqq 0$ satisfying (a) *and* (b) *and we take $0/0 = 0$, then*

$$\|T\|^2 = C_0. \tag{10}$$

Proof. Assume that there is a $\phi(z) \geqq 0$ *satisfying* (a) and (b). Let

$$M = \{x \in R^n \mid \psi(x) = 0\}, \qquad N = \{x \in R^n \mid \phi(x) = 0\},$$
$$M' = R^n - M, \qquad N' = R^n - N.$$

Thus we have

$$\begin{aligned} K(x, y) &= 0 \quad \text{a.e.} \quad x \in M, \quad y \in N \quad \text{by (a)}, \\ &= 0 \quad \text{a.e.} \quad x \in M', \quad y \in N \quad \text{by (b)}, \\ &= 0 \quad \text{a.e.} \quad x \in M, \quad y \in N' \quad \text{by (8)}. \end{aligned}$$

Hence

$$(Tu, v) = \int \int K(x, y)u(y)v(x)^*\, dx\, dy$$
$$= \int_{M'} \int_{N'} K(x, y)^{1/2}\psi(x)^{1/2}\phi(y)^{-1/2}u(y)K(x, y)^{1/2}\phi(y)^{1/2}\psi(x)^{-1/2}v(x)^*\, dx\, dy$$

and

$$|(Tu, v)|^2 \leqq \int_{M'} \int_{N'} K(x, y)\psi(x)\phi(y)^{-1}|u(y)|^2\, dx\, dy$$
$$\cdot \int_{M'} \int_{N'} K(x, y)\phi(y)\psi(x)^{-1}|v(x)|^2\, dx\, dy$$
$$\leqq C\|u\|^2\|v\|^2.$$

Thus T is a bounded operator on L^2 and $\|T\|^2 \leqq C$. Since C_0 is the infimum of all constants C satisfying (b), we see that $\|T\|^2 \leqq C_0$.

Conversely, assume that T is bounded on L^2, and let C be any constant satisfying

$$\|T^*T\| < C. \tag{11}$$

Let $h(x)$ be any positive function in L^2, and define

$$\phi_0 = 0, \qquad \phi_{k+1} = h + C^{-1}T^*T\phi_k.$$

Clearly $\phi_k(x) > 0$ for each k and $\phi_k \to \phi$ in L^2. Then

$$\phi = h + C^{-1}T^*T\phi,$$

and consequently $\phi(x) \geqq h(x) > 0$ almost everywhere. Clearly ϕ satisfies (a) and (b). Consequently, any constant C satisfying (11) satisfies (b). Since C_0 is the infimum of such constants, we have $C_0 \leqq \|T^*T\| \leqq \|T\|^2$. □

The proof of Theorem 3 implies

$$\|T\|^2 = \inf_{\phi>0} \sup_y \frac{1}{\phi(y)} \int \int K(x, y)K(x, z)\phi(z)\, dz\, dx. \tag{12}$$

3. The reduction. Now we show how the proof of Theorem 1 can be based on Theorem 3. We shall need the following facts concerning Bessel potentials (cf., e.g., [1], [3], [4]). Let u be any function in C_0^∞, and let

$$v = (\lambda^2 - \Delta)^{1/2}u \tag{13}$$

(v can be defined by Fourier transforms). Then

$$\|v\|^2 = ([\lambda^2 - \Delta]u, u) = \|\nabla u\|^2 + \lambda^2\|u\|^2. \tag{14}$$

Moreover, we have

$$u(x) = \int G_{1,\lambda}(x - y)v(y)\, dy \tag{15}$$

where

$$G_{1,\lambda}(x) = \frac{|x|^{1-n}}{2\pi^{n/2}\Gamma(\frac{1}{2})} \int_0^\infty e^{-(\lambda^2|x|^2/4t)-t} t^{(n-1)/2-1}\, dt. \tag{16}$$

We also have

$$G_{1,\lambda}^* G_{1,\lambda} = G_\lambda \tag{17}$$

where G_λ is given by (3). Using these facts we can give the proof of Theorem 1.

Proof of Theorem 1. Let $\varepsilon > 0$ be given, and let $C_\lambda^*(V)$ denote the right-hand side of (2). If $C_\lambda^*(V) < \infty$, there is a $\rho > 0$ such that

$$\int V(z)\rho(z)G_\lambda(y - z)\, dz \leqq (C_\lambda^*(V) + \varepsilon)\rho(y).$$

Put $\phi(z) = V(z)^{1/2}\rho(z)$, $K(x, y) = G_{1,\lambda}(x - z)V(y)^{1/2}$. Then

$$\psi(x) = \int G_{1,\lambda}(x - z)V(z)\rho(z)\, dz$$

and by (17)

$$\int K(x,y)\psi(x)\,dx = \int G_{1,\lambda}(x-y)\,V(y)^{1/2}\int G_{1,\lambda}(x-z)\,V(z)\rho(z)\,dz\,dx$$

$$= V(y)^{1/2}\int\left[\int G_{1,\lambda}(x-y)G_{1,\lambda}(x-z)\,dx\right]V(z)\rho(z)\,dz$$

$$= V(y)^{1/2}\int G_{\lambda}(y-z)\,V(z)\rho(z)\,dz$$

$$\leqq (C_{\lambda}^{*}(V)+\varepsilon)\,V(y)^{1/2}\rho(y) = (C_{\lambda}^{*}(V)+\varepsilon)\phi(y).$$

Thus condition (b) of Theorem 3 holds. Moreover, the only way that $\psi(x)$ can vanish for some x is if $V(z)\rho(z)\equiv 0$. Since $\rho(z)\neq 0$ almost everywhere, this implies $V(z)\equiv 0$ almost everywhere. This in turn implies $K(x,y)\equiv 0$ almost everywhere. Hence conditions (a) of Theorem 3 are also satisfied. Thus the operator T given by (7) is bounded on L^2 with $\|T\|^2\leqq C_{\lambda}^{*}(V)+\varepsilon$. Since ε was arbitrary we have $\|T\|^2\leqq C_{\lambda}^{*}(V)$. Thus, by (14) and (15)

$$(Vu,u) = \|T^{*}v\|^2 \leqq \|T^{*}\|^2\|v\|^2$$

$$= \|T\|^2(\|\nabla u\|^2+\lambda^2\|u\|^2)$$

$$\leqq C_{\lambda}^{*}(V)(\|\nabla u\|^2+\lambda^2\|u\|^2).$$

Consequently, $C_{\lambda}(V)\leqq C_{\lambda}^{*}(V)$.

Conversely, assume that

$$(Vu,u)\leqq C(\|\nabla u\|^2+\lambda^2\|u\|^2), \qquad u\in C_0^{\infty}. \tag{18}$$

Then by (14) and (15)

$$\|T^{*}v\|^2 = (Vu,u)\leqq C\|v\|^2.$$

Since the range of $(\lambda^2-\Delta)^{1/2}$ on C_0^{∞} is dense in L^2, we see that T^{*} is a bounded operator on L^2 with norm $\leqq C^{1/2}$. Hence $\|T\|^2\leqq C$. By (12) for each $\varepsilon>0$ there is a $\phi>0$ such that

$$\int\int K(x,y)K(x,z)\phi(z)\,dz\,dx\leqq(\|T\|^2+\varepsilon)\phi(y). \tag{19}$$

This is equivalent to

$$\int G_{\lambda}(y-z)\,V(y)^{1/2}V(z)^{1/2}\phi(z)\,dz\leqq(\|T\|^2+\varepsilon)\phi(y). \tag{20}$$

Define ρ by

$$\rho(y) = \frac{\phi(y)}{V(y)^{1/2}}, \qquad V(y)\neq 0$$

$$= (\|T\|^2+\varepsilon)^{-1}\int G_{\lambda}(y-z)\,V(z)^{1/2}\phi(z)\,dz, \qquad V(y)=0.$$

If $V(y)\neq 0$, we have by (20)

$$\int G_{\lambda}(y-z)\,V(z)\rho(z)\,dz\leqq(\|T\|^2+\varepsilon)\rho(y). \tag{21}$$

If $V(y)=0$, we have by the definition of ρ

$$\int G_\lambda(y-z)V(z)\rho(z)\,dz = \int G_\lambda(y-z)V(z)^{1/2}\phi(z)\,dz$$
$$= (\|T\|^2+\varepsilon)\rho(y).$$

Thus (21) holds for all y. Since $\rho(y)>0$ for all y, we see that

$$C_\lambda^*(V) \leqq \|T\|^2+\varepsilon \leqq C+\varepsilon$$

where C is any constant satisfying (18). Thus $C_\lambda^*(V)\leqq C_\lambda(V)$, and the proof is complete. □

4. An application. We can apply Theorem 1 to the study of the spectral theory of the Schrödinger operator. For instance, we have Theorem 4.

THEOREM 4. *Let $V(x)\geqq 0$ be a measurable function on $\mathbf{R}^n$. If $C_\lambda(V)\leqq 1$, then $-\Delta-V$ has a self-adjoint realization H on $L^2(\mathbf{R}^n)$ having no spectrum below $-\lambda^2$. If $C_\lambda(V)>1$, then every self-adjoint realization has spectrum below $-\lambda^2$.*

Proof. If $C_\lambda(V)\leqq 1$, then $(Vu,u)\leqq([\lambda^2-\Delta]u,u)$, $u\in C_0^\infty$. It is well known that this implies that a self-adjoint realization H of $-\Delta-V$ exists such that $-\lambda^2\|u\|^2\leqq(Hu,u)$ (cf., e.g., [3]). This implies that the spectrum of H is contained in the interval $[-\lambda^2,\infty)$. If $C_\lambda(V)>1$, then there is a $u\in C_0^\infty$ such that $(Vu,u)>([\lambda^2-\Delta]u,u)$. Thus $(Hu,u)<-\lambda^2\|u\|^2$ for any self-adjoint realization of $-\Delta-V$. This means that H has spectrum below $-\lambda^2$. □

NONLOCAL VARIATIONAL PROBLEMS IN NONLINEAR ELECTROMAGNETO-ELASTOSTATICS*

ROBERT C. ROGERS†

Abstract. The effects of arbitrary applied electric and magnetic fields on unshielded, nonlinear, deformable, polarizable, magnetizable, nonconducting bodies are studied. Both monotone materials (dielectric, paramagnetic, etc.) and classical ferromagnetic materials are considered. The lack of shielding forces us to consider unknown fields outside of the material. This leads to nonlocal ("shape-dependent") effects. The work of Ball is extended ["Convexity conditions and existence theorems in nonlinear elasticity," *Arch. Rat. Mech. Anal.*, 63 (1977), pp. 337-403] to get an existence theory using direct methods of the calculus of variations.

Key words. electromagneto-elasticity, ferromagnetism, polyconvex materials

AMS (MOS) subject classifications. 73R05, 49A29, 73C60

1. Introduction.

Rogers and Antman [15] initiated a program to extend the modern existence theories for elastic materials (cf. [3], [8]) to materials that admit coupled elastic and electromagnetic effects. Such problems are of great practical interest (high current devices such as fusion reaction containment vessels and magnetic levitation trains and acoustic devices using piezoelectric materials are highly dependent on the coupling of mechanical and electromagnetic fields), and the nonlocal nature of the resultant equations is of intrinsic mathematical interest. The problems considered in [15] involved self-effects of conducting bodies; but for simplicity, electromagnetic boundary conditions that shielded the body from applied fields were employed. In this work, we consider an unshielded body and study the effects of applied electric and magnetic fields. We assume the body is nonconducting; but we allow it to be deformable, polarizable, and magnetizable. We study both monotone materials (dielectric, paramagnetic, etc.) and classical ferromagnetic materials.

Our problem is rather easy to formulate in spatial (Eulerian) coordinates (we do so in §2.3), but such a formulation is, in general, intractable. (For example, the boundary conditions are posed at points that depend on the deformation, a principal unknown.) A more useful formulation uses spatial coordinates for the resultant electric and magnetic fields E_r and H_r (which must be known both in the interior and exterior of the body) and material (Lagrangian) coordinates for the deformation $\hat{\mathbf{y}}$, deformation gradient $\mathbf{F}$, polarization $\mathbf{p}$, and magnetization $\mathbf{m}$. The variational form of this problem involves finding stationary points of an energy of the form

$$\begin{aligned}\tilde{\mathcal{E}}(\hat{\mathbf{y}}, E_r, \mathbf{p}, H_r, \mathbf{m}) &= \int_\Omega \mathcal{W}(\mathbf{F}(\mathbf{x}), \mathbf{p}(\mathbf{x}), \mathbf{m}(\mathbf{x}))dv_x \\ &\quad - \int_\Omega \{[E_r(\hat{\mathbf{y}}(\mathbf{x})) + E_0(\hat{\mathbf{y}}(\mathbf{x}))] \cdot \mathbf{F}(\mathbf{x}) \cdot \mathbf{p}(\mathbf{x}) \\ &\quad\quad + [H_r(\hat{\mathbf{y}}(\mathbf{x})) + H_0(\hat{\mathbf{y}}(\mathbf{x}))] \cdot \mathbf{F}(\mathbf{x}) \cdot \mathbf{m}(\mathbf{x})\}dv_x \\ &\quad - \frac{1}{2}\int_{\mathbf{R}^3} |E_r(\mathbf{y})|^2 + |H_r(\mathbf{y})|^2 dv_y.\end{aligned}$$

* Received by the editors September 4, 1987; accepted for publication (in revised form) January 6, 1988.

† Department of Mathematics, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061. The work of this author was completed at the Center for Mathematical Sciences and Department of Mathematics, University of Wisconsin-Madison, and was supported in part by the National Science Foundation under grants DMS–8521687 and DMS–8620303.

Here, $\mathcal{W}$ is the stored energy and E_0 and H_0 are the applied fields.

Unfortunately, this energy is neither coercive nor weakly lower-semicontinuous. We overcome this difficulty by replacing the spatial fields E_r and H_r with solution operators that depend on the *global* values of material fields:

$$\begin{aligned} E_r(\mathbf{y}) &= \hat{E}_r(\mathbf{p}(\cdot), \hat{\mathbf{y}}(\cdot); \mathbf{y}), \\ H_r(\mathbf{y}) &= \hat{H}_r(\mathbf{m}(\cdot), \hat{\mathbf{y}}(\cdot); \mathbf{y}). \end{aligned}$$

If $\mathbf{p}$, $\mathbf{m}$, and $\hat{\mathbf{y}}$ are sufficiently smooth these are simply the usual Coulomb integral operators. We show below that after the substitution of these nonlocal operators and some manipulation we get an energy of the form

$$\begin{aligned} \mathcal{E}(\hat{\mathbf{y}}, \mathbf{p}, \mathbf{m}) &= \int_\Omega \mathcal{W}(\mathbf{F}(\mathbf{x}), \mathbf{p}(\mathbf{x}), \mathbf{m}(\mathbf{x}))dv_x \\ &\quad - \int_\Omega [E_0(\hat{\mathbf{y}}(\mathbf{x})) \cdot \mathbf{F}(\mathbf{x}) \cdot \mathbf{p}(\mathbf{x}) + H_0(\hat{\mathbf{y}}(\mathbf{x})) \cdot \mathbf{F}(\mathbf{x}) \cdot \mathbf{m}(\mathbf{x})]dv_x \\ &\quad + \frac{1}{2}\int_{\mathbf{R}^3} \{|\hat{E}_r(\mathbf{p}, \hat{\mathbf{y}}; \mathbf{y})|^2 + |\hat{H}_r(\mathbf{m}, \hat{\mathbf{y}}; \mathbf{y})|^2\}dv_y. \end{aligned}$$

Note that now the only unknowns are material fields; the spatial fields involved are either data or well-defined operators on material fields. Moreover, the new energy is coercive and (though this is not obvious) weakly lower-semicontinuous under appropriate hypotheses on $\mathcal{W}$. However, we have paid a price for these gains: While the first two integrals in the new energy involve *local* densities (e.g., at a particle $\mathbf{x}$, the stored energy density $\mathcal{W}$ depends only on the values of the fields at that particle), the final integral involves *nonlocal* energy densities (e.g., at every point $\mathbf{y}$, the electric field operator $\hat{E}_r$ depends on the *global* values of the fields $\mathbf{p}$ and $\hat{\mathbf{y}}$). The most novel difficulties in our existence theory involve these nonlocal terms. In particular, we must examine the weak convergence properties of the solution operators $\hat{E}$ and $\hat{H}$ under composite limits of sequences of deformations, polarizations, and magnetizations.

Variational problems with nonlocal energy densities have been considered before. Notably, Auchmuty and Beals [2] gave existence and regularity theorems for some model problems from astrophysics in which self-gravitation plays an important role.

The remainder of this paper is organized as follows: In §2 we present several mathematical formulations of our physical problem, culminating in the nonlocal variational problem that we eventually solve. In §3 we give some results on how the electric and magnetic fields react under simultaneous limits of deformations, polarizations, and magnetizations. In §4 we prove existence results. Finally, in §5 we offer some concluding observations.

2. Formulation of the problem. In this section we formulate the problem of a deformable, polarizable, magnetizable, nonconducting body subjected to arbitrary applied static electromagnetic fields.

2.1. Kinematics. We consider a body whose reference configuration is given by a bounded set Ω in $\mathbf{R}^3$ with typical material particle $\mathbf{x}$ and Lipschitz continuous boundary. We refer to fields with independent variable $\mathbf{x}$ as *material* or *Lagrangian*. The familiar differential operators Grad, Div, and Curl operate on such fields. The deformation of the body Ω is given by the map

$$\Omega \ni \mathbf{x} \mapsto \hat{\mathbf{y}}(\mathbf{x}) \in \mathbf{R}^3. \tag{2.1}$$

The operators grad, div, and curl operate on fields in *spatial* or *Eulerian* coordinates (fields with typical independent variable $\mathbf{y}$). The *deformation gradient* $\mathbf{F}$ and the *right Cauchy-Green deformation tensor* $\mathbf{C}$ are given by

$$\mathbf{F}(\mathbf{x}) = \operatorname{Grad} \hat{\mathbf{y}}(\mathbf{x})^*, \qquad \mathbf{C}(\mathbf{x}) = \mathbf{F}^*(\mathbf{x}) \cdot \mathbf{F}(\mathbf{x}). \tag{2.2}$$

Here the star $*$ indicates *transpose*, and $\mathbf{A} \cdot \mathbf{B}$ indicates the *product* of two tensors. To ensure that the orientation of the material is preserved under deformation we require

$$\det \mathbf{F} > 0. \tag{2.3}$$

To ensure that there is no interpenetration of the material we require (cf. Ciarlet and Nečas [8]):

$$\int_\Omega \det \mathbf{F}(\mathbf{x}) dv_x \leq |\hat{\mathbf{y}}(\Omega)|, \tag{2.4}$$

where $|S|$ is the three-dimensional Lebesgue measure of the set S.

2.2. Applied fields. We assume that the total electric and magnetic fields E and H can be decomposed as

$$E = E_0 + E_r \quad \text{and} \quad H = H_0 + H_r,$$

where E_0 and H_0 are the respective *applied electric and magnetic fields* (fields that are generated by sources not connected to the body) and E_r and H_r are the respective *resultant electric and magnetic fields* (fields generated by the polarization and magnetization of the body).

We think of the applied fields as data and assume only that they satisfy

$$E_0, H_0 \in \{\mathbf{v} \in L^2(\mathbf{R}^3) | \mathbf{v} = \operatorname{grad} \phi, \phi \in H^1_{\text{loc}}(\mathbf{R}^3)\}. \tag{2.5}$$

Here $H^s = W^{s,2}$ where $W^{s,p}$ is the usual Sobolev space of functions with generalized derivatives of order up to s in L^p (cf. Adams [1]), and $H^1_{\text{loc}}(\mathbf{R}^3)$ is the space of functions ϕ such that $\phi\psi \in H^1(\mathbf{R}^3)$ for any $\psi \in C_0^\infty(\mathbf{R}^3)$. Our assumption implies that the applied fields are fixed and are not changed by the resultant fields. We think of the sources of these fields as being outside the deformed body, though this is not implied by (2.5).

2.3. Spatial formulation. In this formulation our principal unknowns are the deformation $\hat{\mathbf{y}}$ and the resultant electric and magnetic fields E_r and H_r defined above, the *Cauchy stress* $\mathbf{T}$, the *spatial polarization* P, and the *spatial magnetization* M. We require that the support of $\mathbf{T}$, P, and M be contained in the image of the deformed body $\hat{\mathbf{y}}(\Omega)$.

We assume that the Cauchy stress $\mathbf{T}$ can be decomposed[1] in the following way:

$$\mathbf{T} = \mathbf{T}_M + \mathbf{T}_{ms}, \tag{2.6}$$

[1] This decomposition is not unique. Hutter and van de Ven [12] discuss various possible formulations of electromagnetism in deformable media and subsequent variations in the form of the Maxwell stress tensor. In the static case, all of the formulations they consider are shown to be equivalent under appropriate choices of constitutive equations. Our constitutive assumptions are compatible with any of these choices.

where $\mathbf{T}_M$ is the *mechanical stress* and $\mathbf{T}_{ms}$ is the *Maxwell stress*, which is given by

$$\mathbf{T}_{ms} = EE + EP + HH + HM - \frac{1}{2}[E \cdot (E+P) + H \cdot (H+M)]\mathbf{I}. \tag{2.7}$$

Here EE, EP, etc. are dyadic (tensor) products and $\mathbf{I}$ is the identity tensor.

We also assume that the *electromagnetic body couple* $\mathbf{L}$ is given by

$$\mathbf{L} = EP - PE + HM - MH. \tag{2.8}$$

(See Rogers and Antman [15] for a discussion of the absorption of electromagnetic body forces into a generalized stress tensor and the subsequent form of the body couple.)

We now state a local, spatial formulation of our physical problem. For the present, we assume that all of our functions are smooth enough for the equations in which they appear to hold in a classical sense.

Problem 2.1. Given functions $\mathbf{y}_0$, $\mathbf{s}_0$, E_0, and H_0, we seek $\hat{\mathbf{y}}$, $\mathbf{T}$, E_r, H_r, P, and M such that:

1. The deformation $\hat{\mathbf{y}}$ satisfies (2.3) and (2.4). At points $\mathbf{y} \in \hat{\mathbf{y}}(\Omega)$ inside the deformed body the *balance of linear momentum*

$$\operatorname{div} \mathbf{T} = \mathbf{0}, \tag{2.9}$$

the *balance of torque*

$$\mathbf{L} = \mathbf{T} - \mathbf{T}^*, \tag{2.10}$$

and the *static version of Maxwell's equations*

$$\operatorname{curl} E_r(\mathbf{y}) = \mathbf{0}, \tag{2.11}$$

$$\operatorname{div} E_r(\mathbf{y}) = -\operatorname{div} P(\mathbf{y}), \tag{2.12}$$

$$\operatorname{curl} H_r(\mathbf{y}) = \mathbf{0}, \tag{2.13}$$

$$\operatorname{div} H_r(\mathbf{y}) = -\operatorname{div} M(\mathbf{y}), \tag{2.14}$$

are satisfied.

2. We assume that the boundary of the reference configuration $\partial\Omega$ can be represented as the disjoint union of two sets with Lipschitz boundary, S_1 and S_2. On S_1 we prescribe Dirichlet boundary conditions

$$\hat{\mathbf{y}}(\mathbf{x}) = \mathbf{y}_0(\mathbf{x}), \quad \mathbf{x} \in S_1, \tag{2.15}$$

and on the deformed image of S_2 we prescribe dead-load boundary conditions

$$\mathbf{T}(\hat{\mathbf{y}}(\mathbf{x})) \cdot \hat{\mathbf{n}}(\hat{\mathbf{y}}(\mathbf{x})) = \det \mathbf{F}(\mathbf{x})\mathbf{s}_0(\mathbf{x}), \quad \mathbf{x} \in S_2. \tag{2.16}$$

Here $\hat{\mathbf{n}}$ is the unit outward normal to $\partial\hat{\mathbf{y}}(\Omega)$. On the entire surface $\partial\hat{\mathbf{y}}(\Omega)$ we require

$$[|E_r(\mathbf{y})|] \times \hat{\mathbf{n}}(\mathbf{y}) = 0, \tag{2.17}$$

$$[|E_r(\mathbf{y})|] \cdot \hat{\mathbf{n}}(\mathbf{y}) = -[|P(\mathbf{y})|] \cdot \hat{\mathbf{n}}(\mathbf{y}), \tag{2.18}$$

$$[|H_r(\mathbf{y})|] \times \hat{\mathbf{n}}(\mathbf{y}) = 0, \tag{2.19}$$

$$[|H_r(\mathbf{y})|] \cdot \hat{\mathbf{n}}(\mathbf{y}) = -[|M(\mathbf{y})|] \cdot \hat{\mathbf{n}}(\mathbf{y}). \tag{2.20}$$

Here $[|f|]$ indicates the jump in the field f in the direction of $\hat{\mathbf{n}}$.

3. At points $\mathbf{y} \in \mathbf{R}^3 \setminus \hat{\mathbf{y}}(\bar{\Omega})$ in the exterior of the body we require

$$\text{div } E = 0, \tag{2.21}$$

$$\text{curl } E = 0, \tag{2.22}$$

$$\text{div } H = 0, \tag{2.23}$$

$$\text{curl } H = 0. \tag{2.24}$$

4. We also require that the resultant electric and magnetic fields be *regular at infinity*

$$|\mathbf{y}|^2|E_r(\mathbf{y})| + |\mathbf{y}|^2|H_r(\mathbf{y})| = O(1) \text{ as } |\mathbf{y}| \to \infty. \tag{2.25}$$

While this statement of the problem is clear, it presents several impediments to a solution: One set of difficulties is common to all elasticity problems posed entirely in spatial coordinates (e.g., constitutive theory for nonhomogeneous media is difficult to formulate and the support of the unknowns is itself an unknown). In the next section we present a formulation that overcomes these problems by introducing material coordinates. A second set of troubles arises from the addition of electromagnetic effects and the lack of shielding. This forces us to solve for the electric and magnetic fields in the exterior of the body with jump conditions at the unknown points of the deformed boundary. The solution of this problem must wait until §2.7 where we introduce solution operators that give the electric and magnetic fields in terms of material fields.

2.4. Mixed formulation. The *referential* or *(First) Piola-Kirchhoff stress* $\mathbf{S}$ at a material particle $\mathbf{x} \in \Omega$ is defined by

$$\mathbf{S}(\mathbf{x})^* = \det \mathbf{F}(\mathbf{x})\mathbf{F}^{-1}(\mathbf{x}) \cdot \mathbf{T}(\hat{\mathbf{y}}(\mathbf{x}))^*. \tag{2.26}$$

The Piola-Kirchhoff versions of the mechanical and Maxwell portions of the stress ($\mathbf{S}_M$ and $\mathbf{S}_{ms}$) have an analogous relation to their spatial counterparts. We also introduce the *material versions of the polarization and magnetization*:

$$\mathbf{p}(\mathbf{x}) = \det \mathbf{F}(\mathbf{x})\ \mathbf{F}^{-1}(\mathbf{x}) \cdot P(\hat{\mathbf{y}}(\mathbf{x})), \tag{2.27}$$

$$\mathbf{m}(\mathbf{x}) = \det \mathbf{F}(\mathbf{x})\ \mathbf{F}^{-1}(\mathbf{x}) \cdot M(\hat{\mathbf{y}}(\mathbf{x})), \tag{2.28}$$

and the *material version of the electromagnetic body couple*:

$$\tilde{\mathbf{L}}(\mathbf{x}) = (\det \mathbf{F}(\mathbf{x}))\mathbf{L}(\hat{\mathbf{y}}(\mathbf{x})). \tag{2.29}$$

Since we need to consider the electric and magnetic fields at points in the exterior of the body, we are primarily interested in their spatial versions, but at points in the interior of the body we can introduce *material versions of the electric and magnetic fields*:

$$\mathbf{e}(\mathbf{x}) = E(\hat{\mathbf{y}}(\mathbf{x})) \cdot \mathbf{F}(\mathbf{x}), \tag{2.30}$$

$$\mathbf{h}(\mathbf{x}) = H(\hat{\mathbf{y}}(\mathbf{x})) \cdot \mathbf{F}(\mathbf{x}). \tag{2.31}$$

Material versions of the applied and resultant fields ($\mathbf{e}_0$ and $\mathbf{e}_r$) are defined in an analogous way.

Three pieces of our data remain unchanged: The applied electric and magnetic fields E_0 and H_0 are still best given in spatial coordinates, and the Dirichlet data $\mathbf{y}_0$ was always given as a material field. However, we will replace the live-load traction boundary condition and the spatial data $\mathbf{t}_0$ with a dead-load condition and material data $\mathbf{s}_0$. As we indicated above, we consider the dead-load condition our primary problem and merely introduced the live-load condition to present a similar problem with an easy exposition. With this change, we state Problem 2.1 in terms of the material coordinates introduced above.

Problem 2.2. Given functions $\mathbf{y}_0$, $\mathbf{s}_0$, E_0, and H_0, we seek $\hat{\mathbf{y}}$, $\mathbf{S}$, E_r, H_r, $\mathbf{p}$, and $\mathbf{m}$ such that:

1. The deformation $\hat{\mathbf{y}}$ satisfies (2.3) and (2.4). At material particles $\mathbf{x} \in \Omega$ we have

$$\text{Div } \mathbf{S} = \mathbf{0}, \tag{2.32}$$

$$\tilde{\mathbf{L}} = \mathbf{S} \cdot \mathbf{F}^* - \mathbf{F} \cdot \mathbf{S}^*, \quad \text{and} \tag{2.33}$$

$$\text{Curl } \mathbf{e}_r(\mathbf{x}) = \mathbf{0}, \tag{2.34}$$

$$\text{Div } (\det \mathbf{F}(\mathbf{x})\mathbf{C}^{-1}(\mathbf{x}) \cdot \mathbf{e}_r(\mathbf{x})) = -\text{Div } \mathbf{p}(\mathbf{x}), \tag{2.35}$$

$$\text{Curl } \mathbf{h}_r(\mathbf{x}) = \mathbf{0}, \tag{2.36}$$

$$\text{Div } (\det \mathbf{F}(\mathbf{x})\mathbf{C}^{-1}(\mathbf{x}) \cdot \mathbf{h}_r(\mathbf{x})) = -\text{Div } \mathbf{m}(\mathbf{x}). \tag{2.37}$$

2. The Dirichlet conditions

$$\hat{\mathbf{y}}(\mathbf{x}) = \mathbf{y}_0(\mathbf{x}) \quad \forall \mathbf{x} \in S_1 \tag{2.38}$$

are satisfied, the dead-load conditions

$$\mathbf{S}(\mathbf{x}) \cdot \mathbf{n}(\mathbf{x}) = \mathbf{s}_0(\mathbf{x}) \quad \forall \mathbf{x} \in S_2 \tag{2.39}$$

are satisfied, and for every $\mathbf{x} \in \partial\Omega$ the jump conditions

$$[|E_r(\hat{\mathbf{y}}(\mathbf{x}))|] \cdot \mathbf{F}(\mathbf{x}) \times \cdot \mathbf{n}(\mathbf{x}) = 0, \tag{2.40}$$

$$\det \mathbf{F}(\mathbf{x})\mathbf{C}(\mathbf{x})^{-1} \cdot [|E_r(\hat{\mathbf{y}}(\mathbf{x}))|] \cdot \mathbf{n}(\mathbf{x}) = \mathbf{p}(\mathbf{x}) \cdot \mathbf{n}(\mathbf{x}), \tag{2.41}$$

$$[|H_r(\hat{\mathbf{y}}(\mathbf{x}))|] \cdot \mathbf{F}(\mathbf{x}) \times \mathbf{n}(\mathbf{x}) = 0, \tag{2.42}$$

$$\det \mathbf{F}(\mathbf{x})\mathbf{C}(\mathbf{x})^{-1} \cdot [|H_r(\hat{\mathbf{y}}(\mathbf{x}))|] \cdot \mathbf{n}(\mathbf{x}) = \mathbf{m}(\mathbf{x}) \cdot \mathbf{n}(\mathbf{x}), \tag{2.43}$$

are satisfied. Here $\mathbf{n}$ is the unit outward normal to $\partial\Omega$.

3. In the exterior of the body E_r and H_r satisfy (2.21)–(2.25) just as they did in Problem 2.1.

Of course, Problems 2.1 and 2.2 are both underdetermined. We introduce constitutive equations to remedy this.

2.5. Constitutive equations. Our constitutive equations for electromagnetoelastic materials are fully coupled and nonlinear. (Thus, we allow for such effects as electrostriction and magnetostriction.) In the variational problems we consider, it is

convenient to adopt $\mathbf{F}$, $\mathbf{p}$, and $\mathbf{m}$ as independent constitutive variables and $\mathbf{S}$, $\mathbf{e}$, and $\mathbf{h}$ as dependent constitutive variables.[2]

We first direct our attention to materials that exhibit monotone electromagnetic effects. These include many common materials such as dielectrics, certain pyroelectrics, paramagnetics, and even (at least for approximate constitutive equations) soft ferromagnetics. Our constitutive equations have the general form:

$$\begin{aligned} \mathbf{S}_M(\mathbf{x}) &= \tilde{\mathbf{S}}_M(\mathbf{F}(\mathbf{x}), \mathbf{p}(\mathbf{x}), \mathbf{m}(\mathbf{x}), \mathbf{x}), \\ \mathbf{e}(\mathbf{x}) &= \tilde{\mathbf{e}}(\mathbf{F}(\mathbf{x}), \mathbf{p}(\mathbf{x}), \mathbf{m}(\mathbf{x}), \mathbf{x}), \\ \mathbf{h}(\mathbf{x}) &= \tilde{\mathbf{h}}(\mathbf{F}(\mathbf{x}), \mathbf{p}(\mathbf{x}), \mathbf{m}(\mathbf{x}), \mathbf{x}), \end{aligned} \tag{2.47}$$

but we consider only materials for which there is a *stored energy function* $\mathcal{W}(\mathbf{F}, \mathbf{p}, \mathbf{m}, \mathbf{x})$, continuously differentiable in $\mathbf{F}$, $\mathbf{p}$, and $\mathbf{m}$ and measurable in $\mathbf{x}$ for all values of the remaining arguments, such that

$$\begin{aligned} \tilde{\mathbf{S}}_M(\mathbf{F}, \mathbf{p}, \mathbf{m}, \mathbf{x}) &= \frac{\partial \mathcal{W}}{\partial \mathbf{F}}(\mathbf{F}, \mathbf{p}, \mathbf{m}, \mathbf{x}), \\ \tilde{\mathbf{e}}(\mathbf{F}, \mathbf{p}, \mathbf{m}, \mathbf{x}) &= \frac{\partial \mathcal{W}}{\partial \mathbf{p}}(\mathbf{F}, \mathbf{p}, \mathbf{m}, \mathbf{x}), \\ \tilde{\mathbf{h}}(\mathbf{F}, \mathbf{p}, \mathbf{m}, \mathbf{x}) &= \frac{\partial \mathcal{W}}{\partial \mathbf{m}}(\mathbf{F}, \mathbf{p}, \mathbf{m}, \mathbf{x}). \end{aligned} \tag{2.48}$$

In the existence theorems of §4 we state our convexity and growth hypotheses on $\mathcal{W}$.

We also consider ferromagnetics: a type of nonmonotone material. For this material we drop consideration of electric effects; we assume the body does not polarize and that the solutions of the electric field equations are independent of solutions of the balance laws of elasticity and magnetism. Following the classical model of ferromagnetism (cf. Landau and Lifshitz [14] and Brown [5]), we consider a stored energy function

$$\mathcal{V}(\mathbf{F}, \mathbf{m}, \mathbf{x}) \tag{2.49}$$

[2] In other problems it is convenient to take $\mathbf{F}$, $\mathbf{e}$, and $\mathbf{h}$ as independent variables and $\mathbf{S}$, $\mathbf{p}$, and $\mathbf{m}$ as dependent variables:

$$\begin{aligned} \mathbf{S}(\mathbf{x}) &= \check{\mathbf{S}}(\mathbf{F}(\mathbf{x}), \mathbf{e}(\mathbf{x}), \mathbf{h}(\mathbf{x}), \mathbf{x}), \\ \mathbf{p}(\mathbf{x}) &= \check{\mathbf{p}}(\mathbf{F}(\mathbf{x}), \mathbf{e}(\mathbf{x}), \mathbf{h}(\mathbf{x}), \mathbf{x}), \\ \mathbf{m}(\mathbf{x}) &= \check{\mathbf{m}}(\mathbf{F}(\mathbf{x}), \mathbf{e}(\mathbf{x}), \mathbf{h}(\mathbf{x}), \mathbf{x}). \end{aligned} \tag{2.44}$$

Such a choice can be shown to be equivalent to the one chosen in this work under appropriate monotonicity and growth hypotheses. For instance, we could adopt a monotonicity assumption such as the *restricted strong ellipticity condition*:

$$\begin{aligned} 0 \;<\; & \mathbf{ab} : \frac{\partial \check{\mathbf{S}}}{\partial \mathbf{F}} : \mathbf{ab} + \mathbf{ab} : \frac{\partial \check{\mathbf{S}}}{\partial \mathbf{e}} \cdot \mathbf{u} + \mathbf{ab} : \frac{\partial \check{\mathbf{S}}}{\partial \mathbf{h}} \cdot \mathbf{v} \\ & + \mathbf{u} \cdot \frac{\partial \check{\mathbf{p}}}{\partial \mathbf{F}} : \mathbf{ab} + \mathbf{u} \cdot \frac{\partial \check{\mathbf{p}}}{\partial \mathbf{e}} \cdot \mathbf{u} + \mathbf{u} \cdot \frac{\partial \check{\mathbf{p}}}{\partial \mathbf{h}} \cdot \mathbf{v} \\ & + \mathbf{v} \cdot \frac{\partial \check{\mathbf{m}}}{\partial \mathbf{F}} : \mathbf{ab} + \mathbf{v} \cdot \frac{\partial \check{\mathbf{m}}}{\partial \mathbf{e}} \cdot \mathbf{u} + \mathbf{v} \cdot \frac{\partial \check{\mathbf{m}}}{\partial \mathbf{h}} \cdot \mathbf{v} \end{aligned} \tag{2.45}$$

for all $(\mathbf{ab}, \mathbf{u}, \mathbf{v}) \neq (\mathbf{0}, \mathbf{0}, \mathbf{0})$ ($\mathbf{ab}$ is a dyad, a typical tensor of rank one) and a growth condition such as

$$[\check{\mathbf{p}}(\mathbf{F}, \mathbf{e}, \mathbf{h}, \mathbf{x}) \cdot \mathbf{e} + \check{\mathbf{m}}(\mathbf{F}, \mathbf{e}, \mathbf{h}, \mathbf{x}) \cdot \mathbf{h}]/[|\mathbf{e}| + |\mathbf{h}|] \to \infty \text{ as } [|\mathbf{e}| + |\mathbf{h}|] \to \infty. \tag{2.46}$$

Equations (2.45) and (2.46) imply that for every fixed $\mathbf{F}$ and $\mathbf{x}$, the map $(\mathbf{e}, \mathbf{h}) \mapsto (\check{\mathbf{p}}, \check{\mathbf{m}})$ can be globally inverted, so that constitutive equations (2.44) are equivalent to (2.47).

for which $\mathcal{V}(\mathbf{F}, \cdot, \mathbf{x})$ is *nonconvex.* We also include in the total energy (cf. (2.74) below) an *exchange energy* term of the form

$$\mathcal{X}(\mathbf{F}, \text{Grad } \mathbf{m}) \tag{2.50}$$

for which we make appropriate convexity assumptions below. The most commonly used term is of the form $|\text{Grad } \mathbf{m}|^2$. Once again, we reserve more detailed continuity and growth hypotheses until the statement of our existence theorems in §4.

2.6. Mixed variational formulation with local densities. In this section we present a variational formulation for monotone materials. We postpone consideration of ferromagnetic materials until the final, nonlocal formulation.

The usual variational form of Problem 2.2 is obtained by defining an energy depending on *all* of the unknown electromagnetic fields:

$$\begin{aligned}\tilde{\mathcal{E}}(\hat{\mathbf{y}}, E_r, \mathbf{p}, H_r, \mathbf{m}) &= \int_\Omega \mathcal{W}(\mathbf{F}(\mathbf{x}), \mathbf{p}(\mathbf{x}), \mathbf{m}(\mathbf{x}), \mathbf{x}) dv_x \\ &\quad - \int_\Omega \{[E_r(\hat{\mathbf{y}}(\mathbf{x})) + E_0(\hat{\mathbf{y}}(\mathbf{x}))] \cdot \mathbf{F}(\mathbf{x}) \cdot \mathbf{p}(\mathbf{x}) \\ &\quad + [H_r(\hat{\mathbf{y}}(\mathbf{x})) + H_0(\hat{\mathbf{y}}(\mathbf{x}))] \cdot \mathbf{F}(\mathbf{x}) \cdot \mathbf{m}(\mathbf{x})\} dv_x \\ &\quad - \frac{1}{2} \int_{\mathbf{R}^3} |E_r(\mathbf{y})|^2 + |H_r(\mathbf{y})|^2 dv_y.\end{aligned} \tag{2.51}$$

Problem 2.3. Given functions $\mathbf{y}_0$, $\mathbf{s}_0$, E_0, and H_0, we seek $\hat{\mathbf{y}}$, E_r, H_r, $\mathbf{p}$, and $\mathbf{m}$ such that:

1. The deformation $\hat{\mathbf{y}}$ satisfies (2.3), (2.4), and (2.38).
2. The fields E_r and H_r satisfy (2.11) and (2.13), respectively.
3. The variational equation

$$\delta \tilde{\mathcal{E}}(\hat{\mathbf{y}}, E_r, \mathbf{p}, H_r, \mathbf{m}) = \int_{S_2} \mathbf{s}_0(\mathbf{x}) \cdot \delta \hat{\mathbf{y}}(\mathbf{x}) da_x, \tag{2.52}$$

is satisfied.

It follows from the work of Toupin [17] and Tiersten [16] that sufficiently regular solutions of Problem 2.3 are solutions of Problem 2.2 as well.

Two difficulties to finding solutions of Problem 2.3 are immediately apparent. First, solutions of (2.52) are not extrema of (2.51); we must simultaneously minimize $\tilde{\mathcal{E}}$ with respect to $\hat{\mathbf{y}}$, $\mathbf{p}$, and $\mathbf{m}$ and maximize with respect to E_r and H_r. Second, the comments at the end of §2.3 still hold: the use of spatial coordinates for the fields E_r and H_r give us trouble; we must optimize these fields without knowing in advance the points at which they must jump, much less the magnitude or direction of the jump. To eliminate these difficulties, we define, in the section below, solution operators that give the electric and magnetic fields in terms of the material fields $\hat{\mathbf{y}}$, $\mathbf{p}$, and $\mathbf{m}$.

2.7. Solution operators. In defining our first solution operator we think of the spatial fields P and M as being prescribed functions in $L^2(\mathbf{R}^3)$ with support in the deformed body $\hat{\mathbf{y}}(\Omega)$, and we solve for the electric and magnetic fields they generate. Note that we can do this without reference to the deformation.

PROPOSITION 2.1. *Let*

$$\mathcal{A} \equiv \{V \in L^2(\mathbf{R}^3) | \text{curl } V = \mathbf{0} \quad \text{in } H^{-1}(\mathbf{R}^3)\}. \tag{2.53}$$

For every pair of functions $(P, M) \in L^2(\hat{\mathbf{y}}(\Omega))$ *there exists a unique pair* $(E_r, H_r) \in \mathcal{A}$*:*

$$\begin{aligned} E_r(\mathbf{y}) &= \check{E}_r(P;\mathbf{y}), \\ H_r(\mathbf{y}) &= \check{H}_r(M;\mathbf{y}) \end{aligned}$$

that satisfies

$$\int_{\mathbf{R}^3} (E_r \cdot E^\sharp + H_r \cdot H^\sharp) dv = -\int_{\hat{\mathbf{y}}(\Omega)} (P \cdot E^\sharp + M \cdot H^\sharp) dv \quad \forall\, E^\sharp, H^\sharp \in \mathcal{A}. \tag{2.54}$$

Furthermore,

$$\|\check{E}_r(P;\cdot)\|_{L^2(\mathbf{R}^3)} \le C\|P\|_{L^2(\hat{\mathbf{y}}(\Omega))}, \quad \textit{and} \tag{2.55}$$

$$\|\check{H}_r(M;\cdot)\|_{L^2(\mathbf{R}^3)} \le C\|M\|_{L^2(\hat{\mathbf{y}}(\Omega))}. \tag{2.56}$$

If P *and* M *are in* $H^1(\hat{\mathbf{y}}(\Omega))$*, then the solution operators are given by the following integral equations:*

$$\begin{aligned} E_r(\mathbf{y}) &= \check{E}_r(P;\mathbf{y}) \\ &\equiv \tfrac{1}{4\pi}\left[\int_{\hat{\mathbf{y}}(\Omega)} \frac{-\operatorname{div} P(\mathbf{y}')(\mathbf{y}-\mathbf{y}')}{|\mathbf{y}-\mathbf{y}'|^3} dv_{y'} + \int_{\partial\hat{\mathbf{y}}(\Omega)} \frac{P(\mathbf{y}')\cdot\hat{\mathbf{n}}(\mathbf{y}')(\mathbf{y}-\mathbf{y}')}{|\mathbf{y}-\mathbf{y}'|^3} da_{y'}\right]. \end{aligned} \tag{2.57}$$

$$\begin{aligned} H_r(\mathbf{y}) &= \check{H}_r(M;\mathbf{y}) \\ &\equiv \tfrac{1}{4\pi}\left[\int_{\hat{\mathbf{y}}(\Omega)} \frac{-\operatorname{div} M(\mathbf{y}')(\mathbf{y}-\mathbf{y}')}{|\mathbf{y}-\mathbf{y}'|^3} dv_{y'} + \int_{\partial\hat{\mathbf{y}}(\Omega)} \frac{M(\mathbf{y}')\cdot\hat{\mathbf{n}}(\mathbf{y}')(\mathbf{y}-\mathbf{y}')}{|\mathbf{y}-\mathbf{y}'|^3} da_{y'}\right]. \end{aligned} \tag{2.58}$$

Here, $\hat{\mathbf{n}}$ *is the unit outward normal to* $\partial\hat{\mathbf{y}}(\Omega)$*.*

If P *and* M *are in* $C^1(\hat{\mathbf{y}}(\bar{\Omega}))$ *then* E_r *and* H_r *satisfy* (2.11)–(2.14) *in the interior and exterior of the body,* (2.17)–(2.20) *at the boundary of the body, and are regular at infinity.*

This result follows from the Lax-Milgram lemma and standard results of potential theory (cf., e.g., Kellogg [13]).

We now define solution operators that tie E_r and H_r directly to the material fields $\hat{\mathbf{y}}$, $\mathbf{p}$, and $\mathbf{m}$. Let $(\hat{\mathbf{y}}, \mathbf{p}, \mathbf{m})$ be prescribed functions in the set

$$\mathcal{B} \equiv \left\{ (\hat{\mathbf{y}}, \mathbf{p}, \mathbf{m}) \;\middle|\; \begin{array}{l} \hat{\mathbf{y}} \in W^{1,p}(\Omega), p \ge 2; \text{(2.15) holds in the sense of trace;} \\ \mathbf{F}^\times \in L^q(\Omega), q \ge (p-1)/p; \;\; \det\mathbf{F} \in L^r(\Omega), r > 1; \\ \det\mathbf{F} > 0 \text{ a.e. in } \Omega; \;\; \int_\Omega \det\mathbf{F} dv \le |\hat{\mathbf{y}}(\Omega)|; \\ \dfrac{\mathbf{F}\cdot\mathbf{p}}{\sqrt{\det\mathbf{F}}}, \dfrac{\mathbf{F}\cdot\mathbf{m}}{\sqrt{\det\mathbf{F}}} \in L^2(\Omega). \end{array} \right\} \tag{2.59}$$

Here $\mathbf{F}^\times$ indicates the formal adjoint or cofactor matrix of $\mathbf{F}$. Before continuing we observe that for any $(\hat{\mathbf{y}}, \mathbf{p}, \mathbf{m}) \in \mathcal{B}$ we have:

1. Ciarlet and Nečas [8] imply that the map $\hat{\mathbf{y}} : \Omega \mapsto \mathbf{R}^3$ is invertible on $\hat{\mathbf{y}}(\Omega)$. We denote the inverse by $\hat{\mathbf{x}}$.

2. The composite functions

$$\tilde{P}(\hat{\mathbf{x}}, \mathbf{p}; \mathbf{y}) \equiv \begin{cases} [\det\mathbf{F}(\hat{\mathbf{x}}(\mathbf{y}))]^{-1}\mathbf{F}(\hat{\mathbf{x}}(\mathbf{y}))\cdot\mathbf{p}(\hat{\mathbf{x}}(\mathbf{y})), & \mathbf{y} \in \hat{\mathbf{y}}(\Omega), \\ \mathbf{0} & \text{elsewhere} \end{cases} \tag{2.60}$$

and

$$\tilde{M}(\hat{\mathbf{x}}, \mathbf{m}; \mathbf{y}) \equiv \begin{cases} [\det\mathbf{F}(\hat{\mathbf{x}}(\mathbf{y}))]^{-1}\mathbf{F}(\hat{\mathbf{x}}(\mathbf{y}))\cdot\mathbf{m}(\hat{\mathbf{x}}(\mathbf{y})), & \mathbf{y} \in \hat{\mathbf{y}}(\Omega), \\ \mathbf{0} & \text{elsewhere} \end{cases} \tag{2.61}$$

are in $L^2(\mathbf{R}^3)$.

3. Hölder's inequality implies that the functions $\mathbf{F}\cdot\mathbf{p}$ and $\mathbf{F}\cdot\mathbf{m}$ are in $L^s(\Omega)$ with $s=\frac{2r}{r+1}$.

We also observe that without further assumptions on p, q, and r we cannot ensure that $\mathbf{p}$ and $\mathbf{m}$ are in an L^p space with $p\geq 1$.

Now, as in the spatial case, we can define solution operators that describe the electric and magnetic fields as being generated by material fields in the set $\mathcal{B}$.

PROPOSITION 2.2. *For every triple of functions* $(\hat{\mathbf{y}},\mathbf{p},\mathbf{m})\in\mathcal{B}$ *there exists a unique pair* $(E_r,H_r)\in\mathcal{A}$*:*

$$\begin{aligned} E_r(\mathbf{y}) &= \hat{E}_r(\hat{\mathbf{y}},\mathbf{p};\mathbf{y}),\\ H_r(\mathbf{y}) &= \hat{H}_r(\hat{\mathbf{y}},\mathbf{m};\mathbf{y}) \end{aligned}$$

that satisfies

$$\begin{aligned} &\int_{\mathbf{R}^3} E_r(\mathbf{y})\cdot E^\sharp(\mathbf{y})+H_r(\mathbf{y})\cdot H^\sharp(\mathbf{y})\,dv_y\\ &\qquad=-\int_\Omega[\mathbf{F}(\mathbf{x})\cdot\mathbf{p}(\mathbf{x})\cdot E^\sharp(\hat{\mathbf{y}}(\mathbf{x}))+\mathbf{F}(\mathbf{x})\cdot\mathbf{m}(\mathbf{x})\cdot H^\sharp(\hat{\mathbf{y}}(\mathbf{x}))]\,dv_x \end{aligned} \tag{2.62}$$

for every $(E^\sharp,H^\sharp)\in\mathcal{A}$. *Furthermore,*

$$\|\hat{E}_r(\hat{\mathbf{y}},\mathbf{p};\cdot)\|_{L^2(\mathbf{R}^3)}\leq C\|\mathbf{F}\cdot\mathbf{p}/\sqrt{\det\mathbf{F}}\|_{L^2(\Omega)},\quad \textit{and} \tag{2.63}$$

$$\|\hat{H}_r(\hat{\mathbf{y}},\mathbf{m};\cdot)\|_{L^2(\mathbf{R}^3)}\leq C\|\mathbf{F}\cdot\mathbf{m}/\sqrt{\det\mathbf{F}}\|_{L^2(\Omega)}. \tag{2.64}$$

The material versions of these solution operators can then be defined by

$$\mathbf{e}_r(\mathbf{x})=\hat{\mathbf{e}}_r(\hat{\mathbf{y}},\mathbf{p};\mathbf{x})\equiv\hat{E}_r(\hat{\mathbf{y}},\mathbf{p};\hat{\mathbf{y}}(\mathbf{x}))\cdot\mathbf{F}(\mathbf{x}), \tag{2.65}$$

$$\mathbf{h}_r(\mathbf{x})=\hat{\mathbf{h}}_r(\hat{\mathbf{y}},\mathbf{m};\mathbf{x})\equiv\hat{H}_r(\hat{\mathbf{y}},\mathbf{m};\hat{\mathbf{y}}(\mathbf{x}))\cdot\mathbf{F}(\mathbf{x}). \tag{2.66}$$

As before, the proof of this result follows directly from the Lax-Milgram lemma.

Note that the operators $\check{E}_r$ and $\check{H}_r$ (which operate on spatial fields) and the operators $\hat{E}_r$ and $\hat{H}_r$ (which operate on material fields) are related by

$$\hat{E}_r(\hat{\mathbf{y}},\mathbf{p};\mathbf{y}) = \check{E}_r(\tilde{P}(\hat{\mathbf{x}},\mathbf{p};\cdot);\mathbf{y}), \tag{2.67}$$

$$\hat{H}_r(\hat{\mathbf{y}},\mathbf{m};\mathbf{y}) = \check{H}_r(\tilde{M}(\hat{\mathbf{x}},\mathbf{m};\cdot);\mathbf{y}), \tag{2.68}$$

where $\tilde{P}$ and $\tilde{M}$ are defined in (2.60) and (2.61).

2.8. Energy with nonlocal densities. Given any material functions $(\hat{\mathbf{y}},\mathbf{p},\mathbf{m})\in\mathcal{B}$ we can compose the solution operators $\hat{E}_r$ and $\hat{H}_r$ with $\tilde{\mathcal{E}}$ and use the relation

$$\begin{aligned} &\int_{\mathbf{R}^3}|\hat{E}_r(\mathbf{p},\hat{\mathbf{y}};\mathbf{y})|^2+|\hat{H}_r(\mathbf{m},\hat{\mathbf{y}};\mathbf{y})|^2\,dv_y\\ &\qquad=-\int_\Omega\hat{\mathbf{e}}_r(\mathbf{p},\hat{\mathbf{y}};\mathbf{x})\cdot\mathbf{p}(\mathbf{x})+\hat{\mathbf{h}}_r(\mathbf{m},\hat{\mathbf{y}};\mathbf{x})\cdot\mathbf{m}(\mathbf{x})\,dv_x \end{aligned} \tag{2.69}$$

(which is simply (2.62) with $E^\sharp=\hat{E}_r$ and $H^\sharp=\hat{H}_r$) to get the following representation for the energy:

$$\tilde{\mathcal{E}}(\hat{\mathbf{y}},\hat{E}_r(\mathbf{p},\hat{\mathbf{y}};\cdot),\mathbf{p},\hat{H}_r(\mathbf{m},\hat{\mathbf{y}};\cdot),\mathbf{m})=\mathcal{L}(\hat{\mathbf{y}},\mathbf{p},\mathbf{m})+\mathcal{G}(\hat{\mathbf{y}},\mathbf{p},\mathbf{m}), \tag{2.70}$$

where

$$\mathcal{L}(\hat{\mathbf{y}}, \mathbf{p}, \mathbf{m}) \equiv \int_\Omega \{\mathcal{W}(\mathbf{F}(\mathbf{x}), \mathbf{p}(\mathbf{x}), \mathbf{m}(\mathbf{x}), \mathbf{x}) - [\mathbf{e}_0(\mathbf{x}) \cdot \mathbf{p}(\mathbf{x}) + \mathbf{h}_0(\mathbf{x}) \cdot \mathbf{m}(\mathbf{x})]\}\, dv_x, \tag{2.71}$$

$$\begin{aligned} \mathcal{G}(\hat{\mathbf{y}}, \mathbf{p}, \mathbf{m}) &\equiv \tfrac{1}{2} \int_{\mathbf{R}^3} |\hat{E}_r(\mathbf{p}, \hat{\mathbf{y}}; \mathbf{y})|^2 + |\hat{H}_r(\mathbf{m}, \hat{\mathbf{y}}; \mathbf{y})|^2 dv_y \\ &= -\tfrac{1}{2} \int_\Omega [\hat{\mathbf{e}}_r(\mathbf{p}, \hat{\mathbf{y}}; \mathbf{x}) \cdot \mathbf{p}(\mathbf{x}) + \hat{\mathbf{h}}_r(\mathbf{m}, \hat{\mathbf{y}}; \mathbf{x}) \cdot \mathbf{m}(\mathbf{x})] dv_x. \end{aligned} \tag{2.72}$$

Accordingly we define

$$\mathcal{E}(\hat{\mathbf{y}}, \mathbf{p}, \mathbf{m}) \equiv \tilde{\mathcal{E}}(\hat{\mathbf{y}}, \hat{E}_r(\mathbf{p}, \hat{\mathbf{y}}; \cdot), \mathbf{p}, \hat{H}_r(\mathbf{m}, \hat{\mathbf{y}}; \cdot), \mathbf{m}). \tag{2.73}$$

In getting the energy functional $\mathcal{E}$ we have made the trade-off indicated at the outset: The new energy is simpler because our unknowns are defined only on the reference configuration of the body; but it is also more complicated because the energy density now depends (through $\hat{\mathbf{e}}_r$ and $\hat{\mathbf{h}}_r$) on the global values of the unknowns.

We now adapt this final form of the energy to the ferromagnetic materials considered in this paper. Adopting the constitutive assumptions (2.49) and (2.50), we consider an energy of the form

$$\begin{aligned} \check{\mathcal{E}}(\hat{\mathbf{y}}, \mathbf{m}) = \int_\Omega \{&\mathcal{V}(\mathbf{F}(\mathbf{x}), \mathbf{m}(\mathbf{x}), \mathbf{x}) - \mathbf{h}_0(\mathbf{x}) \cdot \mathbf{m}(\mathbf{x}) \\ &+ \mathcal{X}(\mathbf{F}(\mathbf{x}), \operatorname{Grad} \mathbf{m}(\mathbf{x}))\} dv_x + \mathcal{G}(\hat{\mathbf{y}}, \mathbf{m}), \end{aligned} \tag{2.74}$$

where the nonlocal energy $\mathcal{G}$ has been modified in the obvious way to account for our neglect of electric effects.

2.9. Minimization problems. Note that for either type of material, the nonlocal form of the energy, $\mathcal{E}$ and $\check{\mathcal{E}}$, respectively, is coercive. (This assumes, of course, that we put reasonable growth conditions on $\mathcal{W}$ and $\mathcal{V}$, as we do in §4.) Thus, it is reasonable to pose minimization problems. We begin with monotone materials.

Problem 2.4. Given $\mathbf{y}_0 \in W^{1,p}(\Omega)$ satisfying (2.3) and (2.4), $\mathbf{s}_0 \in L^{\frac{p}{p-1}}(S_2)$, and (E_0, H_0) satisfying (2.5); find $(\hat{\mathbf{y}}, \mathbf{p}, \mathbf{m}) \in \mathcal{B}$ such that

$$I(\hat{\mathbf{y}}, \mathbf{p}, \mathbf{m}) \equiv \mathcal{E}(\hat{\mathbf{y}}, \mathbf{p}, \mathbf{m}) - \int_{S_2} s_0 \cdot \hat{\mathbf{y}} da,$$

is minimized.

It follows from Brown [6] and Ciarlet and Nečas [8] that sufficiently regular solutions of the minimization Problem 2.4 combined with the solution operators $\hat{E}_r$ and $\hat{H}_r$ solve the variational Problem 2.3. Furthermore, it follows from the work of Brown [6], [5] that sufficiently regular solutions of the weak form of the Euler-Lagrange equations for the functional I,

$$\delta \mathcal{E}(\hat{\mathbf{y}}, \mathbf{p}, \mathbf{m}) = \int_{S_2} s_0(\mathbf{x}) \cdot \delta \hat{\mathbf{y}}(x) da_x, \tag{2.75}$$

again combined with the electric and magnetic fields given by E_r and H_r, solve the local Problem 2.2. However, regularity theory for solutions to such problems remains incomplete. In particular, conditions such as (2.3) pose serious difficulties.

We now consider ferromagnetic materials. We begin by modifying the admissible states of the body to account for our omission of electric effects: Let

$$\tilde{\mathcal{B}} = \left\{ (\hat{\mathbf{y}}, \mathbf{m}) \;\middle|\; \begin{array}{l} \mathbf{m} \in W^{1,s}(\Omega), \quad s > \frac{2pr}{p(r+1)+2r}, \\ \text{such that there exists } \mathbf{p} \text{ with } (\hat{\mathbf{y}}, \mathbf{p}, \mathbf{m}) \in \mathcal{B} \end{array} \right\}. \tag{2.76}$$

Our problem can then be stated as follows.

Problem 2.5. Given $\mathbf{y}_0 \in W^{1,p}(\Omega)$ satisfying (2.3) and (2.4), $\mathbf{s}_0 \in L^{\frac{p}{p-1}}(\mathcal{S}_2)$, and H_0 satisfying (2.5), find $(\hat{\mathbf{y}}, \mathbf{m}) \in \tilde{\mathcal{B}}$ such that

$$\check{I}(\hat{\mathbf{y}}, \mathbf{m}) \equiv \check{\mathcal{E}}(\hat{\mathbf{y}}, \mathbf{m}) - \int_{\mathcal{S}_2} \mathbf{s}_0 \cdot \hat{\mathbf{y}} da \tag{2.77}$$

is minimized.

3. Continuity and compactness results. In this section we give some results on the convergence of the solution operators defined above for various sequences of data.

It follows directly from (2.54) that the spatial version of the solution operator is weakly continuous.

THEOREM 3.1. *For any sequence of polarizations* $\{P^j\}$ *and magnetizations* $\{M^j\}$ *such that*

$$\left.\begin{array}{l} P^j \rightharpoonup \bar{P} \\ M^j \rightharpoonup \bar{M} \end{array}\right\} \text{ in } L^2(\mathbf{R}^3),$$

it follows that

$$\left.\begin{array}{l} \check{E}(P^j; \cdot) \rightharpoonup \check{E}(\bar{P}, \cdot) \\ \check{H}(M^j; \cdot) \rightharpoonup \check{H}(\bar{M}, \cdot) \end{array}\right\} \text{ in } L^2(\mathbf{R}^3),$$

where the half arrow $\rightharpoonup$ *indicates weak convergence.*

The situation in material coordinates is not so simple. Here, we must consider composite limits of deformations, polarizations, and magnetizations. The following lemma is useful in this context.

LEMMA 3.2. *For any sequence* $\{\hat{\mathbf{y}}^j, G^j\}$ *such that*

$$\det \mathbf{F}^j > 0 \text{ a.e.}, \tag{3.1}$$

$$\int_\Omega \det \mathbf{F}^j \leq |\hat{\mathbf{y}}^j(\Omega)|, \tag{3.2}$$

$$\text{spt } G^j \subset \hat{\mathbf{y}}^j(\Omega), \tag{3.3}$$

and

$$\hat{\mathbf{y}}^j \rightharpoonup \bar{\mathbf{y}} \quad \text{in } W^{1,p}(\Omega), \tag{3.4}$$

$$\det \mathbf{F}^j \rightharpoonup \det \bar{\mathbf{F}} \quad \text{in } L^r(\Omega), \tag{3.5}$$

$$G^j \rightharpoonup \bar{G} \quad \text{in } L^q(\mathbf{R}^3) \tag{3.6}$$

for some $p \geq 2$, $r > 1$, $q > 1$ *it follows that*

$$\det \mathbf{F}^j(\cdot) G^j(\hat{\mathbf{y}}^j(\cdot)) \rightharpoonup \det \bar{\mathbf{F}}(\cdot) \bar{G}(\bar{\mathbf{y}}(\cdot)) \text{ in } L^{q'}(\Omega) \tag{3.7}$$

with $q' = \frac{qr}{r+q-1}$.

Proof. Using Hölder's inequality, (3.5), (3.6), and the boundedness of weakly convergent sequences, we get

$$\begin{aligned}
&\int_\Omega |\det \mathbf{F}^j(\mathbf{x}) G^j(\hat{\mathbf{y}}^j(\mathbf{x}))|^{q'} dv_x \\
&\leq \left\{\int_\Omega |\det \mathbf{F}^j(\mathbf{x})|^r dv_x\right\}^{\frac{q-q'}{q}} \left\{\int_\Omega |G^j(\hat{\mathbf{y}}^j(\mathbf{x}))|^q \det \mathbf{F}^j(\mathbf{x}) dv_x\right\}^{\frac{q'}{q}} \\
&\leq \left\{\int_\Omega |\det \mathbf{F}^j(\mathbf{x})|^r dv_x\right\}^{\frac{q-q'}{q}} \left\{\int_{\mathbf{R}^3} |G(\mathbf{y})|^q \det dv_y\right\}^{\frac{q'}{q}} \\
&\leq C.
\end{aligned} \tag{3.8}$$

Thus, by the weak compactness of bounded sets in $L^{q'}$, there exists an $f \in L^{q'}(\Omega)$ such that at least for a subsequence

$$\det \mathbf{F}^j(\cdot) G^j(\hat{\mathbf{y}}^j(\cdot)) \rightharpoonup f(\cdot) \quad \text{in } L^{q'}(\Omega).$$

We now show that

$$f(\cdot) = \det \bar{\mathbf{F}}(\cdot) \bar{G}(\bar{\mathbf{y}}(\cdot)).$$

Let $\hat{\mathbf{x}}^j$ and $\bar{\mathbf{x}}$ denote the respective inverses of $\hat{\mathbf{y}}^j$ and $\bar{\mathbf{y}}$. (The invertibility of $\hat{\mathbf{y}}^j$ follows from (3.1) and (3.2); the invertibility of $\bar{\mathbf{y}}$ is shown in [8].) Now for any $\phi \in C(\Omega)$ we define the spatial fields

$$\phi^j(\mathbf{y}) = \begin{cases} \phi(\hat{\mathbf{x}}^j(\mathbf{y})), & \mathbf{y} \in \hat{\mathbf{y}}^j(\Omega), \\ 0 & \text{elsewhere;} \end{cases}$$

and

$$\bar{\phi}(\mathbf{y}) = \begin{cases} \phi(\bar{\mathbf{x}}(\mathbf{y})), & \mathbf{y} \in \bar{\mathbf{y}}(\Omega), \\ 0 & \text{elsewhere.} \end{cases}$$

Since $\hat{\mathbf{x}}^j \to \bar{\mathbf{x}}$ almost everywhere (at least for a subsequence) and ϕ is continuous we have

$$\phi^j \to \bar{\phi} \quad \text{a.e. in } \mathbf{R}^3.$$

Also, for any $s \in [1, \infty)$ we have

$$\begin{aligned}
\int_{\mathbf{R}^3} |\phi^j(\mathbf{y})|^s dv_y &= \int_\Omega |\phi(\mathbf{x})|^s \det \mathbf{F}^j(\mathbf{x}) dv_x \\
&\to \int_\Omega |\phi(\mathbf{x})|^s \det \bar{\mathbf{F}}(\mathbf{x}) dv_x \\
&= \int_{\mathbf{R}^3} |\bar{\phi}(\mathbf{y})|^s dv_y.
\end{aligned}$$

It follows from a standard exercise in real variable theory that

$$\phi^j \to \bar{\phi} \quad \text{(strongly) in } L^s(\mathbf{R}^3).$$

Thus, for any $\phi \in C(\Omega)$

$$\begin{aligned}
\int_\Omega \det \mathbf{F}^j(\mathbf{x}) G^j(\hat{\mathbf{y}}^j(\mathbf{x})) \phi(\mathbf{x}) dv_x &= \int_{\mathbf{R}^3} G^j(\mathbf{y}) \phi^j(\mathbf{y}) dv_y \\
&\to \int_{\mathbf{R}^3} \bar{G}(\mathbf{y}) \bar{\phi}(\mathbf{y}) dv_y \\
&= \int_\Omega \det \bar{\mathbf{F}}(\mathbf{x}) \bar{G}(\bar{\mathbf{y}}(\mathbf{x})) \phi(\mathbf{x}) dv_x.
\end{aligned}$$

Here we have used the fact that the product of a weakly convergent and a strongly convergent sequence (in the appropriate spaces) converges weakly in the sense of distributions. The conclusion of the lemma follows directly from a density argument and the uniqueness of weak limits. □

The following theorem on the limits of material functions will be used in our existence theorem for monotone magnetic materials.

THEOREM 3.3. *Let* $\{\hat{\mathbf{y}}^j, \mathbf{p}^j, \mathbf{m}^j\} \subset \mathcal{B}$ *satisfy*

$$\|\mathbf{F}^j\|_{L^p(\Omega)} + \|\mathbf{F}^{j\times}\|_{L^q(\Omega)} + \|\det \mathbf{F}^j\|_{L^r(\Omega)} + \left\| \frac{\mathbf{F}^j \cdot \mathbf{p}^j}{\sqrt{\det \mathbf{F}^j}} \right\|_{L^2(\Omega)} + \left\| \frac{\mathbf{F}^j \cdot \mathbf{m}^j}{\sqrt{\det \mathbf{F}^j}} \right\|_{L^2(\Omega)} \leq C, \tag{3.9}$$

and

$$\int_\Omega \mathcal{W}(\mathbf{F}^j(\mathbf{x}), \mathbf{p}^j(\mathbf{x}), \mathbf{m}^j(\mathbf{x}), x) dv_x \leq C; \tag{3.10}$$

then there exists $(\bar{\mathbf{y}}, \bar{\mathbf{p}}, \bar{\mathbf{m}}) \in \mathcal{B}$ *such that (at least for a subsequence)*

$$\hat{\mathbf{y}}^j \rightharpoonup \bar{\mathbf{y}} \quad \text{in } W^{1,p}(\Omega), \tag{3.11}$$

$$\mathbf{F}^{j\times} \rightharpoonup \bar{\mathbf{F}}^\times \quad \text{in } L^q(\Omega), \tag{3.12}$$

$$\det \mathbf{F}^j \rightharpoonup \det \bar{\mathbf{F}} \quad \text{in } L^r(\Omega), \tag{3.13}$$

$$\mathbf{F}^j \cdot \mathbf{p}^j \rightharpoonup \bar{\mathbf{F}} \cdot \bar{\mathbf{p}} \quad \text{in } L^s(\Omega), \tag{3.14}$$

$$\mathbf{F}^j \cdot \mathbf{m}^j \rightharpoonup \bar{\mathbf{F}} \cdot \bar{\mathbf{m}} \quad \text{in } L^s(\Omega), \tag{3.15}$$

$$\hat{E}(\hat{\mathbf{y}}^j, \mathbf{p}^j; \cdot) \rightharpoonup \hat{E}(\bar{\mathbf{y}}, \bar{\mathbf{p}}; \cdot) \quad \text{in } L^2(\mathbf{R}^3), \tag{3.16}$$

$$\hat{H}(\hat{\mathbf{y}}^j, \mathbf{m}^j; \cdot) \rightharpoonup \hat{H}(\bar{\mathbf{y}}, \bar{\mathbf{m}}; \cdot) \quad \text{in } L^2(\mathbf{R}^3), \tag{3.17}$$

where $s = \frac{2r}{r+1}$.

Proof. The existence of a $\bar{\mathbf{y}}$, suitable as a component of an element of $\mathcal{B}$, such that (3.11), (3.12), and (3.13) hold, follows from the work of Ball [3] and the refinements of Ciarlet and Nečas [8]. To deduce the existence of $\bar{\mathbf{p}}$ and $\bar{\mathbf{m}}$ we define

$$P^j(\mathbf{y}) = \tilde{P}(\hat{\mathbf{x}}^j, \mathbf{p}^j; \mathbf{y}) \tag{3.18}$$

and

$$M^j(\mathbf{y}) = \tilde{M}(\hat{\mathbf{x}}^j, \mathbf{m}^j; \mathbf{y}) \tag{3.19}$$

where $\tilde{P}$ and $\tilde{M}$ are defined in (2.60) and (2.61), respectively. We note that

$$\|P^j\|_{L^2(\mathbf{R}^3)} = \left\| \frac{\mathbf{F}^j \cdot \mathbf{p}^j}{\sqrt{\det \mathbf{F}^j}} \right\|_{L^2(\Omega)}, \quad \text{and}$$

$$\|M^j\|_{L^2(\mathbf{R}^3)} = \left\| \frac{\mathbf{F}^j \cdot \mathbf{m}^j}{\sqrt{\det \mathbf{F}^j}} \right\|_{L^2(\Omega)}.$$

Thus, by (3.9) and the weak compactness of bounded sets in L^2, there exists $(\bar{P}, \bar{M})$ such that (at least for a subsequence)

$$P^j \rightharpoonup \bar{P} \quad \text{in } L^2(\mathbf{R}^3) \quad \text{and } M^j \rightharpoonup \bar{M} \quad \text{in } L^2(\mathbf{R}^3). \tag{3.20}$$

It follows from Theorem 3.1 that

$$\check{E}_r(P^j;\cdot) \rightharpoonup \check{E}_r(\bar{P};\cdot) \quad \text{and} \tag{3.21}$$

$$\check{H}_r(M^j;\cdot) \rightharpoonup \check{H}_r(\bar{M};\cdot). \tag{3.22}$$

If we define

$$\begin{aligned} \bar{\mathbf{p}} &= (\det \bar{\mathbf{F}})\bar{\mathbf{F}}^{-1} \cdot \bar{P}(\bar{\mathbf{y}}(\cdot)) \text{ and} \\ \bar{\mathbf{m}} &= (\det \bar{\mathbf{F}})\bar{\mathbf{F}}^{-1} \cdot \bar{M}(\bar{\mathbf{y}}(\cdot)), \end{aligned} \tag{3.23}$$

then (3.14)–(3.17) follow directly from (2.67), (2.68), (3.20), and Lemma 3.2. Thus, our theorem is proved. □

The final result of this section is useful in our theorems on classical ferromagnetic materials.

THEOREM 3.4. *If for some sequence* $\{\hat{\mathbf{y}}^j, \mathbf{m}^j\}$ *such that*

$$\det \mathbf{F}^j > 0 \text{ a.e.}, \tag{3.24}$$

$$\int_\Omega \det \mathbf{F}^j \leq |\hat{\mathbf{y}}^j(\Omega)|, \tag{3.25}$$

$$\left\| \frac{\mathbf{F}^j \cdot \mathbf{m}^j}{\sqrt{\det \mathbf{F}^j}} \right\|_{L^2(\Omega)} \leq C, \tag{3.26}$$

and for some $r > 1$, $p > \frac{2r}{r-1}$, $s > \frac{2pr}{p(r+1)+2r}$

$$\hat{\mathbf{y}}^j \rightharpoonup \bar{\mathbf{y}} \quad \textit{(weakly) in } W^{1,p}(\Omega), \tag{3.27}$$

$$\det \mathbf{F}^j \rightharpoonup \det \bar{\mathbf{F}} \quad \textit{(weakly) in } L^r(\Omega), \textit{ and} \tag{3.28}$$

$$\mathbf{m}^j \to \bar{\mathbf{m}} \quad \textit{(strongly) in } L^s(\Omega), \tag{3.29}$$

then $\bar{\mathbf{y}}$ *is invertible with inverse* $\bar{\mathbf{x}}$, *and if* M^j *is defined as in* (3.19) *and*

$$\bar{M}(\mathbf{y}) \equiv \begin{cases} [\det \bar{\mathbf{F}}(\bar{\mathbf{x}}(\mathbf{y}))]^{-1}\bar{\mathbf{F}}(\bar{\mathbf{x}}(\mathbf{y})) \cdot \bar{\mathbf{m}}(\bar{\mathbf{x}}(\mathbf{y})), & \mathbf{y} \in \bar{\mathbf{y}}(\Omega), \\ \mathbf{0} & \textit{elsewhere} \end{cases} \tag{3.30}$$

then it follows that

$$M^j \rightharpoonup \bar{M} \quad \textit{in } L^2(\mathbf{R}^3), \tag{3.31}$$

and

$$\hat{H}_r(\mathbf{y}^j, \mathbf{m}^j, \cdot) \rightharpoonup \hat{H}_r(\bar{\mathbf{y}}, \bar{\mathbf{m}}, \cdot) \quad \textit{in} \quad L^2(\mathbf{R}^3). \tag{3.32}$$

Proof. As in the previous theorem, (3.26) implies that there exists $\check{M} \in L^2(\mathbf{R}^3)$ such that at least for a subsequence

$$M^j \rightharpoonup \check{M} \text{ in } L^2(\mathbf{R}^3).$$

We must show that $\bar{M} = \check{M}$. We first observe that Lemma 3.2 implies that at least for a subsequence

$$\mathbf{F}^j \cdot \mathbf{m}^j = (\det \mathbf{F}^j) M^j(\mathbf{y}^j(\cdot)) \rightharpoonup (\det \bar{\mathbf{F}}) \check{M}(\bar{\mathbf{y}}(\cdot)) \quad \text{in } L^{q'}(\Omega)$$

with $q' = \frac{2r}{r+1}$. But (3.27) and (3.29) imply

$$\mathbf{F}^j \cdot \mathbf{m}^j \rightharpoonup \bar{\mathbf{F}} \cdot \bar{\mathbf{m}} \quad \text{in } L^q(\Omega) \tag{3.33}$$

with $q = \frac{ps}{p+s} > q'$. Thus, by (3.30) and the uniqueness of weak limits we have $\bar{M} = \check{M}$ and (3.31) is proved. It follows from Theorem 3.1 that

$$\check{H}_r(M^j; \cdot) \rightharpoonup \check{H}_r(\bar{M}; \cdot), \tag{3.34}$$

and (3.32) follows from (2.68). □

4. Existence. We state and prove an existence theorem for the minimization Problem 2.4 for monotone materials.

THEOREM 4.1. *Let* $\mathbf{y}_0 \in W^{1,p}(\Omega)$ *satisfying* (2.3) *and* (2.4), $\mathbf{s}_0 \in L^{\frac{p}{p-1}}(S_2)$, *and* (E_0, H_0) *satisfying* (2.5) *be given. Let* $\mathcal{W}$ *be* polyconvex, *i.e., let it satisfy*

$$\mathcal{W}(\mathbf{F}, \mathbf{p}, \mathbf{m}, \mathbf{x}) = \Upsilon(\mathbf{F}, \mathbf{F}^\times, \det \mathbf{F}, \mathbf{F} \cdot \mathbf{p}, \mathbf{F} \cdot \mathbf{m}, \mathbf{x}), \tag{4.1}$$

with $\Upsilon(\cdot, \cdot, \cdot, \cdot, \cdot, \mathbf{x})$ *convex for each* $\mathbf{x} \in \Omega$. *(See Ball* [3] *for the definition of polyconvexity in a purely elastic material.) Let* Υ *satisfy*

$$\Upsilon(\mathbf{F}, \mathbf{F}^\times, \delta, \mathbf{F} \cdot \mathbf{p}, \mathbf{F} \cdot \mathbf{m}, \mathbf{x}) \to \infty \text{ as } \delta \to 0, \tag{4.2}$$

and suppose that there exist numbers $k > 0$, $p \geq 2$, $q > p/(p-1)$, $r > 1$, *and a function* $\omega \in L^1(\Omega)$ *such that*

$$\Upsilon(\mathbf{F}, \mathbf{F}^\times, \delta, \mathbf{F}\cdot\mathbf{p}, \mathbf{F}\cdot\mathbf{m}, \mathbf{x}) \geq \omega(\mathbf{x}) + k \left(|\mathbf{F}|^p + |\mathbf{F}^\times|^q + \delta^r + \frac{|\mathbf{F} \cdot \mathbf{p}|^2}{\det \mathbf{F}} + \frac{|\mathbf{F} \cdot \mathbf{m}|^2}{\det \mathbf{F}} \right) \tag{4.3}$$

for every $\mathbf{x} \in \Omega$. *Suppose further that there exists an element* $(\hat{\mathbf{y}}_1, \mathbf{p}_1, \mathbf{m}_1) \in \mathcal{B}$ *such that* $I(\hat{\mathbf{y}}_1, \mathbf{p}_1, \mathbf{m}_1) < \infty$. *Then there exists a solution* $(\bar{\mathbf{y}}, \bar{\mathbf{p}}, \bar{\mathbf{m}}) \in \mathcal{B}$ *to Problem* 2.4.

Proof. Since I is bounded below there exists an infimizing sequence $(\hat{\mathbf{y}}^j, \mathbf{p}^j, \mathbf{m}^j) \subset \mathcal{B}$. It follows from Theorem 3.3 that there exists $(\bar{\mathbf{y}}, \bar{\mathbf{p}}, \bar{\mathbf{m}}) \in \mathcal{B}$ such that (3.11)–(3.17) hold. The weak lower-semicontinuity of $\mathcal{L}$ follows from the convexity of Υ and Tonelli's theorem (cf. [9, p.7]). The weak lower-semicontinuity of $\mathcal{G}$ follows from (3.16), (3.17), and Tonelli's theorem. Thus

$$I(\bar{\mathbf{y}}, \bar{\mathbf{p}}, \bar{\mathbf{m}}) \leq \liminf I(\hat{\mathbf{y}}^j, \mathbf{p}^j, \mathbf{m}^j). \tag{4.4}$$

So $I(\bar{\mathbf{y}}, \bar{\mathbf{p}}, \bar{\mathbf{m}})$ is minimal, and our theorem is proved. □

We now prove an existence theorem for the minimization Problem 2.5 for ferromagnetic materials. Our result is a generalization of that of Visintin [18] which considered ferromagnetism of rigid bodies. The proof is very similar to that of Theorem 4.1, but here we use the additional compactness in $\mathbf{m}$ given by the exchange energy $\mathcal{X}$ to compensate for the nonconvexity of the stored energy $\mathcal{V}$. To do this we employ the following lemma.

LEMMA 4.2. *We consider the function*

$$\mathbf{R}^m \times \mathbf{R}^l \times \Omega \ni (u, v, \mathbf{x}) \mapsto F(u, v, \mathbf{x}) \in \mathbf{R}. \tag{4.5}$$

We assume that $\mathbf{F}$ *is measurable in* $\mathbf{x}$, *continuous in its other arguments, and convex in* u. *Then if* (u^j, v^j) *is a sequence of functions on* Ω *such that*

$$u^j \rightharpoonup \bar{u} \qquad \text{in } L^1(\Omega), \tag{4.6}$$

$$v^j \to \bar{v} \qquad \text{a.e in } (\Omega), \tag{4.7}$$

and

$$F(u^j(\mathbf{x}), v^j(\mathbf{x}), \mathbf{x}) \geq f(\mathbf{x}), \quad F(\bar{u}(\mathbf{x}), \bar{v}(\mathbf{x}), \mathbf{x}) \geq f(\mathbf{x}) \tag{4.8}$$

for some $f \in L^1(\Omega)$, *then*

$$\int_\Omega F(\bar{u}(\mathbf{x}), \bar{v}(\mathbf{x}), \mathbf{x}) \leq \liminf_{j\to\infty} \int_\Omega F(u^j(\mathbf{x}), v^j(\mathbf{x}), \mathbf{x}). \tag{4.9}$$

The proof of this can be found in Eisen [10] and Ball, Currie, and Olver [4].

THEOREM 4.3. *Let* $\mathbf{y}_0 \in W^{1,p}(\Omega)$ *satisfying* (2.3) *and* (2.4), $\mathbf{s}_0 \in L^{\frac{p}{p-1}}(S_2)$, *and* H_0 *satisfying* (2.5) *be given. Let* $\mathcal{V}$ *be measurable in* $\mathbf{x}$, *continuously differentiable in its other arguments, and satisfy*

$$\mathcal{V}(\mathbf{F}, \mathbf{m}, \mathbf{x}) = \tilde{\Upsilon}(\mathbf{F}, \mathbf{F}^\times, \det \mathbf{F}, \mathbf{m}, \mathbf{x}), \tag{4.10}$$

with $\Upsilon(\cdot, \cdot, \cdot, \mathbf{m}, \mathbf{x})$ *convex for each* $(\mathbf{m}, \mathbf{x}) \in \mathbf{R}^3 \times \Omega$. *Assume also that*

$$\tilde{\Upsilon}(\mathbf{F}, \mathbf{F}^\times, \delta, \mathbf{m}, \mathbf{x}) \to \infty \text{ as } \delta \to 0; \tag{4.11}$$

that there exist numbers $k_1 > 0$, $r > 1$, $p \geq \frac{2r}{r-1}$, $q > p/(p-1)$, $s > \frac{2pr}{p(r+1)+2r}$, *and a function* $\omega \in L^1(\Omega)$ *such that*

$$\tilde{\Upsilon}(\mathbf{F}, \mathbf{F}^\times, \delta, \mathbf{m}, \mathbf{x}) \geq \omega(\mathbf{x}) + k_1 \left(|\mathbf{F}|^p + |\mathbf{F}^\times|^q + \delta^r + |\mathbf{m}|^s + \frac{|\mathbf{F}\cdot\mathbf{m}|^2}{\det \mathbf{F}} \right) \tag{4.12}$$

for every $\mathbf{x} \in \Omega$. *Assume further that the exchange energy density satisfies*

$$\mathcal{X}(\mathbf{F}, \mathbf{G}) = \tilde{\mathcal{X}}(\mathbf{F}, \mathbf{F}^\times, \det \mathbf{F}, \mathbf{G}), \tag{4.13}$$

where $\tilde{\mathcal{X}}(\cdot, \cdot, \cdot, \cdot)$ *is convex and*

$$\mathcal{X}(\mathbf{F}, \mathbf{G}) \geq k_2 + k_3(|\mathbf{F}|^p + |\mathbf{F}^\times|^q + |\det \mathbf{F}|^r + |\mathbf{G}|^s), \tag{4.14}$$

for some positive constants k_2 *and* k_3. *Then if there exists an element* $(\hat{\mathbf{y}}_1, \mathbf{m}_1) \in \tilde{\mathcal{B}}$ *such that* $\check{I}(\hat{\mathbf{y}}_1, \mathbf{m}_1) < \infty$, *there exists a solution* $(\bar{\mathbf{y}}, \bar{\mathbf{m}}) \in \tilde{\mathcal{B}}$ *to Problem* 2.5.

Proof. As usual, let $\{\hat{\mathbf{y}}^j, \mathbf{m}^j\}$ be an infimizing sequence for $\check{I}$. The growth conditions (4.12) and (4.14) imply that

$$\|\mathbf{m}^j\|_{W^{1,s}(\Omega)} < C.$$

Thus, there exists $\bar{\mathbf{m}} \in W^{1,s}(\Omega)$ such that (at least for a subsequence)

$$\mathbf{m}^j \rightharpoonup \bar{\mathbf{m}} \quad \text{in } W^{1,s}(\Omega), \tag{4.15}$$

and

$$\mathbf{m}^j \to \bar{\mathbf{m}} \quad \text{in } L^s(\Omega). \tag{4.16}$$

As before, there also exists $\bar{\mathbf{y}} \in W^{1,p}(\Omega)$ such that

$$\begin{aligned} &\hat{\mathbf{y}}^j \rightharpoonup \bar{\mathbf{y}} \quad \text{in } W^{1,p}(\Omega), \\ &\mathbf{F}^{j\times} \rightharpoonup \bar{\mathbf{F}}^{\times} \quad \text{in } L^q(\Omega), \text{ and} \\ &\det \mathbf{F}^j \rightharpoonup \det \bar{\mathbf{F}} \quad \text{in } L^r(\Omega). \end{aligned}$$

Thus, it follows from (3.32) of Theorem 3.4, the convexity of $\mathcal{G}$ (in its spatial form), and Tonelli's theorem that

$$\mathcal{G}(\bar{\mathbf{F}}, \bar{\mathbf{m}}) \leq \liminf \mathcal{G}(\mathbf{F}^j, \mathbf{m}^j).$$

The weak lower-semicontinuity of $\mathcal{V}$ follows from Lemma 4.2, and the weak lower-semicontinuity of the other terms follows as in the proof of Theorem 4.1. □

As a simple example of an energy density satisfying our hypotheses, consider

$$\begin{aligned} \mathcal{V}(\mathbf{F}, \mathbf{m}, \mathbf{x}) \quad &= \quad \mathcal{W}(\mathbf{F}, \mathbf{F}^{\times}, \det \mathbf{F}, \mathbf{x}) + \kappa_1 \left(\frac{|\mathbf{m}|^4}{4} - m_0^2 \frac{|\mathbf{m}|^2}{2} + \frac{m_0^4}{4} \right)^{\frac{s}{4}} \\ &\quad + \kappa_2 \frac{|\mathbf{F} \cdot \mathbf{m}|^2}{(\det \mathbf{F})}. \end{aligned} \tag{4.17}$$

Here κ_1 and κ_2 are positive constants, and we take $\mathcal{W}$ to be polyconvex. Thus the first term represents a purely elastic part of the energy. The second term describes the pure magnetic part (this would be the energy of a rigid ferromagnetic material with preferred magnetization m_0); and the third term ensures that the energy of the spatial magnetic field is bounded above. We could of course introduce other coupled terms modeling such effects as magnetostriction.

5. Comments. We conclude with some remarks on possible extensions of these results.

1. In the linear theory of *diamagnetic materials* one assumes a constitutive relation of the form

$$M = \chi H$$

with χ negative but $|\chi| < 1$. Thus, while map $H \mapsto M$ is "monotone decreasing," the map $H \mapsto \mathfrak{b}$ where

$$\mathfrak{b} \equiv H + M = H + \chi H$$

is monotone (increasing).

The results of [15], where we chose $\mathbf{h}$ as an independent variable and $\mathbf{b}$ as a dependent variable, depended on the monotonicity of $\mathbf{b}$ without regard to $\mathbf{m}$, and thus applied to diamagnetic materials. In this regard, we note that one should be able to obtain an existence result for materials for which the map $\mathbf{m} \mapsto \mathcal{W}$ is *concave* from the results above as long as proper coercivity assumptions are placed on the entire energy.

2. In ferroelectric materials one usually assumes that the stored energy is nonconvex, but that unlike ferromagnetic materials there is no exchange energy. Thus, we can expect neither the weak continuity found in the problems for monotone materials nor the compactness given by the exchange energy in the problems for ferromagnetic materials. It may instead be possible to consider "measure valued" solutions such as

those considered in the theory of twinning in crystals as developed by Ericksen [11], and Chipot and Kinderlehrer [7]. The idea here is that while the weak limit of an infimizing sequence may not minimize a nonconvex energy functional, the Young's measure for the sequence (a probability measure whose center of mass is the weak limit) may represent the physical situation that minimizes energy. It may be possible to model the microscopic structure of the domains (highly discontinuous regions of uniform polarization) found in ferromagnetic materials by a macroscopic Young's measure indicating the distribution of the domains.

Acknowledgments. The author would like to thank the referees of this paper and John Ball for their helpful suggestions.

THE INTEGRAL REPRESENTATION OF THE POSITIVE SOLUTIONS OF THE GENERALIZED WEINSTEIN EQUATION ON A QUARTER-SPACE*

ÖMER AKIN†

Abstract. The present paper gives a unique integral representation for the positive solutions to the generalized Weinstein equation

$$L[u]=L_{p,q}[u]\equiv\sum_{i=1}^{n}u_{x_ix_i}+\frac{p}{x_{n-1}}u_{x_{n-1}}+\frac{q}{x_n}u_{x_n}.$$

This integral representation is explicitly described in terms of hypergeometric functions. The methods used are those of potential theory; the technique of Martin plays a particularly crucial role.

Key words. potential theory, Martin boundary, Weinstein equation, integral representation, minimal harmonic functions

AMS(MOS) subject classifications. 31, 31B, 31D

1. Introduction.

The equation

$$L[u]=L_{p,q}[u]\equiv\sum_{i=1}^{n}u_{x_ix_i}+\frac{p}{x_{n-1}}u_{x_{n-1}}+\frac{q}{x_n}u_{x_n} \tag{1.1}$$

has been treated by Gilbert [1], [2] by integral operator methods, and fundamental solutions to (1.1) were given by Weinacht [3]. Kapilevich [4] and Celebi [5] have given mean value theorems for a class of equations (1.1). Hall, Quinn, and Weinacht [6] have also given some mean value theorems for (1.1). Quinn and Weinacht have given existence and uniqueness theorems covering all parameter ranges of p and q [7].

In (1.1) if $p=0$ then the equation reduces to the form $L_q[u]=0$, which has been treated in [8]-[12]. The method used by Brelot in [12] is essentially different from those used in the other papers. He was the first mathematician to treat the equation $L_q[u]=0$ by using Martin's technique [13]. Brelot described all the positive solutions of that equation, in terms of an integral kernel given by Huber in [9]. We would like to use the potential theoretic methods of Martin; however, the problem is significantly more complicated than the problem treated by Brelot [12], because the symmetries of a quarter-space are more sparse than for a half-space.

The papers [7] and [11] introduced fundamental solutions for the operator $L_{p,q}$. It will be important to identify the minimal positive fundamental solutions (or, in other words, the classical Green functions). We do this when $p, q<1$ and use the correspondence principle to identify the minimal positive fundamental solutions if p or q is bigger than one. (The correspondence principle is as follows: A function u is a solution of $L_{2-p,2-q}[u]=0$ if and only if $v=x_{n-1}^{1-p}\cdot x_n^{1-q}\cdot u$ is a solution of $L_{p,q}[v]=0$.) After we have done this we follow Martin's method in considering the ratio of these Green functions. Standard results from potential theory tell us how to obtain an integral kernel describing all positive harmonic functions [13]-[17]. We will also identify the Martin boundary points corresponding to minimal positive harmonic functions and

so obtain a unique representation for every positive harmonic function in the domain Q:

$$Q=\{x\colon (x_1, x_2, \cdots, x_n)\in \mathbb{R}^n,\ x_{n-1}>0,\ x_n>0\}.$$

Our formula is reasonably explicit.

2. Potentials for $L_{p,q}$. Let us suppose a function $\hat{E}_{p,q}(x,\xi)$ is given as follows:

$$\frac{-\Gamma(k)}{\pi^{n/2}\Gamma(p/2)\Gamma(q/2)}\int_0^{\pi}\int_0^{\pi}\sigma^{-2k}\sin^{p-1}\theta_1\sin^{q-1}\theta_2\,d\theta_1\,d\theta_2$$

where

$$\sigma\equiv\left[|x-\xi|^2+4x_{n-1}\xi_{n-1}\sin^2\left(\frac{\theta_1}{2}\right)+4x_n\xi_n\sin^2\left(\frac{\theta_2}{2}\right)\right]^{1/2},$$

$$2k=n+p+q-2,\qquad p,\ q\geqq 1.$$

We shall use $E_{p,q}(x,\xi)$ obtained from $\hat{E}_{p,q}$ as follows:

$$E_{p,q}(x,\xi)=-\xi_{n-1}^{p}\xi_n^{q}\hat{E}_{p,q}(x,\xi). \tag{2.1}$$

It is already known that (2.1) is a fundamental solution of $L_{p,q}$ with pole ξ [7]. We also know that

$$E^1_{p,q}(x,\xi)=x_{n-1}^{1-p}\cdot x_n^{1-q}\cdot E_{2-p,2-q}(x,\xi) \tag{2.2}$$

is a fundamental solution of (1.1) when $p<1$, $q<1$ [7].

We want to describe an integral kernel which will yield all positive harmonic functions on the Q. To do this we will apply the Martin's method as described in [13]. To apply the technique found there it is necessary that our fundamental solutions be potentials.

We need to prove that $E_{p,q}(x,\xi)$ is a potential on the quarter-space Q. To do this it is enough to show $E^1_{p,q}$ is a potential for $p,\ q<1$, because the correspondence principle conserves harmonicity[1] (superharmonicity, subharmonicity) and also preserves the order structure.

Applying the maximum principle on relatively compact open subsets of Q, we see that it will suffice to prove that

$$E^1_{p,q}(x,\xi)\to 0\quad \text{as } x\to\partial Q\quad \text{or } \infty$$

where ∂Q is the boundary of the quarter-space Q.

Let us suppose ξ is a fixed point in Q:

$$\lim_{x\to\partial Q}E^1_{p,q}(x,\xi)=\lim_{x\to\partial Q}x_n^{1-p}x_n^{1-q}\cdot\lim_{x\to\partial Q}E_{2-p,2-q}(x,\xi). \tag{2.3}$$

It is clear that in (2.3) the first limit is zero. We need to understand the second limit. We can assume that there is a δ such that $|x-\xi|>\delta$. It is easily shown that

$$\overline{\lim_{x\to\partial Q}}E_{2-p,2-q}(x,\xi)<\pi^2\delta^{p+q-n-2}.$$

This result shows that in (2.3) the second limit is bounded from above. It follows that

$$\lim_{x\to\partial Q}E^1_{p,q}(x,\xi)=0.$$

[1] In this paper as in Brelot-Collin and Brelot's article [12] harmonic, superharmonic, etc. are used relative to L rather than Δ.

Now, we need to show

$$\lim_{|x|\to\infty} E_{p,q}(x,\xi)=0.$$

To show this, we use the fact that $\delta<|x-\xi|$ so

$$\int_0^{\pi}\int_0^{\pi}\sigma^{p+q-n-2}\sin^{1-p}\theta_1\sin^{1-q}\theta_2\,d\theta_1\,d\theta_2\leqq|x-\xi|^{p+q-n-2}\pi^2.$$

This estimate only holds because $p, q<1$. So,

$$\lim_{|x|\to\infty} E^1_{p,q}(x,\xi)\leqq\lim_{|x|\to\infty} x_{n-1}^{1-p}\cdot x_n^{1-q}|x-\xi|^{p+q-n-2}\cdot\pi^2.$$

We note that the convergence of the right-hand side is uniform in the direction of approaching ∞.

Thus, $E^1_{p,q}(x,\xi)$ is a potential in the quarter-space Q for $L_{p,q}$ if $p, q<1$. Consequently, $E(x,\xi)$ is a potential in the same space for $L_{p,q}$ if $p, q\geqq 1$. The function $E(x,\xi)$ is a Green function and Q, with E, is a Green space in the sense of potential theory [15].

3. The Martin boundary.

(a) The case where $p, q>1$. In the previous part we proved that $E_{p,q}$, defined at (2.1), is a Green function. In this part, we will construct the minimal harmonic functions for $L_{p,q}$ by considering limits of ratios of Green functions. In other words, we will use Martin's technique. To apply that technique we will prove that the ratio of Green functions $E(x,\xi)/E(x_0,\xi)$ has a continuous extension to the compact space $Q\cup\partial Q\cup\{\infty\}$ as a function of ξ for any x, x_0 in Q. We keep x_0 fixed and denote the extension of $E(x,\xi)/E(x_0,\xi)$ by $K(x,\Xi)$ where $\Xi\in\partial Q\cup\{\infty\}$ and $x\in Q$.

Let us find $K(x,\Xi)$

$$\lim_{\xi\to\Xi}\frac{E(x,\xi)}{E(x_0,\xi)}=\lim_{\xi\to\Xi}\frac{\hat{E}(x,\xi)}{\hat{E}(x_0,\xi)}=K(x,\Xi). \tag{3.1}$$

To calculate the limit (3.1) we will treat two cases: $\Xi\in\partial Q$ and $\Xi=\{\infty\}$. In the first case, without loss of generality, we may assume that Ξ_n, the nth coordinate of Ξ, is zero in (3.1); otherwise, we merely interchange the last two coordinates, namely,

$$\Xi=(\Xi_1,\Xi_2,\cdots,\Xi_{n-1},0).$$

It is easily seen that

$$\hat{E}(x,\xi)=2^{p+q-2}\frac{\Gamma(k)}{\pi^{n/2}}\cdot\frac{\Gamma(p/2)}{\Gamma(p)}\cdot\frac{\Gamma(q/2)}{\Gamma(q)}\cdot|x-\xi|^{-2k}\cdot F_A\left(k,\frac{p}{2},\frac{q}{2},p,q,-\varepsilon_1^{-2},-\varepsilon_2^{-2}\right)$$

where

$$(\varepsilon_1,\varepsilon_2)=\left(\frac{|x-\xi|}{\sqrt{4x_{n-1}\xi_{n-1}}},\frac{|x-\xi|}{\sqrt{4x_n\xi_n}}\right)$$

and F_A is the function of Lauricella [16]. So,

$$\lim_{\xi\to\Xi}\hat{E}(x,\xi)=\frac{2^{p+q-2}\Gamma(p/2)\Gamma(q/2)}{\pi^{n/2}\Gamma(p)\Gamma(q)}\cdot|x_0-\Xi|^{-2k}\cdot F_A\left(k,\frac{p}{2},\frac{q}{2},p,q,-\frac{4\Xi_{n-1}x_{n-1}}{|x-\Xi|^2},0\right)$$

and also

$$\lim_{\xi\to\Xi}\hat{E}(x_0,\xi)=\frac{2^{p+q-2}\Gamma(p/2)\Gamma(q/2)}{\pi^{n/2}\Gamma(p)\Gamma(q)}|x_0-\Xi|^{-2k}\cdot F_A\left(k,\frac{p}{2},\frac{q}{2},p,q,\frac{-4\Xi_{n-1}x_{0_{n-1}}}{|x_0-\Xi|^2},0\right).$$

Thus we consider $\lim_{\xi\to\Xi}\hat{E}(x,\xi)/\hat{E}(x_0,\xi)$.

It is obvious from the integral representation for $\hat{E}_{p,q}(x,\xi)$ that the denominator and numerator are both nonzero and so this is equal to

$$\left|\frac{x-\Xi}{x_0-\Xi}\right|^{-2k}\cdot\frac{F_A\left(k,\frac{p}{2},\frac{q}{2},p,q,-\frac{4\Xi_{n-1}x_{n-1}}{|x-\Xi|^2},0\right)}{F_A\left(k,\frac{p}{2},\frac{q}{2},p,q,-\frac{4\Xi_{n-1}x_{0_{n-1}}}{|x_0-\Xi|^2},0\right)}=K(x,\Xi). \tag{3.2}$$

Furthermore, if the $(n-1)$th coordinate of Ξ, Ξ_{n-1} is zero then it is clear that

$$\lim_{\xi\to\Xi}\frac{E(x,\xi)}{E(x_0,\xi)}=\left|\frac{x-\Xi}{x_0-\Xi}\right|^{-2k}=K(x,\Xi). \tag{3.3}$$

In the second case, $|\xi|\to\infty$, and by using (2.1), (3.1) a calculation shows that

$$\lim_{|\xi|\to\infty}\frac{E(x,\xi)}{E(x_0,\xi)}=1. \tag{3.4}$$

Now

$$\lim_{|\xi|\to\infty}\left[\frac{\frac{|x-\xi|^2}{|\xi|^2}+\frac{4x_{n-1}\xi_{n-1}}{|\xi|^2}\sin^2\frac{\theta_1}{2}+\frac{4x_n\xi_n}{|\xi|^2}\sin^2\frac{\theta_2}{2}}{\frac{|x_0-\xi|^2}{|\xi|^2}+\frac{4x_{0_{n-1}}\xi_{n-1}}{|\xi|^2}\sin^2\frac{\theta_1}{2}+\frac{4x_n\xi_n}{|\xi|^2}\sin^2\frac{\theta_2}{2}}\right]^{-k}=\lim_{|\xi|\to\infty}\left[\frac{\sigma(x,\xi)}{\sigma(x_0,\xi)}\right]^{-2k}\to 1.$$

This limit is uniform in θ_1, θ_2 and it leads us to the result (3.4).

(b) The case where p and $q<1$. In this case we can use the correspondence principle; i.e., a function u is a solution of $L_{2-p,2-q}[u]=0$ if and only if $v=x_{n-1}^{1-p}\cdot x_n^{1-q}\cdot u$ is a solution of $L_{p,q}[v]=0$.

Note that the transformation is order preserving and so it preserves minimality, etc.

Using (3.1) we take $K(x,\Xi)$ as u and we get K^1 as v where

$$K^1(x,\Xi)=x_{n-1}^{1-p}\cdot x_n^{1-q}K(x,\Xi).$$

We replace p and q by $2-p$, $2-q$ in (3.1):

$$x_{0_{n-1}}^{1-p}\cdot x_{0_n}^{1-q}\cdot K^1=\begin{cases}x_{n-1}^{1-p}\cdot x_n^{1-q}\cdot K(x,\Xi), & \Xi_{n-1}\neq 0, \quad (3.2')\\ x_{n-1}^{1-p}\cdot x_n^{1-q}\cdot\left|\frac{x-\Xi}{x_0-\Xi}\right|^{p+q-2-n}, & \Xi_{n-1}=\Xi_n=0, \quad (3.3')\\ x_{n-1}^{1-p}\cdot x_n^{1-q}\cdot 1, & |\xi|\to\infty \quad (3.4')\end{cases}$$

where $K(x,\Xi)$ is defined in (3.2) with the parameters $2-p$, $2-q$.

(c) The case where p (or q) <1 and q (or p) >1. We can use the correspondence principle in the following form: a function u is a solution of $L_{2-p,q}[u]=0$ (or $L_{p,2-q}[u]=0$) if and only if $v=x_{n-1}^{1-p}\cdot u$ (or $v=x_n^{1-q}\cdot u$) is a solution of $L_{p,q}[v]=0$. Using the same argument as we did in case (b), we can find

$$x_{0_{n-1}}^{1-p}\cdot K^2=\begin{cases}x_{n-1}^{1-p}K(x,\Xi)[\text{or } x_n^{1-q}K(x,\Xi)], & \Xi_{n-1}\neq 0, \quad (3.2'')\\ x_{n-1}^{1-p}\left|\frac{x-\Xi}{x_0-\Xi}\right|^{p-q-n}\left(\text{or } x_n^{1-q}\left|\frac{x-\Xi}{x_0-\Xi}\right|^{q-p-n}\right), & \Xi_{n-1}=\Xi_n=0, \quad (3.3'')\\ x_{n-1}^{1-p}\cdot 1(\text{or } x_n^{1-q}\cdot 1), & |\xi|\to\Xi=\infty, \quad (3.4'')\end{cases}$$

where $K(x,\Xi)$ is also defined in (3.2) with the parameters $2-p$, q (or p, $2-q$).

4. The integral representation of the positive solutions of (1.1). Using the Harnack theorem we readily see that $K(x,\Xi)$ is a locally uniform limit of harmonic functions

in x and so in turn is harmonic [17]. Thus if μ is a finite positive measure on ∂Q, and we see that

$$h(x)=\int_{\partial Q} K(x,\Xi)\,d\mu(\Xi) \tag{4.1}$$

is a positive harmonic function on Q.

Letting Φ be a collection of functions $E(x,\xi)/E(x_0,\xi)$ and $\Omega=Q$, we see that $Q\cup\partial Q\cup\{\infty\}$ satisfies the role of $\hat{\Omega}$ in [14] and $\hat{\Omega}$ is the Constantinescu-Cornea compactification of Q. $\partial Q\cup\{\infty\}$ is the Martin boundary and also $\hat{\Omega}$ is called Martin space. Following Martin, as described in [14] or in the original article by Martin [13], any positive harmonic function u on Q may be expressed in the form

$$u(x)=\int_{\partial Q} K(x,\Xi)\,d\mu(\Xi) \tag{4.2}$$

where μ is a finite positive Radon measure. Moreover, if

$$\partial\tilde{Q}=\{\Xi|K(x,\Xi)\text{ is a minimal harmonic function}\}$$

then there is a measure $\tilde{\mu}$ on $\partial\tilde{Q}$ that also gives u and among measures supported by $\partial\tilde{Q}$ it is unique. This is because the cone of all positive harmonic functions on Q that are one at x_0 is a compact Choquet simplex and so every positive harmonic function is the barycenter of a unique measure on the extreme points and these in turn are just minimal harmonic functions.

The following definition is Martin's [13]: A function positive and harmonic in a given domain is called minimal— for this domain—if it dominates no positive harmonic function on the entire domain except for its own constant submultiples.

We wish to identify the minimal harmonic functions. It is evident that $\tilde{\partial}Q$ is nonempty—indeed, it must contain at least one $\Xi\neq\infty$ that does have $\Xi_n>0$; otherwise we note that in the case $p,q<1$ every positive harmonic function on Q (being an integral combination of such functions) would be zero on the boundary hyperplane $\Xi_n>0$. By a scaling argument if $K(x,\Xi)$ is minimal so is $K(x,\lambda\Xi)$, etc. Thus every $\Xi\in\partial Q$ with $\Xi_n>0$ (or $\Xi_{n-1}>0$) is in $\tilde{\partial}Q$.

PROPOSITION. *Let us suppose $p,q<1$, $u>0$ is a solution of* (1.1) *and u tends to zero on the ∂Q. Then u is proportional to $x_{n-1}^{1-p}\cdot x_n^{1-q}$ and so $x_{n-1}^{1-p}x_n^{1-q}$ is minimal.*

Proof. It is already known [6] that

$$u(x)=x_{n-1}^{1-p}\cdot x_n^{1-q}\int_{Q_r}\xi_{n-1}\xi_n J(x,\xi)g(\xi)\,dQ_r \tag{4.3}$$

is the unique solution of (1.1) in $Q\cap B_r^+$ taking on the boundary values g

$$\lim_{\substack{x\to\xi\\ \xi\in\partial B_r^+}} u(x)=g(\xi),\qquad x\in B_r^+,\quad \xi\in\partial B_r^+$$

where

$$J(x,\xi)=\frac{2(r^2-|x|^2)\Gamma\left(\dfrac{n+4-p-q}{2}\right)}{r\cdot\pi^{n/2}\cdot\Gamma\left(\dfrac{2-p}{2}\right)\Gamma\left(\dfrac{2-q}{2}\right)}\int_0^{\pi}\int_0^{\pi}\sigma^{p+q-n-4}\sin^{1-p}\theta_1\cdot\sin^{1-q}\theta_2\,d\theta_1\,d\theta_2,$$

$$B_r^+=\{x\colon |x|<r,\ x=(x_1,\cdots,x_n)\in\mathbb{R}^n,\ x_{n-1},x_n>0\},$$

$$Q_r=\{x\colon |x|=r,\ x=(x_1,\cdots,x_n)\in\mathbb{R}^n,\ x_{n-1},x_n>0\}.$$

Now we need to show that for each $x', x'' \in B_r^+$

$$\lim_{|\Xi|=r\to\infty} \frac{u(x')/x_{n-1}'^{1-p} \cdot x_n'^{1-q}}{u(x'')/x_{n-1}''^{1-p} \cdot x_n''^{1-q}} \to 1. \tag{4.4}$$

It is obvious that

$$\lim_{r\to\infty} \frac{(r^2-|x'|^2)/r}{(r^2-|x''|^2)/r} \to 1, \qquad \lim_{r\to\infty} \frac{\sigma^{p+q-n-4}(x')}{\sigma^{p+q-n-4}(x'')} \to 1.$$

The last limit is uniform in θ_1, θ_2. Thus,

$$\lim_{|\Xi|\to\infty} \frac{\int_0^\pi \int_0^\pi \sigma^{p+q-n-4}(x') \sin^{1-p}\theta_1 \sin^{1-q}\theta_2 \, d\theta_1 \, d\theta_2}{\int_0^\pi \int_0^\pi \sigma^{p+q-n-4}(x'') \sin^{1-p}\theta_1 \sin^{1-q}\theta_2 \, d\theta_1 \, d\theta_2} \to 1.$$

From this result, we can see that (4.4) is satisfied.

In this proof, $x', x'' \in B_r^+$ are any points in B_r^+, so (4.4) is true in whole B_r^+. Then we can write the following result:

$$\frac{u(x')/x_{n-1}'^{1-p} x_n'^{1-q}}{(x'')/x_{n-1}''^{1-p} \cdot x_n''^{1-q}} = 1. \tag{4.5}$$

This leads to the following result:

$$u(x) = \alpha \cdot x_{n-1}^{1-p} \cdot x_n^{1-q}. \tag{4.6}$$

In (4.5) and (4.6) x, x', x'' are any points in B_r^+. If $u(x)$ is a solution of (1.1) then the function

$$u\left(\frac{x_1}{|x|^2}, \ldots, \frac{x_n}{|x|^2}\right) \cdot |x|^{2-n-p-q}$$

is also a solution of the same equation.

This transformation preserves the property of being minimal (and other properties coming from order structure). It is a Kelvin transformation [12], [18]. Using this inversion we deduce that $K(x, \Xi)$ is minimal for all Ξ in $\Xi_{n-1} = \Xi_n = 0$, and hence for all Ξ on the Martin boundary when $p, q < 1$. In this case we therefore have that any positive solution u to $L_{p,q}(u) = 0$ is of the form

$$u(x) = \int_{\partial Q \cup \{\infty\}} K(x, \Xi) \, d\mu$$

where μ is a uniquely determined Radon measure.

We can transfer to the other cases for p, q by using the correspondence principle. The appropriate formulae for $K(x, \Xi)$ are given by

(a) (3.2), (3.3), (3.4) when $p, q > 1$,

(b) (3.2′), (3.3′), (3.4′) when $p, q < 1$,

(c) (3.2″), (3.3″), (3.4″) when $p < 1$, $q > 1$ (or $p > 1$, $q < 1$).

Using Theorem 3 of [6] the kernel gives a unique integral representation for every positive solution of (1.1).

The cases where $p = 1$ (or $q = 1$) and $p = q = 1$ can be treated easily.

Acknowledgment. The author expresses his gratitude to Professor Terry J. Lyons, Department of Mathematics, University of Edinburgh, for suggesting the topic and for his guidance throughout the development of this work.

EXISTENCE OF SOLUTIONS TO THE STOMMEL–CHARNEY MODEL OF THE GULF STREAM*

V. BARCILON†, P. CONSTANTIN‡, AND E. S. TITI§

Abstract. The existence of weak solutions to the equations proposed by Stommel [*Trans. Amer. Geophys. Union*, 29 (1948), pp. 202–206] and Charney [*Proc. Nat. Acad. Sci. U.S.A.*, 41 (1955), pp. 731–740] as a model of the Gulf Stream are established by means of the method of artificial viscosity.

Key words. Navier–Stokes equations, artificial viscosity, ocean circulation

AMS(MOS) subject classifications. 35Q10, 76U05

1. Introduction. In this paper, we examine the mathematical properties of an equation arising in the theory of ocean circulation. In order to understand the role of this problem in oceanography, a brief review of the subject is necessary. The first successful attempt to provide a mathematical description of the mid-latitude ocean currents was made by Stommel [13] in 1948. He showed conclusively that a Gulf Stream-like intensification on the western side of an ocean basin could be explained by the so-called β-effect. This is the geophysical terminology for the latitudinal variation of the normal component of the earth's rotation. Aside from this variable Coriolis force, the other forces which entered into Stommel's model were those due to the pressure gradient, the surface winds, and friction. For the sake of simplicity, this last force was taken to be proportional to the velocity fields. All the effects of density stratification were neglected by making the assumption that the ocean was homogeneous. Finally, by working with vertical averages, Stommel essentially treated the ocean circulation as a two-dimensional horizontal motion. Somewhat surprisingly, Stommel's ad hoc, linear model was shown later to provide an accurate description of an actual experimental setup [12]. In particular, it is now well known that the Rayleigh friction terms included in Stommel's model arise quite naturally from a consideration of frictional effects near the ocean bottom.

The subsequent work in the field has attempted to overcome the two oversimplifications of Stommel's model, namely, to take into account inertial forces that are known to be important in the vicinity of the Gulf Stream and to represent more adequately the complex mixing/dissipative processes. These two broad generalizations were initiated by Charney [5] and Munk and Carrier [10], respectively. Although these early papers make use of analytical techniques, the bulk of the recent work in the field has relied on numerical techniques to study the nonlinear problems arising in the mathematical formulation of wind-driven ocean circulation models. The papers by Bryan [4] and Veronis [15], [16] fall within this category.

In this paper, we study the inertial extension of Stommel's model, namely

$$\varepsilon\Delta\psi+\frac{\partial\psi}{\partial x_1}+R\left(\frac{\partial\psi}{\partial x_1}\frac{\partial\Delta\psi}{\partial x_2}-\frac{\partial\psi}{\partial x_2}\frac{\partial\Delta\psi}{\partial x_1}\right)=f \tag{1.1}$$

in a bounded domain Ω in R^2 with Dirichlet boundary conditions. Just as in Stommel's paper, ψ is the streamfunction of the vertically averaged horizontal velocity fields. Hence, $\Delta\psi$ is the vertically integrated relative planetary vorticity which we will also denote by ω. The right-hand side f represents the driving due to the curl of the applied surface wind stress. Each of the terms on the left-hand side has a physical interpretation: the first represents the loss of vorticity by frictional processes along the ocean bottom, the second the gain in vorticity due to a northern flow (this is the β-effect), and the third the advection of vorticity by the circulation. Thus, the above equation represents the vorticity budget of a column of fluid in the ocean. The parameters R and ε arise as a result of the nondimensionalization of the various fields. Such a nondimensionalization can be carried out in several different ways depending upon which process controlling the vorticity is perceived as being crucial. In the ocean, measurements suggest that the prevailing balance is the so-called Sverdrup balance in which the β-effect is comparable to the wind curl. This is why the corresponding terms in (1.1) have unit coefficients. The other terms in (1.1) represent small departures from this balance. Thus, we consider both R and ε as small parameters. They represent, respectively, the importance of inertial and frictional effects relative to the β-effect. The interested reader is referred to Pedlosky [11] for a very thorough discussion of the derivation of this equation.

The main result of this paper is the proof of the existence of weak solutions to (1.1). These weak solutions are obtained as limits of solutions of auxiliary equations with artificial viscosity and artificial boundary conditions. Physically, this auxiliary problem corresponds to the addition of side-wall friction and stress-free boundary conditions. We derive uniform L^∞ bounds for the solutions of the auxiliary equations. This procedure cannot yield classical solutions because the artificial boundary conditions give rise to boundary layers in the classical limit. Nevertheless, we expect the solutions to be classical in certain parameter ranges.

The same method was used by Yudovitch [17] in his paper dealing with the time-dependent two-dimensional Euler equations. This method cannot be extended to the time-independent Euler equations. Actually, it is known [9] that the time-independent Euler equations have no solutions for two- and three-dimensional axisymmetric domains and generic driving forces. However, because of the presence of the bottom friction term $\varepsilon\Delta\psi$, the method can be used for (1.1).

Once the estimates for the stationary problem (1.1) are understood, solutions for the time-dependent version of this problem

$$\frac{\partial\Delta\psi}{\partial t}+\varepsilon\Delta\psi+\frac{\partial\psi}{\partial x_1}+R\left(\frac{\partial\psi}{\partial x_1}\frac{\partial\Delta\psi}{\partial x_2}-\frac{\partial\psi}{\partial x_2}\frac{\partial\Delta\psi}{\partial x_1}\right)=f \tag{1.2}$$

with given initial conditions on $\Delta\psi$ can be obtained by applying the method of Yudovitch in a straightforward manner. The β-effect term does not create any serious difficulties. We can show that (1.2) has unique global solutions.

The problem of describing the set of stationary solutions is still open. We expect the solution to be unique only when ε is large compared to R.

2. Preliminaries. Let Ω be an open bounded set of R^2 with sufficiently smooth boundary $\partial\Omega$. We consider the system

$$\begin{aligned} &\varepsilon\omega + \frac{\partial\psi}{\partial x_1} + R\left(\frac{\partial\psi}{\partial x_1}\frac{\partial\omega}{\partial x_2} - \frac{\partial\psi}{\partial x_2}\frac{\partial\omega}{\partial x_1}\right) = f \quad \text{in } \Omega, \\ &\Delta\psi = \omega \qquad\qquad\qquad\qquad\qquad\qquad \text{in } \Omega, \\ &\psi = 0 \qquad\qquad\qquad\qquad\qquad\qquad\quad \text{on } \partial\Omega, \end{aligned} \tag{2.1}$$

where $f(x)$, $\varepsilon > 0$ and $R \geqq 0$ are given.

In this paper we study the existence of weak solutions of (2.1).

We denote by $H^s(\Omega)$ the usual Sobolev spaces of order s and by $H_0^1(\Omega)$ the closure of $C_0^\infty(\Omega)$ in the $H^1(\Omega)$ norm. We define

$$A = -\Delta$$

to be the negative Laplacian with domain $D(A) = H^2(\Omega) \cap H_0^1(\Omega)$. It is well known that A^{-1} is a compact linear self-adjoint positive operator in $L^2(\Omega)$ (cf. [2], [8]). The spectrum of A consists of an infinite sequence $0 < \lambda_1 < \lambda_2 \leqq \cdots$ of eigenvalues counted according to their multiplicities; $\lambda_n \to \infty$ as $n \to \infty$; the eigenfunctions $\{w_n\}$ provide an orthonormal basis in $L^2(\Omega)$. Finally, there exists a scale invariant constant c_0 such that $|\Omega| = c_0\lambda_1^{-1}$ where $|\Omega|$ denotes the area of Ω. The scalar product and norm in $L^2(\Omega)$ are denoted by $(\cdot,\cdot)$ and $|\cdot|$, respectively. A scalar product in $H_0^1(\Omega)$, in view of Poincaré's inequality, is

$$((u, v)) = \int_\Omega \nabla u(x) \cdot \nabla v(x)\, dx \quad \forall u, v \in H_0^1(\Omega),$$

and the corresponding norm is denoted by $\|\cdot\|$. The norm in $L^p(\Omega)$ for $1 \leqq p \leqq \infty$ is denoted by $\|\cdot\|_p$. It is known (cf. [2]) that on $D(A)$ the $H^2(\Omega)$ norm is equivalent to the $|A\cdot|$ norm, i.e., there exists a constant $c_1 > 0$ such that

$$c_1^{-1}|Au| \leqq \|u\|_{H^2(\Omega)} \leqq c_1|Au| \quad \forall u \in D(A).$$

Moreover, $D(A^{1/2}) = H_0^1(\Omega)$ and $\|\cdot\| = |A^{1/2}\cdot|$.

The bilinear bounded operator $J: H^1(\Omega) \times H^1(\Omega) \to L^1(\Omega)$ is defined as

$$J(\psi, \omega) = \frac{\partial\psi}{\partial x_1}\frac{\partial\omega}{\partial x_2} - \frac{\partial\psi}{\partial x_2}\frac{\partial\omega}{\partial x_1} \quad \forall \psi, \omega \in H^1(\Omega). \tag{2.2}$$

We need the following inequalities that correspond to various continuity properties of the operator J.

PROPOSITION 2.1. *Let $s_1, s_2, s_3 \geqq 0$ satisfy*

$$s_1 + s_2 + s_3 \geqq 1 \quad \text{if } s_i \neq 1 \quad \text{for all } i = 1, 2, 3$$

and

$$s_1 + s_2 + s_3 > 1 \quad \text{if } s_i = 1 \quad \text{for some } i = 1, 2, 3.$$

Then, there exists a scale invariant constant $c(s_1, s_2, s_3)$ such that

$$|(J(\psi, \omega), v)| \leqq c(s_1, s_2, s_3)\lambda_1^{(s_1+s_2+s_3)/2}\|\psi\|_{H^{s_1+1}(\Omega)} \cdot \|\omega\|_{H^{s_2+1}(\Omega)} \cdot \|v\|_{H^{s_3}(\Omega)}. \tag{2.3}$$

The reader is referred to [14] and [6] for the idea of the proof. We also note that

$$(J(\psi, \omega), v) = -(J(\omega, \psi), v) \tag{2.4}$$

for every $\psi \in H^{s_1+1}(\Omega)$, $\omega \in H^{s_2+1}(\Omega)$, and $v \in H^{s_3}(\Omega)$.

PROPOSITION 2.2. *For every* $\psi \in H^2(\Omega)$, $\omega \in H^1(\Omega)$ *and* $v \in H_0^1(\Omega)$ *we have*

$$(J(\psi, \omega), v) = -(J(\psi, v), \omega). \tag{2.5}$$

Proof. Because of Proposition 2.1 it is sufficient to show that (2.5) holds for $v \in C_0^\infty(\Omega)$ and $\psi, \omega \in C^\infty(\Omega)$. Let $\mathbf{u}$ be the vector $(-\partial\psi/\partial x_2, \partial\psi/\partial x_1)$; then we can write

$$(J(\psi, \omega), v) = \int_\Omega \nabla \cdot (\omega(x)\mathbf{u}(x))v(x)\, dx$$

$$= -\int_\Omega (\mathbf{u}(x) \cdot \nabla v(x))\omega(x)\, dx.$$

The following corollary is an immediate consequence of the above proposition.

COROLLARY 2.3.

$$(J(\psi, \omega), \omega) = 0 \quad \forall \psi \in H^2(\Omega), \quad \omega \in H_0^1(\Omega), \tag{2.6}$$

$$(J(\psi, \omega), \omega^p) = 0 \quad \forall \psi \in H^2(\Omega), \quad \omega \in D(A), \quad p = 1, 2, \cdots. \tag{2.7}$$

Proof. Equation (2.6) is a direct consequence of (2.5). Since $H^2(\Omega)$ is a Banach algebra (cf. [1]) we can easily verify that $\omega^p \in D(A)$, for $p = 1, 2, \cdots$, whenever $\omega \in D(A)$. We can then use (2.5) to deduce that

$$(J(\psi, \omega), \omega^p) = -(J(\psi, \omega^p), \omega),$$

while from direct computations

$$(J(\psi, \omega^p), \omega) = -p(J(\psi, \omega), \omega), \qquad p = 1, 2, \cdots,$$

which verifies (2.7), in view of (2.6). Let us note that (2.6) also holds for $\psi \in C^1(\bar{\Omega})$, $\omega \in C^1(\bar{\Omega})$, and $\nabla\psi$ normal to $\partial\Omega$.

3. A stationary problem with artificial viscosity. In this section we consider a singular perturbation of the stationary problem (2.1) obtained by adding an artificial viscosity term $-\nu A\omega$ and imposing homogeneous Dirichlet boundary conditions on ω. The artificial viscosity equation provides an approximate solution. Uniform bounds, independent of the viscosity ν will enable us to pass to the weak limit. In this process the boundary condition on ω is lost. The auxiliary problem is:

$$-\nu\Delta\omega + \varepsilon\omega + \frac{\partial\psi}{\partial x_1} + RJ(\psi, \omega) = f \quad \text{in } \Omega, \tag{3.1a}$$

$$-\Delta\psi + \omega = 0 \quad \text{in } \Omega, \tag{3.1b}$$

$$\psi = 0, \quad \omega = 0 \quad \text{on } \partial\Omega, \tag{3.1c}$$

where ν is given such that $0 < \nu < \varepsilon^3/8$ and $f \in L^\infty(\Omega)$.

3.1. Existence of solutions of the perturbed problem. We restate the problem: Find $(\omega, \psi) \in D(A) \times D(A)$ such that

$$\nu A\omega + \varepsilon\omega + \frac{\partial\psi}{\partial x_1} + RJ(\psi, \omega) = f, \tag{3.2a}$$

$$A\psi + \omega = 0. \tag{3.2b}$$

It is obvious that every solution (ω, ψ) of (3.2) is a solution to (3.1) in the distribution sense.

The following a priori estimates of the solutions of (3.2) will be needed.

LEMMA 3.1. *Let* $(\omega, \psi) \in D(A) \times D(A)$ *be a solution of* (3.2). *Then*

$$\nu \|\omega\|^2 + \frac{\varepsilon}{4} |\omega|^2 \leqq \frac{|f|^2}{\varepsilon} K(\varepsilon, \lambda_1), \tag{3.3}$$

$$\|\psi\|^2 \leqq 2|f|^2 K(\varepsilon, \lambda_1), \tag{3.4}$$

$$|A\psi|^2 \leqq \frac{4|f|^2}{\varepsilon^2} K(\varepsilon, \lambda_1), \tag{3.5}$$

and

$$\nu |A\omega| \leqq 2|f| + 2\sqrt{2}|f| K^{1/2}(\varepsilon, \lambda_1) \left[1 + \frac{R^2 c^2(\tfrac{1}{2}, \tfrac{1}{2}, 0) c_2^2}{\nu^{3/2} \varepsilon^{1/2}} |f|^2 K(\varepsilon, \lambda_1) \right], \tag{3.6}$$

where

$$K(\varepsilon, \lambda_1) = \left(1 + \frac{1}{\varepsilon^2 \lambda_1} \right).$$

Proof. Let $(\omega, \psi) \in D(A) \times D(A)$ be a solution to (3.2). Taking the scalar product of (3.2a) with ψ we get

$$\nu(A\omega, \psi) + \varepsilon(\omega, \psi) + \left(\frac{\partial \psi}{\partial x_1}, \psi \right) + R(J(\psi, \omega), \psi) = (f, \psi). \tag{3.7}$$

In view of (2.4) and (2.5), and of the fact that $(\partial\psi/\partial x_1, \psi) = 0$, (3.7) reduces to

$$\nu(A\omega, \psi) + \varepsilon(\omega, \psi) = (f, \psi),$$

or, because of (3.2b), to

$$\varepsilon \|\psi\|^2 \leqq \nu |\omega|^2 + |f||\psi|.$$

Using first Poincaré's inequality we can write

$$\varepsilon \|\psi\|^2 \leqq \nu |\omega|^2 + |f| \lambda_1^{-1/2} \|\psi\|.$$

Then by Young's inequality, we can write

$$\varepsilon \|\psi\|^2 \leqq \nu |\omega|^2 + \frac{|f|^2}{2\varepsilon\lambda_1} + \frac{\varepsilon}{2} \|\psi\|^2.$$

Finally, since $0 \leqq \nu \leqq \varepsilon^3/8$, we deduce

$$\|\psi\|^2 \leqq (2\nu/\varepsilon)|\omega|^2 + \frac{|f|^2}{\varepsilon^2 \lambda_1} \leqq \frac{\varepsilon^2}{4} |\omega|^2 + \frac{|f|^2}{\varepsilon^2 \lambda_1}.$$

If we take the scalar product of (3.2a) with ω and use (2.6) we obtain

$$\begin{aligned} \nu \|\omega\|^2 + \varepsilon |\omega|^2 &= -(\partial\psi/\partial x_1, \omega) + (f, \omega) \\ &\leqq \|\psi\| |\omega| + |f||\omega|, \end{aligned}$$

and by Young's inequality

$$\nu \|\omega\|^2 + \frac{\varepsilon}{2} |\omega|^2 \leqq \frac{\|\psi\|^2}{\varepsilon} + \frac{|f|^2}{\varepsilon}.$$

From the above inequality and (3.8) we deduce (3.3). From (3.3) and (3.8) we can easily obtain (3.4). Finally, (3.2b) and (3.3) directly imply (3.5).

To establish (3.6) we take the scalar product of (3.2a) with $A\omega$, from which we see that

$$\nu|A\omega|^2+\varepsilon\|\omega\|^2\leqq|(\partial\psi/\partial x_1, A\omega)|+R|(J(\psi,\omega), A\omega)|+|(f, A\omega)|,$$

$$\leqq\|\psi\|\,|A\omega|+R|(J(\psi,\omega), A\omega)|+|(f, A\omega)|.$$

By using (2.3) for $s_1=s_2=\frac{1}{2}$ and $s_3=0$, we get

$$\nu|A\omega|^2+\varepsilon\|\omega\|^2\leqq(\|\psi\|+Rc(\tfrac{1}{2},\tfrac{1}{2},0)\|\psi\|_{H^{3/2}(\Omega)}\|\omega\|_{H^{3/2}(\Omega)}+|f|)|A\omega|,$$

and by an interpolation inequality, we get

$$\nu|A\omega|^2+\varepsilon\|\omega\|^2\leqq(\|\psi\|+Rc(\tfrac{1}{2},\tfrac{1}{2},0)c_2\|\psi\|^{1/2}\|A\psi\|^{1/2}\|\omega\|^{1/2}|A\omega|^{1/2}+|f|)|A\omega|;$$

hence

$$\frac{\nu}{2}|A\omega|^2+\varepsilon\|\omega\|^2\leqq\left(\|\psi\|+\frac{R^2}{2\nu}c^2(\tfrac{1}{2},\tfrac{1}{2},0)c_2^2\|\psi\|\,|A\psi|\,\|\omega\|+|f|\right)|A\omega|.$$

Making use of (3.3), (3.4), and (3.5), we obtain (3.6).

LEMMA 3.2. *There exists at least one solution to problem* (3.2). *Moreover, every solution of* (3.2) *satisfies* (3.3)–(3.6).

Proof. One approach is to use the Galerkin approximation method based on the eigenfunctions of the operator A as in Constantin and Foias [6] and Temam [14] to show the existence of a solution to (3.2). The crucial point in this approach is to establish similar a priori estimates to the ones in (3.5)–(3.6) for the approximate solution.

Another approach is by the Leray–Schauder degree theory. Indeed, problem (3.2) is equivalent to

$$\begin{pmatrix}\omega\\ \psi\end{pmatrix}+\mathbf{K}(\psi,\omega)=\begin{pmatrix}A^{-1}f\\ 0\end{pmatrix} \tag{3.8}$$

where

$$\mathbf{K}(\psi,\omega)=\begin{pmatrix}\nu^{-1}A^{-1}[\varepsilon\omega+\partial\psi/\partial x_1+RJ(\psi,\omega)]\\ A^{-1}\omega\end{pmatrix}. \tag{3.9}$$

By Rellich's lemma and (2.3), we can show that the nonlinear mapping

$$\mathbf{K}: D(A)\times D(A)\to L^2(\Omega)\times L^2(\Omega)$$

is compact. Therefore, making use of the a priori estimates (3.5)–(3.6), we can conclude that (3.8) has at least one solution [3].

Remark 3.3. If $f\in C^\infty(\bar\Omega)$, then every solution $(\omega,\psi)\in D(A)\times D(A)$ of (3.2) satisfies (3.1) in the classical sense, namely $\psi, \omega\in C^\infty(\bar\Omega)$.

3.2. Uniform L^∞ bounds for the artificial viscosity problem. In (3.3), (3.4), and (3.5) we gave estimates for $|\omega|$, $\|\psi\|$, and $|A\psi|$, which were independent of ν. In this section we shall derive uniform (i.e., independent of ν) L^∞ estimates for every solution of (3.2) and for $0<\nu<\varepsilon^3/8$. We recall first the following known result in potential theory (see, e.g., [7]).

THEOREM 3.4. *Let $G(x, y)$ denote the Green function of the Laplacian operator in the domain with Dirichlet boundary conditions. Then, there exists two scale invariant constants c_3, c_4 such that*

$$|G(x, y)| \leqq c_3(1+|\log(\lambda_1^{1/2}|x-y|)|) \quad \forall x, y \in \Omega, \quad x \neq y, \tag{3.10}$$

and

$$\left|\frac{\partial G(x, y)}{\partial x_k}\right| \leqq \frac{c_4}{|x-y|} \quad \forall k = 1, 2, \quad x, y \in \Omega, \quad x \neq y. \tag{3.11}$$

Moreover, since

$$\phi(x) = \int_\Omega G(x, y)\Delta\phi(y)\, dy,$$

it follows that

$$\frac{\partial \phi(x)}{\partial x_k} = \int_\Omega \frac{\partial G(x, y)}{\partial x_k} \Delta\phi(y)\, dy. \tag{3.12}$$

THEOREM 3.5 (Uniform L^∞ bounds). *Let $(\omega, \psi) \in D(A) \times D(A)$ be a solution of* (3.2) (*or equivalently a solution of* (3.1)). *Then*

$$\|\omega\|_\infty \leqq \frac{2}{\varepsilon}\|f\|_\infty + \frac{64\pi^2 c_4^2 c_0^{1/2}}{\varepsilon^3 \lambda_1^{1/2}} |f| K^{1/2}(\varepsilon, \lambda_1) \tag{3.13}$$

and

$$\|\nabla\psi\|_\infty \leqq 4\sqrt{2\pi} c_4 c_0^{1/4} \lambda_1^{-1/4} \sqrt{\|\omega\|_\infty |\omega|}. \tag{3.14}$$

Note that (3.3) *provides a uniform upper bound for* $|\omega|$.

Proof. Let $\delta > 0$. We denote by $B_\delta(z)$ the ball in R^2 that is centered at z with radius δ. From (3.1a) and (3.13) we have

$$\nabla\psi(x) = \int_\Omega \nabla_x G(x, y)\omega(y)\, dy,$$

which, because of (3.11), implies

$$|\nabla\psi(x)| \leqq 2c_4 \int_\Omega \frac{|\omega(y)|}{|x-y|}\, dy,$$

or

$$|\nabla\psi(x)| \leqq 2c_4 \left\{ \int_{\Omega \cap B_\delta(x)} \frac{|\omega(y)|}{|x-y|}\, dy + \int_{\Omega \setminus B_\delta(x)} \frac{|\omega(y)|}{|x-y|}\, dy \right\}.$$

Using Hölder's inequality, we see that for odd integers $p \geqq 3$

$$|\nabla\psi(x)| \leqq 2c_4 \left\{ \|\omega\|_{p+1} \left(\int_{B_\delta(x)} |x-y|^{-(p+1)/p}\, dy \right)^{p/p+1} + \frac{|\omega|}{\delta} |\Omega|^{1/2} \right\},$$

i.e.,

$$|\nabla\psi(x)| \leqq 2c_4 \left\{ \|\omega\|_{p+1} (2\pi)^{p/p+1} \delta^{(p-1)/(p+1)} + \frac{|\omega|}{\delta} |\Omega|^{1/2} \right\}.$$

Therefore

$$\|\nabla\psi\|_\infty \leqq (4\pi c_4)\|\omega\|_{p+1} \delta^{p-1/p+1} + 2c_4 |\Omega|^{1/2} \frac{|\omega|}{\delta}. \tag{3.15}$$

In order to get an estimate for $\|\omega\|_{p+1}$, we multiply (3.1a) by $\omega^p(x)$ and integrate over Ω. This leads to

$$-\nu\int_\Omega \Delta\omega(x)\omega^p(x)\,dx+\varepsilon\int_\Omega \omega^{p+1}(x)\,dx+R(J(\psi,\omega),\omega^p)=-\left(\frac{\partial\psi}{\partial x_1},\omega^p\right)+(f,\omega),$$

or, after integrating by parts and using (2.7), to

$$p\nu\int_\Omega |\nabla\omega(x)|^2\omega^{p-1}(x)\,dx+\varepsilon\int_\Omega \omega^{p+1}(x)\,dx=-\left(\frac{\partial\psi}{\partial x_1},\omega^p\right)+(f,\omega).$$

Using Hölder's inequality as well as the fact that p is an odd integer, we conclude that

$$\varepsilon\|\omega\|_{p+1}^{p+1}\leqq\|\nabla\psi\|_\infty\|\omega\|_p^p+\|f\|_{p+1}\|\omega\|_{p+1}^p,$$

or

$$\varepsilon\|\omega\|_{p+1}^{p+1}\leqq(\|\nabla\psi\|_\infty|\Omega|^{1/p+1}+\|f\|_{p+1})\|\omega\|_{p+1}^p. \tag{3.16}$$

Substituting (3.15) in (3.16) we see that

$$\varepsilon\|\omega\|_{p+1}\leqq\|f\|_{p+1}+(4\pi c_4)|\Omega|^{1/(p+1)}\delta^{(p-1)/(p+1)}\|\omega\|_{p+1}+2c_4|\Omega|^{(p+3)/2(p+1)}\frac{|\omega|}{\delta}. \tag{3.17}$$

If we choose $\delta=(\varepsilon/8\pi c_4)|\Omega|^{-1/(p-1)}$, then (3.17) implies that

$$\|\omega\|_{p+1}\leqq\frac{2}{\varepsilon}\|f\|_{p+1}+\frac{4\pi c_4}{\varepsilon}\left(\frac{8\pi c_4}{\varepsilon}|\Omega|^{1/2}\right)^{p+1/p-1}|\Omega|^{1/p+1}|\omega|. \tag{3.18}$$

Passing to the limit as $p\to\infty$, we conclude that

$$\|\omega\|_\infty\leqq\frac{2}{\varepsilon}\|f\|_\infty+\frac{32\pi^2c_4^2}{\varepsilon^2}|\Omega|^{1/2}|\omega|. \tag{3.19}$$

After replacing $|\Omega|$ in the above expression by $c_0\lambda_1^{-1}$ and using (3.3), we obtain (3.13).

In order to derive (3.14), we observe that (3.15) holds for every $\delta>0$. Therefore

$$\|\nabla\psi\|_\infty\leqq(4\pi c_4)\|\omega\|_\infty\delta+2c_4|\Omega|^{1/2}\frac{|\omega|}{\delta}. \tag{3.20}$$

Minimizing the right-hand side, we deduce that

$$\|\nabla\psi\|_\infty\leqq4\sqrt{2\pi}c_4|\Omega|^{1/4}\sqrt{\|\omega\|_\infty|\omega|},$$

and after replacing $|\Omega|$ by $c_0\lambda_1^{-1}$, we obtain (3.14).

4. Existence of weak solutions. Let $\{\nu_k\}_{k=1}^\infty$ be an arbitrary sequence of real numbers, $\nu_k\in(0,\varepsilon^3/8)$ for $k=1,2,\cdots$, and such that $\nu_k\to0$ as $k\to\infty$. Let (ω_k,ψ_k) be a sequence of solutions to problem (3.1) corresponding to $\nu=\nu_k$ for $k=1,2,\cdots$, respectively. By Lemma 3.2, we know that such sequences exist.

THEOREM 4.1. *There exists a $\psi\in D(A)$ and an $\omega\in L^\infty(\Omega)$ that are weak solutions of the stationary problem* (2.1), *i.e.*,

$$\begin{aligned}&\varepsilon\omega+\frac{\partial\psi}{\partial x_1}+R\nabla\cdot(\omega\mathbf{u})=f && \text{in } \Omega,\\ &\Delta\psi=\omega && \text{in } \Omega,\\ &\psi=0 && \text{on } \partial\Omega,\end{aligned} \tag{4.1}$$

where $\mathbf{u}=(-\partial\psi/\partial x_2, \partial\psi/\partial x_1)$. *Furthermore,* ψ *and* ω *satisfy*

$$|\omega| \leqq \frac{2|f|}{\varepsilon} K^{1/2}(\varepsilon, \lambda_1), \tag{4.2}$$

$$\|\omega\|_\infty \leqq \frac{2}{\varepsilon}\|f\|_\infty + \frac{64\pi^2 c_4^2 c_0^{1/2}}{\varepsilon^3 \lambda_1^{1/2}} |f| K^{1/2}(\varepsilon, \lambda_1), \tag{4.3}$$

$$\|\nabla\psi\|_\infty \leqq 4\sqrt{2\pi} c_4 c_0^{1/4} \lambda_1^{-1/4} \sqrt{\|\omega\|_\infty |\omega|}. \tag{4.4}$$

Proof. Let (ω_k, ψ_k) be as mentioned above. From (3.5) we know that

$$|A\psi_k| \leqq \frac{2|f|}{\varepsilon} K^{1/2}(\varepsilon, \lambda_1).$$

Therefore, there exists a subsequence, say $\{\psi_{k_1}\}$, that converges weakly in $H^2(\Omega)$ to $\psi \in H^2(\Omega)$, and by virtue of Rellich's lemma, ψ_{k_1} converges strongly to $\psi \in H^1(\Omega)$; hence $\psi \in D(A)$. From (3.13) we know that

$$\|\omega_{k_1}\|_\infty \leqq \frac{2}{\varepsilon}\|f\|_\infty + \frac{64\pi^2 c_4^2 c_0^{1/2}}{\varepsilon^3 \lambda_1^{1/2}} |f| K^{1/2}(\varepsilon, \lambda_1),$$

and therefore

$$\|\omega_{k_1}\|_p \leqq |\Omega|^{1/p}\left(\frac{2}{\varepsilon}\|f\|_\infty + \frac{64\pi^2 c_4^2 c_0^{1/2}}{\varepsilon^3 \lambda_1^{1/2}} |f| K^{1/2}(\varepsilon, \lambda_1)\right) \quad \forall p = 1, 2, \cdots. \tag{4.5}$$

By means of (4.5) we can inductively find, for every $p = 2, 3, \cdots$ a subsequence $\{\omega_{k_p}\}$ of $\{\omega_k\}$ that converges weakly in $L^p(\Omega)$ to the same limit $\omega \in L^p(\Omega)$ for every $p = 2, 3, \cdots$. In particular, we have

$$\|\omega\|_p \leqq \liminf_{k_p \to \infty} \|\omega_{k_p}\| \quad \forall p = 2, 3, \cdots,$$

which by (4.5) entails

$$\|\omega\|_p \leqq |\Omega|^{1/p}\left(\frac{2}{\varepsilon}\|f\|_\infty + \frac{64\pi^2 c_4^2 c_0^{1/2}}{\varepsilon^3 \lambda_1^{1/2}} |f| K^{1/2}(\varepsilon, \lambda_1)\right) \quad \forall p = 2, 3, \cdots. \tag{4.6}$$

Passing to the limit, we deduce (4.3). The derivations of (4.2) and (4.4) follow simply from (3.3) and (3.14). We will omit their proofs.

In conclusion, the diagonal subsequence $\{\omega_{k_k}\}$ converges weakly to $\omega \in L^p(\Omega)$ for every $p = 2, 3, \cdots$, and $\{\psi_{k_k}\}$ converges weakly to $\psi \in H^2(\Omega)$ and strongly in $H^1(\Omega)$. Because $\nabla\psi_{k_k}$ converges strongly in $L^2(\Omega)$ to $\nabla\psi$ and ω_{k_k} converges weakly in $L^2(\Omega)$, it follows that the product $(\nabla\psi_{k_k})(\omega_{k_k})$ converges to $(\nabla\psi)(\omega)$ in the distribution sense. Since $\{\omega_{k_k}, \psi_{k_k}\}$ solves (3.1) for $\nu = \nu_k$, by passing to the limit we can verify that (ω, ψ) solves (4.1).

Up to now, the parameter R did not enter at all in our estimates. In the next theorem, we give an upper bound to the "diameter" of the set of stationary solutions of problem (4.1).

THEOREM 4.2. *Let* (ψ_1, ω_1) *and* (ψ_2, ω_2) *be two weak solutions to problem* (4.1) *satisfying* (4.2)–(4.4). *Then*

$$\|\psi_1 - \psi_2\| \leqq \frac{4R}{\varepsilon} |f|^2 K(\varepsilon, \lambda_1)\left(\frac{2}{\varepsilon}\|f\|_\infty + \frac{64\pi^2 c_4^2 c_0^{1/2}}{\varepsilon^3 \lambda_1^{1/2}} |f| K^{1/2}(\varepsilon, \lambda_1)\right). \tag{4.7}$$

Proof. From (4.1) we have

$$\varepsilon\Delta(\psi_1-\psi_2)+\frac{\partial}{\partial x_1}(\psi_1+\psi_2)+R\ \mathrm{div}\,(\omega_1\mathbf{u}_1-\omega_2\mathbf{u}_2)=0,$$

or

$$\varepsilon\Delta(\psi_1+\psi_2)+\frac{\partial}{\partial x_1}(\psi_1-\psi_2)+R\ \mathrm{div}\,(\omega_1(\mathbf{u}_1-\mathbf{u}_2)+(\omega_1-\omega_2)\mathbf{u}_2)=0.$$

We form the scalar product with $(\psi_1-\psi_2)$ and, since $\psi_1-\psi_2\in H_0^1(\Omega)$, we can integrate by parts and obtain

$$\varepsilon\|\psi_1-\psi_2\|^2+R(\mathbf{u}_2(\omega_1-\omega_2),\nabla(\psi_1-\psi_2))=0. \tag{4.8}$$

From (4.8) we get

$$\varepsilon\|\psi_1-\psi_2\|^2\leqq R\|\omega_1-\omega_2\|_\infty|\mathbf{u}_2|\,\|\psi_1-\psi_2\|,$$

and hence

$$\|\psi_1-\psi_2\|\leqq\frac{R}{\varepsilon}\|\omega_1-\omega_2\|_\infty\|\psi_2\|. \tag{4.9}$$

As a consequence of Lemma 3.1 and Theorem 4.1,

$$\|\psi_2\|\leqq 2|f|^2K(\varepsilon,\lambda_1).$$

Substituting this expression and (4.3) in (4.9) we arrive at (4.7).

MULTIPLE TRAVELING WAVES IN A COMBUSTION MODEL*

S. P. HASTINGS†

Abstract. A model reaction scheme, consisting of two simple competing reactions $A \to P_1$ and $A \to P_2$, is studied using Arrhenius kinetics with a cut-off to handle the cold boundary difficulty. It is shown that for appropriate values of the parameters in the problem, the model equations have three distinct traveling wave solutions. The middle solution, presumably unstable, is obtained from a singularly perturbed problem by rigorous matching.

Key words. combustion, traveling waves

AMS(MOS) subject classifications. 35K57, 80A3D

1. Introduction. Recently there has been progress in the mathematical analysis of planar fronts in premixed combustion, thereby putting some rigorous buttressing around the walls of high activation energy asymptotics. For example, there are existence theorems for the simple reaction scheme $R \to P$, where R is the reactant and P the product, and also results justifying the inner and outer expansions developed by formal methods [1], [5], [8]. Similar results have been obtained for a chain reaction with two steps [7]. However, these models do not support strict traveling waves, unless artifical modifications are made in the usual Arrhenius reaction rate, because of the cold boundary difficulty [2]. By introducing intermediate variables, or radicals, this problem disappears, but the mathematical difficulties are considerably greater. Again, some progress has been made in proving existence of a flame [4], but much remains to be done.

One phenomenon that has not yet received a rigorous treatment is the possibility of several flames existing under the same conditions of temperature and concentration of the unburned mixture. Formal analysis was carried out by Clavin, Fife, and Nicolaenko [3], for the case of two competing reactions, with the scheme

(i) $R \to P_1$,
(ii) $R \to P_2$.

It was found that if the activation energies and rates of heat release of the two reactions are ordered correctly, then for a range of unburned reactant concentrations, two flames traveling at different speeds are possible. The relevant equations actually have three distinct solutions, but only two of these seem to be stable and therefore representative of real flames.

This is perhaps the simplest model from premixed combustion where such multiplicity is found, and our purpose here is to demonstrate rigorously the existence of at least three solutions. A defect in our result is that the simple model (i)-(ii) again suffers from the cold boundary difficulty, and the reaction rate term must be modified in order for any solution to exist. We hope eventually to combine the techniques used here with those from [4] to obtain a multiplicity result for a reaction scheme involving intermediate species and unmodified Arrhenius kinetics.

2.1. Statement of the result for simple kinetics. Let $k_1(T)$ and $k_2(T)$ define the temperature dependence of the reaction rates for (i) and (ii), respectively. It is assumed that there is a cutoff temperature T_-, below which k_1 and k_2 are both zero. Further,

it is assumed that there is a crossover temperature T^* such that $k_1(T) < k_2(T)$ for $T_- < T < T^*$ and $k_1(T) > k_2(T)$ for $T > T^*$. This results in expressions of the form

$$k_i(T) = e^{\theta_i(T-T^*)/TT^*} \quad \text{for } i = 1, 2, \text{ and } T > T_-$$

where $\theta_1 > \theta_2 > 0$. (It is convenient, but not necessary, for us to assume that both reactions are cut off at the same temperature.)

By appropriate rescaling, the differential equations become

$$Ley'' = y' + Dyk_1(T) + Dyk_2(T), \tag{1}$$

$$T'' = T' - Q_1 Dyk_1(T) - Q_2 Dyk_2(T), \tag{2}$$

where Le, Q_1, and Q_2 are given positive constants and D is an adjustable parameter. The boundary conditions to be considered are

$$y(-\infty) = y_u, \qquad T(-\infty) = 0 \tag{3}$$

and

$$y(\infty) = 0, \qquad T'(\infty) = 0, \tag{4}$$

where $y_u > 0$ is given. It is easily shown that the conditions (4) imply that $\lim_{x\to\infty} T(x)$ exists. However, this number, denoted by T_b for "burned state," is not specified ahead of time.

By a "solution" of (1)-(4) we mean a triple (D, y, T) where y and T satisfy the equations for the given value of D.

THEOREM. *Suppose that $Q_1 y_u > T^* > Q_2 y_u$. For any μ with $0 < \mu < 1$, there is a θ^* such that if $\theta^* \leqq \theta_2 \leqq \mu\theta_1$, then there are at least three distinct solutions of* (1)-(4).

2.2. Preliminary calculations and outline of proof. Henceforth we shall always assume that μ has been chosen and that $\theta_2 \leqq \mu\theta_1$. We use a shooting method, starting from $x = 0$, where x is the independent variable. We assume always that $T(0) = T_-$, $T'(0) = T_-$. Therefore $T(x) = T_- e^x$ for $x \leqq 0$, and T automatically satisfies the correct condition at $-\infty$. Also, if $y(0) = y'(0) + y_u$, then $y(x) = y'(0)e^x + y_u$ for $x \leqq 0$, and y also satisfies the desired condition at $-\infty$.

LEMMA 1. *Let*

$$\Gamma = \{(D, y'(0)) \mid y \text{ decreases on } (-\infty, \infty) \text{ and } y(+\infty) = 0\}.$$

Then Γ contains a continuum γ, which, for any $\bar{D} > \underline{D} > 0$, connects the line $D = \bar{D}$ with the line $D = \underline{D}$.

The proof will be given in § 2.3.

Let Δ denote the point $(D, y'(0))$. We assume from now on that Δ lies in γ. The problem is to choose this point so that $T'(\infty) = 0$. For each $D > 0$, let

$$\gamma_D = \{(\tilde{D}, y'(0)) \in \gamma \mid \tilde{D} = D\}.$$

We now define two subsets of the continuum γ:

$$A = \{\Delta \mid \text{for some } x > 0,\ T'(x) < 0\}$$

and

$$B = \{\Delta \mid \text{for some } x > 0,\ T(x) > T_1 = Q_1 y_u\}.$$

The following results will also be proved below.

LEMMA 2. *If D is positive but Δ does not lie in $A \cup B$, then the corresponding solution satisfies* (1)-(4).

LEMMA 3. *The sets A and B are open and disjoint.*

LEMMA 4. *If D is sufficiently large (depending on θ_1 and θ_2), then $\gamma_D \subset A$ and T' becomes negative before $T = T_2 \equiv Q_2 y_u$, while if D is positive but sufficiently small, then $\gamma_D \subset B$. Furthermore, there is an $\eta > 0$ such that for sufficiently large θ_2 and $\theta_2 \leqq \mu\theta_1$, T' cannot have a zero at a point where $T^* - \eta < T < T^* - \eta/2$.*

LEMMA 5. *For each sufficiently large θ_1, the set A is a disconnected subset of γ with at least three boundary points in γ.*

Lemma 5 is by far the most difficult of these results to prove. Lemmas 2-5 imply that there are at least three points in γ which do not lie in either A or B, and each of these corresponds to a solution of (1)-(4). Hence they imply the truth of our theorem.

2.3. Proofs of Lemmas 1–4. The first assertion of Lemma 1 follows from a straightforward shooting argument. We observe that y and y' cannot vanish simultaneously, unless y is identically zero. Also, if $y' = 0$ and $T > T_-$, then sign $(y'') =$ sign (y). This implies that the planar set

$$\Omega = \{(D, y'(0)) | D > 0,\ y'(0) > -y_u,$$
$$\text{and } y'(x) > 0 \text{ for some positive } x\}$$

is open and disjoint from the open set

$$\Lambda = \{(D, y'(0)) | D > 0,\ y'(0) > -y_u,$$
$$\text{and } y(x) < 0 \text{ for some } x > 0\}.$$

Furthermore, for fixed $D > 0$, if $y'(0) > 0$ then $(D, y'(0))$ lies in Ω, while if $y'(0)$ is sufficiently close to $-y_u$, then this point lies in Λ. Lemma 1 now follows from a result in topology.

PROPOSITION [6]. *If S is a square and P and Q are disjoint open sets containing, respectively, the right and left sides of S, then there is a continuum connecting the top and bottom of S within S and this continuum lies in the complement of $A \cup B$.*

Lemmas 2 and 3 are easily proved, and we omit the details.

The proof of Lemma 4 is a little harder, and requires the use of some techniques to be employed for Lemma 5 as well. Integrate (1) and (2) from $-\infty$ to x, using the boundary conditions (3), which we know are satisfied by our choice of $T(0)$, $T'(0)$, and $y(0)$ as a function of $y'(0)$. We obtain

$$Ley'(x) = y(x) - y_u + \alpha(x) + \beta(x), \tag{5}$$

$$T'(x) = T(x) - Q_1\alpha(x) - Q_2\beta(x) \tag{6}$$

where

$$\alpha(x) = \int_{-\infty}^{x} Dy(s) k_1(T(s))\, ds$$

and

$$\beta(x) = \int_{-\infty}^{x} Dy(s) k_2(T(s))\, ds.$$

It is obvious from (6) that $T'(x) \leqq T_2$ as long as $T \leqq T_2$, so we can find an $x_1 > 0$ such that $T(x_1) \leqq (T_2 + T_-)/2$ for any $\Delta \in \gamma$. (Recall that $T(0) = T'(0) = T_- < T_2$.) When we let $D \to \infty$, with Δ remaining in γ, there are two possibilities: either $y(x_1) \to 0$, or there is a $\delta > 0$ and a sequence of D's tending to ∞ such that $y(x_1) \geqq \delta$. In the latter

case it is clear that $Dyk_1(T)$ tends to infinity uniformly on $[0, x_1]$, which implies that T' becomes negative. In the former case, $y(x_1)$ and $y'(x_1)$ must both tend to zero. From (5) we see that $\alpha(x_1)+\beta(x_1)\to y_u$. Then, from (6),

$$Q_1\alpha(x_1)+Q_2\beta(x_1)>Q_2(y_u-\varepsilon)>T(x_1),$$

for some small $\varepsilon>0$ and sufficiently large D, which again implies that $T'(x_1)<0$.

The assertion that if D is small then $\gamma_D\subset B$ is easier and we omit the proof. For the last statement, suppose that $T'(x_0)=0$. From (6), $Q_1\alpha(x_0)+Q_2\beta(x_0)=T(x_0)$ and $\alpha(x_0)+\beta(x_0)<y_u$. Since T is increasing up to x_0, $\beta(x_0)/\alpha(x_0)\geqq k_2(T(x_0))/k_1(T(x_0))$. The latter ratio tends to infinity with θ_2 if $\theta_2\leqq\mu\theta_1$ and $T(x_0)<T^*-\delta$, for any fixed δ. Combining these shows that for some small η and for large θ_2, $T(x_0)\leqq T^*-\eta$.

2.4. Proof of Lemma 5 for a special case. We begin by discussing a restricted set of parameters in order to concentrate on the main idea of the proof. Later the extension to a full range as described in the theorem will be covered. Our assumption for the moment is that

$$T_2<T^*<(T_1+T_2)/2. \tag{7}$$

There are several steps in this proof, as given in the following additional lemmas.

LEMMA 6. *Fix $D=D^*$, an arbitrary positive number. Then for sufficiently large θ_1 and θ_2, chosen independently of Δ in γ_{D^*}, and $\theta_2\leqq\mu\theta_1$, Δ lies in the set A, but T increases to above T^* before T' becomes negative.*

Proof. This is the key result. Use is made of (5) and (6). Let

$$Q(x)=Q_1\alpha(x)+Q_2\beta(x).$$

Roughly, it is observed from (6) that T' becomes negative when $Q_1\alpha+Q_2\beta$ exceeds T. From (5) it is seen that $\alpha(x)+\beta(x)\to y_u$, as $x\to\infty$. As long as $T<T^*$, β/α is large, so Q cannot grow much above $Q_2y_u=T_2$. The type of solution described in Lemma 5 is only possible if T increases beyond T^* in such a way that α/β becomes large enough for Q to exceed T.

Reference must be made to a certain limiting solution of (1)-(3). Let y_0 and T_0 be the unique solution to (1)-(3) when $D=0$ such that $y_0(x)=0$ when $T_0(x)=T^*$. Thus,

$$y_0(x)=-y_ue^{(x-x^*)/Le}+y_u$$

and

$$T_0(x)=T_-e^x,$$

where $x^*=\log(T^*/T_-)$.

LEMMA 7. *For any fixed positive D, $T\to T_0$ uniformly in $[0, x^*]$ and uniformly in γ as long as D is held constant, as $\theta_2\to\infty$.*

Proof. It is easy to see that $T(x)<T_0(x)$ and $T'(x)<T_0'(x)$ for all $x>0$. If the result is false, then there must be a $\delta>0$ such that for a sequence of θ_2's tending to infinity, $T(x)\leqq T^*-\delta$ on $[0, x^*]$. Then, however, $k_1(T(x))$ and $k_2(T(x))\to 0$ uniformly on this interval. The initial conditions of T are the same as those for T_0, irrespective of θ_1 and θ_2, and Δ. It follows that T must tend to T_0 as claimed.

COROLLARY 1. *$\alpha(x)\to 0$ and $\beta(x)\to 0$ as $\theta_2\to\infty$, uniformly on $[-\infty, x^*]$ and in γ.*

Proof. The functions α and β are nondecreasing, with derivatives bounded by Dy_u as long as $T\leqq T^*$. The result follows from (6) and Lemma 7, since $T_0'=T_0$.

In the following result, D is still held constant.

LEMMA 8. *As $\theta_2\to\infty$, $y(x)\to y_0(x)$ uniformly on $[0, x^*]$.*

Proof. We first show that $y'(0)\to y_0'(0)$. First suppose that there is a $\delta>0$ such that, for arbitrarily large values of θ_2, $y'(0)\leqq y_0'(0)-\delta$. From Lemma 7 it follows that

the $k_i(T(x))$ tend to zero uniformly on compact subintervals of $[0, x^*)$, and this implies that y becomes negative for sufficiently large θ_2, because the solution of $y''=y'$, $y'(0)=y_0'(0)-\delta$, $y(0)=y'(0)+y_u$ becomes negative on the interval $[0, x^*]$. This contradicts the way $y'(0)$ is chosen.

Next, we suppose that for some $\delta>0$,

$$y'(0)\geqq y_0'(0)+\delta,$$

for an unbounded sequence of (positive) θ_2's. Then for these θ_2's,

$$y(x^*)\geqq\delta. \tag{8}$$

Also, $|y'|\leqq y_u$. Hence we see that

$$y(x)\geqq\delta-y_u(x-x^*) \tag{9}$$

on $I=[x^*, x^*+\delta_1]$, where $\delta_1=\delta/y_u$.

LEMMA 9. *Under our present assumptions, at least one of the terms $Dy(x)k_i(x)$ is unbounded on the interval $I_2=[x^*, x^*+\delta_1/2]$, that is, $\max_{x\in I_2}|Dyk_i(x)|\to\infty$ as $\theta\to\infty$.*

Proof. Suppose not, and there is an M such that $|Dy(x)k_i(x)|\leqq M$ on I_2, for each i. Then on this interval $|Q(x)|\leqq o(1)+M_1(x-x^*)$, where $M_1=m(Q_1+Q_2)$ and where $o(1)$ is a term which tends to 0 as $\theta_2\to\infty$. (We use the corollary above.) From (6) it then follows that unless T' becomes negative there is an $\varepsilon>0$ such that for large θ_2, $T(x)\geqq T^*+\varepsilon$ on $I_3=[x^*+\delta_1/4, x^*+\delta_1/2]$. However, this implies that $k_1(T)\to\infty$ uniformly on this interval, and this with (10) contradicts the assumption that $|Dyk_i|\leq M$ on I_2.

COROLLARY 2. *For at least one i, $Dyk_i(T)\to\infty$ as $\theta\to\infty$, uniformly in $[x^*+\delta_1/2, x^*+\delta_1]$.*

Proof. This follows because $d(yk_i(T))/dx$ is bounded below.

This corollary, with (9), leads immediately to the conclusion that y' becomes positive. This is a contradiction, and so we have proved that $y'(0)\to y_0'(0)$, which is Lemma 8.

In fact, what we have shown is that (8) is impossible for large enough θ_2. This proves the following lemma.

LEMMA 10. *As $\theta_2\to\infty$, $y(x)\to y_0(x)$ uniformly on $[0, x^*]$, and $y'(x)\to y_0'(x)$ uniformly on any compact subinterval of $[0, x^*)$, for a fixed value of D, and $\Delta\in\gamma_D$.*

Since $y(x^*)=0$, $y'(x)<0$, and $y(x)>0$ for all x, we have demonstrated that there is a "corner layer" at x for large θ_2 and fixed D. The following limits are all uniform in γ_{D^*}.

LEMMA 11. $\lim_{\rho\to0}\lim_{\theta\to\infty}y'(x^*-\rho)-y'(x^*+\rho)=-y_u$.

Proof. This follows from Lemma 8, because $y_0'(x^*)=-y_u$.

COROLLARY 3. $\lim_{\rho\to0}\lim_{\theta\to\infty}\{(\alpha+\beta)|_{x^*+\rho}-(\alpha+\beta)|_{x^*-\rho}\}=y_u$.

Proof. This follows by integrating (5) from $x^*-\rho$ to $x^*+\rho$ and using the definitions of α and β.

LEMMA 12. $\lim_{\rho\to0}\liminf_{\theta\to\infty}\alpha(x^*+\rho)/\beta(x^*+\rho)\geqq1$.

Proof. This crucial result requires several steps to prove.

(i) $T(x^*)\to T^*$ as $\theta_2\to\infty$. If not, then there is a $\delta>0$ and sequence of θ_2's tending to infinity such that $T(x^*)\leqq T^*-\delta$. Then $T(x)\leqq T^*-\delta$ on $[0, x^*]$. But this implies that each $k_i(T(x))\to0$ uniformly on $[0, x^*]$, which in turn implies that $T(x^*)$ does tend to $T_0(x^*)$, a contradiction.

(ii) As $\theta_2\to\infty$, $\alpha(x^*)\to0$ and $\beta(x^*)\to0$. Choose some $\varepsilon>0$. Then there is a $\delta>0$ such that $T\leqq T^*-\delta$ on $[0, x^*-\varepsilon]$, for all large θ_2. Then $\alpha(x^*-\varepsilon)\to0$. Also, $\alpha(x^*)\leqq\alpha(x^*-\varepsilon)+\varepsilon Dy_u$ because $T(x^*)\leqq T^*$. The proof for β is the same.

(iii) There is an $\hat{x} > x^*$ such that $T(\hat{x}) = T^*$, and $\hat{x} \to x^*$ as $\theta_2 \to \infty$. For each $\delta > 0$, $T'(x^* - \delta) \to T_0'(x^* - \delta)$. Also, $T_0'(x) \geqq T_-$ and $T'' \geqq T - Q_1 D - Q_2 D$ as long as $T \leqq T^*$. Therefore T crosses T^* near x^*.

(iv) As $\theta_2 \to \infty$, $\alpha(\hat{x}) \to 0$ and $\beta(\hat{x}) \to 0$. This is shown in the same way as (ii). Lemma 12 now follows because $\theta_1 \geqq \theta_2$ and $T(x^* + \rho) > T^*$ for large θ_2 and any given ρ.

LEMMA 13. $\lim_{\rho \to 0} \lim_{\theta_2 \to \infty} Q(x^* + \rho) > T^*$.

This follows from Lemmas 8 and 12, Corollary 3, and inequality (7).

In fact, for large θ_2, both α and β remain about constant beyond x^*. More precisely, we have Lemma 14.

LEMMA 14. *For any* $\rho > 0$, $\lim_{\theta_2 \to \infty} (\alpha(x) - \alpha(x^* + \rho)) = 0$ *and* $\lim_{\theta_2 \to \infty} (\beta(x) - \beta(x^* + \rho)) = 0$, *uniformly in* $[x^* + \rho, \infty)$. *Furthermore,* $\alpha(x^* + \rho) + \beta(x^* + \rho) \to y_u$.

Proof. The second assertion was already proved. The first assertion follows because α and β are nondecreasing, and from (5), because $y(\infty) = 0$.

COROLLARY 4. $\lim_{\theta_2 \to \infty} (Q(x) - Q(x^* + \rho)) = 0$ uniformly on $[x^* + \rho, \infty)$, and $\lim_{\theta_2 \to \infty} Q(x^* + \rho)$ exists and is greater than T^*.

The final step in the proof of Lemma 6 for the special case under consideration is to solve the differential equation (6) starting at $x = x^*$. We obtain

$$T(x) = e^{x - x^*}[T^* - Q(x^* + \rho) + O(\rho) + o(1) + O(e^{-x})]$$

for small ρ and large x as $\theta_2 \to \infty$. The desired conclusion that T' becomes negative for sufficiently large θ_2 follows.

The remainder of the proof of Lemma 5 is relatively routine, and we merely outline the steps. Fix some small $\delta < T^* - T_2$. For $T \leqq T^* - \delta$, k_2/k_1 is small for large θ_2, if $\theta_2 \leqq \mu\theta_1$. Therefore the second reaction (ii) dominates. It is not hard to show, using simple shooting, that this reaction supports a traveling wave, with final temperature $T_b = T_2$. For large θ_2, we can show that the pair of reactions supports a flame with T_b close to T_2. More precisely, we have seen that if D is sufficiently large, then $\Delta \in A$ and $T' = 0$ before $T = T_1$. In particular, consider some unbounded component γ_1 of A. By Lemmas 2 and 4, γ_1 is entirely contained in the region $D > D^*$, since the point where $T' = 0$ depends continuously on initial conditions and cannot jump from below $T^* - \eta$ to above T^*. Some point of γ_{D^*} defines a second component γ_2 of A, separated from γ_1 in γ. If D is sufficiently small, then $\Delta \in B$. Therefore γ_2 has at least two boundary points, one with $D > D^*$ and one with D below D^*. Any boundary point corresponds to a solution of (1)-(4). Suppose that there are only two boundary points of γ_2, and let p be the one with $D > D^*$.

LEMMA 15. *The point p is not a limit point of the set* γ_1.

Proof. p is a limit point of points in γ_2, and all these points correspond to solutions where T has a maximum above T^*. Therefore p corresponds to a solution such that $T(\infty) \geqq T^*$. It follows that nearby solutions must also reach at least $T^* - \eta/2$. This is impossible for points in γ_1.

It follows, therefore, that γ_1 has a boundary point different from any boundary point of γ_2. This proves Lemma 5 and our theorem in the special case.

2.5. The general case. We wish to remove the restriction (7), and allow any T^* between T_1 and $T_2 = Q_2 y_u$. This is accomplished by improving the estimate on α/β. In order to achieve a sufficiently large ratio α/β, it is clearly necessary that T increases beyond T^*. The statement to this effect in Lemma 6 must now be more precise.

Lemma 16. *Let* $K = ((T_1 - T_2)/(T_1 - T^*)) - 1$. *Choose a number* λ *so that*

$$e^{\lambda(1-\mu)} > K.$$

Then for sufficiently large θ_2, $(T - T^*)/TT^*$ *must exceed* λ/θ_1, *at some* x^{**} *such that* $x^{**} \to x^*$ *as* $\theta_2 \to \infty$. *Furthermore,* $\alpha(x^{**}) \to 0$ *and* $\beta(x^{**}) \to 0$ *as* $\theta_2 \to \infty$.

Proof. This improved estimate is obtained by modifying the argument for Corollary 1 of Lemma 7. The derivatives of α and β are bounded independent of θ_1, for fixed D, as long as $(T - T^*)/TT^* \leqq \lambda/\theta_1$. (Here λ is fixed as above, while $\theta_1 \to \infty$.) Therefore the same reasoning as used in Corollary 1 yields this improved result.

Now all the arguments subsequent to Corollary 1 are the same, if x^* is replaced by x^{**}. Note that

$$k_1/k_2 \geqq e^{\lambda(1-\mu)}$$

for $x \geqq x^{**}$. Therefore, for given $\rho > 0$ and sufficiently large θ, $\alpha(x^{**} + \rho)/\beta(x^{**} + \rho) \geqq K$. The definition of K, and the further result that $(\alpha + \beta)|_{x^{**}+\rho} \to y_u$ as $\theta \to \infty$, imply that $Q(x^{**} + \rho) > T^*$ for sufficiently large θ_2, and the result follows as before.

MAXWELL EQUATIONS IN POLARIZABLE MEDIA*

BERNARDO COCKBURN† AND PATRICK JOLY†

Abstract. The resolution of Maxwell equations in polarizable conductive media led to the resolution of a linear integrodifferential system. A method for the numerical approximation of this system was proposed in [B. Cockburn, *SIAM J. Sci. Statist. Comput.*, 6 (1985), pp. 843-852]. Here the mathematical results that justify this method are given.

Key words. Maxwell equations, polarizable media, integrodifferential systems, nonlocal operators, approximation by rational fractions

AMS(MOS) subject classifications. 41A20, 45K05, 78A99

Introduction. In [2], Cockburn proposed and described a method for the numerical approximation for the solution of the following integrodifferential system:

$$\mu \frac{\partial u}{\partial t}(x, t)+\frac{\partial v}{\partial x}(x, t)=0, \tag{0.1}_1$$

$$\sigma_\infty(x)v(x, t)+\int_0^t \tilde{\sigma}_1(x, t-s)v(x, s)\, ds+\frac{\partial u}{\partial x}(x, t)=0. \tag{0.1}_2$$

From both mathematical and numerical points of view, the main difficulty lies in the treatment of the nonlocal time-convolution operator appearing in $(0.1)_2$. Such a system arises when we consider the propagation of an electromagnetic field $(\mathbf{E}, \mathbf{H})$ in a one-dimensional conductive and polarizable medium. $(\mathbf{E}, \mathbf{H})$ satisfies the Maxwell equations that can be written in the space-frequency $(\mathbf{x}=(x, y, z), \omega)$ domain as follows:

$$\operatorname{curl} \mathbb{E}(\mathbf{x}, \omega)=i\mu\omega\, \mathbb{H}(\mathbf{x}, \omega), \qquad \operatorname{curl} \mathbb{H}(\mathbf{x}, \omega)=\sigma(x, \omega)\mathbb{E}(\mathbf{x}, \omega)$$

(here $\mathbb{E}$ and $\mathbb{H}$ denote the time Fourier transforms of $\mathbf{E}$ and $\mathbf{H}$).

The function $\sigma(x, \omega)$ is the (complex) conductivity of the medium. The dependence of σ on the frequency ω is determined by the polarizability of the medium (see Diaz [5] or Goldman [6] for further details concerning the physical model).

One of the most classical polarization laws is Warbourg's law, which corresponds to the formula

$$\sigma(\omega)=\sigma_0\left(\left(1+\lambda\left(i\frac{\omega}{\omega_c}\right)^{1/2}\right)\Big/\left(1+\left(i\frac{\omega}{\omega_c}\right)^{1/2}\right)\right) \qquad (\operatorname{Re}(\mathbf{Z}^{1/2})>0). \tag{0.2}$$

If the data are independent on y and z it can be shown that the fields $\mathbf{E}$ and $\mathbf{H}$ can be expressed as follows:

$$\mathbf{E}(\mathbf{x}, t)=E(x, t)\vec{y}_0, \qquad \mathbf{H}(\mathbf{x}, t)=H(x, t)\vec{z}_0.$$

Assuming that

$$\sigma(x, \omega)=\sigma_\infty(x)+\frac{1}{\sqrt{2\pi}}\int_0^{+\infty} \tilde{\sigma}_1(x, t)\, e^{-i\omega t}\, dt,$$

we then easily show that the pair $(u, v)=(E, H)$ is a solution of the system (0.1).

Of course, for the two- and three-dimensional cases, the fields $\mathbf{E}$ and $\mathbf{H}$ are solutions of an integrodifferential system analogous to (0.1) and our analysis will still be valid.

For the sake of simplicity, in this article we will only present results concerning the system (0.1).

The idea developed in [2] for treating the convolution operator consists in approximating this nonlocal operator by a local one. This can be achieved by approximating the kernel $t \to \tilde{\sigma}_1(x, t)$ by a sum of decreasing exponential functions, or equivalently, by approximating the time Fourier transform $\sigma_1(x, \omega)$ of this kernel by a sum of simple rational fractions.

More precisely, if we approximate $\sigma(x, \omega)$ by the following function:

$$\sigma_\infty(x) + \sum_{k=1}^{n} \frac{b_k(x)}{1 + i a_k(x)\omega}, \qquad b_k(x) > 0, \quad a_k(x) > 0, \quad k = 1, 2, \cdots, n, \tag{0.3}$$

then, as will be proved in §2, the system (0.1) can be approximated by the new system

$$\begin{cases} \mu \dfrac{\partial u}{\partial t} + \dfrac{\partial v}{\partial x} = 0, \\ \sigma_\infty v + \displaystyle\sum_{k=1}^{n} f_k + \frac{\partial u}{\partial x} = 0, \\ a_k \dfrac{\partial f_k}{\partial t} + f_k = b_k u, \qquad k = 1, 2, \cdots, n, \end{cases} \tag{0.4}$$

where the functions f_k are auxiliary functions related to the approximate kernel (0.3).

Thus, we have replaced a system of two integrodifferential equations by a system of $(n+2)$ differential equations, the numerical approximation of which is now classical (see [2], [3]).

In this article, our aim is to give some theoretical justifications of this approach. In § 1 we establish some preliminary results about the time convolution operator. In § 2 we give the mathematical analysis of the system (0.1) (existence, uniqueness, regularity, and continuity results with respect to σ).

Finally, in § 3, we provide a complete justification of our method in the case where the polarization is given by Warbourg's law (0.2). More precisely, we give the following: (1) A constructive process for obtaining the approximate polarization's law; and (2) An error estimate for the approximation of the solution of (0.1) by the solution of (0.4).

1. Mathematical properties of the convolution operator. Let us introduce the following notation. For $I \subset \mathbb{R}$, $\mathbb{L}^p(I)$ $(1 \leqq p < +\infty)$ will denote the space of L^p functions with complex values and $L^p(I)$ the subspace of $\mathbb{L}^p(I)$ of functions with real values. We will identify $\mathbb{L}^p(\mathbb{R}^+)$ with the subspace of functions $f(t)$ in $\mathbb{L}^p(\mathbb{R})$ that are 0 equal for $t < 0$. By $\mathscr{F}$ we will denote the Fourier transform in $\mathbb{L}^2(\mathbb{R})$ defined for regular functions $u(t)$ by

$$(\mathscr{F}u)(\omega) = \frac{1}{\sqrt{2\Pi}} \int_{-\infty}^{+\infty} u(t)\, e^{-i\omega t}\, dt.$$

($\mathscr{F}$ is an isometry in $\mathbb{L}^2(\mathbb{R})$.)

As a first step, we assume that the convolution kernel σ does not depend on the space variable x and we study the convolution operator formally defined by

$$(\phi_\sigma u)(t) = \sigma_\infty u(t) + \int_0^t \sigma_1(t-s) u(s)\, ds. \tag{1.1}$$

1.1. Study of the operator ϕ_σ.

1.1.1. The class of admissible polarization laws. We introduce the following set of complex functions:

$$\Sigma_\omega(\mathbb{R}) = \{\sigma(\omega) : \mathbb{R} \to \mathbb{C} \text{ satisfying (1.3), (1.4)}\}, \tag{1.2}$$

$$\exists(\sigma_\infty, \tilde{\sigma}_1(t)) \in \mathbb{R}_*^+ \times L^1(\mathbb{R}^+) \quad \forall \omega \in \mathbb{R} \quad \sigma(\omega) = \sigma_\infty + \frac{1}{\sqrt{2\Pi}} \int_{-\infty}^{+\infty} \tilde{\sigma}_1(t)\, e^{-i\omega t}\, dt, \tag{1.3}$$

$$\exists \sigma_* \in \mathbb{R}_*^+ \quad \forall \omega \in \mathbb{R} \quad \mathcal{R}e(\sigma(\omega)) \geqq \sigma_* > 0. \tag{1.4}$$

It is easy to verify that $\Sigma_\omega(\mathbb{R})$ has the following properties:

(1) $\Sigma_\omega(\mathbb{R})$ is an open, convex subset of the space $C_b^0(\mathbb{R})$ of complex functions that are continuous and bounded (with the L^∞ norm).

(2) For any σ in $\Sigma_\omega(\mathbb{R})$, we have the following:

$$\|\sigma\|_{L^\infty(\mathbb{R})} \leqq \sigma^* \qquad (\sigma^* = \sigma_\infty + \|\tilde{\sigma}_1\|_{L^1(\mathbb{R}^1)}),$$

$$\lim_{\omega \to \infty} \sigma(\omega) = \sigma_\infty,$$

$$\sigma(-\omega) = \overline{\sigma(\omega)},$$

$$|\sigma(\omega)| \geqq \mathcal{R}e(\sigma(\omega)) \geqq \sigma_*.$$

1.1.2. The operator $\hat{\phi}_\sigma$. We introduce the linear operator for $\sigma \in \Sigma_\omega(\mathbb{R})$:

$$\hat{\phi}_\sigma : \mathbb{L}^2(\mathbb{R}) \to \mathbb{L}^2(\mathbb{R}),$$

$$U(\omega) \to V(\omega) = (\hat{\phi}_\sigma U)(\omega),$$

$$V(\omega) = \sigma(\omega) U(\omega) \quad \text{a.e. } \omega \in \mathbb{R}.$$

Using the properties of σ it is easy to obtain the following Theorem.

THEOREM 1.1. *$\hat{\phi}_\sigma$ is a linear continuous operator in $\mathbb{L}^2(\mathbb{R})$, with continuous inverse $\hat{\phi}_\sigma^{-1}$. Moreover, we have*

$$\forall U \in \mathbb{L}^2(\mathbb{R}) \quad \sigma_* \|U\|_{L^2}^2 \leqq \mathcal{R}e(\hat{\phi}_\sigma U, U)_{L^2} \leqq \sigma^* \|U\|_{L^2}^2.$$

COROLLARY 1.1. *We have the following estimates*:

$$\|\hat{\phi}_\sigma\| \leqq \sigma^*, \qquad \|\hat{\phi}_\sigma^{-1}\| \leqq (\sigma_*)^{-1}.$$

1.1.3. The operator ϕ_σ in $\mathbb{L}^2(\mathbb{R})$. For every σ in $\Sigma_\omega(\mathbb{R})$, we define $\phi_\sigma = \mathcal{F}^{-1} \circ \hat{\phi}_\sigma \circ \mathcal{F}$

$$\begin{array}{ccc} \mathbb{L}^2(\mathbb{R}) & \xrightarrow{\phi_\sigma} & \mathbb{L}^2(\mathbb{R}) \\ \mathcal{F} \downarrow & & \downarrow \mathcal{F} \\ \mathbb{L}^2(\mathbb{R}) & \xrightarrow{\hat{\phi}_\sigma} & \mathbb{L}^2(\mathbb{R}) \end{array}$$

Since the operator $\mathcal{F}$ is unitary, we clearly have the following theorem.

THEOREM 1.2. *ϕ_σ is a continuous linear mapping in $\mathbb{L}^2(\mathbb{R})$. ϕ_σ is invertible and ϕ_σ^{-1} is continuous. Moreover,*

$$\forall u \in \mathbb{L}^2(\mathbb{R}) \quad \sigma_* \|u\|_{L^2}^2 \leqq \mathcal{R}e(\phi_\sigma u, u)_{L^2} \leqq \sigma^* \|u\|_{L^2}^2,$$

$$\|\phi_\sigma\| \leqq \sigma^* \quad \textit{and} \quad \|\phi_\sigma^{-1}\| \leqq (\sigma_*)^{-1}.$$

Using the properties of the Fourier transform with respect to the convolution and the fact that $\tilde{\sigma}_1$ is a causal integrable function, we easily establish the following theorem.

THEOREM 1.3. *For any u in $\mathbb{L}^2(\mathbb{R})$, $v = \phi_\sigma u$ is given by*

$$v(t) = \sigma_\infty u(t) + \int_{-\infty}^{t} \tilde{\sigma}_1(t-s)u(s)\,ds.$$

Knowing that $\tilde{\sigma}_1$ is a real function we deduce the following corollary.

COROLLARY 1.2. *ϕ_σ is a bijective operator from $L^2(\mathbb{R}^2)$ to itself. It maps $\mathbb{L}^2(\mathbb{R}^+)$ to $\mathbb{L}^2(\mathbb{R}^+)$ and when u belongs to $\mathbb{L}^2(\mathbb{R}^+)$*

$$\forall u \in \mathbb{L}^2(\mathbb{R}^+) \quad (\phi_\sigma u)(t) = \sigma_\infty(t) + \int_0^t \tilde{\sigma}_1(t-s)u(s)\,ds.$$

In this last formula, we can see that when the function u is causal, the value of $\phi_\sigma u$ at time t only depends on the values of u in the interval $[0, t]$ (we then say that the operator ϕ_σ is causal). This allows us to define the operator ϕ_σ on $L^2(0, T)$.

1.1.4. The operator ϕ_σ on $L^2(0, T)$. We now define

$$\phi_\sigma : L^2(0, T) \to L^2(0, T),$$
$$u \to \phi_\sigma u,$$
$$\phi_\sigma u(t) = \sigma_\infty u(t) + \int_0^t \tilde{\sigma}_1(t-s)u(s)\,ds.$$

The main result of this section is the following theorem.

THEOREM 1.4. *ϕ_σ is a linear, continuous, bijective mapping from $L^2(0, T)$ to $L^2(0, T)$, with continuous inverse ϕ_σ^{-1}. Moreover*

$$\forall u \in L^2(0, T) \quad \sigma_* \int_0^T |u(t)|^2 dt \leqq \int_0^T \phi_\sigma u(t)u(t)\,dt \leqq \sigma^* \int_0^T |u(t)|^2\,dt, \tag{1.5}$$

$$\|\phi_\sigma\| \leqq \sigma^* \quad \text{and} \quad \|\phi_\sigma^{-1}\| \leqq (\sigma_*)^{-1}$$

Proof of (1.5). Let u be in $L^2(0, T)$. We define the function $u^*(t)$ in $L^2(\mathbb{R})$ by

$$\begin{aligned} &u^*(t) = u(t) \quad \text{if } t \in [0, T], \\ &u^*(t) = 0 \qquad \text{if } t \notin [0, T]. \end{aligned} \tag{1.6}$$

Now we set

$$v = \phi_\sigma u \in L^2(0, T), \qquad v^* = \phi_0 u^* \in L^2(\mathbb{R}).$$

Since ϕ_σ is causal, we know that

$$\text{a.e.} \quad t \in [0, T] \quad v^*(t) = v(t). \tag{1.7}$$

From Theorem 1.2, we have

$$\sigma_*\left(\int_{-\infty}^{+\infty} |u^*(t)|^2\,dt\right) \leqq \int_{-\infty}^{+\infty} u^*(t)v^*(t)\,dt \leqq \sigma^*\left(\int_{-\infty}^{+\infty} |u^*(t)|^2\,dt\right).$$

But, thanks to (1.6) and (1.7), we have

$$\int_{-\infty}^{+\infty} u^*(t)v^*(t)\,dt = \int_0^T u(t)v(t)\,dt,$$
$$\int_{-\infty}^{+\infty} |u^*(t)|^2\,dt = \int_0^T |u(t)|^2\,dt.$$

Then (1.5) follows immediately. □

Remarks. It is clear that the inequalities (1.5) still hold if we replace T by any t in the interval $[0, t]$:

$$\forall t \in [0, T] \quad \sigma_* \int_0^t \|u(s)\|^2 \, ds \leqq \int_0^t \phi_\sigma u(s) u(s) \, ds \leqq \sigma^* \int_0^t \|u(s)\|^2 \, ds.$$

Note that the essential assumption to obtain the properties of ellipticity for ϕ_σ is

$$\mathcal{R}e(\sigma(\omega)) \geqq \sigma_* > 0 \quad \forall \omega > 0.$$

Finally, let us give a property of the operator ϕ_σ with respect to time derivation.

THEOREM 1.5. *For any function u in $H^1(0, T)$, we have*

$$\frac{d}{dt}(\phi_\sigma u) = \phi_\sigma\left(\frac{du}{dt}\right) + u(0)\tilde{\sigma}_1 \quad \text{in } \mathcal{D}'(0, t).$$

This identity is easily obtained in the sense of distributions. Note that this equality makes sense since $H^1(0, T) \hookrightarrow C^0(0, T)$ and $\tilde{\sigma}_1 \in L^1(0, T)$, so that $u(0)\,\tilde{\sigma}_1$ belongs to $L^1(0, T)$ and thus to $\mathcal{D}'(0, T)$.

1.1.5. Continuity of the mapping $\sigma \to \phi_\sigma$. $\Sigma_\omega(\mathbb{R})$ is a metric space with the distance induced by the L^∞-norm

$$\|\sigma_1 - \sigma_2\|_\infty = \sup_{\omega \in \mathbb{R}} |\sigma_1(\omega) - \sigma_2(\omega)|.$$

We now consider the mapping

$$\phi : \Sigma_\omega(\mathbb{R}) \to \mathcal{L}(L^2(0, T)),$$
$$\sigma \to \phi_\sigma.$$

Then we have Theorem 1.6.

THEOREM 1.6. *The application ϕ is a contraction from $\Sigma_\omega(\mathbb{R})$ onto $\mathcal{L}(L^2(0, T))$:*

$$\forall (\sigma_1, \sigma_2) \in \Sigma_\omega(\mathbb{R}) \quad \|\phi_{\sigma_1} - \phi_{\sigma_2}\| \leqq \|\sigma_1 - \sigma_2\|_\infty.$$

Proof. The result is obvious for the difference $\|\hat{\phi}_{\sigma_1} - \hat{\phi}_{\sigma_2}\|$. The result then follows using causality and Plancherel's theorem. □

Now we can consider the case where σ is also a function of the space variable x. Then we consider the operator ψ_σ formally defined by

$$(\psi_\sigma u)(x, t) = \sigma_\infty(x) u(x, t) + \int_0^t \tilde{\sigma}_1(x, t - s) u(x, s) \, ds.$$

1.2. Study of the operator ψ_σ.

Notation for § § 1.2 *and* 2. $\Omega =]0, +\infty[$; $x \in \Omega$ is the space variable. $(\cdot, \cdot)$ and $\|\cdot\|$ denote the usual scalar product and norm in $L^2(\Omega)$.

1.2.1. The class $\Sigma(\Omega; \mathbb{R})$ of admissible polarization laws. We now introduce the following set of functions:

$$\Sigma(\Omega; \mathbb{R}) = \{\sigma : \Omega \times \mathbb{R} \to \mathbb{C} / (1.8) \text{ and } (1.9)\},$$

(1.8) $\exists (\sigma_\infty, \tilde{\sigma}_1) \in L^\infty(\Omega) \times L^\infty(\Omega; L^1(\mathbb{R}^+))$ such that $\sigma_\infty(x) \geqq (\sigma_\infty)_* > 0$ a.e. $x \in \Omega$, and $\forall \omega \in \mathbb{R} \quad \sigma(x, \omega) = \sigma_\infty(x) + 1/\sqrt{2\Pi} \int_0^{+\infty} \tilde{\sigma}_1(x, t)\, e^{-i\omega t} \, dt$ a.e. $x \in \Omega$,

(1.9) $$\exists \sigma_* \in \mathbb{R}_*^+ / \text{a.e. } (x, \omega) \in \Omega \times \mathbb{R} \quad \mathcal{R}e(\sigma(x, \omega)) \geqq \sigma_* > 0.$$

Properties of $\Sigma(\Omega; \mathbb{R})$. (1) $\Sigma(\Omega; \mathbb{R})$ is an open and convex subset of $L^\infty(\Omega; C_b^0(\mathbb{R}))$ for the topology of $L^\infty(\Omega \times \mathbb{R})$.

(2) For any σ in $\Sigma(\Omega;\mathbb{R})$, almost everywhere $x\in\Omega\ \sigma(x,\cdot)\in\Sigma_\omega(\mathbb{R})$, and almost everywhere $(x,\omega)\in\Omega\times\mathbb{R}\quad 0<\sigma_*\leqq\sigma(x,\omega)\leqq\sigma^*<+\infty$ (where $\sigma^*=\|\sigma_\infty\|_{L^\infty(\Omega)}+\|\tilde{\sigma}_1\|_{L^\infty(0,\,L^1(\mathbb{R}^+))}$).

1.2.2. Definition and properties of ψ_σ. We define the operator

$$\psi_\sigma: L^2(0,T;L^2(\Omega))\to L^2(0,T;L^2(\Omega)),$$
$$u(x,t)\to v(x,t)=(\psi_\sigma u)(x,t),$$
$$v(x,t)=\sigma_\infty(x)u(x,t)+\int_0^t\tilde{\sigma}_1(x,t-s)u(x,s)\,ds.$$

All the results concerning ψ_σ can be deduced from those obtained in § 1.1 for ϕ_σ. It suffices to note that

$$\text{a.e. } x\in\Omega\quad(\psi_\sigma u)(x,\cdot)=\phi_{\sigma(x,\cdot)}u(x,\cdot).$$

Then Theorems 1.4 and 1.5 lead to the two following results.

THEOREM 1.7. *ψ_σ is a linear, continuous, invertible operator in $L^2(0,T;L^2(\Omega))$. Its inverse ψ_σ^{-1} is continuous and we have* ($t\in[0,T]$)

$$\forall u L^2(0,T;L^2(\Omega))\quad \sigma_*\int_0^t\|u(s)\|^2\,ds\leqq\int_0^t(\psi_\sigma u(s),u(s))\,ds\leqq\sigma^*\int_0^t\|u(s)\|^2\,ds,$$

$$\|\psi_\sigma\|\leqq\sigma^*\quad\textit{and}\quad\|\psi_\sigma^{-1}\|\leqq(\sigma_*)^{-1}.$$

THEOREM 1.8. *For any u in $H^1(0,T;L^2(\Omega))$, we have*

$$\frac{d}{dt}(\psi_\sigma u)=\psi_\sigma\left(\frac{du}{dt}\right)+\tilde{\sigma}_1(t)\times u(x,0)\quad\textit{in }\mathcal{D}'(0,T;L^2(\Omega)).$$

Finally, let us give to $\Sigma(\Omega;\mathbb{R})$ a metric space structure with the following distance:

$$\|\sigma_1-\sigma_2\|_\infty=\sup_{(x,\omega)\in\Omega\times\mathbb{R}}|\sigma_1(x,\omega)-\sigma_2(x,\omega)|$$

and let us consider the mapping

$$\psi:\Sigma(\Omega;\mathbb{R})\to\mathcal{L}(L^2(0,T;L^2(\Omega)),$$
$$\sigma\to\psi_\sigma.$$

From Theorem 1.6, we deduce Theorem 1.9.

THEOREM 1.9. *The mapping ψ is a contraction from $\Sigma(\Omega,\mathbb{R})$ into $\mathcal{L}(L^2(0,T;L^2(\Omega)))$:*

$$\forall(\sigma_1,\sigma_2)\in\Sigma(\Omega;\mathbb{R})^2\quad\|\psi_{\sigma_1}-\psi_{\sigma_2}\|\leqq\|\sigma_1-\sigma_2\|_\infty.$$

1.3. Two particular subsets of $\Sigma(\Omega;\mathbb{R})$.

1.3.1. The subset $\Sigma_w(\Omega;\mathbb{R})$ of Warbourg's law. Warbourg's law is defined by

$$\sigma(x,\omega)=\sigma_0(x)\left(1+\lambda(x)\left(i\frac{\omega}{\omega_c(x)}\right)^{1/2}\Big/1+\left(i\frac{\omega}{\omega_c(x)}\right)^{1/2}\right)\qquad(\mathcal{R}\mathrm{e}\,(\mathbf{Z}^{1/2})>0)\tag{1.10}$$

where $\sigma_0(x)$, $\lambda(x)$, and $\omega_c(x)$ are strictly positive functions. Note that we can write

$$\sigma(x,\omega)=\sigma_\infty(x)+(1-\lambda(x))\left(\sigma_0(x)\Big/1+\left(i\frac{\omega}{\omega_c(x)}\right)^{1/2}\right),$$

$$\sigma_\infty(x)=\lambda(x)\sigma_0(x)=\lim_{\omega\to\infty}\sigma(x,\omega).$$

THEOREM 1.10. *Under the following assumptions*:

$$0<(\sigma_0)_*\leqq\sigma_0(x)\leqq(\sigma_0)^* \quad a.e.\ x\in\Omega,$$

$$1\leqq\lambda_*\leqq\lambda(x)\leqq\lambda^* \quad a.e.\ x\in\Omega,$$

$$0<(\omega_c)_*\leqq\omega_c(x)\leqq(\omega_c)^* \quad a.e.\ x\in\Omega,$$

the law σ *defined by* (1.10) *belongs to* $\Sigma(\Omega;\mathbb{R})$.

Proof. We have to check that σ satisfies both properties (1.8) and (1.9). To prove this result we will use Lemma 1.1.

LEMMA 1.1. *Let* $f(t)$ *be the real and causal function defined by*

$$f(t)=\frac{1}{\sqrt{\Pi}}\left(\frac{1}{\sqrt{t}}-2\,e^{t}\int_{\sqrt{t}}^{+\infty}e^{-s^2}\,ds\right) \quad \text{if } t>0,$$

$$f(t)=0 \quad \text{if } t\leqq 0.$$

Then, f *is positive, belongs to* $L^1(\mathbb{R}^+)$, *and satisfies*

$$\|f\|_{L^1(\mathbb{R}^+)}=1.$$

Moreover its Fourier transform is given by

$$F(\omega)=(\mathscr{F}f)(\omega)=\frac{1}{1+(i\omega)^{1/2}}.$$

Proof of Lemma 1.1. (i) The calculation of $f(t)$ (as inverse Fourier transform of $\omega\to(1+(i\omega)^{1/2})^{-1}$) can be found in [4].

(ii) The positivity of $f(t)$ is a consequence of the following inequality:

$$\int_{\sqrt{t}}^{+\infty}e^{-s^2}\,ds=\int_{\sqrt{t}}^{+\infty}\frac{s\,e^{-s^2}}{s}\,ds\leqq\frac{1}{\sqrt{t}}\int_{\sqrt{t}}^{+\infty}s\,e^{-s^2}\,ds=\frac{1}{2\sqrt{t}}\,e^{-t}.$$

(iii) As $\lim_{t\to 0}e^{t}\int_{\sqrt{t}}^{+\infty}e^{-s^2}\,ds<+\infty$, we have

$$f(t)=\frac{1}{\sqrt{\Pi t}}+O(1) \quad \text{when } t\to 0.$$

(iv) A double integration by parts (see [4] for details) leads to the following identity:

$$\int_{\sqrt{t}}^{+\infty}e^{-s^2}\,ds=\frac{1}{2}\frac{e^{-t}}{\sqrt{t}}-\frac{1}{4}\frac{e^{-t}}{t^{3/2}}+\frac{3}{4}\int_{\sqrt{t}}^{+\infty}\frac{e^{-s^2}}{s^4}\,ds$$

from which we easily deduce that

$$f(t)=\frac{1}{2\sqrt{\Pi}}\frac{e^{-t}}{t^{3/2}}\left(1+O\left(\frac{1}{t}\right)\right) \quad \text{when } t\to+\infty.$$

Stems (iii) and (iv) prove that f belongs to $L^1(\mathbb{R}^+)$ and as f is positive

$$\|f\|_{L^1(\mathbb{R}^+)}=f(0)=1. \qquad \square$$

By Lemma 1.1, we can write

$$\sigma(x,\omega)=\sigma_\infty(x)+\frac{1}{\sqrt{2\Pi}}\int_0^\infty\tilde{\sigma}_1(x,t)\,e^{-i\omega t}\,dt$$

with

$$\tilde{\sigma}_1(x, t) = (1-\lambda(x))\sigma_0(x) f(\omega_c(x)t).$$

This proves that (1.8) is satisfied. Now, a simple calculation gives

$$\mathcal{R}\mathrm{e}(\sigma(x, \omega)) = \lambda(x)\sigma_0(x) + (1-\lambda(x))\sigma_0(x)\psi\left(\frac{\omega}{\omega_c(x)}\right)$$

where

$$\psi(y) = \frac{1+y\sqrt{2}/2}{1+y\sqrt{2}+y^2}.$$

It is easy to check that

$$\forall y \in \mathbb{R} \quad 0 < \psi(y) \leqq 1.$$

Then, as $1-\lambda(x) < 0$, we obtain

$$\mathcal{R}\mathrm{e}(\sigma(x, \omega)) \geqq \lambda(x)\sigma_0(x) + (1-\lambda(x))\sigma_0(x) \geqq (\sigma_0)_* > 0,$$

which proves (1.9) and the theorem. □

We will denote by $\Sigma_w(\Omega; \mathbb{R})$ the subset of Warbourg's law defined by (1.10) with the assumptions of Theorem 1.10.

1.3.2. The subset $\Sigma_a(\Omega; \mathbb{R})$ of approximate laws. We define an approximate polarization law by the formula

$$\sigma(x, \omega) = \sigma_\infty(x) + \sum_{k=1}^{n} \frac{b_k(x)}{1 + i a_k(x)\omega} \tag{1.11}$$

with the following assumptions (for each $k = 1, 2, \cdots, n$):

$$0 < (a_k)_* \leqq a_k(x) \leqq (a_k)^* < +\infty, \tag{1.12}_1$$

$$b_k(x) \leqq (b_k)^* < +\infty, \tag{1.12}_2$$

$$\inf_{(x, \omega)} \left\{ \sigma_\infty(x) + \sum_{k=1}^{n} \frac{b_k(x)}{1 + a_k(x)^2\omega^2} \right\} > 0. \tag{1.12}_3$$

THEOREM 1.11. *Under assumptions* (1.12), *the function* σ *defined by* (1.11) *belongs to* $\Sigma(\Omega; \mathbb{R})$.

Proof. We have the identity

$$\sigma(x, \omega) = \sigma_\infty(x) + \frac{1}{\sqrt{2\Pi}} \int_0^{+\infty} \tilde{\sigma}_1(x, t)\, e^{-i\omega t}\, dt$$

where

$$\tilde{\sigma}_1(x, t) = \sum_{k=1}^{n} \frac{b_k(x)}{a_k(x)} e^{-t/a_k(x)},$$

which proves (1.8). Moreover, (1.9) is nothing but assumption $(1.12)_3$ (which is true if $b_k(x) \geqq 0$ for each k). □

We will denote by $\Sigma_a(\Omega; \mathbb{R})$ the set of approximate laws defined by (1.11). Of course the main interest of $\Sigma_a(\Omega; \mathbb{R})$ lies in the fact that, for σ in $\Sigma_a(\Omega; \mathbb{R})$, the corresponding operator ψ_σ can be defined with the help of ordinary differential operators. More precisely we have the following result.

THEOREM 1.12. *The operator ψ_σ associated with the law* (1.11) *is defined by*

$$\forall u \in L^2(0, T; L^2(\Omega)) \quad (\psi_\sigma u)(x, t) = \sigma_\infty(x, t) + \sum_{k=1}^{n} f_k(x, t)$$

where each function $f_k(x, t)$ is the unique solution of

$$a_k(x)\frac{\partial f_k}{\partial x}(x, t) + f_k(x, t) = b_k(x)u(x, t), \qquad f_k(x, 0) = 0.$$

2. Mathematical analysis of system (1.1). Let σ be an element of $\Sigma(\Omega; \mathbb{R})$. We consider the following initial boundary value problem:

$$\text{(2.1)} \quad \begin{cases} \mu\dfrac{\partial u}{\partial t} + \dfrac{\partial v}{\partial x} = 0, & (x, t) \in \Omega \times \mathbb{R}^+, \\ \psi_\sigma v + \dfrac{\partial u}{\partial x} = 0, & (x, t) \in \Omega \times \mathbb{R}^+, \\ u(x, 0) = u_0(x), & x \in \Omega, \\ v(0, t) = \phi(t), & t \in \mathbb{R}^+. \end{cases}$$

In view of the study of continuity with respect to σ, we are going to deal with the nonhomogeneous problem:

$$\text{(2.2)} \quad \begin{cases} \mu\dfrac{\partial u}{\partial t} + \dfrac{\partial v}{\partial x} = 0, & (x, t) \in \Omega \times \mathbb{R}^+, \\ \psi_\sigma v + \dfrac{\partial u}{\partial x} = g, & (x, t) \in \Omega \times \mathbb{R}^+, \\ u(x, 0) = u_0(x), & x \in \Omega, \\ v(0, t) = \phi(t), & t \in \mathbb{R}^+, \end{cases}$$

with the following assumptions

$$\text{(2.3)} \qquad u_0 \in L^2(\Omega), \quad \phi \in L^2(0, T), \quad g \in L^2(0, T; L^2(\Omega)).$$

2.1. Existence, uniqueness, and regularity results.

2.1.1. Notation and functional spaces. We introduce the Banach space

$$\mathcal{H}(0, T) = W(0, T) \times L^2(0, T; L^2(\Omega))$$

where $W(0, T) = \{u \in L^\infty(0, T; L^2(\Omega)) \cap L^2(0, T; H^1(\Omega)) / du/dt \in L^2(0, T; H^{-1}(\Omega))\}$ with the following norms:

$$\|(u, v)\|_{\mathcal{H}(0,T)} = \|u\|_{W(0,T)} + \|v\|_{L^2(0,T;L^2(\Omega))},$$

$$\|u\|_{W(0,T)} = \|u\|_{L^\infty(0,T;L^2(\Omega))} + \|u\|_{L^2(0,T;H^1(\Omega))} + \left\|\frac{du}{dt}\right\|_{L^2(0,T;H^{-1}(\Omega))}.$$

We are going to look for solutions of (2.2) in the space $\mathcal{H}$. Note that for (u, v) in $\mathcal{H}$, it is not possible to give a meaning (in the classical sense) to the boundary condition $v(0, t) = \phi(t)$

Nevertheless, it is possible to give a "weak" meaning to this condition via the following definition.

DEFINITION. An element (u, v) in $\mathcal{H}(0, T)$ is a weak solution of (2.2) if and only if

$$\forall u^* \in H^1(\Omega) \quad \mu \frac{d}{dt}(u(t), u^*) - \left(v(t), \frac{du^*}{dx}\right) + u^*(0)\phi(t) = 0 \quad \text{in } \mathcal{D}'(0, T),$$

$$\forall v^* \in H^1(\Omega) \quad (\psi_\sigma v(t), v^*) + \left(\frac{\partial u}{\partial x}(t), v^*\right) = (g(t), v^*) \quad \text{in } \mathcal{D}'(0, T),$$

$$u(0) = u_0.$$

Remarks. (1) If (u, v) is a weak solution we have

$$\mu \frac{\partial u}{\partial t} - \frac{\partial v}{\partial x} = 0 \quad \text{in } L^2(0, T; H^{-1}(\Omega)),$$

$$\psi_\sigma v - \frac{\partial u}{\partial x} = g \quad \text{in } L^2(0, T; L^2(\Omega)).$$

(2) As soon as v belongs to $L^2(0, T; H^1(\Omega))$ we have

$$v(0, t) = \phi(t) \quad \text{in } L^2(0, T).$$

(3) The initial condition $u(0) = u_0$ makes sense since $W(0, T) \hookrightarrow C^0(0, T; H^{-1}(\Omega))$.

2.1.2. The existence and uniqueness theorem.

THEOREM 2.1. *Under assumption* (2.3), *problem* (2.2) *admits a unique weak solution* (u, v) *in* $\mathcal{H}(0, T)$. *Moreover, we have the following a priori estimates*:

$$\|u\|_{L^\infty(0,T;L^2(\Omega))} \leqq \|u_0\| + C\left(\|g\| + \|\phi\| + \int_0^T |\phi(t)|\, dt\right),$$

$$\|v\|_{L^2(0,T;L^2(\Omega))} \leqq C\left(\|u_0\| + \|g\| + \|\phi\| + \int_0^T |\phi(t)|\, dt\right),$$

$$\left\|\frac{\partial u}{\partial x}\right\|_{L^2(0,T;L^2(\Omega))} \leqq C\left(\|u_0\| + \|g\| + \|\phi\| + \int_0^T |\phi(t)|\, dt\right),$$

$$\left\|\frac{\partial u}{\partial t}\right\|_{L^2(0,T;H^{-1}(\Omega))} \leqq C\left(\|u_0\| + \|g\| + \|\phi\| + \int_0^T |\phi(t)|\, dt\right),$$

where the constants C *only depend on* μ, σ_*, *and* σ^* *and where we have set*

$$\|\phi\| = \|\phi\|_{L^2(0,T)}, \qquad \|g\| = \|g\|_{L^2(0,T;L^2(\Omega))}.$$

Proof of the theorem. (1) *The a priori estimates.*

$$\mu \frac{\partial u}{\partial t} + \frac{\partial v}{\partial x} = 0, \tag{2.4}_1$$

$$\psi_\sigma v + \frac{\partial u}{\partial x} = g. \tag{2.4}_2$$

Multiply $(2.4)_1$ by u, $(2.4)_2$ by v, add the two equations, and integrate in space. Integrating by parts, we easily obtain

$$\frac{\mu}{2}\frac{d}{dt}\|u(s)\|^2 + (\psi_\sigma v(s), v(s)) = \phi(s)u(0, s) + (g(s), v(s)).$$

Now, integrating in time between 0 and t ($t \in [0, T]$) gives the following identity:

$$\frac{\mu}{2}\|u(t)\|^2 + \int_0^t (\psi_\sigma v(s), v(s))\, ds = \frac{\mu}{2}\|u_0\|^2 + \int_0^t (g(s), v(s))\, ds + \int_0^t \phi(s) u(0, s)\, ds.$$

We use the ellipticity of the operator ψ_σ (Theorem 1.7) to obtain

$$\frac{\mu}{2}\|u(t)\|^2 + \sigma_* \int_0^t \|v(s)\|^2\, ds \leqq \frac{\mu}{2}\|u_0\|^2 + \int_0^t \|g(s)\|\, \|v(s)\|\, ds + \int_0^t |\phi(s)|\, |u(0, s)|\, ds.$$

The trace theorem furnishes the following estimate:

$$\begin{aligned} |u(0, s)| &\leqq \|u(s)\| + \left\|\frac{\partial u}{\partial x}(s)\right\| \\ &\leqq \|u(s)\| + \|g(s)\| + \|\psi_\sigma u(s)\| \qquad ((2.4)_2). \end{aligned}$$

Then, standard techniques (Young inequalities and a generalized Gronwall inequality) together with the continuity property of ψ_σ lead to the estimates on $\|u\|_{L^\infty(0,T;L^2(\Omega))}$ and $\|v\|_{L^2(0,T;L^2(\Omega)}$.

The estimate on $\partial u/\partial x$ stems from $(2.4)_1$ and from the fact that ψ_σ belongs to $\mathscr{L}(L^2(0, T; L^2(\Omega)))$, the estimate on $\partial u/\partial t$ from $(2.4)_4$, and from the fact that $\partial/\partial x \in \mathscr{L}(L^2(\Omega); H^{-1}(\Omega))$.

Clearly the uniqueness result is a consequence of the a priori estimates.

(2) *Existence proof by Galerkin's method.* Let $w_1, \cdots, w_n, \cdots$ be a Hilbert space basis of $H^1(\Omega)$. We construct an approximate solution (u_n, v_n) in the following way:

(2.5) Find $(u_n(t), v_n(t)) : [0, T] \to V_n \times V_n$ (where $V_n = \operatorname{span}[w_1, w_2, \cdots, w_n]$) such that ($g_n \in L^2(0, T; V_n)$)

$$\forall u^* \in V_n \qquad \mu \frac{d}{dt}(u_n(t), u^*) - \left(u_n(t), \frac{\partial u^*}{\partial x}\right) + u^*(0)\Phi(t) = 0,$$

$$\forall u^* \in V_n \qquad (\Psi_\sigma v_n(t), v^*) + \left(\frac{\partial u_n}{\partial x}(t), v^*\right) = (g_n(t), v^*),$$

$$u_n(0) = u_{0,n} \in V_n.$$

Decomposing the approximate solution on the basis $\{w_1, w_2, \cdots, w_n\}$ it is easy to see that solving P_n is equivalent to solving the following integrodifferential system in $\mathbb{R}^n$:

$$\begin{aligned} &A_n \frac{dU_n}{dt}(t) - B_n V_n(t) + \phi_n(t) = 0 \quad \text{in } \mathbb{R}^n, \\ &\Sigma_\infty^n V_n(t) + \int_0^t \Sigma_1^n(t - s) V_n(s)\, ds + {}^t B_n U_n(t) = G_n(t) \quad \text{in } \mathbb{R}^n, \\ &U_n(0) = U_{0,n} \in \mathbb{R}^n, \end{aligned} \tag{2.6}$$

where the different matrices occurring in (2.6) are the following:

$$(A_n)_{ij} = \mu(w_i, w_j) \quad \text{(symmetric positive definite)},$$

$$(B_n)_{ij} = \left(\frac{dw_i}{dx}, w_j\right) \quad \text{(antisymmetric)},$$

$$(\Sigma_\infty^n)_{ij} = \int_\Omega \sigma_\infty(x) w_i(x) w_j(x)\, dx \quad \text{(symmetric positive definite)},$$

$$(\Sigma_1^n)_{ij}(t) = \int_\Omega \tilde{\sigma}_1(x, t) w_i(x) w_j(x)\, dx \quad \text{(belongs to } L^1(0, T; \mathscr{L}(\mathbb{R}^n))).$$

The only nonstandard point is the following lemma.

LEMMA 2.1. *The approximate problem* (2.5) *admits one unique solution*

$$(u_n, v_n) \in H^1(0, T; V_n) \times C^0(0, T; V_n).$$

Proof. We write system (2.6) in its integral form:

$$A_n(U_n(t) - U_0^n) - B_n \int_0^t V_n(s)\, ds + \int_0^t \phi(s)\, ds = 0,$$

$$\Sigma_\infty^n V_n(t) + {}^tB_n U_n(t) + \int_0^t \Sigma_1^n(t-s) V_n(s)\, ds = \int_0^t G_n(s)\, ds,$$

which is strictly equivalent to

$$\Sigma_\infty^n V_n(t) = \int_0^t G_n(s) ds + \int_0^t \Sigma_1^n(t-s) V_n(s)\, ds - {}^tB_n\left(U_0 + A_n^{-1} B_n \int_0^t V_n(s)\, ds - A_n^{-1} \int_0^t \phi_n(s)\, ds \right), \tag{2.7}$$

$$U_n(t) = U_0^n + A_n^{-1} B_n \int_0^t V_n(s)\, ds - A_n^{-1} \int_0^t \phi_n(s)\, ds. \tag{2.8}$$

Let us introduce, in the Banach space $C^0(0, T_n: \mathbb{R})$ $(0 < T_n \leqq T)$

$$\Phi_n : C^0(0, T_n; \mathbb{R}^n) \to C^0(0, T_n; \mathbb{R}^n),$$

$$V(t) \to \Phi_n V(t),$$

$$\Phi_n V(t) = (\Sigma_\infty^n)^{-1} \left\{ \int_0^t G_n(s)\, ds - \int_0^t \Sigma_1^n(t-s) V(s)\, ds \right\} - (\Sigma_\infty^n)^{-1}\, {}^tB_n \left\{ U_0^n + A_n^{-1} B_n \int_0^t V(s)\, ds - A_n^{-1} \int_0^t \phi_n(s)\, ds \right\}.$$

A simple calculation shows that, for any (V_1, V_2) in $C^0(0, T_n; V_n)$,

$$\|\Phi_n V_2 - \Phi_n V_1\| \leqq |(\Sigma_\infty^n)^{-1}| \left(\int_0^{T_n} |(\Sigma_1^n(t)|\, dt) + |(\Sigma_\infty^n)^{-1}\, {}^tB_n A_n^{-1} B_n|\, T_n \right) \| V_2 - V_1 \|_{L^\infty(0, T_n)}$$

(where $|\cdot|$ denotes a convenient norm in $\mathscr{L}(\mathbb{R}^n)$). As $\Sigma_1(t)$ belongs to $L^1(0, T; \mathscr{L}(\mathbb{R}^n))$, we can choose T_n small enough so that

$$\operatorname*{Max}_{a \in \mathbb{R}} \left\{ |(\Sigma_\infty^n)^{-1}| \int_a^{a+T_n} |\Sigma_1^n(s)|\, ds + T_n |(\Sigma_\infty^n)^{-1}\, {}^tB_n A_n^{-1} B_n| \right\} < \frac{1}{2}.$$

Then for all $(V_1, V_2) \in C^0(0, T_n; \mathbb{R})^2$, $\|\Phi_n V_1 - \Phi_n V_2\|_{L^\infty(0, T_n)} \leqq \frac{1}{2} \| V_2 - V_1 \|_{L^\infty(0, T_n)}$.

So, using the Contraction Mapping Theorem, we show that there exists a unique V_n in $C^0(0, T_n; \mathbb{R}^n)$ such that $\Phi_n V_n = V_n (\Leftrightarrow (2.7))$. Of course, we can iterate the process on the interval $[T_n, 2T_n]$, $[2T_n, 3T_n]$, $\cdots$ and construct a solution in $C^0(0, T; \mathbb{R}^n)$. U_n is then obtained by (2.8), which shows that U_n belongs to $H^1(0, T; V_n)$. □

It is then standard to prove that, if we choose $u_{0,n}$ and g_n such that

$$(u_{0,n}, g_n) \to (u_0, g) \text{ in } L^2(\Omega) \times L^2(0, T; L^2(\Omega)),$$

the sequence (u_n, v_n) converges (weakly in $L^2(0, T; L^2(\Omega))^2$) to a solution (u, v) of (2.2) (see, for example, [8]). □

2.1.3. Regularity results. Let us consider two different groups of assumptions:

$$\begin{cases} \phi \in H^1(0, T), \\ u_0 = 0, \\ \phi(0) = 0 \qquad \text{(compatibility condition)}, \end{cases} \tag{2.9}$$

$$\begin{cases} (\phi, \tilde{\sigma}_1) \in H^1(0, T) \times L^2(0, T), \\ \dfrac{\partial}{\partial x}\left(\sigma_\infty^{-1} \dfrac{\partial u_0}{\partial x}\right) \in L^2(\Omega), \\ \phi(0) = \left(\sigma_\infty^{-1} \dfrac{\partial u_0}{\partial x}\right)(0) \qquad \text{(compatibility condition)}. \end{cases} \tag{2.10}$$

Remark. For $\sigma \in \Sigma_a(\Omega; \mathbb{R})$, $\tilde{\sigma}_1$ belongs to $L^2(0, T)$; however, for σ in $\Sigma_w(\Omega; \mathbb{R})$, $\tilde{\sigma}_1$ does not belong to $L^2(0, T)$.

We can show (see [4] for details) the following theorem.

THEOREM 2.2. *Under assumptions* (2.9) *or* (2.10), *the unique solution* (u, v) *of* (2.1) *satisfies*

$$u \in W^{1,\infty}(0, T; L^2(\Omega)) \cap H^1(0, T; H^1(\Omega)) \cap H^2(0, T; H^{-1}(\Omega)),$$

$$v \in L^2(0, T; H^1(\Omega)) \cap H^1(0, T; L^2(\Omega)),$$

and therefore, we have the following equality:

$$v(0, t) = \phi(t) \quad \text{in } L^2(0, T).$$

Comments. (1) This result can be easily obtained by considering the system satisfied by $(\partial u/\partial t, \partial v/\partial t)$. (We use Theorem 1.8 to obtain it.)

(2) The assumptions (2.9) or (2.10) are necessary to obtain the time regularity up to the boundary, but they are not necessary to obtain "interior" time regularity. There is, as for the diffusion equation, a regularizing effect as soon as $x > 0$, which is due to the property

$$|\sigma(x, \omega)| \geqq \sigma_* > 0.$$

(See [4] for a more precise result.)

(3) It is not clear whether there exists a maximum principle for this system.

2.2. Continuity of the solution of (2.1) with respect to the polarization law σ. Using Theorem 2.1 (with $g = 0$), we can construct the mapping

$$\mathcal{U}_T: L^2(\Omega) \times L^2(0, T) \times \Sigma(\Omega; \mathbb{R}) \to \mathcal{H}(0, T),$$

$$(u_0, \phi, \sigma) \to (u, v),$$

(u, v) is the unique solution of (2.1).

The mapping $(u_0, \phi) \to \mathcal{U}_T(\sigma, u_0, \phi)$ is linear and continuous (Theorem 2.1).

The mapping $\sigma \to \mathcal{U}_T(\sigma, u_0, \phi)$ is nonlinear.

THEOREM 2.3. *For given* (ϕ, u_0), *the mapping* $\sigma \to \mathcal{U}_T(\sigma, u_0, \phi)$ *is locally Lipschitz continuous from* $\Sigma(\Omega, \mathbb{R})$ *into* $\mathcal{H}(0, T)$:

$$\forall (\sigma_1, \sigma_2) \in \Sigma(\Omega; \mathbb{R}), \quad \exists C(\mu, \sigma_1, \sigma_2, u_0, \phi, T) \text{ such that}$$

$$\|\mathcal{U}_T(\sigma_2, u_0, \phi) - \mathcal{U}_T(\sigma_1, u_0, \phi)\|_{\mathcal{H}(0,T)} \leqq C \|\sigma_1 - \sigma_2\|_\infty.$$

Proof. Let $(u_1, v_1) = \mathcal{U}_T(\sigma_1, u_0, \phi)$, $(u_2, v_2) = \mathcal{U}_T(\sigma_2, u_0, \phi)$, and $(\tilde{u}, \tilde{v}) = (u_1 - u_2, v_1 - v_2)$. Then, $(\tilde{u}, \tilde{v})$ is the solution of the following system:

$$\mu \frac{\partial \tilde{u}}{\partial t} + \frac{\partial \tilde{v}}{\partial x} = 0, \qquad \psi_{\sigma_1} \tilde{v} + \frac{\partial \tilde{u}}{\partial x} = (\psi_{\sigma_2} - \psi_{\sigma_1}) v_2,$$

$$\tilde{u}(x, 0) = 0, \qquad \tilde{v}(0, t) = 0.$$

Using Theorem 2.1 with $(u_0, \phi, g) = (0, 0, (\psi_{\sigma_2} - \psi_{\sigma_1}) v_2)$, we can obtain the estimate

$$\|(\tilde{u}, \tilde{v})\|_{\mathcal{H}(0,T)} \leqq C(\mu, \sigma_1) \|(\psi_{\sigma_2} - \psi_{\sigma_1}) v_2\|_{L^2(0,T;L^2(\Omega))}.$$

However, by Theorem 1.9 we know that

$$\|(\psi_{\sigma_2} - \psi_{\sigma_1}) v_2\|_{L^2(0,T;L^2(\Omega))} \leqq \|\sigma_2 - \sigma_1\|_\infty \|v_2\|_{L^2(0,\, T;\, L^2(\Omega))}$$

and the result follows with

$$C(\mu, \sigma_1, \sigma_2, u_0, \phi, T) = C_1(\mu, \sigma_1) \|v_2\|_{L^2(0,\, T;\, L^2(\Omega))}. \qquad \square$$

Remark. In view of the solution of the identification problem, it would also be interesting to study the differentiability of the mapping $\sigma \to \mathcal{U}_T(\sigma, u_0, \phi)$.

3. Convergence result and error estimate.

3.1. A general approximation result. Let us recall that the numerical method we propose for solving problem (1.1) begins by substituting for the exact polarization law σ an approximate law σ_a belonging to $\Sigma_a(\Omega; \mathbb{R})$ (cf. § 1.3.2), which reduces the approximate system to a system of two linear partial differential equations coupled to n ordinary differential equations (cf. Theorem 1.12 and (0.4)).

From a theoretical point of view, the continuity result obtained in § 2.2 justifies this approach for any function σ that belongs to the closure of $\Sigma_a(\Omega; \mathbb{R})$ in $\Sigma(\Omega; \mathbb{R})$. Indeed, by assuming that

$$\sigma \in \overline{\Sigma_a(\Omega; \mathbb{R})}^{\Sigma(\Omega;\mathbb{R})},$$

there exists a sequence σ_n in $\Sigma_a(\Omega; \mathbb{R})$ such that

$$\sigma_n \to \sigma \quad \text{in } \Sigma(\Omega; \mathbb{R}).$$

Then, by Theorem 2.3, the approximate solution (u_n, v_n) of problem (2.1) associated with σ_n converges in $\mathcal{H}(0, T)$ to the exact solution (u, v) associated with σ and we have the error estimate (Theorem 2.3):

$$\|(u_n, v_n) - (u, v)\|_{\mathcal{H}(0,T)} \leqq C(\sigma) \|\sigma_n - \sigma\|_\infty.$$

The aim of this section is to prove that such a sequence exists for any Warbourg law, in other words,

$$\Sigma_w(\Omega; \mathbb{R}) \subset \overline{\Sigma_a(\Omega; \mathbb{R})}^{\Sigma(\Omega;\mathbb{R})}.$$

3.2. Approximation of Warbourg's law by rational fractions. First we notice that if we make the approximation

$$f(\omega) = \frac{1}{1 + (i\omega)^{1/2}} \simeq f_n(i\omega) = \sum_{k=1}^{n} \frac{\beta_n^k}{1 + i\alpha_n^k \omega},$$

then Warbourg's law (cf. § 1.3.1),

$$\sigma(x, \omega) = \sigma_\infty(x) + [\lambda(x) - 1] \sigma_0(x) f\left(i \frac{\omega}{\omega_c(x)}\right),$$

can be approximated by

$$\sigma_a(x,\omega)=\sigma_\infty(x)+[\lambda(x)-1]\sigma_0(x)f_n\left(i\frac{\omega}{\omega_c(x)}\right),$$

which can be written in the form (1.11) with

$$a_k(x)=\alpha_n^k\omega_c(x)^{-1},\qquad b_k(x)=\beta_n^k\sigma_0(x)(\lambda(x)-1).$$

To approximate $f(z)=(1+z^{1/2})^{-1}$ by rational fractions, a rather classical method (see [1] or [7] for other applications) consists in using continued fractions (see [9] for the general theory)

Remarking that $f(z)$ is a fixed point of an homographic function,

$$f(z)=\frac{1}{2+(z-1)f(z)}\quad \forall z\notin\mathbb{R}^-, \tag{3.1}$$

we apply the process of successive approximations to define $f_n^*(z)$ by

$$f_{n+1}^*(z)=\frac{1}{2+(z-1)f_n^*(z)},\qquad f_0^*(z)=0. \tag{3.2}$$

LEMMA 3.1. *For each n in* $\mathbb{N}$, $f_n^*(z)$ *is a rational fraction.*

Proof. By induction it is easy to check that

$$f_{2n}^*(z)=\frac{P_{n-1}(x)}{Q_n(z)},\qquad f_{2n+1}^*(z)=\frac{Q_n(z)}{P_n(z)},$$

where (P_n, Q_n) are the sequences of polynomials defined by the following relations:

$$P_{n+1}(z)=(z-1)P_n(z)+2Q_n(z),$$
$$Q_{n+1}(z)=(z-1)Q_n(z)+2P_n(z),$$
$$P_0(z)=0,\qquad Q_0(z)=2,$$

which show that $d^0P_n=d^0Q_n=n$. □

LEMMA 3.2. *The sequence* $f_n^*(z)$ *is given by*

$$\forall z\in\mathbb{C}\backslash\mathbb{R}^-\quad f_n^*(z)=f(z)\left\{\left(1-\left(\frac{1-z^{1/2}}{1+z^{1/2}}\right)^n\right)\Big/\left(1-\left(\frac{1-z^{1/2}}{1+z^{1/2}}\right)^{n+1}\right)\right\},$$

$$f_n^*(0)=1-\frac{1}{n+1}.$$

Proof. Let us set $f(z)=(1+\sqrt{z})^{-1}$ and $g(z)=(1+\sqrt{z})^{-1}$, which are the two solutions of $y=1/(2+(z-1)y)$. We easily check that

$$\frac{f_{n+1}^*(z)-f(z)}{f_{n+1}^*(z)-g(z)}=\frac{1-\sqrt{z}}{1-\sqrt{z}}\frac{f_n^*(z)-f(z)}{f_n^*(z)-g(z)},$$

so that

$$\frac{f_n^*(z)-f(z)}{f_n^*(z)-g(z)}=\left(\frac{1-\sqrt{z}}{1-\sqrt{z}}\right)^n\frac{f(z)}{g(z)},$$

which leads to Lemma 3.3. □

LEMMA 3.3. *For each z in* $\mathbb{C}\backslash\mathbb{R}^-$,

$$\lim_{n\to+\infty} f_n^*(z)=f(z).$$

Moreover, for each compact subset K of $\mathbb{C}\backslash\mathbb{R}^-$, *there exists a constant* $\alpha(K)\in[0,1]$ *such that*

$$|f_n^*(z)-f(z)|\leqq C\alpha(K)^n.$$

Proof. From Lemma 3.2, we deduce the equality

$$f(z)-f_n^*(z)=\frac{2\sqrt{z}}{1+\sqrt{z}}\left(\left(\frac{1-\sqrt{z}}{1+\sqrt{z}}\right)^n\Big/\left(1-\left(\frac{1-\sqrt{z}}{1+\sqrt{z}}\right)^{n+1}\right)\right);$$

then it suffices to remark that, as $\mathcal{R}e(\sqrt{z})>0$, the function $\phi(z)=(1-\sqrt{z})/(1+\sqrt{z})$ maps $\mathbb{C}\backslash i\mathbb{R}^-$ to the unit open disk $D=\{z\in\mathbb{C}/|z|<1\}$. □

We can now state the first important result of this section.

THEOREM 3.1. *For any n, the rational fractions* $f_n^*(z)$ *admit the following expansions*:

(i) $$f_{2n}^*(z)=\frac{2}{2n+1}\sum_{k=1}^{n}1\Big/\left(1+z\,\mathrm{cotg}^2\frac{k\Pi}{2n+1}\right).$$

(ii) $$f_{2n+1}^*(z)=\frac{2}{2n+1}+\frac{2}{2n+2}\sum_{k=1}^{n}1\Big/\left(1+z\,\mathrm{cotg}^2\frac{k\Pi}{2n+2}\right).$$

Proof. Let us give the proof for $f_{2n}^*(z)$.

(1) *Determination of the poles of* f_{2n}^*. Using Lemma 3.2, the poles of $f_{2n}^*(z)$ are the solution of

$$\left(\frac{1-\sqrt{z}}{1+\sqrt{z}}\right)^{2n+1}=1 \quad\text{and}\quad \left(\frac{1-\sqrt{z}}{1+\sqrt{z}}\right)\neq 1.$$

$$\Leftrightarrow((1-\sqrt{z})/(1+\sqrt{z}))=e^{2ik\Pi/(2n+1)},\qquad k=1,2,\cdots,2n.$$

$$\Leftrightarrow z=-\mathrm{tg}^2(k\Pi/(2n+1)),\qquad k=1,2,\cdots,2n.$$

(2) Using Lemma 3.1, we know that $f_{2n}^*(z)$ has an expansion in the form

$$f_{2n}^*(z)=\sum_{k=1}^{n}\frac{r_{2n}^k}{z+\mathrm{tg}^2(\mathrm{k}\Pi/(2\mathrm{n}+1))}.$$

As each pole $z_{2n}^k=-\mathrm{tg}^2(k\Pi/(2n+1))$ is simple, we have $r_{2n}^k=\{(1/f_{2n}^*)'(z_{2n}^k)\}^{-1}$. Then, if we use the expression of $f_n^*(z)$ given in Lemma 3.2, it is rather easy to obtain

$$r_{2n}^k=\frac{2}{2n+1}\mathrm{tg}^2\left(\frac{k\Pi}{2n+1}\right)$$

which completes the proof. □

We now consider the sequence $f_n(z)$ defined by

$$\forall n\in\mathbb{N}\quad f_n(z)=f_{2n+1}^*(z),$$

for which we can establish the following approximation result.

THEOREM 3.2. *For any integer n in* $\mathbb{N}$, *we have the equality*

$$\sup_{\mathcal{R}e(z)\geqq\phi}|f_n(z)-f(z)|=\frac{1}{2(n+1)}.$$

Proof of the theorem. (1) A first calculation proves that for any $z\neq 0$, we have the identity

$$f_n\left(\frac{1}{z}\right)-f\left(\frac{1}{z}\right)=f(z)-f_n(z).$$

(2) Now we can restrict the study to $|z|\leqq 1$.

From Lemma 3.2, we deduce the identity

$$f_n(z)-f(z)=\frac{1}{1+\sqrt{z}}\frac{1-\psi(z)}{1-\psi(z)^{2n+2}} \quad \text{where } \psi(z)=\frac{1+\sqrt{z}}{1-\sqrt{z}}.$$

Thus we can also write

$$f_n(z)-f(z)=\frac{1}{(1+\sqrt{z})(1+\psi(z))}\left\{\prod_{\substack{k=1\\k\neq n+1}}^{2n+1}(\psi(z)-e^{ik\pi/(n+1)})\right\}^{-1}.$$

A simple calculation gives

$$\psi(z)-e^{ik\pi/(n+1)}=\left(\sqrt{z}-i\,\mathrm{tg}\frac{k\Pi}{2(n+1)}\right),$$

from which we deduce

$$f_n(z)-f(z)=\frac{(1-\sqrt{z})^{2n}}{(1+\sqrt{z})(1+\psi(z))}\,\delta_n(z), \tag{3.4}$$

$$\delta_n(z)=\left\{\prod_{\substack{k=1\\k\neq n+1}}^{2n+1}(1+e^{ik\Pi/(n+1)})\left(\sqrt{z}-i\,\mathrm{tg}\frac{k\Pi}{2(n+1)}\right)\right\}^{-1}. \tag{3.5}$$

A rearrangement of the terms of the product leads to

$$\delta_n(z)=\left(\prod_{k=1}^{n}|1+e^{ik\Pi/(n+1)}|^2\left(z+\mathrm{tg}^2\frac{k\Pi}{2(n+1)}\right)\right)^{-1}.$$

But, for $\mathcal{R}\mathrm{e}\,(z)\geqq 0$, we have

$$\left|z+\mathrm{tg}^2\frac{k\Pi}{2(n+1)}\right|\geqq \mathrm{tg}^2\frac{k\Pi}{2(n+1)}.$$

Then, for $\mathcal{R}\mathrm{e}\,(z)\geqq 0$

$$|\delta_n(z)|\leqq\left(\prod_{k=1}^{n}|1+e^{ik\pi/(n+1)}|^2\,\mathrm{tg}^2\frac{k\pi}{2(n+1)}\right)^{-1}=\delta_n(0).$$

But, as $\psi(0)=1$, we deduce from (3.4) that

$$\delta_n(0)=2(f_n(0)-f(0))=\frac{1}{n+1}.$$

Consequently,

$$\forall z/\mathcal{R}\mathrm{e}\,(z)\geqq 0 \quad |f_n(z)-f(z)|\leqq\frac{1}{n+1}\left|\frac{(1-\sqrt{z})^{2n}}{(1+\sqrt{z})(1+\psi(z))}\right|.$$

Then, using

$$(1+\sqrt{z})(1+\psi(z))=2\left(\frac{1+\sqrt{z}}{1-\sqrt{z}}\right) \quad \forall|z|\leqq 1/\mathcal{R}\mathrm{e}\,z\geqq 0, \qquad |1-\sqrt{z}|\leqq 1,$$

we easily obtain

$$\forall z/\mathcal{R}\mathrm{e}(z)\geqq 0 \text{ and } |z|\leqq 1\ |f_n(z)-f(z)|\leqq\frac{1}{2(n+1)}\left|\frac{1-\sqrt{z}}{1+\sqrt{z}}\right||1-\sqrt{z}|^{2n}\leqq\frac{1}{2(n+1)}.$$

Using (1), the result follows immediately. □

Now, using Theorems 3.1 and 3.2, and Lemma 3.3, we can summarize our results in Theorem 3.3.

THEOREM 3.3. *Let* $f_n(z)=f^*_{2n+1}(z)$, *where the sequence* f^*_n *is defined by* (3.2); *then we have the following*:

(i) $$f_n(i\omega)=\frac{1}{2(n+1)}+\frac{1}{n+1}\sum_{k=1}^{n}\frac{1}{1+i\omega\,\operatorname{cotg}^2(k\Pi/2(n+1))}.$$

(ii) $$\sup_{\omega\in\mathbb{R}}|f_n(i\omega)-f(i\omega)|=\frac{1}{2(n+1)}.$$

(iii) For $0<\omega_*<\omega^*<+\infty$, there exists a constant $\alpha(\omega_*,\omega_*)\in\,]0,1[$ $/\sup_{[\omega_*,\omega^*]}|f_n(i\omega)-f(i\omega)|\leqq C(\omega_*,\omega^*)\cdot\alpha(\omega_*,\omega^*)^n$.

In Fig. 1 we illustrate the convergence of the sequence $f^*_n(i\omega)$ to $f(i\omega)$, for $\omega\in\mathbb{R}$.

3.3. The error estimate. We now consider the approximate law σ_n defined by

$$\sigma_n(x,\omega)=\sigma_\infty(x)+[\lambda(x)-1]\sigma_0(x)f_n\left(i\frac{\omega}{\omega_c(x)}\right)$$

where f_n is the sequence defined in § 3.2.

From Theorem 3.3 and properties of the functions $\lambda(x)$, $\sigma_0(x)$, and $\omega_c(x)$ we deduce

$$\|\sigma_n-\sigma\|_\infty\leqq\frac{\sigma^*(\lambda^*-1)}{2(n+1)}.$$

This proves that $\Sigma_w(\Omega;\mathbb{R})\subset\overline{\Sigma_a(\Omega;\mathbb{R})}^{\Sigma(\Omega;\mathbb{R})}$. Moreover we have Theorem 3.4.

THEOREM 3.4. *Let* (u,v) *be the solution of problem* (2.1) *associated with Warbourg's law* σ *and let* (u_n,v_n) *be the solution of the same problem* (2.1) *associated with the approximate law* σ_n; *then we have the error estimate*

$$\|(u_n,v_n)-(u,v)\|_{\mathscr{H}(0,T)}\leqq C(\sigma)\frac{\sigma^*(\lambda^*-1)}{2(n+1)}.$$

Comments. The method we have adopted furnishes a constructive way to obtain an approximate polarization law. Of course there is no reason for the law σ_n we consider here to be optimal for a given number n of rational fractions; for example, we can change the initial element of the sequence f^*_n (and take $f^*_0(z)=a\in\mathbb{R}$) without

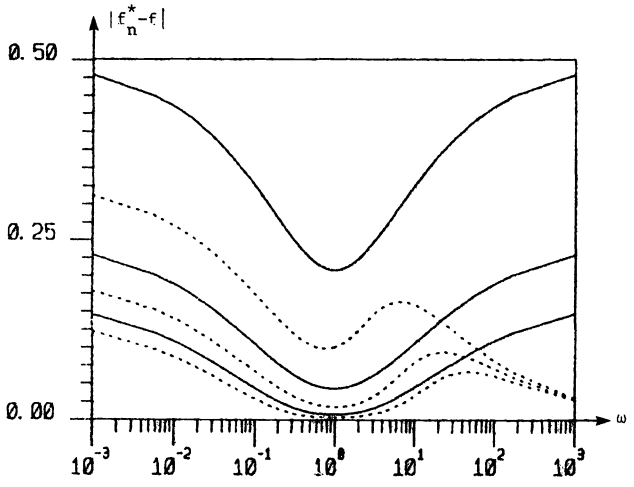

FIG. 1. ——— n odd (1, 3, 5); ---- n even (2, 4, 6).

affecting the rate of convergence of σ_n to σ. In [2], a process for the determination of such an optimal approximate law is described (for any polarization law). It essentially consists of minimizing an appropriate norm of the difference $\sigma_a - \sigma$. Nevertheless, it is clear that the law σ_n we obtain here gives a good initial point for the optimization algorithm. Let us recall that in practice it is sufficient to take $n = 3$, 4 (three simple rational fractions, which implies three auxiliary unknown functions) to get a reasonable approximation of the exact law (see [3]).

4. Conclusion. Our study allowed us to define a good class of polarization laws σ (§ 1) for which the integrodifferential system (0.1) is well posed (§ 2). The approximation result given in § 3 is interesting from both theoretical and practical points of view. It brings a mathematical justification to the numerical method proposed in [3] and gives a way to construct a "good" approximate polarization law.

To conclude, let us mention that looking at result (iii) of Theorem 3.3 we can expect to improve the error estimate given in Theorem 3.4. Moreover our conjecture is that the approximation result we obtain for Warbourg's law could be generalized to any polarization law in the class $\Sigma(\Omega; \mathbb{R})$. A nonconstructive proof using the Stone-Weierstrass Theorem seems to be possible but is still an open and interesting question.

FORMATION OF SHOCKS FOR A SINGLE CONSERVATION LAW*

SHIZUO NAKANE†

Abstract. The initial value problem for an equation of scalar conservation law in several space dimensions is considered. By the method of characteristics, the solution of this problem with C^∞-initial datum is concretely constructed. Generally, this solution becomes multivalued in finite time. By virtue of the theory of singularities of C^∞-mappings, its structure as a multivalued function is completely revealed. The entropy solution is constructed by making it single-valued. In this process, shocks occur. Shock surfaces are constructed by using the stable manifold theory. Thus propagation of shocks is described.

Key words. entropy condition, singularities of C^∞-mappings, stable manifold

AMS(MOS) subject classifications. 35L65, 35L67

1. Introduction. In this paper, we will consider the Cauchy problem for a single conservation law:

$$\begin{cases} \dfrac{\partial u}{\partial t}+\sum_{i=1}^{n}\dfrac{\partial f_i(u)}{\partial x_i}=0 \quad \text{in } \{(t,x)\in\mathbb{R}^{n+1};\ t>0\}, \\ u(0,x)=\varphi(x) \quad \text{on } \mathbb{R}^n. \end{cases} \tag{1.1}$$

Here, $f=(f_1,\cdots,f_n)$ is a C^∞-mapping; $\mathbb{R}\to\mathbb{R}^n$ and φ is a real-valued C^∞ rapidly decreasing function on $\mathbb{R}^n$. Generally, we cannot expect the global existence of C^∞-solutions for (1.1). That is, shocks occur (cf. Conway [3]). The purpose of this paper is to investigate concretely how shocks occur and propagate.

Consequently, we consider (1.1) in a weak sense. A weak solution for (1.1) is a function u satisfying the following for any $g\in C_0^\infty(\mathbb{R}^{1+n})$:

$$\iint_{\mathbb{R}^+\times\mathbb{R}^n}\left(u\frac{\partial g}{\partial t}+\sum_{i=1}^{n}f_i(u)\frac{\partial g}{\partial x_i}\right)dt\,dx+\int_{\mathbb{R}^n}\varphi(x)g(0,x)\,dx=0. \tag{1.2}$$

Since uniqueness of weak solutions for (1.1) does not generally hold, we impose an entropy condition in order to eliminate physically meaningless solutions. A weak solution for (1.1) satisfies the entropy condition if the following holds for any $g\in C_0^\infty(\mathbb{R}^{1+n})$, $g\geqq 0$, and for any $k\in\mathbb{R}$,

$$\iint_{\mathbb{R}^+\times\mathbb{R}^n}\operatorname{sgn}(u-k)\left\{(u-k)\frac{\partial g}{\partial t}+\sum_{i=1}^{n}(f_i(u)-f_i(k))\frac{\partial g}{\partial x_i}\right\}dt\,dx\geqq 0. \tag{1.3}$$

We call such a solution an entropy solution. For the existence and uniqueness of entropy solutions, see, for example, Kruzkov [11].

Our main result is that, under a nondegeneracy hypothesis corresponding to that of Guckenheimer [7], we can construct the entropy solution locally and this solution is piecewise C^∞, with C^1-shock surfaces. More precisely, see the theorem in § 6.

Many authors have studied the global structure of shock waves in the case $n=1$ (see, for example, Chen [1], [7], Jennings [10], and Schaeffer [13]). On the other hand, when $n\geqq 2$, there are few results (see Debeneix [4]). These authors either constructed the solutions explicitly by the method of characteristics or they represented the solutions by using the elementary catastrophe theory. Recently Tsuji [14], [15] investigated the

† Tokyo Institute of Polytechnics, 1583 Iiyama, Atsugi City, Kanagawa 243-02, Japan.

formation and propagation of singularities of solutions for Hamilton-Jacobi equations in two space dimensions. He used the theory of singularities of mappings of the plane into the plane obtained by Whitney [17]. Our result is much inspired by his, which suggests that we can treat higher-dimensional cases if we use the theory of singularities of mappings in higher-dimensional spaces. Here we carry out this program.

Our result is an extension of that of § 1 in [7] to n-dimensional cases. The method of proof is also a refinement of the argument in [7], which seems to be incomplete.

An equation of single conservation law in two space dimensions arises in petroleum engineering. See Glimm, Marchesin, and McBryan [5] and Wagner [16].

The plan of this paper is as follows: in § 2, we will construct the solution explicitly by the method of characteristics. As the solution becomes multivalued in finite time, in § 3 and § 4, we will clarify its structure as a multivalued function by virtue of the theory of singularities of mappings and make it single valued. Shocks appear in this process. In §§ 5 and 6, we will construct shock surfaces by using the stable manifold theory, which we have surveyed in Appendix A1. In § 7, we will give an example which arises in petroleum engineering. In Appendix A2, we will prove the smoothness of the stable manifolds with respect to the parameter according to the argument in [2].

2. The method of characteristics. We will construct the solution for (1.1) by the method of characteristics. Set $a_i(u)=f_i'(u)$, $1\leqq i\leqq n$. Then the characteristic line associated with (1.1) through $(0, y)$ is the solution line $(t, x(t))$ of the following:

$$dx_i(t)/dt = a_i(u(t, x(t))), \qquad x_i(0)=y_i \quad (1\leqq i\leqq n). \tag{2.1}$$

Since $du(t, x(t))/dt\equiv 0$ if u is a smooth solution for (1.1), $u(t, x(t))\equiv u(0, x(0))=\varphi(y)$. Therefore the solution of (2.1) can be expressed by $x(t)=y+ta(\varphi(y))$.

We define C^∞-mappings Φ_t and Φ associated with these characteristics as follows:

$$\Phi_t:\mathbb{R}^n_y\to\mathbb{R}^n_x, \qquad \Phi_t(y)=y+ta(\varphi(y)),$$

$$\Phi:\mathbb{R}^{1+n}_{(t,y)}\to\mathbb{R}^{1+n}_{(t,x)}, \qquad \Phi(t, y)=(t, \Phi_t(y)).$$

From the classical theory of characteristics, it follows that the solution of (1.1) is expressed by $u(t, x)=\varphi(\Phi_t^{-1}(x))$ and is C^∞ at (t, x) which is not the critical value of φ. Then our next problem is to study the singularities of mapping Φ_t or Φ. We shall consider mapping Φ, which can be treated more easily than Φ_t.

Set $\lambda(y)=\sum_{i=1}^n a_i'(\varphi(y))\partial\varphi/\partial y_i$. Then, a direct calculation shows that the Jacobian $|J(\Phi)|=\det J(\Phi)$ of Φ is equal to $1+t\lambda(y)$ (see [3]). Here $J(\Phi)$ is the Jacobian matrix of Φ. If $\lambda(y)\geqq 0$, there exists a global C^∞-solution since $|J(\Phi)|\geqq 1$. Thus we assume

$$\min_y \lambda(y)=\lambda(y^0)=-M<0. \tag{A.1}$$

Note that, since φ is rapidly decreasing, λ must attain its minimum at some finite point y^0 unless $\lambda(y)\geqq 0$. Set $t^0=1/M$ and $x^0=\Phi_{t^0}(y^0)$. For $t<t^0$, $|J(\Phi)|>0$ and u is C^∞. Therefore, from now on we will consider for $t\geqq t^0$ near (t^0, y^0). The following assumption corresponds to the first nondegeneracy condition of [7]:

(A.2) The singularities of λ are nondegenerate, i.e., $\nabla\lambda(y)=0$ implies rank Hess $\lambda(y)=n$.

From (A.1) and (A.2), we can easily see that Hess $\lambda(y^0)$ is positive definite. We also remark that the same argument follows for y^0: minimal point of $\lambda(y)$.

3. Structure of singularities of mapping Φ. Under assumptions (A.1) and (A.2), we have the following results.

LEMMA 1. *By affine transformations of coordinates, we may assume the following*:

$$a_i'(\varphi(y^0)) = 0 \quad (1 \leqq i \leqq n-1), \tag{3.1}$$

$$a_n'(\varphi(y^0)) > 0, \tag{3.2}$$

$$a_i(\varphi(y^0)) = 0 \quad (1 \leqq i \leqq n-1). \tag{3.3}$$

Proof. Let $a_n^i = a_i'(\varphi(y^0))$ and $a_n = (a_n^1, \cdots, a_n^n)$. Then, from (A.1), $a_n \neq 0$. We choose b_i $(1 \leqq i \leqq n)$ so that $b_n = a_n/|a_n|$ and $b_1, \cdots, b_n$ form an orthonormal basis of $\mathbb{R}^n$. First we consider the transformation

$$T = t,$$

$$X_j = y_j^0 + \sum_{i=1}^{n} b_j^i (x_i - y_i^0) \quad (1 \leqq j \leqq n).$$

Then, we have

$$\begin{aligned} 0 &= \partial u/\partial t + \sum_{i=1}^{n} a_i(u)\partial u/\partial x_i \\ &= \partial u/\partial T + \sum_{j=1}^{n} \left(\sum_{i=1}^{n} b_j^i a_i(u) \right) \partial u/\partial X_j \\ &= \partial u/\partial T + \sum_{j=1}^{n} b_j(u)\partial u/\partial X_j \end{aligned}$$

and $b_j'(\varphi(y^0)) = \sum_{i=1}^{n} b_j^i a_i'(\varphi(y^0)) = 0$ $(1 \leqq j \leqq n-1)$, > 0 $(j = n)$. Thus we obtain (3.1) and (3.2). Next, by the following transformation

$$T = t,$$

$$X_j = x_j - a_j(\varphi(y^0))t \quad (1 \leqq j \leqq n-1),$$

$$X_n = x_n,$$

(3.3) is easily seen to be satisfied. This completes the proof. □

Remark 1. It is easy to see that the above transformations preserve assumptions (A.1) and (A.2).

Before stating the proposition, we need a definition.

DEFINITION 1. The singularity y^0 of a C^∞-mapping $M: \mathbb{R}_y^m \to \mathbb{R}_x^m$ is said to be fold (respectively, cusp), if, by diffeomorphisms in $\mathbb{R}_y^m$ and in $\mathbb{R}_x^m$ sending y^0 and $M(y^0)$ to the origins, M is transformed into the following form:

$$\begin{array}{l} x_1 = y_1, \\ \vdots \\ x_{m-1} = y_{m-1}, \\ x_m = y_m^2 \end{array} \quad \left(\text{respectively,} \quad \begin{array}{l} x_1 = y_1, \\ \vdots \\ x_{m-1} = y_{m-1}, \\ x_m = y_m^3 - y_1 y_m. \end{array} \right)$$

PROPOSITION 2. *Near $t = t^0$, the singularities of Φ must be fold or cusp.*

Proof. Consider the C^∞-mapping $h: \mathbb{R}_{(t,y)}^{1+n} \to \mathbb{R}_{(T,Y)}^{1+n}$,

$$T = t,$$

$$Y_i = y_i + t a_i(\varphi(y)) \quad (1 \leqq i \leqq n-1),$$

$$Y_n = y_n.$$

From (3.1), it follows that h is a diffeomorphism near (t^0, y^0). We represent h^{-1} by

$$t = T,$$
$$y_i = b_i(T, Y) \qquad (1 \leqq i \leqq n),$$

where $b_n(T, Y) = Y_n$ and b_j satisfy

$$Y_j = b_j(T, Y) + Ta_j(\varphi(b(T, Y))) \qquad (1 \leqq j \leqq n-1) \tag{3.4}$$

Then, $\tilde{\Phi} = \Phi \circ h^{-1}$ is expressed by

$$t = T,$$
$$x_j = Y_j \qquad (1 \leqq j \leqq n-1),$$
$$x_n = Y_n + Ta_n(\varphi(b(T, Y))).$$

Note that (T, Y) is the "adapted system of coordinates" in the terminology of Morin [12]. We only have to show that the singularities of $\tilde{\Phi}$ must be cusp unless they are fold. In order to do so, we use the characterization of fold points and cusp points obtained in [12]. That is, we have only to show

$$\partial^3 x_n / \partial Y_n^3 \neq 0, \tag{3.5}$$

$$\partial^2 x_n / \partial T \partial Y_n \neq 0, \tag{3.6}$$

on the set

$$\Sigma^{1,1} = \{(T, Y);\ \partial x_n / \partial Y_n = \partial^2 x_n / \partial Y_n^2 = 0\}.$$

Since

$$\partial x_n / \partial Y_n = |J(\tilde{\Phi})| = |J(\Phi)| / |J(h)| = \{1 + T\lambda(b)\} / |J(h)|,$$
$$\Sigma^{1,1} = \{(T, Y);\ 1 + T\lambda(b) = \textstyle\sum_{j=1}^{n} \partial\lambda / \partial y_j \cdot \partial b_j / \partial Y_n = 0\}.$$

On this set, we have

$$\partial^3 x_n / \partial Y_n^3 = T\left(t_b \cdot \mathrm{Hess}\, \lambda \cdot b + \sum_{i=1}^{n} \partial\lambda / \partial y_i \cdot \partial b_i / \partial Y_n \right) / |J(h)|,$$

$$\partial^2 x_n / \partial T \partial Y_n = \left(\lambda + T \sum_{i=1}^{n} \partial\lambda / \partial y_i \cdot \partial b_i / \partial Y_n \right) \Big/ |J(h)|,$$

where $b = {}^t(\partial b_1 / \partial Y_n, \cdots, \partial b_n / \partial Y_n)$. From (A.1), (A.2), (3.1), and (3.2), we have $\partial^3 x_n / \partial Y_n^3 > 0$ and $\partial^2 x_n / \partial T \partial Y_n < 0$ on $\Sigma^{1,1}$. This completes the proof. □

Remark 2. The following facts, which will be used later, can be easily seen:

$$\partial^2 x_n / \partial Y_j \partial Y_n = 0 \quad \text{at } (T^0, Y^0) = h(t^0, y^0) \quad \text{for any } j. \tag{3.7}$$

These imply that the singularity y^0 of mapping Φ_{t^0} is neither fold nor cusp. Thus we consider Φ instead of Φ_t. On the other hand, it is shown by the same argument as in Proposition 2 that, for $t > t^0$, the singularities of Φ_t must be fold or cusp.

Remark 3. When $n = 1$, Chen [1] has proved the same result.

Remark 4. Tsuji [14], [15] studied the singularities of mapping H_t, which corresponds to Φ_t, for the Hamilton-Jacobi equation. He assumed that the singularities of H_t must be fold or cusp.

We set $\Sigma^1 = \{(T, Y) \in \mathbb{R}^{n+1};\ 1 + T\lambda(b(T, Y) = 0\}$. Then, Σ^1 (respectively, $\Sigma^{1,1}$) is the set of singularities (respectively, cusp points) of $\tilde{\Phi}$.

LEMMA 3. *Near* (T^0, Y^0), $\Sigma^{1,1}$ *is a* C^∞*-submanifold of* $\mathbb{R}^{n+1}$ *with codimension* 2 *parametrized by* $Y' = (Y_1, \cdots, Y_{n-1})$.

This lemma follows from the implicit function theorem. The following lemma is also easy to see.

LEMMA 4. $\tilde{\Phi}(\Sigma^{1,1})$ *is a* C^∞*-submanifold of* $\mathbb{R}^{n+1}$ *with codimension* 2 *parametrized by* x'.

We represent $\Sigma^{1,1} = \{(T, Y);\ T = \tilde{\alpha}(Y'),\quad Y_n = \tilde{\beta}(Y')\}$ and $\tilde{\Phi}(\Sigma^{1,1}) = \{(t, x);\ t = \alpha(x'),\ x_n = \beta(x')\}$.

4. Formation of shocks. From the argument of the preceding section, the structure of singularities of mapping $\tilde{\Phi}$ (and therefore of Φ) has been completely clarified. From the canonical form of mappings at cusp points (cf. Definition 1), it follows that the inverses $\Phi^{-1}, \tilde{\Phi}^{-1}$ are triple-valued. See Fig. 1.

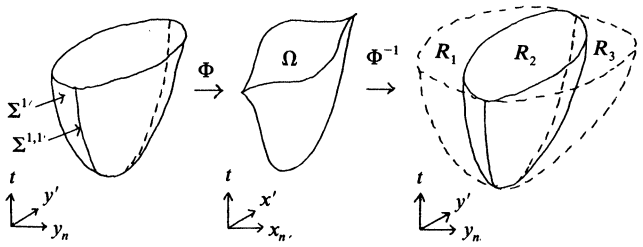

FIG. 1

We set $\Omega = \tilde{\Phi}(\{1 + T\lambda(b(T, Y)) < 0\})$, and we write the three inverse images of Ω by $\tilde{R}_i$ $(1 \leqq i \leqq 3)$ and three branches of $\tilde{\Phi}^{-1}$ in Ω by

$$(\tilde{\Phi}|_{\tilde{R}_i})^{-1}: \begin{cases} T = t, \\ Y' = x', \\ Y_n = \tilde{g}_n^{(i)}(t, x), \end{cases}$$

where $\tilde{g}_n^{(1)}(t, x) < \tilde{g}_n^{(2)}(t, x) < \tilde{g}_n^{(3)}(t, x)$ in Ω. Since $\Phi = \tilde{\Phi} \circ h$, we can write three branches of Φ^{-1} by

$$t = t, \qquad y = g^{(i)}(t, x).$$

We set $u_i(t, x) = \varphi(g^{(i)}(t, x))$ in Ω $(1 \leqq i \leqq 3)$. Then we have the following lemma.

LEMMA 5. $\partial u_1/\partial x_n,\ \partial u_3/\partial x_n < 0$, *and* $\partial u_2/\partial x_n > 0$ *in* Ω.

Proof. Set $\tilde{\varphi}(T, Y) = \varphi \circ h^{-1}(T, Y) = \varphi(b(T, Y))$. Then, $u_i(t, x) = \tilde{\varphi}(t, x', g_n^{(i)}(t, x))$ and $\partial u_i/\partial x_n = (\sum_{i=1}^n \partial\varphi/\partial y_i \cdot \partial b_i/\partial Y_n)\partial g_n^{(i)}/\partial x_n$. From (3.1), (3.2), (3.4), and (A.1), it follows that, at (T^0, Y^0), $\partial b_i/\partial Y_n = 0$ $(1 \leqq i \leqq n-1)$, $\equiv 1$ $(i = n)$ and at (t^0, y^0), $\partial\varphi/\partial y_n < 0$. Then $\partial g_n^{(i)}/\partial x_n = \partial Y_n/\partial x_n = (\partial x_n/\partial Y_n)^{-1} > 0$ $(i = 1, 3)$, < 0 $(i = 2)$. Thus we get $\partial u_i/\partial x_n < 0$ $(i = 1, 3)$, > 0 $(i = 2)$ in Ω near (T^0, Y^0). This completes the proof.

Thus we have completely clarified the structure of the solution u of (1.1) as a multivalued function.

Since we are looking for a single-valued solution, we must make u single valued in Ω. For this reason, u must be discontinuous in Ω. We consider a weak solution having C^1-shock surface $S = \{\nu(t, x) = 0\}$ near (t^0, x^0). Let $\mathbf{n} = \mathbf{n}(p)$ be the unit normal vector to S at $p \in S$ and let $u_\pm(p) = \lim_{\varepsilon \to +0} u(p \pm \varepsilon\mathbf{n})$. Then the Rankine-Hugoniot condition (4.1) follows from (1.2):

$$\mathbf{n} \cdot F(u_+, u_-) = 0, \tag{4.1}$$

where $F(u_+, u_-) = ([u], [f_1(u)], \cdots, [f_n(u)])$, $[u] = u_+ - u_-$, $[f_i(u)] = f_i(u_+) - f_i(u_-)$. If $S = \{\nu(t, x) = 0\}$, (4.1) is expressed by

$$\frac{\partial \nu}{\partial t} + \sum_{i=1}^{n} \frac{[f_i(u)]}{[u]} \cdot \frac{\partial \nu}{\partial x_i} = 0 \quad \text{on } S. \tag{4.2}$$

Furthermore, since S issues from $\tilde{\Phi}(\Sigma^{1,1})$, ν must satisfy

$$\nu(\alpha(x'), x', \beta(x')) = 0. \tag{4.3}$$

On the other hand, if we orient $\mathbf{n}$ so that $u_+ > u_-$, the entropy condition implies

$$\mathbf{n} \cdot F(k, u_+) \geqq 0, \tag{4.4}$$

for any k, $u_- \leqq k \leqq u_+$.

Later we will construct S so that S is parametrized by (t, x'), i.e., S is expressed by $x_n = \psi(t, x')$. Then, (4.3)-(4.4) implies

$$\frac{\partial \psi}{\partial t} + \sum_{i=1}^{n-1} \frac{[f_i(u)]}{[u]} \frac{\partial \psi}{\partial x_i} = \frac{[f_n(u)]}{[u]} \quad \text{on } S, \tag{4.5}$$

$$\psi(\alpha(x'), x') = \beta(x'). \tag{4.6}$$

Now we define, in Ω, a single-valued function $u(t, x)$ by

$$u(t, x) = \begin{cases} u_1(t, x) & \text{if } x_n < \psi(t, x'), \\ u_3(t, x) & \text{if } x_n > \psi(t, x'). \end{cases} \tag{4.7}$$

And let $\psi = \psi(t, x')$ be the solution of (4.5), (4.6) with $u_+ = u_1$ and $u_- = u_3$. Then we have the following lemma.

LEMMA 6. *Suppose $\partial\psi/\partial x_i$ $(1 \leqq i \leqq n-1)$ are bounded in Ω. Then the entropy condition is satisfied.*

Proof. From the definition, $\mathbf{n} = (\partial\psi/\partial t, \partial\psi/\partial x', -1)$. Hence (4.4) is equivalent to

$$\frac{\partial \psi}{\partial t} + \sum_{i=1}^{n-1} \frac{f_i(k) - f_i(u_1)}{k - u_1} \frac{\partial \psi}{\partial x_i} \leqq \frac{f_n(k) - f_n(u_1)}{k - u_1} \quad (u_3 \leqq k \leqq u_1), \tag{4.8}$$

where $u_i = u_i(t, x', \psi(t, x'))$.

It follows from (4.5) that (4.8) is equivalent to

$$\begin{aligned} &\sum_{i=1}^{n-1} \left(\frac{f_i(u_1) - f_i(k)}{u_1 - k} - \frac{f_i(u_1) - f_i(u_3)}{u_1 - u_3} \right) \frac{\partial \psi}{\partial x_i} \\ &\leqq \frac{f_n(u_1) - f_n(k)}{u_1 - k} - \frac{f_n(u_1) - f_n(u_3)}{u_1 - u_3} \quad (u_3 \leqq k \leqq u_1). \end{aligned} \tag{4.9}$$

From (3.2) and the assumption, $|\partial\psi/\partial x_i| \leqq C$ $(1 \leqq i \leqq n-1)$ and $a_n'(u) \geqq c$ in some small neighborhood of (t^0, x^0) for some C, $c > 0$. And it follows from (3.2) that, for any $\varepsilon > 0$, there exists an open neighborhood of (t^0, x^0) such that we have $|a_i'(u)| \leqq \varepsilon$ there. Then the following lemma shows:

$$|\text{The left-hand side of (4.9)}| \leqq \frac{1}{2} \varepsilon C (k - u_3),$$

$$\text{The right-hand side of (4.9)} \geqq \frac{c}{2} (k - u_3),$$

which is easily seen. By taking ε sufficiently small, we have (4.9). This completes the proof. □

LEMMA 7. *Let* $g(u)=\{f(u)-f(w)\}/(u-w)$. *Then we have the following*:
(i) *if* $f''(u)\geqq c>0$, $g'(u)\geqq c/2$,
(ii) *if* $|f''(u)|\leqq\varepsilon$, $|g'(u)|\leqq\varepsilon/2$.

Later we shall prove the existence of ψ and the boundedness of $\partial\psi/\partial x_i$.

Remark 5. When Tsuji [14], [15] made the solution u of Hamilton-Jacobi equation single valued, he proved that u must jump from u_1 to u_3.

5. Construction of shock surfaces (I). Now we will construct the soution of (4.2)-(4.3) or (4.5)-(4.6). It is a noncharacteristic Cauchy problem of a first-order nonlinear partial differential equation. Note that, since $\tilde{\Phi}(\Sigma^1)$ is the set of critical values of $\tilde{\Phi}$, u_i are not Lipschitz continuous on $\tilde{\Phi}(\Sigma^1)$. Thus we cannot use the usual method of characteristics. According to the argument in [7], we pull back the problem by $\tilde{\Phi}$. We define a vector field X in Ω by

$$X=(1+t\lambda(y))\left(\frac{\partial}{\partial t}+\sum_{i=1}^{n}\frac{[f_i(u)]}{[u]}\frac{\partial}{\partial x_i}\right), \tag{5.1}$$

where $[u]=u_1(t,x)-u_3(t,x)$, etc. and a vector field $\tilde{X}$ in $\tilde{R}_2$ by

$$\begin{aligned}\tilde{X}=&(1+T\lambda(b(T,Y)))\frac{\partial}{\partial T}+(1+T\lambda)\sum_{i=1}^{n-1}\frac{[f_i(u)]}{[u]}\frac{\partial}{\partial Y_i}\\&+|J(h)|^{-1}\left\{(1+T\lambda)\left(\frac{[f_n(u)]}{[u]}-a_n(\varphi)\right)\right.\\&\left.-Ta_n'(\varphi)\sum_{k=1}^{n}\frac{\partial\varphi}{\partial y_k}\left(\frac{[f_k(u)]}{[u]}-a_k(\varphi)\right)\right\}\frac{\partial}{\partial Y_n},\end{aligned} \tag{5.2}$$

where $[u]=u^{(1)}-u^{(3)}$, etc., $u^{(i)}=u^{(i)}(T,Y)=\tilde{\varphi}\circ(\tilde{\Phi}|_{\tilde{R}_i})^{-1}\circ\tilde{\Phi}(T,Y)$ $(i=1,3)$. By a direct calculation, we have $X=\tilde{\Phi}_*\tilde{X}$. In this section, we will investigate some properties of $\tilde{X}$.

LEMMA 8. $\tilde{X}$ *can be continued, as a* C^∞*-vector field, to a neighborhood of* (T^0, Y^0).

Proof. Since the smoothness of a vector field is preserved under diffeomorphisms, we may assume that $\tilde{\Phi}$ is the canonical form at cusp points. That is, we may take $\tilde{\Phi}$ as follows:

$$t=T,\quad x'=Y',\quad x_n=Y_n^3-TY_n.$$

What we have to show is the smoothness of $[f_i(u)]/[u]$. Since the roots of $\tilde{Y}_n^3-T\tilde{Y}_n=Y_n^3-TY_n$ are $\tilde{Y}_n=Y_n$, $(-Y_n\pm\Delta)/2$, where $\Delta=(4T-3Y_n^2)^{1/2}$, we have

$$u^{(1)}(T,Y)=\tilde{\varphi}\left(T,Y',\frac{-Y_n-\Delta}{2}\right),\qquad u^{(3)}(T,Y)=\tilde{\varphi}\left(T,Y',\frac{-Y_n+\Delta}{2}\right).$$

Then

$$\begin{aligned}\frac{[f_i]}{[u]}&=\frac{1}{u^{(1)}-u^{(3)}}\int_0^1\frac{d}{ds}f_i(su^{(1)}+(1-s)u^{(3)})\,ds\\&=\int_0^1 a_i\left(s\tilde{\varphi}\left(T,Y',\frac{-Y_n-\Delta}{2}\right)+(1-s)\tilde{\varphi}\left(T,Y',\frac{-Y_n+\Delta}{2}\right)\right)ds\\&=F_i(T,Y,\Delta).\end{aligned}$$

From the hypothesis, F_i is C^∞ with respect to (T,Y,Δ) and $F_i(T,Y,-\Delta)=F_i(T,Y,\Delta)$. Then the function $G_i(T,Y,\xi)=F_i(T,Y,\xi^{1/2})$, defined in $\xi>0$, is smoothly continued

to $\xi \leqq 0$. Now we have $F_i(T, Y, \Delta) = G_i(T, Y, \Delta^2) = G_i(T, Y, 4T - 3Y_n^2)$, which implies $[f_i]/[u]$ is smoothly extended to a neighborhood of (T^0, Y^0). This completes the proof. □

LEMMA 9. *Let Σ be the set of singularities of the vector field $\tilde{X}$. Then $\Sigma = \Sigma^{1,1}$.*

Proof. It is easy to see $\Sigma^{1,1} \subset \Sigma \subset \Sigma^1$. Hence we show $\Sigma \subset \Sigma^{1,1}$. Note that $a_i(u) = a_i(\tilde{\varphi}) + a_i'(\tilde{\varphi})(u - \tilde{\varphi}) + (u - \tilde{\varphi})^2 \int_0^1 (1-s) a_i''(\tilde{\varphi} + s(u - \tilde{\varphi}))\, ds$. We set

$$\begin{aligned}
\frac{[f_i]}{[u]} - a_i(\tilde{\varphi}) &= \frac{1}{u^{(1)} - u^{(3)}} \int_{u^{(3)}}^{u^{(1)}} \{a_i(u) - a_i(\tilde{\varphi})\}\, du \\
&= \frac{a_i'(\tilde{\varphi})}{u^{(1)} - u^{(3)}} \int_{u^{(3)}}^{u^{(1)}} (u - \tilde{\varphi})\, du \\
&\quad + \frac{1}{u^{(1)} - u^{(3)}} \int_{u^{(3)}}^{u^{(1)}} (u - \tilde{\varphi})^2 \int_0^1 (1-s) a_i''(\tilde{\varphi} + s(u - \tilde{\varphi}))\, ds\, du \\
&= I_1 + I_2.
\end{aligned}$$

Then

$$I_1 = \frac{1}{2} a_i'(\tilde{\varphi})(u^{(1)} + u^{(3)} - 2\tilde{\varphi}),$$

$$\begin{aligned}
|I_2| &\leqq \frac{C}{u^{(1)} - u^{(3)}} \int_{u^{(3)}}^{u^{(1)}} (u - \tilde{\varphi})^2\, du \\
&\leqq C' |(u^{(1)} - \tilde{\varphi}, u^{(3)} - \tilde{\varphi})|^2.
\end{aligned}$$

Thus we have

$$\begin{aligned}
&- T a_n'(\tilde{\varphi}) \sum_{k=1}^{n} \frac{\partial \varphi}{\partial y_k} \left(\frac{[f_k]}{[u]} - a_k \right) \\
&\quad = - T a_n'(\tilde{\varphi}) \sum_{k=1}^{n} \frac{\partial \varphi}{\partial y_k} \left\{ \frac{1}{2} a_k'(\tilde{\varphi})(u^{(1)} + u^{(3)} - 2\tilde{\varphi}) + O(|(u^{(1)} - \tilde{\varphi}, u^{(3)} - \tilde{\varphi})|^2) \right\} \\
&\quad = - \frac{T}{2} a_n'(\tilde{\varphi}) \{ \lambda (u^{(1)} + u^{(3)} - 2\tilde{\varphi}) + O(|(u^{(1)} - \tilde{\varphi}, u^{(3)} - \tilde{\varphi})|^2) \}.
\end{aligned}$$

Since $u^{(1)} = \tilde{\varphi} \neq u^{(3)}$ or $u^{(1)} \neq \tilde{\varphi} = u^{(3)}$ on $\Sigma^1 - \Sigma^{1,1}$, $|u^{(1)} + u^{(3)} - 2\tilde{\varphi}| = |(u^{(1)} - \tilde{\varphi}, u^{(3)} - \tilde{\varphi})|$ on $\Sigma^1 - \Sigma^{1,1}$. These imply that the points in $\Sigma^1 - \Sigma^{1,1}$ are not singularities of $\tilde{X}$. This completes the proof.

Next we shall compute the Jacobian matrix $J(\tilde{X})$ of $\tilde{X}$ at (T^0, Y^0). To do so, we study how it is exchanged by diffeomorphisms. Suppose that a vector field $X_1 = \sum c_i(x)(\partial/\partial x_i)$ in $\mathbb{R}^n$, is, by a diffeomorphism: $x = g(y)$, transformed into $X_2 = \sum d_j(y)(\partial/\partial y_j)$. Then we have the following lemma

LEMMA 10. *At singularities of X_1, $J(X_2) = J(g)^{-1} J(X_1) J(g)$.*

We omit the proof. Now we will transform $\tilde{\Phi}$ into the canonical form at cusp points by diffeomorphisms. We set $g(T, Y) = Y_n + T a_n(b(T, Y))$. Then from the proof of Proposition 2, we have $\partial g/\partial Y_n = \partial^2 g/\partial Y_n^2 = 0$ and $\partial^3 g/\partial Y_n^3$, $\partial^2 g/\partial T \partial Y_n \neq 0$ on $\Sigma^{1,1}$. The unfolding theorem (see [13]) shows that there exist C^∞-functions $h(T, Y)$ near (T^0, Y^0), $a_0(T, Y')$, $a_1(T, Y')$ near $(T^0, Y^{0\prime})$ such that

$$g(T, Y) = h(T, Y)^3 - a_1(T, Y') h(T, Y) + a_0(T, Y')$$

and $\partial h/\partial Y_n \neq 0$. By a direct calculation, we have $\Sigma^{1,1} = \{(T, Y);\ h(T, Y) = a_1(T, Y') = 0\}$ and $\partial a_1/\partial T \neq 0$ on $\Sigma^{1,1}$.

Consider the following mapping $P:\mathbb{R}^{n+1}\to\mathbb{R}^{n+1}$,

$$s=a_1(T, Y'),\quad p'=Y',\quad p_n=h(T, Y).$$

Then, $J(P)$ is equal to

$$\begin{bmatrix}\partial a_1/\partial T & \partial a_1/\partial Y' & 0\\ 0 & I_{n-1} & 0\\ \partial h/\partial T & \partial h/\partial Y' & \partial h/\partial Y_n\end{bmatrix}.$$

From (3.7) it follows that $\partial a_1/\partial Y'=0$ at (T^0, Y^0), which implies that $J(P)(T^0, Y^0)$ is equal to

$$\begin{bmatrix}\partial a_1/\partial T & 0 & 0\\ 0 & I_{n-1} & 0\\ \partial h/\partial T & \partial h/\partial Y' & \partial h/\partial Y_n\end{bmatrix}$$

and $|J(P)|(T^0, Y^0)=\partial a_1/\partial T\cdot\partial h/\partial Y_n\neq 0$. Hence P is a diffeomorphism near (T^0, Y^0). We write its inverse P^{-1} by

$$T=T(s, p'),\quad Y'=p',\quad Y_n=Y_n(s, p).$$

Then, $\tilde{\Phi}'=\tilde{\Phi}\circ P^{-1}$ is expressed by

$$t=T(s, p'),\quad x'=p',\quad x_n=p_n^3-sp_n+a_0(T(s, p'), p').$$

Now we set a C^∞-mapping $Q:\mathbb{R}^{n+1}_{(t,x)}\to\mathbb{R}^{n+1}_{(r,q)}$:

$$r=a_1(t, x'),\quad q'=x',\quad q_n=x_n-a_0(t, x').$$

Since $J(Q)(t^0, x^0)$ is equal to

$$\begin{bmatrix}\partial a_1/\partial t & 0 & 0\\ 0 & I_{n-1} & 0\\ * & * & 1\end{bmatrix},$$

Q is a diffeomorphism near (t^0, x^0). Then the C^∞-mapping $\tilde{\Phi}''=Q\circ\tilde{\Phi}'$ is expressed by

$$r=s,\quad q'=p',\quad q_n=p_n^3-sp_n,$$

which is the desired canonical form.

Now we write $\tilde{X}=c_0(T, Y)(\partial/\partial T)+\sum_{i=1}^n c_i(T, Y)(\partial/\partial Y_i)$ and $\tilde{X}'=P_*\tilde{X}=d_0(s, p)(\partial/\partial s)+\sum_{i=1}^n d_i(s, p)(\partial/\partial p_i)$.

LEMMA 11. *At* $(s^0, p^0)=P(T^0, Y^0)$, $J(\tilde{X}')$ *is equal to*

$$\begin{bmatrix}\lambda(y^0) & 0 & 0\\ 0 & 0_{n-1} & 0\\ * & * & -\frac{3}{2}\lambda(y^0)\end{bmatrix}.$$

Proof. Since c_i $(0\leqq i\leqq n)$, $\partial a_1/\partial Y_i$ $(1\leqq i\leqq n-1)$, $\partial c_0/\partial Y_n=0$ at (T^0, Y^0) and $d_0=c_0(\partial a_1/\partial T)+\sum_{i=1}^{n-1} c_i(\partial a_1/\partial Y_i)$, we have $(\partial d_0/\partial s)=(\partial a_1/\partial T)\cdot(\partial c_0/\partial T)\cdot(\partial T/\partial s)=\lambda$ at (s^0, p^0). In the same way, we get $\partial d_0/\partial p_j=0$ at (s^0, p^0) $(1\leqq j\leqq n)$.

Next note that $d_i=c_i=(1+T\lambda)([f_i(u)]/[u])$ $(1\leqq i\leqq n-1)$ and $[f_i(u)]/[u]=a_i(\tilde{\varphi})$ on $\Sigma^{1,1}$. Then, from (3.3), $\partial d_i/\partial s=\partial d_i/\partial p_j=0$ at (s^0, p^0) $(1\leqq i\leqq n-1,\ 1\leqq j\leqq n)$.

Now we consider $d_n = c_0(\partial h/\partial T) + \sum_{j=1}^{n} c(\partial h/\partial Y_j)$. By the same argument as above, we have only to consider the term $c_n(\partial h/\partial Y_n)$. If we set $\tilde{\tilde{\varphi}} = \tilde{\varphi} \circ P^{-1}$, $u^{(1)} = u^{(1)}(s, p) = \tilde{\tilde{\varphi}}(s, p', (-p_n - \Delta)/2)$, $u^{(3)} = u^{(3)}(s, p) = \tilde{\tilde{\varphi}}(s, p', (-p_n + \Delta)/2)$, where $\Delta = (4s - 3p_n^2)^{1/2}$. The same argument as in the proof of Lemma 8 shows

$$\begin{aligned}\frac{[f_i]}{[u]} &= \int_0^1 a_i\left(r\tilde{\tilde{\varphi}}\left(s, p', \frac{-p_n - \Delta}{2}\right) + (1-r)\tilde{\tilde{\varphi}}\left(s, p', \frac{-p_n + \Delta}{2}\right)\right) dr \\ &= \tilde{F}_i(s, p, \Delta) \\ &= \tilde{G}_i(s, p, 4s - 3p_n^2),\end{aligned}$$

where $\tilde{F}_i(s, p, \Delta)$, $\tilde{G}_i(s, p, \xi)$ are C^∞. Then, on $P(\Sigma^{1,1}) = \{s = p_n = 0\}$,

$$\frac{\partial}{\partial p_n}\frac{[f_i]}{[u]} = \frac{\partial \tilde{F}_i}{\partial p_n} - 6p_n\frac{\partial \tilde{G}_i}{\partial p_n} = -\frac{1}{2}a_i'(\tilde{\tilde{\varphi}}(0, p', 0))\frac{\partial \tilde{\tilde{\varphi}}}{\partial p_n}(0, p', 0).$$

Hence, at (s^0, p^0),

$$\frac{\partial}{\partial p_n}\left\{\frac{[f_i]}{[u]} - a_i\right\} = \begin{cases} 0 & (1 \leqq i \leqq n-1), \\ -\dfrac{3}{2}a_n'(\tilde{\tilde{\varphi}}(0, p', 0))\dfrac{\partial \tilde{\tilde{\varphi}}}{\partial p_n}(0, p', 0) & (i = n). \end{cases}$$

Here we have

$$\frac{\partial \tilde{\tilde{\varphi}}}{\partial p_n} = \frac{\partial \tilde{\varphi}}{\partial Y_n}\frac{\partial Y_n}{\partial p_n} = \frac{\partial \varphi}{\partial y_n}\Big/\frac{\partial h}{\partial Y_n} \qquad \text{at } (s^0, p^0).$$

Consequently,

$$\begin{aligned}\frac{\partial d_n}{\partial p_n} &= \frac{\partial h}{\partial Y_n}|J(h)|^{-1}\left\{-Ta_n'\sum_{j=1}^{n}\frac{\partial \varphi}{\partial y_j}\frac{\partial}{\partial p_n}\left(\frac{[f_j]}{[u]} - a_j\right)\right\} \\ &= -Ta_n'\frac{\partial \varphi}{\partial y_n}\left\{-\frac{3}{2}a_n'(\varphi(y^0))\frac{\partial \varphi}{\partial y_n}(y^0)\right\} \\ &= -T\lambda(y^0)\left(-\frac{3}{2}\lambda(y^0)\right) \\ &= -\frac{3}{2}\lambda(y^0).\end{aligned}$$

This completes the proof. □

From Lemmas 10 and 11, we have the following lemma.

LEMMA 12. *$J(\tilde{X})(T^0, Y^0)$ is equal to*

$$\begin{bmatrix} \lambda(y^0) & 0 & 0 \\ 0 & 0_{n-1} & 0 \\ * & * & -\frac{3}{2}\lambda(y^0) \end{bmatrix}. \tag{5.3}$$

6. Construction of shock surfaces (II). Recall that we are looking for a solution to (4.2)-(4.3) or (4.5)-(4.6). Instead of (4.2), we consider

$$(1 + T\lambda)\left\{\frac{\partial \nu}{\partial t} + \sum_{i=1}^{n}\frac{[f_i(u)]}{[u]}\cdot\frac{\partial \nu}{\partial x_i}\right\} = 0. \tag{6.1}$$

If $1 + T\lambda \neq 0$ on $\nu = 0$, the solution ν of (6.1) satisfies (4.2). Since the coefficients of the vector field X do not have enough regularity, we consider $\tilde{X}$ instead of X. Lemma

8 assures us that $\tilde{X}$ is a C^∞-vector field near (T^0, Y^0). Lemma 9 tells us that $\tilde{X}$ has singularities on $\Sigma^{1,1}$. Lemma 12 suggests that we can make use of the stable manifold theory in order to obtain integral curves of $\tilde{X}$ tending to $\Sigma^{1,1}$.

Recall that $\tilde{X} = c_0(T, Y)(\partial/\partial T) + \sum_{i=1}^n c_i(T, Y)(\partial/\partial Y_i)$ and $\Sigma^{1,1} = \{(T, Y);\ T = \tilde{\alpha}(Y'),\ Y_n = \tilde{\beta}(Y')\}$. Thus our purpose is to get a function $\Psi(t) = \Psi(t, y') = {}^t(T(t, y'), Y_1(t, y'), \cdots, Y_n(t, y'))$ satisfying

$$\begin{aligned} &\frac{d}{dt}\Psi(t) = c(\Psi(t)), \\ &\lim_{t\to+\infty} \Psi(t, y') = {}^t(\tilde{\alpha}(y'), y', \tilde{\beta}(y')), \end{aligned} \tag{6.2}$$

where $c = c(T, Y) = {}^t(c_0(T, Y), c_1(T, Y), \cdots, c_n(T, Y))$ and $y' \in \mathbb{R}^{n-1}$ parametrizes $\Sigma^{1,1}$. If we define $u = {}^t(u_0, u_1, \cdots, u_n)$ by

$$\begin{aligned} &u_0(t, y') = T(t, y') - \tilde{\alpha}(y'), \\ &u_j(t, y') = Y_j(t, y') - y_j \quad (1 \leqq j \leqq n-1), \\ &u_n(t, y') = Y_n(t, y') - \tilde{\beta}(y'), \end{aligned} \tag{6.3}$$

then u must satisfy

$$\begin{aligned} &\frac{d}{dt}u = A(y')u + f(y', u), \\ &\lim_{t\to+\infty} u = 0. \end{aligned} \tag{6.4}$$

Here $A(y') = J(\tilde{X})|_{\Sigma^{1,1}}$ and $f(y', u)$ is C^∞ near $(y', u) = (Y^{0\prime}, 0)$ and satisfies $f(y', 0) = 0$, $\nabla_u f(y', 0) = 0$.

We set $u(t, y') = e^{-at}v(t, y')$ for some $a > 0$. Then v satisfies

$$\frac{d}{dt}v = (A(y') + aI)v + e^{at}f(y', e^{-at}v). \tag{6.5}$$

Lemma 12 implies that, by taking a appropriately, the real part of one eigenvalue of $A(y') + aI$ is negative and the real parts of the other n eigenvalues are positive for y' near $Y^{0\prime}$. Then there exist one-dimensional stable manifolds. As for the stable manifold theory, see Coddington and Levinson [2, Chap. 13].

We will state it more precisely. First we blockwise diagonalize $A(y') + aI$. Because of the distinctness of its eigenvalues, there exists a matrix-valued C^∞-function $P(y')$ near $Y^{0\prime}$ satisfying

$$(A(y') + aI)P(y') = P(y')D(y'), \tag{6.6}$$

where

$$D(y') = \begin{bmatrix} d(y') & 0 \\ 0 & D_1(y') \end{bmatrix} = \begin{bmatrix} d(y') & 0 & 0 \\ 0 & D_2(y') & 0 \\ 0 & 0 & e(y') \end{bmatrix}, \tag{6.7}$$

where $D_1(y')$ (respectively, $D_2(y')$) is an $n \times n$ (respectively, $(n-1) \times (n-1)$) matrix (see, for example, Hsieh and Sibuya [9]). Set $P(y') = [p_{ij}(y')]_{0 \leqq i,j \leqq n}$. Then, by a direct calculation, we have

$$p_{00}(Y^{0\prime}) \neq 0 \quad \text{and} \quad p_{i0}(Y^{0\prime}) = 0 \quad (1 \leqq i \leqq n-1). \tag{6.8}$$

If we set $v = P(y')w$, w satisfies

$$\frac{d}{dt}w = D(y')w + g(t, y', w), \tag{6.9}$$

where $g(t, y', w) = P(y')^{-1} e^{at} f(y', e^{-at}P(y')w)$. It is easy to see that g is C^∞ and $g(t, y', 0) = 0$, $\nabla_w g(t, y', 0) = 0$. Now we define $U(t) = U(t, y') = U_0(t, y') + U_1(t, y')$, where

$$U_0(t) = \begin{bmatrix} e^{td(y')} & 0 \\ 0 & 0_n \end{bmatrix}, \quad U_1(t) = \begin{bmatrix} 0 & 0 \\ 0 & e^{tD_1(y')} \end{bmatrix}.$$

Then, if we take a sufficiently small neighborhood V' of $y' = Y^{0\prime}$, there exist α, σ, $C > 0$, independent of y', such that in V',

$$|U_0(t)| \leqq e^{-(\alpha+\sigma)t} \quad (t \geqq 0), \tag{6.10}$$

$$|U_1(t)| \leqq C e^{\sigma t} \quad (t \leqq 0). \tag{6.11}$$

Theorems 4.1 and 4.2 of [2, Chap. 18] shows that there exist C^1-functions $r_i(w_0)$ near the origin in $\mathbb{R}$ satisfying $r_i(0) = r_i'(0) = 0$, and a solution w of (6.9) such that

$$b\, e^{td(y')} \leqq |w_0(t, y')| \leqq c\, e^{td(y')}, \tag{6.12}$$

$$w_i(t, y') = r_i(w_0(t, y')) \quad (1 \leqq i \leqq n), \tag{6.13}$$

for some constants b, $c > 0$. Furthermore we will show that w is C^1 with respect to y'. See the Appendices. Thus we conclude that $u = e^{-at}P(y')w$ is also C^1 with respect to (t, y').

LEMMA 13. *For any $\varepsilon > 0$, there exists a small neighborhood V' of $y' = Y^{0\prime}$ such that*

$$u_0(t, y') \sim e^{-(\alpha - d(y'))t}, \tag{6.14}$$

$$|u_i(t, y')| \leqq \varepsilon |u_0(t, y')| \quad (1 \leqq i \leqq n-1), \tag{6.15}$$

in V' as $t \to +\infty$.

Proof. We can easily obtain (6.14) from (6.12). We show (6.15). Recall that $u_i = e^{-at} \sum_{j=0}^{n} p_{ij}(y')w_j$. From (6.8) and (6.13), we have

$$u_0 \sim e^{-at} w_0,$$

$$|u_i| \leqq \varepsilon\, e^{-at} |w_0| \quad (1 \leqq i \leqq n-1).$$

This completes the proof. □

Thus we obtain a family of integral curves of $\tilde{X}$.

LEMMA 14. *There exists a constant $c > 0$ such that*

$$\left| \det \frac{\partial(T, Y')}{\partial(t, y')} \right| \geqq c |u_0(t, y')|. \tag{6.16}$$

Proof. A direct calculation implies

$$\frac{\partial(T, Y')}{\partial(t, y')} = \begin{bmatrix} \partial u_0/\partial t & * \\ \partial u_1/\partial t & \\ \vdots & I_{n-1} + [\partial u_i/\partial y_j]_{1 \leqq i,j \leqq n-1} \\ \partial u_{n-1}/\partial t & \end{bmatrix}. \tag{6.17}$$

Since $\partial u_0/\partial t \sim u_0$, $|\partial u_i/\partial t| \leqq \varepsilon |u_0|$ $(1 \leqq i \leqq n-1)$, we get the conclusion (6.16). This completes the proof. □

Now we conclude that the orbits of $\tilde{X}$ flow from a C^1-hypersurface in $\mathbb{R}^{n+1}_{(T,Y)}$ parametrized by (T, Y'), which we write $\tilde{S}=\{Y_n=\tilde{\psi}(T, Y')\}$.

LEMMA 15. *$\partial\tilde{\psi}/\partial Y_j$ $(1\leqq j\leqq n-1)$ are bounded.*

Proof. Let Ψ' be the C^1-mapping: $\mathbb{R}^n_{(t,y')}\to\mathbb{R}^n_{(T,Y')}$ defined by $\Psi'(t, y')=(T(t, y'), Y'(t, y'))$. Then $\tilde{\psi}(T, Y')=Y_n\circ\Psi'^{-1}(T, Y')$, and $\partial\tilde{\psi}/\partial Y_j=\partial Y_n/\partial t\cdot\partial t/\partial Y_j+\sum_{i=1}^{n-1}\partial Y_n/\partial y_i\cdot\partial y_i/\partial Y_j$. It easily follows from (6.17) that $\partial y_i/\partial Y_j$ are bounded and $\partial t/\partial Y_j=O(u_0^{-1})$. Since $\partial Y_n/\partial t=O(u_0)$, $\partial\tilde{\psi}/\partial Y_j$ are bounded. This completes the proof. □

Now the function $\tilde{\nu}(T, Y)=Y_n-\tilde{\psi}(T, Y')$ satisfies $\tilde{X}\tilde{\nu}=0$ and $\tilde{\nu}|_{\Sigma^{1,1}}=0$. Moreover, since $|u_i|\leqq\varepsilon|u_0|$ $(1\leqq i\leqq n-1)$, $|u_n|\leqq C|u_0|$ on $\tilde{\nu}=0$, $1+T\lambda\neq 0$ on $\tilde{\nu}=0$. Let $\nu(t, x)=\tilde{\nu}\circ(\tilde{\Phi}|_{\tilde{R}_2})^{-1}(t, x)$. Then ν satisfies (4.2)-(4.3). By the mapping $\tilde{\Phi}$, $\tilde{S}=\{Y_n=\tilde{\psi}(T, Y')\}$ is transformed into $S=\{x_n=\psi(t, x')\}$. Here ψ is a C^1-function near $(t^0, x^{0\prime})$. S is the desired shock surface. Lemma 15 implies that $\partial\psi/\partial x_i$ $(1\leqq i\leqq n-1)$ are bounded. Thus we obtain the following theorem.

THEOREM. *Suppose* (A.1) *and* (A.2) *are true. Then the function u constructed above is the entropy solution for* (1.1) *having C^1-shock surface near (t^0, x^0).*

7. An example. Consider the following equation in two space dimensions:

$$\frac{\partial u}{\partial t}+\sum_{i=1}^{2}\frac{\partial}{\partial x_i}(v_i f(u))=0.$$

This equation arises in oil reservoir problems; see [5] and [16]. We assume that v_i are positive constants and that $f(u)=u^2/2$. We treat the Cauchy problem with the following initial condition:

$$u(0, x)=\varphi(x)=(x_1^3+x_2^3)/3-(x_1+x_2).$$

Then we have

$$\Phi_t\colon x_i=y_i+tv_i\varphi(y), \qquad i=1, 2$$

$$\lambda(y)=\sum_{i=1}^{2}v_i(y_i^2-1),$$

$$\min\lambda(y)=\lambda(0)=-(v_1+v_2)<0.$$

$$\text{Hess }\lambda=\text{diag}\,(2v_1, 2v_2),$$

$$\Sigma^1=\{v_1y_1^2+v_2y_2^2=v_1+v_2-1/t\},$$

$$\Sigma^{1,1}=\{(t, y)\in\Sigma^1;\ v_1^2y_1+v_2^2y_2=0\}.$$

Especially, if we set $v_1=v_2=1$, then,

$$\Sigma^1=\{y_1^2+y_2^2=2-1/t\}, \qquad \Sigma^{1,1}=\{y_1^2+y_2^2=2-1/t,\ y_1+y_2=0\}$$

and we can easily construct the entropy solution explicitly, whose shock surface is expressed by $x_1+x_2=0$, $|x_1|\leqq 1-1/2t$.

Appendices.

A1. The stable manifold theory.

In the Appendices, we will show the smoothness of the solution w of (6.9) with respect to the parameter y'. First we will survey the stable manifold theory as preliminaries in this section. For the details, see [2].

LEMMA 16. *A function w is a bounded solution of* (6.9) *if and only if it is a bounded solution of the following*:

$$\begin{aligned} w(t) &= U_0(t)\xi + \int_0^t U_0(t-s)g(s, y', w(s))\,ds \\ &\quad - \int_t^\infty U_1(t-s)g(s, y', w(s))\,ds \\ &\quad (= T_\xi w) \end{aligned} \tag{A1.1}$$

for some $\xi \in \mathbb{R}^{n+1}$.

We prepare some notation:

$$X_k = \{w(t) \in C^0([0,\infty)); |w|_k = \sup_{t\geqq 0} e^{\alpha k t}|w(t)| < \infty\},$$

$$B_k(r) = \{u \in X_k; |u|_k \leqq r\} \quad (k = 0, 1),$$

$$\gamma(\rho) = \sup\{|\nabla_w g(t, y', w)|, |\nabla_w(\partial g/\partial y_j)(t, y', w)|;\ t \geqq 0,\ y' \in V',\ |w| \leqq \rho,\ 1 \leqq j \leqq n-1\}.$$

Note that $\gamma(\rho)$ is continuous near $\rho = 0$ and $\gamma(0) = 0$.

LEMMA 17. *Let* $C_1 = C_0 + 1$. *Then,*

$$|T_\xi w|_k \leqq |\xi| + \sigma^{-1}C_1\gamma(|w|_0)|w|_k,$$

$$|T_\xi w - T_\xi v|_k \leqq \sigma^{-1}\gamma(\max(|w|_0, |v|_0))|w - v|_k,$$

for $k = 0, 1$.

If we take ρ such that $\gamma(2\rho) < \sigma/(2C_1)$, then Lemma 17 implies, for $|\xi| \leqq \rho$, $k = 0, 1$,

$$T_\xi : B_k(2\rho) \to B_k(2\rho), \qquad |T_\xi w - T_\xi v|_k \leqq \tfrac{1}{2}|w - v|_k.$$

Thus we have the following lemma.

LEMMA 18. *Suppose* $|\xi| \leqq \rho$. *Then the equation* $T_\xi w = w$ *has a unique solution* $w = w(t, y', \xi)$ *in* $B_1(2\rho)$.

We can take $\xi = {}^t(\xi, 0, \cdots, 0)$, $\xi \in \mathbb{R}$. Set $w = {}^t(w_0, w')$ and $g = {}^t(g_0, g')$. Then (A1.1) implies:

$$w_0(0, y', \xi) = \xi,$$

$$\begin{aligned} w'(0, y', \xi) &= -\int_0^\infty U_1(-s)g'(s, y', w(s, y', \xi))\,ds \\ &\quad (= S(\xi)). \end{aligned}$$

LEMMA 19. $S(\xi)$ *is of* C^1 *near* $\xi = 0$ *and satisfies*:

$$|S(\xi)| \leqq \frac{2|\xi|}{\alpha + \sigma}\gamma(2|\xi|),$$

$$|S'(\xi)| \leqq \frac{2C_0}{\alpha + \sigma}\gamma(2|\xi|).$$

A2. The existence of $\partial w/\partial y_j$. We will show the smoothness of w with respect to y'. The method of proof is the same as in the proof of Theorem 4.2 in [2, Chap. 13].

Let us differentiate (A1.1) formally with respect to y_j. Then, $\eta = \partial w/\partial y_j$, if it exists, must satisfy:

$$\begin{aligned}\eta = t\frac{\partial d}{\partial y_j}U_0(t)\xi &+ \int_0^t (t-s)\frac{\partial d}{\partial y_j}U_0(t-s)g(s,y',w(s))\,ds\\ &+\int_0^t U_0(t-s)\frac{\partial g}{\partial y_j}(s,y',w(s))\,ds\\ &+\int_0^t U_0(t-s)\nabla_w g(s,y',w(s))\cdot\eta(s)\,ds\\ &-\int_t^\infty \frac{\partial D_1}{\partial y_j}(t-s)U_1(t-s)g(s,y',w(s))\,ds\\ &-\int_t^\infty U_1(t-s)\frac{\partial g}{\partial y_j}(s,y',w(s))\,ds\\ &-\int_t^\infty U_1(t-s)\nabla_w g(s,y',w(s))\cdot\eta(s)\,ds\\ &= I_1+I_2+\cdots+I_7.\end{aligned} \tag{A2.1}$$

We will show the existence of η satisfying (A2.1). Let us estimate I_j. We estimate I_2 for example. From (6.11) and the definition of γ, we have, for some $C>0$,

$$\begin{aligned}|I_2| &\leqq C\int_0^t (t-s)\,e^{-(\alpha+\sigma)(t-s)}|g(s,y',w(s))|\,ds\\ &\leqq C\,e^{-\alpha t}\gamma(|w|_0)|w|_1\int_0^t (t-s)\,e^{-\sigma(t-s)}\,ds\\ &\leqq \sigma^{-2}C\,e^{-\alpha t}\gamma(|w|_0)|w|_1.\end{aligned}$$

Then $|I_2|_1 \leqq \sigma^{-2}C\gamma(|w|_0)|w|_1$. The same argument shows there exists $C>0$ such that $|I_1+I_2+I_3+I_5+I_6|_1 \leqq C\gamma(|w|_0)|w|_1$ and $|I_4+I_7|_1 \leqq \sigma^{-1}C_1\gamma(|w|_0)|\eta|_1$. Set $I_4+I_7 = U\eta$. By taking $|\xi|<\rho$ sufficiently small, we have $|I_1+I_2+I_3+I_5+I_6|_1 \leqq 1$ and $|U\eta|_1 \leqq \frac{1}{2}|\eta|_1$. Hence there exists $(I-U)^{-1} = \sum_{j=0}^\infty U^j$ and $|(I-U)^{-1}|_1 \leqq 2$. Then $\eta = (I-U)^{-1}(I_1+I_2+I_3+I_5+I_6)$ is the unique solution of (A2.1) in X_1.

Next we set $w_h = w(t,y'+he_j,\xi)$, $U_{i,h}(t) = U_i(t,y'+he_j)$, $g_h(t,y',w) = g(t,y'+he_j,w)$, where $e_j \in \mathbb{R}^{n-1}$, $e_{ji} = \delta_{ji}$, and consider

$$\begin{aligned}w_h - w = \{U_{0,h}(t)-U_0(t)\}\xi &+ \int_0^t U_{0,h}(t-s)\{g_h(s,y',w_h)-g(s,y',w_h)\}\,ds\\ &+\int_0^t \{U_{0,h}(t-s)-U_0(t-s)\}g(s,y',w_h)\,ds\\ &+\int_0^t U_0(t-s)\{g(s,y',w_h)-g(s,y',w)\}\,ds\\ &-\int_t^\infty U_{1,h}(t-s)\{g_h(s,y',w_h)-g(s,y',w_h)\}\,ds\\ &-\int_t^\infty \{U_{1,h}(t-s)-U_1(t-s)\}g(s,y',w_h)\,ds\\ &-\int_t^\infty U_1(t-s)\{g(s,y',w_h)-g(s,y',w)\}\,ds\\ &= I_1+\cdots+I_7.\end{aligned}$$

A direct calculation shows that there exists $C>0$ such that

$$|I_1+I_2+I_3+I_5+I_6|_1 \leqq C|h|,$$

$$|I_4|_1 \leqq \sigma^{-1}\gamma(\max(|w_h|_0, |w|_0))|w_h-w|_1,$$

$$|I_7|_1 \leqq (\alpha+\sigma)^{-1}C_0\gamma(\max(|w_h|_0, |w|_0))|w_h-w|_1.$$

Hence, if $|w_h|_0, |w|_0 \leqq 2|\xi|$, there exists $C>0$ such that $|w_h-w|_1 \leqq C|h|$.

Now, consider $\varepsilon=(w_h-w)/h-\eta$. Then,

$$\begin{aligned}
\varepsilon = &\frac{1}{h}\{U_{0,h}(t)-U_0(t)\}\xi-\frac{\partial U_0}{\partial y_j}(t)\xi+\int_0^t U_{0,h}(t-s)\left\{\frac{1}{h}(g_h(w_h)-g(w_h))-\frac{\partial g}{\partial y_j}(w_h)\right\}ds\\
&+\int_0^t U_{0,h}(t-s)\left\{\frac{\partial g}{\partial y_j}(w_h)-\frac{\partial g}{\partial y_j}(w)\right\}ds\\
&+\int_0^t \{U_{0,h}(t-s)-U_0(t-s)\}\frac{\partial g}{\partial y_j}(w)\,ds\\
&+\int_0^t \left\{\frac{1}{h}(U_{0,h}(t-s)-U_0(t-s))-\frac{\partial U_0}{\partial y_j}(t-s)\right\}g(w_h)\,ds\\
&+\int_0^t \frac{\partial U_0}{\partial y_j}(t-s)\{g(w_h)-g(w)\}\,ds\\
&+\int_0^t U_0(t-s)\left\{\frac{1}{h}(g(w_h)-g(w))-\nabla_w g(w)\cdot\eta\right\}ds\\
&-\int_t^\infty U_{1,h}(t-s)\left\{\frac{1}{h}(g_h(w_h)-g(w_h))-\frac{\partial g}{\partial y_j}(w_h)\right\}ds\\
&-\int_t^\infty U_{1,h}(t-s)\left\{\frac{\partial g}{\partial y_j}(w_h)-\frac{\partial g}{\partial y_j}(w)\right\}ds\\
&-\int_t^\infty \{U_{1,h}(t-s)-U_1(t-s)\}\frac{\partial g}{\partial y_j}(w)\,ds\\
&-\int_t^\infty \left\{\frac{1}{h}(U_{1,h}(t-s)-U_1(t-s))-\frac{\partial U_1}{\partial y_j}(t-s)\right\}g(w_h)\,ds\\
&-\int_t^\infty \frac{\partial U_1}{\partial y_j}(t-s)\{g(w_h)-g(w)\}\,ds\\
&-\int_t^\infty U_1(t-s)\left\{\frac{1}{h}(g(w_h)-g(w))-\nabla_w g(w)\cdot\eta\right\}ds\\
=&\,I_1+\cdots+I_{13}.
\end{aligned}$$

We estimate I_2 for example. Since

$$I_2=\int_0^t U_{0,h}(t-s)\left\{\int_0^1\int_0^1 rh\frac{\partial^2 g}{\partial y_j^2}(s, y'+qrhe_j, w_h)\,dq\,dr\right\}ds,$$

$$\left|\frac{\partial^2 g}{\partial y_j^2}(s, y'+qrhe_j, w_h)\right| \leqq C|w_h|,$$

for some $C>0$, we have $|I_2|_1 \leqq \sigma^{-1}C|w_h|_1|h|$. Similar estimates follow for $I_1 \sim I_6$, $I_8 \sim I_{12}$. Now we estimate I_7. Since

$$I_7 = \int_0^t U_0(t-s)\left[\int_0^1 \nabla_w g((1-r)w+rw_h)\,dr\cdot\left\{\frac{1}{h}(w_h-w)-\eta\right\}\right.$$
$$\left.+\int_0^1 \{\nabla_w g((1-r)w+rw_h)-\nabla_w g(w)\}\,dr\cdot\eta\right]ds,$$

we have for some C, $C'>0$,

$$|I_7|_1 \leqq \sigma^{-1}\gamma(\max(|w_h|_0, |w|_0))|\varepsilon|_1 + C|w_h-w|_1|\eta|_1$$
$$\leqq d^{-1}\gamma(\max(|w_h|_0, |w|_0))|\varepsilon|_1 + C'|h|.$$

In the same way, we have

$$|I_{13}|_1 \leqq (\alpha+\sigma)^{-1}C_0\gamma(\max(|w_h|_0, |w|_0))|\varepsilon|_1 + C'|h|.$$

Thus we obtain

$$|\varepsilon|_1 \leqq \sigma^{-1}C_1\gamma(\max(|w_h|_0, |w|_0))|\varepsilon|_1 + C|h| \leqq \tfrac{1}{2}|\varepsilon|_1 + C|h|.$$

Then $|\varepsilon|_1 \leqq 2C|h|$ and $\lim_{h\to 0}|\varepsilon|_1 = 0$. Hence $\partial w/\partial y_j$ exists and equals η. Similar argument shows the continuity of $\partial w/\partial y_j$.

Acknowledgments. The author would like to express his hearty gratitude to Professor M. Tsuji for his kind advice and encouragement. He also thanks Professor T. Ishii for helpful discussions.

ON THE STRONGLY DAMPED WAVE EQUATION: $u_{tt}-\Delta u-\Delta u_t+f(u)=0$*

DANG DINH ANG† AND ALAIN PHAM NGOC DINH‡

Abstract. The following initial boundary value problem is considered

$$u_{tt}-\Delta u-\lambda\Delta u_t+f(u)=0,\quad (x,t)\in\Omega\times]0,T[,\quad \lambda>0,$$
$$u=0\quad \text{on } \partial\Omega\times[0,T),$$
$$u(x,0)=w_0(x),\qquad u_t(x,0)=w_1(x)$$

where Ω is a bounded domain in R^N with a sufficiently regular boundary $\partial\Omega$. In Part 1, a theorem on local existence and uniqueness is proved for w_0 in $H_0^1(\Omega)$ and w_1 in $L^2(\Omega)$, under a certain Lipschitzian condition on f.

In Part 2, the question of global existence and asymptotic behavior for $t\to\infty$ is studied, under more restrictive conditions, namely $1\leqq N\leqq 3$, $f\in C^1(\mathbb{R},\mathbb{R})$, $f(0)=0$, and $f'\geqq -c$ with $c>0$ "small" and $w_0\in H_0^1(\Omega)\cap H^2(\Omega)$, $w_1\in L^2(\Omega)$. It is proved that under these conditions, a unique solution $u(t)$ exists on $\mathbb{R}_+$ such that $\|u_t(t)\|$ and $\|\Delta u(t)\|$ decay exponentially to 0 as $t\to\infty$. ($\|\cdot\|$ denotes the $L^2(\Omega)$ norm.) The method followed in this paper is that of successive linearizations (Part 1) and Galerkin (Part 2).

Key words. linear recursive schemes, local existence, global existence, decay exponentially

Introduction. We will consider the following initial boundary value problem:

$$u_{tt}-\Delta u-\lambda\Delta u_t+f(u)=0,\quad (x,t)\in\Omega\times(0,T),\quad \lambda>0, \tag{0.1}$$

$$u=0\quad \text{on } \partial\Omega\times[0,T), \tag{0.2}$$

$$u(x,0)=w_0(x),\qquad u_t(x,0)=w_1(x), \tag{0.3}$$

where Ω is a bounded in $\mathbb{R}^N$ with a sufficiently regular boundary $\partial\Omega$. The problem was considered by Webb in [9] for $N=1,2,3$. For $\lambda=0$ and $N=1$, the problem was treated in [7] and [8], and in [2] for a function f depending on u and u_t or monotone in u_t. We consider the problem with $\lambda>0$ under various conditions on f and on the initial values. For $1\leqq N\leqq 2$, (0.1) governs the motion of a linear Kelvin solid (a bar if $N=1$ and a plate if $N=2$) subjected to nonlinear elastic constraints.

The paper consists of two parts. In Part 1 under a certain local Lipschitzian condition on f with w_0 in $H_0^1(\Omega)$ and w_1 in $L^2(\Omega)$, a local existence and uniqueness theorem is proved, using the method of successive linearizations. Some of the results on local existence are also contained in [1] and [4]. In [4] Sandefur factors (0.1) and then uses semigroups and successive approximations to get existence and uniqueness. The results in [1] are generalizations of work done in [4].

In Part 2, we strengthen the hypotheses and assume as in [9] that $1\leqq N\leqq 3$, $w_0\in H_0^1(\Omega)\cap H^2(\Omega)$, and $w_1\in L^2(\Omega)$ while f satisfies no condition other than $f(0)=0$, $f'\geqq -c$ for $c>0$ "small." It is then proved that under these conditions, a unique solution $u(t)$ exists for all $t\geqq 0$, with the property that $\|u_t(t)\|$ and $\|\Delta u(t)\|$ decay exponentially to 0 as $t\to\infty$ generalizing a result of Webb [9]. (Here and elsewhere $\|\cdot\|$

stands for the $L^2(\Omega)$ norm.) In Part 2 we limit ourselves to the case $1 \leqq N \leqq 3$ in order to use the imbedding theorem of Sobolev: $H^2(\Omega) \subset C(\bar{\Omega})$. Asymptotic results for strongly damped wave equations can also be found in [5]. In [3] we study an extension of equation (0.1), namely the strong solutions for an operator generalizing the Laplacian. The method used in Part 1 can serve as a starting point for computing algorithms [6]. Note that in this sequel we will consider (0.1) as an ordinary differential equation in a Banach space for $u(t)$, so that we will write $u'(t)$ for $u_t(\cdot, t)$. For simplicity of writing, we will take $\lambda = 1$.

1. Part 1. Let

$$L^2 = L^2(\Omega), \quad H_0^1 = H_0^1(\Omega), \quad H^2 = H^2(\Omega).$$

Here $H_0^1(\Omega)$ and $H^2(\Omega)$ denote the usual Sobolev spaces on Ω. Let $(\cdot)$ denote either the L^2 inner product or the paring of a continuous linear functional with an element of a function space. Let $\|\cdot\|_x$ be a norm on a Banach space X, and let X^* be its dual. We denote by $L^p(0, T; X)$, $1 \leqq p \leqq \infty$, the space of functions f on $(0, T)$ to X such that

$$\|f\|_{L^p(0,T;X)} = \left(\int_0^T \|f(t)\|_x^p \, dt \right)^{1/p} < +\infty \quad \text{for } 1 \leqq p < \infty,$$

$$\|f\|_{L^\infty(0,T;X)} = \operatorname*{ess\,sup}_{(0,T)} \|f(t)\|_x \quad \text{for } p = \infty.$$

We will make the following assumption

(A_1) $\qquad f: H_0^1 \to H^{-1}$ satisfies:

for each bounded subset B of $H_0^1(\Omega)$, there exists $k_B > 0$ such that

$$\|f(y) - f(z)\|_{H^{-1}} \leqq k_B \|\nabla y - \nabla z\| \quad \forall y, z \in B$$

where $\|\cdot\|_{H^{-1}}$ is the dual norm on H^{-1}, the dual of $H_0^1(\Omega)$.

Then we have the following theorem.

THEOREM 1. *Suppose f satisfies (A_1) and let $w_0 \in H_0^1$, $w_1 \in L^2$. Then there exists a $T > 0$ such that the initial and boundary value problem (0.1)-(0.3) admits a unique solution $u(t)$ in the following sense*:

(i) $u \in C(0, T; H_0^1)$,

(ii) $u' \in C(0, T; L^2) \cap L^2(0, T; H_0^1)$,

(iii) $d/dt(u'(t), v) + a(u'(t), v) + a(u(t), v) + (f(u(t)), v) = 0 \quad \forall v \in H_0^1$,

$u(0) = w_0, \quad u'(0) = w_1$

with $a(u, v) = (\nabla u, \nabla v)$.

Furthermore, $u(t)$ is the limit of the sequence $\{u_n(t)\}$ of solutions of the following initial boundary value problems (i.b.v. problem):

$$u_n'' - \Delta u_n' - \Delta u_n = -f(u_{n-1}), \quad n \geqq 1, \quad u_0 = 0, \tag{1.1}$$

$$u_n = 0 \quad \text{on } \partial\Omega, \tag{1.2}$$

$$u_n(0) = w_0, \quad u_n'(0) = w_1. \tag{1.3}$$

The sequence $\{u_n\}$ converges uniformly to u in $C(0, T; H_0^1)$ and the sequence $\{u_n'\}$ converges to u' in $L^2(0, T; H_0^1)$ and uniformly in $C(0, T; L^2)$.

The proof of the theorem relies on a number of propositions.

PROPOSITION 1. *Under assumption* (A_1), *there exists a* $T>0$ *such that for each* n *the initial boundary value problem* (1.1)–(1.3) *admits a unique solution* u_n *in* $C(0, T; H_0^1)$ *with* u_n' *in* $C(0, T; L^2) \cap L^2(0, T; H_0^1)$. *Furthermore the sequence* $\{u_n\}$ *lies in a bounded subset of* $C(0, T; H_0^1)$ *and the sequence* $\{u_n'\}$ *lies in a bounded subset of* $C(0, T; L^2) \cap L^2(0, T; H_0^1)$.

Proof. Consider the following equation in H_0^1 for $u_1(t)$:

$$u_1'' - \Delta u_1 - \Delta u_1' = -f(0) \tag{1.4}$$

with the initial conditions

$$u_1(0) = w_0, \qquad u_1'(0) = w_1. \tag{1.5}$$

It is easily proved, using a Galerkin approximation scheme, that for each $K>0$, a unique solution $u_1(t)$ exists on $[0, K]$. Suppose by induction that $u_{n-1}(t)$ is a solution of the i.b.v. problem

$$u_{n-1}'' - \Delta u_{n-1} - \Delta u_{n-1}' = -f(u_{n-2}), \tag{1.6}$$

$$u_{n-1}(0) = w_0, \qquad u_{n-1}'(0) = w_1 \tag{1.7}$$

satisfying

$$\|\nabla u_{n-1}(t)\|^2 + \|u_{n-1}'(t)\|^2 + \int_0^t \|\nabla u_{n-1}'(\tau)\|^2 \, d\tau \leqq M^2, \qquad 0 \leqq t \leqq T \tag{1.8}$$

where

$$M^2 > 3(\|\nabla w_0\|^2 + \|w_1\|^2), \tag{1.9}$$

$$T(k_M \cdot M + |f(0)|(\operatorname{mes}\Omega)^{1/2})^2 < 2M^2/3 \qquad (\operatorname{mes}\Omega = \text{Lebesgue measure of } \Omega), \tag{1.10}$$

k_M a constant >0 such that

$$\|f(y) - f(z)\|_{H^{-1}} \leqq k_M \|\nabla y - \nabla z\| \quad \forall y, z, \quad \text{with } \|\nabla y\| \leqq M, \quad \|\nabla z\| \leqq M. \tag{1.11}$$

We claim that the (unique) solution $u_n(t)$ of the i.b.v. problem

$$u_n'' - \Delta u_n - \Delta u_n' = -f(u_{n-1}), \tag{1.12}$$

$$u_n(0) = w_0, \qquad u_n'(0) = w_1 \tag{1.13}$$

satisfies Proposition 1.

The existence of a solution of (1.12), (1.13) can be proved using a Galerkin approximation scheme. Taking the inner product of (1.12) with u_n' and integrating with respect to the time variable from 0 to t give, after some rearrangements,

$$\begin{aligned} &\|u_n'(t)\|^2 + \|\nabla u_n(t)\|^2 + 2\int_0^t \|\nabla u_n'(\tau)\|^2 \, d\tau \\ &= \|w_1\|^2 + \|\nabla w_0\|^2 - 2\int_0^t (f(u_{n-1}(\tau)), u_n'(\tau)) \, d\tau. \end{aligned} \tag{1.14}$$

We have

$$\left| -2\int_0^t (f(u_{n-1}(\tau)), u_n'(\tau)) \, d\tau \right| \leqq \int_0^t \|f(u_{n-1}(\tau))\|_{H^{-1}}^2 \, d\tau + \int_0^t \|\nabla u_n'(\tau)\|^2 \, d\tau. \tag{1.15}$$

Therefore,

$$\left|-2\int_0^t (f(u_{n-1}(\tau)), u_n'(\tau))\,d\tau\right| \leqq T[k_M M + |f(0)|(\operatorname{mes}\Omega)^{1/2}]^2 + \int_0^t \|\nabla u_n'(\tau)\|^2\,d\tau \tag{1.16}$$

as can be seen from the induction hypothesis (1.8) and condition (A_1). From (1.16), (1.9), and (1.10) we can then deduce

$$\|u_n'(t)\|^2 + \|\nabla u_n(t)\|^2 + \int_0^t \|\nabla u_n'(\tau)\|^2\,d\tau \leqq M^2 \quad \forall 0 \leqq t \leqq T. \tag{1.17}$$

We conclude that the latter inequality holds for all n. The continuity of $u_n : [0, T) \to H_0^1$ results from the fact that, by (1.17),

$$\int_0^t \|\nabla u_n'(\tau)\|^2\,d\tau \leqq M^2, \qquad 0 \leqq t \leqq T. \tag{1.18}$$

The mapping: $t \to \|u_n'(t)\|$ which is defined by (1.14) is continuous. On the other hand, for each v in H_0^1 the mapping, $t \to (u_n'(t), v)$, is a continuous mapping as can be seen from

$$\begin{aligned}(u_n'(t), v) + \int_0^t (\nabla u_n(\tau), \nabla v)\,d\tau + (\nabla u_n(t), \nabla v)\\ = (w_1, v) - \int_0^t (f(u_{n-1}(\tau)), v)\,d\tau + (\nabla u_n(0), \nabla v)\end{aligned} \tag{1.19}$$

which is obtained from (1.12) by taking the inner product with v in H_0^1 and integrating with respect to the time variable from 0 to t. Hence u_n' is continuous on $[0, T)$ to L^2. □

PROPOSITION 2. *Let T satisfy* (1.10) *and furthermore let*

$$k_M^2 T < 1 \tag{1.20}$$

with M and k_M as in (1.9)-(1.11). *Then the sequence $\{u_n\}$ constructed in the proof of Proposition* 1 *is a Cauchy sequence in $C(0, T; H_0^1)$. Furthermore the sequence $\{u_n'\}$ is a Cauchy sequence in $C(0, T; L^2) \cap L^2(0, T; H_0^1)$.*

Proof. Let $v_n = u_n - u_{n-1}$. Then v_n satisfies

$$v_n'' - \Delta v_n - \Delta v_n' = -[f(u_{n-1}) - f(u_{n-2})], \tag{1.21}$$

$$v_n(0) = v_n'(0) = 0. \tag{1.22}$$

Taking the inner product with $v_n'(t)$, integrating, and rearranging gives

$$\begin{aligned}\|v_n'(t)\|^2 + \|\nabla v_n(t)\|^2 + \int_0^t \|\nabla v_n'(\tau)\|^2\,d\tau &\leqq k_M^2 \int_0^t \|\nabla v_{n-1}(\tau)\|^2\,d\tau\\ &\leqq k_M^2 T \sup_t \|\nabla v_{n-1}(t)\|^2\end{aligned} \tag{1.23}$$

where the sup is taken over $0 \leqq t \leqq T$.

It follows from (1.23) that

$$\sup_t \|\nabla v_n(t)\|^2 \leqq \sigma \sup_t \|\nabla v_{n-1}(t)\|^2 \quad \text{for } \sigma = k_M^2 T < 1.$$

Hence

$$\sup_t \|\nabla u_n(t) - \nabla u_m(t)\| \to 0 \quad \text{for } n, m \to \infty. \tag{1.24}$$

Furthermore we have for $n > m$

$$u_n'' - u_m'' - \Delta(u_n - u_m) - \Delta(u_n' - u_m') = -[f(u_{n-1}) - f(u_{m-1})]. \tag{1.25}$$

Taking the inner product with $u_n'(t)-u_m'(t)$, integrating with respect to t, and making use of the Lipschitzian property of f gives after some rearrangements

$$\begin{aligned}&\|u_n'(t)-u_m'(t)\|^2+\|\nabla u_n(t)-\nabla u_m(t)\|^2+\int_0^t \|\nabla u_n'(\tau)-\nabla u_m'(\tau)\|^2\,d\tau\\ &\leqq k_M^2\int_0^t \|\nabla u_{n-1}(\tau)-\nabla u_{m-1}(\tau)\|^2\,d\tau.\end{aligned}\tag{1.26}$$

It follows from (1.24) and (1.26) that

$$\sup_t \|u_n'(t)-u_m'(t)\|\to 0 \quad \text{for } n, m\to\infty \tag{1.27}$$

and

$$\int_0^T \|\nabla u_n'(\tau)-\nabla u_m'(\tau)\|^2\,d\tau\to 0 \quad \text{for } n, m\to\infty. \tag{1.28}$$

□

We turn to the proof of Theorem 1.

Proof of Theorem 1. It is immediate that there is at most one solution of (0.1)-(0.3). We will prove existence. Since H_0^1 is complete and since, by Proposition 2, u_n is a Cauchy sequence in $C(0, T; H_0^1)$, there is a u in $C(0, T; H_0^1)$ such that

$$\sup_t \|\nabla u_n(t)-\nabla u(t)\|\to 0 \quad \text{for } n\to\infty. \tag{1.29}$$

Since clearly

$$u_n'\to u' \quad \text{weak * in } L^\infty(0, T; L^2) \tag{1.30}$$

and

$$u_n'\to u' \quad \text{weakly in } L^2(0, T; H_0^1),$$

we also have by Proposition 2

$$\sup_t \|u_n'(t)-u'(t)\|\to 0 \quad \text{as } n\to\infty, \tag{1.31}$$

$$\int_0^T \|\nabla u_n'(\tau)-\nabla u'(\tau)\|^2\,d\tau\to 0 \quad \text{as } n\to\infty. \tag{1.32}$$

From (1.1), we have

$$\begin{aligned}&(u_n'(t), v)+\int_0^t (\nabla u_n'(\tau), \nabla v)\,d\tau+\int_0^t (\nabla u_n(\tau), \nabla v)\,d\tau\\ &=-\int_0^t (f(u_{n-1}(\tau)), v)\,d\tau+(w_1, v) \quad \forall v\in H_0^1.\end{aligned}\tag{1.33}$$

From (1.29), (1.31), (1.32) we obtain, using the Lipschitzian property of f, and passing to the limit as $n\to\infty$ in (1.33):

$$\begin{aligned}&(u'(t), v)+\int_0^t (\nabla u'(\tau), \nabla v)\,d\tau+\int_0^t (\nabla u(\tau), \nabla v)\,d\tau\\ &=-\int_0^t (f(u(\tau)), v)\,d\tau+(w_1, v) \quad \forall v\in H_0^1.\end{aligned}\tag{1.34}$$

It follows from (1.34) and (1.17) that $u(t)$ satisfies

$$d/dt(u'(t), v)+(\nabla u'(t), \nabla v)+(\nabla u(t), \nabla v)=-(f(u(t)), v)$$

(1.35) almost everywhere on $(0, T)$ and $\forall v \in H_0^1$

$$u(0)=w_0, \qquad u'(0)=w_1. \qquad \square$$

2. Part 2. We will consider the problem of global existence and asymptotic behavior for $t \to \infty$. To this end, we will limit ourselves, in what follows, to the case $1 \leqq N \leqq 3$, and furthermore, we will restrict the hypotheses on f and on the regularity of the initial data. Thus we will consider the following conditions on f:

(A_2) $$f \in C^1(\mathbb{R}, \mathbb{R}), \qquad f(0)=0,$$

(A_3) $$(f(u)+\varepsilon u)u \geqq 0 \quad \forall |u| \geqq a,$$

with $0<\varepsilon<1$ satisfying $\varepsilon\alpha^2<1$ where $\alpha>0$ such that

(2.1) $$\|u\| \leqq \alpha \|\nabla u\| \quad \text{and} \quad \|\nabla u\| \leqq \alpha \|\Delta u\| \quad \forall u \in H_0^1 \cap H^2,$$

(A_4) $$f' \geqq -c, \qquad c>0.$$

The problem (0.1)-(0.3) with $w_0 \in H_0^1 \cap H^2$, $w_1 \in L^2$ was studied by Webb [9] under conditions on f which are similar to (A_2)-(A_4). We will show that Webb's result [9] on asymptotic decay for $t \to \infty$ can be considerably strengthened.

PROPOSITION 3. *Let $w_0 \in H_0^1 \cap H^2$ and $w_1 \in L^2$ and let f satisfy (A_2)-(A_4). Then there is a unique solution $u(t)$ of the i.b.v. problem (0.1)-(0.3) defined on $[0, \infty)$. Moreover the quantity*

$$\|\Delta u(t)\|^2+\|u'(t)\|^2+\int_0^t \|\nabla u'(\tau)\|^2 \, d\tau$$

is bounded on compact subsets of $[0, \infty)$.

Proof. Let the approximated problem be, after rewriting $f(u)=g(u)-\varepsilon u$ with $\varepsilon>0$

(2.2) $$u_n''-\Delta u_n-\Delta u_n'+g(u_n)-\varepsilon u_n=0.$$

Here the finite-dimensional spaces considered in the Galerkin approximation are eigenspaces of the Laplacian.

Taking the inner product of (2.2) with $u_n'(t)$ and integrating from 0 to t, we obtain

(2.3) $$\|u_n'(t)\|^2+\|\nabla u_n(t)\|^2+2\int_0^t \|\nabla u_n'(\tau)\|^2 \, d\tau+2\int_\Omega \int_0^{u_n} g(u) \, du-\varepsilon\|u_n(t)\|^2$$
$$=-\varepsilon\|w_0\|^2+\|w_1\|^2+\|\nabla w_0\|^2+2\int_\Omega \int_0^{w_0} g(u) \, du.$$

Since $w_0 \in H_0^1 \cap H^2$ and $1 \leqq N \leqq 3$, for ε sufficiently small we obtain from (2.3)

(2.4) $$\|u_n'(t)\|^2+\tilde{\beta}\|\nabla u_n(t)\|^2+2\int_0^t \|\nabla u_n'(\tau)\|^2 \, d\tau+2\int_\Omega \int_0^{u_n} g(u) \, du \leqq M'$$

where $\tilde{\beta}=1-\varepsilon\alpha^2>0$ and M' a constant independent of t.

For any argument $u_n>0$

(2.5) $$\int_0^{u_n} g(u) \, du=\int_0^a g(u) \, du+\int_a^{u_n} g(u) \, du \geqq -\int_{-a}^a |g(u)| \, du$$

since the second integral is nonnegative due to (A_3), u_n being larger than a. A similar argument applies for negative arguments u_n.

Finally from (2.4) we can deduce the following inequality:

$$\|u_n'(t)\|^2+\tilde{\beta}\|\nabla u_n(t)\|^2+2\int_0^t\|\nabla u_n'(\tau)\|^2\,d\tau\leqq 2(\operatorname{mes}\Omega)\int_{-a}^{a}|g(u)|\,du+M'=M \tag{2.6}$$

with M constant independent of t.

Likewise, by taking the inner product of (2.2) (with $\varepsilon=c$) with $-\Delta u_n(t)$ and integrating from 0 to t give, after some rearrangements:

$$\begin{aligned}&\int_0^t\|\Delta u_n(\tau)\|^2\,d\tau+\frac{1}{2}\|\Delta u_n(t)\|^2+\int_0^t\left(\int_\Omega g'(u_n)|\nabla u_n|^2\,dx\right)d\tau\\ &=c\int_0^t\|\nabla u_n(\tau)\|^2\,d\tau+\int_\Omega u_n'\Delta u_n\,dx+\int_0^t\|\nabla u_n'(\tau)\|^2\,d\tau\\ &\quad+\frac{1}{2}\|\Delta w_0\|^2-\int_\Omega w_1\Delta w_0\,dx\quad\forall t\geqq 0.\end{aligned} \tag{2.7}$$

By (2.6), (2.7), and hypothesis (A_4) it follows that, for each $T>0$

$$\int_0^t\|\Delta u_n(\tau)\|^2+\frac{1}{2}\|\Delta u_n(t)\|^2\leqq M_T+\|u_n'(t)\|\cdot\|\Delta u_n(t)\|\quad\forall 0\leqq t\leqq T \tag{2.8}$$

where M_T is a constant depending on T.

Inequalities (2.8) and (2.6) involve

$$\|\Delta u_n(t)\|\leqq M_T\quad\forall 0\leqq t\leqq T, \tag{2.9}$$

M_T always indicating a bound depending on T.

Inequalities (2.6) and (2.9) show that from the sequence $\{u_n\}$ we can deduce a subsequence still denoted $\{u_n\}$ which converges weak * to an element $u\in L^\infty(0,T;H_0^1\cap H^2)$ such that $u'\in L^\infty(0,T;L^2)\cap L^2(0,T;H_0^1)$.

Consider the sequence $\{f(u_n)\}$. We have

$$(f(u_n(t)),v)\to(f(u(t)),v)\quad\forall v\in H_0^1\quad\text{in } L^\infty(0,T)\text{ weak *} \tag{2.10}$$

since $f\in C^1(\mathbb{R},\mathbb{R})$ and u_n converges to u almost everywhere on $Q=(0,T)\times\Omega$.

If we pass to the limit in the variational form associated with the approximated equation (2.2), we find that u satisfies equation (1.35).

Finally for each $T>0$ there exists a unique solution $u(t)$, $0\leqq t<T$ of the i.b.v. problem (0.1)-(0.3) with u in $L^\infty(0,T;H_0^1\cap H^2)$ and u' in $L^\infty(0,T;L^2)\cap L^2(0,T;H_0^1)$ and such that

$$\|\Delta u(t)\|^2+\|u'(t)\|^2+\int_0^T\|\nabla u'(\tau)\|^2\,d\tau\quad\text{is bounded on } [0,T). \qquad\square$$

Remark 1. As shown in Webb [9] the solution $u(t)$ is actually more regular with respect to t than has been asserted in Proposition 3 above.

Remark 2. Under hypotheses analogous to the ones in Proposition 3 above, Webb [9, Thm. 3.1] claims that there exists a global bound on $\|\Delta u(t)\|^2+\|u'(t)\|^2$ for all $t\geqq 0$. However his proof is not valid, since the inequality [9, (3.18)] is not proved. On the other hand, on the question of global bound we have the following proposition.

PROPOSITION 4. *If $f\in C^1(\mathbb{R},\mathbb{R})$, satisfies $\underline{\lim}_{|x|\to\infty}f(x)$, $x\geqq 0$, then under the sole condition $w_0\in H_0^1$ and $w_1\in L^2$, there exists a global bound $\|u'(t)\|$ and $\|\nabla u(t)\|$ for all $t\geqq 0$.*

Proof. Let $g(u)=f(u)+\varepsilon u$ ($\varepsilon>0$). By using the same arguments as in Proposition 3 it is possible to obtain, for ε sufficiently small, a constant M' independent of t such that

$$\|u'(t)\|^2+\tilde{\beta}\|\nabla u(t)\|^2+2\int_0^t\|\nabla u'(\tau)\|^2\,d\tau+2\int_\Omega\int_{w_0}^{u}g(u)\,du\leqq M'. \tag{2.11}$$

The condition $\underline{\lim}_{|x|\to\infty}f(x)x\geqq 0$ can be written as $\underline{\lim}_{|u|\geqq a}ug(u)\geqq 0$ for a sufficiently large, and we can always assume that $a\geqq|w_0(x)|$ almost everywhere $x\in\Omega$.

We can prove as in Proposition 3 that

$$\left|\int_\Omega\int_{w_0}^{u}g(u)\,du\right|\leqq(\operatorname{mes}\Omega)\int_{-a}^{a}|g(u)|\,du$$

which implies (2.6) for all $t\geqq 0$. □

We can now state the main result of Part 2.

THEOREM 2. *Let $w_0\in H_0^1\cap H^2$ and $w_1\in L^2$. Let* (A_2) *hold and let*

$$f'\geqq -c,\quad c \text{ satisfying the following conditions: } 0<c<\tfrac{1}{2}, \tag{A_4'}$$

$$c\alpha^2<1\quad(\alpha \text{ as in } (2.1)).$$

Then the solution $u(t)$, which exists for all $t\geqq 0$ as per Proposition 3, decays exponentially to 0 as $t\to\infty$ in the following sense: there exists an $M>0$ and $\gamma>0$ such that

$$\|u'(t)\|^2+\|\Delta u(t)\|^2\leqq M e^{-\gamma t}\quad\forall t\geqq 0.$$

Proof. Let c be as in Theorem 2. We write

$$f(u)=g(u)-cu;$$

then $g'(u)\geqq 0$, and hence f satisfies (A_3). Thus by Proposition 3 the solution $u(t)$ exists on $[0,\infty)$.

If we take the inner product of (0.1) with $u'(t)$ and integrate with respect to the time variable from 0 to t, we find using the property $u.g(u)\geqq 0$ (see (2.3)) that there exists an $M_1>0$ independent of t such that

$$\|u'(t)\|^2+(1-c\alpha^2)\|\nabla u(t)\|^2+2\int_0^t\|\nabla u(\tau)\|^2\,d\tau\leqq M_1^2\quad\text{for all } t\geqq 0. \tag{2.12}$$

Likewise, by taking the inner product of (0.1) with $-\Delta u(t)$ and integrating from 0 to t, we get (see (2.7)), taking into account (2.12), two constants C_1 and C_2 independent of t such that

$$(1-c\alpha^2)\int_0^t\|\Delta u(\tau)\|^2\,d\tau+\tfrac{1}{2}\|\Delta u(t)\|^2\leqq C_1\|\Delta u(t)\|+C_2\quad\forall t\geqq 0. \tag{2.13}$$

Clearly (2.13) implies

$$\|\Delta u(t)\|\leqq M_2\quad\forall t\geqq 0. \tag{2.14}$$

M_2 is a constant independent of t.

Taking the inner product of (0.1) first with $u'(t)\,e^{\gamma t}$, then with $-\beta\Delta u\,e^{\gamma t}$ and integrating with respect to the time variable from 0 to t, we find, after rearranging and

summing up, and taking (2.14) into account:

$$
\begin{aligned}
&(1-c-2\beta)\, e^{\gamma t}\|u'(t)\|^2/2+(1-\alpha^2 c)\, e^{\gamma t}\|\nabla u(t)\|^2/2+\beta\, e^{\gamma t}\|\Delta u(t)\|^2/4\\
&\quad+[1-\beta-\gamma(1+\beta)\alpha^2/2]\int_0^t e^{\gamma t}\|\nabla u'(t)\|^2\, d\tau\\
&\quad+[-\gamma/2-c\beta-\gamma k'\alpha^2+\beta(1-\gamma)/\alpha^2]\int_0^t e^{\gamma\tau}\|\nabla u(\tau)\|^2\, d\tau\\
&\quad+e^{\gamma t}\int_\Omega G(u(x,t))\, dx+\beta\int_0^t g'(u)\|\nabla u(\tau)\|^2\, e^{\gamma\tau}\, d\tau\\
&\quad+(c\gamma/2)\int_0^t e^{\gamma\tau}\|u(\tau)\|^2\, d\tau\leqq C(w_0, w_1, \beta, \gamma)
\end{aligned}
\tag{2.15}
$$

where

$$
G(u)=\int_0^u g(z)\, dz, \tag{2.16}
$$

$$
k'=(\text{mes }(\Omega)/2)\operatorname*{Sup}_t |g'(\|u(t)\|_\infty)|. \tag{2.17}
$$

If in (2.15) we take $\beta=(1-2c)/2$ and

$$
\gamma=(1/\alpha^2)\min[(1+2c)2/(3-2c), (1-\alpha^2 c)(1-2c)/(1+k'\alpha^2+(1-2c)/\alpha^2)]
$$

then the coefficient of each term of the left-hand side of the inequality is positive and hence there exists an $M>0$ such that

$$
\|u'(t)\|^2+\|\Delta u(t)\|^2\leqq M\, e^{-\gamma t}\quad \forall t>0. \qquad \square
$$

Webb proved a very interesting result [9, Thm. 4.1] on the asymptotic behavior of the solution under the hypotheses

$$
f\in C^1(\mathbb{R},\mathbb{R}),\quad f(0)=0,\quad \underline{\lim}_{|x|\to\infty} f(x).\, x\geqq 0,\quad f'(x)\geqq -c\quad \text{where } c>0.
$$

From his theorem he deduced, under the foregoing hypotheses with an additional condition on the smallness of $c>0$, that $\|u'(t)\|$ and $\|\Delta u(t)\|$ tend to 0 as $t\to\infty$ [9, Cor. 4.1]. Our theorem is therefore a considerably stronger result than Webb's result of the asymptotic decay of the solution for $t\to\infty$, since on one hand the hypothesis $\underline{\lim}_{|x|\to\infty} f(x).\, x\geqq 0$ is not used and on the other hand our asymptotic decay is exponential.

Remark 3. As remarked by one of the referees, the restriction on c $(0<c<\frac{1}{2})$ can be removed by a scaling argument. In fact write (0.1) in terms of $\xi=\mu x$, $\tau=\mu t$. Then we have

$$
u_{\tau\tau}-\lambda\mu\Delta_\xi u_\tau-\Delta_\xi u+f(u)/\mu^2=0.
$$

Let $g(u)=f(u)/\mu^2$, with $f(u)$ always satisfying (A_4); then the previous conditions on c become

$$
0<c<\text{Min }(\mu^2/2, 1/\alpha^2)
$$

with $\mu>1/2\lambda$ (the coefficient of $e^{\gamma t}\|\Delta u(t)\|^2$ in (2.15) becomes $(\beta/4)(2\lambda\mu-1)$).

Acknowledgments. The authors wish to thank the referees for their constructive criticism and most pertinent remarks, leading to improvements in the original manuscript.

ON THE NODAL SETS OF THE EIGENFUNCTIONS OF THE STRING EQUATION*

CHAO-LIANG SHEN†

Abstract. In this paper the nodal sets of the eigenfunctions of the string equation are investigated. For n sufficiently large it is found that the shortest nodal domain of the nth eigenfunction must be one of the neighboring nodal domains of the maximum points, and the longest nodal domain of the nth eigenfunction must be one of the neighboring nodal domains of the minimum points of the density function of the string equation. A limit formula for the ratio of the longest length and the shortest length of the nodal domains of the nth eigenfunction is also proved, and some average formulae for the nodal domains are derived.

Key words. string equation, eigenvalues, eigenfunctions, nodal sets, nodal domains

AMS(MOS) subject classifications. 34B25, 34C10

Introduction. The subject of this paper is the investigation of the nodal sets of the eigenfunctions of the string equation

$$\begin{aligned} &y''(x)+\lambda\rho(x)y(x)=0, \qquad 0<x<\beta, \\ &y(0)=y(\beta)=0 \end{aligned} \tag{0.1}$$

where the *density function* $\rho(x)$ is a strictly positive C^2-function on the interval $[0, \beta]$. In § 1 we study the relation between the location of the nodal domains of extreme lengths of the nth eigenfunction $\varphi_n(x)$ of (0.1) and the extremal points of $\rho(x)$. We also prove a limit formula (Theorem 1.3) for the ratio of the lengths of the longest and the shortest nodal domains of φ_n. In § 2 we prove some average formulae for the lengths of nodal domains, and the nodal points of the eigenfunctions of (0.1).

1. Length of the nodal domains and the extreme values of the density function. Let $\varphi_n(x)$ be the nth eigenfunction of the string equation (0.1). We will denote $x_1^{(n)}<x_2^{(n)}<\cdots<x_{n-1}^{(n)}$ the nodal points of φ_n in the open interval $(0, \beta)$, and we denote $x_0^{(n)}=0$, $x_n^{(n)}=\beta$, $I_{n,j}=[x_{j-1}^{(n)}, x_j^{(n)}]$. Then, by the variational formula for λ_n, and the monotonicity principle for the comparison of the eigenvalues, we have

$$\begin{aligned} &\lambda_n=\int_{x_{j-1}^{(n)}}^{x_j^{(n)}}[\varphi_n'(x)]^2\,dx \Big/ \int_{x_{j-1}^{(n)}}^{x_j^{(n)}}\rho(x)[\varphi_n(x)]^2\,dx, \\ &\frac{\pi^2}{\max(\rho, I_{n,j})|I_{n,j}|^2}\leqq\lambda_n\leqq\frac{\pi^2}{\min(\rho, I_{n,j})|I_{n,j}|^2}, \end{aligned} \tag{1.1}$$

where $\max(\rho, I_{n,j})$ (respectively, $\min(\rho, I_{n,j})$) denotes the maximum (respectively, the minimum) of ρ in $I_{n,j}$, and $|I_{n,j}|$ denotes the length of the interval $I_{n,j}$.

LEMMA 1.1. *For $\delta>0$, there exists $n_0(\delta)$ such that*

$$|I_{n,k}|<\delta, \qquad k=1, 2, \cdots, n$$

for all $n\geqq n_0$.

Proof. Suppose there exists a $\delta > 0$ such that there is a sequence n_j, $\lim_{j\to\infty} n_j = \infty$, and for each n_j there is a nodal domain I_{n_j,k_j} such that $|I_{n_j,k_j}| \geqq \delta$. Then, by (1.1)

$$\lambda_{n_j} \leqq \frac{1}{\min(\rho, [0,\beta])} \cdot \frac{\pi^2}{\delta^2},$$

which contradicts the fact that $\lim_{n\to\infty} \lambda_n = \infty$. □

In the rest of this section we will assume, for simplicity, that the density function $\rho(x)$ satisfies the following *condition* (A): *ρ has only finitely many critical points in* $[0,\beta]$, where the *critical points* of ρ are those points at which the derivative of ρ vanishes. We will call the values of ρ at its critical points the *critical values* of ρ.

We define the *neighboring nodal domains* of the extreme points of $\rho(x)$ as follows. Let x_* be one of the maximum (respectively, minimum) points of $\rho(x)$. If $x_* \in$ Interior $(I_{n,j})$, we call $I_{n,j-1}$, $I_{n,j}$, $I_{n,j+1}$ the neighboring nodal domains of x_*. If $x_* = x_j^{(n)}$, we call $I_{n,j}$, $I_{n,j+1}$ the neighboring nodal domains of x_*. Note that if $x_* = \beta$, the only neighboring nodal domain is $I_{n,n}$. If $x_* = 0$, $I_{n,1}$ is the neighboring nodal domain. The following theorem tells us the nodal domains of φ_n of extreme lengths have to be the neighboring nodal domains of the extreme points of $\rho(x)$.

THEOREM 1.2. *Suppose $\rho(x)$ satisfies condition* (A). *Then there exists n_0 such that for $n > n_0$ a shortest* (*respectively, a longest*) *nodal domain of the nth eigenfunction of* (0.1) *must be one of the neighboring nodal domains of the maximum* (*respectively, minimum*) *points of the density function $\rho(x)$.*

Proof. Let $\rho_1 > \rho_2 > \cdots > \rho_l$ (>0) be the sequence of the maximum value, the critical values, and the minimum value of ρ. Denote $\varepsilon_1 = \frac{1}{3}\min\{\rho_1-\rho_2, \rho_2-\rho_3, \cdots, \rho_{l-1}-\rho_l\}$, and define ε as follows:

$$\varepsilon = \begin{cases} \varepsilon_1 & \text{if } \rho_1 = \rho(\beta) = \rho(0), \\ \min\left\{\varepsilon_1, \dfrac{\rho_1-\rho(\beta)}{3}\right\} & \text{if } \rho_1 \neq \rho(\beta), \quad \rho(0) = \rho_1, \\ \min\left\{\varepsilon_1, \dfrac{\rho_1-\rho(0)}{3}\right\} & \text{if } \rho_1 = \rho(\beta), \quad \rho(0) \neq \rho_1, \\ \min\left\{\varepsilon_1, \dfrac{\rho_1-\rho(0)}{3}, \dfrac{\rho_1-\rho(\beta)}{3}\right\} & \text{if } \rho_1 \neq \rho(\beta), \quad \rho_1 \neq \rho(0). \end{cases}$$

Then, for this ε, there exists $\delta > 0$ such that $|\rho(x)-\rho(x')| < \varepsilon$ if $|x-x'| < \delta$. By Lemma 1.1, for this δ, there exists an n_0, such that for $n > n_0$, $|I_{n,k}| < \delta/2$, $k = 1, 2, \cdots, n$.

Suppose there is an $n > n_0$ such that one of the shortest nodal domains, say $I_{n,j}$, of φ_n is not a neighboring nodal domain of the maximum points of $\rho(x)$. We consider the three possible behaviors of $\rho(x)$ in $I_{n,j}$ separately: (1) $\rho(x)$ is strictly increasing in $I_{n,j}$; (2) $\rho(x)$ is strictly decreasing in $I_{n,j}$; (3) one of the local extreme points of ρ lies in the interior of $I_{n,j}$. Note that by the choice of ε, δ, if x is in one of the neighboring nodal domains of the maximum points of $\rho(x)$, then

$$\rho(x) > \rho_1 - \varepsilon \geqq \rho_1 - \frac{\rho_1-\rho_2}{3} = \frac{2\rho_1+\rho_2}{3}, \qquad \rho(x) > \rho_1 - \frac{\rho_1-\rho(\beta)}{3} = \frac{2\rho_1+\rho(\beta)}{3}$$

if $\rho_1 > \rho(\beta)$.

If case (3) happens, since $I_{n,j}$ is not a neighboring nodal domain of the maximum points of ρ, the maximum of the local extremal values of ρ in $I_{n,j}$ is less than or equal to ρ_2. Thus, by the choice of ε, δ, and the fact $|I_{n,j}| < \delta/2$, $\rho(x) < \rho_2 + \varepsilon \leqq \rho_2 + (\rho_1-\rho_2)/3 = (2\rho_2+\rho_1)/3$ for all x in $I_{n,j}$. Since $2\rho_2+\rho_1 < 2\rho_1+\rho_2$, for x in $I_{n,j}$, ξ

in any of the neighboring nodal domains of the maximum points of ρ we have $\rho(x)<\rho(\xi)$.

If case (1) happens, let $\xi_j=\sup\{x\in[0,\beta]\colon \rho \text{ is increasing in } [x_{j-1}^{(n)}, x]\}$. Then ξ_j is either a critical point of ρ in $(0,\beta)$, or is β itself. Suppose ξ_j is a critical point of ρ in $(0,\beta)$. If ξ_j is not a maximum point of ρ, then for all x in $I_{n,j}$ $\rho(x)\leqq\rho_2<(2\rho_1+\rho_2)/3<\rho(\xi)$ for all ξ in any of the neighboring nodal domains of the maximum points of ρ. If ξ_j is a maximum point of ρ, since $I_{n,j}$ is not a neighboring nodal domain of ξ_j, there is a neighboring nodal domain $I_{n,k}$ of ξ_j such that $\rho(x)<\rho(\xi)$ for all x in $I_{n,j}$, ξ in $I_{n,k}$. That is, if ρ is increasing in $I_{n,j}$, then there exists a neighboring nodal domain $I_{n,k}$ of the maximum points of ρ such that $\rho(x)<\rho(\xi)$ for all x in $I_{n,j}$, ξ in $I_{n,k}$. The same conclusion holds for the case $\xi_j=\beta$ and for case (2).

By the previous argument, we find that if $I_{n,j}$ is one of the shortest nodal domains of the nth eigenfunction φ_n, $n>n_0$, which is not a neighboring nodal domain of the maximum points of ρ, then we can find a neighboring nodal domain $I_{n,k}$ of the maximum points of ρ such that $\rho(x)<\rho(\xi)$ for all x in $I_{n,j}$, ξ in $I_{n,k}$. Since $|I_{n,j}|\leqq|I_{n,k}|$, for x in $I_{n,j}$, $x+x_{k-1}^{(n)}-x_{j-1}^{(n)}$ is in $I_{n,k}$. For x in $I_{n,j}$ let $\tilde{\rho}(x)=\rho(x+x_{k-1}^{(n)}-x_{j-1}^{(n)})$, $u(x)=\varphi_n(x+x_{k-1}^{(n)}-x_{j-1}^{(n)})$. Then

$$u''(x)+\lambda_n\tilde{\rho}(x)u(x)=0 \quad \text{in } I_{n,j}.$$

Note that $\tilde{\rho}(x)>\rho(x)$ for x in $I_{n,j}$ because $\rho(\xi)>\rho(x)$ for ξ in $I_{n,k}$, x in $I_{n,j}$. Since

$$\varphi_n''(x)+\lambda_n\rho(x)\varphi_n(x)=0 \quad \text{in } I_{n,j},$$
$$\varphi_n(x_{j-1}^{(n)})=\varphi_n(x_j^{(n)})=0,$$
$$\rho(x)<\tilde{\rho}(x) \quad \text{in } I_{n,j},$$

Sturm's comparison theorem (see [2, Thm. 3.1] or [1, § 10.3]) tells us that $u(x)$ has a zero ξ in the interior of $I_{n,j}$; i.e., the eigenfunction φ_n has a nodal point $\xi+x_{k-1}^{(n)}-x_{j-1}^{(n)}$,

$$x_{k-1}^{(n)}<\xi+x_{k-1}^{(n)}-x_{j-1}^{(n)}<x_k^{(n)},$$

which is absurd. Thus the shortest nodal domains of the nth eigenfunction φ_n, $n>n_0$, are among neighboring nodal domains of the maximum points of $\rho(x)$. A similar argument implies the longest nodal domains of φ_n are among neighboring nodal domains of the minimum points of $\rho(x)$. □

Theorem 1.2 has an interesting application.

THEOREM 1.3. *Let L_n, ℓ_n denote, respectively, the lengths of the longest and shortest nodal domains of the nth eigenfunction φ_n of* (0.1). *Then*

$$\lim_{n\to\infty}\left(\frac{L_n}{\ell_n}\right)^2=\frac{\max(\rho,[0,\beta])}{\min(\rho,[0,\beta])}. \tag{1.2}$$

Proof. By Theorem 1.2, if we let $I_{n,j_1(n)},\cdots,I_{n,j_{k_n}(n)}$ be the shortest (respectively, longest) nodal domains of φ_n, then $\max(\rho,[0,\beta])$ (respectively, $\min(\rho,[0,\beta])$) is the limit point of the sequence

$$\rho(x_{j_1(n_0+1)-1}^{(n_0+1)}),\ \rho(x_{j_1(n_0+1)}^{(n_0+1)}),\cdots,\rho(x_{j_{k_{n_0+1}}(n_0+1)-1}^{(n_0+1)}),$$
$$\rho(x_{j_{k_{n_0+1}}(n_0+1)}^{(n_0+1)}),\cdots,\rho(x_{j_1(n)-1}^{(n)}),\ \rho(x_{j_1(n)}^{(n)}),\cdots,$$
$$\rho(x_{j_{k_n}(n)-1}^{(n)}),\ \rho(x_{j_{k_n}(n)}^{(n)}),\cdots.$$

Let $I_{n,\ell(n)}$ be a nodal domain of φ_n of shortest length and let $I_{n,L(n)}$ be a nodal domain of φ_n of longest length. Then $\lim_{n\to\infty}\max(\rho,I_{n,\ell(n)})=\lim_{n\to\infty}\min(\rho,I_{n,\ell(n)})=\max(\rho,[0,\beta])$, $\lim_{n\to\infty}\max(\rho,I_{n,L(n)})=\lim_{n\to\infty}\min(\rho,I_{n,L(n)})=\min(\rho,[0,\beta])$, and

these limits are independent of the choice of $I_{n,\ell(n)}$, $I_{n,L(n)}$. Since, by (1.1), we have

$$\frac{\min(\rho, I_{n,\ell(n)})}{\max(\rho, I_{n,L(n)})} \leqq \frac{L_n^2}{\ell_n^2} \leqq \frac{\max(\rho, I_{n,\ell(n)})}{\min(\rho, I_{n,L(n)})}.$$

These inequalities and previous limit formulae imply (1.2). □

2. Some average formulae. Let $x_1^{(n)} < x_2^{(n)} < \cdots < x_{n-1}^{(n)}$ be the nodal points of the nth eigenfunction φ_n of (0.1) in the open interval $(0, \beta)$. Denote $x_0^{(n)} = 0$, $x_n^{(n)} = \beta$.

THEOREM 2.1.

$$\lim_{n\to\infty} \frac{1}{n^2} \sum_{j=1}^{n} \frac{1}{x_j^{(n)} - x_{j-1}^{(n)}} = \left\{ \int_0^\beta \rho(x)\, dx \right\} \left\{ \int_0^\beta \sqrt{\rho(x)}\, dx \right\}^{-2}. \tag{2.1}$$

Proof. By (1.1) we have

$$\begin{aligned} \lambda_n \sum_{j=1}^{n} \min(\rho, I_{n,j}) \cdot (x_j^{(n)} - x_{j-1}^{(n)}) &\leqq \sum_{j=1}^{n} \frac{\pi^2}{x_j^{(n)} - x_{j-1}^{(n)}} \\ &\leqq \lambda_n \sum_{j=1}^{n} \max(\rho, I_{n,j}) \cdot (x_j^{(n)} - x_{j-1}^{(n)}). \end{aligned} \tag{2.2}$$

Since $\lim_{n\to\infty} (\lambda_n / n^2) = \pi^2 / (\int_0^\beta \sqrt{\rho(x)}\, dx)^2$, (2.2) implies

$$\frac{\pi^2 \int_0^\beta \rho(x)\, dx}{(\int_0^\beta \sqrt{\rho(x)}\, dx)^2} = \pi^2 \lim_{n\to\infty} \frac{1}{n^2} \sum_{j=1}^{n} \frac{1}{x_j^{(n)} - x_{j-1}^{(n)}},$$

which is (2.1). □

Remark. We know that $(\int_0^\beta \sqrt{\rho(x)}\, dx)^2 \leqq \beta \int_0^\beta \rho(x)\, dx$, and the equality holds if and only if ρ is a nonnegative constant. If the limit of (2.1) is $1/\beta$, then $\rho(x)$ must be a constant. The following inverse spectral result is a consequence of Theorem 2.1: "If there are infinitely many eigenvalues λ_{n_j} of (0.1) such that the nodal domains of the corresponding eigenfunctions are of length β/n_j, then $\rho(x)$ is a constant."

It will be interesting to find the limit

$$\lim_{n\to\infty} \frac{1}{n^3} \sum_{j=1}^{n} \frac{1}{(x_j^{(n)} - x_{j-1}^{(n)})^2}. \tag{2.3}$$

If we follow the idea of the proof of Theorem 2.1, we find that in order to evaluate the limit (2.3), we have to be able to calculate the limit

$$\lim_{n\to\infty} \frac{\sum_{j=1}^{n} \rho(\bar{x}_j^{(n)})}{n}, \tag{2.4}$$

where $\bar{x}_j^{(n)} \in [x_{j-1}^{(n)}, x_j^{(n)}]$ such that $\rho(\bar{x}_j^{(n)})$ is equal to the maximum (respectively, minimum) of $\rho(x)$ in the interval $[x_{j-1}^{(n)}, x_j^{(n)}]$. Since $\rho(x)$ is uniformly continuous on $[0, \beta]$, to evaluate the limit (2.4), it suffices to evaluate the following limit:

$$\lim_{n\to\infty} \frac{\sum_{j=1}^{n} \rho(x_j^{(n)})}{n}. \tag{2.5}$$

In the course of studying the convergence of (2.3), we found that the limit (2.5) does exist, and can be evaluated explicitly as follows.

THEOREM 2.2.

$$\lim_{n\to\infty} \frac{\sum_{j=1}^{n} \rho(x_j^{(n)})}{n} = \frac{\int_0^\beta [\rho(x)]^{3/2}\, dx}{\int_0^\beta \sqrt{\rho(x)}\, dx}. \tag{2.6}$$

Theorem 2.2 is a corollary of the following interesting theorem.

THEOREM 2.3. *Let* $x_1^{(n)} < \cdots < x_n^{(n)}$ *be the zeros of the nth eigenfunction* $\varphi_n(x)$ *of* (0.1) *in* $(0, \beta]$. *Then for* $f \in C^1[0, \beta]$, *we have*

$$\lim_{n\to\infty} \frac{f(x_1^{(n)}) + \cdots + f(x_n^{(n)})}{n} = \int_0^\beta f(x)\sqrt{\rho(x)}\, dx \Big/ \int_0^\beta \sqrt{\rho(x)}\, dx. \tag{2.7}$$

Proof. Denote by $N_n(t)$ the number of points among $x_1^{(n)}, \cdots, x_n^{(n)}$, which lie in the interval $(0, t]$. Then by Problem 147 of [3, Part II] we have

$$f(x_1^{(n)}) + \cdots + f(x_n^{(n)}) = nf(\beta) - \int_0^\beta N_n(t) f'(t)\, dt. \tag{2.8}$$

We claim that

$$\lim_{n\to\infty} \frac{N_n(x)}{n} = \frac{\int_0^x \sqrt{\rho(t)}\, dt}{\int_0^\beta \sqrt{\rho(t)}\, dt}. \tag{2.9}$$

Then (2.7) follows immediately from (2.8) and (2.9).

Now we prove (2.9). We may assume φ_n is normalized so that $\int_0^\beta \varphi_n^2(x)\, dx = 1$. It is known (see [1, § 11.4], [2, p. 13]) that $\varphi_n(x)$ has the following asymptotic formula:

$$\varphi_n(x) = \left(\frac{2}{\pi}\right)^{1/2} \sin\left(n\pi \frac{\int_0^x \sqrt{\rho(t)}\, dt}{\int_0^\beta \sqrt{\rho(t)}\, dt}\right) + O\left(\frac{1}{n}\right). \tag{2.10}$$

We denote $\int_0^x \sqrt{\rho(t)}\, dt / \int_0^\beta \sqrt{\rho(t)}\, dt$ by $g(x)$. Equation (2.10) means that there exist constants K and n_0, such that

$$\left|\varphi_n(x) - \left(\frac{2}{\pi}\right)^{1/2} \sin(n\pi g(x))\right| \leqq \frac{K}{n},$$

for $n \geqq n_0$.

Choose $n_1 \geqq n_0$ such that $(K/n) < \frac{1}{3}(2/\pi)^{1/2}$ for $n \geqq n_1$. For $n \geqq n_1$, let $y_j^{(n)}$ be the point in $[0, \beta]$ such that

$$ng(y_j^{(n)}) = j - \tfrac{1}{2}, \qquad j = 1, 2, \cdots, n.$$

Note that for a fixed n, $y_1^{(n)}, \cdots, y_n^{(n)}$ are distinct because g is strictly increasing. For $n \geqq n_1$ we have

$$\left|\varphi_n(y_j^{(n)}) - \left(\frac{2}{\pi}\right)^{1/2} \sin(n\pi g(y_j^{(n)}))\right| = \left|\varphi_n(y_j^{(n)}) - \left(\frac{2}{\pi}\right)^{1/2} \sin\left(j - \frac{1}{2}\right)\pi\right|$$
$$< \frac{1}{3}\left(\frac{2}{\pi}\right)^{1/2}.$$

Hence $\varphi_n(y_j^{(n)}) \neq 0$, and the sign of $\varphi_n(y_j^{(n)})$ is $(-1)^{j-1}$. By the Intermediate Value Theorem and by the fact that φ_n has only $n-1$ zeros in the open interval $0 < x < \beta$, we see that φ_n has one and only one zero $x_j^{(n)}$ in each of the open intervals $(y_j^{(n)}, y_{j+1}^{(n)})$, $j = 1, 2, \cdots, n-1$. Since $g(x)$ is strictly increasing, we have

$$j - \tfrac{1}{2} = ng(y_j^{(n)}) < ng(x_j^{(n)}) < ng(y_{j+1}^{(n)}) = j + \tfrac{1}{2}.$$

Thus when $n \geqq n_1$, for x in the interval $(0, \beta)$, if $N_n(x) = j$, i.e., $x_j^{(n)} \leqq x < x_{j+1}^{(n)}$, then

$$j - \tfrac{1}{2} < ng(x) < j + \tfrac{3}{2}.$$

Now it is clear that for $n \geqq n_1$, $0 \leqq x \leqq \beta$, the following inequality holds:

$$\left|g(x) - \frac{N_n(x)}{n}\right| < \frac{3}{2n}. \tag{2.11}$$

Equation (2.9) follows immediately from (2.11). This completes the proof of Theorem 2.3. □

Now we evaluate the limit (2.3).

THEOREM 2.4.

$$\lim_{n\to\infty}\frac{1}{n^3}\sum_{j=1}^{n}\frac{1}{(x_j^{(n)}-x_{j-1}^{(n)})^2}=\frac{\int_0^\beta[\rho(x)]^{3/2}\,dx}{[\int_0^\beta\sqrt{\rho(x)}\,dx]^3}. \tag{2.12}$$

Proof. By (1.1) we have

$$\begin{aligned}\frac{\lambda_n}{n^2}\cdot\frac{\sum_{j=1}^{n}\min(\rho,I_{n,j})}{n}&\leqq\frac{\pi^2}{n^3}\sum_{j=1}^{n}\frac{1}{(x_j^{(n)}-x_{j-1}^{(n)})^2}\\&\leqq\frac{\lambda_n}{n^2}\cdot\frac{\sum_{j=1}^{n}\max(\rho,I_{n,j})}{n}.\end{aligned} \tag{2.13}$$

Using the formulae $\lim_{n\to\infty}\lambda_n n^{-2}=\pi^2(\int_0^\beta\sqrt{\rho(x)}\,dx)^{-2}$, (2.7), (2.13), and the uniform continuity of $\rho(x)$, we obtain (2.12). □

Remark. Formula (2.7) has the following interesting consequence: "Suppose we can 'hear' infinitely many eigenvalues λ_{n_j} of the string equation (0.1), and we can 'see' the corresponding nodal points $x_1^{(n_j)},\cdots,x_{n_j-1}^{(n_j)}$ of λ_{n_j}, then $\rho(x)$ can be determined." Since by (2.7) and $\lim_{j\to\infty}\lambda_{n_j}n_j^{-2}=\pi^2/(\int_0^\beta\sqrt{\rho(x)}\,dx)^2$, we have all the moments c_n of $\sqrt{\rho(x)}$, where c_n is defined as follows:

$$c_n=\int_0^\beta x^n\sqrt{\rho(x)}\,dx,\qquad n=1,2,\cdots.$$

By the theory of moments (see [4, Chap. III]), $\sqrt{\rho(x)}$ can be determined from the moments c_n.

A RESOLUTION METHOD FOR RICCATI DIFFERENTIAL SYSTEMS COUPLED IN THEIR QUADRATIC TERMS*

L. JODAR† AND H. ABOU-KANDIL†

Abstract. By means of algebraic transformations a Riccati differential matrix system coupled in its quadratic terms is reduced to another one for which the successive approximation method is available. An iterative algorithm for solving the problem and an error upper bound for the approximation are given.

Key words. iterative algorithm, matrix differential system, initial value problem, convergence interval, error bound, approximate solution, coupled Riccati system

AMS(MOS) subject classifications. 34A15, 34A50, 65L05, 65F35, 15A24

1. Introduction. When trying to solve many interesting control problems we are often led to a set of coupled Riccati matrix differential equations. Examples are found in singular [3, p. 41] and hybrid system control [9], reduced order compensator design [2], and nonzero sum differential games [12]. Depending on the problem under consideration, different types of coupling will appear. However, the common feature in all the cases mentioned above is that such differential systems are difficult to solve. A general class of coupled Riccati equations is considered here, i.e.,

$$\begin{aligned} \dot{K}_1 &= -Q_1(t) - A_1(t)K_1 - K_1A_2(t) + K_1S_1(t)K_1 + K_1S_2(t)K_2, \\ \dot{K}_2 &= -Q_2(t) - B_1(t)K_2 - K_2B_2(t) + K_2S_2(t)K_2 + K_2S_1(t)K_1. \end{aligned} \tag{1.1}$$

The problem is then to find $K_1(t)$, $K_2(t)$, for $t \in [0, t_f]$ with the terminal conditions

$$K_1(t_f) = K_{1f}, \qquad K_2(t_f) = K_{2f}. \tag{1.2}$$

It is clear here that the coupling appears only through the quadratic terms. In fact (1.1) is a generalized form for Riccati systems appearing when a Nash equilibrium solution is sought for a two-player linear differential game with quadratic cost functionals [12]. For the time-invariant case and under some assumptions relating the constant coefficients, a number of methods have been developed to obtain numerical [11] or series solutions [5]. Moreover, under the further assumption: $Q_2 = \alpha Q_1$, where α is a scalar, an explicit solution has been proposed in [1].

The purpose of this paper is to show that after an appropriate algebraic transformation, the successive approximation method may be used to solve (1.1). This leads to a straightforward algorithm for which the convergence conditions are clearly stated. Furthermore, a bound of the approximation error is obtained so that the number of iterations required for a given precision can be predetermined. The solution procedure developed here is related to the method proposed in [7] to solve coupled Lyapunov equations.

2. Basic notation and preliminary results. In order to make the paper somewhat self-contained, definitions and results to be used later are recalled in this section.

If A and B are matrices in $R_{m\times n}$ and $R_{k\times s}$, respectively, then the tensor product of A and B, denoted $A\otimes B$, is defined as the partitioned matrix

$$A\otimes B=\begin{bmatrix} a_{11}B & a_{12}B & \dots & a_{1n}B \\ a_{21}B & a_{22}B & \dots & a_{2n}B \\ \vdots & & & \vdots \\ a_{m1}B & a_{n2}B & \dots & a_{mn}B \end{bmatrix}.$$

If $A\in R_{m\times n}$, we denote

$$A_{.j}=\begin{bmatrix} a_{1j} \\ \vdots \\ a_{mj} \end{bmatrix}, \qquad 1\leqq j\leqq n$$

and

$$\operatorname{vec} A=\begin{bmatrix} A_{.1} \\ \vdots \\ A_{.n} \end{bmatrix}.$$

Note that if $A=[A_1, A_2]$, then

$$\operatorname{vec} A=\begin{bmatrix} \operatorname{vec} A_1 \\ \operatorname{vec} A_2 \end{bmatrix}.$$

If M, N, and P are matrices of suitable dimensions, then using the column lemma [10], we get

$$\operatorname{vec}(MNP)=(P^T\otimes M)\operatorname{vec} N \tag{2.1}$$

where P^T is the transpose of P.

The Frobenius norm of a matrix $A\in R_{m\times n}$ is defined by

$$\|A\|_F=\left\{\sum_{i=1}^{m}\sum_{j=1}^{n}|a_{ij}|^2\right\}^{1/2}. \tag{2.2}$$

In the sequel, since only the Frobenius norm is used, it will be simply denoted by $\|\ \|$. The following properties are then verified for $A\in R_{m\times n}$ and $B\in R_{n\times q}$ [6, p. 274]:

$$\|AB\|\leqq\|A\|\,\|B\|, \tag{2.3}$$

$$\|A\|=\|\operatorname{vec} A\|, \tag{2.4}$$

$$\|A\otimes B\|=\|A\|\,\|B\|. \tag{2.5}$$

Finally, if $F_{ij}\in R_{n\times n}$, for $1\leqq i, j\leqq 2$, then

$$\left\|\begin{bmatrix} F_{11} & F_{12} \\ F_{21} & F_{22} \end{bmatrix}\right\|\leqq 4\max\{\|F_{ij}\|;\ 1\leqq i, j\leqq 2\}. \tag{2.6}$$

The following theorem may now be stated.

THEOREM 1. *Let K_i, P_i be matrices in $R_{n\times n}$ for $i=1, 2$, with $K=[K_1, K_2]$, $P=[P_1, P_2]$, and let $S=[S_1, S_2]$ be a fixed matrix in $R_{n\times 2n}$; then if $\Psi_S: R_{2n}2_{x1}\to R_{2n}2_{x1}$ is the function defined by the expression*

$$\Psi_S(\operatorname{vec} K)=\begin{bmatrix} K_1^T\otimes K_1 & K_2^T\otimes K_1 \\ K_1^T\otimes K_2 & K_2^T\otimes K_2 \end{bmatrix}[\operatorname{vec} S], \tag{2.7}$$

it follows that

$$\|\Psi_S(\text{vec } K)-\Psi_S(\text{vec } P)\| \leqq 4\|S\|(\|K\|+\|P\|)\|\text{vec } K-\text{vec } P\|. \tag{2.8}$$

Proof. From the definition of Ψ_S, we have

$$\Psi_S(\text{vec } K)-\Psi_S(\text{vec } P)=\begin{bmatrix} K_1^T\otimes K_1-P_1^T\otimes P_1 & K_2^T\otimes K_1-P_2^T\otimes P_1 \\ K_1^T\otimes K_2-P_1^T\otimes P_2 & K_2^T\otimes K_2-P_2^T\otimes P_2 \end{bmatrix}[\text{vec } S]. \tag{2.9}$$

Taking norms on both sides and using (2.3), (2.6), we find that

$$\|\Psi_S(\text{vec } K)-\Psi_S(\text{vec } P)\| \leqq 4\|\text{vec } S\|\max\{\|K_i^T\otimes K_j-P_i^T\otimes P_j\|;\ 1\leqq i\, j\leqq 2\}. \tag{2.10}$$

The elements of the partitioned matrix (2.9) can be rewritten as

$$K_i^T\otimes K_j-P_i^T\otimes P_j=(K_i^T-P_i^T)\otimes K_j+P_i^T\otimes(K_j-P_j), \qquad 1\leqq i, j\leqq 2; \tag{2.11}$$

then

$$\|K_i^T\otimes K_j-P_i^T\otimes P_j\| \leqq \|K_i-P_i\|\,\|K_j\|+\|P_i\|\,\|K_j-P_j\|, \tag{2.12}$$

since

$$\|K_i\|=\|\text{vec } K_i\| \leqq \|\text{vec}(K)\|, \qquad \|P_i\|=\|\text{vec } P_i\| \leqq \|\text{vec}(P)\|, \quad i=1,2.$$

Equation (2.12) leads to

$$\|K_i^T\otimes K_j-P_i^T\otimes P_j\| \leqq \|\text{vec } K-\text{vec } P\|(\|\text{vec } K\|+\|\text{vec } P\|). \tag{2.13}$$

Considering (2.10) and (2.13), we immediately obtain the result given in (2.8).

COROLLARY 1. *Let* $M=(M_1, M_2)\in R_{n\times 2n}$ *and* $\delta>0$. *If* K, P *are matrices in* $R_{n\times 2n}$ *such that* $\|K-M\| \leqq \delta$, $\|P-M\| \leqq \delta$, *then*

$$\|\Psi_S(\text{vec } K)-\Psi_S(\text{vec } P)\| \leqq 8\|S\|(\delta+\|M\|)\|\text{vec } K-\text{vec } P\|. \tag{2.14}$$

Proof. It is clear that (2.14) is a direct consequence of (2.8).

3. Main results. The initial value problem (1.1)-(1.2) is now considered. By introducing tensor products in the two members of (1.1), and taking into account the column lemma (equation 2.1) [10], it follows that

$$\begin{aligned} d/dt(\text{vec } K_1(t)) &= -\text{vec } Q_1(t)-(I\otimes A_1(t))(\text{vec } K_1(t))-(A_2^T(t)\otimes I)(\text{vec } K_1(t)) \\ &\quad +(K_1^T(t)\otimes K_1(t))(\text{vec } S_1(t))+(K_2^T(t)\otimes K_1(t))(\text{vec } S_2(t)), \\ d/dt(\text{vec } K_2(t)) &= -\text{vec } Q_2(t)-(I\otimes B_1(t))(\text{vec } K_2(t))-(B_2^T(t)\otimes I)(\text{vec } K_2(t)) \\ &\quad +(K_2^T(t)\otimes K_2(t))(\text{vec } S_2(t))+(K_1^T(t)\otimes K_2(t))(\text{vec } S_1(t)), \\ \text{vec } K_1(t_f) &= \text{vec } K_{1f}, \qquad \text{vec } K_2(t_f)=\text{vec } K_{2f}. \end{aligned} \tag{3.1}$$

Define

$$D_1(t)=(I\otimes A_1(t))+(A_2(t)\otimes I), \qquad D_2(t)=(I\otimes B_1(t))+(B_2(t)\otimes I). \tag{3.2}$$

System (3.1) can be rewritten as

$$\begin{aligned} \frac{d}{dt}(\text{vec } K(t)) &= -\text{vec } Q(t)-\begin{bmatrix} D_1(t) & 0 \\ 0 & D_2(t) \end{bmatrix}[\text{vec } K(t)] \\ &\quad +\begin{bmatrix} K_1^T(t)\otimes K_1(t) & K_2^T(t)\otimes K_1(t) \\ K_1^T(t)\otimes K_2(t) & K_2^T(t)\otimes K_2(t) \end{bmatrix}[\text{vec } S(t)], \\ \text{vec } K(t_f) &= \text{vec}(K_{1f}, K_{2f}) \end{aligned} \tag{3.3}$$

where $Q(t)=[Q_1(t), Q_2(t)]$, $S(t)=[S_1(t), S_2(t)]$, and $K(t)=[K_1(t), K_2(t)]$ are matrices in $R_{n\times 2n}$, for all $t\in[0, t_f]$. Writing (3.3) in a compact form, we have

$$\begin{aligned} &d/dt(\operatorname{vec} K(t)) = F(t, \operatorname{vec} K(t)),\\ &\operatorname{vec} K(t_f) = \operatorname{vec}(K_{1f}, K_{2f}) \end{aligned} \tag{3.4}$$

where $F: [0, t_f]\times R_{2n^2\times 1}\to R_{2n^2\times 1}$, is defined by (3.3); i.e.,

$$F(t, \operatorname{vec} K(t)) = -\operatorname{vec} Q(t) - D(t)(\operatorname{vec} K(t)) + \Psi_{S(t)}(\operatorname{vec} K(t)) \tag{3.5}$$

with

$$D(t)=\begin{bmatrix} D_1(t) & 0\\ 0 & D_2(t)\end{bmatrix}$$

and $\Psi_{S(t)}$ is given by (2.7).

Assuming the continuity of the coefficient matrix functions occurring in (1.1) on the interval $[0, t_f]$, the following constants are finite and well defined:

$$\begin{aligned} &s=\max_{0\leqq t\leqq t_f}\|\operatorname{vec} S(t)\|, \qquad q=\max_{0\leqq t\leqq t_f}\|\operatorname{vec} Q(t)\|,\\ &d=n^{1/2}\max_{0\leqq t\leqq t_f}\{\|A_i(t)\|, \|B_i(t)\|;\ i=1,2\}. \end{aligned} \tag{3.6}$$

When we exploit the special structure of $D(t)$ and use (2.2), it is easy to show that

$$\max_{0\leqq t\leqq t_f}\|D(t)\|\leqq 2\max_{0\leqq t\leqq t_f}\{\|D_i(t)\|, 1\leqq i\leqq 2\}\leqq 4d \tag{3.7}$$

because the Frobenius norm of the identity matrix in $R_{n\times n}$ is $\|I\|=n^{1/2}$, and, from (2.5), we have $\|D_1(t)\|\leqq n^{1/2}(\|A_1(t)\|+\|A_2(t)\|)$ and $\|D_2(t)\|\leqq n^{1/2}(\|B_1(t)\|+\|B_2(t)\|)$.

The following theorem gives a successive approximation procedure used to solve the problem (1.1)-(1.2) and an upper bound for the approximation error.

THEOREM 2. *Let $\delta>0$, $\gamma=\|\operatorname{vec} K_f\|+\delta$, and let M be the constant defined by the expression*

$$M=q+2d\gamma+4s\gamma^2 \tag{3.8}$$

where q, d, and s are given by (3.6). *If $\alpha=\min\{t_f, \delta/M\}$ and assuming that the coefficient matrix functions $A_i(t)$, $B_i(t)$ and $S_i(t)$ are continuous on the interval $[0, t_f]$, then problem* (1.1)-(1.2) *has a unique solution $K(t)$ on the interval $[t_f-\alpha, t_f]$ such that $K(t)$ is the Frobenius norm limit of the sequence of successive approximations*:

$$\{K^{(p)}(t)\}_{p\geqq 0},\ \textit{where } K^{(p)}=[K_1^{(p)}, K_2^{(p)}] \textit{ are given by } K_i^{(0)}(t)=K_{if},\quad i=1,2$$

and

$$\begin{aligned} K_1^{(p+1)}(t) &= K_{1f}-\int_{t_f}^{t}(Q_1(u)+A_1(u)K_1^{(p)}(u)+K_1^{(p)}(u)A_2(u))\,du\\ &\quad+\int_{t_f}^{t}(K_1^{(p)}(u)S_1(u)K_1^{(p)}(u)+K_1^{(p)}(u)S_2(u)K_2^{(p)}(u))\,du,\\ K_2^{(p+1)}(t) &= K_{2f}-\int_{t_f}^{t}(Q_2(u)+B_1(u)K_2^{(p)}(u)+K_2^{(p)}(u)B_2(u))\,du\\ &\quad+\int_{t_f}^{t}(K_2^{(p)}(u)S_2(u)K_2^{(p)}(u)+K_2^{(p)}(u)S_1(u)K_1^{(p)}(u))\,du. \end{aligned} \tag{3.9}$$

Moreover, for $t \in [t_f - \alpha, t_f]$, *the error upper bound for the pth approximation is given by*

$$e_p(t) = \|\text{vec}\,(K(t)) - \text{vec}\,(K^{(p)}(t))\| \leqq \frac{M(\alpha\rho)^{p+1}}{\rho(p+1)!}\exp(\alpha\rho) \tag{3.10}$$

where

$$\rho = 8\gamma s + 2d. \tag{3.11}$$

Proof. Using the definition of $F(t, \text{vec}\,K(t))$ (equation (3.5)) and (3.6), we get

$$\|F(t, \text{vec}\,K)\| \leqq q + 2d\|\text{vec}\,K\| + 4s\|\text{vec}\,K\|^2; \tag{3.12}$$

thus

$$\begin{aligned}\sup\{\|F(t, \text{vec}\,K)\|;\ 0 \leqq t \leqq t_f;\ \|K - K_f\| \leqq \delta\} &\leqq q + 2d(\delta + \|K_f\|) + 4s(\delta + \|K_f\|)^2 \\ &= q + 2d\gamma + 4s\gamma^2.\end{aligned} \tag{3.13}$$

From Theorem 1, we have that $F(t, \text{vec}\,K)$ satisfies a Lipschitz condition of the type

$$\|F(t, \text{vec}\,K) - F(t, \text{vec}\,P)\| \leqq \rho\|\text{vec}\,K - \text{vec}\,P\|$$

where ρ is given by (3.11) and $\|\text{vec}\,K - \text{vec}\,K_f\| \leqq \delta$, $\|\text{vec}\,P - \text{vec}\,K_f\| \leqq \delta$. Now, from the theorem of the successive approximations [8, p. 129], [4, Chap. 5], the unique solution of the problem (3.4) on the interval $[t_f - \alpha, t_f]$, is given by the Frobenius norm limit of the sequence $\{\text{vec}\,K^{(p)}(t)\}_{p \geqq 0}$, where

$$(\text{vec}\,K^{(0)}(t)) = (\text{vec}\,K_f)$$

and

$$\begin{aligned}\text{vec}\,K^{(p+1)}(t) &= \text{vec}\,K_f + \int_{t_f}^{t} F(u, \text{vec}\,K^{(p)}(u))\,du \\ &= \text{vec}\,K_f + \int_{t_f}^{t} \begin{bmatrix} -Q_1(u) - D_1(u)K_1^{(p)}(u) \\ -Q_2(u) - D_2(u)K_1^{(p)}(u) \end{bmatrix} du \\ &+ \int_{t_f}^{t} \begin{bmatrix} (K_1^{(p)}(u) \otimes K_1^{(p)}(u))(\text{vec}\,S_1(u)) + ((K_2^{(p)}(u))^T \otimes K_1^{(p)}(u))(\text{vec}\,S_2(u)) \\ ((K_1^{(p)}(u))^T \otimes K_2^{(p)}(u))(\text{vec}\,S_1(u)) + ((K_2^{(p)}(u))^T \otimes K_2^{(p)}(u))(\text{vec}\,S_2(u)) \end{bmatrix} du.\end{aligned} \tag{3.14}$$

When we take into account the column lemma [10] and the definitions (3.2), the sum of the two integrands occurring on the right-hand side of (3.14) is equivalent to the following expression:

$$\text{vec}\,(W_1^{(p)}(u), W_2^{(p)}(u))$$

where

$$\begin{aligned}W_1^{(p)}(u) &= -Q_1(u) - A_1(u)K_1^{(p)}(u) - K_1^{(p)}(u)A_2(u) \\ &\quad + K_1^{(p)}(u)S_1(u)K_1^{(p)}(u) + K_1^{(p)}(u)S_2(u)K_2^{(p)}(u), \\ W_2^{(p)}(u) &= -Q_2(u) - B_1(u)K_2^{(p)}(u) - K_2^{(p)}(u)B_2(u) \\ &\quad + K_2^{(p)}(u)S_2(u)K_2^{(p)}(u) + K_2^{(p)}(u)S_1(u)K_1^{(p)}(u).\end{aligned} \tag{3.15}$$

Equation (3.9) is directly obtained using (3.14) and (3.15). The error upper bound of the pth approximation defined by (3.10) is a consequence of the theorem of the successive approximations [8, p. 129], [4, Chap. 5].

Remark. It should be noted that the convergence interval for the proposed algorithm described in Theorem 2 depends on the ratio δ/M, where δ is a free positive number, while M is a function of δ as given by (3.8). Therefore, it is interesting to find a $\delta > 0$ such that δ/M is maximized, because the convergence interval is $[t_f - \alpha, t_f]$, and $\alpha = \min\{t_f, \delta/M\}$. In order to maximize δ/M, let us consider

$$r(\delta) = \delta/M = \delta\{q + 2d(\|\text{vec } K_f\| + \delta) + 4s(\|\text{vec } K_f\| + \delta)^2\}^{-1}.$$

If we assume that all elements of $Q(t) = [Q_1(t), Q_2(t)]$, $S(t) = [S_1(t), S_2(t)]$, are not identically zero, then maximum of $r(\delta)$ is obtained when $d/d\delta(r(\delta)) = 0$, i.e., for

$$\delta^* = \{(4s)^{-1}(q + 2d\|\text{vec } K_f\| + 4s\|\text{vec } K_f\|^2)\}^{1/2}.$$

Acknowledgment. The authors thank an anonymous referee for his constructive remarks.

ON SMOOTHEST INTERPOLANTS*

A. PINKUS†

Abstract. This paper is concerned with the problem of characterizing those functions of minimum L^p-norm on their nth derivative, $1 \leqq p \leqq \infty$, that sequentially take on the given values $(e_i)_1^N$. For $p = \infty$ the unique minimizing function is characterized. For $p < \infty$ fairly explicit necessary conditions are given.

Key words. minimum norm interpolation, Sobolev spaces, splines

AMS(MOS) subject classifications. 41A05, 46E35

1. Introduction. Let $n \geqq 2$ be fixed. For $p \in (1, \infty]$, $W_p^{(n)}$ will denote the usual Sobolev space of real-valued functions on $[0, 1]$ with $n-1$ absolutely continuous derivatives and nth derivative existing almost everywhere as a function in $L^p[0, 1]$. Equivalently,

$$W_p^{(n)} = \left\{ f: f(x) = \sum_{i=0}^{n-1} a_i x^i + \frac{1}{(n-1)!} \int_0^1 (x-y)_+^{n-1} h(y)\, dy,\ h \in L^p,\ a_i \in R,\ i = 0, 1, \cdots, n-1 \right\}.$$

(Here $a_i = f^{(i)}(0)/i!$, $i = 0, 1, \cdots, n-1$, and $h \equiv f^{(n)}$.) For $p = 1$, rather than considering the analogous $W_1^{(n)}$, we introduce $V^{(n)}$. To define $V^{(n)}$, let M denote the space of real Baire measures on $[0, 1]$. For $\mu \in M$, $\|\mu\|$ will denote the total variation of the measure μ. Then

$$V^{(n)} = \left\{ f: f(x) = \sum_{i=0}^{n-1} a_i x^i + \frac{1}{(n-1)!} \int_0^1 (x-y)_+^{n-1}\, d\mu(y),\ \|\mu\| < \infty \right\}.$$

We will shortly explain our reasons for considering $V^{(n)}$ rather than $W_1^{(n)}$.

Let $e_1, \cdots, e_N$ be given real fixed data, $e_i \neq e_{i+1}$, $i = 1, \cdots, N-1$. Set

$$\Xi_N = \{\mathbf{t}: \mathbf{t} = (t_1, \cdots, t_N),\ 0 \leqq t_1 < \cdots < t_N \leqq 1\}.$$

For each $\mathbf{t} \in \Xi_N$, set

$$W_p^{(n)}(\mathbf{t}; \mathbf{e}) = \{f: f \in W_p^{(n)}, f(t_i) = e_i,\ i = 1, \cdots, N\}$$

for $p \in (1, \infty]$, and

$$V^{(n)}(\mathbf{t}; \mathbf{e}) = \{f: f \in V^{(n)}, f(t_i) = e_i,\ i = 1, \cdots, N\}.$$

The following problems are considered in [2] and [6]:

$$\inf \{\|f^{(n)}\|_p : f \in W_p^{(n)}(\mathbf{t}; \mathbf{e})\} \tag{1}$$

for $p \in (1, \infty]$, and

$$\inf \{\|\mu\| : f \in V^{(n)}(\mathbf{t}; \mathbf{e})\}. \tag{2}$$

(It is understood that f and μ in (2) are related as in the definition of $V^{(n)}$.) Later we will describe the solutions to problems (1) and (2). An understanding of their exact form is crucial to a solution of the problems we consider. We do note, however, that there exist $f \in W_p^{(n)}(\mathbf{t}; \mathbf{e})$ and $f \in V^{(n)}(\mathbf{t}; \mathbf{e})$ for which the above infima are in fact attained.

† Technion, Israel Institute of Technology, Haifa 32000, Israel.

If we replace the extremum problem (2) by the analogous problem where $W_1^{(n)}$ takes the place of $V^{(n)}$, then this is not necessarily the case, i.e., the infimum need not be attained by some $f \in W_1^{(n)}$. However, the value of the infimum in (2), or in (2) with $W_1^{(n)}$ replacing $V^{(n)}$, is the same. This is one reason for considering $V^{(n)}$ rather than $W_1^{(n)}$. A more detailed discussion of this matter can be found in de Boor [2], and in Fisher and Jerome [5], [6].

In this work, we are interested in solutions to the problems

$$\inf_{\mathbf{t}\in\Xi_N} \inf\{\|f^{(n)}\|_p : f \in W_p^{(n)}(\mathbf{t}; \mathbf{e})\} \tag{3}$$

for $p \in (1, \infty]$, and

$$\inf_{\mathbf{t}\in\Xi_N} \inf\{\|\mu\| : f \in V^{(n)}(\mathbf{t}; \mathbf{e})\}, \tag{4}$$

and in functions for which the infima are attained. Thus, for each fixed $n \geqq 2$, $p \in [1, \infty]$, and data $(e_i)_1^N$, we wish to characterize those functions f that take on the values $(e_i)_1^N$ sequentially, and minimize the L^p-norm of their nth derivative. (Here we are abusing notation in the case where $p = 1$.)

Before continuing, we note three simple facts.

(I) It suffices to assume that $(e_i - e_{i-1})(e_{i+1} - e_i) < 0$, $i = 2, \cdots, N-1$. This follows from continuity considerations. If, for example, $e_{i-1} < e_i < e_{i+1}$ for some $i \in \{2, \cdots, n-1\}$, then we may delete the condition $f(t_i) = e_i$ since f will always attain the value e_i at some point in (t_{i-1}, t_{i+1}).

(II) We may assume that $N > n$. If $N \leqq n$, then for any choice of $\mathbf{t} \in \Xi_N$, there exists a polynomial q of degree $\leqq n-1$ for which $q(t_i) = e_i$, $i = 1, \cdots, N$. Moreover $q^{(n)} \equiv 0$ and our problem is trivially solved.

(III) We always have $t_1 = 0$ and $t_N = 1$. Assume, for example, that $t_N < 1$ for some f which solves (3) or (4). Set $g(x) = f(xt_N)$ for $x \in [0, 1]$. Then g is "admissible" in (3) or (4), and since $g^{(n)}(x) = t_N^n f^{(n)}(xt_N)$, it easily follows that $\|g^{(n)}\|_p < \|f^{(n)}\|_p$ for $p \in (1, \infty]$, with the analogous strict inequality in (4).

Thus in what follows we will always assume that

(a) $(e_i - e_{i-1})(e_{i+1} - e_i) < 0$, $i = 2, \cdots, N-1$;

(b) $N > n$;

(c) $t_1 = 0$, $t_N = 1$.

There always exist functions $f \in W_p^{(n)}$ which solve (3) (or $f \in V^{(n)}$ which solve (4)). The proof of this fact is not difficult and we omit it. It follows from the existence already alluded to in (1) and (2), and from the fact that there exists a $\mathbf{t}^* \in \Xi_N$ (and not in $\bar{\Xi}_N \backslash \Xi_N$) for which the left-most infima in (3) or (4) are attained.

We will prove that solutions to (3) and (4) must be of a particular form, given by solutions to (1) and (2), respectively, and must also "oscillate" strictly between the values $(e_i)_1^N$. To explain what we mean by this latter term, we introduce the following definition.

DEFINITION. Let $(e_i - e_{i-1})(e_{i+1} - e_i) < 0$, $i = 2, \cdots, N-1$, and $0 = t_1 < \cdots < t_N = 1$. Let $f \in C[0, 1]$ satisfy $f(t_i) = e_i$, $i = 1, \cdots, N$. We say that f *oscillates* between the $(e_i)_1^N$ on $(t_i)_1^N$ if f is monotone on $[t_i, t_{i+1}]$ for each $i = 1, \cdots, N-1$. We say that f *oscillates strictly* between the $(e_i)_1^N$ on $(t_i)_1^N$ if f is strictly monotone on $[t_i, t_{i+1}]$ for each $i = 1, \cdots, N-1$.

Because of the nature of the problem, we divide our analysis into three parts, namely, $1 < p < \infty$, $p = \infty$, and $p = 1$. Both $p = 1 (V^{(n)})$ and $p = \infty$ may be considered as limiting cases, but they are much more special and will be considered separately.

In § 2 we quite easily prove that solutions to (3) for $p \in (1, \infty)$ must be of a particular form and oscillate strictly between the $(e_i)_1^N$, on some $(t_i)_1^N$. However, we are unable to prove either the uniqueness of the solution or the fact that functions of this particular form are necessarily solutions to (3). In other words, we prove necessary but not sufficient conditions for a solution to (3). We do conjecture, however, that these conditions are sufficient and that (3) has a unique solution.

In § 3 we consider the case $p = \infty$. We somewhat surprisingly are able to explicitly characterize the solution and we show that it is unique. The uniqueness is especially surprising since for fixed $\mathbf{t} \in \Xi_N$ and $p = \infty$, the solution to (1) is not necessarily unique. (While for $p \in (1, \infty)$ the solution to (1) is unique.)

In § 4 we consider the case $p = 1$. We prove that the solution to (2) is unique and is of a particularly simple form (splines of degree $n-1$ with $N-n$ knots). We again prove a necessary condition for the solution to (4). Here again both the full characterization and uniqueness is lacking, except in the case $n = 2$ where it is easily seen that every solution to (2) necessarily oscillates strictly between the $(e_i)_1^N$. For $n \geqq 3$, we conjecture that the characterization leads to a unique solution.

Let us review the history of and motivation behind this problem. The above problem in a multidimensional setting (x still runs over $[0, 1]$, but we are dealing with a d-dimensional vector of single-valued functions and d-dimensional data vectors $\mathbf{e}^i$, $i = 1, \cdots, N$) was discussed by Marin [9] and Töpfer [12]. Physical motivation for this problem comes from problems of geometric curve fitting and design of a trajectory for a robot manipulator (see Marin [9] and Töpfer [12]). Marin explicitly proved existence and uniqueness for the one-dimensional problem in the case $p = 2$ and $n = 2$. Here we are dealing with natural cubic splines (solutions of (1)) and we can explicitly calculate the solution. More recently Scherer and Smith [11] dealt with the problem of existence in the multidimensional setting for the case $p = 2$. It is our hope that the one-dimensional problem considered herein will not only be of interest in and of itself but will also provide insight into the multidimensional problem.

Finally it should be noted that generalizations of the results of this paper exist since many of these results are consequences of the underlying total positivity structure of the problem. However, this is not true of all of the results and generally only weaker versions hold. Thus, for example, we might consider an nth order disconjugate differential equation L on $[0, 1]$, and the problem

$$\inf_{\mathbf{t} \in \Xi_N} \inf \{ \| Lf \|_p : f \in W_p^{(n)}(\mathbf{t}; \mathbf{e}) \}$$

for $p \in (1, \infty]$, with an analogue of (4) for $p = 1$. The main result of § 2, Theorem 2.2, will hold in an analogous form except that it is not necessary that $t_1 = 0$, $t_N = 1$, or that every optimal f^* oscillate strictly between the $(e_i)_1^N$ on some $(t_i^*)_1^N$, but only that f^* on $[t_i^*, t_{i+1}^*]$ take on only values between e_i and e_{i+1}, $i = 1, \cdots, N-1$. For $p = 1$, and especially $p = \infty$, the results are substantially weaker than those obtained herein.

Another generalization that can be dealt with using the techniques of this paper is the following. Consider the problem

$$\inf_{\mathbf{t} \in \Xi_N} \inf \left\{ \| h \|_p : \int_0^1 K(t_i, y) h(y)\, dy = e_i, i = 1, \cdots, N \right\}$$

(and the analogous problem for $p = 1$) where K is a strictly totally positive kernel. Here again weaker results of the above form are obtained, but only in the case where $e_i e_{i+1} < 0$, $i = 1, \cdots, N-1$.

2. $p\in(1,\infty)$. To understand the solution to (3) we must first consider the problem (1).

Recall that for $f\in W_p^{(n)}$,

$$f(x)=\sum_{i=0}^{n-1}a_ix^i+\frac{1}{(n-1)!}\int_0^1(x-y)_+^{n-1}h(y)\,dy, \tag{5}$$

where $a_i=f^{(i)}(0)/i!$, $i=0,1,\cdots,n-1$, and $h\equiv f^{(n)}\in L^p$.

Let $\mathbf{t}\in\Xi_N$ be fixed, $t_1=0$, $t_N=1$, $N\geqq n+1$. $f[t_i,\cdots,t_{i+n}]$ will denote the nth divided difference of f at the points $t_i,\cdots,t_{i+n}$, $i=1,\cdots,N-n$. For $f\in W_p^{(n)}(\mathbf{t};\mathbf{e})$, set

$$E_i=f[t_i,t_{i+1},\cdots,t_{i+n}],\qquad i=1,\cdots,N-n.$$

When we assume $(e_i-e_{i-1})(e_{i+1}-e_i)<0$, $i=2,\cdots,N-1$, it easily follows that $E_iE_{i+1}<0$, $i=1,\cdots,N-n-1$ (since $n\geqq 1$). Applying the nth divided difference at the points $t_i,\cdots,t_{i+n}$ to $f\in W_p^{(n)}(\mathbf{t};\mathbf{e})$ as in (5), we obtain

$$E_i=\int_0^1 M_{i,n}(y)h(y)\,dy,\qquad i=1,\cdots,N-n,$$

where $M_{i,n}$ is a positive multiple (easily computed) of the B-spline of degree $n-1$ with knots $t_i,\cdots,t_{i+n}$, $i=1,\cdots,N-n$. Problem (1) is equivalent to

$$\inf\left\{\|h\|_p\colon\int_0^1 M_{i,n}(y)h(y)\,dy=E_i,\ i=1,\cdots,N-n\right\}. \tag{6}$$

Problem (6) (see de Boor [2], and Fisher and Jerome [6]) (and thus (1)) has a unique solution of the form

$$h_p(y)=\left|\sum_{i=1}^{N-n}b_iM_{i,n}(y)\right|^{q-1}\operatorname{sgn}\left(\sum_{i=1}^{N-n}b_iM_{i,n}(y)\right) \tag{7}$$

where $1/p+1/q=1$, and

$$E_i=\int_0^1 M_{i,n}(y)h_p(y)\,dy,\qquad i=1,\cdots,N-n. \tag{8}$$

Equation (8) uniquely determines the coefficients $(b_i)_1^{N-n}$ in (7). To obtain the unique solution f_p to (1), we write

$$f_p(x)=\sum_{i=0}^{n-1}a_ix^i+\frac{1}{(n-1)!}\int_0^1(x-y)_+^{n-1}h_p(y)\,dy$$

and uniquely determine the $(a_i)_0^{n-1}$ so that $f_p(t_i)=e_i$, $i=1,\cdots,n$. From (8) it follows that $f_p\in W_p^{(n)}(\mathbf{t};\mathbf{e})$.

The following notation will prove useful. For $f\in C[a,b]$, let $S(f)$ denote the number of sign changes of f on $[a,b]$, i.e.,

$$S(f)=\sup\{k\colon a\leqq x_1<\cdots<x_{k+1}\leqq b,\ f(x_i)f(x_{i+1})<0,\ i=1,\cdots,k\}.$$

Of course, if f is either nonnegative or nonpositive on $[a,b]$, then we set $S(f)=0$. Similarly, for a vector $\mathbf{x}\in R^m\backslash\{\mathbf{0}\}$, $S^-(\mathbf{x})$ will denote the number of sign changes of the vector $\mathbf{x}$, i.e.,

$$S^-(\mathbf{x})=\max\{k\colon 1\leqq i_1<\cdots<i_{k+1}\leqq m,\ x_{i_j}x_{i_{j+1}}<0,\ j=1,\cdots,k\},$$

unless $\mathbf{x}$ is nonnegative or nonpositive in which case $S^-(\mathbf{x})=0$.

Let $Q(x)=\sum_{i=1}^{N-n} b_i M_{i,n}(x)$ where the $(b_i)_1^{N-n}$ are as determined by (8).

PROPOSITION 2.1. *Q has exactly $N-n-1$ sign changes on $(0,1)$, and $\sigma Q^{(n-1)}(x)(-1)^i>0$ for $x\in(t_i, t_{i+1})$, $i=1,\cdots,N-1$, where $\sigma\in\{-1,1\}$, fixed.*

Proof. It is well known (see, e.g., de Boor [3]) that

$$S\left(\sum_{i=1}^{N-n} b_i M_{i,n}\right)\leqq S^-((b_1,\cdots,b_{N-n})).$$

Since $S^-((b_1,\cdots,b_{N-n}))\leqq N-n-1$, it follows that Q has at most $N-n-1$ sign changes on $(0,1)$. Assume Q has k sign changes on $(0,1)$. Then

$$h_p(y)=|Q(y)|^{q-1}\operatorname{sgn}(Q(y))$$

has k sign changes on $(0,1)$. Let $0=\xi_0<\xi_1<\cdots<\xi_{k+1}=1$ be such that $\delta h_p(y)(-1)^j\geqq 0$ for all $y\in[\xi_{j-1},\xi_j]$, $j=1,\cdots,k+1$, where $\delta\in\{-1,1\}$, fixed. Set

$$a_{ij}=\int_{\xi_{j-1}}^{\xi_j} M_{i,n}(y)|h_p(y)|\,dy,\qquad i=1,\cdots,N-n,\quad j=1,\cdots,k+1.$$

From properties of B-splines (see, e.g., de Boor [3]) it follows that $A=(a_{ij})_{i=1,j=1}^{N-n,k+1}$ is a totally positive (TP) matrix. Furthermore,

$$\sum_{j=1}^{k+1} a_{ij}(-1)^j\delta=E_i,\qquad i=1,\cdots,N-n.$$

From the above, $N-n\geqq k+1$. As a consequence of the variation diminishing property of TP matrices (see Karlin [7]), we have

$$S^-((E_1,\cdots,E_{N-n}))\leqq\min\{\operatorname{rank}(A)-1, S^-(-\delta,\delta,\cdots,(-1)^{k+1}\delta)\}.$$

Since $E_iE_{i+1}<0$, $i=1,\cdots,N-n-1$, it follows that the left-hand side equals $N-n-1$ and that $N-n-1\leqq k$. Therefore $k=N-n-1$ and Q has exactly $N-n-1$ sign changes on $(0,1)$.

Since $k=N-n-1$, we have that $S^-((b_1,\cdots,b_{N-n}))=N-n-1$, and thus $b_i(-1)^i\sigma>0$, $i=1,\cdots,N-n$, for some $\sigma\in\{-1,1\}$, fixed. It is well known that the $(n-1)$st derivative of $M_{i,n}(x)$ strictly alternates in sign as we go from (t_j,t_{j+1}) to (t_{j+1},t_{j+2}), $j=1,\cdots,i+n-2$. In particular,

$$M_{i,n}^{(n-1)}(x)(-1)^{i+j}>0,\quad x\in(t_j,t_{j+1}),\quad j=i,\cdots,i+n-1.$$

Thus for $x\in(t_j,t_{j+1})$,

$$Q^{(n-1)}(x)=\sum_{i=1}^{N-n} b_iM_{i,n}^{(n-1)}(x)=\sigma(-1)^j\sum_{i=1}^{N-n}|b_iM_{i,n}^{(n-1)}(x)|.$$

Since $b_i\neq 0$ for all i, and $M_{i,n}^{(n-1)}(x)\not\equiv 0$ on (t_j,t_{j+1}) for some i, it follows that $\sigma(-1)^jQ^{(n-1)}(x)>0$ on (t_j,t_{j+1}), $j=1,\cdots,N-1$. This proves the proposition. □

With the above proposition we easily prove the following theorem.

THEOREM 2.2. *Let $p\in(1,\infty)$, and let $f^*\in W_p^{(n)}$ be a solution of* (3). *There exists a $\mathbf{t}^*=(t_1^*,\cdots,t_N^*)$, $0=t_1^*<\cdots<t_N^*=1$ such that $f^*\in W_p^{(n)}(\mathbf{t}^*;\mathbf{e})$. Furthermore,*

$$\text{(a)}\quad f^{*(n)}(y)=\left|\sum_{i=1}^{N-n} b_i^*M_{i,n}(y)\right|^{q-1}\operatorname{sgn}\left(\sum_{i=1}^{N-n} b_i^*M_{i,n}(y)\right)$$

where $1/p+1/q=1$, $M_{i,n}$ is a positive multiple of the B*-spline of degree $n-1$ with knots*

$t_i^*, \cdots, t_{i+n}^*$, $i=1, \cdots, N-n$, *and the* $(b_i^*)_1^{N-n}$ *satisfy*

$$\int_0^1 M_{i,n}(y) f^{*(n)}(y)\, dy = f[t_i^*, \cdots, t_{i+n}^*], \qquad i=1, \cdots, N-n.$$

(b) f^* *oscillates strictly between the* $(e_i)_1^N$ *on* $(t_i^*)_1^N$.

Proof. Let f^* solve (3). Existence implies that there exists a $\mathbf{t}^*$ as above for which $f^* \in W_p^{(n)}(\mathbf{t}^*; \mathbf{e})$. Since f^* must also solve (1) for $\mathbf{t}^*$, it follows that f^* necessarily satisfies (a). It remains to prove that (b) holds.

Since $(e_i - e_{i-1})(e_{i+1} - e_i) < 0$, $i=2, \cdots, N-1$, f^* has at least $N-2$ interior extrema, i.e., $f^{*\prime}$ has at least $N-2$ distinct zeros. From Proposition 2.1, $f^{*(n)}$ does not vanish on any subinterval of $[0, 1]$ and has exactly $N-n-1$ sign changes. From Rolle's theorem applied to $f^{*\prime}$, it follows that $f^{*\prime}$ has exactly $N-2$ (simple) zeros in $(0, 1)$. Let $0 < s_2 < \cdots < s_{N-1} < 1 (s_1 = 0, s_N = 1)$ denote the unique extrema of f^*. Thus f^* oscillates strictly between the $(f^*(s_i))_1^N$ on $(s_i)_1^N$. It remains to prove that $s_i = t_i^*$, $i=2, \cdots, N-1$. Note that $t_{j-1}^* < s_j < t_{j+1}^*$ for $j=2, \cdots, N-1$.

Assume $s_i \neq t_i^*$ for some $i \in \{2, \cdots, N-1\}$. Consider problem (1) at the points $(s_i)_1^N$ with the values $e_i^1 = f^*(s_i)$, $i=1, \cdots, N$. There is a unique solution to this new problem which we denote by g^*. It follows from Proposition 2.1 that $g^* \not\equiv f^*$. Furthermore f^* is "admissible" for this problem. Thus $\|g^{(n)}\|_p < \|f^{*(n)}\|_p$. From continuity considerations, there exist points $0 \leqq w_1 < \cdots < w_N \leqq 1$ such that $g^*(w_i) = e_i$, $i = 1, \cdots, N$. Thus g^* is "admissible" in (3). However, this contradicts the minimality property of f^*. Thus $s_i = t_i^*$, $i=2, \cdots, N-1$, and f^* oscillates strictly between the $(e_i)_1^N$ on $(t_i^*)_1^N$. □

On the basis of the above result, it is natural to ask whether the solution to (3) is unique, and in particular, whether there is a unique function satisfying (a) and (b) of Theorem 2.2. Marin [9] showed by construction that there is a unique function satisfying (a) and (b) in the particular case $n=p=2$.

Remark. For the case $n=1$, it is easily seen that every solution to (1) a spline of degree one with simple knots at $t_2, \cdots, t_{N-1}$. Thus it oscillates strictly between the $(e_i)_1^N$ on $(t_i)_1^N$ for any choice of $\mathbf{t} \in \Xi_N$. However, a bit of calculation shows that the solution to (3) is in fact unique. The optimal choice of $\mathbf{t}^*$ is given by $t_1^* = 0$, $t_N^* = 1$, and

$$t_i^* = \sum_{j=1}^{i-1} |e_{j+1} - e_j| \Big/ \sum_{j=1}^{N-1} |e_{j+1} - e_j|, \qquad i=2, \cdots, N-1.$$

Note that this unique choice is independent of $p \in (1, \infty)$.

3. $p=\infty$. For fixed $0 = t_1 < \cdots < t_N = 1$, $N > n \geqq 2$, and $(e_i - e_{i-1})(e_{i+1} - e_i) < 0$, $i=2, \cdots, N-1$, the problem (1) for $p=\infty$, i.e.,

$$\inf \{\|f^{(n)}\|_\infty : f \in W_\infty^{(n)}(\mathbf{t}; \mathbf{e})\}, \tag{9}$$

may have many solutions. There is always at least one solution of particular interest. It is a perfect spline of degree n with exactly $N-n-1$ knots, i.e., a function P of the form

$$P(x) = \sum_{i=0}^{n-1} a_i x^i + \frac{c}{n!}\left[x^n + 2\sum_{i=1}^{N-n-1} (-1)^i (x - \xi_i)_+^n\right]$$

where $\xi_0 = 0 < \xi_1 < \cdots < \xi_{N-n-1} < \xi_{n-n} = 1$ (see, e.g., Karlin [8]). Note that $|P^{(n)}(x)| = |c|$ for all $x \in [0, 1] \backslash \{\xi_1, \cdots, \xi_{N-n-1}\}$.

The main idea used in the proof of Theorem 2.2 does not carry over to the case $p=\infty$ since the g^* constructed therein is generally identically equal to the f^*. However, much research has been done on perfect splines and we will use some of those results to prove not only an analogue of Theorem 2.2, but also the uniqueness of our solution.

We first state two deep results due to Bojanov. Recall that we always assume that $N > n \geqq 2$ and $(e_i - e_{i-1})(e_{i+1} - e_i) < 0$, $i = 2, \cdots, N-1$.

THEOREM 3.1 (Bojanov [1]). *There exists a unique perfect spline P^* of degree n with $N-n-1$ knots, and a unique set of points $0 = t_1^* < \cdots < t_N^* = 1$ for which*

(i) $P^*(t_i^*) = e_i$, $i = 1, \cdots, N$;

(ii) $P^{*\prime}(t_i^*) = 0$, $i = 2, \cdots, N-1$.

THEOREM 3.2 (Bojanov [1]). *Let $P^*(\cdot\,; \mathbf{e})$ denote the unique perfect spline as given in Theorem 3.1, where we indicate the dependence on $\mathbf{e} = (e_1, \cdots, e_N)$. In a neighborhood of every $\mathbf{e}$ satisfying $(e_i - e_{i-1})(-1)^i > 0$, $i = 2, \cdots, N$, we have that $\|P^{*(n)}(\cdot\,; \mathbf{e})\|_\infty$ is a strictly increasing function of each $(-1)^i e_i$, $i = 1, \cdots, N$.*

On the basis of Theorems 3.1 and 3.2, we immediately obtain the following result.

THEOREM 3.3. *There exists a unique perfect spline P^* of degree n with $N-n-1$ knots which satisfies (3) for $p = \infty$. P^* is uniquely characterized by the fact that it oscillates strictly between the $(e_i)_1^N$ on some $(t_i^*)_1^N$.*

Proof. The only fact that is not an immediate consequence of Theorems 3.1 and 3.2 is the fact that P^* is strictly monotone on $[t_i^*, t_{i+1}^*]$ for each $i = 1, \cdots, N-1$. However, a simple Rolle's theorem argument shows that $P^{*\prime}$ has exactly $N-2$ zeros. Thus P^* is strictly monotone on $[t_i^*, t_{i+1}^*]$, $i = 1, \cdots, N-1$. □

In the above theorem, uniqueness is proved only for the class of perfect splines. There is more that is true, namely, Theorem 3.4.

THEOREM 3.4. *The perfect spline of Theorem 3.3 is the unique solution to (3) for $p = \infty$.*

Proof. Let P^* be as in Theorem 3.3 with $P^*(t_i^*) = e_i$, $i = 1, \cdots, N$, $0 = t_1^* < \cdots < t_N^* = 1$. Assume $f \in W_\infty^{(n)}(\mathbf{t}; \mathbf{e})$ for some $\mathbf{t} \in \Xi_N$. There exists a perfect spline P of degree n with $N-n-1$ knots for which $P(t_i) = f(t_i) = e_i$, $i = 1, \cdots, N$, and $\|P^{(n)}\|_\infty \leqq \|f^{(n)}\|_\infty$. If $\mathbf{t} \neq \mathbf{t}^*$, then from Theorem 3.3, $\|P^{*(n)}\|_\infty < \|P^{(n)}\|_\infty$. Thus if $f \in W_\infty^{(n)}$, f is "admissible" in (3), and $\|f^{(n)}\|_\infty = \|P^{*(n)}\|_\infty$, then it necessarily follows that $f \in W_\infty^{(n)}(\mathbf{t}^*; \mathbf{e})$.

We next prove that $f'(t_i^*) = 0$, $i = 2, \cdots, N-1$ for any f as above. Assume $f'(t_j^*) \neq 0$ for some $j \in \{2, \cdots, N-1\}$. Replace t_j^* by $s_j \in (t_{j-1}^*, t_{j+1}^*)$ so that if $g \in W_\infty^{(n)}$, $g(t_i^*) = e_i$, $i = 1, \cdots, N$, $i \neq j$, and $g(s_j) = f(s_j)$, then g attains the value e_j at least twice in (t_{j-1}^*, t_{j+1}^*), and g is "admissible" in (3). Let P be a perfect spline of degree n with $N-n-1$ knots such that $P(t_i^*) = e_i$, $i = 1, \cdots, N$, $i \neq j$, and $P(s_j) = f(s_j)$. Then $P \not\equiv P^*$. Thus $\|P^{(n)}\|_\infty \leqq \|f^{(n)}\|_\infty$ and from Theorem 3.3, $\|P^{*(n)}\|_\infty < \|P^{(n)}\|_\infty$. This contradicts the minimality property of f. Thus $f'(t_i^*) = 0$, $i = 2, \cdots, N-1$.

Assume $f \not\equiv P^*$. Then $f \not\equiv P^*$ on (t_j^*, t_{j+1}^*) for some $j \in \{1, \cdots, N-1\}$. Since $(P^* - f)(t_i^*) = 0$, $i = j, j+1$, $(P^* - f)'(x)$ must change sign on (t_j^*, t_{j+1}^*). Thus for $\sigma > 0$, sufficiently small, $(P^* - (1-\sigma)f)'(x)$ has a sign change in (t_j^*, t_{j+1}^*). Furthermore $(P^* - (1-\sigma)f)'(t_i^*) = 0$, $i = 2, \cdots, N-1$. Thus $(P^* - (1-\sigma)f)'(x)$ has at least $N-1$ distinct zeros in $[0, 1]$. Since $|P^{*(n)}(x)| \geqq |f^{(n)}(x)| > (1-\sigma)|f^{(n)}(x)|$ almost everywhere on $[0, 1]$, it follows from Rolle's theorem that $(P^* - (1-\sigma)f)^{(n)}(x)$ has at least $N-n$ sign changes on $[0, 1]$. But $P^{*(n)}(x)$, and thus $(P^* - (1-\sigma)f)^{(n)}(x)$, has exactly $N-n-1$ sign changes thereon. This contradiction proves the theorem. □

Remark. For $N = n+1$, P^* is the unique polynomial of degree n that satisfies $P^*(t_i^*) = e_i$, $i = 1, \cdots, n+1$, and $P^{*\prime}(t_i^*) = 0$, $i = 2, \cdots, n$. Such polynomials have been considered previously (see, e.g., Davis [4] and Mycielski and Paszkowski [10]). It seems that it was not previously noted that such polynomials satisfy an extremal property with respect to their nth derivative.

Remark. In the case $n = 1$ both Theorems 3.3 and 3.4 are valid. However, the proofs are somewhat different. The unique solution is identical for all $p \in (1, \infty]$ (see the remark at the end of § 2), and is a perfect spline with knots $(t_i^*)_2^{N-1}$.

4. $p=1$. We first consider in some detail solutions to (2) for fixed $0=t_1<t_2<\cdots<t_N=1$ with $N>n\geqq 2$ and $(e_i-e_{i-1})(e_{i+1}-e_i)<0$, $i=2,\cdots,N-1$. We recall that $f\in V^{(n)}(\mathbf{t};\mathbf{e})$ if

$$f(x)=\sum_{i=0}^{n-1}a_ix^i+\frac{1}{(n-1)!}\int_0^1(x-y)_+^{n-1}\,d\mu(y), \tag{10}$$

where $\|\mu\|<\infty$, and $f(t_i)=e_i$, $i=1,\cdots,N$. We are concerned with the problem

$$\min\{\|\mu\|: f\in V^{(n)}(\mathbf{t};\mathbf{e})\} \tag{11}$$

where μ is associated with f as in (10).

As in § 2, set

$$E_i=f[t_i,t_{i+1},\cdots,t_{i+n}],\qquad i=1,\cdots,N-n.$$

Thus (11) is equivalent to

$$\min\left\{\|\mu\|:\int_0^1 M_{i,n}(y)\,d\mu(y)=E_i,\ i=1,\cdots,N-n\right\}. \tag{12}$$

Since $n\geqq 1$, we have $E_iE_{i+1}<0$, $i=1,\cdots,N-n-1$.

It is well known that $(M_{i,n})_1^{N-n}$ is a weak Chebyshev (WT-) system on $[0,1]$. Thus there exists a nontrivial

$$h(y)=\sum_{i=1}^{N-n}c_iM_{i,n}(y)$$

and points $0<\xi_1<\cdots<\xi_{N-n}<1$ such that

$$h(\xi_i)=(-1)^i\|h\|_\infty,\qquad i=1,\cdots,N-n.$$

Without loss of generality, we normalize h so that $\|h\|_\infty=1$. Before showing how we use h to construct a solution to (12), let us consider h and the points of equi-oscillation $(\xi_i)_1^{N-n}$ in more detail.

PROPOSITION 4.1. *Let h be as above. Then we have the following:*

(i) *h is unique.*

(ii) *$c_i(-1)^i>0$, $i=1,\cdots,N-n$.*

(iii) *The $(\xi_i)_1^{N-n}$ are uniquely defined.*

(iv) *If $n\geqq 3$, then $t_{i+1}<\xi_i<t_{i+n-1}$, $i=1,\cdots,N-n$.*

Proof. For $n=2$, h is continuous and piecewise linear with knots $t_2,\cdots,t_{N-1}$, and satisfies $h(0)=h(1)=0$. h is easily seen to exist and satisfy (i), (ii), and (iii) with $\xi_i=t_{i+1}$, $i=1,\cdots,N-2$.

Assume $n\geqq 3$. By construction h has at least $N-n-1$ sign changes. From Proposition 2.1 and the proof thereof, it follows that h has exactly $N-n-1$ sign changes, $h^{(n-1)}$ strictly changes sign at each t_i, $i=2,\cdots,N-1$, and $c_i(-1)^i>0$, $i=1,\cdots,N-n$.

For each $j\in\{1,\cdots,N\}$, $(M_{i,n})_{i=1,i\neq j}^{N-n}$ is a WT-system on $[0,1]$. Since h equi-oscillates at $N-n$ points, it follows that $-c_j^{-1}\sum_{i=1,i\neq j}^{N}c_iM_{i,n}$ is a best approximant to $M_{j,n}$ on $[0,1]$ in the uniform norm from span $\{M_{i,n}\}_{i=1,i\neq j}^{N-n}$. Furthermore, the error in the best approximation is exactly $|c_j|^{-1}$. If $\tilde{h}=\sum_{i=1}^{N-n}d_iM_{i,n}$ satisfies $\|\tilde{h}\|_\infty=1$, and $\tilde{h}(\eta_i)=(-1)^i$, $i=1,\cdots,N-n$ for some $0<\eta_1<\cdots<\eta_{N-n}<1$, then it follows as above that $(-1)^jd_j^{-1}=|d_j|^{-1}=|c_j|^{-1}=(-1)^jc_j^{-1}$. Thus $d_j=c_j$ for each j proving the

uniqueness of h. (A different proof of the uniqueness of h follows from the analysis in the proof of Theorem 4.2.)

Since

$$\sum_{i=1}^{N-n} c_i M_{i,n}(\xi_j) = (-1)^j, \qquad j = 1, \cdots, N-n,$$

and $(M_{i,n}(\xi_j))_{i,j=1}^{N-n}$ is TP, it follows that this matrix is nonsingular and thus $\xi_i \in (t_i, t_{i+n})$, $i = 1, \cdots, N-n$. However, we wish to prove more, namely, $\xi_i \in (t_{i+1}, t_{i+n-1})$, $i = 1, \cdots, N-n$. To this end we use Rolle's theorem and the fact that $h'(\xi_i) = 0$, $i = 1, \cdots, N-n$. Since $n \geqq 3$, h' is continuous and vanishes on $(0, \xi_i]$ at the points $\xi_1, \cdots, \xi_i$. Furthermore $h^{(j)}(0) = 0, j = 0, 1, \cdots, n-2$. When we apply Rolle's theorem, it follows that $h^{(n-2)}$ has at least $i+1$ distinct zeros in $[0, \xi_i]$, and $h^{(n-1)}$ has at least i sign changes in $(0, \xi_i)$ (since $h^{(n-1)}$ does not vanish identically on any subinterval). But $h^{(n-1)}$ changes sign exactly at $t_2, \cdots, t_{N-1}$. Thus $t_{i+1} < \xi_i$. Similarly we prove that $\xi_i < t_{i+n-1}$.

It remains to prove (iii) for $n \geqq 3$. Property (iii) follows if we can show that h' has no zeros in $(0, 1)$ other than $(\xi_i)_1^{N-n}$. This fact may be proven by a simple Rolle's theorem argument. Alternatively, we can argue as follows:

$$h'(y) = \sum_{i=1}^{N-n+1} d_i M_{i,n-1}(y)$$

where $\operatorname{supp} M_{i,n-1} = (t_i, t_{i+n-1})$, $i = 1, \cdots, N-n+1$. If $h'(\xi) = 0$ for some $\xi \in (0, 1) \backslash \{\xi_1, \cdots, \xi_{N-n}\}$, then by setting $\{\eta_1, \cdots, \eta_{N-n+1}\} = \{\xi_1, \cdots, \xi_{N-n}, \xi\}$ where $0 < \eta_1 < \cdots < \eta_{N-n+1} < 1$, it follows from (iv) that $t_i < \eta_i < t_{i+n-1}$, $i = 1, \cdots, N-n+1$. But this implies that $h' \equiv 0$, which is a contradiction. □

We can now construct a unique solution to (11).

THEOREM 4.2. *Let h and $(\xi_i)_1^{N-n}$ be as given above. Set*

$$\mu_t = \sum_{j=1}^{N-n} b_j \delta_{\xi_j}$$

where the $(b_j)_1^{N-n}$ are chosen so that

$$\sum_{j=1}^{N-n} b_j M_{i,n}(\xi_j) = E_i, \qquad i = 1, \cdots, N-n.$$

Then $\|\mu_t\| = \sum_{j=1}^{N-n} |b_j|$ and μ_t is the unique solution to (11).

Proof. Let μ_t be as given above. Such a μ_t exists and is unique since $(M_{i,n}(\xi_j))_{i,j=1}^{N-n}$ is nonsingular. Since $E_i(-1)^i \sigma > 0$, $i = 1, \cdots, N-n$ for some $\sigma \in \{-1, 1\}$, fixed, it follows from the total positivity of $(M_{i,n}(\xi_j))_{i,j=1}^{N-n}$ that $b_j(-1)^j \sigma > 0$, $j = 1, \cdots, N-n$. Furthermore since $c_i(-1)^i > 0$, $i = 1, \cdots, N-n$, it is easily seen that

$$\sum_{j=1}^{N-n} |b_j| = \left| \sum_{i=1}^{N-n} c_i E_i \right| = \sum_{i=1}^{N-n} |c_i E_i|.$$

For any μ, $\|\mu\| < \infty$, satisfying

$$\int_0^1 M_{i,n}(y)\, d\mu(y) = E_i, \qquad i = 1, \cdots, N-n,$$

we have

$$\left| \sum_{i=1}^{N-n} c_i E_i \right| = \left| \int_0^1 h(y)\, d\mu(y) \right| \leqq \|h\|_\infty \|\mu\|.$$

Since $\|h\|_\infty = 1$,

$$\|\mu_{\mathbf{t}}\| = \sum_{j=1}^{N-n} |b_j| = \left| \sum_{i=1}^{N-n} c_i E_i \right| \leqq \|\mu\|,$$

which implies that $\mu_{\mathbf{t}}$ is a solution to (11). Assume $\|\mu_{\mathbf{t}}\| = \|\mu\|$. Then necessarily

$$\left| \int_0^1 h(y)\, d\mu(y) \right| = \|h\|_\infty \|\mu\|.$$

By Proposition 4.1(iii), h attains its norm only at the values $(\xi_j)_1^{N-n}$. Thus μ has support only on the $(\xi_j)_1^{N-n}$. Since $(M_{i,n}(\xi_j))_{i,j=1}^{N-n}$ is nonsingular, it follows that $\mu \equiv \mu_{\mathbf{t}}$. □

We now turn our attention to the problem as stated in (4), namely,

$$\min_{\mathbf{t} \in \Xi_N} \min \{\|\mu\| : f \in V^{(n)}(\mathbf{t}; \mathbf{e})\}. \tag{13}$$

From Theorem 4.2 we know that any solution must be of the specific form given therein. We will prove that any solution must also oscillate strictly between the $(e_i)_1^N$ on some $(t_i)_1^N$. For $n = 2$, this result is simple, and yet disappointing. For any $\mathbf{t} \in \Xi_N$, $t_1 = 0 < t_2 < \cdots < t_N = 1$, construct $\mu_{\mathbf{t}}$ and the associated $f(x) = a_0 + a_1 x + \sum_{j=1}^{N-2} b_j (x - \xi_j)_+^1$. As noted earlier $\xi_j = t_{j+1}, j = 1, \cdots, N-2$. Since $(e_i - e_{i-1}) \times (e_{i+1} - e_i) < 0$, $i = 2, \cdots, N-1$, it is easily seen that for any choice of $\mathbf{t} \in \Xi_N$, f oscillates strictly between the $(e_i)_1^N$ on $(t_i)_1^N$. Thus our result clearly holds, but obviously this condition is not sufficient in (13). However, it is possible, by calculation, to verify that the solution to (13) is unique.

We now turn our attention to the case $n \geqq 3$. Here it is unclear as to whether the following necessary conditions are also sufficient for a solution to (13), and also as to whether uniqueness holds.

THEOREM 4.3. *Let $n \geqq 3$ and let f^* be any solution to* (13). *There exists a $\mathbf{t}^* = (t_1^*, \cdots, t_N^*)$, $0 = t_1^* < \cdots < t_N^* = 1$ such that $f^* \in V^{(n)}(\mathbf{t}^*; \mathbf{e})$. Furthermore,*

(a) $$f^*(x) = \sum_{i=0}^{n-1} a_i x^i + \sum_{j=1}^{N-n} b_j (x - \xi_j)_+^{n-1}$$

where the $(b_j)_1^{N-n}$ and $(\xi_j)_1^{N-n}$ are as in Theorem 4.2 *with respect to $(t_i^*)_1^N$.*

(b) *f^* oscillates strictly between the $(e_i)_1^N$ on $(t_i^*)_1^N$.*

Proof. Let f^* be a solution to (13). There then exists a $\mathbf{t}^*$ as above for which $f^* \in V^{(n)}(\mathbf{t}^*; \mathbf{e})$. Since f^* must also solve (11) for $\mathbf{t}^*$, it follows that f^* necessarily satisfies (a). It remains to prove (b).

We first prove that $f^{*\prime}(t_i^*) = 0$, $i = 2, \cdots, N-1$. Assume to the contrary that $f^{*\prime}(t_k^*) \neq 0$ for some $k \in \{2, \cdots, N-1\}$. Without loss of generality we will assume that $(e_k - e_{k-1}) > 0$. Thus there exists an s_k as near as we wish to t_k^* for which $f(s_k) > e_k$. Recall from Proposition 4.1 that $t_{i+1}^* < \xi_i < t_{i+n-1}^*$, $i = 1, \cdots, N-n$. Taking s_k close to t_k^*, this implies the existence of a unique

$$g(x) = \sum_{i=0}^{n-1} c_i x^i + \sum_{j=1}^{N-n} d_j (x - \xi_j)_+^{n-1}$$

that satisfies $g(t_i^*) = e_i$, $i = 1, \cdots, N$, $i \neq k$, and $g(s_k) = e_k$. Furthermore $\operatorname{sgn} d_j = \operatorname{sgn} b_j = (-1)^j \sigma$, $j = 1, \cdots, N-n$, where $\sigma \in \{-1, 1\}$, fixed. g is "admissible" in (13) with $\|\mu\| = \sum_{j=1}^{N-n} |d_j|$. We will prove that $\sum_{j=1}^{N-n} |d_j| < \sum_{j=1}^{N-n} |b_j|$, contradicting the minimality of f^*. To this end, note that

$$(f^* - g)(x) = \sum_{i=0}^{n-1} (a_i - c_i) x^i + \sum_{j=1}^{N-n} (b_j - d_j)(x - \xi_j)_+^{n-1}$$

satisfies $(f^*-g)(t_i^*)=0$, $i=1,\cdots,N$, $i\neq k$, and $(f^*-g)(s_k)>0$. The conditions $t_{i+1}^*<\xi_i<t_{i+n-1}^*$, $i=1,\cdots,N-n$, easily imply that f^*-g vanishes only at $(t_i^*)_{i=1,i\neq j}^N$. Thus, in particular, $(f^*-g)(t_k^*)>0$.

Set $(f^*-g)[t_i^*,\cdots,t_{i+n}^*]=F_i$, $i=1,\cdots,N-n$. Then

$$F_i=\sum_{j=1}^{N-n}(b_j-d_j)M_{i,n}(\xi_j),\qquad i=1,\cdots,N-n$$

and $F_i(-1)^i\sigma\geqq 0$, $i=1,\cdots,N-n$. Furthermore the $(F_i)_1^{N-n}$ are not all zero. From the total positivity of $(M_{i,n}(\xi_j))_{i,j=1}^{N-n}$ it follows that $(b_j-d_j)(-1)^j\sigma\geqq 0, j=1,\cdots,N-n$, and not all the $(b_j-d_j)_1^{N-n}$ are zero (in fact all are nonzero). Thus

$$\sum_{j=1}^{N-n}|b_j|=\sum_{j=1}^{N-n}b_j(-1)^j\sigma>\sum_{j=1}^{N-n}d_j(-1)^j\sigma=\sum_{j=1}^{N-n}|d_j|.$$

Therefore $f^{*\prime}(t_i^*)=0$, $i=2,\cdots,N-1$.

It remains to prove that f^* is strictly monotone on $[t_i^*,t_{i+1}^*]$ for each $i=1,\cdots,N-1$. Using the fact that $t_{i+1}^*<\xi_i<t_{i+n-1}^*$, $i=1,\cdots,N-n$, it follows that $f^{*\prime}(x)$ has no zeros in $[0,1]$ other than $t_2^*,\cdots,t_{N-1}^*$. Thus f^* oscillates strictly between the $(e_i)_1^N$ on $(t_i^*)_1^N$. □

EXTENSION OF SZEGÖ'S THEOREM ON THE SECTIONS OF UNIVALENT FUNCTIONS*

STEPHAN RUSCHEWEYH†

Abstract. In this paper a far-reaching extension of Szegö's theorem on the univalence of partial sums of the power series expansion of univalent functions in the class $\mathcal{S}$ is given. In particular, it is shown that the property "univalent" can be replaced by the stronger one "starlike univalent" and that the conclusion is not only true for $\mathcal{S}$ but also for the closed convex hull of $\mathcal{S}$. The paper concludes with the discussion of a new conjecture on $\mathcal{S}$, stronger than the former "Bieberbach conjecture."

Key words. univalent functions, partial sums, Hadamard product

AMS(MOS) subject classification. 30C45

1. Introduction and statement of the results. Let $\mathcal{A}$ denote the set of analytic functions f in the unit disk $\mathbb{D}$ satisfying $f(0)=0, f'(0)=1$, and let $\mathcal{S}$ be the set of univalent functions in $\mathcal{A}$. For

$$f(z)=\sum_{k=1}^{\infty} a_k z^k \in \mathcal{A},$$

let

$$f_n(z)=\sum_{k=1}^{n} a_k z^k \qquad (n \in \mathbb{N}).$$

In 1928, G. Szegö [5] proved the following nice result.

THEOREM A. *For $f \in \mathcal{S}$ all sections f_n are univalent in $\mathbb{D}_{1/4}$.*

Here $\mathbb{D}_R$ denotes the set $\{z: |z|<R\}$. A function $f \in \mathcal{A}$ is said to be convex (starlike) in $\mathbb{D}_R$ if it is univalent in $\mathbb{D}_R$ with $f(\mathbb{D}_R)$ convex (starlike with respect to the origin). By $\mathcal{C}$, $\mathcal{S}^*$ we denote the subclasses of functions in $\mathcal{S}$ which are convex or starlike in $\mathbb{D}$, respectively. Szegö also proved the following theorem.

THEOREM B. *If $f \in \mathcal{C}$ ($\mathcal{S}^*$), then all sections f_n are convex (starlike) in $\mathbb{D}_{1/4}$.*

In the present paper we show that both Theorems A and B are very special cases of a general convolution theorem. We recall that for

$$f(z)=\sum_{k=0}^{\infty} a_k z^k, \qquad g(z)=\sum_{k=0}^{\infty} b_k z^k$$

the Hadamard product (or convolution) is defined by

$$(f * g)=\sum_{k=0}^{\infty} a_k b_k z^k$$

and that $\mathcal{A}$ is closed under convolution, i.e., $f, g \in \mathcal{A}$ implies $f * g \in \mathcal{A}$.

Let

$$\mathcal{F} := \operatorname{clco}\left\{\sum_{k=1}^{n} x^{k-1} z^k : |x| \leqq 1\right\}$$

* Received by the editors March 5, 1986; accepted for publication (in revised form) January 11, 1987.

† Math. Institut d. Universität, D-8700 Würzburg, Federal Republic of Germany. Current address, Depto. Matemáticas, Universidad Técnica F.S.M. Casilla 110-V, Valparaiso, Chile.

where clco stands for the closed convex hull (in this case with respect to the linear space of analytic functions in $\mathbb{D}$ with the topology of compact convergence in $\mathbb{D}$). $\mathcal{F}$ contains two interesting subsets:

$$\mathcal{R} := \{f \in \mathcal{A}: \operatorname{Re}(f(z)/z) > \tfrac{1}{2}, z \in \mathbb{D}\} \subset \mathcal{F}, \tag{1.1}$$

$$\mathcal{Q} := \left\{f(z) = \sum_{k=1}^{\infty} a_k z^k \in \mathcal{A}: 0 \leqq a_{k+1} \leqq a_k, k \in \mathbb{N}\right\} \subset \mathcal{F}. \tag{1.2}$$

In particular, since $\mathcal{C} \subset \mathcal{R}$ (compare Duren [2, pp. 72-73]), we have

$$\mathcal{C} \subset \mathcal{F}. \tag{1.3}$$

We will show that $\mathcal{F}$ is closed under convolutions:

$$f, g \in \mathcal{F} \Rightarrow f * g \in \mathcal{F} \tag{1.4}$$

and, in particular,

$$f \in \mathcal{F} \Leftrightarrow f_n \in \mathcal{F} \quad \text{for } n \in \mathbb{N}. \tag{1.5}$$

Our main result is as follows.

THEOREM 1. *Let $f \in \operatorname{clco} \mathcal{S}$ and $g \in \mathcal{F}$. Then $f * g$ is starlike in $\mathbb{D}_{1/4}$. The constant $\frac{1}{4}$ is best possible.*

This obviously contains both Theorems A and B using the special choices $g = s_n$ where

$$s_n(z) = \sum_{k=1}^{n} z^k \qquad (n \in \mathbb{N}).$$

But, in fact, Theorem A is considerably improved by Theorem 1; the result is true not only for $f \in \mathcal{S}$ but for all $f \in \operatorname{clco} \mathcal{S}$, a much larger set, which includes, for instance, all normalized typically real functions in $\mathbb{D}$; and the conclusion "univalent" is replaced by a stronger one, "starlike".[1] Also Theorem B is extended by Theorem 1, as can be seen from Corollary 1 and the above-mentioned inclusion $\mathcal{C} \subset \mathcal{R} \subset \mathcal{F}$.

COROLLARY 1. *If $f \in \mathcal{F}$ then f is convex in $\mathbb{D}_{1/4}$. In particular, f_n is convex in $\mathbb{D}_{1/4}$ for $n \in \mathbb{N}$. The constant $\frac{1}{4}$ is best possible.*

Note that this also gives the sharp "radius of convexity" within the class $\mathcal{Q} \subset \mathcal{F}$: the function $s_2 \in \mathcal{Q}$ is convex in $\mathbb{D}_{1/4}$ but in no larger disk.

Theorem 1 is related to a general convolution conjecture we are proposing. Let

$$\mathcal{D} = \{g \in \mathcal{A}: |g''(z)| \leqq \operatorname{Re} g'(z), z \in \mathbb{D}\}.$$

Conjecture. Let $f \in \operatorname{clco} \mathcal{S}$, $g \in \mathcal{D}$. Then $f * g \in \mathcal{S}^*$.

We can prove that $h \in \mathcal{F}$ implies $g(z) := 4h(z/4) \in \mathcal{D}$ and this shows that Theorem 1 is a partial verification of the conjecture.

Regarding $\mathcal{D}$ we prove the following theorem.

THEOREM 2. (i) *$\mathcal{D}$ is a compact convex subset of $\mathcal{C}$, closed under convolutions.*

(ii) *Let $g(z) = \sum_{k=1}^{\infty} a_k z^k \in \mathcal{A}$ with*

$$\sum_{k=2}^{\infty} k^2 |a_k| \leqq 1. \tag{1.6}$$

Then $g \in \mathcal{D}$ and the conjecture is true for g.

[1] After completing this manuscript I became aware of the paper entitled, "On a theorem of Szegö," by K. Hu and Y. F. Pan, *J. Math. Res. Exposition*, 4 (1984), pp. 41-44. The authors also show that "univalent" can be replaced by "starlike univalent" in the conclusion of Theorem A. Their method, however, does not extend to clco $\mathcal{S}$.

We also note that the conjecture is stronger than the (former) Bieberbach conjecture (de Branges' theorem). In fact, assume

$$f(z)=\sum_{k=1}^{\infty} a_k z^k \in \mathcal{S}$$

and that the conjecture holds. Since, by Theorem 2,

$$g_n(z)=z+z^n/n^2 \in \mathcal{D},$$

we see that $(f * g_n)(z)=z+a_n z^n/n^2 \in \mathcal{S}^*$, which gives $|a_n| \leqq n$, $n=2,3,\cdots$.

2. Proofs. We first verify the claims (1.1)-(1.5). Since $\mathcal{F}$ is closed by definition, it contains the functions

$$f_x(z) := \frac{z}{1-xz}, \qquad |x|=1,$$

and hence also clco $\{f_x: |x|=1\}$, which is known to equal $\mathcal{R}$. This proves (1.1).

For the proof of (1.2) we note that the set of polynomials in $\mathcal{Q}$ is dense in $\mathcal{Q}$, and since $\mathcal{F}$ is closed it suffices to show that every such polynomial is in $\mathcal{F}$. But these polynomials are finite convex combinations of the $s_n \in \mathcal{F}$, $n \in \mathbb{N}$, and $\mathcal{F}$ is convex.

Let $1 \leqq n \leqq m$ and

$$f(z)=\sum_{k=1}^{n} x^{k-1} z^k, \qquad g(z)=\sum_{k=1}^{m} y^{k-1} z^k$$

for certain $x, y \in \bar{\mathbb{D}}$. Then

$$(f * g)(z)=\sum_{k=1}^{n} (xy)^{k-1} z^k \in \mathcal{F}.$$

Since $\mathcal{F}$ is obviously compact we can apply [3, Thm. 1.17] (with a slight modification concerning the normalization) to deduce (1.4). Then from (1.4) with $g=s_n$ and $f \in \mathcal{F}$ we have $f * s_n = f_n \in \mathcal{F}$, $n \in \mathbb{N}$, which is one direction of (1.5). The other direction follows from the compactness of $\mathcal{F}$.

For the proof of Theorem 1 we require a fairly large number of results on $\mathcal{S}$ which we state in the following three theorems. Except for (2.5) (de Branges' theorem [1]), these results can be found in the standard textbooks on univalent functions (see, for example, Duren [2]).

THEOREM C. *For $f \in \mathcal{S}$ and $z \in \mathbb{D}$ we have*

$$\left|\log \frac{f(z)}{z}+\log (1-|z|^2)\right| \leqq \log \frac{1+|z|}{1-|z|}, \tag{2.1}$$

$$\left|\log \frac{zf'(z)}{f(z)}\right| \leqq \log \frac{1+|z|}{1-|z|}, \tag{2.2}$$

$$|\arg f'(z)| \leqq 4 \arcsin |z| \qquad (|z|<1/\sqrt{2}), \tag{2.3}$$

$$|f'(z)| \geqq \frac{1-|z|}{(1+|z|)^3}. \tag{2.4}$$

THEOREM D. *Let $f(z)=\sum_{k=1}^{\infty} a_k z^k \in \mathcal{S}$. Then*

$$|a_n| \leqq n \qquad (n \in \mathbb{N}), \tag{2.5}$$

$$|a_3-a_2^2| \leqq 1. \tag{2.6}$$

THEOREM E. *Let*

$$V_3 = \{(a_2, a_3) \in \mathbb{C}^2 : \exists f(z) = z + a_2 z^2 + a_3 z^3 + \cdots \in \mathcal{S}\}.$$

Then the set of points (a_2, a_3) *with*

$$a_2 = -2\int_0^1 x(t)\,dt, \qquad a_3 = a_2^2 - 2\int_0^1 t x^2(t)\,dt,$$

where $x(t)$ *is continuous with* $|x(t)| = 1$, *is dense in* V_3.

We now give a series of lemmas based on these theorems. The results derived in these lemmas are not sharp but sufficient for our purposes. Let

$$\beta = \log \tfrac{5}{3} = 0.5108\cdots.$$

We note that $e^{\beta z}$ is a (not normalized) convex univalent function in $\bar{\mathbb{D}}$.

LEMMA 1. *We have*

$$\left|\frac{1 - e^{\beta z}}{1 + e^{\beta z}}\right| \leqq \sigma \qquad (z \in \bar{\mathbb{D}}), \tag{2.7}$$

where $\sigma = \sqrt{2}/3\,(1 + \cos\beta)^{-1/2} = 0.3445\cdots$.

Proof. Let $f(z) = (1 - e^{\beta z})/(1 + e^{\beta z})$. Then f is analytic in $\bar{\mathbb{D}}$ since $\operatorname{Re} e^{\beta z} > 0$, $z \in \bar{\mathbb{D}}$. It therefore suffices to prove (2.7) on $|z| = 1$. Also, since

$$|F(z)| = |F(-z)| = |F(\bar{z})|,$$

we can restrict our attention to $z = e^{i\theta}$, $0 \leqq \theta \leqq \pi/2$. But in that range we have

$$|e^{\beta z}| = e^{\beta \cos\theta} \geqq 1,$$

and, since $e^{\beta z}$ is convex univalent in $\bar{\mathbb{D}}$, we see that in the same range $\operatorname{Re} e^{\beta z} \geqq \operatorname{Re} e^{i\beta}$. Simple geometry now shows that

$$|1 + e^{\beta z}| \geqq |1 + e^{i\beta}| = \sqrt{2(1 + \cos\beta)},$$

which together with the trivial estimate

$$|1 - e^{\beta z}| \leqq e^{\beta} - 1 = \tfrac{2}{3}$$

gives (2.7).

LEMMA 2. *Let* $f \in \mathbb{D}_{1/4}$. *Then*

$$\left|f'(z) - \frac{f(z)}{z}\right| \leqq \alpha \operatorname{Re}\left(f'(z) + \frac{f(z)}{z}\right), \tag{2.8}$$

where $\alpha < 0.53$.

Proof. From (2.2) we conclude that in $\mathbb{D}_{1/4}$

$$\frac{zf'(z)}{f(z)} = e^{\rho(z)\beta} \tag{2.9}$$

where $|\rho(z)| \leqq 1$. Hence, by Lemma 1,

$$\left|f'(z) - \frac{f(z)}{z}\right| \leqq \sigma \left|f'(z) + \frac{f(z)}{z}\right| \qquad (z \in \mathbb{D}_{1/4}). \tag{2.10}$$

Now we estimate the entity

$$\frac{|f(z) + f(z)/z|}{\operatorname{Re}\,(f'(z) + f(z)/z)} = \frac{1}{\cos\,(\arg\,(f'(z) + f(z)/z))}. \tag{2.11}$$

From (2.1) we obtain

$$|\arg f(z)/z| \leqq \beta \qquad (z \in \mathbb{D}_{1/4}). \tag{2.12}$$

It is the consequence of Lemma 1 and (2.9) that

$$1+\frac{zf'(z)}{f(z)} = 1+\frac{1+\sigma^2}{1-\sigma^2}+\varepsilon(z)\frac{2\sigma}{1-\sigma^2}$$

with $|\varepsilon(z)| \leqq 1$, and therefore

$$\left|\arg\left(1+\frac{zf'(z)}{f(z)}\right)\right| = |\arg(1+\varepsilon(z)\sigma)| \leqq \arcsin\sigma.$$

This together with (2.12) shows that the function (2.11) is bounded by

$$1/\cos(\beta+\arcsin\sigma) < \frac{0.53}{\sigma}, \tag{2.13}$$

and a combination of (2.10), (2.11), and (2.13) yields (2.8).

LEMMA 3. *For $f \in \mathcal{S}$ and $z \in \mathbb{D}_{1/4}$ we have*

$$\operatorname{Re}\left(f'(z)+\frac{f(z)}{z}\right) \geqq \frac{211}{250}. \tag{2.14}$$

Proof. From (2.1), with $|z| = \frac{1}{4}$, we obtain

$$\left|\log\left(\frac{15}{16}\frac{f(z)}{z}\right)\right| \leqq \beta$$

which extends, by the maximum principle, to $|z| \leqq \frac{1}{4}$. Hence there exists an analytic function ρ in $\mathbb{D}_{1/4}$ with

$$\frac{f(z)}{z} = \frac{16}{15}e^{\rho(z)\beta} \qquad (|\rho(z)| \leqq 1)$$

and, again using the convexity of $e^{\beta z}$ in $\mathbb{D}$, we get

$$\operatorname{Re}\frac{f(z)}{z} \geqq \frac{16}{15}e^{-\beta} = \frac{16}{25} \qquad (z \in \mathbb{D}_{1/4}). \tag{2.15}$$

On the other hand,

$$\operatorname{Re} f'(z) = |f'(z)|\cos(\arg f'(z))$$

and a combination of (2.3), (2.4) yields

$$\operatorname{Re} f'(z) \geqq \frac{1-\frac{1}{4}}{(1+\frac{1}{4})^3}\cos\left(4\arcsin\frac{1}{4}\right) = \frac{51}{250} \qquad (z \in \mathbb{D}_{1/4}). \tag{2.16}$$

Formulae (2.15) and (2.16) give (2.14).

LEMMA 4. *Let $(a_2, a_3) \in V_3$. Then*

$$|2a_2+a_3| \leqq 16+6\operatorname{Re} a_2+2\operatorname{Re} a_3. \tag{2.17}$$

Proof. We show first that

$$\operatorname{Re}(3a_2+a_3) \geqq -\frac{21}{4}. \tag{2.18}$$

Using the representations of Theorem E we obtain

$$\begin{aligned}
\operatorname{Re}(3a_2+a_3) &= \operatorname{Re}\left\{-6\int_0^1 x(t)\,dt+4\left(\int_0^1 x(t)\,dt\right)^2-2\int_0^1 tx^2(t)\,dt\right\}\\
&= -\frac{9}{4}+4\operatorname{Re}\left(\int_0^1\left(x(t)-\frac{3}{4}\right)dt\right)^2-2\operatorname{Re}\int_0^1 tx^2(t)\,dt\\
&= -\frac{5}{4}+4\left(\int_0^1 \operatorname{Re}\left(x(t)-\frac{3}{4}\right)dt\right)^2-4\left(\int_0^1 \operatorname{Im} x(t)\,dt\right)^2\\
&\quad -4\int_0^1 t(\operatorname{Re} x(t))^2\,dt\\
&\geqq -\frac{5}{4}+4\left(\int_0^1 \operatorname{Re}\left(x(t)-\frac{3}{4}\right)dt\right)^2-4\int_0^1 (\operatorname{Im} x(t))^2\,dt\\
&\quad -4\int_0^1 t(\operatorname{Re} x(t))^2\,dt\\
&= -\frac{21}{4}+4\left(\int_0^1 \operatorname{Re}\left(x(t)-\frac{3}{4}\right)dt\right)^2+4\int_0^1 (1-t)(\operatorname{Re} x(t))^2\,dt\\
&\geqq -\frac{21}{4}.
\end{aligned}$$

Here we made use of the Cauchy-Schwarz inequality and the relations

$$\operatorname{Re} A^2=(\operatorname{Re} A)^2-(\operatorname{Im} A)^2=-|A|^2+2(\operatorname{Re} A)^2 \qquad (A\in\mathbb{C}).$$

When we use the bounds $|a_2|\leqq 2, |a_3|\leqq 3$ it follows immediately that (2.17) holds if

$$\operatorname{Re} a_2\geqq -\frac{1}{2}.$$

Also, by (2.18) we deduce that (2.17) holds if

$$|2a_2+a_3|\leqq 16-\frac{21}{2}=\frac{11}{2} \tag{2.19}$$

which is, in particular, the case if

$$|a_2|\leqq\frac{5}{4}.$$

Now let $\operatorname{Re} a_2<-\frac{1}{2}, |a_2|>\frac{5}{4}$ and write $a_3=a_2^2+\rho$ where $|\rho|\leqq 1$ by (2.6). Then we have

$$\begin{aligned}
|2a_2+a_3|^2 &= 4|a_2|^2+|a_3|^2+4\operatorname{Re} a_2\overline{a_3}\\
&\leqq 25+4\operatorname{Re} a_2(\overline{a_2}^2+\bar{\rho})\\
&\leqq 25-4\left(\frac{5}{4}\right)^2\cdot\frac{1}{2}+8\\
&= \frac{239}{8}<\left(\frac{11}{2}\right)^2.
\end{aligned}$$

This shows that also in this case (2.19), and hence (2.17) holds.

LEMMA 5. *Let $f \in \mathcal{S}$. Then for $n \in \mathbb{N}$ and $z \in \mathbb{D}_{1/4}$ we have*

$$\left| f_n'(z) - \frac{f_n(z)}{z} \right| \leqq \operatorname{Re}\left(f_n'(z) + \frac{f_n(z)}{z} \right). \tag{2.20}$$

Proof. We write $f_n = f - p_n$ such that by Lemma 2 for $z \in \mathbb{D}_{1/4}$

$$\begin{aligned} \left| f_n'(z) - \frac{f_n(z)}{z} \right| &\leqq \left| f'(z) - \frac{f(z)}{z} \right| + \left| p_n'(z) - \frac{p_n(z)}{z} \right| \\ &\leqq \alpha \operatorname{Re}\left(f'(z) + \frac{f(z)}{z} \right) + \left| p_n'(z) - \frac{p_n(z)}{z} \right|. \end{aligned}$$

In order to estimate the right-hand side using

$$\operatorname{Re}\left(f_n'(z) + \frac{f_n(z)}{z} \right) = \operatorname{Re}\left(f'(z) + \frac{f(z)}{z} \right) - \operatorname{Re}\left(p_n'(z) + \frac{p_n(z)}{z} \right)$$

it suffices to show that

$$\left| p_n'(z) - \frac{p_n(z)}{z} \right| + \left| p_n'(z) + \frac{f_n(z)}{z} \right| \leqq (1-\alpha) \operatorname{Re}\left(f'(z) + \frac{f(z)}{z} \right).$$

From (2.5) we obtain

$$\left| p_n'(z) \pm \frac{p_n(z)}{z} \right| \leqq \sum_{k=n+1}^{\infty} \frac{k^2 \pm k}{4^{k-1}} \qquad (z \in \mathbb{D}_{1/4})$$

and, using Lemma 3, we are left with the inequality

$$\sum_{k=n+1}^{\infty} \frac{k^2}{4^{k-1}} \leqq \frac{0.47}{2} \cdot \frac{211}{250} = 0.198 \cdots.$$

A simple calculation shows that this is true for $n \geqq 4$. Formula (2.20) is immediately verified for $n = 2$. For $n = 3$ we have to show that

$$|a_2 z + 2a_3 z^2| \leqq 2 + \operatorname{Re}(3a_2 z + 4a_3 z^2) \qquad (z \in \mathbb{D}_{1/4}). \tag{2.21}$$

Since $(a_2, a_3) \in V_3$ implies $(a_2 x, a_3 x^2) \in V_3$ for $x \in \bar{\mathbb{D}}$ we see that (2.21) is equivalent to

$$\left| \frac{a_2}{4} + \frac{a_3}{8} \right| \leqq 2 + \operatorname{Re}\left(\frac{3}{4} a_2 + \frac{1}{4} a_3 \right)$$

for $(a_2, a_3) \in V_3$. This, however, is the content of Lemma 4.

Proof of Theorem 1. Let $\mathcal{H}_R$ denote the class of functions $h \in \mathcal{A}$ with

$$\left| h'(z) - \frac{h(z)}{z} \right| \leqq \operatorname{Re}\left(h'(z) + \frac{h(z)}{z} \right) \qquad (z \in \mathbb{D}_R). \tag{2.22}$$

Then (2.22) implies

$$\left| \left(\frac{zh'(z)}{h(z)} - 1 \right) \Big/ \left(\frac{zh'(z)}{h(z)} + 1 \right) \right| \leqq 1 \qquad (z \in \mathbb{D}_R),$$

and hence $\operatorname{Re}(zh'(z)/h(z)) > 0$ in $\mathbb{D}_R$. Thus (2.22) implies the starlikeness of $h \in \mathcal{H}_R$ in $\mathbb{D}_R$. We also note that $\mathcal{H}_R$ is convex and compact (this class was introduced by Singh [4]). In Lemma 5 we have seen that for $f \in \mathcal{S}$ and

$$g(z) = \sum_{k=1}^{n} x^{k-1} z^k \qquad (|x| \leqq 1, n \in \mathbb{N})$$

we have

$$f * g \in \mathcal{H}_{1/4}. \tag{2.23}$$

By the convexity and compactness of $\mathscr{H}_{1/4}$ and the linearity of the convolution we deduce that (2.23) holds also for $f \in \operatorname{clco} \mathscr{S}$, $g \in \mathscr{F}$, which is an even stronger result than that which we have claimed in Theorem 1. That the constant $\frac{1}{4}$ is best possible is readily seen from the example

$$f(z) = \frac{z}{(1-z)^2} \in \mathscr{S}, \qquad g(z) = z + z^2 \in \mathscr{F}.$$

Then $(f * g)(z) = z + 2z^2$ is starlike in $\mathbb{D}_{1/4}$ but in no larger disk.

It follows from Theorem 1 that for $f \in \mathscr{F}$ the function $z/(1-z)^2 * f = zf'(z)$ is starlike in $\mathbb{D}_{1/4}$. But this is equivalent to the assertion of Corollary 1.

Proof of Theorem 2. The functions $g \in \mathbb{D}$ fulfill, in particular, $|zg''(z)| \leqq |g'(z)|$ and therefore $\operatorname{Re}(zg''(z)/g'(z)) + 1 > 0$ in $\mathbb{D}$. Hence $\mathscr{D} \subset \mathscr{C}$, a compact set. That $\mathscr{D}$ is closed and convex is obvious. Now let $f, g \in \mathscr{D}$. Then $g \in \mathscr{C} \subset \mathscr{R}$ and therefore

$$g(z) = \int_{|x|=1} \frac{z}{1-xz}\, d\mu$$

for a certain probability measure μ on $|x| = 1$. Thus

$$(f * g)(z) = \int_{|x|=1} \frac{1}{x} f(xz)\, d\mu \in \operatorname{clco} \mathscr{D} = \mathscr{D},$$

which shows that $\mathscr{D}$ is closed under convolutions. A simple calculation shows that a function

$$h(z) = z + \alpha z^n \tag{2.24}$$

belongs to $\mathscr{D}$ if and only if $|\alpha| \leqq 1/n^2$. The functions (1.6) are in the closed convex hull of the functions (2.24) with $|\alpha| \leqq 1/n^2$ and thus in $\mathscr{D}$. Let g satisfy (1.6) and

$$f(z) = \sum_{k=1}^{\infty} b_k z^k \in \operatorname{clco} \mathscr{S}.$$

Then

$$f * g = \sum_{k=1}^{\infty} a_k b_k z^k$$

satisfies (using (2.5))

$$\sum_{k=2}^{\infty} k|a_k b_k| \leqq \sum_{k=2}^{\infty} k^2 |a_k| \leqq 1,$$

which is the well-known sufficient condition for $f * g \in \mathscr{S}^*$.

ON THE ZEROS OF DERIVATIVES OF BESSEL FUNCTIONS*

LEE LORCH† AND PETER SZEGO‡

Abstract. Bessel functions of the first and second kind are denoted as usual by $J_\nu(x)$, $Y_\nu(x)$, the general cylinder function $AJ_\nu(x)+BY_\nu(x)$, where A, B are independent of x and ν, by $C_\nu(x)$, their respective positive zeros and those of their derivatives by $j_{\nu k}$, $y_{\nu k}$, $c_{\nu k}$, $j'_{\nu k}$, $y'_{\nu k}$, $c'_{\nu k}$, etc. It is shown here that for $-1<\nu<0$, (i) $j'_{\nu k}$ increases in ν, $k=1,2,\cdots$, (ii) $j'_{\nu 1}>j'_{11}=1.84\cdots$, and (iii) $(-1)^k J''_\nu(j'_{\nu k})>0$. It is also established that $c'_{\nu k}-c_{\nu l}$ increases in $\nu>0$, provided $c'_{\nu k}>c_{\nu l}>\nu>0$, where the ranks k, l may or may not be equal but are kept fixed as ν varies. Further, (iii') $(-1)^k J''_\nu(j'_{\nu k})<0$ for $0<\nu\leqq 1$, $k=1,2,\cdots$; $J''_0(j'_{01})=0$, $(-1)^k J''_0(j'_{0k})<0$, $k=2,3,\cdots$.

Key words. Bessel functions, zeros

AMS(MOS) subject classification. 33A

1. Introduction. The Bessel function of the first kind and order ν is defined to be [2, p. 4 (2)]

$$J_\nu(x)=2^{-\nu}\sum_{m=0}^{\infty}\frac{(-1)^m x^{2m+\nu}}{4^m m!\Gamma(m+\nu+1)}. \tag{1}$$

It satisfies the differential equations [2, p. 4 (1); p. 13 (67)]

$$x^2y''+xy'+(x^2-\nu^2)y=0, \tag{2}$$

and

$$x^2(x^2-\nu^2)y'''+x(x^2-3\nu^2)y''+[(x^2-\nu^2)^2-(x^2+\nu^2)]y'=0. \tag{3}$$

Here we shall consider only real values of x, y, and ν, and concern ourselves chiefly with the interval $-1<\nu<0$. The kth positive zero of $J_\nu(x)$ is denoted by $j_{\nu k}$, of $J'_\nu(x)$ by $j'_{\nu k}$, except that $j'_{01}=0$. For the standard second solution of (2), $Y_\nu(x)$, and its derivative, positive zeros are denoted by $y_{\nu k}$, $y'_{\nu k}$, respectively.

General solutions $C_\nu(x)$ of (2) will also be considered here, in the form

$$C_\nu(x)=AJ_\nu(x)+BY_\nu(x),$$

where the constants A, B are independent of both x and ν. The positive zeros of $C_\nu(x)$ and $C'_\nu(x)$ are denoted by $c_{\nu k}$, $c'_{\nu k}$, respectively, and generically by c_ν, c'_ν or simply by c, c'.

It is well known, for each fixed $k=1,2,\cdots$, that $j_{\nu k}$ increases with ν, provided $\nu>-1$ [7, p. 508] and that $j'_{\nu k}$ increases with ν provided that $\nu>0$ [5, p. 248].

This last result follows also from [7, p. 510 (4)], since $j'_{\nu 1}>\nu$ when $\nu>0$ [5, p. 246], [7, p. 485 (1)]. This formula, which will be used below, states

$$\frac{dc'}{d\nu}=\frac{2c'}{c'^2-\nu^2}\int_0^\infty (c'^2\cosh 2t-\nu^2)K_0(2c'\sinh t)\,e^{-2\nu t}\,dt, \tag{4}$$

where the positive decreasing function $K_0(x)$ is the modified Bessel function of the second kind and order 0 [7, p. 78].

An alternative proof of the monotonicity of $j'_{\nu k}$, $\nu > 0$, can be based on Sturm comparison techniques instead of (4) [3].

2. Statement of results to be established. If the inequality $j'_{\nu 1} > |\nu|$, known [5, p. 246] to be valid for $\nu > 0$, could be established also for $-1 < \nu < 0$, then (4) would imply also that $j'_{\nu k}$ is an increasing function of ν, $-1 < \nu < 0$, $k = 1, 2, \cdots$. In fact, somewhat more is true, namely,

$$j'_{\nu 1} > \max\{j'_{11}|\nu|, j_{\nu 1}, j'_{-\nu 1}\}, \qquad -1 < \nu < 0, \tag{5}$$

where [6, p. 30] $j'_{11} = 1.84118378 > 3^{1/2}$. Indeed,

$$j'_{\nu 1} > j'_{11}, \qquad -1 < \nu < 0. \tag{5'}$$

Hence, as stated, for $k = 1, 2, \cdots$,

$$j'_{\nu k} \textit{ increases with } \nu, \qquad -1 < \nu < 0, \tag{6}$$

as well as for $\nu > 0$.

This does *not* assert that $j'_{\nu k}$ increases for $-1 < \nu < \infty$. Indeed, such a claim would be false, as the third inequality in (5) shows. The function $j'_{\nu 1}$ is discontinuous at $\nu = 0$, although it is continuous from above at $\nu = 0$, i.e., $j'_{\nu 1} \to j'_{01} = 0$ as $\nu \to 0+$. In the transition from negative ν to positive ν, the zero $j'_{\nu k}$ goes over into $j'_{\nu, k+1}$.

As a consequence of (5) and (3), it will be established that

$$(-1)^k J''_\nu(j'_{\nu k}) > 0, \qquad -1 < \nu < 0. \tag{7}$$

Analogous results hold for $\nu = 0$ and $0 < \nu \leqq 1$, namely,

$$J''_0(j'_{01}) = J''_0(0) = 0, \quad (-1)^k J''_0(j'_{0k}) < 0, \quad k = 2, 3, \cdots, \tag{8}$$

and

$$(-1)^k J''_\nu(j'_{\nu k}) < 0, \quad 0 < \nu \leqq 1, \quad k = 1, 2, \cdots. \tag{9}$$

This last set of inequalities cannot hold for general $\nu > 0$, since they depend on the inequality $j'_{\nu k} > 3^{1/2}\nu$, valid for $0 < \nu \leqq 1$ (in fact for somewhat larger ν as well) but not for sufficiently large ν, as can be noted from the well-known fact that $j'_{\nu 1}/\nu \to 1$ as $\nu \to \infty$.

It will be shown also that

$$c'_\nu - c_\nu \textit{ increases with } \nu, \textit{ provided } c'_\nu > c_\nu > \nu > 0. \tag{10}$$

Here c'_ν and c_ν need not be of the same rank. Special cases of (10) worth noting are, for fixed $k = 1, 2, \cdots$,

$$y'_{\nu k} - y_{\nu k} \textit{ increases with } \nu > 0, \tag{11}$$

and

$$j'_{\nu, k+1} - j_{\nu k} \textit{ increases with } \nu > 0. \tag{12}$$

Remark. The monotonicity result (10) and its corollaries (11) and (12) are reminiscent of the results in [4] where it was shown, e.g., that $j_{\nu, k+1} - j_{\nu k}$ and similar differences are increasing functions of $\nu > 0$ for each fixed $k = 1, 2, \cdots$. Proof was done by employing the integral representation for $dc/d\nu$ which will be used here to establish (10). These and other results were later derived by Sturm techniques in [3].

For the corresponding differences such as $j'_{\nu,k+1}-j'_{\nu k}$, $k=1,2,\cdots$, we have not proved any monotonicity properties. Numerical values suggest these differences and the differences $j_{\nu k}-j'_{\nu k}$ possess regularities which are less uniform. Thus, $j_{\nu 1}-j'_{\nu 1}$ decreases over the values $\nu=0, \frac{1}{4}, \frac{1}{3}, \frac{1}{2}, \frac{2}{3}$ but increases when $\nu=\frac{3}{4}, 1, \frac{3}{2}, \cdots$.

3. Proof of (5) and (6). As a preliminary to (5), but sufficient to establish (6), we note first

$$j'_{\nu 1}>|\nu|, \qquad -1<\nu<0. \tag{13}$$

This is a consequence of $J'_\nu(x)<0$, $|x|\leqq|\nu|$, $-1<\nu<0$, which in turn follows on differentiating (1) and isolating the first term of the resulting infinite series to obtain

$$2^\nu x^{1-\nu}J'_\nu(x)=\frac{\nu}{\Gamma(\nu+1)}-\sum_{m=1}^{\infty}\frac{(-1)^{m+1}(2m+\nu)x^{2m}}{4^m m!\Gamma(m+\nu+1)}.$$

The isolated term on the right side is negative for $-1<\nu<0$ and the (alternating) infinite series is positive for $0<|x|\leqq|\nu|$, since its successive terms decrease in absolute value for these x. Hence, (13) holds.

This implies also (6), on taking $c'=j'_{\nu k}$ in (4).

Putting $x=j'_{\nu 1}$ in the differential equation (2), with $y=J_\nu(x)$, we now infer also that

$$J_\nu(j'_{\nu 1})<0, \qquad -1<\nu<0, \tag{14}$$

since $x=j'_{\nu 1}$ yields a minimum for $J_\nu(x)$, $-1<\nu<0$. Thus, $j'_{\nu 1}>j_{\nu 1}$, as asserted in the second inequality in (5), since $J_\nu(0+)=+\infty$ for such ν.

To establish the third inequality in (5), we recall the Wronskian [7, p. 76]

$$J_\nu(x)J'_{-\nu}(x)-J'_\nu(x)J_{-\nu}(x)=-(2\sin\nu\pi)/(\pi x). \tag{15}$$

This implies $J_\nu(j'_{\nu 1})J'_{-\nu}(j'_{\nu 1})>0$ when, as here, $-1<\nu<0$, so that $J'_{-\nu}(j'_{\nu 1})<0$, from (14). Hence $j'_{\nu 1}>j'_{-\nu 1}$, as the third inequality in (5) states, since $-\nu>0$.

It remains to verify the first inequality in (5). When we know that $j'_{\nu 1}$ and $j'_{-\nu 1}$ are monotonic for $-1<\nu<0$, it follows that their respective limits exist as $\nu\to-1+$. Since $j'_{\nu 1}>j'_{-\nu 1}$, $-1<\nu<0$, we have

$$\lim_{\nu\to-1+} j'_{\nu 1}\geqq\lim_{\nu\to-1+} j'_{-\nu,1}=j'_{11},$$

in view of the continuity of $j'_{\nu 1}$ at $\nu=1$ [5, p. 246]. The first inequality in (5) now follows, since (6) has already been verified. The reasoning provided establishes also the stronger assertion (5′).

4. Proof of (7), (8), and (9). The first inequality in (5), slightly weakened, implies

$$j'_{\nu k}>3^{1/2}|\nu|, \qquad -1<\nu<0. \tag{16}$$

In differential equation (3), we substitute $x=j'_{\nu k}$, with $y=J_\nu(x)$, and recall that $j'_{\nu 1}, j'_{\nu 3}, \cdots$, yield minima, $j'_{\nu 2}, j'_{\nu 4}, \cdots$, yield maxima when $-1<\nu<0$. The y' term vanishes; the coefficients of y'' and y''' are positive in view of (16), so that (7) follows from (3).

The results (8) and (9) can be shown similarly, except that, for the first part of (8), we start by remembering that $j'_{01}=0$. That $J'''_0(j'_{01})=0$ then follows by differentiating (1) three times and then putting $x=0$. For $0<\nu\leqq 1$, we need to know that $j'_{\nu 1}>\sqrt{3}\nu$. This follows from the inequality [7, p. 486 (3)]

$$j'_{\nu 1}>\sqrt{\nu(\nu+2)}, \qquad \nu>0.$$

Remark. In fact, $j'_{\nu 1} > j'_{11}\nu$, $0 < \nu < 1$. This follows from the concavity of $j'_{\nu k}$, established by Elbert and Laforgia [1], since $j'_{01} = 0$ so that the chord joining the origin with $(1, j'_{11})$ lies below the curve $j'_{\nu 1}$ in the $(\nu, j'_{\nu 1})$ plane.

5. Proof of (10), (11), and (12). These are consequences of (4) and the lemma of [4], since $\cosh 2t > 1$, $t > 0$. Thus, from (4) and [4],

$$\begin{aligned}\frac{dc'_\nu}{d\nu} &= 2c'_\nu \int_0^\infty \frac{c'^2_\nu \cosh 2t - \nu^2}{c'^2_\nu - \nu^2} K_0(2c'_\nu \sinh t)\, e^{-2\nu t}\, dt \\ &> 2c'_\nu \int_0^\infty K_0(2c'_\nu \sinh t)\, e^{-2\nu t}\, dt \\ &> 2c_\nu \int_0^\infty K_0(2c_\nu \sinh t)\, e^{-2\nu t}\, dt,\end{aligned}$$

where the last inequality follows from the lemma of [4] since $c'_\nu > c_\nu > \nu > 0$. But this last expression equals $dc_\nu/d\nu$ [7, p. 508 (3)], verifying (10). The remaining assertions (11) and (12) are corollaries.

6. An additional remark. When we put $x = j'_{\nu 1}$ in the Wronskian

$$W(J_\nu, Y_\nu) = J_\nu(x) Y'_\nu(x) - J'_\nu(x) Y_\nu(x) = 2/(\pi x),$$

it follows that $J_\nu(j'_{\nu 1}) Y'_\nu(j'_{\nu 1}) > 0$. When $-1 < \nu < 0$, the factor $J_\nu(j'_{\nu 1}) < 0$, and so for this interval of ν, $Y'_\nu(j'_{\nu 1}) < 0$. When $-\frac{1}{2} < \nu < 0$, $Y_\nu(0+) = -\infty$, while $Y_{-1/2}(x) = J_{1/2}(x)$, so that $Y_{-1/2}(0) = 0$. Hence

$$y'_{\nu 1} < j'_{\nu 1}, \qquad -\tfrac{1}{2} \leqq \nu < 0, \tag{17}$$

reversing the inequality which obtains for $\nu > 0$ [6, p. xvi (1.04)].

It is perhaps worth noticing the significance of (16) by inferring (17) from another "Wronskian" [7, p. 76 (8)], namely

$$J'_\nu(x) Y'''_\nu(x) - J'''_\nu(x) Y'_\nu(x) = \frac{2}{\pi x^2}\left(\frac{3\nu^2}{x^2} - 1\right). \tag{18}$$

When $x = j'_{\nu 1}$, this implies

$$J'''_\nu(j'_{\nu 1}) Y'_\nu(j'_{\nu 1}) > 0, \qquad -1 < \nu < 0,$$

in view of (16). From (7), it follows now that $Y'_\nu(j'_{\nu 1}) < 0$, as in the previous proof, leading again to (17).

Note added in proof. The zeros of $J'_\nu(x)$ are simple when $\nu > -1$, except possibly for $x = 0$. This follows on applying inequality (13) to the differential equation (2), since (13) holds also when $\nu \geqq 0$. For $\nu < -1$, this is no longer the case. This is pointed out by Kerimov and Skorokhodov, "Calculation of the multiple zeros of the derivatives of the cylindrical Bessel functions $J_\nu(z)$ and $Y_\nu(z)$," *Zh. Vychisl. Mat. i Mat. Fiz.*, 25 (1985), pp. 1749–1760 (*U.S.S.R. Comput. Math. and Math. Phys.*, 25 (1985), pp. 101–107, especially p. 107).

A COMBINATORIAL INTERPRETATION OF THE INTEGRAL OF THE PRODUCT OF LEGENDRE POLYNOMIALS*

J. GILLIS†, J. JEDWAB‡, AND D. ZEILBERGER§

Abstract. Denote by $P_n(x)$ the Legendre polynomial of degree n and let

$$I_{n_1,\cdots,n_k} = \int_{-1}^{1} P_{n_1}(x)\cdots P_{n_k}(x)\,dx.$$

$I_{n_1,\cdots,n_k}$ is written as a sum involving binomial coefficients and the sum is interpreted via a combinatorial model. This makes possible a combinatorial proof of a number of general theorems concerning $I_{n_1,\cdots,n_k}$, not all of which seem analytically straightforward, including a direct combinatorial derivation of the known formula for $I_{a,b,c}$ and the expression of $I_{a,b,c,d}$ as a simple finite sum. In addition, a number of apparently new combinatorial identities are obtained.

Key words. Legendre polynomials, integrals, digraph

AMS(MOS) subject classifications. primary 33A45; secondary 05A10

1. Introduction.

We will be concerned with the Legendre polynomials, defined by

$$P_n(x) = 2^{-n} \sum_{\alpha \leqq n/2} (-1)^{\alpha} \binom{n}{\alpha} \binom{2n-2\alpha}{n} x^{n-2\alpha} \qquad (-1 \leqq x \leqq 1;\ n = 0, 1, 2, \cdots),$$

which may be written in the equivalent form [4, p. 38]

$$P_n(x) = 2^{-n} \sum_{\alpha} \binom{n}{\alpha}^2 (x+1)^{\alpha}(x-1)^{n-\alpha}. \tag{1}$$

In (1), as in other combinatorial sums in what follows, we shall omit the limits of summation where these coincide with the natural cut-offs implied by the fact that $\binom{a}{b} = 0$ wherever a, b are integers and $b > a > 0$ or $a > 0 > b$.

Let

$$I_{n_1,\cdots,n_k} = \int_{-1}^{1} P_{n_1}(x)\cdots P_{n_k}(x)\,dx, \tag{2}$$

where $n_1, \cdots, n_k$ are nonnegative integers. We will express $I_{n_1,\cdots,n_k}$ as a sum involving binomial coefficients and use a combinatorial interpretation of this sum to derive a number of analytical and combinatorial results.

To simplify notation, write $\underline{n} = (n_1, \cdots, n_k)$ and $\underline{\alpha} = (\alpha_1, \cdots, \alpha_k)$. It is convenient to write $x = 2y - 1$ in (1) to obtain

$$P_n(x) = p_n(y) = \sum_{\alpha} \binom{n}{\alpha}^2 y^{\alpha}(y-1)^{n-\alpha} \qquad (0 \leqq y \leqq 1),$$

which on substitution in (2) gives

$$\begin{aligned} I_{\underline{n}} &= 2 \sum_{\underline{\alpha}} \binom{n_1}{\alpha_1}^2 \cdots \binom{n_k}{\alpha_k}^2 \int_0^1 y^{\Sigma\alpha_i}(y-1)^{\Sigma n_i - \Sigma\alpha_i}\,dy \\ &= 2 \sum_{\underline{\alpha}} \binom{n_1}{\alpha_1}^2 \cdots \binom{n_k}{\alpha_k}^2 \left\{ \frac{(-1)^{\Sigma\alpha_i}(\Sigma\alpha_i)!\,(\Sigma n_i - \Sigma\alpha_i)!}{(1+\Sigma n_i)!} \right\} \end{aligned} \tag{3}$$

* Received by the editors March 25, 1987; accepted for publication (in revised form) March 1, 1988.
† Department of Applied Mathematics, The Weizmann Institute of Science, Rehovot 76100, Israel.
‡ Emmanuel College, Cambridge, United Kingdom.
§ Department of Mathematics, Drexel University, Philadelphia, Pennsylvania 19104.

$$(4) \qquad = \frac{2}{1+\Sigma n_i} \cdot \sum_{\alpha} (-1)^{\Sigma \alpha_i} \left(\binom{n_1}{\alpha_1}^2 \cdots \binom{n_k}{\alpha_k}^2 \Big/ \binom{\Sigma n_i}{\Sigma \alpha_i} \right).$$

Now consider a set of elements of k different types, ordered by type number i ($i = 1, \cdots, k$) and, within each type number, by a serial number r ($r = 1, \cdots, n_i$). We represent these by points and form a directed graph by connecting them, with one edge going into and one coming out of each of the points. We then color each of the Σn_i edges blue or yellow according to the following *balance condition*:

(*) For each i the number of points of type i at the beginning of blue edges, α_i (say), equals the number at the end of blue edges.

Call each such colored graph a *system*, and let T denote the set of all possible distinct systems. Class a system as *even* or *odd* according to the parity of the total number of blue edges, $\sum_{i=1}^{k} \alpha_i$. Let the difference between the number of even and odd systems, in any subset E of T, be $\Pi_n(E)$. Clearly,

$$(5) \qquad \begin{aligned} \frac{2}{(1+\Sigma n_i)!} \Pi_n(T) &= \frac{2}{(1+\Sigma n_i)!} \left\{ \sum_{\alpha} (-1)^{\Sigma \alpha_i} \binom{n_1}{\alpha_1}^2 \cdots \binom{n_k}{\alpha_k}^2 (\Sigma \alpha_i)! (\Sigma n_i - \Sigma \alpha_i)! \right\} \\ &= I_n \end{aligned}$$

by (3).

2. Some elementary considerations. Denote the set of distinct graphs formed by omitting the coloring of each system, in any subset E of T, by E^*. We will refer to an edge beginning at a point of type i and ending at a point of type j ($1 \leqq i, j \leqq k$) as "an $i \to j$ edge," calling it *pure* if $i = j$ and *mixed* if $i \neq j$. Where desired we will indicate the edge color by $i \overset{B}{\to} j$ or $i \overset{Y}{\to} j$.

We recall that any vertex is characterized by a pair of natural numbers (i, j) where i is the number of the type to which it belongs and j ($1 \leqq j \leqq n_i$) is its serial number in that type. If two points P, P' are characterized by (i, j), (i', j'), respectively, then P is said to be of *lower rank* than P' if

$$\text{either} \quad i < i'$$

$$\text{or} \quad i = i', \quad j < j'.$$

Now let P be the set of systems containing at least one pure edge. Given any system in P, select from among the pure edges the one beginning at the point of lowest rank and change its color. This leaves the balance condition (*) satisfied but produces a new system of opposite parity, so that the two systems together give a canceling contribution to $\Pi_n(T)$. Since this process defines a (1, 1) parity-changing map from P to itself, $\Pi_n(P) = 0$. Writing $T \backslash P = U$, say, this is equivalent to

$$\Pi_n(T) = \Pi_n(U);$$

thus, we may disregard P and count only the contribution of systems in U to $\Pi_n(T)$.

Now consider any graph belonging to U. Take the lowest ranking vertex and call it X^0. Since there is exactly one edge starting at each vertex, there will be a uniquely defined cycle of the form

$$(6) \qquad X^0 \to X^1 \to X^2 \to \cdots \to X^{P-1} \to X^P (= X^0).$$

Since there are no pure edges it follows that $P \geqq 2$ and that each edge $X^i \to X^{i+1}$ is mixed. If this cycle does not cover the entire graph, let Y^0 be the lowest ranking vertex

not lying on it. As before, we define a cycle

$$Y^0 \to Y^1 \to \cdots \to Y^{q-1} \to Y^q (= Y^0) \tag{7}$$

and continue until the entire graph has been covered in this way.

Consider any such cycle, e.g., (6). It can be divided up into segments each of which begins and ends with vertices of the same *type* as X^0. For example, if the cycle (6) were

$$(1,1) \to (2,5) \to (3,7) \to (1,6) \to (2,4) \to (7,1) \to (4,3) \to (1,2) \to (2,1) \to (1,1),$$

we should have the segments

$$(1,1) \to (2,5) \to (3,7) \to (1,6),$$

$$(1,6) \to (2,4) \to (7,1) \to (4,3) \to (1,2),$$

$$(1,2) \to (2,1) \to (1,1).$$

We can thus describe the graph structure by a set of segments, which we may order by the ranks of their initial vertices. A segment will be called *odd* or *even* according to the parity of the number of edges which compose it. Now let V be the set of graphs whose structures contain at least one odd segment. Suppose such a graph, G (say), contains the segment

$$Z^0 \to Z^1 \to \cdots \to Z^{r-1} \to Z^r \tag{8}$$

where r is odd, and suppose, moreover, that (8) is the lowest ranking such odd segment in this graph. We change the graph, and its coloring, according to the following rules:

(a) Change the connecting edges of (8) to produce the segment

$$Z^0 \to Z^{r-1} \to Z^{r-2} \to \cdots \to Z^1 \to Z^r. \tag{9}$$

(b) Color these new edges so that the ith edge of (9) ($1 \leqq i \leqq r$) has the opposite color to that of the $(r+1-i)$th edge of (8).

Call the new system, with its coloring, G'. It is easily verified that G' also satisfies the rule (*). On the other hand, since r is odd, the graphs G, G' will have opposite parities. Moreover the transformation is clearly an involution. We thus have a $(1,1)$ parity changing surjection of V onto itself. It follows that

$$\Pi_{\underline{n}}(V) = 0. \tag{10}$$

Therefore if we write $W = U \setminus V$ we have

$$\Pi_{\underline{n}}(U) = \Pi_{\underline{n}}(W), \tag{11}$$

and therefore it is sufficient to construct the systems belonging to W and calculate their contribution to $\Pi_{\underline{n}}(T)$.

3. Application to the case $k=3$. We now apply these considerations to the particular case $k=3$, writing $\underline{n} = (a, b, c)$. Since the product $P_a(x)P_b(x)P_c(x)$ is a polynomial of parity equal to that of $a+b+c$, its integral will be zero for odd $a+b+c$. We therefore limit the discussion to $a+b+c = 2s$, where s is an integer. Moreover it follows from the orthogonality of the polynomials that the integral will vanish unless $s \geqq \max(a, b, c)$. We proceed to study the integral under these assumptions. Let G be any graph of the set W^*, let E be the number of even systems that can be constructed

by coloring G, and let Ω be the number of odd systems. By the definition of W, each such graph is made up of segments of one of the following forms:

$$\begin{aligned} &\text{(i)} \quad (2\to 3\to)^{l_i}2, \\ &\text{(ii)} \quad 1\to(3\to 2\to)^{m_i}3\to 1, \\ &\text{(iii)} \quad 1\to(2\to 3\to)^{n_i}2\to 1, \end{aligned} \tag{12}$$

where the 1, 2, 3 indicate the types to which the vertices belong and $l_i \geqq 1$, $m_i \geqq 0$, $n_i \geqq 0$. Let the segments in each of these three classes be ordered by the rank of their initial vertex.

For each i, j $(i, j = 1, 2, 3)$ denote by E_{ij} the number of $i \to j$ edges. In any segment of type (i), (ii), or (iii) the number of $i \to j$ edges equals that of $j \to i$ edges and, hence, for the whole graph $E_{ij} = E_{ji}$. Since, by hypothesis, there are no pure edges, it follows that

$$\begin{aligned} &E_{12} = E_{21} = s - c, \\ &E_{13} = E_{31} = s - b, \quad \text{and} \\ &E_{23} = E_{32} = s - a. \end{aligned} \tag{13}$$

To simplify the notation we write A, B, C for $s-a, s-b, s-c$, respectively. It is easily seen that the only possible distributions of colors consistent with (*) must be as shown in the following table:

	$2\to 3$	$3\to 2$	$3\to 1$	$1\to 3$	$1\to 2$	$2\to 1$
Blue	$\alpha + t$	α	$\beta + t$	β	$\gamma + t$	γ
Yellow	$A - \alpha - t$	$A - \alpha$	$B - \beta - t$	$B - \beta$	$C - \gamma - t$	$C - \gamma$

where t, α, β, γ may take any values for which the table entries are all nonnegative integers. Now the distribution of colors among the $2\to 3$ and $3\to 2$ edges is determined when we have chosen $(\alpha + t)$ of the $2\to 3$ edges and $A - \alpha$ from the $3\to 2$ edges, and this can clearly be done in $\binom{2A}{A+t}$ ways. Similar results hold for $3\to 1$ and for $1\to 2$. The total number of blue edges in any such coloring is $2(\alpha+\beta+\gamma)+3t \equiv t \pmod 2$. Hence the difference between the numbers of even and odd systems possible on any such graph is

$$\begin{aligned} &\sum_t (-1)^t \binom{2A}{A+t}\binom{2B}{B+t}\binom{2C}{C+t} \\ &\quad = \frac{(2A)!(2B)!(2C)!}{(B+C)!(C+A)!(A+B)!} \sum_t (-1)^t \binom{A+B}{A+t}\binom{B+C}{B+t}\binom{C+A}{C+t}. \end{aligned} \tag{14}$$

But

$$\sum_t (-1)^t \binom{A+B}{A+t}\binom{B+C}{B+t}\binom{C+A}{C+t} = \frac{(A+B+C)!}{A!B!C!}. \tag{15}$$

(For an elegant combinatorial proof of this known identity, see [3, p. 65].) Substituting into (17), we obtain

$$\sum_t (-1)^t \binom{2A}{A+t}\binom{2B}{B+t}\binom{2C}{C+t}$$

$$
\begin{aligned}
&= \frac{(2A)!(2B)!(2C)!}{(B+C)!(C+A)!(A+B)!} \cdot \frac{(A+B+C)!}{A!B!C!} \\
&= \frac{(2s-2a)!(2s-2b)!(2s-2c)!s!}{a!b!c!(s-a)!(s-b)!(s-c)!} \\
&= \binom{2s-2a}{s-a}\binom{2s-2b}{s-b}\binom{2s-2c}{s-c} \cdot \frac{s!(s-a)!(s-b)!(s-c)!}{a!b!c!}.
\end{aligned} \tag{16}
$$

In particular the number is the same for all the graphs of W^*. It remains to determine how many such graphs there are.

Consider (12). Since there are B edges of type $1 \to 3$ in the graph, this will also be the number of segments of type (ii). Similarly there will be C segments of type (iii). Hence the total number of m_i's and n_i's is $B+C=a$. If we write $L=\Sigma l_i$ we see we have to determine the numbers $L, \{m_i\}, \{n_i\}$. Since $L+\Sigma m_i+\Sigma n_j$ equals the number of $2 \to 3$ edges, i.e., A, it follows that $L, \{m_i\}, \{n_j\}$ are the nonnegative integer solutions of

$$\sum_{i=1}^{a+1} x_i = A$$

and this number is known to be $\binom{A+a}{a} = \binom{s}{a}$.

The number of possibilities with the segments in each of (ii) and (iii) ranked in order is therefore $\binom{s}{a}/(B!C!)$. If the segments of forms (ii), (iii) are connected via vertices of type 1 (and this may be done in $a!$ ways), the graph will be determined except for the numbers l_i and the ranks of the vertices. The vertices not involved in segments of form (i) may be ranked in $a!(b!/L!)(C!/L!)$ ways while it is easily seen that the remaining pairs of $(1, 2)$ points may be connected in cycles and ranked in $(L!)^2$ ways. Hence the total number of possible graphs in W^* is

$$\left\{\binom{s}{a}\Big/(B!C!)\right\} \cdot a! \cdot \{a!b!c!\} = \frac{s!a!b!c!}{A!B!C!}. \tag{17}$$

It follows from (5), (16), and (17) that

$$I_{a,b,c} = \frac{2}{(a+b+c+1)} \cdot \binom{2s-2a}{s-a}\binom{2s-2b}{s-b}\binom{2s-2c}{s-c}\binom{2s}{s}^{-1}. \tag{18}$$

This result was first obtained by Adams [1]. His approach was to evaluate the integral for some low values of the subscripts and, on the basis of this, to guess a general formula, which he then proved by induction. For a succinct history of the problem see Askey [2, pp. 39–40]. In the special case $a=b=c=2\lambda$, (18) becomes

$$\int_{-1}^{1} \{P_{2\lambda}(x)\}^3 \, dx = \frac{2\{(3\lambda)!\}^2}{(6\lambda+1)!}\binom{2\lambda}{\lambda}^3. \tag{19}$$

Substituting (18) into (4), we get the binomial identity

$$
\begin{aligned}
&\sum_{\alpha,\beta,\gamma} (-1)^{\alpha+\beta+\gamma}\binom{a}{\alpha}^2\binom{b}{\beta}^2\binom{c}{\gamma}^2\binom{a+b+c}{\alpha+\beta+\gamma}^{-1} \\
&= \begin{cases} \binom{2s-2a}{s-a}\binom{2s-2b}{s-b}\binom{2s-2c}{s-c}\binom{2s}{s}^{-1} & \text{for } a+b+c=2s, \\ 0 & \text{for } a+b+c \text{ odd.} \end{cases}
\end{aligned} \tag{20}
$$

In the special case $a=b=c=2\lambda$, this becomes

$$\sum_{\alpha,\beta,\gamma} (-1)^{\alpha+\beta+\gamma}\binom{2\lambda}{\alpha}^2\binom{2\lambda}{\beta}^2\binom{2\lambda}{\gamma}^2\binom{6\lambda}{\alpha+\beta+\gamma}^{-1} = \binom{2\lambda}{\lambda}^3\binom{6\lambda}{3\lambda}^{-1}. \tag{21}$$

4. The case $k=4$. Since the product $P_{n_1}, P_{n_2} \cdots P_{n_k}$ is a polynomial, it may be written in the form

$$P_{n_1}(x)P_{n_2}(x)\cdots P_{n_k}(x)=\sum_{\alpha} C_{n_1,n_2,\cdots,n_k,\alpha}P_\alpha(x) \tag{22}$$

where the $C_{n_1,\cdots,n_k}$, α are constants. Now if we apply the well-known relation

$$\int_{-1}^{1} P_m(x)P_n(x)\,dx=\frac{2}{2m+1}\delta_{m,n}, \tag{23}$$

we get

$$\frac{2}{2\alpha+1}C_{n_1,n_2,\cdots,n_k,\alpha}=I_{n_1,n_2,\cdots,n_k,\alpha}. \tag{24}$$

Now let a, b, c, d be nonnegative integers. By (23) and (24)

$$\begin{aligned} P_a(x)P_b(x)&=\sum_{\alpha}\left(\alpha+\frac{1}{2}\right)I_{a,b,\alpha}P_\alpha(x), \quad \text{and} \\ P_c(x)P_d(x)&=\sum_{\beta}\left(\beta+\frac{1}{2}\right)I_{c,d,\beta}P_\beta(x). \end{aligned} \tag{25}$$

Hence,

$$\begin{aligned} I_{a,b,c,d}&=\int_{-1}^{1} P_a(x)P_b(x)P_c(x)P_d(x)\,dx \\ &=\sum_{\alpha,\beta}\left(\alpha+\frac{1}{2}\right)\left(\beta+\frac{1}{2}\right)I_{a,b,\alpha}I_{c,d,\beta}\int_{-1}^{1}P_\alpha(x)P_\beta(x)\,dx \\ &=\sum_{\alpha,\beta}\left(\alpha+\frac{1}{2}\right)\left(\beta+\frac{1}{2}\right)I_{a,b,\alpha}I_{c,d,\beta}\frac{\delta_{\alpha,\beta}}{\alpha+\frac{1}{2}} \quad \text{by (22)} \\ &=\sum_{\alpha}\left(\alpha+\frac{1}{2}\right)I_{a,b,\alpha}I_{c,d,\alpha}. \end{aligned} \tag{26}$$

Since $I_{a,b,c,d}=0$, unless $a+b+c+d$ is even, we may assume in (26) that $a+b\equiv c+d \pmod 2$. Thus we may write

$$\begin{aligned} I_{a,b,c,d}&=\sum_{\gamma}\left(2\gamma+\frac{1}{2}\right)I_{a,b,2\gamma}I_{c,d,2\gamma} \quad \text{if } a+b\equiv c+d\equiv 0 \pmod 2 \\ &=\sum_{\gamma}\left(2\gamma+\frac{3}{2}\right)I_{a,b,2\gamma+1}I_{c,d,2\gamma+1} \quad \text{if } a+b\equiv c+d\equiv 1 \pmod 2. \end{aligned} \tag{27}$$

Moreover, since $I_{a,b,c,d}$ is clearly symmetric in the subscripts, we see that

$$\sum_{\alpha}\left(\alpha+\frac{1}{2}\right)I_{a,b,\alpha}I_{c,d,\alpha}=\sum_{\beta}\left(\beta+\frac{1}{2}\right)I_{a,c,\beta}I_{b,d,\beta}. \tag{28}$$

A special case of some interest arises if we take $a=b=c=d$. By (27) we get

$$I_{a,a,a,a}=\sum_{\gamma}\left(2\gamma+\frac{1}{2}\right)I_{a,a,2\gamma}^2,$$

i.e.,

$$\int_{-1}^{+1}[P_a(x)]^4\,dx=2\sum_{\gamma}(4\gamma+1)\left\{\frac{[(a+\gamma)!]^2}{(2a+2\gamma+1)}\binom{2\gamma}{\gamma}^2\binom{2a-2\gamma}{a-\gamma}\right\}^2. \tag{29}$$

A BETA INTEGRAL ASSOCIATED WITH THE ROOT SYSTEM G_2*

F. G. GARVAN†

Abstract. Some conjectures of Askey are proven that have to do with adding roots in the Macdonald-Morris conjecture for G_2. This is done by extending Aomoto's proof of Selberg's integral. This yields a new proof of the Macdonald-Morris root system conjecture for G_2 which should extend to other root systems.

1. Introduction.

Let

(1.1)

$$\begin{aligned} G(x_1,x_2;a,b) &= (1-x_1)^a\left(1-\frac{1}{x_1}\right)^a(1-x_2)^a\left(1-\frac{1}{x_2}\right)^a(1-x_1x_2)^a\left(1-\frac{1}{x_1x_2}\right)^a \\ &\cdot\left(1-\frac{x_1}{x_2}\right)^b\left(1-\frac{x_2}{x_1}\right)^b(1-x_1^2x_2)^b\left(1-\frac{1}{x_1^2x_2}\right)^b(1-x_2^2x_1)^b\left(1-\frac{1}{x_2^2x_1}\right)^b. \end{aligned}$$

Then the Macdonald-Morris root system conjecture for G_2 is

$$\text{(1.2)}\qquad \text{C.T. } G(x_1,x_2;a,b)=\frac{(3a+3b)!(3b)!(2a)!(2b)!}{(2a+3b)!(a+2b)!(a+b)!a!b!b!}=g(a,b).$$

Here C.T. means the constant term in the Laurent expansion as a polynomial in x_1, x_1^{-1}, x_2, x_2^{-1}. This has been proved independently by Habsieger [5] and Zeilberger [12]. They have also proved the q-analogue of (1.2). Although their proofs are elegant, they are special to G_2. Recently Zeilberger [13] has also proved the $G_2^\vee$ case of the Macdonald-Morris conjectures. His proof should extend to other root systems.

In this paper we give a new proof of (1.2) which is entirely in terms of integrals and which should also extend to other root systems. Our proof is an extension of Aomoto's [1] proof of Selberg's [11] integral. See Askey [3] for a good exposition of Aomoto's proof. We were led to this by considering conjectures of Askey [3] that have to do with adding roots in the Macdonald-Morris root system conjecture for G_2. Askey conjectured

$$\text{(1.3)}\qquad \text{C.T. } (1-x_1)\left(1-\frac{1}{x_1}\right)G(x_1,x_2;a,b)=\frac{2(3a+3b+1)}{2a+3b+1}g(a,b),$$

$$\text{(1.4)}\qquad \text{C.T. } (1-x_1)\left(1-\frac{1}{x_1}\right)(1-x_2)\left(1-\frac{1}{x_2}\right)G(x_1,x_2;a,b)$$
$$=\frac{2(3a+3b+2)(3a+3b+1)}{(2a+3b+1)(a+2b+1)}g(a,b),$$

(1.5)

$$\text{C.T. } (1-x_1^2x_2)\left(1-\frac{1}{x_1^2x_2}\right)G(x_1,x_2;a,b)=\frac{2(3a+3b+1)(3b+1)}{(2a+3b+1)(a+2b+1)}g(a,b),$$

(1.6)

$$\text{C.T. } (1-x_1^2x_2)\left(1-\frac{1}{x_1^2x_2}\right)(1-x_2^2x_1)\left(1-\frac{1}{x_2^2x_1}\right)G(x_1,x_2;a,b)$$
$$=\frac{6(3a+3b+2)(3a+3b+1)(3b+1)(3b+2)}{(2a+3b+3)(2a+3b+2)(2a+3b+1)(a+2b+1)}g(a,b).$$

In §2 we give the idea of the proof of (1.2). It is well known that (1.2) may be written as a trigonometric integral formula (see, for example, Morris [10, p.46]). The starting point of our proof is to write (1.2) as

$$\frac{4^{3a+3b}}{\pi^2}\int_{\mathbb{R}^2}\frac{(t_1+t_2)^{2a}(t_1-t_2)^{2b}(t_2^2+2t_1t_2-1)^{2b}(t_1^2+2t_1t_2-1)^{2b}}{(1+t_1^2)^{2a+4b+1}(1+t_2^2)^{2a+4b+1}}dt_1dt_2 \tag{1.7}$$
$$=g(a,b).$$

The left-hand side of (1.7) is the integral referred to in the title of this paper. This is done via three changes of variables: first, by letting $x_j=e^{2i\theta_j}$ $(j=1,2)$ in (1.1) and using the orthogonality of the exponentials on $[0,\pi]$ to obtain an integral on $[0,\pi]^2$; second, by linear change of variables to obtain an integral on $[-\frac{\pi}{2},\frac{\pi}{2}]^2$; and finally by letting $t_j=\tan\theta_j$ to obtain the integral over $\mathbb{R}^2$. We note that this is the same change of variables that Morris used in transforming his constant terms formula for A_n [10, p. 95] into the Cauchy-Selberg integral [10, (6.6)]. The advantage of this integral over the trigonometric integrals is that the integrand is a rational function of t_1,t_2, which can be easily manipulated using a computer algebra package like REDUCE. In §3 we prove some preliminary results. In §4 we complete the proof of (1.2) and prove (1.3)–(1.5) as well.

Macdonald [8, conjecture(6.1)] has also conjectured generalizations of Mehta's integral formula for arbitary root systems [9], [8, (4.1)]. The G_2 case does not seem to be related to our integral given in (1.7). The Macdonald-Mehta integral conjecture involves parameters that are constant on root length. We note that the two parameter case of the G_2 Macdonald-Mehta integral may be proved in the same way as the one parameter case, which was proved by Macdonald [8, p.1002]. This is done by transforming to polar coordinates. The resulting integral turns out to be the product of a gamma integral and a beta integral.

We should mention that (1.3)–(1.6) and their q-analogues may be proved by other methods. Zeilberger [12] proved (1.2) using the result of Morris, mentioned above, related to A_n and Dixon's [4, §3.1] summation of a well-poised ${}_3F_2$. Equations (1.3)–(1.6) could be proved by trying to generalize Morris's results and Dixon's summation. See Kadell [6] for such generalizations of q-analogues of Morris's results and Askey [2] for some extensions of Dixon's summation. The author has proved (1.3)–(1.6), as well as other similar results, by these methods. In §4 we state these other results without proof. For the most part we restrict attention to (1.2)–(1.5), preferring to take a more direct approach.

Kadell [7] has found yet another approach to proving (1.2) which should extend to other root systems. This involves working with the function $G(x_1,x_2;a,b)$ directly rather than writing it as an integral, and using the fact that derivatives have no residues. Finally, (1.2)–(1.6) could be proved by extending Zeilberger's [13] method for the $G_2^\vee$ case and then letting $q\to 1$.

2. The idea of the proof. We label the roots of G_2 as in Fig. 1.

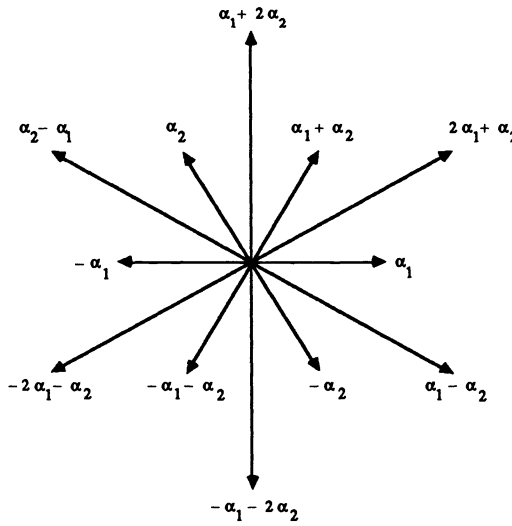

FIG. 1

Let

$$g'(a,b) = \text{C.T. } G(x_1,x_2;a,b). \tag{2.1}$$

Our goal is to prove that $g'(a,b) = g(a,b)$ for all $a,b \geq 0$. The idea is to proceed by induction on a. However to jump from a to $a+1$ in one step would be too much to ask for. Considering (1.3) and (1.4) we break it up into three stages:

Stage 1. $$\text{C.T. } [\alpha_1]G = \frac{2(3a+3b+1)}{2a+3b+1}g'(a,b).$$

Stage 2. $$\text{C.T. } [\alpha_1][\alpha_2]G = \frac{2(3a+3b+1)(3a+3b+2)}{(2a+3b+1)(a+2b+1)}g'(a,b).$$

Stage 3.

$$\text{C.T. } [\alpha_1][\alpha_2][\alpha_1+\alpha_2]G = \frac{6(3a+3b+2)(3a+3b+1)(2a+1)}{(2a+3b+2)(2a+3b+1)(a+2b+1)}g'(a,b)$$

where

$$[k_1\alpha_1+k_2\alpha_2] = (1-x_1^{k_1}x_2^{k_2})(1-x_1^{-k_1}x_2^{-k_2}),$$

for $k_1,k_2 \in \mathbb{Z}$. Each stage corresponds to adding an additional pair of opposite short roots. After Stage 3 all that will remain is to prove the result for $a=0$ since

$$\frac{g(a+1,b)}{g(a,b)} = \frac{6(3a+3b+2)(3a+3b+1)(2a+1)}{(2a+3b+2)(2a+3b+1)(a+2b+1)}. \tag{2.2}$$

The case $a=0$ is equivalent to $b=0$ since we have

$$\text{Long roots of } G_2 \cong \text{Short roots of } G_2 \cong A_2.$$

The result is trivially true for $a=b=0$. The case $b=0$ follows from (2.2) and Stage 3 by induction.

To prove Stages 1–3 we rewrite each stage as an integral and use an idea of Aomoto. To give the reader a taste of our method we work through the proof of Stage 1. If we let

(2.3)
$$w(\underset{\sim}{t}) = w(t_1, t_2; a, b) = \frac{(t_1+t_2)^{2a}(t_1-t_2)^{2b}(t_2^2+2t_1t_2-1)^{2b}(t_1^2+2t_1t_2-1)^{2b}}{(1+t_1^2)^{2a+4b+1}(1+t_2^2)^{2a+4b+1}},$$

then we may write Stage 1 as

$$\frac{4^{3a+3b}}{\pi^2}\int_{\mathbf{R}^2}\frac{4}{(1+t_1^2)}w(\underset{\sim}{t})\,d\underset{\sim}{t} = \frac{2(3a+3b+1)}{(2a+3b+1)}\frac{4^{3a+3b}}{\pi^2}\int_{\mathbf{R}^2}w(\underset{\sim}{t})\,d\underset{\sim}{t}, \tag{2.4}$$

using the same change of variables used to derive (1.7). It is here that we use Aomoto's idea. To get $\int_{\mathbf{R}^2}\frac{1}{1+t_1^2}w(\underset{\sim}{t})\,d\underset{\sim}{t}$ in terms of $\int_{\mathbf{R}^2}w(\underset{\sim}{t})\,d\underset{\sim}{t}$ we use

$$\begin{aligned}0 &= \int_{\mathbf{R}^2}\frac{\partial}{\partial t_1}t_1w(\underset{\sim}{t})\,d\underset{\sim}{t} \\ &= \int_{\mathbf{R}^2}w(\underset{\sim}{t})\,d\underset{\sim}{t} - (2a+4b+1)\int_{\mathbf{R}^2}\frac{2t_1^2}{1+t_1^2}w(\underset{\sim}{t})\,d\underset{\sim}{t} + 2a\int_{\mathbf{R}^2}\frac{t_1}{t_1+t_2}w(\underset{\sim}{t})\,d\underset{\sim}{t} \\ &\quad + 2b\int_{\mathbf{R}^2}\frac{t_1}{t_1-t_2}w(\underset{\sim}{t})\,d\underset{\sim}{t} + 2b\int_{\mathbf{R}^2}\frac{2t_1t_2}{t_2^2+2t_1t_2-1}w(\underset{\sim}{t})\,d\underset{\sim}{t} \\ &\quad + 2b\int_{\mathbf{R}^2}\frac{2t_1(t_1+t_2)}{t_1^2+2t_1t_2-1}w(\underset{\sim}{t})\,d\underset{\sim}{t}.\end{aligned} \tag{2.5}$$

We can make some progress by using the fact that $w(\underset{\sim}{t})$ is invariant under the transposition $t_1 \leftrightarrow t_2$.

$$\frac{t_1}{t_1 \pm t_2} = 1 \mp \frac{t_2}{t_1 \pm t_2}. \tag{2.6}$$

It follows that

$$\int_{\mathbf{R}^2}\frac{t_1}{t_1 \pm t_2}w(\underset{\sim}{t})\,d\underset{\sim}{t} = \frac{1}{2}\int_{\mathbf{R}^2}w(\underset{\sim}{t})\,d\underset{\sim}{t}. \tag{2.7}$$

$$\begin{aligned}&\int_{\mathbf{R}^2}\frac{t_1t_2}{t_2^2+2t_1t_2-1}w(\underset{\sim}{t})\,d\underset{\sim}{t} + \int_{\mathbf{R}^2}\frac{t_1(t_1+t_2)}{t_1^2+2t_1t_2-1}w(\underset{\sim}{t})\,d\underset{\sim}{t} \\ &\quad = \int_{\mathbf{R}^2}\frac{t_1t_2}{t_1^2+2t_1t_2-1}w(\underset{\sim}{t})\,d\underset{\sim}{t} + \int_{\mathbf{R}^2}\frac{t_1(t_1+t_2)}{t_1^2+2t_1t_2-1}w(\underset{\sim}{t})\,d\underset{\sim}{t} \\ &\qquad\qquad \text{(via } t_1 \leftrightarrow t_2 \text{ on the first integral)} \\ &\quad = \int_{\mathbf{R}^2}w(\underset{\sim}{t})\,d\underset{\sim}{t} + \int_{\mathbf{R}^2}\frac{1}{t_1^2+2t_1t_2-1}w(\underset{\sim}{t})\,d\underset{\sim}{t}.\end{aligned} \tag{2.8}$$

Then (2.5) becomes

$$\begin{aligned}0 &= (-3a-3b-1)\int_{\mathbf{R}^2}w(\underset{\sim}{t})\,d\underset{\sim}{t} + 2(2a+4b+1)\int_{\mathbf{R}^2}\frac{1}{1+t_1^2}w(\underset{\sim}{t})\,d\underset{\sim}{t} \\ &\quad + 4b\int_{\mathbf{R}^2}\frac{1}{t_1^2+2t_1t_2-1}w(\underset{\sim}{t})\,d\underset{\sim}{t}.\end{aligned} \tag{2.9}$$

The problem that remains is to get $\int_{\mathbf{R}^2} \frac{1}{t_1^2+2t_1t_2-1}\, w(\underset{\sim}{t})\, d\underset{\sim}{t}$ in terms of $\int_{\mathbf{R}^2} w(\underset{\sim}{t})\, d\underset{\sim}{t}$ and $\int_{\mathbf{R}^2} \frac{1}{1+t_1^2}\, w(\underset{\sim}{t})\, d\underset{\sim}{t}$. The transformation $t_1 \leftrightarrow t_2$ is not helpful here. We need another transformation that leaves $w(\underset{\sim}{t})\, d\underset{\sim}{t}$ invariant. The real reason why $w(\underset{\sim}{t})$ is invariant under $t_1 \leftrightarrow t_2$ is that the root system G_2 is invariant under the linear transformation given by

$$\alpha_1 \longmapsto \alpha_2 \qquad \text{and} \qquad \alpha_2 \longmapsto \alpha_1,$$

which is also the reflection through the plane orthogonal to the vector $\alpha_2 - \alpha_1$. Recall that a root system is invariant under any element of the Weyl group, the group generated by the w_α, where α is a root and w_α is the reflection through the hyperplane orthogonal to α. The Weyl group for G_2 is generated by $w_{\alpha_2-\alpha_1}$ and w_{α_1}. The extra integral transformation that we need will correspond to w_{α_1}. We study the action of this reflection on the roots:

$$\begin{aligned} &\alpha_1 \leftrightarrow -\alpha_1, && \alpha_2 \leftrightarrow \alpha_1 + \alpha_2, \\ &\alpha_2 - \alpha_1 \leftrightarrow 2\alpha_1 + \alpha_2, && \alpha_1 + 2\alpha_2 \leftrightarrow \alpha_1 + 2\alpha_2. \end{aligned}$$

We need a transformation

$$f : \mathbf{R}^2 \longrightarrow \mathbf{R}^2, \qquad (t_1, t_2) \longmapsto (f_1(t_1, t_2), f_2(t_1, t_2)) \tag{2.10}$$

with the following action:

$$\begin{gathered} \frac{1}{1+t_1^2} \leftrightarrow \frac{1}{1+t_1^2}, \quad \frac{1}{1+t_2^2} \leftrightarrow \frac{(t_1+t_2)^2}{(1+t_1^2)(1+t_2)^2}, \\ \frac{(t_1-t_2)^2}{(1+t_1^2)(1+t_2^2)} \leftrightarrow \frac{(t_1^2+2t_1t_2-1)^2}{(1+t_1^2)^2(1+t_2^2)}, \quad \frac{(t_2^2+2t_1t_2-1)^2}{(1+t_1^2)(1+t_2^2)^2} \leftrightarrow \frac{(t_2^2+2t_1t_2-1)^2}{(1+t_1^2)(1+t_2^2)^2}. \end{gathered} \tag{2.11}$$

The transformation that does the job is

$$f_1(t_1, t_2) = t_1, \qquad f_2(t_1, t_2) = \frac{1 - t_1t_2}{t_1 + t_2} \qquad (t_1 \neq -t_2). \tag{2.12}$$

In §3 we show that

$$\int_{\mathbf{R}^2} g(\underset{\sim}{t}) w(\underset{\sim}{t})\, d\underset{\sim}{t} = \int_{\mathbf{R}^2} g(f(\underset{\sim}{t})) w(\underset{\sim}{t})\, d\underset{\sim}{t}, \tag{2.13}$$

for a certain restricted class of functions g.

Now we return to the problem of evaluating $\int_{\mathbf{R}^2} \frac{1}{t_1^2+2t_1t_2-1}\, w(\underset{\sim}{t})\, d\underset{\sim}{t}$. A routine calculation shows that

$$\frac{1}{t_1^2 + 2t_1t_2 - 1} \xrightarrow{f} \frac{(t_1+t_2)}{(1+t_1^2)(t_1-t_2)}, \tag{2.14}$$

$$\frac{(t_1+t_2)}{(1+t_1^2)(t_1-t_2)} = -\frac{(t_1+t_2)^2}{(1+t_1^2)(1+t_2^2)} + \frac{(t_1+t_2)}{(1+t_2^2)(t_1-t_2)}. \tag{2.15}$$

It follows that

(2.16)

$$\int_{\mathbf{R}^2} \frac{1}{t_1^2 + 2t_1t_2 - 1}\, w(\underset{\sim}{t})\, d\underset{\sim}{t} = \int_{\mathbf{R}^2} \frac{(t_1+t_2)}{(1+t_1^2)(t_1-t_2)}\, w(\underset{\sim}{t})\, d\underset{\sim}{t}$$

(by (2.13) and (2.14))

$$= -\frac{1}{2}\int_{\mathbf{R}^2} \frac{(t_1+t_2)^2}{(1+t_1^2)(1+t_2^2)}\, w(\underset{\sim}{t})\, d\underset{\sim}{t}$$

(by applying $t_1 \leftrightarrow t_2$ and using (2.15))

$$= -\frac{1}{2}\int_{\mathbf{R}^2} \frac{1}{1+t_1^2}\, w(\underset{\sim}{t})\, d\underset{\sim}{t}$$

(by applying f, then $t_1 \leftrightarrow t_2$).

Substituting this into (2.9) gives

$$(3a+3b+1)\int_{\mathbf{R}^2} w(\underset{\sim}{t})\, d\underset{\sim}{t} = 2(2a+3b+1)\int_{\mathbf{R}^2} \frac{1}{1+t_1^2}\, w(\underset{\sim}{t})\, d\underset{\sim}{t}$$

and Stage 1 follows. The proof of Stages 2–3 is analogous and will be given in §4.

3. Preliminary results. The main result of this section is Lemma 3.6. It contains a list of integrals that we will need in the proof of Stages 2–3. In the proof of this lemma we will use the transformation formula (2.13) for f. A more formal statement of this formula is given in Lemma 3.2. The idea of the proof of Lemma 3.2 is to write both sides of (2.13) as an integral over $[0,\pi]^2$, using the same change of variables mentioned after (1.7) in the introduction, use the transformation $T(\theta_1,\theta_2) = (-\theta_1, \theta_1+\theta_2)$ and apply Lemma 3.1. The proofs of Lemmas 3.1 and 3.2 are omitted. In the proof of Lemma 3.6 we will also need to calculate the image of certain rational functions in t_1, t_2 under f. This was done using the computer algebra package REDUCE.

LEMMA 3.1. *Let $h : [0,\pi]^2 \longrightarrow \mathbb{R}$ be continuous; then*

$$\int_{[0,\pi]^2} h(\theta_1,\theta_2)\, d\theta_1 d\theta_2 = \int_{[0,\pi]^2} h^*(\theta_1,\theta_2)\, d\theta_1 d\theta_2$$

where

$$h^*(\theta_1,\theta_2) = \begin{cases} h(\pi-\theta_1, \theta_1+\theta_2) & \text{if } 0 \le \theta_1+\theta_2 \le \pi, \\ h(\pi-\theta_1, \theta_1+\theta_2-\pi) & \text{if } \pi < \theta_1+\theta_2 \le 2\pi. \end{cases}$$

Let

$$w_0(\underset{\sim}{t}) = (1+t_1^2)(1+t_2^2)w(\underset{\sim}{t}).$$

LEMMA 3.2. *Suppose $g : \mathbb{R}^2 \longrightarrow \mathbb{R}$ is a continuous function that satisfies*

(i) *gw_0 is bounded on $\mathbb{R}^2$,*

(ii) *$(g \circ f)w_0$ can be extended to a continuous function on $\mathbb{R}^2$, where f is defined in (2.10) and (2.12). Then*

$$\int_{\mathbf{R}^2} g(\underset{\sim}{t})\, w(\underset{\sim}{t})\, d\underset{\sim}{t} = \int_{\mathbf{R}^2} g(f(\underset{\sim}{t}))\, w(\underset{\sim}{t})\, d\underset{\sim}{t}. \tag{3.3}$$

For notational convenience we let

$$(3.4)\qquad <\alpha_1>=\frac{1}{1+t_1^2},\quad <\alpha_2>=\frac{1}{1+t_2^2},\quad <\alpha_1+\alpha_2>=\frac{(t_1+t_2)^2}{(1+t_1^2)(1+t_2^2)}.$$

This notation is related to the notation introduced in Stages 1–3. Using the same change of variables used to derive (1.7) we have

$$(3.5)\quad \text{C.T.}[\alpha_1]^{k_1}[\alpha_2]^{k_2}[\alpha_1+\alpha_2]^{k_3}G = \frac{4^{3a+3b+k_1+k_2+k_3}}{\pi^2}\int_{\mathbf{R}^2} <\alpha_1>^{k_1}<\alpha_2>^{k_2}<\alpha_1+\alpha_2>^{k_3} w(\underset{\sim}{t})\,d\underset{\sim}{t},$$

where $w(\underset{\sim}{t})$ is defined in (2.3) and k_1, k_2, k_3 are nonnegative integers.

LEMMA 3.6.

$$(3.7)\qquad \int_{\mathbf{R}^2}(t_2^2+2t_1t_2-1)<\alpha_1> w(\underset{\sim}{t})\,d\underset{\sim}{t}=0,$$

$$(3.8)\qquad \int_{\mathbf{R}^2}\frac{t_1}{t_1+t_2}<\alpha_2> w(\underset{\sim}{t})\,d\underset{\sim}{t}=\frac{5}{4}\int_{\mathbf{R}^2}<\alpha_1> w(\underset{\sim}{t})\,d\underset{\sim}{t} - \int_{\mathbf{R}^2}<\alpha_1><\alpha_2> w(\underset{\sim}{t})\,d\underset{\sim}{t},$$

$$(3.9)\qquad \int_{\mathbf{R}^2}\frac{t_1}{t_1-t_2}<\alpha_2> w(\underset{\sim}{t})\,d\underset{\sim}{t}=\frac{3}{4}\int_{\mathbf{R}^2}<\alpha_1> w(\underset{\sim}{t})\,d\underset{\sim}{t},$$

$$(3.10)\qquad \int_{\mathbf{R}^2}\frac{t_2(t_1+t_2)}{t_2^2+2t_1t_2-1}<\alpha_1> w(\underset{\sim}{t})\,d\underset{\sim}{t}=\frac{1}{2}\int_{\mathbf{R}^2}<\alpha_1> w(\underset{\sim}{t})\,d\underset{\sim}{t},$$

$$(3.11)\qquad \int_{\mathbf{R}^2}\frac{1-t_1t_2}{t_1^2+2t_1t_2-1}<\alpha_1> w(\underset{\sim}{t})\,d\underset{\sim}{t}=-\frac{3}{4}\int_{\mathbf{R}^2}<\alpha_1> w(\underset{\sim}{t})\,d\underset{\sim}{t},$$

$$(3.12)\qquad \int_{\mathbf{R}^2}\frac{1}{t_1^2+2t_1t_2-1}<\alpha_1> w(\underset{\sim}{t})\,d\underset{\sim}{t}=-\int_{\mathbf{R}^2}<\alpha_1><\alpha_2> w(\underset{\sim}{t})\,d\underset{\sim}{t},$$

$$(3.13)\qquad \int_{\mathbf{R}^2}<\alpha_1><\alpha_2><\alpha_1+\alpha_2> w(\underset{\sim}{t})\,d\underset{\sim}{t}=-\frac{3}{4}\int_{\mathbf{R}^2}<\alpha_1>^2 w(\underset{\sim}{t})\,d\underset{\sim}{t} + \frac{3}{2}\int_{\mathbf{R}^2}<\alpha_1><\alpha_2> w(\underset{\sim}{t})\,d\underset{\sim}{t},$$

$$(3.14)\qquad \int_{\mathbf{R}^2}\frac{1}{t_2^2+2t_1t_2-1}<\alpha_1> w(\underset{\sim}{t})\,d\underset{\sim}{t}=-\frac{1}{2}\int_{\mathbf{R}^2}<\alpha_1>^2 w(\underset{\sim}{t})\,d\underset{\sim}{t},$$

$$(3.15)\qquad \int_{\mathbf{R}^2}\frac{t_1t_2}{t_2^2+2t_1t_2-1}<\alpha_1> w(\underset{\sim}{t})\,d\underset{\sim}{t}=\frac{1}{2}\int_{\mathbf{R}^2}<\alpha_1> w(\underset{\sim}{t})\,d\underset{\sim}{t} - \frac{1}{2}\int_{\mathbf{R}^2}<\alpha_1>^2 w(\underset{\sim}{t})\,d\underset{\sim}{t}.$$

Proof. Equation (3.7) follows from (3.3) and

$$(t_2^2 + 2t_1t_2 - 1) <\alpha_1><\alpha_2> \xrightarrow{f} -(t_2^2 + 2t_1t_2 - 1) <\alpha_1><\alpha_2> .$$

We note that $(t_2^2 + 2t_1t_2 - 1) <\alpha_1><\alpha_2>$ satisfies the conditions of Lemma 3.2 since it is equal to $<\alpha_1+\alpha_2> - <\alpha_2>$. Whenever we apply f to a rational function in the remainder of the proof we leave it to the reader to verify that the function involved satisfies the conditions of Lemma 3.2.

Equation (3.8) follows from (3.7) and

$$\frac{t_1}{t_1+t_2} <\alpha_2> + \frac{t_2}{t_1+t_2} <\alpha_1>$$
$$= \frac{1}{2} <\alpha_1><\alpha_2> \{-(t_2^2 + 2t_1t_2 - 1) + 3(1+t_2^2) + 2(1+t_1^2) - 4\}.$$

Similarly (3.9) follows from

$$\frac{t_1}{t_1-t_2} <\alpha_2> + \frac{t_2}{t_2-t_1} <\alpha_1>$$
$$= \frac{1}{2} <\alpha_1><\alpha_2> \{(t_2^2 + 2t_1t_2 - 1) + (1+t_2^2) + 2(1+t_1^2)\}.$$

We have

$$\frac{t_2(t_1+t_2)}{t_2^2 + 2t_1t_2 - 1} <\alpha_1> = <\alpha_1> + \frac{(1-t_1t_2)}{t_2^2 + 2t_1t_2 - 1} <\alpha_1>, \tag{3.16}$$
$$\frac{(1-t_1t_2)}{t_2^2 + 2t_1t_2 - 1} <\alpha_1> \xrightarrow{f} -\frac{t_2(t_1+t_2)}{t_2^2 + 2t_1t_2 - 1} <\alpha_1>$$

and (3.10) follows.

$$\frac{(1-t_1t_2)}{t_1^2 + 2t_1t_2 - 1} <\alpha_1> \xrightarrow{f} \xrightarrow{t_1 \leftrightarrow t_2} -\frac{t_1}{t_1-t_2} <\alpha_2>$$

and (3.11) follows by (3.9).

$$\frac{<\alpha_1>}{t_1^2 + 2t_1t_2 - 1} + <\alpha_1><\alpha_2>$$
$$= \frac{<\alpha_1+\alpha_2>}{t_1^2 + 2t_1t_2 - 1} \xrightarrow{t_1 \leftrightarrow t_2} \xrightarrow{f} \xrightarrow{t_1 \leftrightarrow t_2} -\frac{<\alpha_1+\alpha_2>}{t_1^2 + 2t_1t_2 - 1}$$

and (3.12) follows.

We observe that (3.13) is equivalent to

$$\int_{\mathbf{R}^2} A(\underset{\sim}{t}) w(\underset{\sim}{t})\, d\underset{\sim}{t} = 0,$$

where

$$A(\underset{\sim}{t}) = 4I(\underset{\sim}{t}) + 3 <\alpha_1+\alpha_2>^2 - 6 <\alpha_1><\alpha_1+\alpha_2>,$$
$$I(\underset{\sim}{t}) = <\alpha_1><\alpha_2><\alpha_1+\alpha_2>,$$

since

$$<\alpha_1>^2 \xrightarrow{t_1 \leftrightarrow t_2} \xrightarrow{f} <\alpha_1+\alpha_2>^2,$$
$$<\alpha_1><\alpha_2> \xrightarrow{f} <\alpha_1><\alpha_1+\alpha_2> .$$

$$A(\underset{\sim}{t}) = I(\underset{\sim}{t})(-2 + 3t_1^2 + 6t_1t_2 - 3t_2^2)$$

so that

$$\int_{\mathbf{R}^2} A(\underset{\sim}{t})w(\underset{\sim}{t})\,d\underset{\sim}{t} = -2\int_{\mathbf{R}^2} I(\underset{\sim}{t})(1-3t_1t_2)w(\underset{\sim}{t})\,d\underset{\sim}{t},$$

since $I(\underset{\sim}{t})$ is invariant under $t_1 \leftrightarrow t_2$.

$$(1-t_1t_2) \xrightarrow{f} \frac{t_2(1+t_1^2)}{(t_1+t_2)},$$
$$\frac{t_2(1+t_1^2)}{(t_1+t_2)} + \frac{t_1(1+t_2^2)}{(t_1+t_2)} = (1+t_1t_2).$$

It follows that

$$2\int_{\mathbf{R}^2} I(\underset{\sim}{t})(1-t_1t_2)w(\underset{\sim}{t})\,d\underset{\sim}{t} = \int_{\mathbf{R}^2} I(\underset{\sim}{t})(1+t_1t_2)w(\underset{\sim}{t})\,d\underset{\sim}{t},$$

since $I(\underset{\sim}{t})$ is invariant under f and $t_1 \leftrightarrow t_2$. Therefore,

$$\int_{\mathbf{R}^2} I(\underset{\sim}{t})(1-3t_1t_2)w(\underset{\sim}{t})\,d\underset{\sim}{t} = 0,$$

as required. This completes the proof of (3.13).

Equation (3.14) follows from

$$\frac{<\alpha_1>}{t_2^2+2t_1t_2-1} \xrightarrow{f} -\frac{<\alpha_1>}{t_2^2+2t_1t_2-1} - <\alpha_1>^2 .$$

Finally, (3.15) follows easily from (3.10), (3.14), and (3.16). □

4. Proof of Stages 2–3 and (1.2)–(1.5). In this section we use Lemma 3.6 to prove Stages 2–3, thus completing the proof of (1.2)–(1.4). Finally, we show how (1.5) follows from (1.3) and (1.4). For $k_1, k_2 \geq 0$ we have

$$\begin{aligned}
(4.1)\qquad 0 &= \int_{\mathbf{R}^2} \frac{\partial}{\partial t_1} t_1 <\alpha_1>^{k_1}<\alpha_2>^{k_2} w(\underset{\sim}{t})\,d\underset{\sim}{t} \\
&= -(4a+8b+2k_1+1)\int_{\mathbf{R}^2} <\alpha_1>^{k_1}<\alpha_2>^{k_2} w(\underset{\sim}{t})\,d\underset{\sim}{t} \\
&\quad + 2(2a+4b+k_1+1)\int_{\mathbf{R}^2} <\alpha_1>^{k_1+1}<\alpha_2>^{k_2} w(\underset{\sim}{t})\,d\underset{\sim}{t} \\
&\quad + 2a\int_{\mathbf{R}^2} \frac{t_1}{t_1+t_2} <\alpha_1>^{k_1}<\alpha_2>^{k_2} w(\underset{\sim}{t})\,d\underset{\sim}{t} \\
&\quad + 2b\int_{\mathbf{R}^2} \frac{t_1}{t_1-t_2} <\alpha_1>^{k_1}<\alpha_2>^{k_2} w(\underset{\sim}{t})\,d\underset{\sim}{t} \\
&\quad + 4b\int_{\mathbf{R}^2} \frac{t_1(t_1+t_2)}{t_1^2+2t_1t_2-1} <\alpha_1>^{k_1}<\alpha_2>^{k_2} w(\underset{\sim}{t})\,d\underset{\sim}{t} \\
&\quad + 4b\int_{\mathbf{R}^2} \frac{t_1t_2}{t_2^2+2t_1t_2-1} <\alpha_1>^{k_1}<\alpha_2>^{k_2} w(\underset{\sim}{t})\,d\underset{\sim}{t}.
\end{aligned}$$

Letting $k_1 = 0$, $k_2 = 1$ in (4.1) and using (3.8)–(3.12), we find that

$$\int_{\mathbb{R}^2} <\alpha_1><\alpha_2> w(\underset{\sim}{t})\, d\underset{\sim}{t} = \frac{(3a+3b+2)}{4(a+2b+1)} \int_{\mathbb{R}^2} <\alpha_2> w(\underset{\sim}{t})\, d\underset{\sim}{t}. \tag{4.2}$$

Hence, by (3.5) we have

$$\begin{aligned}
\text{C.T.}\,[\alpha_1][\alpha_2]G &= \frac{4^{3a+3b}}{\pi^2} \int_{\mathbb{R}^2} 16 <\alpha_1><\alpha_2> w(\underset{\sim}{t})\, d\underset{\sim}{t} \\
&= \frac{(3a+3b+2)}{(a+2b+1)} \frac{4^{3a+3b}}{\pi^2} \int_{\mathbb{R}^2} 4 <\alpha_1> w(\underset{\sim}{t})\, d\underset{\sim}{t} \\
&= \frac{(3a+3b+2)}{(a+2b+1)} \text{C.T.}\,[\alpha_1]G \\
&= \frac{2(3a+3b+1)(3a+3b+2)}{(2a+3b+1)(a+2b+1)} g'(a,b) \qquad \text{(by Stage 1).}
\end{aligned}$$

This completes the proof of Stage 2.

We cannot prove Stage 3 directly. Instead we use (4.1) to get $\int_{\mathbb{R}^2} <\alpha_1>^2 w(\underset{\sim}{t})\, d\underset{\sim}{t}$ in terms of $\int_{\mathbb{R}^2} <\alpha_1> w(\underset{\sim}{t})\, d\underset{\sim}{t}$ and $\int_{\mathbb{R}^2} <\alpha_1><\alpha_2> w(\underset{\sim}{t})\, d\underset{\sim}{t}$. Then we show how Stage 3 will follow from Stages 1 and 2 using (3.13). Letting $k_1 = 1$, $k_2 = 0$ in (4.1) and using (3.8), (3.9), (3.11), and (3.15) we find that

$$\begin{aligned}
&2(2a+3b+2) \int_{\mathbb{R}^2} <\alpha_1>^2 w(\underset{\sim}{t})\, d\underset{\sim}{t} \\
&\quad = \frac{3}{2}(3a+3b+2) \int_{\mathbb{R}^2} <\alpha_1> w(\underset{\sim}{t})\, d\underset{\sim}{t} - 2a \int_{\mathbb{R}^2} <\alpha_1><\alpha_2> w(\underset{\sim}{t})\, d\underset{\sim}{t} \\
&\quad = 2(2a+6b+3) \int_{\mathbb{R}^2} <\alpha_1><\alpha_2> w(\underset{\sim}{t})\, d\underset{\sim}{t} \qquad \text{(by (4.2)).}
\end{aligned} \tag{4.3}$$

We have

$$\begin{aligned}
&\text{C.T.}\,[\alpha_1][\alpha_2][\alpha_1+\alpha_2]G \\
&= \frac{4^{3a+3b}}{\pi^2} \int_{\mathbb{R}^2} 64 <\alpha_1><\alpha_2><\alpha_1+\alpha_2> w(\underset{\sim}{t})\, d\underset{\sim}{t} \\
&= -3 \cdot \frac{4^{3a+3b}}{\pi^2} \int_{\mathbb{R}^2} 16 <\alpha_1>^2 w(\underset{\sim}{t})\, d\underset{\sim}{t} \\
&\qquad + 6 \cdot \frac{4^{3a+3b}}{\pi^2} \int_{\mathbb{R}^2} 16 <\alpha_1><\alpha_2> w(\underset{\sim}{t})\, d\underset{\sim}{t} \qquad \text{(by (3.13))} \\
&= \frac{(-3(2a+6b+3)+6(2a+3b+2))}{(2a+3b+2)} \frac{4^{3a+3b}}{\pi^2} \int_{\mathbb{R}^2} 16 <\alpha_1><\alpha_2> w(\underset{\sim}{t})\, d\underset{\sim}{t} \\
&\qquad \text{(by (4.3))} \\
&= \frac{3(2a+1)}{(2a+3b+2)} \text{C.T.}\,[\alpha_1][\alpha_2]G
\end{aligned}$$

$$= \frac{6(3a+3b+2)(3a+3b+1)(2a+1)}{(2a+3b+2)(2a+3b+1)(a+2b+1)} g'(a,b) \qquad \text{(by Stage 2).}$$

This completes the proof of Stage 3.

At the beginning of §2 we showed how Stage 3 implies (1.2). We remark that (1.3) and (1.4) follow from Stages 1 and 2 together with (1.2). We have been unable to find a proof of (1.5) or (1.6) in terms of integrals. However (1.5) follows easily from (1.3) and (1.4). In order to show this we need to recall how the Weyl group acts on polynomials. For $\alpha = k_1\alpha_1 + k_2\alpha_2$, where $k_1, k_2 \in \mathbb{Z}$ and α_1, α_2 are the roots from the root system G_2 as in Fig. 1, we let

$$x^\alpha = x_1^{k_1} x_2^{k_2}.$$

The elements w of the Weyl group W act on monomials by

$$w(x^\alpha) = x^{w(\alpha)},$$

and by linearity on Laurent polynomials that are linear combinations of the x^α. For w in the Weyl group W we have

$$\text{C.T.}\, x^\alpha G = \text{C.T.}\, x^{w(\alpha)} G, \tag{4.4}$$

since G is symmetric with respect to the Weyl group and w does not change the constant term. Utilizing (4.4) we find that the left-hand sides of (1.3)–(1.5) can be written as

$$\text{C.T.}\,[\alpha_1]G = 2\text{C.T.}(1-x_1)G, \tag{4.5}$$

$$\text{C.T.}\,[\alpha_1][\alpha_2]G = 2\text{C.T.}\left(2 - 3x_1 + \frac{x_1}{x_2}\right) G, \tag{4.6}$$

$$\text{C.T.}\,[2\alpha_1+\alpha_2]G = 2\text{C.T.}\left(1 - \frac{x_1}{x_2}\right) G. \tag{4.7}$$

Hence,

$$\begin{aligned}\text{C.T.}\,[2\alpha_1+\alpha_2]G &= 3\text{C.T.}\,[\alpha_1]G - \text{C.T.}\,[\alpha_1][\alpha_2]G \\ &= \left\{\frac{6(3a+3b+1)}{(2a+3b+1)} - \frac{2(3a+3b+2)(3a+3b+1)}{(2a+3b+1)(a+2b+1)}\right\} g(a,b) \\ &\qquad\qquad \text{(by (1.3), (1.4))} \\ &= \frac{2(3a+3b+1)(3b+1)}{(2a+3b+1)(a+2b+1)} g(a,b),\end{aligned}$$

which is (1.5).

5. Other results. In this section we state other results that are similar to (1.3)–(1.6). These may be proved by extending Zeilberger's [12] proof of the ordinary G_2 case as mentioned in §1.

(5.1)

$$\text{C.T.}\,[\alpha_1][\alpha_1-\alpha_2]G = \frac{4(3a+3b+2)(3a+3b+1)(3b+1)}{(2a+3b+2)(2a+3b+1)(a+2b+1)} g(a,b),$$

(5.2)

$$\begin{aligned}&\text{C.T.}\,[\alpha_1][\alpha_1+\alpha_2][\alpha_1-\alpha_2]G \\ &\qquad = \frac{6(4a+3b+4)(3a+3b+2)(3a+3b+1)(3b+1)}{(2a+3b+3)(2a+3b+2)(2a+3b+1)(a+2b+1)} g(a,b),\end{aligned}$$

(5.3)

$$\text{C.T.}\,[\alpha_1][\alpha_2][\alpha_1-\alpha_2]G = 6\left\{\frac{(3a+3b+2)(3a+3b+1)(3b+1)}{(2a+3b+1)(a+2b+2)(a+2b+1)} - \frac{b(4a+3b+4)(3a+3b+2)(3a+3b+1)(3b+1)}{(2a+3b+3)(2a+3b+2)(2a+3b+1)(a+2b+2)(a+2b+1)}\right\} g(a,b),$$

(5.4)

$$\text{C.T.}\,[\alpha_1][\alpha_1-\alpha_2][\alpha_1+2\alpha_2]G = \frac{6(3a+4b+4)(3a+3b+2)(3a+3b+1)(3b+2)(3b+1)}{(2a+3b+3)(2a+3b+2)(2a+3b+1)(a+2b+2)(a+2b+1)}g(a,b),$$

(5.5)

$$\text{C.T.}\,[\alpha_1][\alpha_1-\alpha_2][2\alpha_1+\alpha_2]G = \frac{6(6a^2+20ab+23a+12b^2+28b+16)}{(2a+3b+4)(2a+3b+3)(2a+3b+2)} \cdot \frac{(3a+3b+2)(3a+3b+1)(3b+2)(3b+1)}{(2a+3b+1)(a+2b+2)(a+2b+1)}g(a,b),$$

(5.6)

$$\text{C.T.}\,[\alpha_1][\alpha_1+\alpha_2][\alpha_1-\alpha_2][\alpha_1+2\alpha_2]G = \frac{18(3a+3b+4)(3a+3b+2)(3a+3b+1)}{(2a+3b+4)(2a+3b+3)(2a+3b+2)} \cdot \frac{(2a+2b+3)(3b+2)(3b+1)}{(2a+3b+1)(a+2b+2)(a+2b+1)}g(a,b).$$

Acknowledgments. I would like to thank many people: Richard Askey for introducing me to the Macdonald conjectures, for his conjectures on G_2, and for help and encouragement; Murad Ozaydin for helpful discussions on root systems and Weyl groups; William Long for getting me started on REDUCE; and Dennis Stanton for his suggestions in writing this paper.

UNE q-INTÉGRALE DE SELBERG ET ASKEY*

LAURENT HABSIEGER†

Résumé. Nous prouvons une conjecture de R. Askey ("Some basic hypergeometric extensions of integrals of Selberg and Andrews," *SIAM J. Math. Anal.*, 11 (1980), pp. 938-951), qui propose une q-généralisation de l'intégrale de Selberg:

$$\int_0^1 \cdots \int_0^1 \prod_{1\leq i<j\leq n} |t_i - t_j|^{2z} \prod_{i=1}^{n} t_i^{x-1}(1-t_i)^{y-1}\, dt_1 \cdots dt_n.$$

Nous en déduisons une conjecture de Morris sur le terme constant de:

$$\prod_{j=1}^{l} (x_0/x_j)_a (qx_j/x_0)_b \prod_{1\leq i<j\leq l} (x_i/x_j)_c (qx_j/x_i)_c,$$

où $(x)_k = (1-x)(1-qx)\cdots(1-q^k x)$. En appendice se trouve la preuve d'une autre conjecture Askey, liée à la q-conjecture de Dyson.

Abstract. We prove a conjecture by R. Askey ("Some basic hypergeometric extensions of integrals of Selberg and Andrews," *SIAM J. Math. Anal.*, 11 (1980), pp. 938-951) on a basic extension of Selberg's integral:

$$\int_0^1 \cdots \int_0^1 \prod_{1\leq i<j\leq n} |t_i - t_j|^{2z} \prod_{i=1}^{n} t_i^{x-1}(1-t_i)^{y-1}\, dt_1 \cdots dt_n.$$

We deduce from this a conjecture due to Morris about the constant term in the expansion of

$$\prod_{j=1}^{l} (x_0/x_j)_a (qx_j/x_0)_b \prod_{1\leq i<j\leq l} (x_i/x_j)_c (qx_j/x_i)_c,$$

where $(x)_k = (1-x)(1-qx)\cdots(1-q^k x)$. In the appendix there can be found a proof of another conjecture by Askey related to the Dyson q-conjecture.

1. Introduction.

Commençons par définir les notations que nous utiliserons par la suite. Dans tout l'article, q désignera un nombre réel de l'intervalle ouvert $]0, 1[$. En fait, on peut, la plupart du temps, considérer q comme une indéterminée et se placer dans l'algèbre des séries formelles associées à q; les résultats démontrés restent en général valides. Toutefois cette restriction à $]0, 1[$ permet de donner un sens évident à l'expression "faire tendre q vers 1."

Posons $(a)_\infty = \prod_{n=0}^{\infty}(1-aq^n)$ et pour $n \in \mathbf{C}$, $(a)_n = (a)_\infty/(aq^n)_\infty$. La q-fonction gamma, introduite par Jackson [7], est définie sur $\mathbf{C}\backslash\mathbf{Z}^-$ par

$$\Gamma_q(a) = \frac{(q)_\infty}{(q^a)_\infty}(1-q)^{1-a}.$$

Jackson [7] définit également la q-intégration par

$$\int_0^1 f(t)\, d_q t = (1-q)\sum_{n=0}^{\infty} f(q^n)q^n. \tag{1.1}$$

* Received by the editors June 2, 1986; accepted for publication (in revised form) June 12, 1987.

† Département de mathématique, Université Louis-Pasteur, 7, rue René-Descartes, F-67084 Strasbourg, France.

Les dernières notations à introduire pour comprendre la q-généralisation sont, en prenant pour k un entier naturel:

$$\Delta_k^0(t_1,\cdots,t_n)=\prod_{1\leqq i\neq j\leqq n}(\varepsilon_{ij}t_i/t_j)_k,\qquad \text{où } \varepsilon_{ij}=\begin{cases}1 & \text{si } i<j,\\ q & \text{si } i>j,\end{cases}$$

$$\Delta_k(t_1,\cdots,t_n)=\frac{1}{n!}\sum_{\sigma\in S_n}\Delta_k^0(t_{\sigma 1},\cdots,t_{\sigma n}),$$

$$\Delta_k^1(t_1,\cdots,t_n)=\prod_{1\leqq i<j\leqq n}\prod_{l=0}^{k-1}(t_j-q^l t_i)(t_j-q^{-l}t_i).$$

L'intégrale de Selberg est une intégrale à plusieurs variables généralisant la fonction bêta. Elle vaut:

$$\int_0^1\cdots\int_0^1\prod_{1\leqq i<j\leqq n}(t_i-t_j)^{2k}\prod_{i=1}^n t_i^{x-1}(1-t_i)^{y-1}\,dt_1\cdots dt_n$$
$$=\prod_{j=1}^n\frac{\Gamma(x+(j-1)k)\Gamma(y+(j-1)k)\Gamma(jk+1)}{\Gamma(x+y+(n+j-2)k)\Gamma(k+1)}. \tag{1.2}$$

Askey [3] en a proposé plusieurs q-extensions. Nous allons prouver sa première conjecture, à savoir:

$$\int_0^1\cdots\int_0^1\prod_{1\leqq i<j\leqq n}t_i^{2k}\left(\frac{t_j}{t_i}q^{1-k}\right)_{2k}\prod_{i=1}^n t_i^{x-1}\frac{(t_iq)_\infty}{(t_iq^y)_\infty}\,d_qt_1\cdots d_qt_n$$
$$=q^{kx\binom{n}{2}+2k^2\binom{n}{3}}\prod_{j=1}^n\frac{\Gamma_q(x+(j-1)k)\Gamma_q(y+(j-1)k)\Gamma_q(jk+1)}{\Gamma_q(x+y+(n+j-2)k)\Gamma_q(k+1)}. \tag{1.3}$$

De manière équivalente, en notant que

$$t_i^{2k}\left(\frac{t_j}{t_i}q^{1-k}\right)_{2k}=(-1)^k(t_it_j)^kq^{-\binom{k}{2}}\left(\frac{t_i}{t_j}\right)_k\left(\frac{t_j}{t_i}q\right)_k,$$

nous montrerons que:

$$\int_{[0,1]^n}\Delta_k^0(\mathbf{t})\prod_{i=1}^n t_i^{x+(n-1)k-1}\frac{(t_iq)_\infty}{(t_iq^y)_\infty}\,d_qt$$
$$=(-1)^{k\binom{n}{2}}q^{\binom{n}{2}\binom{k}{2}+k\binom{n}{2}x+2k^2\binom{n}{3}}$$
$$\cdot\prod_{j=1}^n\frac{\Gamma_q(x+(j-1)k)\Gamma_q(y+(j-1)k)\Gamma_q(jk+1)}{\Gamma_q(x+y+(n+j-2)k)\Gamma_q(k+1)}, \tag{1.4}$$

où x et y sont deux nombres complexes de parties réelles suffisamment grandes pour assurer la convergence de l'intégrale et où k est un entier naturel.

Regardons maintenant ce qui se passe lorsque q tend vers 1. Askey [4] a prouvé que $\lim_{q\to 1}\Gamma_q(x)=\Gamma(x)$. De plus on vérifie sans peine que $\lim_{q\to 1}(qt)_\infty/(q^yt)_\infty=\lim_{q\to 1}\sum_{n=0}^\infty(q^{1-y})_n(tq^y)^n/(q)_n=\sum_{n=0}^\infty(1-y)_nt^n/n!=(1-t)^{y-1}$ et le théorème de convergence des sommes de Riemann nous assure que $\lim_{q\to 1}\int_0^1 f(t)\,d_qt=\int_0^1 f(t)\,dt$. Ces remarques nous permettent de vérifier que lorsqu'on fait tendre q vers 1 dans (1.3) et (1.4), on retrouve bien (1.2).

Dans le deuxième paragraphe, nous étudierons quelques propriétés utiles de la q-fonction gamma et de la q-intégration puis nous calculerons Δ_k. Nous montrerons ensuite au troisième paragraphe qu'il suffit alors d'évaluer la quantité

$$\int_{[0,1]^n}\Delta_k^1(t)\prod_{i=1}^n t_i^{x-1}\frac{(t_iq)_\infty}{(t_iq^y)_\infty}\,d_qt. \tag{1.5}$$

Nous suivrons alors la preuve de Selberg pour montrer que (1.5) peut se mettre sous la forme

$$\prod_{j=1}^{n} \frac{\Gamma_q(x+(j-1)k)\Gamma_q(y+(j-1)k)}{\Gamma_q(x+y+(n+j-2)k)} \cdot \frac{R(q^x, q^y)}{P(q^y)},$$

où R et P sont des polynômes à deux et une variables respectivement.

A ce stade, dans la preuve classique, on utilisait la symétrie en x et y pour montrer que $R(X, Y)/P(Y)$ était une constante, indépendante de X et Y. Ici cet argument n'est plus valable car (1.5) n'est pas symétrique en x et y. Nous démontrerons toutefois au quatrième paragraphe que l'on a $R(X, Y)/P(Y) = C_n(k)X^{k\binom{n}{2}}$, où $C_n(k)$ est une constante, indépendante de X et Y, grâce à l'utilisation appropriée de développements limités.

Le cinquième paragraphe sera consacré au calcul de $C_n(k)$, suivant deux méthodes. Au sixième paragraphe, nous utiliserons (1.4) pour prouver une conjecture due à Morris [9]:

$$CT \prod_{j=1}^{l} \left(\frac{x_0}{x_j}\right)_a \left(q\frac{x_j}{x_0}\right)_b \prod_{1\leqq i<j\leqq l} \left(\frac{x_i}{x_j}\right)_c \left(q\frac{x_j}{x_i}\right)_c = \prod_{j=0}^{l-1} \frac{(q)_{a+b+jc}(q)_{(j+1)c}}{(q)_{a+jc}(q)_{b+jc}(q)_{jc}}.$$

Enfin, en appendice, nous prouverons une autre conjecture d'Askey, tirée du même article que (1.3), en montrant qu'elle est essentiellement équivalente à la q-conjecture de Dyson.

Après rédaction de cet article, Kadell nous a communiqué son mémoire [8] dans lequel il démontre également la conjecture d'Askey sur la q-intégrale de Selberg. Il reprend, en les généralisant, les méthodes développées par Aomoto [2]. Les techniques de démonstration de Kadell ne recouvrent absolument pas les nôtres.

2. Calculs préliminaires. Tout d'abord, montrons quelques formules relatives à la q-fonction gamma.

PROPRIÉTÉS. On a:

$$\Gamma_q(n+1) = \frac{(q)_n}{(1-q)^n} \quad \text{pour } n \in \mathbf{N}, \tag{2.1}$$

$$\frac{\Gamma_q(a+n)}{\Gamma_q(a)} = \frac{(q^a)_n}{(1-q)^n} \quad \text{et} \quad \frac{\Gamma_q(a-n)}{\Gamma_q(a)} = \frac{(1-q)^n}{(q^{a-n})_n} \quad \text{pour } n \in \mathbf{N}, \tag{2.2}$$

$$\lim_{x\to\infty} \frac{\Gamma_q(x+a)}{\Gamma_q(x)} = (1-q)^{-a}, \tag{2.3}$$

$$\lim_{\varepsilon\to 0} \frac{1-q^{\varepsilon}}{1-q}\Gamma_q(-a+\varepsilon) = \frac{(1-q)^a(-1)^a q^{\binom{a+1}{2}}}{(q)_a} \quad \text{pour } a \in \mathbf{N}. \tag{2.4}$$

Preuves. Propriété (2.1) est une conséquence triviale des définitions de Γ_q et $(q)_n$. Pour $n \in \mathbf{N}$,

$$\frac{\Gamma_q(a+n)}{\Gamma_q(a)} = \frac{(1-q)^{1-a-n}(q)_\infty/(q^{a+n})_\infty}{(1-q)^{1-a}(q)_\infty/(q^a)_\infty}$$

$$= (1-q)^{-n}\frac{(q^a)_\infty}{(a^{a+n})_\infty} = \frac{(q^a)_n}{(1-q)^n}.$$

La deuxième partie de (2.2) est une conséquence de la première.

On a:

$$\frac{\Gamma_q(x+a)}{\Gamma_q(x)} = (1-q)^{-a}\frac{(q^x)_\infty}{(q^{x+a})_\infty}$$

et

$$\lim_{x\to+\infty}(q^x)_\infty = \lim_{x\to+\infty}(q^{x+a})_\infty = (0)_\infty = 1,$$

ce qui entraîne (2.3).

De même,

$$\begin{aligned}\Gamma_q(-a+\varepsilon) &= (1-q)^{1+a-\varepsilon}\frac{(q)_\infty}{(q^{-a+\varepsilon})_\infty}\\ &= \frac{(1-q)^{1+a-\varepsilon}}{1-q^\varepsilon}\cdot\frac{(q)_\infty}{(q^{1+\varepsilon})_\infty}\cdot\frac{1}{\prod_{l=1}^{a}(1-q^{-l+\varepsilon})},\end{aligned}$$

donc

$$\lim_{\varepsilon\to 0}\frac{1-q^\varepsilon}{1-q}\Gamma_q(-a+\varepsilon) = \frac{(1-q)^a}{\prod_{l=1}^{a}(1-q^{-l})} = \frac{(1-q)^a(-1)^a q^{\binom{a+1}{2}}}{(q)_a}.$$

Le point de départ de la théorie des fonctions hypergéométriques basiques est le théorème q-binômial:

$$\frac{(ax)_\infty}{(x)_\infty} = \sum_{n=0}^{\infty}\frac{(a)_n}{(q)_n}x^n. \tag{2.5}$$

En fait il est équivalent à la formule intégrale fondamentale:

$$\int_0^1 t^{x-1}\frac{(qt)_\infty}{(q^y t)_\infty}\,d_q t = \frac{\Gamma_q(x)\Gamma_q(y)}{\Gamma_q(x+y)}. \tag{2.6}$$

Pour le voir, il suffit d'appliquer les définitions:

$$\begin{aligned}\int_0^1 t^{x-1}\frac{(qt)_\infty}{(q^y t)_\infty}\,d_q t &= (1-q)\sum_{n=0}^{\infty} q^{nx}\frac{(q^{n+1})_\infty}{(q^{n+y})_\infty} \quad \text{(d'après (1.1))}\\ &= (1-q)\sum_n \frac{(q)_\infty}{(q^y)_\infty}\frac{(q^y)_n}{(q)_n}(q^x)^n\\ &= (1-q)\frac{(q)_\infty}{(q^y)_\infty}\frac{(q^{x+y})_\infty}{(q^x)_\infty} \quad \text{(grâce à (2.5))}\\ &= \frac{\Gamma_q(x)\Gamma_q(y)}{\Gamma_q(x+y)}, \quad \text{par définition de } \Gamma_q.\end{aligned}$$

On remarquera que la formule (2.6) est une q-généralisation de la formule d'Euler: $\int_0^1 t^{x-1}(1-t)^{y-1}\,dt = \Gamma(x)\Gamma(y)/\Gamma(x+y)$.

Notons aussi l'égalité suivante, valable pour $\sigma \in S_n$:

$$\int_{[0,1]^n} f(\sigma\mathbf{t})\,d_q\mathbf{t} = \int_{[0,1]^n} f(t)\,d_q t. \tag{2.7}$$

En effet $\int_{[0,1]^n} f(\sigma\mathbf{t})\,d_q\mathbf{t} = (1-q)^n\sum_{m\in\mathbf{N}^n}\prod_i q^{m_{\sigma i}}\times f(q^{m_{\sigma 1}},\cdots,q^{m_{\sigma n}}) = (1-q)^n\sum_{\mu\in\mathbf{N}^n}\cdot\prod_i q^{\mu_i}\times f(q^{\mu_1},\cdots,q^{\mu_n}) = \int_{[0,1]^n} f(\mathbf{t})\,d_q\mathbf{t}$. Passons maintenant au calcul de Δ_k.

PROPOSITION. *On a la formule explicite suivante*:

$$\Delta_k(\mathbf{t}) = \frac{\Gamma_{q^k}(n+1)}{n!} \prod_{1\le i\ne j\le n} \left(\frac{t_i}{t_j}\right)_k . \tag{2.8}$$

Démonstration. Posons

$$R(\mathbf{t}) = \frac{n!\Delta_k(\mathbf{t})}{\prod_{1\le i\ne j\le n}(t_i/t_j)_k}.$$

On a

$$R(t) = \sum_{\sigma\in S_n} \frac{\Delta_k^0(\sigma\mathbf{t})}{\prod_{i\ne j}(t_i/t_j)_k} = \sum_\sigma \prod_{i<j} \frac{(qt_{\sigma j}/t_{\sigma i})_k}{(t_{\sigma j}/t_{\sigma i})_k}$$
$$= \sum_\sigma \prod_{i<j} \frac{1-q^k t_{\sigma j}/t_{\sigma i}}{1-t_{\sigma j}/t_{\sigma i}} = \sum_\sigma \varepsilon(\sigma) \prod_{i<j} \frac{q^k t_{\sigma j} - t_{\sigma i}}{t_j - t_i},$$

en notant $\varepsilon(\sigma)$ la signature de la permutation σ. Posons $V(\mathbf{t}) = \prod_{1\le i<j\le n}(t_j - t_i)$. On voit que le produit

$$R(\mathbf{t})V(\mathbf{t}) = \sum_\sigma \varepsilon(\sigma) \prod_{i<j} (q^k t_{\sigma j} - t_{\sigma i})$$

est un polynôme antisymétrique, qui est de degré au plus $\binom{n}{2}$. C'est donc un multiple scalaire de $V(\mathbf{t})$, ou encore $R(\mathbf{t})$ est une constante en $\mathbf{t}$. Pour évaluer cette constante, on calcule le coefficient de $t_n^{n-1}\cdots t_2^1 t_1^0$ dans $RV(\mathbf{t})$. Notons $I(\sigma)$ le nombre d'inversions de la permutation σ, de sorte que $\varepsilon(\sigma) = (-1)^{I(\sigma)}$. On vérifie alors aisément que la contribution du terme $\varepsilon(\sigma)\prod_{i<j}(q^k t_{\sigma j} - t_{\sigma i})$ au coefficient de $t_n^{n-1}\cdots t_2^1 t_1^0$ dans la somme $RV(\mathbf{t})$ est donnée par $\varepsilon(\sigma)q^{k\binom{n}{2}-kI(\sigma)}(-1)^{I(\sigma)}$, c'est-à-dire $q^{k\binom{n}{2}-kI(\sigma)}$. De là, $R(\mathbf{t})q^{-k\binom{n}{2}}$ n'est autre que la fonction génératrice, sur le groupe des permutations, du nombre des inversions. La variable utilisée étant q^{-k}, cette fonction génératrice est égale à $\Gamma_{q^{-k}}(n+1)$, comme il est bien connu (cf. [6]), ce qui donne $R(\mathbf{t}) = \Gamma_{q^k}(n+1)$.

3. Factorisation de la q-intégrale de Selberg. Prenons comme point de départ la forme (1.4) de la conjecture. Puisque pour tout $\sigma\in S_n$,

$$\int_{[0,1]^n} \Delta_k^0(\sigma\mathbf{t}) \prod_i t_i^{x+(n-1)k-1} \frac{(t_i q)}{(t_i q^y)_\infty} d_q\mathbf{t}$$
$$= \int_{[0,1]^n} \Delta_k^0(\sigma\mathbf{t}) \prod_i t_{\sigma i}^{x+(n-1)k-1} \frac{(t_{\sigma i} q)_\infty}{(t_{\sigma i} q^y)_\infty} d_q\mathbf{t}$$
$$= \int_{[0,1]^n} \Delta_k^0(\mathbf{t}) \prod_i t_i^{x+(n-1)k-1} \frac{(t_i q)_\infty}{(t_i q^y)_\infty} d_q\mathbf{t} \quad \text{grâce à (2.7)},$$

on a forcément

$$\int_{[0,1]^n} \Delta_k^0(\mathbf{t}) \prod_i t_i^{x+(n-1)k-1} \frac{(t_i q)_\infty}{(t_i q^y)_\infty} d_q\mathbf{t} = \int_{[0,1]^n} \Delta_k(\mathbf{t}) \prod_i t_i^{x+(n-1)k-1} \frac{(t_i q)_\infty}{(t_i q^y)_\infty} d_q\mathbf{t}.$$

Or

$$\Delta_k(t) = \frac{\Gamma_{q^k}(n+1)}{n!} \prod_{i\ne j} \left(\frac{t_i}{t_j}\right)_k \quad \text{(grâce à (2.8))}$$
$$= \frac{\Gamma_{q^k}(n+1)}{n!} \prod_{i<j} \prod_{l=0}^{k-1} \left(1 - q^l \frac{t_i}{t_j}\right)\left(1 - q^l \frac{t_j}{t_i}\right)$$
$$= \frac{\Gamma_{q^k}(n+1)}{n!} \prod_{i<j} \prod_{l=0}^{k-1} \left(-\frac{q^l}{t_i t_j}\right)(t_i - q^l t_j)(t_i - q^{-l} t_j),$$

c'est-à-dire:

$$\Delta_k(\mathbf{t}) = \frac{\Gamma_{q^k}(n+1)}{n!}(-1)^{k\binom{n}{2}} q^{\binom{k}{2}\binom{n}{2}} \Delta_k^1(\mathbf{t}) \prod_{i=1}^{n} t_i^{-(n-1)k}. \tag{3.1}$$

Posons donc:

$$F_n(x, y, k) = q^{-kx\binom{n}{2}} \int_{[0,1]^n} \Delta_k^1(\mathbf{t}) \prod_i t_i^{x-1} \frac{(t_i q)_\infty}{(t_i q^y)_\infty} d_q\mathbf{t}. \tag{3.2}$$

En confrontant ce qui précède à (1.4), on voit qu'on est ramené à prouver le théorème suivant.

THÉORÈME. *La formule suivante est valide.*

$$F_n(x, y, k) = \frac{n! q^{2k^2\binom{n}{3}}}{\Gamma_{q^k}(n+1)} \prod_{j=1}^{n} \frac{\Gamma_q(x+(j-1)k)\Gamma_q(y+(j-1)k)\Gamma_q(jk+1)}{\Gamma_q(x+y+(n+j-2)k)\Gamma_q(k+1)}. \tag{3.3}$$

Démonstration. On suit tout d'abord la preuve classique: on développe $\Delta_k^1(\mathbf{t}) = \sum_{\alpha \in \mathbf{N}^n} c(\alpha) t^\alpha$, où les $c(\alpha)$ sont presque tous nuls, de sorte que

$$\begin{aligned} F_n(x, y, k) &= q^{-kx\binom{n}{2}} \sum_\alpha c(\alpha) \int_{[0,1]^n} \prod_i t_i^{x+\alpha_i-1} \frac{(qt_i)_\infty}{(q^y t_i)_\infty} d_q\mathbf{t} \\ &= q^{-kx\binom{n}{2}} \sum_\alpha c(\alpha) \prod_i \frac{\Gamma_q(x+\alpha_i)\Gamma_q(y)}{\Gamma_q(x+y+\alpha_i)}, \quad \text{grâce à (2.6).} \end{aligned}$$

Or $\Delta_k(\mathbf{t})$ est symétrique, par construction, donc $\Delta_k^1(\mathbf{t})$ est aussi symétrique, grâce à (3.1). On a donc

$$F_n(x, y, k) = q^{-kx\binom{n}{2}} \sum_{0 \leqq \beta_1 \leqq \cdots \leqq \beta_n} c'(\beta) \prod_i \frac{\Gamma_q(x+\beta_i)\Gamma_q(y)}{\Gamma_q(x+y+\beta_i)}, \tag{3.4}$$

où

$$\begin{aligned} c'(\beta) &= c(\beta) \cdot \#\{\alpha \in \mathbf{N}^n : \exists \sigma \in S_n \,|\, \sigma\alpha = \beta\} \\ &\quad (= c(\beta) \cdot n! \text{ si } \beta \text{ a toutes ses coordonnées distinctes}). \end{aligned}$$

Or $\Delta_k^1(\mathbf{t})$ est homogène de degré $2k\binom{n}{2}$, donc $kn(n-1) = \beta_1 + \cdots + \beta_n \leqq n\beta_n$ et ainsi $\beta_n \geqq k(n-1)$.

De plus, $\Delta_k^1(t_1, \cdots, t_j)$ divise $\Delta_k^1(t_1, \cdots, t_n)$, pour $1 \leqq j \leqq n$, et ainsi la puissance de t_j dans $\Delta_k^1(t_1, \cdots, t_n)$ est au moins celle de t_j dans $\Delta_k^1(t_1, \cdots, t_j)$. On en déduit que:

$$\text{pour } j \in \{1, \cdots, n\}, \qquad \beta_j \geqq k(j-1). \tag{3.5}$$

En outre,

$$\begin{aligned} \Delta_k^1\left(\frac{1}{t_1}, \cdots, \frac{1}{t_n}\right) &= \prod_{i<j} \prod_l \left(\frac{1}{t_i} - \frac{q^l}{t_j}\right)\left(\frac{1}{t_i} - \frac{q^{-l}}{t_j}\right) \\ &= \prod_{i<j} \prod_l \left(-\frac{q^l}{t_i t_j}\right)\left(-\frac{q^{-l}}{t_i t_j}\right)(t_i - q^{-l}t_j)(t_i - q^l t_j) \\ &= \prod_i t_i^{-2(n-1)k} \Delta_k^1(\mathbf{t}). \end{aligned}$$

Alors $2(n-1)k - \beta_{n+1-j} \geqq (j-1)k$, en utilisant (3.5). Donc

$$\beta_j \leqq 2(n-1)k - (n+1-j-1)k = (n+j-2)k \quad \text{pour } 1 \leqq j \leqq n. \tag{3.6}$$

De (3.5) et (2.2), on déduit que

$$\frac{\Gamma_q(x+\beta_j)}{\Gamma_q(x+(j-1)k)}$$

est un polynôme en q^x, pour $1 \leqq j \leqq n$. Il résulte alors de (3.6) et (2.2) que, pour $1 \leqq j \leqq n$,

$$\frac{\Gamma_q(x+y+(n+j-2)k)}{\Gamma_q(x+y+\beta_j)}$$

est un polynôme en q^{x+y}, de degré $(n+j-2)k-\beta_j$. En reportant dans (3.4), on trouve

$$F_n(x, y, k) = q^{-k\binom{n}{2}x} \sum_{\beta} c'(\beta) \prod_j \frac{\Gamma_q(x+(j-1)k)\Gamma_q(y)}{\Gamma_q(x+y+(n+j-2)k)} R_\beta(q^x, q^y),$$

où $R_\beta(X, Y)$ est un polynôme en deux variables, de degré en Y égal à

$$\sum_j ((n+j-2)k-\beta_j) = k\binom{n}{2}.$$

Le produit mis en évidence ne dépend plus de β; donc $F_n(x, y, k)$ peut se mettre sous la forme

$$\prod_j \frac{\Gamma_q(x+(j-1)k)\Gamma_q(y)}{\Gamma_q(x+y+(n+j-2)k)} \cdot \frac{R_0(q^x, q^y)}{q^{k\binom{n}{2}x}}.$$

De plus,

$$\frac{\Gamma_q(y)}{\Gamma_q(y+(j-1)k)} = \frac{(1-q)^{(j-1)k}}{(q^y)_{(j-1)k}} \quad \text{pour } 1 \leqq j \leqq n.$$

Donc

$$F_n(x, y, k) = \prod_j \frac{\Gamma_q(x+(j-1)k)\Gamma_q(y+(j-1)k)}{\Gamma_q(x+y+(n+j-2)k)} \cdot \frac{R(q^x, q^y)}{q^{k\binom{n}{2}x} P(q^y)}, \tag{3.7}$$

où R est un polynôme en deux variables, de degré en Y inférieur ou égal à $k\binom{n}{2}$ et où P est un polynôme en Y de degré $k\binom{n}{2}$:

$$P(Y) = \prod_{j=1}^{n} (Y)_{(j-1)k} = \prod_{j=1}^{n-1} (Y)_{jk}. \tag{3.8}$$

Il faut maintenant démontrer que $R(X, Y)/(X^{k\binom{n}{2}}P(Y))$ est une constante, indépendante de X et Y.

4. Simplification de $R(X, Y)/(X^{k\binom{n}{2}}P(Y))$. Prenons $F_n(x, y, k)$ sous la forme (1.1):

$$F_n(x, y, k) = (1-q)^n q^{-k\binom{n}{2}x} \sum_{m \in \mathbf{N}^n} \Delta_k^1(q^{m_1}, \cdots, q^{m_n}) \prod_{i=1}^{n} q^{m_i x} \frac{(q^{m_i+1})_\infty}{(q^{m_i+y})_\infty}.$$

La fonction Δ_k^1 est symétrique. Elle est de plus nulle si deux des variables sont égales (en fait pour $k \geqq 1$, le cas $k=0$ étant trivial). Donc

$$\begin{aligned} F_n(x, y, k) = n!\, q^{-k\binom{n}{2}x}(1-q)^n \sum_{0 \leqq m_1 \leqq \cdots \leqq m_n} \Delta_k^1(q^{m_1}, \cdots, q^{m_n}) \\ \cdot \prod_i q^{m_i x} \frac{(q^{m_i+1})_\infty}{(q^{m_i+y})_\infty}. \end{aligned} \tag{4.1}$$

Or

$$\Delta_k^1(q^{m_1}, \cdots, q^{m_n}) = \prod_{i<j} \prod_l (q^{m_i} - q^{l+m_j})(q^{m_i} - q^{-l+m_j});$$

donc s'il existe une paire $\{i,j\}\subset\{1,\cdots,n\}$ telle que $|m_i-m_j|<k$, alors $\Delta_k^1(q^{m_1},\cdots,q^{m_n})=0$. Ainsi, en supposant les m_i ordonnés, on a

(4.2) $$\Delta_k^1(q^{m_1},\cdots,q^{m_n})\neq 0\Leftrightarrow 0\leqq m_1\leqq m_2-k\leqq\cdots\leqq m_n-(n-1)k.$$

(4.3) En particulier (4.2) entraîne que $m_1+\cdots+m_n\geqq k\binom{n}{2}$. Il y a de plus égalité si et seulement si $m_i=(i-1)k$ pour $1\leqq i\leqq n$.

Faisons tendre x vers $+\infty$: grâce à (4.3),

$$F_n(x,y,k)\to n!(1-q)^n\Delta_k^1(1,q^k,\cdots,q^{(n-1)k})\prod_i\frac{(q^{(i-1)k+1})_\infty}{(q^{(i-1)k+y})_\infty}.$$

En utilisant (2.3), on voit que

$$\prod_j\frac{\Gamma_q(x+(j-1)k)\Gamma_q(y+(j-1)k)}{\Gamma_q(x+y+(n+j-2)k)}\cdot\frac{R(q^x,q^y)}{q^{k\binom{n}{2}x}P(q^y)}\sim C_1(y)\frac{R(q^x,q^y)}{q^{k\binom{n}{2}x}}.$$

On en déduit que nécessairement $X^{k\binom{n}{2}}$ divise $R(X,Y)$. On peut donc écrire $F_n(x,y,k)$ sous la forme

$$\prod_{j=1}^n\frac{\Gamma_q(x+(j-1)k)\Gamma_q(y+(j-1)k)}{\Gamma_q(x+y+(n+j-2)k)}\cdot\frac{Q(q^x,q^y)}{P(q^y)},$$

où $P(Y)=\prod_{j=1}^{n-1}(Y)_{jk}$.

Pour $a\in\{0,\cdots,n-2\}$ et $b\in\{0,\cdots,k-1\}$, posons $Y_{a,b}=q^{-(ak+b)}$.

(4.4) On remarque que les $Y_{a,b}$ sont les seuls zéros de P et que la multiplicité de $Y_{a,b}$ dans P est $n-1-a$.

Prenons $y=-ak-b+\varepsilon$ où $\varepsilon\in]0,\frac{1}{2}[$, $a\in\{0,\cdots,n-2\}$, $b\in\{0,\cdots,k-1\}$ et x tel que $x-[x]\in]0,\frac{1}{2}[$. La seconde condition ne fait que nous assurer qu'il n'y a aucun problème de définition et ne nuit pas à la généralité du problème. On fait tendre ε vers zéro. D'après (2.4),

(4.5) $$\prod_j\Gamma_q((j-1)k-ak-b+\varepsilon)\sim C_2(a,b)(1-q^\varepsilon)^{-a-1},$$

car $(j-1)k-ak-b\leqq 0\Leftrightarrow j\leqq a+1$. Grâce à (4.4), on a:

(4.6) $$P(q^{-ak-b+\varepsilon})\sim C_3(a,b)(1-q^\varepsilon)^{n-1-a}.$$

Dans (4.1), on pose $m_j=p_j+(j-1)k$, ce qui est licite, grâce à (4.2). On a:

$$\prod_j(q^{(j-1)k-ak-b+\varepsilon+p_j})_\infty\sim C_4(a,b,p)(1-q^\varepsilon)^{\omega(p)}\quad\text{avec }\omega(p)\leqq a+1,$$

car $\{j:(j-1)k-ak-b+p_j\leqq 0\}\subset\{j:(j-1)k-ak-b\leqq 0\}=\{1,\cdots,a+1\}$.

Récrivant (4.1) à l'aide des p_j, on trouve (pour $k\geqq 1$):

(4.7)
$$F_n(x,y,k)=n!(1-q)^n\sum_{0\leqq p_1\leqq\cdots\leqq p_n}\Delta_k^1(q^{p_1},\cdots,q^{p_n+(n-1)k})\cdot\prod_i q^{p_ix}\frac{(q^{p_i+(i-1)k+1})_\infty}{(q^{p_i+(i-1)k+y})_\infty}.$$

Dans cette somme, seul le dénominateur varie quand y tend vers $-ak-b$ et donc, en utilisant ce qui précède,

(4.8) $$F_n(x,-ak-b+\varepsilon,k)\sim C_5(a,b,x)(1-q^\varepsilon)^{-\omega}\quad\text{avec }\omega\leqq a+1.$$

En combinant (4.5), (4.6) et (4.8), on obtient

$$Q(q^x,q^{-ak-b+\varepsilon})\sim C_6(a,b,x)(1-q^\varepsilon)^{n-\omega}\quad\text{avec }\omega\leqq a+1.$$

Ceci montre que $Y_{a,b}$ est zéro de $Q(X, Y)$, d'ordre au moins $n-(a+1)$. D'après (4.4), on peut en déduire que $P(Y)$ divise $Q(X, Y)$. Or, d'après (3.8), $d_Y^0 R(X, Y) \leqq k\binom{n}{2} = d^0 P$. Ceci prouve que $Q(X, Y)/P(Y)$ est un polynôme en X, disons $Q_0(X)$.

Pour déterminer Q_0, prenons $y = -(n-1)k+\varepsilon$ et faisons tendre ε vers zéro. On a alors:

$$\prod_j \frac{\Gamma_q(x+(j-1)k)\Gamma_q(\varepsilon-(n-j)k)}{\Gamma_q(x+(j-1)k+\varepsilon)} \sim C_7(1-q^\varepsilon)^{-n}. \tag{4.9}$$

De plus, pour $0 \leqq p_1 \leqq \cdots \leqq p_n$ et $p_n > 0$, on a:

$$\prod_j (q^{p_j-(n-j)k+\varepsilon})_\infty^{-1} = o((1-q^\varepsilon)^{-n})$$

et

$$\prod_j (q^{-(n-j)k+\varepsilon})_\infty^{-1} \sim C_8(1-q^\varepsilon)^{-n}.$$

Donc, grâce à (4.7),

$$F_n(x, -(n-1)k+\varepsilon, k) \sim C_9(1-q^\varepsilon)^{-n}, \tag{4.10}$$

où C_9 est indépendante de q^x car le terme prépondérant de la somme est celui correspondant à $p_1 = \cdots = p_n = 0$. En confrontant (4.9) et (4.10), on trouve donc $Q_0(X) = C_9/C_7$: c'est bien une constante indépendante de x. Posons désormais $Q_0(X) = C_n(k)$.

5. Calcul de la constante $C_n(k)$. Il existe plusieurs manières pour déterminer $C_n(k)$. Suivons tout d'abord la preuve classique. Pour $\lambda \in \mathbf{C}$,

$$\int_0^1 t^{x-1}t^\lambda \, d_q t = \frac{1-q}{1-q^{x+\lambda}} \qquad (\mathrm{Re}\,(x+\lambda) > 0), \tag{5.1}$$

donc

$$\lim_{x\to 0} \frac{1-q^x}{1-q} \int_0^1 t^{x-1}t^\lambda \, d_q t = 0 \quad \text{si } \mathrm{Re}\,\lambda > 0.$$

Ainsi on a le q-analogue de $\lim_{x\to 0} x\int_0^1 t^{x-1}f(t)\,dt = f(0)$, à savoir:

$$\lim_{x\to 0} \frac{1-q^x}{1-q} \int_0^1 t^{x-1}f(t) \, d_q t = f(0) \quad \text{si } f \text{ est continue en 0.}$$

Par symétrie, on a la formule correspondant à (4.1):

$$F_n(x, y, k) = q^{-k\binom{n}{2}x} n! \int_0^1 \int_{t_n}^1 \cdots \int_{t_2}^1 \Delta_k^1(t_1, \cdots, t_n) \prod_{i=1}^n t_i^{x-1} \frac{(qt_i)_\infty}{(q^y t_i)_\infty} \, d_q t,$$

d'où

$$\lim_{x\to 0} \frac{1-q^x}{1-q} F_n(x, y, k)$$
$$= n! \int_0^1 \int_{t_{n-1}}^1 \cdots \int_{t_2}^1 \Delta_k^1(t_1, \cdots, t_{n-1}) \prod_{i=1}^{n-1} t_i^{2k-1} \frac{(qt_i)_\infty}{(q^y t_i)_\infty} \, d_q t,$$

car

$$\prod_{i=1}^{n-1} \prod_{l=0}^{k-1} (0-q^l t_i)(0-q^{-l}t_i) = \prod_{i=1}^{n=1} t_i^{2k}.$$

Ainsi

$$\lim_{x\to 0}\frac{1-q^x}{1-q}F_n(x,y,k)=nF_{n-1}(2k,y,k)q^{2k^2\binom{n-1}{2}}.$$

On a alors

$$C_n(k)\cdot\prod_{j=1}^{n-1}\frac{\Gamma_q(jk)\Gamma_q(y+jk)}{\Gamma_q(y+(n+j-1)k)}\cdot\frac{\Gamma_q(y)}{\Gamma_q(y+(n-1)k)}$$
$$=q^{2k^2\binom{n-1}{2}}nC_{n-1}(k)\prod_{j=1}^{n-1}\frac{\Gamma_q((j+1)k)\Gamma_q(y+(j-1)k)}{\Gamma_q(y+(n+j-1)k)};$$

d'où

$$C_n(k)=n!\frac{\Gamma_q(nk)}{\Gamma_q(k)}q^{2k^2\binom{n-1}{2}}C_{n-1}(k)=\cdots=n!\prod_{j=1}^{n}\frac{\Gamma_q(jk)}{\Gamma_q(k)}q^{2k^2\binom{n}{3}},$$

car $C_1(k)=1$. Or

$$\prod_j\frac{\Gamma_q(jk+1)}{\Gamma_q(k+1)}=\prod_j\frac{\Gamma_q(jk)}{\Gamma_q(k)}\cdot\prod_j\frac{1-q^{jk}}{1-q^k}=\prod_j\frac{\Gamma_q(jk)}{\Gamma_q(k)}\cdot\Gamma_{q^k}(n+1),$$

donc

$$C_n(k)=\frac{n!}{\Gamma_{q^k}(n+1)}\prod_{j=1}^{n}\frac{\Gamma_q(jk+1)}{\Gamma_q(k+1)},$$

ce qui achève la démonstration du théorème (3.3).

On peut également trouver $C_n(k)$ de manière plus explicite, en précisant les identités (4.9) et (4.10). En effet, pour $y=-(n-1)k+\varepsilon$ et ε tendant vers zéro, on a, à partir de (4.1):

$$F_n(x,-(n-1)k+\varepsilon,k)$$
$$\sim n!\Delta_k^1(1,\cdots,q^{(n-1)k})\prod_{j=1}^{n}\frac{(q^{(j-1)k+1})_\infty}{(q^{-(n-j)k+\varepsilon})_\infty}(1-q)^n$$
$$\sim n!\Delta_k^1(1,\cdots,q^{(n-1)k})\prod_j\frac{\Gamma_q(-(n-j)k+\varepsilon)(1-q)^{-(n-1)k+\varepsilon}}{\Gamma_q((j-1)k+1)}$$
$$\sim\frac{n!\Delta_k^1(1,\cdots,q^{(n-1)k})(1-q)^{-2k\binom{n}{2}}}{\prod_j\Gamma_q((j-1)k+1)}\prod_j\Gamma_q(-(n-j)k+\varepsilon).$$

D'autre part, on sait que

$$F_n(x,y,k)\sim\prod_{j=1}^{n}\frac{\Gamma_q(x+(j-1)k)\Gamma_q(-(n-j)k+\varepsilon)}{\Gamma_q(x+(j-1)k+\varepsilon)}C_n(k).$$

On en déduit que:

$$C_n(k)=\frac{n!\Delta_k^1(1,\cdots,q^{(n-1)k})(1-q)^{-2k\binom{n}{2}}}{\prod_j\Gamma_q((j-1)k+1)}. \tag{5.2}$$

Rappelons que

$$\Delta_k^1(1,\cdots,q^{(n-1)k})=\prod_{0\leqq i<j\leqq n-1}\prod_{l=0}^{k-1}(q^{ik}-q^{jk+l})(q^{ik}-q^{jk-l}).$$

On pourra sortir de ce produit une puissance de q dont l'exposant vaut:

$$\sum_{0\leqq i<j\leqq n-1}\sum_{l=0}^{k-1} 2ik = \sum_{0\leqq i<j\leqq n-1} 2ik^2 = 2k^2\sum_{i=0}^{n-1} i(n-1-i)$$

$$= k^2 n(n-1)\left(n-1-\frac{2n-1}{3}\right) = 2k^2\binom{n}{3}.$$

On en déduit que:

$$\Delta_k^1(1,\cdots,q^{(n-1)k}) = q^{2k^2\binom{n}{3}} \prod_{0\leqq i<j\leqq n-1}\prod_{l=0}^{k-1}(1-q^{(j-i)k+l})(1-q^{(j-i)k-l})$$

$$= q^{2k^2\binom{n}{3}} \prod_{l=0}^{k-1}\prod_{r=1}^{n-1}(1-q^{rk+l})^{n-r}\prod_{l=1}^{k}\prod_{r=0}^{n-2}(1-q^{rk+l})^{n-r-1}$$

$$= q^{2k^2\binom{n}{3}} \prod_{j=1}^{n}\frac{(q)_{jk-1}}{(q)_{k-1}}\prod_{j=1}^{n-1}(q)_{jk}$$

$$= q^{2k^2\binom{n}{3}} \prod_{j=1}^{n-1}\frac{\Gamma_q(jk)\Gamma_q((j-1)k+1)}{\Gamma_q(k)}(1-q)^{2(j-1)k}.$$

En remplaçant dans (5.2), ceci nous donne:

$$C_n(k) = n!\,q^{2k^2\binom{n}{3}}\prod_j \frac{\Gamma_q(jk)}{\Gamma_q(k)} = \frac{n!\,q^{2k^2\binom{n}{3}}}{\Gamma_{q^k}(n+1)}\prod_j\frac{\Gamma_q(jk+1)}{\Gamma_q(k+1)},$$

pour le mêmes raisons que précédemment.

Le lecteur attentif notera que l'on peut aussi obtenir (5.2) en faisant tendre x vers $+\infty$.

6. Application à une conjecture de Morris. Il s'agit de calculer le terme constant de

$$\prod_{i=1}^{l}\left(\frac{t_0}{t_i}\right)_a\left(q\frac{t_i}{t_0}\right)_b\prod_{1\leqq i\neq j\leqq l}\left(\varepsilon_{ij}\frac{t_i}{t_j}\right)_c.$$

On pose $x_i = q^{-a}t_i/t_0$, ce qui ne change pas le terme constant. Alors

$$\left(\frac{t_0}{t_i}\right)_a\left(q\frac{t_i}{t_0}\right)_b = \prod_{l=0}^{a-1}\left(1-\frac{q^{l-a}}{x_i}\right)\prod_{l=1}^{b}(1-q^{l+a}x_i)$$

$$= (-1)^a q^{-\binom{a+1}{2}}x_i^{-a}(qx_i)_{a+b}.$$

On a donc

$$CT\prod_{i=1}^{l}\left(\frac{t_0}{t_i}\right)_a\left(q\frac{t_i}{t_0}\right)_b\prod_{i\neq j}\left(\varepsilon_{ij}\frac{t_i}{t_j}\right)_c$$

$$= (-1)^{la}q^{-l\binom{a+1}{2}}CT\prod_{i\neq j}\left(\varepsilon_{ij}\frac{x_i}{x_j}\right)_c\prod_i x_i^{-a}\frac{(qx_i)_\infty}{(q^{a+b+1}x_i)_\infty}.$$

Donnons maintenant une généralisation de (5.1). Comme me l'a fait remarquer Askey dans une correspondance privée, celle-ci correspond au q-analogue de la notion d'intégrale généralisée introduite par Hadamard. On pose, pour $\lambda\in\mathbf{C}$:

$$\int_0^1 t^{\lambda-1}\,d_qt = \frac{1-q}{1-q^\lambda}.$$

Ainsi, si f est une série formelle, on peut définir $\int_0^1 t^{x-1} f(t)\, d_q t$, pour $x \in \mathbf{C}\backslash\mathbf{Z}$. On aura de plus:

$$\lim_{x\to 0} \frac{1-q^x}{1-q} \int_0^1 t^{x-1} f(t)\, d_q t = CTf, \tag{6.1}$$

où le symbole $\int$ désigne l'opérateur formel défini ci-dessus. On choisit pour paramètres dans la q-intégrale de Selberg: $n = l$, $x = -(n-1)k - a + \varepsilon$, $\varepsilon \in]0, 1[$, $y = a + b + 1$, $k = c$. On fait tendre ε vers zéro. D'après (6.1),

$$\begin{aligned}
&CT \prod_{i\neq j} \left(\varepsilon_{ij} \frac{x_i}{x_j}\right)_c \prod_i x_i^{-a} \frac{(qx_i)_\infty}{(q^{a+b+1}x_i)_\infty} \\
&= \lim_{\varepsilon\to 0} \left(\frac{1-q^\varepsilon}{1-q}\right)^n \int_{[0,1]^n} \Delta_c^0(\mathbf{t}) \prod_i t_i^{-a+\varepsilon-1} \frac{(qt_i)_\infty}{(q^{a+b+1}t_i)_\infty}\, d_q\mathbf{t} \\
&= (-1)^{c\binom{n}{2}} q^{\binom{n}{2}\binom{c}{2} + c(-(n-1)c-a)\binom{n}{2} + 2c^2\binom{n}{3}} \lim_{\varepsilon\to 0} \left(\frac{1-q^\varepsilon}{1-q}\right)^n \\
&\quad \cdot \prod_{j=1}^n \frac{\Gamma_q(-a-(n-j)c+\varepsilon)\Gamma_q(a+b+(j-1)c+1)\Gamma_q(jc+1)}{\Gamma_q(b+(j-1)c+1+\varepsilon)\Gamma_q(c+1)},
\end{aligned}$$

d'après (1.4). En effet, le membre de gauche de (1.4) n'était défini que pour Re x assez grand. Avec la nouvelle définition introduite ci-dessus, on peut, par analyticité, l'étendre à tout $\mathbf{C}\backslash\mathbf{Z}$. Or

$$\lim_{\varepsilon\to 0} \frac{1-q^\varepsilon}{1-q} \Gamma_q(-a-jc+\varepsilon) = \frac{(1-q)^{a+jc}(-1)^{a+jc} q^{\binom{a+jc+1}{2}}}{(q)_{a+jc}},$$

grâce à (2.4), et on a le système d'égalités:

$$\begin{aligned}
\Gamma_q(a+b+jc+1) &= (1-q)^{-a-b-jc}(q)_{a+b+jc}, \\
\Gamma_q(b+jc+1) &= (1-q)^{-b-jc}(q)_{b+jc}, \\
\Gamma_q((j+1)c+1) &= (1-q)^{-(j+1)c}(q)_{(j+1)c}, \\
\Gamma_q(c+1) &= (1-q)^{-c}(q)_c.
\end{aligned}$$

On trouve donc:

$$\begin{aligned}
&CT \prod_{i=1}^n \left(\frac{t_0}{t_i}\right)_a \left(q\frac{t_i}{t_0}\right)_b \prod_{1\leqq i\neq j\leqq n} \left(\varepsilon_{ij}\frac{t_i}{t_j}\right)_c \\
&= (-1)^{na+c\binom{n}{2}+na+c\binom{n}{2}} q^\alpha \prod_{j=0}^{n-1} \frac{(q)_{a+b+jc}(q)_{(j+1)c}}{(q)_{a+jc}(q)_{b+jc}(q)_c},
\end{aligned}$$

où

$$\begin{aligned}
\alpha &= -n\binom{a+1}{2} + \binom{n}{2}\binom{c}{2} - c(a+(n-1)c)\binom{n}{2} + 2c^2\binom{n}{3} \\
&\quad + n\binom{a+1}{2} + c\left(a+\frac{1}{2}\right)\binom{n}{2} + \frac{c^2}{2}\frac{n(n-1)(2n-1)}{6} \\
&= \binom{n}{2}\binom{c}{2} - (n-1)c^2\binom{n}{2} + 2c^2\binom{n}{3} + \frac{c}{2}\binom{n}{2} + \frac{c^2 n(n-1)(2n-1)}{12} \\
&= \frac{c}{2}\binom{n}{2}\left(c-1-2c(n-1) + \frac{4c(n-2)}{3} + 1 + \frac{c(2n-1)}{3}\right) \\
&= \frac{c}{2}\binom{n}{2}\left(c(3-2n) + \frac{c}{3}(6n-9)\right) = 0.
\end{aligned}$$

On trouve donc bien la forme "Cauchy-Selberg" de la conjecture B de Morris [9]:

$$CT \prod_{i=1}^{l} \left(\frac{t_0}{t_i}\right)_a \left(q\frac{t_i}{t_0}\right)_b \prod_{1\leqq i\neq j\leqq l} \left(\varepsilon_{ij}\frac{t_i}{t_j}\right)_c = \prod_{j=0}^{l-1} \frac{(q)_{a+b+jc}(q)_{(j+1)c}}{(q)_{a+jc}(q)_{b+jc}(q)_c}.$$

On remarquera que lorsque $a=b=0$, ceci fournit la q-conjecture de Dyson avec tous les paramètres égaux (cf. [1]).

Appendice: Une autre conjecture d'Askey. Posons

$$F_n(a_1,\cdots,a_n;x)=\int_{[0,1]^n} \prod_{i\neq j}\left(\varepsilon_{ij}\frac{t_i}{t_j}\right)_{a_i} \prod_i t_i^{x-1}\frac{(t_iq)_\infty}{(t_iq^{a_i+1-x})_\infty} d_q\mathbf{t},$$

$$\text{où } \varepsilon_{ij}=\begin{cases}1 & \text{si } i<j,\\ q & \text{si } i>j.\end{cases}$$

On définit aussi:

$$G_n(a_1,\cdots,a_n;x)=\frac{F_n(a_1,\cdots,a_n;x)}{F_n(0,\cdots,0;x)}$$

et

$$H_n(a_1,\cdots,a_n;x)=\frac{\Gamma_q(a_1+\cdots+a_n+1-x)}{\Gamma_q(a_1+1)\cdots\Gamma_q(a_n+1)\Gamma_q(1-x)}.$$

THÉORÈME. *Pour* $(a_1,\cdots,a_n)\in\mathbf{N}^n$ *et* $x\in\mathbf{C}\backslash\mathbf{N}^*$, *on a la formule suivante*:

$$G_n(a_1,\cdots,a_n;x)=H_n(a_1,\cdots,a_n;x).$$

La conjecture initiale d'Askey [3, Conjecture 4] disait que:

$$F_n(a_1,\cdots,a_n;x)=H_n(a_1,\cdots,a_n;x)\cdot[\Gamma_q(x)\Gamma_q(1-x)]^n.$$

Il y a équivalence avec le théorème car

$$F_n(0,\cdots,0;x)=\int_{[0,1]^n}\prod_i t_i^{x-1}\frac{(t_iq)_\infty}{(t_iq^{1-x})_\infty}d_q\mathbf{t}=\prod_{i=1}^n\Gamma_q(x)\Gamma_q(1-x),$$

d'après (2.6). Askey avait mis en évidence le fait que sa conjecture entrainait la q-conjecture de Dyson à n paramètres:

$$CT\prod_{1\leqq i\neq j\leqq n}\left(\varepsilon_{ij}\frac{t_i}{t_j}\right)_{a_i}=\frac{(q)_{a_1+\cdots+a_n}}{(q)_{a_1}\cdots(q)_{a_n}}.$$

Nous allons en fait montrer que le théorème est une conséquence de la q-conjecture de Dyson à $n+1$ paramètres. Puisque cette conjecture a été prouvée (cf. Bressoud et Zeilberger, [5]), ceci démontrera le théorème. Il va sans dire qu'une preuve directe du théorème serait bien plus intéressante mais nous n'en avons pas trouvé.

D'après (2.2), $H_n(a_1,\cdots,a_n;x)$ est une fraction rationnelle en q^x, définie sur $\mathbf{C}\backslash\mathbf{N}^*$. Développons

$$\prod_{i\neq j}\left(\varepsilon_{ij}\frac{t_i}{t_j}\right)_{a_i}=\sum_\alpha A(\alpha)\mathbf{t}^\alpha,$$

où la somme est prise sur les n-uplets d'entiers relatifs $\alpha=(\alpha_1,\cdots,\alpha_n)$ tels que $\alpha_1+\cdots+\alpha_n=0$. Alors:

$$\begin{aligned}
&G_n(a_1,\cdots,a_n;x)\\
&=\sum_\alpha A(\alpha)\int_{[0,1]^n}\prod_i t_i^{x+\alpha_i-1}\frac{(t_iq)_\infty}{(t_iq^{a_i+1-x})_\infty}\,d_q\mathbf{t}\cdot[\Gamma_q(x)\Gamma_q(1-x)]^{-n}\\
&=\sum_\alpha A(\alpha)\prod_i\frac{\Gamma_q(x+\alpha_i)}{\Gamma_q(x)}\,\frac{\Gamma_q(a_i+1-x)}{\Gamma_q(1-x)}\,\frac{1}{\Gamma_q(a_i+1+\alpha_i)}.
\end{aligned}$$

Cette dernière relation montre bien que G_n est définie sur $\mathbf{C}\backslash\mathbf{Z}$. C'est de plus une fraction rationnelle en q^x. Montrons que G_n admet un prolongement continu aux entiers négatifs, qui coïncide avec H_n. Ceci suffira à prouver que G_n et H_n sont égales car deux fractions rationnelles qui coïncident en une infinité de valeurs distinctes sont forcément égales.

Soient $a_0\in\mathbf{N}$, $x\in]0,1[$. On a:

$$G_n(a_1,\cdots,a_n;-a_0+x)=\sum_\alpha A(\alpha)\prod_i\frac{\Gamma_q(\alpha_i-a_0+x)\Gamma_q(a_i+1+a_0-x)}{\Gamma_q(-a_0+x)\Gamma_q(1+a_0-x)\Gamma_q(a_i+\alpha_i+1)}.$$

Si $\alpha\geqq 0$, alors

$$\frac{\Gamma_q(\alpha-a_0+x)}{\Gamma_q(-a_0+x)}=\frac{(q^{-a_0+x})_\alpha}{(1-q)^\alpha}\to\frac{(q^{-a_0})_\alpha}{(1-q)^\alpha}$$

quand x tend vers zéro et

$$\frac{(q^{-a_0})_\alpha}{(1-q)^\alpha}=\begin{cases}0 & \text{si } \alpha\geqq a_0,\\ \dfrac{(-1)^\alpha q^{\binom{\alpha}{2}-a_0\alpha}}{(1-q)^\alpha}\cdot\dfrac{(q)_{a_0}}{(q)_{a_0-\alpha}} & \text{si } \alpha\leqq a_0.\end{cases}$$

Si $\alpha\leqq 0$, alors

$$\frac{\Gamma_q(\alpha-a_0-x)}{\Gamma_q(-a_0+x)}=\frac{(1-q)^{-\alpha}}{(q^{\alpha-a_0+x})_{-\alpha}}\to\frac{(1-q)^{-\alpha}}{(q^{\alpha-a_0})_{-\alpha}},$$

quand x tend vers zéro. Et de même:

$$\frac{(1-q)^{-\alpha}}{(q^{\alpha-a_0})_{-\alpha}}=\frac{(-1)^\alpha q^{-\binom{\alpha+1}{2}-(a_0-\alpha)\alpha}}{(1-q)^\alpha}\cdot\frac{(q)_{a_0}}{(q)_{a_0-\alpha}}.$$

Ainsi, dans tous les cas, on trouve que:

$$\lim_{x\to 0}\frac{\Gamma_q(\alpha-a_0+x)}{\Gamma_q(-a_0+x)}=\frac{(-1)^\alpha q^{\binom{\alpha}{2}-a_0\alpha}}{(1-q)^\alpha}\cdot\frac{(q)_{a_0}}{(q)_{a_0-\alpha}}.$$

On en déduit que $G_n(a_1,\cdots,a_n;-a_0+x)$ admet pour limite quand x tend vers zéro:

$$\begin{aligned}
&G_n(a_1,\cdots,a_n;-a_0)\\
&=\sum_\alpha A(\alpha)\prod_i\frac{(-1)^{\alpha_i}q^{\binom{\alpha_i}{2}-a_0\alpha_i}}{(1-q)^{\alpha_i}}\,\frac{(q)_{a_0}}{(q)_{a_0-\alpha_i}}\,\frac{\Gamma_q(a_i+1+a_0)}{\Gamma_q(a_i+1+\alpha_i)\Gamma_q(a_0+1)}\\
&=\sum_\alpha A(\alpha)\prod_i(-1)^{\alpha_i}q^{\binom{\alpha_i}{2}}\frac{(q)_{a_0+a_i}}{(q)_{a_0-\alpha_i}(q)_{a_i+\alpha_i}},
\end{aligned}$$

grâce à (2.1) et au fait que $\prod q^{-a_0\alpha_i}=q^{-a_0\sum\alpha_i}=1$.

Or, pour $i \in \{1, \cdots, n\}$, on a la formule suivante, conséquence classique de (2.5):

$$\left(\frac{t_0}{t_i}\right)_{a_0}\left(q\frac{t_i}{t_0}\right)_{a_i} = \sum_{\alpha_i} \frac{(-1)^{\alpha_i} q^{\binom{\alpha_i}{2}} (q)_{a_0+a_i}}{(q)_{a_0-\alpha_i}(q)_{a_i+\alpha_i}} \left(\frac{t_0}{t_i}\right)^{\alpha_i}.$$

On voit donc que:

$$\begin{aligned} G_n(a_1, \cdots, a_n; -a_0) &= CT \prod_{0 \leqq i \neq j \leqq n} \left(\varepsilon_{ij}\frac{t_i}{t_j}\right)_{a_i} \\ &= \frac{(q)_{a_0+\cdots+a_n}}{(q)_{a_0}\cdots(q)_{a_n}} \\ &= \frac{\Gamma_q(a_0+\cdots+a_n+1)}{\Gamma_q(a_0+1)\cdots\Gamma_q(a_n+1)} \quad \text{grâce à (2.1).} \end{aligned}$$

Ainsi $G_n(a_1, \cdots, a_n; -a_0) = H_n(a_1, \cdots, a_n; -a_0)$ et le théorème est prouvé.

Remerciements. J'aimerais remercier M. Foata pour les nombreuses lectures qu'il m'a communiquées et l'oreille attentive qu'il m'a tendue. J'aimerais aussi remercier M. Bressoud pour le cours intéressant qu'il nous a dispensé cette année à Strasbourg, en particulier pour son remarquable exposé sur l'intégrale de Selberg.

A PROOF OF RAMANUJAN'S IDENTITY BY USE OF LOOP INTEGRALS*

KATSUHISA MIMACHI†

Abstract. Ramanujan's identity means the following:

$$\sum_{n=-\infty}^{+\infty} \frac{(a;q)_n}{(b;q)_n} x^n = \frac{(ax;q)_\infty (q/ax;q)_\infty (b/a;q)_\infty (q;q)_\infty}{(x;q)_\infty (b/ax;q)_\infty (q/a;q)_\infty (b;q)_\infty},$$

where $(a;q)_\infty = \prod_{j=0}^{+\infty}(1-aq^j)$, $(a;q)_n = (a;q)_\infty/(aq^n;q)_\infty$ for $-\infty < n < +\infty$, and $|b/a| < |x| < 1$, $|q| < 1$. This identity plays an important role in the theory of "q-analysis" (see, for example, [1], [3]). Various proofs of it are known ([2], [4], etc.). The aim of this paper is to derive the identity by another method, that of loop integrals.

Key words. Ramanujan's ${}_1\Psi_1$ identity, residue calculus

AMS(MOS) subject classifications. primary 33A30; secondary 10A45

1. Notation.

Set

$$C_n := \{\rho_n \exp(\sqrt{-1}\varphi) \mid \rho_n := \tfrac{1}{2}(|q|^n + |q|^{n+1}),\ 0 \leqq \varphi \leqq 2\pi\},$$

$$\tilde{C}_n := \{\tilde{\rho}_n \exp(\sqrt{-1}\varphi) \mid \tilde{\rho}_n := \tfrac{1}{2}|a/b|(|q|^{-n-1} + |q|^{-n}),\ 0 \leqq \varphi \leqq 2\pi\}$$

in the usual counterclockwise direction. Define

$$f(t) := \frac{(tq^2/a;q)_\infty (a/tq;q)_\infty}{(tx;q)_1 (1/t;q)_\infty (tb/a;q)_\infty},$$

$$F(t) := \frac{(a;q)_\infty (b/a;q)_\infty (q;q)_\infty (tq^2/a;q)_\infty (a/tq;q)_\infty}{(b;q)_\infty (a/q;q)_\infty (q^2/a;q)_\infty (tx;q)_1 (1/t;q)_\infty (tb/a;q)_\infty}$$

$$= \frac{(a;q)_\infty (b/a;q)_\infty (q;q)_\infty}{(b;q)_\infty (a/q;q)_\infty (q^2/a;q)_\infty} f(t),$$

$$I(C) := \frac{1}{2\pi\sqrt{-1}} \int_C f(t)\, dt,$$

$$\operatorname*{Res}_{t=y} \varphi(t) := \text{"the residue of } \varphi(t) \text{ at } t = y\text{"}.$$

2. The function $F(t)$ has simple poles at $t = q^j$, $t = a/bq^j$ $(j = 0, 1, 2, \cdots)$, and $t = 1/x$. The infinite point ∞ and the origin 0 are essential singularities.

LEMMA 1. *If* $|b/a| < |x| < 1$, $|a| < 1$, $|q| < |b|$, *then we have*

$$\sum_{n=-\infty}^{+\infty} \frac{(a;q)_n}{(b;q)_n} x^n - \frac{(ax;q)_\infty (q/ax;q)_\infty (b/a;q)_\infty (q;q)_\infty}{(x;q)_\infty (b/ax;q)_\infty (q/a;q)_\infty (b;q)_\infty}$$

$$= \sum_{j=0}^{+\infty} \operatorname*{Res}_{t=q^j} F(t) + \operatorname*{Res}_{t=1/x} F(t) + \sum_{j=0}^{+\infty} \operatorname*{Res}_{t=a/bq^j} F(t).$$

† Department of Mathematics, Faculty of Science, Nagoya University, Furocho, Chikusa-Ku, Nagoya 464, Japan.

Proof. By summing up the part of nonnegative powers in the left-hand side, we have

$$\begin{aligned}\sum_{n=0}^{+\infty}\frac{(a;q)_n}{(b;q)_n}x^n &= \frac{(a;q)_\infty}{(b;q)_\infty}\sum_{n=0}^{+\infty}\sum_{j=0}^{+\infty}\frac{(b/a;q)_j(aq^n)^j}{(q;q)_j}x^n\\ &= \frac{(a;q)_\infty}{(b;q)_\infty}\sum_{j=0}^{+\infty}\sum_{n=0}^{+\infty}(xq^j)^n\frac{a_j\cdot(b/a;q)_j}{(q;q)_j}\\ &= \frac{(a;q)_\infty}{(b;q)_\infty}\sum_{j=0}^{+\infty}\frac{a^j\cdot(b/a;q)_j}{(xq^j;q)_1(q;q)_j}\\ &= \sum_{j=0}^{+\infty}\operatorname*{Res}_{t=q^j}F(t).\end{aligned}$$

The above expansions are valid when $|a|<1$, $|x|<1$. Similarly,

$$\begin{aligned}\sum_{-\infty}^{-1}\frac{(a;q)_n}{(b;q)_n}x^n &= \sum_{n=1}^{+\infty}\frac{(q/b;q)_n}{(q/a;q)_n}\left(\frac{b}{ax}\right)^n\\ &= \frac{(q/b;q)_\infty}{(q/a;q)_\infty}\sum_{n=1}^{+\infty}\frac{(q^{n+1}/a;q)_\infty}{(q^{n+1}/b;q)_\infty}\left(\frac{b}{ax}\right)^n\\ &= \frac{(q/b;q)_\infty}{(q/a;q)_\infty}\sum_{n=1}^{+\infty}\sum_{j=0}^{+\infty}\frac{(b/a;q)_j(q^{n+1}/b)^j}{(q;q)_j}\left(\frac{b}{ax}\right)^n\\ &= \frac{(q/b;q)_\infty}{(q/a;q)_\infty}\sum_{j=0}^{+\infty}\sum_{n=1}^{+\infty}\left(\frac{bq^j}{ax}\right)^n\frac{(b/a;q)_j(q/b)^j}{(q;q)_j}\\ &= \frac{(q/b;q)_\infty}{(q/a;q)_\infty}\left(\frac{b}{ax}\right)\sum_{j=0}^{+\infty}\frac{(b/a;q)_j(q^2/b)^j}{(bq^j/ax;q)_1(q;q)_j}\\ &= \sum_{j=0}^{+\infty}\operatorname*{Res}_{t=a/bq^j}F(t).\end{aligned}$$

We note that the above expansions are valid when $|q/b|<1$, $|b/ax|<1$. On the other hand, we have simply that

$$\operatorname*{Res}_{t=1/x}F(t) = -\frac{(ax;q)_\infty(q/ax;q)_\infty(b/a;q)_\infty(q;q)_\infty}{(x;q)_\infty(b/ax;q)_\infty(q/a;q)_\infty(b;q)_\infty},$$

which completes the proof. □

What remains to be done is to estimate the effect of essential singularities at ∞ and zero. We obtain the following lemma.

LEMMA 2. *Under the condition* $|a|<1$, $|q^2|<|b|$, $|b/a|<|x|<1$, *we have*

$$\sum_{j=0}^{+\infty}\operatorname*{Res}_{t=q^j}F(t)+\operatorname*{Res}_{t=1/x}F(t)+\sum_{j=0}^{+\infty}\operatorname*{Res}_{t=a/bq^j}F(t)=0.$$

Proof. Due to the definition, we only have to prove

$$\sum_{j=0}^{+\infty}\operatorname*{Res}_{t=q^j}f(t)+\operatorname*{Res}_{t=1/x}f(t)+\sum_{j=0}^{+\infty}\operatorname*{Res}_{t=a/bq^j}f(t)=0.$$

Cauchy's theorem shows

$$\sum_{j=0}^{m}\operatorname*{Res}_{t=q^j}f(t)+\operatorname*{Res}_{t=1/x}f(t)+\sum_{j=0}^{n}\operatorname*{Res}_{t=a/bq^j}f(t)=I(\tilde{C}_n)-I(C_m).$$

Therefore the proof is completed from the following lemma.

LEMMA 3. *Under the condition* $|b/a|<|x|<1$,

(1) *if* $|a|<1$, *then* $|I(C_m)|\to 0$ *for* $m\to+\infty$;
(2) *if* $|q^2|<|b|$, *then* $|I(\tilde{C}_n)|\to 0$ *for* $n\to+\infty$.

Proof. (1) For $m=1,2,3,\cdots$, we have from the definition

$$f(|q|^m t)=(a/q)^m(tq^2|q|^m/aq^m;q)_m(aq^m/tq|q|^m;q)_\infty(tq^2|q|^m/a;q)_\infty \cdot(tq|q|^m/q^m;q)_m^{-1}(q^m/t|q|^m;q)_\infty^{-1}(tb|q|^m/a;q)_\infty^{-1}(tx|q|^m;q)_1^{-1}.$$

Hence for $0\leqq\varphi\leqq 2\pi$,

$$\begin{aligned}|f(\rho_m e^{\sqrt{-1}\varphi})| &= |f(\rho_0|q|^m e^{\sqrt{-1}\varphi})| \\ &= |a/q|^m\times|(\rho_0 q^2|q|^m e^{\sqrt{-1}\varphi}/aq^m;q)_m| \\ &\quad\times|(aq^m/\rho_0 q|q|^m e^{\sqrt{-1}\varphi};q)_\infty(\rho_0 q^2|q|^m e^{\sqrt{-1}\varphi}/a;q)_\infty| \\ &\quad\times|(\rho_0 q|q|^m e^{\sqrt{-1}\varphi}/q^m;q)_m(q^m/\rho_0|q|^m e^{\sqrt{-1}\varphi};q)_\infty|^{-1} \\ &\quad\times|(\rho_0 b|q|^m e^{\sqrt{-1}\varphi}/a;q)_\infty(\rho_0 x|q|^m e^{\sqrt{-1}\varphi};q)_1|^{-1}.\end{aligned} \tag{1}$$

For each factor in the right-hand side, we have the following estimates:

$$\begin{aligned}|(\rho_0 q^2|q|^m e^{\sqrt{-1}\varphi}/aq^m;q)_m| &= \prod_{j=0}^{m-1}\left|1-\frac{\rho_0 q^{2+j}|q|^m e^{\sqrt{-1}\varphi}}{aq^m}\right| \\ &\leqq \prod_{j=0}^{m-1}\left(1+\left|\frac{\rho_0 q^{2+j}}{a}\right|\right)\leqq\prod_{j=0}^{+\infty}\left(1+\left|\frac{\rho_0 q^{2+j}}{a}\right|\right),\end{aligned} \tag{2}$$

$$|(aq^m/\rho_0 q|q|^m e^{\sqrt{-1}\varphi};q)_\infty|\leqq\prod_{j=0}^{+\infty}\left|1-\frac{aq^{m+j}}{\rho_0 q|q|^m e^{\sqrt{-1}\varphi}}\right|\leqq\prod_{j=0}^{+\infty}\left(1+\left|\frac{aq^{j-1}}{\rho_0}\right|\right), \tag{3}$$

$$\begin{aligned}|(\rho_0 q^2|q|^m e^{\sqrt{-1}\varphi}/a;q)_\infty| &\leqq \prod_{j=0}^{+\infty}\left|1-\frac{\rho_0 q^{2+j}|q|^m e^{\sqrt{-1}\varphi}}{a}\right| \\ &\leqq \prod_{j=0}^{+\infty}\left(1+\left|\frac{\rho_0 q^{m+2+j}}{a}\right|\right)\leqq\prod_{j=0}^{+\infty}\left(1+\left|\frac{\rho_0 q^{2+j}}{a}\right|\right),\end{aligned} \tag{4}$$

$$\begin{aligned}|(\rho_0 q|q|^m e^{\sqrt{-1}\varphi}/q^m;q)_m| &= \prod_{j=0}^{m-1}\left|1-\frac{\rho_0 q^{1+j}|q|^m e^{\sqrt{-1}\varphi}}{q^m}\right| \\ &\geqq \prod_{j=0}^{m-1}(1-|\rho_0 q^{1+j}|)\geqq\prod_{j=0}^{+\infty}(1-|\rho_0 q^{1+j}|)>0,\end{aligned} \tag{5}$$

$$\begin{aligned}|(q^m/\rho_0|q|^m e^{\sqrt{-1}\varphi};q)_\infty| &= \prod_{j=0}^{+\infty}\left|1-\frac{q^{m+j}}{\rho_0|q|^m e^{\sqrt{-1}\varphi}}\right|\geqq\left|1-\frac{q^m}{\rho_0|q|^m e^{\sqrt{-1}\varphi}}\right|\prod_{j=1}^{+\infty}\left(1-\left|\frac{q^j}{\rho_0}\right|\right) \\ &\geqq\frac{1-\rho_0}{\rho_0}\prod_{j=1}^{+\infty}\left(1-\left|\frac{q^j}{\rho_0}\right|\right)>0,\end{aligned} \tag{6}$$

$$|(\rho_0 x|q|^m e^{\sqrt{-1}\varphi};q)_1|\geqq 1-|\rho_0 xq^m|\geqq 1-|\rho_0 x|>0, \tag{7}$$

$$\begin{aligned}|(\rho_0 b|q|^m e^{\sqrt{-1}\varphi}/a;q)_\infty| &= \prod_{j=0}^{+\infty}\left|1-\frac{\rho_0 bq^j|q|^m e^{\sqrt{-1}\varphi}}{a}\right| \\ &\geqq\prod_{j=0}^{+\infty}\left(1-\left|\frac{\rho_0 bq^{m+j}}{a}\right|\right)\geqq\prod_{j=0}^{+\infty}\left(1-\left|\frac{\rho_0 bq^j}{a}\right|\right)>0.\end{aligned} \tag{8}$$

By (1)-(8), there exists a positive number M such that

$$|f(\rho_m e^{\sqrt{-1}\varphi})|\leqq M\cdot\left|\frac{a}{q}\right|^m \qquad (0\leqq\varphi\leqq 2\pi). \tag{9}$$

Hence,

$$|I(C_m)| = \left|\frac{1}{2\pi\sqrt{-1}}\int_{C_m} f(t)\,dt\right| \leqq \frac{\rho_m}{2\pi}\int_0^{2\pi} |f(\rho_m e^{\sqrt{-1}\varphi})| \cdot |d\varphi|$$

$$\leqq \frac{\rho_m}{2\pi} \cdot \operatorname*{Max}_{0\leqq\varphi\leqq 2\pi} |f(\rho_m e^{\sqrt{-1}\varphi})| \cdot 2\pi \leqq \rho_m \cdot M \cdot \left|\frac{a}{q}\right|^m \leqq \rho_0 \cdot M \cdot |a|^m.$$

Consequently, for $|a|<1$, $|I(C_m)|\to 0$ if $m\to+\infty$.

(2) The proof is similar to (1). □

THEOREM. *Under the condition* $|b/a|<|x|<1$, $|q|<1$, *we have*

$$\sum_{n=-\infty}^{+\infty} \frac{(a;q)_n}{(b;q)_n} x^n = \frac{(ax;q)_\infty (q/ax;q)_\infty (b/a;q)_\infty (q;q)_\infty}{(x;q)_\infty (b/ax;q)_\infty (q/a;q)_\infty (b;q)_\infty}. \tag{10}$$

Proof. Lemmas 1 and 2 verify (10), if $|b/a|<|x|<1$, $|q|<1$, $|q|<|b|$, $|a|<1$. Analytic continuation implies it is valid for $|q|<1$, $|b/a|<|x|<1$. □

Acknowledgments. The author expresses his thanks to Professors Kazuhiko Aomoto and Yoshifumi Kato for useful suggestions.
