DEGENERATE HOPF BIFURCATION AND NERVE IMPULSE. PART II*

ISABEL SALGADO LABOURIAU†

Abstract. The bifurcation from equilibrium of periodic solutions of the Hodgkin and Huxley equations for the nerve impulse is studied. In earlier work singularity theory techniques were used to establish that these equations have a branch of periodic solutions undergoing two Hopf bifurcations, and the equations were conjectured to be equivalent to a member of a one-parameter family of generalized Hopf bifurcation problems. Here the invariants for equivalence to this family and the value of the modal parameter are computed (see [W. W. Farr et al., "Degenerate Hopf bifurcation formulas and Hilbert's 16th problem," *SIAM J. Math. Anal.*, 20 (1989), pp. 13-30]). The value of this parameter determines the type of bifurcation, and in this way it is decided which of the proposed bifurcation diagrams are actually to be found. Thus a topological description of periodic orbits of the Hodgkin and Huxley equations near the equilibrium solution is obtained. In this way, a periodic solution branch is found that does not arise through a classical Hopf bifurcation.

Key words. Hopf bifurcation, Hodgkin-Huxley equations, nerve impulse

1. Introduction. It is well known [9] that many nerve cells generate trains of impulses as a response to a constant stimulus. In this paper we describe periodic solutions of the clamped Hodgkin and Huxley equations for the nerve impulse (HH), a system of four nonlinear ordinary differential equations, that contain several auxiliary parameters [5]. As in an earlier article [10], here we study the equations HH as a bifurcation problem, regarding the stimulus intensity **I** as a bifurcation parameter. We also describe the dependence of the periodic solutions on some of the other parameters involved in HH, such as the temperature T and the maximum sodium conductance $\bar{g}_{Na}$ that measures the maximum permeability of the nerve cell membrane to Na^+ ions.

Both here and in [10] we have studied the effect of varying $\bar{g}_{Na}$ away from the value, here called *normal*, of 120 m.mho/cm^2 obtained by Hodgkin and Huxley [5] in experiments on the squid giant axon; all other values of $\bar{g}_{Na}$ are called *perturbed* and the HH equations with $\bar{g}_{Na}$ different from normal are referred to as *perturbed* HH. The reader should not be deceived by the word normal; the actual value of $\bar{g}_{Na}$ varies from cell to cell. Hodgkin and Huxley [5] report measurements of $\bar{g}_{Na}$ in the interval [65, 260] m.mho/cm^2 in normal giant squid axons. This variability may be largely due to difficulties in the measurement of $\bar{g}_{Na}$ in experiments, but all the same it makes sense to ask what the equations yield for values different from the average of 120 m.mho/cm^2. The maximum sodium conductance can also be modified by the experimental conditions; low concentrations of local anesthetics or tetrodoxin have the effect of lowering $\bar{g}_{Na}$ and do not seem to affect the conductance of other ions (see [9, Chap. 11]).

In this article, we obtain qualitative amplitude diagrams for the periodic solutions of the perturbed HH (see Figs. 3 and 7) showing the response of a nerve cell to a steadily applied current. This corresponds to a usual experimental procedure ([9] and references therein).

In § 2 we describe the results of [10] on the temperature dependence of the amplitude diagrams and the conjecture presented there concerning the hidden organizing centre for HH; we also give a naive description of the singularity theory concepts used (we refer the reader to [2] for the rigorous construction and for proofs).

The main results are presented in § 3 where the invariants for generalized Hopf bifurcation are evaluated numerically for HH. We determine which of the two possible cases conjectured in [10] takes place and we discuss the behavior near the hidden organizing center, thus obtaining a qualitative description of the amplitude of periodic solutions of HH. We also show that around a critical temperature T_c, the HH equations must have a branch of periodic solutions that does not arise through a classical Hopf bifurcation. These solutions are not easy to find in a numerical integration of the equations—in order to find them we have to know where they are.

Amplitude diagrams for low $\bar{g}_{Na}$ are described in § 4, with a discussion of the possible form of transition from the hidden organizing center to this second family of bifurcation problems.

2. Preliminary results and definitions. In what follows we use the notation and sign conventions of [10]. The perturbed HH equations have a unique temperature-independent, steady-state solution for each value of **I**. This is only true for values of the ionic equilibrium voltages $\bar{V}_{ion}$ close to those determined in [5], as is shown in [6]. After a change of variables, we introduced in [10] a new bifurcation parameter λ, so that for all values of λ the origin of $\mathbb{R}^4$ is a steady-state and $f(\lambda) = \mathbf{I}$ is a monotonically *decreasing* function. In this way we eliminate one error factor in numerical computations since we no longer compute the coordinates of the steady-state as a function of the parameters, and we may think of HH as a family of ordinary differential equations $\dot{y} = \mathrm{HH}(y, \lambda)$ with HH: $\mathbb{R}^5 \to \mathbb{R}^4$ and HH $(0, \lambda) = 0$ where HH also depends on the parameters T and $\bar{g}_{Na}$.

For fixed T and $\bar{g}_{Na}$ and below a critical temperature $T_c(\bar{g}_{Na})$, there are two values $\lambda_1 < \lambda_2$ of the bifurcation parameter where the linearization of HH at the origin has a pair of eigenvalues crossing the imaginary axis transversely. Therefore, by the Hopf bifurcation theorem [7], two distinct periodic solution branches emerge from the equilibrium solution at $(0, \lambda_1)$ and $(0, \lambda_2)$.

For $T > T_c$ no Hopf bifurcation was observed. At $T = T_c$ the two bifurcations coalesce at $\lambda_1 = \lambda_2 = \lambda_c$. We call $(0, \lambda_c)$ a *generalized Hopf bifurcation point*; at this point the linearization of HH has a pair of purely imaginary eigenvalues $\pm i\omega$; all other eigenvalues are real and negative, but some of the other hypotheses in the classical Hopf theorem [7] are violated.

Generalized Hopf bifurcation is studied in [1], [2] (see also [0]), for a system of ordinary differential equations

$$\dot{y} = g(y, \lambda), \quad g(0, \lambda) = 0, \quad y \in \mathbb{R}^n, \quad \lambda \in \mathbb{R} \tag{2.1}$$

such that $D_y g\ (0, 0)$ has simple eigenvalues $\pm i\omega$ and no other eigenvalues of the form $\pm ik\omega$ with $k \in \mathbb{Z}$. The Lyapunov-Schmidt reduction and symmetry considerations are used to represent periodic solutions of (2.1) as the solutions of an equation of the following form:

$$x\mathbf{a}(x^2, \lambda) = 0, \quad \mathbf{a}: \mathbb{R}^2 \to \mathbb{R}, \quad x \geqq 0. \tag{2.2}$$

Intuitively the reduction amounts to rewriting the original vector field locally in "polar coordinates" on a suitable λ-parametrized family of two-dimensional invariant submanifolds of $\mathbb{R}^n$, with periodic orbits corresponding, for each λ, to solutions of $\dot{r} = r\mathbf{a}(r^2, \lambda) = 0$. The steady-state solution is represented by the $x = 0$ solution of (2.2),

and points where periodic orbits bifurcate from it are multiple roots of (2.2) at $x=0$. The set $\{(x, \lambda)\colon x\mathbf{a}(x^2, \lambda)=0\}$ is called a *bifurcation diagram*, and its graph represents a qualitative amplitude diagram for periodic solution branches.

As an example, a vector field (2.1) satisfying the hypotheses of the Hopf theorem [7] at $\lambda=\lambda_c$ after reduction yields a map $\mathbf{a}(x^2, \lambda)$ that for $u=x^2$ satisfies:

$$\mathbf{a}(0, \lambda_c)=0, \quad \mathbf{a}_u=\frac{\partial \mathbf{a}}{\partial u}(0, \lambda_c)\neq 0, \quad \mathbf{a}_\lambda=\frac{\partial \mathbf{a}}{\partial \lambda}(0, \lambda_c)\neq 0. \tag{2.3}$$

Therefore near $(0, \lambda_c)$ there is a unique solution φ to the equation $\mathbf{a}(u, \varphi(u))\equiv 0$ with $\varphi(0)=\lambda_c$, $\varphi'(0)=-\mathbf{a}_u/\mathbf{a}_\lambda$; thus (2.2) has exactly two solution branches through $(0, \lambda_c)$ given by $x=0$ and by $\lambda(x)=\varphi(x^2)$. If $\varphi'(0)<0$, then $\lambda(x)\leqq\lambda_c$ for x near 0 and (2.1) has a periodic solution of nonzero amplitude near $(0, \lambda_c)$ for each $\lambda<\lambda_c$ (Fig. 1(a)). Thus the sign of $\varphi'(0)$ determines the *direction of bifurcation* of periodic solutions of (2.1).

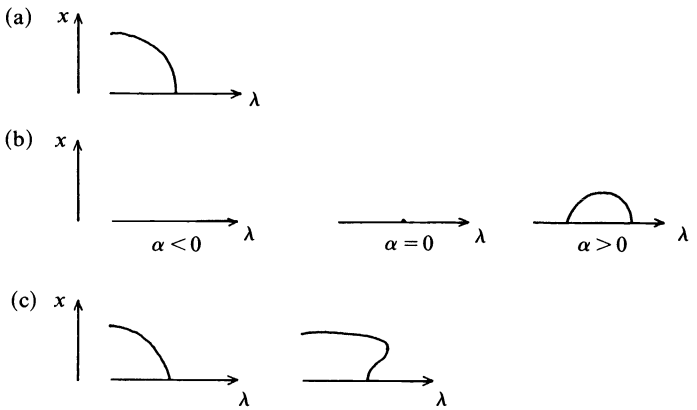

FIG. 1. *Examples of bifurcation diagrams for generalized Hopf bifurcation, ordinates always standing for amplitude* (x): (a) *Classical Hopf bifurcation* (2.3). (b) *Generic perturbation (unfolding) of the codimension* 1 *Hopf bifurcation* (2.7) *in the case* $\mathbf{c}_u>0$, $\mathbf{c}_\lambda=0$, $\mathbf{c}_{\lambda\lambda}>0$. (c) *Generic perturbation (unfolding) of the codimension* 1 *Hopf bifurcation in the case* $\mathbf{h}_u=0$, $\mathbf{h}_\lambda>0$, $\mathbf{h}_{uu}<0$.

The Lyapunov-Schmidt reduction uses the implicit function theorem in a suitable function space and therefore all the results on generalized Hopf bifurcation mentioned here are local both in the variables and in the parameters. In order to avoid repeating phrases like "in some neighborhood of the point $(0, \lambda_c)$," we refer to the *germ of a map* f at a point p—the class of all maps that agree with f in some neighborhood of p. Similarly, we may define the *germ of a set* S at p as the class of all sets that coincide with S in some neighborhood of p.

The germs at $(0, \lambda_c)$ of two maps $\mathbf{a}$, $\bar{\mathbf{a}}$ of the form (2.2), obtained by Lyapunov-Schmidt reduction, are called *contact equivalent* when there are smooth germs $T(x, \lambda)$, $X(x, \lambda)$ and $\Lambda(\lambda)$ transforming one into the other, i.e.,

$$x\mathbf{a}(x^2, \lambda)=T(x^2, \lambda)\circ[x\bar{\mathbf{a}}(X^2(x^2, \lambda)x, \Lambda(\lambda)\lambda)] \tag{2.4}$$

with $T\colon \mathbb{R}^2\to\mathbb{R}$, $T(0, 0)\neq 0$, $X(0, 0)>0$, and $\Lambda(0)>0$. The new parameter Λ does not depend on x, so two systems such as (2.1) reducing to $\mathbf{a}$ and $\bar{\mathbf{a}}$ have the same number of periodic solutions near $y=0$ for corresponding values of λ near λ_c. In other words,

if two equations reduce to contact equivalent maps, the sets of their periodic orbits can be smoothly transformed into each other (see [10]). For instance, any two germs at $(0, 0)$ of maps $\mathbf{a}, \bar{\mathbf{a}}: \mathbb{R}^2 \to \mathbb{R}$ satisfying (2.3) will be contact equivalent, provided their partial derivatives at $(0, 0)$ have the same sign (see [1]).

Another concept used here is that of *universal unfolding* of a germ $\mathbf{a}$, a parametrized family of germs that exhibit all the possible bifurcation diagrams present in a neighborhood of $\mathbf{a}$; the *codimension* of $\mathbf{a}$ is the minimum number of parameters necessary to obtain a universal unfolding. For rigorous singularity theory results and definitions we refer the reader to [1] and [2], where some methods for computing codimensions and unfoldings are given.

Using singularity theory techniques, the germs of problems of the form (2.2) have been classified up to contact equivalence in [1] and [2], where a representative in simple polynomial form is given for each contact class occurring generically in three-parameter families of generalized Hopf bifurcations and for its universal unfolding. Each contact class is characterized in [1] and [2] by necessary and sufficient conditions on the Taylor expansion of $\mathbf{a}(x^2, \lambda)$ around the bifurcation point $(0, \lambda_c)$. Explicit formulae for the calculation of derivatives of $\mathbf{a}$ up to third order from those of the original vector field can be found in [0].

For example, if the germ at $(0, 0)$ of $\mathbf{a}: \mathbb{R}^2 \to \mathbb{R}$ satisfies

$$\begin{aligned} &\mathbf{a}(0,0) = 0 \quad \text{and for } u = x^2, \\ &\mathbf{a}_u = \frac{\partial \mathbf{a}}{\partial u}(0,0) > 0, \quad \mathbf{a}_\lambda = \frac{\partial \mathbf{a}}{\partial \lambda}(0,0) = 0, \quad \mathbf{a}_{\lambda\lambda} = \frac{\partial^2 \mathbf{a}}{\partial \lambda^2}(0,0) > 0, \end{aligned} \tag{2.5}$$

then it can be shown [1], [2] that the germ of $\mathbf{a}(x^2, \lambda)$ is contact equivalent at $(0, 0)$ to

$$\mathbf{c}(x^2, \lambda) = x^2 + \lambda^2. \tag{2.6}$$

Since $\mathbf{c}(x^2, \lambda) = 0$ only when $x = \lambda = 0$, the germ of the solution set of both $x\mathbf{c}\,(x^2, \lambda) = 0$ and of $x\mathbf{a}(x^2, \lambda) = 0$ is the λ-axis. If $\mathbf{a}$ has ben obtained from a system like (2.1), this means there are no periodic solutions near $(0, 0)$.

The contact class of (2.6) is not *structurally stable.* An arbitrarily small perturbation of the form

$$\mathbf{C}_\alpha(x^2, \lambda) = \mathbf{c}(x^2, \lambda) - \alpha = x^2 + \lambda^2 - \alpha, \qquad \alpha \in \mathbb{R} \tag{2.7}$$

is not contact equivalent to $\mathbf{c}$ for $\alpha \neq 0$; the set $\mathbf{C}_\alpha = 0$ is either a circle of radius $\sqrt{\alpha}$ or the empty set. If $\mathbf{C}_\alpha$ is the reduced form of a vector field, then for each $\alpha > 0$ it undergoes two classical Hopf bifurcations at $\lambda = \pm\sqrt{\alpha}$ (see Fig. 1(b)). For $\alpha < 0$ the periodic solution set is still trivial (steady-state only) but $\mathbf{C}_\alpha = 0$ has no solutions, and thus $\mathbf{C}_\alpha$ with $\alpha \neq 0$ is not contact equivalent to $\mathbf{c}$. Moreover, for $\alpha \neq 0$, each germ (2.7) is structurally stable and (2.6) is not. It can be shown [1] that the germ (2.6) has codimension 1 and the family of bifurcation problems $\mathbf{C}_\alpha$ is a universal unfolding for it. The one-parameter family of bifurcation problems (2.7) is structurally stable as a whole, although this is not true of any germ satisfying (2.5).

Let $x\mathbf{h}(x^2, \lambda)$ be the germ of the perturbed HH after reduction. We have computed the first-order derivatives of $\mathbf{h}$ and established the following results, appearing in [10].

(A) At the critical temperature $T_c(\bar{g}_{\mathrm{Na}})$ where the two bifurcation points coalesce, we have $\mathbf{h}_\lambda = \partial/\partial\lambda\, \mathbf{h}(0, \lambda_c) = 0$ for every choice of $\bar{g}_{\mathrm{Na}}$ in the interval [85, 130] (we will omit units from now on). For normal HH if $\mathbf{h}_{\lambda\lambda} > 0$ then $\mathbf{h}$ is equivalent to the generalized Hopf bifurcation germ (2.6). The effect of small temperature variations on the zero

set of $\mathbf{h}$ is the same as that of variations in the value of α over the zero set of (2.7), as in Fig. 1(b). Thus for $T < T_c$, HH has a single stable periodic solution branch undergoing two classical Hopf bifurcations.

(B) For normal HH, the direction of bifurcation changes at one of the Hopf bifurcation points $(0, \lambda_2)$ at a lower temperature, T_1, following a change in the sign of $\partial/\partial u\, \mathbf{h}(0, \lambda_2) = \mathbf{h}_u$. The corresponding periodic solution branch loses stability. If at this temperature $\mathbf{h}_{uu} \neq 0$, then the system is contact equivalent to another generalized Hopf bifurcation germ, also of codimension 1. The study of its universal unfolding, as in the case above, provides the description of the amplitude of periodic solutions (Fig. 1(c) for the case $\mathbf{h}_{uu} < 0$, $\mathbf{h}_\lambda > 0$) as T is varied around T_1. Clearly, the neighborhood of the bifurcation point where the contact equivalence holds does not include the other (nondegenerate) Hopf bifurcation point of HH present at the same temperature.

In both cases above, the study of HH at the degenerate Hopf bifurcation points provides additional information about periodic solutions at nearby parameter values. In case (A) it shows that the two Hopf bifurcations involve the same periodic solution branch, a nontrivial observation in a four-dimensional phase space. In the second case, for $T < T_1$, the classical Hopf bifurcation theorem shows the existence of unstable periodic solutions for $\lambda < \lambda_2$. Thus the presence of a degeneracy not only explains the transition from one type of diagram to another, it also makes the analysis "more global." Here, a point in parameter space where a degenerate Hopf bifurcation occurs will be called an *organizing center* for the equations.

(C) For the perturbed HH the function

$$\bar{g}_{\mathrm{Na}} \to \mathbf{h}_u(\bar{g}_{\mathrm{Na}}) = \mathbf{h}_u(0, \lambda_c) \quad \text{at } T = T_c(\bar{g}_{\mathrm{Na}}) \quad (\text{where } \mathbf{h}_\lambda = 0) \tag{2.8}$$

changes sign twice in the interval [85, 130] and one of its zeros lies within ten percent of the normal value of $\bar{g}_{\mathrm{Na}}$. This point we called a *hidden organizing center* for the equations—it is hidden in the sense that HH had to be perturbed in order to find it.

Even if this value of $\bar{g}_{\mathrm{Na}}$ were never assumed in practice, we would expect the study of the degeneracy to bring together the two descriptions (A) and (B) above, in the same way local information about the two classical Hopf bifurcations in (A) was put together by the study of (2.7). At the hidden organizing center, HH should be equivalent after reduction to a germ containing the two original ones in its universal unfolding, i.e., a family of germs (A_α) such that each first derivative of (A_α) is zero for values of α arbitrarily close to zero. It is easy to see that this is possible only in a structurally stable family if the parameter α is at least two-dimensional.

The simplest (lowest codimension) problems containing in its universal unfolding both germs mentioned in (A) and (B) above are members of a family of codimension 3 problems. The family is characterized by zero first-order derivatives at the organizing center, by the signs of its second-order derivatives, as well as by the value of a modal parameter $\mathbf{b}$. We discussed the geometry of the periodic solution branches for different values of $\mathbf{b}$ when we conjectured in [10] that HH is contact equivalent to this family at the zero of $\mathbf{h}_u(\bar{g}_{\mathrm{Na}})$ closest to the normal value of 120.

In the next section we present the result of the numerical evaluation for HH of the nondegeneracy conditions for equivalence to the one-parameter family discussed above, and of the calculation of the modal parameter $\mathbf{b}$. Our goal is to obtain a description of all nonequivalent bifurcation diagrams that appear in HH at temperatures close to T_c, a subset of those on the universal unfolding of $\mathbf{h}$. As the value of the modal parameter determines the type of bifurcation appearing on the unfolding of $\mathbf{h}$, in this way we decide which of the proposed bifurcation diagrams are actually to be found

in HH. This is discussed in § 3 for the hidden organizing center, and in § 4 for the second zero of $\mathbf{h}_u(\bar{g}_{\mathrm{Na}})$.

3. Diagrams near the hidden organizing center. The hidden organizing center for HH is a point in parameter space where the reduction $\mathbf{h}$ of the perturbed HH satisfies

$$\mathbf{h}(0, \lambda_c) = \mathbf{h}_u(0, \lambda_c) = \mathbf{h}_\lambda(0, \lambda_c) = 0 \quad \text{with } u = x^2. \tag{3.1}$$

We conjectured in [10] that around this point $\mathbf{h}$ is equivalent to a member of the family

$$\mathbf{a}_{\mathbf{b}}(u, \lambda) = \varepsilon u^2 + 2\mathbf{b}\lambda u + \delta\lambda^2 \tag{3.2}$$

studied in [1] and [12]. It is shown in [1] that a germ $\bar{\mathbf{a}}$ is contact equivalent to (3.2) if and only if it satisfies

$$\begin{aligned} &\bar{\mathbf{a}}(0, \lambda_c) = \bar{\mathbf{a}}_u(0, \lambda_c) = \bar{\mathbf{a}}_\lambda(0, \lambda_c) = 0, \\ &\bar{\mathbf{a}}_{uu}(0, \lambda_c) = \bar{\mathbf{a}}_{uu} \neq 0 \neq \bar{\mathbf{a}}_{\lambda\lambda}(0, \lambda_c) = \bar{\mathbf{a}}_{\lambda\lambda}, \quad \text{and} \\ &\mathbf{b} = \bar{\mathbf{a}}_{u\lambda} / |\bar{\mathbf{a}}_{uu}\bar{\mathbf{a}}_{\lambda\lambda}|^{1/2} \neq 0 \\ &\text{with } \delta\mathbf{b}^2 \neq 1 \quad \text{where } \varepsilon = \operatorname{sign}(\bar{\mathbf{a}}_{uu}), \quad \delta = \operatorname{sign}(\bar{\mathbf{a}}_{\lambda\lambda}). \end{aligned} \tag{3.3}$$

The numbers $\varepsilon\delta$ and $\mathbf{B} = \varepsilon\mathbf{b}$ form a complete set of invariants for the family (3.2) under contact equivalence [11], i.e., two members of this family are contact equivalent if and only if $\varepsilon\delta$ and $\mathbf{B}$ are the same for them. The situation differs markedly from the example of § 2, where a similar set of conditions defined a single contact equivalence class. Here each choice of signs in the second-order derivatives of $\bar{\mathbf{a}}$ defines a continuum of nonequivalent bifurcation problems.

Using the methods of [2] it can be shown that (3.2) has universal unfolding given by

$$A(u, \lambda, \alpha, \beta, \mathbf{b}) = \varepsilon u^2 + 2\mathbf{b}\lambda u + \delta\lambda^2 + \operatorname{sign}(\mathbf{b})\beta\lambda + \alpha. \tag{3.4}$$

Therefore, for any sufficiently small perturbation of a germ satisfying (3.3) there are smooth changes of coordinates of the form (2.4) transforming it into one of the germs (3.4) for some choice of α, β, and $\mathbf{b}$. At $\alpha = \beta = 0$ the family (3.4) coincides with (3.2).

The definition of contact equivalence can be weakened so as to obtain a discrete classification of the family (3.2). We define *topological contact equivalence* in the same way as the (smooth) contact equivalence (2.4), with continuity substituted for smoothness (see [2]). Two germs belonging to the same equivalence class (called *modal class*) have homeomorphic bifurcation diagrams.

Let $(3.2)_\pm$ be the family (3.2) with $\varepsilon\delta = +1$ or -1, respectively. Under topological contact equivalence, $(3.2)_+$ splits into four equivalence classes (called *modal classes*), corresponding to values of $\mathbf{B}$ in the intervals $]-\infty, -1[$; $]-1, 0[$; $]0, 1[$, and $]1, +\infty[$. The solutions of $A(u, \lambda, \alpha, \beta, \mathbf{b}) = 0$ are either ellipses or the empty set in the (u, λ)-plane for $0 < |\mathbf{B}| < 1$ (Fig. 2) or hyperbolas for $|\mathbf{B}| > 1$ (Fig. 3). In the unfolding of $(3.2)_-$, only two modal classes occur corresponding to $\mathbf{B} > 0$ and $\mathbf{B} < 0$, and the solution to $A(u, \lambda, \alpha, \beta, \mathbf{b}) = 0$ is always a hyperbola in the (u, λ)-plane (Fig. 7).

By comparing the bifurcation diagrams for (3.4) to the results summarized in § 2 as well as to those in [4] and [13], we conjectured that $\varepsilon\delta = +1$, and $\mathbf{B} < 0$ for HH. Besides checking the conjecture numerically, we obtain here an estimate of $\mathbf{B}$, and thus of the modal class of $\mathbf{h}$.

The derivatives $\mathbf{h}_\lambda$ and $\mathbf{h}_u$ are simultaneously zero for $\bar{g}_{\mathrm{Na}} = \bar{g}_c$ in the interval [109, 110], and around this point we have the values of Table 1.

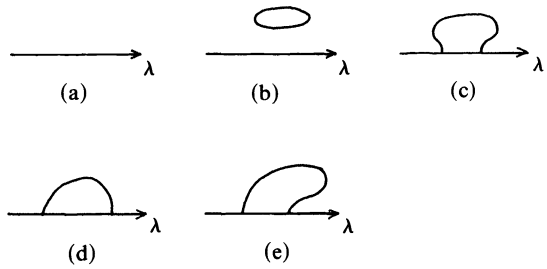

FIG. 2. *Bifurcation (or amplitude) diagrams for stable germs in the universal unfolding* (3.4) *of* $(3.2)_+$ *with* $-1<\mathbf{B}<0$, *for the following parameter values*: (a) $\alpha>\beta^2/4$ *or* $\alpha>\beta^2/4(\mathbf{B}-1)$ *and* $\beta<0$; (b) $\beta>0$ *and* $\beta^2/4(\mathbf{B}-1)<\alpha<\beta^2/4$; (c) $\beta>0$ *and* $0<\alpha<\beta^2/4(\mathbf{B}-1)$; (d) $\beta<0$ *and* $0<\alpha<\beta^2/4(\mathbf{B}-1)$; *and* (e) $\alpha<0$.

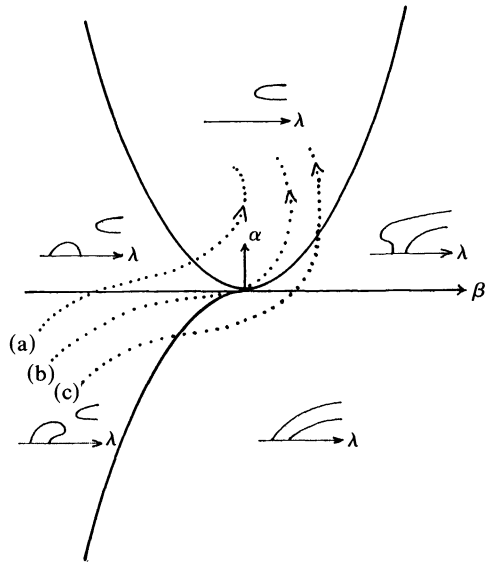

FIG. 3. *The universal unfolding* (3.4) *of* $(3.2)_+$ *with* $B<-1$. *Each bifurcation (or amplitude) diagram is drawn inside the region in* (α,β)*-plane where it occurs*; *the* λ *axis is the steady-state in each case. Dotted lines represent* HH *as temperature-parametrized curves on the unfolding of* $(3.2)_+$, *with temperature increasing as indicated by the arrows*: (a) $\bar{g}_{Na}>\bar{g}_c$; (b) $\bar{g}_{Na}=\bar{g}_c$; and (c) $\bar{g}_{Na}<\bar{g}_c$.

TABLE 1

$\bar{g}_{Na}$ m.mho/cm^2	λ_c mV	$\mathbf{I}(\lambda_c)$ mA/cm^2	$T_c(\lambda_c)$ °C
109	−15.97	74.06	26.278
110	−16.01	74.22	26.546

Numerical estimates of the second-order derivatives of $\mathbf{h}$ at $T_c(\bar{g}_{Na})$ were obtained for several values of $\bar{g}_{Na}$, by using the formulae of [0], a correction to those of § 5 of [1] for the case when the imaginary eigenvalues are $\pm i\omega$, with $\omega\neq 1$. Thus the numerical results of Table 1 differ both from the preliminary calculations presented in [2] and from those in [11], but the qualitative behavior remains the same. For $\bar{g}_{Na}$ in the interval [85, 130] we have found the following:

(D) $\mathbf{h}_{u\lambda}$ is always negative and decreases with $\bar{g}_{Na}$ (Fig. 4).

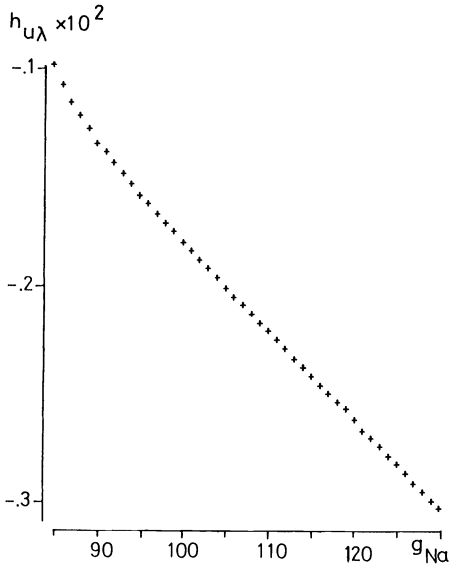

FIG. 4. *The derivative* $\mathbf{h}_{u\lambda}$ *at the point where there is a single generalized Hopf bifurcation, as a function of* $\bar{g}_{Na}$, *for the perturbed Hodgkin and Huxley equations.*

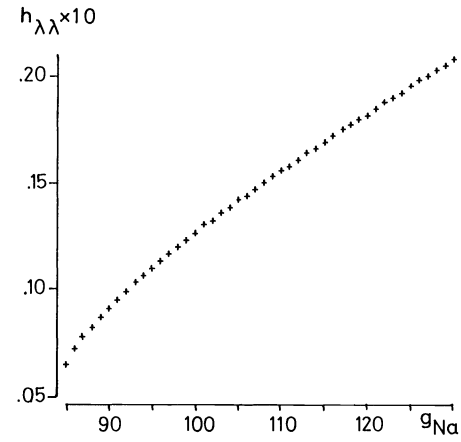

FIG. 5. *The derivative* $\mathbf{h}_{\lambda\lambda}$ *at the point where there is a single generalized Hopf bifurcation, as a function of* $\bar{g}_{Na}$, *for the perturbed Hodgkin and Huxley equations.*

(E) $\mathbf{h}_{\lambda\lambda}$ is always positive and increases with $\bar{g}_{Na}$ (Fig. 5).

(F) $\mathbf{h}_{uu}$ increases with $\bar{g}_{Na}$ and changes sign for $\bar{g}_{Na}$ in the interval]96, 97[(Fig 6).

We have confirmed the following conjecture presented in [10]: at the hidden organizing center, conditions (3.4) are satisfied, and therefore *the perturbed* HH, *in reduced form, are equivalent to a member of the family* (3.2) *with* $\varepsilon = +1 = \delta$.

The modal parameter $\mathbf{b}$ was found to be $\mathbf{b} = -7.0$ at $\bar{g}_{Na} = 109.0$, and $\mathbf{b} = -6.8$ at $\bar{g}_{Na} = 110.0$, where both values are rounded to the number of digits shown, and all digits are believed to be correct. Thus we have also determined that *at the hidden organizing center the reduced* HH *are in the modal class* $\mathbf{B} < -1$ *of the family* $(3.2)_+$.

For $\bar{g}_{Na}$ and T near $\bar{g}_c$ and $T_c(\bar{g}_c)$, respectively, the perturbed HH are equivalent to one of the germs (3.4). In this way we can visualize HH as a surface on $\mathbb{R}^3$ ($(\alpha, \beta, \mathbf{b})$-space) fibered by the T-parametrized curves corresponding to fixed values of $\bar{g}_{Na}$. A zero of $\mathbf{h}_u(\bar{g}_{Na}, T_c(\bar{g}_{Na}))$ will correspond to a curve through the organizing

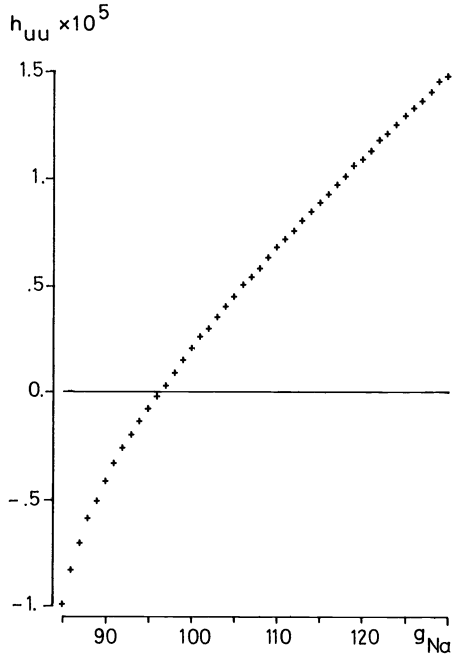

FIG. 6. *The derivative* $\mathbf{h}_{uu}$ *at the point where there is a single generalized Hopf bifurcation, as a function of* $\bar{g}_{Na}$, *for the perturbed Hodgkin and Huxley equations.*

center $(0, 0, \mathbf{b})$, if we recall that $\mathbf{h}_\lambda(\bar{g}_{Na}, T_c(\bar{g}_{Na}))$ is always zero. We have represented in Fig. 3 the perturbed HH as T-parametrized curves on the unfolding of $(3.2)_+$ for $\mathbf{B} < -1$. Each persistent bifurcation diagram is drawn inside the corresponding region in the (α, β)-plane. The **B** direction has been omitted since bifurcation diagrams look the same along it, due to the topological contact equivalence.

The curves representing HH in Fig. 3 were obtained by inspecting the bifurcation diagrams for $(3.2)_+$ and comparing them to data on the direction of bifurcation from [10], [11], and [13] and were confirmed for $\bar{g}_{Na} = 100$.

We find that for $\bar{g}_{Na} = \bar{g}_c$ only two persistent bifurcation diagrams are present. For $T < T_c$ there is a single periodic solution branch undergoing two nondegenerate Hopf bifurcations in the same direction as observed in (B) of § 2; this branch disappears at $T = T_c(\bar{g}_c)$. Both bifurcation diagrams contain a solution branch isolated from the trivial solution $x = 0$.

The two persistent bifurcation diagrams described above occur for normal HH along with a third diagram where the periodic solution branches grow toward each other, corresponding to the situation described in (A) of § 2. In this way our knowledge of the hidden organizing center allows us to put together the partial information of § 2, (A) and (B).

All diagrams for $\bar{g}_{Na} \geqq \bar{g}_c$ contain a branch of solutions not connected to the trivial solution $x = 0$, a characteristic of the modal classes $|\mathbf{B}| > 1$ with $\varepsilon\delta = 1$. Indeed it is natural to find two disconnected branches in some of the bifurcation diagrams since the zeros of $(3.4)_+$ are hyperbolas in the (u, λ)-plane in this case. This is not possible for $|\mathbf{B}| < 1$, where $A(u, \lambda, \alpha, \beta, \mathbf{b}) = 0$ on a bounded set.

The isolated solution branch has never been found in a numerical integration of HH. Since these solutions do not arise through a classical Hopf bifurcation, they could

easily be missed in a numerical tracing of the solutions. It is also possible, however, that at the normal value of $\bar{g}_{Na}$ the isolated branch has either disappeared through some global bifurcation not captured by the Lyapunov-Schmidt reduction, or moved to a region of parameter space without physiological meaning. On the other hand, the presence of this solution branch may explain the damped oscillations observed both numerically [5], [8] and in experiments described in [8], [3].

For $\bar{g}_{Na} < 109$ the following two new types of diagram appear. As T increases the two unconnected branches meet and form two periodic solution branches arising through Hopf bifurcation; a further increase of T yields a change in the direction of bifurcation, before the two Hopf bifurcation points coalesce. This change of direction affects the first Hopf bifurcation point $(0, \lambda_1)$ in contrast to the findings of [10] for normal HH (cf. (B) of § 2). For $\bar{g}_{Na} = 100$ the first-order derivatives of $\mathbf{h}$ at nondegenerate Hopf bifurcation points have been calculated, confirming the change in the direction of bifurcation and thus providing furher evidence for the position of the T-parametrized curve.

Changes in the direction of bifurcation would be observed experimentally as the appearance of hysteresis at the onset of periodic behavior around $\lambda = \lambda_1$. Recall that the parameter λ is a decreasing function of stimulus intensity **I**. When $\bar{g}_{Na} < \bar{g}_c$, a cell under overstimulation would stop its repetitive activity at a value of $\mathbf{I} > f(\lambda_1)$ when **I** increases. If **I** were subsequently decreased, then firing would resume at $\mathbf{I} = f(\lambda_1)$. For $\bar{g}_{Na} \geqq \bar{g}_c$ there is hysteresis at $T < T_c(\bar{g}_{Na})$, around 28°C for normal $\bar{g}_{Na}$. For $\bar{g}_{Na} < \bar{g}_c$, hysteresis is also obtained at high temperature values.

Hysteresis at the offset of repetitive firing for an overstimulated cell has been observed in experiments on squid axons bathed in low Ca^{++} sea water [3]. The reduction in $[Ca^{++}]$ lowers the potential outside the cell membrane and is thus equivalent to the effect of depolarization; a smaller stimulus will be required in order to obtain the same response from the nerve cell [9]. The effective stimulus that can be applied without damaging the cell will be larger and high stimulation effects may become experimentally observable. However, the HH equations have to be modified if they are to describe the new experimental situation [8].

4. Bifurcation diagrams for small $\bar{g}_{Na}$. The derivative $\mathbf{h}_u$, computed for each value of $\bar{g}_{Na}$ at the temperature where the two Hopf bifurcation points coalesce, has a second zero for $\bar{g}_{Na}$ in the interval $]89, 90[$. This singularity is probably of less significance for the nerve impulse than the one of the previous section, since $\bar{g}_{Na}$ is far from the normal value, although it is still physiologically meaningful. At this point, the characteristics are (see Figs. 4–6):

$$\begin{aligned} &\mathbf{h}_u = \mathbf{h}_\lambda = 0, \\ &\mathbf{h}_{uu} < 0, \quad \mathbf{h}_{u\lambda} < 0, \quad \mathbf{h}_{\lambda\lambda} > 0. \end{aligned} \tag{4.1}$$

Again, $\mathbf{h}$ is equivalent to a member of the family (3.2). Around this point the data are as shown in Table 2.

TABLE 2

$\bar{g}_{Na}$ m.mho/cm^2	λ_c mV	$\mathbf{I}(\lambda_c)$ mA/cm^2	$T_c(\lambda_c)$ °C	ε	δ	$\varepsilon\delta$	$\mathbf{B} = \varepsilon\mathbf{b}$
89	−14.61	65.39	17.500	−1	+1	−1	+6.0
90	−14.72	66.22	18.264	−1	+1	−1	+6.8

At this second zero $\bar{g}_p$ of $\mathbf{h}_u$, the perturbed HH are equivalent to a member of the family $(3.2)_-$, in the modal class $\mathbf{B}>0$. The persistent bifurcation diagrams for the germs in the unfolding of $(3.2)_-$ are shown in Fig. 7, where the perturbed HH are represented as a T-parametrized curve on (α, β)-space for values of $\bar{g}_{Na}$ near $\bar{g}_p$.

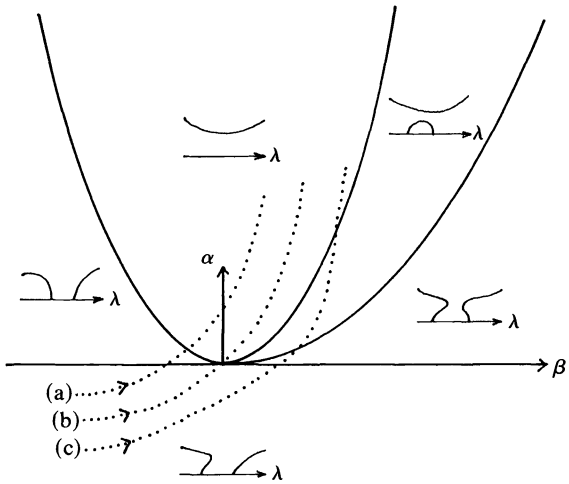

FIG. 7. *The universal unfolding* (3.5) *of* $(3.2)_-$ *with* $\mathbf{B}>0$. *Bifurcation diagrams are drawn inside the regions in* α-β-*space where they occur; the* λ *axis is the steady-state in each diagram. Dotted lines represent* HH *as temperature-parametrized curves on the unfolding of* $(3.2)_-$, *with temperature increasing as indicated by the arrows*: (a) $\bar{g}_{Na}>\bar{g}_p$; (b) $\bar{g}_{Na}=\bar{g}_p$; *and* (c) $\bar{g}_{Na}<\bar{g}_p$.

The diagrams present on the unfolding of $(3.2)_-$ differ markedly from those discussed in § 2. First, most diagrams of Fig. 7 exhibit two Hopf bifurcations that generate disjoint periodic solution branches. Second, for all diagrams in the unfolding of $(3.2)_+$, the set of bifurcation parameter values for which the equation $\mathbf{a}(u, \lambda)=0$ has a nonzero solution is bounded below. This is not true of any diagram in Fig. 7, where in all cases there is a periodic solution branch that can be extended indefinitely in the $\lambda \to -\infty$ direction. These differences may be due to global bifurcations, but it is probable that they are simply an artifact of the local analysis; the methods used here provide a local description of the bifurcation diagrams but give no information as to the size and shape of the neighborhood where they can be applied. It is also clear that as $\bar{g}_{Na}$ increases from 90 to 109, the local behavior of HH is best explained by the analysis of last section.

The situation here is analogous to the results of [10]; initially we knew HH had two classical Hopf bifurcations at $\lambda_1<\lambda_2$ with the same direction of bifurcation and there was no a priori reason for the two periodic solution branches to meet. The proximity of a degeneracy, in the first case a change in the direction of bifurcation as described in (2.3) coinciding with the coalescence of the two bifurcation points given by (2.2), made the analysis "more global." The apparent lack of information about the periodic solution branches away from the bifurcation points was introduced by the local analysis.

The same discussion applies to the two hidden organizing centers presented here. Bifurcation diagrams appear either "capped off" or with an extended branch, depending on whether they are interpreted as part of the unfolding of $(3.2)_+$ or of $(3.2)_-$ (cf. Figs. 3 and 7). Moreover, the unfolding of $(3.2)_+$ contains no germ equivalent to $(3.2)_-$ and vice versa.

Different bifurcation diagrams are obtained for (2.1) when it is studied on its own or as part of the unfolding of a more degenerate (i.e., higher codimension) germ. The presence of a degeneracy close by is extra information about the germ, and this is reflected in the diagrams we obtain for it. The only codimension 3 germs whose universal unfolding contains germs equivalent to (3.2) with $\mathbf{B} \to \pm\infty$ as they approach the origin of the unfolding space are defined by the following conditions (see [2]):

$$\begin{aligned} &\mathbf{a}_{uu} = \mathbf{a}_u = \mathbf{a}_\lambda = 0, \\ &\mathbf{a}_{u\lambda} < 0, \quad \mathbf{a}_{\lambda\lambda} > 0, \quad \mathbf{a}_{uuu} \neq 0, \end{aligned} \tag{4.2}$$

where each sign of $\mathbf{a}_{uuu}$ corresponds to a contact equivalence class.

It may be possible to perturb HH so as to satisfy (4.2), but the perturbation may introduce some further degeneracy into the problem. This is particularly crucial in the present case, since the zero of $\mathbf{a}_{uu}$ is very close to the minimum of the function $\bar{g}_{\mathrm{Na}} \to \mathbf{h}_u(\bar{g}_{\mathrm{Na}})$ defined in (2.8).

The comments made above for the second zero of $\mathbf{h}_u$ apply equally well to this hypothetical organizing center. Given the large number of parameters involved, it is natural to expect HH to have a high codimension. Calculations become more complicated as the codimension increases (see [0]), and therefore it only makes sense to look for a second organizing center if evidence of low $\bar{g}_{\mathrm{Na}}$ persistence of isolated periodic branches is found.

Acknowledgment. We thank W. Farr for the important correction mentioned in § 3.

DEGENERATE HOPF BIFURCATION FORMULAS AND HILBERT'S 16th PROBLEM*

W. W. FARR†, CHENGZHI LI‡, I. S. LABOURIAU§, AND W. F. LANGFORD¶

Abstract. This paper presents explicit formulas for the solution of degenerate Hopf bifurcation problems for general systems of differential equations of dimension $n \geqq 2$, with smooth vector fields. The main new result is the general solution of the problem for a weak focus of order 3. For bifurcation problems with a distinguished parameter, we present the formulas for the defining conditions of all cases with codimension $\leqq 3$. The formulas have been applied to Hilbert's 16th problem, yielding a new proof of Bautin's theorem, and correcting an error in Bautin's formula for the third focal value. The approach used is the Lyapunov-Schmidt method. A review of five other approaches is given, along with literature references and comparisons to the present work.

1. Introduction.

The Hopf Bifurcation Theorem has become the standard tool in applied mathematics for the study of the birth (or death) of a periodic solution of a differential equation at an equilibrium point. This is fitting, since the classical Hopf theorem states generic conditions on the differential equation for this bifurcation to occur, and also provides an explicit formula (or algorithm) for calculating the periodic solution and its stability. However, there is growing interest in degenerate cases, to which the classical Hopf formula does not apply. This paper is concerned with degeneracies in which multiple periodic solutions may coexist, as well as degeneracies in the dependence on a parameter. Explicit formulas are given for the defining conditions of all degeneracies having codimension $\leqq 3$, as defined in Golubitsky and Langford [14].

The main new result of this paper is the general solution of the focal values of a weak focus of order 3, for a system of dimension $n \geqq 2$, and an arbitrary smooth vector field. A weak focus of order 3 implies the existence of up to three coexisting limit cycles, under small perturbations. Previously, only the focus of order 2 had been solved in this generality, and work on the weak focus of order 3 had been restricted to special cases, such as dimension $n = 2$ and quadratic nonlinearities.

The formulas presented here are applicable to investigations of oscillations in chemical reactions (Farr and Aris [12]), biological systems (Labouriau [21], [22]), and many other fields. Admittedly, the formulas are long and complex. The authors feel that the effort involved in deriving and checking them is justified by the generality of the results. The formulas are explicit in terms of the Taylor coefficients of the original vector field. No preliminary transformations or reductions of the differential equations are required; for example, the equilibrium is not required to be "trivial" (i.e., identically zero), and the basic frequency need not be scaled to 1. The formulas can be programmed

in a symbolic computation language, such as MACSYMA or Maple, to compute the bifurcation coefficients for specific examples conveniently and with minimal risk of error.

As a nontrivial application of these formulas, we consider the second part of Hilbert's 16th problem, concerning the number and position of limit cycles of planar (two-dimensional) differential equations with polynomial nonlinearities. This problem is still unsolved, even in the quadratic case (see the surveys of Coppel [9], [10], and references therein). Locally, the quadratic case was studied by Bautin in 1952 (see Bautin [4]), who proved, after a long calculation by the succession function method, that in a neighborhood of an equilibrium point of a planar quadratic system, there can be 0, 1, 2, or 3 limit cycles and no more; otherwise the equilibrium point is a center. This paper presents the first new derivation of Bautin's results and corrects an error in one of Bautin's coefficients.

The approach used in this paper is the Lyapunov–Schmidt method, also known as the Fredholm Alternative Method, or Method of Alternative Problems. It is essentially the same method used by Hopf in his classic paper [18]. Recently, Golubitsky and Langford [14] combined singularity theory with the Lyapunov–Schmidt method to classify degenerate Hopf bifurcations and their unfoldings. They gave formulas for the bifurcation coefficients for some degenerate cases. This paper extends those results, giving formulas that are more readily applicable, and including the case of a weak focus of order three.

In the existing literature on degenerate Hopf bifurcation, we can identify six different methods of solution. These are: the method of Poincaré–Birkhoff normal forms; the method of Lyapunov constants; the method of the succession function; the method of averaging; the method of intrinsic harmonic balancing; and the Lyapunov–Schmidt method, which is the one used here. Unfortunately the literature on the six methods is nearly disjoint; there have been no comparative studies to guide the user to a choice among these methods. Therefore, in this paper we briefly describe all of the methods and relate them to the approach used here.

The plan of the paper is as follows. Section 2 briefly reviews the classical Hopf theorem, and defines and compares the six different methods listed above for degenerate Hopf bifurcation problems. Section 3 outlines the calculation and presents the new formulas for the degenerate Hopf bifurcation coefficients. Section 4 applies these formulas to a new proof of Bautin's theorem for Hilbert's 16th problem.

2. Degenerate Hopf bifurcations: alternative approaches. This section reviews six different methods that have been used in studies of degenerate Hopf bifurcation problems. Salient features of each of the methods are described; however, this review is not intended to be an exhaustive comparative analysis. References to more complete presentations of each of the methods are given. Most authors in the field have focused on only one of these methods and have not related their work to the other approaches. We hope this review may help reduce this fragmentation of the field and facilitate comparison of the results presented here with previous work, for example, on Hilbert's 16th problem.

First it is necessary to establish more precisely some terminology and notation, and to briefly review the classical Hopf theorem. Let us consider a parametrized family of differential equations

$$u' = f(u, \mu) \tag{2.1}$$

where $f: \mathbb{R}^n \times \mathbb{R}^p \to \mathbb{R}^n$, and f is a smooth (C^∞) function of the state variables u and parameters μ, and $n \geqq 2$, $p \geqq 1$. For some applications it is important to preserve a

physical control parameter λ, in which case we define

$$\mu = (\lambda, \alpha). \tag{2.2}$$

Then λ represents a distinguished bifurcation parameter, as in [14], and α represents additional "unfolding" or free parameters; not all authors make this distinction. We assume the existence of an equilibrium point, translated to the origin for convenience,

$$f(0, 0) = 0 \tag{2.3}$$

and at this equilibrium, the derivative with respect to u,

$$A \equiv (D_u f)|_{(0,0)} \tag{2.4}$$

has a simple pair of imaginary eigenvalues $\pm i\omega_0$, and no others with zero real part. Then A is nonsingular, and the Implicit Function Theorem implies that the equilibrium (2.3) has a smooth extension $u(\mu)$ for μ near zero. Usually it is assumed that this branch of equilibria has been translated to the trivial solution $u \equiv 0$; however, to facilitate applications, we do not make this assumption here. Now the derivative A has a smooth extension along the branch of equilibria,

$$A(\mu) \equiv (D_u f)|_{(u(\mu),\mu)}, \tag{2.5}$$

and the simplicity of the imaginary eigenvalues implies that they too have smooth extensions along the branch, for μ near 0,

$$\sigma(\mu) \pm i\omega(\mu), \quad \sigma(0) = 0, \quad \omega(0) = \omega_0. \tag{2.6}$$

The classical Hopf theorem assumes the Hopf transversality or crossing condition, with respect to a distinguished parameter λ [18]

$$\sigma_\lambda(0) \neq 0. \tag{2.7}$$

(The consequences of the failure of this hypothesis have been explored in [14].) Then the main conclusion of the Hopf theorem is that there is a unique (up to phase) smooth branch of periodic solutions, in any small neighborhood of $u = 0$, which can be parametrized by an amplitude of the periodic solution, here denoted r, and there is a smooth relationship between the parameters μ and the amplitude r, of the form

$$r[c_0 + c_2 r^2 + c_4 r^4 + \cdots] = 0, \tag{2.8}$$

where $\cdots$ denotes higher-order terms in r. The coefficients c_0, c_2, etc. are functions of μ. Hopf showed that (2.7) is equivalent to

$$(c_0)_\lambda(0) \neq 0, \tag{2.9}$$

so that, by the Implicit Function Theorem, (2.8) can be solved uniquely for λ as a function of $r > 0$ near the origin. Hopf [18] also presented a formula for $c_2(0)$, in terms of the Taylor coefficients of f. The nondegenerate (or classical) case of Hopf bifurcation is that for which (2.7) holds and in addition

$$c_2(0) \neq 0. \tag{2.10}$$

Then it is clear that (2.8) near (0, 0) defines a curve, asymptotically parabolic in shape, with a unique $r > 0$ for each λ of one sign, and no r for λ of the opposite sign. This curve is the classical Hopf bifurcation diagram. Additional parameters α do not qualitatively change this picture when (2.7) and (2.10) hold, but become important if either condition fails.

The computation of the coefficients $c_2, c_4, \cdots$ is one principal theme of this paper. In fact every one of the methods reviewed here can be described as a means of arriving at an equation of the form (2.8), and then computing the coefficients c_{2j}.

Degenerate Hopf bifurcation occurs when either of conditions (2.7) or (2.10) fails. In this paper we are concerned mainly with (2.10). Then the problem is to calculate the first nonvanishing c_{2k} in (2.8) (only even powers of r appear in any of the methods). Adopting the terminology used in much of the literature cited below, we will say that the differential equation has a *weak focus of order k*, if

$$c_0(0) = \cdots = c_{2(k-1)} = 0, \qquad c_{2k} \neq 0, \tag{2.11}$$

and the constant $c_{2j}(0)$ is the jth *focal value*. When (2.11) holds we obtain multiple periodic solutions from the following standard result.

THEOREM 2.1. *Suppose that the differential equation* (2.1) *has a weak focus of order k. Then by generic perturbations involving k parameters in the differential equation, it is possible to obtain j limit cycles, in a neighborhood of* $u = 0$, *for each j satisfying* $1 \leqq j \leqq k$, *but not for any* $j > k$.

A proof of Theorem 2.1 using singularity theory is given in [14], where a more explicit prescription of the "generic perturbations," as well as the effects of a distinguished parameter, can be found. Corresponding proofs for the other approaches to degenerate Hopf bifurcation can be found in the references given below.

Several of the methods to be described here are applicable only in the two-dimensional case. In principle, under the above hypotheses, the Center Manifold Theorem can be used to reduce a system of dimension $n > 2$ to a planar system. However, in practice this reduction is rarely easy to carry out explicitly, so such methods are severely limited. Let us proceed to the review of the methods.

Method of Poincaré-Birkhoff normal forms. This is one of the best-known methods. Excellent references are the books of Arnold [2] and Guckenheimer and Holmes [16]. After a reduction to two dimensions, a sequence of near-identity nonlinear transformations brings the differential equation to a normal form. Written in amplitude-phase coordinates (r, θ), the differential equation for r has right-hand side of the form (2.8), up to a finite order, and the equation for θ has a similar form except it is even in r instead of odd. Higher-order terms do not have this symmetry, but it can be shown that the nonsymmetric higher-order terms are not important, and Theorem 2.1 holds. It should be noted that the reduction to two dimensions and the transformation to normal form can be combined into one calculation for greater efficiency (see Bibikov [5], Coullet and Spiegel [11]). This method has been applied to Hilbert's 16th problem by Rousseau [28], who found that the calculation of the third focal value $c_6(0)$ for a particular example, using MACSYMA, strained the memory capacity of a modern minicomputer.

Method of Lyapunov constants. A good reference for this method is Göbber and Willamowski [13]. We begin with a two-dimensional system, and instead of transforming the system, we construct a positive definite Lyapunov functional $V(u, \mu)$ (as in Lyapunov's method for asymptotic stability) for which the derivative along trajectories is

$$V = \nabla V \cdot f = \sum v_j r^{2j}. \tag{2.12}$$

The coefficients v_j are called the Lyapunov constants and are functions of the parameters. There is an algorithm for constructing V for which the leading v_j's are zero. The level curves of finite truncations of the series (2.12) define Poincaré-Bendixson domains, from which the existence of limit cycles is obtained. Recently, Bonin and Legault [6]

have shown that (2.12) is equivalent to (2.8), and have verified that Theorem 2.1 holds for this approach. They estimate that this approach is more efficient than the method of Poincaré–Birkhoff normal forms, mainly because it involves computing one Taylor series instead of two. The method was applied to the quadratic Liénard equation (a subcase of Hilbert's 16th problem) by Kohda, Imamura, and Oono [20].

Method of the succession function. A thorough exposition of this method can be found in the book of Andronov, Leontovich, Gordon, and Maier [1]. Again we assume a two-dimensional system, with a weak focus at the origin. We select a ray from the origin (typically the x-axis) and choose initial points on this ray. Sufficiently near the weak focus, the Poincaré map, which follows a solution from the ray back to the ray, is well defined. This map is called the succession function. Locally it can be expanded in a Taylor series in the coordinate along the ray, and this Taylor series can be put in the form (2.8). Zeros of the succession function correspond to periodic solutions, and again Theorem 2.1 holds for the succession function. This is the method used by Bautin [4] on Hilbert's 16th problem, and he proved Theorem 2.1 for that case. A formula for the first focal value, derived by this method, is given in Andronov et al. [1].

Method of averaging. There are many good references for the method of averaging as applied to bifurcation problems (see Chow and Hale [8], Guckenheimer and Holmes [16], Sanders and Verhulst [29]). In a two-dimensional system near a weak focus, the phase angle θ is a strictly monotone function of time t. Therefore it is possible to transform the independent variable from t to θ, and reduce the dimension of the system by one, but the new system is 2π-periodic in θ, instead of autonomous. Integral averaging now leads to a vector field of the form (2.8), and Theorem 2.1 applies.

Method of intrinsic harmonic balancing. For this method, refer to Huseyin and Yu [19] and the references therein. Harmonic balancing involves formally expanding a trial solution in a Fourier series and matching coefficients. Certain inconsistencies that arise in the naive approach are overcome in the method of intrinsic harmonic balancing. It has only recently been applied to degenerate Hopf bifurcation problems.

Method of Lyapunov–Schmidt. We summarize the Lyapunov–Schmidt method, as used in [14]. For a thorough exposition, see Golubitsky and Schaeffer [15] and Vanderbauwhede [31]. The first step is to rescale the time in (2.1), to make the period constant and equal to 2π, by

$$s = \omega_0(1+\tau)t, \tag{2.13}$$

where the new parameter τ is the correction to the period, and is to be determined. Then (2.1) is rewritten

$$N(u, \lambda, \alpha, \tau) \equiv -\omega_0(1+\tau)\frac{du}{ds} + f(u, \lambda, \alpha) = 0, \tag{2.14}$$

and we seek solutions to (2.14) in the space $C^1_{2\pi}$ of continuously differentiable, 2π-periodic vector-valued functions.

The reader is warned that N in (2.14) is defined with the opposite sign to the corresponding N in [14]. As a result, many of the formulas in this paper have differences in sign from the formulas in the earlier paper. The motivation for this change is that it leads to eigenvalue and focal values with the same signs as in the traditional approaches described above, and so comparisons are made easier. We obtain the usual correspondence that negative values imply stability. This is a consequence of the fact that in (2.14), N and f have the same sign, so that eigenvalues and focal values computed from N have the same sign as if they were computed directly from the vector field f.

The linearization of (2.14) is

$$Lu \equiv \left[-\omega_0 \frac{d}{ds} + A\right] u = 0, \tag{2.15}$$

with A defined by (2.4). The kernel of L is spanned by

$$\phi_1(s) = \mathrm{Re}\,(c\,e^{is}), \qquad \phi_2(s) = \mathrm{Im}\,(c\,e^{is}) \tag{2.16}$$

where c is an eigenvector of A satisfying

$$Ac = i\omega_0 c, \qquad c^* c = 2. \tag{2.17}$$

Here * denotes complex conjugate transpose. Similarly, we define adjoint eigenfunctions ψ_1 and ψ_2 as the real and imaginary parts of de^{is}, where d^* is the left eigenvector satisfying

$$d^* A = i\omega_0 d^*, \qquad d^* c = 2. \tag{2.18}$$

The vectors c and d are needed in the formulas in the next section.

The Lyapunov-Schmidt method proceeds by projecting (2.14) onto Ker (L) and a complement, solving on the complement where L is invertible, and substituting that solution into the equation in the kernel. The result is a two-dimensional map, called the bifurcation equation,

$$g : \mathbb{R}^2 \times \mathbb{R}^p \times \mathbb{R} \to \mathbb{R}^2, \qquad g(x, y; \mu, \tau) = 0. \tag{2.19}$$

From the phase-shift symmetry of the periodic functions g is S^1 equivariant. We may arbitrarily fix the phase and define an amplitude, for example, $y = 0$ and $x \geqq 0$. Then the bifurcation equation has the form

$$g_1 = p(x^2, \mu, \tau)x = 0, \qquad g_2 = q(x^2, \mu, \tau)x = 0, \tag{2.20}$$

where $p(0) = q(0) = 0$, and $q_\tau(0) = \omega_0 \neq 0$. Periodic solutions correspond to nontrivial solutions of $p = q = 0$. By the Implicit Function Theorem, the q-equation can be solved for τ, which we then substitute into the p-equation, which gives the final equation

$$a(x^2, \mu)x = p(x^2, \mu, \tau(x^2, \mu))x = 0. \tag{2.21}$$

Now (2.21) has the form (2.8), and it has been shown that Theorem 2.1 holds once again. It remains to calculate the Taylor coefficients of a, which include the $c_{2j}(0)$ in (2.8). This is accomplished by repeated implicit differentiation of (2.20)-(2.21), and the solution of linear differential equations in the complementary space. The results are presented in the next section.

Recall that $\mu = (\lambda, \alpha)$, where λ is a distinguished parameter. The possible degeneracies involving the distinguished parameter λ have not been discussed here, but are explored thoroughly in Golubitsky and Langford [14].

3. The bifurcation coefficients. In this section we present the explicit formulas for the Hopf bifurcation coefficients, for the cases of weak foci up to order 3 (as defined in § 2). The general solution for a weak focus of order 2 has been obtained by Golubitsky and Langford [14], and earlier by Hassard and Wan [17]. The weak focus of order 3 seems not to have been solved before, except in special cases; for example, Bautin [4] treated the case of a two-dimensional system with only quadratic nonlinearities.

Furthermore, the formulas presented here remove two simplifying assumptions that were made in [14]. From the theoretical point of view of that paper, there is no loss of generality in assuming that the imaginary eigenvalues are scaled to $\pm i$ and that even as μ varies the equilibrium solution remains fixed at the origin (i.e., is a trivial solution). In applications, however, these simplifying assumptions are rarely satisfied. The necessary extensions to the general case are presented here. Note also that our formulas include those necessary to determine degeneracies involving the distinguished parameter as defined in [14], as well as the focal values discussed in § 2. These formulas allow the calculation of the defining conditions of all possible degeneracies of codimension up to 3, as defined in [14].

To avoid repetition, it is assumed that the reader is familiar with the notation and formulas in § 5 of [14]. However, the reader is warned that, since the nonlinear operator N is defined here with a sign opposite to that in the earlier paper (for reasons explained in § 2), some of the formulas have signs reversed.

First we provide the formulas that remove the assumption of a trivial solution. Let $f(u, \lambda, \alpha)$ be the right-hand side of our set of ordinary differential equations, and assume that it does not have a trivial solution. (In this section we will suppress the dependence of f on α, the vector of free parameters, for convenience.) We define a function G that has a trivial solution locally by

$$G(v, \lambda) = f(v + \hat{u}(\lambda), \lambda) \tag{3.1}$$

where $\hat{u}(\lambda)$ satisfies

$$f(\hat{u}(\lambda), \lambda) = 0, \tag{3.2}$$

for λ in some neighborhood of the Hopf bifurcation point. That is, $\hat{u}(\lambda)$ is the steady-state solution written as a function of the distinguished parameter λ. The formulas we will present below for the derivatives of the functions p and q, as defined in (2.20), will be in terms of G; we present immediately below the formulas relating derivatives of G to derivatives of the original vector field f. Our purpose in splitting up the calculations in this fashion is twofold. First, the subsequent formulas are simplified to a certain extent, and second, some applications will have trivial solutions and the most general formulas would entail quite a few needless calculations. Note first of all that $D_v^k G = D_v^k f$ for all k, where by $D_v^k G$ we mean the kth derivative of G with respect to v thought of as a symmetric k-linear form. Thus if all we seek is the focal values of § 2, it is irrelevant whether or not f has a trivial solution. It is only when derivatives with respect to the distinguished bifurcation parameter occur that complications arise. The extension of our notation to mixed v and λ derivatives is trivial, since we are considering λ to be a single real parameter. The formulas we will need are given below (in our calculations below all derivatives are to be evaluated at the Hopf point, so we will supply as arguments only the k vectors on which the form is to act):

$$D_v D_\lambda G(x) = D_v^2 f(v_1, x) + D_v D_\lambda f(x),$$

$$D_v^2 D_\lambda G(x, y) = D_v^3 f(v_1, x, y) + D_v^2 D_\lambda f(x, y),$$

$$D_v D_\lambda^2 G(x) = D_v^3 f(v_1, v_1, x) + D_v^2 f(v_2, x) + 2D_v^2 D_\lambda f(v_1, x) + D_v D_\lambda^2 f(x),$$

$$D_v^3 D_\lambda G(x, y, z) = D_v^4 f(v_1, x, y, z) + D_v^3 D_\lambda f(x, y, z),$$

$$D_v^2 D_\lambda^2 f(x, y) = D_v^4 f(v_1, v_1, x, y) + D_v^3 f(v_2, x, y) + 2D_v^3 D_\lambda f(v_1, x, y)$$

$$
\begin{aligned}
&\qquad + D_v^2 D_\lambda^2 f(x, y),\\
D_v D_\lambda^3 G(x) &= D_v^4 f(v_1, v_1, v_1, x) + 3D_v^3 f(v_1, v_2, x) + D_v f(v_3, x)\\
&\quad + 3D_v^3 D_\lambda f(v_1, v_1, x) + 3D_v^2 D_\lambda f(v_2, x) + 3D_v^2 D_\lambda^2 f(v_1, x)\\
&\quad + D_v D_\lambda^3 f(x),\\
D_v^4 D_\lambda G(x, y, z, w) &= D_v^5 f(v_1, x, y, z, w) + D_v^4 D_\lambda f(x, y, z, w),\\
D_v^3 D_\lambda^2 f(x, y, z) &= D_v^5 f(v_1, v_1, x, y, z) + D_v^4 f(v_2, x, y, z) + 2D_v^4 D_\lambda f(v_1, x, y, z)\\
&\quad + D_v^3 D_\lambda^2 f(x, y, z),\\
D_v^5 D_\lambda G(x, y, z, w, t) &= D_v^6 f(v_1, x, y, z, w, t) + D_v^5 D_\lambda f(x, y, z, w, t),
\end{aligned}
\tag{3.3}
$$

where x, y, z, w, and t are vectors in $\mathbb{R}^n$, and the quantities v_i are derivatives of $\hat{u}(\lambda)$ defined by

$$
\begin{aligned}
v_1 &= -(D_v f)^{-1}(D_\lambda f),\\
v_2 &= -(D_v f)^{-1}(D_v^2 f(v_1, v_1) + 2D_v D_\lambda f(v_1) + D_\lambda^2 f),\\
v_3 &= -(D_v f)^{-1}(D_v^3 f(v_1, v_1, v_1) + 3D_v^2 f(v_1, v_2)\\
&\quad + 3D_v^2 D_\lambda f(v_1, v_1) + 3D_v D_\lambda f(v_2) + 3D_v D_\lambda^2 f(v_1) + D_\lambda^3 f).
\end{aligned}
\tag{3.4}
$$

Next we present the formulas for the derivatives of $a(z, \lambda)$ in terms of the derivatives of p and q (we let $z \equiv x^2$, see (2.20)-(2.21)). The notation is that of [14], that is, we write

$$a(z, \lambda) = \sum a_{jk} z^k \lambda^j. \tag{3.5}$$

Note that the derivatives of $a(z, \lambda)$ with respect to z, at $(z, \lambda) = (0, 0)$, are equivalent to the focal values defined in § 2.

The p_{ijk} notation is a shorthand defined like that for the a_{ij} coefficients, which we give below for completeness, although we assume readers of this paper are familiar with either the paper of Golubitsky and Langford [14] or the treatment given in Golubitsky and Schaeffer [15]. The notation depends on the two functions g_1 and g_2 defined above in § 2 and the series expression

$$p(z, \lambda, \tau) = \sum p_{ijk} z^i \lambda^j \tau^k \tag{3.6}$$

where $z = x^2$ as before. Hence p_{ijk} is given by

$$p_{ijk} = \frac{1}{(2i+1)!\, j!\, k!} \frac{\partial^{2i+1+j+k} g_1(0, 0, 0)}{\partial x^{2i+1}\, \partial \lambda^j\, \partial \tau^k} \tag{3.7}$$

with analogous expressions for q_{ijk} involving g_2. The formulas for the a_{ij} coefficients are given below. Their derivation involves only elementary calculus, but they are given here because there are sign changes from [14] due to the new definition of N and also because they are for the case $\omega_0 \neq 1$:

$$
\begin{aligned}
&a_{00} = 0, \quad a_{10} = p_{100}, \quad a_{01} = p_{010},\\
&a_{20} = p_{200} - p_{101}\, q_{100}/\omega_0, \quad a_{11} = p_{110} - p_{101}\, q_{010}/\omega_0, \quad a_{02} = p_{020},\\
&a_{30} = p_{300} - p_{201}\, q_{100}/\omega_0 + p_{102}\, q_{100}^2/\omega_0^2 - p_{101}(q_{200}/\omega_0 - q_{101}\, q_{100}/\omega_0^2)\\
&a_{21} = p_{210} - p_{111}\, q_{100}/\omega_0 - p_{201}\, q_{010}/\omega_0 + 2p_{102}\, q_{100}\, q_{010}/\omega_0^2\\
&\qquad - p_{101}(q_{110}/\omega_0 - q_{101}\, q_{010}/\omega_0^2)\\
&a_{12} = p_{120} - p_{111}\, q_{010}/\omega_0 + p_{102}\, q_{010}^2/\omega_0^2 - p_{101}\, q_{020}/\omega_0 - p_{021}\, q_{100}/\omega_0\\
&a_{03} = p_{030} - p_{021}\, q_{010}/\omega_0.
\end{aligned}
\tag{3.8}
$$

Finally we present the formulas for the derivatives of p and q. Deriving these formulas is straightforward though tedious, and the labor involved especially in the p_{m00} coefficients increases rapidly with m. The formulas assume that G has a trivial solution, so for where this is not true and where we are using a distinguished bifurcation parameter, they should be modified according to the prescription above.

Computation of the coefficients proceeds in two steps. In the first step, linear algebra problems must be solved to obtain complex-valued vectors that actually are coefficients in a Fourier series for the function $w(x, \lambda, \tau)$, and in the second, these vectors are used to evaluate the p and q coefficients of the bifurcation equations. As shown in Golubitsky and Langford [14], certain coefficients are identically zero or have special values. These are

$$\begin{aligned} &p_{00j}=0, \quad j=0,1,2,\cdots, \qquad q_{00j}=0, \quad j=2,3,4,\cdots, \\ &q_{000}=0, \qquad q_{001}=\omega_0, \\ &p_{01j}=q_{01j}=0, \quad j=1,2,3,\cdots. \end{aligned} \tag{3.9}$$

The formulas for the first-order derivatives of $a(z, \lambda)$ at the origin have very simple forms. The set of vectors for the p_{100} coefficient, which determines stability in the case of nondegenerate Hopf bifurcation, is found by solving

$$Aa_0=-\tfrac{1}{2}D_v^2G(c,\bar{c}), \qquad (A-2i\omega_0 I)a_2=-\tfrac{1}{4}D_v^2G(c,c) \tag{3.9}$$

where A is the Jacobian matrix of F at the Hopf point and c is the right eigenvector of A corresponding to the eigenvalue $i\omega_0$, as in § 2. In computations it is useful to form the intermediate PQ100 and PQ010 quantities, given by

$$\begin{aligned} &\mathrm{PQ100}=D_v^2G(c,a_0)+D_v^2G(\bar{c},a_2)+\tfrac{1}{4}D_v^3G(c,c,\bar{c}), \\ &\mathrm{PQ010}=D_vD_\lambda G(c), \end{aligned} \tag{3.10}$$

before computing

$$p_{100}=\tfrac{1}{4}\,\mathrm{Real}\,(d^*\mathrm{PQ100}), \qquad p_{010}=\tfrac{1}{2}\,\mathrm{Real}\,(d^*\mathrm{PQ010}). \tag{3.11}$$

The coefficients q_{100} and q_{010} are obtained by taking imaginary instead of real parts and inserting a minus sign. It is a simple matter to identify p_{010} with $\sigma_\lambda(0,0)$, so that a nonzero value means the transversality condition is satisfied. If p_{100} is not zero, then a negative value indicates a stable periodic orbit and vice versa.

Higher-order calculations become increasingly complex. We need eight more vectors to compute the second-order coefficients; six are obtained by solving:

(3.12)

$$\begin{aligned} &(A-3i\omega_0 I)a_3=-\tfrac{3}{2}D_v^2G(c,a_2)-\tfrac{1}{8}D_v^3G(c,c,c), \\ &Ab_0=-2[D_v^2G(c,\bar{a}_1)+D_v^2G(\bar{c},a_1)]-3D_v^2G(a_0,a_0)-6D_v^2G(a_2,\bar{a}_2) \\ &\qquad -3D_v^3G(c,\bar{c},a_0)-\tfrac{3}{2}D_v^3G(c,c,\bar{a}_2)-\tfrac{3}{2}D_v^3G(\bar{c},\bar{c},a_2)-\tfrac{3}{8}D_v^4G(c,c,\bar{c},\bar{c}), \\ &(A-2i\omega_0 I)b_2=-2D_v^2G(c,a_1)-2D_v^2G(\bar{c},a_3)-6D_v^2G(a_0,a_2) \\ &\qquad -3D_v^3G(c,\bar{c},a_2)-\tfrac{3}{2}D_v^3G(c,c,a_0)-\tfrac{1}{4}D_v^4G(c,c,c,\bar{c}), \\ &(A-2i\omega_0 I)c_2=2i\omega_0 a_2, \\ &Ad_0=-\tfrac{1}{2}D_v^2G(c,\bar{c}_1)-\tfrac{1}{2}D_v^2G(\bar{c},c_1)-\tfrac{1}{2}D_v^2D_\lambda G(c,\bar{c})-D_vD_\lambda G(a_0) \\ &(A-2i\omega_0 I)d_2=-\tfrac{1}{2}D_v^2G(c,c_1)-\tfrac{1}{4}D_v^2D_\lambda G(c,c)-D_vD_\lambda G(a_2). \end{aligned}$$

The remaining two vectors require some explanation, since the left-hand sides of the equations are singular. According to the Fredholm alternative, the solution exists and is unique if we specify that the solution be orthogonal to the eigenvector of the adjoint problem and if the right-hand side of the equation is orthogonal to the same eigenvector. This eigenvector d is found from

$$(A^* + i\omega_0 I)d = 0 \tag{3.13}$$

(where A^* is the transpose of A) and normalized so that $d^*c = 2$. The two remaining vectors thus are uniquely determined from

$$\begin{aligned} &(A - i\omega_0 I)a_1 = -\tfrac{3}{2}\mathrm{PQ100} + \tfrac{3}{4}[d^*\mathrm{PQ100}]c, \qquad d^*a_1 = 0, \\ &(A - i\omega_0 I)c_1 = -\mathrm{PQ010} + \tfrac{1}{2}[d^*\mathrm{PQ010}]c, \qquad d^*c_1 = 0. \end{aligned} \tag{3.14}$$

The next step in determining the second-order coefficients is to compute the following PQijk quantities, which will lead directly to the p_{ijk} and q_{ijk} quantities we desire:

(3.15)

$$\mathrm{PQ101} = D_v^2 G(\bar{c}, c_2), \qquad \mathrm{PQ020} = D_v D_\lambda G(c_1) + \tfrac{1}{2} D_v D_\lambda^2 G(c),$$

$$\begin{aligned} \mathrm{PQ110} = {} & D_v^2 G(c_1, a_0) + D_v^2 G(\bar{c}_1, a_2) + D_v^2 G(c, d_0) + D_v^2 G(\bar{c}, d_2) + D_v^2 D_\lambda G(c, a_0) \\ & + D_v^2 D_\lambda G(\bar{c}, a_2) + \tfrac{2}{3} D_v D_\lambda G(a_1) + \tfrac{1}{4} D_v^3 G(c, c, \bar{c}_1) \\ & + \tfrac{1}{2} D_v^3 G(c, \bar{c}, c_1) + \tfrac{1}{4} D_v^3 D_\lambda G(c, c, \bar{c}) \end{aligned}$$

$$\begin{aligned} \mathrm{PQ200} = {} & \tfrac{1}{2} D_v^2 G(c, b_0) + \tfrac{1}{2} D_v^2 G(\bar{c}, b_2) + 2 D_v^2 G(a_0, a_1) + 2 D_v^2 G(a_2, \bar{a}_1) + 2 D_v^2 G(\bar{a}_2, a_3) \\ & + \tfrac{1}{2} D_v^3 G(c, c, \bar{a}_1) + D_v^3 G(c, \bar{c}, a_1) + \tfrac{1}{2} D_v^3 G(\bar{c}, \bar{c}, a_3) \\ & + 3 D_v^3 G(c, a_2, \bar{a}_2) + 3 D_v^3 G(\bar{c}, a_0, a_2) + \tfrac{3}{2} D_v^3 G(c, a_0, a_0) \\ & + \tfrac{1}{4} D_v^4 G(c, c, c, \bar{a}_2) + \tfrac{3}{4} D_v^4 G(c, c, \bar{c}, a_0) + \tfrac{3}{4} D_v^4 G(c, \bar{c}, \bar{c}, a_2) \\ & + \tfrac{1}{16} D_v^5 G(c, c, c, \bar{c}, \bar{c}). \end{aligned}$$

The p_{ijk} coefficients for $i+j+k=2$ are now obtained from the formulas

$$\begin{aligned} &p_{101} = \tfrac{1}{4}\,\mathrm{Real}\,(d^*\mathrm{PQ101}), \qquad p_{020} = \tfrac{1}{2}\,\mathrm{Real}\,(d^*\mathrm{PQ020}), \\ &p_{110} = \tfrac{1}{4}\,\mathrm{Real}\,(d^*\mathrm{PQ110}), \qquad p_{200} = \tfrac{1}{24}\,\mathrm{Real}\,(d^*\mathrm{PQ200}), \end{aligned} \tag{3.16}$$

and the analogous q_{ijk} coefficients, by changing the sign and taking the imaginary instead of the real part.

Computing the third-order coefficients is even more complicated, but proceeds in exactly the same way. We first compute 24 vectors; these vectors, along with the ten already computed, could be used to obtain approximations to the periodic orbits, but we have not done this. We will only use them to obtain the p_{ijk} coefficients for $i+j+k=3$. As far as we know, these coefficients have not been obtained before.

The first set of vectors are required for the PQ300 quantity and are obtained by solving the following series of problems:

(3.17)

$$(A - 4i\omega_0 I)b_4 = -3D_v^2 G(a_2, a_2) - 2D_v^2 G(c, a_3) - \tfrac{3}{2} D_v^3 G(c, c, a_2) - \tfrac{1}{16} D_v^4 G(c, c, c, c),$$

$$(A - i\omega_0 I)e_1 = -5\mathrm{PQ200} + \tfrac{5}{2}[d^*\mathrm{PQ200}]c, \qquad d^*e_1 = 0,$$

$$(A-3i\omega_0 I)e_3 = -\tfrac{5}{2}D_v^2 G(\bar{c}, b_4) - \tfrac{5}{2}D_v^2 G(c, b_2) - 10D_v^2 G(a_0, a_3) - 10D_v^2 G(a_2, a_1)$$
$$- 5D_v^3 G(c, \bar{c}, a_3) - \tfrac{5}{2}D_v^3 G(c, c, a_1) - 15D_v^3 G(c, a_0, a_2)$$
$$- \tfrac{15}{2}D_v^3 G(\bar{c}, a_2, a_2)$$
$$- \tfrac{15}{4}D_v^4 G(c, c, \bar{c}, a_2) - \tfrac{5}{4}D_v^4 G(c, c, c, a_0) - \tfrac{5}{32}D_v^5 G(c, c, c, c, \bar{c}),$$

$$Ah_0 = -3D_v^2 G(\bar{c}, e_1) - 3D_v^2 G(c, \bar{e}_1) - 15D_v^2 G(a_2, \bar{b}_2) - 15D_v^2 G(\bar{a}_2, b_2)$$

$$\text{PQ030} = D_v D_\lambda G(r_1) + \tfrac{1}{2} D_v D_\lambda^2 G(c_1) + \tfrac{1}{6} D_v D_\lambda^3 G(c). \tag{3.30}$$

Finally we obtain the p_{ijk} coefficients from

$$\begin{aligned} p_{300} &= \text{Real}\,(d^*\text{PQ300})/6!, & p_{210} &= \text{Real}\,(d^*\text{PQ210})/4!, \\ p_{201} &= \text{Real}\,(d^*\text{PQ201})/4!, & p_{111} &= \text{Real}\,(d^*\text{PQ111})/2, \\ p_{102} &= \text{Real}\,(d^*\text{PQ102})/4, & p_{120} &= \text{Real}\,(d^*\text{PQ120})/4, \\ p_{021} &= \text{Real}\,(d^*\text{PQ021}), & p_{030} &= \text{Real}\,(d^*\text{PQ030})/2, \end{aligned} \tag{3.31}$$

and the analogous q_{ijk} coefficients can be obtained by changing the sign and taking imaginary parts instead of real parts.

4. Application to Hilbert's 16th problem. There is a large literature on Hilbert's 16th problem; the reader is referred to the review articles of Coppel [9], [10] and Ye [32], [33]. As remarked in the Introduction, the maximum number of limit cycles of a quadratic system in the plane is still not known. The general quadratic system is

$$\frac{dx}{dt} = \sum_{i+j\leqq 2} A_{ij} x^i y^j, \qquad \frac{dy}{dt} = \sum_{i+j\leqq 2} B_{ij} x^i y^j. \tag{4.1}$$

Let $H_2(A, B)$ denote the total number of limit cycles of (4.1) for given A_{ij} and B_{ij}. Then it is known that

$$H_2(A, B) < \infty, \qquad \sup_{A,B} H_2(A, B) \geqq 4. \tag{4.2}$$

It was shown by Bamón [3] that $H_2(A, B)$ is finite, after several false proofs dating back to Dulac. Examples of (4.1) with 4 limit cycles were constructed only recently by Shi [30] and Chen and Wang [7]. Both of these examples employ Theorem 2.1, or what is known as Bautin's technique: perturbation of a weak focus to create multiple limit cycles locally. Shi's example has a weak focus of order 3 and a strong focus surrounded by a unique limit cycle; Wang's example has a weak focus of order 2 and a strong focus, each of which is surrounded by a finite limit cycle. These local arguments gain added significance in view of the following result.

THEOREM (Li [24]). *There is no limit cycle around a weak focus of order* 3, *for any quadratic system.*

Thus it is not possible to construct an example of a quadratic system with 4 limit cycles about the same equilibrium, using Bautin's technique.

The remainder of this section is devoted to a new derivation of Bautin's formulas [4]. First we restate Bautin's results. Assuming that (4.1) has an equilibrium that is a focus, Bautin makes a linear transformation to the system

$$\begin{aligned} x' &= -y + \lambda_1 x - \lambda_3 x^2 + (2\lambda_2 + \lambda_5) xy + \lambda_6 y^2, \\ y' &= x + \lambda_1 y + \lambda_2 x^2 + (2\lambda_3 + \lambda_4) xy - \lambda_2 y^2. \end{aligned} \tag{4.3}$$

Then the focal value $c_0(0)$ defined in § 2 is clearly equal to λ_1, and corresponding to the focal values $c_2(0)$, $c_4(0)$, and $c_6(0)$, Bautin calculated (by the method of the succession function) the following quantities:

$$\begin{aligned} v_3 &= -(\pi/4)\lambda_5(\lambda_3 - \lambda_6), \\ v_5 &= (\pi/24)\lambda_2\lambda_4(\lambda_3 - \lambda_6)[\lambda_4 + 5(\lambda_3 - \lambda_6)], \\ v_7 &= (25\pi/32)\lambda_2\lambda_4(\lambda_3 - \lambda_6)^2[\lambda_3\lambda_6 - 2\lambda_6^2 - \lambda_2^2]. \end{aligned} \tag{4.4}$$

The origin for (4.3) is a weak focus of order k, for $1 \leqq k \leqq 3$, if

$$\lambda_1 = \cdots = v_{2k-1} = 0, \qquad v_{2k+1} \neq 0. \tag{4.5}$$

Moreover, Bautin showed that the origin is a center, if and only if

$$\lambda_1 = v_3 = v_5 = v_7 = 0. \tag{4.6}$$

(Recently Li [23] has reformulated Bautin's results, in terms of the coefficients of the untransformed equation (4.1), for greater convenience in application.)

Now let us apply the formulas of § 3 to (4.3), with $\lambda_1 = 0$. Note that there exists a trivial solution $(x, y) = (0, 0)$, the frequency is scaled to be 1, and all of the derivatives higher than second-order are zero, so the calculation is greatly simplified. We find

$$\begin{gathered} A = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \qquad c = d = \begin{pmatrix} i \\ 1 \end{pmatrix}, \\ a_0 = \begin{pmatrix} 0 \\ -(\lambda_3 - \lambda_6) \end{pmatrix}, \qquad a_2 = (1/6)\begin{pmatrix} 2(\lambda_2 + \lambda_5) + i(\lambda_4 - 2\lambda_6) \\ 3\lambda_3 + 2\lambda_4 - \lambda_6 + i(2\lambda_2 - \lambda_5) \end{pmatrix}. \end{gathered} \tag{4.7}$$

From this we obtain the first focal value

$$\begin{aligned} a_{10} = p_{100} &= \tfrac{1}{4}\,\mathrm{Real}\,[d^*(D_u^2 f(c, a_0) + D_u^2 f(c, a_2))] \\ &= -\tfrac{1}{8}\lambda_5(\lambda_3 - \lambda_6), \end{aligned} \tag{4.8}$$

in agreement with Bautin's result, up to a scaling factor of 2π.

Before proceeding, we make a simplifying assumption. The second focal value is of interest only if the first focal value is 0. Therefore we may assume that $a_{10} = 0$ in (4.8). It can be shown directly that the origin is a center for (4.3) if

$$\lambda_1 = (\lambda_3 - \lambda_6) = 0. \tag{4.9}$$

Therefore the only possibility for the origin to be a weak focus of order 2 for (4.3) is if

$$\lambda_1 = \lambda_5 = 0, \tag{4.10}$$

which we assume henceforth. Then for the second focal value the formulas in § 3 give

$$a_{20} = \tfrac{1}{48}\lambda_2\lambda_4(\lambda_3 - \lambda_6)[\lambda_4 + 5(\lambda_3 - \lambda_6)], \tag{4.11}$$

again in agreement with Bautin, up to a scaling factor of 2π.

Before calculating a_{30} we may assume that $a_{20} = 0$, by the same argument. However, when (4.10) holds, the origin is again a center if either $\lambda_2 = 0$ or $\lambda_4 = 0$, so again there is only one choice, namely

$$\lambda_4 = -5(\lambda_3 - \lambda_6) \tag{4.12}$$

which we assume, in addition to (4.10). After a long calculation, by the formulas of § 3, the third focal value is obtained as

$$a_{30} = \tfrac{25}{64}\lambda_2(\lambda_3 - \lambda_6)^3(\lambda_3\lambda_6 - \lambda_2^2 - 2\lambda_6^2). \tag{4.13}$$

Comparing this with Bautin's formula using (4.12), we find

$$v_7 = -5(2\pi)a_{30}. \tag{4.14}$$

Thus the two formulas differ not only in scaling, but also in sign.

Evidence for a sign error in Bautin's formula came to light only recently, in the example of Shi [30] and in computer analysis by Qin and Liu [27]. The sign is important,

because it determines the stability of the weak focus of order 3, and also determines the signs of the perturbations necessary to produce the three limit cycles of Theorem 2.1.

THE INSTABILITY OF AXISYMMETRIC SOLUTIONS IN PROBLEMS WITH SPHERICAL SYMMETRY*

PASCAL CHOSSAT† AND REINER LAUTERBACH‡

Abstract. Among all possible equilibria that may bifurcate from the trivial state for one-parameter vector fields with $O(3)$-symmetry, one generically exists, whatever the (absolutely irreducible) representation of $O(3)$ is. This state is characterized by its group of symmetry, which includes rotations about a fixed axis, and for that reason is called "axisymmetric." Recall that invariant spaces under irreducible representations of $O(3)$ have dimension $2l+1$ and are generated by spherical harmonics $Y_m^l(\theta, \phi)$, $-l \leqq m \leqq l$. If l is even, the instability of the axisymmetric solutions follows from a theorem of Ihrig and Golubitsky [*Phys. D* (1984), pp. 1-33]. If l is odd, this theorem fails because it requires a condition on the quadratic part of the Taylor expansion of the equivariant vector field, but in that case it must have a zero quadratic part. However, the linearized vector field along an axisymmetric solution is diagonal in this basis and the computation of its eigenvalues is easy once the equivariant structure of the vector field is known.

In this paper, using this idea, it is shown that two eigenvalues, namely those with eigendirections given by $m=2$ and $m=3$ in the basis of spherical harmonics, are simply related and have opposite signs whatever l.

Key words. differential equations, stability, bifurcation, spherical symmetry

AMS(MOS) subject classifications. 68F, 74D

Introduction. Bifurcations with spherical symmetry appear in a number of problems in mechanics, such as in models of the onset of convective flows inside planets and stars (Busse [1975]) and the buckling of a spherical shell (Knightly and Sather [1980]). These bifurcation problems also provide examples where the kernel V of the linearized equations is forced by symmetry to be of "high" dimension. Indeed, for each l there is a unique irreducible representation of $SO(3)$ having dimension $2l+1$, and in general the group of symmetry acts irreducibly on V. For the lower-dimensional cases ($l=1$ or 2), the stationary bifurcation problem has been solved completely, because they reduce to dimension one or two (Golubitsky and Schaeffer [1982], Chossat [1982]). For $l>2$, so far only partial results have been obtained, either by an explicit computation of the lowest-order coefficients of the bifurcation equation (for $l=3$, 4, 6, see Busse [1975] and Busse and Riahi [1982]), or by means of group-theoretic methods (Sattinger [1983], Ihrig and Golubitsky [1984]), which imply the following: to each isotropy subgroup Σ of $O(3)$ (having a one-dimensional fixed-point space in V), there corresponds a branch of bifurcated solutions whose symmetries are precisely Σ. Of course solutions in the same group orbit have isotropy subgroups conjugate to Σ. Then a study of the (conjugacy classes of) isotropy subgroups of $O(3)$ has led to a complete classification of solutions associated with such Σ's. In particular, for every $l \geqq 1$ there exists a branch of *axisymmetric* solutions, i.e, of solutions whose isotropy group contains $SO(2)$. This branch is the easiest to compute, and for a long time people dealing with the numerical solution of partial differential equations (PDE's) with spherical symmetry restricted themselves to spaces of axisymmetric functions. On the other hand, it was shown by Ihrig and Golubitsky [1984, Thm. 3.2B] that these solutions are unstable when l is even. The crucial hypothesis in their result is that the

quadratic terms in the Taylor expansion of the bifurcation equation are not identically equal to 0. However, when l is odd the vector field must be odd and the quadratic terms are precisely null, so that the theorem does not apply in this case. On the other hand, a direct computation by Busse and Riahi [1982] of the eigenvalues of the Jacobian matrix at an axisymmetric solution in the case $l=3$ shows that at least one of these must be positive (they are real). Hence the axisymmetric solution is still unstable when $l=3$. Further calculations by hand (for $l=5\cdots$) and by computer (MacIntosh) allowed us to verify the validity of this result up to $l=15$ (the limit of our computer's capability $\cdots$). This was enough to convince us that the instability of the axisymmetric solution must be true for every odd value of l. In the present paper we present a proof of this fact. More precisely, let

$$\frac{dx}{dt}=F(x,\lambda) \tag{0.1}$$

be the equation in V (it can, for example, derive from a PDE by the center manifold reduction). We make the following hypotheses.

(H1) $O(3)$ acts absolutely irreducibly on V by its natural odd representation: $\dim V=2l+1$, l odd, and the inversion $\mathbf{x}\to-\mathbf{x}$ in $O(3)$ acts as $-\mathrm{Id}$ on V. We recall that a real representation is *absolutely irreducible* if the only linear maps that commute with it are scalar multiples of the identity. We note this representation by D^l.

(H2) $F(.,\lambda)$ is $O(3)$-equivariant, i.e., $F(gx,\lambda)=gF(x,\lambda)$ for all $g\in O(3)$, $(x,\lambda)\in V\times\mathbf{R}$.

It follows from (H1)-(H2) that: (i) 0 is an equilibrium of (0.1) for every λ; and (ii) $L_\lambda=D_xF(0,\lambda)=c(\lambda)\mathrm{Id}_V$.

We further assume the following:

(H3) $c(0)=0$ and $c'(0)\neq 0$ (we can set $c'(0)=1$).

Hypothesis (H3) implies that the "equivariant branching lemma" holds (Cicogna [1981], Vanderbauwhede [1980]): given an isotropy subgroup Σ of $O(3)$ and its fixed-point subspace $V^\Sigma=\{x\in V:\ \gamma x=x\ \forall\gamma\in\Sigma\}$, if $\dim V^\Sigma=1$ there exists a branch of solutions in V^Σ (it is straightforward algebra to check that V^Σ is invariant under equivariant F's).

THEOREM. *Let hypotheses* (H1)-(H3) *hold*; *then generically the axisymmetric equilibria of* (0.1) *bifurcating at* $\lambda=0$ *are unstable.*

Remark. We make the "generic" condition precise in § 2.2, Lemma 2. In the two next sections we (1) recall some basic group-theoretic facts and construct the axisymmetric bifurcated solutions; and (2) study the linearized equations at an axisymmetric solution and show the instability result.

1. The existence of axisymmetric solutions. In this section we indicate which solutions of an $O(3)$-equivariant bifurcation problem are axisymmetric and we compute them using the equivariant branching lemma (stated in the Introduction).

For each odd number $n=2l+1$ there exists (up to equivalence) precisely one absolutely irreducible representation of $SO(3)$ on an n-dimensional real vector space. It is equivalent to the natural representation on the space V_l of spherical harmonics of order l, which are defined in spherical coordinates by

$$Y_m^l(\theta,\phi)=P_m^l(\cos\theta)e^{mi\phi},\qquad -l\leqq m\leqq l,$$

and the P_m^l's are the associate Legendre polynomials (Miller [1972]). For the group $O(3)$ there exist two representations on V_l according to whether the inversion in $O(3)$ acts as ld or $-$ld on V. These representations are called the plus or minus representation of order l, respectively. For even l the plus representation is the natural one to occur while the minus one is natural for odd l. Recall that a spherical harmonic $h(x)$ of order l is a homogeneous polynomial on $\mathbf{R}^3$ of degree l restricted to the 2-sphere. Thus it is easily seen from the action of an element γ on a spherical harmonic $h(x)$ by

$$(\gamma h)(x) = h(\gamma x),$$

where $x \in \mathbf{S}^2$ and γ acts on x by matrix multiplication, that $(-\mathrm{ld})h(x) = (-1)^l h(x)$, and hence the natural representation of $O(3)$ is the one indicated above. We consider bifurcation problems

$$F: V_l \times \mathbf{R} \to V_l,$$

which are $O(3)$ equivariant with respect to the natural action of $O(3)$ on V_l. The existence of axisymmetric solutions follows from the following remarks and the equivariant branching lemma (Ihrig and Golubitsky [1984]): if l is *even*, all isotropy subgroups have the form $H \oplus \{-\mathrm{ld}\}$, where H is a subgroup of $SO(3)$; therefore it suffices to look at representations of $SO(3)$. The subgroup $O(2)$ of $SO(3)$ has a one-dimensional fixed point space. It is a maximal closed subgroup of $SO(3)$ and therefore it is maximal with respect to the property of having a one-dimensional fixed point space. If l is *odd* then $SO(2)$ has a one-dimensional fixed point space; however, it is not maximal with this property. The normalizer of $SO(2)$ in $SO(3)$ is $O(2)$ and it acts as minus identity on $V^{SO(2)}$. Therefore the product of an element in $O(2)\backslash SO(2)$ with $-$ld fixes $V^{SO(2)}$. The group generated by $SO(2)$ and this particular element is denoted by $O(2)^-$ and is isomorphic to $O(2)$. The spherical harmonic, which is invariant under $SO(2)$, is given by $Y_0^l(\theta, \phi)$. In either case the equivariant branching lemma guarantees a unique branch with symmetry group $O(2)$ or $O(2)^-$, respectively. We call either of these solutions the *axisymmetric* solutions.

As was pointed out in the Introduction, the axisymmetric solutions are *generically* transcritical, therefore unstable, when l is even. This result goes back to Busse [1975], whose method of proof was different. When l is odd however, the branches of axisymmetric solutions are of *pitchfork* type, because the inversion in $O(3)$ acts as $-$ld in $V^{SO(2)}$. For $l=1$ the representation is equivalent to the action of $O(3)$ in $\mathbf{R}^3$, and every element in V is axisymmetric. The problem, therefore, is similar to having a bifurcation from a simple eigenvalue, and the bifurcated solutions are stable if supercritical.

2. Instability for odd l, $l>1$.

2.1. Construction of the bifurcation equations. We briefly recall a method described in more detail in Sattinger [1979], to construct the lowest-order terms in the Taylor expansion of an equivariant bifurcation problem.

The Lie algebra $so(3)$ is generated by the matrices

$$L_1 = \begin{vmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{vmatrix}, \quad L_2 = \begin{vmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{vmatrix}, \quad L_3 = \begin{vmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{vmatrix}. \tag{2.1}$$

Using these operators, we define $J_+ = L_2 + iL_1$, $J_- = -L_2 + iL_1$, and $J_3 = -iL_3$. We further note

$$\gamma_m = \{(l-m)(l+m+1)\}^{1/2}. \tag{2.2}$$

We then conclude from Theorem 5.21 in Sattinger [1979] that there exists a basis $\{\xi_{-l}, \cdots, \xi_l\}$ in the complexification of V_l such that

$$J_3\xi_m = m\xi_m, \quad J_+\xi_m = \gamma_m\xi_{m+1}, \quad J_-\xi_m = \gamma_{-m}\xi_{m-1}. \tag{2.3}$$

Moreover, since V_l is real, the ξ_m's must satisfy the relation (Sattinger [1979])

$$\xi_m = (-1)^m\bar{\xi}_{-m}, \qquad -l \leqq m \leqq l. \tag{2.4}$$

These relations allow us to compute the terms in the Taylor expansion of $F(.,\lambda)$ up to any given order. First we observe that the linear term is $c(\lambda)\,\mathrm{Id}$. Second, the constant and quadratic terms are 0 because $-\mathrm{Id}$ commutes with F (l is odd). Therefore we are interested in the third-order terms. We use coordinates z_j in terms of the basis $\{\xi_j, j=-l, \cdots, l\}$. The third-order terms may be written in coordinates as

$$F_m^{(3)} = \sum_{-l\leqq r+s+t\leqq l} a_{mrst} z_r z_s z_t, \qquad -l \leqq m \leqq l. \tag{2.5}$$

The infinitesimal generators J_3, J_+, J_- act as derivations on the z_j's; hence the following relations hold for the cubic terms:

$$\begin{aligned} J_3(z_rz_sz_t) &= (r+s+t)z_rz_sz_t, \\ J_+(z_rz_sz_t) &= \gamma_r z_{r+1}z_sz_t + \gamma_s z_r z_{s+1} z_t + \gamma_t z_r z_s z_{t+1}, \\ J_-(z_rz_sz_t) &= \gamma_{-r} z_{r-1}z_sz_t + \gamma_{-s} z_r z_{s-1} z_t + \gamma_{-t} z_r z_s z_{t-1}. \end{aligned} \tag{2.6}$$

Applying J_3 to $F_m^{(3)}$ we see that $a_{mrst}=0$ if $r+s+t \neq m$. Acting with J_+ on F_m we get

$$J_+F_{m+1} = \gamma_m F_m \quad (-l \leqq m \leqq l-1), \qquad J_+F_l = 0. \tag{2.7}$$

The latter equation gives a linear system for the coefficients a_{lrst}. It is underdetermined and can be solved with respect to a certain number $n(l)$ of parameters (independent coefficients).

LEMMA 1. $n(l) = [l/3]+1$.

Proof. Let $T(l, m)$ be the set of triples $t=(i,j,k)$ of integers $-l \leqq i,j,k \leqq l$ such that $i+j+k=m$ and $i \leqq j \leqq k$. We can view the equation $J_+F_l=0$ as a linear equation from $V_{l,l}$ to $V_{l,l+1}$, where we note $V_{l,m}$ the free vector space over $T(l,m)$. We want to prove that the kernel of the associated operator A has dimension $n(l)=[l/3]+1$. Let us first define an ordering in $T(l,m)$: $(i_1,j_1,k_1) < (i_2,j_2,k_2)$ if $i_1 < i_2$ or $i_1=i_2$ and $j_1<j_2$ or $i_1=i_2$, $j_1=j_2$ and $k_1<k_2$. Then there exists an integer r such that $T(l,l+1) = \{\tau_1, \cdots, \tau_r\}$ with $\tau_i < \tau_{i+1}$, $i=1,\cdots,r-1$. We write the system to solve in the coordinates along the basis elements $\tau=(i,j,k) \in T(l,l+1)$: each coordinate equation has the form

$$\gamma_{i-1}a_{l,i-1,j,k} + \gamma_{j-1}a_{l,i,j-1,k} + \gamma_{k-1}a_{l,i,j,k-1} = 0.$$

We can now order the elements of $T(l,l)$ as follows:

(1) $\tau'_1, \cdots, \tau'_r$ where each τ' is deduced from τ by taking $\tau' = (i-1,j,k)$; (2) the remaining elements (in whatever order). Observe the following: (i) $\tau_i < \tau_j \Rightarrow \tau'_i < \tau'_j$, for all $i,j=1,\cdots,r$; and (ii) $\tau' < (i,j-1,k)$ and $\tau' < (i,j,k-1)$. It now follows that the matrix of A in this basis, truncated to the first r columns, is triangular and has only nonzero elements on its diagonal, which proves that A is surjective.

To prove the lemma it remains to show that $\dim V_{l,l} - \dim V_{l,l+1} = [l/3]+1$. Let $j^+(i,j,k) = (i,j,k+1)$ be a map from $T(l,l)$ to $T(l,l+1)$. It is not defined if $k=l$, and the image of j^+ is complementary to set $\{(i,j,j) \in T(l,l+1)\}$. There are $l+1$ elements in $T(l,l)$ with $k=l$. On the other hand, the number of triples $(i,j,j) \in T(l,l+1)$ is equal to the number of integer solutions of

$$i+2j = l+1, \quad \text{where } -l \leqq i \leqq l/3, \quad j>0.$$

If l is odd, this equals the number of even integers between $-[l/2]$ and $[(l+1)/3]$, which is $[l/2]+[[(l+1)/3]/2]+1$. From here we get

$$n(l)=l+1-[(l+1)/3]-[l/2]+[[(l+1)/3]/2]-1=[l/3]+1. \qquad \square$$

A similar argument works in the case of even l.

It follows that the size of the linear system derived from the equation $J_+F_l=0$ grows rapidly with l. Once the structure of $F_l^{(3)}$ is known, we apply J_- recursively to $F_l^{(3)}, \cdots, F_1^{(3)}$, in order to get the coefficients of $F_{l-1}^{(3)}, \cdots, F_0^{(3)}$. We remark that F_{-m} is deduced from F_m by means of (2.4). Also, it follows easily that all the coefficients a_{mrst} are real.

From (2.1) we see that the one-parameter subgroup $\exp(tJ_3)$ acts as a rotation on the two-dimensional subspace spanned by $\{\xi_k, \xi_{-k}\}$ for $k=1, \cdots, l$. Therefore it fixes the linear span of ξ_0 (i.e., $V^{SO(2)}=\operatorname{span}[\xi_0]$), and the branch of axisymmetric solutions can be computed by solving the equation in $\operatorname{span}[\xi_0]$:

$$c(\lambda)z_0+F_0^{(3)}(0, \cdots, z_0, \cdots, 0)=0. \tag{2.8}$$

The leading part of the solution is determined by the third-order terms. In the following we set

$$\beta_m=a_{mm00} \quad \text{for } m=0, \cdots, l. \tag{2.9}$$

Then we have

$$(\lambda+o(|\lambda|)z_0)+\beta_0 z_0^3+o(|z_0|^3)=0,$$

the limits being taken for $\lambda, z_0 \to 0$. After eliminating the trivial solution and applying the implicit function theorem, we can solve for

$$\lambda(z_0)=-\beta_0 z_0^2+o(|z_0|^2). \tag{2.10}$$

The next step is to express the eigenvalues of the linearization D_xF along the branch of axisymmetric solutions in terms of the β's. We consider partial derivatives

$$\frac{\partial F_m^{(3)}(0, \cdots, z_0, \cdots, 0)}{\partial z_k}, \qquad 0 \leqq k, \qquad m \leqq l. \tag{2.11}$$

If $r+k+t=m$ and $k \neq m$, at least one of the numbers r or t is nonzero and the expression in (2.11) is zero. Therefore the linearization of f along the axisymmetric solution has diagonal form (this in fact is due to the form of the Cartan decomposition of D' into irreducible representation of $O(2)^-$). If $m=k$ the expression in (2.11) is the coefficient of $z_0^2 z_m$, which is by definition β_m. Therefore the linearization near $\mathbf{z}=0$ along the axisymmetric solutions takes the form

$$-\beta_0 z_0^2 \operatorname{Id}+\operatorname{diag}(\beta_{-l}z_0^2, \cdots, 3\beta_0 z_0^2, \cdots, \beta_l z_0^2)+o(|z_0|^2). \tag{2.12}$$

The eigenvalues are

$$\sigma_m=(\beta_m-\beta_0)z_0^2+o(|z_0|^2) \quad \text{for } m=-l, \cdots, l, \quad m \neq 0, \tag{2.13}$$

and $\sigma_0=2\beta_0 z_0^2+o(|z_0|^2)$. If the quotient of two of the constants $\beta_m-\beta_0$ is negative, then the solution is unstable. Observe that two eigenvalues must be equal to 0, since the orbit of axisymmetric solutions is two-dimensional (Chossat [1982]). These eigenvalues are σ_1 and σ_{-1} since the tangent space to the orbit at z_0 is spanned by ξ_1 and ξ_{-1}. This program can be carried through numerically. We can compute $(\beta_2-\beta_0)/(\beta_3-\beta_0)$ by solving the equation $j_+F_l^{(3)}=0$, applying J_-, and reading of the β's. The symmetry of the problem seems to stabilize the numerics since, for example, for $l=15$, the linear

equation is a 85×85 matrix, where the solution depends on five parameters and still the numerical results are very precise. We give a short list of the numerical results:

l	$(\beta_2-\beta_0)/(\beta_3-\beta_0)$
3	−0.6667
5	−2.6667
7	−5.5556
9	−9.3333
11	−14.0000
13	−19.5556
15	−26.00

By the method of computation we obtain $n(l)$ numbers, which should be all equal. This numerical result gives a strong indication that all axisymmetric solutions should be unstable. The purpose of the next section will be to show that the quotient $(\beta_2-\beta_0)/(\beta_3-\beta_0)$ is always negative for $l>1$.

2.2. Computation of $\beta_2-\beta_0$ and $\beta_3-\beta_0$.

LEMMA 2. *If the coefficient of $z_{-1}^2 z_2$ in $F_0^{(3)}$ is not zero, we have*

$$\frac{\beta_2-\beta_0}{\beta_3-\beta_0}=\frac{6-l(l+1)}{9}.$$

Remark. The hypothesis in this lemma is *generic* (it holds for a wide class of problems with $O(3)$-symmetry).

Proof. We need to compute the β_k's, $k=0,2,3$, in terms of the independent coefficients appearing in $F^{(3)}$. For this we proceed as follows: (1) determine those terms in $F_0^{(3)}$ that contribute to the β_k's by successive application of the operator J_+ to $F_k^{(3)}$, $k=0,1,2$; (2) compute the equivariant relations between these terms, by means of the following expression (Miller [1972]):

$$J_-J_+F_0=l(l+1)F_0; \tag{2.14}$$

and (3) deduce from (1) and (2) the relations between the β_k's.

The part in $F_0^{(3)}$ that gives a contribution to $\beta_k z_0^2 z_k$ in $F_k^{(3)}(k=1,2,3)$ by applying relations (2.7) is

$$az_{-3}z_0z_3+bz_{-2}z_{-1}z_3+cz_{-3}z_1z_2+dz_{-2}z_0z_2+ez_{-1}^2z_2+fz_{-1}z_0z_1+gz_0^3+hz_1^2z_{-2}. \tag{2.15}$$

Of course, we have $g=\beta_0$. In addition, the following terms are needed for computing the equivariant relations between the foregoing coefficients $a,\cdots,h$ in F_0, because they are generated by applying J_+J_- to (2.15):

$$rz_{-4}z_0z_4+sz_{-4}z_1z_3+tz_{-4}z_2^2+uz_{-3}z_{-1}z_4+vz_{-2}^2z_4. \tag{2.16}$$

The terms in (2.15) are obtained in a straightforward way by applying formula (2.6) for J_- recursively, starting from $\beta_3 z_0^2 z_3$ in $F_3^{(3)}$. The terms in (2.16) are obtained by applying J_+J_- to (2.15), using (2.6). Now applying (2.14) to (2.15), we obtain a system of eight linear equations for the corresponding coefficients. Recall that the coefficients of the equivariant polynomial mappings are real, and that ξ_0 is a real vector. Therefore

the coefficients of $z_i z_j z_k$ and $z_{-i} z_{-j} z_{-k}$ $(i+j+k=0)$ must be equal. Using these remarks and formula (2.2), we finally obtain the following eight equations:

$$
\begin{aligned}
&b-c=0, \qquad e-h=0,\\
&a(\gamma_2^2+\gamma_3^2)+2b\gamma_0\gamma_2+d\gamma_2^2=-s\gamma_{-1}\gamma_{-4}-u\gamma_{-1}\gamma_{-4}-r\gamma_{-4}^2,\\
&a\gamma_0\gamma_2+b(2\gamma_1^2+\gamma_3^2)+d\gamma_0\gamma_2+2e\gamma_1\gamma_2=-u\gamma_{-3}\gamma_{-4}-2v\gamma_{-2}\gamma_{-4},\\
&a\gamma_2^2+2b\gamma_0\gamma_2+d(\gamma_1^2+\gamma_2^2)+4e\gamma_0\gamma_1+f\gamma_1^2=0, \qquad (2.17)\\
&b\gamma_1\gamma_2+d\gamma_0\gamma_1+e(\gamma_1^2+\gamma_2^2)+f\gamma_0\gamma_1=0,\\
&d\gamma_1^2+4e\gamma_0\gamma_1+f(3\gamma_0^2+\gamma_1^2)+6g\gamma_0^2=0,\\
&f\gamma_0^2+2g\gamma_0^2=0,
\end{aligned}
$$

where the γ_m's are defined in (2.2). It is clear from this that only two coefficients can be chosen independently from the others. For example, choosing d and e as these coefficients, we get the relations

$$
a=-d+2e\gamma_0/\gamma_1(1-3\gamma_0^2/\gamma_2^2), \qquad b=c=3e(\gamma_0^2-\gamma_2^2)/\gamma_1\gamma_2
$$

$$
h=d, \quad f=-d-4e\gamma_0/\gamma_1, \quad g=-f/2.
$$

It remains to apply J_+ three times to F_0. We obtain successively

$$
\beta_1=\beta_0=d/2+2e\gamma_0/\gamma_1, \quad \beta_2=d/2, \quad \beta_3=d/2-(\gamma_0/\gamma_1-3\gamma_0^3/\gamma_1\gamma_2^2)e,
$$

from which it follows that

$$
\frac{\beta_2-\beta_0}{\beta_3-\beta_0}=\frac{6-l(l+1)}{9} \qquad (2.18)
$$

provided

$$
e\neq 0. \qquad (2.19)
$$

□

Thus, when $l\geqq 3$, (2.19) is a generic condition implying that the eigenvalues σ_2 and σ_3 have opposite signs, and thus we have proved the theorem stated in the Introduction.

Acknowledgments. We began considering this problem while visiting the Institute for Mathematics and Its Applications at Minneapolis in June 1985. The theorem was proved when the authors met again at the Michigan State University at East Lansing in March 1987. We are grateful to Professor Shui-Nee Chow for giving us the opportunity to finish this work and to Professor Martin Golubitsky for helping us improve the clarity of the mathematics in the text.

ON A REDUCTION PROCESS FOR NONLINEAR EQUATIONS*

A. D. JEPSON† AND A. SPENCE‡

Abstract. A method is discussed for reducing a nonlinear problem to a smaller (finite-dimensional) equivalent problem. The method is a generalization of the Lyapunov-Schmidt reduction, and provides a theoretical basis for more computationally convenient approaches. Our main results are on the equivalence of reduced problems obtained from various forms of this reduction procedure.

Key words. Lyapunov-Schmidt reduction, singularity theory, bifurcation.

1. Introduction. Nonlinear parameter dependent problems of the form

$$F(x, \lambda, \alpha) = 0, \tag{1.1}$$

arise in the study of the equilibrium states of many nonlinear systems. Here x, the state variable, lies in some Banach space X, $\lambda \in R$ is some distinguished parameter, which is called the *bifurcation* parameter, and $\alpha \in R^p$ is a vector of *control* parameters. It is assumed that the nonlinear function F maps $X \times R \times R^p$ to Y, a Banach space, and is sufficiently smooth so that any necessary derivatives exist. In physical situations interest often centres on the critical points of (1.1), namely, the points $(x_0, \lambda_0, \alpha_0)$, say, at which $F_x^0 \equiv F_x(x_0, \lambda_0, \alpha_0)$ is singular, since it is at such points that a physical system may lose stability (see, for example, [2], [3]).

The fundamental tools for the study of solutions of (1.1) in a neighborhood of a critical point are the Lyapunov-Schmidt reduction [7], [11], [13]-[15], and the closely related alternative method [1], [5]. No matter what the form of the original equation, provided these reduction processes can be applied, a *reduced problem* is obtained of the form

$$h(\varepsilon, \lambda, \alpha) = 0, \qquad h: R^m \times R \times R^p \to R^m, \tag{1.2}$$

whose solutions are in a one-to-one correspondence with those of (1.1). Typically the dimension of the reduced problem is very small, say $m = 1$ or 2, and hence it can be readily analyzed using singularity theory. Recently this approach has led to significant advances in our understanding of nonlinear phenomena arising from a wide variety of problems (see [14] and the references cited therein). The reduction process we shall describe and discuss is a generalization of the Lyapunov-Schmidt reduction.

The standard Lyapunov-Schmidt reduction requires a precise characterization of both the null space of F_x^0 and the range of F_x^0, which we denote by $N[F_x^0]$ and $R[F_x^0]$, respectively. The particular form of the reduction process is determined by this knowledge along with choices for complementary spaces of $N[F_x^0]$ and $R[F_x^0]$. Different choices of the complementary spaces lead to different reduced problems. However, Golubitsky and Schaeffer [7] show that this nonuniqueness is unimportant in that all reduced problems derived from one original problem (through the use of

the Lyapunov-Schmidt procedure) are equivalent in the sense that their solutions exhibit the same qualitative behavior. Furthermore, the solutions of the finite-dimensional reduced problem (1.2) are qualitatively similar (for a precise definition see § 3) to the solutions of the original problem (1.1). Therefore the local structure of solutions for (1.1) near a singular point $(x_0, \lambda_0, \alpha_0)$ can be studied by analyzing any reduced problem obtained through the Lyapunov-Schmidt procedure.

The motivation for this work arose in considering numerical techniques for computing the location and type of singular points for (1.1). It is hoped that these numerical techniques will form a bridge between the local results of singularity theory and the global properties often of interest in physical applications. In [9] the singularity theory of Golubitsky and Schaeffer [6] is used to derive numerically convenient defining equations for singularities arising in problems of the form (1.2) with $m = 1$. In effect it is assumed in [9] that the reduced problem (1.2) is given explicitly, as in the example calculation described there. Clearly, an important extension is to develop numerical techniques for obtaining a suitable reduction for problems of the general form (1.1). Some preliminary ideas to this end are presented in [4] and [8], and a more complete treatment is given in [10].

The fact that it is not necessary to know $N[F_x^0]$ or $R[F_x^0]$ in order to carry out a successful reduction is described in [11, § 22] and this observation leads to a generalised reduction process, described in § 2, which provides more flexibility than the standard Lyapunov-Schmidt procedure. This additional flexibility is important in the numerical computation of singular points. The typical situation in this application is that some point $(x_1, \lambda_1, \alpha_1)$, near a singular point $(x_0, \lambda_0, \alpha_0)$ of a particular type, is known. The known point need not be a singular point of (1.1), in fact, usually it is not a solution point of (1.1). However, crude approximations to $N[F_x^0]$ and $N[(F_x^0)^*]$ (and therefore $R[F_x^0]$) are available. Given this starting data, the goal of the computation is to accurately locate $(x_0, \lambda_0, \alpha_0)$. In this paper we show that crude approximations of $N[F_x^0]$ and $N[(F_x^0)^*]$ are sufficient to calculate a suitable reduced problem of the form (1.2). This result is central in the development of computationally efficient and robust numerical techniques (see [8] and [10]). Finally, we mention that the generalised reduction might also be used to advantage in analytical calculations where the null vectors of F_x^0 and $(F_x^0)^*$ are not available in simple closed form.

In § 3 we prove our main result. In particular we show that all reduced problems of the form (1.2), obtained from one original problem using the generalised procedure, are equivalent. This is an extension of the result given in [7] for the Lyapunov-Schmidt reduction. (We are grateful to a referee of this paper for supplying a shorter proof of the result for the Lyapunov-Schmidt reduction, which is presented in the Appendix.) A simple form of this result appears without proof in [8]. Independently Beyn [4] has shown that if F in (1.1) is finite-dimensional then, no matter how the generalised reduction is carried out, F is equivalent to a nonsingular linear system together with the particular reduced equation obtained. The equivalence of the reduced problems, however, is not proved there.

Finally in § 4 we consider the nonlinear differential system

$$\dot{x} + F(x, \lambda, \alpha) = 0$$

where $x \in X \times [0, \infty)$. If $(x_0, \lambda_0, \alpha_0)$ is an equilibrium solution with F_x^0 singular and all other eigenvalues have positive real part, then it is often important to ascertain the asymptotic stability of equilibrium solutions near $(x_0, \lambda_0, \alpha_0)$. If F_x^0 has zero as a simple eigenvalue Golubitsky and Schaeffer [7] show how this may be done by examination of the reduced equation derived using the Lyapunov-Schmidt reduction.

We show that the same stability information may be obtained from the generalised procedure.

2. The generalised reduction. In this section we describe the generalised reduction process as given in [11], and give necessary and sufficient conditions for its application (Theorem 2.10).

First we remark that, although in applications it is often important to keep λ a distinguished parameter, here it is convenient to put $\lambda = \alpha_0$ and write (1.1) as

$$F(x, \alpha) = 0, \qquad \alpha = (\alpha_0, \cdots, \alpha_p) \in \mathbb{R}^{p+1}. \tag{2.1}$$

Furthermore, without loss of generality, we take $(x_0, \alpha_0) = 0 \in X \times \mathbb{R}^{p+1}$, so that

$$F(0, 0) = 0. \tag{2.2}$$

Throughout this paper we assume that the Frechet derivative $L \equiv F_x(0, 0)$ satisfies

(2.3a) $L: X \to Y$ is a Fredholm operator of index zero,

with

$$N[L] = \text{span}\,\{\Phi_1, \cdots, \Phi_l\}, \qquad \dim N[L] = l, \tag{2.3b}$$

$$N[L^*] = \text{span}\,\{\Psi_1^*, \cdots, \Psi_l^*\}, \qquad \dim N[L^*] = l. \tag{2.3c}$$

Here $L^*: Y^* \to X^*$ is the adjoint operator associated with L.

As was mentioned in the Introduction, the aim of a reduction process is to obtain a small (finite) system of equations which is, in some sense, equivalent to (1.1). The first step in the generalised reduction is to choose closed subspaces X_1, $X_2 \subset X$ and Y_1, $Y_2 \subset Y$ with

$$X = X_1 \oplus X_2, \qquad \dim X_2 = m, \tag{2.4a}$$

$$Y = Y_1 \oplus Y_2, \qquad \dim Y_2 = m. \tag{2.4b}$$

Here $m \geqq l$ is taken to be finite. Let P and Q be the projections

$$P: X \to X, \quad R[P] = X_2, \quad N[P] = X_1, \tag{2.5a}$$

$$Q: Y \to Y, \quad R[Q] = Y_2, \quad N[Q] = Y_1. \tag{2.5b}$$

The fundamental assumption is that the decompositions in (2.4a), (2.4b) are such that

$$N[P] \cap N[(I - Q)L] = \{0\}. \tag{2.6}$$

Using the projections in (2.5) we rewrite (2.1) in the equivalent form

$$(I - Q)F(x_1 + x_2, \alpha) = 0 \in Y_1, \tag{2.7a}$$

$$QF(x_1 + x_2, \alpha) = 0 \in Y_2, \tag{2.7b}$$

where $x_1 \in X_i$ for $i = 1, 2$. In particular, notice that (2.7b) is a system of dimension m. We emphasize that there is no need to restrict attention to reduced problems of dimension l, and reduced problems of dimension $m \geqq l$ may be considered if deemed necessary (for example, near a singularity of higher multiplicity).

The reduction proceeds by first solving (2.7a) for x_1 in terms of x_2 and α, and, second, substituting this problem into (2.7b) to obtain

$$QF(x_1(x_2, \alpha) + x_2, \alpha) = 0. \tag{2.8}$$

The key step is the first, and the Implicit Function Theorem ensures that this is possible provided $A \equiv (I-Q)L(I-P)$ satisfies

$$A: X_1 \to Y_1 \text{ is nonsingular.} \tag{2.9}$$

Under assumption (2.6) A is indeed nonsingular. In fact, we have Theorem 2.10.

THEOREM 2.10. *Let L, P, Q, and A be as above. Then* (2.6) *is a necessary and sufficient condition for A to be nonsingular.*

The proof of Theorem 2.10 is given at the end of this section. The theorem shows that, under condition (2.6), the Implicit Function Theorem provides the existence and local uniqueness of a solution $x_1(x_2, \alpha)$ of (2.7a) for (x_2, α) near 0, and with $x_1(0,0)=0$. At this point it is convenient to introduce bases $\{v_i\}_{i=1}^m$ and $\{w_i\}_{i=1}^m$ of X_2 and Y_2, respectively, and to let $V_2: \mathbb{R}^m \to X_2$ and $W_2: Y_2 \to \mathbb{R}^m$ be defined by

$$V_2\varepsilon = \sum_{i=1}^{m} \varepsilon_i v_i, \qquad \varepsilon \equiv (\varepsilon_1, \cdots, \varepsilon_m), \tag{2.11a}$$

$$W_2\left\{\sum_{i=1}^{m} \eta_i w_i\right\} = \eta \equiv (\eta_1, \cdots, \eta_m). \tag{2.11b}$$

The final step in the reduction process is to obtain the reduced problem by writing (2.8) in terms of these bases, that is,

$$h(\varepsilon, \alpha) \equiv W_2 QF(\Omega(\varepsilon, \alpha), \alpha) = 0, \tag{2.12a}$$

where $h: \mathbb{R}^m \times \mathbb{R}^{p+1} \to \mathbb{R}^m$, and

$$\Omega(\varepsilon, \alpha) \equiv x_1(V_2\varepsilon, \alpha) + V_2\varepsilon. \tag{2.12b}$$

The Lyapunov-Schmidt reduction is a special case of the above procedure; in particular, the decompositions in (2.4) are taken to satisfy

$$X = X_1 \oplus X_2, \quad \dim X_2 = l, \quad X_2 = N[L], \tag{2.13a}$$

$$Y = Y_1 \oplus Y_2, \quad \dim Y_2 = l, \quad Y_1 = R[L]. \tag{2.13b}$$

Notice that (2.5b) and (2.13b) imply that $I-Q$ projects onto $R[L]$. Therefore (2.6) becomes simply $N[P] \cap N[L] = \{0\}$, which follows from (2.13a). That is, the decompositions used in the Lyapunov-Schmidt reduction are sufficient to guarantee (2.6) and hence that A is nonsingular. By contrast, in the generalised reduction we have more freedom in the choice of the decompositions of X and Y; in effect, the only restriction is that the decompositions produce a nonsingular A.

A second reduction technique is the alternative method [1], [5]. For the case of Fredholm operators treated here it is natural to consider only reduced problems of the form (2.12). In this situation the alternative method assumes that the decompositions (2.4a), (2.4b) are chosen such that

$$X_2 = N[(I-Q)L], \tag{2.14a}$$

$$LX_2 \subset Y_2, \tag{2.14b}$$

$$L(I-P): X_1 \to Y_1 \text{ is nonsingular.} \tag{2.14c}$$

Therefore, if L is a Fredholm operator of index zero, the alternative method is also a special case of the generalised reduction. However, it is important to note that the alternative method can also be applied to more general problems.

We end this section with the following proof.

Proof of Theorem 2.10. Define

$$\bar{A} \equiv (I-Q)L(I-P), \qquad \bar{A}: X \to Y. \tag{2.15}$$

Then $\bar{A}$ is the product of three Fredholm operators, each of which has index zero. Therefore it follows that (see [12]),

(2.16) $\bar{A}$ is Fredholm with index zero.

Assume that (2.6) is satisfied, that is,

(2.17) $$R[I-P]\cap N[(I-Q)L]=\{0\}.$$

By (2.15) we have

(2.18) $$N[\bar{A}]=N[I-P]\oplus\{R[I-P]\cap N[(I-Q)L]\}.$$

Therefore, by (2.5a), (2.17), and (2.18),

(2.19a) $$N[\bar{A}]=X_2, \qquad \dim X_2=m.$$

Furthermore, by (2.15), we have $R[\bar{A}]\subset R[I-Q]=X_1$. But by (2.16) and (2.19a) we have codim $R[\bar{A}]=m$. It follows from (2.4b) and (2.5b) that codim $R[I-Q]=m$, and hence

(2.19b) $$R[\bar{A}]=R[I-Q]=Y_1, \qquad \operatorname{codim} R[\bar{A}]=m.$$

It now follows that $A=\bar{A}|_{X_1}$ is one-to-one and onto Y_1. By the Closed Graph Theorem we conclude that A is nonsingular, and therefore (2.6) is sufficient.

Conversely, suppose that $\phi\in N[P]\cap N[(I-Q)L]$, $\phi\neq 0$. Then $\phi=(I-P)\phi$ and $A\phi=\bar{A}\phi=(I-Q)L\phi=0$. That is $\phi\in N[A]$, and hence (2.6) is necessary. □

3. Equivalence of the reduced problems. The reduction processes discussed in § 2 all have the same goal, namely, the construction of a finite-dimensional reduced problem from (1.1). The type and unfolding behavior of a singular point of F is to be determined by studying the singular behavior of the reduced problem. However, the reduction process is not unique; in particular there are infinitely many ways to choose the decompositions in (2.4) such that (2.6) is satisfied. The usefulness of the reduction process therefore lies, in part, in the fact that the singular behavior of the reduced problem depends only on the function F and not on the details of the reduction. We make this precise through the use of the following notion of equivalence.

DEFINITION 3.1. Suppose $h(\varepsilon,\alpha)$, $g(\varepsilon,\alpha):\mathbb{R}^m\times\mathbb{R}^{p+1}\to\mathbb{R}^m$ are two smooth functions such that $h(0,0)=g(0,0)=0$. Then h and g are said to be equivalent, which we denote by $h\sim g$, if there exist smooth (C^∞) functions $T(\varepsilon,\alpha)$ and $E(\varepsilon,\alpha)$ such that

(3.2a) $T(0,0)$ is nonsingular,

(3.2b) $E(0,0)=0$, $E_\varepsilon^0\equiv E_\varepsilon(0,0)$ is nonsingular,

and, for (ε,α) near $(0,0)$,

(3.3) $$h(\varepsilon,\alpha)=T(\varepsilon,\alpha)g(E(\varepsilon,\alpha),\alpha).$$

For the case in which F is C^∞ in a neighbourhood of zero then (3.3) essentially states that h and g are *contact equivalent* in the sense of the singularity theory of Golubitsky and Schaeffer [6]. To be precise, (3.3) states that h is contact equivalent to $R_1 g(R_2\varepsilon,\alpha)$ for constant matrices R_1 and R_2 chosen so that $T(0,0)R_1^{-1}$ and $E_\varepsilon^0 R_2$ are positive definite. These matrices are important when the dynamical stability of various steady states are investigated in § 4; however, we can ignore them for the moment. As discussed in [6], this notion of contact equivalence is an appropriate mathematical formulation of the statement that solutions of (3.2a) and (3.2b) show the same *qualitative behavior* near $(\varepsilon,\alpha)=(0,0)$. Our main result is Theorem 3.4.

THEOREM 3.4 (Equivalence Theorem). *Let*

$$h(\varepsilon, \alpha) = 0, \qquad h : \mathbb{R}^m \times \mathbb{R}^{p+1} \to \mathbb{R}^m, \tag{3.4a}$$

$$\hat{h}(\hat{\varepsilon}, \alpha) = 0, \qquad \hat{h} : \mathbb{R}^{\hat{m}} \times \mathbb{R}^{p+1} \to \mathbb{R}^{\hat{m}} \tag{3.4b}$$

be two reduced problems obtained from (1.1) *by the generalised reduction procedure with* (2.6) *satisfied in each case. Suppose* $\hat{m} \leqq m$ *and let* $k : \mathbb{R}^m \times \mathbb{R}^{p+1} \to \mathbb{R}^m$ *be the trivial extension of* $\hat{h}$ *given by*

$$k(\varepsilon, \alpha) = (\hat{h}(\varepsilon_1, \cdots, \varepsilon_{\hat{m}}, \alpha), \quad e_{\hat{m}+1}, \cdots, \varepsilon_m). \tag{3.5}$$

Then

$$h(\varepsilon, \alpha) \sim k(\varepsilon, \alpha). \tag{3.6}$$

Before proving the theorem we first note that a similar result has been proved in [7] for the case of the Lyapunov-Schmidt reduction applied to problems with one-dimensional null spaces (i.e., (2.3) is satisfied with $l = 1$). Our proof of the more general result is guided by the proof presented there.

Proof of Theorem 3.4. It is convenient to first consider the case in which the dimensions of the reduced systems are the same, that is, $\hat{m} = m$. In this case we need to show $h \sim \hat{h}$. It is obvious that if h and $\hat{h}$ are obtained through the use of the same P and Q but with different choices of V_2 and W_2 in (2.9), then $h \sim \hat{h}$. (Use $T_{(\varepsilon,\alpha)} = T_0$ and $E(\varepsilon, \alpha) = E_0 \varepsilon$ where T_0 and E_0 are constant $m \times m$ matrices.) An h obtained from a particular choice of P and Q is denoted by h_{PQ}. Our first major task, then, is to show

$$h_{PQ} \sim h_{\hat{P}\hat{Q}} \tag{3.7}$$

whenever P, Q and $\hat{P}$, $\hat{Q}$ satisfy (2.4), (2.5), and (2.6) with the same value of m.

In order to prove (3.7) we first show that a third projection $\bar{P}$ exists such that $h_{\bar{P}Q}$ and $h_{\bar{P}\hat{Q}}$ can be constructed (see Lemma 3.8 below). Second, we show that $h_{PQ} \sim h_{\bar{P}Q}$ and $h_{\hat{P}\hat{Q}} \sim h_{\bar{P}\hat{Q}}$ (see Lemma 3.9). Finally (3.7) follows by showing that $h_{\bar{P}Q} \sim h_{\bar{P}\hat{Q}}$ (see Lemma 3.19).

LEMMA 3.8. *Assume that* P, Q *and* $\hat{P}$, $\hat{Q}$ *are two pairs of projections with each projection having a range of dimension* m, *and with each pair satisfying* (2.5) *and* (2.6). *Then there is a continuous projection* $\bar{P} : X \to X$ *such that*

$$\dim R[\bar{P}] = m, \tag{3.8a}$$

$$N[\bar{P}] \cap N[(I - Q)L] = \{0\}, \tag{3.8b}$$

$$N[\bar{P}] \cap N[(I - \hat{Q})L] = \{0\}. \tag{3.8c}$$

Proof. Let $X_3 = N[(I - Q)L]$, and similarly define $\hat{X}_3$ using $\hat{Q}$. In order to calculate $\dim X_3$, notice that $(I - Q)L$ is a product of two Fredholm operators with index zero, and hence $(I - Q)L$ is Fredholm with index zero. Therefore

$$\dim X_3 = \operatorname{codim} R[(I - Q)L] \geqq \operatorname{codim} R[I - Q] = m.$$

However, by (2.6), we have

$$\dim X_3 \leqq \operatorname{codim} X_1 = m.$$

Therefore $\dim X_3 = m$, and a similar argument with $\hat{Q}$ shows that $\dim \hat{X}_3 = m$.

Now we choose $\bar{X}_1$ such that it is the simultaneous complement of X_3 and $\hat{X}_3$. To be precise, $\bar{X}_1$ is a closed subspace of X such that

$$X = \bar{X}_1 \oplus X_3 = \bar{X}_1 \oplus \hat{X}_3.$$

(To prove that such an $\bar{X}_1$ exists, consider $\bar{X}_1$ to be the direct sum of a finite-dimensional space and a complement of $X_3 \oplus \hat{X}_3$. This reduces the problem to the finite-dimensional space $X_3 \oplus \hat{X}_3$. We omit the remaining details.) Finally, let $\bar{X}_2$ be a complement of $\bar{X}_1$, say X_3, and define $\bar{P}$ to be the projection onto $\bar{X}_2$ along $\bar{X}_1$. Conditions (3.8a)-(3.8c) easily follow.

We remark that if $l = m$ then $\bar{P}$ can be taken to be the projection used in the standard Lyapunov-Schmidt procedure. □

The generalised reduction procedure can be used to construct $h_{\bar{P}Q}$ and $h_{\bar{P}\hat{Q}}$, since Lemma 3.8 ensures that conditions (2.4) and (2.6) are satisfied for the appropriate pairs of projections. We now have Lemma 3.9.

LEMMA 3.9. *In the notation used above,*

$$h_{PQ}(\varepsilon, \alpha) \sim h_{\bar{P}Q}(\varepsilon, \alpha), \tag{3.9a}$$

$$h_{\bar{P}\hat{Q}}(\varepsilon, \alpha) \sim h_{\bar{P}\hat{Q}}(\varepsilon, \alpha). \tag{3.9b}$$

Proof. We begin by considering (3.9a). In order to obtain h_{PQ} and $h_{\bar{P}Q}$ we must solve

$$(I - Q)F(x_1 + x_2, \alpha) = 0, \tag{3.10a}$$

$$(I - Q)F(\bar{x}_1 + \bar{x}_2, \alpha) = 0, \tag{3.10b}$$

for $x_1 \in X_1$ and $\bar{x}_1 \in \bar{X}_1$, respectively. As was mentioned in § 2, locally unique smooth solutions $x_1(x_2, \alpha)$ and $\bar{x}_1(\bar{x}_2, \alpha)$ can be obtained for (x_2, α) and $(\bar{x}_2, \alpha)$ near $(0, 0)$. With these solutions, define

$$u(x_2, \alpha) = (I - \bar{P})\{x_1(x_2, \alpha) + x_2\}, \tag{3.11a}$$

$$\mu(x_2, \alpha) = \bar{P}\{x_1(x_2, \alpha) + x_2\}. \tag{3.11b}$$

The local uniqueness of $\bar{x}_1(\bar{x}_2, \alpha)$ as a solution of (3.10b) can now be used to show that

$$u(x_2, \alpha) = \bar{x}_1(\bar{x}_2, \alpha) \quad \text{for } \mu(x_2, \alpha) = \bar{x}_2. \tag{3.12}$$

Therefore, by (3.11) and (3.12) we have

$$\begin{aligned} QF(x_1(x_2, \alpha) + x_2, \alpha) &= QF(u(x_2, \alpha) + \mu(x_2, \alpha), \alpha) \\ &= QF(\bar{x}_1(\mu(x_2, \alpha), \alpha) + \mu(x_2, \alpha), \alpha). \end{aligned}$$

From this and (2.12) it follows that

$$h_{PQ}(\varepsilon, \alpha) = h_{\bar{P}Q}(E(\varepsilon, \alpha), \alpha), \tag{3.13a}$$

with

$$E(\varepsilon, \alpha) = \bar{V}_2^{-1}\mu(V_2\varepsilon, \alpha). \tag{3.13b}$$

Here $\bar{V}_2 : \mathbb{R}^m \to \bar{X}_2$ is the coordinate function (see (2.11a)) used in constructing $h_{\bar{P}Q}$.

We are left with showing that E_ε^0 is nonsingular. To do this, notice that (3.13b) gives

$$\bar{V}_2 E_\varepsilon^0 = \mu_{x_2}^0 V_2. \tag{3.14a}$$

Furthermore, by (3.11b) we find

$$\mu_{x_2}^0 = \bar{P}\left\{\frac{\partial x_1}{\partial x_2}(0, 0) + I\right\}. \tag{3.14b}$$

Let $\phi \in N[E_\varepsilon^0]$; then by (3.14),

$$0 = \bar{V}_2 E_\varepsilon^0 \phi = \bar{P}\left\{\frac{\partial x_1}{\partial x_2}(0, 0) + I\right\} V_2 \phi. \tag{3.15}$$

By differentiating (3.10a) with respect to x_2 we find

$$x(\phi) \equiv \left\{ \frac{\partial x_1}{\partial x_1}(0,0) + I \right\} V_2 \phi \in N[(I-Q)L]. \tag{3.16}$$

Together, (3.8b), (3.15), and (3.16) imply

$$x(\phi) \in N[\bar{P}] \cap N[(I-Q)L] = \{0\}.$$

That is, $x(\phi) = 0$ and therefore, by applying P to (3.16), we obtain $V_2\phi = 0$. Since V_2 is nonsingular we finally have $\phi = 0$, and therefore E_ε^0 is nonsingular.

The proof of (3.9b) is similar, with (3.8c) being used in place of (3.8b). □

We are left with proving that $h_{\bar{P}Q} \sim h_{\bar{P}\hat{Q}}$. To do this we will use the following proposition, which is the analogue of Proposition I, 4.2 in [7] for vector-valued functions.

PROPOSITION 3.17. *Let $g(\varepsilon, \alpha)$ and $\hat{g}(\varepsilon, \alpha)$ be two smooth functions, g, $\hat{g}: \mathbb{R}^m \times \mathbb{R}^{p+1} \to \mathbb{R}^m$. Suppose*

$$\operatorname{rank} \left\{ \frac{\partial g(0,0)}{\partial(\varepsilon, \alpha)} \right\} = \operatorname{rank} \left\{ \frac{\partial \hat{g}(0,0)}{\partial(\varepsilon, \alpha)} \right\} = m, \tag{3.17a}$$

and, for (ε, α) in a neighbourhood of zero,

$$g(\varepsilon, \alpha) = 0 \text{ implies } \hat{g}(\varepsilon, \alpha) = 0. \tag{3.17b}$$

Then there exists a nonsingular $m \times m$ matrix $T(\varepsilon, \alpha)$ such that

$$\hat{g}(\varepsilon, \alpha) = T(\varepsilon, \alpha) g(\varepsilon, \alpha), \tag{3.18}$$

for (ε, α) in a neighbourhood of zero. Furthermore, $T(\varepsilon, \alpha)$ inherits the smoothness of g and $\hat{g}$.

A proof of Proposition 3.17 can be obtained by a straightforward generalisation of the proof of Proposition I, 4.2 given in [7]. We omit the details. This proposition is used in the proof of Lemma 3.19.

LEMMA 3.19. *Let $h_{\bar{P}Q}$ and $h_{\bar{P}\hat{Q}}$ be as above. Then $h_{\bar{P}Q} \sim h_{\bar{P}\hat{Q}}$.*

Proof. If $h_{\bar{P}Q}(\varepsilon, \alpha) = 0$ then $F(\bar{x}_1(\bar{V}_2\varepsilon, \alpha) + \bar{V}_2\varepsilon, \alpha) = 0$, and so $h_{\bar{P}\hat{Q}}(\varepsilon, \alpha) \equiv \hat{W}_2\hat{Q}F(\bar{x}_1(\bar{V}_2\varepsilon, \alpha) + \bar{V}_2\varepsilon, \alpha) = 0$. Therefore (3.17b) is satisfied for $g \equiv h_{\bar{P}Q}$ and $\hat{g} \equiv h_{\bar{P}\hat{Q}}$. In order to apply Proposition 3.17 we must arrange for (3.17a) to be satisfied.

Specifically, we unfold F by writing

$$G(x, \alpha, \beta) \equiv F(x, \alpha) + B\beta = 0, \tag{3.20}$$

where $\beta \in \mathbb{R}^m$ and $B: \mathbb{R}^m \to Y$ is a bounded linear map. Let $g(\varepsilon, \alpha, \beta)$ and $\hat{g}(\varepsilon, \alpha, \beta)$ be the reduced functions obtained by using $\bar{P}$, Q and $\bar{P}$, $\hat{Q}$, respectively, on problem (3.20). In particular, we have

$$g(\varepsilon, \alpha, 0) = h_{\bar{P}Q}(\varepsilon, \alpha), \tag{3.21a}$$

$$\hat{g}(\varepsilon, \alpha, 0) = h_{\bar{P}\hat{Q}}(\varepsilon, \alpha), \tag{3.21b}$$

for (ε, α) near 0. Furthermore, from (3.20) it follows that

$$g_\beta^0 = KB, \; \hat{g}_\beta^0 = \hat{K}B, \tag{3.22}$$

where K, $\hat{K}: Y \to \mathbb{R}^m$ are given by

$$K \equiv [-W_2 Q F_x^0 A_{\bar{P}Q}^{-1}(I-Q) + W_2 Q], \qquad A_{\bar{P}Q} \equiv (I-Q)F_x^0(I-\bar{P}), \tag{3.23a}$$

$$\hat{K} \equiv [-\hat{W}_2 \hat{Q} F_x^0 A_{\bar{P}\hat{Q}}^{-1}(I-\hat{Q}) + \hat{W}_2 \hat{Q}], \qquad A_{\bar{P}\hat{Q}} \equiv (I-\hat{Q})F_x^0(I-\bar{P}). \tag{3.23b}$$

We need to choose B such that g_β^0 and $\hat{g}_\beta^0$ are nonsingular. This can be done as follows. By (2.11b) and (3.23) we see that

$$K Y_2 = W_2 Y_2 = \mathbb{R}^m, \qquad \hat{K}\hat{Y}_2 = \mathbb{R}^m, \tag{3.24}$$

and

$$\operatorname{codim} N[K] = m = \operatorname{codim} N[\hat{K}].$$

It is easily proved that there exists a simultaneous complement, $\bar{Y}_2$, such that

$$\begin{aligned} &N[K] \oplus \bar{Y}_2 = Y = N[\hat{K}] \oplus \bar{Y}_2, \\ &\dim \bar{Y}_2 = m, \end{aligned} \tag{3.25}$$

and hence we may define B such that $R[B] = \bar{Y}_2$. It now follows from (3.22), (3.24), and (3.25) that

$$\operatorname{rank}[g_\beta^0] = \operatorname{rank}[\hat{g}_\beta^0] = m, \tag{3.26}$$

as desired.

Now Proposition 31.7 implies that

$$\hat{g}(\varepsilon, \alpha, \beta) = T(\varepsilon, \alpha, \beta) g(\varepsilon, \alpha, \beta) \tag{3.27}$$

for $(\varepsilon, \alpha, \beta)$ near zero. By setting $\beta = 0$ it follows from (3.21) that

$$h_{\bar{P}\hat{Q}}(\varepsilon, \alpha) = T(\varepsilon, \alpha, 0) h_{\bar{P}Q}(\varepsilon, \alpha)$$

for (ε, α) near zero. Furthermore, by differentiating (3.27), it follows that $\hat{g}_\beta^0 = T^0 g_\beta^0$, with (3.26) ensuring that T^0 is nonsingular. □

Lemmas 3.8, 3.9, and 3.19 complete the proof that $h_{PQ} \sim h_{\hat{P}\hat{Q}}$ when $\hat{m} = m$. That is, for a given $m \geqq l$ the particular choice of P and Q does not effect the qualitative behavior of the reduced equation near $(\varepsilon, \alpha) = 0$.

The next major step is to show the equivalence of the reduced problems (3.4a), (3.4b) obtained with $\hat{m} < m$. In fact, it is sufficient to consider only the case $l = \hat{m} < m$, since all other cases can be derived from this case in a straightforward manner.

In view of the above results for $\hat{m} = m$, we are free to choose convenient projections P, Q and $\hat{P}$, $\hat{Q}$ to define h and $\hat{h}$. In particular, we take the splittings

$$X = X_1 \oplus X_2 \oplus X_3 \tag{3.28a}$$

$$Y = Y_1 \oplus Y_2 \oplus Y_3 \tag{3.28b}$$

where

$$N[F_x^0] = X_3, \qquad \dim X_2 = m - l, \tag{3.28c}$$

$$R[F_x^0] = Y_1 \oplus Y_2, \qquad \dim Y_2 = m - l, \tag{3.28d}$$

$$Y_2 = F_x^0 X_2. \tag{3.28e}$$

We choose $\hat{P}$ and $\hat{Q}$ such that

$$\hat{P}: X \to X_3, \qquad N[\hat{P}] = X_1 \oplus X_2, \tag{3.29a}$$

$$\hat{Q}: Y \to Y_3, \qquad N[\hat{Q}] = R[F_x^0] = Y_1 \oplus Y_2 \tag{3.29b}$$

(which corresponds to the standard Lyapunov-Schmidt reduction). Similarly, we choose P and Q such that

$$P: X \to X_2 \oplus X_3, \qquad N[P] = X_1, \tag{3.30a}$$

$$Q: Y \to Y_2 \oplus Y_3, \qquad N[Q] = Y_1 \tag{3.30b}$$

(which corresponds to the alternative method [1], [5]). It is straightforward to check that both pairs of projections satisfy (2.6), and therefore h_{PQ} and $h_{\hat{P}\hat{Q}}$ exist. The proof of Theorem 3.4 is now completed by the use of Lemma 3.31.

LEMMA 3.31. *In the above notation*

$$h_{PQ}(\varepsilon_1, \cdots, \varepsilon_m, \alpha) \sim (h_{\hat{P}\hat{Q}}(\varepsilon_1, \cdots, \varepsilon_l, \alpha), \varepsilon_{l+1}, \cdots, \varepsilon_m). \tag{3.31}$$

Proof. The reduced equation $h_{PQ} = 0$ can be written as (see 2.12)

$$h_{PQ}(\sigma, \delta, \alpha) \equiv \begin{pmatrix} W_2(I-Q)Q \\ W_2\hat{Q}Q \end{pmatrix} F(\hat{x}(\sigma, \delta, \alpha), \alpha) = 0 \tag{3.32}$$

where $\varepsilon = (\sigma, \delta)$, $\sigma \in \mathbb{R}^{m-l}$, $\delta \in \mathbb{R}^l$, and

$$W_2 : Y_2 \to \mathbb{R}^{m-l}, \qquad W_3 : Y_3 \to \mathbb{R}^l, \tag{3.33a}$$

$$V_2 : \mathbb{R}^{m-l} \to X, \qquad V_3 : \mathbb{R}^l \to X_3, \tag{3.33b}$$

are nonsingular linear mappings. Furthermore, $\hat{x}(\sigma, \delta, \alpha)$ satisfies

$$(I-Q)F(\hat{x}(\sigma, \delta, \alpha), \alpha) = 0, \tag{3.34a}$$

$$\hat{x}(\sigma, \delta, \alpha) = x_1(\sigma, \delta, \alpha) + V_2\sigma + V_3\delta, \qquad x_1 \in X_1, \tag{3.34b}$$

for (σ, δ, α) near zero.

We claim that, with the above definitions,

$$h_{PQ}(\sigma, \delta, \alpha) \sim \begin{pmatrix} \sigma \\ h_0(\delta, \alpha) \end{pmatrix} \tag{3.35}$$

for some smooth function $h_0 : \mathbb{R}^l \times \mathbb{R}^{p+1} \to \mathbb{R}^l$. Indeed, upon differentiating (3.32) with respect to σ, we find

$$H^0 \equiv \left(\frac{\partial}{\partial \sigma} h_{PQ}\right)^0 = \begin{pmatrix} W_2(Q-\hat{Q}) \\ W_2\hat{Q} \end{pmatrix} F_x^0 V_2. \tag{3.36}$$

Here we have used $\hat{Q}Q = \hat{Q}$ (see (3.29b), (3.30b)), and $\partial x_1/\partial \sigma\ (0, 0, 0) = 0$ (see (3.28), (3.30), (3.34)). It is easy to verify that the top block of H^0, namely $W_2(Q-\hat{Q})F_x^0 V_2$, is a nonsingular $(m-l) \times (m-l)$ matrix. A standard argument now ensures the existence of a smooth coordinate transformation $(\sigma, \delta, \alpha) \to (D(\sigma, \delta, \alpha), \delta, \alpha)$ such that

$$D^0 = 0, \qquad D_\delta^0 = 0, \tag{3.37a}$$

$$D_\sigma^0 \quad \text{is nonsingular} \tag{3.37b}$$

and

$$h_{PQ}(D(\sigma, \delta, \alpha), \delta, \alpha) = \begin{pmatrix} \sigma \\ W_2\hat{Q}F(\hat{x}(D(\sigma, \delta, \alpha), \delta, \alpha), \alpha) \end{pmatrix} \tag{3.38}$$

for (σ, δ, α) near zero. Finally it follows from (3.38) that there exists a nonsingular matrix $T_1(\sigma, \delta, \alpha)$ such that

$$T_1(\sigma, \delta, \alpha) h_{PQ}(D(\sigma, \delta, \alpha), \delta, \alpha) = \begin{pmatrix} \sigma \\ h_0(\delta, \alpha) \end{pmatrix}$$

where

$$h_0(\delta, \alpha) = W_2\hat{Q}F(\hat{x}(D(0, \delta, \alpha), \delta, \alpha), \alpha). \tag{3.39}$$

That is, we have verified (3.35) for h_0 as in (3.39).

We are only left with relating h_0 to $h_{\hat{P}\hat{Q}}$. Note that (3.34) and (3.38) imply that $\hat{x}(D(0, \delta, \alpha), \delta, \alpha)$ satisfies

$$(I-Q)F(\hat{x}, \alpha)=0 \quad \text{and} \quad (I-\hat{Q})QF(\hat{x}, \alpha)=(Q-\hat{Q})F(\hat{x}, \alpha)=0.$$

Hence

$$(I-\hat{Q})F(\hat{x}, \alpha)=0. \tag{3.40a}$$

In addition, we find from (3.34b) that

$$\hat{P}\hat{x}=V_3\delta. \tag{3.40b}$$

These are precisely the equations that need to be solved to obtain $h_{\hat{P}\hat{Q}}$, and therefore it follows from (3.39) and (3.40) that

$$h_0(\delta, \alpha)=h_{\hat{P}\hat{Q}}(\delta, \alpha) \tag{3.41}$$

(where V_3 and W_3 are used as the coordinate mappings in $h_{\hat{P}\hat{Q}}$). The equivalence (3.31) is a consequence of (3.35) and (3.41). This completes the proof of Lemma 3.31, and hence the proof of the Equivalence Theorem. □

4. Linearized stability and the generalised reduction. Consider now the case that (1.1) arises in the study of the differential system

$$\dot{x}+F(x, \alpha)=0, \qquad \alpha \in \mathbb{R}^{p+1} \tag{4.1}$$

where $x=x(t)\in X$, $t>0$ and we again write $\lambda=\alpha_0$. It is convenient to take $X=Y$ a Hilbert space. Assume $(0, 0)$ is an equilibrium solution. It is well known that the asymptotic stability of $(0, 0)$ depends on the spectrum of $L=F_x(0, 0)$ and that an equilibrium solution that is a singular point of L, with all other eigenvalues of L having positive real part, lies on a stability boundary. Golubitsky and Schaeffer [7, §4, Chap. I] consider such a case with L having zero as a simple eigenvalue and discuss the stability of an equilibrium solution (x, α) near $(0, 0)$. In particular, suppose Φ_0 and Ψ_0^* are the null vectors of F_x^0 and $(F_x^0)^*$, respectively, with

$$\Psi_0^*\Phi_0>0. \tag{4.2}$$

(Here and in the sequel we denote the inner product $\langle\Psi_0, \Phi_0\rangle$ by $\Psi_0^*\Phi_0$.) Furthermore, suppose $h(\varepsilon, \alpha)$ is obtained from the Lyapunov-Schmidt reduction (use $W_2=\Psi_0^*$, $V_2=\Phi_0$ in § 2); then it is shown in [7] that the solution $(x, \alpha)=(\Omega(\varepsilon, \alpha), \alpha)$ of (1.1) is stable if $h_\varepsilon(\varepsilon, \alpha)>0$ and unstable if $h_\varepsilon(\varepsilon, \alpha)<0$. The main result of this section is to show how the analogous stability results can be obtained from a reduced function computed through the use of the generalised reduction.

In the remainder of this section we assume that Ψ_0^* and Φ_0 are as above with $\Psi_0^*\Phi_0\neq 0$, but we do not assume (4.2) is satisfied. Then zero is a simple eigenvalue of F_x^0 and it follows (from the Implicit Function Theorem) that there are smooth functions $\Phi(\varepsilon, \alpha)$, $\Psi(\varepsilon, \alpha)$, and $\mu(\varepsilon, \alpha)$ such that

$$F_x(\Omega(\varepsilon, \alpha), \alpha)\Phi(\varepsilon, \alpha)=\mu(\varepsilon, \alpha)\Phi(\varepsilon, \alpha), \tag{4.3a}$$

$$\Phi^*\Phi=1, \tag{4.3b}$$

$$\Psi^*F_x(\Omega(\varepsilon, \alpha), \alpha)=\mu(\varepsilon, \alpha)\Psi^*(\varepsilon, \alpha), \tag{4.3c}$$

$$\Psi^*\Psi=1, \tag{4.3d}$$

with $\mu(0, 0)=\mu^0=0$, $\Phi(0, 0)=\Phi_0$, $\Psi(0, 0)=\Psi_0$.

As discussed above, in order to determine the (linear) stability of the steady state $(x, \alpha)=(\Omega(\varepsilon, \alpha), \alpha)$ we need only know the sign of $\mu(\varepsilon, \alpha)$, which, in turn, is to be determined from the reduced function.

Suppose $h: \mathbb{R}^m + \mathbb{R}^{p+1} \to \mathbb{R}^m$ is a reduced function obtained from (1.1) through the use of the generalised reduction. Then the connection between the null spaces of h_ε and F_x is given in Lemma 4.4.

LEMMA 4.4. *For* $\phi, \psi \in \mathbb{R}^m$ *define*

$$\Phi(\varepsilon, \alpha, \phi) \equiv \Omega_\varepsilon(\varepsilon, \alpha)\phi = (I - P)\Omega_\varepsilon(\varepsilon, \alpha)\phi + V_2\phi, \tag{4.4a}$$

$$\Psi^*(\varepsilon, \alpha, \psi) \equiv \psi^* W_2 Q[I - F_x(\Omega(\varepsilon, \alpha), \alpha)(I - P)A^{-1}(\varepsilon, \alpha)(I - Q)]. \tag{4.4b}$$

Here $A(\varepsilon, \alpha): X_1 \to Y_1$ *is defined by* (*cf.* (2.9))

$$A(\varepsilon, \alpha) \equiv (I - Q)F_x(\Omega(\varepsilon, \alpha), \alpha)(I - P). \tag{4.4c}$$

Then, for (ε, α) *near* $(0, 0)$,

$$N[F_x(\Omega(\varepsilon, \alpha), \alpha)] \subset \Phi(\varepsilon, \alpha, \mathbb{R}^m) \equiv \{\Phi(\varepsilon, \alpha, \phi) | \phi \in \mathbb{R}^m\}, \tag{4.5a}$$

$$N[(F_x(\Omega(\varepsilon, \alpha), \alpha))^*] \subset \Psi^*(\varepsilon, \alpha, \mathbb{R}^m). \tag{4.5b}$$

Furthermore,

$$h_\varepsilon(\varepsilon, \alpha)\phi = 0, \tag{4.6a}$$

$$\psi^* h_\varepsilon(\varepsilon, \alpha) = 0, \tag{4.6b}$$

if and only if

$$F_x(\Omega(\varepsilon, \alpha), \alpha)\Phi(\varepsilon, \alpha, \phi) = 0, \tag{4.7a}$$

$$\Psi^*(\varepsilon, \alpha, \psi)F_x(\Omega(\varepsilon, \alpha), \alpha) = 0. \tag{4.7b}$$

Proof. First note that $A(0, 0)$ is precisely the A used in (2.9), which is assumed to be nonsingular, and therefore $A^{-1}(\varepsilon, \alpha)$ exists for (ε, α) near $(0, 0)$. Also, recall from § 2 that $\Omega(\varepsilon, \alpha)$ is defined to be the solution of

$$(I - Q)F(\Omega(\varepsilon, \alpha), \alpha) = 0, \tag{4.8a}$$

$$P\Omega(\varepsilon, \alpha) = V_2\varepsilon, \tag{4.8b}$$

and the reduced function is

$$h(\varepsilon, \alpha) = W_2 QF(\Omega(\varepsilon, \alpha), \alpha). \tag{4.8c}$$

By differentiating (4.7) we obtain

$$(I - Q)F_x(\Omega(\varepsilon, \alpha), \alpha)\Omega_\varepsilon(\varepsilon, \alpha) = 0, \tag{4.9a}$$

$$P\Omega_\varepsilon(\varepsilon, \alpha) = V_2, \tag{4.9b}$$

$$h_\varepsilon(\varepsilon, \alpha) = W_2 QF_x(\Omega(\varepsilon, \alpha), \alpha)\Omega_\varepsilon(\varepsilon, \alpha). \tag{4.9c}$$

Equations (4.9a) and (4.9b) can be solved to give

$$\Omega_\varepsilon(\varepsilon, \alpha) = [I - (I - P)A^{-1}(\varepsilon, \alpha)(I - Q)]V_2, \tag{4.10}$$

which we make use of below.

Now suppose (4.6) is satisfied. Then (4.7a) clearly follows from (4.4a), (4.6a), (4.9a), (4.9c), and the nonsingularity of W_2. In order to show that (4.7b) follows from (4.6b), we rewrite (4.7b) as

$$\Psi^* F_x = \Psi^* F_x(I - P) + \Psi^* F_x P = 0$$

and consider the two components in the sum separately. By (4.4b) and (4.4c) we have

$$\Psi^* F_x(I - P) = \psi^* W_2 Q[F_x(I - P) - F_x(I - P)A^{-1}A(I - P)] = 0.$$

Similarly, by (4.4b), (4.9), and (4.10)

$$\begin{aligned}\Psi^* F_x P &= \psi^* W_2 Q F_x [P - (I-P)A^{-1}(I-Q)F_x P] \\ &= \psi^* W_2 Q F_x \Omega_\varepsilon V_2^{-1} \\ &= \psi^* h_\varepsilon V_2^{-1} \\ &= 0.\end{aligned}$$

Therefore (4.7b) is satisfied.

The converse result, namely that (4.7) implies (4.6), can be obtained from (4.9) and (4.10) in a straightforward manner. We omit the details. Finally, we are left with showing (4.5), that is any null vector of $F_x(\Omega(\varepsilon, \alpha), \alpha)$ can be written in one of the forms in (4.4). Suppose $\Phi_1 \in N[F_x(\Omega(\varepsilon, \alpha), \alpha)]$ for (ε, α) near $(0, 0)$. Then set $\phi_1 = V^{-1}P\Phi_1$. Moreover, we have $0 = (I-Q)F_x(\Omega(\varepsilon, \alpha), \alpha)[(I-P)\Phi_1 + P\Phi_1]$ and therefore $(I-P)\Phi_1 = -A^{-1}(\varepsilon, \alpha)(I-Q)F_x V_2 \phi_1$.

Now using (4.10), we obtain

$$\Phi_1 = P\Phi_1 + (I-P)\Phi_1 = \Omega_\varepsilon(\varepsilon, \alpha)\phi_1.$$

Similarly, if $\Psi_1^* \in N[(F_x(\Omega(\varepsilon, \alpha), \alpha))^*]$ then it can be shown that $\Psi_1^* = \Psi^*(\varepsilon, \alpha, \psi_1)$ where $\psi_1 = W_2 Q \Psi_1$. □

From Lemma 4.4 we see that the assumption that $l = 1$ implies $h_\varepsilon(0, 0)$ has a one-dimensional null space, with right and left null vectors ϕ_0, ψ_0 such that $\Phi_0 = \Phi(0, 0, \phi_0)$, $\Psi_0 = \Psi(0, 0, \psi_0)$. However, the zero eigenvalue of h_ε^0 need not be simple, that is, it is possible that $\psi_0^* \phi_0 = 0$. But the eigenstructure of h_ε^0 depends on the choice of basis elements used to define V_2 and W_2 in (2.11). Indeed we note from (4.9c) and (4.10) that

$$h_\varepsilon(\varepsilon, \alpha) = W_2[QF_x\{I - A^{-1}(I-Q)\}]V_2.$$

Therefore, by reordering the basis vectors used to define V_2 and W_2, the rows and columns of h_ε can be rearranged. Similarly, by changing the sign of a basis vector, the sign of a row or column of h_ε can be reversed. The effect on ψ_0 and ϕ_0 is, of course, that their elements can be permuted and reversed in sign. By choosing an appropriate rearrangement the condition

$$\psi_0^* \phi_0 \neq 0 \tag{4.11}$$

can be obtained. (For example, change all negative coefficients in ψ_0 and ϕ_0 to positive coefficients, and then move the largest elements to the first position in each vector. Then (4.11) is a consequence of ψ_0 and ϕ_0 being nonzero.) Finally, we note that when (4.11) is satisfied, zero is a simple eigenvalue of h_ε^0 and therefore there exist smooth functions $\phi(\varepsilon, \alpha)$, $\psi(\varepsilon, \alpha)$, and $\bar{\mu}(\varepsilon, \alpha)$ such that

$$h_\varepsilon \phi = \bar{\mu}\phi, \ \psi^* h_\varepsilon = \mu \psi^* \tag{4.12a}$$

for (ε, α) near $(0, 0)$ with

$$\phi(0, 0) = \phi_0, \ \psi(0, 0) = \psi_0, \tag{4.12b}$$

$$\bar{\mu}(0, 0) = 0. \tag{4.12c}$$

We can now state the main result of this section.

THEOREM 4.13. *Suppose* $l = 1$ *and* $\Psi_0^* \Phi_0 \neq 0$. *Also, assume that* V_2 *and* W_2 *are such that* (4.11) *is satisfied. Then, for* (ε, α) *near* $(0, 0)$,

$$\mu(\varepsilon, \alpha) = a(\varepsilon, \alpha)\bar{\mu}(\varepsilon, \alpha) \tag{4.13a}$$

for some smooth function $a(\varepsilon, \alpha)$. *Moreover,*

$$\text{sign}\{a(0,0)\} = \text{sign}\{(\psi_0^* \phi_0)(\Psi_0^* \Phi_0)\}. \tag{4.13b}$$

Before proving Theorem 4.13 we remark that in the case $m = 1$ the result can be rewritten as

$$\mu(\varepsilon, \alpha) = a(\varepsilon, \alpha) h_\varepsilon(\varepsilon, \alpha)$$

where

$$\text{sign}\{a(0,0)\} = \text{sign}\{\Psi_0^* \Phi_0\}.$$

This is the result obtained in [7] for the Lyapunov-Schmidt decomposition. In particular, it provides the desired stability information for (ε, α) near $(0,0)$ in terms of a reduced function obtained from the generalised reduction procedure. For the case $m > 1$ the theorem illustrates how the stability information can be obtained from the behavior of the eigenvalue of $h_\varepsilon(\varepsilon, \alpha)$ that passes through zero at $(\varepsilon, \alpha) = 0$. In both cases the application of the theorem is trivial.

Proof of Theorem 4.13. Our proof is a simple modification of the proof of Theorem 4.1 presented in [7, p. 38]. It is clear from Lemma 4.4 that

$$\bar{\mu}(\varepsilon, \alpha) = 0 \quad \text{implies } \mu(\varepsilon, \alpha) = 0. \tag{4.14}$$

If $\nabla \mu^0 \equiv \partial \mu(0,0)/\partial(\varepsilon, \alpha) \neq 0$ and $\nabla \bar{\mu}^0 \neq 0$ then Proposition I.4.2 of [7] guarantees (4.13a) with a smooth (nonzero) $a(\varepsilon, \alpha)$.

Unfortunately, $\nabla \mu^0$ or $\nabla \bar{\mu}^0$ could be zero, in which case the proposition does not apply directly. It is convenient to add a new unfolding parameter to $F(x, \alpha)$ to ensure the applicability of Proposition I.4.2. of [7].

In particular, consider

$$\tilde{F}(x, \alpha, \beta) \equiv F(x, \alpha) + \beta \Psi_0 \Phi_0^* x = 0. \tag{4.15}$$

Then the same generalised reduction can be applied to (4.15). In particular, define $\tilde{\Omega}(\varepsilon, \alpha, \beta)$ to be the solution of (cf. (4.8a), (4.8b).

$$(I - Q)\tilde{F}(\tilde{\Omega}(\varepsilon, \alpha, \beta), \alpha, \beta) = 0, \tag{4.16a}$$

$$P\tilde{\Omega}(\varepsilon, \alpha, \beta) = V_2 \varepsilon, \tag{4.16b}$$

for $(\varepsilon, \alpha, \beta)$ near $(0,0,0)$. Then the reduced function is given by

$$\tilde{h}(\varepsilon, \alpha, \beta) \equiv W_2 Q \tilde{F}(\tilde{\Omega}(\varepsilon, \alpha, \beta), \alpha, \beta). \tag{4.17}$$

Note that this construction implies

$$h(\varepsilon, \alpha) = \tilde{h}(\varepsilon, \alpha, 0). \tag{4.18}$$

With some abuse of notation we extend μ, $\bar{\mu}$, Φ, Ψ, to be functions of $(\varepsilon, \alpha, \beta)$.

Next consider $\partial \mu / \partial \beta \ (0,0,0) \equiv \mu_\beta^0$. By differentiating

$$\tilde{F}_x(\tilde{\Omega}(\varepsilon, \alpha, \beta), \alpha, \beta)\Phi = \mu \Phi$$

with respect to β and evaluating at $(0,0,0)$, we find

$$\tilde{F}_{xx}^0 \Phi_0 \tilde{\Omega}_\beta^0 + \tilde{F}_{x\beta}^0 \Phi_0 + \tilde{F}_x^0 \Phi^0 = \mu_\beta^0 \Phi_0. \tag{4.19}$$

However, it follows from (4.16) that $\tilde{\Omega}_\beta^0 \equiv 0$. Furthermore, from (4.15) we have $\tilde{F}_{x\beta}^0 = \Psi_0 \Phi_0^*$. When we use these facts in (4.19), and apply Ψ_0^*, we are provided with

$$(\Psi_0^* \Psi_0)(\Phi_0^* \Phi_0) = \mu_\beta^0 \Psi_0^* \Phi_0. \tag{4.20}$$

In particular, $\mu_\beta^0 \neq 0$ and $\text{sign}\,(\mu_\beta^0) = \text{sign}\,(\psi_0^* \Phi_0)$.

A similar calculation based on

$$\tilde{h}_\varepsilon \phi = \bar{\mu}\phi$$

shows that

$$\bar{\mu}^0_\beta \psi_0^\top h^0_{\varepsilon\beta}\phi_0. \tag{4.21}$$

However, it follows from (4.17) and $\tilde{\Omega}^0_\beta = 0$ that

$$\tilde{h}^0_{\varepsilon\beta} = W_2 Q\{\tilde{F}^0_{x\beta}\tilde{\Omega}^0_\varepsilon + \tilde{F}^0_x \tilde{\Omega}^0_{\varepsilon\beta}\}.$$

By differentiating (4.16) twice we find

$$A^0(I-P)\tilde{\Omega}^0_{\varepsilon\beta} = -(I-Q)\tilde{F}^0_{x\beta}\tilde{\Omega}^0_\varepsilon, \qquad P\tilde{\Omega}^0_{\varepsilon\beta=0}.$$

By solving this expression for $\tilde{\Omega}^0_{\varepsilon\beta}$ and substituting the result into the above formula for $h^0_{\varepsilon\beta}$ we obtain

$$\tilde{h}^0_{\varepsilon\beta} = W_2 Q[I - F^0_x(I-P)A^{-1}(I-Q)]\tilde{F}^0_{x\beta}\Omega^0_\varepsilon.$$

Here we have used $\tilde{F}^0_x = F^0_x$, $A = A^0$, and $\tilde{\Omega}^0_\varepsilon = \Omega^0_\varepsilon$.

Finally, from $\tilde{F}^0_{x\beta} = \Psi_0 \Phi_0^*$ and (4.4), we have

$$\psi_0 \tilde{h}^0_{\varepsilon\beta}\phi_0 = \Psi_0^* \tilde{F}^0_{x\beta}\Phi_0 = (\Psi_0^*\Psi_0)(\Phi_0^*\Phi_0),$$

and so (4.21) becomes

$$\bar{\mu}^0_\beta = (\Psi_0^*\Psi_0)(\Phi_0^*\Phi_0)/(\psi_0^*\phi_0) \neq 0. \tag{4.22}$$

Now Proposition 4.2 of [7, § 4, Chap. I] ensures the existence of a smooth function $a(\varepsilon, \alpha, \beta)$ for $(\varepsilon, \alpha, \beta)$ near $(0, 0, 0)$ such that

$$\mu(\varepsilon, \alpha, \beta) = a(\varepsilon, \alpha, \beta)\bar{\mu}(\varepsilon, \alpha, \beta). \tag{4.23}$$

By differentiating (4.23) and using (4.20), (4.22) we find

$$a(0,0,0) = \bar{\mu}^0_\beta / \mu^0_\beta = \frac{\psi_0^*\phi_0}{(\Psi_0^*\Phi_0)} \neq 0. \tag{4.24}$$

The theorem follows now from (4.24) by setting $\beta = 0$ in (4.23). □

Appendix by A. Vanderbauwhede. In [7] Golubitsky and Schaeffer give a proof of the (contact) equivalence of the bifurcation functions that we obtain for different choices of the projections in a Lyapunov-Schmidt reduction. Here we give an alternative proof that, in our view, illustrates quite well the essential ideal of the Lyapunov-Schmidt reduction.

In the notation of § 2, suppose that the projections P and Q satisfy (2.5) with

$$X_2 = N[F^0_x], \qquad Y_1 = R[F^0_x].$$

It follows that (2.6) is satisfied, and therefore there is a local solution, $x_1 = \hat{v}(x_2, \alpha)$, to (2.7a). In fact, we find it more convenient to define $v: X_2 \times Y_1 \times R^k \to X_2$, where $k \equiv p+1$, and $v(u, w, \alpha)$ is the local solution of

$$(I-Q)F(u+v, \alpha) = w. \tag{A.1}$$

Clearly $v(u, 0, \alpha) = \hat{v}(u, \alpha)$. Substitution of this solution into (2.7b) provides the *bifurcation mapping* $g: X_2 \times R^k \to R[Q]$ defined by

$$g(u, \alpha) \equiv QF(u + v(u, 0, \alpha), \alpha). \tag{A.2}$$

For P and Q as above, this reduction provides one version of the Lyapunov-Schmidt procedure. The bifurcation mapping depends on the choice of projections P and Q; however, as the following theorem shows, different choices lead to equivalent mappings.

THEOREM. *Let $g: X_2 \times R^k \to R[Q]$ and $g_1: X_2 \times R^k \to R[Q_1]$ be two bifurcation mappings, obtained by choosing projections (P, Q) and (P_1, Q_1), respectively, in the reduction described above. Then there exist smooth mappings*

$$T: X_2 \times R^k \to L(R[Q_1], R[Q]),$$
$$U: X_2 \times R^k \to X_2,$$

such that

$$g(u, \alpha) = T(u, \alpha) g_1(U(u, \alpha), \alpha), \tag{A3a}$$

$$T(0, 0) = Q|_{R[Q_1]}, \tag{A3b}$$

$$U(0, 0) = 0 \quad \textit{and} \quad U_u(0, 0) = I_{X_2}. \tag{A3c}$$

Remark. All mappings in the statement and in the proof that follows are defined and smooth in a neighbourhood of the origin. The result shows that g and g_1 are contact equivalent at the origin (see [7]).

Proof. With $v(u, w, \alpha)$ defined as above, we set $V: X_2 \times Y_1 \times R^k \to X \times R^k$ to be

$$V(u, w, \alpha) \equiv (u + v(u, w, \alpha), \alpha). \tag{A4}$$

Then we have

$$V(0, 0, 0) = (0, 0), \tag{A5a}$$

$$\frac{\partial V}{\partial u}(0, 0, 0) = I_{X_2}, \quad \text{and} \quad F_x^0 \frac{\partial V}{\partial w}(0, 0, 0) = I_{Y_1}. \tag{A5b}$$

Therefore, we easily see that V is a local diffeomorphism. Moreover, from (A1), we have

$$F(V(u, w, \alpha)) = w + G(u, w, \alpha), \tag{A6}$$

for $G: X_2 \times Y_1 \times R^k \to R[Q]$ defined by

$$G(u, w, \alpha) \equiv QF(V(u, w, \alpha)). \tag{A7}$$

It is clear from the construction that

$$g(u, \alpha) = G(u, 0, \alpha). \tag{A8}$$

Now, by replacing (P, Q) by (P_1, Q_1) we find a similar local diffeomorphism $V_1: X_2 \times Y_1 \times R^k \to X \times R^k$ and a mapping $G_1: X_2 \times Y_1 \times R^k \to R[Q_1]$ such that

$$F(V_1(u, w, \alpha)) = w + G_1(u, w, \alpha), \tag{A9}$$

with

$$G_1(u, w, \alpha) \equiv Q_1 F(V_1(u, w, \alpha)). \tag{A10}$$

A second bifurcation mapping is given by

$$g_1(u, \alpha) = G_1(u, 0, \alpha). \tag{A11}$$

Our task is to show that g and g_1 are contact equivalent.

It is convenient to introduce $D: X_2 \times Y_1 \times R^k \to X_2 \times Y_1 \times R^k$ defined by $D \equiv V_1^{-1} \circ V$. It follows that D is a local diffeomorphism with $D(0, 0, 0) = (0, 0, 0)$. Furthermore, we define U and W by

$$D(u, 0, \alpha) = (U(u, \alpha), W(u, \alpha), \alpha). \tag{A12}$$

Upon differentiating $V_1 \circ D = V$ with respect to u and evaluating the result at $(0, 0, 0)$, we find from (A5b) that

$$U_u(0, 0) = I_{X_2}. \tag{A13}$$

We are now left with showing that (A3a) and (A3b) are satisfied for this definition of $U(u, \alpha)$.

From (A6) and (A9) it follows that

$$\begin{aligned} g(u, \alpha) &= F(V_1 \circ D(u, 0, \alpha)) \\ &= W(u, \alpha) + G_1(U(u, \alpha), W(u, \alpha), \alpha). \end{aligned} \tag{A14}$$

But (A11) and a first-order Taylor expansion together imply

$$G_1(u, w, \alpha) = g_1(u, \alpha) + T_1(u, w, \alpha) w \tag{A15}$$

for some smooth $T_1 : X_2 \times Y_1 \times R^k \to L(Y_1, R[Q_1])$. Since $\partial G_1 / \partial w\,(0, 0, 0) = 0$ we also have

$$T_1(0, 0, 0) = 0. \tag{A16}$$

Combining (A12), (A14), and (A15), we obtain

$$g(u, \alpha) = W(u, \alpha) + g_1(U(u, \alpha), \alpha) + T_1(D(u, 0, \alpha))\, W(u, \alpha).$$

Applying Q and $(I - Q)$ to this equation gives

$$\begin{aligned} g(u, \alpha) &= Q g_1(U, \alpha) + Q T_1(D)\, W, \\ (I_{Y_1} + (I - Q) T_1(D))\, W &= -(I - Q) g_1(U, \alpha), \end{aligned}$$

for $U = U(u, \alpha)$, $W = W(u, \alpha)$, and $D = D(u, 0, \alpha)$. Solving the second equation for W, and substituting the result into the first equation, provides (A3a) with

$$T(u, \alpha) = Q|_{R[Q_1]} - Q T_1(D)(I_{Y_1} + (I - Q) T_1(D))^{-1} (I - Q)|_{R[Q_1]}.$$

Equation (A3b) now follows from (A16). □

The central idea of the Lyapunov-Schmidt reduction is clearly revealed in (A6). Since V is a local diffeomorphism, we see from (A4) and (A5) that $F(x, \alpha) = 0$ is contact equivalent to

$$w + G(u, w, \alpha) = 0. \tag{A17}$$

Applying Q and $(I - Q)$ to this equation, we find that (A17) is equivalent to solving the reduced equation $g(u, \alpha) \equiv G(u, 0, \alpha) = 0$.

Acknowledgment. The authors thank Martin Golubitsky for providing an early draft of [7].

VORTEX RINGS WITH SWIRL: AXISYMMETRIC SOLUTIONS OF THE EULER EQUATIONS WITH NONZERO HELICITY*

BRUCE TURKINGTON†

Abstract. This work introduces a new class of steady solutions of the axisymmetric Euler equations for an incompressible inviscid fluid. Each solution represents a three-dimensional vortex flow whose azimuthal components of vorticity and velocity are nonzero inside a toroidal region determined by the solution. The governing free-boundary problem is solved by variational techniques. The underlying variational principle is formulated from the natural invariants associated with the evolution equations for axisymmetric flows, and involves a family of invariants that generalizes the standard angular impulse and helicity integrals. A direct method is employed to prove the existence of steady solutions in a bounded domain and steadily translating solutions in space. Qualitative properties of these vortices are discussed and concentrated vortex rings with large swirl are shown to constitute a desingularization of the classical circular vortex filament.

Key words. Euler fluid dynamical equations, vortex, helicity, variational methods, free-boundary problems

AMS(MOS) subject classifications. 76C05, 49H05

Introduction. In this paper we examine a new class of steady solutions of the Euler equations governing the motion of an ideal fluid in three dimensions. The solutions that we consider are axisymmetric: they define flows that are invariant under rotation about the z-axis, when expressed in cylindrical coordinates (z, r, θ). Furthermore, each solution has the property that there is a (solid) toroidal region inside of which the θ-components of velocity u^θ and of vorticity ω^θ are nonzero, and outside of which the flow is irrotational. Therefore, we shall refer to these solutions, and the flows that they represent, as "vortex rings with swirl."

The objectives of our work are, first, to establish the existence of these steady solutions in a general and physically natural setting, and second, to derive some of their qualitative and asymptotic properties. We obtain our results by appealing to a variational formulation of the free-boundary problem satisfied by these solutions. The variational principle underlying our analysis of steady flows follows directly from the structure of the evolution equations governing the dynamics of axisymmetric vortex flows, which we express as a nonlinear, nonlocal system of equations for the quantities $\zeta = \omega^\theta / r$ and $\gamma = ru^\theta$. It is based on the reformulation of the steady equations in terms of ζ alone, which is accomplished easily through the elimination of γ. In this way we obtain a constrained maximization problem in ζ, the solutions of which define the desired steady vortex rings with swirl, and which is readily treated analytically and numerically. We utilize this approach to study both steady solutions in a bounded (axisymmetric) domain and steadily translating solutions in all of space.

An alternate variational characterization to ours has been given by Arnold [1], who considers fully three-dimensional flows, as well as by Benjamin [4], who specializes it to axisymmetric flows expressed in terms of ζ and γ. In this approach the variational principle is derived from the (noncanonical) Hamiltonian structure of the equations governing ζ and γ, and is formulated in the class of so-called isovortical variations of a given (extremal) flow. The resulting variational problem, though it arises very naturally

† Department of Mathematics and Statistics, University of Massachusetts, Amherst, Massachusetts 01003.

from the dynamical problem, is, unfortunately, highly nonconvex, and so is not amenable to the standard methods of analysis. Our variational problem, on the other hand, is designed to avoid such difficulties; instead, we take a wider class of competing functions, and compensate for this by adding to the objective (energy) functional certain terms that are invariant under all isovortical variations. These additional terms are constructed from the angular impulse (momentum) and helicity integrals. In fact, the construction involves a family of integrals generalizing the classical helicity integral; consequently, we are lead to introduce a family of conserved quantities—certain functionals of ζ and γ that we call "generalized angular impulse" and "generalized helicity integrals"—valid for evolving axisymmetric flows, which have not been used before in the literature. In turn, the variational principle that we give serves to clarify the role played by these generalized conserved quantities in determining the nature of steady axisymmetric flows.

The outline of the paper is as follows. In § 1, we discuss the axisymmetric Euler equations and the various conserved quantities associated with these equations. We begin § 2 by reviewing the general variational principles that characterize steady flows, and we conclude it by formulating the specific constrained maximization problem that we use in the further analysis. Section 3 is devoted to proving our main existence theorems for vortex rings with swirl. Finally, in § 4 we summarize some qualitative and asymptotic properties of the solutions found in § 3. In particular, we indicate how the parameters defining the angular impulse and helicity integrals determine the structure of the vortex ring and the flow field within it, and we identify the salient features of the solutions corresponding to extreme values of those parameters.

In a sequel to this paper [8] Eydeland and Turkington study propagating vortex rings with swirl in free space using an iterative numerical method allied with the variational structure of the governing problem formulated herein. The reader is referred there for a further exposition of these particularly interesting vortices and for a full discussion of their quantitative properties and physical characteristics.

1. Evolution equations and their invariants. Let (z, r, θ) denote the usual cylindrical coordinates in $\mathbf{R}^3$. Let $\hat{D} \subseteq \mathbf{R}^3$ be an axisymmetric domain, the axis of symmetry being $r = 0$; in the sequel, $\hat{D}$ will be either a bounded domain with a smooth boundary or all of space. We consider the axisymmetric flow of an ideal fluid with unit density in the domain $\hat{D}$, and we write the velocity and pressure fields in the form

$$u = u^z(z, r, t)e_z + u^r(z, r, t)e_r + u^\theta(z, r, t)e_\theta, \qquad p = p(z, r, t)$$

where $\{e_z, e_r, e_\theta\}$ is the usual coordinate frame. The governing equations are standard (see [2], for instance):

$$\begin{aligned} &u_t^z + u \cdot \nabla u^z = -p_z, \\ &u_t^r + u \cdot \nabla u^r - \frac{1}{r}(u^\theta)^2 = -p_r, \\ &u_t^\theta + u \cdot \nabla u^\theta + \frac{1}{r} u^r u^\theta = 0, \end{aligned} \tag{1.1}$$

$$u_z^z + \frac{1}{r}(ru^r)_r = 0, \tag{1.2}$$

where $u \cdot \nabla = u^z(\partial/\partial z) + u^r(\partial/\partial r)$ in view of the axisymmetry. For simplicity we will

impose the standard boundary conditions

$$\hat{v} \cdot u = 0 \quad \text{on } \partial\hat{D}, \tag{1.3}$$

where $\hat{v}$ is the outer unit normal on $\partial\hat{D}$.

The vorticity field, $\omega = \nabla \times u$, which plays a basic role in the subsequent development, is given by

$$\begin{aligned} \omega &= \omega^z(z, r, t)e_z + \omega^r(z, r, t)e_r + \omega^\theta(z, r, t)e_\theta \\ &= \frac{1}{r}(ru^\theta)_r e_z - u_z^\theta e_r + (u_z^r - u_r^z)e_\theta. \end{aligned} \tag{1.4}$$

The dynamical equations (1.1) are most conveniently expressed as evolution equations for the modified azimuthal vorticity, $\zeta = \zeta(z, r, t)$, and the azimuthal circulation (density), $\gamma = \gamma(z, r, t)$, which are defined by

$$\zeta = \frac{1}{r}\omega^\theta, \qquad \gamma = ru^\theta. \tag{1.5}$$

The equation for ζ is derived by taking the curl of the first two component equations in (1.1):

$$\begin{aligned} 0 &= \left[u_t^r + u \cdot \nabla u^r - \frac{1}{r}(u^\theta)^2\right]_z - [u_t^z + u \cdot \nabla u^z]_r \\ &= r\left[\left(\frac{\omega^\theta}{r}\right)_t + u \cdot \nabla\left(\frac{\omega^\theta}{r}\right) - 2r^{-2}u^\theta u_z^\theta\right]; \end{aligned} \tag{1.6}$$

thus, we obtain the first evolution equation

$$\zeta_t + u \cdot \nabla\zeta - 2r^{-4}\gamma\gamma_z = 0. \tag{1.7}$$

The equation for γ is equivalent to the conservation of circulation (Kelvin theorem), and it results from a manipulation of the third component equation in (1.1):

$$0 = u_t^\theta + u \cdot \nabla u^\theta + r^{-1}u^r u^\theta = r^{-1}[(ru^\theta)_t + u \cdot \nabla(ru^\theta)];$$

thus, we obtain the second evolution equation

$$\gamma_t + u \cdot \nabla\gamma = 0. \tag{1.8}$$

The continuity equation (1.2) furnishes a Stokes streamfunction $\psi = \psi(z, r, t)$ satisfying $u^z = \psi_r/r$ and $u^r = -\psi_z/r$. Consequently, ψ is determined by ζ alone according to

$$\zeta = r^{-1}[u_z^r - u_r^z] = L\psi$$

where L is the linear elliptic operator

$$L = -\frac{1}{r^2}\frac{\partial^2}{\partial z^2} - \frac{1}{r}\frac{\partial}{\partial r}\left(\frac{1}{r}\frac{\partial}{\partial r}\right). \tag{1.9}$$

In terms of ψ, the boundary condition (1.3) becomes $\psi = \text{const.}$ on $\partial\hat{D}$; we will assume that $\partial\hat{D}$ is connected, and that $\psi = 0$ on $\partial\hat{D}$.

We now introduce a new notation which simplifies the various formulas encountered in the rest of the paper. Let D denote the cross section of the spatial domain $\hat{D}$ in a meridional plane so that $\hat{D} = \{(z, r, \theta) \in \mathbf{R}^3 : (z, r) \in D\}$, and let $x = z$, $y = r^2/2$ be new (spatial) variables in D. Then, $\partial/\partial x = \partial/\partial z$, $\partial/\partial y = (1/r)\partial/\partial r$, and the volume

element dv (in $\hat{D}$) is replaced by $2\pi\, dx\, dy$. Also, the Jacobian of any two functions ϕ, ψ transforms according to $\partial(\phi, \psi)/\partial(x, y) = r^{-1}\partial(\phi, \psi)/\partial(z, r)$; we will abbreviate this expression to $\partial(\phi, \psi)$ throughout the sequel. The elliptic operator L is now given by

$$L = -\frac{1}{2y}\frac{\partial^2}{\partial x^2} - \frac{\partial^2}{\partial y^2}. \tag{1.10}$$

We let G denote the Green operator for L in D (with Dirichlet boundary conditions), so that $\psi = G\zeta$ defines the solution of

$$L\psi = \zeta \quad \text{in } D, \qquad \psi = 0 \quad \text{on } \partial D. \tag{1.11}$$

In this notation we may now write the governing equations (1.1)–(1.3) as a system of nonlinear, nonlocal evolution equations for ζ and γ:

$$\zeta_t + \partial(\zeta, G\zeta) + \partial(\gamma, \gamma/2y) = 0 \tag{1.12}$$

$$\gamma_t + \partial(\gamma, G\zeta) = 0 \qquad \text{in } D \times (0, T). \tag{1.13}$$

This form of the axisymmetric Euler equations is also given in [4].

The construction of the operator G merits further comment in view of the apparent singularity of L at $y = 0$. In the axisymmetric domain $\hat{D} \subseteq \mathbf{R}^3$ (which may contain a portion of the axis $r = 0$), let axisymmetric vector fields $\hat{\zeta}$ and $\hat{\psi}$ corresponding to the functions ζ and ψ be defined by $\hat{\zeta} := r\zeta e_\theta$ and $\hat{\psi} := (\psi/r)e_\theta$. Then, using $\nabla \cdot \hat{\psi} = 0$, we find that $L\psi = \zeta$ in D is equivalent to $-\Delta\hat{\psi} = \nabla \times \nabla \times \hat{\psi} = \hat{\zeta}$ in $\hat{D}$. Thus, the Green operator G takes L^2 into H_0^1 in the sense that the relevant norms are:

$$\int\int_D 2y\zeta^2\, dx\, dy = \int_{\hat{D}} |\hat{\zeta}|^2 \frac{dv}{2\pi} < +\infty, \qquad \int\int_D \left[\frac{1}{2y}\psi_x^2 + \psi_y^2\right] dx\, dy = \int_{\hat{D}} |\nabla\hat{\psi}|^2 \frac{dv}{2\pi} < +\infty.$$

Furthermore, since $\hat{\psi} \in H_0^1(\hat{D}) \cap H^2(\hat{D}) \subseteq C(\hat{D} \cup \partial\hat{D})$ it follows that $\psi = 0$ on ∂D and, by axisymmetry, that $\psi = 0$ at $y = 0$. (More details about this construction appear in the proofs of Theorems 1 and 2.)

In general, the existence and uniqueness of solutions of the initial value problem for (1.12), (1.13) can be asserted only on a sufficiently small time interval $0 \leqq t < T$; this result is just a special case of the known theory for fully three-dimensional flows. Thus, in our discussion of these equations we will proceed (formally) by assuming that a classical solution exists on some time interval $0 \leqq t < T$. Of course, when γ is identically zero (axisymmetric flow *without* swirl), equation (1.12) is solvable globally in time [15].

We now turn our attention to the conserved quantities associated with the evolution equations for ζ and γ. In this discussion we impose an additional boundary condition, namely,

$$\gamma = 0 \quad \textit{on } \partial D; \tag{1.14}$$

we note that if (1.14) holds at $t = 0$, then it holds also for all $t > 0$, by (1.13). With this (nonessential) condition in force, the derivation of the conserved quantities is simplified. Furthermore, all of the steady solutions that we construct in § 3 satisfy (1.14), and the purpose of the discussion here is to motivate the formulation of the main results of that section.

We claim that the following functionals are constant in the evolution governed by (1.12) and (1.13):

$$A(\gamma)=\iint_D a(\gamma)\,dx\,dy \qquad \text{(generalized angular impulse)}, \tag{1.15}$$

$$B(\zeta,\gamma)=\iint_D \zeta b(\gamma)\,dx\,dy \qquad \text{(generalized helicity)}, \tag{1.16}$$

$$C(\gamma)=\iint_D \zeta\,dx\,dy \qquad \text{(meridional circulation)}, \tag{1.17}$$

$$H(\zeta,\gamma)=\frac{1}{2}\iint_D\left[\zeta G\zeta+\frac{\gamma^2}{2y}\right]dx\,dy \qquad \text{(kinetic energy)}, \tag{1.18}$$

where a and b are arbitrary (suitably smooth) real functions. We leave to the reader the verification of the claims, which is easily accomplished with the aid of the integration by parts formula

$$\iint_D \phi_1\partial(\phi_2,\psi)\,dx\,dy=-\iint_D \phi_2\partial(\phi_1,\psi)\,dx\,dy,$$

which holds whenever either $\psi=\text{const.}$ or $\phi_1=0$ or $\phi_2=0$ on ∂D.

The classical cases of (1.15) and (1.16) occur when $a(\gamma)=\gamma$ and $b(\gamma)=\gamma$, since then we have

$$2\pi\iint_D \gamma\,dx\,dy=-\frac{1}{2}\int_{\hat{D}} r^2\omega^z\,dv, \qquad 2\pi\iint_D \zeta\gamma\,dx\,dy=\frac{1}{2}\int_{\hat{D}}\omega\cdot u\,dv.$$

We identify these integrals with the z-component of angular impulse (see [2]) and the helicity (see [12]), respectively, which are known invariants even for fully three-dimensional flows. The *generalized* angular impulse integral $A(\gamma)$ and helicity integral $B(\zeta,\gamma)$, valid for arbitrary functions a and b, seem to be new, however. The circulation integral

$$\iint_D \zeta\,dx\,dy=\iint_D \omega^\theta\,dz\,dr$$

has a standard interpretation by the Stokes theorem (see [2]). Upon integration by parts, the kinetic energy functional is recognized as

$$\pi\iint_D\left[\zeta G\zeta+\frac{\gamma^2}{2y}\right]dx\,dy=\frac{1}{2}\int_{\hat{D}}|u|^2\,dv.$$

The system of equations (1.12), (1.13) has a (noncanonical) Hamiltonian (or Poisson) structure, as has been noted in [4]. The functional $H(\zeta,\gamma)$ defined in (1.18) is the Hamiltonian, and a Poisson bracket $\{\cdot,\cdot\}$ can be defined so that $dF/dt=\{F,H\}$ for all (suitably smooth) functionals $F=F(\zeta,\gamma)$ defined on the appropriate phase space. Naturally, the functionals $F=A, B, C$ defined by (1.15)–(1.17) satisfy $\{F,H\}=0$, as can easily be verified.

2. Variational problems. The discussion in this section is divided into two parts. First, we present the fundamental variational principle that characterizes steady solutions of (1.12) and (1.13) directly in terms of the dynamical quantities ζ and γ. Second, we derive another version of this variational principle that involves only ζ (γ being eliminated algebraically), and that, when appropriately normalized, forms the basis of the subsequent analysis. This line of development is intended to motivate the specific variational problem that we employ in §§ 3 and 4 to study vortex rings with swirl.

We characterize a steady solution pair $\zeta = \zeta(x, y)$, $\gamma = \gamma(x, y)$ of (1.12), (1.13) variationally as follows. The governing equations become

$$\partial(\zeta, G\zeta) + \partial(\gamma, \gamma/2\gamma) = 0 \tag{2.1}$$

$$\partial(\gamma, G\zeta) = 0 \qquad \text{in } D. \tag{2.2}$$

Thus, to solve (2.2) we set

$$G\zeta = b(\gamma), \tag{2.3}$$

where b is a specified (suitably smooth) function with $b(0) = 0$ (recalling (1.14)). Substitution of (2.3) into (2.1) then yields

$$0 = \partial(\zeta, b(\gamma)) + \partial(\gamma, \gamma/2y) = \partial(\zeta b'(\gamma) - \gamma/2y, \gamma).$$

Thus, to solve this equation we set

$$\zeta b'(\gamma) - \gamma/2y = -a'(\gamma), \tag{2.4}$$

where a is a specified (suitably smooth) function. Therefore, given (essentially arbitrary) a and b, it suffices to solve (2.3) and (2.4) for the desired pair ζ, γ. We now define the modified energy functional (assuming that appropriate dimensional constants scale the given functions a and b):

$$\tilde{H}(\zeta, \gamma) = H(\zeta, \gamma) - A(\gamma) - B(\zeta, \gamma) \tag{2.5}$$

where the specified functions a, b determine the functionals A, B in (1.15), (1.16). Then it is obvious that (2.3) and (2.4) are equivalent to $\tilde{H}_\zeta = 0$ and $\tilde{H}_\gamma = 0$, respectively, where $\tilde{H}_\zeta$ and $\tilde{H}_\gamma$ denote the Fréchet derivatives of $\tilde{H}$ with respect to ζ and γ. In this straightforward manner, we arrive at the variational principle:

(VP1) Any critical point (ζ, γ) for the functional $\tilde{H}(\zeta, \gamma)$ is a solution of (2.1), (2.2), and hence yields a steady flow in $\hat{D}$.

An alternate variational principle given in [4] (and implicit in [1]) can be summarized as follows. For arbitrary test functions ϕ_1, ϕ_2 (each ϕ_i is smooth in $\bar{D}$ and vanishes on ∂D), consider the variations $\tilde{\zeta} = \tilde{\zeta}(x, y; s)$, $\tilde{\gamma} = \tilde{\gamma}(x, y; s)$ defined by solving the equations

$$\tilde{\zeta}_s + \partial(\tilde{\zeta}, \phi_1) + \partial(\tilde{\gamma}, \phi_2) = 0, \qquad \tilde{\gamma}_s + \partial(\tilde{\gamma}, \phi_1) = 0,$$

with $\tilde{\zeta}|_{s=0} = \zeta$, $\tilde{\gamma}|_{s=0} = \gamma$. Then (2.1), (2.2) result from the variational equation

$$\frac{d}{ds} H(\tilde{\zeta}, \tilde{\gamma})|_{s=0} = 0 \quad \text{for arbitrary } \phi_1, \phi_2.$$

As is remarked in [4], this characterization of solutions of (2.1), (2.2) is quite cumbersome to use in analysis because of the particular form of the class of variations involved. In contrast, (VP1) permits arbitrary variations by replacing H with $\tilde{H} = H - A - B$. In this regard, we note that $A(\gamma)$, $B(\zeta, \gamma)$, and $C(\gamma)$ are invariant under the variations $\tilde{\zeta}$, $\tilde{\gamma}$ defined above, as is easily checked.

We now reduce (VP1) to a more special variational principle that does not involve γ explicitly. For this reduction we require that

$$a(0)=0, \quad b(0)=0, \quad a'(t)\leqq 0, \quad b'(t)>0 \quad \text{for all } t\geqq 0, \tag{2.6}$$

and we define

$$f(y, s) := [b^{-1}(s)]^2/4y - a(b^{-1}(s)), \qquad s\geqq 0. \tag{2.7}$$

Then we see that a pair ζ, γ satisfies (2.1), (2.2) whenever γ is defined by $\gamma = b^{-1}(G\zeta)$ and ζ satisfies the equation

$$\zeta = f_s(y, G\zeta). \tag{2.8}$$

We now assume further that a and b are such that $f(y, s)$ is strictly convex in s (this holds in the "classical" case when both a and b are linear, for instance). Let $f^*(y, \sigma)$, the conjugate function to $f(y, s)$, be defined by

$$f^*(y, \sigma) = \sup_s [s\sigma - f(y, s)]. \tag{2.9}$$

Then f^* has the well-known properties

$$f^*(y, \sigma) = sf_s(y, s) - f(y, s), \qquad f^*_{\sigma\sigma}(y, \sigma) = [f_{ss}(y, s)]^{-1}$$

with $\sigma = f_s(y, s)$ or, equivalently, $s = f^*_\sigma(y, \sigma)$. Equation (2.7) may be rewritten in this notation as

$$G\zeta = f^*_\sigma(y, \zeta), \tag{2.10}$$

and this is clearly the variational equation for the functional

$$\Phi(\zeta) = \int\int_D \left[\frac{1}{2}\zeta G\zeta - f^*(y, \zeta)\right] dx\, dy. \tag{2.11}$$

Consequently, we have the variational principle:

(VP2) Any extremal ζ for the functional $\Phi(\zeta)$ yields a solution of (2.1), (2.2) with $\gamma = b^{-1}(G\zeta)$.

The algebraic elimination of γ in terms of ζ may also be viewed as a restriction on the admissible variations in (VP1). As is readily verified using the properties of the convex conjugate function, the expression for γ implied by (2.4) is

$$\gamma = \Gamma(\zeta) := b^{-1}(f^*_\sigma(y, \zeta)); \tag{2.12}$$

indeed, this inverts the equation (equivalent to (2.4))

$$\zeta = \gamma/2yb'(\gamma) - a'(\gamma)/b'(\gamma).$$

We now claim that the identity (2.12) reduces the objective functional in (VP1) as follows:

$$\Phi(\zeta) = \tilde{H}(\zeta, \Gamma(\zeta)) \quad \text{for arbitrary admissible } \zeta. \tag{2.13}$$

To check this it suffices to observe that

$$-f^*(y, \sigma) = \frac{[b^{-1}(s)]^2}{4y} - a(b^{-1}(s)) - \frac{s}{b'(b^{-1}(s))}\left\{\frac{b^{-1}(s)}{2y} - a'(b^{-1}(s))\right\},$$

and, consequently, that

$$\begin{aligned} f^*(y, \zeta) &= \frac{\gamma^2}{4y} - a(\gamma) - \frac{b(\gamma)}{b'(\gamma)}\left\{\frac{\gamma}{2y} - a'(\gamma)\right\} \\ &= \frac{\gamma^2}{4y} - a(\gamma) - \zeta b(\gamma). \end{aligned}$$

On the basis of the foregoing discussion, we now formulate the specific constrained maximization problems that we solve in § 3 to obtain steady and steadily translating vortex rings with swirl. These problems involve free boundaries, since the solutions have the property that $\zeta, \gamma > 0$ in a subdomain $\Omega \subset D$ and $\zeta, \gamma = 0$ in $D \backslash \Omega$. Therefore, we introduce some additional constraints and normalizations into (VP2). We assume that $a(t)$ and $b(t)$ are specified satisfying (2.6) and that $f_{ss}(y, s) > 0$. We consider the problem:

(2.14) maximize $\Phi(\zeta)$ subject to the constraints $\zeta \geqq 0$ in D, $C(\zeta) := \iint_D \zeta \, dx \, dy = C_0$,

where C_0 is a (suitably specified) positive constant. We claim that such a maximizer ζ yields a solution of (2.1), (2.2) having the form

$$\begin{aligned} &\zeta = f_s(y, G\zeta - \mu), \quad \gamma = b^{-1}(G\zeta - \mu) \quad \text{in } \Omega := \{G\zeta > \mu\}, \\ &\zeta = 0, \quad \gamma = 0 \quad \text{in } D \backslash \Omega, \end{aligned} \tag{2.15}$$

where μ is the Lagrange multiplier for the constraint $C(\zeta) = C_0$. To verify the claim we calculate the variational conditions at a maximizer ζ; we get

$$\Phi'(\zeta) - \mu = 0 \quad \text{on } \{\zeta > 0\}, \qquad \Phi'(\zeta) - \mu \leqq 0 \quad \text{on } \{\zeta = 0\},$$

where $\Phi'(\zeta) = G\zeta - f_\sigma^*(y, \zeta)$ is the Fréchet derivative of Φ at ζ. These conditions imply the claimed expression for ζ, since $\{0 < \zeta < f_s(y, 0)\} \subseteq \{G\zeta = \mu\}$, and hence, invoking the argument of Corollary 2.3 in [13], meas $\{0 < \zeta < f_s(y, 0)\} = 0$. (If $f_s(y, 0) = 0$, then ζ is continuous across $\partial\Omega$.) The claimed expression for γ is immediate from (2.12). That ζ and γ given by (2.15) satisfy (2.1) and (2.2) follows exactly as in the deviation of (VP2). Thus, we have the desired variational characterization of steady vortex rings with swirl in a bounded domain $\hat{D}$.

We formulate the constrained maximization problem for steadily translating vortex rings with swirl in $\mathbf{R}^3$ in the same way. In this case the objective functional $\Phi(\zeta)$ (defined by (2.11) with $\mathbf{R}^2_+$ replacing D) is maximized subject to the constraints

$$\zeta \geqq 0 \quad \text{in} \quad \mathbf{R}^2_+, \quad C(\zeta) := \iint_{\mathbf{R}^2_+} \zeta \, dx \, dy = C_0, \quad P(\zeta) := \iint_{\mathbf{R}^2_+} y\zeta \, dx \, dy = P_0. \tag{2.16}$$

The maximizer ζ then yields a solution of (2.1), (2.2) having the form

$$\begin{aligned} &\zeta = f_s(y, G\zeta - cy - \mu), \quad \gamma = b^{-1}(G\zeta - cy - \mu) \quad \text{in } \Omega := \{G\zeta > cy + \mu\}, \\ &\zeta = 0, \quad \gamma = 0 \quad \text{in } \mathbf{R}^2_+ \backslash \Omega, \end{aligned} \tag{2.17}$$

where c and μ are the Lagrange multipliers for the constraints $P(\zeta) = P_0$ and $C(\zeta) = C_0$, respectively. The additional constraint, $P(\zeta) = P_0$ fixes the z-component of linear impulse (see [2]), a further conserved quantity in this case given by

$$2\pi \iint_{\mathbf{R}^2_+} y\zeta \, dx \, dy = \frac{1}{2} \int_{R^3} r\omega^\theta \, dv.$$

The constant c represents the translational velocity, and is determined by the solution.

It is important to note that both the problem in D with constraints (2.14) and the problem in $\mathbf{R}^2_+$ with constraints (2.16) can be naturally nondimensionalized by appropriately normalizing their constraint values. Indeed, if L and U are characteristic length and velocity scales, respectively, then the constraint values scale according to $C_0 = ULC_0^*$ and $P_0 = UL^4P_0^*$ when expressed in terms of dimensionless variables (indicated by stars): $x = Lx^*$, $y = L^2y^*$, $\zeta = UL^{-2}\zeta^*$, etc. Therefore, throughout the sequel we

will assume that $C_0 = 1$ and diameter $(D) = 1$ (say) when dealing with solutions in a bounded domain $\hat{D}$, and that $C_0 = 1$ and $P_0 = 1$ when dealing with solutions in all of space $\mathbf{R}^3$.

We remark that the steady flows considered above can also be characterized in terms of their streamfunctions ψ, and a variational problem for ψ, which is dual to (VP2), can be given. However, we prefer the equivalent formulation in ζ because (i) it is more closely tied to governing dynamical equations (through (VP1)), (ii) the constraints imposed in (2.14) and (2.16) are more natural physically than a specification of μ and c, and (iii) the asymptotic properties of concentrated vortex rings with swirl are more readily obtained (see § 4). These advantages have been utilized in the theory of steady vortex rings without swirl in [3] and [11].

3. Existence theorems. In this section we state and prove two existence theorems for vortex rings with swirl: Theorem 1 concerns steady solutions in a bounded (axisymmetric) domain $\hat{D} \subset \mathbf{R}^3$, while Theorem 2 concerns steadily translating solutions in $\mathbf{R}^3$. We establish both of these theorems by applying direct variational methods to the corresponding constrained maximization problems formulated in § 2. This approach is quite standard and has been used before in similar problems. The results obtained in [5] parallel those in our Theorem 1, but unlike that paper we treat the case when the domain $\hat{D}$ contains a portion of the z-axis (where certain singularities arise). Also, the results of our Theorem 2 are analogous to those established in [11], although the approach we take in the present paper is more direct.

For the sake of simplicity in the exposition we will restrict our detailed discussion in this section to the "classical" case when

$$a(t) = -\alpha t, \quad b(t) = \beta t \quad \text{for given positive constants } \alpha \text{ and } \beta. \tag{3.1}$$

This special case illustrates well the general case: some instances of the general case for which the same results hold are discussed later in this section.

In the first theorem the constrained maximization problem under consideration is defined on the class of competing functions

$$K(D) = \left\{ \zeta \in L^1(D) : \zeta \geqq 0 \text{ a.e.}, \iint_D \zeta \, dx\, dy \leqq 1, \iint_D y\zeta^2 \, dx\, dy < +\infty \right\}. \tag{3.2}$$

The constraint $C(\zeta) = 1$ is relaxed to an inequality here for technical reasons related to the range of the given parameters α and β. We recall that the objective functional introduced in § 2, specialized according to (3.1), is defined as

$$\Phi(\zeta) = \iint_D \left[\frac{1}{2} \zeta G\zeta - y\beta^2 \left(\zeta - \frac{\alpha}{\beta} \right)_+^2 \right] dx\, dy. \tag{3.3}$$

We let χ_Ω denote the characteristic function of $\Omega \subseteq D$.

THEOREM 1. *For every prescribed $0 \leqq \alpha < +\infty$, $0 < \beta < +\infty$ there exists a solution $\zeta \in K(D)$ of the problem*

$$\text{maximize } \Phi(\zeta) \text{ subject to } \zeta \in K(D), \tag{3.4}$$

and there exists a multiplier $\mu > 0$ such that

$$\zeta = \frac{1}{2y\beta^2} (G\zeta - \mu)_+ + \frac{\alpha}{\beta} \chi_{\{G\zeta - \mu > 0\}} \text{ in } D. \tag{3.5}$$

Furthermore, whenever $\mu > 0$ there holds

$$\zeta \text{ has compact support in } D, \ C(\zeta) = 1. \tag{3.6}$$

Remark. The condition that $\mu > 0$ is ensured whenever β is small enough depending on α, and this property is proved in § 4. The exact range of the parameter β, an interval $0 < \beta < \beta^*(\alpha)$, for which solutions satisfying (3.6) exist is best determined numerically using the method given in [8].

Proof. We first construct a maximizer for Φ over $K(D)$. To be able to treat the case when $\hat{D} \cap \{r = 0\} \neq \varnothing$, it is necessary to reexpress the problem in terms of the (z, r, θ) coordinates and the naturally associated vector fields:

$$\hat{\zeta} = r\zeta(z, r)e_\theta, \quad \hat{\psi} = \frac{1}{r}\psi(z, r)e_\theta \quad \text{in } D. \tag{3.7}$$

We verify that $L\psi = \zeta$ in D with $\psi = 0$ on ∂D if and only if $-\Delta\hat{\psi} = \hat{\zeta}$ in $\hat{D}$ with $\hat{\psi} = 0$ on $\partial\hat{D}$; we see this equivalence by virtue of the identity $-\Delta\hat{\psi} = \nabla \times \nabla \times \hat{\psi}$, since $\nabla \cdot \hat{\psi} = 0$. Now the terms in the objective functional Φ can be expressed in $\hat{\zeta}$ and $\hat{\psi}$. In particular, we have

$$\frac{1}{2}\int\int_D \zeta G\zeta \, dx\, dy = \frac{1}{2}\int_{\hat{D}} \hat{\zeta} \cdot \hat{\psi} \, dm = \frac{1}{2}\int_{\hat{D}} |\nabla\hat{\psi}|^2 \, dm, \qquad \int\int_D y\zeta^2 \, dx\, dy = \frac{1}{2}\int_{\hat{D}} |\hat{\zeta}|^2 \, dm,$$

where we write $dm = r\, dr\, dz = (1/2\pi)\, dv$. Also, we have

$$\int\int_D |\hat{\zeta}| \, dm \leqq R := \max_{\hat{D}} r,$$

by the circulation constraint. An upper bound for Φ on $K(D)$ is obtained as follows. By the Sobolev inequality, we have

$$\int_{\hat{D}} |\nabla\hat{\psi}|^2 \, dm = \int_{\hat{D}} \hat{\zeta} \cdot \hat{\psi} \, dm \leqq \|\hat{\zeta}\|_{6/5}\|\hat{\psi}\|_6 \leqq C_1\|\hat{\zeta}\|_{6/5}\left\{\int_{\hat{D}} |\nabla\hat{\psi}|^2 \, dm\right\}^{1/2}.$$

This yields the estimate

$$\left\{\int_{\hat{D}} |\nabla\hat{\psi}|^2 \, dm\right\}^{1/2} \leqq C_2\|\hat{\zeta}\|_{6/5} \leqq C_2\|\hat{\zeta}\|_1^{2/3}\|\hat{\zeta}\|_2^{1/3} \leqq C_3(R)\|\hat{\zeta}\|_2^{1/3},$$

on application of the standard interpolation inequality. We now obtain the desired bound for Φ: for $\zeta \in K(D)$,

$$\begin{aligned} \Phi(\zeta) &\leqq \frac{1}{2}\int_{\hat{D}} |\nabla\hat{\psi}|^2 \, dm - \frac{\beta^2}{2}\int_{\hat{D}} |\hat{\zeta}|^2 \, dm + \alpha\beta \int_{\hat{D}} r|\hat{\zeta}| \, dm \\ &\leqq C_4(R)\left\{\int_{\hat{D}} |\hat{\zeta}|^2 \, dm\right\}^{1/3} - \frac{\beta^2}{2}\int_{\hat{D}} |\hat{\zeta}|^2 \, dm + \alpha\beta R^2 \\ &\leqq C_5(D, \alpha, \beta) < +\infty. \end{aligned} \tag{3.8}$$

Consequently, we may take a sequence $\zeta_j \in K(D)$ such that (i) $\Phi(\zeta_j) \to \sup\{\Phi(\tilde{\zeta}): \tilde{\zeta} \in K(D)\}$, (ii) $\|\hat{\zeta}_j\|_2 \leqq C_6$, and (iii) $\hat{\zeta}_j \to \hat{\zeta} \in L^2(\hat{D})$ weakly. It follows that $\hat{\psi}_j \to \hat{\psi}$ weakly in $H^2(\hat{D})$ and hence, by the standard imbedding theorem, that $\hat{\psi}_j \to \hat{\psi}$ strongly in $H_0^1(\hat{D})$. Thus, we have the continuity of the first term of Φ, namely,

$$\int\int_D \zeta_j G\zeta_j \, dx\, dy = \int_{\hat{D}} |\nabla\hat{\psi}_j|^2 \, dm \to \int_{\hat{D}} |\nabla\hat{\psi}|^2 \, dm = \int\int_D \zeta G\zeta \, dx\, dy.$$

Also, we have the lower semicontinuity of the second term, namely,

$$\liminf_{j\to+\infty} \int\int_D y\left(\zeta_j - \frac{\alpha}{\beta}\right)_+^2 dx\, dy \geqq \int\int_D y\left(\zeta - \frac{\alpha}{\beta}\right)_+^2 dx\, dy.$$

This follows from the convexity of this term combined with the identity $2y\zeta = re_\theta \cdot \hat{\zeta}$, which implies that $\zeta_j \to \zeta$ weakly in $L^2(D)$ with respect to the measure $y\,dx\,dy$. Consequently, we may conclude that $\Phi(\zeta) = \lim_{j\to+\infty} \Phi(\zeta_j) = \sup \Phi$, with $\zeta \in K(D)$. (We note that the statement that limits $\hat{\zeta}$ and $\hat{\psi}$ have the form (3.7) is easily checked.)

The derivation of the variational conditions (3.5) is sketched in § 2 in the general case. In the present case, if μ is the multiplier accounting for the constraint $C(\zeta) \leqq 1$, then we have, by maximality,

$$0 \geqq \int\int_D [G\zeta - \mu - 2y\beta^2(\zeta - \alpha/\beta)_+]\delta\zeta\,dx\,dy$$

for all variations $\delta\zeta$ that respect the constraint $\zeta \geqq 0$ almost everywhere in D. This inequality implies that

$$\begin{aligned} &G\zeta - \mu = 2y\beta^2(\zeta - \alpha/\beta)_+ \quad \text{whenever } \zeta > 0, \\ &G\zeta - \mu \leqq 0 \qquad\qquad\qquad\quad \text{whenever } \zeta = 0, \end{aligned} \tag{3.9}$$

which further implies that $\{0 < \zeta < \alpha/\beta\} \subseteq \{G\zeta = \mu\}$. The stated form (3.5) then follows immediately.

To complete the proof we must establish (3.6) when $\mu > 0$, by assumption. Since $\hat{\zeta} \in L^2(\hat{D})$, we have that $\hat{\psi} \in H_0^1(\hat{D}) \cap H^2(\hat{D}) \subseteq C^{1/2}(\hat{D} \cup \partial\hat{D})$, by the Morrey-Sobolev imbedding theorem. Then we must have $\hat{\psi}|_{r=0} = 0$, by continuity, and hence $\psi = r|\hat{\psi}| = o(r)$ as $r \to 0^+$. Now since $\mu > 0$, it follows that supp $\zeta \subseteq \{\psi \geqq \mu\} \subseteq D \cap \{y > \delta\}$ for some $\delta > 0$, and thus we conclude that supp ζ is a compact subset of D. The fact that the corresponding multiplier is nonzero ensures that equality holds in the circulation constraint.

The above theorem provides a solution pair ζ, γ of the system (2.1), (2.2) in the "classical" case (3.1), and that solution pair is expressed as

$$\zeta = \frac{1}{2y\beta^2}\tilde{\psi}_+ + \frac{\alpha}{\beta}\chi_{\{\tilde{\psi}>0\}}, \quad \gamma = \frac{1}{\beta}\tilde{\psi}_+ \quad \text{with } \tilde{\psi} = G\zeta - \mu. \tag{3.10}$$

The theorem generalizes in a straightforward way to a class of problems where the structure functions $a, b \in C^2[0, +\infty)$ satisfy (2.6) and $f(y, s)$ defined in (2.7) is strictly convex in s for $s > 0$. In particular, it suffices that $a(t)$ and $b(t)$ satisfy

$$a(0) = 0, \quad -\alpha_1 \leqq a'(t) \leqq 0, \quad a''(t)b'(t) \geqq a'(t)b''(t), \tag{3.11}$$

$$b(0) = 0, \quad \beta_0 \leqq b'(t) \leqq \beta_1, \quad b'(t) > tb''(t), \tag{3.12}$$

for all $t \geqq 0$, where $\alpha_1, \beta_0, \beta_1$ are positive constants. The solution pair ζ, γ is then expressible as

$$\begin{aligned} &\zeta = \frac{b^{-1}(\tilde{\psi})}{2yb'(b^{-1}(\tilde{\psi}))} - \frac{a'(b^{-1}(\tilde{\psi}))}{b'(b^{-1}(\tilde{\psi}))} \quad \text{in } \{\tilde{\psi} > 0\}, \quad \zeta = 0 \quad \text{in } \{\tilde{\psi} \leqq 0\}, \\ &\gamma = b^{-1}(\tilde{\psi}) \quad \text{in } \{\tilde{\psi} > 0\}, \quad \gamma = 0 \quad \text{in} \quad \{\tilde{\psi} \leqq 0\}. \end{aligned} \tag{3.13}$$

It follows from this that $\zeta \in L^\infty(D)$ and that ζ jumps by the constant $|a'(0)|/b'(0)$ across the free boundary $\partial\{\tilde{\psi} > 0\}$; it also follows that $\gamma \in C^{0,1}(D)$ and that, in general, γ_x and γ_y are discontinuous across the free boundary. In physical terms, the velocity field is continuous everywhere (and that condition defines the free-boundary condition), while the vorticity field may be discontinuous across the boundary of the vortex ring. Of course, further generalizations are certainly possible (for instance, the quadratic growth of $f(y, s)$ in s can be relaxed and solutions with higher regularity can be obtained), but these extensions are left to the reader.

In the second theorem, we replace the domain D by $\mathbf{R}^2_+ = \{y > 0\}$, and we impose the additional constraint $P(\zeta) = 1$. The class of competing functions is now taken to be

$$K(\mathbf{R}^2_+) = \Big\{ \zeta \in L^1(\mathbf{R}^2_+) : \zeta \geqq 0 \text{ a.e.}, \iint_{\mathbf{R}^2_+} \zeta \, dx\, dy \leqq 1, \tag{3.14}$$
$$\iint_{\mathbf{R}^2_+} y\zeta \, dx\, dy \leqq 1, \iint_{\mathbf{R}^2_+} y\zeta^2 \, dx\, dy < +\infty \Big\}.$$

Both of the constraints $C(\zeta) = 1$ and $P(\zeta) = 1$ are relaxed to inequalities here again for technical reasons. The proof of existence of solutions follows much as in the preceding theorem, except that it is complicated by the fact that the domain is now unbounded. □

THEOREM 2. *For every prescribed $0 \leqq \alpha < +\infty$, $0 < \beta < +\infty$, there exists a solution $\zeta \in K(\mathbf{R}^2_+)$ of the problem*

$$\text{maximize } \Phi(\zeta) \text{ subject to } \zeta \in K(\mathbf{R}^2_+) \tag{3.15}$$

and there exist multipliers $\mu \geqq 0$ and $c > 0$ such that

$$\zeta = \frac{1}{2y\beta^2}(G\zeta - cy - \mu)_+ + \frac{\alpha}{\beta}\chi_{\{G\zeta - cy - \mu > 0\}} \text{ in } \mathbf{R}^2_+; \tag{3.16}$$

also, ζ is symmetrized about $x = 0$, in the sense that

$$\zeta(x, y) = \zeta(-x, y) \text{ and } \zeta(x, y) \geqq \zeta(x', y) \text{ whenever } 0 \leqq x \leqq x'. \tag{3.17}$$

Furthermore, $P(\zeta) = 1$ holds and whenever $\mu > 0$ there also holds

$$\zeta \text{ has compact support in } \mathbf{R}^2_+, \ C(\zeta) = 1. \tag{3.18}$$

Remark. As in Theorem 1, the condition that $\mu > 0$ is ensured whenever β is small enough depending on α. In fact, the range $0 < \beta < \beta^*(\alpha)$ in Theorem 2 is known explicitly, since the limiting case $\beta = \beta^*(\alpha)$ corresponds to a spherical vortex with swirl found by Moffatt [12]. A complete discussion of these Moffatt vortices and the role they play in determining the range of the given parameters α and β is given in [8], where the vortex rings with swirl proven to exist in this theorem are exhibited numerically.

Proof. We use the same direct variational method as in the proof of Theorem 1, leaving some of the technical details to the reader. As before, we introduce $\hat{\zeta}$ and $\hat{\psi}$ defined by (3.7). However, the constraints $C(\zeta) \leqq 1$ and $P(\zeta) \leqq 1$ now imply the bound

$$\int_{\mathbf{R}^3} |\hat{\zeta}| \, dm \leqq \int_{\mathbf{R}^3} \frac{1}{2}(r + r^{-1})|\hat{\zeta}| \, dm = \iint_{\mathbf{R}^2_+} \left(y + \frac{1}{2}\right)\zeta \, dx\, dy \leqq \frac{3}{2}.$$

In turn, this yields the bound

$$\Phi(\zeta) \leqq C_4 \left\{ \int_{\mathbf{R}^3} |\hat{\zeta}|^2 \, dm \right\}^{1/3} - \frac{\beta}{2\lambda} \int_{\mathbf{R}^3} |\hat{\zeta}|^2 \, dm + 2\alpha\beta \leqq C_5(\alpha, \beta) < +\infty, \tag{3.19}$$

where, in contrast to (3.8), the constant C_4 is independent of the size of the support of $\hat{\zeta}$. It follows that there is a sequence $\zeta_j \in K(\mathbf{R}^2_+)$ such that (i) $\Phi(\zeta_j) \to \sup\{\Phi(\tilde{\zeta}) : \tilde{\zeta} \in K(\mathbf{R}^2_+)\}$, (ii) $\|\hat{\zeta}_j\|_2 \leqq C_6$, and (iii) $\hat{\zeta}_j \to \hat{\zeta} \in L^2(\mathbf{R}^3)$ weakly. Furthermore, using the standard arguments (see [9]), we may replace each $\zeta_j(x, y)$ by its symmetrical rearrangement in the x variable so that the properties (3.16) hold for each ζ_j; in this procedure we use the fact that symmetrization in x does not alter the constraints and

does not decrease the objective functional. Now, however, we are able to assert only that $\hat{\psi}_j \to \hat{\psi}$ strongly in $H^1(B_\rho)$, where $B_\rho = \{z^2 + r^2 < \rho^2\}$ for every fixed $\rho < +\infty$. Consequently, the proof of continuity of the first term of Φ_λ requires careful justification. This is provided by the estimate

$$|\hat{\psi}_j(z, r)| \leqq \eta(\sqrt{z^2 + r^2}) \quad \text{where } \eta(\rho) \downarrow 0 \quad \text{as } \rho \to +\infty. \tag{3.20}$$

Indeed, given such a rate of decay for $|\hat{\psi}_j|$ (independently of j) we conclude that

$$\iint_{z^2+r^2 \geqq \rho^2} \zeta_j G\zeta_j \, dx \, dy = \int_{\mathbf{R}^3 \setminus B_\rho} \hat{\zeta}_j \cdot \hat{\psi}_j \, dm \leqq \frac{3}{2} \eta(\rho),$$

and similarly for ζ; this combined with the fact that

$$\iint_{z^2+r^2<\rho^2} \zeta_j G\zeta_j \, dx \, dy = \int_{B_\rho} |\nabla \hat{\psi}_j|^2 \, dm \to \int_{B_\rho} |\nabla \hat{\psi}|^2 \, dm = \iint_{z^2+r^2<\rho^2} \zeta G\zeta \, dx \, dy$$

for arbitrarily large $\rho < +\infty$, clearly yields the desired conclusion. The proof of the claimed estimate (3.20) depends upon the fact that $\hat{\psi}_j$ is expressible as the potential of $\hat{\zeta}_j$, namely, $\hat{\psi}_j = k_* \hat{\zeta}_j$ (component-wise), where $k = k(\rho) = 1/4\pi\rho$ is the fundamental solution of $-\Delta$ in $\mathbf{R}^3$—and $|\hat{\zeta}_j|$ is axisymmetric, symmetrized in z, and $\|\hat{\zeta}_j\|_1 \leqq C_1$, $\|\hat{\zeta}_j\|_2 \leqq C_2$ for constants C_1, C_2 independent of j. A derivation of such an estimate can be given by modifying the calculations made in [10], where an analogous result is proved with the L^∞-bound $\|\hat{\zeta}_j\|_\infty \leqq C_2$ replacing the L^2-bound; the resulting estimate shown in Theorem 2.5 of [10] involves $\eta(\rho) = C_3 \rho^{-1} \log(1 + C_4 \rho)$, and an analogous expression follows in the present case. Since the details of this argument are rather lengthy and are of technical interest only, we will omit them here. The lower semicontinuity of the second term in Φ follows as before. Therefore, we have that $\Phi(\zeta) = \lim_{j \to \infty} \Phi(\zeta_j) = \sup_K \Phi$, with $\zeta \in K(\mathbf{R}^2_+)$.

The variational conditions (3.15) follow using the standard methods, with multipliers c, $\mu \in \mathbf{R}$ uniquely determined by the extremal ζ. That c, $\mu \geqq 0$ follows from the observation that $|\hat{\zeta}| = r\zeta = (\psi - cr/2 - \mu/r)^+ \geqq (-cr/2 - \mu/r)^+$ in $\mathbf{R}^3$ with $|\hat{\zeta}| \in L^1(\mathbf{R}^3)$. Thus, $c < 0$ implies $|\hat{\zeta}| \geqq |c| r/2 - |\mu|/r$ for large r, which is impossible; and, $\mu < 0$ implies $|\hat{\zeta}| \geqq |\mu|/r - |c| r/2$ for small r, which is impossible. The strict positivity of c is an immediate consequence of the following identity, which is interesting in itself:

$$2c = \iint_{\mathbf{R}^2_+} \left[\frac{1}{2} \zeta G\zeta + \beta^2 y \left(\zeta - \frac{\alpha}{\beta} \right)_+^2 + 6\alpha\beta y \left(\zeta - \frac{\alpha}{\beta} \right)_+ \right] dx \, dy. \tag{3.21}$$

To prove this we use an alternative expression for the energy associated with flow in the meridional planes, namely,

$$\frac{1}{2} \iint_{\mathbf{R}^2_+} \left[\frac{1}{2y} \psi_x^2 + \psi_y^2 \right] dx \, dy = \iint_{\mathbf{R}^2_+} (x\psi_x + 2y\psi_y) L\psi \, dx \, dy. \tag{3.22}$$

This formula is verified by an integration by parts argument; its complete derivation is given in Lemma 3.1 of [11]. Now we let $\tilde{\psi} = \psi - cy - \mu$, and using (3.22) we obtain the expression

$$\begin{aligned} \frac{1}{2} \iint_{\mathbf{R}^2_+} \zeta G\zeta \, dx \, dy &= \frac{1}{2} \iint_{\mathbf{R}^2_+} \left[\frac{1}{2y} \psi_x^2 + \psi_y^2 \right] dx \, dy \\ &= \iint_{\mathbf{R}^2_+} [x\tilde{\psi}_x + 2y(\tilde{\psi} + cy)_y] \zeta \, dx \, dy. \end{aligned}$$

But an integration by parts yields

$$\iint_{\mathbf{R}^2_+} x\tilde{\psi}_x\zeta\,dx\,dy = \iint_{\mathbf{R}^2_+} x\tilde{\psi}_x\left[\frac{1}{2y\beta^2}\tilde{\psi}_+ + \frac{\alpha}{\beta}\chi_{\{\tilde{\psi}>0\}}\right]dx\,dy$$

$$= -\iint_{\mathbf{R}^2_+}\left[\frac{1}{4y\beta^2}\tilde{\psi}_+^2 + \frac{\alpha}{\beta}\tilde{\psi}_+\right]dx\,dy,$$

$$\iint_{\mathbf{R}^2_+} 2y(\tilde{\psi}+cy)_y\zeta\,dx\,dy = \iint_{\mathbf{R}^2_+}\tilde{\psi}_y\left[\frac{1}{\beta^2}\tilde{\psi}_+ + \frac{2y\alpha}{\beta}\chi_{\{\tilde{\psi}>0\}}\right]dx\,dy$$

$$+2c\iint_{\mathbf{R}^2_+} y\zeta\,dx\,dy$$

$$= -\iint_{\mathbf{R}^2_+}\frac{2\alpha}{\beta}\tilde{\psi}_+\,dx\,dy + 2c.$$

The claimed identity (3.21) now follows using the substitution $\tilde{\psi}_+ = 2y\beta^2(\zeta - \alpha/\beta)_+$.

We note that equality must hold in the constraint $P(\zeta)\leqq 1$ since c is nonzero. It remains to establish (3.17) when $\mu > 0$, by assumption. First, we note, as before, that equality must hold in the constraint $C(\zeta)\leqq 1$. Next, we demonstrate that supp $\zeta \subseteq \{|x|\leqq\delta^{-1},\ \delta\leqq y\leqq\delta^{-1}\}$ for some $\delta > 0$. The required bounds in y follow directly from the fact that $\psi \geqq cy+\mu$ in supp ζ, since this implies that $cr/2+\mu r^{-1}\leqq|\hat{\psi}|\leqq C_6$ in supp ζ. The required bounds in x follow from the inequality

$$2|x|y \leqq c^{-2}\iint_{\mathbf{R}^2_+}\zeta G\zeta\,dx'\,dy' \quad \text{for all } (x,y)\in\text{supp }\zeta.$$

To show this we use the fact that $\psi(x',y)=\psi(-x',y)$ and $\psi(x',y)\geqq\psi(x,y)$ for all $0<x'<x$ (a consequence of (3.16)), because then we obtain

$$2c|x|y \leqq \int_{-|x|}^{|x|}\psi(x',y)\,dx' = \int_{-|x|}^{|x|}\int_0^y \psi_{y'}(x',y')\,dx'\,dy'$$

$$\leqq (2|x|y)^{1/2}\left\{\iint_{\mathbf{R}^2_+}\psi_{y'}^2\,dx'\,dy'\right\}^{1/2},$$

which clearly gives the desired inequality. This completes the proof. □

The above theorem supplies a solution pair ζ, γ of the system (2.1), (2.2) in the "classical" case (3.1), and that solution pair is expressed as

$$\zeta = \frac{1}{2y\beta^2}\tilde{\psi}_+ + \frac{\alpha}{\beta}\chi_{\{\tilde{\psi}>0\}}, \quad \gamma = \frac{1}{\beta}\tilde{\psi}_+ \quad \text{with } \tilde{\psi} = G\zeta - cy - \mu. \tag{3.23}$$

Remarks made after Theorem 2 concerning the generalization of the existence result to a class of structure functions a and b satisfying (3.11) apply equally well to the results of Theorem 2.

4. Qualitative properties of vortex rings with swirl. Here we summarize some of the qualitative properties of the solutions found in Theorems 1 and 2. The specific form of the constrained maximization problem we employ in the analysis of solutions provides an especially convenient framework for the derivation of these results, particularly those pertaining to asymptotic properties. However, we will be content merely to sketch the proofs of the results stated here, since our method of analysis has appeared in several papers [7], [11], [13], [14] concerning very similar problems.

As in § 3 and in our sequel paper [8], we restrict our attention to the "classical" case in which the structure functions a and b satisfy (3.1). Then it is of interest to determine how the solutions $\zeta = \zeta_{\alpha,\beta}$, $\gamma = \gamma_{\alpha,\beta}$ depend on the given parameters α and β. We will first consider the dependence upon β (for fixed α), emphasizing the asymptotic limit $\beta \to 0+$ that gives concentrated vortex rings with swirl. We will then consider the dependence of these β-parametrized branches of solutions on α, which dictates the flow structure within the vortex.

The asymptotic analysis of solutions as $\beta \to 0+$ can be accomplished with a modification of the methods given in [13]. The crucial estimates are as follows (C_1, C_2, etc. denote generic positive constants independent of β):

$$\text{diam}\,(\Omega) \leqq C_1\beta, \tag{4.1}$$

$$\max\,(G\zeta - \mu)_+ \leqq C_2, \quad \max\,\zeta \leqq C_3\beta^{-2}, \quad \max\,\gamma \leqq C_4\beta^{-1}. \tag{4.2}$$

The geometric estimate (4.1) on the vortex core $\Omega = \{\tilde{\psi} > 0\}$ may be derived using an extension of the arguments of Theorem 3.3 in [13]. We now briefly indicate the main steps in this derivation for the solutions found in Theorem 1. First, we note the identity

$$\mu = 2\Phi(\zeta) - 2\alpha\beta \iint_D y\left(\zeta - \frac{\alpha}{\beta}\right)_+ dx\,dy, \tag{4.3}$$

which follows immediately from (3.5). Second, we establish that

$$2\Phi(\zeta) \geqq 2\Phi(\hat{\zeta}) \geqq \frac{\hat{r}}{2\pi}\log\beta^{-1} - C_1,$$

taking an admissible function $\hat{\zeta} = (1/\pi\beta^2)\chi_{B_\beta(\hat{x},\hat{y})}$ approximating a delta function centered at some point $(\hat{x}, \hat{y}) \in D$. This estimate depends upon some precise information about the Green function for L in D; in particular, the Green function is known to have the same singular behavior as the fundamental solution for L in $\mathbf{R}^2_+$ (the stream-function for the classical circular vortex filament), which is given by

$$k(z, r, z', r') = \frac{(rr')^{1/2}}{2\pi}\log\xi^{-1} + O(1) \quad \text{as } \xi \to 0+$$

where $\xi = [(z-z')^2 + (r-r')^2]^{1/2}/2(rr')^{1/2}$, when expressed in terms of the variables $z = x$, $r = \sqrt{2y}$ (see [11]). It follows that for any $(x, y) \in \Omega$

$$G\zeta(x, y) \geqq \mu \geqq 2\Phi(\hat{\zeta}) - C_2 \geqq \frac{\hat{r}}{2\pi}\log\beta^{-1} - C_3.$$

A relatively crude argument using this estimate will demonstrate that diam $(\Omega) = o(1)$ as $\beta \to 0+$, and with this fact in hand (and taking $(\hat{x}, \hat{y}) \in \Omega$) the sharp version of the argument ([13, Thm. 3.3) yields the desired estimate (4.1). These arguments rely on showing that, as a consequence of the latter inequality, if $(x, y) \in \Omega$ then

$$\iint_{D \setminus B_{M\beta}(x,y)} \zeta(x', y')\,dx'\,dy' \leqq c_4(\log M)^{-1} \quad \text{for } M > 1,$$

and hence that diam $(\Omega) \leqq 2M\beta$, when M is fixed large enough that $C_4(\log M)^{-1} < \frac{1}{2}$. Once (4.1) is proved, the asymptotically sharp estimates (4.2) follow from the scaling arguments given in Theorems 4.4 and 4.5 of [13]. We omit any further details here.

An obvious consequence of the identity (4.3) is the positivity of μ for small β; in fact, $\mu \geqq a_0 \log\beta^{-1}$ for some constant $a_0 > 0$ as $\beta \to 0+$. Thus, we have justified the remark following Theorem 1, and hence equality must hold in the constraint $C(\zeta) \leqq 1$

for small β. (Presumably, μ is positive for some parameter range $0<\beta<\beta^*(\alpha)$, which could be determined numerically using the method in [8].)

We see from (4.1), (4.2) that ζ tends to a unit delta function in the sense of distributions as $\beta\to 0+$. (The location at which the delta function is concentrated can be deduced from the Green function for L in D, as is explained in Theorem 4.3 of [13].) Also, we see that γ tends to zero in the sense of distributions as $\beta\to 0+$, even though $\max \gamma\to+\infty$. This rather curious property is shared by all concentrated vortex rings with (nonzero) swirl. Consequently, the limit solution is a (typically unique) vortex filament (without swirl) in D which is independent of α. A further manifestation of this phenomenon is that the angular impulse $A(\gamma)\to 0$, while the helicity $B(\zeta,\gamma)=0(\beta^{-1})$ as $\beta\to 0+$.

Similar asymptotic results hold for the solutions found in Theorem 2, namely, steadily translating vortex rings with swirl in all of space. First, recalling (3.21), we observe that the translational speed c satisfies

$$2c=\Phi(\zeta)+\int\int_{\mathbf{R}^2_+}\left[2\beta^2 y\left(\zeta-\frac{\alpha}{\beta}\right)_+^2+6\alpha\beta y\left(\zeta-\frac{\alpha}{\beta}\right)_+\right]dx\,dy. \tag{4.4}$$

Then, since (4.1), (4.2) are also valid for these solutions, it follows that $c\geqq b_0\log\beta^{-1}$ for some constant $b_0>0$ as $\beta\to 0+$. The identity (4.3) now holds with μ replaced by $\mu+c$, and so, in turn, it follows that $\mu\geqq a_0\log\beta^{-1}$ for some constant $a_0>0$. (In fact, the following asymptotic formulas as $\beta\to 0+$ are easily established: $\Phi(\zeta)\sim(\sqrt{2}/4\pi)\log\beta^{-1}$, $c\sim\frac{1}{2}\Phi(\zeta)$, $\mu\sim\frac{3}{2}\Phi(\zeta)$.) As before, we see that as $\beta\to 0+$

$$\zeta\to\delta(x,y-1),\ \gamma\to 0 \text{ in the sense of distributions,}$$

where $\delta(x,y-1)$ is the unit delta function at $(x,y)=(0,1)$. In other words, the unique circular vortex filament with unit linear impulse is obtained as the limit solution, independently of α.

These results justify the remark following Theorem 2, since μ is positive for small β, and hence $C(\zeta)\leqq 1$ holds as an equality. However, much more precise information on the parameter range $0<\beta<\beta^*(a)$ over which this holds is available and is given in [8]. There it is shown that the extreme case $\beta=\beta^*(\alpha)$, for which $\mu=0$, corresponds to an explicit spherical vortex found by Moffatt [12], and the function $\beta^*(\alpha)$ is calculated. The reader is referred there for the details as well as for a quantitative description of the solutions over the full parameter range.

We now turn to the dependence of the solutions on the parameter α. While β determines the cross-sectional diameter of the vortex ring with swirl, α controls the structure of the vortical flow within the vortex ring. When $\alpha=0$, it is readily verified that (3.10) is equivalent to the identity $u=\beta\omega$ in the vortex core. Thus, every solution with $\alpha=0$ defines a vortex ring that consists of a Beltrami flow within its vortex core. Roughly speaking, these solutions represent steady vortex flows whose swirl is maximal with respect to their meridional circulation. (Unlike simple quasi-two-dimensional flows it is not possible for the swirl γ to take essentially arbitrary values, because of the presence of the coupling term $\partial(\gamma,\gamma/2y)$ in (1.12).) The opposite extreme occurs when $\alpha\to+\infty$. Since $\beta^*(\alpha)\to+\infty$ as $\alpha\to+\infty$ (as can be checked), there exist limit solutions $\hat{\zeta}_\lambda:=\lim\zeta_{\alpha,\beta}$ when $\alpha,\beta\to+\infty$ and $\alpha/\beta\to\lambda$ (provided that $\lambda>\lambda^*$, say). In the case of Theorem 1, these solutions satisfy

$$\hat{\zeta}_\lambda=\lambda\chi_{\{G\hat{\zeta}_\lambda>\mu\}},\quad \hat{\gamma}_\lambda=0 \quad \text{in } D,$$

which corresponds to the limit of the free-boundary problems (3.10) for finite α,β. Consequently, such a limit solution represents a classical steady vortex ring without

swirl (see [3], [10]). The relevant parameter range is $\lambda^* < \lambda < +\infty$ where $(\lambda^*)^{-1} = \iint_D dx\,dy$. Similar results apply in the case of Theorem 2, where a branch of steadily translating vortex rings is obtained for which $\lambda = \lambda^*$ gives the Hill spherical vortex and $\lambda = +\infty$ gives the circular vortex filament (both normalized by the constraints $C(\zeta) = 1$, $P(\zeta) = 1$). In either case the general situation with $0 < \alpha < +\infty$ may be viewed as mediating between the extremes described above. Hence the two-parameter family of solutions $\zeta_{\alpha,\beta}$, $\gamma_{\alpha,\beta}$ furnishes a very natural and precise extension of the familiar concept of a vortex ring.

We conclude by commenting that our theoretical results are tied to some interesting phenomena on the physical side. In an unpublished experiment, Bergerud [6] devised an apparatus for imparting azimuthal swirl to concentrated vortex rings, and observed that steady flows were produced when the swirl had a certain critical magnitude, while unsteady (azimuthally oscillating) flows were produced for other swirl magnitudes. It is noteworthy that the steady vortex rings with swirl he observed in water share some qualitative features with our model flows in an ideal fluid. In particular, the bound $A(\gamma) \leqq \beta P(\zeta)$, which holds for all of the solutions given in Theorem 2, confirms that the total angular impulse of any steadily translating vortex ring must be small if it is concentrated (β small) and has a given linear impulse ($P(\zeta)$ prescribed). However, further experimentation is needed before a convincing evaluation of the relevance of our solutions to vortex motions in real fluids can be made.

STATIONARY STOKES AND NAVIER–STOKES SYSTEMS ON TWO- OR THREE-DIMENSIONAL DOMAINS WITH CORNERS. PART I: LINEARIZED EQUATIONS*

MONIQUE DAUGE†

Abstract. The H^s-regularity (s being real and nonnegative) of solutions of the Stokes system in domains with corners is studied. In particular, a H^2-regularity result on a convex polyhedron that generalizes Kellogg and Osborn's result on a convex polygon to three-dimensional domains is stated. Sharper regularity on a cube and on other domains with corners is attained. Conditions for the problem to be Fredholm are also given, and its singular functions along with those of the nonlinear problem are studied in the second part of this paper.

Key words. Stokes, corner, edge, polyhedron, regularity of solutions

AMS(MOS) subject classifications. 35Q, 76N

1. Introduction. The linearized equations corresponding to the Navier–Stokes system describing gas-dynamics consist of the following Stokes system in $\mathbf{R}^n$ ($n=2$ or 3):

$$-\Delta \vec{u} + \nabla p = \vec{f}, \qquad \operatorname{div} \vec{u} = g \tag{1.1}$$

where $\vec{u} = (u_1, \cdots, u_n)$ is the speed of the fluid, p its pressure, and $\vec{f}$ the strength field. On a domain Ω, the boundary conditions are

$$\vec{u}_{|\partial\Omega} = 0. \tag{1.2}$$

The problem (1.1)–(1.2) can be approached as an elliptic boundary value problem as in the paper by Agmon, Douglis, and Nirenberg [1]. On the other hand, it may be proved by a variational method (see Temam [22]) that for a bounded domain Ω and data $(\vec{f}, g)$ in the product of Sobolev spaces $[H^{-1}(\Omega)]^n \times L^2(\Omega)$ with the compatibility condition

$$\int_\Omega g \, dX = 0, \tag{1.3}$$

there exists a unique solution $(\vec{u}, p)$ of (1.1)–(1.2) in the space $[\mathring{H}^1(\Omega)]^n \times [L^2(\Omega)/\mathbf{C}]$. Here, as usual, $\mathring{H}^1(\Omega)$ denotes the H^1-space with null traces on the boundary, and H^{-1} is its dual with respect to the L^2-duality.

Thus, if $(\vec{f}, g)$ is more regular, let us say

$$\vec{f} \in [H^{s-1}(\Omega)]^n \quad \text{and} \quad g \in H^s(\Omega), \quad s > 0, \tag{1.4}$$

then, when Ω has a smooth boundary, we draw from [1] and interpolation (cf. [23]), that

$$\vec{u} \in [H^{s+1}(\Omega)]^n \quad \text{and} \quad p \in H^s(\Omega). \tag{1.5}$$

But, in the case of physical domains, or for partition of domains in numerical analysis, it is natural to study the case when Ω has corners.

In two-dimensional domains (2D), when Ω is a polygon, we have Kondrat'ev's [12] and Grisvard's [10] results for the divergence-free system ($g=0$: incompressible fluid) in spaces with integer exponents; for the general system (1.1), we have Osborn's

results [19], Dauge's results [5] in weighted Sobolev spaces, and the regularity result of Kellogg and Osborn [11].

In three-dimensional domains (3D), Maz'ja and Plamenevskii study the problem (1.1)-(1.2) for a large class of domains in weighted Sobolev spaces: the results are announced in [15] and proved in [16], [17a], [17b]. The spaces are general L^p-Sobolev spaces with weight (of Kondrat'ev type) and also Hölder classes with weight. Merigot [18] and Grisvard [10] have also used L^p-Sobolev spaces in the 2D divergence-free problem on a polygon.

In this paper we state precise results of regularity in the ordinary spaces (1.4), (1.5). Among other things, the Sobolev spaces with real exponents are useful for studying the nonlinear Navier-Stokes system (Part II of this work is forthcoming), and for successive approximation schemes (see [20]).

Theorems 5.4 and 5.5 in 2D are a generalization of [10] and [11]. In 3D we get new results. For several examples of domains, we hereafter indicate a condition on s under which the solution $(\vec{u}, p)$ of (1.1)-(1.2) with $(\vec{f}, g)$ in the space (1.4) has the regularity of (1.5), provided g is zero at the singular points of Ω if $s \geqq 1$ (cf. [11] and the definition (9.17)):

(1.6) If Ω is any domain in our class of domains with corners $\mathcal{O}_3$ (introduced in § 2 below), $s < 0.5$.

(1.7) If $\Omega = Q_1 \backslash Q_2$ where Q_1 and Q_2 are two rectangular parallelepipeds with the same axes, $s \leqq 0.544$ (approximate value).

(1.8) If Ω is any convex domain in our class $\mathcal{O}_3$, $s \leqq 1$.

(1.9) If Ω is any convex domain with wedge angles $\leqq 2\pi/3$, $s < 3/2$.

(1.10) If Ω is any cylinder with convex polygonal base, and angles $< 2\pi/3$, $s \leqq 3/2$.

(1.11) If Ω is any cylinder with smooth base, $s < 2$.

(1.12) If Ω is a half-ball, $s < 2$.

When we say a cylinder, we mean a bounded cylinder truncated perpendicularly to its generating lines.

The plan of this paper is as follows. In § 2 we introduce our classes of domains and the functional spaces. In § 3 we recall general results from Dauge's works [6] and [9], and we apply them to the problem (1.1)-(1.2). As these results are based on a special condition of injectivity about tangent problems, in § 4 we link that condition to the usual one used by Kondrat'ev in [12]. In § 5 we recall some properties of the characteristic equation $\sin^2 \lambda\omega - \lambda^2 \sin^2 \omega = 0$, we give a graph and tables of values for its roots, and we state results in 2D. In § 6 we study the domains in 3D that have edges, but no vertices. In § 7 we study the tangent problem in a three-dimensional cone, which gives rise to a quantity linked with the Laplace-Beltrami operator that we estimate in § 8. Finally, we state 3D results in § 9.

2. Classes of domains and functional spaces. Our classes of domains contain various curvilinear polygons (in 2D) and polyhedra or domains with piecewise-smooth boundary (in 3D).

2.1. Plane and spherical domains. Our class $\mathcal{O}_2(\mathbf{R}^2)$ of plane domains consists of all curvilinear polygons, possibly with cracks but without cusps (or turning points): Ω is in $\mathcal{O}_2(\mathbf{R}^2)$ if and only if it enjoys the following properties:

(i) Ω is bounded and connected.

(ii) The boundary of Ω consists of a finite number of smooth closed arcs $\Gamma_1, \cdots, \Gamma_N, \Gamma_{N+1} = \Gamma_1$.

(iii) Let A_j and A_{j+1} be the ends of Γ_j; the A_j for $j=1,\cdots,N$ are the vertices of Ω and at the neighborhood of A_j, Ω is locally diffeomorphic to a neighborhood of zero in a plane sector Γ_{A_j}.

In the case when one of the sectors Γ_{A_j} has its opening equal to 2π, we have a *crack* and we dissociate the two sides of the crack as in Fig. 1.

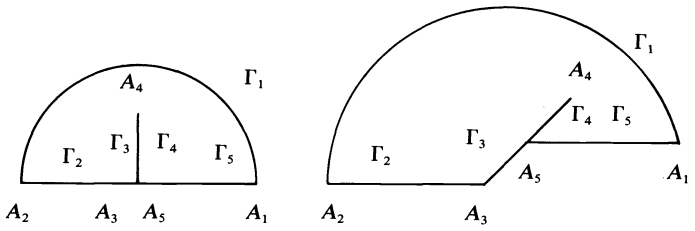

FIG. 1

In both cases, A_4 is at the bottom of the crack and Γ_3 and Γ_4 coincide in the neighborhood of A_4.

Let us note that condition (iii) may be rewritten in the following form. If the tangents of Γ_j and Γ_{j+1} coincide in A_j, then Γ_j and Γ_{j+1} coincide in a neighborhood of A_j.

We denote by $A_0(\Omega)$ the set $\{A_1,\cdots,A_N\}$ and denote simply by x any element of $A_0(\Omega)$. Thus, for $x=A_j$, Γ_{A_j} is denoted by Γ_x.

In the same way we define the class $\mathcal{O}_2(S^2)$ of curvilinear polygons on the unit sphere of $\mathbf{R}^3$.

2.2. Three-dimensional domains. Ω belongs to $\mathcal{O}_3(\mathbf{R}^3)$ if and only if it satisfies the following conditions:

(i) Ω is bounded and connected.

(ii) At each point x of its "stretched" boundary, Ω is locally diffeomorphic to a neighborhood of zero in one of the following three kinds of domains:

(1) A half-space: then x is a **regular** point;

(2) A dihedron isomorphic to $\mathbf{R}\times\Gamma_x$, with Γ_x a plane sector with an opening ω_x different from π: then x belongs to an **edge**;

(3) A cone Γ_x with vertex zero (which is not a dihedron), such that its intersection G_x with S^2 belongs to $\mathcal{O}_2(S^2)$: then x is a **vertex**.

Let $A_0(\Omega)$ be the set of vertices and $A_1(\Omega)$ be the union of the edges.

The **stretched boundary** is the notion corresponding to the doubling of the boundary when there is a crack in 2D. This is more completely explained in § 2 of [9].

Note that if Ω has a piecewise-smooth boundary, and its faces meet two by two or three by three with independent normals at meeting points, then Ω belongs to our class $\mathcal{O}_3(\mathbf{R}^3)$.

2.3. Sobolev spaces. For a positive integer s, $H^s(\Omega)$ is the usual Sobolev space of all distributions u in $\mathcal{D}'(\Omega)$ such that each derivative $D^\alpha u$ with length $|\alpha|\leqq s$, in Ω, belongs to $L^2(\Omega)$. For a positive noninteger real number s, let $[s]$ be the integer part of s and $\sigma=s-[s]$. $H^s(\Omega)$ is the space of all u in $H^{[s]}(\Omega)$ that satisfy

$$\forall\alpha,\ |\alpha|=[s]\quad \iint_\Omega |D^\alpha u(x)-D^\alpha u(y)|^2\, d(x,y)^{-n-2s}\, dx\, dy<+\infty$$

where $d(x,y)$ is the infimum of length of the paths joining x to y and included in Ω.

$\mathring{H}^s(\Omega)$ is the closure of $\mathscr{D}(\Omega)$ in $H^s(\Omega)$ and $H^{-s}(\Omega)$ its dual with respect to the L^2-duality.

2.4. Stokes operators. We denote by $D_n^s(\Omega)$ the product of Sobolev spaces $[\mathring{H}^1 \cap H^{s+1}(\Omega)]^n \times H^s(\Omega)$ (cf. (1.5)) and by $E_n^s(\Omega)$ the product $[H^{s-1}(\Omega)]^n \times H^s(\Omega)$. We then denote by $\mathscr{S}_n$ the operator (1.1) applying $(\vec{u}, p)$ on $(\vec{f}, g)$, and we write especially $\mathscr{S}_n[s, \Omega]$ for $\mathscr{S}_n$ acting from $D_n^s(\Omega)$ to $E_n^s(\Omega)$. We suppose everywhere that $s \neq \frac{1}{2}$.

3. General Fredholm properties. General Fredholm properties rely on general statements of [9] that we apply here to the Stokes system (1.1)-(1.2).

In [9], we develop general conditions for a strongly elliptic operator to be Fredholm between Sobolev spaces H^s (in the above sense; § 2.3), e.g., with Dirichlet conditions. Moreover, we extend that theory to strongly elliptic systems, and other ones satisfying a weaker ellipticity property that holds in particular for the Stokes system (see (7.7) in [9]).

We will apply those results. To do so, we recall the characteristic conditions concerning the operator and the domain. When Ω is a polygon, it is well known that such conditions are related to the angle openings of Ω and to associated discriminant functions (cf. [10], [12]). In fact it is related with the spectrum of a holomorphic operator family; in three dimensions the condition may be written only in that form. We show in [9] that those "spectral" conditions are fully convenient for "homogeneous" weighted Sobolev spaces, and that, for ordinary Sobolev spaces, they must be replaced with a new type of condition we call "injectivity modulo polynomials."

Although that distinction is of lesser use for regularity properties than for Fredholm properties, we introduce it in anticipation of the forthcoming Part II of this paper where we will describe the singularities of solutions.

Our conditions are related to tangent (or frozen) operators at each singular point of Ω.

3.1. Frozen operators at a vertex. Let Ω be a domain in $\mathscr{O}_n(\mathbf{R}^n)$, $n = 2, 3$ and $x \in A_0(\Omega)$. We will suppose that the diffeomorphism χ, which implies a neighborhood of x in Ω on a neighborhood of zero in Γ_x, is such that

$$D\chi(x) = I \text{ is the identity matrix.}$$

Then, the operator L_x, obtained by taking the principal part of the operator $\chi \circ \mathscr{S}_n \circ \chi^{-1}$ frozen in zero, just coincides with $\mathscr{S}_n$ on the cone Γ_x.

3.2. Frozen operators along an edge. As in the case of a vertex, if $x \in A_1(\Omega)$, the frozen operator on the wedge $\mathbf{R} \times \Gamma_x$ is $\mathscr{S}_3$. But, we have to define a new frozen operator L_x on the plane sector Γ_x (cf. [9, (3.3)]). Let (y, z) be coordinates such that $y \in \mathbf{R}$ and $z \in \Gamma_x$. The operator L_x is defined as

$$L_x(D_z) = \mathscr{S}_3(0, D_z)$$

(we remove tangential derivatives along the edge). Thus, we have

$$L_x(u_1, u_2, u_3, p) = (f_1, f_2, f_3, g) \tag{3.1}$$

if and only if

$$\mathscr{S}_2(u_1, u_2, p) = (f_1, f_2, g) \quad \text{and} \quad \Delta u_3 = f_3. \tag{3.2}$$

3.3. Injectivity modulo polynomials. For $\lambda \in \mathbf{C}$, $S_n^\lambda(\Gamma_x)$ denotes the set of vector functions $(u_1, \cdots, u_n, p)$ of the form:

$$u_j = r^\lambda \sum_{0 \leqq q \leqq Q} u_{jq}(\Psi) \log^q r \quad \text{with } u_{jq} \in \mathring{H}^1(G_x),$$

$$p = r^{\lambda - 1} \sum_{0 \leqq q \leqq Q} p_q(\Psi) \log^q r \quad \text{with } p_q \in L^2(G_x)$$

where $(r, \Psi) = (|z|, z/|z|)$ are the polar coordinates and G_x is the intersection of Γ_x with the unit sphere S^{n-1}.

We say that L is injective modulo polynomial on $S_n^\lambda(\Gamma_x)$ if

$$(\vec{u}, p) \in S_n^\lambda(\Gamma_x) \text{ and } L(\vec{u}, p) \text{ is polynomial implies that } (\vec{u}, p) \text{ is polynomial.}$$

Here "polynomial" means polynomial with respect to *cartesian variable* $z = (z_1, z_2)$ or (z_1, z_2, z_3). For instance, $r^\alpha \sin \alpha\theta$ is polynomial in $\mathbf{R}^2$ for $\alpha \in \mathbf{Z}$. Of course, the zero function is polynomial.

3.4. Index and regularity results.

THEOREM 3.3. *Let $\Omega \in \mathcal{O}_n(\mathbf{R}^n)$. The Stokes operator $\mathcal{S}_n[s, \Omega]$ is a Fredholm operator if and only if both the following conditions are satisfied*:

(3.4) $\forall x \in A_0(\Omega)$, $\forall \lambda$ *with* $\operatorname{Re} \lambda = s + 1 - n/2$, L_x *is injective modulo polynomials on* $S_n^\lambda(\Gamma_x)$;

(3.5) $\exists \varepsilon > 0$, $\forall x \in A_1(\Omega)$, $\forall \lambda$ *with* $\operatorname{Re} \lambda \in [0, s + \varepsilon]$, L_x *is injective modulo polynomials on* $S_3^\lambda(\Gamma_x)$.

This statement is derived from (7.15) in [9], with the variant (6.8) in [9].

If Ω has only conical points (which is the case when $n = 2$), the condition (3.5) is void. If Ω has no vertex (cf. examples (1.11), (1.12)), the condition (3.4) is void and (3.5) may be replaced with (3.5′):

(3.5′) $\forall x \in A_1(\Omega)$, $\forall \lambda$ with $\operatorname{Re} \lambda \in [0, s]$, L_x is injective modulo polynomials on $S_3^\lambda(\Gamma_x)$.

If Ω is a three-dimensional polyhedron with plane faces, (3.5) may still be replaced with (3.5′): the ε in (3.5) is useful in the case when Ω is a three-dimensional domain with smooth curved faces; that ε allows an easier formulation without introducing "subsections" or "singular chains," which describe the limit geometrical behavior at the neighborhood of a vertex.

THEOREM 3.6. *Assume that the conditions* (3.5) *and* (3.7) *are fulfilled*:

(3.7) $\forall x \in A_0(\Omega)$, $\forall \lambda$ *with* $\operatorname{Re} \lambda \in [1 - n/2, s + 1 - n/2]$, L_x *is injective modulo polynomials on* $S_n^\lambda(\Gamma_x)$.

Then, each solution $(\vec{u}, p) \in D_n^0(\Omega)$ of (1.1) *with $(\vec{f}, g)$ in $E_n^s(\Omega)$ has the regularity $D_n^s(\Omega)$.*

When (3.4) is satisfied, and not (3.7), there are singular functions. We will study these in Part II of this paper, along with the nonlinear Navier-Stokes system.

Now, we will study (3.5) and (3.7) in order to give more precise regularity results in two and three dimensions.

4. The link between the injectivity condition and the usual spectral condition.

4.1. Generalities. Let us study condition (3.4). In view of § 3.1, $L_x = \mathcal{S}_n$. If we consider $\vec{u}$ of the form $r^\lambda \vec{u}(\Psi)$ and $p = r^{\lambda-1} \not{p}(\Psi)$, then we get

$$\mathcal{S}_n(\vec{u}, p) = (\vec{f}, g)$$

where $\vec{f} = r^{\lambda-2} \vec{\not{f}}(\Psi)$ and $g = r^{\lambda-1} \not{g}(\Psi)$, with

$$\mathcal{L}_n(\lambda)(\vec{u}, \not{p}) = (\vec{\not{f}}, \not{g}), \tag{4.1}$$

$\mathcal{L}_n(\lambda)$ being a system on the sphere S^{n-1}, depending in a polynomial way on λ. As in [17], we can derive from the writing of $\mathcal{S}_n$ in polar coordinates that (4.1) may be written in the form

$$[\delta_n - \lambda(\lambda + 1)]\vec{u} + [(\lambda - 1)\vec{\Psi} + \vec{\nabla}_s]\not{p} = \vec{\not{f}}, \qquad \langle \lambda \vec{\Psi} + \vec{\sigma}, \vec{u} \rangle = \not{g}$$

where δ_n is the positive Laplace-Beltrami operator on S^{n-1}, $\vec{\Psi}$ is the vector $x/|x|$ in $\mathbf{R}^n$, and $\vec{\nabla}_s$ is the tangential component of the gradient on the sphere

$$\vec{\nabla}_s = \vec{\nabla} - \vec{\Psi}\partial/\partial_r.$$

$\mathscr{L}_n(\lambda)$ gives rise to an operator acting from $D_n^0(G_x)$ to $E_n^0(G_x)$. It is almost everywhere invertible. The set of λ for which $\mathscr{L}_n(\lambda)$ is not invertible is called the **spectrum** of $\mathscr{L}_n$, and the condition used by Kondrat'ev [12] or Maz'ja and Plamenevskii is that the straight line $\operatorname{Re}\lambda = s+1-n/2$ does not meet the spectrum of $\mathscr{L}_n$. As we have already said, this type of condition is correct for weighted Sobolev spaces (of the type $r^{\gamma+|\alpha|}D^\alpha v \in L^2$), but it is not always suitable for ordinary Sobolev spaces. Nevertheless, we have (cf. (4.2) for $s=0$ and (4.6) in [9]):

LEMMA 4.2. *If λ is not a positive integer, $\mathscr{S}_n$ is injective modulo polynomials on $S^\lambda(\Gamma_x)$ if and only if λ does not belong to the spectrum of $\mathscr{L}_n$ on G_x.*

If λ is an integer number, the comparison depends on the difference $d(\lambda)$ between the dimensions of two spaces of polynomial functions:

$$d(\lambda) = \dim P^\lambda(\Gamma_x) - \dim Q^{\lambda-2}$$

where $P^\lambda(\Gamma_x)$ is the set of the elements of $S^\lambda(\Gamma_x)$ that are polynomials *in cartesian variables*, and $Q^{\lambda-2}$ is the set of the $(\vec{f}, g)$ with f_j (respectively, g) homogeneous polynomial of degree $\lambda-2$ (respectively, $\lambda-1$) in z. $d(\lambda)$ depends only on Γ_x. According to [9, Annex D], there exists a homogeneous polynomial A that is zero on the boundary of Γ_x and such that if B is a polynomial that is zero on $\partial\Gamma_x$, then A divides B (i.e., $P^\lambda(\Gamma_x)$ is a principal ideal).

If the degree of A is two, then $d(\lambda)=0$; and according to (4.9) and (7.14) in [9], we have the following lemma.

LEMMA 4.3. *If $d^0A=2$, for each integer λ we have the same equivalence as in* (4.2).

According to (4.8) and (7.14) in [9], we have the following lemma.

LEMMA 4.4. *If $d^0A \geqq 3$, for $\lambda=1$ we have the same equivalence as in* (4.2); *but for each integer $\lambda \geqq 2$, $\mathscr{S}_n$ is not injective modulo polynomials on $S^\lambda(\Gamma_x)$.*

According to (4.10) and (7.14) in [9], we have Lemma 4.5.

LEMMA 4.5. *If $d^0A=1$, and $\lambda \in \mathbf{N}^*$, then $\mathscr{S}_n$ is injective modulo polynomials on $S^\lambda(\Gamma_x)$ if and only if $\mathscr{L}_n(\mu)^{-1}$ has a pole of order one in $\mu=\lambda$ and if*

$$\dim \operatorname{Ker} \mathscr{L}_n(\lambda) = d(\lambda).$$

4.2. Application to two-dimensional cones. It is well known that the poles $\mathscr{L}_2(\lambda)^{-1}$ coincide with the roots of the following equations:

$$F_\omega(\lambda)=0 \quad \text{where} \quad F_\omega(\lambda) = \frac{\sin^2\lambda\omega - \lambda^2\sin^2\omega}{\lambda^2} \tag{4.6}$$

because, more precisely, $\mathscr{L}_2(\lambda)^{-1}F_\omega(\lambda)$ is holomorphic on $\mathbf{C}$ (cf. [12], [10], [11], [5]).

When the opening ω of the plane sector Γ_x is not 2π, then the two sides of Γ_x are independent and $d^0A=2$. So, the condition (3.4) is that F_ω has no zero with real part s.

When $\omega=2\pi$, then $d^0A=1$ and $d(\lambda)>0$ for all positive integer numbers. As in § 15.B in [9] for fourth-order operators, we show in the Annex that, according to Lemma 4.5, $\mathscr{S}_2$ is injective modulo polynomials on S^λ for each $\lambda \in \mathbf{N}^*$ (including $\lambda=1$). As the roots of (4.6) are the half integers, we find that condition (3.4) is reduced to

$$s \neq k+\tfrac{1}{2}, \quad \forall k \in \mathbf{N}.$$

4.3. Application to three-dimensional cones. If Γ_x is a revolution cone, then $d^0A=2$ and we apply Lemmas 4.2 and 4.3.

If Γ_x is a polyhedral cone, let D be the number of distinct planes containing at least one side of Γ_x. For a cube, $D=3$. For a pyramid with a square basis, $D=4$. If $D \geqq 3$, we apply Lemmas 4.2 and 4.4.

5. Precise results in two-dimensional domains.

5.1. More about the discriminant function F_ω. The roots of (4.6) have been studied by Seif [21], Lozi [13], Dauge [7], Bernardi and Raugel [2], [3], and Maslovskaya [14]. Bernardi and Raugel give a table for the roots of (4.6) with the lowest positive real part. Here, we complete that work by a table for the roots of (4.6) with their real parts $\xi \in [0, 4]$ and by the corresponding graph (Fig. 2) of ξ in function of ω.

Let us denote λ by $\xi + i\eta$, with ξ, η real. We are interested in roots of (4.6) with $\xi \geqq 0$. $\lambda = 1$ is always a root of (4.6) and plays a particular role (see § 5.2).

We denote by $\xi_k(\omega)$ the real part of the kth root of

$$(\lambda - 1)^{-1} F_\omega(\lambda) = 0$$

the roots being ordered with increasing real part and repeated according to their multiplicities. The following can be shown (cf. [7], [2]):

(a) If $\omega \in]0, \pi[$, $\xi_1(\omega) > \pi/\omega$.

(b) If $\omega \in]\pi, 2\pi[$, $\xi_1(\omega) \in]\sup(\frac{1}{2}, \omega_1/\omega), \pi/\omega[$, where $\omega_1 = 0.812825\pi$; ω_1 is the root of

$$\omega \in]0, \pi[\quad \text{and} \quad \frac{\sin \omega}{\omega} = -\cos \omega_0 \quad \text{with } \tan \omega_0 = \omega_0.$$

Tables 1 and 2 and Fig. 2 give values for $\xi_1, \cdots, \xi_{14}$ that occur in $[0, 4]$. A dash means a value greater than four.

For $j \geqq 1$, let I_j be the set of ω such that $\xi_{2j}(\omega)$ and $\xi_{2j+1}(\omega)$ coincide. In the interior of I_j, ξ_{2j} and ξ_{2j+1} are the real parts of two conjugate nonreal numbers. For $\omega \in \partial I_j$ and $\omega \neq 0$, there is a real double root and the bifurcation of two real roots.

TABLE 1

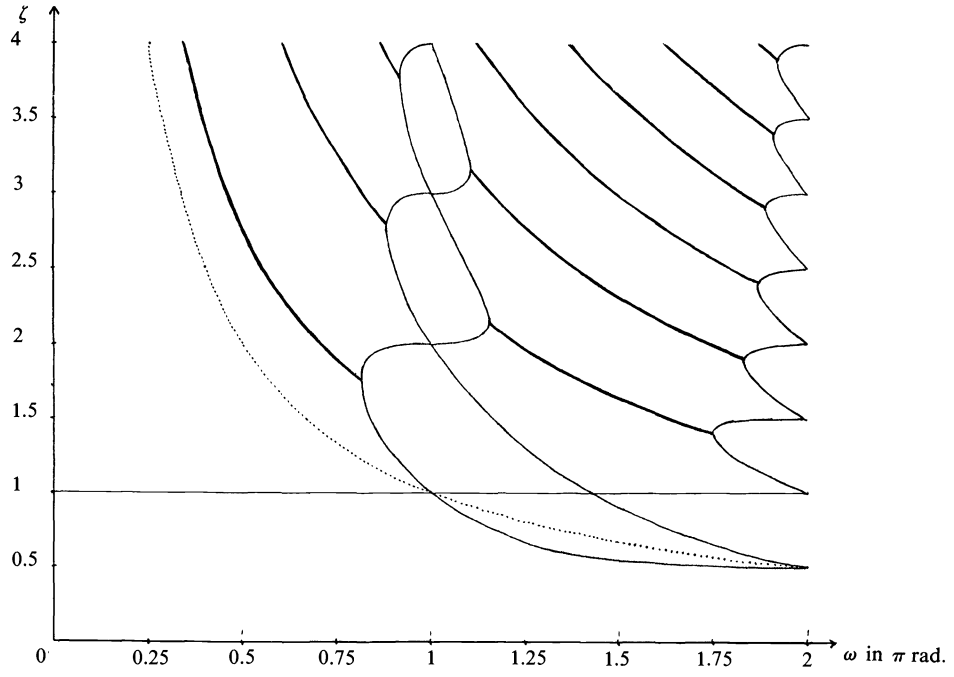

FIG. 2

I_1 has only one connected component: $I_1 =]0, \omega_1]$. For $j \geqq 2$, I_j has two connected components: $]0, \omega_j]$ and $[\omega_j', \omega_j'']$. When $j \to +\infty$, $\omega_j \to \pi$ and $\omega_j'' \to 2\pi$ increase, while $\omega_j' \to \pi$ decreases. All integers are double roots for $\omega = \pi$, and all half integers are double roots for $\omega = 2\pi$.

On the graph, the dotted line is the graph of $\omega \to \pi/\omega$. The heavy lines represent a double value for the ξ_k (conjugate roots), and the ordinary lines represent real roots.

Table 3 gives the values of the ω_j, ω_j', ω_j'' that occur in Fig. 2.

5.2. The special case of the pole $\lambda = 1$. As we have already shown $\lambda = 1$ is always a pole for $\mathscr{L}_2(\lambda)^{-1}$. But, if the opening of the cone Γ is $\omega = 2\pi$, $\mathscr{S}_2$ is injective modulo polynomials on $S^\lambda(\Gamma)$. If $\omega \neq 2\pi$, this is not so for $\mathscr{S}_2$.

It is easy to show that $\operatorname{Ker} \mathscr{L}_2(1)$ is one-dimensional and is generated by $(\vec{0}, 1)$ (see [11], [5]). As a consequence, we get the following lemma.

TABLE 3

	ω	ω'	ω''

3	0.915	1.102	1.825

LEMMA 5.1. *Let s be such that $1 \leqq s < \xi_1(\omega)$. Let $(\vec{u}, p)$ be in $D_2^0(\Gamma)$ such that $\mathcal{S}_2(\vec{u}, p) = (\vec{f}, g) \in E_2^s(\Gamma)$. Moreover, if $s > 1$, we suppose that $g(0) = 0$; if $s = 1$ we suppose that $r^{-1}g \in L^2(\Gamma)$. Then, if B denotes the unit ball, we have*

$$(\vec{u}, p) \in D_2^s(\Gamma \cap B).$$

Proof. We derive the proof from the methods of [9]. For $s = 1$, it is the result of [11].

By a cut-off, we assume that $(\vec{u}, p)$ has compact support. We use the Mellin transform $\mathcal{M}$ of $(\vec{u}, rp)$, which is defined for $\operatorname{Re} \lambda \leqq 0$; we have

$$\mathcal{L}_2(r\partial_r)(\vec{u}, rp) = (r^2\vec{f}, rg), \tag{5.2}$$

and thus using the Mellin transform we have

$$\mathcal{L}_2(\lambda)(\vec{U}(\lambda), P(\lambda)) = (\vec{F}(\lambda), G(\lambda)). \tag{5.3}$$

But $(\vec{F}(\lambda), G(\lambda))$ is defined for $\operatorname{Re} \lambda < s$. If $s \neq 1$, then we deduce from [9] (see the condensed proof in [8]) that there exists $(\vec{u}_0, p_0) \in D_2^s(\Gamma \cap B)$ such that for $\operatorname{Re} \lambda = 1 + \varepsilon$ with $\varepsilon \in]0, \min(1, s-1)[$,

$$\mathcal{M}(\vec{u}_0, rp_0)(\lambda) = (\vec{U}(\lambda), P(\lambda))$$

where $(\vec{U}, P)(\lambda)$ is the extension determined by (5.3). And we have

$$(\vec{u}, p) - (\vec{u}_0, p_0) = \sum_{0 < \operatorname{Re}\lambda < 1+\varepsilon} \operatorname{Res}\,[r^\lambda \vec{U}(\lambda), r^{\lambda-1}P(\lambda)].$$

Since $s < \xi_1(\omega)$, the sum is reduced to $\lambda = 1$. And we have

$$\begin{aligned} \mathcal{S}_2 \operatorname{Res}\,(r^\lambda \vec{U}(\lambda), r^{\lambda-1}P(\lambda)) &= \operatorname{Res}\,\mathcal{S}_2(r^\lambda \vec{U}(\lambda), r^{\lambda-1}P(\lambda)) \\ &= \operatorname{Res}_{\lambda=1}\,(r^{\lambda-2}\vec{F}(\lambda), r^{\lambda-1}G(\lambda)) \\ &= (\vec{0}, g(0)). \end{aligned}$$

The second equality is given by (5.3) and by the equivalence of $\mathcal{S}_2(\vec{u}, p) = (\vec{f}, g)$ with (5.2). Since $g(0) = 0$, we get

$$\mathcal{S}_2 \operatorname{Res}_{\lambda=1}\,(r^\lambda \vec{U}(\lambda), r^{\lambda-1}P(\lambda)) = 0.$$

Therefore

$$\mathcal{L}_2(1) \operatorname{Res}_{\lambda=1}\,(\vec{U}(\lambda), P(\lambda)) = 0.$$

The residue belongs to the kernel of $\mathcal{L}_2(1)$. Thus it is equal to $(\vec{0}, c)$, with c a constant. We finally get

$$(\vec{u}, p) - (\vec{u}_0, p_0) = (\vec{0}, c).$$

Thus $(\vec{u}, p) \in D_2^s(\Gamma \cap B)$.

If $s = 1$, since $r^{-1}g \in L^2$, $G(\lambda)$ is defined up to $\operatorname{Re} \lambda = 1$ (such is not the case if $g \in H^1$ only). Since $\operatorname{Res}_{\lambda=1} \mathcal{L}_2(\lambda)^{-1} = (\vec{0}, 1)\chi$, where χ is a linear form, we get that $\Pi\mathcal{L}_2(\lambda)^{-1}$ is holomorphic in the neighborhood of $\lambda = 1$, where Π is the projection on

the speed component. Thus, $\Pi\mathscr{L}_2(\lambda)^{-1}(F, G)(\lambda)$ is defined up to $\operatorname{Re}\lambda = 1$, with suitable estimates. Then, we deduce that $\vec{u} \in H^2(\Gamma \cap B)$. Since $p \in L^2$, and $\vec{\nabla} p = \Delta\vec{u} + \vec{f} \in L^2(\Gamma \cap B)$, then $p \in H^1(\Gamma \cap B)$. □

5.3. Index and regularity results.

THEOREM 5.4. *Let $\Omega \in \mathscr{O}_2(\mathbf{R}^2)$, and let $s > 0$. $\mathscr{S}_2(\Omega, s)$ is Fredholm if and only if the three following conditions are fulfilled*:

(a) $s \neq 1$;

(b) $\forall x \in A_0(\Omega)$ *such that* $\omega_x \neq 2\pi$, $\forall k$, $s \neq \xi_k(\omega_x)$;

(c) $\forall x \in A_0(\Omega)$ *such that* $\omega_x = 2\pi$, $\forall k$, $s \neq k + \frac{1}{2}$.

Let us recall that ξ_k is defined in § 5.1. It is a straightforward consequence of Theorem 3.3 and §§ 4.2, 4.3, and 5.1. From Theorem 3.6 and § 5.2 we derive Theorem 5.5.

THEOREM 5.5. *Let $\Omega \in \mathscr{O}_2(\mathbf{R}^2)$ and $s > 0$. Let $(\vec{u}, p) \in D_2^0(\Omega)$ be the solution of* (1.1) *with $(\vec{f}, g) \in E_2^s(\Omega)$*:

(a) **If** $s < 1$ *and* $s < \min_{x \in A_0(\Omega)} \xi_1(\omega_x)$, *then* $(\vec{u}, p) \in D_2^s(\Omega)$;

(b) **If** $s > 1$ *and moreover* $g(x) = 0$ *for each vertex* x, *and if* $s < \min_{x \in A_0(\Omega)} \xi_1(\omega_x)$, *then* $(\vec{u}, p) \in D_2^s(\Omega)$;

(c) **If** $s = 1$ *and moreover* $r_x^{-1} g \in L^2(\Omega)$ *for each vertex* x, *and if* $1 < \min_{x \in A_0(\Omega)} \xi_1(\omega_x)$, *then* $(\vec{u}, p) \in D_2^2(\Omega)$.

As $\xi_1(\pi) = 1$ and ξ_1 is a decreasing function, $1 < \min_{x \in A_0(\Omega)} \xi_1(\omega_x)$ holds if Ω is convex. It coincides with the result in [11].

6. Precise results in three-dimensional domains when there are edges, but no vertex.

6.1. The statements. In such a case, we study condition (3.5): since, for $x \in A_1(\Omega)$, L_x is given by (3.1)-(3.2), it is obvious that L_x is injective modulo polynomials on $S_3^\lambda(\Gamma_x)$ and only if we have (6.1) and (6.2):

(6.1) $\mathscr{S}_2$ is injective modulo polynomials on $S_2^\lambda(\Gamma_x)$,

(6.2) Δ is injective modulo polynomials on $S_0^\lambda(\Gamma_x)$,

where $S_0^\lambda(\Gamma) = \{v = r^\lambda \sum v_q(\Psi) \log^q r,\ v_q \in \mathring{H}^1(G)\}$.

If $\omega_x \neq 2\pi$, (6.2) is equivalent to $\lambda \notin \{(k\pi/\omega_x)/k \in \mathbf{N}^*\}$ and if $\omega_x = 2\pi$, (6.2) is equivalent to $\lambda \notin \{k + \frac{1}{2},\ k \in \mathbf{N}\}$ (for $\operatorname{Re}\lambda \geqq 0$). Our statement follows.

THEOREM 6.3. *Let $\Omega \in \mathscr{O}_3(\mathbf{R}^3)$ such that $A_0(\Omega) = \varnothing$. Let $(\vec{u}, p) \in D_3^0(\Omega)$ be the solution of* (1.1) *with $(\vec{f}, g) \in E_3^s(\Omega)$.*

(a) **If** $s < 1$ *and* $s < \min_{x \in A_1(\Omega)} \xi_1(\omega_x)$, *then* $(\vec{u}, p) \in D_3^s(\Omega)$;

(b) **If** $s > 1$ *and* $s < \min_{x \in A_1(\Omega)} \pi/\omega_x$, *and moreover* $g(x) = 0$ *for each* $x \in A_1(\Omega)$, *then* $(\vec{u}, p) \in D_3^s(\Omega)$;

(c) **If** $s = 1$ *and* Ω *is convex, and moreover* $\rho_1^{-1} g \in L^2(\Omega)$, *where* ρ_1 *is the distance from* $A_1(\Omega)$, *then* $(\vec{u}, p) \in D_3^2(\Omega)$.

Proof. First, here are the main arguments of the proof.

(a) If $s < 1$, then (6.1) (respectively, (6.2)) is true for all λ such that $\operatorname{Re}\lambda \in [0, s]$ if $s < \xi_1(\omega_x)$ (respectively, $s < \pi/\omega_x$). But, if $\xi_1(\omega_x) < 1$, then $\xi_1(\omega_x) < \pi/\omega_x$. Thus (a) is derived from (3.6).

(b) As $s > 1$, if $s < \pi/\omega_x$, then $\omega_x < \pi$ and $\xi_1(\omega_x) > \pi/\omega_x$. Thus, for each $\lambda \neq 1$ in the strip $\operatorname{Re}\lambda \in [0, s]$, and for each $x \in A_1(\Omega)$, L_x is injective modulo polynomials on $S_3^\lambda(\Gamma_x)$. We have that (b) is an adaptation of the proof of (5.12) in [9] by taking advantage of Lemma 5.1 above. See some details that follow this proof.

(c) When Ω is convex, $\xi_1(\omega_x)$ and π/ω_x are greater than one for each vertex x. Like (b), (c) is derived from Lemma 5.1.

6.2. A more detailed proof of Theorem 6.3. Because of the special role of the pole $\lambda = 1$ (cf. Lemma 5.1) we are led to revise the proofs in § 12.C of [9] to take into account the cancellation assumptions concerning g.

Let Γ be a plane sector. We first study $\mathcal{S}_3$ on $\mathbf{R}\times\Gamma$. We denote by y the coordinate in $\mathbf{R}$ and by z the coordinates in Γ; $r = |z|$. We introduce the space $H_0^1(\mathbf{R}\times\Gamma)$ as the set of functions v such that

$$\forall \alpha, |\alpha| \leqq 1 \quad r^{|\alpha|-1} D^\alpha v \in L^2(\mathbf{R}\times\Gamma).$$

$\mathring{H}_0^1(\mathbf{R}\times\Gamma)$ is the closure of $\mathcal{D}(\mathbf{R}\times\Gamma)$ in $H_0^1(\mathbf{R}\times\Gamma)$ and $H_0^{-1}(\mathbf{R}\times\Gamma)$ is its dual space.

LEMMA 6.4. *$\mathcal{S}_3$ induces an isomorphism from $\mathring{H}_0^1\times\mathring{H}_0^1\times\mathring{H}_0^1\times L^2(\mathbf{R}\times\Gamma)$ to $H_0^{-1}\times H_0^{-1}\times H_0^{-1}\times L^2(\mathbf{R}\times\Gamma)$.*

Sketch of the Proof (cf. [9, (8.1), (12.6)]). It is sufficient to prove that $\mathcal{S}_3$ is injective and has a closed range because its adjoint has the same form. Let B_ρ be the ball with center zero and radius ρ. For $(\vec{u}, p) \in (\mathring{H}^1)^3 \times L^2$ with its support in B_1, we have the following estimate:

$$\sum_{j=1}^{3} \|u_j\|_{H^1} + \|p\|_{L^2} \leqq C\left(\sum_{j=1}^{3} \|f_j\|_{H^{-1}} + \|g\|_{L^2} + \sum_{j=1}^{3} \|u_j\|_{L^2} + \|p\|_{H^{-1}} \right).$$

But $\mathring{H}^1(B_1) \subset H_0^1(B_1)$ and $H_0^{-1}(B_1) \subset H^{-1}(B_1)$. Moreover, if $\operatorname{supp}(\vec{u}, p) \subset B_\rho$, we have

$$\|u_j\|_{L^2} \leqq \rho \|u_j\|_{H_0^1} \quad \text{and by duality} \quad \|p\|_{H^{-1}} \leqq \rho \|p\|_{L^2}.$$

Thus, if $\operatorname{supp}(\vec{u}, p) \subset B_\rho$, we have the following estimate, for $\rho > 0$ small enough:

$$\sum \|u_j\|_{H_0^1} + \|p\|_{L^2} \leqq 2C\left(\sum \|f_j\|_{H_0^{-1}} + \|g\|_{L^2} \right). \tag{6.5}$$

We deduce the same estimates for all $(\vec{u}, p)$ in $(\mathring{H}_0^1)^3 \times L^2$ by homogeneity and density of functions with compact support. □

$\mathcal{S}_3$ may be written $\mathcal{S}_3(D_y, D_z)$.

LEMMA 6.6. *$\mathcal{S}_3(\pm 1, D_z)$ induces an isomorphism from $\mathring{H}^1\times\mathring{H}^1\times\mathring{H}^1\times L^2(\Gamma)$ to $H^{-1}\times H^{-1}\times H^{-1}\times L^2(\Gamma)$.*

Sketch of the Proof. Let $(\vec{u}, p) \in (\mathring{H}^1)^3 \times L^2(\Gamma)$. With φ a cut-off function in $\mathbf{R}$, $\varphi \equiv 1$ in the neighborhood of zero, we consider

$$(\vec{v}, q)(y, z) = \varphi(y)\, e^{i\rho y} (\vec{u}, p)(z),$$

for $\rho \geqq 1$ and apply the estimate (6.5) to $(\vec{v}, q)$. Denoting $(\vec{f}, g) = \mathcal{S}_3(\rho, D_z)(\vec{u}, p)$, we have

$$\mathcal{S}_3(\vec{v}, q) = \varphi(y)\, e^{i\rho y} (\vec{f}, g)(z) + e^{i\rho y} (\vec{f}_R, g_R).$$

Let us introduce the $H_0^1(\Gamma, \rho)$-norm on $\mathring{H}^1(\Gamma)$:

$$\|W\|^2_{H_0^1(\Gamma,\rho)} \equiv \rho^2 \|W\|^2_{L^2} + \|r^{-1} W\|^2_{L^2} + \sum_{|\alpha|=1} \|D^\alpha W\|^2_{L^2} \tag{6.7}$$

and $H_0^{-1}(\Gamma, \rho)$ the dual norm. We have the equivalences:

$$\|v_j\|_{H_0^1(\mathbf{R}\times\Gamma)} \approx \|u_j\|_{H_0^1(\Gamma,\rho)} \quad \text{and} \quad \|\varphi\, e^{i\rho y} f_j\|_{H_0^{-1}(\mathbf{R}\times\Gamma)} \approx \|f_j\|_{H_0^{-1}(\Gamma,\rho)}.$$

So the estimate (6.5) implies that

$$\begin{aligned} \sum \|u_j\|_{H_0^1(\Gamma,\rho)} + \|p\|_{L^2(\Gamma)} \leqq C\Big(& \sum \|f_j\|_{H_0^{-1}(\Gamma,\rho)} + \|e^{i\rho y} f_{R,j}\|_{H_0^{-1}(\mathbf{R}\times\Gamma)} \\ & + \|g\|_{L^2(\Gamma)} + \|e^{i\rho y} g_R\|_{L^2(\mathbf{R}\times\Gamma)} \Big). \end{aligned} \tag{6.8}$$

The support of g_R is included in supp φ, and

$$g_R(y, z) = \sum a_j(y) u_j(z), \text{ with } a_j \text{ smooth.}$$

So,

$$\| e^{i\rho y} g_R \|_{L^2(\mathbf{R}\times\Gamma)} \leqq C\rho^{-1} (\sum \| u_j \|_{H^1_0(\Gamma,\rho)} + \| p \|_{L^2(\Gamma)}),$$

and we can prove the same estimate for $\| e^{i\rho y} f_{R,j} \|$ in (6.8). So, for ρ large enough,

$$\sum \| u_j \|_{H^1_0(\Gamma,\rho)} + \| p \|_{L^2(\Gamma)} \leqq 2C (\sum \| f_j \|_{H_0^{-1}(\Gamma,\rho)} + \| g \|_{L^2(\Gamma)}),$$

which is an a priori estimate for $\mathcal{S}_3(\rho; D_z)$. Using a suitable scaling, we get an estimate for $\mathcal{S}_3(1, D_z)$. The proof for $\mathcal{S}_3(-1, D_z)$ is the same, with $e^{-i\rho y}$ instead of $e^{i\rho y}$. □

For $s > 1$, we replace $E^s_3(\Gamma)$ by $F^s_3(\Gamma)$, which is the space of the $(\vec{f}, g) \in E^s_3(\Gamma)$ such that $g(0) = 0$. For $s = 1$, $F^1_3(\Gamma)$ is characterized by $r^{-1} g \in L^2(\Gamma)$. When $\mathcal{S}_3(1, D_z)$-$(\vec{u}, p) = (\vec{f}, g)$, we have

$$\partial_1 u_1 + \partial_2 u_2 + i u_3 = g.$$

Let us suppose that the opening ω of Γ is not 2π. When the u_j belong to $H^{s+1}(\Gamma)$, with $s > 1$, since they are zero on $\partial\Gamma$, $\nabla u_j(0) = 0$; thus $g(0) = 0$. On the other hand, if $s = 1$ and $u_j \in H^2 \cap \mathring{H}^1(\Gamma)$, then $r^{|\alpha|-2} D^\alpha u_j \in L^2(\Gamma)$ for $|\alpha| \leqq 2$ (cf. [9 (AC.6)]; thus $r^{-1} g \in L^2(\Gamma)$.

Therefore $\mathcal{S}_3(\pm 1, D_z)$ operate from $D^s_3(\Gamma)$ to $F^s_3(\Gamma)$. As a consequence of Lemmas 6.6 and 5.1, we get Proposition 6.9.

PROPOSITION 6.9. *Let $s \geqq 1$ be such that $s < \pi/\omega$. Then $\mathcal{S}_3(\pm 1, D_z)$ is an isomorphism from $D^s_3(\Gamma)$ to $F^s_3(\Gamma)$.*

By partial Fourier transform with respect to y the equation $\mathcal{S}_3(D_y, D_z)(u, p) = (f, g)$ becomes

$$\mathcal{S}_3(\pm\rho, D_z)(\hat{u}, \hat{p})(\pm\rho, z) = (\hat{f}, \hat{g})(\pm\rho, z), \qquad \rho \geqq 0.$$

We define $F^s_3(\mathbf{R}\times\Gamma)$ by the condition $g(y, 0) = 0$ if $s > 1$ and $|z|^{-1} g(y, z) \in L^2(\mathbf{R}\times\Gamma)$ if $s = 1$. If $(f, g) \in F^s_3(\mathbf{R}\times\Gamma)$, then for all ρ, $(\hat{f}, \hat{g})(\pm\rho) \in F^s_3(\Gamma)$. By a scaling argument, we deduce from Proposition 6.9 the uniform estimate for $\rho \geqq 1$:

$$\| (\hat{u}, \hat{p})(\pm\rho) \|_{D^s_3(\Gamma,\rho)} \leqq C \| (\hat{f}, \hat{g})(\pm\rho) \|_{F^s_3(\Gamma,\rho)}$$

where $H^s(\Gamma, \rho)$ means the norm $\| \ \|_{H^s} + \rho^s \| \ \|_{L^2}$ which obviously defines $D^s_3(\Gamma, \rho)$ and $F^s_3(\Gamma, \rho)$ when $s \neq 1$; $F^1_3(\Gamma, \rho) = L^2(\Gamma)^3 \times H^1_0(\Gamma, \rho)$ (see (6.7)). We also have an a priori estimate for $\rho \leqq 1$.

So, in the same way as in 9.C of [9], we get the following lemma.

LEMMA 6.10. *$1 \leqq s < \pi/\omega$. $\Gamma_\rho \equiv \Gamma \cap B_\rho$. Then the inverse operator $(\mathcal{S}_3)^{-1}$ of (6.4) induces a continuous operator from $F^s_3(\mathbf{R}\times\Gamma_2)$ to $D^s_3(\mathbf{R}\times\Gamma_1)$.*

Now, if we go back to the operator $\mathcal{S}_3$ on Ω, for each $x \in A_1(\Omega)$, we get an operator equal to $\mathcal{S}_3 + \mathcal{T}$, $\mathcal{T}$ being a perturbation. It is important to note that the fourth equation of $(\mathcal{S}_3 + \mathcal{T})(\vec{u}, p) = (\vec{f}, g)$ has the following form:

$$\sum_{1 \leqq j,k \leqq 3} a_{j,k}(y, z) \partial_j u_k = g \quad \text{with } a_{j,k} \text{ smooth.}$$

Thus, if $(\vec{u}, p) \in D^s_3(\mathbf{R}\times\Gamma)$, then $(\vec{f}, g) \in F^s_3(\mathbf{R}\times\Gamma)$. So, we are able to use Lemma 6.10 along with the perturbation argument and Neumann series of 10.D in [9] in order to get the local regularity result in the neighborhood of each $x \in A_1(\Omega)$.

7. Study of the parametrical operator associated to the Stokes system in three-dimensional domains: Description of areas free of poles.

7.1. First identities. Let Γ be a cone in $\mathbf{R}^3$ and let G be its intersection with the unit sphere S^2.

In § 4.1 we introduced an operator $\mathscr{L}_3(\lambda)$ acting from $D_3^0(G)$ to $E_3^0(G)$. In view of Lemmas 4.2 and 4.3, we wish to find areas in $\mathbf{C}$ where $\mathscr{L}_3(\lambda)$ is everywhere invertible. As the index of $\mathscr{L}_3(\lambda)$ is zero, it is equivalent to find where $\mathscr{L}_3(\lambda)$ is injective. But, from the definition of $\mathscr{L}_3(\lambda)$ we deduce that

$$\mathscr{L}_3(\lambda)(\mathbf{u}, p) = 0 \Leftrightarrow \mathscr{S}_3(r^\lambda \mathbf{u}, r^{\lambda-1} p) = 0.$$

For $\operatorname{Re}\lambda = -\frac{1}{2}$, $\mathscr{L}_3(\lambda)$ is always injective; it is a consequence of Theorem 3.3 for $s = 0$ (see also [16]). On the other hand, according to condition (3.7), we are interested in the strip $\operatorname{Re}\lambda \in [-\frac{1}{2}, s - \frac{1}{2}]$. Thus, we suppose the following:

$$\operatorname{Re}\lambda > -\tfrac{1}{2}, \tag{7.1}$$

$$(\mathbf{u}, p) \in (\mathring{H}^1(G))^3 \times L^2(G), \qquad (\mathbf{u}, p) \neq 0, \tag{7.2}$$

$$-\Delta(r^\lambda \mathbf{u}) + \nabla(r^{\lambda-1} p) = 0, \tag{7.3}$$

$$\operatorname{div}(r^\lambda \mathbf{u}) = 0. \tag{7.4}$$

We denote

$\xi = \operatorname{Re}\lambda$, $\eta = \operatorname{Im}\lambda$;

z the cartesian coordinates in $\mathbf{R}^3$; $\Psi = z/|z|$;

$\mathbf{u}_r = \langle \vec{\mathbf{u}}, \vec{\Psi} \rangle$, the radial component of $\mathbf{u}$;

δ the positive Laplace-Beltrami operator on $\mathring{H}^1(G)$;

∇_s the spherical part of the gradient.

If C is $\Gamma \cap \{1 < r < 2\}$, we get by integrating (7.3) with $r^{\bar\lambda}\bar{\mathbf{u}}$ and (7.4) with $r^{\bar\lambda - 1}\bar p$:

$$\int_C \langle -\Delta(r^\lambda \mathbf{u}) + \nabla(r^{\lambda-1} p), r^{\bar\lambda}\bar{\mathbf{u}} \rangle + \operatorname{div} r^\lambda \mathbf{u} \cdot r^{\bar\lambda - 1}\bar p = 0.$$

As in [16], it implies by integration by parts:

$$\int_G |\nabla_s \mathbf{u}|^2 - \lambda(\lambda+1)|\mathbf{u}|^2 + (2\xi + 1)\int_G p\bar{\mathbf{u}}_r = 0. \tag{7.5}$$

And, again as in [16], we deduce from

$$\langle -\Delta(r^\lambda \mathbf{u}) + \nabla(r^{\lambda-1} p), z \rangle = 0$$

and from (7.4) that

$$\delta \mathbf{u}_r - (\lambda+1)(\lambda+2)\mathbf{u}_r + (\lambda - 1)p = 0. \tag{7.6}$$

By integrating (7.6) on G with $\bar{\mathbf{u}}_r$, we get

$$\int_G |\nabla_s \mathbf{u}_r|^2 - (\lambda+1)(\lambda+2)|\mathbf{u}_r|^2 + (\lambda - 1)p\bar{\mathbf{u}}_r = 0. \tag{7.7}$$

And from (7.4), which implies

$$\int_C \operatorname{div}(r^\lambda \mathbf{u}) = 0,$$

we get

$$(\lambda + 2)\int_G \mathbf{u}_r = 0. \tag{7.8}$$

7.2. The case when λ is not real.

LEMMA 7.9. *Let us assume that we have* (7.1)-(7.4) *and moreover that* $\eta \neq 0$. *Then*

$$\xi \geqq \frac{1}{\sqrt{3}}(\Lambda_1 + 1 + \eta^2)^{1/2}$$

where Λ_1 *is the first eigenvalue of* δ.

Proof. We take the imaginary part of (7.5) and divide it by $(2\xi+1)$ and obtain

$$\text{Im} \int_G p\bar{\mathbf{u}}_r = \eta \int_G |\mathbf{u}|^2. \tag{7.10}$$

We take the imaginary part of (7.7) and use (7.10); after we divide that by η we obtain

$$-(2\xi+3)\int_G |\mathbf{u}_r|^2 + (\xi-1)|\mathbf{u}|^2 + \text{Re}\int_G p\bar{\mathbf{u}}_r = 0. \tag{7.11}$$

We take the real part of (7.5) and eliminate $\text{Re}\int_G p\bar{\mathbf{u}}_r$ by using (7.11). Then we obtain

$$\int_G |\nabla_s \mathbf{u}|^2 + [\eta^2 - \xi(\xi+1) - (2\xi+1)(\xi-1)]|\mathbf{u}|^2 + (2\xi+1)(2\xi+3)\int_G |\mathbf{u}_r|^2 = 0.$$

Since $(2\xi+1)(2\xi+3) > 0$, it implies

$$\int_G |\nabla_s \mathbf{u}|^2 \leqq (3\xi^2 - 1 - \eta^2)\int_G |\mathbf{u}|^2. \tag{7.12}$$

If $\mathbf{u}$ were zero, then (7.3) would yield

$$\nabla(r^{\lambda-1}p) = 0.$$

Thus $r^{\lambda-1}p$ would be constant, which implies, as $\lambda \neq 1$, that p would be zero. Therefore, if we have (7.2), then $\mathbf{u} \neq 0$. So we have

$$\int_G |\nabla_s \mathbf{u}|^2 \geqq \Lambda_1 \int_G |\mathbf{u}|^2 \tag{7.13}$$

and, with (7.12) it implies that

$$3\xi^2 - 1 - \eta^2 \geqq \Lambda_1,$$

i.e.,

$$\xi \geqq \frac{1}{\sqrt{3}}(\Lambda_1 + 1 + \eta^2)^{1/2}.$$

As $\xi > -\frac{1}{2}$, it is equivalent to

$$\xi > \frac{1}{\sqrt{3}}(\Lambda_1 + 1 + \eta^2)^{1/2}. \qquad \square$$

7.3. The case when λ is real: $-\frac{1}{2} < \lambda < 1$. As $\lambda \neq 1$, we determine $\int_G p\bar{\mathbf{u}}_r$ by using (7.7), and putting that into (7.3), we get

$$\int_G |\nabla_s \mathbf{u}|^2 - \lambda(\lambda+1)|\mathbf{u}|^2 = \frac{2\lambda+1}{\lambda-1}\int_G |\nabla_s \mathbf{u}_r|^2 - (\lambda+1)(\lambda+2)|\mathbf{u}_r|^2. \tag{7.14}$$

But, with (7.13), we have

$$\begin{aligned} \int_G |\nabla_s \mathbf{u}|^2 - \lambda(\lambda+1)|\mathbf{u}|^2 &\geqq [\Lambda_1 - \lambda(\lambda+1)]\int_G |\mathbf{u}|^2 \\ &\geqq [\Lambda_1 - \lambda(\lambda+1)]\int_G |\mathbf{u}_r|^2 \end{aligned} \tag{7.15}$$

whenever

$$\Lambda_1 \geqq \lambda(\lambda+1). \tag{7.16}$$

So, with (7.15), (7.14) yields

$$\frac{2\lambda+1}{\lambda-1}\int_G |\nabla_s \mathbf{u}_r|^2 - (\lambda+1)(\lambda+2)|\mathbf{u}_r|^2 \geqq [\Lambda_1 - \lambda(\lambda+1)]\int_G |\mathbf{u}_r|^2.$$

As $\lambda-1$ is negative, this may be written in the form

$$\int_G |\nabla_s \mathbf{u}_r|^2 \leqq \phi(\lambda)\int_G |\mathbf{u}_r|^2 \tag{7.17}$$

with

$$\phi(\lambda) = (\lambda+1)(\lambda+2) - [\Lambda_1 - \lambda(\lambda+1)]\frac{1-\lambda}{2\lambda+1}. \tag{7.18}$$

Just as in [16], we introduce Definition 7.19.

DEFINITION 7.19. *Let Λ' be the minimum of $\int_G |\nabla_s v|^2$ when $v \in \mathring{H}^1(G)$, $\|v\|_{L^2(G)} = 1$ and $\int_G v = 0$.*

Formulae (7.17) and (7.8) imply that if $\phi(\lambda) < \Lambda'$, then $\mathbf{u}_r = 0$. With (7.16), this implies that $\mathbf{u} = 0$ and $p = 0$ since $\lambda \neq 1$. Therefore, we get the following lemma.

LEMMA 7.20. *Let us suppose that we have* (7.1)-(7.4) *and moreover that λ is real and smaller than one. Then, with* (7.18) *and Definition* 7.19, *we have*

$$\lambda(\lambda+1) > \Lambda_1 \quad \textit{or} \quad \phi(\lambda) \geqq \Lambda'.$$

This statement is close to what is proved in [16].

7.4. The case when $\lambda = 1$. Equations (7.6) and (7.8), respectively, give

$$\delta \mathbf{u}_r - 6\mathbf{u}_r = 0, \tag{7.21}$$

$$\int_G \mathbf{u}_r = 0. \tag{7.22}$$

Then if $\mathbf{u}_r$ is nonzero, six is an eigenvalue of δ. But since the first eigenfunction has a constant sign (cf. [4] and (19.B) in [9]), six cannot be equal to Λ_1. Therefore, if $6 < \Lambda_2$ (the second eigenvalue of δ), then $\mathbf{u}_r = 0$. So (7.5) implies that

$$\int_G |\nabla_s \mathbf{u}|^2 - 2|\mathbf{u}|^2 = 0.$$

If $2 < \Lambda_1$, then $\mathbf{u} = 0$ and p is a constant. We have just proved Lemma 7.23.

LEMMA 7.23. *Let us suppose that $\lambda = 1$ and that*

$$\Lambda_1 > 2 \quad \textit{and} \quad \Lambda_2 > 6.$$

Then the solutions of (7.2)-(7.4) *are proportional to* $(\vec{0}, 1)$.

Now, we are going to prove Lemma 7.24.

LEMMA 7.24. *If $\Lambda_1 \geqq 6$, then the pole of $\mathscr{L}_3(\lambda)^{-1}$ in $\lambda = 1$ has the order one.*

Proof. Because no confusion is possible, we drop the index 3 in $\mathscr{L}_3(\lambda)$.

Since $\mathscr{L}(1)$ is not injective, $\mathscr{L}^{-1}(\lambda)$ has a pole in $\lambda = 1$. Let us write the Laurent expansion of $\mathscr{L}^{-1}(\lambda)$ in the neighborhood of $\lambda = 1$, and the power series of $\mathscr{L}(\lambda)$:

$$\mathscr{L}(\lambda)^{-1} = \sum_{j \geqq -J} (\lambda-1)^j A_j$$

where J is the order of the pole

$$\mathscr{L}(\lambda) = \sum_{j \geqq 0} (\lambda - 1)^j \mathscr{L}^{(j)}(1)/j!$$

where $\mathscr{L}^{(j)}(\lambda)$ is the jth derivative of $\mathscr{L}$ with respect to λ. As $\mathscr{L}(\lambda)\mathscr{L}^{-1}(\lambda) = I$, we get the relation

$$\mathscr{L}(1)A_{-J} = 0, \tag{7.25}$$

and, only if $J \geqq 2$,

$$\mathscr{L}^{(1)}(1)A_{-J} + \mathscr{L}(1)A_{-J+1} = 0. \tag{7.26}$$

Thus, (7.25) implies that $A_{-J} = \Phi \cdot (0, 1)$ where Φ is a linear form, and using (7.26) we get that if

$$\mathscr{L}^{(1)}(1)(0, 1) \notin \mathscr{L}(1)D^0(G), \tag{7.27}$$

then $J = 1$. On the other hand

$$\mathscr{L}^{(1)}(1)(0, 1) = (\vec{\Psi}, 0), \tag{7.28}$$

and

$$\mathscr{L}(1)D^0(G) = (\ker \mathscr{L}(1)^*)^{\perp}. \tag{7.29}$$

But, according to [16], we have

$$\mathscr{L}(1)^*(\mathbf{u}, p) = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \mathscr{L}(-2)(\mathbf{u}, -p). \tag{7.30}$$

So we search the kernel of $\mathscr{L}(-2)$, which is one-dimensional just like the kernel of $\mathscr{L}(1)$. We may suppose that a basis of ker $\mathscr{L}(-2)$ has the radial form $(\mathbf{u}, p) = (v\vec{\Psi}, p)$. According to (7.6), we have

$$p = \tfrac{1}{3}\delta v. \tag{7.31}$$

We also have

$$\begin{aligned} \operatorname{div}(r^{-2}v\vec{\Psi}) &= \langle \vec{\nabla}, r^{-3}v\vec{z} \rangle \\ &= r^{-3}v\langle \vec{\nabla}, \vec{z} \rangle + \langle \vec{z}, \vec{\nabla} \rangle (r^{-3}v) \\ &= 3r^{-3}v + (r\partial_r)(r^{-3}v) = 0. \end{aligned}$$

As a consequence, relation (7.4) is satisfied for any v (see also (7.8)). To take into account relation (7.3), we notice that

$$\begin{aligned} &\Delta(r^{-3}z_j v) = z_j \Delta(r^{-3}v) + 2\partial_j(r^{-3}v), \\ &-\Delta(r^3 v) = r^{-5}(\delta v - 6v), \\ &\partial_j(r^{-3}v) = -3z_j r^{-5}v + r^{-3}\partial_j v. \end{aligned}$$

So (7.3), which may be written as

$$-\Delta(r^{-3}z_j v) + \tfrac{1}{3}\partial_j(r^{-3}\delta v) = 0, \qquad j = 1, 2, 3,$$

is equivalent to

$$\partial_j(\delta v - 6v) = 0, \qquad j = 1, 2, 3.$$

We have just proved Lemma 7.32. □

LEMMA 7.32. *A basis of* $\ker \mathscr{L}(-2)$ *is given by* $(v\vec{\Psi}, p)$, *where* $p = \delta v/3$ *and*

(i) *If six is an eigenvalue of* δ: v *is an eigenfunction of* δ *associated with six*;

(ii) *If not,* v *is the unique solution of* $\delta v - 6v = 1$.

End of the proof of Lemma 7.4. Using (7.28)-(7.30), we may rewrite condition (7.27):

$$\int_G \langle \vec{\Psi}, v\vec{\Psi} \rangle \neq 0,$$

i.e.,

$$\int_G v \neq 0. \tag{7.33}$$

If $\Lambda_1 = 6$, v has a constant sign and (7.33) is fulfilled. If $\Lambda_1 \neq 6$, according to the assumptions of Lemma 7.24, $\Lambda_1 > 6$. Let (Λ_k, v_k) be the eigenvalues and eigenfunctions sequence of δ. Using Lemma 7.32, we have

$$v = \sum_k c_k v_k \quad \text{with } c_k = (\Lambda_k - 6)^{-1} \int_G v_k.$$

So

$$\int_G v = \sum_k (\Lambda_k - 6)^{-1} \left(\int_G v_k \right)^2,$$

which is positive since $\Lambda_1 > 6$. Thus (7.33) is true. □

8. Study of the minimum value Λ'.

8.1. Minoration of $\Lambda'(G)$. We study the minimum $\Lambda'(G)$ of $\int_G |\nabla_s v|^2$ when $v \in \mathring{H}^1(G)$, $\|v\|_{L^2(G)} = 1$ and $\int_G v = 0$ (cf. Definition 7.19) occurring in Lemma 7.20. As the extension by zero preserves the above conditions of v, we get (as in [16]):

$$\text{if } G_1 \subset G_2, \text{ then } \Lambda'(G_1) \geqq \Lambda'(G_2). \tag{8.1}$$

The minimum $\Lambda'(G)$ is reached for some function v. We recall that (Λ_k, v_k) is the eigenvalues and eigenfunctions sequence of the Laplace-Beltrami operator δ on $\mathring{H}^1(G)$. We denote

$$\gamma_k = \gamma \int_G v_k \, d\Psi \quad \text{where } \gamma = \left(\int_G d\Psi \right)^{-1/2}$$

(we suppose that $\|v_k\|_{L^2(G)} = 1$). We have

$$v = \sum_k c_k v_k \quad \text{with } \sum c_k^2 = 1, \tag{8.2}$$

$$\sum_k c_k \gamma_k = 0, \tag{8.3}$$

$$\Lambda'(G) = \sum_k \Lambda_k c_k^2. \tag{8.4}$$

If $G = S^2$, as $\gamma_1 = 1$ and the other γ_k are zero, it is obvious that (cf. [16])

$$\Lambda'(S^2) = \Lambda_2 = 2. \tag{8.5}$$

So, by (8.1) and (8.5), we get

$$\Lambda'(G) \geqq 2. \tag{8.6}$$

We will obtain further information about $\Lambda'(G)$.

LEMMA 8.7. *Let K be $(\int_G v_1\, d\Psi)^2(\int_G d\Psi)^{-1}$. Then*

$$\Lambda'(G) \geqq (1-K)\Lambda_1(G) + K\Lambda_2(G).$$

Proof. Using (8.3), we get

$$c_1^2\gamma_1^2 \leqq \left(\sum_{k\geqq 2} c_k^2\right)\left(\sum_{k\geqq 2}\gamma_k^2\right) = (1-c_1^2)(1-\gamma_1^2).$$

So, we have

$$c_1^2 \leqq 1-\gamma_1^2. \tag{8.8}$$

Equation (8.4) implies that

$$\Lambda'(G) \geqq \Lambda_1 c_1^2 + \Lambda_2(1-c_1^2).$$

Using (8.8), we get

$$\Lambda'(G) \geqq \Lambda_1(1-\gamma_1^2) + \Lambda_2\gamma_1^2.$$

And as K is exactly γ_1^2, we get the lemma. □

Now, if $\gamma_2 = 0$, instead of (8.8) we get

$$c_1^2 \leqq (1-\gamma_1^2)(1-c_2^2).$$

And, with (8.4), we have

$$\Lambda'(G) \geqq \Lambda_1 c_1^2 + \Lambda_2 c_2^2 + \Lambda_3(1-c_1^2-c_2^2).$$

Thus

$$\Lambda'(G) \geqq [(1-\gamma_1^2)\Lambda_1 + \gamma_1^2\Lambda_3](1-c_2^2) + \Lambda_2 c_2^2. \tag{8.9}$$

And, it is easy to show that, if moreover $\gamma_3, \cdots, \gamma_{N-1} = 0$, Λ_3 may be replaced by Λ_N in (8.9). So we get Lemma 8.10.

LEMMA 8.10. *If $\gamma_2, \cdots, \gamma_{N-1} = 0$, then*

$$\Lambda'(G) \geqq \min\{[(1-K)\Lambda_1 + K\Lambda_N], \Lambda_2\}.$$

8.2. The exact value of Λ' in some special cases. For $\omega \in]0, 2\pi]$ and (θ, φ) the spherical coordinates in $[0, \pi]\times[0, 2\pi[$, we denote by G_ω:

$$G_\omega = \{\Psi \in S^2 / \theta \in]0, \pi[, \varphi \in]0, \omega[\}.$$

The associated cone Γ_ω is a dihedron with interior angle ω. Since v_1 is proportional to $\sin(\pi/\omega)\varphi$, it is easy to compute the following:

$$K(G_\omega) = 8/\pi^2 \approx 0.81057. \tag{8.11}$$

The main result is Proposition 8.12.

PROPOSITION 8.12. $\Lambda'(G_\omega) = \Lambda_2(G_\omega)$.

Proof. We denote π/ω by ν. As a consequence of (18.6′) in [9] we obtain

$$\Lambda_k = \mu_k(\mu_k + 1),$$

(μ_k) being the increasing sequence of positive numbers

$$l\nu + d \quad \text{with } l \in \mathbf{N}^* \text{ and } d \in \mathbf{N}.$$

(The multiplicity of μ is given by the number of couples (l, d) providing μ.)

From (18.9) in [9], we derive that an eigenfunction associated with $\mu_k(\mu_k+1)$ with $\mu_k = l\nu + d$ has the following form:

$$v_k = \sum_{0 \leqq 2p \leqq d} \alpha_p \cos^{d-2p}\theta \cdot \sin l\nu\varphi$$

where the α_p are some constants.

As a consequence

(8.13) if $\mu_k = \nu+1$, $v_k = \alpha \cos\theta \sin\nu\varphi$ and $\gamma_k = 0$,

(8.14) if $\mu_k = 2\nu$, $v_k = \alpha \sin 2\nu\varphi$ and $\gamma_k = 0$.

(a) If $\nu \in [\frac{1}{2}, 1]$: $\mu_1 = \nu$, $\mu_2 = 2\nu$, $\mu_3 = \nu+1$, $\mu_4 = 3\nu$.
So γ_2 and γ_3 are zero; and according to (8.10) it is sufficient to prove that

$$(1-K)\nu(\nu+1)+3K\nu(3\nu+1) \geqq 2\nu(2\nu+1).$$

With (8.11), this is easy to check.

(b) If $\nu \in [1, 2]$: $\mu_1 = \nu$, $\mu_2 = \nu+1$, $\mu_3 = 2\nu$, $\mu_4 = \nu+2$.
So γ_2 and γ_3 are zero again. And we can prove that

$$(1-K)\nu(\nu+1)+K(\nu+2)(\nu+3) \geqq (\nu+1)(\nu+2). \tag{8.15}$$

Using Lemma 8.10 we get Proposition 8.12.

(c) If $\nu \geqq 2$: $\mu_1 = \nu$, $\mu_2 = \nu+1$, $\mu_3 = \nu+2$. $\gamma_2 = 0$ and as in case (b), (8.15) is true and implies Proposition 8.12 by using Lemma 8.10. □

COROLLARY 8.16. *If* $\omega \in [\pi, 2\pi]$, $\Lambda'(G_\omega) = (2\pi/\omega)(1+2\pi/\omega)$.

9. Precise regularity results in three-dimensional domains.

9.1. Strips free of poles. Let Ω be a domain in $\mathcal{O}_3(\mathbf{R}^3)$. If Ω has no vertex, it has been studied in § 6 (Theorem 6.3). If not, for each vertex x of Ω, we must check condition (3.7).

Let us assume that

$$s < \tfrac{3}{2}. \tag{9.1}$$

So, using Lemma 4.2, we have that (3.7) is equivalent to

$$\forall\lambda,\ \mathrm{Re}\,\lambda \in [-\tfrac{1}{2}, s-\tfrac{1}{2}],\ \mathscr{L}_3(\lambda) \text{ is invertible on } D^0_3(G_x). \tag{9.2}$$

We are going to determine $s(G_x)$ so that (9.2) is true for $s = s(G_x)$.

We denote

$$\xi_0 = s(G_x) - \tfrac{1}{2}.$$

As a consequence of Lemmas 7.9 and 7.20, if we have the three following conditions, for a $\xi \in]-\frac{1}{2}, 1[$:

$$\xi(\xi+1)+(2\xi+1)(\xi-1) < \Lambda_1(G), \tag{9.3}$$

$$\xi(\xi+1) < \Lambda_1(G), \tag{9.4}$$

$$\phi(\xi) < \Lambda'(G), \tag{9.5}$$

then

$$\forall\lambda,\ \mathrm{Re}\,\lambda = \xi,\ \mathscr{L}_3(\lambda) \text{ is invertible on } D^0_3(G). \tag{9.6}$$

Condition (9.4) implies (9.3), and (9.5) may be written as

$$(\xi+1)(\xi^2+6\xi+2) < (2\xi+1)\Lambda' + (1-\xi)\Lambda_1. \tag{9.7}$$

Using (8.6), $\Lambda' \geqq 2$ and $\Lambda_1 > 0$, we obtain (9.7) if

$$(\xi+1)(\xi^2+6\xi+2) \leqq 2(2\xi+1).$$

It is easy to check that for all $\xi \in [-\frac{1}{2}, 0]$.

So

$$\xi_0 \geqq 0, \quad \text{i.e.} \quad s(G) \geqq \tfrac{1}{2}. \tag{9.8}$$

For $\xi > 0$, we may use one of the following three conditions, each implying (9.7):

$$(\xi+1)(\xi^2+6\xi+2) < 2(2\xi+1)+(1-\xi)\Lambda_1, \tag{9.9}$$

$$(\xi+1)(\xi^2+6\xi+2) \leqq (2\xi+1)\Lambda', \tag{9.10}$$

$$(\xi+1)(\xi^2+6\xi+2) \leqq (\xi+1)\Lambda'+\Lambda_1 \tag{9.11}$$

(since $\Lambda' > \Lambda_1$). Each of these conditions has the form

$$\psi(\xi) \leqq 0,$$

ψ being a strictly convex function on $[-7/3, +\infty[$. To have $\psi(\xi) \leqq 0$ on $\xi \in [0, \xi_0]$, it is enough to check that

$$\psi(0) \leqq 0 \quad \text{and} \quad \psi(\xi_0) \leqq 0.$$

Using (9.9), we find Proposition 9.12, as in [16].

PROPOSITION 9.12. *$s(G)$ may be taken as $\frac{1}{2}+\mu/(\mu+4)$, where $\mu > 0$ is such that $\mu(\mu+1) = \Lambda_1(G)$.*

Now, if we consider condition (9.11) with $\Lambda' \geqq 2$, we get

$$(\xi+1)(\xi^2+6\xi) \leqq \Lambda_1,$$

and it is easy to prove the following proposition.

PROPOSITION 9.13. *If $\Lambda_1(G) \leqq 2$, $s(G)$ may be taken to be $\frac{1}{2}\,\Lambda_1(G)/8$.*

It is better than Proposition 9.12 if $\Lambda_1 \geqq 1.20$.

We notice that the right-hand side of (9.11) increases when the domain G decreases. So, we may determine ξ such that (9.11) is satisfied for G_ω (cf. 8.3), and then we are sure that (9.11) is also satisfied for all $G \subset G_\omega$. It is not difficult to check Proposition 9.14.

PROPOSITION 9.14. *If $G \subset G_\omega$ with $\omega \in]\pi, 2\pi]$, $s(G)$ may be taken as $6\pi/5\omega$.*

Here, we use Corollary 8.16:

$$\Lambda'(G_\omega) = 2\nu(\nu+1) \quad \text{and} \quad \Lambda_1(G_\omega) = \nu(\nu+1), \quad \text{with} \quad \nu = \pi/\omega.$$

In the important case when $\omega = \pi$, we have

$$\Lambda'(G_\pi) = 6$$

and we immediately see that (9.10) is true for all $\xi \leqq 1$. Therefore, we have (9.5) for $\xi < 1$ and as $\Lambda_1 = 2$, we have (9.4) also. Thus we have Proposition 9.15.

PROPOSITION 9.15. *If $G \subset G_\pi$, then we may take $s(G) = \frac{3}{2} - \varepsilon$, for all $\varepsilon > 0$.*

Finally, for $G_{\pi/2}$, $\Lambda_1 = 6$ and according to Lemma 7.24 we get Proposition 9.16.

PROPOSITION 9.16. *If $G \subset G_{\pi/2}$, $\mathscr{L}_3(\lambda)^{-1}$ has only one pole in the strip* $\operatorname{Re}\lambda \in [-\frac{1}{2}, 1]$. *That pole is $\lambda = 1$, it is simple, and* $\operatorname{Ker}\mathscr{L}(1)$ *is generated by* $(\vec{0}, 1)$. *Here let $s(G)$ be 3/2.*

9.2. Regularity results. Just as in Theorem 6.3, we make various assumptions concerning the behavior of g at the singular points of Ω, according to the value of s.

DEFINITION 9.17. Let g be in $H^{s-1}(\Omega)$ for $s \geqq 1$. g is said to be *zero at the singular points of* Ω

(i) When $s=1$: $\rho_1^{-1} g \in L^2(\Omega)$ with $\rho_1(x)$ the distance of x from $A_1(\Omega)$, the edges of Ω;

(ii) When $1<s<\frac{3}{2}$: $g=0$ on $A_1(\Omega)$;

(iii) When $s=\frac{3}{2}$: $g=0$ on $A_1(\Omega)$ and $\rho_0^{-3/2} g \in L^2(\Omega)$ where ρ_0 is the distance from $A_0(\Omega)$, the vertices of Ω;

(iv) When $s>\frac{3}{2}$: $g=0$ on $A_1(\Omega) \cup A_0(\Omega)$.

Remarks 9.18.

(1) If $g \in H^{s-1} \cap \mathring{H}^1(\Omega)$, then it is zero at the singular points of Ω.

(2) If each vertex x is in the closure of an edge, then the conditions concerning $A_0(\Omega)$ are implied by conditions concerning $A_1(\Omega)$; such is the case when Ω is a polyhedron.

This may be proved as is (AC.3) in [9].

DEFINITION 9.19. For each vertex $x \in A_0(\Omega)$, we denote by s_x the best value of $s(G_x)$ drawn from Propositions 9.12-9.16.

THEOREM 9.20. *Let* $\Omega \in \mathcal{O}_3(\mathbf{R}^3)$. *Let* $(\vec{u}, p) \in D_3^0(\Omega)$ *be the solution of* (1.1) *with* $(\vec{f}, g) \in E_3^s(\Omega)$.

(a) *If* $s<1$, $s \leqq \min_{x \in A_0(\Omega)} s_x$ *and* $s < \inf_{x \in A_1(\Omega)} \xi_1(\omega_x)$, *then* $(\vec{u}, p) \in D_3^s(\Omega)$.

(b) *If* $s \geqq 1$, $s \leqq \min_{x \in A_0(\Omega)} s_x$, $s < \inf_{x \in A_1(\Omega)} \pi/\omega_x$ *and moreover* g *is zero at the singular points of* Ω, *then* $(\vec{u}, p) \in D_3^s(\Omega)$.

For $s<1$, it is a straightforward consequence of Theorem 3.6, as in the case of Theorem 6.3.

For $s \geqq 1$, in view of Theorems 3.6 and 6.3, and the methods of proofs of [9], it is enough to note that the Mellin transform $(\vec{F}(\lambda), G(\lambda))$ of $(r^2 \vec{f}, rg)$, after localization in the neighborhood of any vertex, is defined up to $\operatorname{Re} \lambda \leqq s - \frac{1}{2}$, with values in $F_3^s(G_x)$.

Now, we derive from Theorem 9.20 the statements (1.6)-(1.12).

Since $s_x > \frac{1}{2}$ and $\xi_1(\omega_x) \geqq \frac{1}{2}$, (1.6) is a straightforward consequence of Theorem 9.20a.

In situation (1.7), the openings of the edges are $\pi/2$ or $3\pi/2$. $\xi_1(3\pi/2) > 0.544$, so $0.544 < \inf_{x \in A_1(\Omega)} \xi_1(\omega_x)$. If x is a vertex of Ω, then the associated cone Γ_x is an octant or the complementary of an octant. In the first case, Proposition 9.16 yields $s(G_x) = \frac{3}{2}$. In the last case, we note that Γ_x is included in the revolution cone

$$\Gamma = \{z \in \mathbf{R}^3 / \theta \in [0, \theta_0[\}$$

with $\theta_0 = \pi - \theta_1$, $\theta_1 = \arcsin(1/\sqrt{3})$; so $\theta_0 \approx 144.74°$. As a consequence of 18.D in [9], we find that $\Lambda_1(G_x) = \mu(\mu+1)$ with $\mu > 0.35$. By Proposition 9.12 we get

$$s(G_x) > \frac{1}{2} + \frac{0.35}{4.35} \approx 0.580 > 0.544.$$

When Ω is convex, we have $\pi/\omega_x > 1$ for any $x \in A_1(\Omega)$, and by Proposition 9.15 $s_x > 1$. Thus, we get (1.8).

If, for each $x \in A_1(\Omega)$, $\pi/\omega_x \geqq \frac{3}{2}$, as by Proposition 9.15 we have $s_x \geqq \frac{3}{2} - \varepsilon$, then for all $\varepsilon > 0$, we get (1.9).

In the situation (1.10), $\min_{x \in A_1(\Omega)} \pi/\omega_x > \frac{3}{2}$ and, for each vertex x, owing to Proposition 9.16, we have $s_x = \frac{3}{2}$.

In the situations (1.11) or (1.12), we have: $\min_{x \in A_1(\Omega)} \pi/\omega_x = 2$ and there is no vertex.

Appendix. Behavior of $\mathcal{L}_2(\lambda)^{-1}$ in the neighborhood of positive integer numbers, on the domain $]0, 2\pi[$ (the model for a crack). Given suitable changes of functions (see [11] and [5]), the problem

$$\mathcal{L}_2(\lambda)(u_1, u_2, p) = (f_1, f_2, g) \text{ with } u_1, u_2 \in \mathring{H}^1(]0, 2\pi[)$$

is equivalent to the other:

$$\text{(A1)} \qquad \begin{cases} u'' + (\lambda+1)^2 u + (1-\lambda) q = l_1, \\ (\lambda-1)u' + (1-\lambda^2)v + q' = l_2, \\ (1+\lambda)u + v' = l_3, \end{cases}$$

$$\text{(A2)} \qquad u, v \in \mathring{H}^1(]0, 2\pi[).$$

As in the above references, it can be proved that (A1) is holomorphically solvable. To solve (A1)-(A2), it remains to solve (A1) with $l_j = 0$, and for any $(c_1, c_2, c_3, c_4) \in \mathbf{C}^4$

$$\text{(A3)} \qquad \begin{aligned} v(0) &= \gamma_1, \qquad v(2\pi) = \gamma_2, \\ u(0) &= \gamma_3, \qquad u(2\pi) = \gamma_4. \end{aligned}$$

Problem (A1) with the zero right-hand side is equivalent to (A4)-(A6):

$$\text{(A4)} \qquad u = -v'(1+\lambda)^{-1},$$

$$\text{(A5)} \qquad q = (v^{(3)} + (1+\lambda)^2 v')(1-\lambda^2)^{-1},$$

$$\text{(A6)} \qquad v^{(4)} + 2(1+\lambda^2)v^{(2)} + (1-\lambda^2)^2 v = 0.$$

For $\operatorname{Re}\lambda > 0$, a basis of solutions of (A6) is given by

$$v_1 = \sin(\lambda+1)\theta, \quad v_2 = \frac{\sin(\lambda-1)\theta}{\lambda-1}, \quad v_3 = \cos(\lambda+1)\theta, \quad v_4 = \cos(\lambda-1)\theta.$$

Let $M(\lambda)$ be the four $\times$ four matrix, the columns of which are

$${}^t[v_j(0), v_j(2\pi), -v_j'(0)(1+\lambda)^{-1}, -v_j'(2\pi)(1+\lambda)^{-1}].$$

The solvability of (A3), (A4), and (A6) is equivalent to finding $\alpha = {}^t(\alpha_1, \cdots, \alpha_4)$ such that

$$\text{(A7)} \qquad M(\lambda)\alpha = \gamma$$

where $\gamma = {}^t(\gamma_1, \cdots, \gamma_4)$. Then the solution of (A3), (A4), and (A6) is

$$\text{(A8)} \qquad v = \sum \alpha_j v_j \quad \text{and} \quad u = -v'(\lambda+1)^{-1}.$$

The determinant of $M(\lambda)$ is

$$4\sin^2 2\pi\lambda(\lambda-1)^{-1}(\lambda+1)^{-2}.$$

So, in $\lambda = 1$, $M(\lambda)^{-1}$ has a simple pole. On the other hand, when λ is an integer number and $\lambda \geqq 2$, it is easy to see that the first and the third rows (respectively, the second and the fourth) are equal; then the cofactors of $M(\lambda)$ are zero and the pole is simple again.

It is obvious that, for integer λ

$$\text{(A9)} \qquad \dim \operatorname{Ker} M(1) = 1 \quad \text{and} \quad \dim \operatorname{Ker} M(\lambda) = 2 \quad \text{when } \lambda \geqq 2.$$

To deduce the properties of $\mathscr{L}_2(\lambda)^{-1}$, we must take (A5) into account. For $\lambda \geqq 2$, it is holomorphic. It remains to study the case when $\lambda = 1$.

For $v = v_1$, or $v = v_3$, (A5) yields $q = 0$.

For $v = v_4$, (A5) yields $q = ((\lambda+1)^2 - (\lambda-1)^2) \sin(\lambda-1)\theta/(\lambda+1)$.

For $\lambda = 1$, it is zero again.

For $v = v_2$, (A5) yields $q_2 = ((\lambda+1)^2 - (\lambda-1)^2) \cos(\lambda-1)\theta/(1-\lambda^2)$.

With (A8), we have $q = \alpha_2 q_2$.

As q_2 has a simple pole in $\lambda = 1$, it remains to state that α_2 is holomorphic. That arises from the structure of $M(\lambda)$: the matrix $M_2(\lambda)$ obtained by removing the second column of $M(\lambda)$ has its rank equal to two, and the corresponding cofactors balance the determinant of $M(\lambda)$.

So, for any $\lambda \in \mathbf{N}$, $\lambda \geqq 1$, $\mathscr{L}(\lambda)^{-1}$ has a simple pole, and with (A9), it is clear that

$$\dim \operatorname{Ker} \mathscr{L}_2(\lambda) = d(\lambda).$$

With Lemma 4.5, we get that $\mathscr{S}_2$ is injective modulo polynomial on $S^\lambda(\mathbf{R}^2 \backslash \mathbf{R}^+)$.

CAUCHY FORMULAE FOR FUNCTIONS ANALYTIC OF ORDER TWO ON C^1 DOMAINS WITH APPLICATIONS TO ELASTOSTATICS AND HYDROSTATICS*

JONATHAN COHEN†

Abstract. This paper gives Cauchy-type formulae for functions analytic of order two on C^1 domains obtained from the solutions of corresponding biharmonic problems. Functions analytic of order two are shown to be potentials for the solutions of systems of linear partial differential equations in two-dimensional elastostatics and hydrostatics. When combined with Cauchy formulae, integral representations are obtained for the traction problem and the linearized Stokes problem that are valid even for C^1 domains.

Key words. Cauchy formulae, analytic of order two, traction problem, stationary Stokes problem, biharmonic equation, layer potentials

AMS(MOS) subject classifications. 30, 35, 42, 45, 73, 76

1. Introduction. In this paper, we give Cauchy-type formulae for functions analytic of order two on C^1 domains obtained from the solutions of corresponding biharmonic problems. We show how functions analytic of order two are potentials for the solutions of systems of linear partial differential equations in two-dimensional elastostatics and hydrostatics. When combined with Cauchy formulae we obtain integral representations for the traction problem and the linearized Stokes problem that are valid even for C^1 domains.

The traction problem in elastostatics is to determine the components of stress and displacement from a system of partial differential equations satisfied within a domain and the forces applied on the boundary. Airy showed [2] that in the absence of body forces this problem could be reduced to finding a scalar biharmonic potential called the stress function. The stationary Stokes problem in hydrostatics is the following. Solve a system of partial differential equations satisfied by the velocity and pressure that can likewise be reduced to a biharmonic problem. (See Mikhlin [11, pp. 176–178] for an outline of these reductions.)

In [7] and [8] Cohen and Gosselin obtained solutions to the following biharmonic problems on C^1 domains in $\mathbb{R}^2$:

$$\begin{aligned} &\Delta^2 u = 0 \quad \text{in } \Omega, \\ &\nabla u|_{\partial\Omega} = \mathbf{g} \quad \text{where } \int \mathbf{g}\cdot\mathbf{T}\,ds = 0, \end{aligned} \tag{1.1}$$

$\mathbf{T}$ is the unit tangent vector and $\mathbf{g} \in L^p \times L^p(\partial\Omega)$, $1 < p < \infty$

$$\Delta^2 u = 0, \qquad (u_{xx}x_s + u_{xy}y_s,\ u_{xy}x_s + u_{yy}y_s) = \boldsymbol{\varphi} \tag{1.2}$$

where $\boldsymbol{\varphi} = (\varphi, \psi) \in L^q \times L^q(\partial\Omega)$ and $\int_{\partial\Omega} \varphi = \int_{\partial\Omega} \psi = \int_{\partial\Omega} x\varphi + y\psi\, ds = 0$.

The first of these problems involves Dirichlet-type boundary conditions and solves the stationary Stokes problem. The second involves adjoint or Neumann-type boundary conditions and solves the traction problem.

The solutions are given by potentials that are modified versions of the multiple layer potentials introduced by Agmon in [1]. The analysis at the boundary is obtained

for C^1 domains via an application of Calderon's theorem on the Cauchy integral along Lipschitz curves [5].

In practice it can be difficult to obtain the appropriate biharmonic potentials. Muskhelishvili's book on elasticity [12, Chap. 5] shows how assuming the existence of Airy's stress function leads to the reformulation of the traction problem as a boundary value problem for a system of analytic functions. The crucial point in the introduction of analytic functions is that biharmonic functions can be represented as $\operatorname{Re}\{\bar{z}f(z)+g(z)\}$ where f and g are analytic. If we define $\bar{\partial}=\partial_x+i\partial_y$, a simple calculation shows that $\bar{\partial}^2(\bar{z}f(z)+g(z))=0$. This suggests a connection between elasticity and the $\bar{\partial}^2$ equation.

In fact, this connection is neither new nor surprising. In the 1920s Burgatti, in [3] and [4], studied solutions of $\bar{\partial}^n f=0$ and introduced solutions of the equation $\bar{\partial}^2 f=0$ into the equations of elasticity to obtain Kolosoff's formula for the complex displacement [4, pp. 90–91].

In this paper we look at the complex function $U+i\tilde{U}$ where U is the Airy stress function and $\tilde{U}$ is a biharmonic conjugate of U in the sense that $\bar{\partial}^2(U+i\tilde{U})=0$. We show how the displacements can be computed, up to a rigid infinitesimal deformation, as a linear combination of the first derivatives of the stress function and its biharmonic conjugate $\tilde{U}$. We then show how the layer potential representation of the solution to the biharmonic reformulation of the traction problem can be extended to a "Cauchy type" formula that automatically produces the biharmonic conjugate of the stress function.

This procedure is simpler than the method outlined on pages 106–109 of Muskhelishvili [12]. Furthermore, for half planes with any orientation, the layer potential solutions reduce to Poisson integrals of the boundary forces.

2. The $\bar{\partial}^2$ equation. Functions satisfying the equation $\bar{\partial}^2\psi=0$ are called analytic of order two where $\bar{\partial}=\partial_x+i\partial_y$ and ψ is complex valued. In this section we review some of the basic properties of these functions, some of which are discussed in a more general context in the articles by Burgatti [3] and [4].

We let ∂ denote the operator $\partial_x-i\partial_y$ and assume that ψ is complex valued and satisfies $\bar{\partial}^2\psi(z)=0$ in a domain Ω. If we write $\psi=U+i\tilde{U}$ where U and $\tilde{U}$ are smooth real-valued functions and observe that $\bar{\partial}^2=\partial_{xx}-\partial_{yy}+2i\partial_{xy}$, then $\bar{\partial}^2\psi=0$ implies

$$U_{xx}-U_{yy}-2\tilde{U}_{xy}+i(2U_{xy}+\tilde{U}_{xx}-\tilde{U}_{yy})=0. \tag{2.1}$$

Equating real and imaginary parts, we obtain the following system of second-order partial differential equations:

$$U_{xx}-U_{yy}=2\tilde{U}_{xy}, \tag{2.2}$$

$$2U_{xy}=-(\tilde{U}_{xx}-\tilde{U}_{yy}), \tag{2.3}$$

which is analogous to the Cauchy-Riemann equations.

Since the Laplace operator can be factored as $\Delta=\bar{\partial}\partial$ we observe the following:

$$\Delta U+i\Delta\tilde{U} \quad \text{is analytic} \tag{2.4}$$

since $\bar{\partial}(\Delta U+i\Delta\tilde{U})=\partial\bar{\partial}^2(U+i\tilde{U})=0$;

$$\Delta^2 U=\operatorname{Re}\Delta^2(U+i\tilde{U})=\operatorname{Re}\partial^2\bar{\partial}^2(U+i\tilde{U})=0; \tag{2.5}$$

$$\Delta^2\tilde{U}=\operatorname{Im}\Delta^2(U+i\tilde{U})=\operatorname{Im}\partial^2\bar{\partial}^2(U+i\tilde{U})=0. \tag{2.6}$$

Thus U and $\tilde{U}$ are biharmonic and since $\Delta U + i\Delta\tilde{U}$ is analytic, the pair of functions ΔU and $\Delta\tilde{U}$ satisfy the Cauchy-Riemann equations:

$$(\Delta U)_x = (\Delta\tilde{U})_y, \tag{2.7}$$

$$(\Delta U)_y = -(\Delta\tilde{U})_x. \tag{2.8}$$

The system of real second-order equations (2.2) and (2.3) together with (2.8) and (2.9) will be referred to as the biharmonic Cauchy-Riemann equations.

Analytic functions of order two can be represented as

$$\psi(z) = \frac{\bar{z}}{2} f(z) + g(z) \tag{2.9}$$

where f and g are analytic. It follows that $f(z) = \bar{\partial}\psi(z)$ and $g(z) = \psi(z) - (\bar{z}/2)\bar{\partial}\psi(z)$. We then write

$$\psi(z) = \frac{\bar{z}}{2}\bar{\partial}\psi(z) + \left(\psi(z) - \frac{\bar{z}}{2}\bar{\partial}\psi(z)\right), \tag{2.10}$$

and applying Cauchy's formula to the analytic functions $\bar{\partial}\psi(z)$ and $\psi(z) - (\bar{z}/2)\bar{\partial}\psi(z)$, we obtain the Cauchy-type representation

$$\psi(z) = \frac{1}{2\pi i}\int_\gamma \frac{\psi(w)}{w - z}\, dw - \frac{1}{4\pi i}\int_\gamma \bar{\partial}\psi(w)\frac{\bar{w} - \bar{z}}{w - z}\, dw \tag{2.11}$$

where γ is a simple closed contour in Ω containing z.

Formula (2.11) appears (except for a small error) on page 88 of Burgatti [4], and we will refer to (2.11) as Burgatti's formula.

3. The traction problem. The traction problem is to obtain the elastostatic state of a thin plate from the forces at the edge. In this section we assume that Ω is a bounded C^1 simply connected domain in $\mathbb{R}^2$. We let $S = \left[\begin{smallmatrix} A & B \\ B & C \end{smallmatrix}\right]$ denote the stress tensor and let u, v denote the components of displacement. In the absence of body forces the equilibrium equations are

$$A_x + B_y = 0, \qquad B_x + C_y = 0 \tag{3.1}$$

and the equations relating displacement and stress are

$$A = (\lambda + 2\mu)u_x + \lambda v_y, \qquad B = \mu(u_y + v_x), \qquad C = \lambda u_x + (\lambda + 2\mu)v_y. \tag{3.2}$$

If we let (X_n, Y_n) denote the normal stress along the boundary $\partial\Omega$ and (x_s, y_s) the unit tangent vector on $\partial\Omega$, then the traction problem is to find components of stress A, B, C and displacements u, v satisfying (3.1) and (3.2) in Ω and for which

$$\begin{bmatrix} A & B \\ B & C \end{bmatrix}\begin{bmatrix} y_s \\ -x_s \end{bmatrix} = \begin{bmatrix} X_n \\ Y_n \end{bmatrix} \quad \text{on } \partial\Omega.$$

Airy showed that the equilibrium equations (3.1) imply the existence of a function w such that $A = w_{yy}$, $B = -w_{xy}$, and $C = w_{xx}$. Furthermore, substituting the second partials of w for A, B, and C into (3.2), it easily follows that $\Delta^2 w = 0$. This means that the traction problem can be reformulated as the biharmonic problem:

$$\begin{aligned} &\Delta^2 w = 0, \\ &\begin{bmatrix} w_{yy} & -w_{xy} \\ -w_{xy} & w_{xy} \end{bmatrix}\begin{bmatrix} y_s \\ -x_s \end{bmatrix} = \begin{bmatrix} X_n \\ Y_n \end{bmatrix} \quad \text{in } \partial\Omega. \end{aligned} \tag{3.3}$$

A quick inspection shows that this is problem (1.2) in the Introduction. The solution w is called the Airy stress function.

To complete the solution to the traction problem it is necessary to compute the displacements from the stress function. This procedure, as outlined in Muskhelishvili [12, pp. 106–109], is somewhat complicated. We will now show how, if a biharmonic conjugate can be found for the stress function, the computation can be simplified considerably.

If we substitute the appropriate second partials of w for A and C in the first and third equations of (3.1) and solve for u_x and v_y we get

$$u_x = \frac{-\lambda w_{xx} + (\lambda + 2\mu) w_{yy}}{4\mu(\lambda + \mu)}, \tag{3.4}$$

$$v_y = \frac{(\lambda + 2\mu) w_{xx} - \lambda w_{yy}}{4\mu(\lambda + \mu)}. \tag{3.5}$$

We now assume there exists a function $\tilde{w}$ such that $\bar{\partial}^2(w + i\tilde{w}) = 0$. Using the biharmonic Cauchy-Riemann equations we can substitute $w_{xx} - 2\tilde{w}_{xy}$ for w_{yy} in (3.4) and $w_{yy} + 2\tilde{w}_{xy}$ for w_{xx} in (3.5) to get

$$u_x = \frac{\partial}{\partial x}\left(\frac{\mu w_x - (\lambda + 2\mu)\tilde{w}_y}{2\mu(\lambda + \mu)}\right), \tag{3.6}$$

$$v_y = \frac{\partial}{\partial x}\left(\frac{\mu w_y + (\lambda + 2\mu)\tilde{w}_x}{2\mu(\lambda + \mu)}\right). \tag{3.7}$$

This is the main point. The introduction of the biharmonic conjugate $\tilde{w}$ enables us to integrate u_x and v_y to obtain

$$u = \frac{\mu w_x - (\lambda + 2\mu)\tilde{w}_y}{2\mu(\lambda + \mu)} + F_1(y), \tag{3.8}$$

$$v = \frac{\mu w_y + (\lambda + 2\mu)\tilde{w}_x}{2\mu(\lambda + \mu)} + F_2(x). \tag{3.9}$$

Substituting for u and v in (3.2), we have

$$\begin{aligned} \frac{-1}{\mu} w_{xy} &= (u_y + v_x) \\ &= \frac{\mu w_{xy} - (\lambda + 2\mu)\tilde{w}_{yy}}{2\mu(\lambda + \mu)} + F_1'(y) + \frac{\mu w_{xy} - (\lambda + 2\mu)\tilde{w}_{xx}}{2\mu(\lambda + \mu)} + F_2'(x) \\ &= \frac{2\mu w_{xy} - (\lambda + 2\mu)(\tilde{w}_{yy} - \tilde{w}_{xx})}{2\mu(\lambda + \mu)} + F_1'(y) + F_2'(x), \end{aligned} \tag{3.10}$$

which, by the biharmonic Cauchy-Riemann equations,

$$\begin{aligned} &= \frac{2\mu w_{xy} - (\lambda + 2\mu)(2w_{xy})}{2\mu(\lambda + \mu)} + F_1'(y) + F_2'(x) \\ &= -\frac{1}{\mu} w_{xy} + F_1'(y) + F_2'(x). \end{aligned}$$

Thus we have $0 = F_1'(y) + F_2'(x)$. This implies that $F_1'(y) = -F_2'(x) = \varepsilon$ and so $F_1(y) = \varepsilon y + \tau$, $F_2(x) = -\varepsilon x + \sigma$.

The choice of biharmonic conjugate $\tilde{w}$ was arbitrary. However, it follows from Lemma 13.1 of Agmon [1] that if $\bar{\partial}^2(w+i\tilde{w})=0$ and $\bar{\partial}^2(w+i\tilde{w}_1)=0$, then $\tilde{w}_1-\tilde{w}=\alpha x+\beta y+\frac{1}{2}(x^2+y^2)+\delta$. Substituting $\tilde{w}_1$ for $\tilde{w}$ in (3.8) and (3.9), we get a displacement (u_1, v_1) that differs from (u, v) by

$$u_1-u=\frac{-(\lambda+2\mu)}{2\mu(\lambda+\mu)}(\gamma y+\beta), \tag{3.11}$$

$$v_1-v=\frac{(\lambda+2\mu)}{2\mu(\lambda+\mu)}(\gamma x+\alpha). \tag{3.12}$$

This means that two distinct "biharmonic conjugates" give rise to displacements that differ by, at worst, an infinitesimal rigid displacement. In other words, we have introduced no new pure deformation by computing the displacement from the derivatives of $\tilde{w}_1$ rather than $\tilde{w}$. Up to an infinitesimal rigid displacement we have the formula

$$(u, v)=\left(\frac{\mu w_x-(\lambda+2\mu)\tilde{w}_y}{2\mu(\lambda+\mu)}, \frac{\mu w_y+(\lambda+2\mu)\tilde{w}_x}{2\mu(\lambda+\mu)}\right). \tag{3.13}$$

4. The stationary Stokes problem. The stationary Stokes problem in hydrostatics has the formulation in a domain Ω:

$$\begin{aligned} &\Delta\mathbf{u}=\nabla p \quad \text{in } \Omega \\ &\operatorname{div}\mathbf{u}=0 \quad \text{in } \Omega, \\ &\mathbf{u}|_{\partial\Omega}=\mathbf{f} \end{aligned} \tag{4.1}$$

where $\mathbf{u}=(u, v)$ is the velocity of the fluid, p is the pressure, and $\mathbf{f}=(f_1, f_2)$ is the velocity at the boundary. The second equation, $\operatorname{div}\mathbf{u}=0$, implies there exists a function Φ satisfying $\nabla\Phi=(-v, u)$. It then follows from substitution for u and v in the first equation that $\Delta^2\Phi=\operatorname{div}(\Delta\Phi_x, \Delta\Phi_y)=-p_{xy}+p_{xy}=0$. The Stokes problem then has the biharmonic formulation:

$$\begin{aligned} &\Delta^2\Phi=0 \quad \text{in } \Omega, \\ &\nabla\Phi|_{\partial\Omega}=(-f_2, f_1). \end{aligned} \tag{4.2}$$

It remains to obtain the pressure p from the solution Φ of (4.2). If we assume there exists a $\tilde{\Phi}$ such that $\bar{\partial}^2(\Phi+i\tilde{\Phi})=0$, then by the second part of the biharmonic Cauchy-Riemann equations,

$$(\Delta\tilde{\Phi})_x=-(\Delta\Phi)_y=-\Delta u=-p_x, \qquad (\Delta\tilde{\Phi})_y=(\Delta\Phi)_x=-\Delta v=-p_y. \tag{4.3}$$

Hence $\nabla(-\Delta\tilde{\Phi})=\nabla p$ so that $-\Delta\tilde{\Phi}$ differs from the pressure by a constant. If a second biharmonic conjugate $\tilde{\Phi}_1$ is used, then $\Delta\tilde{\Phi}_1-\Delta\tilde{\Phi}$ is a constant.

It is clear that this same calculation shows that any harmonic conjugate of $\Delta\Phi$ will suffice to give the pressure. However, we will point out that the layer potential solution of (4.2) automatically produces a biharmonic conjugate $\tilde{\Phi}$ so that no additional integrations are necessary to find the pressure.

5. The biharmonic results. We assume that Ω is a bounded, simply connected C^1 domain in R^2 with boundary $\partial\Omega$. We next introduce the following spaces of boundary data.

DEFINITION 5.1.

$$C_p=\left\{\mathbf{g}=(g, h)\in(L^p\times L^p)(\partial\Omega): \int_{\partial\Omega} g\,dx+h\,dy=0\right\}.$$

DEFINITION 5.2. $(L^p \times L^p)_0(\partial\Omega) = \{\boldsymbol{\varphi} = (\varphi, \psi) \in (L^q \times L^q)(\partial\Omega)$: $\int_{\partial\Omega} \nabla w \cdot \boldsymbol{\varphi}\, ds = 0$ for all $w(x, y) = \alpha x + \beta y + \gamma(x^2 + y^2) + \delta$ and $1 < q < \infty\}$.

Let $\tilde{F}(x, y) = (-1/4\pi)\{(x^2 + y^2) \arg(x + iy) - xy\}$ for some particular choice of the argument. In what follows we will let X denote points in the domain Ω and P, and Q will denote points on the boundary.

DEFINITION 5.3. For $Q \in \partial\Omega$ and $X \in \Omega$ we define the boundary differential operator $\mathbf{L} = \mathbf{L}_Q$ by

$$\mathbf{L}v(X) = (L_1 v(X), L_2 v(X))$$

where

$$L_1 v(X) = v_{xx}(X)x_s(Q) + v_{xy}(X)y_s(Q), \qquad L_2 v(X) = v_{xy}(X)x_s(Q) + v_{yy}(X)y_s(Q) \tag{5.4}$$

with $(x(s), y(s))$ being the arclength parameterization of $\partial\Omega$ and $(x_s(Q), y_s(Q))$ being the unit tangent at Q.

DEFINITION 5.5. For $\mathbf{g} \in C_p$ we define the modified multiple layer potential by

$$u_m(\mathbf{g}: X) = \int_{\partial\Omega} g(Q)L_1\tilde{F}(X - Q) + h(Q)L_2\tilde{F}(X - Q)\, ds(Q). \tag{5.6}$$

For $\boldsymbol{\varphi} \in (L^q \times L^q)_0(\partial\Omega)$ we define the modified lower-order potential by

$$v_m(\boldsymbol{\varphi}; X) = \int_{\partial\Omega} \varphi(P)\tilde{F}_x(P - X) + \psi(P)\tilde{F}_y(P - X)\, ds(P). \tag{5.7}$$

For $X \notin \partial\Omega$ we can differentiate (5.6) and (5.7) under the integral signs to get

$$\nabla u_m = \int_{\partial\Omega} \mathbf{g}(Q)l(X, Q)\, ds(Q) \tag{5.8}$$

where

$$l(X, Q) = \begin{bmatrix} \partial_x^X L_1\tilde{F}(X - Q) & \partial_y^X L_1\tilde{F}(X - Q) \\ \partial_x^X L_2\tilde{F}(X - Q) & \partial_y^X L_2\tilde{F}(X - q) \end{bmatrix} \tag{5.9}$$

and

$$\mathbf{L}v_m(X)^T = \int_{\partial\Omega} l(X, P, Q)\boldsymbol{\varphi}(P)^T\, ds(P) \tag{5.10}$$

where

$$l(X, P, Q) = \begin{bmatrix} \partial_x^P L_1\tilde{F}(P - X) & \partial_y^P L_1\tilde{F}(P - X) \\ \partial_x^P L_2\tilde{F}(P - X) & \partial_y^P L_2\tilde{F}(P - X) \end{bmatrix}, \tag{5.11}$$

and the superscript T denotes the transpose of a row vector. Note that the dependence of l on Q is built into the definition of L_1 and L_2.

DEFINITION 5.12. For $P \neq Q$, $P, Q \in \partial\Omega$, we can define the matrix kernels in (5.9) and (5.11) by letting $X = Q$. Both kernels are then the same and we call them $l(P, Q)$. We define the operators

$$\mathscr{L}_\varepsilon \mathbf{g}(P) = \int_{|P-Q|>\varepsilon} \mathbf{g}(Q, Q)l(P, Q)\, ds(Q) \tag{5.13}$$

and

$$\mathscr{L}_\varepsilon^* \boldsymbol{\varphi}(P) = \int_{|P-Q|>\varepsilon} l(P, Q)\boldsymbol{\varphi}(P)^T\, ds(P). \tag{5.14}$$

We tentatively define the operators $\mathscr{L}\mathbf{g}(P) = \lim_{\varepsilon\to 0} \mathscr{L}_\varepsilon \mathbf{g}(P)$ and $\mathscr{L}^*\boldsymbol{\varphi}(Q) = \lim_{\varepsilon\to 0} \mathscr{L}_\varepsilon^*\boldsymbol{\varphi}(Q)$.

THEOREM 5.15. *For $\mathbf{g}\in C_p$, we have the following*:

(i) *$\mathscr{L}\mathbf{g}(P)$ exists almost everywhere with respect to arclength, $\mathscr{L}$ is bounded from C_p to itself in the $(L^p\times L^p)(\partial\Omega)$ norm and in fact is compact from C_p to itself.*

(ii) *The nontangential*

$$\lim_{X\to P} \nabla u_m(X) = \begin{cases} (I+\mathscr{L})\mathbf{g}(P), & X\in\Omega, \\ (-I+\mathscr{L})\mathbf{g}(P), & X\notin\bar{\Omega} \end{cases}$$

for almost every $P\in\partial\Omega$,

(iii) *$(I+\mathscr{L})^{-1}$ exists on C_p and $(-I+\mathscr{L})^{-1}$ exists on the space $(-I+\mathscr{L})(C_p)$.*

COROLLARY 5.16. *The interior Dirichlet problem $\Delta^2 u = 0$ in Ω, $\nabla u = \mathbf{g}\in C_p$ on $\partial\Omega$ is solvable with $u = u_m((I+\mathscr{L})^{-1}\mathbf{g}; X)$.* The exterior Dirichlet problem $\Delta^2 u = 0$ *in $\bar{\Omega}^C$, $\nabla u = \mathbf{g}\in C_p$ on $\partial\Omega$ is solvable with $u = u_m((-I+\mathscr{L})^{-1}\mathbf{g}_0; X) + \nabla w$ where for $\mathbf{g}\in C_p$, $\mathbf{g}$ can be written uniquely as $\mathbf{g} = \mathbf{g}_0 + \nabla w$ with $\mathbf{g}_0\in(-I+\mathscr{L})(C_p)$ and $w = \alpha x + \beta y + \gamma(x^2+y^2) + \delta$.*

THEOREM 5.17. *For $\boldsymbol{\varphi}\in(L^q\times L^q)_0(\partial\Omega)$ we have the following*:

(i) *$\mathscr{L}^*\boldsymbol{\varphi}(Q)$ exists almost everywhere with respect to arclength, $\mathscr{L}$ is bounded from $(L^q\times L^q)_0(\partial\Omega)$ to itself in the $(L^q\times L^q)(\partial\Omega)$ norm and is compact from $(L^q\times L^q)_0(\partial\Omega)$ to itself.*

(ii) *The nontangential*

$$\lim_{X\to Q} \mathbf{L}v_m(X) = \begin{cases} (-I+\mathscr{L}^*)\boldsymbol{\varphi}(Q), & X\in\Omega, \\ (I+\mathscr{L}^*)\boldsymbol{\varphi}(Q), & X\notin\bar{\Omega} \end{cases}$$

for almost every $Q\in\partial\Omega$.

(iii) *$(-I+\mathscr{L}^*)^{-1}$ exists on $(L^q\times L^q)_0(\partial\Omega)$.*

COROLLARY 5.18. *The adjoint boundary value problem $\Delta^2 v = 0$ in Ω, $\mathbf{L}v = \boldsymbol{\varphi}\in(L^q\times L^q)_0(\partial\Omega)$ is solvable by $v = v_m((-I+\mathscr{L}^*)^{-1}\boldsymbol{\varphi}; X)$.*

Remark. It is important to note that the operator $-I+\mathscr{L}^*$ is not exactly the adjoint of $-I+\mathscr{L}$. The adjoint of $-I+\mathscr{L}$ acts on the dual of C_p, which is a coset space. The space $(L^q\times L^q)_0(\partial\Omega)$ is a function space that is close to the dual of C_p, however, work is required to extend the invertibility of the adjoint of $-I+\mathscr{L}$ from the dual of C_p to invertibility on $(L^q\times L^q)_0(\partial\Omega)$. The details of the proofs can be found in Cohen and Gosselin [7] and [8].

6. Cauchy formulae. In the theory of Hardy spaces of the upper half plane, functions $f\in L^p(\mathbb{R})$, $1<p<\infty$ can be identified with analytic functions $f(z)$ on the upper half plane satisfying $\sup_{y>0}\int |f(x+iy)|_{dx}^p < \infty$. This identification is obtained by convolving the boundary function f with the complex kernel $(i\pi z)^{-1}$. For an arbitrary C^1 (or even a Lipschitz domain if $f\in L^p(\partial\Omega)$ for $p\geqq 2$) we can obtain the same type of identification by applying the properties of the classical double layer potential to the Cauchy integral of the boundary data. (See Fabes, Jodeit, and Riviere [9], Fabes and Kenig [10], or Verchota [13] for more details.)

An analogous kind of identification of compatible triples of boundary functions with analytic functions of order two can be obtained from Burgatti's formula (2.11). (By compatible triples we mean the space $\mathscr{B}_p = \{\dot{f} = (f, g, h)\in L_1^p\times L^p\times L^p(\partial\Omega)$: $f_s = gx_s + hy_s$ almost everywhere with respect to arclength$\}$.) For $\dot{f} = (f, g, h)\in\mathscr{B}_p$ we define the complex potential

$$\varphi_{\dot{f}}(w) = \frac{1}{2\pi i}\int_{\partial\Omega}\frac{f(z)}{z-w}\,dz - \frac{1}{4\pi i}\int_{\partial\Omega}(g(z)+ih(z))\frac{\bar{z}-\bar{w}}{z-w}\,dz. \tag{6.1}$$

It follows from the article by Cohen and Gosselin on the Dirichlet problem for the biharmonic equation [6] that if $\mathcal{U}_f = \operatorname{Re} \varphi_f$ and $\dot{\mathcal{U}}_f = (\mathcal{U}_f, (\mathcal{U}_p)_x, (\mathcal{U}_p)_y)$, then there exists an invertible operator $T: \mathcal{B}_p \to \mathcal{B}_p$ such that the nontangential $\lim_{X \to P \in \partial\Omega} \dot{\mathcal{U}}_{T^{-1}\dot{f}}(X) = \dot{f}(P)$ almost everywhere. The map $\dot{f} \to \varphi_f$ then identifies the boundary space $\mathcal{B}_p$ with a space of functions analytic of order two in Ω.

We have seen in §§ 3 and 4 that the solutions to the traction problem and stationary Stokes problem can be obtained by solving a biharmonic problem and finding a biharmonic conjugate. An examination of the matrix kernels (5.8) and (5.10) suggests that we can obtain biharmonic conjugates to the solutions of (1.1) and (1.2) from a Cauchy-type formula if we can find a biharmonic conjugate to the function $\tilde{F}$.

But $\tilde{F}(z) = (-1/4\pi) \operatorname{Im}\{\bar{z}z \log z - \frac{1}{2}\bar{z}z + \frac{1}{2}z^2\}$ and $\bar{\partial}^2\{\bar{z}z \log z - \frac{1}{2}\bar{z}z + \frac{1}{2}z\} = 0$. If we let $F(z) = \operatorname{Re}(-1/4\pi)\{\bar{z}z \log z - \frac{1}{2}\bar{z}z + \frac{1}{2}z^2\}$, then $\bar{\partial}^2(F + i\tilde{F}) = 0 = i\bar{\partial}^2(\tilde{F} - iF)$. This implies that $\tilde{F} - iF$ is analytic of order two, which suggests the following Cauchy-type potentials.

DEFINITION 6.2. For $\mathbf{g} \in C_p$ define the complex modified multiple layer potential

$$(u_m + i\tilde{u}_m)(\mathbf{g}; X) = \int_{\partial\Omega} \mathbf{g}(Q)\mathbf{L}^Q(\tilde{F} - iF)(X - Q)^T \, ds(Q). \tag{6.3}$$

DEFINITION 6.4. For $\boldsymbol{\varphi} \in (L^q \times L^q)_0(\partial\Omega)$ define the complex modified lower-order potential

$$(v_m + i\tilde{v}_m)(\boldsymbol{\varphi}, X) = \int_{\partial\Omega} \varphi(\beta)(\tilde{F} - iF)_x(P - X) + \psi(P)(\tilde{F} - iF)(P - X) \, ds(P). \tag{6.5}$$

It then follows immediately that $(u_m + i\tilde{u}_m)((I + \mathcal{L})^{-1}(f_2, -f_1); X)$ gives the function analytic of order two, which solves the stationary Stokes problem and $(v_m + i\tilde{v}_m) \cdot ((-I + \mathcal{L}^*)^{-1}(-Y_n, X_n); X)$ solves the traction problem. That is, all dependent variables can be obtained from the real and imaginary parts of these complex potentials by differentiation. Furthermore, explicit integral representations of the stresses, displacements, velocity components, and pressure can be obtained from taking the appropriate derivatives of the matrix kernels.

BOUNDS FOR EFFECTIVE COEFFICIENTS OF PERIODIC FIBER-REINFORCED MATERIALS*

GELU I. PAŞA†

Abstract. This paper contains a generalization of the estimates obtained by Tartar [*Estimation de coefficients homogenisés*, Lecture Notes in Mathematics 704, Springer-Verlag, Berlin, New York, 1977, pp. 364–377] for linear elasticity, without the symmetry condition $A_{ijkh} = A_{khij}$. A problem of this type appears when dealing with nonorthogonal coordinates. Moreover, the paper includes a comparison to similar estimates obtained by Hashin and Rosen [3].

Key words. composite periodic materials, homogenizations, compensated compactness

AMS(MOS) subject classifications. 73K20, 35B40, 35B10

Introduction. We consider an elastic medium and assume that the associated coefficients A_{ijkh} are Y-periodic, Y being a parallelepiped in R^n. An example of such a medium may be given by the composite materials, i.e., a low-resistance matrix with periodically inserted fibers of higher resistance.

Among the composite materials, we are mostly interested in those for which the dimension of the periodicity cell Y is very small compared to that of the entire medium. By introducing a suitable topology, we can obtain convergence of the initially periodic and bounded coefficients, thus replacing the former problem with another one with constant coefficients, which may be determined by solving it for a single cell.

In order to handle the one-cell problem with better results, it is very helpful to have some a priori estimates for these constant coefficients (the so-called "homogenized" or "effective" coefficients). Among the methods already proposed in this direction, we refer in the following sections to variational methods, as well as to the homogenization method (see [1], [5]).

Using variational principles in linear elasticity, Hashin and Shtrikman in 1963 obtained limits for effective moduli of quasi-homogeneous and quasi-isotropic composite materials of arbitrary phase geometry [8].

In their 1964 paper, Hashin and Rosen studied a composite material with hexagonal periodicity and nonisotropic components [3]. Their method is based on the minimum principle for the potential energy, and they need an exact solution for the given configuration.

Estimates for the effective thermic conductivity of a composite material with general periodic configuration were obtained by Tartar in his 1976 paper [6], by using the homogenization method along with his own and F. Murat's method of compensated compactness (see [4]).

Tartar's results were generalized to the case of linear elasticity by Francfort and Murat in 1986 [7]. They deal with symmetric matrices of elasticity, and the composite materials have isotropic components. Their paper also includes a comparison of their results with those from [8]. While the "bulk modulus" limits are the same in both papers, the "shear modulus" limits are more accurate in [8].

Here we present a different type of generalization for Tartar's results, namely, the case of linear elasticity without the symmetry condition $A_{ijkh} = A_{khij}$. Such a situation

* Received by the editors May 27, 1986; accepted for publication (in revised form) February 25, 1988.
† Department of Mathematics, The National Institute for Scientific and Technical Creation, Badul Păcii 220, 79622 Bucharest, Romania.

may appear when applying Tartar's method to a configuration for which periodicity directions do not coincide with the coordinate axes, i.e., as in [3]. Moreover, we consider a two-phase composite with nonisotropic elastic components and compare our results with those obtained in [3]. We emphasize that instead of the symmetry condition we introduce condition (*) (in 1), which allows for an estimation of the upper bound limits for the matrix A (in the sense of Tartar). On the contrary, the lower bound limit cannot be obtained unless we deal with a particular element, which, in the configuration mentioned in [3], is of the "shear modulus" type. The second section contains an example as well as a comparison between our results and the estimations obtained by Hashin and Rosen [3]; their limits are more accurate, in accordance with the result mentioned in [7].

1. Bounds for homogenized coefficients. As we have already mentioned in the Introduction, the principal results of this section (contained in Proposition 2 and Theorem 2) give an estimation of the homogenized coefficients appearing in linear elasticity, obtained by using a generalization of Tartar's method along with an idea of McConnel [2].

The following definitions will be needed in the sequel.

DEFINITION 1. Let $A_{ijkh} = A_{ijhk} = A_{jikh}$ be Y-periodic and strongly elliptic:

$$A^{\varepsilon}_{ijkh}(x) = A_{ijkh}(x/\varepsilon).$$

Let the equation

$$-\partial(A^{\varepsilon}_{ijkh}\partial u^{\varepsilon}_k/\partial x_h)/\partial x_i = F_j \quad \text{in } \Omega \subset R^n,$$
$$\underline{u}^{\varepsilon}/\partial\Omega = 0.$$

Using the result of the homogenization theory (Sanchez-Palencia [5], Benssoussan, Lions, and Papanicolaou [1]) it is possible to prove the existence of A^0_{ijkh} and $\underline{u}^0$ such that $\underline{u}^{\varepsilon} \rightharpoonup \underline{u}^0$ in the weak topology of the Sobolev space $H^1_0(\Omega)$, when $\varepsilon \to 0$, and

$$-\partial(A^0_{ijkh}\partial u^0_k/\partial x_h)/\partial x_i = F_j \quad \text{in } \Omega \subset R^n,$$
$$\underline{u}^0/\partial\Omega = 0.$$

In this case, A^{ε}_{ijkh} are H-convergent to A^0_{ijkh}:

$$A^{\varepsilon}_{ijkh} \overset{H}{\rightharpoonup} A^0_{ijkh}.$$

DEFINITION 2. Assume M and N are two "matrices" of coefficients such that $M_{ijkh} = M_{ijhk} = M_{jikh}$. Then $M \leqq N \Leftrightarrow (Mc, c) \leqq (Nc, c)$ for all $c_{ij} = c_{ji} \in R^3 \times R^3$, $(,)$ being the scalar product in R^9.

Remark 1. If $A^{\varepsilon}_{ijkh} \overset{H}{\rightharpoonup} A^0_{ijkh}$, then $A^{\varepsilon}_{ijkh}(\partial u^{\varepsilon}_k/\partial x_h)(\partial u^{\varepsilon}_i/\partial x_j) \rightharpoonup A^0_{ijkh}(\partial u^0_k/\partial x_h) \times (\partial u^0_i/\partial x_j)$ weakly in $L_2(\Omega)$ as a direct consequence of the convergence theorem. Notice that in the local problem we use the transposed matrix of A^{ε}_{ijkh}.

PROPOSITION 1. *Let $p^{\varepsilon}_{ij} \in H^1(\Omega)$ be such that $p^{\varepsilon}_{ij} \rightharpoonup p^*_{ij}$ weakly in $L_2(\Omega)$ and $\|\partial(p^{\varepsilon}_{ij})/\partial x_i\|_{L_2(\Omega)} \leqq$ const. Assume that $\underline{u}^{\varepsilon} \in H^1(\Omega)$ are such that $\underline{u}^{\varepsilon} \rightharpoonup u^*$ weakly in $H^1(\Omega)$. Then*

$$\int_{\Omega} p^{\varepsilon}_{ij}\partial u^{\varepsilon}_i/\partial x_j\phi \to \int_{\Omega} p^*_{ij}\partial u^*_i/\partial x_j\phi \quad \forall \phi \in C^{\infty}_0(\Omega).$$

Proof. Define

$$\underline{h}^{\varepsilon_i} = (p^{\varepsilon}_{i1}, p^{\varepsilon}_{i2}, \cdots, p^{\varepsilon}_{in}), \quad \underline{v}^{\varepsilon_i} = (\partial u^{\varepsilon}_i/\partial x_1, \partial u^{\varepsilon}_i/\partial x_2, \cdots, \partial u^{\varepsilon}_i/\partial x_n).$$

Then we have $\|\operatorname{div}(\underline{h}^{\varepsilon_i})\|_{L_2(\Omega)} \leqq$ const,

$$(\operatorname{rot} \underline{v}^{\varepsilon_i})_{sq} = \partial^2 u^{\varepsilon}_i/\partial x_s\partial x_q - \partial^2 u^{\varepsilon}_i/\partial x_q\partial x_s = 0,$$

and we may apply the compensated compactness method for vectors, (cf. [1]; see also [4]). □

Let us consider now the following assumption concerning the elastic coefficients:

(∃) A coefficient with $j = kh$ (for example, A_{1313}) such that

(*) $A_{13sq} = A_{sq13}$.

First we shall prove a result that does not use the compensated compactness method.

THEOREM 1. *Let* $A^\varepsilon \overset{H}{\rightharpoonup} Q$ *and* $A^\varepsilon \rightharpoonup A$, $(A^\varepsilon)^{-1} \rightharpoonup (B)^{-1}$ *weakly in* $L_2(\Omega)$. *Then*

(a) $Q \geqq A$,

(b) $Q_{1313} \geqq B_{1313}$.

Proof. (a) We consider $c_{ij} = c_{ji} \in R^3 \times R^3$ and start with

$$(A^\varepsilon(v^\varepsilon - c), v^\varepsilon - c) \geqq 0, \tag{1}$$

where v^ε is defined by

$$\begin{aligned} &\partial(A^\varepsilon_{ijkh}\partial u^\varepsilon_k/\partial x_h)/\partial x_i = 0, \qquad v^\varepsilon_{kh} = \partial u^\varepsilon_k/\partial x_h, \\ &u^\varepsilon_k - c_{kh}\cdot x_h \in H^1_0(\Omega). \end{aligned} \tag{2}$$

Passing to the limit with $\varepsilon \to 0$ in (1) and using $v^\varepsilon \rightharpoonup c$ we obtain

$$(Qc, c) - 2\cdot(Qc, c) + (Ac, c) \geqq 0.$$

Consequently, $Q \geqq A$. Therefore, condition (*) was not necessary for the first part of the theorem.

(b) In order to determine the lower bound we consider

$$((A^\varepsilon)^{-1}(A^\varepsilon v^\varepsilon + d), A^\varepsilon v^\varepsilon + d) \geqq 0, \tag{3}$$

where v^ε is given by (2) for $c_{13} \neq 0$ and $c_{sq} = 0$, $sq \neq 13$, and $d_{ij} = -B_{ijkh}c_{kh}$. We have

$$(A^\varepsilon)^{-1}_{pqst}A^\varepsilon_{stij}\frac{\partial u^\varepsilon_i}{\partial x_j}A^\varepsilon_{pqmn}\frac{\partial u^\varepsilon_m}{\partial x_n} = \delta_{pi}\cdot\delta_{qj}A^\varepsilon_{pqmn}\frac{\partial u^\varepsilon_i}{\partial x_j}\frac{\partial u^\varepsilon_m}{\partial x_n} \rightharpoonup (Qc, c), \tag{4}$$

$$(A^\varepsilon)^{-1}_{pqst}A^\varepsilon_{stij}\partial u^\varepsilon_i/\partial x_j d_{pq} = \delta_{pi}\cdot\delta_{qj}\partial u^\varepsilon_i/\partial x_j \cdot d_{pq} \rightharpoonup (d, c), \tag{5}$$

$$(A^\varepsilon)^{-1}_{pqst}\cdot d_{pq}\cdot d_{st} \rightharpoonup (B^{-1}d, d), \tag{6}$$

the convergences being in the weak topology of $L_2(\Omega)$. Notice that only the symmetric part of $\partial u^\varepsilon_i/\partial x_j$ appeared in the above relations and that we have used the inversion formula $A_{ijkh}(A)^{-1}_{khpq} = \delta_{ip}\cdot\delta_{jq}$. A closer look at the three terms defined above shows that no condition of symmetry for A^ε was ever needed.

Let us consider, for any $\phi \in C^\infty_0(\Omega)$,

$$\begin{aligned} I &\equiv \int_\Omega (A^\varepsilon)^{-1}_{pqst}d_{st}A^\varepsilon_{pqij}\frac{\partial u^\varepsilon_i}{\partial x_j}\phi \\ &= \int_\Omega (A^\varepsilon)^{-1}_{pqst}d_{st}A^\varepsilon_{pqij}\left(\frac{\partial u^\varepsilon_i}{\partial x_j} - c_{ij}\right)\phi + \int_\Omega (A^\varepsilon)^{-1}_{pqst}d_{st}A^\varepsilon_{pqij}c_{ij}\phi \\ &\equiv I_1 + I_2. \end{aligned}$$

Since the "vector" c and the "matrices" A^ε, B, and $(A^\varepsilon)^{-1}$ are all bounded, it follows that

$$I_1 \leqq \text{const.}\left|\int_\Omega (\partial u^\varepsilon_i/\partial x_j - c_{ij})\phi\right| \to 0.$$

Condition (*) together with $c_{ij}=0$ for $ij\neq 13$ imply

$$I_2=\int_\Omega (A^\varepsilon)^{-1}_{pqst}d_{st}A^\varepsilon_{pq13}c_{13}\phi=\int_\Omega \delta_{s1}\delta_{t3}d_{st}c_{13}\phi=\int_\Omega d_{13}c_{13}\phi.$$

Consequently, we have proved that

$$(A^\varepsilon)^{-1}_{pqst}d_{st}A^\varepsilon_{pqij}\partial u^\varepsilon_i/\partial x_j \rightharpoonup d_{13}c_{13}, \tag{7}$$

weakly in $L_2(\Omega)$. Using (3)-(7) we obtain

$$Q_{1313}c_{13}^2+2\cdot d_{13}c_{13}+(B)^{-1}_{pqst}d_{pq}d_{st}\geqq 0. \tag{8}$$

But

$$\begin{aligned}(B)^{-1}_{pqst}d_{pq}d_{st}&=(B)^{-1}_{pqst}d_{pq}(-B_{stmn}c_{mn})\\&=-(B)^{-1}_{pqst}B_{st13}c_{13}d_{pq}=-d_{13}c_{13}.\end{aligned}$$

Notice that any symmetry properties of A^ε are inherited by B and A, since they are obtained by averaging the coefficients of A^ε. In the sample presented in § 2 we will prove the condition (*) for A^ε. The last relation together with relation (8) implies

$$Q_{1313}c_{13}^2+d_{13}c_{13}\geqq 0,\qquad Q_{1313}c_{13}^2-B_{1313}c_{13}^2\geqq 0.$$

Therefore, condition (*) was needed only in the last part of the theorem.

In [6] Tartar showed that the bounds obtained by using the above theorem are not precise enough when A^ε is not continuous and the values of A^ε in the fiber tend to zero or to infinity.

To obtain better limits, we define the following notion of convergence, which generalizes that introduced by Tartar.

DEFINITION 3. $A^\varepsilon \overset{13}{\rightharpoonup} A$ if and only if

$$\begin{aligned}&1/A^\varepsilon_{1313}\rightharpoonup 1/A_{1313},\qquad A^\varepsilon_{13sq}/A^\varepsilon_{1313}\rightharpoonup A_{13sq}/A_{1313},\\&A^\varepsilon_{sq13}/A^\varepsilon_{1313}\rightharpoonup A_{sq13}/A_{1313},\\&A^\varepsilon_{sqkh}-A^\varepsilon_{sq13}A^\varepsilon_{13kh}/A^\varepsilon_{1313}\rightharpoonup A_{sqkh}-A_{sq13}A_{13kh}/A_{1313},\end{aligned}$$

where all convergences are in the weak topology of $L_2(\Omega)$ and $(sq),(kh)\neq(13)$.

First we prove a preliminary result.

PROPOSITION 2. *Let $A^\varepsilon \overset{13}{\rightharpoonup} A$ and $c_{kh}=c_{hk}\in R^3\times R^3$. Assume $A^\varepsilon_{13sq}=A^\varepsilon_{sq13}$. Then there exists $w^\varepsilon_{kh}\in L_2(\Omega)$ such that we have the following*:

(1) $w^\varepsilon_{kh}\rightharpoonup c_{kh}$ *weakly in* $L_2(\Omega)$.

(2) $A^\varepsilon_{ijkh}w^\varepsilon_{ij}w^\varepsilon_{kh}\rightharpoonup A_{ijkh}c_{ij}c_{kh}$ *weakly in* $L_2(\Omega)$.

Proof. Define

$$\begin{aligned}&p^\varepsilon_{ij}=A^\varepsilon_{ijkh}w^\varepsilon_{kh}\quad\text{for } (ij)\neq(13),\\&p^\varepsilon_{13=K}\ \text{(a constant that will be defined later)},\\&w^\varepsilon_{13}=\text{variable},\qquad w^\varepsilon_{sq}=c_{sq}\quad\text{for } (sq)\neq(13).\end{aligned}$$

For $(sq)\neq(13)$ we have

$$\begin{aligned}&K=p^\varepsilon_{13}=A^\varepsilon_{1313}w^\varepsilon_{13}+A^\varepsilon_{13sq}c_{sq},\\&w^\varepsilon_{13}=K/A^\varepsilon_{1313}-A^\varepsilon_{13sq}c_{sq}/A^\varepsilon_{1313}\rightharpoonup K/A_{1313}-A_{13sq}c_{sq}/A_{1313}.\end{aligned}$$

By replacing w^ε_{13} we obtain, for (ij) and $(sq)\neq(13)$

$$p^\varepsilon_{ij}\rightharpoonup c_{sq}(A_{ijsq}-A_{ij13}A_{13sq}/A_{1313})+K\cdot A_{ij13}/A_{1313}.$$

Using the last relation, we can compute the weak limit of the product $p^\varepsilon_{rt} w^\varepsilon_{rt}$, since p^ε_{13} and w^ε_{sq} are constant for $(sq) \neq (13)$:

$$\begin{aligned} p^\varepsilon_{rt} w^\varepsilon_{rt} \rightharpoonup\ & K(K/A_{1313} - A_{13sq}c_{sq}/A_{1313}) \\ & + c_{ij}\{A_{ij13}K/A_{1313} + c_{sq}(A_{ijsq} - A_{ij13}A_{13sq}/A_{1313})\} \\ = & K^2/A_{1313} - K \cdot A_{13sq}c_{sq}/A_{1313} + K \cdot A_{ij13}c_{ij}/A_{1313} \\ & + c_{sq}A_{ijsq}c_{ij} - c_{ij}c_{sq}A_{ij13}A_{13sq}/A_{1313}. \end{aligned}$$

From the conditions $A^\varepsilon_{13sq} = A^\varepsilon_{sq13}$ and $K = c_{13}A_{1313} + A_{13sq}c_{sq}$ it follows that

$$p^\varepsilon_{rt} w^\varepsilon_{rt} \rightharpoonup A_{1313}c^2_{13} + 2 \cdot c_{13}A_{13sq}c_{sq} + c_{sq}c_{ij}A_{sqij}.$$

Taking into account the choice of K, we obtain $w^\varepsilon_{13} \rightharpoonup c_{13}$. □

Now we define the following:

MA3 = arithmetical mean with respect to $x_1, x_2, x_4, \cdots, x_n$,

MA2 = arithmetical mean with respect to $x_1, x_3, x_4, \cdots, x_n$.

THEOREM 2. *Let* MA3 $(A^\varepsilon) \xrightarrow{13} B$, $A^\varepsilon \xrightarrow{H} Q$, $A^\varepsilon_{13sq} = A^\varepsilon_{sq13}$. *Then* $Q \leqq B$.

Proof. We consider $c_{ij} = c_{ji} \in R^3 \times R^3$, w^ε_{ij} the sequence defined in Proposition 2 for MA3 (A^ε) and c_{ij}, and v^ε_{kh} given by (2). Then we have the following convergence relations in the weak sense of $L_2(\Omega)$:

$$\begin{aligned} & v^\varepsilon_{kh} \rightharpoonup c_{kh}, \qquad w^\varepsilon_{ij} \rightharpoonup c_{ij}, \\ & \text{MA3}\,(A^\varepsilon v^\varepsilon, v^\varepsilon) \rightharpoonup \text{MA3}\,(Qc, c) = (Qc, c), \\ & \text{MA3}\,(A^\varepsilon v^\varepsilon, w^\varepsilon) \rightharpoonup \text{MA3}(Qc, c) = (Qc, c), \\ & \text{MA3}\,(A^\varepsilon w^\varepsilon, w^\varepsilon) = (\text{MA3}\,(A^\varepsilon) w^\varepsilon, w^\varepsilon) \rightharpoonup (Bc, c), \end{aligned}$$

where we have used the fact that, for $(ij) \neq (13)$, w^ε_{ij} are constant and w^ε_{13} depends only on x_3; therefore

$$\begin{aligned} & \text{rot}\,(0, 0, w^\varepsilon_{13}, 0, \cdots, 0) = 0, \\ & \|\text{div}\,(p^\varepsilon_{11}, p^\varepsilon_{12}, p^\varepsilon_{13}, \cdots p^\varepsilon_{1n})\|_{L_2(\Omega)} \leqq \text{const}, \end{aligned}$$

with $p^\varepsilon_{ij} = A^\varepsilon_{ijkh} \partial u^\varepsilon_k / \partial x_h$. Now we may use the compensated compactness method for MA3 $(A^\varepsilon v^2, w^\varepsilon)$. Starting with

$$\text{MA3}\,(A^\varepsilon(v^\varepsilon - w^\varepsilon), v^\varepsilon - w^\varepsilon) \geqq 0, \tag{10}$$

we obtain, by using the above convergence relations,

$$(Qc, c) - 2(Qc, c) + (Bc, c) \geqq 0.$$

THEOREM 3. *Let* A^ε *satisfy the condition* (*), MA2 $[(A^\varepsilon)^{-1}] \xrightarrow{13} (E)^{-1}$, $A^\varepsilon \xrightarrow{H} Q$. *Then* $Q_{1313} \geqq E_{1313}$.

Proof. We consider v^ε_{kh} given by (2) with $c_{13} \neq 0$, $c_{sq} = 0$ for $(sq) \neq (13)$, $d_{ij} = -E_{ijkh}c_{kh}$, and w^ε_{kh} the sequence given in Proposition 2 for MA2 $[(A^\varepsilon)^{-1}]$ and the constants d_{ij}. Considering

$$\text{MA2}\,((A^\varepsilon)^{-1}(A^\varepsilon v^\varepsilon + w^\varepsilon), A^\varepsilon v^\varepsilon + w^\varepsilon) \geqq 0, \tag{11}$$

we notice that w^ε_{13} depends only on x_2. Consequently,

$$\begin{aligned} & \text{div}\,(w^\varepsilon_{13}, 0, \cdots, 0) = 0, \qquad & & \text{rot}\,(\partial u^\varepsilon_3/\partial x_1, \partial u^\varepsilon_3/\partial x_2, \cdots, \partial u^\varepsilon_3/\partial x_n) = 0, \\ & \text{div}\,(0, 0, w^\varepsilon_{13}, 0, \cdots, 0) = 0, \qquad & & \text{rot}\,(\partial u^\varepsilon_1/\partial x_1, \partial u^\varepsilon_1/\partial x_2, \cdots, \partial u^\varepsilon_1/\partial x_n) = 0. \end{aligned}$$

Using the compensated compactness method for MA2$(v^\varepsilon, w^\varepsilon)$, we obtain

$$\int_\Omega w_{13}^\varepsilon(\partial u_1^\varepsilon/\partial x_3+\partial u_3^\varepsilon/\partial x_1)/2\cdot\phi\to\int_\Omega c_{13}d_{13}\phi,\quad \forall\phi\in C_0^\infty(\Omega).$$

Remark 1, together with condition (*), implies the following convergence relations, in the weak sense of $L_2(\Omega)$:

$$MA2\,((A^\varepsilon)^{-1}(A^\varepsilon v^\varepsilon), A^\varepsilon v^\varepsilon)\rightharpoonup(Qc, c),$$
$$\mathrm{MA2}((A^\varepsilon)^{-1}(A^\varepsilon v^\varepsilon), w^\varepsilon)\rightharpoonup d_{13}c_{13},$$
$$\mathrm{MA2}\,((A^\varepsilon)^{-1}(w^\varepsilon), w^\varepsilon)=(\mathrm{MA2}\,(A^\varepsilon)^{-1}w^\varepsilon, w^\varepsilon)\rightharpoonup(E^{-1}d, d).$$

Taking into account condition (*) we obtain, by a proof similar to the second part of Theorem 1, MA2 $((A^\varepsilon)^{-1}w^\varepsilon, A^\varepsilon v^\varepsilon)\rightharpoonup d_{13}c_{13}$. The above convergence relations together with relation (11) imply, as in Theorem 1, that $Q_{1313}-E_{1313}\geqq 0$. □

2. A particular configuration. The example given in this section is meant to illustrate the above theoretical results. Hashin and Rosen studied in [3] a composite material formed by cylindrical fibers of radii r, disposed in the vertex of a hexagonal array, surrounded by a matrix. Their method is based on an exact solution in cylindrical coordinates, and for this reason the interior of each hexagon is partially filled by the matrix, which is formed of cylinders of radii $\frac{1}{2}$ if the edge lengths of these hexagons are equal to one. We consider the medium formed by periodic parallelograms (Fig. 1).

The stress-strain relation is written in the reduced form:

$$\begin{aligned}
&\sigma_{11}=C_{11}e_{11}+C_{12}e_{22}+C_{12}e_{33},\\
&\sigma_{22}=C_{12}e_{11}+C_{22}e_{22}+C_{23}e_{33},\\
&\sigma_{33}=C_{12}e_{11}+C_{23}e_{22}+C_{22}e_{33},\\
&\sigma_{12}=2C_{44}e_{12},\qquad \sigma_{13}=2C_{44}e_{13},\\
&\sigma_{23}=(C_{22}-C_{23})\cdot e_{23},
\end{aligned}\tag{12}$$

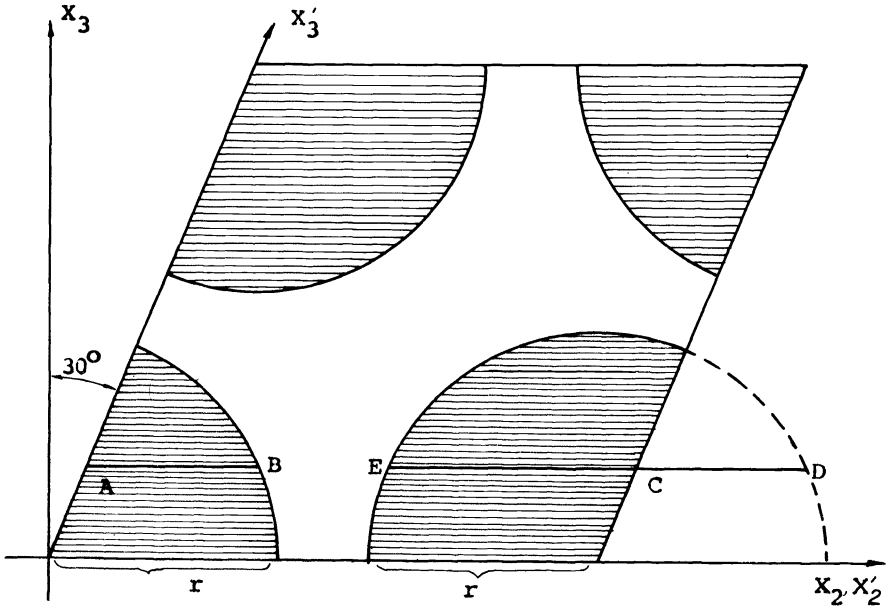

FIG. 1

where the usual six-by-six matrix notation has been used. C_{11} stands for a_{1111}, C_{12} stands for a_{1122}, and so on. The coefficients have the usual symmetry properties and depend only on x_2 and x_3; $a_{1313}=a_{1212}$.

The same type of isotropy is considered for the corresponding homogeneous medium. In [6] the estimates are obtained in a coordinate system parallel to the directions of a periodicity. We have to transform the original Cartesian form of the equation

$$\partial(a^{\varepsilon}_{ijkh}\partial u^{\varepsilon}_k/\partial x_h)/\partial x_j = F_i \tag{13}$$

for the new system since this one has angles of 60° between the coordinate axes. If $\underline{g}_k$ and $\underline{f}_p$ are, respectively, the unit vectors of the Cartesian and oblique coordinates, we have

$$\underline{g}_k = \alpha_{pk}\cdot \underline{f}_p, \qquad \underline{f}_p = \beta_{kp}\cdot \underline{g}_k,$$

$$\alpha = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & -1/\sqrt{3} \\ 0 & 0 & 2/\sqrt{3} \end{pmatrix}, \qquad \beta = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 1/2 \\ 0 & 0 & \sqrt{3}/2 \end{pmatrix}.$$

Then from (13) we obtain

$$\partial(A^{\varepsilon}_{pqst}\partial u^{\varepsilon'}_s/\partial x'_t)/\partial x'_q = F'_p$$

where $'$ denotes the components in the new system and

$$2\cdot A_{pqst} = \alpha_{pi}\beta_{qj}(\beta_{hs}\alpha_{tk}+\beta_{ks}\alpha_{th})a_{ijkh}.$$

Consequently, the stress-strain relations in the new system have the following form:

$$\begin{aligned}
&\sigma'_{11} = a_{1111}e'_{11}+a_{1122}e'_{22}+a_{1133}e'_{33},\\
&\sigma'_{22} = (4a_{2211}/3)e'_{11}+(5a_{2222}-a_{3322})/3\cdot e'_{22}+(5a_{2233}-a_{2222})/3\cdot e'_{33}-(4a_{2323}/3)e'_{23},\\
&\sigma'_{33} = (4a_{3311}/3)e'_{11}+(4a_{3322}/3)e'_{22}+(4a_{3333}/3)e'_{33},\\
&\sigma'_{12} = (4a_{1313}/3)e'_{12}-(2a_{1313}/3)e'_{13},\\
&\sigma'_{13} = -(2a_{1313}/3)e'_{12}+(4a_{1313}/3)e'_{13},\\
&\sigma'_{23} = -(2a_{3311}/3)e'_{11}-(2a_{2222}/3)e'_{22}-(2a_{2233}/3)e'_{33}+(4a_{2323}/3)e'_{23},
\end{aligned} \tag{14}$$

therefore $A_{1313}=A_{1212}=4a_{1313}/3$. Notice that the matrix A^{ε}_{pqst} satisfies the conditions (*): $A^{\varepsilon}_{13sq}=A^{\varepsilon}_{sq13}$.

We note that

$$(A^{\varepsilon})^{-1}_{12st}=(A^{\varepsilon})^{-1}_{st12} \quad \text{and} \quad (A\varepsilon)^{-1}_{13st}=(A^{\varepsilon})^{-1}_{st13}.$$

These are direct consequences of the fact that columns 12 and 13 become proportional after we eliminate row 13, as well as rows 12 and 13, which become proportional after we eliminate column 13. Therefore

$$(A^{\varepsilon})^{-1}_{sq13}=0, \quad (A^{\varepsilon})^{-1}_{sq12}=0, \quad (A^{\varepsilon})^{-1}_{13sq}=0, \quad (A^{\varepsilon})^{-1}_{12sq}=0$$

for $sq\neq 13$ and 12. The minors of the elements A^{ε}_{1312} and A^{ε}_{1213} are both equal to

$$-(2a^{\varepsilon}_{1313}/3)\begin{vmatrix} A^{\varepsilon}_{1111} & A^{\varepsilon}_{1122} & A^{\varepsilon}_{1133} & 0 \\ A^{\varepsilon}_{2211} & A^{\varepsilon}_{2222} & A^{\varepsilon}_{2233} & A^{\varepsilon}_{2323} \\ A^{\varepsilon}_{2311} & A^{\varepsilon}_{2322} & A^{\varepsilon}_{2323} & 0 \end{vmatrix},$$

and, consequently, we have $(A^{\varepsilon})^{-1}_{13sq}=(A^{\varepsilon})^{-1}_{sq13}$, $(A^{\varepsilon})^{-1}_{12sq}=(A^{\varepsilon})^{-1}_{sq12}$.

The element $(A^\varepsilon)^{-1}_{1313}$, obtained using the development of $\det(A^\varepsilon)$ with respect to the row A^ε_{12sq}, is given by

$$(A^\varepsilon)^{-1}_{1313} = 1/a^\varepsilon_{1313}. \tag{15}$$

We note that $(A^\varepsilon)^{-1}_{1313}$ is used to construct the sequence w^ε defined in Theorem 3; it is important to see that the homogenized coefficient corresponding to a^ε_{1313} is estimated in [3] using only the values of this coefficient; in the method presented here, the estimates may generally depend on the other coefficients.

Following Definition 3, we must compute the 13-limit of the harmonical mean with respect to x'_3 and the 13-limit of the arithmetical mean with respect to x'_2 of the coefficient A^ε_{1313}, thus obtaining upper and lower bounds for it:

$$\lim_{13\ \varepsilon\to 0} \mathrm{MA3}\,(A^\varepsilon_{1313}) = B_{1313}, \qquad \lim_{13\ \varepsilon\to 0} \mathrm{MA2}\,[(A^\varepsilon)^{-1}_{1313}] = E^{-1}_{1313}.$$

Finally we obtain $E_{1313} \leqq Q_{1313} \leqq B_{1313}$, where $A^\varepsilon \xrightarrow{H} Q$. Using the method described here, it is possible to obtain bounds for the effective coefficients in the case when the space between the periodical fibers is completely filled by the matrix of low resistance. We consider this situation in the sequel.

Now we analyze the geometry of the periodicity cell (Fig. 1). In the vertex of the romb of edge lengths 1 and 60° in the origin are situated sectors of radii r and 60° (respectively, 120°), filled by the fiber. The rest of the romb is filled by the matrix of low resistance. We can see that $AB = CD$. For simplicity we put $x'_3 = t$, $x'_2 = s$. We have (see Fig. 2)

$$t = OM, \qquad OZ = t\sqrt{3}/2,$$
$$ZH = (\sqrt{4r^2 - 3t^2})/2, \qquad UH = 2 \cdot ZH = \sqrt{4r^2 - 3t^2}.$$

The maximum value of t for which a parallel line to Os intersects the circle of radii r is $ON = 2r/\sqrt{3}$. We consider the case when such a parallel may intersect only two circles (the centers of which are situated on Os), then we consider $r \leqslant \sqrt{3}/4$, which is in accordance with the above hypothesis.

We let $A_{1313} = h$ in the fiber, $A_{1313} = 1$ in the matrix.

For the upper bound we have

$$\mathrm{MA2}\,(A_{1313}) = \begin{cases} h\sqrt{4r^2 - 3t^2} + 1 - \sqrt{4r^2 - 3t^2}, & t \in (0, 2r/\sqrt{3}), \\ 1, & t \in (2r/\sqrt{3}, 1/2), \end{cases}$$

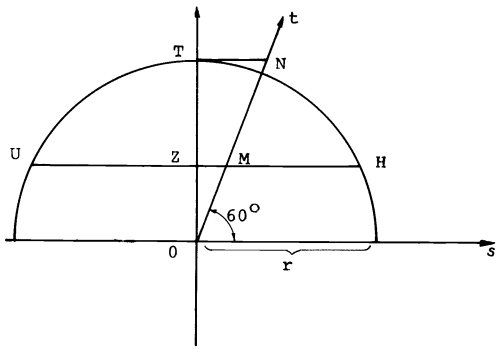

FIG. 2

and using the fact that the weak limit in $L_2(\Omega)$ of a periodic function of (x/ε), for $\varepsilon \to 0$, is the mean value on a cell (see [5]), we obtain

$$A^+_{1313} = \left\{ 2 \cdot \int_0^{2r/\sqrt{3}} [(h-1)\sqrt{4r^2-3t^2}+1]^{-1}\, dt + 1 - 4r/\sqrt{3} \right\}^{-1}. \tag{17}$$

The lower bound is given by

$$A^-_{1313} = 2 \cdot \int_0^{2r/\sqrt{3}} \left[\left(\frac{1}{h} - 1 \right) \sqrt{4r^2-3t^2}+1 \right]^{-1} dt + 1 - 4r/\sqrt{3}. \tag{18}$$

Hashin and Rosen [3] obtained the following bounds:

$$G^+(m_g v_1 + v_2), \tag{19}$$

$$G^-(v_1/m_g + v_2)^{-1} \tag{20}$$

where

$$m_g = [h(1+b^2)+1-b^2]/[h(1-b^2)+1+b^2], \qquad b = 2r,$$

$$v_1 = 0.918, \qquad v_2 = 0.082 = 1 - v_1.$$

In order to compare these two methods, we compute the expressions (17)-(20) for different values of h and r. Considering, for example, $r = 0.2$ and $r = 0.3$, we obtain the results in Tables 1 and 2. We can see that in general the estimates given in [3] are more precise than those given by the method presented here.

TABLE 1
$r = 0.2$.

h	A^-_{1313}	G^-	G^+	A^+_{1313}
2	0.819	1.103	1.112	0.840
3	0.846	1.157	1.159	0.907
6	0.879	1.232	1.236	1.037
10	0.889	1.275	1.282	1.140
20	0.908	1.302	1.310	1.236
30	0.909	1.314	1.323	1.271
50	0.912	1.323	1.333	1.315
100	0.914	1.331	1.341	1.351
⋮	⋮	⋮	⋮	⋮
∞	0.917	1.339	1.349	1.393

TABLE 2
$r = 0.3$.

h	A^-_{1313}	G^-	G^+	A^+_{1313}
5	1.086	1.551	1.579	1.341
15	1.198	1.785	1.844	1.846
35	1.236	1.872	1.945	2.116
65	1.250	1.905	1.984	2.249
115	1.258	1.922	2.005	2.326
195	1.262	1.931	2.016	2.371
⋮	⋮	⋮	⋮	⋮
∞	1.268	1.945	2.032	2.441

We want to emphasize that only for A_{1313} is it possible to obtain both upper and lower limits using the above theoretical results. Generally, only the upper limit may be computed, since A^ε verifies the condition (*) (see Definition 2).

Hashin and Rosen [3] also presented the bounds corresponding to the following constants:

$$K_{23} = (a_{2222} + a_{2233}), \qquad G_{23} = (a_{2222} - a_{2233}),$$
$$E_1 = a_{1111} - 2a_{1122}/(a_{2222} + a_{2233}).$$

If we consider $\lambda_{22} = \lambda_{33} = 1$, $\lambda_{ij} = 0$ for $(ij) \neq (22)$ and (33), then relations (14) and (12) give us

$$A_{ijkh}\lambda_{ij}\lambda_{kh} = 8 \cdot (a_{2222} + a_{2233})/3.$$

For $\lambda_{23} = 1$, $\lambda_{ij} = 0$ if $(ij) \neq (23)$, we obtain

$$A_{ijkh}\lambda_{ij}\lambda_{kh} = 4 \cdot a_{2323}/3 = 4(C_{22} - C_{23})/3$$
$$= 4(a_{2222} - a_{2233})/3.$$

Therefore we can apply our method to obtain upper bounds for the constants K_{23} and G_{23}. Since in general the coefficients with $ij \neq kh$ cannot be directly estimated, it seems that the method presented here is not applicable for E_1 (which represents the longitudinal Young modulus).

SMOOTHING PROPERTIES OF LINEAR VOLTERRA INTEGRODIFFERENTIAL EQUATIONS*

W. DESCH† AND R. GRIMMER‡

Abstract. Boundary value problems for hyperbolic linear partial differential integral equations of convolution type on an interval are studied. A necessary and sufficient condition on the convolution kernel is given such that discontinuities of the boundary data are smoothed in the interior of the interval. The result is applied to consider dynamics of viscoelastic media.

Key words. integrodifferential equations, Rayleigh problem, viscoelastic material, propagation of singularities

AMS(MOS) subject classifications. 45K05, 73D99

1. Introduction. We study propagation of singularities by a linear first-order hyperbolic partial differential integral equation in one space variable, namely

$$u_t(t,\xi) = au_\xi(t,\xi) + cu(t,\xi) + \int_0^t [d(t-s)u_\xi(s,\xi) + \dot{h}(t-s)u(s,\xi)]\,ds, \tag{1}$$
$$(t \geqq 0, \quad \xi \in (\xi_1, \xi_2))$$

with initial boundary conditions

$$u(0,\xi) = 0, \quad b_j u(t,\xi_j) = v_j(t) \quad (j = 1, 2).$$

u is considered to be vector valued and a, c, d, h, b_j are matrices. Thus the problem includes the standard first-order transcription of

$$u_{tt}(t,\xi) = G(0)u_{\xi\xi}(t,\xi) + \int_0^t G'(t-s)u_{\xi\xi}(s,\xi)\,ds \tag{2}$$

with suitable initial and boundary conditions.

The latter equation describes the dynamics of a linearly viscoelastic homogeneous medium (given sufficient symmetry to reduce the problem to one space dimension). (See, e.g., [2], [3].) Considerable effort has been spent investigating how a discontinuity in the initial or boundary data is propagated to the interior of the interval. A major part of the literature, such as [1], [6]-[9], [12]-[15], [20a-c], treats the case that the kernel d is sufficiently smooth (i.e., it admits at least two locally integrable derivatives). Reference [5] considers a similar situation in a nonlinear setting. In this case, a jump discontinuity in the boundary data gives rise to a jump discontinuity in the solution, traveling back and forth between the boundaries. The presence of a memory term does not affect the hyperbolic character of the equation, not even the wave speed of the discontinuity; its only effect is exponential damping of the stepsize of the discontinuity. However, in [19], Renardy has pointed out that the scene changes drastically as d is allowed to be unbounded at $t = 0$. He shows that singular kernels may generate solutions

that are infinitely often differentiable in the interior of the interval, though discontinuous on the boundary. This fits very well to a result in [10], showing that unboundedness of the kernel together with suitable monotonicity conditions implies that the resolvent operator to the integrodifferential equation is compact; smoothing is likely to be expected in this case.

A recent paper by Hrusa and Renardy [11] shows that the situation is even a bit more complicated. When kernels with different types of singularities at $t=0$ are compared, they indicate that whether the solution is C^∞ across the characteristics at any time $t>0$ or does not gain any differentiability at all depends on the boundedness of $G'(t)/\ln(t)$ rather than $G'(t)$. In the limiting case that G' has a logarithmic singularity, the solution gains smoothness gradually as time increases. (Dealing with inhomogeneous boundary data rather than initial data, this means that the solution becomes smoother and smoother as we proceed deeper into the space interval.)

While writing this paper, we became aware of a contemporaneous study by Prüss, [17], which examines an integrated version of (2). The second derivative of u with respect to ξ is replaced by the generator of a cosine family, while the scalar function $G(t)$ may be replaced by a Stieltjes measure of specified type that includes the case G is completely monotone. We will compare our work with both [11] and [17] in the last section of this paper.

While the work in [11] is done by explicit computation of various examples, this paper means to give a general theorem characterizing the kernels d that lead to smoothing of the solution of a first-order hyperbolic system. Moreover, we give a formula for the space interval needed to gain one degree of differentiability in the limiting case. Unfortunately, our results for the general case (1) are very technical. If $d(t)$ is a scalar multiple $\varphi(t)d$ of a constant matrix d, considerable simplifications can be carried out. In particular, if φ is convex decreasing, smoothing depends on $\lim_{t\to 0}\varphi(t)/\ln(t)$, in accordance with [11].

In the last section of this paper, we apply our results to some nonscalar problems in viscoelasticity where we encounter equations in which $d(t)$ is not a scalar multiple of a constant matrix, e.g., a Timoshenko beam. It will be seen that many such problems can be treated with our techniques.

2. The main theorems. We consider the following equation:

$$
\begin{aligned}
&u_t(t,\xi) = au_\xi(t,\xi) + cu(t,\xi) + \int_0^t [d(t-s)u_\xi(s,\xi) + h(t-s)u(s,\xi)]\,ds,\\
&b_j u(t,\xi_j) = v_j(t) \qquad (j=1,2),\\
&u(0,\xi) = 0\\
&\text{for } t\geqq 0,\ \xi\in[\xi_1,\xi_2].
\end{aligned}
\tag{2.1}
$$

The solution u is supposed to be an $\mathbb{R}^n$-valued function on $[0,\infty)\times[\xi_1,\xi_2]$. Our hypotheses on the coefficients are the following.

Hypothesis 2.1. (a) a is a real $n\times n$-matrix that has n distinct real eigenvalues $\lambda_1<\cdots<\lambda_m<0<\lambda_{m+1}<\cdots<\lambda_n$. By $\{e_i\colon i=1\cdots n\}$ we denote a system of eigenvectors of a corresponding to the eigenvalues λ_i, respectively. $\{f_i\colon i=1\cdots n\}$ is a system of eigenvectors of the transposed matrix a^*, such that $f_i^* e_j=\delta_{ij}$. r is the $n\times n$-matrix $(f_1\cdots f_n)^*$; thus $r^{-1}=(e_1\cdots e_n)$, and $rar^{-1}=\operatorname{diag}(\lambda_1\cdots\lambda_n)$. We put $\kappa_i=\lambda_i^{-1}$, and for $i=1\cdots m$, $\delta_i=-1$, while $\delta_i=1$ for $i=m+1\cdots n$.

(b) Putting $m_1 = m$ and $m_2 = n - m$, we assume for $j = 1, 2$ that b_j is a real $m_j \times n$-matrix and that the matrices $(b_1 e_1 \cdots b_1 e_m)$ and $(b_2 e_{m+1} \cdots b_2 e_n)$ are invertible. (We may assume without loss of generality that they are $m_j \times m_j$ unit matrices.)

(c) c is a real $n \times n$-matrix.

(d) For some $\gamma \geqq 0$, the function $t \to e^{-\gamma t} d(t)$ is a real $n \times n$-matrix valued integrable function on $[0, \infty)$ and $te^{-\gamma t} d(t)$ is in $W^{1,1}(0, \infty)$.

(h) The function $t \to e^{-\gamma t} h(t)$ is a real $n \times n$-matrix valued integrable function on $[0, \infty)$.

(v) The functions $t \to e^{-\gamma t} v_j(t)$, $(j = 1, 2)$ are in $L^2([0, \infty), \mathbb{R}^{m_j})$.

(Hypothesis 2.1(a), (b), (c), (v) makes (2.1) without the convolution terms a hyperbolic first-order initial boundary value problem that is well posed in $L^2([\xi_1, \xi_2], \mathbb{R}^n)$. Parts (d), (h) of the hypothesis are minimal boundedness assumptions on the convolution kernels.)

Before we can state our second hypothesis, we need to introduce the Laplace transform $\hat{}$:

$$\hat{d}(\tau) = \int_0^\infty e^{-t\tau} d(t)\, dt \quad \text{(which exists for Re } \tau \geqq \gamma).$$

Since $\lim_{|\tau| \to \infty,\, \mathrm{Re}\, \tau \geqq \gamma} \hat{d}(\tau) = 0$, we may choose some θ sufficiently large such that for $\mathrm{Re}\, \tau \geqq \theta$ the matrix $a + \hat{d}(\tau)$ has n distinct eigenvalues $\lambda_1(\tau) \cdots \lambda_n(\tau)$ (converging to $\lambda_1 \cdots \lambda_n$ as $|\tau| \to \infty$), and that $\operatorname{sgn} \mathrm{Re}\, \lambda_i(\tau) = \operatorname{sgn} \lambda_i = \delta_i \neq 0$. In particular, $(a + \hat{d}(\tau))^{-1}$ exists with eigenvalues $\kappa_i(\tau) = \lambda_i^{-1}(\tau)$.

Hypothesis 2.2. There exists a constant M such that for $\rho \geqq \theta$, $\sigma \in \mathbb{R}$, $j = 1 \cdots n$, $\delta_j \sigma\, \mathrm{Im}\, \kappa_j(\rho + i\sigma) \leqq M$.

(A discussion of ways to verify this hypothesis will be given in § 4.)

Taking Laplace transforms in (2.1), we obtain

$$\begin{aligned} &\tau \hat{u}(\tau, \xi) = (a + \hat{d}(\tau)) \hat{u}_\xi(\tau, \xi) + (c + \hat{h}(\tau)) \hat{u}(\tau, \xi), \\ &b_j \hat{u}(\tau, \xi_j) = \hat{v}_j(\tau) \qquad (j = 1, 2) \\ &\text{for Re } \tau \text{ sufficiently large and } \xi \in [\xi_1, \xi_2]. \end{aligned} \tag{2.2}$$

It has been suggested by one of the referees that Hypothesis 2.2 may be equivalent to the well-posedness of (2.1). It seems clear that this hypothesis is intimately related to the well-posedness of (2.1) in $L^2((\xi_1, \xi_2), \mathbb{R}^n)$ with arbitrary boundary matrices b_j that are subject to Hypothesis 2.1; however, the proof of such a relation would seem to be quite lengthy and technical. Being interested in propagation of singularities rather than problems of well-posedness, we confine ourselves to the following existence result.

THEOREM 2.1. *Suppose Hypotheses* 2.1 *and* 2.2 *are valid. Then there exists a unique function* $u : [0, \infty) \times [\xi_1, \xi_2] \to \mathbb{R}^n$, *such that for sufficiently large* θ *and each* $\xi \in [\xi_1, \xi_2]$, *the function* $t \to e^{-\theta t} u(t, \xi)$ *is in* $L^2([0, \infty), \mathbb{R}^n)$, *and the Laplace transform* $\hat{u}(\tau)$ *satisfies* (2.2).

To state our main result on smoothing we introduce the numbers

$$\tilde{\beta}_1(\tau) = \max_{j = 1 \cdots m} (-\mathrm{Im}\, \kappa_j(\tau)), \qquad \tilde{\beta}_2(\tau) = \max_{j = m+1 \cdots n} (\mathrm{Im}\, \kappa_j(\tau))$$

for $\mathrm{Re}\, \tau \geqq \theta$, $\mathrm{Im}\, \tau \geqq 0$, and

$$\alpha_j^+ = \lim_{\sigma \to \infty} \sup -\sigma \tilde{\beta}_j(\theta + i\sigma)/\ln \sigma, \qquad \alpha_j^- = \lim_{\sigma \to \infty} \inf -\sigma \tilde{\beta}_j(\theta + i\sigma)/\ln \sigma.$$

(By Hypothesis 2.2, $-\sigma \tilde{\beta}_j(\theta + i\sigma)$ is bounded from below, thus $\alpha_j^\pm \in [0, \infty]$.)

THEOREM 2.2. *Suppose Hypotheses* 2.1 *and* 2.2 *are valid and choose* θ *sufficiently large (according to the hypotheses of this section and Theorem* 2.1*). Let* $k>0$ *be a real number. If* $(\xi-\xi_1)\alpha_1^- > k$ *and* $(\xi_2-\xi)\alpha_2^- > k$, *then for all boundary data* v_j *according to* (v) *the solution* $t \to e^{-\theta t}u(t,\xi)$ *is in* $W^{k,2}([0,\infty),\mathbb{R}^n)$. *If* $(\xi-\xi_1)\alpha_1^+ < k$ *or* $(\xi_2-\xi)\alpha_2^+ < k$, *then there exist boundary data* v_1 *and* v_2 *such that* $e^{-\theta t}u(t,\xi)$ *is not contained in* $W^{k,2}([0,\infty),\mathbb{R}^n)$.

Thus, if $\alpha_j^- = \alpha_j^+ = \alpha_j$, then $\alpha_1(\alpha_2)$ may be viewed as the reciprocal of the distance from the left (right) boundary needed to gain one degree of differentiability. If $\alpha_j^+ = 0$, no differentiability is obtained unless the boundary data are sufficiently smooth themselves. On the other hand, if $\alpha_j^- = \infty$, all boundary data are immediately smoothed to C^∞. Notice also, that $\alpha_j^\pm$ depends only on d and a, while c and h have no bearing on the degree of smoothing.

Remark. The definitions of the $\alpha_j^\pm$ are independent of θ for sufficiently large θ. This follows from the assumption that $e^{-\gamma t}t\,d(t) \in W^{1,1}(0,\infty)$. This independence is, in fact, the only reason for this smoothness assumption. To see this independence, we note that because a has distinct nonzero eigenvalues, we can appeal to the differentiability of $(a+\hat{d}(\tau))^{-1}$ to obtain $|\kappa_j(\tau_1)-\kappa_j(\tau)| = O(\|\hat{d}(\tau_1)-\hat{d}(\tau)\|)$ where $\tau_1 = \theta_1 + i\sigma$ and $\tau = \theta + i\sigma$. However, for $\theta > \theta_1$,

$$\hat{d}(\tau)-\hat{d}(\tau_1) = \int_0^\infty e^{-(\theta_1+i\sigma)t}\frac{[e^{-(\theta-\theta_1)t}-1]}{t}\,t\,d(t)\,dt$$
$$= O(\sigma^{-1}),$$

as it is the transform of a $W^{1,1}$ function. Hence,

$$\left|\frac{\sigma}{\ln\sigma}(\kappa_j(\tau_1)-\kappa_j(\tau))\right| \to 0 \quad \text{as } \sigma\to\infty.$$

3. Proof of Theorems 2.1 and 2.2. Throughout this section, let us assume that θ is sufficiently large, and $\tau = \rho + i\sigma$ with $\rho \geqq \theta$ and $\sigma > 0$.

From (2.2) we obtain

$$\hat{u}_\xi(\tau,\xi) = \tau(a+\hat{d}(\tau))^{-1}(I-\tau^{-1}(c+\hat{h}(\tau)))\hat{u}(\tau,\xi) =: \tau l(\tau)\hat{u}(\tau,\xi). \tag{3.1}$$

(I denotes the $n\times n$ unit matrix.)

As θ is chosen sufficiently large and $\lim_{|\tau|\to\infty,\,\mathrm{Re}\,\tau\geqq\gamma} l(\tau) = a^{-1}$, the matrix $l(\tau)$ possesses n distinct eigenvalues $\mu_1(\tau)\cdots\mu_n(\tau)$ converging to $\kappa_1\cdots\kappa_n$. In particular, $\operatorname{sgn}\mathrm{Re}\,\mu_j(\tau) = \delta_j$. Now, for $|\tau|\to\infty$, $\|l(\tau)-(a+\hat{d}(\tau))^{-1}\| = O(|\tau^{-1}|)$; thus also $|\mu_j(\tau)-\kappa_j(\tau)| = O(|\tau^{-1}|)$. This implies that Hypothesis 2.2 as well as the values for $\alpha_j^\pm$ remain the same if κ_i is replaced by μ_i and $\tilde{\beta}_j$ is replaced by $\beta_1 = \max_{j=1\cdots m} -\mathrm{Im}\,\mu_j(\tau)$, $\beta_2 = \max_{j=m+1\cdots n}\mathrm{Im}\,\mu_j(\tau)$.

Moreover, $l(\tau)$ can be diagonalized by a matrix $r(\tau)$ converging to r as $|\tau|\to\infty$, so that

$$r(\tau)l(\tau)r^{-1}(\tau) = \operatorname{diag}(\mu_1(\tau)\cdots\mu_n(\tau)) = k(\tau)\to\operatorname{diag}(\kappa_1\cdots\kappa_n).$$

We write $r^{-1}(\tau)$ in the form $(e_1(\tau)\cdots e_n(\tau))$ where $e_j(\tau)\to e_j$.

Putting $\tilde{u}(\tau,\xi) = r(\tau)\hat{u}(\tau,\xi)$, we obtain from (3.1) and the boundary conditions

$$\tilde{u}_\xi(\tau,\xi) = \tau k(\tau)\tilde{u}(\tau,\xi), \qquad b_j r^{-1}(\tau)\tilde{u}(\tau,\xi_j) = \hat{v}_j(\tau). \tag{3.2}$$

Consequently, the ith coefficient $\tilde{u}_i$ of $\tilde{u}$ satisfies

$$\tilde{u}_i(\tau,\xi) = \exp(\tau\mu_i(\tau)(\xi-\xi_1))\tilde{u}_i(\tau,\xi_1) = \exp(-\tau\mu_i(\tau)(\xi_2-\xi))\tilde{u}_i(\tau,\xi_2).$$

We put $U(\tau)=(\tilde{u}_1(\tau,\xi_1)\cdots\tilde{u}_m(\tau,\xi_1),\tilde{u}_{m+1}(\tau,\xi_2)\cdots\tilde{u}_n(\tau,\xi_2))^t$ and let U_i be the ith coefficient of U. So

$$\begin{aligned}&\tilde{u}_i(\tau,\xi)=\exp(-\delta_i\tau\mu_i(\tau)(\xi-\xi_1))U_i(\tau)\quad\text{for } i=1\cdots m,\quad\text{and}\\&\tilde{u}_i(\tau,\xi)=\exp(-\delta_i\tau\mu_i(\tau)(\xi_2-\xi))U_i(\tau)\quad\text{for } i=m+1\cdots n.\end{aligned}\tag{3.3}$$

To estimate the solution, we use Hypothesis 2.2 and obtain

$$\operatorname{Re}(\delta_i\tau\mu_i(\tau))=\rho\delta_i\operatorname{Re}\mu_i(\tau)-\sigma\delta_i\operatorname{Im}\mu_i(\tau)\geqq\theta\delta_i\operatorname{Re}\mu_i(\tau)-M.$$

As $\operatorname{Re}\mu_i(\tau)$ is bounded away from 0 (for large θ) and θ may be chosen large, we can achieve that $\operatorname{Re}(\delta_i\tau\mu_i(\tau))>0$ is arbitrarily large. In particular, by (3.3), we have $\|\tilde{u}(\tau,\xi)\|\leqq\|U(\tau)\|$.

The values of $U(\tau)$ are determined by the boundary conditions: As the matrices $b_1(e_1\cdots e_m)$ and $b_2(e_{m+1}\cdots e_n)$ are invertible, the matrices $p_1(\tau)=b_1(e_1(\tau)\cdots e_m(\tau))$ and $p_2(\tau)=b_2(e_{m+1}(\tau)\cdots e_n(\tau))$ are also (provided θ is chosen large). We put $q_1(\tau)=b_1(e_{m+1}(\tau)\cdots e_n(\tau))$ and $q_2(\tau)=b_2(e_1(\tau)\cdots e_m(\tau))$. Then the boundary conditions can be written in the form

$$\begin{bmatrix}\tilde{u}_1(\tau,\xi_1)\\\vdots\\\tilde{u}_m(\tau,\xi_1)\end{bmatrix}+p_1^{-1}(\tau)q_1(\tau)\begin{bmatrix}\tilde{u}_{m+1}(\tau,\xi_1)\\\vdots\\\tilde{u}_n(\tau,\xi_1)\end{bmatrix}=p_1^{-1}(\tau)\hat{v}_1(\tau),$$

$$\begin{bmatrix}\tilde{u}_{m+1}(\tau,\xi_2)\\\vdots\\\tilde{u}_n(\tau,\xi_2)\end{bmatrix}+p_2^{-1}(\tau)q_2(\tau)\begin{bmatrix}\tilde{u}_1(\tau,\xi_2)\\\vdots\\\tilde{u}_m(\tau,\xi_2)\end{bmatrix}=p_2^{-1}(\tau)\hat{v}_2(\tau).$$

Let $Q(\tau)$ be the block matrix

$$\begin{bmatrix}0 & p_2^{-1}(\tau)q_2(\tau)\operatorname{diag}_{i=1\cdots m}(e^{\tau\mu_i(\tau)(\xi_2-\xi_1)})\\ p_1^{-1}(\tau)q_1(\tau)\operatorname{diag}_{i=m+1\cdots n}(e^{-\tau\mu_i(\tau)(\xi_2-\xi_1)}) & 0\end{bmatrix}.$$

Then we obtain from (3.3)

$$U(\tau)+Q(\tau)U(\tau)=\begin{bmatrix}p_1^{-1}(\tau)\hat{v}_1(\tau)\\p_2^{-1}(\tau)\hat{v}_2(\tau)\end{bmatrix}.\tag{3.4}$$

Choosing θ sufficiently large, we can achieve that $\|Q(\tau)\|<1/4n$, so that there exists a unique solution $U(\tau)$ to (3.4) with some bound $\|U(\tau)\|\leqq N(\|\hat{v}_1(\tau)\|+\|\hat{v}_2(\tau)\|)$.

If $\theta\geqq\gamma$, the function $\sigma\to\hat{v}_j(\theta+i\sigma)$ is in $L^2(\mathbb{R},\mathbb{C}^n)$ by Plancherel's theorem. Hence for fixed $\xi\in[\xi_1,\xi_2]$, $\hat{u}(\theta+i\sigma,\xi)=r^{-1}(\theta+i\sigma)\tilde{u}(\theta+i\sigma,\xi)$ is also in $L^2(\mathbb{R},\mathbb{C}^n)$. Inverting the Laplace transform by a contour integral from $\theta-i\infty$ to $\theta+i\infty$, we obtain, again by Plancherel's theorem, that the function $t\to e^{-\theta t}u(t,\xi)$ is contained in $L^2(\mathbb{R},\mathbb{R}^n)$. This proves Theorem 2.1.

Let us now assume that $\alpha_1^-(\xi-\xi_1)>k$ and $\alpha_2^-(\xi_2-\xi)>k$, i.e., for sufficiently large $\sigma>0$,

$$-\sigma\beta_1(\theta+i\sigma)(\xi-\xi_1)/\ln\sigma>k\quad\text{and}\quad-\sigma\beta_2(\theta+i\sigma)(\xi_2-\xi)/\ln\sigma>k.$$

Consequently, for $j=1\cdots m$, $\sigma(\xi-\xi_1)\operatorname{Im}\mu_j(\theta+i\sigma)/\ln\sigma>k$, and for $j=m+1\cdots n$, $-\sigma(\xi_2-\xi)\operatorname{Im}\mu_j(\theta+i\sigma)/\ln\sigma>k$. Thus for sufficiently large σ and $j=1\cdots m$,

$$\begin{aligned}\operatorname{Re}((\theta+i\sigma)\mu_j(\theta+i\sigma)(\xi-\xi_1))&=\theta\operatorname{Re}\mu_j(\theta+i\sigma)(\xi-\xi_1)-\sigma\operatorname{Im}\mu_j(\theta+i\sigma)(\xi-\xi_1)\\&<-k\ln\sigma,\end{aligned}$$

while for $j = m+1 \cdots n$,

$$\operatorname{Re}((\theta+i\sigma)\mu_j(\theta+i\sigma)(\xi_2-\xi)) > k \ln \sigma.$$

By (3.3) we have for sufficiently large σ and $j = 1 \cdots m$,

$$\begin{aligned}|\tilde{u}_j(\theta+i\sigma, \xi)| &= \exp(\operatorname{Re}((\theta+i\sigma)\mu_j(\theta+i\sigma)(\xi-\xi_1)))|U_j(\theta+i\sigma)| \\ &\leqq \sigma^{-k}|U_j(\theta+i\sigma)|.\end{aligned}$$

Similarly for $j = m+1 \cdots n$,

$$\begin{aligned}|\tilde{u}_j(\theta+i\sigma, \xi)| &= \exp(-\operatorname{Re}((\theta+i\sigma)\mu_j(\theta+i\sigma)(\xi_2-\xi)))|U_j(\theta+i\sigma)| \\ &\leqq \sigma^{-k}|U_j(\theta+i\sigma)|.\end{aligned}$$

This implies that the function

$$\sigma \to \sigma^k \hat{u}(\theta+i\sigma, \xi) = \sigma^k r^{-1}(\theta+i\sigma)\tilde{u}(\theta+i\sigma, \xi)$$

is contained in $L^2([0,\infty), \mathbb{C}^n)$; thus by Plancherel's theorem, the function $t \to e^{-\theta t}u(t, \xi)$ is in $W^{k,2}([0,\infty), \mathbb{R}^n)$.

Assume conversely, that $(\xi-\xi_1)\alpha_1^+ < k$ or $(\xi_2-\xi)\alpha_2^+ < k$. Without loss of generality, we restrict our consideration to the first case; the second case is done similarly.

We choose some small $\varepsilon > 0$, such that $(\xi-\xi_1)\alpha_1^+ < k-2\varepsilon$, and a scalar function w such that $e^{-\gamma t}w(t) \in L^2([0,\infty), \mathbb{R})$, but $e^{-\theta t}w(t) \notin W^{\varepsilon,2}([0,\infty), \mathbb{R})$. Our boundary conditions are $v_1(t) = w(t) \cdot (1 \cdots 1)^t$, $v_2(t) = 0$. For sufficiently large $|\tau|$, we infer from (3.4) and $\|Q(\tau)\| \leqq 1/4n$ the following:

$$\left\| U(\tau) - \begin{bmatrix} p_1(\tau)\hat{v}_1(\tau) \\ p_2(\tau)\hat{v}_2(\tau) \end{bmatrix} \right\| \leqq \frac{1}{4n} \cdot \|U(\tau)\|; \quad \text{thus}$$

$$\|U(\tau)\| \leqq \frac{4}{3} \cdot \left\| \begin{bmatrix} p_1(\tau)\hat{v}_1(\tau) \\ p_2(\tau)\hat{v}_2(\tau) \end{bmatrix} \right\|, \quad \text{and}$$

$$\left\| U(\tau) - \begin{bmatrix} p_1(\tau)\hat{v}_1(\tau) \\ p_2(\tau)\hat{v}_2(\tau) \end{bmatrix} \right\| \leqq \frac{1}{3} \cdot \left\| \begin{bmatrix} p_1(\tau)\hat{v}_1(\tau) \\ p_2(\tau)\hat{v}_2(\tau) \end{bmatrix} \right\|.$$

Moreover, as $p_1(\tau) = b_1(e_1(\tau) \cdots e_m(\tau)) \to b_1(e_1 \cdots e_m) = I$, we have for sufficiently large $|\tau|$ that

$$p_1(\tau)(1 \cdots 1)^t = (\pi_1(\tau) \cdots \pi_m(\tau))^t \quad \text{with} \frac{3}{4} < |\pi_j(\tau)| < \frac{5}{4}.$$

Thus for $j = 1 \cdots m$

$$\begin{aligned}|U_j(\tau) - \hat{w}(\tau)\pi_j(\tau)| &\leqq 1/3n \cdot \|\hat{w}(\tau)(\pi_1(\tau) \cdots \pi_m(\tau), 0 \cdots 0)^t\| \\ &< 5|\hat{w}(\tau)|/12,\end{aligned}$$

$$\begin{aligned}|U_j(\tau)| &> |\hat{w}(\tau)\pi_j(\tau)| - 5|\hat{w}(\tau)|/12 > \left(\frac{3}{4} - \frac{5}{12}\right)|\hat{w}(\tau)| \\ &= |\hat{w}(\tau)|/3.\end{aligned}$$

As $(\xi-\xi_1)\alpha_1^+ < k-2\varepsilon$, we infer for sufficiently large σ that $-(\xi-\xi_1)\sigma\beta_1(\theta+i\sigma)/\ln\sigma < k-2\varepsilon$; thus there exists at least one $j \in \{1 \cdots m\}$ with $(\xi-\xi_1)\sigma \operatorname{Im}\mu_j(\theta+i\sigma) < (k-2\varepsilon)\ln\sigma$. Again considering sufficiently large σ, we obtain

$$\begin{aligned}(\xi-\xi_1)\operatorname{Re}((\theta+i\sigma)\mu_j(\theta+i\sigma)) &= (\xi-\xi_1)\theta \operatorname{Re}\mu_j(\theta+i\sigma) - (\xi-\xi_1)\sigma \operatorname{Im}\mu_j(\theta+i\sigma) \\ &> (\varepsilon-k)\ln\sigma.\end{aligned}$$

Thus

$$|\tilde{u}_j(\theta+i\sigma,\xi)| = \exp((\xi-\xi_1)\operatorname{Re}((\theta+i\sigma)\mu_j(\theta+i\sigma)))\cdot|U_j(\theta+i\sigma)|$$
$$> \sigma^{\varepsilon-k}|\hat{w}(\theta+i\sigma)|/3.$$

Suppose now that the function $t\to e^{-\theta t}u(t,\xi)$ is in $W^{k,2}([0,\infty),\mathbb{R}^n)$. By Plancherel's theorem, this implies that the function $\sigma\to\sigma^k\hat{u}(\theta+i\sigma,\xi)$; hence also $\sigma^k\tilde{u}(\theta+i\sigma,\xi)$ is in $L^2(\mathbb{R},\mathbb{C}^n)$. This implies $\sigma^\varepsilon\hat{w}(\theta+i\sigma)\in L^2(\mathbb{R},\mathbb{C})$, in contradiction to the assumption that $e^{-\theta t}w(t)\notin W^{\varepsilon,2}([0,\infty),\mathbb{R})$.

4. Simplifications and examples. The verification of Hypothesis 2.2, as well as the computation of the numbers $\alpha_j^\pm$, will in general give rise to tedious calculations, if at all possible. Therefore it seems worthwhile to point out some simplifications that may be applied to certain special cases to obtain explicit results.

We have already noticed in § 2, that the matrix c and the convolution kernel h do not contribute to the degree of smoothing. We improve this result and also show that bounded variation parts of the kernel d can be ignored.

PROPOSITION 4.1. *Suppose Hypothesis* 2.1 *is verified with two different kernels* d *and* $\tilde{d}$. *Moreover, let the function* $t\to e^{-\gamma t}(d(t)-\tilde{d}(t))$ *be of bounded variation and integrable on* $[0,\infty)$. *Then Hypothesis* 2.2 *is valid with* d *if and only if it is valid with* $\tilde{d}$, *and the values of* $\alpha_1^+(\alpha_1^-,\alpha_2^+,\alpha_2^-)$ *are the same for* d *and* $\tilde{d}$.

Proof. As a has distinct and nonzero eigenvalues, the eigenvalues and inverse matrices depend continuously differentiably on matrices in a sufficiently small neighborhood V of a. We pick θ sufficiently large, such that for $\operatorname{Re}\tau>\theta$ both matrices, $(a+\hat{d}(\tau))$ and $(a+\hat{\tilde{d}}(\tau))$, are contained in V. Thus the jth eigenvalue $\kappa_j(\tau)$ of $(a+\hat{d}(\tau))^{-1}$ and $\tilde{\kappa}_j(\tau)$ of $(a+\hat{\tilde{d}}(\tau))^{-1}$ satisfy $|\kappa_j(\tau)-\tilde{\kappa}_j(\tau)|=O(\|\hat{d}(\tau)-\hat{\tilde{d}}(\tau)\|)$. Since $e^{-\gamma t}(d(t)-\tilde{d}(t))$ is of bounded variation, $\|\hat{d}(\tau)-\hat{\tilde{d}}(\tau)\|=O(|\tau|^{-1})$. Thus $\tau(\kappa_j(\tau)-\tilde{\kappa}_j(\tau))$ is bounded for $\operatorname{Re}\tau>\theta$, implying that Hypothesis 2.2 is equivalent for the two cases. Moreover, $\sigma(\kappa_j(\theta+i\sigma)-\tilde{\kappa}_j(\theta+i\sigma))/\ln\sigma$ converges to 0 as $|\sigma|\to\infty$; thus we obtain the same values for $\alpha_1^+(\alpha_2^+,\alpha_1^-,\alpha_2^-)$ in both cases.

As an immediate consequence of this proposition and Theorem 2.2 we obtain Corollary 4.2.

COROLLARY 4.2. *Let Hypothesis* 2.1 *be satisfied with* d *such that* $e^{-\gamma t}d(t)$ *is integrable and of bounded variation. Then Hypothesis* 2.2 *is satisfied, and* L^2 *boundary data are not smoothed inside the interval.*

Proof. By Proposition 4.1 we may replace d by 0, so that $\kappa_j(\tau)=\kappa_j$ is real. This implies Hypothesis 2.2 and $\alpha_j^\pm=0$.

When we linearize the eigenvalues of $a+\hat{d}(\tau)$ at a, this leads to the following lemma.

LEMMA 4.3. *Suppose Hypothesis* 2.1 *holds. Then for* $|\tau|\to\infty$,

$$\operatorname{Im}\kappa_j(\tau) = -\lambda_j^{-2}\operatorname{Im}(f_j^*\hat{d}(\tau)e_j)+o(\|\operatorname{Im}\hat{d}(\tau)\|)+o(|\operatorname{Im}\kappa_j(\tau)|).$$

In particular, if $\|\operatorname{Im}\hat{d}(\tau)\|=O(|\operatorname{Im}(f_j^*\hat{d}(\tau)e_j)|)$, *then*

$$\operatorname{Im}\kappa_j(\tau)/\operatorname{Im}(f_j^*\hat{d}(\tau)e_j)\to-\lambda_j^{-2}.$$

Proof. $\operatorname{Im}(\lambda_j^2\kappa_j(\tau)|)=(\lambda_j^2-|\lambda_j^2(\tau)|)\operatorname{Im}\kappa_j(\tau)+|\lambda_j^2(\tau)|\operatorname{Im}\lambda_j^{-1}(\tau)=o(|\operatorname{Im}\kappa_j(\tau)|)-\operatorname{Im}\lambda_j(\tau)$. Since the eigenvalues of a are pairwise distinct, the eigenvalues $\lambda_j(q)$ of $a+q$ depend continuously differentiably on q, provided that q is a sufficiently small complex $n\times n$-matrix. Moreover, the derivative $\nabla\lambda_j(0)$ at $q=0$ is a linear map from the space

of $n \times n$-matrices into $\mathbb{C}$ given by $(\nabla\lambda_j(0))q = f_j^* q e_j$. If $|\tau|$ is large, so that $\hat{d}(\tau)$ is sufficiently small, then

$$\begin{aligned}\operatorname{Im}\lambda_j(\tau) &= \operatorname{Im}(\lambda_j(\tau)-\lambda_j)\\ &= \operatorname{Im}[i\nabla\lambda_j(\operatorname{Re}\hat{d}(\tau))\cdot\operatorname{Im}\hat{d}(\tau)+o(\|\operatorname{Im}\hat{d}(\tau)\|)]\\ &= \operatorname{Im}[i\nabla\lambda_j(0)\cdot\operatorname{Im}\hat{d}(\tau)+i(\nabla\lambda_j(\operatorname{Re}\hat{d}(\tau))-\nabla\lambda_j(0))\cdot\operatorname{Im}\hat{d}(\tau)]\\ &\quad+o(\|\operatorname{Im}\hat{d}(\tau)\|)\\ &= f_j^*\operatorname{Im}\hat{d}(\tau)e_j+o(\|\operatorname{Im}\hat{d}(\tau)\|).\end{aligned}$$

The hypothesis of this lemma again is technical enough; however, it is true if d is a scalar multiple of a constant matrix. The rest of this section is devoted to this case.

PROPOSITION 4.4. *Suppose that Hypothesis* 2.1 *is satisfied, and that* $d(t)=\varphi(t)d$ *with a scalar-valued function* φ *and a constant real matrix* d. *Moreover assume that for all* $j=1\cdots n$, $f_j^* de_j \neq 0$. *Then Hypothesis* 2.2 *is equivalent to the following. If* $\sigma\operatorname{Im}\hat{\varphi}(\rho+i\sigma)$ *is unbounded from above (below) for* $\rho\geqq\theta$, $\sigma\geqq 0$, *then for each* $j=1\cdots n$, $\delta_j f_j^* de_j > 0\ (<0)$. *Moreover, in this case we have*

$$\alpha_1^+ = \lim_{\sigma\to\infty}\sup[\sigma|\operatorname{Im}\hat{\varphi}(\theta+i\sigma)|/\ln\sigma]\cdot\min_{j=1\cdots m}\lambda_j^{-2}|f_j^* de_j|,$$

$$\alpha_1^- = \lim_{\sigma\to\infty}\inf[\sigma|\operatorname{Im}\hat{\varphi}(\theta+i\sigma)|/\ln\sigma]\cdot\min_{j=1\cdots m}\lambda_j^{-2}|f_j^* de_j|,$$

$$\alpha_2^+ = \lim_{\sigma\to\infty}\sup[\sigma|\operatorname{Im}\hat{\varphi}(\theta+i\sigma)|/\ln\sigma]\cdot\min_{j=m+1\cdots n}\lambda_j^{-2}|f_j^* de_j|,$$

$$\alpha_2^- = \lim_{\sigma\to\infty}\inf[\sigma|\operatorname{Im}\hat{\varphi}(\theta+i\sigma)|/\ln\sigma]\cdot\min_{j=m+1\cdots n}\lambda_j^{-2}|f_j^* de_j|.$$

Proof. Evidently, $\|\operatorname{Im}\hat{d}(\tau)\| = |\operatorname{Im}\hat{\varphi}(\tau)|\cdot\|d\| = O(|\operatorname{Im}\hat{\varphi}(\tau)f_j^* de_j|) = O(|\operatorname{Im} f_j^*\hat{d}(\tau)e_j|)$, so that the previous lemma applies and $\operatorname{Im}\kappa_j(\theta+i\sigma)/\operatorname{Im}\hat{\varphi}(\theta+i\sigma)\to -\lambda_j^{-2}f_j^* de_j$. Thus $\delta_j\operatorname{Im}\kappa_j(\theta+i\sigma)$ is bounded from above if and only if either $\operatorname{Im}\hat{\varphi}(\theta+i\sigma)$ is bounded, or $\operatorname{Im}\hat{\varphi}(\theta+i\sigma)$ is bounded from below, and $-\delta_j\lambda_j^{-2}f_j^* de_j<0$, or $\operatorname{Im}\hat{\varphi}(\theta+i\sigma)$ is bounded from above, and $-\delta_j\lambda_j^{-2}f_j^* de_j>0$. Now assume that one of these conditions is satisfied. Then

$$\begin{aligned}\tilde{\beta}_1(\theta+i\sigma) &= \max_{j=1\cdots m}(-\operatorname{Im}\kappa_j(\theta+i\sigma))\\ &= \max_{j=1\cdots m}[\lambda_j^{-2}f_j^* de_j\operatorname{Im}\hat{\varphi}(\theta+i\sigma)]+o(|\operatorname{Im}\hat{\varphi}(\theta+i\sigma)|).\end{aligned}$$

Employing the definition of α_1^+, we obtain

$$\alpha_1^+ = \lim_{\sigma\to\infty}\sup[-\max_{j=1\cdots m}\lambda_j^{-2}f_j^* de_j\operatorname{Im}\hat{\varphi}(\theta+i\sigma)/\ln\sigma],$$

which equals 0 if $\sigma|\operatorname{Im}\hat{\varphi}(\theta+i\sigma)|$ is bounded. If for some sequence $\sigma_k\to\infty$, $|\sigma_k\operatorname{Im}\hat{\varphi}(\theta+i\sigma_k)|\to\infty$, then for large k, $\operatorname{Im}\hat{\varphi}(\theta+i\sigma_k)$ and $f_j^* de_j$ have the opposite sign; thus

$$\alpha_1^+ = \lim_{\sigma\to\infty}\sup[\sigma|\operatorname{Im}\hat{\varphi}(\theta+i\sigma)|/\ln\sigma]\cdot\min_{j=1\cdots m}\lambda_j^{-2}|f_j^* de_j|.$$

The formulae for the other $\alpha_j^{\pm}$ are proved similarly.

Our last result shows how this is related to the singularity of the kernel $\varphi(t)$ at $t=0$.

PROPOSITION 4.5. *Suppose that $d(t)=\varphi(t)\,d$ with a constant $n\times n$-matrix d and a scalar, nonnegative, nonincreasing, convex function $\varphi(t)\,e^{-\gamma t}$. Moreover, for each $j=1\cdots n$ let $\delta_j f_j^*\,de_j<0$. Then Hypothesis 2.2 is satisfied, and*

$$\liminf_{t\to 0}[-\varphi(t)/\ln t]\cdot\min_{j=1\cdots m}|f_j^*\,de_j|\cdot\lambda_j^{-2}$$
$$\leqq\alpha_1^-\leqq\alpha_1^+\leqq 2\limsup_{t\to 0}[-\varphi(t)/\ln t]\cdot\min_{j=1\cdots m}|f_j^*\,de_j|\cdot\lambda_j^{-2},\quad \textit{and}$$
$$\liminf_{t\to 0}[-\varphi(t)/\ln t]\cdot\min_{j=m+1\cdots m}|f_j^*\,de_j|\cdot\lambda_j^{-2}$$
$$\leqq\alpha_2^-\leqq\alpha_2^+\leqq 2\limsup_{t\to 0}[-\varphi(t)/\ln t]\cdot\min_{j=m+1\cdots m}|f_j^*\,de_j|\cdot\lambda_j^{-2}.$$

In particular, if φ has a singularity weaker than logarithmic at 0, there are L^2 boundary data that never get smoothed in the interior of the interval. On the other hand, if φ has a singularity stronger than logarithmic, all boundary data are smoothed immediately to C^∞.

Proof. As for $\theta>\gamma$, the function $e^{-\gamma t}\varphi(t)$ is again nonnegative, convex, and nonincreasing; we may assume without loss of generality that φ itself is also, and put $\theta=0$. Since φ is nonincreasing, we obtain for $\sigma>0$, $\operatorname{Im}\hat\varphi(i\sigma)=-\int_0^\infty\sin(\sigma t)\varphi(t)\,dt<0$. Thus $\sigma\operatorname{Im}\hat\varphi(i\sigma)$ is bounded from above, and as $\delta_j f_j^*\,de_j<0$, Hypothesis 2.2 is satisfied.

To estimate the $\alpha_j^\pm$, we start out with

$$-\sigma\operatorname{Im}\hat\varphi(i\sigma)=\sigma\int_0^\infty\sin(\sigma t)\varphi(t)\,dt=\int_0^\infty\sin\tau\varphi\left(\frac{\tau}{\sigma}\right)d\tau$$
$$=\int_0^\pi\sin\tau\sum_{j=0}^\infty\left[\varphi\left(\frac{\tau+2\pi j}{\sigma}\right)-\varphi\left(\frac{\tau+\pi(2j+1)}{\sigma}\right)\right]d\tau.$$

Using the convexity of φ, we obtain

$$-\sigma\operatorname{Im}\hat\varphi(i\sigma)\geqq\int_0^\pi\sin\tau\sum_{j=0}^\infty\left[\varphi\left(\frac{\tau+2\pi j}{\sigma}\right)-\frac{1}{2}\left(\varphi\left(\frac{\tau+2\pi j}{\sigma}\right)+\varphi\left(\frac{\tau+2\pi(j+1)}{\sigma}\right)\right)\right]d\tau$$
$$=\frac{1}{2}\int_0^\pi\sin\tau\varphi\left(\frac{\tau}{\sigma}\right)d\tau,$$
$$-\sigma\operatorname{Im}\hat\varphi(i\sigma)=\int_0^\pi\sin\tau\left[\varphi\left(\frac{\tau}{\sigma}\right)-\sum_{j=1}^\infty\left[\varphi\left(\frac{\tau+\pi(2j-1)}{\sigma}\right)-\varphi\left(\frac{\tau+2\pi j}{\sigma}\right)\right]\right]d\tau$$
$$\leqq\int_0^\pi\sin\tau\varphi\left(\frac{\tau}{\sigma}\right)d\tau-\frac{1}{2}\int_0^\pi\sin\tau\sum_{j=1}^\infty\left[\varphi\left(\frac{\tau+\pi(2j-1)}{\sigma}\right)\right.$$
$$\left.-\varphi\left(\frac{\tau+\pi(2j+1)}{\sigma}\right)\right]d\tau$$
$$=\int_0^\pi\sin\tau\varphi\left(\frac{\tau}{\sigma}\right)d\tau-\frac{1}{2}\int_0^\pi\sin\tau\varphi\left(\frac{\tau+\pi}{\sigma}\right)d\tau\leqq\int_0^\pi\sin\tau\varphi\left(\frac{\tau}{\sigma}\right)d\tau.$$

Therefore,

$$\liminf_{\sigma\to\infty}(-\sigma\operatorname{Im}\hat\varphi(i\sigma)/\ln\sigma)\geqq\liminf_{\sigma\to\infty}\frac{1}{2\ln\sigma}\int_0^\pi\sin\tau\varphi\left(\frac{\tau}{\sigma}\right)d\tau$$
$$=\liminf_{\sigma\to\infty}\int_0^\pi\frac{\sin\tau(\ln\sigma-\ln\tau)}{2\ln\sigma}\cdot\frac{-\sigma(\tau/\sigma)}{\ln(\tau/\sigma)}\,d\tau$$
$$\geqq\liminf_{t\to 0}-\varphi(t)/\ln t\quad\text{since}$$

$$\int_0^\pi \frac{\sin \tau(\ln \sigma - \ln \tau)}{2 \ln \sigma}\, d\tau \to 1 \quad \text{as } \sigma \to \infty.$$

Similarly,

$$\begin{aligned}\limsup_{\sigma\to\infty} (-\sigma \operatorname{Im} \hat{\varphi}(i\sigma)/\ln \sigma) &\leqq \limsup_{\sigma\to\infty} \frac{1}{\ln \sigma} \int_0^\pi \sin \tau \varphi\left(\frac{\tau}{\sigma}\right) d\tau \\ &= \limsup_{\sigma\to\infty} \int_0^\pi \frac{\sin \tau(\ln \sigma - \ln \tau)}{\ln \sigma} \cdot \frac{-\varphi(\tau/\sigma)}{\ln(\tau/\sigma)}\, d\tau \\ &\leqq 2 \limsup_{t\to 0} -\varphi(t)/\ln t.\end{aligned}$$

This and Proposition 4.4 yield the desired estimates.

Example 1. To give an example, let us show how our results apply to a shear flow in a linearly viscoelastic fluid bordered by two parallel (infinite) plates. We assume that the fluid is initially quiescent and that it is then perturbed by moving the plates in a fixed, tangential direction. The resulting velocity field depends only on one space variable orthogonal to the boundaries. The direction of the velocity vector is parallel to the motion of the plates, so that the velocity field can be viewed as a scalar. Let $v(t, \xi)$ denote the velocity, $\sigma(t, \xi)$ the shear stress, and ρ the density of the fluid. $G(t)$ is the stress relaxation modulus. Then we have the constitutive equation

$$\sigma(t, \xi) = \int_0^t G(t-s) v_\xi(s, \xi)\, ds,$$

and the momentum equation

$$\rho v_t(t, \xi) = \sigma_\xi(t, \xi).$$

The initial and boundary conditions are

$$v(0, \xi) = 0, \quad \sigma(0, \xi) = 0, \quad v(t, \xi_1) = v_1(t), \quad v(t, \xi_2) = v_2(t).$$

Combining the equations and putting $u(t, \xi) = (v(t, \xi), \sigma(t, \xi))^t$, we obtain

$$\begin{aligned}u_t(t, \xi) &= \begin{bmatrix} 0 & \rho^{-1} \\ G(0) & 0 \end{bmatrix} u_\xi(t, \xi) + \int_0^t G'(t-s) \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} u_\xi(s, \xi)\, ds \\ &= a u_\xi(t, \xi) + \int_0^t G'(t-s)\, d u_\xi(s, \xi)\, ds,\end{aligned}$$

$$u(0, \xi) = 0, \quad b u(t, \xi_j) = (1, 0) u(t, \xi_j) = v_j(t) \quad (j = 1, 2).$$

It is a matter of elementary linear algebra to compute

$$\lambda_1 = -\left(\frac{G(0)}{\rho}\right)^{1/2}, \qquad \lambda_2 = \left(\frac{G(0)}{\rho}\right)^{1/2},$$

$$e_1 = \begin{bmatrix} 1 \\ -\sqrt{G(0)\rho} \end{bmatrix}, \qquad e_2 = \begin{bmatrix} 1 \\ \sqrt{G(0)\rho} \end{bmatrix},$$

$$f_1 = \begin{bmatrix} \frac{1}{2} \\ -\frac{1}{2}\sqrt{G(0)\rho} \end{bmatrix}, \qquad f_2 = \begin{bmatrix} \frac{1}{2} \\ \frac{1}{2}\sqrt{G(0)\rho} \end{bmatrix},$$

$$\delta_j f_j^*\, de_j = \tfrac{1}{2}\sqrt{G(0)\rho} \quad \text{for } j = 1, 2.$$

From physical considerations it is reasonable to assume that G' is negative, nondecreasing, convex down, and integrable. Replacing d by $-d$ and G' by $-G'$, we may apply Proposition 4.5 to see that Hypothesis 2.2 holds. Moreover, if G' has no

singularity or a singularity weaker than logarithmic at $t=0$, no smoothing occurs. If the singularity is stronger than logarithmic, the solutions are C^∞ with respect to time for each fixed ξ in the interior of the interval. In the limiting case that the singularity is logarithmic, the solution gains differentiability gradually as we go away from the boundary. The space interval needed to gain one degree of differentiability is α^{-1} with

$$\alpha = \sqrt{\rho}/2\sqrt{G(0)^3} \cdot \lim_{\sigma\to\infty} [\sigma \operatorname{Im} \hat{G}'(i\sigma)/\ln \sigma]$$

(provided that the limit exists, otherwise we must include the space interval between $(\alpha^+)^{-1}$ and $(\alpha^-)^{-1}$). This also implies that step discontinuities are smoothed immediately to continuous functions, as a step function is contained in $W^{1/2-\varepsilon,2}$ for any $\varepsilon>0$, while $W^{1/2+\varepsilon,2}$ is already embeddable in the space of continuous functions.

Let us briefly compare how our work relates to the results in [11]. The equation treated there is

$$u_{tt}(t,\xi) = \ell u_{\xi\xi}(t,\xi) + \int_{-\infty}^{t} m(t-s)(u_{\xi\xi}(t,\xi) - u_{\xi\xi}(s,\xi))\, ds.$$

Putting $u=v$, $\ell = \rho^{-1}(G(0) - \int_0^\infty G'(s)\, ds)$, $m(t) = -\rho^{-1}G'(t)$, this may be viewed as a second-order transcription of our problem. While we treat inhomogeneous boundary conditions on a finite interval, in [11] homogeneous boundary conditions and a nonzero initial condition are treated.

If the kernel m exhibits a singularity stronger than logarithmic, the boundary value problem shows immediate smoothing to C^∞. The same is true for the initial value problem, as far as smoothness across the characteristics is concerned. The "vertical" characteristic, showing always a singularity one degree weaker than the initial singularity, of course does not appear if the discontinuity comes in from the boundary. If the singularity of the kernel is weaker than logarithmic, no differentiability is gained in both cases. The effect observed in [11], that initial data of bounded variation may be smoothed to C^1, evidently requires more refined methods than the one developed in our paper.

The example of a kernel with logarithmic singularity in [11] is $m(t) = \sum_{k=0}^\infty \exp(-e^k t)$. It is shown that differentiability is gained gradually. It is easy to compute α by our formula:

$$\alpha = \sqrt{\rho}/2\sqrt{G(0)^3} \cdot \lim_{\sigma\to\infty} [\sigma \operatorname{Im} \hat{G}'(i\sigma)/\ln \sigma]$$

$$= \frac{1}{2} \cdot \left(\ell + \int_0^\infty m(s)\, ds\right)^{-3/2} \cdot \lim_{\sigma\to\infty} [-\sigma \operatorname{Im} \hat{m}(i\sigma)/\ln \sigma].$$

Now $\hat{m}(i\sigma) = \sum_{k=0}^\infty 1/(e^k + i\sigma)$; in particular,

$$\int_0^\infty m(s)\, ds = \hat{m}(0) = e/(e-1),$$

$$-\lim_{\sigma\to\infty} \sigma \operatorname{Im} \hat{m}(i\sigma)/\ln \sigma = \lim_{\sigma\to\infty} \sum_{k=0}^{\infty} \sigma^2/(e^{2k}+\sigma^2) \ln \sigma$$

$$= \lim_{\sigma\to\infty} \frac{1}{\ln \sigma} \sum_{k=0}^{\infty} 1/(e^{2k}/\sigma^2 + 1)$$

$$= \lim_{\sigma\to\infty} \frac{1}{\ln \sigma} \int_0^\infty 1/(e^{2t}/\sigma^2 + 1)\, dt$$

$$= \lim_{\sigma\to\infty} \frac{1}{2\ln \sigma} \int_{1/\sigma^2}^\infty 1/(z+1)z\, dz$$

$$= \lim_{\sigma\to\infty} \ln(1+\sigma^2)/2\ln\sigma = 1.$$

Thus $\alpha = 1/2(\ell + e/(e-1))^{3/2}$.

We will also use Example 1 to compare our work with that of Prüss [17]. We are indebted to R. Wheeler for drawing our attention to this work. The equation examined in [17] is the abstract integrodifferential equation in a Banach space X:

$$u_t(t) = \int_0^t da(t-s)Au(s)$$

where $a(t) = a_0 + a_\infty t + \int_0^t a_1(s)\,ds$ with $a_0 \geqq 0$, $a_\infty \geqq 0$ and $a_1(t)$ completely monotone. In addition, A is the generator of a cosine family in X. In order to make a reasonable comparison, we consider the equation

$$u_t(t) = \int_0^t G(t-s)Au(s)\,ds$$

where $G(t) = a_\infty + a_1(t)$.

It is shown in [17] that the resolvent operator associated with this equation becomes C^∞ in time for any $t > 0$ if

$$\lim_{\sigma\to\infty} \frac{-\ln\sigma \operatorname{Im}\hat{G}(i\sigma)}{\sigma \operatorname{Re}\hat{G}(i\sigma)} = 0.$$

If the expression above is finite but nonzero, the resolvent operator gains smoothness as time goes on.

The abstract setting can be adapted to Example 1, if nonsmooth initial conditions but homogeneous boundary conditions are considered.

In our setting we require that $G(0)$ is finite; hence $\lim_{\sigma\to\infty} i\sigma\hat{G}(i\sigma) = G(0)$. As

$$\frac{\sigma \operatorname{Im}\hat{G}'(i\sigma)}{\ln\sigma} \sim \frac{\sigma^2 \operatorname{Re}\hat{G}(i\sigma)}{\ln\sigma} \sim G(0)\frac{\sigma^2 \operatorname{Re}\hat{G}(i\sigma)}{\ln\sigma \operatorname{Re} i\sigma\hat{G}(i\sigma)}$$

$$= -G(0)\frac{\sigma \operatorname{Re}\hat{G}(i\sigma)}{\ln\sigma \operatorname{Im}\hat{G}(i\sigma)},$$

our condition for infinite smoothing is the same as that of Prüss [17].

Example 2. Our methods work as well for a system of wave equations coupled by boundary conditions. In [3], Chen, Coleman, and West have considered small transversal vibrations in a cable consisting of two or more elastic strings, linked together by a dashpot-like damping device at their ends. To find out how a step discontinuity in stress or velocity is transmitted along the cable, we must take care of the internal viscoelastic damping of the material. Assuming a linear Boltzmann constitutive law, we obtain the following system:

$$v_t^-(t,\xi) = \rho_-^{-1}\sigma_\xi^-(t,\xi), \qquad t \geqq 0, \quad \xi \in [-l, 0],$$

$$\sigma^-(t,\xi) = \int_0^t G_-(t-s)v^-(s,\xi)\,ds,$$

$$v_t^+(t,\xi) = \rho_+^{-1}\sigma_\xi(t,\xi), \qquad t \geqq 0, \quad \xi \in [0, l],$$

$$\sigma^+(t,\xi) = \int_0^t G_+(t-s)v^+(s,\xi)\,ds,$$

with the boundary conditions

$$v^-(t,-l)=v^-(t), \qquad v^+(t,l)=v^+(t),$$
$$k[v^+(t,0)-v^-(t,0)]=\sigma^+(t,0) \qquad (k>0),$$
$$\sigma^+(t,0)=\sigma^-(t,0).$$

Here $v^\pm$ denotes (transversal) velocity in either string, $\sigma^\pm$ is stress, $\rho_\pm$ is mass density, and $G_\pm$ is the stress relaxation modulus. For simplicity we have assumed both strings to have the same length l and normalized cross-section areas to one.

To fit these equations formally in our framework, we put

$$v_1(t,\xi)=v_+(t,\xi), \qquad \sigma_1(t,\xi)=\sigma_+(t,\xi),$$
$$v_2(t,\xi)=v_-(t,-\xi), \quad \sigma_2(t,\xi)=\sigma_-(t,-\xi), \quad t\geqq 0, \quad \xi\in[0,l],$$

and obtain

$$\begin{bmatrix} v_1 \\ \sigma_1 \\ v_2 \\ \sigma_2 \end{bmatrix}_t (t,\xi) = \begin{bmatrix} 0 & \rho_+^{-1} & 0 & 0 \\ G_+(0) & 0 & 0 & 0 \\ 0 & 0 & 0 & -\rho_-^{-1} \\ 0 & 0 & -G_-(0) & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ \sigma_1 \\ v_2 \\ \sigma_2 \end{bmatrix}_\xi (t,\xi)$$
$$+\int_0^t \begin{bmatrix} 0 & 0 & 0 & 0 \\ G_+'(t-s) & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -G_-'(t-s) & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ \sigma_1 \\ v_2 \\ \sigma_2 \end{bmatrix}_\xi (s,\xi)\, ds,$$

with boundary conditions

$$\begin{bmatrix} k & -1 & -k & 0 \\ 0 & 1 & 0 & -1 \end{bmatrix} \begin{bmatrix} v_1 \\ \sigma_1 \\ v_2 \\ \sigma_2 \end{bmatrix} (t,0)=0,$$

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ \sigma_1 \\ v_2 \\ \sigma_2 \end{bmatrix} (t,l)=0.$$

The same computations as in the previous example yield

$$\lambda_1=-\sqrt{\rho_+^{-1}G_+(0)}, \qquad \lambda_2=-\sqrt{\rho_-^{-1}G_-(0)},$$
$$\lambda_3=\sqrt{\rho_-^{-1}G_-(0)}, \qquad \lambda_4=\sqrt{\rho_+^{-1}G_+(0)},$$

$$e_1=\begin{bmatrix} 1 \\ -\sqrt{\rho_+G_+(0)} \\ 0 \\ 0 \end{bmatrix}, \qquad e_2=\begin{bmatrix} 0 \\ 0 \\ 1 \\ \sqrt{\rho_-G_-(0)} \end{bmatrix},$$

$$e_3=\begin{bmatrix} 0 \\ 0 \\ 1 \\ -\sqrt{\rho_-G_-(0)} \end{bmatrix}, \qquad e_4=\begin{bmatrix} 1 \\ \sqrt{\rho_+G_+(0)} \\ 0 \\ 0 \end{bmatrix}.$$

Since

$$\begin{bmatrix} k & -1 & -k & 0 \\ 0 & 1 & 0 & -1 \end{bmatrix} [e_1, e_2] = \begin{bmatrix} k+\sqrt{\rho_+ G_+(0)} & -k \\ -\sqrt{\rho_+ G_+(0)} & -\sqrt{\rho_- G_-(0)} \end{bmatrix}$$

and

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} [e_3, e_4] = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$$

are both invertible, the boundary conditions fit in Hypothesis 2.1(b).

The further analysis depends only on the eigenvalues of

$$a + \hat{d}(\tau) = \begin{bmatrix} 0 & \rho_+^{-1} & 0 & 0 \\ \tau \hat{G}_+(\tau) & 0 & 0 & 0 \\ 0 & 0 & 0 & -\rho_-^{-1} \\ 0 & 0 & -\tau \hat{G}_-(\tau) & 0 \end{bmatrix},$$

which is of block-diagonal form, each block corresponding to a viscoelastically damped wave equation.

To each of the blocks the results of the previous example apply. We see again that singularities in the boundary data $v^{\pm}$ are smoothed to C^{∞} in the interior of the interval, if

$$\lim_{\sigma \to \infty} \frac{\sigma \operatorname{Im} \hat{G}'_{\pm}(i\sigma)}{\ln \sigma} = \infty$$

for convex decreasing positive $-G'_{\pm}$, this means again that G' has a singularity stronger than logarithmic at 0.

If $G'(0)$ is finite, no smoothing occurs and singularities travel from end to end. It is only this case where the damping device linking the strings has influence on the propagation of singularities. Reflection and transmission occur at the connection point. The methods of [6, Ex. 3.2] show that reflection and transmission at the link are the same as if the strings were purely elastic, while the viscoelastic nature of the material leads to exponential damping of the stepsize, as waves propagate along the strings.

Example 3. Once the behavior of a single string is known, the results of the example above are in fact obvious from physical intuition. It is more interesting, however, that also a Timoshenko beam equation decouples in two wave equations, if high frequency behavior such as propagation of singularities is considered.

Consider a viscoelastic beam pinned on both ends, such that one end can be forced to move in a transversal direction at a given velocity. (Other boundary conditions may be treated similarly.) We investigate how a discontinuity in the velocity forced on the end of an initially quiescent beam is propagated along the beam. It is known that for wave phenomena with high frequencies Timoshenko's beam equation is preferable to the Euler-Bernoulli equation [21], [22]. From [21, (11.9)-(11.11)] we take

$$\rho A y_{tt} = [\kappa A G^*_{\omega}(y_{\xi} - \psi)]_{\xi},$$

$$\rho I \psi_{tt} = [E^*_{\omega} I \psi_{\xi}]_{\xi} + \kappa A G^*_{\omega}(y_{\xi} - \psi):$$

G^*_{ω} and E^*_{ω} being complex elasticity moduli. We reset the problem in the form of Boltzmann viscoelasticity, and subsequently put it in a first-order system:

$$\rho A y_{tt}(t, \xi) = \left[\kappa A G_0 (y_{\xi} - \psi)(t, \xi) + \int_0^t \kappa A G(t-s)(y_{\xi} - \psi)(s, \xi)\, ds \right]_{\xi}, \tag{4.1}$$

$$\rho I\psi_{tt}(t,\xi)=\left[E_0 I\psi_\xi(t,\xi)+\int_0^t IE(t-s)\psi_\xi(s,\xi)\,ds\right]_\xi + \kappa AG_0(y_\xi-\psi)(t,\xi)+\int_0^t \kappa AG(t-s)(y_\xi-\psi)(s,\xi)\,ds, \tag{4.2}$$

with boundary conditions

$$y_t(t,0)=v(t), \qquad y_t(t,l)=0,$$
$$\psi_\xi(t,0)=0, \qquad \psi_\xi(t,l)=0.$$

Here y is the transverse displacement of the beam, ψ is the angle of rotation for a cross-section element, when shear is neglected. G_0 and E_0 are instantaneous elasticity moduli, G and E are stress relaxation moduli. The meaning of the other constants is as in [21].

To obtain a first-order system put

$$u(t,\xi)=\begin{bmatrix} u_1(t,\xi)\\ \vdots\\ u_4(t,\xi)\end{bmatrix} \quad \text{with}$$

$$u_1=y_\xi, \quad u_2=y_t, \quad u_3=\psi_\xi, \quad u_4=\psi_t.$$

To take care of ψ in (4.2) we put $G_1(t)=G_0+\int_0^t G(s)\,ds$ and perform an integration by parts:

$$G_0\psi(t)+\int_0^t G(t-s)\psi(s)\,ds=\int_0^t G_1(t-s)\psi_t(s)\,ds.$$

(As the beam is initially quiescent, $\psi(0)=0$.) Now we can set up the first-order system:

$$u_t(t,\xi)=\begin{bmatrix} 0 & 1 & 0 & 0\\ \kappa G_0/\rho & 0 & 0 & 0\\ 0 & 0 & 0 & 1\\ 0 & 0 & E_0/\rho & 0\end{bmatrix}u_\xi(t,\xi) + \begin{bmatrix} 0 & 0 & 0 & 0\\ 0 & 0 & -\kappa G_0/\rho & 0\\ 0 & 0 & 0 & 0\\ \kappa AG_0/I\rho & 0 & 0 & 0\end{bmatrix}u(t,\xi) + \int_0^t \begin{bmatrix} 0 & 0 & 0 & 0\\ \kappa G(t-s)/\rho & 0 & 0 & 0\\ 0 & 0 & 0 & 0\\ 0 & 0 & E(t-s)/\rho & 0\end{bmatrix}u_\xi(s,\xi)\,ds + \int_0^t \begin{bmatrix} 0 & 0 & 0 & 0\\ 0 & 0 & -\kappa G(t-s)/\rho & 0\\ 0 & 0 & 0 & 0\\ \kappa AG(t-s)/I\rho & 0 & 0 & -\kappa AG_1(t-s)/I\rho\end{bmatrix}u(s,\xi)\,ds,$$

$$\begin{bmatrix} 0 & 1 & 0 & 0\\ 0 & 0 & 1 & 0\end{bmatrix}u(t,0)=\begin{bmatrix} v(t)\\ 0\end{bmatrix},$$

$$\begin{bmatrix} 0 & 1 & 0 & 0\\ 0 & 0 & 1 & 0\end{bmatrix}u(t,l)=\begin{bmatrix} 0\\ 0\end{bmatrix}.$$

As the smoothing properties depend only on the matrices a and $d(t)$ appearing with u_ξ, we may ignore c and $h(t)$ and obtain two uncoupled viscoelastically damped wave equations exhibiting the same behavior:

$$\begin{bmatrix} u_1 \\ u_2 \end{bmatrix}_t (t,\xi) = \begin{bmatrix} 0 & 1 \\ \kappa G_0/\rho & 0 \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix}_\xi (t,\xi) + \int_0^t \begin{bmatrix} 0 & 0 \\ \kappa G(t-s)/\rho & 0 \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix}_\xi (s,\xi)\, ds,$$

$$u_2(t,0) = v(t), \qquad u_2(t,l) = 0,$$

$$\begin{bmatrix} u_3 \\ u_4 \end{bmatrix}_t (t,\xi) = \begin{bmatrix} 0 & 1 \\ E_0/\rho & 0 \end{bmatrix}_\xi \begin{bmatrix} u_3 \\ u_4 \end{bmatrix} (t,\xi) + \int_0^t \begin{bmatrix} 0 & 0 \\ E(t-s)/\rho & 0 \end{bmatrix} \begin{bmatrix} u_3 \\ u_4 \end{bmatrix}_\xi (s,\xi)\, ds,$$

$$u_3(t,0) = u_3(t,l) = 0.$$

Now the computations of Example 1 show that singularities in boundary data are smoothed to C^∞ in the interior of the interval if G and E are positive, decreasing, convex with singularities stronger than logarithmic at 0.

If G and E are bounded and sufficiently smooth at $t=0$, again the methods of [6] can be applied to show that a discontinuity in boundary data for y_t and ψ_x gives rise to two waves, one carrying a discontinuity in y_t at speed $\sqrt{\kappa G_0/\rho}$, the other propagating a discontinuity in ψ_x at speed $\sqrt{E_0/\rho}$. The stepsizes are subject to exponential damping, due to the memory of the material.

ANALYSIS OF A CONVECTIVE REACTION-DIFFUSION EQUATION II*

H.A. LEVINE†‡, L. E. PAYNE§, P. E. SACKS†‡, AND B. STRAUGHAN¶

Abstract. We study the large time behavior of positive solutions of the semilinear parabolic equation $u_t = u_{xx} + \varepsilon(g(u))_x + f(u)$, $0 < x < L$, $\varepsilon \in \mathbf{R}$, subject to $u(0,t) = u(L,t) = 0$. The model problem in which the results apply is $g(u) = u^m$ and $f(u) = u^p$ $1 \leqq m < p$. The steady state problem is analyzed in some detail, and results about finite time blow up are proved.

Key words. Nonlinear parabolic equations, asymptotic behavior

AMS(MOS) subject classifications. 35K

Introduction. In this paper, we continue our study, begun in [1], of the longtime behavior of nonnegative solutions of

$$u_t = u_{xx} + \varepsilon(g(u))_x + f(u), \quad 0 < x < L, \quad t > 0 \tag{1.1(ε)}$$

$$u(0,t) = u(L,t) = 0, \quad t > 0 \tag{1.2}$$

$$u(x,0) = u_0(x), \quad 0 < x < L, \tag{1.3}$$

where ε is a constant ($\geqq 0$ without loss of generality) and f, g are given point functions of u. We will be primarily concerned with the power law cases $f(u) = u^p$, $g(u) = u^m$, $m, p > 1$. In the earlier paper [1], we analyzed the case $1 < p \leqq m$ and proved some general results for stationary solutions for any $p, m > 1$. We will repeat the statements of these results in the following sections. Also, in [1], we discussed some of the recent literature concerning (1.1)–(1.3). We will not repeat that discussion here.

We might point out, however, where equations of form (1.1) occur in physical situations or where (1.1) is a simplified model for a physical process. Cox and Mortell [2] show how a variety of modified Burgers' equations may be obtained by studying the equations of gas dynamics in a tube, under various boundary conditions. Horgan and Olmstead [5] investigate a system which arises from Burgers' original work and their paper contains many other relevant references. Another area is non-Boussinesq convection, where nonlinear density dependence on temperature leads to higher-order temperature effects in the momentum equation, see e.g., Veronis [12], Payne and Straughan [11].

The plan of the paper is as follows. In §2, we obtain some general propositions concerning positive stationary solutions when $p > m$. These propositions are preliminary to the main results concerning stationary solutions we obtain in §3. In that section we analyze the cases $1 < m < p < 2m - 1$ (Theorem 3.1), $p = 2m - 1$ (Theorem 3.2) and finally, $1 < 2m - 1 < p$ (Theorem 3.3). In §4, we analyze the longtime

¶The work of this author was partly carried out while he was a visitor at the Mathematical Sciences Institute of Cornell University, Ithaca, New York 14853.

behavior of solutions of (1.1)–(1.3). We show that when $p > m$, large data solutions cannot be global in time. Finally, in the last section, we indicate how these results may be generalized to nonlinearities that are not exact power laws.

Perhaps we should remark that when $\varepsilon = 0$, there is a close relationship between problems of the form (1.1(0)) and those of the form (1.4(0)) where for arbitrary ε,

$$u_t = u_{xx} + \varepsilon\big(g(u)\big)_x \tag{1.4(ε)}$$

$$u(0,t) = 0 \tag{1.5}$$

$$u_x(L,t) = f\big(u(L,t)\big). \tag{1.6}$$

However, when $\varepsilon \neq 0$, the sign of ε becomes crucial for the analysis of (1.4(ε)) and the correspondence between the two problems is not so close. See [7] for a discussion of (1.4(ε)).

2. Preliminary results about steady state solutions. In this section and the next, we state and prove results concerning the multiplicity of positive solutions of the steady state problem

$$\begin{aligned} &u_{xx} + \varepsilon(u^m)_x + u^p = 0, \quad 0 < x < L \\ &u(0) = u(L) = 0, \\ &u > 0, \qquad\qquad\qquad 0 < x < L \end{aligned} \tag{2.1(ε)}$$

The case $1 < p \leqq m$ has been analyzed in [1], thus we are interested here in the case $p > m \geqq 1$.

The nature of the solution set may of course depend on the parameter ε. Since a solution of (2.1(ε)) is uniquely identified by its L^∞ norm (by uniqueness of solution for the initial value problem for an ordinary differential equation) we may conveniently represent the solution of (2.1(ε)), for fixed m and p as a set of points in the $(\varepsilon, \|u\|_{L^\infty})$ plane. Also, since the change of variable $x \to L - x$ takes ε to $-\varepsilon$ we may restrict attention to $\varepsilon \geqq 0$ only. Let

$$\Gamma = \{(\varepsilon, M) : \varepsilon \geqq 0,\ M > 0 \text{ and } (2.1(\varepsilon)) \text{ has a solution } u \text{ with } \|u\|_{L^\infty} = M\}$$

be the set of points corresponding to solutions of (2.1(ε)) for some fixed values of m and p.

We begin by recalling some results from [1].

PROPOSITION 2.1. *Let $p > 1$, $m \geqq 1$.*

(i) [1, Thm. 2.2] *There is a unique positive solution of* (2.1(0)). *Denote by β_0 its L^∞ norm.*

(ii) [1, Prop. 2.6] *There exists $M_0 > 0$ such that if u solves* (2.1(ε)) *for some $\varepsilon \geqq 0$ then $\|u\|_{L^\infty} \geqq M_0$.*

(iii) [1, Prop. 2.9] *Γ is locally a simple curve.*

(iv) [1, Cor. 2.5] *In some neighborhood of $\varepsilon = 0$, $M = \beta_0$, $\Gamma = \{(\varepsilon, \beta(\varepsilon)\}$ for a continuous function β, with $\beta(0) = \beta_0$.*

(v) [1, Prop. 2.7] *The component of Γ containing $(0, \beta_0)$ is not bounded.*

(vi) [1, Lemma 2.1] *If u_1, u_2 are solutions of* (2.1(ε)), *$u_1 \not\equiv u_2$ then $u_1 < u_2$ or $u_2 < u_1$.*

Thus there is a curve of solutions emanating from the known $\varepsilon = 0$ solution. This curve may be continued indefinitely and along it either $\varepsilon \to \infty$ or $\|u\|_{L^\infty} \to \infty$ or both. We will see that for $m < p \leqq 2m - 1$ we must have $\|u\|_{L^\infty} \to \infty$ along the branch, while for $p > 2m - 1$ we must have $\varepsilon \to \infty$.

In the rest of this section we prove some results which are valid whenever $p > m \geqq 1$. We begin with some lemmas.

LEMMA 2.2. *Let u be a solution of (2.1(ε)) with $p > m - 1$. Then there exists $0 < x_0 < x_1 < L$ such that*

$$u_x \geqq 0, \quad u_{xx} \leqq 0 \quad \text{on } (0, x_0) \tag{2.2}$$

$$u_x \leqq 0, \quad u_{xx} \leqq 0 \quad \text{on } (x_0, x_1) \tag{2.3}$$

$$u_x \leqq 0, \quad u_{xx} \geqq 0 \quad \text{on } (x_1, L) \tag{2.4}$$

Proof. Clearly u_x can change sign exactly once (at some point x_0 say) and $u_{xx} \leqq 0$ on $(0, x^*)$ some $x^* > x_0$. Also since $u_x(L) < 0$ and $p > m - 1$ we must have $u_{xx} > 0$ near L, hence there exists $x_1 \in (x_0, L)$ such that $u_{xx} < 0$ on $(0, x_1)$ and $u_{xx}(x_1) = 0$. If we set $v = -u_{xx} = \varepsilon(u^m)_x + u^p$ then we obtain the following differential inequality for v;

$$\begin{aligned} v_x &= \varepsilon m u^{m-1} u_{xx} + \varepsilon m(m-1) u^{m-2} u_x^2 + p u^{p-1} u_x \\ &= \left((m-1)\frac{u_x}{u} - \varepsilon m u^{m-1}\right) v + (p - m + 1) u^{p-1} u_x \\ &< \left((m-1)\frac{u_x}{u} - \varepsilon m u^{m-1}\right) v \qquad x_1 \leqq x < L \end{aligned} \tag{2.5}$$

Since $v(x_1) = 0$ we conclude that $v(x) \leqq 0$ on $[x_1, L)$. □

LEMMA 2.3. *Let u be a solution of (2.1(ε)), $p > m - 1$. Define*

$$y(x) = \int_0^x u^{m-1}(s)\,ds \tag{2.6}$$

$$h(y) = u^m\big(x(y)\big) \tag{2.7}$$

Then

$$h_{yy} + \varepsilon m h_y + m h^{(p+1-m)/m} = 0 \tag{2.8}$$

$$h(0) = h(R) = 0 \qquad R = \int_0^L u^{m-1}(s)\,ds. \tag{2.9}$$

Furthermore if $\varepsilon_0 > 0$ there exists $R_0 > 0$, depending only on ε_0, p, m, and L such that if $0 \leqq \varepsilon \leqq \varepsilon_0$ then $R \geqq R_0$.

Proof. The fact that (2.8) holds is a straightforward computation. To prove the lower bound for R, we first claim that there exists $\alpha_0 > 0$, (depending on ε_0, p, m and L) such that

$$u_x(L) < -\alpha_0 \tag{2.10}$$

if u is a solution of (2.1(ε)) with $\varepsilon \leqq \varepsilon_0$. Allowing this for the moment, there are two possibilities. First if $x_1 < L/2$ (x_1 from Lemma 2.1) then $u(x) \geqq \alpha_0(L - x)$ for

$L/2 \leqq x \leqq L$ which clearly implies a lower bound for $\int_0^L u^{m-1}(s)ds$. If, on the other hand $x_1 > L/2$ then u is concave on $(0, x_1)$ hence is bounded below by the piecewise linear function $p(x)$ satisfying $p(0) = p(x_1) = 0$, $p(x_0) = \|u\|_{L^\infty}$. Since $\|u\|_{L^\infty}$ is bounded below by Proposition 2.1(ii) we again obtain a lower bound for R.

Finally, to prove (2.10) we see from the equation that

$$(u_x + \varepsilon u^m)_x \leqq 0 \qquad 0 < x < L \tag{2.11}$$

so that

$$u_x \geqq -\varepsilon u^m + u_x(L). \tag{2.12}$$

From this differential inequality we see that

$$\int_0^{\|u\|_{L^\infty}} \frac{du}{\varepsilon u^m - u_x(L)} \leqq L$$

so that, since $m \geqq 1$, $\|u\|_{L^\infty}$ tends to zero as $u_x(L)$ tends to zero. Hence, by Proposition 2.1(ii), $u_x(L)$ must be bounded away from zero. □

Let us denote $\psi(x) = \frac{\pi}{2L} \sin((\pi/L)\, x)$, i.e., ψ is the first eigenfunction of $-d^2/dx^2$ on $(0, L)$ normalized in $L^1(0, L)$.

LEMMA 2.4. *Let $p > m$, $\varepsilon_0 > 0$. There exists C_1 depending only on ε_0, p, m, and L such that if u is a solution of (2.1(ε)) with $\varepsilon \leqq \varepsilon_0$ then*

$$\int_0^L u\psi^{p/(p-m)} dx \leqq C_1 \tag{2.13}$$

$$\int_0^L u^p \psi^{p/(p-m)} dx \leqq C_1 \tag{2.14}$$

Proof. Let $n = \frac{p}{p-m}$, $\lambda = \left(\frac{\pi}{L}\right)^2$, multiply the equation by ψ^n and integrate from 0 to L. Simple integration by parts yields

$$\int_0^L u^p \psi^n dx + \int_0^L n(n-1) u\psi^{n-2}\psi_x^2 dx = \lambda n \int_0^L u\psi^n dx + \varepsilon n \int_0^L u^m \psi^{n-1}\psi_x \, dx. \tag{2.15}$$

Using Hölder's and Young's inequalities we find

$$\int_0^L u^p \psi^n dx \leqq \lambda n \int_0^L u\psi^n dx + \varepsilon n \left(\delta \int_0^L u^p \psi^n + C(\delta) \int_0^L |\psi_x|^n \, dx \right). \tag{2.16}$$

Choosing $\delta = 1/2\varepsilon n$, we get

$$\int u^p \psi^n \, dx \leqq 2\lambda n \int u\psi^n \, dx + C(\varepsilon_0, n, L). \tag{2.17}$$

Now from Jensen's inequality the left-hand side of (2.17) is bounded below by

$$\frac{\left(\int u\psi^n dx\right)^p}{\left(\int \psi^n dx\right)^{p-1}} \tag{2.18}$$

and the conclusion follows easily. □

LEMMA 2.5. *Let $p > m$, $\varepsilon_0 > 0$ and $0 < a < b < L$. There exists C_2 depending on $\varepsilon_0, p, m, L, a$, and b such that if u is a solution of (2.1(ε)) with $\varepsilon \leqq \varepsilon_0$ then*

$$\|u\|_{L^\infty(a,b)} \leqq C_2 \tag{2.19}$$

$$\|u_x\|_{L^1(a,b)} \leqq C_2. \tag{2.20}$$

Proof. We claim that there exists a constant $C = C(\varepsilon_0, p, m, L)$ and $x_2 \in [L/8, 7L/8]$ such that

$$|u_x(x_2)| + \varepsilon|u^m(x_2)| \leqq C. \tag{2.21}$$

Assuming (2.21) for the moment, we have from (2.1(ε)) the equation

$$u_x(x) + \varepsilon u^m(x) = u_x(x_2) + \varepsilon u^m(x_2) + \int_{x_2}^{x} u^p(s)\,ds. \tag{2.22}$$

By Lemma 2.4 u is bounded in $L^p_{\text{loc}}(0, L)$, uniformly in ε for $\varepsilon \leqq \varepsilon_0$. Hence from (2.21) and (2.22), we see that $u_x + \varepsilon u^m$ is bounded in $L^\infty_{\text{loc}}(0, L)$. Since $m < p$, u^m is bounded in $L^1_{\text{loc}}(0, L)$, again uniformly in ε for $\varepsilon \leqq \varepsilon_0$, and (2.20) follows. The estimate (2.19) follows immediately from (2.20) and (2.21).

It remains to prove the claim (2.21). From (2.13) it follows that $\text{meas}\{u\psi^n \geqq k\} < L/16$ for large enough $k = k(\varepsilon_0, p, m, L)$. Suppose u achieves its maximum at $x_0 < L/2$ (the argument is similar if $x_0 > L/2$). There must exist $x^* \in (L/2, 5L/8)$ such that $u(x^*)\psi^n(x^*) \leqq k$ and $u(x) \leqq u(x^*)$ for $x \geqq x^*$. By the mean value theorem there must exist $x_2 \in (x^*, 7L/8)$ such that

$$-u_x(x_2) = \frac{u(x^*) - u\left(\frac{7L}{8}\right)}{\frac{7L}{8} - x^*} \leqq \frac{4k}{\psi^n\left(\frac{5L}{8}\right) L} \tag{2.23}$$

Since $u(x_2) \leqq u(x^*) \leqq \frac{k}{\psi^n(5L/8)}$ the claim is proved. □

We now prove that for $p > m$ there is exactly one solution of (2.1(ε)) for ε sufficiently small. Let us denote by $\underline{u}_\varepsilon$ the known solution given by Proposition 2.1 for ε near 0.

PROPOSITION 2.6. *Let $p > m$. There exists $\varepsilon_1 > 0$ such that (2.1(ε)) has exactly one solution for $0 < \varepsilon < \varepsilon_1$.*

Proof. Suppose the conclusion is false. Then there exists $\varepsilon_j \to 0$ and u_j, a solution of (2.1ε_j), with $u_j \neq \underline{u}_{\varepsilon_j}$. Let $\zeta \in C_0^\infty(0, L)$; we have

$$\int_0^L u_j\zeta_{xx} - \varepsilon_j u_j^m\zeta_x + u_j^p\zeta\,dx = 0 \tag{2.24}$$

By Proposition 2.5 $\{u_j\}$ is precompact in $L^2_{\text{loc}}(0, L)$. Hence (passing to a subsequence) there exists $u^* \in L^2_{\text{loc}}(0, L)$ such that

$$\int_0^L [u^*\zeta_{xx} + (u^*)^p\zeta]\,dx = 0. \tag{2.25}$$

Since ζ is arbitrary we conclude that $(u^*)_{xx} \leqq 0$ weakly, and hence strongly on $(0, L)$.

Now let x_{1j} be the inflection point for u_j. We claim that $x_{1j} \to L$ as $j \to \infty$. Otherwise (for a further subsequence) there exists $L_1 < L$ such that u_j is convex on (L_1, L). Then we must have $(u^*)_{xx} \geqq 0$ on (L_1, L), a contradiction.

Hence for large enough j, u_j is concave on $(0, 3L/4)$.

We now consider two cases. If there is a subsequence $j_k \to \infty$ such that $\|u_{j_k}\|_{L^\infty} \to \infty$, then using the fact that u_{j_k} is concave on $(0, 3L/4)$ it follows that we must have $\int_0^L u_{j_k}\psi^n\,dx \to \infty$ which contradicts Lemma 2.4. If, on the other hand, $\|u_j\|_{L^\infty}$ is bounded independently of j, then one easily checks that u^* must be a solution of

(2.1(0)) or else $u^* \equiv 0$. Now $u^* \equiv 0$ is impossible because of Proposition 2.1(ii). Thus u^* must be the unique solution of (2.1(0)). This contradicts Proposition 2.1(iv) since $\underline{u}_{\varepsilon_j} \neq u_j$. □

3. Description of the set of steady state solutions In this section we complete our discussion of the steady state problem (2.1(ε)) by proving results about the multiplicity of solutions. As the exponents m and p are varied, there are at least four distinct cases which arise. Solution diagrams for these cases may be found in [1, §5].

THEOREM 3.1. *Let $1 < m < p < 2m - 1$. Then there exist $\varepsilon_0, \varepsilon_1$ such that $0 < \varepsilon_1 < \varepsilon_0 < \infty$ and such that*

(i) (2.1(ε)) *has exactly one solution for $0 \leqq \varepsilon < \varepsilon_1$;*
(ii) (2.1(ε)) *has no solution for $\varepsilon > \varepsilon_0$;*
(iii) *If p is close enough to m then there exists ε such that* (2.1(ε)) *has at least two solutions, i.e. $\varepsilon_1 < \varepsilon_0$.*

THEOREM 3.2. *Let $p = 2m - 1$, $m > 1$. Then*

(i) (2.1(ε)) *has exactly one solution for $0 \leqq \varepsilon < \varepsilon_0 \equiv \sqrt{\frac{4}{m}}$;*
(ii) (2.1(ε)) *has no solution for $\varepsilon \geqq \varepsilon_0$.*

THEOREM 3.3. *Let $p > 2m - 1$. Then* (2.1(ε)) *has exactly one solution for all $\varepsilon \geqq 0$.*

As one can see, the results are not complete for $m < p < 2m - 1$. We conjecture that $\varepsilon_1 < \varepsilon_0$ for all m, p in this range.

For the readers convenience we recall the result of [1] for the case $p \leqq m$.

THEOREM 3.4. *Let $1 < p \leqq m$. Then there exists $\varepsilon_0 > 0$ such that*

(i) (2.1(ε)) *has at least two solutions for $0 < \varepsilon < \varepsilon_0$;*
(ii) (2.1(ε)) *has at least one solution for $\varepsilon = \varepsilon_0$;*
(iii) (2.1(ε)) *has no solution for $\varepsilon > \varepsilon_0$.*

We begin the proofs with the easiest case, $p = 2m - 1$. Note that this is exactly the case in which equation (2.8) is linear.

Proof of Theorem 3.2. Define y, h, and R as in Lemma 2.3. If $\varepsilon \geqq \sqrt{4/m}$ all solutions of (2.8) are nonoscillatory, hence $h(0) = h(R) = 0$ cannot be satisfied for any $R > 0$ except if $h \equiv 0$.

To show the existence of at least one solution for $\varepsilon < \sqrt{4/m}$, then by Proposition 2.1 it is enough to obtain an a priori bound for solutions of (2.1(ε)) when $\varepsilon < \sqrt{4/m}$. Thus suppose u is a solution for such an ε. We have by explicit calculation

$$h(y) = Ce^{-(\varepsilon m/2)y} \sin\left(\sqrt{m - \frac{\varepsilon^2 m^2}{4}}\, y\right) \tag{3.1}$$

for some constant C. Since $h > 0$

$$\int_0^L u^{m-1}(s)\,ds = R = \frac{\pi}{\sqrt{m - \frac{\varepsilon^2 m^2}{4}}}. \tag{3.2}$$

The constant C can be determined from

(3.3)

$$y' = u^{m-1} = h^{(m-1)/m} = C^{(m-1)/m} e^{\varepsilon((m-1)/2)y} \sin^{(m-1)/m}\left(\left(\sqrt{m - \frac{\varepsilon^2 m^2}{4}}\right) y\right);$$

i.e.,

$$C^{(m-1)/m} = \frac{1}{L}\int_0^R \frac{e^{\varepsilon\left((m-1)/2\right)y}\,dy}{\sin^{(m-1)/m}\left(\left(\sqrt{m - \frac{\varepsilon^2 m^2}{4}}\right) y\right)}. \tag{3.4}$$

Hence

$$\|u\|_{L^\infty} \leqq C^{m-1} \tag{3.5}$$

and C clearly remains bounded when ε is bounded away from $\sqrt{4/m}$.

Finally, if for some ε there exists two solutions $u_1 \not\equiv u_2$ then the preceding argument shows $\int_0^L u_1^{m-1}\,dx = \int_0^L u_2^{m-1}\,dx$. However, by Proposition 2.1(vi) $u_1 < u_2$ or $u_2 < u_1$, a contradiction. □

Remark. The uniqueness of positive solutions of (2.1(ε)) when $p = 2m - 1$ can also be shown by a scaling argument as follows. The differential equation is invariant under the transformation $u(x) \to \lambda^{1/(p-m)} u(\lambda x)$ for any $\lambda > 0$. Thus, if there existed two distinct positive solutions of (2.1(ε)) then we could find two functions u_i $i = 1, 2$ with $u_1(0) = u_2(0) = 0$, $\|u_1\|_{L^\infty} = \|u_2\|_{L^\infty}$ and both satisfying $u_{xx} + \varepsilon(u^m)_x + u^p = 0$. By uniqueness of solutions of the initial value problem for u, we may conclude that $u_1 \equiv u_2$.

For the proof of Theorem 3.3 we need the following.

LEMMA 3.4. *Let $p > 2m - 1$. Fix $\varepsilon \geqq 0$ and let h_i be positive solutions of* (2.8), (2.9) *on* $[0, R_i]$ *for* $i = 1, 2$. *If* $R_2 > R_1$ *then* $\|h_2\|_{L^\infty} < \|h_1\|_{L^\infty}$.

Proof. If $\|h_2\|_{L^\infty} = \|h_1\|_{L^\infty}$ then $h_1 \equiv h_2$ by uniqueness of solutions of the initial value problem and hence $R_1 = R_2$. Now suppose $\|h_2\|_{L^\infty} > \|h_1\|_{L^\infty}$. By consideration of the phase plane diagram for (2.8) we see that

$$h_2'(R_2) < h_1'(R_1) < 0 < h_1'(0) < h_2'(0). \tag{3.6}$$

We first observe that it is not possible that $h_2(y) \geqq h_1(y)$ for $0 \leqq y \leqq R_1$. Indeed, otherwise

$$(h_1 h_2' - h_2 h_1')' + \varepsilon(h_1 h_2' - h_2 h_1') = h_2 h_1^{(p-m+1)/m} - h_1 h_2^{(p-m+1)/m} < 0 \tag{3.7}$$

since $p > 2m - 1$, so that

$$h_1 h_2' - h_2 h_1' \leqq \big(h_1(0)h_2'(0) - h_2(0)h_1'(0)\big)e^{-\varepsilon y} = 0. \tag{3.8}$$

and in particular

$$-h_2(R_1)h_1'(R_1) \leqq 0,$$

which is a contradiction.

Thus there must exist $y_1 \in (0, R_1)$ such that $h_2 > h_1$ on $(0, y_1)$ and $h_2(y_1) = h_1(y_1)$. There are now two cases. First suppose $h_2'(y_1) \geqq 0$.

Since (3.8) holds on $(0, y_1]$ it follows that $h_1'(y_1) > h_2'(y_1)$. Denote by h_i^{-1} the branches of the inverse function with values in $[0, y_1]$. We see that $h_1'\big(h_1^{-1}(x)\big) - h_2'\big(h_2^{-1}(z)\big)$ must have a root in $\big(0, h_1(y_2)\big)$, i.e., there exist points y_2, y_2^* such that $h_1(y_2) = h_2(y_2^*)$ and $h_1'(y_2) = h_2'(y_2^*)$. Thus by uniqueness for the initial value problem, $h_1(y) = h_2(y + y_2^* - y_2)$, and since $h_1(0) = h_2(0) = 0$ we must have $h_1 \equiv h_2$, a contradiction.

Finally suppose $h_2'(y_1) < 0$. Since $h_2(R_1) > h_1(R_1) = 0$ there must exist $y_2 \in (y_1, R_1)$ such that $h_2(y) > h_1(y)$ on (y_2, R_1) and $h_2(y_2) = h_1(y_2)$. Also we must have $h_1'(y_2) < 0$ and $h_1'(y_2) < h_2'(y_2) < 0$. Using (3.6) we again have a contradiction as in the previous case. □

Proof of Theorem 3.3. First we prove uniqueness. Suppose u_1 and u_2 are both solutions of (2.1(ε)); by Proposition 2.1(vi) we may assume $0 < u_1 < u_2$. Let h_i, R_i $i = 1, 2$ be as in Lemma 2.3, $i = 1, 2$, so that $R_2 > R_1$. Then, from Lemma 3.4, it follows that $\|u_2\|_{L^\infty} < \|u_1\|_{L^\infty}$ a contradiction.

We next show the existence of a solution for all $\varepsilon \geqq 0$. By Proposition 2.1(v) it is enough to show that if $\varepsilon_0 > 0$ there exists $C = C(\varepsilon_0, p, m, L)$ such that if u is a solution of (2.1(ε)) for $\varepsilon \leqq \varepsilon_0$, then $\|u\|_{L^\infty} \leqq C$. Using Lemmas 3.4 and 2.3 it is enough to prove the same statement for solutions of (2.8), (2.9) for a fixed $R = R_0 > 0$.

Let $\psi_\varepsilon(y)$, $\lambda_\varepsilon > 0$ satisfy

$$\psi_\varepsilon'' - \varepsilon m \psi_\varepsilon' = -\lambda_\varepsilon \psi_\varepsilon \tag{3.9}$$

$$\psi_\varepsilon(0) = \psi_\varepsilon(R_0) = 0 \tag{3.10}$$

$$\int_0^{R_0} \psi_\varepsilon(y)\, dy = 1. \tag{3.11}$$

Multiplying (2.8) by ψ_ε and integrating gives

$$\int_0^{R_0} \psi_\varepsilon(y) h^{(p+1-m)/m}(y)\, dy = \frac{\lambda_\varepsilon}{m} \int \psi_\varepsilon(y) h(y)\, dy. \tag{3.12}$$

Hence using Jensen's inequality,

$$\int_0^{R_0} \psi_\varepsilon(y) h^{(p+1-m)/m}(y)\, dy \leqq C(\varepsilon_0, p, m, L). \tag{3.13}$$

Now let $G_\varepsilon(y, \xi)$ be the Green's function for

$$\varsigma'' + \varepsilon m \varsigma' = f \qquad 0 < y < R_0 \tag{3.14}$$

$$\varsigma(0) = \varsigma(R_0) = 0 \tag{3.15}$$

so that

$$h(y) = m \int_0^{R_0} G_\varepsilon(y, \xi) h^{(p+1-m)/m}(\xi)\, d\xi. \tag{3.16}$$

It is a straightforward calculation to check that

$$\left| \frac{G_\varepsilon(y, \xi)}{\psi_\varepsilon(\xi)} \right| \leqq C(\varepsilon_0, m, R_0) \qquad \varepsilon \leqq \varepsilon_0. \tag{3.17}$$

Hence, from (3.13) and (3.17), one obtains the required uniform estimate for h. □

For the proof of Theorem 3.1 we begin with the nonexistence result.

PROPOSITION 3.5. *Let $1 < m < p < 2m - 1$. Then there exists $\varepsilon_0 > 0$ such that (2.1(ε)) has no solution for $\varepsilon \geqq \varepsilon_0$.*

Proof. First we make the following claim. There exists $\alpha_0 > 0$, $\varepsilon^* > 0$ such that if u is a solution of (2.1(ε)) for $\varepsilon > \varepsilon^*$ then there exists $x_2 > x_1$ (x_1 from Lemma 2.2) such that

$$u(x_2) \geqq \alpha_0 \tag{3.18}$$

$$mu_x(x_2) \leqq -\frac{2}{\varepsilon}u^{p-m+1}(x_2) \tag{3.19}$$

To see this define

$$\tilde{x}_2 = \sup\left\{x : mu_x(\hat{x}) + \frac{2}{\varepsilon}u^{p-m+1}(\hat{x}) \geqq 0 \quad \hat{x} < x\right\}. \tag{3.20}$$

Since

$$mu_x(x) + \frac{1}{\varepsilon}u^{p-m+1}(x) \geqq 0 \qquad x \leqq x_1$$

and

$$mu_x(L) + \frac{1}{\varepsilon}u^{p-m+1}(L) < 0,$$

$\tilde{x}_2$ is well defined, and $\tilde{x}_2 \in (x_1, L)$. Now recalling from Proposition 2.1(ii) that $u(x_0) \geqq M_0 > 0$ and integrating the differential inequality $mu_x + (2/\varepsilon)\,u^{p-m+1}(x) \geqq 0$ on $[x_0, \tilde{x}_2]$, we find that $u(\tilde{x}_2) \geqq M_0/2$ for say $\varepsilon > \varepsilon^*$. Choosing $\alpha_0 = M_0/4$ we have that the conditions (3.18) and (3.19) are satisfied by some $x_2 > \tilde{x}_2$.

Next define the function $h(y)$ as in Lemma 2.3 and let $\varsigma(y)$ satisfy

$$\varsigma'' + \varepsilon m\varsigma' + mh(y_2)^{(p+1-2m)/m}\varsigma = 0 \tag{3.21}$$

$$\varsigma(y_2) = h(y_2) \tag{3.22}$$

$$\varsigma'(y_2) = h'(y_2), \tag{3.23}$$

where $y_2 = y(x_2)$. The inequalities (3.18), (3.19) in terms of h are

$$h(y_2) \geqq \alpha_0^m \tag{3.24}$$

$$h'(y_2) < -\frac{2}{\varepsilon}h^{\frac{p-m+1}{m}}(y_2) \tag{3.25}$$

Let $\varepsilon^2 > \max(\varepsilon^{*2}, (4/m)\alpha_0^{p+1-2m})$. We claim that $\varsigma'(y) \leqq 0$ for $y \leqq y_2$. Accepting this for the moment, we have (since $p + 1 - 2m < 0$)

$$(h\varsigma' - h'\varsigma)' + \varepsilon m(h\varsigma' - h'\varsigma) = -m\varsigma h\left(h(y_2)^{(p+1-2m)/m} - h^{(p+1-2m)/m}\right). \tag{3.26}$$

There is an interval $[y_3, y_2]$ on which $h(y) \geqq h(y_2) = h(y_3)$ and so

$$[e^{\varepsilon m y}(h\varsigma' - h'\varsigma)]' \leqq 0 \qquad \text{on } [y_3, y_2] \tag{3.27}$$

and in particular

$$h(y)\varsigma'(y) - h'(y)\varsigma(y) \geqq 0 \qquad y_3 \leqq y \leqq y_2. \tag{3.28}$$

But the interval $[y_3, y_2]$ contains the point $y(x_0)$, where the maximum of h is achieved, and evaluating (3.28) at this point we obtain $\varsigma'(y(x_0)) > 0$, a contradiction.

It remains to verify that $\varsigma'(y) \leqq 0$ for $y \leqq y_2$. This may be checked by writing out explicitly the solution $\varsigma(y)$, and using (3.21)–(3.25). The computation can be made a little less painful by arguing in the following way. First, the characteristic roots for the ς equation are real, hence ς can have no more than one critical point. Since $\varsigma'(y_2) < 0$, if we check that $\varsigma'(y) < 0$ for large negative y we will be done. Now as $y \to -\infty$ it is easy to check that $\varsigma(y) \sim Ce^{ry}$ where $r = -(A + \sqrt{A^2 - 4B})/2$, $C = (rh(y_2) - h'(y_2))/\sqrt{A^2 - 4B}$ and $A = \varepsilon m$, $B = mh(y_2)^{(p+1-2m)/m}$. Thus to conclude we need $h'(y_2) < rh(y_2)$, and because of (3.25) it is enough that $2/\varepsilon\, h^{(p+1-2m)/m}(y_2) \geqq A/2[1 - \sqrt{1 - 4B/A^2}]$. But the left side is $2B/A$, and since $4B/A^2 < 1$ the conclusion follows from the obvious inequality $1 - \sqrt{1 - \xi} < \xi$ for $0 < \xi < 1$. □

Proof of Theorem 3.1. We have already proved (i) in Proposition 2.6 and (ii) in Proposition 3.5. For the proof of (iii) we will need to recall some results from [1]. In that paper solutions of (2.1(ε)) were found by looking for zeros of a function $H(\alpha, \varepsilon) = v(L)$, where $v(x)$ satisfies

$$v_{xx} + \varepsilon(v^m)_x + v^p = 0 \qquad x > 0 \tag{3.29}$$

$$v(0) = 0 \tag{3.30}$$

$$v_x(0) = \alpha. \tag{3.31}$$

Let us fix m and regard H as a function of p also, $H = H(\alpha, \varepsilon, p)$. For $p > 1$ H is C^1 in all variables and by Proposition 2.9 of [1] either $\partial H/\partial\alpha$ or $\partial H/\partial\varepsilon$ is nonzero at any root of H. Also by Proposition 2.4 of [1] $\partial H/\partial\alpha(\alpha_0, 0) > 0$, where α_0 is the initial slope for the unique solution of (2.1(0)). Thus it is not hard to check that there exists $\overline{\varepsilon} > 0$, $\overline{\alpha} > \alpha_0$ and $\overline{m} > m$ such that for $p \in [m, \overline{m}]$, (2.1(ε)) has a solution for all $\varepsilon \in [0, \overline{\varepsilon}]$ with initial slope $\alpha = \alpha(\varepsilon) \leqq \overline{\alpha}$.

Now for $p = m$ it was shown in Proposition 3.5 of [1] that (2.1(ε)) has at least two solutions for all $0 < \varepsilon < \varepsilon_0$, and in particular there is a maximal solution $\overline{u}_\varepsilon$ of (2.1(ε)) with $\overline{u}_{\varepsilon x}(0) \to \infty$ as $\varepsilon \to 0$. Choosing $\varepsilon_2 \in (0, \overline{\varepsilon})$ such that $\overline{u}_{\varepsilon_2 x}(0) > \overline{\alpha}$ yields a curve of roots of H in the form $\alpha = \alpha(\varepsilon, p)$ or $\varepsilon = \varepsilon(\alpha, p)$ containing the point $(u_{\varepsilon_2 x}(0), \varepsilon_2, m)$ and hence for p close enough to m there must be a second solution of (2.1(ε)) for some ε near ε_2. □

4. The time dependent problem. In this section we discuss the large time behavior for the time dependent problem

$$\begin{aligned} (4.1(\varepsilon)) \qquad u_t &= u_{xx} + \varepsilon(u^m)_x + u^p \qquad 0 < x < L \qquad t > 0 \\ u(0,t) &= u(L,t) = 0 \qquad\qquad\qquad\quad t > 0 \\ u(x,0) &= u_0(x) \geqq 0 \qquad\quad 0 < x < L \end{aligned}$$

It is known (e.g., [1], [8]) that for any $u_0 \in L^\infty(0, L)$ there is a solution $u(x,t)$ of (4.1(ε)) on some interval $0 \leqq t \leqq T_{\max}$, for some $T_{\max} \in (0, \infty]$, and if $T_{\max} < \infty$ then $\lim_{t \to T_{\max}^-} \|u(\cdot, t)\|_{L^\infty(0,L)} = \infty$.

Our first result gives sufficient conditions that $T_{\max}$ be finite, i.e. that the solution of (4.1(ε)) blow up in finite time. Recall we have defined $\psi(x) = (\pi/2L)\, sin\, ((\pi/L)x)$ and $n = p/(p - m)$.

PROPOSITION 4.1. *Let $p > m$. Then there exists $C_0 = C_0(\varepsilon, p, m, L) < \infty$ such that if*

$$\int_0^L u_0(x)\psi^n(x)\,dx > C_0 \tag{4.2}$$

then the solution of (4.1(ε)) blows up in finite time.

Remark. The proof is a variation of the eigenfunction method (e.g., Kaplan [6], Levine [14] and Payne [10]). The nature of the blow-up set has been studied by Friedman and Lacey [4]. Recall from [1] that if $\varepsilon \neq 0$ and $p \leqq m$ then $T_{\max} = \infty$ for any $u_0 \in L^\infty(0, L)$. See Chipot and Weissler [3] for another recent result about blow-up for an equation with nonlinear gradient dependence; previous work on blow-up has generally only dealt with the reaction-diffusion case.

Proof. Set

$$F(t) = \int_0^L u(x,t)\psi^n(x)\,dx. \tag{4.3}$$

A short calculation shows that

$$F'(t) \geqq -(\pi^2/L^2)\,n\int_0^L \psi^n(x)u(x,t)\,dx - \varepsilon n\int_0^L u^m(x,t)\psi^{n-1}(x)\psi_x(x)\,dx + \int_0^L u^p(x,t)\psi^n(x)\,dx. \tag{4.4}$$

Using Jensen's inequality we see that

$$\varepsilon n\int_0^L u^m(x,t)\psi^{n-1}(x)\psi_x(x)\,dx \leqq A_1\left(\int_0^L u^p(x,t)\psi^n(x)\,dx\right)^{m/p} \tag{4.5}$$

$$\frac{\pi^2}{L^2}n\int_0^L u(x,t)\psi^n(x)\,dx \leqq A_2\left(\int_0^L u^p(x,t)\psi^n(x)\,dx\right)^{1/p} \tag{4.6}$$

with

$$A_1 = \varepsilon n\|\psi_x\|_{L^\infty(0,L)}L^{1-m/p} \tag{4.7}$$

$$A_2 = \frac{\pi^2}{L^2}n\left(\int_0^L \psi^n(x)\,dx\right)^{(p-1)/p}. \tag{4.8}$$

Therefore

$$F'(t) \geqq Q\left(\int_0^L u^p(x,t)\psi^n(x)\,dx\right) \tag{4.9}$$

with

$$Q(s) = s - A_1 s^{m/p} - A_2 s^{1/p}. \tag{4.10}$$

If s_0 is the largest positive root of Q, then $Q(s), Q'(s) > 0$ for $s > s_0$. If

$$F(0) > C_0 \equiv A_2 s_0^{1/p}, \tag{4.11}$$

then one sees easily that $\int_0^L u^p(x,t)\psi^n(x)\,dx > s_0$ for all t and so

$$F'(t) \geqq Q\left(\frac{1}{A_2}F^p(t)\right). \tag{4.12}$$

Since $p > 1$, $F(t)$ must blow up in finite time. □

We next recall some results from [1].

PROPOSITION 4.2. *Let $m \geqq 1$, $p > 1$, $\varepsilon \in \mathbf{R}$*

(i) *$u \equiv 0$ is an asymptotically stable steady state solution of (4.1(ε)).*
(ii) *If (4.1(ε)) has any positive steady state then it has a minimal one, $\underline{u}_\varepsilon$, which is unstable from below.*
(iii) *Let $E = \{\varepsilon : \underline{u}_\varepsilon$ is stable from above$\}$. Then E is nowhere dense and there exists $\varepsilon_2 > 0$ such that $E \cap (-\varepsilon_2, \varepsilon_2) = \varnothing$.*

Remark. In general the possibility that a steady state is stable from above and unstable from below (i.e., is not hyperbolic) cannot be ruled out, such behavior being necessary at the "turning points" of the solution curve Γ (defined at the beginning of §2), which may occur for $1 < p \leqq m$.

Another important result concerning the asymptotic behavior of solutions of (4.1(ε)) follows from general theorems due to Zelenyak [13].

PROPOSITION 4.3. *Let $u(x,t)$ be a solution of (4.1(ε)) such that $\|u(\cdot,t)\|_{L^\infty(0,L)}$ is uniformly bounded for $t > 0$. Then there exists a nonnegative steady state u^* of (4.1(ε)) such that $u(x,t) \to u^*(x)$ uniformly as $t \to \infty$.*

Remark. We may conclude, for example, from Propositions 4.2(ii), 4.3 and the maximum principle that if $u_0(x) \leqq \underline{u}_\varepsilon(x)$, $u_0(x) \not\equiv \underline{u}_\varepsilon(x)$ then the solution of (4.1(ε)) tends to 0 as $t \to \infty$.

To conclude we summarize all that we can say about the asymptotic behavior of solutions of (4.1(ε)) under various conditions on m, p, and ε. In what follows, the numbers ε_0, ε_1, and ε_2 have the meaning assigned to them in Theorems 3.1, 3.2, 3.3, and Proposition 4.2.

Case 1. $m < p < 2m - 1$ and $\varepsilon > \varepsilon_0$ or $p = 2m - 1$ and $\varepsilon \geqq \varepsilon_0$. In this case the only nonnegative steady state is $u \equiv 0$, which is asymptotically stable. If $u(x,t)$ is the solution of (4.1(ε)) then either it converges to 0 as $t \to \infty$ or it tends to infinity in finite or infinite time. If u_0 is small enough (in $L^\infty(0,L)$ say) then u must tend to zero, while if u_0 is large enough so that 4.2 holds, then u must go to ∞ in finite time. We mention that Matano has shown ([9]), for the case of a reaction-diffusion equation in one space dimension, that blow up cannot occur if the maximal nonnegative solution is stable from above. The present example shows that Matano's result is false in general if the equation has some first derivative terms.

Case 2. $m < p < 2m - 1$ and $\varepsilon < \varepsilon_1$ or $p = 2m - 1$ and $\varepsilon < \varepsilon_0$ or $p > 2m - 1$. In this case there is exactly one positive steady state $\underline{u}_\varepsilon$ which is unstable from below. For any u_0 the solution must either tend to 0 as $t \to \infty$ or tend to $\underline{u}_\varepsilon$ as $t \to \infty$ or tend to infinity in finite or infinite time. If $u_0 \leqq \underline{u}_\varepsilon$, $u_0 \not\equiv \underline{u}_\varepsilon$ or if u_0 is sufficiently small in $L^\infty(0,L)$ then $u \to 0$ as $t \to \infty$. If u_0 is large enough so that (4.2) holds then u tends to infinity in finite time.

Case 3. Same as Case 2 and also $\varepsilon \notin E$ (in particular $0 < \varepsilon < \varepsilon_2$). In this case we also have $\underline{u}_\varepsilon$ unstable from above so we can assert in addition that if $u_0 \geqq \underline{u}_\varepsilon$, $u_0 \not\equiv \underline{u}_\varepsilon$, then u tends to infinity in finite or infinite time.

Case 4. $m < p < 2m-1$, $\varepsilon_1 < \varepsilon < \varepsilon_0$. In this case there are one or more positive steady states. For any u_0, the solution u must tend to a nonnegative steady state or tend to infinity in finite or infinite time. Again if $u_0 \leqq \underline{u}_\varepsilon$, $u_0 \not\equiv \underline{u}_\varepsilon$ or if u_0 is small enough in $L^\infty(0,L)$ then $u \to 0$ as $t \to \infty$ while if 4.2 holds then u tends to infinity in finite time. If $\varepsilon \notin E$ then there must exist another steady state solution $\overline{u}_\varepsilon > \underline{u}_\varepsilon$ which is stable from below.

5. More general nonlinearities. In this section we describe briefly how the results of §§2-4 can be generalized to the case of nonpower-law nonlinearities. We will write the steady state problem as

$$(5.1\varepsilon) \qquad \begin{aligned} u_{xx} + \varepsilon\big(g(u)\big)_x + f(u) &= 0 \qquad 0 < x < L \\ u(0) = u(L) &= 0 \\ u(x) &> 0 \qquad 0 < x < L. \end{aligned}$$

Let us first list all of the hypotheses that may be used

(H1) $f \in C^1\big([0,\infty)\big)$, $f(0) = 0$, $f(u)/u$ is strictly increasing on $\mathbf{R}^+$

$$0 \leqq \lim_{u\to 0} \frac{f(u)}{u} < \left(\frac{\pi}{L}\right)^2 < \lim_{u\to\infty} \frac{f(u)}{u}.$$

(H2) $g \in C^1\big([0,\infty)\big)$, $g(0) = 0$, $g'(u) > 0$ for $u > 0$.

(H3) $f(u)/g'(u)$ is nondecreasing on $\mathbf{R}^+$.

(H4) $f(u)/g(u)g'(u)$ is strictly increasing on $\mathbf{R}^+$ with $\lim_{u\to\infty} f(u)/g(u)g'(u) = \infty$.

(H5) $f(u)/g(u)g'(u)$ is strictly decreasing on $\mathbf{R}^+$ with $\lim_{u\to\infty} f(u)/g(u)g'(u) = 0$.

(H6) $f(u)/g(u)g'(u) \equiv \lambda$ (a constant).

(H7) $f(u) \geqq C_1 u^p - C_2$, $u \geqq 0$, some $C_1, C_2 \geqq 0$.

(H8) $g(u) \leqq C_3 u^m + C_4$, $u \geqq 0$, some $C_3, C_4 \geqq 0$.

THEOREM 5.1. *Let (H1), (H2) and (H3) hold*

(i) *Assume* (H5), (H7) *and* (H8) *hold with* $p > m$. *Then there exists* $\varepsilon_0, \varepsilon_1$ *such that* $0 < \varepsilon_1 \leqq \varepsilon_0 < \infty$ *and such that* (5.1(ε)) *has exactly one solution for* $0 \leqq \varepsilon < \varepsilon_1$ *and no solution for* $\varepsilon > \varepsilon_0$.

(ii) *Assume* (H6). *Then* (5.1(ε)) *has exactly one solution for* $0 \leqq \varepsilon < \sqrt{4\lambda}$ *and no solution for* $\varepsilon \geqq \sqrt{4\lambda}$.

(iii) *Assume* (H4). *Then* (5.1(ε)) *has exactly one solution for all* $\varepsilon \geqq 0$.

Let us make some remarks about which hypotheses are necessary for the various Lemmas and Propositions. Proposition 2.1 is true if the conditions $p > 1$ and $m \geqq 1$ are replaced by (H1) and (H2), except possibly for part (iii) which is proved in [1] only for the case that (H1) holds and $g(u) = u^m$, $m \geqq 1$. However, the fact that Γ is locally a simple curve is not explicitly used in what follows. The conclusion of Lemma 2.2 is still true if we assume (H1), (H2), and (H3). In Lemma 2.3 we set

$$(5.2) \qquad y(x) = \int_0^x g'\big(u(s)\big)ds$$

$$(5.3) \qquad h(y) = g\big(u(y)\big)$$

and in place of (2.8) we have

$$(5.4) \qquad h_{yy} + \varepsilon h_y + F(h) = 0$$

with

$$F(h) = f(g^{-1}(h))/g'(g^{-1}(h)). \tag{5.5}$$

The lower bound for $R = \int_0^L g'(u(s))ds$ in Lemma 2.3 remains valid if we assume (H1), (H2), and (H3). Lemmas 2.4 and 2.5 are true if we assume (H7) and (H8) with $p > m$; in (2.14), we replace u^p by $f(u)$. The conclusion of Proposition 2.6 still holds if we assume (H1), (H2), (H3), (H7), and (H8) with $p > m$. In §3, Lemma 3.4 will be true under hypotheses (H1), (H2), and (H4), and for Propositon 3.5 we assume (H1), (H2), (H3), and (H5).

Concerning the time dependent problem

$$\begin{aligned} (5.6(\varepsilon)) \qquad & u_t = u_{xx} + \varepsilon(g(u))_x + f(u) && 0 < x < L \qquad t > 0 \\ & u(0,t) = u(L,t) = 0 \\ & u(x,0) = u_0(x) \geqq 0 && 0 < x < L \end{aligned}$$

an adequate existence, uniqueness, and continuation theory will be true, provided (H1) and (H2) hold, and an analogue of the blow-up result Proposition 4.1 is proved as before if we assume also H7 and H8 with $p > m$.

In Proposition 4.2, parts (i) and (ii) are true assuming (H1) and (H2). The set E in part (iii) still cannot intersect an interval $(-\varepsilon_2, \varepsilon_2)$ but the fact that it is nowhere dense was proved in [1] assuming only that (H1) holds and $g(u) = u^m$ $m \geqq 1$. The stabilization result, Proposition 4.2, is true under conditions (H1) and (H2), although more regularity is assumed in [13]. We leave to the interested reader the formulation of results about the asymptotic behavior analogous to those stated at the end of §4.

NONMONOTONE CLINES IN HOMOGENEOUS SPACE CANNOT BE STABLE*

EBBE THUE POULSEN†

Abstract. This paper deals with models for the space-time variation of the genetic composition of populations. Both the standard reaction-diffusion equation and two nonlinear integral operator models are discussed. A simple argument is presented, explaining that nonconstant stationary solutions, so-called *clines*, in a homogeneous space cannot be stable unless they are monotone.

In the integral operator case the proof uses differentiation along the orbits of the translation group and the Perron–Frobenius Theorem for integral operators with nonnegative kernel. For the reaction-diffusion equation stronger results are known, and only a heuristic argument is given.

Key words. clines, instability, equilibria, discrete-time dynamical systems, Perron-Frobenius property, nonlinear integral operators

AMS(MOS) subject classifications. primary 45M10; secondary 92A10.

1. Some models in population genetics and dynamics. Population genetics has given rise to an abundance of mathematical models distinguished by various characteristic properties: deterministic or stochastic models; continuous or discrete time; haploid or diploid species; one locus or many loci, and, in the one-locus-case: two or more alleles; one habitat, several discrete habitats, or a habitat that is a region in $\mathbf{R}^n$ for $n=1$, 2, or 3. The mathematical problems considered in this paper correspond to deterministic models for one locus with two alleles (denoted A and a) in a diploid population distributed over all of $\mathbf{R}$.

As the literature amply testifies, even the very simplest problem of a population with one locus and two alleles in just one habitat has given rise to an impressive number of different models, and for some of these the analysis of the dynamics is quite complicated. Part of the reason for this complexity is the fact that the natural state space is three-dimensional, the three natural variables being the population sizes (u, v, w) of the genotypes AA, Aa, and aa. Two important additional variables are the total population size $N=u+v+w$ and the gene frequency (i.e., the fraction of the gene A in the total gene pool) $p=(2u+v)/(2N)$. The latter, in particular, is the focus of attention in population genetics, and models formulated only in terms of this one variable are of special interest.

For a population with separate generations (and under the usual assumption of random mating), the two variables N and p completely determine the state immediately after the creation of a new generation, namely

$$(u, v, w)=(Np^2, 2Np(1-p), N(1-p)^2).$$

Simple assumptions concerning the nature of the selection process lead to a formula of the form

$$p_1=g_0(p)$$

for the gene frequency of the next generation, where

$$g_0(p)=\frac{W_1p^2+W_2p(1-p)}{W_1p^2+2W_2p(1-p)+W_3(1-p)^2}, \tag{1}$$

and the positive numbers W_i, $i = 1, 2, 3$ can be interpreted as "fitnesses" of the three genotypes (they can arise in different ways in different models).

When the assumption is added that the population is distributed over a region in space, models can be formulated in terms of variables u, v, w, and N with similar interpretations as above, except that they are functions of space and time, and should be thought of as spatial densities. p is also a function of space and time with values that are real numbers between 0 and 1.

The papers by Felsenstein [9] and Weinberger [29] and the book by Fife [11] give impressions of the many different deterministic models that have been proposed for the description of the combined processes of selection, population size dynamics, and migration, as well as of the mathematical results obtained.

Whether or not the dynamics of a spatially distributed population with separate generations can be described in terms of the sole variable p depends on the assumptions concerning the interplay between the processes of selection, population regulation, and migration. If each generation is subject first to selection, then to population regulation (in the form that population density is set to a global constant without change in the local genotype proportions), and finally to migration, then the gene frequency distribution p_{n+1} of the offspring generation is derived from the gene frequency distribution p_n of the parent generation by

$$p_{n+1} = Qp_n, \tag{2}$$

where Q is a nonlinear integral operator of the form

$$Qp(x) = \int k(x, y) g(p(y))\, dy. \tag{3}$$

Here g denotes the function g_0 given by (1), and the kernel k describes the migration process (cf. Weinberger [29, formulae (2.1)-(2.4)]). If, on the other hand, regulation acts first, followed by selection and migration, then the gene frequency distribution p_{n+1} is given by

$$p_{n+1} = Rp_n, \tag{4}$$

where

$$Rp(x) = \frac{\int k(x, y) g(p(y))\, W(p(y))\, dy}{\int k(x, y)\, W(p(y))\, dy}. \tag{5}$$

Here, again, g is the function given by (1), and $W(p)$ is the denominator in (1):

$$W(p) = W_1 p^2 + 2W_2 p(1-p) + W_3(1-p)^2 \tag{6}$$

(cf. Weinberger [29, formula (2.12)]). It seems that, roughly speaking, these two situations are the only ones for which a model with one-dimensional state space is appropriate.

In the derivation of (2) and (4), the assumption of nonoverlapping generations is crucial. The standard model in the absence of this assumption is a differential equations model of the type considered by Fisher [13] and by Kolmogorov, Petrovskii, and Piskunov [19] in 1937:

$$\frac{\partial p}{\partial t} = \frac{\partial}{\partial x}\left(a \frac{\partial p}{\partial x}\right) + f(p) \tag{7}$$

(or its equivalent in higher-dimensional space). This model can be justified if the processes of selection and migration are slow when measured in terms of the life span

of individuals (cf., for instance, Nagylaki [23] and Weinberger [28, §8]). The selection process is slow if W_1, W_2, and W_3 are of the same order of magnitude, say $\bar{W}$. Then $W(p) \approx \bar{W}$ for $0 \leqq p \leqq 1$, and $g_0(p) - p \approx f_0(p)$, where

$$f_0(p) = p(1-p)(d_1 p - d_3(1-p)) \tag{8}$$

with

$$d_1 = (W_1 - W_2)/\bar{W}, \qquad d_3 = (W_3 - W_2)/\bar{W}.$$

Usually, the function f in (7) is assumed to be of the form (8) with (d_1, d_3) proportional to $(W_1 - W_2,\ W_3 - W_2)$. If the time scales of the processes of selection, migration, and reproduction are comparable, it seems that much more complicated models, such as models with age structure, are required.

2. Equilibrium distributions. Existence and stability. Known results. At the present stage of the presentation we will not be very specific about properties of the functions entering in the models (2), (4), and (7). As already indicated, we restrict ourselves to the case $n = 1$. We denote by Q and R, the operator given by (3) and (5), respectively where

p is a function from $\mathbf{R}$ to $[0, 1]$;

$g : [0, 1] \to [0, 1]$ is continuously differentiable and monotone;

$g(0) = 0$, $g(1) = 1$;

$W(p)$ is given by (6);

k is nonnegative and satisfies $\int k(x, y)\, dy = 1$ for all x.

Similarly, in order to talk conveniently about (7), we introduce the nonlinear differential operator A defined by

$$A(p) = \frac{\partial}{\partial x}\left(a \frac{\partial p}{\partial x}\right) + f(p),$$

where

the function $a : \mathbf{R} \to \mathbf{R}$ is strictly positive;

$f : [0, 1] \to \mathbf{R}$ is continuously differentiable; and

$f(0) = f(1) = 0$.

Depending on the model considered, an *equilibrium solution* is a function $p : \mathbf{R} \to [0, 1]$ satisfying $Qp = p$, $Rp = p$, or $Ap = 0$, respectively.

The constant functions $p(x) = 0$ and $p(x) = 1$ are trivial equilibria. Other obvious equilibria are constant functions $p(x) = \bar{p}$, where $\bar{p}$ is such that $g(\bar{p}) = \bar{p}$, or $f(\bar{p}) = 0$ respectively.

Less obvious, and mathematically and genetically more interesting, are nonconstant equilibrium solutions, so-called *clines*.

The existence of clines and their stability has been discussed by a large number of authors. It is a typical feature of these papers that stability rests on an assumption about spatial inhomogeneity (in this connection a subdivision of space into a finite or infinite collection of separate habitats is an extreme case of spatial inhomogeneity). See, e.g., Karlin and McGregor [16] for the case of several discrete habitats; Downham and Shah [7], Diekmann [6], and Lui [20] for the discrete time model (2); and Slatkin [27], Conley [4], Fleming [14], May, Endler, and McMurtrie [21], Nagylaki [23], Fife and Peletier [12], and Keller [18] for the diffusion equation model (7).

It is much less clear what to expect in homogeneous space, i.e., in the situation where the region considered is all of $\mathbf{R}$, and the operator Q, R, or A commutes with

translations. For the operators Q and R, this assumption means that W_1, W_2, and W_3 (and hence g) do not depend explicitly on x, and that k is of the form $k(x, y) = h(x-y)$. For the operator A it means that a is constant and f does not depend explicitly on x.

For (7) the situation is well understood. If $f(p)$ is of the form (8), and if $W_2 \geqq \min(W_1, W_3)$, then every equilibrium is constant. If $W_2 < \min(W_1, W_3)$ (the heterozygote is inferior), then there exist nonconstant equilibria, and every nonconstant equilibrium p_0 has one of the following properties:

(1) p_0 is periodic;

(2) p_0 has a single maximum, and $p_0(x) \to 0$ for $|x| \to \infty$, i.e., p_0 represents a "pocket" containing the (superior) gene A surrounded by a population in which the gene a is predominant;

(3) p_0 has a single minimum, and $p_0(x) \to 1$ for $|x| \to \infty$, i.e., p_0 represents a "pocket" containing the (inferior) gene a surrounded by a population in which the gene A is predominant;

(4) p_0 is a monotone cline, and $p_0(x) \to 0$ for $x \to -\infty$, $p_0(x) \to 1$ for $x \to \infty$ or conversely.

For a given set of W's, exactly one of the cases (2)-(4) occurs, depending on whether $W_1 > W_3$, $W_1 < W_3$, or $W_1 = W_3$. Furthermore, a nonconstant equilibrium is unstable unless it is monotone. See, for instance, McKean [22], Bazykin [3], Fife [10], Fife [11, §4.3], Razževaĭkin [24], Rosen [25], and Hagan [15].

Much less is known about the time evolution given by (2) or (4). It can be deduced from Theorem 6.5 in Weinberger [29] that if $g(p)$ is of the form (1), and if $W_2 \geqq \min(W_1, W_3)$, then every equilibrium is constant. In a forthcoming paper we will prove that if the heterozygote is inferior, then there exist nonconstant equilibria. It is not known, however, whether in the inferior heterozygote case, every nonconstant equilibrium has one of the properties (1)-(4), but we conjecture that this is the case. The purpose of the present paper is to prove an instability result analogous to the one mentioned above, viz. that a nonconstant equilibrium for (2) or (4) is unstable unless it is monotone. Since we must assume that the equilibrium considered has one of the properties (1)-(3), we do not quite succeed in this purpose.

3. The role of spatial homogeneity. Heuristics. A number of the assertions in this section should be taken with a grain of salt, for in order to bring out the basic ideas we will not worry about specifying precise conditions under which all steps are valid.

We consider the case of homogeneous space and assume that p_0 is an equilibrium solution to (2). For $r \in \mathbf{R}$ we let p_r denote the translate of p_0 defined by

$$p_r(x) = p_0(x+r). \tag{9}$$

Then, by the assumption of homogeneity, p_r is also an equilibrium solution, i.e.,

$$Qp_r = p_r \quad \text{for all real } r. \tag{10}$$

Consequently, *if* we work in a space F of functions having a differentiable structure, say F is a Banach space or a Banach manifold, and *if* the curve $r \mapsto p_r$ in F is differentiable at 0, and *if* Q is differentiable at p_0, then it follows by differentiation in (10) that

$$Q'p' = p'. \tag{11}$$

Here Q' denotes the derivative of Q at p_0 and p' denotes the derivative of p_r at the point $r = 0$. Now, with p_r defined by (9), it is true in "most" function spaces F that if the derivative p' exists, it is equal to the usual derivative p_0' of p_0 with respect

to x (for this to be true it is sufficient that the natural injection of F into the space $\mathcal{D}'$ of distributions is continuous and that p_0' is taken in the distribution sense). Also, in "most" function spaces it is true that if the derivative Q' exists at p, it is given by the linear integral operator

$$Q'(p_0)u(x) = \int h(x-y)g'(p_0(y))u(y)\,dy.$$

Since g is monotone, g' is nonnegative, so $Q'(p_0)$ is an integral operator with nonnegative kernel, and by (11) the function p_0' is an eigenfunction corresponding to the eigenvalue 1. Finally we note that "a lot of" integral operators with nonnegative kernal have the "Perron-Frobenius property," i.e., there exists a nonnegative eigenfunction, and its corresponding eigenvalue is simple and numerically maximal, i.e., it is equal to the spectral radius of the operator.

Clearly, if the preceding results apply, then an equilibrium solution p_0 to (2) that is not monotone must be unstable. This is true because p_0' is an eigenfunction for $Q'(p_0)$, and the Perron-Frobenius property implies that the corresponding eigenvalue, which is 1, is not the largest eigenvalue of $Q'(p_0)$ since the eigenfunction p_0' takes both positive and negative values. But if $Q'(p_0)$ has an eigenvalue larger than 1, then p_0 is an unstable equilibrium.

Next, consider an equilibrium solution of (4), i.e.,

$$p_0 = Rp_0 = \frac{Mp_0}{Np_0},$$

where

$$Mp(x) = \int h(x-y)g(p(y))W(p(y))\,dy, \tag{12}$$

$$Np(x) = \int h(x-y)W(p(y))\,dy. \tag{13}$$

As above, it follows from the assumption of spatial homogeneity that p_0' is an eigenfunction of the derivative $R'(p_0)$ corresponding to the eigenvalue 1, and, as above, under mild regularity assumptions, the operator $R'(p_0)$ is a linear integral operator with kernel

$$\begin{aligned} K(x,y) &= h(x-y)[Np_0(x)]^{-2}[Np_0(x)(gW)'(p_0(y)) - Mp_0(x)W'(p_0(y))] \\ &= h(x-y)[Np_0(x)]^{-1}[(gW)'(p_0(y)) - p_0(x)W'(p_0(y))]. \end{aligned} \tag{14}$$

Since $0 \leqq p_0(x) \leqq 1$ for all x, the kernel K is nonnegative if

$$(gW)'(p) \geqq \max(0, W'(p)) \quad \text{on } [0,1]. \tag{15}$$

Precisely as above we see that if $R'(p_0)$ has the Perron-Frobenius property, then p_0 cannot be stable unless it is monotone.

Finally, if p_0 is an equilibrium solution of

$$\frac{\partial p}{\partial t} = Ap, \tag{16}$$

then it follows from the translation invariance of the equation that the derivative p_0' is a solution to the linear differential equation

$$a\frac{d^2u}{dx^2} + f'(p_0(x))u = 0.$$

For "a lot of" second-order differential operators of the form

$$Lu = a\frac{d^2u}{dx^2} + qu$$

with positive a there is a positivity result related to the Sturm oscillation theorems that, in this connection, can replace the Perron-Frobenius property. The result in question states that if the upper part of the spectrum of L is discrete, then L has a positive eigenfunction, and the corresponding eigenvalue is simple and is the largest point in the spectrum of L.

Again, if the preceding results apply, then an equilibrium solution p_0 to (16) that is not monotone must be unstable. To see this, observe that since p_0' is an eigenfunction for L, and since it takes both positive and negative values, by the above-mentioned positivity result the corresponding eigenvalue, which is zero, is not the largest eigenvalue of L. But if L has an eigenvalue larger than zero, then p_0 is unstable. See Remark 2 below for a strengthening of this statement.

4. Formulation of assumptions and theorems.

Assumptions A. The function $g:[0,1]\to[0,1]$ satisfies the following:

(i) $g(0)=0$, $g(1)=1$;
(ii) g is differentiable with Hölder continuous derivative;
(iii) $g'(p)>0$ on $]0,1[$;
(iv) $g'(0)<1$.

Assumptions B. The function $h:\mathbf{R}\to\mathbf{R}$ satisfies the following:

(i) $h(x)\geqq 0$ on $\mathbf{R}$;
(ii) h is continuously differentiable;
(iii) $\int h(x)\,dx = 1$;
(iv) $\int |h'(x)|\,dx < \infty$;
(v) the closed additive subsemigroup of $\mathbf{R}$ generated by supp (h) is all of $\mathbf{R}$.

Assumptions C. The function $W:[0,1]\to\mathbf{R}$ satisfies the following:

(i) $W(p)>0$ on $[0,1]$;
(ii) W is differentiable with Hölder continuous derivative;
(iii) $(gW)'(p)\geqq \max(0, W'(p))$ for $p\in]0,1[$.

DEFINITION. By P we denote the subset of L^∞ defined by

$$P=\{p\in L^\infty : 0\leqq p(x)\leqq 1 \text{ a.e.}\}.$$

THEOREM 1. *Let Assumptions* A *and* B *be satisfied, and let Q be defined by* (*cf.* (3))

$$Qp(x) = \int h(x-y)g(p(y))\,dy. \tag{17}$$

Let p_0 be a solution to the equation $Qp=p$, assume that p_0 is not constant, and that either

$$p_0(x)\to 0 \quad \textit{for } |x|\to\infty, \quad \textit{or}$$

$$p_0 \quad \textit{is periodic.}$$

Then p_0 is an unstable equilibrium for (2) *considered as a discrete dynamical system in P.*

THEOREM 2. *Let Assumptions* A, B, *and* C *be satisfied, and let R be defined by* (*cf.* (5))

$$Rp(x) = \frac{\int h(x-y)g(p(y))W(p(y))\,dy}{\int h(x-y)W(p(y))\,dy}. \tag{18}$$

Let p_0 be a solution to the equation $Rp = p$, assume that p_0 is not constant, and that either

$$p_0(x) \to 0 \quad \textit{for } |x| \to \infty, \quad \textit{or}$$

$$p_0 \quad \textit{is periodic.}$$

Then p_0 is an unstable equilibrium for (4) *considered as a discrete dynamical system in P.*

Remark 1. For the sake of wider applicability, the results have been given a formulation independent of population genetics. Let us briefly describe their application to the models of population genetics.

If g is given by (1), then Assumptions A(i)-(iii) hold for all positive W_1, W_2, W_3, and Assumption A(iv) holds if and only if the heterozygote is inferior. If W is given by (6), then Assumptions C(i)-(ii) hold for all positive W_1, W_2, W_3, and Assumption C(iii) holds if and only if $W_2 \leqq 2 \min(W_1, W_3)$. Thus, if the heterozygote is inferior, Assumptions A and C hold. In this case it is also true that $g'(1) < 1$, and then the conclusions of Theorems 1 and 2 hold also for equilibria p_0 that satisfy $p_0(x) \to 1$ for $|x| \to \infty$.

Let us also note that (as mentioned above) if the heterozygote is not inferior, then all equilibria are constant.

Remark 2. As mentioned in § 2, it is known that nonmonotone equilibrium solutions of the nonlinear diffusion equation (16) are unstable. Actually, they have the so-called "hair-trigger" instability property (cf. Aronson and Weinberger [1], [2]), which is much stronger than that which can be proved along the lines considered in this paper. Instability results of hair-trigger type have also been proved for the unstable *constant* equilibria of (2) and (4) (cf. Weinberger [29]), and although we have not been able to prove it, we conjecture that similar results are valid for nonmonotone clines.

5. Proofs of the theorems.

Proof of Theorem 1. The proof is divided into several steps.

(i) p_0 does not assume the values 0 or 1.

Let us prove that p_0 does not assume the value 0. That it does not assume the value 1 follows by means of the transformation $p \mapsto 1 - p$ and Assumption B(iii).

Since p_0 is not constant, it is not identically 0, and $g(p_0)$ is different from 0 where p_0 is. Since both h and $g(p_0)$ are nonnegative, it follows from (17) that the support of p_0 contains the set $\operatorname{supp}(p_0) + \operatorname{supp}(h)$.

But then we first deduce from Assumption B(v) that $\operatorname{supp}(p_0)$ is all of $\mathbf{R}$, and, next, that $p_0(x) > 0$ for all x.

(ii) p_0 is twice continuously differentiable.

Since $p_0 = Qp_0$, it follows from Assumptions B(iv) and A(ii) that p_0 is differentiable with

$$p_0'(x) = \int h'(x-y) g(p_0(y))\, dy$$

$$= \int h(x-y) g'(p_0(y)) p_0'(y)\, dy.$$

Here, h can again be differentiated, and the claim follows.

(iii) Q is differentiable.

In fact, Q is differentiable at any $p \in P$ with

$$Q'(p)u(x) = \int h(x-y) g'(p(y)) u(y)\, dy. \tag{19}$$

It is clear that the linear map given by (19) is bounded in L^∞. To see that it is the derivative of Q note that

$$Q(p+u)-Q(p)=\int h(x-y)[g(p(y)+u(y))-g(p(y))]\,dy$$

$$=\int dy\int_0^1 h(x-y)g'(p(y)+tu(y))u(y)\,dt,$$

and use the uniform continuity of g'. See also the remark following the proof.

(iv) Q' is Hölder continuous.

This is an immediate consequence of the Hölder continuity of g'. We note in passing that it is essential that the topology in P be derived from the L^∞-norm and not from an L^r-norm with $r<\infty$.

In the rest of the proof we consider separately the case $p_0(x)\to 0$ at ∞ ((v)-(viii) below) and the case of periodic p_0 ((x) below).

First we discuss the case $p_0(x)\to 0$ at ∞.

(v) The linear map $K=Q'(p_0)$ has the Perron-Frobenius property.

More precisely, the spectral radius r of K is an eigenvalue of multiplicity 1, and it has a nonnegative eigenvector.

We will deduce this from the following result (cf. Schaefer [26, Thm. 3.2, p. 270]).

Let E be a Banach lattice and K an irreducible positive continuous linear mapping in E with spectral radius r. If r is a pole of the resolvent of K, then r has algebraic multiplicity 1, *and there exists a nonnegative eigenvector.*

The positivity of K follows from Assumption A(iv) and its irreducibility from Assumption B(v), so in order to establish (v) it remains to prove that r is a pole of the resolvent. As we shall see in (vii) below, this statement follows from step (vi).

(vi) There exist operators K_1 and K_2 in L^∞ such that $K=K_1+K_2$, $\|K_1\|<1$, K_2 is compact.

To prove this, we note that by Assumption A(iv) and the assumption that $p_0\to 0$ at ∞, there exist real numbers $c<1$ and C such that

$$g'(p_0(y))\leqq c \quad \text{for } |y|>C. \tag{20}$$

Then define the operators K_1 and K_2 by

$$K_1u(x)=\int_{|y|>C} h(x-y)g'(p_0(y))u(y)\,dy,$$

$$K_2u(x)=\int_{|y|\leqq C} h(x-y)g'(p_0(y))u(y)\,dy.$$

It is clear that $K=K_1+K_2$, and from Assumption B(iii) and (20) it follows that $\|K_1\|\leqq c<1$.

Let h_y denote the function $h_y(x)=h(x-y)$. Since h is uniformly continuous, the function $y\mapsto h_y$ from $\mathbf{R}$ to L^∞ is continuous, and hence the set $H=\{h_y:|y|\leqq C\}$ is a compact subset of L^∞.

By a theorem of Mazur (cf. Dunford and Schwartz [8, p. 416]), the closed convex hull $\hat{H}$ of $H\cup(-H)$ is also compact, and for any u in L^∞ we have $K_2u\in 2CM\|u\|\hat{H}$, where M denotes the maximum of g'.

The compactness of K_2 follows.

(vii) The spectral radius r of K is a pole of the resolvent of K.

Let $\sigma_e(K)$ denote the *essential spectrum* of the linear operator K, i.e., the set of complex numbers λ such that $\lambda I - K$ is *not* a semi-Fredholm operator (cf. Kato [17, p. 243]).

Then $\sigma_e(K_1)$ is contained in the spectrum of K_1, and hence in the closed disc of radius $\|K_1\|$. Since K_2 is compact, it follows from the Stability Theorem 5.35 in Kato [17, p. 244] that $\sigma_e(K)$ is contained in the same disc. Since K is bounded, it follows from Kato [17, p. 243] that, except for a discrete set of eigenvalues of finite algebraic multiplicity, the complement of this disc belongs to the resolvent set of K.

Now observe that 1 is an eigenvalue of K (with the eigenvector p_0'), and that, consequently, $r \geqq 1 > \|K_1\|$.

It is well known (cf., for instance, Schaefer [26, p. 264]), that r is a point in the spectrum of K, and the facts collected above show that it is an isolated eigenvalue of finite algebraic multiplicity. Thus (cf., for instance, Kato [17, III.6.5]), it is a pole of the resolvent of K.

(viii) p_0 is unstable.

By (v), r has multiplicity 1, and there exists a positive eigenvector corresponding to r. Since p_0' takes both positive and negative values, it cannot be an eigenvector corresponding to the eigenvalue r. On the other hand, p_0' *is* an eigenvector for K corresponding to the eigenvalue 1, and it follows that $r > 1$.

The instability of p_0 is now a consequence of (ix) below. The required regularity of Q was established in (iv). Also see the remark following the proof.

(ix) A discrete instability theorem.

Let U be a neighborhood of 0 in a Banach space F, let $f: U \to F$ be of class $C^{1+\alpha}$ for some α with $0 < \alpha < 1$, and assume that 0 is a fixed point of f. If the spectral radius r of the differential $K = df$ of f at 0 satisfies $r > 1$, then 0 is an unstable equilibrium of f considered as a discrete dynamical system in U.

This result is a straightforward adaptation to the discrete time situation of Theorem 2.3 in Daleckiĭ and Kreĭn [5, Chap. VII].

(x) The case of periodic p_0.

Let l denote the period of p_0, define L^∞_{per} to be the subspace of L^∞ consisting of functions of period l, and put $P_{\text{per}} = P \cap L^\infty_{\text{per}}$. Then it is clear that P_{per} is invariant under Q, and in order to prove that p_0 is unstable in P it is sufficient to prove that it is unstable in P_{per}.

Define

$$h_{\text{per}}(x) = \sum_{n=-\infty}^{\infty} h(x - nl),$$

then h_{per} is periodic with period l, and it follows from Assumptions B that

$h_{\text{per}}(x) \geqq 0$ for $x \in \mathbf{R}$;

$\int_0^l h_{\text{per}}(x)\, dx = 1$;

h_{per} is absolutely continuous; and

$\int_0^l |h_{\text{per}}'(x)|\, dx < \infty$.

Clearly, the restriction of Q to P_{per} is given by

$$Qp(x) = \int_0^l h_{\text{per}}(x - y) g(p(y))\, dy,$$

and, similarly, the restriction of the differential $K = Q'(p_0)$ to L^∞_{per} is given by

$$Ku(x) = \int_0^l h_{\text{per}}(x - y) g'(p_0(y)) u(y)\, dy. \tag{21}$$

The proof now proceeds as above, but it is simplified by the fact that the operator K defined on L^∞_{per} by (21) is compact. □

Remark. Strictly speaking, the statements about differentiability of Q and the use of the instability theorem (ix) require P to be an open subset of L^∞, and this is clearly not the case. This difficulty is most easily overcome by extending g to an *open* interval containing $[0, 1]$.

To prove instability of p_0 *inside* P we must restrict ourselves to the consideration of initial values in P. The initial values which, in the proof of (ix), are used to prove the instability, are of the form εu, where u is an eigenvector for K corresponding to the eigenvalue r. In the application to the present situation u is nonnegative, so that, fortunately, $p_0 + \varepsilon u \in P$ for ε small and positive.

Proof of Theorem 2. The proof is quite similar to the proof of Theorem 1, and many details will be omitted.

Note that $W(p)$ is bounded away from 0 for all $p \in P$ in view of Assumption C(i), and hence, so is the denominator in (18).

Define the operators M and N as in (12) and (13).

(i) First, we prove that p_0 does not assume the values 0 and 1, and that it is twice continuously differentiable.

Also, R is differentiable,

$$R'(p_0)u(x) = \int K(x, y)u(y)\, dy,$$

where the kernel K is given by (14), and, consequently, R' is Hölder continuous.

It follows from Assumptions C(i), (iii) that K is nonnegative. The proof of the irreducibility of $R'(p_0)$ uses the strict inequalities in Assumption C(iii), the fact that p_0 does not assume the values 0 and 1, and Assumption B(v). In the periodic case $R'(p_0)$ is compact, just as $Q'(p_0)$ was, so only the case $p_0 \to 0$ at ∞ requires further consideration.

(ii) As in (v) in the proof of Theorem 1 we will show that there exist operators K_1 and K_2 in L^∞ such that $R'(p_0) = K_1 + K_2$, $\|K_1\| < 1$, K_2 is compact.

First note that $W(p_0(y)) \to W(0)$ for $|y| \to \infty$, and hence, by dominated convergence,

$$Np_0(x) = \int h(y)\, W(p_0(x-y))\, dy \to \int h(y)\, W(0)\, dy = W(0) \quad \text{for } |x| \to \infty.$$

Now define

$$H_1(x, y) = h(x-y)[Np_0(x)]^{-1} W(p_0(y))g'(p_0(y)),$$
$$H_2(x, y) = h(x-y)[Np_0(x)]^{-1} g(p_0(y))\, W'(p_0(y)),$$
$$H_3(x, y) = -h(x-y)[Np_0(x)]^{-1} p_0(x)\, W'(p_0(y)).$$

If we choose c such that $g'(0) < c < 1$ (cf. Assumption A(iv)), then there exists a real number C such that

$$|x| > C \text{ and } |y| > C \quad \Rightarrow \quad [Np_0(x)]^{-1} W(p_0(y))g'(p_0(y)) \leqq c. \tag{22}$$

Let χ denote the characteristic function of the interval $[-C, C]$, define

$$H_{11}(x, y) = H_1(x, y)(1-\chi(x))(1-\chi(y)),$$
$$H_{12}(x, y) = H_1(x, y)(1-\chi(x))\chi(y),$$
$$H_{13}(x, y) = H_1(x, y)\chi(x),$$

and note that the kernel K can be written

$$K = H_{11} + H_{12} + H_{13} + H_2 + H_3.$$

It follows from (22) that the integral operator K_{11} with kernel H_{11} has operator norm at most equal to c, and, as in (vi) in the proof of Theorem 1, that the integral operator K_{12} with kernel H_{12} is compact.

Since $g(p_0(y)) \to 0$ at ∞, the operator K_2 with kernel H_2 is the uniform limit of the compact operators K_{2n} defined by

$$K_{2n}u(x) = \int_{-n}^{n} H_2(x, y)u(y)\, dy,$$

and consequently K_2 is compact.

The operators K_{13} and K_3 with kernels H_{13} (respectively H_3), are the adjoints in L^∞ of integral operators in L^1 with kernels that are the transposes of H_{13}, (respectively H_3). The proofs of the compactness of these L^1-operators are identical with the proofs of the compactness of K_{12} and K_2. But when the L^1-operators are compact, then so are their adjoints K_{13} and K_3.

We have now shown that

$$R'(p_0) = K_{11} + K_{12} + K_{13} + K_2 + K_3$$

with $\|K_{11}\| \leqq c < 1$ and K_{12}, K_{13}, K_2, and K_3 compact, and from here the proof proceeds as for Theorem 1. □

Acknowledgment. The author expresses his gratitude toward Tim Prout, who originally called the topic of cline stability to his attention.

EXISTENCE OF BEST PARAMETRIC INTERPOLATION BY CURVES*

K. SCHERER† AND P. W. SMITH‡

Abstract. Given n points in $\mathbb{R}^d$, find an acceptable interpolating curve. This problem is addressed in this paper. Analogues of the natural spline interpolators are examined, and the nonlinear problem that arises when the interpolation abscissae are treated as variables in the minimum seminorm problem is discussed in detail.

Key words. splines, interpolation, parametric curves

AMS(MOS) subject classifications. 41A15, 41A05

1. Introduction. The following problem is addressed. Given vectors $\mathbf{z}_1, \cdots, \mathbf{z}_n \in \mathbb{R}^d$, the d-dimensional Euclidean space, and given points

$$\mathbf{t}: a = t_1 < t_2 < \cdots < t_n = b, \tag{1}$$

we introduce the class

$$U_{k,\mathbf{t}}(\{\mathbf{z}_i\}_{i=1}^n) := \{\mathbf{f}(t) = (f_1(t), \cdots, f_d(t)): f_j \in L_2^k(a, b), \mathbf{f}(t_i) = \mathbf{z}_i, 1 \leqq i \leqq n\} \tag{2}$$

where $L_2^k(a, b)$ is the space of functions with $k-1$ absolutely continuous derivatives and kth derivative in $L_2(a, b)$. Hence $U_{k,\mathbf{t}}$ is the class of all smooth curves in $\mathbb{R}^d$ which pass through the points $\mathbf{z}_i \in \mathbb{R}^d$ at the time t_i, $1 \leqq i \leqq n$. Then we look for a best interpolating curve in the sense that

$$I = \inf_{\mathbf{t}} \inf \{|||\mathbf{f}^{(k)}|||: \mathbf{f}^{(k)} := (f_1^{(k)}, \cdots, f_d^{(k)}), \mathbf{f} \in U_{k,\mathbf{t}}(\{\mathbf{z}_i\}_{i=1}^n)\} \tag{3}$$

is attained, where

$$|||\mathbf{f}||| := \sqrt{\int_a^b \sum_{i=1}^d |f_i(t)|^2 \, dt}. \tag{4}$$

We are interested in existence and uniqueness of solutions of (3), in particular in determining optimal knots $\mathbf{t} = \{t_1, \cdots, t_n\}$. If we work with fixed knots, i.e., we take in (3) the infimum only with respect to $U_{k,\mathbf{t}}(\{\mathbf{z}_i\}_{i=1}^n)$, the problem reduces to the classical spline problem. The geometric motivation for (3) comes from the fact that curves may be parametrized differently, which influences the choice of the t_i. An interesting physical interpretation in case $k = 2$ is that a solution of (3) presents a trajectory with the least kinetic energy through prescribed points in $\mathbb{R}^d$ (see, e.g., Töpfer [3], Marin [2]). In the latter paper, existence and uniqueness of a solution of (3) has been shown in case $k = 2$, $d = 1$.

2. Existence. We assume from now on that $n > k$, since otherwise (3) would have a trivial solution in π_k, the class of curves with component functions being polynomials of degree $< k$. Next we introduce the following subclass of $U_{k,\mathbf{t}}$ (for data $\{\mathbf{w}_i\}_{i=1}^n$ with $\mathbf{w}_1 = 0$):

$$U_{k,\mathbf{t}}^0(\{\mathbf{w}_i\}_{i=2}^n) := \{\mathbf{g} \in U_{k,\mathbf{t}}(\{\mathbf{w}_i\}_{i=1}^n): \mathbf{g}^{(\nu)}(a) = 0, 1 \leqq \nu \leqq k-1, g(a) \equiv \mathbf{w}_1 = 0)\}. \tag{5}$$

With the help of this notion the problem can be reformulated.

LEMMA 1. *The following relation holds*:

$$I = \inf_{\mathbf{p}\in\pi_k} \{\inf_{\mathbf{t}} I_{\mathbf{t},\mathbf{p}}: p(a) = \mathbf{z}_1\} \tag{6}$$

where for fixed $\mathbf{t}$ *satisfying* (1)

$$I_{\mathbf{t},\mathbf{p}} := \inf\{|||\mathbf{g}^{(k)}|||: \mathbf{g}\in U^0_{k,\mathbf{t}}(\{\mathbf{z}_i - \mathbf{p}(t_i)\}_{i=2}^n)\}. \tag{7}$$

Furthermore, to any solution $\mathbf{t}^*$, $\mathbf{f}^*$ *of* (3) *there corresponds a solution* $\mathbf{t}^*$, $\mathbf{g}^*$, *and* $\mathbf{p}^*$ *of the right-hand side of* (6) *and conversely. In this case* $\mathbf{p}^*$ *is the Taylor polynomial* $\in \pi_k^*$ *of* $\mathbf{f}^*$ *at the point* a.

Proof. For each $\mathbf{f}\in U_{k,\mathbf{t}}$ we write

$$\mathbf{f}(t) = \sum_{\nu=0}^{k-1} \mathbf{f}^{(\nu)}(a)(t-a)^\nu/\nu! + \mathbf{g}(t) \equiv \mathbf{p}_f(t) + \mathbf{g}(t). \tag{8}$$

Then we have $\mathbf{f}^{(k)} = \mathbf{g}^{(k)}$, $\mathbf{p}_f \in \pi_k$ with $\mathbf{p}_f(a) = \mathbf{z}_1$ and $\mathbf{g}\in U^0_{k,\mathbf{t}}(\{\mathbf{z}_i - \mathbf{p}_f(t_i)\}_{i=2}^n)$ so that for any fixed set $\mathbf{t} = (t_1, \cdots, t_n)$ it follows that

$$\inf\{|||f^{(k)}|||: f\in U_{k,\mathbf{t}}(\{z_i\}_{i=1}^n)\} \geqq I_{\mathbf{t},\mathbf{p}} \geqq \inf_{\mathbf{p}\in\pi_k} \{\inf_{\mathbf{t}} I_{\mathbf{t},\mathbf{p}}: \mathbf{p}(a) = \mathbf{z}_1\}.$$

Taking the inf with respect to $\mathbf{t}$, we obtain "$\geqq$" in (6). On the other hand, for any fixed $\mathbf{p}\in\pi_k$ we have trivially

$$I \leqq \inf_{\mathbf{t}} \inf\{|||\mathbf{g}^{(k)}|||: \mathbf{g}\in U^0_{k,t}(\{\mathbf{z}_i - \mathbf{p}(t_i)\}_{i=2}^n)\}, \mathbf{g}(t_i) + \mathbf{p}(t_i) = \mathbf{z}_i, \mathbf{p}(a) = \mathbf{z}_1\},$$

which proves equality in (6) after taking the inf with respect to $\mathbf{p}$. Now if there were a solution $\mathbf{t}^*$, $\mathbf{f}^*$ with $\mathbf{f}^*$ attaining I, it could be decomposed as in (8) with $I = |||\mathbf{g}^{*(k)}|||$ so that $\mathbf{g}^*$, $\mathbf{p}^*$, $\mathbf{t}^*$ would form a solution triple of the right-hand side of (6). On the other hand, such a solution triple yields via $\mathbf{f}^* := \mathbf{g}^* + \mathbf{p}^*$ a solution pair $\mathbf{t}^*, \mathbf{f}^*$ attaining I. □

Now we investigate the infimum problem (7).

LEMMA 2. *For each fixed* $\mathbf{p}\in\pi_k$ *and* $\mathbf{t} = (t_1, \cdots, t_n)$ *satisfying* (1) *the infimum* $I_{\mathbf{t},\mathbf{p}}$ *is uniquely attained by a function* $\mathbf{g}^*\in U^0_{k,\mathbf{t}}(\{\mathbf{z}_i - \mathbf{p}(t_i)\}_{i=2}^n)$ *of the form*

$$g^{*(k)}(t) = \sum_{i=2}^n \boldsymbol{\alpha}_i \varphi_i(t), \qquad \varphi_i(t) := (t_i - t)_+^{k-1}/(k-1)!. \tag{9}$$

The vectors $\boldsymbol{\alpha}_i \in \mathbb{R}^d$ *are uniquely determined via the system*

$$\sum_{i=2}^n \boldsymbol{\alpha}_i G_{ij} = \mathbf{z}_j - \mathbf{p}(t_j), \qquad 2\leqq j\leqq n \tag{10}$$

where $G_{\mathbf{t}} = (G_{ij})$ *is the Gramian matrix*

$$G_{ij} := (\varphi_i, \varphi_j) = \int_a^b \varphi_i(t)\varphi_j(t)\,dt, \qquad 2\leqq i,j\leqq n. \tag{11}$$

The value of the infimum $I_{\mathbf{t},\mathbf{p}}$ *is given by*

$$I^2_{\mathbf{t},\mathbf{p}} = \langle G_{\mathbf{t}}\boldsymbol{\alpha}, \boldsymbol{\alpha}\rangle = \langle G_{\mathbf{t}}^{-1}(\mathbf{z} - p_{\mathbf{t}}), \mathbf{z} - p_{\mathbf{t}}\rangle. \tag{12}$$

Here the scalar product is to be understood as a sum of n *scalar products in* $\mathbb{R}^d$ *namely between the* n *components* $\mathbf{z} - p_{\mathbf{t}}$ *and* $G_{\mathbf{t}}^{(-1)}(\mathbf{z} - p_{\mathbf{t}})$ *where* $\mathbf{z} = \{\mathbf{z}_i\}_{i=1}^n$, $p_{\mathbf{t}} = \{\mathbf{p}(t_i)\}_{i=1}^n$ *and* $G_{\mathbf{t}}^{-1}$ *denote the inverse of* $G_{\mathbf{t}}$ *above. (The scalar products are formed with respect to the subsequences of* $\mathbf{z} - p_{\mathbf{t}}$, *which arise by taking in* $\mathbf{z}_i$, $\mathbf{p}(t_i)$ *their* $\mathbb{R}^d$*-components.)*

Proof. The principal observation is that for $\mathbf{g} \in U^0_{k,\mathbf{t}}(\{\mathbf{w}_j\}_{j=2}^n)$ the point functional $g(t_i)$, $2 \leqq i \leqq n$, can be written as

$$g(t_i) = \int_a^b \varphi_i(t)\mathbf{g}^{(k)}(t)\,dt. \tag{13}$$

This follows easily by repeated partial integration yielding

$$\int_a^b \frac{(t_j - t)_+^{k-1}}{(k-1)!}\mathbf{g}^{(k)}(t)\,dt = \int_a^b \frac{(t_j - t)_+^{k-2}}{(k-2)!}\mathbf{g}^{(k-1)}(t)\,dt$$

$$= \int_a^b (t_j - t)_+^0 \mathbf{g}'(t)\,dt = \int_a^{t_j} \mathbf{g}'(t)\,dt = \mathbf{g}(t_i) = \mathbf{w}_i.$$

After choosing a function $\mathbf{g}_0 \in U^0_{k,\mathbf{t}}(\{\mathbf{w}_j\}_{j=2}^0)$, we can now write

$$I_{\mathbf{t},\mathbf{p}} = \inf\{|||\mathbf{g}^{(k)} + \mathbf{g}_0^{(k)}|||: \mathbf{g} \in U^0_{k,\mathbf{t}}(\{0\}_{j=2}^n)\}$$

$$= \inf\left\{|||\mathbf{g}^{(k)} + \mathbf{g}_0^{(k)}|||: \int_a^b \mathbf{g}^{(k)}(t)\varphi_j(t)\,dt = 0,\ 2 \leqq j \leqq n\right\}.$$

Hence we conclude, in the standard manner for Hilbert spaces, that the solution $\mathbf{g}^*(k)$ must be in the $\mathbb{R}^d$-valued span of $\{\varphi_j\}_{j=2}^n$. This gives (9) and conditions $\mathbf{g}^*(t_j) = \mathbf{w}_j = \mathbf{z}_j - \mathbf{p}(t_j)$, $2 \leqq j \leqq n$, determine g^* uniquely via (10) in view of (13). Finally, (12) is obtained by direct calculation. □

Remark. The procedure of Lemma 2 is well known for the classical spline problem, where a relation of type (13) is usually employed with divided differences and B-splines. The point here—to be used later—is that the right-hand side of (10) has a much simpler form than would be the case for the classical spline approach. Information about the size of the eigenvalues of the matrix $G_{\mathbf{t}}$ gives the following.

LEMMA 3. *For a sequence* $\mathbf{t}$ *satisfying* (1) *set*

$$\delta := \min(t_{j+1} - t_j). \tag{14}$$

Then for any sequence $\{\beta_i\}_{i=2}^n$, $\beta_i \in \mathbb{R}$ *there holds*

$$C(b-a)\delta^{2k} \sum_{i=2}^n |\beta_i|^2 \leqq \sum_{i,j=2}^n G_{ij}\beta_i\beta_j \leqq n(b-a)^{2k-1} \sum_{i=2}^n |\beta_i|^2 \tag{15}$$

where C *is an absolute constant.*

Proof. We have by definition

$$\sum_{i,j=2}^n G_{ij}\beta_i\beta_j = \int_a^b \left|\sum_{i=2}^n \beta_i\varphi_i(t)\right|^2 dt \leqq \sum_{i=2}^n |\beta_i|^2 \int_a^b \sum_{i=2}^n |\varphi_i(t)|^2.$$

From this the inequality from above in (15) follows immediately in view of the (rough) estimate $|\varphi_i(t)|^2 \leqq (b-a)^{2k-2}$ for $t \in [a, b]$.

For the converse inequality we construct functions $\psi_i \in L_\infty^{(k)}(a, b)$ with

$$\delta_{ij} = \int_a^b \varphi_j(t)\psi_i^{(k)}(t)\,dt, \qquad 2 \leqq i,\ j \leqq n. \tag{16}$$

Relation (13) says that this is equivalent to

$$\delta_{ij} = \psi_i(t_j).$$

Hence the choice $\psi_i(t) = h((t-t_i)/\delta)$ where h is a fixed function $\in L_\infty^k(-\infty, \infty)$ with support $(0, 1)$ will achieve this. It follows from (16) that (setting $s = \sum_{j=2}^n \beta_j \varphi_j$)

$$|\beta_i|^2 = \left[\int_a^b s(t)\psi_i^{(k)}(t)\right]^2 \leqq \int_a^b |\psi_i^{(k)}|^2 \int_a^b |s|^2 \leqq C(t_{i+1}-t_{i-1})\delta^{-2k}\int_a^b |s|^2.$$

Summing over i yields the other inequality in (15). □

Remark. The lower bound quantitatively exhibits the ill conditioning of the truncated power basis.

In the next step we settle the question of the dependence of $I_{\mathbf{t},\mathbf{p}}$ of $\mathbf{p}$.

LEMMA 4. *For each* $\mathbf{t}$ *satisfying* (1) *there is a unique* $\mathbf{p}_t^*$ *satisfying*

$$I_{\mathbf{t}} \equiv \inf_{\mathbf{p}} I_{\mathbf{t},\mathbf{p}} = \sqrt{\langle G_{\mathbf{t}}^{-1}(\mathbf{z}-p_{\mathbf{t}}^*), \mathbf{z}-p_{\mathbf{t}}^*\rangle} = \sqrt{\langle G_{\mathbf{t}}^{-1}\mathbf{z}, \mathbf{z}\rangle - \langle G_{\mathbf{t}}^{-1}p_{\mathbf{t}}^*, p_{\mathbf{t}}^*\rangle}. \tag{17}$$

Proof. Since $G_{\mathbf{t}}$ is symmetric and positive definite, so is $G_{\mathbf{t}}^{-1}$. Hence we can define the inner product

$$\langle \mathbf{u}, \mathbf{v}\rangle_G := \langle G_{\mathbf{t}}^{-1}\mathbf{u}, \mathbf{v}\rangle \tag{18}$$

for vectors $\mathbf{u}, \mathbf{v}$ with $n-1$ components in $\mathbb{R}^d$. Then (17) reduces to a problem of best approximation with respect to the norm induced by (18), where $\mathbf{z}$ is approximated by the linear space $V \equiv \{\{\mathbf{p}(t_j)\}_{j=2}^n : \mathbf{p} = \text{polynomial curve of degree } < k\}$. Thus (17) has a unique solution characterized by the relation

$$\langle G_{\mathbf{t}}^{-1}(\mathbf{z}-p_{\mathbf{t}}^*), \mathbf{q}\rangle = 0, \qquad \mathbf{q} \in V$$

from which the second inequality in (17) follows. □

We now turn to the question of existence. We observe that

$$I = \inf\{I_{\mathbf{t}} : \mathbf{t} \text{ satisfies (1)}\}. \tag{19}$$

Indeed we obviously have $I_{\mathbf{t},\mathbf{p}} \geqq I_{\mathbf{t}}$ and so by Lemma 1

$$I \geqq \inf_{\mathbf{p}} \inf_{\mathbf{t}} I_{\mathbf{t}} = \inf_{\mathbf{t}} I_{\mathbf{t}}.$$

On the other hand, (6) of Lemma 1 yields for any $\mathbf{t}$ satisfying (1)

$$I \leqq \inf_{\mathbf{p}} I_{\mathbf{t},\mathbf{p}} = I_{\mathbf{t}}$$

so that (19) must hold.

Next we introduce a definition.

DEFINITION. The data $\{\mathbf{z}_i\}_{i=1}^n$ are called asymptotically polynomial of order k if there is a sequence of polynomial curves $\mathbf{p}_N(t) \in \pi_k$ and a sequence of nodes $\{t_i^{(N)}\}_{i=1}^n$ satisfying (1) such that

$$\mathbf{z}_i = \lim_{N\to\infty} \mathbf{p}_N(t_i^{(N)}), \qquad 1 \leqq i \leqq n. \tag{20}$$

THEOREM. *If the data* $\{\mathbf{z}_i\}_{i=1}^n$ *are not asymptotically polynomial of order* k *and if the data are "rough," i.e.,*

$$\mathbf{z}_{i+1} \neq \mathbf{z}_i, \qquad 1 \leqq i \leqq n-1, \tag{21}$$

there exists a solution of (3), *i.e., a sequence* $\mathbf{t}^* = \{t_i^*\}_{i=1}^n$ *of simple knots* (*satisfying* (1)) *and a polynomial curve* $\mathbf{p}^* \in \pi_k$ *such that* $I = I_{\mathbf{t}^*,\mathbf{p}^*}$ *and* $I_{\mathbf{t}^*,\mathbf{p}^*}$ *has a unique solution* $\mathbf{g}^*$ *according to Lemma* 2. *The solution* f^* *of* (3) *is then obtained as described in Lemma* 1.

Proof. According to (19) we can assume

$$I = \lim_{N\to\infty} I_{\mathbf{t}^{(N)}}$$

for a sequence $\mathbf{t}^{(N)}$ of knot sequences satisfying (1). Let p_N^* be the corresponding "best" polynomials in the sense of (17) in Lemma 4. We then show that the values of

these polynomial curves at $\mathbf{t}^{(N)}$ remain uniformly bounded with the respect to N, i.e., for the Euclidean norm in $\mathbb{R}^d$

$$\sup_{2\leqq j\leqq n} \| p_N^*(t_j^{(N)})\| \leqq M, \qquad N\to\infty. \tag{22}$$

To this end, note that in view of the fact that the smallest eigenvalue of $G_{\mathbf{t}}^{-1}$ is the reciprocal of the largest eigenvalue of $G_{\mathbf{t}}$, relation (15) allows us to conclude that (with notation G_N for $G_{\mathbf{t}^{(N)}}$ and $p_{N,\mathbf{t}}$ for $\{p_N^*(t_i^{(N)})\}_{i=1}^n$)

$$\begin{aligned} 2I^2 &\geqq I_{\mathbf{t}(N)}^2 = \langle G_N^{-1}(\mathbf{z}-p_{N,\mathbf{t}}), \mathbf{z}-p_{N,\mathbf{t}}\rangle \\ &\geqq n^{-1}(b-a)^{1-2k}|\mathbf{z}-p_{N,\mathbf{t}}|^2 \geqq n^{-1}(b-a)^{1-2k}[|p_{N,\mathbf{t}}|-|z|]^2 \end{aligned} \tag{23}$$

where $|\ |$ notes the Euclidean norm on $\mathbb{R}^{(n-1)d}$. From this (22) follows.

We cannot conclude at this point that the polynomials themselves are bounded (but see (30)). However, we can assume (eventually passing to a subsequence) that

$$\lim_{N\to\infty} p_N^*(t_j^{(N)}) = \mathbf{q}_j \in \mathbb{R}^d, \qquad 2\leqq j\leqq n. \tag{24}$$

Now suppose (by way of contradiction) that

$$\lim_{N\to\infty} t_i^{(N)} = t_i^* \in [a, b] \tag{25}$$

and that there are only $r<k$ distinct values among the t_i^*; thus

$$a = t_1^* = \cdots = t_{i_1}^* < t_{i_2}^* < \cdots < t_{i_r}^* = \cdots = t_n^* = b. \tag{26}$$

Next we observe that (10) can be written as

$$\mathbf{z}_j - \mathbf{p}_N^*(t_j^{(N)}) = (\mathbf{g}_N^{(k)}(t), \varphi_{j,N}(t)) = \left(\sum_{i=2}^n \boldsymbol{\alpha}_i^{(N)}\varphi_{i,N}, \varphi_{i,N}\right) \tag{27}$$

where $\varphi_{i,N}(t) := (t_i^{(N)}-t)_+^{k-1}/(k-1)!$ and $\mathbf{g}_N^{(k)}(t) := \sum_{i=2}^n \boldsymbol{\alpha}_i^{(N)}\varphi_{i,N}(t)$ satisfies

$$|||\mathbf{g}_N^{(k)}|||^2 = \langle G_{\mathbf{t}}\boldsymbol{\alpha}^{(N)}, \boldsymbol{\alpha}^{(N)}(t)\rangle \to I^2, \qquad N\to\infty. \tag{28}$$

Subtraction of equations (27) for j, j' with $i_\nu < j, j' \leqq i_{\nu+1}$ gives

$$\begin{aligned} \|\mathbf{z}_j - \mathbf{z}_{j'} - \mathbf{p}_N^*(t_j^{(N)}) + \mathbf{p}_N^*(t_{j'}^{(N)})\| &= \|(\mathbf{g}_N^{(k)}, \varphi_{j,N}-\varphi_{j',N})\| \\ &\leqq |||\mathbf{g}_N^{(k)}|||\left(\int_a^b |\varphi_{j,N}(t)-\varphi_{j',N}(t)|^2\,dt\right)^{1/2}. \end{aligned}$$

Passing to the limit we obtain, in view of (24), (28),

$$\mathbf{z}_j - \mathbf{q}_j = \mathbf{z}_{j'} - \mathbf{q}_{j'}, \qquad i_\nu < j, j' \leqq i_{\nu+1}. \tag{29}$$

Now let $\tilde{p}$ be the polynomial curve in $\pi_r \subseteq \pi_k$ interpolating the values $\{\mathbf{z}_{i_j} - \mathbf{q}_{i_j}\}_{j=1}^r$ at the points $\{t_{i_j}^*\}$. Then consider the polynomials

$$\tilde{\mathbf{p}}_N(t) := \mathbf{p}_N^*(t) - \tilde{p}(t)$$

and the data

$$\mathbf{w}_j^{(N)} := \tilde{\mathbf{p}}_N(t_j^{(N)}).$$

In view of

$$\mathbf{w}_j^{(N)} = p_N^*(t_j^{(N)}) - (q_j - z_j) + \tilde{p}(t_j^*) - \tilde{p}(t_j^{(N)})$$

and (24), (29), this implies

$$\lim_{N\to\infty} w_j^{(N)} = \mathbf{z}_j, \qquad 1\leqq j\leqq n,$$

which is by (20) a contradiction to our assumption on the data. Therefore, we must have $r \geqq k$ in (26). Then we can use Newton's formula with the knots $t_{i_1}^{(N)}, \cdots, t_{i_k}^{(N)}$ for the representation of the polynomials $p_N^*(t)$. In view of (24) and (26) we have (for a subsequence)

$$\lim_{N\to\infty} p_N^*(t) = p^*(t) \tag{30}$$

uniformly in t for some polynomial curve $p^*(t)$. But then (24) and (29) imply that all knots are simple since otherwise we would have a contradiction to (21). Therefore, the matrices $G_N^{-1} \equiv G_{\mathbf{t}(N)}^{-1}$ tend to a nonsingular Gramian matrix $(G^*)^{-1}$ where $G^* \equiv (G_{ij}^*)$:

$$G_{ij}^* = (\varphi_i^*, \varphi_j^*), \qquad \varphi_i^*(t) := (t_i^* - t)_+^{k-1}/(k-1)!.$$

Hence passing to limit $N \to \infty$ in (27), we see that there exist $\boldsymbol{\alpha}_i^* \in \mathbb{R}^d$

$$\mathbf{z}_j - \mathbf{p}^*(t_j^*) = \left(\sum_{i=2}^{n} \boldsymbol{\alpha}_i^* \varphi_i^*, \varphi_j^* \right) =: (\mathbf{g}^{*(k)}, \varphi_j^*).$$

Therefore, the spline curve $\mathbf{g}^*$ satisfies $\mathbf{g}^*(t_j^*) = \mathbf{z}_j - \mathbf{p}^*(t_j^*)$ and is determined by the condition in (5). In addition it follows from (28) that $\|\|g^*\|\| = I$. Hence $\mathbf{g}^* + \mathbf{p}^*$ is a solution of (3). □

The motivation for working in the above theorem with the additional hypothesis of nonasymptotic-polynomial data came from the fact that a simple sufficient condition for this would be that $I \equiv I(\mathbf{z})$ is continuous with respect to the data $\mathbf{z} = \{z_i\}_{i=1}^n$ and that $I(\mathbf{z}) > 0$. Namely, the continuity implies $I(\mathbf{z}) = 0$ in case the data are asymptotically polynomial (of order k). We can show that $I(\mathbf{z})$ is always upper semicontinuous, but unfortunately there exist asymptotically polynomial data for which $I(\mathbf{z}) > 0$. A simple example is given for $k = 3$ by the data (in $\mathbb{R}^2$)

$$\mathbf{z}_1 = (-1, 1), \quad \mathbf{z}_2 = (-1, 0), \quad \mathbf{z}_3 = (1, 0), \quad \mathbf{z}_4 = (1, 1). \tag{31}$$

Then we easily check that the parabola $(x(t), y(t))$ given by

$$x(t) = t, \qquad y(t) = 1 + N - Nt^2$$

passes through $\mathbf{z}_1, \mathbf{z}_4$ for $t = -1$ and $t = 1$, respectively, and $(\pm\sqrt{1+1/N}, 0)$ for $t = \pm\sqrt{1+1/N}$. Hence it approximates the data (31) arbitrarily close as $N \to \infty$.

We note that here the nodes coalesce in the limit, which is exactly what is avoided in the theorem by our additional hypotheses. In fact, we can see from subsequent considerations that we have continuity with respect to the data if they allow a solution in the sense of the theorem.

In order to show that $I(\mathbf{z}) > 0$ for the data (31) we use the classical approach via divided differences and B-splines mentioned above. According to it (cf. de Boor [1]) the solution for $I_{\mathbf{t}}$ with $\mathbf{t}$ satisfying (1) can be written as

$$\mathbf{f}^{*(k)} = \sum_{i=1}^{n-k} \boldsymbol{\beta}_i M_{i,k,2} \tag{32}$$

where the $M_{i,k,2}$ are the B-splines normalized via $M_{i,k,2}(x) = [(t_{i+k} - t_i)/k]^{1/2} M_{i,k}(x)$ and $\int M_{i,k} = 1$, and $\boldsymbol{\beta}_i \in \mathbb{R}^d$ are determined by

$$\sum_{i=1}^{n-k} \boldsymbol{\beta}_i (M_{i,k,2}, M_{j,k,2}) = Z_j \equiv [(t_{j+k} - t_j)/k]^{1/2} [t_j, \cdots, t_{j+k}]\mathbf{z} \cdot k!. \tag{33}$$

From this we derive the formula

$$I_{\mathbf{t}}^2 = \sum_{i,j=1}^{n-k} K_{ij}(Z_i, Z_j)$$

where the K_{ij} are elements of the inverse of the Gramian $\{(M_{i,k,2}, M_{j,k,2})\}_{i,j=1}^{n-k}$. According to the well-known Isomorphism Theorem of de Boor [1], we know there is a constant D_k depending only on k such that

$$D_k^{-2}\sum_i |\alpha_i|^2 \leqq \int \left|\sum_i \alpha_i M_{i,k,2}(x)\right|^2 dx \leqq \sum_i |\alpha_i|^2 \tag{34}$$

for arbitrary knot sequences $\mathbf{t}$. Hence we can conclude similarly, as in the proof of the theorem, that for any $\mathbf{t}$

$$\sum_{i=1}^{n-k} \|Z_i\|^2 \leqq I_{\mathbf{t}}^2 \leqq D_k^2 \sum_{i=1}^{n-k} \|Z_i\|^2. \tag{35}$$

With the help of (35) we can show now that $I(\mathbf{z})>0$ for the data (31). Namely, we can easily check that in this case

$$\begin{aligned} Z_1 &= \sqrt{24}[t_1, t_2, t_3, t_4]\mathbf{z} \\ &= \sqrt{6}\left[\frac{(\mathbf{z}_4-\mathbf{z}_3)/h_3-(\mathbf{z}_3-\mathbf{z}_2)/h_2}{h_3+h_2} - \frac{(\mathbf{z}_3-\mathbf{z}_2)/h_2-(\mathbf{z}_2-\mathbf{z}_1)/h_1}{h_2+h_1}\right] \end{aligned}$$

where $h_i = t_{i+1}-t_i$ and $-1=t_1<t_2<t_3<t_4=1$. For the data (31) the first component is given by

$$-\sqrt{24}\left[\frac{1}{h_2(h_3+h_2)}+\frac{1}{h_2(h_2+h_1)}\right] < -\sqrt{6} < 0.$$

We therefore have $\inf_{\mathbf{t}} \|Z_1\|^2 > 0$ so that by (35) it follows that $I(z)>0$.

By the nature of our example (31) we wonder whether this phenomenon can occur in the case of one-dimensional data. Instead of investigating this question further we show here existence on the basis of the approach (32)-(34). To this end, we assume first that the data are "rough" in the sense that

$$(z_{i+1}-z_i)(z_i-z_{i-1})<0, \qquad 2 \leqq i \leqq n-1. \tag{36}$$

Visually this means the data oscillate as much as possible. In this case the divided differences in (33) have, by introducing $w_i \equiv (z_{i+1}-z_i)/(t_{i+1}-t_i)$, the form

$$[t_j, \cdots, t_{j+k}]\mathbf{z} = [t_j, \cdots, t_{j+k-1}]\mathbf{w} = \sum_{i=j}^{j+k-1} w_i \Big/ \prod_{l\neq i} (t_i - t_l).$$

Since both the w_i (by (36)) and the factors $\prod_{l\neq i}(t_i-t_l)$ alternate in sign we can write

$$|Z_j| = [(t_{j+k}-t_j)/k]^{1/2} \sum_{i=j}^{j+k-1} |w_i| \Big/ \prod_{l\neq i} |t_i - t_l|. \tag{37}$$

Now let $\mathbf{t}_N$ be, as in the proof of the theorem, a sequence of knot sequences such that $I_{\mathbf{t}_N} \to I$, $N \to \infty$. By (35) we then see that the $|Z_j|$ formed with respect to $\mathbf{t}_N$ are uniformly bounded in N. Then (37) implies that $\min_i (t^{(N)} - t_i^{(N)})$ must be uniformly bounded from below with respect to N. Hence the $\{t_i^{(N)}\}_{i=1}^n$ tend to a limiting sequence $\{t_i^*\}_{i=1}^n$ with simple knots, and existence follows as in theorem.

The case of nonrough data can be reduced to the case (36) as follows. If (36) is violated for just $i = i_0+1, \cdots, i_1$, say, then the data $z_{i_0}, \cdots, z_{i_1+1}$ are strictly monotone increasing or decreasing. We then consider a new problem ($\tilde{3}$) for the data sequence where the $z_{i_0+1}, \cdots, z_{i_1}$ are eliminated. These data then satisfy (36), and the reduced problem has a solution, which is a continuous spline function $\tilde{s}$ assuming the values z_{i_0} and z_{i_1+1} at some knots $t_{i_0}^*$ and $t_{i_1+1}^*$. Hence we can find values $t_{i_0+1}^* < \cdots < t_{i_1}^*$ in

$(t_{i_0}^*, t_{i_1+1}^*)$ such that $\tilde{s}(t_i^*) = z_i$ for $i = i_0+1, \cdots, i_1$. Since the value for I in problem $(\tilde{3})$ is a priori smaller than or equal to that of the original problem (3), we have found a solution for this latter problem also. Finally, we see that the case when (36) is violated for several strings of indices can be handled similarly.

We mention further that existence can also be proved without the additional assumption of nonasymptotic polynomial data when $k=2$. Indeed, in this case the conclusion $r \geqq 2$ required in the proof of the theorem for any distribution of t_i^*'s as in (26) is trivial.

3. Additional remarks. Further questions concerning the minimization problem (3) are the characterization and uniqueness of the solution.

The first question can be treated conveniently by variations analysis, which has been done in case $k=2$ in [3]. It can be easily extended to all k as follows. With the help of Lagrange multipliers, problem (3) is equivalent to minimizing the functional

$$\phi(\mathbf{t}, \boldsymbol{\lambda}, f) := \|\|\mathbf{f}^{(k)}\|\|^2 + \sum_{i=1}^{n} (\mathbf{f}(t_i) - \mathbf{z}_i) \cdot \boldsymbol{\lambda}_i, \qquad \boldsymbol{\lambda}_i \in \mathbb{R}^d. \tag{38}$$

Necessary conditions for this are obtained by differentiating

$$0 = \frac{\delta \phi}{\delta t_i} = \boldsymbol{\lambda}_i \cdot \mathbf{f}'(t_i), \qquad 2 \leqq i \leqq n-1, \tag{39}$$

$$0 = \frac{\delta \phi}{\delta \boldsymbol{\lambda}_i} = \mathbf{f}(t_i) - \mathbf{z}_i, \tag{40}$$

$$0 = \frac{\delta \phi}{\delta \mathbf{f}}(\mathbf{h}) = 2 \int_a^b \mathbf{f}^{(k)}(x) \cdot \mathbf{h}^{(k)}(x)\, dx + \sum_{i=1}^{n} \boldsymbol{\lambda}_i \cdot \mathbf{h}(t_i). \tag{41}$$

Here and in (38) all products are to be understood as scalar products in $\mathbb{R}^d$. Equation (41) is obtained by taking the Gateaux derivative in the sense that

$$[\phi(\mathbf{t}, \boldsymbol{\lambda}, \mathbf{f} + \delta \cdot \mathbf{h}) - \phi(\mathbf{t}, \boldsymbol{\lambda}, \mathbf{f})]/\delta \to 0, \qquad \delta \to 0.$$

Now condition (40) is just the interpolating condition in (3). Choosing the variational curves (41) as elements of $U_{k,\mathbf{t}}(\{0\})$ (cf. (2)), we show that $\mathbf{f}^{(k)}$ lies (componentwise) in the orthogonal complement of this space, and hence is a spline curve of degree $<k$.

Next we choose $\mathbf{h}_i \geqq 0$ in C^∞ with $\mathbf{h}_i(t_j) = \mathbf{e}_i$ where the $\mathbf{e}_i$ are the standard unit vectors in $\mathbb{R}^d$ and support in $(t_j - \delta, t_j + \delta)$ with $\delta \ll 1$. This yields

$$2 \int_{t_{j-1}}^{t_{j+1}} \mathbf{f}^{(k)} \mathbf{h}_i^{(k)} + \boldsymbol{\lambda}_j \cdot \mathbf{e}_i = 0.$$

Integrating by parts $k-1$ times leads to

$$2(-1)^{k-1} \int_{t_j-\delta}^{t_j+\delta} \mathbf{f}^{(2k-1)}\, d\mathbf{h}_i + \boldsymbol{\lambda}_j \cdot \mathbf{e}_i = 0.$$

Thus one more integration by parts yields

$$2(-1)^k [\mathbf{f}^{(2k-1)}]_{t_j-}^{t_j+} + \boldsymbol{\lambda}_i = 0.$$

Solving for λ_i and inserting into (39), we obtain

$$\mathbf{f}'(t_j) \cdot (\mathbf{f}^{(2k-1)}(t_{j+}) - \mathbf{f}^{(2k-1)}(t_j - 0)) = 0, \qquad 2 \leqq k \leqq n-1. \tag{42}$$

In the scalar case $d=1$ these equations imply that $\mathbf{f}$ is either **one** polynomial of degree $2k-1$ on (t_{j-1}, t_{j+1}) or else $\mathbf{f}'(t_j) = 0$. We can interpret this as an additional smoothness

property resulting from minimizing with respect to the knots. In the case $k=2$ this can be used for a uniqueness proof, which will not be produced here in view of the proof in [2].

Another approach for determining an optimal set of knots could be based on formula (17) obtained for $I_{\mathbf{t}}$ by minimizing this functional with respect to $\mathbf{t}$. However, there is the alternative formulation (34) made possible by using B-splines. On the basis of this, successful algorithms have been developed by Marin [2].

We conclude with some remarks concerning the uniqueness of a solution of (3). There is an easy counterexample showing that there will be no positive answer to this without additional assumptions. Suppose that the data $\mathbf{z}_1, \cdots, \mathbf{z}_n$ are points of a polynomial curve $\mathbf{p} \in \pi_{[k/2]}$ on the interval $[0, 1]$. Then the infimum in (3) is trivially equal to zero and attained by $\mathbf{p}(t)$ as well as by the function $\mathbf{p}(t^2) \in \pi_k$. But the latter function also interpolates the data, namely at points $t_i^* = \sqrt{t_i}$ where $\mathbf{p}(t_i) = \mathbf{z}_i$. Therefore we make the following conjecture.

CONJECTURE. If there is at most one polynomial curve in π_k interpolating the data $\{z_i\}_{i=1}^n$ at some point sequence $\mathbf{t} = \{t_i\}_{i=1}^n$ of form (1), the solution of (3) is unique (we assume (5)).

By definition this condition is necessary for uniqueness. In the special case $k=2$ of cubic spline curves, it would imply that there is always a unique solution since π_k then consists of straight lines. This is in agreement with the numerical experience gained in this case.

REPEATED INTEGRALS AND DERIVATIVES OF *K* BESSEL FUNCTIONS*

DONALD E. AMOS†

Abstract. Repeated integrals of Bessel functions $K_\nu(x)$ on $0<x<\infty$, denoted by $Ki_{\nu,n}(x)$, are considered. Series are derived in terms of exponential integrals that are direct extensions of known results for the Bickley functions $Ki_n(x)$. The basic result for $n=0$ can also be extended to $n<0$ by repeated differentiation. For ν a nonnegative integer, it is also shown that $Ki_{\nu,n}(x)$ can be represented as a finite sum of Bickley functions of which $Ki_{\nu,0}(x)=K_\nu(x)$ is a special case.

Key words. *K* Bessel functions, modified Bessel functions, Bickley functions, derivatives of Bessel functions, exponential integrals

AMS(MOS) subject classification. 33A40

1. Introduction. The Bickley functions are defined as repeated integrals of the K_0 Bessel function [1]:

$$Ki_0(x)=K_0(x), \quad Ki_n(x)=\int_x^\infty Ki_{n-1}(t)\,dt, \quad n\geq 1, \quad x>0. \tag{1.1}$$

These functions have application in heat convection problems, neutron transport, and nuclear reactor codes [4]. Reference [1, Chap. 11] gives a formula for $Ki_1(x)$ in terms of modified Struve functions, asymptotic approximations for large and small $x>0$, and citations to several tables for $Ki_n(x)$. Reference [4] summarizes the classical formulae and presents a number of highly accurate rational Chebyshev approximations designed to cover the range $n=1$ through $n=10$ and all $x>0$. The results of [3] give some basic inequalities and asymptotic expansions satisfied by the Bickley functions, as well as a computational technique to sum slowly convergent series of exponential integrals $E_k(x)$, $k\geq 0$. In particular, for $x>0$,

$$K_0(x)=\sum_{k=0}^{\infty} A_k E_{2k+1}(x), \quad Ki_n(x)=\sum_{k=0}^{\infty} A_k E_{2k+n+1}(x), \quad n\geq 0, \tag{1.2a}$$

are considered and implemented in Algorithm 609 [3] where

$$A_0=1, \quad A_k=\frac{(\frac{1}{2})_k}{k!}, \quad k\geq 1,$$
$$(a)_0\equiv 1, \quad (a)_k=a(a+1)\cdots(a+k-1), \quad k\geq 1, \tag{1.2b}$$

and $E_k(x)$ is defined in (2.1). Equation (1.2) also holds for $n<0$ since

$$Ki_{-n-1}(x)=-\frac{d}{dx}Ki_{-n}(x), \quad E_{-n-1}(x)=-\frac{d}{dx}E_{-n}(x), \quad n\geq 0.$$

These relations express the fact that $Ki_{-n}(x)$ and $E_{-n}(x)$ are, except for sign, repeated derivatives of $K_0(x)$ and $E_0(x)$, respectively. Notice that only a finite number of

† Numerical Mathematics Division 1422, Sandia National Laboratories, Albuquerque, New Mexico 87185.

negative indices occurs on the exponential integrals in (1.2) when $n<0$. Functions of negative indices are conveniently generated by the following recurrences:

$$E_0(x)=e^{-x}/x, \quad E_{k-1}(x)=[e^{-x}-(k-1)E_k(x)]/x, \quad k\leqq 0, \tag{1.3}$$

$$Ki_{k-3}(x)=Ki_{k-1}(x)+[(k-1)Ki_k(x)-(k-2)Ki_{k-2}(x)]/x, \qquad k\leqq 2, \tag{1.4}$$

starting with values $Ki_2(x)$, $Ki_1(x)$, and $Ki_0(x)$ in (1.4). Stability with numerical recurrence is achieved by forward or backward recurrence away from the index $k=[x]$ where $[x]$ denotes the integer part of x [4], [6].

It is apparent from (2.3) and (3.1) that

$$Ki_{-n}(x)=(-1)^n K_0^{(n)}(x), \qquad n=0, 1, 2, \cdots. \tag{1.5}$$

That this result is consistent with (1.4) can be verified directly in the cases $k=1$ and 2, and by repeated differentiation of the differential equation

$$xK_0''(x)=-K_0'(x)+xK_0(x)$$

for other values of k.

The main results presented below extend (1.1) and (1.2) to repeated integrals of $K_\nu(x)$ defined by

$$Ki_{\nu,0}(x)=K_\nu(x), \quad Ki_{\nu,n}(x)=\int_x^\infty Ki_{\nu,n-1}(t)\,dt, \quad n\geqq 1, x>0, \nu\geqq 0. \tag{1.6}$$

Luke defines these integrals in [8] and cites a variety of formulas in [8]-[10]. We use the notation $Ki_{\nu,n}(x)$ in keeping with the notation for the Bickley functions $Ki_{0,n}(x)=Ki_n(x)$, although [3] and [8]-[10] use $K_{n,\nu}(x)$ for these functions.

In § 2, we derive a relation reciprocal to (1.2) and introduce some notation and formulae required in later sections. In § 3, we use the similarity between integral representations of $E_n(x)$ and $Ki_n(x)$ to derive series for $Ki_{\nu,n}(x)$ when ν is not an integer. The extension of these series to make ν an integer is carried out in § 4. In § 5, we derive bounds on the coefficients of the series and show asymptotic rates of convergence. While only real values of order and argument are considered in this paper, most of the results can be extended to complex orders and arguments.

2. Exponential integrals in terms of Bickley functions. We now derive a relation reciprocal to that in (1.2). Write the exponential integral $E_\nu(x)$ in the form

$$E_\nu(x)\equiv\int_1^\infty \frac{e^{-xt}}{t^\nu}\,dt=\int_0^\infty \frac{e^{-x\cosh\theta}\sinh\theta}{\cosh^\nu\theta}\,d\theta, \qquad \nu>0, \tag{2.1}$$

and substitute

$$\sinh\theta=\cosh\theta\sqrt{1-\frac{1}{\cosh^2\theta}}=\sum_{k=0}^\infty B_k\frac{1}{\cosh^{2k-1}\theta}, \qquad B_0=1, \quad B_k=\frac{(-1/2)_k}{k!}, \quad k\geqq 1 \tag{2.2}$$

into (2.1). Then, using an integral representation for $Ki_\nu(x)$ [1, p. 483],

$$Ki_\nu(x)=\int_0^\infty \frac{e^{-x\cosh\theta}}{\cosh^\nu\theta}\,d\theta, \qquad x\geqq 0, \nu\geqq 0, x+\nu>0, \tag{2.3}$$

we have exponential integrals in terms of Bickley functions

$$E_\nu(x)=\sum_{k=0}^\infty B_k Ki_{2k+\nu-1}(x). \tag{2.4}$$

We can also see from the integral forms (2.1) and (2.3) that (1.2) and (2.4) are valid if we do repeated differentiation (ν a negative integer) on the case $\nu = 0$.

3. Generalizations of (1.2). In this section we exploit (2.1) and (2.3) to derive series representations for $K_\nu(x)$ and $Ki_{\nu,n}(x)$. We start with a well-known integral representation for $K_\nu(x)$ [1, p. 376]:

$$K_\nu(z) = \int_0^\infty e^{-z\cosh\theta} \cosh \nu\theta \, d\theta, \qquad z > 0, \tag{3.1}$$

and write $K_\nu(z)$ in the form $K_\nu(z) = U_\nu(z) + L_\nu(z)$ where

$$U_\nu(z) = \frac{1}{2}\int_0^\infty e^{-z\cosh\theta+\nu\theta}\, d\theta, \qquad L_\nu(z) = \frac{1}{2}\int_0^\infty e^{-z\cosh\theta-\nu\theta}\, d\theta. \tag{3.2}$$

In order to carry out the derivation, we need the following relations [5, p. 101]:

$$e^{-\nu\theta} = \frac{\sinh\theta}{2^\nu \cosh^{\nu+1}\theta} F\left[1+\frac{\nu}{2}, \frac{1+\nu}{2}; 1+\nu; \frac{1}{\cosh^2\theta}\right], \qquad 0 < \theta < \infty, \tag{3.3}$$

$$e^{-\nu\theta} = \frac{1}{2^\nu \cosh^\nu\theta} F\left[\frac{\nu}{2}, \frac{1+\nu}{2}; 1+\nu; \frac{1}{\cosh^2\theta}\right], \qquad 0 \leqq \theta < \infty, \tag{3.4}$$

for the exponential terms in $U_\nu(z)$ and $L_\nu(z)$ where F is the Gauss hypergeometric function. Equations (3.3) and (3.4) are related by the Kummer transformation [1, eq. (15.3.3)]. These relations can be derived from equations (15.1.1), (15.3.23), and (15.3.3) of [1]. Notice that the parameterization of $F(a, b; c; z)$ in these cases has a relation $a - b + \frac{1}{2} = 0$ that makes [1, eq. (15.3.23)] reduce to

$$F\left[\frac{\nu}{2}, \frac{1+\nu}{2}; 1+\nu; z\right] = \left[\frac{2}{1+\sqrt{1-z}}\right]^\nu, \qquad |z| < 1. \tag{3.5}$$

The Kummer relation (5.2) [1, eq. (15.3.3)] applied to this result gives

$$F\left[1+\frac{\nu}{2}, \frac{1+\nu}{2}; 1+\nu; z\right] = \frac{1}{\sqrt{1-z}}\left[\frac{2}{1+\sqrt{1-z}}\right]^\nu, \qquad |z| < 1, \tag{3.6}$$

and with $z = 1/\cosh^2\theta$ we get (3.3) and (3.4). Notice that the series form of (3.3) is correct as $\theta \to \infty$, but does not converge at $\theta = 0$, making (3.3) indeterminant there. The proper form near the origin is given by the power series form of (3.4) (see § 5 for rates of convergence).

To derive series expansions for (3.1) we expand the right-hand side of (3.3) in a power series using the definition

$$F(a, b; c; z) = \sum_{k=0}^\infty \frac{(a)_k (b)_k}{(c)_k k!} z^k, \qquad |z| < 1, \tag{3.7}$$

and substitute the result in the second form of (3.2). With the help of (2.1) we have

$$L_\nu(z) = \sum_{k=0}^\infty A_k(\nu) \int_0^\infty \frac{e^{-z\cosh\theta}\sinh\theta}{\cosh^{2k+\nu+1}\theta}\, d\theta = \sum_{k=0}^\infty A_k(\nu) E_{2k+\nu+1}(z). \tag{3.8}$$

Similarly, if we use (3.4) in place of (3.3), we obtain, using (2.3),

$$L_\nu(z) = \sum_{k=0}^\infty B_k(\nu) Ki_{2k+\nu}(z) \tag{3.9}$$

where $A_k(\nu)$ and $B_k(\nu)$ are defined by (3.3) and (3.4):

$$A_0(\nu)=2^{-\nu}, \qquad B_0(\nu)=2^{-\nu},$$

(3.10)

$$A_k(\nu)=\left(1+\frac{\nu}{2}\right)_k\left(\frac{1+\nu}{2}\right)_k\Big/2^\nu k!(1+\nu)_k, \quad B_k(\nu)=\left(\frac{\nu}{2}\right)_k\left(\frac{1+\nu}{2}\right)_k\Big/2^\nu k!(1+\nu)_k, \quad k\geqq 1.$$

Notice that $A_k(0)$ is the A_k of (1.2), but $B_k(0)$ is not the B_k of (2.2). To compute the dominant or upper piece of (3.2) we need $e^{\nu\theta}$. Formally, we write (3.3) and (3.4) with ν replaced by $-\nu$ and consider noninteger values for ν. Then,

$$e^{\nu\theta}=\cosh^{\nu-1}\theta\sinh\theta\sum_{k=0}^{\infty}\frac{C_k(\nu)}{\cosh^{2k}\theta}, \qquad e^{\nu\theta}=\cosh^{\nu}\theta\sum_{k=0}^{\infty}\frac{D_k(\nu)}{\cosh^{2k}\theta}, \tag{3.11}$$

where

(3.12)

$$C_k(\nu)=2^\nu\left(1-\frac{\nu}{2}\right)_k\left(\frac{1-\nu}{2}\right)_k\Big/k!(1-\nu)_k, \qquad D_k(\nu)=2^\nu\left(\frac{-\nu}{2}\right)_k\left(\frac{1-\nu}{2}\right)_k\Big/k!(1-\nu)_k.$$

Here ν is considered nonintegral because the terms of (3.12) become indeterminant for $k\geqq\nu$ when ν is an integer. We shall resolve this indeterminacy in § 4. The reciprocals can be taken because the closed forms obtained from (3.5) and (3.6),

$$\sum_{k=0}^{\infty}B_k(\nu)z^k=\left[\frac{1}{1+\sqrt{1-z}}\right]^\nu, \qquad \sum_{k=0}^{\infty}A_k(\nu)z^k=\frac{1}{\sqrt{1-z}}\left[\frac{1}{1+\sqrt{1-z}}\right]^\nu, \tag{3.13}$$

show a radius of convergence $|z|<1$ and neither has any zeros in $|z|<1$. Thus, applying (3.11) to the dominant or upper part of (3.1) yields

$$U_\nu(z)=\sum_{k=0}^{\infty}C_k(\nu)E_{2k-\nu+1}(z) \quad\text{and}\quad U_\nu(z)=\sum_{k=0}^{\infty}D_k(\nu)Ki_{2k-\nu}(z), \tag{3.14}$$

after using the integral representations of $E_\nu(z)$ and $Ki_\nu(z)$ from § 2.

To summarize the derivation, (3.1) reduces to

$$K_\nu(z)=\begin{cases}\dfrac{1}{2}\displaystyle\sum_{k=0}^{\infty}C_k(\nu)E_{2k-\nu+1}(z)+\frac{1}{2}\sum_{k=0}^{\infty}A_k(\nu)E_{2k+\nu+1}(z),\\[2ex] \dfrac{1}{2}\displaystyle\sum_{k=0}^{\infty}D_k(\nu)Ki_{2k-\nu}(z)+\frac{1}{2}\sum_{k=0}^{\infty}B_k(\nu)Ki_{2k+\nu}(z).\end{cases} \tag{3.15}$$

Since $E_\nu(z)$ satisfies an integral recurrence such as (1.1), we get, with repeated integrations ($n\geqq 0$) or repeated differentiations ($n<0$) on (3.15),

$$Ki_{\nu,n}(z)=\begin{cases}\dfrac{1}{2}\displaystyle\sum_{k=0}^{\infty}C_k(\nu)E_{2k-\nu+n+1}(z)+\frac{1}{2}\sum_{k=0}^{\infty}A_k(\nu)E_{2k+\nu+n+1}(z),\\[2ex] \dfrac{1}{2}\displaystyle\sum_{k=0}^{\infty}D_k(\nu)Ki_{2k-\nu+n}(z)+\frac{1}{2}\sum_{k=0}^{\infty}B_k(\nu)Ki_{2k+\nu+n}(z).\end{cases} \tag{3.16}$$

It is apparent from repeated integrations of (3.1) that $Ki_{\nu,n}(z)$ has an integral representation

$$Ki_{\nu,n}(z)=\int_0^\infty\frac{e^{-z\cosh\theta}\cosh\nu\theta}{\cosh^n\theta}\,d\theta, \qquad \operatorname{Re}z>0, \quad \nu\geqq 0, \tag{3.17}$$

which generalizes (2.3). Repeated differentiation of this relation for $n=0$ produces

$$Ki_{\nu,-n-1}(z)=-\frac{d}{dz}Ki_{\nu,-n}(z)=(-1)^{n+1}\frac{d^{n+1}}{dz^{n+1}}K_\nu(z). \tag{3.18}$$

4. Identification of $C_k(\nu)$ and $D_k(\nu)$ for $\nu=m$ a nonnegative integer. We noted in § 3 that ν had to be nonintegral in order to make sense of (3.15) because the coefficients of the hypergeometric relation become indeterminant for $k\geqq\nu$ when ν is a nonnegative integer. Thus, for ν not an integer, we write $C_k(\nu)$ in terms of gamma functions

$$\begin{aligned}C_k(\nu)=2^\nu\Gamma\left(1-\frac{\nu}{2}+k\right)\Gamma\left(\frac{1-\nu}{2}+k\right)\Big/\Gamma(k+1)\Gamma(1-\nu+k)\\ \cdot\Gamma(1-\nu)\Big/\Gamma\left(1-\frac{\nu}{2}\right)\Gamma\left(\frac{1-\nu}{2}\right),\end{aligned} \tag{4.1}$$

with similar manipulations for $D_k(\nu)$. The duplication relation for $\Gamma(2z)$ [1, p. 256] applied to $\Gamma(1-\nu)$ resolves the indeterminacy. At this point ν can be considered an integer m and the substitution $k=m+s$, $s=0, 1, \cdots$ gives

$$C_{m+s}(m)=\frac{1}{\sqrt{\pi}}\left(\Gamma\left(1+\frac{m}{2}+s\right)\Gamma\left(\frac{1+m}{2}+s\right)\Big/\Gamma(1+m+s)\Gamma(1+s)\right)=A_s(m),\qquad s\geqq 0. \tag{4.2}$$

Similar manipulations on $D_k(\nu)$ for $k\geqq\nu$ give $D_{m+s}(m)=-B_s(m)$, $s\geqq 0$. To summarize, we have

$$C_s(m)=\begin{cases}A_s(-m), & s<m,\\ A_{s-m}(m), & s\geqq m,\end{cases}\qquad D_s(m)=\begin{cases}B_s(-m), & s<m,\\ -B_{s-m}(m), & s\geqq m.\end{cases} \tag{4.3}$$

Thus, (3.16) reduces to

$$Ki_{m,n}(z)=\begin{cases}\frac{1}{2}\sum_{k=0}^{m-1}A_k(-m)E_{2k-m+n+1}(z)+\sum_{k=0}^{\infty}A_k(m)E_{2k+m+n+1}(z), & \text{(4.4a)}\\ \frac{1}{2}\sum_{k=0}^{m-1}B_k(-m)Ki_{2k-m+n}(z), & \text{(4.4b)}\end{cases}\qquad m\geqq 1.$$

If we specialize m or n, we get the following special cases:

$$\begin{aligned}&Ki_{1,n}(z)=Ki_{n-1}(z),\qquad Ki_{1,1}(z)=Ki_0(z)=K_0(z),\\ &Ki_{1,0}(z)=Ki_{-1}(z)=K_1(z),\\ &Ki_{m,0}(z)=K_m(z)=\frac{1}{2}\sum_{k=0}^{m-1}B_k(-m)Ki_{2k-m}(z).\end{aligned} \tag{4.5}$$

Equation (4.4b) shows that $Ki_{\nu,n}(z)$ can be computed as a finite sum of Bickley functions when ν is a nonnegative integer. Reference [3] provides a Bickley function code for nonnegative indices while (1.4) extends these results to negative indices.

In (4.4a), the upper limit $m-1$ is actually $(m/2)-1$ if m is even and $(m-1)/2$ if m is odd because the succeeding coefficients are zero. The corresponding upper limit in (4.4b) is $(m/2)$ if m is even and $(m-1)/2$ if m is odd. This can be seen from (3.10) by replacing ν by $-m$. There is an index k such that one of the terms (as well as

succeeding terms) will be zero. For this index, $A_k(-m)$ and $B_k(-m)$ from (3.11) terminate with one of the following factors:

$$\begin{array}{lll} & m \text{ even} & m \text{ odd} \\ A_k(-m): & 1-\frac{m}{2}+k-1=0 \quad \text{or} & \frac{1-m}{2}+k-1=0, \\ B_k(-m): & -\frac{m}{2}+k-1=0 \quad \text{or} & \frac{1-m}{2}+k-1=0. \end{array}$$

Since these values of k yield the first zero term, the index of the last nonzero term is one less. This shows that the sum for $K_m(z)$ in (4.5) and its derivatives ($n<0$) in (4.4b) contain only Bickley functions of nonpositive indices which, according to (1.5), means only derivatives of $K_0(z)$ are involved.

5. Bounds and asymptotic estimates for $A_k(\nu)$ and $B_k(\nu)$, $\nu\geqq 0$, $k\geqq 0$. The relation

$$B_n(\nu)=\sum_{k=0}^{n} A_k(\nu)B_{n-k}, \qquad n\geqq 0, \quad \nu\geqq 0 \tag{5.1}$$

is derived from (3.7) by substituting the power series (3.7) into the Kummer relation

$$F\left(\frac{\nu}{2}, \frac{1+\nu}{2}; 1+\nu; z\right)=(1-z)^{1/2}F\left(1+\frac{\nu}{2}, \frac{1+\nu}{2}; 1+\nu; z\right), \qquad \nu\geqq 0, \tag{5.2}$$

and equating like powers of z. Multiplication of (5.2) by $(1-z)^{-1}$ and equating like powers of z again gives

$$\sum_{k=0}^{n} B_k(\nu)=\sum_{k=0}^{n} A_k(\nu)A_{n-k}(0), \qquad n\geqq 0. \tag{5.3}$$

On the other hand, multiplication of (5.2) by $(1-z)^{-1/2}$ gives

$$\sum_{k=0}^{n} B_k(\nu)A_{n-k}(0)=A_n(\nu), \qquad n\geqq 0, \tag{5.4}$$

and with $A_k(0)\leqq 1$, $k\geqq 0$, we get

$$A_k(\nu)\leqq \sum_{k=0}^{n} B_k(\nu), \qquad n\geqq 0.$$

Now, (2.2) shows that $B_0=1$ and $B_k<0$ for $k\geqq 1$. Therefore, (5.1) shows that

$$B_n(\nu)\leqq A_n(\nu), \qquad n\geqq 0. \tag{5.5}$$

Equation (3.13) for $z=1$ gives

$$\sum_{k=0}^{n} B_k(\nu)<\sum_{k=0}^{\infty} B_k(\nu)=1, \qquad \nu\geqq 0, \quad n\geqq 0, \tag{5.6}$$

and combining (5.3)-(5.6) we get

$$B_n(\nu)\leqq A_n(\nu)\leqq \sum_{k=0}^{n} B_k(\nu)=\sum_{k=0}^{n} A_k(\nu)A_{n-k}(0)<1, \qquad \nu\geqq 0, \quad n\geqq 0. \tag{5.7}$$

In order to estimate the rate of convergence of the series in (4.4) we need asymptotic estimates of the coefficients. The asymptotic estimate [1, p. 257]

$$\frac{\Gamma(z+a)}{\Gamma(z+b)}\sim z^{a-b}, \qquad z\to\infty, \tag{5.8}$$

applied to $A_k(\nu)$ and $B_k(\nu)$ gives

$$(5.9)\qquad A_k(\nu)\sim\frac{1}{\sqrt{\pi}}k^{-1/2}=O(k^{-1/2}),\quad B_k(\nu)\sim\frac{1}{\sqrt{\pi}}k^{-3/2}=O(k^{-3/2})\quad\text{as } k\to\infty.$$

Equation (5.9) and the estimates [1, p. 229]

$$\frac{e^{-z}}{z+k}<E_k(z)\leqq\frac{e^{-z}}{z+k-1},\quad k=1,2,\cdots,\quad z\geqq 0,$$

on the terms of (4.4a) give an order relation $O(k^{-3/2})$ as $k\to\infty$. Consequently, the series after summing N terms has a truncation error $O(N^{-1/2})$ as $N\to\infty$. Reference [3] deals with the numerical problems of summing slowly convergent series of exponential integrals. These results can be applied directly to that part of (4.4a) where $2k+m+n+1>0$ provided that the truncation error bound in [3] uses $A_n(m)<1$ from (5.7). The corresponding changes for Algorithm 609 [3] would be trivial.

A POSITIVE TRIGONOMETRIC SUM*

JOAQUIN BUSTOZ† AND MOURAD E. H. ISMAIL‡

Abstract. The positivity of

$$\sum_{k=0}^{n} \frac{(\lambda)_k(\lambda)_{n-k}}{k!(n-k)!} \frac{\sin(k+1)\theta}{k+1}$$

on $[\pi/3, \pi)$ when $3<\lambda\leqq 4$ is established.

Key words. Fejer's inequality, ultraspherical polynomials

AMS(MOS) subject classification. 33A45, 42A05

1. Introduction. Let $(\lambda)_0=1$ and $(\lambda)_n=\lambda(\lambda+1)\cdots(\lambda+n-1)$, $n=1,2,\cdots$. The trigonometric inequality

$$\sum_{k=0}^{n} \frac{(\lambda)_k}{k!} \frac{(\lambda)_{n-k}}{(n-k)!} \frac{\sin(k+1)\theta}{k+1}>0, \qquad 0<\theta<\pi, \quad n=0,1,2,\cdots, \tag{1.1}$$

is known to hold for $0\leqq\lambda\leqq 3$ [1]-[3]. When $\lambda>3$, it is known that (1.1) fails for infinitely many values of n [1]. In this note we will prove that if $3<\lambda\leqq 4$, then (1.1) holds in $\pi/3\leqq\theta<\pi$ and that when $\lambda=4$ the $\pi/3$ is best possible. When $\lambda=1$, then (1.1) reduces to Fejer's classic inequality

$$\sum_{k=0}^{n} \frac{\sin(k+1)\theta}{k+1}>0, \qquad 0<\theta<\pi.$$

Let $P_n^{\lambda}(x)$ denote the ultraspherical polynomial defined by

$$(1-2xz+z^2)^{-\lambda}=\sum_{n=0}^{\infty} P_n^{\lambda}(x)z^n,$$

and set

$$T_n(\theta,\lambda)=\sum_{k=0}^{\infty} \frac{(\lambda)_k}{k!} \frac{(\lambda)_{n-k}}{(n-k)!} \frac{\sin(k+1)\theta}{k+1}.$$

Write $x=\cos\theta/2$ and set

$$\Delta_n(x,\lambda)=\sin[(n+1)\theta/2]P_{n+1}^{\lambda}(x)-\sin[(n+2)\theta/2]P_n^{\lambda}(x).$$

It has been proved in [3] that

$$T_n(\theta,\lambda)=\frac{\Delta_n(x,\lambda)}{2(\lambda-1)x}, \qquad 0<x<1,$$

and, consequently, if $\lambda>1$ positivity of $T_n(\theta,\lambda)$ follows from positivity of $\Delta_n(x,\lambda)$. In [3] it was also proved that the generating function for $P_n^{\lambda}(x)$ implies (recall

$x = \cos \theta/2)$

$$\sum_{n=0}^{\infty} \Delta_n(x, \lambda) t^{n+1} = (1-t)^{-\lambda} \operatorname{Im} (1 - te^{i\theta})^{-\lambda+1}. \tag{1.2}$$

By applying Darboux's method [4] to (1.2), we find that

$$\frac{n!\Delta_{n-1}(x, \lambda)}{(\lambda)_n} = \left(2 \sin\left(\frac{\theta}{2}\right)\right)^{(1-\lambda)} \sin\left[(\lambda - 1)\left(\frac{\pi - \theta}{2}\right)\right] + O\left(\frac{1}{n}\right), \qquad 0 < \theta < \pi. \tag{1.3}$$

It follows from (1.3) that if $\lambda > 3$ and $(\lambda - 3/\lambda - 1)\pi \leqq \theta \leqq \pi$, then $T_n(\theta, \lambda)$ is positive for large n. We conjecture that $T_n(\theta, \lambda) > 0$ for $n = 0, 1, 2, \cdots$ if $\lambda > 3$, $(\lambda - 3/\lambda - 1)\pi \leqq \theta < \pi$. The lower limit $(\lambda - 3/\lambda - 1)\pi$ is clearly best possible for large n because of (1.3) (in particular at $\lambda = 4$, $\pi/3$ is best possible).

2. The case $\lambda = 4$. In this section we will prove the following theorem.

THEOREM 1.

$$\sum_{k=0}^{n} \frac{(4)_k}{k!} \frac{(4)_{n-k}}{(n-k)!} \frac{\sin(k+1)\theta}{k+1} > 0, \qquad \frac{\pi}{3} \leqq \theta < \pi, \quad n = 0, 1, 2, \cdots.$$

Proof. Set $\lambda = 4$ in (1.2). Then by partial fractions

$$\begin{aligned} \frac{1}{(1-t)^4(1-te^{i\theta})^3} &= \frac{A_1}{1-t} + \frac{A_2}{(1-t)^2} + \frac{A_3}{(1-t)^3} + \frac{A_4}{(1-t)^4} + \frac{B_1}{1-te^{i\theta}} \\ &\quad + \frac{B_2}{(1-te^{i\theta})^2} + \frac{B_3}{(1-te^{i\theta})^3}. \end{aligned} \tag{2.1}$$

Expand $(1 - te^{i\theta})^{-3}$ in a Taylor series about $t = 1$ to get

$$(1-te^{i\theta})^{-3} = (1-e^{i\theta})^{-3} \sum_{n=0}^{\infty} \frac{(3)_n}{n!} \left(\frac{e^{i\theta}}{e^{i\theta}-1}\right)^n (1-t)^n.$$

Hence, the coefficients A_i in (2.1) are given by

$$A_1 = -10\, e^{3i\theta}(e^{i\theta}-1)^{-6}, \qquad A_2 = -6\, e^{2i\theta}(e^{i\theta}-1)^{-5},$$
$$A_3 = -3\, e^{i\theta}(e^{i\theta}-1)^{-4}, \qquad A_4 = -(e^{i\theta}-1)^{-3}.$$

Expand $(1-t)^{-4}$ about $t = e^{-i\theta}$ to get

$$(1-t)^{-4}(1-te^{i\theta})^{-3} = e^{4i\theta} \sum_{n=0}^{\infty} \frac{(4)_n}{n!} (1-e^{i\theta})^{-n-4}(1-e^{i\theta}t)^{n-3}.$$

Hence, the coefficients B_i in (2.1) are given by

$$B_1 = 10\, e^{4i\theta}(1-e^{i\theta})^{-6}, \quad B_2 = 4\, e^{4i\theta}(1-e^{i\theta})^{-5}, \quad B_3 = e^{4i\theta}(1-e^{i\theta})^{-4}.$$

From (1.2) and (2.1), we have

$$\Delta_{n-1}(x, 4) = \sum_{k=1}^{4} \frac{(k)_n}{n!} \operatorname{Im} A_k + \sum_{k=1}^{3} \frac{(k)_n}{n!} \operatorname{Im} B_k\, e^{in\theta}. \tag{2.2}$$

Write $\beta = 2 \sin \theta/2$ for notational convenience. Then the imaginary parts in (2.2) are given by

$$\operatorname{Im} A_1 = 0, \qquad \operatorname{Im} A_2 = 6\beta^{-5} \cos\frac{\theta}{2},$$

$$\operatorname{Im} A_3 = 3\beta^{-4} \sin\theta, \qquad \operatorname{Im} A_4 = -\beta^{-3} \cos\frac{3\theta}{2},$$

$$\operatorname{Im} B_1\, e^{in\theta} = -10\beta^{-6} \sin(n+1)\theta, \qquad \operatorname{Im} B_2\, e^{in\theta} = 4\beta^{-5} \cos\left(n + \frac{3}{2}\right)\theta,$$

$$\operatorname{Im} B_3\, e^{in\theta} = \beta^{-4} \sin(n+2)\theta.$$

Replace these imaginary parts in (2.2) and do some minor simplification to get

$$
\begin{aligned}
96\left(\sin\frac{\theta}{2}\right)^6\Delta_{n-1}(x,4) &= -2(n+3)(n+2)(n+1)\left(\sin\frac{\theta}{2}\right)^3\cos\frac{3\theta}{2}\\
&\quad +9(n+2)(n+1)\left(\sin\frac{\theta}{2}\right)^2\sin\theta+9(n+1)\sin\theta\\
&\quad -15\sin(n+1)\theta+12(n+1)\sin\frac{\theta}{2}\cos\left(n+\frac{3}{2}\right)\theta\\
&\quad +3(n+2)(n+1)\left(\sin\frac{\theta}{2}\right)^2\sin(n+2)\theta.
\end{aligned}
\tag{2.3}
$$

The proof now consists of showing that the trigonometric polynomial on the right-hand side of (2.3) is positive in $[\pi/3, \pi)$ for $n=1, 2, 3, \cdots$. The interval $[\pi/3, \pi)$ will be broken into the three subintervals: $[\pi/3, \pi/2]$, $(\pi/2, 2\pi/3]$, $(2\pi/3, \pi)$. For notational convenience, write $D_n = 96(\sin\theta/2)^6\Delta_{n-1}(x,4)$ and denote the six terms on the right-hand side of (2.3) by $a_1, a_2, a_3, a_4, a_5, a_6$ in the order in which they appear. Thus, (2.3) is rewritten as

$$D_n = a_1+a_2+a_3+a_4+a_5+a_6.$$

First consider the interval $[\pi/3, \pi/2]$. In this interval $a_1 \geqq 0$, and thus $D_n \geqq a_2+a_3+a_4+a_5+a_6$. Clearly $|a_4| \leqq 15$, $|a_5| \leqq 12(n+1)\sin\theta/2$, and $|a_6| \leqq 3(n+2)(n+1)(\sin\theta/2^2)$. Hence,

$$D_n \geqq 3(n+1)(n+2)(3\sin\theta-1)\sin^2\frac{\theta}{2}+6(n+1)\left(3\cos\frac{\theta}{2}-2\right)\sin\frac{\theta}{2}-15. \tag{2.4}$$

For $\theta \in [\pi/3, \pi/2]$, $3(3\sin\theta-1)\sin^2\theta/2 > 1.19$ and $6(3\cos\theta/2-2)\sin\theta/2 \geqq 9-6\sqrt{2} > 0.51$. Replacing these lower bounds in (2.4), we obtain

$$D_n \geqq (1.19)(n+2)(n+1)+(0.51)(n+1)-15 > 0, \qquad n=2, 3, \cdots.$$

The case $n=1$ is trivial.

Next consider the interval $\pi/2 < \theta \leqq 2\pi/3$. In this interval, the first two terms on the right-hand side of (2.3), a_1 and a_2, are increasing. Hence, $a_1+a_2 \geqq \frac{1}{2}(n+3)(n+2)(n+1)+9/2(n+2)(n+1)$. Also, $\sin\theta \geqq \sqrt{3}/2$ in this interval, and hence $a_3 \geqq 9\sqrt{3}/2\,(n+1)$. Clearly, $a_4 \geqq -15$. Since $\sin\theta/2 \leqq \sqrt{3}/2$, we have $a_5 \geqq -6\sqrt{3}(n+1)$ and $a_6 \geqq -9/4(n+2)(n+1)$. Putting these estimates together, we have

$$4D_n \geqq 2(n+3)(n+2)(n+1)+9(n+2)(n+1)-6\sqrt{3}(n+1)-15 > 0, \qquad n=1, 2, \cdots.$$

The final subinterval $(2\pi/3, \pi)$ requires a preliminary lemma.

LEMMA 1. *If* $2\pi/3 \leqq \theta \leqq \pi$, *then*

$$\frac{\sin(n+2)\theta}{n+2} \geqq \frac{\sin 2\theta}{2} \text{ and } \frac{\cos(n+3/2)\theta}{n+3/2} \geqq \frac{\cos 3/2\theta}{3/2}$$

for $n=0, 1, 2, \cdots$.

Proof. Set $f(\theta) = \sin(n+2)\theta/(n+2)-\sin 2\theta/2$. Since $\sin(n+2)\,2\pi/3$ assumes the values $0, \sqrt{3}/2, -\sqrt{3}/2$ and since $\sin 4\pi/3 = -\sqrt{3}/2$, we see that $f(2\pi/3) \geqq 0$. Also $f(\pi)=0$. Now $f'(\theta) = \cos(n+2)\theta-\cos 2\theta = -2\sin(n+4)\theta/2\sin n\theta/2$, so that $f'(\theta) = 0$ when $\sin(n+4)\theta/2=0$ and when $\sin n\theta/2=0$. That is, at the points $\theta_k = 2k\pi/(n+4)$ and $\theta_k' = 2k\pi/n$ where $\theta_k, \theta_k' \varepsilon (2\pi/3, \pi)$. We have $f(\theta_k) = -(n+4)/2(n+2) \cdot \sin 4k\pi/(n+4) > 0$ because $4k\pi/(n+4)$ must be a third or fourth quadrant angle since $2k\pi/(n+4) \in (2\pi/3, \pi)$. Similarly, $f(\theta_k') = -n/2(n+2)\sin 4k\pi/n > 0$ because $2k\pi/n \in (2\pi/3, \pi)$. This proves the first inequality.

To prove the second inequality, set $g(\theta)=\cos(n+3/2)\theta/(n+3/2)-(\cos 3\theta/2)(3/2)$. Clearly, $g(2\pi/3)\geqq\frac{2}{3}-1/(n+3/2)\geqq 0$ for $n=1, 2, \cdots$, also $g(\pi)=0$. Now $g'(\theta)=-2\cos(n+3)\theta/2\sin n\theta/2$ and so $g'(\theta)=0$ at the points $\theta_k=(2k+1)\pi/(n+3)$ and $\theta'_k=4k\pi/n$. We consider only those values of k for which θ_k, $\theta'_k\in(2\pi/3, \pi)$. We have $f(\theta_k)=-(4n+3)(6n+9)\cos(6k+3)(2n+6)\pi$. Then $f(\theta_k)>0$ since $(6k+3)(2n+6)\pi$ is a third quadrant angle. Similarly, $f(\theta'_k)=-4n/(6n+9)\cos 6k\pi/n$ and $f(\theta'_k)>0$ since $6k\pi/n$ is a third quadrant angle. This proves the lemma.

Now we turn to the interval $(2\pi/3, \pi)$. First, by the identity $\sin\theta/2\cos 3\theta/2=\sin\theta(\cos\theta-\frac{1}{2})$ we rewrite a_1 as $a_1=-2(n+3)(n+2)(n+1)(\cos\theta-\frac{1}{2})\sin\theta\sin^2\theta/2$. Then dividing through (2.3) by $\sin\theta$ we have

$$\begin{aligned}\frac{D_n}{\sin\theta}=&-2(n+3)(n+2)(n+1)\left(\cos\theta-\frac{1}{2}\right)\sin^2\frac{\theta}{2}+9(n+2)(n+1)\sin^2\frac{\theta}{2}+9(n+1)\\ &-15\frac{\sin(n+1)\theta}{\sin\theta}+12(n+1)\left(n+\frac{3}{2}\right)\frac{\sin\theta/2}{\sin\theta}\frac{\cos(n+3/2)\theta}{n+3/2}\\ &+3(n+2)^2(n+1)\frac{\sin^2\theta/2}{\sin\theta}\frac{\sin(n+2)\theta}{n+2}.\end{aligned}\tag{2.5}$$

Next, replacing the last two terms in (2.5) in accordance with the lemma and using $|\sin(n+1)\theta/\sin\theta|\leqq n+1$ in the fourth term, we have

$$\begin{aligned}\frac{D_n}{\sin\theta}\geqq&(n+3)(n+2)(n+1)(1-2\cos\theta)\sin^2\frac{\theta}{2}+9(n+2)(n+1)\sin^2\frac{\theta}{2}\\ &+9(n+1)-15(n+1)+8(n+1)\left(n+\frac{3}{2}\right)\frac{\sin\theta/2\cos 3\theta/2}{\sin\theta}\\ &+3(n+2)^2(n+1)\sin^2\frac{\theta}{2}\cos\theta.\end{aligned}\tag{2.6}$$

In the fifth term in (2.6) again write $\sin\theta/2\cos 3\theta/2=\sin\theta(\cos\theta-\frac{1}{2})$ and divide through by $n+1$ to get

$$\begin{aligned}\frac{D_n}{(n+1)\sin\theta}\geqq&(n+3)(n+2)(1-2\cos\theta)\sin^2\frac{\theta}{2}+9(n+2)\sin^2\frac{\theta}{2}\\ &+8\left(n+\frac{3}{2}\right)\left(\cos\theta-\frac{1}{2}\right)+3(n+2)^2\sin^2\frac{\theta}{2}\cos\theta-6.\end{aligned}\tag{2.7}$$

Multiplying out the factors involving n in (2.7) and collecting terms gives

$$\frac{D_n}{(n+1)\sin\theta}\geqq\left[(1+\cos\theta)\sin^2\frac{\theta}{2}\right]n^2+\left[6\sin^2\frac{\theta}{2}+4\cos\theta+2\sin^2\frac{\theta}{2}\cos\theta\right]n.\tag{2.8}$$

The trigonometric polynomial in the second term in (2.8) can be rewritten as $(3-\cos\theta)(1+\cos\theta)$.

Replacing this in (2.8) and dividing by $n(1+\cos\theta)$ gives

$$\frac{D_n}{n(n+1)(1+\cos\theta)\sin\theta}\geqq n\sin^2\frac{\theta}{2}+3-\cos\theta>0.\tag{2.9}$$

This completes the proof of Theorem 1.

3. The case $3<\lambda<4$. In this section we will prove the following positivity result.

THEOREM 2. *$T_n(\theta, \lambda)>0$ for $\pi/3\leqq\theta<\pi$, $3<\lambda<4$, $n=0, 1, 2, \cdots$.*

Proof. The inequality proved in Theorem 1 is equivalent to

$$P_n^1(x)P_{n+1}^4(x)-P_{n+1}^1(x)P_n^4(x)>0, \qquad 0<x\leqq\frac{\sqrt{3}}{2}, \quad n=0, 1, 2, \cdots \tag{3.1}$$

and the inequality in Theorem 2 is equivalent to

$$P_n^1(x)P_{n+1}^\lambda(x)-P_{n+1}^1(x)P_n^\lambda(x)>0, \qquad 0<x\leqq\frac{\sqrt{3}}{2}, \quad 3<\lambda<4, \quad n=0, 1, 2, \cdots. \tag{3.2}$$

To prove (3.2) we will use Theorem 2.4 of [2], which states that the inequality

$$P_n^\alpha(x)P_{n+1}^\beta(x)-P_{n+1}^\alpha(x)P_n^\beta(x)>0 \tag{3.3}$$

holds for $0<x<1$ if $\frac{1}{2}<\alpha<\beta\leqq\alpha+2$.

It follows from the expansion

$$P_n^\lambda(x)=\sum_{k=0}^{[n/2]}\frac{(-1)^k(\lambda)_{n-k}}{k!(n-2k)!}(2x)^{n-2k}$$

that if n is odd then

$$P_n^1(x)P_{n+1}^\lambda(x)-P_{n+1}^1(x)P_n^\lambda(x)=A_n(\lambda)x^3+\cdots$$

where $A_n(\lambda)>0$ for $\lambda>1$. Similarly, if n is even then

$$P_n^1(x)P_{n+1}^\lambda(x)-P_{n+1}^1(x)P_n^\lambda(x)=B_n(\lambda)x+\cdots$$

where $B_n(\lambda)>0$ for $\lambda>1$. Consequently, (3.2) holds in a right-hand neighborhood of 0, and if (3.2) is not true in $(0, \sqrt{3}/2]$, then there exist n, x, λ with $0<x\leqq\sqrt{3}/2$, $3<\lambda<4$ such that

$$P_n^1(x)P_{n+1}^\lambda(x)-P_{n+1}^1(x)P_n^\lambda(x)=0. \tag{3.4}$$

By (3.3) we have, for $n\geqq0$ and $0<x<1$:

(i) $P_n^\lambda(x)P_{n+1}^4(x)-P_{n+1}^\lambda(x)P_n^4(x)>0$, if $2\leqq\lambda<4$,

(ii) $P_n^3(x)P_{n+1}^\lambda(x)-P_{n+1}^3(x)P_n^\lambda(x)>0$ for $3<\lambda<5$,

(iii) $P_n^1(x)P_{n+1}^3(x)-P_{n+1}^1(x)P_n^3(x)>0$.

And by Theorem 1,

(iv) $P_n^1(x)P_{n+1}^4(x)-P_n^4(x)P_{n+1}^1(x)>0$ for $n\geqq0$, $0<x\leqq\sqrt{3}/2$.

Now (3.4) implies that (for some $n\geqq0$, x and λ with $0<x\leqq\sqrt{3}/2$ and $3<\lambda<4$),

(v) $P_n^1(x)P_{n+1}^\lambda(x)=P_{n+1}^1(x)P_n^\lambda(x)$.

It follows from (v) that (for the same n, λ, x)

(vi) $$P_{n+1}^1(x)[P_n^\lambda(x)P_{n+1}^N(x)-P_{n+1}^\lambda(x)P_n^N(x)] = P_{n+1}^\lambda(x)[P_n^1(x)P_{n+1}^N(x)-P_{n+1}^1(x)P_n^N(x)]$$

for $N=3$ and for $N=4$. But for $N=3$ the quantities in square brackets on either side of (vi) have opposite signs, by (ii) and (iii); for $N=4$ they have the same sign, by (i) and (iv).

It follows that if (v) holds, then (for the same n, x, λ) we have

$$P_{n+1}^{1}(x) = P_{n+1}^{\lambda}(x) = 0.$$

But then, because of (i)-(iv), we would have simultaneously

$$P_n^{\lambda}(x)P_{n+1}^{4}(x) > 0, \qquad P_n^{1}(x)P_{n+1}^{4}(x) > 0,$$

$$P_n^{\lambda}(x)P_{n+1}^{3}(x) < 0, \qquad P_n^{1}(x)P_{n+1}^{3}(x) > 0,$$

which is impossible. Therefore (v) cannot occur.

Acknowledgment. The authors express their appreciation to the unknown referee who so patiently read, corrected, and recorrected this manuscript.

STURM SEQUENCES FOR NONLINEAR EIGENVALUE PROBLEMS*

LEON GREENBERG†

Abstract. An axiomatic treatment of Sturm sequences is presented, and applied to nonlinear eigenvalue problems of the form $\det[A(\lambda)]=0$. Here, $A(\lambda)$ is a symmetric, tridiagonal matrix, whose coefficients $a_{ij}(\lambda)$ satisfy certain monotonicity conditions. This is applied to a finite difference scheme for a Sturm-Liouville problem of the form

$$\begin{cases}(p(x,\lambda)u')'+q(x,\lambda)u=0 & \text{for } a\leqq x\leqq b,\\ \alpha_0(\lambda)u(a)+\beta_0(\lambda)u'(a)=0,\\ \alpha_1(\lambda)u(b)+\beta_1(\lambda)u'(b)=0.\end{cases}$$

The coefficients of this problem are required to satisfy the same kind of monotonicity conditions as those that occur in the Sturm oscillation theorem and that guarantee the existence of eigenvalues.

Key words. Sturm sequence, eigenvalue, nonlinear, symmetric tridiagonal matrix, Sturm-Liouville problem

AMS(MOS) subject classifications. 65H15, 65L15

1. Introduction.

Sturm sequences provide a standard method for finding eigenvalues of symmetric matrices, especially tridiagonal matrices. The case of tridiagonal matrices is of special interest because they arise in the discretization of Sturm-Liouville equations. Also, the Sturm sequence can be calculated recursively in this case. In this paper, we will show that Sturm sequences work for certain kinds of nonlinear eigenvalue problems. The method can then be applied to certain Sturm-Liouville equations in which the eigenvalue occurs nonlinearly. As we will see, this includes cases where the eigenvalue occurs in the boundary conditions.

We recall the main facts about Sturm sequences (see Weber [15, Chap. 8], Givens [3]). Consider a symmetric, tridiagonal matrix:

$$A=\begin{bmatrix} a_1 & b_1 & & & & & \\ b_1 & a_2 & b_2 & & & & \\ & b_2 & a_3 & b_3 & & & \\ & & \ddots & \ddots & \ddots & & \\ & & & b_{n-2} & a_{n-1} & b_{n-1} & \\ & & & & b_{n-1} & a_n & \end{bmatrix}, \tag{1.1}$$

in which $b_i\neq 0$ $(1\leqq i\leqq n-1)$. For a fixed choice of λ_0, let $S_i(\lambda_0)$ be the ith principal minor of $A-\lambda_0 I$. Thus, for $1\leqq i\leqq n$,

$$S_i(\lambda_0)=\begin{vmatrix} a_1-\lambda_0 & b_1 & & & & \\ b_1 & a_2-\lambda_0 & b_2 & & & \\ & \ddots & \ddots & \ddots & & \\ & & b_{i-2} & a_{i-1}-\lambda_0 & b_{i-1} & \\ & & & b_{i-1} & a_i-\lambda_0 & \end{vmatrix}. \tag{1.2}$$

We also define $S_0(\lambda_0)=1$. The (finite) sequence $S_0(\lambda_0), S_1(\lambda_0), \cdots, S_n(\lambda_0)$ is the Sturm sequence for the matrix A at λ_0. Let $c(\lambda_0)$ be the number of sign changes in the Sturm

* Received by the editors March 30, 1987; accepted for publication (in revised form) April 6, 1988.
† Mathematics Department, University of Maryland, College Park, Maryland 20742.

sequence (i.e., the number of indices i, such that $S_{i-1}(\lambda_0)S_i(\lambda_0)<0$). If some of the $S_i(\lambda_0)$ are zero, then all zeros are omitted from the sequence, and $c(\lambda_0)$ is the number of sign changes in the remaining sequence. The following three theorems are the main facts about Sturm sequences.

THEOREM A (Eigenvalue count). *$c(\lambda_0)$ equals the number of eigenvalues of A that are less than λ_0.*

THEOREM B (Interlacing theorem). *For $1 \leqq i \leqq n$, the zeros of $S_i(\lambda)$ and $S_{i-1}(\lambda)$ are interlaced (i.e., each function has a unique zero between two consecutive zeros of the other function).*

THEOREM C (Simple eigenvalues). *$S_n(\lambda)$ has exactly n different zeros.*

We also will need to refer to the following weak form of Theorem A.

THEOREM A (Weak form). *If $\lambda' < \lambda''$, then the number of eigenvalues in the interval $[\lambda', \lambda'')$ is $c(\lambda'') - c(\lambda')$.*

Perhaps the most important of these theorems is Theorem A, because it provides a method for calculating eigenvalues. If the eigenvalues of A are $\lambda_1 < \lambda_2 < \cdots < \lambda_n$, we can approximate the kth eigenvalue λ_k by using the bisection method with Theorem A. By bisection, we find a nested sequence of intervals $[\lambda', \lambda'']$ such that $c(\lambda') = k-1$ and $c(\lambda'') = k$. Theorem A guarantees that $\lambda' \leqq \lambda_k < \lambda''$.

We will show that, under certain conditions, Theorems A, B, and C remain true when $A - \lambda I$ is replaced by a more general (symmetric, tridiagonal) matrix $A(\lambda)$, whose coefficients $a_{ij}(\lambda)$ may be nonlinear functions of λ. (Here, an eigenvalue is a zero of $\det[A(\lambda)]$.) In § 2, Sturm sequences are considered from a general, axiomatic point of view. Versions of Theorems A, B, and C are proved in this context. In § 3, the results of § 2 are applied to nonlinear eigenvalue problems for tridiagonal matrices. In § 4, we consider a discretization of a Sturm–Liouville problem. Both the continuous and discrete problems are nonlinear eigenvalue problems. It is shown that Sturm sequences may be applied to the discrete problem, if the coefficients of the continuous problem satisfy the monotonicity conditions in the Sturm oscillation theorem.

Historical note. Sturm sequences first made their appearance in 1829, when Sturm announced his results in [12] and [13]. The announcement [12] was followed by a memoir [14] in 1835, where Sturm proves his well-known theorem relating the number of zeros of a polynomial in an interval to the number of sign changes in a Sturm sequence. The connection of Sturm sequences to eigenvalue problems first appeared in Sturm's announcement [13]. Here, Sturm states versions of Theorems A and B for a matrix of the form $A(\lambda) = K + \lambda G$, where K and G are symmetric matrices (not necessarily tridiagonal), and G is positive definite. Unfortunately, this was not followed by published proofs. The first proof of Theorem A seems to be due to Jacobi [7], in 1857. Here, Jacobi proves the formula

$$\sum_{i,j=1}^{n} a_{ij}x_i x_j = \frac{y_1^2}{S_1} + \sum_{k=2}^{n} \frac{y_k^2}{S_{k-1}S_k},$$

where y_k is a linear, homogeneous function of $x_k, x_{k+1}, \cdots, x_n$, and S_k is the kth principal minor of the symmetric matrix $A = (a_{ij})$. This formula implies that the number of negative eigenvalues of A is equal to the number of sign changes in the sequence $1, S_1, S_2, \cdots, S_n$. Theorem A follows from this fact. The algebra book [10], published by Salmon in 1859, includes a proof of Theorem A, using Sturm sequences. (The proof can be found in § 156 of the first edition. It occurs in § 46 of the fifth edition, which has been published as a Chelsea reprint.) An extensive discussion of Sturm sequences can be found in Chapter 8 of Weber's algebra book (1895) [15], including proofs of

Theorems A and B, and further developments by Hurwitz and Kronecker. Bôcher (1912) [1] has written an excellent review of Sturm's work, in which he discusses Sturm's motivation from problems in mechanics and heat flow.

2. Sturm sequences. In this section, we give an axiomatic development of Sturm sequences. Similar axiomatic treatments can be found in Weber [15], Isaacson and Keller [6], and Stoer and Bulirsch [11], where the weak form of Theorem A (in § 1) is proved within the axiomatic framework. We will develop the properties needed to yield analogues of Theorems A, B, and C. In § 3, this will be applied to nonlinear eigenvalue problems for symmetric, tridiagonal matrices.

DEFINITION 2.1. Let $S_0(\lambda), S_1(\lambda), \cdots, S_n(\lambda)$ be continuous functions on an interval $\Lambda_1 < \lambda < \Lambda_2$. (The possibilities $\Lambda_1 = -\infty$, $\Lambda_2 = \infty$ are included.) We say that the (finite) sequence $S_0(\lambda), S_1(\lambda), \cdots, S_n(\lambda)$ has the *Sturm property* if:

(a) $S_0(\lambda)$ has no zeros in (Λ_1, Λ_2).

(b) For $1 \leqq i \leqq n$, the set of zeros of $S_i(\lambda)$ is discrete (i.e., the set of zeros has no limit point in (Λ_1, Λ_2); equivalently, each function $S_i(\lambda)$ has only isolated zeros).

(c) For $1 \leqq i \leqq n-1$, if $S_i(\lambda_0) = 0$, then $S_{i-1}(\lambda_0) S_{i+1}(\lambda_0) < 0$.

(d) If $S_n(\lambda_0) = 0$, then for sufficiently small $\varepsilon_1, \varepsilon_2 > 0$, $S_{n-1}(\lambda_0)[S_n(\lambda_0 + \varepsilon_2) - S_n(\lambda_0 - \varepsilon_1)] < 0$.

Remarks. (1) Conditions (c) and (d) imply that for each λ_0 in (Λ_1, Λ_2), the sequence of numbers $S_0(\lambda_0), S_1(\lambda_0), \cdots, S_n(\lambda_0)$ does not contain two consecutive zeros.

(2) Condition (d) implies that if $S_n(\lambda_0) = 0$, then $S_n(\lambda)$ changes sign as λ passes through λ_0. This need not be true for $S_i(\lambda) (i < n)$. For example, the sequence $1, -\lambda^2, \lambda - 1$ has the Sturm property, but $S_1(\lambda) = -\lambda^2$ does not change sign as λ passes through 0.

(3) Condition (d) is equivalent to two other conditions: If $S_n(\lambda_0) = 0$, then for sufficiently small $\varepsilon > 0$,

(d1) $S_n(\lambda_0 - \varepsilon) S_n(\lambda_0 + \varepsilon) < 0$, and

(d2) $S_{n-1}(\lambda_0)[S_n(\lambda_0 + \varepsilon) - S_n(\lambda_0 - \varepsilon)] < 0$.

(4) In case $S_n(\lambda)$ is differentiable, condition (d) follows from the following condition: If $S_n(\lambda_0) = 0$, then $S_{n-1}(\lambda_0) S_n'(\lambda_0) < 0$.

(5) Condition (d) implies that if $S_n(\lambda_0) = 0$, then for sufficiently small $\varepsilon > 0$, $S_{n-1}(\lambda_0 - \varepsilon) S_n(\lambda_0 - \varepsilon) > 0$ and $S_{n-1}(\lambda_0 + \varepsilon) S_n(\lambda_0 + \varepsilon) < 0$. Thus, a sign change is generated between $S_{n-1}(\lambda)$ and $S_n(\lambda)$, when λ passes through λ_0 from left to right.

DEFINITION 2.2. Let $\alpha_0, \alpha_1, \cdots, \alpha_n$ be a sequence of (real) numbers. $c(\alpha_0, \alpha_1, \cdots, \alpha_n)$ denotes the number of sign changes in $\alpha_0, \alpha_1, \cdots, \alpha_n$ after the zero terms have been omitted. Corresponding to a sequence of functions $S_0(\lambda), S_1(\lambda), \cdots, S_n(\lambda)$, the number of sign changes $c(S_0(\lambda_0), S_1(\lambda_0), \cdots, S_n(\lambda_0))$ will usually be denoted simply by $c(\lambda_0)$.

The following theorem is analogous to the weak form of Theorem A in § 1.

THEOREM 2.1. *Suppose that the sequence $S_0(\lambda), S_1(\lambda), \cdots, S_n(\lambda)$, has the Sturm property on (Λ_1, Λ_2). Let $\lambda' < \lambda''$ be numbers in (Λ_1, Λ_2). Then $S_n(\lambda)$ has exactly $c(\lambda'') - c(\lambda')$ different zeros in the interval $[\lambda', \lambda'')$.*

Proof. Consider what happens to $c(\lambda)$ as λ increases from λ' to λ''. The interval $[\lambda', \lambda'']$ contains only a finite number of zeros (perhaps none) of any of the functions $S_i(\lambda), 1 \leqq i \leqq n$. (Recall that $S_0(\lambda)$ has no zeros.) $c(\lambda)$ does not change in any subinterval that contains no zeros of $S_i(\lambda), 1 \leqq i \leqq n$.

Suppose that λ_0 is a zero of $S_i(\lambda)$, where $i < n$. By condition (c) in Definition 2.1, $S_{i-1}(\lambda)$ and $S_{i+1}(\lambda)$ have opposite signs in an interval $(\lambda_0 - \varepsilon, \lambda_0 + \varepsilon)$. We suppose that ε is small enough so that the functions $S_j(\lambda), 1 \leqq j \leqq n$, have no zeros other than λ_0 in

$(\lambda_0-\varepsilon, \lambda_0+\varepsilon)$. The subsequence $S_{i-1}(\lambda)$, $S_i(\lambda)$, $S_{i+1}(\lambda)$ has exactly one sign change, for all λ in this interval. (For $\lambda=\lambda_0$, $S_i(\lambda_0)$ is omitted from the subsequence.) The same is true for any other j, $1\leqq j\leqq n-1$, if $S_j(\lambda_0)=0$. Therefore, if $S_n(\lambda_0)\neq 0$, then $c(\lambda)$ does not change in the interval $(\lambda_0-\varepsilon, \lambda_0+\varepsilon)$.

Now suppose that λ_0 is a zero of $S_n(\lambda)$. As we mentioned before (Remark (5)), condition (d) in Definition 2.1 implies that, for small $\varepsilon>0$, $S_{n-1}(\lambda_0-\varepsilon)S_n(\lambda_0-\varepsilon)>0$ and $S_{n-1}(\lambda_0+\varepsilon)S_n(\lambda_0+\varepsilon)<0$. We suppose that λ_0 is the only zero of $S_n(\lambda)$ in $(\lambda_0-\varepsilon, \lambda_0+\varepsilon)$, and $S_{n-1}(\lambda)$ has no zeros in this interval. Then $S_{n-1}(\lambda)S_n(\lambda)>0$ for $\lambda_0-\varepsilon\leqq\lambda<\lambda_0$, and $S_{n-1}(\lambda)S_n(\lambda)<0$ for $\lambda_0<\lambda\leqq\lambda_0+\varepsilon$. Therefore $c(\lambda)=c(\lambda_0)$ for $\lambda_0-\varepsilon\leqq\lambda<\lambda_0$, and $c(\lambda)=c(\lambda_0)+1$ for $\lambda_0<\lambda\leqq\lambda_0+\varepsilon$. In other words, $c(\lambda)$ increases by 1 as λ passes through λ_0 from left to right.

Now consider the interval $[\lambda', \lambda'']$ again. If λ' is a zero of $S_n(\lambda)$, then for small ε, $c(\lambda'+\varepsilon)=c(\lambda')+1$. Thus $c(\lambda)$ "counts" λ'. Similarly, $c(\lambda)$ counts the zeros of S_n in the interior of $[\lambda', \lambda'']$. If λ'' is a zero of $S_n(\lambda)$, then for small ε, $c(\lambda''-\varepsilon)=c(\lambda'')$, so $c(\lambda)$ does not count λ''. □

COROLLARY 2.1. *If the sequence $S_0(\lambda), S_1(\lambda), \cdots, S_n(\lambda)$ has the Sturm property on (Λ_1, Λ_2), then $S_n(\lambda)$ has at most n different zeros in (Λ_1, Λ_2).*

Proof. For any λ in (Λ_1, Λ_2), $c(\lambda)\leqq n$. □

We now mention a theorem analogous to the strong form of Theorem A in § 1.

THEOREM 2.2. *Let $S_0(\lambda), S_1(\lambda), \cdots, S_n(\lambda)$ have the Sturm property on (Λ_1, Λ_2), and suppose that $S_0(\lambda)>0$ on (Λ_1, Λ_2). The following are equivalent:*

(1) *There is a number λ_+ in (Λ_1, Λ_2), such that $S_i(\lambda_+)\geqq 0$, for $1\leqq i\leqq n$.*

(2) *For any λ_0 in (Λ_1, Λ_2), $c(\lambda_0)$ equals the number of zeros of $S_n(\lambda)$ in the interval (Λ_1, λ_0).*

Proof. Suppose (1) is true. Then $c(\lambda_+)=0$. Note that Theorem 2.1 implies that $c(\lambda)$ is a nondecreasing function. Therefore $c(\lambda)=0$ for $\Lambda_1<\lambda\leqq\lambda_+$. The theorem also implies that $S_n(\lambda)$ has no zeros in (Λ_1, λ_+).

If $\Lambda_1<\lambda_0\leqq\lambda_+$, then the number of zeros of $S_n(\lambda)$ in (Λ_1, λ_0) is $0=c(\lambda_0)$. If $\lambda_+<\lambda_0<\Lambda_2$, then the zeros of $S_n(\lambda)$ in (Λ_1, λ_0) lie in the subinterval $[\lambda_+, \lambda_0)$. Thus the number of zeros in (Λ_1, λ_0) equals the number of zeros in $[\lambda_+, \lambda_0)$, which equals $c(\lambda_0)-c(\lambda_+)=c(\lambda_0)$. This proves (2).

Now suppose that (2) is true. By Corollary 2.1, $S_n(\lambda)$ has only a finite number of zeros in (Λ_1, Λ_2). Let λ_+ be a number in (Λ_1, Λ_2), which lies to the left of all zeros of $S_n(\lambda)$. By (2), $c(\lambda_+)=0$. Therefore the sequence $S_0(\lambda_+), S_1(\lambda_+), \cdots, S_n(\lambda_+)$ has no sign changes. Therefore $S_i(\lambda_+)\geqq 0$, for $1\leqq i\leqq n$. (Necessarily, $S_n(\lambda_+)>0$.) This proves (1). □

Remark. We have seen that the Sturm property implies the weak form of Theorem A. However, it does not imply Theorem B. For example, the sequence $S_0(\lambda)=1$, $S_1(\lambda)=1-\lambda^2$, $S_2(\lambda)=\lambda-2$ has the Sturm property, but the zeros of S_1 and S_2 are not interlaced. In the following definition, we consider an additional property, which will imply Theorem B.

DEFINITION 2.3. A *Sturm sequence* is a sequence of functions $S_0(\lambda), S_1(\lambda), \cdots, S_n(\lambda)$, such that for $1\leqq i\leqq n$, the initial subsequence $S_0(\lambda), S_1(\lambda), \cdots, S_i(\lambda)$ has the Sturm property. In other words, a Sturm sequence satisfies all conditions in Definition 2.1, except that condition (d) is replaced by the stronger condition:

(d′) For $1\leqq i\leqq n$, if $S_i(\lambda_0)=0$, then for sufficiently small $\varepsilon_1, \varepsilon_2>0$, $S_{i-1}(\lambda_0)[S_i(\lambda_0+\varepsilon_2)-S_i(\lambda_0-\varepsilon_1)]<0$.

Remark. Condition (d′) implies that for $1\leqq i\leqq n$, if $S_i(\lambda_0)=0$, then $S_i(\lambda)$ changes sign as λ passes through λ_0.

THEOREM 2.3. *Suppose that* $S_0(\lambda), S_1(\lambda), \cdots, S_n(\lambda)$ *is a Sturm sequence. Then, for* $1 \leqq i \leqq n$, *the zeros of* $S_i(\lambda)$ *and* $S_{i-1}(\lambda)$ *are interlaced.*

Proof. We use induction on i. The statement is true for $i=1$, since $S_0(\lambda)$ has no zeros, and by Corollary 2.1, $S_1(\lambda)$ has at most one zero. Suppose the statement is true for $i \leqq k$. We will prove it for $i=k+1$.

Let $\lambda_1 < \lambda_2$ be consecutive zeros of $S_{k+1}(\lambda)$. We will show that $S_k(\lambda)$ has a zero between λ_1 and λ_2. ($S_k(\lambda)$ cannot have more than one zero in (λ_1, λ_2), because we will later show that $S_{k+1}(\lambda)$ has a zero between two zeros of $S_k(\lambda)$.) Condition (d') in Definition 2.3 implies that for sufficiently small $\varepsilon > 0$, and for $j=1, 2$, $S_k(\lambda_j - \varepsilon) S_{k+1}(\lambda_j - \varepsilon) > 0$ and $S_k(\lambda_j + \varepsilon) S_{k+1}(\lambda_j + \varepsilon) < 0$. Thus, $S_k(\lambda_1 + \varepsilon)$ and $S_{k+1}(\lambda_1 + \varepsilon)$ have opposite signs, while $S_k(\lambda_2 - \varepsilon)$ and $S_{k+1}(\lambda_2 - \varepsilon)$ have the same sign. Since λ_1 and λ_2 are consecutive zeros, $S_{k+1}(\lambda)$ does not change sign in the interval (λ_1, λ_2). Therefore, for small $\varepsilon > 0$, $S_k(\lambda_1 + \varepsilon)$ and $S_k(\lambda_2 - \varepsilon)$ have opposite signs, so $S_k(\lambda)$ has a zero in (λ_1, λ_2).

Now let $\lambda_1 < \lambda_2$ be consecutive zeros of $S_k(\lambda)$. We will show that $S_{k+1}(\lambda)$ has a zero between λ_1 and λ_2. (As before, this zero must be unique.) By condition (c) in Definition 2.1, $S_{k-1}(\lambda_j) S_{k+1}(\lambda_j) < 0$, for $j=1, 2$. By inductive hypothesis, $S_{k-1}(\lambda)$ has a unique zero λ_0 between λ_1 and λ_2. $S_{k-1}(\lambda)$ changes sign at any zero, so $S_{k-1}(\lambda_1)$ and $S_{k-1}(\lambda_2)$ have opposite signs. Since $S_{k-1}(\lambda_j) S_{k+1}(\lambda_j) < 0$, for $j=1, 2$, it follows that $S_{k+1}(\lambda_1)$ and $S_{k+1}(\lambda_2)$ have opposite signs. Therefore $S_{k+1}(\lambda)$ has a zero between λ_1 and λ_2. □

Remark. If $S_0(\lambda), S_1(\lambda), \cdots, S_n(\lambda)$ is a Sturm sequence on (Λ_1, Λ_2), $S_n(\lambda)$ need not have n zeros in (Λ_1, Λ_2), since we may have omitted some of the zeros by taking the interval too small. Even if the interval is $(-\infty, \infty)$, $S_n(\lambda)$ may not have n zeros. An example of this is $S_0(\lambda)=1$, $S_1(\lambda)=-\lambda-1$, $S_2(\lambda)=\lambda-1$. The following theorem (analogous to Theorem C in § 1) gives necessary and sufficient conditions for $S_n(\lambda)$ to have n zeros.

THEOREM 2.4. *Suppose that the sequence* $S_0(\lambda), S_1(\lambda), \cdots, S_n(\lambda)$ *is a Sturm sequence on* (Λ_1, Λ_2), *and that* $S_0(\lambda) > 0$, *for* $\Lambda_1 < \lambda < \Lambda_2$. *Then* $S_n(\lambda)$ *has exactly n different zeros in* (Λ_1, Λ_2) *if and only if there are numbers* $\lambda_+ < \lambda_-$ *in* (Λ_1, Λ_2), *such that, for* $1 \leqq i \leqq n$,

(1) $S_i(\lambda_+) \geqq 0$, *and*

(2) *the sign of* $S_i(\lambda_-)$ *is* $(-1)^i$.

If these conditions are satisfied, then $S_i(\lambda)$ *has exactly i different zeros in* (Λ_1, Λ_2), *for* $1 \leqq i \leqq n$.

Proof. First suppose that $S_n(\lambda)$ has n different zeros in (Λ_1, Λ_2). Since the zeros of $S_{n-1}(\lambda)$ and $S_n(\lambda)$ are interlaced, $S_{n-1}(\lambda)$ has $n-1$ zeros in (Λ_1, Λ_2). Similarly, by induction, we can show that $S_i(\lambda)$ has i zeros in (Λ_1, Λ_2). Let $c_i(\lambda)$ denote the number of sign changes in the sequence $S_0(\lambda), S_1(\lambda), \cdots, S_i(\lambda)$, after the zero terms have been omitted. Let $\lambda_+ < \lambda_-$ be numbers in (Λ_1, Λ_2), such that λ_+ lies to the left of all zeros of all $S_j(\lambda)$, and λ_- lies to the right of these zeros. Then the number of zeros of $S_i(\lambda)$ in (Λ_1, Λ_2) is $i = c_i(\lambda_-) - c_i(\lambda_+)$. Since $0 \leqq c_i(\lambda) \leqq i$, this implies that $c_i(\lambda_+) = 0$ and $c_i(\lambda_-) = i$. Therefore, $S_i(\lambda_+) \geqq 0$ and $S_i(\lambda_-)$ has sign $(-1)^i$. This proves (1) and (2).

Now suppose conditions (1) and (2) are satisfied. Then $c_i(\lambda_+) = 0$ and $c_i(\lambda_-) = i$. By Theorem 2.1, $S_i(\lambda)$ has $c_i(\lambda_-) - c_i(\lambda_+) = i$ zeros in the interval $[\lambda_+, \lambda_-)$. By Corollary 2.1, $S_i(\lambda)$ has at most i zeros. Therefore it has exactly i zeros in (Λ_1, Λ_2). □

3. Tridiagonal matrices. We will apply the results of § 2 to symmetric, tridiagonal matrices $A(\lambda)$. In each case, the eigenvalues are the zeros of $\det[A(\lambda)]$, $S_i(\lambda)$ (for $1 \leqq i \leqq n$) is the ith principal minor of $A(\lambda)$, and $S_0(\lambda) = 1$. We will begin with matrices

of the form

$$(3.1)\quad A(\lambda)=\begin{bmatrix} (b_0+b_1-a_1) & -b_1 & & & & & \\ -b_1 & (b_1+b_2-a_2) & -b_2 & & & & \\ & -b_2 & (b_2+b_3-a_3) & -b_3 & & & \\ & & \cdots & \cdots & \cdots & & \\ & & & -b_{n-2} & (b_{n-2}+b_{n-1}-a_{n-1}) & -b_{n-1} & \\ & & & & -b_{n-1} & (b_{n-1}+b_n-a_n) \end{bmatrix},$$

where the $a_i=a_i(\lambda)$ and $b_j=b_j(\lambda)$ are continuous functions on an interval (Λ_1,Λ_2). (The possibilities $\Lambda_1=-\infty$, $\Lambda_2=\infty$ are included.)

The following is a well-known recursion relation for the $S_i(\lambda)$.

LEMMA 3.1. *$S_{i+1}=(b_i+b_{i+1}-a_{i+1})S_i-b_i^2S_{i-1}$, for $1\leqq i\leqq n-1$.*

Proof. This is the cofactor expansion of the determinant

$$S_{i+1}=\begin{vmatrix} (b_0+b_1-a_1) & -b_1 & & & & & \\ -b_1 & (b_1+b_2-a_2) & -b_2 & & & & \\ & -b_2 & (b_2+b_3-a_3) & -b_3 & & & \\ & & \cdots & \cdots & \cdots & & \\ & & & -b_{i-1} & (b_{i-1}+b_i-a_i) & -b_i & \\ & & & & -b_i & (b_i+b_{i+1}-a_{i+1}) \end{vmatrix}$$

by the last row. □

Remark. If $b_i(\lambda)$ has no zeros (for $1\leqq i\leqq n-1$), then Lemma 3.1 implies that two consecutive functions S_i, S_{i+1} cannot have a common zero. If $S_i(\lambda_0)=0=S_{i+1}(\lambda_0)$, then the recursion relation implies that $S_{i-1}(\lambda_0)=0$. This in turn implies $0=S_{i-1}(\lambda_0)=S_{i-2}(\lambda_0)=S_{i-3}(\lambda_0)=\cdots=S_0(\lambda_0)$, which contradicts $S_0(\lambda)=1$. The recursion relation also implies that if $S_i(\lambda_0)=0$, then $S_{i+1}(\lambda_0)S_{i-1}(\lambda_0)\leqq 0$. Since two consecutive functions have no common zero, $S_{i+1}(\lambda_0)S_{i-1}(\lambda_0)<0$. This is condition (c) in Definition 2.1.

LEMMA 3.2. *Suppose that*

(1) *$a_i(\lambda)$ is strictly increasing, for $1\leqq i\leqq n$;*

(2) *$b_j(\lambda)$ is nonincreasing, for $0\leqq j\leqq n$;*

(3) *$b_i(\lambda)$ has no zeros, for $1\leqq i\leqq n-1$.*

Then,

(a) *$S_i(\lambda)$ has only isolated zeros, for $1\leqq i\leqq n$;*

(b) *$b_i-b_i^2(S_{i-1}/S_i)$ is a strictly decreasing function on any interval containing no zeros of $S_i(\lambda)$, for $1\leqq i\leqq n-1$.*

Proof. We will prove (a) and (b) simultaneously by induction on i. Note that $i=n$ is permitted in (a), while $i\leqq n-1$ in (b). The reason for the restriction in (b) is that $b_n(\lambda)$ is allowed to have zeros or even to be identically zero.

For $i=1$, $S_1=b_0+b_1-a_1$ is strictly decreasing, so it can have at most one zero. We must show that $b_1-b_1^2(S_0/S_1)$ is strictly decreasing on any interval that contains no zeros of S_1. We first consider an interval that has no zeros of S_1 or b_0-a_1:

$$b_1-b_1^2\frac{S_0}{S_1}=b_1-\frac{b_1^2}{b_0+b_1-a_1}=\frac{b_1(b_0-a_1)}{b_1+(b_0-a_1)}.$$

This shows that $b_1-b_1^2(S_0/S_1)$ has no zeros in the given interval, and

$$\left[b_1-b_1^2\frac{S_0}{S_1}\right]^{-1}=\frac{1}{b_0-a_1}+\frac{1}{b_1}.$$

Since b_0-a_1 is strictly decreasing and b_1 is nonincreasing, this shows that $[b_1-b_1^2(S_0/S_1)]^{-1}$ is strictly increasing, so $b_1-b_1^2(S_0/S_1)$ is strictly decreasing in the given interval.

Since $b_0 - a_1$ is strictly decreasing, it has at most one zero λ_0. Suppose that (α, β) is an interval that contains λ_0, but no zeros of S_1. By the previous paragraph, $b_1 - b_1^2(S_0/S_1)$ is strictly decreasing in (α, λ_0) and (λ_0, β). By continuity, it is strictly decreasing in (α, β). This concludes the inductive step $i = 1$.

Now suppose that statements (a) and (b) are true for $i \leqq k$; we will prove them for $i = k+1$. First we consider (a). By Lemma 3.1,

$$S_{k+1} = (b_k + b_{k+1} - a_{k+1})S_k - b_k^2 S_{k-1}, \quad \text{or}$$

$$S_{k+1} = S_k\left[(b_{k+1} - a_{k+1}) + \left(b_k - b_k^2 \frac{S_{k-1}}{S_k}\right)\right]. \tag{3.2}$$

As we mentioned in the remark following Lemma 3.1, S_{k+1} and S_k cannot have a common zero. By induction, the set of zeros of S_k is discrete, and $b_k - b_k^2(S_{k-1}/S_k)$ is strictly decreasing in any interval that contains no zeros of S_k. Therefore the function $(b_{k+1} - a_{k+1}) + (b_k - b_k^2(S_{k-1}/S_k))$ is strictly decreasing between any two consecutive zeros of S_k. Equation (3.2) shows that S_{k+1} can have at most one zero between any two consecutive zeros of S_k. This proves statement (a) for $i = k+1$.

Now we consider statement (b). Here we assume that $k+1 \leqq n-1$. Consequently, $b_{k+1}(\lambda)$ has no zeros. From the recursion relation

$$S_{k+1} = (b_k + b_{k+1} - a_{k+1})S_k - b_k^2 S_{k-1},$$

we obtain

$$\frac{S_{k+1}}{S_k} = (b_k + b_{k+1} - a_{k+1}) - b_k^2 \frac{S_{k-1}}{S_k},$$

$$\frac{S_k}{S_{k+1}} = \frac{1}{(b_k + b_{k+1} - a_{k+1}) - b_k^2(S_{k-1}/S_k)},$$

$$b_{k+1} - b_{k+1}^2 \frac{S_k}{S_{k+1}} = b_{k+1} - \frac{b_{k+1}^2}{(b_k + b_{k+1} - a_{k+1}) - b_k^2(S_{k-1}/S_k)},$$

and finally

$$b_{k+1} - b_{k+1}^2 \frac{S_k}{S_{k+1}} = \frac{b_{k+1}\left[\left(b_k - b_k^2 \dfrac{S_{k-1}}{S_k}\right) - a_{k+1}\right]}{b_{k+1} + \left[\left(b_k - b_k^2 \dfrac{S_{k-1}}{S_k}\right) - a_{k+1}\right]}. \tag{3.3}$$

Taking reciprocals in (3.3), we obtain

$$\frac{1}{b_{k+1} - b_{k+1}^2(S_k/S_{k+1})} = \frac{1}{(b_k - b_k^2(S_{k-1}/S_k)) - a_{k+1}} + \frac{1}{b_{k+1}}. \tag{3.4}$$

Let I be an interval that contains no zeros of S_{k+1}, S_k or $(b_k - b_k^2(S_{k-1}/S_k)) - a_{k+1}$. Equation (3.3) shows that I has no zeros of $b_{k+1} - b_{k+1}^2(S_k/S_{k+1})$. Since $(b_k - b_k^2(S_{k-1}/S_k)) - a_{k+1}$ is strictly decreasing in I, and b_{k+1} is nonincreasing, (3.4) shows that $b_{k+1} - b_{k+1}^2(S_k/S_{k+1})$ is strictly decreasing in I. Now let J be an interval that has no zeros of S_{k+1}. The zeros of S_k and $(b_k - b_k^2(S_{k-1}/S_k)) - a_{k+1}$ form a discrete set Z in J, and $b_{k+1} - b_{k+1}^2(S_k/S_{k+1})$ is strictly decreasing in any interval contained in $J - Z$. By continuity, $b_{k+1} - b_{k+1}^2(S_k/S_{k+1})$ is strictly decreasing in J. □

Remark. Conclusion (b) in Lemma 3.2 will be vital to the proof of Theorem 3.1 and all the theorems in this section that follow from it. This crucial fact was found by studying the finite difference matrices arising from Sturm-Liouville problems of type (4.1), in § 4. If the Sturm sequence S_i is compared to the finite difference solution u_i of (4.1), then it turns out that $b_i - b_i^2(S_{i-1}/S_i) \approx hp_{i+1/2}(u'_{i+1}/u_{i+1})$. Under the conditions indicated in Theorem D of § 4, one of the Sturm comparison theorems states that $p(x,\lambda)(u'(x,\lambda)/u(x,\lambda))$ is a decreasing function of λ. This fact suggested conclusion (b) in Lemma 3.2. The relationship between the Sturm sequence and the finite difference solution will be treated by Greenberg and Babuška in [4].

THEOREM 3.1. *Suppose that*

(1) $a_i(\lambda)$ *is strictly increasing, for* $1 \leqq i \leqq n$;

(2) $b_j(\lambda)$ *is nonincreasing, for* $0 \leqq j \leqq n$;

(3) $b_j(\lambda)$ *has no zeros, for* $1 \leqq j \leqq n-1$.

Then the sequence $S_0(\lambda), S_1(\lambda), \cdots, S_n(\lambda)$ *is a Sturm sequence (in the sense of* § 2).

Proof. By Definition 2.3, we must verify (a)-(c) in Definition 2.1 and (d') in Definition 2.3. Condition (a) is obvious, since $S_0(\lambda) = 1$. Condition (b) was proved in Lemma 3.2(a). Condition (c) follows from the remark after Lemma 3.1. It remains to verify the condition:

(d') For $1 \leqq i \leqq n$, if $S_i(\lambda_0) = 0$, then for sufficiently small $\varepsilon_1, \varepsilon_2 > 0$,

$$S_{i-1}(\lambda_0)[S_i(\lambda_0+\varepsilon_2) - S_i(\lambda_0-\varepsilon_1)] < 0.$$

To verify the ith statement (d'), we will need the $(i-1)$st statement in Lemma 3.2(b), which is valid for $1 \leqq i-1 \leqq n-1$. Because of this, we need a separate calculation for $i=1$ in (d'):

$$S_0(\lambda_0)[S_1(\lambda_0+\varepsilon_2) - S_1(\lambda_0-\varepsilon_1)] < 0.$$

This inequality follows from the fact that $S_0(\lambda) = 1$, and $S_1(\lambda) = b_0(\lambda) + b_1(\lambda) - a_1(\lambda)$ is a strictly decreasing function.

Now consider (d') for $2 \leqq i \leqq n$.

By Lemma 3.1,

$$S_i = (b_{i-1} + b_i - a_i)S_{i-1} - b_{i-1}^2 S_{i-2}, \quad \text{or}$$

$$S_i = S_{i-1}\left[\left(b_{i-1} - b_{i-1}^2 \frac{S_{i-2}}{S_{i-1}}\right) + (b_i - a_i)\right]. \tag{3.5}$$

Choose $\varepsilon_1, \varepsilon_2 > 0$ small enough so that the interval $[\lambda_0-\varepsilon_1, \lambda_0+\varepsilon_2]$ contains no zeros of $S_{i-1}(\lambda)$. Thus S_{i-1} does not change sign in this interval. $S_i/S_{i-1} = (b_{i-1} - b_{i-1}^2(S_{i-2}/S_{i-1})) + (b_i - a_i)$ is a strictly decreasing function in $[\lambda_0-\varepsilon_1, \lambda_0+\varepsilon_2]$ (by Lemma 3.2(b) and hypotheses (1) and (2) of this theorem). Therefore S_i/S_{i-1} changes sign from (+) to (−) as λ passes through λ_0 from left to right. The same must be true for $S_{i-1}S_i = S_{i-1}^2(S_i/S_{i-1})$. Thus

$$S_{i-1}(\lambda_0-\varepsilon_1)S_i(\lambda_0-\varepsilon_1) > 0 > S_{i-1}(\lambda_0+\varepsilon_2)S_i(\lambda_0+\varepsilon_2).$$

Since $S_{i-1}(\lambda)$ does not change sign in $[\lambda_0-\varepsilon_1, \lambda_0+\varepsilon_2]$, it follows that

$$S_{i-1}(\lambda_0)S_i(\lambda_0-\varepsilon_1) > 0 > S_{i-1}(\lambda_0)S_i(\lambda_0+\varepsilon_2), \quad \text{or}$$

$$S_{i-1}(\lambda_0)[S_i(\lambda_0+\varepsilon_2) - S_i(\lambda_0-\varepsilon_1)] < 0.$$

This proves condition (d'). □

The following theorem is a weak version of Theorem A (in § 1) for the matrix $A(\lambda)$.

THEOREM 3.2. *Let $A(\lambda)$ be a matrix of type* (3.1), *and suppose that*

(1) *$a_i(\lambda)$ is strictly increasing, for $1 \leqq i \leqq n$;*

(2) *$b_j(\lambda)$ is nonincreasing, for $0 \leqq j \leqq n$;*

(3) *$b_j(\lambda)$ has no zeros, for $1 \leqq j \leqq n-1$.*

Let $\lambda' < \lambda''$ be numbers in (Λ_1, Λ_2). Then $\det[A(\lambda)]$ has exactly $c(\lambda'') - c(\lambda')$ different zeros in the interval $[\lambda', \lambda'')$.

Proof. This follows from Theorems 2.1 and 3.1. □

LEMMA 3.3. *Let A be a matrix of the form* (3.1), *where the $a_i (1 \leqq i \leqq n)$ and $b_j (0 \leqq j \leqq n)$ are constants. Suppose that*

(1) *$b_j \geqq 0$, for $0 \leqq j \leqq n$,*

(2) *$a_i \leqq 0$, for $1 \leqq i \leqq n$.*

Then $\det[A] \geqq 0$.

Proof. A is the matrix of the quadratic form $Q(x) = xAx^T$, where $x = (x_1, x_2, \cdots, x_n)$:

$$Q(x) = \sum_{i=1}^{n} (b_{i-1} + b_i - a_i)x_i^2 - 2\sum_{j=1}^{n-1} b_j x_j x_{j+1}$$

$$= b_0 x_1^2 + b_n x_n^2 - \sum_{i=1}^{n} a_i x_i^2 + \sum_{j=1}^{n-1} b_j (x_j^2 - 2x_j x_{j+1} + x_{j+1}^2)$$

$$= b_0 x_1^2 + b_n x_n^2 - \sum_{i=1}^{n} a_i x_i^2 + \sum_{j=1}^{n-1} b_j (x_j - x_{j+1})^2.$$

Thus $Q(x)$ is positive semidefinite, and therefore $\det[A] \geqq 0$. □

The following theorem is a strong version of Theorem A for the matrix $A(\lambda)$.

THEOREM 3.3. *Let $A(\lambda)$ be a matrix of type* (3.1), *and suppose that*

(1) *$a_i(\lambda)$ is strictly increasing, for $1 \leqq i \leqq n$;*

(2) *$b_j(\lambda)$ is nonincreasing, for $0 \leqq j \leqq n$;*

(3) *$b_j(\lambda) > 0$, for $1 \leqq j \leqq n-1$;*

(4) *There is a number λ_+ in (Λ_1, Λ_2), such that $b_0(\lambda_+) \geqq 0$, $b_n(\lambda_+) \geqq 0$ and $a_i(\lambda_+) \leqq 0$ for $1 \leqq i \leqq n$.*

Then for any λ_0 in (Λ_1, Λ_2), $\det[A(\lambda)]$ has exactly $c(\lambda_0)$ different zeros in the interval (Λ_1, λ_0).

Proof. Lemma 3.3 implies that $S_i(\lambda_+) \geqq 0$, for $0 \leqq i \leqq n$. The theorem now follows from Theorems 2.2 and 3.1. □

The following theorem is analogous to Theorem B (in § 1).

THEOREM 3.4. *Let $A(\lambda)$ be a matrix of type* (3.1), *and suppose that*

(1) *$a_i(\lambda)$ is strictly increasing, for $1 \leqq i \leqq n$;*

(2) *$b_j(\lambda)$ is nonincreasing, for $0 \leqq j \leqq n$;*

(3) *$b_j(\lambda)$ has no zeros, for $1 \leqq j \leqq n-1$.*

Then for $1 \leqq i \leqq n$ the zeros of $S_i(\lambda)$ and $S_{i-1}(\lambda)$ are interlaced.

Proof. This follows from Theorems 2.3 and 3.1. □

LEMMA 3.4. *Suppose that*

(1) *$b_j(\lambda)$ is nonincreasing, for $0 \leqq j \leqq n$;*

(2) *There is a number K, so that $b_j(\lambda) \geqq K$, for $0 \leqq j \leqq n$;*

(3) *$\lim_{\lambda \to \Lambda_2} a_i(\lambda) = \infty$, for $1 \leqq i \leqq n$.*

Then $\lim_{\lambda \to \Lambda_2} S_i(\lambda) = (-1)^i \infty$, for $1 \leqq i \leqq n$.

Proof. Let λ_0 be in (Λ_1, Λ_2). Conditions (1) and (2) imply that $K \leqq b_j(\lambda) \leqq b_j(\lambda_0)$, for $\lambda_0 < \lambda < \Lambda_2$, $0 \leqq j \leqq n$. Thus the $b_j(\lambda)$ are bounded (above and below) in the interval

(λ_0, Λ_2). The determinant $S_i(\lambda)$ can be expanded in the form:

$$S_i(\lambda) = (-1)^i a_1 a_2 \cdots a_i + A_{i-1} + A_{i-2} + \cdots + A_1 + A_0,$$

where

$$A_k = \sum_{1 \leqq j_1 < j_2 < \cdots < j_k \leqq i} B_{j_1 j_2 \cdots j_k} a_{j_1} a_{j_2} \cdots a_{j_k}$$

and $B_{j_1 j_2 \cdots j_k}$ is a sum of products of the $b_j(\lambda)$. The last term A_0 is also a sum of products of the $b_j(\lambda)$. Since the $b_j(\lambda)$ are bounded in the interval (λ_0, Λ_2), so are the coefficients $B_{j_1 j_2 \cdots j_k}$ and A_0. Therefore,

$$\frac{A_k}{a_1 a_2 \cdots a_i} = \sum_{1 \leqq j_1 \leqq j_2 < \cdots < j_k \leqq i} B_{j_1 j_2 \cdots j_k} \frac{a_{j_1} a_{j_2} \cdots a_{j_k}}{a_1 a_2 \cdots a_i} \to 0 \quad \text{as } \lambda \to \Lambda_2.$$

Consequently,

$$\lim_{\lambda \to \Lambda_2} S_i(\lambda) = \lim_{\lambda \to \Lambda_2} a_1 a_2 \cdots a_i \left[(-1)^i + \frac{A_{i-1}}{a_1 a_2 \cdots a_i} + \cdots + \frac{A_0}{a_1 a_2 \cdots a_i} \right] = (-1)^i \infty. \qquad \square$$

The following theorem is analogous to Theorem C (in § 1).

THEOREM 3.5. *Let $A(\lambda)$ be a matrix of type* (3.1), *and suppose that*

(1) *$a_i(\lambda)$ is strictly increasing, for $1 \leqq i \leqq n$;*

(2) *$b_j(\lambda)$ is nonincreasing, for $0 \leqq j \leqq n$;*

(3) *$b_j(\lambda) > 0$, for $1 \leqq j \leqq n-1$, $b_0(\lambda) \geqq 0$, $b_n(\lambda) \geqq 0$;*

(4) *There is a number λ_+ in (Λ_1, Λ_2), such that $a_i(\lambda_+) \leqq 0$, for $1 \leqq i \leqq n$;*

(5) *$\lim_{\lambda \to \Lambda_2} a_i(\lambda) = \infty$, for $1 \leqq i \leqq n$.*

Then $\det[A(\lambda)]$ *has exactly n different zeros in the interval (Λ_1, Λ_2).*

Proof. Lemma 3.4 implies that $\lim_{\lambda \to \Lambda_2} S_i(\lambda) = (-1)^i \infty$, for $1 \leqq i \leqq n$. Lemma 3.3 implies that $S_i(\lambda_+) \geqq 0$, for $0 \leqq i \leqq n$. The theorem now follows from Theorems 2.4 and 3.1. $\square$

Remark. Theorems 3.1–3.5 remain valid if the matrix $A(\lambda)$ in (3.1) is replaced by

$$A(\lambda) = \begin{bmatrix} (b_0 + b_1 - a_1) & b_1 & & & & & \\ b_1 & (b_1 + b_2 - a_2) & b_2 & & & & \\ & b_2 & (b_2 + b_3 - a_3) & b_3 & & & \\ & & \ddots & \ddots & \ddots & & \\ & & & b_{n-2} & (b_{n-2} + b_{n-1} - a_{n-1}) & b_{n-1} & \\ & & & & b_{n-1} & (b_{n-1} + b_n - a_n) \end{bmatrix} \tag{3.6}$$

or

$$A(\lambda) = \begin{bmatrix} (b_0 + b_1 - a_1) & \varepsilon_1 b_1 & & & & & \\ \varepsilon_1 b_1 & (b_1 + b_2 - a_2) & \varepsilon_2 b_2 & & & & \\ & \varepsilon_2 b_2 & (b_2 + b_3 - a_3) & \varepsilon_3 b_3 & & & \\ & & \ddots & \ddots & \ddots & & \\ & & & \varepsilon_{n-2} b_{n-2} & (b_{n-2} + b_{n-1} - a_{n-1}) & \varepsilon_{n-1} b_{n-1} & \\ & & & & \varepsilon_{n-1} b_{n-1} & (b_{n-1} + b_n - a_n) \end{bmatrix}, \tag{3.7}$$

where $\varepsilon_i = \pm 1$, for $1 \leqq i \leqq n-1$. This is true because all of these matrices have the same principal minors $S_1(\lambda), S_2(\lambda), \cdots, S_n(\lambda)$.

We will now consider a symmetric tridiagonal matrix of general form:

$$A(\lambda)=\begin{bmatrix} a_1(\lambda) & b_1(\lambda) & & & & & \\ b_1(\lambda) & a_2(\lambda) & b_2(\lambda) & & & & \\ & b_2(\lambda) & a_3(\lambda) & b_3(\lambda) & & & \\ & & \cdots & \cdots & \cdots & & \\ & & & b_{n-2}(\lambda) & a_{n-1}(\lambda) & b_{n-1}(\lambda) & \\ & & & & b_{n-1}(\lambda) & a_n(\lambda) & \end{bmatrix}, \tag{3.8}$$

where the functions $a_i(\lambda)$, $1\leqq i\leqq n$, and $b_j(\lambda)$, $1\leqq j\leqq n-1$, are continuous on an interval (Λ_1, Λ_2). The above matrix can be transformed to a matrix of the form (3.1), which has the same principal minors $S_1(\lambda), S_2(\lambda), \cdots, S_n(\lambda)$. To see this, first multiply the nondiagonal terms $b_j(\lambda)$ by (-1) to obtain

$$\begin{bmatrix} a_1 & -b_1 & & & & & \\ -b_1 & a_2 & -b_2 & & & & \\ & -b_2 & a_3 & -b_3 & & & \\ & & \cdots & \cdots & \cdots & & \\ & & & -b_{n-2} & a_{n-1} & -b_{n-1} & \\ & & & & -b_{n-1} & a_n & \end{bmatrix}. \tag{3.9}$$

Next, for $1\leqq i\leqq n$, define $\bar{a}_i=b_{i-1}+b_i-a_i$, where $b_0=0=b_n$. Then $a_i=b_{i-1}+b_i-\bar{a}_i$, so the matrix (3.9) has the form

$$\bar{A}(\lambda)=\begin{bmatrix} (b_1-\bar{a}_1) & -b_1 & & & & & \\ -b_1 & (b_1+b_2-\bar{a}_2) & -b_2 & & & & \\ & -b_2 & (b_2+b_3-\bar{a}_3) & -b_3 & & & \\ & & \cdots & \cdots & \cdots & & \\ & & & -b_{n-2} & (b_{n-2}+b_{n-1}-\bar{a}_{n-1}) & -b_{n-1} & \\ & & & & -b_{n-1} & (b_{n-1}-\bar{a}_n) & \end{bmatrix}. \tag{3.10}$$

$\bar{A}(\lambda)$ has the form (3.1), with $b_0=0=b_n$. Therefore Theorems 3.1-3.5 apply, and we immediately obtain analogous results for the matrix $A(\lambda)$ in (3.8). We will state these results by referring to the following list of conditions. (When any statement involves b_0 or b_n, it will be understood that $b_0=0=b_n$.)

Condition List 3.1.

(1) $b_{i-1}(\lambda)+b_i(\lambda)-a_i(\lambda)$ is strictly increasing, for $1\leqq i\leqq n$.

(2) $b_j(\lambda)$ is nonincreasing, for $1\leqq j\leqq n-1$.

(3) $b_j(\lambda)$ has no zeros, for $1\leqq j\leqq n-1$.

(4) $b_j(\lambda)>0$, for $1\leqq j\leqq n-1$.

(5) There is a number λ_+ in (Λ_1, Λ_2), such that $b_{i-1}(\lambda_+)+b_i(\lambda_+)-a_i(\lambda_+)\leqq 0$, for $1\leqq i\leqq n$.

(6) $\lim_{\lambda\to\Lambda_2}[b_{i-1}(\lambda)+b_i(\lambda)-a_i(\lambda)]=\infty$, for $1\leqq i\leqq n$.

We continue to use our standard notation: $S_i(\lambda)$ is the ith principal minor of the matrix $A(\lambda)$ in (3.8); $S_0(\lambda)=1$; $c(\lambda)$ is the number of sign changes in the sequence $S_0(\lambda), S_1(\lambda), \cdots, S_n(\lambda)$ after the zero terms have been omitted.

THEOREM 3.6. *Let $A(\lambda)$ be a matrix of type* (3.8), *which satisfies conditions* (1), (2), *and* (3) *in Condition List* 3.1. *Let $\lambda'<\lambda''$ be numbers in (Λ_1, Λ_2). Then* $\det[A(\lambda)]$ *has exactly $c(\lambda'')-c(\lambda')$ different zeros in the interval $[\lambda', \lambda'')$.*

THEOREM 3.7. *Let $A(\lambda)$ be a matrix of type* (3.8), *which satisfies conditions* (1), (2), (4), *and* (5) *in Condition List* 3.1. *Then for any λ_0 in (Λ_1, Λ_2), $\det[A(\lambda)]$ has exactly $c(\lambda_0)$ different zeros in the interval (Λ_1, λ_0).*

THEOREM 3.8. *Let $A(\lambda)$ be a matrix of type* (3.8), *which satisfies conditions* (1), (2), *and* (3) *in Condition List* 3.1. *Then for $1 \leqq i \leqq n$, the zeros of $S_i(\lambda)$ and $S_{i-1}(\lambda)$ are interlaced.*

THEOREM 3.9. *Let $A(\lambda)$ be a matrix of type* (3.8), *which satisfies conditions* (1), (2), (4), (5), *and* (6) *in Condition List* 3.1. *Then $\det[A(\lambda)]$ has exactly n different zeros in the interval (Λ_1, Λ_2).*

We mention a special case of (3.8), in which the functions $b_j(\lambda)$ are constant, $1 \leqq j \leqq n-1$.

THEOREM 3.10. *Let $A(\lambda)$ be a matrix of type* (3.8) *in which the functions $b_j(\lambda)$ are nonzero constants for $1 \leqq j \leqq n-1$. Suppose that, for $1 \leqq i \leqq n$,*

(i) *$a_i(\lambda)$ is strictly decreasing*;

(ii) $\lim_{\lambda \to \Lambda_1} a_i(\lambda) = \infty$;

(iii) $\lim_{\lambda \to \Lambda_2} a_i(\lambda) = -\infty$.

Then,

(a) *For any λ_0 in (Λ_1, Λ_2), $\det[A(\lambda)]$ has exactly $c(\lambda_0)$ different zeros in the interval (Λ_1, λ_0)*;

(b) *The zeros of $S_i(\lambda)$ and $S_{i-1}(\lambda)$ are interlaced, for $1 \leqq i \leqq n$*;

(c) *$\det[A(\lambda)]$ has exactly n different zeros in (Λ_1, Λ_2).*

Proof. (a) By Theorem 3.7, it suffices to verify conditions (1), (2), (4), (5) in Condition List 3.1. Condition (1) follows from (i). Condition (2) is true because the $b_j(\lambda)$ are constants. Condition (5) follows from (ii). Condition (4) requires that $b_j > 0$. Although this might not be true, the principal minors of $A(\lambda)$ are not changed if b_j is replaced by $-b_j$. Therefore, we may assume that $b_j > 0$.

(b) By Theorem 3.8, we need to verify conditions (1), (2), and (3) in Condition List 3.1. We have already verified (1) and (2). Since the b_j are assumed to be nonzero, (3) is also true.

(c) By Theorem 3.9, (c) follows from conditions (1), (2), (4)-(6) in Condition List 3.1. The first four of these conditions were verified in the proof of (a). Condition (6) follows from (iii). □

Remarks. We can obtain results similar to Theorems 3.2-3.5 for the matrix (3.1), if the $a_i(\lambda)$ are strictly decreasing, and the $b_j(\lambda)$ are nondecreasing. These results follow immediately from the previous theorems by considering the functions $\bar{a}_i(\lambda) = a_i(-\lambda)$, which are strictly increasing, and $\bar{b}_j(\lambda) = b_j(-\lambda)$, which are nonincreasing on the interval $(-\Lambda_2, -\Lambda_1)$. For example, the following is a weak version of Theorem A, analogous to Theorem 3.2.

THEOREM 3.2′. *Let $A(\lambda)$ be a matrix of type* (3.1), *and suppose that*

(1) *$a_i(\lambda)$ is strictly decreasing, for $1 \leqq i \leqq n$*;

(2) *$b_j(\lambda)$ is nondecreasing, for $0 \leqq j \leqq n$*;

(3) *$b_j(\lambda)$ has no zeros, for $1 \leqq j \leqq n-1$.*

Let $\lambda' < \lambda''$ be numbers in (Λ_1, Λ_2). Then $\det[A(\lambda)]$ has exactly $c(\lambda') - c(\lambda'')$ different zeros in the interval $(\lambda', \lambda'']$.

Similarly, we can obtain results analogous to Theorems 3.6-3.10 for the matrix (3.8). For example, Theorem 3.10 has the following analogue.

THEOREM 3.10′. *Let $A(\lambda)$ be a matrix of type* (3.8) *in which the functions $b_j(\lambda)$ are nonzero constants for $1 \leqq j \leqq n-1$. Suppose that, for $1 \leqq i \leqq n$,*

(i) *$a_i(\lambda)$ is strictly increasing*;

(ii) $\lim_{\lambda \to \Lambda_1} a_i(\lambda) = -\infty$;

(iii) $\lim_{\lambda \to \Lambda_2} a_i(\lambda) = \infty$.

Then,

(a) *For any* λ_0 *in* (Λ_1, Λ_2), $\det[A(\lambda)]$ *has exactly* $c(\lambda_0)$ *different zeros in the interval* (λ_0, Λ_2);

(b) *The zeros of* $S_i(\lambda)$ *and* $S_{i-1}(\lambda)$ *are interlaced, for* $1 \leqq i \leqq n$;

(c) $\det[A(\lambda)]$ *has exactly* n *different zeros in* (Λ_1, Λ_2).

To illustrate the previous theorem, let $m_1, m_2, \cdots, m_n$ be odd, positive integers, let $\alpha_1, \alpha_2, \cdots, \alpha_n$ be arbitrary real numbers, and let $\beta_1, \beta_2, \cdots, \beta_{n-1}$ be arbitrary, nonzero real numbers. Then the matrix

$$A(\lambda) = \begin{bmatrix} (\lambda^{m_1} - \alpha_1) & \beta_1 & & & & \\ \beta_1 & (\lambda^{m_2} - \alpha_2) & \beta_2 & & & \\ & \beta_2 & (\lambda^{m_3} - \alpha_3) & \beta_3 & & \\ & & \cdots & \cdots & \cdots & \\ & & & \beta_{n-2} & (\lambda^{m_{n-1}} - \alpha_{n-1}) & \beta_{n-1} \\ & & & & \beta_{n-1} & (\lambda^{m_n} - \alpha_n) \end{bmatrix}$$

satisfies Theorem 3.10′. In particular, $p(\lambda) = \det[A(\lambda)]$ has exactly n different real zeros. For example,

$$p(\lambda) = (\lambda^{17} - \alpha_1)(\lambda^{25} - \alpha_2) - \beta^2$$

has exactly two different real zeros, if $\beta \neq 0$, and

$$p(\lambda) = (\lambda^{15} - \alpha_1)(\lambda^{29} - \alpha_2)(\lambda^{53} - \alpha_3) - \beta_2^2(\lambda^{15} - \alpha_1) - \beta_1^2(\lambda^{53} - \alpha_3)$$

has exactly three real zeros, if $\beta_1 \beta_2 \neq 0$.

4. Sturm–Liouville equations. We will apply the results of § 3 to a Sturm–Liouville eigenvalue problem of the form

$$\begin{cases} (p(x, \lambda)u')' + q(x, \lambda)u = 0 \quad \text{for } a \leqq x \leqq b, \\ \alpha_0(\lambda)u(a) + \beta_0(\lambda)u'(a) = 0, \\ \alpha_1(\lambda)u(b) + \beta_1(\lambda)u'(b) = 0, \end{cases} \tag{4.1}$$

where we assume the following:

(i) $p(x, \lambda)$, $(\partial/\partial x)p(x, \lambda)$ and $q(x, \lambda)$ are continuous functions on $[a, b] \times (\Lambda_1, \Lambda_2)$;

(ii) $p(x, \lambda) \geqq k > 0$, for $a \leqq x \leqq b$, $\Lambda_1 < \lambda < \Lambda_2$;

(iii) $\alpha_0(\lambda)$, $\beta_0(\lambda)$, $\alpha_1(\lambda)$, $\beta_1(\lambda)$, are continuous on (Λ_1, Λ_2);

(iv) $\alpha_i(\lambda)^2 + \beta_i(\lambda)^2 \neq 0$, for $i = 0, 1$ and $\Lambda_1 < \lambda < \Lambda_2$;

(v) For $i = 0, 1$, either $\beta_i(\lambda) \equiv 0$ or $\beta_i(\lambda) > 0$, for $\Lambda_1 < \lambda < \Lambda_2$.

We will use the following notation:

$$\begin{cases} p^*(\lambda) = \max\limits_{a \leqq x \leqq b} p(x, \lambda), & p_*(\lambda) = \min\limits_{a \leqq x \leqq b} p(x, \lambda), \\ q^*(\lambda) = \max\limits_{a \leqq x \leqq b} q(x, \lambda), & q_*(\lambda) = \min\limits_{a \leqq x \leqq b} q(x, \lambda). \end{cases} \tag{4.2}$$

The following theorem (with somewhat different notation) can be found in Bôcher [2, Chap. 3] and Ince [5, Chap. 10].

THEOREM D (Sturm Oscillation Theorem). *Suppose that*

(1) *For each* x, $q(x, \lambda)$ *is a strictly increasing function of* λ;

(2) *For each* x, $p(x, \lambda)$ *is a nonincreasing function of* λ;

(3) *If* $\beta_0(\lambda) \not\equiv 0$, *then* $p(a, \lambda)\alpha_0(\lambda)/\beta_0(\lambda)$ *is nondecreasing*;

(4) *If* $\beta_1(\lambda) \not\equiv 0$, *then* $p(b, \lambda)\alpha_1(\lambda)/\beta_1(\lambda)$ *is nonincreasing*;

(5) $\lim_{\lambda \to \Lambda_2} q_*(\lambda)/p^*(\lambda) = \infty$.

Then the eigenvalues of (4.1) *form an infinite, increasing sequence* $\lambda_m < \lambda_{m+1} < \lambda_{m+2} < \cdots$, *which tends to* Λ_2. *The eigenfunction* $\varphi_i(x)$, *corresponding to* λ_i, *has exactly* i *zeros in the interval* (a, b). *Furthermore, suppose that* (4.1) *satisfies either*

(6) $\lim_{\lambda \to \Lambda_1} q^*(\lambda)/p_*(\lambda) = -\infty$, *or*

(7) *There is a number* λ_+ *in* (Λ_1, Λ_2), *so that* $\alpha_0(\lambda_+)\beta_0(\lambda_+) \leqq 0$, $\alpha_1(\lambda_+)\beta_1(\lambda_+) \geqq 0$, *and* $q^*(\lambda_+) \leqq 0$. (*If the coefficient functions in* (4.1) *can be extended continuously to* $\lambda = \Lambda_1$, *we may take* $\lambda_+ = \Lambda_1$.)

Then the sequence of eigenvalues begins with λ_0, *whose eigenfunction* $\varphi_0(x)$ *has no zeros in* (a, b).

We will discretize the boundary value problem (4.1) by finite elements, thereby generating a finite difference scheme. Our goal will then be to show that Sturm sequences may be applied to the finite difference matrix, under the kind of assumptions made in Theorem D.

Recall that the energy inner product for (4.1) is

$$B(u, v) = \frac{\alpha_0(\lambda)}{\beta_0(\lambda)} p(a, \lambda)u(a)v(a) - \frac{\alpha_1(\lambda)}{\beta_1(\lambda)} p(b, \lambda)u(b)v(b) + \int_a^b (-pu'v' + quv)\, dx. \tag{4.3}$$

A weak solution of (4.1) is a function u in the Sobolev space $H^1[a, b]$, such that

$$B(u, v) = 0 \quad \text{for all } v \in H^1[a, b]. \tag{4.4}$$

If (4.4) admits a nontrivial solution $u_0(x)$ for a particular value $\lambda = \lambda_0$, then λ_0 is an eigenvalue, and $u_0(x)$ is a corresponding eigenfunction. (If $\beta_0(\lambda) \equiv 0$, then α_0/β_0 is set equal to 0 in (4.3), and $H^1[a, b]$ is replaced by the subspace of functions $v \in H^1[a, b]$, such that $v(a) = 0$. The case $\beta_1(\lambda) \equiv 0$ is treated similarly. We will carry out the calculations in the generic case $\beta_0(\lambda) \neq 0$, $\beta_1(\lambda) \neq 0$.)

The problem will be discretized using piecewise linear functions, with uniform mesh $h = (b - a)/n$. Consider the partition $x_0 < x_1 < \cdots < x_n$ of the interval $[a, b]$ by the nodes $x_i = a + ih$. The finite element space S_h is the space of continuous functions on $[a, b]$ that are linear on each interval $[x_{i-1}, x_i]$. The inner product (4.3) will now be restricted to S_h, and the integrals in (4.3) will be approximated by quadrature formulas. We will use the midpoint rule for the integral $\int_a^b pu'v'\, dx$, and the trapezoid rule for the integral $\int_a^b quv\, dx$. This defines an inner product $B_h(u, v)$ on S_h. The finite element solution is a function $u \in S_h$, such that

$$B_h(u, v) = 0 \quad \text{for all } v \in S_h. \tag{4.5}$$

A basis $v_0, v_1, \cdots, v_n$ for S_h can be obtained as follows:

$$v_0(x) = \begin{cases} -(x - x_0)/h + 1 & \text{for } x_0 \leqq x \leqq x_1, \\ 0 & \text{elsewhere;} \end{cases} \tag{4.6a}$$

$$v_i(x)=\begin{cases}(x-x_i)/h+1 & \text{for } x_{i-1}\leqq x\leqq x_i,\\ -(x-x_i)/h+1 & \text{for } x_i\leqq x\leqq x_{i+1},\\ 0 & \text{elsewhere,}\end{cases} \tag{4.6b}$$

for $1\leqq i\leqq n-1$;

$$v_n(x)=\begin{cases}(x-x_n)/h+1 & \text{for } x_{n-1}\leqq x\leqq x_n,\\ 0 & \text{elsewhere.}\end{cases} \tag{4.6c}$$

This basis is uniquely determined by the property:

(1) $v_i(x_j)=\delta_{ij}$ $(0\leqq i, j\leqq n)$.

It also satisfies the property:

(2) The support of $v_i(x)$ is contained in the one or two intervals that contain x_i.

A function $u\in S_h$ can be expressed in the form $u(x)=\sum_{i=0}^{n} u_i v_i(x)$, where $u_i=u(x_i)$. Equation (4.5) is now equivalent to the system of equations

$$\sum_{i=0}^{n} u_i B_h(v_i, v_j)=0, \qquad j=0, 1, \cdots, n. \tag{4.7}$$

Because of property (2) above, $B_h(v_i, v_j)=0$ if $|i-j|>1$. A simple calculation shows that

$$\begin{cases} B_h(v_0, v_0)=\dfrac{\alpha_0}{\beta_0}p_0-\dfrac{p_{1/2}}{h}+\dfrac{h}{2}q_0,\\[2ex] B_h(v_n, v_n)=-\dfrac{\alpha_1}{\beta_1}p_n-\dfrac{p_{n-1/2}}{h}+\dfrac{h}{2}q_n,\\[2ex] B_h(v_i, v_i)=-\dfrac{1}{h}(p_{i-1/2}+p_{i+1/2})+hq_i, \qquad 1\leqq i\leqq n-1,\\[2ex] B_h(v_i, v_{i+1})=\dfrac{p_{i+1/2}}{h}, \qquad 0\leqq i\leqq n-1. \end{cases} \tag{4.8}$$

Here, $p_j=p_j(\lambda)$ denotes $p(a+jh, \lambda)$, where j is an integer or half-integer, and similarly for $q_j=q_j(\lambda)$. Multiplying the equations (4.7) by $-h$, we obtain a system of equations:

$$A(\lambda)u=0, \tag{4.9}$$

where $u=(u_0, u_1, \cdots, u_n)^T$ and $A(\lambda)$ is the matrix

$$A(\lambda)=\begin{bmatrix} (b_0-a_0) & -b_0 & & & & & \\ -b_0 & (b_0+b_1-a_1) & -b_1 & & & & \\ & -b_1 & (b_1+b_2-a_2) & & -b_2 & & \\ & & \ddots & \ddots & & \ddots & \\ & & & -b_{n-2} & (b_{n-2}+b_{n-1}-a_{n-1}) & -b_{n-1} & \\ & & & & -b_{n-1} & (b_{n-1}-a_n) \end{bmatrix}. \tag{4.10}$$

The matrix coefficients here are

$$\begin{cases} a_0(\lambda)=\dfrac{h^2}{2}q_0(\lambda)+\dfrac{h\alpha_0(\lambda)}{\beta_0(\lambda)}p_0(\lambda),\\[2ex] a_n(\lambda)=\dfrac{h^2}{2}q_n(\lambda)-\dfrac{h\alpha_1(\lambda)}{\beta_1(\lambda)}p_n(\lambda),\\[2ex] a_i(\lambda)=h^2q_i(\lambda) \quad \text{for } 1\leqq i\leqq n-1,\\[2ex] b_i(\lambda)=p_{i+1/2}(\lambda) \quad \text{for } 0\leqq i\leqq n-1. \end{cases} \tag{4.11}$$

Recall that we have assumed (for $i=0, 1$) that either $\beta_i(\lambda)\equiv 0$, or $\beta_i(\lambda)>0$. If $\beta_0(\lambda)\equiv 0$, then $u_0=0$ and the zeroth row and column in $A(\lambda)$ are omitted. If $\beta_1(\lambda)\equiv 0$, then $u_n=0$ and the nth row and column are omitted. Thus $A(\lambda)$ is an $m\times m$ matrix, where m can be $n-1$, n or $n+1$. We will continue to confine our calculations to the generic case $\beta_i(\lambda)>0$, for $i=0, 1$. In this case, $A(\lambda)$ is an $(n+1)\times(n+1)$ matrix of the form (3.1), where the first row and column are indexed by $i=0$ instead of $i=1$. The term b_0 in (3.1) corresponds to a term b_{-1} in (4.10), and $b_{-1}=b_n=0$ in (4.10).

The assumptions after (4.1) imply that the $a_i(\lambda)$ and $b_j(\lambda)$ are continuous functions, and $b_j(\lambda)>0$. If the assumptions (1)-(4) in Theorem D are satisfied, then the functions $a_i(\lambda)$ are strictly increasing and the $b_j(\lambda)$ are nonincreasing. Therefore we may apply Theorems 3.1, 3.2, and 3.4 to $A(\lambda)$. We will now verify that assumptions (6) or (7) in Theorem D enable us to apply Theorem 3.3, and if we also assume condition (5) in Theorem D, then we may apply Theorem 3.5.

LEMMA 4.1. *Suppose that*

(1) $p(a,\lambda)\alpha_0(\lambda)/\beta_0(\lambda)$ *is a nondecreasing function of* λ;

(2) $p(b,\lambda)\alpha_1(\lambda)/\beta_1(\lambda)$ *is a nonincreasing function of* λ.

Furthermore, assume that either

(3) $\lim_{\lambda\to\Lambda_1} q^*(\lambda)/p_*(\lambda)=-\infty$; *or*

(4) *There is a number* λ_+ *in* (Λ_1,Λ_2), *such that* $\alpha_0(\lambda_+)\beta_0(\lambda_+)\leqq 0$, $\alpha_1(\lambda_+)\beta_1(\lambda_+)\geqq 0$, *and* $q^*(\lambda_+)\leqq 0$.

Then there is a number λ^+ *such that* $a_i(\lambda^+)\leqq 0$, *for* $0\leqq i\leqq n$. (*If* (4) *applies, then* $\lambda^+=\lambda_+$.)

Proof. Suppose that condition (3) applies. Then $\lim_{\lambda\to\Lambda_1} q^*(\lambda)/p_*(\lambda)=-\infty$, and by condition (ii) after (4.1), $p_*(\lambda)\geqq k>0$. This implies that $\lim_{\lambda\to\Lambda_1} q^*(\lambda)=-\infty$. For $1\leqq i\leqq n-1$, $a_i(\lambda)=h^2q_i(\lambda)\leqq h^2q^*(\lambda)$. Therefore $a_i(\lambda)<0$, for λ near Λ_1, $1\leqq i\leqq n-1$. Concerning

$$a_0(\lambda)=\frac{h^2}{2}q_0(\lambda)+\frac{h\alpha_0(\lambda)}{\beta_0(\lambda)}p_0(\lambda),$$

we see condition (1) implies that, for $\Lambda_1<\lambda<\lambda_0$,

$$a_0(\lambda)\leqq\frac{h^2}{2}q_0(\lambda)+\frac{h\alpha_0(\lambda_0)}{\beta_0(\lambda_0)}p_0(\lambda_0)\leqq\frac{h^2}{2}q^*(\lambda)+\frac{h\alpha_0(\lambda_0)}{\beta_0(\lambda_0)}p_0(\lambda_0).$$

Since $\lim_{\lambda\to\Lambda_1} q^*(\lambda)=-\infty$, it follows that $a_0(\lambda)<0$, for λ near Λ_1. Similarly, for

$$a_n(\lambda)=\frac{h^2}{2}q_n(\lambda)-\frac{h\alpha_1(\lambda)}{\beta_1(\lambda)}p_n(\lambda),$$

conditions (2) and (3) imply that $a_n(\lambda)<0$, for λ near Λ_1.

Now suppose that condition (4) applies. Then, for $1\leqq i\leqq n-1$, $a_i(\lambda_+)=h^2q_i(\lambda_+)\leqq h^2q^*(\lambda_+)\leqq 0$. Since $\alpha_0(\lambda_+)\beta_0(\lambda_+)\leqq 0$ and $p_0(\lambda)>0$,

$$a_0(\lambda_+)=\frac{h^2}{2}q_0(\lambda_+)+\frac{h\alpha_0(\lambda_+)}{\beta_0(\lambda_+)}p_0(\lambda_+)\leqq\frac{h^2}{2}q_0(\lambda_+)\leqq\frac{h^2}{2}q^*(\lambda_+)\leqq 0.$$

Similarly,

$$a_n(\lambda_+)=\frac{h^2}{2}q_n(\lambda_+)-\frac{h\alpha_1(\lambda_+)}{\beta_1(\lambda_+)}p_n(\lambda_+)\leqq\frac{h^2}{2}q^*(\lambda_+)\leqq 0.$$

□

LEMMA 4.2. *Assume conditions* (1), (2) *in Lemma* 4.1 *and*

$$\lim_{\lambda \to \Lambda_2} q_*(\lambda)/p^*(\lambda) = \infty. \tag{3}$$

Then $\lim_{\lambda \to \Lambda_2} a_i(\lambda) = \infty$, *for* $0 \leqq i \leqq n$.

Proof. Since $p^*(\lambda) \geqq k > 0$, condition (3) implies that $\lim_{\lambda \to \Lambda_2} q_*(\lambda) = \infty$. For $1 \leqq i \leqq n-1$, $a_i(\lambda) = h^2 q_i(\lambda) \geqq h^2 q_*(\lambda)$. Therefore $\lim_{\lambda \to \Lambda_2} a_i(\lambda) = \infty$, for $1 \leqq i \leqq n-1$. Next, consider

$$a_0(\lambda) = \frac{h^2}{2} q_0(\lambda) + \frac{h\alpha_0(\lambda)}{\beta_0(\lambda)} p_0(\lambda).$$

Because of condition (1),

$$a_0(\lambda) \geqq \frac{h^2}{2} q_0(\lambda) + \frac{h\alpha_0(\lambda_0)}{\beta_0(\lambda_0)} p_0(\lambda_0), \quad \text{for } \lambda_0 < \lambda < \Lambda_2.$$

Therefore $\lim_{\lambda \to \Lambda_2} a_0(\lambda) = \infty$. Similarly, condition (2) implies that $\lim_{\lambda \to \Lambda_2} a_n(\lambda) = \infty$. □

We can now use Theorems 3.1-3.5 to show that Sturm sequences can be applied to the finite difference matrix $A(\lambda)$ in (4.10), for the Sturm-Liouville problem (4.1). We will use our usual notation: $S_i(\lambda)$ is the ith principal minor of $A(\lambda)$; $S_0(\lambda) = 1$; $c(\lambda)$ is the number of sign changes in the sequence $S_0(\lambda), S_1(\lambda), \cdots, S_{n+1}(\lambda)$ after the zero terms have been omitted.

THEOREM 4.1. *Let* $A(\lambda)$ *be the finite difference matrix in* (4.10). *Suppose that conditions* (1)-(4) *in Theorem* D *are satisfied. Then*

(a) *For any numbers* $\lambda' < \lambda''$ *in* (Λ_1, Λ_2), $\det[A(\lambda)]$ *has exactly* $c(\lambda'') - c(\lambda')$ *different zeros in the interval* $[\lambda', \lambda'')$;

(b) *The zeros of* $S_i(\lambda)$ *and* $S_{i-1}(\lambda)$ *are interlaced, for* $1 \leqq i \leqq n+1$.

If (4.1) *also satisfies either* (6) *or* (7) *in Theorem* D, *then*

(c) *For any* λ_0 *in* (Λ_1, Λ_2), $\det[A(\lambda)]$ *has exactly* $c(\lambda_0)$ *different zeros in the interval* (Λ_1, λ_0).

If (4.1) *satisfies conditions* (1)-(5) *and either* (6) *or* (7) *in Theorem* D, *then*

(d) $\det[A(\lambda)]$ *has exactly* $n+1$ *different zeros in* (Λ_1, Λ_2).

Remarks. (1) Theorem 4.1 has been stated for the generic case, where $\beta_0(\lambda) > 0$, $\beta_1(\lambda) > 0$, and $A(\lambda)$ has size $(n+1) \times (n+1)$. It is also valid in case one or both functions $\beta_0(\lambda)$, $\beta_1(\lambda)$ are identically zero. In these cases, $A(\lambda)$ has size $n \times n$ or $(n-1) \times (n-1)$.

(2) Theorem 4.1 allows us to use the bisection method with Sturm sequences to find the kth eigenvalue of the finite difference matrix $A(\lambda)$. This in turn provides a method for approximating the kth eigenvalue of the Sturm-Liouville problem (4.1).

(3) If we interchange the words "increasing" and "decreasing" in Theorem D, we can prove another version of Theorem 4.1 (analogous to Theorem 3.2′ in § 3). This kind of Sturm-Liouville problem occurs in physical applications. For example, the equation

$$\begin{aligned} &\left(\frac{u'}{(\omega - \lambda u^0(x))^2}\right)' + \left(\frac{1}{c(x)^2} - \frac{\lambda^2}{(\omega - \lambda u^0(x))^2}\right) u = 0 \quad \text{for } 0 \leqq x \leqq d, \\ &u(0) = 0 = u'(d) \end{aligned} \tag{4.12}$$

occurs in acoustic problems (see Porter and Reiss [8], [9]).

Acknowledgments. I am grateful to Ivo Babuška for his encouragement, and for many helpful conversations. I would also like to thank the referee, whose comments led to a simplification of Theorem 4.1.

ON THE CONDITIONING OF MULTIPOINT AND INTEGRAL BOUNDARY VALUE PROBLEMS*

F. R. DE HOOG† AND R. M. M. MATTHEIJ‡

Abstract. Linear multipoint boundary value problems are investigated from the point of view of the condition number and properties of the fundamental solution. It is found that when the condition number is not large, the solution space is polychotomic. On the other hand, if the solution space is polychotomic then there exist boundary conditions such that the associated boundary value problem is well conditioned.

Key words. boundary value problem, conditioning, Green function, integral conditions

AMS(MOS) subject classifications. 34B10, 65L10

1. Introduction.

Consider a system of first-order ordinary differential equations

$$\mathscr{L}y := y' - Ay = f, \qquad 0 < t < 1 \tag{1.1}$$

where $A \in L_1^{n\times n}(0, 1)$ and $f \in L_1^n(0, 1)$. We are interested in the solution of (1.1) that satisfies the multipoint boundary condition (BC)

$$\mathscr{B}y := \sum_{i=1}^{N} B_i y(t_i) = b. \tag{1.2}$$

Here, $0 = t_1 < \cdots < t_N = 1$ and the matrices $B_i \in \mathbb{R}^{n\times n}$, $k = 1, \cdots, N$, have been scaled so that, for instance,

$$\sum_{i=1}^{N} B_i B_i^T = I. \tag{1.3}$$

The restriction $t_1 = 0$, $t_N = 1$ has been introduced for notational convenience and is not restrictive provided we allow for the possibility that $B_0 = 0$ and $B_N = 0$.

One of the simplest examples of a multipoint boundary value problem is that of a dynamical system with n states which are observed at different times. Further examples and a description of numerical schemes for the solution of such equations may be found in [12], [1], and [11].

From the theory of boundary value problems, (1.1), (1.2) has a unique solution if $\mathscr{B}Y$ is nonsingular for any fundamental solution Y of $\mathscr{L}$ (see, for example, Keller [8]). In the sequel we assume this is the case. Then, given any fundamental solution Y of (1.1), we may write the solution of (1.1), (1.2) as

$$y(t) = \Phi(t)b + \int_0^1 G(t, s)f(s)\, ds, \qquad 0 \leqq t \leqq 1 \tag{1.4}$$

where

$$\Phi(t) := Y(t)(\mathscr{B}Y)^{-1} \tag{1.5a}$$

and

$$G(t,s)=\begin{cases}\Phi(t)\sum_{i=1}^{k}B_i\Phi(t_j)\Phi^{-1}(s), & t_k<s<t_{k+1},\quad t>s,\\ -\Phi(t)\sum_{i=k+1}^{N}B_i\Phi(t_j)\Phi^{-1}(s), & t_k<s<t_{k+1},\quad t<s.\end{cases}\tag{1.5b}$$

The function G is the *Green function* associated with (1.1), (1.2).

We can now use (1.4) to examine the conditioning of (1.1), (1.2). Let $|\cdot|$ denote the usual Euclidean norm in $\mathbb{R}^n$ and define

$$\|u\|_\infty := \sup_t |u(t)|, \qquad u\in[L_\infty(0,1)]^n,$$

$$\|u\|_1 = \int_0^1 |u(t)|\,dt, \qquad u\in[L_1(0,1)]^n.$$

Then it follows from (1.3) that

$$\|y\|_\infty \leqq \beta|\mathcal{B}y| + \alpha\|\mathcal{L}y\|_1 \tag{1.6}$$

where

$$\alpha := \sup_{t,s}|G(t,s)| \tag{1.7a}$$

and

$$\beta := \sup_t |\Phi(t)|. \tag{1.7b}$$

The quantities α, β defined by (1.7) serve quite well as condition numbers for the boundary value problem in the sense that they give a measure for the sensitivity of (1.1), (1.2) to changes in the data. Consequently, if α or β is large, we may expect to have difficulties in obtaining an accurate numerical approximation to the solution of (1.1), (1.2).

If α is of moderate size, the solution space of (1.1) has properties that can (and should) be used in the construction of algorithms for calculating an approximate solution of (1.1), (1.2). For the two-point case (i.e., $N=2$), de Hoog and Mattheij [5], [6] have shown that the solution space is dichotomic when α is not too large. A dichotomic solution space (see § 4 for a more detailed discussion of dichotomy) essentially means that nonincreasing modes of the solution space can be controlled by boundary conditions imposed on the left while nondecreasing modes can be controlled by boundary conditions imposed on the right. This concept is the basis for algorithms using decoupling ideas (see, for example, [10], [11]). The aim of this paper is to generalize the results of [5], [6] to (1.1), (1.2) with $N\geqq 2$. In this case the notion of dichotomy has to be generalized, and it turns out that, for well-conditioned problems, the solution space consists of modes that can be controlled at one of the points $t_1,\cdots,t_N$ (see § 4). This has allowed us to generalize the ideas of decoupling to multipoint problems, but that is discussed elsewhere [7].

In general we may say that if $N>n$ there is a redundancy in the number of conditions involved. It is therefore crucial to pick precisely n appropriate points from which modes are actually controlled by suitable conditions. It is quite natural to consider then a limit case of multipoint BC, viz., an integral condition (which incidentally generalizes two and multipoint conditions in an obvious way), so

$$\mathcal{B}y := \int_0^1 B(\tau)y(\tau)\,d\tau = b. \tag{1.8}$$

Such BC arise directly when L_p norms are used to scale the solution (possibly after linearization) as in eigenvalue problems.

We may treat the (discrete) multipoint case separately from (1.8). However, as it turns out, it is possible to construct a general mechanism that handles the integral BC as well. The price to be paid for this is that our proofs will be based on functional analytic arguments and thus are less constructive than could be given for the discrete case. The reward though is that we have been able to get sharp bounds in our estimates, sharpening even the bounds given for the two-point case in [6].

2. Notation and assumptions. In this section we review some basic results that we need later in our analysis. For some general references regarding Green functions we may consult, e.g., [2] and [9].

2.1. Boundary conditions and their normalization. Consider the general *boundary condition* (BC):

$$\mathcal{B}y = b \tag{2.1}$$

where $\mathcal{B}$ is a bounded linear operator from $L^n_{1,1}(0,1)$ to $\mathbb{R}^n$. Note that this includes the BC of type (1.2) and (1.8) as well. By $L^n_{1,1}(0,1)$ we mean those functions the first derivative of which is in $L^n_1(0,1)$. We introduce the norm

$$\|u\|_\infty = \max_{0\leqq t\leqq 1} |u(t)|, \qquad u \in L^n_{1,1}(0,1)$$

where

$$|a| = \left(\sum_{i=1}^{n} a_i^2\right)^{1/2}, \qquad a \in \mathbb{R}^n.$$

For any $a \in \mathbb{R}^n$, $a^T\mathcal{B}$ is a linear functional from $L^n_{1,1}[0,1]$ to $\mathbb{R}$. We define

$$\|a^T\mathcal{B}\|_\infty := \sup_{u\in L^n_{1,1}(0,1)} \frac{|a^T\mathcal{B}u|}{\|u\|_\infty},$$

$$\rho_1(\mathcal{B}) := \max_{a\in\mathbb{R}^n} \frac{\|a^T\mathcal{B}\|_\infty}{|a|} = \|\mathcal{B}\|_\infty,$$

$$\rho_n(\mathcal{B}) := \min_{a\in\mathbb{R}^n} \frac{\|a^T\mathcal{B}\|_\infty}{|a|}.$$

LEMMA 2.1. *Let* $0 < \rho_1(\mathcal{B}) < \infty$. *Then, there exists a matrix* $C \in \mathbb{R}^{n\times n}$ *such that*

$$\|C\mathcal{B}\|_\infty = \rho_1(C\mathcal{B}) = 1$$

and

$$\rho_n(C\mathcal{B}) \geqq \frac{\rho_n(E\mathcal{B})}{\rho_1(E\mathcal{B})} \quad \forall E \in \mathbb{R}^{n\times n}.$$

Proof. If $\rho_n(\mathcal{B}) = 0$, then the result is trivial. We therefore assume $\rho_n(\mathcal{B}) > 0$ and let

$$\mathcal{D} = \{E \in \mathbb{R}^{n\times n} \mid \rho_1(E\mathcal{B}) = 1\}.$$

Since $\rho_n(E\mathcal{B})$ is continuous in E and $\mathcal{D}$ is closed and bounded, it follows that there is a matrix $C \in \mathcal{D}$ such that

$$\rho_n(C\mathcal{B}) \geqq \rho_n(E\mathcal{B}) \quad \forall E \in \mathcal{D}.$$

This is equivalent to the statement of the lemma. □

This now gives us the possibility of scaling the BC, cf. (1.3), in a meaningful way.

Assumption 2.1. In the sequel, we shall assume that the BC (2.1) has been scaled so that

$$\rho_1(\mathcal{B}) = \|\mathcal{B}\|_\infty = 1 \tag{2.2a}$$

and

$$\rho_n(\mathcal{B}) \geqq \rho_n(E\mathcal{B})/\rho_1(E\mathcal{B}) \quad \forall E \in \mathbb{R}^{n\times n}. \tag{2.2b}$$

In addition to Assumption 2.1 we have the following assumption.

Assumption 2.2. Let (1.1), (2.1) have a solution for every $f \in L_1^n(0,1)$ and $b \in \mathbb{R}^n$. Then, $\mathcal{B}Y \in \mathbb{R}^{n\times n}$ is nonsingular, where $Y \in L_{1,1}^{n\times n}(0,1)$ is the solution of

$$\mathcal{L}Y = 0, \qquad Y(0) = F \tag{2.3a}$$

and $F \in \mathbb{R}^{n\times n}$ is nonsingular.

On defining

$$\Phi(t) := Y(t)(\mathcal{B}Y)^{-1}, \tag{2.3b}$$

we can write any function $y \in L_{1,1}^n(0,1)$ as

$$y = \mathcal{P}y + (I-\mathcal{P})y = \mathcal{P}y + \mathcal{G}(\mathcal{L}y), \tag{2.4}$$

where

$$\mathcal{P}y := \Phi(\mathcal{B}y), \tag{2.5a}$$

$$\mathcal{G}f := \int_0^1 \mathcal{G}(t,s)f(s)\,ds, \qquad f \in L_1^n(0,1) \tag{2.5b}$$

and $\mathcal{G}$ is the *Green function* defined by

$$\mathcal{G}(t,s) = \Phi(t)\{H(t,s) - \mathcal{B}(\Phi H(\cdot,s))\}\Phi^{-1}(s) \tag{2.6a}$$

with

$$H(t,s) = \begin{cases} I, & t > s, \\ 0, & t < s \end{cases} \tag{2.6b}$$

(cf. the special case (1.4), where $\mathcal{B}$ is given by (1.2)).

Remark 2.1. The operator $\mathcal{B}$ in the term $\mathcal{B}(\Phi H(\cdot,s))$ above should be interpreted as an extension of $\mathcal{B}$ to an operator from $L_\infty^n(0,1)$ to $\mathbb{R}^n$. Note however that a sensible extension of $\mathcal{B}$ to $L_\infty^n(0,1)$ is assured by the Hahn-Banach theorem.

Remark 2.2. $\mathcal{P}$ is a projection from $L_{1,1}^n(0,1)$ onto the solution space $\{Ya \mid a \in \mathbb{R}^n\}$. Given such a projection $\mathcal{P}$, we can define a linear operator

$$\mathcal{B} = CY^{-1}\mathcal{P}$$

where $C \in \mathbb{R}^{n\times n}$ is a scaling matrix chosen so that (1.1), (2.2a), and (2.2b) hold. Lemma 2.1 ensures the existence of such a matrix.

Remark 2.3. It is easy to verify that the Green function has the form

$$\mathcal{G}(t,s) = \begin{cases} Y(t)(I-E(s))Y^{-1}(s), & t > s, \\ -Y(t)(E(s))Y^{-1}(s), & t < s \end{cases} \tag{2.7}$$

where $E \in L_\infty^{n\times n}(0,1)$. Conversely, given a function of the form (2.7), we have

$$\mathcal{L}\left\{\int_0^1 \mathcal{G}(\cdot,s)f(s)\,ds\right\} = f, \qquad f \in L_1^n(0,1).$$

In addition, if we define

$$(\mathscr{P}y)(t) := y(t) - \int_0^1 \mathscr{G}(t, s)(\mathscr{L}y)(s)\, ds,$$

then

$$(\mathscr{P}y)(t) = y(t) - \int_0^t Y(t)Y^{-1}(s)(\mathscr{L}y)(s)\, ds + Y(t)\int_0^1 E(s)Y^{-1}(s)(\mathscr{L}y)(s)\, ds$$

$$= Y(t)\left\{ Y^{-1}(0)y(0) + \int_0^1 E(s)Y^{-1}(s)(\mathscr{L}y)(s)\, ds \right\}.$$

We can easily verify that $\mathscr{P}$ is a projection. Thus, $\mathscr{B}$ defined by

$$\mathscr{B}y := C\left\{ Y^{-1}(0)y(0) + \int_0^1 E(s)Y^{-1}(s)(\mathscr{L}y(s))\, ds \right\},$$

where $C \in \mathbb{R}^{n\times n}$ is a scaling matrix chosen so that (2.2a), (2.2b) holds, gives a bounded linear operator for which $\mathscr{G}$ is the associated Green function.

2.2. Auerbach's lemma. Let $\mathscr{V}$ be a normed linear space of dimension k with norm denoted by $\|\cdot\|$ and let $\mathscr{V}^*$ be the space of all linear functionals from $\mathscr{V} \to \mathbb{R}$.

Define a norm on $\mathscr{V}^*$ by

$$\|y^*\|^* = \sup_{x\in\mathscr{V}} \frac{y^*(x)}{\|x\|}, \qquad y^* \in \mathscr{V}^*. \tag{2.8}$$

DEFINITION 2.1. A *boundary* of $\mathscr{V}$ is any set

$$\mathscr{D} \subseteq \{y^* \in \mathscr{V}^* \mid \|y^*\|^* \leqq 1\}$$

such that

$$\|x\| = \sup_{y^*\in\mathscr{D}} y^*(x) \quad \forall x \in \mathscr{V}.$$

LEMMA 2.2 (*for Auerbach's lemma see* [4, *Lemma* 4]). *If $\mathscr{D}$ is a closed boundary of $\mathscr{V}$ then there exist $y_i^* \in \mathscr{D}$, $y_j \in \mathscr{V}$; $i, j = 1, \cdots, k$ such that*

$$y_i^*(y_j) = \delta_{ij}, \qquad \|y_i^*\|^* = 1, \qquad \|y_j\| = 1, \qquad i, j = 1, \cdots, k.$$

Since $\{y^* \in \mathscr{V}^* \mid \|y^*\|^* \leqq 1\}$ is a closed boundary, Corollary 2.1 follows immediately.

COROLLARY 2.1. *There exist $y_i^* \in \mathscr{V}^*$, $y_j \in \mathscr{V}$; $i, j = 1, \cdots, k$ such that*

$$y_i^*(y_j) = \delta_{ij}, \qquad \|y_i^*\|^* = 1, \qquad \|y_j\| = 1, \qquad i, j = 1, \cdots, k.$$

3. Conditioning of differential equations. In this section we consider the relation between α and β and the effect of the normalization of the BC as in Assumption 2.1. Recall that for $y \in L^n_{1,1}(0, 1)$ (cf. (2.4))

$$y(t) = \Phi(t)\mathscr{B}y + \int_0^1 \mathscr{G}(t, s)(\mathscr{L}y)(s)\, ds.$$

Hence, on taking norms

$$\|y\|_\infty \leqq \beta|\mathscr{B}y| + \alpha\|\mathscr{L}y\|_1$$

where

$$\beta = \|\Phi\|_\infty = \max_{a\in\mathbb{R}^n} \frac{\|\Phi a\|_\infty}{|a|}, \qquad \alpha = \sup_{t,s} |G(t, s)|.$$

In addition to α and β, it is also useful to consider

$$\mathscr{P}\cdot := Y(\mathscr{B}Y)^{-1}\mathscr{B}\cdot.$$

LEMMA 3.1. $\rho_n(\mathscr{B})\beta \leqq \|\mathscr{P}\|_\infty \leqq \rho_1(\mathscr{B})\beta$.

Proof. The result follows immediately from the definition of $\rho_1(\mathscr{B})$ and $\rho_n(\mathscr{B})$. □

LEMMA 3.2. *Let $\hat{\mathscr{B}}$ be a linear operator from $L^n_{1,1}(0,1)$ to $\mathbb{R}^n$, and let $\hat{\alpha}$ be the constant associated with $\hat{\mathscr{B}}$ and the differential equation* (1.1). *Then,*

$$\hat{\alpha} \leqq (1+\|\hat{\mathscr{P}}\|_\infty)\alpha, \quad \textit{where } \hat{\mathscr{P}}Y = Y(\hat{\mathscr{B}}Y)^{-1}\hat{\mathscr{B}}Y.$$

Proof. Let

$$\hat{\Phi} := Y(\hat{\mathscr{B}}Y)^{-1} \quad \text{and} \quad \hat{\mathscr{G}}f := \int_0^1 \hat{\mathscr{G}}(\cdot, s)f(s)\,ds,$$

where $\hat{\mathscr{G}}$ is defined similarly to $\mathscr{G}$ in (2.6a), i.e., $\mathscr{B}$ replaced by $\hat{\mathscr{B}}$. Clearly, $\hat{\Phi} = Y(\hat{\mathscr{B}}Y)^{-1}$ and consequently $\mathscr{P} = \mathscr{P}\hat{\mathscr{P}}$. That is, $\hat{\mathscr{G}}f = (I-\hat{\mathscr{P}})\mathscr{G}f$, and hence

$$\|\hat{\mathscr{G}}f\|_\infty \leqq (1+\|\hat{\mathscr{P}}\|_\infty)\|\mathscr{G}f\|_\infty.$$

Thus, $\hat{\alpha} \leqq (1+\|\hat{\mathscr{P}}\|_\infty)\alpha$. □

It is clear that the result of Lemmas 3.1 and 3.2 can be combined to give

$$\hat{\alpha} \leqq (1+\rho_1(\tilde{\mathscr{B}})\tilde{\beta})\alpha.$$

Since it has been assumed that (2.2a), (2.2b) hold, we obtain the estimate

$$\hat{\alpha} \leqq (1+\hat{\beta})\alpha. \tag{3.1}$$

Note, however, that α and $\|\mathscr{P}\|_\infty$ are independent of the scaling (2.2a), (2.2b) but that $\rho_1(\mathscr{B})$, $\rho_n(\mathscr{B})$, and β are not. Therefore we examine some of the ramifications of Assumption 2.1.

LEMMA 3.3. $\rho_n(\mathscr{B}) \geqq n^{-1}$.

Proof. Let

$$\mathscr{V} = \{a^T\mathscr{B} \mid a \in \mathbb{R}^n\}.$$

That is, $\mathscr{V}$ are the linear functionals of the form $a^T\mathscr{B}$. Since $\mathscr{B}\Phi = I$, $\dim(\mathscr{V}) = n$. For $\ell \in \mathscr{V}$, define

$$\|\ell\| = \sup_{y \in L^n_{1,1}(0,1)} \frac{(\ell y)}{\|y\|_\infty} = \|\ell\|_\infty.$$

$\mathscr{V}$ equipped with the norm $\|\cdot\|$ is an n-dimensional normed space. From Auerbach's theorem (Corollary 2.1), there exist $\ell_j^* \in \mathscr{V}^*$, $\ell_i \in \mathscr{V}$; $i,j = 1, \cdots, n$ such that

$$\ell_j^*(\ell_i) = \delta_{ij}, \quad \|\ell_j^*\|^* = \|\ell_i\| = 1, \quad i,j = 1, \cdots, n.$$

Clearly, for some $E \in \mathbb{R}^{n\times n}$,

$$a^TE\mathscr{B} = \sum_{i=1}^n a_i\ell_i \quad \forall a = (a_1, \cdots, a_n)^T \in \mathbb{R}^n.$$

Furthermore,

$$\begin{aligned}\|a^TE\mathscr{B}\|_\infty &= \left\|\sum_{i=1}^n a_i\ell_i\right\|_\infty \\ &\geqq \frac{|\sum_{j=1}^n a_j l_j^*(\sum_{i=1}^n a_i\ell_i)|}{\|\sum_{j=1}^n a_j\ell_j^*\|^*} \\ &\geqq \frac{|a|}{\sqrt{n}}.\end{aligned}$$

Thus, $\rho_n(E\mathcal{B}) \geqq 1/\sqrt{n}$. In addition,

$$\|a^T E\mathcal{B}\|_\infty = \left\| \sum_{i=1}^{n} a_i \ell_i \right\|_\infty$$

$$\leqq \sum_{i=1}^{n} |a_i| \, \|\ell_i\|_\infty \leqq n^{1/2}|a|.$$

Thus, $\rho_1(E\mathcal{B}) \leqq n^{1/2}$, and hence from (2.2b)

$$\rho_n(\mathcal{B}) \geqq \frac{\rho_n(E\mathcal{B})}{\rho_1(E\mathcal{B})} \geqq n^{-1}.$$

For boundary conditions of the form (1.2) we can obtain somewhat sharper estimates.

LEMMA 3.4. *For $\mathcal{B}$ given by* (1.2) *and satisfying* (1.1), (2.1), *we have*

$$\rho_n(\mathcal{B}) \geqq N_1^{-1/2}$$

where N_1 is the number of nontrivial matrices B_i in (1.2).

Proof. Without loss of generality, we take $N_1 = N$

$$\|a^T E\mathcal{B}\|_\infty = \sum_{i=1}^{N} |B_i^T E^T a|$$

$$\leqq N^{1/2} \left(a^T E \sum_{i=1}^{N} B_i B_i^T E^T a \right)^{1/2}$$

$$\leqq N^{1/2} \left| E \sum_{i=1}^{N} B_i B_i^T E^T \right|^{1/2} |a|.$$

Thus, $\rho_1(E\mathcal{B}) \leqq N^{1/2} \left| E \sum_{i=1}^{N} B_i B_i^T E^T \right|^{1/2}$. On the other hand,

$$\|a^T E\mathcal{B}\|_\infty = \sum_{i=1}^{N} |B_i^T E^T a|$$

$$\geqq \left(a^T E \sum_{i=1}^{N} B_i B_i^T E^T a \right)^{1/2} \geqq |a| \Big/ \left| \left(E \sum_{i=1}^{N} B_i B_i^T E^T \right)^{-1} \right|^{1/2}.$$

Thus, $\rho_n(E\mathcal{B}) \geqq 1/\left| E \sum_{i=1}^{N} B_i B_i^T E^T \right)^{-1} \Big|^{1/2}$. Now if we take $E = \left(\sum_{i=1}^{N} B_i B_i^T \right)^{-1/2}$, then, from (2.2b), $\rho_n(\mathcal{B}) \geqq \rho_n(E\mathcal{B})/\rho_1(E\mathcal{B}) \geqq N^{-1/2}$. □

For an important class of boundary conditions, the bound in Lemma 3.4 is attained.

LEMMA 3.5. *Let $\mathcal{B}$ be given by* (1.2),

$$\sum_{i=1}^{N} \operatorname{rank}(B_i) = n$$

and N_1 be the number of nontrivial matrices B_i in (1.2). *Then,*

$$\frac{\rho_n(\mathcal{B})}{\rho_1(\mathcal{B})} \leqq N_1^{-1/2}.$$

In addition, (2.2*a*), (2.2*b*) *hold if and only if*

$$\sum_{i=1}^{N} B_i B_i^T = N_1^{-1} I.$$

Proof. Let us assume without loss of generality that $N_1 = N$,

$$B_i^T B_i \eta_i = \sigma_i^2 \eta_i, \quad |\eta_i| = 1, \quad i = 1, \cdots, N$$

and

$$w_1 = 1, \quad w_k = \operatorname{sign}\left\{\eta_k^T B_k^T \sum_{i=1}^{k-1} w_i B_i \eta_i\right\}, \quad k = 2, \cdots, N.$$

Now,

$$\rho_1(\mathscr{B}) = \max_a \left\{\frac{\sum_{i=1}^N |a^T B_i|}{|a|}\right\} \geqq \max_a \left\{\frac{\left|\sum_{i=1}^N w_i a^T B_i \eta_i\right|}{|a|}\right\}$$
$$= \left|\sum_{i=1}^N w_i B_i \eta_i\right| \geqq \left(\sum_{i=1}^N \eta_i^T B_i^T B_i \eta_i\right)^{1/2} = \left(\sum_{i=1}^N \sigma_i^2\right)^{1/2}.$$

This result holds for all singular values σ_i, and we may therefore take $\sigma_i = |B_i|$. Then $\rho_1(\mathscr{B}) \geqq (\sum_{i=1}^N |B_i|^2)^{1/2}$.

In addition, for $\sigma_k \neq 0$,

$$\rho_n(\mathscr{B}) = \min_a \left\{\frac{\sum_{i=1}^N |a^T B_i|}{|a|}\right\} = \sigma_k \min_a \left\{\frac{\sum_{i=1}^N |a^T B_i|}{|a||B_k \eta_k|}\right\}$$
$$\leqq \sigma_k \min_a \left\{\frac{\sum_{i=1}^N |a^T B_i|}{|a^T B_k \eta_k|}\right\} = \sigma_k.$$

Note that the last equality is not valid if $\sum \operatorname{rank}(B_i) > n$. Nor is it valid for an arbitrary vector η_k. Thus,

$$\frac{\rho_n(\mathscr{B})}{\rho_1(\mathscr{B})} \leqq \min_k \frac{\sigma_k}{(\sum_{i=1}^N |B_i|^2)^{1/2}} \leqq N^{-1/2},$$

which proves the first part of the lemma.

Now let (2.2a), (2.2b) hold. From Lemma 3.4 and the result above

$$\sigma_k = N^{-1/2}\left(\sum_{i=1}^N |B_i|^2\right)^{1/2}.$$

Since, σ_k is an arbitrary singular value, all the singular values are equal, and using (2.2a) we obtain that $\sum_{i=1}^N B_i B_i^T = N^{-1} I$.

Finally, let $\sum_{i=1}^N B_i B_i^T = N^{-1} I$. Then, as previously,

$$\rho_1(\mathscr{B}) \geqq \left(\sum_{i=1}^N |B_i|^2\right)^{1/2} = 1 \quad \text{and} \quad \rho_1(\mathscr{B}) \leqq N^{1/2} \left|\sum_{i=1}^N B_i B_i^T\right|^{1/2} = 1.$$

Thus, $\rho_1(\mathscr{B}) = 1$. In addition, as in Lemma 3.4,

$$\rho_n(\mathscr{B}) \geqq 1 \Big/ \left|\left(\sum_{i=1}^N B_i B_i^T\right)^{-1}\right|^{1/2} = N^{-1/2}$$

and since this is the best possible, (2.2b) holds. □

We now have the tools to assess the condition numbers α, β. Let us consider in particular (1.1) and the multipoint BC (1.2),

$$\mathscr{B} y = \sum_{i=1}^N B_i y(t_i),$$

for which we have the following useful properties:

$$\Phi(t) B_i = G^+(t, t_i) - G^-(t, t_i), \qquad i = 1, \cdots, N, \tag{3.2}$$

where

$$G^+(t, t_i) = \lim_{s \to t_i^+} G(t, s), \qquad i = 1, \cdots, N-1, \tag{3.3a}$$

$$G^-(t, t_i) = \lim_{s \to t_i^-} G(t, s), \qquad i = 2, \cdots, N, \tag{3.3b}$$

$$G^+(t, 1) = G^-(t, 0) = 0. \tag{3.3c}$$

THEOREM 3.1. *For $\mathcal{B}$ given by* (2.1) *and satisfying* (2.2a), (2.2b), *we have*

$$\beta \leqq \frac{2N_1\alpha}{\rho_n(\mathcal{B})} \leqq 2N_1\alpha \min(n, N^{1/2}),$$

where N_1 is the number of nontrivial matrices B_1 in (3.2). *If, in addition* $\sum_{i=1}^{N} \operatorname{rank}(B_i) = n$, *then* $\beta \leqq 2N_1\alpha$.

Proof. Without loss of generality, we take $N_1 = N$. From (3.2), (3.3)

$$|\Phi(t)B_i| \leqq 2\alpha,$$

and hence

$$|\Phi(t)| \leqq \left(\sum_{i=1}^{N} |\Phi(t)B_i|^2\right)^{1/2} \left|\left(\sum_{i=1}^{N} B_iB_i^T\right)^{-1}\right|^{1/2}$$

$$\leqq 2\alpha N^{1/2} \left|\left(\sum_{i=1}^{N} B_iB_i^T\right)^{-1}\right|^{1/2}.$$

The first result now follows from the inequality

$$\rho_n(\mathcal{B}) \leqq N^{1/2} \Big/ \left|\left(\sum_{i=1}^{N} B_iB_i^T\right)^{-1}\right|^{1/2}$$

and Lemmas 3.3 and 3.4.

However, if $\sum_{i=1}^{N} \operatorname{rank}(B_i) = n$, it follows from Lemma 3.5 that $|(\sum_{i=1}^{N} B_iB_i^T)^{-1}|^{1/2} = GN^{1/2}$ and this establishes the second part of the theorem. □

Thus, when $\mathcal{B}$ is given by (2.1) and N is not too large, the single parameter α is a suitable measure of the conditioning of the problem. However, as $N \to \infty$ we cannot bound β in terms of α using the results of Theorem 3.1, which suggests that in general it is not possible to obtain such bounds. This is confirmed by the following example.

Example 3.1. Consider the problem

$$\mathcal{L}y = y' + ay, \qquad a > 0.$$

$$\mathcal{B}y = \int_0^1 y(s)\, ds,$$

for which $\alpha = 1$, $\beta = a(1 - e^{-a})$ and $\rho_1(\mathcal{B}) = 1$. Clearly, β becomes unbounded as $a \to \infty$.

Thus, *in general both α and β need to be addressed in a discussion of stability.*

4. Polychotomy. For two-point boundary value problems (i.e., $N = 2$) it has become almost traditional to assume that the solution space

$$\mathcal{S}(t) = \{\Phi(t)c \mid c \in \mathbb{R}^n\}$$

can be separated into a space

$$\mathcal{I}(t) = \{\Phi(t)Pc \mid c \in \mathbb{R}^n\}, \qquad P^2 = P$$

of nondecreasing solutions and a space

$$\mathcal{D}(t) = \{\Phi(t)(I - P)c \mid c \in \mathbb{R}^n\}$$

of nonincreasing solutions. In addition, if neither $\mathcal{S}(t)$ nor $\mathcal{D}(t)$ is trivial (i.e., $P \neq 0, I$), it is usually assumed that the angle $0 < \eta(t) < \pi/2$ between $\mathcal{S}(t)$ and $\mathcal{D}(t)$, defined by

$$\cos \eta(t) = \max_{y_1 \in \mathcal{S}(t), y_2 \in \mathcal{D}(t)} \frac{|y_1^T y_2|}{|y_1||y_2|}$$

is not too small. This has led to the following definition.

DEFINITION 4.1. The solution space is *dichotomic* if there exists a projector P and a constant κ such that

$$|\Phi(t)P\Phi^{-1}(s)| < \kappa, \qquad t > s, \tag{4.1a}$$

$$|\Phi(t)(I-P)\Phi^{-1}(s)| < \kappa, \qquad t < s; \tag{4.1b}$$

κ is called the *dichotomy constant.*

Although a projector always exists such that (4.1) is valid for some constant κ, we are primarily interested in the case when κ is of moderate size. In fact a more precise definition would involve the size of κ as well; we do not dwell on this, however. It turns out that dichotomy is intimately connected with the conditioning of two-point boundary value problems. Specifically, de Hoog and Mattheij [5], [6] have shown the following.

THEOREM 4.1. *When $N = 2$, there exists a projector P such that* (4.1) *holds with $\kappa = \alpha + 4\alpha^2$. Alternatively, if* (4.1) *holds, then there exist matrices $B_1, B_2 \in \mathbb{R}^{n \times n}$ such that $\alpha \leqq \kappa$.*

Thus, if $N = 2$ and α is of moderate size, the solution space is dichotomic (i.e., κ is also of moderate size). Conversely, if the solution space is dichotomic, there is a two-point boundary value problem for which the condition number is not too large.

However, a well-conditioned multipoint problem does not necessarily have a dichotomic solution space as can be seen from Example 4.1.

Example 4.1. Consider the problem

$$y' + 2\lambda(t - \tfrac{1}{2})y = f, \qquad \lambda > 0,$$
$$y(\tfrac{1}{2}) = 1.$$

For this example,

$$\Phi(t) = \exp(-\lambda(t-\tfrac{1}{2})^2),$$
$$y(t) = \Phi(t) + \int_{1/2}^{t} \Phi(t)\Phi^{-1}(s)f(s)\,ds,$$

and hence

$$\alpha = 1 \quad (\text{for all } \lambda).$$

Thus the problem is well conditioned but the fundamental solution now increases on the interval $0 < t < \frac{1}{2}$ and decreases on $\frac{1}{2} < t < 1$. Such behavior is quite common in multipoint problems. Indeed, the results of de Hoog and Mattheij [5], [6] can be used to show that there exist projectors $\hat{P}_i$, $i = 1, \cdots, N-1$ such that

$$|\Phi(t)\hat{P}_i\Phi^{-1}(s)| < \kappa, \qquad t_i < s < t < t_{i+1},$$
$$|\Phi(t)(I-\hat{P}_i)\Phi^{-1}(s)| < \kappa, \qquad t_i < t < s < t_{i+1},$$

where κ is of moderate size if α is not large. Thus, on each interval $t_i < t < t_{i+1}$, $i = 1, \cdots, N-1$ the solution space is dichotomic.

However, the examination of a number of well-conditioned multipoint problems has suggested that additional structure is present in the solution space. This leads to the following generalization of dichotomy.

DEFINITION 4.2. The solution space $\mathcal{S}(t)$ is *polychotomic* if, for some $M \in \mathbb{N}$, and $0 = x_1 \leqq x_2 \leqq \cdots \leqq x_M = 1$, there exist projectors P_k, $k = 1, \cdots, M$ and a constant κ such that

$$\sum_{k=1}^{M} P_k = I, \qquad P_i P_j = P_j P_i = \delta_{ij} P_j,$$

$$\left| \Phi(t) \sum_{j=1}^{k} P_j \Phi^{-1}(s) \right| < \kappa, \quad x_k < s < x_{k+1}, \quad t > s, \tag{4.2a}$$

$$\left| \Phi(t) \sum_{j=k+1}^{M} P_j \Phi^{-1}(s) \right| < \kappa, \quad x_k < s < x_{k+1}, \quad t < s. \tag{4.2b}$$

In § 5 we show that the concept of polychotomy is closely related to the conditioning of multipoint boundary value problems in the sense that κ will be of moderate size when α is not too large. It turns out that this relationship can be exploited in the construction of efficient numerical schemes for the solution of (1.1), (1.2); this is discussed in detail in [7].

5. Bounds for polychotomy. In this section we show how the condition number α can be used to obtain bounds for κ. Initially we consider separable boundary conditions.

5.1. Separable boundary conditions.

DEFINITION 5.1. The boundary condition (1.2) is called *separable* if

$$\sum_{i=1}^{N} \operatorname{rank}(B_i) = n.$$

Thus for separable boundary conditions, the solution space consists of a number of modes each of which is controlled by a condition at one of the points when $\operatorname{rank}(B_i) \neq 0$.

We shall see that when the boundary condition (1.2) is separable, the solution space is polychotomic with constant $\kappa = \alpha$. Before we can show this, however, some preliminary results are required.

LEMMA 5.1. *If* $C_k \in \mathbb{R}^{n \times n}$, $k = 1, \cdots, N$

$$\sum_{k=1}^{N} C_k = I \quad \textit{and} \quad \sum_{k=1}^{N} \operatorname{rank}(C_k) = n,$$

then C_k, $k = 1, \cdots, N$ *are projectors* (*i.e.*, $C_i C_j = C_j C_i = \delta_{ij} C_j$).

Proof. The result follows from the arguments used in [6, Thm. 3.2]. □

LEMMA 5.2. *For* $E_k \in \mathbb{R}^{n \times n}$, $k = 1, \cdots, N$, *let*

$$\sum_{k=1}^{N} E_k = I, \qquad \sum_{k=1}^{N} \operatorname{rank}(E_k) = n,$$

and define

$$\hat{G}(t, s) = \begin{cases} Y(t) \sum_{k=1}^{i} E_k Y^{-1}(s), & t_i < s < t_{i+1}, \quad t > s, \\ -Y(t) \sum_{k=i+1}^{N} E_k Y^{-1}(s), & t_i < s < t_{i+1}, \quad t < s, \end{cases}$$

where Y *is a fundamental solution of* (1.1). *Then there exists a boundary condition*

$$\hat{\mathcal{B}} y := \sum_{i=1}^{N} \hat{B}_i y(t_i) \tag{5.1}$$

satisfying $\operatorname{rank}(\hat{B}_i) = \operatorname{rank}(E_i)$ *and*

$$\sum_{i=1}^{N} \hat{B}_i \hat{B}_i^T = N_1^{-1} I$$

such that $\hat{G}$ *is the Green function associated with* (1.1), (5.1) *and* N_1 *is the number of nontrivial matrices* E_i.

Proof. Consider the LQ^T decomposition

$$[E_1 Y^{-1}(t_1) | E_2 Y^{-1}(t_2)| \cdots | E_N Y^{-1}(t_N)] = LQ^T$$

where $L \in \mathbb{R}^{n\times n}$ is lower triangular and nonsingular and $Q \in \mathbb{R}^{(N+1)n\times n}$ is orthogonal (i.e., $Q^TQ = I$). Now define $\hat{B}_i \in \mathbb{R}^{n\times n}$, $k = 1, \cdots, N$ by

$$[\hat{B}_1 | \hat{B}_2| \cdots | \hat{B}_N] := N_1^{-1} Q^T.$$

If we define

$$\hat{\Phi}(t) := Y(t)(\hat{\mathcal{B}} Y)^{-1},$$

we see that $\hat{\Phi}(t) = Y(t)L$. Then it is easy to verify that $\hat{G}$ is the Green function associated with (1.1), (5.1), viz.,

$$\hat{G}(t, s) = \begin{cases} \hat{\Phi}(t) \sum_{i=1}^{K} \hat{B}_i \Phi(t_i)\Phi^{-1}(s), & t > s, \\ -\hat{\Phi}(t) \sum_{i=k+1}^{N} \hat{B}_i \Phi(t_i)\Phi^{-1}(s), & t < s \end{cases}$$

can be identified with $\hat{G}(t, s)$. □

The relationship between polychotomy and the condition number for separable boundary conditions is now straightforward. Specifically we have the following theorem.

THEOREM 5.1. *If the boundary condition* (1.2), *is separable, then the solution space is polychotomic with* $\kappa \leqq \alpha$.

Conversely, if the solution space of (1.1) *is polychotomic with constant* κ, *then there exists a separable boundary condition* (1.2), *satisfying Assumption* 2.1, *such that* $\alpha \leqq \kappa$.

Proof. If the boundary condition (1.2) is separable

$$\sum_{i=1}^{N} \operatorname{rank}(B_i) = n$$

and

$$\sum_{i=1}^{N} B_i \Phi(t_i) = I \quad \text{(cf. (2.3b))}.$$

Thus

$$\sum_{i=1}^{N} \operatorname{rank}(B_i \Phi(t_i)) = n$$

and from Lemma 5.1,

$$P_i = B_i \Phi(t_i), \qquad i = 1, \cdots, N$$

are projectors. On substituting for P_i in the Green function (1.5) and comparing the resulting expression with the definition of polychotomy (see Definition 5.1), we find that (4.2) holds with $\kappa = \alpha$, $M = N$ and $x_j = t_j$.

If on the other hand the solution is polychotomic, then

$$|G(t, s)| \leqq \kappa$$

where

$$G(t,s) = \begin{cases} Y(t) \sum_{i=1}^{k} P_i Y^{-1}(s), & x_k < s < x_{k+1}, \quad t > s, \\ -Y(t) \sum_{i=k+1}^{M} P_i Y^{-1}(s), & x_k < s < x_{k+1}, \quad t < s \end{cases}$$

and

$$\sum_{i=1}^{M} P_i = I, \qquad P_i P_j = P_j P_i = \delta_{ij} P_j.$$

But from Lemmas 5.2 and 3.5 there exists a separable boundary condition of the form (1.2) which satisfies Assumption 2.1 and is such that G is the Green function associated with (1.1), (1.2) when $N = M$ and $t_i = x_i$. □

5.2. General boundary condition. We again turn to the general BC (2.1) and show how we can select appropriate separable BC from them; this is based on the theory given in § 2.

Let

$$\mathcal{S} = \{ Ya \mid a \in \mathbb{R}^n \}$$

with

$$\|y\| = \|y\|_\infty, \qquad y \in \mathcal{S}.$$

Clearly, $\mathcal{S}$ equipped with the norm $\|\cdot\|$ is a normed space of dimension n. In addition,

$$\mathcal{D} = \{ y^* \in \mathcal{S}^* \mid y^*(y) = c^T y(t), \quad |c| = 1, \quad 0 \leqq t \leqq 1 \}$$

is a closed boundary for $\mathcal{S}$. Hence, from Auerbach's lemma (Lemma 2.2) there exist $y_j^* \in \mathcal{D}$, $y_i \in \mathcal{S}$; $i, j = 1, \cdots, n$ such that

$$y_j^*(y_i) = \delta_{ij}, \quad \|y_j^*\|^* = 1, \quad \|y_i\|_\infty = 1, \quad i, j = 1, \cdots, n.$$

That is, there exist $c_j \in \mathbb{R}_1^n$, $|c_j| = 1$, points t_j with $0 \leqq t_j \leqq 1$, $j = 1, \cdots, n$ and $y_i \in \mathcal{S}$, $i = 1, \cdots, n$ such that

$$c_j^T y_i(t_j) = \delta_{ij}, \quad |c_j| = \|y_i\|_\infty = 1, \quad i, j = 1, \cdots, n. \tag{5.2}$$

Furthermore,

$$c_j = y_j(t_j),$$

and hence

$$c_i^T c_j = 0 \quad \text{if } i \neq j \text{ and } t_i = t_j. \tag{5.3}$$

Let

$$(\hat{\mathcal{P}} y)(t) := \sum_{i=1}^{n} y_i(t) c_i^T y(t_i).$$

Thus,

$$\|\hat{\mathcal{P}} y\|_\infty \leqq \sum_{i=1}^{n} \|y_i\|_\infty \|y\|_\infty$$

$$\leqq n \|y\|_\infty.$$

Hence

$$\|\hat{\mathscr{P}}\|_\infty \leqq n$$

and, as in Lemma 3.2, we find that

$$\begin{aligned}\hat{\alpha} &\leqq (1+\|\hat{\mathscr{P}}\|_\infty)\alpha \\ &\leqq (n+1)\alpha.\end{aligned}$$

In addition, we have

$$\hat{\mathscr{B}}\hat{\Phi} = I$$

where

$$\hat{\Phi} = N_1^{1/2}[y_1|\cdots|y_n], \tag{5.4}$$

$$\begin{aligned}\hat{\mathscr{B}}y &:= \sum_{i=1}^{N} \hat{\mathscr{B}}y(t_i), \\ B_k &= N_1^{-1/2}\begin{bmatrix}0\\ C_k\\ 0\end{bmatrix} \leftarrow k\text{th position},\end{aligned} \tag{5.5}$$

and N_1 is the number of *distinct points* in the set $\{t_k\}$. From (5.2), (5.3)

$$\sum_{k=1}^{n} \hat{B}_k \hat{B}_k^T = N_1^{-1} I,$$

and hence from Lemma 3.5, the boundary condition $\tilde{B}$ defined by (5.5), which is clearly separable, satisfies (2.2a), (2.2b). Finally from (5.2), (5.5)

$$|\hat{\Phi}(t)| \leqq N_1^{1/2} n^{1/2}.$$

Thus, we have shown the following theorem.

THEOREM 5.2. *For a general* BC (2.1) *we can construct a separable* BC $\hat{\mathscr{B}}$ *of the form* $\hat{\mathscr{B}}y := \sum_{i=1}^{n} \hat{B}_i y(t_i)$, *with* $t_i \in [0,1]$, *such that* $\hat{\mathscr{B}}$ *satisfies* (2.2a) *and* (2.2b) *and for which* (cf. (1.7))

$$\hat{\beta} := \sup_t |\hat{\Phi}(t)| \leqq n, \qquad \hat{\alpha} := \sup_{s,t} |\hat{G}(s,t)| \leqq (n+1)\alpha.$$

COROLLARY 5.1. *If the* BVP (1.1), (2.1) *has a condition number* α, *then the solution space is polychotomic with*

$$\kappa \leqq (n+1)\alpha.$$

Note that the result of this corollary is somewhat different from Theorem 3.16 of [6], where bounds are derived $\sim \alpha^2$ for the two-point case. For large α we may therefore say that this more general result is sharper, though not constructive.

THE BOHL TRANSFORMATION AND OSCILLATION OF LINEAR DIFFERENTIAL SYSTEMS*

STUART GOFF† AND DONALD F. ST. MARY‡

Abstract. The Bohl transformation is a nonlinear transformation that, like the Riccati transformation, relates linear and nonlinear differential equations. Recently, we have extended that transformation to differential systems. In this paper the utility of the transformation for extending scalar oscillation results to linear differential systems is demonstrated.

Key words. oscillation, linear differential systems, nonlinear transformation

AMS(MOS) subject classification. 34C10, 34C20

1. Introduction. The use of transformations in studying qualitative properties of linear differential systems has proven most effective. Probably the best-known such transformation is the Riccati transformation, which has been used in numerous ways. Another example is the Prüfer or generalized polar coordinate transformation, which has been employed most successfully in the study of eigenvalue problems and is used in the current development. In [6], [7], the authors were successful in extending the Bohl transformation to systems of differential equations. In this paper we shall demonstrate the use of the Bohl transformation in establishing oscillation criteria for the self-adjoint differential system

$$X''+P(t)X=0. \tag{1}$$

In general the Bohl transformation can be described as follows: for $X_1(t)$ and $X_2(t)$ solutions of (1) on $[a,\infty)$ satisfying the initial conditions $X_1(a)=X_2'(a)=E$ and $X_1'(a)=X_2(a)=0$, E the $n\times n$ identity matrix, set $V(t)\equiv[X_1^2(t)+X_2^2(t)]^{1/2}$, then $V(t)$ is the *Bohl transformation* of the pair $X_1(t)$, $X_2(t)$ and satisfies

$$V''+P(t)V=V^{-3} \tag{2}$$

on $[a,\infty)$. Equation (2) is the *Bohl differential system* corresponding to (1).

In [7] it is established that, under appropriate hypotheses on P, system (2) has a positive definite Hermitian solution on $[a,\infty)$ satisfying $V(a)=E$, $V'(a)=0$. Furthermore, it is shown that if $V(t)$ is a positive definite Hermitian solution of (2) on $[a,\infty)$ satisfying $V(a)=E$, $V'(a)=0$, then $X_1(t)=V(t)C(t;a,V^{-2}(t))$, $X_2(t)=V(t)S(t;a,V^{-2}(t))$ are conjoined solutions of (1) on $[a,\infty)$ whose Wronskian is E where $C(t;a,Q(t))$ and $S(t;a,Q(t))$ are the matrix analogues of the sine and cosine functions, respectively. These matrix trigonometric functions have been developed in the context of studying the generalized polar coordinate transformation. See, e.g., [1], [3], and [12].

The Bohl transformation is established in [7] under the assumption that $P(t)$ is an $n\times n$ functionally commutative Hermitian matrix the elements of which are continuous complex-valued functions of a real variable $t\in[a,\infty)$. To say $P(t)$ is *functionally commutative* on $[a,\infty)$ means that $P(s)P(t)=P(t)P(s)$, for all $s,t\in[a,\infty)$.

For our purposes a *solution* of (1) is an $n \times n$ matrix function, the elements of which are twice continuously differentiable, which satisfies (1) on $[a, \infty)$. For the discussion of the oscillatory behavior of solutions of (1), it is necessary to restrict our attention to the class of solutions called conjoined. A solution X of (1) defined on an interval I is said to be *conjoined* if X is not identically singular on any subinterval of I and X satisfies

$$X^*(t)X'(t) \equiv X'^*(t)X(t)$$

on I. The system (1) is said to be *oscillatory* on $[a, \infty)$ if there exists a conjoined solution $X(t)$ for which there is a sequence $\{t_j\}$, $t_j \to \infty$, such that $\det X(t_j) = 0$, $j = 1, 2, \cdots$. It follows from the Sturm-type separation theorem [9] that if (1) is oscillatory then every conjoined solution is singular on some sequence $\{t_j\}$, $j \to \infty$. Thus, (1) is *nonoscillatory* if there exists a conjoined solution $X(t)$ for which $\det X(t) \neq 0$ for $t > t_0 \geq a$, for some t_0.

2. Oscillation via the Bohl transformation. In [7], with $P(t)$ as described above, we have established an oscillation theorem that is one of the central elements to be used in the further development of the theory. For purposes of convenience we state it as a lemma.

LEMMA 1. *Let $V(t)$ be a positive definite Hermitian solution of* (2) *on* $[a, \infty)$ *for which $V(a) = E$, $V'(a) = 0$. Then* (1) *is oscillatory if and only if* $\int_a^\infty \operatorname{tr}[V^{-2}(t)]\, dt = \infty$.

To continue our discussion of oscillation we further require that $P(t)$ is analytic on $[a, \infty)$. When we say a matrix $M(t)$ is *analytic* on an interval I, we mean that for every $t_0 \in I$, each element of $M(t)$ (and thus $M(t)$ itself) can be represented as a Taylor series centered at t_0 converging in some neighborhood of t_0.

Some properties of analytic Hermitian matrices follow. A proof of Lemma 2 may be found in [14, pp. 36–45].

LEMMA 2. *Let $M(t)$ be an $n \times n$ analytic Hermitian matrix function on I. Then for $i = 1, \cdots, n$ eigenvalues $\lambda_i(t)$ (perhaps repeated), and an orthonormal set of eigenvectors $z_i(t)$ and eigenprojections $G_i(t)$ (perhaps repeated) for $M(t)$ can be chosen such that $\lambda_i(t)$, $z_i(t)$, and $G_i(t)$ are analytic on I.*

LEMMA 3. *If $M(t)$ is an analytic, Hermitian, functionally commutative matrix on I, then $M(t)M'(t) = M'(t)M(t)$ on I.*

Proof. $M(s)M(t) = M(t)M(s)$ and so $M(s)M'(t) = M'(t)M(s)$ for all $s, t \in I$. Thus, when we let $s = t$, the result follows. □

If $\lambda_i(t)$ and $\lambda_j(t)$ are analytic eigenvalues of $M(t)$ on I, then we say that $\lambda_i(t)$ and $\lambda_j(t)$ are *distinct* if $\lambda_i(t) \not\equiv \lambda_j(t)$ on I. Because $\lambda_i(t)$ and $\lambda_j(t)$ are analytic, it is clear that if they are distinct on I, then they must also be distinct on every subinterval of I. We do allow for the possibility that $\lambda_i(t) = \lambda_j(t)$ for some $t \in I$, but this will be true only on a set of isolated points.

The next lemma is an immediate consequence of the Spectral Representation Theorem (see, e.g., [10, p. 175]), the previous two lemmas, and a result in [5, p. 38] which establishes that the eigenprojections are constant.

LEMMA 4. *Let $M(t)$ be an analytic, Hermitian, functionally commutative matrix on I, and let r be the number of distinct analytic eigenvalues of $M(t)$. Then, $M(t) = \sum_{i=1}^{r} \lambda_i(t) G_i$, where the analytic eigenprojections G_i are constant Hermitian matrices for which $G_i^2 = G_i$, $G_i G_j = 0$ (if $i \neq j$) and $\sum_{i=1}^{r} G_i = E$.*

LEMMA 5. *If $M(t)$ is an analytic, Hermitian, functionally commutative matrix on I, then $M(t)$ may be diagonalized by a constant unitary matrix.*

Proof. By Lemma 3, $M(t)$ commutes with its derivative and thus [5, p. 37] each of the eigenspaces of the analytic eigenvalues of $M(t)$ has a constant basis. Hence,

an orthonormal set of constant eigenvectors for $M(t)$ may be found. Let the matrix H be such that its columns are these constant eigenvectors. Then $H^*M(t)H = Q(t)$ is a diagonal matrix consisting of the analytic eigenvalues of $M(t)$. By construction, H is a constant unitary matrix. □

Our first oscillation theorem for systems will use this matrix H along with the transformation described in the following lemma. A proof of this lemma may be found in [15, pp. 393-394].

LEMMA 6. *For $R(t)$ and $P(t)$ continuous Hermitian matrix functions, let $H(t)$ be an $n \times n$ matrix function such that H and RH' are absolutely continuous on $[a, \infty)$ and $(RH')^*H = H^*(RH')$ on $[a, \infty)$. Put $\mathcal{R}(t) = H^*RH$ and $\mathcal{P}(t) = H^*[(RH')' + PH]$. Then $H^*[(RU')' + PU] = (\mathcal{R}X')' + \mathcal{P}X$ where $U = HX$. Furthermore, if H is nonsingular on $[a, \infty)$ then the system $(RU')' + PU = 0$ is oscillatory on $[a, \infty)$ if and only if the system $(\mathcal{R}X')' + \mathcal{P}X = 0$ is oscillatory on $[a, \infty)$.*

THEOREM 7. *Let $P(t)$ be analytic, Hermitian, and functionally commutative on $[a, \infty)$. Let H be a constant unitary matrix which diagonalizes $P(t)$ and put $Q(t) = H^*P(t)H$. Then (1) is oscillatory on $[a, \infty)$ if and only if $X'' + Q(t)X = 0$ is oscillatory on $[a, \infty)$.*

Proof. H exists as described because of Lemma 5. Moreover, H trivially satisfies the hypotheses of Lemma 6. In the notation of that lemma, $R(t) = E$ and thus $\mathcal{R} = H^*H = E$ since H is unitary, and $\mathcal{P} = H^*PH = Q$ since $H' = 0$. The result follows by applying the second conclusion of Lemma 6. □

COROLLARY 8. *Let $P(t)$ be analytic, Hermitian, and functionally commutative on $[a, \infty)$. Then, the system (1) is oscillatory on $[a, \infty)$ if and only if the scalar equation $x'' + \lambda(t)x = 0$ is oscillatory on $[a, \infty)$ for at least one of the analytic eigenvalues $\lambda(t)$ of $P(t)$.*

Proof. Because of Lemma 5, Theorem 7 is applicable. Since $Q(t) = \operatorname{diag}(\lambda_1(t), \cdots, \lambda_n(t))$ where $\{\lambda_i(t) \mid i = 1, \cdots, n\}$ are the (perhaps repeated) analytic eigenvalues of $P(t)$, it is easy to see that the system $X'' + Q(t)X = 0$ is oscillatory on $[a, \infty)$ if and only if $x'' + \lambda(t)x = 0$ is oscillatory on $[a, \infty)$ for at least one of these eigenvalues. The result now follows from Theorem 7. □

In Theorem 2.1 of [2] a similar result is obtained in which $P(t)$ is assumed to be continuous, symmetric, functionally commutative, and implicitly conservative on $[a, \infty)$ (see Theorem 8 and the general *conservative* hypothesis on p. 108 of [4]). It is easy to demonstrate matrices $P(t)$ that are conservative but not analytic and vice versa, while still satisfying the other hypotheses.

We will next concern ourselves with the extension to systems of M. Ráb's so-called "Haupsatz" (sic) [11, p. 339]:

Let $p(t)$ be continuous on $[a, \infty)$. The scalar differential equation $x'' + p(t)x = 0$ is oscillatory on $[a, \infty)$ if and only if there exists a C^1 function $g(t) > 0$ which satisfies

$$\int_a^\infty \exp\left(-2\int_a^x \frac{1}{g^2(s)}\left[\int_a^s [(g'(t))^2 - p(t)g^2(t)]\,dt + k\right]ds\right)dx = \infty$$

for every constant k.

Our integral condition will involve the solution of a certain differential system; in the scalar case, this solution will result in the above exponential function. To this end, define the matrix function

$$Q(t; g, A) = \frac{1}{g^2(t)}\left\{A + \int_a^t [(g'(s))^2 E - g^2(s)P(s)]\,ds\right\}$$

where $g(t) > 0$ is C^1 on $[a, \infty)$ and A is a constant Hermitian matrix. In addition, let

$Y_{g,A}(t; T)$ denote the solution on $[a, \infty)$ of the initial value problem

$$Y' = Q(t; g, A)Y, \qquad Y(T) = E. \tag{3}$$

In the next lemma we list, in the context of (3), some standard properties of linear differential systems we shall need.

LEMMA 9. *For all $s, t, T \in [a, \infty)$ and with $Y_{g,A}$ as defined above*:

(a) $Y_{g,A}(t; s)Y_{g,A}(s; T) = Y_{g,A}(t; T)$,

(b) $Y_{g,A}^{-1}(s; t) = Y_{g,A}(t; s)$,

(c) $d/dt\,[Y_{g,A}(s; t)] = -Y_{g,A}(s; t)Q(t; g, A)$.

Before proceeding with the extension of the Hauptsatz to systems, let us note some additional properties of the solutions of (1) resulting from the analyticity of $P(t)$. The next lemma follows from standard existence theorems (see, e.g., [8, p. 70]).

LEMMA 10. *Let $P(t)$ be analytic on $[a, \infty)$. Then every solution of* (1) *is analytic on $[a, \infty)$.*

In [5, p. 38] it has been shown that a Hermitian analytic matrix function that commutes with its derivative is functionally commutative. In [7], the existence on $[a, \infty)$ of Hermitian conjoined solutions of (1) that satisfy $X'X = XX'$ is established. Thus, in view of these results and the previous lemma we have the following result.

LEMMA 11. *Let $P(t)$ be analytic, Hermitian, and functionally commutative on $[a, \infty)$. Then, the Hermitian conjoined solutions of* (1) *are functionally commutative on $[a, \infty)$.*

LEMMA 12. *If $X(t)$ is a functionally commutative solution of* (1) *on $[a, \infty)$, then $P(s)X(t) = X(t)P(s)$ for all $s, t \in [a, \infty)$.*

Proof. $X(s)X(t) = X(t)X(s)$ leads to $X''(s)X(t) = X(t)X''(s)$, resulting in $P(s)X(s)X(t) = X(t)P(s)X(s)$, and so $P(s)X(t)X(s) = X(t)P(s)X(s)$. Since the singularities of $X(s)$ are isolated, the result follows. □

We are now prepared to extend Ráb's Hauptsatz to systems.

THEOREM 13. *Let $P(t)$ be analytic, Hermitian, and functionally commutative on $[a, \infty)$. Then, the system* (1) *is oscillatory on $[a, \infty)$ if and only if there exists a C^1 function $g(t) > 0$ that satisfies*

$$\int_c^\infty \operatorname{tr}\{[Y_{g,A}(t; \tau)Y_{g,A}^*(t; \tau)]^{-1}\}\, dt = \infty \tag{4}$$

for some $c, \tau \in [a, \infty)$ and for every $n \times n$ constant Hermitian matrix A that is a linear combination of the eigenprojections of $P(t)$.

Proof. Let (4) hold for c, τ, A and $g(t)$ as described and assume that (1) is nonoscillatory on $[a, \infty)$. In view of the remarks preceding Lemma 11 along with Lemmas 10 and 11, there exists a pair $X_1(t)$ and $X_2(t)$ of functionally commutative, analytic Hermitian conjoined solutions of (1) whose Wronskian is E, both of which are nonsingular on some interval $[t_0, \infty)$. Letting $X(t)$ denote either $X_1(t)$ or $X_2(t)$, we have by the Riccati transformation [13, p. 101] that $(X'X^{-1})' + (X'X^{-1})^2 + P = 0$. Multiplying this equation by $g^2(t)$, integrating from t_0 to t followed by an integration by parts, and then completing the square, we obtain

$$g^2(t)X'(t)X^{-1}(t) = g^2(t_0)X'(t_0)X^{-1}(t_0) - \int_{t_0}^t [g(s)X'(s)X^{-1}(s) - g'(s)E]^2\, ds$$

$$+ \int_{t_0}^t [(g'(s))^2 E - g^2(s)P(s)]\, ds.$$

Since X is conjoined, $gX'X^{-1} - g'E$ is Hermitian and so its square must be nonnegative

definite. Thus we have

$$(5)\qquad g^2(t)X'(t)X^{-1}(t) \geqq g^2(t_0)X'(t_0)X^{-1}(t_0) + \int_{t_0}^{t} [(g'(s))^2 E - g^2(s)P(s)]\, ds.$$

Let λ_0 be the maximum of the absolute values of the eigenvalues of the matrices $X_i'(t_0)X_i^{-1}(t_0)$ for $i=1,2$. Then we have $g^2(t_0)X'(t_0)X^{-1}(t_0) \leqq \lambda_0 g^2(t_0)E$. Now when we let

$$A = \lambda_0 g^2(t_0)E - \int_a^{t_0} [(g'(s))^2 E - g^2(s)P(s)]\, ds,$$

(5) yields

$$(6)\qquad X'(t)X^{-1}(t) \leqq \frac{1}{g^2(t)}\left\{A + \int_a^t [(g'(s))^2 E - g^2(s)P(s)]\, ds\right\} \equiv Q(t; g, A)$$

for all $t \geqq t_0$. In view of Lemma 4, A is a linear combination of the eigenprojections of P. Since P is Hermitian, it is clear that A and thus Q are Hermitian. Moreover, X is Hermitian and conjoined and so $Q - X'X^{-1}$ is also Hermitian. By Lemma 12, $P(s)X(t) = X(t)P(s)$ and so A and thus Q also commutes with $X(t)$. Since X and X' commute, it is clear that $Q - X'X^{-1}$ will commute with X^2. Therefore for $t \geqq t_0$, (6) yields $X'X \leqq QX^2$.

Recalling that X represents either X_1 or X_2 and defining $U = X_1^2 + X_2^2$, we have that $U' = 2(X_1'X_1 + X_2'X_2) \leqq 2QU$. Since Q commutes with X and thus also X^2, we have that Q and U commute. So,

$$(7)\qquad U'(t) \leqq Q(t; g, A)U(t) + U(t)Q(t; g, A).$$

Multiplying (7) on the left by $Y_{g,A}(s, t)$, on the right by $Y_{g,A}^*(s; t)$, rearranging the terms, and making use of (3) and Lemma 9(c), we obtain $(d/dt) \cdot [Y_{g,A}(s; t)U(t)Y_{g,A}^*(s; t)] \leqq 0$. Therefore for any fixed $T \geqq t_0$ and for all $t \geqq T \geqq t_0$ and for every $s \in [a, \infty)$, integrating this last result from T to t yields

$$(8)\qquad Y_{g,A}(s; t)U(t)Y_{g,A}^*(s; t) \leqq Y_{g,A}(s; T)U(T)Y_{g,A}^*(s; T).$$

Multiplying (8) on the left by $Y_{g,A}(t; s)$, on the right by $Y_{g,A}^*(t; s)$, and using Lemma 9(a) and (b), we obtain $U(t) \leqq Y_{g,A}(t; T)U(T)Y_{g,A}^*(t; T)$ and thus $\operatorname{tr}[U^{-1}(t)] \geqq 1/\beta \operatorname{tr}\{[Y_{g,A}(t; T)Y_{g,A}^*(t; T)]^{-1}\}$, where $\beta > 0$ is the maximum eigenvalue of $U(T) > 0$. Hence, for any $b \in [T, \infty)$,

$$(9)\qquad \int_b^\infty \operatorname{tr}[U^{-1}(t)]\, dt \geqq \frac{1}{\beta}\int_b^\infty \operatorname{tr}\{[Y_{g,A}(t; T)Y_{g,A}^*(t; T)]^{-1}\}\, dt.$$

With τ as described in the statement of the theorem, Lemma 9(a) yields

$$\begin{aligned} Y_{g,A}(t; \tau)Y_{g,A}^*(t; \tau) &= Y_{g,A}(t; T)Y_{g,A}(T; \tau)Y_{g,A}^*(T; \tau)Y_{g,A}^*(t; T) \\ &\geqq \alpha Y_{g,A}(t; T)Y_{g,A}^*(t; T) \end{aligned}$$

where $\alpha > 0$ is the minimum eigenvalue of $Y_{g,A}(T; \tau)Y_{g,A}^*(T; \tau) > 0$. So, (9) leads to

$$\int_b^\infty \operatorname{tr}[U^{-1}(t)]\, dt \geqq \frac{\alpha}{\beta}\int_b^\infty \operatorname{tr}\{[Y_{g,A}(t; \tau)Y_{g,A}^*(t; \tau)]^{-1}\}\, dt,$$

and thus with c as defined in the statement of the theorem, we have

$$\begin{aligned} \int_b^\infty \operatorname{tr}[U^{-1}(t)]\, dt \geqq \frac{\alpha}{\beta}\Bigg[&\int_b^c \operatorname{tr}\{[Y_{g,A}(t; \tau)Y_{g,A}^*(t, \tau)]^{-1}\}\, dt \\ &+ \int_c^\infty \operatorname{tr}\{[Y_{g,A}(t; \tau)Y_{g,A}^*(t; \tau)]^{-1}\}\, dt\Bigg]. \end{aligned}$$

Because of the hypothesis (4), we have that $\int_b^\infty \operatorname{tr}[U^{-1}(t)]\,dt = \infty$. Since $U(t)$ as defined is simply $V^2(t)$, where $V(t)$ is a positive definite Hermitian solution of (2), we may conclude from Lemma 1 that (1) is in fact oscillatory on $[a, \infty)$.

To prove the converse, suppose the contrary; then for any choice of a C^1 function $g(t) > 0$ and $c, \tau \in [a, \infty)$ there exist scalar constants $k_1, \cdots, k_r$ with $A = \sum_{i=1}^r k_i G_i$ such that

$$\int_c^\infty \operatorname{tr}\{[Y_{g,A}(t;\tau)\,Y_{g,A}^*(t,\tau)]^{-1}\}\,dt < \infty. \tag{10}$$

Because of Lemma 4, A is a Hermitian constant matrix and also $Q(t; g, A)$ may be written as $Q(t; g, A) = \sum_{i=1}^r q_i(t; g, A) G_i$ where

$$q_i(t; g, A) = \frac{1}{g^2(t)}\left\{k_i + \int_a^t [(g'(s))^2 - \lambda_i(s) g^2(s)]\,ds\right\}.$$

Hence, the solution to (3) is expressible as $Y_{g,A}(t; T) = \sum_{i=1}^r G_i Y_{i,g,A}(t; T)$ where $Y_{i,g,A}(t; T)$ is the solution to the initial value problem

$$Y_i' = q_i(t; g, A)\,Y_i, \qquad Y_i(T) = E. \tag{11}$$

But for each $i = 1, \cdots, r$ the solution to (11) is easily seen to be

$$Y_{i,g,A}(t; T) = \exp\left(\int_T^t q_i(u; g, A)\,du\right)E,$$

and so

$$Y_{g,A}(t; T) = \sum_{i=1}^r G_i \exp\left(\int_T^t q_i(u; g, A)\,du\right). \tag{12}$$

Because of the properties of G_i specified in Lemma 4, using (12) we get

$$[Y_{g,A}(t; T)\,Y_{g,A}^*(t; T)]^{-1} = \sum_{i=1}^r G_i \exp\left(-2\int_T^t q_i(u; g, A)\,du\right),$$

and thus

$$\operatorname{tr}[Y_{g,A}(t; T)\,Y_{g,A}^*(t; T)]^{-1} = \sum_{i=1}^r \gamma_i \exp\left(-2\int_T^t q_i(u; g, A)\,du\right),$$

where $\gamma_i = \operatorname{tr} G_i$. Now $\gamma_i > 0$ since G_i is idempotent, and hence from (10) we conclude that

$$\int_c^\infty \exp\left(-2\int_T^t q_i(u; g, A)\,du\right)dt < \infty$$

for $i = 1, \cdots, r$. Now using Ráb's Hauptsatz we have that $x'' + \lambda_i(t)x = 0$ is nonoscillatory on $[a, \infty)$ for all $i = 1, \cdots, r$, and so from Corollary 8 it follows that (1) is nonoscillatory on $[a, \infty)$. □

It is appropriate at this juncture to look at a somewhat similar result in [16]. With much less restrictive assumptions on P, we can obtain from the main theorem in [16] the following.

If β is some number in the interval $(0, 2]$ and if $X'' + \beta^{-1}PX = 0$ is nonoscillatory on $[\alpha, \infty)$, then $\int_\alpha^\infty \operatorname{tr}\{[Y_B(t;\tau)\,Y_B^*(t;\tau)]^{-1}\}\,dt = \infty$, where $Y_B(t;\tau)$ satisfies $Y' = [B - \int_\alpha^t P(s)\,ds]Y$, $Y(\tau) = E$ and B is the specific constant matrix $\lim_{t\to\infty} (t-\alpha)^{-1}\int_\alpha^t \int_\alpha^s P(u)\,du\,ds$.

If in fact P in this result is assumed to have the same properties as in Theorem 13, we note that B is Hermitian and can be written as a linear combination of the eigenprojections of P. Now the contrapositive of the sufficiency portion of Theorem 13 yields the following corollary.

COROLLARY 14. *Let $P(t)$ be analytic, Hermitian, and functionally commutative on $[a, \infty)$. If (1) is nonoscillatory on $[a, \infty)$, then there exists a Hermitian constant matrix A, which is a linear combination of the eigenprojections of P such that*

$$\int_a^\infty \operatorname{tr}\{[Y_A(t;\tau)Y_A^*(t;\tau)]^{-1}\}\,dt < \infty$$

where $Y_A(t;\tau)$ satisfies $Y' = [A - \int_a^t P(s)\,ds]Y$, $Y(\tau) = E$.

A comparison of this corollary with the result stated above from [16] when $\beta = 1$, indicates that the corollary is not true for all such A.

For our final result, let us consider the maximum eigenvalue of $P(t)$. For each t, let $\lambda_{\max}(t) = \max_i \lambda_i(t)$ where we recall that $\{\lambda_i(t) \mid i = 1, \cdots, r\}$ is the set of distinct analytic eigenvalues for the analytic, Hermitian, functionally commutative matrix $P(t)$. We note that, in general, $\lambda_{\max}(t)$ will not be one of these analytic eigenvalues.

THEOREM 15. *Let $P(t)$ be analytic, Hermitian, and functionally commutative on $[a, \infty)$. If (1) is oscillatory on $[a, \infty)$, then the scalar equation $x'' + \lambda_{\max}(t)x = 0$ is* oscillatory on $[a, \infty)$.

Proof. By Corollary 8, $x'' + \lambda(t)x = 0$ is oscillatory on $[a, \infty)$ for at least one of the analytic eigenvalues $\lambda(t)$ of $P(t)$. Since $\lambda(t) \leqq \lambda_{\max}(t)$, the result follows from the Sturm comparison theorem. □

A similar result is attained in [15, p. 398].

BOUNDARY LOCAL TIME AND SMALL PARAMETER EXIT PROBLEMS WITH CHARACTERISTIC BOUNDARIES*

MARTIN V. DAY†

Abstract. The exit problem for an asymptotically small random perturbation of a stable dynamical system $x(t)$ in a region D is considered. The connection between the distribution of the position of first exit and the equilibrium density of the perturbed system subject to reflection from the boundary of D is developed. Earlier work treated the case in which $x(t)$ enters D nontangentially. Here the case in which $x(t)$ is everywhere tangent to the boundary is examined. The "small-noise" asymptotics of the boundary local time turn out to be of primary importance.

Key words. exit problem, small noise, reflecting diffusion, local time

AMS(MOS) subject classifications. Primary 60H10; secondary 60J55, 60J60

1. Introduction. In this paper we will extend the results of [3], which are central to our treatment [2] of the small parameter exit problem for diffusions, to cases in which the classical assumption (1.5) fails. Our specific assumptions are given in §2. This introduction provides an overview.

Let $D \subseteq \mathbb{R}^d$ be a bounded open domain. The "exit problem" is to determine the (weak) limit (or limit points)

$$\lim_{\epsilon \downarrow 0} \mu^{\epsilon}_{x_0}(dy) = ?,$$

where $\mu^{\epsilon}_{x_0}$ is the exit distribution

$$\mu^{\epsilon}_{x_0}(dy) = P_{x_0}[x^{\epsilon}(\tau_{\partial D}) \in dy] \tag{1.1}$$

for a diffusion $x^{\epsilon}(t)$ whose generator in D is given by a (nondegenerate) second-order operator

$$\mathscr{L}^{\epsilon}u(x) = \frac{\epsilon}{2}\sum_{i,j=1}^{d} a_{ij}(x)u_{x_ix_j} + \sum_{1}^{d} b_i(x)u_{x_i}, \tag{1.2}$$

and where

$$\tau_{\partial D} = \inf\{t > 0 : x^{\epsilon}(t)\epsilon\partial D\} \tag{1.3}$$

is the first exit time from D. The cases of particular interest to us are those in which the limiting deterministic flow

$$\dot{x}^0(t) = b(x^0(t)),\ x^0(0) = x_0 \tag{1.4}$$

is in some way stable in D, with points x_0 near ∂D being repelled deeper into the interior of D as t increases.

In the most familiar version of this problem (1.4) is assumed to cross ∂D nontangentially into D:

$$\langle b(y), n(y)\rangle < 0 \quad \forall y \in \partial D. \tag{1.5}$$

*Received by the editors October 16, 1988; accepted for publication (in revised form) June 27, 1988. This research was supported in part by National Science Foundation grant DMS-8420755. The work began while the author was visiting the Institute for Mathematics and Its Applications, University of Minnesota, Minneapolis, Minnesota 55455.

†Department of Mathematics, Virginia Polytechnic Institute and State University, Blacksburg, Virginia 24061-0123.

(Here and throughout $n(y)$ is the unit outward normal vector at $y \in \partial D$.) This is the famous problem discussed by Wentzell and Freidlin [6]. Culminating in [2], our approach to this problem reduced it to the asymptotic evaluation of a Laplace integral over ∂D. That reduction was based on an asymptotic connection [3] between the exit measures and the equilibrium density $p^\epsilon(x)$ for $x^\epsilon(t)$. The approach was inspired by the asymptotic calculations of Matkowsky and Schuss [12], although as noted in [2], the connection with the equilibrium density was observed in earlier work of Y. I. Kifer.

In this paper we will develop the connection between the equilibrium density and the exit problem in cases for which

$$\langle b(y), n(y)\rangle = 0 \quad \forall y \in \partial D. \tag{1.6}$$

(See (2.9) for an additional hypothesis.) In [11] and [13] the Matkowsky and Schuss approach is developed for two-dimensional examples of this type. Our probabilistic development is again strongly motivated by their work.

The treatment of this paper is incomplete in that we do not include a study of the asymptotics of p^ϵ itself. We leave that for the future. As we will see, this means we must leave our conclusions for the exit problem in a somewhat awkward form; see (6.2). We will, however, venture a conjecture which, if true, renders a considerable simplification (6.4) of our conclusions.

We pointed out in [2] that the relationship between the exit measure and equilibrium density involved the expected "local time" of $x^\epsilon(t)$ on ∂D. Because it is in fact at the heart of that relationship, we have chosen to include it explicitly in our characterization of $x^\epsilon(t)$ by taking $x^\epsilon(t)$ to be the diffusion with generator $\mathscr{L}^\epsilon$ in D and instantaneous conormal reflection off ∂D. The boundary local time occurs explicitly as the continuous, nondecreasing process $l^\epsilon(t)$ in the stochastic differential equation characterization of the reflecting diffusion $x^\epsilon(t)$, (2.13) below. Of course, given $x_0 \in D$ the presence of the reflection does not effect the exit measures $\mu^\epsilon_{x_0}$. It does, however, make $x^\epsilon(t)$ a process with compact state space $\overline{D}$, so that its equilibrium density $p^\epsilon(x)$ will exist without the modifications on D^c that were needed in [2] and [3].

The reason for the choice of conormal as the reflection direction is perhaps not apparent in the analysis below. Indeed the results below can be generalized to any nontangential reflection direction. However, there are reasons for choosing the conormal which will become apparent in subsequent work. One is that the boundary conditions satisfied by $p^\epsilon(x)$ on ∂D are simpler in the conormal case, so that future study of $p^\epsilon(x)$ will be more convenient in that context. Secondly, large deviations results for the reflected process $x^\epsilon(t)$ are simpler in the conormal case.

Section 2 presents our technical assumptions and notation. Sections 3-6 contain the main arguments relating to the exit problem, with the more distracting technical arguments and proofs deferred to §7-9. In §3 we will derive the "fundamental equation" (3.7) that connects the exit measures μ^ϵ with the equilibrium density p^ϵ via an operator B^ϵ on $C(\partial D)$. In §4 we will see that the asymptotic behavior of B^ϵ is given by $B^\epsilon \sim \epsilon^{-1/2}B$, where B is another operator on $C(\partial D)$. To deduce the limit points of μ^ϵ we need to invert B in the limiting form of the fundamental equation. Explicit formulas for B and B^{-1} are obtained in §5.

In §6 we will exhibit the resulting formula for the limit points of μ^ϵ and conclusions for the exit problem. Also in §6 is the conjecture regarding asymptotic behavior of p^ϵ mentioned above. Section 7 contains some estimates that will be used in the proof of Theorem 2.1 given in §8 and the proof of Theorem 4.1 given in §9.

2. Assumptions and preliminaries. Here we will outline our technical assumptions. First, regarding regularity of the coefficient functions and ∂D, we assume the following. The $\mathbb{R}^d$ valued function $b(\cdot)$ is in $C^{1,\lambda}(\overline{D})$. The $d\times d$ matrix valued function $\sigma(x)$ is $C^{2,\lambda}(\overline{D})$ and nonsingular everywhere in $\overline{D}$; $a(x) = \sigma(x)\sigma(x)^T$. $D \subseteq \mathbb{R}^d$ is bounded, open, connected with ∂D being C^3. (The notation $C^{n,\lambda}(\overline{D})$ refers to functions which, together with all partials of order $\leq n$, are Hölder continuous with exponent $0 < \lambda \leq 1$.)

One consequence of the above is that

$$\rho(x) = \operatorname{dist}(x, \partial D) \tag{2.1}$$

is then C^3 in a narrow (closed) strip G adjoining ∂D:

$$G = \{x \epsilon \overline{D} : 0 \leq \rho(x) \leq h_0\}.$$

Several additional restrictions on h_0 will be imposed below to insure various properties of G used throughout the paper. For instance, provided h_0 is sufficiently small, for $x \in G$ we can write

$$\nabla\rho(x) = -n(y(x)) \tag{2.2}$$

where $x \to y(x)$ is a C^2 mapping of G to ∂D with $y(x) = x$ for $x \in \partial D$, and $n(y)$ is the unit outward normal to D at $y \in \partial D$. Thus

$$n(x) = -\nabla\rho(x) \tag{2.3}$$

provides a C^2 extension of the normal vector field from ∂D to G. The conormal vector field

$$\eta(x) = a(x)n(x)$$

is thereby defined on G also.

Define the positive $C(G)$ function $\alpha(\cdot)$ by

$$\alpha(x)^2 = \langle n(x), a(x)n(x)\rangle = \langle n(x), \eta(x)\rangle. \tag{2.4}$$

The following bounds will appear in our analysis:

$$A_0 = \inf_G \frac{1}{2}\sum_{i,j} a_{ij}\rho_{x_i x_j}, \tag{2.5}$$

$$A_1 = \sup_{x\in\overline{D},|z|=1} \langle z, a(x)z\rangle, \tag{2.6}$$

$$\alpha_0^2 = \inf_G \alpha(x)^2 > 0. \tag{2.7}$$

Note that

$$\sup_G \alpha(x)^2 \leq A_1. \tag{2.8}$$

The solution of (1.4) with $x^0(0) = x_0$ will be denoted $x^0(t)$, or $x^0(t; x_0)$ when we want the dependence on the initial condition to be explicit. As indicated in the introduction, we assume that

$$\langle b(y), n(y)\rangle = 0 \ \forall\ y \in \partial D.$$

This means that ∂D is an invariant set for (1.4); i.e., $x^0(t; y) \in \partial D$ whenever $y \in \partial D$. Our analysis depends heavily on the assumption that ∂D is repelling for (1.4) with

x_0 in D. Specifically, we assume that there exists a positive function $b_1 \in C^1(\partial D)$ so that

$$\lim_{x \to y} \frac{-1}{\rho(x)} \langle b(x), n(x) \rangle = b_1(y) \tag{2.9}$$

uniformly over $y \in \partial D$. Using the projection $y(x) : G \to \partial D$ as above, we can extend b_1 to a strictly positive $C^1(G)$ function by

$$b_1(x) = b_1(y(x)).$$

We can express (2.9) as

$$b(x) = -\rho(x) b_1(x) n(x) + b_0(x) + o(\rho(x)), \text{ as } \rho(x) \to 0, \tag{2.10}$$

where $b_0(x)$ is $C(G)$ with $\langle b_0(x), n(x) \rangle = 0$, for all $x \in G$. Provided h_0 is sufficiently small,

$$K = \inf_{x \in G} \frac{-\langle b(x), n(x) \rangle}{\rho(x)} \tag{2.11}$$

will be a positive constant. In particular

$$\langle n, b \rangle \leq 0 \quad \text{everywhere in } G. \tag{2.12}$$

We take $(\Omega, \mathscr{F}, P)$ to be a complete probability space with a right continuous nondecreasing family $\{\mathscr{F}_t\}_{t \geq 0}$ of complete sub σ-algebras of $\mathscr{F}$. $w(t)$ is a d-dimensional $\mathscr{F}_t$ adapted Brownian motion. For a given $x_0 \in \overline{D}$ we take $x^\epsilon(t)$ and $l^\epsilon(t)$ to be the continuous $\mathscr{F}_t$ adapted processes with $l^\epsilon(\cdot) \in [0, \infty)$ nondecreasing and $x^\epsilon(\cdot) \in \overline{D}$ which satisfy

$$dx^\epsilon(t) = b(x^\epsilon(t))dt + \epsilon^{1/2} \sigma(x^\epsilon(t))dw(t) - \frac{\epsilon}{2} \eta(x^\epsilon(t)) dl^\epsilon(t), \; x^\epsilon(0) = x_0 \tag{2.13}$$

$$dl^\epsilon(t) = \chi_{\partial D}(x^\epsilon(t)) dl^\epsilon(t), \; l^\epsilon(0) = 0.$$

The existence of a unique solution pair $(x^\epsilon(\cdot), l^\epsilon(\cdot))$ is demonstrated in [1] or [10]. As is typical, we will let P_{x_0} denote the distribution of the solution $(x^\epsilon(\cdot), l^\epsilon(\cdot))$, i.e., the induced probability measure on

$$C([0, \infty); \overline{D}) \times C([0, \infty); [0, \infty)).$$

The uniqueness of solutions to (2.13) implies the strong Markov property.

The exit time $\tau_{\partial D}$ and exit measures $\mu^\epsilon_{x_0}(dy)$ on ∂D are defined as in (1.3) and (1.1) above. In addition Γ will denote the "inne" boundary of G and, for $x_0 \epsilon G, \tau_\Gamma$ its hitting time:

$$\Gamma = \{x \epsilon D : \rho(x) = h_0\},$$
$$\tau_\Gamma = \inf\{t > 0 : x^\epsilon(t) \epsilon \Gamma\}.$$

With regard to stability of (1.4) in D, the only feature that we will actually use is the following "leveling" property, which we therefore assume:

$$\text{for any compact } \; K \subseteq D \; \text{ and } \; f \in C(\partial D)$$

$$\sup_{x,y \in K} \left| \int_{\partial D} f(z) \mu^\epsilon_x(dz) - \int_{\partial D} f(z) \mu^\epsilon_y(dz) \right| \to 0 \quad \text{as } \epsilon \downarrow 0. \tag{2.14}$$

This holds for instance if D is a domain of attraction for an isolated exponentially stable critical point of (1.4); see [4]. Equation (2.14) will also hold for some other

types of stability. Essentially it says that the set of (weak) limit points of μ_x^ϵ as $\epsilon \downarrow 0$ is independent of $x \epsilon D$.

Next we want to indicate briefly how the existence of a continuous stationary density follows from our assumptions. The results of Sato and Ueno [14] imply the existence of a transition density $p^\epsilon(x;t,y)$ which is continuous on $(0,\infty)\times\overline{D}\times\overline{D}$. The nondegeneracy of the diffusion matrix $a(\cdot)$ and compactness of $\overline{D}$ imply that $x^\epsilon(t)$ is positive recurrent, satisfying the condition (B) of Hasminskii [7, p. 118]. Theorems 4.1 and 5.1 of [7] imply that $x^\epsilon(t)$ has a unique stationary distribution, $\pi^\epsilon(dx)$. It follows then that $\pi^\epsilon(dx)$ has a continuous density $p^\epsilon(x)$ on $\overline{D}$ given by

$$p^\epsilon(x) = \int_{\overline{D}} p^\epsilon(z;1,x)\pi^\epsilon(dz).$$

The following properties of the nondecreasing process $l^\epsilon(t)$ can be deduced from the fact that $x^\epsilon(t) \in \overline{D}$ for all $t \geq 0$ and standard features of the Brownian term in (2.13):

$$l^\epsilon(t) \to +\infty \quad \text{a.s. as } t \to +\infty;$$

$$\text{if } x_0 \in \partial D, \text{ then } l^\epsilon(t) > 0 \quad \text{a.s. } \forall \ t > 0.$$

Moreover, for any $T < \infty$

$$\int_0^T \chi_{\partial D}(x^\epsilon(t))dt = 0 \quad \text{a.s.} \tag{2.15}$$

(See [1].)

$l^\epsilon(t)$ is called the "local time on ∂D" since it is a sort of spatial density for the time spent by $x^\epsilon(t)$ on ∂D, roughly analogous to the classical Brownian local time. The following theorem tailors a statement of this fact that to our needs below. Certainly a stronger statement is true. In particular we expect the convergence to be almost sure since it is in the purely Brownian case; see Hsu [8]. We defer the proof to §8.

THEOREM 2.1. *Let $x^\epsilon(0) \in G$ be given any initial distribution, independent of $w(\cdot)$. For any $f \in C(\partial D)$*

$$\lim_{h\downarrow 0} E\left[\frac{1}{h}\int_0^{\tau_\Gamma} \chi_{[0,h]}(\rho(x^\epsilon(t))f(x^\epsilon(t))dt\right] = E\left[\int_0^{\tau_\Gamma} f(x^\epsilon(t))dl^\epsilon(t)\right].$$

3. The fundamental equation for the exit measure. We will now derive (3.7), which describes the connection between the exit measures $\mu_\cdot^\epsilon(dy)$ and the stationary density $p^\epsilon(x)$. The derivation is much the same as in [3]. Assumption (2.9) is not used at all here, but (2.14) is fundamental. At the end of the section we will indicate a second way to understand the equation in terms of the "boundary process" associated with the reflecting diffusion.

The starting point is the following construction of Hasminskii [7] for the stationary distribution $\pi^\epsilon(dx) = p^\epsilon(x)dx$. Define a double sequence of stopping times by

$$\tau_{\partial D}^0 = 0$$

and recursively for $n \geq 1$,

$$\tau_\Gamma^n = \inf\{t > \tau_{\partial D}^n : x^\epsilon(t) \in \Gamma\}$$
$$\tau_{\partial D}^n = \inf\{t > \tau_\Gamma^{n-1} : x^\epsilon(t) \in \partial D\}.$$

The nondegeneracy of $a(\cdot)$ implies that all of these are almost surely finite. The $x^\epsilon(\tau^n_{\partial D})$ form a Markov chain on ∂D for which there is a unique stationary distribution $\mu^\epsilon(dy)$. The stationary distribution $p^\epsilon(x)dx$ is expressed in terms of μ^ϵ as a (normalized) expected path integral over one "cycle" of the chain from ∂D at $t = \tau^n_{\partial D}$ to Γ at $t = \tau^n_\Gamma$ and back to ∂D at $t = \tau^{n+1}_{\partial D}$, i.e., over $t \in (\tau^n_{\partial D}, \tau^{n+1}_{\partial D}]$. Specifically in terms of $n = 0$,

$$\int_D g(x)p^\epsilon(x)dx = c^\epsilon E_{\mu^\epsilon}\left[\int_0^{\tau^1_{\partial D}} g(x^\epsilon(s))ds\right] \tag{3.1}$$

for any bounded measurable g on $\overline{D}$. The normalizing constant is $c^\epsilon = E_{\mu^\epsilon}[\tau^1_{\partial D}]^{-1}$. ($E_\mu[\cdot]$ means $\int E_x[\cdot]\mu(dx)$.) For our purposes it is advantageous to break the cycle into its two halves: $[\tau^n_{\partial D}, \tau^n_\Gamma] \cup [\tau^n_\Gamma, \tau^{n+1}_{\partial D}]$. Define the measure $\lambda^\epsilon(dz)$ on Γ by

$$\lambda^\epsilon(A) = P_{\mu^\epsilon}[x^\epsilon(\tau^0_\Gamma) \in A], A \subseteq \Gamma \quad \text{measurable.}$$

It follows that for measurable $A \subseteq \partial D$

$$\mu^\epsilon(A) = E_{\lambda^\epsilon}[x^\epsilon(\tau_{\partial D}) \in A] = \int_\Gamma \mu^\epsilon_z(A)\lambda^\epsilon(dz).$$

The leveling assumption (2.14) implies that convergence as $\epsilon \downarrow 0$ of μ^ϵ is the same as for any $\mu^\epsilon_{x_0}$.

LEMMA 3.1. *The weak limit points, as $\epsilon \downarrow 0$, of μ^ϵ and $\mu^\epsilon_{x_0}$ agree and are independent of $x_0 \in D$.*

Proof. If $\{\epsilon_n\}_1^\infty$ is a sequence decreasing to 0, then for any $x_0 \in D$ and $f \in C(\partial D)$,

$$\begin{aligned}\left|\int_{\partial D} f d\mu^\epsilon - \int_{\partial D} f d\mu^\epsilon_{x_0}\right| &\le \int_\Gamma \left|\int_{\partial D} f d\mu^\epsilon_z - \int_{\partial D} f d\mu^\epsilon_{x_0}\right| \lambda^\epsilon(dz) \\ &\le \sup_{z \in \Gamma \cup \{x_0\}} \left|\int f d\mu^\epsilon_z - \int f d\mu^\epsilon_{x_0}\right|\end{aligned}$$

which converges to 0 by (2.14). □

Our goal then is to identify the limit points of μ^ϵ in terms of p^ϵ as $\epsilon \downarrow 0$. Using the two halves of the cycle, we can rewrite (3.1) as

$$\int_D g(x)p^\epsilon(x)dx = c^\epsilon\left(E_{\mu^\epsilon}\left[\int_0^{\tau_\Gamma} g(x^\epsilon(s))ds\right] + E_{\lambda^\epsilon}\left[\int_0^{\tau_{\partial D}} g(x^\epsilon(s))ds\right]\right). \tag{3.2}$$

Now we perform a sort of spatial differentiation in (3.2). To be precise, let $f \in C(\partial D)$. Extend f to $f \in C(G)$, and for $0 < h < h_0$ define

$$f^{(h)}(x) = h^{-1}\chi_{[0,h]}(\rho(x))f(x).$$

Use this in (3.2) and pass to the limit as $h \downarrow 0$. By virtue of the continuity of p^ϵ we get a surface integral on the left:

$$\lim_{h \downarrow 0} \int_D \frac{1}{h}\chi_{[0,h]}(\rho(x))f(x)p^\epsilon(x)dx = \int_{\partial D} f(y)p^\epsilon(y)dy. \tag{3.3}$$

According to Corollary 1 of [3], the second term on the right vanishes:

$$\lim_{h \downarrow 0} E_{\lambda^\epsilon}\left[\int_0^{\tau_{\partial D}} f^{(h)}(x^\epsilon(s))ds\right] = 0 \tag{3.4}$$

(The notation here is slightly different from [3]; the λ^ϵ and $\tau_{\partial D}$ used here were denoted by ν^ϵ and τ_D there.) The convergence of the first term on the right in (3.2) is given by Theorem 2.1 above. We find then that for all $f \epsilon C(\partial D)$ the following equation holds:

$$\int_{\partial D} f(y)p^\epsilon(y)dy = c^\epsilon \int_{\partial D} E_y \left[\int_0^{\tau_\Gamma} f(x^\epsilon(t))dl^\epsilon(t)\right] \mu^\epsilon(dy). \tag{3.5}$$

Define the "local time operator" B^ϵ on $C(\partial D)$ by

$$B^\epsilon[f](y) = E_y \left[\int_0^{\tau_\Gamma} f(x^\epsilon(t))dl^\epsilon(t)\right].$$

Also define the measure ν^ϵ on ∂D by

$$\nu^\epsilon(dy) = c^\epsilon p^\epsilon(y)dy, \tag{3.6}$$

where c^ϵ is a new normalizing constant to make ν^ϵ a probability measure. (We will use c^ϵ as a generic ϵ-dependent normalizing constant; its actual value may vary from one equation to the next.) Equation (3.5) may now be written

$$\int_{\partial D} f(y)\nu^\epsilon(dy) = c^\epsilon \int_{\partial D} B^\epsilon[f](y)\mu^\epsilon(dy) \quad \forall f \epsilon C(\partial D). \tag{3.7}$$

We will call (3.7) the "fundamental equation" for the exit measure because it describes precisely the connection between μ^ϵ and p^ϵ. It is true that both μ^ϵ and B^ϵ are dependent on the choice of G through the hitting times τ_Γ^n. However, in the limit as $\epsilon \downarrow 0$ this dependence vanishes. (For μ^ϵ this is a consequence of the leveling property; for B^ϵ it follows from the asymptotic formula of the next section.) The goal of the subsequent sections is to invert B^ϵ in the limit as $\epsilon \downarrow 0$ so that the limit points of μ^ϵ can be determined from those of ν^ϵ.

There is a second way to understand our fundamental equation, based on what is called the boundary process $y^\epsilon(l)$ associated with $x^\epsilon(t)$. Since none of our proofs will be based on this interpretation, we will limit ourselves to a summary discussion. (See [14] and [15] for more on the boundary process.)

The boundary process can be obtained from $x^\epsilon(t)$ by making a random time change so that $l = l^\epsilon(t)$ becomes the independent time parameter, rather than the "real" time t. This is done by defining the right continuous inverse $t_+^\epsilon(l)$ of $l^\epsilon(t)$:

$$t_+^\epsilon(l) = \sup\{t > 0 : l^\epsilon(t) \leq l\}.$$

The boundary process is given by

$$y^\epsilon(l) = x^\epsilon(t_+^\epsilon(l)).$$

This turns out to be a right continuous strong Markov process on ∂D, moving only by discontinuous jumps. Also,

$$\eta^n = l^\epsilon(\tau_{\partial D}^n)$$

form a sequence of stopping times for $y^\epsilon(l)$ (using the σ-algebras $\mathscr{F}_{t_+^\epsilon(l)}$) and

$$y^\epsilon(\eta^n) = x^\epsilon(\tau_{\partial D}^n).$$

As before, μ^ϵ is the stationary distribution for this Markov chain. We can now construct a stationary distribution $\bar{\nu}^\epsilon$ for $y^\epsilon(l)$ analogously to (3.1):

$$\int_{\partial D} f(y)\bar{\nu}^\epsilon(dy) = c^\epsilon E_{\mu^\epsilon}\left[\int_0^{\eta^1} f(y^\epsilon(l))dl\right]. \tag{3.8}$$

However we may check that

$$\begin{aligned} E_y\left[\int_0^{\eta^1} f(y^\epsilon(l))dl\right] &= E_y\left[\int_0^{\tau^1_{\partial D}} f(x^\epsilon(t))dl^\epsilon(t)\right] \\ &= E_y\left[\int_0^{\tau_\Gamma} f(x^\epsilon(t))dl^\epsilon(t)\right] \\ &= B^\epsilon[f](y). \end{aligned}$$

Thus (3.8) becomes

$$\int_{\partial D} f(y)\bar{\nu}^\epsilon(dy) = c^\epsilon \int_{\partial D} B^\epsilon[f](y)\mu^\epsilon(dy), \quad \forall f \in C(\partial D).$$

We recognize this as our fundamental equation (3.7). What we learn is that ν^ϵ defined by (3.6) is in fact a stationary distribution $\bar{\nu}^\epsilon$ for $y^\epsilon(l)$, and that (3.7) can be thought of as its construction in terms of the embedded Markov chain. We should point out that this connection between the stationary density of a reflected diffusion and the stationary distribution of its boundary process has been noted before by Freidlin [6, p. 174].

4. Asymptotic evaluation of B^ϵ. We now consider the behavior of the boundary local time operator B^ϵ as $\epsilon \downarrow 0$. The asymptotic behavior is revealed by considering the one-dimensional process $\varsigma^\epsilon(t)$ defined for $0 \le t \le \tau_\Gamma$ by

$$\varsigma^\epsilon(t) = \epsilon^{-1/2}\rho(x^\epsilon(t)). \tag{4.1}$$

The asymptotic properties of $\varsigma^\epsilon(t)$ give a "boundary layer" description of $x^\epsilon(t)$ which is roughly analogous to the boundary layer calculations in [12], [13]. Note that

$$\begin{aligned} \tau_\Gamma &= \inf\{t > 0 : x^\epsilon(t) \in \Gamma\} \\ &= \inf\{t > 0 : \rho(x^\epsilon(t)) = h_0\} \\ &= \inf\{t > 0 : \varsigma^\epsilon(t) = \epsilon^{-1/2}h_0\} \\ &= \eta^\epsilon_{\epsilon^{-1/2}h_0}, \end{aligned} \tag{4.2}$$

where in general for $\epsilon^{1/2}\varsigma^\epsilon(0) = \rho(x^\epsilon(0)) < r < h_0$ we will write

$$\eta^\epsilon_r = \inf\{t > 0 : \varsigma^\epsilon(t) = r\}. \tag{4.3}$$

Using the fact that $\langle \nabla\rho(y), \eta(y)\rangle = -\alpha(y)^2$ on ∂D, Itô's formula (see [9, p. 66]) gives

$$d\varsigma^\epsilon(t) = \epsilon^{-1/2}\mathscr{L}^\epsilon\rho(x^\epsilon(t))dt + \langle \sigma^T\nabla\rho(x^\epsilon(t)), dw(t)\rangle + \frac{1}{2}\epsilon^{1/2}\alpha(x^\epsilon(t))^2 dl^\epsilon(t), \tag{4.4}$$

with $l^\epsilon(t)$ increasing only when $\varsigma^\epsilon(t) = 0$.

Now if $\varsigma \in [0,\infty)$ and $x \in G$ are variables related by $\varsigma = \epsilon^{-1/2}\rho(x)$, then (2.10) implies that

$$\begin{aligned} \epsilon^{-1/2}\mathscr{L}^\epsilon\rho(x) &= \frac{\epsilon^{1/2}}{2}\sum_{i,j} a_{ij}(x)\rho_{x_ix_j}(x) + \epsilon^{-1/2}\langle \nabla\rho(x), b(x)\rangle \\ &= \epsilon^{-1/2}\langle \nabla\rho(x), b(x)\rangle + O(\epsilon^{1/2}) \\ &= \epsilon^{-1/2}\langle -n(x), -\rho(x)b_1(x)n(x)\rangle + O(\epsilon^{1/2})\rangle + \epsilon^{-1/2}o(\rho) \\ &= b_1(x)\varsigma + o(1), \end{aligned} \tag{4.5}$$

the $o(1)$ being uniform for ς in compact sets, as $\epsilon \downarrow 0$.

Using $\alpha(\cdot)$ as in (2.4), the second term of (4.4) is of the form

$$\langle \sigma^T(x^\epsilon(t))n(x^\epsilon(t)), dw(t)\rangle = \alpha(x^\epsilon(t))d\beta(t), \tag{4.6}$$

where $\beta(t)$ is a one-dimensional Brownian motion adapted to the $\mathscr{F}_t$. To be precise, given $\epsilon > 0$, (4.6) defines an $\mathscr{F}_t$ adapted process $\beta(t)$. (To extend the definition to $t > \tau_\Gamma$, replace $x^\epsilon(t)$ by $x^\epsilon(t \wedge \tau_\Gamma)$ on both sides.) It is simple to check that $\beta(t)$ is a Brownian motion using $\|\sigma^T n\| = \alpha$ and a martingale characterization, such as [9, Thm. II-6.1]. (Although this definition of β is ϵ-dependent, we ignore this dependence in our present heuristic discussion. For our purposes this can be justified because we are only concerned with the distributions of $\varsigma^\epsilon(\cdot)$ and $\varsigma(\cdot)$ below. See the paragraph preceding Lemma 9.2 for more on this point.)

As $\epsilon \downarrow 0$, $x^\epsilon(\cdot) \to x^0(\cdot)$. (We will prove this in §9 below). Thus if $x^\epsilon(0) = y \in \partial D$, we would expect that $\varsigma^\epsilon(t)$ converges in distribution to the one-dimensional reflecting diffusion $\varsigma(t)$ on $[0, \infty)$ described by

$$d\varsigma(t) = b_1(x^0(t))\varsigma(t)dt + \alpha(x^0(t))d\beta(t) + \frac{1}{2}\alpha(x^0(t))^2 dl(t),\ \varsigma(0) = \varsigma_0 \tag{4.7}$$

$$dl(t) = \chi_{\{0\}}(\varsigma(t))dl(t),\ l(0) = 0 \tag{4.8}$$

$$\dot{x}^0(t) = b(x^0(t)),\ x^0(0) = y, \tag{4.9}$$

with $\varsigma_0 = \varsigma^\epsilon(0) = 0$. As usual, this is to be solved simultaneously for the pair of continuous processes $(\varsigma(t), l(t))$ under the restrictions that $l(t)$ is nondecreasing and $\varsigma(t) \geq 0$. Probabilities and expectations with respect to (4.7), (4.8), and (4.9) will be indicated using $P_{\varsigma_0, y}$ and $E_{\varsigma_0, y}$.

Comparing the local time terms in (4.4) and (4.7), we would also expect that $\epsilon^{1/2} l^\epsilon(t)$ converges to $l(t)$. Moreover, (4.2) suggests that $\tau_\Gamma \to +\infty$ almost surely as $\epsilon \downarrow 0$. Thus we anticipate that

$$\begin{aligned} B^\epsilon[f](y) &= E_y\left[\int_0^{\tau_\Gamma} f(x^\epsilon(t))dl^\epsilon(t)\right] \\ &= \epsilon^{-1/2} E_y\left[\int_0^{\tau_\Gamma} f(x^\epsilon(t))d(\epsilon^{1/2} l^\epsilon(t))\right] \\ &\sim \epsilon^{-1/2} E_{0,y}\left[\int_0^{\infty} f(x^0(t))dl(t)\right]. \end{aligned}$$

Define the operator B on $C(\partial D)$ by

$$B[f](y) = E_{0,y}\left[\int_0^{\infty} f(x^0(t))dl(t)\right].$$

Note that $y \in \partial D$ determines the solution $x^0(t)$ of (4.9), which is a deterministic trajectory on ∂D. This path then determines the time dependent coefficients in the equation for $\varsigma(t)$, from which we get $l(t)$, which in turn provides a weighting of points on $x^0(\cdot)$. Thus $B[f](y)$ is a certain integral of the values of f along the solution of (4.9) with $x^0(0) = y$.

The above considerations suggest the following result.

THEOREM 4.1. *Given any $f \in C(\partial D)$, $\epsilon^{1/2} B^\epsilon[f]$ converges to $B[f](y)$ uniformly on ∂D.*

A fair amount of technical work is needed to make the above discussion into a proof of this theorem. We therefore postpone the proof until §9, so as not to interrupt the continuity of our consideration of the exit problem itself.

5. A canonical time scale and calculation of $B[f]$. We will now see that a change of variables uncouples the equations (4.7) and (4.9) and allows the derivation of explicit formulas for $B[f]$ and $B^{-1}[f]$. The idea is to select a positive function $\gamma(\cdot) \in C(\partial D)$ and change from ς, t to new variables ξ, s according to

$$\xi(s) = \gamma(x^0(t))\varsigma(t), \quad s = \int_0^t \alpha(x^0(u))^2\gamma(x^0(u))^2 du.$$

In these variables (4.7) becomes

$$\begin{aligned} d\xi(s) = \alpha(x^0(t))^{-2}\gamma(x^0(t))^{-2}\left[b_1(x^0(t)) + \gamma(x^0(t))^{-1}\frac{d}{dt}\gamma(x^0(t))\right]\xi(s)ds \\ +d\bar{\beta}(s) + \frac{1}{2}\gamma(x^0(t))\alpha(x^0(t))^2 dl(t), \end{aligned} \tag{5.1}$$

where $\bar{\beta}(s) = \int_0^t \alpha\gamma(x^0(u))d\beta(u)$ is a Brownian motion on the s time scale. We want to choose $\gamma(\cdot) > 0$ so that

$$\alpha^{-2}\gamma^{-2}\left[b_1(x^0) + \gamma^{-1}\frac{d}{dt}\gamma(x^0)\right] = 1 \text{ everywhere on } \partial D, \tag{5.2}$$

or

$$\frac{d}{dt}\gamma(x^0(t)) + b_1(x^0)\gamma(x^0) = \alpha^2(x^0)\gamma(x^0)^3.$$

LEMMA 5.1. *There exists a unique positive function $\gamma \in C(\partial D)$, differentiable along every trajectory of $\dot{x}^0 = b(x^0)$ on ∂D, satisfying* (5.2).

By "differentiable along every trajectory" we mean that for every $y = x^0(0) \in \partial D$, $\gamma(x^0(t))$ is differentiable in t. This is weaker than saying simply that $\gamma(\cdot)$ is differentiable, which may in fact be false.

Proof. Note that the change of variable $Z(y) = \gamma(y)^{-2}$ makes (5.2) linear:

$$-\frac{1}{2}\frac{d}{dt}Z(x^0) + b_1(x^0)Z(x^0) = \alpha(x^0)^2.$$

A simple integrating factor calculation shows that, for any such $Z(\cdot)$ and any solution $x^0(t)$ of $\dot{x}^0 = b(x^0)$ on ∂D,

$$Z(x^0(0)) = Z(x^0(T))\exp\left[-2\int_0^T b_1(x^0(t))dt\right] + 2\int_0^T \alpha(x^0(t))^2 \exp\left[-2\int_0^t b_1(x^0(u))du\right]dt$$

for all $T > 0$. Since $b_1 > 0$ on ∂D, the first term vanishes as $T \to \infty$, showing that Z is given uniquely by

$$Z(y) = 2\int_0^\infty \alpha(x^0(t))^2 \exp\left[-2\int_0^t b_1(x^0(u))du\right]dt,$$

where $x^0(0) = y \in \partial D$. This is easily argued to be positive, continuous on ∂D, and differentiable along any trajectory $x^0(t)$. □

This choice of $\gamma(\cdot)$ simplifies (5.1) to

$$d\xi(s) = \xi(s)ds + d\bar{\beta}(s) + \frac{1}{2}\gamma(x^0(t))\alpha(x^0(t))^2 dl(t).$$

It is natural to complete this new system of variables by defining a rescaled local time,

$$\bar{l}(s) = \int_0^t \gamma(x^0(u))\alpha(x^0(u))^2 dl(u).$$

Equation (4.9) can be recast in terms of s as

$$\frac{d}{ds}x^0(s) = \bar{b}(x^0(s)), \tag{5.3}$$

where $\bar{b}$ is defined in ∂D by

$$\bar{b}(y) = \frac{b(y)}{\alpha(y)^2\gamma(y)^2}.$$

Thus in the new variables (4.7), (4.8), and (4.9) become

$$\begin{aligned} &d\xi(s) = \xi(s)ds + d\bar{\beta}(s) + \frac{1}{2}d\bar{l}(s), \ \xi(0) = 0 \\ &\bar{l}(s) = \int_0^s \chi_{\{0\}}(\xi(v))d\bar{l}(v) \\ &\frac{d}{ds}x^0(s) = \bar{b}(x^0(s)), \ x^0(0) = y \end{aligned} \tag{5.4}$$

with the usual nonnegativity and nondecreasing requirements for $\xi(\cdot)$ and $\bar{l}(\cdot)$, respectively.

This change of variables has accomplished two things. One is that the ξ and x^0 equations are uncoupled, and the other is that the ξ equation is linear with constant coefficients. In fact, a solution is given by $\xi(t) = |z(t)|$, where $z(t)$ is the unreflected diffusion in $\mathbb{R}^1$ with generator $\frac{1}{2}\left(\frac{d}{dz}\right)^2 + z\frac{d}{dz}$, an (unstable) Ornstein-Uhlenbeck process. This allows us to carry out some explicit calculations for $\xi(t)$. In particular the transition density for $\xi(\cdot)$ is given by

$$q(\xi_0; s, \xi_1) = [\pi\theta^2(s)]^{-1/2}[e^{-(\xi_1+e^s\xi_0)^2/\theta^2(s)} + e^{-(\xi_1-e^s\xi_0)^2/\theta^2(s)}], \tag{5.5}$$

where

$$\theta(s) = (e^{2s} - 1)^{1/2}.$$

This may be checked for instance by verifying that q is the fundamental solution of the backward PDE associated with $\xi(\cdot)$. We leave the details to the reader. We may also check that $\xi(t)$ is nonexploding, and so is defined for all $0 \le t < \infty$.

We are now in a position to derive an explicit formula for the operator B. The first step is to express it in the new variables.

$$\begin{aligned} B[f](y) &= E_{0,y}\left[\int_0^\infty f(x^0(t))dl(t)\right] \\ &= E_0\left[\int_0^\infty \frac{f}{\gamma\alpha^2}(x^0(s))d\bar{l}(s)\right], \ x^0(0) = y \\ &= \overline{B}\left[\frac{f}{\gamma\alpha^2}\right](y), \end{aligned}$$

where

$$\overline{B}[g](y) = E_0\left[\int_0^\infty g(x^0(s;y))d\bar{l}(s)\right].$$

(The notation $x^0(s;y)$ indicates the solution of (5.3) with $x^0(0) = y$). Now if $y \in \partial D$ and $g \in C(\partial D)$, then $g(x^0(s;y))$ is a bounded continuous function of $s \in [0,\infty)$. We can describe $\overline{B}$ in terms of the following operator $\mathscr{B}$ on $C_b[0,\infty)$:

$$\mathscr{B}[\varphi](s) = E_0\left[\int_0^\infty \varphi(s+v)d\bar{l}(v)\right].$$

That $\mathscr{B}[\varphi] \in C_b[0,\infty)$ follows from the explicit formula of the next lemma. $\overline{B}$ is reconstructed from $\mathscr{B}$ according to

$$\overline{B}[g](x^0(s;y)) = \mathscr{B}[\varphi](s), \text{ where } \varphi(\cdot) = g(x^0(\cdot;y)).$$

LEMMA 5.2. *For any* $\varphi \in C_b[0,\infty)$,

$$\mathscr{B}[\varphi](s) = \int_0^\infty \varphi(s+v)\frac{2}{\sqrt{\pi}}(e^{2v}-1)^{-1/2}dv.$$

Proof. The key is to calculate $E_0[\bar{l}(s)]$. By virtue of (5.4), for $\xi(0) = 0$ we have

$$\frac{1}{2}\bar{l}(s) = \xi(s) - \int_0^s \xi(v)dv - \overline{\beta}(s) \tag{5.5}$$

and so

$$\begin{aligned} E_0[\bar{l}(s)] &= 2E_0\left[\xi(s) - \int_0^s \xi(v)dv\right] \\ &= 2\{E_0[\xi(s)] - \int_0^s E_0[\xi(v)]dv\}. \end{aligned} \tag{5.6}$$

Using the density (5.5),

$$E_0[\xi(s)] = \int_0^\infty zq(0;s,z)dz = \frac{2}{\sqrt{\pi}}\int_0^\infty \frac{z}{\theta(s)}e^{-z^2/\theta^2(s)}dz = \frac{1}{\sqrt{\pi}}\theta(s).$$

Using this in (5.6), we find

$$E_0[\bar{l}(s)] = \frac{2}{\sqrt{\pi}}\left[\theta(s) - \int_0^s \theta(v)dv\right].$$

Now one easily checks that $\theta'(s) = \theta(s) + 1/\theta(s)$, with $\theta(0) = 0$, so that the preceding can be rewritten as

$$E_0\left[\int_0^s d\bar{l}(v)\right] = \frac{2}{\sqrt{\pi}}\int_0^s \theta(v)^{-1}dv.$$

This implies that

$$E_0\left[\int_0^\infty \varphi(v)d\bar{l}(v)\right] = \frac{2}{\sqrt{\pi}}\int_0^\infty \varphi(v)\theta(v)^{-1}dv \tag{5.7}$$

for φ piecewise constant with compact support. Since $\varphi \in C_b[0,\infty)$ can be uniformly approximated on compacts by piecewise constant functions, and since $\theta(v)^{-1} \in L^1[0,\infty)$, (5.7) follows for all $\varphi \in C_b[0,\infty)$. The lemma is just (5.7) applied to a translation of φ. □

The next lemma tells us how to invert $\mathscr{B}$.

LEMMA 5.3. $\mathscr{B}$ *is 1-1 on* $C_b[0,\infty)$. *If* $\psi \in C_b^1[0,\infty)$, *then* $\psi = \mathscr{B}[\varphi]$ *where* $\varphi \in C_b[0,\infty)$ *is given by*

$$\varphi(s) = \frac{1}{\sqrt{\pi}}\{\psi(s) + \int_0^\infty \psi'(s+v)[1-(1-e^{-2v})^{-1/2}]dv\}. \tag{5.8}$$

Proof. This is essentially calculation, the principal part of which we exhibit at the outset: for all $v > 0$

$$\begin{aligned} &\int_0^v \left(e^{2(v-s)}-1\right)^{-1/2}[1-(1-e^{-2s})^{1/2}]ds \\ &= \left[-Tan^{-1}((e^{2(v-s)}-1)^{1/2}) - \frac{1}{2}Sin^{-1}\left(\frac{2e^{2s}-e^{2v}-1}{e^{2v}-1}\right)\right]_0^v \\ &= Tan^{-1}((e^{2v}-1)^{1/2}) - \frac{\pi}{2}. \end{aligned} \tag{5.9}$$

Suppose then that $\psi \in C_b^1[0,\infty)$ and define ϕ by (5.8). $\phi \in C_b[0,\infty)$ since $[1-(1-e^{-2v})^{1/2}] \in L^1[0,\infty)$. Now a change of variable and interchange of order of integration show that

$$\begin{aligned}
&\frac{2}{\sqrt{\pi}}\int_0^\infty \left\{\int_0^\infty \psi'(s+v+u)[1-(1-e^{-2u})^{-1/2}]du\right\}(e^{2v}-1)^{-1/2}dv \\
&\qquad = \frac{2}{\sqrt{\pi}}\int_0^\infty \psi'(s+v)\int_0^v (e^{2(v-u)}-1)^{-1/2}[1-(1-e^{-2u})^{-1/2}]dudv \qquad (5.10)\\
&\qquad = \frac{2}{\sqrt{\pi}}\int_0^\infty \psi'(s+v)[Tan^{-1}((e^{2v}-1)^{1/2})-\frac{\pi}{2}]dv,
\end{aligned}$$

by the identity (5.9). Integrating by parts, this becomes

$$= \frac{2}{\sqrt{\pi}}\left[\frac{\pi}{2}\psi(s) - \int_0^\infty \psi(s+v)(e^{2s}-1)^{-1/2}ds\right].$$

After rearrangement this reduces to $\psi = \mathscr{B}[\varphi]$.

All that remains is to show that $\mathscr{B}$ is 1-1. First suppose only $\varphi' \in C_b[0,\infty)$, and let $\psi = \mathscr{B}[\varphi]$. Since φ grows at most linearly and $v\cdot(e^{2v}-1)^{-1/2} \in L^1[0,\infty)$, it follows that $\psi' \in C_b[0,\infty)$ and

$$\psi'(s) = \frac{2}{\sqrt{\pi}}\int_0^\infty \varphi'(s+v)(e^{2v}-1)^{-1/2}dv. \qquad (5.11)$$

Therefore

$$\begin{aligned}
&\int_0^\infty \psi'(s+u)[1-(1-e^{-2u})^{-1/2}]du \\
&\qquad = \frac{2}{\sqrt{\pi}}\int_0^\infty \left\{\int_0^\infty \varphi'(s+u+v)(e^{2v}-1)^{-1/2}dv\right\}[1-(1-e^{-2u})]^{-1/2}du.
\end{aligned}$$

Calculating as in (5.10), we see that

$$\begin{aligned}
\int_0^\infty \psi'(s+u)[1(1-e^{-2u})^{-1/2}]du &= \sqrt{\pi}\varphi(s) - \mathscr{B}[\varphi](s) \\
&= \sqrt{\pi}\varphi(s) - \psi(s).
\end{aligned}$$

That is, if $\varphi' \in C_b[0,\infty)$ then (5.8) recovers φ from $\psi = \mathscr{B}[\varphi]$. In particular, $\mathscr{B}$ is 1-1 on $\{\varphi \in C[0,\infty) : \varphi' \in C_b[0,\infty)\}$. To see that it must be 1-1 on all of $C_b[0,\infty)$, argue as follows. If $\varphi \in C_b[0,\infty)$ and $\mathscr{B}[\varphi] \equiv 0$, then consider

$$\Phi(t) = \int_0^t \varphi(u)du.$$

$\Phi'(t) = \varphi(t) \in C_b[0,\infty)$ and by (5.11)

$$\frac{d}{dt}\mathscr{B}[\Phi] = \mathscr{B}[\phi] \equiv 0$$

or $\mathscr{B}[\Phi] \equiv c$, some constant. By what we just proved, Φ is recovered by using $\psi \equiv c$ in (5.8):

$$\Phi(t) \equiv \frac{1}{\sqrt{\pi}}c.$$

Therefore $\varphi(t) \equiv \Phi'(t) \equiv 0$. □

Now we can collect the implications for $\overline{B}$.

THEOREM 5.1. *$\overline{B}$ is a 1-1 mapping of $C(\partial D)$ into itself. If $h = \overline{B}[g]$ then*

$$h(y) = \frac{2}{\sqrt{\pi}} \int_0^\infty g(x^0(s;y))(e^{2s} - 1)^{-1/2} ds. \tag{5.12}$$

If $h \in C^1(\partial D)$ then $h = \overline{B}[g]$, where $g \in C(\partial D)$ is given by

$$g(y) = \frac{1}{\sqrt{\pi}} \left\{ h(y) + \int_0^\infty \frac{d}{ds} h(x^0(s;y)) \cdot [1 - (1 - e^{-2s})^{-1/2}] ds \right\}. \tag{5.13}$$

In particular the range of $\overline{B}$ is dense in $C(\partial D)$.

Proof. If $g \in C(\partial D)$, then $h = \overline{B}[g]$ if and only if, for every $y \in \partial D$, $\psi = \mathscr{B}[\varphi]$, where $\psi(s) = h(x^0(s;y))$ and $\varphi(s) = g(x^0(s;y))$. Equation (5.12) follows from Lemma 5.2. If $h \equiv 0$ then $\psi \equiv 0$, so by the same lemma $\varphi \equiv 0$, i.e., $g = 0$ along every trajectory $x^0(s)$ on ∂D. Therefore $g \equiv 0$. That $h \in C(\partial D)$ follows from (5.12) and dominated convergence.

If $h \in C^1(\partial D)$ then $\frac{d}{ds} h(x^0(s;y))$ is bounded and continuous. Dominated convergence implies that g defined by (5.13) is in fact in $C(\partial D)$. That $h = \overline{B}[g]$ is Lemma 5.3 applied along every trajectory $x^0(s)$. The final assertion follows immediately since $C^1(\partial D)$ is dense in $C(\partial D)$. □

6. Inversion of the fundamental equation and a conjecture. We can now return to the consideration of our fundamental equation (3.7). Suppose $\{\epsilon_n\}_1^\infty$ is a sequence decreasing to 0 and that along this sequence $\nu^{\epsilon_n} \to \nu$ and $\mu^{\epsilon_n} \to \mu$ (weakly). Passing to the limit in (3.7) using Theorem 4.1, we obtain, for some constant c,

$$\int_{\partial D} f d\nu = c \int_{\partial D} B[f] d\mu = c \int_{\partial D} \overline{B}\left[\frac{f}{\gamma \alpha^2}\right] d\mu \quad \forall f \in C(\partial D).$$

This is equivalent to

$$\int_{\partial D} g \cdot \gamma \alpha^2 d\nu = c \int_{\partial D} \overline{B}[g] d\mu \quad \forall g \in C(\partial D). \tag{6.1}$$

Since the range of $\overline{B}$ is dense in $C(\partial D)$, this equation determines μ uniquely in terms of ν. To be explicit, using (5.13) in (6.1) we have that for all $h \in C^1(\partial D)$,

$$\int_{\partial D} h d\mu = c \cdot \left\{ \int_{\partial D} h \gamma \alpha^2 d\nu + \int_0^\infty \left(\int_{\partial D} \frac{d}{ds} h(x^0(s;y)) \gamma(y) \alpha(y)^2 d\nu \right) \cdot [1 - (1 - e^{2s})^{-1/2}] ds \right\}, \tag{6.2}$$

where again c is the appropriate normalizing constant. It might be natural to write

$$\frac{d}{ds} h(x^0(s;y)) = \langle \nabla h(x^0), \bar{b}(x^0) \rangle, \quad \text{where } x^0 = x^0(s;y),$$

although technically since h is only defined in ∂D, only the tangential components of ∇h are defined. The point is simply that $(d/ds)h(x^0)$ is a first-order differential operator applied to h evaluated at $x^0(s) \in \partial D$.

Our conclusions for the exit problem are collected in the following theorem.

THEOREM 6.1. *Let $\nu^\epsilon(dy)$ be the probability measures on ∂D defined by*

$$\nu^\epsilon(dy) = c^\epsilon p^\epsilon(y) dy.$$

For any $x \in D$ and sequence $\{\epsilon_n\}_1^\infty$ decreasing to 0, the exit measures $\mu_x^{\epsilon_n}(dy)$ converge (weakly) to a measure $\mu(dy)$ if and only if $\nu^{\epsilon_n}(dy)$ converges (weakly) to a measure $\nu(dy)$, in which case $\mu(dy)$ is uniquely determined by $\nu(dy)$ according to (6.1) or (6.2).

Proof. Everything has already been argued except the "if and only if" assertion. If μ^{ϵ_n} converges to a probability measure μ, and $f \in C(\partial D)$ then we know from (3.7) that

$$\int_{\partial D} f d\nu^\epsilon = c^\epsilon \int_{\partial D} B^\epsilon[f] d\mu^\epsilon = \epsilon^{-1/2} c^\epsilon \cdot \int_{\partial D} \epsilon^{1/2} B^\epsilon[f] d\mu^\epsilon \tag{6.3}$$

and

$$\int_{\partial D} \epsilon^{1/2} B^\epsilon[f] d\mu^\epsilon \to \int_{\partial D} B[f] d\mu.$$

First consider $f \equiv 1$. Since the left side in (6.3) is 1, we conclude that $\epsilon^{-1/2} c^\epsilon$ converges to the constant c which satisfies

$$1 = c \int_{\partial D} B[1] d\mu.$$

Thus for an arbitrary $f \in C(\partial D)$ we have

$$\int_{\partial D} f d\nu^{\epsilon_n} \to c \int_{\partial D} B[f] d\mu.$$

The right side of this defines a probability measure ν on ∂D. This proves the "only if" assertion.

Suppose ν^{ϵ_n} converges to ν. Since ∂D is compact, the set of probability measures on ∂D is precompact. All convergent subsequences of $\{\mu^{\epsilon_n}\}$ must have the same limit μ, uniquely determined from ν by μ. Thus $\{\mu^{\epsilon_n}\}$ converges. This proves the "if". □

Perhaps it is disheartening that the "inversion formula" (6.2) is not more simple (compare (6.6) of [2] for the case of (1.5)). However (6.2) is the best that can be said without more information about ν. (It is tempting to integrate by parts in (6.2), however $(d/ds)[1-(1-e^{-2s})^{-1/2}] \notin L^1$.) As indicated in the introduction, we are not going to pursue the asymptotic analysis of p^ϵ and implications for ν here. However, we will make the following conjecture:

CONJECTURE. *If $\nu^\epsilon \to \nu$ weakly as $\epsilon \downarrow 0$, then $\gamma(y)\alpha(y)^2\nu(dy)$ is necessarily an invariant measure for the boundary flow $x^0(s)$ with respect to the variable s : $\dot{x}^0(s) = \bar{b}(x^0(s))$. That is*

$$\int_{\partial D} f(y)\gamma(y)\alpha(y)^2\nu(dy) = \int_{\partial D} f(x^0(s;y))\gamma(y)\alpha(y)^2\nu(dy)$$

for all $s \geq 0, f \in C(\partial D)$.

This conjecture agrees with the formal calculations of [11]. The following theorem allows an equivalent formulation of the conjecture in terms of $\mu = \lim \mu^\epsilon$.

THEOREM 6.2. *Let ν and μ be the respective limits of sequences $\{\nu^{\epsilon_n}\}$ and $\{\mu^{\epsilon_n}\}$, as in Theorem* 6.1. *The measure $\gamma(y)\alpha(y)^2\nu(dy)$ is invariant for $x^0(s;y)$ if and only if $\mu(dy)$ is also, in which case*

$$\mu(dy) = c\gamma(y)\alpha(y)^2\nu(dy), \tag{6.4}$$

with the appropriate normalizing constant c.

Proof. If $\gamma(y)\alpha(y)^2\nu(dy)$ is invariant as claimed, then for $h \in C^1(\partial D)$ for all $s \geq 0$,

$$0 = \frac{d}{ds}\int_{\partial D} h(x^0(s;y))\gamma(y)\alpha(y)^2\nu(dy) = \int_{\partial D} \frac{d}{ds} h(x^0(s;y))\gamma(y)\alpha(y)^2\nu(dy).$$

With this fact (6.2) reduces to (6.4) and of course μ is therefore $x^0(s)$ invariant.

Conversely, suppose μ is $x^0(s)$ invariant. Then using (6.1) and (5.12),

$$\begin{aligned}\int_{\partial D} g(x^0(s;y))\gamma(y)\alpha(y)^2\nu(dy) &= c\int_{\partial D}\overline{B}[g(x^0(s;\cdot))]\mu(dy)\\ &= c\int_0^\infty \frac{2}{\sqrt{\pi}}(e^{2v}-1)^{-1/2}\left[\int_{\partial D} g(x^0(s+v;y))\mu(dy)\right]ds\\ &= c\int_0^\infty \frac{2}{\sqrt{\pi}}(e^{2v}-1)^{-1/2}\left[\int_{\partial D} g(x^0(s;y))\mu(dy)\right]ds\\ &= c\int_{\partial D}\overline{B}[g]\mu(dy)\\ &= \int_{\partial D} g(y)\gamma(y)\alpha(y)^2\nu(dy).\end{aligned}$$

This establishes the invariance of $\gamma(y)\alpha(y)^2\nu(dy)$. □

To close this section consider the case studied in [11]: $d=2$ and ∂D consisting of a single periodic orbit of (1.4), $|b(y)|>0$ everywhere on ∂D. There is then a unique (up to a scalar) $x^0(s)$ invariant measure on ∂D given by

$$\frac{dy}{|\bar{b}(y)|} = \frac{\alpha(y)^2\gamma(y)^2}{|b(y)|}dy.$$

Thus, supposing our conjecture above to be true, there is only one possible limit ν of ν^ϵ as $\epsilon \downarrow 0$. Therefore if $\mu^\epsilon(dy)$ converges, then its limit must be the measure

$$\mu(dy) = c\frac{\alpha(y)^2\gamma(y)^2}{|b(y)|}.$$

This agrees with (2.46) of [11] since $Z(y)=\gamma(y)^{-2}$ and $\alpha(y)\equiv 1$ (they assumed $a(x)\equiv I$).

7. Some estimates. The remainder of this paper is technical, leading to proofs of Theorems 2.1 and 4.1. In this section we will derive upper bounds for several quantities associated with the processes $\varsigma^\epsilon(t)$ and $\varsigma(t)$, as defined in §4. In each case the idea is the same: calculate the analogous quantity explicitly for a one-dimensional diffusion in $[0,\infty]$ with generator

$$Gf(z) = \frac{1}{2}\alpha_0^2 f''(z) + k(z)f'(z)$$

and instantaneous reflection at 0. Then use Itô's lemma to show that this quantity bounds the desired quantity for ς^ϵ and ς. The key to success is a careful choice of the drift coefficient $k(z)$.

We will take

$$k(z) = \frac{\alpha_0^2}{A_1}Kz - 1,$$

where K is the positive constant of (2.11). Note then that for any $x\in G$, with $\varsigma = \epsilon^{-1/2}\rho(x)$,

$$\begin{aligned}\epsilon^{-1/2}\mathscr{L}^\epsilon\rho(x) &= \epsilon^{-1/2}\langle -n(x), b(x)\rangle + \frac{\epsilon^{1/2}}{2}\sum_{i,j} a_{ij}\rho_{x_i,x_j}\\ &\geq K\cdot\epsilon^{-1/2}\rho(x) + \epsilon^{1/2}A_0\\ &\geq K\varsigma - \epsilon^{1/2}|A_0|\end{aligned}$$

where A_0 is as in (2.5). Using (2.6) and (2.7) we have that

$$\begin{aligned}\left(\frac{\alpha_0}{\alpha(x)}\right)^2 \epsilon^{-1/2}\mathscr{L}^\epsilon \rho(x) &\geq \left(\frac{\alpha_0}{\alpha(x)}\right)^2 K\varsigma - \left(\frac{\alpha_0}{\alpha(x)}\right)^2 \epsilon^{1/2}|A_0| \\ &\geq \frac{\alpha_0^2}{A_1} K\varsigma - \epsilon^{1/2}|A_0| \\ &\geq \frac{\alpha_0^2}{A_1} K\varsigma - 1 \\ &= k(\varsigma),\end{aligned} \tag{7.1}$$

provided $\epsilon^{1/2}|A_0| \leq 1$. Define $\epsilon_0 = |A_0|^{-1/2}$, or $\epsilon_0 = 1$ if $A_0 = 0$. Then (7.1) holds for all $0 < \epsilon \leq \epsilon_0$. This value of ϵ_0 will remain unchanged in all that follows. Note also that (2.11) implies that $b_1(y) \geq K$ everywhere on ∂D. Therefore for all $y \in \partial D, \varsigma \geq 0$

$$\left(\frac{\alpha_0}{\alpha(y)}\right)^2 b_1(y)\varsigma \geq \frac{\alpha_0^2}{A_1} K\varsigma \geq k(\varsigma). \tag{7.2}$$

The following lemma contains our basic comparison argument. The stopping times η_r^ϵ were defined in (4.3). Their analogues for $\varsigma(t)$ are

$$\eta_r = \inf\{t > 0 : \varsigma(t) = r\},$$

defined for $0 < \varsigma(0) < r$.

LEMMA 7.1. *Suppose* $0 < r < \infty$ *and* $u \in C^2([0,r])$ *is nonincreasing. Suppose that for some constant* $c \geq 0$

$$Gu(z) + c = 0 \quad \forall\, 0 \leq z \leq r.$$

Then for any stopping time $\tau \leq \eta_r^\epsilon$, *all* $0 < \epsilon \leq \epsilon_0$ *and* $x_0 \in G$ *with* $\varsigma^\epsilon(0) < r \leq \epsilon^{-1/2}h_0$, *the following holds:*

$$E_{x_0}[u(\varsigma^\epsilon(\tau))] + cE_{x_0}[\tau] - \frac{1}{2}\alpha_0^2 u'(0)E_{x_0}[\epsilon^{1/2}l^\epsilon(\tau)] \leq u(\varsigma^\epsilon(0)) \leq u(0) \tag{7.3}$$

Likewise, in the case of $\varsigma(t)$, *for any stopping time* $\tau \leq \eta_r, 0 \leq \varsigma(0) < r, x^0(0) = y \in \partial D$, *the following holds*

$$E_{\varsigma(0),y}[u(\varsigma(\tau)); \tau < \infty] + cE_{\varsigma(0),y}[\tau] - \frac{1}{2}\alpha_0^2 u'(0)E_{\varsigma(0),y}[l(\tau)] \leq u(\varsigma(0)) \leq u(0). \tag{7.4}$$

We also allow $r = \infty, \tau \leq \infty$ *in the case of* $\varsigma(t)$, *provided* u *is bounded.*

Proof. We will give the argument for $\varsigma^\epsilon(t)$, the case of $\varsigma(t)$ is analogous. Applying Itô's formula,

$$du(\varsigma^\epsilon(t)) = \mathscr{G}^\epsilon u(t)dt + \alpha(x^\epsilon(t))u'(\varsigma^\epsilon(t))d\beta(t) + \frac{\epsilon^{1/2}}{2}u'(0)\alpha(x^\epsilon(t))^2 dl^\epsilon(t),$$

where

$$\begin{aligned}\mathscr{G}^\epsilon u(t) &= \frac{1}{2}\alpha(x^\epsilon(t))^2 u''(\varsigma^\epsilon(t)) + [\epsilon^{-1/2}\mathscr{L}^\epsilon \rho(x^\epsilon(t))] \cdot u'(\varsigma^\epsilon(t)) \\ &\leq \frac{\alpha(x^\epsilon(t))^2}{\alpha_0^2}\left[\frac{1}{2}\alpha_0^2 u''(\varsigma^\epsilon) + k(\varsigma^\epsilon)u'(\varsigma^\epsilon)\right] \leq -c.\end{aligned}$$

The first inequality follows from (7.1) and the hypothesis that $u' \leq 0$; the second follows from (2.7) and $c \geq 0$. Thus for any finite T,

$$E[u(\varsigma^\epsilon(T \wedge \tau))] - u(\varsigma^\epsilon(0)) \leq -cE[T \wedge \tau] + \frac{1}{2}u'(0)\alpha_0^2 E[\epsilon^{1/2}l^\epsilon(T \wedge \tau)]. \tag{7.5}$$

Rearranging (7.5), and using the monotonicity of u,

$$E[u(\zeta^\epsilon(T\wedge\tau))]+cE[T\wedge\tau]-\frac{1}{2}\alpha_0^2u'(0)E[\epsilon^{1/2}l^\epsilon(T\wedge\tau)]\le u(\zeta^\epsilon(0))\le u(0)$$

Letting $T\to\infty$ yields (7.3). □

We now exhibit the particular choices of u that yield the esimates we want. Define

$$\Phi(z)=\frac{2}{\alpha_0^2}\int_0^z k(s)ds \text{ for } z\ge 0.$$

It follows from $K>0$ that $e^{-\Phi(z)}$ is integrable. Take

$$u_1(z)=\frac{2}{\alpha_0^2}\int_z^\infty e^{-\Phi(s)}ds \quad \textit{for all } z\ge 0,$$

$$u_2(z)=\frac{u_1(z)}{u_1(0)},$$

and, for any specified $r>0$,

$$u_{3,r}(z)=2\alpha_0^{-2}\int_z^r\int_0^s e^{\Phi(u)-\Phi(s)}duds \text{ for } 0\le z\le r.$$

Each of these is C^2 and nonincreasing.

In the case of u_1 we have

$$Gu_1=0, u_1'(0)=-\frac{2}{\alpha_0^2}.$$

LEMMA 7.2. *For all* $0<\epsilon\le\epsilon_0, x_0\in G$ *with* $\zeta^\epsilon(0)<\epsilon^{-1/2}h_0, y\in\partial D$ *and* $\zeta_0>0$,

$$E_{x_0}[\epsilon^{1/2}l^\epsilon(\tau_\Gamma)]\le u_1(0)$$
$$E_{\zeta_0,y}[l(\infty)]\le u_1(0).$$

Proof. The first follows by using $r=\epsilon^{-1/2}h_0$ in Lemma 7.1, noting that $\eta_r^\epsilon=\tau_\Gamma$, and using $u_1(r)\ge 0$. The second uses $r=\infty$ and $u_1(\infty)=0$. □

Considering u_2 yields the next estimate.

LEMMA 7.3. *For all* $0<\epsilon\le\epsilon_0, x_0\in G$ *with* $\zeta^\epsilon(0)<\epsilon^{-1/2}h_0, y\in\partial D$ *and* $\zeta_0>0$,

$$P_{x_0}[\tau_{\partial D}<\tau_\Gamma]\le u_2(\zeta^\epsilon(0))$$
$$P_{\zeta_0,y}[\eta_0<\infty]\le u_2(\zeta_0)$$

Proof. Again $Gu_2=0$. For the case of ζ^ϵ let $r=\epsilon^{-1/2}h_0$ and $\tau=\tau_{\partial D}\wedge\eta_r^\epsilon=\tau_{\partial D}\wedge\tau_\Gamma$. Since $u_2'(0)\le 0, u_2(0)=1$, and $u_2(r)\ge 0$

$$\begin{aligned}P_{x_0}[\tau_{\partial D}<\tau_\Gamma]&=E_{x_0}[u_2(\zeta^\epsilon(\tau));\tau=\tau_{\partial D}]\\&\le E_{x_0}[u_2(\zeta^\epsilon(\tau))]\\&\le u_2(\zeta^\epsilon(0)).\end{aligned}$$

The argument is similar for ζ, using $r=\infty$ and $\tau=\eta_0$. □

Using $u_{3,r}$, we obtain the following.

LEMMA 7.4. *For all* $0 < \epsilon \le \epsilon_0, x_0 \in G$ *with* $\varsigma^\epsilon(0) < r \le \epsilon^{-1/2}h_0, y \in \partial D$ *and* $\varsigma_0 < r$

$$E_{x_0}[\eta_r^\epsilon] \le u_{3,r}(0)$$
$$E_{zz_0,y}[\eta_r] \le u_{3,r}(0).$$

Proof. This time we have

$$Gu_{3,r} = -1;\ u'_{3,r}(0) = 0,\ u_{3,r}(r) = 0.$$

Simply apply Lemma 7.1 using $\tau = \eta_r^\epsilon$ (or η_r in the case of $\varsigma(t)$) and observe that $0 \le E[u(\varsigma^\epsilon(\tau))]$.

COROLLARY 7.1. *For all* $0 < \epsilon \le \epsilon_0, x_0 \in G$ *with* $\varsigma^\epsilon(0) < r \le \epsilon^{1/2}h_0, y \in \partial D, \varsigma_0 < r$ *and* $T < \infty$,

$$P_{x_0}[\eta_r^\epsilon > T] \le \frac{1}{T}u_{3,r}(0)$$
$$P_{\varsigma_0,y}[\eta_r > T] \le \frac{1}{T}u_{3,r}(0)$$

Proof. The proof is Chebyshev's inequality. □

8. Proof of Theorem 2.1. Take any fixed $\epsilon > 0$. To prove Theorem 2.1 consider the process $r(t) = \rho(x^\epsilon(t))$ defined on $[0, \tau_\Gamma]$. According to Itô's formula

$$dr(t) = \mathscr{L}^\epsilon\rho(x^\epsilon(t))dt + \epsilon^{1/2}\langle\sigma^T\nabla\rho(x^\epsilon(t)), dw(t)\rangle + \frac{\epsilon}{2}\alpha(x^\epsilon(t))^2 dl^\epsilon(t),$$

since $\langle\nabla\rho(y), \eta(y)\rangle = -\alpha(y)^2$ for $y \in \partial D$. For each $h > 0$ define a C^1, piecewise C^2 function $\psi_h : [0, \infty) \to \mathbb{R}$ by

$$\psi_h''(u) = -h^{-1}\chi_{[0,h]}(u),\ \psi_h'(0) = 1,\ \psi_h(0) = 0.$$

It is elementary to check that

$$\psi_h'(u) = \begin{cases} 1 - u/h & 0 \le u \le h \\ 0 & h \le u \end{cases} \tag{8.1}$$

and

$$0 \le \psi_h(u) \le \frac{1}{2}h. \tag{8.2}$$

We want to apply Itô's formula to $\psi_h(r(t)) \cdot f(x^\epsilon(t))$, so assume that $f \in C^2(G)$. (Although ψ_h is not C^2, we can use a sequence of smooth approximants to justify the following.)

$$\begin{aligned} d[\psi_h(r(t))f(x^\epsilon(t))] = {} & [f \cdot \psi_h' \cdot \mathscr{L}^\epsilon\rho + \frac{\epsilon}{2}f\psi_h''\langle\nabla\rho, a\nabla\rho\rangle]dt \\ & + f \cdot \psi_h' \cdot \epsilon^{1/2}\langle\sigma^T\nabla\rho, dw\rangle + \frac{\epsilon}{2}f\psi_h'\alpha^2 dl^\epsilon \\ & + \psi_h \cdot \mathscr{L}^\epsilon f dt + \psi_h \cdot \epsilon^{1/2}\langle\sigma^T\nabla f, dw\rangle - \frac{\epsilon}{2}\psi_h\langle\nabla f, \eta\rangle dl^\epsilon \\ & + \frac{\epsilon}{2}\sum_1^n \psi_h' \cdot \langle\nabla\rho, a\nabla f\rangle dt. \end{aligned}$$

By construction, on ∂D we know that $\psi_h' = 1$ and $\psi_h \langle \nabla f, \eta \rangle = 0$. Because dl^ϵ is supported on $\{t : x^\epsilon(t) \in \partial D\}$, we can express the above as

$$\begin{aligned}\int_0^\tau \frac{1}{h}\chi_{[0,h]}(r) f(x) \cdot \langle n, an\rangle dt = &\int_0^{\tau_\Gamma} f(x^\epsilon)\alpha(x^\epsilon)^2 dl^\epsilon(t) \\ &+ \int_0^{\tau_\Gamma} \psi_h \cdot \Phi_1 dt + \int_0^{\tau_\Gamma} \psi_h' \cdot \Phi_2 dt \\ &+ \int_0^{\tau_\Gamma} \psi_h \cdot \langle \Phi_3, dw\rangle + \int_0^{\tau} \psi_h' \langle \Phi_4, dw\rangle \\ &+ f(x^\epsilon(0))\psi_h(r(0)) - f(x^\epsilon(\tau_\Gamma))\psi_h(r(\tau_\Gamma)).\end{aligned} \tag{8.3}$$

Here $\Phi_i, i = 1, \cdots, 4$ are bounded continuous functions on G (depending on f and ϵ) evaluated at $x^\epsilon(t)$.

It follows from Lemma 7.4 that for $\epsilon > 0$ fixed, $E_{x_0}[\tau_\Gamma]$ is uniformly bounded over $x_0 \in G$. This together with (8.2) implies that all the terms in (8.3) with a factor of ψ_h converge to 0 in the mean, as $h \downarrow 0$. From (8.1) it follows that the terms involving ψ_h' converge in the mean to

$$\int_0^{\tau_\Gamma} \chi_{\{0\}}(r(t))\Phi_2 dt$$

and

$$\int_0^{\tau_\Gamma} \chi_{\{0\}}(r(t))\langle \Phi_4, dw\rangle.$$

But these are both 0 almost surely, by virtue of (2.15). This proves Theorem 1 for $f \in C^2(G)$. The general $f \in C(G)$ can be uniformly approximated by $C^2(G)$ functions to yield Theorem 1 in its stated generality.

9. Proof of Theorem 4.1. Our proof of Theorem 4.1 will use the fact that, on bounded time intervals, $x^\epsilon(t)$ converges to $x^0(t)$ uniformly in t, and uniformly over all $x^\epsilon(0) = x^0(0) = y \in \partial D$. This follows from large deviations results, such as in [1]. However, it is not necessary to appeal to such deep results. We will give an independent proof, suited to our particular context.

Two special notations will be useful. First, for $\phi : [0, T] \to \mathbb{R}^d$ (or $\mathbb{R}^1$), define

$$[\phi]_t = \sup_{0 \le u \le t} |\varphi(u)|, t \le T.$$

Secondly, for functions $f : \partial D \to \mathbb{R}$ define

$$\|f\|_{\partial D} = \sup_{y \in \partial D} |f(y)|.$$

At several stages below we will have a one-dimensional Skorohod equation of the form

$$\psi(t) = \varphi(t) + m(t); \psi(t) \ge 0, \tag{9.1}$$

where all 3 functions are continuous and $m(t)$ is nondecreasing and obeys

$$dm(t) = \chi_{\{0\}}(\psi(t))dm(t).$$

We will use the fact that the solution is determined uniquely from $\varphi(\cdot)$ by the formula

$$m(t) = -\inf_{0 \le u \le t}(\varphi(u) \wedge 0); \tag{9.2}$$

see [9, Lemma 4.2, p. 119].

LEMMA 9.1. $[x^\epsilon - x^0]_T \to 0$ *in probability, uniformly over* $x^\epsilon(0) = x^0(0) = y \in \partial D$; *i.e., given any* $T, \delta > 0$

$$\sup_{y \in D} P_y[[x^\epsilon - x^0]_T > \delta] \to 0 \text{ as } \epsilon \downarrow 0.$$

Proof. It suffices to consider $0 < \delta < h_0$. Since $x^0(0) = y \in \partial D$ we know that $x^0(t) \in \partial D$, for all $t \geq 0$. Thus

$$\{\tau_\Gamma < T\} \subseteq \{[x^\epsilon - x^0]_{\tau_\Gamma \wedge T} > \delta\}.$$

Therefore

$$\{[x^\epsilon - x^0]_T > \delta\} \subseteq \{[x^\epsilon - x^0]_T > \delta; \tau_\Gamma \geq T\} \cup \{\tau_\Gamma < T\}$$

$$\subseteq \{[x^\epsilon - x^0]_{\tau_\Gamma \wedge T} > \delta\}.$$

Now applying Itô's formula, we have, for $0 \leq t \leq \tau_\Gamma$,

$$\rho(x^\epsilon(t)) = \Phi^\epsilon(t) + \frac{\epsilon}{2}\alpha(x^\epsilon(t))^2 l^\epsilon(t), \ \rho(x^\epsilon(t)) \geq 0$$

$$l^\epsilon(t) = \int_0^t \chi_{\{0\}}(\rho(x^\epsilon(t))dl^\epsilon(t),$$

where

$$\Phi^\epsilon(t) = \int_0^t \mathscr{L}^\epsilon \rho(x^\epsilon(s))ds + \epsilon^{1/2}\int_0^t \langle \sigma^T \nabla \rho(x^\epsilon(s)), dw(s)\rangle.$$

This is a one-dimensional Skorohod equation (9.1), so that by (9.2) we have (almost surely)

$$\frac{\epsilon}{2}\alpha_0^2 l^\epsilon(t) \leq \frac{\epsilon}{2}\alpha(x^\epsilon(t))^2 l^\epsilon(t) = -\inf_{[0,t]}(\Phi^\epsilon(t) \wedge 0).$$

Now by (2.5) and (2.12),

$$\Phi^\epsilon(t) = \int_0^t \frac{\epsilon}{2}\sum a_{ij}\rho_{x_i x_j}(x^\epsilon(s)) + \langle b(x^\epsilon(s)), \nabla\rho(x^\epsilon(s))\rangle ds$$

$$+ \epsilon^{1/2}\int_0^t \langle \sigma^T \nabla \rho(x^\epsilon(s)), dw(s)\rangle$$

$$\geq \epsilon A_0 t - \epsilon^{1/2}\left|\int_0^t \langle \sigma^T \nabla \rho, dw(s)\rangle\right|$$

Thus for all $0 \leq t \leq \tau_\Gamma \wedge T$,

$$\frac{\epsilon}{2}\alpha_0^2 l^\epsilon(t) \leq \epsilon|A_0|t + \epsilon^{1/2}\left[\int_0^\cdot \langle \sigma^T \nabla \rho(x^\epsilon(s)), dw(s)\rangle\right]_{T \wedge \tau_\Gamma}$$

But a standard application of Gronwall's inequality applied to (2.13) tells us that

$$[x^\epsilon - x^0]_{\tau_\Gamma \wedge T} \leq e^{MT}\left[\epsilon^{1/2}\int_0^\cdot \sigma dw(s) - \int_0^\cdot \frac{\epsilon}{2}\eta(x^\epsilon)dl^\epsilon\right]_{\tau_\Gamma \wedge T}$$

$$\leq e^{MT}\left(\epsilon^{1/2}\left[\int_0^\cdot \sigma dw\right]_{\tau_\Gamma \wedge T} + \frac{\epsilon}{2}C[l^\epsilon]_{\tau_\Gamma \wedge T}\right),$$

where M is a Lipschitz constant for $b(\cdot)$, and C is a bound on $|\eta(y)|$ over ∂D. Therefore

$$
\begin{aligned}
[x^\epsilon - x^0]_{\tau_\Gamma \wedge T} \leq e^{MT} \Bigg(& \epsilon |A_0| \frac{C}{\alpha_0^2} T + \epsilon^{1/2} \left[\int_0^{\cdot} \sigma(x^\epsilon(s)) dw(s) \right]_{\tau_\Gamma \wedge T} \\
& + \epsilon^{1/2} \frac{C}{\alpha_0^2} \left[\int_0^{\cdot} \langle \sigma^T \nabla \rho(x^\epsilon(s)), dw(s) \rangle \right]_{\tau_\Gamma \wedge T} \Bigg).
\end{aligned} \tag{9.3}
$$

By a standard estimation argument (e.g. [15, (2.1), p. 87]),

$$
\begin{aligned}
& P_y \left[\left[\int_0^{\cdot} \sigma(x^\epsilon(s)) dw(s) \right]_T \geq \lambda \right]_T \leq 2d \cdot \exp\left(\frac{-\lambda^2}{2dA_1 T} \right) \\
& P_y \left[\left[\int_0^{\cdot} \langle \sigma \nabla \rho(x^\epsilon(s)), dw(s) \rangle \right]_{T \wedge \tau_\Gamma} \geq \lambda \right] \leq 2 \exp\left(\frac{-\lambda^2}{2A_1 T} \right),
\end{aligned} \tag{9.4}
$$

where A_1 is as in (2.6). Using these estimates in (9.3) implies the lemma. □

Next we want to establish convergence of $\varsigma^\epsilon(\cdot)$, defined by (4.1), to $\varsigma(\cdot)$ of (4.7), and $\epsilon^{1/2} l^\epsilon(\cdot)$ to $l(\cdot)$. Defining the one-dimensional Brownian motion $\beta(\cdot)$ by (4.6), (4.4) becomes

$$
d\varsigma^\epsilon(t) = \epsilon^{1/2} \mathscr{L}^\epsilon \rho(x^\epsilon(t)) + \alpha(x^\epsilon(t)) d\beta(t) + \frac{\epsilon^{1/2}}{2} dl^\epsilon(t).
$$

We noted previously that the $\beta(\cdot)$ here is ϵ-dependent and distinct from the $\beta(\cdot)$ in (4.7), so we should talk about weak or distributional convergence of $\varsigma^\epsilon(\cdot)$ to $\varsigma(\cdot)$. However, the distribution of $\varsigma(\cdot)$ is the same regardless of the choice of $\beta(\cdot)$ in (4.7). So, for each ϵ, we can take the $\beta(\cdot)$ of (4.7) to be that defined by (4.6), with a suitable extension to $t > \tau_\Gamma$. Now $\varsigma^\epsilon(\cdot)$ and $\varsigma(\cdot)$ are defined on a common (but ϵ-dependent) probability space so we can make pathwise comparisons. We do, however, need to limit $x^\epsilon(0) = x^0(0) = y$ to points $y \in \partial D$ and $\varsigma(0) = \varsigma^\epsilon(0) = 0$, since (4.7) is only well defined for $x^0(\cdot) \in \partial D$. Under these conventions, the expectation $E_{0,y}$ (associated with $\varsigma(\cdot)$) coincides with E_y (associated with $x^\epsilon(\cdot)$ and $\varsigma^\epsilon(\cdot)$); i.e., both symbols refer to integrals with respect to the same probability measure on the same probability space. With this understanding we have the following result.

LEMMA 9.2. *$[\varsigma^\epsilon - \varsigma]_{T \wedge \eta_r^\epsilon}$ and $[\epsilon^{1/2} l^\epsilon - l]_{T \wedge \eta_r^\epsilon}$ converge to 0 in L^2, uniformly over $y = x^\epsilon(0) = x^0(0) \in \partial D$; i.e., given any $T, \delta, r > 0$,*

$$
\sup_{y \in \partial D} E_y [[\varsigma^\epsilon - \varsigma]^2_{T \wedge \eta_r^\epsilon}] \to 0,
$$

and

$$
\sup_{y \in \partial D} E_y [[\epsilon^{1/2} l^\epsilon - l]^2_{T \wedge \eta_r^\epsilon}] \to 0,
$$

as $\epsilon \downarrow 0$.

Proof. Let us abbreviate (4.4) and (4.7) as

$$
\begin{aligned}
& \varsigma^\epsilon(t) = \Psi^\epsilon(t) + M^\epsilon(t), \ M^\epsilon(t) = \int_0^t \chi_{\{0\}}(\varsigma^\epsilon(s)) dM^\epsilon(s) \\
& \varsigma(t) = \Psi(t) + M(t), \ M(t) = \int_0^t \chi_{\{0\}}(\varsigma(s)) dM(s).
\end{aligned} \tag{9.5}
$$

where

$$
\Psi^\epsilon(t) = \int_0^t \epsilon^{-1/2} \mathscr{L}^\epsilon \rho(x^\epsilon(s)) ds + \int_0^t \alpha(x^\epsilon(s)) d\beta(s),
$$

$$\Psi(t) = \int_0^t b_1(x^0(s))\varsigma(s)ds + \int_0^t \alpha(x^0(s))d\beta(s),$$

and

$$M^\epsilon(t) = \frac{\epsilon^{1/2}}{2}\int_0^t \alpha(x^\epsilon(s))^2 dl^\epsilon(s)$$

$$M(t) = \frac{1}{2}\int_0^t \alpha(x^0(s))^2 dl(s).$$

From (9.2) we have

$$M^\epsilon(t) = -\inf_{[0,t]}(0 \wedge \Psi^\epsilon),\ M(t) = -\inf_{[0,t]}(0 \wedge \Psi).$$

Therefore for $t \leq \tau_\Gamma$

$$[M^\epsilon - M]_t \leq [\Psi^\epsilon - \Psi]_t, \tag{9.6}$$

and, by subracting the two equations in (9.5),

$$[\varsigma^\epsilon - \varsigma]_{t\wedge\eta_r^\epsilon} \leq 2[\Psi^\epsilon - \Psi]_{t\wedge\eta_r^\epsilon}. \tag{9.7}$$

Now we also know that

$$\Psi^\epsilon(t) - \Psi(t) = \int_0^t b_1(x^\epsilon(s))\varsigma^\epsilon(s) - b_1(x^0(s))\varsigma(s) + o(1)ds + \int_0^t \alpha(x^\epsilon(s)) - \alpha(x^0(s))d\beta(s),$$

and so

$$[\Psi^\epsilon - \Psi]_t \leq \int_0^t |b_1(x^0(s))| \cdot [\varsigma^\epsilon - \varsigma]_s + [b_1(x^\epsilon(\cdot)) - b_1(x^0(\cdot))]_s|\varsigma^\epsilon(s)| + o(1)\ ds + \left[\int_0^\cdot \alpha(x^\epsilon(s)) - \alpha(x^0(s))d\beta(s)\right]_t. \tag{9.8}$$

Recall that the $o(1)$ is uniform so long as ς^ϵ stays in a compact set. Since $|\varsigma^\epsilon(s)| \leq r$ for $s \leq \eta_r^\epsilon$, we can write

$$[\Psi^\epsilon - \Psi]_{t\wedge\eta_r^\epsilon} \leq \int_0^t N[\varsigma^\epsilon - \varsigma]_{s\wedge\eta_r^\epsilon}ds + D_b^\epsilon + D_\beta^\epsilon + o(1) \tag{9.9}$$

where

$$N = \sup_{y\in\partial D}|b_1(y)|$$

$$D_b^\epsilon = T \cdot r \cdot [b_1(x^\epsilon) - b_1(x^0)]_T$$

$$D_\beta^\epsilon = \left[\int_0^\cdot \alpha(x^\epsilon(s)) - \alpha(x^0(s))d\beta\right]_{T\wedge\eta_r^\epsilon}.$$

Putting (9.7) and (9.9) together, we can apply Gronwall's lemma to conclude that

$$[\varsigma^\epsilon - \varsigma]_{T\wedge\eta_r^\epsilon} \leq 2[o(1) + D_b^\epsilon + D_\beta^\epsilon]e^{2NT}.$$

We want to argue that $\|D_b^\epsilon\|_2$ and $\|D_\beta^\epsilon\|_2$ converge to 0 as $\epsilon \downarrow 0$, uniformly over $y \in \partial D$. For D_b^ϵ this follows from Lemma 9.1 and the continuity of b_1 on G. For D_β^ϵ,

we can use Doob's martingale inequality to estimate

$$P[|D_\beta^\epsilon| \geq \lambda] \leq \lambda^{-2} E\left[\left(\int_0^{T\wedge\eta_r^\epsilon} \alpha(x^\epsilon(s)) - \alpha(x^0(s))d\beta(s)\right)^2\right]$$
$$\leq \lambda^{-2} E\left[\int_0^T |\alpha(x^\epsilon(s)) - \alpha(x^0(s))|^2 ds\right],$$

which converges to 0, uniformly over $y \in \partial D$, by virtue of Lemma 9.1 and the continuity of α. Thus $D_\beta^\epsilon \to 0$ in probability, uniformly over ∂D. Next since $\|D_\beta^\epsilon\|_p$ is bounded in y, any $2 < p < \infty$ (by virtue of an estimate similar to (9.4)), $|D_\beta^\epsilon|^2$ is uniformly integrable over $\epsilon > 0$ and $y \in \partial D$. These two facts together imply that $\|D_\beta^\epsilon\|_2 \to 0$ as claimed.

We have now shown that $[\varsigma^\epsilon - \varsigma]_{T\wedge\eta_r^\epsilon}$ and, by (9.9), $[\Psi^\epsilon - \Psi]_{T\wedge\eta_r^\epsilon}$ both $\to 0$ in L^2. It follows from (9.5) that $[M^\epsilon - M]_{T\wedge\eta_r^\epsilon} \to 0$ in L^2 as well. To finish, write

$$\epsilon^{1/2} l^\epsilon(t) - l(t) = \int_0^t \frac{2}{\alpha(x^\epsilon(s))^2} dM^\epsilon - \int_0^t \frac{2}{\alpha(x^0(s))^2} dM.$$

It follows from this that

$$[\epsilon^{1/2} l^\epsilon - l]_{T\wedge\eta_r^\epsilon} \leq \|\frac{2}{\alpha}\|_{\partial D} [M^\epsilon - M]_{T\wedge\eta_r^\epsilon} + \left[\frac{2}{\alpha(x^0(\cdot))^2} - \frac{2}{\alpha(x^\epsilon(\cdot))^2}\right]_{T\wedge\eta_r^\epsilon} M^\epsilon_{T\wedge\eta_r^\epsilon}.$$

We know that the first term on the right $\to 0$ in L^2. For the second, one argues uniform integrability of $M^\epsilon_{T\wedge\eta_r^\epsilon}$ and then applies Lemma 9.1, using the continuity of $\frac{2}{\alpha(\cdot)^2}$. □

As an immediate corollary we have the following.

COROLLARY 9.1. *For any $r, T > 0, \epsilon^{1/2} l^\epsilon(T \wedge \eta_r^\epsilon)$ are uniformly integrable over all $0 < \epsilon \leq \epsilon_0$ with $e^{1/2} r < h_o$ and $y \in \partial D$.*

At last we are ready to undertake a proof of Theorem 4.1. First, by virtue of Lemma 7.2, for all $0 < \epsilon \leq \epsilon_0$,

$$\|\epsilon^{1/2} B^\epsilon[f] - \epsilon^{1/2} B^\epsilon[g]\|_{\partial D} \leq u_1(0)\|f - g\|_{\partial D}$$

and

$$\|B[f] - B[g]\|_{\partial D} \leq u_1(0)\|f - g\|_{\partial D}.$$

It therefore suffices to prove Theorem 4.1 for f in a dense subset of $C(\partial D)$. We will assume that $f \in C^1(\partial D)$. The idea is to estimate the individual terms in the following inequality, for given $r, T < \infty$.

$$|\epsilon^{1/2} B^\epsilon[f](y) - B[f](y)| \leq I + II + III + IV \tag{9.10}$$

where

$$I = \left|E_y\left[\int_{T\wedge\eta_{r^\epsilon}}^{\tau_\Gamma} f(x^\epsilon(t))\epsilon^{1/2} dl^\epsilon\right]\right|,$$

$$II = E_y\left[\int_0^{T\wedge\eta_r^\epsilon} |f(x^\epsilon(t)) - f(x^0(t))|\epsilon^{1/2} dl^\epsilon\right],$$

$$III = E_y\left[\left|\int_0^{T\wedge\eta_r^\epsilon} f(x^0(t))\epsilon^{1/2} dl^\epsilon - \int_0^{T\wedge\eta_r^\epsilon} f(x^0(t))dl\right|\right],$$

$$IV = E_y\left[\int_{T\wedge\eta_{r^\epsilon}}^{\infty} |f(x^0(t))|dl\right].$$

First consider I. Define

$$\tau^*_{\partial D} = \inf\{t \geq T \wedge \eta^\epsilon_r : x^\epsilon(t) \in \partial D\}.$$

By the strong Markov property and Lemma 7.2

$$E_y\left[\int_{T\wedge\eta^\epsilon_r}^{\tau_\Gamma} \epsilon^{1/2} dl^\epsilon\right] = E_y[E_{x^\epsilon(\tau^*_{\partial D})}[\epsilon^{1/2} l(\tau_\Gamma)],\ \tau^*_{\partial D} < \tau_\Gamma]$$

$$\leq u_1(0) P_y[\tau^*_{\partial D} < \tau_\Gamma]. \tag{9.11}$$

Now on $\{\eta^\epsilon_r \leq T\}$ the event $\{\tau^*_{\partial D} < \tau_\Gamma\}$ requires that $\varsigma^\epsilon(t)$ return from r to 0 before τ_Γ. Using Lemma 7.3, it follows that

$$P_y[\tau^*_{\partial D} < \tau_\Gamma; \eta^\epsilon_r \leq T] \leq u_2(r).$$

Thus

$$P_y[\tau^*_{\partial D} < \tau_r] \leq u_2(r) + P_y[\eta^\epsilon_r > T]$$

$$\leq u_2(r) + \frac{1}{T} u_{3,r}(0),$$

where we have appealed to Corollary 7.1. Using this in (9.11), we see that

$$I \leq \|f\|_{\partial D} u_1(0) \cdot \left[u_2(r) + \frac{1}{T} u_{3,r}(0)\right]. \tag{9.12}$$

Now consider II. If we extend f continuously from ∂D to all of $\overline{D}$, then we can write

$$II \leq E_y\left[[f(x^\epsilon(\cdot) - f(x_0(\cdot))]_T \cdot \epsilon^{1/2} l^\epsilon(T \wedge \eta^\epsilon_r)\right].$$

It follows from Lemma 9.1 that $[f(x^\epsilon) - f(x^0)]_T \to 0$ in probability, uniformly over $y \in \partial D$. This and Corollary 9.1 imply that

$$II \to 0 \text{ as } \epsilon \downarrow 0, \text{uniformly over } y \in \partial D. \tag{9.13}$$

Next consider III. Since $f \in C^1(\partial D)$, $f(x^0(t))$ is continuously differentiable. Let $\varphi(t) = d/dt\, f(x^0(t))$. We can integrate by parts to write

$$\int_0^{T\wedge\eta^\epsilon_r} f(x^0(t)) \epsilon^{1/2} dl^\epsilon = f(x^0(T \wedge \eta^\epsilon_r)) \cdot \epsilon^{1/2} l^\epsilon(T \wedge \eta^\epsilon_r) - \int_0^{T\wedge\eta^\epsilon_r} \varphi(t) \epsilon^{1/2} l^\epsilon(t) dt,$$

and likewise for the second integral in III. Therefore

$$III \leq |E_y[f(x^0(T \wedge \eta^\epsilon_r)) \cdot (\epsilon^{1/2} l^\epsilon(T \wedge \eta^\epsilon_r) - l(T \wedge \eta^\epsilon_r))]|$$

$$+ |E_y[\int_0^{T\wedge\eta^\epsilon_r} \varphi(t)[\epsilon^{1/2} l^\epsilon(t) - l(t)] dt]|$$

$$\leq (\|f\|_{\partial D} + \|\varphi\|_\infty) E_y[[\epsilon^{1/2} l^\epsilon - l]_{T\wedge\eta^\epsilon_r}].$$

Now Lemma 9.2 tells us that

$$III \to 0 \text{ as } \epsilon \downarrow 0, \text{ uniformly over } y \in \partial D. \tag{9.14}$$

Finally consider IV. Define

$$\eta^*_0 = \inf\{t \geq T \wedge \eta^\epsilon_r : \varsigma(t) = 0\}.$$

Then just as in (9.11),

$$E_y\left[\int_{T\wedge\eta^\epsilon_r}^{\infty} dl\right] = E_{0,y}[E_{0,x^0(\eta^*_0)}[l(\infty)]; \eta^*_0 < \infty] \leq u_1(0) \cdot P_{0,y}[\eta^*_0 < \infty] \tag{9.15}$$

and

$$P_{0,y}[\eta_0^* < \infty] \leq P_{0,y}[\eta_0^* < \infty; \eta_r^\epsilon \leq T] + P_{0,y}[\eta_r^\epsilon > T]. \tag{9.16}$$

From Corollary 7.1,

$$P_{0,y}[\eta_r^\epsilon > T] \leq \frac{1}{T} u_{3,r}(0). \tag{9.17}$$

Now for any $0 < \delta < r$ if $[\zeta - \zeta^\epsilon]_{T \wedge \eta_r^\epsilon} \leq \delta$ and $\eta_r^\epsilon \leq T$, then $\zeta(\eta_r^\epsilon) \geq \zeta^\epsilon(\eta_r^\epsilon) = r - \delta$, so that $\eta_{r-s} \leq \eta_r^\epsilon \leq T$. Therefore

$$P_{0,y}[\eta_0^*; \eta_r^\epsilon \leq T] \leq P_{0,y}[\eta_0^*; \eta_{r-\delta} \leq T \wedge \eta_r^\epsilon] + P_y[[\zeta - \zeta^\epsilon]_{T \wedge \eta_r^\epsilon} > \delta]. \tag{9.18}$$

The second term on the right converges to 0 as $\epsilon \downarrow 0$, uniformly over $y \in \partial D$. The first requires that $\zeta(t)$ return from $r - \delta$ to 0 in finite time. Therefore, appealing to Lemma 7.3 again

$$P_{0,y}[\eta_0^* < \infty; \eta_{r-\delta} \leq T \wedge \eta_r^\epsilon] \leq u_2(r - \delta). \tag{9.19}$$

Putting (9.15)-(9.19) together, we conclude that

$$\overline{\lim}_{\epsilon \downarrow 0} \sup_{y \in D} IV \leq \|f\|_{\partial D} \cdot u_1(0)(u_2(r - \delta) + \frac{1}{T} u_{3,r}(0)]. \tag{9.20}$$

When we put (9.12)–(9.14) and (9.20) back into (9.10) we see that, for any $r, T < \infty$ and $0 < \delta < r$,

$$\overline{\lim}_{\epsilon \downarrow 0} \|\epsilon^{1/2} B^\epsilon[f] - B[f]\|_{\partial D} \leq \|f\|_{\partial D} u_1(0) \left[u_2(r) + u_2(r - \delta) + \frac{2}{T} u_{3,r}(0) \right].$$

Finally since $u_2(r) \to 0$ as $r \to \infty$, the right side can be made arbitrarily small by choosing $\delta = 1$ and r, T sufficiently large. This proves Theorem 4.1. □

A DIFFERENTIAL-DELAY EQUATION ARISING IN OPTICS AND PHYSIOLOGY*

JOHN MALLET-PARET† AND ROGER D. NUSSBAUM‡

Abstract. In recent papers the authors have studied differential-delay equations E_ε of the form $\varepsilon\dot{x}(t) = -x(t)+f(x(t-1))$. For functions like $f(x)=\mu_1+\mu_2\sin(\mu_3 x+\mu_4)$, such equations arise in optics, while for choices like $f(x)=\mu x^\nu e^{-x}$ and $f(x)=\mu x^\nu(1+x^\lambda)^{-1}$ and for $x\geqq 0$, the equation has been suggested in physiological models. Under varying hypotheses on f (labeled (I), (II), and (III) below), previous work has given theorems concerning existence and asymptotic properties as $\varepsilon\to 0^+$ of periodic solutions of E_ε which oscillate about a value α such that $f(\alpha)=\alpha$. However, verifying (I), (II), or (III) for specific examples can be difficult. This paper gives general principles that help in verifying (I), (II), or (III), and then applies these results to specific classes of functions of interest.

Key words. singularly perturbed differential-delay equation, slowly oscillating periodic solution, Schwarzian derivative

1. Introduction.

The singularly perturbed differential-delay equation

$$\varepsilon\dot{x}(t) = -x(t)+f(x(t-1)), \tag{1.1}$$

which arises in various models in optics, biology, and physiology, has been studied by many authors. See, for example, [2], [4], [5], [7]-[14], [17]-[22], [24], [25], and the references in [20]-[22]. Recently, Mallet-Paret and Nussbaum [20]-[22] have explored the relation between (1.1) and the discrete system

$$x_n = f(x_{n-1}) \tag{1.2}$$

obtained by formally setting $\varepsilon = 0$ in (1.1). Some of the main results of [20], [21] concern the existence and asymptotic behavior of square-wavelike periodic solutions of (1.1) for small ε. However, these results require that f satisfy various hypotheses, which will be given in § 2 below and which may be nontrivial to verify. Typical nonlinearities of interest are

$$f(x) = \mu_1+\mu_2\sin(\mu_3 x+\mu_4), \tag{1.3}$$

which arise in optics, and

$$f(x) = \mu x^\nu e^{-x}, \quad x\geqq 0, \tag{1.4}$$

$$f(x) = \mu x^\nu(1+x^\lambda)^{-1}, \quad x\geqq 0, \tag{1.5}$$

which arise in biological and physiological models. See, for example, [16], where the function in (1.5) is used in (1.1) (for $\nu=0$ or $\nu=1$, $\lambda>0$ and $\mu>0$) to model blood diseases. (Note that various constants appear in the equations in [16], but that by

change of variables the equations (4a) and (4b) in [16] are subsumed by our equation (1.1) with f as in (1.5).)

Unfortunately, verifying the hypotheses of § 2 even for the above simple-looking functions is not trivial and was not carried out in [21] (primarily for reasons of space). For example, one of our hypotheses involves global conditions expressed as qualitative properties of the dynamical system (1.2) and may be hard to check. It seems a significant body of theory is needed, even for the functions in (1.3)-(1.5), to determine exactly when our hypotheses are satisfied; routine calculations are insufficient. Our purpose here is to develop such a theory and then to apply it to determine parameter values for which the above nonlinearities satisfy various hypotheses. Although we have not given actual numerical ranges of parameters where our hypotheses are satisfied, we can, with a simple computer program easily obtain most of them from our results. Thus, this paper may be viewed as a companion to [21], for here we show how to apply the general results of [21] to specific systems of scientific interest.

Our interest naturally extends beyond the nonlinearities in (1.3)-(1.5); however, because so many of the basic difficulties are already apparent for these nonlinearities, we will view them as models and work out their theory in as much detail as possible. Even so, we will leave open questions for these examples.

2. Hypotheses on f and their implications. The following hypotheses were shown in [20], [21] to imply various results about the differential equation (1.1). Note that these hypotheses are arranged in increasing order of strength, and that all assume the condition $f(0)=0$. This assumption is merely a normalization; more generally the functions of interest will have a nonzero fixed point $f(x_0)=x_0$, and it will be necessary to translate this point to the origin before analyzing the function.

We say a function f is *monotone decreasing* in an interval I in case $f(x_1)\geqq f(x_2)$ whenever $x_1<x_2$ and $x_1, x_2\in I$. We say f is *strictly decreasing* in I in case $f(x_1)>f(x_2)$ for all such x_1 and x_2. We make analogous definitions of *monotone increasing* and *strictly increasing.*

We let $f^n:\mathbb{R}\to\mathbb{R}$ denote the n-fold composition of the function f with itself.

We now present four hypotheses a function f can satisfy. These were introduced in [20], [21].

(0) The function $f:\mathbb{R}\to\mathbb{R}$ is continuous, satisfies $f(0)=0$, is differentiable at $x=0$ satisfying $f'(0)<-1$, and is monotone decreasing in some neighborhood of $x=0$.

(I) The function f satisfies hypothesis (0). In addition there exist numbers $A>0$ and $B>0$ such that

$$f([-B, A])\subseteq[-B, A],$$
$$xf(x)<0 \quad \text{if } x\in[-B, A]-\{0\}.$$

(II) There exist A and B such that (I) holds. In addition there exist positive numbers $a\leqq A$ and $b\leqq B$ such that if $x_0\in[-B, A]-\{0\}$ and x_n is given by (1.2), then

$$f^n(x)=x_n\to\{-b, a\} \quad \text{as } n\to\infty.$$

(III) There exist A and B such that (I) holds. In addition f is monotone decreasing in $[-B, A]$ and (II) holds with $a=A$ and $b=B$.

Note that $f(a)=-b$ and $f(-b)=a$ must hold in hypothesis (II). If f only satisfies (I), then there still must exist a and b satisfying $f(a)=-b$ and $f(-b)=a$, respectively. However, the orbit $\{-b, a\}$ of (1.2) need not be stable and attract iterates x_n, and a and b need not be unique.

If (I) holds and f is monotone decreasing on $[-B, A]$ and if f^2 has a unique positive fixed point $a \in (0, A]$, then it is easy to show that (III) is satisfied. To see this, first observe that f^2 has a unique negative fixed point $-b \in [-B, 0)$, $-b = f(a)$. If $-b_1$ and $-b_2$ were negative fixed points of f^2, then $f(-b_1)$ and $f(-b_2)$ would be positive fixed points of f^2, so

$$a = f(-b_1) = f(-b_2),$$

and we could conclude that

$$f(a) = f^2(-b_1) = -b_1 = f^2(-b_2) = -b_2.$$

Next, note that f^2 is monotone increasing on $[-B, A]$ (because f is monotone decreasing) and that there exists $\varepsilon > 0$ such that $|f^2(x)| > x$ for $0 < |x| < \varepsilon$ (because f is monotone decreasing and $f'(0) < -1$). It follows that $f^2(x) > x$ for $0 < x < a$; otherwise, the intermediate value theorem would imply that f^2 has a positive fixed point x_1, with $0 < x_1 < a$. If $0 < y_0 < a$ and $y_n = f^{2n}(y_0)$ we conclude that

$$y_0 < f^2(y_0) = y_1 < f^2(a) = a,$$

and generally that

$$y_n < y_{n+1} < a \quad \forall n \geqq 1.$$

It follows that y_n converges to a limit y, and since $f^2(y) = y$, it must be true that $y = a$. A similar argument shows that if $-b < z_0 < 0$, then

$$\lim_{n \to \infty} f^{2n}(z_0) = -b.$$

Finally, we can deduce that if $-b \leqq x \leqq a$ and $x \neq 0$, then

$$\lim_{n \to \infty} f^n(x) = \{-b, a\}.$$

In fact we can conclude slightly more. If $A > a$, the uniqueness of the positive fixed point of f implies that $f^2(A) < A$ (we know $f^2(A) \leqq A$). Thus the intermediate value theorem implies that if $a < x \leqq A$, $f^2(x) < x$. Using this fact and the fact that f^2 is monotone increasing, we see that if $a < y_0 \leqq A$ and $y_n = f^{2n}(y_0)$, then

$$a < y_{n+1} < y_n \quad \text{for all } n.$$

As before this implies $y_n \to a$. A similar argument shows that if $-B \leqq z_0 < -b$, then

$$\lim_{n \to \infty} f^{2n}(z_0) = -b.$$

Finally, we can conclude that if $-B \leqq x \leqq A$ and $x \neq 0$, then

$$\lim_{n \to \infty} f^n(x) = \{-b, a\}.$$

If, however, f is not monotone decreasing on $[-B, A]$, then verifying (II) directly may be quite difficult, as it involves examining all iterates $x_n = f^n(x_0)$ of an arbitrary initial condition x_0. Furthermore, even if $f'(x) < 0$ for $x \in [-B, A]$, a direct proof that f^2 has exactly one fixed point in $(0, A]$ may not be easy. Fortunately, our theorems will eliminate the need for such an approach, at least in the cases of interest. Instead, checking (II) will involve only local calculations, with no need to iterate f. The main property of f that allows for such a simplification is that it possess a negative Schwarzian derivative. This property was first used in the study of interval maps by Allwright [1] and Singer [27]. If $f'(x) < 0$ for $-B < x < A$ and f has negative Schwarzian derivative on $(-B, A)$, the results of § 7 will imply f^2 has a unique fixed point in $(0, A]$.

In [21], we showed that (I), (II), and (III) each imply results about solutions of (1.1). The solutions of interest are *slowly oscillating periodic solutions*, or SOP-*solutions*. A solution $x(t)$ of (1) is called an SOP-solution if there exist quantities

$$q>1 \quad \text{and} \quad \bar{q}>q+1$$

such that

$$x(0)=x(q)=x(\bar{q})=0,$$
$$x(t)>0 \quad \text{in } (0,q),$$
$$x(t)<0 \quad \text{in } (q,\bar{q}),$$
$$x(t+\bar{q})=x(t) \quad \forall t.$$

For the functions of interest it will always be the case that $xf(x)<0$ whenever $x\neq 0$ is in the range of such a solution. In particular this will imply that the zeros of $x(t)$ are all simple.

An SOP solution $x(t)$ is called an *S-solution* if it satisfies

$$x(t+q)=-x(t) \quad \forall t,$$

in addition to the above conditions. Necessarily f is an odd function throughout the range of an S-solution. Also, $\bar{q}=2q$ for any S-solution.

The following results, which are proved in [21], describe the existence and asymptotic properties for small ε of SOP-solutions and S-solutions when (I), (II), or (III) holds.

THEOREM 2.1. *Assume f satisfies* (I). *Then there exists $\varepsilon_0>0$ such that for each positive $\varepsilon<\varepsilon_0$* (1) *possesses an* SOP-*solution satisfying*

$$x(t)\in(-B,A) \quad \forall t. \tag{2.1}$$

In addition, there exist positive numbers ε_1, γ, K_1, K_2, r_1, and r_2 such that if $x(t)$ is any SOP-*solution of* (1.1) *satisfying* (2.1), *and if $0<\varepsilon<\varepsilon_1$, then*

$$x(t)>\gamma \quad \text{for } K_2\varepsilon\leqq t\leqq q-K_2\varepsilon,$$
$$x(t)<-\gamma \quad \text{for } q+K_2\varepsilon\leqq t\leqq\bar{q}-K_2\varepsilon,$$
$$|\dot{x}(t)|\geqq K_1/\varepsilon \quad \text{whenever } |x(t)|\leqq\gamma,$$
$$1+\varepsilon r_1\leqq q\leqq 1+\varepsilon r_2,$$
$$1+\varepsilon r_1\leqq\bar{q}-q\leqq 1+\varepsilon r_2.$$

THEOREM 2.2. *Assume f satisfies* (II). *Then given $\delta>0$ there exist $\varepsilon_2>0$ and $K_2>0$ such that if $x(t)$ is any* SOP-*solution of* (1) *satisfying* (2.1), *and if $0<\varepsilon<\varepsilon_2$, then*

$$|x(t)-\mathrm{sqw}\,(t)|\leqq\delta \quad \text{in } [\varepsilon K_2, q-\varepsilon K_2]\cup[q+\varepsilon K_2,\bar{q}-\varepsilon K_2]$$

where sqw (t) *is the two-periodic square-wavefunction defined by*

$$\mathrm{sqw}(t)=\begin{cases} a & \text{in } [0,1),\\ -b & \text{in } [1,2),\end{cases}$$
$$\mathrm{sqw}\,(t+2)=\mathrm{sqw}\,(t) \quad \forall t.$$

THEOREM 2.3. *Assume f satisfies* (III). *Let $x(t)$ be any* SOP-*solution of* (1) *satisfying* (2.1) *for some $\varepsilon>0$ (with $a=A$ and $b=B$), and let $p\in(0,q)$ and $\bar{p}\in(q,\bar{q})$ be such that*

$$x(p)=\max x(t) \quad \text{and} \quad x(\bar{p})=\min x(t).$$

Then $x(t)$ is monotone increasing in $(0, p)$, monotone decreasing in $(p, \bar{p})$, and monotone increasing in $(\bar{p}, \bar{q})$.

THEOREM 2.4. *Assume f satisfies* (I) *and that in addition $A = B$ and $f(-x) = -f(x)$ for all $x \in [-A, A]$. Then there exists $\varepsilon_0 > 0$ such that for each positive $\varepsilon < \varepsilon_0$,* (2.1) *possesses an S-solution satisfying*

$$x(t) \in (-A, A) \quad \forall t.$$

In the case of Theorem 2.2 we easily see that

$$x(t) \to \operatorname{sqw}(t) \quad \text{as } \varepsilon \to 0$$

uniformly on compact subsets of $\mathbb{R} - \mathbb{Z}$, for SOP-solutions $x(t)$. Also, when f is odd the S-solutions obtained in Theorem 2.4 are of course SOP-solutions, and hence satisfy the conclusions of Theorems 2.1, 2.2, and 2.3 when the appropriate hypotheses hold.

3. Some specific functions f. We consider $f_k : \mathbb{R} \to \mathbb{R}$, for $1 \leqq k \leqq 5$, defined as follows:

$$f_1(x) = \mu - x^2,$$

$$f_2(x) = x^3 - \mu x,$$

$$f_3(x) = -\mu[\sin(x + \theta) - \sin\theta],$$

$$f_4(x) = \mu x^\nu e^{-x}, \qquad x \geqq 0,$$

$$f_5(x) = \frac{\mu x^\nu}{x^\lambda + 1}, \qquad x \geqq 0.$$

The values of f_4 and f_5 for $x < 0$ are immaterial, so for definiteness we set

$$f_k(x) = f_k(0) \quad \text{if } x < 0 \text{ and } k = 4 \text{ or } 5,$$

always assuming $\nu \geqq 0$ and $\lambda \geqq 0$. The functions f_1 and f_2 give model problems with the simplest possible nonlinearities; in particular f_1 is the much-studied quadratic map of the interval [6], [15]. The function f_2 is an odd function, so by Theorem 2.4 there is the possibility of obtaining S-solutions of (1.1). The function f_3 seems at first to be a special case of the general trigonometric nonlinearity (1.3) arising in optical models; we will show, however, that f_3 can always be obtained from (1.3) by means of a linear transformation of the differential equation (1.1). The function f_4 occurs in biological and physiological models as noted earlier, as does f_5 when $\nu = 1$ or $\nu = 0$.

Our object is to determine ranges of the parameters μ, θ, ν, and λ for which the hypotheses (0), (I), (II), and (III) hold for a suitable translate of each f_k. By "suitable translate" we mean that a transformation taking a fixed point x_0 of f_k to the origin must generally be made before verifying the hypothesis in question. Indeed, for f_4 and f_5 it is not the fixed point $x = 0$ that is of interest, but rather some nontrivial fixed point $x_0 > 0$ about which we do our analysis. If $f : \mathbb{R} \to \mathbb{R}$ possesses a fixed point x_0, then letting $y = x - x_0$ in (1) yields

$$\varepsilon \dot{y}(t) = -y(t) + g(y(t-1)) \tag{3.1}$$

where

$$g(y) = f(y + x_0) - f(x_0) \tag{3.2}$$

satisfies $g(0) = 0$. When we say *a hypothesis* (such as (0), (I), (II), or (III)) *holds for a function f at a fixed point x_0*, we mean that the hypothesis holds for the transformed function g as stated.

We complete this section by showing how the function f in (1.3) can be reduced to the normal form f_3. In fact, we will show that the parameters μ and θ can always be chosen to satisfy

$$\mu \geqq 0 \quad \text{and} \quad 0 \leqq \theta \leqq \pi. \tag{3.3}$$

First note that the function f in (1.3) is bounded and so must have at least one fixed point, and possibly more than one. Let x_0 denote such a point. Then the function g in (3.2) has the same form as in (1.3) but possibly with a different value of μ_4; we continue to denote the new value by μ_4. The fact that $g(0)=0$ implies from the form (1.3) that $\mu_1 = -\mu_2 \sin \mu_4$, and so

$$g(y) = \mu_2[\sin(\mu_3 y + \mu_4) - \sin \mu_4].$$

Now assuming $\mu_2 \neq 0$ and $\mu_3 \neq 0$ (otherwise g is identically zero), we set

$$z = \pm \mu_3 y \tag{3.4}$$

with the sign $\pm$ to be determined later. The differential equation (3.1) now becomes

$$\varepsilon \dot{z}(t) = -z(t) + h(z(t-1))$$

where

$$h(z) = \mu_2 \mu_3[\sin(z \pm \mu_4) - \sin(\pm \mu_4)].$$

Upon setting

$$\mu = |\mu_2 \mu_3|,$$

$$\theta = \begin{cases} \pm \mu_4 (\bmod 2\pi) & \text{if } \mu_2 \mu_3 < 0, \\ \pm \mu_4 + \pi (\bmod 2\pi) & \text{if } \mu_2 \mu_3 > 0, \end{cases}$$

we see that the function h has precisely the form of f_3. In addition, an appropriate choice of sign in (3.4) ensures that μ and θ satisfy (3.3).

In our subsequent analysis we will usually assume that the function $f(x)$ in (1.3) has been written in the normal form:

$$f_3(x) = -\mu[\sin(x+\theta) - \sin \theta] \tag{3.5}$$

with $\mu > 0$ and $0 \leqq \theta \leqq \pi$. However, the reader should remember that writing the function in normal form conceals certain difficulties. First, as previously noted, the function f in (1.3) may have several fixed points. For each such fixed point of f, different parameters μ and θ in the normal form f_3 will, in general, be obtained. Second, we usually want to know for what ranges of the *original* parameters μ_1, μ_2, μ_3, and μ_4 in (1.3) does the function $f(x)$ satisfy hypotheses (0), (I), (II), or (III). The parameters in the normal form are written in terms of a fixed point of f in (1.3), and this fixed point is typically not explicitly known. Thus transferring information about the normal form back to the original function may present some nontrivial calculus problems.

4. The local condition (0). Here we discuss the existence of a fixed point of f_k at which condition (0) holds; clearly this is the case at a fixed point x_0 if and only if $f_k'(x_0) < -1$. For each function f_k, with parameters θ, ν, and λ in appropriate ranges, we will show that a critical value μ_0 of the parameter μ exists such that (0) holds at an appropriate fixed point x_0 if and only if $\mu > \mu_0$.

We begin with the model functions f_1 and f_2. If $\mu > -1/4$ then f_1 has two fixed points; the larger one,

$$x_0 = \frac{-1+\sqrt{4\mu+1}}{2},$$

interests us here. We see that $f_1'(x_0) = 1-\sqrt{4\mu+1}$, and a short calculation reveals that (0) holds there if and only if $\mu > \mu_0 = \frac{3}{4}$. For the nonlinearity f_2, with the fixed point $x_0 = 0$, we have $f_2'(0) = -\mu$; thus (0) holds there if and only if $\mu > \mu_0 = 1$.

At the fixed point $x_0 = 0$ of f_3, we have $f_3'(0) = -\mu \cos\theta$, so a necessary and sufficient condition for (0) to hold here is that $\mu \cos\theta > 1$. In particular this condition and the restrictions (3.3) imply that $\mu > 0$ and $0 \leqq \theta < \pi/2$. Thus we obtain $\mu_0 = 1/\cos\theta$.

Before discussing the functions f_4 and f_5 it is convenient to prove a simple theorem.

THEOREM 4.1. *Let $\bar{f}:[0,\infty)\to[0,\infty)$ be a continuous function that is C^1 on $(0,\infty)$. Assume there exists $\theta \geqq 0$ such that $\bar{f}'(x) > 0$ for $0 < x < \theta$ and $\bar{f}'(x) < 0$ for $x > \theta$, and there exists $s_0 > 0$ such that $(d/dx)(x\bar{f}(x))$ is positive for $0 < x < s_0$ and negative for $x > s_0$. Then for $\mu \geqq \theta(\bar{f}(\theta))^{-1}$, the equation $\mu\bar{f}(x) = x$ has a unique solution $x = x_0(\mu)$ such that $x_0(\mu) \geqq \theta$ and $\mu\bar{f}$ satisfies (0) at $x_0(\mu)$ if and only if $\mu > s_0(\bar{f}(s_0))^{-1}$.*

Proof. The existence and uniqueness of $x_0(\mu)$ is trivial. Since $s(\bar{f}(s))^{-1}$ is strictly increasing for $s > \theta$, we can define $\mu(s) = s(\bar{f}(s))^{-1}$ and parameterize by $s \geqq \theta$, so $\mu(s)\bar{f}(s)$ has fixed point $s \geqq \theta$. Thus the set of μ such that $\mu f'(x_0(\mu)) < -1$ is the same as $\{\mu(s): \mu(s)\bar{f}'(s) < -1\}$. A calculation shows that $\mu(s)\bar{f}'(s) < -1$ if and only if $(d/ds)(s\bar{f}(s)) < 0$, i.e., if and only if $s > s_0$. □

For the function $\bar{f}_4(x) = x^\nu e^{-x}$ we easily compute that the conditions of Theorem 4.1 are satisfied for $\nu \geqq 0$ and that $s_0 = \nu+1$ and $\mu\bar{f}_4(x)$ satisfies (0) at x_0 if and only if $\mu > (\nu+1)(\bar{f}_4(\nu+1))^{-1}$. For the function $\bar{f}_5(x) = x^\nu(1+x^\lambda)^{-1}$, we easily compute that the hypotheses of Theorem 4.1 are satisfied if $\nu \geqq 0$ and $\lambda > \nu+1$ and that $s_0^\lambda = (\nu+1)(\lambda-\nu-1)^{-1}$. Thus $\mu\bar{f}_5(x)$ satisfies condition (0) at x_0 if and only if $\mu > s_0(\bar{f}_5(s_0))^{-1}$, where $s_0^\lambda = (\nu+1)(\lambda-\nu-1)^{-1}$.

Table 1 summarizes the previous results by giving the range of parameters for which f_k satisfies (0) at a fixed point x_0. Note again that in the case of f_3 only the point $x_0 = 0$ is considered, even though there may be other fixed points at which (0) holds.

TABLE 1

Fixed points x_0 of f_k and critical parameter values μ_0. We have (0) holding at x_0 if and only if $\mu > \mu_0$, provided the parameters θ, ν, and λ satisfy the given restrictions.

k	x_0	μ_0	Restrictions
1	$\frac{-1+\sqrt{4\mu+1}}{2}$	$\frac{3}{4}$	
2	0	1	
3	0	$\frac{1}{\cos\theta}$	$0 \leqq \theta < \frac{\pi}{2}$
4	unique fixed point $x_0 > \nu$	$(\nu+1)^{1-\nu}e^{\nu+1}$	$\nu \geqq 0$
5	unique fixed point $x_0 > \left(\frac{\nu}{\lambda-\nu}\right)^{1/\lambda}$	$\log\mu_0 = \log\lambda - \left(\frac{\nu-1}{\lambda}\right)\log(\nu+1) - \left(\frac{\lambda-\nu+1}{\lambda}\right)\log(\lambda-\nu-1)$	$\nu \geqq 0, \quad \lambda > \nu+1$

When $\nu = 1$ in the function $f_5(x)$, we can explicitly compute $x_0 = (\mu - 1)^{1/\lambda}$, and the conditions on the parameters become $\lambda < 2$ and $\mu > \lambda(\lambda - 2)^{-1}$. More generally, it is of interest to locate the fixed points of f_4 and f_5 more precisely. The following result gives the asymptotic behavior of $x_0(\mu)$ for large μ; we omit the proof because we will not actually use the result here and because the proof involves only standard arguments from asymptotic analysis. Note that we use the standard "big O" and "little o" notation: If $h(\mu)$ and $g(\mu)$ are complex-valued functions defined for large positive μ and if $g(\mu)$ is nonzero for large μ, then we write

$$h(\mu) = O(g(\mu)) \quad \text{if and only if } \limsup_{\mu \to +\infty} \frac{|h(\mu)|}{|g(\mu)|} < \infty,$$

$$h(\mu) = o(g(\mu)) \quad \text{if and only if } \limsup_{\mu \to +\infty} \frac{|h(\mu)|}{|g(\mu)|} = 0.$$

THEOREM 4.2. *For $\nu \geqq 0$ and $\lambda > \nu + 1$ define numbers $\theta_4 = \nu$ and $\theta_5^{\lambda} = \nu(\lambda - \nu)^{-1}$. The functions $f_4(x) = \mu \bar{f}_4(x)$ and $f_5(x) = \mu \bar{f}_5(x)$ have (for sufficiently large μ) a unique fixed point $x_0(\mu)$ such that $x_0(\mu) > \theta_j$ and $x_0(\mu)$ satisfies*

$$x_0(\mu) = \log(\mu) - (1 - \nu)\log(\log \mu) + O\left(\frac{\log(\log \mu)}{\log \mu}\right) \quad \text{for } f_4,$$

$$x_0(\mu) = \mu^{(1/(\lambda+1-\nu))} - \left(\frac{1}{\lambda + 1 - \nu}\right)\mu^{((1-\lambda)/(\lambda+1-\nu))} + O(\mu^{((1-2\lambda)/(\lambda+1-\nu))}) \quad \text{for } f_5,$$

where log *denotes natural logarithm.*

5. General results on piecewise monotone functions. We wish to determine when a hypothesis (I), (II), or (III) holds for f_k at a point x_0 given in Table 1. As noted earlier these three conditions are global, and verifying them for specific functions may be difficult. To aid us in this task we will first obtain some general criteria for these hypotheses to hold; we will then apply these criteria to the functions f_k of interest.

To begin, we introduce condition (PM) (piecewise monotone) on a function f; observe that each f_k satisfies (PM) at the fixed point x_0 and parameter ranges of Table 1:

(PM) *The function $f: \mathbb{R} \to \mathbb{R}$ satisfies hypothesis* (0). *In addition, there exist (possibly infinite) quantities $0 < \xi \leqq \alpha \leqq \infty$ and $0 < \eta \leqq \beta \leqq \infty$ such that*

(i) *$f(-\beta) = 0$ if $\beta < \infty$;*

(ii) *f is monotone increasing and strictly positive in $(-\beta, -\eta)$ if $\eta < \infty$;*

(iii) *f is monotone decreasing in $(-\eta, \xi)$ but not in any larger open interval;*

(iv) *f is monotone increasing and strictly negative in (ξ, α) if $\xi < \infty$;*

(v) *$f(\alpha) = 0$ if $\alpha < \infty$.*

Furthermore, if $\xi = \eta = \infty$ (so f is monotone decreasing in all of $\mathbb{R}$), then $|f^2(x)| < |x|$ for some x.

Figure 1 depicts a function satisfying (PM). (Note that $f(\alpha) = 0$ is *not* required for this function as $\alpha = \infty$. That is, $\lim_{x \to \infty} f(x)$ may either be zero or strictly negative.) For any function satisfying (PM) we have $xf(x) < 0$ if $|x| \neq 0$ is sufficiently small, since $f(0) = 0$ and $f'(0) < -1$ by (0). A first question we consider for such a function is when it also satisfies (I).

Suppose both (PM) and (I) hold for f. Then the quantities A and B in (I) clearly satisfy

$$A < \alpha \quad \text{and} \quad B < \beta. \tag{5.1}$$

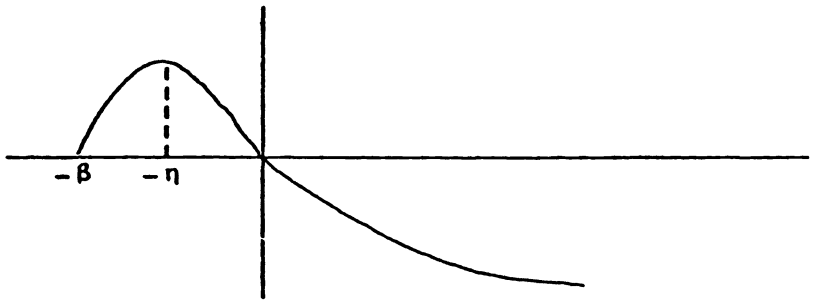

FIG. 1

On the other hand, if f satisfies (PM) and A and B are positive numbers satisfying (5.1), then f also satisfies (I) if and only if

$$f([-B, A]) \subseteq [-B, A]. \tag{5.2}$$

Finally, if both (5.1) and (5.2) hold for a function satisfying (PM), then there exists a minimal interval $[-B_*, A_*] \subseteq (-\beta, \alpha)$, with both A_* and B_* strictly positive, for which (5.2) is an equality:

$$f([-B_*, A_*]) = [-B_*, A_*].$$

This is so because $f'(0) < -1$.

Now assume f satisfies (PM) and define a continuous monotone decreasing function $f_*: R \to R$ by

$$f_*(x) = \begin{cases} f(-\eta) & \text{in } (-\infty, -\eta] \quad \text{if } \eta < \infty, \\ f(x) & \text{in } (-\eta, \xi), \\ f(\xi) & \text{in } [\xi, \infty) \quad \text{if } \xi < \infty. \end{cases} \tag{5.3}$$

If A and B are positive numbers satisfying (5.1), then clearly

$$f([-B, A]) = [f_*(A), f_*(-B)], \tag{5.4}$$

so that the equality in (5.2) holds at $A = A_*$ and $B = B_*$ if and only if

$$f_*(A_*) = -B_* \quad \text{and} \quad f_*(-B_*) = A_*. \tag{5.5}$$

Thus, (I) holds if and only if there exist two distinct points in the interval $(-\beta, \alpha)$ that are mapped into one another by f_*. From this basic fact we conclude the following result.

PROPOSITION 5.1. *Assume f satisfies* (PM), *define the function f_* by* (5.3), *and define quantities*

$$\begin{aligned} A_* &= \inf \{A > 0 \mid f_*^2(A) = A\}, \\ B_* &= \inf \{B > 0 \mid f_*^2(-B) = -B\}. \end{aligned} \tag{5.6}$$

Then A_* and B_* are well-defined positive numbers satisfying (5.5). *Hypothesis* (I) *holds for f if and only if*

$$A_* < \alpha \quad \text{and} \quad B_* < \beta$$

And in such a case we can take $A = A_*$ and $B = B_*$ in the statement of (I). *A sufficient condition for* (I) *to hold is that both*

$$f_*^2(\alpha) < \alpha \quad \text{if} \quad \alpha < \infty, \qquad f_*^2(-\beta) > -\beta \quad \text{if } \beta < \infty. \tag{5.7}$$

Another sufficient condition for (I) *to hold is that*

$$f_*(\alpha) > -\beta, \quad f_*^2(\alpha) < \alpha, \quad \alpha < \infty, \tag{5.8}$$

while a third sufficient condition for (I) *to hold is that*

$$f_*(-\beta) < \alpha, \quad f_*^2(-\beta) > -\beta, \quad \beta < \infty. \tag{5.9}$$

Proof. The existence and positivity of A_* and B_* follow from the fact that $|f_*^2(x)| > |x|$ for small $|x| \neq 0$ (since $(f_*^2)'(0) > 1$) and from the fact that $|f_*^2(x)| < |x|$ for some x. The latter inequality holds because f_*^2 is a bounded function if either ξ or η is finite; if $\xi = \eta = \infty$, the inequality is assumed in the definition of (PM). The first part of the proposition now follows easily from the monotonicity of f_* and the discussion above.

The assumptions on f imply that f_*^2 always has a positive fixed point and a negative fixed point. If $\alpha = \beta = \infty$, f satisfies (I) by what we have already proved. In all other cases it suffices to prove that f_*^2 has a fixed point in $(0, \alpha)$ and a fixed point in $(-\beta, 0)$. The reader can easily verify that (5.7), (5.8), or (5.9) are all sufficient to ensure this. For example, if $\alpha < \infty$ and (5.8) is satisfied, f_*^2 has a fixed point x_0 in $(0, \alpha)$ because $f_*^2(\alpha) < \alpha$ and $(f_*^2)'(0) > 1$, and then $f_*(x_0)$ is a fixed point of f_*^2 in $(-\beta, 0)$ (because f_* is monotone and $f_*(\alpha) > -\beta$). □

The following related result tells when the monotonicity condition (III) holds for a function that satisfies (PM).

PROPOSITION 5.2. *Assume f satisfies* (PM), *and let f_*, A_*, and B_* be as in Proposition* 5.1. *Then* (III) *holds for f if and only if*

$$A_* \leqq \xi \quad \text{and} \quad B_* \leqq \eta. \tag{5.10}$$

As before, we have $A = A_*$ and $B = B_*$ in the statement of (III). *A sufficient condition for* (5.10) *to hold is that both*

$$f_*^2(\xi) \leqq \xi \quad \text{if } \xi < \infty, \qquad f_*^2(-\eta) \geqq -\eta \quad \text{if } \eta < \infty \tag{5.11}$$

should hold.

Another sufficient condition for (5.10) *to be satisfied is that*

$$f_*(\xi) \geqq -\eta, \quad f_*^2(\xi) \leqq \xi, \quad \xi < \infty \tag{5.12}$$

while a third sufficient condition for (5.10) *to hold is that*

$$f_*(-\eta) \leqq \xi, \quad f_*^2(-\eta) \geqq -\eta, \quad \eta < \infty. \tag{5.13}$$

Proof. This follows the proof of Proposition 5.1 once we recall f is monotone in $(-\eta, \xi)$, but in no larger open interval. □

Suppose the function f_*^2 has exactly one fixed point in $(0, \infty)$. Then an easy argument implies that f_*^2 has a unique fixed point in $(-\infty, 0)$. If $A_* < \alpha$ and $B_* < \infty$ (A_* and B_* as in (5.6)), we must have $f_*^2(\alpha) < \alpha$ (if $\alpha < \infty$) and $f_*^2(-\beta) > -\beta$ (if $\beta < \infty$): otherwise the intermediate value theorem would imply that f_*^2 has a fixed point in $[\alpha, \infty)$ or $(-\infty, -\beta]$, contradicting uniqueness. Thus if f_*^2 has a unique positive fixed point, the sufficient condition in (5.7) that f satisfy (I) is also necessary. Furthermore, a little additional thought shows that (5.7) is satisfied if and only if (5.8) is satisfied, or (5.9) is satisfied, or $\alpha = \beta = \infty$ (assuming f_*^2 has a unique positive fixed point).

Similarly, if f is as in Proposition 5.2 and f_*^2 has a unique positive fixed point, then f satisfies (III) if and only if f satisfies (5.11). Also f satisfies (III) if and only if f satisfies (5.12), or (5.13), or $\xi = \eta = \infty$.

Inequalities (5.7) and (5.11) are, in general, easier to verify than (5.6) and (5.10), so it is useful to have theorems that ensure f_*^2 has a unique positive fixed point. Furthermore, we have already seen in the discussion in § 2 the importance of knowing that $f^2:[-B, A]\to[-B, A]$ (A and B as in § 2) has a unique positive fixed point. For example, if f is monotone decreasing and $f([-B, A])\subset[-B, A]$, we saw in § 2 that f satisfies (III) on $[-B, A]$ if f^2 has a unique positive fixed point in $[-B, A]$.

If the function f_*^2 were convex downward in (τ, ∞) and convex upward in $(-\infty, \tau)$ for some real τ, then f_*^2 would have a unique fixed point in $(0, \infty)$. This type of convexity assumption is clumsy to deal with, but a related concept, that of negative Schwarzian derivative, is readily verifiable for many functions of interest and can be used to prove a variety of results, including the uniqueness of the positive fixed point of f_*^2. Remarkably, each of the five functions f_k has a negative Schwarzian derivative for most of the parameter values of interest, so it will be natural for us to make the assumption of negative Schwarzian derivative in most of our subsequent theorems.

6. The Schwarzian derivative. The Schwarzian derivative Sf of a function $f: I\to R$ in an interval I is defined to be the function

$$Sf(x)=\frac{f'''(x)}{f'(x)}-\frac{3}{2}\left(\frac{f''(x)}{f'(x)}\right)^2$$

at those points $x\in I$ where f is three times differentiable and $f'(x)\neq 0$. At all other points of I we consider Sf to be undefined. The Schwarzian derivative originated in the theory of conformal mappings and was first used in the study of interval maps by Allwright [1] and Singer [27].

In this section we present several basic properties of Schwarzian derivatives and of functions whose Schwarzian derivative is negative. An important sufficient condition for the Schwarzian derivative of a function to be negative is given in Proposition 6.2.

Our first proposition collects some well-known results about the Schwarzian derivative (see [6], [27]). Statement (v) in Proposition 6.1, although elementary, is quite useful and does not appear to have been explicitly stated in the literature.

PROPOSITION 6.1. *Let $f: I\to\mathbb{R}$ and $y: J\to\mathbb{R}$ be functions defined on intervals I and J. Then*

(i) $S(g\circ f)(x)=Sf(x)+[f'(x)]^2 Sg(f(x))$ *and*

(ii) $S(g\circ f)(x)<0$ *if* $Sf(x)<0$ *and* $Sg(f(x))<0$

hold whenever Sf is defined at $x\in I$ and Sg is defined at $f(x)\in J$. Also, if m is the Möbius transformation

$$m(x)=\frac{c_1x+c_2}{c_3x+c_4},\qquad c_1c_4-c_2c_3\neq 0,$$

then

(iii) $Sm(x)=0$ *where defined, and hence*

$$S(m\circ f)(x)=Sf(x)$$

if Sf is defined at $x\in I$ and $c_3f(x)+c_4\neq 0$. Finally,

(iv) $(d^2/dx^2)(|f'(x)|^{-1/2})>0$ *if and only if* $Sf(x)<0$, *and*

(v) *if* $(d^2/dx^2)\log|f'(x)|<0$ *then* $Sf(x)<0$

hold whenever Sf is defined.

Proof. These are straightforward but tedious calculations, which we omit. We do note that (ii) and (iii) follow easily from (i). Also,

$$h''(x) > 0 \quad \text{implies } \frac{d^2}{dx^2}(e^{h(x)}) > 0;$$

so with $h(x) = -\frac{1}{2}\log|f'(x)|$ we obtain (v) from (iv). □

COROLLARY 6.1 [27, Prop. 2.4]. *Let $f: I \to \mathbb{R}$ be three times differentiable in an open interval I, and assume*

$$f'(x) \neq 0 \quad \textit{and} \quad Sf(x) < 0 \quad \textit{for all } x \in I.$$

Then the function $|f'(x)|$ does not attain a minimum in I. That is, there does not exist $w \in I$ such that $|f'(w)| \leqq |f'(x)|$ for all $x \in I$.

Proof. This follows immediately from (iv) of Proposition 6.1. □

LEMMA 6.1. *Let $f: I \to I$ be three times differentiable in an interval I (not necessarily open), with range in I, and assume that $Sf(x) < 0$ at each $x \in I$ for which $f'(x) \neq 0$. Assume that for some $w \in I$ (possibly an endpoint) we have*

$$f(w) = w \quad \textit{and} \quad |f'(w)| \leqq 1.$$

In addition, assume

$$f''(w) = 0 \quad \textit{if } f'(w) = 1$$

at this fixed point w. Then there exists a relatively open neighborhood $U \subseteq I$, with $w \in U$, such that

$$f(U) \subseteq U,$$

$$f^n(x) \to w \quad \textit{as } n \to \infty, \quad \textit{for each } x \in U.$$

Proof. In the case of a strict inequality $|f'(w)| < 1$ it is an elementary exercise to show that the set

$$U = (w - \delta, w + \delta) \cap I$$

satisfies the conclusions of the lemma if $\delta > 0$ is small enough. The same set also works if $f'(w) = 1$: we have $f''(w) = 0$ (by assumption) and $f'''(w) < 0$ (since $Sf(w) < 0$). It follows that if $g(x) = f(x) - x$, $g^{(j)}(w) = 0$ for $0 \leqq j \leqq 2$ and $g^{(3)}(w) < 0$. Thus Taylor's theorem implies that there exists $\delta > 0$ such that $f(x) < x$ for $x \in (w, w + \delta) \cap I$ and $f(x) > x$ for $x \in (w - \delta, w) \cap I$. Since $f'(w) = 1$ we also have $f(x) \geqq w$ for $x \in (w, w + \delta) \cap I$ and $f(x) \leqq w$ for $x \in (w - \delta, w) \cap I$. It follows that if $x \in (w - \delta, w + \delta) \cap I$, $x_n = f^n(x)$ is a monotonic sequence bounded above by w (if $x \leqq w$) or below by w (if $w \leqq x$). Thus the sequence (x_n) converges to ξ and necessarily $f(\xi) = \xi$. By construction w is the only fixed point of f in $(w - \delta, w + \delta) \cap I$, so $\xi = w$ and x_n converges to ξ.

In the remaining case, when $f'(w) = -1$, we have $f^2(w) = w$ and $(f^2)'(w) = 1$, and a simple calculation (see [27, p. 261]) gives us that $(f^2)''(w) = 0$. By (ii) of Proposition 6.1 the Schwarzian derivative of f^2 satisfies $Sf^2(x) < 0$ whenever $(f^2)'(x) \neq 0$. Thus f^2 satisfies the conditions on f already considered in the preceding paragraph, so there exists $U_0 \subseteq I$ satisfying the conclusions of the lemma for the function f^2 instead of f. From this we see that the set $U = U_0 \cap f(U_0)$ satisfies the conclusions of the lemma for the function f. □

The next result gives an easily verified condition for the Schwarzian derivative of a function to be negative. Recall first that the order ω of an entire function $f: \mathbb{C} \to \mathbb{C}$ is the infimum of all numbers $\kappa > 0$ such that $|f(z)|\, e^{-|z|^\kappa}$ is bounded on $\mathbb{C}$. (If no such

κ exists then f is said to have infinite order.) Nontrivial entire functions of finite order possess a product representation

$$f(z) = e^{\Omega(z)} z^k \prod_n \left(1 - \frac{z}{z_n}\right) E_M\left(\frac{z}{z_n}\right)$$

with at most countably many factors, where Ω is a polynomial of degree at most $[\omega]$ (the greatest integer less than or equal to the order), $k \geqq 0$ is the multiplicity of $z = 0$ as a root of f, the numbers z_n are the other roots of f listed according to multiplicity, E_M is the function

$$E_M(z) = \exp\left(\sum_{n=1}^{M} \frac{z^n}{n}\right)$$

with $E_0(z) = 1$, and $M \geqq 0$ is an integer satisfying $M \leqq \omega \leqq M+1$. In addition, it is the case that

$$\sum_n \frac{1}{|z_n|^{M+1}} < \infty, \tag{6.1}$$

and the infinite product converges uniformly on compact subsets of $\mathbb{C}$. We also recall that the order of the derivative f' equals the order ω of f.

PROPOSITION 6.2. *Let f be an entire function of order $\omega < 2$ such that $f(x) \in \mathbb{R}$ whenever $x \in \mathbb{R}$, and such that all zeros of the derivative f' are real. Then either*

$$Sf(x) < 0 \quad \textit{whenever } f'(x) \neq 0 \textit{ and } x \in \mathbb{R},$$

or f is a linear function $f(x) = c_0 x + c_1$.

Proof. We note that $M = 0$ or 1 in the infinite product representation for the derivative f'. Denoting the zeros of f' by $x_n \in \mathbb{R}$ we have for this function either

$$f'(x) = e^{\Omega(x)} x^k \prod_n \left(1 - \frac{x}{x_n}\right), \quad \text{or} \tag{6.2}$$

$$f'(x) = e^{\Omega(x)} x^k \prod_n \left(1 - \frac{x}{x_n}\right) e^{x/x_n}, \tag{6.3}$$

where we restrict our attention to real values x of the argument. In either case (6.2) or (6.3) we have $\Omega''(x) = 0$ for all x, and

$$\sum_n \frac{1}{|x_n|^2} < \infty. \tag{6.4}$$

Now assume that f' does possess a root; otherwise $f'(x) = e^{\Omega(x)}$ and the result is easily checked. In the first case, (6.2), we have

$$\log|f'(x)| = \Omega(x) + k \log|x| + \sum_n \log\left|1 - \frac{x}{x_n}\right|,$$

so term-by-term differentiation (justified by (6.1)*) gives*

$$\frac{d^2}{dx^2} \log|f'(x)| = -\frac{k}{x^2} - \sum_n \frac{1}{(x - x_n)^2} < 0 \tag{6.5}$$

for $x \neq x_n$ and $x \neq 0$ if $k > 0$. In the second case, (6.3), the same formula, (6.5), holds. In either case the result $Sf(x) < 0$ follows from (v) of Proposition 6.1. □

7. Verifying (I), (II), and (III). The following hypotheses are strengthened versions of (PM) involving a negative Schwarzian derivative condition. Under these conditions, verifying (I), (II), and (III) reduces to essentially local calculations.

(NS_1) *The function* $f:\mathbb{R}\to\mathbb{R}$ *satisfies hypothesis* (PM). *In addition* f *is three times differentiable in* $(-\eta, \xi)$ *and satisfies* $f'(x)<0$ *and* $Sf(x)<0$ *in* $(-\eta, \xi)$.

(NS_2) *The function* $f:\mathbb{R}\to\mathbb{R}$ *satisfies* (PM). *In addition,* f *is three times differentiable in* $(-\beta, \alpha)$ *and satisfies* $f'(x)\neq 0$ *and* $Sf(x)<0$ *if* $x\in(-\beta, \alpha)$ *and* $x\neq \xi, -\eta$.

Under hypothesis (NS_1), Theorem 7.1 gives necessary and sufficient condition for (I) and (III) to hold, thereby extending Propositions 5.1 and 5.2. Under hypothesis (NS_2), Theorem 7.3 gives an easily verified necessary and sufficient condition for (II) to hold provided (I) also holds. Theorem 7.2 will be useful in verifying (I), (II), and (III) for specific functions.

THEOREM 7.1. *Assume* f *satisfies* (NS_1) *and define* f_* *by* (5.3) *as before. Then* f *satisfies* (I) *if and only if*

$$f_*^2(\alpha)<\alpha \quad \text{if } \alpha<\infty, \qquad f_*^2(\beta)>-\beta \quad \text{if } \beta>\infty. \tag{7.1}$$

Also, f *satisfies* (I) *if and only if at least one of the following three conditions holds*:

(1) $\alpha=\beta=\infty$; *or* (2) $\alpha<\infty$ *and* $f_*(\alpha)>-\beta$ *and* $f_*^2(\alpha)<\alpha$; *or* (3) $\beta<\infty$ *and* $f_*(-\beta)<\alpha$ *and* $f_*^2(-\beta)>-\beta$.

The function f *satisfies* (III) *if and only if*

$$f_*^2(\xi)\leqq\xi \quad \text{if } \xi<\infty, \qquad f_*^2(-\eta)\geqq-\eta \quad \text{if } \eta<\infty. \tag{7.2}$$

Also, f *satisfies* (III) *if and only if at least one of the following three conditions is satisfied*:

(1) $\xi=\eta=\infty$; *or* (2) $\xi<\infty$ *and* $f_*(\xi)\geqq-\eta$ *and* $f_*^2(\xi)\leqq\xi$; or (3) $\eta<\infty$ *and* $f_*(-\eta)\leqq\xi$ *and* $f_*^2(-\eta)\geqq-\eta$.

Recall that we have

$$f_*^2(\alpha)=f_*^2(\xi) \quad \text{and} \quad f_*^2(-\beta)=f_*^2(-\eta) \tag{7.3}$$

for the quantities in Theorem 7.1.

THEOREM 7.2. *Assume* f *satisfies* (NS_1), *except that*

$$f'(0)=-k, \qquad 0<k\leqq 1,$$

holds instead of $f'(0)<-1$. *If* $0<k<1$, *assume that* $f''(0)\geqq 0$. *Then with* $f_*(x)$ *given by* (5.3) *we have*

$$|f_*^2(x)|<|x| \quad \forall x\neq 0.$$

Note that (7.1) and (7.2) hold under the hypotheses of Theorem 7.2.

THEOREM 7.3. *Assume* f *satisfies both* (NS_2) *and* (I). *Then* f *satisfies* (II) *if and only if both*

(i) $|(f^2)'(x)|\leqq 1$, *and*

(ii) $(f^2)''(x)=0$ *if* $(f^2)'(x)=1$

hold whenever

$$f^2(x)=x, \qquad x\in(0,\alpha), \quad f(x)\in(-\beta, 0). \tag{7.4}$$

Equivalently, f *satisfies* (II) *if and only if both* (i) *and* (ii) *hold whenever*

$$f^2(x)=x, \qquad x\in(-\beta, 0), \quad f(x)\in(0,\alpha). \tag{7.5}$$

LEMMA 7.1. *Assume* f *satisfies* (NS_1), *and define* f_*, A_*, *and* B_* *by* (5.3) *and* (5.6). *Then* A_* *and* $-B_*$ *are the unique nonzero fixed points of* f_*^2. *Moreover,* $f_*^2(x)-x$

changes sign at these points, with $|f_*^2(x)|>|x|$ *in* $(-B_*, A_*)-\{0\}$, *and* $|f_*^2(x)|<|x|$ *in* $(-\infty, -B_*)\cup(A_*, \infty)$.

Proof. First observe that a (possibly infinite) quantity $\xi_*>0$ exists such that

$$(f_*^2)'(x)>0 \quad \text{in } [0, \xi_*),$$

$$f_*^2(x)=f_*^2(\xi_*) \quad \text{in } [\xi_*, \infty) \quad \text{if } \xi_*<\infty.$$

This follows easily from the definition of f_*, and we see that $\xi_*=\xi$ if $f_*(\xi)\geqq-\eta$ and $\xi_*=f_*^{-1}(-\eta)<\xi$ if $f_*(\xi)<-\eta$ (these formulas hold even if ξ or η is infinite). Also,

$$Sf_*^2(x)<0 \quad \text{in } [0, \xi_*)$$

by (ii) of Proposition 6.1. By assumption, we have

$$(f_*^2)'(0)>1. \tag{7.6}$$

Now A_* is the smallest positive fixed point of f_*^2 in $(0, \infty)$. If $A_*\geqq\xi_*$, then clearly A_* is the only such fixed point; so suppose that $A_*<\xi_*$. Because A_* is the smallest positive fixed point of f_*^2, we have $f_*^2(x)>x$ for $0<x<A_*$, which implies

$$(f_*^2)'(A_*)\leqq 1. \tag{7.7}$$

By Lemma 6.1 the derivative $(f_*^2)'$ does not attain a minimum in any open subinterval of $(0, \xi_*)$. Using this and the fact that $(f_*^2)'(0)>1$, we conclude from (7.7) that

$$(f_*^2)'(x)<1 \quad \text{for } A_*<x<\xi_*. \tag{7.8}$$

Integrating (7.8) from A_* to u for $A_*<u\leqq\xi_*$, we obtain

$$f_*^2(u)-f_*^2(A_*)=f_*^2(u)-A_*<\int_{A_*}^{u} 1\,dx=u-A_*, \tag{7.9}$$

and (7.9) implies $f_*^2(x)<x$ for $A_*<x\leqq\xi_*$, and hence for all $x>A_*$.

The analysis for $-B_*$ is similar and is left to the reader. □

Proof of Theorem 7.1. As was noted in § 5, the sufficient conditions (5.7) and (5.11) in Propositions 5.1 and 5.2 are also necessary if f_*^2 has a unique positive fixed point. Lemma 7.1 shows that f_*^2 has a unique positive fixed point.

Proof of Theorem 7.2. Obviously f^2 and f_*^2 agree on $[0, \xi_*]$. A simple calculation (see [27, p. 261]) shows that

$$(f_*^2)''(0)=f''(0)[k^2-k]. \tag{7.10}$$

Since we assume that $f''(0)\geqq 0$ if $0<k<1$, (7.10) implies

$$(f_*^2)''(0)\leqq 0 \tag{7.11}$$

for $0<k\leqq 1$. If strict inequality holds in (7.11), the mean value theorem implies that there exists $\delta>0$ such that

$$0<(f_*^2)'(x)<(f_*^2)'(0)=k^2 \quad \text{for } 0<x<\delta. \tag{7.12}$$

If $(f_*^2)''(0)=0$, the negative Schwarzian condition implies

$$(f_*^2)'''(0)<0,$$

and by using Taylor's formula we again see that there exists $\delta>0$ such that (7.12) is satisfied. Lemma 6.1 now implies

$$(f_*^2)'(x)<k^2 \quad \text{for } 0<x<\xi_*, \tag{7.13}$$

for if (7.13) failed for some x, $(f_*^2)'$ would achieve its minimum at an interior point of $(0, x)$. By integrating inequality (7.13) from zero to x for $x \leqq \xi_*$, we easily obtain

$$f_*^2(x) < x \quad \text{for } 0 < x \leqq \xi_*,$$

and hence

$$f_*^2(x) < x \quad \text{for } 0 < x. \tag{7.14}$$

Inequality (7.14) implies that f_*^2 has no negative fixed points y (otherwise $f_*(y)$ would be a positive fixed point of f_*^2), and since $f_*^2(x) > x$ for small negative x, we conclude that $f_*^2(x) > x$ for all $x < 0$. □

LEMMA 7.2. *Assume f satisfies both* (NS_1) *and* (I). *If $a \in (-\beta, \alpha)$ is such that $f(a) \in (-\beta, \alpha)$ and $f^2(a) = a$, then we have in fact $a, f(a) \in [-B, A] \subseteq (-\beta, \alpha)$ where A and B are as in* (I).

Proof. Assume without loss of generality that $a > 0$. The monotonicity of f_* and the fact that $|f(x)| \leqq |f_*(x)|$ in $(-\beta, \alpha)$ imply

$$a = f^2(a) \leqq f_*(f(a)) \leqq f_*^2(a),$$

and from this we have

$$a \leqq A_* \tag{7.15}$$

by Lemma 7.1. On the other hand, the inclusion $f^2([-B, A]) \subset [-B, A]$ (which follows from (I)) and (5.3) imply that $f_*^2(A) \leqq A$, so

$$A_* \leqq A \tag{7.16}$$

by Lemma 7.1. From (7.15) and (7.16) we have $a \in [-B, A]$. The proof that $f(a) \in [-B, A]$ is analogous. □

LEMMA 7.3. *Assume f satisfies both* (PM) *and* (I), *and is differentiable in $(-\beta, \alpha)$ with $f'(x) \neq 0$ there, except at $x = \xi$ and $x = -\eta$ (this is true in particular if f satisfies* (NS_2) *and* (I)). *Then with A as in* (I), *the following hold*:

(i) *The critical points of f^2 in $(0, A)$ are isolated, and $(f^2)'$ changes sign at each such point.*

(ii) *If a point w in the open interval $(0, A)$ is a local maximum of f^2, then it is a global maximum in $[0, A]$*:

$$f^2(w) = \max_{[0,A]} f^2(x). \tag{7.17}$$

(iii) *If f^2 possesses a critical point in the closed interval $[0, A]$ and if w in the closed interval $[0, A]$ is as in* (7.17), *then w is a critical point*:

$$(f^2)'(w) = 0.$$

Proof. This lemma follows directly from several elementary observations based on the shape of the graph of f as in (PM), and the fact that f maps the interval $[-B, A] \subseteq (-\beta, \alpha)$ into itself.

At a critical point $x \in (0, A)$ of f^2 we have

$$(f^2)'(x) = f'(f(x)) f'(x) = 0$$

and so either $x = \xi$ or $f(x) = -\eta$. As $f(x) = -\eta$ for at most two points in $(0, \alpha)$, we conclude that f^2 has at most three critical points in $(0, A)$. Of course, these points are isolated. If either $A \leqq \xi$ or $f(\xi) \geqq -\eta$, then f^2 has at most one critical point in $(0, A)$, and this point, if it exists, is a local maximum. In this case (i), (ii), and (iii) clearly hold, so the lemma is proved.

On the other hand, suppose $A > \xi$ and $f(\xi) < -\eta$. Then we see that $x = \xi$ is a local minimum of f^2, that $f(x) = -\eta$ has either one or two solutions ζ in $(0, A]$ and that they are local maxima for f^2 with the (common, if there are two solutions ζ) value

$$f^2(\zeta) = f(-\eta) = \max_{[-B,0]} f(x) = \max_{[0,A]} f^2(x). \tag{7.18}$$

In particular, (i) and (ii) hold. To prove (iii), we note that if $w \in [0, A]$ satisfies (7.17), then from (7.18) we have $f^2(w) = f(-\eta)$, and hence $f(w) = -\eta$. Thus $(f^2)'(w) = f'(-\eta)f'(w) = 0$ as claimed. □

LEMMA 7.4. *Assume f satisfies the hypotheses of Lemma* 7.3. *Suppose there exists an interval $J = [r, s]$ with $0 \leqq r < s \leqq A$ such that*

$$f^2(J) = J,\ f^2(\partial J) = \partial J,\ \text{where } \partial J = \{r, s\},\ \text{and } J - \partial J \text{ contains a critical point of } f^2. \tag{7.19}$$

Furthermore, assume that it is not true that $f^2(r) = s = f^2(s)$. Then there exists $v \in J - \partial J$ such that $f^2(v) = s$. Also, if $w \in \partial J$ is such that $f^2(w) = s$, then $(f^2)'(w) = 0$.

Proof. Our assumptions imply that (a) $f^2(r) = s$ and $f^2(s) = r$, or (b) $f^2(r) = r$ and $f^2(s) = s$, or (c) $f^2(r) = r = f^2(s)$. In case (a), let $v = \sup\{x < s: (f^2)'(x) = 0\}$. By using (i) of Lemma 7.3, the fact that f^2 achieves its minimum on J at s and the assumption that f^2 has a critical point in (r, s), we see that $r < v < s$, and $(f^2)'(x) < 0$ for $v < x < s$. Lemma 7.3 implies that $(f^2)'(x)$ changes sign at v, so f^2 has a local maximum at v. A similar argument applies in cases (b) and (c) and shows that f^2 always has a critical point v in (r, s) at which f^2 has a local maximum. Note, however, that this argument fails if $f^2(r) = s = f^2(s)$.

Because $f^2(J) \subset J$, we have $f^2(v) \leqq s$; but part (ii) of Lemma 7.3 implies

$$f^2(v) = \max_{[0,A]} f^2(x) \geqq s, \tag{7.20}$$

so we conclude that

$$f^2(v) = s = \max_{[0,A]} f^2(x). \tag{7.21}$$

If there exists $w \in \partial J$ such that $f^2(w) = s$, (7.21) and part (iii) of Lemma 7.3 imply that $(f^2)'(w) = 0$. □

Proof of Theorem 7.3. We establish the last statement of the theorem first, by showing (i) and (ii) both hold for all fixed points of f^2 satisfying (7.4) if and only if they hold for all fixed points of f^2 satisfying (7.5). Indeed, this is an easy consequence of the following two observations. First, if $f^2(x) = x$ then $f^2(y) = y$, where $y = f(x)$, and we have $(f^2)'(x) = (f^2)'(y)$. Second, if $(f^2)'(x) = 1$ for this point, then $(f^2)''(x) = (f^2)''(y)$. Thus, we need only consider fixed points of f^2 satisfying (7.5).

By Lemma 7.2 we may further restrict our attention to fixed points $x \in (0, A]$ (with $f(x) \in [-B, 0)$ holding automatically), where A and B are as in (I). We will therefore prove that for f to satisfy (II) it is necessary and sufficient that each fixed point of f^2 in $(0, A]$ should satisfy both (i) and (ii).

Necessity. Assume that f satisfies (II) for some a and b, but that either (i) or (ii) fails for $x = a$. From (II) we see that $x = a$ is the only fixed point of both f^2 and of f^4 in $(0, A]$, and so we have

$$\begin{aligned} &f^n(x) > x \quad \text{in } (0, a), \\ &f^n(x) < x \quad \text{in } (a, A] \quad \text{if } a < A \end{aligned} \tag{7.22}$$

for $n=2$ and 4, because $(f^n)'(0)>1$ and $f^n(A)\leqq A$. Observing that $f^2(a)=a$ implies $(f^4)'(a)=[(f^2)'(a)]^2\geqq 0$, we conclude from (7.22) that $(f^4)'(a)\leqq 1$; hence $|(f^2)'(a)|\leqq 1$. Thus (i) holds for $x=a$.

We therefore assume that (ii) fails for $x=a$, and so

$$(f^2)'(a)=1 \quad \text{and} \quad (f^2)''(a)\neq 0. \tag{7.23}$$

We now see that in order for (7.22) to hold with $n=2$ it is necessary that

$$(f^2)''(a)>0. \tag{7.24}$$

Furthermore, the fixed point a must be located at the endpoint A of the interval, that is,

$$f^2(A)=A \quad \text{as } a=A.$$

Now observe that the interval $(0, A)$ contains a critical point of f^2. Indeed if this were not so, then $(f^2)'$ would attain a positive minimum in $(0, A)$ because of (7.23) and the fact that $(f^2)'(0)>1$; however, this would contradict Corollary 6.1.

Thus we see that the interval $J=[0, A]$ satisfies the hypotheses of Lemma 7.4. But then we conclude from this result, with $w=A$, that $(f^2)'(A)=0$. This contradicts (7.23), completing the proof of necessity.

Sufficiency. Assume that f satisfies (NS_2) and (I) for some A and B, and that (i) and (ii) in the statement of the theorem hold at each fixed point of f^2 in $(0, A]$. First note that f^2 has at least one fixed point in $(0, A]$; this follows from the inclusion $f^2([\delta, A])\subseteq[\delta, A]$, which is true for sufficiently small $\delta>0$ because $(f^2)'(0)>1$. Choose any such fixed point a, that is,

$$f^2(a)=a\in(0, A],$$

and consider its domain of attraction W in $[0, A]$ defined by

$$W=\{x\in[0, A]\,|\,f^{2n}(x)\to a \text{ as } n\to\infty\}.$$

Clearly $a\in W$ and $0\notin W$. By using Lemma 6.1 with f^2 in place of f we see that the set W is relatively open in $[0, A]$. Let $I\subseteq W$ denote the maximal connected component of W containing $x=a$; thus I is an interval of the form

$$I=(r, s), \quad \text{or else} \quad I=(r, A]$$

where in either case the quantities r and s satisfy

$$0\leqq r<a, \quad a<s\leqq A \quad \text{if } a<A.$$

Because $f(W)\subseteq W$, $f(I)$ is a connected subset of W containing a, the maximality of the connected component implies

$$f(I)\subseteq I. \tag{7.25}$$

Continuity implies that $f^2(\bar{I})\subset\bar{I}$. However, if $I=(r, s)$, we must have that

$$f^2(r), f^2(s)\in\{r, s\}; \tag{7.26}$$

otherwise r or s would be in I. If $I=(r, A]$, the same reasoning implies

$$f^2(r)=r. \tag{7.27}$$

Now observe that neither the point r nor s (if $I=(r, s)$) can be a nonzero fixed point of f^2. By Lemma 6.1 we know that each fixed point of f^2 in $(0, A]$ attracts iterates

$f^{2n}(x)$ of all nearby points x. However, we know that those points $x \in I$ near r or s satisfy $f^{2n}(x) \to a$ instead. Therefore, if $I = (r, s)$, we must have

$$f^2(s) = r,$$

and we must have $f^2(r) = s$ unless $r = 0$. If $I = (r, A]$, we must have $f^2(r) = r$, and we have just seen that this implies $r = 0$. Thus, if $I = (r, A]$, the domain of attraction of the fixed point a of f^2 is the entire interval $(0, A]$, so condition (II) holds. Therefore for the remainder of the proof we assume $I = (r, s)$.

Because $f^2(s) = r$ and $s > 0$ we have $r > 0$, so the previous remarks imply that $f^2(r) = s$. Define $g = f^4$, so g maps $[r, s]$ into itself, g has negative Schwarzian derivative on $[r, s]$, and r, a, and s are fixed points of g. Note that

$$f'(x) = (f^2)'(f^2(x))(f^2)'(x), \tag{7.28}$$

so

$$0 \leqq g'(a) = ((f^2)'(a))^2 \leqq 1. \tag{7.29}$$

Lemma 2.6 of [27] proves that if g is any continuous function on an interval $[r, s]$ and if $g(r) = r$, $g(s) = s$, g is C^3 on (r, s) and $g'(x) \neq 0$ and $(Sg)(x) < 0$ for $x \in (r, s)$, then $g'(a) < 1$ if $a \in (r, s)$ and $g(a) = a$. (Note that the proof of Lemma 2.6 in [27] requires only that g' not vanish on (r, s), although the result is stated slightly less generally.) Thus by Lemma 2.6 of [27] and (7.29) we obtain a contradiction unless $g'(x_0) = 0$ for some $x_0 \in (r, s)$. Because $f^2(I) \subset I$, (7.28) implies f^2 has a critical point in I. Lemma 7.4 now implies there exists $v \in I$ such that $f^2(v) = s$. Since $\lim_{n \to \infty} f^{2n}(x) = a$ for any $x \in I$ and $f^{2n}(v) = r$ or s, we have a contradiction, and the proof is complete. □

If $g(x, \theta)$ is defined for (x, θ) near $(0, \theta_*)$, and if $g(0, \theta) = 0$ and $\partial g(0, \theta_*)/\partial x = -1$, it is natural to ask whether the map $x \to g(x, \theta)$ satisfies (III) at zero for some interval $(\theta_* - \delta, \theta_*)$ or $(\theta_*, \theta_* + \delta)$, $\delta > 0$. This question was answered by Allwright in [1]. He assumed that $x \to g(x, \theta)$ has negative Schwarzian derivative for all x, but his proof only requires that $x \to g(x, \theta)$ have negative Schwarzian derivative for x near zero and θ near θ_*. Thus we obtain the following result, which may also be obtained as a simple consequence of Theorem 7.2.

COROLLARY 7.1 (see Allwright [1]). *Assume $g(x, \theta)$ is defined and continuous for $|x| < \delta_1$ and $|\theta - \theta_*| < \delta_2$. In addition suppose g is C^3 in the x-variable and g has a negative Schwarzian derivative (with respect to the x-variable) at $x = 0$ and $\theta = \theta_*$. Assume $g(0, \theta) = 0$ for $|\theta - \theta_*| < \delta_2$ and $g'(0, \theta_*) = \partial g(0, \theta_*)/\partial x = -1$. Finally, assume $\partial^2 g/\partial\theta\partial x$ is defined and continuous on the domain of g and $\partial^2 g(0, \theta_*)/\partial\theta\partial x \neq 0$. Then there exists $\delta > 0$ such that the map $x \to g(x, \theta)$ satisfies (III) for $\theta_* < \theta < \theta_* + \delta$ if $\partial^2 g(0, \theta_*)/\partial\theta\partial x < 0$, while the map $x \to g(x, \theta)$ satisfies (III) for $\theta_* - \delta < \theta < \theta_*$ if $\partial^2 g(0, \theta_*)/\partial\theta\partial x > 0$.*

Of course what Allwright really shows is that fixed points of period 2 of the map $x \to g(x, \theta)$ are bifurcating at $\theta = \theta_*$ from the trivial fixed point $x = 0$. The negative Schwarzian condition at $x = 0$ ensures that the bifurcation is such that (III) is satisfied. In fact, the negative Schwarzian condition is also essentially necessary for (III) to be satisfied locally. The following proposition indicates the sense in which necessity is meant. Since the proposition follows by standard arguments in local bifurcation theory, the proof is omitted.

PROPOSITION 7.1. *Assume $g(x, \theta)$ is a C^4 function defined on an open neighborhood of $(0, \theta_*)$. Assume $g(0, \theta) = 0$ for $(0, \theta)$ in the domain of g, $\partial g(0, \theta_*)/\partial x = -1$, and $\partial^2 g(0, \theta_*)/\partial\theta\partial x = \eta_1 \neq 0$. Suppose the Schwarzian derivative of g (with respect to the x-variable) at $x = 0$ and $\theta = \theta_*$ is nonzero and denote this Schwarzian derivative by η_2.*

Then there exist positive numbers ε and δ and continuous functions $\xi_+(\theta)$ and $\xi_-(\theta)$ that are defined for $\theta_* \leqq \theta \leqq \theta_* + \delta$ if $\eta_1\eta_2 > 0$ and for $\theta_* - \delta \leqq \theta \leqq \theta_*$ if $\eta_1\eta_2 < 0$ and that have the following properties:

(1) $g(\xi_+(\theta), \theta) = \xi_-(\theta)$ *and* $g(\xi_-(\theta), \theta) = \xi_+(\theta)$,

(2) $\xi_+(\theta_*) = 0 = \xi_-(\theta_*)$ *and the range of* ξ_+ *is in* $[0, \varepsilon]$ *and the range of* ξ_- *is in* $[-\varepsilon, 0]$, *and*

(3) *if* $g(g(x, \theta), \theta) = x$ *for some* (x, θ) *with* $0 < |x| < \varepsilon$ *and* $|\theta - \theta_*| \leqq \delta$, *then* θ *must be in the domain of* ξ_+ *and* $x = \xi_+(\theta)$ *or* $x = \xi_-(\theta)$.

Note that if the Schwarzian derivative is positive, the map $x \to g(x, \theta)$ takes $[\xi_-(\theta), \xi_+(\theta)]$ into itself, but $\partial g(0, \theta)/\partial x > -1$ for θ in the domain of ξ_+.

We need one more theorem for our applications in § 9. Roughly speaking, our next result asserts that for functions with negative Schwarzian derivative, (II) fails before (I).

THEOREM 7.4. *Assume f satisfies* (PM) *and α or β is finite (α, β, ξ, and η are as in the definition of* (PM)). *Suppose f is C^3 on $[-\beta, \alpha]$, $f'(x) \neq 0$ for $x \neq -\eta$ and $x \neq \xi$, and the Schwarzian derivative $Sf(x)$ is negative on $(-\beta, \alpha)$ for $x \neq -\eta, \xi$. If $f([-\beta, \alpha]) \subset [-\beta, \alpha]$ and $f_*^2(\alpha) = \alpha$ or $f_*^2(-\beta) = -\beta$ (f_* as in* (5.3)), *then there exists $\gamma \in (-\beta, \alpha)$, $\gamma \neq 0$, such that $(f^2)(\gamma) = \gamma$ and $(f^2)'(\gamma) < -1$.*

Proof. Assume for definiteness that $f_*^2(\alpha) = \alpha$. We assume that the theorem is false, so $(f^2)'(\gamma) \geqq -1$ for every nonzero $\gamma \in [-\beta, \alpha]$ such that $f^2(\gamma) = \gamma$, and we try to obtain a contradiction. Recall that Lemma 6.1 implies that if $f^2(\gamma) = \gamma$ and $-1 \leqq (f^2)'(\gamma) < 1$, then γ is a "locally stable fixed point of f^2" in the sense that there exists $\delta > 0$ such that $\lim_{n\to\infty} f^{2n}(x) = \gamma$ for all x such that $|x - \gamma| < \delta$.

There are two cases to consider, each corresponding to a different qualitative appearance of f^2.

Case 1. Assume that $-\eta < f(\xi) = f_*(\alpha)$. In this case we have $f_*^2(\alpha) = f^2(\xi) = \alpha$, and we can easily verify that $(f^2)'(x) > 0$ for $0 \leqq x \leqq \xi$ and $(f^2)'(x) < 0$ for $\xi < x < \alpha$. For notational convenience, define $\xi = \xi_2$ in Case 1.

Case 2. Assume that $f(\xi) = f_*(\alpha) \leqq -\eta$. In this case we have $f_*^2(\alpha) = f(-\eta) = \alpha$. Furthermore, there exist a unique number ξ_1, $0 < \xi_1 \leqq \xi$ and a unique number ξ_2, $\xi \leqq \xi_2 < \alpha$ such that $f(\xi_1) = f(\xi_2) = -\eta$. Using this information, we can easily check that $(f^2)'(x) > 0$ for $0 \leqq x < \xi_1$, $(f^2)'(x) < 0$ for $\xi_1 < x < \xi$, $(f^2)'(x) > 0$ for $\xi < x < \xi_2$ and $(f^2)'(x) < 0$ for $\xi_2 < x < \alpha$.

It follows that (in Case 1 or Case 2), $f^2(\xi_2) = \alpha$ and $(f^2)'(x) < 0$ for $\xi_2 < x < \alpha$. Because $f^2(\alpha) = \alpha$, the intermediate value theorem implies that there is a unique number γ, $\xi_2 < \gamma < \alpha$, such that $f^2(\gamma) = \gamma$. Our assumptions imply

$$-1 \leqq (f^2)'(\gamma) \leqq 0,$$

so our previous remarks imply that γ is a locally stable fixed point of f^2.

Just as in the proof of Theorem 7.3, let $U = \{x \in [0, \alpha] : f^{2n}(x) \to \gamma\}$, so U is an open set, and let U_1 be the maximal connected component of U containing γ, so U_1 is also an open set and $f^2(U_1) \subset U_1$. (Note that $0 \notin U$ and $\alpha \notin U$.) Since U_1 is connected, we can write $U_1 = (r, s)$. If $r < \xi_2$, we have $\xi_2 \in U_1$, so $f^4(\xi_2) = 0 \in U_1$, a contradiction. Thus we must have $\xi_2 \leqq r$. If $s = \alpha$, we obtain $0 = f^2(\alpha) \in U_1$ (because $f^2(U_1) \subset U_1$), and this is impossible because $r \geqq \xi_2$. Thus we must have $s < \alpha$. Just as in the proof of Theorem 7.3, we must have $f^2(r) \in \{r, s\}$ and $f^2(s) \in \{r, s\}$.

There are several possibilities to consider. If $f^2(r) = r$ or $f^2(s) = s$, we contradict the fact that γ is the unique fixed point of f^2 in the interval $[\xi_2, \alpha]$. The only other possibility is that $f^2(r) = s$ and $f^2(s) = r$. If we write $g = f^4$, we know that g has a negative Schwarzian derivative on $[r, s]$ and that r, s and γ are fixed points of g. If

$g'(x) \neq 0$ for $r < x < s$, Lemma 2.6 of [27] implies that $g'(\gamma) > 1$, which is a contradiction. Thus there must exist $x_0 \in (r, s)$ such that $g'(x_0) = 0$. By using the chain rule we see that

$$x_0 = \xi \quad \text{or } f^2(x_0) = \xi \quad \text{or } f(x_0) = -\eta \quad \text{or } f^3(x_0) = -\eta.$$

Because $f^2(x_0) \in (r, s)$, $x_0 \in (r, s)$, and $r \geqq \xi_2$, the only possibility is that $f(x_0) = -\eta$ or $f^3(x_0) = -\eta$. In particular, we must be in Case 2 and have $f(\xi) \leqq -\eta$ and $f(-\eta) = \alpha$. But then we again obtain a contradiction: either $\alpha = f^2(x_0) \in (r, s)$ or $\alpha = f^4(x_0) \in (r, s)$. Since we have obtained a contradiction in all cases, the theorem is proved. □

Remark 7.1. Note that we have actually proved somewhat more than is claimed. If f is as in Theorem 7.4 and $f_*^2(\alpha) = \alpha$ and ξ_2 is as defined in the proof, an examination of the previous argument shows that there exists γ with $\xi_2 < \gamma < \alpha$ such that $f^2(\gamma) = \gamma$ and $(f^2)'(\gamma) < -1$. An analogous statement is true if $f_*^2(-\beta) = -\beta$.

In fact, the same kinds of arguments used in Theorem 7.4 allow a much more detailed picture of the fixed points of $g = f^2$. If f is as in Theorem 7.4 and $f_*^2(\alpha) = \alpha$, and ξ_1 and ξ_2 are as in the proof of Theorem 7.4 (so that $\xi_1 = \xi_2 = \xi$ if $f(\xi) \geqq -\eta$), then we can prove g has no nonzero fixed points on $[0, \xi_1]$. If $g(\xi) \leqq \xi$, then g has unique fixed points γ_1 in $[\xi_1, \xi]$ and γ_2 in $(\xi, \xi_2]$, and $g'(\gamma_2) > 1$. If $g(\xi) > \xi$, then g has no fixed points in $[\xi_1, \xi]$ and g either has zero, 1, or 2 fixed points in $[\xi, \xi_2]$. If g has exactly one fixed point γ_1 in $[\xi, \xi_2]$, then $g'(\gamma_1) = 1$ and $g''(\gamma_1) > 0$. If g has exactly two fixed points $\gamma_1 < \gamma_2$ in $[\xi, \xi_2]$, then $0 < g'(\gamma_1) < 1$ and $g'(\gamma_2) > 1$. Because it is very long, we omit the proof.

COROLLARY 7.2. *Suppose f is as in Theorem* 7.4 *and $f_n : \mathbb{R} \to \mathbb{R}$, $n \geqq 1$, is a sequence of C^1 functions such that $f_n(x) \to f(x)$ and $f_n'(x) \to f'(x)$ uniformly on compact intervals. Assume f_n satisfies condition* (0) *and positive numbers A_n and B_n exist such that $f_n([-B_n, A_n]) \subset [-B_n, A_n]$, $xf_n(x) < 0$ for all $x \in [-B_n, A_n] - \{0\}$, and $A_n \to \alpha$ and $B_n \to \beta$ as $n \to \infty$ (α and β are as in the definition of* (PM) *for f). If $f_*^2(\alpha) = \alpha$ or $f_*^2(\beta) = \beta$, then there exists $\gamma \in (-\beta, \alpha)$ such that $f^2(\gamma) = \gamma$ and $(f^2)'(\gamma) < -1$, and there exists a sequence $(\gamma_n) \to \gamma$, defined for n sufficiently large, such that $\gamma_n \in (-B_n, A_n)$, $f_n^2(\gamma_n) = \gamma_n$ and $(f_n^2)'(\gamma_n) < -1$.*

Proof. This follows immediately from Theorem 7.4 and elementary calculus arguments. □

8. The Schwarzian derivative of f_k. To apply the theory of § 7 to the functions f_k, we must first show $Sf_k(x) < 0$ for the appropriate ranges of x. As the Schwarzian derivative is invariant under translation, it is sufficient to work directly with the functions f_k rather than with the corresponding normalized functions

$$g_k(x) = f_k(x + x_0) - f_k(x_0). \tag{8.1}$$

PROPOSITION 8.1. *For the functions f_k we have*

$$Sf_k(x) < 0 \quad \text{whenever } f_k'(x) \neq 0 \tag{8.2}$$

for the ranges of parameters and values of x in Table 2. *Also, hypothesis* (NS_1) *or* (NS_2) *holds at the fixed point x_0 for all $\mu > \mu_0$ as indicated in Table* 2, *where x_0 and μ_0 are as in Table* 1.

The data of Table 2 are sufficient but not necessary for the Schwarzian derivative of f_k to be negative, or for (NS_1) or (NS_2) to hold. For example, we have not ruled out the possibility that in at least part of the range $0 < \nu < 1$ the condition (NS_2) might hold for f_4 or f_5, rather than the weaker condition (NS_1).

Proof. Rather than prove this result by direct (but lengthy) calculation of the Schwarzian derivatives, we use the results of § 6 to simplify our work.

TABLE 2

Ranges where the Schwarzian derivative of f_k is negative (provided $f_k'(x) \neq 0$), and where (NS_1) *or* (NS_2) *holds at the fixed point x_0 for all $\mu > \mu_0$. The values of x_0 and μ_0 are as in Table* 1.

k	Range where the Schwarzian derivative is negative (where (8.2) holds)	Hypothesis (NS_1) or (NS_2) holding at x_0 for all $\mu > \mu_0$
1	all $x \in \mathbb{R}$, $\mu \in \mathbb{R}$	(NS_2)
2	all $x \in \mathbb{R}$ when $\mu \geqq 0$	(NS_2)
3	all $x \in \mathbb{R}$, $\mu, \theta \in \mathbb{R}$	(NS_2) when $0 \leqq \theta < \pi/2$
4	$x > 0$ when $\nu \geqq 1$	(NS_2) when $\nu \geqq 1$ or $\nu = 0$
	$x > \nu$ when $0 \leqq \nu < 1$	(NS_1) when $0 < \nu < 1$
5	$x > 0$ when $\nu \geqq 1$ and $\lambda > \nu + 1$	(NS_2) when $\nu \geqq 1$ and $\lambda > \nu + 1$, or when $\nu = 0$ and $\lambda > 1$
	$x > \left(\frac{\nu}{\lambda - \nu}\right)^{1/\lambda}$ when $0 \leqq \nu < 1$ and $\lambda > \nu + 1$	(NS_1) when $0 < \nu < 1$ and $\lambda > \nu + 1$

The cases $k = 1$, 2, and 3 follow immediately from Proposition 6.2. (An easy alternate proof in the case of f_3 is to note that $Sf_3(x) \leqq f_3'''(x)/f_3'(x) = -1$ wherever $f_3'(x) \neq 0$.) Essentially the same argument as in the proof of Proposition 6.2 also works for f_4, even though this is not an entire function when ν is not an integer. Assuming $\mu \neq 0$, for $x > 0$ and $x \neq \nu$ we have

$$\frac{d^2}{dx^2} \log |f_4'(x)| = -\frac{\nu - 1}{x^2} - \frac{1}{(x - \nu)^2}, \tag{8.3}$$

which is negative if $\nu \geqq 1$. If $0 < \nu < 1$ and $x > \nu$ then (8.3) is bounded above by $-(\nu - 1)/x^2 - 1/x^2 = -\nu/x^2$, and hence is again negative. When $\nu = 0$, a direct calculation of the Schwarzian derivative shows that $Sf_4(x) = -\frac{1}{2}$ for $x > 0$. The claims of the proposition now follow directly. In particular, we see that (NS_1) holds for f_4 when $0 < \nu < 1$ and $\mu > \mu_0$, when we note that f_4 achieves its maximum at $x = \nu$ and this critical point lies to the left of the fixed point x_0.

The calculations for f_5 are somewhat more involved, but some simplification can be achieved by considering the reciprocal of this function. Setting $m(x) = \mu/x$ where $\mu \neq 0$, from (iii) of Proposition 6.1 we have that for $x > 0$ and $f_5'(x) \neq 0$

$$Sf_5(x) = Sh(x)$$

where

$$h(x) = m(f_5(x)) = x^{-\nu} + x^{\lambda - \nu}.$$

Further calculation yields

$$Sh(x) = -\frac{Py^2 + Qy + R}{x^2[(\lambda - \nu)y - \nu]^2}$$

where

$$P = \tfrac{1}{2}(\lambda - \nu)^2[(\lambda - \nu)^2 - 1],$$

$$Q = \nu(\lambda - \nu)[(\lambda - \nu)^2 + 3\nu(\lambda - \nu) + \nu^2 + 1],$$

$$R = \tfrac{1}{2}\nu^2(\nu^2 - 1),$$

$$y = x^{\lambda}, \qquad y \neq \frac{\nu}{\lambda - \nu}.$$

If $\nu \geqq 0$ and $\lambda > \nu+1$ as in Table 1 then $P>0$ and $Q>0$. If in addition either $\nu \geqq 1$ or $\nu = 0$, then $R \geqq 0$, and so $Sf_5(x)<0$ for $x>0$. In this case f_5 satisfies (NS_2) when $\mu > \mu_0$, as claimed. On the other hand, if $\lambda > \nu+1$ but $0<\nu<1$, then a calculation reveals $Py^2+Qy+R>0$ at $y=\nu/(\lambda-\nu)$. Thus,

$$Py^2+Qy+R>0 \quad \text{for } y \geqq \frac{\nu}{\lambda-\nu}$$

because $P>0$ and $Q>0$; hence $Sf_5(x)<0$ for $x>(\nu/(\lambda-\nu))^{1/\lambda}$. Again, as f_5 achieves its maximum at $x=(\nu/(\lambda-\nu))^{1/\lambda}$ and this point lies to the left of x_0 when $\mu>\mu_0$, it follows that f_5 satisfies (NS_1), as claimed. □

9. Applications of the general theory to the function f_k. We will now use the results of § 7 to determine ranges of parameters for which hypothesis (I), (II), or (III) holds for f_k at a fixed point x_0 of Table 1. In this connection it will first be useful to make a few general remarks.

Suppose that $f(x)$ is a continuous function with fixed point x_0 and assume that the function $g(x)$ defined by

$$f(x+x_0)-x_0=g(x)$$

satisfies (PM). Recall that f satisfies (I), (II), or (III) at x_0 if and only if g satisfies the corresponding hypothesis at zero. If α, β, ξ, and η are the quantities in (PM) for g, then define $x_1=x_0-\beta$, $x_2=x_0-\eta$, $x_3=x_0+\xi$, and $x_4=x_0+\alpha$. We are considering the function $f(x)$ on the interval $[x_1, x_4]$, and $f(x)>x_0$ for $x_1<x<x_0$, $f(x_1)=x_0$ if $x_1>-\infty$, $f(x)<x_0$ for $x_0<x<x_4$, and $f(x_4)=x_0$ if $x_4<\infty$. Furthermore, $[x_2, x_3]$ is the maximum interval containing x_0 on which f is monotone decreasing and f is monotone increasing on $[x_1, x_2]$ and $[x_3, x_4]$. Upon defining the function $f_*:\mathbb{R}\to\mathbb{R}$ by

$$f_*(x)=\begin{cases} f(x_2) & \text{in } (-\infty, x_2] \quad \text{if } x_2>-\infty, \\ f(x) & \text{in } [x_2, x_3], \\ f(x_3) & \text{in } [x_3, \infty) \quad \text{if } x_3<\infty, \end{cases}$$

we see that (7.1) and (7.2) of Theorem 7.2 for g become

$$\begin{aligned} &(f_*^2)(x_4)<x_4 \quad \text{if } x_4<\infty, \\ &(f_*^2)(x_1)>x_1 \quad \text{if } x_1>-\infty, \end{aligned} \tag{9.1}$$

and

$$\begin{aligned} &f^2(x_3)\leqq x_3 \quad \text{if } x_3<\infty, \\ &f_*^2(x_2)\geqq x_2 \quad \text{if } x_2>-\infty. \end{aligned} \tag{9.2}$$

Thus if g satisfies (PM) and f is C^3 with negative Schwarzian derivative on (x_2, x_3), then f satisfies hypothesis (I) at x_0 if and only if the inequalities (9.1) hold, and f satisfies (III) if and only if (9.2) holds.

Now suppose that f is a continuous function with fixed point x_0, that g satisfies (PM), and x_1, x_2, x_3, and x_4 are as defined above. Suppose that φ is a C^1 function defined on an interval (y_1, y_4), that $\varphi'(y)>0$ for $y_1<y<y_4$, and that $\varphi(y_1)=x_1$ and $\varphi(y_4)=x_4$. If $x_1=-\infty$, then assume for convenience that $y_1=-\infty$, and similarly if $x_4=\infty$, then assume $y_4=\infty$. It is easy to check that f satisfies hypothesis (I), (II), or (III) at x_0 if and only if $\varphi^{-1}f\varphi$ satisfies the corresponding hypothesis at $y_0=\varphi^{-1}(x_0)$. Furthermore, writing $h=\varphi^{-1}f\varphi$, we easily verify that

$$h_*=\varphi^{-1}f_*\varphi. \tag{9.3}$$

If f is C^3 on $[x_2, x_3]$ and $Sf(x) < 0$ for $x_2 < x < x_3$, it follows from (9.1)-(9.3) and the above remarks that $h = \varphi^{-1} f \varphi$ satisfies (I) at y_0 if and only if

$$(h_*^2)(y_4) < y_4 \quad \text{and} \quad (h_*^2)(y_1) > y_1, \tag{9.4}$$

where $y_j = \phi^{-1}(x_j)$ for $0 \leqq j \leqq 4$. Similarly, h satisfies (III) at y_0 if and only if

$$(h_*^2)(y_3) \leqq y_3 \quad \text{and} \quad (h_*^2)(y_1) \geqq y_1. \tag{9.5}$$

Note that h need not have negative Schwarzian derivative on (y_2, y_3).

The above observation sometimes simplifies calculations, since it may be easier to work with h and h_* than with f and f_*.

We now begin the analyses of the functions f_k. Consider first the function f_1. We easily see that with x_0 as in Table 1 and $\mu > \mu_0 = \frac{3}{4}$ we have $\alpha + x_0 = \xi + x_0 = \infty$, $-\beta + x_0 = -x_0$, and $-\eta + x_0 = 0$, so

$$f_{1*}(x) = \begin{cases} \mu & \text{in } (-\infty, 0], \\ \mu - x^2 & \text{in } (0, \infty). \end{cases}$$

We have $f_{1*}^2(-\eta + x_0) \geqq -\eta + x_0$ if and only if $\mu - \mu^2 \geqq 0$, and $f_{1*}^2(-\beta + x_0) \geqq -\beta + x_0$ if and only if $\mu - \mu^2 \geqq -x_0$, that is,

$$2\mu^2 - 2\mu + 1 < \sqrt{4\mu + 1}. \tag{9.6}$$

Inequality (9.6) is equivalent to

$$\mu^3 - 2\mu^2 + 2\mu - 2 < 0,$$

as a short calculation shows; and this in turn is equivalent to

$$\mu < \mu_* \cong 1.5437$$

where μ_* is the unique real root of $\mu^3 - 2\mu^2 + 2\mu - 2 = 0$. By Theorem 7.1 we conclude from these calculations, and the data of Table 1, that (I) holds at x_0 if and only if $\frac{3}{4} < \mu < \mu_*$, and that (III) holds if and only if $\frac{3}{4} < \mu \leqq 1$.

To determine those values of μ between $\mu = \frac{3}{4}$ and $\mu = \mu_*$ at which (II) holds, we must consider points of period 2 for the map f_1 in the interval $(-\beta + x_0, \alpha + x_0) = (-x_0, \infty)$. Assuming that $\frac{3}{4} < \mu < \mu_*$, we consider points x_1 and x_2 satisfying

$$f_1(x_1) = x_2 \quad \text{and} \quad f_1(x_2) = x_1 \tag{9.7}$$

and lying on either side of x_0 in the above interval:

$$-x_0 < x_1 < x_0 < x_2. \tag{9.8}$$

As noted earlier such points do exist; in fact, in the closed interval $[-B + x_0, A + x_0] \subseteq (-\beta + x_0, \alpha + x_0)$. Writing out the equations in (9.7) gives, after some manipulation, that $x_1 + x_2 = 1$ and

$$\mu = 1 - x_1 x_2.$$

Further, the derivative of f_1^2 at either of these points is

$$(f_1^2)'(x_1) = (f_1^2)'(x_2) = f_1'(x_1) f_1'(x_2) = 4x_1 x_2 = 4(1 - \mu).$$

In the range $\frac{3}{4} < \mu \leqq \frac{5}{4}$ we therefore have $-1 \leqq (f_1^2)'(x_1) < 1$, so (II) holds by Theorem 7.3. Theorem 7.3 also implies the uniqueness of solutions of (9.7) and (9.8) for $\frac{3}{4} < \mu \leqq \frac{5}{4}$. Of course, since $x_1 + x_2 = 1$, we can also solve for x_1 and x_2 and directly obtain uniqueness. If, on the other hand, $\frac{5}{4} < \mu < \mu_*$, the same calculations show $|(f_1^2)'(x_j)| > 1$, and (II) does not hold. Table 3 summarizes our results for f_1 by indicating the parameter ranges where (I), (II), or (III) holds.

The situation for f_2 is very similar to that for f_1. In particular the same sort of analysis as above yields intervals of the parameter μ in which various hypotheses hold. Thus we easily find that f_2 satisfies (I) for $1<\mu<3\sqrt{3}/2$ and (III) for $1<\mu<\frac{3}{2}$. If $f_2(x_1)=x_2$ and $f_2(x_2)=x_1$, where $-\sqrt{\mu}<x_2<0<x_1<\sqrt{\mu}$, then $x_1f_2(x_1)-x_2f_2(x_2)=0$, from which we derive $\mu=x_1^2+x_2^2$, if $x_1\neq -x_2$, or $x_1=-x_2$. The equation

$$f_2(x_1)-x_2-f_2(x_2)+x_1=0$$

implies

$$x_1^2+x_1x_2+x_2^2=\mu-1,$$

so if $x_1\neq -x_2$ we have $x_1^2+x_2^2=\mu$ and

$$x_1x_2=-1. \tag{9.9}$$

Now if $x_2=-x_1^{-1}$, a simple calculation shows that the defining equations for x_2 and x_1 are equivalent to the single equation

$$x_1^4-\mu x_1^2=-1. \tag{9.10}$$

The quadratic equation (9.10) has a real, positive solution if and only if $\mu\geqq 2$. Therefore, if $1<\mu<2$, we must have $x_2=-x_1$. Since f_2 is odd, the defining equations for x_1 and x_2 reduce to the single equation

$$f_2(x_1)=x_1^3-\mu x_1=-x_1,$$

so we obtain

$$x_1=\sqrt{\mu-1} \quad \text{and} \quad x_2=-\sqrt{\mu-1}. \tag{9.11}$$

Substituting (9.11) into the following equation, we obtain

$$\begin{aligned}(f_2^2)'(x_1)=f_2'(x_2)f_2'(x_1)&=(3x_2^2-\mu)(3x_1^2-\mu)\\&=(2\mu-3)^2.\end{aligned} \tag{9.12}$$

Equation (9.12) implies that $|(f_2^2)'(x_j)|<1$ if $1<\mu<2$, so (II) holds for $1<\mu<2$. On the other hand, if $\mu>2$ and we take $x_2=-x_1$, Theorem 7.3 and (9.12) imply that (II) is not satisfied.

Finally, if $\mu=2$, a direct calculation using the above information shows that $x_1=1$ and $x_2=-1$ are the only nonzero fixed points of f_2^2 and

$$(f_2^3)''(x_1)=0,$$

so Theorem 7.3 again implies that (II) is satisfied. All of this information is summarized in Table 3.

TABLE 3

$f_k(x)$ satisfies (I) *at x_0 if and only if $\mu_0<\mu<\mu_1$, $f_k(x)$ satisfies* (II) *if and only if $\mu_0<\mu\leqq\mu_2$, and $f_k(x)$ satisfies* (III) *at x_0 if and only if $\mu_0<\mu\leqq\mu_3$.*

k	x_0	μ_0	μ_1	μ_2	μ_3
1	$(-1+\sqrt{4\mu+1})/2$	$\frac{3}{4}$	$\mu_1^3-2\mu_1^2+2\mu_1-2=0$ $\mu_1\cong 1.5437$	$\frac{5}{4}$	1
2	0	1	$3\sqrt{3}/2$	2	$\frac{3}{2}$

For the map f_3 with fixed point $x_0 = 0$ and parameter θ chosen in the range $0 \leqq \theta < \pi/2$ established earlier, we again find intervals of μ in which (I) and (III) hold. The range where (II) holds, however, is still not clear. Recall the critical value $\mu_0 = \mu_0(\theta) = 1/\cos\theta$ from Table 1.

THEOREM 9.1. *There exist continuous functions*

$$\rho_3, \tau_3 : \left[0, \frac{\pi}{2}\right) \to (0, \infty)$$

satisfying

$$\mu_0(\theta) = \frac{1}{\cos\theta} < \rho_3(\theta) < \tau_3(\theta)$$

such that if $0 \leqq \theta \leqq \pi/2$, *then* (I) *holds for* f_3 *at* $x_0 = 0$ *if and only if* $\mu_0(\theta) < \mu < \tau_3(\theta)$, *and* (III) *holds if and only if* $\mu_0(\theta) < \mu \leqq \rho_3(\theta)$.

Motivated by the results for f_1 and f_2, we might expect the existence of a third function σ_3 satisfying $\rho_3(\theta) < \sigma_3(\theta) < \tau_3(\theta)$ and such that (II) holds if and only if $\mu_0(\theta) < \mu \leqq \sigma_3(\theta)$. We believe this to be the case, but we have not pursued this question here. However, we can easily prove by an implicit function theorem argument that condition (II) holds for $\mu_0(\theta) < \mu < \rho_3(\theta) + \delta_3(\theta)$ for some sufficiently small $\delta_3(\theta) > 0$: the period 2 points $\{x_1 x_2\}$ of f_3 for $\mu = \rho_3(\theta)$ are "super-stable" (that is, $(f_3^2)'(x_1) = (f_3^2)'(x_2) = 0$) and so must persist for μ slightly larger than $\rho_3(\theta)$. On the other hand, Corollary 7.2 implies that there exists $\delta_4(\theta) > 0$ such that for $\tau_3(\theta) - \delta_4(\theta) < \mu < \tau_3(\theta)$ the function f_3^2 has a fixed point γ (in the relevant interval) such that $(f_3^2)'(\gamma) < -1$, and this implies (II) fails for $\tau_3(\theta) - \delta_4(\theta) < \mu < \tau_3(\theta)$. By using Remark 7.1 we can also show that, for θ near zero and μ near $\tau_3(\theta)$, f_3^2 has a second fixed point $\bar{\gamma}$ for which $(f_3^2)'(\bar{\gamma}) > 1$.

Proof of Theorem 9.1. Assuming $\mu > 0$ and $0 \leqq \theta < \pi/2$, we note the following values:

$$\alpha = \pi - \theta \leqq \beta = \pi + \theta, \qquad \xi = \frac{\pi}{2} - \theta \leqq \eta = \frac{\pi}{2} + \theta$$

for f_3 in condition (PM). We also note the following formulas:

$$f_{3*}(\alpha) = f_{3*}(\xi) = -\mu(1 - \sin\theta),$$
$$f_{3*}(-\beta) = f_{3*}(-\eta) = \mu(1 + \sin\theta).$$

In order to use Theorem 7.1 for determining when (I) or (III) holds, we must calculate both $(f_{3*}^2)(\alpha) = (f_{3*}^2)(\xi)$ and $(f_{3*}^2)(-\beta) = (f_{3*}^2)(-\eta)$, and examine (7.1) or (7.2). In fact, we claim

$$\begin{aligned} &f_{3*}^2(\alpha) < \alpha \quad \text{implies } f_{3*}^2(-\beta) > -\beta, \\ &f_{3*}^2(\xi) \leqq \xi \quad \text{implies } f_{3*}^2(-\eta) \geqq -\eta. \end{aligned} \tag{9.13}$$

Thus, we need only verify the inequality $f_{3*}^2(\alpha) < \alpha$ to conclude (I), and $f_{3*}^2(\xi) \leqq \xi$ to conclude (III).

We prove only the first implication (9.13), as the proof of the other is similar. Suppose

$$f_{3*}^2(-\beta) \leqq -\beta. \tag{9.14}$$

Then as f_{3*} achieves its minimum at $x = \xi$, we have

$$f_{3*}(\xi) \leqq -\beta \tag{9.15}$$

from (9.14), and so

$$f_{3*}^2(\xi) = f_{3*}(-\beta) \tag{9.16}$$

as f_{3*} is constant to the left of $-\beta$. Thus, from (9.14)-(9.16) we obtain

$$\begin{aligned} f_{3*}^2(\alpha) = f_{3*}^2(\xi) = f_{3*}(-\beta) &= \mu(1+\sin\theta) \\ &\geqq \mu(1-\sin\theta) = -f_{3*}(\xi) \geqq \beta \geqq \alpha. \end{aligned}$$

The required inequality $f_{3*}^2(\alpha) \geqq \alpha$, from which the implication (9.13) follows, is now proved.

We now calculate the quantity

$$(f_{3*}^2)(\xi) = (f_{3*}^2)(\alpha) = f_{3*}(-\mu(1-\sin\theta)) \tag{9.17}$$

and compare it with either α or ξ, as described above. Let $h_3(\mu, \theta)$ denote $(f_{3*}^2)(\alpha)$; then we easily see

$$h_3(\mu, \theta) = \begin{cases} \mu[\sin\theta - \sin(\theta - \mu(1-\sin\theta))] & \text{if } \mu \leqq \dfrac{\pi/2+\theta}{1-\sin\theta}, \\ \mu(1+\sin\theta) & \text{if } \mu \geqq \dfrac{\pi/2+\theta}{1-\sin\theta}. \end{cases}$$

A simple calculation shows that $\partial h_3(\mu, \theta)/\partial\mu > 0$ for all $\mu > 0$ in the two ranges of μ for which h_3 is defined. Thus $h_3(\mu, \theta)$ is strictly increasing in μ, for each fixed $\theta \in [0, \pi/2)$, and assumes every positive value exactly once for $\mu > 0$. Thus there exist continuous functions $\rho_3, \tau_3 : [0, \pi/2) \to (0, \infty)$ satisfying

$$h_3(\rho_3(\theta), \theta) = \alpha = \pi - \theta, \qquad h_3(\tau_3(\theta), \theta) = \xi = \pi/2 - \theta.$$

By Theorem 7.2 we also have

$$h_3(1/\cos, \theta) < \xi,$$

since $f_3'(0) = -1$ when $\mu = 1/\cos\theta$. Thus,

$$1/\cos\theta < \rho_3(\theta) < \tau_3(\theta)$$

and the result follows immediately. □

As has already been noted in § 3, if the function f_3 is not in our normal form, there may be some difficulties in determining the ranges of the original parameters for which (I) or (III) is satisfied. To illustrate this point, we consider

$$\varepsilon\dot{x}(t) = -x(t) + \mu(1-\sin(x(t-1))), \tag{9.18}$$

which has been studied numerically by Chow and Green [4]. For each $\mu > 0$, we can easily see that

$$\mu(1-\sin x) = x, \qquad 0 < x < \pi/2, \tag{9.19}$$

has a unique fixed point $\theta = \theta(\mu) \in (0, \pi/2)$, and using the implicit function theorem we can see that $\theta'(\mu) > 0$ for $\mu > 0$. The question is does $\mu(1-\sin x)$ satisfy condition (I) or (III) at $x = \theta(\mu)$.

PROPOSITION 9.1. *For each $\mu > 0$, the function $\mu f(x) = \mu(1-\sin x)$ has a unique fixed point $\theta = \theta(\mu) \in (0, \pi/2)$. There exist numbers μ_0 (μ_0 is approximately equal to* 1.1773) *and μ_1 (μ_1 is approximately equal to* 2.3879) *such that $\mu f(x)$ satisfies* (I) *at*

$\theta(\mu)$ if and only if $\mu_0 < \mu < \mu_1$ and $\mu f(x)$ satisfies (III) *at $\theta(\mu)$ if and only if $\mu_0 < \mu \leqq \pi/2$. The equation*

$$\frac{\theta \cos \theta}{1-\sin \theta} = 1, \qquad 0 < \theta < \frac{\pi}{2},$$

has a unique solution $\theta_0 \in (0, \pi/2)$ and $\mu_0 = \theta_0/(1-\sin \theta_0)$. The equation

$$\theta + \left(\frac{\theta}{1-\sin \theta}\right) = \pi, \qquad 0 < \theta < \frac{\pi}{2},$$

has a unique solution $\theta_1 \in (0, \pi/2)$ and $\mu_1 = \theta_1/(1-\sin \theta_1)$.

Proof. The idea of the proof is to parameterize by the fixed point $\theta \in (0, \pi/2)$ instead of by μ. If $\theta \in (0, \pi/2)$ is the fixed point of $\mu f(x)$, then

$$\mu = \frac{\theta}{1-\sin \theta}.$$

Thus, for $0 < \theta < \pi/2$, define $g(x, \theta) = g_\theta(x)$ by

$$g(x, \theta) = g_\theta(x) = \left(\frac{\theta}{1-\sin \theta}\right)(1 - \sin(x+\theta)) - \theta.$$

We can easily check that the map $\theta \to (\theta/1-\sin \theta))$ is strictly increasing for $0 < \theta < \pi/2$ and

$$\{\mu : \mu f(x) \text{ satisfies (III) at } \theta(\mu)\}$$
$$= \{\theta/(1-\sin \theta) : 0 < \theta < \pi/2 \text{ and } g_\theta(x) \text{ satisfies (III) at zero}\},$$

with an analogous equation concerning (I). If the numbers $\alpha = \alpha(\theta), \beta = \beta(\theta), \xi = \xi(\theta)$, and $\eta = \eta(\theta)$ are as in the definition of condition (PM) for g_θ, then $\alpha = \pi - 2\theta$, $\beta = \pi + 2\theta$, $\xi = \pi/2 - \theta$, and $\eta = \pi/2 + \theta$. The same argument as in Theorem 9.1 shows that g_θ satisfies (III) if and only if

$$(g_{\theta^*}^2)\left(\frac{\pi}{2} - \theta\right) \leqq \frac{\pi}{2} - \theta, \tag{9.20}$$

$$g_\theta'(0) = -\left(\frac{\theta \cos \theta}{1-\sin \theta}\right) < -1. \tag{9.21}$$

Since $g_{\theta^*}(\pi/2 - \theta) = -\theta > -\eta$, we easily compute that (9.20) holds if and only if

$$\left(\frac{\theta}{1-\sin \theta}\right) \leqq \frac{\pi}{2}. \tag{9.22}$$

Thus $g_\theta, 0 < \theta < \pi/2$, satisfies (III) if and only if (9.21) and (9.22) hold. Similarly, we see that g_θ satisfies (I) if and only if (9.21) is valid and

$$(g_{\theta^*}^2)(\pi - 2\theta) = \left(\frac{\theta}{1-\sin \theta}\right) - \theta < \pi - 2\theta, \quad \text{that is,}$$
$$\left(\frac{\theta}{1-\sin \theta}\right) + \theta < \pi, \qquad 0 < \theta < \tfrac{\pi}{2}. \tag{9.23}$$

It remains to study where (9.21)-(9.23) hold. Obviously the function $(\theta/(1-\sin \theta)) + \theta = h(\theta)$ satisfies $h(0) = 0$, $\lim_{\theta \to \pi/2} h(\theta) = \infty$ and $h'(\theta) > 0$ for $0 < \theta < \pi/2$, so there is a unique number θ_1 such that

$h(\theta_1) = \pi$ and $h(\theta) < \pi$ if and only if $0 < \theta_1 < \pi$.

In order to study where $k(\theta)=(\theta\cos\theta/(1-\sin\theta))>1$ for $\theta\in(0,\pi/2)$, first observe that the mean value theorem gives

$$1-\sin\theta=\left(\frac{\pi}{2}-\theta\right)\cos(\psi),\qquad \theta<\psi<\frac{\pi}{2}.$$

If $\pi/4\leqq\theta\leqq\pi/2$, this implies

$$k(\theta)=\left(\frac{\theta}{\pi/2-\theta}\right)\left(\frac{\cos\theta}{\cos\psi}\right)>1.$$

On the other hand, if $0<\theta<\pi/4$ we have

$$k'(\theta)=[(\cos\theta-\theta\sin\theta)(1-\sin\theta)+\theta\cos^2\theta](1-\sin\theta)^{-2}.$$

Because we also have

$$\cos\theta-\theta\sin\theta>\cos\theta-\sin\theta\geqq 0\quad\text{for } 0<\theta\leqq\pi/4,$$

we conclude that $k'(\theta)>0$ for $0<\theta\leqq\pi/4$. From the above facts it follows that $k(\theta)=1$ has a unique solution $\theta_0\in(0,\pi/2)$, that $0<\theta_0<\pi/4$, and that $k(\theta)>1$ for $\theta\in(0,\pi/2)$ if and only if $\theta_0<\theta<\pi/2$. This completes the proof of the proposition. (Approximate values of θ_0 and θ_1, and hence of μ_0 and μ_1, can easily be computed using Newton's method.) □

Proposition 9.1 and the results summarized in § 2 provide some explanation of the numerical results in [4]. For example, if $\mu_0<\mu\leqq\pi/2$ we see for small ε the regular SOP-solutions predicted by Theorem 2.3. Theorem 2.1 asserts that SOP-solutions persist for $\mu_0<\mu<\mu_1$ and $\varepsilon>0$ sufficiently small. However, these solutions apparently lose stability for μ near μ_1 and $\varepsilon>0$ small: for μ near μ_1 Chow and Green appear to have found, numerically, periodic solutions that are *not* SOP-solutions.

We now want to examine when (I), (II), or (III) is satisfied by the functions f_4 or f_5. With $k=4$ or $k=5$ and fixed parameters $\nu\geqq 0$ and $\lambda>\nu+1$ (when $k=5$), we will write

$$f_k(x)=\mu\bar{f}_k(x), \tag{9.24}$$

where the function $\bar{f}_k(x)$ does not depend on μ. In our next several theorems we will discuss the range of μ for which the functions f_4 and f_5 satisfy (I) or (III), and we will return later to (II). The next theorem provides a reasonably sharp and general answer concerning when (III) holds for functions $\mu\bar{f}(x)$; the question of (I) seems more difficult.

THEOREM 9.2. *Assume $\bar{f}:(0,\infty)\to(0,\infty)$ is a C^3 function and there exists a number $\theta\geqq 0$ such that $\bar{f}'(s)>0$ for $0<s<\theta$ and $\bar{f}'(s)<0$ for $s>\theta$. Assume there exists a unique number $s_0>\theta$ such that*

$$\frac{d}{ds}(s\bar{f}(s))|_{s=s_0}=0,$$

and assume also

$$\frac{d}{ds}(s\bar{f}(s))|_{s=s_0}<0\quad\forall s>s_0.$$

Finally, assume $(S\bar{f})(x)<0$ for $x>\theta$. Define functions $\mu(s)$, $x_1(s)$, $x_2(s)$, and $x_3(s)$ by $\mu(s)=s(\bar{f}(s))^{-1}$, $x_1(s)=\mu(s)\bar{f}(\theta)$, and

$$x_j(s)=\mu(s)\bar{f}(x_{j-1}(s))\quad\text{for } j\geqq 2.$$

If $x_0(\mu)$ denotes the unique fixed x of $\mu f(x)$ such that $x \geqq \theta$ (for $\mu \geqq \theta(\bar{f}(\theta))^{-1}$), then

$$\{\mu\colon \mu\bar{f}(x) \text{ satisfies (I) at } x_0(\mu)\} = \{\mu(s)\colon s > s_0 \text{ and } x_3(s) > s\}$$

and

$$\{\mu\colon \mu f(x) \text{ satisfies (III) at } x_0(\mu)\} = \{\mu(s)\colon s > s_0 \text{ and } x_2(s) \geqq \theta\}.$$

There exists a number $\rho > \mu(s_0) \equiv \mu_0$ such that

$$\{\mu\colon \mu f(x) \text{ satisfies (III) at } x_0(\mu)\} = (\mu_0, \rho],$$

and $\rho < \infty$ if $\lim_{x\to\infty} x\bar{f}(x) = 0$. The number ρ is $z(\bar{f}(\theta))^{-1}$ where z is the unique solution of $z\bar{f}(z) = \theta\bar{f}(\theta)$ such that $z > s_0$ (if such a solution exists).

If D is an open subset of $\mathbb{R}^m$ and $\bar{f}\colon (0,\infty)\times D \to (0,\infty)$ is a C^3 map such that $x \to \bar{f}(x,\gamma)$ satisfies the conditions of our theorem for each $\gamma \in D$ (so $\theta = \theta(\gamma)$ and $s_0 = s_0(\gamma)$ exist and are easily proven to be continuous), then the number $\rho = \rho(\gamma)$ is also a continuous function of γ. (If $\rho(\gamma) = \infty$ for some γ, continuity is interpreted in the obvious way.)

Proof. First assume $\bar{f}$ is independent of $\gamma \in D$. For a given $\mu > 0$ let $x_0 = x_0(\mu) \geqq \theta$ and define $\delta = \delta(\mu) \leqq \theta$ by

$$\bar{f}(\delta) = \bar{f}(x_0).$$

Theorem 4.1 implies that $\mu\bar{f}(x)$ satisfies condition (0) at x_0 if and only if $\mu > \mu_0 = s_0(\bar{f}(s_0))^{-1} = \mu(s_0)$, and the results of § 7 imply that $\mu\bar{f}(x)$ satisfies (III) at x_0 if and only if $\mu > \mu_0$ and

$$(\mu\bar{f})^2(\theta) \geqq \theta \tag{9.25}$$

where $(\mu\bar{f})^j$ is the composition of $\mu\bar{f}$ with itself j times. Similarly, $\mu\bar{f}(x)$ satisfies (I) at x_0 if and only if $\mu > \mu_0$ and

$$(\mu\bar{f})^2(\theta) > \delta = \delta(\mu),$$

or equivalently $\mu > \mu_0$ and

$$(\mu\bar{f})^3(\theta) > x_0(\mu). \tag{9.26}$$

(Note that $\mu\bar{f}(\theta) > \mu\bar{f}(x_0) = x_0$, so $(\mu\bar{f})^2(\theta) < x_0$.)

As in Theorem 4.1 the key idea is to parameterize by $s = x_0(\mu)$ instead of μ. Since $\mu\bar{f}(x_0) = x_0$, this gives

$$\mu = s(\bar{f}(s))^{-1} = \mu(s),$$

which is an increasing function of s for $s \geqq \theta$. In terms of this parameterization we find that $\mu(s)\bar{f}(x)$ satisfies (III) at $s > \theta$ if and only if $s > s_0$ and

$$x_2(s) \geqq \theta. \tag{9.27}$$

Similarly, we see that $\mu(s)\bar{f}(x)$ satisfies (I) at s if and only if $s > s_0$ and

$$x_3(s) > s. \tag{9.28}$$

Since Theorem 7.2 and Corollary 7.1 imply that there exists $\delta > 0$ such that $\mu(s)\bar{f}(x)$ satisfies (III) for $s_0 < s \leqq s_0 + \delta$, we have proved the first part of the theorem.

It remains to prove that (III) is satisfied on an interval $(\mu_0, \rho]$. Equivalently, it suffices to prove that

$$\{s\colon s > s_0, x_2(s) \geqq \theta\}$$

is an interval. We know that $x_2(s) > \theta$ for s near s_0, so it suffices to prove $x_2'(s) < 0$ for $s > s_0$. A calculation gives

$$x_1'(s) = \bar{f}(\theta)(\bar{f}(s))^{-2}[\bar{f}(s) - s\bar{f}'(s)],$$

and since $\bar{f}'(s) < 0$ for $s > s_0$, $x_1'(s) > 0$ for all $s > s_0$. Note that we have

$$\mu(s)\bar{f}(\theta) = x_1(s) > \mu(s)\bar{f}(s) = s > s_0,$$

so we find that

$$\lim_{s\to\infty} x_1(s) = \infty.$$

We can write

$$\mu(s) = x_1(s)(\bar{f}(\theta))^{-1},$$

so if we define $g(x) = (\bar{f}(\theta))^{-1}x\bar{f}(x)$,

$$x_2(s) = g(x_1(s)), \qquad x_2'(s) = g'(x_1(s))x_1'(s).$$

However, $x_1(s) > s_0$ and we have assumed that $g'(x) < 0$ for $x > s_0$, so $x_2'(s) < 0$.

If $\sigma > s_0$ is such that $x_2(\sigma) = \theta$, and if $z = x_1(\sigma)$ the above calculation shows that $z\bar{f}(z) = \theta\bar{f}(\theta)$ and $\rho = \mu(\sigma) = z(\bar{f}(\theta))^{-1}$.

If we assume $\lim_{x\to\infty} x\bar{f}(x) = 0$, we obtain (because $x_1(s) \to \infty$ as $s \to \infty$) the following

$$\lim_{s\to\infty} x_2(s) = \lim_{s\to\infty} g(x_1(s)) = 0.$$

This implies that for all large s, $x_2(s) < \theta$, so ρ is finite in this case.

If $\bar{f}$ depends on a parameter $\gamma \in D$, the continuity of $\rho(\gamma)$ follows easily from the implicit function theorem at points where $\rho(\gamma) < \infty$, and continuity at points γ where $\rho(\gamma) = \infty$ is also easy. Details are left to the reader. □

Remark (9.1). *If* $\bar{f}: (0, \infty) \to (0, \infty)$ is as Theorem 9.2 and $\varphi: (\alpha, \beta) \to (0, \infty)$ is a C^1 map onto $(0, \infty)$ with positive derivative, the remarks at the beginning of this section show that $\varphi^{-1}(\mu\bar{f})\varphi$ satisfies (I) or (III) if and only if $\mu\bar{f}$ satisfies (I) or (III).

As an immediate consequence of Theorem 9.2 we obtain Theorem 9.3.

THEOREM 9.3. *Let* $f_k(x)$, $k = 4$ *or* 5, *be as usual and assume* $\nu > 0$ *and* $\lambda > \nu + 1$ *if* $k = 5$. *Define* $\mu_k(s) = s(\bar{f}_k(s))^{-1}$ *and define* $\theta_k = \nu$ *for* $k = 4$ *and* $\theta_k^\lambda = \nu(\lambda - \nu)^{-1}$ *for* $k = 5$. *Define* $\sigma_k = \nu + 1$ *for* $k = 4$ *and* $\sigma_k^\lambda = (\nu + 1)(\lambda - v - 1)^{-1}$ *for* $k = 5$. *Define* z_k *to be the unique solution* $z > \sigma_k$ *of*

$$z\bar{f}_k(z) = \theta_k\bar{f}_k(\theta_k).$$

If x_0 *denotes generically the unique fixed point greater than* θ_k *of* $\mu\bar{f}_k(x)$, *then*

$$\{\mu: \mu\bar{f}_k(x) \text{ satisfies (III) at } x_0\} = (\mu_k(\sigma_k), \rho_k],$$

where $\rho_k = z_k(\bar{f}_k(\theta_k))^{-1}$ *is a continuous function of* ν *and* λ. *If* $x_1(s) = \mu_k(s)\bar{f}_k(\theta_k)$ *and* $x_j(s) = \mu_k(s)\bar{f}_k(x_{j-1}(s))$ *for* $j \geqq 2$, *then*

$$\{\mu: \mu\bar{f}_k(x) \text{ satisfies (I) at } x_0\} = \{\mu_k(s): s > \sigma_k \text{ and } x_3(s) > s\}.$$

If $\nu = 0$, *then* $\mu\bar{f}_k(x)$ *satisfies* (III) *at* x_0 *for all* $\mu > \mu_0$.

Proof. The number θ_k plays the role of θ in Theorem 9.2, and σ_k the role of s_0. We have already verified the negative Schwarzian condition on $\bar{f}_k$ and the other hypotheses of Theorem 9.2 are easily verified, so Theorem 9.3 follows directly from Theorem 9.2. □

We now want to study more precisely when $\mu\bar{f}_4(x)$ satisfies (I). It is convenient to give a calculus lemma first.

LEMMA 9.1. *If* $\nu > 0$, *then*

$$\left(\frac{\nu+2}{\nu}\right)^{\nu+1} > e^2, \tag{9.29}$$

and if $\nu \geqq 1$

$$e < \left(\frac{\nu+2}{\nu+1}\right)\left(\frac{\nu+1}{\nu}\right)^{\nu}. \tag{9.30}$$

If $0 \leqq c < \sqrt{5}-2$, *then there exists* $\nu(c) \geqq 1$ *such that the following inequality is valid for* $\nu \geqq \nu(c)$:

$$e^{1+c} \leqq \left(\frac{\nu+1+c}{\nu}\right)^{\nu}\left(\frac{\nu+2}{\nu+1+c}\right). \tag{9.31}$$

Proof. By taking natural logarithms we see that (9.29) is equivalent to proving

$$(\nu+1)\log\left(1+\frac{2}{\nu}\right) > 2,$$

and the above inequality is equivalent to

$$(\nu+1)\int_0^{2/\nu}\left(\frac{1}{1+t}\right)dt > \int_0^{2/\nu} \nu\, dt.$$

The above inequality is equivalent to

$$\int_0^{1/\nu}\left(\frac{1-\nu t}{1+t}\right)dt = I_1 > \int_{1/\nu}^{2/\nu}\left(\frac{\nu t-1}{1+t}\right)dt = I_2.$$

Change variables in I_1 by setting $t = 1/\nu - \rho$ to obtain

$$I_1 = \int_0^{1/\nu}\left(\frac{\nu\rho}{1+(1/\nu)-\rho}\right)d\rho$$

and change variables in I_2 by setting $t = 1/\nu + \rho$ to obtain

$$I_2 = \int_0^{1/\nu}\left(\frac{\nu\rho}{1+(1/\nu)+\rho}\right)d\rho.$$

Since $\nu > 0$, we have

$$\nu\rho(1+\nu^{-1}-\rho)^{-1} > \nu\rho(1+\nu^{-1}+\rho)^{-1} \quad \text{for } 0 < \rho < \nu^{-1},$$

so $I_1 > I_2$.

The proofs of (9.30) and (9.31) are like the proof of (9.29). If $\nu \geqq 1$, (9.30) is equivalent to

$$1 < \log\left(1+\frac{1}{\nu+1}\right) + \nu\log\left(1+\frac{1}{\nu}\right).$$

Expressing both sides as integrals, the above inequality is equivalent to proving

$$\int_0^{1/\nu} \nu\, dt < \int_0^{1/\nu}\left(\frac{\nu+1}{1+t}\right)dt - \int_{1/(\nu+1)}^{1/\nu}\left(\frac{1}{1+t}\right)dt.$$

Simplification shows that the above inequality is equivalent to

$$0 < \int_0^{1/(\nu+1)}\left(\frac{1-\nu t}{1+t}\right)dt - \int_{1/(\nu+1)}^{1/\nu}\left(\frac{\nu t}{1+t}\right)dt = J_1 - J_2. \tag{9.32}$$

Making the change of variables $t = 1/\nu - \rho$ in J_2, we have

$$J_2 = \int_0^{1/\nu - 1/(\nu+1)} \left(\frac{1-\nu t}{1+\nu^{-1}-t}\right) dt. \tag{9.33}$$

Since $\nu \geqq 1$ we can easily verify that

$$(\nu+1)^{-1} \geqq \nu^{-1} - (\nu+1)^{-1},$$

and using (9.32) and (9.33) we see that $J_1 > J_2$ if

$$(1-\nu t)(1+t)^{-1} > (1-\nu t)(1+\nu^{-1}-t)^{-1} \quad \text{for } 0 < t < \nu^{-1} - (\nu+1)^{-1}. \tag{9.34}$$

However, again using that $\nu \geqq 1$, we can check that inequality (9.34) holds, so $J_1 > J_2$.

By taking logarithms we see that inequality (9.31) is equivalent to

$$1 + c \leqq \nu \log\left(1 + \frac{1+c}{\nu}\right) + \log\left(1 + \frac{1-c}{\nu+1+c}\right),$$

or, by expressing both sides as integrals,

$$\int_0^{(1+c)/\nu} \nu \, dt \leqq \int_0^{(1+c)/\nu} \left(\frac{\nu}{1+t}\right) dt + \int_0^{(1-c)/(\nu+1+c)} \left(\frac{1}{1+t}\right) dt.$$

By simplifying we see that inequality (9.31) is equivalent to

$$K_1 = \int_0^{(1+c)/\nu} \left(\frac{\nu t}{1+t}\right) dt \leqq \int_0^{(1-c)/(\nu+1+c)} \left(\frac{1}{1+t}\right) dt = K_2.$$

Since $(1+t)^{-1} < 1$ for $t > 0$ we see that

$$K_1 < \int_0^{(1+c)/\nu} (\nu t)\, dt = \left(\frac{1}{2}\right)\frac{(1+c)^2}{\nu}. \tag{9.35}$$

On the other hand, $(1+t)^{-1} > 1 - t$, so

$$K_2 > \int_0^{(1-c)/(\nu+1+c)} (1-t)\, dt = \left(\frac{1-c}{\nu+1+c}\right) - \frac{1}{2}\left(\frac{1-c}{\nu+1+c}\right)^2. \tag{9.36}$$

For a given c, $0 < c < 1$, it follows from (9.35) and (9.36) that $K_1 < K_2$ if

$$\left(\frac{1}{2}\right)\frac{(1+c)^2}{\nu} < \left(\frac{1-c}{\nu+1+c}\right) - \frac{1}{2}\left(\frac{1-c}{\nu+1+c}\right)^2.$$

Multiplying by $2\nu(\nu+1+c)$, we see that the above inequality is equivalent to

$$0 < (1-4c-c^2)\nu - (1+c)^3 - (1-c)^2\left(\frac{\nu}{\nu+1+c}\right). \tag{9.37}$$

If $1-4c-c^2 > 0$, i.e., $c < \sqrt{5}-2$, then inequality (9.37) will be satisfied for all $\nu \geqq \nu(c)$, where

$$\nu(c) = (1-4c-c^2)^{-1}[(1+c)^3 + (1-c)^2] = (1-4c-c^2)^{-1}[c^3+4c^2+c+2]. \tag{9.38}$$ □

THEOREM 9.4. *There exists a continuous function*

$$\tau_4 : (0, \infty) \to (0, \infty)$$

satisfying $\mu_0(\nu) = (\nu+1)^{1-\nu} e^{\nu+1} < \rho_4(\nu) < \tau_4(\nu)$, *where* $\rho_4 = \rho_4(\nu)$ *is as in Theorem* 9.3, *such that* (I) *holds for* $\mu \bar{f}_4(x)$ (*at its unique fixed point in* (ν, ∞)) *if and only if* $\mu_0(\nu) < \mu < \tau_4(\nu)$. *Furthermore, we have that*

$$\lim_{\nu \to 0^+} \tau_4(\nu) = \infty \text{ and } \lim_{\nu \to \infty} [\tau_4(\nu) - \mu_0(\nu)] = 0, \text{ and for } \nu \geqq 2 \tag{9.39}$$

$$\tau_4(\nu) - \mu_0(\nu) \leqq \mu(2\nu) - \mu(\nu+1) \leqq (e^2/2\nu)^\nu (2\nu),$$

where we have defined $\mu(s) = s^{1-\nu} e^s$. *For* $0 < c < \sqrt{5} - 2$ *and for* $\nu \geqq \nu(c)$ ($\nu(c)$ *as in* (9.38)) *we have*

$$[\mu_0(\nu), \rho_4(\nu)] \supset \{s^{1-\nu} e^s : \nu + 1 < s \leqq \nu + 1 + c\}. \tag{9.40}$$

Proof. For notational convenience we write $\bar{f}_4(x) = \bar{f}(x)$, $\theta = \nu$, and $s_0 = \nu + 1$, and define $x_j(s)$ as in Theorem 9.2. Theorems 9.2 and 9.3 imply

$$[\mu_0(\nu), \rho_4(\nu)] = \{\mu(s) : x_2(s) \geqq \theta\},$$

$$\{\mu : \mu \bar{f}(x) \text{ satisfies (I)}\} = \{\mu(s) : s > s_0 \text{ and } x_3(s) > s\}.$$

Furthermore, we have already shown that

$$x_1'(s) > 0, \quad x_2'(s) < 0 \quad \forall s > s_0.$$

We fix $\nu > 0$ and first show $x_3(s) < s$ for all large s or, equivalently, that

$$\log (s^{-1} x_3(s)) < 0 \quad \forall \text{ large } s.$$

Using the definition of $x_j(s)$, we find

$$\begin{aligned} \log (s^{-1} x_3(s)) &< -\nu \log s + s + \nu \log x_2 \\ &= -\nu^3 \log s + (1 + \nu + \nu^2) s + \nu^3 \log \nu - \nu^3 - \nu^{\nu+1} e^{-\nu} s^{1-\nu} e^s. \end{aligned} \tag{9.41}$$

Because the e^s term is dominant for large s, the right-hand side of (9.41) is negative for all large s, so (for fixed $\nu > 0$) for every sufficiently large μ, $\mu \bar{f}(x)$ does not satisfy (I).

If $\nu \geqq 1$, it is a calculus exercise (which we leave to the reader) to prove that the derivative of the right-hand side of (9.41) with respect to s is negative for $s \geqq 2\nu$. Another calculus exercise left to the reader is to verify that

$$\frac{d}{d\nu} (\log (s^{-1} x_3(s))|_{s=2\nu}) < 0 \quad \text{for } \nu \geqq 2.$$

A direct calculation shows that the right-hand side of (9.41) is negative for $\nu = 2$ and $s = 4 = 2\nu$, and combining the above information we conclude that

$$\log (s^{-1} x_3(s)) < 0 \quad \text{for } s \geqq 2\nu \text{ and } \nu \geqq 2. \tag{9.42}$$

It follows from inequality (9.42) that, for $\nu \geqq 2$,

$$\{\mu : \mu \bar{f}(x) \text{ satisfies (I)}\} \subset \{\mu(s) : \nu + 1 < s < 2\nu\} = (\mu(\nu + 1), \mu(2\nu)).$$

Because $\mu(s)$ is increasing for $s > \nu - 1$ we have

$$\begin{aligned} \mu(2\nu) - \mu(\nu + 1) < \mu(2\nu) - \mu(\nu) &= \nu \left(\frac{e}{\nu}\right)^{\nu} \left[2\left(\frac{e}{2}\right)^{\nu} - 1\right] \\ &\leqq (2\nu)\left(\frac{e^2}{2\nu}\right)^{\nu}, \end{aligned}$$

which immediately gives (9.39) (although we have not yet proved that $\tau_4(\nu)$ exists).

To prove that $\tau_4(\nu) \to \infty$ as $\nu \to 0^+$ (assuming the existence of $\tau_4(\nu)$), it suffices

to prove that given any $M>0$, there exists $\delta=\delta(M)$ such that for $0<\nu<\delta(M)$ and $\nu+1<s\leqq M$,

$$\log(s^{-1}x_3(s))=-\nu^3\log s+(1+\nu+\nu^2)s+\nu^3\log\nu-\nu^3-\nu^{\nu+1}s^{1-\nu}e^{s-\nu}-x_2>0. \tag{9.43}$$

Because $\nu^\nu e^{-\nu}$ converges to one as $\nu\to 0^+$, we see that $x_1(s)=s^{1-\nu}e^s\nu^\nu e^{-\nu}$ converges uniformly on $[1, M]$ to se^s as $\nu\to 0^+$, and using this we see that

$$\lim_{\nu\to 0^+}x_2(s)=\lim_{\nu\to 0^+}s^{1-\nu}e^s x_1^\nu e^{-x_1}=s\exp(s-se^s),$$

and that the convergence is uniform in $s\in[1, M]$. Using this information, we see that

$$\lim_{\nu\to 0^+}(\log(s^{-1}x_3(s)))=s-s\exp(s-se^s), \tag{9.44}$$

and that the convergence is uniform in $s\in[1, M]$. Since the right-hand side of (9.44) is positive on $(0,\infty)$, there exists $\delta=\delta(M)>0$ such that

$$\log(s^{-1}x_3(s))>0 \quad \text{for } 1\leqq s\leqq M,\quad 0<\nu<\delta.$$

We need only prove the existence of $\tau_4(\nu)$, or equivalently that

$$\{s>\nu+1:\log(s^{-1}x_3(s))<0\} \quad \text{is an interval.}$$

It is convenient to make the following observation first.

We claim that if $x_1(s)\leqq\nu+2$ and $s>\nu+1$, then $x_2(s)>\nu$. Because $x_1'(s)>0$ and $x_2'(s)<0$ for $s>\nu+1$, it suffices to prove that if $x_1(s)=\nu+2$, then $x_2(s)>\nu$. However, if $x_1(s)=\nu+2$, we find as in the proof of Theorem 9.2, that

$$x_2=x_1\bar f(x_1)(\bar f(\theta))^{-1}=\nu^{-\nu}e^\nu(\nu+2)(\nu+2)^\nu e^{-(\nu+2)},$$

so $x_2(s)>\nu$ if

$$\left(\frac{\nu+2}{\nu}\right)^{\nu+1}>e^2,$$

which is (9.25). We conclude that if $x_1(s)\leqq\nu+2$, then $\mu(t)\bar f(x)$ satisfies (III) for $\nu+1<t\leqq\nu+2$. A calculation shows that $x_1(\nu+1+c)\leqq\nu+2$ if and only if

$$e^{1+c}\leqq\left(\frac{\nu+1+c}{\nu}\right)^\nu\left(\frac{\nu+2}{\nu+1+c}\right), \tag{9.45}$$

and Lemma 9.1 implies that if $0<c<\sqrt{5}-2$ and $\nu\geqq\nu(c)$, inequality (9.45) holds. This proves the inclusion (9.40).

Logarithmic differentiation easily yields the following formulas:

$$\begin{aligned}
&\frac{dx_1}{ds}=x_1\left[\frac{s+1-\nu}{s}\right],\\
&\frac{dx_2}{ds}=x_2\left[\frac{s+1-\nu}{s}\right][\nu+1-x_1],\\
&\frac{d}{ds}\left(\log\left(\frac{x_3(s)}{s}\right)\right)=\left(\frac{s+1-\nu}{s}\right)[1+(\nu-x_2)(\nu+1-x_1)]-\left(\frac{1}{s}\right).
\end{aligned} \tag{9.46}$$

Define s_* to be the first $s>\nu+1$ such that $\log(s^{-1}x_3(s))=0$, so we know

$$\frac{d}{ds}\log(s^{-1}x_3(s))|_{s=s_*}=s_*^{-1}[(s_*+1-\nu)(1-(\nu-x_2)(x_1-\nu-1))-1]\leqq 0. \tag{9.47}$$

Theorem 9.3 implies $x_2(s_*) < \nu$, and the remarks above show $x_1(s_*) > \nu + 2$. To complete the proof we need only show

$$(s+1-\nu)[1-(\nu-x_2(s))(x_1(s)-\nu-1)]-1 \equiv \phi(s) < 0$$

for $s > s_*$, and because $\phi(s_*) \leqq 0$, it suffices to prove

$$\begin{aligned} \phi'(s) &= (\nu-x_2)(x_1-\nu-1)-(s+1-\nu)^2 s^{-1}(x_1-\nu-1)^2 x_2 \\ &\quad -(s+1-\nu)^2 x^{-1} x_1(\nu-x_2) < 0 \end{aligned} \tag{9.48}$$

for $s > s_*$.

Case 1. Assume $\nu \geqq 1$. Using the estimates $x_1 - \nu - 1 > 1$ and $\nu - x_2 > 0$ in the formula for $\phi'(s)$ for $s > s_*$, we obtain

$$\begin{aligned} \phi'(s) &< 1-(\nu-x_2)-x_2(s+1-\nu)^2 s^{-1}-(s+1-\nu)^2 s^{-1}(\nu+2)(\nu-x_2) \\ &= 1-(\nu-x_2)[1+(\nu+1)(s+1-\nu)^2 s^{-1}]-(s+1-\nu)^2 s^{-1}\nu. \end{aligned}$$

The previous inequality shows

$$\phi'(s) < 1-(s+1-\nu)^2 s^{-1}\nu. \tag{9.49}$$

The function on the right-hand side of (9.49) is decreasing for $s > \nu+1$, so inequality (9.49) implies that, for $s \geqq s_*$,

$$\phi'(s) < 1-\frac{4\nu}{\nu+1} < 0.$$

Case 2. Assume $0 < \nu < 1$. Because x_2 is decreasing and less than ν for $s \geqq s_*$ and x_1 is increasing and greater than $\nu+1$ for $s > \nu+1$, $(\nu - x_2)(x_1 - \nu - 1)$ is an increasing function of s for $s \geqq s_*$. At $s = s_*$, inequality (9.47) implies

$$\begin{aligned} &\tfrac{1}{2} < 1-(s_*+1-\nu)^{-1} \leqq (\nu-x_2(s_*))(x_1(s_*)-\nu-1), \quad \text{so} \\ &\tfrac{1}{2} < (\nu-x_2(s))(x_1(s)-\nu-1) \quad \text{for } s \geqq s_*. \end{aligned} \tag{9.50}$$

Using the equation for $\phi'(s)$ in (9.48), we see

$$\phi'(s) < 1-(\nu-x_2)(x_1-1-\nu)-(s+1-\nu)^2 s^{-1}(\nu-x_2)x_1. \tag{9.51}$$

Because $0 < \nu < 1$, we have $(s+1-\nu)^2 s^{-1} > s > 1$, so from (9.50) and (9.51) we derive

$$\phi'(s) < 1-(\nu-x_2)(x_1-1-\nu)-(\nu-x_2)(x_1-1-\nu) < 0$$

for $s > s_*$. The proof is now complete. □

Next we want to analyze when $\mu \bar{f}_5(x)$ satisfies (I). Unfortunately, our results are incomplete. We conjecture that there exists a continuous function $\tau_5(\nu, \lambda)$ (allowing $\tau_5(\nu, \lambda) = \infty$) defined for $\nu > 0$ and $\lambda > \nu + 1$ such that $\mu \bar{f}_5(x)$ satisfies (I) if and only if $\mu_0(\nu, \lambda) < \mu < \tau_5(\nu, \lambda)$ (where $\mu_0(\nu, \lambda)$ is as in Table 1). By using Theorem 9.3 and Theorem 9.5, we have given a computer-assisted proof of this conjecture for various specific ν and λ, but we have not proved it in general.

THEOREM 9.5. *Assume $\nu > 0$ and $\lambda > \nu + 1$, and let $x_0 = x_0(\mu, \nu, \lambda)$ and $\mu_0 = \mu_0(\nu, \lambda)$ be as in Table 1 for the function $f_5(x) = \mu \bar{f}_5(x)$. The function $\mu \bar{f}_5(x)$ satisfies* (I) *at x_0 for all large μ if*

$$\nu + 1 < \lambda \leqq \nu + \left(\frac{1}{2\nu}\right) + \left(\frac{1}{2\nu}\right)\sqrt{4\nu^2+1} \equiv \phi(\nu), \tag{9.52}$$

while if $\lambda > \phi(\nu)$, there exists a number $\gamma = \gamma(\nu, \lambda) < \infty$ such that $\mu \bar{f}_5(x)$ does not satisfy (I) *at x_0 for any $\mu > \gamma(\nu, \lambda)$. If $\nu + 1 < \lambda \leqq \nu + 1 + (1/2\nu)$, $\mu \bar{f}_5(x)$ satisfies condition* (I) *at x_0 for all $\mu > \mu_0(\nu, \lambda)$.*

Proof. While not essential, a change of variables will simplify our calculations. For $x>0$, define $\psi(x)=x^{1/\lambda}$, so

$$(\psi^{-1}(\mu\bar{f}_5)\psi)(x)=\mu^\lambda x^\nu(1+x)^{-\lambda}\equiv\mu^\lambda\bar{h}_5(x).$$

The remarks at the beginning of this section show that $\mu\bar{f}_5(x)$ satisfies (I) at x_0 if and only if $\mu^\lambda\bar{h}_5(x)$ satisfies (I) at x_0^λ. As in Theorem 9.2 we see that $\mu^\lambda\bar{h}_5(x)$ satisfies (I) at x_0^λ if and only if $\mu>\mu_0$ and

$$(\mu^\lambda\bar{h}_5)^3(\theta)>x_0^\lambda, \tag{9.53}$$

where $\theta=\nu(\lambda-\nu)^{-1}$, the point where $\bar{h}_5$ achieves its maximum.

As before, it is convenient to parameterize by $s=x_0^\lambda$, the fixed point of $\mu^\lambda\bar{h}_5$. Define a function $\mu(s)$ by

$$\mu(s)^\lambda=s^{1-\nu}(1+s)^\lambda=s(\bar{h}_5(s))^{-1},$$

so s is a fixed point of $\mu(s)^\lambda\bar{h}_5(x)$. Define $x_1(s)=\mu(s)\bar{h}_5(\theta)$ and $x_j(s)=\mu(s)\bar{h}_5(x_{j-1}(s))$ for $j>1$. Just as in Theorem 9.2 we obtain from (9.53) that

$$\{\mu:\ \mu\bar{f}_5(x)\text{ satisfies (I) at }x_0\}=\{\mu(s):\ s>s_0\text{ and }x_3(s)>s_0\}, \tag{9.54}$$

where $s_0=(\nu+1)(\lambda-\nu-1)^{-1}$ as in (9.51). The proof that $x_1'(s)>0$ and $x_2'(s)<0$ for all $s>s_0$ is as in Theorem 9.2 and is left to the reader.

A calculation shows

$$\begin{aligned}&x_1(s)=x_1=s^{\lambda+1-\nu}(1+s^{-1})^\lambda\theta_1,\quad\text{where}\\&\theta_1=\left(\frac{\nu}{\lambda}\right)^\nu\left(\frac{\lambda-\nu}{\lambda}\right)^{\lambda-\nu}<1.\end{aligned} \tag{9.55}$$

A further calculation yields

$$x_2(s)=x_2=s^{1-(\lambda-\nu)^2}\theta_1^{\nu-\lambda}(1+s^{-1})^{\lambda+\nu\lambda-\lambda^2}(1+x_1^{-1})^{-\lambda}. \tag{9.56}$$

Equation (9.55) shows $\lim_{s\to\infty}x_1(s)=\infty$, and (9.56) gives

$$\lim_{s\to\infty}x_2(s)=\lim_{s\to\infty}s^{1-(\lambda-\nu)^2}\theta_1^{\nu-\lambda}=0,$$

because $\lambda>\nu+1$. Substituting (9.56) in the formula for $x_3(s)$, we obtain

$$\begin{aligned}&s^{-1}x_3(s)=s^{\lambda-\nu(\lambda-\nu)^2}\theta_1^{\nu(\nu-\lambda)}(1+s^{-1})^\delta(1+x_1^{-1})^{-\nu\lambda}(1+x_2)^{-\lambda}\quad\text{where}\\&\delta=\lambda+\nu\lambda+\nu^2\lambda-\nu\lambda^2.\end{aligned} \tag{9.57}$$

Equation (9.56) implies

$$\lim_{s\to\infty}s^{-1}x_3(s)=\lim_{s\to\infty}s^{\lambda-\nu(\lambda-\nu)^2}\theta_1^{\nu(\nu-\lambda)}.$$

Because $\lambda-\nu(\lambda-\nu)^2=0$ for $\lambda=\phi(\nu)$, $\lambda-\nu(\lambda-\nu)^2>0$ for $\nu+1<\lambda<\phi(\nu)$, and $\lambda-\nu(\lambda-\nu)^2<0$ for $\lambda>\phi(\nu)$, we obtain

$$\lim_{s\to\infty}s^{-1}x_3(s)=\begin{cases}\infty & \text{for }\nu+1<\lambda<\phi(\nu),\\ \theta_1^{\nu(\nu-\lambda)} & \text{for }\lambda=\phi(\nu),\\ 0 & \text{for }\lambda>\phi(\nu).\end{cases} \tag{9.58}$$

Using (9.58) and (9.54) and recalling that $0<\theta_1<1$, we obtain the first part of the theorem.

It remains to prove the final part of the theorem. We know (from Theorem 7.2 and the remarks at the beginning of this section) that $s^{-1}x_3(s) > 1$ for $s = s_0$. Therefore, to prove that $\mu\bar{f}_5(x)$ satisfies (I) for all $\mu > \mu_0$ (when $\nu+1 < \lambda \leqq \nu+1+(1/2\nu)$) we need only prove that $s^{-1}x_3(s)$ is an increasing function for $s \geqq s_0$. Because $x_1'(s) > 0$ and $x_2'(s) < 0$ for $s \geqq s_0$, it is clear that $(1+x_1^{-1})^{-\nu\lambda}(1+x_2)^{-\lambda}$ is an increasing function of s. Thus, by using (9.57) we see that $s^{-1}x_3(s)$ is increasing if

$$\frac{d}{ds} s^{\lambda-\nu(\lambda-\nu)^2}(1+s^{-1})^{\lambda+\nu\lambda+\nu^2\lambda-\nu\lambda^2} \geqq 0 \quad \text{for } s \geqq s_0. \tag{9.59}$$

By differentiating logarithmically, we see that inequality (9.59) will hold if

$$s^{-1}(s+1)^{-1}[(\lambda-\nu(\lambda-\nu)^2)(s+1)-\lambda(1+\nu+\nu^2-\nu\lambda)] \geqq 0 \quad \text{for } s \geqq s_0. \tag{9.60}$$

Since $s+1 \geqq \lambda(\lambda-\nu-1)^{-1}$ for $s \geqq s_0$ we see that (9.60) will be satisfied if

$$[\lambda-\nu(\lambda-\nu)^2]\left(\frac{\lambda}{\lambda-\nu-1}\right)-\lambda[1+\nu(1+\nu-\lambda)] \geqq 0. \tag{9.61}$$

Recalling that $\lambda > \nu+1$ and simplifying, we see that (9.61) will be satisfied if

$$\lambda \leqq 1+\nu+(1/2\nu),$$

and this completes the proof. □

If $\nu = 1$, Theorem 9.5 ensures that $\mu\bar{f}_5(x)$ satisfies (I) at x_0 for all $\mu > \mu_0$ if $2 < \lambda \leqq 2.5$, while the number $\phi(1)$ equals $(\frac{1}{2})(3+\sqrt{5})$ or approximately 2.618. We can, however, give an ad hoc argument (which we omit) and prove that, for $\nu = 1$ and $2 < \lambda \leqq (\frac{1}{2})(3+\sqrt{5})$, $\mu\bar{f}_5(x)$ satisfies (I) for all $\mu > \mu_0$.

We now want to study when a function $\mu\bar{f}(x)$ satisfies (II) at a fixed point x_0; our particular interest, of course, is $\bar{f} = \bar{f}_4$ or $\bar{f} = \bar{f}_5$. We first make some preliminary calculations concerning local stability of period 2 points of $\mu\bar{f}(x) = f(x)$.

Suppose, for some μ, there exist numbers $0 < x_1 < x_2$ satisfying

$$\mu\bar{f}(x_1) = x_2 \quad \text{and} \quad \mu\bar{f}(x_2) = x_1. \tag{9.62}$$

Then we have

$$x_1\bar{f}(x_1) = x_2\bar{f}(x_2) = c, \tag{9.63}$$

$$\mu = \frac{x_1x_2}{c}. \tag{9.64}$$

Conversely, if $0 < x_1 < x_2$, with x_1 and x_2 satisfying (9.60), and μ is defined by (9.64), then x_1 and x_2 also satisfy (9.62).

Define κ to be the derivative

$$\kappa = (f^2)'(x_1) = f'(x_1)f'(x_2) = \mu^2\bar{f}'(x_1)\bar{f}'(x_2)$$

occurring in Theorem 7.3. A short calculation gives

$$\kappa = u(x_1)u(x_2), \tag{9.65}$$

where $u(x)$ is the function

$$u(x) = \frac{x\bar{f}'(x)}{\bar{f}(x)}. \tag{9.66}$$

Our basic idea is to use c as a parameter and to express x_1, x_2, μ, and κ as functions of c. To make this rigorous, assume that $\bar{f}:[0,\infty)\to[0,\infty)$ is continuous and C^2 on $(0,\infty)$ and that, if $g(x)=x\bar{f}(x)$, then there exists a number $s_0>0$ such that

$$g'(x)>0 \quad \text{for } 0<x<s_0, \qquad g'(x)<0 \quad \text{for } x>s_0. \tag{9.67}$$

For simplicity in the statement of our theorems, further assume that

$$\lim_{x\to\infty} g(x)=0. \tag{9.68}$$

Define c_* by

$$c_*=g(s_0)=\max_{x>0} g(x), \tag{9.69}$$

and $g_1=g\,|\,[0,c_*]$ and $g_2=g\,|\,[c_*,\infty)$. Then for $0<c\leqq c_*$ (9.63) and the condition $0<x_1<x_2$ determine x_1 and x_2 as functions of c:

$$x_1=x_1(c)=g_1^{-1}(c)\in(0,s_0] \quad \text{and} \quad x_2=x_2(c)=g_2^{-1}(c)\in[s_0,\infty), \tag{9.70}$$

where g_1^{-1} and g_2^{-1} are the inverse functions of g_1 and g_2, respectively. Because $g_1'(x)>0$ for $0<x<s_0$ and g_1 is continuous on $[0,s_0]$, we obtain that x_1 is continuous on $[0,c_*]$ and C^1 on $(0,c_*)$, $x_1(0)=0$, $x_1(c_*)=s_0$ and $x_1'(c)>0$ for $0<c<c_*$. Similarly, we find that x_2 is continuous on $(0,c_*]$ and C^1 on $(0,c_*)$, $x_2(c_*)=s_0$ and $x_2'(c)<0$ for $0<c<c_*$. Note that (9.68) ensures that the domain of x_2 is $(0,c_*]$ and $\lim_{c\to0^+}x_2(c)=\infty$. Having defined $x_1(c)$ and $x_2(c)$, we then have that $\mu=\mu(c)$ and $\kappa=\kappa(c)$, given by (9.64) and (9.65), respectively, are functions of c. To make further progress we must establish some of the properties of $\mu(c)$ and $\kappa(c)$.

LEMMA 9.2. *Assume $\bar{f}:[0,\infty)\to[0,\infty)$ is continuous and C^2 on $(0,\infty)$. If $g(x)=x\bar{f}(x)$ assume there exists $s_0>0$ such that $g'(x)>0$ for $0<x<s_0$ and $g'(x)<0$ for $x>s_0$ and $\lim_{x\to\infty}g(x)=0$. Let $x_1(c)$ and $x_2(c)$ be as defined before for $0<c\leqq c_*=g(s_0)$, and let $\kappa(c)$ and $\mu(c)$ be defined by* (9.64) *and* (9.65). *Then $\mu(c)$ and $\kappa(c)$ have the following properties*:

(i) *$\mu(c)\to s_0^2/c_*>0$ and $\kappa(c)\to1$ as $c\to c_*$.*

(ii) *$\mu(c)\to\infty$ as $c\to0^+$. If $u(x)$ is defined by equation* (9.66), *assume that $\lim_{x\to0+}u(x)=L_1$, where L_1 is finite, and that $\lim_{x\to\infty}u(x)=L_2$, where we allow $L_2=-\infty$. Then we have $\lim_{c\to0^+}\kappa(c)=L_1L_2$.*

(iii) *Suppose that there exists $\theta\geqq0$ such that $\bar{f}'(x)>0$ for $0<x<\theta$ and $\bar{f}'(x)<0$ for $x>\theta$ (so $\theta<s_0$), and that $u'(x)<0$ for $x>\theta$. Define $v(x)=-u(x)$ for $x\geqq\theta$ and let $v^{-1}(\gamma)$ denote the inverse map. Note that $\lim_{x\to\infty}v(x)=-L_2>1$ under our assumptions, define $\delta=\max(-L_2^{-1},-L_1)$, and assume that*

$$g(v^{-1}(\gamma))>g(v^{-1}(1/\gamma)) \quad \text{for } \delta<\gamma<1. \tag{9.71}$$

Then we have $\kappa(c)<1$ for $0<c<c_*$. If we define $\Phi(t)=\log(g(v^{-1}(t)))$ for $\delta<t<1$, inequality (9.71) *will be satisfied if*

$$\Phi'(t)<-\left(\frac{1}{t^2}\right)\Phi'\left(\frac{1}{t}\right) \quad \text{for } \delta<t<1. \tag{9.72}$$

(iv) *If $\kappa(c)<1$ for $0<c<c_*$, then $\mu'(c)<0$ for $0<c<c_*$.*

(v) *If $u'(x)<0$ for all $x>0$ and if $c\in(0,c_*)$ is such that $\kappa(c)\leqq0$, then $\kappa'(c)>0$.*

Proof. (i) By definition of s_0, $g'(s_0)=f(s_0)+s_0f'(s_0)=0$, so we obtain $u(s_0)=-1$. Since we have already noted that $x_1(c)$ and $x_2(c)$ approach s_0 as $c\to c_*$, we conclude that

$$\lim_{c\to c_*}\kappa(c)=\lim_{c\to c_*}u(x_1)u(x_2)=(-1)^2=1.$$

Using the same sort of reasoning, we obtain

$$\lim_{c\to c_*}\mu(c)=\lim_{c\to c_*}\frac{x_1x_2}{c}=\frac{s_0^2}{c_*}.$$

(ii) Because $\bar f$ is continuous at zero, there exists a constant M such that

$$Mx\geqq g(x)\quad\text{for } x \text{ small and positive.}$$

For $c>0$ and small it follows that

$$Mx_1(c)\geqq g(x_1(c))=c\quad\text{or}\quad x_1\geqq c/M.$$

Using this estimate, we see that for $c>0$ small,

$$\mu(c)\geqq(1/M)x_2(c),$$

and because $x_2(c)\to\infty$ as $c\to 0^+$, $\mu(c)\to\infty$ as $c\to 0^+$. Because $\lim_{c\to 0^+}x_1(c)=0$ and $\lim_{c\to 0^+}x_2(c)=\infty$, $\lim_{c\to 0^+}\kappa(c)=\lim_{x\to 0}u(x)\lim_{x\to\infty}u(x)=L_1L_2$.

(iii) Assume that u, f, and g satisfy the given assumptions but that there exists c, $0<c<c_*$, such that $\kappa(c)\geqq 1$. Our assumptions imply $L_1\geqq 0$ and $L_2\leqq 0$, so $\lim_{c\to 0^+}\kappa(c)\leqq 0$. Thus, by choosing a different number c, $0<c<c_*$, we can assume that $\kappa(c)=1$. Because $u(x_2)<\mu(\sigma)=-1$ (since $x_2(c)>\sigma$) and because $u(x)>0$ for $x<\theta$, we must have $x_1(c)\geqq\theta$. If $\theta>0$, so $u(\theta)=0$, then we must in fact have $x_1(c)>0$ and of course $x_1(c)>\theta$ if $\theta=0$. If we write $\gamma=v(x_1(c))$, then we must have $0=v(\theta)<\gamma<1=v(s_0)$ if $\theta>0$ and $-L_1<\gamma<1$ if $\theta=0$. Furthermore, we must have $\gamma^{-1}=v(x_2(c))$, so $\gamma^{-1}\in(1,-L_2)$, and we obtain the estimates $\delta<\gamma<1$. Now (9.63) gives

$$g(v^{-1}(\gamma))=g(v^{-1}(1/\gamma)),$$

which contradicts (9.71).

Note that (9.71) is equivalent to

$$\Phi(1)-\Phi(\gamma)<\Phi(1)-\Phi(\gamma^{-1})\quad\text{for } \delta<\gamma<1. \tag{9.73}$$

Using the fundamental theorem of calculus and changing variables in the integral for the right-hand side, we see that (9.73) is equivalent to

$$\int_\gamma^1\Phi'(t)\,dt<\int_\gamma^1-\left(\frac{1}{t^2}\right)\Phi'\left(\frac{1}{t}\right)dt,$$

so (9.72) implies (9.73) and (9.71).

(iv) A calculation shows

$$(\mu(c))^2=\frac{x_1x_2}{\bar f(x_1)\bar f(x_2)}\quad\text{where } x_j=x_j(c), \tag{9.74}$$

so it suffices to show that if $\kappa(c)<1$, then

$$\frac{d}{dc}\log\left(\frac{x_1x_2}{\bar f(x_1)\bar f(x_2)}\right)<0. \tag{9.75}$$

Using the formula $x_j'(c)=(\bar f(x_j)^{-1}(1+u(x_j)))^{-1}$ (which we obtain by differentiating $x_j\bar f(x_j)=c$), we find that (9.75) is equivalent to

$$\sum_{j=1}^2(x_j\bar f(x_j)(1+u(x_j)))^{-1}-\sum_{j=1}^2\bar f'(x_j)(\bar f(x_j)^2(1+u(x_j)))^{-1}<0.$$

Multiplying the above inequality by $x_1x_2\bar{f}(x_1)\bar{f}(x_2)=c^2$ and simplifying, we find that the above inequality is equivalent to

$$2c(1+u(x_1))^{-1}(1+u(x_2))^{-1}(1-\kappa(c))<0. \tag{9.76}$$

Recall that $g'(x)>0$ for $0<x<s_0$ and $g'(x)<0$ for $x>s_0$, which implies $u(x)>-1$ for $0<x<s_0$ and $u(x)<-1$ for $x>s_0$. From this we conclude that $(1+u(x_1))(1+u(x_2))$ is negative and that $\mu'(c)<0$ if and only if $\kappa(c)<1$.

(v) If $\kappa(c)\leqq 0$, we must have $u(x_1(c))\geqq 0$, since $u(x_2(c))<-1$ for $0<c<c_*$. It follows that

$$\kappa'(c)=u'(x_1)x_1'u(x_2)+u(x_1)u'(x_2)x_2'>0,$$

because we are assuming that $u'(x)<0$ for all $x>0$, and that $x_1'(c)>0$ and $x_2'(c)<0$ for $0<c<c_*$. □

With $j=4$ or 5 and parameters $\nu>0$ and $\lambda>\nu+1$, let $\bar{f}_j$ be defined as in (9.24) and let functions $\mu_j(c)$ and $\kappa_j(c)$ be defined by substituting $\bar{f}_j$ for $\bar{f}$ in (9.63)-(9.65). Define $g_j(x)=x\bar{f}_j(x)$, so that $g_j'(x)>0$ for $0<x<\sigma_j$ (where σ_j is given in Theorem 9.3), and $g_j'(x)<0$ for $x>\sigma_j$. Also recall that $\bar{f}_j'(x)>0$ for $0<x<\theta_j$ and $\bar{f}_j'(x)<0$ for $x>\theta_j$, where θ_j is an in Theorem 9.3. From Lemma 9.2 we obtain Lemma 9.3.

LEMMA 9.3. *With $j=4$ or 5 and parameters $\nu>0$ and $\lambda>\nu+1$, the functions $\mu_j(c)$ and $\kappa_j(c)$ (defined for $0<c\leqq c_{*j}=g_j(\sigma_j)$) have the following properties*:

(i) $u_j(c)\to\sigma_j^2/c_{*j}>0$ *and* $\kappa_j(c)\to 1$ *as* $c\to c_{*j}$.
(ii) $\mu_j(c)\to\infty$, $\kappa_4(c)\to-\infty$ *and* $\kappa_5(c)\to-\nu(\lambda-\nu)<0$ *as* $c\to 0^+$.
(iii) $\kappa_j(c)<1$, *if* $0<c<c_{*j}$.
(iv) $\mu_j'(c)<0$, *if* $0<c<c_{*j}$.
(v) $\kappa_j'(c)>0$, *if* $0<c<c_{*j}$.

Proof. Define $u_j(x)=x\bar{f}_j'(x)(\bar{f}_j(x))^{-1}$ and $v_j(x)=-u_j(x)$. A calculation gives

$$u_4(x)=\nu-x, \qquad u_5(x)=[\nu-(\lambda-\nu)x^\lambda](1+x^\lambda)^{-1},$$

so $u_j'(x)<0$ for all $x>0$. A further calculation gives

$$v_4^{-1}(t)=\nu+t, \qquad (v_5^{-1}(t))^\lambda=(\nu+t)(\lambda-\nu-t)^{-1}.$$

Lemma 9.2 will imply Lemma 9.3 if we can prove that (9.71) is satisfied with g_j and v_j replacing g and v, and Lemma 9.2 implies that this will be the case if

$$\Phi_j'(t)<-\left(\frac{1}{t^2}\right)\Phi_j'\left(\frac{1}{t}\right) \quad \text{for } \delta_j<t<1, \tag{9.77}$$

where $\Phi_j(t)=\log g_j(v_j^{-1}(t))$ and $\delta_4=0$ and $\delta_5=(\lambda-\nu)^{-1}$. We can easily check that

$$\Phi_4'(t)=(1-t)(\nu+t)^{-1}, \qquad \Phi_5'(t)=(1-t)(\nu+t)^{-1}(\lambda-\nu-t)^{-1},$$

so for $j=4$ inequality (9.77) is equivalent to

$$(1-t)(\nu+t)^{-1}<(1-t)(\nu t^3+t^2)^{-1} \quad \text{for } 0<t<1 \tag{9.78}$$

and for $j=5$ inequality (9.77) is equivalent to

$$\begin{aligned}&(1-t)(\nu+t)^{-1}(\lambda-\nu-t)^{-1}<(1-t)t^{-1}(\nu t+1)^{-1}(\lambda t-\nu t-1)^{-1}\\ &\text{for } (\lambda-\nu)^{-1}<t<1.\end{aligned} \tag{9.79}$$

Since $0<t<1$, (9.78) is obviously true. Because $0<t<1$ we have $\nu+t>\nu t^2+t>0$;

and by using the fact that $\lambda > \nu$ we can see

$$\lambda - \nu - t > \lambda t - \nu t - 1 > 0 \quad \text{for } (\lambda - \nu)^{-1} < t < 1,$$

so inequality (9.79) is valid. □

With the aid of Lemma 9.2 we can give conditions under which a function $\mu\bar{f}(x)$ satisfies (II) precisely for $\mu \in (\mu_0, \sigma]$, where $\sigma > \mu_0$.

THEOREM 9.6. *Assume $\bar{f}:[0,\infty)\to[0,\infty)$ is a continuous map that is C^3 on $(0,\infty)$. Assume there exists $\theta \geqq 0$ such that $\bar{f}'(x) > 0$ for $0 < x < \theta$ and $\bar{f}'(x) < 0$ for $x > \theta$. If $g(x) = x\bar{f}(x)$, assume there exists $s_0 > 0$ such that $g'(x) > 0$ for $0 < x < s_0$ and $g'(x) < 0$ for $x > s_0$. Define $u(x) = x\bar{f}'(x)(\bar{f}(x))^{-1}$ and $v(x) = -u(x)$ and assume $u'(x) < 0$ for all $x > 0$ and*

$$g(v^{-1}(\gamma)) > g(v^{-1}(1/\gamma)) \quad \text{for } \delta < \gamma < 1, \tag{9.80}$$

where δ is defined as in Lemma 9.2 and v^{-1} is the inverse map of v. (Recall that inequality (9.80) is satisfied if inequality (9.72) holds.) Finally, suppose there exists a C^3 map ψ of an interval (a, b) onto $(0,\infty)$ such that $\psi'(x) > 0$ for $x \in (a, b)$ and $\psi^{-1}(\mu\bar{f})\psi$ has negative Schwarzian derivative for all $x \in (a, b)$. Then there exists $\sigma > \mu_0 = \bar{f}(s_0)s_0^{-1}$ such that $\mu\bar{f}(x)$ satisfies (II) at $x_0(\mu) = x_0$, the unique fixed point of $\mu f(x)$ in the interval (θ,∞), if and only if $\mu_0 < \mu \leqq \sigma$. If $\mu(c)$ and $\kappa(c)$ are defined as in Lemma 9.2 and $\kappa(c_2) = -1$, then $\mu(c_2) = \sigma$.

Proof. If $f = \mu\bar{f}$ is as in Theorem 7.3 or 7.4, but we assume that $\psi^{-1}f\psi$ (ψ as in Theorem 9.6) has negative Schwarzian derivative everywhere instead of supposing that f has, we can still easily see (using the remarks at the beginning of this section) that the conclusions of Theorem 7.3 and 7.4 are satisfied.

Now let $\mu(c)$ and $\kappa(c)$ be as in Lemma 9.2. Theorem 9.3 implies that $\mu\bar{f}(x)$ satisfies condition (0) at $x_0(\mu)$ if and only if $\mu > \mu_0 = \bar{f}(s_0)s_0^{-1}$, and Lemma 9.2 implies that $\mu_0 = \mu(c_*)$ and that $\mu(c) > \mu_0$ for $0 < c < c_*$. Since (Lemma 9.2) $\mu'(c) < 0$ for $0 < c < c_*$ and $\lim_{c\to 0^+}\mu(c) = \infty$, we will work with the parameter c instead of $\mu > \mu_0$. Define a number c_1 by

$$c_1 = \inf\{c > 0: \mu(\gamma)\bar{f}(x) \text{ satisfies (I) at } x_0 \text{ for } c \leqq \gamma < c_*\}.$$

Corollary 7.1 implies that $c_1 < c_*$. Define c_2 as in the statement of the theorem if $\kappa(c) = -1$ has a solution $c > 0$; otherwise define $c_2 = 0$. Lemma 9.2 implies that $\kappa(c) < 1$ for $0 < c < c_*$ and $\kappa(c) \geqq -1$ if and only if $c \geqq c_2$. Thus Theorem 7.3 will imply that $\mu(c)\bar{f}(x)$ satisfies (II) if and only if $c_2 \leqq c < c_*$ if we can prove that $c_2 > c_1$ when $c_1 > 0$. However, if $c_1 > 0$, Theorem 7.4 and Corollary 7.2 imply that there exists $\delta < 0$ such that $\mu(c_1) \leqq \mu < \mu(c_1) + \delta$, $(\mu\bar{f})^2$ has a fixed point x such that $(d/dx)(\mu\bar{f})^2(x) < -1$. If $c_2 \leqq c_1$, this contradicts Lemma 9.2, so we must have $c_2 > c_1$. □

As an immediate consequence of Theorem 9.6 and Lemma 9.3 we obtain Corollary 9.1.

COROLLARY 9.1. *For parameters $\nu \geqq 1$ and $\lambda > \nu + 1$ let $\bar{f}_4(x)$ and $\bar{f}_5(x)$ be as defined before and let $\mu_0(\nu)$ and $\mu_0(\nu, \lambda)$ be as defined in Table 1 for the functions $\bar{f}_4$ and $\bar{f}_5$, respectively. If $\bar{f}_j$ has its maximum on $(0,\infty)$ at θ_j, there exist continuous functions $\sigma_4(\nu)$ and $\sigma_5(\nu, \lambda)$ such that μf_j satisfies condition (II) at the unique fixed point of μf_j in (θ_j,∞) if and only if $\mu_0(\nu) < \mu \leqq \sigma_4(\nu)$ for $j = 4$ or $\mu_0(\nu, \lambda) < \mu \leqq \sigma_5(\nu, \lambda)$ for $j = 5$.*

Proof. We need prove the continuity and finiteness of σ_j, and this follows easily from the results of Lemma 9.3. □

If $\psi:(a, b)\to(0,\infty)$ is as in Theorem 9.6, the results of this section also apply to the functions $\psi^{-1}(\mu\bar{f}_j)\psi$ for $\nu \geqq 1$ and $\lambda > \nu + 1$. Taking $\psi(x) = ax$, $a > 0$, we obtain, for example, the conclusion of Corollary 9.1 for $\mu_1 x^\nu e^{-ax}$ and $\mu_1 x^\nu(1 + bx^\lambda)^{-1}$, where

$\mu_1 > 0$ and $b = a^\lambda$ is an arbitrary positive number. Taking $\psi(x) = x^p$ for $p > 0$, we obtain the same results for $\mu_2 x^\nu e^{-bx^p}$ and $\mu_2 x^\nu (1+bx^{\lambda p})^{-1/p}$, where $\mu_2 > 0$, $b > 0$, and $p > 0$.

Although we will not pursue this here, we can establish the conclusions of Corollary 9.1 for other classes of functions, e.g., $\mu \bar{f}_6(x)$, where

$$\bar{f}_6(x) = x^\nu \exp(-x(1+ax)),$$

where $\nu \geqq 1$ and $a > 0$. The major problem is verifying (9.71) or (9.72).

SINGULAR SOLUTIONS AND ILL-POSEDNESS FOR THE EVOLUTION OF VORTEX SHEETS*

RUSSEL E. CAFLISCH† AND OSCAR F. ORELLANA‡

Abstract. The evolution of a planar vortex sheet is described by the Birkhoff-Rott equation. Duchon and Robert [*C.R. Acad. Sci. Paris*, 302 (1986), pp. 183-186], [Comm. Partial Differential Equations, 13 (1988), pp. 1265-1295] have constructed exact solutions of this equation that are analytic for all $t<0$ but have a possible singularity in the curvature of the sheet at $t=0$. This shows that smooth initial data for a vortex sheet can lead to singularity formation at a finite time, in agreement with the results of numerical computation [*J. Fluid Mech.*, 167 (1986), pp. 65-93], [*J. Fluid Mech.*, 114 (1982), pp. 283-298] and of asymptotic expansion [*Proc. Roy. Soc. London Ser.* A, 365 (1979), pp. 105-119], [*Theoretical and Applied Mechanics*, in Proc. XVI Internat. Congr. Theoret. Appl. Mech., F. I. Niordson and N. Olhoff, eds., North-Holland, Amsterdam, 1984, pp. 629-633]. We present an independent construction of these solutions and use these results to infer that the vortex sheet problem is ill-posed in Sobolev class H_n with $n>3/2$. Earlier results show well-posedness in an analytic function class [Comm. Pure Appl. Math., 39 (1986), pp. 807-838], [*Comm. Math. Phys.*, 80 (1981), pp. 485-516]. Our method is to construct an explicit singular function that is a solution of the linearized equation, with a correction term added on to make the sum an exact solution of the nonlinear equation. The correction term is analyzed using the Cauchy-Kowalewski method.

1. Introduction.

A planar vortex sheet is a curve in a two-dimensional, inviscid, incompressible flow along which the fluid velocity is discontinuous. Vortex sheets, and the Kelvin-Helmholtz instability that they undergo, play an important role in many flows, such as mixing layers, two-fluid interfaces and flow past airfoils. Asymptotic analysis by Moore [11], [12] and numerical computation by Krasny [8] and Meiron, Baker, and Orszag [10] have shown that a vortex sheet may develop a singularity, i.e., infinite curvature at a point, in a finite time. The appearance of this singularity is important because it is immediately followed by rollup of the sheet [9]. A more mathematical reason for interest in such singularity formation is that it may serve as a simple analogue of singularity formation for the three-dimensional Euler equations.

Duchon and Robert [6, 16] perform a general construction of vortex sheet solutions that are analytic for all $t>0$, by choosing initial data to lie on the stable manifold for the Birkhoff-Rott equation ((1.1) below). The initial data can have singularities in the $(1+\nu)$th derivative for any $\nu>0$ (for a precise statement see [6], [16]; fractional derivatives can be understood in the Hölder sense as in (1.6)). Our aim is to present an independent construction of these singular solutions and to discuss their significance. We also obtain slightly more precise pointwise information on the singularity, by using a pointwise norm rather than the Fourier norm in [6], [16].

The singular solutions found here or in [6], [16] can be used to construct exact solutions for vortex sheets that develop singularities at finite time starting from smooth

initial data, as described in the concluding § 7. This shows that for the two-dimensional Euler equations, singular initial data (a vortex sheet) can become more singular in finite time. Furthermore, the existence of such singular solutions shows the vortex sheet problem to be ill posed in Sobolev space H^n for $n > 3/2$. A somewhat different proof of ill-posedness for vortex sheets was given by Ebin [15].

The vortex sheet is parametrized by a real variable γ defined so that it is Lagrangian (the value of γ is constant on a given fluid particle) and so that the density of circulation with respect to the γ variable on the sheet is 1. The position of the vortex sheet is defined by a complex variable $z(\gamma, t)$ that satisfies the Birkhoff-Rott equation [1]:

$$\frac{\partial}{\partial t}\bar{z}(\gamma, t) = \frac{1}{2\pi i} PV \int_{-\infty}^{\infty} \frac{d\gamma'}{z(\gamma, t) - z(\gamma', t)}, \tag{1.1}$$

in which the integral is a Cauchy principal value. An arbitrary constant in the definition of the Cauchy integral is irrelevant since the right-hand side involves a difference. Moreover, we will assume for simplicity that z is odd in γ, i.e.,

$$z(-\gamma, t) = -z(\gamma, t) \tag{1.2}$$

so that $z(0, t) = 0$. The function $z = \gamma$ is a steady solution of (1.1) and corresponds to a flat vortex sheet with a uniform density of circulation.

Linearization of (1.1) about the steady solution $z = \gamma$ yields the following equation for $z = \gamma + s$:

$$\partial_t \bar{s}(\gamma, t) = \tfrac{1}{2} H[s_\gamma] = \tfrac{1}{2}(s_{+\gamma} - s_{-\gamma}) \tag{1.3}$$

in which H is the Hilbert transform defined by $H[s] = s_+ - s_-$, s_+ is the upper analytic part of s, i.e., the part with positive Fourier wavenumbers, and s_- is the lower analytic part. The linearized equation (1.3) is unstable with modes $e^{ik\gamma \pm kt/2}$. In this paper we are investigating the nonlinear behavior of this Kelvin-Helmholtz instability. Since the linearized modes have arbitrarily large temporal growth rates, we find that singularities may develop in finite time for the solutions of the nonlinear equation.

An explicit example of our singular solutions is

$$z(\gamma, t) = \gamma + s_0 + r, \tag{1.4}$$

$$s_0(\gamma, t) = \varepsilon(1-i)\{(1 - e^{-t/2 - i\gamma})^{1+\nu} - (1 - e^{-t/2 + i\gamma})^{1+\nu}\} \tag{1.5}$$

in which ε is small. The dominant term s_0 is an exact solution of the linearized equation (1.3) and the correction term r is negligible relative to s_0 as explained in Theorem 1. Since $s_0 \simeq c\gamma^{1+\nu}$ for $t = 0$ and $\gamma \simeq 0$, then $z_{\gamma\gamma} \simeq s_{0\gamma\gamma} \simeq c\gamma^{\nu-1}$ (with a different constant c). Therefore the vortex sheet has an infinite curvature at $\gamma = 0$, $t = 0$ for $0 < \nu < 1$. For the approximate singular solution $z_0 = \gamma + s_0$, with s_0 given by (1.5), the vortex strength $|z_{0\gamma}|^{-1}$ $(t = 0)$ is plotted in Fig. 1. The cusp at $\gamma = 0$ is due to the singularity. An explanation of the terms in (1.5) is as follows. The $e^{\pm i\gamma}$ makes s_0 periodic and odd. The exponent $-t$ gives a solution that decays in time. Such a decaying solution requires the factors $(1-i)$ and $\frac{1}{2}$.

To define a more general class of functions s_0, let ε be a small real number and let $1 > \nu > \alpha > 0$. For s analytic in $|\mathrm{Im}\ \gamma| < \rho$ define the Hölder norm

$$|s|_\rho = \sup_{|\mathrm{Im}\ \gamma| < \rho} |s(\gamma)| + \sup_{\substack{|\mathrm{Im}\ \gamma|, |\mathrm{Im}\ \gamma'| < \rho \\ \gamma \neq \gamma'}} \frac{|s(\gamma) - s(\gamma')|}{|\gamma - \gamma'|^\alpha}. \tag{1.6}$$

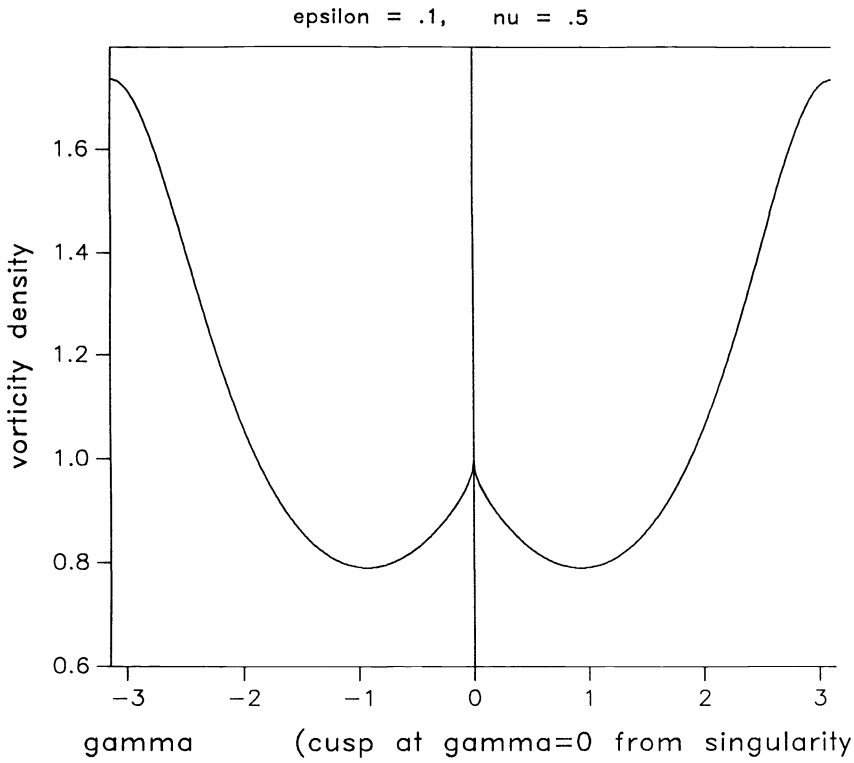

FIG. 1. *Approximate vorticity density* $\sigma = |z_{0\gamma}|^{-1} = |1 + s_{0\gamma}|^{-1}$ *with* s_0 *defined by* (1.5), $\varepsilon = 0.1$, $\nu = 0.5$. *The cusp at* $\gamma = 0$ *corresponds to the singularity.*

We require s_0 to satisfy the following:

(i) s_0 solves the linearized equation (1.3);

(ii) s_0 is analytic in the time-dependent strip $|\text{Im } \gamma| < |t|/2$ for $t > 0$;

(iii) s_0 is small and decays to zero as $t \to \infty$. At $t = 0$ s_0 has (at most) a singularity in its $(1+\nu)$th derivative, i.e.,

$$|s_0|_\rho + |s_{0\gamma}|_\rho < c\varepsilon\, e^{-(|t|/2-\rho)}, \tag{1.7}$$

$$|s_{0\gamma\gamma}|_\rho < c\varepsilon(1+(|t|-2\rho)^{\nu-\alpha-1})\, e^{-(|t|/2-\rho)} \tag{1.8}$$

for $t > 0$.

Note that the function s_0 in (1.5) satisfies (i)-(iii). Our main result is the following existence theorem.

THEOREM 1. *Let* ε *be a sufficiently small real number and let* $1 > \nu > \alpha > 0$. *Let* s_0 *satisfy* (i)-(iii) *above*; *i.e.*, s_0 *is an analytic solution of the linearized equation* (1.3) *that decays to zero at* $t = \infty$ *and has a mild singularity at* $t = 0$. *Then there is a function* $r(\gamma, t)$ *such that*

$$z(\gamma, t) = \gamma + s_0 + r \tag{1.9}$$

is an analytic solution of the Birkhoff-Rott equation (1.1) *for* $t > 0$ *and* $\kappa|\text{Im } \gamma| < t$ *in which* $\kappa > 2$ *and* $\kappa \to 2$ *as* $\varepsilon \to 0$. *Moreover, r can be chosen so that the decaying mode* $r_+ + i\bar{r}_- = 0$ *at* $t = 0$ *and that*

$$|r|_0 + |r_\gamma|_0 < c\varepsilon^2 \exp(-|t|/2), \tag{1.10}$$

$$|r_{\gamma\gamma}|_0 < c\varepsilon^2(1+|t|^{\nu-\alpha-1}) \exp(-|t|/2) \tag{1.11}$$

in which c is some constant that is independent of ε *and depends smoothly on* α^{-1} *and* $(\nu-\alpha)^{-1}$ (*i.e., c may be infinite at* $\alpha = 0$ *or* $\alpha = \nu$).

Since $r_+ + i\bar{r}_- = 0$ at $t = 0$, in some sense half of the initial data of z is given by $\gamma + s_0$. The norm in (1.10), (1.11) is that of (1.6) with $\rho = 0$. These estimates show that r is as smooth as s_0, but much smaller. Stronger estimates for r on the strip $\kappa|\text{Im } \gamma| < t$ are given at the end of § 6.

There are three main ideas in this construction: The first is to extend the Birkhoff-Rott equation to complex γ. Linearization (or equivalently the form of the Kelvin-Helmholtz instability) shows the Birkhoff-Rott equation to be approximately hyperbolic in the imaginary γ direction, so that singularities will move in that direction. This was first pointed out by Moore [11]. Of course, only real values of γ are physically meaningful; i.e., singularities are physically observable only when they lie on the real γ line.

The second idea is to put the singularity in the initial data. By proper choice of initial data, the singularities can be expected to travel approximately on the lines Im $\gamma = \pm t/2$. Although our method cannot track these singularities exactly, we are able to show that the resulting solution is analytic in the wedge $|\text{Im } \gamma| < \kappa t/2$, $t > 0$, as shown in Fig. 2. Note that for all $t > 0$ this wedge contains the line Im $\gamma = 0$. Therefore the vortex sheet is analytic for all $t > 0$.

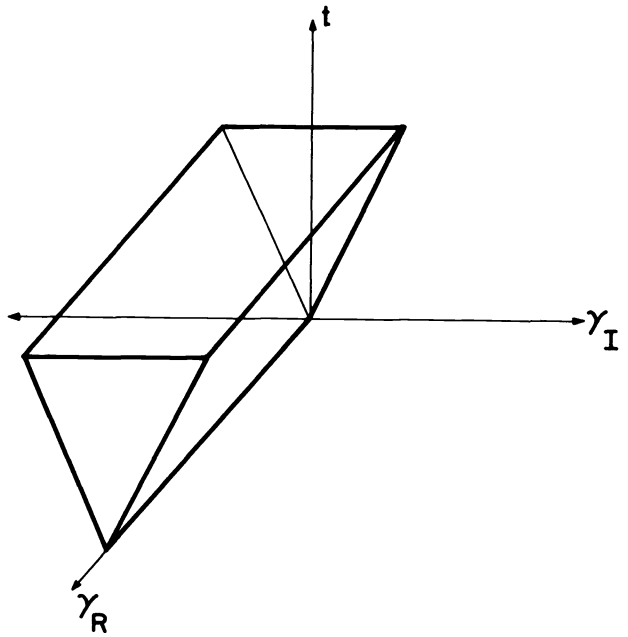

FIG. 2. *Domain of analyticity (in γ) for $z(\gamma, t)$ (equivalently for $r(\gamma, t)$)*: $\{|\text{Im } \gamma| < ct, t > 0\}$.

The third idea is to construct the solution within the class of analytic functions. In this function class the Birkhoff-Rott equation has been shown to be well posed; while in almost any larger class it is expected to be ill posed. For the Sobolev spaces, ill-posedness is shown in § 7. Use of analytic functions provides the stabilization necessary to construct exact solutions in the presence of physical instability. Aside from this practical justification, our belief that the imposition of analyticity is consistent with the zero viscosity limit justifies the use of analytic functions, at least for some flow regimes.

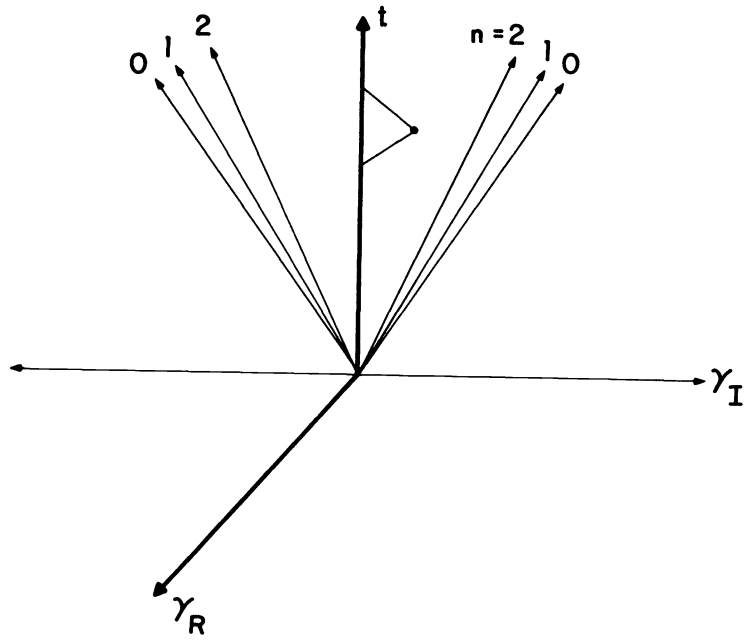

FIG. 3. *Domain of analyticity for the iterates* r_n *(or equivalently* p_n, q_n*). The width of the domain decreases as n increases. The line segments emanating from the plane* $\{\text{Im } \gamma = 0\}$ *are the characteristics used to extend the iterates to complex* γ*, as in* (2.12), (2.13), *or* (3.3).

The correction term r of Theorem 1 is constructed using the Cauchy-Kowalewski method, somewhat modified from that in [13] involving an iteration. At each iteration in our construction, the approximate solution is analytic in a wedge $|\text{Im } \gamma| < ct$, with an angle c that is slightly reduced at each step, as indicated in Fig. 3. The final solution is valid in a limiting wedge, which is shown to be nonempty.

Other analytic results for vortex sheets include a proof of short-time existence by Sulem, Sulem, Bardos, and Frisch and a proof of existence almost up to the expected time of singularity formation by Caflisch and Orellana [2]. The singularities described in the present paper are not accompanied by concentrations of energy. Thus they are much weaker than those discussed by DiPerna and Majda [3]-[5], which possibly appear on a vortex sheet at a later time. On the other hand, there are no known examples for which such energy concentrations develop from less singular initial data.

The outline of this paper follows. Section 2 contains a reformulation of (1.1) and shows the sense in which the problem is hyperbolic. In particular, an equation for the error term r is derived. In § 3 we describe an iteration method for solving the equation for r. Each iteration involves solving an elliptic problem in t and Re γ, then extending the solution to complex γ by solving a hyperbolic problem. The elliptic problem is solved using a Green's function; we solve the hyperbolic problem by integrating along characteristics. Estimates on the first iterate are obtained in § 4, the induction method is described in § 5 and estimates for the successive iterates are derived using a Cauchy-Kowalewski method in § 6. At the end of that section, we summarize the proof of Theorem 1, and we derive two consequences of Theorem 1 in the concluding section.

2. Formulation. We write z as a perturbation of the flat sheet by $z = \gamma + s$ and assume that s is 2π-periodic, i.e.,

$$s(\gamma + 2\pi, t) = s(\gamma, t). \tag{2.1}$$

The Birkhoff-Rott equation (1.1) is equivalent to the following equation for s, which is now written in a way that is analytic for complex γ,

$$\frac{\partial}{\partial t} s^*(\gamma, t) = B[s] \equiv \frac{1}{2\pi i} PV \int_{-\infty}^{\infty} \frac{d\zeta}{-\zeta + s(\gamma) - s(\gamma+\zeta)}, \tag{2.2}$$

in which s^* is the analytic extension of $\bar{s}$, i.e., $s^*(\gamma) = \overline{s(\bar{\gamma})}$. The operator B is expanded as $B[s] = B_1[s] + B_r[s]$ in which

$$B_1[s](\gamma) = -\frac{1}{2\pi i} PV \int_{-\infty}^{\infty} \frac{s(\gamma) - s(\gamma+\zeta)}{\zeta^2} d\zeta = \frac{1}{2} H[s_\gamma] \tag{2.3}$$

is the linear part of B and B_r is the nonlinear remainder. The linearized equation (1.3) is analytically extended as $s_t^* = B_1[s]$.

Since s_0 is an exact solution of this linearized equation, the Birkhoff-Rott equation (1.1) for $z = \gamma + s_0 + r$ can be rewritten as follows:

$$r_t^* = B_1[r] + B_r[s_0 + r]. \tag{2.4}$$

Define the decaying component p and growing component q for r as follows:

$$p = r_+ + i(r_-)^*, \qquad q = r_+ - i(r_-)^*. \tag{2.5}$$

Then (2.4) can be rewritten as

$$p_t = \frac{i}{2} p_\gamma + a, \tag{2.6}$$

$$q_t = \frac{-i}{2} q_\gamma + b, \tag{2.7}$$

in which

$$a = (B_-)^* + iB_+, \qquad b = (B_-)^* - iB_+ \tag{2.8}$$

and B_+ and B_- are the upper and lower analytic components of $B_r[s_0 + r]$. Note that a and b, and thus also p and q, have only components with positive wave numbers.

The system (2.6), (2.7) is elliptic in γ, t for real γ, but it is hyperbolic in γ, t for imaginary γ (or more precisely, in the imaginary γ direction).

We solve (2.6), (2.7) in two parts. For γ real, $t \geqq 0$, we solve the elliptic equation using a Green's function. For $\operatorname{Im} \gamma \neq 0$, $t \geqq 0$, we solve the hyperbolic equation (2.4) by integration along characteristics using the values of r on $\operatorname{Im} \gamma = 0$ as "initial values." These characteristics are indicated in Fig. 3.

We require p and q to be 2π-periodic, to vanish at $t = \infty$, and to have only components with positive wave numbers and $p = 0$ at $t = 0$; i.e.,

$$\begin{gathered} (p, q)(\gamma, t) = (p, q)(\gamma + 2\pi, t), \\ (p, q) \to 0 \quad \text{as } t \to \infty, \qquad p(t=0) = 0, \\ (\hat{p}, \hat{q})(k, t) = \int_0^{2\pi} e^{-ik\gamma} (p, q)(\gamma, t)\, d\gamma = 0 \quad \text{for } k \leqq 0. \end{gathered} \tag{2.9}$$

Under these conditions and for a and b having only components with positive wave numbers, the solution of (2.6), (2.7) is uniquely given by

$$p(\gamma, t) = \int_0^t \int_0^{2\pi} g(\gamma', t - t') a(\gamma - \gamma', t')\, d\gamma'\, dt', \tag{2.10}$$

$$q(\gamma, t) = \int_t^{\infty} \int_0^{2\pi} g(\gamma', t - t') b(\gamma - \gamma', t')\, d\gamma'\, dt' \tag{2.11}$$

for γ real and by

$$p(\gamma+i\mu, t)=p(\gamma, t+2\mu)-2\int_0^\mu a(\gamma+i\mu', t+2(\mu-\mu'))\,d\mu', \tag{2.12}$$

$$q(\gamma+i\mu, t)=q(\gamma, t-2\mu)+2\int_0^\mu b(\gamma+i\mu', t-2(\mu-\mu'))\,d\mu' \tag{2.13}$$

for $\gamma+i\mu$ complex in which

$$g(\gamma, t)=\begin{cases}\xi(-t/2+i\gamma), & t>0,\\ -\xi(-t/2+i\gamma), & t<0,\end{cases} \tag{2.14}$$

$$\xi(z)=\frac{1}{2\pi}\frac{e^z}{1-e^z}. \tag{2.15}$$

If a and b are analytic in γ, then p and q defined by (2.10)-(2.13) are also analytic.

According to (2.5), $r=\frac{1}{2}(p+q)+i\frac{1}{2}(p^*-q^*)$. Let $A[s_0+r]$ denote the corresponding combination of the right-hand sides of (2.10)-(2.13). The Birkhoff-Rott equation (1.1) or (2.4) for $z=\gamma+s_0+r$ can be rewritten as follows:

$$r=A[s_0+r]. \tag{2.16}$$

Equations (2.10)-(2.13) for p, q or the equivalent equation (2.16) for r are the main results of this section.

3. Iteration method. In the previous section, the Birkhoff-Rott equation, for $z=\gamma+s_0+r$ was reduced to (2.16) for r. We now solve this equation by iteration. Define $r_0=0$ and for $n\geqq 0$ let r_{n+1} solve

$$r_{n+1}(\gamma, t)=A[s_0+r_n] \tag{3.1}$$

In terms of p_n, q_n, defined as in (2.5), equation (3.1) is written as in (2.10)-(2.13):

$$\begin{aligned} p_{n+1}(\gamma, t)&=\int_0^t\int_0^{2\pi} g(\gamma', t-t')a_n(\gamma-\gamma')\,d\gamma'\,dt',\\ q_{n+1}(\gamma, t)&=\int_t^\infty\int_0^{2\pi} g(\gamma', t-t')b_n(\gamma-\gamma')\,d\gamma'\,dt', \end{aligned} \tag{3.2}$$

$$\begin{aligned} p_{n+1}(\gamma+i\mu, t)&=p_{n+1}(\gamma, t+2\mu)-2\int_0^\mu a_n(\gamma+i\mu', t+2(\mu-\mu'))\,d\mu',\\ q_{n+1}(\gamma+i\mu, t)&=q_{n+1}(\gamma, t-2\mu)+2\int_0^\mu b_n(\gamma+i\mu', t-2(\mu-\mu'))\,d\mu' \end{aligned} \tag{3.3}$$

for γ and μ real, in which a_n, b_n are defined as in (2.8) with r replaced by r_n. To show convergence of r_n we obtain estimates on the difference

$$R_n=r_n-r_{n-1}.$$

Let $Q_n=q_n-q_{n-1}$, $P_n=p_n-p_{n-1}$. We use the following differentiated equations for R_n, or equivalently for P_n, Q_n:

$$\begin{aligned} \partial_\gamma^k P_{n+1}(\gamma, t)&=\int_0^t\int_0^{2\pi} g\partial_\gamma^k(a_n-a_{n-1})\,d\gamma'\,dt',\\ \partial_\gamma^k Q_{n+1}(\gamma, t)&=\int_t^\infty\int_0^{2\pi} g\partial_\gamma^k(b_n-b_{n-1})\,d\gamma'\,dt', \end{aligned} \tag{3.4}$$

$$\begin{aligned}\partial_\gamma^k P_{n+1}(\gamma+i\mu, t) &= \partial_\gamma^k P_{n+1}(\gamma, t+2\mu) - 2\int_0^\mu \partial_\gamma^k (a_n - a_{n-1})\, d\mu' \\ \partial_\gamma^k Q_{n+1}(\gamma+i\mu, t) &= \partial_\gamma^k Q_{n+1}(\gamma, t-2\mu) + 2\int_0^\mu \partial_\gamma^k (b_n - b_{n-1})\, d\mu'\end{aligned} \tag{3.5}$$

for $k = 1, 2$.

For the Hölder norm $|s|_\rho$ defined in (1.6), the Cauchy estimate for the derivative of an analytic function is

$$|s_\gamma(\cdot, t)|_\rho \leqq (\rho' - \rho)^{-1} |s(\cdot, t)|_{\rho'} \quad \text{if } \rho' > \rho. \tag{3.6}$$

The nonlinear part B_r of the Birkhoff-Rott integral operator is estimated as

$$\begin{aligned}&|B_r[s]|_\rho \leqq c_0 |s_\gamma|_\rho^2, \\ &|B_r[s]_\gamma|_\rho \leqq c_0 |s_\gamma|_\rho |s_{\gamma\gamma}|_\rho, \\ &|B_r[s] - B_r[\tilde{s}]|_\rho \leqq c_1 |s_\gamma - \tilde{s}_\gamma|_\rho (|s_\gamma|_\rho + |\tilde{s}_\gamma|_\rho), \\ &|B_r[s]_\gamma - B_r[\tilde{s}]_\gamma|_\rho \leqq c_1 |s_\gamma - \tilde{s}_\gamma|_\rho (|s_{\gamma\gamma}|_\rho + |\tilde{s}_{\gamma\gamma}|_\rho) + c_1 |s_{\gamma\gamma} - \tilde{s}_{\gamma\gamma}|_\rho (|s_\gamma|_\rho + |\tilde{s}_\gamma|_\rho)\end{aligned} \tag{3.7}$$

for any s, $\tilde{s}$ in which $c_0 = c(1 - |s_\gamma|_\rho)^{-1}$ and $c_1 = c(1 - |s_\gamma|_\rho)^{-1} + c(1 - |\tilde{s}_\gamma|_\rho)^{-1}$. For these estimates we assume that $|s_\gamma|_\rho < 1$, $|\tilde{s}_\gamma|_\rho < 1$.

From these general estimates it follows that a_n, b_n satisfy

$$\begin{aligned}&|a_0|_\rho + |b_0|_\rho \leqq c |s_{0\gamma}|_\rho^2, \\ &|a_{0\gamma}|_\rho + |b_{0\gamma}|_\rho \leqq c |s_{0\gamma}|_\rho |s_{0\gamma\gamma}|_\rho,\end{aligned} \tag{3.8}$$

$$|a_n - a_{n-1}|_\rho + |b_n - b_{n-1}|_\rho \leqq c |R_{n\gamma}|_\rho (|s_{0\gamma}|_\rho + |r_{n-1\gamma}|_\rho + |r_{n\gamma}|_\rho), \tag{3.9}$$

$$\begin{aligned}|(a_n - a_{n-1})_\gamma|_\rho + |(b_n - b_{n-1})_\gamma|_\rho \leqq{}& c |R_{n\gamma}|_\rho (|s_{0\gamma\gamma}|_\rho + |r_{n-1\gamma\gamma}|_\rho + |r_{n\gamma\gamma}|_\rho) \\ &+ c |R_{n\gamma\gamma}|_\rho (|s_{0\gamma}|_\rho + |r_{n-1\gamma}|_\rho + |r_{n\gamma}|_\rho)\end{aligned} \tag{3.10}$$

if $|r_{m\gamma}|_\rho < |s_{0\gamma}|_\rho < \frac{1}{2}$, $|r_{m\gamma\gamma}|_\rho < |s_{0\gamma\gamma}|_\rho < \frac{1}{2}$ for $m = n, n-1$.

For use in estimating the iterates r_n, we state a general lemma. Its proof is a straightforward extension of the proof of Hölder bounds on the Hilbert transform (Katznelson [7]).

LEMMA 3.1. *Suppose that* $\int_0^{2\pi} a\, d\gamma = \int_0^{2\pi} b\, d\gamma = 0$ *and let* p *and* q *satisfy*

$$\begin{aligned}p(\gamma, t) &= \int_0^t \int_0^{2\pi} g(\gamma', t-t') a(\gamma - \gamma', t')\, d\gamma'\, dt', \\ q(\gamma, t) &= \int_t^\infty \int_0^{2\pi} g(\gamma', t-t') b(\gamma - \gamma', t')\, d\gamma'\, dt'\end{aligned} \tag{3.11}$$

and suppose that

$$|a_\gamma|_0 + |b_\gamma|_0 \leqq c\varepsilon^2 (1 + t^{\nu-\alpha-1})\, e^{-t}. \tag{3.12}$$

Let r *be related to* p *and* q *as in* (2.5). *Then* r *satisfies*

$$|r_\gamma|_0 \leqq c\varepsilon^2 e^{-t/2}, \qquad |r_{\gamma\gamma}|_0 \leqq c\varepsilon^2 (1 + t^{\nu-\alpha-1})\, e^{-t/2}. \tag{3.13}$$

The same estimates are true for p *and* q.

4. First approximation. The first approximation $r_1 = R_1$ satisfies $r_1 = A[s_0]$, i.e.,

$$p_1(\gamma, t) = \int_0^t \int_0^{2\pi} g a_0 \, d\gamma' \, dt', \qquad q_1(\gamma, t) = \int_t^\infty \int_0^{2\pi} g b_0 \, d\gamma' \, dt', \tag{4.1}$$

$$\begin{aligned} p_1(\gamma + i\mu, t) &= p_1(\gamma, t+2\mu) - 2\int_0^\mu a_0 \, d\mu', \\ q_1(\gamma + i\mu, t) &= q_1(\gamma, t-2\mu) + 2\int_0^\mu b_0 \, d\mu' \end{aligned} \tag{4.2}$$

in which the arguments inside the integrals are as in (3.2)-(3.3). From (3.8), (1.7), and (1.8) it follows that a_0, b_0 satisfy

$$|a_{0\gamma}|_\rho + |b_{0\gamma}|_\rho \leqq c\varepsilon^2 (1 + (t-2\rho)^{\nu-\alpha-1}) \, e^{-(t-2\rho)},$$

for $t > 2\rho$. In particular,

$$|a_{0\gamma}|_0 + |b_{0\gamma}|_0 \leqq c\varepsilon^2 (1 + t^{\nu-\alpha-1}) \, e^{-t}.$$

Application of Lemma 3.1 implies

$$|r_{1\gamma}|_0 \leqq c\varepsilon^2 \, e^{-t/2} \qquad |r_{1\gamma\gamma}|_0 \leqq c\varepsilon^2 (1 + t^{\nu-\alpha-1}) \, e^{-t/2}. \tag{4.3}$$

Next estimate $r_{1\gamma}$ for $\gamma + i\mu$ complex from (4.2) as

$$\begin{aligned} |r_{1\gamma}(\cdot, t)|_\rho &\leqq 2 \sup_{|\mu| \leqq \rho} |r_{1\gamma}(\cdot, t+2\mu)|_0 + 2\int_0^\rho |a_{0\gamma}(t+2\mu')|_{\rho-\mu'} + |b_{0\gamma}(t-2\mu')|_{\rho-\mu'} \, d\mu' \\ &\leqq c\varepsilon^2 e^{-(t-2\rho)/2} + c\varepsilon^2 \rho (1 + (t-2\rho)^{\nu-\alpha-1}) \, e^{-(t-2\rho)} \\ &\leqq c\delta^{\nu-\alpha-1} \varepsilon^2 \, e^{-(t-2\rho)/2} \end{aligned} \tag{4.4}$$

for $\kappa_1 \rho < t$ with $\kappa_1 = 2(1+\delta)$ with $\delta > 0$. Similarly,

$$\begin{aligned} |r_{1\gamma\gamma}(\cdot, t)|_\rho &\leqq 2 \sup_{|\mu| \leqq \rho} |r_{1\gamma\gamma}(\cdot, t+2\mu)|_0 + 2\int_0^\rho |a_{0\gamma\gamma}(t+2\mu')|_{\rho-\mu'} + |b_{0\gamma\gamma}(t-2\mu')|_{\rho-\mu'} \, d\mu' \\ &\leqq c\varepsilon^2 (1 + (t-2\rho)^{\nu-\alpha-1}) \, e^{-(t-2\rho)/2} \\ &\quad + (\delta\rho)^{-1} \int_0^\rho (|a_{0\gamma}|_{(1+\delta)\rho-\mu'} + |b_{0\gamma}|_{(1+\delta)\rho-\mu'}) \, d\mu' \\ &\leqq c\varepsilon^2 (1 + (t-2\rho)^{\nu-\alpha-1}) \, e^{-(t-2\rho)/2} + 2\varepsilon^2 \delta^{-1} (1 + (t-\kappa_1\rho)^{\nu-\alpha-1}) \, e^{-(t-\kappa_1\rho)/2} \\ &\leqq c\delta^{-1} \varepsilon^2 (1 + (t-\kappa_1\rho)^{\nu-\alpha-1}) \, e^{-(t-\kappa_1\rho)/2} \end{aligned} \tag{4.5}$$

for $\kappa_1 \rho < t$.

5. Induction hypothesis. Successive approximations r_n and their convergence are analyzed using an analogue of the Cauchy-Kowalewski method [13] for the integral equations (3.2), (3.3). In each iteration the wedge of existence $|\text{Im } \gamma| < \kappa_n^{-1} t$ is slightly decreased, so that the general estimate (3.6) can be employed. The object of the modified Cauchy-Kowalewski method is to show that there is a limiting, nonempty wedge in which the solution r is analytic. The key point of the method is overcoming the large factor $(\rho - \rho')^{-1}$ in the Cauchy estimate (3.6). As a result of this factor the singularity in the solution r may be one order higher than the singularity in s_0 on the lines $|\text{Im } \gamma| = \kappa_n^{-1} t$. However, the additional singularity has amplitude proportional to t, so that at $t = 0$, r is no more singular than s_0.

The induction argument follows that of Nishida [13] with some change in notation and indexing. Define

$$\kappa_{n+1} = \kappa_n (1 - \varepsilon^{\mu}(n+2)^{-2})^{-1} \tag{5.1}$$

for $n \geqq 1$, in which $\mu > 0$ is to be chosen later. Then

$$\kappa_n \to \kappa = \kappa_1 \prod_1^{\infty} (1 - \varepsilon^{\mu}(m+2)^{-2})^{-1}, \tag{5.2}$$

which is finite and note that $\kappa_{n+1} > \kappa_n > \cdots > \kappa_1 > 2$. Define the norm

$$\begin{aligned} A_m(R) = \sup_{t > \kappa_m \rho} & \varepsilon^{-2} e^{(t-\kappa_m\rho)/2} t^{-1}(t - \kappa_m \rho) \\ & \times \{|R_\gamma(t)|_\rho + (1 + (t - \kappa_m\rho)^{\nu-\alpha-1})^{-1} |R_{\gamma\gamma}(t)|_\rho\}. \end{aligned} \tag{5.3}$$

Since $\kappa_{m+1} > \kappa_m$, then $A_{m+1}(R) \leqq A_m(R)$ for any R. The size of the mth correction $R_m = r_m - r_{m-1}$ is measured by

$$\lambda_m = A_m(R_m). \tag{5.4}$$

As mentioned above, the factor $(t - \kappa_m\rho)/t$ indicates possible additional singularity on the line $|\operatorname{Im} \gamma| = \rho = \kappa_m^{-1} t$, but note that it does not affect the size of R_m on the physical line $\operatorname{Im} \gamma = \rho = 0$.

The induction hypothesis is

$$\sum_{j=1}^{n} \lambda_j \left(1 - \frac{\kappa_j}{\kappa_{j+1}}\right) \leqq d. \tag{5.5}$$

The constant d as well as κ_1 will be chosen later. In the previous section, we showed that $\lambda_1 \leqq c(\kappa_1 - 2)^{-1}$ so that the hypothesis for $n = 1$ is satisfied if $d \geqq c(\kappa_1 - 2)^{-1}$.

Now suppose that (5.5) is true for $n \geqq 1$. If $\kappa_{n+1}\rho < t$, then for $n \geqq j \geqq 1$,

$$\begin{aligned} |R_{j\gamma}(t)|_\rho &< \lambda_j \left(1 - \frac{\kappa_j}{\kappa_{n+1}}\right)^{-1} \varepsilon^2 e^{-(t-\kappa_j\rho)/2} \\ &< \lambda_j \left(1 - \frac{\kappa_j}{\kappa_{j+1}}\right)^{-1} \varepsilon^2 e^{-(t-\kappa_n\rho)/2}, \end{aligned} \tag{5.6}$$

$$\begin{aligned} |R_{j\gamma\gamma}(t)|_\rho &< \lambda_j \left(1 - \frac{\kappa_j}{\kappa_{n+1}}\right)^{-1} \varepsilon^2 (1 + (t - \kappa_j\rho)^{\nu-\alpha-1}) e^{-(t-\kappa_j\rho)/2} \\ &< \lambda_j \left(1 - \frac{\kappa_j}{\kappa_{j+1}}\right)^{-1} \varepsilon^2 (1 + (t - \kappa_n\rho)^{\nu-\alpha-1}) e^{-(t-\kappa_n\rho)/2}. \end{aligned} \tag{5.7}$$

Since $r_0 = 0$, $r_{n\gamma} = \sum_{j=1}^{n} R_{j\gamma}$, $r_{n\gamma\gamma} = \sum_{j=1}^{n} R_{j\gamma\gamma}$, and using the induction hypothesis at n, this yields

$$\begin{aligned} |r_{j\gamma}(t)|_\rho &\leqq \varepsilon^2 \left(\sum_{j=1}^{n} \lambda_j (1 - \kappa_j/\kappa_{j+1})^{-1} \right) e^{-(t-\kappa_n\rho)/2} \\ &\leqq d\,\varepsilon^2 e^{-(t-\kappa_n\rho)/2}, \end{aligned} \tag{5.8}$$

$$|r_{j\gamma\gamma}(t)|_\rho \leqq d\varepsilon^2 (1 + (t - \kappa_n\rho)^{\nu-\alpha-1}) e^{-(t-\kappa_n\rho)/2}, \tag{5.9}$$

for any $j \leqq n$ and $\kappa_{n+1}\rho < t$. The bounds (5.8), (5.9) will be used in § 6 for estimation of R_{n+1}.

6. Successive approximations. To verify the induction hypothesis (5.5) for $n+1$, the correction terms R_{n+1} that solve (3.4), (3.5) must be estimated. Using (1.7), (1.8) for s_0, (5.8), (5.9) for r_n, r_{n-1}, and (5.4) for $R_{n\gamma}$, $R_{n\gamma\gamma}$ in (3.10), the forcing term in (3.4), (3.5) is bounded for $\kappa_{n+1}\rho < t$ by

$$|(a_n - a_{n-1})_\gamma|_\rho + |(b_n - b_{n-1})_\gamma|_\rho \tag{6.1}$$
$$\leqq c\varepsilon^3(1+\varepsilon d)\lambda_n\left(\frac{t}{t-\kappa_n\rho}\right)(1+(t-\kappa_n\rho)^{\nu-\alpha-1})\, e^{-(t-\kappa_n\rho)}.$$

In particular for $\rho = 0$,

$$|(a_n - a_{n-1})_\gamma|_0 + |(b_n - b_{n-1})_\gamma|_0 \leqq c\varepsilon^3(1+\varepsilon d)\lambda_n(1+t^{\nu-\alpha-1})\, e^{-t}. \tag{6.2}$$

First, estimate R_{n+1} for γ real, i.e., $\rho = 0$. Application of Lemma 3.1 to (3.4) using (6.2) implies that

$$|R_{n+1\gamma}|_0 \leqq c\varepsilon^3(1+\varepsilon d)\lambda_n\, e^{-t/2}, \tag{6.3}$$

$$|R_{n+1\gamma\gamma}|_0 \leqq c\varepsilon^3(1+\varepsilon d)\lambda_n(1+t^{\nu-\alpha-1})\, e^{-t/2}. \tag{6.4}$$

Second, estimate $R_{n+1\gamma}$ for complex $\gamma + i\mu$, i.e., for $\rho \geqq 0$, solving (3.5). For $\kappa_{n+1}\rho < t$ bound

$$|R_{n+1\gamma}(t)|_\rho \leqq 2\sup_{|\mu|<\rho}|R_{n+1\gamma}(t+2\mu)|_0 + \int_0^\rho (|(a_n - a_{n-1})_\gamma(t+2\mu)|_{\rho-\mu}$$
$$+ |(b_n - b_{n-1})_\gamma(t-2\mu)|_{\rho-\mu})\, d\mu \tag{6.5}$$
$$\leqq 2c\varepsilon^3(1+\varepsilon d)\lambda_n\, e^{-(t-\rho)/2} + I,$$

in which I denotes the integral. The inequalities $\kappa_{n+1} > \kappa_n > 2$ and $\kappa_{n+1}\rho < t$ imply $\kappa_{n+1}(\rho-\mu) < (t-2\mu)$. Then we may use (6.1) to bound I by

$$I \leqq c\varepsilon^3(1+\varepsilon d)\lambda_n \int_0^\rho \left(\frac{t\pm 2\mu}{(t\pm 2\mu) - \kappa_n(\rho-\mu)}\right)(1+(t\pm 2\mu - \kappa_n(\rho-\mu))^{\nu-\alpha-1})$$
$$\cdot\, e^{-(t\pm 2\mu - \kappa_n(\rho-\mu))}\, d\mu$$
$$\leqq c\varepsilon^3(1+\varepsilon d)\lambda_n(t+\rho)\, e^{-(3/4)(t-\kappa_n\rho)} \int_0^\rho (t-\kappa_n\rho + (\kappa_n - 2)\mu)^{\nu-\alpha-2}\, d\mu \tag{6.6}$$
$$\leqq c\varepsilon^3(1+\varepsilon d)(\kappa_n-2)^{-1}\lambda_n(t+\rho)(t-\kappa_n\rho)^{\nu-\alpha-1}\, e^{-(3/4)(t-\kappa_n\rho)}$$
$$\leqq c\varepsilon^3(1+\varepsilon d)(\kappa_n-2)^{-1}\lambda_n\left(\frac{t}{t-\kappa_n\rho}\right) e^{-(t-\kappa_n\rho)/2}.$$

Since $\kappa_{n+1} > \kappa_n$, this combines with (6.5) to show that

$$|R_{n+1\gamma}(t)|_\rho \leqq c\varepsilon^3(1+\varepsilon d)(\kappa_n-2)^{-1}\lambda_n\left(\frac{t}{t-\kappa_{n+1}\rho}\right) e^{-(t-\kappa_{n+1}\rho)/2}, \tag{6.7}$$

for $\kappa_{n+1}\rho < t$.

Third, estimate $R_{n+1\gamma\gamma}$ for complex $\gamma + i\mu$, i.e., for $\rho \geqq 0$, solving (3.5). This is the crucial estimate of the Cauchy-Kowalewski method. For $\kappa_{n+1}\rho < t$ estimate

$$|R_{n+1\gamma\gamma}(t)|_\rho \leqq 2\sup_{|\mu|\leqq\rho}|R_{n+1\gamma\gamma}(t+2\mu)|_0$$
$$+ \int_0^\rho \{|(a_n - a_{n-1})_{\gamma\gamma}(t+2\mu)|_{\rho-\mu} + |(b_n - b_{n-1})_{\gamma\gamma}(t-2\mu)|_{\rho-\mu}\}\, d\mu \tag{6.8}$$
$$\leqq c\varepsilon^3(1+\varepsilon d)\lambda_n(1+(t-2\rho)^{\nu-\alpha-1})\, e^{-(t-2\rho)/2} + I_2,$$

in which I_2 is the integral. Define ρ_1 by

$$\rho_1 = \tfrac{1}{2}(\kappa_{n+1}^{-1}(t-2\mu)+(\rho-\mu)), \tag{6.9}$$

which satisfies

$$\rho-\mu < \rho_1 < \kappa_{n+1}^{-1}(t-2\mu), \tag{6.10}$$

$$\begin{aligned} t-2\mu-\kappa_{n+1}\rho_1 &= \kappa_{n+1}(\rho_1-(\rho-\mu)) = (t-\kappa_{n+1}\rho+(\kappa_{n+1}-2)\mu)/2 \\ &\geqq (t-\kappa_{n+1}\rho)/2. \end{aligned} \tag{6.11}$$

Estimate I_2 using the Cauchy estimate (3.6), the bound (6.1), and the relations (6.10), (6.11) to obtain

$$\begin{aligned} I_2 &\leqq 2\int_0^\rho (\rho_1-(\rho-\mu))^{-1}|(a_n-a_{n-1})_\gamma(t+2\mu)|_{\rho_1}+|(b_n-b_{n-1})_\gamma(t-2\mu)|_{\rho_1}\,d\mu \\ &\leqq c\varepsilon^3(1+\varepsilon d)\lambda_n\int_0^\rho (\rho_1-(\rho-\mu))^{-1}\frac{t+2\mu}{(t-2\mu-\kappa_n\rho_1)}(1+(t-2\mu-\kappa_n\rho_1)^{\nu-\alpha-1}) \\ &\quad\cdot e^{-(t-2\mu-\kappa_{n+1}\rho_1)}\,d\mu \\ &\leqq c\varepsilon^3(1+\varepsilon d)\lambda_n(t+\rho)\,e^{-(t-\kappa_{n+1}\rho)/2}\int_0^\rho (t-\kappa_{n+1}\rho+(\kappa_{n+1}-2)\mu)^{-2} \\ &\quad+(t-\kappa_{n+1}\rho+(\kappa_{n+1}-2)\mu)^{\nu-\alpha-3}\,d\mu \\ &\leqq c\varepsilon^3(1+\varepsilon d)\lambda_n(t+\rho)\,e^{-(t-\kappa_{n+1}\rho)/2}(\kappa_{n+1}-2)^{-1} \\ &\quad\cdot(t-\kappa_{n+1}\rho)^{-1}(1+(t-\kappa_{n+1}\rho)^{\nu-\alpha-1}). \end{aligned} \tag{6.12}$$

Combine this with (6.8) to find

$$\begin{aligned} |R_{n+1\gamma\gamma}|_\rho &\leqq c\varepsilon^3(1+d)\lambda_n(\kappa_{n+1}-2)^{-1}\left(\frac{t}{t-\kappa_{n+1}\rho}\right) \\ &\quad\cdot(1+(t-\kappa_{n+1}\rho)^{\nu-\alpha-1})\,e^{-(t-\kappa_{n+1}\rho)/2} \end{aligned} \tag{6.13}$$

for $\kappa_{n+1}\rho < t$.

Inequalities (6.7) for $R_{n+1\gamma}$ and (6.13) for $R_{n+1\gamma\gamma}$ and the definition (5.4) of λ_{n+1} imply that

$$\begin{aligned} \lambda_{n+1} &\leqq c\varepsilon(1+\varepsilon d)(\kappa_{n+1}-2)^{-1}\lambda_n \\ &\leqq c\varepsilon(1+\varepsilon d)(\kappa_1-2)^{-1}\lambda_n. \end{aligned} \tag{6.14}$$

This inequality is also true for λ_{j+1} in terms of λ_j for any $j \leqq n$, so that

$$\begin{aligned} \lambda_{n+1} &\leqq \{c\varepsilon(1+\varepsilon d)(\kappa_1-2)^{-1}\}^n\lambda_1 \\ &\leqq \{c\varepsilon(1+\varepsilon d)(\kappa_1-2)^{-1}\}^n(\kappa_1-2)^{-1}. \end{aligned} \tag{6.15}$$

With these estimates finished, we are ready to verify the induction hypothesis (5.5) for $n+1$ by choosing d and κ_1. Let

$$\kappa_1 = 2+a\varepsilon^\mu, \qquad d = \varepsilon^{-2\mu} \tag{6.16}$$

in which a and the parameters μ from (5.1) are still to be chosen.

Estimate

$$\sum_{j=1}^{n+1} \lambda_j(1-\kappa_j/\kappa_{j+1})^{-1} \leqq (\kappa_1-2)^{-1} \sum_{j=1}^{\infty} (c\varepsilon(1+\varepsilon d)(\kappa_1-2)^{-1})^{j-1}(1-\kappa_j/\kappa_{j+1})^{-1}$$

$$= a^{-1}\varepsilon^{-2\mu} \sum_{j=1}^{\infty} (ca^{-1}\varepsilon^{1-\mu}(1+\varepsilon^{1-2\mu}))^{j-1}(j+2)^2 \tag{6.17}$$

$$< \varepsilon^{-2\mu}$$

for any μ with $0 \leqq \mu \leqq 2/3$ and a chosen (independently of μ) to be sufficiently large. This verifies the induction hypothesis (5.5) for $(n+1)$, for any n.

Completion of the induction proof shows that the inequalities (5.6), (5.7) on the jth corrections R_j are valid for all j and that therefore the approximate solutions r_n have a limit r that solves (2.16). Finally the combination $z(\gamma, t) = \gamma + s_0(\gamma, t) + r(\gamma, t)$ solves the Birkhoff-Rott equation (1.1).

Moreover, the solution $r = \lim_{n\to\infty} r_n$ is analytic in $\kappa\rho < t$ with

$$\kappa = \lim_{m\to\infty} \kappa_m = \kappa_1 \Pi(1-\varepsilon^{\mu}(m+2)^2)^{-1}$$

$$= 2 + Q(\varepsilon^{\mu}).$$

The bounds (5.8), (5.9) show that for $\kappa\rho < t$, r satisfies

$$|r(t)|_{\rho} + |r_{\gamma}(t)|_{\rho} \leqq c\varepsilon^{2-2\mu}\, e^{-(t-\kappa\rho)/2}$$

$$|r_{\gamma\gamma}(t)|_{\rho} \leqq c\varepsilon^{2-2\mu}(1+(t-\kappa\rho)^{\nu-\alpha-1})\, e^{-(t-\kappa\rho)/2}. \tag{6.18}$$

By choosing $\mu = \frac{2}{3}$, its largest permissible size, we find that r is analytic in the region $(2+Q(\varepsilon^{2/3}))\ \rho < t$. By choosing $\mu = 0$, we obtain the optimal bounds on the size of r, although on a restricted domain. In particular for $\rho = 0$, i.e., on the physical line γ real, the bounds are

$$|r(t)|_0 + |r_{\gamma}(t)|_0 \leqq c\varepsilon^2\, e^{-t/2}$$

$$|r_{\gamma\gamma}(t)|_0 \leqq c\varepsilon^2(1+t^{\nu-\alpha-1})\, e^{-t/2}. \tag{6.19}$$

This completes the proof of Theorem 1.

7. Conclusions. We will use Theorem 1 to derive solutions of the Birkhoff-Rott equation that develop singularities (i.e., infinite curvature) at finite time starting from analytic initial data. Then we show that the initial value problem for this equation is ill posed in Sobolev space H^n $(n > \frac{3}{2})$, since the derivative of order $1+\nu$, for any $\nu > 0$, can become infinite in an arbitrarily small time from arbitrarily small initial data (fractional derivatives are understood in the Hölder sense). On the other hand, the vortex sheet problem is known to be well posed in an analytic function setting for at least a short time [2], [14]. DiPerna and Majda [3]-[5] address the related question of finding an appropriate function space that is preserved by the Euler flow and by limits of Euler solutions, as well as by limits of regularized solutions (i.e., of the Navier-Stokes equations or the numerical vortex method).

The Birkhoff-Rott equation has the following three symmetry properties: If $z(\gamma, t)$ is a solution of (1.1) then so are $z_b(\gamma, t) = z^*(\gamma, -t)$, $z_s(\gamma, t) = z(\gamma, t-t_0)$, and $z_n(\gamma, t) = n^{-1}z(n\gamma, nt)$.

When we use z_b, Corollary 1 follows from Theorem 1.

COROLLARY 1. *Let ε, ν, α be as in Theorem* 1 *and let s_0 satisfy properties* (i)-(iii) *except for $t < 0$; i.e., s_0 is an analytic solution of the linearized equation* (1.3) *which decays to zero at $t = -\infty$ (decaying backwards in time) and has a mild singularity at $t = 0$. Then*

there is a function $r(\gamma, t)$ *such that* $z(\gamma, t) = \gamma + s_0 + r$ *is an analytic solution of the Birkhoff-Rott equation* (1.1) *for* $t < 0$ *and* $\kappa |\operatorname{Im} \gamma| < |t|$ *in which* $\kappa > 2$ *and* $\kappa \to 2$ *as* $\varepsilon \to 0$. *Moreover,* r *can be chosen so that the backward decaying mode* $r_+ - i\bar{r}_- = 0$ *at* $t = 0$ *and so that* r *satisfies* (1.10), (1.11) *for* $t < 0$.

By shifting the origin of time in the solution z of Corollary 1, we obtain Corollary 2.

COROLLARY 2. *There is initial data* $z(\gamma, 0)$, *which is analytic in a neighborhood of* γ *real, such that the solution* $z(\gamma, t)$ *of the Birkhoff-Rott equation* (1.1) *develops an infinite* $(1+\nu)$*th derivative at a finite time* t_0.

Finally we use the rescaling of z to z_n. Take z to be a solution for $t < 0$ that develops an infinite $(1+\nu)$th derivative at $t = 0$, as in Corollary 1. Let $z_N(\gamma, t) = N^{-2} z(N^2\gamma, N^2 t - 2N)$ so that $s_N = z_N - \gamma = N^{-2} s(N^2\gamma, N^2 t - 2N)$. Then at $t = 0$ the kth Sobolev norm of s_N is bounded as

$$
\begin{aligned}
|s_N(\cdot, t=0)|_{H^k} &= N^{-2+2k+3} |s(\cdot, -2N)|_{H^k} \\
&\leqq N^{2k+1} e^{-N} \qquad (7.1) \\
&\to 0 \quad \text{as } N \to \infty.
\end{aligned}
$$

However, the time T_N of singularity formation is $T_N = 2N^{-1} \to 0$ as $N \to \infty$. For $\nu > 0$, denote $\sup |\partial_\gamma^{1+\nu} z| = \sup_{\gamma \neq \gamma' \text{ real}} |z'(\gamma) - z'(\gamma')| / |\gamma - \gamma'|^\nu$. This shows the following.

COROLLARY 3. *For any positive numbers* ν, k, ε, *and* δ *there is initial data* $z = \gamma + s_0$ *with* $|s|_{H^k} < \varepsilon$ *such that* $\sup |\partial_\gamma^{1+\nu} z|$ *goes to infinity for* $t = t_0 < \delta$. *In particular the initial value problem for the Birkhoff-Rott equation* (1.1) *is ill posed for any Sobolev space* H^k *for* $k > 3/2$.

In other words, smallness of the initial perturbation s is not sufficient to insure existence with bounded $(1+\nu)$th derivative on any time interval for (1.1).

ARTIFICIAL BOUNDARY CONDITIONS FOR INCOMPRESSIBLE VISCOUS FLOWS*

LAURENCE HALPERN† AND MICHELLE SCHATZMAN‡

Abstract. Artificial boundary conditions for the linearized incompressible Navier-Stokes equations are designed by approximating the symbol of the transparent operator. The related initial boundary value problems are well posed in the same spaces as the original Cauchy problem. Furthermore, error estimates for small viscosity are proved.

Key words. incompressible Navier-Stokes equation, artificial boundary conditions, initial boundary value problems, Oseen approximation

AMS(MOS) subject classifications. 35Q10, 35G15, 76D99

1. Introduction.

Many problems arising in fluid mechanics lead to the resolution of a partial differential equation in an unbounded domain. Depending on the applications, various strategies have been developed.

For stationary flows around a body, integral equations are often used (see for instance [6]) or we can also bound the domain and prescribe on the artificial boundary the so-called "transparent" boundary condition, i.e., the boundary condition which simulates the missing part of the domain. This boundary condition is integral on the boundary, and the associated initial boundary value problem is solved numerically using either an eigenvalues expansion on the boundary [2], [22], [10] or a coupling between finite elements in the interior and integral equations on the boundary [18], [26].

For time dependent problems, the "transparent" boundary condition is integral in time and space and thus impractical in general. Tremendous research effort has attempted to design useful boundary conditions for inviscid flows. Most of the studies rely on a linearization of the equation near the boundary (for a nonlinear treatment of the problem see [16] and [29]). Of course in the applications we solve the nonlinear equations in the interior together with the linear boundary conditions.

There are two mathematical frames for these studies. On one hand, Engquist and Majda in [8] and [9] designed absorbing boundary conditions with wave propagation tools. On the other hand, Bayliss and Turkel in [4] and [5] used far field expansions. Both works write sequences of boundary conditions that are local (i.e., differential) in time and space on the boundary. This feature is due to the hyperbolicity or quasi-hyperbolicity of the operators they handle.

The problem becomes less clear when it comes to viscous flows. Some numerical answers have been given for compressible fluids (see Rudy and Strikwerda [25]). On the other hand, calculations have been performed in [11], [12], and [19] on the case of a parabolic equation. Moreover, the case of linear advection-diffusion has been treated in [13]. For incompressible flows it is still, as far as we know, an open mathematical question.

Our previous results were announced in [15].

We are concerned here with the incompressible Navier-Stokes equation,

for $N=2$ or 3:

$$\text{(1.1)}\qquad \begin{cases} u_t+(u\cdot\nabla)u-\nu\Delta u+\nabla p=f & \text{in } \mathbb{R}^N\times]0,\ T[,\\ \operatorname{div}(u)=0 & \text{in } \mathbb{R}^N\times]0,\ T[,\\ u(0)=u^0 & \text{in } \mathbb{R}^N, \end{cases}$$

where $u=(u_1,\cdots,u_N)$.

It is important to set the artificial boundaries outside of turbulent regime, sufficiently far for the flow to be considered as constant. We are then allowed to linearize around the constant state and to consider the Oseen approximation as follows.

$$\text{(1.2)}\qquad \begin{cases} u_t+(a\cdot\nabla)u-\nu\Delta u+\nabla p=f & \text{in } \mathbb{R}^N\times]0,\ T[,\\ \operatorname{div}(u)=0 & \text{in } \mathbb{R}^N\times]0,\ T[,\\ u(0)=u^0 & \text{in } \mathbb{R}^N. \end{cases}$$

The data f and u^0 are supposed to be compactly supported.

All throughout this paper we study the model problem: writing artificial boundary conditions on the hyperplane $\mathbb{R}^{N-1}$, i.e., such that the Oseen equation in the half-space $\mathbb{R}^N_-=\{(x,y)\in\mathbb{R}^N, x<0\}$ with the boundary condition prescribed on the hyperplane $x=0$ is an approximation of the Oseen equation in $\mathbb{R}^N$. This enables us to use the Fourier transform as an essential tool. The problem of designing artificial conditions on a closed artificial boundary will be treated in a forthcoming paper.

In [13], as a first step, the linear advection diffusion equation has been studied. This article concluded with a family of approximate boundary conditions that are local in time and space. In contrast, here the divergence-free condition implies a coupling, which makes the analysis more troublesome. In particular, the symbol of the operator to be approximated contains $|k|$, with k the dual variable of the tangential spatial variable, and it does not seem easy to approximate this symbol by polynomials or rational fractions of low degree in space. Thus, the approximate boundary conditions will be local in time and global in the tangential space variables.

In the course of justifying our calculations precisely, we will prove a number of interesting results on the spaces of divergence-free functions on a half space, without a Dirichlet boundary condition.

The analysis is made in $\mathbb{R}^2$, but is valid in $\mathbb{R}^3$ with slight modifications (see [14]).

In § 2, we define the spaces of divergence-free functions in $\mathbb{R}^2$ and prove trace theorems on $\Gamma=\{(x,y), x=0\}$. We then introduce the Oseen equation, give the formalism necessary for a variational formulation, and state a well-posedness theorem for the Cauchy problem in $\mathbb{R}^2$. We finish by specific trace results for the solution of Stokes equation, which emphasize the regularity of $u_1+\mathcal{H}u_2$ ($\mathcal{H}$ is the Hilbert transform along the boundary), solution of a heat equation.

In § 3 we compute the transparent boundary condition on Γ according to the following principle: Problem (1.2) in $\mathbb{R}^2$ is equivalent (in a sense we will make precise) to the transmission problem in $\Omega_-\times\Omega_+$, where $\Omega_\pm=\{(x,y), \pm x>0\}$ and

$$\begin{aligned} &\frac{\partial u_-}{\partial t}+(a\cdot\nabla)u-\nu\Delta u_-+\nabla p_-=f && \text{in } \Omega_-\times]0,\ T[,\\ &\operatorname{div}(u_-)=0 && \text{in } \Omega_-\times]0,\ T[,\\ &\frac{\partial u_+}{\partial t}+(a\cdot\nabla)u_+-\nu\Delta u_++\nabla p_+=0 && \text{in } \Omega_+\times]0,\ T[,\\ &\operatorname{div}(u_+)=0 && \text{in } \Omega_+\times]0,\ T[, \end{aligned}$$

with the initial data

$$\begin{cases} u_-(0) = u^0 & \text{in } \Omega_-, \\ u_+(0) = 0 & \text{in } \Omega_+, \end{cases}$$

and the transmission conditions

$$\begin{cases} u_-|_\Gamma = u_+|_\Gamma, \\ \sigma_n(u_-)|_\Gamma = \sigma_n(u_+)|_\Gamma, \end{cases}$$

where σ_n is the normal constraint.

We study the Oseen equation for u_+ in Ω_+, with nonhomogeneous Dirichlet boundary conditions, and prove the well-posedness in spaces where the partial Fourier-Laplace transform in time and tangential space is permissible. We write then a pseudodifferential relation between u_+ and $\sigma_n(u_+)$ on Γ. Thanks to the transmission conditions, it leads to the same pseudo-differential relation between u_- and $\sigma_n(u_-)$. We call it the transparent boundary condition after proving the uniqueness for the related initial boundary value problem in Ω_-.

In § 4 we design a family of approximations to the transparent boundary condition by approximating its symbol. These approximations are local in time and integral along the boundary. Using the tools developed in the previous sections we prove them to be well-posed with the same regularity as the solution of the Cauchy problem in $\mathbb{R}^2$. Even at low order these boundary conditions appear to be good approximations for small viscosity.

Finally in Appendix A, we give some information on Beppo-Levi spaces, and in Appendix B, we show why we cannot use spaces of fast-decreasing functions at infinity in the analysis of the present incompressible problems.

2. Definitions, notations and basic results. In this section, we describe a number of functional spaces which are useful for our study of Stokes problem with an advection term, otherwise called an Oseen system. We need spaces in which we are able to treat nonhomogeneous boundary conditions, and thus transparent and artificial boundary conditions. The typical space is the space of divergence-free functions, which are square integrable, with a square integrable gradient, but without any boundary condition. We give density results relative to these spaces, and corresponding trace results. Then we give rather classical results on the solution of the Oseen problem, in $\mathbb{R}^2$. Finally, if u is the solution of this problem, and if $\mathcal{H}$ is the Hilbert transform in the direction x_2, the function $u_1 + \mathcal{H}u_2$ has a number of special properties which will be useful everywhere in the sequel. In particular, if the support of the data of the Oseen problem is in the region $\{x_1 \leqq -X < 0\}$, the restriction of $u_1 + \mathcal{H}u_2$ to the boundary $\{x_1 = 0\} \times \mathbb{R} \times \mathbb{R}$ is arbitrarily smooth.

2.1. Classical functional spaces. We use the formalism of [24] in many instances. The domain W of $\mathbb{R}^N$ has boundary Γ; the scalar product in $L^2(\Omega)$ is denoted $(\cdot, \cdot)$, with associated norm $\| \ \|$. The classical Sobolev space $H^m(\Omega)$ is the space of square integrable functions, whose derivatives of order at most m are square integrable; the scalar product in $H^m(\Omega)$ is denoted $(\cdot, \cdot)_m$, and the norm $\| \ \|_m$; the scalar product in $L^2(\Omega)$ is denoted $(\cdot, \cdot)_\Omega$ with associated norm $\| \ \|_\Omega$. The Fourier transform is defined on the Schwarz space $\mathcal{S}$ by

$$\hat{v}(k) = \int_{\mathbb{R}^N} v(x) \exp(-ik \cdot x)\, dx, \tag{2.1}$$

where $k \cdot x = k_1 x_1 + k_2 x_2 + \cdots + k_N x_N$; it is extended to $\mathcal{S}'$, and we will often write (2.1) for temperate distributions by an abuse of notation.

For any real s, the Sobolev space of fractional order $H^s(\mathbb{R}^N)$ is defined as

$$H^s(\mathbb{R}^N) = \left\{ v \in \mathcal{S}' \Big/ \int (1+|k|^2)^s |\hat{v}(k)|^2 \, dk < \infty \right\},$$

this space is a Hilbert space, equipped with the norm

$$\|v\|_s = \left[\int (1+|k|^2)^s |\hat{v}(k)|^2 \, dk \right]^{1/2}.$$

In particular, we will need the Sobolev spaces $H^{1/2}(\Gamma)$ and $H^{-1/2}(\Gamma)$, when Γ is $\mathbb{R}^N$; the norm of $H^{1/2}(\Gamma)$ will be denoted $\|\cdot\|_{1/2,\Gamma}$, and the norm of $H^{-1/2}(\Gamma)\|\cdot\|_{-1/2,\Gamma}$.

We denote the right-hand side half-space as

$$\Omega_+ = \mathbb{R}^N_+ = \{x = (x_1, x_2, \cdots, x_N)/x_1 > 0\},$$

and the left-hand side half-space as

$$\Omega_- = \mathbb{R}^N_- = \{x = (x_1, x_2, \cdots, x_N)/x_1 < 0\}.$$

A convenient characterization of $H^m(\Omega_+)$ is given by

$$H^m(\Omega_+) = \{u \in L^2(0, \infty; H^m(\mathbb{R}^{N-1}))/ \quad \forall k = 1, 2, \cdots, m,$$

$$\frac{\partial^k u}{\partial x_1^k} \in L^2(0, \infty; H^{m-k}(\mathbb{R}^{N-1}))\}.$$

Then the norm on $H^m(\Omega_+)$ can be written as

$$\|u\|_m^2 = \sum \left| \frac{\partial^k u}{\partial x_1^k} \right|^2_{L^2(0,\infty;\, H^{m-1}(\mathbb{R}^{N-1}))}.$$

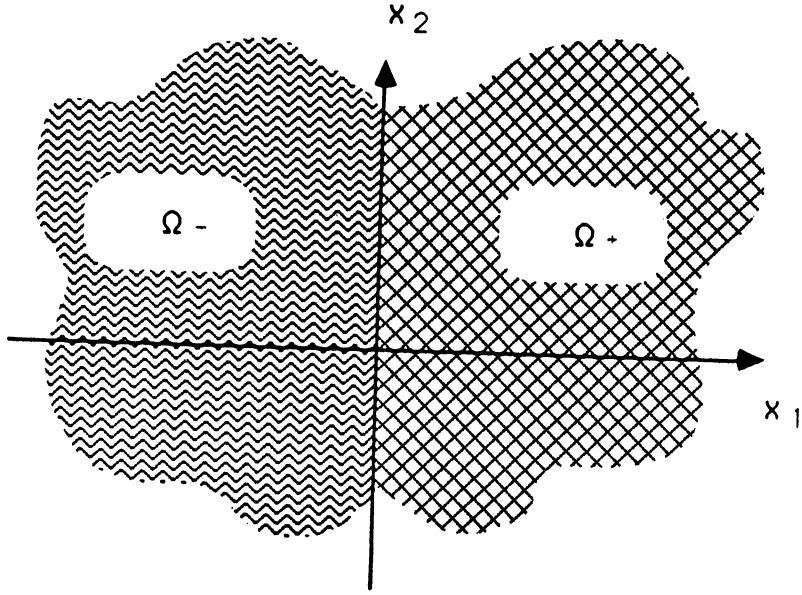

FIG. 1

We can define a partial Fourier transform operating on the tangential variables; for v in $\mathcal{S}'(\Omega_+)$, it is defined formally as

$$\mathcal{F}_{x'\to k'}v(x_1, k') = \int_{\mathbb{R}^{N-1}} v(x_1, x') \exp(-ik\cdot x')\, dx',$$

where $x' = (x_2, \cdots, x_N)$ and $k' = (k_2, \cdots, k_N)$.
The space $H^m(\Omega_+)$ can be characterized too with the help of a partial Fourier transform.

We define the Sobolev spaces of vector-valued functions:

$$\mathbf{H}^s(\Omega) = (H^s(\Omega))^N \text{ and } \mathbf{H}_0^s(\Omega) = (H_0^s(\Omega))^N.$$

The scalar product and the associated norm will be denoted as for the scalar Sobolev spaces.

We denote the gradient by ∇, and the divergence by $\nabla\cdot$.

Finally, we will need the Beppo-Levi spaces, defined as follows.

DEFINITION 2.1. Let Ω be an open domain of $\mathbb{R}^N$. The Beppo-Levi space $BL(H^s(\Omega))$ constructed on $H^s(\Omega)$ is the space of distributions u such that ∇u belongs to $H^s(\Omega)$.

The space $BL(H^s(\Omega))$ is a subspace of $H^{s+1}_{loc}(\Omega)\cap\mathcal{S}'(\Omega)$; more information on the Beppo-Levi spaces is given in Appendix A. Let it suffice here to observe that $BL(H^s(\Omega))$ is a Hilbert space, with Hilbert seminorm $\|\nabla u\|_s$; the kernel of this seminorm is the space of constant functions. Moreover, if Ω is unbounded, $BL(H^s(\Omega))$ contains unbounded elements. Examples of such behavior are given in Appendix A.

2.2. Spaces of divergence-free functions. Spaces of divergence-free functions are an essential tool for the study of fluid motion in Eulerian coordinates. One classical set of spaces is defined starting from

$$\mathcal{V}(\Omega) = \{v\in\mathcal{D}(\Omega)^2/\nabla\cdot v = 0\}.$$

The respective closures of v in $\mathbf{L}^2(\Omega)$ and $\mathbf{H}^1(\Omega)$ are denoted $H_0(\Omega)$ and $V(\Omega)$; they are very well adapted to the study of a problem with Dirichlet boundary conditions; they admit the following characterization, when $\Omega = \mathbb{R}^2$.

$$\begin{aligned} V(\mathbb{R}^2) &= \{v\in\mathbf{H}^1(\mathbb{R}^2)/\nabla\cdot v = 0\} \\ H_0(\mathbb{R}^2) &= \{v\in\mathbf{L}^2(\mathbb{R}^2)/\nabla\cdot v = 0\} \end{aligned} \tag{2.2}$$

When Ω is a domain with smooth boundary Γ, the characterization is modified as follows.

$$\begin{aligned} V(\Omega) &= \{v\in\mathbf{H}_0^1(\Omega)/\nabla\cdot v = 0\} \\ H_0(\Omega) &= \{v\in\mathbf{L}^2(\Omega)/\nabla\cdot v = 0 \text{ and } v\cdot n = 0 \text{ on } \Gamma\}, \end{aligned} \tag{2.3}$$

where n is the exterior normal to Γ.
This last characterization makes sense because, on the space

$$E(\Omega) = \{v\in\mathbf{L}^2(\Omega)/\nabla\cdot v\in L^2(\Omega)\},$$

the normal trace $v\cdot n$ is defined, belongs to $\mathbf{H}^{1/2}(\Gamma)$, and the mapping

$$v\to v\cdot n$$

from $E(\Omega)$ to $\mathbf{H}^{1/2}(\Gamma)$ is onto.

A convenient reference for the above classical results is [28]. Nevertheless, we are interested in boundary conditions which are not Dirichlet boundary conditions, and we introduce spaces which are not classical:

$$\mathcal{W}(\Omega_-) = \{v\in\mathcal{D}(\Omega_-)^2/\nabla\cdot v = 0\}, \tag{2.4}$$

where Ω_- is the closed half-plane. Moreover, we introduce

$$W(\Omega_-) = \{v \in \mathbf{H}^1(\Omega_-)/\nabla \cdot v = 0\} \tag{2.5}$$

$$H(\Omega_-) = \{v \in \mathbf{L}^2(\Omega_-)/\nabla \cdot v = 0\}. \tag{2.6}$$

The relations between $\mathcal{W}(\Omega_-)$, $W(\Omega_-)$, and $H(\Omega_-)$ as well as the trace properties of these spaces will be stated below. The results presented here differ from the standard ones in two respects: first, we want to allow for nonzero boundary data; second, the open set Ω contains points at an infinite distance from its boundary. The case with zero boundary data can be found in [28]; the case where the points of Ω are at a bounded distance from its boundary can be found in [1].

PROPOSITION 2.2. *The closure of $\mathcal{W}(\Omega_-)$ in $\mathbf{H}^1(\Omega_-)$ is precisely $W(\Omega_-)$.*

Proof. To prove this result, we consider an element orthogonal to the closure of $\mathcal{W}(\Omega_-)$ in $W(\Omega_-)$. The potential of this element u satisfies a homogeneous partial differential equation; as u is in a Sobolev space, it is a temperate distribution. This enables us to deduce estimates on the traces of u on the boundary, and, in the same time, the nullity of u.

Let W^* be the closure of $\mathcal{W}(\Omega_-)$ in $\mathbf{H}^1(\Omega_-)$; clearly, W^* is included in $W(\Omega_-)$. To prove that W^* is precisely $W(\Omega_-)$, let u be an element of $W(\Omega_-)$ that is orthogonal to W^*, or equivalently to $\mathcal{W}(\Omega_-)$; then, for any v in $\mathcal{W}(\Omega_-)$,

$$(u_1, v_1) + (u_2, v_2) + \left(\frac{\partial u_1}{\partial x_1}, \frac{\partial v_1}{\partial x_1}\right) + \left(\frac{\partial u_1}{\partial x_2}, \frac{\partial v_1}{\partial x_2}\right) + \left(\frac{\partial u_2}{\partial x_1}, \frac{\partial v_2}{\partial x_1}\right) + \left(\frac{\partial u_2}{\partial x_2}, \frac{\partial v_2}{\partial x_2}\right) = 0 \tag{2.7}$$

As v belongs to $\mathcal{W}(\Omega_-)$, there is a C^∞ function φ such that

$$v_1 = \frac{\partial \varphi}{\partial x_2}, \qquad v_2 = -\frac{\partial \varphi}{\partial x_1}, \tag{2.8}$$

v vanishes outside of a compact set of Ω_-. Conversely, any φ in $\mathcal{D}(\Omega_-)$ defines a v in $\mathcal{W}(\Omega_-)$, with the help of (2.4). Similarly, the theory of Beppo-Levi spaces shows that there exists ψ in $L^2_{\text{loc}}(\Omega_-) \subset \mathcal{S}'(\Omega_-)$ such that

$$u_1 = \frac{\partial \psi}{\partial x_2}, \qquad u_2 = -\frac{\partial \psi}{\partial x_1}. \tag{2.9}$$

If we substitute u and v in (2.7) with their expressions in terms of φ and ψ, we obtain:

$$\left(\frac{\partial \psi}{\partial x_2}, \frac{\partial \varphi}{\partial x_2}\right) + \left(\frac{\partial \psi}{\partial x_1}, \frac{\partial \varphi}{\partial x_1}\right) + 2\left(\frac{\partial^2 \psi}{\partial x_1 \partial x_2}, \frac{\partial^2 \varphi}{\partial x_1 \partial x_2}\right) + \left(\frac{\partial^2 \psi}{\partial x_2^2}, \frac{\partial^2 \varphi}{\partial x_2^2}\right) + \left(\frac{\partial^2 \psi}{\partial x_1^2}, \frac{\partial^2 \varphi}{\partial x_1^2}\right) = 0, \quad \forall \varphi \in \mathcal{D}(\Omega_-). \tag{2.10}$$

Therefore, in the sense of distributions, ψ satisfies the equation

$$-\Delta \psi + \Delta^2 \psi = 0 \text{ in } \Omega_-. \tag{2.11}$$

If we perform a Fourier transform in the tangential variable x_2, which is sent to k, it is not difficult to see that the general solution of (2.11) is of the form

$$\hat{\psi}(x_1, k) = \alpha \exp(|k|x_1) + \beta \exp((1+|k|^2)^{1/2} x_1) + \gamma \exp(-|k|x_1) + \delta \exp(-(1+|k|^2)^{1/2} x_1).$$

For $\hat{\psi}$ to be a temperate distribution, the coefficients γ and δ must vanish, because the corresponding modes increase exponentially at $x_1 = -\infty$. Therefore, $\hat{\psi}$ is of the form

$$\hat{\psi}(x_1, k) = \alpha \exp(|k|x_1) + \beta \exp(x_1 \sqrt{1+|k|^2}). \tag{2.12}$$

We will prove that α and β vanish identically. For this purpose, we need some regularity. We integrate $|k\hat{\psi}(x_1, k)|^2 = |\hat{u}_1|^2$ on Ω_-, and we obtain an estimate on α and β.

$$\int |k|^2 \left\{ \frac{|\alpha(k)|^2}{|k|} + \frac{|\beta(k)|^2}{\sqrt{1+|k|^2}} + 4 \operatorname{Re} \frac{\alpha(k)\overline{\beta(k)}}{|k|+\sqrt{1+|k|^2}} \right\} dk < +\infty. \tag{2.13}$$

We compute the smallest eigenvalue of the quadratic form that appears in (2.13). This shows that there is a positive weight $h(k)$ such that

$$\int |\hat{u}_1|^2 \, dk \, dx_1 \geqq \int |k|^2 h(k)[|\alpha|^2 + |\beta|^2](k) \, dk,$$

the weight h satisfies the estimates:

$$h(k) \simeq \tfrac{1}{2} \quad \text{in a neighborhood of } k = 0$$

$$h(k) \simeq \frac{1}{16|k|^5} \quad \text{in a neighborhood of } |k| = +\infty.$$

Therefore,

$$ik\alpha \text{ and } ik\beta \text{ belong to the space } H^{-5/2}. \tag{2.14}$$

If we return to formulation (2.10), written in Fourier variables, we obtain the variational problem

$$-(|k|^2\hat{\psi}, \bar{\hat{\varphi}}) + \left(\frac{\partial\hat{\psi}}{\partial x_1}, \frac{\partial\bar{\hat{\varphi}}}{\partial x_1}\right) + (|k|^4\hat{\psi}, \bar{\hat{\varphi}}) + \left(|k|^2\frac{\partial\hat{\psi}}{\partial x_1}, \frac{\partial\bar{\hat{\varphi}}}{\partial x_1}\right) + \left(\frac{\partial^2\hat{\psi}}{\partial x_1^2}, \frac{\partial^2\bar{\hat{\varphi}}}{\partial x_1^2}\right) = 0$$
$$\forall \varphi \in \mathcal{D}(\Omega_-). \tag{2.15}$$

According to (2.14) and (2.12), $\partial\hat{\psi}/\partial x_1$, $\partial^2\hat{\psi}/\partial x_1^2$ and $\partial^3\hat{\psi}/\partial x_1^3$ have a trace on Γ, even if it is in a very weak sense. Accordingly, we can perform several integrations by parts on (2.15), and we obtain the relations

$$\left[\frac{\partial\hat{\psi}}{\partial x_1} + |k|^2\frac{\partial\hat{\psi}}{\partial x_1} - \frac{\partial^3\hat{\psi}}{\partial x_1^3}\right]\Bigg|_\Gamma = 0$$
$$\left[\frac{\partial^2\hat{\psi}}{\partial x_1^2}\right]\Bigg|_\Gamma = 0,$$

substituting (2.12), we obtain a linear system:

$$|k|(1+|k|^2)\alpha + |k|^2\sqrt{1+|k|^2}\beta = 0$$
$$|k|^2\alpha + (1+|k|^2)\beta = 0.$$

This system is not singular, thus α and β vanish identically, and so does the potential ψ thanks to (2.12). This proves that u is zero, and that the orthogonal of the closure of $\mathcal{W}(\Omega_-)$ in $W(\Omega_-)$ is zero. □

We have an analogous result for the space $H(\Omega_-)$.

PROPOSITION 2.3. *The closure of $\mathcal{W}(\Omega_-)$ in $\mathbf{L}^2(\Omega_-)$ is precisely $H(\Omega_-)$.*

Proof. The technique of proof is absolutely identical to the technique employed for the previous proposition. It is in fact easier; the main steps begins with an analogue of equation (2.11):

$$\Delta\psi = 0 \quad \text{in } \Omega_-.$$

Then the Fourier transform of the potential y is of the form

$$\hat{\psi}(x_1, k) = \alpha \exp(|k|x_1),$$

and it is very easy to prove that $\alpha\sqrt{\gamma|k|}$ is square integrable; the remainder of the proof is left to the reader. □

Let us consider now the trace spaces of $W(\Omega_-)$ and $H(\Omega_-)$. The main result we need is as follows.

PROPOSITION 2.4. *For any $u=(u_1, u_2)^T$ in $W(\Omega_-)$, the trace of u_1 on Γ is in $H^{1/2}(\Gamma)$ and satisfies*

$$\int_{\mathbb{R}} |\hat{u}_1(0, k)|^2 \sqrt{|k|^2+\frac{1}{|k|^2}}\, dk < +\infty. \tag{2.16}$$

If $W^{1/2}$ is the space of functions that satisfy (2.16), *then the trace mapping $u \to u_1|_\Gamma$ from $W(\Omega_-)$ to $W^{1/2}$ is onto.*

Proof. Let u belong to $\mathcal{W}(\Omega_-)$; we may write

$$\frac{\partial}{\partial x_1}\left(\frac{|\hat{u}_1(x_1, k)|^2}{|k|}\right) = \frac{2}{|k|}\operatorname{Re}\left(u_1(x_1, k)\,\overline{\frac{\partial \hat{u}_1(x_1, k)}{\partial x_1}}\right)$$

$$= \frac{2}{|k|}\operatorname{Re}\left(u_1(x_1, k)\, ik\,\overline{\hat{u}_2(x_1, k)}\right),$$

since u is divergence free. The function u vanishes for x_1 small enough, because the support of u is compact. Thus we obtain

$$\int \frac{|\hat{u}_1(x_1, k)|^2}{|k|}\, dk \leqq \|u\|^2. \tag{2.17}$$

The trace space of $W(\Omega_-)$ is included in $\mathbf{H}^{1/2}(\Gamma)$; together with (2.17), we obtain the first statement of the proposition, because $\mathcal{W}(\Omega_-)$ is dense in $W(\Omega_-)$. To see that the trace mapping is onto, take the orthogonal of the image of $W(\Omega_-)$ in $W^{1/2}$ by the normal trace mapping. For all φ in $\mathcal{D}(\Omega_-)$, we have

$$\operatorname{Re}\left(\int_{\mathbb{R}} \left(|k|^2+\frac{1}{|k|^2}\right)^{1/2} \hat{u}_1 ik\, \bar{\hat{\varphi}}\, dk\right) = 0,$$

and this shows immediately that the mapping is onto. □

From the proof of Proposition 2.4, we deduce

COROLLARY 2.5. *For any u in $H(\Omega_-)$, the trace of u on Γ exists and satisfies*

$$\int_{\mathbb{R}} \frac{|\hat{u}_1(x_1, k)|^2}{|k|}\, dk < +\infty.$$

Moreover, the expression

$$s(u, v) = (u, v) + \int_{\mathbb{R}} \frac{\hat{u}_1(x_1, k)\,\overline{\hat{v}_1(x_1, k)}}{|k|}\, dk \tag{2.18}$$

is a scalar product on $H(\Omega_-)$, which is equivalent to the scalar product $(\cdot, \cdot)$ induced by $L^2(\Omega_-)$.

Proof. It is clear that

$$s(u, u) \geqq (\|u\|_0)^2;$$

the inequality

$$s(u, u) \leqq 2(\|u\|_0)^2$$

follows from (2.17). □

The dual space of $W^{1/2}$ will be denoted $W^{-1/2}$ and is the space of functions which satisfy

$$u \in W^{-1/2} \Leftrightarrow \int_{\mathbb{R}} |\hat{u}_1(0,k)|^2 \left(|k|^2 + \frac{1}{|k|^2}\right)^{1/2} dk < +\infty. \tag{2.19}$$

Remark 2.6. The space $W^{1/2}$ is included in $H^{1/2}$ because the weight $(|k|^2 + 1/|k|^2)^{1/2}$ satisfies the inequality

$$\left(|k|^2 + \frac{1}{|k|^2}\right)^{1/2} \geqq \frac{1+|k|^2}{2} \quad \forall k \in \mathbb{R}^*.$$

Dually, $W^{-1/2}$ contains $H^{-1/2}$.
This completes our review of divergence-free functional spaces.

2.3. Oseen system in full space. Consider the Navier-Stokes system in $\mathbb{R}^2 \times \mathbb{R}^+$:

$$u_t + (u \cdot \nabla)u - \nu \Delta u + \nabla p = 0; \nabla \cdot u = 0. \tag{2.20}$$

Here ∇ is the gradient operator, Δ is the Laplacian operator; $v \cdot \nabla$ denotes the differential operator $v_1 \partial/\partial x_1 + v_2 \partial/\partial x_2$.

We linearize this system around a constant state $a = (a_1, a_2)$, with a_1 positive, and we obtain a Stokes system with an advection term or Oseen system:

$$u_t + (a \cdot \nabla)u - \nu \Delta u + \nabla p = 0; \tag{2.21}$$

$$\nabla \cdot u = 0. \tag{2.22}$$

A differential operator $\mathcal{A}$ is defined by

$$\mathcal{A}(u, p) = u_t + (a \cdot \nabla)u - \nu \Delta u + \nabla p. \tag{2.23}$$

For functional analysis reasons, it will be convenient to study the differential operator $\mathcal{A}_\mu$ defined, for $\mu > 0$, by

$$\mathcal{A}_\mu(u, p) = u_t + \mu u + (a \cdot \nabla)u - \nu \Delta u + \nabla p. \tag{2.23}_\mu$$

We define a bilinear form $\mathbf{a}$ on $\mathbf{H}^1(\Omega)$ by

$$a(u, v) = ((\mathbf{a} \cdot \nabla)u, v) + \nu(\nabla u, \nabla v), \tag{2.24}$$

where

$$(\nabla u, \nabla v) = (\nabla u_1, \nabla v_1) + (\nabla u_2, \nabla v_2).$$

Clearly, $\mathbf{a}$ is continuous on $\mathbf{H}^1(\Omega)$; moreover, we have

$$((a \cdot \nabla)u, u) = \frac{1}{2} \int_\Omega a \cdot \nabla(|u|^2)\, dx = \frac{1}{2} \int_\Gamma a \cdot n |u|^2\, d\Gamma.$$

If $\Omega = \mathbb{R}^2$, this expression vanishes; if $\Omega = \Omega_-$, this expression is greater than or equal to zero. Therefore,

$$\mathbf{a}(u, u) \geqq \nu(\|\nabla u\|_0)^2;$$

there exists a positive constant α such that

$$(\|u\|_0)^2 + \mathbf{a}(u, u) \geqq \alpha(\|u\|_1)^2, \quad \forall u \text{ in } \mathbf{H}^1(\Omega). \tag{2.25}$$

We will need a partially antisymmetrized form of $\mathbf{a}$, in order to uncouple the boundary part of Green's formula; let

$$\tilde{\mathbf{a}}(u, v) = \tfrac{1}{2}[((a \cdot \nabla)u, v) - ((a \cdot \nabla)v, u)] + \nu(\nabla u, \nabla v). \tag{2.26}$$

As a is constant, $\mathbf{a}$ and $\tilde{\mathbf{a}}$ can differ only by a boundary term; if $\Omega = \mathbb{R}^2$, there is no such term; if $\Omega = \Omega_-$,

$$\tilde{\mathbf{a}}(u, v) - \mathbf{a}(u, v) = -\frac{1}{2}\int_\Gamma a_1 u \cdot v \, d\Gamma. \tag{2.27}$$

In particular, in the full space case,

$$\mathbf{a}(u, u) = \tilde{\mathbf{a}}(u, u) = \nu \int |\nabla u|^2 \, dx. \tag{2.28}$$

Consider now the linearized Navier-Stokes system in the plane:

$$\mathcal{A}_\mu(u, p) = f \quad \text{in } \mathbb{R}^2 \times \mathbb{R}^+; \tag{2.29}$$

$$\nabla \cdot u = 0 \quad \text{in } \mathbb{R}^2 \times \mathbb{R}^+; \tag{2.30}$$

$$u(\cdot, 0) = u^0 \quad \text{in } \mathbb{R}^2. \tag{2.31}$$

This system is well posed, if we take u^0 and f in adequate functional spaces.

PROPOSITION 2.7. *For all u^0 in $H(\mathbb{R}^2)$, and all f in $L^2(0, \infty; L^2(\mathbb{R}^2))$, and for all nonnegative μ, there exists a unique u and a p unique up to an additive constant such that* (2.29)-(2.31) *hold and*

$$u \in L^\infty_{\text{loc}}([0, \infty); H(\mathbb{R}^2)),$$
$$\nabla u \in L^2_{\text{loc}}([0, \infty); \mathbf{L}^2(\mathbb{R}^2)),$$
$$u_t \in L^2_{\text{loc}}([0, \infty); V'(\mathbb{R}^2)),$$
$$p = \frac{\partial P}{\partial t},\ P \in L^2_{\text{loc}}([0, \infty); BL(H^{-1}(\mathbb{R}^2))).$$

Here $V'(\mathbb{R}^2)$ is the dual of $V(\mathbb{R}^2)$ and $BL(H^1(\mathbb{R}^2))$ is the Beppo-Levi space of functions whose gradient is in $H^1(\mathbb{R})$. The function u belongs to $L^p_{\text{loc}}([0, \infty); X)$ if any restriction of u to a finite time interval $[0, T]$ belongs to $L^p([0, T]; X)$.

Moreover, for any strictly positive μ, the following global estimates hold:

$$u \in L^\infty([0, \infty); H(\mathbb{R}^2)),$$
$$\nabla u \in L^2([0, \infty); L^2(\mathbb{R}^2)),$$
$$u_t \in L^2([0, \infty); V'(\mathbb{R}^2)),$$
$$p = \frac{\partial P}{\partial t},\ P \in L^2([0, \infty); BL(H^{-1}(\mathbb{R}^2))).$$

Remark 2.8. If Ω were a bounded open set with smooth enough boundary, it would be an exercise to extend the existence proof in [28] for the Stokes problem to the present situation. Though the forthcoming proof is quite classical, it does not appear to be written with all the necessary details in the literature of which we know.

Proof. We know from [24] that for every positive and finite T, there exists a unique u in $L^2(0, T; V(\mathbb{R}^2))$ with $\partial u/\partial t$ in $L^2(0, T; V'(\mathbb{R}^2))$ such that

$$(u_t, v) + \mathbf{a}(u, v) + \mu(u, v) = (f, v) \quad \forall v \in V(\mathbb{R}^2); \tag{2.32}_\mu$$

$$u(0) = u^0. \tag{2.33}$$

Let us first consider the case $\mu = 0$. Relation (2.28) implies an energy estimate

$$\frac{1}{2}\frac{d}{dt}\|u\|_0^2 + \nu\|\nabla u\|_0^2 \leqq \|f(t)\|_0 \|u\|_0.$$

From this inequality we make a classical Gronwall estimate and deduce the estimates on u and ∇u, using the coerciveness; the variational formulation $(2.32)_\mu$ gives the estimate on u_t. Precisely, we get the following estimates

$$\|u(t)\|_0 \leqq \|u^0\|_0 + \sqrt{t}\|f\|_{L^2([0,t]\times\mathbb{R}^2)},$$

$$\int_0^t (\|\nabla u\|_0)^2\, ds \leqq C(\|f\|_{L^2([0,t]\times\mathbb{R}^2)})(\|u^0\|_0 + \|f\|_{L^2([0,t]\times\mathbb{R}^2)})(1+t).$$

These two estimates show polynomial growth in time. In order to have an estimate on p, we proceed as in [28]. Let

$$U(t) = \int_0^t u(s)\, ds, \qquad F(t) = \int_0^t f(s)\, ds.$$

Then ∇U belongs to $L^2(0, T; L^2(\mathbb{R}^2))$. If we integrate (2.21) in time, we obtain

$$(u(t) - u^0 + (a\cdot\nabla)U - \nu\Delta U, v) = (F, v) \quad \forall v \text{ in } V(\mathbb{R}^2).$$

The expression $u(t) - u^0 + (a\cdot\nabla)U - \nu\Delta U - F$ is orthogonal to divergence-free vectors, and belongs to $L^\infty(0, T; \mathbf{H}(\mathbb{R}^2)) + L^2(0, T; \mathbf{H}^{-1}(\mathbb{R}^2))$, which is included in $L^2(0, T; \mathbf{H}^{-1}(\mathbb{R}^2))$. Therefore, there exists P in $L^2(0, T; BL(H^{-1}(\mathbb{R}^2))$ such that

$$u(t) - u^0 + (a\cdot\nabla)U - \nu\Delta U + \nabla P = F.$$

If we define $p = \partial P/\partial t$, we obtain the announced estimate.

For the last statement, we observe that (u, p) is a solution of $(2.32)_0$ if and only if $(w, q) = (ue^{-\mu t}, pe^{-\mu t})$ is solution of $(2.32)_\mu$.

Thus, the polynomial growth estimates for u ensure the global estimates for w. □

There is a regularity result which will be useful in what follows; denote

$$H^\infty(\mathbb{R}^2) = \bigcap_{m\geqq 0} H^m(\mathbb{R}^2); \tag{2.34}$$

this is a Frechet space, with an obvious topology. The regularity result is as follows:

LEMMA 2.9. *Let u^0 belong to $H^\infty(\mathbb{R}^2)$, and f to $C^\infty(\mathbb{R}^+; H^\infty(\mathbb{R}^2))$. Then, the solution (u, p) of (2.29)-(2.31) belongs to $C^\infty(\mathbb{R}^+; H^\infty(\mathbb{R}^2))$.*

Proof. The spatial derivatives of u are divergence free, and satisfy (2.24); if we apply the estimates of Proposition 2.7 to the differentiated equation, we obtain the desired estimates. In order to differentiate in time, we check that the time derivative $u_t(., t)$ is in $H(\mathbb{R}^2)$; from (2.29), $u_t(., t)$ is the projection of $\nu\Delta u - (a\cdot\nabla)u$ onto $H(\mathbb{R}^2)$; u_t satisfies (2.29), (2.30), and thus Proposition 2.6 is applicable. By induction,

$$u \in H^m(0, T; H^m(\mathbb{R}^2)), \quad \forall\, m \text{ in } \mathbb{N}.$$

Leaving all details to the reader, this ends the proof. □

Remark 2.10. For μ strictly positive, it is possible to prove that if u^0 belongs to $H^\infty(\mathbb{R}^2)$, and f belongs to $\mathcal{S}([0,\infty); H^\infty(\mathbb{R}^2))$, then u belongs to $\mathcal{S}([0,\infty); H^\infty(\mathbb{R}^2))$. This result will be proved indeed for the case of the half-plane in the next section. The reader is referred to Proposition 3.1, whose proof can be completely copied to obtain this result. In any case, it is a question of estimating solutions of linear equations with a nice exponentially decreasing behavior, and the proof is an easy application of semigroup theory.

Remark 2.11. The solution of (2.29)-(2.31) does not decrease fast at infinity in space, in general; the trouble is with the pressure. Assume that f vanishes for large x; by taking the divergence of (2.29), in the smooth case, one can see that $\Delta p = \nabla\cdot f$, so that the pressure is harmonic; if p decreased rapidly at infinity in space to a constant,

it would be identically equal to this constant (see Appendix B for a proof of this result); this is not a general situation. If ∇p decays like some power of x, at infinity, then, once ∇p is known, u is essentially a solution of the heat equation with source $\nabla p + f$, and it cannot, in general, decrease rapidly at infinity in space.

2.4. On specific trace results for the solution of Oseen system. Consider the solution u of (2.29)-(2.31). Extend u and p by 0 for $t \leqq 0$, and denote the extended functions still by u and p. Then,

$$\mathcal{A}_\mu(u, p) = u^0 \otimes \delta^t + f \text{ in } \mathbb{R}^2 \times \mathbb{R};\ \nabla \cdot u = 0. \tag{2.35}$$

We cannot expect that u restricted to $\sum = \{(0, x_1, t)/(x_1, t) \in \mathbb{R}^2\}$ will be smooth in time, even if we assume that

(2.36) The support of u^0 is compact and included in Ω_-,

(2.37) The support of f is in the product of a compact subset of Ω_- with $\mathbb{R}_+$.

Remark 2.12. We explain why smoothness in time cannot be expected in general, and give sufficient conditions to have it. Denote by Π the projection in $\mathbf{L}^2(\mathbb{R}^2)$ onto $H(\mathbb{R}^2)$; assume that u^0 is smooth enough for the foregoing computations. Then, interpreting the pressure as a Lagrange multiplier, we can take a limit as t decreases to zero:

$$u_t(\cdot, 0^+) = \Pi f + u^0 \otimes \delta^t - (a \cdot \nabla) u^0 + \nu \Delta u^0 - \mu u^0.$$

In this relation all the terms containing u^0 vanish on $\sum \cap \{t = 0\}$, thanks to assumption (2.36). Nevertheless, there is no reason why Πf should vanish there, since Π is not a local operator. Thus, in order to have some smoothness in time, we should ask that f, and a number of its time derivatives vanish at time 0. This assumption is not reasonable, and we shall not make it because it turns out that we are interested in less than the regularity of u.

More precisely, let $\sigma = \operatorname{sgn}(k)$ and let $\mathcal{H}$ denote the Hilbert transform on Γ [27, Chap. V and VI]:

$$(\mathcal{H}u)\hat{}(k) = -i\sigma \hat{u}(k). \tag{2.38}$$

In physical variables, the Hilbert transform is defined as the convolution with the principal value $v.p.\,(1/\pi x_2)$. We shall see later that we are interested only in the trace of $u_1 + \mathcal{H}u_2$ on Σ. It turns out that this trace is very regular in t and x_2, under the support conditions (2.36), (2.37).

A sequence of lemmas will describe the precise regularity of the trace of $u_1 + \mathcal{H}u_2$.

LEMMA 2.13. *Let u_0 belong to $\mathbf{H}(\mathbb{R}^2)$, and f to $L^2(0, \infty; \mathbf{H}(\mathbb{R}^2))$, and let u be the solution of* (2.29)-(2.31). *Assume* (2.36) *and* (2.37). *Let*

$$z = u_1 + \mathcal{H}u_2. \tag{2.39}$$

Then z belongs to $L^2_{\text{loc}}([0, \infty); H^1(\mathbb{R}^2)) \cap L^\infty_{\text{loc}}([0, \infty); L^2(\mathbb{R}^2))$ and satisfies a heat equation of the form

$$z_t + \mu u + a \cdot \nabla u - \nu \Delta u = g, \tag{2.40}$$

with an initial condition

$$z(\cdot, 0) = u_1(\cdot, 0) + \mathcal{H}u_2(\cdot, 0) \tag{2.41}$$

belonging to $L^2(\mathbb{R}^2)$. Here, g has support in $(-\infty, -X) \times \mathbb{R} \times \mathbb{R}^+$, and X is some strictly positive number.

Proof. The function z is well defined as a function of x_1, x_2, and t, because $\mathcal{H}$ is an isometry from $L^2(\mathbb{R})$ to itself. Moreover, z belongs to the spaces mentioned in the lemma, because $\mathcal{H}$ commutes with the differentiations, so that if w is in $H^1(\mathbb{R}^2)$, so is $\mathcal{H}w$. If we compute the right-hand side of (2.40) in the sense of distributions, we obtain

$$g = f_1 + \mathcal{H}f_2 - \frac{\partial p}{\partial x_1} - \mathcal{H}\frac{\partial p}{\partial x_2}.$$

It remains to show that $\partial p/\partial x_1 + \mathcal{H}(\partial p/\partial x_2)$ has its support in $\{x_1 \leqq -X\}$, because assumption (2.37) shows that f has its support in this set. If we take the divergence of (2.29) in the sense of distributions, we have

$$\Delta p = \nabla \cdot f.$$

Therefore, p is harmonic in the region $\{x_1 \geqq -X\} \times \mathbb{R} \times \mathbb{R}^+$. By partial Fourier transform in x_2,

$$\frac{\partial^2 \hat{p}}{\partial x_1^2} - |k|^2 \hat{p} = 0.$$

As p is temperate in x_1, x_2, p is necessarily of the form, for $x_1 \geqq -X$,

$$\hat{p} = \hat{p}(0, k, .)\, e^{-|k|x_1},$$

and therefore,

$$\frac{\partial \hat{p}}{\partial x_1} + \left(\mathcal{H}\frac{\partial p}{\partial x_2}\right)^{\wedge} = (-|k| + ik(-i\sigma))\hat{p} = 0 \text{ for } x_1 \geqq -X.$$

This proves that the support of g is indeed in the region $\{x_1 \leqq -X\}$. □

LEMMA 2.14. *Let w be a solution of*

$$w_t + a_2 \partial w/\partial x_2 - \nu \Delta w = g \quad \text{for } x \in \mathbb{R}^2, \quad t \in \mathbb{R},$$

$$w = 0 \quad \text{for } t \leqq T_1,$$

where the support of the distribution g is included in $(-\infty, -X] \times \mathbb{R} \times \mathbb{R}^+$. If g belongs to $H^s(\mathbb{R}^2 \times \mathbb{R})$, then the trace of w on $\Sigma = \{0\} \times \mathbb{R} \times \mathbb{R}$ belongs to $H^\infty(\mathbb{R} \times [0, T])$, for all T.

Proof. Among the many possible ways of proving this result, we choose the one which is the closest to the spirit of this article; namely, we consider the problem with respect to the variable x_1, instead of a problem in time. We will perform a Fourier transform in time and in the partial space variable x_2 and perform a Fourier analysis of the ordinary differential equation obtained in this fashion. For a correct argument, we multiply w by $e^{-\mu t}$, where μ is a strictly positive number. Then $v = w\, e^{-\mu t}$ satisfies the equation

$$v_t + \mu v + a_2 \frac{\partial v}{\partial x_2} - \Delta v = g\, e^{-\mu t} = h, \tag{2.42}$$

where h has the same support properties and smoothness properties as g. This amounts to performing a Fourier–Laplace transform in time instead of a Fourier transform. If ω denotes the dual variable of t, and k the dual variable of x_2, the partial Fourier transform of (2.42) is

$$(i\omega + \mu + ia_2 k + \nu|k|^2)\hat{v} - \nu \frac{\partial^2 \hat{v}}{\partial x_1^2} = \hat{h}. \tag{2.43}$$

Let ρ be the root of $\nu\rho^2-(i(\omega+a_2k)+\mu+\nu|k|^2)=0$ which has positive real part. An elementary computation shows that the unique solution of (2.43) which is temperate is given by

$$\hat{v}(x_1, k, \omega) = -\frac{1}{2\rho\nu}\left[2\int_{-\infty}^{x_1} \operatorname{sh}(\rho(y-x_1))\hat{h}(y, k, \omega)\, dy\right] + \int_{-\infty}^{\infty} \exp(\rho(x_1-y))\hat{h}(y, k, \omega)\, dy.$$

Thus, we can write

$$\hat{v}(0, k, \omega) = -\frac{1}{2\rho\nu}\left[2\int_{-\infty}^{-X} \operatorname{sh}(\rho y)\hat{h}(y, k, \omega)\, dy + \int_{-\infty}^{-X} \exp(-\rho y)\hat{h}(y, k, \omega)\, dy\right]$$
$$= \frac{1}{2\rho\nu}\int_{-\infty}^{X} e^{\rho y}\hat{h}(y, k, \omega)\, dy.$$

We can see that

$$\operatorname{Re}(\rho) \geqq C(1+|k|+\sqrt{|\omega|}), \tag{2.44}$$

for some constant C strictly positive, and thus, it is possible to estimate

$$\int (1+|k|^2+|\omega|^2)^m |\hat{v}(0, k, \omega)^2\, dk\, d\omega$$
$$\leqq \int (1+|k|^2+|\omega|^2)^m \int_{-\infty}^{-X} |e^{\rho y}\hat{h}(x_1, k, \omega)\, dy|^2\, dk\, d\omega$$
$$\leqq \int (1+|k|^2+|\omega|^2)^m \left\{\int_{-\infty}^{X} |e^{2\rho y}|\, dy\right\}\left\{\int |\hat{h}(x, k, \omega)|^2\, dx\right\} dk\, d\omega.$$

If we first strengthen somewhat the hypotheses by assuming that, for some n,

$$\int (1+|k|^2+|\omega|^2)^n |\hat{h}(x, k, \omega)|^2\, dx\, dk\, d\omega < \infty,$$

then, the result we look for can be easily deduced:

$$\int_{-\infty}^{-X} |e^{2\rho y}|\, dy = \frac{e^{-2X \operatorname{Re}(\rho)}}{2 \operatorname{Re}(\rho)},$$

and thanks to (2.24), this quantity is dominated by all powers of k and ω, and the result is proved. To get rid of the extra assumption we made, we observe that an h in $H^s(\mathbb{R}^2\times\mathbb{R})$ is a finite sum of x_1 derivatives of some functions h_j, and the h_j can be taken with the same support property as h, and each h_j satisfies

$$\int_{-\infty}^{-X} (1+|k|^2+|\omega|^2)^n |\hat{h}_j(x, k, \omega)|^2\, dx\, dk\, d\omega < \infty.$$

We treat the terms

$$\int_{-\infty}^{-X} e^{\rho y}\frac{\partial^j \hat{h}_j(y, k, \omega)}{\partial y^j}\, dy$$

by performing an integration by parts, which will amount to a multiplication by some extra powers of ρ; these powers will be nevertheless dominated by $\exp(2X \operatorname{Re}(\rho))$, and

$$\int (1+|k|^2+|\omega|^2)^m \left| \int_{-\infty}^{-X} e^{\rho y} \frac{\partial^j \hat{h}_j(x_1, k, \omega)}{\partial y^j} dy \right|^2 dk\, d\omega$$

is finite for all real m.

Going back to w, we obtain the required result. □

To conclude this sequence of results, we can state now the

LEMMA 2.15. *Let z be as in Lemma 2.13. Then, the trace of z on Σ belongs to $H^\infty(\Sigma)$.*

Proof. Consider the new variables

$$t' = t,\ x_1' = x_1 - a_1 t,\ x_2' = x_2.$$

In these new variables, the equation satisfied by z becomes

$$z_{t'} + a_2 \frac{\partial z}{\partial x_2} - \nu \Delta' z = g,$$

and the support of g is included in the set

$$\{(x', t')/t' \geqq 0 \text{ and } x_1' + a_1 t' \leqq -X\}.$$

As a_1 is strictly positive, $a_1 t'$ is less than or equal to zero, and we are in the case of Lemma 2.14. □

3. Analysis of the transparent boundary condition.

3.1. Introduction. Let (u, p) be the solution of (2.29)-(2.31) with initial data satisfying (2.36)-(2.37). The normal constraint σ_n is defined by

$$\sigma_n = (\sigma_{11}, \sigma_{12}); \quad \sigma_{11} = \nu \frac{\partial u_1}{\partial x_1} - p; \quad \sigma_{12} = \nu \frac{\partial u_2}{\partial x_1}. \tag{3.1}$$

We will show in this section that the restrictions to $\Sigma = \{0\} \times \mathbb{R} \times \mathbb{R}^+$ of u and the normal constraint σ_n satisfy a linear pseudo-differential relation. This relation will be computed by Fourier techniques, working on the problem

$$\begin{cases} a(u, p) = 0 & \text{in } \Omega_+ \times \mathbb{R}; \\ \nabla \cdot u = 0 & \text{in } \Omega_+ \times \mathbb{R}; \\ u(0, x_2, t) = g(x_2, t) & \text{in } \mathbb{R} \times \mathbb{R}. \end{cases} \tag{3.2}$$

We assume here that g is given in $\mathcal{S}(\mathbb{R}; \mathbf{H}^\infty(\mathbb{R}))$. The choice of $\mathbf{H}^\infty(\mathbb{R})$ is justified by Remark 2.11. On the other hand, there is no such constraint in time, and it is permissible to have a solution with values in $\mathbf{H}^m(\mathbb{R})$ which decreases fast in time for all nonnegative m. Moreover, we ask that

$$k \to \frac{1}{\sqrt{|k|}} \hat{g}(k, \omega) \in \mathbf{L}^2(\mathbb{R}), \quad \forall\ \omega.$$

Under these assumptions, we will show at Proposition 3.1 that for all such g, (3.2) admits a unique solution u in $C^\infty(\Omega_+ \times \mathbb{R})$.

The mapping

$$\mathcal{E} : g \to \sigma_n$$

can be completely described in Fourier variables:

$$(\mathcal{E}g)\hat{}(k, \omega) = E(k, \omega) \hat{g}(k, \omega), \tag{3.3}$$

where E is a two-by-two matrix that will be given explicitly in terms of k and ω at Corollary 3.3.

From this operator $\mathscr{E}$, we will define another operator $\mathscr{L}$, which is a nice pseudo-differential operator, such that the restriction of the solution of Oseen system to the left half-plane Ω_- satisfies the variational equation

$$s(u_t, v) + \tilde{\mathbf{a}}(u, v) + \langle \mathscr{L}g, v|\Sigma\rangle = 0, \tag{3.4}$$

where s is the scalar product defined at (2.18) and $\mathscr{L}$ is defined with the help of an explicit matrix L by

$$(\mathscr{L}g)\hat{}(k, \omega) = L(k, \omega)\hat{g}(k, \omega).$$

The next step is to study the properties of $\mathscr{L}$. This operator is causal, which means that if g vanishes for $t \leqq 0$, so does $\mathscr{L}g$. This property plus some estimates will enable us to extend $\mathscr{L}$ to much larger spaces.

In view of well-posedness results, we shall prove that $\mathscr{L}$ has some useful positivity properties; in particular, the symmetrized matrix $(L+L^*)/2$ is positive semidefinite.

With this detailed study of $\mathscr{L}$, we prove an existence and uniqueness result for the solution of

$$\mathscr{A}(u, p) = 0 \quad \text{in } \Omega_- \times \mathbb{R}, \tag{3.5}$$

$$\nabla \cdot u = 0 \quad \text{in } \Omega_- \times \mathbb{R}, \tag{3.6}$$

$$u(x_1, x_2, 0) = u^0(x_1, x_2) \quad \text{in } \Omega_-, \tag{3.7}$$

$$\sigma_n|_\Sigma = \mathscr{E}(u|_\Sigma). \tag{3.8}$$

This problem is written in variational form, and, with very smooth data, it admits a solution that is simply the restriction of the full-space problem with initial data extended by zero in Ω_+; the uniqueness will be a consequence of the positivity of the operators. Once we have the uniqueness, we can extend the class of solutions for which we have a solution, and, then, conditions (3.8) may be called transparent.

Most of the time, it will be convenient to replace (3.5) by $(3.5)_\mu$ where

$$\mathscr{A}_\mu(u, p) = \mathscr{A}(u, p) + \mu u; \tag{3.5}_\mu$$

here, μ is a positive number. This amounts to considering the system solved by $(u, p)e^{-\mu t}$, or, in other words, to extend the frequency ω to the half plane $Im(\omega) < 0$. This is permissible because we work with causal operators, and we can apply the Paley–Wiener–Schwarz theorem.

3.2. The boundary problem for Oseen system. In this section, we consider the problem

$$\begin{cases} \mathscr{A}_\mu(u, p) = 0 \quad \text{in } \Omega_+ \times \mathbb{R}, \\ \nabla \cdot u = 0 \quad \text{in } \Omega_+ \times \mathbb{R}, \\ u(0, x_2, t) = g(x_2, t) \quad \text{in } \mathbb{R} \times \mathbb{R}, \end{cases} \tag{3.9}$$

where

$$\mathscr{A}_\mu(u, p) = \partial u/\partial t + \mu u + (a \cdot \nabla)u - \nu \Delta u + \nabla p \tag{3.10}$$

and

$$\mu > 0.$$

If g vanishes for $t \leqq t_0$, and if (u, p) is a solution of (3.9) for $\mu > 0$, then $(ue^{\mu t}, pe^{\mu t})$ is a solution of (3.9) for $\mu = 0$, with data $g_\mu(x_2, t) = g(x_2, t)\, e^{\mu t}$.

We first prove a result of existence and regularity.

PROPOSITION 3.1. *Let Z be the subspace of $\mathscr{S}'(\mathbb{R})$ defined by*

$$g \in Z \text{ iff } g \in H^\infty(\mathbb{R}) \text{ and } \mathscr{F}^{-1}\left(\frac{\hat{g}_1(k)}{\sqrt{|k|}}\right) \in H^\infty(\mathbb{R}). \tag{3.11}$$

Assume that

$$g \in \mathscr{S}(\mathbb{R}; Z). \tag{3.12}$$

Then (3.9) *possesses a unique solution (u, p) such that,*

$$u \in L^\infty(\mathbb{R}; H(\Omega_+)), \tag{3.13}$$

$$\nabla u \in L^2(\mathbb{R}; \mathbf{L}^2(\Omega_+)), \tag{3.14}$$

$$\frac{\partial u}{\partial t} \in L^2(\mathbb{R}; W'(\Omega_+)), \tag{3.15}$$

$$\nabla p \in L^\infty(\mathbb{R}; \mathbf{L}^2(\Omega_+)) + L^2(\mathbb{R}; \mathbf{H}^{-1}(\Omega_+)). \tag{3.16}$$

Moreover, u is infinitely differentiable, and if $\mu > 0$,

$$u, p \in \mathscr{S}(\mathbb{R}; \mathbf{H}^\infty(\Omega_+)). \tag{3.17}$$

Proof. Let us first construct a function z such that

$$\begin{cases} z \in \mathscr{S}(\mathbb{R}; \mathbf{H}^\infty(\Omega_+)), \\ \nabla \cdot z = 0, \\ z|_\Sigma = g. \end{cases} \tag{3.18}$$

the function z will be a sum of two functions defined by different means. We first extend g_1; let ζ be defined by

$$\hat{\zeta}_1(x_1, k, \omega) = \hat{g}_1(k, \omega) \exp(-|k|x_1),$$
$$\hat{\zeta}_2(x_1, k, \omega) = -i\sigma \hat{g}_1(k, \omega) \exp(-|k|x_1),$$

where

$$\sigma = \operatorname{sign}(k).$$

We have used the Hilbert transform, of symbol $-i\sigma$, mentioned in § 2, and defined at (2.38):

$$\zeta_2(x_1, \cdot, t) = \mathscr{H}\zeta_1(x_1, \cdot, t).$$

Moreover,

$$\nabla \cdot \zeta = 0;\ \zeta_1(0, x_2, t) = g_1(x_2, t).$$

Now, in order to compensate for the bad boundary condition of the second component, we define a function h by

$$h(x_1, x_2, t) = \psi(x_1)[g_2(x_2, t) - (\mathscr{H}g_1)(x_2, t)],$$

where ψ belongs to $\mathscr{D}(\Omega_+)$, $\psi(0) = 0$, $\psi'(0) = 1$, and finally, we let

$$z_1 = \zeta_1 - \frac{\partial h}{\partial x_2}; \qquad z_2 = \zeta_2 + \frac{\partial h}{\partial x_1}.$$

Clearly h satisfies the boundary conditions. If (3.12) holds, then an integration in x_1 shows that

$$\int_0^\infty \int_{\mathbb{R}} \int_{\mathbb{R}} (1+|k|^2)^m |\hat{\zeta}_1(x_1, k, \omega)|^2 dx_1 dk\, d\omega$$

$$= \int_{\mathbb{R}} \int_{\mathbb{R}} (1+|k|^2)^m (2|k|)^{-1} |\hat{g}_1(k, \omega)|^2\, dk\, d\omega < \infty.$$

Similarly,

$$\int_{\mathbb{R}} \int_{\mathbb{R}} \int_0^\infty \left| \frac{\partial^m \hat{\zeta}_1(x_1, k, \omega)}{\partial x_1^m} \right|^2 dx_1\, dk\, d\omega = \int_{\mathbb{R}} \int_{\mathbb{R}} \int_0^\infty |k|^{2m} |\hat{\zeta}_1(x_1, k, \omega)|^2\, dx_1\, dk\, d\omega$$

$$= \frac{1}{2} \int_{\mathbb{R}} \int_{\mathbb{R}} |k|^{2(m-1/2)} |\hat{g}_1(k, \omega)|^2\, dk\, d\omega < \infty.$$

This shows that ζ_1 belongs to $L^2(\mathbb{R}; H^m(\Omega_+))$, for all m. We look at time derivatives multiplied by polynomials in t, and we show by induction that ζ_1 belongs to $\mathcal{S}(\mathbb{R}; H^\infty(\Omega_+))$. A similar argument shows that ζ_2 belongs to $\mathcal{S}(\mathbb{R}; H^\infty(\Omega_+))$. By construction, g_1 and g_2 belong to $\mathcal{S}(\mathbb{R}; H^\infty(\mathbb{R}))$; the Hilbert transform in the variable x_2 leaves this space invariant; therefore, $\mathcal{H}g_1$ belongs to it, and so h and its gradient belong to $\mathcal{S}(\mathbb{R}; H^\infty(\Omega_+))$. The function z we obtain finally satisfies (3.18).

Let now

$$u = v + z;$$

then (u, p) solves (3.9) if and only if (v, p) solves

$$\begin{cases} \mathcal{A}_\mu(v, p) = -\mathcal{A}_\mu(z, 0) & \text{in } \Omega_+ \times \mathbb{R}, \\ \nabla \cdot v = 0 & \text{in } \Omega_+ \times \mathbb{R}, \\ v(0, x_2, t) = 0 & \text{in } \mathbb{R} \times \mathbb{R}. \end{cases} \tag{3.19}$$

The existence of a solution of (3.19) is obtained by many classical methods; for instance, define the generator A_0 of the Stokes semigroup (without advection) by

$$D(A_0) = \{u \in H_0(\Omega_+) / v \to \int \nabla u \cdot \nabla v\, dx \text{ is continuous}\}$$

and

$$(A_0 u, v)_{H_0} = \nu \int \nabla u \cdot \nabla v\, dx. \tag{3.20}$$

The operator A_0 is defined starting from a quadratic form on the Hilbert space H_0; therefore, according to Phillips' theorem, it generates a contraction semigroup in H_0. Its domain can be computed explicitly and is equal to

$$D(A_0) = \left\{ u \in H_0(\Omega_+) \cap \mathbf{H}^2(\Omega_+) \Big/ \frac{\partial u_2}{\partial x_1}(0, x_2) = 0 \right\}.$$

Let A be defined by

$$D(A) = D(A_0);$$

$$(Au, v)_{H_0} = \int [(a \cdot \nabla) u \cdot v + \nu \nabla u \cdot \nabla v]\, dx. \tag{3.21}$$

Then A is obtained from A_0 by adding a strongly relatively bounded perturbation to A_0; this is because we have the inequality for all ε

$$\|\nabla u\|_0 \leqq \varepsilon \|\Delta u\|_0 + C(\varepsilon)\|u\|_0.$$

Therefore, A generates a strongly continuous semigroup $\mathcal{T}(t)$; this semigroup turns out to satisfy the estimate,

$$\|\mathcal{T}(t)\| \leqq e^{-\mu t}, \text{ for all } t \geqq 0,$$

because, for all u in $D(A)$, $(Au, u) \geqq \mu(\|u\|_0)^2$. The solution of (3.20) is given by

$$v(\cdot, t) = \int_{-\infty}^{t} \mathcal{T}(t-s)(-\mathcal{A}_\mu(z, 0)(s))\, ds,$$

and it is clear that $v(\cdot, t)$ is bounded uniformly on $\mathbb{R}$, with values in H_0, and that, if μ is positive, it decreases fast to zero as t tends to $\pm\infty$. All the other estimates are easy to obtain by differentiation and semigroups estimates, and they are global on $\mathbb{R}$. Details are left to the reader. □

We now perform the Fourier analysis of (3.9). For simplicity of notation, the frequency variable ω can be real, or complex with negative imaginary part; if needed, it will be denoted $\tau = \omega - i\mu$ when this negative imaginary part is present. We need a few notations; the differential operator C is given by

$$Cf = -\nu \frac{\partial^2 f}{\partial x_1^2} + a_1 \frac{\partial f}{\partial x_1} + (\nu|k|^2 + i\tau + a_2 ik) f; \tag{3.22}$$

its associated characteristic polynomial is given by

$$P(k, \tau; \lambda) = -\nu\lambda^2 + a_1\lambda + \nu|k|^2 + i\tau + a_2 ik. \tag{3.23}$$

The discriminant of P is given by:

$$a_1^2 + 4\nu(i(\tau + a_2 k) + \nu|k|^2). \tag{3.24}$$

The real part of (3.24) is positive for all ω and k, and for all $\mu \geqq 0$, because we assumed $a_1 > 0$. We denote by ρ the determination of the square root of (3.24) with positive real part:

$$\rho^2 = a_1^2 + 4\nu(i(\tau + a_2 k) + \nu|k|^2), \text{ Re } \rho > 0. \tag{3.25}$$

Then, the roots of $P(k, \tau, \cdot)$ are given by

$$\lambda = \frac{a_1 - \rho}{2\nu}; \quad \lambda' = \frac{a_1 + \rho}{2\nu},$$

and it is not difficult to check that

$$\text{Re } \lambda < 0 \text{ except if } k = \tau = 0. \tag{3.26}$$

Moreover, we have immediately the following important estimate; there exists a strictly positive constant γ such that

$$\frac{1}{\gamma}(1 + |k| + \sqrt{|\tau|}) \leqq |\rho| \leqq \gamma(1 + |k| + \sqrt{|\tau|}). \tag{3.27}$$

The first result pertaining to the Fourier analysis of (3.9) is as follows.

PROPOSITION 3.2. *Let (u, p) be the solution of* (3.9). *Then, there exist locally integrable functions α and β such that*

$$\hat{u}(x_1, k, \tau) = \exp(-|k|x_1)\alpha(k, \tau) + \exp(\lambda x_1)\beta(\alpha, \tau), \tag{3.28}$$

where

$$\text{(3.29)}\qquad \begin{cases} \alpha_1 = \dfrac{\lambda \hat{g}_1 + ik\hat{g}_2}{\lambda + |k|}, \beta_1 = k\dfrac{\sigma \hat{g}_1 - i\hat{g}_2}{\lambda + |k|}, \\ \alpha_2 = -i\sigma\dfrac{\lambda \hat{g}_1 + ik\hat{g}_2}{\lambda + |k|}, \beta_2 = i\lambda\dfrac{\sigma \hat{g}_1 - i\hat{g}_2}{\lambda + |k|}. \end{cases}$$

Moreover, any couple of distributions (α', β') *which satisfies* (3.27) *is equal to* (α, β), *up to the addition of* $(1, -1)S$, *where* S *is an arbitrary distribution with values in* $\mathbb{R}^2$ *and support in* $\{0\}_{k,\omega}$.

Proof. We perform a partial Fourier transform on u and p; the transformed quantities are denoted $\hat{u} = (\hat{u}_1, \hat{u}_2)$ and $\hat{p}$; they satisfy a system of ordinary differential equations, with respect to the variable x_1, with k and τ as parameters; this system can be written

$$\text{(3.30)}\qquad C\hat{u}_1 + \frac{\partial \hat{p}}{\partial x_1} = 0,$$

$$\text{(3.31)}\qquad C\hat{u}_2 + ik\hat{p} = 0,$$

$$\text{(3.32)}\qquad \frac{\partial \hat{u}_1}{\partial x_1} + ik\hat{u}_2 = 0.$$

If we eliminate the pressure from this system, by multiplying (3.30) by $-ik$, differentiating (3.31) with respect to x_1, and adding the two resulting inequalities, we obtain

$$\text{(3.33)}\qquad C\left(-ik\hat{u}_1 + \frac{\partial \hat{u}_2}{\partial x_1}\right) = 0.$$

With the help of (3.32), we eliminate $\hat{u}_2$; then $\hat{u}_1$ satisfies

$$C\left(\frac{\partial^2 \hat{u}_1}{\partial x_1^2} - |k|^2 \hat{u}_1\right) = 0.$$

This is an ordinary differential equation of the fourth order in x_1 parameterized by k and τ; its general solution is of the form

$$\alpha_1(k, \tau) \exp(-|k|x_1) + \beta_1(k, \tau) \exp(\lambda x_1) + \gamma_1(k, \tau) \exp(|k|x_1) + \delta_1(k, \tau) \exp(\lambda' x_1).$$

From Proposition 3.1, u_1 belongs to $L^2(\mathbb{R}_+ \times \mathbb{R} \times \mathbb{R})$ if $\mu > 0$, and so does $\hat{u}_1$; thus, for almost every k and τ, $\hat{u}_1(\cdot, k, \tau)$ is square integrable. Therefore, γ_1 and δ_1 vanish for almost every k and τ; thus,

$$\text{(3.34)}\qquad \hat{u}_1 = \alpha_1(k, \tau) \exp(-|k|x_1) + \beta_1(k, \tau) \exp(\lambda x_1).$$

Similarly, eliminating $\hat{u}_1$ from (3.33) and (3.34), we obtain

$$C\left(\frac{\partial^2 \hat{u}_2}{\partial x_1^2} - |k|^2 \hat{u}_2\right) = 0.$$

With the same argument as above,

$$\text{(3.35)}\qquad \hat{u}_2 = \alpha_2(k, \tau) \exp(-|k|x_1) + \beta_2(k, \tau) \exp(\lambda x_1).$$

The divergence-free relation (3.32) implies immediately that

$$\text{(3.36)}\qquad -|k|\alpha_1 + ik\alpha_2 = 0, \quad \lambda\beta_1 + ik\beta_2 = 0.$$

If we take into account the boundary conditions,

$$\hat{g}_1 = \alpha_1 + \beta_1, \quad \hat{g}_2 = \alpha_2 + \beta_2, \tag{3.37}$$

we will now express α_1, α_2, β_1, and β_2 in terms of $\hat{g}_1$ and $\hat{g}_2$. To obtain α_1 and β_1. we have to divide by $\lambda + |k|$, which vanishes only for $k = \tau = 0$. In order to obtain α_2 and β_2, we have to divide moreover by k. In order to obtain locally integrable functions α and β, we have to show that $\lambda/\lambda + |k|$ is bounded in a neighborhood of zero. But,

$$\lambda = -2\frac{i(\tau + a_2 k) + |k|^2}{a_1 + \rho}$$

and

$$\lambda + |k| = -2\frac{\tau + a_2 k}{a_1 + \rho + 2\nu|k|},$$

which shows immediately the desired estimate. Eliminating between (3.36) and (3.37), we can write

$$\alpha_1 = \frac{\lambda\hat{g}_1 + ik\hat{g}_2}{\lambda + |k|} = \frac{\lambda(\hat{g}_1 - i\sigma\hat{g}_2) + i\sigma(\lambda + |k|)}{\lambda + |k|},$$

and there is a locally integrable function α_1 which is almost everywhere equal to the expression given by the first of formulae (3.29). The second of these formulae gives a locally integrable β_1, because $\beta_1 = \hat{g}_1 - \alpha_1$. From the first formula of (3.36) divided by k, α_2 is locally integrable. From the second formula of (3.36) and the expression of β_1, a division by k gives the formula for β_2. If α' and β' are distributions which satisfy (3.28), they differ from a and β by distributions S and T with support in $\mathbb{R}_k \times \{0\}_\omega$. We must have

$$S \exp(-|k|x_1) + T \exp(\lambda x_1) = 0, \text{ for all } x_1.$$

This is possible only if S and T have their support in $\{0\}_{k,\omega}$, and $T + S = 0$. Therefore, we can say that α and β are respectively determined up to the addition of S and $-S$, with S a distribution with support in $\{0\}_{k,\omega}$. □

The most important consequence of the previous proposition is the following result on the operator, which assigns to the boundary value of u the normal constraint at the boundary.

COROLLARY 3.3. *Let (u, p) be the solution of* (3.9). *Let E be the two-by-two matrix given by*

$$E(k, \tau) = -\begin{pmatrix} (i\tau/|k|) + ia_2\sigma + \nu(|k| - \lambda) & i\sigma(\nu\lambda - a_1) \\ -i\sigma\nu\lambda & \nu(|k| - \lambda) \end{pmatrix}. \tag{3.38}$$

Then the normal constraint $(-p + \nu\,\partial u_1/\partial x_1,\ \nu\,\partial u_2/\partial x_1)|_\Sigma = \sigma_n$ is given by

$$\sigma_n = \mathscr{E}g,$$

or equivalently

$$\hat{\sigma}_n(k, \tau) = E(k, \tau)\hat{g}(k, \tau).$$

Proof. From (3.29), we compute $\partial\hat{u}_1/\partial x_1$ and $\partial\hat{u}_2/\partial x_1$ on the boundary:

$$\frac{\partial\hat{u}}{\partial x_1} = -|k|\alpha + \lambda\beta = -|k|\alpha + \lambda(\hat{g} - \alpha) = \lambda\hat{g} - \begin{pmatrix} \lambda\hat{g}_1 + ik\hat{g}_2 \\ -i\sigma(\lambda\hat{g}_1 + ik\hat{g}_2) \end{pmatrix}.$$

We observe that the distribution S does not contribute, because $-(|k|+\lambda)S=0$. The above formula proves that

$$\frac{\partial \hat{u}_1}{\partial x_1} = -ik\hat{g}_2, \tag{3.39}$$

$$\frac{\partial \hat{u}_2}{\partial x_1} = i\lambda\sigma\hat{g}_1 + (\lambda - |k|)\hat{g}_2. \tag{3.40}$$

To obtain an expression for the pressure, we observe that, from (3.31), we can write

$$ik\hat{p} = -C\hat{u}_2 = -P(k, \tau; -|k|)\alpha_2 \exp(-|k|x_1) - P(k, \tau; \lambda)\beta_2 \exp(\lambda x_1).$$

The second term of this expression vanishes by definition of λ; in the first term,

$$P(k, \tau; |k|) = -a_1|k| + i(\tau + a_2 k).$$

Thus,

$$ik\hat{p} = \frac{i\sigma(\lambda\hat{g}_1 + ik\hat{g}_2)(-a_1|k| + i(\tau + a_2 k))}{\lambda + |k|}.$$

This expression can be simplified by algebraic manipulations: let $y = \lambda + |k|$; then

$$P(k, \tau, y - |k|) = 0$$

so that

$$-\nu y^2 + 2\nu|k|y + a_1 y - a_1|k| + i(\tau + a_2 k) = 0.$$

Hence,

$$y(-\nu y + 2\nu|k| + a_1) = a_1|k| - i(\tau + a_2 k),$$

that is

$$\frac{a_1|k| - i(\tau + a_2 k)}{\lambda + |k|} = a_1 + \nu|k| - \nu\lambda.$$

If we substitute this in the above expression of $ik\hat{p}$, we obtain

$$ik\hat{p} = -i\sigma(a_1 + \nu|k| - \nu\lambda)(\lambda\hat{g}_1 + |k|\hat{g}_2).$$

Using once again the equation which defines λ, we have

$$a_1\lambda + \nu|k|\lambda - \nu\lambda^2 = \nu|k|\lambda - \nu|k|^2 - i(\tau + a_2 k),$$

and from here, we obtain

$$ik\hat{p} = ik\left[\hat{g}_1\left\{\nu(|k| - \lambda) + i\left(a_2\sigma + \frac{\tau}{|k|}\right)\right\} + \hat{g}_2 i\sigma\{\nu(\lambda - |k|) - a_1\}\right].$$

If we divide both sides of this equation by k, we obtain, with the help of (3.39) the unique locally integrable function equal to $\hat{p}$; thus

$$-\nu\frac{\partial \hat{u}_1}{\partial x_1} + \hat{p} = \hat{g}_1\left\{(\nu(|k| - \lambda) + i\left(a_2\sigma + \frac{\tau}{|k|}\right)\right\} + \hat{g}_2 i\sigma(\nu\lambda - a_1).$$

Putting together this last expression and (3.40), we obtain the matrix E. A distribution $\hat{p}$ which is solution of our equations is equal to the expression $\hat{g}_1\{\nu(|k| - \lambda) + i(a_2\sigma + |k|^{-1}\tau)\} + \hat{g}_2 i\sigma\{\nu(\lambda - |k|) - a_1\}$ up to the addition of a distribution with support in $\{k = 0\}$. This corresponds to the addition of a space independent constant to p,

which is natural because p is defined only via its gradient. But, as our problem was obtained through linearization, around a constant velocity field and a constant pressure, this constant is equal to zero. □

3.2. Variational formulation for the problem with transparent condition. To obtain a tractable formulation for the Oseen problem and "transparent" boundary conditions, we will write a variational formulation. The existence of a solution of the variational problem will be ensured by simply taking the restriction of a full-space problem. A functional problem has to be settled in order to justify this formulation; a certain pseudo-differential operator $\mathscr{L}$ acts on the trace of u on Σ. Originally $\mathscr{L}$ is defined only on very smooth functions, and it has to be extended to a larger functional class. After this is done, we have a clean presentation of the problem with "transparent" condition. The quotes will be removed only after uniqueness is proved.

Let μ be strictly positive, let f satisfy the assumptions of Lemma 2.9, and let u^0 equal zero. According to Lemma 2.9, the solution (u, p) of (2.29)-(2.31) belongs to $C^\infty(\mathbb{R}^+; H^\infty(\mathbb{R}^2))$. Assume that f satisfies (2.37). We assume moreover that:

$$f \in \mathscr{S}((0,\infty); \mathbf{H}^\infty(\mathbb{R}^2)). \tag{3.41}$$

In particular, f vanishes of infinite order at $t=0$. Then, the solution of (2.29)-(2.31) extended by 0 for $t \leqq 0$ belongs to $C^\infty(\mathbb{R}; \mathbf{H}^\infty(\mathbb{R}^2))$. Arguing as in Proposition 3.1, u belongs to $\mathscr{S}(\mathbb{R}; \mathbf{H}^\infty(\mathbb{R}^2))$, and its trace on Σ belongs to $\mathscr{S}(\mathbb{R}; \mathbf{H}^\infty(\mathbb{R}))$. In the region $\Omega_+ \times \mathbb{R}$, u satisfies (3.9), with

$$g = u|_\Sigma.$$

If we still denote u the restriction of u to $\Omega_- \times \mathbb{R}$, and if we multiply the equation satisfied by u on $\Omega_- \times \mathbb{R}$ by an arbitrary v in $W(\Omega_-)$, and integrate, we obtain, thanks to Green's formula

$$(u_t, v) + \mu(u, v) + \tilde{\mathbf{a}}(u, v) + \int_{\mathbb{R}} \left(\frac{a_1}{2} g \cdot v|_\Sigma - \sigma_n \cdot v|_\Sigma \right) dx_2 = (f, v).$$

From Corollary 3.3, this relation can be written

$$(u_t, v) + \mu(u, v) + \tilde{\mathbf{a}}(u, v) + \int_{\mathbb{R}} \left[\left\{ \frac{a_1}{2} g - \mathscr{E} g \right\} \cdot v|_\Sigma \right] dx_2 = (f, v). \tag{3.42}$$

Let us write down the matrix $a_1(I/2) + E$:

$$\frac{a_1 I}{2} - E(k, \tau) = \begin{pmatrix} (a_1/2) + (i\tau/|k|) + ia_2\sigma + \nu(|k| - \lambda) & i\sigma(\nu\lambda - a_1) \\ -i\sigma\nu\lambda & (a_1/2) + \nu|k| - \lambda \end{pmatrix}. \tag{3.43}$$

We can decompose this matrix into the sum of two matrices:

$$\frac{a_1 I}{2} - E = K_1 + L,$$

where K_1 is given by

$$K_1 = \begin{pmatrix} 1/|k| & 0 \\ 0 & 0 \end{pmatrix} i\tau. \tag{3.44}$$

Let $\mathscr{K}_1$ be the operator of symbol K_1. From the definition (2.18) of the scalar product s, we can see that

$$(u_t, v) + \mu(u, v) + \langle \mathscr{K}_1 u, v \rangle = s(u_t, v) + \mu s(u, v). \tag{3.45}$$

The matrix L can be written as follows, recalling that $(a_1/2)-\nu\lambda=\rho/2$:

$$L=\begin{pmatrix} ia_2\sigma+\nu|k|+\dfrac{\rho}{2} & \dfrac{-i\sigma(a_1+\rho)}{2} \\ \dfrac{i\sigma(\rho-a_1)}{2} & \nu|k|+\dfrac{\rho}{2} \end{pmatrix}. \tag{3.46}$$

It is convenient to write L as a sum of two matrices, one of which has ρ as a factor:

$$L=M+N_1,\ N_1=\rho\frac{N}{2}. \tag{3.47}$$

The expressions of M and N are given by

$$M=\begin{pmatrix} ia_2\sigma+\nu|k| & -i\sigma a_1/2 \\ -i\sigma a_1/2 & \nu|k| \end{pmatrix}, \tag{3.48}$$

$$N=\begin{pmatrix} 1 & -i\sigma \\ i\sigma & 1 \end{pmatrix}. \tag{3.49}$$

The matrix N is Hermitian positive semidefinite; we have

$$\mathcal{N}u=(u_1+\mathcal{H}u_2,\ \mathcal{H}(u_1+\mathcal{H}u_2)). \tag{3.50}$$

This relation explains why, as we mentioned in § 2, the trace of $u_1+\mathcal{H}u_2$ on Σ plays a particular role in the analysis of transparent boundary conditions. As $\mathrm{Re}(\rho)$ is strictly positive, we have

$$\mathrm{Re}\,(N\hat{u},\hat{u})=(\mathrm{Re}\,\rho)|\hat{u}_1-i\sigma\hat{u}_2|^2\geqq 0.$$

The matrix M is not Hermitian, but the symmetrized M, $(M+M^*)/2$ is equal to

$$\frac{M+M^*}{2}=\begin{pmatrix} \nu|k| & 0 \\ 0 & \nu|k| \end{pmatrix}. \tag{3.51}$$

This is a Hermitian positive definite matrix, for all nonzero k. Therefore L satisfies

$$\mathrm{Re}\,(L\hat{u},\hat{u})\geqq 0 \quad \forall\hat{u}\text{ in }\mathbb{C}^2. \tag{3.52}$$

In particular, $L+I$ is invertible, for all values of the parameters τ and k, and in Hermitian norm on $\mathbb{C}^2$, we have

$$|(L+I)^{-1}\hat{u}|\leqq|\hat{u}| \quad \forall\hat{u}\text{ in }\mathbb{C}^2. \tag{3.53}$$

We have thus shown the following result.

PROPOSITION 3.4. *For any f satisfying* (2.37) *and* (3.41), *for $u^0=0$, and for any positive μ, let (u,p) be the solution of* (2.29)-(2.31). *If we denote still by u the function u restricted to $\Omega_-\times\mathbb{R}^+$ and extended by 0 for $t\leqq 0$, then u satisfies the variational inequality*

$$s(u_t,v)+\mu s(u,v)+\tilde{\mathbf{a}}(u,v)+\langle\mathcal{L}u,v\rangle=(f,v) \quad \forall v\in W(\Omega_-), \tag{3.54}$$

where the pseudo-differential operator $\mathcal{L}$ is defined by its symbol L, given by (3.46).

3.3. Functional analysis of the operator $\mathcal{L}$. The class of data u^0 and f for which we have a solution of (3.54) is much too restricted. Thus, we extend it in several steps, by giving first a suitable definition of the domain of $\mathcal{L}$. We rely, of course, on the positivity of the matrix L observed in (3.47) to (3.52). Then, we shall give a dense subset of the domain of $\mathcal{L}$, and prove that $\mathcal{L}$ is a causal operator. Finally, the expression $\int_0^T\langle(\mathcal{L}u)(t),u(t)\rangle\,dt$ is greater than or equal to zero, if u is in the domain of $\mathcal{L}$, and vanishes for $t\leqq 0$.

The operator $\mathscr{L}$ is a pseudo-differential operator that belongs to the class $S^1_{1,0}$ of [17], [20], and [30]; it belongs in fact to a certain anisotropic class, which could be defined. As we do not seek the highest possible generality, we will be content with results specific to our variational problem:

DEFINITION 3.5. The domain $D(\mathscr{L})$ of $\mathscr{L}$ is the space of functions g such that there exists an h in $L^2(\mathbb{R};\ W^{-1/2}(\mathbb{R})\times H^{-1/2}(\mathbb{R}))$ such that

$$\hat{g} = (I+L)^{-1}\hat{h}. \tag{3.55}$$

Then, on $D(\mathscr{L})$, $\mathscr{L}$ is defined by

$$\mathscr{L}g = h - g. \tag{3.56}$$

An obvious consequence of the definition and of estimate (3.53) is that $D(\mathscr{L})$ is a subspace of $L^2(\mathbb{R};\ W^{1/2}\times H^{-1/2})$. A sufficient condition for g to belong to the domain of $\mathscr{L}$ is given by the following lemma.

LEMMA 3.6. *The set Y of functions g on Σ such that*

$$g\in L^2(\mathbb{R};\mathbf{H}^{1/2}(\mathbb{R})) \quad \textit{and} \quad g_1+\mathscr{H}g_2\in H^{1/2}(\mathbb{R};\ H^{-1/2}(\mathbb{R})) \tag{3.57}$$

is a subset of $D(\mathscr{L})$; moreover, if Z is the space defined at (3.11), *$\mathscr{S}(\mathbb{R};\ Z)$ is dense in $L^2(\mathbb{R};\ W^{1/2}\times H^{-1/2})$ in the following sense; for every g in $D(\mathscr{L})$, there exists a sequence of elements g_n of $\mathscr{S}(\mathbb{Q};\ Z)$ such that g_n converges to g and $\mathscr{L}g_n$ converges to $\mathscr{L}g$ in $L^2(\mathbb{R};\ W^{-1/2}\times H^{-1/2})$.*

Proof. According to estimate (3.27), there exists a decomposition

$$\rho = \rho_1+\rho_2,$$

such that

$$|\rho_1|\leqq \gamma\sqrt{1+|k|^2},\quad |\rho_2|\leqq \gamma\sqrt[4]{1+|\tau|^2}.$$

We decompose L as a sum

$$L=\left(M+\frac{\rho_1 N}{2}\right)+\left(\frac{\rho_2 N}{2}\right).$$

The first functional assumption on g implies that

$$\int_{\mathbb{R}}\int_{\mathbb{R}}\sqrt{1+|k|^2}|\hat{g}|^2\,dk\,d\omega<+\infty.$$

The coefficients of M are bounded by $\gamma'(1+|k|)$, and thus,

$$\int_{\mathbb{R}}\int_{\mathbb{R}}\frac{1}{\sqrt{1+|k|^2}}\left|\left(M+\frac{\rho_1 N}{2}\right)\hat{g}\right|^2 dk\,d\omega\leqq(\gamma+\gamma')\int_{\mathbb{R}}\int_{\mathbb{R}}\sqrt{1+|k|^2}|\hat{g}|^2\,dk\,d\omega<+\infty.$$

The second functional assumption means that

$$\int_{\mathbb{R}}\int_{\mathbb{R}}\sqrt{\frac{1+|\tau|^2}{1+|k|^2}}|\hat{g}_1-i\sigma\hat{g}_2|^2\,dk\,d\omega<+\infty.$$

The second piece of $L\hat{g}$ is estimated by

$$\int_{\mathbb{R}}\int_{\mathbb{R}}\frac{|\rho_2 N\hat{g}|^2}{\sqrt[4]{1+|k|^2}}\,dk\,d\omega\leqq\gamma\int_{\mathbb{R}}\int_{\mathbb{R}}\sqrt{\frac{1+|\tau|^2}{1+|k|^2}}|\hat{g}_1-i\sigma\hat{g}_2|^2\,dk\,d\omega<+\infty.$$

This proves that $\mathscr{L}g$ belongs to $L^2(\mathbb{R},\ W^{-1/2}(\mathbb{R})\times H^{-1/2}(\mathbb{R}))$, since $H^{-1/2}$ is a subspace of $W^{-1/2}$. On the other hand, g belongs to $L^2(\mathbb{R};\ W^{-1/2}(\mathbb{R})\times H^{-1/2}(\mathbb{R}))$, and thus, g belongs to $D(\mathscr{L})$.

To build a sequence g_n with the required properties, let g belong to $D(\mathscr{L})$, and let $h = \mathscr{L}g$; let φ_n, ψ_n and χ_n be elements of $\mathscr{S}(\mathbb{R})$ such that

$$\hat{\varphi}_n(k) = 0 \text{ if } |k| \leqq \frac{1}{n} \text{ or if } |k| \geqq n;\ \hat{\varphi}_n = 1 \quad \text{if } \frac{2}{n} \leqq |k| \leqq n-1,$$

$$0 \leqq \hat{\varphi}_n \leqq 1 \text{ everywhere;}$$

$$\psi_n(t) = n\psi(nt-1) \text{ with } \psi \text{ belonging to } \mathscr{D}(\mathbb{R}),\ \int_{\mathbb{R}} \psi\, dx = 1,$$

$$\chi_m(t) = \exp\left(-\frac{t^2}{2m}\right) \Rightarrow \hat{\chi}_m(\omega) = \sqrt{\frac{m}{2\pi}} \exp\left(-\frac{m\omega^2}{2}\right).$$

We define

$$h_n = h * (\varphi_n \psi_n).$$

Clearly, h_n belongs to $\mathbf{H}^\infty(\mathbb{R}, Z)$, because the choice of φ_n disposes of all problems at $k = 0$. Moreover, for any given ε, there exists an $n(\varepsilon)$ such that for $n > n(\varepsilon)$,

$$\|h - h_n\|_{L^2(\mathbb{R}; W^{-1/2}(\mathbb{R}) \times H^{-1/2}(\mathbb{R}))} \leqq \frac{\varepsilon}{2}.$$

Fix n such that this inequality holds. We define now

$$g_n = (\mathscr{L}+1)^{-1} h_n;\ g_{mn} = \chi_m g_n.$$

From estimate (3.53),

$$\|g - g_n\|_{L^2(\mathbb{R};\ W^{-1/2}(\mathbb{R}) \times H^{-1/2}(\mathbb{R}))} \leqq \frac{\varepsilon}{2}.$$

Let

$$h_{mn} = (\mathscr{L}+1) g_{mn},$$

which is well defined thanks to the first part of the lemma. In the Fourier variable,

$$\hat{h}_{mn}(k, \tau) - \hat{h}_n(k, \tau) = (L(k, \tau)+1)\{(\hat{\chi}_m(\cdot) - \delta^\omega) * \hat{g}_n(k, \cdot)\}(\tau).$$

As m tends to infinity, $\hat{\chi}_m * \hat{g}_n$ converges to $\hat{g}_n$ in $\mathscr{F}\mathbf{H}^m(\Sigma)$, for all m. As the multiplication by $L(k, \tau)$ maps $\mathscr{F}\mathbf{H}^1(\Sigma)$ continuously into $\mathscr{F}\mathbf{L}^2(\Sigma)$, there exists an m such that

$$\|h_{mn} - h_n\|_{L^2(\mathbb{R};\ W^{-1/2}(\mathbb{R}) \times H^{-1/2}(\mathbb{R}))} \leqq \frac{\varepsilon}{2}.$$

this proves the density of $\mathscr{S}(\mathbb{R}; Z)$ in $D(\mathscr{L})$. □

Now, we are able to prove that $\mathscr{L}$ is a causal operator.

LEMMA 3.7. *If g belongs to $D(\mathscr{L})$, and vanishes for $t < 0$, then $\mathscr{L}g$ vanishes for $t < 0$.*

Proof. Let g be an element of $D(\mathscr{L})$, and let $h = (\mathscr{L}+1)g$; assume that g vanishes for $t \leqq 0$. Let φ_n, ψ_n and g_n, h_n be as in the previous lemma. Then, as we can see in the Fourier variable,

$$g_n = g * (\varphi_n \psi_n).$$

The choice we made of ψ_n implies that

$$g_n = 0 \text{ for } t > 0.$$

The choice of φ_n implies that

$$\hat{g}_n(k, \omega) = 0 \text{ for } |k| \geqq n.$$

If θ is a square integrable function on $\mathbb{R}$ that vanishes on $\mathbb{R}_-$, we can write

$$\hat{\theta}(\omega - i\mu) = \int_0^\infty \theta(t) \exp(-it(\omega - i\mu))\, dt,$$

for $\mu = 0$, with the estimate

$$|\hat{\theta}(\omega - i\mu)| \leqq |\theta|_{L^2(\mathbb{R})} \sqrt{\int_0^\infty e^{-2t\mu}\, dt} \leqq |\theta|_{L^2(\mathbb{R})} \frac{1}{\sqrt{2\mu}}.$$

Therefore, for g_n, we have the estimate

$$|\hat{g}_n(k, \omega - i\mu)| \leqq |\mathcal{F}_{x_2 \to k} g_n(k, \cdot)|_{L^2(\mathbb{R}^t)} \frac{1}{\sqrt{2\mu_0}} \text{ if } \mu \geqq \mu_0 > 0,$$

where $L^2(\mathbb{R}^t)$ is the space of square integrable functions of time.
We define an operator $\mathcal{L}_k$ by its symbol:

$$\mathcal{L}_k v = (\mathcal{F}_{t \to \omega})^{-1}\{L(k, \cdot)\tilde{v}(\cdot)\},$$

where the tilda $\tilde{}$ denotes the Fourier transform with respect to the time variable. If v belongs to $L^2(\mathbb{R})$, then $\mathcal{L}_k v$ belongs to $H^{-1/2}(\mathbb{R})$. The root ρ can be extended to the half-plane $\tau = \omega - i\mu$, $\mu \geqq 0$, as an analytic function of ω, with the estimate

$$|\rho(k, \omega)| \leqq C(1 + |k| + \sqrt{|\omega|} + \sqrt{|\mu|}).$$

We can apply the Paley-Wiener-Schwarz theorem to $\mathcal{L}_k \mathcal{F}_{x_2 \to k} g_n(k, \cdot)$; from the previous considerations, for almost every k, $L(k, \tau)\hat{g}_n(k, \tau)$ is analytic in τ for $\mu = -\mathrm{Im}(\tau) > 0$, and satisfies an estimate of the form

$$|L(k, \tau)\hat{g}_n(k, \tau)| \leqq C(k, \mu_0)(1 + |\tau| + |\mu|) \quad \forall \mu \geqq \mu_0.$$

Thus, for almost every k, $\omega \to L(k, \omega - i\mu)\hat{g}_n(k, \omega - i\mu)$ is the Fourier-Laplace transform of a distribution with support in $[0, \infty)$. On the other hand, $L(k, \omega - i\mu)\hat{g}_n(k, \omega - i\mu)$ is square integrable with respect to ω, and therefore,

$$(\mathcal{F}_{t \to \omega})^{-1}(L(k, \cdot)\hat{g}_n(k, \cdot)) = 0 \quad \forall\, t \leqq 0, \text{ and a.e. } k,$$

and finally,

$$\mathcal{L} g_n = 0 \quad \forall\, t \leqq 0, \text{ and for all } x_2.$$

By density, the same result holds for g. □

An immediate consequence of Lemma 3.7 is the following.

LEMMA 3.8. *Let u^0 belong to $\mathbf{H}(\mathbb{R}^2)$, and f to $L^2(0, \infty; \mathbf{L}^2(\mathbb{R}^2))$. Assume that u^0 and f satisfy respectively the support conditions* (2.36) *and* (2.37). *If μ is strictly positive, and if (u, p) is the solution of* (2.29)-(2.31), *extended by zero for negative time, then the trace of u on Σ belongs to $D(\mathcal{L})$.*

Proof. According to Proposition 2.7, u belongs to $L^2(0, \infty, W(\Omega_-))$, and according to Proposition 2.4, the trace of u on Σ belongs to $L^2(0, \infty, W^{1/2} \times H^{1/2})$. On the other hand, the support condition enables us to apply Lemma 2.14, and therefore, $(u_1 + \mathcal{H}u_2)|_\Sigma$ belongs to $H^\infty(\Sigma)$. □

We first obtain a result of existence, under the support condition on u^0 and f, with some functional analysis on $\mathcal{L}$.

PROPOSITION 3.9. *For all u^0 in $H(\Omega_-)$ and all f in $L^2(0,\infty,L^2(\Omega_-))$ that satisfy the support conditions* (2.36), (2.37), *and for all strictly positive μ, there exists a function u satisfying the variational equality* (3.54) *with initial data u^0, and such that*

$$u \in L^\infty([0,\infty);\, H(\Omega_-)),$$
$$\nabla u \in L^2([0,\infty);\, L^2(\Omega_-)),$$
$$u_t \in L^2([0,\infty);\, W'(\Omega_-)).$$

Proof. We have to approximate a right-hand side $f + u^0 \otimes \delta'$ by a smooth right-hand side f_n belonging to $\mathscr{S}([0,\infty);\, H^\infty(\mathbb{R}^2))$. This is clearly possible by truncation and regularization. The passage to the limit in the variational inequality is easy.

We will obtain a much better result of existence, not only for the sake of exhaustivity, but also to have a convenient frame for the proof of uniqueness. We write (3.52) as a problem with time in the full real line, extending u by 0 for $t \geqq 0$; after an integration by parts in time, we have for all v in $L^2(\mathbb{R};\, W(\Omega_-))$ such that v_t belongs to $L^2(\mathbb{R};\, H(\Omega_-))$

$$(3.58)\quad \int_{\mathbb{R}} \{-s(u, v_t) + \mu s(u, v) + \tilde{\mathbf{a}}(u, v)\}\, dt + \langle u, \mathscr{L}^* v\rangle_\Sigma = s(u^0, v(0)) + \int_{\mathbb{R}} (f, v)\, dt.$$

Here, of course, $\mathscr{L}^*$ has L^* for symbol, the domain of $\mathscr{L}^*$ is defined similarly to the domain of $\mathscr{L}$, and the trace of a test function v on Σ belongs to $D(\mathscr{L}^*)$ thanks to Lemma 3.6 and simple interpolation. We need to define three more operators to prove existence and uniqueness.

DEFINITION 3.10. The operator A is an operator from $W(\Omega_-)$ to $W'(\Omega_-)$ defined by

$$(3.59)\qquad s(Au, v) = \tilde{\mathbf{a}}(u, v) \quad \forall v \in W(\Omega_-).$$

The operator $B(\tau)$ is an operator from $W(\Omega_-)$ to $W'(\Omega_-)$ defined by

$$(3.60)\qquad s(B(\tau)u, v) = \int_{\mathbb{R}} L(k, \tau)\hat{u}(0, k)\bar{\hat{v}}(k, \tau)\, dk, \quad \forall v \in W(\Omega_-).$$

The operator S is an operator from $L^2(\Omega_-)$ to $H(\Omega_-)$ defined by

$$(3.61)\qquad s(Sf, v) = (f, v) \quad \forall v \in H(\Omega_-).$$

The operator A is well defined; this is a classical result. The mapping which assigns to a pair $(u; v)$ belonging to $W(\Omega_-) \times W(\Omega_-)$ the expression

$$\int_{\mathbb{R}} L(k, \tau)\hat{u}(0, k)\bar{\hat{v}}(0, k)\, dk$$

is clearly a sesquilinear continuous mapping, and thus $B(\tau)$ is well defined. Finally, the mapping

$$v \to (f, v)$$

is linear continuous on $H(\Omega_-)$, and Sf is thus well defined.

The existence and uniqueness theorem reads.

THEOREM 3.11. *For all u^0 in $H(\Omega_-)$ and all f in $L^2(0,\infty;\mathbf{L}^2(\Omega_-))$, and for all strictly positive μ, there exists a unique u in $L^\infty([0,\infty);\, H(\Omega_-)) \cap L^2([0,\infty);\, W(\Omega_-))$ such that u_t belongs to $L^2([0,\infty);\, W(\Omega_-))$ and*

$$(3.62)\qquad \int_{\mathbb{R}} \{-s(u, v_t) + \mu s(u, v) + \tilde{\mathbf{a}}(u, v)\}\, dt + \langle u, \mathscr{L}^* v\rangle_\Sigma = s(u^0, v(0)) + \int_{\mathbb{R}} (f, v)\, dt.$$

for all v in $L^2(\mathbb{R};\, W(\Omega_-))$ such that v_t belongs to $L^2(\mathbb{R};\, H(\Omega_-))$.

In order to prove this theorem, we need a positivity result which will be useful for the existence part.

LEMMA 3.12. *Let g belong to the space Y defined at* (3.57). *Assume that u vanishes for negative time. Then, for all positive T, we have*

$$\int_0^T (\mathscr{L}g, g)\, dx_2\, dt \geqq 0.$$

Proof. Assume first that g belongs to $\mathscr{S}(\mathbb{R}; Z)$, and vanishes for negative time. Let u be the solution of (3.9). Then, if we multiply the equation $\mathscr{A}_\mu(u, p) = 0$ by u and integrate over Ω_+, we obtain

$$\int_0^T (\mathscr{L}g, g)\, dt = \|u(\cdot, T)\|^2 + \mu \int_0^T \{\tilde{\mathbf{a}}(u, u) + \|u(\cdot, t)\|^2\}\, dt - (\mathscr{K}_1 g_1(\cdot, T), g_1(\cdot, T))_\Gamma$$
$$- \mu \int_0^T (\mathscr{K}_1 g_1(\cdot, t), g_1(\cdot, t))_\Gamma\, dt,$$

where $\mathscr{K}$ is the boundary operator of symbol $|k|^{-1}$. We check that $\|u\|^2 - (\mathscr{K}g, g)_\Gamma$ is greater than or equal to zero. By an argument analogous to the one we used at proposition 2.4, we have the identity

$$(\mathscr{K}g_1, g_1)_\Gamma = -2(u_1, \mathscr{K}u_2),$$

and

$$\|u\|^2 - (\mathscr{K}u_1, u_1) = \|u_1 - \mathscr{K}u_2\|^2 \geqq 0.$$

Thus the positivity holds for smooth data. By density and causality, it will hold as stated in the statement of the lemma. □

Proof of the theorem. We first prove uniqueness; denote $\tilde{u}$ the partial Fourier transform of u in time. If u is the solution of (3.62), it satisfies

$$i\omega\tilde{u}(\tau) + \mu\tilde{u}(\tau) + A\tilde{u}(\tau) + B(\tau)\tilde{u}(\tau) = u^0 + S\tilde{f}(\tau). \tag{3.63}$$

If the data vanish, we have

$$i\omega\tilde{u}(\tau) + \mu\tilde{u}(\tau) + A\tilde{u}(\tau) + B(\tau)\tilde{u}(\tau) = 0.$$

For almost every ω, $\tilde{u}(\tau)$ belongs to $W(\Omega_-)$. If we multiply the above equation scalarly by $\tilde{u}(\tau)$ and take the real part, we obtain

$$\operatorname{Re}\{\mu s(\tilde{u}(\tau), \bar{\tilde{u}}(\tau)) + \tilde{\mathbf{a}}(\tilde{u}(\tau), \bar{\tilde{u}}(\tau)) + s(B(\tau)\tilde{u}(\tau), \bar{\tilde{u}}(\tau))\} = 0. \tag{3.64}$$

The definition of $\tilde{\mathbf{a}}$ and $B(\tau)$ implies that the corresponding terms in (3.64) are nonnegative; there remains

$$\operatorname{Re}(\mu s(\tilde{u}(\tau), \bar{\tilde{u}}(\tau))) \leqq 0,$$

and this implies that $\tilde{u}$ vanishes almost everywhere. We can conclude the uniqueness of the solution of (3.62).

Let us prove the existence under the assumptions of our theorem; if u and f satisfy our support condition, we know that there exists a unique solution to (3.62). If this support condition is not satisfied, extend u^0 and f by 0 in Ω_+, and approximate these extended u^0 and f by translated data u_n^0 and f_n that satisfy the support condition. For the solution u_n the positivity of $\mathscr{L}$ implies the estimate

$$s(u_n(T), u_n(T)) + \int_0^T \{\mu s(u_n(t), u_n(t)) + \tilde{\mathbf{a}}(u_n(t), u_n(t))\}\, dt \leqq s(u_n^0, u_n^0) \leqq s(u^0, u^0).$$

An easy passage to the limit gives the result. □

4. Absorbing boundary conditions. This section is dedicated to the approximation of the pseudo-differential operator $\mathscr{L}$ by more manageable operators. We have seen that the symbol L of $\mathscr{L}$ is a two-by-two matrix which is algebraic in τ, k and $\sigma = \operatorname{sgn}(k)$. We would like our approximation of $\mathscr{L}$ to be local in space and time, which would mean that its symbol is polynomial or rational in τ and k. Unfortunately, we do not know how to approximate σ or $|k|$ by rational fractions of low degree; thus, we will be content with an approximation which is rational in τ, k and σ. The idea is to approximate the root ρ by a sequence of r_n which keeps the essential property $\operatorname{Re}(r_n) \geqq 0$. We need a number of technical results that precisely describes the properties of the sequence of approximations. These properties enable us to prove a rather weak existence and uniqueness theorem for the problem with absorbing boundary conditions. Then, we estimate the difference between the solution of the problem with absorbing boundary conditions and the solution of the problem with transparent conditions. From this estimate, we deduce a better existence theorem. If ν is small, the difference between the two solutions is small with a power of ν; when u^0 and f satisfy the support conditions (2.36), (2.37), the difference is estimated in a space of smooth functions.

4.1. Approximation of the symbol L. We approximate the transparent boundary conditions in constraint formulation. If we approximated the symbol of the operator $g \to (\partial u/\partial x_1, p)$, we could run into trouble and obtain an ill-posed problem.

We recall that we obtained at (3.47) a decomposition of the matrix $L(k, \tau)$, which we write now with an explicit dependance on the viscosity ν.

$$L(k, \tau, \nu) = M(k, \nu) + \rho(k, \tau, \nu)\frac{N(k)}{2}. \tag{4.1}$$

The matrix M is of degree 1 in ν; $N(k)$ and the Hermitian symmetrization of $M(k, \nu)$ are both positive semidefinite matrices.

Now, we have to approximate $\rho(k, \tau, \nu)$ so that the successive approximations, denoted r_n, will satisfy the essential property

$$\operatorname{Re}(r_n(k, \tau, \nu)) \geqq 0 \quad \forall k, \omega, \nu. \tag{4.2}$$

This problem has been solved in [13] but with very few proofs. The principle of the approximation has been obtained by observing that for all complex number d we have

$$\lambda = \frac{\lambda d - |k|^2 - i\omega'\alpha}{-\lambda + \alpha + d}, \tag{4.3}$$

where $\alpha = a_1/\nu$ and $\omega' = (\tau + a_2 k)/a_1$.

The choice of $d = i\omega'$ and of the initialization $\lambda_1 = -i\omega'$ (because λ_0 might be a special case) defines a sequence recursively by:

$$\lambda_{n+1} = \frac{\lambda_n d - |k|^2 - i\omega'\alpha}{-\lambda_n + \alpha + d},$$

which has the three important properties:

(i) Each of the λ_n is rational in k, τ and σ;

(ii) The associated initial boundary value problem is, at least formally, well-posed because $\operatorname{Re}(\lambda_n) \leqq 0$, and we will prove that it is actually well-posed;

(iii) λ_n is the $[n-1, n-1]$ Padé approximant of λ around $\nu = 0$ (see [13]).

More precisely, we have the

DEFINITION 4.1. Denote

$$\omega' = \frac{\tau + a_2 k}{a_1}, \tag{4.4}$$

$$\alpha = \frac{a_1}{\nu}. \tag{4.5}$$

We define:

$$\lambda_0 = 0, \tag{4.6}$$

$$\lambda_1 = -i\omega', \tag{4.7}$$

$$\lambda_{n+1} = \frac{-i\omega'\lambda_n + i\alpha\omega' + k^2}{\lambda_n - \alpha - i\omega'}, \tag{4.8}$$

$$r_n = a_1 - 2\nu\lambda_n. \tag{4.9}$$

We will give now a sequence of technical lemmas on r_n and λ_n.

LEMMA 4.2. *For all* $n \geqq 0$, $k \in \mathbb{R}$, $\omega \in \mathbb{R}$, $\nu > 0$, r_n *is well defined and*

$$\operatorname{Re}(\lambda_n) \leqq 0. \tag{4.10}$$

Proof. For $n = 0$ or 1, the result is obvious. Assume that $\operatorname{Re}(\lambda_n) \leqq 0$; then, the expression $\lambda_n - \alpha + i\omega'$ has a strictly negative real part; moreover,

$$\lambda_{n+1} = \frac{(-i\omega'\lambda_n + i\alpha\omega' + k^2)(\bar{\lambda}_n - \alpha + i\omega')}{|\lambda_n - \alpha + i\omega'|^2}$$

so that,

$$\operatorname{Re}(\lambda_{n+1}) = \frac{[k^2 + \omega'^2] \operatorname{Re}(\lambda_n - \alpha)}{|\lambda_n - \alpha + i\omega'|^2},$$

and by induction, the results holds true. □

LEMMA 4.3. *Let* ρ *be as in* (3.24) *and* $\lambda = (a_1 - \rho)/2\nu$; *then, the following relation holds*:

$$\lambda_{n+1} - \lambda = -\frac{(\lambda_n - \lambda)[k^2 + \omega'^2]}{[\lambda_n - \alpha - i\omega'][\lambda - \alpha - i\omega']}. \tag{4.11}$$

Proof. We substitute $d = -i\omega'$ in (4.2)

$$\lambda = \frac{-i\omega'\lambda + i\alpha\omega' + k^2}{\lambda - \alpha - i\omega'}.$$

Therefore, subtracting this expression λ from the expression (4.7), we obtain immediately (4.10). □

The recursive definition of λ_n by a sequence of homographic transformations shows that λ_n is a rational fraction in k and ω. To obtain more information on the sequence λ_n, we study the particular case $\alpha = 1$. Then (4.8) becomes

$$\lambda_{n+1} = \frac{-i\omega'\lambda_n + i\omega' + k^2}{\lambda_n - i\omega' - 1}; \tag{4.12}$$

we define P_n and Q_n by

$$P_1 = -i\omega' \tag{4.13}$$

$$Q_1 = 1 \tag{4.14}$$

and

$$P_{n+1} = -i\omega' P_n + (i\omega' + k^2) Q_n \tag{4.15}$$

$$Q_{n+1} = P_n - (i\omega' + 1) Q_n. \tag{4.16}$$

Then, we have

$$\lambda_n = \frac{P_n}{Q_n}. \tag{4.17}$$

An obvious induction shows that P_n is at most of degree n, and that Q_n is at most of degree $n-1$, globally in k and ω'. Let P_n and Q_n be decomposed as a sum of globally homogeneous polynomials in k and ω', of decreasing degree:

$$P_n = P_n^n + P_n^{n-1} + \cdots + P_n^0, \tag{4.18}$$

$$Q_n = Q_n^{n-1} + Q_n^{n-2} + \cdots + Q_n^0; \tag{4.19}$$

we now define the polynomial Z_n by

$$Z_n = P_n + kQ_n. \tag{4.20}$$

Let

$$z = k - i\omega'. \tag{4.21}$$

Then Z_n satisfies the following relation:

$$Z_{n+1} = z(Z_n - Q_n), \tag{4.22}$$

and if we decompose Z_n into a sum of homogeneous polynomials

$$Z_n = Z_n^n + Z_n^{n-1} + \cdots + Z_n^1, \tag{4.23}$$

then we can deduce Q_n and P_n from Z_n by

$$P_n = i \operatorname{Im}(Z_n^1) + \operatorname{Re}(Z_n^2) + i \operatorname{Im}(Z_n^3) + \cdots \tag{4.24}$$

$$Q_n = \frac{\operatorname{Re}(Z_n^1) + i \operatorname{Im}(Z_n^2) + \operatorname{Re}(Z_n^3) + \cdots}{k}. \tag{4.25}$$

Of course, these expressions terminate differently according to the parity of n. □

LEMMA 4.4. *Assume that $\alpha = 1$. Then, there exists a polynomial R_n of degree $n-1$ in one variable such that Q_n^{n-1} can be written as*

$$Q_n^{n-1}(k, \omega') = k^{n-1} R_n\left(\frac{\omega'}{k}\right).$$

The zeros ζ_p of R_n are real and simple and except for $k = 0$, the next term $Q_n^{n-2}(k, k\zeta_p)$ does not vanish.

Proof. A simple induction shows that P_n^n and Q_n^{n-1} are given for n odd by

$$\begin{cases} P_n^n = i \operatorname{Im}(z^n), \\ Q_n^{n-1} = \operatorname{Re}(z^n)/k. \end{cases} \tag{4.26}$$

When n is even, they are given by

$$\begin{cases} P_n^n = \operatorname{Re}(z^n), \\ Q_n^{n-1} = [i \operatorname{Im}(z^n)]/k. \end{cases} \tag{4.27}$$

The polynomial $R_n(X)$ is given by

$$R_n(X) = i \operatorname{Im}(1 - iX)^i \quad \text{if } n \text{ is even},$$

$$R_n(X) = \operatorname{Re}(1 - iX)^n \quad \text{if } n \text{ is odd}.$$

From these formulae, R_n is of degree $n-1$ and the roots of R_n are real and simple. Geometrically, these roots are the ordinates of the intersection of the straight lines $\zeta = 1 + r e^{i\pi k/n}$ with the imaginary axis, when n is even; when n is odd, they are the abscissae of the intersection of these same lines with the real axis. There are exactly n of these lines. When n is even, one of these lines is parallel to the imaginary axis and another is the real axis; this yields the announced $n-1$ real solutions, one of which is zero. If n is odd, one of the lines is the real axis, which we discard, and there remain $n-1$ real distinct nonzero solutions. For the last assertion, we consider first the case of n even:

$$Q_n^{n-2} = \frac{\operatorname{Re}(Z_n^{n-1})}{k}.$$

Relation (4.22) implies that

$$Z_n = z^n - \sum_{j=1}^{n-1} z^j Q_{n-j}.$$

With the help of (4.26) and (4.25), we obtain

$$\begin{aligned}
\operatorname{Re}(Z_n^{n-1}) &= -\operatorname{Re}\left(\sum_{j=1}^{n-1} z^j Q_{n-j}^{n-j-1}\right) \\
&= -\operatorname{Re}\left(\sum_{\substack{j=1 \\ j \text{ even}}}^{n-1} z^j \frac{i \operatorname{Im} z^{n-j}}{k} + \sum_{\substack{j=1 \\ j \text{ odd}}}^{n-1} z^j \frac{\operatorname{Re} z^{n-j}}{k}\right) \\
&= \frac{1}{k}\left(\sum_{\substack{j=1 \\ j \text{ even}}}^{n-1} \operatorname{Im}(z^j) \operatorname{Im}(z^{n-j}) - \sum_{\substack{j=1 \\ j \text{ odd}}}^{n-1} \operatorname{Re}(z^j) \operatorname{Re}(z^{n-j})\right).
\end{aligned}$$

Assume now that z is a root of Q_n^{n-1} which does not vanish. Then, it is real and the above formula reduces to

$$\operatorname{Re}(Z_n^{n-1}) = -\frac{n}{2}\frac{z^n}{k},$$

which does not vanish.

The proof in the case of n odd is analogous and left to the reader. □

In the next lemma we give an estimate on $\lambda_n + (i\omega'/n)$, which will enable us to work on the variational problem for absorbing boundary conditions.

LEMMA 4.5. Assume that $\alpha = 1$. Then, for each n, there is a constant C_n, which depends neither on k nor on ω', such that

$$\left|\lambda_n + \frac{i\omega'}{n}\right| \leqq C_n(1+|k|)^2. \tag{4.28}$$

Proof. We observe that in

$$\lambda_n + \frac{i\omega'}{n} = \frac{nP_n + i\omega' Q_n}{nQ_n};$$

the term of highest degree in ω' of P_n is $(-i\omega')^n$, and the term of highest degree in ω' of Q_n is $(-i\omega')^{n-1}$, so that $nP_n + i\omega' Q_n$ does not have a term of degree n in ω'. Thus, we have the estimate

$$|nP_n + i\omega' Q_n| \leqq C_{1n}\{1 + |z|^{n-1} + |k||z|^{n-1}\}. \tag{4.29}$$

To estimate from below the denominator Q_n, we consider first the case when n is even. Let $(\zeta_p)_{1\leqq p\leqq n-1}$ denote the zeros of R_n, and let ξ_q denote the zeros of $X \to (Q_n^{n-2})(1, X)$. We make the convention that

$$\zeta_1 = 0.$$

Lemma 4.4 implies that there exists a β such that

$$\min_{\substack{1\leqq q\leqq n-2\\ 1\leqq p\leqq n-1}} |\xi_q - \zeta_p| = \beta > 0.$$

Therefore, this suggests an estimate on three different regions:

$$\mathcal{R}_1\colon \{k, \omega')/|k|^2+|\omega'|^2 < r^2\},$$

$$\mathcal{R}_2\colon \{(k, \omega')/|k|^2+|\omega'|^2 \geqq r^2 \text{ and } \min_p |\zeta_p - \omega'/k| \leqq \gamma\},$$

$$\mathcal{R}_3\colon \{(k, \omega')/|k|^2+|\omega'|^2 \geqq r^2 \text{ and } \min_p |\zeta_p - \omega'/k| > \gamma\}.$$

For any positive r, Q_n is bounded away from zero on $\mathcal{R}_1$; this is a consequence of Lemma 4.2. The precise choice of r and γ will be made below.

We can see that Q_n^{n-1} is the product with k^{n-1} of an imaginary polynomial R_n whose roots are all real. On the other hand, Q_n^{n-2} is real. Therefore,

$$|Q_n| \geqq \min(|Q_n^{n-1}|, |Q_n^{n-2}|) - \sum_{j=1}^{n-3} |Q_n^j|$$

$$\geqq \min(|Q_n^{n-1}|, |Q_n^{n-2}|) - \sum_{j=1}^{n-3}) C_j |z|^j,$$

where the C_j are positive numbers depending only on n. We have the relations

$$Q_n^{n-2} = K' k^{n-2} \prod_{q=1}^{n-2} \left(\frac{\omega'}{k} - \xi_q\right)$$

and

$$Q_n^{n-1} = K k^{n-1} \prod_{p=1}^{n-1} \left(\frac{\omega'}{k} - \zeta_p\right).$$

In the region $\mathcal{R}_2$, $|(\omega'/k) - \xi_p| \geqq \beta - \gamma$. Therefore, if we choose γ so that

$$\gamma \leqq \frac{\beta}{2}, \tag{4.30}$$

we obtain the estimate

$$|Q_n^{n-2}| \geqq |K'||k|^{n-2} \left(\frac{\beta}{2}\right)^{n-2}.$$

In the region $\mathcal{R}_2$, $|\omega'| \leqq |k|(\gamma + \max_p |\zeta_p|)$, and therefore, there exists a constant C_{2n} such that

$$|Q_n^{n-2}| \geqq C_{2n} |z|^{n-2}. \tag{4.31}$$

We argue similarly in the region $\mathcal{R}_3$; the homogeneous term Q_n^{n-1} satisfies

$$|Q_n^{n-1}| \geqq |K||k|^{n-1} \prod_{p=1}^{n-1} \left|\frac{\omega'}{k} - \zeta_p\right| = |K||\omega'|^{n-1} \prod_{p=1}^{n-1} \left|\frac{k\zeta_p}{\omega'} - 1\right|.$$

If $|k/\omega'| \leqq \varepsilon$, where ε is so chosen that $\varepsilon \max_p |\zeta_p| \leqq \frac{1}{2}$, then

$$|Q_n^{n-1}| \geqq |K||\omega'|^{n-1} \frac{1}{2^{n-1}\varepsilon^{n-1}} \geqq C_{3n}|z|^{n-1}.$$

If the converse inequality holds, then

$$|Q_n^{n-1}| \geqq |K||\gamma k|^{n-1} \geqq C_{4n}|z|^{n-1}.$$

Finally there exists a constant C_{5n} such that

$$|Q_n^{n-1}| \geqq C_{5n}|z|^{n-1} \quad \forall\, z \text{ in } \mathcal{R}_3. \tag{4.32}$$

The number r must be chosen so that

$$|z| \geqq r \Rightarrow \min\left(C_{2n}|z|^{n-2}, C_{5n}|z|^{n-1}\right) \geqq 2 \sum_{j=1}^{n-3} C_j |z|^j.$$

Then, there exists a constant C_{6n} such that

$$|Q_n| \geqq C_{6n}(1+|z|^{n-2}) \qquad \text{on } \mathcal{R}_2,$$

$$|Q_n| \geqq C_{6n}(1+|z|^{n-1}) \qquad \text{on } \mathcal{R}_3.$$

Finally,

$$\left|\lambda_n + \frac{i\omega'}{n}\right| \leqq \frac{C_{1n}\{1+|z|^{n-1}+|k||z|^{n-1}\}}{C_{6n}(1+|z|^{n-2})} \leqq C_{8n}(1+|z|+|k||z|) \text{ on } \mathcal{R}_2;$$

the inequality of the statement of the lemma is satisfied, because $|\omega'| \leqq$ constant $|k|$ on $\mathcal{R}_2$. On the other region,

$$\left|\lambda_n + \frac{i\omega'}{n}\right| \leqq \frac{C_{1n}(1+|z|^{n-1}+|k||z|^{n-1})}{C_{7n}(1+|z|^{n-1})} \leqq C_{9n}(1+|k|) \text{ on } \mathcal{R}_3.$$

Here, the inequality stated is clearly satisfied. No difficulty can come from region $\mathcal{R}_3$. The proof when n is odd is analogous and left to the reader. □

We can now state an estimate in the general case.

PROPOSITION 4.6. *There exists a constant c_n depending only on a_1 and a_2, such that*

$$\left|\lambda_n + \frac{i\omega'}{n}\right| \leqq c_n \frac{(1+\nu|k|)^2}{\nu}. \tag{4.33}$$

Proof. In the general case,

$$\lambda_{n+1} = \frac{-i\omega'\lambda_n + i\alpha\omega' + k^2}{\lambda_n - \alpha - i\omega'},$$

then,

$$\lambda_n(k, \omega', \alpha) = \frac{P_n(k, \omega', \alpha)}{Q_n(k, \omega', \alpha)},$$

where

$$P_n(k, \omega', \alpha) = P_n^n + \alpha P_n^{n-1} + \cdots + \alpha^n P_n^0,$$

$$Q_n(k, \omega', \alpha) = Q_n^{n-1} + \alpha Q_n^{n-2} + \cdots + \alpha^{n-1} Q_n^0,$$

or, in other terms,

$$P_n(k, \omega', \alpha) = \alpha^n P_n\left(\frac{k}{\alpha}, \frac{\omega'}{\alpha}, 1\right),$$

$$Q_n(k, \omega', \alpha) = \alpha^{n-1} Q_n\left(\frac{k}{\alpha}, \frac{\omega'}{\alpha}, 1\right).$$

Now, we can use (4.26):

$$\left|\lambda_n(k, \omega', \alpha) + \frac{i\omega'}{n}\right| = \left|\alpha\left\{\lambda_n\left(\frac{k}{\alpha}, \frac{\omega'}{\alpha}, 1\right) + \frac{i\omega'}{\alpha n}\right\}\right| \leqq C_n \alpha (1 + |k/\alpha|)^2.$$

This proves the proposition. □

4.2. Variational formulation: existence, uniqueness, error estimates. In this section, we shall state a variational formulation which is suitable for the analysis of absorbing conditions. Given data u^0 and f, we obtain by the Fourier method a unique solution of the problem with absorbing boundary conditions of any order n. This is not enough to obtain existence in nice spaces. One expects that the larger n, the closer the solution with artificial boundary conditions to the full space solution. This result is obtained by the analysis of the error, if the data satisfy the support conditions (2.36) and (2.37). It turns out that the error is in a better space than the solution u_n; using causality and positivity, we obtain the existence and uniqueness in convenient spaces.

DEFINITION 4.7. Let, for $n = 0$

$$L_0(k, \tau, \nu) = M(k, \tau, 0) + \frac{a_1}{2} N(k) \tag{4.34}$$

and

$$L_n(k, \tau, \nu) = M(k, \tau, \nu) + r_n(k, \tau, \nu) N(k)/2. \tag{4.35}$$

The operator $\mathscr{L}_n$ is defined by its symbol L_n:

$$\mathscr{L}_n(u) = \mathscr{F}^{-1}(L_n(\cdot, \cdot, \nu)\hat{u}(0, \cdot, \cdot)). \tag{4.36}$$

The variational formulation (3.58) is approximated by:

$$\int_{\mathbb{R}} \{-s(u, v_t) + \mu s(u, v) + \tilde{\mathbf{a}}(u, v)\}\, dt + \langle u, \mathscr{L}_n^* v\rangle_\Sigma = s(u^0, v(0)) + \int_{\mathbb{R}} (f, v)\, dt,$$
$$\forall\, v \in L^2(\mathbb{R}; W(\Omega_-)) \text{ such that } v_t \in L^2(\mathbb{R}; H(\Omega_-)). \tag{4.37}$$

We have a first result of existence and uniqueness, as follows.

PROPOSITION 4.8. *Let u^0 belong to H, and let f belong to $L^2(\mathbb{R}; H(\Omega_-))$. Then, for $n \geqq 1$, there exists a unique u in $H^{-\varepsilon}(\mathbb{R}; H)$, such that, for all v in $H^1(\mathbb{R}; W(\Omega_-))$, (4.37) holds.*

Proof. Define an operator $B_n(\omega)$ by

$$s(B_n(\tau)u, v) = \int L_n(k, \tau)\hat{u}(0, k) \cdot \bar{\hat{v}}(0, k)\, dk \quad \forall\, v \in W. \tag{4.38}$$

We solve (4.37) by Fourier transform in time:

$$i\omega \tilde{u}_n(\tau) + A\tilde{u}_n(\tau) + \mu \tilde{u}_n(\tau) + B_n(\tau)\tilde{u}_n(\tau) = u^0 + S\tilde{f}(\tau). \tag{4.39}$$

Here A and S are defined respectively at (3.59) and (3.61).

We estimate the solution of

$$i\omega\tilde{v}_n(\tau)+A\tilde{v}_n(\tau)+\mu\tilde{v}_n(\tau)+B_n(\tau)\tilde{v}_n(\tau)=v^0 \tag{4.40}$$

in terms of $\|v^0\|_H$ and $\|v^0\|_W$. If we multiply (4.40) scalarly by the conjugate of $\tilde{v}_n(t)$ and take the real part of the result, we obtain the estimate

$$\|\tilde{v}_n(\tau)\|_W \leqq C\|v^0\|_{W'}, \tag{4.41}$$

from the positivity of the operator B_n.

In order to obtain the $H^{-\varepsilon}$ estimate, we take the imaginary part of (4.40) scalarly multiplied by the conjugate of $\tilde{v}_n(\omega)$, and we obtain, for $n \geqq 1$,

$$\begin{aligned}
&\omega s(\tilde{v}_n(\tau), \bar{\tilde{v}}_n(\tau))+\left(a_1+\frac{2\tau\nu}{na_1}\right)\int N\hat{v}_n(0,k,\tau)\cdot\bar{\hat{v}}_n(0,k,\omega)\,dk \\
&\quad=\operatorname{Im}\left\{s(v^0,\bar{\tilde{v}}_n(\tau))-s(A\bar{\tilde{v}}_n(\tau),\tilde{v}_n(\tau))\right. \\
&\qquad-\int M\hat{v}_n(0,k,\tau)\cdot\bar{\hat{v}}_n(0,k,\tau)\,dk \\
&\qquad\left.+\int 2\nu\left[\lambda_n+\frac{i\omega'}{n}-i\frac{a_1}{na_2}\right]N\hat{v}_n(0,k,\tau)\cdot\bar{\hat{v}}_n(0,k,\tau)\,dk\right\}.
\end{aligned} \tag{4.42}$$

The most interesting term in the right-hand side of the above relation is the integral term which has $(\lambda_n+i\omega'/n)$ as a factor of the integrand; to estimate this term, we use Proposition 4.6. We will have a result if we are able to estimate $k\hat{v}_n(0,\cdot,\omega)$. This will depend on additional regularity on $\tilde{v}_n(\tau)$. Let D denote the differentiation with respect to x_2; if we apply D to (4.40), we can write, because $B_n(\tau)$ commutes obviously with D,

$$i\omega D\tilde{v}_n(\tau)+\mu\tilde{v}_n(\tau)+AD\tilde{v}_n(\tau)+B_n(\tau)D\tilde{v}_n(\tau)=Dv^0. \tag{4.43}$$

From (4.41), we have

$$\|D\tilde{v}_n(\tau)\|_W \leqq C\|Dv^0\|_{W'} \leqq C\|v^0\|_H.$$

Now, this inequality enables us to conclude that, for $\omega \neq 0$,

$$|\omega| s(\tilde{v}_n(\tau),\tilde{v}_n(\tau)) \leqq C(\|v^0\|_H)^2. \tag{4.44}$$

This relation concludes the proof of the existence. The uniqueness is as in the proof of Theorem 3.12. □

There is an analogous result for $n=0$; as it is easier, its proof is left to the reader.

PROPOSITION 4.9. *Let u^0 belong to W'; then, there exists a unique u in $H^{-\varepsilon}(\mathbb{R}; H)$ such that, for all v in $H^1(\mathbb{R}; W)$, (4.34) holds.*

These $H^{-\varepsilon}$ estimates are of course very bad, but we will obtain better after we make error estimates. Let us denote

$$e_n = u_n - u. \tag{4.45}$$

THEOREM 4.10. *Assume that u^0 and f satisfy the support conditions* (2.36) *and* (2.37); *then, for $n \geqq 1$, and for all positive p, the error e_n satisfies the estimate*

$$\|e_n\|_{H^p(\mathbb{R};\,W)} \leqq C'_{p,n}\nu^{2n}(\|u^0\|_H+\|f\|_{L^2(\mathbb{R};\,H)}). \tag{4.46}$$

For $n=0$, the exponent $2n$ has to be replaced by 1 in relation (4.46).

Proof. We subtract (3.63) from (4.39), and we obtain

$$i\omega\tilde{e}_n+A\tilde{e}_n+\mu\tilde{e}_n+B_n(\tau)\tilde{e}_n=(B-B_n)(\tau)\tilde{u}. \tag{4.47}$$

The point now is to estimate the norm of $(B-B_n)(\tau)\tilde{u}(\tau)$ in $W'(\Omega_-)$, so as to utilize (4.38). For $n \geqq 1$, we deduce from (4.8) and (4.32) that

$$s((B-B_n)(\tau)\tilde{u}(\tau), v) = \int \nu(\lambda_n - \lambda) N\hat{u}(0, \cdot, \tau) \cdot \hat{v}(0, \cdot, \tau)\, dk.$$

We already know from (4.10) that

$$|\lambda_n - \lambda| \leqq C^{n-1}\nu^{2n-2}|\lambda_1 - \lambda|(|k|^2+|\tau|^2)^{n-1}.$$

An easy algebraic computation shows that there exists a constant c' such that

$$|\lambda_1 - \lambda| \leqq c'\nu(|k|^2+|\tau|^2).$$

On the other hand, under the support conditions, $\mathcal{N}u|_\Sigma$ belongs to $H^\infty(\mathbb{R}^2)$. Thus, for all p, there exists a constant c_p such that

$$|N\hat{u}(0, k, \tau)| \leqq c_p(1+|k|^2+|\tau|^2)^{-p}.$$

These considerations imply the estimate

$$|s((B-B_n)(\tau)\tilde{u}(\tau), v)| \leqq C^{n-1}\nu^{2n}c_p c' \int (|k|^2+|\tau|^2)^n(1+|k|^2+|\tau|^2)^{-p}|\hat{v}(k)|\, dk.$$

If v is taken in W, then $\hat{v}$ is integrable on Σ, and there is a constant $C_{p,n}$ such that

$$|s((B-B_n)(\tau)\tilde{u}(\tau), v)| \leqq C_{p,n}\nu^{2n}\|v\|_W(1+|\tau|^2)^{p-n}.$$

Thus, we obtain

$$\|(B-B_n)(\tau)\tilde{u}(\tau)\|_{W'} \leqq C_{p,n}\nu^{2n}(1+|\tau|^2)^{p-n}.$$

From here, the conclusion of the theorem is immediate. The case $n=0$ is completely analogous. □

Remark 4.11. The constant $C_{p,n}$ which appears in (4.46) increases with n; moreover, the sequence λ_n converges to λ only for bounded values of λ and ω. If one wanted to prove that the limit of the sequence u_n is u, one would have to estimate an integral involving arbitrary powers of (ω'^2+k^2). Therefore, it is likely that a convergence theorem would need very strong conditions over the data.

COROLLARY 4.12. Under the assumptions of Theorem 4.10, u_n is an element of $L^\infty(\mathbb{R}^+, H(\Omega_-)) \cap L^2(\mathbb{R}^+; W(\Omega_-))$.

Proof. From Theorem 3.12, we know that u is an element of $L^\infty(\mathbb{R}^+, H(\Omega_-)) \cap L^2(\mathbb{R}^+; W(\Omega_-))$; as the error e_n belongs to the same space, the corollary holds.

In order to get rid of the support conditions, we prove some positivity results for $\mathcal{L}_n$.

LEMMA 4.13. The operator $\mathcal{L}_n$ is causal; if g is an element of $H^\infty(\mathbb{R}^2)$, which vanishes for t lesser than or equal to zero, then

$$\text{Re} \int_0^T \langle \mathcal{L}_n g, g\rangle_\Gamma\, dt \geqq 0. \tag{4.48}$$

Proof. The causality of $\mathcal{L}_n$ comes from the inductive construction of λ_n; it suffices to observe that λ_1 admits an extension to the half-plane $\text{Im}(\tau) < 0$, and that this extension has polynomial growth. By induction, the same holds for the λ_n. Details of this proof are left to the reader. The second part of the lemma relies on the decomposition

$$\mathcal{L}_n = \mathcal{R}_n + \frac{1}{n}\frac{d}{dt}, \tag{4.49}$$

where the symbol of $\mathcal{R}_n$ is bounded with respect to τ. This decomposition is an immediate consequence of Lemma 4.6. Arguing as in the proof of Lemma 3.7, and with the help of a technique used in [21], we define $\mathcal{L}_n^{\#}(k, \cdot)$ by

$$\mathcal{L}_n^{\#}(k, \cdot)u(t) = \mathcal{F}_{\omega \to t}\{L_n(k, \tau)\hat{u}(\tau)\}$$

and similarly $N^{\#}(k, \cdot)$, recalling the definition (3.50) of $\mathcal{N}$.

If we let

$$u_\varepsilon(t) = \begin{cases} u(t) \text{ if } 0 \leqq t \leqq T, \\ u(T)(T - t + \varepsilon)\varepsilon^{-1} \quad \text{if } T \leqq t \leqq T + \varepsilon, \\ 0 \text{ if } T + \varepsilon \leqq t, \end{cases}$$

then

$$\operatorname{Re} \int \mathcal{L}_n^{\#}(k, \cdot)u_\varepsilon(t) \cdot u_\varepsilon(t)\, dt = \operatorname{Re} \int L_n(k, \tau)\hat{u}_\varepsilon(\tau) \cdot \bar{\hat{u}}_\varepsilon(\tau)\, d\omega \geqq 0.$$

On the other hand, by causality,

$$\operatorname{Re} \int_0^T \mathcal{L}_n^{\#}(k, \cdot)u(t) \cdot u(t)\, dt = \operatorname{Re} \int \mathcal{L}_n^{\#}(k, \cdot)u_\varepsilon(t) \cdot u_\varepsilon(t)\, dt - \operatorname{Re} \int_T^{T+\varepsilon} \mathcal{L}_n^{\#}(k, \cdot)u_\varepsilon(t) \cdot u_\varepsilon(t)\, dt.$$

The first term is greater than or equal to zero; we estimate the second one as ε tends to zero; with the help of decomposition (4.49),

$$\lim_{\varepsilon \to 0} \operatorname{Re} \int_T^{T+\varepsilon} \mathcal{R}_n^{\#}(k, \cdot)u_\varepsilon(t) \cdot u_\varepsilon(t)\, dt = 0,$$

because $\mathcal{R}_n$ is bounded with respect to τ;

$$\lim_{\varepsilon \to 0} \operatorname{Re} \int_T^{T+\varepsilon} \mathcal{N}^{\#}(k, .) \frac{du_\varepsilon(t)}{dt} \cdot u_\varepsilon(t)\, dt = -\frac{1}{2}\mathcal{N}^{\#}(k, .)u(T) \cdot u(T),$$

as is shown by a straightforward computation. This shows the lemma. □

Now we can give a much more precise estimate under the assumptions of Theorem 4.10.

COROLLARY 4.14. *Under the assumptions of Theorem* 4.10, *the solution* u_n *with absorbing boundary conditions satisfies the estimate*

$$\frac{1}{2}s(u_n(t), u_n(t)) + \int_0^T \{\mu s(u_n(t), u_n(t)) + \tilde{\mathbf{a}}(u_n(t), u_n(t))\}\, dt$$

(4.50)

$$\leqq \frac{1}{2}s(u^0, u^0) + \int_0^T (f(t), u_n(t))\, dt.$$

Proof. This result is an immediate consequence of Lemma 4.13; one has only to substitute v by u_n in the variational equality (4.37). We can do this for smooth enough data; if u^0 and f are smooth enough, u_t belongs to $L^2(\mathbb{R}^+; H(\Omega_-))$. By error estimate (4.43), u_n belongs to the same space. Therefore, using the integration over $[0, T]$, the positivity and a density argument, one obtains the desired result. □

Finally, we obtain the most general existence and uniqueness theorem.

THEOREM 4.15. *For all* u^0 *in* $H(\Omega_-)$ *and all* f *in* $L^2(0, \infty; \mathbf{L}^2(\Omega_-))$, *and for all strictly positive* μ *there exists a unique* u *in* $L^\infty(\mathbb{R}^+; H(\Omega_-)) \cap L^2(\mathbb{R}^+; W(\Omega_-))$ *such that* u_t *belongs to* $L^2(\mathbb{R}; W'(\Omega_-))$ *and the variational equality* (4.37) *and the energy inequality* (4.50) *hold.*

Proof. It is enough to approximate any initial data by initial data satisfying the support condition. Then, the energy estimate gives the existence by standard procedure of extraction of subsequences. The uniqueness depends only on the positivity and still holds. □

4.3. Explicit formulations. We write problem (4.37) explicitly for $n=0$ and $n=1$. The variational form will be convenient for computations. We give the associated boundary conditions; for $n=2$, we use an auxiliary unknown.

Let us recall first that a product in Fourier space corresponds to a convolution in physical space. One of the important operators is the convolution by the inverse Fourier transform of $\mathrm{pf}(1/|k|)$; it is defined by

$$\mathcal{K}u(y)=\bar{\mathcal{F}}(u(k)pf(1/|k|)).$$

The kernel K of $\mathcal{K}$ is given by

$$K(x)=\frac{1}{\pi}(\gamma-\mathrm{Log}\,|x|), \tag{4.51}$$

where $\gamma\simeq 0.57721\ldots$ is the Euler constant. Then, the scalar product s admits the expression

$$\begin{cases} s(u,v)=\displaystyle\int_{\Omega_-} u(x_1,x_2)v(x_1,x_2)\,dx_1\,dx_2 \\ +\dfrac{1}{\pi}\left(\gamma\displaystyle\int_\Gamma u_1(0,x_2)v_1(0,x_2)\,dx_2-\barint_{\Gamma\times\Gamma}\mathrm{Log}\,|x_2-y_2|u_1(0,x_2)v_1(0,y_2)\,dx_2\,dy_2\right) \end{cases} \tag{4.52}$$

where the barred integral means that a principal value has to be taken.

Another important kernel is the kernel of the Hilbert transform, which is equal to $vp(1/\pi x)$. This distribution is not locally square integrable, but from the relation

$$\langle\mathcal{H}\varphi,\psi\rangle=-\frac{1}{2\pi}\int_{\mathbb{R}} i\sigma\hat{\varphi}\bar{\hat{\psi}}\,dk=\frac{1}{2\pi}\int_{\mathbb{R}}\frac{1}{|k|}\,\overline{\hat{\varphi}ik}\,\bar{\hat{\psi}}\,dk.$$

We deduce

$$\langle\mathcal{H}\varphi,\psi\rangle=\left\langle\mathcal{H}\varphi,\frac{\partial\psi}{\partial x_2}\right\rangle, \tag{4.53}$$

and the kernel K of $\mathcal{K}$ is locally integrable.

According to Definition 4.7, the symbol of $\mathcal{L}_0$ is the matrix L_0 given by

$$L_0(k,\tau,\nu)=M(k,\tau,0)+\frac{r_0}{2}N(k).$$

the value of r_0 is given by (4.6) and (4.9); $r_0=a_1$. Therefore,

$$L_0(k,\tau,\nu)=\begin{pmatrix} ia_2\sigma+(a_1/2) & -i\sigma a_1 \\ 0 & a_1/2 \end{pmatrix}. \tag{4.54}$$

Therefore,

$$(L_0\hat{u},\hat{v})=\frac{a_1}{2}(\hat{u},\hat{v})_\Gamma+(-i\sigma(a_1\hat{u}_2-a_2\hat{u}_1),\hat{v}_1)_\Gamma.$$

If the vector product is denoted by the symbol $\times$, this last expression can be rewritten as

$$(L_0\hat{u}, \hat{v}) = \frac{a_1}{2}(\hat{u}, \hat{v})_\Gamma + (-i\sigma\, a \times \hat{u}, \hat{v}_1)_\Gamma.$$

We obtain the following expression of $(\mathscr{L}_0 u, v)$:

$$(\mathscr{L}_0 u, v) = \frac{a_1}{2}(u, v)_\Gamma + (a \times \mathscr{H}u, v_1)_\Gamma,$$

or, with the help of (4.53),

$$(\mathscr{L}_0 u, v) = \frac{a_1}{2}(u, v)_\Gamma + \left(a \times \mathscr{H}u, \frac{\partial v_1}{\partial x_2}\right)_\Gamma. \tag{4.55}$$

Finally, the variational formulation for 0-artificial conditions is stated in the following proposition.

PROPOSITION 4.16. *For $n = 0$, the variational formulation* (4.37) *is equivalent to*

$$s(u, v) = (u, v)_{\Omega_-} + (\mathscr{H}u, v)_\Gamma; \tag{4.56}$$

$$s(u_t, v) + \mu s(u, v) + \tilde{\mathbf{a}}(u, v) + \frac{a_1}{2}(u, v)_\Gamma + \left(a \times \mathscr{H}u, \frac{\partial v_1}{\partial x_2}\right)_\Gamma = (f, v) \qquad \forall v \in W(\Omega_-). \tag{4.57}$$

Proof. The above dictionary of kernels proves that the following variational equality holds:

$$\int_{\mathbb{R}} \left[-s(u, v_t) + \mu s(u, v) + \tilde{\mathbf{a}}(u, v) + \frac{a_1}{2}(u, v)_\Sigma + \left(a \times \mathscr{H}u, \frac{\partial v_1}{\partial x_2}\right)_\Sigma \right] dt$$

$$= \int_{\mathbb{R}} (f, v)\, dt + s(u^0, v(0)).$$

for all test functions v in $L^2(\mathbb{R};\, W(\Omega_-))$ such that v_t belongs to $L^2(\mathbb{R};\, H(\Omega_-))$. Observe that the second integral along Γ makes sense because of the characterization of the trace on Γ. Using a test function of the form

$$v = W \otimes \varphi,$$

where v belongs to $W(\Omega_-)$ and φ is a smooth function, we obtain (4.57). □

In the case $n = 1$, L_1 is more complicated:

$$L_1(k, \tau, \nu) = M(k, \tau, \nu) + \frac{r_1}{2} N(k),$$

r_1 is given by

$$r_1 = a_1 + \frac{2\nu i}{a_1}(\tau + a_2 k).$$

Therefore,

$$L_1(k, \tau, \nu) = L_0(k, \tau, \nu) + \nu|k| \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \frac{\nu i}{a_1}(\tau + a_2 k) N(k). \tag{4.58}$$

Therefore, we have only to compute the extra terms which did not appear before:

$$\frac{1}{2\pi} \int_{\mathbb{R}} |k| \hat{u} \cdot \bar{\hat{v}}\, dk = \left(\mathscr{H} \frac{\partial u}{\partial x_2}, \frac{\partial v}{\partial x_2}\right)_\Gamma.$$

In the same fashion,

$$\frac{1}{2\pi}\int_{\mathbb{R}} ik\,N(k)\hat{u}\cdot\bar{\hat{v}}\,dk=\frac{1}{2\pi}\int_{\mathbb{R}} ik\hat{u}\cdot\bar{\hat{v}}\,dk+\frac{1}{2\pi}\int_{\mathbb{R}}|k|\bar{\hat{v}}\times\hat{u}\,dk$$
$$=\left(u,\frac{\partial v}{\partial x_2}\right)_\Gamma+\left(\mathcal{K}\frac{\partial v}{\partial x_2}\times\frac{\partial u}{\partial x_2},1\right)_\Gamma,$$
$$\frac{1}{2\pi}\int_{\mathbb{R}} N(k)\hat{u}\cdot\bar{\hat{v}}\,dk=\frac{1}{2\pi}\int_{\mathbb{R}}\hat{u}\cdot\bar{\hat{v}}\,dk+\frac{1}{2\pi}\int_{\mathbb{R}}(-i\sigma)\bar{\hat{v}}\times\hat{u}\,dk$$
$$=(u,v)_\Gamma+(\mathcal{K}v\times u,1)_\Gamma.$$

We can summarize this calculation:

$$(\mathcal{L}_1u,v)=(\mathcal{L}_0u,v)+\nu\left(\mathcal{K}\frac{\partial u}{\partial x_2},\frac{\partial v}{\partial x_2}\right)_\Gamma+\frac{\nu a_2}{a_1}\left(u,\frac{\partial v}{\partial x_2}\right)_\Gamma$$
$$+\left(\mathcal{K}\frac{\partial v}{\partial x_2}\times\frac{\partial u}{\partial x_2},1\right)_\Gamma+\frac{\nu}{a_1}(u_t+\mu u,v)_\Gamma+(\mathcal{K}v\times(u_t+\mu u),1)_\Gamma.$$

Finally, we have the following result:

PROPOSITION 4.17. *For $n=1$, the variational formulation* (4.37) *is equivalent to*

$$s(u_t,v)+\frac{\nu}{a_1}(u_t,v_t)_\Gamma+(\mathcal{K}v\times u_t,1)_\Gamma+\mu s(u,v)+\tilde{\mathbf{a}}(u,v)+\frac{a_1}{2}(u,v)_\Gamma$$
$$+\left(a\times\mathcal{K}u,\frac{\partial v_1}{\partial x_2}\right)_\Gamma+\nu\left(\mathcal{K}\frac{au}{\partial x_2},\frac{\partial v}{\partial x_2}\right)_\Gamma+\frac{\nu a_2}{a_1}\left(u,\frac{\partial v}{\partial x_2}\right)_\Gamma+\left(\mathcal{K}\frac{\partial v}{\partial x_2}\times\frac{\partial u}{\partial x_2},1\right)_\Gamma \tag{4.59}$$
$$=(f,v)\quad\forall\, v \text{ in } W(\Omega_-).$$

Proof. This is simply a consequence of the previous computation. □

In order to obtain the strong formulation of the boundary conditions, we observe that if the matrix E_m is defined by

$$E_m=\frac{a_1 I}{2}-K_1-L_m, \tag{4.60}$$

where K_1 is given by (3.44), then the associated operator $\mathscr{E}_m$ gives the boundary condition

$$\sigma_n=\mathscr{E}_m u|_\Sigma. \tag{4.61}$$

The matrix E_0 is given by

$$E_0=\begin{pmatrix} ia_2\sigma-(i\tau/|k|) & ia_1\sigma \\ 0 & 0\end{pmatrix}.$$

Therefore, the corresponding boundary condition is given by

$$\sigma_{11}=-\mathcal{K}\frac{\partial u_1}{\partial t}+\mathcal{H}u\times a, \tag{4.62}$$

$$\sigma_{12}=0. \tag{4.63}$$

The same kind of computation gives the result for $n=1$:

$$\sigma_{11}=-\mathcal{K}\frac{\partial u_1}{\partial t}+\mathcal{H}u\times a+\nu\mathcal{H}\frac{\partial u_1}{\partial x_2}-\frac{\nu}{a_1}\left(\frac{\partial}{\partial t}+a_2\frac{\partial}{\partial x_2}\right)(u_1+\mathcal{H}u_2), \tag{4.64}$$

$$\sigma_{21}=\nu\mathcal{H}\frac{\partial u_2}{\partial x_2}+\frac{\nu}{a_1}\left(\frac{\partial}{\partial t}+a_2\frac{\partial}{\partial x_2}\right)(-\mathcal{H}u_1+u_2). \tag{4.65}$$

In [13], the family λ_n defined by (4.4)–(4.8) had been introduced to design absorbing boundary conditions for the advection-diffusion equation $u_t + a\nabla u - \nu\Delta u = 0$. It turned out that with this special choice, the boundary conditions assumed a very special form, namely

$$\left(\frac{\partial}{\partial t} + a\nabla\right)^n u = 0.$$

The analysis is much more intricate here, and we will merely outline a possible strategy for the case $n = 2$. It relies on the introduction of an unknown auxiliary, defined on the boundary. This technique had been initiated in [23] and proved to be very useful [3]. Using the symbols and the expression of λ_2 and λ_1, we get a formulation of L_2 as

$$L_2 = L_1 + \nu(\lambda_1 - \lambda_2)N, \quad \text{or} \quad L_2 = L_1 - \nu^2 \frac{k^2 + \omega'^2}{1 + 2i\omega'\nu} N.$$

Let us introduce the auxiliary function φ defined on the boundary through its Fourier transform by the expression

$$-\nu \frac{k - i\omega'}{1 + 2i\omega'} N\hat{u} = \hat{\varphi}, \tag{4.66}$$

or equivalently, using the fact that $(Nu)_1 - \mathcal{H}(Nu)_2 = 0$, $\varphi_1 + \mathcal{H}\varphi_2 = 0$;

$$\left(1 + \frac{2\nu}{a_2}\left(\frac{\partial}{\partial t} + a_2 \frac{\partial}{\partial x_2}\right)\right)(\varphi_1 + \mathcal{H}\varphi_2) + 2\nu\mathcal{H}\left(i\frac{\partial}{\partial x_2} + \frac{1}{a}\left(\frac{\partial}{\partial t} + a_2\frac{\partial}{\partial x_2}\right)\right)(u_1 + \mathcal{H}u_2) = 0. \tag{4.67}$$

then $L_2\hat{u}$ is given by

$$L_2\hat{u} = L_1\hat{u} + \nu(k + i\omega')\hat{\varphi}. \tag{4.68}$$

We conclude that the boundary condition associated with the second approximation $\mathscr{L}_2$ reads

$$\begin{aligned}\sigma_{11} = &-\mathscr{K}\frac{\partial u_1}{\partial t} + \mathcal{H}u \times a + \nu\mathcal{H}\frac{\partial u_1}{\partial x_2} \\ &-\frac{\nu}{a_1}\left(\frac{\partial}{\partial t} + a_2\frac{\partial}{\partial x_2}\right)(u_1 + \mathcal{H}u_2 + \varphi_1) + i\nu\frac{\partial \varphi_1}{\partial x_2},\end{aligned} \tag{4.69}$$

$$\sigma_{21} = \nu\mathcal{H}\frac{\partial u_2}{\partial x_2} - \frac{\nu}{a_1}\left(\frac{\partial}{\partial t} + a_2\frac{\partial}{\partial x_2}\right)(u_2 - \mathcal{H}u_1 + \varphi_2) + i\nu\frac{\partial \varphi_2}{\partial x_2} = 0. \tag{4.70}$$

These formulae have to be supplemented with (4.67).

Remark 4.12. The first boundary condition (4.62), (4.63) is actually local and can be written in the form:

$$\frac{\partial u_1}{\partial t} + (a \cdot \nabla)u_1 = 0 \tag{4.71}$$

$$\frac{\partial u_2}{\partial x_1} = 0. \tag{4.72}$$

Appendix A. The standard spaces of Beppo-Levi functions are studied in [7]; the distribution spaces described by Definition 2.1 are of the very same nature. The common property of the spaces $BL(H^s(\Omega))$ is that their local properties are the same as the local properties of $H^{s+1}(\Omega)$, but their properties in the large are quite different. In particular,

LEMMA A.1. *For any n, for any unbounded open set* Ω *of* $\mathbb{R}^n$, *and for any real s, there exists an unbounded function in* $BL(H^s(\Omega))$.

Proof. If is enough to exhibit examples; outside of a compact subset, we require u to be equal to

$$r^{1/4} \text{ if } n=1;$$

$$\text{Log Log } r \text{ if } n=2;$$

$$r^{-1/4} \text{ if } n \geqq 3.$$

Checking that these functions give the answer is an exercise left to the reader.

Though the elements of $BL(H^s(\Omega))$ may be unbounded, they are nonetheless elements of $\mathcal{S}'$. This is a consequence of the fact that $vp(1/ik)$ in dimension 1, and proper generalizations of this in dimension greater than or equal to 2 admit a Fourier transform, which is known explicitly. Moreover, the growth of the elements of $BL(H^s(\Omega))$ is polynomial at most and can be estimated precisely.

Finally, the Beppo-Levi spaces are natural spaces on an unbounded domain, where the only estimate is an energy estimate that involves only the gradient.

Appendix B. In this appendix, we prove a result on the behavior at infinity of harmonic functions. This result is probably part of the folklore of the subject, but we know no source where to find it in simple form.

LEMMA B.1. *Let p be a function on* $\mathbb{R}^N$ *such that* Δp (*computed in the sense of distributions*) *has compact support. If p decreases fast at infinity to zero, then p is constant outside of a compact set of* $\mathbb{R}^N$.

Proof. Let ρ be a C^∞ test function that is radial and has support in the ball of center 0 and radius 1. Denote $\rho_\varepsilon(x)=\varepsilon^{-N}\rho(x/\varepsilon)$. If p is harmonic for all x in $E_{R-2}=\{x/|x|\geqq R-2\}$, then it has the mean property in this region, and, whenever $|x|\geqq R-2+\varepsilon$, we have

$$u(x)=u*\rho_\varepsilon(x).$$

Therefore, u has derivatives of all orders in int (E_{R-2}), and all of its derivatives decrease rapidly at infinity. Let φ be an infinitely differentiable function on $\mathbb{R}^N$ such that

$$\varphi=0 \text{ for } |x|\leqq R-1$$

$$\varphi=1 \text{ for } |x|\geqq R.$$

Then $q=p\varphi$ is in $\mathcal{S}(\mathbb{R}^N)$, and

$$\psi=\Delta q \text{ has support in the ball of center 0 and radius } R.$$

We perform a Fourier transform on the equation $\Delta q=\psi$, and we obtain

$$|\xi|^2\hat{q}(\xi)=\hat{\psi}(\xi). \tag{B.1}$$

Thanks to the Paley-Wiener theorem, $\hat{\psi}(\xi)$ can be extended to all of $\mathbb{C}^N$ and is an entire function of ξ; moreover, for all n, there is a constant C_n such that

$$|\hat{\psi}(\xi)|\leqq C_n(1+|\xi|)^n e^{R|\mathrm{Im}(\xi)|}.$$

From (B.1), we can see that $\hat{q}$ can be extended to all $\mathbb{C}^N$ as a meromorphic function of ξ, with possibly a pole at zero. But, since q is in $\mathcal{S}(\mathbb{R}^N)$, $\hat{q}$ is in $\mathcal{S}(\mathbb{R}^N)$, too, and there is no pole of $\hat{q}$ at zero. Thus $\hat{q}$ satisfies the estimate

$$|\hat{q}(\xi)|\leqq C_0 \quad \text{for } |\xi|\leqq 1,$$

$$|\hat{q}(\xi)|\leqq C_n(1+|\xi|)^n e^{R|\mathrm{Im}(\xi)|}, \quad \text{for } |\xi|\geqq 1.$$

Thus q has compact support in the ball $|x| \leqq R$, and therefore p vanishes for $|x| \geqq R$. □

If p is known in (2.29)-(2.31), then u is the solution of an advection diffusion with right-hand side $f - \nabla p$; therefore, if p does not decrease rapidly to zero at infinity, and if f has compact support, for instance, u cannot generally decrease rapidly to zero at infinity. Therefore, a smooth solution u is in a space of function with polynomial estimates at infinity, and the dual of this space is a strict subspace of $\mathcal{S}'$.

BLOW-UP ESTIMATES FOR A NONLINEAR HYPERBOLIC HEAT EQUATION*

HAMID BELLOUT† AND AVNER FRIEDMAN‡

Abstract. Consider the Cauchy problem for

$$\varepsilon u_{tt} + u_t - u_{xx} = F(u);$$

u represents the temperature when the standard Fourier law $q = u_x$ (q flux) is relaxed and $F(u)$ is a nonlinear source of energy. It is established that the solution exists for $0 < t < \phi_\varepsilon(x)$, and it blows up as $t \to \phi_\varepsilon(x)$. Further, $\phi_\varepsilon(x) \to T_0$ as $\varepsilon \to 0$ where T_0 is the blow-up time for $u_t - u_{xx} = F(u)$.

Key words. blow-up of solutions, blow-up time, hyperbolic equations

AMS(MOS) subject classifications. 35L05, 35L67, 35L70

1. Introduction. Recently there has been increasing interest in the blow-up of solutions of nonlinear heat equations, such as

$$u_t - u_{xx} = F(u), \tag{1.1}$$

and nonlinear wave equations, such as

$$u_{tt} - u_{xx} = F(u); \tag{1.2}$$

typically $F(u) \sim Au^p$ ($p > 1$) or $F(u) \sim e^u$ as $u \to \infty$; see [10], [11], [13], [16], [17] and the references given there regarding (1.1), and [4], [5], [14] regarding (1.2).

Equation (1.1) models the heat equation when the flux q is given by the Fourier law $q = -u_x$ and the conservation of energy equation is

$$u_t + q_x = G \quad (G \text{ a source of energy}). \tag{1.3}$$

Fourier's law implies infinite velocity of heat propagation, and there have been a number of modified laws that rule out this feature. One common version is [1], [2], [3], [6], [7], [18], and [19]

$$q(x, t+\varepsilon) = -u_x(x, t) \quad (\varepsilon > 0)$$

or its approximation

$$q(x, t) + \varepsilon q_t(x, t) = -u_x(x, t). \tag{1.4}$$

The conservation of energy equation (1.3) then needs to be modified also (see [8]), but for ε small it is approximately the same as before. From (1.3), (1.4) we deduce

$$\varepsilon u_{tt} + u_t - u_{xx} = F \tag{1.5}$$

where $F = G + \varepsilon G_t$ ($G_t = \partial G(u(x, t))/\partial t$); for ε small, $F \approx G$.

In this paper we study the Cauchy problem for (1.5) with $F = F(u)$. If

$$\begin{aligned} u(x,0) &= f(x), \\ u_t(x,0) &= g(x) \end{aligned} \tag{1.6}$$

then, since it is natural to assume that, initially, the temperature satisfies the heat equation, we are led to the assumption that

$$g = f_{xx} + F(f). \tag{1.7}$$

In § 2 we represent (1.5), (1.6) in two equivalent but useful forms. In § 3 we establish the existence of unique solution u_ε of (1.5), (1.6) for $0 < t < \phi_\varepsilon(x)$, which blows up to $+\infty$ as $t \to \phi_\varepsilon(x)$. The method of Caffarelli and Friedman [4], [5] shows that if $f(u) \sim u^p$ as $u \to \infty$ then $\phi_\varepsilon(x)$ is continuously differentiable. Additional estimates on u_ε (independent of ε) are established in § 4.

Next, in § 5 we prove that

$$\liminf_{\varepsilon \to 0} \phi_\varepsilon(x) \geqq T_0 \tag{1.8}$$

where T_0 is the blow-up time for (1.1) with $u(x,0) = f(x)$. Finally, in § 6 we prove that

$$\limsup_{\varepsilon \to 0} \phi_\varepsilon(x) \leqq T_0. \tag{1.9}$$

Some generalizations and extensions are given in § 7.

Results of the type (1.8), (1.9) have been established for other types of equations in [12], [14], [15].

Assumptions. Throughout this paper we assume that $F \in C^2$,

$$\begin{aligned} &F(x) \geqq 0, \qquad F''(s) \geqq 0 \quad \text{if } s \geqq 0, \\ &F'(s) > 0 \quad \text{if } s > 0, \\ &\int_1^\infty \frac{ds}{F(s)} < \infty; \end{aligned} \tag{1.10}$$

$$f \geqq 0, \qquad f + \varepsilon g \geqq 0 \quad \text{(for all small } \varepsilon > 0), \tag{1.11}$$

$$f, g \quad \text{belong to } C^3(\mathbb{R}), \tag{1.12}$$

$$\begin{aligned} &f(x) + |g(x)| \leqq \frac{C}{(1+|x|)^\alpha}, \\ &\sum_{i=1}^{3} [|f^{(i)}(x)| + |g^{(i)}(x)|] \leqq C \quad \text{for more constants } C > 0,\ \alpha > 0 \end{aligned} \tag{1.13}$$

and (1.7) holds. In § 6 we will also need the assumption

$$g \geqq 0. \tag{1.14}$$

The results of this paper extend also to the case where (1.7) is not valid and to space dimension $\leqq 3$ (under some additional assumptions on F); see § 7.

2. Equivalent formulation for the Cauchy problem. We denote by u_ε the solution (if existing) of

$$\begin{aligned} &\mathcal{L}_\varepsilon u \equiv \varepsilon u_{tt} + u_t - u_{xx} = F(u), \\ &u(x,0) = f(x), \\ &u_t(x,0) = g(x). \end{aligned} \tag{P_ε^1}$$

Setting

$$v(x,t)=u(x,t)\,e^{t/(2\varepsilon)} \tag{2.1}$$

we get the equivalent system

$$\varepsilon v_{tt}-v_{xx}=F(v\,e^{-t/(2\varepsilon)})\,e^{t/(2\varepsilon)}+\frac{1}{4\varepsilon}\,v,$$

$$(P_\varepsilon^2)\qquad v(x,0)=f(x),$$

$$v_t(x,0)=\frac{1}{2\varepsilon}f(x)+g(x).$$

Setting

$$w(x,\tau)=v(x,t)\quad\text{where }\tau=\frac{t}{\sqrt{\varepsilon}}, \tag{2.2}$$

we get

$$w_{\tau\tau}-w_{xx}=F(w\,e^{-\tau/(2\sqrt{\varepsilon})})\,e^{\tau/(2\sqrt{\varepsilon})}+\frac{1}{4\varepsilon}\,w,$$

$$(P_\varepsilon^3)\qquad w(x,0)=f(x),$$

$$w_\tau(x,0)=\frac{1}{2\sqrt{\varepsilon}}f(x)+\sqrt{\varepsilon}\,g(x).$$

The concept of a solution of (P_ε^i) is always understood in the classical sense. Using the representation formula

$$\begin{aligned}z(x,t)=&\frac{1}{2}[z(x+t,0)+z(x-t,0)]+\frac{1}{2}\int_{x-t}^{x+t}z_t(\xi,0)\,d\xi\\&+\frac{1}{2}\int_0^t ds\int_{x-t+s}^{x+t-s}(z_{tt}-z_{xx})(y,s)\,dy\end{aligned} \tag{2.3}$$

for $z=w$ we then obtain for u the representation:

$$\begin{aligned}u(x_0,t_0)=&\frac{e^{-t_0/(2\varepsilon)}}{2\sqrt{\varepsilon}}\iint_{K_-^\varepsilon(x_0,t_0)}e^{t/(2\varepsilon)}\mathscr{L}_\varepsilon(u)\,dx\,dt+\frac{e^{-t_0/(2\varepsilon)}}{8\varepsilon^{3/2}}\iint_{K_-^\varepsilon(x_0,t_0)}e^{t/(2\varepsilon)}u\,dx\,dt\\&+\frac{1}{2}\,e^{-t_0/(2\varepsilon)}\left[f\left(x_0+\frac{t_0}{\sqrt{\varepsilon}}\right)+f\left(x_0-\frac{t_0}{\sqrt{\varepsilon}}\right)\right]\\&+\frac{1}{2}\,e^{-t_0/(2\varepsilon)}\int_{x_0-t_0/\sqrt{\varepsilon}}^{x_0+t_0/\sqrt{\varepsilon}}\left[\frac{1}{2\sqrt{\varepsilon}}f(x)+\sqrt{\varepsilon}\,g(x)\right]dx,\end{aligned} \tag{2.4}$$

where $x_0\in\mathbb{R}$, $t_0>0$ and

$$K_-^\varepsilon(x_0,t_0)=\left\{(x,t)\in\mathbb{R}\times(0,\infty),\,|x-x_0|<\frac{t_0-t}{\sqrt{\varepsilon}}\right\}.$$

THEOREM 2.1. *Let* (1.7) *and* (1.10)-(1.13) *hold. Then there exist functions* $\phi_\varepsilon(x)$, $u_\varepsilon(x, t)$ *satisfying*

$$0 < c \leqq \phi_\varepsilon(x) \leqq \infty \quad \text{for some } c > 0 \quad (c \text{ independent of } \varepsilon); \tag{2.5}$$

$$\text{if } \phi_\varepsilon(x) \not\equiv \infty \text{ then } \phi_\varepsilon(x) < \infty \text{ for all } x \in \mathbb{R} \quad \text{and} \quad \frac{|\phi_\varepsilon(x) - \phi_\varepsilon(x')|}{|x - x'|} \leqq \sqrt{\varepsilon} \ \forall x, x'; \tag{2.6}$$

u_ε *is a solution of* (P_ε^1) *in the region*

$$\Omega_\varepsilon = \{(x, t) \in \mathbb{R} \times [0, \infty);\ y < \phi_\varepsilon(x)\}$$

and

$$u_\varepsilon \geqq 0, \tag{2.7}$$

$$u_\varepsilon(x, t) \to \infty \quad \text{if } t \to \phi_\varepsilon(x); \tag{2.8}$$

The pair $(\phi_\varepsilon, u_\varepsilon)$ *is uniquely determined.*

3. *Proof of Theorem* 2.1. Let

$$F_n(u) = \begin{cases} F(\min(u, n)) & \text{if } u > 0 \quad (n = 1, 2, \cdots) \\ F(0) & \text{if } u \leqq 0 \end{cases}$$

and denote by u_n the solution of (P_ε^1) corresponding to F_n. The corresponding $w = w_n$ satisfy:

$$w^n_{\tau\tau} - w^n_{xx} = F_n(w^n e^{-\tau/(2\sqrt{\varepsilon})})\, e^{\tau/(2\sqrt{\varepsilon})} + \frac{1}{4\varepsilon} w^n,$$

$$w^n(x, 0) = f(x), \tag{3.1}$$

$$w^n_\tau(x, 0) = \frac{1}{2\sqrt{\varepsilon}} f(x) + \sqrt{\varepsilon} g(x).$$

Using (1.11) in the representation (2.3) for w^n, we can deduce by a continuity argument that $w^n(x, t) \geqq 0$ for $x \in \mathbb{R}$ and all $t > 0$.

Next we apply the arguments in [4] to w^n to deduce that, for a subsequence $w_{n'}$, $w \equiv \lim w_{n'}$ exists if $0 \leqq \tau < \tilde{\phi}_\varepsilon(x)$ and $w \equiv \infty$ if $\tau > \tilde{\phi}_\varepsilon(x)$, and, if $\tilde{\phi}_\varepsilon \not\equiv +\infty$, $\tilde{\phi}_\varepsilon$ is Lipschitz continuous with coefficient 1. The last fact is based on the inequalities

$$w_\tau \geqq \pm w_x - c_0 \quad (c_0 \text{ constant})$$

whose proof is as in [4]. Next, instead of (1.22) in [4] we have

$$\frac{w_{n,\tau}}{F(w_n + C_0)} \leqq C \quad \text{for some } C_0 > 0,\ C > 0$$

and this implies (using the last condition in (1.10)) that

$$w(x, \tau) \to \infty \quad \text{it } \tau \to \tilde{\phi}_\varepsilon(x).$$

In view of (2.1), (2.2) we conclude that the corresponding subsequence $u_{n'}$ converge to u_ε which is finite if $t < \phi_\varepsilon(x)$ and $+\infty$ if $t > \phi_\varepsilon(x)$, where $\phi_\varepsilon(x) = \sqrt{\varepsilon}\tilde{\phi}_\varepsilon(x)$, and $u_\varepsilon(x, t) \to \infty$ if $t \to \phi_\varepsilon(x)$.

We have thus established (2.6)-(2.8). To prove the first inequality in (2.5) it suffices to establish the following lemma.

LEMMA 3.1. *There exist positive constants* M, T *independent of* n, ε *such that*

$$\sup_{\mathbb{R}^n \times (0, T)} u^n(x, t) \leqq M. \tag{3.2}$$

Proof. We compare u^n with the solution $\gamma(t)=\gamma_n(t)$ of

$$\begin{aligned} &\varepsilon\gamma''+\gamma'=F_n(\gamma), \\ &\gamma(0)=a, \\ &\gamma'(0)=F_n(a) \end{aligned} \tag{3.3}$$

where a is sufficiently large positive constant. The functions $z^n=u^n-\gamma_n$ satisfy:

$$\mathscr{L}_\varepsilon(z^n)=F_n(u^n)-F_n(\gamma_n)=c(x,t)z^n, \qquad c\geqq 0,$$

$$z^n(x,0)<0, \qquad z_t^n(x,0)\leqq 0.$$

Representing z^n by the integral formula (2.3) we can establish by continuity in t that $z^n(x,t)<0$ for all x, t. Thus in order to complete the proof of Lemma 3.1 it remains to prove:

$$\gamma_n(T)\leqq 2a \quad \text{for some } T \text{ independent of } n, \varepsilon. \tag{3.4}$$

To prove (3.4) we rewrite the differential equation for $\gamma=\gamma_n$ in the form

$$\varepsilon(e^{t/\varepsilon}\gamma')'=F_n(\gamma)\,e^{t/\varepsilon}\geqq 0.$$

Since $\gamma'(0)>0$, we deduce that $\gamma'(t)>0$ as long as $\gamma(t)$ is positive. Differentiating the equation in (3.3) once in t, we also have

$$\varepsilon(e^{t/\varepsilon}\gamma'')'=F_n'(\gamma)\gamma'\,e^{t/\varepsilon}\geqq 0$$

and, since $\gamma''(0)=0$, we deduce that $\gamma''(t)>0$ as long as $\gamma(t)>0$. It follows that $\gamma''(t)>0$ for all t. Therefore

$$\gamma'=F_n(\gamma)-\varepsilon\gamma''\leqq F(\gamma).$$

Defining T_n by $\gamma(T_n)=2a$, we conclude that

$$\tilde{T}\equiv\int_a^{2a}\frac{ds}{F_n(s)}=\int_0^{T_n}\frac{\gamma'(t)}{F(\gamma(t))}\leqq T_n.$$

Since $T_n\geqq\tilde{T}>0$ and $\tilde{T}$ is independent of n if n is large enough, the assertion (3.4) follows.

We have completed the proof of existence of a solution $(u_\varepsilon, \phi_\varepsilon)$. Uniqueness now follows by an easy argument; see [4] or [5] for details. (Note that for uniqueness we need not use the fact that c in (2.5) is independent of ε.)

As in [4] we can establish that u_ε is in $C^{2,1}$ in Ω_ε.

The following fact will be used in § 6.

THEOREM 3.2. *If in addition to the assumptions* (1.7), (1.10)-(1.13) *we also assume that* (1.14) *holds, then*

$$\frac{\partial u_\varepsilon}{\partial t}\geqq 0 \quad \text{in } \Omega_\varepsilon. \tag{3.5}$$

Proof. Set

$$z(x,\tau)=u_t^n(x,t)\,e^{t/(2\varepsilon)}, \qquad \tau=\frac{t}{\sqrt{\varepsilon}}. \tag{3.6}$$

Then

$$z_{\tau\tau} - z_{xx} = F_n'(u^n)z + \frac{1}{4\varepsilon} z,$$

$$z(x, 0) = g(x), \tag{3.7}$$

$$z_\tau(x, 0) = \frac{1}{2\sqrt{\varepsilon}} g(x).$$

Consider first the case where $g(x) \geqq \delta > 0$. Then representing z by an integral formula (2.3) and proceeding by continuity on τ, we can establish that $z(x, \tau) > 0$ for all x, τ. Applying this to (3.7) with $g \geqq 0$ replaced by $g + \delta$, and letting $\delta \to 0$, yields $z \geqq 0$ where z is given by (3.6), and (3.5) is then proved by taking $n \to \infty$. □

4. Additional estimates on u_ε.

LEMMA 4.1. *Assume that for some positive constants M, T the solution of (P_1^ε) (established in Theorem 1.1) satisfies*:

$$u_\varepsilon(x, t) \leqq M \quad \text{in } \mathbb{R} \times [0, T], \quad \text{for all small } \varepsilon. \tag{4.1}$$

Then there exists a positive constant C_1 independent of ε such that

$$u_\varepsilon(x, t) + |u_{\varepsilon,t}(x, t)| \leqq \frac{C_1}{(1+|x|)^\alpha} \quad \text{in } \mathbb{R} \times [0, T], \tag{4.2}$$

$$|u_{\varepsilon,x}| + |u_{\varepsilon,t}| + |u_{\varepsilon,xx}| + |u_{\varepsilon,tx}| + |u_{\varepsilon,xxx}| + |u_{\varepsilon,txx}| \leqq C_1 \quad \text{in } \mathbb{R} \times [0, T]. \tag{4.3}$$

Proof. Consider the function

$$W_\alpha(x, t) = \frac{e^{At}}{(1+x^2)^{\alpha/2}}, \quad A > 0.$$

For any A (no matter how large), if ε is small enough then

$$\mathscr{L}_\varepsilon W_\alpha \geqq \frac{A}{2} W_\alpha.$$

On the other hand

$$\mathscr{L}_\varepsilon u_\varepsilon = \tilde{F}(u_\varepsilon) u_\varepsilon \quad \left(\tilde{F}(v) = \frac{F(v)}{v}\right)$$

and therefore the function $z = W - u_\varepsilon$ satisfies

$$\mathscr{L}_\varepsilon z \geqq \frac{A}{2} W_\alpha - \tilde{F}(u_\varepsilon) u_\varepsilon \geqq \tilde{F}(u_\varepsilon) z \quad \text{if } t < T$$

provided we choose A such that $A > 2\tilde{F}(m)$. Noting that

$$z(x, 0) > 0, \qquad z_t(x, 0) > 0$$

if A is large, we can represent z by the integral representation (2.3) and then deduce by continuity on t, that $z \geqq 0$ if $t < T$. Thus

$$u_\varepsilon \leqq W_\alpha = \frac{e^{AT}}{(1+x^2)^{\alpha/2}}.$$

Similarly, from the equation

$$\mathscr{L}_\varepsilon(u_{\varepsilon,t}) = F'(u_\varepsilon) u_{\varepsilon,t}$$

and the fact that $|F'(u_\varepsilon)| \leqq F'(M)$ we can proceed as before to estimate $u_{\varepsilon,t}$ from above by the same function W (with a different constant A). The function $-u_{\varepsilon,t}$ is estimated similarly. Thus (4.2) is proved.

The function $u_{\varepsilon,x}$ is estimated similarly using the comparison function W_α with $\alpha = 0$.

Next we differentiate $\mathscr{L}_\varepsilon u_\varepsilon = F$ once in t and once in x and obtain

$$\mathscr{L}_\varepsilon u_{\varepsilon,tx} = F'(u_\varepsilon)u_{\varepsilon,tx} + F''(u_\varepsilon)u_{\varepsilon,t}u_{\varepsilon,x}.$$

Noting that

$$|F''(u_\varepsilon)u_{\varepsilon,t}u_{\varepsilon,x}| \leqq C,$$

we can proceed as before to compare $u_{\varepsilon,tx}$ with $W_0 \equiv e^{At}$ provided A is sufficiently large. We thus obtain the estimate

$$|u_{\varepsilon,tx}| \leqq C_1; \quad C_1 \text{ constant.}$$

Similarly we establish the estimate

$$|u_{\varepsilon,xx}| \leqq C_1.$$

Differentiating $\mathscr{L}(u_\varepsilon) = F$ three times and using the estimates derived so far, we can again compare $u_{\varepsilon,xxx}$ and $u_{\varepsilon,txx}$ with W_0 and thus complete the proof of (4.3). □

Remark 4.1. Lemma 4.1 implies that any sequence $\varepsilon \to 0$ has a subsequence such that

$$\begin{aligned} &u_\varepsilon \to u, \quad u_{\varepsilon,x} \to u_x, \quad u_{\varepsilon,xx} \to u_{xx} \\ &\text{uniformly in compact subsets of } \mathbb{R} \times [0, T]. \end{aligned} \tag{4.4}$$

However, we cannot establish the boundedness of $u_{\varepsilon,tt}$ by the method of Lemma 4.1 (since $u_{\varepsilon,ttt}(x, 0)$ is unbounded as $\varepsilon \to 0$), and thus we cannot assert that

$$u_{\varepsilon,t} \to u_t \quad \text{uniformly in compact subsets of } \mathbb{R} \times [0, T]. \tag{4.5}$$

LEMMA 4.2. *Under the assumption of Lemma* 4.1

$$u_\varepsilon(x, t) \to u(x, t), \qquad u_{\varepsilon,t}(x, t) \to u_t(x, t) \tag{4.6}$$

as $\varepsilon \to 0$, *uniformly in compact subsets of* $\mathbb{R} \times (0, T]$, *where u is a solution of* (1.1).

Proof. Multiplying $\mathscr{L}_\varepsilon(u_\varepsilon) = F(u_\varepsilon)$ by $e^{t/\varepsilon}$ and integrating in t we find that

$$u_{\varepsilon,t}(x, t_0) = \frac{1}{\varepsilon} e^{-t/\varepsilon} g(x) + \frac{1}{\varepsilon} e^{-t/\varepsilon} \int_0^t [u_{\varepsilon,xx}(x, s) + F(u_\varepsilon(x, s))]\, e^{s/\varepsilon}\, ds.$$

Set

$$H_\varepsilon = u_{\varepsilon,xx} + F(u_\varepsilon)$$

and write

$$\begin{aligned} u_{\varepsilon,t} &= \frac{1}{\varepsilon} e^{-t/\varepsilon} g(x) + \frac{1}{\varepsilon} \int_0^t [H_\varepsilon(x, s) - H(x, t)]\, e^{s/\varepsilon}\, ds + H_\varepsilon(x, t)[1 - e^{t/\varepsilon}] \\ &\equiv J_1^\varepsilon + J_2^\varepsilon + J_3^\varepsilon. \end{aligned} \tag{4.7}$$

Then

$$|J_1^\varepsilon| \leqq \frac{c}{\varepsilon} e^{-t/\varepsilon} \to 0$$

uniformly in $t \in [\delta, T]$.

Next, by Lemma 4.1, $|H_{\varepsilon,t}| \leqq C_0$ where C_0 is independent of ε. Hence

$$|J_2^\varepsilon| \leqq \frac{C_0}{\varepsilon} \int_0^t (t-s)\, e^{(s-t)/\varepsilon}\, ds$$

$$= C_0 \varepsilon \left[-\frac{t}{\varepsilon} e^{-t/\varepsilon} - e^{-t/\varepsilon} + 1 \right] \leqq C_0 \varepsilon.$$

Finally, by Remark 4.1, any sequence $\varepsilon \to 0$ has a subsequence such that (4.4) holds; therefore

$$J_3^\varepsilon \to u_{xx} + F(u).$$

Thus, by (4.7),

$$u_{\varepsilon,t} \to u_{xx} + F(u)$$

uniformly in compact subsets of $\mathbb{R} \times (0, T]$; the right-hand side must coincide with u_t (since $u_\varepsilon \to u$ uniformly) and thus u is a solution of (1.1).

Since u is also continuous up to $t = 0$ and $u(x, 0) = f(x)$, and since

$$|u| \leqq M \quad \text{by (4.1)},$$

u is uniquely determined [9; Chap. 2]. It follows that (4.6) (and (4.4)) hold for the full range of the parameter ε.

Consider now the parabolic equation

$$\begin{aligned} &u_t - u_{xx} = F(u), \\ &u(x, 0) = f(x), \end{aligned} \tag{4.8}$$

and set

$$N(t) \equiv \sup_{0<s<t} \sup_{x \in \mathbb{R}} u(x, t).$$

Then there exists a largest T_0 such that

$$N(t) < \infty \quad \forall\, t < T_0.$$

We assume that $T_0 < \infty$; T_0 is then called the *blow-up time* for (4.8).

LEMMA 4.3. *If the assumptions of Lemma* 4.1 *hold with* $T < T_0$, *then*

$$u_\varepsilon + |u_{\varepsilon,t}| \leqq A_T \quad \text{in } \mathbb{R} \times [0, T] \tag{4.9}$$

for all ε *sufficiently small, where*

$$A_T = \sup_{\mathbb{R} \times [0,T]} (u + |u_t|) + 1 \tag{4.10}$$

(*which is a positive constant independent of* M).

Proof. By Lemma 4.1, if ρ is sufficiently large then

$$u_\varepsilon(x, t) + |u_{\varepsilon,t}(x, t)| < 1 \quad \text{if } |x| > \rho,\ 0 \leqq t \leqq T.$$

On the other hand, if $|x| \leqq \rho$, $0 \leqq t \leqq T$ then, by (4.2) and Lemma 4.2, (4.9) holds provided ε is sufficiently small. □

5. lim inf $\phi_\varepsilon \geqq T_0$.

THEOREM 5.1. *Under the assumptions of Theorem* 2.1, *for any* $T_1 < T_0$, $\phi_\varepsilon(x) > T_1$ *for all* $x \in \mathbb{R}$ *provided* ε *is small enough, and*

$$u_\varepsilon \to u \text{ uniformly in } \mathbb{R} \times [0, T] \tag{5.1}$$

as $\varepsilon \to 0$.

Proof. From the proof of Theorem 2.1 we have that the conditions of Lemma 4.1 hold for some small T (see (3.2)). Lemma 4.3 thus implies that M in (4.1) can be replaced by the constant

$$A = \sup_{\mathbb{R}\times[0,T_1]} (u+|u_t|)+1,$$

provided ε is small enough.

Let $v(t)$ be the solution of

$$\begin{aligned} &\varepsilon v_{tt} + v_t = F(v), \\ &v(0) = A, \\ &v_t(0) = F(A). \end{aligned} \tag{5.2}$$

By (3.3), (3.4),

$$v(t) < 2A \quad \text{if } 0 < t \leq \sigma, \tag{5.3}$$

where σ is a positive constant independent of ε.

We wish to compare u_ε with $v(t-T+\delta)$ (for any $\delta > 0$) provided ε is sufficiently small (so that (4.9) is valid) in order to deduce that $u_\varepsilon(x, t)$ exist in $\mathbb{R}\times[0, \tilde{T}]$ for $\tilde{T} = T-\delta+\sigma$ (as long as $\tilde{T} \leqq T_1$), and

$$u_\varepsilon(x, t) \leqq \tilde{M} \quad \text{in } \mathbb{R}\times[0, \tilde{T}].$$

To do this we work with the solutions u^n of the truncated problems and proceed precisely as in the proof of Lemma 3.1, with $t=0$ replaced by $t = T-\delta$.

Since δ is arbitrary we deduce that the conditions of Lemma 4.1 hold with T replaced by $T+\sigma$. We can proceed in this way step-by-step until we reach the value $t = T_1$. □

COROLLARY 5.2. *Under the assumptions of Theorem* 2.1

$$\liminf_{\varepsilon\to 0} [\inf_x \phi_\varepsilon(x)] \geqq T_0. \tag{5.4}$$

6. lim sup $\phi_\varepsilon \leqq T_0$.

THEOREM 6.1. *Let the assumptions of Theorem* 2.1 *hold and assume also that* (1.14) *holds. Then, for any* $x \in \mathbb{R}$,

$$\limsup_{\varepsilon\to 0} \phi_\varepsilon(x) \leqq T_0. \tag{6.1}$$

Remark 6.1. Baras and Cohen [0] proved that if one approximates $F(u)$ in (1.1) by uniformly bounded smooth functions $F_n(u)$, then the corresponding solutions $u_n(x, t)$ converge to $+\infty$ for $t > T_0$. Theorem 6.1 is a somewhat analogous result for a different type of approximation, namely, for the solutions of (P_ε^1) as $\varepsilon \to 0$.

Proof. Suppose the assertion is not true. Then there exist $x_0 \in \mathbb{R}$ and $\delta > 0$ such that for a sequence $\varepsilon \to 0$,

$$\phi_\varepsilon(x_0) > T_0 + 2\delta.$$

By (2.6) we then get, for any $\rho > 0$,

$$\phi_\varepsilon(x) > T_0 + \delta \quad \forall x \in (-\rho, \rho), \tag{6.2}$$

provided ε is small enough.

From the definition of T_0 it follows that there is a sequence (x_n, η_n) with $\eta_n \downarrow 0$ such that

$$u(x_n, T_0 - \eta_n) \to \infty \quad \text{if } n \to \infty.$$

Choose any large positive constant M and let n_0 be such that

$$u_\varepsilon(x_{n_0}, T_0 - \eta_{n_0}) > M.$$

By Theorem 3.2, $u_\varepsilon(x, t)$ is monotone increasing in t and therefore

$$u_\varepsilon(x_{n_0}, t) > M \quad \text{if } T_0 - \eta_{n_0} \leqq t \leqq \phi_\varepsilon(x_{n_0}). \tag{6.3}$$

We choose ρ in (6.2) such that $\rho > |x_{n_0}| + 1$. Then

$$\phi_\varepsilon(x) > T_0 + \delta \quad \text{if } |x - x_{n_0}| \leqq 1. \tag{6.4}$$

Introduce the function

$$\psi(x) = \frac{\pi}{2} \sin \pi(x - x_{n_0}).$$

It satisfies

$$\begin{aligned} &\psi'' = -\pi^2 \psi, \quad \psi > 0 \quad \text{in } x_{n_0} < x < x_{n_0} + 1, \\ &\psi(x_{n_0}) = \psi(x_{n_0} + 1) = 0, \\ &\int_{x_{n_0}}^{x_{n_0}+1} \psi(x)\, dx = 1. \end{aligned} \tag{6.5}$$

Multiplying $\mathscr{L}_\varepsilon(u_\varepsilon) = F(u_\varepsilon)$ by ψ and integrating over $\{x_{n_0} < x < x_{n_0} + 1\}$, we find that the function

$$a(t) = \int_{x_{n_0}}^{x_{n_0+1}} u_\varepsilon(x, T_0 - \eta_{n_0} + t)\psi(x)\, dx$$

satisfies:

$$\varepsilon a'' + a' = -\pi^2 a + F(a) + [u_\varepsilon(x, T_0 - \eta_{n_0} + t)\psi_x(x)]_{x_{n_0}}^{x_{n_0+1}}.$$

Since

$$\psi_x(x_{n_0}) = -c < 0, \qquad \psi_x(x_{n_0} + 1) > 0,$$

it follows that

$$\varepsilon a'' + a' \geqq -\pi^2 a + F(a) + cM \tag{6.6}$$

where (6.3) was used; also

$$a(0) > 0, \quad a'(0) \geqq 0, \quad a'(t) \geqq 0. \tag{6.7}$$

□

LEMMA 6.2. *The solution $a(t)$ of* (6.6), (6.7) *blows up in time $t \leqq \delta$ provided M is sufficiently large and ε is sufficiently small.*

Assuming the lemma we conclude that

$$\phi_\varepsilon(x) < T_0 - \eta_{n_0} + \delta \quad \text{for some } x \in (x_{n_0}, x_{n_0+1}),$$

which is a contradiction to (6.4).

Proof of Lemma 6.2. Let $b(t)$ denote the solution of

$$\varepsilon b'' + b' = c_0(F(b) + M), \tag{6.8}$$

$$0 \leqq b(0) < a(0), \qquad b'(0) = a'(0) \tag{6.9}$$

where

$$c_0 = \min\left(\frac{1}{2}, \frac{c}{2}\right), \quad c \text{ as in (6.6).} \tag{6.10}$$

Writing (6.8) in the form

$$\varepsilon(e^{t/\varepsilon}b')' = c_0\, e^{t/\varepsilon}(F(b)+M) \geqq 0$$

we see that $b' \geqq 0$.

We claim that if M is large enough then, for any $\varepsilon > 0$,

$$b(t) \quad \text{blows up in time} \quad \leqq \delta. \tag{6.11}$$

Indeed, suppose $b(t)$ exists for all $t \leqq \delta$. We claim that there exists a t_0 such that

$$t_0 \in \left(0, \frac{\delta}{2}\right), \qquad b''(t_0) \geqq 0. \tag{6.12}$$

Indeed, otherwise we have

$$b''(t) < 0 \quad \forall t \in (0, \delta/2)$$

and therefore, by (6.8),

$$b' \geqq c_0(F(b)+M).$$

Hence

$$\int_0^{\delta/2} \frac{b'}{c_0(F(b)+M)} \geqq \frac{\delta}{2}.$$

But the left-hand side is bounded above by

$$\int_{a(0)}^{\infty} \frac{ds}{c_0(F(s)+M)}$$

which is $< \delta/2$ if M is sufficiently large; this is a contradiction.

Having proved (6.12), we differentiate (6.8) in t and obtain, after multiplying by $e^{t/\varepsilon}$,

$$\varepsilon(e^{t/\varepsilon}b'') = c_0\, e^{t/\varepsilon}F'(b)b' \geqq 0.$$

Using (6.12) we deduce that

$$b''(t) \geqq 0 \quad \text{if } t > t_0.$$

Hence

$$b'' + b' = c_0(F(b)+M) + (1-\varepsilon)b'' \geqq c_0(F(b)+M) \quad \text{if } t \geqq t_0.$$

Denoting by $\gamma(t)$ the solution of

$$\gamma'' + \gamma' = c_0(F(\gamma)+M), \quad \gamma(t_0) = b(t_0), \quad \gamma'(t_0) = b'(t_0), \tag{6.13}$$

we deduce that

$$\varepsilon(e^{t/\varepsilon}(b-\gamma)')' \geqq 0, \qquad (b-\gamma)(t_0) = (b-\gamma)'(t_0) = 0.$$

It follows that $b(t) \geqq \gamma(t)$. On the other hand, we can easily see that if M is sufficiently large then $\gamma(t)$ blows up in time $t \leqq t_0 + \gamma/2$. Therefore

$$b(t) \quad \text{blows up in time} \quad t < \delta. \tag{6.14}$$

To complete the proof of the lemma we compare $a(t)$ with $b(t)$. From (6.10) and (6.6), (6.8) we find that

$$\varepsilon(e^{t/\varepsilon}(a-b)')' \geqq c_0 F'(a-b)\, e^{t/\varepsilon}.$$

Also since $(a-b)(0)>0$, $(a-b)'(0)\geqq 0$, we easily deduce that $a(t)\geqq b(t)$ for all t for which $b(t)$ exists. It follows that $a(t)$ blows up in time $<\delta$.

7. Generalizations.

7.1. The results of this paper extend to the case where (1.7) is replaced by

$$g=f_{xx}+F(f)+\varepsilon h$$

provided h satisfies

$$|h(x)|\leqq \frac{C}{(1+|x|)^{\alpha}} \quad \text{for some } \alpha>0, \tag{7.1}$$

$$\sum_{i=1}^{3}|h^{(i)}(x)|\leqq C, \tag{7.2}$$

and

$$g\geqq 0. \tag{7.3}$$

These conditions ensure that (1.13) holds and that

$$\sum_{i=1}^{3}|D_x^i u_{tt}^{\varepsilon}(x,0)|\leqq M<\infty,$$

which is the only condition that $u_{tt}^{\varepsilon}(x,0)$ needed to satisfy in the previous analysis.

7.2. The results of this paper extend to the case where x is N-dimensional with $N=2$ or $N=3$, provided F, f and g satisfy the following additional conditions:

$$sF'(s)-F(s)\leqq 0 \quad \forall s\geqq 0, \tag{7.4}$$

$$\left(\frac{t}{2\varepsilon}+1\right)f(x)+tg(x)\geqq\frac{t}{\sqrt{\varepsilon}}|\nabla f(x)| \quad \forall t\geqq 0,\ x\in\mathbb{R}^N, \tag{7.5}$$

$$\begin{aligned}\frac{1}{2\sqrt{\varepsilon}}f(x)+\sqrt{\varepsilon}g(x)-\lambda|\nabla f(x)|+\frac{t}{\sqrt{\varepsilon}}\left[g(x)+\frac{1}{4\varepsilon}f(x)\right]-\lambda\left[\frac{1}{\sqrt{\varepsilon}}|\nabla f(x)|+\sqrt{\varepsilon}|\nabla g(x)|\right]\\ \geqq\frac{t}{\sqrt{\varepsilon}}|\nabla g(x)|+\lambda\frac{t}{\sqrt{\varepsilon}}|\nabla^2 f(x)| \quad \forall t\geqq 0,\ x\in\mathbb{R}^N\end{aligned} \tag{7.6}$$

where $\lambda>1$ (λ constant) (here $g=\Delta f+F(f)$). These conditions are satisfied if

$$F(s)=e^{\theta s}, \quad 0<\theta\leqq 1,$$

$$f(x)=A+f_1(x), \quad |D^{\alpha}f_1(x)|\leqq\frac{C}{(1+|x|)^{\beta}} \tag{7.7}$$

for $0\leqq|\alpha|\leqq 5$ and some $\beta>0$, and A is a sufficiently large positive constant.

Under these conditions the existence and uniqueness of a solution u_{ε} can be established using the formulation (P_{ε}^3) and the approximating sequence considered in [5]. Condition (7.5) ensures that $u_{\varepsilon}\geqq 0$. The existence of $\phi_{\varepsilon}(x)$ and (2.5), (2.6) result from the inequality

$$w_{\varepsilon,t}\geqq\lambda|\nabla w_{\varepsilon}|$$

which is proved using the extension of the representation formula (2.3) to N dimensions [5] and the conditions (7.4), (7.5). The results of §§ 4, 5 extend with minor changes to dimension N. Finally, in § 6 we need a stronger assumption than (1.14), namely,

$$g(x)\geqq\delta_0>0. \tag{7.8}$$

Using this we can prove as in [5] that $\exists \delta_1 > 0$ such that

$$u_{\varepsilon,t} \geqq \delta_1 |\nabla u_\varepsilon|.$$

This guarantees that, for any $t > T_0 + \sigma/2$ (σ arbitrarily small),

$$u_\varepsilon(x, t) > M \quad \text{for } x \text{ in a fixed ball } B \text{ of radius } \delta_1 \sigma/4.$$

Introducing the function

$$a(t) = \int_B u_\varepsilon\left(x, T_0 + \frac{\sigma}{4} + t\right) \psi(x)\, dx$$

where ψ is the principal eigenfunction of $-\Delta$ in B, $\psi > 0$ in B, $\int_B \psi = 1$, we again derive (6.6), (6.7), and conclude that $a(t)$ blows up in time $\leqq T_0 + \sigma$.

A STRONG MAXIMUM PRINCIPLE FOR A NONCOOPERATIVE ELLIPTIC SYSTEM*

GUIDO SWEERS†

Abstract. In this note it is shown that on a ball in $\mathbb{R}^N$, with $N>2$, a maximum principle holds for a special elliptic system. This system is such that the classical maximum principle is not applicable.

Key words. maximum principle, positive solutions, elliptic systems, Green's function

AMS(MOS) subject classifications. 35B50, 35J55

Introduction and results. A linear elliptic system

$$-\Delta u_\alpha + \sum_{\beta=1}^{k} h_{\alpha\beta} u_\beta = f_\alpha \quad \text{with } \alpha \in \{1, 2, \cdots, k\} \tag{1}$$

is called cooperative (see [3]) if

$$h_{\alpha\beta} \leqq 0 \quad \text{for } \alpha \neq \beta. \tag{2}$$

If, moreover,

$$\sum_{\beta=1}^{k} h_{\alpha\beta} \geqq 0 \quad \text{for } \alpha \in \{1, 2, \cdots, k\} \tag{3}$$

we can extend the results of the maximum principle to system (1) (see [4, p. 191]).

The motivation for this note was the question of whether or not the cooperative property is necessary for obtaining a maximum principle. Recent results for noncooperative systems have been obtained by De Figueiredo and Mitidieri [1], and Weinberger [5].

We consider an elliptic system, with Dirichlet boundary conditions, which is in some sense the simplest noncooperative system:

$$\begin{aligned} -\Delta u &= f_1 - \lambda v \quad \text{in } \Omega, \\ -\Delta v &= f_2 \quad \text{in } \Omega, \\ u &= v = 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{4}$$

where Ω is the unit ball in $\mathbb{R}^N$, $N>2$. The classical maximum principle gives the following positivity result, which is not uniform.

LEMMA 1. *Let $f_1, f_2 \in C^\gamma(\bar{\Omega})$ for some $\gamma>0$ with $f_1 \geqq 0$ and $f_1 \neq 0$. Then there is $\lambda(f_1, f_2)>0$ such that for all $\lambda \in [0, \lambda(f_1, f_2))$ the solution u_λ of (4) satisfies*

$$u_\lambda > 0 \quad \text{in } \Omega. \tag{5}$$

The classical maximum principle does not show that it is possible to find a uniform result for $f_2 \leqq f_1$. Nevertheless, we prove for

$$\begin{aligned} -\Delta u &= f - \lambda v \quad \text{in } \Omega, \\ -\Delta v &= f \quad \text{in } \Omega, \\ u &= v = 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{6}$$

the following theorem. (The same result holds for (4) if $f_2 \leqq f_1$ and $f_1 = f$.)

* Received by the editors November 30, 1987; accepted for publication (in revised form) June 15, 1988.
† Department of Mathematics and Informatics, Delft University of Technology, 2600 AJ Delft, the Netherlands.

THEOREM 2. (a) *There is a largest $\lambda_0 > 0$ for which the following holds. For all $(u, v) \in C^2(\bar{\Omega}) \times C^2(\bar{\Omega})$ satisfying* (6), *such that $\lambda < \lambda_0$, $f \geqq 0$ and $f \neq 0$, we find that*

$$u > 0 \quad \text{in } \Omega. \tag{7}$$

(b) $\lambda_0 \leqq (\lambda_1^{-1} + \lambda_2^{-1})^{-1} (< \lambda_1)$, *where λ_1, λ_2 are, respectively, the first and second eigenvalue of*

$$\begin{aligned} -\Delta\varphi &= \lambda\varphi \quad \text{in } \Omega, \\ \varphi &= 0 \quad \text{on } \partial\Omega. \end{aligned} \tag{8}$$

Remark 1. If $N = 1$ then

$$u(x) = \int_{-1}^{1} \frac{1}{2}(1 - |x-y| - xy)\left(1 - \frac{\lambda}{6}(2 + 2|x-y| - x^2 - y^2)\right) f(y)\, dy. \tag{9}$$

Since $\max\{\frac{1}{6}(2 + 2|x-y| - x^2 - y^2); -1 \leqq x, y \leqq 1\} = \frac{2}{3}$ we find that $\lambda_0 = 3/2 \leqq (\lambda_1^{-1} + \lambda_2^{-1})^{-1} = \pi^2/5 \approx 1.97$. A direct calculation shows that $(\lambda_1^{-1} + \lambda_2^{-1} + \lambda_3^{-1} + \cdots)^{-1} = 3/2$. I cannot explain this similarity.

Remark 2. Let H be a subspace of $C(\bar{\Omega})$ such that the inverse B of $-\Delta$, with zero Dirichlet boundary condition, into $C^2(\bar{\Omega})$ is well defined. Theorem 2(a) then shows that

$$B(I - \lambda B)f > 0 \quad \text{in } \Omega \tag{10}$$

for all $\lambda < \lambda_0$ and $f \in H$ with $f \geqq 0$, $f \neq 0$.

Remark 3. The classical maximum principle [4, Thm. 2.2] shows that $Bf > 0$ for f as in (10). If also $f(x_0) = 0$ for some $x_0 \in \Omega$, then

$$((I - \lambda B)f)(x_0) < 0 \quad \text{for all } \lambda > 0. \tag{11}$$

Remark 4. Consider the system

$$\begin{aligned} -\Delta u &= f - \lambda^2 v \quad \text{in } \Omega, \\ -\Delta v &= u \quad \text{in } \Omega, \\ u &= v = 0 \quad \text{on } \partial\Omega. \end{aligned}$$

Hence for B as in Remark 2 and $\lambda < \lambda_1$

$$u = \left(\sum_{k=0}^{\infty} (\lambda^4 B^4)^k\right)(I + \lambda B)(I - \lambda B)Bf.$$

If $\lambda < \lambda_0$ as well, then Theorem 2(a) together with the classical maximum principle shows that if $f \geqq 0, f \neq 0$ then $u > 0$ in Ω. Both this system and (6) cannot be uncoupled as in [1, Remark 1.7] to find a maximum principle. Recent results concerning [1, Remark 1.7] can be found in [5].

Remark 5. Let Ω be an arbitrary domain, and let φ_1, φ_2 be the first and second eigenfunctions of (8), respectively. Set $H = \{c_1\varphi_1 + c_2\varphi_2;\ c_1, c_2 \in \mathbb{R}\}$. We can prove that $B(I - \lambda B)$ from H into H is positive if and only if $\lambda \leqq \lambda_0 = (\lambda_1^{-1} + \lambda_2^{-1})^{-1}$. We can also hope that in general $\lambda_0 = (\sum \lambda_i^{-1})^{-1}$, with the summation over all eigenfunctions. However, direct but tedious computations show that with $\Omega = (0, 1)$ and $H = \{c_1\varphi_1 + c_2\varphi_2 + c_3\varphi_3;\ c_1 \in \mathbb{R}\}$ the following inequality holds:

$$\lambda_0 < (\lambda_1^{-1} + \lambda_2^{-1} + \lambda_3^{-1})^{-1}.$$

Proofs. Lemma 1 can be proved by a straightforward application of the classical strong maximum principle. Let φ_1 be the first eigenfunction of (8) with $\varphi_1 > 0$ in Ω. Since $v = 0$ on $\partial\Omega$ and $v \in C^2(\bar{\Omega})$, there is $c_1 > 0$ such that

$$v \leqq c_1 \varphi_1 \quad \text{in } \Omega. \tag{12}$$

Let $w \in C^2(\bar{\Omega})$ be the solution of

$$\begin{aligned} -\Delta w &= v \quad \text{in } \Omega, \\ w &= 0 \quad \text{on } \partial\Omega. \end{aligned} \tag{13}$$

The maximum principle, [4, Thm. 2.6], then shows that

$$w \leqq \frac{c_1}{\lambda_1} \varphi_1 \quad \text{in } \Omega. \tag{14}$$

Since $-\Delta(u + \lambda w) = f_1 \geqq 0$ and $f_1 \not\equiv 0$, the strong maximum principle [4, Thms. 2.6, 2.7] implies that $u + \lambda w > c_2 \varphi_1$ in Ω for some $c_2 > 0$. Hence,

$$u > c_2 \varphi_1 - \lambda w \geqq c_2 \varphi_1 - \lambda \frac{c_1}{\lambda_1} \varphi_1 \geqq 0 \quad \text{in } \Omega \text{ if } \lambda \leqq \lambda_1 \frac{c_2}{c_1}. \tag{15}$$

□

Proof of Theorem 2(a, b). Equations (6) can be rewritten as

$$\begin{aligned} u(x) &= \int_\Omega G(x, y)(f(y) - \lambda v(y))\, dy \\ &= \int_\Omega G(x, y)\left(f(y) - \lambda \int_\Omega G(y, z) f(z)\, dz\right) dy \\ &= \int_\Omega \left(G(x, y) - \lambda \int_\Omega G(x, z) G(z, y)\, dz\right) f(y)\, dy, \end{aligned} \tag{16}$$

where (see [2, eqs. (2.12), (2.13)]),

$$\begin{aligned} G(x, y) &= g_n(|x - y|^{2-n} - |(|y|x - |y|^{-1}y)|^{2-n}), \qquad y \neq 0, \\ G(x, 0) &= g_n(|x|^{2-n} - 1). \end{aligned} \tag{17}$$

The Euclidean norm is denoted by $|\cdot|$, and $g_n = (n(n-2)\omega_n)^{-1}$, where ω_n is the volume of the unit ball in $\mathbb{R}^N$.

To prove the theorem, it is sufficient to show that

$$M(x, y) := (G(x, y))^{-1} \int_\Omega G(x, z) G(z, y)\, dz < M \tag{18}$$

for some $M < \infty$. We then find that $u > 0$ for all $\lambda \leqq \lambda_0 = M^{-1}$.

We will prove (18) by direct computations.

To simplify the notations we set

$$(xy) = |x - y|, \qquad (XY) = |(|y|x - |y|^{-1}y)|, \text{ etc.}$$

Note that $(XY)=(|y|^2|x|^2-2(x,y)+1)^{1/2}=(YX)$, and hence

$$(XY)^2-(xy)^2=|y|^2|x|^2+1-|x|^2-|y|^2 \tag{19}$$
$$=(1-|x|^2)(1-|y|^2)>0 \quad \text{for } x,y\in\Omega,$$

$$(xy)^{-1}-(XY)^{-1}=\frac{(1-|x|^2)(1-|y|^2)}{(XY)+(xy)}(xy)^{-1}(XY)^{-1} \quad \text{for } x\neq y. \tag{20}$$

Using (17)-(20) we find that

$$g_n^{-1}M(x,y)=\int_\Omega \frac{((xz)^{2-n}-(XZ)^{2-n})((yz)^{2-n}-(YZ)^{2-n})}{(xy)^{2-n}-(XY)^{2-n}}\,dz$$
$$=\int_\Omega \frac{((xz)^{-1}-(XZ)^{-1}\sum_{k=0}^{n-3}(xz)^{3-n+k}(XZ)^{-k}}{((xy)^{-1}-(XY)^{-1})\sum_{k=0}^{n-3}(xy)^{3-n+k}(XY)^{-k}}$$
$$\cdot((yz)^{-1}-(YZ)^{-1})\sum_{k=0}^{n-3}(yz)^{3-n+k}(YZ)^{-k}\,dz$$
$$=\int_\Omega \frac{(1-|x|^2)(1-|z|^2)}{1+(xz)(XZ)^{-1}}\,\frac{1+(xy)(XY)^{-1}}{(1-|x|^2)(1-|y|^2)}\,\frac{(1-|y|^2)(1-|z|^2)}{1+(yz)(YZ)^{-1}}$$
$$\cdot\frac{(\sum_{k=0}^{n-3}(xz)^{2-n+k}(XZ)^{-2-k})(\sum_{k=0}^{n-3}(yz)^{2-n+k}(YZ)^{-2-k})}{\sum_{k=0}^{n-3}(xy)^{2-n+k}(XY)^{-2-k}}\,dz \tag{21}$$
$$=(xy)^{n-2}(XY)^2\left(\sum_{k=0}^{n-3}\left(\frac{(xy)}{(XY)}\right)^k\right)^{-1}\int_\Omega \frac{(1-|z|^2)^2(1+(xy)(XY)^{-1})}{(1+(xz)(XZ)^{-1})(1+(yz)(YZ)^{-1})}$$
$$\cdot\left(\sum_{k=0}^{n-3}\left(\frac{(xz)}{(XZ)}\right)^k\right)\left(\sum_{k=0}^{n-3}\left(\frac{(yz)}{(YZ)}\right)^k\right)(yz)^{2-n}(xz)^{2-n}(YZ)^{-2}(XZ)^{-2}\,dz$$
$$\leqq(xy)^{n-2}(XY)^2\int_\Omega(1-|z|^2)^2 2(n-2)^2(yz)^{2-n}(xz)^{2-n}(YZ)^{-2}(XZ)^{-2}\,dz.$$

Assume $x\neq y$ and split Ω in Ω_1 and Ω_2, where

$$\Omega_1=\{z\in\Omega;\,|x-z|<|y-z|\},\qquad \Omega_2=\{z\in\Omega;\,|x-z|>|y-z|\}.$$

If $|x-z|<|y-z|$, then $|y-z|\geqq|y-x|-|x-z|\geqq|y-x|-|y-z|$ and

$$|(|y|x-|y|^{-1}y)|\leqq|y||x-z|+|(|y|z-|y|^{-1}y)|$$
$$\leqq|y-z|+|(|y|z-|y|^{-1}y)|.$$

Hence

$$(xy)\leqq 2(yz), \quad \text{and} \tag{22}$$

$$(XY)\leqq 2(YZ) \quad \text{for } z\in\Omega_1. \tag{23}$$

By exchanging x and y, respectively X and Y, we find equivalent inequalities for $z\in\Omega_2$. Moreover,

$$(XZ)^2=|x|^2|z|^2-2(x,z)+1$$
$$\geqq|x|^2|z|^2-2|x||z|+1$$
$$=(1-|x||z|)^2$$
$$\geqq(1-|z|)^2\geqq\tfrac{1}{4}(1-|z|^2)^2 \quad \text{for } z\in\Omega. \tag{24}$$

Combining (21)-(24) yields

$$
\begin{aligned}
M(x,y) &\leqq 2(n-2)^2 g_n \left(\int_{\Omega_1} \left(\frac{1-|z|^2}{(XZ)} \right)^2 \left(\frac{(xy)}{(yz)} \right)^{n-2} \left(\frac{(XY)}{(YZ)} \right)^2 (xz)^{2-n}\, dz \right. \\
&\qquad \left. + \int_{\Omega_2} \left(\frac{1-|z|^2}{(YZ)} \right)^2 \left(\frac{(xy)}{(xz)} \right)^{n-2} \left(\frac{(XY)}{(XZ)} \right)^2 (yz)^{2-n}\, dz \right) \\
&\leqq 2^{n+3}(n-2)^2 g_n \left(\int_{\Omega_1} (xz)^{2-n}\, dz + \int_{\Omega_2} (yz)^{2-n}\, dz \right) \\
&< 2^{n+4}(n-2)^2 g_n \int_{2\Omega} |z|^{2-n}\, dz = 2^{n+5} \frac{(n-2)\omega_{n-1}}{n\omega_n},
\end{aligned} \tag{25}
$$

which completes the proof of Theorem 2(a).

To prove Theorem 2(b) let φ_1 and φ_2 be, respectively, the first and second eigenfunctions of (8), with $\varphi_1 > 0$ in Ω.

First note that $\lambda_0 \leqq \lambda_1$. Indeed, if $\lambda > \lambda_1$ then $u = \lambda_1^{-1}(1-\lambda/\lambda_1)\varphi_1$ is a solution of (6) with $f = \varphi_1 > 0$ in Ω, while $u < 0$ in Ω. Suppose $(\lambda_1^{-1}+\lambda_2^{-1})^{-1} < \lambda \leqq \lambda_1$ and let $c > 0$ be the largest constant such that

$$
\varphi_1 - c\varphi_2 \geqq 0 \quad \text{in } \Omega. \tag{26}
$$

Let U be the solution of (6) with $f = \varphi_1 - c\varphi_2$. Then

$$
U = \lambda_1^{-2}(\lambda_1 - \lambda)(\varphi_1 - c\varphi_2) - c(\lambda_1^{-2} - \lambda_2^{-2})(\lambda - (\lambda_1^{-1}+\lambda_2^{-1})^{-1})\varphi_2. \tag{27}
$$

If $\lambda = \lambda_1$ then U is negative somewhere in Ω since φ_2 changes sign. If $\lambda < \lambda_1$ then U is negative somewhere since c is the largest constant such that (26) holds, which is a contradiction. □

A SINGULAR PERTURBATION ANALYSIS OF REVERSE-BIASED SEMICONDUCTOR DIODES*

F. BREZZI†, A. C. S. CAPELO‡, AND L. GASTALDI§

Abstract. The one-dimensional equations of semiconductor devices are presented and studied here as a singular perturbation problem. It is shown that the limit problem, for reverse-biased devices, is a variational inequality of double obstacle type, which justifies, in some sense, the so-called total depletion assumption often used by engineers. It is also proven that the solution is unique if the value of the singular perturbation parameter is small enough.

Key words. semiconductors, singular perturbations

1. Introduction. The basic equations governing carrier transport in semiconductor devices are [10]:

$$\operatorname{div}(\varepsilon\nabla\psi) = -q(D-n+p) \quad \text{in } \Omega\times[0,T], \tag{1.1}$$

$$\frac{\partial p}{\partial t} = \operatorname{div}(D_p\nabla p + \mu_p p\nabla\psi) + R \quad \text{in } \Omega\times[0,T], \tag{1.2}$$

$$\frac{\partial n}{\partial t} = \operatorname{div}(D_n\nabla n - \mu_n n\nabla\psi) + R \quad \text{in } \Omega\times[0,T], \tag{1.3}$$

(1.4) suitable initial and boundary conditions,

where $\psi(t,x)$, the electric potential; $p(t,x)$, the concentration of positively charged holes; and $n(t,x)$, the concentration of negatively charged conduction electrons, are the unknowns. The function $D(x)$, the doping profile, is supposed to be known, as well as $\varepsilon(x)$, the permitivity of the semiconductor material. On the other hand, $\mu_p(\nabla\psi)$ and $\mu_n(\nabla\psi)$, the hole and electron mobilities, $D_p(\nabla\psi)$ and $D_n(\nabla\psi)$, the hole and the electron diffusion coefficients, and the generation-recombination term $R(p,n,\nabla\psi)$ are supposed to be known functions of $\nabla\psi$ and $p, n, \nabla\psi$, respectively. Finally q is the charge of the electron.

In the present paper we study a simplified version of (1.1)-(1.4). In particular:

(1) We consider a one-dimensional case: $\Omega =]-a, b[$ with $a, b > 0$.

(2) We assume ε, μ_p, μ_n, D_p, D_n to be constants.

(3) We consider the stationary case: $\partial p/\partial t = \partial n/\partial t = 0$.

(4) We neglect the generation-recombination term: $R \equiv 0$; this makes sense at least for reverse-biased devices, such as those we will consider.

(5) We assume $D(x)$ to be of the form

$$D(x) = D_0 \operatorname{sign} x, \qquad (D_0 > 0) \tag{1.5}$$

(in particular this implies that the junction is at $x=0$); in fact, to assume that $D(x) = D_1 < 0$ for $x < 0$ and $D(x) = D_2 > 0$ for $x > 0$ (which is far more realistic) would only complicate the notation, and would not change the results.

With assumptions (1)-(5), (1.1)-(1.3) can now be rewritten, after a suitable scaling, as follows:

$$\psi_s'' = -D_s + n_s - p_s \quad \text{in }]-a, b[, \qquad (\psi_s = \varepsilon\psi/qD_0;\ D_s = D/D_0), \tag{1.6}$$

$$(\lambda p_s' + p_s\psi_s')' = 0 \quad \text{in }]-a, b[, \qquad (p_s = p/D_0), \tag{1.7}$$

$$(\lambda n_s' - n_s\psi_s')' = 0 \quad \text{in }]-a, b[, \qquad (n_s = n/D_0). \tag{1.8}$$

Note that the same λ appears in (1.7) and (1.8) because we assume Einstein's relations

$$D_p/\mu_p = D_n/\mu_n = kT/q \tag{1.9}$$

hold (here k is the Boltzmann constant and T is the absolute temperature). The dependence of λ on the other physical quantities is given by

$$\lambda = \varepsilon kT/q^2 D_0, \tag{1.10}$$

which shows that $[\lambda]$ = square meters. For a piece of silicon at room temperature and a doping $D_0 = 10^{23}/\text{m}^3$, (1.10) gives $\lambda \simeq 10^{-16}\,\text{m}^2$. Let d be the actual length of the device (a typical value would be $d = 10^{-5}$ m). By scaling the domain to one, we obtain $\lambda/d^2 \simeq 10^{-16}\,(\text{m}/d)^2$, which is now a good dimensionless "stiffness parameter." From now on we will assume that d is used as the unit for length. In particular, $b + a = 1d$. Hence, a typical value for λ would be $\lambda \simeq 10^{-6}\,d^2$. Note that equations (1.6)-(1.8) are not dimensionless. In particular, $[\psi_s] = [d^2] = L^2$, $[p_s] = [1]$, $[n_s] = [1]$, and $[x] = [d] = L$.

It is natural to ask what is the limit of the solutions of (1.6)-(1.8) (with suitable boundary conditions) as λ/d^2 goes to zero. This has been done previously [2]-[4] with some additional simplifications. In particular, in [2] and [4] the unipolar case (say $D_s \equiv -1$ and $n_s \equiv 0$) has been studied for one-dimensional and two-dimensional domains (respectively), while in [3] the full set of three equations has been considered (in one dimension) but with simplified boundary conditions. In the present paper we consider the limit of (1.6)-(1.8) for λ/d^2 going to zero with more realistic boundary conditions. More precisely, the physical boundary conditions are given (before scaling) by

$$p(-a) = D_0(1+\beta), \qquad p(b) = D_0\beta, \tag{1.11}$$

$$n(-a) = D_0\beta, \qquad n(b) = D_0(1+\beta), \tag{1.12}$$

$$\psi(-a) = -V - \frac{kT}{2q}\log\frac{1+\beta}{\beta}, \qquad \psi(b) = V + \frac{kT}{2q}\log\frac{1+\beta}{\beta}. \tag{1.13}$$

Here the externally applied potential is assumed to be $-V$ *at* $x = -a$ and V at $x = b$ (reverse bias). In (1.11)-(1.13) β is the solution of

$$\beta(1+\beta) = \nu_i^2 = n_i^2/D_0^2 \tag{1.14}$$

with

$$n_i = 2(2\pi kT/h^2)^{3/2}(m_n m_p)^{3/4}\, e^{-W_f/2kT} \tag{1.15}$$

(h is Planck's constant, m_n and m_p are the effective mass of an electron and hole, respectively, and W_f is the width of the semiconductor forbidden band). After scaling, (1.11)-(1.13) become

$$p_s(-a) = 1+\beta, \qquad p_s(b) = \beta, \tag{1.16}$$

$$n_s(-a) = \beta, \qquad n_s(b) = 1+\beta, \tag{1.17}$$

$$\psi_s(-a) = -\bar{\psi} = -\alpha - \gamma, \qquad \psi_s(b) = \bar{\psi} = \alpha + \gamma, \tag{1.18}$$

with

$$\alpha = \frac{\varepsilon}{qD_0} V, \qquad \gamma = \frac{\lambda}{2} \log \frac{1+\beta}{\beta}. \tag{1.19}$$

In [3] the simplified boundary conditions

$$p_s(-a) = 1, \qquad p_s(b) = 0, \tag{1.20}$$

$$n_s(-a) = 0, \qquad n_s(b) = 1, \tag{1.21}$$

$$\psi_s(-a) = -\alpha, \qquad \psi_s(b) = \alpha \tag{1.22}$$

were assumed instead of (1.16)-(1.18).

If we want to study the limit of the problem (1.6)-(1.8) plus (1.16)-(1.18) for λ going to zero, we should express the dependence on λ of the boundary conditions (1.16)-(1.18) as well. Let us look again at (1.10). Since it is not reasonable to assume that k, ε, or q can change, we may think either the temperature T goes to zero or the doping D_0 goes to infinity. At first sight perhaps the second possibility looks physically more appealing, but it has the drawback that D_0 also enters in the scaling so that in the end we would not clearly understand the significance of the limit problem for the original unscaled variables. The first possibility does not have this drawback, and therefore we choose to let the *temperature* go to zero both in (1.10) (as was done first in [2] and then in [1], [3]) and in (1.15). Still we point out explicitly that the limit for $T \to 0$ has to be understood as just a mathematical "trick" in order to have better insight into the qualitative behavior of the solutions for the *physical* value of λ (or, rather λ / d^2), which is actually very small.

If we assume that the variable parameter in (1.10) is the temperature T, we can then express the behavior of the boundary conditions (1.16)-(1.18) as a function of λ as follows:

$$\beta = \tfrac{1}{2}(\sqrt{1+4B\lambda^3 e^{-A/\lambda}} - 1), \tag{1.23}$$

$$\gamma = \frac{\lambda}{2} \log (\sqrt{1+4B\lambda^3 e^{-A/\lambda}} + 1)/(\sqrt{1+4B\lambda^3 e^{-A/\lambda}} - 1), \tag{1.24}$$

with

$$A = W_f \varepsilon / q^2 D_0, \tag{1.25}$$

$$B = 4D_0(2\pi q^2/h^2\varepsilon)^3 (m_n m_p)^{3/2}. \tag{1.26}$$

Note that A is the scaled value of the potential difference associated with the energy gap between valence and conduction band, which is a kind of built-in potential at 0°K.

In the present paper we study the limit for $\lambda \to 0$ of (1.6)-(1.8) with the boundary conditions (1.16)-(1.18) and the relations (1.23)-(1.24). We show that as $\lambda \to 0$ the solutions of this problem tend to the solution of the double obstacle problem: find $\psi_0 \in C^1([-a, b])$ such that

$$\psi_0(-a) = -(\alpha + A/2), \qquad \psi_0(b) = \alpha + A/2, \tag{1.27}$$

$$-(\alpha + A/2) \leqq \psi_0 \leqq \alpha + A/2 \quad \text{in }]-a, b[, \tag{1.28}$$

$$\psi_0'' \geqq -D_s(x) \quad \text{when } \psi_0 > -(\alpha + A/2), \tag{1.29}$$

$$\psi_0'' \leqq -D_s(x) \quad \text{when } \psi_0 < \alpha + A/2. \tag{1.30}$$

Moreover, p_0 and n_0 are then the characteristic functions of the sets $\{\psi_0 = -\alpha - A/2\}$ and $\{\psi_0 = \alpha + A/2\}$, respectively. In some sense this justifies the so-called "total depletion assumption," which is often used for reverse-biased devices.

We also show that the solution of (1.6)-(1.8) plus (1.16)-(1.18) is unique for λ small enough. To our knowledge, three techniques are available for proving the uniqueness of the solution of this problem.

(1) For λ big enough, the nonlinearity of (1.7)-(1.8) becomes negligible and the uniqueness of the solution is trivial. However, this case is physically unreasonable.

(2) For α small enough we have a small perturbation of the nonlinear problem $\psi_s'' = -D_s(x) - \nu_i e^{-\psi_s/\lambda} + \nu_i e^{\psi_s/\lambda}$ that is of monotone type. This approach is followed, for instance, in [9]. See also [7] for additional references.

(3) For λ small enough, we can take advantage of the uniqueness of the limit for $\lambda \to 0$ of the solutions of the problem itself. This approach has been followed in [3] for the simplified boundary conditions.

Here the result is proved for the physical boundary conditions. However, we point out that uniqueness is not expected to hold in more general two-dimensional cases.

Finally, we remark that, although the difference between the simplified boundary conditions (1.20)-(1.22) and the physical ones (1.16)-(1.18) is very small (of order 10^{-10} or less for silicon at room temperature, for example), the qualitative behavior of the solutions changes. For instance, with the simplified boundary conditions we have, in general, $\psi_s'(-a) < 0$ and $\psi_s'(b) < 0$, while with the physical boundary conditions we have $\psi_s'(x) > 0$ everywhere. Similarly, we have $J_p := (\lambda p_s' + p_s \psi_s') < 0$ with the simplified boundary conditions and $J_p > 0$ with the "true" boundary conditions.

For a different scaling and a different asymptotic analysis see, for instance, [6], [7], and the references therein. For an analysis of the present scaling in some time-dependent problems, see [8].

2. An existence theorem. For the reader's convenience we rewrite the full problem in its scaled version here. We delete the subscript s.

PROBLEM 1. Given the positive constants a, b, λ, α, A, and B, find functions ψ, p, and n such that

$$\psi'' = -\operatorname{sign} x - p + n \quad \text{in }]-a, b[, \tag{2.1}$$

$$|(\lambda p' + p\psi')' = 0 \quad \text{in }]-a, b[, \tag{2.2}$$

$$(\lambda n' - n\psi')' = 0 \quad \text{in }]-a, b[, \tag{2.3}$$

$$\psi(-a) = -\bar{\psi}, \qquad \psi(b) = \bar{\psi}, \tag{2.4}$$

$$p(-a) = 1 + \beta, \qquad p(b) = \beta, \tag{2.5}$$

$$n(-a) = \beta, \qquad n(b) = 1 + \beta \tag{2.6}$$

where

$$\bar{\psi} = \alpha + \frac{\lambda}{2} \log \frac{1+\beta}{\beta}, \tag{2.7}$$

and β is the positive solution of

$$\beta(1+\beta) = B\lambda^3 e^{-A/\lambda} =: \nu_i^2. \tag{2.8}$$

In the following we use, as an abbreviation, the notation

$$D(x) = -\operatorname{sign} x. \tag{2.9}$$

We also introduce the so-called Slotboom variables:

$$\rho(x) = p(x) \exp[(\psi - \bar{\psi})/\lambda], \tag{2.10}$$

$$\sigma(x) = n(x) \exp[-(\bar{\psi} + \psi)/\lambda]. \tag{2.11}$$

We use them at once to show some interesting properties of the solutions of Problem 1 (if any exist). Substituting (2.10) and (2.11) into (2.2),(2.5) and (2.3),(2.6), respectively, we get

$$(\exp[-(\psi-\bar{\psi})/\lambda]\rho')'=0, \quad \rho(-a)=\beta\exp(-2\alpha/\lambda), \quad \rho(b)=\beta, \tag{2.12}$$

$$(\exp[(\psi+\bar{\psi})/\lambda]\sigma')'=0, \quad \sigma(-a)=\beta, \quad \sigma(b)=\beta\exp(-2\alpha/\lambda). \tag{2.13}$$

From this and the maximum principle we obtain

$$\beta\exp(-2\alpha/\lambda)\leqq\rho\leqq\beta, \tag{2.14}$$

$$\beta\exp(-2\alpha/\lambda)\leqq\sigma\leqq\beta, \tag{2.15}$$

and moreover it follows that ρ is a nondecreasing function and σ is a nonincreasing function. Finally, from (2.10)-(2.15) we obtain the well-known properties (see, e.g. [9], [11])

$$\beta(\beta+1)\exp(-2\alpha/\lambda)\leqq pn=\rho\sigma\exp(2\bar{\psi}/\lambda)\leqq\beta(\beta+1)\exp(2\alpha/\lambda) \tag{2.16}$$

and

$$p>0, \qquad n>0, \tag{2.17}$$

which are the properties we mentioned above. Let us remark also that solving (2.2) and (2.3) for p and n, using the boundary conditions (2.4)-(2.6), we get, respectively,

$$p(x)=\exp[(\bar{\psi}-\psi)/\lambda]\beta\left\{e^{-2\alpha/\lambda}\int_x^b e^{\psi/\lambda}\Big/\int_{-a}^b e^{\psi/\lambda}+\int_{-a}^x e^{\psi/\lambda}\Big/\int_{-a}^b e^{\psi/\lambda}\right\}, \tag{2.18}$$

$$n(x)=\exp[(\bar{\psi}+\psi)/\lambda]\beta\left\{e^{-2\alpha/\lambda}\int_{-a}^x e^{-\psi/\lambda}\Big/\int_{-a}^b e^{-\psi/\lambda}+\int_x^b e^{-\psi/\lambda}\Big/\int_{-a}^b e^{-\psi/\lambda}\right\} \tag{2.19}$$

and then we can write (2.2) and (2.3) in the form

$$\lambda p'+p\psi'=:C_p=\lambda\nu_i(e^{\alpha/\lambda}-e^{-\alpha/\lambda})\Big/\int_{-a}^b e^{\psi/\lambda}, \tag{2.20}$$

$$\lambda n'-n\psi'=:C_n=\lambda\nu_i(e^{-\alpha/\lambda}-e^{\alpha/\lambda})\Big/\int_{-a}^b e^{-\psi/\lambda}. \tag{2.21}$$

With these preliminaries we outline the proof of the following well-known result (see, for instance, [5], [7]).

THEOREM 1. *For every $\lambda>0$ there exists at least one solution $\{\psi, p, n\}$ of Problem* 1.

Proof. Let

$$\chi=(1+\sqrt{1+4\nu_i^2\exp(2\alpha/\lambda)})/2 \tag{2.22}$$

be the maximum root of the second-degree equation

$$\chi^2-\chi-\nu_i^2e^{2\alpha/\lambda}=0 \tag{2.23}$$

and consider the set

$$K_\chi=\{(p, n): 0\leqq p\leqq\chi, 0\leqq n\leqq\chi\}\subset(L^\infty(-a, b))^2. \tag{2.24}$$

Now we define on K_χ a mapping $T:(p, n)\to(\bar{p}, \bar{n})$ in the following way. For fixed $(p, n)\in K_\chi$ let Ψ be the solution of

$$\Psi''=D-p+n \quad \text{in }]-a, b[, \quad \Psi(-a)=-\bar{\psi}, \quad \Psi(b)=\bar{\psi}, \tag{2.25}$$

and then let P and N be the solution of

$$\lambda P''+P'\Psi'+P\Psi''=0 \quad \text{in }]-a, b[, \quad P(-a)=1+\beta, \quad P(b)=\beta, \tag{2.26}$$

$$\lambda N''-N'\Psi'-N\Psi''=0 \quad \text{in }]-a, b[, \quad N(-a)=\beta, \quad N(b)=1+\beta \tag{2.27}$$

(which are given explicitly by (2.18) and (2.19), respectively, with Ψ in the place of ψ). Now let us set

$$\bar{p}=\min(\chi, P), \qquad \bar{n}=\min(\chi, N). \tag{2.28}$$

This defines the operator T. Obviously, T maps K_χ into itself. On the other hand, T is compact and therefore has a fixed point. Let $(\tilde{p}, \tilde{n})$ be such a fixed point and $\tilde{\psi}$ the corresponding solution of (2.1). To prove that $(\tilde{p}, \tilde{n}, \tilde{\psi})$ is a solution of Problem 1, it is enough to show that the corresponding functions $\tilde{P}$, $\tilde{N}$ satisfy $\tilde{P}\leqq\chi$, $\tilde{N}\leqq\chi$. Suppose to the contrary that, e.g., $\tilde{P}$ has a maximum $\tilde{P}(\bar{x})>\chi$ at $\bar{x}\in]-a, b[$. Then $\tilde{P}''(\bar{x})\leqq 0$, $\tilde{P}'(\bar{x})=0$, and from (2.26) it follows that $\tilde{P}(\bar{x})\tilde{\Psi}''(\bar{x})\geqq 0$, so that $\tilde{\Psi}''(\bar{x})\geqq 0$. Now

$$\begin{aligned} 0\leqq\tilde{\Psi}''(\bar{x}) &= D(\bar{x})-\tilde{p}(\bar{x})+\tilde{n}(\bar{x}) \\ &\leqq 1-\chi+\tilde{N}(\bar{x})\leqq 1-\chi+\nu_i^2\, e^{2\alpha/\lambda}/\tilde{P}(\bar{x})<1-\chi+\nu_i^2\, e^{2\alpha/\lambda}/\chi \end{aligned} \tag{2.29}$$

(where we have used the fact that $\tilde{P}$ and $\tilde{N}$ satisfy (2.16)), and this contradicts the definition of χ. □

Finally, let us note, as follows from (2.1), (2.18), and (2.19), that any solution of Problem 1 is of class C^1 in $]-a, b[$ and analytic in $]-a, 0[$ and in $]0, b[$.

3. Qualitative properties of the solutions. In this section we will study some qualitative properties of the solutions of Problem 1. The objective is twofold. On the one hand, we want to know the behavior of p, n, and ψ, which is of interest in itself, and on the other hand, the results obtained in this section will be used to prove an important a priori estimate in the next section.

PROPOSITION 1. *Let $\bar{x}\in[-a, b]$, $\bar{x}\neq 0$. Then the following two assertions hold:*

(a) *If $p(\bar{x})-D(\bar{x})<n(\bar{x})$, then $p-D$ cannot have a minimum at $\bar{x}$ and n cannot have a maximum at $\bar{x}$.*

(b) *If $p(\bar{x})-D(\bar{x})>n(\bar{x})$, then $p-D$ cannot have a maximum at $\bar{x}$ and n cannot have a minimum at $\bar{x}$.*

Proof. The result is an easy consequence of the maximum principle applied to (2.2) and (2.3). □

Remark 1. Let $\bar{x}\in[-a, b]$. If $p(\bar{x})-D(\bar{x}-)<n(\bar{x})$ and $p'(\bar{x})=0$, then p cannot be decreasing in a left neighborhood of $\bar{x}$. To see this it is enough to calculate $\lim_{x\to\bar{x}-} p''(x)$. Mutatis mutandis we can state and prove several similar results (with n instead of p, $>$ instead of $<$ and $\bar{x}+$ instead of $\bar{x}-$). □

Now let us define the following two functions:

$$M(x)=\max(p-1, n) \quad \text{in } [-a, 0], \tag{3.1}$$

$$m(x)=\min(p-1, n), \quad \text{in } [-a, 0]. \tag{3.2}$$

PROPOSITION 2. *M has no maxima and m has no minima in $]-a, 0[$.*

Proof. Let us suppose that M has a maximum at $\bar{x}\in]-a, 0[$. From Proposition 1, it follows at once that $p(\bar{x})-1=n(\bar{x})$ and therefore $M(\bar{x})=m(\bar{x})$. On the other

hand, we will have also $M'(\bar{x}) = m'(\bar{x}) = 0$ and $p'(\bar{x}) = n'(\bar{x}) = 0$. From this and (2.1)-(2.3), we infer that $p''(\bar{x}) = n''(\bar{x}) = 0$. Now, taking successive derivatives of (2.1)-(2.3), we conclude that all the derivatives of p and n vanish at $\bar{x}$. Since p and n are analytic we have $p = 1+\beta$ and $n = \beta$ in $[-a, 0]$. Note that in this case we have $\psi''(0-) = 0$. On the other hand, since $p(x)$ and $n(x)$ are continuous at 0, (2.1) implies $\psi''(0+) = -2$, so that, from (2.2) and (2.3), $p''(0+) > 0$ and $n''(0+) < 0$. Then in $[0, b]$ $p - D$ is increasing near zero and n is decreasing near zero. Since $p - D = 2+\beta$ and $n = \beta$ at 0+ while $p - D = 1+\beta = n$ at b, we would contradict Proposition 1 in $[0, b]$. The same reasoning shows that m cannot have a minimum in $]-a, 0[$. □

PROPOSITION 3. *ψ satisfies $\psi'(-a) > 0$ and $\psi'(b) > 0$.*

Proof. The proofs of the two assertions are similar. Let us prove the first one. Assume to the contrary that $\psi'(-a) \leqq 0$. Equations (2.20) and (2.21) imply that $p'(-a) > 0$ and $n'(-a) < 0$. Then $M = p - 1$ and $m = n$ in $[-a, 0]$ and for every $x \in [-a, 0]$ we have $M'(x) > 0$ and $m'(x) < 0$ (otherwise Proposition 1 or Remark 1 would be contradicted). Hence $p - D > 2+\beta$ at 0+, with $p'(0) > 0$, $n'(0) < 0$, and $p(0) - 1 > n(0)$. This is impossible because of Proposition 1 and $p - D = 1+\beta$ at b. □

PROPOSITION 4. *If m is decreasing in $[-a, 0]$, then $z := n - p + 1 > 0$ in $]-a, 0]$.*

Proof. To the contrary assume first that z has a negative minimum at $\bar{x} \in]-a, 0[$. Hence we have $z(\bar{x}) < 0$, $z'(\bar{x}) = 0$, and $z''(\bar{x}) \geqq 0$. Since $z'(\bar{x}) = 0$ we have $n'(\bar{x}) = p'(\bar{x})$ and, since $m(x)$ is decreasing, $n'(\bar{x}) = p'(\bar{x}) \leqq 0$. Inserting this in (2.20) we get $\psi'(\bar{x}) > 0$. Now, subtracting (2.3) from (2.2), we get

$$-\lambda z'' + (p' + n')\psi' + (p + n)z = 0, \tag{3.3}$$

which is impossible. Now assume that z has a zero minimum at $\bar{y} \in]-a, 0[$. Hence we have $z(\bar{y}) = 0$, $z'(\bar{y}) = 0$, and $z''(\bar{y}) \geqq 0$, and therefore $p'(\bar{y}) = n'(\bar{y}) \leqq 0$ and $\psi'(\bar{y}) > 0$. Because of (3.3), $z''(\bar{y}) = 0$ and $p'(\bar{y}) = n'(\bar{y}) = 0$. This implies, according to the reasoning given in the proof of Proposition 2, that $p = 1+\beta$ and $n = \beta$ in $]-a, 0[$, which is impossible. Hence we have shown that z cannot have a nonpositive minimum in $]-a, 0[$. To conclude the proof we must show that $z(0) > 0$. Let us assume that this is not true, i.e., $z(0) \leqq 0$, that is $n(0) \leqq p(0) - 1$ and $z(0) < z(x)$ for all $x \in [-a, 0]$. This and the hypothesis on m imply that $n(0) < \beta$ and $n'(0) \leqq 0$, which contradicts Propositions 1 and 2 (or Remark 1) because $p(0+) - D(0+) > 2 > n(0+)$ and $n(b) = p(b) - D(b) = 1+\beta$. □

PROPOSITION 5. *If m is decreasing in $[-a, 0]$ then we have the following:*

(i) *$m = p - 1 < M = n$ in $]-a, 0]$;*

(ii) *$m = p - 1$ is strictly decreasing in $[-a, 0]$;*

(iii) *$M = n$ has at most one minimum (and here $n < \beta$) in $]-a, 0]$;*

(iv) *If there exists $\bar{x} \in]-a, 0]$ such that $n(\bar{x}) > \beta$, then $n'(\bar{x}) > 0$.*

Proof. Assertions (i) and (ii) follow from Proposition 4 and the hypothesis. Assertion (iii) follows from Proposition 2. Finally Proposition 1 (or Remark 1) gives (iv). □

Analogous results hold in $[0, b]$ for the functions

$$\bar{M}(x) = \max(p, n - 1) \quad \text{in } [0, b], \tag{3.4}$$

$$\bar{m}(x) = \min(p, n - 1) \quad \text{in } [0, b]. \tag{3.5}$$

More precisely we have the following propositions.

PROPOSITION 6. *If $\bar{m}$ is increasing in $[0, b]$, then $z := n - p - 1 < 0$ in $[0, b[$.*

PROPOSITION 7. *If $\bar{m}$ is increasing in $[0, b]$, then we have the following:*

(i) *$\bar{m} = n - 1 < \bar{M} = p$, in $[0, b[$;*

(ii) *$\bar{m} = n - 1$ is strictly increasing in $[0, b]$;*

(iii) *$\bar{M} = p$ has at most one minimum (and here $p < \beta$) in* $[0, b[$;

(iv) *If there exists $\bar{y} \in [0, b[$ such that $p(\bar{y}) > \beta$, then $p'(\bar{y}) < 0$.*

We now verify the hypotheses on m and $\bar{m}$.

PROPOSITION 8. *The function m is decreasing in* $[-a, 0]$.

Proof. If m is not decreasing, we must have $m'(-a) \geqq 0$ by Proposition 2. Hence $p'(-a) \geqq 0$ and $n'(-a) \geqq 0$. Now, adding (2.20) and (2.21), we get

$$\lambda(p' + n') = C_p + C_n + (n - p)\psi'. \tag{3.6}$$

This yields, for $x = -a$,

$$\lambda(p'(-a) + n'(-a)) = C_p + C_n - \psi'(-a) \geqq 0 \tag{3.7}$$

so that, by Proposition 3,

$$C_p + C_n > 0. \tag{3.8}$$

On the other hand, (3.6) for $x = b$ yields

$$\lambda(p'(b) + n'(b)) = C_p + C_n + \psi'(b) > 0, \tag{3.9}$$

from which it follows that $p'(b) > 0$ and/or $n'(b) > 0$, so that $\bar{m}'(b) > 0$. Hence, again by the obvious analogy of Proposition 2, $\bar{m}$ is increasing in $[0, b]$, so that, by Proposition 7, $n - 1 = \bar{m} < \bar{M} = p$ in $[0, b[$ and n is strictly increasing in $[0, b]$. Now, let us consider the two following cases: (I) m is increasing in $[-a, 0]$; (II) m has a maximum at $\bar{x} \in]-a, 0[$. Next we prove that both (I) and (II) are impossible, and in this way we prove the proposition. In fact, (I) implies that M is increasing in $[-a, 0]$ also; hence $p'(x) \geqq 0$ and $n'(x) \geqq 0$ in $[-a, 0]$, so that $p(0) - 1 > \beta$ and $n(0) > \beta$. Then $\bar{M}'(0) \geqq 0$ and $\bar{M}(0) > \beta + 1$. On the other hand, $\bar{M}(b) = \beta$, so that $\bar{M}$ has a maximum in $[0, b[$, which contradicts Proposition 2. Let us consider case (II) now. If m has a maximum at $\bar{x} \in]-a, 0[$, then M is increasing in $[-a, 0]$ and m is decreasing in $[\bar{x}, 0]$, with $m'(x) < 0$ and $M'(x) > 0$ in $]\bar{x}, 0]$ (see Remark 1). Moreover, $m = p - 1$ in $[\bar{x}, 0]$, since otherwise $\bar{M}$ would have a maximum. Summing up, we can say that: (1) $n' > 0$ and $\beta < n < 1 + \beta$ in $]\bar{x}, b[$; (2) $p' < 0$ in $]\bar{x}, 0]$ and, due to Proposition 7, in $[0, b[$ $p(x) = \bar{M}(x)$ has at most one minimum where $p < \beta$, and $p' < 0$ where $p > \beta$. From (1) and (2) it follows that the equation $p(x) - n(x) = 0$ has a unique root $x^* \in]\bar{x}, b[$ and $p(x^*) = n(x^*) > \beta$. Let us now consider the function pn. Since p and n are increasing in $[-a, \bar{x}]$, we have $(pn)(\bar{x}) > (pn)(-a) = \beta(1 + \beta)$ and also $(pn)'(\bar{x}) \geqq 0$. On the other hand, multiplying (2.20) by n, (2.21) by p, and adding we obtain

$$\lambda(pn)' = C_p n + C_n p, \tag{3.10}$$

and therefore

$$\lambda(pn)'' = C_p n' + C_n p'. \tag{3.11}$$

Now, by definition of x^* we have $n \geqq p$ in $[x^*, b]$, which together with (3.8) and (3.10) yields $(pn)' > 0$ in $[x^*, b]$. Yet, from (3.11) and $C_p > 0$, $C_n < 0$, $n' > 0$ and $p' < 0$, we get $(pn)'' > 0$ in $[\bar{x}, x^*[$. Therefore pn is strictly increasing in $[\bar{x}, b]$, so that $(1 + \beta)\beta = (pn)(b) > (pn)(\bar{x}) > \beta(1 + \beta)$. This concludes the proof. □

The proof of the following result is entirely analogous.

PROPOSITION 9. *The function $\bar{m}$ is increasing in* $[0, b]$.

Finally we can prove that ψ is monotone. More precisely we have the following proposition.

PROPOSITION 10. *The function ψ is such that $\psi' > 0$ in* $[-a, b]$.

Proof. From Propositions 8 and 5 it follows that $p' \leqq 0$ in $[-a, 0]$. Hence from (2.20) we get $p\psi' = -\lambda p' + C_p > 0$, and therefore $\psi' > 0$ in $[-a, 0]$, The proof that $\psi' > 0$ in $[0, b]$ is completely analogous. □

Summary. Summing up the results of this section, we can say that the solutions (ψ, p, n) of Problem 1 have the following qualitative behavior. In $[-a, 0]$ p is decreasing, n has at most one minimum, and ψ is convex. In $[0, b]$ n is increasing, p has at most one minimum, and ψ is concave. In $[-a, b]$ p and n are positive functions bounded above by $1+\beta$ and ψ is an increasing function.

4. A convergence theorem. In this section we study the behavior of the solutions of Problem 1 as λ tends to zero. It is convenient to write explicitly the dependence of such solutions on λ, and therefore from now on we denote by $(\psi_\lambda, p_\lambda, n_\lambda)$ a solution of the problem for a given λ. Our study is based on the following a priori estimate that follows at once from the results of the previous section.

THEOREM 2. *There exists a constant C independent of λ such that for every $\lambda > 0$*

$$\|\psi_\lambda\|_{W^{2,\infty}} + \|p_\lambda\|_{W^{1,1}} + \|n_\lambda\|_{W^{1,1}} \leqq C. \tag{4.1}$$

Proof. In the following C denotes several constants, all independent of λ. Since p_λ is decreasing in $[-a, 0]$ and has no maxima in $]0, b[$ it follows that $0 < p_\lambda \leqq 1+\beta$. Analogously, we obtain $0 < n_\lambda \leqq 1+\beta$. Hence $\|p_\lambda\|_{L^1} \leqq C$ and $\|n_\lambda\|_{L^1} \leqq C$. However, since p_λ and n_λ have at most one minimum in $]-a, b[$, we obtain $\|p'_\lambda\|_{L^1} \leqq C$ and $\|n'_\lambda\|_{L^1} \leqq C$. Therefore, $\|p_\lambda\|_{W^{1,1}} \leqq C$ and $|n_\lambda\|_{W^{1,1}} \leqq C$.

From these estimates and (2.1) it follows that $\|\psi''_\lambda\|_{L^\infty} \leqq C$. From the monotonicity of ψ_λ it follows that $\|\psi_\lambda\|_{L^\infty} \leqq C$. Finally, we obtain $\|\psi'_\lambda\|_{L^\infty} \leqq C$, and therefore $\|\psi_\lambda\|_{W^{2,\infty}} \leqq C$. □

Before turning to the convergence thereom, which is in a certain sense the central result of the paper, we prove the following lemma.

LEMMA 1. *There exists a constant C independent of λ such that*

$$0 < C_p(\lambda) \leqq C\beta, \tag{4.2}$$

$$-C\beta \leqq C_n(\lambda) < 0, \tag{4.3}$$

where $C_p(\lambda)$ and $C_n(\lambda)$ are given by (2.20) *and* (2.21), *respectively. In particular,*

$$\lim_{\lambda \to 0} C_p(\lambda) = \lim_{\lambda \to 0} C_n(\lambda) = 0. \tag{4.4}$$

Proof. Let us prove (4.2), since the proof of (4.3) is similar. From (2.7) it follows that

$$e^{\alpha/\lambda} = e^{\bar{\psi}/\lambda}\sqrt{\beta/(1+\beta)}, \tag{4.5}$$

$$e^{-\alpha/\lambda} = e^{-\bar{\psi}/\lambda}\sqrt{(\beta+1)/\beta}, \tag{4.6}$$

and from this and (2.20) we get

$$C_p = (\lambda\beta\, e^{\bar{\psi}/\lambda} - \lambda(1+\beta)\, e^{-\bar{\psi}/\lambda}) \Big/ \int_{-a}^{b} e^{\psi/\lambda}. \tag{4.7}$$

Now, introducing

$$\phi := e^{\psi/\lambda}, \tag{4.8}$$

we can write

$$C_p = \left(\lambda\beta \int_{-a}^{b} \phi' - \lambda\phi(-a)\right) \Big/ \int_{-a}^{b} \phi \leqq \lambda\beta \int_{-a}^{b} \phi' \Big/ \int_{-a}^{b} \phi, \tag{4.9}$$

and since

$$\phi' = \frac{\psi'}{\lambda}\phi \tag{4.10}$$

we have

$$\int_{-a}^{b} \phi' = \frac{\psi'(\theta)}{\lambda} \int_{-a}^{b} \phi \tag{4.11}$$

with $\theta \in]-a, b[$. From (4.11), (4.9) and (4.1), (4.2) follows at once. □.

THEOREM 3. *Every sequence* $\{\psi_\lambda, p_\lambda, n_\lambda\}_{\lambda>0}$ *of solutions of Problem* 1 *converges, as* $\lambda \to 0$, *to the solution* $\{\psi_0, p_0, n_0\}$ *of the following double obstacle problem.*

PROBLEM 2. Find $\psi_0 \in C^1([-a, b])$ and ξ_p, ξ_n such that $-a \leqq -\xi_p < \xi_n \leqq b$,

$$\psi_0 = -\left(\alpha + \frac{A}{2}\right) \quad \text{in } [-a, -\xi_p], \tag{4.12}$$

$$\psi_0'' = -\operatorname{sign} x \quad \text{in }]-\xi_p, \xi_n[, \tag{4.13}$$

$$\psi_0 = \alpha + \frac{A}{2} \quad \text{in } [\xi_n, b], \tag{4.14}$$

and define

$$p_0 = 1 \quad \text{in }]-a, -\xi_p[, \qquad p_0 = 0 \quad \text{in }]-\xi_p, b[, \tag{4.15}$$

$$n_0 = 0 \quad \text{in }]-a, \xi_n[, \qquad n_0 = 1 \quad \text{in }]\xi_n, b[. \tag{4.16}$$

Proof. By Theorem 2 there exists a subsequence of $\{\psi_\lambda, p_\lambda, n_\lambda\}$—which we denote in the same way—such that

$$\psi_\lambda \to \psi_0 \quad \text{in } H^2(-a, b) \text{ weak}, \tag{4.17}$$

$$p_\lambda \to p_0 \quad \text{in } L^2(-a, b), \tag{4.18}$$

$$n_\lambda \to n_0 \quad \text{in } L^2(-a, b), \tag{4.19}$$

when $\lambda \to 0$. To prove Theorem 3 we show that these limit functions verify (4.12)-(4.16). Taking the limit as $\lambda \to 0$ in (2.1), (2.4), we can write, thanks to (4.17)-(4.19) and taking into account (2.7) and (2.8),

$$\psi_0'' = -\operatorname{sign} x - p_0 + n_0 \quad \text{in }]-a, b[, \tag{4.20}$$

$$\psi_0(-a) = -\left(\alpha + \frac{A}{2}\right), \qquad \psi_0(b) = \alpha + \frac{A}{2}. \tag{4.21}$$

However, again by Theorem 2, we have

$$\lambda p_\lambda' \to 0 \quad \text{in } L^1(-a, b), \tag{4.22}$$

$$\lambda n_\lambda' \to 0 \quad \text{in } L^1(-a, b), \tag{4.23}$$

when $\lambda \to 0$. Now taking the limit as $\lambda \to 0$ in (2.20)-(2.21), we deduce from (4.17)-(4.19) and (4.22)-(4.23) and using Lemma 1, that

$$p_0 \psi_0' = 0 \quad \text{in }]-a, b[, \tag{4.24}$$

$$n_0 \psi_0' = 0 \quad \text{in }]-a, b[. \tag{4.25}$$

Moreover, from the results of § 3 we get that

$$\psi_0'(x) \geqq 0 \quad \text{in } [-a, b], \tag{4.26}$$

$$\psi_0''(x) \geqq 0 \quad \text{in }]-a, 0[, \qquad \psi_0''(x) \leqq 0 \quad \text{in }]0, b[, \tag{4.27}$$

and we have also that

$$0 \leqq p_0 \leqq 1 \quad \text{in }]-a, b[, \tag{4.28}$$

$$0 \leqq n_0 \leqq 1 \quad \text{in }]-a, b[. \tag{4.29}$$

Now let us set

$$-\xi_p = \inf\{x \mid -a \leqq x \leqq b,\ \psi_0'(x) > 0\}, \tag{4.30}$$

$$\xi_n = \sup\{x \mid -a \leqq x \leqq b,\ \psi_0'(x) > 0\}. \tag{4.31}$$

From (4.26)-(4.27) it follows that $\xi_n, \xi_p > 0$. Hence we have (1) $\psi_0' > 0$ in $]-\xi_p, \xi_n[$ and, (2) $\psi_0' = 0$ in $]-a, -\xi_p[$ and in $]\xi_n, b[$. From (1), (4.24)-(4.25) and (4.20) it follows that ψ_0 satisfies (4.13) and $p_0 = n_0 = 0$ in $]-\xi_p, \xi_n[$, and from (2) and (4.21) it follows that ψ_0 satisfies (4.12) and (4.14). On the other hand, if $-a < -\xi_p$ we have $n_0 = 0$ and $p_0 = 1$ in $[-a, -\xi_p[$ because, from (4.20) and (4.28)-(4.29), $1 \geqq p_0 = n_0 + 1 \geqq 1$. In a similar way we prove that, if $\xi_n < b$, $p_0 = 0$ and $n_0 = 1$ in $]\xi_n, b]$. Since the limit is unique, by standard arguments we then deduce that the whole sequence $(\psi_\lambda, p_\lambda, n_\lambda)$ converges to (ψ_0, p_0, n_0). □

Remark 2. It is well known that (4.12)-(4.14) (which is clearly equivalent to (1.27)-(1.30)) can also be written as a minimum problem: Set

$$\mathbb{K} = \left\{ \phi(x) \in H^1(-a, b):\ \phi(-a) = -\left(\alpha + \frac{A}{2}\right),\right.$$
$$\left. \phi(b) = \alpha + \frac{A}{2},\ -\left(\alpha + \frac{A}{2}\right) \leqq \phi(x) \leqq \alpha + \frac{A}{2} \text{ in }]-a, b[\right\}; \tag{4.32}$$

then $\psi_0(x)$ is the unique minimum in $\mathbb{K}$ of the functional

$$J(\phi) = \frac{1}{2}\int_{-a}^{b} (\phi')^2\, dx + \int_{-a}^{b} \phi \operatorname{sign} x\, dx. \tag{4.33}$$

□

5. A uniqueness theorem. As we said in the Introduction, we are not able to prove that the solution of Problem 1 is unique for every $\lambda > 0$. In this section we prove that the solution is unique provided that λ is small enough. The proof is similar to that contained in [3] but is somewhat more involved.

THEOREM 4. *There exists λ^* such that the solution of Problem* 1 *is unique provided $\lambda < \lambda^*$.*

Proof. The scheme of the proof is the following one (as usual C denotes different constants independent of λ). First we remark that from Theorems 2 and 3 it follows that there exists a $\bar{\lambda}$ such that every solution $(\psi_\lambda, p_\lambda, n_\lambda)$ of Problem 1 satisfies

$$\|\psi_\lambda - \psi_0\|_{L^\infty} \leqq \alpha \tag{5.1}$$

whenever $\lambda < \bar{\lambda}$. Next we suppose that there exist two solutions $(\psi_{1\lambda}, p_{1\lambda}, n_{1\lambda})$, $(\psi_{2\lambda}, p_{2\lambda}, n_{2\lambda})$ and set

$$\delta_\lambda := \psi_{2\lambda} - \psi_{1\lambda}. \tag{5.2}$$

Then from the previous remark we can say that for $\lambda < \bar{\lambda}$

$$\|\delta_\lambda\|_{L^\infty} \leqq 2\alpha. \tag{5.3}$$

From this estimate we will obtain the following:

$$\|\delta_\lambda'\|_{L^2}^2 \leqq \frac{C\beta}{\lambda} \|\delta_\lambda\|_{L^\infty}. \tag{5.4}$$

From (5.4), since

$$\|\delta_\lambda\|_{L^\infty} \leqq C\|\delta'_\lambda\|_{L^2} \tag{5.5}$$

(remark that $\delta_\lambda(-a) = \delta_\lambda(b) = 0$), we get that

$$\|\delta'_\lambda\|_{L^2} \leqq \frac{C\beta}{\lambda} \tag{5.6}$$

and

$$\|\delta_\lambda\|_{L^\infty} \leqq \frac{C\beta}{\lambda}. \tag{5.7}$$

This last estimate is an improvement on (5.3). Actually from (1.23) we have $\beta = 0(\lambda^3)$, so that (5.7) can be written as

$$\|\delta_\lambda\|_{L^\infty} \leqq C\lambda^2. \tag{5.8}$$

From (5.8) we will obtain the estimate

$$\|\delta'_\lambda\|^2_{L^2} \leqq C^{\beta}_{\bar{\lambda}^2}\|\delta_\lambda\|^2_{L^\infty} \quad \text{for } \lambda \leqq \hat{\lambda} \leqq \bar{\lambda}, \tag{5.9}$$

which will enable us to conclude the proof. Indeed from (5.5) and (1.23) we can write, using (5.9),

$$\|\delta_\lambda\|^2_{L^\infty} \leqq C\lambda\, e^{-A/\lambda}\|\delta_\lambda\|^2_{L^\infty}, \tag{5.10}$$

or

$$\|\delta_\lambda\|^2_{L^\infty}(1 - C\lambda\, e^{-A/\lambda}) \leqq 0. \tag{5.11}$$

Now, since there exists $\tilde{\lambda}$ such that $1 - C\lambda\, e^{-A/\lambda} > 0$ whenever $\lambda \leqq \tilde{\lambda}$, we get $\|\delta_\lambda\|_{L^\infty} = 0$, i.e., $\psi_{1\lambda} = \psi_{2\lambda}$ for $\lambda < \lambda^* = \min\{\hat{\lambda}, \tilde{\lambda}\}$. From (2.18), (2.19) we get at once $p_{1\lambda} = p_{2\lambda}$, $n_{1\lambda} = n_{2\lambda}$.

Now it remains to prove first that (5.3) implies (5.4) and then to prove that (5.8) implies (5.9).

Proof of (5.4.). In the following we delete the subscript λ to simplify the notation. Let (ψ_1, p_1, n_1) and (ψ_2, p_2, n_2) be two solutions and let $\delta = \psi_2 - \psi_1$. From (2.10), (2.11) we write $p_i = \rho_i \exp[(\bar{\psi} - \psi_i)/\lambda]$, $n_i = \sigma_i \exp[(\bar{\psi} + \psi_i)/\lambda]$ for $i = 1, 2$, so that from the equation

$$\delta'' = p_1 - p_2 + n_2 - n_1 \tag{5.12}$$

we get

$$\begin{aligned} -\delta'' + \rho_1 \exp[(\bar{\psi} - \psi_1)/\lambda](1 - \exp(-\delta/\lambda)) - \sigma_1 \exp[(\bar{\psi} + \psi_1)/\lambda](1 - \exp(\delta/\lambda)) \\ = \exp[(\bar{\psi} - \psi_2)/\lambda](\rho_2 - \rho_1) + \exp[(\bar{\psi} + \psi_2)/\lambda](\sigma_1 - \sigma_2). \end{aligned} \tag{5.13}$$

From (2.18) and (2.19) we can write ρ_i and σ_i for $i = 1, 2$ in terms of ψ_i as follows:

$$\rho_i = \beta \exp(-2\alpha/\lambda)(1 - r_i) + \beta r_i \quad \text{with } r_i = \frac{\int_{-a}^{x} \exp(\psi_i/\lambda)}{\int_{-a}^{b} \exp(\psi_i/\lambda)}, \tag{5.14}$$

$$\sigma_i = \beta \exp(-2\alpha/\lambda)(1 - s_i) + \beta s_i \quad \text{with } s_i = \frac{\int_{x}^{b} \exp(-\psi_i/\lambda)}{\int_{-a}^{b} \exp(-\psi_i/\lambda)}. \tag{5.15}$$

Then we insert (5.14) and (5.15) in (5.13), multiply by δ, and integrate, to obtain

$$
\begin{aligned}
(5.16)\qquad \|\delta'\|_{L^2}^2 &+ \int_{-a}^{b} \delta \exp[(\bar{\psi}-\psi_1)/\lambda]\rho_1(1-\exp(-\delta/\lambda)) \\
&- \int_{-a}^{b} \delta \exp[(\bar{\psi}+\psi_1)/\lambda]\sigma_1(1-\exp(\delta/\lambda)) \\
&= \int_{-a}^{b} \delta \exp[(\bar{\psi}-\psi_2)/\lambda]\beta \exp(-2\alpha/\lambda)(r_1-r_2) \\
&+ \int_{-a}^{b} \delta \exp[(\bar{\psi}-\psi_2)/\lambda]\beta(r_2-r_1) \\
&+ \int_{-a}^{b} \delta \exp[(\bar{\psi}+\psi_2)/\lambda]\beta \exp(-2\alpha/\lambda)(s_2-s_1) \\
&+ \int_{-a}^{b} \delta \exp[(\bar{\psi}+\psi_2)/\lambda]\beta(s_1-s_2) = \mathrm{I}+\mathrm{II}+\mathrm{III}+\mathrm{IV}.
\end{aligned}
$$

Let us estimate the term I; for this we write

$$
\mathrm{I} = \beta e^{-2\alpha/\lambda}\left[\frac{\exp(\bar{\psi}/\lambda)}{\int_{-a}^{b}\exp(\psi_1/\lambda)}\int_{-a}^{b}\left(\delta \exp(-\delta/\lambda)\exp(-\psi_1/\lambda)\int_{-a}^{x}\exp(\psi_1/\lambda)\right)\right.
$$
$$
\left.-\frac{\exp(\bar{\psi}/\lambda)}{\int_{-a}^{b}\exp(\psi_2/\lambda)}\int_{-a}^{b}(\exp(-\psi_2/\lambda)\int_{-a}^{x}\exp(\psi_2/\lambda))\right].
$$

Since ψ_1 and ψ_2 are increasing in $[-a, b]$, it follows that

$$
(5.17)\qquad \exp[-\psi_i(x)/\lambda]\int_{-a}^{x}\exp(\psi_i(t)/\lambda)\,dt \leqq x+a.
$$

Hence (5.3) and (5.17) yield

$$
(5.18)\qquad \mathrm{I} \leqq \beta\|\delta\|_{L^\infty}\frac{(b+a)^2}{2}\exp(\bar{\psi}/\lambda)\left[\frac{1}{\int_{-a}^{b}\exp(\psi_1/\lambda)}+\frac{\exp(-2\alpha/\lambda)}{\int_{-a}^{b}\exp(\psi_2/\lambda)}\right].
$$

Let us now estimate $\int_{-a}^{b}\exp(\psi_i/\lambda)$. Working as in the proof of Lemma 1 (see (4.8) and (4.11)), we have, for suitable $\theta_i \in]-a, b[$,

$$
(5.19)\qquad \frac{1}{\int_{-a}^{b}\exp(\psi_i/\lambda)} = \frac{\psi_i'(\theta_i)\exp(-\bar{\psi}/\lambda)}{\lambda(1-\exp(-2\bar{\psi}/\lambda))} \leqq \frac{C}{\lambda}\exp(-\bar{\psi}/\lambda)
$$

so that the following bound holds:

$$
(5.20)\qquad \mathrm{I} \leqq C\frac{\beta}{\lambda}\|\delta\|_{L^\infty}.
$$

For the next term we obtain

$$
\begin{aligned}
\mathrm{II} = \beta \exp(\bar{\psi}/\lambda)&\int_{-a}^{b}\delta[\exp(-\psi_2/\lambda)r_2-\exp(-\psi_1/\lambda)r_1] \\
&+\beta\exp(\bar{\psi}/\lambda)\int_{-a}^{b}\delta(1-\exp(-\delta/\lambda))\exp(-\psi_1/\lambda)r_1
\end{aligned}
$$

and, using (5.14), (5.17), and (5.19), we have

$$\text{II} \leqq C\frac{\beta}{\lambda}\|\delta\|_{L^\infty}+\beta\int_{-a}^{b}\delta(1-\exp(-\delta/\lambda))\exp((\bar{\psi}-\psi_1)/\lambda)r_1. \tag{5.21}$$

Analogously, we have

$$\exp[\psi_i(x)/\lambda]\int_{x}^{b}\exp(-\psi_i(t)/\lambda)\,dt \leqq b-x \tag{5.22}$$

and

$$\frac{1}{\int_{-a}^{b}\exp(-\psi_i/\lambda)} \leqq \frac{C}{\lambda}\exp(-\bar{\psi}/\lambda), \tag{5.23}$$

so that

$$\text{III} \leqq C\frac{\beta}{\lambda}\|\delta\|_{L^\infty}, \tag{5.24}$$

$$\text{IV} \leqq C\frac{\beta}{\lambda}\|\delta\|_{L^\infty}+\beta\int_{-a}^{b}\delta\exp((\bar{\psi}+\psi_1)/\lambda)(\exp(\delta/\lambda)-1)s_1. \tag{5.25}$$

Summarizing (5.16), (5.20), (5.21), (5.24), and (5.25), and recalling (5.14) and (5.15), we have

$$\begin{aligned}\|\delta'\|_{L^2}^2&+\int_{-a}^{b}\delta\exp((\bar{\psi}-\psi_1)/\lambda)\beta\exp(-2\alpha/\lambda)(1-r_1)(1-\exp(-\delta/\lambda))\\&+\int_{-a}^{b}\delta\exp((\bar{\psi}+\psi_1)/\lambda)\beta\exp(-2\alpha/\lambda)(1-s_1)(\exp(\delta/\lambda)-1)\\&\leqq C\frac{\beta}{\lambda}\|\delta\|_{L^\infty}.\end{aligned}$$

Hence (5.4) follows, since $\delta(\exp(\delta/\lambda)-1)\geqq 0$, $\delta(1-\exp(-\delta/\lambda))\geqq 0$, $1-r_1\geqq 0$, $1-s_1\geqq 0$. □

Proof of (5.9). From (2.20) and (2.21) we obtain

$$\lambda(p_2-p_1)'+\psi_2'(p_2-p_1)=c_1-p_1\delta', \tag{5.26}$$

$$\lambda(n_2-n_1)'-\psi_2'(n_2-n_1)=c_2+n_1\delta'. \tag{5.27}$$

Solving for p_2-p_1 in (5.26) and for n_2-n_1 in (5.27), we obtain

$$p_2-p_1=\frac{\exp(-\psi_2/\lambda)}{\lambda}\left(r_2\int_{-a}^{b}\exp(\psi_2/\lambda)p_1\delta'-\int_{-a}^{x}\exp(\psi_2/\lambda)p_1\delta'\right), \tag{5.28}$$

$$n_2-n_1=\frac{\exp(\psi_2/\lambda)}{\lambda}\left(s_2\int_{-a}^{b}\exp(-\psi_2/\lambda)n_1\delta'-\int_{x}^{b}\exp(-\psi_2/\lambda)n_1\delta'\right). \tag{5.29}$$

After integrating by parts in (5.28) and (5.29), we substitute them in (5.12), multiply by δ, and integrate, to obtain

$$\begin{aligned}\|\delta'\|_{L^2}^2=&\int_{-a}^{b}\left(\frac{\delta}{\lambda}\exp((\bar{\psi}-\psi_2)/\lambda)\left[-r_2\int_{-a}^{b}\delta(\exp(\delta/\lambda)\rho_1)'+\int_{-a}^{x}\delta(\exp(\delta/\lambda)\rho_1)'\right]\right)\\&+\int_{-a}^{b}\left(\frac{\delta}{\lambda}\exp((\bar{\psi}+\psi_2)/\lambda)\right.\end{aligned}$$

$$\times\left[s_2\int_{-a}^{b}\delta(\exp(-\delta/\lambda)\sigma_1)'-\int_{x}^{b}\delta(\exp(-\delta/\lambda)\sigma_1)'\right]\Big) \tag{5.30}$$
$$-\frac{1}{\lambda}\int_{-a}^{b}\delta^2(p_1+n_1)$$
$$=\mathrm{V}+\mathrm{VI}+\mathrm{VII}+\mathrm{VIII}-\frac{1}{\lambda}\int_{-a}^{b}\delta^2(p_1+n_1).$$

Then from the definition of ρ_1 ((5.14)), we have

$$\mathrm{V}=-\frac{\exp(\bar{\psi}/\lambda)}{\lambda}\int_{-a}^{b}\delta\exp(-\psi_2/\lambda)r_2\int_{-a}^{b}\delta\beta(1-\exp(-2\alpha/\lambda))\frac{\exp(\psi_2/\lambda)}{\int_{-a}^{b}\exp(\psi_1/\lambda)}$$
$$-\frac{\exp(\bar{\psi}/\lambda)}{\lambda^2}\int_{-a}^{b}\delta\exp(-\psi_2/\lambda)r_2\int_{-a}^{b}\delta\delta'\exp(\delta/\lambda)\rho_1.$$

Since $0\leqq\rho_1\leqq\beta$, from (2.14), and since (5.17), (5.19) hold, we have

$$\mathrm{V}\leqq C\frac{\beta}{\lambda^2}\|\delta\|_{L^\infty}^2+C\frac{\beta}{\lambda^3}\|\delta\|_{L^\infty}^2\int_{-a}^{b}|\delta'|\exp(\delta/\lambda) \tag{5.31}$$
$$\leqq C\frac{\beta}{\lambda^2}\|\delta\|_{L^\infty}^2,$$

where we also used the Cauchy-Schwarz inequality and (5.6), (5.7). Let us integrate by parts the following term:

$$\mathrm{VI}=\int_{-a}^{b}\left(\frac{\delta}{\lambda}\exp((\bar{\psi}-\psi_2)/\lambda)\left[\int_{-a}^{x}\delta\exp(\delta/\lambda)\rho_1'+\int_{-a}^{x}\delta\frac{\delta'}{\lambda}\exp(\delta/\lambda)\rho_1\right]\right)$$
$$=\int_{-a}^{b}\left(\frac{\delta}{\lambda}\exp((\bar{\psi}-\psi_2)/\lambda)\left[\int_{-a}^{x}\delta\exp(\delta/\lambda)\rho_1'+\frac{\delta^2}{2\lambda}\exp(\delta/\lambda)\rho_1\right.\right.$$
$$\left.\left.-\int_{-a}^{x}\frac{\delta^2}{2\lambda}(\exp(\delta/\lambda)\rho_1)'\right]\right)$$
$$=\mathrm{VI}_1+\int_{-a}^{b}\frac{\delta^3}{2\lambda^2}p_1+\mathrm{VI}_2.$$

We estimate separately VI_1 and VI_2. For the former, recalling the definition of ρ_1 and (5.17), (5.19), we get

$$\mathrm{VI}_1\leqq\|\delta\|_{L^\infty}^2\frac{\beta}{\lambda}(1-\exp(-2\alpha/\lambda))\frac{\exp(\bar{\psi}/\lambda)}{\int_{-a}^{b}\exp(\psi_1/\lambda)}\int_{-a}^{b}\left(\exp(-\psi_2/\lambda)\int_{-a}^{x}\exp(\psi_2/\lambda)\right)$$
$$\leqq C\frac{\beta}{\lambda^2}\|\delta\|_{L^\infty}^2.$$

Analogously, considering also (5.6) and (5.7), we have

$$\mathrm{VI}_2\leqq\frac{\beta}{2\lambda^2}(1-\exp(-2\alpha/\lambda))\|\delta\|_{L^\infty}^3\frac{\exp(\bar{\psi}/\lambda)}{\int_{-a}^{b}\exp(\psi_1/\lambda)}\int_{-a}^{b}\left(\exp(-\psi_2/\lambda)\int_{-a}^{x}\exp(\psi_2/\lambda)\right)$$
$$+\frac{1}{2\lambda^3}\|\delta\|_{L^\infty}^3\int_{-a}^{b}\left(\exp((\bar{\psi}-\psi_2)/\lambda)\int_{-a}^{x}|\delta'|\exp(\delta/\lambda)\rho_1\right)$$
$$\leqq C\frac{\beta}{\lambda^3}\|\delta\|_{L^\infty}^3+\frac{1}{2\lambda^3}\|\delta\|_{L^\infty}^3\int_{-a}^{b}\int_{-a}^{x}|\delta'|\exp((\psi_2(t)-\psi_2(x))/\lambda)p_1\,dt\,dx.$$

Finally, since $0 \leqq p_1 \leqq 1+\beta \leqq 2$ and ψ_2 is increasing, we get the following estimate for the term VI, using (5.6), (5.7) once more:

$$\text{VI} \leqq C\frac{\beta}{\lambda^2}\|\delta\|_{L^\infty}^2 + \int_{-a}^{b} \frac{\delta^3}{2\lambda^2} p_1. \tag{5.32}$$

Analogously,

$$\text{VII} \leqq C\frac{\beta}{\lambda^2}\|\delta\|_{L^\infty}^2 \tag{5.33}$$

and

$$\text{VIII} \leqq C\frac{\beta}{\lambda^2}\|\delta\|_{L^\infty}^2 - \int_{-a}^{b} \frac{\delta^3}{2\lambda^2} n_1. \tag{5.34}$$

Gathering (5.30)-(5.34), we obtain

$$\|\delta'\|_{L^2}^2 \leqq C\frac{\beta}{\lambda^2}\|\delta\|_{L^\infty}^2 - \frac{1}{\lambda^2}\int_{-a}^{b} \delta^2 p_1\left(\lambda - \frac{\delta}{2}\right) - \frac{1}{\lambda^2}\int_{-a}^{b} \delta^2 n_1\left(\lambda + \frac{\delta}{2}\right).$$

Since (5.8) holds there exists $\hat{\lambda} \leqq \bar{\lambda}$ such that for $\lambda \leqq \hat{\lambda}$, the two last integrals are positive; hence we obtain (5.9). □

PERSISTENCE IN INFINITE-DIMENSIONAL SYSTEMS*

JACK K. HALE† AND PAUL WALTMAN‡

Abstract. The concept of persistence reflects the survival of all components of a model ecosystem. Most of the results to date are restricted to ordinary differential equations or to dynamics on locally compact spaces. The concept is investigated here in the setting of a C^0-semigroup which is asymptotically smooth. Since the equations of population dynamics often involve delays or diffusion this seems the appropriate setting. Conditions are placed on the flow on the boundary which, given the presence of a global attractor provided by the assumption of dissipativeness and asymptotic smoothness, are necessary and sufficient for persistence.

Key words. persistence, asymptotically smooth, global attractor

AMS(MOS) subject classifications. 34C35, 34G20

1. Introduction. The notion of persistence (defined below) captures a basic idea in ecology by expressing the ultimate survival of the component populations of a model ecosystem. Most of the applications have been to autonomous systems of ordinary differential equations and thus make use of dynamics in Euclidean spaces. (Exceptions are: Dunbar, Rybakowski, and Schmitt [5] and Hutson and Moran [11], who apply this idea to reaction diffusion equations; Gatica and So [6], who work with non-autonomous ordinary differential equations; and Burton and Hutson [2], who work with delay equations.) The notion of persistence is basically a dynamic one and has been explored in the context of locally compact metric spaces in [3] and [4]. However, many of the models of population dynamics naturally involve such concepts as delays or diffusion resulting in functional differential equations or partial differential equations. There is still a natural setting for the application of the ideas of dynamical systems [7], [10] but it is in spaces that are not locally compact.

The purpose of this note is to develop this idea of persistence under a reasonable set of hypotheses so that it can be applied to biological problems with delays or diffusion. The general setting is that of a semigroup and the basic hypothesis is that of being asymptotically smooth, a notion that has been helpful in developing the dynamics in infinite-dimensional systems. The work blends the ideas of [7] and [3].

The hypotheses naturally are more difficult to check in this setting. The basic one involves knowledge of the attracting set (defined below), which is difficult to obtain in an infinite-dimensional system. Nevertheless, we feel that this is the natural and proper setting for the concept of persistence and that the theorems may be useful when specific equations are studied.

2. Preliminaries. In this section we give some background material on dynamical systems and the existence of global attractors. Let X be a complete metric space (with metric d) and suppose that $T(t): X \to X$, $t \geqq 0$, is a C^0-semigroup on X; that is, $T(0) = I$, $T(t+s) = T(t)T(s)$ for $t, s \geqq 0$, and $T(t)x$ is continuous in t, x. The positive

orbit $\gamma^+(x)$ through x is defined as $\gamma^+(x) = \cup_{t\geq 0}\{T(t)x\}$. The ω-limit set is defined as

$$\omega(x) = \bigcap_{\tau\geqq 0} \operatorname{Cl} \bigcup_{t\geqq\tau} \{T(t)x\}.$$

This is equivalent to saying that $y\in\omega(x)$ if and only if there is a sequence $t_n\to\infty$ as $n\to\infty$ such that $T(t_n)x\to y$ as $n\to\infty$. If B is a subset of X, we define the ω-limit set of B as

$$\omega(B) = \bigcap_{\tau\geqq 0} \operatorname{Cl} \bigcup_{t\geqq\tau} T(t)B,$$

where

$$T(t)B = \bigcup_{x\in B} \{T(t)x\}.$$

This is equivalent to saying that $y\in\omega(B)$ if and only if there are sequences $t_n\to\infty$, $x_n\in B$ such that $T(t_n)x_n\to y$ as $n\to\infty$. Note that double sequences are needed to define $\omega(B)$.

It is important to make another remark about $\omega(B)$. It is tempting to consider the set

$$\bigcup_{x\in B} \omega(x)$$

as a candidate for the limiting behavior of the set B since it contains the ω-limit set of each point. This set is generally much smaller than the set $\omega(B)$. In fact, ω-limit sets of points in B could be disconnected even when $\omega(B)$ is connected. From the point of view of the qualitative behavior of the dynamics generated by the semigroup $T(t)$, it is necessary to consider the sets $\omega(B)$ defined above.

If the points x or the sets B have negative orbits, we can define the α-limit set $\alpha(x)$ of x and α-limit set $\alpha(B)$ of B in a similar manner taking into account the possibility of multiple backward orbits. When the points or sets belong to an invariant set A, we will restrict the backward orbits to those remaining in the invariant set and denote this by $\alpha_A(x)$. Sometimes it is convenient to have the alpha limit set of a specific full orbit, $\gamma(x)$ through a point x. We denote this by $\alpha_\gamma(x)$.

A set B in X is said to be *invariant* if $T(t)B = B$ for $t\geqq 0$; that is, the mapping $T(t)$ takes B onto B for each $t\geqq 0$. This implies, in particular, that there is a negative orbit through each point of an invariant set.

A nonempty invariant subset M of X is called an *isolated invariant set* if it is the maximal invariant set of a neighborhood of itself. The neighborhood is called an *isolating neighborhood.* The *stable* (*or attracting*) set of a compact invariant set A is denoted by W^s and is defined as

$$W^s(A) = \{x \mid x\in X,\ \omega(x)\neq\phi,\ \omega(x)\subset A\}.$$

The *unstable* (*or repelling*) set, W^u is defined by

$$W^u(A) = \{x \mid x\in X, \text{there exists a backward orbit } \gamma^-(x) \text{ such that } \alpha_\gamma(x)\neq\phi,\ \alpha_\gamma(x)\subset A\}.$$

The weakly stable and unstable sets are defined as follows:

$$W^s_w(A) = \{x \mid x\in X,\ \omega(x)\neq\phi,\ \omega(x)\cap A\neq\phi\}$$
$$W^u_w(A) = \{x \mid x\in X,\ \alpha(x)\neq\phi,\ \alpha(x)\cap A\neq\phi\}.$$

A set A in X is said to be a *global attractor* if it is compact, invariant and, for any bounded set B in X, $\delta(T(t)B, A)\to 0$ as $t\to\infty$, where $\delta(B, A)$ is the distance from the set B to the set A:

$$\delta(B, A) = \sup_{y\in B} \inf_{x\in A} d(y, x).$$

In particular, this implies $\omega(B)$ exists and belongs to A. A global attractor is always a maximal compact invariant set. The semigroup $T(t)$ is said to be *asymptotically smooth* [9] if for any bounded subset B of X, for which $T(t)B \subset B$ for $t \geqq 0$, there exists a compact set K such that $\delta(T(t)B, K) \to 0$ as $t \to \infty$. In particular, $\omega(B) \subset K$. The semigroup $T(t)$ is said to be *point dissipative in* X if there is a bounded nonempty set B in X such that, for any $x \in X$, there is a $t_0 = t_0(x, B)$ such that $T(t)x \in B$ for $t \geqq t_0$.

A basic result on the existence of global attractors is the following theorem.

THEOREM 2.1 [7] [8]. *If*

(i) $T(t)$ *is asymptotically smooth,*

(ii) $T(t)$ *is point dissipative in* X,

(iii) $\gamma^+(U)$ *is bounded in* X *if* U *is bounded in* X,

then there is a nonempty global attractor A *in* X.

If there is a $t_0 \geqq 0$ such that $T(t)$ is compact for $t > t_0$ then $T(t)$ is asymptotically smooth. In this case we can dispense with hypothesis (iii) of Theorem 2.1 and prove Theorem 2.2.

THEOREM 2.2 [1]. *If*

(i) *there is a* $t_0 \geqq 0$ *such that* $T(t)$ *is compact for* $t > t_0$,

(ii) $T(t)$ *is point dissipative in* X,

then there is a nonempty global attractor A *in* X.

3. Persistence. In this section we consider a particular system motivated by biological considerations. We will assume that the metric space X is the closure of an open set X^0; that is, $X = X^0 \cup \partial X^0$, where ∂X^0 (assumed to be nonempty) is the boundary of X^0. We will also suppose that the C^0-semigroup $T(t)$ on X satisfies

$$T(t): X^0 \to X^0, \qquad T(t): \partial X^0 \to \partial X^0 \tag{3.1}$$

and let $T_0(t) = T(t)|_{X^0}$, $T_\partial(t) = T(t)|_{\partial X^0}$.

The set ∂X^0 is a complete metric space (with metric d). Therefore, if $T(t)$ satisfies the conditions of Theorem 2.1 in X, then T_∂ will satisfy the same conditions in ∂X^0. Therefore there will be a global attractor A_∂ in ∂X^0.

When $T(t)$ satisfies the conditions of Theorem 2.1 or Theorem 2.2, it may not be the case that $T_0(t)$ even has a maximal compact invariant set in X^0. There may be points x in X^0 for which $\omega(x) \cap \partial X^0 \neq \phi$. In this case, there is clearly no maximal compact invariant set in X^0. It can also happen that $\omega(x) \cap \partial X^0 = \phi$ for all x and there does not exist a maximal compact invariant set in X^0, for example, a simple predator prey model with families of periodic orbits. From the biological point of view, these concepts are important for they are related to the coexistence of populations.

The concept of persistence is introduced to assist in the understanding of these last remarks. The semigroup $T(t)$ is said to be *persistent* if for any $x \in X^0$, $\liminf_{t \to \infty} d(T(t)x, \partial X^0) > 0$. The semigroup $T(t)$ is said to be *uniformly persistent* if there is an $\eta > 0$ such that, for any $x \in X^0$, $\liminf_{t \to \infty} d(T(t)x, \partial X^0) \geqq \eta$. If $T(t)$ is persistent, it need not be uniformly persistent [4].

To obtain an equivalent formulation of persistence in terms of attractors, it is convenient to introduce two definitions. We say that a set U in X^0 is *strongly bounded in* X^0 if it is bounded in X and there is an $\eta > 0$ such that $d(x, \partial X^0) \geqq \eta$ for x in U. When we restrict the semigroup $T(t)$ to X^0 we can think of ∂X^0 as being part of "infinity." The "bounded" sets in X^0 should then be the strongly bounded sets in X. We say that $T(t)$ is *strongly point dissipative in* X^0 if there exists a strongly bounded set B in X^0 such that for any $x \in X^0$, there is a $t_0 = t_0(x, B)$ such that $T(t)x \in B$ for $t \geqq t_0$. The following proposition is obvious.

PROPOSITION 3.1. *Suppose that $T(t)$ is point dissipative in X. Then we have the following*:

(i) *$T(t)$ is persistent if and only if $\omega(x)$ is strongly bounded for each $x \in X^0$.*

(ii) *$T(t)$ is uniformly persistent if and only if $T(t)$ is strongly point dissipative in X^0.*

We need the following definition. A_0 is said to be a *global attractor for $T(t)$ in X^0 relative to strongly bounded sets* if $A_0 \subset X^0$ is compact, invariant, and $\delta(T(t)U, A_0) \to 0$ as $t \to \infty$ for all strongly bounded sets U. In particular, $\omega(U) \subset A_0$ for each strongly bounded set U in X^0. In the case in which X is a finite-dimensional Banach space (or when there is a $t_0 \geqq 0$ such that $T(t)$ is a compact for $t \geqq t_0$ and $T(t)$ is strongly point dissipative in X^0) we can use the same arguments as in the proof of Theorem 2.2 to obtain the existence of a global attractor in X^0. We can also prove Theorem 3.2.

THEOREM 3.2. *Suppose $T(t)$ satisfies* (3.1) *and we have the following*:

(i) *There is a $t_0 \geqq 0$ such that $T(t)$ is compact for $t > t_0$;*

(ii) *$T(t)$ is point dissipative in X;*

(iii) *$T(t)$ is uniformly persistent.*

Then there are global attractors A in X and A_∂ in ∂X^0 and a global attractor A_0 in X^0 relative to strongly bounded sets. Furthermore,

$$A = A_0 \cup W^u(A_\partial)$$

where

$$W^u(A_\partial) = \{x \in A \mid \alpha_A(x) \subset A_\partial\}.$$

Proof. Theorem 2.2 implies the existence of the global attractor in X and ∂X^0. With the interpretation of ∂X^0 as part of infinity for X^0 the existence of the attractor in X^0 follows from the proof of Theorem 2.2. It remains to prove that A has the specific representation stated in the theorem. Suppose $x \in A \setminus A_0$. Then there exists a full orbit $\omega(x)$ in A. Since A is compact, it follows that $\alpha_\gamma(x)$ exists, is compact, invariant, and belongs to A. Since A_0 is uniformly asymptotically stable, there is a $\delta > 0$ such that distance $d(y, A_0) \geqq \delta$ for $y \in \alpha(x)$. If $y \notin \partial X^0$, then $\omega(y) \subset A_0$. However, the previous inequality implies that this is impossible. Therefore, $\alpha(x) \subset \partial X^0$. Since $\alpha(x)$ is compact and invariant, it follows that $\alpha(x) \subset A_\partial$. The theorem is proved. □

The first hypothesis in Theorem 3.2 has little to do with the global properties of orbits. For example, it is generally satisfied for delay equations with finite delay or systems of parabolic equations. Hypothesis (ii) is a global property of the orbits, but it is expected to hold for most systems, since it essentially says that infinity is unstable. The most difficult hypothesis to verify is (iii), the uniform persistence.

We would like to verify uniform persistence by discussing only properties of the flow in a neighborhood of ∂X^0. The Lyapunov approach is an attractive way to do this, and this approach has been used in [5] and [11]. In [11] a type of Lyapunov function has been employed to show that the corresponding semigroup $T(t)$ is strongly point dissipative in X^0. Thus, a global attractor in X^0 exists from Theorem 3.2; this is a stronger conclusion that the one asserted in [11]. In the next section we give another method for obtaining uniform persistence.

If the map $T(t)$ is only asymptotically smooth then the analogue of Theorem 3.2 is Theorem 3.3.

THEOREM 3.3. *Suppose $T(t)$ satisfies* (3.1) *and we have the following*:

(i) *$T(t)$ is asymptotically smooth;*

(ii) *$T(t)$ is point dissipative in X;*

(iii) *$\gamma^+(U)$ is bounded if U is bounded in X;*

(iv) *$T(t)$ is uniformly persistent;*

(v) $\gamma^+(V)$ *is strongly bounded in* X^0 *if* V *is strongly bounded in* X^0.

Then the conclusions of Theorem 3.2 *are valid.*

4. Chains and uniform persistence. In this section we give characterizations of uniform persistence in terms of the behavior of the flow on ∂X^0. We need some additional definitions.

Let M, N be isolated invariant sets (not necessarily distinct). M is said to be *chained* to N, written $M \to N$, if there exists an element x, $x \notin M \cup N$ such that $x \in W^u(M) \cap W^s(N)$. A finite sequence $M_1, M_2, \cdots, M_k$ of isolated invariant sets will be called a *chain* if $M_1 \to M_2 \to \cdots \to M_k (M_1 \to M_1$, if $k = 1)$. The chain will be called a *cycle* if $M_k = M_1$.

The particular invariant sets of interest are

$$\tilde{A}_\partial = \bigcup_{x \in A_\partial} \omega(x). \tag{4.1}$$

$\tilde{A}_\partial$ is *isolated* if there exists a covering $M = \cup_{i=1}^k M_k$ of $\tilde{A}_\partial$ by pairwise disjoint, compact, isolated invariant sets $M_1, M_2, \cdots, M_k$ for T_∂ such that each M_i is also an isolated invariant set for T. M is called an *isolated covering*. $\tilde{A}_\partial$ will be called *acyclic* if there exists some isolated covering $M = \cup_{i=1}^k M_i$ of $\tilde{A}_\partial$ such that no subset of the M_i's forms a cycle. An isolated covering satisfying this condition will be called acyclic.

The principal result on persistence can now be stated.

THEOREM 4.1. *Suppose* $T(t)$ *satisfies* (3.1) *and we have the following*:

(i) *There is a* $t_0 \geqq 0$ *such that* $T(t)$ *is compact for* $t > t_0$;

(ii) $T(t)$ *is point dissipative in* X;

(iii) $\tilde{A}_\partial$ *is isolated and has an acyclic covering* M.

Then $T(t)$ *is uniformly persistent if and only if for each* $M_i \in M$

$$W^s(M_i) \cap X^0 = \phi. \tag{4.2}$$

For the case in which $T(t)$ is only asymptotically smooth, we have the following theorem.

THEOREM 4.2. *Suppose* $T(t)$ *satisfies* (3.1) *and we have the following*:

(i) $T(t)$ *is asymptotically smooth*;

(ii) $T(t)$ *is point dissipative in* X;

(iii) $\gamma^+(U)$ *is bounded in* X *if* U *is bounded in* X;

(iv) $\tilde{A}_\partial$ *is isolated and has an acyclic covering.*

Then the conclusions of Theorem 4.1 *are valid.*

For the proof we need the following lemma.

LEMMA 4.3. *Assume that* T *satisfies* (i)-(iii) *of Theorem* 4.2. *Let* γ_n^+ *be a sequence of precompact semiorbits, with* ω*-limit sets* ω_n. *Suppose that* M *is a compact, isolated invariant set with* $\omega_n \cap M = \phi$ *for* n *large. If* $p_n \in \omega_n$ *is such that* $d(p_n, M) \to 0$, *then there exist sequences* $\{q_n\}$, $\{r_n\}$, $q_n, r_n \in \omega_n$ *and elements* $q \in W^s(M) \backslash M$, $r \in W^u(M) \backslash M$ *with* $\lim_{n\to\infty} q_n = q$ *and* $\lim_{n\to\infty} r_n = r$. *The* q *and* r *can be found in an arbitrarily small neighborhood of* M.

Proof. Let us first prove that the set $\{\omega_n\}$ contains a subsequence that converges in the Hausdorff metric to an invariant set ω. The omega-limit set of a semiorbit γ^+ consists of full orbits and belongs to the global attractor A for $T(t)$. Let K be the set of nonempty compact subsets of $\Omega = \mathrm{Cl} \cup_{x \in X} \omega(x)$ with Hausdorff metric ρ. The subsets ω_n are uniformly bounded compact subsets of Ω. Since each element of K is a subset of A which is compact, there is a subsequence, which we again label ω_n such that $\rho(\omega_n, \omega) \to 0$, $\omega \in K$. Clearly ω is invariant.

Let U be an isolating neighborhood of M and V an open set such that $M \subset V \subset \mathrm{Cl}(V) \subset U$. Then $p_n \in V$ for large n. Since $p_n \in \omega_n$, which is invariant, there is a full orbit through p_n. Since $p_n \in V$, there is a corresponding $y_n \in \partial V$, with $T(\tau_n)p_n = y_n$ and $T(t)p_n \in V$, for $0 > t > \tau_n$. Since $y_n \in \Omega$ we may select a convergent subsequence, again called y_n, such that $\lim_{n\to\infty} y_n = y \in \partial V \cap \omega$ and, in particular, $y \notin M$.

If $\{\tau_n\}$ were bounded, we could select a convergent subsequence $\tau_n \to \tau$ which, by continuity, makes $T(\tau)y \in M$. Hence $T(t)y \in M$ for $t > \tau$, and $y \in W^s(M) \backslash M$. Thus we may assume that $\tau_n \to -\infty$. This has the consequence that $\gamma^+(y) \subset V$ or $y \in W^s(M)$.

Since $y \in \omega$ we may select the q_n's as stated. The proof for the r_n's follows similarly, taking into account the possibility of multiple backward orbits. (Note that in this case we need only one backward orbit to remain in V.) This completes the proof of the lemma. □

Remark 4.4. If, in Lemma 4.3, there is a single orbit $\gamma^+(x)$, with $p_n \in \gamma^+(x)$ and $\lim_{t\to\infty} d(p_n, M) = 0$, and $x \notin W^s(M)$, the proof provides similar sequences $\{r_n\}$ and $\{q_n\}$ on $\gamma^+(x)$ (see [3, Thm. 4.1] and [5, Thm. 2.2]).

Proof of Theorem 4.2. The necessity of (4.2) is clear. Suppose (4.2) holds and $T(t)$ is not uniformly persistent. There are two cases to be considered in the proof. There is a sequence of points p_n with either $p_n = \gamma^+(t_n)$ for some orbit $\gamma^+(x)$, $x \in X^0$ or $p_n \in \omega_n$ for some sequence of omega limits sets, such that $d(p_n, \partial X^0) \to 0$ as $n \to \infty$. Choose a subsequence such that $p_n \to q$ and, if in the second case, such that $\omega_n \to \omega$ as in the proof of Lemma 4.3. Let Ω be $\omega(x)$ in the first case or the ω of Lemma 4.3 in the second. Clearly, $\gamma^+(q) \subset \partial X^0$ and $q \in W^s_w(M_i)$ for some M_i, say for M_1. By Lemma 4.3 (or Remark 4.4), there exists a point $q_1 \in W^s(M_1) \cap \Omega$. Since Ω is invariant, there exists a full orbit $\gamma(q_1)$ through q_1 that lies in Ω. $\alpha_\gamma(q_1)$ exists, and, since $\alpha_\gamma(q_1)$ is invariant, $\alpha_\gamma(q_1) \cap W^u_w(M_j) \neq \phi$, say for $j = 2$. If $\alpha_\gamma(q_1) \subset M_2$, then M_2 is chained to M_1. Clearly we can choose a new sequence of points p_n either on the sets ω_n or on the orbit $\gamma^+(x)$ whose distance from M_2 tends to zero. Using Lemma 4.3 or Remark 4.4, choose q_2 and repeat the argument. If $\alpha_\gamma(p_1)$ is not a proper subset of M_2, then we proceed essentially as in the proof of [3, Thm. 3.1] to reach a contradiction of the no cycle condition. The proof now follows the general scheme of the proof of Theorem 3.1 of [3], keeping in mind the two cases mentioned above and taking care to use a full orbit when constructing the alpha limit sets needed to chain sets. The reference in the proof in [3], [4], however, is not needed in view of the statement of Lemma 4.3. □

5. An example. Suppose that $x(t)$ and $y(t)$ represent populations that grow according to the delayed logistic equation

$$x'(t) = r_1 x(t)(1 - x(t-1)), \qquad y'(t) = r_2 y(t)(1 - y(t-1)).$$

If r_1 and r_2 are sufficiently small, each population grows to the carrying capacity [12, p. 14]—in this case, to one. Suppose that each produces a metabolic product or a toxin that inhibits the growth of the other, i.e., each reduces the current intrinsic growth rate of its competitor. The equations then take the form

$$(5.1) \qquad x'(t) = r_1 x(t)[1 - x(t-1) - \mu_1 y(t)], \qquad y'(t) = r_2 y(t)[1 - y(t-1) - \mu_2 x(t)].$$

This is one of a large variety of possible competition equations with delays that may be modeled on the Lotka–Volterra equations. We show that if, in addition to the above assumption on the r_i's, μ_1 and μ_2 are less than one, the system is persistent.

The appropriate space X is the positive cone of $C[0,1] \times C[0,1]$. The form of the system of (5.1) insures that solutions corresponding to positive initial conditions (positive functions on $[-1, 0]$) remain positive, i.e., the positive cone X is invariant.

For any pair of initial functions $(\phi, \psi) \in X$, let $x(t, \phi, \psi)$ be the solution of (5.1) and define $T(t)(\phi, \psi) \in X$, $t \geqq 0$, by $T(t)(\phi, \psi)(\theta) = (x(t+\theta, \phi, \psi), y(t+\theta, \phi, \psi))$, $-1 \leqq \theta \leqq 0$.

Then $T(t)$ is completely continuous for $t > 1$. Simple comparison arguments show that $T(t)$ is point dissipative. There are three constant solutions on the boundary of X corresponding to $x(t) = 0$ and $y(t) = 0$, $x(t) = 1$ and $y(t) = 0$, and $x(t) = 0$ and $y(t) = 1$. The origin is clearly unstable. Let us linearize around $(0, 1)$ to find

$$h_1'(t) = r_1 h_1(t)(1-\mu_1), \qquad h_2'(t) = r_2[-h_2(t-1) - \mu_2 h_1(t)].$$

The characteristic equation factors as

$$[\lambda - r_1(1-\mu_1)][\lambda + r_2 e^{-\lambda}] = 0.$$

There is a unique positive (since $\mu_1 < 1$) eigenvalue corresponding to the first square bracket being set equal to zero. This corresponds to an eigenvector of the form $[1, 0]^T$. The eigenvalues from the second square bracket can be shown to have negative real parts. These correspond to an eigenvector of the form $[0, 1]^T$, and hence correspond to solutions that remain in the part of the boundary of X given by $x(t) \equiv 0$. Thus the stable set of this constant solution does not intersect the interior of the cone X. A similar argument applies at the constant solutions $x(t) = 1$, $y(t) = 0$, when $\mu_2 < 1$. Since the origin is unstable, $\tilde{A}_\partial$ is just the union of the constant solutions. Taking the M_i's to be these constant solutions, there are no cycles in the boundary of X. The constant solutions are also isolated invariant sets. Hence (5.1) is uniformly persistent, and there is a global attractor in the interior of $C[0, 1] \times C[0, 1]$.

When the number of equilibrium points is small (as expected in population equations) and the dimension of the unstable manifolds is small, we can anticipate checking the chain condition directly as in the example by letting the sets M_i be the equilibrium points. The results, however, allow for greater flexibility in the choice of the cover. For example, if one face had three equilibria P_i, $i = 1, 2, 3$, and connecting orbits γ_{ij} for $(i, j) \in I = \{(1, 2), (2, 3), (3, 1)\}$, connecting P_i to P_j, then we could select as an element of the cover the three points and the connecting orbits. We would then need to show that the attracting set of this element of the cover does not intersect the interior of the space. Often there can be a good biological reason that prevents cycles. In the example above, the instability of the origin (common for competition problems) precludes the connection of invariant sets in the two faces $(x, 0)$ and $(0, y)$, $x, y \in C[0, 1]$. In predator-prey problems there are no compact invariant sets on the predator axis (corresponding to extinction in the absence of prey), which is often helpful. There are obvious difficulties when the limit sets are more complex than equilibria or periodic orbits. Ideally we would like to devise a criterion that would make the sets $\tilde{A}_\partial$ "uniformly repelling." $\tilde{A}_\partial$, of course, if it is isolated, is a one-element cover so, in principle, the theorem can be applied directly to it.

SOMMERFELD DIFFRACTION PROBLEMS WITH FIRST AND SECOND KIND BOUNDARY CONDITIONS*

F.-O. SPECK†

Abstract. A class of interface problems is considered where the solutions of one Helmholtz equation in the upper half-plane $x_2 > 0$ and of another in the lower half-plane $x_2 < 0$, respectively, are related by two transmission conditions on the line $x_2 = 0$. One of these is of the first kind, the other one of the second kind, and they are different for $x_1 > 0$ and $x_1 < 0$, respectively. In general, there appears a coupled system of Wiener-Hopf equations. Necessary and sufficient conditions for the correctness of the problem in a Sobolev space setting are presented as well as explicit formulas for a factorization of the Fourier symbol matrix of the one-medium problem, the solution in closed form, and its asymptotics near the origin.

Key words. diffraction problem, Wiener-Hopf operator, factorization, matrix function, Helmholtz equation

AMS(MOS) subject classifications. 47B35, 35J05, 45E10

1. Introduction. We investigate a certain class of diffraction problems $\mathcal{P}$ leading to simultaneous 2×2 systems of Wiener-Hopf equations. These can be considered in two ways, which we combine in this paper.

First, the classical Wiener-Hopf technique, represented by Noble [17], for instance, centers around a *function theoretic factorization* of the Fourier symbol matrix function $\sigma(\xi)$, $\xi \in \mathbb{R}$, i.e., an *explicit representation* $\sigma = \sigma_- \sigma_+$ with upper/lower holomorphic matrix functions $\sigma_\pm(\xi)$ for $\operatorname{Im} \xi \gtrless 0$ with algebraic behavior at infinity. In contrast to factoring rational matrices [1], this is a very subtle problem (see Heins [6], [7], Daniele [2], [3], Rawlins [19], Khrapkov [10], and others [8], [9], [13], [14], [23]), and it seems to be the only method for obtaining a *closed form solution.*

On the other hand, we may be interested in finding a function space setting such that $\mathcal{P}$ is well posed. This is equivalent to a certain *operator factorization* type in a more general context (see Devinatz and Shinbrot [4], Mikhlin and Prössdorf [16], and Speck [21]) where some invariant subspaces are involved.

For the one-medium problems we will find a class of symbol matrices σ depending on a parameter λ that can be factored by Daniele's method—provided λ is not exceptional (see Theorem 3.1). It is remarkable that this factorization does not correspond to a factorization of a bounded operator into bounded operators (Lemma 4.1); for only a small subclass of problems (a parameter subset $(0, 1) \subset \mathbb{C}$ of measure zero) can this be achieved by rearrangement (Theorem 4.4). For the majority of problems there exists only a *generalized factorization* corresponding to an operator factorization into *unbounded operators* (Corollary 4.6), which is best understood in the theory of systems of Cauchy type singular integral equations (see [16]). However, it helps to solve the well-posed problem (Corollary 5.1), to find the asymptotic behavior (Theorem 5.2) and to illuminate the various structures of $\mathcal{P}_\lambda$ in a function space setting based on the energy norm (Theorem 2.1 and Corollary 4.6).

We now formulate problem $\mathscr{P}$. Find

$$
\begin{aligned}
&u \in L^2(\mathbb{R}^2),\\
&u_{|\Omega^\pm} \in H^1(\Omega^\pm), \qquad \Omega^\pm\colon x_2 \gtrless 0,\\
&(\Delta + k_1^2)u = 0 \quad \text{in } \Omega^+,\\
&(\Delta + k_2^2)u = 0 \quad \text{in } \Omega^-
\end{aligned} \tag{1.1}
$$

where $\operatorname{Im} k_j > 0$ holds and the Dirichlet data $u_0^\pm = u_{|x_2=\pm 0}$ and the Neumann data $u_1^\pm = \partial u/\partial x_{2|_{x_2=\pm 0}}$ satisfy

$$
\begin{aligned}
&a_0 u_0^+ + b_0 u_0^- = h_0\\
&a_1 u_1^+ + b_1 u_1^- = h_1
\end{aligned} \quad \text{on } \mathbb{R}_+,
\qquad
\begin{aligned}
&a_0' u_0^+ + b_0' u_0^- = h_0'\\
&a_1' u_1^+ + b_1' u_1^- = h_1'
\end{aligned} \quad \text{on } \mathbb{R}_- \tag{1.2}
$$

with known constant coefficients $a_0, \dots, b_1' \in \mathbb{C}$ and $h_0 \in H^{1/2}(\mathbb{R}_+)$, $h_1 \in H^{-1/2}(\mathbb{R}_+)$, $h_0' \in H^{1/2}(\mathbb{R}_-)$, $h_1' \in H^{-1/2}(\mathbb{R}_-)$.

The following facts are known from [22], which is used for reference.

Let $1_\pm$ denote the characteristic function of $\mathbb{R}_\pm$, F the Fourier transformation, $\hat{u}(\xi_1, \xi_2) = Fu(x_1, x_2) = \int \exp(i(\xi_1 x_1 + \xi_2 x_2))u(x_1, x_2)d(x_1, x_2)$ and $t_j(\xi_1) = (\xi_1^2 - k_j^2)^{1/2}$, $j = 1, 2$, with branch cuts $\pm k_j \pm i\tau$, $\tau \geqq 0$, and $t_j(\xi_1) \sim \xi_1$ at $+\infty$. For brevity ξ_1 is replaced by ξ in what follows.

First, any solution of (1.1) satisfies the *representation formula*

$$
\begin{aligned}
u(x_1, x_2) &= G\begin{pmatrix} u_0^+ \\ u_0^- \end{pmatrix}(x_1, x_2)\\
&= F^{-1}_{\xi \mapsto x_1}\{e^{-x_2 t_1(\xi)}\hat{u}_0^+(\xi)1_+(x_2) + e^{x_2 t_1(\xi)}\hat{u}_0^-(\xi)1_-(x_2)\}.
\end{aligned} \tag{1.3}
$$

Second, we introduce the *boundary operators*

$$
\begin{aligned}
&B_\pm\colon H^{1/2}(\mathbb{R})^2 \to H^{1/2}(\mathbb{R}) \times H^{-1/2}(\mathbb{R}),\\
&B_+ = F^{-1}\begin{pmatrix} a_0 & b_0 \\ -a_1 t_1 & b_1 t_2 \end{pmatrix} \cdot F = F^{-1}\sigma_{B_+} \cdot F,\\
&B_- = F^{-1}\begin{pmatrix} a_0' & b_0' \\ -a_1' t_1 & b_1' t_2 \end{pmatrix} \cdot F = F^{-1}\sigma_{B_-} \cdot F,
\end{aligned} \tag{1.4}
$$

which correspond to (1.2) but act on functions living on the whole axis. Problem $\mathscr{P}$ is said to be of *normal type*, if $\sigma_{B_\pm}(\xi)$ are regular for $\xi \in \mathbb{R}$ and both are *stable at infinity*:

$$
[\det \sigma_{B_\pm}(\xi)]^{\pm 1} = O(|\xi|^{\pm 1}), \qquad |\xi| \to \infty. \tag{1.5}
$$

This assumption is equivalent to the bijectivity of $B_\pm$ and can also be written in the following form:

$$
\begin{aligned}
&a_0 b_1 t_2(\xi) + b_0 a_1 t_1(\xi) \neq 0, \qquad \xi \in \mathbb{R},\\
&a_0 b_1 + b_0 a_1 \neq 0
\end{aligned} \tag{1.6}
$$

supplemented by analogous conditions for the primed coefficients.

Third, there is the following theorem.

EQUIVALENCE THEOREM. *Let $\mathscr{P}$ be of normal type (or only B_- invertible). Then u solves Problem $\mathscr{P}$, if and only if* (i) *u is represented by* (1.3) *where $u_0^\pm$ are given by*

$$
\begin{pmatrix} u_0^+ \\ u_0^- \end{pmatrix} = B_-^{-1}\left\{\begin{pmatrix} v_+ \\ w_+ \end{pmatrix} + \begin{pmatrix} l_e h_0' \\ l_o h_1' \end{pmatrix}\right\} \tag{1.7}
$$

with even or odd extension of the data onto the whole axis and (ii) *the functions* (*more precisely*: *functionals*) v_+, w_+ *are solutions of the Wiener–Hopf system*

$$W\begin{pmatrix} v_+ \\ w_+ \end{pmatrix} = \begin{pmatrix} h_0 \\ h_1 \end{pmatrix} - 1_+ \cdot B_+ B_-^{-1} \begin{pmatrix} l_e h_0' \\ l_o h_1' \end{pmatrix} = \begin{pmatrix} h_0^* \\ h_1^* \end{pmatrix},$$

$$W = 1_+ \cdot F^{-1}\sigma \cdot F : \tilde{H}^{1/2}(\mathbb{R}_+) \times \tilde{H}^{-1/2}(\mathbb{R}_+) \to H^{1/2}(\mathbb{R}_+) \times H^{-1/2}(\mathbb{R}_+), \tag{1.8}$$

$$\sigma = \sigma_{B_+}\sigma_{B_-}^{-1}.$$

Note that $\tilde{H}^s(\mathbb{R}_+)$ is defined to be the closed subspace of $H^s = H^s(\mathbb{R})$ functions supported on $\overline{\mathbb{R}_+}$ (the natural embedding into $H^s(\mathbb{R}_+)$ is not closed with respect to the $H^s(\mathbb{R}_+)$ topology for $s = \frac{1}{2} \bmod 1$). This space is sometimes denoted by $H^s_{00}(\mathbb{R}_+)$ for $s = \mu + \frac{1}{2}$, $\mu \in \mathbb{N}_0$ [12], H_s^+ [5], $\tilde{W}^{s,2}(\mathbb{R}_+)$, or $H^+_{s,2}(\mathbb{R})$ [20]. The multiplication operator 1_+ acts on distributions as a restriction on test functions supported on $\overline{\mathbb{R}_+}$. Other (continuous) extensions instead of l_e, l_o are admissible.

2. The structure of Wiener–Hopf operators corresponding to problem $\mathscr{P}$.

THEOREM 2.1. *Let $\mathscr{P}$ be of normal type. The operator W given by* (1.8) *is Fredholm, if and only if the elements of the matrix*

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} = \frac{1}{a_0'b_1' + b_0'a_1'} \begin{pmatrix} a_0b_1' + b_0a_1' & -a_0b_0' + b_0a_0' \\ -a_1b_1' + b_1a_1' & a_1b_0' + b_1a_0' \end{pmatrix} \tag{2.1}$$

satisfy the conditions

$$ad = 0, \qquad bc \neq 0 \tag{2.2}$$

or

$$ad \neq 0, \qquad \lambda^{-1} = bc/ad \notin [0, 1]. \tag{2.3}$$

In both cases, the analytical index of W equals zero (*we call $\lambda = ad/bc$ the characteristic parameter of $\mathscr{P}$*).

Proof. The symbol matrix σ reads explicitly

$$\sigma = \frac{1}{a_0'b_1't_2 + b_0'a_1't_1} \begin{pmatrix} a_0b_1't_2 + b_0a_1't_1 & -a_0b_0' + b_0a_0' \\ (-a_1b_1' + b_1a_1')t_1t_2 & a_1b_0't_1 + b_1a_0't_2 \end{pmatrix}. \tag{2.4}$$

Now put $t(\xi) = (\xi^2 - k^2)^{1/2}$ with an auxiliary wave number k (that we only need in the case $k_1 \neq k_2$) and

$$t(\xi) = t_-(\xi)t_+(\xi) = (\xi - k)^{1/2}(\xi + k)^{1/2} \tag{2.5}$$

with the usual choice of branches, see above. It is known [5, Thm. 4.4, Lemma 4.6], [22] that the mappings

$$\begin{aligned} &F^{-1}t_+^r \cdot F : \tilde{H}^s(\mathbb{R}_+) \to \tilde{H}^{s-r/2}(\mathbb{R}_+), \\ &1_+ \cdot F^{-1}t_-^r \cdot Fl : H^s(\mathbb{R}_+) \to H^{s-r/2}(\mathbb{R}_+) \end{aligned} \tag{2.6}$$

are bijective for any extension l and arbitrary $r, s \in \mathbb{R}$. Therefore W is equivalent to (coincides up to invertible factors with) the *lifted operator*

$$W_0 = 1_+ \cdot F^{-1}\sigma_0 \cdot F : L^2(\mathbb{R}_+)^2 \to L^2(\mathbb{R}_+)^2 \tag{2.7}$$

where the *lifted matrix*

$$\begin{aligned} \sigma_0 &= \begin{pmatrix} t_- & 0 \\ 0 & t_-^{-1} \end{pmatrix} \sigma \begin{pmatrix} t_+^{-1} & 0 \\ 0 & t_+ \end{pmatrix} \\ &= \frac{1}{a_0'b_1't_2 + b_0'a_1't_1} \begin{pmatrix} (a_0b_1't_2 + b_0a_1't_1)(t_-/t_+) & (-a_0b_0' + b_0a_0')t \\ (-a_1b_1' + b_1a_1')(t_1t_2/t) & (a_1b_0't_1 + b_1a_0't_2)(t_+/t_-) \end{pmatrix} \end{aligned} \tag{2.8}$$

is also invertible in $C(\mathbb{R})^{2\times 2}$ and tends to

$$\sigma_0(\pm\infty)=\begin{pmatrix}\pm a & b\\ c & \pm d\end{pmatrix} \tag{2.9}$$

at infinity, i.e., σ_0 is *piecewise continuous* on the (one-point-)compactified axis $\dot{\mathbb{R}}$.

The theory of systems of Cauchy-type singular integral equations on the unit circle, which can be transferred to the real line case by the stereographic projection (or Cayley transformation) [16, Chaps. V, IV.6], implies that the Fredholm property of W_0 (and thus of W) is equivalent to

$$\begin{aligned}&\det \sigma_0(\xi)\neq 0, \qquad \xi\in\mathbb{R},\\ &\det[\mu\sigma_0(-\infty)+(1-\mu)\sigma_0(+\infty)]\neq 0, \qquad \mu\in[0,1].\end{aligned} \tag{2.10}$$

This can easily be rewritten in the form (2.2)-(2.3). Furthermore, we obtain the index formula

$$\begin{aligned}\operatorname{Ind} W&=\dim N(W)-\operatorname{codim} R(W)\\ &=\operatorname{Ind} W_0=-\operatorname{ind}\det\sigma_0=0\end{aligned} \tag{2.11}$$

where the winding number of $\det\sigma_0$ vanishes, since

$$\begin{aligned}\det\sigma_0(\xi)&=\det\sigma(\xi)=\det\sigma_{B_+}(\xi)/\det\sigma_{B_-}(\xi)\\ &=(a_0b_1t_2(\xi)+b_0a_1t_1(\xi))/(a_0'b_1't_2(\xi)+b_0'a_1't_1(\xi))\end{aligned} \tag{2.12}$$

is an even function in ξ.

COROLLARY 2.2. *There exists a generalized factorization* [16, V.5-6] *in* $L^2(\mathbb{R})^2$

$$\sigma_0(\xi)=\sigma_{0-}(\xi)\begin{pmatrix}\left(\dfrac{\xi-i}{\xi+i}\right)^{\kappa_1} & 0\\ 0 & \left(\dfrac{\xi-i}{\xi+i}\right)^{\kappa_2}\end{pmatrix}\sigma_{0+}(\xi), \tag{2.13}$$

i.e., with $\kappa_1,\kappa_2\in\mathbb{Z}$, $\sigma_{0\pm}^{\pm 1}\in L^2(\mathbb{R},\rho)^{2\times 2}$ *are holomorphically extendable into the upper/lower complex half-plane where* $\rho(\xi)=(\xi^2+1)^{-1/2}$ *holds (the elements of* $\rho\sigma_{0\pm}^{\pm 1}$ *belong to* $L^2(\mathbb{R})$ *where* $\sigma_{0\pm}^{-1}$ *denote the inverse matrices), if and only if* $\mathcal{P}$ *is of normal type and* (2.2)-(2.3) *are satisfied. This also yields* $\operatorname{Ind} W=-\kappa_1-\kappa_2=0$.

Remarks 2.3. (1) There corresponds a *bounded operator factorization* $A_0=F^{-1}\sigma_0\cdot F=A_{0-}CA_{0+}$, $A_{0\pm}$, $C\in\mathcal{L}(L^2(\mathbb{R})^2)$, with (2.13), if and only if the matrix functions are bounded invertible, i.e., $\sigma_{0\pm}^{\pm 1}\in L^\infty(\mathbb{R})^{2\times 2}$. This is also called *a cross factorization* in the context of general Wiener-Hopf operators [21], which yields a generalized inverse of W_0 (cf. [16, Thm. 4.2].). If the additional factors satisfy $\sigma_{0\pm}\in C(\dot{\mathbb{R}})^{2\times 2}$, then (2.13) is said to be a *right canonical (matrix) factorization* [16, V.3.2.]. But here this is not true in general according to discontinuities at infinity (see (2.9)).

(2) So far we do not know about $\kappa_1=\kappa_2=0$ and the invertibility of W. The previous result is not constructive.

(3) Obviously, the system decomposes, i.e., σ is triangular (see (2.4)) if and only if (i) the vectors (a_0,b_0) and (a_0',b_0') or the vectors (a_1,b_1) and (a_1',b_1') are parallel, which means that the corresponding data are given along the full line, or (ii) $a_0=a_1'=0$ (or similar) according to a pure boundary value problem for the lower (or upper) half-plane, which can be treated separately, or (iii) in the case $t_1=t_2$ only: the vectors (a_0,b_0) and (a_1',b_1') or (a_1,b_1) and (a_0',b_0') are antiparallel. The first case (i) $bc=0$ is excluded by (2.2)-(2.3). The range of W is not closed in $H^{1/2}(\mathbb{R}_+)\times H^{-1/2}(\mathbb{R}_+)$;

there appear compatibility conditions and problems that are well-posed in other space settings where at most a single Wiener-Hopf equation must be solved. The other two cases do not disturb the conditions (2.2)-(2.3) and we have an invertible system according to two isolated equations of the type that appears for Sommerfeld's half-plane problem. All these cases have been discussed in [22].

3. The explicit function theoretic factorization for one-medium problems. We consider the nondecomposing case of a normal type problem $\mathcal{P}$ with $t_1 = t_2 = t$ and write σ from (2.4) in the standard form

$$\sigma = \begin{pmatrix} a & bt^{-1} \\ ct & d \end{pmatrix} \to \begin{pmatrix} 1 & t^{-1} \\ \lambda^{-1}t & 1 \end{pmatrix} \tag{3.1}$$

after some elementary transformations.

The following factorization of this nonrational matrix function is based on the work of Daniele [2] and others (see above). Only the case $\lambda = -1$ corresponding to the mixed Dirichlet-Neumann problem

$$\begin{aligned} &u_0^+ = h_0, \quad u_1^- = h_1 \quad \text{on } \mathbb{R}_+, \\ &u_0^+ - u_0^- = u_1^+ - u_1^- = 0 \quad \text{on } \mathbb{R}_- \end{aligned} \tag{3.2}$$

has been solved before [7], [14], [18]. The exceptional (decomposing) case $\lambda = 0$ or ∞ is excluded here, $\lambda = 1$ is nonnormal and $\lambda = 2$ corresponds to the strange reference problem where, for instance, u_0^+, $u_1^+ - u_1^- \in \mathbb{R}_+$ and u_1^-, $u_0^+ - u_0^-$ on $\mathbb{R}_-$ are given, (see [22]) and where W_0 is not Fredholm in our (L^p, $p = 2$) setting (see (2.3)).

THEOREM 3.1. *For any $\lambda \in \mathbb{C}$, $0 \neq \lambda \neq 1$, a factorization $\sigma = \sigma_- \sigma_+$ into lower/upper holomorphic function matrices is given by*

$$\begin{aligned} \sigma_\pm = (1-\lambda^{-1})^{1/4} \Big\{ &\cosh [C \cdot \log \gamma_\pm] \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \\ &- \sinh [C \cdot \log \gamma_\pm] \begin{pmatrix} 0 & \sqrt{\lambda}/t \\ t/\sqrt{\lambda} & 0 \end{pmatrix} \Big\} \end{aligned} \tag{3.3}$$

with

$$C = \frac{i}{\pi} \log \frac{\sqrt{\lambda}+1}{\sqrt{\lambda}-1}, \qquad \gamma_\pm(\xi) = \frac{\sqrt{k \pm \xi} + i\sqrt{k \mp \xi}}{\sqrt{2k}} \tag{3.4}$$

and algebraic behavior as $\xi \to \pm\infty$ (e.g., put $\arg \sqrt{\lambda} \in [0, \pi)$, $\arg (\sqrt{\lambda}+1)/(\sqrt{\lambda}-1) \in [-\pi, 0]$, $\operatorname{Re} C \in [0, 1]$, $\arg \sqrt{k} = \frac{1}{2} \arg k$ *and branch cuts as before*).

Proof. To construct $\sigma_\pm$ we write [2]

$$\sigma = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \frac{1}{\lambda t} \begin{pmatrix} 0 & \lambda \\ t^2 & 0 \end{pmatrix} \tag{3.5}$$

where the latter matrix has polynomial elements and find a matrix $M = \log \sigma$ in the sense of $\sigma = \exp M$ (which is defined as a series) by putting

$$\log \sigma = \frac{1}{2} \log g \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \frac{1}{2} \tau \begin{pmatrix} 0 & \lambda \\ t^2 & 0 \end{pmatrix} \tag{3.6}$$

with

$$g = \det \sigma = 1 - \lambda^{-1}, \qquad \tau = \frac{-1}{\sqrt{\lambda}\, t} \log \frac{\sqrt{\lambda}+1}{\sqrt{\lambda}-1}. \tag{3.7}$$

Surely, τ does not depend on the branch of $\sqrt{\lambda}$. An additive decomposition

$$\begin{aligned}\frac{1}{t(\xi)} &= \frac{-2i}{\pi t(\xi)}\left\{\log\frac{\sqrt{k+\xi}+i\sqrt{k-\xi}}{\sqrt{2k}}+\log\frac{\sqrt{k-\xi}+i\sqrt{k+\xi}}{\sqrt{2k}}\right\} \\ &= \frac{-2i}{\pi t(\xi)}\{\log\gamma_+(\xi)+\log\gamma_-(\xi)\}\end{aligned} \tag{3.8}$$

($\gamma_\pm$ are not upper/lower functions themselves) yields

$$\tau = \tau_+ + \tau_-, \qquad \tau_\pm(\xi) = \frac{2C}{\sqrt{\lambda}\, t(\xi)}\log\gamma_\pm(\xi) \tag{3.9}$$

where $\tau_\pm$ are holomorphic in $\operatorname{Im}\xi > -\operatorname{Im} k$ and $\operatorname{Im}\xi < \operatorname{Im} k$, respectively. A factorization of $g = g_- g_+$, $g_\pm = (1-\lambda^{-1})^{1/2}$ is trivial here.

Associating

$$(\log\sigma)_\pm = \frac{1}{2}\log g_\pm\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix} + \frac{1}{2}\tau_\pm\begin{pmatrix}0 & \lambda\\ t^2 & 0\end{pmatrix}, \tag{3.10}$$

which obviously commute with each other, we have

$$\sigma_\pm = \exp(\log\sigma)_\pm \tag{3.11}$$

in coincidence with (3.3). It is also possible to check (3.3) directly.

The behavior at infinity is determined by

$$\begin{aligned}\gamma_+(\xi) &\sim \begin{cases}\sqrt{k}\,\xi^{-1/2}, & \xi\to+\infty,\\ \sqrt{2/k}\,i|\xi|^{1/2}, & \xi\to-\infty,\end{cases}\\ \gamma_-(\xi) &\sim \begin{cases}(i/\sqrt{k})\xi^{1/2}, & \xi\to+\infty,\\ \sqrt{k/2}\,|\xi|^{-1/2}, & \xi\to-\infty.\end{cases}\end{aligned} \tag{3.12}$$

Thus the arguments of $\gamma_\pm$ are bounded and the entries of exponential type in $\sigma_\pm$ behave as

$$\begin{aligned}|\exp[C\cdot\log\gamma_\pm(\xi)]| &= O(\exp\{\operatorname{Re} C\cdot\log|\gamma_\pm(\xi)|\})\\ &= \begin{cases}O(|\xi|^{\mp\operatorname{Re}C/2}), & \xi\to+\infty\\ O(|\xi|^{\pm\operatorname{Re}C/2}), & \xi\to-\infty.\end{cases}\end{aligned} \tag{3.13}$$

Note that this is bounded (the hyperbolic terms oscillate), if and only if $C\in i\mathbb{R}$ holds or equivalently $\lambda > 1$ corresponding to the case that was excluded in (2.3).

4. How to find a generalized factorization. To end up with the inverse of W we try to consider (3.3) as a factorization in the sense of (2.13)—after the lifting process described in (2.6)–(2.8).

It will be seen that this is not possible without an additional modification: the splitting-off of a polynomial matrix in the middle of (3.3). In our opinion this phenomenon is typical of problems with more general boundary or transmission conditions.

Furthermore, we will see that here usually (in contrast to the scalar Dirichlet or Neumann problems) the plus/minus factors correspond to unbounded operators on $L^2(\mathbb{R})^2$, i.e., $\sigma_{0\pm}\in L^\infty(\mathbb{R})^{2\times 2}$ holds only in "exceptional cases," which makes the interpretation in the spirit of singular equations [16] most important.

For a better understanding of the (linear) operator theoretical structure of the factorization, we consider W_0 in (2.7) rather on the whole scale of L^p spaces $L^p(\mathbb{R})^2$, $1 \leqq p \leqq \infty$ (the elements occurring in (2.8) are L^p multipliers [11]), or at least for $1 < p < \infty$ (because of relations to singular integral operators). This, in fact, means that we seek $u_{|\Omega^\pm} \in W^{s,p}(\Omega^\pm)$ with $s - 1/p = \frac{1}{2}$, i.e., $s = \frac{1}{2} + 1/p$, which is physically less important.

It is known that the Fredholm property of W_0 on $L^p(\mathbb{R}_+)^2$ is equivalent to a factorization (2.13) with upper/lower function matrices

$$\begin{aligned} &\sigma_{0-},\ \sigma_{0+}^{-1} \in L^p(\mathbb{R}, \rho^{2/p})^{2\times 2}, \\ &\sigma_{0+},\ \sigma_{0-}^{-1} \in L^q(\mathbb{R}, \rho^{2/q})^{2\times 2}, \qquad 1/p + 1/q = 1 \end{aligned} \tag{4.1}$$

(see [16, V, Thm. 5.2]). Further note that $\varphi(\xi) = |\xi - k|^\mu$, $\xi \in \mathbb{R}$, implies

$$\varphi \in L^p(\mathbb{R}, \rho^{2/p}) \Leftrightarrow \mu p < 1. \tag{4.2}$$

We call $\operatorname{ord} \varphi = \mu$ the *exact order of* φ (at $\pm\infty$), and the order of a matrix function is defined elementwise.

Now we are able to test whether the lifted function theoretic factorization defined by

$$\tilde{\sigma}_{0-}\tilde{\sigma}_{0+} = \begin{pmatrix} t_- & 0 \\ 0 & t_-^{-1} \end{pmatrix} \sigma_- \cdot \sigma_+ \begin{pmatrix} t_+^{-1} & 0 \\ 0 & t_+ \end{pmatrix} \tag{4.3}$$

is a generalized factorization with trivial middle term ($\kappa_1 = \kappa_2 = 0$).

LEMMA 4.1. *Formula* (4.3) *is not a generalized factorization for any* $p \in (1, \infty)$ *and any parameter* $\lambda \in \mathbb{C}$.

Proof. From (3.3), (3.13), and (4.3) we obtain for $0 \neq \lambda \neq 1$ and $\delta = \operatorname{Re} C \in [0, 1]$ (see the Appendix)

$$\begin{aligned} \operatorname{ord} \tilde{\sigma}_{0-} = \operatorname{ord} \tilde{\sigma}_{0+}^{-1} &= \begin{pmatrix} \frac{1}{2}(\delta+1) & \frac{1}{2}(\delta-1) \\ \frac{1}{2}(\delta+1) & \frac{1}{2}(\delta-1) \end{pmatrix}, \\ \operatorname{ord} \tilde{\sigma}_{0+} = \operatorname{ord} \tilde{\sigma}_{0-}^{-1} &= \begin{pmatrix} \frac{1}{2}(\delta-1) & \frac{1}{2}(\delta-1) \\ \frac{1}{2}(\delta+1) & \frac{1}{2}(\delta+1) \end{pmatrix} \end{aligned} \tag{4.4}$$

with regard to $\operatorname{ord} \det \sigma_\pm = 0$.

Thus (4.1)-(4.2) cannot be satisfied for any p, since $\mu = \frac{1}{2}(\delta+1)$, $1/p > \mu \geqq \frac{1}{2}$ and $1/q > \mu \geqq \frac{1}{2}$ contradicts $1/p + 1/q = 1$.

LEMMA 4.2. *For* $\delta = \operatorname{Re} C = \operatorname{Re}(i/\pi) \log(\sqrt{\lambda}+1)/(\sqrt{\lambda}-1) \in [0, 1)$ *and* $|1/p - \frac{1}{2}| > \delta/2$, *a generalized factorization reads*

$$\begin{aligned} \sigma_0 &= \sigma_{0-} \begin{pmatrix} ((\xi-i)/(\xi+i))^{\kappa_1} & 0 \\ 0 & ((\xi-i)/(\xi+i))^{\kappa_2} \end{pmatrix} \sigma_{0+} \\ &= \begin{cases} \tilde{\sigma}_{0-} \begin{pmatrix} (\xi-i)^{-1} & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} (\xi-i)/(\xi+i) & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \xi+i & 0 \\ 0 & 1 \end{pmatrix} \tilde{\sigma}_{0+}, & p < \dfrac{2}{1+\delta} \\ \tilde{\sigma}_{0-} \begin{pmatrix} 1 & 0 \\ 0 & \xi-i \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & (\xi+i)/(\xi-i) \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & (\xi+i)^{-1} \end{pmatrix} \tilde{\sigma}_{0+}, & p > \dfrac{2}{1-\delta}. \end{cases} \end{aligned} \tag{4.5}$$

Thus the index of W_0 *acting on* $L^p(\mathbb{R}_+)^2$ *is given by*

$$\operatorname{Ind} W_0 = -(\kappa_1 + \kappa_2) = \mp 1 \tag{4.6}$$

for $p<2/(1+\delta)$ and $p>2/(1-\delta)$, respectively, and a left/right inverse is given by

$$W_0^- = A_{0+}^{-1}1_+ \cdot U^{-1}1_+ \cdot A_{0-}^{-1}|_{L^p(\mathbb{R}_+)^2} \tag{4.7}$$

with $A_{0\pm} = F^{-1}\sigma_{0\pm} \cdot F$ and $U = F^{-1}(((\xi-i)/(\xi+i))^{\kappa_j}\delta_{jk}) \cdot F$.

Proof. It is easy to verify the properties (4.1), since all elements of σ_{0-} and σ_{0+} are of order $\frac{1}{2}(\delta-1)$ and $\frac{1}{2}(\delta+1)$. Since ord det $\sigma_{0-} = -1$ in the first case (see (2.8), (3.3), (4.5) (det $\sigma_\pm = $ const!)), we have ord $\sigma_{0-}^{-1} = +1+\frac{1}{2}(\delta-1) = \frac{1}{2}(\delta+1)$ in any place etc., which yields the corresponding properties (4.1) of the inverse matrices. Thus (4.5) represents a generalized factorization and the following conclusions are standard [16], [21].

Remark 4.3. This trick obviously does not work for $1/p \in [\frac{1}{2}(1-\delta), \frac{1}{2}(1+\delta)]$, and in particular not for $p=2$ where Ind $W_0 = 0$ holds.

For $\delta = \operatorname{Re} C = 0$, i.e., $\lambda \in (1, \infty)$, see the Appendix, where only the case $p=2$ is excluded (cf. the remark after (3.13)).

For $\delta = 1$, i.e., $\lambda \in (0, 1)$, we do not have any result so far.

THEOREM 4.4. *For $\delta \in (0, 1]$, and $|1/p - \frac{1}{2}| < \delta/2$, a generalized factorization reads*

$$\sigma_0 = \sigma_{0-} \cdot \sigma_{0+} = \tilde{\sigma}_{0-}\begin{pmatrix} 1 & 0 \\ \xi_1/\sqrt{\lambda} & 1 \end{pmatrix} \cdot \begin{pmatrix} 1 & 0 \\ -\xi_1/\sqrt{\lambda} & 1 \end{pmatrix}\tilde{\sigma}_{0+}. \tag{4.8}$$

Thus W_0 and W are invertible and

$$W_0^{-1} = A_{0+}^{-1}1_+ \cdot A_{0-}^{-1}|_{L^p(\mathbb{R}_+)^2} \tag{4.9}$$

holds according to this factorization.

Proof. The following cancellation in the asymptotic behavior of the terms in (3.3) becomes most important. Abbreviating the hyperbolic terms there by $c_\pm$, $s_\pm$, and the exponential by $e_\pm$ we obtain

$$\begin{aligned} c_+\xi + s_+t &= e_+(\xi+t) + e_+^{-1}(\xi-t) \\ &= \begin{cases} O(|\xi|^{\delta/2+1}) + O(|\xi|^{\delta/2-1}), & \xi \to +\infty \\ O(|\xi|^{\delta/2-1}) + O(|\xi|^{-\delta/2+1}), & \xi \to -\infty \end{cases} \\ &= O(|\xi|^{1-\delta/2}), \qquad |\xi| \to \infty \end{aligned} \tag{4.10}$$

according to (3.13), $\delta \in (0, 1]$ and

$$\xi - t = \frac{k^2}{\xi+t} = O(\xi^{-1}), \qquad \xi \to +\infty. \tag{4.11}$$

By analogy, there holds

$$c_-t - s_-t = O(|\xi|^{1-\delta/2}), \qquad |\xi| \to \infty \tag{4.12}$$

in contrast to

$$c_+\xi - s_+t,\ c_-t + s_-\xi = O(|\xi|^{1+\delta/2}). \tag{4.13}$$

Thus we obtain the following lifted modified factors and their orders:

$$\begin{aligned} \sigma_{0+} &= \begin{pmatrix} 1 & 0 \\ -\xi/\sqrt{\lambda} & 1 \end{pmatrix}\sigma_+\begin{pmatrix} t_+^{-1} & 0 \\ 0 & t_+ \end{pmatrix} \\ &= (1-\lambda^{-1})^{1/4}\begin{pmatrix} c_+ & -s_+\sqrt{\lambda}/t \\ -c_+\xi/\sqrt{\lambda} - s_+t/\sqrt{\lambda} & s_+\xi/t + c_+ \end{pmatrix}\begin{pmatrix} t_+^{-1} & 0 \\ 0 & t_+ \end{pmatrix}, \\ \operatorname{ord}\sigma_{0+} &= \begin{pmatrix} \frac{1}{2}(\delta-1) & \frac{1}{2}(\delta-1) \\ \frac{1}{2}(1-\delta) & \frac{1}{2}(1-\delta) \end{pmatrix} \end{aligned} \tag{4.14}$$

and

$$
\begin{aligned}
\sigma_{0-} &= \begin{pmatrix} t_- & 0 \\ 0 & t_-^{-1} \end{pmatrix} \sigma_- \begin{pmatrix} 1 & 0 \\ \xi/\sqrt{\lambda} & 1 \end{pmatrix} \\
&= (1-\lambda^{-1})^{1/4} \begin{pmatrix} t_- & 0 \\ 0 & t_-^{-1} \end{pmatrix} \begin{pmatrix} c - s_-\xi/t & -s_-\sqrt{\lambda}/t \\ -s_- t/\sqrt{\lambda} + c_-\xi/\sqrt{\lambda} & c_- \end{pmatrix}, \\
\operatorname{ord} \sigma_{0-} &= \begin{pmatrix} \frac{1}{2}(1-\delta) & \frac{1}{2}(\delta-1) \\ \frac{1}{2}(1-\delta) & \frac{1}{2}(\delta-1) \end{pmatrix}.
\end{aligned} \tag{4.15}
$$

Now we ask to which $L^p(\mathbb{R}, \rho^{2/p})$ spaces the elements φ of $\sigma_{0\pm}^{\pm 1}$ belong. Obviously,

$$
\operatorname{ord} \varphi = \mu \leqq \max\{\tfrac{1}{2}(1-\delta), \tfrac{1}{2}(\delta-1)\} = \tfrac{1}{2}(1-\delta) \tag{4.16}
$$

holds for $\delta \in (0, 1]$. So p is determined by, see (4.1)-(4.2)

$$
1/p > \tfrac{1}{2}(1-\delta) \tag{4.17}
$$

and the same condition must be satisfied for $1/q = 1 - 1/p$, i.e., $|1/p - \frac{1}{2}| < \delta/2$.

Remark 4.5. The operators $A_{0\pm}^{\pm 1}$ are not bounded for $\delta \neq 1$ but the composition $A_{0-}^{-1} 1_+ \cdot A_{0-}$ is (see [16, V.5]).

COROLLARY 4.6. *In terms of the characteristic parameter $\lambda = ad/bc$ (see Theorem 2.1) we obtain the following alternative conclusions for the $p = 2$ theory of W_0.*

(1) *$\lambda = 0$: σ_0 is triangular. W_0 decomposes into two single Wiener-Hopf equations that are invertible (see [22]).*

(2) *$\lambda = 1$: σ_0 degenerates, and $R(W_0)$ is not closed (for any p).*

(3) *$\lambda \in (1, \infty)$: σ_0 admits a function theoretic factorization, but not a generalized factorization in $L^2(\mathbb{R}_+)^2$ (but in $L^p(\mathbb{R}_+)^2$, $p \neq 2/(1 \pm \delta)$), and W_0 is not Fredholm for $p = 2$.*

(4) *$\lambda \in (0, 1)$: σ_0 admits a bounded factorization due to $\delta = \operatorname{Re} C = 1$, and W_0 is invertible (for every $p \in (1, \infty)$).*

(5) *$\lambda \notin [0, \infty)$: σ_0 admits an unbounded factorization due to $\delta < 1$ with vanishing partial indices, and W_0 is invertible (also for $p \in (2/(1+\delta), 2/(1-\delta))$ and one-sided invertible for p outside the closed interval).*

5. The explicit solution and its asymptotics. We continue with the one-medium case and assume σ to have standard form (3.1), which leads to the one-parameter family of reference problems $\mathcal{P}_\lambda$:

$$
\begin{aligned}
&(\Delta + k^2) u = 0 && \text{in } \Omega^+ \cup \Omega^-, \\
&-2u_0^- = h_0 && \text{on } \mathbb{R}_+, \\
&(1-\lambda^{-1}) u_1^+ - (1+\lambda^{-1}) u_1^- = h_1 && \text{on } \mathbb{R}_+, \\
&u_0^+ - u_0^- = h_0' && \text{on } \mathbb{R}_-, \\
&u_1^+ - u_1^- = h_1' && \text{on } \mathbb{R}_-
\end{aligned} \tag{5.1}
$$

(see (1.1)-(1.2) and (2.4)). Other realizations for the same parameter are available.

COROLLARY 5.1. *$\mathcal{P}_\lambda$ is well-posed (with respect to the space setting in (1.1)-(1.2)), if and only if $\lambda^{-1} \in \mathbb{C} \setminus [0, 1]$ holds. The solution is then given by (1.3), (1.7) where the unique solution of the Wiener-Hopf system (1.8) must be inserted. This reads*

$$
\begin{aligned}
\begin{pmatrix} v_+ \\ w_+ \end{pmatrix} &= W^{-1} \begin{pmatrix} h_0^* \\ h_1^* \end{pmatrix} \\
&= A_+^{-1} 1_+ \cdot A_-^{-1} \begin{pmatrix} l_e h_0^* \\ l_o h_1^* \end{pmatrix}
\end{aligned} \tag{5.2}
$$

where the Fourier symbols $\Phi_\pm$ *of* $A_\pm$ *are represented by*

$$\Phi_+ = \begin{pmatrix} 1 & 0 \\ -\xi/\sqrt{\lambda} & 1 \end{pmatrix} \sigma_+, \qquad \Phi_- = \sigma_- \begin{pmatrix} 1 & 0 \\ \xi/\sqrt{\lambda} & 1 \end{pmatrix} \tag{5.3}$$

(*see* (4.14)-(4.15)). *Again,* $A_\pm$ *are not bounded operators in* $\mathscr{L}(H^{1/2} \times H^{-1/2}, L^2 \times L^2)$ *and* $\mathscr{L}(L^2 \times L^2, H^{1/2} \times H^{-1/2})$, *respectively, for* $\delta \neq 1$. *But there hold* (*despite the unboundedness*)

$$\begin{gathered} A_-^{-1} 1_+ \cdot A_- \in \mathscr{L}(L^2 \times L^2), \\ W^{-1} \in \mathscr{L}(H^{1/2}(\mathbb{R}_+) \times H^{-1/2}(\mathbb{R}_+), \tilde{H}^{1/2}(\mathbb{R}_+) \times \tilde{H}^{-1/2}(\mathbb{R}_+)). \end{gathered} \tag{5.4}$$

THEOREM 5.2. *If the data* h_0^*, h_1^* *in problem* $\mathscr{P}_\lambda$ *are sufficiently smooth and rapidly decreasing* (*like* $e^{-x_1} 1_+(x_1)$), *the singular behavior of the solution is described by*

$$\nabla u(x) \sim \text{const} \cdot |x|^{\delta/2-1}, \qquad |x| \to 0 \tag{5.5}$$

with $\delta = \operatorname{Re}(i/\pi) \log(\sqrt{\lambda}+1)/(\sqrt{\lambda}-1) \in (0, 1]$ *provided* $\lambda \notin [1, \infty)$.

Proof. By standard arguments [5], [6], [17] the singular behavior depends on the maximal order in the symbol matrix of A_+^{-1};

$$\operatorname{ord} \Phi_+^{-1} = \begin{pmatrix} \delta/2 & \delta/2-1 \\ 1-\delta/2 & -\delta/2 \end{pmatrix}. \tag{5.6}$$

So the gradient of the solution behaves like the inverse Fourier transform of $(\xi^2+1)^{1/2(1-\delta/2)}(\xi+i)^{-1}$.

6. On the two-media case. We finish with some remarks about problems $\mathscr{P}$ where the wave numbers k_1, k_2 differ and continue considering the matrices $\sigma(\xi) = \sigma(\xi; k_1, k_2)$ and $\sigma_0(\xi) = \sigma_0(\xi; k_1, k_2, k)$ in (2.4) and (2.8), respectively.

Remark 6.1. If $\mathscr{P}$ is of normal type, $k_1 \neq k_2$ holds and if σ is of Khrapkov type [10]

$$\sigma = \mu_1 R_1 + \mu_2 R_2 \tag{6.1}$$

with scalar functions μ_j and polynomial matrices R_j, then it must be even of triangular form, i.e., the Wiener-Hopf system decomposes. More precisely there holds that (i) both of the main diagonal elements disappear (two isolated boundary value problems), or (ii) they are linear dependent and at least one of the other two disappears (excluded due to an isolated Wiener-Hopf equation with another suitable space setting; see Remark 2.3.3(i) or (iii) where both of the off-diagonal elements disappear (trivial, since σ is constant)).

So the explicit factorization method of § 3 does not help in any case where $k_1 \neq k_2$ although the existence question is completely answered by Corollary 2.2 (with unknown partial indices).

Remark 6.2. The idea to invert W_0 using the fixed point principle [15], [21] works in the case $\lambda \in (0, 1)$ where we have a bounded factorization. Consider $\sigma_0(\xi; k_1, k_2)$ as a perturbation of $\sigma_0(\xi; k)$ with $k = \frac{1}{2}(k_1+k_2)$, $\operatorname{Im} k_j > 0$, and the same coefficients, i.e., the same characteristic parameter λ. Using the factorization (4.8) $\sigma_0 = \sigma_{0-}\sigma_{0+}$ of $\sigma_0(\xi; k)$ we obtain

$$\sigma_0(\xi; k_1, k_2) = \sigma_0(\xi; k)(I + \sigma_\varepsilon(\xi))$$

with $\|\sigma_\varepsilon\|_{L^\infty(\mathbb{R})^{2\times 2}} < 1$ for $|k_1 - k_2| < \delta(\varepsilon)$ and further

$$= \sigma_{0-}(\xi; k)(I + \tilde{\sigma}_\varepsilon(\xi))\sigma_{0+}(\xi; k)$$

with $\|\tilde{\sigma}_\varepsilon\|_{L^\infty(\mathbb{R})^{2\times 2}} < 1$ for $\|k_1 - k_2\| < \tilde{\delta}(1)$.

This yields the (usual) representation

$$W_0^{-1} = F^{-1}\sigma_{0+}^{-1} \cdot F \sum_{j=0}^{\infty} (1_+ \cdot F^{-1}\tilde{\sigma}_\varepsilon(\xi) \cdot F)^j 1_+ \cdot F^{-1}\sigma_{0-}^{-1} \cdot F|_{L^2(\mathbb{R}_+)^2}.$$

Sufficient estimates for k_j can be obtained easily, in contrast to the case $\lambda \in \mathbb{C}\backslash[0, \infty)$ where the factors are unbounded and we only know about the invertibility in a nonspecified neighborhood of W.

Acknowledgments. The author thanks Robert Allan Hurd who was a guest professor at the Technical University of Darmstadt, funded by the DFG in 1986, for many fruitful discussions that initiated this work and that lead to the explicit factorization of the symbol matrices under consideration.

Appendix. The parameter regions. The admissible values of C in (3.3) are described dependent of $\lambda \in \mathbb{C}$. Another choice of the branches leads to the same factorization. Here we have Re $C \in [0, 1]$, Im $C \in (0, \infty)$ or Re $C \in (0, 1)$, Im $C \in (-\infty, 0]$ (Figs. 1-4).

GREEN-RIEMANN FUNCTIONS FOR A CLASS OF HYPERBOLIC FOCAL POINT PROBLEMS*

NEZAM IRANIPARAST†

Abstract. Focal point problems such as those in [*Hiroshima Math J.*, 14 (1984), pp. 203-210] in a characteristic triangle have been extended to similar problems for hyperbolic equations of the form $u_{tt}-u_{ss}+q(s,t)u=-\lambda p(s,t)u$. Criteria for the existence of eigenvalues are established by means of Riemann and the generalized Green functions.

Key words. focal point, eigenvalue, Riemann function, Green-Riemann function, Riemann's method, Cauchy problem

AMS(MOS) subject classification. 35L05

1. Introduction. In [5], Kreith has used d'Alembert's method and the theory of positive operators to study certain hyperbolic boundary value problems. In this paper we extend some of the results of [5] to a more general problem using Riemann's method and the theory of positive operators.

Historically, one of the basic assumptions underlying mathematical models of a vibrating string has been the notion of "simultaneous crossing of the axis" [1]. This assumption refers to the phenomenon of the string passing through its equilibrium state, a quite feasible occurrence for free strings. However, for a string under an arbitrary linear restoring force, such a phenomenon is more difficult to establish. Kreith [4] has studied one such formulation, a semidiscrete case of the following problem:

$$u_{tt}-u_{ss}+p(s,t)u=0, \qquad 0<s<L, \quad t>0, \tag{1.1}$$

$$u_s(0,t)=u_s(L,t)=0, \qquad t>0, \tag{1.2}$$

$$u(s,0)=0, \quad u_t(s,0)=g(s), \quad 0\leqq s\leqq L, \tag{1.3}$$

$$u(s,T)=0, \quad T=\text{const.}, \quad 0\leqq s\leqq L. \tag{1.4}$$

In a related paper by Kreith [5], the spatial boundary conditions (1.2) are left out and the differential equation (1.1) is considered over the characteristic triangle

$$R(s,t)=\{(\sigma,\tau): s-(t-\tau)<\sigma<s+(t-\tau), 0<\tau<t\}.$$

Under suitable initial conditions of the type (1.3) the string is then required either to pass through its equilibrium or to be at rest at a single point $s=0$ at time $t=T$, which constitutes a modification of condition (1.4). The "hyperbolic focal point problems" of [5] are then many-degrees-of-freedom analogues of the boundary value problems for $d^2u/dt^2+pu=0$, $(p>0)$.

In this paper we extend the techniques of [5] involving an equation of the type

$$u_{tt}-u_{ss}+\lambda p(s,t)u=0, \quad (s,t) \text{ in } R(0,T),$$

under appropriate initial and time boundary conditions, to the equation

$$u_{tt}-u_{ss}+(q(s,t)+\lambda p(s,t))u=0, \quad (s,t) \text{ in } R(0,T), \tag{1.5}$$

under the same conditions.

In § 2 we use the Green function method of [5] to establish a positive eigenvalue and its corresponding nonnegative eigenfunction for (1.5) when q is a constant. Under the initial and boundary conditions of § 3, the method runs into difficulty (as in [5]) when $q \equiv 0$, but succeeds when $q = c \not\equiv 0$. Under the conditions of § 4, we see that (1.5) can only be transformed into an integral equation. No solution has been established in this case.

2. Right focal points. We apply the technique of [5] to the problem

$$\begin{aligned} &u_{tt} - u_{ss} + q(s,t)u = -\lambda p(s,t)u \quad \text{in } R(0,T), \\ &u_t(s,0) = 0 \qquad\qquad\qquad\qquad\quad \text{in } [-T,T], \\ &u(0,T) = 0. \end{aligned}$$

First the data $u(s,0) = kg(s)$ will be assigned to solve the Cauchy problem

$$\begin{aligned} &u_{tt} - u_{ss} + q(s,t)u = -\lambda p(s,t)u \quad \text{in } R(0,T), \\ &u(s,0) = kg(s), \quad u_t(s,0) = 0 \quad \text{in } [-T,T], \end{aligned} \tag{2.1}$$

and then the condition $u(0,T) = 0$ will be imposed to find k.

By Riemann's method

$$u(s,t) = \frac{1}{2}\left(u(s+t,0) + u(s-t,0) + \int_{s-t}^{s+t} (vu_\tau - uv_\tau)\, d\sigma + \iint_{R(s,t)} -\lambda pvu\, d\sigma\, d\tau \right),$$

therefore (2.1) has the solution

$$u(s,t) = \frac{1}{2}\left(kg(s+t) + kg(s-t) - \int_{s-t}^{s+t} kg(\sigma) v_\tau(\sigma, 0; s, t)\, d\sigma \right.$$
$$\left. - \iint_{R(s,t)} \lambda p(\sigma,\tau) v(\sigma,\tau; s, t) u\, d\sigma\, d\tau \right),$$

where $v(\sigma, \tau; s, t)$ satisfies

$$\begin{aligned} &v_{\tau\tau} - v_{\sigma\sigma} + q(\sigma,\tau)v = 0 \quad \text{in } R(s,t), \\ &v \equiv 1 \quad \text{along } \tau = -\sigma + (s+t), \\ &v \equiv 1 \quad \text{along } \tau = \sigma - (s-t). \end{aligned} \tag{2.2}$$

Hence $u(0,T) = 0$ implies

$$k = \frac{\iint_{R(0,T)} \lambda p(\sigma,\tau) v(\sigma,\tau; 0, T)\, u\, d\sigma\, d\tau}{g(T) + g(-T) - \int_{-T}^{T} g(\sigma) v_\tau(\sigma, 0; 0, T)\, d\sigma},$$

and the solution to

$$\begin{aligned} &u_{tt} - u_{ss} + q(s,t)u = -\lambda p(s,t)u \quad \text{in } R(s,t), \\ &u(s,0) = kg(s), \quad u_t(s,0) = 0 \quad \text{in } [-T,T], \\ &u(0,T) = 0, \end{aligned} \tag{2.3}$$

can be written in the form

$$\frac{1}{\lambda} u(s,t) = \iint_{R(0,T)} G(s,t;\sigma,\tau) p(\sigma,\tau) u\, d\sigma\, d\tau,$$

where

$$G(s,t;\sigma,\tau) = \frac{1}{2} \frac{g(s+t) + g(s-t) - \int_{s-t}^{s+t} g(\sigma) v_\tau(\sigma, 0; s, t)\, d\sigma}{g(T) + g(-T) - \int_{-T}^{T} g(\sigma) v_\tau(\sigma, 0; 0, T)\, d\sigma} v(\sigma,\tau; 0, T) \tag{2.4}$$

for (σ, τ) in $R(0, T)-R(s, t)$,

$$=\frac{1}{2}\frac{g(s+t)+g(s-t)-\int_{s-t}^{s+t} g(\sigma)v_\tau(\sigma, 0; s, t)\,d\sigma}{g(T)+g(-T)-\int_{-T}^{T} g(\sigma)v_\tau(\sigma, 0; 0, T)\,d\sigma}\, v(\sigma, \tau; 0, T)$$

$$-\frac{1}{2}v(\sigma, \tau; s, t)$$

for (σ, τ) in $R(s, t)$.

For $q(s, t)\equiv 0$ the Riemann function $v(\sigma, \tau; s, t)\equiv 1$ and the Green-Riemann function (2.4) reduces to

$$G(s, t; \sigma, \tau)=\frac{1}{2}\frac{g(s+t)+g(s-t)}{g(T)+g(-T)} \quad \text{for } (\sigma, \tau) \text{ in } R(0, T)-R(s, t),$$

$$=\frac{1}{2}\frac{g(s+t)+g(s-t)}{g(T)+g(-T)}-\frac{1}{2} \quad \text{for } (\sigma, \tau) \text{ in } R(s, t).$$

In [5] it has been pointed out that such a Green function is not symmetric but is nonnegative for positive concave g in $[-T, T]$. To show that $G(s, t; \sigma, \tau)$ can be made nonnegative in $R(0, T)$ for $q(s, t)\geqq 0$, we need the following lemmas.

LEMMA 2.1. *Let $q(s, t)\geqq 0$ and $v(\sigma, \tau; s, t)\geqq 0$ in $R(s, t)$. Then $v_\tau(\sigma, \tau; s, t)\geqq 0$ in $R(s, t)$.*

Proof. Choose the change of independent variables $x=\sqrt{2}/2((t-\tau)+(s-\sigma))$ and $y=\sqrt{2}/2((t-\tau)-(s-\sigma))$ to transform (2.2) into

$$v_{xy}+\tfrac{1}{2}q(x, y)v=0, \tag{2.5}$$

$$v(x, 0)=1, \quad x \text{ in } [0, \sqrt{2}T],$$

$$v(0, y)=1, \quad y \text{ in } [0, \sqrt{2}T].$$

Equation (2.5) integrated over $[0, y]$ and $[0, x]$ yields

$$v_x(x, y)=-\frac{1}{2}\int_0^y q(x, \eta)v(x, \eta)\,d\eta\leqq 0,$$

$$v_y(x, y)=-\frac{1}{2}\int_0^x q(\xi, y)v(\xi, y)\,d\xi\leqq 0;$$

therefore

$$v_\tau=-\sqrt{2}/2(v_x+v_y)\geqq 0.$$

LEMMA 2.2. *Let $q(s, t)\equiv C>0$, C be a constant, and ω be the first zero of J_0 the Bessel function of order zero. Then for $T\leqq \omega/\sqrt{C}$, $v(\sigma, \tau; s, t)\geqq 0$ for all (s, t) in $R(0, T)$ and (σ, τ) in $R(s, t)$.*

Proof. With $q\equiv C$, the Riemann function $v(\sigma, \tau; s, t)=J_0(\sqrt{C}\Gamma)$, where $\Gamma=\sqrt{(t-\tau)^2-(s-\sigma)^2}$. The function J_0 is nonnegative for $\sqrt{C}\Gamma\leqq\omega$. This implies that J_0 is nonnegative for all (σ, τ) lying in the region between the two branches of the hyperbola $(t-\tau)^2-(s-\sigma)^2=\omega^2/C$. Therefore $R(s, t)$ will lie in this region, for all (s, t) in $R(0, T)$, if $T\leqq\omega/\sqrt{C}$.

It follows from Lemmas 2.1 and 2.2 that for $q\equiv C>0$ and $T\leqq\omega/\sqrt{C}$ the inequalities $v(\sigma, \tau; s, t)\geqq 0$ and $v_\tau(\sigma, \tau; s, t)\geqq 0$ are satisfied for all (s, t) in $R(0, T)$ and (σ, τ) in $R(s, t)$. Let $T_0<\omega/\sqrt{C}$ be chosen such that $v(\sigma, 0; 0, T_0)\geqq m$ for $-T_0\leqq\sigma\leqq T_0$. Let $v_\tau(\sigma, 0; s, t)\leqq M$ for (s, t) in $R(0, T)$, $s-t\leqq\sigma\leqq s+t$. Assume that g is

positive and concave with a maximum g_0 and minimum $g(T)=g(-T)$ over the interval $[-T, T]$, where T satisfies

$$T \leqq \min\,(g(T)/Mg_0,\ T_0). \tag{2.6}$$

Then with T_0, m, M, g_0, $g(T)$, and T so defined we have the following lemma.

LEMMA 2.3. *Let T be defined by* (2.6) *and let g be a positive continuous function with $g'' \leqq 0$ in $[T, -T]$. Then the values of g in $(-T, T)$ can be chosen so that $G(s, t; \sigma, \tau) \geqq 0$ in $R(0, T)$.*

Proof. For the integrals in the numerator and denominator of the expression for G we have

$$\int_{s-t}^{s+t} g(\sigma)v_\tau(\sigma, 0; s, t)d\sigma < 2Tg_0M \leqq (2g(T)/Mg_0)g_0M = 2g(T),$$

$$\int_{-T}^{T} g(\sigma)v_\tau(\sigma, 0; 0, T)d\sigma < 2Tg_0M \leqq (2g(T)/Mg_0)g_0M = 2g(T).$$

Therefore $g(s+t)+g(s-t)$ can be chosen large enough in $(-T, T)$ so that

$$\frac{g(s+t)+g(s-t)-\int_{s-t}^{s+t} g(\sigma)v_\tau(\sigma, 0; s, t)\,d\sigma}{g(T)+g(-T)-\int_{-T}^{T} g(\sigma)v_\tau(\sigma, 0; 0, T)\,d\sigma} \geqq \frac{1}{m} \geqq \frac{v(\sigma, \tau; s, t)}{v(\sigma, \tau; 0, T)}.$$

Hence $G(s, t; \sigma, \tau) \geqq 0$ for all (s, t) and (σ, τ) in $R(0, T)$.

For $p \geqq 0$, define A to be the operator

$$A[u] = \iint_{R(0,T)} G(s, t; \sigma, \tau)p(\sigma, \tau)u\,d\sigma\,d\tau.$$

Then A is u_0-positive and completely continuous in $L^q(1 < q < \infty)$ due to the boundedness of G and p [3, Chap. 2, pp. 230–232]. When we choose K to be the cone of functions u nonnegative in $R(0, T)$, the operator A maps K into K. The theory of Krasnoselskii [3, Chap. 2] then yields the following theorem.

THEOREM 2.1. *There exists a T and a function g positive in $[-T, T]$ such that for $p \geqq 0$ in $R(0, T)$ and $q \equiv C > 0$ the eigenvalue problem* (2.3) *has a unique eigenvalue $\lambda_g > 0$ and a corresponding unique nontrivial solution that is nonnegative in $R(0, T)$. All other eigenvalues of* (2.3) *satisfy $|\lambda| > \lambda_g$.*

3. Left focal points. An argument similar to the one in § 2 can be applied to the following eigenvalue problem:

$$\begin{aligned} &u_{tt} - u_{ss} + q(s, t)u = -\lambda p(s, t)u \quad \text{in } R(0, T), \\ &u(s, 0) = 0, \quad u_t(s, 0) = kg(s) \quad \text{in } [-T, T], \end{aligned} \tag{3.1}$$

$$u_t(0, T) = 0. \tag{3.2}$$

However, for $q(s, t) \equiv 0$ the technique of § 2 fails. In this case a result has been established in [5] for the existence of a focal point for

$$\begin{aligned} &u_{tt} - u_{ss} + p(s, t)u = 0 \quad \text{in } R(0, T), \\ &u(s, 0) = 0, \quad u_t(s, 0) = kg(s) \quad \text{in } [-T, T], \\ &u_t(0, T) = 0. \end{aligned}$$

Again solve the Cauchy problem (3.1) by the Riemann method to obtain

$$u(s, t) = \frac{1}{2}\left(\int_{s-t}^{s+t} kg(\sigma)v(\sigma, 0; s, t)\,d\sigma - \iint_{R(s,t)} \lambda p(\sigma, \tau)v(\sigma, \tau; s, t)u\,d\sigma\,d\tau\right),$$

and so

$$u_t(s,t)=\frac{1}{2}\Big(k(g(s+t)v(s+t,0;s,t)+g(s-t)v(s-t,0;s,t)$$
$$+\int_{s-t}^{s+t} g(\sigma)v_t(\sigma,0;s,t)\,d\sigma)$$
$$-\lambda\int_0^t (p(-\tau+(s+t),\tau)v(-\tau+(s+t),\tau;s,t)u(-\tau+(s+t),\tau)$$
$$+p(\tau+(s-t),\tau)v(\tau+(s-t),\tau;s,t)u(\tau+(s-t),\tau))\,d\tau$$
$$-\lambda\iint_{R(s,t)} p(\sigma,\tau)v_t(\sigma,\tau;s,t)u(\sigma,\tau)\,d\sigma\,d\tau\Big).$$

Impose condition (3.2) and assume that $p(-\tau+T,\tau)=p(\tau-T,\tau)\equiv 0$, $0\leqq\tau\leqq T$ to obtain

$$k=\frac{\lambda\iint_{R(0,T)} p(\sigma,\tau)v_t(\sigma,\tau;0,T)u\,d\sigma\,d\tau}{g(T)+g(-T)+\int_{-T}^{T} g(\sigma)v_t(\sigma,0;0,T)\,d\sigma}.$$

The solution of (3.1), (3.2) can now be written in the form

$$\frac{1}{\lambda}u(s,t)=\iint_{R(0,T)} G(s,t;\sigma,\tau)p(\sigma,\tau)u\,d\sigma\,d\tau,$$

where

$$G(s,t;\sigma,\tau)$$
$$=\frac{1}{2}\frac{\int_{s-t}^{s+t} g(\sigma)v(\sigma,0;s,t)\,d\sigma}{g(T)+g(-T)+\int_{-T}^{T} g(\sigma)v_t(\sigma,0;0,T)\,d\sigma}\,v_t(\sigma,\tau;0,T)$$
$$\text{for } (\sigma,\tau) \text{ in } R(0,T)-R(s,t),$$
$$=\frac{1}{2}\frac{\int_{s-t}^{s+t} g(\sigma)v(\sigma,0;s,t)\,d\sigma}{g(T)+g(-T)+\int_{-T}^{T} g(\sigma)v_t(\sigma,0;0,T)\,d\sigma}$$
$$\cdot v_t(\sigma,\tau;0,T)-\frac{1}{2}v(\sigma,\tau;s,t)\quad \text{for } (\sigma,\tau) \text{ in } R(s,t).$$

As in § 2, for $q\equiv C>0$ the function $v(\sigma,\tau;s,t)=J_0(\sqrt{C}\Gamma)$ and we have the following lemma.

LEMMA 3.1. *Let ω be the first zero of J_0. Then for $T\leqq\omega/\sqrt{C}$ the Riemann function $v(\sigma,\tau;s,t)=J_0(\sqrt{C}\Gamma)$ satisfies $v_t(\sigma,\tau;0,T)\leqq 0$ in $R(0,T)$.*

Proof. Note that for $\Gamma=\sqrt{(T-\tau)^2-(\sigma)^2}$

$$v_t(\sigma,\tau;0,T)=(\sqrt{C}(T-\tau)/\Gamma)\sum_{k=1}^{k=\infty}((-1)^k k/(k!)^2)(\sqrt{C}\Gamma/2)^{2k-1}.$$

To have $v_t(\sigma,\tau;0,T)\leqq 0$ in $R(0,T)$ we let

$$(k/(k!)^2)(\sqrt{C}\Gamma/2)^{2k-1}\geqq((k+1)/((k+1)!)^2)(\sqrt{C}\Gamma/2)^{2k+1}\quad \text{for } k=1,2,3,\cdots,$$

which implies that Γ must satisfy $\Gamma\leqq\sqrt{8}/\sqrt{C}$, i.e., $(T-\tau)^2-(\sigma)^2\leqq 8/C$. The characteristic triangle $R(0,T)$ now lies completely between the two branches of the hyperbola $(T-\tau)^2-(\sigma)^2=8/C$ if $T\leqq\sqrt{8}/\sqrt{C}$. But T already satisfies $T\leqq\omega/\sqrt{C}<\sqrt{8}/\sqrt{C}$, so we are done.

Let g be positive in $[-T, T]$ and $C > 4\omega^2$. Then $T < \frac{1}{2}$ and the values of g at the endpoints of $[-T, T]$ can be chosen large enough so that

$$g(T) + g(-T) + \int_{-T}^{T} g(\sigma) v_t(\sigma, 0; 0, T)\, d\sigma > 0. \tag{3.3}$$

Now by Lemmas 2.2 and 3.1, $G(s, t; \sigma, \tau) \leqq 0$ in $R(0, T)$. If p is chosen nonpositive in $R(0, T)$, then the operator A defined by

$$A[u] = \iint_{R(0,T)} G(s, t; \sigma, \tau) p(\sigma, \tau) u \, d\sigma \, d\tau,$$

is a positive operator on the cone K of functions u nonnegative in $R(0, T)$. Once more Krasnoselskii's theory [3] implies the following theorem.

THEOREM 3.1. *Let $q(s, t) \equiv C > 4\omega^2$ and $T \leqq \omega/\sqrt{C}$ where ω is the first zero of the Bessel function J_0 of order zero. Let $p(s, t) \leqq 0$ in $R(0, T)$ with $p \not\equiv 0$ along the characteristic boundaries of $R(0, T)$. Finally let $g(s) > 0$ in $[-T, T]$ satisfy* (3.3). *Then there is a unique eigenvalue $\lambda_g > 0$ to which there corresponds a unique nontrivial solution of* (3.1), (3.2) *which is nonnegative in $R(0, T)$. All other eigenvalues of* (3.1), (3.2) *satisfy $|\lambda| > \lambda_g$.*

4. Conjugate points. It appears that even the introduction of an extra function q to the conjugate point problem of [5] does not help resolve the establishment of a conjugate point. By the method of the last two sections the problem

$$\begin{aligned} &u_{tt} - u_{ss} + q(s, t)u = -\lambda p(s, t)u \quad \text{in } R(0, T), \\ &u(s, 0) = 0, \quad u_t(s, 0) = kg(s) \quad \text{in } [-T, T], \\ &u(0, T) = 0, \end{aligned} \tag{4.1}$$

can be written in the equivalent form

$$\frac{1}{\lambda} u(s, t) = \iint_{R(0,T)} G(s, t; \sigma, \tau) p(\sigma, \tau) u \, d\sigma \, d\tau,$$

where

$$G(s, t; \sigma, \tau) = \frac{1}{2} \frac{\int_{s-t}^{s+t} g(\sigma) v(\sigma, 0; s, t)\, d\sigma}{\int_{-T}^{T} g(\sigma) v(\sigma, 0; 0, T)\, d\sigma} v(\sigma, \tau; 0, T)$$

for (σ, τ) in $R(0, T) - R(s, t)$,

$$= \frac{1}{2} \frac{\int_{s+t}^{s+t} g(\sigma) v(\sigma, 0; s, t)\, d\sigma}{\int_{-T}^{T} g(\sigma) v(\sigma, 0; 0, T)\, d\sigma} v(\sigma, \tau; 0, T) - \frac{1}{2} v(\sigma, \tau; s, t)$$

for (σ, τ) in $R(s, t)$.

Nevertheless, the Green-Riemann function $G(s, t; \sigma, \tau)$ cannot be made nonnegative or nonpositive in $R(0, T)$. However, the conjugate point problem (4.1), in a slightly different form, has recently been studied by Kreith [6] and Haws [2]. Their method involves construction of a symmetric Green function. The results of [6] and [2] show the existence of such conjugate points.

THE REGULARITY OF SOLUTIONS OF NONLINEAR WAVE EQUATIONS*

BERNARD MARSHALL†

Abstract. For the wave equation with lower-order nonlinearities a regularity theorem is given which ensures that solutions in certain L^q are in fact smooth solutions to the equation. For equations with energy estimates the existence of global classical solutions in lower dimensions is obtained.

Key words. nonlinear, wave equation, regularity

AMS(MOS) subject classifications. 35L70, 35L15

1. Introduction. The purpose of this paper is to study the regularity of solutions to the Cauchy problem for equations of the form

$$u_{tt}+(-\Delta)^m u+au+f(u)=g \tag{1}$$

in $R_+\times R^n$ with initial data

$$u(0,x)=u_0(x), \qquad u_t(0,x)=u_1(x) \tag{2}$$

where $m\geqq 1$, $\partial^\alpha=\prod(\partial/\partial x_i)^{\alpha_i}$, $|\alpha|=\sum|\alpha_i|$, and $a\geqq 0$. The nonlinear term $f(u)$ is described in § 3. The results we prove apply also to the analogous class associated to the Schrödinger equation:

$$iu_t+(-\Delta)^m u+f(u)=g \tag{3}$$

with initial data $u(0,x)=u_0(x)$.

The existence of classical (C^2) solutions, particularly of (1), has been studied by many authors. The results, however, all have some restriction on the dimension. In the case $m=1$, Jörgens [4] proved the existence of classical solutions if $n=3$. This was extended to $n<10$ by Brenner and von Wahl in [2]. In the case $m\geqq 2$ these solutions have been proven to exist by Pecher [7] and Narasaki [6], who extended this to $n\leqq 6(m-k)+4$. Similar results have been obtained for the Schrödinger equation (3). For example, Tsutsumi and Hayashi [10] have shown the existence of classical solutions when $m=1$ and $n\leqq 9$.

In this paper we present a regularity theorem, valid in all dimensions, which states roughly that a solution is smooth if it contains a critical amount k_0 of differentiability. Since there is no positivity condition imposed on $f(u)$ this theorem applies also to solutions that eventually blow-up. If a positivity condition is added then the existence of global classical solutions in lower dimensions is obtained.

2. The linear estimates. Let $a\geqq 0$. The solution of the Cauchy problem for

$$u_{tt}+(-\Delta)^m u+au=0, \qquad (t,x)\in R_+\times R^n$$

can be written in terms of Fourier multipler transformations with multipliers

$$\cos(t\sqrt{a+|\xi|^{2m}}) \quad \text{and} \quad (a+|\xi|^{2m})^{-1/2}\sin(t\sqrt{a+|\xi|^{2m}}).$$

Denote the corresponding transformations by K_t^C and K_t, respectively. Let $L_k^p(R^n)=(I-\Delta)^{-k/2}(L^p(R^n))$ with norm $|f|_{k,p}\equiv|(I-\Delta)^{k/2}f|_{L^p}$. If k is a nonnegative integer, then an equivalent norm is $|f|_p+\sum_{|\alpha|=k}|\partial^\alpha f|_p$. See [9].

The following lemma summarizes work by previous authors on these transformations.

THEOREM 1. *Suppose* $p^{-1}+q^{-1}=1$ *and* $0 \leqq A \leqq m$.

(i) *If* $A+mn|1/2-1/p|<m$ *then* K_t^C *is a bounded linear transformation from* $L^p(R^n)$ *to* $L^p_{A-m}(R^n)$ *with norm* $\tilde{\sigma}(t) \leqq C(1+t)^M$, *where* $M=M(n)$. *Similarly* K_t *is a bounded linear transformation from* $L^p(R^n)$ *to* $L^p_A(R^n)$ *with norm* $\sigma(t) \leqq C(1+t)^M$.

(ii) *Assume* $1<p \leqq 2$. *If* $m=1$, *suppose that* $A+(n+1)|1/p-1/2| \leqq 1$. *If* $m>1$, *suppose that* $A+2n|1/p-1/2|<2m$. *Then* K_t *is a bounded linear operator from* $L^p(R^n)$ *to* $L^q_A(R^n)$ *with norm* $\kappa(t)$ *such that* $\int_0^t \kappa(s)\,ds<\infty$ *for all* $t<\infty$.

Proof. (i) Let $\eta(x)$ be a C^∞ function of R^n such that $\eta(x)=0$ if $|x| \leqq 1$ and $\eta(x)=1$ if $|x| \geqq 2$. The multiplier

$$(1-\eta(t^{1/m}\xi))\cos(t\sqrt{a+|\xi|^{2m}})(1+|\xi|^{2m})^{(A-m)/2m}$$

determines a transformation on L^p with norm $\leqq C(1+t)^M$ by the Mikhlin-Hörmander multiplier theorem [3 Thm. 2.5]). The remaining part of the multiplier for K_t^C consists of two terms of the form

$$\frac{\eta(t^{1/m}\xi)\,e^{it\xi_a}}{\xi_*^k}=\frac{\eta(t^{1/m}\xi)\,e^{it|\xi|^m}}{\xi_t^k}\left\{\left(\frac{\xi_t}{\xi_*}\right)^k\right\}\{e^{it(\xi_a-|\xi|^m)}\},$$

where $\xi_t=\sqrt{1+t^2|\xi|^{2m}}$, $\xi_a=\sqrt{a+|\xi|^{2m}}$, $\xi_*=\sqrt{1+|\xi|^{2m}}$, and $k=(m-A)/m$. Each of the multipliers in $\{\ \}$ brackets is bounded on all L^p, $1<p<\infty$, with norms $\leqq C(1+t)^k \leqq C(1+t)$ and $\leqq C(1+t)^M$ by the Mikhlin-Hörmander theorem. A simple change of variables shows that the first multiplier has norm independent of t. But $\eta(\xi)\exp(i|\xi|^m)(1+|\xi|^{2m})^{-k/2}$ is a multiplier on $L^p(R^n)$ if $|1/2-1/p|<k/n=(m-A)/2mn$. If $n=1$, $m=1$, $A=0$ then it is a multiplier for $1<p<\infty$. See [9], p. 113. The proof for K_t is the same. In fact in this case the norm goes to zero as $t \to 0$.

(ii) In this case Pecher [9] has shown that

$$\exp(it\sqrt{a+|\xi|^{2m}})(a+|\xi|^{2m})^{-1/2}(1+|\xi|^2)^{A/2}$$

defines a bounded transformation from $L^p(R^n)$ to $L^q(R^n)$ with norm $\leqq Ct^\rho(1+t)^M$, where $\rho=(n(1-2/p)+m-A)/m$ and $\rho \leqq 0$. If $m=1$, then $1/p \leqq 1/2+(m-A)/(mn+m)$. This shows that $(I-\Delta)^{A/2}K_t$ is bounded with norm $\leqq \kappa(t) \leqq Ct^\rho(1+t)^M$. From the Plancherel theorem this operator is also bounded for L^2 to L^2 with norm $\leqq Ct^{(m-A)/m}$. If $m-A<n$ then $\rho<0$ when $p=1$ and so $(I-\Delta)^{A/2}K_t$ is also bounded from L^p to L^q for p arbitrarily close to one. This shows that the operator is bounded for all $1<p \leqq 2$ and removes the restriction $\rho \leqq 0$ when $m>1$. On the other hand, if $m-A \geqq n$, then the multiplier can be written as

$$(1+|\xi|^2)^{-(m-A)/2}\left\{\frac{\sin(t\sqrt{a+|\xi|^{2m}})}{\sqrt{a+|\xi|^{2m}}}(1+|\xi|^2)^{m/2}\right\}(1+|\xi|^2)^{-(m-A)/2}.$$

The combination of Sobolev's theorem, the Plancherel theorem, and Sobolev's theorem shows that this is bounded from $L^p \to L^2 \to L^2 \to L^q$ with norm $\leqq C$ for all $1<p \leqq 2$.

The only restriction that now remains on p is when $m=1$. It is, however, necessary that $\kappa(t)$ be locally integrable. For this we need $\rho>-1$. For $m>1$ this is equivalent to

$$A+2n\left(\frac{1}{p}-\frac{1}{2}\right)<2m. \tag{4}$$

When $m=1$ this is weaker than the other condition:

$$A+(n+1)\left(\frac{1}{p}-\frac{1}{2}\right) \leqq 1. \tag{5}$$

For the application of Theorem 1, (4) and (5) can be rewritten as

$$2 \leqq q \leqq 2(n+1)/(n-1+2A) \quad \text{if } m=1 \tag{6}$$

$$2 \leqq q < 2n/(n-2m+A) \quad \text{if } m>1. \tag{7}$$

If the denominator is zero or negative this is interpreted as $2 \leqq q < \infty$.

In Example 1 below, the first part of Theorem 1 will be used. This imposes a stronger condition

$$2 \leqq q < 2mn/(mn-2m+2A) \quad \text{if } m>1. \tag{8}$$

For the Schrödinger equation

$$iu_t + (-\Delta)^m = 0$$

the multiplier is $\exp(it|\xi|^{2m})$. Let K_t^S denote the corresponding transformation.

THEOREM 2. *Assume* $1<p\leqq 2$ *and* $p^{-1}+q^{-1}$. *If* $n(1/p-1/2)<m$ *then* K_t^S *is a bounded linear transformation from* $L^p(R^n)$ *to* $L^q(R^n)$ *with norm* $\kappa_S(t)$ *satisfying* $\int_0^t \kappa_S(s)\,ds<\infty$ *for all* $t<\infty$.

The proof of Theorem 2 is similar to that of Theorem 1. For the Schrödinger equation the condition on q is

$$2 \leqq q < 2n/(n-2m) \tag{9}$$

if $2m<n$ and $2\leqq q<\infty$ if $2m \geqq n$.

3. The nonlinear terms. Several types of nonlinearity will be considered for (1). The important information is summarized in the parameters k_0, γ, q, T and two functions $\tilde{\kappa}$ and ω. The basic property is that for all $k \geqq k_0$ there exist a locally integrable function $\tilde{\kappa}$ and a continuous function ω on $[0, T]$ such that

$$|K_t(f(u)(s))|_{k+1,q} \leqq \tilde{\kappa}(t)\omega(|u(s)|_{k,q})|u(s)|_{k+1,q} \tag{10}$$

for s, $t \in [0, T]$. This inequality together with Gronwall's inequality will allow us to show that a solution u in L_k^q is actually in L_{k+1}^q, and so on. The particular values of q, $\tilde{\kappa}$, and ω will not be important in the final result. We will concentrate therefore more on k_0, γ, and T.

Example 1. Consider (1). Let $k_0 \geqq A$ and

$$\begin{aligned} &1 \leqq \gamma \leqq 1+4n(1-A)/(n(n-1+2A)-2(n+1)(k_0-A)) \quad \text{if } m=1 \\ &1 \leqq \gamma < 1+4(m-A)/(mn-2m+2A-2m(k_0-A)) \quad \text{if } m>1. \end{aligned} \tag{11}$$

Let u be a function on $[0, T]$ with values in $L_A^q(R^n)$, where q is a value satisfying (6), (8) and $q \leqq \gamma+1$. The function $u(t)(x)$ will be written as $u(t, x)$. Let N be the number of multi-indices α such that $|\alpha| \leqq A$: $N = 1+n+\cdots n^A$. The nonlinear terms will be assumed to be of the following form

$$f(u)(t, x) = \psi(t, x, u(t, x), \cdots, \partial^\alpha u(t, x), \cdots),$$

where ψ is a real-valued C^∞ function on $[0, T]\times R^{n+N}$. We place the following growth condition on the function ψ:

$$|\partial_t^b \partial_x^\delta \partial_z^\alpha \omega(t, x, z)| \leqq C(1+|z|)^{\max(\gamma-|\alpha|,0)} \tag{12}$$

for all $(t, x, z) \in [0, T]\times R^{n+N}$ and $(b, \delta, \alpha) \in Z_0 \times Z_0^{n+N}$. Also assume that $\partial_x^\delta \psi(t, x, 0) = 0$ for all $\delta \in Z_0^n$, $(t, x) \in [0, T]\times R^n$. Thus $|\partial_x^\delta \psi(t, x, z)| \leqq C|z|$.

For simplicity ψ is assumed to be a real-valued function on $[0, T]\times R^{n+N}$, but the proofs are the same if ψ is a complex-valued function on $[0, T]\times R^n\times C^N$. In fact, for the Schrödinger equation it is necessary to consider such complex-valued nonlinearities.

Let $\eta\in C^\infty(R^n)$ be such that $\eta(z)=0$ if $|z|\leqq 1$ and $\eta(z)=1$ if $|z|\geqq 2$. Define $\psi_0(t, x, z)=(1-\eta(z))\psi(t, x, z)$, $\psi_1=\eta\psi$, and

$$f_i(u)(t, x)=\psi_i(t, x, \cdots, \partial^\alpha u(t, x), \cdots) \tag{13}$$

for $i=0, 1$. Now ψ_0 and its derivatives are bounded, and ψ_1 satisfies

$$|\partial_t^b\partial_x^\delta\partial_z^\alpha\psi_1(t, x, z)|\leqq C|z|^{\gamma-|\alpha|} \quad \text{if } |\alpha|\leqq\gamma. \tag{14}$$

Let $\beta\in Z^n$. We now describe the decomposition of $\partial^\beta(f(u))$ used in the proof of (9). By differentiating (13) we see that

$$\partial^\beta(f_j(u)(t))=\sum_\delta\sum_\alpha(\partial_x^\delta\partial_z^\alpha\psi_j)(u)(t)\sum_\nu c_\nu\prod_{i=1}^{|\alpha|}\partial^{\nu_i}u(t), \tag{15}$$

where $|\nu_i|\geqq 1$, $|\beta|\leqq|\delta|+\sum|\nu_i|$. We may assume that $|\nu_1|\geqq|\nu_2|\geqq\cdots$. Define

$$\begin{aligned}\phi_1(t)&=\partial^\beta(f_1(u)(t))+\sum_\delta\sum_{|\alpha|>\gamma}(\partial_x^\delta\partial_z^\alpha\psi_0)(u)(t)\sum_\nu c_\nu\prod_{i=1}^{|\alpha|}\partial^{\nu_i}u(t)\\ \phi_{j+2}(t)&=\sum_\delta\sum_{|\alpha|=j}(\partial_x^\delta\partial_z^\alpha\psi_0)(u)(t)\sum_\nu c_\nu\prod_{i=1}^{|\alpha|}\partial^{\nu_i}u(t)\end{aligned} \tag{16}$$

for $0\leqq j<\gamma$. Also $p_1=p$, $p_2=q$, $p_{j+2}=q/j$ for $1\leqq j<\gamma$.

LEMMA 1. *Let k_0, q, γ be as described above. If $(k-A)^2+n(1-2/q)\geqq(k-A)n/q$, $k\in Z$ and $k\geqq k_0$ then there exists a continuous function ω_1 on R such that*

$$|f_1(u)(t)|_{k+1-A,p}\leqq\omega_1(|u(t)|_{k,q})|u(t)|_{k+1,q} \tag{17}$$

for all $u(t)\in L^q_{k+1}(R^n)$, $t\in[0, T]$.

Proof. If $|\beta|=k-A+1$ then $\partial^\beta(f_1(u)(t))$ has an expansion as in (15). First consider the terms in (15) where $|\alpha|>\gamma$. In this case $\partial_x^\delta\partial_z^\alpha\psi_1\in L^\infty$, and so this function can be ignored. We wish to apply Hölder's and Sobolev's inequalities to get

$$\left|\prod_{i=1}^{|\alpha|}\partial^{\nu_i}u(t)\right|_p\leqq\prod_{i=1}^{|\alpha|}|\partial^{\nu_i}u(t)|_{p/a_i}\leqq|u(t)|_{k,q}^{|\alpha|-1}|u(t)|_{k+1,q}. \tag{18}$$

To do this we must find $a_i\in[0, 1]$ such that $\sum a_i=1$ and

$$\begin{aligned}\left(\frac{1}{q}-\frac{k+1-|\nu_i|}{n}\right)^+&\leqq\frac{a_i}{p}\leqq\frac{1}{q}, \qquad i=1\\ \left(\frac{1}{q}-\frac{k-|\nu_i|}{n}\right)^+&\leqq\frac{a_i}{p}\leqq\frac{1}{q}, \qquad i\geqq 2,\end{aligned}$$

where $\sum|\nu_i|\leqq(k-A+1)(A+1)$ and $s^+=\max\{s, 0\}$. These inequalities can be written equivalently as

$$\begin{aligned}\frac{p}{n}\left(\frac{n}{q}+|\nu_i|-k-1\right)^+&\leqq a_i\leqq\frac{p}{q}, \qquad i=1\\ \frac{p}{n}\left(\frac{n}{q}+|\nu_i|-k\right)^+&\leqq a_i\leqq\frac{p}{q}, \qquad i\geqq 2.\end{aligned} \tag{19}$$

The sum over $i=1,\cdots,|\alpha|$ of the right-hand terms is $|\alpha|p/q \geqq |\alpha|/\gamma > 1$. If we can show that the sum of the left-hand terms is less than or equal to one then a suitable collection $\{a_i\}$ must exist.

Let

$$S=\left(\frac{n}{q}+|\nu_1|-K-1\right)^+ + \sum_{i=2}^{|\alpha|}\left(\frac{n}{q}+|\nu_i|-k\right)^+.$$

Consider the effect on S of differentiating in (15). Differentiating $\partial^{\nu_i}u$ adds at most one to S while differentiating ψ_1 can add as much as $A+1$ because of the chain rule. If $(n/q)+(A+1)-k<1$ (that is, $k>A+n/q$), then S is largest when $|\alpha|=1$ and $|\nu_1|=k+1$. In this case

$$S\leqq\left(\frac{n}{q}+k+1-k-1\right)=\frac{n}{q}$$

and the sum of the left-hand sides of (19) is bounded by $p/q\leqq 1$. On the other hand, if $k\leqq A+n/q$ when S is largest for terms where $|\alpha|=k-A+1$ and $|\nu_i|=A+1$. In this case

$$\begin{aligned} S &\leqq\left(\frac{n}{q}+A+1-k-1\right)+\sum_{i=2}^{k-A+1}\left(\frac{n}{q}+A+1-k\right) \\ &=(k-A+1)\left(\frac{n}{q}+A+1-k\right)-1=-(k-A)^2+(k-A)\frac{n}{q}+\frac{n}{q}. \end{aligned} \tag{20}$$

Thus the sum of the left-hand sides of (19) is bounded by

$$\frac{p}{n}\left\{-(k-A)^2+(k-A)\frac{n}{q}+\frac{n}{q}\right\}.$$

The condition on k given in the statement of the lemma guarantees that this is less than or equal to one. This completes the justification of (18).

The proof for $|\alpha|\leqq\gamma$ is similar except that in this case the functions $\partial_x^\delta\partial_z^\alpha\psi_1$ are no longer bounded. The terms in (15) are bounded by

$$U(t)=\left(\sum_{|\eta|\leqq A}|\partial^\eta u(t)|\right)^{\gamma-|\alpha|}\prod_{i=1}^{|\alpha|}|\partial^{\nu_i}u(t)| \tag{21}$$

Hölder's and Sobolev's inequalities give

$$\begin{aligned} |U(t)|_p &\leqq\left(\sum_{|\eta|\leqq A}|\partial^\eta u(t)|\right)_{p/a_0}^{\gamma-|\alpha|}\prod_{i=1}^{|\alpha|}|\partial^{\nu_i}u(t)|_{p/a_i} \\ &\leqq|u(t)|_{k,q}^{\gamma-1}|u(t)|_{k+1,q}, \end{aligned}$$

assuming that we can find constants $a_i\in[0,1]$ such that $a_0(\gamma-|\alpha|)+\sum_{i=1}^{|\alpha|}a_i=1$ and

$$\left(\frac{1}{q}-\frac{k-A}{n}\right)^+\leqq\frac{a_0}{p}\leqq\frac{1}{q}, \qquad i=0$$

$$\left(\frac{1}{q}-\frac{k+1-|\nu_i|}{n}\right)^+\leqq\frac{a_1}{p}\leqq\frac{1}{q}, \qquad i=1$$

$$\left(\frac{1}{q}-\frac{k-|\nu_i|}{n}\right)^+\leqq\frac{a_i}{p}\leqq\frac{1}{q}, \qquad i\geqq 2.$$

Equivalently,

$$\frac{p}{n}\left(\frac{n}{q}-k+A\right)^{+} \leqq a_0 \leqq \frac{p}{q}$$

$$\frac{p}{n}\left(\frac{n}{q}+|\nu_1|-k-1\right)^{+} \leqq a_1 \leqq \frac{p}{q}$$

$$\frac{p}{n}\left(\frac{n}{q}+|\nu_i|-k\right)^{+} \leqq a_i \leqq \frac{p}{q}.$$

The weighted sum of the right-hand sides is $\gamma p/q \geqq 1$. For the left-hand sides consider

$$S=(\gamma-|\alpha|)\left(\frac{n}{q}-k+A\right)^{+}+\left(\frac{n}{q}+|\nu_1|-k-1\right)^{+}+\sum_{i=2}^{|\alpha|}\left(\frac{n}{q}+|\nu_i|-k\right)^{+}.$$

If $k-A \geqq n/q$ the maximum of S occurs when $|\alpha|=1$ and $|\nu_1|=A+|\beta|=k+1$. Then

$$S \leqq 0+\left(\frac{n}{q}+|\nu_1|-k-1\right)^{+}=\frac{n}{q} \leqq \frac{n}{p}$$

If $k-A<n/q$ then $|\nu_i| \leqq A+v_i$ where $1 \leqq v_i$ and $\sum v_i \leqq |\beta|=k+1-A$. Then

$$S \leqq (\gamma-|\alpha|)\left(\frac{n}{q}-k+A\right)+\left(\frac{n}{q}+A+v_1-k-1\right)+\sum_{i=2}^{|\alpha|}\left(\frac{n}{q}+v_i-k+A\right)$$

$$=\gamma\frac{n}{q}-(k-A)(\gamma-1)+\sum_{i=1}^{|\alpha|} v_i+A-k-1 \leqq \gamma\frac{n}{q}-(k-A)(\gamma-1).$$

Therefore to ensure that $S \leqq n/p=n-n/q$ we require

$$\gamma n/q \leqq n-n/q+(k-A)(\gamma-1).$$

In terms of γ this is equivalent to

$$\gamma \leqq 1+n(q-2)/(n-(k-A)q). \tag{22}$$

Since the right-hand side is an increasing function of q for $(k-A) \leqq n/2$, we substitute the upper bounds for q given in (6) and (8). Since $k \geqq k_0$, this gives (11).

The proof of the lemma is concluded by summing over $|\beta|=k-A+1$. □

LEMMA 2. *If k_0 is a constant such that $k_0 \geqq A$ and $(k-A)^2+n(1-2/q) \geqq (k-A)n/q$ for all $k \geqq k_0$ then estimate* (10) *holds for all $k \geqq k_0$.*

Proof. Let $|\beta|=k+1-A$. Lemma 1 gives the appropriate estimate for $f_1(u)$. Next we prove the corresponding estimate for $\phi_j(t)$, as defined in (16). The proof of Lemma 1 shows that $|\phi_1(t)|_p$ is bounded by the right-hand side of (17).

For $\phi_2(t)$ we use the fact that

$$|(\partial_x^{\delta}\psi_0)(u)(t)| \leqq C \sum_{|\eta| \leqq A} |\partial_x^{\eta} u(t)| \quad \text{pointwise in } x,$$

because $|(\partial_x^{\delta}\psi_0)(t, x, z)| \leqq C|z|$. Hence

$$|\phi_2(t)|_q \leqq |u(t)|_{A,q} \leqq |u(t)|_{k,q}.$$

For each $1 \leqq j<\gamma$, $p_{j+2}=q/j$ and the derivatives of ψ_0 are bounded. Therefore by Hölder's inequality

$$|\phi_{j+2}(t)|_{q/j} \leqq C \prod_{i=1}^{j} |\partial^{\nu_i} u(t)|_q \leqq C|u(t)|_{k,q}^{j-1}|u(t)|_{k+1,q}.$$

By Theorem 1, K_t is bounded from L^p to L^q_A and from L^q to L^q_A with norms $\kappa(t)$ and $\sigma(t)$. Therefore by interpolation K_t is bounded from L^{p_j} to L^q with norm $\leqq \kappa(t)+\sigma(t)=\tilde{\kappa}(t)$. Using Lemma 1 and the estimates for the ϕ_j gives the inequality (10). As explained in (8) the condition on γ is given in (11).

The other property of $f(u)$ that is used is the observation from (14) that differentiation with respect to t does not change any of the estimates. This is used later in Lemma 9.

Example 2. The condition on k_0 can be relaxed if we consider fractional orders of integration. The use of Besov spaces to accomplish this appears in Brenner [1] and Brenner and von Wahl [2]. The cost of this extra freedom in k, however, is that in (12) we must add the condition

$$|\partial_t^b \partial_x^\sigma \partial_z^\alpha \psi(t, x, z)| \leqq C(1+|z|)^{\gamma-|\alpha|} \quad \text{if } |\alpha| < \gamma+1. \tag{23}$$

Thus certain derivatives of ψ must decay. A condition of this type appears in [2, 5^0, p. 112]. All other conditions are the same as in Example 1.

LEMMA 3. *If $k_0 \in R$ is such that $(r-A)^2+n(1-1/q) > (1+n/q)(r-A)$ for all $r \in R$, $r \geqq k_0$ then there exists $\varepsilon > 0$ such that for all $r \geqq k_0$ there exists a continuous function ω_2 on $[0, T]$ satisfying*

$$|K_t(f(u)(s))|_{r+\varepsilon,q} \leqq \tilde{\kappa}(t)\omega_2(|u(s)|_{r,q})|u(s)|_{r+\varepsilon,q}$$

for all s, $t \in [0, T]$.

Proof. Lemmas 1 and 2 settle the case when $r \in Z$ and $\varepsilon = 1$. The proof of Lemma 3 is a modification of this argument. It suffices to consider two cases, the first case is when $r+\varepsilon \in Z$. The second case is when $[r+\varepsilon] \leqq r < r+\varepsilon$ ($[r+\varepsilon]$ is the integral part of $r+\varepsilon$).

Case (i). Suppose that $r+\varepsilon \in Z$. The difficulty is proving Lemma 1 arose when trying to satisfy (19). In this case $|\beta| = r+\varepsilon-A$ and S becomes

$$S = \left(\frac{n}{q}+|\nu_1|-r-\varepsilon\right)^+ + \sum_{i=2}^{|\alpha|}\left(\frac{n}{q}+|\nu_i|-r\right)^+.$$

As before, the case $r \geqq A+n/q$ presents little problem. If $r < A+n/q$ then the largest value of S occurs when $|\alpha| = r+\varepsilon-A$ and $|\nu_i| = A+1$. Thus

$$S \leqq \left(\frac{n}{q}+A+1-r-\varepsilon\right) + \sum_{i=2}^{r-A+\varepsilon}\left(\frac{n}{q}+A+1-r\right)$$

$$= -(r-A)^2+(r-A)\left(\frac{n}{q}+1-\varepsilon\right)+\varepsilon\frac{n}{q}.$$

The expression is bounded by $n/p = n-n/q$ if

$$\varepsilon(A+n/q-r) \leqq (r-A)^2+n-\frac{n}{q}-\left(\frac{n}{q}+1\right)(r-A).$$

Therefore an appropriate value of $\varepsilon > 0$ exists if

$$(r-A)^2+n-\frac{n}{q} > \left(\frac{n}{q}+1\right)(r-A). \tag{24}$$

Case (ii). Suppose that $[r+\varepsilon] \leqq r < r+\varepsilon$. Let $k = [r+\varepsilon] = [r]$ and $|\beta| = k-A$. Here it is appropriate to obtain estimates in terms of the Besov spaces $B^r_{p,q}(R^n)$. See [2], [9], [10]. Let ω_p represent the L^p modulus of continuity of $g \in L^p(R^n)$:

$$\omega_p(\delta, g) = \sup_{|h| \leqq \delta} |g(\cdot+h)-g(\cdot)|_p, \qquad p \geqq 1.$$

Then the norm of $B^r_{p,q}(R^n)$ is given by

$$|||g|||_{r,p,q} \equiv |g|_p + \left(\int_0^\infty \left(\delta^{-r+k} \sum_{|\alpha|=k} \omega_p(\delta, \partial^\alpha g) \right)^q \frac{d\delta}{\delta} \right)^{1/q}.$$

These spaces are close to the $L^p_r(R^n)$ spaces in the sense that for any $r \in R$, $1 < p < \infty$, $1 < q \leqq \infty$, $\varepsilon > 0$,

$$L^p_{r+\varepsilon}(R^n) \subset B^r_{p,q}(R^n) \subset L^p_{r-\varepsilon}(R^n),$$

and the inclusions are continuous.

Here $|\beta| = k - A$, and we will prove that

$$|||\partial^\beta f_1(u)(t)|||_{r+\varepsilon_1-\varepsilon-k,p,q} \leqq \omega_2(|u(t)|_{r,q}) |||u(t)|||_{r-\varepsilon_1,q,q},$$

where $\varepsilon_1 > 0$ and $k \leqq r + \varepsilon_1 < k+1$. If we can prove this inequality then the statement of the lemma will follow by replacing the Besov space norms with L^p_r norms and then applying the operator K_t.

The function $\partial^\beta(f_1(u)(t))$ can be written as a sum of products as in (15). To calculate the L^p modulus of continuity of the terms where $|\alpha| \leqq \gamma$ it is necessary to prove that

$$|\partial_t^b \partial_x^\sigma \partial_z^\alpha \psi_1(t, x, z_1) - \partial_t^b \partial_x^\sigma \partial_z^\alpha \psi_1(t, x, z_2)| \leqq C(|z_1| + |z_2|)^{\gamma - |\alpha| - 1} |z_1 - z_2| \quad \text{if } |\alpha| \leqq \gamma - 1. \tag{25}$$

This is an easy calculation. However, when $\gamma - 1 < |\alpha| < \gamma$ the extra condition (23) is needed to prove that

$$|\partial_t^b \partial_x^\sigma \partial_z^\alpha \psi_1(t, x, z_1) - \partial_t^b \partial_x^\sigma \partial_z^\alpha \psi_1(t, x, z_2)| \leqq C|z_1 - z_2|^{\gamma - |\alpha|}. \tag{26}$$

With these two inequalities it is not hard to calculate the Besov space norm of the terms with $|\alpha| \leqq \gamma$. The Besov norms for the terms with $|\alpha| > \gamma$ are straightforward. The only problem is to check the condition imposed on the parameter r.

Equation (18) is replaced by

$$\left|\left|\left| \prod_{i=1}^{|\alpha|} \partial^{\nu_i} u(t) \right|\right|\right|_{r+\varepsilon_1-k,p,q} \leqq \sum_{j=1}^{|\alpha|} |||\partial^{\nu_j} u(t)|||_{r+\varepsilon_1-k,p/a_j,q} \prod_{i \neq j} |\partial^{\nu_i} u(t)|_{p/a_i}$$
$$\leqq C|u(t)|_{r,q}^{|\alpha|-1} |u(t)|_{r+\varepsilon,q},$$

where $\varepsilon_1 < \varepsilon$. The sum over j comes from the use of the triangle inequality in calculating the modulus of continuity. The conditions analogous to (19) are

$$\frac{p}{n}\left(\frac{n}{q} + |\nu_i| + \varepsilon_1 - \varepsilon - k\right)^+ \leqq a_j \leqq \frac{p}{q} \quad \text{if } i = j$$

$$\frac{p}{n}\left(\frac{n}{q} + |\nu_i| - r\right)^+ \leqq a_i \leqq \frac{p}{q} \quad \text{if } i \neq j.$$

We must ensure that

$$\left(\frac{n}{q} + |\nu_j| + \varepsilon_1 - \varepsilon - k\right)^+ + \sum_{i \neq j} \left(\frac{n}{q} + |\nu_i| - r\right)^+ < \frac{n}{p}. \tag{27}$$

As in Lemma 1 the case $r \geqq A + n/q$ is easy. Suppose that $r < A + n/q$. This sum is largest when $|\alpha| = k - A$ and $|\nu_i| = A + 1$. Now (27) becomes

$$\left(\frac{n}{q} + A + 1 - r\right)(k - A) + (\varepsilon_1 - \varepsilon - k + r) < \frac{n}{p}$$

or

$$(r-A)^2+n-\frac{n}{q}>(r-A)\left(\frac{n}{q}+1\right)-(r-k)\left(A+\frac{n}{q}+2-r\right)-(\varepsilon-\varepsilon_1).$$

Since this condition is weaker than (24) we are done. Therefore in this example k_0 can be any real number such that $k_0 \geqq A$ and

$$(r-A)^2+\gamma\left(\frac{n}{q}\right)>\left(1+\frac{n}{q}\right)(r-A)$$

for all $r \geqq k_0$.

LEMMA 4. *Let* $r \in R$, $r \geqq k$ *then*

(i) $|K_t(f(u)(s))|_{r,q} \leqq \tilde{\kappa}(t)\omega(|u(s)|_{r,q})|u(s)|_{r,q}$

(ii) $|K_t(f(v_1)(s)-f(v_2)(s))|_{r,q} \leqq \tilde{\kappa}(t)\omega_1(s)|v_1(s)-v_2(s)|_{r,q}^d$

where $\omega_1(s)=\omega_2(|v_1(s)|+|v_2(s)|)$ *and* ω_2 *is a continuous function on* $[0, T]$.

Proof. The power d comes from (23) and (26). Statement (i) follows from the proof of Lemma 3 with $\varepsilon=0$. The proof of (ii) is virtually the same. □

Example 3. The fact that L^q to L^p estimates were used for K_t resulted in the restriction (11) being imposed on γ. The growth condition on γ can be relaxed for $m>1$ if we assume that

$$|\partial_t^b\partial_x^\sigma\partial_z^\alpha\psi(t, x, z)| \leqq C|z|^{\max(\gamma-|\alpha|,0)} \tag{28}$$

and $\partial_t^b\partial_x^\delta\psi(t, x, 0)=0$ for all (t, x, z) and (b, δ, α). This is not a serious restriction in higher dimensions, where $\gamma<2$. However, where γ is permitted to be large it requires that ψ has a certain number of zero derivatives at $z=0$. In this case $\tilde{\kappa}(t)=\kappa(t)$ and K_t is considered only as a mapping from L^p to L^q. The proof of the analogue of Lemma 1 is easier here since the splitting $f=f_0+f_1$ and the ϕ_j are not necessary. As in the proof of Lemma 1, γ must satisfy

$$\gamma \leqq 1+n(q-2)/(n-(k-A)q).$$

If the upper bound in (7) is used for q then the new range is

$$1 \leqq \gamma<1+(4m-2A)/(n-2m+A-2(k_0-A)) \quad \text{if } m>1. \tag{29}$$

For the Schrödinger equation (22) and (9) imply that

$$1 \leqq \gamma<1+4m/(n-2m-2n(k_0-A)) \quad \text{if } 2m+2(k_0-A)<n$$

and

$$1 \leqq \gamma<\infty \quad \text{if } 2m+2(k_0-A) \geqq n.$$

Example 4. In some cases the critical index k_0 can be lowered. Let $0 \leqq A_1 \leqq A$ and suppose that $f(u)$ is a function as in Example 1 except that $f(u)$ is a polynomial as a function of $\partial^\alpha u$ for all α, $|\alpha|>A_1$. The nonlinearities studied by Pecher [7] and Narazaki [5] have the form $g(u)(t)=\sum_{|\beta| \leqq A/2}\partial^\beta(g_\beta(\partial^\beta u(t)))$, where g_β is a smooth function on R such that

$$|g_\beta^{(j)}(r)| \leqq C(1+|r|)^{\max(\gamma-j,0)}, \quad r \in R, j \geqq 0$$

and $g(0)=0$. This is a special case where ψ is a polynomial in $\partial^\alpha u$ for $|\alpha|>A/2$ (A is even). In this case from (20)

$$S \leqq (k+1-A/2)\left(\frac{n}{q}+A/2+1-k\right)-1$$

and the restriction on k becomes

$$(k-A/2)^2+n-\frac{n}{q}>(k-A/2)\frac{n}{q}.$$

The condition for γ is $\gamma\leqq 1+n(q-2)/(n-(k-A/2)q)$. This can be relaxed as in (29) if

$$|g_\beta^{(j)}(r)|\leqq C|r|^{\max(\gamma-j,0)},\quad r\in R$$

Example 5. Like polynomials, nonlinearities involving convolution can be quite simple. For example, if $f(u)=(V*u^2)u$ where $V\in L^r$, $n/2\leqq r\leqq\infty$, then

$$|f(u)|_{k+1,q}\leqq C|u(t)|_{k,q}^2|u(t)|_{k+1,q},$$

$A=0$, $\gamma=3$, and we may take $k_0=0$. Here we use estimates of K_t as an operator from L^q to L^q. The fact that $k_0=0$ will imply by Theorem 3 that all solutions with this type of nonlinearity are classical solutions, assuming that V and the initial conditions are smooth.

The implications of all of these inequalities for $f(u)$ will be discussed in §§ 5 and 6.

4. Existence. Define $W_k^q(T)$ to be the space of continuous bounded functions from $[0, T]$ to $L_k^q(R^n)$ with norm

$$\|g\|=\sup\{|g(t)|_{k,q}: 0\leqq t\leqq T\}.$$

The integral equation corresponding to the nonlinear wave equation (1) is

$$u(t)=K_t^C(u_0)+K_t(u_1)+\int_0^t K_{t-s}(g(s)-f(u)(s))\,ds \tag{30}$$

The solution for the corresponding linear equation is

$$h(t)=K_t^C(u_0)+K_t(u_1)+\int_0^t K_{t-s}(g(s))\,ds.$$

Thus

$$u(t)=h(t)-\int_0^t K_{t-s}(f(u)(s))\,ds\equiv F(u)(t).$$

Rather than using u_0, u_1, g it will usually be convenient to express our regularity assumptions in terms of h, the solution of the linear equation. For the existence of solutions we use the standard procedure of setting up a contraction mapping in the space $W_k^q(T_1)$.

LEMMA 5. *For a nonlinear equation* (30) *with corresponding parameters* k_0, γ, q, $T\leqq\infty$, *if* $h\in W_k^q(T)$ *and* $k\geqq k_0$ *then there exists* T_1, $0<T_1<T$ *such that* (30) *has a solution* $u\in W_k^q(T_1)$.

Proof. Let $k=k_0$. By Lemma 4 or its equivalent

$$\left|\int_0^t K_{t-s}(f(u)(s))\,ds\right|_{k,q}\leqq C_1\int_0^t\tilde{\kappa}(t-s)\omega(|u(s)|_{k,q})|u(s)|_{k,q}\,ds.$$

We may assume that ω and ω_2 are increasing. Hence, using the norm of $W_k^q(T_1)$,

$$\|F(u)\|\leqq\|h\|+C_1\left(\int_0^{T_1}\tilde{\kappa}(s)\,ds\right)\omega(\|u\|)\|u\|. \tag{32}$$

This shows that F maps $W_k^q(T_1)$ to itself.

Similarly, by Lemma 4,

$$
\begin{aligned}
|F(v_1)(t)-F(v_2)(t)|_{k,q} &\leqq \left| \int_0^t K_{t-s}(f(v_1)(s)-f(v_2)(s))\, ds \right|_{k,q} \\
&\leqq C_2\left(\int_0^{T_1} \tilde{\kappa}(s)\, ds \right) \omega_2(\|v_1\|+\|v_2\|)\|v_1-v_2\|^d/2.
\end{aligned} \tag{33}
$$

Let $M > 2\|h\|$, and suppose that T_1 is so small that

$$
\left(C_1\omega(M) + C_2\omega_2(M)M^{d-1} \right) \int_0^{T_1} \tilde{\kappa}(s)\, ds < \frac{1}{2}.
$$

If $\|u\| \leqq M$, $\|v_1\| \leqq M$, $\|v_2\| \leqq M$ then (32) and (33) become

$$
\|F(u)\| \leqq M \quad \text{and} \quad \|F(v_1)-F(v_2)\| \leqq \|v_1-v_2\|/2.
$$

Thus F is a contraction of the ball of radius M in $W_k^q(T_1)$. Consequently F has a unique fixed point $u \in W_k^q(T_1)$.

5. Regularity. The proof of the regularity of u uses repeated applications of the following well-known inequality.

LEMMA 6 (Gronwall's inequality). *Let $T>0$. If $U \in C([0, T])$, $H \in C(R_+)$, and $\kappa_1 \in L^1_{loc}(R_+)$ are positive functions satisfying*

$$
U(t) \leqq H(t) + \int_0^t \kappa_1(t-s)U(s)\, ds
$$

for all $0 < t < T$, then there exists $\omega_2 \in C(R_+)$, depending only on κ_1, such that

$$
U(t) \leqq \omega_2(t) \max_{0 \leqq s \leqq t} H(s)
$$

for all $0 \leqq t < T$.

The proof is a straightforward induction on T.

LEMMA 7. *Suppose that $f(u)$ is a nonlinearity from § 3 with parameters k_0, γ, q, and T. For any $k \geqq k_0$, if $h \in W_k^q(T)$ and $u \in W_{k_0}^q(T)$ is a solution of the integral equation* (30), *then $u \in W_k^q(T)$.*

Proof. From the integral equation and (10),

$$
\begin{aligned}
|u(t)|_{k+1,q} &\leqq |h(t)|_{k+1,q} + \int_0^t \tilde{\kappa}(t-s)\omega(|u(s)|_{k,q})|u(s)|_{k+1,q}\, ds \\
&\leqq |h(t)|_{k+1,q} + \tilde{\omega} \int_0^t \tilde{\kappa}(t-s)|u(s)|_{k+1,q}\, ds
\end{aligned} \tag{34}
$$

when $\tilde{\omega} = \sup\{\omega|u(s)|_{k,q}): 0 \leqq s \leqq T\}$. The proof will be completed by induction on k. The lemma is obviously true when $k = k_0$. Suppose it holds also for some $k \geqq k_0$. By Lemma 5 there exists $T_1 \leqq T$ such that $u \in W_{k+1}^q(T_1)$. Let T_1 be the largest such constant. Gronwall's inequality applied to (34) shows that

$$
|u(t)|_{k+1,q} \leqq \omega_2(t)\|h\|
$$

for $0 \leqq t \leqq T_1$, where ω_2 depends on $\tilde{\kappa}$ and $\tilde{\omega}$ but not on $|u(t)|_{k+1,q}$. If $T_1 < T$ then $\lim_{t \to T_1} |u(t)|_{k+1,q} < \infty$ and $u(t)$ can be extended past T_1 by a contraction argument as in Lemma 5. Since this contradicts the maximality of T_1 then $T_1 = T$. As t approaches T, $|u(t)|_{k+1,q}$ remains bounded. Consequently $u \in W_{k+1}^q(T)$. In the case of a nonlinearity from Example 2 the argument is the same except that we conclude that $u \in W_{k+\varepsilon}^q(T)$. The result is the same in either case.

LEMMA 8. *If u is a solution of the integral equation* (30), $u \in W_k^q(T)$ *and* $h \in W_k^2(T)$, $k > A + n/q$, $k \geqq k_0$, *then* $u \in W_k^2(T)$.

Proof. Since by Sobolev's inequality $L_k^q \subset L_A^\infty$ then

$$|f(u)(t)|_2 \leqq C(1+|u(t)|_{A,\infty})^{\gamma-1}|u(t)|_{A,2}.$$

Because $A \leqq m$ and K_t maps L^2 to L_m^2 then an application of Gronwall's inequality to the integral equation shows that $u \in W_A^2(T_1)$.

Let β be a multi-index with $|\beta| = k - A + 1$. Since $u(t) \in L_A^q \subset L_A^\infty$ then as in the proof of Lemma 1

$$|\partial^\beta (f(u)(t))|_2 \leqq C\omega(|u(t)|_{k,q}) \sum_{\alpha,\nu} \left| \prod_{i=1}^{|\alpha|} \partial^{\nu_i} u(t) \right|_2. \tag{35}$$

To apply Hölder's and Sobolev's inequalities as in Lemma 1 it is necessary to find constants $a_i \in [0, 1]$ such that $\sum a_i = 1$ and

$$\begin{aligned} \left(\frac{1}{2} - \frac{k+1-|\nu_i|}{n}\right)^+ &\leqq \frac{a_i}{2} \leqq \frac{1}{2} \quad i = 1 \\ \left(\frac{1}{q} - \frac{k-|\nu_i|}{n}\right)^+ &\leqq \frac{a_i}{2} \leqq \frac{1}{q} \quad i \geqq 2. \end{aligned} \tag{36}$$

The sum of the right-hand sides is $\frac{1}{2} + (|\alpha| - 1)/q \geqq \frac{1}{2}$. Note that $|\nu_i| \leqq |\beta| + A = k + 1$ and $|\nu_i| \leqq k$ for $i \geqq 2$. Since $k > A + n/q$ then

$$\frac{1}{q} - \frac{k-|\nu_i|}{n} \leqq \frac{1}{n}(|\nu_i| - A).$$

This means that the sum of the left-hand sides of (36) is largest when $|\alpha| = 1$ and is $\leqq \frac{1}{2}$. Consequently an appropriate collection on $\{a_i\}$ does exist and

$$|\partial^\beta (f(u)(t))|_2 \leqq C\omega(|u(t)|_{k,q})|u(t)|_{k+1,2}.$$

hence $|f(u)(t)|_{k+1-A,2}$ is bounded by the same expression. Now an application of Gronwall's inequality completes the proof that $u \in W_{k+1}^2(T_1)$.

LEMMA 9. *Let $k > n/2$. If $\phi \in L_k^2(R^n)$ then $K_t(\phi)$ is differentiable in t, $\partial(K_t(\phi))/\partial t = K_t^C(\phi) \in C(R_+^{n+1}) \cap W_k^2(\infty)$.*

If $\phi \in L_{k+m}^2(R^n)$ then $K_t^C(\phi)$ is differentiable in t, $\partial(K_t^C(\phi))/\partial t = -(aI + (-\Delta)^m)K_t(\phi) \in C(R_+^{n+1}) \cap W_k^2(\infty)$.

Proof. Let $\xi_* = \sqrt{a + |\xi|^{2m}}$ and $\phi_* = (I - \Delta)^{k/2}\phi$. The function ϕ_* is continuous by Sobolev's theorem. The Lebesgue dominated convergence theorem implies that

$$\Phi_s(\xi) = \hat{\phi}_*(\xi)\left\{\frac{\sin((t+s)\xi_*) - \sin(t\xi_*)}{s\xi_*} - \cos(t\xi_*)\right\}$$

converges in L^2 norm to zero as $s \to 0$. Since

$$\left|\frac{K_{t+s}(\phi) - K_t(\phi)}{s} - K_t^C(\phi)\right|_\infty \leqq \left|\frac{1}{s}(K_{t+s}(\phi_*) - K_t(\phi_*)) - K_t^C(\phi_*)\right|_2 = |\Phi_s|_2,$$

then the difference quotients converge uniformly to $K_t^C(\phi) = \partial\phi/\partial t$. The Plancherel theorem also implies that $K_t(\phi)$ and $K_t^C(\phi)$ are continuous functions of t with values in $C(R^n)$ whenever $\phi \in L_k^2$. The proof that $K_t^C(\phi)$ has a continuous derivative is similar. The lemma applies also to $K_t(\phi(s))$, where $\phi \in W_k^2(T)$.

Let $\tilde{W}_{k,J}^2(T)$ be the space of functions u such that $\partial_t^j u \in W_k^2(T)$ for all $0 \leqq j \leqq J$.

LEMMA 10. *Suppose that* $k_1 > (J-1)m + (J+1)A + n/2$, $J \leqq 1$, *and* u *and* h *are solutions of* (30) *and* (31), *respectively. If* $h \in \tilde{W}^2_{k_1,J}(T)$ *and* $u \in W^2_{k_1}(T)$ *then* $u \in \tilde{W}^2_{k,J}(T)$, *where* $k = k_1 - (J-1)m - JA$.

Proof. Analogous to (15),

$$\partial_t^j(f(u)(t)) = \sum_b \sum_\alpha (\partial_t^b \partial_z^\alpha \psi)(u)(t) \sum_\nu c_\nu \prod_{i=1}^{|\alpha|} \partial_t^{r_i} \partial_x^{\nu_i} u(t) \tag{37}$$

where $|\nu_i| \leqq A$, $|\tau_i| \leqq j$. If $u \in W^2_{k_2}$ and $k_2 > A + n/2$ then $\partial^\alpha u \in L^\infty$ for all $|\alpha| \leqq A$ and $(\partial_t^b \partial_z^\alpha \psi)(u)(t) \in L^\infty$. Also $\partial_t^{r_i} \partial_x^{\nu_i} u(t) \in L^\infty$ for all i. Therefore $u \in \tilde{W}^2_{k_2,j}(T)$ implies that $f(u) \in \tilde{W}^2_{k_2-A,j}(T)$. In particular, $f(u) \in \tilde{W}^2_{k_2-A,0}(T) = W^2_{k_2-A}(T)$.

Differentiating the integral equation (30) gives

$$\partial_t u = \partial_t h - \int_0^t K^C_{t-s}(f(u)(s))\, ds$$

$$\partial_t^2 u = \partial_t^2 h - f(u)(t) + \int_0^t (aI + (-\Delta)^m) K_{t-s}(f(u)(s))\, ds.$$

From the first equation $\partial_t u \in W^2_{k_1-A}(T)$, $u \in \tilde{W}^2_{k_1-A,1}(T)$, and $f(u) \in \tilde{W}^2_{k_1-2A,1}(T)$. Since the integrand is in $\tilde{W}^2_{k_1-m-2A}(T)$, the second equation gives $\partial_t^2 u \in W^2_{k_1-m-2A}(T)$, $u \in \tilde{W}^2_{k_1-m-2A,2}(T)$, and $f(u) \in \tilde{W}^2_{k_1-m-3A,2}(T)$. In general, $\partial_t^j u \in \tilde{W}^2_{k_1-(j-1)m-jA,2}(T)$. This proves the lemma.

THEOREM 3. *Let* $f(u)$ *be the nonlinearity described in* § 3 *with parameters* k_0, γ, q *and* T_1. *Let* $T \leqq T_1$, $k \geqq 1$, $k_1 > k(m+A) + n/2$, $k_1 \geqq k_0$. *Suppose that* $u_0 \in L^2_{k_1+km}(R^n)$, $u_1 \in L^2_{k_1+km-m}(R^n)$, $g \in \tilde{W}^2_{k_1-m,k}(T)$.

If $u \in W^q_{k_0}(T)$ *is a solution of the integral equation* (25) *then* $u \in \tilde{W}^2_{km,k}(T)$. *If* $k \geqq J$ *and* $km > J + n/2$ *then* $u \in C^J([0, T] \times R^n)$. *In particular, if* $J = 2$ *then* u *is a classical solution of the differential equation* (1).

Proof. Since $k_1 > n/2$, Lemma 9 proves that $K^C_t(u_0)$, $K_t(u_1)$ and $K_{t-s}(g(s))$ are in $\tilde{W}^2_{k_1,k}$. Therefore $h \in \tilde{W}^2_{k_1,k}(T)$. Lemmas 7 and 8 combine to show that $u \in W^q_{k_0}(T)$ implies $u \in W^q_{k_1}(T)$. Since $k_1 > k(m+A) + n/2$ then Lemma 10 proves that $u \in \tilde{W}^2_{km,k}(T)$.

This theorem applies also in the case where blow-up occurs: $T \leqq \infty$. If u has a critical amount of regularity k_0 then the smoothness of u_0, u_1, and g imply that u is smooth. Conditions that guarantee this critical amount of smoothness are discussed in the next section. It turns out that the conditions for solutions to be classical for $0 \leqq t \leqq T$ are similar to the conditions proved elsewhere for global classical solutions. Also, note from (11) that the power γ can increase as k_0 does.

The main difficulty for a specific equation is calculating the best values of k_0 such that

$$|K_t(f(u)(s))|_{k+\varepsilon,q} \leqq \tilde{\kappa}(t)\omega(|u(s)|_{k,q})|u(s)|_{k+\varepsilon,q}$$

for all $k \geqq k_0$ (the general form of (10)). For the nonlinearities of Example 1 satisfying (12), $k_0 - A$ is either zero or the largest root of the quadratic $x^2 - xn/q + n(1-2/q) = 0$ (Lemma 2). In Example 2 with the extra condition (23), $k_0 - A$ is either zero or the larger root of the quadratic $x^2 - (1+n/q)x + n(1-1/q) = 0$ (Lemma 3). In Example 5, $k_0 - A$ is zero. If $k_0 - A = 0$ then every solution in W^q_A with smooth initial conditions u_0, u_1, g will be smooth. If we take Example 2 with the upper bound given for q in (6),

$$k_0 = \frac{\{(n^2+n+2) + \sqrt{(n^2+n+2)^2 - 8n(n+3)(n+1)}\}}{n+1}, \quad \text{if } m = 1, \quad n \geqq 10.$$

As $n \to \infty$, $q \to 2$, and $k_0/n \to 1/2$. If $k_0 > n/2$ then Sobolev's theorem guarantees that $u \in L^\infty$. A similar earlier result by von Wahl [11, p. 269] proved that if $f(u)$ has polynomial growth, and $u \in W^2_{k_0}(T)$ where $k_0 \in Z$, $k_0 \geqq n/2$, then u is a classical solution of (1).

6. Classical solutions and energy estimates. Let $f(u)$ be a nonlinearity as in Example 2 with the extra condition (28). For simplicity assume that u_0, u_1, and g are sufficiently smooth. In this section we derive several simple consequences of Theorem 3.

If $m = 1$ then

$$1 \leqq \gamma \leqq 1 + 4n(1-A)/(n(n-1+2A) - 2(n+1)(k_0 - A)). \tag{38}$$

In this case $q = 2(n+1)/(n-1+2A)$ and k_0 can be calculated from Lemma 3; that is,

$$(k-A)^2 + n(1-1/q) > (1+n/q)(k-A) \quad \text{for all } k \geqq k_0.$$

This quadratic in $k_0 - A$ has no real roots if $(1+n/q)^2 < 4n(1-1/q)$ or

$$(n^2+n+2+2An)^2 < 8n(n+3-2A)(n+1). \tag{39}$$

in particular, if $A = 0$ then this is satisfied for $n < 10$. Theorem 3 implies that a solution of the integral equation (30) such that $u \in W^q_0(T)$ is a classical solution of (1) for $0 < t < T$ if $n < 10$. Similarly $u \in W^q_A(T)$ is a classical solution whenever n satisfies (39).

If $f(u)$ is a nonlinearity from Example 4 of the form

$$f(u)(t) = \sum_{|\beta| \leqq A/2} (-1)^{|\beta|} \partial^\beta (f_\beta(\partial^\beta u(t)))$$

where f_β is a smooth real-valued function on R, and $f_\beta(0) = 0$. We make the extra assumption that

$$\int_0^r f_\beta(s)\, ds \geqq 0 \quad r \in R.$$

For these nonlinearities the energy norm

$$E(t) = |\partial_t u(t)|^2_2 + |u(t)|^2_{m,2}$$

is bounded as a function of t for all t. This shows that a weak L^2 solution $u(t)$ exists for $0 \leqq t < \infty$. Suppose for simplicity that $m = 1$. It follows from Hölder's and Sobolev's inequalities that $u \in W^q_1(\infty)$ since

$$|\partial_i (f(u)(t))|_p \leqq |u(t)|^{\gamma-1}_{1,2} |\partial_i u(t)|_q$$

if $q \leqq \gamma + 1 \leqq 2n(q-2)/q(n-2) + 2$. The restriction on q leads to the following upper bound on γ:

$$\gamma < 1 + 4n(1-A)/(n-2)(n+1). \tag{40}$$

If $k_0 = 1$ then (38) becomes $1 \leqq \gamma \leqq 1 + 4n(1-A)/(n^2-3n-2-2A)$. This upper bound is slightly larger than $1 + 4/(n-3)$ when $A = 0$. The limit on γ is imposed therefore by the transition from L^2_1 to L^q_1 rather than by Theorem 3. By Theorem 3, $u(t)$ is a classical solution if $n < 10$ and (40) holds. The power (40) also appears in Lemma III.5 of [2], however, for lower dimensions, $n < 10$, Brenner and von Wahl are able to prove the existence of classical solutions for $\gamma < 1 + 4/(n-2)$.

If $m > 1$ then from (7) $q < 2n/(n-2m+A)$. The condition for k_0 is

$$(k-A)^2 + n(1-(n-2m+A)/2n) > (1+n(n-2m+A)/2n)(k-A) \quad \text{if } k \geqq k_0. \tag{41}$$

This quadratic has no real roots if

$$(n-2m+A+2)^2 < 8(n+2m-A).$$

Let $A=0$. From (29), $1 \leqq \gamma < 1+4m/(n-2m-2k_0)$. From Theorem 3 it follows that a solution u of (30) in $W_0^q(T)$ is a classical solution of (1) if $n<2m+2+4\sqrt{2m}$. Similarly a weak L^q solution ($u \in W_m^q(T)$) is a classical solution of (1) for $0<t<T$ if $n<4m+4m/(m-1)$ and a strong L^q solution ($u \in W_{2m}^q(T)$) is classical if $n<6m-m/(m-1/2)$.

These results appear quite weak when compared to the results in [7] and [6]. In these papers there is a positivity assumption to guarantee a finite energy norm. The difference is that in this case, in contrast to $m=1$, more essential use is made of the energy norm. See, for example, Lemma 9 in [6].

For the Schrödinger equation, $A=0$ and $\gamma < 1+4m/(n-2m-2k_0)$. The condition for the dimension is $(n-2m+2)^2<8(n+2m)$. Therefore every solution in $W_0^{\gamma+1}(T)$ is a classical solution for $0<t<T$ if $n<2m+2+4m\sqrt{2m}$. This agrees with the result of Tsutsumi and Hayashi, who assuming a finite energy norm, proved that for $m=1$, $n \leqq 9$, global classical solutions exist. The nonlinearities in this case typically are of the form $f_0(u)u$, where u is complex-valued and f_0 is a real-valued function on C.

Acknowledgment. I thank T. Narasaki for many interesting conversations on the regularity theorem and positivity conditions.

INFINITE-ORDER DIFFERENTIAL EQUATIONS AND THE HEAT EQUATION*

NORMAN L. HILLS† AND JOHN M. IRWIN‡

Abstract. A method is given for solving certain infinite-order differential equations whose characteristic function is an entire function of order less than 1. The infinite-order operator is expressed as an infinite product of first-order operators and is then inverted by a sequence of integral operators. The method is a natural generalization of a finite-order method and can be computed numerically. The method is shown to converge and an error estimate is given. Applications to solutions of some heat equation problems are indicated.

Key words. infinite-order differential equation, entire functions, heat equation

AMS(MOS) subject classifications. primary 34A35, secondary 35K05

1. Introduction. It has seemed natural to many people to extend the idea of a linear ordinary differential equation with constant coefficients

$$\sum_{n=0}^{N} a_n f^{(n)}(t) = g(t)$$

to an equation with an infinite-order differential operator

$$\sum_{n=0}^{\infty} a_n f^{(n)}(t) = g(t). \tag{1}$$

In fact, during the first half of this century the subject received a great deal of attention. In 1936, Davis [3] published a book on the subject with a bibliography of over 40 pages. In more recent times infinite-order differential operators were used by Hirschman and Widder [4] to invert convolution transforms and by Widder [7] in his study of the heat equation. Significant work, frequently by Russian mathematicians, is still being done. We know of no efforts, however, to use modern numerical methods to solve practical problems related to equations of type (1).

Here we give a method for solving certain of these equations and a brief discussion showing how the method can be implemented numerically. We also give examples showing the connection of (1) to the heat equation. Many other types of infinite-order differential equations can be used for other problems, and we intend to treat some of them in later papers.

2. Basic assumptions and definitions. If we write (1) as $\sum_{n=0}^{\infty} a_n D^n f(t) = g(t)$, $(D = d/dt)$, then by analogy with the characteristic polynomial of a finite-order equation, the characteristic function is defined as $A(z) = \sum_{n=0}^{\infty} a_n z^n$. The infinite-order differential operator is then written as $A(D)$ and (1) becomes $A(D)f = g$.

To obtain a reasonable theory we must make certain assumptions about the functions $A(z)$, $f(t)$, and $g(t)$.

We will assume that $A(z)$ is an entire function of exponential type of order $\alpha < 1$. This means that for any $\varepsilon > 0$ there exists an N such that $|a_n| < n^{-n/(\alpha+\varepsilon)}$ for $n > N$. Except for polynomials, entire functions of order less than one always have an infinite number of zeros. We also assume that all zeros of $A(z)$ are real and negative. The

following examples: $\cosh(\sqrt{z})$, $z^{-1/2}\sinh(\sqrt{z})$, and the modified Bessel function $I_0(\sqrt{z})$, each of which is of order $\frac{1}{2}$, satisfy all our assumptions. (Our results can be immediately extended to the case where $A(z)$ has only a finite number of positive zeros.)

For $A(D)f$ to be defined, f must be infinitely differentiable and $\sum_{n=0}^{\infty} a_n f(t)^{(n)}$ must converge, but $f(t)$ need not be analytic.

To insure uniqueness of the solution of an Nth-order differential equation, N boundary conditions are prescribed. Here we prescribe the infinite number of conditions $f^{(n)}(t)\to 0$ for $t>0$, $t\to 0$. These conditions are required if $f(t)$ is to represent the temperature at an interior point of a region whose initial temperature is zero.

The function $g(t)$ is assumed to be continuous for $t\geqq 0$, and $g(t)=0$ if $t\leqq 0$. We do not assume $g(t)$ to be analytic or even differentiable. In our applications $g(t)$ will represent the temperature at the boundary of a region or the average over the boundary of the temperature. The behavior of $f(t)$ for negative t is of no concern.

In general our assumptions about $A(z)$ are more restrictive than those found in most of the classical literature, while the assumptions about $f(t)$ and $g(t)$ are considerably less restrictive.

3. Examples of applications to the heat equation. Consider the one-dimensional problem with variable end conditions:

$$\begin{aligned} &u_t(x,t)=u_{xx}(x,t), && -1<x<1, \quad 0<t,\\ &u(x,0)=0, && -1\leqq x\leqq 1,\\ &u(-1,t)=\phi_1(t), && 0\leqq t,\\ &u(1,t)=\phi_2(t), && 0\leqq t; \end{aligned}$$

$u(x,t)$ is required to be continuous for $-1\leqq x\leqq 1$, $0\leqq t$. We assume $\phi_1(t)$ and $\phi_2(t)$ are continuous for $t\geqq 0$ and vanish for $t\leqq 0$.

Let $g(t)=\frac{1}{2}[\phi_1(t)+\phi_2(t)]$ and let $f(t)=u(0,t)$. We will show that $f(t)$ satisfies the equation $\cosh(\sqrt{D})f(t)=g(t)$ together with the condition $f^{(n)}(0+)=0$. The expression

$$u(x,t)=\sum_{n=0}^{\infty}\left\{\frac{x^{2n}}{(2n)!}f^{(n)}(t)+\frac{x^{2n+1}}{(2n+1)!}h^{(n)}(t)\right\} \tag{2}$$

represents a solution to the heat equation if $f(t)$ and $h(t)$ are in a suitable class of infinitely differentiable functions. See Widder [7, p. 43] and Cannon [2, p. 27]. It is seen from this expression that $f(t)=u(0,t)$ and that

$$g(t)=\tfrac{1}{2}[u(1,t)+u(-1,t)]=\sum_{n=0}^{\infty}\frac{D^n}{(2n)!}f(t)=\cosh(\sqrt{D})f(t)$$

so that $\cosh(\sqrt{D})f(t)=g(t)$. As for the condition $f^{(n)}(0+)=0$, the fact that $\phi_1(t)$ and $\phi_2(t)$ are both zero for $t\leqq 0$ implies that $u(x,t)$ can be defined to be zero for negative t and will still satisfy the heat equation. In fact the extended $u(x,t)$ can be taken as the solution to the following problem whose boundary data are continuous:

$$\begin{aligned} &u_t(x,t)=u_{xx}(x,t), && -1<x<1, \quad -1<t,\\ &u(x,-1)=0, && -1\leqq x\leqq 1,\\ &u(-1,t)=\phi_1(t) && \text{if } 0\leqq t, \qquad u(-1,t)=0 \quad \text{if } t<0,\\ &u(1,t)=\phi_2(t) && \text{if } 0\leqq t, \qquad u(-1,t)=0 \quad \text{if } t<0. \end{aligned}$$

Since every solution to the heat equation is analytic in x and infinitely differentiable in t (Widder [7, p. 84]) we see that

$$f^{(n)}(0+) = \lim_{t\to 0+} \frac{\partial^n}{\partial t^n} u(0, t) = \frac{\partial^{2n}}{\partial x^{2n}} u(x, t)\Big|_{x=0} = 0.$$

In a similar manner we can show that $u_x(0, t) = h(t)$ satisfies $A(D)h(t) = \frac{1}{2}[\phi_1(t) - \phi_2(t)]$, where now $A(D) = \sinh(\sqrt{D})/\sqrt{D}$. It is also true that $h^{(n)}(0+) = 0$ for $n = 0, 1, 2, \cdots$.

If $f(t)$ is the temperature at the center of a long cylinder of radius 1 and if the temperature in the cylinder is zero at $t = 0$, then $f(t)$ will satisfy $I_0(\sqrt{D})f(t) = g(t)$, where $g(t)$ is the average temperature on the surface, $r = 1$, of the cylinder.

All these examples can be derived, at least formally, by using the Laplace transform to obtain an equation, $A(s)F(s) = G(s)$, where F and G are transforms of our f and g. The solution is then the inverse transform of $G(s)/A(s)$. The difficulties we encounter are that the transform of $g(t)$ and the inverse transform of G/A may be very difficult to find or may not even exist. If numerical methods are used, our method may be preferable since finding $f(t)$ may require less effort than the computation of $G(s)$ alone.

4. Infinite products and a method of solution. Entire functions of order less than one always have an infinite product expansion

$$A(z) = A(0) \prod_{n=0}^{\infty} \left(1 - \frac{z}{\lambda_n}\right) \tag{3}$$

where the λ_n are the zeros of $A(z)$. Moreover,

$$\frac{A'(z)}{A(z)} = \frac{d}{dz} \log A(z) = \sum_{n=0}^{\infty} (z - \lambda_n)^{-1}$$

so that

$$\frac{A'(0)}{A(0)} = -\sum_{n=0}^{\infty} \lambda_n^{-1}. \tag{4}$$

For functions of order α less than one it is also true that $\sum |\lambda_n|^{-\beta}$ converges for any $\beta > \alpha$. This will be used in the proof of Lemma 5.

For a discussion of all these facts see Chapters 1 and 2 of Boas [1]. Section 12.10 of [1] in which Boas discusses infinite-order differential equations with analytic $f(t)$ and $g(t)$ may also be of interest.

The operator $A(D)$ is now written as a product of operators:

$$A(D) = A(0) \prod_{n=0}^{\infty} \left(1 - \frac{D}{\lambda_n}\right). \tag{5}$$

The use of the infinite product rather than the infinite sum seems to be due to Ritt [6]. It has since been used by many others, e.g., Korobeinik [5], whose methods are related but differ considerably from those discussed here.

Although Ritt has made the same assumptions about the characteristic function $A(z)$ as we have, his objectives differ from ours. One result, however, his Theorem V, is important to us. He introduces the notation A and (A) as follows:

$$Af = \lim_{N\to\infty} A(0) \prod_{n=0}^{N} \left(1 - \frac{D}{\lambda_n}\right) f(t), \qquad (A)f = \lim_{N\to\infty} \sum_{n=0}^{N} a_n D^n f(t).$$

Theorem V states that $(A)f = Af$ if f is analytic. His proof, however, does not really require the analyticity of f. Infinite differentiability and the convergence of $(A)f$ will suffice. This more general result will be used in the proof of Theorem 2.

Equation (5) displays $A(D)$ as an infinite product of first-order operators. We denote them as $K_n = (1 - D/\lambda_n)$. To find the inverse of K_n we solve $K_n f(t) = f(t) - (1/\lambda_n) f'(t) = g(t)$ subject to the condition $f(0) = 0$. The well-known elementary solution is

$$f(t) = -\lambda_n e^{t\lambda_n} \int_0^t e^{-s\lambda_n} g(s)\, ds.$$

We define the operators L_n by

$$L_n g(t) = -\lambda_n e^{t\lambda_n} \int_0^t e^{-s\lambda_n} g(s)\, ds. \tag{6}$$

The L_n are inverses of the K_n in the sense that for any continuous g, $K_n L_n g = g$ and for any differentiable f satisfying $f(0) = 0$, $L_n K_n f = f$. We solve $A(D)f = g$ by the sequence of inverse operators, i.e., the solution to (1) is to be given by $f = \prod_{n=0}^{\infty} L_n g / A(0)$. In Theorem 1 we will prove the convergence of this infinite product of operators and in Theorem 2 we show that it indeed yields a solution to (1).

To construct a practical algorithm we let $f_0(t) = g(t)/A(0)$ and then define $f_{n+1}(t)$ recursively by $f_{n+1}(t) = L_n f_n(t)$. A numerical method for computing $L_n f_n(t)$ is given at the end of the paper.

THEOREM 1. *If $A(z)$ satisfies the above conditions, then for any continuous $g(t)$ the sequence $\{f_n\}$ defined by*

$$f_0(t) = \frac{g(t)}{A(0)}, \qquad f_{n+1}(t) = -\lambda_n e^{t\lambda_n} \int_0^t e^{-s\lambda_n} f_n(s)\, ds$$

converges uniformly in any bounded interval $0 \leqq t \leqq T$. We have the explicit error estimate

$$\|f - f_n\| < 2|\lambda_0| \, \|g\| A(0)^{-2} \left[A'(0) - A(0) \sum_{k=0}^{n-1} |\lambda_k|^{-1} \right].$$

Remarks. We use the sup norm: $\|f\| = \sup |f(t)|$ for $0 \leqq t \leqq T$ so that we can exploit the completeness of $C[0, T]$ and the fact that convergence in this norm is uniform convergence.

We will repeatedly use the formula

$$f_{n+1}(t) = -\lambda_n e^{t\lambda_n} \int_0^t e^{-s\lambda_n} f_n(s)\, ds \tag{7}$$

for the solution to the initial value problem

$$f_{n+1}(t) - (1/\lambda_n) f'_{n+1}(t) = f_n(t), \qquad f_{n+1}(0) = 0. \tag{8}$$

It is convenient to rearrange the first part of (8) as $f_{n+1}(t) - f_n(t) = (1/\lambda_n) f'_{n+1}(t)$ and take norms to get

$$\|f_{n+1} - f_n\| = |1/\lambda_n| \, \|f'_{n+1}\|. \tag{9}$$

The operator $L_n(g)$ in (6) may be written as $\int_0^t -\lambda_n e^{(t-s)\lambda_n} g(s)\, ds$. Define

$$\delta_n(t) = \begin{cases} -\lambda_n e^{t\lambda_n} & \text{if } t \geqq 0, \\ 0 & \text{if } t < 0, \end{cases} \tag{10}$$

so that

$$L_n(g) = \int_0^T \delta_n(t - s) g(s)\, ds. \tag{11}$$

Before proving Theorem 1 we prove two lemmas.

LEMMA 1. $\|f_{n+1}\| < \|f_0\|$ *for all* $n \geqq 0$.

Proof. Using (11) and taking norms, we have

$$\|f_{n+1}\| = \|L_n(f)\| = \sup \left| \int_0^T \delta_n(t-s) f_n(s)\, ds \right|$$

$$\leqq \|f_n\| \sup \left| \int_0^T \delta_n(t-s)\, ds \right|.$$

From (10) we compute $\int_0^T \delta_n(t-s)\, ds = 1 - e^{t\lambda_n}$ so that $\|f_{n+1}\| < \|f_n\| \sup |1 - e^{t\lambda_n}|$. Since $\lambda_n < 0$ and $t \geqq 0$, $|1 - e^{t\lambda_n}| < 1$. Hence $\|f_{n+1}\| < \|f_n\|$. Likewise $\|f_n\| < \|f_{n-1}\|$ etc., so that for all $n \geqq 0$, $\|f_{n+1}\| < \|f_0\|$. □

LEMMA 2. $\|f'_{n+1}\| < \|f'_1\|$ *for all* $n \geqq 1$.

Proof. We assume that $n \geqq 1$ and show that f'_{n+1} is obtained from f'_n in exactly the same way that f_{n+1} is obtained from f_n. Lemma 1 will then imply Lemma 2. We must assume $n \geqq 1$ since we did not assume $f_0(t) = g(t)/A(0)$ to be differentiable. But for $n \geqq 1$, $f_n(t)$ is differentiable and $f_n(0) = 0$, as can be seen from (7).

Let $t = 0$ in (8) and it follows that $f'_{n+1}(0) = 0$. We differentiate (8), and the result, together with $f'_{n+1}(0) = 0$, gives

$$f'_{n+1}(t) - (1/\lambda_n)(f'_{n+1}(t))' = f'_n(t), \quad f'_{n+1}(0) = 0, \quad (n \geqq 1). \tag{12}$$

We see that (12) is the same as (8) with f_n and f_{n+1} replaced by f'_n and f'_{n+1}, and Lemma 2 follows. □

Proof of Theorem 1. From (9), $\|f_{n+1} - f_n\| = |1/\lambda_n| \|f'_{n+1}\|$, and Lemma 2, $\|f'_{n+1}\| < \|f'_1\|$, we have

$$\|f_{n+1} - f_n\| < |1/\lambda_n| \|f'_1\|. \tag{13}$$

If $n < m$ are any two positive integers then $(f_n - f_m) = (f_n - f_{n+1}) + (f_{n+1} - f_{n+2}) + \cdots + (f_{m-1} - f_m)$. Taking norms, we have $\|f_n - f_m\| \leqq \|f_n - f_{n+1}\| + \|f_{n+1} - f_{n+2}\| + \cdots + \|f_{m-1} - f_m\|$. Using (13), we obtain $\|f_m - f_n\| < [|\lambda_n|^{-1} + |\lambda_{n+1}|^{-1} + \cdots + |\lambda_{m-1}|^{-1}] \|f'_1\|$. Hence

$$\|f_m - f_n\| < \|f'_1\| \sum_{k=n}^{m-1} |\lambda_k|^{-1}. \tag{14}$$

The right-hand side of (14) can be made arbitrarily small by making n sufficiently large. Therefore $\{f_n\}$ is a Cauchy sequence and $\lim_{m\to\infty} f_m = f$ exists.

To derive the error estimate we take the limit of (14) as $m \to \infty$ to obtain $\|f - f_n\| < \|f'_1\| \sum_{k=n}^{\infty} |\lambda_k|^{-1}$. Using (4), we have $\sum_{k=n}^{\infty} |\lambda_k|^{-1} = A'(0)/A(0) - \sum_{k=0}^{n-1} |\lambda_n|^{-1}$. From (9) with $n = 0$, we have $\|f'_1\| = |\lambda_0| \|f_1 - f_0\|$. But $\|f_1 - f_0\| < \|f_1\| + \|f_0\| < 2\|f_0\|$ so that $\|f'_1\| < 2|\lambda_0| \|f_0\|$. Since $f_0 = g/A(0)$ we have the final result:

$$\|f - f_n\| < 2|\lambda_0| \|g\| A(0)^{-2} \left[A'(0) - A(0) \sum_{k=0}^{n-1} |\lambda_k|^{-1} \right]. \tag{15}$$

Before proving Theorem 2 we need five more lemmas. The reader may wish to look at the proof of Theorem 2 before reading the proofs of these lemmas.

In the lemmas that follow $F(t)$ is any continuous function such that $F(0) = 0$ if $t < 0$.

LEMMA 3. *For any* $\varepsilon \geqq 0$, *there is an* ξ *with* $0 \leqq \xi \leqq \varepsilon$ *and a function* $r(t)$ *such that* $L_n F(t) = F(t - \xi) + r(t)$. *Moreover,* $F(t - \xi)$ *and* $r(t)$ *are continuous and* $\|r(t)\| \leqq 2e^{\varepsilon\lambda_n} \|F(t)\|$.

Proof. Since $\delta_n(t-s)=0$ if $s>t$, and $F(s)=0$ if $s\leqq 0$ we have

$$L_nF(t)=\int_0^T \delta_n(t-s)F(s)\,ds$$

$$=\int_{-\infty}^{t-\varepsilon}\delta_n(t-s)F(s)\,ds+\int_{t-\varepsilon}^{t}\delta_n(t-s)F(s)\,ds.$$

Because $\delta_n(t)$ is nonnegative, the generalized mean value theorem for integrals implies

$$\int_{-\infty}^{t-\varepsilon}\delta_n(t-s)F(s)\,ds=F(t-\zeta)\int_{-\infty}^{t-\varepsilon}\delta_n(t-s)\,ds \quad (\text{where } \varepsilon\leqq\zeta), \text{ and}$$

$$\int_{t-\varepsilon}^{t}\delta_n(t-s)F(s)\,ds=F(t-\xi)\int_{t-\varepsilon}^{t}\delta_n(t-s)\,ds \quad (\text{where } 0\leqq\xi\leqq\varepsilon).$$

From (10) we compute $\int_{-\infty}^{t-\varepsilon}\delta_n(t-s)\,ds=e^{\varepsilon\lambda}$ and $\int_{t-\varepsilon}^{t}\delta_n(t-s)\,ds=1-e^{\varepsilon\lambda}$ (where we write λ in place of λ_n to simplify notation). Even though ξ and ζ may be discontinuous functions of t, the functions $F(t-\xi)$ and $F(t-\zeta)$ are continuous since

$$F(t-\xi)=(1-e^{\varepsilon\lambda})^{-1}\int_{t-\varepsilon}^{t}\delta_n(t-s)F(s)\,ds, \quad \text{and}$$

$$F(t-\zeta)=e^{-\varepsilon\lambda}\int_0^{t-\varepsilon}\delta_n(t-s)F(s)\,ds.$$

We now have $L_nF(t)=[1-e^{\varepsilon\lambda}]F(t-\xi)+e^{\varepsilon\lambda}F(t-\zeta)$ or $L_nF(t)=F(t-\xi)-e^{\varepsilon\lambda}F(t-\xi)+e^{\varepsilon\lambda}F(t-\zeta)=F(t-\xi)+r(t)$, where $r(t)=-e^{\varepsilon\lambda}F(t-\xi)+e^{\varepsilon\lambda}F(t-\zeta)=e^{\varepsilon\lambda}[F(t-\zeta)-F(t-\xi)]$. Hence $\|r(t)\|\leqq 2e^{\varepsilon\lambda}\|F\|$. □

We return to subscripts and write ε_k and ξ_k in the next two lemmas, which deal with sequences of the operators L_k.

LEMMA 4. *If for each λ_k we choose an ε_k, then for each k there is an ξ_k with $0\leqq\xi_k\leqq\varepsilon_k$ and a function $R(t)$ such that $\prod_{k=n}^{m}L_k(F)=F(t-\chi)+R(t)$, where $\chi=\sum_{k=n}^{m}\xi_k$. Moreover, $F(t-\chi)$ and $R(t)$ are continuous and $\|R\|\leqq[\prod_{k=n}^{m}(1+2e^{\varepsilon_k\lambda_k})-1]\|F\|$.*

Proof. Use induction on the number, $m-n+1$, of factors in the product. If $m=n$, there is only a single $L_k=L_n$, and Lemma 3 gives the result. Assume the lemma is true for $m-n$ factors

$$\prod_{k=n}^{m-1}L_k(F)=F(t-\chi_{m-1})+R_{m-1},$$

where $\chi_{m-1}=\sum_{k=n}^{m-1}\xi_k$ and

$$\|R_{m-1}\|\leqq\left[\prod_{k=n}^{m-1}(1+2e^{\varepsilon_k\lambda_k})-1\right]\|F\|.$$

Applying L_m and using Lemma 3, we have

$$\prod_{k=n}^{m}L_kF=L_m\left[\prod_{k=n}^{m-1}L_k(F)\right]=L_m[F(t-\chi_{m-1})+R_{m-1}]$$

$$=F(t-\chi)+R_{m-1}(t-\xi_m)+r(t) \quad \text{where } \|r\|\leqq 2e^{\varepsilon_m\lambda_m}\|F+R_{m-1}\|.$$

Let $R = R_{m-1} + r$. Then R is continuous since r is continuous by Lemma 3 and R_{m-1} is continuous by the induction hypothesis. The function $F(t-\chi)$ is continuous since $F(t-\chi) = \prod_{k=n}^{m} L_k(F) - R(t)$. As for the norm of R, we have

$$\|R\| \leqq \|R_{m-1}\| + \|r\| \leqq \|R_{m-1}\| + 2e^{\varepsilon_m \lambda_m} \|F + R_{m-1}\|,$$

$$\|R\| \leqq (1 + 2e^{\varepsilon_m \lambda_m}) \|R_{m-1}\| + 2e^{\varepsilon_m \lambda_m} \|F\|.$$

Using the induction hypothesis on $\|R_{m-1}\|$, we have

$$\|R\| \leqq (1 + 2e^{\varepsilon_m \lambda_m}) \left[\prod_{k=n}^{m-1} (1 + 2e^{\varepsilon_k \lambda_k}) - 1 \right] \|F\| + 2e^{\varepsilon_m \lambda_m} \|F\|,$$

$$\|R\| \leqq \left[\prod_{k=n}^{m} (1 + 2e^{\varepsilon_k \lambda_k}) - 1 \right] \|F\|. \qquad \square$$

LEMMA 5. *There is a sequence of positive numbers ε_k such that $\sum_{k=n}^{\infty} \varepsilon_k$ and the product $\prod_{k=n}^{\infty} (1 + 2e^{\varepsilon_k \lambda_k})$ both converge.*

Proof. Since α, the order of $A(z)$, is less than one, there is a β such that $\alpha < \beta < 1$. Recall that the series $\sum_{n=0}^{\infty} |\lambda_n|^{-\beta}$ will converge if $\beta > \alpha$. We let $\varepsilon_k = |\lambda_k|^{-\beta}$ so that $\sum_{k=n}^{\infty} \varepsilon_k = \sum_{k=n}^{\infty} |\lambda_n|^{-\beta}$ converges.

The infinite product $\prod_{k=n}^{\infty} (1 + 2e^{\varepsilon_k \lambda_k})$ will converge if $\sum_{k=0}^{\infty} e^{\varepsilon_k \lambda_k} = \sum_{k=0}^{\infty} \exp(-|\lambda_k|^{(1-\beta)})$ converges. To show that this latter sum converges, let N be any fixed integer such that $N(1-\beta) > 1$. For any $x > 0$ we have $e^{-x} < N! x^{-N}$; hence $\exp(-|\lambda_k|^{(1-\beta)}) < N! |\lambda_k|^{-N(1-\beta)}$ and therefore $\sum_{k=n}^{\infty} \exp(-|\lambda_k|^{(1-\beta)}) < N! \sum_{k=n}^{\infty} |\lambda_k|^{-1} < \infty$. $\square$

LEMMA 6.

$$\lim_{n \to \infty} \prod_{k=n}^{\infty} L_k F = F.$$

Proof. Choose ε_k as in Lemma 5. The $F(t-\chi)$ and $R(t)$ of Lemma 4 are continuous and $\chi = \sum_{k=n}^{\infty} \xi_k$ converges since $0 \leqq \xi_k \leqq \varepsilon_k$. We can therefore take the limit as $m \to \infty$ in Lemma 4 to obtain $\prod_{k=n}^{\infty} L_k(F) = F(t-\chi) + R(t)$, where

$$\|R\| \leqq \left[\prod_{k=n}^{\infty} (1 + 2e^{\varepsilon_k \lambda_k}) - 1 \right] \|F\|.$$

Taking the limit as $n \to \infty$, we prove the lemma. $\square$

LEMMA 7.

$$\prod_{k=0}^{\infty} L_k F = \prod_{k=0}^{n-1} L_k \prod_{k=n}^{\infty} L_k F.$$

Proof. From the proof of Theorem 1 we know that $\prod_{k=n}^{\infty} L_k F$ converges uniformly so that $\prod_{k=0}^{n-1} L_k \prod_{k=n}^{\infty} L_k F = \prod_{k=n}^{\infty} L_k \prod_{k=0}^{n-1} L_k F = \prod_{k=0}^{\infty} L_k F$. $\square$

THEOREM 2. *If $f = A(0)^{-1} \prod_{k=0}^{\infty} L_k g$, then $A(D)f = g$, that is to say, the function constructed by Theorem 1 is a solution to (1).*

Proof. By Theorem V of [5], we have

$$A(D)f = \lim_{N \to \infty} \sum_{n=0}^{N} a_n D^n f(t) = \lim_{N \to \infty} A(0) \prod_{n=0}^{N} \left(1 - \frac{D}{\lambda_n}\right) f(t).$$

Introducing the definitions of f, K_n, L_n, and canceling $A(0)$, we have

$$A(D)f = \lim_{n \to \infty} A(0) \prod_{k=0}^{n} K_k \prod_{k=0}^{\infty} \frac{L_k g}{A(0)} = \lim_{n \to \infty} \prod_{k=0}^{n} K_k \prod_{k=0}^{\infty} L_k g.$$

Applying Lemma 7, we have,

$$A(D) = \lim_{n\to\infty} \prod_{k=0}^{n-1} K_k \prod_{k=0}^{n-1} L_k \prod_{k=n}^{\infty} L_k g.$$

Using the fact that the K_n and L_n are inverses, we have

$$A(D)f = \lim_{n\to\infty} \prod_{k=0}^{n-1} K_k \prod_{k=0}^{n-1} L_k \prod_{k=n}^{\infty} L_k g = \lim_{n\to\infty} \prod_{k=n}^{\infty} L_k g.$$

Applying Lemma 6, we have $A(D)f = \lim_{n\to\infty} \prod_{k=n}^{\infty} L_k g = g$. □

5. Numerical method for computing $L_n f(t)$. Our method necessitates computing $L_n f(t)$ for large values of $|\lambda_n|$. We will show how this can be done without computing the extremely large $e^{-s\lambda_n}$ or the extremely small $e^{t\lambda_n}$. To simplify notation we omit subscripts by writing $L(f) = F(t) = -\lambda\, e^{t\lambda} \int_0^t e^{-s\lambda} f(s)\, ds$. The integral is evaluated by standard interpolatory quadrature formulas with $e^{-s\lambda}$ as a weight function. Taking a stepsize of h, the two-point formula has the following form:

$$\int_t^{t+h} e^{-s\lambda} f(s)\, ds = \lambda^{-1}\, e^{(t+h)\lambda}[K_1 f(t) + K_2 f(t+h)].$$

Therefore

$$-\lambda\, e^{-(t+h)} \int_t^{t+h} e^{-s\lambda} f(s)\, ds = K_1 f(t) + K_2 f(t+h) \tag{17}$$

where

$$K_1 = \left[\frac{e^{h\lambda}-1}{-\lambda h} - e^{\lambda h}\right], \qquad K_2 = \left[1 - \frac{e^{h\lambda}-1}{-\lambda h}\right].$$

Note that the terms $\lambda^{-1}\, e^{(t+h)\lambda}$ and $\lambda\, e^{-(t+h)\lambda}$ cancel; thus K_1 and K_2 do not depend on the limits of integration but only on λ and the stepsize h. The same will happen if interpolatory quadrature formulas with more nodes are used, but we omit the details here.

A simple algorithm for computing $F(t) = L_n f$ can be based on (17).

Divide the interval $[0, T]$ into N subintervals each of length h. Let $\lambda = \lambda_n$ and compute K_1 and K_2. Let $K_3 = e^{\lambda h}$ and $F(0) = 0$. Then:

For $k = 1$ to N

Let $F[kh] = f[(k-1)h]K_1 + f[kh]K_2 + F[(k-1)h]K_3$

End of algorithm.

The formula for $F[kh]$ in this algorithm is the sum of the terms $f[(k-1)h]K_1 + f[kh]K_2$, which give $-\lambda\, e^{kh\lambda} \int_{k-1}^{kh} e^{-s\lambda} f(s)\, ds$ according to (15), and the term

$$F[(k-1)h]K_3 = -\lambda\, e^{(k-1)h\lambda} \int_0^{(k-1)h} e^{-s\lambda} f(s)\, ds\, e^{kh}.$$

These terms combine to give $-\lambda\, e^{kh\lambda} \int_0^{kh} e^{-s\lambda} f(s)\, ds$.

Note that as $\lambda \to -\infty$, $K_1 \to 0$ and $K_2 \to 1$ so that $F[kh] \to f[kh]$ agrees with Lemmas 3 and 6.

The algorithm has been tested on a variety of problems and found to be stable. When used on heat equation problems, whose solutions are known from other methods,

the error estimate has been found to be reliable. The speed of convergence can be substantially improved by standard "extrapolation to the limit" methods. We hope to report more fully on the numerical aspects of our method in a later paper.

ON THE BRANCHPOINT OPERATOR AND THE ANNIHILATION OF DIFFERINTEGRATIONS*

L. M. B. C. CAMPOS†

Abstract. A differintegration operator of rational, real or complex order ν, is defined in the literature [*Fractional Calculus and Applications*, Springer-Verlag, Berlin, New York, 1974; *Fractional Calculus and Integral Transforms of Generalized Functions*, Pitman, Boston, 1979; *IMA J. Appl. Math.*, 33 (1984), pp. 109-133; *Portugal. Math.*, 43 (1985), pp. 347-376], as a generalization of the ordinary nth derivative and nth primitive, which are the particular cases of order, respectively, a positive $\nu = +n$ or negative $\nu = -n$ integer $n \in \mathbb{N}$. In the present paper we introduce a branchpoint operator, which can annihilate the differintegration operator of any noninteger complex order, i.e., in all cases except ordinary derivatives and primitives. It is shown that branchpoint operator is distinct from, but related to, the rule of composition of differintegrations, and can arise if (a) the two systems of differintegration named after Liouville and Riemann are combined, or (b) if certain double-loop integrals are interchanged, in such a way that the inner path goes through a branchpoint. The differintegration operator has been used widely in connection with special functions [*Fractional Calculus*, Academic Press, New York, 1974; *Fractional Calculus*, 2 Vols., Descartes Press, Koryama, Japan 1984; *IMA J. Appl. Math.*, 36 (1986), pp. 191-206; *Mat. Vesnik*, 38 (1986), 375-390], and should not be confused with the branchpoint operator, which can lead to different formulas, as shown by the example of Hermite functions.

Key words. annihilation, differintegration, complex integration, cut-plane, branched functions, Hermite functions

1. Introduction.

The differintegration operator of complex order ν can be defined [16], [12] as a generalization of both the ordinary nth derivative and nth primitive, which correspond to the particular cases of order, respectively, $\nu = +n$, $-n$ a positive, negative integer $n \in \mathbb{N}$. There is one system of differintegration, or one type of derivative of complex order, for each set of branchcuts in the complex plane [1]; the two most important systems [21], [13] are the Liouville [11] operator D^ν / Dz^ν applying to analytic functions, and the Riemann [20] operator d^ν / dz^ν applying to functions with a branchpoint. The two systems are generally incompatible [2]; e.g., they lead to formulas for the differintegration of exponential (Liouville type) and power (Riemann type) that are inconsistent for nonintegral complex orders of derivation. The rules of Liouville and Riemann differintegration may be similar (e.g., for zero) or distinct (e.g., for a nonzero constant). Here we introduce a distinct, but related concept, namely, the branchpoint operator $\delta^\mu / \delta z^\mu$ of order μ.

The branchpoint operator arises if some "invalid" manipulations are performed with the differintegration operator, e.g.; (§ 2) if the operator is applied under integral sign at a branchpoint; (§ 3) if the order of integration in a double integral is interchanged so as to make one path go through a branchpoint. From this viewpoint some care should be taken when using the differintegration operator repeatedly because, when applied outside its conditions of validity, it may still give quite definite results that are no longer differintegrations, but rather the outcome of a distinct operator, the branchpoint operator. The branchpoint operator $\delta^\mu / \delta z^\mu$ can only be applied after the Liouville differintegration D^ν / Dz^ν, and the result is a Riemann differintegration $d^{\mu+\nu} / dz^{\mu+\nu}$, multiplied by a factor $A(\mu, \nu)$. Apart from the latter factor, the result looks like a

† Instituto Superior Técnico, 1096 Lisboa Codex, Portugal. The work of this author was supported by a research grant from J.N.I.C.T., and also by CAUTL, Instituto de Fisica-Matemática, INIC.

composition of derivatives, albeit of different types. Since the coefficient does not involve the independent z or dependent variables, the branchpoint operator retains the linear property of derivation operators. The coefficient $A(\mu, \nu)$ depends on the orders μ, ν of the operators, however, and can, in certain conditions (§ 3): (a) become equal to unity, in which case the branchpoint operator reduces to a differintegration; (b) vanish, in which case the branchpoint operator annihilates the differintegration to which it is applied. More precisely, the case (b) above shows that a branchpoint operator can be found such that it annihilates a Liouville differintegration operator of any complex order other than an integer (§ 4) so that the annihilation property fails to exist only for ordinary derivatives and primitives.

The differintegration operator provides a powerful method of study of the properties of special functions [16], [15], because the latter are specified by the differintegration of elementary functions [9], [8]. The application of rules of differintegration can be used to give convenient proofs of a number of properties of special functions, viz., both shorter proofs of known results [3] or new results [4] possibly harder to find by other methods. Since several of the proofs of properties of special functions involve repeated differintegrations, care must be taken not to confuse differintegration and branchpoint operators. This point is illustrated by the example of Hermite functions, which can be defined by the differintegration of the Gaussian function (§ 5); this definition agrees with the integral representation of Hermite functions of complex order and, in the case of positive integer order, reduces to the Hermite [7] polynomials. The branchpoint operator can be used to annihilate a Hermite function of nonintegral complex order, i.e., any Hermite function other than a polynomial. If the branchpoint operator is replaced by a differintegration, the result is no longer zero, but rather another Hermite function. The difference between branchpoint and differintegration operators is made clear by noting that they lead, when applied to Hermite functions, to distinct integral identities.

2. Relation between branchpoint and differintegration operators. Before we can define the branchpoint operator, we must recall the definition of differintegration operator, in the context [10], [14], [15], [1] of the theory of analytic functions.

DEFINITION 1. The derivative of complex order D^ν, of an analytic function $F(z)$, is defined by means of the generalized Cauchy integral:

$$\frac{D^\nu F}{Dz^\nu} \equiv \{\Gamma(1+\nu)/2\pi i\} \int_{\infty \exp\{i \arg(z)\}}^{(z+)} (\zeta - z)^{-\nu-1} F(\zeta)\, d\zeta, \tag{1}$$

along Fig. 1, a Hankel [6] loop going around $\zeta = z$ in the positive direction, and starting and ending at infinity, respectively, above and below the branchcut $C \equiv \{\zeta: |\zeta| > |z|, \arg(\zeta) = \arg(z)\}$. The integral is assumed uniformly convergent with regard to z in a region D and ν is not a negative integer.

Remark 1. The expression (1) with complex ν is designated "generalized Cauchy integral" because in the case where $\nu = n$ is a nonnegative integer $n \in \mathbb{N}_0$, the integrand

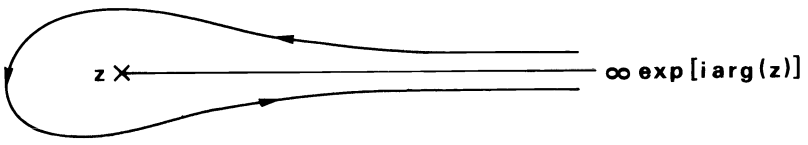

FIG. 1. *The differintegration of an analytic function involves a contour integral* (1) *along the Hankel* [6] *path, going counterclockwise around the branchpoint* $\zeta = z$, *and starting and ending at infinity in the* ζ*-plane, respectively, above and below the semi-infinite branchcut, joining* z *to infinity in the direction of* $\arg(z)$.

has a pole of order $n+1$, and the loop can be closed around it, so that we regain the original form of the Cauchy integral for the nth order derivative of an analytic function.

Remark 2. Formula (1) holds for all complex values of ν, other than negative integers $\nu=-n$ with $n\in\mathbb{N}$; this case is covered by the analytic continuation of (1) in the ν-plane for $\mathrm{Re}(\nu)<0$, by Weyl's (1917) formula:

$$\frac{D^{\nu}F}{dz^{\nu}}=\{\Gamma(-\nu)\}^{-1}\int_{\infty\exp\{i\arg(z)\}}^{z}(z-x)^{-\nu-1}F(x)\,dx, \tag{2}$$

which is proved elsewhere [1].

Remark 3. The convergence of the integrals (1) and (2) requires a restriction on the asymptotic behavior of the function $F(z)$ in a sector about the branchcut, e.g.,

$$\arg(\zeta)-\delta<\arg(z)<\arg(\zeta)+\delta: f(\zeta)\sim O(\zeta^{\mathrm{Re}(\nu)-\varepsilon}), \tag{3}$$

for some ε, $\delta>0$.

Remark 4. The case where $\nu=-n$ is a negative integer $n\in\mathbb{N}$, which was excluded from (1), and is included in (2), is the ordinary nth primitive.

The latter remark suggests that the preceding definition could be restated in terms of integration with complex order.

DEFINITION 2. The operator integration I^{ν} with complex order ν is defined by the derivative $D^{-\nu}$ of complex order $-\nu$.

Remark 5. The integration operator with complex order $I^{\nu}\equiv D^{-\nu}$ is defined by (1) with ν replaced by $-\nu$, for ν complex other than a positive integer; for $\mathrm{Re}(\nu)>0$, the integration operator I^{ν} is also specified by (2), with ν replaced by $-\nu$. In both cases an asymptotic condition is needed, e.g., (3) with $+\nu$ replaced by $-\nu$.

Remark 6. The similarity of Definitions 1 and 2, respectively, in terms of derivative and integral, has led to the adoption [21], [16] of the term "differintegration."

As an example, we consider the analytic function $F(z)=e^{az}$.

THEOREM 1. *The rule of differintegration of the exponential is*

$$\frac{D^{\nu}(e^{az})}{Dz^{\nu}}=a^{\nu}e^{az}. \tag{4}$$

Proof. Substitute $F(z)=e^{az}$ into (1) for ν complex other than a negative integer, and into (2) for $\mathrm{Re}\,(\nu)<0$. Evaluation of the integrals in terms of gamma functions leads [2] to (4).

Remark 7. Formula (4) was used by Liouville [11] to define a "derivation of nonintegral order."

Remark 8. Definition (1) can be designated, on historical precedent, as the "Liouville differintegration."

If function $F(z)$ has one branchpoint $z=a$, Definition (1) must be modified because now the branchcut is finite [9], [8], [1], [2], viz., Definition 3.

DEFINITION 3. The derivative of complex order ν of the function $(z-a)^{\mu}F(z)$, where $F(z)$ is analytic, and $(z-a)^{\mu}$ has a branchpoint at $\zeta=a$ with exponent μ, is defined by the generalized Cauchy integral:

$$\frac{d^{\nu}\{(z-a)^{\mu}F(z)\}}{dz^{\nu}}=\{\Gamma(1+\nu)/2\pi i\}\int_{a}^{(z+)}(\zeta-a)^{\mu}F(\zeta)(\zeta-z)^{-\nu-1}\,d\zeta, \tag{5}$$

along Fig. 2, a teardrop loop, going around $\zeta=z$ in the positive direction, and passing through $\zeta=a$. The integral is assumed to be uniformly convergent with regard to z in a region D, ν is complex other than a negative integer, and $\mathrm{Re}\,(\mu)>-1$.

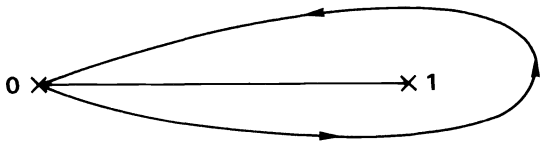

FIG. 2. *Teardrop loop in the t-plane, passing through the branchpoint* $t=0$ $(t=1)$ *and going in the positive direction around the other branchpoint* $t=1$ $(t=0)$, *so that the finite branchcut along the straight line* $(0,1)$ *lies in its interior.*

Remark 9. The definition can be extended [2] to all other values of μ, ν, by using integrals similar to (5), along: (i) the straight line joining $\zeta=a$ to $\zeta=z$; (ii) the teardrop loop, Fig. 3, passing through $\zeta=z$ and going around $\zeta=a$; and (iii) a Pochhammer [19] double-laced loop going around both $\zeta=a$ and $\zeta=z$, twice, in opposite directions.

THEOREM 2. *Definition* (5) *leads to the rule of derivation of the power*:

$$\frac{d^{\nu}(z^{\mu})}{dz^{\nu}}=\{\Gamma(1+\mu)/\Gamma(1+\mu-\nu)\}z^{\mu-\nu}, \tag{6}$$

with μ *not a negative integer.*

Proof. The proof is given in the literature (e.g., [2]).

Remark 10. Formula (6) was used as the definition of a "derivative of general order" by Riemann [20], so that (5) may be designated the Riemann system of differintegration.

The Liouville (1) and Riemann (5) differintegrations are the two simplest systems, since they involve only one branchcut in the complex plane, viz., respectively, infinite and finite. Other systems of differintegration involving more than one branchcut in the complex plane exist [1], but they are not needed to define the branchpoint operator. To introduce the latter, we consider a repeated Liouville (1) differintegration:

$$D^{\mu}\left(\frac{D^{\nu}F}{Dz^{\nu}}\right)\Big/Dz^{\mu}\equiv\{\Gamma(1+\mu)/2\pi i\}\int_{\infty\exp\{i\arg(z)\}}^{(z+)}(\zeta-z)^{-\mu-1}\left(\frac{D^{\nu}F}{D\zeta^{\nu}}\right)d\zeta, \tag{7}$$

where μ, ν are complex numbers other than negative integers. Substitution of (1) into (7) would lead to a double integral, the evaluation of which is deferred to § 3, since it leads to a less direct approach to the branchpoint operator. A simple and direct way of applying the differintegration of order μ to (1) would be to take the differintegration under integral sign, as a "Riemann differintegration":

$$\delta^{\mu}\left(\frac{D^{\nu}F}{Dz^{\nu}}\right)\Big/\delta z^{\mu}\equiv\{\Gamma(1+\nu)/2\pi i\}\int_{\infty\exp\{i\arg(z)\}}^{(z+)}F(\zeta)\frac{d^{\mu}\{(\zeta-z)^{-\nu-1}\}}{dz^{\mu}}d\zeta; \tag{8}$$

note that (8) is not equivalent to (7), because a Liouville differintegration D^{μ}/Dz^{μ}, outside the integral sign in (7), is replaced inside the integral sign in (8), by a Riemann differintegration d^{μ}/dz^{μ}, which is that appropriate (6) to the power $(\zeta-z)^{-\nu-1}$. Thus we are not calculating a repeated Liouville differintegration, as in (7), but rather (8) defines a new concept, which we call the branchpoint operator.

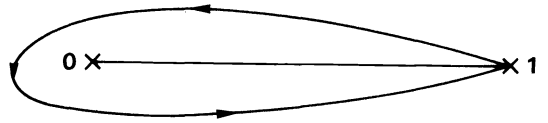

FIG. 3. *Mirror image of Fig.* 2.

DEFINITION 4. The branchpoint operator $\delta^\mu/\delta z^\mu$ of complex order μ, applied to the Liouville differintegration (1) of order ν, complex other than a negative integer, is defined by (8) applying a Riemann differintegration (5) under integral sign.

We have now to show that the branchpoint operator is unique, and indicate how it can be calculated.

THEOREM 3. *The branchpoint operator $\delta^\mu/\delta z^\mu$ of order μ, applied to a Liouville differintegration D^ν/Dz^ν of order ν, yields a Liouville differintegration of order $\mu+\nu$, to within a factor, in curly brackets, which depends only on μ, ν:*

$$\delta^\mu\left(\frac{D^\nu F}{Dz^\nu}\right)\Big/\delta z^\mu = \{\Gamma(1+\nu)\Gamma(-\nu)/\Gamma(1+\mu+\nu)\Gamma(-\mu-\nu)e^{i\pi\mu}\}\frac{D^{\mu+\nu}F}{Dz^{\mu+\nu}}; \tag{9}$$

the formula holds for complex μ, ν, $\mu+\nu$, excluding integer ν and negative integer $\mu+\nu$.

Proof. Apply the Riemann rule of differintegration (6) to (8), to obtain

$$\begin{aligned}\delta^\mu\left(\frac{D^\nu F}{Dz^\nu}\right)\Big/\delta z^\mu &= \{\Gamma(1+\nu)\Gamma(-\nu)/2\pi i\Gamma(-\nu-\mu)\}\cdot e^{-i\pi\mu}\\ &\quad\cdot\int_{\infty\exp\{i\arg(z)\}}^{(z+)} F(\zeta)(\zeta-z)^{-\mu-\nu-1}\,d\zeta,\end{aligned} \tag{10}$$

where we have used $\{d(-z)/dz\}^\mu = (-)^\mu = e^{-i\pi\mu}$, because the transformation $-z\to z$ along the Hankel loop is equivalent to a change of argument $-\pi$, i.e., argument π in the clockwise direction. Formula (6) applies in (8) if $-\nu-1$ is not a negative integer, i.e., ν is neither zero nor a positive integer; since ν, a negative integer, has already been excluded by (8) Definition 1, all integer values of ν are excluded in (10). The latter simplifies to (9), by using (1), for $\mu+\nu$, not a negative integer.

3. Derivation at and inversion of integrals through a branchpoint. Starting from the repeated Liouville differintegration (7), we may: (i) evaluate the double integral, leading to the rule of composition of differintegrations (Theorem 4); and (ii) interchange the integrals, so that one of the paths goes through a branchpoint, and the branchpoint operator is obtained instead (Theorem 5). Before we can indicate the deformation of path that leads (ii) to the branchpoint operator, we must revise the proof of the composition rule (i), to show where the change takes place.

THEOREM 4. *The Liouville differintegration operator satisfies the composition rule*:

$$D^\mu\left(\frac{D^\nu F}{Dz^\nu}\right)\Big/Dz^\mu = \frac{D^{\mu+\nu}F}{Dz^{\mu+\nu}} = D^\nu\left(\frac{D^\mu F}{Dz^\mu}\right)\Big/Dz^\nu, \tag{11}$$

where μ, ν, $\mu+\nu$ are complex other than negative integers.

Proof. When we substitute (1) into (7), the repeated Liouville differintegration is given by

$$\begin{aligned}D^\mu\left(\frac{D^\nu F}{Dz^\nu}\right)\Big/Dz^\mu &= -\{\Gamma(1+\nu)\Gamma(1+\mu)/4\pi^2\}\\ &\quad\cdot\int_{\infty\exp\{i\arg(\zeta)\}}^{(z_+)}(\zeta-z)^{-\mu-1}\\ &\quad\cdot\int_{\infty\exp\{i\arg(\zeta)\}}^{(\zeta+)}(\eta-\zeta)^{-\nu-1}F(\eta)\,d\eta\,d\zeta,\end{aligned} \tag{12}$$

with μ, ν complex other than negative integers. The $d\eta$ integration is performed (Fig. 4) along a Hankel loop around $\eta=\zeta$, and the $d\zeta$ integration along another Hankel

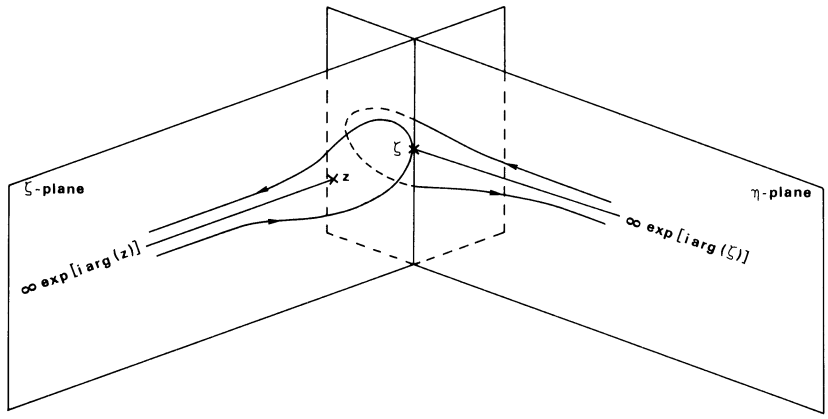

FIG. 4. *The double differintegration involves two Hankel paths in intersecting ζ- and η-planes, such that the branchpoint $\eta = \zeta$ in the η-plane lies on the path of integration in the ζ-plane and the branchpoint $\zeta = z$ in the ζ-plane lies on no path of integration, i.e., no path touches a branchpoint in its own plane.*

loop around $\zeta = z$, so that none of the loops touches a branchpoint in its own plane (although the Hankel loop in the ζ-plane touches the branchpoint $\zeta = \eta$ in the η-plane, which is not a problem). Since the integrals (12) are uniformly convergent, the order of integration can be reversed:

$$D^{\mu}\left(\frac{D^{\nu}F}{Dz^{\nu}}\right)\Big/ Dz^{\mu} = -\{\Gamma(1+\nu)\Gamma(1+\mu)/4\pi^2\}\int_{\infty \exp\{i \arg(z)\}}^{(z+)} F(\eta)\Phi(z,\eta)\, d\eta, \tag{13a}$$

where the function Φ is given by

$$\Phi(z,\eta) \equiv \int_{\infty \exp\{i \arg(\eta)\}}^{(\eta+)} (\zeta - z)^{-\mu-1}(\eta - \zeta)^{-\nu-1}\, d\zeta, \tag{13b}$$

which is an Eulerian integral of the second kind.

To evaluate (13b), we perform the change of variable $t = (\eta - z)/(\zeta - z)$, which maps the points $\zeta = \infty$, η to $t = 0$, 1, so that we obtain (Fig. 2) a teardrop loop passing through $t = 0$, and going counterclockwise around the branchpoint $t = 1$; the integral along this loop can be evaluated in terms [5] of beta functions:

$$(\eta - z)^{\mu+\nu+1}\Phi(z,\eta) = \int_0^{(1+)} t^{\mu+\nu}(t-1)^{-\nu-1}\, dt = -2i \sin(\pi\nu) B(\mu+\nu+1, -\nu); \tag{14a}$$

the integral (14a) converges only for $\mathrm{Re}\,(\mu+\nu) > -1$, but it can be extended, using a Pochhammer [19] double-laced loop, to [5] all nonintegral values of $\mu+\nu$. Thus (14a) holds for all complex values of $\mu+\nu$, except negative integers. The formula (14a) may be simplified using the relation between beta and gamma functions, and the symmetry properties of the latter:

$$\begin{aligned}\Phi(z,\eta) &= -2i \sin(\pi\nu)\Gamma(-\nu)\{\Gamma(1+\mu+\nu)/\Gamma(1+\mu)\}(\eta - z)^{-\mu-\nu-1} \\ &= 2\pi i\{\Gamma(1+\mu+\nu)/\Gamma(1+\mu)\Gamma(1+\nu)\}(\eta - z)^{-\mu-\nu-1}.\end{aligned} \tag{14b}$$

Substituting (14b) into (13a), we obtain

$$\begin{aligned}D^{\mu}\left(\frac{D^{\nu}F}{Dz^{\nu}}\right)\Big/ Dz^{\mu} &= \{\Gamma(1+\mu+\nu)/2\pi i\}\int_{\infty \exp\{i \arg(z)\}}^{(z+)} (\eta - z)^{-\mu-\nu-1}F(\eta)\, d\eta \\ &= \frac{D^{\mu+\nu}F}{Dz^{\mu+\nu}},\end{aligned} \tag{15}$$

where (1) was used, because $\mu+\nu$ is not a negative integer. The proof of (15), which coincides with (11) when the symmetry in $\mu+\nu$ is taken into account, thus holds for all complex μ, ν, $\mu+\nu$ other than negative integers. □

To obtain the branchpoint operator, in addition to the inversion of integrals (13a), (13b), we interlock the two paths of integration (Fig. 5), by replacing the inner Hankel path in (13b) with a teardrop loop.

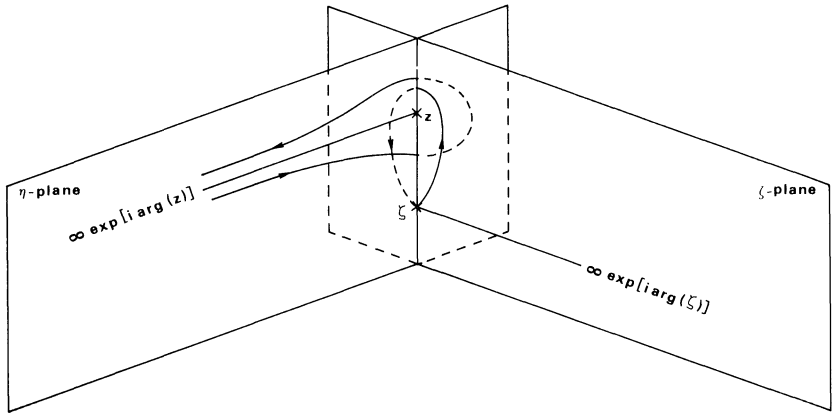

FIG. 5. *The deduction of the composition rule requires only the interchange of the η- and ζ-planes in Fig. 4, but if the first Hankel path is replaced with a teardrop loop, a distinct, branchpoint operator arises, because the two loops are interlocked and there is a finite branchcut along part of the intersection of the two planes.*

DEFINITION 5. The branchpoint operator $\delta^\mu/\delta z^\mu$ of order μ, applied to the Liouville differintegration D^ν/Dz^ν of order ν, not a negative integer, is defined as the composition of Liouville differintegrations (12) of orders μ, ν, in which the outer path of integration is unchanged (13a):

$$\text{(16a)}\quad \delta^\mu\left(\frac{D^\nu F}{Dz^\nu}\right)\Big/\delta z^\mu \equiv -\{\Gamma(1+\nu)\Gamma(1+\mu)/4\pi^2\}\int_{\infty\exp\{i\arg(z)\}}^{(z+)} F(\eta)\psi(z,\eta)\,d\eta,$$

and the inner Hankel path (13b) in Fig. 4, is replaced with a teardrop loop in Fig. 5:

$$\text{(16b)}\qquad \psi(z,\eta)\equiv\int_{\zeta=\eta}^{(z+)}(\zeta-z)^{-\mu-1}(\eta-\zeta)^{-\nu-1}\,d\zeta,$$

which goes round $\zeta=z$ in the positive direction, and passes through the branchpoint $\zeta=\eta$.

Remark 11. The substitution of two Liouville differintegrations in (13a), (13b), with one Liouville and one Riemann differintegration in (16a), (16b), is analogous to the change from (8) to (9), to define the branchpoint operator.

Thus we may expect the present Definition 5 of branchpoint operator (16a), (16b), to be consistent with Definition 4, i.e., it leads to the same result (9), as was deduced from (7).

THEOREM 5 (Consistency of Definitions 4 and 5 of branchpoint operator). *The branchpoint operator, introduced* ((16a), (16b)) *by Definition* 5, *coincides with* (9), *which was introduced by Definition* 3:

$$\text{(17)}\qquad \delta^\mu\left(\frac{D^\nu F}{Dz^\nu}\right)\Big/\delta z^\mu = e^{-i\pi\mu}\{\sin\{\pi(\mu+\nu)\}/\sin(\pi\nu)\}\frac{D^{\mu+\nu}F}{Dz^{\mu+\nu}}.$$

Remark 12. We will prove Theorem 5, using the same steps as for Theorem 4, to show that the only difference between the composition rule (11) and branchpoint operator (17) lies in the deformation of the inner path of integration from (13b) to (16b).

Thus we can start the proof by evaluating (16b).

Proof. To evaluate (16b), we may perform the change of variable $s = (\zeta - z)/(\eta - z)$, which is the inverse $s = 1/t$ of the transformation $t = (\eta - z)/(\zeta - z)$ used to evaluate (13b); the reason is that the inversion $s = 1/t$ maps a Hankel path in the t-plane to a teardrop loop in the s-plane. The transformation $s = (\zeta - z)/(\eta - z)$ maps the teardrop loop in (16b) into a rescaled loop, going round $\zeta = z$ or $s = 0$ in the positive direction and passing through $\zeta = \eta$ or $s = 1$; this teardrop loop, in Fig. 3, is the mirror image of that in Fig. 2, which was used in the evaluation of (14a). The latter is replaced, in the present case, with

$$(18a)\quad (\eta - z)^{\mu+\nu+1}\psi(z, \eta) = \int_1^{(0+)} s^{-\mu-1}(1-s)^{-\nu-1}\, ds = -2i \sin(\pi\mu)\, e^{-i\pi\mu} B(-\mu, -\nu),$$

where $B(\cdots, \cdots)$ denotes Euler's beta function, and the integral converges for $\mathrm{Re}\,(\nu) < 0$. By using the Pochhammer loop, it can be extended to all complex, noninteger values of ν. Thus the evaluation of (18a) holds for all ν, other than zero or positive integers. We had assumed earlier, in Definition 5, that ν is not a negative integer; thus, the derivation so far excludes all integer values of ν. The beta function is related [5] to the gamma function:

$$(18b)\quad \begin{aligned}\psi(z, \eta) &= -2i \sin(\pi\mu)\, e^{-i\pi\mu}\Gamma(-\mu)\{\Gamma(-\nu)/\Gamma(-\mu-\nu)\}(\eta - z)^{-\mu-\nu-1} \\ &= e^{-i\pi\mu}\{2\pi i\Gamma(1+\mu)\Gamma(-\nu)/\Gamma(-\mu-\nu)\}(\eta - z)^{-\mu-\nu-1}.\end{aligned}$$

Substituting (18b), which replaces (14b), into (16a), which replaces (13a), we obtain

$$\begin{aligned}\delta^\mu\left(\frac{D^\nu F}{Dz^\nu}\right) \Big/ \delta z^\mu &= \{\Gamma(1+\nu)\Gamma(-\nu)/\Gamma(1+\mu+\nu)\Gamma(-\mu-\nu)\}\, e^{-i\pi\mu} \\ &\quad \cdot \{\Gamma(1+\mu+\nu)/2\pi i\} \int_{\infty \exp\{i \arg(z)\}}^{(z+)} (\eta - z)^{-\mu-\nu-1} F(\eta)\, d\eta \qquad (19) \\ &= \{\sin\{\pi(\mu+\nu)\}/\sin(\pi\nu)\, e^{i\pi\mu}\} \frac{D^{\mu+\nu}F}{Dz^{\mu+\nu}},\end{aligned}$$

where we have used (1), assuming that $\mu + \nu$ is not a negative integer. The result (19) differs from the composition rule (15) in the term in curly brackets. The conditions of validity are the same on $\mu + \nu$, i.e., not a negative integer, but are distinct on: (i) μ, unrestricted in (19), not a negative integer in (15), because of the Liouville differintegration; (ii) ν, not a negative integer in (15) and not an integer in (19), i.e., the branchpoint operator does not apply to ordinary derivatives or primitives. □

4. Composition and annihilation of derivates of complex order. Definition 4 and Theorem 3 in § 2, or Definition 5 and Theorem 5 in § 3, give two distinct, but equivalent ((9) ≡ (17)) approaches to the branchpoint operator, which may be summarized in the following "anomalous" property A1.

PROPERTY 1. The repeated Liouville D^μ, D^ν differintegration (12), with orders μ, ν, if either (Definition 4) the outer differintegration is taken under integral sign as Riemann d^μ differintegration (8), or (Definition 5) in the inversion of integrals (13a), (13b) the inner Hankel path is deformed (16a), (16b) into a teardrop loop, then the

branchpoint operator δ^{μ} is obtained, which, when applied to the Liouville D^{ν} differintegration of order ν, differs from the compound Liouville $D^{\mu+\nu}$ differintegration of order $\mu+\nu$:

$$\delta^{\mu}\left(\frac{D^{\nu}F}{Dz^{\nu}}\right)\delta z^{\mu} = A(\mu,\nu)\frac{D^{\mu+\nu}F}{Dz^{\mu+\nu}}, \tag{20}$$

by a factor A, which does not involve the dependent $F(z)$ or independent z variables:

$$\begin{aligned} A(\mu,\nu) &\equiv e^{-i\pi\mu}\{\sin\{\pi(\mu+\nu)\}/\sin(\pi\nu)\} \\ &= \{1-\exp(-i\pi(\mu+\nu))\}/\{1-\exp(-i\pi\nu)\}, \end{aligned} \tag{21}$$

but depends only on the orders μ, ν, such that ν is not an integer, and $\mu+\nu$ not a negative integer.

Remark 13. The exclusion of $\mu+\nu$ a negative integer means that the result of a branchpoint operator applied to a Liouville differintegration cannot be an ordinary primitive.

Remark 14. The exclusion of ν an integer implies that the branchpoint operator applies only to Liouville differintegration other than ordinary derivatives or primitives for which there is no branchpoint in the integrand of (1).

Since the branchpoint operator δ^{μ_1} applied to a Liouville differintegration D^{ν} yields to within a factor not involving the dependent or independent variables, another Liouville differintegration $D^{\mu_1+\nu}$, a second branchpoint operator δ^{μ_2} may be applied, and so on, iteratively, up to δ^{μ_N} for any positive integer N. Concerning the factor (21), it can be decomposed into the following ratio:

$$A(\mu,\nu) = a(\mu+\nu)/a(\nu), \tag{22a}$$

$$a(\alpha) \equiv 1-\exp(-i2\pi\alpha), \tag{22b}$$

which satisfies the following recursive rule:

$$\begin{aligned} \prod_{k=1}^{N} A(\mu_k, \mu_{k-1}+\cdots+\mu_1+\nu) &= \prod_{k=1}^{N}\{a(\mu_k+\cdots+\mu_1+\nu)/a(\mu_{k-1}+\cdots+\mu_1+\nu)\} \\ &= a(\mu_N+\cdots+\mu_1+\nu)/a(\nu) = A(\mu_N+\cdots+\mu_1,\nu); \end{aligned} \tag{23}$$

the latter, when multiplied by the Liouville differintegration D^{ν}:

$$\prod_{k=1}^{N} A(\mu_k, \mu_{k-1}+\cdots+\mu_1+\nu)\frac{D^{\nu}F}{Dz^{\nu}} = A(\mu_N+\cdots+\mu_1,\nu)\frac{D^{\nu}F}{Dz^{\nu}}, \tag{24}$$

proves, by (20), the iteration rule for branchpoint operators.

PROPERTY 2. The iterated branchpoint operators of orders $\mu_1,\cdots,\mu_N$, applied to a Liouville differintegration of order ν, is equal to the Liouville differintegration of order $\mu_1+\cdots+\mu_N+\nu$:

$$\left(\frac{\delta}{\delta z}\right)^{\mu_N}\cdots\left(\frac{\delta}{\delta z}\right)^{\mu_1}\left(\frac{D^{\nu}F}{Dz^{\nu}}\right) = A(\mu_N+\cdots+\mu_1,\nu)\left(\frac{D}{Dz}\right)^{\mu_N+\cdots+\mu_1+\nu}F(z), \tag{25}$$

with a factor given by (21) with $\mu\equiv\mu_1+\cdots+\mu_N$: formula (24) assumes that ν is not an integer, and none of the $\mu_1+\nu,\cdots,\mu_N+\cdots+\mu_1+\nu$ are negative integers.

Remark 15. Although the coefficient of (25) is similar to that of (20) with $\mu\equiv\mu_1+\cdots+\mu_N$, the restrictions on the parameters are not. The condition $\mu+\nu$ not a negative integer is necessary, but not sufficient, in (25); there are further $(N-1)$

intermediate restrictions, namely, $\mu_1+\cdots+\mu_k+\nu$ not a negative integer, for $k=1,\cdots,N-1$.

Substituting $\mu\equiv\mu_1+\cdots+\mu_N$ in (20), viz.:

$$\left(\frac{\delta}{\delta z}\right)^{\mu_N+\cdots+\mu_1}\left(\frac{D^\nu F}{Dz^\nu}\right)=A(\mu_N+\cdots+\mu_1,\nu)\left(\frac{D}{Dz}\right)^{\mu_N+\cdots+\mu_1+\nu}F(z), \tag{26}$$

and comparing with (20), we follow the rule of composition of branchpoint operators.

PROPERTY 3. The iterated branchpoint operators of orders $\mu_1,\cdots,\mu_N$ are equivalent to a single branchpoint operator of order $\mu\equiv\mu_1+\cdots+\mu_N$, applied to a Liouville differintegration D^ν:

$$\left(\frac{\delta}{\delta z}\right)^{\mu_N}\cdots\left(\frac{\delta}{\delta z}\right)^{\mu_1}\left(\frac{D^\nu F}{Dz^\nu}\right)=\left(\frac{\delta}{\delta z}\right)^{\mu_N+\cdots+\mu_1}\left(\frac{D^\nu F}{Dz^\nu}\right), \tag{27}$$

assuming that ν is not an integer, and none of the $\mu_1+\nu,\cdots,\mu_N+\cdots+\mu_1+\nu$ are negative integers.

The branchpoint operator satisfies the same composition rule (27) as the Liouville differintegration, although the two operators are generally distinct. From (20) they coincide only if the coefficient is unity $A(\mu,\nu)=1$, which is the case in (21), with ν not an integer, if and only if μ is an integer. Thus we have the following degenerate rule.

PROPERTY 4. The branchpoint operator δ^μ coincides with the Liouville differintegration D^μ if and only if the order μ is an integer, i.e., both are ordinary derivatives or primitives:

$$\delta^\mu\left(\frac{D^\nu F}{Dz^\nu}\right)\Big/\delta z^\mu=\frac{D^{\mu+\nu}F}{Dz^{\mu+\nu}}\leftrightarrow\mu\in Z, \tag{28}$$

where ν is not an integer.

Remark 16. The branchpoint and differintegration operators would have to coincide for ordinary derivations or integrations. The theorem shows that they are distinct generalizations, for all complex, nonintegral orders μ.

The degenerate rule can be extended to iterated branchpoint operators by using (25) instead of (20), viz., Property 5.

PROPERTY 5. The iterated branchpoint operators $\delta^{\mu_N}\cdots\delta^{\mu_1}$ of orders $\mu_N,\cdots,\mu_1$ coincide with the Liouville differintegration D^μ of order equal to the sum $\mu\equiv\mu_1+\cdots+\mu_N$ if and only if the latter is an integer:

$$\left(\frac{\delta}{\delta z}\right)^{\mu_N}\cdots\left(\frac{\delta}{\delta z}\right)^{\mu_1}\left(\frac{D^\nu F}{Dz^\nu}\right)=\left(\frac{D}{Dz}\right)^{\mu_N+\cdots+\mu_1+\nu}F(z)\leftrightarrow\mu\equiv\mu_1+\cdots+\mu_N\in\mathbb{Z}, \tag{29}$$

where ν is not an integer, and none of $\mu_1+\nu,\cdots,\mu_N+\cdots+\mu_1+\nu$ is a negative integer.

Remark 17. Property A5 follows by applying A3 to A4, i.e., (27) and (28) yield (29).

Remark 18. The result (29) shows that the composition of branchpoint operators $\delta^{\mu_1},\cdots,\delta^{\mu_N}$, with complex nonintegral orders $\mu_1,\cdots,\mu_N$, which are not Liouville differintegrations by property A4, may be equivalent to a Liouville differintegration of order $\mu\equiv\mu_1+\cdots+\mu_N$, if and only if the latter is an integer.

Property 4, in the form of Remark 16, that the branchpoint and differintegration operators do not coincide for nonintegral complex orders, opens the way for the annihilation of the latter by the former (since they must be applied in this order, this is the only annihilation possible). To find the cases, i.e., properties A4 and A5, of coincidence of branchpoint and differintegration operators, we have required that the coefficient (21) be unity; the annihilation of the latter by the former generally requires

the coefficient (21) to vanish. This is possible, for nonintegral complex ν, if and only if $\mu+\nu$ is an integer, i.e., $\mu=p-\nu$ where p is any integer $p\in\mathbb{Z}$. We have proved the following annihilation property.

PROPERTY 6. The Liouville differintegration D^ν of nonintegral complex order ν, is annihilated by the branchpoint operator δ^μ, if and only if its order $\mu=p-\nu$ differs from $-\nu$ by an integer p:

$$\nu\in\mathbb{C}-\mathbb{Z},\ p\in\mathbb{Z}\colon\ \delta^{p-\nu}\left(\frac{D^\nu F}{Dz^\nu}\right)\Big/\delta z^{p-\nu}=0. \tag{30}$$

Remark 19. All Liouville differintegrations D^ν can be annihilated by a suitable branchpoint operator, except the function itself $\nu=0$, an ordinary derivative $\nu\in\mathbb{N}$, or an ordinary primitive $-\nu\in\mathbb{N}$.

Remark 20. For each Liouville differintegration D^ν of complex nonintegral order ν, there is a denumerable infinity of branchpoint operators $\delta^{p-\nu}$ with integer p that annihilates it.

Property A6 extends to annihilation by iterated branchpoint operators.

PROPERTY 7. The iterated branchpoint operators $\delta^{\mu_N},\cdots,\delta^{\mu_1}$ of orders $\mu_N,\cdots,\mu_1$ annihilate a Liouville differintegration D^ν of order ν, if and only if the sum of all orders is an integer:

$$\left(\frac{\delta}{\delta z}\right)^{\mu_N}\cdots\left(\frac{\delta}{\delta z}\right)^{\mu_1}\left(\frac{D^\nu F}{Dz^\nu}\right)=0\leftrightarrow\mu_N+\cdots+\mu_1+\nu\in\mathbb{Z}, \tag{31}$$

where ν is not an integer, and none of $\mu_1+\nu,\cdots,\mu_N+\cdots+\mu_1+\nu$ are negative integers.

Remark 21. The use of iterated branchpoint operators (31) increases the number of possibilities of annihilating any given Liouville differintegration of nonintegral complex order ν, relative to that stated in Remark 19; i.e., we have a continuum of possibilities instead of a denumerable set.

Remark 22. If we exclude the possibility of annihilating functions and ordinary derivatives and primitives, then the branchpoint operator goes as far as we could expect, i.e., (i) it can annihilate every other instance of the Liouville differintegration, and (ii) it offers an infinity of possibilities of doing so.

5. Discussion. Although the Liouville differintegration and branchpoint operator are generally distinct, they are both derivation operators since they are linear and satisfy the Leibnitz rule, in the extended form [17], [18], [2], [4], which we quote first.

THEOREM 6. *The Liouville differintegration of order ν, of the product of two analytic functions $F(z)$, $G(z)$, satisfies the generalized Leibnitz rule*:

$$\frac{D^\nu\{F(z)G(z)\}}{Dz^\nu}=\sum_{k=0}^{\infty}\binom{\nu}{k}G^{(k)}z\frac{D^{\nu-k}F}{Dz^{\nu-k}} \tag{32}$$

where $F(z)$, and $F(z)G(z)$ satisfy the asymptotic condition (3).

Proof. Since the proof differs from those in the literature in matters of detail, we give a brief outline here. The asymptotic condition (3) for $F(z)G(z)$ implies that we need consider only part L of the Hankel path in (1) that lies within a circle of finite radius $|\zeta|\leqq R$; the remainder of the path gives a term $O(R^{-\varepsilon})\to 0$ uniformly as $R\to\infty$. Thus we have

$$\frac{D^\nu\{F(z)G(z)\}}{Dz^\nu}=\{\Gamma(1+\nu)/2\pi i\}\int_L F(\zeta)G(\zeta)(\zeta-z)^{-\nu-1}\,d\zeta. \tag{33}$$

The function $G(z)$ is analytic in the circle $|\zeta| \leqq R+\delta$ for some $\delta > 0$, and thus has the Taylor series

$$G(\zeta) = \sum_{k=0}^{\infty} \{(\zeta - z)^k / k!\} G^{(k)}(z), \tag{34}$$

uniformly convergent in a closed subcircle $|\zeta| \leqq R$. The latter (34) may be substituted into (33), and integrated term by term:

$$\frac{D^\nu\{F(z)G(z)\}}{Dz^\nu} = \sum_{k=0}^{\infty} \{\Gamma(1+\nu)/k!2\pi i\} G^{(k)}(z) \int_L F(\zeta)(\zeta - z)^{-\nu+k-1}\, d\zeta. \tag{35}$$

Since $F(z)$ satisfies the asymptotic condition (3) with ε, it also satisfies $\varepsilon - k$ for all positive integer k, and path L may be extended back to the Hankel loop:

$$\begin{aligned} \frac{D^\nu\{F(z)G(z)\}}{Dz^\nu} &= \sum_{k=0}^{\infty} \{\Gamma(1+\nu)/k!\Gamma(1+\nu-k)\} G^{(k)}(z) \\ &\quad \cdot \{\Gamma(1+\nu-k)/2\pi i\} \int_{\infty \exp\{i \arg(z)\}}^{(z+)} F(\zeta)(\zeta - z)^{-\nu+k-1}\, d\zeta; \end{aligned} \tag{36}$$

applying (1), we obtain

$$\frac{D^\nu\{F(z)G(z)\}}{Dz^\nu} = \sum_{k=0}^{\infty} \{\Gamma(1+\nu)/k!\Gamma(1+\nu-k)\} G^{(k)}(z) \frac{D^{\nu-k}F}{Dz^{\nu-k}}, \tag{37}$$

which is equivalent to (32), with the notation

$$\binom{\nu}{k} \equiv \Gamma(1+\nu)/\Gamma(1+k)\Gamma(1+\nu-k). \tag{38}$$

We have proved the extended Leibnitz rule. □

We may now proceed to prove that δ^μ is a differentiation operator, by the following sequence of reasoning.

Remark 23. In the case where $\nu = n$ is a positive integer, $(\nu - k)! = \infty$ for $k > n$, and (32) reduces to the ordinary Leibnitz rule:

$$\frac{D^n\{F(z)G(z)\}}{Dz^n} = \sum_{k=0}^{n} \binom{m}{k} F^{(n-k)}(z) G^{(k)}(z). \tag{39}$$

Remark 24. The ordinary Leibnitz rule (33) looks like a binomial expansion of derivates, and the extended Leibnitz rule (32) looks like a binomial series of Liouville differintegrations.

THEOREM 7. *The Liouville differintegration D^ν is a derivation operator, because* (i) *it is linear, and* (ii) *it satisfies the extended Leibnitz rule.*

Proof. (i) The linear property results from Definition 1 as a generalized Cauchy integral (1).

(ii) The extended Leibnitz rule is proved in Theorem 6.

A similar result holds for the branchpoint operator.

PROPERTY 8. The branchpoint operator δ^μ is a derivation operator, since (i) it is linear, and (ii) it satisfies the extended Leibnitz rule in the following form:

$$\delta^\mu \left\{ \frac{D^\nu(F(z)G(z))}{Dz^\nu} \right\} \Big/ \delta z^\mu = \sum_{k=0}^{\infty} \binom{\mu+\nu}{k} G^{(k)}(z) \delta^{\mu-k} \left(\frac{D^\nu F}{Dz^\nu} \right) \Big/ \delta z^{\mu-k}, \tag{40}$$

where μ, ν are not integers.

Proof. The linear property (i) of the branchpoint operator δ^{μ} follows from that of the Liouville differintegration because the factor (21) connecting them (20) does not involve the independent z or dependent $F(z)$ $G(z)$ variables.

The factor (21) is unchanged if we add to the arguments any integer numbers p, q, viz.,

$$p, q \in \mathbb{Z}: A(\mu+p, \nu+q) = A(\mu, \nu). \tag{41}$$

Writing the Leibnitz rule (32) with ν replaced by $\mu+\nu$, and multiplying by (41), we obtain

$$A(\mu, \nu)\frac{D^{\mu+\nu}\{F(z)G(z)\}}{Dz^{\mu+\nu}} = \sum_{k=0}^{\infty}\binom{\nu}{k}G^{(k)}(z)A(\mu-k, \nu)\frac{D^{\mu+\nu-k}F}{Dz^{\mu+\nu-k}}; \tag{42}$$

substituting (20) into (42), yields (40), which is (ii), the extended Leibnitz rule for the branchpoint operator. We must exclude integer ν, and also the negative integer μ, $\mu-1, \cdots, \mu-k, \cdots$; the latter set of conditions is equivalent to stating that μ is not an integer. □

As an example of the application of the branchpoint δ^{μ} and differintegration D^{μ} operators to special functions, we consider the Hermite function.

DEFINITION 6. The Hermite function $H_{\nu}(z)$ of complex order ν and variable z is defined by Liouville differintegration with order ν of the Gaussian function of variable z:

$$H_{\nu}(z) \equiv e^{i\pi\nu}e^{z^2}\frac{D^{\nu}(e^{-z^2})}{Dz^{\nu}}. \tag{43}$$

Remark 25. In the case where $\nu = n$ is a positive integer, Definition (43) agrees with that of the Hermite [7] polynomial:

$$H_n(z) = (-)^n e^{z^2}\{e^{-z^2}\}^{(n)}. \tag{44}$$

Remark 26. Using (1), the Hermite function of complex ν, nonnegative integral order, has the following integral representation:

$$H_{\nu}(z) = \{\Gamma(1+\nu)/2\pi i\}\, e^{z^2}\int_{\infty \exp\{i \arg(z)\}}^{(z+)} (z-\zeta)^{-\nu-1}\, e^{-\zeta^2}\, d\zeta, \tag{45}$$

along a Hankel loop (Fig. 1).

Remark 27. When we use (2), the Hermite function of complex order ν, with negative real part $\mathrm{Re}(\nu) < 0$, has the integral representation

$$H_{\nu}(z) = \{e^{z^2}/\Gamma(-\nu)\}\int_{\infty \exp\{i \arg(z)\}}^{z} (x-z)^{-\nu-1}\, e^{x^2}\, dx, \tag{46}$$

along a semi-infinite straight line (Fig. 1).

Remarks 24–26 show that the definition of the Hermite function via the Liouville differintegration (43) agrees with other definitions in the literature [5], and applies to all complex orders ν.

We proceed to prove the annihilation property.

PROPERTY 9. The Hermite function (43) of nonintegral complex order ν, multiplied by a Gaussian function e^{-z^2} of the independent variable z, is annihilated by the branchpoint operator $\delta^{p-\nu}$ of order $p-\nu$, differing from $-\nu$ by an integer p:

$$\nu \in \mathbb{C}-\mathbb{Z}, \quad p \in \mathbb{Z}: \delta^{p-\nu}\{e^{-z^2}H_{\nu}(z)\}/\delta z^{p-\nu} = 0. \tag{47}$$

Remark 28. The need for the Gaussian function e^{-z^2} as a factor in the curly brackets in (47), follows from (30), the general annihilation Property 5, in the particular form:

$$0 = e^{i\pi\nu}\delta^{p-\nu}\left\{\frac{D^{\nu}(e^{-z^2})}{Dz^{\nu}}\right\}\Big/\delta z^{p-\nu} = \delta^{p-\nu}\{e^{-z^2}H_{\nu}(z)\}/\delta z^{p-\nu}. \tag{48}$$

Proof. Remark 28 may serve as a short, indirect proof of (47). We may also prove Property 9 directly, by substituting (48) into Definition 4 of branchpoint operator (6):

$$\begin{aligned}\delta^{p-\nu}\left\{\frac{D^{\nu}(e^{-z^2})}{Dz^{\nu}}\right\}\Big/\delta^{p-\nu} &\equiv \{\Gamma(1+\nu)/2\pi i\}\int_{\infty\exp\{i\arg(z)\}}^{(z+)}\frac{d^{p-\nu}\{(\zeta-z)^{-\nu-1}\}}{dz^{p-\nu}}\,e^{-\zeta^2}\,d\zeta,\\ &= \{\Gamma(-\nu)\Gamma(1+\nu)/2\pi i\Gamma(-p)\}\,e^{i\pi(p-\nu)}\cdot\int_{\infty\exp\{i\arg(z)\}}^{(z+)}(\zeta-z)^{-p-1}\,e^{-\zeta^2}\,d\zeta \qquad (49)\\ &= \{\Gamma(-\nu)\Gamma(1+\nu)/\Gamma(-p)\Gamma(1+p)\,e^{i\pi\nu}\}H_p(z),\end{aligned}$$

where (45) was used. The Hermite polynomial in (49) does not vanish, but the coefficient in curly brackets does:

$$C(\nu,p)\equiv\Gamma(-\nu)\Gamma(1+\nu)/\Gamma(-p)\Gamma(1+p) = \sin(\pi p)/\sin(\pi\nu) = 0, \tag{50}$$

because p is an integer. Substitution of (50) into (49) proves (48) and (47). □

If in (47) we set $\mu \equiv p-\nu$, and replace the branchpoint operator δ^{μ} with a Liouville differintegration, the result is not zero, but rather, as follows from (43) and (11):

$$\begin{aligned}\frac{D^{\mu}\{e^{-z^2}H_{\nu}(z)\}}{Dz^{\mu}} &= e^{i\pi\nu}D^{\mu}\left\{\frac{D^{\nu}(e^{-z^2})}{Dz^{\nu}}\right\}\Big/Dz^{\mu}\\ &= e^{i\pi\nu}D^{\mu+\nu}(e^{-z^2})Dz^{\mu+\nu} = e^{-i\pi\mu}\,e^{-z^2}H_{\mu+\nu}(z),\end{aligned} \tag{51}$$

a Hermite function of order $\mu+\nu$. The result (51) can be stated as an integral identity.

THEOREM 8. *The Hermite function satisfies the integral identities*:

$$e^{-z^2}H_{\mu+\nu}(z) = \{\Gamma(1+\mu)/2\pi i\}\int_{\infty\exp\{i\arg(z)\}}^{(z+)}(z-\zeta)^{-\mu-1}H_{\nu}(\zeta)\,e^{-\zeta^2}\,d\zeta \tag{52}$$

$$= \{\Gamma(-\mu)\}^{-1}\int_{\infty\exp\{i\arg(z)\}}^{z}(\zeta-x)^{-\mu-1}H_{\nu}(x)\,e^{-x^2}\,dx, \tag{53}$$

where the Hankel path (52) *applies for* μ *not a negative integer, and the straight path* (53) *for* $\operatorname{Re}(\mu)<0$.

Proof. Substitution of (1) and (2) into (51), yields, respectively, (52) and (53).

The integral identities (52) and (53) allow the evaluation of certain integrals of Hermite functions in terms of other Hermite functions. They are similar to results holding for other special functions [2].

ON A GENERALIZED MITTAG-LEFFLER THEOREM AND IMPLICIT DIFFERINTEGRATION*

L. M. B. C. CAMPOS†

Abstract. The differintegration operator is defined in the literature [B. Ross, ed., *Fractional Calculus and Applications*, Springer-Verlag, Berlin, New York, 1974; *Fractional Calculus*, Academic Press, New York, 1974; *Fractional Calculus*, 2 vols., Descartes Press, New York, 1974; *IMA J. Appl. Math.*, 33 (1984), pp. 109-133] as an extension to real or complex order ν, of the ordinary nth derivative and primitive, which correspond to, respectively, $\nu = +n$, $-n$, a positive, negative integer. The differintegration operator has been used to generalize [*SIAM J. Math. Anal.*, 1 (1970), pp. 288-293; *SIAM J. Math. Anal.*, 2 (1971), pp. 37-48; *Mat. Vesnik*, 38 (1986), pp. 375-390; Mat. Vesnik, 40 (1988), p. 85] the power series associated with the names of Taylor, Laurent, Lagrange, and Teixeira. Here we generalize the Mittag-Leffler theorem on series of fractions, as a representation of the differintegration of a meromorphic function (§ 3); the proof uses the principal parts of the Laurent series expansion, and of the differintegration of a function near a pole (§ 2). The rules of derivation with complex order have been discussed in the literature [*SIAM J. Appl. Math.*, 18 (1970), pp. 658-674; *SIAM J. Math. Anal.*, 3 (1972), pp. 1-16; *Portugal Math.*, 43 (1985), pp. 347-376], and we prove (§ 3) a new rule of differintegration of implicit functions. The differintegration operator has many applications to special functions [Ross, op. cit., pp. 323-356; *SIAM Rev.*, 18 (1976), pp. 240-268; *IMA J. Appl. Math.*, 36 (1986), pp. 191-206], and we illustrate our results in this regard (§ 5) with Hermite functions.

Key words. implicit differintegration, series of fractions, meromorphic functions, singularities, residues, Hermite functions

1. Introduction.

The differintegration operator has been defined in the context of real [23], [18], generalized [14], [15], and complex [17], [1] functions, as an extension of the ordinary derivatives and primitives. It has some properties analogous to those of ordinary derivatives, e.g., if $F(z)$ is an analytic function, its Liouville differintegration $D^\nu F/Dz^\nu$ with $\mathrm{Re}\,(\nu) > 0$ is also analytic (§ 2). This extends the known result that an analytic function is infinitely differentiable from $\nu = n$ positive integer to the whole right-hand ν-half-plane. It suggests that the differintegration D^ν of an analytic function $F(z)$ has a Taylor series type of expansion in ascending powers of z. If the function $F(z)$ has an isolated singularity at $z = \zeta$, its differintegration $D^\nu F/Dz^\nu$ has a Laurent series type of expansion, involving ascending and descending powers of $z - \zeta$. It is not the purpose of this paper to address the representation of the differintegration of functions into power series, which is discussed elsewhere in the literature [19], [21], [3]. For our purposes, it is sufficient to note that the Laurent series type of expansion specifies the principal part of the differintegration of a function $D^\nu F/Dz^\nu$ near singularity, either essential or pole.

The latter remark suggests a form of representation of the differintegration of a rational function; such a function is analytic except for a finite number of poles, and the principal parts near these specify its differintegration to within an added constant, which may be evaluated at any regular point. This process can be extended to a function with an infinite number of poles and no essential singularities, i.e., such that the poles "spread" to infinity, and do not "cluster" in the neighborhood of an accumulation point (which would be an essential singularity). This leads to a generalization of the Mittag-Leffler theorem [24], by representing the differintegration of a meromorphic

† Instituto Superior Técnico, 1096 Lisboa Codex, Portugal.

function as a series of fractions, viz., the principal parts at the poles. The added constant can be evaluated at any regular point, provided that the series converges uniformly in its neighborhood. The question of convergence is the only point where the proof of the generalized Mittag-Leffler theorem for the differintegration of a meromorphic function goes beyond the analogous finite expansion for a rational function.

Since the differintegration is a generalization of the ordinary derivative, the question arises of extending the rules of derivation to complex order, e.g., differintegration of elementary functions [10], [2]. The Leibnitz rule can also be extended [20], [22], [2] into an infinite chain rule, which shows that several important special functions are differintegrations of products of elementary functions [11], [2]. Here we prove (§ 4) a rule of implicit differintegration of a function with regard to another; this rule may be combined with the chain rule, and both lead to series expansions. The use of Riemann differintegration to obtain properties of special functions, both short proofs of known results and new formulas, is well documented in the literature [18], [6]. The Riemann [10] rather than the Liouville [17] differintegration should be used for hypergeometric, confluent, Legendre, Laguerre, Jacobi, Gegenbauer, and Chebyshev functions, because these involve branchpoints. The Hermite function involves the Liouville differintegration of an integral function, namely [5] the Gaussian, and we choose it (§ 5) for examples of application of rules of differintegration, since it appears to have received less attention in the literature.

2. Extensions of the Laurent series and calculation of residues. We recall the definition of the Liouville [13] system of differintegration, in the context [12], [16], [17], [1] of functions of a complex variable.

DEFINITION 1. The differintegration D^ν of complex order ν, not a negative integer, of an analytic function $F(z)$ is defined by the generalized Cauchy integral:

$$\frac{D^\nu F}{Dz^\nu} = \{\Gamma(1+\nu)/2\pi i\} \int_{\infty \exp\{i \arg(z)\}}^{(z+)} (\zeta - z)^{-\nu-1} F(\zeta)\, d\zeta, \tag{1}$$

along a Hankel [8] loop (Fig. 1) going round $\zeta = z$ in the counterclockwise direction, and starting and ending at infinity, respectively, above and below the branchcut $C \equiv \{\zeta: |\zeta| > |z|, \arg(\zeta) = \arg(z)\}$. The function satisfies the following asymptotic condition:

$$\arg(\zeta) - \delta < \arg(z) < \arg(\zeta) + \delta: F(\zeta) \sim O(\zeta^{\mathrm{Re}(\nu)-\varepsilon}), \tag{2}$$

for some $\varepsilon, \delta > 0$ in a sector about the branchcut C, so that the improper integral in $d\zeta$ converges (1). It is assumed that the convergence is uniform with regard to z in a region D.

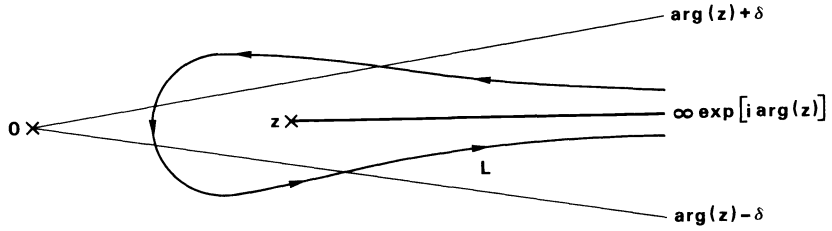

FIG. 1. *The differintegration of an analytic function involves a contour integral* (1) *along the Hankel* [8] *path, going counterclockwise around the branchpoint* $\zeta = z$, *and starting and ending at infinity in the* ζ*-plane, respectively, above and below the semi-infinite branchcut, joining* z *to infinity in the direction of* arg (z), *so that in an angular sector containing the branchcut the function satisfies an asymptotic condition* (2).

Remark 1. The extension of Definition 1 to negative integer order ν, the relation with ordinary derivatives and primitives, and the integration with complex order are summarized [5] and proved [1] elsewhere. For the present we note as an immediate consequence of Definition 1 that the asymptotic condition (2), for the convergence of (1), is still met with ν replaced by μ, such that $\mathrm{Re}(\mu) \geqq \mathrm{Re}(\nu)$, thus proving Theorem 1.

THEOREM 1. *If the differintegration $D^\nu F/Dz^\nu$ of an analytic function $F(z)$, with complex order ν exists, then the differintegration $D^\mu F/Dz^\mu$ with complex order μ, such that* $\mathrm{Re}(\mu) \geqq \mathrm{Re}(\nu)$, *also exists.*

Remark 2. If we set $\mu \neq \nu$ and $\mathrm{Re}(\mu) = \mathrm{Re}(\nu)$, i.e., $\mathrm{Im}(\mu) \neq \mathrm{Im}(\nu)$, Theorem 1 still holds, showing that the imaginary part of the order of differintegration $D^\nu F$ of a function $F(z)$ does not affect existence.

If we set $\mu = \nu+1, \cdots, \nu+n, \cdots$ in Theorem 1, it follows that $D^\nu F/Dz^\nu$, if it exists, is infinitely differentiable, and thus, in the context of complex analysis, specifies an analytic function.

THEOREM 2. *The differintegration D^ν (1) of (2) an analytic function $F(z)$, if it exists, specifies a function $G(z) \equiv D^\nu F/Dz^\nu$, which is analytic in the region D, of uniform convergence of the integral* (1).

An analytic function has a Taylor series expansion, which we may expect to hold for the function $G(z) \equiv D^\nu F/Dz^\nu$ in Theorem 2. Noting that $G^{(k)}(z) \equiv D^{\nu+k}F/Dz^{\nu+k}$ by the rule of composition of derivatives [1], [5], we may expect the following theorem to hold.

THEOREM 3 (extended Taylor series). *The differintegration D^ν, with complex order ν, of an analytic function $F(z)$, can be represented by an extended Taylor series of ascending powers*:

$$\frac{D^\nu F}{Dz^\nu} = \sum_{k=0}^{\infty} \{(z-\zeta)^k/k!\} \frac{D^{\nu+k}F}{D\zeta^{\nu+k}}, \tag{3}$$

whose coefficients involve differintegrations of orders $\nu, \nu+1, \cdots, \nu+k, \cdots$, equal to ν plus a nonnegative integer, at a regular point ζ. If η is the singularity of $F(z)$ closest to the regular point ζ, and $R \equiv |\eta-\zeta|$, then the series (3) *converges:* (i) *absolutely, in the open circle $|z-\zeta| < R$*; (ii) *uniformly, in the closed subcircle $|z-\zeta| \leqq R-\varepsilon$, for some ε, such that $0 < \varepsilon < R$.*

Remark 3. The regions of absolute and uniform convergence of the extended Taylor series (3) are the same as for the original Taylor series, which is obtained by setting $\nu = 0$, in which case only ordinary derivatives are needed.

Proof. The proof of (3) is broadly similar to the standard demonstration of the Taylor series [24], except that the binomial rather than the geometric series is needed to establish the extended Taylor series [4]. The details are too extensive [6] to be reproduced here.

If the function $F(z)$ has an isolated singularity at $z = \zeta$, it can be expanded in the neighborhood in a Laurent series [24], and its differintegration D^ν with complex order has an extended Laurent series [6], viz., Theorem 4.

THEOREM 4 (extended Laurent series). *The differintegration D^ν, with complex order ν, of a function $F(z)$, having an isolated singularity at $z = \zeta$, can be represented by an extended Laurent series*:

$$\frac{D^\nu F}{Dz^\nu} = \sum_{k=0}^{\infty} A_k (z-\zeta)^k + \sum_{k=1}^{\infty} A_{-k} (z-\zeta)^{-\nu-k}, \tag{4}$$

where the coefficients A_k of the ascending integral powers, and A_{-k} of the descending

complex powers, are given, respectively, by

$$A_k \equiv \{\Gamma(1+\nu+k)/k!2\pi i\} \int_L (z-\zeta)^{-\nu-k-1} F(z)\, dz, \tag{5}$$

$$A_{-k} \equiv e^{i\pi\nu}\{\Gamma(\nu+k)/(k-1)!2\pi i\} \int_l (z-\zeta)^{k-1} F(z)\, dz, \tag{6}$$

where L, l are Hankel paths like (1), *with l lying within L. If* $z=\eta$ *is the singularity of* $F(z)$ *closest to* $z=\zeta$, *then the series* (4) *converges*: (i) *absolutely in the open disk* $0<|z-\zeta|<R$ *of radius* $R\equiv|\zeta-\eta|$; (ii) *uniformly in the closed subdisk* $\varepsilon \leqq |z-\zeta| \leqq R-\delta$, *with* $\varepsilon, \delta > 0$ *and* $\varepsilon+\delta<R$.

Remark 4. In the absence of differintegration $\nu=0$, the factors in curly brackets in (5), (6) reduce to $(2\pi i)^{-1}$, and only integral powers appear in (4), which reduces to the original Laurent series.

Remark 5. If the function $F(z)$ is analytic at $z=\zeta$, then the inner path l can be shrunk to zero, so that (6) vanishes and (4) reduces to the first sum, where the coefficients (5) can be evaluated using (1):

$$A_k = (k!)^{-1} D^{\nu+k}F/D\zeta^{\nu+k}, \tag{7a}$$

$$A_{-k} = 0. \tag{7b}$$

Substituting (7a), (7b) into (4), we regain the extended Taylor series (3).

Remark 6. The regions of absolute and uniform convergence of the extended Laurent series (5), (6) are the same as for the original Laurent series with $\nu=0$, because they are independent of ν; they differ from the regions of absolute and uniform convergence of the Taylor series (extended (3) and original $\nu=0$) only in excluding, respectively, an open (closed) neighborhood of the singularity $z=\zeta$.

The descending powers of the extended Laurent series, viz., the second term on the right-hand side of (4), specify the principal part of the differintegration $D^\nu F/Dz^\nu$ in the neighborhood of the singularity, viz., Property 1.

PROPERTY 1 (principal part of a differintegration). The differintegration D^ν, with complex order ν, of a function $F(z)$, with an isolated singularity at $z=\zeta$, has principal part consisting of: (i) an unending sequence of powers with exponents $-\nu-1, \cdots, -\nu-k, \cdots$:

$$\frac{D^\nu F}{Dz^\nu} \sim A_{-1}(z-\zeta)^{-\nu-1} + A_{-2}(z-\zeta)^{-\nu-2} + \cdots, \tag{8}$$

if $z=\zeta$ is an essential singularity; (ii) a sequence of m powers of exponents $-\nu, -\nu-1, \cdots, -\nu-m$;

$$\frac{D^\nu F}{Dz^\nu} \sim A_{-1}(z-\zeta)^{-\nu-1} + \cdots + A_{-m}(z-\zeta)^{-\nu-m}, \tag{9}$$

if $z=\zeta$ is a pole of order m.

The coefficient A_{-1} is the residue and can be calculated, at a pole, from the differintegration (9), as follows.

PROPERTY 2. The residue A_{-1} of the differintegration $D^\nu F/Dz^\nu$ at a pole of order m (9), can be calculated by

$$A_{-1} = \lim_{z\to\zeta} \{(m-1)!\}^{-1} \left(\frac{d}{dz}\right)^{m-1} \{(z-\zeta)^{m+\nu} D^\nu F/Dz^\nu\} \tag{10}$$

where $(d/dz)^{m-1}$ is an ordinary derivative.

Remark 7. In the case $m=1$ of a simple pole, the residue (10) can be calculated without derivations, by

$$A_{-1}=\lim_{z\to\zeta}(z-\zeta)^{1+\nu}\frac{D^{\nu}F}{Dz^{\nu}}. \tag{11}$$

Not only the residue A_{-1}, but also all other coefficients A_{-k}, of principal part of the differintegration at a multiple pole (9), can be calculated by a formula analogous to (10).

PROPERTY 3. The coefficients A_{-k} with $k=1,\cdots,m$, of the principal part (9) of the differintegration at a pole of order m, can be calculated by

$$A_{-k}=\lim_{z\to\zeta}\{(m-k)!\}^{-1}\left(\frac{d}{dz}\right)^{m-k}\left\{(z-\zeta)^{m+\nu}\frac{D^{\nu}F}{Dz^{\nu}}\right\}. \tag{12}$$

Remark 8. The residue A_{-1} (10) is the particular case $k=1$ of (12).

3. The generalized Mittag–Leffler theorem for meromorphic functions. The identification of the principal part of a differintegration $D^{\nu}F/Dz^{\nu}$ at a singularity opens the way to the representation of functions having no singularities other than poles by sequences of fractions. For rational and meromorphic functions, which have, respectively, a finite and an infinite number of poles, the representation by means of regular or singular power series, e.g., Taylor (3) or Laurent (4)-(6) type, requires extensive use of analytic continuation because the radius of convergence of each series is limited by the nearest singularity. Also, the form of the coefficients tends to be complicated in such cases, e.g., they involve Bernoulli or Euler numbers for the compound trigonometric and hyperbolic functions, viz., the tangent, cotangent, secant, and cosecant, which are meromorphic. The representation by means of series of fractions is much more convenient, since a single expansion holds over the whole complex plane, and the coefficients are determined by the principal parts at the poles. We start with the case of rational functions, having a finite number M of poles, for which questions of convergence do not arise. We assume that the differintegration $D^{\nu}F/Dz^{\nu}$ is a rational function, with a finite number M of poles, at the points $z=a_k$, with orders b_k, for $k=1,\cdots,M$, with A^{j}_{-k} as coefficients of the principal parts:

$$\frac{D^{\nu}F}{Dz^{\nu}}\sim\sum_{j=1}^{b_k}A^{k}_{-j}(z-a_k)^{-\nu-j}; \tag{13}$$

the point at infinity may also be a pole, of order b_0, with coefficients A^{0}_{-j} of the principal part of the differintegration:

$$\frac{D^{\nu}F}{Dz^{\nu}}\sim\sum_{j=0}^{b_0}A^{0}_{-j}z^{\nu+j}. \tag{14}$$

Thus the function $G(z)$, obtained by subtracting from $D^{\nu}F/Dz^{\nu}$ its principal parts (14), (13) at all the poles, has no singularities in the extended complex plane and reduces to a constant:

$$G(z)\equiv\frac{D^{\nu}F}{Dz^{\nu}}-\sum_{j=0}^{b_0}A^{0}_{-j}z^{\nu+j}-\sum_{k=1}^{M}\sum_{j=1}^{b_k}A^{k}_{-j}(z-a_k)^{-\nu-j}=\text{const.}=G(\zeta), \tag{15}$$

e.g., its value at any regular point $z=\zeta$.

The result (15) may be stated formally as the following theorem.

THEOREM 5 (expansion in fractions). *If the differintegration $D^{\nu}F/Dz^{\nu}$ with complex order ν is a rational function, with M poles a_k of orders b_k, with $k=1,\cdots,M$ in the z-plane, with coefficients A^{k}_{-j} with $j=1,\cdots,b_k$ of the principal parts* (13), *plus possibly*

a pole of order b_0 at infinity, with coefficients A^0_{-j} with $j = 1, \cdots, b_0$, of the principal part (14), *then it can be represented by a finite expansion in fractions*:

$$\frac{D^\nu F}{Dz^\nu} = \frac{D^\nu F}{D\zeta^\nu} + \sum_{j=1}^{b_0} A^0_{-j}(z^{\nu+j} - \zeta^{\nu+j}) + \sum_{k=1}^{M} \sum_{j=1}^{b_k} A^k_{-j}\{(z-a_k)^{-\nu-j} - (\zeta - a_k)^{-\nu-j}\}, \tag{16}$$

where ζ is any point distinct from the poles $\zeta \neq a_k$, with $k = 1, \cdots, M$.

To extend the theorem to the case when the differintegration $D^\nu F/Dz^\nu$ is a meromorphic function with an infinite $M = \infty$ number of poles, we must first consider their location in the complex z-plane, as illustrated in Fig. 2. (i) The poles a_k with $k = 1, \cdots, M$, can have no accumulation point (because the latter would be an essential singularity, contradicting that $D^\nu F/Dz^\nu$ be meromorphic); (ii) a compact region, e.g., a circle $|z| < R$ of center at the origin and radius R, can contain only a finite number of poles (otherwise, if the number of poles were infinite, at least one accumulation point would exist); (iii) if the poles are ordered by modulus $|a_k| \leqq |a_{k+1}|$, they must tend to infinity $|a_k| \to \infty$ as $k \to \infty$ (otherwise if $|a_k| < R$ for all $k = 1, \cdots, \infty$, a circle of finite radius would contain an infinite number of poles); (iv) a sequence of regions

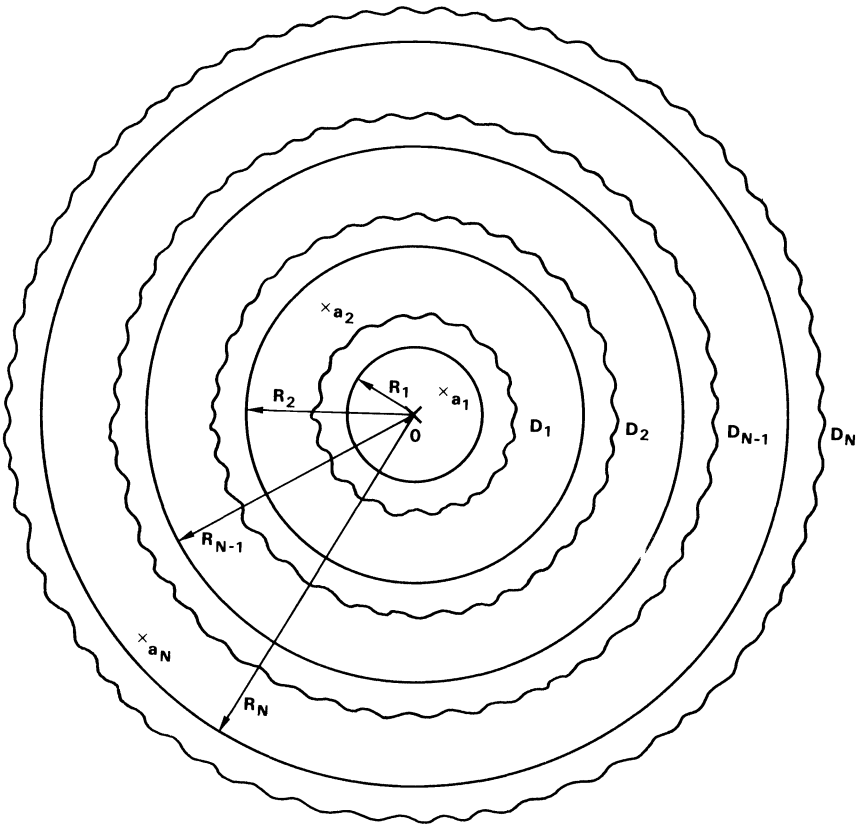

FIG. 2. *If the differintegration of a function is meromorphic, it has an infinity of poles a_k, which when ordered by nondecreasing modulus $|a_{k+1}| \geqq |a_k|$ tend to infinity as $k \to \infty$, allowing the construction of a sequence of regions D_k, each containing the first k poles $a_1, \cdots, a_k$, and all of the preceding regions $D_1, D_2, \ldots, D_{k-1}$, with boundary ∂D_k lying outside a circle of center at the origin, and radius $R_k \to \infty$ growing without bound as $k \to \infty$.*

D_k can be constructed, such that D_k contains only the poles $a_1, \cdots, a_k$ and in its interior can be drawn a circle of radius $R_k \geqq |a_{k-1}|$, such that $R_k \to \infty$ as $k \to \infty$. These remarks show that to extend (16) to meromorphic functions, the following modifications are needed: (i) the second term on the right-hand side should be omitted, since the point at infinity of a meromorphic function is not a pole, but rather a "point of accumulation" of poles; (ii) the sum over the number of poles $M = \infty$, in the last term on the right-hand side of (16) becomes a series, provided that its convergence be assumed by the asymptotic behavior of the differintegration $D^\nu F/Dz^\nu$ as $z \to \infty$.

It will turn out that, in the present case, a sufficient condition for the convergence stated in (ii), is the same as for the original Mittag-Leffler theorem, namely [24], that the differintegration $D^\nu F/Dz^\nu$ be bounded on the boundaries ∂D_k of the sequence of regions D_k tending to infiinity in Fig. 2. This leads to the generalized Mittag-Leffler theorem, for the differintegration of meromorphic functions.

THEOREM 6 (series of fractions). *The differintegration $D^\nu F/Dz^\nu$, with complex order ν of a meromorphic function $F(z)$, with an infinity of poles a_k of orders b_k, with $k = 1, \cdots, \infty$, with coefficients A^k_{-j} with $j = 1, \cdots, b_k$ of the principal parts* (13), *can be represented by a series of fractions*:

$$\frac{D^\nu F}{Dz^\nu} = \frac{D^\nu F}{D\zeta^\nu} + \sum_{k=1}^{\infty} \sum_{j=1}^{b_k} A^k_{-j} \{(z-a_k)^{-\nu-j} - (\zeta - a_k)^{-\nu-j}\}, \tag{17}$$

where $\zeta \neq a_k$ for $k = 1, \cdots, \infty$, is any regular point. Assuming that the differintegration $D^\nu F/Dz^\nu$ is bounded, as $k \to \infty$ on a sequence of loops ∂D_k, each containing the first N poles $a_1, \cdots, a_k$ (Fig. 2), the series (17) *converges*: (i) *simply outside the poles, i.e., for $|z - a_k| > 0$ for all $k = 1, \cdots, \infty$*; (ii) *uniformly outside a closed neighborhood of the poles, viz., for $|z - a_k| \geqq \delta_k > 0$ for some δ_k, with $k = 1, \cdots, \infty$.*

Remark 9. The existence of a pole at infinity, as in the second term on the right-hand side of (16), is incompatible with the boundedness condition on the sequence of loops ∂D_N, which assures the convergence of (17).

Remark 10. The asymptotic condition (2) on the function $F(z)$, even if it could be restated in terms of the differintegration $D^\nu F/Dz^\nu$, would not satisfy the requirement for convergence of (17); the latter is an isotropic condition, applying as $|z| \to \infty$ for all directions $0 \leqq \arg(z) < 2\pi$, whereas the asymptotic condition (2) is restricted to a narrow sector about the branchline.

Remark 11. The main differences between Theorems 5 and 6 are that: (i) the functions

$$G_M(z) \equiv \frac{D^\nu F}{Dz^\nu} - \sum_{k=1}^{M} A^k_{-j} (z - a_k)^{-\nu-j}, \tag{18}$$

are analytic in the compact region D_M, but not in $D_{M+1}, \cdots$, and thus do not reduce to constants; (ii) the Hankel path in Fig. 1 lies partly outside the region D_N in Fig. 2, so that a loop integral for (18) uses a path distinct from Hankel's.

Remark 11 points to the two difficulties (i) and (ii) that must be resolved to prove the convergence of (17) and, in fact, lead to the restrictions in Theorem 6, which appear in addition to those in Theorem 5.

Proof. Since the function (18) is analytic in the region D_M, we may use the generalized Cauchy integral for its differintegration:

$$\frac{D^\nu \{G_M(z)\}}{Dz^\nu} = \{\Gamma(1+\nu)/2\pi i\} \int_{\partial D_M} (\eta - z)^{-\nu-1} G_M(\eta)\, d\eta + \delta_M(z), \tag{19}$$

where the last term on the right-hand side of (19) accounts for the part of the Hankel path (Fig. 1) outside the loop ∂D_M (Fig. 2) and gives a negligible contribution $\delta_M(z) \to 0$ as $M \to \infty$, because of the asymptotic condition (2). The remainder of the series (17) after M terms, is given:

$$\begin{aligned}\Delta_M(z,\zeta) &\equiv \sum_{k=M+1}^{\infty} \sum_{j=1}^{b_k} A_{-j}^{k}\{(z-a_k)^{-\nu-j} - (\zeta-a_k)^{-\nu-j}\} \\ &= G_M(z) - G_M(\zeta),\end{aligned} \tag{20}$$

where (18) was used. Substituting (19) with $\nu = 0$ into (20), we obtain the following integral:

$$\begin{aligned}&\Delta_M(z,\zeta) - \delta_M(z) + \delta_M(\zeta) \\ &= (2\pi i)^{-1} \int_{\partial D_M} G_M(\eta)\eta^{-1}\{(1-z/\eta)^{-1} \\ &\quad -(1-\zeta/\eta)^{-1}\}\, d\eta \\ &= (2\pi i)^{-1}(z-\zeta) \int_{|\eta|=R_M} \eta^{-2}\{1+O(\eta^{-1})\}G_M(\eta)\, d\eta,\end{aligned} \tag{21}$$

which has an upper bound:

$$\begin{aligned}|\Delta_M(z,\zeta) - \delta_M(z) + \delta_M(\zeta)| &\leqq (B|2\pi)\cdot|z-\zeta| \\ &\quad \cdot 2\pi R_M \cdot R_M^{-2}\{1+O(R_M^{-1})\},\end{aligned} \tag{22}$$

because: (i) the differintegration $D^\nu F/Dz^\nu$, and hence (18), is bounded by B on the sequence of loops ∂D_M; (ii) the points z, ζ are fixed points and hence $|\zeta - z|$ is bounded; (iii) the other bounds for terms in (21) show that (22) is $O(R_M^{-1})$, and since $R_M \to \infty$ as $M \to \infty$, the expression (22) vanishes. Also, $\delta_M(z)$, $\delta_M(\zeta) \to 0$ as $M \to \infty$, implying that the remainder of the series (17) vanishes $\Delta_M(z,\zeta) \to 0$ as $M \to \infty$, proving its simple convergence. The convergence is improved from simple to uniform for points at a finite distance $|\zeta - a_k| \geqq \delta_k > 0$ from all $k = 1, \cdots, \infty$ the poles a_k. □

4. Rules of differintegration of products and implicit functions. The prototype of series expansion for a differintegration is the extended Taylor series (3) from which the theory may be developed in two directions: (i) by allowing one or more singularities of the function $F(z)$, we are led to the extended Laurent series (4)-(6), the principal parts in the neighborhood of singularities (8), (9), and the generalized Mittag-Leffler theorem (17) developed in §§ 2-3; (ii) in §§ 4-5, we consider the consequences of replacing the independent variable z by an auxiliary analytic function $f(z)$ in the extended Taylor series (3), leading to an extended Lagrange series:

$$\frac{D^\nu\{F(z)\}}{D\{f(z)\}^\nu} = \sum_{k=0}^{\infty} \{f(z)\}^k (k!)^{-1} \frac{D^{\nu+k}\{F(\zeta)\}}{D\{f(\zeta)\}^{\nu+k}}, \tag{23}$$

provided that the implicit differintegration appearing in the last factor of (23) can be evaluated. The extended Lagrange series (23), expressing the differintegration of an analytic function as an ascending power series of a suitable auxiliary analytic function $f(z)$, can be further generalized [3], [6] to the extended Teixeira series; the latter allows the dependent variable $F(z)$ to have an isolated singularity at $z = \zeta$, in which case the power series expansion involves descending as well as ascending powers of

the independent variable $f(z)$, e.g., the particular case $f(z)=z$ is the extended Laurent series (4)–(6). Our present aim is not to obtain the most general power series expansion, as that question is addressed elsewhere [19], [21], [4], [6]. Thus, we leave these remarks in passing and return to the rule of implicit differintegration, which is of use in connection with problems other than the extended Lagrange series (23).

If in Definition 1 of differintegration (1) the independent variable z is replaced by an analytic function $f(z)$, we obtain the integral

$$\frac{D^{\nu}\{F(z)\}}{D\{f(z)\}^{\nu}} \equiv \{\Gamma(1+\nu)/2\pi i\} \int_{\infty \exp\{i \arg (f(z))\}}^{(f(z)+)} \{f(\zeta)-f(z)\}^{-\nu-1} F(\zeta) f'(\zeta)\, d\zeta, \tag{24}$$

the evaluation of which leads to the rule of implicit differintegration.

PROPERTY 4. The implicit differintegration (24), with complex order ν of an analytic function $F(z)$, with regard to an auxiliary analytic function $f(z)$, at a point $\zeta = z$ that is not a zero of the latter $f'(z) \neq 0$, is given by

$$\frac{D^{\nu}\{F(z)\}}{D\{f(z)\}^{\nu}} = \lim_{\zeta \to z} \left(\frac{\partial}{\partial \zeta}\right)^{\nu} \{F(\zeta)\{(\zeta - z)/(f(\zeta)-f(z))\}^{\nu+1} f'(\zeta)\}. \tag{25}$$

Remark 12. The assumption that the auxiliary analytic function $f(\zeta)$ is not zero at $\zeta = z$ implies that the equation

$$f(\zeta)-f(z) = (\zeta - z) H(\zeta, z), \tag{26a}$$

$$H(z, z) \neq 0, \tag{26b}$$

has a single root $\zeta = z$, and thus the function

$$G(\zeta, z) \equiv F(\zeta)\{(f(\zeta)-f(z))/(\zeta - z)\}^{-\nu-1} f'(\zeta) \tag{27}$$

is also analytic at $\zeta = z$.

Proof. The function (27) may be substituted into (24), which gives

$$\frac{D^{\nu}\{F(z)\}}{D\{f(z)\}^{\nu}} = \{\Gamma(1+\nu)/2\pi i\} \int G(\zeta, z)(\zeta - z)^{-\nu-1}\, d\zeta = \lim_{\zeta \to z} \frac{\partial^{\nu}\{G(\zeta, z)\}}{\partial \zeta^{\nu}}, \tag{28}$$

allowing its evaluation by (1). The expression (28) with (27) leads to (25). □

We may apply Property 4 to the evaluation of the coefficients of the extended Lagrange series (23), viz., the following theorem.

THEOREM 7 (extended Lagrange series). *The differintegration* (24) *with complex order* ν *of an analytic function* $F(z)$, *with regard to an auxiliary analytic function* $f(z)$, *without zeros* $f'(z) \neq 0$, *can be expanded in an ascending power series of the latter* (23), *with coefficients given by* (25). *The series converges*: (i) *absolutely in the open region*:

$$D - \partial D \equiv \{z: |f(z)| < R\}; \tag{29}$$

(ii) *uniformly in the closed subregion*:

$$0 < \varepsilon < R\text{: } D_{\varepsilon} \equiv \{z: |f(z)| \leqq R - \varepsilon\} \subset D - \partial D, \tag{30}$$

where R *is the largest positive real number such that the region* D *excludes all singularities of* $F(z)$.

Proof. The only results not proved before concern the conditions of convergence, which are similar to those for the extended Taylor series in Theorem 3, replacing $f(z)=z-\zeta$, as suggested by a comparison of (23) and (3). □

To develop the rule of implicit differintegration (Property 4) further, we need the extended Leibnitz rule, in one of the forms [20], [22], [2], [4], that appear in the literature, viz., Property 5.

PROPERTY 5. The differintegration (1) of complex order ν of the product of two analytic functions $F(z)E(z)$, such that $F(z)$ and $F(z)E(z)$ satisfy the asymptotic condition (2), is given by the infinite chain rule:

$$\frac{D^{\nu}\{F(z)E(z)\}}{Dz^{\nu}}=\sum_{k=0}^{\infty}\binom{\nu}{k}E^{(k)}(z)\frac{D^{\nu+k}F}{Dz^{\nu+k}}, \tag{31}$$

$$\binom{\nu}{k}\equiv\Gamma(1+\nu)/\{k!\Gamma(1+\nu-k)\}. \tag{32}$$

Proof. A direct proof of the extended Leibnitz rule in the form (31) can be found elsewhere [5].

To apply the infinite chain rule (31) to (25), we split the term in curly brackets into two factors, namely, $F(\zeta)$ and $E(z,\zeta)$:

$$\frac{d^{\nu}\{F(z)\}}{d\{f(z)\}^{\nu}}=\lim_{\zeta\to z}\left(\frac{\partial}{\partial\zeta}\right)^{\nu}\{F(\zeta)E(z,\zeta)\}, \tag{33}$$

$$E(z,\zeta)\equiv f'(\zeta)\{(\zeta-z)/(f(\zeta)-f(z))\}^{\nu+1}, \tag{34}$$

to obtain Property 6.

PROPERTY 6. The differintegration (24), with complex order ν of an analytic function $F(z)$, with regard to an auxiliary analytic function $f(z)$, at a point z that is not a zero of the latter $f'(z)\neq 0$, is given by

$$\begin{aligned}\frac{D^{\nu}\{F(z)\}}{D\{f(z)\}^{\nu}}&=\sum_{k=0}^{\infty}\binom{\nu}{k}\frac{D^{k}F}{Dz^{k}}\frac{D^{\nu-k}E}{Dz^{\nu-k}}\\&=\sum_{k=0}^{\infty}\binom{\nu}{k}\frac{D^{k}E}{Dz^{k}}\frac{D^{\nu-k}F}{Dz^{\nu-k}},\end{aligned} \tag{35}$$

$$\frac{D^{\mu}E}{Dz^{\mu}}\equiv\lim_{\zeta\to z}\left(\frac{\partial}{\partial\zeta}\right)^{\mu}f'(\zeta)\{(\zeta-z)/(f(\zeta)-f(z))\}^{\nu+1}, \tag{36}$$

where $F(z)$, and $F(z)E(z,\zeta)$ are assumed (see (34)) to satisfy the asymptotic condition (3).

Proof. Substitute (31) into (33) to obtain (35), with (36) given by (34). □

The application of the rule (35) of implicit differintegration is facilitated by the following remark.

Remark 13. The series (35) terminates at $k=n$: (i) for $\nu=n$ a positive integer, i.e., an ordinary derivative of order n, or (ii) if one of the functions $f(z)$, $E(z,\zeta)$ has derivatives vanishing beyond the order n, i.e., is a polynomial.

The latter case (ii) can be illustrated by the implicit differintegration of a power $F(z)=z^{m}$, with a positive integral exponent m:

$$\frac{d^{\nu}(z^{m})}{d\{f(z)\}^{\nu}}=\sum_{k=0}^{m}\binom{\nu}{k}\{m!/(m-k)!\}z^{m-k}\frac{d^{\nu-k}E}{dz^{\nu-k}}; \tag{37}$$

in (37) we have used Riemann d^{ν} instead of Liouville D^{ν} differintegrations, since Properties 4–6 hold for the former [1], [2], as well as for the latter. Of the two series

(35), one may be simpler than the other, e.g., for the implicit differintegration of the logarithm:

$$\frac{d^\nu(\log z)}{d\{f(z)\}^\nu}=\log z\frac{d^\nu E}{dz^\nu}+\sum_{k=1}^{\infty}\{(-)^k/k\}\{\Gamma(1+\nu)/\Gamma(1+\nu-k)\}z^{-k}\frac{d^{\nu-k}E}{dz^{\nu-k}}. \tag{38}$$

Both in (37) and (38) the coefficients (36) still need to be calculated; an example is the case of implicit differintegration with regard to the square $f(z)=z^2$, away from the origin $f'(z)=2z\neq 0$, viz.,

$$\begin{aligned}\frac{d^{\nu-k}E}{dz^{\nu-k}}&=\lim_{\zeta\to z}\left(\frac{\partial}{\partial\zeta}\right)^{\nu-k}\{2\zeta(\zeta+z)^{-\nu-1}\}\\ &=\lim_{\zeta\to z}2\left\{\zeta\left(\frac{\partial}{\partial\zeta}\right)^{\nu-k}+(\nu-k)\left(\frac{\partial}{\partial\zeta}\right)^{\nu-k-1}\right\}(\zeta+z)^{-\nu-1}\\ &=\{\Gamma(1-\nu)/\Gamma(1+k-2\nu)\}(2z)^{k-2\nu}.\end{aligned} \tag{39}$$

Substituting (39) into (37) and (38), we obtain

$$\frac{d^\nu(z^m)}{d(z^2)^\nu}=\sum_{k=0}^{m}\binom{m}{k}C_{\nu,k}2^{k-2\nu}z^{m-2\nu}, \tag{40}$$

$$\frac{d^\nu(\log z)}{d(z^2)^\nu}=\log z\{\Gamma(1-\nu)/\Gamma(1-2\nu)\}(2z)^{-2\nu}+\sum_{k=1}^{\infty}\left\{\frac{(-)^k}{k}\right\}2^{k-2\nu}z^{-2\nu}C_{\nu,k}, \tag{41}$$

$$C_{\nu,k}\equiv\Gamma(1+\nu)\Gamma(1-\nu)/\Gamma(1+\nu-k)\Gamma(1+k-2\nu), \tag{42}$$

as worked-out examples of the implicit differintegration rule.

5. Discussion. The differintegration applied most often to special functions [11], [10], [2], [4] is the Riemann type, since the hypergeometric function and several of its particular cases involve branchpoints. The Liouville differintegration [17] is not suitable for these functions, but rather for those defined from analytic functions; an example is the Hermite function of complex order ν and variable z, which is defined [5] by the Liouville differintegration of the Gaussian function:

$$H_\nu(z)\equiv e^{i\pi\nu}\,e^{z^2}\frac{D^\nu(e^{-z^2})}{Dz^\nu}. \tag{43}$$

Substituting ν by $\nu+1$, and using the chain rule (31):

$$\begin{aligned}e^{i\pi(\nu+1)}\,e^{z^2}\left(\frac{D}{Dz}\right)^{\nu+1}e^{-z^2}&=e^{i\pi\nu}\,e^{z^2}\left(\frac{D}{Dz}\right)^{\nu}\{2z\,e^{-z^2}\}\\ &=e^{i\pi\nu}\,e^{z^2}\left\{2z\left(\frac{D}{Dz}\right)^{\nu}+2\nu\left(\frac{D}{Dz}\right)^{\nu-1}\right\}e^{-z^2},\end{aligned} \tag{44}$$

we obtain the recurrence formula

$$H_{\nu+1}(z)=2zH_\nu(z)-2\nu H_{\nu-1}(z). \tag{45}$$

Differentiating (43) with regard to z:

$$\left(\frac{D}{Dz}\right)e^{i\pi\nu}\,e^{z^2}\left(\frac{D}{Dz}\right)^{\nu}e^{-z^2}=e^{i\pi\nu}\,e^{z^2}\left\{2z\left(\frac{D}{Dz}\right)^{\nu}+\left(\frac{D}{Dz}\right)^{\nu+1}\right\}e^{-z^2}, \tag{46}$$

we obtain the derivation formula

$$\frac{D\{H_\nu(z)\}}{Dz} = 2zH_\nu(z) - H_{\nu+1}(z) = 2\nu H_{\nu-1}(z), \tag{47}$$

which was simplified using the recurrence formula (45).

Both the recurrence (45) and derivation (47) formulas hold for all complex values of ν and lead to

$$\begin{aligned}\frac{D^2\{H_\nu(z)\}}{Dz^2} &= \frac{D\{2zH_\nu(z)\}}{Dz} - \frac{D\{H_{\nu+1}(z)\}}{Dz} \\ &= 2H_\nu(z) + 2z\frac{D\{H_\nu(z)\}}{Dz} - 2(\nu+1)H_\nu(z),\end{aligned} \tag{48}$$

which is the differential equation satisfied by Hermite functions,

$$\left\{\frac{D^2}{Dz^2} - 2z\frac{D}{Dz} + 2\nu\right\} H_\nu(z) = 0. \tag{49}$$

Substituting (1) into (43), we obtain the integral representation of Hermite functions:

$$H_\nu(z) = \{\Gamma(1+\nu)/2\pi i\}\, e^{z^2} \int_{\infty \exp\{i \arg(z)\}}^{(z+)} (z-\zeta)^{-\nu-1}\, e^{-\zeta^2}\, d\zeta; \tag{50}$$

the change of variable $\eta = z - \zeta$ can be performed to move the branchpoint $\zeta = z$ of the integrand to the origin $\eta = 0$ of the η-plane:

$$H_\nu(z) = \{\Gamma(1+\nu)/2\pi i\} \int_{\infty \exp(i0)}^{(0+)} \eta^{-\nu-1}\, e^{-\eta^2+2\eta z}\, d\eta; \tag{51}$$

this can be interpreted again using (1) to show that the Hermite function is specified by the limit:

$$H_\nu(z) = \lim_{\eta \to 0} D^\nu\{\exp(-\eta^2 + 2\eta z)\}/D\eta^\nu. \tag{52}$$

Using the chain rule (31) once more:

$$\frac{D^\nu\{e^{-\eta^2}\, e^{2\eta z}\}}{D\eta^\nu} = e^{2\eta z} \sum_{k=0}^{\infty} \binom{\nu}{k} (2z)^k \frac{D^{\nu-k}(e^{-\eta^2})}{D\eta^{\nu-k}}, \tag{53}$$

in (52), we obtain the expansion of the Hermite function in power series:

$$H_\nu(z) = e^{-i\pi\nu} \sum_{k=0}^{\infty} \binom{\nu}{k} (-2z)^k H_{\nu-k}(0), \tag{54}$$

with coefficients involving its value at the origin, e.g., for $\nu = \eta$ a positive integer:

$$H_n(z) = (-)^n \sum_{k=0}^{n} \binom{n}{k} (-2z)^k H_{n-k}(0), \tag{55}$$

we have an identity for Hermite [9] polynomials.

We conclude the examples of differintegrations applied to Hermite functions with the deduction of an addition formula. The latter is derived from the definition (43):

$$H_\nu(z) = e^{i\pi\nu}\, e^{z^2} (D/Dz)^\nu \{e^{-az^2}\, e^{-(1-a)z^2}\}, \tag{56}$$

by applying the chain rule (31):

$$\left(\frac{D}{Dz}\right)^{\nu}\{e^{-az^2}\,e^{-(1-a)z^2}\}=\sum_{k=0}^{\infty}\binom{\nu}{k}\left(\frac{D}{Dz}\right)^{k}e^{-az^2}\left(\frac{D}{Dz}\right)^{\nu-k}e^{-(1-a)z^2}. \tag{57}$$

Introducing the new variables:

$$x\equiv z\sqrt{a}, \tag{58a}$$

$$y\equiv z\sqrt{1-a}, \tag{58b}$$

the factors in (57) become, respectively,

$$\left(\frac{D}{Dz}\right)^{k}e^{-az^2}=a^{k/2}\left(\frac{D}{Dx}\right)^{k}e^{-x^2}, \tag{59a}$$

$$\left(\frac{D}{Dz}\right)^{\nu-k}e^{-(1-a)z^2}=(1-a)^{(\nu-k)/2}\left(\frac{D}{Dy}\right)^{\nu-k}e^{-y^2}. \tag{59b}$$

Substitution of (59a), (59b) into (57) and (56) gives

$$\begin{aligned}H_{\nu}(z)=\sum_{k=0}^{\infty}\binom{\nu}{k}e^{i\pi k}\,e^{x^2}\left(\frac{D}{Dx}\right)^{\nu}e^{-x^2}a^{k/2}\\ \cdot(1-a)^{(\nu-k)/2}\,e^{i\pi(\nu-k)}\,e^{y^2}\left(\frac{D}{Dy}\right)^{\nu-k}e^{-y^2},\end{aligned} \tag{60}$$

where we have used (61a):

$$x^2+y^2=z^2, \tag{61a}$$

$$a=1/(1+y^2/x^2), \tag{61b}$$

which follows from (58a), (58b) together with (61b). Recalling (43), we may interpret (60), with (61a), (61b), as Property 7.

PROPERTY 7. The Hermite functions satisfy the addition theorem:

$$\begin{aligned}H_{\nu}(\sqrt{x^2+y^2})=\sum_{k=0}^{\infty}\binom{\nu}{k}(1+y^2/x^2)^{-k/2},\\ H_k(x)(1+x^2/y^2)^{-(\nu-k)/2}H_{\nu-k}(y),\end{aligned} \tag{62}$$

which terminates only at $k=n$, a positive integer, only for Hermite polynomials H_n.

EXISTENCE THEOREMS FOR BOUNDARY VALUE PROBLEMS FOR *n*th-ORDER NONLINEAR DIFFERENCE EQUATIONS*

JOHNNY HENDERSON†

Abstract. For the nth-order nonlinear difference equation $u(m+n)=f(m, u(m), u(m+1), \cdots, u(m+n-1))$, where $f:[a, +\infty)\times \mathbf{R}^n \to \mathbf{R}$ is continuous, and the equation $u_n = f(m, u_0, \cdots, u_{n-1})$ can be solved for u_0 as a continuous function of $u_1, \cdots, u_n$ for each $m \in [a, +\infty)$, it is shown that the uniqueness of solutions implies the existence of solutions for conjugate boundary value problems on $[a, +\infty)$. Shooting methods are used in conjunction with an induction.

Key words. nonlinear difference equation, boundary value problem, uniqueness implies existence

AMS(MOS) subject classifications. 34B10, 34B15, 39A10, 39A12

1. Introduction. For $a \in \mathbf{R}$, let the interval $[a, +\infty)=\{a, a+1, a+2, \cdots\}$, and if $b=a+m$, for some $m \in \mathbf{N}$, let the closed interval $[a, b]=\{a, a+1, \cdots, b\}$, and let the intervals $[a, b)$, $(a, b]$, and (a, b) denote the analogous discrete sets. In this paper, we will be concerned with uniqueness of solutions implying the existence of solutions of certain boundary value problems for the nth-order nonlinear difference equation

$$u(m+n)=f(m, u(m), u(m+1), \cdots, u(m+n-1)), \qquad n \geqq 2, \tag{1}$$

where

(A) $f:[a, +\infty)\times \mathbf{R}^n \to \mathbf{R}$ is continuous and the equation $u_n = f(m, u_0, \cdots, u_{n-1})$ can be solved for u_0 as a continuous function of $u_1, \cdots, u_n$ for each $m \in [a, +\infty)$.

We remark here that (A) implies (1) is an nth-order difference equation on any subinterval of $[a, +\infty)$, that solutions of initial value problems for (1) are unique and exist on $[a, +\infty)$, and that solutions of (1) depend continuously on initial conditions.

Recently, much research activity has focused on the existence of solutions of boundary value problems for finite difference equations. Much of this activity has been motivated by Hartman's landmark paper [18] and has been devoted to analogues of results for boundary value problems for ordinary differential equations. In particular, Ahlbrandt and Hooker [7]-[8], Eloe [11]-[13], Hankerson [14], and Peterson [25]-[28] have published a number of results concerning the disconjugacy or disfocality of linear difference equations, whereas other papers by Ahlbrandt and Hooker [6], Hankerson and Peterson [15]-[16], Hooker et al. [19]-[22], Patula [24], and Smith and Taylor [31] have dealt with oscillation and nonoscillation of linear difference equations. Moreover, in papers by Agarwal [1]-[4], Eloe [9]-[10], Hankerson [14], Peterson [29], and Rodriguez [30], questions have been addressed dealing with boundary value problems for the nonlinear difference equation (1).

In this work, the types of boundary value problems for (1), for which we address the question of uniqueness of solutions implying the existence of solutions, are analogous in some sense to those known as conjugate problems for ordinary differential equations.

DEFINITION. Given $m_1 \in [a, +\infty)$ and $m_2, \cdots, m_n \in \mathbf{N}$, let $s_1, \cdots, s_n \in [a, +\infty)$ be defined by $s_1 = m_1$ and $s_i = s_{i-1} + m_i$, $2 \leqq i \leqq n$. A boundary value problem for (1) satisfying the conditions

$$u(s_i) = y_i, \qquad 1 \leqq i \leqq n, \tag{2}$$

* Received by the editors July 20, 1987; accepted for publication (in revised form) June 1, 1988.
† Department of Algebra, Combinatorics and Analysis, Auburn University, Auburn, Alabama 36849.

where $y_i \in \mathbf{R}$, $1 \leqq i \leqq n$, will be called an $(m_1, \cdots, m_n)$ *conjugate boundary value problem for* (1). (In the case when $m_i = 1$, $2 \leqq i \leqq n$, the problem becomes an initial value problem for (1).)

For $(m_1, \cdots, m_n)$ conjugate boundary value problems for (1), our main result is motivated by a theorem for conjugate boundary value problems for ordinary differential equations proved by Hartman [17] and Klaasen [23].

We will use some of the terminology introduced by Hartman [18] and employed in many of the above-cited papers dealing with difference equations. For a function $u : [a, +\infty) \to \mathbf{R}$, Hartman defined $m_0 \in [a, +\infty)$, in the case that $m_0 = a$, to be a *node* of u if $u(a) = 0$, and $m_0 > a$ to be a *node* of u if $u(m_0) = 0$ or $u(m_0 - 1)u(m_0) < 0$. Moreover, Hartman defined $m_0 = a$ to be a *generalized zero* of u if $u(a) = 0$, and $m_0 > a$ to be a *generalized zero* of u if $u(m_0) = 0$ or there is an integer $j \geqq 1$ such that $(-1)^j u(m_0 - j)u(m_0) > 0$ and if $j > 1$, $u(m_0 - j + 1) = \cdots = u(m_0 - 1) = 0$. (Note that if m_0 is a node of u, then m_0 is a generalized zero of u.)

In view of this terminology, our uniqueness assumption on $(m_1, \cdots, m_n)$ conjugate boundary value problems for (1) takes the following form:

(B) Given $m_1 \in [a, +\infty)$ and $m_2, \cdots, m_n \in \mathbf{N}$, if $s_1 = m_1$ and $s_i = s_{i-1} + m_i$, $2 \leqq i \leqq n$, and if $u(m)$ and $v(m)$ are solutions of (1) such that $u(s_1) = v(s_1)$ and $u(m) - v(m)$ has a generalized zero at s_i, $2 \leqq i \leqq n$, then it follows that $u(m) = v(m)$ on $[s_1, s_n]$ (hence on $[a, +\infty)$).

In § 2, we will state for convenience and reference some theorems concerning continuous dependence of solutions of (1) on initial and boundary conditions. Then, in § 3, we prove that under assumptions (A) and (B), each $(m_1, \cdots, m_n)$ conjugate boundary value problem for (1) has a unique solution on $[a, +\infty)$. The proof employs shooting methods in conjunction with an induction on the indices $m_2, \cdots, m_n$.

2. Continuous dependence. In this section, we will state standard theorems concerning the continuous dependence of solutions of initial value problems and $(m_1, \cdots, m_n)$ conjugate boundary value problems for (1). We state these results for convenience and reference, and hence will eliminate repeating them later.

Our first theorem follows immediately from condition (A).

THEOREM 1. *Assume that condition* (A) *is satisfied. If there exist a sequence* $\{y_k(m)\}$ *of solutions of* (1), *an interval* $[m_0, m_0 + n - 1] \subset [a, +\infty)$, *and an* $M > 0$ *such that* $|y_k(m)| \leqq M$, *for all* $m \in [m_0, m_0 + n - 1]$, *for all* $k \in \mathbf{N}$, *then there exists a subsequence* $\{y_{k_j}(m)\}$ *that converges pointwise on* $[a, +\infty)$ *to a solution of* (1).

In turn it follows that if (B) is also assumed, then the continuous dependence of solutions on initial conditions, coupled with an application of the Brouwer Theorem on the invariance of domain, imply that solutions of conjugate problems depend continuously on boundary conditions; for a typical argument with difference equations, see [14].

THEOREM 2. *Assume that with respect to* (1), *conditions* (A) *and* (B) *are satisfied. Given a solution* $u(m)$ *of* (1) *on* $[a, +\infty)$, *points* $s_1 < s_2 < \cdots < s_n$ *belonging to* $[a, +\infty)$, *an interval* $[s_1, b]$, *where* $b \geqq s_n$, *and* $\varepsilon > 0$, *there exists* $\delta(\varepsilon, [s_1, b]) > 0$ *such that, if* $|u(s_i) - y_i| < \delta$, $1 \leqq i \leqq n$, *then there exists a solution* $v(m)$ *of* (1) *satisfying* $v(s_i) = y_i$, $1 \leqq i \leqq n$, *and* $|v(m) - u(m)| < \varepsilon$, *for all* $m \in [s_1, b]$.

From Theorem 2, we can state a theorem similar to Theorem 1.

THEOREM 3. *Assume that* (A) *and* (B) *are satisfied and suppose that, given* $m_1 \in [a, +\infty)$ *and for some* $m_2, \cdots, m_n \in N$, *there exist unique solutions of* (1), (2). *Let* s_i, $1 \leqq i \leqq n$, *be corresponding points in* $[a, +\infty)$. *If there exist a sequence* $\{y_k(m)\}$ *of solutions of* (1) *and an* $M > 0$ *such that* $|y_k(s_i)| \leqq M$, $1 \leqq i \leqq n$, *for all* $k \in N$, *then there exists a*

subsequence $\{y_{k_j}(m)\}$ *that converges pointwise on* $[a, +\infty)$. *In particular, for this subsequence, if* $\lim_j y_{k_j}(s_i) = y_i$, $1 \leqq i \leqq n$, *then* $\{y_{k_j}(m)\}$ *converges pointwise on* $[a, +\infty)$ *to the solution of the* $(m_1, \cdots, m_n)$ *conjugate boundary value problem for* (1) *satisfying*

$$y(s_i) = y_i, \qquad 1 \leqq i \leqq n.$$

3. Uniqueness implies existence. In this section, we prove that hypotheses (A) and (B) imply the existence of solutions of $(m_1, \cdots, m_n)$ conjugate boundary value problems for (1). The method of shooting is employed in conjunction with an induction on $m_2, \cdots, m_n$. Shooting methods, frequently paired with comparison results for uniqueness, have been used by Agarwal [4], Hankerson [14], and Peterson [29] in obtaining the existence of solutions of two-point problems for (1). For linear difference equations, results appear in [5] where shooting methods are used for multipoint boundary value problems.

The theorem we present here is analogous to the uniqueness implies existence result that Hartman [17] and Klaasen [23] proved for conjugate boundary value problems for ordinary differential equations.

To better illustrate the inductive pattern used with the shooting method in the proof, we will specifically detail the inductive steps on the indices m_{n-2}, m_{n-1}, m_n. Then, the general inductive step is outlined in the latter part of the proof.

THEOREM 4. *Assume that with respect to* (1), *conditions* (A) *and* (B) *are satisfied. Then given* $m_1 \in [a, +\infty)$ *and* $m_2, \cdots, m_n \in N$, *each* $(m_1, \cdots, m_n)$ *conjugate boundary value problem for* (1) *has a unique solution on* $[a, +\infty)$.

Proof. We remark first that the uniqueness of all such solutions follows from (B). As stated above, the proof is by induction on $m_2, \cdots, m_n$, and throughout the proof, let $y_i \in R$, $1 \leqq i \leqq n$, be given.

To begin, let $m_1 \in [a, +\infty)$ be given, let $m_2 = \cdots = m_n = 1$, and let $s_1 = m_1$ and $s_i = s_{i-1} + m_i$, $2 \leqq i \leqq n$. From the existence of unique solutions of initial value problems for (1), it follows that there exists a unique solution $u(m)$ of (1) on $[a, +\infty)$ satisfying

$$u(s_i) = y_i, \qquad 1 \leqq i \leqq n.$$

Assume now that $m_n > 1$ and that, given $m_1 \in [a, +\infty)$ and $m_2 = \cdots = m_{n-1} = 1$, there exists a unique solution of each $(m_1, 1, \cdots, 1, h)$ conjugate boundary value problem, where $1 \leqq h < m_n$, for (1) on $[a, +\infty)$.

Under this assumption, let $m_1 \in [a, +\infty)$ be given, let $m_2 = \cdots = m_{n-1} = 1$, let $s_1 = m_1$, $s_i = s_{i-1} + m_i$, $2 \leqq i \leqq n$, and let $z_1(m)$ be the solution (given by the induction hypotheses), of the $(m_1, 1, \cdots, 1, m_n - 1)$ conjugate boundary value problem for (1) satisfying

$$z_1(s_i) = y_i, \qquad 1 \leqq i \leqq n-1,$$
$$z_1(s_n - 1) = 0.$$

Now define $S_1 = \{r \in \mathbf{R} \mid$ there is a solution $y(m)$ of (1) satisfying $y(s_i) = z_1(s_i)$, $1 \leqq i \leqq n-1$, and $y(s_n) = r\}$. Since $z_1(s_n) \in S_1$, S_1 is nonempty. Moreover, it follows from Theorem 2 that S_1 is an open subset of $\mathbf{R}$.

We claim that S_1 is also a closed subset of $\mathbf{R}$. Assuming the claim is false, it follows that there exist $r_0 \in \bar{S}_1 \backslash S_1$ and a strictly monotone sequence $\{r_k\} \subset S_1$ such that $\lim_k r_k = r_0$. We may assume without loss of generality that $r_k \uparrow r_0$. For each $k \in \mathbf{N}$, let $y_k(m)$ denote the corresponding solution of (1) satisfying

$$y_k(s_i) = z_1(s_i), \qquad 1 \leqq i \leqq n-1,$$
$$y_k(s_n) = r_k.$$

It follows from (B) that $y_k(m) < y_{k+1}(m)$ on $(s_{n-1}, +\infty)$, for all $k \in \mathbf{N}$. Furthermore, the induction hypothesis implies the existence of unique solutions of $(m_1, 1, \cdots, 1, m_n - 1)$ boundary value problems for (1), which, when coupled with Theorem 3 along with $r_0 \notin S$, implies that $y_k(s_n - 1) \uparrow +\infty$, as $k \to +\infty$. Moreover, by Theorem 1, there exists $m_0 \in (s_n, s_n + n - 1]$ such that $y_k(m_0) \uparrow +\infty$, as $k \to +\infty$.

Now let $u(m)$ denote the solution at the points $s_2, \cdots, s_{n-1}, s_{n-1}+1, s_n$ of the $(m_1+1, 1, \cdots, 1, m_n - 1)$ conjugate boundary value problem for (1) satisfying

$$u(s_i) = z_1(s_i), \qquad 2 \leqq i \leqq n-1,$$
$$u(s_{n-1}+1) = 0,$$
$$u(s_n) = r_0.$$

Since $y_k(s_n - 1) \uparrow +\infty$ and $y_k(m_0) \uparrow +\infty$, whereas $y_k(s_n) = r_k < r_0 = u(s_n)$, for all k, it follows that, for some $K \in \mathbf{N}$, $u(m) - y_K(m)$ has a generalized zero at s_n and also a generalized zero (or zero) at some $n_0 \in (s_n, m_0]$. Furthermore, $u(s_i) - y_K(s_i) = 0$, $2 \leqq i \leqq n-1$, and hence from (B), $u(m) = y_K(m)$ on $[a, +\infty)$, a contradiction.

Hence S_1 is also closed and consequently $S_1 = \mathbf{R}$. Choosing $y_n \in S_1$, it follows that there exists a solution $y(m)$ of (1) satisfying

$$y(s_i) = y_i, \qquad 1 \leqq i \leqq n.$$

In particular, given $m_1 \in [a, +\infty)$, $m_2 = \cdots = m_{n-1} = 1$, and $m_n \geqq 1$, each $(m_1, 1, \cdots, 1, m_n)$ conjugate boundary value problem for (1) has a unique solution on $[a, +\infty)$.

For the next part of the proof we induct on m_{n-1}. For this part, we now assume that $m_{n-1} > 1$ and that given $m_1 \in [a, +\infty)$, $m_2 = \cdots = m_{n-2} = 1$, and $m_n \geqq 1$, there exists a unique solution of each $(m_1, 1, \cdots, 1, l, m_n)$ conjugate boundary value problem, where $1 \leqq l < m_{n-1}$, for (1) on $[a, +\infty)$.

With that assumption, let $m_1 \in [a, +\infty)$ be given, let $m_2 = \cdots = m_{n-2} = m_n = 1$, let $s_1 = m_1$, $s_i = s_{i-1} + m_i$, $2 \leqq i \leqq n$, and let $z_2(m)$ be the solution at $s_1, \cdots, s_{n-2}, s_{n-1} - 1$, s_{n-1} of the $(m_1, 1, \cdots, 1, m_{n-1} - 1, 1)$ conjugate boundary value problem for (1) satisfying

$$z_2(s_i) = y_i, \qquad 1 \leqq i \leqq n-2,$$
$$z_2(s_{n-1} - 1) = 0,$$
$$z_2(s_{n-1}) = y_{n-1}.$$

This time, define $S_2 = \{r \in \mathbf{R} \mid$ there is a solution $y(m)$ of (1) satisfying $y(s_i) = z_2(s_i)$, $1 \leqq i \leqq n-1$, and $y(s_n) = r\}$. Again, since $z_2(s_n) \in S_2$, S_2 is nonempty. Also, Theorem 2 implies that S_2 is an open subset of $\mathbf{R}$.

We now claim that S_2 is also closed. Assuming that S_2 is not closed, it follows that there exist $r_0 \in \bar{S}_2 \backslash S_2$ and a strictly monotone sequence $\{r_k\} \subset S_2$ such that $\lim_k r_k = r_0$. We may assume again that $r_k \uparrow r_0$ and as before, let $y_k(m)$ denote the corresponding solution of (1) satisfying

$$y_k(s_i) = z_2(s_i), \qquad 1 \leqq i \leqq n-1,$$
$$y_k(s_n) = r_k.$$

It follows from (B) that $y_k(m) > y_{k+1}(m)$ on (s_{n-2}, s_{n-1}) and $y_k(m) < y_{k+1}(m)$ on $[s_n, +\infty)$, for all $k \in \mathbf{N}$. Since $r_0 \notin S_2$ and since there exist unique solutions of $(m_1, 1, \cdots, 1, m_{n-1} - 1, 1)$ problems, Theorem 3 implies that $y_k(s_{n-1} - 1) \downarrow -\infty$, as $k \to +\infty$, and Theorem 1 implies that there exists $m_0 \in (s_n, s_n + n - 1]$ such that $y_k(m_0) \uparrow +\infty$, as $k \to +\infty$.

Let $u(m)$ be the solution at the points $s_2, \cdots, s_{n-2}, s_{n-2}+1, s_{n-1}, s_n$ of the $(m_1+1, 1, \cdots, 1, 1, m_{n-1}-1, 1)$ conjugate problem for (1) satisfying

$$u(s_i) = z_2(s_i), \qquad 2 \leqq i \leqq n-2,$$
$$u(s_{n-2}+1) = 0,$$
$$u(s_{n-1}) = z_2(s_{n-1}),$$
$$u(s_n) = r_0.$$

Since $y_k(s_{n-1}-1)\downarrow -\infty$, whereas $u(s_{n-1}) - y_k(s_{n-1}) = 0$ and $u(s_n) - y_k(s_n) > 0$ for all $k \in \mathbf{N}$, it follows that for all k sufficiently large, $u(m) - y_k(m)$ has a generalized zero at s_n. Since $y_k(m_0)\uparrow +\infty$, there exists $K \in \mathbf{N}$ such that $u(m) - y_K(m)$ has a generalized zero at s_n and a generalized zero (or zero) at some $n_0 \in (s_n, m_0]$. We also have that $u(s_i) - y_K(s_i) = 0$, $2 \leqq i \leqq n-1$, and (B) implies that $u(m) = y_K(m)$ on $[a, +\infty)$; again, this is a contradiction.

Thus, S_2 is closed and $S_2 = R$. Choosing $y_n \in S_2$, it follows that there exists a solution $y(m)$ of (1) satisfying

$$y(s_i) = y_i, \qquad 1 \leqq i \leqq n.$$

In summary, given $m_1 \in [a, +\infty)$, $m_2 = \cdots = m_{n-2} = m_n = 1$, each $(m_1, 1, \cdots, 1, m_{n-1}, 1)$ conjugate boundary value problem for (1) has a unique solution on $[a, +\infty)$.

Still assuming the induction hypotheses associated with $m_{n-1} > 1$, we assume in addition that $m_n > 1$ and that given $m_1 \in [a, +\infty)$ and $m_2 = \cdots = m_{n-2} = 1$, there exists a unique solution of each $(m_1, 1, \cdots, 1, m_{n-1}, h)$ conjugate boundary value problem, where $1 \leqq h < m_n$, for (1) on $[a, +\infty)$.

With this latter assumption, let $m_1 \in [a, +\infty)$ be given, let $m_2 = \cdots = m_{n-2} = 1$, let $s_1, \cdots, s_n$ be defined in the usual way, and let $z_3(m)$ be the solution at the points $s_1, \cdots, s_{n-2}, s_{n-1}, s_n - 1$ of the $(m_1, 1, \cdots, 1, m_{n-1}, m_n - 1)$ conjugate problem for (1) satisfying

$$z_3(s_i) = y_i, \qquad 1 \leqq i \leqq n-1,$$
$$z_3(s_n - 1) = 0.$$

Define $S_3 = \{r \in \mathbf{R} \mid$ there is a solution $y(m)$ of (1) satisfying $y(s_i) = z_3(s_i)$, $1 \leqq i \leqq n-1$, and $y(s_n) = r\}$. As before S_3 is a nonempty open subset of $\mathbf{R}$, and we claim that S_3 is also closed. Assuming again that the claim is false, let $r_0 \in \bar{S}_3 \backslash S_3$ and $\{r_k\} \subset S_3$, with $r_k \uparrow r_0$, be as in the previous considerations, and let $y_k(m)$ denote the solution of (1) satisfying

$$y_k(s_i) = z_3(s_i), \qquad 1 \leqq i \leqq n-1,$$
$$y_k(s_n) = r_k.$$

Condition (B) implies that $y_k(m) < y_{k+1}(m)$ on $(s_{n-1}, +\infty)$, for all $k \in \mathbf{N}$, and because of the existence of unique solutions of $(m_1, 1, \cdots, 1, m_{n-1}, m_n - 1)$ problems for (1) along with $r_0 \notin S_3$, Theorem 3 implies $y_k(s_n - 1)\uparrow +\infty$, as $k \to +\infty$, and Theorem 1 implies that for some $m_0 \in (s_n, s_n + n - 1]$, $y_k(m_0)\uparrow +\infty$, as $k \to +\infty$.

Now, let $u(m)$ be the solution at $s_2, \cdots, s_{n-2}, s_{n-2}+1, s_{n-1}, s_n$ of the $(m_1+1, 1, \cdots, 1, 1, m_{n-1}-1, m_n)$ boundary value problem for (1) satisfying

$$u(s_i) = z_3(s_i), \qquad 2 \leqq i \leqq n-2,$$
$$u(s_{n-2}+1) = 0,$$
$$u(s_{n-1}) = z_3(s_{n-1}),$$
$$u(s_n) = r_0.$$

Such a solution $u(m)$ exists by the primary induction hypotheses on m_{n-1} in this section of the proof. Because of the unbounded conditions on $\{y_k(s_n-1)\}$ and $\{y_k(m_0)\}$, while $u(s_n)>y_k(s_n)$, for all $k\in\mathbf{N}$, there exists $K\in\mathbf{N}$ such that $u(m)-y_K(m)$ has a generalized zero at s_n and a generalized zero at some $n_0\in(s_n, m_0]$. Moreover, $u(s_i)-y_K(s_i)=0$, $2\leqq i\leqq n-1$, from which it follows that $u(m)=y_K(m)$ on $[a,+\infty)$, a contradiction.

Consequently, S_3 is closed, $S_3=\mathbf{R}$, and choosing $y_n\in S_3$, the corresponding solution $y(m)$ of (1) satisfying $y(s_n)=y_n$ is the desired solution. In particular, given $m_1\in[a,+\infty)$, $m_2=\cdots=m_{n-2}=1$, and $m_n\geqq 1$, each $(m_1,1,\cdots,1,m_{n-1},m_n)$ conjugate boundary value problem for (1) has a unique solution on $[a,+\infty)$.

This completes the induction on m_{n-1}. That is, given $m_1\in[a,+\infty)$, $m_2=\cdots=m_{n-2}=1$, and m_{n-1}, $m_n\geqq 1$, each $(m_1,1,\cdots,1,m_{n-1},m_n)$ conjugate boundary value problem for (1) has a unique solution on $[a,+\infty)$.

To illustrate the pattern of the induction better, we will give some of the details of the four steps involved in the induction on m_{n-2}.

For this section of the proof, our outstanding assumption is that $m_{n-2}>1$, and that given $m_1\in[a,+\infty)$, $m_2=\cdots=m_{n-3}=1$, and m_{n-1}, $m_n\geqq 1$, there exists a unique solution of each $(m_1,1,\cdots,1,k,m_{n-1},m_n)$ conjugate boundary value problem, where $1\leqq k<m_{n-2}$, for (1) on $[a,+\infty)$. Under that assumption, we will be concerned with solutions of $(m_1,1,\cdots,1,m_{n-2},1,1)$ followed by $(m_1,1,\cdots,1,m_{n-2},1,m_n)$, $m_n>1$, followed by $(m_1,1,\cdots,1,m_{n-2},m_{n-1},1)$, $m_{n-1}>1$, followed by $(m_1,1,\cdots,1,m_{n-2},m_{n-1},m_n)$, m_{n-1}, $m_n>1$, boundary value problems for (1).

Let $m_1\in[a,+\infty)$, let $m_2=\cdots=m_{n-3}=m_{n-1}=m_n=1$, let s_i, $1\leqq i\leqq n$, be as usual, and let $z_4(m)$ be the solution of the $(m_1,1,\cdots,1,m_{n-2}-1,1,1)$ conjugate boundary value problem for (1) satisfying

$$z_4(s_i)=y_i,\qquad 1\leqq i\leqq n-3,$$
$$z_4(s_{n-2}-1)=0,$$
$$z_4(s_i)=y_i,\qquad i=n-2,n-1.$$

Defining $S_4=\{r\in\mathbf{R}\,|\,$ there is a solution $y(m)$ of (1) satisfying $y(s_i)=z_4(s_i)$, $1\leqq i\leqq n-1$, and $y(s_n)=r\}$, S_4 is nonempty and open.

If we assume S_4 is not closed, then let r_0 and $\{r_k\}$, with $r_k\uparrow r_0$, be as usual and let $y_k(m)$ denote the corresponding solution of (1). It follows in this case that $y_k(s_{n-2}-1)\uparrow+\infty$, as $k\to+\infty$, and for some $m_0\in(s_n, s_n+n-1]$, $y_k(m_0)\uparrow+\infty$, as $k\to+\infty$.

Denoting by $u(m)$ the solution of the $(m_1+1,1,\cdots,1,1,m_{n-2}-1,1,1)$ problem for (1) satisfying

$$u(s_i)=y_i,\qquad 2\leqq i\leqq n-3,$$
$$u(s_{n-3}+1)=0,$$
$$u(s_i)=y_i,\qquad i=n-2,n-1,$$
$$u(s_n)=r_0,$$

it follows that for some $K\in\mathbf{N}$, $u(m)-y_K(m)$ has a generalized zero at s_n, a generalized zero at some $n_0\in(s_n, m_0]$, and zeros at s_i, $2\leqq i\leqq n-1$. Again, we contradict (B), and hence S_4 is closed. Select $y_n\in S_4$ and the corresponding solution is the desired solution of the $(m_1,1,\cdots,1,m_{n-2},1,1)$ problem for (1).

In addition to our assumptions on $m_{n-2}>1$, we assume that $m_n>1$ and that given $m_1\in[a,+\infty)$, $m_2=\cdots=m_{n-3}=m_{n-1}=1$, each $(m_1,1,\cdots,1,m_{n-2},1,h)$ conjugate boundary value problem, where $1\leqq h<m_n$, for (1) has a unique solution on $[a,+\infty)$.

Given $m_1 \in [a, +\infty)$ and $m_2 = \cdots = m_{n-3} = m_{n-1} = 1$ with s_i, $1 \leqq i \leqq n$, as usual, let $z_5(m)$ be the solution of the $(m_1, 1, \cdots, 1, m_{n-2}, 1, m_n - 1)$ problem for (1) satisfying

$$z_5(s_i) = y_i, \qquad 1 \leqq i \leqq n-1,$$
$$z_5(s_n - 1) = 0.$$

Defining S_5 in the standard way, S_5 is nonempty and open.

If we assume S_5 is not closed, then let r_0 and $\{r_k\}$, with $r_k \uparrow r_0$, be as usual, and let $y_k(m)$ be the appropriate solution of (1). By the existence of unique solutions of $(m_1, 1, \cdots, 1, m_{n-2}, 1, m_n - 1)$ problems for (1), we have that $y_k(s_n - 1) \uparrow +\infty$. Also, $y_k(m_0) \uparrow +\infty$, where m_0 is as usual. In this case, now let $u(m)$ be the solution of the $(m_1 + 1, 1, \cdots, 1, m_{n-2} - 1, 1, m_n)$ problem for (1) satisfying

$$u(s_i) = z_5(s_i), \qquad 2 \leqq i \leqq n-3,$$
$$u(s_{n-3} + 1) = 0,$$
$$u(s_i) = z_5(s_i), \qquad i = n-2, n-1,$$
$$u(s_n) = r_0.$$

In this case, there exists $K \in \mathbf{N}$ such that $u(m) - y_K(m)$ has a generalized zero at s_n, a generalized zero at some $n_0 \in (s_n, m_0]$, and zeros at s_i, $2 \leqq i \leqq n-1$, the usual contradiction.

Thus S_5 is closed, and we conclude the existence of unique solutions of $(m_1, 1, \cdots, 1, m_{n-2}, 1, m_n)$ conjugate boundary value problems for (1) on $[a, +\infty)$.

In addition to the primary induction hypotheses on m_{n-2}, we assume now that $m_{n-1} > 1$ and that given $m_1 \in [a, +\infty)$, $m_2 = \cdots = m_{n-3} = 1$, and $m_n \geqq 1$, there exists a unique solution of each $(m_1, 1, \cdots, 1, m_{n-2}, l, m_n)$ conjugate boundary value problem, where $1 \leqq l < m_{n-1}$, for (1) on $[a, +\infty)$.

In this case, we let $m_1 \in [a, +\infty)$, $m_2 = \cdots = m_{n-3} = m_n = 1$, and we let $z_6(m)$ be the solution of the $(m_1, 1, \cdots, 1, m_{n-2}, m_{n-1} - 1, 1)$ problem for (1) satisfying

$$z_6(s_i) = y_i, \qquad 1 \leqq i \leqq n-2,$$
$$z_6(s_{n-1} - 1) = 0,$$
$$z_6(s_{n-1}) = y_{n-1}.$$

The corresponding set S_6 will be nonempty and open. Repeating the pattern, we assume S_6 is not closed and make the usual arguments using r_0, $\{r_k\}$, and the corresponding solutions of (1). In this case $y_k(s_{n-1} - 1) \downarrow -\infty$, as $k \to +\infty$, and for some $m_0 \in (s_n, s_n + n - 1]$, $y_k(m_0) \uparrow +\infty$, as $k \to +\infty$.

With $u(m)$ the solution at $s_2, \cdots, s_{n-3}, s_{n-3} + 1, s_{n-2}, s_{n-1}, s_n$ of the $(m_1 + 1, 1, \cdots, 1, m_{n-2} - 1, m_{n-1}, 1)$ boundary value problem for (1) satisfying

$$u(s_i) = z_6(s_i), \qquad 2 \leqq i \leqq n-3,$$
$$u(s_{n-3} + 1) = 0,$$
$$u(s_i) = z_6(s_i), \qquad i = n-2, n-1,$$
$$u(s_n) = r_0,$$

it follows that for some $K \in \mathbf{N}$, $u(m) - y_K(m)$ has a generalized zero at s_n, a generalized zero at some $n_0 \in (s_n, m_0]$, and zeros at s_i, $2 \leqq i \leqq n-1$. This is a contradiction to (B), and hence S_6 is closed; consequently each $(m_1, 1, \cdots, 1, m_{n-2}, m_{n-1}, 1)$ problem for (1) has a unique solution.

For the final step under the primary induction hypotheses on $m_{n-2}>1$ and the induction hypotheses on $m_{n-1}>1$, assume in addition that $m_n>1$ and that given $m_1\in[a,+\infty)$ and $m_2=\cdots=m_{n-3}=1$, there exists a unique solution of each $(m_1,1,\cdots,1,m_{n-2},m_{n-1},h)$ conjugate boundary value problem, where $1\leqq h<m_n$, for (1) on [a, $+\infty$).

To complete the argument, let $m_1\in[a,+\infty)$ be given, let $m_2=\cdots=m_{n-3}=1$, and let $z_7(m)$ be the solution of the $(m_1,1,\cdots,1,m_{n-2},m_{n-1},m_n-1)$ boundary value problem for (1) satisfying

$$z_7(s_i)=y_i,\qquad 1\leqq i\leqq n-1$$
$$z_7(s_n-1)=0.$$

Defining the nonempty open set S_7 in our standard manner, and making the usual assumption that S_7 is not closed, let r_0, $\{r_k\}$, and $y_k(m)$ be the appropriate values and solutions. We can argue that $y_k(s_n-1)\uparrow+\infty$ and $y_k(m_0)\uparrow+\infty$, for some $m_0\in(s_n,s_n+n-1]$. If $u(m)$ is the solution of the $(m_1+1,1,\cdots,1,m_{n-2}-1,m_{n-1},m_n)$ conjugate boundary value problem for (1) satisfying

$$u(s_i)=z_7(s_i),\qquad 2\leqq i\leqq n-3,$$
$$u(s_{n-3}+1)=0,$$
$$u(s_i)=z_7(s_i),\qquad i=n-2,n-1,$$
$$u(s_n)=r_0,$$

then there exists $K\in\mathbf{N}$ such that $u(m)-y_K(m)$ has a generalized zero at s_n, a generalized zero at some $n_0\in(s_n,m_0]$, and zeros at s_i, $2\leqq i\leqq n-1$. This contradicts (B); hence S_7 is closed, and as in each of the above cases, the $(m_1,1,\cdots,1,m_{n-2},m_{n-1},m_n)$ problem has a unique solution.

That concludes the induction on m_{n-2}; in particular, given $m_1\in[a,+\infty)$, $m_2=\cdots=m_{n-3}=1$, and $m_{n-2},m_{n-1},m_n\geqq 1$, each $(m_1,1,\cdots,1,m_{n-2},m_{n-1},m_n)$ conjugate boundary value problem for (1) has a unique solution on $[a,+\infty)$.

Although our above arguments exhibit the entire pattern for the induction scheme in obtaining solutions of the boundary value problems, for completeness we will include some of the details involved in the general induction step. To that end, assume that $2\leqq p\leqq n-3$, that $m_p>1$, and that given $m_1\in[a,+\infty)$, $m_2=\cdots=m_{p-1}=1$, and $m_{p+1},\cdots,m_n\geqq 1$, there exists a unique solution of each $(m_1,1,\cdots,1,k,m_{p+1},\cdots,m_n)$ conjugate boundary value problem, where $1\leqq k<m_p$, for (1) on $[a,+\infty)$.

Under that assumption we will be concerned with establishing the existence of solutions of $(m_1,1,\cdots,1,m_p,m_{p+1},\cdots,m_n)$ problems by proceeding through 2^{n-p} inductive steps, wherein we induct on $m_n,m_{n-1},\cdots,m_{p+1}$, following the pattern in the above parts of this proof. Now for each one of these 2^{n-p} steps, there exist natural numbers $1\leqq j_1<j_2<\cdots<j_s\leqq n-p$, such that we are concerned with the $(2^{j_s}+2^{j_{s-1}}+\cdots+2^{j_2}+2^{j_1})$st inductive step or with the $(2^{j_s}+2^{j_{s-1}}+\cdots+2^{j_2}+2^{j_1}+1)$st inductive step.

(a) In the case of the $(2^{j_s}+2^{j_{s-1}}+\cdots+2^{j_2}+2^{j_1})$st inductive step, our concern is with showing the existence of solutions of $(m_1,1,\cdots,1,m_p,1,\cdots,1,m_{n-j_s},1,\cdots,1,m_{n-j_{s-1}},1,\cdots,1,m_{n-j_2},1,\cdots,1,m_{n-j_1+1},m_{n-j_1+2},\cdots,m_n)$ problems for (1), where the reader realizes the significance of the entries in the n-tuple from previous arguments.

For this problem, in addition to appropriate assumptions from preceding steps on $m_p,m_{n-j_s},\cdots,m_{n-j_2},m_{n-j_1+1},\cdots,m_{n-1}$, our assumptions are that $m_n>1$ and that given $m_1\in[a,+\infty)$, each $(m_1,1,\cdots,1,m_p,1,\cdots,1,m_{n-j_s},1,\cdots,1,m_{n-j_{s-1}},1,\cdots,1,$

$m_{n-j_2}, 1, \cdots, 1, m_{n-j_1+1}, \cdots, m_{n-1}, h)$ conjugate boundary value problem, where $1 \leqq h < m_n$, for (1) has a unique solution on $[a, +\infty)$.

Given $m_1 \in [a, +\infty)$, let $z(m)$ be the solution at the points $s_1, \cdots, s_{n-1}, s_n - 1$ of the $(m_1, 1, \cdots, 1, m_p, 1, \cdots, 1, m_{n-j_s}, 1, \cdots, 1, m_{n-j_{s-1}}, 1, \cdots, 1, m_{n-j_2}, 1, \cdots, 1, m_{n-j_1+1}, \cdots, m_{n-1}, m_n - 1)$ conjugate boundary value problem for (1) satisfying

$$z(s_i) = y_i, \qquad 1 \leqq i \leqq n-1,$$

$$z(s_n - 1) = 0.$$

The set $S = \{r \in \mathbf{R} \mid$ there is a solution $y(m)$ of (1) satisfying $y(s_i) = z(s_i)$, $1 \leqq i \leqq n-1$, and $y(s_n) = r\}$ is nonempty and open.

If we assume as above that S is not closed, and if r_0, $\{r_k\}$, with $r_k \uparrow r_0$, and $y_k(m)$ are also as in our previous arguments, then it follows from (B) that $y_k(m) < y_{k+1}(m)$, for each $k \in \mathbf{N}$, on $(s_{n-1}, +\infty)$. In complete analogy also, $y_k(s_n - 1) \uparrow +\infty$, as $k \to +\infty$, and for some $m_0 \in (s_n, s_n + n - 1]$, $y_k(m_0) \uparrow +\infty$, as $k \to +\infty$.

If $u(m)$ is the solution at the points $s_2, s_3, \cdots, s_{p-1}, s_{p-1}+1, s_p, s_{p+1}, \cdots, s_{n-1}, s_n$ of the $(m_1+1, 1, \cdots, 1, 1, m_p - 1, 1, \cdots, 1, m_{n-j_s}, 1, \cdots, 1, m_{n-j_{s-1}}, 1, \cdots, 1, m_{n-j_2}, 1, \cdots, 1, m_{n-j_1+1}, \cdots, m_{n-1}, m_n)$ conjugate boundary value problem for (1) satisfying

$$u(s_i) = z(s_i), \qquad 2 \leqq i \leqq p-1,$$

$$u(s_{p-1} + 1) = 0,$$

$$u(s_i) = z(s_i), \qquad p \leqq i \leqq n-1,$$

$$u(s_n) = r_0,$$

then we can argue that, for some $K \in \mathbf{N}$, $u(m) - y_K(m)$ has a generalized zero at s_n, a generalized zero at some $n_0 \in (s_n, m_0]$, and zeros at s_i, $2 \leqq i \leqq n-1$. This contradicts (B), and it follows that S is also closed. For $y_n \in S$, the corresponding solution $y(m)$ is the desired solution. This completes this case.

(b) For the case of the $(2^{j_s} + 2^{j_{s-1}} + \cdots + 2^{j_2} + 2^{j_1} + 1)$st inductive step, we are concerned with the existence of solutions of $(m_1, 1, \cdots, 1, m_p, 1, \cdots, 1, m_{n-j_s}, 1, \cdots, 1, m_{n-j_{s-1}}, 1, \cdots, 1, m_{n-j_2}, 1, \cdots, 1, m_{n-j_1}, 1, \cdots, 1)$ problems for (1).

As in (a), in addition to appropriate assumptions on $m_p, m_{n-j_s}, \cdots, m_{n-j_2}$, our assumptions are that $m_{n-j_1} > 1$ and that given $m_1 \in [a, +\infty)$, each $(m_1, 1, \cdots, 1, m_p, 1, \cdots, 1, m_{n-j_s}, 1, \cdots, 1, m_{n-j_{s-1}}, 1, \cdots, 1, m_{n-j_2}, 1, \cdots, 1, l, m_{n-j_1+1}, m_{n-j_1+2}, \cdots, m_n)$ conjugate boundary value problem, where $1 \leqq l < m_{n-j_1}$, for (1) has a unique solution on $[a, +\infty)$.

Given $m_1 \in [a, +\infty)$, let $z(m)$ be the solution at the points $s_1, \cdots, s_{n-j_1-1}, s_{n-j_1} - 1, s_{n-j_1}, s_{n-j_1+1}, \cdots, s_{n-2}, s_{n-1}$ of the $(m_1, 1, \cdots, 1, m_p, 1, \cdots, 1, m_{n-j_s}, 1, \cdots, 1, m_{n-j_{s-1}}, 1, \cdots, 1, m_{n-j_2}, 1, \cdots, 1, m_{n-j_1} - 1, 1, \cdots, 1)$ conjugate boundary value problem for (1) satisfying

$$z(s_i) = y_i, \qquad 1 \leqq i \leqq n - j_1 - 1,$$

$$z(s_{n-j_1} - 1) = 0,$$

$$z(s_i) = y_i, \qquad n - j_1 \leqq i \leqq n-1.$$

If $S = \{r \in \mathbf{R} \mid$ there is a solution $y(m)$ of (1) satisfying $y(s_i) = z(s_i)$, $1 \leqq i \leqq n-1$, and $y(s_n) = r\}$, then S is a nonempty open subset of $\mathbf{R}$.

If we assume S is not closed, and if $r_0, \{r_k\}$, with $r_k \uparrow r_0$, and $y_k(m)$ are the standard points and solutions, then $y_k(m) < y_{k+1}(m)$ on $[s_n, +\infty)$, for all $k \in \mathbf{N}$. Moreover, since $y_k(s_i) = z(s_i)$, $n - j_1 \leqq i \leqq n-1$, it follows from (B) that either

(i) $y_k(s_{n-j_1}-1) < y_{k+1}(s_{n-j_1}-1)$, for each $k \in \mathbf{N}$, if j_1 is even, or

(ii) $y_k(s_{n-j_1}-1) > y_{k+1}(s_{n-j_1}-1)$, for each $k \in \mathbf{N}$, if j_1 is odd.

Since the arguments for both cases are analogous, we may assume case (i) is the situation. In this case, since $r_0 \notin S$, it follows from Theorem 3 that $y_k(s_{n-j_1}-1) \uparrow +\infty$, as $k \to +\infty$. Furthermore, it is again the case that, for some $m_0 \in (s_n, s_n + n - 1]$, $y_k(m_0) \uparrow +\infty$, as $k \to +\infty$.

Now let $u(m)$ be the solution at the points $s_2, \cdots, s_{p-1}, s_{p-1}+1, s_p, s_{p+1}, \cdots, s_{n-1}, s_n$ of the $(m_1+1, 1, \cdots, 1, 1, m_p - 1, 1, \cdots, 1, m_{n-j_s}, 1, \cdots, 1, m_{n-j_{s-1}}, 1, \cdots, 1, m_{n-j_2}, 1, \cdots, 1, m_{n-j_1}, 1, \cdots, 1)$ conjugate boundary value problem for (1) satisfying

$$
\begin{aligned}
&u(s_i) = z(s_i), \qquad 2 \leqq i \leqq p-1,\\
&u(s_{p-1}+1) = 0,\\
&u(s_i) = z(s_i), \qquad p \leqq i \leqq n-1,\\
&u(s_n) = r_0.
\end{aligned}
$$

As with previous similar cases, there exists $K \in \mathbf{N}$ such that $u(m) - y_K(m)$ has a generalized zero at s_n, a generalized zero at some $n_0 \in (s_n, m_0]$, and zeros at s_i, $2 \leqq i \leqq n-1$. This is a contradiction to (B), and we conclude that S is closed; hence $S = \mathbf{R}$. Choosing $y_n \in S$, the associated solution $y(m)$ is the unique solution of (1) that we sought. This completes case (b).

The proof is complete. □

Remark. We remark here that the half-line $[a, +\infty)$ is not necessary. In particular, the results can be extended to a finite interval $[a, b+n]$, where b is the right-most point at which conditions are specified, so that our application of Theorem 1 can still be made in the arguments.

UNIFORM APPROXIMATION OF SINGULAR PERTURBATION PROBLEMS HAVING SINGULAR REGULAR EXPANSIONS*

WALTER G. KELLEY†

Abstract. The singular perturbation problem $\varepsilon^2 u'' = h(x, u, \varepsilon)$, $u(a) = u(b) = 0$ is studied under the assumption that h vanishes for some $x \in [a, b]$. Uniform asymptotic approximations are obtained for solutions exhibiting boundary layer behavior. Approximate Green's functions are constructed to show existence of solutions and verify formal approximations.

Key words. singular perturbations, semilinear boundary value problem, singular expansion, boundary layer, asymptotic approximations

AMS(MOS) subject classifications. 34E15, 34E05

1. Introduction.

Elliptic singularly perturbed boundary value problems of the form

$$\varepsilon^2 \nabla^2 u = f(x, u, \varepsilon), \qquad x \in \Omega, \tag{1.1}$$

$$u(x) = 0, \qquad x \in \partial\Omega, \tag{1.2}$$

where ε is a small positive parameter, have been studied by Fife [2], van Harten [3] and others under the following hypotheses:

(a) There is a smooth u_0 so that $f(x, u_0(x), 0) = 0$ for $x \in \Omega \cup \partial\Omega$.

(b) $f_u(x, u_0(x), 0) > 0$ for $x \in \Omega \cup \partial\Omega$.

(c) $\int_{u_0(x)}^{A} f(x, s, 0)\, ds > 0$ for $x \in \partial\Omega$ and A between $u_0(x)$ and 0.

They have shown that, for sufficiently small values of ε, problem (1.1), (1.2) has a solution u_ε with a boundary layer of width ε along $\partial\Omega$ and that asymptotic approximations of all orders can be constructed.

Recently, we have obtained equations similar to (1.1) while using regularization methods for optimization problems that arise in the identification of parameters. However, in these problems the function f vanishes identically for some x in the domain so that hypothesis (b) is violated. Note that (c) is also violated if x happens to be a boundary point.

In this paper, as a first step in analyzing such problems, we consider ordinary differential equations

$$\varepsilon^2 u'' = h(x, u, \varepsilon) \tag{1.3}$$

with Dirichlet boundary conditions, where $h(0, u, 0) = 0$ for all u and $x = 0$ belongs to the domain of interest, and show that there is a solution with boundary layers at both endpoints. The exact behavior of the solution will be obtained by constructing and verifying a uniform asymptotic approximation. The analysis has some connection with classical turning point theory for linear equations (see Wasow [10]). However, our hypotheses rule out the possibility that solutions exhibit rapid oscillations. Cochran [1] has given a method for constructing solutions for linear boundary value problems under similar hypotheses.

In § 3 we consider first the case when $x = 0$ is in the interior of the interval. One interesting aspect of the computation is that the regular expansion has a singularity at $x = 0$. Nevertheless, a composite approximation is easily constructed and is verified

by the use of an approximate Green's function. We do not consider higher-order approximations.

In the final section, we treat the case where $x=0$ is a boundary point. Despite the fact that h vanishes at the boundary, it is shown that an integral condition similar to hypothesis (c) suffices to obtain a solution with boundary layer behavior. We also verify that a lowest-order approximation consisting of the reduced solution with boundary layer corrections is uniformly valid. In contrast to the situation where hypotheses (a)-(c) hold, the boundary layer at $x=0$ is found to be thicker than the other one.

2. Preliminaries. In the following sections, we will use the method of approximate Green's functions introduced in van Harten and Vader-Burger [4] to show the existence of solutions and to verify formal approximations. Consequently, this section will summarize the results of [4] as they apply to (1.3) with Dirichlet boundary conditions

$$u(a)=u(b)=0. \tag{2.1}$$

We will assume throughout that all functions are smooth enough to make the arguments valid, but class C^2 is sufficient in all cases.

Suppose a formal approximation $A(x,\varepsilon)$ has been obtained, in the sense that

$$\varepsilon^2 A''-h(x,A,\varepsilon)=E(x,\varepsilon)=\mathcal{O}(\varepsilon^{\alpha}) \tag{2.2}$$

for some $\alpha>0$ and all $x\in[a,b]$ and A satisfies (2.1). Then

$$L_\varepsilon(v)=\varepsilon^2 v''-h_u(x,A,\varepsilon)v \tag{2.3}$$

is the linearization of (2.2) about A and the residual nonlinear operator is given by

$$N_\varepsilon(v)=-\int_0^1 (1-s)\frac{d^2}{ds^2}h(x,A+sv,\varepsilon)\,ds. \tag{2.4}$$

Let $\|\ \|$ denote the supremum norm on $C[a,b]$.

DEFINITION. A function $\mathrm{Gr}(x,t,\varepsilon)$ is said to be an "approximate Green's function" for (1.3), (2.1) if it satisfies the following conditions:

(1) $\mathrm{Gr}\in C([a,b]^2)$ and Gr is smooth except across the diagonal $x=t$;

(2) The jump in Gr_x at $x=t$ satisfies

$$[\mathrm{Gr}_x]_{x=t}=1+\mathcal{O}(\varepsilon);$$

(3) There is a $\nu>0$ so that

$$\int_a^b |L_\varepsilon\,\mathrm{Gr}(x,t)-\delta(x-t)|\,dt=\mathcal{O}(\varepsilon^{\nu})$$

uniformly for $x\in[a,b]$, where δ is the Dirac delta function;

(4) Gr satisfies $\mathrm{Gr}(a,t,\varepsilon)=\mathrm{Gr}(b,t,\varepsilon)=0$ for all $t\in[a,b]$.

If Gr is an approximate Green's function, we define an approximate right inverse L_ε^{-1} for L_ε by

$$L_\varepsilon^{-1}u(x)=\int_a^b \mathrm{Gr}(x,t)u(t)\,dt. \tag{2.5}$$

The proof of the following theorem in [4] is based on a contraction mapping argument.

THEOREM 1. *Suppose that A satisfies* (2.1), (2.2), N_ε *and* L_ε^{-1} *are given by* (2.4), *and* (2.5), *respectively, where* Gr *is an approximate Green's function, and*

$$\|N_\varepsilon L_\varepsilon^{-1}u_1 - N_\varepsilon L_\varepsilon^{-1}u_2\| \leqq \frac{\rho}{\beta(\varepsilon)}\|u_1 - u_2\| \tag{2.6}$$

for $\|u_1\|, \|u_2\| < \rho$, $0 < \rho < \bar{\rho}(\varepsilon)$, ε *sufficiently small and* $\beta(\varepsilon) > 0$. *If*

$$\|E\| \leqq \min\{\bar{\rho}(\varepsilon)/4, \beta(\varepsilon)/16\}, \tag{2.7}$$

then for $\varepsilon > 0$ *sufficiently small,* (1.3), (2.1), *has a locally unique solution* $u(x, \varepsilon)$ *so that*

$$\|u(x, \varepsilon) - A(x, \varepsilon)\| \leqq 4|L_\varepsilon^{-1}|\,\|E\|,$$

where $|\ |$ *is the norm of the operator* L_ε^{-1} *as a mapping from* $C[a, b]$ *into* $C[a, b]$.

This theorem with minor modification holds as well for a variety of perturbation problems and Banach spaces.

Now the calculations in [3] imply that

$$\|N_\varepsilon v_1 - N_\varepsilon v_2\| = \mathcal{O}(\rho)\|v_1 - v_2\|$$

for ρ and ε small, where ρ is independent of ε, so (2.6) is true with $\beta = C/|L_\varepsilon^{-1}|$. Then (2.7) is satisfied if

$$\|E\| \times |L_\varepsilon^{-1}| \to 0 \quad \text{as } \varepsilon \to 0. \tag{2.8}$$

COROLLARY. *If the error term E in* (2.2) *satisfies* (2.8), *then for small* ε, (1.3), (2.1) *has a locally unique solution* $u(x, \varepsilon)$ *so that*

$$\|u - A\| \leqq 4|L_\varepsilon^{-1}|\,\|E\|. \tag{2.9}$$

3. Problems with an interior singularity. Consider now the problem

$$\varepsilon^2 u'' = x^m f(x, u) + \varepsilon^2 g(x, u, \varepsilon), \tag{3.1}$$

$$u(-1) = u(1) = 0, \tag{3.2}$$

where m is an even positive integer. More general problems could be considered; for example, we could replace x^m by $|x|^m$, where m is allowed to be odd. We will assume the following:

(a) There is a smooth u_0 so that $f(x, u_0(x)) = 0$, $-1 \leqq x \leqq 1$;

(b) $f_u(x, u_0) > k^2 > 0$, $-1 \leqq x \leqq 1$;

(c) $\int_{u_0(-1)}^{\theta} f(-1, s)\,ds > 0$ for θ between $u_0(-1)$ and 0;

(d) $\int_{u_0(1)}^{\theta} f(1, s)\,ds > 0$ for θ between $u_0(1)$ and 0.

The first step is to construct an approximation of the solution of (3.1), (3.2) valid near $x = 0$. If a regular expansion $u = u_0(x) + \varepsilon^2 u_1(x) + \cdots$ is substituted into (3.1), we find that

$$u_1(x) = \frac{u_0''(x) - g(x, u_0, 0)}{x^m f_u(x, u_0)}, \tag{3.3}$$

which is generally singular at $x = 0$. We consider only the worst case, namely that

(e) $F(x) \equiv u_0''(x) - g(x, u_0(x), 0) \neq 0$ at $x = 0$.

To correct the singularity, we try as an approximation near zero

$$u_0(x) + \varepsilon^{4/(m+2)} v(\xi, \varepsilon) \tag{3.4}$$

with $\xi = x\varepsilon^{-2/(m+2)}$. If we put (3.4) into (3.1), we find that v satisfies the non-homogeneous equation

$$\frac{d^2 v}{d\xi^2} = \xi^m f_u(0, u_0(0))v - F(0). \tag{3.5}$$

To obtain matching with the first two terms of the regular expansion, we want a solution of (3.5) so that

$$v(\xi, \varepsilon) \sim \frac{F(0)}{\xi^m f_u(0, u_0(0))} \quad \text{as } \xi \to \pm\infty. \tag{3.6}$$

Now let $\eta = \xi f_u(0, u_0(0))^{1/(m+2)}$ and write (3.5) in terms of the independent variable η:

$$\frac{d^2v}{d\eta^2} = \eta^m v - \frac{F(0)}{f_u(0, u_0(0))^{2/(m+2)}}. \tag{3.7}$$

It is well known (see, for example, [11]) that the homogeneous portion of (3.7) has the solution

$$w(\eta) = \eta^{1/2} K_{1/(m+2)}\left(\frac{2\eta^{(m+2)/2}}{m+2}\right), \tag{3.8}$$

for $\eta \geqq 0$, where $K_{1/(m+2)}$ is a modified Bessel function; furthermore, w can be continued to an analytic function defined for all η. Note that $w(-\eta)$ is also a solution of the homogeneous part of (3.7).

Define

$$v(\eta) = \frac{F(0)}{\mathrm{Wr}}\left(\frac{1}{f_u(0, u_0(0))}\right)^{2/(m+2)} \left\{ w(-\eta) \int_\eta^\infty w(t)\, dt + w(\eta) \int_{-\infty}^\eta w(-t)\, dt \right\}, \tag{3.9}$$

where Wr is the Wronskian of $w(\eta)$, $w(-\eta)$:

$$\mathrm{Wr} = -2w(0)w'(0) > 0.$$

Then v satisfies (3.7). Using the well-known asymptotic expansions of the modified Bessel functions or the Liouville-Green approximations (see [7]), we easily obtain

$$w(\eta) \sim \begin{cases} c_1 \eta^{-m/4} \exp\left(-\dfrac{2}{m+2}\eta^{(m+2)/2}\right) & \text{as } \eta \to \infty, \\ c_2(-\eta)^{-m/4} \exp\left(\dfrac{2}{m+2}\eta^{(m+2)/2}\right) & \text{as } \eta \to -\infty \end{cases} \tag{3.10}$$

for some constants c_1, c_2. It is then straightforward to verify (3.6) by using (3.9) and (3.7).

A formal composite approximation can be defined by

$$a(x, \xi, \varepsilon) = u_0(x) + \varepsilon^{4/(m+2)} \frac{F(x)}{F(0)} \frac{f_u(0, u_0(0))}{f_u(x, u_0(x))} v(\xi). \tag{3.11}$$

We show in the Appendix that for any constant $\delta > 0$,

$$\varepsilon^2 a'' - x^m f(x, a) - \varepsilon^2 g(x, a, \varepsilon) = \begin{cases} \mathcal{O}(\varepsilon^4), & \text{for } \delta \leqq |x| \leqq 1, \\ \mathcal{O}(\varepsilon^{4((m+3)/(2m+5))}) & \text{for } |x| \leqq 1. \end{cases} \tag{3.12}$$

For large $|\xi|$, we have

$$a(x, \varepsilon) = u_0(x) + \frac{\varepsilon^2 F(x)}{x^m f_u(x, u_0(x))} + \mathcal{O}\left(\frac{1}{\xi^2}\right).$$

Define

$$\bar{a}(x)=\begin{cases} a(x) & \text{if } |x|\leqq .5, \\ u_0(x)+\dfrac{\varepsilon^2 F(x)}{x^m f_u(x, u_0(x))}+\Lambda(x)\mathcal{O}\left(\dfrac{1}{\xi^2}\right) & \text{if } |x|>.5, \end{cases} \tag{3.13}$$

where Λ is a cutoff function on the interval $[-1, 1]$ having the value 1 near $x=0$ and having the value zero near $x=-1$ and $x=1$.

Finally, to obtain an approximation that is also valid near the endpoints, we require boundary layer corrections of the form

$$B_1\left(\frac{1-x}{\varepsilon}, \varepsilon\right)=B_1\left(\frac{1-x}{\varepsilon}, 0\right)+\mathcal{O}(\varepsilon),$$

$$B_{-1}\left(\frac{x+1}{\varepsilon}, \varepsilon\right)=B_{-1}\left(\frac{x+1}{\varepsilon}, 0\right)+\mathcal{O}(\varepsilon),$$

at the endpoints $x=1$ and $x=-1$, respectively. Since the construction of these corrections has been given by many authors (see [2], [3], [9]), we refer the reader to these sources for the details. The global approximation is

$$A=\bar{a}+\Gamma B_{-1}+(1-\Gamma)B_1 \tag{3.14}$$

where Γ is a cutoff function that is 1 near $x=-1$ and is zero near $x=1$. Then A satisfies (3.12) as well as (3.2).

The next theorem will demonstrate that A gives a uniform approximation of a solution u of (3.1), (3.2) for sufficiently small $\varepsilon>0$. Note that since $A-u_0(x)=\mathcal{O}(\varepsilon^{4/(m+2)})$ near $x=0$, the theorem implies that the graph of $u-u_0(x)$ has a small "bump" as a result of the singularity at $x=0$ and the size of the bump increases with m.

THEOREM 2. *Assume hypotheses* (a)-(e). *For* $\varepsilon>0$ *sufficiently small,* (3.1), (3.2) *has a locally unique solution* $u(x, \varepsilon)$ *so that*

$$u(x, \varepsilon)-A(x, \varepsilon)=\mathcal{O}(\varepsilon^{(10m+24/(2m+5)(m+2))})$$

uniformly in $[0, 1]$, *where* A *is defined by* (3.14), (3.13), (3.9), *and* (3.8).

Proof. The key element in the proof is the construction of an appropriate approximate Green's function for (3.1), (3.2). Let $\lambda(t)=f_u^{1/2}(t, u_0(t))$ for $-1\leqq t\leqq 1$. We will define $H_m(x, t, \varepsilon)$ to be the solution of the problem:

$$\begin{aligned} &\varepsilon^2\frac{d^2H_m}{dx^2}-\lambda^2 x^m H_m=\delta(t-x), \\ &H_m(-1, t)=H_m(1, t)=0. \end{aligned} \tag{3.15}$$

Now $w(\pm(\lambda/\varepsilon)^{2/(m+2)}x)$ are independent solutions of the homogeneous equation. Define

$$h_1\left(\left(\frac{\lambda}{\varepsilon}\right)^{2/(m+2)}x\right)=w\left(\left(\frac{\lambda}{\varepsilon}\right)^{2/(m+2)}x\right)-\frac{w((\lambda/\varepsilon)^{2/(m+2)})}{w(-(\lambda/\varepsilon)^{2/(m+2)})}w\left(-\left(\frac{\lambda}{\varepsilon}\right)^{2/(m+2)}x\right),$$

$$h_2\left(\left(\frac{\lambda}{\varepsilon}\right)^{2/(m+2)}x\right)=w\left(-\left(\frac{\lambda}{\varepsilon}\right)^{2/(m+2)}x\right)-\frac{w((\lambda/\varepsilon)^{2/(m+2)})}{w(-(\lambda/\varepsilon)^{2/(m+2)})}w\left(\left(\frac{\lambda}{\varepsilon}\right)^{2/(m+2)}x\right),$$

so that h_1, h_2 satisfy the homogeneous equation, h_1 vanishes at $x=1$, h_2 vanishes at $x=-1$, and

$$(3.16)\quad h_2(-\eta),\, h_1(\eta)=\begin{cases}\mathcal{O}\left(\eta^{-m/4}\exp\left(-\dfrac{2}{m+2}\,\eta^{(m+2)/2}\right)\right) & \text{as } \eta\to\infty,\\ \mathcal{O}\left((-\eta)^{-m/4}\exp\left(\dfrac{2}{m+2}\,\eta^{(m+2)/2}\right)\right) & \text{as } \eta\to-\infty.\end{cases}$$

Then specifically we have

$$(3.17)\quad H_m(x,t,\varepsilon)=\begin{cases}-C\varepsilon^{-(2m+2)/(m+2)}h_1\left(\left(\dfrac{\lambda}{\varepsilon}\right)^{2/(m+2)}t\right)h_2\left(\left(\dfrac{\lambda}{\varepsilon}\right)^{2/(m+2)}x\right) & \text{if } -1\leqq x\leqq t\leqq 1,\\ -C\varepsilon^{-(2m+2)/(m+2)}h_1\left(\left(\dfrac{\lambda}{\varepsilon}\right)^{2/(m+2)}x\right)h_2\left(\left(\dfrac{\lambda}{\varepsilon}\right)^{2/(m+2)}t\right) & \text{if } -1\leqq t\leqq x\leqq 1,\end{cases}$$

where C is a constant independent of ε.

Let L_ε be the linearization of (3.1) about A (see (2.3)). Then

$$\begin{aligned}L_\varepsilon H_m &= \varepsilon^2\frac{d^2H_m}{dx^2}-x^m f_u(x,A)H_m+\mathcal{O}(\varepsilon^2)\\ (3.18)\qquad &= \varepsilon^2\frac{d^2H_m}{dx^2}-\lambda^2x^mH_m+[\lambda^2-f_u(x,A)]x^mH_m+\mathcal{O}(\varepsilon^2)\\ &= \delta(t-x)+\{\mathcal{O}(|t-x|)-f_{uu}(x,\sim)[\mathcal{O}(\varepsilon^{4/(m+2)}v)+B_{-1}+B_1]\}x^mH_m+\mathcal{O}(\varepsilon^2),\end{aligned}$$

where $\sim$ is between u_0 and A.

In a similar way, $H_0(x,t,\varepsilon)$ is defined to be the solution of

$$\varepsilon^2\frac{d^2H_0}{dx^2}-\lambda^2t^mH_0=\delta(t-x),$$

$$H_0(-1,t)=H_0(1,t)=0.$$

Note that the explicit formula for H_0 involves only exponential functions. Now

$$\begin{aligned}L_\varepsilon H_0 &= \varepsilon^2\frac{d^2H_0}{dx^2}-x^mf_u(x,A)H_0+\mathcal{O}(\varepsilon^2)\\ (3.19)\qquad &= \varepsilon^2\frac{d^2H_0}{dx^2}-\lambda^2t^mH_0+[\lambda^2t^m-f_u(x,A)x^m]H_0+\mathcal{O}(\varepsilon^2)\\ &= \delta(t-x)+\mathcal{O}(|x-t|)H_0-f_{uu}(\varepsilon^{4/(m+2)}v+B_{-1}+B_1)x^mH_0+\mathcal{O}(\varepsilon^2).\end{aligned}$$

According to the calculations in [2], we can choose M_{-1}, M_1 to be solutions of

$$(3.20)\quad \varepsilon^2\frac{d^2M_{-1}}{dx^2}-f_u\left(-1,u_0(-1)+B_{-1}\left(\frac{x+1}{\varepsilon},0\right)\right)M_{-1}=f_{uu}B_{-1}\left(\frac{x+1}{\varepsilon},0\right)H_0,$$

$$(3.21)\quad \varepsilon^2\frac{d^2M_1}{dx^2}-f_u\left(1,u_0(1)+B_1\left(\frac{1-x}{\varepsilon},0\right)\right)M_1=f_{uu}B_1\left(\frac{1-x}{\varepsilon},0\right)H_0,$$

which vanish at $x=-1$, $x=1$, respectively, and satisfy

$$M_{-1}=\mathcal{O}\left(\varepsilon^{-1}\exp\left(\frac{-x-1}{\varepsilon}\right)\right),\qquad M_1=\mathcal{O}\left(\varepsilon^{-1}\exp\left(\frac{x-1}{\varepsilon}\right)\right).$$

For M_1 we have

$$\begin{aligned} L_\varepsilon M_1 &= \varepsilon^2 M_1 - f_u(x, A)M_1 + \mathcal{O}(\varepsilon^2) \\ &= f_{uu}B_1\left(\frac{1-x}{\varepsilon}, 0\right)H_0 + \mathcal{O}(|x-1|M_1) + \mathcal{O}(\varepsilon M_1) + \mathcal{O}(\varepsilon^2). \end{aligned} \tag{3.22}$$

A similar equation holds for M_{-1}.

The approximate Green's function is defined as follows:

$$\begin{aligned} \mathrm{Gr}\,(x, t, \varepsilon) &= \Lambda(t)H_m(x, t, \varepsilon) + (1-\Lambda(t))H_0 + \Gamma(x)\chi\left(\frac{t+1}{\varepsilon^\alpha}\right)M_{-1} \\ &\quad + (1-\Gamma(x))\chi\left(\frac{1-t}{\varepsilon^\alpha}\right)M_1, \end{aligned} \tag{3.23}$$

where χ is a cutoff function defined on $[0, \infty]$ which is 1 near zero and is zero when its argument is greater than 1, and $0 < \alpha < 2/(m+2)$.

Among the conditions for a function to be an approximate Green's function, only the third condition is not immediate. Using (3.18), (3.19), and (3.22), we have

$$\begin{aligned} L_\varepsilon\,\mathrm{Gr} - \delta(x-t) &= \Lambda(t)[\mathcal{O}(|t-x|) - f_{uu}(\mathcal{O}(\varepsilon^{4/(m+2)}v) + B_{-1} + B_1)]x^m H_m \\ &\quad + (1-\Lambda(t))[\mathcal{O}(|t-x|) - f_{uu}(\mathcal{O}(\varepsilon^{4/(m+2)}v) + \mathcal{O}(\varepsilon))x^m \\ &\quad + \mathcal{O}((1-x)B_1) + \mathcal{O}((x+1)B_{-1})]H_0 \\ &\quad + [(1-\Gamma(x))\chi((1-t)/\varepsilon^\alpha) \\ &\quad - (1-\Lambda(t))]f_{uu}B_1((1-x)/\varepsilon, 0)H_0 \\ &\quad + [\Gamma(x)\chi((1+t)/\varepsilon^\alpha) \\ &\quad - (1-\Lambda(t))]f_{uu}B_{-1}((1+x)/\varepsilon, 0)H_0 \\ &\quad + (1-\Gamma(x))\chi((1-t)/\varepsilon^\alpha)[\mathcal{O}(1-x) + \mathcal{O}(\varepsilon)]M_1 \\ &\quad + \Gamma(x)\chi((1-t)/\varepsilon^\alpha)[\mathcal{O}(x+1) + \mathcal{O}(\varepsilon)]M_{-1} + \mathcal{O}(\varepsilon^2). \end{aligned} \tag{3.24}$$

The following estimates are valid uniformly for $x \in [-1, 1]$ and for all nonnegative even integers m:

$$\int_{-1}^{1} |t-x||x^m H_m|\, dt = \mathcal{O}(\varepsilon^{2/(m+2)}), \tag{3.25}$$

$$\int_{-1}^{1} |H_m|\, dt = \mathcal{O}(\varepsilon^{-2m/(m+2)}), \tag{3.26}$$

$$\int_{-1}^{1} |vx^m H_m|\, dt = \mathcal{O}(1), \tag{3.27}$$

$$\int_{0}^{1-C\varepsilon^\alpha} \left| B_1\left(\frac{1-x}{\varepsilon}, 0\right)H_0 \right| dt = \text{transcendentally small}. \tag{3.28}$$

We prove estimate (3.25) in Appendix B. The others can be established more easily. It follows from these estimates that Gr is an approximate Green's function.

Finally, from (3.26) we obtain

$$\int_{-1}^{1} |\mathrm{Gr}|\, dt = \mathcal{O}(\varepsilon^{-2m/(m+2)})$$

uniformly for $x \in [-1, 1]$, so

$$|L_\varepsilon^{-1}| = \mathcal{O}(\varepsilon^{-2m/(m+2)}).$$

The result then follows immediately from the corollary to Theorem 1.

Remark. We can show by comparison techniques that $u(x, \varepsilon) - A(x, \varepsilon) = \mathcal{O}(\varepsilon^4)$ uniformly for $0 < \delta \leqq |x| \leqq 1$, where δ is independent of ε and ε is sufficiently small. We omit the details.

4. Problems with a singularity at the boundary. In this final section, we treat the boundary value problem

$$\varepsilon^2 u'' = x^m f(x, u) + \varepsilon^2 g(x, u, \varepsilon), \tag{4.1}$$

$$u(0) = u(1) = 0, \tag{4.2}$$

where m is a positive integer and f satisfies the hypotheses of § 3 with the exception that the inequality in (c) is replaced by

(c)′ $\int_{u_0(0)}^{\theta} f(0, s)\, ds > 0$ for θ between $u_0(0)$ and 0.

Once again, we anticipate boundary layer behavior at the endpoints, but the layer at $x = 0$ will be thicker than the one at $x = 1$. The lowest-order approximation will consist of the reduced solution u_0 plus boundary layer corrections.

With $\xi = x\varepsilon^{-2/(m+2)}$, we find that the first term in the boundary layer correction at zero, $\Theta(\xi)$, satisfies

$$\frac{d^2\Theta}{d\xi^2} = \xi^m f(0, u_0(0) + \Theta), \tag{4.3}$$

$$\Theta(0) = -u_0(0), \quad \Theta(\xi) \to 0 \quad \text{as } \xi \to \infty. \tag{4.4}$$

Let $\lambda(t) = f_u^{1/2}(t, u_0(t))$.

LEMMA. *The problem* (4.3), (4.4) *has a monotone solution* $\Theta(\xi)$ *for which, given* $\delta > 0$, *there is a* $C > 0$ *so that*

$$|\Theta(\xi)| \leqq C \exp\left(\frac{-2\lambda(0) + \delta}{m+2}\, \xi^{(m+2)/2}\right) \tag{4.5}$$

for $\xi \geqq 0$.

Proof. Suppose that $u_0(0) < 0$; the other case is similar. We define a positive, monotone decreasing function $\beta(\xi)$, $\xi \geqq 0$ by

$$\frac{2}{m+2}\, \xi^{(m+2)/2} = \int_\beta^{-u_0(0)} d\tau \Big/ \sqrt{2 \int_0^\tau f(0, u_0(0) + s)\, ds}. \tag{4.6}$$

Note that $\beta(0) = -u_0(0)$,

$$\frac{d\beta}{d\xi} = -\xi^{m/2} \sqrt{2 \int_0^\beta f(0, u_0(0) + s)\, ds} \tag{4.7}$$

and

$$\frac{d^2\beta}{d\xi^2} = \xi^m f(0, u_0(0) + \beta) - \frac{m}{2}\, \xi^{(m-2)/2} \sqrt{2 \int_0^\beta f(0, u_0(0) + s)\, ds}. \tag{4.8}$$

Furthermore, we can use an argument like the one given by Fife [2] for the case $m = 0$ to show that for each $\delta > 0$ there is a $C > 0$ so that

$$\beta(\xi) \leqq c \exp\left(\frac{-2\lambda(0) + \delta}{m+2}\, \xi^{(m+2)/2}\right)$$

for $\xi \geqq 0$.

Now (4.8) implies that β is an upper solution for (4.3), (4.4). In the case $m=1$, β'' is singular at $\xi=0$, but singularities of this type at the boundary are permissible. Since zero is a lower solution, it follows that (4.3), (4.4) has a solution $\Theta(\xi)$ satisfying (4.5).

It remains to show that Θ is monotone decreasing. From (4.3), (4.5), it is clear that $\Theta'(\xi)\to 0$ exponentially fast as $\xi\to\infty$. Multiplying (4.3) by Θ', integrating both sides from ∞ to ξ and using integration by parts, we obtain

$$\begin{aligned}.5\Theta'^2(\xi) &= \int_\infty^\xi \Theta'\Theta''\,d\tau \\ &= \int_\infty^\xi \tau^m f(0, u_0(0)+\Theta)\Theta'\,d\tau \\ &= \xi^m \int_0^{\Theta(\xi)} f(0, u_0(0)+s)\,ds + \int_\xi^\infty m\tau^{m-1}\int_0^{\Theta(\tau)} f(0, u_0(0)+s)\,ds\,d\tau,\end{aligned}$$

so hypothesis (c)′ implies that $\Theta'(\xi)\neq 0$ for all $\xi\geqq 0$, and the proof is complete.

The next theorem yields the existence of a solution having a boundary layer of width $\varepsilon^{2/(m+2)}$ at $x=0$ and a boundary layer of width ε at $x=1$.

THEOREM 3. *Assume hypotheses* (a), (b), (c)′, *and* (d) *are satisfied for the interval* $[0, 1]$. *For all* $\delta>0$ *and sufficiently small* $\varepsilon>0$, (4.1), (4.2) *has a solution* $u(x,\varepsilon)$ *so that* $u(x,\varepsilon)-u_0(x,\varepsilon)=\mathcal{O}(\varepsilon^2)$ *uniformly for* $\delta\leqq x\leqq 1-\delta$.

Proof. We consider the case that $u_0(0)$ and $u_0(1)$ are negative. Existence will follow from the construction of upper and lower solutions for (4.1), (4.2).

An upper solution can be chosen to have the form

$$u_0(x)+\beta(\xi)+\gamma\left(\frac{1-x}{\varepsilon}\right)+C\varepsilon^{4/(m+2)}V(\xi), \tag{4.9}$$

where β is defined by (4.6), γ is a certain positive solution of

$$\varepsilon^2\frac{d^2\gamma}{dx^2}-f(1, u_0(1)+\gamma)<0, \qquad \gamma(0)=-u_0(1),$$

so that $\gamma\to 0$ as $\varepsilon\to 0$ for $x<1$, and C is a positive constant to be determined. The definition of V is similar to the definition of v in § 3. Let $\bar\eta=\xi k^{2/(m+2)}$ and let $w(\bar\eta)$ be defined as in (3.8). Define

$$\bar w(\bar\eta)=\bar\eta^{1/2}I_{1/(m+2)}\left(\frac{2\bar\eta^{(m+2)/2}}{m+2}\right), \tag{4.10}$$

where I is a modified Bessel function, and

$$V(\bar\eta)=Wr^{-1}\left\{\bar w(\bar\eta)\int_{\bar\eta}^\infty w(t)\,dt + w(\bar\eta)\int_0^{\bar\eta}\bar w(t)\,dt\right\},$$

where Wr is the Wronskian. Then V satisfies the equation

$$\frac{d^2V}{d\bar\eta^2}-\bar\eta^m V=-1 \tag{4.11}$$

and

$$V(\bar\eta)\sim\bar\eta^{-m}$$

as $\bar\eta\to\infty$.

It suffices to verify that (4.9) satisfies the requisite differential inequality near $x=0$; see Howes [6, Thm. 4.1] for the verification near $x=1$.

Substituting (4.9) into (4.1), using a prime to denote differentiation with respect to x, and neglecting γ, which is exponentially small, we have

$$\begin{aligned} & x^m f(x, u_0+\beta+C\varepsilon^{4/(m+2)}V(\xi))-\varepsilon^2(u_0''+\beta''+C\varepsilon^{4/(m+2)}V'')+\mathcal{O}(\varepsilon^2) \\ & \quad = x^m[f(x, u_0(x)+\beta)-f(0, u_0(0)+\beta)]+x^m f(0, u_0(0)+\beta)-\varepsilon^2\beta'' \\ & \quad\quad +x^m[f_u(x, \sim)-k^2]C\varepsilon^{4/(m+2)}V+[k^2x^mV-\varepsilon^2V'']C\varepsilon^{4/(m+2)}+\mathcal{O}(\varepsilon^2) \\ & \quad \geqq \mathcal{O}(x^{m+1}\beta)+\frac{m}{2}x^{(m-2)/2}\varepsilon\left(2\int_0^\beta f(0, u_0(0)+s)\,ds\right)^{1/2} \\ & \quad\quad +\mathcal{O}(x^mC\varepsilon^{4/(m+2)}V)+Ck^{4/(m+2)}\varepsilon^2+\mathcal{O}(\varepsilon^2) \end{aligned} \tag{4.12}$$

by the Mean Value Theorem, (4.8), and (4.11). Consider an interval $0 \leqq x \leqq D\varepsilon^{2/(m+2)}$. The second and fourth terms in the last expression in (4.12) are positive and dominate the other terms on this interval for large enough C, so (4.12) is positive on such an interval. Also, we can assume that

$$f_u(x, u+\beta+C\varepsilon^{4/(m+2)}V) \geqq k^2$$

for $x \geqq D\varepsilon^{2/(m+2)}$.

For $x \geqq D\varepsilon^{2/(m+2)}$, the expression (4.12) is at least as large as

$$\begin{aligned} & \mathcal{O}(x^{m+1}\beta)+\frac{m}{2}x^{(m-2)/2}\varepsilon\left(2\int_0^\beta f(0, u_0(0)+s)\,ds\right)^{1/2} \\ & \quad\quad +C\varepsilon^{4/(m+2)}[-\varepsilon^2V''+x^mf_u(x, \sim)V]+\mathcal{O}(\varepsilon^2) \\ & \quad \geqq \mathcal{O}(x^{m+1}\beta)+\frac{m}{2}x^{(m-2)/2}\varepsilon\left(2\int_0^\beta f(0, u_0(0)+s)\,ds\right)^{1/2} \\ & \quad\quad +Ck^{4/(m+2)}\varepsilon^2+\mathcal{O}(\varepsilon^2). \end{aligned}$$

Note that the second term in the last expression dominates the first term for $x \ll \varepsilon^{2/(m+4)}$ and β is exponentially small for $x \gg \varepsilon^{2(m+2)}$. Consequently, (4.12) is positive for all x in a neighborhood of zero if C is large and ε is small.

It is routine to check that $u_0(x)-C\varepsilon^{4/(m+2)}V$ serves as a lower solution for large enough C. These calculations, together with the asymptotic behavior of V, complete the proof for the case considered.

An approximation for a solution of (4.1), (4.2) is defined by

$$A\left(x, \xi, \frac{1-x}{\varepsilon}, \varepsilon\right) = u_0(x)+\Gamma(x)\Theta(\xi)+(1-\Gamma(x))B_1\left(\frac{1-x}{\varepsilon}, \varepsilon\right), \tag{4.13}$$

where B_1 is an appropriate boundary layer correction at $x=1$ and Γ is a cutoff function which has the value 1 near zero and the value zero near 1. A straightforward calculation yields

$$\varepsilon^2A''-x^mf(x, A)-\varepsilon^2g(x, A, \varepsilon) = \mathcal{O}(\varepsilon^{(2m+2)/(m+2)}), \tag{4.14}$$

uniformly for $x \in [0, 1]$ and $A(0)=A(1)=0$. Of course, higher-order approximations would involve terms such as the one in (3.11) to correct the singularity in the regular expansion, as well as additional boundary layer terms.

We can verify the formal approximation (4.13) if hypothesis (c)′ is strengthened.

THEOREM 4. *Assume hypotheses* (a), (b), *and* (d) *are satisfied for the interval* $[0, 1]$, *and*

(c)″ $f(0, s)>0$ *for* s *between zero and* $u_0(0)$.

For all sufficiently small positive ε, (4.1), (4.2) *has a locally unique solution* $u(x, \varepsilon)$ *so that*

$$u(x, \varepsilon) - A(x, \varepsilon) = \mathcal{O}(\varepsilon^{2/(m+2)})$$

uniformly for $0 \leqq x \leqq 1$, *where A is defined by* (4.13), (4.3), *and* (4.4).

Proof. As in the proof of Theorem 2, we let $\lambda(t) = f_u^{1/2}(t, u_0(t))$ and define $H_m(t, x)$ to be the solution of

$$\begin{aligned} &\varepsilon^2 \frac{d^2 H_m}{dx^2} - \lambda^2 x^m H_m = \delta(t-x), \\ &H_m(0, t) = H_m(1, t) = 0. \end{aligned} \tag{4.15}$$

Since m is allowed to be odd, the construction of H_m is slightly different from that given previously. Let w be defined by (3.8), $\bar{w}$ by (4.10), $h_2(s) = \bar{w}(s)$, and

$$h_1(s) = w(s) - \frac{w((\lambda/\varepsilon)^{2/(m+2)})}{h_2((\lambda/\varepsilon)^{2/(m+2)})} h_2(s).$$

Then

$$h_1(s) = \mathcal{O}\left(s^{-m/4} \exp\left(-\frac{2}{m+2} s^{(m+2)/2}\right)\right),$$

$$h_2(s) = \mathcal{O}\left(s^{-m/4} \exp\left(\frac{2}{m+2} s^{(m+2)/2}\right)\right)$$

as $s \to \infty$. With $s = (\lambda/\varepsilon)^{2/(m+2)} x$, h_2, h_2 satisfy the homogeneous portion of (4.11), h_1 vanishes at $x = 1$ and h_2 vanishes at $x = 0$.

Then H_m is defined as in (3.17). Also, H_0 is defined much as in the proof of Theorem 2 with the obvious modifications needed to accommodate the interval [0, 1]. With L_ε as in (2.3),

$$L_\varepsilon H_m = \delta(t-x) + \{\mathcal{O}(|t-x|) - f_{uu}[\Gamma\Theta + (1-\Gamma)B_1]\} x^m H_m + \mathcal{O}(\varepsilon^2), \tag{4.16}$$

$$L_\varepsilon H_0 = \delta(t-x) + \mathcal{O}(|t-x|) H_0 - f_{uu}[\Gamma\Theta + (1-\Gamma)B_1] x^m H_0 + \mathcal{O}(\varepsilon^2). \tag{4.17}$$

The function

$$M_1 = \mathcal{O}(\varepsilon^{-1} \exp(x-1)/\varepsilon)$$

is chosen as in the proof of Theorem 2 to be a solution of (3.21) that vanishes at $x = 1$. M_0 is chosen to be a solution of

$$\frac{d^2 M_0}{d\xi^2} - \xi^m f_u(0, u_0(0) + \Theta) M_0 = f_{uu} \Theta \xi^m H_m, \qquad M_0(0) = 0, \tag{4.18}$$

so that

$$|M_0(\xi)| \leqq C \exp\left(-\frac{2m+2}{m+2}\right) \exp(-\mu \xi^{(m+2)/2}) \tag{4.19}$$

for $\xi \geqq 0$ and some positive constants C and μ. A similar estimate will be valid for M_0'.

Such an M_0 can be constructed in the following way. Note that hypothesis (c)″ implies that $-\theta'$ is a positive upper solution for the homogeneous portion of (4.18). It follows that there is a positive function $z(\xi)$ which satisfies

$$\begin{aligned} &z'' - \xi^m f_u(0, u_0(0) + \Theta) z = 0, \qquad (\xi \geqq 0), \\ &z(0) = -\Theta'(0), \end{aligned}$$

and $z \to 0$ as $\xi \to \infty$. According to the Liouville-Green approximations, for any small $\delta > 0$ there is a $C > 0$ so that

$$C^{-1} \exp\left(-\frac{2}{m+2}(\lambda(0)+\delta)\xi^{(m+2)/2}\right) \leqq z(\xi) \leqq C \exp\left(-\frac{2}{m+2}(\lambda(0)-\delta)\xi^{(m+2)/2}\right)$$

for $\xi \geqq 0$. Define

$$M_0(\xi, t) = z(\xi) \int_0^{\xi} z^{-2}(s) \int_s^{\infty} z(\tau) f_{uu} \tau^m \Theta(\tau) H_m(\tau, t)\, d\tau\, ds.$$

Then M_0 satisfies (4.18) and (4.19).

Now an approximate Green's function is

$$\text{(4.20)} \quad \mathrm{Gr}(x, t, \varepsilon) = \Gamma(t) H_m + (1-\Gamma(t)) H_0 + \Gamma(x)\Gamma\left(\frac{t}{\varepsilon^{\alpha}}\right) M_0 + (1-\Gamma(x))\Gamma\left(\frac{1-t}{\varepsilon^{\alpha}}\right) M_1,$$

where $0 < \alpha < 2/(m+2)$.

The verification that Gr is an approximate Green's function follows from (4.16)-(4.19) and is similar to that given in the proof of Theorem 2. We also have that

$$|L^{-1}| = \mathcal{O}(\varepsilon^{-2m/(m+2)}),$$

which together with the Corollary to Theorem 1 and (4.14) completes the proof of the theorem.

Theorems 2, 3, and 4 contain all the basic ideas needed for investigating a nonoscillatory semilinear singular perturbation problem in which the right-hand side vanishes at one or more points in the interval. In the following example, there are three such points.

Example. Consider the boundary value problem

$$\varepsilon^2 u'' = x^4(1-x^2) f(u) + \varepsilon^2 g(u),$$
$$u(-1) = u(1) = 0.$$

Suppose there is a $C \neq 0$ so that $f(C) = 0$, $f_u(C) > 0$, $\int_C^{\theta} f(u)\, ds > 0$ for θ between C and zero, and $g(C) \neq 0$. Then the hypotheses of Theorems 2 and 3 are satisfied (with appropriate translation of the x-axis) and the boundary value problem has a solution $u(x, \varepsilon)$ if ε is small enough. Furthermore,

$$u(x, \varepsilon) - C = \begin{cases} \mathcal{O}(1) & \text{near } x = -1 \text{ and } x = 1, \\ \mathcal{O}(\varepsilon^{2/3}) & \text{near } x = 0, \\ \mathcal{O}(\varepsilon^2) & \text{elsewhere in } [-1, 1]. \end{cases}$$

The boundary layers at $x = -1$ and $x = 1$ have width $\varepsilon^{2/3}$. We could construct a uniform approximation for $u(x, \varepsilon)$ using the calculations of §§ 3 and 4.

There is a relationship between the problems discussed here and turning point problems for quasilinear equations (see [5], [8]). We will study these latter problems in a future paper.

Appendix A. Verification of (3.12). For the sake of brevity, we write (3.11) as

$$\text{(A1)} \qquad a = u_0 + \varepsilon^{4/(m+2)} b(x) v(\xi).$$

Then

$$\text{(A2)} \qquad \begin{aligned} \varepsilon^2 a'' - x^m f(x, a) - \varepsilon^2 g &= \varepsilon^2(u_0'' - g) + \varepsilon^{2+4/(m+2)}\left(b'' v + \frac{2b'\dot{v}}{\varepsilon^{2/(m+2)}} + \frac{b\ddot{v}}{\varepsilon^{4/(m+2)}}\right) \\ &\quad - x^m[f_u(x, u_0)\varepsilon^{4/(m+2)} b v + \mathcal{O}(\varepsilon^{8/(m+2)} v^2)], \end{aligned}$$

where the prime indicates differentiation with respect to x and the dot indicates differentiation with respect to ξ.

Now the asymptotic expansion for v in negative powers of ξ begins:

$$v(\xi)\sim\frac{(u_0''-g)(0)}{\xi^m f_u(0)}+\frac{m(m+1)(u_0''-g)(0)}{\xi^{2m+2}f_u^2(0)}+\mathcal{O}(\xi^{-3m-4}) \tag{A3}$$

as $\xi\to\pm\infty$. If $|x|\gg\varepsilon^{2/(m+2)}$, (A2) can be written in the form

$$\begin{aligned}&\varepsilon^2(u_0''-g)(x)+\mathcal{O}(\xi^{-m}\varepsilon^{2+(4/(m+2))})+\mathcal{O}(\xi^{-m-1}\varepsilon^{2+(2/(m+2))})\\&\quad+\varepsilon^2 b\frac{(u_0''-g)(0)m(m+1)}{\xi^{m+2}f_u(0)}+\mathcal{O}(\varepsilon^2\xi^{-2m-4})-x^m f_u(x,u_0)\varepsilon^{4/(m+2)}b\\&\quad\cdot\left[\frac{(u_0''-g)(0)}{\xi^m f_u(0)}+\frac{m(m+1)(u_0''-g)(0)}{\xi^{2m+2}f_u^2(0)}\right]\\&\quad+\mathcal{O}(x^m\varepsilon^{4/(m+2)}\xi^{-3m-4})+\mathcal{O}(x^m\varepsilon^{8/(m+2)}\xi^{-2m}),\end{aligned} \tag{A4}$$

where $f_u(0)=f_u(0,u_0(0))$. Using $\xi=x\varepsilon^{-2/(m+2)}$ and

$$b(x)=\frac{u_0''(x)-g(x,u_0(x),0)}{u_0''(0)-g(0,u_0(0),0)}\,\frac{f_u(0,u_0(0))}{f_u(x,u_0(x))},$$

we have

$$(\mathrm{A4})=\mathcal{O}(\varepsilon^4x^{-m-1})+\mathcal{O}(\varepsilon^4x^{-m})+\mathcal{O}(\varepsilon^6x^{-2m-4}). \tag{A5}$$

It follows immediately from (A5) that

$$(\mathrm{A2})=\mathcal{O}(\varepsilon^4)\quad\text{if } |x|\geqq\delta>0,$$

where δ is independent of ε, and

$$(\mathrm{A2})=\mathcal{O}(\varepsilon^{2+2\gamma})+\mathcal{O}(\varepsilon^{(2+(\gamma m+\gamma+2)/(m+2))})\quad\text{if } 1\geqq|x|\geqq M\varepsilon^{(2-\gamma)/(m+2)},$$

where γ and M are any positive ε-independent constants.

Finally, consider the case that $|x|\leqq\varepsilon^{(2-\gamma)/(m+2)}$. We have

$$\begin{aligned}(\mathrm{A2})&=\varepsilon^2(u_0''-g)(x)+\mathcal{O}(\varepsilon^{(2+4/(m+2))}v)+\mathcal{O}(\varepsilon^{2+2/(m+2)}\dot v)+\varepsilon^2 b[\ddot v-\xi^m f_u(0,u_0(0))v]\\&\quad+\mathcal{O}(\varepsilon^2x\xi^m v)+\mathcal{O}(\varepsilon^{8/(m+2)}x^m v^2),\end{aligned}$$

which by (3.5) and the fact that $b(0)=1$ yields

$$\begin{aligned}(\mathrm{A2})&=\mathcal{O}(\varepsilon^2x)+\mathcal{O}(\varepsilon^{(2+4/(m+2))}v)+\mathcal{O}(\varepsilon^{(2+2/(m+2))}\dot v)+\mathcal{O}(\varepsilon^2x\xi^m v)+\mathcal{O}(\varepsilon^{8/(m+2)}x^m v^2)\\&=\mathcal{O}(\varepsilon^{(2m+6-\gamma)/(m+2)}).\end{aligned}$$

From the preceding calculations, it follows that the best estimate is obtained by setting $2\gamma=(2-\gamma)/(m+2)$, so that $\gamma=2/(2m+5)$. The uniform estimate

$$(\mathrm{A2})=\mathcal{O}(\varepsilon^{(4m+12)/(2m+5)})$$

is obtained, which agrees with (3.12).

Appendix B. Verification of (3.25). We will show only that

$$\int_0^x |t-x| x^m H_m(x, t, \varepsilon)\, dt = \mathcal{O}(\varepsilon^{2/(m+2)}) \tag{B1}$$

uniformly for $0 \leqq x \leqq 1$ since estimates over the other t intervals are similar.

Let M be a positive constant and consider first the case $0 \leqq x \leqq \varepsilon^{2/(m+2)}$. Using (3.17), we have that the integral in (B1) is (except for an inessential constant multiple)

$$\begin{aligned} &\varepsilon^{-(2m+2)/(m+2)} x^m h_1\left(\left(\frac{\lambda}{\varepsilon}\right)^{2/(m+2)} x\right) \int_0^x (x-t) h_2\left(\left(\frac{\lambda}{\varepsilon}\right)^{2/(m+2)} t\right) dt \\ &= \frac{x^m h_1((\lambda/\varepsilon)^{2/(m+2)} x)}{\lambda^{2/(m+2)} \varepsilon^{(2m-2)/(m+2)}} \int_0^{x\varepsilon^{-2/(m+2)}} \left(\frac{x}{\varepsilon^{2/(m+2)}} - \frac{s}{\lambda^{2/(m+2)}}\right) h_2(s)\, ds \qquad \text{(B2)} \\ &= \mathcal{O}(\varepsilon^{2/(m+2)}). \end{aligned}$$

Next, for $x \geqq M\varepsilon^{2/(m+2)}$, we have

$$\begin{aligned} &\frac{x^m h_1((\lambda/\varepsilon)^{2/(m+2)} x)}{\varepsilon^{(2m+2)/(m+2)}} \int_0^{M\varepsilon^{2/(m+2)}} (x-t) h_2\left(\left(\frac{\lambda}{\varepsilon}\right)^{2/(m+2)} t\right) dt \\ &= \frac{x^{m+1} h_1((\lambda/\varepsilon)^{2/(m+2)} x)}{\lambda^{2/(m+2)} \varepsilon^{2m/(m+2)}} \left[\int_0^M h_2(s)\, ds + \mathcal{O}(1)\right] \qquad \text{(B3)} \\ &= \mathcal{O}(\varepsilon^{2/(m+2)}). \end{aligned}$$

Finally, from (3.16) we have

$$\begin{aligned} &\frac{x^m h_1((\lambda/\varepsilon)^{2/(m+2)} x)}{\varepsilon^{(2m+2)/(m+2)}} \int_{M\varepsilon^{2/(m+2)}}^x (x-t) h_2\left(\left(\frac{\lambda}{\varepsilon}\right)^{2/(m+2)} t\right) dt \\ &\leqq \frac{x^m}{\varepsilon^{(2m+2)/(m+2)}} \int_{M\varepsilon^{2/(m+2)}}^x (x-t) \\ &\quad \cdot \left(\exp\left(-\frac{2}{\varepsilon(m+2)} x^{(m+2)/2}\right) \Big/ (x\varepsilon^{-(2/(m+2))})^{m/4}\right) \qquad \text{(B4)} \\ &\quad \cdot \left(\exp\left(\frac{2}{\varepsilon(m+2)} t^{(m+2)/2}\right) \Big/ (t\varepsilon^{-(2/(m+2))})^{m/4}\right) dt \\ &= \frac{x^{3m/4}}{\varepsilon} \int_{M\varepsilon^{2/(m+2)}}^x \frac{(x-t)}{t^{m/4}} \exp\left(\frac{2}{\varepsilon(m+2)} (t^{(m+2)/2} - x^{(m+2)/2})\right) dt \\ &\leqq C \frac{x^{3m/4}}{\varepsilon} \int_{M\varepsilon^{2/(m+2)}}^x \frac{(x-t)}{t^{m/4}} \exp\left(\frac{2(t-x)}{\varepsilon(m+2)} x^{m/2}\right) dt \end{aligned}$$

since $t^{(m+2)/2} - x^{(m+2)/2} \leqq (t-x)x^{m/2}$ for $0 \leqq t \leqq x$. Using integration by parts on the last expression in (B4), we have that the first expression in (B4) is no greater than

$$\begin{aligned} C \frac{x^{3m/4}}{\varepsilon^{(3m+4)/(2m+4)}} \Bigg[&(M\varepsilon^{2/(m+2)} - x) \frac{\varepsilon(m+2)}{2x^{m/2}} \exp\left(\frac{2}{\varepsilon(m+2)} (M\varepsilon^{2/(m+2)} - x) x^{m/2}\right) \\ &+ \frac{\varepsilon^2 (m+2)^2}{4x^m} \left(1 - \exp\left(\frac{2}{\varepsilon(m+2)} (M\varepsilon^{2/(m+2)} - x) x^{m/2}\right)\right)\Bigg] \qquad \text{(B5)} \\ = \mathcal{O}(\varepsilon^{2/(m+2)+\delta m/4}) \end{aligned}$$

if $x = \mathcal{O}(\varepsilon^{2/(m+2)-\delta})$ and $0 < \delta < 2/(m+2)$.

The estimates (B2), (B3), and (B5) imply that (B1) is valid uniformly for $x \in [0, 1]$.

ON THE EXISTENCE OF SOLUTIONS OF A TWO-POINT BOUNDARY VALUE PROBLEM ARISING FROM FLOWS IN A CYLINDRICAL FLOATING ZONE*

CHUNQUING LU† AND NICHOLAS D. KAZARINOFF‡

Abstract. Existence of one solution for a two-point boundary value problem arising from flows in a cylindrical floating zone is proved using forward and backward shooting and the Schauder fixed point theorem. If $Q = 2A^3$ Re, where A is the aspect ratio and Re is the Reynolds number, then the existence theorem holds only for $Q < 1$.

Key words. nonautonomous two-point boundary value problem, nonlinear backward shooting, Schauder fixed point theorem

AMS(MOS) subject classification. 34

1. Introduction. We consider solutions of the following nonautonomous two-point boundary value problem (TPBVP) on $[0, 1]$:

$$\begin{aligned} &\text{(a)} \quad [\eta(f'/\eta)']' + Q[f(f'/\eta)' - \eta(f'/\eta)^2] = \beta\eta \qquad (' = d/d\eta), \\ &\text{(b)} \quad f(0) = f(1) = 0 \quad \text{and} \quad (f'/\eta)'|_{\eta=0} = (f'/\eta)'|_{\eta=1} - 1 = 0. \end{aligned} \tag{1.1}$$

This problem arises in the study of surface-tension induced flows of a liquid metal or semiconductor in a cylindrical floating zone of length $2L$ and radius R. In dimensionless coordinates (r, x), points of the cylinder are given by $-1 \leqq x = X/L \leqq 1$, $0 \leqq \eta = r/R \leqq 1$, with free surface $\eta = 1$. The (x, r)-components of dimensionless velocity (u, v) are, respectively, $u = 2A^3(\text{Re})f/\eta$ and $v = -2A^3(\text{Re})f'/\eta$, where Re is the Reynolds number ($Q = 2A^3$ Re), and $A = L/R$ is the aspect ratio. Assuming that the dimensionless pressure p is a quadratic function of x, we find that the r-component of the acceleration equation in the Navier–Stokes energy system describing the flow of fluid and its temperature in the cylinder becomes (1.1)(a). The physical boundary conditions reduce to the conditions (1.1)(b) if we make the assumption that the free boundary is time-independent but not "flat."

Numerical solutions of (1.1) have been found [1] for $0 \leqq Q \leqq 32.7$ and $Q \geqq 1749$ (see Fig. 1). At $Q = 0$, the unique solution of (1.1) is $\eta^2(\eta^2 - 1)/8$. We prove existence of at least one solution of (1.1) for $Q \in [0, Q_0)$, with Q_0 sufficiently small by applying the Schauder fixed point theorem (see [2], where Lu et al. have used the same method to study a simpler TPBVP). The nonautonomous nature of (1.1) makes the proof of our main theorem longer, more complex, and more delicate than the proof of the corresponding result, Theorem 2 of [2]. We are also able to give a crude estimate of how small Q must be for our existence theorem to hold, namely, $Q < Q_0 = 1.0$.

The solutions we have found all correspond to two-cell solutions on the left-hand branch in Fig. 1; they all have $f(\eta) < 0$ on $(0, 1)$ with f' vanishing just once there. Thus u preserves its sign and v vanishes exactly once on $(0, 1)$, which means that these solutions give rise to but two flow cells, one in each half ($x > 0$ and $x < 0$) of the cylinder. For some of the numerically found solutions on the right-hand branch, f does change sign once on $(0, 1)$. These solutions correspond to three-cell flows in the

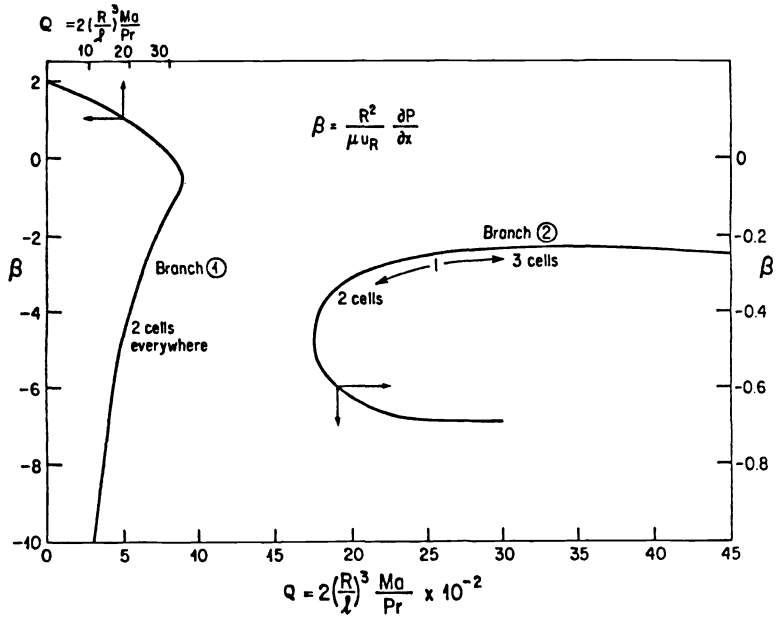

FIG. 1

cylinder. The mathematical existence of such solutions, as well as the existence of others, is still an open question.

2. A nonlinear operator T. Let $g=(f'/\eta)'$. Then (1.1)(a) can be rewritten as

$$g'+[(1+Qf)/\eta]g-Q(f'/\eta)^2=\beta. \tag{2.1}$$

We differentiate (1.2) once with respect to η and obtain the equation

$$g''+[(1+Qf)/\eta]g'-[\{1+Q(\eta f)'\}/\eta^2]g=0 \qquad (0<\eta<1) \tag{2.2}$$

to which we add the conditions

$$\lim_{\eta\searrow 0} g(\eta)=g(0)=g(1)-1=0. \tag{2.3}$$

Let

$$\Omega=\{f\,|\,f\in C^1[0,1], f(0)=0, f'(0)=0, f(1)=0, -\tfrac{1}{3}\leqq f(\eta)\leqq 0,$$
$$-\tfrac{2}{3}\leqq f'(\eta)\leqq 1, \text{ and } \|f\|\leqq\tfrac{4}{3}\}$$

where $\|f\|=\max|f|+\max|f'|$, and the maxima are taken over $[0,1]$. It is easy to check that Ω is a nonempty, closed, bounded, convex subset of $C^1[0,1]$.

Given any $f\in\Omega$, find the solution g of the linear TPBVP (2.2)-(2.3), and let f^* be the solution of the TPBVP $(f^{*\prime}/\eta)'=g(\eta\in(0,1))$ with $f^*(0)=f^*(1)=0$. Then define $Tf=f^*$. Thus, given a $Q\in[0,Q_0]$ for some $Q_0>0$, if we can find an $f\in\Omega$ for which $Tf=f$, then f will be a solution of (1.1) with

$$f(\eta)=\int_0^\eta\left[\int_0^s g(t)\,dt\right]ds+\frac{1}{2}\eta^2 f''(0) \quad\text{and}\quad f''(0)=-2\int_0^1\left[s\int_0^s g(t)\,dt\right]ds.$$

We carry out the above program for defining f^* and $Tf=f^*$ in the next section. In § 4 we show that $T(\Omega)\subseteq\Omega$, T is continuous and T maps bounded subsets of Ω

into compact subsets of Ω. Having thus set the stage, in § 5, we apply Schauder's fixed point theorem [3] and obtain our main theorem.

3. Some lemmas. We now consider the following backward initial value problem on $(0, 1)$:

$$g''+[(1+Qf)/\eta]g'-[\{1+Q(\eta f)'\}/\eta^2]g=0 \quad \text{with } g(1)=1 \text{ and } g'(1)=\alpha. \tag{3.1}$$

We multiply (3.1) by the integrating factor $I(\eta)=\exp\{\int_1^\eta [(1+Qf(s))/s]\,ds\}$, integrate the differential equation in (3.1) from 1 to η, and obtain

$$g'(\eta)I(\eta)=\int_1^\eta \{[1+Q(tf)']/t^2\}g(t)I(t)\,dt+\alpha. \tag{3.2}$$

In each of the eight lemmas below the following hypotheses are to be understood: $f\in\Omega$, g is a solution of (3.1), and $Q\in[0, 1)$.

LEMMA 1. *If $\alpha=g'(1)\leqq 0$, then $g'(\eta)\leqq 0$ for all $\eta\in(0, 1)$.*

Proof. Observe that since $f\in Q$,

$$1+Q(tf)'=1+Q(f+tf')>1-Q(\tfrac{1}{3}+2t/3)>0 \tag{3.3}$$

for all $Q\in[0, 1]$ and all $t\in(0, 1)$. If $g'(1)\leqq 0$, then initially for $t<1$, $g(t)\geqq 1$. Hence, the integral on the right-hand side of (3.2) is negative as long as $g(t)>0$, and so, we claim, $g'(\eta)\leqq 0$ for all $\eta\in(0, 1)$. If not, $g'(\eta_0)>0$ for some $\eta_0\in(0, 1)$, and there must be a first zero $\eta_1>\eta_0$ of g' (closest to one) for which $g''(\eta_1)<0$. But from the differential equation (3.1) $g''(\eta_1)>0$. This is a contradiction, and the proof of Lemma 1 is complete. □

LEMMA 2. *If $g(\eta_0)=0$ for some $\eta_0\in(0, 1)$, then $g(\eta)<0$ for $0<\eta<\eta_0$; that is, g has no more than one zero and*

$$\lim_{\eta\searrow 0} g(\eta)<0.$$

Proof. Suppose not. Let $\eta_0<1$ be the zero of g closest to 1 and let η_1 be the next zero of g. Then there must be an $\eta_2\in(\eta_1, \eta_0)$ such that $g(\eta_2)<0$ and $g'(\eta_2)=0$. To see this we note that, since η_1 is the first zero of g less than η_0 and $g(1)=0$, $g(\eta)<0$ on (η_1, η_0), $g(\eta_2)$ is a local minimum of g and $g''(\eta_2)>0$. However, the differential equation in (3.1) implies $g''(\eta_2)<0$ since $g'(\eta_2)=0$, $g(\eta_2)<0$ and $1-Q(tf)'>0$. This is a contradiction.

It remains to prove that $\lim_{\eta\searrow 0} g(\eta)<0$. We first observe that since $g(\eta_0)=0$, $g'(\eta_0)\neq 0$, for otherwise $g\equiv 0$. Then $g'(\eta_0)>0$, and by (3.1), $g''(\eta_0)<0$. Thus $g'(\eta)>g'(\eta_0)$ and $g(\eta)<0$ for $\eta<\eta_0$ and close to η_0. Moreover, $g'(\eta)$ remains positive on $(0, \eta_0)$, because $g''(\eta)<0$ wherever $g'(\eta)=0$ for $\eta<\eta_0$. Therefore, $\lim_{\eta\searrow 0} g(\eta)<0$ (the limit may be $-\infty$). This completes the proof. □

LEMMA 3. *Let $Q\in[0, 1)$ be given, $f\in\Omega$, and $g(\eta, \alpha)$ solve the backward initial value problem* (3.1). *Then there exists an $\alpha_0>0$ such that $\alpha>\alpha_0$ implies an $\eta\in(\frac{3}{4}, 1)$ exists at which $g(\eta, \alpha)=0$.*

Proof. Rewrite the differential equation in (3.1) as follows:

$$g''=-[(1+Qf)/\eta]g'+[\{1+Q(\eta f)'\}/\eta^2]g. \tag{3.4}$$

Let α_1 satisfy the condition

$$-(1-Q/3)\alpha_1+(1+Q\|f\|)/(\tfrac{1}{2})^2<0. \tag{3.5}$$

Then for all $\alpha>\alpha_1$ and $\eta\in[\frac{1}{2}, 1)$,

$$-(1-Q/3)\alpha/\eta+g(1; a)(1+Q\|f\|)/(\eta)^2<0;$$

hence, $g''(1;\alpha)<0$. This implies that for $\eta<1$ and η close to 1, $g'(\eta;\alpha)>g'(1;\alpha)=\alpha$ and $g(\eta;\alpha)<1$. We claim $g''(\eta;\alpha)<0$ as long as $g'(\eta;\alpha)>\alpha$ for $\eta\in[\frac{1}{2},1)$. To see this, we use (3.4)-(3.5) together with $g'(\eta;\alpha)>\alpha$ and $g(\eta;\alpha)<g(1;\alpha)=1$ to obtain the following estimate: for $\alpha>\alpha_1$,

$$\begin{aligned} g''(\eta;\alpha) &< -(1-Q/3)\alpha/\eta+g(1,\alpha)(1+Q\|f\|)/(\eta)^2 \\ &< -(1-Q/3)\alpha_1+(1+Q\|f\|)/(\tfrac{1}{2})^2 \qquad (\eta\in[\tfrac{1}{2},1)) \\ &< 0. \end{aligned} \tag{3.6}$$

Then g' increases as η decreases; hence, $g''(\eta;\alpha)<0$ and $g'(\eta;\alpha)>\alpha$ for $\eta\in[\frac{1}{2},1)$.

Using Taylor's formula, for $\eta\in[\frac{1}{2},1)$ we can write

$$g(\eta;\alpha)=g(1;\alpha)+g'(1;\alpha)(\eta-1)+g''(\xi;\alpha)(\eta-1)^2/2,$$

for some $\xi\in(\eta;1)$. From this and (3.6) we see that if $\alpha_0=\max[\alpha_1,4]$, then $g(\frac{3}{4};\alpha)<0$ for $\alpha>\alpha_0$. Finally, since $g(1;\alpha)=1$, we conclude that g must vanish somewhere on $(\frac{3}{4},1)$. The proof of the lemma is complete. □

LEMMA 4. *There is a nonempty set A such that $A\subset(0,\alpha_0)$ and*

$$0\leqq\lim_{\eta\searrow 0} g(\eta;\alpha)<1 \quad \textit{for } \alpha\in A.$$

Proof. We define two subsets of the real line as follows:

$$A_1=\{\alpha\,|\,g'(\eta;\alpha)\leqq 0 \text{ for some } \eta\in(0,1]\},$$
$$A_2=\{\alpha\,|\,g(\eta;\alpha)=0 \text{ for some } \eta\in(0,1)\}.$$

By Lemma 3, $A_2\neq\varnothing$; and A_2 is open since, by (3.1), $g'(\eta;\alpha)\neq 0$ if $g(\eta;\alpha)=0$. By Lemma 1, $A_1\neq\varnothing$, and A_1 is also open since, by (3.1), $g(\eta;\alpha)\neq 0$ if $g'(\eta;\alpha)=0$. We claim $A_1\cap A_2=\varnothing$. Suppose not. First, we observe that it is impossible for $g'(\eta)<0$ and the $g(\eta)=0$ to hold simultaneously. If $g(\eta)$ vanishes farther from 1 than $g'(\eta)$ becomes negative, then there must be a local maximum of g at a point η_1 where $g'(\eta_1)=0$, $g''(\eta_1)<0$, and $g(\eta_1)>0$. This contradicts (3.1). If $g'(\eta)<0$ farther from one than an $\eta<1$ exists where $g(\eta)=0$, then g must take on a negative local minimum, which also contradicts (3.1).

It is clear from the definitions of A_1 and A_2 that the complement $(A_1\cup A_2)^c$ in $\mathbb{R}^1$ of $A_1\cup A_2$ is not empty and $(A_1\cup A_2)^c\subset(0,\alpha_0)$, where α_0 is defined in the proof of Lemma 3 above. Let $A=(A_1\cup A_2)^c$. Then for $\alpha\in A$, $g'(\eta,\alpha)$ and $g(\eta,\alpha)$ are positive on $(0,1)$. Therefore, $\lim_{\eta\searrow 0} g(\eta)$ exists and $0\leqq\lim_{\eta\searrow 0} g(\eta)<1$. This completes the proof. □

We next prove that if $\alpha\in A$, $\lim_{\eta\searrow 0} g(\eta;\alpha)=0$.

LEMMA 5. *If $\lim_{\eta\searrow 0} g(\eta;\alpha)$ exists and is finite, and, in particular, if $\alpha\in A$, then this limit is zero.*

Proof. Recall from § 2 that for $f\in\Omega$, $f(0)=f'(0)=0$ and $f(\eta)<0$ on $(0,1)$. We begin with (3.2). Suppose $\eta_0>0$ is so small that

$$\tfrac{1}{2}<1+Q(\eta f)' \qquad (0\leqq\eta<\eta_0).$$

Then the integral appearing on the right-hand side of (3.2) can be rewritten as

$$\begin{aligned} \int_1^\eta \{[1+Q(tf)']/t^2\}g(t)I(t)\,dt &\equiv \int_1^\eta F(t)\,dt, \\ &= \int_1^{\eta_0} F(t)\,dt+\int_{\eta_0}^{\eta} F(t)\,dt, \\ &\equiv M(\eta_0)+B(\eta). \end{aligned} \tag{3.7}$$

Clearly, $M(\eta_0)<0$. Since $g(t)>0$ on $(0, 1]$, for $0<\eta<\eta_0$

$$\frac{1}{2}\int_{\eta_0}^{\eta} g(t)I(t)/t^2\,dt \geqq B(\eta) \tag{3.8}$$

where $I(t)$ is defined at the beginning of this section. Note that $f'(0)=0$ and $f(\eta)<0$ on $(0, 1)$ imply that given $\varepsilon>0$ there exists an $\eta_1=\eta_1(\varepsilon)>0$ such that

$$-\varepsilon<f(v)/v<0 \qquad (v\in(0, \eta_1)). \tag{3.9}$$

We rewrite the integral $h(t)$ in the exponent for $I(t)$ as

$$\begin{aligned} h(t) &= \int_1^{\eta_1}\{(1+Qf)/v\}\,dv+\int_{\eta_1}^{t}\{(1+Qf)/v\}\,dv \\ &\equiv N(\eta_1)+\ln t-\ln\eta_1+Q\int_{\eta_1}^{t}\left(\frac{f}{v}\right)dv. \end{aligned}$$

Therefore, for $0<t<\eta_1$

$$-Q\varepsilon(\eta_1-t)<h(t)-[N(\eta_1)+\ln t-\ln\eta_1]<Q\varepsilon(\eta_1-t). \tag{3.10}$$

Let $\eta_2=\min[\eta_0, \eta_1]$. Then (3.8) and (3.10) both hold for $0<t<\eta_2$. Therefore,

$$tN^-(\eta_2, \varepsilon)\,e^{+Q\varepsilon t}<I(t)<tN^+(\eta_2, \varepsilon)\,e^{-Q\varepsilon t} \tag{3.11}$$

where

$$N^{\pm}(\eta, \varepsilon)=(1/\eta)\,e^{N(\eta)(\pm Q\varepsilon\eta)}.$$

It follows that for $0<\eta<\eta_2$ the function $B(\eta)$ defined in (3.8) satisfies the following inequalities:

$$B(\eta)<\frac{1}{2}\int_{\eta_2}^{\eta} t^{-1}g(t)N^+(\eta_2, \varepsilon)\,e^{-Q\varepsilon t}\,dt. \tag{3.12}$$

Finally, from (3.2), (3.7), and (3.12), for $0<\eta<\eta_2$ we obtain the inequality

$$\eta N^-(\eta_2, \varepsilon)g'(\eta)\,e^{+Q\varepsilon\eta}<\frac{1}{2}\int_{\eta_2}^{\eta} t^{-1}g(t)N^+(\eta_2, \varepsilon)\,e^{-Q\varepsilon t}\,dt+M(\eta_2)+g'(1). \tag{3.13}$$

If we let $\eta\searrow 0$ in (3.13) and $\lim_{\eta\searrow 0} g(\eta)=\beta>0$, then the integral (3.13) approaches $-\infty$. Thus there is an $\eta^*>0$ such that $g'(\eta)<0$ for $0<\eta<\eta^*$. This is a contradiction. Consequently, $\lim_{\eta\searrow 0} g(\eta; \alpha)=0$. The proof of the lemma is complete. □

LEMMA 6. *There exists only one* $\alpha\in A$ *such that* $\lim_{\eta\searrow 0} g(\eta; \alpha)=0$.

Proof. We prove this by contradiction. Suppose there exist two solutions $g_1(\eta)=g(\eta; \alpha_1)$ and $g_2(\eta)=g(\eta; \alpha_2)$ that approach zero as $n\searrow 0$. Let $g_1-g_2=h$. Then h satisfies the differential equation

$$h''+[(1+Qf)/\eta]h'-[\{1+Q(\eta f)'\}/\eta^2]h=0 \tag{3.14}$$

with $h(1)=0$, $h'(1)=\alpha_1-\alpha_2\neq 0$. Suppose $\alpha_1<\alpha_2$. Then $h(\eta)>0$ and $h''(\eta)>0$ as long as $h'(\eta)<0$. Suppose that for some first point $\eta_0\in(0, 1)$ (closest to 1) $h'(\eta_0)=0$. Then it must be that $h(\eta_0)>0$. Then, by (3.14) we see that $h''(\eta_0)>0$, which is a contradiction. Therefore, (a) $g_1'(\eta)<g_2'(\eta)$ and (b) $g_1(\eta)>g_2(\eta)$. Integrating (a) from zero to η and using our assumption that $g_1(+0)=g_2(+0)=0$, we find that $g_1(\eta)<g_2(\eta)$, which contradicts (b), and the proof is complete. □

The proof of Lemma 5 implies that not only $\lim_{\eta \searrow 0} g(\eta) = 0$ but that $\eta g'(\eta)$ remains bounded as $\eta \searrow 0$. We now show that, under the hypotheses of Lemma 4, $\lim_{\eta \searrow 0} \eta g'(\eta) = 0$.

LEMMA 7. *Under the hypotheses of Lemma* 4, $\lim_{\eta \searrow 0} \eta g'(\eta) = 0$.

Proof. It is obvious that $\lim_{\eta \searrow 0} g'(\eta) I(\eta) \geqq 0$ exists and

$$0 \leqq \lim_{\eta \searrow 0} g'(\eta) I(\eta) < \alpha.$$

Also, $I(\eta)/\eta$ has a finite limit as $\eta \searrow 0$. Hence, $\lim_{\eta \searrow 0} \eta g'(\eta)$ exists and is nonnegative. Suppose this limit is $\nu > 0$. Then given $\varepsilon > 0$ with $0 < \varepsilon < \nu$, there exists an $\eta^{\#} > 0$ such that for $0 < \eta < \eta^{\#}$,

$$\nu - \varepsilon < \eta g'(\eta) < \nu + \varepsilon.$$

We divide these inequalities by η and integrate from η to $\eta^{\#}$. The result is

$$(\nu - \varepsilon)[\ln(\eta^{\#}/\eta)] < g(\eta^{\#}) - g(\eta) < (\nu + \varepsilon)[\ln(\eta^{\#}/\eta)].$$

These inequalities imply that as $\eta \searrow 0$, $g \to -\infty$, which is a contradiction. Hence, $\lim_{\eta \searrow 0} \eta g'(\eta) = 0$. □

Remark. If $\lim_{\eta \searrow 0} g(\eta)$ exists (including $\pm\infty$) and g' has constant sign near $\eta = 0$, then all integral curves of (3.1) are asymptotic to either $\pm\infty$ as $\eta \searrow 0$, except for one that approaches the origin.

We next obtain bounds for g and g' on $[0, 1]$.

LEMMA 8. *If the hypotheses of Lemma* 4 *are satisfied and* $\alpha \in A$, *then the solution* g *of* (3.1) *satisfies the inequalities*

$$\eta^{1+2Q/3} \leqq g(\eta) \leqq \eta^{1-Q/3}, \tag{3.15}$$

$$(1 - Q/3)\eta^{1+2Q/3} \leqq \eta g'(\eta) \leqq (1 + 2Q/3)\eta^{1-Q/3} \tag{3.16}$$

for all $\eta \in [0, 1]$.

Proof. Rewrite (3.1):

$$(\eta^2 g')' - (\eta g)' - Q(\eta f g)' = -2Q\eta f g'. \tag{3.17}$$

We integrate (3.17) from zero to η and apply Lemmas 5 and 6 ($g(0) = 0$ and $\eta g'(\eta)|_{\eta=0} = 0$) to obtain

$$g' = [(1 + Qf)/\eta]g - (2Q/\eta^2) \int_0^{\eta} tfg'\, dt \qquad (0 < \eta < 1). \tag{3.18}$$

Since $-\frac{1}{3} \leqq f(\eta) \leqq 0$ and $g'(\eta) \geqq 0$, using (3.18), we obtain the inequalities

$$[(1 - \tfrac{1}{3}Q)/\eta]g(\eta) \leqq g'(\eta) \leqq (1/\eta)g(\eta) + [2Q/(3\eta^2)] \int_0^{\eta} tg'\, dt \qquad (0 < \eta < 1). \tag{3.19}$$

We apply integration by parts to the integral in (3.19) to find

$$\int_0^{\eta} tg'\, dt = \eta g(\eta) - \int_0^{\eta} g\, dt \qquad (0 < \eta < 1). \tag{3.20}$$

Finally, combining (3.19) and (3.20) and using the positivity of g for $\alpha \in A$, we obtain the inequalities

$$[(1 - \tfrac{1}{3}Q)/\eta]g(\eta) \leqq g'(\eta) \leqq (1/\eta)g(\eta) + [2Q/(3\eta^2)][\eta g(\eta)] = [(1 + 2Q/3)/\eta]g,$$

namely,

$$(1 - \tfrac{1}{3}Q)/\eta \leqq g'(\eta)/g(\eta) \leqq (1 + 2Q/3)/\eta \qquad (0 < \eta < 1). \tag{3.21}$$

If we integrate (3.21) from η to 1 and exponentiate the result, we obtain (3.15). The combination of (3.15) with (3.21) then yields (3.16), and the lemma is proved. □

4. Definition, continuity, compactness of the operator T. We recall the definitions of Ω and T from § 2. The domain Ω of T consists of the functions in $C^1[0,1]$ for which $f(0)=f'(0)=f(1)=0$, $-\frac{1}{3}\leqq f(\eta)\leqq 0$, $-\frac{2}{3}\leqq f'(\eta)\leqq 1$ and $\|f\|\leqq\frac{4}{3}$. The operator T is defined on Ω by $Tf=f^*$, where f^* satisfies the equation $(f^{*\prime}/\eta)'=g$, subject to the boundary conditions $f^*(0)=f^*(1)=f^{*\prime}(0)=0$, and where g is *the* solution of the backward initial value problem (3.1), found in the last section, with α chosen so that $g(0)=0$ and on $(0,1)$ both $g(\eta)$ and $g'(\eta)$ are positive. We first prove Lemma 9.

LEMMA 9. *If the hypotheses of Lemma* 8 *are satisfied, then the operator T is well defined and maps any bounded subset of Ω into a compact subset of Ω.*

Proof. We first show that for $\|f\|\leqq\frac{4}{3}$, as in the definition of Ω, T maps Ω into itself. We integrate the equation $(f^{*\prime}/\eta)'=g$ from zero to η and use the conditions $f^*(0)=f^{*\prime}(0)=0$ and obtain the results that

$$f^{*\prime}(\eta)=k\eta+\eta\int_0^\eta g(t)\,dt, \tag{4.1}$$

and

$$f^*(\eta)=\frac{1}{2}k\eta^2+\int_0^\eta\left\{x\int_0^x g(t)\,dt\right\}dx, \tag{4.2}$$

where

$$k=-2\int_0^1\left\{x\int_0^x g(t)\,dt\right\}dx=f^{*\prime\prime}(0).$$

Then, $f^*(1)=0$. Differentiating (4.1), we find that

$$f^{*\prime\prime}(\eta)=k+\int_0^\eta g(t)\,dt+\eta g(\eta). \tag{4.3}$$

Since g is positive and strictly increasing on $(0,1)$, $f^{*\prime\prime}$ has at most one zero on $(0,1)$, and hence f^* does not change sign on $(0,1)$. But $f^{*\prime\prime}(0)=k<0$ and $f^*(0)=f^{*\prime}(0)=0$ imply that f^* is negative near zero. Thus, $f^*(\eta)<0$ on $[0,1]$.

We now show that f^* and its derivatives have the bounds necessary for f^* to lie in Ω and for T to have the property that if $K\in\Omega$ is closed and bounded, then the closure, cl $(T(K))$, of $T(K)$ is compact. From (4.3) we see that

$$k<f^{*\prime\prime}(\eta)<\int_0^\eta g(t)\,dt+\eta g(\eta)<2, \tag{4.4}$$

where

$$-k=|k|\leqq 2\int_0^1\left\{x\int_0^x dt\right\}dx=\frac{2}{3},$$

and

$$-\tfrac{2}{3}\leqq k<0. \tag{4.5}$$

Using this result in (4.2), we obtain the inequalities

$$0\geqq f^*(\eta)\geqq\tfrac{1}{2}k\eta^2\geqq k/2\geqq-\tfrac{1}{3}.$$

Thus

$$|f^*(\eta)|\leqq\tfrac{1}{3}, \tag{4.6}$$

and, by (4.4)

$$|f^{*\prime\prime}(\eta)| \leqq 2. \tag{4.7}$$

Finally, using the above results in (4.1) we obtain the inequalities

$$-\tfrac{2}{3} \leqq f^{*\prime}(\eta) \leqq 1. \tag{4.8}$$

From (4.6) and (4.8) it now follows that $\|f^*\| \leqq 1+\frac{1}{3}=\frac{4}{3}$. Therefore, if $0 \leqq Q < 1.0 = Q_0$, then $1 = Q(\eta f)' > 0$, and the hypotheses of the previous lemmas hold. Thus g has the desired properties, T is well defined, and $T(\Omega) \subseteq \Omega$. It also follows that if K is a closed and bounded subset of Ω, then cl $(T(K))$ is compact. Suppose $\{f_i\}$ is a sequence of functions in K with images f_i^* under T. Then $|f_i^{*\prime\prime}| \leqq 2$, $|f_i^{*\prime}| \leqq 1$ and $|f_i^*| \leqq \frac{1}{3}$ on $[0, 1]$ for each i.

Therefore, $\{f_i^*\}$ and $\{f_i^{*\prime}\}$ are equicontinuous on $[0, 1]$. Hence, by the Arzela-Ascoli theorem, there exist a subsequence $\{f_{n(i)}^*\}$ of $\{f_i\}$ and a $g \in$ cl $(T(K))$ such that $\|f_{n(i)}^* - g\| \to 0$ as $i \to \infty$. Thus, cl $(T(K))$ is compact. The lemma is proved. □

Last, we prove Lemma 10.

LEMMA 10. *The operator T is continuous.*

Proof. By (4.2) and the definition of k, it is sufficient to prove that for any given $f_0 \in \Omega$ and any $\varepsilon > 0$, there exists a $\delta > 0$ such that if $\|f - f_0\| < \delta$ and $f \in \Omega$, then $\max_{[0,1]} (|g(\eta) - g_0(\eta)|) < \varepsilon$, where g and g_0 are solutions of (3.1) corresponding to coefficients f and f_0, respectively, that are positive and have positive first derivatives on $(0, 1)$ and that vanish at $\eta = 0$.

Step 1. Since the estimates for g in (3.16) hold for any $f \in \Omega$, we obtain from (3.15) the estimate

$$|g(\eta) - g_0(\eta)| \leqq 2\eta^{1-Q/3} \qquad (0 \leqq \eta \leqq 1). \tag{4.9}$$

Then by (4.9), for $0 \leqq \eta \leqq \varepsilon$,

$$|g(\eta) - g_0(\eta)| \leqq 2\varepsilon^{1-Q/3} \equiv \varepsilon_1. \tag{4.10}$$

Step 2. Let $r(\eta) = g(\eta) - g_0(\eta)$. Then, after performing some manipulation, we find from (3.1) that

$$\begin{aligned} L[r] &\equiv r'' + [(1+Qf_0)/\eta]r' - [(1+Q(\eta f_0)')/\eta^2]r \\ &= -(Q/\eta^2)[(f-f_0)(\eta g' - g) - (f' - f_0')\eta g] \\ &\equiv -F(\eta) \end{aligned} \tag{4.11}$$

with $r(0) = r(1) = 0$. Obviously, (4.10) yields $|r(\varepsilon)| < \varepsilon_1$. We shall consider (4.11) on $[\varepsilon, 1]$ and prove that $|r|$ is uniformly as small as we like on $[\varepsilon, 1]$ if f is sufficiently close to f_0 and $0 \leqq Q < 1$. By Lemma 8, g and g' are bounded independently of $f \in \Omega$. Thus if ε^* is any point of the interval

$$0 < \varepsilon^* < \tfrac{1}{2}(1-Q)\varepsilon_1, \tag{4.12}$$

then, if f is close enough to f_0 and $0 \leqq Q < 1$,

$$(Q/\varepsilon^2)[\max\{|\eta g'| + |\eta g| + |g|\}]\|f - f_0\| \leqq (3+2Q/3)(Q/\varepsilon^2)\|f - f_0\| < \varepsilon^*, \tag{4.13}$$

where the maximum is taken over $[0, 1]$.

We may fix f_0. By (4.13), if r is any solution of (4.11) on $[\varepsilon, 1]$ with $r(1) = 0$ and $|r(\varepsilon)| \leqq \varepsilon_1$,

$$L[r] - \varepsilon^* < L[r] + F(\eta) < L[r] + \varepsilon^* \qquad (\varepsilon \leqq \eta \leqq 1). \tag{4.14}$$

Let $r^{\pm}$ denote the solution of $L[r] \pm \varepsilon^* = 0$ satisfying $r^{\pm}(1) = 0$ and $r^{\pm}(\varepsilon) = r(\varepsilon)$, where $L[r] = -F$ and $r(0) = r(1) = 0$. Then by (4.14) the standard comparison theorem applies to (4.11) and yields

$$r^-(\eta) \leqq r(\eta) \leqq r^+(\eta)$$

for $\eta \in [\varepsilon, 1]$.

Step 3. It remains to prove that both $|r^{\pm}(\eta)|$ are small. Fix r so that $|r(\varepsilon)| < \varepsilon_1$. We shall use (4.12) to show that $|r^{\pm}(\eta)| < \varepsilon_1$ on $[\varepsilon, 1]$. To see this consider the problems

$$L[v] \pm \varepsilon^* = 0 \quad \text{with } v(1) = 0 \text{ and } v(\varepsilon) = r(\varepsilon).$$

These are solved by $r^{\pm}$.

If there exists a point x_+ (x_-) in $(\varepsilon, 1)$ for which $r^+(x_+) > \varepsilon_1$ ($r^-(x_-) > \varepsilon_1$), then there must be a point y_+ (y_-) in $(\varepsilon, 1)$ at which one or both of r^+ and r^- take their maximum value, namely, either $r^{+\prime}(y_+) = 0$, $r^{+\prime\prime}(y_+) < 0$, and $r^+(y_+) > \varepsilon_1$, and/or $r^{-1}(y_-) = 0$, $r^{-\prime\prime}(y_-) < 0$, and $r^-(y_-) > \varepsilon_1$. But we also see from (4.12) that one or both of the following hold:

$$\begin{aligned} r^{\pm\prime\prime}(y_\pm) \pm \varepsilon^* &= \{[1 + Qf_0(y_\pm) + Qf_0'(y_\pm)y_\pm]/y_\pm^2\} r^{\pm}(y_\pm), \\ &> (1 - Q)\varepsilon_1 / y_\pm^2, \\ &> (1 - Q)\varepsilon_1. \end{aligned}$$

Hence,

$$r^{\pm\prime\prime}(y_\pm) > (1 - Q)\varepsilon_1 - (\pm\varepsilon^*) > 0;$$

that is, one or both of $r^{\pm\prime\prime}(y_\pm) > 0$. This is a contradiction. If there exists a point at which r^+ (r^-) is less than $-\varepsilon_1$, we argue similarly, and again we obtain a contradiction.

In summary, for any given $\varepsilon_1 > 0$, if we choose

$$\delta = \varepsilon^* / \{3 + 2Q/3)(Q/\varepsilon^2)\},$$

where ε and ε^* satisfy (4.10) and (4.12), respectively, then for $f \in \Omega$ and $\|f - f_0\| < \delta$, we see that $|g(\eta) - g_0(\eta)| < \varepsilon_1$ for all $\eta \in [0, 1]$. But then, by the estimates (4.1)-(4.3) for f^* in terms of g, it follows that $\|f^* - f_0^*\|$ can be made as small as we please if f is sufficiently close to f_0 and $Q \in [0, 1]$. This proves the continuity of T. □

5. The main theorem. The set Ω, defined in § 2 is a nonempty, closed, bounded, convex subset of $C^1[0, 1]$ with the usual norm ($\|f\|$ is the sum of the maxima over $[0, 1]$ of f and f'). We have shown that the operator $T: \Omega \mapsto \Omega$ is continuous and maps bounded subsets of Ω into compact subsets of Ω; that is, T is compact. Therefore, we may apply the Schauder Fixed Point Theorem to T on Ω and conclude that there exists at least one fixed point $f = Tf \in \Omega$ of T. This fixed point is a desired solution to the TPBVP (1.1a), (1.1b). We state this result as a theorem.

THEOREM. *For* $0 \leqq Q \leqq 1$, *there exists a* β *for which the two-point boundary value problem* (1.1) *has at least one solution* f. *Further, on* $(0, 1)$: $-\frac{1}{3} \leqq f(\eta) < 0$, $-\frac{2}{3} \leqq f'(\eta) \leqq 1$, *and* $-\frac{2}{3} \leqq f''(\eta) \leqq 2$.

Remark. We observe that the β for which the above-described solution exists is given by

$$\beta = 2g'(0) - Qf''(0)^2 = g'(1) + 1 - Qf'(1)^2.$$

We can easily obtain crude bounds for β from Lemma 7 and the bounds on f'' given in the theorem: for $0 \leqq Q < 1.0$, $-Qf''(0)^2 \leqq \beta \leqq 1 + g'(1)$, or $2(1 + \frac{1}{3}Q) \geqq \beta \geqq -4Q$. For $Q = 0$, the upper bound is sharp: if $Q = 0$, $\beta = 2$. But as Q is increased from zero,

the upper bound becomes progressively worse when compared to the numerical results (see (Fig. 1). The upper bound 1.0 on Q in our theorem falls far short of 32.7, the actual numerically found upper bound for existence of solutions having the properties indicated in the theorem. Recently, R. Seydel of the University of Würzburg, Federal Republic of Germany, has informed the second author that he has found a third branch of solutions of (1.1), connecting the two branches in Fig. 1 and running between points not too far from their nodes.

CONSTANT REGRESSION POLYNOMIALS AND THE WISHART DISTRIBUTION*

DONALD ST. P. RICHARDS†

Abstract. Results are obtained for the problems of constructing and characterizing scalar-valued polynomial statistics having constant regression on the mean of a random sample of Wishart matrices. The construction procedure introduced by Heller [*J. Multivariate Anal.*, 14 (1984), pp. 101-104] is generalized to show that certain polynomials in the principal minors of the sample matrices have zero regression on the mean. The zero-regression polynomials are characterized through expectations involving certain matrix-valued Bessel functions of Gross and Kunze [*J. Funct. Anal.*, 22 (1976), pp. 73-105]. It is shown that the zero-regression property characterizes Wishart distributions within a wide family of mixtures of Wishart distributions.

Key words. Wishart distribution, constant regression, polynomial statistics, hyperbolic differential operator, unitary representation, generalized Bessel function

1. Introduction. Suppose that $X_1, X_2, \cdots, X_n$ are independent, identically distributed $m \times m$ random matrices, each having the Wishart distribution $W_m(\Sigma, N)$ with positive definite (symmetric) covariance matrix Σ and N degrees of freedom. A scalar-valued polynomial statistic $P(\underset{\sim}{X})$, $\underset{\sim}{X} = (X_1, \cdots, X_n)$, is said to have *constant regression* on $L = X_1 + \cdots + X_n$ if the conditional expectation

$$E(P(\underset{\sim}{X}) \mid L) = \beta \tag{1.1}$$

almost everywhere, for some constant β. Without loss of generality, we may suppose $\beta = 0$, in which case the polynomial $P(\underset{\sim}{X})$ is called a *zero-regression polynomial.* In this paper, we consider the problems of constructing and characterizing zero-regression polynomials.

In the classical case, Lukacs and Laha [8] have obtained necessary and sufficient conditions for a quadratic polynomial statistic to have zero regression. Their results have been presented, within the more general context of characterizations of probability distributions, by Kagan, Linnik, and Rao [7]. Although these problems were originally motivated by a purely academic desire to determine the theoretical distribution of the parent population from hypothetical properties of a particular statistic, recent applications [9] include the construction of testing procedures.

Recently, Heller [4] has constructed zero-regression polynomials for the Wishart distribution by appropriately generalizing the methods of [8]. Her results are among a small number that have extended the classical developments to the setting of matrix distributions.

The main tool used in [4] is the hyperbolic differential operator of Herz [5]. Using more complex operators, we generalize (in § 2) the construction procedure of [4]. As a consequence, we find that certain polynomials in the principal minors of the sample matrices are zero-regression polynomials.

Section 3 presents several characterizations of zero-regression polynomials using unconditional expectations. The main result characterizes zero-regression polynomials through expectations involving the matrix-valued Bessel functions of Gross and Kunze

[2]. This result presents a new and unexpected link between harmonic analysis and multivariate statistical theory; further, it demonstrates the full complexity of the zero-regression problem in higher dimensions.

Following the results of [4], [8], a natural question is: Given that a polynomial $P(\underset{\sim}{X})$ has zero regression on L, is the underlying distribution necessarily Wishart? We obtain a partial answer, showing that if the parent distribution belongs to a wide class of Wishart mixtures, then the distribution is necessarily Wishart if $P(\underset{\sim}{X})$ is any one of a family of polynomials. In particular, this class of polynomials contains all the examples constructed in [4].

As a final comment, we remark that since the homogeneous zero regression polynomials with fixed degree form a finite-dimensional vector space, it would perhaps be more useful to determine the dimension of the space along with a "natural" basis. These problems have been solved by Kushner [14].

2. Construction of zero-regression polynomials. A partition $\kappa = (k_1, k_2, \cdots, k_m)$ is a vector of nonnegative integers, with $k_1 \geqq k_2 \geqq \cdots \geqq k_m$. For any complex number t,

$$(t)_\kappa = \prod_{i=1}^{m} \left(t - \frac{1}{2}(i-1) \right)_{k_i}$$

where

$$(t)_j = \frac{\Gamma(t+j)}{\Gamma(t)}, \qquad j = 0, 1, 2, \cdots.$$

Further, define the multivariate gamma function [5], [6] by

$$\Gamma_m(t) = \pi^{m(m-1)/4} \prod_{i=1}^{m} \Gamma\left(t - \frac{1}{2}(i-1) \right), \qquad \operatorname{Re}(t) > \tfrac{1}{2}(m-1).$$

For any symmetric $m \times m$ matrix $T = (t_{ij})$, we define

$$|T|_\kappa = \prod_{i=1}^{m} |T_i|^{k_i - k_{i+1}}, \qquad k_{m+1} \equiv 0,$$

where T_i is the ith principal minor of T, and $|\cdot|$ denotes the determinant. With the matrix T, we associate a matrix of differential operators

$$\frac{\partial}{\partial t} := \left(\frac{1}{2}(1+\delta_{ij}) \frac{\partial}{\partial t_{ij}} \right),$$

where δ_{ij} is Kronecker's delta. Whenever the variables of differentiation are clear from the context, we denote $\partial / \partial T$ by D; further, we shall use the notation

$$|D|_\kappa = \prod_{i=1}^{m} |D_i|^{k_i - k_{i+1}}$$

where D_i is the ith principal minor of D. For example, if $\kappa = (4, 2, 0, \cdots, 0)$, then

$$|D|_\kappa = \frac{\partial^2}{\partial t_{11}^2} \left(\frac{\partial^2}{\partial t_{11}\, \partial t_{22}} - \frac{\partial^2}{4 \partial t_{12}^2} \right)^2.$$

The operator $|D| \equiv |D|_{(1,1,\cdots,1)}$ is the hyperbolic operator of Herz [5].

If a random matrix X_1 has $W_m(\Sigma, N)$ distribution, then it is known that the characteristic function of X_1 is

$$\phi(T) := E(e^{i \operatorname{tr}(TX_1)}) = |I - 2iT\Sigma|^{-N/2},$$

where T is a symmetric matrix. Our first result determines the effect of the $|D|_\kappa$ operators on $\phi(T)$.

PROPOSITION 2.1. $|D|_\kappa \phi(T) = i^k (N/2)_\kappa |(\frac{1}{2}\Sigma^{-1} - iT)^{-1}|_\kappa \phi(T)$, *where* $k = k_1 + k_2 + \cdots + k_m$.

In the course of proving Proposition 2.1, we will use the following result by Bellman [1].

LEMMA 2.2 (Bellman). *Let Z be a complex, symmetric, $m \times m$ matrix with* $\operatorname{Re}(Z) > 0$ (*positive-definite symmetric*). *Then,*

$$\int_{X>0} e^{-\operatorname{tr}(XZ)} |X|^{t-p} |X|_\kappa \, dX = (t)_\kappa \Gamma_m(t) |Z|^{-t} |Z^{-1}|_\kappa,$$

with absolute convergence for $\operatorname{Re}(t) > p-1$, $p = (m+1)/2$.

Proof of Proposition 2.1. Let

$$C = (|2\Sigma|^{N/2} \Gamma_m(N/2))^{-1}$$

be the normalizing constant for the Wishart density. Then,

$$|D|_\kappa \phi(T) = C |D|_\kappa \int_{X>0} e^{i \operatorname{tr}(TX)} \, e^{-1/2 \operatorname{tr}(\Sigma^{-1}X)} |X|^{(N-m-1)/2} \, dX.$$

Since

$$|D|_\kappa \, e^{i \operatorname{tr}(TX)} = i^k |X|_\kappa \, e^{i \operatorname{tr}(TX)},$$

then

$$|D|_\kappa \phi(T) = C i^k \int_{X>0} e^{-\operatorname{tr}(1/2\Sigma^{-1} - iT)X} |X|^{(N-m-1)/2} |X|_\kappa \, dX.$$

Applying Lemma 2.2 and simplifying completes the proof. □

If $\kappa = (k_1, \cdots, k_m)$ and $\lambda = (l_1, \cdots, l_m)$ are partitions, we define $\kappa + \lambda = (k_1 + l_1, \cdots, k_m + l_m)$.

THEOREM 2.3. *Let $\{a_{ij}\}_{i,j=1}^n$ be real numbers. For any two partitions κ, λ define*

$$b_{\kappa,\lambda} = (N/2)_\kappa (N/2)_\lambda / (N/2)_{\kappa+\lambda}.$$

If $X_1, \cdots, X_n$ is a random sample from $W_m(\Sigma, N)$, then the polynomial

$$P(\underset{\sim}{X}) = \sum_{i \neq j}^{n} \sum^{n} a_{ij} [|X_i|_\kappa \, |X_j|_\lambda - b_{\kappa,\lambda} |X_i|_{\kappa+\lambda}] \tag{1}$$

is a zero-regression polynomial.

Proof. A necessary and sufficient criterion [4] for a polynomial $P(\underset{\sim}{X})$ to have zero regression on L is that

$$E(e^{i \operatorname{tr}(TL)} P(\underset{\sim}{X})) = 0 \tag{2}$$

for all symmetric T. To apply (2) to the polynomial (1), we shall use the following results:

$$|D|_\kappa \phi(T) = i^k E(e^{i \operatorname{tr}(TX)} |X|_\kappa),$$

$$|D|_\kappa |D|_\lambda \phi(T) = i^{k+l} E(e^{i \operatorname{tr}(TX)} |X|_\kappa |X|_\lambda),$$

where $k = k_1 + \cdots + k_m$, $l = l_1 + \cdots + l_m$. Then, applying (2) to (1), we obtain

$$E(e^{i \operatorname{tr}(TL)} P(\underset{\sim}{X})) = i^{-k-l} \sum_{r \neq s} \sum a_{rs} (\phi(T))^{n-2} \cdot [(|D|_\kappa \phi(T))(|D|_\lambda \phi(T)) - b_{\kappa,\lambda} \phi(T) |D|_{\kappa+\lambda} \phi(T)].$$

However, from Proposition 2.1, we also have

$$(|D|_\kappa \phi)(|D|_\lambda \phi) - b_{\kappa,\lambda}\phi |D|_{\kappa+\lambda}\phi \equiv 0,$$

and hence $P(\underset{\sim}{X})$ has zero regression on L. □

The construction given in Theorem 3.2 leads to a generalization of the results in [4]. To recover the zero regression polynomials of [4] from our result, we need only set $\kappa = \lambda = (1^m)$; this shows that

$$P(\underset{\sim}{X}) = \sum\sum_{i \neq j} a_{ij}[|X_i||X_j| - b_1|X_i|^2] \tag{3}$$

has zero regression on L, where

$$b_1 = (N/2)_{(1^m)}(N/2)_{(1^m)}/(N/2)_{(2^m)}.$$

3. Characterizations of zero-regression polynomials. This section characterizes zero-regression polynomials through several unconditional expectations, including generalizations of (2). First, we need to introduce notation and results pertinent to Fourier analysis on compact topological groups; an introductory account of this theory is given in [12] and [13].

Let G be a compact (Hausdorff) group. A *representation* ρ of G is a continuous homomorphism of G into the group of invertible linear transformations on a complex vector space V_ρ.

A representation ρ is *irreducible* if the only proper invariant (under ρ) subspace of V_ρ is $\{0\}$, the trivial subspace. Since G is compact, then V_ρ is necessarily of finite dimension, say d_ρ. Further, we lose no generality in assuming that the irreducible representations of G are given by unitary matrices.

Two representations ρ_1 and ρ_2 are *unitarily equivalent* if there exists a unitary matrix u such that $u\rho_1(g) = \rho_2(g)u$ for all g in G. The notion of unitary equivalence defines an equivalence relation among the representations of G. We denote by $\hat{G}$ the set of equivalence classes of *irreducible* representations of G. $\hat{G}$ is called the *dual* of G.

Let dg be the unique Haar measure on G, normalized so that G has total mass one. If $f: G \to \mathbb{C}$ is continuous, the *Fourier transform* of f is defined by

$$\rho(f) = \int_G f(g)\rho(g)\, dg, \qquad \rho \in \hat{G}.$$

The Fourier inversion formula then states that

$$f(g) = \sum_{\rho \in \hat{G}} d_\rho \operatorname{tr}(\rho(g)^* \rho(f)), \qquad g \in G, \tag{4}$$

where * denotes the transpose of complex conjugates. The sum in (4) is over a set of representatives for the equivalence classes in $\hat{G}$, one for each class.

Next, we specialize to the case $G = \mathrm{SO}(m)$, the *special orthogonal group*. The group G consists of all $m \times m$ orthogonal matrices g having determinant one.

Definition 3.1 [2], [3]. For symmetric $m \times m$ matrices S, T,

$$J_\rho(S, T) = \int_{\mathrm{SO}(m)} e^{i \operatorname{tr}(g'SgT)} \rho(g)\, dg$$

is the *generalized Bessel function of order* ρ.

The generalized Bessel functions were introduced and studied in [2]. In the jargon of [2], [3], $J_\rho(S, T)$ is the generalized Bessel function of order ρ arising from the two-sided action of $\mathrm{SO}(m)$ on the space of symmetric matrices.

Note that $J_\rho(S, T)$ is the Fourier transform of the function $g \to e^{i \operatorname{tr}(g'SgT)}$, $g \in \mathrm{SO}(m)$. Further, $J_\rho(S, T)$ is a $d_\rho \times d_\rho$ matrix. The Fourier inversion formula (4) shows that for fixed S, T,

$$e^{i \operatorname{tr}(g'SgT)} = \sum_{\rho \in \hat{G}} d_\rho \operatorname{tr}(\rho(g)^* J_\rho(S, T)). \tag{5}$$

Since the function $g \to e^{i \operatorname{tr}(g'SgT)}$ is infinitely differentiable, the series (5) converges uniformly on $\mathrm{SO}(m)$.

Now, we can state the main result of the paper. As before, $L = X_1 + \cdots + X_n$, where the X_i are independently and identically distributed Wishart matrices. Also, the polynomial $P(\underset{\sim}{X})$, $\underset{\sim}{X} = (X_1, \cdots, X_n)$, has zero regression on L.

THEOREM 3.2. *The following conditions are equivalent*:

(a) $P(\underset{\sim}{X})$ *has zero regression on* L;

(b) $E(e^{i \operatorname{tr}(TL)} p(L) P(\underset{\sim}{X})) = 0$ *for all polynomials* $p(L)$ *and symmetric matrices* T;

(c) $E(p(L) P(\underset{\sim}{X})) = 0$ *for all polynomials* $p(L)$;

(d) $E(P(\underset{\sim}{X}) J_\rho(T, L)) = 0$ *for all* $\rho \in \widehat{(\mathrm{SO}(m))}$ *and symmetric* T.

Proof. In § 2, we noted that the zero-regression property is equivalent to

$$E(e^{i \operatorname{tr}(TL)} P(\underset{\sim}{X})) = 0 \tag{6}$$

for all T. Then, it is immediate that (a) implies (b) since

$$E(e^{i \operatorname{tr}(TL)} p(L) P(\underset{\sim}{X})) = p\left(\frac{1}{i} \frac{\partial}{\partial T}\right) E(e^{i \operatorname{tr}(TL)} P(\underset{\sim}{X})).$$

Further, (b) implies (6) trivially, so that (a) and (b) are equivalent. To see that (c) implies (6), note that $e^{i \operatorname{tr}(TL)}$ can be expressed as an absolutely convergent series,

$$e^{i \operatorname{tr}(TL)} = \sum_{\alpha \in A} q_\alpha(T) p_\alpha(L)$$

where A is a countable index set, and p_α and q_α are polynomials for all α. Taking expectations, we find that for T sufficiently close to the zero matrix,

$$E(e^{i \operatorname{tr}(TL)} P(\underset{\sim}{X})) = \sum_{\alpha \in A} q_\alpha(T) E(p_\alpha(T) P(\underset{\sim}{X})) = 0$$

where the interchange of summation and expectation is permitted by the Dominated Convergence Theorem. As a function of T, the left-hand side of (6) is analytic and is zero in a neighborhood of the origin; hence it is identically zero. Since (b) implies (c), then we have established the equivalence of (a), (b), and (c).

Finally, we prove that (6) is equivalent to (d). First, Fubini's theorem and the definition of $J_\rho(S, T)$ show that

$$E(P(\underset{\sim}{X}) J_\rho(S, T)) = \int_{\mathrm{SO}(m)} E(e^{i \operatorname{tr}(g'TgL)} P(\underset{\sim}{X})) \rho(g)\, dg.$$

Therefore, (6) implies (d). Conversely if (d) holds, then by the Fourier inversion formula (5) and the Dominated Convergence Theorem,

$$E(e^{i \operatorname{tr}(g'TgL)} P(\underset{\sim}{X})) = \sum_\rho d_\rho \operatorname{tr}(\rho(g)^* E(P(\underset{\sim}{X}) J_\rho(T, L))) = 0,$$

for any g in $\mathrm{SO}(m)$ and symmetric T. Hence (d) implies (6), and this completes the proof. □

On reviewing the proof of Theorem 3.2, we note that nowhere do we use the fact that the X_i are Wishart matrices. Therefore the result holds for *any* symmetric matrix distribution, as long as the various interchanges of sums and integrals remain valid. In particular, it holds for the multivariate beta and F distributions [6].

To end this section, we make some remarks on the generalized Bessel functions. The *spherical Bessel function* is

$$J_0(S, T) = \int_{SO(m)} e^{i \operatorname{tr}(g'SgT)}\, dg,$$

which corresponds to the trivial one-dimensional representation $\rho(g) \equiv 1$. When $m = 2$, it can be shown using the techniques of [3] that

$$J_0(S, T) = e^{i \operatorname{tr}(S) \operatorname{tr}(T)/2} \tilde{J}_0(\Delta(S)\Delta(T)/2)$$

where $\tilde{J}_0(\cdot)$ denotes the classical Bessel function of the first kind of order zero, and $\Delta(S) = |s_1 - s_2|$ where s_1 and s_2 are the two eigenvalues of S. For any odd $m \geqq 3$, it has been shown [11] that $J_0(S, T) = {}_0F_0(iS, T)$, where ${}_0F_0(\cdot, \cdot)$ is James' hypergeometric function of two matrix arguments. For even $m \geqq 4$, $J_0(\cdot, \cdot)$ can be again related to ${}_0F_0(\cdot, \cdot)$ but the result is more complicated. For general ρ the evaluation of the matrix elements of $J_\rho(S, T)$ requires powerful machinery from the theory of harmonic analysis [2], [3]; however, we also remark that for the case $m = 2$, $J_\rho(S, T)$ can be computed explicitly using the techniques of [3].

4. A characterization of the Wishart distribution. Both here and in [4], it has been shown that the polynomial (3) has zero regression on $L = X_1 + \cdots + X_n$. Given the converse, that (3) has zero regression on the sum of an independently and identically distributed sequence of random matrices, we wish to determine whether the underlying population is necessarily Wishart. From the proof of Theorem 2.3, we observe that the polynomial (3) has zero regression on L if and only if the characteristic function $\phi(T) = E(e^{i \operatorname{tr}(TX_1)})$ satisfies the differential equation

$$(|D|\phi(T))^2 = b_1 \phi(T) |D|^2 \phi(T), \tag{7}$$

for all T. Therefore, it is enough to find all solutions of (7) that are simultaneously characteristic functions.

Consider the class of characteristic functions $\phi(T)$ of the form

$$\phi(T) = \int_H |I - 2iT\Sigma|^{-N/2}\, d\nu(\Sigma) \tag{8}$$

where $\nu(\cdot)$ is a Borel probability measure on the hypersurface $H = \{\Sigma: \Sigma \text{ is positive definite and } |\Sigma| = 1\}$. A random matrix with a characteristic function of form (8) may be regarded as a "covariance mixture" of Wishart distributions; these mixtures have arisen [10] in the context of hyperspherical distributions. We now show that the zero regression polynomial (3) characterizes the Wishart distribution within the class of Wishart mixtures typified by (8).

THEOREM 4.1. *Let $X_1, \cdots, X_n$ be a random sample from a population with characteristic function* (8). *If the polynomial $P(\underset{\sim}{X})$ in* (3) *has zero regression on L, then X_1 has a Wishart distribution.*

Proof. Since $P(\underset{\sim}{X})$ has zero regression on L, then (7) holds. Applying the $|D|$ and $|D|^2$ operators to $\phi(T)$ in (8) shows that

$$\left(\int_H |I - 2iT\Sigma|^{-(N+2)/2}\, d\nu(\Sigma)\right)^2 = \int_H |I - 2iT\Sigma|^{-N/2}\, d\nu(\Sigma) \cdot \int_H |I - 2iT\Sigma|^{-(N+4)/2}\, d\nu(\Sigma), \tag{9}$$

for all symmetric T. By considering discrete approximations to these latter integrals, it is evident that (9) implies $\nu(\cdot)$ to be the Dirac measure at some "point" Σ_0. Consequently, $X_1 \sim W_m(N, \Sigma_0)$.

Stephen Marron has kindly remarked that the above conclusion concerning $\nu(\cdot)$ can also be obtained by working with moment generating functions rather than characteristic functions. Indeed, the generating function analogue of (9) is

$$(9') \qquad \left(\int_H |I-2T\Sigma|^{-(N+2)/2}\, d\nu(\Sigma)\right)^2 = \int_H |I-2T\Sigma|^{-N/2}\, d\nu(\Sigma) \cdot \int_H |I-2T\Sigma|^{-(N+4)/2}\, d\nu(\Sigma),$$

and this holds for all T in a sufficiently small neighborhood of the zero matrix. The Cauchy-Schwarz inequality guarantees that the left-hand side of (9′) is never larger than the right-hand side. Then, the conclusion that $\nu(\cdot)$ is Dirac follows immediately from the criterion for equality in the Cauchy-Schwarz inequality. □

Finally, we remark that results similar to Theorem 4.1 can be obtained for the general polynomials constructed in Theorem 2.3.

Acknowledgments. I am deeply grateful to Kenneth Gross for his patient explanations of harmonic analysis in general, and the generalized Bessel functions in particular.

HOPF BIFURCATION IN THE PRESENCE OF SPHERICAL SYMMETRY: ANALYTICAL RESULTS*

G. IOOSS†‡ AND M. ROSSI‡

Abstract. This paper considers a one-parameter family of vector fields equivariant under the orthogonal group $O(3)$, with an invariant fixed point. Hopf bifurcation of this family is studied assuming $O(3)$ acts on the eigenspaces belonging to each purely imaginary eigenvalue as an $l=2$ representation. The dynamics are then reduced to a ten-dimensional center manifold, and the normal form of the vector field is explicitly given up to fifth order. The five different types of bifurcating periodic solutions, predicted geometrically by Golubitsky and Stewart, are derived analytically: a family of axisymmetric solutions, two types of rotating waves (one rotating at twice the speed of the other), a family of standing waves and a family of tetrahedral waves.

The stability conditions are given for all these solutions. These stabilities depend on the three coefficients appearing at cubic order in the normal form and on one combination of three coefficients occurring at fifth order. All solutions can be stable except for the fastest family of rotating waves. The slower rotating waves and the axisymmetric solutions may be simultaneously stable. Finally it is shown that a family of quasiperiodic solutions may bifurcate directly from the invariant fixed point together with the periodic solutions.

Key words. Hopf bifurcation symmetry breaking, spherical symmetry

AMS(MOS) subject classifications. 58F, 58C

1. Introduction.

Systems possessing a priori a spherical symmetry frequently occur in physics, particularly in hydrodynamics (see, for instance, self-gravitation convection problems [3], and the evolution of the shape of a gas bubble in a liquid [16]). Such phenomena obey a system of partial differential equations of evolution type, which may be written in the form of a differential equation:

$$\frac{dU}{dt} = \mathcal{F}(\lambda, U) \tag{1}$$

in a suitable functional real space E (see [10] for a precise formulation in hydrodynamics. Here $U(t)$ may stand for various physical quantities at time t: the velocity vector field of fluid particles, temperature, location of a free surface, etc. Moreover, $\lambda\ \mathbb{R}^k$ characterizes all the parameters of the underlying physics. In this mathematical frame, spherical symmetry means that $\mathcal{F}(\lambda, \cdot)$ commutes with a representation of the orthogonal group $O(3)$, i.e.,

$$\mathcal{F}(\lambda, \gamma U) = \gamma \mathcal{F}(\lambda, U) \tag{2}$$

for any element γ of the representation of $O(3)$ on the space E. Let us assume that we know a steady solution of (1) invariant under $O(3)$. We take it to be the origin in E. So, we have:

$$\mathcal{F}(\lambda, 0) = 0. \tag{3}$$

We assume in the following that this solution is marginally stable when λ equals zero. More precisely, the spectrum of the linear operator $\mathcal{L}_\lambda = D_U \mathcal{F}(\lambda, \cdot)$ is divided into two parts: one part, denoted by Σ_0, lying on the imaginary axis; the other lying strictly to the left side of this axis. In a neighborhood of $\lambda = 0$, the center manifold theorem implies that the dynamics of (1) near zero in space E is asymptotically

described by the trace of the vector field (1) on a center manifold $\mathcal{V}_0$. This manifold $\mathcal{V}_0$ has the same dimension as E_0 and is both locally invariant and locally attracting in a neighborhood of $U=0$. A complete modern proof of this theorem may be found in [19] for vector fields in finite-dimensional spaces. For evolution problems described by partial differential equations, see [11] or an easy adaptation of [19], which may be done by using, for instance, results reviewed in § II of [10]. This theorem is proved in an easier way for maps (see, for instance, [14], [9]), but then an adaptation for vector fields is needed (see also § V.4 of [9] for partial differential equations). The manifold $\mathcal{V}_0$ may be expressed in the following form:

$$U = X + \Phi(\lambda, X), \quad \Phi(0,0)=0, \quad D_X\Phi(0,0)=0, \tag{4}$$

where X belongs to the subspace E_0 invariant under $\mathcal{L}_0$ and corresponds to the part Σ_0 of the spectrum. In the problems considered, especially in hydrodynamics, this subspace is generally finite-dimensional. Therefore, after projection on the manifold, we are concerned only with a finite-dimensional differential system:

$$\frac{dX}{dt} = F(\lambda, X), \tag{5}$$

where $X(t) \in E_0$, $F(\lambda, 0)=0$.

The linear operator $L_0 = D_X F(0,0)$ is the restriction of $\mathcal{L}_0$ to E_0, so its entire spectrum is located on the imaginary axis. Moreover, the equivariance (2) of $\mathcal{F}$ remains valid for the new vector field on E_0, since a theorem of Ruelle [18] shows that we can find Φ such that

$$F(\lambda, \gamma X) = \gamma F(\lambda, X), \tag{6}$$

$$\Phi(\lambda, \gamma X) = \gamma \Phi(\lambda, X), \tag{7}$$

where γ is an element of the representation Γ of $O(3)$ on E_0. Straightforward consequences of (6) and (7) are: (a) L_0 commutes with every element of the representation Γ; (b) the eigenvalues of L_0 may have a large multiplicity; and (c) E_0 may be large-dimensional. Hence even for simple generic bifurcations of codimension 1, numerous solutions may bifurcate with complex patterns.

Using geometrical arguments from Lie group theory, Golubitsky and Stewart [7] have considered the "simplest" case of a Hopf bifurcation in the presence of $O(3)$ symmetry: they assumed that L_0 possesses a pair of eigenvalues $\pm i\omega$ associated with the decomposition of the complexified space E_0^c denoted hereafter by E_0:

$$E_0 = V \oplus \bar{V},$$

where the representation of $O(3)$ on V (and $\bar{V}$) is absolutely irreducible. Because of this assumption, the above-mentioned authors showed the emergence of branches of bifurcated solutions in each two-dimensional space corresponding to some specified symmetry. The method of restricting the study to subspaces of minimal dimensionality was previously used by Iudovich [12] to search analytically for steady solutions in Bénard convection. The geometric arguments developed in [7] do not say anything about the existence of other solutions (periodic or quasiperiodic), and do not show explicitly the stability of the specific periodic solutions.

Our purpose is to obtain more insight into these questions by studying the amplitude equations for a specific case. The case we investigate is mathematically the simplest leading to multiple solutions—among them one possessing an interesting tetrahedral symmetry. We note that nonstationary solutions might also be found in

cases of mode interaction when the only eigenvalue of L_0 is zero, its multiplicity being high enough: 5 in [3], 8 in [20].

The paper is organized as follows. In § 1 we derive the form of the differential system (5) on the center manifold $\mathcal{V}_0$. Unlike the steady bifurcation case [8], the irreducible representation $l=2$ of $O(3)$ does not possess a simple expression for the Hopf problem on the subspace E_0. This, as well as the dimension $2(2l+1)=10$ of the differential system (5), requires us to make use of rather technical results in this section. Consequently, we have only summarized the essential features of the calculus to get the form (24). The following section reviews and describes explicitly the five time-periodic solutions predicted in [7]: one axisymmetric solution, two rotating waves solutions (one type rotating twice as rapidly as the other), one standing wave solution, and one tetrahedral wave solution. We look exhaustively for their stability and show in particular that the "fastest" rotating wave solution is always unstable and that several solutions may be simultaneously stable. All the stability conditions may be expressed with three coefficients from the third order and *only one* combination of coefficients from the fifth order. In the last section we investigate the possible existence of quasi-periodic solutions directly emerging after a codimension 1 bifurcation, together with periodic solutions.

2. Normal form of the amplitude equations.

2.1. The basic problem. Our purpose is to find, when λ is near zero, how to describe the asymptotic dynamics of the solutions of (5) whenever E_0 can be written in the form

$$E_0 = V \oplus \bar{V},$$

where V, of dimension five, possesses an irreducible representation $l=2$ for the group $O(3)$. Recall that F commutes with this representation.

Each real vector of E_0 may be decomposed as

$$X = \sum_{m=-2}^{m=+2} x_m \xi_m + \bar{x}_m \bar{\xi}_m, \tag{8}$$

where the ξ_m ($m=-2,-1,0,1,2$) are eigenvectors of L_0 for the eigenvalue $i\omega$. This decomposition differs slightly from that of [7]: Golubitsky and Stewart write their hypothesis on a real basis corresponding to the real and imaginary parts of our vectors. It follows from this that the problem now reduces to that of finding vector fields depending on complex amplitudes x_j, $\bar{x}_j$ ($j=-2,-1,0,1,2$) that satisfy (6), i.e., after differentiation, the following relations:

$$D_X F(\lambda, X) \cdot J_k X = J_k F(\lambda, X), \qquad k=1,2,3,$$

or

$$\begin{aligned} &D_X F(\lambda, X) \cdot J_+ X = F(\lambda, X), \\ &D_X F(\lambda, X) \cdot J_- X = J_- F(\lambda, X), \\ &D_X F(\lambda, X) \cdot J_3 X = J_3 F(\lambda, X), \end{aligned} \tag{9}$$

where $-iJ_1, -iJ_2, -iJ_3$ are infinitesimal generators corresponding to rotations about each coordinate axis, and

$$J_\pm = J_1 \pm iJ_2.$$

Remark. Only two of the three relations in (9) are independent, since if F commutes with rotations about two coordinate axes it commutes with the rotation about the third axis.

To derive the general amplitude equation consistent with (9), we must consider the fundamental relations of the irreducible $O(3)$ representation $l=2$. In the following paragraph, we briefly review these properties without proving them. We refer the reader to [6] or [15] for details.

2.2. Irreducible representation $l=2$ of the orthogonal group. The linear operators J_3, J_+, J_- act on the canonical basis $\{\xi_m, m=-2,-1,0,1,2\}$ as follows (see pp. 24-25 of [6]):

$$J_3\xi_m = m\xi_m, \quad J_-\xi_m = \beta_{-m}\xi_{m-1}, \quad J_+\xi_m = \beta_m\xi_{m+1} \tag{10}$$

where $\beta_m = \sqrt{(2-m)(3+m)}$ and $m \in \{-2,-1,0,1,2\}$. Similarly (since $\bar{J}_+ = -J_-$ and $\bar{J}_3 = -J_3$):

$$J_3\bar{\xi}_m = -m\bar{\xi}_m, \quad J_+\bar{\xi}_m = -\beta_{-m}\bar{\xi}_{m-1}, \quad J_-\bar{\xi}_m = -\beta_m\bar{\xi}_{m+1}. \tag{11}$$

In Appendix 1 we describe the action of any finite rotation in this representation. Let us point out here the special case of a rotation of angle π about the axis ox:

$$R_{ox}(\pi)\xi_m = \xi_{-m}, \tag{12}$$

and that of a rotation of angle θ about oz:

$$R_{oz}(\theta)\xi_m = e^{-im\theta}\xi_m. \tag{13}$$

The reflection S through the origin possesses two possible representations: Id and $-\mathrm{Id}$. The choice between these two possibilities depends on the particular physical problem. The natural representation on spherical harmonics $(-\mathrm{Id})^l$ corresponds to the identity when $l=2$. It turns out, however, that the other possibility just modifies the symmetry of the solutions but not the dynamical system itself. In § 2.3 we suppose the natural representation holds: straightforward modifications belonging to the other case are left as an exercise for the reader.

2.3. Normal form of the vector field on the center manifold. To analyze the amplitude equations, we must put them into normal form. The basic result, obtained by Elphick et al. [5], indicates the existence of a nonlinear change of variables (close to the identity) such that the normal form of F commutes with the one-parameter group $\exp(L_0 t)$. After differentiation this property may be put into a more convenient form:

$$D_X F(\lambda, X)\cdot L_0 X = L_0 F(\lambda, X), \tag{14}$$

where we recall that the action of L_0 on the canonical basis is

$$L_0 = i\omega\,\mathrm{Id}_V. \tag{15}$$

Relation (14) is, however, only applicable up to an arbitrarily large but fixed order. Indeed, it is known that normalization of a vector field cannot be done to all orders, due to problems of convergence. The degree of the polynomial F must first be fixed (large N); then the neighborhood of zero, where an estimate $O(\|X\|^N)$ on the higher-order terms still holds, is fixed. This is not the case for the properties (9) of F that are valid exactly, due to the fundamental equivariance (2) of the system and to the results of [18]. From now on, we will say that a property is verified "up to flat terms" if it is verified on polynomial F.

2.4. Computation of the normal form. General approach. To determine the most general expression for F compatible with (9) and (14) let us decompose $F(\lambda, X)$. This yields:

$$F(\lambda, X) = \sum_{m=-2}^{m=+2} F_m\xi_m + \bar{F}_m\bar{\xi}_m, \tag{16}$$

where each component is explicitly expanded in the power series

$$F_m = \sum_P \alpha_m^P x_{-2}^{p_{-2}} \cdots x_2^{p_2} \bar{x}_{-2}^{q_{-2}} \cdots \bar{x}_2^{q_2} \tag{17}$$

with $P = (p_{-2}, \cdots, p_2, q_{-2}, \cdots, q_2)$.

The equalities $(9)_3$ and (14) then select those α_m^P that verify the resonant conditions:

$$\sum_{j=-2}^{2} j(p_j - q_j) = m, \tag{18}$$

$$\sum_{j=-2}^{2} (p_j - q_j) = 1. \tag{19}$$

Remark 1. Since we are looking for a polynomial F, we do not distinguish between the type of conditions generated by $(9)_3$ and (14).

Remark 2. The consequences of $(9)_1$ and $(9)_2$ do not give such simple relations since J_+, J_- are not diagonal operators on the canonical basis.

The general form of F is computed in two steps. First we determine F_{-2}. In addition to (18) and (19), $(9)_1$ implies that the normal form must satisfy

$$D_X F_{-2} \cdot J_+ X = 0. \tag{20}$$

Assume this calculation is done: then we easily obtain F_{-1} and F_0 thanks to $(9)_2$:

$$\beta_1 F_{-1} = D_X F_{-2} \cdot J_- X, \tag{21}$$

$$\beta_0 F_0 = D_X F_{-1} \cdot J_- X. \tag{22}$$

Now, instead of using J_- again to obtain F_1, F_2, we use a shortcut based on the equivariance under the rotation $R_{ox}(\pi)$. This gives F_1 and F_2, since (12) and (16) lead to

$$F_m(\lambda, R_{ox}(\pi)X) = F_{-m}(\lambda, X). \tag{23}$$

Other relations from (9), (18), (19) are then automatically satisfied and the most general normal form is thus found.

2.5. Computation of F_{-2}. To exhibit F_{-2} it is possible to use the pedestrian way of examining by increasing degrees the monomials (17) in (20) and eliminating those incompatible with (9), (18), and (19). This method—although conceptually simple—can, however, hardly ever be applied beyond the third order because of the exponential growth of the number of monomials involved. (For the third-order there are 5,000 for only three vectorial resonating terms.) Furthermore it does not yield a general result on the form of F_{-2}. This difficult question has been solved using Lie theoretic techniques: Cerezo [1] shows, for instance, that the polynomial function F_{-2} may be written as a linear combination of 43 polynomials, the coefficients of which are invariant polynomials of the group $O(3) \times SO(2)$ (generators J_3, J_+, L_0). At order 7, 23 of the 43 terms are present in F_{-2}, and it is necessary to go to the thirteenth order to find all the possible terms. It would be rather tedious to reproduce these results (the interested reader should consult [1] where a thorough study of this matter is given). Here we give only the expression truncated to the fifth order: we must go to this order to analyze the degeneracy occurring in the study of stability of some of the bifurcated solutions.

In what follows we denote by $i\omega + \mu(\lambda)$ the eigenvalue of the operator $\mathscr{L}_\lambda$, which perturbs $i\omega$ when λ is different from zero. All the coefficients in the vector field $F(\lambda, X)$ are functions of λ, but just the dependency in λ of the linear term is explicitly written.

As a matter of fact, the nonlinear terms are supposed to be nonsingular for $\lambda = 0$. This means that only codimension 1 bifurcations are considered and justifies the replacement of λ by μ_r (bifurcation parameter). The complete calculation yields the following for the vector field F:

$$\begin{aligned} F(\lambda, X) = {} & [i\omega + \mu + a|X|^2 + d_1|X|^4 + d_2|S_1(X)|^2] + (b + d_4|X|^2)S_1(X)\tilde{X} \\ & + (c + d_3|X|^2)C(X) + d_5 S_1(X)\tilde{C}(X) + d_6 S_3(X)B_1(X) \\ & + d_7 S_2(X)\tilde{B}_1(X) + d_8 \bar{S}_2(X)B_2(X) + d_9 M(X) + O(|X|^7), \end{aligned} \tag{24}$$

where we denote again by F and X the following vectors (to simplify notation):

$$F = (F_{-2}, F_{-1}, F_0, F_1, F_2), \qquad X = (x_{-2}, x_{-1}, x_0, x_1, x_2).$$

The mapping $Y \to \tilde{Y}$ is defined in $\mathbb{C}^5$ by

$$Y = (y_{-2}, y_{-1}, y_0, y_1, y_2) \to \tilde{Y} = (\bar{y}_2, -\bar{y}_1, \bar{y}_0, -\bar{y}_{-1}, \bar{y}_{-2}).$$

In equality (24), there appear six $O(3)$ scalar invariant quantities $|X|^2$, $S_1(X)$, $\bar{S}_1(X)$, $S_2(X)$, $\bar{S}_2(X)$, $S_3(X)$ as defined below (in the full normal form of F there also appear $\bar{S}_3(X)$ and another real invariant of degree 4 (see [1])):

$$\begin{aligned} |X|^2 &= \sum_{m=-2}^{m=+2} |x_m|^2, \\ S_1(X) &= x_{-1}x_1 - \frac{1}{2}x_0^2 - x_{-2}x_2, \\ S_2(X) &= x_2\left(\sqrt{\frac{3}{2}}\,\bar{x}_1^2 - 2\bar{x}_0\bar{x}_2\right) + x_{-2}\left(\sqrt{\frac{3}{2}}\,x_{-1}^2 - 2\bar{x}_{-2}\bar{x}_0\right) + x_1(\bar{x}_0\bar{x}_1 - \sqrt{6}\bar{x}_{-1}\bar{x}_2) \\ &\quad + x_{-1}(\bar{x}_{-1}\bar{x}_0 - \sqrt{6}\bar{x}_{-2}\bar{x}_1) + x_0(-\bar{x}_{-1}\bar{x}_1 - 2\bar{x}_{-2}\bar{x}_2 + \bar{x}_0^2), \\ S_3(X) &= x_0^3 - 3x_{-1}x_0x_1 + 3\sqrt{\frac{3}{2}}\,(x_{-1}^2x_2 + x_{-2}x_1^2) - 6x_{-2}x_0x_2. \end{aligned} \tag{25}$$

To avoid lengthy expressions, let us now introduce the operator $Y \mapsto \hat{Y}$ in $\mathbb{C}^5$ defined by

$$\hat{Y} = (y_2, y_1, y_0, y_{-1}, y_{-2}).$$

This operator represents $R_{ox}(\pi)$ (see (12)). We may now define:

$$C(X) = (C_{-2}, C_{-1}, C_0, C_1, C_2), \qquad B_j(X) = (B_{-2}^{(j)}, B_{-1}^{(j)}, B_0^{(j)}, B_1^{(j)}, B_2^{(j)})$$

with $C_m(\hat{X}) = C_{-m}(X)$, $B_m^{(j)}(\hat{X}) = B_{-m}^{(j)}(X)$, and

$$C_{-2}(X) = x_{-1}^2\bar{x}_0 + x_{-1}x_0\bar{x}_1 + \frac{1}{\sqrt{6}}\,x_0^2\bar{x}_2 - \sqrt{6}x_{-2}\left(\frac{2}{3}|x_0|^2 + |x_1|^2 + |x_2|^2\right),$$

$$C_{-1}(X) = \sqrt{\frac{2}{3}}\,x_0^2\bar{x}_1 + x_0x_1\bar{x}_2 + x_{-2}x_1\bar{x}_0 + 2x_{-2}x_0\bar{x}_{-1} - \sqrt{\frac{3}{2}}\,x_{-1}\left(|x_{-1}|^2 + \frac{1}{3}|x_0|^2 + |x_1|^2 + 2|x_2|^2\right),$$

$$C_0(x) = (x_1^2\bar{x}_2 + x_{-1}^2\bar{x}_{-2}) + (x_{-2}x_1\bar{x}_{-1} + x_{-1}x_2\bar{x}_1) + \sqrt{\frac{2}{3}}\, x_{-2}x_2\bar{x}_0$$
$$+ 2\sqrt{\frac{2}{3}}\, x_{-1}x_1\bar{x}_0 - \frac{1}{\sqrt{6}}\, x_0[4|x_{-2}|^2 + |x_{-1}|^2 + 3|x_0|^2 + |x_1|^2 + 4|x_2|^2],$$

$$B_0^{(1)}(x) = \sqrt{\frac{2}{3}}\,(\bar{x}_0^2 - \bar{x}_{-1}\bar{x}_1 - 2\bar{x}_{-2}\bar{x}_2),$$

$$B_{-1}^{(1)}(x) = 2\bar{x}_{-1}\bar{x}_2 - \sqrt{\frac{2}{3}}\,\bar{x}_0\bar{x}_1,$$

$$B_{-2}^{(1)}(X) = \bar{x}_1^2 - 2\sqrt{\frac{2}{3}}\,\bar{x}_0\bar{x}_2,$$

$$B_0^{(2)}(X) = |x_{-2}|^2 - \frac{1}{2}|x_{-1}|^2 - |x_0|^2 - \frac{1}{2}|x_1|^2 + |x|_2^2,$$

$$B_{-1}^{(2)}(X) = \sqrt{\frac{3}{2}}\,(x_1\bar{x}_2 - x_{-2}\bar{x}_{-1}) + \frac{1}{2}(x_0\bar{x}_1 - x_{-1}\bar{x}_0),$$

$$B_{-2}^{(2)}(X) = x_{-2}\bar{x}_0 + x_0\bar{x}_2 + \sqrt{\frac{3}{2}}\, x_{-1}\bar{x}_1.$$

Finally, we obtain

$$M(X) = (M_{-2}, M_{-1}, M_0, M_1, M_2), \qquad M_{-j}(X) = M_j(\hat{X}),$$

with

$$M_{-2}(X) = D_{-2}Q_{-2},$$
$$M_{-1}(X) = D_{-1}Q_{-2} + D_{-2}Q_{-1},$$
$$M_0(X) = D_0Q_{-2} + 2\sqrt{\frac{2}{3}}\, D_{-1}Q_{-1} + D_{-2}Q_0,$$

where

$$D_0(X) = -\frac{1}{\sqrt{6}}\, D_{-2}(\hat{X}), \qquad Q_0(X) = -\frac{1}{\sqrt{6}}\, Q_{-2}(\hat{X}),$$

and

$$Q_{-2}(X) = \bar{x}_1x_0 + x_{-1}\bar{x}_0 + \sqrt{\frac{2}{3}}\,(x_1\bar{x}_2 + x_{-2}\bar{x}_{-1}),$$

$$Q_{-1}(X) = \frac{1}{\sqrt{6}}\,(|x_1|^2 - |x_{-1}|^2) + \sqrt{\frac{2}{3}}\,(|x_2|^2 - |x_{-2}|^2),$$

$$D_2(X) = \bar{x}_{-1}\left(2x_{-2}x_0 - \sqrt{\frac{3}{2}}\, x_{-1}^2\right) + \bar{x}_0\left(3x_{-2}x_1 - \sqrt{\frac{3}{2}}\, x_{-1}x_0\right)$$
$$- \sqrt{\frac{3}{2}}\,\bar{x}_1(x_0^2 - x_{-1}x_1 - 2x_{-2}x_2) + \bar{x}_2(\sqrt{6}x_{-1}x_2 - x_0x_1),$$

$$D_{-1}(X) = \bar{x}_{-2}\left(\sqrt{\frac{3}{2}}\, x_{-1}^2 - 2x_{-2}x_0\right) + \bar{x}_{-1}\left(\frac{1}{2}\, x_{-1}x_0 - \sqrt{\frac{3}{2}}\, x_{-2}x_1\right)$$
$$+ \bar{x}_1\left(\sqrt{\frac{3}{2}}\, x_{-1}x_2 - \frac{1}{2}\, x_0x_1\right) + \bar{x}_2\left(2x_0x_2 - \sqrt{\frac{3}{2}}\, x_1^2\right).$$

It is worth noting that (a) only odd degrees appear in (24) because of condition (19), and (b) only three terms are needed to describe F up to the fourth order. Nine additional terms must be included ($d_1, d_2, d_3, \cdots, d_9$) to improve the expansion up to the fifth order. Moreover, in polynomial coefficients of $d_6, \cdots, d_9$ new types of terms $\{S_2(X), S_3(X), B_1(X), B_2(X), M(X)\}$ occur, which do not exist up to third order; hence it is not possible to guess them starting with the knowledge of the cubic terms.

2.6. Effective dimension of the system. The amplitude equation (5) actually depends on eight rather than ten variables. If we express the amplitudes in polar form:

$$x_j = r_j e^{i\psi_j}, \qquad -2 \leqq j \leqq 2, \tag{26}$$

then conditions (18), (19) imply that, in (5), the phases ψ_j appear only inside three linearly independent combinations:

$$\psi_1 + \psi_{-1} - 2\psi_0, \quad \psi_2 + \psi_{-2} - 2\psi_0, \quad 2\psi_{-1} - \psi_0 - \psi_{-2}. \tag{27}$$

An immediate consequence of (27) is the following remark. After a change of variables

$$x_j = y_j e^{i\omega_j t}, \tag{28}$$

where the parameters ω_j are given arbitrarily, the new system remains *autonomous* when these parameters satisfy

$$\omega_j = \beta + j\alpha, \qquad j = -2, -1, 0, 1, 2, \quad \text{where } \alpha, \beta \text{ are real.} \tag{29}$$

The "flat terms," however, do not satisfy this property since we use (19) to derive (29). If we search for a global property we have only to take into account (18). Instead of (29) this leads to

$$\omega_j = j\alpha, \qquad j = -2, -1, 0, 1, 2, \quad \text{where } \alpha \text{ is real,} \tag{30}$$

and then the system is again *completely autonomous.*

3. The five predicted bifurcated solutions. Symmetry and stability. In this section we explicitly derive the five solutions geometrically predicted in [7] and we study their stabilities. Those five branches of solutions for $l = 2$ share the following feature. The vector space remaining invariant under the action of the spatio-temporal symmetry group attached to each branch is two-dimensional. Hence we search for solutions reducing (5) to a system of the same dimension.

3.1. Axisymmetric solution. If $x_j = 0$ for $j = -2, -1, 1, 2$, then (18), (19) lead to

$$F_m = 0 \quad \text{for } m = -2m - 1, 1, 2.$$

In fact, the nonzero monomials correspond to terms such that

$$m = 0, \qquad p_0 - q_0 = 1.$$

Hence (5) reduces to (apart from "flat terms"):

$$\frac{dx_0}{dt} = x_0 \tilde{F}(|x_0|^2). \tag{31}$$

Truncation at fifth order $F(\lambda, X)$ in (24) gives

$$\frac{dx_0}{dt} = x_0(i\omega + \mu + \chi^{(1)}|x_0|^2 + \chi^{(2)}|x_0|^4) \tag{32}$$

with

$$\chi^{(1)} = a - \frac{b}{2} - c\sqrt{\frac{3}{2}},$$

$$\chi^{(2)} = d_1 + \frac{d_2}{4} + \frac{1}{2}\sqrt{\frac{3}{2}}\, d_5 - \sqrt{\frac{3}{2}}\, d_3 - \frac{d_4}{2} + \sqrt{\frac{2}{3}}\,(d_6 + d_7) - d_8.$$

Generically this leads to a standard Hopf bifurcation. The time-periodic solution reads as follows:

$$x_0 = r_0\, e^{i(\omega_0 t + \psi_0)}, \qquad x_j = 0 \quad (j \neq 0), \tag{33}$$

where r_0, ω_0 (index i (respectively, r) denotes imaginary (respectively, real part)) are given by

$$\mu_r + \chi_r^{(1)} r_0^2 + \chi_r^{(2)} r_0^4 + O(r_0^6) = 0, \qquad \omega_0 = \omega + \mu_i + \chi_i^{(1)} r_0^2 + \chi_i^{(2)} r_0^4 + O(r_0^6). \tag{34}$$

In space E, the bifurcated solution (33) takes the following form (up to an arbitrary phase corresponding to the choice of time origin and taken here to be zero):

$$U(t) = r_0\, e^{i\omega_0 t}\xi_0 + r_0\, e^{-i\omega_0 t}\bar{\xi}_0 + \Phi(\lambda, r_0\, e^{i\omega_0 t}\xi_0 + r_0\, e^{-i\omega_0 t}\bar{\xi}_0). \tag{35}$$

The structure of the solution obviously indicates its axisymmetric nature. Every rotation about oz,

$$R_{oz}(\theta) = e^{-i\theta J_3},$$

leaves the principal part of U unchanged ($R_{oz}(\theta)X = X$) because of (13). The complete invariance of U then directly follows from (7):

$$R_{oz}(\theta)U(t) = U(t).$$

Except for this subgroup of $O(3)$, the symmetry $R_{ox}(\pi)$ is the unique rotation acting as the identity on (35) (use (12) instead of (13)). Since we have

$$R_{ox}(\pi)R_{oz}(\theta) = R_{oz}(-\theta)R_{ox}(\pi),$$

we can conclude that $O(2)$ is the symmetry group of U. Hence this solution is nothing else than the axisymmetric solution of [7].

The stability of (35) is investigated by linearizing system (24) about (35) and by using the property stated in § 2.6. Let us introduce variables ρ_0, φ_0, y_j as follows:

$$x_0 = (r_0 + \rho_0)\, e^{i(\omega_0 t + \varphi_0)}, \qquad x_j = y_j\, e^{i\omega_0 t}, \quad j \neq 0. \tag{36}$$

The stability study then relies on an autonomous system that may be divided into three uncoupled subsystems. We write only the principal parts, since these are sufficient for determining the orbital stability. We obtain

$$\frac{d\rho_0}{dt} = 2\chi_r^{(1)} r_0^2 \rho_0, \qquad \frac{d\varphi_0}{dt} = 2\chi_i^{(1)} r_0 \rho_0, \tag{37}$$

$$\frac{dy_{-1}}{dt}=\left(\frac{b}{2}+c\sqrt{\frac{2}{3}}\right)r_0^2(y_{-1}+\bar{y}_1),\qquad \frac{d\bar{y}_1}{dt}=\left(\frac{\bar{b}}{2}+\bar{c}\sqrt{\frac{2}{3}}\right)r_0^2(y_{-1}+\bar{y}_1),$$

(38)

$$\frac{d\bar{y}_2}{dt}=y_{-2}\left[-\left(\frac{\bar{b}}{2}-\frac{\bar{c}}{\sqrt{6}}\right)r_0^2+\left(\bar{d}_8-\frac{\bar{d}_4}{2}-2\sqrt{\frac{2}{3}}\,\bar{d}_6+\frac{1}{\sqrt{6}}(\bar{d}_3+2\bar{d}_5)\right)r_0^4\right]$$
$$+\bar{y}_2\left[\left(\frac{\bar{b}}{2}-\frac{\bar{c}}{\sqrt{6}}\right)r_0^2+\left(2\bar{d}_8+\frac{\bar{d}_4}{2}-\sqrt{\frac{2}{3}}(\bar{d}_6+3\bar{d}_7)-\frac{1}{\sqrt{6}}(d_3+2d_5)\right)r_0^4\right],$$

(39)

$$\frac{dy_{-2}}{dt}=y_{-2}\left[\left(\frac{b}{2}-\frac{c}{\sqrt{6}}\right)r_0^2+\left(2d_8+\frac{d_4}{2}-\sqrt{\frac{2}{3}}(d_6+3d_7)-\frac{1}{\sqrt{6}}(d_3+2d_5)\right)r_0^4\right]$$
$$+\bar{y}_2\left[-\left(\frac{b}{2}-\frac{c}{\sqrt{6}}\right)r_0^2+\left(d_8-\frac{d_4}{2}-2\sqrt{\frac{2}{3}}\,d_6+\frac{1}{\sqrt{6}}(d_3+2d_5)\right)r_0^4\right].$$

We specify the fifth order terms in the expression (39) to remove the degeneracy of the eigenvalue zero present in the system truncated at third order.

The subsystem (37) generates the following eigenvalues:

$$\sigma_1=2\chi_r^{(1)}r_0^2+O(r_0^4),\qquad \sigma_2=0. \tag{40}$$

The eigenvalue $\sigma_2=0$ is the usual one related to the translational invariance in the choice of time origin for the Hopf bifurcating solution.

From system (38) we obtain the following eigenvalues:

$$\sigma_3=\left(b_r+2c_r\sqrt{\frac{2}{3}}\right)r_0^2+O(r_0^4),\qquad \sigma_4=0. \tag{41}$$

These eigenvalues are double since the system (38) may be decomposed into a system in (y_{-1}, y_1) and in its complex conjugate. The emergence of the double eigenvalue $\sigma_4=0$ just relies on the $O(3)$ invariance of F. As a matter of fact, there is a Γ-orbit of axisymmetric solutions generated by the action on the solution (35) of the rotation group. An infinitesimal rotation as written in Appendix 1 induces the emergence of y_{-1} and y_1 components. This explains classically the presence of the double zero eigenvalue in (38). It may seem contradictory that a three parameter family of axisymmetric solutions generates only a multiplicity of two; the "third" zero is actually taken into account by translational invariance.

The system (39) with $(y_{-2}, \bar{y}_2)$ components exhibits a linear operator of the following form:

$$\begin{pmatrix} A & B \\ \bar{B} & \bar{A} \end{pmatrix} \tag{42}$$

the eigenvalues of which are written for (39) as

$$\sigma_\pm=A_r\pm\sqrt{|B|^2-A_i^2}.$$

This leads to the following eigenvalues:

$$\sigma_5=\left(b_r-c_r\sqrt{\frac{2}{3}}\right)r_0^2+O(r_0^4),\qquad \sigma_6=\Delta r_0^4+O(r_0^6) \tag{43}$$

where

$$\Delta=3d_{8r}-\sqrt{6}(d_{6r}+d_{7r})+\frac{b_i-c_i\sqrt{2/3}}{b_r-c_{cr}\sqrt{2/3}}[3d_{8i}-\sqrt{6}(d_{6i}+d_{7i})]. \tag{44}$$

The reader should note the necessity of expanding F up to the fifth order to get a nonzero value for σ_6. Obviously, such an effort would have been hopeless for σ_4. The

number of zero eigenvalues actually coincides with the expected number given by Golubitsky and Stewart [7] using group-theoretic arguments.

Collecting (40), (41), and (43), we obtain three sufficient conditions for the axisymmetric branch to be stable orbitally:

$$
\begin{aligned}
&a_r - \frac{b_r}{2} - c_r\sqrt{\frac{3}{2}} < 0,\\
&b_r\sqrt{\frac{3}{2}} < c_r < -\left(\frac{b_r}{2}\right)\sqrt{\frac{3}{2}},\\
&\Delta < 0.
\end{aligned}
\tag{45}
$$

Note that the first condition means that this branch must bifurcate supercritically. Let us summarize the above results as a theorem.

THEOREM 1. *In the invariant subspace* $\{x_j = 0, |j| \neq 0\}$, *axisymmetric time-periodic solutions of* (I) *bifurcate. The* Γ *orbit of axisymmetric solutions is* (*orbitally*) *stable if the bifurcation is supercritical and if the coefficients of* F *in* (24) *satisfy three additional inequalities* (*see* (45)), *one of them bearing on a combination* Δ *of coefficients of terms of degree* 5.

Remark. Generically, conditions (45) are necessary for orbital stability.

3.2. The first rotating wave and the standing wave solution. If $x_j = 0$ for $j = -1, 0, 1$, then (18), (19) lead to nonzero monomials for F_m when

$$
\begin{aligned}
&2(p_2 - q_2) - 2(p_{-2} - q_{-2}) = m,\\
&p_2 - q_2 + p_{-2} - q_{-2} = 1;
\end{aligned}
$$

hence $F_m = 0$ for $m = -1, 0, 1$. Moreover, we have

$$
F_{-2}(\lambda, X) = x_{-2}\tilde{F}(\lambda, |x_{-2}|^2, |x_2|^2), \qquad F_2(\lambda, X) = x_2\tilde{F}(\lambda, |x_2|^2, |x_{-2}|^2),
\tag{46}
$$

because of $R_{ox}(\pi)$ invariance of the field F (see (12)). Truncated at fifth order, the system (5) reduces to

$$
\begin{aligned}
\frac{d}{dt}x_{-2} = x_{-2}[&i\omega + \mu + a(r_{-2}^2 + r_2^2) + d_1(r_{-2}^2 + r_2^2)^2 + (d_2 + \sqrt{6}d_5)r_{-2}^2 r_2^2\\
&- \{b + \sqrt{6}c + (d_4 + \sqrt{6}d_3)(r_{-2}^2 + r_2^2)\}r_2^2],\\
\frac{d}{dt}x_2 = x_2[&i\omega + \mu + a(r_{-2}^2 + r_2^2) + d_1(r_{-2}^2 + r_2^2)^2 + (d_2 + \sqrt{6}d_5)r_{-2}^2 r_2^2\\
&- \{b + \sqrt{6}c + (d_4 + \sqrt{6}d_3)(r_{-2}^2 + r_2^2)\}r_{-2}^2].
\end{aligned}
\tag{47}
$$

This structure is similar to that observed for a Hopf bifurcation in the presence of $O(2) \times SO(2)$ symmetry (see, for instance, the Couette-Taylor problem treated in [2]). A classical result then indicates that this leads to two kinds of periodic solutions: *rotating waves* for which either x_{-2} or x_2 equals zero, and *standing waves* for which $|x_{-2}| = |x_2|$.

3.2.1. First family of rotating waves. Let us consider the periodic solution of (47) such as $r_{-2} = 0$. The other possible choice $r_2 = 0$ is just a different element belonging to the same Γ-orbit. Thus, we obtain:

$$
x_{-2} = 0, \qquad x_2 = r_2\, e^{i(\omega_2 t + \varphi_2)},
\tag{48}
$$

with

$$\mu_r + a_r r_2^2 + d_{1r} r_2^4 + O(r_2^6) = 0, \qquad \omega_2 = \omega + \mu_i + a_i r_2^2 + d_{1i} r_2^4 + O(r_2^6). \tag{49}$$

Clearly, if $\tau(t)$ denotes the time shift operator, then the solution $X(t)$ given by (48) satisfies the identity (see (13))

$$R_{oz}(\theta)\tau(-2\theta/\omega_2)X = X.$$

Since $R_{oz}(\theta)$ and $\tau(t)$ commute with Φ (see (7)) we obtain as well:

$$R_{oz}(\theta)\tau(-2\theta/\omega_2)U = U. \tag{50}$$

This identity is the characteristic feature of a *rotating wave with two waves about oz.*

To study its stability, we proceed as in § 3.1. Suppressing the terms beyond the third-order we obtain (using obvious notation):

$$\begin{aligned} &\frac{d\rho_2}{dt} = 2a_r r_2^2 \rho_2, \qquad \frac{d\varphi_2}{dt} = 2a_i r_2 \rho_2, \\ &\frac{dy_{-2}}{dt} = -(b + c\sqrt{6}) r_2^2 y_{-2}, \qquad \frac{dy_0}{dt} = -2\sqrt{\frac{2}{3}}\, c r_2^2 y_0, \\ &\frac{dy_1}{dt} = 0, \qquad \frac{dy_{-1}}{dt} = -c\sqrt{6} r_2^2 y_{-1}. \end{aligned} \tag{51}$$

Hence we obtain seven simple eigenvalues:

$$\begin{aligned} &\sigma_1 = 2a_r r_2^2 + O(r_2^4), \qquad \sigma_2 = -(b + c\sqrt{6}) r_2^2 + O(r_2^4), \\ &\sigma_3 = \bar{\sigma}_2, \quad \sigma_4 = -2\sqrt{\frac{2}{3}}\, c r_2^2 + O(r_2^4), \quad \sigma_5 = \bar{\sigma}_4, \\ &\sigma_6 = -c\sqrt{6} r_2^2 + O(r_2^4), \qquad \sigma_7 = \bar{\sigma}_6. \end{aligned} \tag{52}$$

The eighth eigenvalue $\sigma_8 = 0$ is of triple multiplicity: it corresponds to the $O(3)$ invariance, since an infinitesimal rotation on (48) generates a component in y_1 (not considering the one in y_2), while the zero eigenvalue due to the choice of time origin still corresponds to rotations about *oz.*

Conditions for stability of this family may be summarized by

$$a_r < 0, \quad c_r > 0, \quad b_r + c_r\sqrt{6} > 0, \tag{53}$$

where the first condition means that the branch must bifurcate supercritically to be stable.

3.2.2. Standing waves. Let us now consider the time-periodic solution (46) such as $|x_{-2}| = |x_2|$. This yields:

$$x_2 = \tilde{r}_2\, e^{i(\tilde{\omega}_2 t + \psi_2)}, \qquad x_{-2} = \tilde{r}\, ^{i(\tilde{\omega}_2 t + \psi_{-2})} \tag{54}$$

with

$$\begin{aligned} &\mu_r + (2a_r - b_r - c_r\sqrt{6})\tilde{r}_2^2 + \chi_r^{(3)} \tilde{r}_2^4 + O(\tilde{r}_2^6) = 0, \\ &\tilde{\omega}_2 = \omega + \mu_i + (2a_i - b_i - c_i\sqrt{6})\tilde{r}_2^2 + \chi_i^{(3)} \tilde{r}_2^4 + O(\tilde{r}_2^6), \end{aligned} \tag{55}$$

where

$$\chi^{(3)} = 4d_1 + d_2 + \sqrt{6} d_5 - 2(d_4 + \sqrt{6} d_3).$$

The frequency $\tilde{\omega}_2$ differs from the previous one ω_0 of the axisymmetric solutions only at the order $\mu_r^2[O(\tilde{r}_2^4)]$. By a time shift and an appropriate rotation we can suppress the phases: $\psi_2 = \psi_{-2} = 0$ in (54). This solution remains completely invariant under the symmmetry $R_{ox}(\pi)$ and by the composition of a rotation of angle $\pi/2$ about oz with a translation in time of a half-period:

$$R_{ox}(\pi)U = U, \qquad R_{oz}(\pi/2)\tau(\pi/\tilde{\omega}_2)U = U. \tag{56}$$

We easily recognize the symmetry subgroup predicted in [7] for the standing wave. The two standing waves first predicted turn out to belong to the same group orbit.

To compute the stability we proceed as in § 3.1 by changing variables with adapted notation:

$$x_{\pm 2} = (\tilde{r}_2 + \rho_{\pm 2})\, e^{i(\tilde{\omega}_2 t + \varphi_{\pm 2})}, \qquad x_j = y_j\, e^{i\tilde{\omega}_2 t}, \quad j = 0, 1, -1. \tag{57}$$

We then obtain the following linear system:

$$\begin{aligned}
&\frac{d}{dt}\rho_{\pm 2} = 2(a_r - b_r - c_r\sqrt{6})\tilde{r}_2^2\rho_{\mp 2} + 2a_r\tilde{r}_2^2\rho_{\pm 2},\\
&\frac{d}{dt}\varphi_{\pm 2} = 2(a_i - b_i - c_i\sqrt{6})\tilde{r}_2\rho_{\mp 2} + 2a_i\tilde{r}_2\rho_{\pm 2},\\
&\frac{d}{dt}y_{-1} = b\tilde{r}_2^2 y_{-1} + b\tilde{r}_2^2\bar{y}_1,\\
&\frac{d}{dt}\bar{y}_1 = \bar{b}\tilde{r}_2^2 y_{-1} + \bar{b}\tilde{r}_2^2\bar{y}_1,\\
&\frac{d}{dt}y_0 = \left[\left(b - c\sqrt{\frac{2}{3}}\right)\tilde{r}_2^2 + A\tilde{r}_2^4\right]y_0 + \left[-\left(b - c\sqrt{\frac{2}{3}}\right)\tilde{r}_2^2 + B\tilde{r}_2^4\right]\bar{y}_0
\end{aligned} \tag{58}$$

with

$$A = 2\left(d_4 + 2\sqrt{6}d_6 + 2\sqrt{\frac{2}{3}}\,d_7 - \sqrt{\frac{2}{3}}\,d_3 - 2\sqrt{\frac{2}{3}}\,d_5 - 4d_8\right),$$

$$B = -A - 4(3d_8 - \sqrt{6}(d_6 + d_7)).$$

Hence the eigenvalues of (58) are the following:

$$\begin{aligned}
&\sigma_1 = 2(2a_r - b_r - c_r\sqrt{6})\tilde{r}_2^2 + O(\tilde{r}_2^4), \qquad \sigma_2 = 2(b_r + c_r\sqrt{6})\tilde{r}_2^2) + O(\tilde{r}_2^4),\\
&\sigma_3 = 2b_r\tilde{r}_2^2 + O(\tilde{r}_2^4) \quad \text{(double)}, \qquad \sigma_4 = 2\left(b_r - c_r\sqrt{\frac{2}{3}}\right)\tilde{r}_2^2 + O(\tilde{r}_2^4),\\
&\sigma_5 = -4\Delta\tilde{r}_2^4 + O(\tilde{r}_2^6) \quad (\Delta \text{ defined in § 3.1}), \qquad \sigma_6 = 0 \quad \text{(quadruple)}.
\end{aligned} \tag{59}$$

The last eigenvalue is quadruple because of dependency of orbits on four parameters: three of them originate from the action of the orthogonal group, and the remaining one from the arbitrary choice of the temporal phase. Furthermore, we can easily see that an infinitesimal rotation acting on (54) does not generate a y_0 component. This

solution is then stable if

$$
\begin{aligned}
&2a_r < b_r + c_r\sqrt{6} \quad \text{(supercritical bifurcation)},\\
&b_r < \min\left(-c_r\sqrt{6},\, c_r\sqrt{\frac{2}{3}},\, 0\right),\\
&\Delta > 0.
\end{aligned}
\tag{60}
$$

Let us summarize the results of § 3.2 as a theorem.

THEOREM 2. *In the invariant four-dimensional subspace* $\{x_1 = x_{-1} = x_0 = 0\}$ *the subsystem* (47) *satisfies an* $O(2)\times SO(2)$ *equivariance that leads to the two classical types of bifurcating time-periodic solutions: rotating waves and standing waves* (*see* [2]). *The* Γ*-orbits of these two solutions are* (*orbitally*) *stable if* (i) *they bifurcate supercritically*; (ii) *the usual conditions for stability on cubic coefficients of F in* (24) *hold in the four-dimensional subspace, and* (iii) *one additional inequality holds for rotating waves* (*see* (53)) *while three additional inequalities hold for standing waves* (*see* (60)), *one of them depending on the combination* Δ (*see* (44)) *of fifth-order terms of F.*

3.3. Second family of rotating waves. If $x_j = 0$ for $j = -2, 0, 2$ then (18), (19) lead to nonzero monomials for F_m when

$$p_1 - q_1 - p_{-1} + q_{-1} = m, \qquad p_1 - q_1 + p_{-1} - q_{-1} = 1.$$

This implies $F_m = 0$ for $m = -2, 0, 2$, and (up to "flat terms") as for (46):

$$
\begin{aligned}
F_{-1}(\lambda, X) &= x_{-1}\tilde{F}(\lambda, |x_{-1}|^2, |x_1|^2,\\
F_1(\lambda, x) &= x_1\tilde{F}(\lambda, |x_1|^2, |x_{-1}|^2).
\end{aligned}
\tag{61}
$$

Hence, truncated at third order, the system (5) reduces to

$$
\begin{aligned}
\frac{d}{dt}x_{-1} &= x_{-1}\left[i\omega + \mu + \left(a - c\sqrt{\frac{3}{2}}\right)r_{-1}^2 + \left(a - b - c\sqrt{\frac{3}{2}}\right)r_1^2\right],\\
\frac{d}{dt}x_1 &= x_1\left[i\omega + \mu + \left(a - b - c\sqrt{\frac{3}{2}}\right)r_{-1}^2 + \left(a - c\sqrt{\frac{3}{2}}\right)r_1^2\right].
\end{aligned}
\tag{62}
$$

We can proceed as in § 3.2. We obtain the following rotating wave solution:

$$x_{-1} = 0, \qquad x_1 = r_1\, e^{i(\omega_1 t + \psi_1)}, \tag{63}$$

with

$$
\begin{aligned}
&\mu_r + \left(a_r - c_r\sqrt{\frac{3}{2}}\right)r_1^2 + O(r_1^4) = 0,\\
&\omega_1 = \omega + \mu_i + \left(a_i - c_i\sqrt{\frac{3}{2}}\right)r_1^2 + O(r_1^4).
\end{aligned}
\tag{64}
$$

By the same reasoning used in 3.2.1 we can show that

$$R_{oz}(\theta)\tau(-\theta/\omega_1)U = U. \tag{65}$$

This invariance is different from that of the rotating wave of the first kind since (65) implies that this new wave rotates approximately twice as rapidly as the previous one ($\omega_1 - \omega_2 = 0(\mu_r)$).

The stability is governed by the following system (truncated at cubic terms):

$$\frac{d}{dt}\rho_1 = 2\left(a_r - c_r\sqrt{\frac{3}{2}}\right)r_1^2\rho_1, \qquad \frac{d}{dt}\varphi_1 = 2\left(a_i - c_i\sqrt{\frac{3}{2}}\right)r_1\rho_1,$$

$$\frac{d}{dt}y_{-1} = -br_1^2 y_{-1}, \qquad \frac{d}{dt}y_2 = -c\sqrt{\frac{3}{2}}\,r_1^2 y_{-2}, \tag{66}$$

$$\frac{d}{dt}y_0 = c\sqrt{\frac{2}{3}}\,r_1^2 y_0 + cr_1^2\bar{y}_2, \qquad \frac{d}{dt}\bar{y}_2 = \bar{c}\sqrt{\frac{3}{2}}\,r_1^2\bar{y}_2 + \bar{c}r_1^2 y_0,$$

from which the following eigenvalues can be exhibited:

$$\sigma_1 = 2\left(a_r - c_r\sqrt{\frac{3}{2}}\right)r_1^2 + O(r_1^4), \qquad \sigma_2 = -br_1^2 + O(r_1^4),$$

$$\sigma_3 = \bar{\sigma}_2, \quad \sigma_4 = -c\sqrt{\frac{3}{2}}\,r_1^2 + O(r_1^4), \quad \sigma_5 = \bar{\sigma}_4, \tag{67}$$

$$\sigma_6 = \left(c\sqrt{\frac{2}{3}} + \bar{c}\sqrt{\frac{3}{2}}\right)r_1^2 + O(r_1^4), \quad \sigma_7 = \bar{\sigma}_6, \quad \sigma_8 = 0 \quad \text{(triple)}.$$

For the reason already stated, the zero eigenvalue of the rotating bifurcated branch is triple. This branch, however, is generically *unstable* (if c_r is nonzero).

Now it is natural to investigate the standing wave solution given by

$$x_{-1} = \tilde{r}_1\, e^{i(\tilde{\omega}_1 t + \psi_{-1})}, \qquad x_1 = \tilde{r}_1\, e^{i(\tilde{\omega}_1 t + \psi_1)},$$

with

$$\mu_r + (2a_r - b_r - c_r\sqrt{6})\tilde{r}_1^2 + O(\tilde{r}_1^4) = 0, \qquad \tilde{\omega}_1 = \omega + \mu_i + (2a_i - b_i - c_i\sqrt{6})\tilde{r}_1^2 + O(\tilde{r}_1^4). \tag{68}$$

This solution actually belongs to the family spanned by the rotating wave (54) found in § 3.2.2 since the rotation transforms (see Appendix 1) $X = (\tilde{r}_2, 0, 0, 0, \tilde{r}_2)$ into $X' = (0, i\tilde{r}_2, 0, i\tilde{r}_2, 0)$. We can now sum up these results as a theorem.

THEOREM 3. *In the invariant four-dimensional subspace* $\{x_{-1} = x_0 = x_2 = 0\}$ *the subsystem* (62) *satisfies an* $O(2)\times SO(2)$ *equivariance as in Theorem* 2. *The rotating waves rotate approximately twice as rapidly as the ones of Theorem* 2. *Their* Γ *orbit is always unstable. Standing waves belong to the same* Γ*-orbit as those of Theorem* 2.

3.4. Tetrahedral waves. If $x_j = 0$ for $j = -1, 0, 2$ then (18), (19) lead to nonzero monomials for F_m when

$$p_1 - q_1 - 2(p_{-2} - q_{-2}) = m, \qquad p_1 - q_1 + p_{-2} - q_{-2} = 1.$$

This implies $F_m = 0$ for $m = -1, 0, 2$ and (up to "flat terms") as in (46):

$$F_{-2}(\lambda, x) = x_{-2}\tilde{F}_{-2}(\lambda, |x_{-2}|^2, |x_1|^2),$$
$$F_1(\lambda, x) = x_1\tilde{F}_1(\lambda, |x_{-2}|^2, |x_1|^2). \tag{69}$$

Furthermore, equivariance of F with respect to a rotation such as (see Appendix 1):

$$\theta = \alpha, \quad \varphi_1 = -\pi/2, \quad \varphi_2 = -\pi/2, \tag{70}$$

where

$$\sin\alpha = \frac{2}{3}\sqrt{2}, \qquad \cos\alpha = -\frac{1}{3},$$

leads to the following condition for F defined by (69):

$$\tilde{F}_1(\lambda, |x_{-2}|^2, 2|x_{-2}|^2) = \tilde{F}_{-2}(\lambda, |x_{-2}|^2, 2|x_{-2}|^2) \tag{71}$$

due to the fact that the rotation (70) leaves invariant the vector

$$X=(1,0,0,\sqrt{2},0).$$

Suppressing terms higher than sixth order, we have that the governing system takes the following form:

$$\begin{aligned}\frac{d}{dt}x_{-2}&=x_{-2}\Big[i\omega+\mu+ar_{-2}^2+(a-c\sqrt{6})r_1^2+d_1(r_1^2+r_{-2}^2)^2\\&\qquad-\sqrt{6}d_3r_1^2(r_1^2+r_{-2}^2)+3\sqrt{\frac{3}{2}}d_6r_1^4\Big],\\\frac{d}{dt}x_1&=x_1\Big[i\omega+\mu+(a-c\sqrt{6})r_{-2}^2+\Big(a-c\sqrt{\frac{3}{2}}\Big)r_1^2+d_1(r_1^2+r_2^2)^2\\&\qquad-\sqrt{\frac{3}{2}}d_3(r_1^2+r_2^2)(r_1^2+2r_{-2}^2)+3\sqrt{6}d_6r_1^2r_{-2}^2+\frac{d_9}{2}(r_1^2-2r_{-2}^2)^2\Big]\end{aligned}\tag{72}$$

where (71) is clearly satisfied.

System (72) possesses three different kinds of periodic solutions: those rotating waves found in §§ 3.2.1 and 3.3, and a solution such as

$$|x_1|=\sqrt{2}|x_{-2}|.\tag{73}$$

This relation is then valid up to arbitrary order, as can be proved by (71). Thus we obtain

$$\begin{aligned}x_1&=\sqrt{2}\hat{r}\,e^{i(\hat{\omega}t+\psi_1)},\\x_{-2}&=\hat{r}\,e^{i(\hat{\omega}t+\psi_{-2})},\end{aligned}\tag{74}$$

with

$$\begin{aligned}&\mu_r+(3a_r-2c_r\sqrt{6})\hat{r}^2+[9d_{1r}+6\sqrt{6}(d_{6r}-d_{3r})]\hat{r}^4+O(\hat{r}^6)=0,\\&\hat{\omega}=\omega+\mu_i+(3a_i-2c_i\sqrt{6})\hat{r}^2+[9d_{1i}+6\sqrt{6}(d_{6i}-d_{3i})]\hat{r}^4+O(\hat{r}^6).\end{aligned}\tag{75}$$

The phases ψ_1, ψ_{-2} may be eliminated by an appropriate rotation composed with an adequate choice of the time origin. Note that the solution $x_{-1}=\sqrt{2}x_2$, $x_j=0$ for $j=-2, 0, 1$ belongs to the same torus of solutions as (74): just rotate the angle π about ox.

The symmetry of the solution with $\psi_{-2}=\psi_1=0$ is of the form expected from [7]: a tetrahedral type solution. This means that once a rotation of angle $2\pi/3$ about oz is combined with a time translation of the third of a period, the principal part X and therefore U itself remain invariant. More explicitly, (43) implies

$$R_{oz}(2\pi/3)X=j^2X,\qquad j=e^{2i\pi/3},$$

and since

$$\tau(2\pi/3\hat{\omega})X=jX,$$

it is easy to deduce

$$R_{oz}(2\pi/3)\tau(2\pi/3\hat{\omega})U=U.\tag{76}$$

The remaining three ternary axes of this solution are shown in Fig. 1: $\mathbf{k}_1$ is located along oz; $\mathbf{k}_2$ belongs to the xoz plane and makes an angle α with $\mathbf{k}_1$ (α is defined in (70)). The axes $\mathbf{k}_3$ and $\mathbf{k}_4$ are obtained from $\mathbf{k}_2$ by rotation of $2\pi/3$ about $\mathbf{k}_1$. The solution U remains invariant under the combination of a rotation of angle $2\pi/3$ about

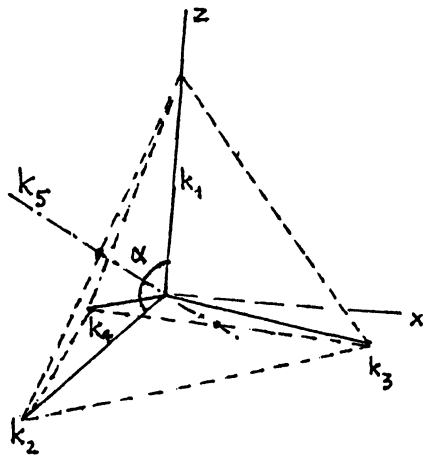

FIG. 1. *Ternary symmetry axes* (k_1, k_2, k_3, k_4) *of the tetrahedral waves.*

the axis k_i followed by a time translation of a third of the period. Let us introduce the rotation G_i that transforms $\mathbf{k}_1$ into $\mathbf{k}_i$:

$$G_i = R_{oz}(-\varphi_i)R_{ox}(-\alpha), \tag{77}$$

with

$$\varphi_2 = -\pi/2, \quad \varphi_3 = -\pi/2 - 2\pi/3, \quad \varphi_4 = -\pi/2 - 4\pi/3. \tag{78}$$

Then the rotation of angle $2\pi/3$ about $\mathbf{k}_i$ takes the following form:

$$G_i' = G_i R_{oz}(2\pi/3)G_i^{-1}. \tag{79}$$

It is clear that G_i' acts like $R_{oz}(2\pi/3)$ on $X = (x_{-2}, 0, 0, \sqrt{2}x_{-2}, 0)$. The bisectors of the ternary axes correspond to binary axes: for instance, the bisector of $(\mathbf{k}_1, \mathbf{k}_2)$ denoted by $\mathbf{k}_5$ is such that the symmetry

$$R_{k_5}(\pi) = G'' R_{oz}(\pi) G''^{-1}, \qquad \text{where } G'' = R_{oz}(\pi/2)R_{ox}(-\alpha/2) \tag{80}$$

leaves X invariant. This concludes the symmetry analysis and shows that this solution is the tetrahedral one predicted in [7].

The study of the stability yields (using obvious notation):

$$\begin{aligned}
\frac{d}{dt}\rho_{-2} &= [2a_r\rho_{-2} + 2\sqrt{2}(a_r - c_r\sqrt{6})\rho_1]\hat{r}^2, \\
\frac{d}{dt}\rho_1 &= [2\sqrt{2}(a_r - c_r\sqrt{6})\rho_{-2} + 2(2a_r - c_r\sqrt{6})\rho_1]\hat{r}^2, \\
\frac{d}{dt}\bar{y}_0 &= [\bar{c}\sqrt{6}\bar{y}_0 + \bar{c}\sqrt{2}y_{-1} + 2\bar{c}y_2]\hat{r}^2, \\
\frac{d}{dt}y_{-1} &= [c\sqrt{2}\bar{y}_0 + (-2b + c\sqrt{6})y_{-1} + b\sqrt{2}y_2]\hat{r}^2, \\
\frac{d}{dt}y_2 &= [2c\bar{y}_0 + b\sqrt{2}y_{-1} + (c\sqrt{6} - b)y_2]\hat{r}^2,
\end{aligned} \tag{81}$$

where equations for phases are omitted. The eigenvalues are now:

$$
\begin{aligned}
&\sigma_1 = 2(3a_r - 2c_r\sqrt{6})\hat{r}^2 + O(\hat{r}^4),\\
&\sigma_2 = 2c_r\sqrt{6}\hat{r}^2 + O(\hat{r}^4) \quad \text{(triple at this order)},\\
&\sigma_3 = (-3b + c\sqrt{6})\hat{r}^2 + O(\hat{r}^4),\\
&\sigma_4 = \bar{\sigma}_3,\\
&\sigma_5 = 0 \quad \text{(quadruple)}.
\end{aligned} \tag{82}
$$

The eigenvalue σ_5 is quadruple because of orbital stability (as for standing waves). The others yield the following conditions for stability:

$$
\begin{aligned}
&3a_r - 2c_r\sqrt{6} < 0 \quad \text{(supercritical bifurcation)},\\
&c_r < \min : \left(b_r \sqrt{\frac{3}{2}}; 0 \right).
\end{aligned} \tag{83}
$$

Let us sum up these results as a theorem.

THEOREM 4. *In the invariant four-dimensional subspace* $\{x_{-1} = x_0 = x_2 = 0\}$ *the subsystem* (72) *possesses three types of time-periodic bifurcating solutions*: (i) *the two different families of rotating waves found in Theorems* 2 *and* 3, *and* (ii) *a solution such that* $|x_1| = \sqrt{2}|x_{-2}|$, *which possesses the tetrahedral symmetry indicated by Golubitsky and Stewart in* [7]. *The* Γ *orbit of this solution is stable if the bifurcation is supercritical and two additional inequalities are realized on the cubic terms of F* (*see* (83)).

3.5. Summary of results. In the plane (b_r, c_r) Fig. 2 shows the domains of stability of the various periodic solutions depending on the sign of a_r. Despite the relatively large number of solutions, Fig. 2 is rather simple and the various domains just overlap on a small part of this plane (for a_r negative). One condition of stability is the usual result of supercriticality; nonetheless, this condition is not sufficient since the second family of rotating waves is proved to be always unstable. The first family of rotating waves and axisymmetric solutions may be simultaneously stable if Δ and a_r are negative.

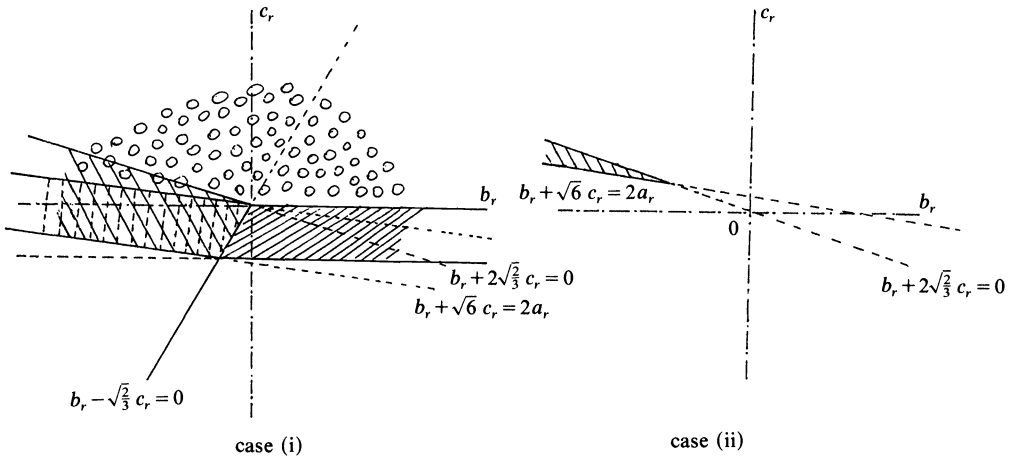

FIG. 2. *Stability domains of the periodic solutions*: *case* (i) $a_r < 0$, *case* (ii) $a_r > 0$. /// *tetrahedral waves*; \\\ *axisymmetric solution if* $\Delta < 0$; //// *standing waves of* $\Delta > 0$ (*axisymmetric solution if* $\Delta < 0$); °°° *rotating waves* (*first family*).

This is not the case for standing waves or axisymmetric waves because of Δ. Note that the fifth order terms appearing in (5) with nine coefficients play a role in the stability study by means of the single combination Δ of three of them (d_6, d_7, d_8). Finally we note that pictures of all five waves are given in Montaldi, Roberts, and Stewart [16].

4. Quasiperiodic solutions. Here we look for the possiblity of bifurcations leading to quasiperiodic patterns. As a matter of fact, the differential system may exhibit such behavior at the onset of instability since it is eight-dimensional: five amplitudes r_m and three phases $\theta_1, \theta_2, \theta_3$ appear in (5) which may be rewritten as:

$$\begin{aligned} \frac{dr_m}{dt} &= f_m(r_{-2}, r_{-1}, r_0, r_1, r_2, \theta_1, \theta_2, \theta_3), \\ \frac{d\psi_m}{dt} &= g_m(r_{-2}, r_{-1}, r_0, r_1, r_2, \theta_1, \theta_2, \theta_3), \end{aligned} \tag{84}$$

where

$$\theta_1 = 2\psi_0 - \psi_1 - \psi_{-1}, \qquad \theta_2 = 2\psi_0 - \psi_2 - \psi_{-2},$$
$$\theta_3 = 2\psi_{-1} - \psi_0 - \psi_{-2}.$$

Steady solutions $\theta_1, \theta_2, \theta_3, r_m (\neq 0)$ may be found in (84) if

$$\begin{aligned} &f_m(r_{-2}, r_{-1}, r_0, r_1, r_2, \theta_1, \theta_2, \theta_3) = 0, \\ &g_m(r_{-2}, r_{-1}, r_0, r_1, r_2, \theta_1, \theta_2, \theta_3) = \omega_m, \qquad m = -2, \cdots, 2, \end{aligned} \tag{85}$$

where

$$2\omega_0 - \omega_1 - \omega_{-1} = 2\omega_0 - \omega_2 - \omega_{-2} = 2\omega_{-1} - \omega_0 - \omega_{-2} = 0,$$

all the ω_m being close to $\omega + \mu_i$. These pulsations satisfy the relations (29) for a pair (α, β). If α and β are not rationally related, the solution is quasiperiodic with two basic frequencies β (close to ω) and α very small. Unfortunately, it is hopeless to consider the full system (84)—or (85)—since it is much too complicated for us to find analytical solutions. One method for avoiding such difficulties is to consider special cases. Systems (47), (62), and (72) have a feature in common with the $O(2) \times SO(2)$ invariant problems where a Hopf bifurcation is present since if, respectively, $b_r + c_r\sqrt{6} = 0$, $b_r = 0$, or $c_r = 0$, it is impossible to determine at cubic order which are the observable time-periodic solutions. (The standing as well as the tetrahedral waves cannot be computed). Such situations are common for codimension 2 problems. They can be treated as in the Couette-Taylor example [4], [13]. Higher-order terms (fifth and seventh order) must be computed to describe the form and stability of these solutions. We will not discuss these cases here because we only consider codimension 1 problems.

Another possibility relies on the analysis of a lower-dimensional subsystem. For instance, requiring the x_1, x_{-1} amplitudes to be zero will lead to the reduction of the system (84) to the following:

$$\begin{aligned} \frac{dr_m}{dt} &= f_m(r_{-2}, r_0, r_2, \theta), \qquad m = -2, 0, 2, \\ \frac{d\psi_m}{dt} &= g_m(r_{-2}, r_0, r_2, \theta), \end{aligned} \tag{86}$$

where

$$\theta = 2\psi_0 - \psi_{-2} - \psi_2.$$

Hence, every set $\{r_{-2}, r_0, r_2 \text{ (all} \neq 0), \theta\}$ satisfying

$$\begin{aligned} &f_m(r_{-2}, r_0, r_2, \theta) = 0, \qquad m = -2, 0, 2, \\ &2g_0 - g_{-2} - g_2 = 0, \end{aligned} \tag{87}$$

where $g_2(r, \theta)$ is different from $g_{-2}(r, \theta)$, corresponds to a quasiperiodic solution of (86) with two basic frequencies. Clearly, r_2 must differ from r_{-2}; if not, we would show via (23) that $f_{-2}(r, \theta)$ (respectively, $g_{-2}) = f_2$ (respectively g_2), which means that the solution is periodic.

System (87) truncated at the third order takes the following form:

$$\begin{aligned} &r_{-2}\left[\mu_r + a_r r_{-2}^2 + \left(a_r - 2\sqrt{\frac{2}{3}}\, c_r\right) r_0^2 + (a_r - b_r - c_r\sqrt{6}) r_2^2\right] \\ &\quad + \frac{1}{2} r_0^2 r_2 \left[\left(-b_r + c_r\sqrt{\frac{3}{2}}\right)\cos\theta - \left(-b_i + c_i\sqrt{\frac{3}{2}}\right)\sin\theta\right] = 0, \\ &r_2\left[\mu_r + \left(a_r - b_r - c_r\sqrt{6}\right) r_{-2}^2 + \left(a_r - 2\sqrt{\frac{2}{3}}\, c_r\right) r_0^2 + a_r r_2^2\right] \\ &\quad + \frac{1}{2} r_0^2 r_{-2} \left[\left(-b_r + c_r\sqrt{\frac{3}{2}}\right)\cos\theta - \left(-b_i + c_i\sqrt{\frac{3}{2}}\right)\sin\theta\right] = 0, \\ &\mu_r + \left(a_r - 2\sqrt{\frac{2}{3}}\, c_r\right)(r_{-2}^2 + r_2^2) + \frac{1}{2}(2a_r - b_r - c_r\sqrt{6}) r_0^2 \\ &\quad + r_2 r_{-2}\left[\left(-b_r + c_r\sqrt{\frac{3}{2}}\right)\cos\theta + \left(-b_i + c_i\sqrt{\frac{3}{2}}\right)\sin\theta\right] = 0, \\ &\left(-b_i + c_i\sqrt{\frac{2}{3}}\right)(r_0^2 - r_2^2 - r_{-2}^2)(1 - \cos\theta) \\ &\quad - \left(-b_i + c_i\sqrt{\frac{2}{3}}\right)\frac{(r_2 - r_{-2})^2}{2r_2 r_{-2}}(r_0^2 + 2r_2 r_{-2})\cos\theta \\ &\quad - \left(-b_r + c_r\sqrt{\frac{2}{3}}\right)[4r_2^2 r_{-2}^2 + r_0^2(r_2^2 + r_{-2}^2)]\frac{\sin\theta}{2r_2 r_{-2}} = 0. \end{aligned} \tag{88}$$

From this, we easily draw an equation for θ alone. Once this equation is solved, we obtain r_0, r_2, r_{-2} from

$$\begin{aligned} &\mu_r + \left[a_r - 2\sqrt{\frac{2}{3}}\, c_r + a_r B(\theta)\right] r_0^2 = 0, \\ &r_2 r_{-2} = A(\theta) r_0^2, \qquad r_2^2 + r_{-2}^2 = B(\theta) r_0^2, \end{aligned} \tag{89}$$

where

$$\begin{aligned} A(\theta) &= \frac{(-b_r + c_r\sqrt{3/2})\cos\theta - (-b_i + c_i\sqrt{3/2})\sin\theta}{2(b_r + c_r\sqrt{6})}, \\ B(\theta) &= \frac{(-b_r + c_r\sqrt{2/3})(b_r + c_r\sqrt{6}) + (-b_r + c_r\sqrt{3/2})^2\cos^2\theta - (-b_i + c_i\sqrt{3/2})^2\sin^2\theta}{4\sqrt{2/3}(b_r + c_r\sqrt{6})c_r}. \end{aligned} \tag{90}$$

The equation for θ then turns out to be:

$$\left(-b_i + c_i\sqrt{\frac{2}{3}}\right)\left\{2A(\theta)[1-B(\theta)] + \cos\theta[4A^{2\prime} - B]\right\}$$
$$-\left(-b_r + c_r\sqrt{\frac{2}{3}}\right)\sin\theta[4A^2 + B] = 0. \tag{91}$$

The left-hand side of (91) is an odd polynomial function of degree three in $(\sin\theta, \cos\theta)$. This implies zero, two, four, or six solutions coupled in pairs $(\theta, \theta+\pi)$. Relations (89) show that only one element in each pair of solutions of (91) is acceptable. Let us show the existence of solutions when it is assumed that

$$-b_i + c_i\sqrt{\frac{2}{3}} = 0.$$

Under such hypothesis (91) simplifies to

$$\sin\theta(4A^2(\theta) + B(\theta)) = 0. \tag{92}$$

Only zero or π are possible choices. As a matter of fact, we can assert that π is impossible because of (89). While $\theta = 0$ is a solution provided

$$\begin{aligned} &b_r \in]-c_r\sqrt{6}, -c_r\sqrt{6}/4[\quad \text{if } c_r > 0, \\ &b_r \in]-c_r\sqrt{6}/4, -c_r\sqrt{6}[\quad \text{if } c_r < 0, \end{aligned} \tag{93}$$

for b_r in this open set, it is clear that the quasiperiodic solution still exists for $-b_i + c_i\sqrt{2/3}$ near zero. Since this condition is not related to a "classical" codimension 2 problem (indicated above) we may assert that the direct bifurcation to a quasiperiodic solution is general here in a "large" open set in the parameter space.

Acknowledgments. We thank P. Chossat for his helpful remarks and we gratefully acknowledge A. Cerezo for taking time to derive the general form of the equivariant vector field $F(\lambda, X)$ (see [1]).

Appendix 1. Representation of a finite rotation. We indicate here the representation $l = 2$ of a finite rotation correcting some misprints in [6]. In the canonical basis a rotation defined by the Euler angles $\varphi_1, \theta, \varphi_2$:

$$R(\varphi_1, \theta, \varphi_2) = R_{oz}(\varphi_2)R_{ox}(\theta)R_{oz}(\varphi_1)$$

is represented by a 5×5 matrix T such that

$$T_{mn}(\varphi_1, \theta, \varphi_2) = e^{-im\varphi_2}\, e^{-im\varphi_1} u_{mn}(\theta),$$

where $u_{mn}(\theta)$ satisfy:

$$u_{mn} = u_{nm},$$

$$u_{-2,-2}(\theta) = u_{2,2}(\theta) = u_{-2,2}(\pi+\theta) = \frac{1}{4}(1+\cos\theta)^2,$$

$$u_{-2,0}(\theta) = u_{0,2}(\theta) = -\frac{1}{2}\sqrt{\frac{3}{2}}(1-\cos^2\theta),$$

$$u_{-2,-1}(\theta) = u_{1,2}(\theta) = u_{-2,1}(\pi+\theta) = u_{-1,2}(\pi+\theta) = -\frac{i}{2}\sin\theta(1+\cos\theta),$$

$$u_{-1,-1}(\theta) = u_{1,1}(\theta) = u_{-1,1}(\pi+\theta) = \frac{1}{2}(2\cos^2\theta + \cos\theta - 1),$$

$$u_{-1,0}(\theta) = u_{0,1}(\theta) = -i\sqrt{\frac{3}{2}}\cos\theta\sin\theta,$$

$$u_{0,0}(\theta) = \frac{1}{2}(3\cos^2\theta - 1).$$

An infinitesimal rotation takes the following form:

$$\begin{pmatrix} 1+2i(\varphi_1+\varphi_2) & -i\theta & 0 & 0 \\ -i\theta & 1+i(\varphi_1+\varphi_2) & -i\sqrt{3/2}\theta & 0 \\ 0 & -i\sqrt{3/2}\theta & 1 & 0 \\ 0 & 0 & -i\sqrt{3/2}\theta & -i\theta \\ 0 & 0 & 0 & 1-2i(\varphi_1+\varphi_2) \end{pmatrix}.$$

BIFURCATION AND ASYMPTOTIC BEHAVIOR OF SOLUTIONS OF A DELAY-DIFFERENTIAL EQUATION WITH DIFFUSION*

MARGARET C. MEMORY†

Abstract. A scalar delay-differential equation with diffusion term in one space dimension, where the diffusivity D is a bifurcation parameter, is considered. The center manifold theory and the method of Lyapunov-Schmidt are used to describe two bifurcations from spatially constant solutions as D decreases. By modifying the equation the order of these bifurcations can be reversed. Then the existence of a compact attractor for a class of such equations is shown and the structure of part of the attractor for the modified equation is investigated. It is known that the solutions are globally L^2-bounded; bounds on the solution operator from one intermediate space to another are constructed to obtain an attractor in the $W^{2,2}$ sense.

Key words. delay-differential equation, small diffusivity, population model, bifurcation, periodic orbit, attractor

AMS(MOS) subject classifications. 34K15, 35B32

Introduction. In this paper we consider

$$\begin{aligned} &\frac{\partial}{\partial t}u(t,x)=D\frac{\partial^2}{\partial x^2}u(t,x)-\left(\frac{\pi}{2}+\mu\right)u(t-1,x)[1+u(t,x)],\ t>0, \qquad x\in(0,\pi), \\ &\frac{\partial}{\partial x}u(t,x)=0, \qquad x=0,\pi. \end{aligned} \tag{1}$$

Throughout the paper μ will be in a neighborhood of zero.

Without space dependence, the equation becomes

$$\frac{d}{dt}u(t)=-\left(\frac{\pi}{2}+\mu\right)u(t-1)[1+u(t)], \tag{2}$$

which has been proposed by Hutchinson [10] to model certain plant-eating populations; it is obtained after a change of variables from a delayed logistic equation. The value of μ depends on the delay and the growth rate of the population.

The constant zero solution of (2) is seen to be stable for $\mu>0$ by analyzing the eigenvalues of the linearized equation. Chow and Mallet-Paret [4] use integral averaging to show that a supercritical Hopf bifurcation occurs at $\mu=0$ (where the linearized equation has a pair of eigenvalues $\pm i\pi/2$) and find the approximate form of the bifurcating periodic solution for $\mu>0$. Stech also takes (2) as an example in [13], where he uses the bifurcation function to study Hopf bifurcations for functional differential equations.

With the addition of a diffusion term, we allow the population density to vary in some domain Ω, imposing no-flux boundary conditions. We want to investigate the effects of diffusion on the long-term behavior of solutions by considering two questions.

First is the local problem. Given a solution of (2) and its stability properties, what are its stability properties as a solution of (1)? In §§ 2-4, we will build on the work of Yoshida [15] and Morita [12] to deal with this question for the zero solution and the periodic solution arising in the Hopf bifurcation. Morita shows that, for fixed

$\mu > 0$, this periodic solution is unstable for D less than a certain D_0. We will show that there is a $D_1 > D_0$ at which another Hopf bifurcation from zero occurs, resulting in an unstable, spatially varying, periodic solution. We also show how to destabilize the original periodic solution (as D is decreased) before this bifurcation occurs by adding nonlinear terms in $u(t-1)$ to (1).

Second is the global problem. How can we use these local analyses to say something about the global structure of solutions? Hale has shown in [7] that if a retarded functional differential equation has a compact attractor, then the corresponding diffusion equation has, for large enough D, a compact attractor with this same structure. Here we are interested in how the attractor changes as D decreases toward zero. In §§ 5 and 6, we show the existence, for arbitrary $D > 0$, of a compact attractor for a class of equations including (1). We then consider the modification of (1) noted above, for which destabilization of the original periodic solution precedes the second Hopf bifurcation, and determine the structure of part of the attractor for this equation.

1. Previous results. The phase space for (1) is $C([-1, 0], X)$ for an appropriate Banach space X of functions from $[0, \pi]$ to $\mathbb{R}$. We write $u_t \in C([-1, 0], X)$ where $u_t(\theta)(x) = u(t+\theta, x)$, $-1 \leqq \theta \leqq 0$, $x \in [0, \pi]$. With the interpretation of "$\partial^2/\partial x^2$" depending on the choice of X, (1) becomes

$$\begin{aligned} &\frac{\partial}{\partial t} u(t, x) = D \frac{\partial^2}{\partial x^2} u(t, x) + f(\mu, u_t(\cdot)(x)), \qquad x \in (0, \pi), \\ &\frac{\partial}{\partial x} u(t, x) = 0, \qquad x = 0, \pi \end{aligned} \tag{3}$$

with initial condition $u_0(\cdot)(\cdot) \in C([-1, 0], X)$ given. Yoshida [15] proves existence and uniqueness of solutions of (3) if $X = W^{2,2}(0, \pi)$. (This is a special case of his general result for domain $\Omega \subset \mathbb{R}^n$.) In addition, he makes the change of variable $U(t, x) = 1 + u(t, x)$ to get positivity of solutions in this new variable. (We will use this in § 3.) Calling $W_N^{2,2} = \{v \in W^{2,2}(0, \pi): \partial v/\partial x = 0 \text{ at } x = 0, \pi\}$, we work in $C = C([-1, 0], W_N^{2,2})$.

First we investigate the stability of the zero solution of (1). The eigenfunctions of $-\partial^2/\partial x^2$ (considered here as a densely defined operator on $L^2(0, \pi)$) are $w_n(x) = \cos nx$ with corresponding eigenvalues n^2 for $n \geqq 0$. Linearizing (1) about zero and looking for solutions $e^{\lambda t} w_n(x)$, we obtain a sequence of characteristic equations

$$\lambda + \left(\frac{\pi}{2} + \mu\right) e^{-\lambda} + Dn^2 = 0, \qquad n \geqq 0. \tag{4.n}$$

Yoshida shows (using a result in Hale [9]) that for $\mu < 0$ and any D, all roots of all the equations (4.n) have negative real parts, so the zero solution is stable.

Note that (4.0) has a pair of roots $\pm i\pi/2$ when $\mu = 0$. (This is the characteristic equation for (2).) We can use Hale's result to show that all other solutions of (4.n) for each n have negative real parts.

Therefore if we fix D and increase μ, the origin is stable until $\mu = 0$, when it loses stability in exactly two directions as a spatially constant periodic orbit grows out of it. Yoshida proves (using the Center Manifold Theory and Chow and Mallet-Paret's averaging scheme) that this orbit is stable for μ in some interval, say $\mu \in (0, \mu_1)$.

Changing our point of view slightly, we think of μ fixed and decrease D. In terms of the population model, this means the animals move more slowly in Ω. We might therefore expect spatial inhomogeneities to persist, with solutions of (1) no longer approaching those of (2). We have already seen that if $\mu < 0$ the zero solution is stable

for any D: the origin cannot be destabilized by decreasing the diffusivity. We turn our attention to small $\mu > 0$ and the possible destabilization of the periodic orbit.

Morita considers this question for a class of problems in [12]. He treats (1) (for $\Omega \subset \mathbb{R}^n$) as an example and shows that for any $\mu > 0$ there is a $D = D(\mu)$ for which the spatially constant periodic orbit is unstable. He uses the Lyapunov-Schmidt method (see, for example, [3]) to compute explicitly one of the characteristic exponents γ of the periodic orbit as a function of μ and D. For small $\mu > 0$, he is able to choose D small enough so that $\gamma(\mu, D) > 0$.

Here we summarize Morita's results for (1), putting them in a slightly different form. First it is necessary to locate the periodic orbit arising in the Hopf bifurcation. We seek a solution $y(t, \varepsilon) = \varepsilon \cos \omega t + O(\varepsilon^2)$, where $\omega = \omega(\varepsilon)$, of (2) with $\mu = \mu(\varepsilon)$. (The phase space here is $C([-1, 0], \mathbb{R})$.) On applying the Lyapunov-Schmidt method, we obtain

$$y(t, \varepsilon) = \varepsilon \cos \omega t + \tfrac{1}{5}\varepsilon^2 \cos 2\omega t + \tfrac{1}{10}\varepsilon^2 \sin \omega t + O(\varepsilon^3),$$

$$\omega(\varepsilon) = \frac{\pi}{2} - \frac{1}{20}\varepsilon^2 + O(\varepsilon^3),$$

$$\mu(\varepsilon) = \frac{3\pi - 2}{40}\varepsilon^2 + O(\varepsilon^3).$$

In practice, we change variables $s = \omega t$ (where ω is to be determined) and look for 2π-periodic solutions. The phase space is still $C([-1, 0], \mathbb{R})$, where $v_{s,\omega}(\theta) = v(s + \omega\theta)$, $-1 \leqq \theta \leqq 0$.

The stability of $p(t, x, \varepsilon) \equiv y(t, \varepsilon)$ as a solution of (1) is investigated by linearizing (1) about p and seeking solutions $e^{\gamma t} v(t) \cos nx$, where v has the same period as p. If $v(t)$ is required to have minimal period $2\pi/\omega(\varepsilon)$, applying the Lyapunov-Schmidt method leads to an equation connecting D and the characteristic exponent γ. By scaling $\gamma = \gamma_2 \varepsilon^2 + O(\varepsilon^3)$, $D = D_2 \varepsilon^2$, we obtain a quadratic equation for γ_2. If $D_2 n^2 > \pi/20$, the roots γ_2 are negative or have negative real part. If $D_2 n^2 = \pi/20$ one root is zero, and if $0 < D_2 n^2 < \pi/20$ it becomes positive. Note that if $n = 0$ the characteristic exponents obtained are those for y as a solution of (2), that is, one trivial exponent and one negative one, so it is only necessary to consider $n > 0$. The periodic solution p must therefore be unstable for $D < D^*(\mu)$, where $\mu(\varepsilon)$ is given above and $D^*(\mu(\varepsilon)) \approx \pi\varepsilon^2/20$. It will lose stability in more directions across each of the approximate bifurcation curves in Fig. 1. (Recall $\mu = \mu(\varepsilon)$.)

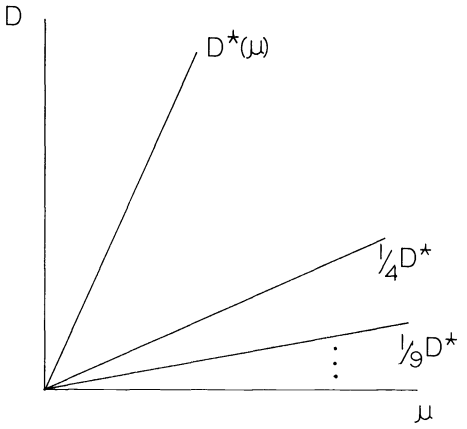

FIG. 1. *Bifurcation curves for destabilization of the periodic orbit.*

2. Second Hopf bifurcation. To study the small solutions of (1) it is certainly necessary to keep track of what is happening at the origin. For fixed $\mu > 0$ and large enough D, the origin has a two-dimensional unstable manifold. Does the origin also become less stable as D is decreased? We can see what is going on more clearly by linearizing (1) about zero and expanding in eigenfunctions $\sum_{n=0}^{\infty} u^n(t) \cos nx$. The equations decouple, and we have

$$\frac{d}{dt}u^n(t) = -Dn^2u^n(t) - \left(\frac{\pi}{2}+\mu\right)u^n(t-1) \tag{5.n}$$

for each $n \geqq 0$. Consider each (5.n) to be a separate delay-differential equation, and consider the stability of the origin as a solution of (5.n).

For the equation $\dot{u}(t) = -au(t) - bu(t-1)$, we have the situation illustrated in Fig. 2.

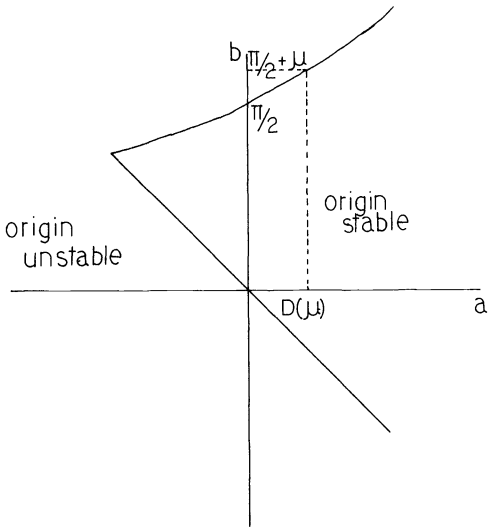

FIG. 2. *Stability of the origin.*

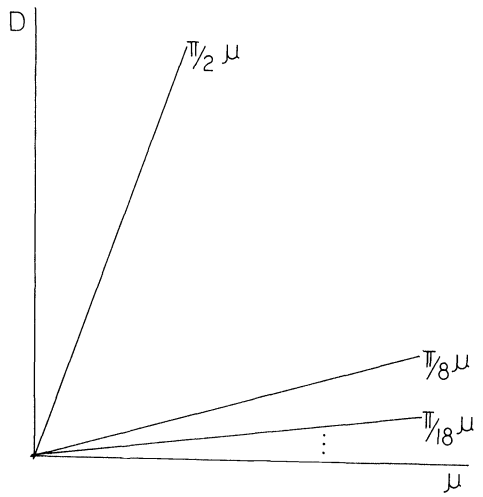

FIG. 3. *Hopf bifurcation curves.*

For (5.0) we know that the origin is unstable (with two-dimensional unstable manifold) for $\mu > 0$ and that no other bifurcations occur at the origin for the μ's we are considering.

For (5.n), $n \geqq 1$, we fix $\mu > 0$ and find $D = D(\mu)$ marked in Fig. 2, where the origin loses stability. We look for pure imaginary roots $\lambda = \pm i\beta$, $\beta > 0$, of the characteristic equation

$$\lambda + \left(\frac{\pi}{2}+\mu\right)e^{-\lambda} + Dn^2 = 0.$$

The real and imaginary parts give

$$0 = Dn^2 + \left(\frac{\pi}{2}+\mu\right)\cos\beta, \qquad \beta = \left(\frac{\pi}{2}+\mu\right)\sin\beta.$$

We expect β close to $\pi/2$, so let $\beta = \pi/2 + \tilde{\beta}$. The second equation above gives $\tilde{\beta} \approx \mu$. The first equation then gives $Dn^2 \approx \pi\tilde{\beta}/2 \approx \pi\mu/2$ for small μ.

Going back to the full equation (1), we again have a set of approximate bifurcation curves shown in Fig. 3, across each of which the already unstable origin loses stability in two more directions.

Consider the first of these bifurcations, when $D \approx \pi\mu/2$. We do not have a Hopf Bifurcation Theorem for equations for the form (1), but we can use the Center Manifold Theory to reduce the equation to a two-dimensional one where the Hopf Bifurcation Theorem holds. Yoshida [15] proves the existence of a local two-dimensional integral manifold at the origin, for fixed D and depending on μ close to μ_c where the equations (5.n) have exactly one pair of pure imaginary roots. We have been holding μ fixed and decreasing D, but the bifurcation curves are such that fixing D and increasing μ is equivalent. For any D, our $\mu_c \approx 2D/\pi$ is positive, so (5.0) has a pair of roots with positive real part. This means the center manifold will not be attracting.

Note that we could also use Carr's Center Manifold Theory for infinite-dimensional systems (see [2]), which requires a semigroup formulation of the problem slightly different from Yoshida's. Using Carr's work we get a two-dimensional center manifold depending on μ and D in a neighborhood of the bifurcation point.

Either way we know a Hopf bifurcation occurs as D decreases through $D \approx \pi\mu/2$, and we have only to determine whether a periodic orbit grows out of the origin or collapses onto it. The calculation proceeds as follows.

Substituting $u(t, x) = \sum_{n=0}^{\infty} u^n(t) \cos nx$ into (1) and calling $\alpha = \pi/2 + \mu$ gives

$$\frac{d}{dt} u^0(t) = -\alpha u^0(t-1) - \alpha u^0(t)u^0(t-1) - \frac{\alpha}{2} \sum_{n=1}^{\infty} u^n(t)u^n(t-1),$$

$$\frac{d}{dt} u^1(t) = -Du^1(t) - \alpha u^1(t-1) - \alpha u^0(t)u^1(t-1) - \alpha u^1(t)u^0(t-1)$$

$$-\frac{\alpha}{2} \sum_{n=1}^{\infty} u^{n-1}(t)u^n(t-1) - \frac{\alpha}{2} \sum_{n=2}^{\infty} u^n(t)u^{n-1}(t-1),$$

(6.p)

$$\frac{d}{dt} u^p(t) = -p^2 Du^p(t) - \alpha u^p(t-1) - \alpha u^0(t)u^p(t-1) - \alpha u^p(t)u^0(t-1)$$

$$-\frac{\alpha}{2} \sum_{n=1}^{p-1} u^{p-n}(t)u^n(t-1) - \frac{\alpha}{2} \sum_{n=1}^{\infty} u^{n+p}(t)u^n(t-1)$$

$$-\frac{\alpha}{2} \sum_{n=1}^{\infty} u^n(t)u^{n+p}(t-1), \qquad p \geqq 2.$$

We are looking for a periodic solution of the form

$$u^1(t) = b_0^1\varepsilon^2 + \varepsilon \cos \nu t + \sum_{n=2}^{\infty} b_n^1\varepsilon^2 \cos \nu nt + \sum_{n=2}^{\infty} c_n^1\varepsilon^2 \sin \nu nt + O(\varepsilon^3),$$

$$u^p(t) = b_0^p\varepsilon^2 + \sum_{n=1}^{\infty} b_n^p\varepsilon^2 \cos \nu nt + \sum_{n=1}^{\infty} c_n^p\varepsilon^2 \sin \nu nt + O(\varepsilon^3), \qquad p \neq 1,$$

with $\nu = \pi/2 + \nu_0 + \nu_1\varepsilon + \nu_2\varepsilon^2 + O(\varepsilon^3)$ for fixed small $\mu > 0$ and $D = D_0 + D_1\varepsilon + D_2\varepsilon^2 + O(\varepsilon^3)$.

As before, we rescale time $s = \nu t$ and rewrite the equations for $q^p(s) = u^p(t)$. We will substitute the desired solution into (6.p) and compare coefficients. We only need to determine the sign of D_2. (We expect the amplitude of the periodic orbit to be approximately proportional to the square root of the Hopf bifurcation parameter, so we expect $D_1 = 0$. The calculations confirm this.) To do this it is sufficient to consider

(6.0)-(6.2) only, retaining terms through $O(\varepsilon^2)$ in (6.0) and (6.2) and through $O(\varepsilon^3)$ in (6.1). In fact, we require the $O(\varepsilon^3)$ term only in the coefficients of $\sin s$ and $\cos s$ in (6.1).

Note that D_2, along with the other constants, depends on μ. Since μ is small, though, we retain only the $O(1)$ term in μ. In addition, we expect ν_0 to be small as a function of μ, so in the calculation we drop all powers of ν_0 higher than the first.

The calculation is lengthy, but we eventually find $D_2 < 0$, so a periodic orbit grows out of the origin as D is decreased (or, equivalently, as μ is increased). Note that neither the origin nor the bifurcating periodic orbit is stable, since the two-dimensional center manifold containing them is not attracting, but the origin loses its stability in the center manifold to the periodic orbit.

3. Direction of bifurcation. We now return to the bifurcation from the spatially constant periodic orbit at $D = D^*(\mu)$. Since the bifurcation occurs when a real characteristic exponent becomes positive, we expect bifurcating periodic orbits rather than an invariant torus. A calculation similar to the preceding one will allow us to determine whether the bifurcation is super-, sub-, or transcritical.

We look for the bifurcating periodic solutions

$$z(t, x, \varepsilon) = \varepsilon \cos \nu t + \varepsilon(a + b \cos \nu t + c \sin \nu t) \cos x + O(\varepsilon^2)$$

of (1) with $\mu = \mu(\varepsilon)$ and $D = D(\varepsilon)$, where $\nu = \nu(\varepsilon)$ is close to $\omega(\varepsilon)$ computed earlier. (Recall that the spatially constant periodic solution $p(t, x, \varepsilon)$ loses stability in the spatial direction $w_1(x) = \cos x$.) We substitute $z(t, x, \varepsilon)$ into (1), expanding in eigenfunctions $\cos nx$ and collecting coefficients of $\cos m\nu t$, $\sin m\nu t$. The computation is essentially an extension of the previous one, with two principal differences.

First, μ is a function of ε rather than a fixed quantity, so $\mu(\varepsilon) = \mu_2\varepsilon^2 + O(\varepsilon^3)$ must also be found. Second, the form of the periodic solution (actually, solutions) to be found is $z(t, x, \varepsilon) = \sum_{n=0}^{\infty} u^n(t) \cos nx$ where

$$u^0(t) = b_0^0\varepsilon^2 + \varepsilon \cos \nu t + \sum_{n=2}^{\infty} b_n^0\varepsilon^2 \cos \nu nt + \sum_{n=2}^{\infty} c_n^0\varepsilon^2 \sin \nu nt + O(\varepsilon^3),$$

$$u^1(t) = a\varepsilon + b_0^1\varepsilon^2 + (b\varepsilon + b_1^1\varepsilon^2 \cos \nu t) + (c\varepsilon + c_1^1\varepsilon^2) \sin \nu t$$
$$+ \sum_{n=2}^{\infty} b_n^1\varepsilon^2 \cos \nu nt + \sum_{n=2}^{\infty} c_n^1\varepsilon^2 \sin \nu nt + O(\varepsilon^3),$$

$$u^p(t) = b_0^p\varepsilon^2 + \sum_{n=1}^{\infty} b_n^p\varepsilon^2 \cos \nu nt + \sum_{n=1}^{\infty} c_n^p\varepsilon^2 \sin \nu nt + O(\varepsilon^3), \qquad p \geqq 2,$$

with $\nu(\varepsilon) = \pi/2 + \nu_2\varepsilon^2 + O(\varepsilon^3)$ and $D(\varepsilon) = D_2\varepsilon^2 + O(\varepsilon^3)$.

Here we outline the computation showing that two periodic orbits grow out of the spatially constant one as D decreases through $D^*(\mu)$. As in the original Hopf bifurcation calculation, we rescale $s = \nu t$ and call $q^n(s) = u^n(t)$.

Substituting into (1), we first collect coefficients of $\cos x$. In no case do we need to retain terms higher than $O(\varepsilon^3)$. We find that the constant term of $q^1(s) = O(\varepsilon^4)$ and, in particular, $a = b_0^1 = 0$. The $\cos 2s$ and $\sin 2s$ terms of the coefficient of $\cos x$ give b_2^1 and c_2^1 in terms of b and c. We use this information to simplify the $\cos s$ and $\sin s$ terms, which will be used later.

Next we look at coefficients of the spatially constant term, obtaining $b_0^0 = 0$ from the (time) constant term and expressions for b_2^0 and c_2^0 in terms of b and c from the

cos $2s$ and sin $2s$ terms. We use these in the cos s and sin s terms to get

$$\nu_2 = -\frac{1}{20} - \frac{3}{40} b - \frac{1}{40} c + \frac{3}{20} bc,$$

$$\mu_2 = \frac{3\pi - 2}{40}\left(1 + \frac{3}{2} b^2 + \frac{1}{2} c^2\right) + \frac{\pi + 6}{40} bc.$$

Note that if $b = c = 0$ then we get the original spatially constant periodic orbit with the proper values for μ_2 and $\nu_2 = \omega_2$.

Finally, the coefficients of cos $2x$ give $b_0^2 = 0$ from the constant term and expressions for b_2^2 and c_2^2 from the cos $2s$ and sin $2s$ terms. Returning to the cos s cos x and sin s cos x terms obtained above, we use this new informations to get

$$D_2 c = \frac{3\pi}{20} b - \frac{9\pi}{160} b^3 - \frac{7\pi}{160} b^2 c + \frac{15\pi}{160} bc^2 + \frac{\pi}{160} c^3,$$

$$D_2 b = \frac{\pi}{20} b - \frac{3\pi}{160} b^3 + \frac{21\pi}{160} b^2 c + \frac{5\pi}{160} bc^2 - \frac{3\pi}{160} c^3.$$

Now write $c = \beta b$. Multiplying the first equation by b and the second by c and subtracting, we obtain

$$b^2 = \frac{8(\beta - 3)}{3\beta^4 - 4\beta^3 - 6\beta^2 - 4\beta - 9}$$

as long as the right-hand side is defined and nonnegative. When $\beta > 3$ we will get two periodic orbits corresponding to the positive and negative choices of b.

We then find

$$D_2 = \left(\frac{1}{1 + \beta^2}\right)\left[\frac{\pi}{20} + \frac{3\pi}{20}\beta + \frac{\pi}{160} b^2(\beta^4 + 12\beta^3 - 2\beta^2 + 12\beta - 3)\right].$$

Note that $\beta = \beta_0 = 3$ gives $D_2 = \pi/20$ as expected.

Finally, we write b^2 and μ_2 as functions of β and

$$D(\beta, \mu) \approx \left(\frac{D_2(\beta)}{\mu_2(\beta)}\right)\mu$$

and compute

$$\frac{d^+}{d\beta^+}\left(\frac{D_2(\beta)}{\mu_2(\beta)}\right) < 0 \quad \text{at } \beta = 3.$$

4. Reversing the order of bifurcation. Recall that we would like to study the structure of all the small solutions of (1) as D is decreased. If ε is fixed with $\mu \approx ((3\pi - 2)/40)\varepsilon^2$, we have analyzed two bifurcations: a Hopf bifurcation from the already unstable origin at $D \approx (\pi/2)((3\pi - 2)/40)\varepsilon^2$, and a destabilization of $p(t, x, \varepsilon)$ at $D \approx \pi\varepsilon^2/20$. Note that since not all the characteristic exponents of p have been determined, we do not know if p is stable until this bifurcation point. In any case, we would like to guarantee that $p(t, x, \varepsilon)$ becomes unstable before the second Hopf bifurcation as D is decreased. We could then study a simpler structure. We will now see that by modifying (1) we can reverse the order of the two bifurcations we have studied, so that we can consider the first destabilization of p (whenever it occurs) without considering any complications caused by bifurcations from the origin.

The new equation, suppressing dependence on x, is

$$\frac{\partial}{\partial t}u(t) = D\frac{\partial^2}{\partial x^2}u(t) - \left(\frac{\pi}{2}+\mu\right)[u(t-1)+hu^3(t-1)][1+u(t)], \qquad x\in(0,\pi),$$
$$\frac{\partial u}{\partial x} = 0, \qquad x = 0, \pi, \tag{7}$$

where h is a constant to be determined. In the next section, h will be considered another parameter. Existence and uniqueness of solutions of (7) in $C([-1,0], W_N^{2,2})$ follows as in Yoshida [15], as does positivity of $U(t)=1+u(t)$.

We now extend the previous calculations to (7). The linear part of the equation is unchanged, so we still expect a Hopf bifurcation at $\mu=0$. To determine the direction of bifurcation we seek $\tilde{y}(t,\varepsilon)=\varepsilon\cos\omega t+O(\varepsilon^2)$ for new functions $\mu=\mu(\varepsilon)$ and $\omega=\omega(\varepsilon)$. We find $\omega_2=-1/20$ as before and $\tilde{y}(t,\varepsilon)=y(t,\varepsilon)+O(\varepsilon^3)$, but $\mu_2=(3\pi-2)/40-3\pi h/8$. We will consider only $h<(3\pi-2)/15\pi$ so $\mu(\varepsilon)=\mu_2\varepsilon^2+O(\varepsilon^3)>0$ for small $\varepsilon>0$ and the direction of bifurcation is unchanged.

Next we look for characteristic exponents of $\tilde{p}(t,x,\varepsilon)=\tilde{y}(t,x)$ as a solution of (7) as described in § 1. The computations are largely unchanged, and for $0\leqq h<(3\pi-2)/15\pi$ we again find one exponent becoming positive as D decreases through $\pi\varepsilon^2/20$. Note the difference here is that μ_2 is smaller for (7) than for (1): the periodic orbit destabilizes for larger D, as a function of μ, in (7) than in (1), even though D is the same as a function of ε.

The direction of bifurcation here is also unchanged. Repeating that calculation, we find that β_0, the value of β giving the single spatially constant periodic orbit at the bifurcation point, depends on h. For the values of h we want to consider (see below), $\beta<\beta_0(h)$ gives two periodic solutions, but we find in this case that $(d^-/d\beta^-)D(\beta_0(h),\mu)>0$.

Finally, we look at the second Hopf bifurcation from the origin. The bifurcation point depends only on the linear part of the equation, so for (7) also it must occur at $D(\mu)\approx\pi\mu/2$.

Repeating the computations for the direction of this bifurcation, we find that, for $h\geqq 0$, D_2 is still negative and the direction of bifurcation is the same.

We have seen that, for (7), $\tilde{p}(t,x,\varepsilon)$ undergoes bifurcation at $D=\pi\varepsilon^2/20$ and the second Hopf bifurcation from zero occurs at

$$D\approx\frac{\pi}{2}\left[\frac{3\pi-2}{40}-\frac{3\pi}{8}h\right]\varepsilon^2$$

if $h<(3\pi-2)/15\pi$. If we choose $(3\pi-6)/15\pi<h<(3\pi-2)/15\pi$, $\tilde{p}$ must lose stability first as D is decreased.

5. Existence and upper semicontinuity of the attractor. In this section we formalize the notion of looking at "all the small solutions" and show that this is possible for (7) and, as a special case, (1). We will prove the existence of a maximal compact attractor in $C=C([-1,0], W_N^{2,2})$: a compact set in C that is invariant and attracts bounded sets under the solution map and that is maximal with respect to these properties. (A set $\mathscr{A}$ attracts $\mathscr{B}$ under $S(t)$ if for any $\delta>0$ there is a t_1 such that $S(t)\mathscr{B}$ is contained in a δ-neighborhood of $\mathscr{A}$ for $t>t_1$.)

There are results on compact attractors for equations of many different types (see Hale [6] and the references therein). According to Billotti and LaSalle [1], we can prove the existence of a compact attractor for our case by showing that the solution

map is a C^0-semigroup on C, is compact for $t>1$, and is point-dissipative. ($S(t)$ is point-dissipative if there is some bounded $B\subset C$ that attracts points under $S(t)$.)

To show that the solution map is point-dissipative, we will start with a result of Luckhaus [11] for equations of the following form (suppressing dependence on x):

$$
\begin{aligned}
&\frac{\partial}{\partial t}u(t)-\frac{\partial^2}{\partial x^2}u(t)\leqq g(u(t),u(t-\tau)), \qquad x\in(0,l), \quad t>0,\\
&\frac{\partial}{\partial x}u(t)=0, \qquad x=0 \text{ and } l,\ t\geqq 0,\\
&u(t)=u_0(t), \qquad t\in[-\tau,0],\\
&u(t)\geqq 0, \qquad t\geqq 0,
\end{aligned}
\tag{8}
$$

where $g:\mathbb{R}^2\to\mathbb{R}$ satisfies

(i) $g(u,v)<u$, $u,v\in\mathbb{R}^+$;

(ii) $\lim_{\lambda\to\infty} g(\lambda u,\lambda v)/\lambda=-\infty$, $u,v\in\mathbb{R}^+$.

We will see below that (7) can be put in this form. The theorem states that, for any solution u with $u_0\in L^2[0,l]$,

$$\overline{\lim_{t\to\infty}}\,\|u(t,\cdot)\|_\infty<K$$

for some constant $K=K(g,l,\tau)$ independent of u_0. (The proof in [11] seems to give only $\overline{\lim}_{t\to\infty}\|u(t,\cdot)\|_2<K$, but we will see below that the L^∞ bound follows from the L^2 bound.) Note that this implies the solution operator is point-dissipative in $C([-\tau,0],L^\infty[0,l])$.

Based on this result, we have the following theorem.

THEOREM. *If $u_0\in L^2[0,l]$ and u is a solution of* (8) *with equality holding in the differential equation, and g satisfies* (i) *and* (ii) *and is a polynomial in u and v, then*

$$\overline{\lim_{t\to\infty}}\,\|u(t,\cdot)\|_{2,2}<K_6$$

for some constant $K_6=K_6(g,l,\tau)$ independent of u_0.

Proof. We suppose throughout that u is a solution of (8) and $\|u(t)\|_2<2K$ for $t\geqq t_0$. To simplify the notation, we take $l=\pi$.

Let $T(t)$ be the solution operator for

$$
\begin{aligned}
&\frac{\partial v}{\partial t}-\frac{\partial^2 v}{\partial x^2}=0, \qquad x\in(0,\pi), \quad t>0,\\
&\frac{\partial v}{\partial x}=0, \qquad x=0,\pi.
\end{aligned}
$$

We will get a bound on $T(t):L^2[0,\pi]\to W^{1,2}[0,\pi]$ and use the variation of constants formula to get a $W^{1,2}$ bound on u. Then a similar procedure will give the $W^{2,2}$ bound. The two steps are required to get sufficiently sharp intermediate estimates.

Let $b\in L^2(0,\pi)$ with $\partial b/\partial x=0$ at $x=0$ and π so $b=\sum_{n=2}^\infty b_n\cos nx$. Then $T(t)b=\sum_{n=0}^\infty b_n e^{-n^2t}\cos nx$, and

$$\|T(t)b\|_{1,2}^2=\sum_{n=0}^\infty b_n^2(1+n^2)\,e^{-2n^2t}\leqq\sum_{n=0}^\infty b_n^2+\sum_{n=0}^\infty n^2b_n^2\,e^{-2n^2t}.$$

For given $t>0$, we find the n for which $n^2e^{-2n^2t}$ is maximum:

$$\frac{\partial}{\partial n}(n^2e^{-2n^2t})=2ne^{-2n^2t}-4n^3te^{-2n^2t}=0$$

gives $n = 1/\sqrt{2t}$ if this is an integer. In any case $n^2 e^{-2n^2 t} \leqq e^{-1}/2t$, so we have

$$\| T(t)b \|_{1,2}^2 \leqq \left(1 + \frac{1}{2et}\right) \| b \|_2^2,$$

giving

$$\| T(t)b \|_{1,2} \leqq \frac{c}{\sqrt{t}} \| b \|_2$$

for $0 \leqq t \leqq 2\tau$, say, for some constant c.

We first use this estimate to verify the L^∞ bound on u in [11]. We can use condition (i) on g, the nonnegativity of u, and the positivity of $T(t)$ for $t \geqq 0$ to write

$$0 \leqq u(t) \leqq T(t - t_0)u(t_0) + \int_{t_0}^{t} T(t-s)u(s)\, ds,$$

pointwise in x. Since $W^{1,2}$ is continuously embedded in $C[0, \pi]$, we have for some c_1

$$\begin{aligned}
\| u(t, \cdot) \|_\infty &\leqq \| T(t - t_0)u(t_0) \|_\infty + \int_{t_0}^{t} \| T(t-s)u(s) \|_\infty \, ds \\
&\leqq c_1 \| T(t - t_0)u(t_0) \|_{1,2} + \int_{t_0}^{t} c_1 \| T(t-s)u(s) \|_{1,2} \, ds \\
&\leqq (cc_1/\sqrt{t - t_0}) \| u(t_0) \|_2 + \int_{t_0}^{t} cc_1/\sqrt{t-s} \, \| u(s) \|_2 \, ds \\
&\leqq (cc_1/\sqrt{t - t_0})(2K) + 2cc_1\sqrt{t - t_0}\,(2K) \\
&\leqq K_1 \quad \text{for } t_0 + \tau \leqq t \leqq t_0 + 2\tau.
\end{aligned}$$

The argument may be repeated with t_0 replaced by $t_0 + n\tau$ for each $n \geqq 1$, and thus, taking $K_2 = \max\{K_1, 2K\}$, we have $\| u(t) \|_2 < K_2$ and $\| u(t) \|_\infty < K_2$ for $t \geqq t_0 + \tau$.

Since $g(u(t), u(t-\tau))$ is a polynomial, we have $\| g(u(t), u(t-\tau)) \|_\infty < K_3$ and $\| g(u(t), u(t-\tau)) \|_2 < K_3$ for $t \geqq t_0 + 2\tau$ and some constant K_3. The variation of constants formula gives (using the equality in the differential equation)

$$\begin{aligned}
\| u(t) \|_{1,2} &\leqq \| T(t - (t_0 + 2\tau))u(t_0 + 2\tau) \|_{1,2} \\
&\quad + \int_{t_0 + 2\tau}^{t} \| T(t-s)g(u(s), u(s-\tau)) \|_{1,2} \, ds \\
&\leqq (c_1/\sqrt{t - (t_0 + 2\tau)})K_2 + 2c\sqrt{t - (t_0 - 2\tau)}\, K_3 \quad \text{for } t_0 + 2\tau \leqq t \leqq t_0 + 4\tau,
\end{aligned}$$

so $\| u(t) \|_{1,2} \leqq K_4$ for $t_0 + 3\tau \leqq t \leqq t_0 + 4\tau$, giving, as before, $\| u(t) \|_{1,2} \leqq K_4$ for $t \geqq t_0 + 3\tau$.

We now bound $T(t)$ as an operator from $W^{1,2}$ to $W^{2,2}$:

$$\begin{aligned}
\| T(t)b \|_{2,2}^2 &= \sum_{n=0}^{\infty} b_n^2 (1 + n^2 + n^4)\, e^{-2n^2 t} \\
&\leqq \sum_{n=0}^{\infty} b_n^2 + 2 \sum_{n=0}^{\infty} n^2 (n^2 b_n^2)\, e^{-2n^2 t}.
\end{aligned}$$

We know $\sum_{n=0}^{\infty} b_n^2 \leqq \| b \|_{1,2}^2$ and $\sum_{n=0}^{\infty} n^2 b_n^2 \leqq \| b \|_{1,2}^2$, and we have from above that $n^2 e^{-2n^2 t} \leqq 1/2et$, so

$$\| T(t)b \|_{2,2} \leqq \frac{c_2}{\sqrt{t}} \| b \|_{1,2}$$

for $0 \leqq t \leqq 2\tau$ and some c_2.

Next note that since $\|u(t)\|_{1,2} \leqq K_3$ for $t \geqq t_0+3\tau$ we have $\|g(u(t), u(t-\tau))\|_{1,2} \leqq K_5$ for $t \geqq t_0+4\tau$ and some K_5 depending on K_4 and g. As above, we use the variation of constants formula to get $\|u(t)\|_{2,2} \leqq K_6$ for $t_0+5\tau \leqq t \leqq t_0+6\tau$ and some K_6. Repeating the argument with t_0 replaced by $t_0+n\tau$ we get $\|u(t)\|_{2,2} \leqq K_6$ for $t \geqq t_0+5\tau$.

For any solution u, then, there is a t_1 such that $\|u(t)\|_{2,2} \leqq K_6$ for $t \geqq t_1$, so $\overline{\lim}_{t\to\infty} \|u(t)\|_{2,2} \leqq K_6$ independent of u_0.

We now put (7) in the form (8). Let $a = (\pi/2+\mu)(1+h)$ and rescale time $t \to t/a$. Rescale space $x \to \sqrt{D/a}\,x$. Change variables $U = U(t) = 1+u(t)$ and $V = U(t-a)$ to get

$$\frac{\partial U}{\partial t} - \frac{\partial^2 U}{\partial x^2} = U\left[1 - \frac{1+3h}{1+h} V + \frac{3h}{1+h} V^2 - \frac{3h}{1+h} V^3\right], \qquad x \in (0, \sqrt{a/D}\,\pi),$$

$$\frac{\partial U}{\partial x} = 0, \qquad x = 0 \text{ and } \sqrt{a/D}\,\pi.$$

We have already noted $U \geqq 0$.

Since $-(1+3h)V + 3hV^2 - 3hV^3 < 0$ for $h \geqq 0$ and $V > 0$, hypothesis (i) on g is satisfied. It is easy to see that (ii) is satisfied also.

Next we need to show that $S(t; h, \mu)$, the solution map for (7), is a C^0-semigroup on C and is compact for $t > 1$. We proceed in two steps. First, using the work of Travis and Webb [14] we show $L(t; \mu)$, the solution map for the linearized equation

$$\frac{\partial}{\partial t} u(t) = D\frac{\partial^2}{\partial x^2} u(t) - \left(\frac{\pi}{2}+\mu\right) u(t-1), \qquad x \in (0, \pi),$$

$$\frac{\partial}{\partial x} u(t) = 0, \qquad x = 0, \pi,$$

is a C^0-semigroup on C and compact for $t > 1$. Then, using the variation of constants formula, we extend the result to $S(t; h, \mu)$.

The map $T(t)$, now considered an operator on $W_N^{2,2}$, is easily seen to have the bound $|T(t)| \leqq 1$, so by Propositions 2.1 and 3.1 in [14], $L(t; \mu)$ is a C^0-semigroup on C.

From Example 5.2 (changing the boundary condition) and Lemma 5.3 of [14], we see that $T(t)$ as an operator on $L^2(0, \pi)$ is compact for $t > 0$. Because $T(t)$ is also continuous from $L^2(0, \pi)$ to $W^{2,2}(0, \pi)$ for $t > 0$, $T(t)$ is compact on $W_N^{2,2}$ for $t > 0$. Proposition 2.4 of [14] gives $L(t; \mu)$ compact on C for $t > 1$.

From Proposition 1.1 of Yoshida [15], we know $S(t; h, \mu)$ is defined on C and continuous in t. Setting

$$g(u_t(\cdot); h, \mu) = -\left(\frac{\pi}{2}+\mu\right) u(t-1)u(t) - \left(\frac{\pi}{2}+\mu\right) hu^3(t-1)[1+u(t)],$$

we have

$$S(t; h, \mu)\phi = L(t; \mu)\phi + \int_0^t L(t-s; \mu) X_0 g(S(s; h, \mu)\phi; h, \mu)\, ds.$$

The following lemma is quoted in Yoshida [15]:

If $u, v \in W^{2,2}(0, \pi)$, then $uv \in W^{2,2}(0, \pi)$ and $\|uv\| \leqq c\|u\| \cdot \|v\|$.

Therefore $g(\cdot; h, \mu)$ maps C to $W^{2,2}(0, \pi)$ and is locally Lipschitz. An application of Gronwall's inequality, as in Corollary 2.2 of Travis and Webb [14], gives $S(t; h, \mu)\phi$

continuous in ϕ. The semigroup property clearly holds. $S(t; h, \mu)$ is compact for $t>1$ because $L(t; \mu)$ is compact.

We have shown the existence of a maximal compact attractor, which must contain any equilibrium points, periodic orbits, and orbits connecting them. The attractor for (7) thus contains all the orbits we have studied, plus any connecting orbits. It may, however, contain other invariant sets not yet identified. The structure of the full attractor is, in fact, an open problem even for (2), the equation with no space dependence.

Next we will show that the attractor for (7) does not change too abruptly as D is decreased. This will imply that, for h close to and greater than $(3\pi-6)/15\pi$ and D in a small enough range, there are no orbits connecting the spatially nonconstant periodic orbit arising in the second Hopf bifurcation from the origin and the periodic orbits arising in the destabilization of the spatially constant periodic orbit.

In practice, we will increase μ rather than decrease D. This is equivalent for the bifurcations with which we are concerned, since the bifurcation curves are nearly straight lines.

We prove that the attractor $\mathscr{A}_\mu$ for (7) (with fixed h) is upper semicontinuous in μ; that is

$$\delta(\mathscr{A}_\mu, \mathscr{A}_{\mu_0}) \to 0 \quad \text{as } \mu \to \mu_0 \text{ for each } \mu_0$$

where

$$\delta(\mathscr{A}, \mathscr{B}) = \sup_{y \in \mathscr{A}} \operatorname{dist}(y, \mathscr{B}).$$

This means that in some sense the limit of $\mathscr{A}_\mu$ is inside $\mathscr{A}_{\mu_0}$. To do this, it is enough to show (Cooperman [5], quoted in Hale [8]) that $S(t; h, \mu)$ is continuous in μ (from the variation of constants formula) and that there is some bounded $\mathscr{B} \subset C$ such that $\mathscr{A}_\mu \subset \mathscr{B}$ for all μ in a neighborhood of μ_0.

To put (7) in the form (8) this time, fix $\mu_1 > \mu_0$ and set $a = (\pi/2+\mu_1)(1+h)$ for each μ in a neighborhood of μ_0. Rescale and change variables as before to get

$$\frac{\partial U}{\partial t} - \frac{\partial^2 U}{\partial x^2} = \left(\frac{\pi}{2}+\mu_1\right)^{-1}\left(\frac{\pi}{2}+\mu\right) U\left[1 - \frac{1+3h}{1+h} V + \frac{3h}{1+h} V^2 - \frac{3h}{1+h} V^3\right]$$

$$\leqq U\left[1 - \frac{1+3h}{1+h} V + \frac{3h}{1+h} V^2 - \frac{3h}{1+h} V^3\right]$$

if $\mu \leqq \mu_1$. The eventual L^2 and L^∞ bounds on U are thus independent of μ. The estimates and constructions of the other bounds above are all continuous in μ, so we can find a constant $\hat{K}$ such that

$$\overline{\lim_{t\to\infty}} |u_t(\cdot, \cdot)|_c \leqq \hat{K}$$

for any solution u of (7) with μ in a given neighborhood of μ_0. Therefore $\mathscr{A}_\mu$ is contained in the ball in C of radius $\hat{K}$ centered at the origin for each μ in this neighborhood, and $\mathscr{A}_\mu$ is upper semicontinuous at μ_0.

6. Structure of the attractor. Fix h close to and greater than $(3\pi-6)/15\pi$ and fix D. Suppose that, for (7), the bifurcation from the spatially constant periodic orbit that we have discussed occurs at $\mu = \mu^*$ and the second Hopf bifurcation occurs at $\mu = \mu^+$. Note $\mu^* < \mu^+$. The pictures below illustrate the part of the attractor we are interested in for various values of μ; they may be thought of as two-dimensional representations of a half-period map. For $\mu \leqq \mu^*$ we have the origin, the spatially

FIG. 4. *Local structure of the attractor for* $\mu \leqq \mu^*$.

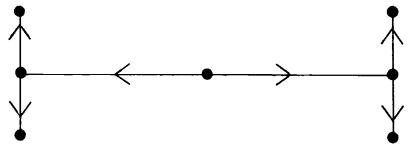

FIG. 5. *Local structure of the attractor for* $\mu^* < \mu \leqq \mu^+$.

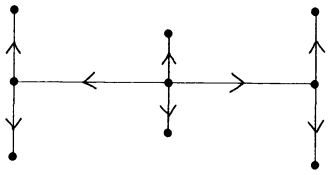

FIG. 6. *Local structure of the attractor for* $\mu > \mu^+$.

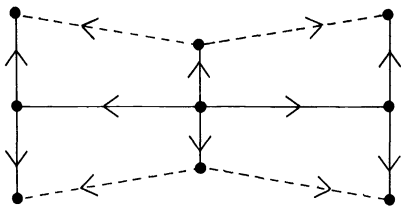

FIG. 7. *Possible connecting orbits.*

constant periodic orbit, and the orbits connecting them, which make up a two-dimensional center manifold shown in Fig. 4. For $\mu^* < \mu \leqq \mu^+$, we add the two new periodic orbits shown in Fig. 5. Note that no connections are between the origin and the new orbits, because the origin has only a two-dimensional unstable manifold, which must lie entirely in the subspace of spatially constant functions. For $\mu^+ < \mu$, we add at least the periodic orbit arising in the second Hopf bifurcation, as shown in Fig. 6.

We are interested in the existence of connecting orbits (represented in Fig. 7 by dashed lines). These connections may be formed through other bifurcations for larger μ, but they cannot exist for all small $\mu > \mu^+$, because this would violate upper semicontinuity of the attractor at μ^+.

Acknowledgments. This paper is based on my Ph.D. thesis (Division of Applied Mathematics, Brown University, 1986). The thesis was written under the direction of Jack Hale, to whom I am grateful for suggesting the problem and answering many questions. Thanks are also due to Bernold Fiedler for calling [11] to my attention, Derek Lane for discussing some estimates with me, and the referees for helpful comments.

A SHADOWING LEMMA WITH APPLICATIONS TO SEMILINEAR PARABOLIC EQUATIONS*

SHUI-NEE CHOW,† XIAO-BIAO LIN,‡ AND KENNETH J. PALMER§

Abstract. The property of hyperbolic sets that is embodied in the Shadowing Lemma is of great importance in the theory of dynamical systems. In this paper a new proof of the lemma is presented, which applies not only to the usual case of a diffeomorphism in finite-dimensional space but also to a sequence of possibly noninvertible maps in a Banach space. The approach is via Newton's method, the main step being the verification that a certain linear operator is invertible. At the end of the paper an application to parabolic evolution equations is given.

Key words. hyperbolic, exponential dichotomy, Shadowing Lemma, pseudo-orbit, Newton's method, parabolic evolution equation

AMS(MOS) subject classifications. 34C35, 35K22, 58F15

1. Introduction. Let f be a diffeomorphism from $\mathbf{R}^k$ into itself. Given an initial point, the iterates of f and its inverse generate a sequence of points $x_{n+1}=f(x_n)$. Then $\{x_n\}_{n\in\mathbf{Z}}$ is called the *orbit* through x_0. A sequence of points $\{y_n\}_{n\in\mathbf{Z}}$ is called a *δ-pseudo-orbit* of f if $|y_{n+1}-f(y_n)|\leqq\delta$ for all n, where $\delta>0$ is a constant. The Shadowing Lemma says that if $S\subset\mathbf{R}^k$ is a *hyperbolic* set for f then for every $\varepsilon>0$ there exists $\delta>0$ such that every δ-pseudo-orbit $\{y_n\}_{n\in\mathbf{Z}}$ in S is *ε-shadowed* by an orbit $\{x_n\}_{n\in\mathbf{Z}}$ of f, that is, $|x_n-y_n|\leqq\varepsilon$ for all n. This lemma was first stated and proved in Anosov [1] and Bowen [3] under slightly different conditions. Several different proofs were given later in Conley [4], Robinson [15], Guckenheimer, Moser, and Newhouse [6], Ekeland [5], Lanford [10], Shub [16], and Palmer [14].

A δ-pseudo-orbit can be thought of as an orbit generated numerically by a computer. If this orbit is in or near a hyperbolic set for f, the Shadowing Lemma implies that an orbit for f can be found near such a "noisy" numerical orbit for an arbitrarily long time. In fact, Hammel, Yorke, and Grebogi [7] showed how we may apply the ideas of the Shadowing Lemma to prove that "noisy" numerical orbits are actually near real orbits for a finite but fixed time even in the nonhyperbolic case. In [12], Palmer showed that the complicated behavior of the orbits of a diffeomorphism near a transversal homoclinic point can be explained by the sole use of the Shadowing Lemma. This has been generalized by Blazquez [2] to infinite-dimensional systems generated by parabolic evolution equations.

When considered abstractly, the problem of finding a shadowing orbit can be approached by Newton's method for finding zeros of functions. To see this, let X be the Banach space of all bounded $\mathbf{R}^k$-valued sequences $\mathbf{x}=\{x_n\}_{n\in\mathbf{Z}}$ with the usual sup norm and define $\mathcal{F}:X\to X$ by $(\mathcal{F}(\mathbf{x}))_n=x_n-f(x_{n-1})$, where $(\mathcal{F}(\mathbf{x}))_n$ denotes the nth element of the sequence $\mathcal{F}(\mathbf{x})\in X$. Thus $\mathbf{x}=\{x_n\}$ is an orbit of f if and only if $\mathcal{F}(\mathbf{x})=0$ and $\mathbf{y}=\{y_n\}$ is a δ-pseudo-orbit if and only if $\|\mathcal{F}(\mathbf{y})\|\leqq\delta$. The Shadowing Lemma says that if f is hyperbolic and there exists a good approximate (δ sufficiently small) solution $\mathbf{y}$ of the equation $\mathcal{F}=0$, then there exists a solution $\mathbf{x}$ near $\mathbf{y}$.

For an analogue in the continuous time case, consider the abstract ordinary differential equation in a Banach space X:

$$\dot{x} + Ax = f(x, t), \tag{1.1}$$

where A is linear and f nonlinear. A typical example of (1.1) is the nonlinear heat equation. Suppose the real line $\mathbf{R}$ is partitioned as $\mathbf{R} = \cup_{n\in\mathbf{Z}}[\tau_{n-1}, \tau_n]$ and each $x_n(t):[\tau_{n-1}, \tau_n] \to X$ is an approximate solution, that is,

$$\dot{x}_n(t) + Ax_n(t) = f(x_n(t), t) + h_n(t),$$

$$x_n(\tau_n) - x_{n+1}(\tau_n) = g_n,$$

where $h_n(t)$ and g_n are the error terms. The problem is to find an analogue of the hyperbolicity condition to guarantee that there exists a solution of (1.1) which, for each n in $\mathbf{Z}$, is close to $x_n(t)$ in the interval $[\tau_{n-1}, \tau_n]$.

In this paper, we will show that a Shadowing Lemma may be derived using Newton's method and that the lemma is applicable to the just-mentioned situation (see § 6). Because of the applications, we will work with C^1 maps in Banach spaces that are not necessarily diffeomorphisms. In fact, we consider a sequence $\{f_n\}_{n\in\mathbf{Z}}$ of mappings rather than a single mapping f. We set up the problem abstractly in a Banach space of sequences and apply a variant of Newton's method. The key tool is Lemma 3.2 in which we show that a certain linear operator is invertible (in the finite-dimensional case, this can also be proved by the perturbation theorem for exponential dichotomies in Palmer [13]). Lin has proved a similar lemma in [11], where the application is to a problem in ordinary differential equations. Here Lemma 3.2 is proved by an iteration method, which means, we believe, that it could be implemented on the computer. Newhouse [6] also used an iteration process but it is rather more involved in that at each step it uses the intersection of the stable and unstable manifolds.

Finally we should mention that as this paper was being written Walther sent us the preprint [18] where he proves the Shadowing Lemma for noninvertible maps. Stoffer [17] has also proved such a theorem. Both of these authors use the methods of Kirchgraber [9], which are quite different from ours.

2. Definition and statement of the Shadowing Lemma. What we are going to prove is a "nonautonomous" Shadowing Lemma for a sequence $f_n: X_n \to X_{n+1} (n \in \mathbf{Z})$ of C^1 maps. Here X_n is a Banach space with norm $|\cdot|_{X_n}$ (or simply $|\cdot|$ if no confusion should arise). Assume $S_n \subset X_n$, $n \in \mathbf{Z}$, is *invariant* under f_n in the sense that $f_n(S_n) \subset S_{n+1}$. Also we assume that $f_n(x)$, $Df_n(x)$ are bounded and continuous in a closed Δ-neighborhood O_n of S_n uniformly in $x \in O_n$ and $n \in \mathbf{Z}$.

We want to define what is meant by saying $\{S_n\}_{n\in\mathbf{Z}}$ is *hyperbolic*. First there is a *splitting* into closed subspaces

$$X_n = E_n^s(x) \oplus E_n^u(x) \tag{2.1}$$

for x in S_n. We require this splitting to be *invariant* in the sense that

$$Df_n(x)E_n^s(x) \subset E_{n+1}^s(f_n(x)),\ Df_n(x)E_n^u(x) \subset E_{n+1}^u(f_n(x))$$

for all x in S_n, and also *continuous*; that is, if $\mathbf{P}_n(x)$ is the projection with range $E_n^s(x)$ and nullspace $E_n^u(x)$, $\mathbf{P}_n(x)$ is continuous in the operator norm, uniformly with respect to $x \in S_n$ and $n \in \mathbf{Z}$. In terms of $\mathbf{P}_n(x)$, the invariance of the splitting is equivalent to

$$Df_n(x)\mathbf{P}_n(x) = \mathbf{P}_{n+1}(f_n(x))Df_n(x) \tag{2.2}$$

for all x in S_n. We also assume that $Df_n(x): E_n^u(x) \to E_{n+1}^u(f_n(x))$ is an isomorphism with a (bounded) inverse $(Df_n(x))^{-1}: E_{n+1}^u(f_n(x)) \to E_n^u(x)$.

Second, we require that there exist constants $K \geqq 1$, $0 \leqq \lambda < 1$ such that for any finite sequence x_m, $x_{m+1} = f_m(x_m)$, $x_{m+2} = f_{m+1}(x_{m+1}), \cdots, x_n = f_{n-1}(x_{n-1})$ with $x_m \in S_m$ and any integers $n \geqq m$,

$$
\begin{aligned}
&|Df_n(x_n)Df_{n-1}(x_{n-1}) \cdots Df_m(x_m)\mathbf{P}_m(x_m)| \leqq K\lambda^{n-m+1}, \\
&|Df_m(x_m)^{-1}Df_{m+1}(x_{m+1})^{-1} \cdots Df_n(x_n)^{-1}(I - \mathbf{P}_{n+1}(x_{n+1}))| \leqq K\lambda^{n-m+1}.
\end{aligned} \tag{2.3}
$$

Also we assume that $|\mathbf{P}_n(x)| \leqq K$, $|I - \mathbf{P}_n(x)| \leqq K$ for $x \in S_n$, $n \in \mathbf{Z}$.

An *orbit* for $\{f_n\}_{n\in\mathbf{Z}}$ is a sequence $\{x_n\}_{n\in\mathbf{Z}}$ with $x_n \in X_n$ and $x_{n+1} = f_n(x_n)$ for all $n \in \mathbf{Z}$. If $\delta > 0$ is a constant, a sequence $\{y_n\}_{n\in\mathbf{Z}}$ with $y_n \in X_n$ is said to be a *δ-pseudo-orbit* for $\{f_n\}$ if

$$|f_n(y_n) - y_{n+1}| \leqq \delta$$

for all integers n. A sequence $\{x_n\}_{n\in\mathbf{Z}}$ with $x_n \in X_n$ is said to *ε-shadow* $\{y_n\}_{n\in\mathbf{Z}}$, $y_n \in X_n$, if

$$|x_n - y_n| \leqq \varepsilon$$

for all $n \in \mathbf{Z}$.

THE SHADOWING LEMMA. *Let $\{X_n\}$, $\{f_n\}$, $\{S_n\}$, $n \in \mathbf{Z}$, be defined as above and satisfy all the properties listed above, that is,*

(i) *S_n is invariant under f_n;*

(ii) *There is a closed Δ-neighborhood O_n of S_n such that $f_n(x)$ and $Df_n(x)$ are bounded and continuous uniformly with respect to x in O_n and n in $\mathbf{Z}$;*

(iii) *$\{S_n\}_{n\in\mathbf{Z}}$ is hyperbolic.*

Then there exists $\varepsilon_0 > 0$ with the property that if $0 < \varepsilon \leqq \varepsilon_0$ there is $\delta = \delta(\varepsilon) > 0$ such that if $\{y_n\}$, $y_n \in S_n$, is a δ-pseudo-orbit for $\{f_n\}$ then there is a unique orbit $\{x_n\}$ which ε-shadows $\{y_n\}$.

To prove the Shadowing Lemma, we will use some facts about linear difference equations and a variant of Newton's method for solving nonlinear equations.

3. Facts about linear difference equations. For each integer n let $A_n : X_n \to X_{n+1}$ be a bounded linear mapping. Denote by $\Phi(n, m)(n \geqq m)$ the *transition matrix* for the *linear difference equation*

$$x_n = A_{n-1}x_{n-1}, \qquad x_n \in X_n, \quad n \in \mathbf{Z}, \tag{3.1}$$

that is,

$$\Phi(n, m) = \begin{cases} A_{n-1}A_{n-2} \cdots A_m, & n > m, \\ I, & n = m. \end{cases}$$

Equation (3.1) is said to have an *exponential dichotomy* if there is a projection valued function $P_n : X_n \to X_n$ and constants $K \geqq 1$, $0 \leqq \lambda < 1$ such that

$$\Phi(n, m)P_m = P_n\Phi(n, m) \quad \text{for } n \geqq m, \tag{3.2}$$

$$|\Phi(n, m)P_m| \leqq K\lambda^{n-m} \quad \text{for } n \geqq m. \tag{3.3}$$

Moreover, it is required that $\Phi(n, m) : \mathcal{N}(P_m) \to \mathcal{N}(P_n)$ ($\mathcal{N}$ denotes nullspace) be an isomorphism. Then for $n \geqq m$ we define $\Phi(m, n) : \mathcal{N}(P_n) \to \mathcal{N}(P_m)$ as the inverse of $\Phi(n, m) : \mathcal{N}(P_m) \to \mathcal{N}(P_n)$ and require that

$$|\Phi(m, n)(I - P_m)| \leqq K\lambda^{n-m} \quad \text{for } n \geqq m. \tag{3.4}$$

It is clear from the definition of hyperbolicity that the following lemma holds.

LEMMA 3.1. *Let $\{S_n\}_{n\in\mathbf{Z}}$ be a hyperbolic set for a sequence $f_n : X_n \to X_{n+1}$ of C^1 mappings. Then if $\{x_n\}$ is an orbit of $\{f_n\}$ with $x_n \in S_n$ for all n, the linear difference equation*

$$u_n = Df(x_{n-1})u_{n-1}$$

has an exponential dichotomy with projections $P_n = \mathbf{P}(x_n)$ *and constants* K, λ, *the projections* $\mathbf{P}(x)$ *and the constants* K, λ *being those defining the hyperbolicity of* $\{S_n\}$.

We denote by ΠX_n the Banach space of bounded sequences $\mathbf{x} = \{x_n\}_{n\in\mathbf{Z}}$, $x_n \in X_n$, with norm

$$\|\mathbf{x}\| = \|\{x_n\}\| = \sup_{n\in\mathbf{Z}} |x_n|_{X_n}.$$

If $\sup_{n\in\mathbf{Z}} |A_n| < \infty$, we can associate with the linear difference equation (3.1) the linear operator $L: \Pi X_n \to \Pi X_n$ defined by

$$(L\mathbf{x})_n = x_n - A_{n-1}x_{n-1}.$$

It turns out that if (3.1) has an exponential dichotomy then L is invertible. Now in the proof of the Shadowing Lemma we are confronted with a linear difference equation for which the existence of an exponential dichotomy is not obvious. For this reason we need the following lemma.

LEMMA 3.2. *Assume* $\sup_{n\in\mathbf{Z}} |A_n| < \infty$. *For each* $n \in \mathbf{Z}$ *let* Q_n *be a projection such that* $|Q_n| \leqq K$, $|I - Q_n| \leqq K$ *and* $|Q_{n+1}A_n(I - Q_n)| \leqq \delta$, $|(I - Q_{n+1})A_nQ_n| \leqq \delta$. *Suppose also that for all* $n \in \mathbf{Z}$ $|A_nQ_n| \leqq \lambda$ *and that* $(I - Q_{n+1})A_n : \mathcal{N}(Q_n) \to \mathcal{N}(Q_{n+1})$ *has an inverse* B_n *with* $|B_n(I - Q_{n+1})| \leqq \lambda$. *Then if* $8K\lambda \leqq 1$, $8\delta \leqq 1$ *the operator* $L: \Pi X_n \to \Pi X_n$ *defined by* $(L\mathbf{x})_n = x_n - A_{n-1}x_{n-1}$ *is invertible with* $\|L^{-1}\| \leqq 2K + 1$.

Proof. First we show L is onto. To do this we define the linear mapping $S: \Pi X_n \to \Pi X_n$ by $(S\mathbf{h})_n = Q_nh_n - B_n(I - Q_{n+1})h_{n+1}$. Then S is bounded with $\|S\| \leqq K + \lambda$ and for all n

$$\begin{aligned}
|(LS\mathbf{h})_n - h_n| &= |Q_nh_n - B_n(I - Q_{n+1})h_{n+1} - A_{n-1}\{Q_{n-1}h_{n-1} - B_{n-1}(I - Q_n)h_n\} - h_n| \\
&= |-B_n(I - Q_{n+1})h_{n+1} - A_{n-1}Q_{n-1}h_{n-1} + Q_nA_{n-1}B_{n-1}(I - Q_n)h_n| \\
&\qquad\qquad \text{since } (I - Q_n)A_{n-1}B_{n-1}(I - Q_n) = I - Q_n \\
&= |-B_n(I - Q_{n+1})h_{n+1} - A_{n-1}Q_{n-1}h_{n-1} + Q_nA_{n-1}(I - Q_{n-1})B_{n-1}(I - Q_n)h_n| \\
&\leqq |B_n(I - Q_{n+1})||h_{n+1}| + |A_{n-1}Q_{n-1}||h_{n-1}| \\
&\quad + |Q_nA_{n-1}(I - Q_{n-1})||B_{n-1}(I - Q_n)||h_n| \\
&\leqq \lambda(2 + \delta)\|\mathbf{h}\| \\
&\leqq \tfrac{1}{2}\|\mathbf{h}\|.
\end{aligned}$$

Hence $\|LS - I\| \leqq \frac{1}{2}$ and so LS has an inverse T with $\|T\| \leqq (1 - \|LS - I\|)^{-1} \leqq 2$. Then $ST = L_R^{-1}$ is a right inverse of L with

$$\|L_R^{-1}\| \leqq \|S\|\,\|T\| \leqq 2(K + \lambda) \leqq 2K + 1.$$

All that remains is to show that L is one-to-one. First note that for all $x \in X_n$,

$$\begin{aligned}
|(I - Q_n)x| &= |B_n(I - Q_{n+1})A_n(I - Q_n)x| \\
&\leqq \lambda|(I - Q_{n+1})A_n(I - Q_n)x|
\end{aligned}$$

so that

$$|(I - Q_{n+1})A_n(I - Q_n)x| \geqq \lambda^{-1}|(I - Q_n)x|. \tag{3.5}$$

Suppose L is not one-to-one. Then there exists a nonzero bounded sequence $\{x_n\}$ in ΠX_n such that $x_n = A_{n-1}x_{n-1}$ for all n. Suppose that for some n

$$|(I-Q_n)x_n| > |Q_n x_n|. \tag{3.6}$$

Then, using (3.5),

$$\begin{aligned}
|(I-Q_{n+1})x_{n+1}| - |Q_{n+1}x_{n+1}| &= |(I-Q_{n+1})A_n x_n| - |Q_{n+1}A_n x_n| \\
&\geqq |(I-Q_{n+1})A_n(I-Q_n)x_n| - |(I-Q_{n+1})A_n Q_n x_n| \\
&\quad - |Q_{n+1}A_n Q_n x_n| - |Q_{n+1}A_n(I-Q_n)x_n| \\
&\geqq \lambda^{-1}|(I-Q_n)x_n| - \delta|x_n| - K\lambda|x_n| - \delta|x_n| \\
&\geqq (\lambda^{-1} - 4\delta - 2K\lambda)|(I-Q_n)x_n| \qquad \text{since } |x_n| \leqq 2|(I-Q_n)x_n| \\
&\geqq 7|(I-Q_n)x_n|.
\end{aligned}$$

This implies that $|(I-Q_{n+1})x_{n+1}| > |Q_{n+1}x_{n+1}|$ and that $|(I-Q_{n+1})x_{n+1}| \geqq 7|(I-Q_n)x_n|$. So if (3.6) holds for some $n = m$, it holds for all $n \geqq m$ and

$$\begin{aligned}
|x_n| \geqq K^{-1}|(I-Q_n)x_n| &\geqq K^{-1}7^{n-m}|(I-Q_m)x_m| \\
&\geqq \tfrac{1}{2}K^{-1}7^{n-m}|x_m|.
\end{aligned}$$

Thus $|x_n| \to \infty$ as $n \to \infty$, contradicting the boundedness of $\{x_n\}$.

Hence it must be that $|Q_n x_n| \geqq |(I-Q_n)x_n|$ *for all* n and then

$$\begin{aligned}
|Q_{n+1}x_{n+1}| &= |Q_{n+1}A_n x_n| \\
&\leqq |Q_{n+1}A_n Q_n x_n| + |Q_{n+1}A_n(I-Q_n)x_n| \\
&\leqq (K\lambda + \delta)|x_n| \\
&\leqq 2(K\lambda + \delta)|Q_n x_n| \\
&\leqq \tfrac{1}{2}|Q_n x_n|.
\end{aligned}$$

Now there exists some m such that $Q_m x_m \neq 0$. Then for all $n \leqq m$, $|Q_n x_n| \geqq 2^{-(n-m)}|Q_m x_m| \to \infty$ as $n \to -\infty$. Again this contradicts the boundedness of $\{x_n\}$. So L must be one-to-one.

4. Newton's method for solving nonlinear equations. In this section we prove the following variant of Newton's method for solving nonlinear equations.

PROPOSITION 4.1. *Let X be a Banach space, $U \subset X$ an open subset and $\mathcal{F}: U \to X$ a C^1 mapping. Let y be a point in U such that $D\mathcal{F}(y)^{-1}$ exists and let $\varepsilon_0 > 0$ be chosen so that*

$$\|D\mathcal{F}(x) - D\mathcal{F}(y)\| \leqq (2\|D\mathcal{F}(y)^{-1}\|)^{-1} \tag{4.1}$$

for $\|x-y\| \leqq \varepsilon_0$. Then if $0 < \varepsilon \leqq \varepsilon_0$ and

$$\|\mathcal{F}(y)\| \leqq \varepsilon(2\|D\mathcal{F}(y)^{-1}\|)^{-1}, \tag{4.2}$$

the equation

$$\mathcal{F}(x) = 0 \tag{4.3}$$

has a unique solution x such that $\|x-y\| \leqq \varepsilon$.

Proof. We write

$$\mathcal{F}(x) = \mathcal{F}(y) + D\mathcal{F}(y)(x-y) + \eta(x).$$

When $\|x_1 - y\|, \|x_2 - y\| \leqq \varepsilon_0$,

$$\begin{aligned} \|\eta(x_1) - \eta(x_2)\| &= \|\mathcal{F}(x_1) - \mathcal{F}(x_2) - D\mathcal{F}(y)(x_1 - x_2)\| \\ &\leqq \left\| \int_0^1 D\mathcal{F}(x_2 + \theta(x_1 - x_2)) - D\mathcal{F}(y)\, d\theta \right\| \cdot \|x_1 - x_2\| \\ &\leqq (2\|D\mathcal{F}(y)^{-1}\|)^{-1} \|x_1 - x_2\|, \end{aligned} \tag{4.4}$$

using (4.1).

We can rewrite (4.3) as

$$x = y - D\mathcal{F}(y)^{-1}\{\mathcal{F}(y) + \eta(x)\} := T(x).$$

For $0 < \varepsilon \leqq \varepsilon_0$, we define $B_\varepsilon = \{x \in X : \|x - y\| \leqq \varepsilon\}$ and show that T is a contraction on B_ε. The proposition will then follow immediately from the contraction mapping principle.

Note first if $x \in B_\varepsilon$ then

$$\begin{aligned} \|T(x) - y\| &= \|D\mathcal{F}(y)^{-1}\{\mathcal{F}(y) + \eta(x)\}\| \\ &\leqq \|D\mathcal{F}(y)^{-1}\|\{\varepsilon(2\|D\mathcal{F}(y)^{-1}\|)^{-1} + (2\|D\mathcal{F}(y)^{-1}\|)^{-1}\|x - y\|\} \\ &= \varepsilon/2 + \|x - y\|/2 \\ &\leqq \varepsilon/2 + \varepsilon/2 = \varepsilon, \end{aligned}$$

where we have used (4.2) and (4.4) with $x_1 = x$, $x_2 = y$. Hence T maps B_ε into itself. Moreover if $x_1, x_2 \in B_\varepsilon$ then, using (4.4),

$$\begin{aligned} \|T(x_1) - T(x_2)\| &= \|D\mathcal{F}(y)^{-1}\{\eta(x_1) - \eta(x_2)\}\| \\ &\leqq \|D\mathcal{F}(y)^{-1}\| \cdot (2\|D\mathcal{F}(y)^{-1}\|)^{-1}\|x_1 - x_2\| \\ &= 1/2\|x_1 - x_2\|. \end{aligned}$$

Thus T is indeed a contraction on B_ε and the proof is completed.

5. Proof of the Shadowing Lemma. We need three lemmas for the proof.

LEMMA 5.1. *Let X be a Banach space and let $P, Q : X \to X$ be projections such that $|P|, |Q| \leqq K$. Then if $|P - Q| < 1/2K$, the operator $J = PQ + (I - P)(I - Q)$ is invertible with $|J^{-1}| \leqq (1 - 2K|P - Q|)^{-1}$. Moreover, $J(\mathcal{R}(Q)) = \mathcal{R}(P)$, $J(\mathcal{N}(Q)) = \mathcal{N}(P)$.*

Proof.

$$\begin{aligned} |J - I| &= |J - P^2 - (I - P)^2| \\ &= |P(Q - P) + (I - P)(P - Q)| \leqq 2K|P - Q| < 1. \end{aligned}$$

So J is invertible with $|J^{-1}| \leqq (1 - |J - I|)^{-1} \leqq (1 - 2K|P - Q|)^{-1}$. Clearly $J(\mathcal{R}(Q)) \subset \mathcal{R}(P)$, $J(\mathcal{N}(Q)) \subset \mathcal{N}(P)$ and equality follows from the invertibility of J. So the proof of the lemma is complete.

Now by assumption $|Df_n(x)|$ is bounded in a closed Δ-neighborhood O_n of S_n, uniformly in $x \in O_n$ and $n \in \mathbf{Z}$. Let this bound be M. Then

$$|f_n(x) - f_n(y)| \leqq M|x - y|$$

for $x \in S_n$, $y \in X_n$, and $|x - y| \leqq \Delta$. This fact is used in the following two lemmas, which make precise a statement of Guckenheimer, Moser, and Newhouse [6] that in the Shadowing Lemma it is enough to shadow a δ-pseudo-orbit for the sequence of mappings $\{f_{nk+k-1} \circ \cdots \circ f_{nk+1} \circ f_{nk}\}_{n \in \mathbf{Z}}$.

LEMMA 5.2. *If $\{y_n\}_{n\in\mathbf{Z}}$ is a δ-pseudo-orbit for $\{f_n\}$ with $y_n \in S_n$ for all n, then $\{y_{nk}\}_{n\in\mathbf{Z}}$ is a $\delta(1+M+\cdots+M^{k-1})$-pseudo-orbit for $\{f_{nk+k-1}\circ\cdots\circ f_{nk+1}\circ f_{nk}\}_{n\in\mathbf{Z}}$.*

Proof. We prove by induction that

$$|y_{nk+i}-(f_{nk+i-1}\circ\cdots\circ f_{nk+1}\circ f_{nk})(y_{nk})|\leqq\delta(1+M+\cdots+M^{i-1})$$

for $1\leqq i\leqq k$. Since $\{y_n\}$ is a δ-pseudo-orbit, it certainly holds for $i=1$. Assuming it for $i\geqq 1$, we prove it for $i+1$ as follows:

$$\begin{aligned}
&|y_{nk+i+1}-(f_{nk+i}\circ\cdots\circ f_{nk+1}\circ f_{nk})(y_{nk})|\\
&\quad\leqq|y_{nk+i+1}-f_{nk+i}(y_{nk+i})|+|f_{nk+i}(y_{nk+i})-f_{nk+i}((f_{nk+i-1}\circ\cdots\circ f_{nk})(y_{nk}))|\\
&\quad\leqq\delta+M|y_{nk+i}-(f_{nk+i-1}\circ\cdots\circ f_{nk})(y_{nk})|\\
&\quad\leqq\delta+M\delta(1+M+\cdots+M^{i-1})=\delta(1+M+\cdots+M^{i}).
\end{aligned}$$

LEMMA 5.3. *Let $\{y_n\}$ be a δ-pseudo-orbit for $\{f_n\}$ with $y_n\in S_n$, and let $\{x_n\}$ be an orbit of $\{f_n\}$ such that $\{x_{nk}\}\varepsilon$-shadows $\{y_{nk}\}$, $k\geqq 1$ being fixed. Set $\varepsilon_1=\max\{\varepsilon,\delta\}$. Then if $\varepsilon_1(1+M+\cdots+M^k)\leqq\Delta$, $\{x_n\}$ $\varepsilon_1(1+M+\cdots+M^k)$-shadows $\{y_n\}$.*

Proof. Note first that

$$\begin{aligned}
|y_{nk+1}-f_{nk}(x_{nk})|&\leqq|y_{nk+1}-f_{nk}(y_{nk})|+|f_{nk}(y_{nk})-f_{nk}(x_{nk})|\\
&\leqq\delta+M\varepsilon\leqq\varepsilon_1(1+M).
\end{aligned}$$

Then we show by induction, as in the proof of Lemma 5.2, that

$$|y_{nk+i}-(f_{nk+i-1}\circ\cdots\circ f_{nk})(x_{nk})|\leqq\varepsilon_1(1+M+\cdots+M^{i})$$

for $1\leqq i\leqq k$.

Proof of the Shadowing Lemma. Let k be a positive integer such that $16K^3\lambda^k\leqq 1$. We first prove the Shadowing Lemma for the sequence of maps $F_n=f_{nk+k-1}\circ\cdots\circ f_{nk}$ and hyperbolic sets $\{S_{nk}\}$. If we define $\omega(\eta)=\sup\{|DF_n(y)-DF_n(x)|\colon x\in S_{nk},\ y\in X_{nk},\ |y-x|\leqq\eta,\ n\in\mathbf{Z}\}$, it follows from the uniform continuity and boundedness of Df_n that $\omega(\eta)\to 0$ as $\eta\to 0$. Then we choose $\varepsilon_0>0$ so that $\varepsilon_0<\Delta$ and $\omega(\varepsilon_0)\leqq 1/(4K+2)$. Also if we define $\bar{\omega}(\eta)=\sup\{\|\mathbf{P}_n(y)-\mathbf{P}_n(x)\|\colon x\in S_n,\ y\in X_n,\ |y-x|\leqq\eta,\ n\in\mathbf{Z}\}$ it follows from the uniform continuity of $\mathbf{P}_n(x)$ that $\bar{\omega}(\eta)\to 0$ as $\eta\to 0$. Then given $0<\bar{\varepsilon}\leqq\varepsilon_0$, we let $\delta_1>0$ be such that $\delta_1\leqq\Delta$, $(4K+2)\delta_1\leqq\bar{\varepsilon}$, $8M^kK\omega(\delta_1)\leqq 1$, $4K\omega(\delta_1)\leqq 1$. (Note: M is defined before Lemma 5.2.)

Now suppose $\{\bar{y}_n\}_{n\in\mathbf{Z}}$ is a δ_1-pseudo-orbit for F_n with $\bar{y}_n\in S_{nk}$ for all n. We show the existence of a unique orbit of F_n that $\bar{\varepsilon}$-shadows $\{\bar{y}_n\}$. First we apply Lemma 3.2 to $A_n=DF_n(\bar{y}_n)$, $Q_n=\mathbf{P}_{nk}(\bar{y}_n)$. For all n, $|A_n|\leqq M^k$, $|Q_n|\leqq K$, $|I-Q_n|\leqq K$. Also by the hyperbolicity, $|A_nQ_n|\leqq K\lambda^k$ for all n and $A_n(I-Q_n)\colon\mathcal{N}(Q_n)\to\mathcal{N}(\mathbf{P}_{(n+1)k}(F_n(\bar{y}_n)))$ is invertible with inverse having norm bounded by $K\lambda^k$. Using the invariance property of $\mathbf{P}_n$,

$$\begin{aligned}
|Q_{n+1}A_n(I-Q_n)|&=|[\mathbf{P}_{(n+1)k}(\bar{y}_{n+1})-\mathbf{P}_{(n+1)k}(F_n(\bar{y}_n))]A_n(I-Q_n)|\\
&\leqq\omega(\delta_1)\cdot M^kK\leqq 1/8
\end{aligned}$$

and, similarly, $|(I-Q_{n+1})A_nQ_n|\leqq 1/8$. Also since $2K\omega(\delta_1)\leqq 1/2$ it follows from Lemma 5.1 that

$$J_n=Q_{n+1}\mathbf{P}_{(n+1)k}(F_n(\bar{y}_n))+(I-Q_{n+1})(I-\mathbf{P}_{(n+1)k}(F_n(\bar{y}_n)))$$

is invertible with $|J_n^{-1}|\leqq(1-2K\omega(\delta_1))^{-1}\leqq 2$ and that $J_n(\mathcal{N}(\mathbf{P}_{(n+1)k}(F_n(\bar{y}_n))))=\mathcal{N}(Q_{n+1})$. Hence

$$(I-Q_{n+1})A_n(I-Q_n)=J_nA_n(I-Q_n)\colon\mathcal{N}(Q_n)\to\mathcal{N}(Q_{n+1})$$

is invertible with inverse B_n satisfying $|B_n| \leqq 2K\lambda^k$ so that $|B_n(I-Q_n)| \leqq 2K^2\lambda^k$. Thus the conditions of Lemma 3.2 are satisfied with X_{nk} instead of X_n and $2K^2\lambda^k$ instead of λ. So if we define $L: \prod_{n=-\infty}^{\infty} X_{nk} \to \prod_{n=-\infty}^{\infty} X_{nk}$ by

$$(L\mathbf{u})_n = u_n - A_{n-1}u_{n-1} = u_n - DF_{n-1}(\bar{y}_{n-1})u_{n-1},$$

L is invertible with $\|L^{-1}\| \leqq 2K+1$.

Let U be the open set in $\prod_{n=-\infty}^{\infty} X_{nk}$ consisting of those $\{x_n\}$, $x_n \in X_{nk}$ satisfying $\sup_n |x_n - \bar{y}_n| < \Delta$. Then we define $\mathscr{F}: U \to \prod_{n=-\infty}^{\infty} X_{nk}$ by

$$(\mathscr{F}(\mathbf{x}))_n = x_n - F_{n-1}(x_{n-1}).$$

$\mathscr{F}$ is C^1 with $(D\mathscr{F}(\mathbf{x})\mathbf{h})_n = h_n - DF_{n-1}(x_{n-1})h_{n-1}$. $L = D\mathscr{F}(\bar{\mathbf{y}})(\bar{\mathbf{y}} = \{\bar{y}_n\})$ is invertible with $\|L^{-1}\| \leqq 2K+1$. Condition (4.1) is satisfied by choice of ε_0 and since $\|\mathscr{F}(\bar{y})\| \leqq \delta_1 \leqq \bar{\varepsilon}/(4K+2)$, condition (4.2) is also satisfied with $\bar{\varepsilon}$ instead of ε. Then it follows from Proposition 4.1 that there exists a unique $\bar{\mathbf{x}} = \{\bar{x}_n\}$ in $\prod_{n=-\infty}^{\infty} X_{nk}$ such that $\mathscr{F}(\mathbf{x}) = 0$ and $\|\bar{\mathbf{x}} - \bar{\mathbf{y}}\| \leqq \bar{\varepsilon}$. That is, $\{\bar{x}_n\}$ is the unique orbit of $\{F_n\}$ such that $|\bar{x}_n - \bar{y}_n| \leqq \bar{\varepsilon}$ for all n.

Now let $0 < \varepsilon \leqq \varepsilon_0$ and let δ_1 correspond to $\bar{\varepsilon} = (1+M+\cdots+M^k)^{-1}\varepsilon$. Set $\delta = (1+M+\cdots+M^k)^{-1}\delta_1$ and let $\{y_n\}$ be a δ-pseudo-orbit for $\{f_n\}$ with $y_n \in S_n$ for all n. Then $\{\bar{y}_n\}_{n\in\mathbf{Z}}$, with $\bar{y}_n = y_{nk}$, is a δ_1-pseudo-orbit for $\{F_n\}$ by virtue of Lemma 5.2. So there exists a unique orbit $\{\bar{x}_n\}$ of $\{F_n\}$ which $\bar{\varepsilon}$-shadows $\{\bar{y}_n\}$. Then we define $x_{nk} = \bar{x}_n$, $n \in \mathbf{Z}$, and each x_{nk+i}, $1 \leqq i \leqq k-1$, $n \in \mathbf{Z}$, in the obvious way so that $\{x_n\}_{n\in\mathbf{Z}}$ is an orbit for $\{f_n\}$. It follows from Lemma 5.3 and the fact that $\max\{\bar{\varepsilon}, \delta\} = \bar{\varepsilon}$ that $\{x_n\}\varepsilon$-shadows $\{y_n\}$. $\{x_n\}$ must be unique because $\{x_{nk}\}$ ε-shadows $\{y_{nk}\}$ and there is a unique such orbit because $\varepsilon \leqq \varepsilon_0$.

6. Application to parabolic evolution equations. Consider the following parabolic evolution equation

$$\dot{x} + Ax = f(x, t) \tag{6.1}$$

in a Banach space X with norm $|\cdot|$. Suppose A is a sectorial operator in X (see Henry [8] for general reference in this section) with $\operatorname{Re}\sigma(A) > 0$. We can define the fractional powers $A^\alpha: \mathscr{D}(A^\alpha) \to X$, $0 \leqq \alpha \leqq 1$, and then $X^\alpha = \mathscr{D}(A^\alpha)$, the domain of A^α, becomes a Banach space with the graph norm $|x|_\alpha = |A^\alpha x|$.

We also assume that $f \in C^1(X^\alpha \times \mathbf{R}, X)$ and that f and $D_x f: X^\alpha \times \mathbf{R} \to \mathscr{L}(X^\alpha, X)$ are Lipschitzian in x and locally Hölder continuous in t. Under these conditions the initial value problem

$$\dot{x} + Ax = f(x, t), \qquad x(t_0) = x_0$$

has for all $(x_0, t_0) \in X^\alpha \times \mathbf{R}$ a unique solution

$$x(t; x_0, t_0) \in C^0([t_0, T), X^\alpha) \cap C^1((t_0, T), X) \cap C^0((t_0, T), \mathscr{D}(A)),$$

where $[t_0, T)$ is the maximal interval of existence. We denote the solution map of (6.1) by $\mathbf{T}(t, t_0)(x_0) = x(t; x_0, t_0)$.

Let $S \subset X^\alpha \times \mathbf{R}$ be a *forward invariant set* for (6.1), that is, if $(x_0, t_0) \in S$ then $\mathbf{T}(t, t_0)(x_0)$ is defined for all $t \geqq t_0$ and $(\mathbf{T}(t, t_0)(x_0), t) \in S$. This means that $\mathbf{T}(t, t_0)S_{t_0} \subset S_t$ for all $t \geqq t_0$, where $S_t = \{x \in X^\alpha : (x, t) \in S\}$ is the t-section of S. We say S is *hyperbolic* if:

(i) For $x \in S_t$, $t \in \mathbf{R}$, there is a splitting

$$X^\alpha = E_t^s(x) \oplus E_t^u(x) \tag{6.2}$$

which is *invariant*, that is,

$$\begin{aligned} D_x\mathbf{T}(t, t_0)(x)E_{t_0}^s(x) &\subset E_t^s(\mathbf{T}(t, t_0)(x)), \\ D_x\mathbf{T}(t, t_0)(x)E_{t_0}^u(x) &\subset E_t^u(\mathbf{T}(t, t_0)(x)) \end{aligned} \tag{6.3}$$

for all $x \in S_{t_0}$ and $t, t_0 \in \mathbf{R}$ with $t \geqq t_0$, and also *continuous*, that is, if $\mathbf{P}_t(x)$ is the projection with range $E_t^s(x)$ and nullspace $E_t^u(x)$, $\mathbf{P}_t(x)$ is continuous uniformly with respect to $x \in S_t$, $t \in \mathbf{R}$. We also assume that $D_x\mathbf{T}(t, t_0)(x): E_{t_0}^u(x) \to E_t^u(\mathbf{T}(t, t_0)(x))$ is an isomorphism with (bounded) inverse

$$(D_x\mathbf{T}(t, t_0)(x))^{-1}: E_t^u(\mathbf{T}(t, t_0)(x)) \to E_{t_0}^u(x).$$

(ii) There exist constants $K \geqq 1$, $\beta > 0$ such that for $x \in S_{t_0}$ and $t, t_0 \in \mathbf{R}$ with $t \geqq t_0$,

$$\begin{aligned} &|D_x\mathbf{T}(t, t_0)(x)\mathbf{P}_{t_0}(x)|_{\mathscr{L}(X^\alpha, X^\alpha)} \leqq K e^{-\beta(t-t_0)}, \\ &|(D_x\mathbf{T}(t, t_0)(x))^{-1}(I - \mathbf{P}_t(\mathbf{T}(t, t_0)(x)))|_{\mathscr{L}(X^\alpha, X^\alpha)} \leqq K e^{-\beta(t-t_0)}. \end{aligned} \tag{6.4}$$

Now we want to define pseudosolutions of (6.1). Let $\bigcup_{n \in \mathbf{Z}} [\tau_{n-1}, \tau_n] = \mathbf{R}$ be a partition of $\mathbf{R}$ with $\inf\{\tau_n - \tau_{n-1}: n \in \mathbf{Z}\} = \tau > 0$. Then, if δ is positive, we say the sequence $\{x_n(t)\}$, $t \in [\tau_{n-1}, \tau_n]$, $n \in \mathbf{Z}$ is a *δ-pseudosolution* of (6.1) if for all n

$$x_n(\cdot) \in C^0([\tau_{n-1}, \tau_n], X^\alpha) \cap C^1((\tau_{n-1}, \tau_n), X) \cap C^0((\tau_{n-1}, \tau_n), \mathscr{D}(A))$$

and

$$\sup\{|h_n(t)|: \tau_{n-1} \leqq t \leqq \tau_n\} \leqq \delta, \qquad |g_n|_\alpha \leqq \delta, \tag{6.5}$$

where $h_n \in C^0([\tau_{n-1}, \tau_n], X)$, defined by

$$h_n(t) = \dot{x}_n(t) + Ax_n(t) - f(x_n(t), t) \tag{6.6}$$

is the *residual error* and

$$g_n = x_n(\tau_n) - x_{n+1}(\tau_n) \tag{6.7}$$

is the *jump* at τ_n.

If ε is positive, a solution $x(t)$ of (6.1) is said to *ε-shadow* the δ-pseudosolution $\{x_n(t)\}$ if $x(t)$ is defined for all t and $|x(t) - x_n(t)| \leqq \varepsilon$ for $\tau_{n-1} \leqq t \leqq \tau_n$, $n \in \mathbf{Z}$.

THEOREM 6.1. *Let A, X, X^α, $f(t, x)$ be as above and suppose $S \subset X^\alpha \times \mathbf{R}$ is a forward invariant hyperbolic set for* (6.1) *such that $f(x, t)$ and $D_x f(x, t)$ are bounded and Lipschitz continuous in a Δ-neighborhood O of S in $X^\alpha \times \mathbf{R}$.*

Let $\{x_n(t)\}$, $\tau_{n-1} \leqq t \leqq \tau_n$, $n \in \mathbf{Z}$, be a δ-pseudosolution of (6.1) *such that for $\tau_{n-1} \leqq t \leqq \tau_n$ and $n \in \mathbf{Z}$, $x_n(t)$ is in a δ-neighborhood of S_t in the X^α norm.*

Then there exist $\varepsilon_0 > 0$ and a positive function $\delta(\varepsilon)$, both depending only on A, f, $\tau = \inf_n(\tau_n - \tau_{n-1})$, such that if $0 < \varepsilon \leqq \varepsilon_0$ and $\delta \leqq \delta(\varepsilon)$, there is a unique solution of (6.1) *that ε-shadows $\{x_n(t)\}$.*

For the proof of Theorem 6.1, we need a lemma.

LEMMA 6.2. *Let the hypotheses of Theorem* 6.1 *hold and let M be the bound for $\mathscr{D}_x f(t, x)$ in O. Let $x(t)$ be a solution of* (6.1) *in S and let $y(t)$ be a solution of the initial value problem*

$$\dot{y} + Ay = f(y, t) + h(t), \qquad y(t_0) = \xi \tag{6.8}$$

for $t \in [t_0, t_0 + 2\tau]$, where $|\xi - x(t_0)|_\alpha \leqq \delta$ and $h \in C^0([t_0, t_0 + 2\tau], X)$ with $\sup|h(t)| \leqq \delta$. If $(y(t), t) \in O$ for $t \in [t_0, t_0 + 2\tau]$, then there exists a constant $C \geqq 1$ depending only on A and M such that $|y(t) - x(t)|_\alpha \leqq C\delta$ on $[t_0, t_0 + 2\tau]$.

Proof. Our assumptions on A imply the existence of positive constants C_1, C_2 and a such that for $t \geqq 0$

$$|e^{-At}|_{\mathscr{L}(X^\alpha, X^\alpha)} \leqq C_1 e^{at}, \qquad |e^{-At}|_{\mathscr{L}(X, X^\alpha)} \leqq C_2 t^{-\alpha} e^{at}.$$

Now $z(t)=y(t)-x(t)$ satisfies the integral equation

$$z(t)=e^{-A(t-t_0)}z(t_0)+\int_{t_0}^{t}e^{-A(t-s)}\{f(x(s)+z(s),s)-f(x(s),s)+h(s)\}\,ds.$$

Then for $t_0\leqq t\leqq t_0+2\tau$,

$$|z(t)|_\alpha\leqq C_1\,e^{a(t-t_0)}\delta+\int_{t_0}^{t}MC_2(t-s)^{-\alpha}\,e^{a(t-s)}|z(s)|_\alpha\,ds+\int_{t_0}^{t}C_2(t-s)^{-\alpha}\,e^{a(t-s)}\delta\,ds.$$

It follows from an inequality in Henry [8, Lemma 7.1.1, p. 188] that $|z(t)|_\alpha<C\delta$ for $t_0\leqq t\leqq t_0+2\tau$. The proof is completed.

Proof of Theorem 6.1. The hypotheses on A and f, Lemma 6.2, and Henry [8] imply that there exists a closed Δ_1-neighborhood O_1 of S in $X^\alpha\times\mathbf{R}$ such that for $(x,t_0)\in O_1$, $\mathbf{T}(t,t_0)(x)$ is defined for $t_0\leqq t\leqq t_0+2\tau$ and both $\mathbf{T}(t,t_0)(x)$ and $D_x\mathbf{T}(t,t_0)(x)$ are bounded and continuous, uniformly with respect to $(x,t_0)\in O_1$ and $t\in[t_0,t_0+2\tau]$. (These functions have ranges in X^α and $\mathscr{L}(X^\alpha,X^\alpha)$, respectively, and the continuity is with respect to these norms.)

Without loss of generality we may assume that $0\leqq\tau\leqq\tau_n-\tau_{n-1}\leqq 2\tau$ for all n. We first consider the case where $h_n(t)=0$ and $x_n(t)\in S_t$ for all t and n. Then if we let X_n be X^α for all n and f_n be $\mathbf{T}(\tau_n,\tau_{n-1}):X^\alpha\to X^\alpha$ the domain of f_n contains a closed Δ_1-neighborhood of $S_{\tau_{n-1}}$ in which f_n and Df_n are both bounded and uniformly continuous, uniformly with respect to $n\in\mathbf{Z}$. From the hyperbolicity of S with respect to (6.1), we see that $\{S_{\tau_{n-1}}\}_{n\in\mathbf{Z}}$ is invariant ($f_n(S_{\tau_{n-1}})\subset S_{\tau_n}$) and hyperbolic for $\{f_n\}_{n\in\mathbf{Z}}$ with projections $\mathbf{P}_{\tau_{n-1}}(x)$ and constants K, $e^{-\beta\tau}$. Hence conditions (i), (ii), (iii) of the Shadowing Lemma hold. Set $y_n=x_n(\tau_{n-1})$, $n\in\mathbf{Z}$. Then $y_n\in S_{\tau_{n-1}}$ for all n and

$$|f_n(y_n)-y_{n+1}|_\alpha=|x_n(\tau_n)-x_{n+1}(\tau_n)|_\alpha\leqq\delta.$$

So if $0<\varepsilon\leqq\varepsilon_1$ and $\delta\leqq\delta_1(\varepsilon)$ (ε_1 and $\delta_1(\varepsilon)$ correspond to ε_0 and $\delta(\varepsilon)$ in the Shadowing Lemma) there is a unique solution $x(t)$ of (6.1) such that $|x(\tau_{n-1})-x_n(\tau_{n-1})|_\alpha\leqq\varepsilon$ for all n.

Now we consider the general case. We suppose $0<\varepsilon\leqq\varepsilon_0=\frac{1}{2}\min\{\Delta,\varepsilon_1\}$ and $\delta\leqq\delta(\varepsilon)=\min\{(2C+1)^{-1}\delta_1(\varepsilon/2C),\varepsilon/2C\}$. Let $\{x_n(\cdot)\}$ be a δ-pseudosolution as in the statement of the theorem. Since for all n, $x_n(\tau_{n-1})$ is in a δ-neighborhood of $S_{\tau_{n-1}}$, we can choose y_n in $S_{\tau_{n-1}}$ so that $|x_n(\tau_{n-1})-y_n|_\alpha\leqq\delta$. Then let $\bar{x}_n(t)$ be the solution of (6.1) satisfying $\bar{x}_n(\tau_{n-1})=y_n$. By Lemma 6.2 with $t_0=\tau_{n-1}$, $x(t)=\bar{x}_n(t)$, $h(t)=h_n(t)$, $y(t)=x_n(t)$ we have

$$|\bar{x}_n(t)-x_n(t)|_\alpha\leqq C\delta$$

for $\tau_{n-1}\leqq t\leqq\tau_n$. This holds for $n\in\mathbf{Z}$. Moreover,

$$\begin{aligned}|\bar{x}_n(\tau_n)-\bar{x}_{n+1}(\tau_n)|_\alpha&\leqq|\bar{x}_n(\tau_n)-x_n(\tau_n)|_\alpha+|x_n(\tau_n)-x_{n+1}(\tau_n)|_\alpha+|x_{n+1}(\tau_n)-\bar{x}_{n+1}(\tau_n)|_\alpha\\&\leqq(2C+1)\delta\leqq\delta_1(\varepsilon/2C).\end{aligned}\tag{6.9}$$

Hence $\{\bar{x}_n(t)\}$ is a $\delta_1(\varepsilon/2C)$-pseudosolution of (6.1) with $\bar{x}_n(t)\in S_t$ for all t and n, where $\varepsilon/2C<\varepsilon_1$. It follows from the first part of the proof that there is a unique solution $x(t)$ of (6.1) such that

$$|x(\tau_{n-1})-\bar{x}_n(\tau_{n-1})|_\alpha\leqq\varepsilon/2C\tag{6.10}$$

for all n. Then for all n

$$\begin{aligned}|x(\tau_{n-1})-x_n(\tau_{n-1})|_\alpha&\leqq|x(\tau_{n-1})-\bar{x}_n(\tau_{n-1})|_\alpha+|\bar{x}_n(\tau_{n-1})-x_n(\tau_{n-1})|_\alpha\\&\leqq\varepsilon/2C+\delta.\end{aligned}$$

By Lemma 6.2 with $t_0 = \tau_{n-1}$, $x(t) = \bar{x}_n(t)$, $y(t) = x(t)$ and $\varepsilon/2C + \delta$ instead of δ (note: $C(\varepsilon/2C + \delta) = \varepsilon/2 + C\delta < \Delta$), we deduce for $\tau_{n-1} \leqq t \leqq \tau_n$, $n \in \mathbf{Z}$ that

$$|x(t) - x_n(t)|_\alpha \leqq \varepsilon/2 + C\delta \leqq \varepsilon.$$

That is, $x(t)$ does ε-shadow the δ-pseudosolution $\{x_n(t)\}$.

Let $\tilde{x}(t)$ be another such solution. Then for all n

$$\begin{aligned}|\tilde{x}(\tau_{n-1}) - \bar{x}_n(\tau_{n-1})|_\alpha &\leqq |\tilde{x}(\tau_{n-1}) - x_n(\tau_{n-1})|_\alpha + |x_n(\tau_{n-1}) - \bar{x}_n(\tau_{n-1})|_\alpha \\ &\leqq \varepsilon + \delta \leqq 3\varepsilon/2 < \varepsilon_1,\end{aligned}$$

where for all n, using (6.9),

$$\begin{aligned}|f_n(\bar{x}_n(\tau_{n-1})) - \bar{x}_{n+1}(\tau_n)|_\alpha &= |\bar{x}_n(\tau_n) - \bar{x}_{n+1}(\tau_n)|_\alpha \\ &\leqq \delta_1(\varepsilon/2C) \\ &\leqq \delta_1(3\varepsilon/2).\end{aligned}$$

(Note: we assume without loss of generality that $\delta_1(\varepsilon)$ is nondecreasing in ε.) That is, the sequence $\{\tilde{x}(\tau_{n-1})\}$ is an orbit of $\{f_n\}$ that $3\varepsilon/2$-shadows the $\delta_1(3\varepsilon/2)$-pseudo-orbit $\{\bar{x}_n(\tau_{n-1})\}$, where $3\varepsilon/2 < \varepsilon_1$. But by (6.10), $\{x(\tau_{n-1})\}$ is another such sequence and so it follows by uniqueness that $\tilde{x}(\tau_{n-1}) = x(\tau_{n-1})$ for all n. Hence $x(t)$ is unique.

QUENCHING FOR SEMILINEAR SINGULAR PARABOLIC PROBLEMS*

C. Y. CHAN† AND HANS G. KAPER‡

Abstract. Let f be a real-valued function that is nondecreasing and continuously differentiable on $[0, c)$ for some finite c ($c>0$), satisfying the conditions $f(0)>0$ and $\lim_{u\to c} f(u)=\infty$. This article is concerned with positive solutions u of the semilinear singular parabolic differential equation $u_t = u_{xx}+(b/x)u_x+f(u)$, $b<1$, on a bounded interval $(0, a)$, which satisfy the initial condition $u(x, 0)=0$ and the boundary conditions $u(0, t)=0$ and $u_x(a, t)=0$. Let $\|\cdot\|$ denote the sup-norm over the interval $[0, a]$. It is shown that a solution u quenches (i.e., there exists a $T<\infty$ such that $\lim_{t\to T, t<T}\|u_t(\cdot, t)\|=\infty$) if $\|u(\cdot, t)\|$ tends to c from below as t approaches T. Furthermore, there exists a critical length a^* such that u may exist for all $t>0$ if $a<a^*$, but $\|u(\cdot, t)\|$ tends to c in finite time if $a>a^*$. A numerical method is given to compute a^*. An upper bound for the quenching time T is obtained. An example is given to illustrate the results.

AMS(MOS) subject classifications. 35K20, 35K55

1. Introduction. The concept of *quenching* of the solution of a nonlinear heat equation was first introduced by Kawarada [8], who studied the following problem:

$$u_t = u_{xx}+(1-u)^{-1}, \qquad (x, t)\in(0, l)\times(0, T), \tag{1.1a}$$

$$u(x, 0)=0, \quad x\in(0, l), \quad u(0, t)=0, \quad u(l, t)=0, \quad t\in(0, T). \tag{1.1b}$$

The solution u of (1.1a, b) *quenches* if there exists a $T<\infty$ such that

$$\lim_{t\to T, t<T}\|u_t(\cdot, t)\|=\infty. \tag{1.2}$$

Here, $\|\cdot\|$ denotes the sup-norm over the interval $[0, l]$. The value of T is referred to as the *quenching time.*

If the solution u of (1.1a, b) quenches at some finite time T, then

$$\lim_{t\to T, t<T}\|u(\cdot, t)\|=1. \tag{1.3}$$

Kawarada has claimed that (1.3) implies quenching of the solution of (1.1a, b). If this claim were correct, it would follow that the conditions (1.2) and (1.3) are equivalent and either can be taken to define quenching. However, Kawarada has assumed without justification that a function $\hat{W}$, constructed in the course of the proof, satisfied the heat equation on curves $s^{(i)}(t)$ for t arbitrarily close to the quenching time T. Hence, Kawarada's claim needs to be reexamined. Furthermore, it would be desirable to extend Kawarada's claim, if true, to nonlinear heat equations with a general forcing term f. Since Kawarada has made use of the explicit expression $f(u)=(1-u)^{-1}$, the extension of his proof is not obvious.

In his investigation [14] of (1.1a, b), Walter has adopted (1.3) as the definition of quenching. The same definition has been adopted by Acker and Walter [1], [2], who have studied the solutions of the general equations

$$u_t = u_{xx} + f(u), \qquad (x, t) \in (0, l) \times (0, T), \tag{1.4}$$

$$u_t = u_{xx} + f(u, u_x), \qquad (x, t) \in (0, l) \times (0, T)$$

subject to the initial and boundary conditions (1.1b). The results of [1] and [2] imply that there is a critical length l^* such that a solution u exists globally (i.e., for all $t > 0$) if $l < l^*$, but u quenches if $l > l^*$. Results on the behavior of the solution of (1.4) and (1.1b) at $l = l^*$ were given subsequently by Levine and Montgomery [11].

An upper bound for l^* for the problem (1.1a, b) can be inferred from Kawarada's article [8], viz., $l^* \leqq 2\sqrt{2} = 2.8284$. Walter [14] has shown that the critical length l^* for (1.1a, b) is in the range $1.5303 \leqq l^* \leqq \frac{1}{2}\pi = 1.5708$. The exact value of l^* has been identified by Acker and Walter [1] as $2M\sqrt{2}$, where M is the maximum value of Dawson's integral, $F(x) = e^{-x^2}\int_0^x e^{t^2}\,dt$, on the interval $(0, \infty)$ (cf. [15, § 7.1]). The numerical value of l^* is 1.53030416 (to eight decimal places).

Further results and references on the phenomenon of quenching for solutions of nonlinear equations can be found in the survey article by Levine [10].

In this article we will study the semilinear singular problem

$$u_t = u_{xx} + (b/x)u_x + f(u), \qquad (x, t) \in (0, a) \times (0, T), \tag{1.5a}$$

$$u(x, 0) = 0, \quad x \in (0, a), \quad u(0, t) = 0, \quad u_x(a, t) = 0, \quad t \in (0, T). \tag{1.5b}$$

Here f is a real-valued function that is nondecreasing and continuously differentiable on the interval $[0, c)$ for some $c > 0$, satisfying the conditions $f(0) > 0$ and $\lim_{u \to c} f(u) = \infty$. The constant b satisfies the inequality $b < 1$. If $b = 0$, then (1.5a, b) reduces to (1.1a, b) with $l = 2a$, because the solution of (1.1a, b) is symmetric about $x = \frac{1}{2}l$. We remark that if $f(0) = 0$, then $u = 0$ is the only solution of (1.5).

Throughout this article we use the abbreviation $\Omega = (0, a) \times (0, T)$. We always assume that T is maximal. We use the symbol L to denote the differential expression $Lu = u_{xx} + (b/x)u_x - u_t$.

The transformation $u(x, t) = v(z, t)$, where $z = \frac{1}{4}x^2$, reduces the degenerate elliptic-parabolic expression $zv_{zz} + \frac{1}{2}(1 + b)v_z - v_t$ to Lu. This degenerate expression arises in probability theory; it has been studied by Brezis, Rosenkrantz, Singer, and Lax [6] for $b > -1$. Also, the stochastic process described by the expression $\frac{1}{2}v_{zz} + \frac{1}{2}(b/z)v_z - v_t$, which has been studied by Lamperti [9] for $b > -1$, reduces to Lu on the transformation $u(x, t) = v(z, t)$, where $z = 2^{-1/2}x$.

The existence of unique solutions of nonhomogeneous problems for the linear differential expression L has been studied by Alexiades [3], [4] and by Alexiades and Chan [5]. In particular, it follows from Alexiades [4] that initial boundary value problems described by equations of the form $Lu = g(x, t)$, where g is a given function on Ω, and the initial and boundary conditions (1.5b), have unique classical solutions if $b < 1$.

In § 2, we prove that the (unique) solution u of (1.5a, b) quenches at some finite time T if $\lim_{t \to T, t < T} \|u(\cdot, t)\| = c$. This result proves and generalizes Kawarada's claim; our method of proof is, however, different from Kawarada's. In § 3, we establish the existence of a critical length a^* and show that a^* is determined by the solution of the corresponding steady state problem. Picard's iteration scheme gives a strictly monotone sequence of functions, which converges upwards to the minimal steady state solution. We also give a procedure to compute a^*. In § 4, we obtain an upper bound for the

quenching time T by solving a singular Sturm-Liouville problem and using a comparison result. In § 5, we illustrate our results by considering the special case $f(u) = (1-u)^{-1}$.

2. Quenching. In this section we prove that (1.5a, b) has at most one solution. This solution is necessarily positive (i.e., nonnegative and nontrivial) and nondecreasing in each variable separately. Assuming that the solution exists before quenching time, we show that it quenches at a finite time T if the value of u at a approaches c, the critical value of f, as t tends to T from below.

LEMMA 1. *The initial boundary value problem* (1.5a, b) *has at most one solution u. This solution has the following properties*: (i) $u(x, t) > 0$ *for all* $(x, t) \in \Omega \cup (\{a\} \times (0, T))$; (ii) $u(x, t)$ *is a strictly increasing function of* t *for each* $x \in (0, a]$; (iii) $u(x, t)$ *is a nondecreasing function of* x *for each* $t \in (0, T)$.

Proof. Let u_1 and u_2 be two distinct solutions of (1.5a, b) and let $y = u_1 - u_2$. Then y satisfies the differential equation $[L + f'(\eta)]y = 0$ in Ω for some η between u_1 and u_2, the initial condition $y(x, 0) = 0$ and the boundary conditions $y(0, t) = 0$ and $y_x(a, t) = 0$. Since $f'(\eta)$ is bounded above, the uniqueness of u follows from the strong maximum principle and the parabolic version of Hopf's lemma (cf. [13, §§ 3.2, 3.3]).

(i) Because $f(0) > 0$, we have $Lu + f(u) - f(0) < 0$ in Ω, so $[L + f'(\eta)]u < 0$ for some η between 0 and u. It follows from the strong maximum principle and the parabolic version of Hopf's lemma that $u > 0$ in $\Omega \cup (\{a\} \times (0, T))$.

(ii) For any $h \in (0, T)$, let u_h be defined in $\Omega_h = (0, a) \times (0, T-h)$ by the expression $u_h(x, t) = u(x, t+h)$ and let $y = u_h - u$. Then $[L + f'(\zeta)]y = 0$ in Ω_h for some ζ between u and u_h. On the parabolic boundary $\partial_p \Omega_h$ of Ω_h we have $y(x, 0) > 0$, $y(0, t) = 0$, and $y_x(a, t) = 0$. The inequality $y > 0$ in Ω_h follows from the strong maximum principle and the parabolic version of Hopf's lemma; hence, $u(x, t)$ is a strictly increasing function of t for each $x \in (0, a)$.

(iii) For any $\varepsilon \in (0, a)$, let $\Omega_\varepsilon = (\varepsilon, a) \times (0, T)$. As in the proof of part (i), we show that the solution u_ε of the (regular) problem

$$Lu_\varepsilon = -f(u_\varepsilon), \qquad (x, t) \in \Omega_\varepsilon, \tag{2.1a}$$

$$u_\varepsilon(x, 0) = 0, \quad u_\varepsilon(\varepsilon, t) = 0, \quad u_{\varepsilon,x}(a, t) = 0, \tag{2.1b}$$

is positive in $\Omega_\varepsilon \cup (\{a\} \times (0, T))$. (Here, $u_{\varepsilon,x}$ denotes the partial derivative of u_ε with respect to x.) Differentiating (2.1a) with respect to x, we obtain

$$[L + f'(u_\varepsilon) - b/x^2]u_{\varepsilon,x} = 0, \qquad (x, t) \in \Omega_\varepsilon.$$

It follows from (2.1b) that $u_{\varepsilon,x}(x, 0) = 0$, $u_{\varepsilon,x}(\varepsilon, t) \geqq 0$, and $u_{\varepsilon,x}(a, t) = 0$, so the strong maximum principle implies that $u_{\varepsilon,x} > 0$ in Ω_ε. It also follows from the strong maximum principle and the parabolic version of Hopf's lemma that u_ε is strictly monotone increasing as ε decreases. In particular, we have $0 < u_\varepsilon < u$ in Ω_ε. Since u_ε is bounded, $\lim_{\varepsilon \to 0} u_\varepsilon$ exists; we denote it by Z. Thus, $Z_x \geqq 0$ and $0 < u_\varepsilon \leqq Z \leqq u$ in Ω_ε.

For any $\sigma \in (\varepsilon, a)$, let $\Omega_\sigma = (\sigma, a) \times (0, T)$. We consider the solution u_σ of the (regular) problem

$$Lu_\sigma = -f(u_\sigma), \qquad (x, t) \in \Omega_\sigma,$$

$$u_\sigma(x, 0) = 0, \quad u_\sigma(\sigma, t) = u_\varepsilon(\sigma, t), \quad u_{\sigma,x}(a, t) = 0.$$

Let L^* denote the adjoint of L (defined with the appropriate adjoint boundary conditions) and let $R^*(\xi, \tau; x, t)$ be its Green's function (cf. [7, § 3.7; Chap. 5, Problem 5] and [12, § 6.2]). We take $u = u_\varepsilon$ and $v(\xi, \tau) = R^*(\xi, \tau; x, t)$ in Green's identity,

$$vLu - uL^*v = [vu_x - uv_x + (b/x)uv]_x - (uv)_t.$$

Integrating over the domain $(\sigma, a)\times(0, t-\delta)$, where δ is some small positive constant less than t, using Green's theorem, and letting δ tend to zero, we find

$$u_\varepsilon(x,t)=\int_0^t\int_\sigma^a R^*(\xi,\tau;x,t)f(u_\varepsilon(\xi,\tau))\,d\xi\,d\tau + \int_0^t R_\xi^*(\sigma,\tau;x,t)u_\varepsilon(\sigma,\tau)\,d\tau, \qquad (x,t)\in\Omega_\sigma.$$

Since $R^*(\xi,\tau;x,t)>0$ for $(\xi,\tau)\in(\sigma,a)\times(0,t)$ (cf. [7, § 3.7]), it follows that $R_\xi^*(\sigma,\tau;x,t)\geqq 0$. Because u_ε and $f(u_\varepsilon)$ are nondecreasing as ε decreases, it follows from the monotone convergence theorem that

$$Z(x,t)=\int_0^t\int_\sigma^a R^*(\xi,\tau;x,t)f(Z(\xi,\tau))\,d\xi\,d\tau + \int_0^t R_\xi^*(\sigma,\tau;x,t)Z(\sigma,\tau)\,d\tau, \qquad (x,t)\in\Omega_\sigma.$$

Thus, $LZ=-f(Z)$ in Ω_σ. Since σ is arbitrary it follows that $LZ=-f(Z)$ in Ω. Also, $Z_x(a,t)=0$ and $Z(x,0)=0$. Because $0\leqq u_\varepsilon\leqq Z\leqq u$ in Ω, it must be the case that $Z(0,t)=0$. Since u is unique, we have $u=Z$; hence, $u_x\geqq 0$. □

THEOREM 2. *Suppose that the function f is such that*

$$\int_0^c f(u)\,du=\infty. \tag{2.2}$$

If

$$\lim_{t\to T} u(a,t)=c, \tag{2.3}$$

for some finite T, then the solution u of (1.5a, b) *quenches.*

Proof. The proof is by contradiction, where we assume that (2.3) holds, but $\|u_t(\cdot,t)\|$ remains bounded as $u(a,t)$ tends to c. (We recall from Lemma 1(iii) that $\|u(\cdot,t)\|=u(a,t)$.)

By assumption, there exists a constant M such that $u_t(x,t)\leqq M$ for all $(x,t)\in\bar{\Omega}$, the closure of Ω. Hence,

$$u_{xx}+(b/x)u_x=x^{-b}(x^b u_x)_x\leqq M-f(u), \qquad (x,t)\in\Omega. \tag{2.4}$$

Because u is a nondecreasing function of each argument and $u(a,t)$ tends to c as $t\to T$, there certainly exists an open rectangle $Q=(\xi,a)\times(\tau,T)$ with $\xi>0$ such that $f(u)\geqq 2M$ in Q. Then

$$2x^{-b}(x^b u_x)_x\leqq -f(u), \qquad (x,t)\in Q. \tag{2.5}$$

If $b<0$, it follows that $2(x^b u_x)(x^b u_x)_x\leqq -f(u)u_x/a^{-2b}$. On integration from ξ to a we find

$$u_x^2(\xi,t)\geqq\left(\frac{\xi}{a}\right)^{-2b}\int_{u(\xi,t)}^{u(a,t)} f(u)\,du, \qquad t\in(\tau,T).$$

As t approaches T, the integral grows beyond bounds, because of (2.2), so the same must be true for the (nonnegative) quantity $u_x(\xi,t)$. If $b\geqq 0$, then it follows from (2.5) that $2u_{xx}\leqq -f(u)$. Since $u_x\geqq 0$, we have

$$u_x^2(\xi,t)\geqq\int_{u(\xi,t)}^{u(a,t)} f(u)\,du, \quad t\in(\tau,T).$$

Again we arrive at the conclusion that $u_x(\xi,t)$ grows beyond bounds as t tends to T.

Since f is nondecreasing and u is nonnegative, we have $f(u) > 0$. The inequality (2.4) therefore yields $(x^b u_x)_x \leqq M x^b$ in Ω. It follows on integration from some point x to ξ that

$$u_x(x, t) \geqq x^{-b}\{\xi^b u_x(\xi, t) - [M/(1+b)](\xi^{1+b} - x^{1+b})\}, \qquad b \neq -1,$$

$$u_x(x, t) \geqq (x/\xi) u_x(\xi, t) - Mx \ln(\xi/x), \qquad b = -1.$$

A second integration from zero to ξ yields

$$u(\xi, t) \geqq \frac{\xi u_x(\xi, t)}{1-b} - \frac{M\xi^2}{1+b}\left(\frac{1}{1-b} - \frac{1}{2}\right), \qquad b \neq -1,$$

$$u(\xi, t) \geqq \frac{1}{2}\xi u_x(\xi, t) - \frac{1}{4} M\xi^2, \qquad b = -1.$$

As t tends to T, these lower bounds become arbitrarily large, so it would follow that $u(\xi, t)$ becomes aribtrarily large. But now we have a contradiction, because $u(\xi, t)$ is less than $u(a, t)$ and the latter quantity tends to the finite limit c. □

3. Critical length. In this section we establish the existence of a critical length and show how the critical length can be determined.

THEOREM 3. *If $T = \infty$ and there exists a constant $C \in (0, c)$ such that $u(x, t) \leqq C$ for all $(x, t) \in \Omega$, then $u(\cdot, t)$ converges from below to a solution U of the singular nonlinear two-point boundary value problem*

$$U'' + (b/x)U' = -f(U), \quad x \in (0, a), \quad U(0) = 0, \quad U'(a) = 0. \tag{3.1}$$

The convergence is uniform on $[0, a]$. Furthermore, $u < U$ on $(0, a] \times (0, \infty)$.

Proof. Since the homogeneous problem corresponding to (3.1) has only the trivial solution, Green's function $G(x; y)$ for (3.1) exists. A direct computation gives

$$G(x; y) = \begin{cases} (1-b)^{-1} x^{1-b}, & 0 \leqq x \leqq y, \\ (1-b)^{-1} y^{1-b}, & y \leqq x \leqq a. \end{cases}$$

Let F denote the function

$$F(x, t) = \int_0^a y^b G(x; y) u(y, t)\, dy, \qquad (x, t) \in \Omega. \tag{3.2}$$

If u satisfies the initial boundary value problem (1.5a, b), then Green's identity yields

$$F_t(x, t) = -u(x, t) + \int_0^a y^b G(x; y) f(u(y, t))\, dy. \tag{3.3}$$

According to Lemma 1(ii), u is strictly increasing in t for $x \in (0, a]$. Since f is nondecreasing, the integrand in (3.3) is monotone nondecreasing with respect to t. It follows from the monotone convergence theorem and the continuity of f that

$$\lim_{t\to\infty} F_t(x, t) = -\lim_{t\to\infty} u(x, t) + \int_0^a y^b G(x; y) f(\lim_{t\to\infty} u(y, t))\, dy.$$

From (3.2) and Lemma 1(ii) we infer that $\lim_{t\to\infty} F_t(x, t) \geqq 0$. We claim that the limit is exactly zero. If the limit were (strictly) positive at some point x, it would follow that $F(x, t)$ would increase without bound as t tends to infinity, so u would reach c in a

finite time, contradictory to the assumption that T is infinite. The identity (3.3) implies that

$$\lim_{t\to\infty} u(x,t) = \int_0^a y^b G(x;y) f(\lim_{t\to\infty} u(y,t))\, dy.$$

That is, $\lim_{t\to\infty} u(x,t) = U(x)$. The uniform convergence follows from Dini's theorem.

Lemma 1(i) and (ii) imply that $U>0$ on $(0,a]$. Furthermore, $[L+f'(\eta)](U-u) = 0$ in Ω for some η between U and u; $U-u>0$ at $t=0$, $U-u=0$ at $x=0$, and $U'-u_x=0$ at $x=a$. Hence, $U-u>0$ for $0<x\leqq a$. □

THEOREM 4. *Let u_α denote the solution of the problem* (1.5a, b), *where a is replaced by $a+\alpha$ for some constant $\alpha>0$. If $\lim_{t\to\infty} u(a,t)=c$, then u_α quenches.*

Proof. Assume that u_α does not quench. Let $y=u_\alpha-u$. Then $[L+f'(\eta)]y=0$ in Ω for some η between u and u_α. Furthermore, $y(x,0)=0$, $y(0,t)=0$, and $y_x(a,t)\geqq 0$ by Lemma 1(iii). Therefore, $u_\alpha\geqq u$ in Ω.

Let ε and t_0 be positive numbers, chosen so that $f(z)\geqq(4\varepsilon/\alpha)(2/\alpha+3|b|/a)+\alpha^2$ for $z\in[c-\varepsilon, c)$ and $u(a,t_0)\geqq c-\varepsilon$. Let S denote the domain $(a,a+\alpha)\times(t_0,\infty)$.

By assumption, u_α exists for all $t>0$; in particular, it must be the case that $u_\alpha<c$ in S. It follows from Lemma 1(ii) and (iii) that $u_\alpha\geqq c-\varepsilon$ on the parabolic boundary $\partial_p S$ of S. Consider the function z, defined by the expression $z(x,t)=c-\varepsilon+(x-a)(a+\alpha-x)(t-t_0)$ on S. Clearly, $z=c-\varepsilon$ on $\partial_p S$. Furthermore,

$$Lz+f(z)\geqq -2(t-t_0)+(b/x)[2(a-x)+\alpha](t-t_0)$$
$$-(x-a)(a+\alpha-x)+(4\varepsilon/\alpha)(2/\alpha+3|b|/a)+\alpha^2, \qquad z\in[c-\varepsilon, c).$$

The lower bound is nonnegative in $(a,a+\alpha)\times(t_0, t_0+4\varepsilon/\alpha^2)$. It follows from the strong maximum principle that $u_\alpha>z$ in this domain; hence, the (nonstrict) inequality $u_\alpha\geqq z$ holds at the point $(x,t)=(a+\alpha/2, t_0+4\varepsilon/\alpha^2)$, where z assumes the value c. But now we have a contradiction, since $u_\alpha<c$ everywhere in S. □

Theorem 3 implies that there exists a critical length a^* such that u exists on $[0,a]$ for all $t>0$ if $a<a^*$. The critical length a^* is determined as the supremum of all positive values a for which a solution U of (3.1) exists; if $U(a^*)$ exists, then $u(a^*,t)$ exists also. According to Theorem 4, u quenches if $a>a^*$.

We now give a procedure to compute the critical length a^*. Let $a<a^*$ and let $U_0=0$ on $[0,a]$. We construct a sequence $\{U_n\}_{n\in N}$ by defining U_n as the solution of the boundary value problem

$$U_n''+(b/x)U_n'+f(U_{n-1})=0, \quad x\in(0,a), \quad U_n(0)=0, \quad U_n'(a)=0.$$

In terms of Green's function G, we have

$$U_n(x) = \int_0^a \xi^b G(x;\xi) f(U_{n-1}(\xi))\, d\xi, \qquad n=1,2,\cdots. \tag{3.4}$$

The sequence is well defined.

THEOREM 5. *The sequence $\{U_n\}_{n\in N}$ converges monotonically upwards to the minimal solution U of the boundary value problem* (3.1). *This minimal solution satisfies the inequality $U<c$ on $[0,a]$.*

Proof. Since $f(0)>0$ and $G(\cdot;\xi)>0$ in Ω, it follows that $U_1>0$ on $(0,a]$. From Lemma 1(ii) and Theorem 3 it follows that $0<U<c$ on $(0,a]$. Since f is nondecreasing, we have $(U-U_1)''+(b/x)(U-U_1)'\leqq 0$; furthermore, $(U-U_1)(0)=0$ and $(U-U_1)'(a)=0$. The positivity of Green's function then yields the inequality $U>U_1$ on $(0,a]$. Similarly $U>U_2>U_1$ on $(0,a]$ and, by induction,

$$0<U_n<U_{n+1}<U<c \quad \text{on } (0,a], \quad n=1,2,\cdots. \tag{3.5}$$

Hence, there exists a function $V(x)$ such that $\lim_{n\to\infty} U_n = V$. The integrand in (3.4) is nondecreasing with respect to n and integrable, so it follows from the monotone convergence theorem that V satisfies the equation

$$V(x) = \int_0^a \xi^b G(x;\xi) f(V(\xi))\, d\xi.$$

Hence, V is a solution of (3.1). It follows from (3.5) that V is minimal. □

We have implemented this result in the following algorithm to determine a^* for a given $b < 1$. Starting with an estimated value A for a^* and taking $U_0 = 0$, we compute U_n by means of (3.4). The integration is done by dividing the interval $[0, a]$ into N equal subintervals; we use the IMSL library subroutine ICSCCU (cubic spline interpolation in single precision) to interpolate the function U_{n-1} at the $N+1$ subdivision points, the subroutine ICSEVU (cubic spline evaluation in single precision) to evaluate U_{n-1} in the integrand, and the subroutine DCADRE (single precision Romberg integration) to do the integration. In this way we obtain $U_n(x)$ at the points $x = \xi_i$, $i = 2, \cdots, N+1$ of the subdivision. If $U_n(a) < c$ and $\max\{U_n(\xi_i) - U_{n-1}(\xi_i): i = 2, 3, \cdots, N+1\} < 0.5 \times 10^{-d}$ (for a desired accuracy of d decimal places), we claim that u exists globally; if $U_n(a) \geqq c$, we claim that u quenches. In the latter case, we decrease A by a small positive amount, to obtain a new estimate of a^*, and repeat the procedure, until we find that u exists globally. We then use the method of bisection to determine a value a^{**} such that u exists globally for $a \leqq a^{**}$, but u quenches for $a > a^{**}$. We then claim that $a^* = a^{**}$ to the accuracy prescribed.

4. Quenching time. It remains to obtain an upper bound for the quenching time T. Consider the singular Sturm-Liouville problem

$$-x^{-b}(x^b w')' = \lambda^2 w, \qquad x \in (0, a), \tag{4.1a}$$

$$w(0) = 0, \qquad w'(a) = 0. \tag{4.1b}$$

The general solution of (4.1a) is $w(x) = x^\nu[c_1 J_\nu(\lambda x) + c_2 Y_\nu(\lambda x)]$, where c_1 and c_2 are arbitrary constants, $\lambda > 0$, and J_ν and Y_ν are Bessel functions of the first and second kind, respectively, with $\nu = \frac{1}{2}(1-b)$ (cf. [15, § 9.1]). The eigenvalues λ^2 of (4.1a, b) are found from the equation $J_{\nu-1}(\lambda a) = 0$. If $j_{\nu-1}$ denotes the first positive zero of $J_{\nu-1}$, then the smallest positive eigenvalue is $\lambda^2 = (j_{\nu-1}/a)^2$; the corresponding eigenfunction is $x^\nu J_\nu(\lambda x)$.

Any function z that satisfies the differential inequality

$$Lz \geqq -f(z), \qquad (x, t) \in \Omega, \tag{4.2}$$

and the initial and boundary conditions $z(x, 0) = 0$, $z(0, t) = 0$, $z_x(a, t) = 0$, is a lower bound for u, by virtue of the strong maximum principle and the parabolic version of Hopf's lemma. We will seek a lower bound of the form

$$z(x, t) = x^\nu J_\nu(j_{\nu-1} x/a) g(t).$$

According to (4.2), we have

$$g'(t) + \left(\frac{j_{\nu-1}}{a}\right)^2 g(t) \leqq \frac{f(x^\nu J_\nu(j_{\nu-1}x/a)g(t))}{x^\nu J_\nu(j_{\nu-1}x/a)}. \tag{4.3}$$

The expression in the left member is independent of x. Since we are looking for a lower bound, we may take the infimum of the expression in the right member with

respect to x; the infimum exists, because $\nu > 0$. Let $G(g(t))$ satisfy the inequality

$$G(g(t)) \leqq \inf\left\{\frac{f(x^\nu J_\nu(j_{\nu-1}x/a)g(t))}{x^\nu J_\nu(j_{\nu-1}x/a)} : x \in [0, a]\right\}.$$

Then we can determine g as the solution of the initial value problem

$$g'(t) + (j_{\nu-1}/a)^2 g(t) = G(g(t)), \quad t > 0, \quad g(0) = 0. \tag{4.4}$$

Here, the initial condition comes from $u(x, 0) = 0$. As the function $x^\nu J_\nu(j_{\nu-1}x/a)$ is nondecreasing on $[0, a]$, it attains its maximum at $x = a$. Denoting this maximum by m, we have $m = a^\nu J_\nu(j_{\nu-1})$. Thus, an upper bound t_1 for the quenching time is found from the equation

$$mg(t_1) = c. \tag{4.5}$$

5. Example. We illustrate the results of the previous sections for $f(u) = (1-u)^{-1}$.

By Theorem 2, u quenches as $u(a, t)$ tends to 1. In this case, the inequality (4.3) is

$$g'(t) + \left(\frac{j_{\nu-1}}{a}\right)^2 g(t) \leqq \frac{1}{x^\nu J_\nu(j_{\nu-1}x/a)[1 - x^\nu J_\nu(j_{\nu-1}x/a)g(t)]}.$$

It follows from (4.4) and elementary calculus that

$$\frac{g'(t)}{g(t)} + \left(\frac{j_{\nu-1}}{a}\right)^2 = \begin{cases} [mg(t)(1-mg(t))]^{-1}, & 0 < g(t) \leqq (2m)^{-1}, \\ 4, & (2m)^{-1} < g(t) \leqq m^{-1}, \end{cases} \tag{5.1}$$

where $g(0) = 0$. The differential equations can be integrated by a separation of variables. Let t_0 denote the time when $g(t_0) = (2m)^{-1}$. Integrating the first of the equations (5.1) from zero to t_0, we obtain

$$t_0 = \frac{a}{j_{\nu-1}}\left[4 - \left(\frac{j_{\nu-1}}{a}\right)^2\right]^{-1/2} \tan^{-1}\left\{\frac{j_{\nu-1}}{a}\left[4 - \left(\frac{j_{\nu-1}}{a}\right)^2\right]^{-1/2}\right\} - \frac{1}{2}\left(\frac{a}{j_{\nu-1}}\right)^2 \ln\left[1 - \left(\frac{j_{\nu-1}}{2a}\right)^2\right]. \tag{5.2}$$

Next, integrating the second of the equations (5.1) from t_0, we obtain

$$g(t) = (2m)^{-1} \exp\left\{\left[4 - \left(\frac{j_{\nu-1}}{a}\right)^2\right](t - t_0)\right\}. \tag{5.3}$$

According to (4.5), an upper bound t_1 of the quenching time is given by $mg(t_1) = 1$. Using (5.3), we find $\exp\{[4 - (j_{\nu-1}/a)^2](t_1 - t_0)\} = 2$, from which we obtain

$$t_1 = t_0 + \frac{\ln 2}{4 - (j_{\nu-1}/a)^2}. \tag{5.4}$$

We deduce from (5.2) that $4 - (j_{\nu-1}/a)^2 > 0$. Hence, u quenches when $a > \frac{1}{2}j_{\nu-1}$. In particular, when $b = 0$, $\nu = \frac{1}{2}$ and $J_{-1/2}(z) = [2/(\pi z)]^{1/2} \cos z$, so $j_{-1/2} = \frac{1}{2}\pi$. Thus, u

TABLE 1
Critical length a^* for four values of b.

b	ν	$\frac{1}{2}j_{\nu-1}$	a^*
0.40000	0.30000	0.58570	0.57840
0.00000	0.50000	0.78540	0.76515
−0.40000	0.70000	0.96140	0.92314
−1.00000	1.00000	1.20241	1.12927

quenches if $a > \frac{1}{4}\pi$. This result agrees with Walter's conclusion [14] that $l^* \leqq \frac{1}{2}\pi$ for (1.1a, b). The solution quenches for $a = \frac{1}{2}\pi$; (5.2) and (5.4) give the following estimate for the quenching time: $t_1 = \pi/6\sqrt{3} + \ln(2^{4/3}/\sqrt{3}) = 0.67719$ (to five decimal places).

Using the procedure of § 3, we have determined a^* to five decimal places for various values of b. We started the algorithm with the estimate $A = \frac{1}{2}j_{\nu-1} - 0.1$ of a^*, since we already knew that u quenched if $a > \frac{1}{2}j_{\nu-1}$. The results are given in Table 1.

We note that $2a^* = 1.5303$ (to four decimal places) if $b = 0$, in agreement with the result of Acker and Walter [1] for the initial boundary value problem (1.1a, b).

Acknowledgment. The authors thank Professor Man Kam Kwong for helpful discussions.

GLOBAL SOLUTIONS AND LONG-TIME BEHAVIOR TO A FITZHUGH–NAGUMO MYELINATED AXON MODEL*

PEI-LI CHEN† AND JONATHAN BELL†‡

Abstract. A class of problems of the following form is considered:

$$u_t = u_{xx} - gu, \qquad x \in \mathbb{R}\backslash Z,$$
$$u_t = u_x(n+, t) - u_x(n-, t) + f(u) - w, \qquad x = n \in Z,$$
$$w_t = \sigma u - \gamma w, \qquad x = n \in Z.$$

In particular, the existence of solutions to the Cauchy problem is proved and the time evolution of solutions to the problem is studied. Such a system models an infinite, myelinated axon with discrete, excitable nodes spaced unit distance apart, and the model dynamics are of Fitzhugh-Nagumo type.

Key words. myelinated axon, Fitzhugh-Nagumo, reaction-diffusion equation

AMS(MOS) subject classifications. 35A05, B40, 92A05

1. Introduction. There has been considerable analytical work done on axon models. Much of this work has been done on models representing an unmyelinated axon that leads to a reaction-diffusion equation, for conservation of current, coupled to one or more ordinary differential equations. A particular form of model that has proved tractable to work with is the so-called Fitzhugh–Nagumo model (see, e.g., [7], [9] and references therein). Particular questions addressed analytically have been the existence and stability of action potentials (traveling wave solutions), as well as various long-time behavior of the solutions.

Myelinated axons, which are much more prevalent in human anatomy than unmyelinated axons, have also been modeled, but analytically such models have been studied much less. Some asymptotic behavior has been considered in the simplest models in [2]–[4]. In such axons their membranes are wrapped in a sheath of lipoprotein, which insulates most of the axon. There are, however, intervals along the axon where gaps, called nodes of Ranvier, appear in the sheathing. This allows a conducting path to the excitable membrane of the axon. Myelination allows the axon to conduct pulses by exciting only a small percentage of membrane, thus permitting transmission at greatly reduced energy expenditure and higher speeds than comparably sized unmyelinated axons.

In this paper we analyze a myelinated axon version of the Fitzhugh–Nagumo model having the following form:

$$u_t = u_{xx} - gu, \qquad x \in \mathbb{R}\backslash Z, \tag{1.1}$$
$$u_t = [u_x]_n + f(u) - w, \qquad x = n \in Z, \tag{1.2}$$
$$w_t = \sigma u - \gamma w, \qquad x = n \in Z. \tag{1.3}$$

Here u represents the transmembrane potential, and w is a "recovery" variable usually associated with long timescale ionic processes. The first equation represents diffusion

of potential in the myelinated segments, while equations (1.2)-(1.3) represent the dynamics at the nodes. The myelinated segments are scaled to have unit length, and the nodes are located at the integer values along the axis. Here $[u_x]_n$ means $\lim_{\varepsilon\to 0+}\{u_x(n+\varepsilon, t)-u_x(n-\varepsilon, t)\}$, and $f(u)$ is a current-voltage relation to be specified. Parameters g, σ, and γ are positive constants.

In § 2 we prove the existence of solutions to the Cauchy problem for (1.1)-(1.3) via Hilbert space methods. The arguments used in § 2 are similar to those used by Cosner in [5], who has studied a boundary value problem without the recovery process being included. In § 3 we study the long-time behavior of a class of problems of the form (1.1)-(1.3). In particular, we show via Lyapunov techniques when $u\to 0$ as $t\to\infty$ and when $u\to Q(x)\not\equiv 0$ as $t\to\infty$, where $Q(x)$ represents an excited state of the axon.

2. Existence. Consider problem (1.1)-(1.3) with $(u, u(\cdot, t), w)_{t=0}=(\varphi(x), \psi, h)$, where $\varphi(x)$ is continuous and bounded on $\mathbb{R}$ and $\lim_{x\to n}\varphi(x)=\psi(n)$. Here g, σ, and γ are fixed positive constants and $f(u)$ is assumed to be extendible to a function on $\mathbb{C}$ which, if viewed as a function of two variables, is considered C^1. In the usual FitzHugh-Nagumo case, f is taken to be the cubic $f(u)=bu(1-u)(u-a)$, $b>0$, and $a\in(0,1)$. Below our approach is to set up the appropriate machinery and show that the hypotheses of the Sobolev Existence Theorem are satisfied.

We define a linear operator $A: X\to H$ by

$$A(u, v, w)=(-u_{xx}+u, ([-u_x]_j+v^j)_Z, (w^j)_Z), \qquad u(j, \cdot)=v^j.$$

Here

$$H=\{(p, q, r): p\in L^2(\mathbb{R}\backslash Z), q\in l^2(\mathbb{R}), r\in l^2(\mathbb{R})\}$$

with the inner product

$$\langle(p_1, q_1, r_1), (p_2, q_2, r_2)\rangle_H=\int_{\mathbb{R}\backslash Z} p_1\bar{p}_2+\Sigma_Z(q_1^i\bar{q}_2^i+r_1^i\bar{r}_2^i)$$

and

$$X=\{(p, q, r)\in H: p', p''\in L^2(\mathbb{R}\backslash Z), p' \text{ is absolutely continuous on } (j-1, j) \text{ for each } j\in Z, ([p']_j)_Z\in l^2, \lim_{x\to j} p(x)=q^j\}.$$

H is a complete complex Hilbert space and X is dense in H. For the analysis we need another subspace in H, namely

$$Y=\{(p, q, r)\in H: p'\in L^2(\mathbb{R}\backslash Z), p \text{ is absolutely continuous on } (j-1, j) \text{ for each } j\in Z, \lim_{x\to j} p(x)=q^j\}$$

with the inner product

$$\langle(p_1, q_1, r_1), (p_2, q_2, r_2)\rangle_Y=\int_{\mathbb{R}\backslash Z}(p_1\bar{p}_2+p_1'\bar{p}_2')+\Sigma_Z(q_1^j\bar{q}_2^j+r_1^j\bar{r}_2^j).$$

It follows that

$$W\subset Y\subset H$$

with

$$\|(u, v, w)\|_H\leqq\|(u, v, w)\|_Y \quad \text{for any } (u, v, w)\in Y.$$

We first show that A has a bounded inverse, so that A is closed (since dom $A = X$ is dense in H). This is equivalent to solving

$$A(u, v, w) = (p, q, r) \in H, \qquad (u, v, w) \in X \tag{2.1}$$

with $\|(u, v, w)\|_H \leqq K\|(p, q, r)\|_H$ for some constant K.

To solve (2.1) we first obtain a generalized solution in Y and then show that such a solution must belong to X.

When we choose a $(p, q, r) \in H$, for any $(x, y, z) \in Y$, since

$$\langle (x, y, z), (p, q, r)\rangle_H \leqq \|(x, y, z)\|_H \|(p, q, r)\|_H \leqq \|(x, y, z)\|_Y \|(p, q, r)\|_H,$$

$\langle (x, y, z), (p, q, r)\rangle_H$ defines a bounded linear functional on Y, so by the Riesz Representation Theorem, there exists a unique $(u, v, w) \in Y$ such that

$$\langle (x, y, z), (u, v, w)\rangle_Y = \langle (x, y, z), (p, q, r)\rangle_H. \tag{2.2}$$

Thus, for any given $(p, q, r) \in H$, we define $B: H \to Y \subset H$ by

$$B(p, q, r) = (u, v, w).$$

By (2.2),

$$\begin{aligned} \|B(p, q, r)\|_Y^2 &= \langle (u, v, w), (u, v, w)\rangle_Y = \langle (u, v, w), (p, q, r)\rangle_H \\ &\leqq \|(u, v, w)\|_Y \|(p, q, r)\|_H \\ &= \|B(p, q, r)\|_Y \|(p, q, r)\|_H. \end{aligned}$$

Therefore

$$\|B(p, q, r)\|_Y \leqq \|(p, q, r)\|_H,$$

$\|B\| \leqq 1$; that is, B is bounded.

It remains to show that B maps H into X and that any solution (u, v, w) to (2.2) in X satisfies $A(u, v, w) = (p, q, r) \in H$.

To prove B maps H into X, the analysis in [6, § I.15] can be used to conclude that $u|_{(a,b)} \in H^2[(a, b)]$ for any a, b with $j-1 < a < b < j$, $j \in Z$. This occurs provided $(u, v, w) \in Y$ satisfies (2.2) for a given $(p, q, r) \in H$, and there exists a constant C such that for any $\varphi \in C_0^\infty[(j-1, j)]$, we have

$$\left| \int_{(j-1,j)} \varphi' \bar{u}' \right| \leqq C\|\varphi\|_{L^2[(j-1,j)]}. \tag{2.3}$$

The inequality (2.3) is essentially the inequality (15.6) in [6, § I.15].

Choose $\varphi \in C_0^\infty(\mathbb{R})$ with supp $\varphi \subset [a, b] \subset (j-1, j)$, and let $\psi = (\psi^k)_Z$, $\eta = (\eta^k)_Z$ be such that $\psi^k = \eta^k = 0$ for all k; then

$$(\varphi, \psi, \eta) \in Y,$$

and (2.2) yields

$$\int_{(j-1,j)} \varphi' \bar{u}' = \int_{(j-1,j)} \varphi(\bar{p} - \bar{u}). \tag{2.4}$$

Hence, by Hölder's inequality,

$$\left| \int_{(j-1,j)} \varphi' \bar{u}' \right| \leqq (\|(p, q, r)\|_H + \|B(p, q, r)\|_H)\|\varphi\|_{L^2[(j-1,j)]}$$

since (p, q, r) is given and $B: H \to H$ is bounded, this establishes (2.3). Therefore, $u''|_{(a,b)} \in L^2(a, b)$ for any $[a, b] \subset (j-1, j)$. By taking complex conjugates in (2.4), we have

$$-\int_{(a,b)} u''\bar{\varphi} = \overline{\int_{(a,b)} \varphi'\bar{u}'} = \int_{(a,b)} \bar{\varphi}(p-u)$$

for any $\varphi \in C_0^\infty[(a, b)]$. By choosing a suitable φ and by (2.2) we also can conclude that $u'', u' \in L^2(\mathbb{R})$.

Since C_0^∞ is dense in L^2, for any $h \in L^2[(a, b)]$,

$$\int_{(a,b)} (-u'')\bar{h} = \int_{(a,b)} (p-u)\bar{h};$$

therefore,

$$-u'' = p-u \quad \text{or} \quad -u''+u = p \quad \text{on } (a, b);$$

hence

$$-u''+u = p \quad \text{on } (j-1, j)$$
$$-u''+u = p \quad \text{on } \mathbb{R}\backslash Z;$$

this is the first equation of (2.1).

Since $L^2[(j-1, j)] \subset L^1[(j-1, j)]$ it follows that u' is absolutely continuous on $(j-1, j)$ and that

$$u'(b)-u'(a) = \int_{(a,b)} u'' \quad \text{for any } (a, b) \subset (j-1, j).$$

Let $a \to j-1$ or $b \to j$ to see that $u'(j-1+)$ and $u'(j-)$ are well defined. Next we verify the last two equations in (2.1).

Let $(w_j, y_j, 0)$ be such that $y_j^k = \delta_{jk}$, and $w_j' = (1/h)\chi_{(j-h,j)}$ on $(j-h, j)$, $w_j' = -(1/h)\chi_{(j,j+h)}$ on $(j, j+h)$, and $w' = 0$ otherwise, where $h > 0$ is arbitrary. Then $w_j = (1/h)(x-j+h)$ on $(j-h, j)$, $w_j = -(1/h)(x-j-h)$ on $(j, j+h)$, and $w_j = 0$ otherwise. It follows that $(w_j, y_j, 0) \in Y$, and (2.2) yields

$$\left(\frac{1}{h}\right)\int_{(j-h,j)} u' + \left(\frac{1}{h}\right)\int_{(j-h,j)} (x-j+h)u - \left(\frac{1}{h}\right)\int_{(j,j+h)} u' - \left(\frac{1}{h}\right)\int_{(j,j+h)} (x-j-h)u + v^j$$

(2.5)

$$= \left(\frac{1}{h}\right)\int_{(j-h,j)} (x-j+h)p - \left(\frac{1}{h}\right)\int_{(j,j+h)} (x-j-h)p + q^j.$$

Noting that

$$\left(\frac{1}{h}\right)\int_{(j-h,j)} u' = \left(\frac{1}{h}\right)[u(j)-u(j-h)] \to u'(j-),$$

$$\left(\frac{1}{h}\right)\int_{(j,j+h)} u' \to u'(j+) \quad \text{as } h \to 0,$$

and $|(1/h)\int_{(j-h,j)} (x-j+h)w| \leqq \int_{(j-h,j)} |w| \to 0$ as $h \to 0$ for any $w \in l^2(\mathbb{R})$, we may let $h \to 0$ in (2.5), to obtain the equation

$$u'(j-)-u'(j+)+v^j = q^j,$$

which is the second equation of (2.1).

Choose $(0, 0, z_j) \in Y$, with $z_j^k = \delta_{jk}$, substitute this into (2.2), i.e.,

$$\langle (0, 0, z_j), (u, v, w) \rangle_Y = \langle (0, 0, z_j), (p, q, r) \rangle_H ;$$

hence $w^j = r^j$, and so we have the third equation.

Thus B is a map from H to X, and for any $(p, q, r) \in H$, $B(p, q, r) = (u, v, w)$, (u, v, w) satisfies (2.3) and $AB(p, q, r) = (p, q, r)$ and also by the construction we have $BA(u, v, w) = (u, v, w)$ for any $(u, v, w) \subset X$.

Since $B = A^{-1}$ is a bounded operator defined on all of H, $X = \operatorname{dom} A$ is dense in H, B is linear, and $\|B\|_H \neq 0$, so $\|B\|_X = \|B\|_H$ and $\|A\|_X = \|B\|_X^{-1} = \|B\|_H^{-1}$. A is a closed, bounded operator, so we have proved the following lemma.

LEMMA 1. *The operator A defined by $A(u, v, w) = (-u_{xx} + u, (-[u_x]_j + v^j)_Z, (w^j)_Z)$ with $\operatorname{dom} A = X$ is a closed operator from X to H with $A^{-1} : H \to H$ bounded.*

To apply semigroup theory to our nonlinear problem, we need to show that the operator A satisfies

$$\|(\lambda - A)^{-1}\| \leqq C/(1 + |\lambda|) \quad \text{for } \operatorname{Re} \lambda \leqq 0 \tag{2.6}$$

for some constant $C > 0$, where $\| \cdot \|$ denotes the operator norm on $B(H)$. Let $\theta(A) \subset \mathbb{C}$ be given by

$$\theta(A) = \{ \langle A(u, v, w), (u, v, w) \rangle_H : (u, v, w) \in \operatorname{dom} A, \|(u, v, w)\|_H = 1 \}$$

and let

$$\Gamma = \operatorname{cl}(\theta(A)), \qquad \Delta = \mathbb{C} \backslash \Gamma.$$

Choosing $\|(u, v, w)\|_H = 1$, we have

$$\begin{aligned} \langle A(u, v, w), (u, v, w) \rangle_H &= \int_{\mathbb{R} \backslash Z} (u'' + u)\bar{u} + \Sigma_Z ((-[u']_j + v^j)\bar{v}^j + w^j \bar{w}^j) \\ &= \int_{\mathbb{R} \backslash Z} (|u'|^2 + |u|^2) + \Sigma_Z u'(j+)\bar{u}(j+) - \Sigma_Z u'(j-)\bar{u}(j-) \\ &\quad - \Sigma_Z [u']_j \bar{v}^j + \Sigma_Z (|v^j|^2 + |w^j|^2); \end{aligned}$$

here $u' = u_x$, $u'' = u_{xx}$. Since

$$u(j+) = u(j-) = v^j \quad \text{for } (u, v, w) \in X$$

and

$$u'(j+) - u'(j-) = [u']_j,$$

then

$$\begin{aligned} \langle A(u, v, w), (u, v, w) \rangle_H &= \int_{\mathbb{R} \backslash Z} (|u'|^2 + |u|^2) + \Sigma_Z (|v^j|^2 + |w^j|^2) \\ &= \|(u, v, w)\|_Y^2 \geqq \|(u, v, w)\|_H^2 = 1. \end{aligned}$$

Now $\theta(A) \subset [1, \infty)$ and $\Gamma \subset [1, \infty)$, and $\Delta = \mathbb{C}/\Gamma$ is connected in $\mathbb{C}$ since $A^{-1} \in B(H)$ and A has deficiency zero on Δ. Later we will use the following lemma, which appears in [5], and which is a special case of Theorem 3.2 of [8, Chap. V].

LEMMA 2. *Suppose that A is closed and Δ is connected. For $\lambda \in \Delta$, $A-\lambda$ has nullity zero and constant deficiency. If the deficiency of $A-\lambda$ is zero, then Δ is contained in the resolvent set of A and*

$$\|(\lambda - A)^{-1}\| \leqq 1/\operatorname{dist}(\lambda, \Gamma) \tag{2.7}$$

where $\operatorname{dist}(\lambda, \Gamma)$ *is the distance from* λ *to* Γ *in* $\mathbb{C}$.

By (2.7) for $\operatorname{Re}\lambda \leqq 0$, if we suppose $\lambda = a + b\vec{i}$, then we can easily conclude that $\operatorname{dist}(\lambda, \Gamma) \geqq (1+\lambda)/2$; hence A satisfies (2.6).

To prove the solution of (1.1)-(1.3) exists, we rewrite (1.1)-(1.3) as follows:

$$\begin{aligned} &u_t - u_{xx} + u = (1-g)u, \\ &v_t^j - [u_x]_j + v^j = v^j + f(v^j) - w^j, \\ &w_t^j + w^j = (1-\gamma)w^j + \sigma v^j, \\ &(u, v, w)|_{t=0} = (\varphi, \psi, \eta), \end{aligned} \tag{2.8}$$

and let

$$F(t, (u, v, w)) = ((1-g)u, (v^j + f(v^j) - w^j)_Z, ((1-\gamma)w^j + \sigma v^j)_Z).$$

Then (2.8) can be written abstractly as

$$\frac{d}{dt}(u, v, w) + A(u, v, w) = F(t, (u, v, w)), \tag{2.9}$$

$$(u, v, w)|_{t=0} = (\varphi, \psi, \eta). \tag{2.10}$$

Here we require that

$$(\varphi, \psi, \eta) \in \operatorname{dom} A = X. \tag{2.11}$$

Next, we use the following lemma (see the Sobolev theorem in [6]) to prove (2.9)-(2.11) has a solution.

LEMMA 3. *Let A be a closed linear operator on a Banach space E such that* (2.7) *holds. Suppose that $F(t, p)$ is a function on $[0, T_0] \times E$ such that for some constants $\alpha, \eta \in (0, 1)$ and for any $R > 0$ there exists a constant $C(R)$ for which*

$$\|F(t_1, A^{-\alpha}p_1) - F(t_2, A^{-\alpha}p_2)\|_E \leqq C(R)[|t_1 - t_2|^\eta + \|p_1 - p_2\|_E] \tag{2.12}$$

for all $t_1, t_2 \in [0, T_0]$, $p_1, p_2 \in E$ with $\|p_1\|_E, \|p\|_E < R$. Then for any $p_0 \in \operatorname{dom}(A)$ and each $R > \|A^\alpha p_0\|_E$, there exists a $t^* = t^*(R, \|A^\alpha p_0\|_E) > 0$ such that the problem

$$\frac{dp}{dt} + Ap = F(t, p), \qquad p(0) = p_0 \tag{2.13}$$

has a unique solution in $[0, t^*]$. Furthermore, if there exists a constant $R' > 0$ such that for any solution p of (2.13) *in $[0, T_1]$, $T_1 \leqq T_0$, we have*

$$\|Ap\|_E < R',$$

then we may choose $R > R'$ and thus apply the local existence assertion to $[0, t^*]$, $[t^*, 2t^*]$, and so on until $[0, T_0]$ is exhausted.

Since the operator A in (2.13) was shown to be closed on X and to satisfy (2.7), we need only establish (2.12) for the function F in (2.9) to conclude the local existence of a solution to (2.1). Let

$$(x_k, y_k, z_k) = A^{-\alpha}(u_k, v_k, w_k) \quad \text{for } k = 1, 2.$$

If $\|(u_k, v_k, w_k)\|_H < R$ for $k = 1, 2$, then

$$|y_k^j| \leqq \|y_k\|_{l^2} \leqq \|(x_k, y_k, z_k)\|_H \leqq \|A^{-\alpha}\| R;$$

so

$$\begin{aligned}
\|(f(y_1^j) - f(y_2^j))_Z\|_{l^2} &\leqq \sup_{|y| \leq \|A^{-\alpha}\| R} |f'(y)| \, \|y_1 - y_2\|_{l^2} \\
&\leqq C_0(R) \|(x_1 - x_2, y_1 - y_2, z_1 - z_2)\|_H \\
&\leqq C_0(R) \|A^{-\alpha}\| \, \|(u_1, v_1, w_1) - (u_2, v_2, w_2)\|_H,
\end{aligned}$$

$$\begin{aligned}
&\|(y_1^j - y_2^j + f(y_1^j) - f(y_2^j) - (z_1^j - z_2^j))_Z\|_{l^2} \\
&\qquad \leqq (C_0(R) + 2) \|A^{-\alpha}\| \, \|(u_1, v_1, w_1) - (u_2, v_2, w_2)\|_H \qquad (2.14) \\
&\qquad = C_1(R) \|(u_1, v_1, w_1) - (u_2, v_2, w_2)\|_H.
\end{aligned}$$

Then

$$\begin{aligned}
&\|F(t_1, A^{-\alpha}(u_1, v_1, w_1)) - F(t_2, A^{-\alpha}(u_2, v_2, w_2))\|_H \\
&\quad = \|F(t_1, (x_1, y_1, z_1)) - F(t_2, (x_2, y_2, z_2))\|_H \\
&\quad = \|(1 - g)(x_1 - x_2), (y_1^j - y_2^j + f(y_1^j) - f(y_2^j) - (z_1^j - z_2^j))_Z, \\
&\qquad\qquad ((1 - \gamma)(z_1^j - z_2^j) + \sigma(y_1^j - y_2^j))_Z\|_H \qquad (2.15) \\
&\quad \leqq |1 - g| \, \|(x_1 - x_2, 0, 0)\|_H \\
&\qquad + \|(0, (y_1^j - y_2^j + f(y_1^j) - f(y_2^j) - (z_1^j - z_2^j))_Z, 0)\|_H \\
&\qquad + |1 - \gamma| \, \|(0, 0, z_1^j - z_2^j)\|_H + \sigma \|(0, 0, y_1^j - y_2^j)_Z\|_H,
\end{aligned}$$

since

$$\begin{aligned}
\|(x, 0, 0)\|_H &\leqq \|(x, y, z)\|_H, \\
\|(0, y, 0)\|_H &\leqq \|(x, y, z)\|_H, \\
\|(0, 0, z)\|_H &\leqq \|(x, y, z)\|_H.
\end{aligned}$$

From (2.14) and (2.15)

$$\begin{aligned}
&\|F(t_1, A^{-\alpha}(u_1, v_1, w_1)) - F(t_2, A^{-\alpha}(u_2, v_2, w_2))\|_H \\
&\quad \leqq (|1 - g| + C_1(R) + |1 + \gamma| + \sigma) \|A^{-\alpha}\| \, \|(u_1, v_1, w_2) - (u_2, v_2, w_2)\|_H. \qquad (2.16)
\end{aligned}$$

Hence we have the local existence of a unique solution to (2.9)-(2.11).

To obtain the global existence we must bound $\|A(u, v, w)\|_H$ for any solution $P = (u, v, w)$ to (2.9)-(2.11). It is sufficient to bound $\|(u, v, w)\|_H$, and $\|(u_t, v_t, w_t)\|$, since, if $\|(u, v, w)\|_H \leqq M$, then $|v^j| \leqq M$ and

$$|f(v^j)| \leqq \sup_{|y| \leqq M} |f'(y)| |v^j|.$$

Hence $f(v^j)$ is bounded provided $\sup_{|y| \leqq M} |f'(y)|$ is bounded.

Now the idea is to construct a Lyapunov function and prove that $\|(u, v, w)\|_H$ and $\|(u_t, v_t, w_t)\|$ are bounded. Let

$$E(t) = (\|(u, v, w)\|_H^2 + \|(u, v, w)_t\|_H^2)/2.$$

If we only consider that u, $(v^j)_Z$, $(w^j)_Z$ are real functions, then

$$
\begin{aligned}
E'(t) &= \int_{\mathbb{R}} (uu_t + u_t u_{tt}) + \Sigma_Z (v_t^j v_{tt}^j + v_t^j v^j + w^j w_t^j + w_t^j w_{tt}^j) \\
&= \int_{\mathbb{R}} u(u_{xx} - gu) + u_t(u_{xxt} - gu_t) \\
&\quad + \Sigma_Z \{ v_t^j [u_{xt}]_j + f'(v^j)|v_t^j|^2 - w_t^j v_t^j + v^j [u_x]_j + f(v^j) v^j - w^j v^j \\
&\qquad - \gamma |w^j|^2 + \sigma v^j w^j - \gamma |w_t^j|^2 + \sigma v_t^j w_t^j \} \qquad (2.17) \\
&= -\int_{\mathbb{R}} (u_x^2 + gu^2 + u_{tx}^2 + gu_t^2) \\
&\quad + \Sigma_Z \{ f'(v^j)|v_t^j|^2 + f'(\theta v^j)|v^j|^2 + (\sigma - 1) w_t^j v_t^j + (\sigma - 1) v^j w^j \\
&\qquad - \gamma((w^j)^2 + (w_t^j)^2) \} \\
&= I_1 + I_2,
\end{aligned}
$$

where

$$
I_1 = -\int_{\mathbb{R}} (u_x^2 + gu^2 + u_{xt}^2 + gu_t^2),
$$

$$
I_2 = \Sigma_Z \{ f'(v^j)|v_t^j|^2 + (\sigma - 1) w_t^j v_t^j - \gamma |w_t^j|^2 + f'(\theta v^j)|v^j|^2 + (\sigma - 1) v^j w^j - \gamma |w^j|^2 \}.
$$

Suppose there exists a positive constant $k_1 > 0$ such that

$$
\sup_{y \in \mathbb{R}} (f'(y)) = k_1; \qquad (2.18)
$$

then

$$
I_2 \leqq \Sigma_Z \{ k_1 (|v^j|^2 + |v_t^j|^2) + (\sigma - 1)(v^j w^j + v_t^j w_t^j) \}.
$$

By Cauchy's inequality, we can find another constant $k_2 > 0$, which makes

$$
I_2 \leqq k_2 \Sigma_Z \{ |w_t^j|^2 + |v_t^j|^2 + |w^j|^2 + |v^j|^2 \};
$$

hence

$$
E'(t) \leqq k_2 E(t),
$$

which implies

$$
E(t) \leqq A E^{k_2 t} \qquad (2.19)
$$

for some constant A.

Since we have already proved the local existence to (2.9)-(2.11) in $[0, T_1]$ for $T_1 \leqq T_0$, by (2.19) we know that $\|(u, v, w)\|_H$, $\|(u, v, w)_t\|_H$ are bounded in $[0, T_0]$. Hence there exists an $R' > 0$ such that $\|A(u, v, w)\|_H < R'$ for any solution of (2.9)-(2.11) in $[0, T_0]$. By using Lemma 3, (2.9)-(2.10) have a unique global solution in $[0, T_0]$. Since T_0 is arbitrary, we have the following theorem.

THEOREM. *If* $(\varphi_0, \psi_0, \eta_0) \in X$ *and condition* (2.18) *holds, then the problem* (2.1) *has a unique solution* $(u, v, w) \in X$ *for all* $t > 0$.

3. Long-time behavior of solutions. Suppose $u(x, t)$, $w^1(n, t)$ is the solution of the following system:

$$
u_t = u_{xx} - gu, \qquad x \in \mathbb{R} \setminus Z, \qquad (3.1)
$$

$$
u_t = [u_x]_n + F(u) - w^1, \qquad x = n \in Z, \qquad (3.2)
$$

$$
w_t^1 = \sigma u - \gamma w^1, \qquad x = n \in Z. \qquad (3.3)
$$

Here g, σ, and γ are positive constants and $F \in C^1(\mathbb{R})$ satisfies the condition that there exists an interval $(\alpha, \beta) \in \mathbb{R}$ and a constant $B > 0$, such that $B \leqq F'(y) < 0$ whenever $y \in (\alpha, \beta)$.

Let $Q(x)$, $w^2(n)$, for $x \in \mathbb{R}$ and $n \in Z$, be such that $(Q, (Q^j)_Z, (w^{2j})_Z)$ $(Q^j = \lim_{x \to j} Q(x))$ is a solution to the stationary problem

$$Q_{xx}(x) - gQ(x) = 0, \qquad x \in \mathbb{R} \setminus Z, \tag{3.4}$$

$$[Q_x(n)]_n + F(Q(n)) - w^2 = 0, \qquad x = n \in Z, \tag{3.5}$$

$$\sigma Q(n) - \gamma w^2(n) = 0, \qquad x = n \in Z. \tag{3.6}$$

We discuss the existence of such solutions in the next section.

Define

$$V(x, t) \equiv u(x, t) - Q(x), \qquad x \in \mathbb{R},$$

$$W(n, t) \equiv w^1(n, t) - w^2(n), \qquad n \in Z,$$

and

$$E_0(t) = \int_{\mathbb{R} \setminus Z} (V^2 + V_x^2)\, dx/2,$$

$$E(t) = \left[\int_{\mathbb{R} \setminus Z} (V^2 + aV_x^2)\, dx + \Sigma_Z b(W^2 + \sigma V^2) \right] \Big/ 2,$$

where

$$a = \min \left\{ 1, \frac{\gamma}{\sigma}, \frac{2}{B} \right\} \quad \text{and} \quad b = \frac{ag + 1}{\sigma}.$$

Suppose u, w^1, Q satisfy the following:

(i) $u(x, t)$ is C^3 in $x \in \mathbb{R} \setminus Z$, C^0 in $x \in \mathbb{R}$, and C^1 in $t \in \mathbb{R}^+$; u_t is C^0 in $x \in \mathbb{R}$; $Q(x)$ is C^3 in $x \in \mathbb{R} \setminus Z$, C^0 in $x \in \mathbb{R}$; $w^1(n, t)$ is C^1 in $t \in \mathbb{R}^+$ for each $n \in Z$.

(ii) There exists a $\delta > 0$ such that $-B \leqq F'(y) \leqq -a_1 < 0$ whenever $y \in (\alpha + \delta/2, \beta - \delta/2)$, the steady-state solution $Q(x) \in (\alpha + \delta, \beta - \delta)$ and $u(x, 0)$ satisfies $|u(x, 0) - Q(x)| < \delta/2$.

(iii) $E(t)$, $(d/dt)E(t)$ are uniformly convergent on $\mathbb{R}$, and suppose

$$\{E(0)\}^{1/2} < \delta\sqrt{a}/(2K),$$

where K is a constant satisfying

$$\sup_{x \in \mathbb{R}} |u(x, t) - Q(x)| \leqq K\{E_0(t)\}^{1/2}$$

(see [1, Lemma 5.15]).

In § 2 we have shown that if the initial data lies in X, so does the solution. In this section we desire a bit more smoothness to the solution, as given by (i). We suppose that given smooth enough initial data, that the resulting solution will be sufficiently smooth, then we can conclude the following theorem.

THEOREM. *If $u(x, t)$, $w^1(n, t)$, and $Q(x)$ satisfy the above conditions, then $u(x, t) \to Q(x)$ uniformly on $\mathbb{R}$ as $t \to \infty$, and $w^1(n, t) \to w^2(n)$ uniformly on Z as $t \to \infty$.*

Proof. By (2.1)-(2.3) and (2.4)-(2.5), $V(x, t)$ and $W(n, t)$ satisfy the following equations:

$$V_t = V_{xx} - gV, \qquad x \in \mathbb{R}\backslash Z, \tag{3.7}$$

$$V_t = [V_x]_n + F'(Q+\theta(u-Q))V - W, \qquad x = n \in Z, \tag{3.8}$$

$$W_t = \sigma V - \gamma W, \qquad x = n \in Z \tag{3.9}$$

where $\theta = \theta(x, t) \in (0, 1)$. Now consider $(d/dt)E(t)$:

$$\begin{aligned} E'(t) &= \int_{\mathbb{R}/Z} (VV_t + aV_xV_{xt})\,dx + \Sigma_Z[bWW_t + \sigma bVV_t] \\ &= \Sigma_Z \left\{ \int_n^{n+1} [V(V_{xx} - gV) + aV_x(V_{xx} - gV)_x]\,dx \right. \\ &\qquad \left. + bW(\sigma V - \gamma W) + \sigma bV([V_x]_n + F'(\xi(x))V - W) \right\}, \end{aligned}$$

where (3.1)-(3.3) has been used, and

$$\xi(x) = Q + \theta(u - Q).$$

We can put this in the following form:

$$E'(t) = -\int_{\mathbb{R}\backslash Z} (V_x^2 + \tilde{g}V^2 + aV_{xx}^2 + a\tilde{g}V_x^2)\,dx - \Sigma_Z\{\tilde{g}([V_x]_n, V) + h([V_x]_n, W)\},$$

where

$$\tilde{g}(x, y) = \frac{ax^2}{2} + aF'(\xi)xy + \sigma b(-F'(\xi))y^2,$$

$$h(x, y) = \frac{ax^2}{2} - axy - b\gamma y^2.$$

If $|u(x, t) - Q(x)| \leqq \delta/2$ and $Q(x) \in (a+\delta, b-\delta)$, then by (ii),

$$-B \leqq F'(\xi) \leqq -a_1 < 0;$$

so

$$\begin{aligned} \left(\frac{a}{2}\right)\sigma b(-F'(\xi)) &= \left(\frac{a}{2}\right)(ag+1)(-F'(\xi)) \\ &> \left(\frac{a}{2}\right)(-F'(\xi)). \end{aligned}$$

Since $a = \min\{\gamma/\sigma, 1, 2/B\}$,

$$1 \geqq \frac{aB}{2} \geqq \frac{a(-F'(\xi))}{2};$$

hence

$$\left(\frac{a}{2}\right)\sigma b(-F'(\xi)) \geqq \left[\frac{a(-F'(\xi))}{2}\right]^2;$$

$\tilde{g}(x, y)$ is positive definite, and there exists a $p > 0$ such that

$$\tilde{g}(x, y) \geqq p(x^2 + y^2) \quad \text{for all } (x, y) \in \mathbb{R}.$$

Similarly, since

$$\frac{ab\gamma}{2}=\frac{a\gamma(ag+1)}{2\sigma}$$

$$\geqq\frac{a^2(ag+1)}{2}>\frac{a^2}{4},$$

there exists a $q>0$, such that

$$h(x, y)\geqq q(x^2+y^2).$$

Therefore

$$E'(t)\leqq-\int_{\mathbb{R}\setminus Z}[(ag+1)V_x^2+gV^2+aV_{xx}^2]\,dx-\Sigma_Z\{p(V^2+aV_x^2)+q([V_x]_n^2+W^2)\}$$

$$\leqq-g\int_{\mathbb{R}/Z}(V^2+aV_x^2)\,dx-\Sigma_Z\{pV^2+qW^2\}.$$

Choose a constant $r_1>0$ such that

$$\frac{(ag+1)r_1}{2\sigma}\leqq p,\quad\frac{(ag+1)r_1}{2}\leqq q,\quad\frac{r_1}{2}\leqq g.$$

Then we have

$$E'(t)\leqq-r_1E(t).$$

Now we claim that

$$R(x, t)=|V(x, t)|=|u(x, t)-Q(x)|\leqq\delta/2\quad\text{for all } t\in\mathbb{R}^+.$$

By the initial condition, $R(0, t)<\delta/2$; so suppose there exists a $t^*>0$ such that $R(x_0, t^*)>\delta/2$ for some $x_0\in\mathbb{R}$. Define $T_1=\inf\{t>0\colon R(x, t)>\delta/2 \text{ for some } x\in\mathbb{R}\}$. Since $R(0, t)<\delta/2$ and $R(x_0, t^*)>\delta/2$, this T_1 exists, and $R(x, t)\leqq\delta/2$ whenever $t<T_1$. This means

$$Q(x)+\theta(u(x, t)-Q(x))\in(a+\delta/2, b-\delta/2);$$

so

$$F'(Q(x)+\theta(u(x, t)-Q(x)))\leqq-a_1<0\quad\text{for all } t<T_1.$$

This implies

$$E'(t)\leqq-r_1E(t)\quad\text{for all } t<T_1,$$

and so we have

$$E(T_1)\leqq E(0).$$

On the other hand,

$$\sup_{x\in\mathbb{R}}R(x, T_1)\leqq K\{E_0(T_1)\}^{1/2}$$

$$\leqq K/\sqrt{a}\{E(T_1)\}^{1/2}$$

$$\leqq K/\sqrt{a}\{E(0)\}^{1/2}<\delta/2.$$

This contradicts the assumption $R(x_0, T_1) \geqq \delta/2$. Therefore, such a point (x_0, T_1) does not exist, and so

$$R(x, t) = |u(x, t) - Q(x)| \leqq \delta/2 \quad \text{for all } t \in \mathbb{R}^+, \quad x \in \mathbb{R}.$$

Also

$$F'(Q(x) + \theta(u(x, t) - Q(x))) \leqq -a_1 < 0 \quad \text{for all } x \in \mathbb{R}, \quad t \in \mathbb{R}^+.$$

With

$$\frac{d}{dt} E(t) \leqq -r_1 E(t) \quad \text{for all } t \in \mathbb{R}^+,$$

we have $E(t) \to 0$ as $t \to \infty$, and since $\sup_{x \in \mathbb{R}} |u(x, t) - Q(x)| \leqq K\{E_0(t)\}^{1/2}$, we have $u(x, t) \to Q(x)$ uniformly on $\mathbb{R}$, as $t \to \infty$. Since

$$\frac{ag+1}{2\sigma} |w_1(n, t) - w_2(n)|^2 \leqq \{E(t)\}^{1/2} \quad \text{for all } n \in Z,$$

$$w_1(n, t) \to w_2(n) = \frac{\sigma}{\gamma} Q(n) \quad \text{uniformly on } Z \text{ as } t \to \infty.$$

This completes the proof.

As an example, consider the function

$$f(x) = x(x - \alpha)(1 - x) \quad \text{where } 0 < \alpha < 1 \text{ and } x \in [0, 1].$$

Now

$$f'(x) = -3x^2 + 2(1+\alpha)x - \alpha, \qquad f''(x) = -6x + 2(1+\alpha).$$

The root of $f''(x) = 0$ is $x = (1+\alpha)/3$ and so we have

$$f'\left(\frac{1+\alpha}{3}\right) = \max_{0 \leqq x \leqq 1} f'(x)$$

$$= \frac{1 + \alpha^2 - \alpha}{3} > 0.$$

Also, $f'(0) = -\alpha < 0$, $f'(1) = -1 + \alpha < 0$. The two roots of $f'(x) = 0$ are

$$x_1 = \frac{\alpha}{1 + \alpha + (1 + \alpha^2 - \alpha)^{1/2}}, \qquad x_2 = \frac{1 + \alpha + (1 + \alpha^2 - \alpha)^{1/2}}{3}.$$

If we choose $F(x) = f(x)$ in the theorem, then $F'(x) < 0$ whenever $x \in (0, x_1)$ or $x \in (x_2, 1)$, and, in fact,

$$-\max\{\alpha, 1 - \alpha\} \leqq F'(x) < 0 \quad \text{on } (0, x_1) \cup (x_2, 1).$$

Hence we have the following corollary.

COROLLARY. *If we choose the function* $F(y) = y(y - \alpha)(1 - y)$, $0 < \alpha < 1$ *and* $y \in [0, 1]$, *and for the interval* $(a, b) = (0, x_1)$ *or* $(a, b) = (x_2, 1)$, *then we have* $u(x, t) \to Q(x)$ *uniformly on* $\mathbb{R}$ *as* $t \to \infty$, *and* $w_1(n, t) \to (\sigma/\gamma) Q(n)$ *uniformly on* Z *as* $t \to \infty$.

If $(a, b) = (0, x_1)$, *it is the subthreshold long-time behavior. If* $(a, b) = (x_2, 1)$, *it is the superthreshold long-time behavior.*

4. Steady-state solutions. It remains to show the steady-state solution exists in the intervals $(0, x_1)$ or $(x_2, 1)$.

Considering u as a function of x, then (1.1)-(1.3) becomes

$$u_{xx} - gu = 0, \qquad x \in \mathbb{R} \setminus Z, \tag{4.1}$$

$$[u_x]_n + f(u) - \frac{\sigma}{\gamma} u = 0, \qquad x = n \in Z \tag{4.2}$$

where now we take the case $f(u) = u(u-\alpha)(1-u)$. In the steady-state case w is given by $w(n) = \sigma u(n)/\gamma$.

From (4.1), the general solution is

$$u(x) = [v_{j+1} \sinh \sqrt{g}(x-j) + v_j \sinh \sqrt{g}(j+1-x)]/\sinh\sqrt{g},$$
$$j \leqq x \leqq j+1, \quad j \in Z,$$

where $v_j = u(j)$, $j \in Z$. Letting $G = \sqrt{g}/\sinh(\sqrt{g})$, we have

$$[u_x]_n = G(v_{n+1} - 2\cosh\sqrt{g}\, v_n + v_{n-1}).$$

Substituting this expression in (4.2), we obtain

$$v_{j+1} - 2v_j + v_{j-1} + F(v_j) = 0 \tag{4.3}$$

where $F(v_j) = \{2(1-\cosh\sqrt{g}) + ((v_j - \alpha)(1-v_j) - \sigma/\gamma)/G\}v_j$.

First, we consider $\{v_j\}$ as a constant solution of (4.3), i.e., $v_j \equiv c > 0$ for $j \in Z$.

Then (4.3) becomes

$$\frac{\sigma}{\gamma} + 2G(\cosh\sqrt{g} - 1) = (c-\alpha)(1-c). \tag{4.4}$$

Let $c = x$ in (4.4) and consider the function

$$y(x) = x^2 - (1+\alpha)x + K$$

where $K = \alpha + 2(\cosh\sqrt{g} - 1)G + \sigma/\gamma$. Then the two roots of $y(x) = 0$ are

$$x_{\sigma/\gamma, g}(\alpha) = (1 + \alpha \pm ((1+\alpha)^2 - 4K)^{1/2})/2. \tag{4.5}$$

To have two distinct, real roots, we must have

$$(1+\alpha)^2 > 4K$$

or, equivalently,

$$(1-\alpha)^2 > 4\frac{\sigma}{\gamma} + 8G(\cosh\sqrt{g} - 1). \tag{4.6}$$

If α, σ, and γ satisfy $(1-\alpha)^2 > 4(\sigma/\gamma)$, since $\lim_{x\to 0}(x/\sinh x) = 1$, $\lim_{x\to 0}\cosh x = 1$, by (4.6) we can find a small $g_b > 0$, such that $y(x) = 0$ has two roots C_{1g}, C_{2g} whenever $0 < g < g_b$.

In this case, (4.1)-(4.2) has two solutions:

$$Q_{1g}(x) = C_{1g}R(x), \tag{4.7}$$

$$Q_{2g}(x) = C_{2g}R(x), \tag{4.8}$$

where

$$R(x) = [\sinh\sqrt{g}(x-j) + \sinh\sqrt{g}(j+1-x)]/\sinh\sqrt{g},$$
$$j \leqq x \leqq j+1, \qquad j \in Z$$

and

$$0 < C_{1g} < C_{2g} < 1.$$

Next, we use this result to see whether there is a solution $Q(x)$ of (4.1)-(4.2) satisfying the corollary in § 3.

Example. If we choose $\alpha = 2/3$, $\sigma/\gamma = 1/40$, and g is small enough, there exists a $Q_{2g}(x)$ that lies entirely in $(x_2, 1)$.

To show this, we see that

$$\begin{aligned} x_2|_{\alpha=2/3} &= (1+\alpha+(1+\alpha^2-\alpha)^{1/2})/3|_{\alpha=2/3} \\ &= (5+\sqrt{7})/9 \\ &\cong 0.8495279. \end{aligned}$$

From (4.5), since $\sigma/\gamma = 1/40$, we have

$$x_{1/40,g}(\tfrac{2}{3}) = (\tfrac{5}{3}+(\tfrac{1}{90}-8G(\cosh\sqrt{g}-1))^{1/2})/2.$$

When $g = 0$,

$$x_{1/40,0}(\tfrac{2}{3}) > 0.88603 > x_2|_{\alpha=2/3};$$

hence we can choose g small enough such that

$$x_{1/40,g}(\tfrac{2}{3}) > x_2|_{\alpha=2/3}.$$

That means there exists a $g^* > 0$ such that the above inequality holds whenever $0 \leqq g < g^*$. Let

$$C_g(\tfrac{1}{40}, \tfrac{2}{3}) = x_{1/40,g}(\tfrac{2}{3});$$

then

$$C_g(\tfrac{1}{40}, \tfrac{2}{3}) \in (x_2|_{\alpha=2/3}, 1),$$

and

$$Q(x) = C_g(\tfrac{1}{40}, \tfrac{2}{3})(\sinh\sqrt{g}(x-j)+\sinh\sqrt{g}(j+1-x))/\sinh\sqrt{g}, \qquad j \leqq x \leqq j+1$$

is a solution of (4.1)-(4.2).

Since

$$\begin{aligned} \min_{j\leqq x\leqq j+1} Q(x) &= Q\left(j+\frac{1}{2}\right) \\ &= C_g\left(\frac{1}{40}, \frac{2}{3}\right)\left(\frac{1}{\cosh\sqrt{g/2}}\right), \end{aligned}$$

there exists a g_* satisfying $g^* \geqq g_* > 0$ such that

$$\min_{j\leqq x\leqq j+1} Q(x) > x_2|_{\alpha=2/3} \quad \text{whenever } 0 \leqq g \leqq g_*.$$

Since

$$\max_{j\leqq x\leqq j+1} Q(x) = Q(j) = Q(j+1) = C_g(\tfrac{1}{40}, \tfrac{2}{3}) < 1,$$

we can conclude that

$$Q(x) \in [x_2|_{\alpha=2/3}, 1] \quad \text{for all } x \in \mathbb{R}$$

whenever $\alpha = 2/3$, $\sigma/\gamma = 1/40$ and $0 < g < g_*$.

THE CAUCHY PROBLEM FOR THE KORTEWEG-DE VRIES EQUATION WITH MEASURES AS INITIAL DATA*

YOSHIO TSUTSUMI†

Abstract. The Cauchy problem of the Korteweg-de Vries equation is considered with measures as initial data. Global weak solutions are constructed for any bounded positive Radon measure on $\mathbb{R}$.

Key words. Korteweg-de Vries equations, Miura transform

AMS(MOS) subject classification. 35Q20

1. Introduction and a main result. In this paper we consider the Cauchy problem for the Korteweg-de Vries equation

$$u_t + u_{xxx} - 6uu_x = 0, \quad t > 0, \quad x \in \mathbb{R}, \tag{1.1}$$

$$u(0, x) = \mu(x), \tag{1.2}$$

where $\mu(x)$ is a bounded positive Radon measure on $\mathbb{R}$.

Many papers cover the global existence of solutions for (1.1)-(1.2) (see, e.g., [1], [2], [4]-[8], [10]-[13], [17]-[18], [21], and [24]-[29]). Roughly speaking, the methods used to solve (1.1)-(1.2) can be divided into two categories. One is the inverse scattering method (see, e.g., [4]-[7], [10], [14], [17], [21], [24], and [25]) and the other is the energy (or L^2-theory) method (see, e.g., [1], [2], [11]-[13], [18], [22], and [26]-[29]). Recently, the smoothing property of solutions for (1.1)-(1.2) has attracted many mathematicians and (1.1)-(1.2) has been solved for irregular initial data. In [10], by the inverse scattering method, Kappeler shows that if the initial datum $\mu(x)$ is a real measure defined on the Borel sets on $\mathbb{R}$ and satisfies the decay condition at infinity

$$\int_{-\infty}^{\infty} (1+|x|)^N \, d|\mu|(x) < \infty, \qquad N \geqq 3, \tag{1.3}$$

then (1.1)-(1.2) has a global classical solution (see also Murray [5] and Sacks [21]). Here $|\mu|$ denotes the absolute variation of μ. On the other hand, by the energy method Kato [12] and Kruzhkov and Faminskii [13] showed that if the initial datum is in $L^2(\mathbb{R})$, then (1.1)-(1.2) has a global solution. In this paper we will prove the following theorem.

THEOREM 1.1. *Let $\mu(x)$ be a positive Radon measure on $\mathbb{R}$ such that*

$$\int_{-\infty}^{+\infty} d\mu(x) < \infty. \tag{1.4}$$

Then (1.1)-(1.2) *has a global weak solution $u(t, x)$ such that*

$$u(t, x) \in L^2((0, T) \times (-R, R)) \quad \textit{for any } T, R > 0, \tag{1.5}$$

$$u(t) \in L^\infty(0, \infty; H^{-1}(\mathbb{R})), \tag{1.6}$$

$$\iint_{\pi_0} (-u\varphi_t - u\varphi_{xxx} + 3u^2\varphi_x) \, dt \, dx = 0, \qquad \varphi \in C_0^\infty(\pi_0), \tag{1.7}$$

$$u(t) \to \mu \textit{ in } H^{-1}(\mathbb{R}) \ (\textit{a.e. } t \to +0), \tag{1.8}$$

where $\pi_0 = (0, \infty) \times \mathbb{R}$.

In Theorem 1.1 the condition of the positivity of $\mu(x)$ is a little strong, but the decay condition at infinity of the initial measure requires only the boundedness of the initial measure, that is, (1.4). If we use the inverse scattering method to solve (1.1)-(1.2), such a decay condition with weight as in (1.3) seems to be indispensable. On the other hand, the energy method cannot directly be applied to (1.1)-(1.2) with the initial datum not in $L^2(\mathbb{R})$.

Our proof is based on the energy method due to Kato [12] and Kruzhkov and Faminskii [13] and the Miura transform

$$u = v_x + v^2. \tag{1.9}$$

It is well known that if $v(t, x)$ is a smooth solution of the modified Korteweg-de Vries equation

$$v_t + v_{xxx} - 6v^2 v_x = 0, \quad t > 0, \quad x \in \mathbb{R}, \tag{1.10}$$

then the function $u(t, x)$ given by (1.9) is a solution of (1.1) (see, e.g., Miura [17]). Accordingly, we can expect that if for the initial measure μ a solution $v_0(x) \in L^2(\mathbb{R})$ exists that satisfies the equation

$$v_{0x} + v_0^2 = \mu \quad \text{in } H^{-1}(\mathbb{R}), \tag{1.11}$$

then (1.9) transforms the solution of (1.10) with $v(0) = v_0$ into the solution of the original problem (1.1)-(1.2).

Recently, many mathematicians have treated the existence problem of solutions for the related nonlinear evolution equations with measures as initial data. For example, McKean [16], Osada and Kotani [20], and Sznitman [23] study the existence and uniqueness of solutions for the Burgers equation

$$u_t + uu_x = \nu u_{xx}, \quad x \in \mathbb{R}, \quad u(0, x) = c\delta(x),$$

where $\nu, c > 0$. In [15] Liu and Pierre study the existence, uniqueness, and asymptotic behavior of solutions for the equation with no dissipativity and no dispersivity

$$u_t + f(u)_x = 0, \quad x \in \mathbb{R}, \quad u(0, x) = \delta(x).$$

In [9] Giga, Miyakawa, and Osada show the existence of solutions for the two-dimensional Navier-Stokes equation with measures as initial vorticity. In [3] Brezis and Friedman study the existence and nonexistence of solutions for the semilinear heat equation

$$u_t - \Delta u + u^p = 0, \quad x \in \mathbb{R}^n, \quad u(0, x) = c\delta(x),$$

where $c > 0$ (see also Niwa [19]).

Our plan in this paper is as follows. In § 2 we present two lemmas needed for the proof of Theorem 1.1. In § 3 we give the proof of Theorem 1.1.

We conclude this section with some notation used in the paper. We abbreviate $L^p(\mathbb{R})$ and $H^m(\mathbb{R})$ to L^p and H^m, respectively. We often use the notation $D = \partial/\partial x$. For $T \geqq 0$ we denote the set $(T, \infty) \times \mathbb{R}$ by π_T. For a positive T and a Hilbert space H, $C_w([0, T]; H)$ denotes the set of all weakly continuous functions from $[0, T]$ to H. We put

$$\rho(t, x) = \begin{cases} A \exp[-1/\{1-(t^2+x^2)\}], & t^2+x^2 < 1, \\ 0, & t^2+x^2 \geqq 1, \end{cases} \tag{1.12}$$

where A is a positive constant such that $\iint_{\mathbb{R}^2} \rho(t, x)\, dt\, dx = 1$. For $\varepsilon > 0$ we let $\rho_\varepsilon(t, x) = \varepsilon^{-2}\rho(\varepsilon^{-1}t, \varepsilon^{-1}x)$.

2. Lemmas. In this section we give two lemmas needed for the proof of Theorem 1.1.

We first show the following lemma concerning the solvability of the Riccati equation.

LEMMA 2.1. *Assume that $\mu(x)$ is a positive Radon measure on $\mathbb{R}$ satisfying* (1.4). *Then there exists a solution $u(x)$ in $L^2 \cap L^\infty$ of the equation*

$$u_x + u^2 = \mu \quad \text{in } H^{-1} \tag{2.1}$$

such that

$$\|u\|_{L^2}^2 \leqq \int_{\mathbb{R}} d\mu(x), \qquad \|u\|_{L^\infty} \leqq 2 \int_{\mathbb{R}} d\mu(x).$$

Proof. We divide the proof into two steps.

Step 1. We first show Lemma 2.1, when $\mu(x)$ is a nonnegative and C^∞ function on $\mathbb{R}$ with compact support. Then, we may let $\operatorname{supp} \mu(x) \subset [a, b]$ for some $a, b \in \mathbb{R}$.

We consider the following initial value problem:

$$u_x + u^2 = \mu, \quad x \in \mathbb{R}, \quad u(a) = 0. \tag{2.2}$$

By the unique local solvability theorem of the ordinary differential equation, we have the unique local solution $u(x)$ in C^1 of (2.2). In addition, since $\mu(x) \geqq 0$, the comparison theorem shows that as long as the solution $u(x)$ exists, $u(x)$ is nonnegative for $x \geqq a$. Since $\mu(x) = 0$ for $x \leqq a$, the solution of (2.2) exists for $x \leqq a$ and

$$u(x) = 0, \qquad x \leqq a. \tag{2.3}$$

We next prove by contradiction

$$0 \leqq u(x) \leqq \sup_{x \geqq a} \sqrt{\mu(x)}, \qquad x \geqq a. \tag{2.4}$$

We assume that an x_0 exists such that $x_0 > a$ and $u(x_0) > \sup_{x \geqq a} \sqrt{\mu(x)}$. Then we put

$$x_1 = \inf \left\{ x_1 \geqq a;\ u(y) > \sup_{x \geqq a} \sqrt{\mu(x)} \text{ for } x_1 < y < x_0 \right\}. \tag{2.5}$$

We note that unless $\mu(x)$ identically vanishes, then $x_1 < x_0$. Formulae (2.2) give us

$$u_x = -u^2 + \mu < 0, \qquad x_1 < x \leqq x_0, \tag{2.6}$$

which implies

$$u(x_1) > u(x_0). \tag{2.7}$$

On the other hand, the definition of x_1 and the continuity of $u(x)$ give us

$$\sup_{x \geqq a} \sqrt{\mu(x)} = u(x_1) < u(x_0), \tag{2.8}$$

which contradicts (2.7). This shows (2.4).

Formulae (2.4) imply that the solution $u(x)$ of (2.2) exists for $x \geqq a$. Since $\mu(x) = 0$ for $x \geqq b$, we have

$$u(x) = u(b)\{u(b)(x-b) + 1\}^{-1}, \qquad x \geqq b. \tag{2.9}$$

Formulae (2.3) and (2.9) show

$$u \in L^2 \cap L^\infty, \tag{2.10}$$

$$u(x) \to 0 \quad (x \to \pm\infty). \tag{2.11}$$

Therefore, integrating (2.2) on $\mathbb{R}$, we have

$$\|u\|_{L^2}^2 = \int_{\mathbb{R}} \mu(y)\, dy. \tag{2.12}$$

In addition, by (2.2) and (2.12), we have

$$\|Du\|_{L^1} \leqq \|u\|_{L^2}^2 + \int_{\mathbb{R}} \mu(y)\, dy \leqq 2 \int_{\mathbb{R}} \mu(y)\, dy. \tag{2.13}$$

Integrating (2.2) on $[z, x]$, we have

$$|u(x)| \leqq |u(z)| + \int_z^x u(y)^2\, dy + \int_z^x \mu(y)\, dy. \tag{2.14}$$

Letting $z \to -\infty$ in (2.14), we obtain

$$|u(x)| \leqq \|u\|_{L^2}^2 + \int_{\mathbb{R}} \mu(y)\, dy \leqq 2 \int_{\mathbb{R}} \mu(y)\, dy, \qquad x \in \mathbb{R}. \tag{2.15}$$

Thus, $u(x)$ is the desired solution of (2.1).

Step 2. By the assumptions of $\mu(x)$, we can choose a function sequence $\{f_n(x)\} \subset C_0^\infty(\mathbb{R})$ such that $f_n \geqq 0$, $\|f_n\|_{L^1} \leqq \int_{\mathbb{R}} d\mu(x)$ and $f_n \to \mu$ in H^{-1} $(n \to \infty)$. For each f_n, Step 1 gives us the solution $u_n(x)$ of the equation

$$Du_n + u_n^2 = f_n \quad \text{in } H^{-1} \tag{2.16}$$

satisfying

$$\|u_n\|_{L^2}^2 \leqq \int_{\mathbb{R}} d\mu(x), \tag{2.17}$$

$$\|Du_n\|_{L^1} \leqq 2 \int_{\mathbb{R}} d\mu(x), \tag{2.18}$$

$$\|u_n\|_{L^\infty} \leqq 2 \int_{\mathbb{R}} d\mu(x). \tag{2.19}$$

Formulae (2.17)-(2.19) and the standard compactness argument show that a subsequence $\{u_{n_k}(x)\} \subset \{u_n(x)\}$ and a limit function $u(x)$ exist such that

$$u \in L^2 \cap L^\infty, \tag{2.20}$$

$$u_{n_k} \to u \quad \text{weakly in } L^2, \tag{2.21}$$

$$u_{n_k} \to u \quad *\text{-weakly in } L^\infty, \tag{2.22}$$

$$u_{n_k}(x) \to u(x) \quad \text{a.e. on } \mathbb{R}, \tag{2.23}$$

$$Du + u^2 = \mu \quad \text{in } H^{-1}, \tag{2.24}$$

$$\|u\|_{L^2}^2 \leqq \int_{\mathbb{R}} d\mu(x), \qquad \|u\|_{L^\infty} \leqq 2 \int_{\mathbb{R}} d\mu(x). \tag{2.25}$$

These complete the proof of Lemma 2.1. □

Remark 2.1. The solution of (2.1) is not necessarily unique. For example, when $\mu(x) = \delta(x)$, for $-\infty \leqq c \leqq -1$ all the functions $u(x; c)$ defined by

$$u(x; c) = \begin{cases} (c+1)/\{(c+1)x + c\}, & x > 0, \\ 1/(x+c), & x < 0, \end{cases} \tag{2.26}$$

are the solutions of (2.1).

We next consider the Cauchy problem of the modified Korteweg-de Vries equation

$$v_t + v_{xxx} - 6v^2 v_x = 0, \quad t > 0, \quad x \in \mathbb{R}, \tag{2.27}$$

$$v(0, x) = v_0(x), \qquad x \in \mathbb{R}. \tag{2.28}$$

We have the following result.

LEMMA 2.2. *For any $v_0 \in L^2$ there exists a solution $v(t)$ of* (2.27)-(2.28) *satisfying*

$$v(t) \in C_w([0, \infty); L^2) \cap L^2(0, T; H^1(-R, R)) \quad \textit{for any } T, R > 0, \tag{2.29}$$

$$\iint_{\pi_0} (-v\varphi_t - v\varphi_{xxx} + 2v^3\varphi_x)\, dt\, dx = 0, \qquad \varphi(t, x) \in C_0^\infty(\pi_0), \tag{2.30}$$

$$v(t) \to v_0 \quad \textit{in } L^2 \quad (t \to +0), \tag{2.31}$$

$$\|v(t)\|_{L^2} \leqq \|v_0\|_{L^2}, \qquad t \geqq 0. \tag{2.32}$$

Since the proof of Lemma 2.2 is essentially identical to that of Theorem 7.1 in [12] and Theorem 2.1 in [13], we omit the proof of this lemma.

3. Proof of Theorem 1.1. In this section we prove Theorem 1.1. For that purpose, we only have to give the following proposition.

PROPOSITION 3.1. *Let $\mu(x)$ be a Radon measure on $\mathbb{R}$ satisfying* (1.4). *We assume that for $\mu(x)$ there exists a solution $v_0 \in L^2$ of the equation*

$$Dv_0 + v_0^2 = \mu \quad \textit{in } H^{-1}. \tag{3.1}$$

By Lemma 2.2 *we can construct the solution $v(t)$ of* (2.27)-(2.28) *for the above v_0. We put*

$$u = Dv + v^2. \tag{3.2}$$

Then $u(t, x)$ is the solution of (1.1)-(1.2) *satisfying* (1.5)-(1.8).

Proof. Let $\varphi(t, x) \in C_0^\infty(\pi_0)$. We set

$$\varepsilon_0 = \operatorname{supp}\{T > 0;\ \varphi(t, x) = 0 \text{ on } [0, T] \times \mathbb{R}\}.$$

Let ε be a constant with $0 < \varepsilon < \varepsilon_0/4$ and let $\gamma = \varepsilon_0/2$. For the solution $v(t)$ of (2.27)-(2.28) we put

$$v_\varepsilon(t, x) = \rho_\varepsilon * v = \iint_{\pi_0} \rho_\varepsilon(t - s, x - y) v(s, y)\, ds\, dy, \quad (t, x) \in \pi_\gamma, \quad 0 < \varepsilon < \gamma/2. \tag{3.3}$$

We note that for each $(t, x) \in \pi_\gamma$

$$\rho_\varepsilon(t - s, x - y) \in C_0^\infty(\pi_0), \qquad 0 < \varepsilon < \gamma/2 \tag{3.4}$$

as a function of s and y and that $v_\varepsilon(t, x)$ is in $C^\infty(\pi_\gamma)$ for $0 < \varepsilon < \gamma/2$. We put $u_\varepsilon = Dv_\varepsilon + v_\varepsilon^2$. Then we have

$$\begin{aligned} \frac{\partial}{\partial t} u_\varepsilon + D^3 u_\varepsilon - 6u_\varepsilon D u_\varepsilon &= (D + 2v_\varepsilon)\left(\frac{\partial}{\partial t} v_\varepsilon + D^3 v_\varepsilon - 6\rho_\varepsilon * (v^2 Dv)\right) \\ &\quad + 6(D + 2v_\varepsilon)(\rho_\varepsilon * (v^2 Dv) - v_\varepsilon^2 D v_\varepsilon), \qquad (t, x) \in \pi_\gamma. \end{aligned} \tag{3.5}$$

By (3.4) and (2.30) we conclude that the first term at the right-hand side of (3.5) vanishes identically. By (3.5) and integration by parts we have

$$\begin{aligned}&\iint_{\pi_0}(-u_\varepsilon\varphi_t-u_\varepsilon\varphi_{xxx}+3u_\varepsilon^2\varphi_x)\,dt\,dx\\&=6\iint_{\pi_0}\{\rho_\varepsilon*(v^2Dv)-v_\varepsilon^2Dv_\varepsilon\}(-D\varphi+2v_\varepsilon\varphi)\,dt\,dx\\&=2\iint_{\pi_0}(\rho_\varepsilon*v^3-v_\varepsilon^3)(D^2\varphi-2\varphi Dv_\varepsilon-2v_\varepsilon D\varphi)\,dt\,dx.\end{aligned}\tag{3.6}$$

Since (2.29) and the Gagliardo-Nirenberg inequality (see, e.g., [30, Thm. 10.1 in Part 1]) imply that $v\in L^6_{\mathrm{loc}}(\pi_\gamma)$, we obtain

$$Dv_\varepsilon\to Dv \quad \text{in } L^2_{\mathrm{loc}}(\pi_\gamma),\tag{3.7}$$

$$v_\varepsilon^2\to v^2 \quad \text{in } L^2_{\mathrm{loc}}(\pi_\gamma),\tag{3.8}$$

$$v_\varepsilon^3\to v^3 \quad \text{in } L^2_{\mathrm{loc}}(\pi_\gamma),\tag{3.9}$$

$$v_\varepsilon^4\to v^4 \quad \text{in } L^1_{\mathrm{loc}}(\pi_\gamma),\tag{3.10}$$

as $\varepsilon\to+0$. Since $u_\varepsilon=Dv_\varepsilon+v_\varepsilon^2$ and the support of φ is compact and included in π_γ, (3.7)-(3.10) give us

$$u_\varepsilon\to u \quad \text{in } L^2_{\mathrm{loc}}(\pi_\gamma),\tag{3.11}$$

$$u_\varepsilon^2\to u^2 \quad \text{in } L^1_{\mathrm{loc}}(\pi_\gamma),\tag{3.12}$$

$$\iint_{\pi_0}(\rho_\varepsilon*v^3-v_\varepsilon^3)(D^2\varphi-\varphi Dv_\varepsilon-v_\varepsilon D\varphi)\,dt\,dx\to 0,\tag{3.13}$$

as $\varepsilon\to+0$. Therefore, letting $\varepsilon\to+0$ in (3.6), we obtain by (3.11)-(3.13)

$$\iint_{\pi_0}(-u\varphi_t-u\varphi_{xxx}+3u^2\varphi_x)\,dt\,dx=0.\tag{3.14}$$

Since φ is an arbitrary function in $C_0^\infty(\pi_0)$, (3.14) shows (1.7). Formulae (2.29) and (2.32) imply (1.5)-(1.6), and (1.8) follows directly from (2.29) and (2.31). This completes the proof of Proposition 3.1. □

Now Theorem 1.1 follows immediately from Lemmas 2.1, 2.2, and Proposition 3.1.

Proof of Theorem 1.1. Let $\mu(x)$ be a positive Radon measure on $\mathbb{R}$ satisfying (1.4). Then by Lemma 2.1 we have the solution $v_0\in L^2\cap L^\infty$ of (3.1). For the above v_0 we obtain by Lemma 2.2 the solution $v(t)$ of (2.27)-(2.28). Proposition 3.1 implies that the Miura transform (3.2) translates $v(t)$ into the solution $u(t)$ of (1.1)-(1.2) satisfying (1.5)-(1.8). This completes the proof of Theorem 1.1. □

Remark 3.1. The uniqueness of solutions satisfying (1.5)-(1.8) is an open problem, and it seems to be a very interesting one. When $\mu(x)=\delta(x)$, we have many different solutions of (3.1), as stated in Remark 2.1. For the different solutions of (3.1), there exist different solutions of (2.27)-(2.28). Does the Miura transform then translate all those different solutions of (2.27)-(2.28) into only one solution of (1.1)-(1.2) or not?

Acknowledgments. The author is grateful to Professors J. Ginibre and J. C. Saut for their kind encouragement and to Professor K. Chadan for his kind hospitality at Laboratoire de Physique Théorique et Hautes Energies, Orsay.

SOMMERFELD DIFFRACTION PROBLEMS WITH THIRD KIND BOUNDARY CONDITIONS*

F.-O. SPECK†§, R. A. HURD‡§, AND E. MEISTER†

Abstract. This paper continues earlier work on diffraction problems with first and second kind boundary conditions. New operator theoretic difficulties appear for third kind conditions corresponding to different behavior of the Fourier symbol matrix of the boundary operators at infinity. Compatibility conditions force another function space setting in order to obtain closed operators. Then well-posed problems can be solved by explicit Wiener-Hopf factorization using Khrapkov's method, which also yields the asymptotics near the origin.

Key words. diffraction problem, Wiener-Hopf operator, factorization, matrix function, Helmholtz equation

AMS(MOS) subject classifications. 47B35, 35J05, 45E10

1. Introduction. From the physical point of view, third kind conditions often make more sense than Dirichlet or Neumann conditions do [21]; for instance, think of the electromagnetic theory where impedance boundary conditions on a screen represent finite as opposed to perfect conductivity. We consider the problem $\mathcal{P}$ of finding

$$\begin{aligned} &u \in L^2(\mathbb{R}^2), \\ &u|_{\Omega^\pm} \in H^1(\Omega^\pm), \qquad \Omega^\pm: x_2 \gtrless 0, \\ &(\Delta + k^2)u = 0 \quad \text{in } \Omega^\pm, \end{aligned} \tag{1.1}$$

where $\operatorname{Im} k > 0$ holds and the Dirichlet data $u_0^\pm = u|_{x_2=\pm 0}$ and the Neumann data $u_1^\pm = \partial u/\partial x_2|_{x_2=\pm 0}$ satisfy

$$\begin{aligned} a_{11}u_0^- + a_{12}u_0^+ + a_{13}u_1^- + a_{14}u_1^+ &= h_1 \quad \text{on } \mathbb{R}_+, \\ a_{21}u_0^- + a_{22}u_0^+ + a_{23}u_1^- + a_{24}u_1^+ &= h_2 \quad \text{on } \mathbb{R}_+, \end{aligned} \tag{1.2}$$

and

$$\begin{aligned} u_0^+ - u_0^- &= 0 \quad \text{on } \mathbb{R}_-, \\ u_1^+ - u_1^- &= 0 \quad \text{on } \mathbb{R}_-. \end{aligned} \tag{1.3}$$

The constants k, $a_{jl} \in \mathbb{C}$ and the functionals $h_j \in H^{-1/2}(\mathbb{R}_+)$ are given.

The transmission conditions (1.3) may be replaced by the assumption that $(\Delta + k^2)u = 0$ also holds across the negative x_1 half-axis. $u_0^\pm \in H^{1/2} = H^{1/2}(\mathbb{R})$ is a consequence of the trace theorem and $u_1^+ \in H^{-1/2}$ makes sense for solutions of the Helmholtz equation. Those are represented by the potential ansatz [20]

$$\begin{aligned} u(x_1, x_2) &= F^{-1}_{\xi \mapsto x_1}\{e^{x_2 t(\xi)}\hat{u}_0^-(\xi)1_-(x_2) + e^{-x_2 t(\xi)}\hat{u}_0^+(\xi)1_+(x_2)\} \\ &= G\begin{pmatrix} u_0^- \\ u_0^+ \end{pmatrix}(x_1, x_2), \end{aligned} \tag{1.4}$$

and we refer to the notation of [20]. In particular, $t(\xi)=(\xi^2-k^2)^{1/2}$ denotes the usual square root function with branch cuts along $\xi=\pm k\pm i\tau$, $\tau\geqq 0$; $1_\pm$ are the characteristic functions of $\mathbb{R}_\pm$, and the Fourier transformation F is defined by

$$\hat{u}_0^\pm(\xi)=F_{x_1\mapsto\xi}u_0^\pm(x_1)=\int_{-\infty}^{\infty}e^{ix_1\xi}u(x_1)\,dx_1. \tag{1.5}$$

The present paper generalizes the impedance and the reactance problems [10], [11], [14] as well as the mixed type Dirichlet-Neumann problem [7], [13], [17]. The first two examples lead to "the usual square root singularity" $\nabla u\sim \text{const}/|x|^{1/2}$ at $x=0$, which is also well known from Sommerfeld's half-plane problem [12], [16]. Surprisingly, the final example is governed by $\nabla u\sim\text{const}/|x|^{3/4}$, and we find $\nabla u\sim\text{const}\,|x|^{\delta/2-1}$ with $\delta\in(0,1]$ in a somewhat wider class of problems [21]. Now which type of a singularity is usual and which one is exceptional? We will answer this question at the end, because it relates to the question of whether a certain bounded Hilbert space operator $A\in\mathcal{L}(L^2(\mathbb{R})^2)$ admits a "general Wiener-Hopf operator factorization" $A=A_-A_+$ with respect to the projector $1_+\cdot$ [4], [18], [19], into bounded ($\delta=1$) or unbounded ($0<\delta<1$) operators $A_\pm$, respectively.

While problems with first and second kind conditions [21] lead to the discussion of factoring a one-parameter family of function matrices, as was done by Daniele's method [3], we obtain here one four-parameter and one six-parameter family of normalized function matrices (apart from the decomposing systems). The corresponding two-media problems with different wave numbers in $\Omega^\pm$ can be treated by analogy to [20], [21]; their functional analytic structure is similar and a fixed point principle can be used, the details of which are not repeated here.

The key lemma for factoring the 2×2 symbol matrices $\sigma=\sigma_-\sigma_+$ into upper/lower holomorphic function matrices with algebraic behavior at infinity is known from Riemann-Hilbert problems as Khrapkov's method [8], [9]. In general it applies to matrix functions depending on $\xi\in\mathbb{R}$ of the form

$$\sigma=\mu_1R_1+\mu_2R_2 \tag{1.6}$$

with rational function matrices R_j and (factorable) scalar functions μ_j. All our Wiener-Hopf matrices are of this type, since they are rational in $t(\xi)=(\xi^2-k^2)^{1/2}$.

2. The Wiener–Hopf system. We define the boundary operators (on the whole axis) as

$$\begin{aligned} &B_\pm=F^{-1}\sigma_{B_\pm}\cdot F: H^{1/2}\times H^{1/2}\to H^{\mp 1/2}\times H^{-1/2}\\ &\sigma_{B_+}=\begin{pmatrix} a_{11}+a_{13}t & a_{12}-a_{14}t\\ a_{21}+a_{23}t & a_{22}-a_{24}t\end{pmatrix},\qquad \sigma_{B_-}=\begin{pmatrix}-1 & 1\\ -t & -t\end{pmatrix}\end{aligned} \tag{2.1}$$

where $F^{-1}t\cdot F: H^{1/2}\to H^{-1/2}$ is a bijection.

PROPOSITION 2.1. *A function u solves problem $\mathcal{P}$, if and only if it can be represented by* (1.4) *where*

$$\begin{pmatrix}f_0\\ f_1\end{pmatrix}=B_-\begin{pmatrix}u_0^-\\ u_0^+\end{pmatrix} \tag{2.2}$$

satisfies the Wiener–Hopf system

$$W\begin{pmatrix}f_0\\ f_1\end{pmatrix}=1_+\cdot B_+B_-^{-1}\begin{pmatrix}f_0\\ f_1\end{pmatrix}=\begin{pmatrix}h_1\\ h_2\end{pmatrix}. \tag{2.3}$$

W acts on the subspaces $\tilde{H}^{\pm 1/2}(\mathbb{R}_+)$ *of* $H^{\pm 1/2}$ *functionals supported on* $\mathbb{R}_+$ *as a bounded linear operator*

$$W = 1_+ \cdot F^{-1}\sigma \cdot F : \tilde{H}^{1/2}(\mathbb{R}_+) \times \tilde{H}^{-1/2}(\mathbb{R}_+) \to H^{-1/2}(\mathbb{R}_+)^2 \tag{2.4}$$

with the Fourier symbol matrix

$$\sigma = \sigma_{B_+}\sigma_{B_-}^{-1} = \sigma_{B+}\frac{1}{2t}\begin{pmatrix} -t & -1 \\ t & -1 \end{pmatrix}. \tag{2.5}$$

Proof. The representation formula (1.4) for H^1 solutions of the Helmoltz equation is known [20]. The (classical) substitution $f_0 = u_0^+ - u_0^-$, $f_1 = u_1^+ - u_1^- = F^{-1}t \cdot F(-u_0^+ - u_0^-)$ is given by the bijection B_-. The transmission conditions (1.3) yield $f_0 \in \tilde{H}^{1/2}(\mathbb{R}_+)$, $f_1 \in \tilde{H}^{-1/2}(\mathbb{R}_+)$ and (1.2), (1.4) imply (2.3). The mapping properties of W and its representation (2.5) are obvious.

Conversely, a solution of (2.3) yields (1.2), (1.3) for the substituted functions $u_0^{\pm}$ in (2.2), which can be inserted into (1.4).

For brevity we put $g_0 = u_0^+ + u_0^-$, $g_1 = u_1^+ + u_1^-$ and obtain the transmission conditions (1.2) in the form

$$\begin{aligned} &\alpha_{j1}f_0 + \alpha_{j2}g_0 + \alpha_{j3}f_1 + \alpha_{j4}g_1 = h_j \quad \text{on } \mathbb{R}_+, \quad j = 1, 2, \\ &= \frac{-a_{j1}+a_{j2}}{2}f_0 + \frac{a_{j1}+a_{j2}}{2}g_0 + \frac{-a_{j3}+a_{j4}}{2}f_1 + \frac{a_{j3}+a_{j4}}{2}g_1. \end{aligned} \tag{2.6}$$

This leads to

$$\sigma = \frac{1}{t}\begin{pmatrix} \alpha_{11}t - \alpha_{14}t^2 & -\alpha_{12} + \alpha_{13}t \\ \alpha_{21}t - \alpha_{24}t^2 & -\alpha_{22} + \alpha_{23}t \end{pmatrix}. \tag{2.7}$$

Remark 2.2. Writing σ in the form (1.6), which we will use for the (function theoretic) factoring, we obtain

$$\sigma = \begin{pmatrix} \alpha_{11} & \alpha_{13} \\ \alpha_{21} & \alpha_{23} \end{pmatrix} - \frac{1}{t}\begin{pmatrix} \alpha_{14}t^2 & \alpha_{12} \\ \alpha_{24}t^2 & \alpha_{22} \end{pmatrix} = R_1 + \mu R_2 \tag{2.8}$$

and conditions like $\det R_1 \neq 0$, etc., become most important.

On the other hand, it is known that the principal part of the symbol

$$\sigma = \sigma_{pr} + \sigma_{sm} = \begin{pmatrix} -\alpha_{14}t & \alpha_{13} \\ -\alpha_{24}t & \alpha_{23} \end{pmatrix} + \frac{1}{t}\begin{pmatrix} \alpha_{11}t & -\alpha_{12} \\ \alpha_{21}t & -\alpha_{22} \end{pmatrix} \tag{2.9}$$

is responsible for functional analytical properties of W where conditions like $\det \sigma_{pr} \neq 0$ become important. So we expect several particular cases, which must be discussed separately and start with the latter aspects.

PROPOSITION 2.3. *The operator W in* (2.4)-(2.5) *is equivalent to* (*coincides up to invertible factors with*) *the "lifted" linear bounded operator* W_0 *defined by*

$$W_0 = 1_+ \cdot F^{-1}\sigma_0 \cdot F : L^2(\mathbb{R}_+)^2 \to L^2(\mathbb{R}_+)^2,$$

$$\sigma_0 = \begin{pmatrix} t_-^{-1} & 0 \\ 0 & t_-^{-1} \end{pmatrix}\sigma\begin{pmatrix} t_+^{-1} & 0 \\ 0 & t_+ \end{pmatrix} = \begin{pmatrix} \dfrac{\alpha_{11} - \alpha_{14}t}{t} & \dfrac{-\alpha_{12} + \alpha_{13}t}{t_-^2} \\ \dfrac{\alpha_{21} - \alpha_{24}t}{t} & \dfrac{-\alpha_{22} + \alpha_{23}t}{t_-^2} \end{pmatrix} \tag{2.10}$$

with $t_{\pm}(\xi) = (\xi \pm k)^{1/2}$.

Proof. See [21, Thm. 2.1].

PROPOSITION 2.4. *For any choice of the coefficients a_{jl}, W is not Fredholm—as an operator into $H^{-1/2}(\mathbb{R}_+)^2$ (see (2.4)).*

Proof. The statement is equivalent to the assertion that W_0 is not Fredholm. But this is a direct consequence of (2.10) where

$$\det \sigma_0(-\infty) = -\det \sigma_0(+\infty) \tag{2.11}$$

since $\sigma_0 \in C(\mathbb{R})^{2\times 2}$ (see [15] or [21, Thm. 2.1]).

Therefore the function space setting must be modified, if we want well-posed problems. We restrict our considerations to nondegenerating stable symbol matrices, which are physically most important. Problem $\mathcal{P}$ and the operator W are said to be of *normal type*, if

$$\begin{aligned} &\det \sigma(\xi) \neq 0, \qquad \xi \in \mathbb{R}, \\ &[\det \sigma(\xi)]^{\pm 1} = O(|\xi|^{\pm d}), \qquad \xi \to \pm\infty \end{aligned} \tag{2.12}$$

hold with $d = 0, \pm 1$ (see (2.7)).

The case $d = -1$ corresponds to a pure Dirichlet problem, so $u_0^{\pm}$ are known on $\mathbb{R}_+$, but this basic Sommerfeld problem has been completely solved before (see [20]). So we center on the other two cases: $d = 0$, where one condition is of the first kind ($\alpha_{23} = \alpha_{24} = 0 = a_{23} = a_{24}$ without loss of generality) and the other is of second or third kind; or the case $d = 1$, where both conditions are essentially different in the principal part. It is convenient to abbreviate the coefficient matrices

$$\begin{aligned} \alpha &= \left(\begin{array}{cc:cc} \alpha_{11} & \alpha_{12} & \alpha_{13} & \alpha_{14} \\ \alpha_{21} & \alpha_{22} & \alpha_{23} & \alpha_{24} \end{array}\right) = \left(\begin{array}{c:c} \alpha_0 & \alpha_1 \end{array}\right), \\ \alpha_2 &= \begin{pmatrix} \alpha_{13} & \alpha_{14} \\ \alpha_{22} & \alpha_{21} \end{pmatrix}. \end{aligned} \tag{2.13}$$

LEMMA 2.5. *The following three assertions are equivalent:*

(i) *Problem $\mathcal{P}$ is of normal type with $d = 1$ or 0;*

(ii) *There hold* $\det \sigma_0 \neq 0$ *on* $\mathbb{R}$ *and* $(d = 1)$

$$\det \alpha_1 = -\frac{1}{2} \det \begin{pmatrix} a_{13} & a_{14} \\ a_{23} & a_{24} \end{pmatrix} = t^{-1} \det \sigma_{pr} \neq 0 \tag{2.14}$$

or $(d = 0)$

$$\operatorname{rank} \alpha_1 = 1, \qquad \det \alpha_2 \neq 0 \tag{2.15}$$

(and $\alpha_{23} = \alpha_{24} = 0$ without loss of generality);

(iii) *The boundary operator B_+ acts bijectively as*

$$B_+ = F^{-1}\sigma_{B_+} \cdot F : H^{1/2} \times H^{1/2} \to H^{-1/2} \times H^{1/2-d}. \tag{2.16}$$

Proof. This is a consequence of

$$\sigma^{-1} = \sigma_{B_-}\sigma_{B_+}^{-1} = \frac{t}{p(t)} \begin{pmatrix} -\alpha_{22} + \alpha_{23} t & \alpha_{12} - \alpha_{13} t \\ -\alpha_{21} + \alpha_{24} t & \alpha_{11} - \alpha_{14} t \end{pmatrix} \tag{2.17}$$

(see (2.7)), where p is polynomial of degree three or two, respectively. Thus (2.12) is equivalent to the fact that σ^{-1} does not degenerate and has maximal order at infinity. The rest of the proof is obvious.

3. The Fredholm property of W, case $d=0$. First we study the case $d=0$ characterized by (2.15) and assume $\alpha_{23}=\alpha_{24}=0$ without loss of generality. Problem $\mathcal{P}$ leads to a discussion of the Wiener-Hopf operator

$$W=1_+\cdot F^{-1}\sigma\cdot F:\tilde{H}^{1/2}(\mathbb{R}_+)\times\tilde{H}^{-1/2}(\mathbb{R}_+)\to H^{-1/2}(\mathbb{R}_+)\times H^{1/2}(\mathbb{R}_+),$$

$$\sigma=\begin{pmatrix}\alpha_{11}-\alpha_{14}t & \alpha_{13}-\alpha_{12}t^{-1}\\ \alpha_{21} & -\alpha_{22}t^{-1}\end{pmatrix} \tag{3.1}$$

(see (2.4), (2.7), (2.16)). This turns out to be completely different from the operator in the case $d=1$, but very similar to the type of operators that appear in connection with first and second kind conditions [21] and correspond to the subscase $\alpha_{11}=\alpha_{12}=0$ (i.e., dropping lower-order terms) in (3.1).

THEOREM 3.1. *The operator W defined by* (3.1) (*instead of* (2.4)-(2.5)) *is Fredholm with index zero, if and only if*

$$\det\sigma(\xi)\neq 0,\qquad \xi\in\mathbb{R},$$
$$\alpha_{14}\alpha_{22}\neq\lambda\alpha_{13}\alpha_{21},\qquad \lambda\in[0,1] \tag{3.2}$$

are satisfied. Otherwise the range of W is not closed in $H^{-1/2}(\mathbb{R}_+)\times H^{1/2}(\mathbb{R}_+)$ (unless $\sigma\equiv 0$ holds).

Proof. Lifting W on $L^2(\mathbb{R}_+)^2$ (see (2.10)), we now obtain equivalence to

$$W_0=1_+\cdot F^{-1}\sigma_0\cdot F,$$

$$\sigma_0=\begin{pmatrix}t_-^{-1} & 0\\ 0 & t_-\end{pmatrix}\sigma\begin{pmatrix}t_+^{-1} & 0\\ 0 & t_+\end{pmatrix}=\begin{pmatrix}\dfrac{\alpha_{11}-\alpha_{14}t}{t} & \dfrac{-\alpha_{12}+\alpha_{13}t}{t_-^2}\\ \alpha_{21}\dfrac{t_-}{t_+} & -\alpha_{22}\end{pmatrix}, \tag{3.3}$$

and the Fredholm property of W_0 is equivalent to [21, Thm. 2.1]

$$\det\sigma_0(\xi)\neq 0,\qquad \xi\in\mathbb{R},$$
$$\det[\mu\sigma_0(-\infty)+(1-\mu)\sigma_0(+\infty)]\neq 0,\qquad \mu\in[0,1]. \tag{3.4}$$

Since $t_-/t_+\to\pm 1$ at $\pm\infty$, the last assertion may be rewritten as $\alpha_{14}\alpha_{22}-(1-2\mu)^2\alpha_{13}\alpha_{21}\neq 0$, $\mu\in[0,1]$. The winding number of $\det\sigma_0(\xi)$ vanishes automatically, since

$$\det\sigma_0(\xi)=\frac{-\alpha_{11}\alpha_{22}+\alpha_{12}\alpha_{21}}{t(\xi)}+\alpha_{14}\alpha_{22}-\alpha_{13}\alpha_{21}$$
$$=-\frac{\det\alpha_0}{t(\xi)}-\det\alpha_2=\det\sigma(\xi) \tag{3.5}$$

is an even function of ξ. This yields $\operatorname{Ind} W=\operatorname{Ind} W_0=-\operatorname{ind}\det\sigma_0=0$.

COROLLARY 3.2. *For W in* (3.1) *to be Fredholm, it is necessary for problem $\mathcal{P}$ to be of normal type* (*compare* (3.2) *with* (2.15)).

COROLLARY 3.3. *The set of parameters α_{jl} where W is Fredholm is characterized by the following three conditions: first,*

$$\det\alpha_2=\alpha_{13}\alpha_{21}-\alpha_{14}\alpha_{22}\neq 0, \tag{3.6a}$$

$$\alpha_{14}\alpha_{22}\neq 0; \tag{3.6b}$$

second,

$$\det\alpha_0=\alpha_{11}\alpha_{22}-\alpha_{12}\alpha_{21}=0\quad \textit{or} \tag{3.7a}$$

$$\det\alpha_0\neq 0,\qquad -\det\alpha_2/\det\alpha_0\notin\Gamma=\{\zeta=t^{-1}(\xi),\ \xi\in\dot{\mathbb{R}}\}; \tag{3.7b}$$

and third,

$$\alpha_{13}\alpha_{21}=0 \quad \textit{or}$$

$$\alpha_{13}\alpha_{21}\neq 0, \qquad \lambda=\frac{\alpha_{14}\alpha_{22}}{\alpha_{13}\alpha_{21}}\notin[0,1]. \tag{3.8}$$

(*The very last condition includes* (3.6).)

Remark 3.4. The special case $\alpha_{11}=\alpha_{12}=0$ of first and second kind conditions corresponds to (3.7a) (see [21, Thm. 2.1]).

Let us note how to proceed when (3.6)-(3.8) are violated.

(1) For $\alpha_{14}\alpha_{22}=0$, one or two compatibility conditions must be satisfied in order to get a well-posed problem; see the following example. It is easy to treat all these cases by analogy.

(2) $\det\alpha_2=0$ or $-\det\alpha_2/\det\alpha_0\in\Gamma$ leads to a problem of nonnormal type. We may introduce weighted spaces, as in the theory of singular integral operators [15], but those cases seem not to be of great physical importance (e.g., u_0^+ and u_1^+ are given on $\mathbb{R}_+$).

(3) If $\lambda\in(0,1)$ holds, replace H^s by $W^{p,s}$ spaces with $p\neq 2$, such that the symbol becomes p-regular [15, Chap. V] and the Wiener-Hopf operator is closed.

Example 3.5. The reactance problem [10], [14]

$$u_0^+=u_0^- \quad (=u_0) \quad \text{on } \mathbb{R}_+, \tag{3.9a}$$

$$u_1^+-u_1^-+\kappa u_0=h_1\in H^{-1/2}(\mathbb{R}_+) \tag{3.9b}$$

leads to conditions (2.6) of the form

$$f_1+\frac{\kappa}{2}g_0=h_1, \qquad f_0=0 \tag{3.10}$$

and therefore

$$\alpha=\begin{pmatrix}\alpha_0 & \vdots & \alpha_1\end{pmatrix}=\begin{pmatrix}0 & \frac{\kappa}{2} & 1 & 0\\ 1 & 0 & 0 & 0\end{pmatrix},$$

$$\alpha_2=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}, \qquad \sigma=\begin{pmatrix}0 & 1-\frac{\kappa}{2t}\\ 1 & 0\end{pmatrix}. \tag{3.11}$$

Thus we have a normal type problem with $d=0$ and the Wiener-Hopf system decomposes. All assertions (3.6)-(3.8) except (3.6b) (because of $\alpha_{14}=\alpha_{22}=0$) are satisfied for reasonable κ ($2/\kappa\notin\Gamma$). Consequently $W=1_+\cdot F^{-1}\sigma\cdot F$ is not Fredholm in the sense of (3.1), but it obviously maps $\tilde{H}^{1/2}(\mathbb{R}_+)\times\tilde{H}^{-1/2}(\mathbb{R}_+)$ into $\tilde{H}^{-1/2}(\mathbb{R}_+)\times\tilde{H}^{1/2}(\mathbb{R}_+)$ where it is invertible (see [14]). This means two compatibility conditions must be satisfied in order to obtain a well-posed problem. The first one, $h_1\in\tilde{H}^{-1/2}(\mathbb{R}_+)$, is obvious and the second, $h_2=u_0^+-u_0^-=0\in\tilde{H}^{1/2}(\mathbb{R}_+)$, is implicitly contained in (3.9a).

Example 3.6. The mixed Dirichlet-Neumann problem [5], [13], [17]

$$u_1^+=h_1\in H^{-1/2}(\mathbb{R}_+), \qquad u_0^-=h_2\in H^{1/2}(\mathbb{R}_+) \tag{3.12}$$

leads by way of (2.6) and (3.1) to

$$\alpha=\begin{pmatrix}0 & 0 & 1/2 & 1/2\\ -1/2 & 1/2 & 0 & 0\end{pmatrix},$$

$$\sigma=-\frac{1}{2}\begin{pmatrix}t & -1\\ 1 & t^{-1}\end{pmatrix}. \tag{3.13}$$

The conditions (3.6)-(3.8) are satisfied with $\det \alpha_0 = 0$ and $\lambda = -1$. W is Fredholm with index zero. It is even invertible in the sense of (3.1) [21] for all the above-mentioned data h_1, h_2.

4. The Fredholm property, case $d = 1$. In the case $d = 0$ we had to replace one data space $H^{-1/2}(\mathbb{R}_+)$ by $H^{1/2}(\mathbb{R}_+)$, since the order of a boundary condition was not maximum. Now another modification becomes relevant.

LEMMA 4.1. *If* $\det \alpha_1 \neq 0$ *holds, the compatibility condition*

$$\alpha_{24} h_1 - \alpha_{14} h_2 \in \tilde{H}^{-1/2}(\mathbb{R}_+) \tag{4.1}$$

(*instead of* $H^{-1/2}(\mathbb{R}_+)$) *is necessary for the problem* $\mathcal{P}$ *to be solvable.*

Proof. We simplify the Wiener-Hopf system (2.3), premultiply by α_1^{-1}, and obtain the system

$$\begin{aligned} &\tilde{W}\begin{pmatrix} f_0 \\ f_1 \end{pmatrix} = 1_+ \cdot F^{-1}\tilde{\sigma} \cdot F\begin{pmatrix} f_0 \\ f_1 \end{pmatrix} = \begin{pmatrix} \tilde{h}_1 \\ \tilde{h}_2 \end{pmatrix} = \alpha_1^{-1}\begin{pmatrix} h_1 \\ h_2 \end{pmatrix}, \\ &\tilde{\sigma} = \alpha_1^{-1}\sigma = \begin{pmatrix} \tilde{\alpha}_{11} & 1 - \dfrac{\tilde{\alpha}_{12}}{t} \\ -t + \tilde{\alpha}_{21} & -\dfrac{\tilde{\alpha}_{22}}{t} \end{pmatrix} \end{aligned} \tag{4.2}$$

with the same space setting (2.4). The Wiener-Hopf equation due to the first line reads

$$\tilde{\alpha}_{11} f_0 + f_1 - \tilde{\alpha}_{12} 1_+ \cdot F^{-1} t^{-1} F f_1 = \tilde{h}_1 = \frac{\alpha_{24} h_1 - \alpha_{14} h_2}{\det \alpha_1}. \tag{4.3}$$

If f_0 and f_1 represent the Dirichlet and Neumann data jumps on $x_2 = 0$ of a solution of problem $\mathcal{P}$, then the trace theorem and embedding yield $f_1 \in \tilde{H}^{-1/2}(\mathbb{R}_+)$, $f_0 \in \tilde{H}^{1/2}(\mathbb{R}_+) \subsetneq \tilde{H}^{-1/2}(\mathbb{R}_+)$, $1_+ \cdot F^{-1} t^{-1} F f_1 \in H^{1/2}(\mathbb{R}_+) \subsetneq \tilde{H}^{-1/2}(\mathbb{R}_+)$, which implies (4.1).

THEOREM 4.2. *Let* $\det \alpha_1 \neq 0$. *Then*

$$\tilde{W} : \tilde{H}^{1/2}(\mathbb{R}_+) \times \tilde{H}^{-1/2}(\mathbb{R}_+) \to \tilde{H}^{-1/2}(\mathbb{R}_+) \times H^{-1/2}(\mathbb{R}_+) \tag{4.4}$$

defined by (4.2) *is a Fredholm operator with index zero, if and only if*

$$\det \tilde{\sigma}(\xi) = \frac{\det \sigma(\xi)}{\det \alpha_1} \neq 0, \qquad \xi \in \mathbb{R} \tag{4.5}$$

holds, i.e., if and only if problem $\mathcal{P}$ *is of normal type* ($d = 1$).

Proof. For simplicity we assume that α_1 is the unit matrix. Note that $\tilde{W}$ maps into a different space than W (see (2.4) and Proposition 2.4).

First we use an idea of [14] for replacing the tilde space on the right of (4.4), extending it to treat coupled systems. We know from the Sommerfeld (Dirichlet) problem [20] that

$$W_S = 1_+ \cdot F^{-1} t^{-1} \cdot F : \tilde{H}^{-1/2}(\mathbb{R}_+) \to H^{1/2}(\mathbb{R}_+) \tag{4.6}$$

is a bijection with

$$W_S^{-1} = F^{-1} t_+ \cdot F 1_+ \cdot F^{-1} t_- \cdot F l \tag{4.7}$$

where $l : H^{1/2}(\mathbb{R}_+) \to H^{1/2}$ denotes any extension onto the axis. So we transform the system (4.2) (dropping the tildes) by substituting

$$u_+ = W_S f_1 \in H^{1/2}(\mathbb{R}_+) \tag{4.8}$$

and applying W_S to the first equation, which becomes

$$\alpha_{11} W_S f_0 + u_+ - \alpha_{12} W_S u_+ = W_S h_1. \tag{4.9a}$$

The second equation is unaltered except by the substitution (4.8):

$$-1_+ F^{-1} t \cdot F f_0 + \alpha_{21} f_0 - \alpha_{22} u_+ = h_2. \tag{4.9b}$$

In operator notation, we obtain equivalently

$$\begin{gathered} \tilde{\tilde{W}} \begin{pmatrix} f_0 \\ u_+ \end{pmatrix} = 1_+ \cdot F^{-1} \begin{pmatrix} \dfrac{\alpha_{11}}{t} & 1 - \dfrac{\alpha_{12}}{t} \\ \alpha_{21} - t & -\alpha_{22} \end{pmatrix} \cdot F \begin{pmatrix} f_0 \\ u_+ \end{pmatrix} = \begin{pmatrix} W_S h_1 \\ h_2 \end{pmatrix}, \\ \tilde{\tilde{W}} : X = \tilde{H}^{1/2}(\mathbb{R}_+) \times H^{1/2}(\mathbb{R}_+) \to Y = H^{1/2}(\mathbb{R}_+) \times H^{-1/2}(\mathbb{R}_+). \end{gathered} \tag{4.10}$$

Now consider the extension of $\tilde{\tilde{W}}$:

$$\bar{W} : \bar{X} = \tilde{H}^{1/2}(\mathbb{R}_+) \times L^2(\mathbb{R}_+) \to \bar{Y} = L^2(\mathbb{R}_+) \times H^{-1/2}(\mathbb{R}_+), \tag{4.11}$$

which is also linear bounded (see the orders in (4.10)). Next we show the statement for $\bar{W}$ instead of $\tilde{W}$.

The lifting procedure leads to the equivalent operator

$$\begin{gathered} \bar{W}_0 : 1_+ \cdot F^{-1} \bar{\sigma}_0 \cdot F : L^2(\mathbb{R}_+)^2 \to L^2(\mathbb{R}_+)^2, \\ \bar{\sigma}_0 = \begin{pmatrix} 1 & 0 \\ 0 & t_-^{-1} \end{pmatrix} \tilde{\tilde{\sigma}} \begin{pmatrix} t_+^{-1} & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} \dfrac{\alpha_{11}}{t t_+} & 1 - \dfrac{\alpha_{12}}{t} \\ \dfrac{\alpha_{21}}{t} - 1 & \dfrac{-\alpha_{22}}{t_-} \end{pmatrix}, \end{gathered} \tag{4.12}$$

whose symbol matrix is in $C(\dot{\mathbb{R}})^{2\times 2}$, continuous at infinity, and we get

$$\begin{aligned} \det \bar{\sigma}_0 &= t^{-1} \det \tilde{\tilde{\sigma}} = t^{-1} \det \tilde{\sigma} \\ &= 1 - \frac{\alpha_{12} + \alpha_{21}}{t} + \frac{\alpha_{12}\alpha_{21} - \alpha_{11}\alpha_{22}}{t^2}. \end{aligned} \tag{4.13}$$

Thus the Fredholm property of $\bar{W}_0$ is equivalent to (4.5) (see [15]). Further we obtain

$$\operatorname{Ind} \bar{W}_0 = -\operatorname{ind} \det \bar{\sigma}_0 = -\arg \det \bar{\sigma}_0(\xi)\big|_{\xi=-\infty}^{+\infty} = 0 \tag{4.14}$$

since $\det \bar{\sigma}_0$ is an even function.

Finally we prove that the kernels and co-kernels of $\tilde{\tilde{W}}$ and $\bar{W}$ have the same dimensions. Because a solution of (4.10) for a given function in Y is automatically in X, we obtain $\ker \tilde{\tilde{W}} = \ker \bar{W}$. If this is finite-dimensional, a complement X_1 of $\ker \tilde{\tilde{W}}$ in X is dense in a complement $\bar{X}_1$ of $\ker \bar{W}$ in $\bar{X}$. Thus the image $\tilde{\tilde{W}} X_1 = \bar{W} X_1$ is dense in $\bar{W}\bar{X}_1$, since $\bar{W}$ is continuous. A finite-dimensional complement of $\tilde{\tilde{W}} X_1$ is a complement of $\bar{W}\bar{X}_1$.

Remark 4.3. The above result reflects the fact that $\tilde{H}^{-1/2}(\mathbb{R}_+) \subsetneq H^{-1/2}(\mathbb{R}_+)$ is dense but not closed. For normal type problems, the images of $\tilde{W}$, $\tilde{\tilde{W}}$, and $\bar{W}$ are closed but the image of W is not. So it is surprising that the corresponding (unlifted) symbols are simply connected by constant factors,

$$\bar{\sigma} = \frac{1}{\alpha_{12}} \begin{pmatrix} 1 & 0 \\ -\alpha_{22} & \alpha_{12} \end{pmatrix} \sigma \begin{pmatrix} 1 & 0 \\ -\alpha_{11} & \alpha_{12} \end{pmatrix}, \tag{4.15}$$

although the lifted symbol matrices are generalized factorable or not, respectively, because of the Fredholm criterion. This shows that function-theoretic factorization

(with just algebraic behavior at infinity) and generalized matrix factorization (related to the function spaces) are quite different—although related—topics.

COROLLLARY 4.4. *Condition* (4.5) *is violated, if and only if one of the characteristic numbers*

$$\lambda_{\pm}=\frac{\tilde{\alpha}_{12}+\tilde{\alpha}_{21}}{2}\pm\frac{1}{2}[(\tilde{\alpha}_{12}-\tilde{\alpha}_{21})^2+4\tilde{\alpha}_{11}\tilde{\alpha}_{22}]^{1/2} \tag{4.16}$$

is situated on the curve $\{\zeta=t(\xi),\ \xi\in\mathbb{R}\}$. *In the special case* $\tilde{\alpha}_{11}\tilde{\alpha}_{22}=0$ *these numbers simply read* $\lambda_+=\tilde{\alpha}_{12}$, $\lambda_-=\tilde{\alpha}_{21}$.

Example 4.5. The impedance problem [11], [14]

$$\begin{aligned} u_1^+ + ipu_0^+ &= h_1 \quad \text{on } \mathbb{R}_+, \\ u_1^- - iqu_0^- &= h_2 \quad \text{on } \mathbb{R}_+, \end{aligned} \tag{4.17}$$

yields the coefficient matrix

$$\tilde{\alpha}=\begin{pmatrix}\tilde{\alpha}_{11} & & \\ & \ddots & \\ & & \tilde{\alpha}_{24}\end{pmatrix}=\begin{pmatrix} i(p-q)/2 & i(p+q)/2 & 1 & 0 \\ i(p+q)/2 & i(p-q)/2 & 0 & 1\end{pmatrix} \tag{4.18}$$

and symbol matrices

$$\tilde{\sigma}=\begin{pmatrix} i\dfrac{p-q}{2} & 1-i\dfrac{p+q}{2t} \\ i\dfrac{p+q}{2}-t & -i\dfrac{p-q}{2t}\end{pmatrix},$$

$$\tilde{\tilde{\sigma}}=\bar{\sigma}=\begin{pmatrix} i\dfrac{p-q}{2t} & 1-i\dfrac{p+q}{2t} \\ i\dfrac{p+q}{2}-t & -i\dfrac{p-q}{2}\end{pmatrix}, \tag{4.19}$$

$$\bar{\sigma}_0=\begin{pmatrix} i\dfrac{p-q}{2tt_+} & 1-i\dfrac{p+q}{2t} \\ i\dfrac{p+q}{2t}-1 & -i\dfrac{p-q}{2t_-}\end{pmatrix}.$$

The system decomposes if and only if $p=q$ holds; the above matrices are then antidiagonal. In any case the determinant of the lifted symbol has the nice form

$$\det\bar{\sigma}_0=1-\frac{i(p+q)}{t}-\frac{pq}{t^2}=\left(1-\frac{ip}{t}\right)\left(1-\frac{iq}{t}\right) \tag{4.20}$$

and does not vanish for positive impedances p, q.

5. Explicit factorization. In this paper we always have the lifted symbol matrices $\sigma_0\in PC(\dot{\mathbb{R}})^{2\times 2}$, which are piecewise continuous with at most one jump at infinity. We briefly recall some facts from linear operator theory. It is well known [15], [21] that the Fredholm property of

$$W_0=1_+\cdot A_0=1_+\cdot F^{-1}\sigma_0\cdot F: L^2(\mathbb{R}_+)^2\to L^2(\mathbb{R}_+)^2 \tag{5.1}$$

is equivalent to the existence of a *generalized factorization*

$$\sigma_0(\xi)=\sigma_{0-}(\xi)\begin{pmatrix}\left(\frac{\xi-i}{\xi+i}\right)^{\kappa_1} & 0\\ 0 & \left(\frac{\xi-i}{\xi+i}\right)^{\kappa_2}\end{pmatrix}\sigma_{0+}(\xi) \tag{5.2}$$

with $\kappa_j\in\mathbb{Z}$ and

$$\sigma_{0\pm},\ \sigma_{0\pm}^{-1}\in L^2(\mathbb{R},\rho),\qquad \rho(\xi)=(\xi^2+1)^{-1/2} \tag{5.3}$$

and (5.2)-(5.3) are furthermore equivalent to the conditions (3.4).

The subcase of a *right canonical factorization* of $\sigma_0\in C(\dot{\mathbb{R}})^{2\times 2}$ is characterized by $\sigma_{0\pm}\in C(\dot{\mathbb{R}})^{2\times 2}$ and corresponds to a factorization of the bounded convolution operator $A_0\in\mathscr{L}(L^2(\mathbb{R})^2)$ into bounded operators $A_{0\pm}=F^{-1}\sigma_{0\pm}\cdot F$ and C according to the diagonal Fourier symbol matrix in the middle. In general $A_{0\pm}$ and $A_{0\pm}^{-1}=F^{-1}\sigma_{0\pm}^{-1}\cdot F$ are unbounded, but combinations like $A_0^{-1}1_+\cdot A_{0-}$ represent bounded operators, if the factors are taken from a generalized factorization.

A continuously invertible Wiener-Hopf operator W_0 and thus a well-posed problem $\mathscr{P}$ corresponds to a factorization (5.2), where $\kappa_1=\kappa_2=0$ holds. But the partial indices κ_j cannot be obtained from considering $\det\sigma_0(\xi)$, which only gives $\operatorname{Ind} W_0=-\kappa_1-\kappa_2=-\operatorname{ind}\det\sigma_0$. So we really need an explicit generalized factorization of the form (5.2)-(5.3) for the decision about invertibility. The inverse then reads

$$W_0^{-1}=A_{0\pm}^{-1}1_+\cdot A_{0-}^{-1}=F^{-1}\sigma_{0+}^{-1}\cdot F1_+\cdot F^{-1}\sigma_{0-}^{-1}\cdot F \tag{5.4}$$

and yields a corresponding formula for W^{-1} or $\tilde{W}^{-1}$ with immediate consequences for the asymptotics (the case $\kappa_j\neq 0$ appears here only, if we switch from L^2 to L^p theory; see [21]).

We are going to factor explicitly the symbol matrices (3.3) and (4.2) in standard form according to the normal type cases $d=0$ with six parameters and $d=1$ with four parameters, provided the assumptions (3.2) and (4.1), (4.5), respectively, for the Fredholm property are satisfied. According to situations, which are different in the operator theoretical or function theoretical sense, the representation splits up into many cases.

The first step for finding a right canonical or a generalized factorization consists in an application of the following theorem by Khrapkov [9], which is mostly equivalent to a simpler version ($a_1=1$, $c=0$) presented independently by Daniele [3], [8] and is connected to ideas of Heins [6] and Čebotarev [1].

THEOREM 5.1. *Let $G\in C(\mathbb{R})^{2\times 2}$ be a matrix function of the form*

$$G=a_1I+a_2R \tag{5.5}$$

where a_j are scalar functions and R is a polynomial matrix of commutant form

$$R(\xi)=\begin{pmatrix}-c(\xi) & a(\xi)\\ b(\xi) & c(\xi)\end{pmatrix},\qquad \xi\in\mathbb{R}(\mathbb{C}). \tag{5.6}$$

Abbreviate the determinants by

$$\begin{aligned}-\det R&=c^2+ab=g^2f,\\ \det G&=a_1^2-a_2^2g^2f\end{aligned} \tag{5.7}$$

where f, g are polynomials and $g(\xi)\neq 0$ for $\xi\in\mathbb{R}$ (we usually want f to have minimal degree, i.e., g contains all square factors apart from those that vanish on $\mathbb{R}$).

Furthermore, let $\det G \neq 0$ *on* $\mathbb{R}$ *and let*

$$\tau = \frac{1}{\sqrt{f}} \log \frac{a_1 + a_2 g\sqrt{f}}{a_1 - a_2 g\sqrt{f}} = \tau_- + \tau_+ \tag{5.8}$$

be an additive decomposition into functions $\tau_\pm$, *which are holomorphically extendable into the upper/lower half-plane* $\mathbb{C}_\pm$: $\operatorname{Im} \xi \gtrless 0$ *and continuous on* $\overline{\mathbb{C}_\pm}$, *respectively, where any consistent branches are chosen. Analogously, let*

$$\sqrt{\det G} = \gamma_- \gamma_+ \tag{5.9}$$

be a multiplicative decomposition, i.e., a (function-theoretical) factorization and also

$$\frac{1}{g} = \frac{1}{g_-} \frac{1}{g_+} \tag{5.10}$$

according to the poles, i.e., $g_\pm(\xi) \neq 0$ *in* $\overline{\mathbb{C}_\pm}$.

Then a factorization of G into lower/upper holomorphic function matrices reads

$$\begin{aligned} G &= G_- G_+, \\ G_\pm &= \gamma_\pm \left\{ \frac{g_\mp \cosh\left(\frac{1}{2}\sqrt{f}\tau_\pm\right)}{g_\pm} I + \frac{\sinh\left(\frac{1}{2}\sqrt{f}\tau_\pm\right)}{g_\pm^2 \sqrt{f}} R \right\}. \end{aligned} \tag{5.11}$$

Proof. See [9] for the choice $g = 1$; the modified result is then obvious [8].

Remark 5.2. (1) For factoring matrices of the form (1.6) $\sigma = \mu_1 R_1 + \mu_2 R_2$ we first can try to factor $R_1 = R_{1-} R_{1+}$ (or R_2) and to consider $\sigma = R_{1-}(\mu_1 I + \mu_2 R_{1-}^{-1} R_2 R_{1+}^{-1}) R_{1+}$ where the middle factor can be rewritten in the *Khrapkov canonical form* [8]

$$\begin{aligned} \mu_1 I + \mu_2 T &= \mu_1 I + \frac{\mu_2}{2}(T + \tilde{T}) + \frac{\mu_2}{2}(T - \tilde{T}) \\ &= a_1 I + a_2 R, \\ \tilde{T} &= \begin{pmatrix} t_{22} & -t_{12} \\ -t_{21} & t_{11} \end{pmatrix}. \end{aligned} \tag{5.12}$$

For our purposes the factorization of rational matrices [2], [22] is straightforward.

(2) R is of commutant form (5.6), if and only if $R^2 = -\det R \cdot I$ holds, i.e., $R^{-1} = -R/\det R$ for regular matrices.

(3) If $\gamma_\pm^{-1}$ are also upper/lower holomorphic, then the inverses of (5.11) yield a (right) factorization $G^{-1} = G_-^{-1} G_+^{-1}$ up to rational scalar factors, since $G_\pm$ commute with each other and

$$\det G_\pm = \gamma_\pm^2 g_\mp^2 / g_\pm^2. \tag{5.13}$$

(4) The Khrapkov formula (5.11) simplifies essentially, if $f \equiv 1$ holds. A factorization of

$$a_1 + a_2 g = \mu = \mu_- \mu_+, \qquad a_1 - a_2 g = \nu = \nu_- \nu_+, \tag{5.14}$$

which are assumed to be nonzero on the line due to $\det G \neq 0$, then yields the simpler formula

$$G_\pm = \frac{1}{2}\left\{ \frac{g_\mp}{g_\pm}[\mu_\pm + \nu_\pm] I + \frac{1}{g_\pm^2}[\mu_\pm - \nu_\pm] R \right\}. \tag{5.15}$$

For our symbol algebra (matrices which are rational in t) the algebraic behavior at infinity is obvious. The only difficulty is that the numerator $g_\mp$ destroys the desired holomorphic properties of $G_\pm^{-1}$. In some cases this leads to the middle factor of (5.2).

(5) In general, if the degree of f is higher than two, the factors $G_\pm$ increase exponentially. Based on the above existence results for generalized factorizations, it can be proven that the following trick of Daniele [3], [8] helps to obtain algebraic behavior. Split a polynomial matrix of the form $p_1 I + p_2 R$ into factors with the same exponential behavior as we found in $G_\pm$ using Khrapkov's method, and split the same matrix, once more elementary with algebraic behavior. Combining appropriate factors we obtain a factorization of G with algebraic growth; see § 9, for instance.

(6) Further tricks to reduce the algebraic growth degree are already known from [21]: split off diagonal matrices as shown in (5.2) or polynomial matrices with a constant determinant such that the increase of $G_\pm$ matrix elements are cancelled simultaneously; also see § 6.

(7) The symmetry observed in the first remark (exchange the roles of R_1, R_2, if both are invertible) leads to an alternate factorization, which is equivalent to the modification $G_- G_+ = (\det R)^{-1}(G_- R)(R G_+)$ of (5.11), and yields factors

$$G'_\pm = \frac{\gamma_\pm}{g_\pm^2 f_\pm}\left\{\cosh\left(\frac{1}{2}\sqrt{f}\tau_\pm\right)R + g\sqrt{f}\sinh\left(\frac{1}{2}\sqrt{f}\tau_\pm\right)I\right\}. \tag{5.16}$$

We are now going to use these ideas in a discussion of the above-mentioned class of parameter-dependent problems, which are listed in the order of growing complexity.

6. The case $d=0$, $\alpha_{13}\alpha_{21}\neq 0$. We continue considering the matrix σ in (3.1), assume (3.2), and start the factoring procedure for the case $\alpha_{13}\alpha_{21}\neq 0$. First write σ in the Khrapkov canonical form (5.5) as

$$\sigma = \begin{pmatrix} \alpha_{11} & \alpha_{13} \\ \alpha_{21} & 0 \end{pmatrix}\{a_1 I + a_2 R\},$$

$$R = \begin{pmatrix} -c & a \\ b & c \end{pmatrix} = \begin{pmatrix} -\dfrac{\alpha_{11}\alpha_{12}-\alpha_{12}\alpha_{21}}{\alpha_{13}\alpha_{21}} & -\dfrac{2\alpha_{22}}{\alpha_{21}} \\ -\dfrac{2\alpha_{14}}{\alpha_{13}}t^2 & \dfrac{\alpha_{11}\alpha_{22}-\alpha_{12}\alpha_{21}}{\alpha_{13}\alpha_{21}} \end{pmatrix}, \tag{6.1}$$

$$a_1 = 1+\frac{c}{2t}, \qquad a_2 = \frac{1}{2t};$$

see (5.12). Therefore, put

$$\begin{aligned} -\det R &= c^2 + ab = c^2 + 4\lambda t^2 \\ &= \left(\frac{\alpha_{11}\alpha_{22}-\alpha_{12}\alpha_{21}}{\alpha_{13}\alpha_{21}}\right)^2 + 4\frac{\alpha_{14}\alpha_{22}}{\alpha_{13}\alpha_{21}}(\xi^2 - k^2) = f; \end{aligned} \tag{6.2}$$

see (5.7) where the characteristic parameter $\lambda = \alpha_{14}\alpha_{22}/\alpha_{13}\alpha_{21} \in \mathbb{C}\backslash[0,1]$ from (3.8) appears (the case $f = 4\lambda\xi^2$ is not excluded). We look at the asymptotic behavior of (5.8):

$$\begin{aligned} a_1 \pm a_2\sqrt{f} &= 1 + \frac{c \pm \sqrt{f}}{2t} \sim 1 \pm \sqrt{\lambda}, \qquad |\xi| \to \infty, \\ \tau &= \frac{1}{\sqrt{f}}\log\frac{a_1 + a_2\sqrt{f}}{a_1 - a_2\sqrt{f}} \sim \frac{1}{2\sqrt{\lambda}\,t}\log\frac{1+\sqrt{\lambda}}{1-\sqrt{\lambda}}. \end{aligned} \tag{6.3}$$

The Wiener-Levy theorem yields that τ is a Wiener algebra element, the Fourier transform of an L^1-function. Using the Hilbert transform projectors, we obtain the

additive decomposition $\tau = \tau_- + \tau_+$ where

$$\begin{aligned}\tau_\pm(\xi) &= \frac{1}{2}\left\{\tau(\xi) \pm \frac{1}{\pi i}\int_{-\infty}^{\infty} \frac{\tau(\zeta)}{\zeta - \xi}\, d\zeta\right\} \\ &\sim \pm \frac{1}{2\pi i}\,\frac{1}{2\sqrt{\lambda}} \log\frac{1+\sqrt{\lambda}}{1-\sqrt{\lambda}}\,\frac{-2}{\xi} \log\frac{2\xi}{ik}, \qquad \xi \to \pm\infty;\end{aligned} \tag{6.4}$$

see [21, (3.8)]. This implies

$$\begin{aligned}\frac{1}{2}\sqrt{f}\tau_\pm &\sim \mp \frac{1}{2\pi i} \log\frac{1+\sqrt{\lambda}}{1-\sqrt{\lambda}} \operatorname{sgn}\xi \log|\xi|, \qquad \xi \to \pm\infty, \\ \exp\left(\frac{1}{2}\sqrt{f}\tau_\pm\right) &= \begin{cases} O(\xi^{\pm\delta/2}), & \xi \to +\infty, \\ O(|\xi|^{\pm\delta/2}), & \xi \to -\infty, \end{cases}\end{aligned} \tag{6.5}$$

where

$$\delta = \operatorname{Re}\frac{1}{i\pi}\log\frac{1+\sqrt{\lambda}}{1-\sqrt{\lambda}} \in (0, 1]. \tag{6.6}$$

It follows that we have the same operator theoretic situation as in [21] (see formulas (3.13) there), which corresponds to the subcase $\alpha_{11} = \alpha_{12} = 0$, i.e., taking into account only the principal part of the boundary operator, in which case the factorization was more explicit due to an evaluation of $\tau_\pm$ in (6.4). Referring to those considerations we mention only the main results.

COROLLARY 6.1. *Let σ be given by* (3.1), $\det\sigma(\xi) \neq 0$, $\alpha_{13}\alpha_{21} \neq 0$, $\lambda = \alpha_{14}\alpha_{22}/\alpha_{13}\alpha_{21} \notin [0, 1]$. *With the notation* (6.1)-(6.6), *we obtain a (function-theoretical) factorization of $G = a_1 I + a_2 R = G_- G_+$ into lower/upper holomorphic function matrices with algebraic behavior at infinity given by*

$$G_\pm = (1+\lambda)^{1/4}\left\{\cosh\left(\frac{1}{2}\sqrt{f}\tau_\pm\right) I + \frac{\sinh\left(\frac{1}{2}\sqrt{f}\tau_\pm\right)}{\sqrt{f}}\, R\right\} \tag{6.7}$$

from Khrapkov's Theorem 5.1 and consequently

$$\begin{aligned}&\sigma = \tilde{\sigma}_-\tilde{\sigma}_+, \quad \tilde{\sigma}_- = \begin{pmatrix} \alpha_{11} & \alpha_{13} \\ \alpha_{21} & 0 \end{pmatrix} G_-, \quad \tilde{\sigma}_+ = G_+, \\ &\sigma_0 = \begin{pmatrix} t_-^{-1} & 0 \\ 0 & t_- \end{pmatrix} \tilde{\sigma}_-\tilde{\sigma}_+ \begin{pmatrix} t_+^{-1} & 0 \\ 0 & t_+ \end{pmatrix} = \tilde{\sigma}_{0-}\tilde{\sigma}_{0+}.\end{aligned} \tag{6.8}$$

The orders of (these candidates for a generalized factorization) $\tilde{\sigma}_{0\pm}$ read (see [21, (4.4)])

$$\begin{aligned}\operatorname{ord}\tilde{\sigma}_{0-} &= \begin{pmatrix} \frac{1}{2}(\delta+1) & \frac{1}{2}(\delta-1) \\ \frac{1}{2}(\delta+1) & \frac{1}{2}(\delta-1) \end{pmatrix}, \\ \operatorname{ord}\tilde{\sigma}_{0+} &= \begin{pmatrix} \frac{1}{2}(\delta-1) & \frac{1}{2}(\delta-1) \\ \frac{1}{2}(\delta+1) & \frac{1}{2}(\delta+1) \end{pmatrix}.\end{aligned} \tag{6.9}$$

Remark 6.2. Therefore, $\tilde{\sigma}_0 = \tilde{\sigma}_{0-}\tilde{\sigma}_{0+}$ does not represent a generalized factorization of $\sigma_0 \in PC(\dot{\mathbb{R}})^{2\times 2}$ (where only orders less than $\frac{1}{2}$ are allowed (cf. [21, Lemma 4.1])). But the inverse factor matrices are also lower/upper holomorphic; see (6.7) and Remark 5.2(3).

COROLLARY 6.3. *A generalized factorization of σ_0 is obtained by putting*

$$\sigma_0 = \sigma_{0-}\sigma_{0+} = \tilde{\sigma}_{0-}\begin{pmatrix} 1 & 0 \\ \xi/\sqrt{\lambda} & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ -\xi/\sqrt{\lambda} & 1 \end{pmatrix}\tilde{\sigma}_{0+} \tag{6.10}$$

(*cf.* [21, 4.4]), *since the asymptotics are governed by the principal part analogue with*

$$\text{ord } \sigma_{0-} = \begin{pmatrix} \frac{1}{2}(1-\delta) & \frac{1}{2}(\delta-1) \\ \frac{1}{2}(1-\delta) & \frac{1}{2}(\delta-1) \end{pmatrix},$$
$$\text{ord } \sigma_{0+} = \begin{pmatrix} \frac{1}{2}(\delta-1) & \frac{1}{2}(\delta-1) \\ \frac{1}{2}(1-\delta) & \frac{1}{2}(1-\delta) \end{pmatrix}. \tag{6.11}$$

Thus the corresponding translation invariant operators $A_{0\pm} = F^{-1}\sigma_{0\pm} \cdot F$ *are bounded on* $L^2(\mathbb{R}^2)$, *if and only if* $\delta = 1$ *is satisfied, which corresponds to* $\lambda \in (1, \infty)$.

COROLLARY 6.4. *Under the same assumptions the following statements hold*:

(1) *The lifted Wiener-Hopf operator* $W_0 = 1_+ \cdot A_0 = 1_+ \cdot F^{-1}\sigma_0 \cdot F : L^2(\mathbb{R}_+)^2 \to L^2(\mathbb{R}_+)^2$ *is invertible as*

$$W_0^{-1} = A_{0+}^{-1}1_+ \cdot A_{0-}^{-1} \tag{6.12}$$

(*defined on a dense subspace, if* $\delta \neq 1$);

(2) *The Wiener-Hopf operator* W *in* (3.1) *is invertible as*

$$W^{-1} = F^{-1}\sigma_+^{-1} \cdot F1_+ \cdot F^{-1}\sigma_-^{-1} \cdot Fl \tag{6.13}$$

with any extension l *from* $H^{-1/2}(\mathbb{R}_+) \times H^{1/2}(\mathbb{R}_+)$ *into* $H^{-1/2} \times H^{1/2}$ (*e.g., odd in the first and even in the second place*; *see* [5, 20]), *where* (6.7) *gives*

$$\sigma_- = \begin{pmatrix} \alpha_{11} & \alpha_{13} \\ \alpha_{21} & 0 \end{pmatrix} G_- \begin{pmatrix} 1 & 0 \\ \xi/\sqrt{\lambda} & 1 \end{pmatrix},$$
$$\sigma_+ = \begin{pmatrix} 1 & 0 \\ -\xi/\sqrt{\lambda} & 1 \end{pmatrix} G_+. \tag{6.14}$$

(3) *Problem* $\mathcal{P}$ *is well posed for* $h_1 \in H^{-1/2}(\mathbb{R}_+)$ *and* $h_2 \in H^{1/2}(\mathbb{R}_+)$. *The solution is given by* (1.4), (2.2)-(2.3), (6.13)-(6.14), (6.7), (6.1)-(6.4), *which yield direct a priori estimates*

$$\|u|_{\Omega^\pm}\|_{H^1(\Omega^\pm)} \leqq \text{const} \cdot \{\|h_1\|_{H^{-1/2}(\mathbb{R}_+)} + \|h_2\|_{H^{1/2}(\mathbb{R}_+)}\}. \tag{6.15}$$

COROLLARY 6.5. *Furthermore, the asymptotics of the first derivatives of the solution at the origin is given by*

$$\nabla u(x_1, x_2) \sim \text{const} \cdot \sqrt{x_1^2 + x_2^2}^{\,\delta/2-1} \tag{6.16}$$

where $\delta = \text{Re}[(i\pi)^{-1}\log((1+\sqrt{\lambda})/(1-\sqrt{\lambda}))] \in (0, 1]$ *provided the data* h_j *are sufficiently smooth. We find a square root singularity similar to Sommerfeld's half-plane problem* [12], [16], [21], *if and only if* $\delta = 1$ *holds.*

7. The case $d = 0$, $\alpha_{13}\alpha_{21} = 0$. Here we find decoupling systems and give only some hints on how to proceed (cf. [20]). Starting with (3.1)-(3.2) and $\alpha_{21} = 0$, which implies $\alpha_{14}\alpha_{22} \neq 0$, we may apply a simple factorization rule for triangular matrices (see [8, formula (1.5)]),

$$\sigma = \begin{pmatrix} \alpha_{11} - \alpha_{14}t & \alpha_{13} - \dfrac{\alpha_{12}}{t} \\ 0 & -\dfrac{\alpha_{22}}{t} \end{pmatrix} = \sigma_-\sigma_+$$
$$= \begin{pmatrix} t_-\varphi_- & t_-\varphi_-\eta_- \\ 0 & -\dfrac{\alpha_{22}}{t_-} \end{pmatrix} \begin{pmatrix} -\alpha_{14}t_+\varphi_+ & \dfrac{\eta_+}{t_+} \\ 0 & \dfrac{1}{t_+} \end{pmatrix}, \tag{7.1}$$

$$\varphi = 1 - \frac{\alpha_{11}}{\alpha_{14} t} = \varphi_- \varphi_+, \qquad \psi = \alpha_{13} - \frac{\alpha_{12}}{t},$$

(7.2)

$$\eta = \frac{t_+ \psi}{t_- \varphi_-}, \qquad H_\pm \eta = \eta_\pm .$$

$H_\pm = F 1_\pm \cdot F^{-1}$ denote the Hilbert transform projectors (see (6.4)) and all elements are in the $\pm$ Wiener subalgebra corresponding to the indices. Note that φ does not vanish on $\mathbb{R}$ due to $\det \sigma \neq 0$; its winding number is zero, since φ is an even function, and thus $\varphi_\pm^{-1}$ are also holomorphic in $\mathbb{C}_\pm$.

Considering the orders, ord $t_\pm = 1/2$ and therefore

$$A_- A_+ = F^{-1}\sigma_- F \cdot F^{-1}\sigma_+ \cdot F : H^{1/2} \times H^{-1/2} \to L^2 \times L^2 \to H^{-1/2} \times H^{1/2} \tag{7.3}$$

as linear bounded and invertible operators (see (7.1)), it is obvious that the lifted factorization (drop $t_\pm$ in (7.1)) consists also of bounded invertible operators according to $\sigma_{0\pm}^{\pm 1} \in C(\dot{\mathbb{R}})^{2\times 2}$, and the inverse symbol matrices $\sigma_{0\pm}^{-1}$ are also holomorphic in $\mathbb{C}_\pm$.

COROLLARY 7.1. *In this case $\mathcal{P}$ is well posed for any data $h_1 \in H^{-1/2}(\mathbb{R}_+)$, $h_2 \in H^{1/2}(\mathbb{R}_+)$. W has a bounded inverse as in* (6.13) *and $\nabla u \sim \text{const} \cdot (x_1^2 + x_2^2)^{-1/2}$ holds near the origin.*

Considering finally the case $\alpha_{13} = 0$, which also implies $\alpha_{14}\alpha_{22} \neq 0$ for W to be Fredholm, we can write

$$\sigma = \begin{pmatrix} \alpha_{11} - \alpha_{14} t & -\dfrac{\alpha_{12}}{t} \\ \alpha_{21} & -\dfrac{\alpha_{22}}{t} \end{pmatrix} = \begin{pmatrix} 1 & \dfrac{\alpha_{12}}{\alpha_{22}} \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \alpha_{11} - \dfrac{\alpha_{12}\alpha_{21}}{\alpha_{22}} - \alpha_{14} t & 0 \\ \alpha_{21} & -\dfrac{\alpha_{22}}{t} \end{pmatrix} \tag{7.4}$$

which leads to a quite similar result after factoring the triangular matrix as before in (7.1).

8. The case $d = 1$, $\alpha_{11}\alpha_{12}\alpha_{21}\alpha_{22} = 0$. We have to factor the matrix $\tilde{\tilde{\sigma}} = \bar{\sigma}$ in (4.10):

$$\bar{\sigma} = \begin{pmatrix} \dfrac{\alpha_{11}}{t} & 1 - \dfrac{\alpha_{12}}{t} \\ \alpha_{21} - t & -\alpha_{22} \end{pmatrix}$$

(8.1)

$$= \begin{pmatrix} 0 & 1 \\ \alpha_{21} & -\alpha_{22} \end{pmatrix} \left\{ I + \frac{1}{\alpha_{21} t} \begin{pmatrix} \alpha_{11}\alpha_{22} - t^2 & -\alpha_{12}\alpha_{22} \\ \alpha_{11}\alpha_{21} & -\alpha_{12}\alpha_{21} \end{pmatrix} \right\}$$

considering first the case $\alpha_{21} \neq 0$. In Khrapkov form (5.5) the term in braces reads

$$G = a_1 I + a_2 R,$$

$$a_1 = 1 + \frac{\alpha_{11}\alpha_{22} - \alpha_{12}\alpha_{21} - t^2}{2\alpha_{21} t}, \qquad a_2 = \frac{1}{2\alpha_{21} t}, \tag{8.2}$$

$$R = \begin{pmatrix} -c & a \\ b & c \end{pmatrix} = \begin{pmatrix} -[t^2 - (\alpha_{11}\alpha_{22} + \alpha_{12}\alpha_{21})] & -2\alpha_{12}\alpha_{22} \\ 2\alpha_{11}\alpha_{21} & t^2 - (\alpha_{11}\alpha_{22} + \alpha_{12}\alpha_{21}) \end{pmatrix}.$$

Further, we put

$$\begin{aligned} -\det R &= c^2 + ab \\ &= t^4 - 2t^2(\alpha_{11}\alpha_{22} + \alpha_{12}\alpha_{21}) + (\alpha_{11}\alpha_{22} - \alpha_{12}\alpha_{21})^2 \\ &= g^2 f. \end{aligned} \tag{8.3}$$

This contains a square factor, if $\alpha_{11}\alpha_{12}\alpha_{21}\alpha_{22}=0$ holds, and then it is even of the form

$$-\det R=(t^2\pm\det\alpha_1)^2=g^2 \tag{8.4}$$

with $f\equiv 1$ where the Khrapkov method works most effectively (see Remark 5.2(4)), unless the subexceptional case $\xi_0^2=k^2\mp\det\alpha_1\in\mathbb{R}$ is given, since real zeros have to be put into the f (see Theorem 5.1).

However, in the case $\alpha_{11}\alpha_{12}\alpha_{22}=0$, $\bar\sigma$ decomposes, and we again easily get similar results to § 7 with a bounded operator factorization, the usual square root singularity, etc. This is not repeated here. But note that the decoupling of the system (in contrast to other cases like Example 3.5) does not imply a modification of the function space setting (4.11) and (4.10). ($H^{-1/2}(\mathbb{R}_+)$ cannot be replaced by $\tilde H^{-1/2}(\mathbb{R}_+)$.)

Another more complicated problem occurs for $\alpha_{21}=0$ and $\alpha_{11}\alpha_{12}\alpha_{22}\neq 0$ where the system does not decouple, but the constant matrix in (8.1) becomes singular. So we write

$$\begin{aligned}\bar\sigma&=\begin{pmatrix}0&1\\0&-\alpha_{22}\end{pmatrix}+\frac{1}{t}\begin{pmatrix}\alpha_{11}&-\alpha_{12}\\-t^2&0\end{pmatrix}\\&=\frac{1}{t_-}\begin{pmatrix}1&0\\0&-t_-^2\end{pmatrix}\left\{I+\frac{1}{\alpha_{12}t}\begin{pmatrix}-t^2&\alpha_{11}t_-^2\\-\alpha_{22}t_+^2&\alpha_{11}\alpha_{22}\end{pmatrix}\right\}\begin{pmatrix}\alpha_{11}&-\alpha_{12}\\t_+^2&0\end{pmatrix}\frac{1}{t_+}\end{aligned} \tag{8.5}$$

and the term in braces reads in Khrapkov form

$$\begin{aligned}&G=a_1I+a_2R,\\&a_1=1-\frac{1}{2\alpha_{12}t}(t^2-\alpha_{11}\alpha_{22}),\qquad a_2=\frac{1}{2\alpha_{12}t},\\&R=\begin{pmatrix}-c&a\\b&c\end{pmatrix}=\begin{pmatrix}-(t^2+\alpha_{11}\alpha_{22})&2\alpha_{11}t_-^2\\-2\alpha_{22}t_+^2&t^2+\alpha_{11}\alpha_{22}\end{pmatrix}.\end{aligned} \tag{8.6}$$

Now, following the factorization method of § 5, we obtain

$$-\det R=c^2+ab=(t^2-\alpha_{11}\alpha_{22})^2=g^2 \tag{8.7}$$

with $f\equiv 1$, if we first consider the case $k^2+\alpha_{11}\alpha_{22}\in\mathbb{C}\backslash[0,\infty)$. Further we have to set (see (5.14))

$$\begin{aligned}&\mu=a_1+a_2g=1,\\&\nu=a_1-a_2g=1-\frac{1}{\alpha_{12}t}(t^2-\alpha_{11}\alpha_{22})=-\frac{t}{\alpha_{12}}\left(1-\frac{\alpha_{12}}{t}-\frac{\alpha_{11}\alpha_{22}}{t^2}\right)\\&\qquad=-\frac{t}{\alpha_{12}}\,\omega=\left(-\frac{t_-\omega_-}{\alpha_{12}}\right)(t_+\omega_+)=\det G,\\&g(\xi)=\xi^2-k^2-\alpha_{11}\alpha_{22}=(\xi-\xi_0)(\xi+\xi_0)=g_-(\xi)g_+(\xi)\end{aligned} \tag{8.8}$$

with $\xi_0=\sqrt{k^2+\alpha_{11}\alpha_{22}}\in\mathbb{C}_+$. Note that the bounded factors of $\omega=\omega_-\omega_+$ are unique up to a constant, since they are Wiener algebra elements. Formula (5.15) yields the factorization $G=G_-G_+$ into lower/upper holomorphic matrix functions

$$\begin{aligned}G_-&=\frac{1}{2}\left\{\frac{\xi+\xi_0}{\xi-\xi_0}\left(1-\frac{t_-\omega_-}{\alpha_{12}}\right)I+\frac{1}{(\xi-\xi_0)^2}\left(1+\frac{t_-\omega_-}{\alpha_{12}}\right)R\right\},\\G_+&=\frac{1}{2}\left\{\frac{\xi-\xi_0}{\xi+\xi_0}(1+t_+\omega_+)I+\frac{1}{(\xi+\xi_0)^2}(1-t_+\omega_+)R\right\}.\end{aligned} \tag{8.9}$$

We conclude

$$\text{ord } G_\pm = \begin{pmatrix} \frac{1}{2} & -\frac{1}{2} \\ -\frac{1}{2} & 0 \end{pmatrix} \tag{8.10}$$

according to a cancellation of two terms of order $\frac{1}{2}$ in the last place. We can see from (4.12) and (8.5) that the lifted factors are bounded, since

$$\begin{aligned} &\text{ord} \begin{pmatrix} 1 & 0 \\ 0 & 1/t_- \end{pmatrix} \frac{1}{t_-} \begin{pmatrix} 1 & 0 \\ 0 & -t_-^2 \end{pmatrix} G_- = \begin{pmatrix} 0 & -1 \\ -\frac{1}{2} & 0 \end{pmatrix}, \\ &\text{ord } G_+ \begin{pmatrix} \alpha_{11} & -\alpha_{12} \\ t_+^2 & 0 \end{pmatrix} \frac{1}{t_+} \begin{pmatrix} 1/t_+ & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} -\frac{1}{2} & 0 \\ 0 & -1 \end{pmatrix} \end{aligned} \tag{8.11}$$

hold. But this does not give a right canonical factorization, because the factors $\xi \pm \xi_0$ in $G_\mp$ destroy the desired holomorphic properties of the inverses.

Choosing the value of the factor $\omega_+(\xi)$ at $\xi = \xi_0$ such that $1 - t_+\omega_+$ vanishes at $\xi = \xi_0$, we may split off a scalar $(\xi - \xi_0)/(\xi + \xi_0)$ from G_+, and it follows that the remainder matrix has a holomorphic inverse in $\mathbb{C}_+$. It can be shown that this determination of $\omega = \omega_-\omega_+$ yields $1 + (t_-\omega_-/\alpha_{12}) = 0$ at $\xi = -\xi_0$, such that a factor $(\xi + \xi_0)/(\xi - \xi_0)$ can be split off in G_- and cancels the previous one.

This together with (8.11) leads to a factorization of the (unlifted) symbol matrix $\bar{\sigma} = \bar{\sigma}_-\bar{\sigma}_+$ into

$$\begin{aligned} \bar{\sigma}_- &= \frac{1}{2t_-} \begin{pmatrix} 1 & 0 \\ 0 & -t_-^2 \end{pmatrix} \left\{ \left(1 - \frac{t_-\omega_-}{\alpha_{12}} \right) I + \frac{1}{\xi^2 - \xi_0^2} \left(1 + \frac{t_-\omega_-}{\alpha_{12}} \right) R \right\}, \\ \bar{\sigma}_+ &= \frac{1}{2t_+} \left\{ (1 + t_+\omega_+) I + \frac{1}{\xi^2 - \xi_0^2} (1 - t_+\omega_+) R \right\} \begin{pmatrix} \alpha_{11} & -\alpha_{12} \\ t_+^2 & 0 \end{pmatrix} \end{aligned} \tag{8.12}$$

(with $t_\pm^2 = \xi \pm k$) and the usual situation of a bounded operator factorization and the square root singularity.

The remaining exceptional case in this section is $\alpha_{21} = 0$, $\alpha_{11}\alpha_{12}\alpha_{22} \neq 0$, $\xi_0^2 = k^2 + \alpha_{11}\alpha_{22} \in [0, \infty)$. Here we have two real double zeros in (8.7). We can use the Khrapkov factorization formulas (5.11) with $g_\pm = 1$ and

$$\sqrt{f} = t^2 - \alpha_{11}\alpha_{22} = \xi^2 - k^2 - \alpha_{11}\alpha_{22} = \xi^2 - \xi_0^2. \tag{8.13}$$

The idea is [8] to compensate for the exponential behavior of $G_\pm$ at infinity by factoring a polynomial matrix of the form

$$Q = b_1 I + b_2 R \tag{8.14}$$

with rational coefficients b_j such that the factors have the inverse asymptotics.

The following more important case uses a similar argument, so we refer to analogy here.

9. The case $d = 1$, $\alpha_{11}\alpha_{12}\alpha_{21}\alpha_{22} \neq 0$. Now we continue from (8.3) writing $-\det R = f$, since it contains no square factor except the factor ξ^2 in the special case of

$$k^4 + 2k^2\lambda_2 + \lambda_1^2 = 0, \tag{9.1}$$

where we abbreviate

$$\begin{aligned} \lambda_1 &= \alpha_{11}\alpha_{22} - \alpha_{12}\alpha_{21} = \det \alpha_1, \\ \lambda_2 &= \alpha_{11}\alpha_{22} + \alpha_{12}\alpha_{21}. \end{aligned} \tag{9.2}$$

In order to apply the Khrapkov formulas (5.11) to (8.2), we compute

$$a_1 \pm a_2\sqrt{f} = 1 + \frac{1}{2\alpha_{21} t}[\lambda_1 - t^2 \pm (t^4 - 2\lambda_2 t^2 + \lambda_1^2)^{1/2}] \tag{9.3}$$

with $\lambda_1 \neq \pm\lambda_2$ according to the headline assumption. This yields

$$a_1 + a_2\sqrt{f} \sim 1, \quad a_1 - a_2\sqrt{f} \sim -\frac{t}{\alpha_{21}}, \quad \text{as } \xi \to \pm\infty,$$

$$\det G = a_1^2 - a_2^2 f \sim -\frac{t}{\alpha_{21}}, \tag{9.4}$$

$$\sqrt{\det G} = \gamma_- \gamma_+ \sim \sqrt{\frac{-1}{\alpha_{21}}}\, t_-^{1/2} t_+^{1/2}$$

due to a factorization in the Wiener algebra. Further,

$$\tau = \frac{1}{\sqrt{f}} \log \frac{a_1 + a_2\sqrt{f}}{a_1 - a_2\sqrt{f}} \sim \frac{1}{t^2} \log \frac{-\alpha_{21}}{t} = \tau_- + \tau_+ \tag{9.5}$$

holds, where

$$\begin{aligned} \tau_\pm(\xi) &= \frac{1}{2}\left\{ \tau(\xi) \pm \frac{1}{\pi i} \int_{-\infty}^{\infty} \frac{\tau(\zeta)}{\zeta - \xi}\, d\zeta \right\} \\ &= \frac{c_1}{\xi} + O\left(\frac{1}{\xi^2} \log |\xi| \right) \end{aligned} \tag{9.6}$$

with a constant c_1 (cf. [23]).

From the Khrapkov formulas (5.11) (with $g_\pm = 1$), we see that the factors

$$\begin{aligned} G_\pm &= \gamma_\pm \left\{ \cosh\left(\tfrac{1}{2}\sqrt{f}\tau_\pm\right) I + \frac{\sinh\left(\tfrac{1}{2}\sqrt{f}\tau_\pm\right)}{\sqrt{f}} R \right\} \\ &\sim \gamma_\pm \exp\left(\tfrac{1}{2} \operatorname{Re} c_1 |\xi|\right) \left\{ I + \frac{1}{\xi^2} R \right\} \end{aligned} \tag{9.7}$$

increase exponentially in general.

PROPOSITION 9.1. *There exists a polynomial matrix $G' = a_1' I + a_2' R$ with Khrapkov factors that behaves at infinity like $G_\pm$ up to the scalar factors $\gamma_\pm$, i.e., there holds the same formula* (9.6) *for $\tau_\pm'$.*

Proof. We consider the ansatz

$$G' = (C - t^2) I + R \tag{9.8}$$

with a constant C. For factoring we have

$$\begin{aligned} \tau' &= \frac{1}{\sqrt{f}} \log \frac{a_1' + a_2'\sqrt{f}}{a_1' - a_2'\sqrt{f}} = \frac{1}{\sqrt{f}} \log \frac{C - t^2 + \sqrt{f}}{C - t^2 - \sqrt{f}} \\ &\sim \frac{1}{t^2} \log \frac{\lambda_2 - C}{2t^2}. \end{aligned} \tag{9.9}$$

Abelian theorems for the Hilbert transformation [23] lead to (9.6), again provided C is chosen suitably (which involves elliptic integrals).

THEOREM 9.2. *In the case $d = 1$, $\alpha_{11}\alpha_{12}\alpha_{21}\alpha_{22} \neq 0$, a factorization of G in* (8.2) *with algebraic behavior at infinity is given by*

$$G = G' G_- G_-'^{-1} G_+'^{-1} G_+. \tag{9.10}$$

(*The polynomial matrix can also be put at another place between the factors.*)

Proof. Matrices of the form $G = a_1 I + a_2 R$ with a fixed commutant R form a commutative algebra. In particular, $G^{-1} = (\det G)^{-1}(a_1 I - a_2 R)$ holds (if $\det G \neq 0$) and the Khrapkov factorization of GG'^{-1} coincides with the product of the two single factorizations after a rearrangement of the factors. Therefore, (9.6) and the preceding result yield a cancelation of the exponential increase, and the stated algebraic behavior at infinity holds.

Remark 9.3. Unfortunately, the explicit representation of this factorization is quite complicated in general. So we do not work out the procedure of constructing a generalized factorization of $\bar{\sigma}$. But the main questions are already answered. First, we may directly use the classical Wiener-Hopf procedure for applications starting with (9.10) to get an explicit solution. Second, the type of the singularity is known to be the same as for the principal part problem; for instance, set $\alpha_{12} = 0$, and see § 8.

A GENERAL CONVERGENCE RESULT FOR A FUNCTIONAL RELATED TO THE THEORY OF HOMOGENIZATION*

GABRIEL NGUETSENG†

Abstract. The convergence, as $\varepsilon \downarrow 0$, of the functional $F_\varepsilon(\Psi) = \int_{\mathbb{R}^N} u_\varepsilon(x)\Psi(x, x/\varepsilon)$ associated with a given L^2 function u_ε with support in a fixed compact set is studied. The test functions $\Psi(x, y)$ are continuous on $\mathbb{R}^N \times \mathbb{R}^N$ and periodic in y. A convergence theorem is proved under the weaker assumption that u_ε remains in a bounded subset of L^2. Finally, the use of multiple-scale expansions in homogenization is justified, and a new approach is proposed for the mathematical analysis of homogenization problems.

Key words. partial differential equations, homogenization, convergence, functional, periodic

AMS(MOS) subject classifications. 35B40, 41A35

1. Introduction. The mathematical analysis of *homogenization* problems for *partial differential equations* (see [1], [9]) utilizes the functionals of the type

$$F_\varepsilon(\Psi) = \int_\Omega u_\varepsilon(x)\Psi\left(x, \frac{x}{\varepsilon}\right) dx \quad (\Omega \text{ a bounded open set in } \mathbb{R}^N).$$

The function u_ε is, say, in $L^2(\Omega)$ and is (or depends on) the solution of a partial differential equation on Ω with coefficients ε-periodic (i.e., periodic with period ε in each variable). The test function $\Psi(x, y)$ is continuous on $\bar{\Omega} \times \mathbb{R}^N$ ($\bar{\Omega}$ denotes the closure of Ω) and, for fixed x, the function $y \to \Psi(x, y)$ is periodic (with period 1 in each variable).

Let us bear in mind that for such a function, i.e., Ψ, the associated sequence $(\Psi^\varepsilon)_{\varepsilon>0}$, with $\Psi^\varepsilon(x) = \Psi(x, x/\varepsilon)$ for $x \in \Omega$, converges to the function

$$x \to \tilde{\Psi}(x) = \int_Y \Psi(x, y)\, dy \quad \text{in } L^2(\Omega)\text{-weak} \quad \text{as } \varepsilon \downarrow 0$$

(see, e.g., [1]), where $Y =]0, 1[^N$.

In view of convergence studies in the theory of homogenization two distinct situations may be considered:

(i) The sequence (u_ε) is assumed to contain a subsequence, still denoted by (u_ε) for simplicity, that converges strongly to a function u_0 in $L^2(\Omega)$ as $\varepsilon \downarrow 0$ (e.g., $u_\varepsilon \in H^1(\Omega)$, $\partial\Omega$ smooth, and (u_ε) is bounded in $H^1(\Omega)$). Hence, the corresponding sequence $(F_\varepsilon(\Psi))$ converges to the integral $\int_\Omega u_0(x)\tilde{\Psi}(x)\, dx$.

(ii) The more difficult situation, which we study here, is that in which the sequence (u_ε) only remains in a bounded subset of $L^2(\Omega)$. We may surely extract a weakly convergent subsequence, but we do not have any classical argument that allows us to pass to the limit in $F_\varepsilon(\Psi)$ for the corresponding subsequence. Indeed, for the convergence of the scalar product of two sequences in $L^2(\Omega)$, we classically need strong convergence for at least one of them.

Several aspects of this situation arise in homogenization. Let us point out two particularly interesting aspects:

(1) u_ε is some derivative of a function v_ε (i.e., $u_\varepsilon = \partial v_\varepsilon/\partial x_i$) that is the solution of a boundary value problem considered in the framework of homogenization, and the sequence (v_ε) is bounded in $H^1(\Omega)$ (see § 6). In general, this is typical of the

* Received by the editors December 17, 1986; accepted for publication (in revised form) April 26, 1988.

† Department of Mathematics, University of Yaounde, P.O.B. 812 Yaounde, Cameroon. This work was partially supported by the University of Yaounde, Cameroon.

so-called *regular* homogenization problems; that is, the class of the homogenization problems associated with a formal expansion (of the solution) of the type

$$v_\varepsilon(x) = v_0(x) + \varepsilon v_1\left(x, \frac{x}{\varepsilon}\right) + \varepsilon^2 v_2\left(x, \frac{x}{\varepsilon}\right) + \cdots, \tag{1.1}$$

where the leading term v_0, which does not depend on the local variables $y = x/\varepsilon$, "ignores" the local effects.

For the study of convergence, i.e., $\lim v_\varepsilon = v_0$ as $\varepsilon \downarrow 0$, which is one of the main objects in homogenization, we possess a method, the so-called Energy Method (see [1], [9]), that solves most of the problems of the above type. However, it does not exhibit the weak limit of the gradient $\partial v_\varepsilon/\partial x_i$, $i = 1, \cdots, N$ (that is, concretely, the local behaviour of v_ε), which is interesting from the physical point of view.

(2) u_ε is the solution of a boundary value problem whose formal analysis (in the framework of homogenization) is based on an asymptotic expansion of the type

$$u_\varepsilon(x) = u_0\left(x, \frac{x}{\varepsilon}\right) + \varepsilon u_1\left(x, \frac{x}{\varepsilon}\right) + \varepsilon^2 u_2\left(x, \frac{x}{\varepsilon}\right) + \cdots, \tag{1.2}$$

with a leading term depending on the local variables $y = x/\varepsilon$. The leading term is affected by the local effects and, consequently, there is no hope of extracting a strongly convergent subsequence from (u_ε). Here, the Energy Method becomes inoperative and, to our knowledge, there is no systematic way of proving convergence for related homogenization problems, referred to as *singular* homogenization problems (see [4], [5], [7, Chaps. 7, 8] for typical examples of this). Although we do not consider that question in this work, we believe the study of singular homogenization problems requires an appropriate approach that should be based on an extensive analysis of functionals of the type

$$F_\varepsilon(\Psi) = \int_\Omega u_\varepsilon(x)\Psi\left(x, \frac{x}{\varepsilon}\right) dx.$$

Our basic result is the proof of a convergence theorem for the functional $F_\varepsilon(\Psi) = \int_{\mathbb{R}^N} u_\varepsilon(x)\Psi(x, x/\varepsilon)\, dx$ (u_ε having its support in a fixed compact set) under the weaker hypothesis that the sequence (u_ε) remains bounded in L^2. There is no need to assume the possibility of extracting a strongly convergent subsequence.

Next, based on the above result, we give a complete justification of the use of multiple-scale asymptotic expansions (such as (1.1) or (1.2)) in the theory of homogenization: Assuming that $u_\varepsilon \in L^2(\Omega)$, with u_ε bounded in the L^2 norm, Theorem 2 gives the leading-order approximation to u_ε (in (1.2)). If u_ε lies in $H^1(\Omega)$ and is bounded in the H^1 norm, Theorem 3 gives the next-order approximation to u_ε. Theoretically, the higher-order approximations are naturally given by similar theorems provided that $u_\varepsilon \in H^2(\Omega)$ with u_ε bounded, $u_\varepsilon \in H^3(\Omega)$ with u_ε bounded, $\cdots$; however, that is quite labourious.

Finally, we propose an alternative way of proving convergence in homogenization. Our approach is carried out on a classical problem (to arrive at a correct understanding of a method, we prefer to start with a classical example). Nevertheless, we anticipate that its flexibility and its "spontaneity" make it more adaptable for unusual problems than the often very fastidious Energy Method. Indeed, the reader familiar with the so-called natural multiple-scale asymptotic method [1] will easily realize that our approach is nothing but its mathematical version. Furthermore, as we shall see in § 6, our approach exhibits the local behaviour of the solution. This is not accessible to the Energy Method, whose basic ingredient is strong convergence.

This paper is organized as follows. In § 2 we present some general notation and preliminaries. Section 3 is devoted to our basic result, the case of the whole space $\mathbb{R}^N$. In § 4 we give a more pragmatic version (in view of the theory of homogenization) of the above result, which takes into account more realistic test functions. In § 5 we prove a convergence theorem for the gradient $\partial u_\varepsilon/\partial x_i$, $i=1,\cdots,N$ (i.e., for a functional $F_\varepsilon(\Psi)$ with $\partial u_\varepsilon/\partial x_i$ in place of u_ε). In practice, such a result furnishes the next term (i.e., $u_1(x, x/\varepsilon)$ in (1.2)) in the asymptotic expansion of the solution u_ε, while the leading term is given by the theorem in § 4. Thus, the use of multiple-scale asymptotic expansions of the form (1.2) (or (1.1)) is rigorously justified in homogenization.

Finally, in § 6, we present a new approach for the mathematical analysis of homogenization problems.

We will be concerned solely with vector spaces over $\mathbb{R}$ although our result and arguments are still rigorously valid in the complex case—providing some minor modifications are made. The only measure considered in this work is the Lebesgue measure.

2. General notation and preliminaries. Let $\mathbb{R}^N (N\in\mathbb{N}, N\geqq 1)$ be the N-dimensional Euclidean space. Points in $\mathbb{R}^N$ are denoted by $x=(x_1,\cdots,x_N)$ (the global variables) or $y=(y_1,\cdots,y_N)$ (the local variables related to periodicity). The cube

$$Y=]0,1[^N=]0,1[\times\cdots\times]0,1[\ (N \text{ times})$$

is considered in the system of the local variables, with closure $\bar{Y}=[0,1]^N$.

By a Y-periodic function we mean a function on $\mathbb{R}^N$ that is periodic with period Y (i.e., with period 1 in each variable y_i).

Generally speaking, if E is a set (e.g., $\mathbb{R}^N$ or any open set in $\mathbb{R}^N$), we denote by $C(E)$ the space of continuous functions on E, by $\mathscr{K}(E)$ the space of those functions in $C(E)$ with compact supports (contained in E), and by $\mathscr{D}(E)$ the subspace of $\mathscr{K}(E)$ made up of C^∞ functions.

In connection with the periodic structure, let us introduce some specific spaces.

$C_p(\mathbb{R}^N)$ (or, for simplicity, C_p) denotes the space of functions $w\in C(\mathbb{R}^N)$, w Y-periodic.

$L^2_p(\mathbb{R}^N)$ (or L^2_p) the space of Y-periodic functions in $L^2_{\text{loc}}(\mathbb{R}^N)$, which is a Hilbert space with the norm

$$\|w\|_{L^2(Y)}=\left(\int_Y |w|^2\,dy\right)^{1/2}.$$

$\mathscr{K}(\mathbb{R}^N; L^2_p)$ the space of continuous functions on $\mathbb{R}^N$ (the Euclidean space of the variables x) with values in L^2_p and having compact supports.

$L^2(\mathbb{R}^N; L^2_p)$ the space of measurable functions $u(x,y)$ on $\mathbb{R}^N\times\mathbb{R}^N$ such that for almost all x the function $y\to u(x,y)$ belongs to L^2_p and $\int_{\mathbb{R}^N\times Y}|u(x,y)|^2\,dx\,dy<\infty$. We endow this space with the norm

$$\|u\|_{L^2(\mathbb{R}^N\times Y)}=\left[\int_{\mathbb{R}^N\times Y}|u(x,y)|^2\,dx\,dy\right]^{1/2}.$$

$L^2(\mathbb{R}^N; L^2_p)$, thus equipped, is a Hilbert space.

Finally, $\mathscr{K}(\mathbb{R}^N; C_p)$ denotes the space of continuous functions on $\mathbb{R}^N$ with values in C_p and having compact supports. We provide the vector space $\mathscr{K}(\mathbb{R}^N; C_p)$ with its natural topology: the inductive limit topology determined by the spaces $\mathscr{K}_K(\mathbb{R}^N; C_p)$ (K ranging over the compact subsets of $\mathbb{R}^N$), where

$$\mathscr{K}_K(\mathbb{R}^N; C_p)=\{\Psi\in\mathscr{K}(\mathbb{R}^N; C_p);\ \text{supp}\,\Psi\subset K\}$$

is a Banach space with the norm

$$\|\Psi\|_K = \sup_{x\in K} \|\Psi(x)\|_{L^\infty} \equiv \sup_{(x,y)\in\mathbb{R}^N\times\mathbb{R}^N} |\Psi(x,y)|$$

(note that C_p, provided with the L^∞ norm, is a Banach space).

In § 3 we will need a very useful result from Bourbaki [2, Prop. 5, p. 46]: Let $\mathscr{K}(\mathbb{R}^N)\otimes C_p$ denote the subset of $\mathscr{K}(\mathbb{R}^N; C_p)$ consisting of all functions of the form $\sum v\otimes w$ ($\otimes$ denotes the tensor product), v (respectively, w) ranging over a finite subset of $\mathscr{K}(\mathbb{R}^N)$ (respectively, C_p). Then $\mathscr{K}(\mathbb{R}^N)\otimes C_p$ is dense in $\mathscr{K}(\mathbb{R}^N; C_p)$.

Finally, for further needs, let us keep in mind the well-known result that asserts that $\mathscr{K}(\mathbb{R}^N; C_p)$ is dense in $L^2(\mathbb{R}^N; L^2_p)$.

In the sequel we will put, for simplicity,

$$\mathscr{K}_p \equiv \mathscr{K}(\mathbb{R}^N; C_p).$$

3. Basic result. A convergence theorem. In all that follows, ε, with $\varepsilon>0$, denotes a real sequence destined to tend to zero, and K_0 is a fixed compact set in $\mathbb{R}^N$ (K_0 does not depend on ε). Next, we introduce $L^2_{K_0}(\mathbb{R}^N)$, the space of all functions in $L^2(\mathbb{R}^N)$ having their (compact) supports in K_0.

3.1. Statement of the theorem. Idea of the proof.

THEOREM 1. *Let $u_\varepsilon \in L^2_{K_0}(\mathbb{R}^N)$. Suppose that there exists a constant $c>0$ such that*

$$\|u_\varepsilon\|_{L^2} \leqq c \quad \text{for any } \varepsilon. \tag{3.1}$$

Then there exist a subsequence from ε, still denoted by ε for simplicity, and a function u_0 in $L^2(\mathbb{R}^N; L^2_p)$ such that

$$\int_{\mathbb{R}^N} u_\varepsilon(x)\Psi\left(x,\frac{x}{\varepsilon}\right)dx \to \int_{\mathbb{R}^N\times Y} u_0(x,y)\Psi(x,y)\,dx\,dy \tag{3.2}$$

as $\varepsilon\downarrow 0$, for all Ψ in $\mathscr{K}_p$.

Remark 1. Instead of the cube $Y=]0,1[^N$, if we consider a parallelepiped $Y=\prod_{i=1}^N]0,a_i[(a_i>0)$, Theorem 1 remains valid provided the right-hand side of (3.2) is multiplied by $1/|Y|$ ($|Y|$ = measure of Y). □

We now give the idea and the main steps of the proof. The first step is to show that a subsequence (still denoted by ε for simplicity) can be extracted from ε such that for $w\in C_p$ the sequence $u_\varepsilon w^\varepsilon$ converges in L^2-weak as $\varepsilon\downarrow 0$, where $w^\varepsilon(x)=w(x/\varepsilon)$. Thus, given a function w in C_p, there will exist z_w in $L^2(\mathbb{R}^N)$ such that, as $\varepsilon\downarrow 0$,

$$\int_{\mathbb{R}^N} u_\varepsilon w^\varepsilon v\,dx \to \int_{\mathbb{R}^N} z_w v\,dx \quad \text{for all } v\in\mathscr{K}(\mathbb{R}^N). \tag{3.3}$$

Next, our task is to extend (3.3) (with the same subsequence ε) to all functions in $\mathscr{K}_p$ (see § 2 for the definition of $\mathscr{K}_p$). Indeed, note that the integrand on the left of (3.3) is nothing but $u_\varepsilon(x)\Psi(x,x/\varepsilon)$ with $\Psi(x,y)=v(x)w(y)$. It is then reasonable to hope that (3.3) could be generalized to all functions in $\mathscr{K}_p$. To this end, we first establish that for any Ψ in $\mathscr{K}_p$ a real number $F_0(\Psi)$ exists such that

$$\int_{\mathbb{R}^N} u_\varepsilon(x)\Psi\left(x,\frac{x}{\varepsilon}\right)dx \to F_0(\Psi). \tag{3.4}$$

This will be obtained from (3.3), because $\mathscr{K}(\mathbb{R}^N)\otimes C_p$ is dense in $\mathscr{K}_p$ (see § 2).

Finally, the last step is devoted to the characterization of the right of (3.4).

3.2. First convergence result. Our goal in this section is to obtain (3.3) for any w in C_p. To begin, let us establish two elementary (but fundamental) lemmas.

LEMMA 1. *Let K_0 be the above compact set. Fix $r>0$ and set $H=\{x\in\mathbb{R}^N;\ d(x,K_0)\leqq r\}$, where d denotes the Euclidean metric. Then for $\varepsilon<\varepsilon_0$ (ε_0 a suitable constant) there exist a natural number n (depending on ε) and a finite family $\varepsilon(\bar{Y}+k_i)$, $1\leqq i\leqq n$, with $k_i\in\mathbb{Z}^N$ ($\mathbb{Z}$ is the set of all integers) such that*

$$K_0\subset\bigcup_{i=1}^{n}\varepsilon(\bar{Y}+k_i)\subset H. \tag{3.5}$$

Proof. For arbitrarily fixed ε, we may express $\mathbb{R}^N$ (the space of the variables x) as the union of all the $\varepsilon(\bar{Y}+k)$, $k\in\mathbb{Z}^N$. Since K_0 is compact, a finite family $\varepsilon(\bar{Y}+k_i)$, $i=1,\cdots,n$, exists such that K_0 intersects each $\varepsilon(\bar{Y}+k_i)$ and K_0 is contained in their union.

Now, for each $i(1\leqq i\leqq n)$, let $x\in\varepsilon(\bar{Y}+k_i)$. Then $d(x,K_0)\leqq d(x,\varepsilon(\bar{Y}+k_i)\cap K_0)\leqq\operatorname{diam}\varepsilon(\bar{Y}+k_i)=\varepsilon\operatorname{diam}Y$ (diam denotes the diameter). Hence, by putting $\varepsilon_0=r/\operatorname{diam}Y$ it follows that for $\varepsilon<\varepsilon_0$ the union of the sets $\varepsilon(\bar{Y}+k_i)$ is contained in H, which completes the proof. □

LEMMA 2. *There exists a constant $c_0>0$ such that for $\varepsilon<\varepsilon_0$ (ε_0 is the constant in Lemma 1) we have*

$$\left|\int_{\mathbb{R}^N}u(x)w\left(\frac{x}{\varepsilon}\right)dx\right|\leqq c_0\|u\|_{L^2}\|w\|_{L^2(Y)}$$

for all u in $L^2_{K_0}(\mathbb{R}^N)$ and all w in L^2_p.

Proof. Let $u\in L^2_{K_0}(\mathbb{R}^N)$, $w\in L^2_p$. By Hölder's inequality we have

$$\left|\int_{\mathbb{R}^N}u(x)w\left(\frac{x}{\varepsilon}\right)dx\right|\leqq\|u\|_{L^2}\left[\int_{K_0}\left|w\left(\frac{x}{\varepsilon}\right)\right|^2dx\right]^{1/2}.$$

Next, by the preceding lemma, let $\varepsilon(\bar{Y}+k_i)$ $(1\leqq i\leqq n)$ be a finite family satisfying (3.5) for $\varepsilon<\varepsilon_0$. Then

$$\int_{K_0}\left|w\left(\frac{x}{\varepsilon}\right)\right|^2dx\leqq\sum_{i=1}^{n}\int_{\varepsilon(Y+k_i)}\left|w\left(\frac{x}{\varepsilon}\right)\right|^2dx.$$

By change of variable, $x=\varepsilon(y+k_i)$, and use of periodicity we have

$$\int_{\varepsilon(Y+k_i)}\left|w\left(\frac{x}{\varepsilon}\right)\right|^2dx=\varepsilon^N\int_Y|w(y)|^2\,dy.$$

It follows that

$$\int_{K_0}\left|w\left(\frac{x}{\varepsilon}\right)\right|^2dx\leqq\varepsilon^Nn\|w\|^2_{L^2(Y)}.$$

But, thanks to (3.5) we have $\varepsilon^Nn=\operatorname{meas}\bigcup_{i=1}^{n}\varepsilon(\bar{Y}+k_i)\leqq\operatorname{meas}H$ (note that n depends on ε), from which the conclusion follows (with, e.g., $c_0=(\operatorname{meas}H)^{1/2}$). □

Remark 2. For $\varepsilon<\varepsilon_0$ we have

$$\int_{K_0}\left|w\left(\frac{x}{\varepsilon}\right)\right|^2dx\leqq c_0^2\|w\|^2_{L^2(Y)}\quad\forall w\in L^2_p.$$ □

As an immediate consequence of Lemma 2, we have the following proposition, which plays an essential role throughout the rest of this section.

PROPOSITION 1. *Let $f \in L^2_{K_0}(\mathbb{R}^N)$ (f may or may not depend on ε). Then for $\varepsilon < \varepsilon_0$, a unique function $f_\varepsilon \in L^2_p$ can be assigned to f such that*

$$\int_{\mathbb{R}^N} f(x) w\left(\frac{x}{\varepsilon}\right) dx = \int_Y f_\varepsilon(y) w(y)\, dy \quad \forall w \text{ in } L^2_p,$$

$$\|f_\varepsilon\|_{L^2(Y)} \leqq c_0 \|f\|_{L^2}.$$

Remark 3. The correspondence $f \to f_\varepsilon$ defined above is linear. □

We are now in a position to prove the main result in this section. First, we must give some notation used frequently in the sequel.

Given w in L^2_p we denote by w^ε the ε-periodic function in $L^2_{\text{loc}}(\mathbb{R}^N)$ defined by

$$w^\varepsilon(x) = w\left(\frac{x}{\varepsilon}\right). \tag{3.6}$$

Also, if $\Psi \in \mathcal{K}_p$ we put

$$\Psi^\varepsilon(x) = \Psi\left(x, \frac{x}{\varepsilon}\right). \tag{3.7}$$

It is clear that $\Psi^\varepsilon \in \mathcal{K}(\mathbb{R}^N)$. Moreover, if the support of Ψ is contained in K (a compact subset of $\mathbb{R}^N$), then the support of Ψ^ε lies in K for any ε.

The aim now is to prove the following proposition.

PROPOSITION 2. *Under the assumptions of Theorem* 1, *a subsequence (still denoted by ε) can be extracted from ε such that for any w in C_p (w independent of ε), the sequence $u_\varepsilon w^\varepsilon$ converges in L^2-weak as $\varepsilon \downarrow 0$.*

Proof. (i) We begin by fixing a (nontrivial) function α in $\mathcal{D}(\mathbb{R}^N)$, α independent of ε. Next, fix x in $\mathbb{R}^N$ and consider the function $s \to f(s) = \alpha(x-s)u_\varepsilon(s)$, which belongs to $L^2_{K_0}(\mathbb{R}^N)$. By Proposition 1 there exists, for $\varepsilon < \varepsilon_0$, a unique function $y \to z_\varepsilon(x, y)$ in L^2_p such that for any w in L^2_p we have

$$\int_{\mathbb{R}^N} \alpha(x-s)u_\varepsilon(s)w^\varepsilon(s)\, ds = \int_Y z_\varepsilon(x, y)w(y)\, dy,$$

that is,

$$[(u_\varepsilon w^\varepsilon) * \alpha](x) = \int_Y z_\varepsilon(x, y)w(y)\, dy, \tag{3.8}$$

where $*$ denotes the convolution product.

Moreover, again by Proposition 1, we have

$$\|z_\varepsilon(x, \cdot)\|_{L^2(Y)} \leqq c_0 \left[\int_{\mathbb{R}^N} |\alpha(x-s)u_\varepsilon(s)|^2\, ds\right]^{1/2}. \tag{3.9}$$

Observe that the function $(u_\varepsilon w^\varepsilon) * \alpha$ lies in $\mathcal{D}(\mathbb{R}^N)$ and has its support in a compact set that does not depend on ε.

Thus, by (3.8) (valid for all x) we assign to u_ε (for $\varepsilon < \varepsilon_0$) a unique function $x \to z_\varepsilon(x)$ [i.e., $x \to z_\varepsilon(x, \cdot)$] from $\mathbb{R}^N$ to L^2_p, with (3.9).

(ii) For further needs we now study a few useful properties of the function z_ε thus constructed. To summarize, let us show that $z_\varepsilon \in L^2(\mathbb{R}^N; L^2_p)$. It suffices to check that $z_\varepsilon \in \mathcal{K}(\mathbb{R}^N; L^2_p)$ (see § 2 for notation). Clearly the function z_ε has compact support; then it remains to show continuity. For this, fix x in $\mathbb{R}^N$. Let $h \in \mathbb{R}^N$. Consider the function $s \to [\alpha(x+h-s) - \alpha(x-s)]u_\varepsilon(s)$, which lies in $L^2_{K_0}(\mathbb{R}^N)$. If we replace in (i)

the function $s \to \alpha(x-s)u_\varepsilon(s)$ by the above function, the associated analogue of $z_\varepsilon(x)$ is, according to the above process, exactly $z_\varepsilon(x+h)-z_\varepsilon(x)$ (see Remark 3). Hence,

$$\|z_\varepsilon(x+h)-z_\varepsilon(x)\|_{L^2(Y)} \leqq c_0\left[\int_{\mathbb{R}^N} |\alpha(x+h-s)-\alpha(x-s)|^2|u_\varepsilon(s)|^2\,ds\right]^{1/2},$$

which is the analogue of (3.9). Observing that the right-hand side is majorized by $cc_0 \sup_s |\alpha(x+h-s)-\alpha(x-s)|$ (c is the constant in Theorem 1) and, furthermore, α being uniformly continuous on $\mathbb{R}^N$, we deduce that $\|z_\varepsilon(x+h)-z_\varepsilon(x)\|_{L^2(Y)} \leqq c|h|$, for all $h \in \mathbb{R}^N$, which shows continuity.

Thus, $z_\varepsilon \in L^2(\mathbb{R}^N; L^2_p)$. Furthermore, by (3.9) we have

$$\|z_\varepsilon\|_{L^2(\mathbb{R}^N \times Y)} \leqq c \ (c>0) \quad \forall \varepsilon < \varepsilon_0 \tag{3.10}$$

(where the constant c does not depend on ε).

(iii) Finally, by (3.10) we can extract a subsequence from ε, still denoted by ε, such that $z_\varepsilon \to z$ in $L^2(\mathbb{R}^N; L^2_p)$-weak as $\varepsilon \downarrow 0$. Therefore, for each $v \in \mathscr{K}(\mathbb{R}^N)$ and each $w \in L^2_p$ we have

$$\int_{\mathbb{R}^N \times Y} z_\varepsilon(x,y)w(y)v(x)\,dx\,dy \to \int_{\mathbb{R}^N \times Y} z(x,y)w(y)v(x)\,dx\,dy,$$

so that, using (3.8) combined with Fubini's theorem, we have

$$\int_{\mathbb{R}^N} [(u_\varepsilon w^\varepsilon) * \alpha](x)v(x)\,dx \to \int_{\mathbb{R}^N \times Y} z(x,y)w(y)v(x)\,dx\,dy. \tag{3.11}$$

From now on, ε denotes exclusively the subsequence extracted above. By (3.11) we finally show that for each w in C_p, the sequence $u_\varepsilon w^\varepsilon$ converges weakly in $L^2(\mathbb{R}^N)$ as $\varepsilon \downarrow 0$ (that is, ε is the desired subsequence in Proposition 2). For this purpose, let w be arbitrarily fixed in C_p. Since $w^\varepsilon \in L^\infty$, we have $u_\varepsilon w^\varepsilon \in L^2$. Furthermore, we evidently have $\|u_\varepsilon w^\varepsilon\|_{L^2} \leqq c$ ($c>0$), for all ε. Therefore, we can extract ε' from ε such that

$$u_{\varepsilon'} w^{\varepsilon'} \to z_w \quad \text{in } L^2\text{-weak} \quad \text{as } \varepsilon' \downarrow 0, \tag{3.12}$$

so that, the transformation $v \to v * \alpha$ being continuous from L^2 into itself,

$$\int_{\mathbb{R}^N} [(u_{\varepsilon'} w^{\varepsilon'}) * \alpha]v\,dx \to \int_{\mathbb{R}^N} (z_w * \alpha)v\,dx$$

for all $v \in \mathscr{K}(\mathbb{R}^N)$. By comparison with (3.11) we necessarily have

$$(z_w * \alpha)(x) = \int_Y z(x,y)w(y)\,dy \quad \text{a.e. in } \mathbb{R}^N. \tag{3.13}$$

Now, since w is the same function as in (3.12), let ε'' be another subsequence from ε such that $u_{\varepsilon''} w^{\varepsilon''} \to z'_w$ in L^2-weak as $\varepsilon'' \downarrow 0$. Following the above process once more, we obtain

$$(z'_w * \alpha)(x) = \int_Y z(x,y)w(y)\,dy \quad \text{a.e. in } \mathbb{R}^N. \tag{3.14}$$

By subtracting (3.14) from (3.13) we have

$$(z'_w - z_w) * \alpha = 0 \tag{3.15}$$

from which it follows that $z'_w = z_w$. Indeed the distributions (represented by the L^2 functions) α, $z'_w - z_w$ (respectively) have compact supports, i.e., they lie in $\mathscr{E}'(\mathbb{R}^N)$, the

subspace of $\mathscr{D}'(\mathbb{R}^N)$ formed of distributions having compact supports. But, since the vector space $\mathscr{E}'(\mathbb{R}^N)$ endowed with the convolution product is an algebra without zero divisor (see [8]), (3.15) implies $z'_w - z_w = 0$.

We have just established that for any subsequence ε' such that $u_{\varepsilon'} w^{\varepsilon'}$ converges weakly in L^2, the corresponding limit does not depend on ε'. That is, the sequence $u_\varepsilon w^\varepsilon$ converges weakly in L^2. The proof is complete. □

3.3. Extension of the first convergence result. Here and throughout the rest of § 3, ε denotes the subsequence involved in Proposition 2. Then, by that proposition, a unique function $z_w \in L^2$ is assigned to each w in C_p such that (3.3) holds. In other words, if we put

$$\Psi(x, y) = v(x)w(y) \quad \text{for } v \in \mathscr{K}(\mathbb{R}^N) \text{ and } w \in C_p \tag{3.16}$$

and $F_0(\Psi) = \int_{\mathbb{R}^N} z_w v \, dx$, we have $\int_{\mathbb{R}^N} u_\varepsilon \Psi^\varepsilon \, dx \to F_0(\Psi)$ for any Ψ in $\mathscr{K}_p$ of the form (3.16) (see (3.7) for the definition of Ψ^ε). This property is, clearly, what we call the first (or primitive) convergence result.

The aim in this section is then to extend the above property to all of $\mathscr{K}_p$.

LEMMA 3. *Let Ψ be fixed in $\mathscr{K}_p$ (Ψ independent of ε). Then the sequence $\varepsilon \to \int_{\mathbb{R}^N} u_\varepsilon \Psi^\varepsilon \, dx$ is Cauchy.*

Proof. Let $\Psi \in \mathscr{K}_p$. Let $\eta > 0$. Since the set $\mathscr{K}(\mathbb{R}^N) \otimes C_p$ is dense in $\mathscr{K}_p$ (see § 2), there exists some Ψ_η in $\mathscr{K}_p$, $\Psi_\eta = \sum_{i \in I} v_i \otimes w_i$ [$v_i \in \mathscr{K}(\mathbb{R}^N)$, $w_i \in C_p$], with I finite, such that the supports of both Ψ and Ψ_η lie in a fixed compact set $K \subset \mathbb{R}^N$ that depends only on Ψ, and

$$\sup_{x \in \mathbb{R}^N} \|\Psi_\eta(x) - \Psi(x)\|_{L^\infty} \leqq \frac{\eta}{2c} \tag{3.17}$$

where c is the constant in (3.1).

On the other hand, we evidently have for all ε

$$\sup_{x \in \mathbb{R}^N} |\Psi_\eta^\varepsilon(x) - \Psi^\varepsilon(x)| \leqq \sup_{x \in \mathbb{R}^N} \|\Psi_\eta(x) - \Psi(x)\|_{L^\infty}. \tag{3.18}$$

Now, consider ε_1, ε_2, destined to decrease independently. By a routine technique we have

$$\begin{aligned}
&\left| \int_{\mathbb{R}^N} u_{\varepsilon_2} \Psi^{\varepsilon_2} \, dx - \int_{\mathbb{R}^N} u_{\varepsilon_1} \Psi^{\varepsilon_1} \, dx \right| \\
&\quad \leqq \left| \int_{\mathbb{R}^N} u_{\varepsilon_2} (\Psi^{\varepsilon_2} - \Psi_\eta^{\varepsilon_2}) \, dx \right| + \left| \int_{\mathbb{R}^N} u_{\varepsilon_1} (\Psi_\eta^{\varepsilon_1} - \Psi^{\varepsilon_1}) \, dx \right| \\
&\qquad + \left| \int_{\mathbb{R}^N} u_{\varepsilon_1} \Psi_\eta^{\varepsilon_1} \, dx - \int_{\mathbb{R}^N} u_{\varepsilon_2} \Psi_\eta^{\varepsilon_2} \, dx \right|.
\end{aligned}$$

But (3.17) combines with (3.18) to give

$$\left| \int_{\mathbb{R}^N} u_{\varepsilon_i} (\Psi_\eta^{\varepsilon_i} - \Psi^{\varepsilon_i}) \, dx \right| \leqq \frac{\eta}{2} \quad \text{for } i = 1, 2.$$

Hence

$$\left| \int_{\mathbb{R}^N} u_{\varepsilon_2} \Psi^{\varepsilon_2} \, dx - \int_{\mathbb{R}^N} u_{\varepsilon_1} \Psi^{\varepsilon_1} \, dx \right| \leqq \eta + \left| \int_{\mathbb{R}^N} u_{\varepsilon_2} \Psi_\eta^{\varepsilon_2} \, dx - \int_{\mathbb{R}^N} u_{\varepsilon_1} \Psi_\eta^{\varepsilon_1} \, dx \right|.$$

Now, thanks to Proposition 2 we observe that for v in $\mathscr{K}(\mathbb{R}^N)$ and w in C_p the sequence $\varepsilon \to \int_{\mathbb{R}^N} u_\varepsilon v w^\varepsilon \, dx$ is Cauchy. Therefore, since $\int_{\mathbb{R}^N} u_\varepsilon \Psi_\eta^\varepsilon \, dx = \sum_{i \in I} \int_{\mathbb{R}^N} u_\varepsilon v_i w_i^\varepsilon$, the sequence $\varepsilon \to \int_{\mathbb{R}^N} u_\varepsilon \Psi_\eta^\varepsilon \, dx$ is Cauchy as a finite sum of Cauchy sequences. So we have $|\int_{\mathbb{R}^N} u_{\varepsilon_2} \Psi_\eta^{\varepsilon_2} \, dx - \int_{\mathbb{R}^N} u_{\varepsilon_1} \Psi_\eta^{\varepsilon_1} \, dx| \to 0$ as $\varepsilon_1 \downarrow 0$ and $\varepsilon_2 \downarrow 0$, and the conclusion follows from the arbitrariness of η. □

This brings us to one of the central preliminary convergence results in this work.

PROPOSITION 3. *For any $\Psi \in \mathscr{K}_p$ (Ψ independent of ε) there exists a unique real number $F_0(\Psi)$ such that*

$$\int_{\mathbb{R}^N} u_\varepsilon \Psi^\varepsilon \, dx \to F_0(\Psi) \quad \text{as } \varepsilon \downarrow 0.$$

3.4. End of the proof. Characterization of F_0. The aim in this section is to show that the above transformation $\Psi \to F_0(\Psi)$ is the restriction to $\mathscr{K}_p$ of a continuous linear form on $L^2(\mathbb{R}^N; L_p^2)$. More precisely, we must check that there exists a unique u_0 in $L^2(\mathbb{R}^N; L_p^2)$ such that

$$F_0(\Psi) = \int_{\mathbb{R}^N \times Y} u_0(x, y) \Psi(x, y) \, dx \, dy \quad \forall \Psi \text{ in } \mathscr{K}_p.$$

Since $\mathscr{K}_p$ is dense in $L^2(\mathbb{R}^N; L_p^2)$ and the transformation $\Psi \to F_0(\Psi)$ is linear, it suffices to establish that there exists a constant $c > 0$ such that

$$|F_0(\Psi)| \leqq c \|\Psi\|_{L^2(\mathbb{R}^N \times Y)} \quad \forall \Psi \text{ in } \mathscr{K}_p. \tag{3.19}$$

In this connection, fix Ψ in $\mathscr{K}_p$ (Ψ independent of ε). Then $|\int_{\mathbb{R}^N} u_\varepsilon \Psi^\varepsilon \, dx| \leqq c(\int_{K_0} |\Psi^\varepsilon|^2 \, dx)^{1/2}$ for all ε, where c is the constant on the right of (3.1).

By Proposition 3 and the fundamental property

$$\int_{K_0} |\Psi^\varepsilon|^2 \, dx \to \int_{K_0 \times Y} |\Psi(x, y)|^2 \, dx \, dy \quad \text{as } \varepsilon \downarrow 0 \quad \text{(see § 1)},$$

assertion (3.19) follows immediately. The proof is complete. □

Remark 4. The function u_0 has its support in the set $K_0 \times \mathbb{R}^N$ (or K_0, if u_0 is regarded as a function from $\mathbb{R}^N$ to L_p^2).

4. The leading-order approximation. A convergence theorem. In what follows, Ω denotes a bounded open set in the Euclidean space $\mathbb{R}^N$ (of the variables $x_1, \cdots, x_N$), Ω independent of ε. We denote by $\mathscr{K}(\bar{\Omega}; C_p)$ [respectively, $\mathscr{K}(\bar{\Omega})$] the set of all restrictions to Ω of functions in $\mathscr{K}_p$ [respectively, $\mathscr{K}(\mathbb{R}^N)$]. We also introduce the space $L^2(\Omega; L_p^2)$, which is a Hilbert space with the norm

$$\|u\|_{L^2(\Omega \times Y)} = \left[\int_{\Omega \times Y} |u(x, y)|^2 \, dx \, dy \right]^{1/2}.$$

The aim in this section is to establish the following theorem.

THEOREM 2. *Let $u_\varepsilon \in L^2(\Omega)$. Suppose that there exists a constant $c > 0$ such that*

$$\|u_\varepsilon\|_{L^2(\Omega)} \leqq c \quad \forall \varepsilon. \tag{4.1}$$

Then a subsequence (still denoted by ε) can be extracted from ε such that, letting $\varepsilon \downarrow 0$,

$$\int_\Omega u_\varepsilon \Psi^\varepsilon \, dx \to \int_{\Omega \times Y} u_0(x, y) \Psi(x, y) \, dx \, dy \quad \forall \Psi \tag{4.2}$$

in $\mathcal{K}(\bar{\Omega}; C_p)$, *where* $u_0 \in L^2(\Omega; L^2_p)$. *Moreover,*

$$\int_\Omega u_\varepsilon v w^\varepsilon \, dx \to \int_{\Omega \times Y} u_0(x, y) v(x) w(y) \, dx \, dy \quad \forall v \tag{4.3}$$

in $\mathcal{K}(\bar{\Omega})$ *and all* w *in* L^2_p.

Proof. Property (4.2) is straightforward by Theorem 1 and Remark 4. As for (4.3), we begin by taking in (4.2) test functions of the form $\Psi(x, y) = v(x)w(y)$ with $v \in \mathcal{K}(\bar{\Omega})$, $w \in C_p$. We obtain as $\varepsilon \downarrow 0$,

$$\int_\Omega u_\varepsilon v w^\varepsilon \, dx \to \int_{\Omega \times Y} u_0(x, y) v(x) w(y) \, dx \, dy \tag{4.4}$$

for all $v \in \mathcal{K}(\bar{\Omega})$ and all $w \in C_p$.

Next, we must extend (4.4) to all functions w in L^2_p. Fix v in $\mathcal{K}(\bar{\Omega})$ and w in L^2_p. Let (w_n) be a sequence from C_p (dense subspace of L^2_p) such that $w_n \to w$ in L^2_p as $n \to \infty$. Utilizing the fact that the transformation $z \to z^\varepsilon$ is continuous linear from L^2_p to $L^2(\Omega)$ (see Remark 2), we have

$$\| w_n^\varepsilon - w^\varepsilon \|_{L^2(\Omega)} \leqq c_0 \| w_n - w \|_{L^2(Y)} \quad \forall n, \quad \forall \varepsilon < \varepsilon_0 \tag{4.5}$$

(c_0 and ε_0 are the constants in Lemma 2 with $K_0 = \bar{\Omega}$).

Now we write

$$\begin{aligned} &\int_\Omega u_\varepsilon v w^\varepsilon \, dx - \int_{\Omega \times Y} u_0 v w \, dx \, dy \\ &\quad = \int_\Omega u_\varepsilon v (w^\varepsilon - w_n^\varepsilon) \, dx + \int_{\Omega \times Y} u_0 v (w_n - w) \, dx \, dy \\ &\qquad + \int_\Omega u_\varepsilon v w_n^\varepsilon \, dx - \int_{\Omega \times Y} u_0 v w_n \, dx \, dy \end{aligned}$$

and estimate each of the first two integrals on the right-hand side separately (use (4.5)). This yields

$$\begin{aligned} &\left| \int_\Omega u_\varepsilon v w^\varepsilon \, dx - \int_{\Omega \times Y} u_0 v w \, dx \, dy \right| \\ &\qquad \leqq c_1 \| w_n - w \|_{L^2(Y)} + \left| \int_\Omega u_\varepsilon v w_n^\varepsilon \, dx - \int_{\Omega \times Y} u_0 v w_n \, dx \, dy \right| \end{aligned} \tag{4.6}$$

for all n and all $\varepsilon < \varepsilon_0$ (where c_1 is constant with respect to both ε and n).

Finally, let $\eta > 0$. Choose in (4.6) the natural number n so that $c_1 \| w_n - w \|_{L^2(Y)} \leqq \eta$. Then letting $\varepsilon \downarrow 0$ and using (4.4), it follows that the limit of the left-hand side of (4.6) is bounded from above by η. The desired conclusion then results from the arbitrariness of η.

Remark 5. Let u_ε be as in Theorem 2. First, let us observe that, by weak compactness, we may assume that in addition to (4.2) and (4.3) in Theorem 2, the subsequence ε satisfies the following property.

There exists $u \in L^2(\Omega)$ such that $u_\varepsilon \to u$ in $L^2(\Omega)$-weak. Next, taking $w = 1$ in (4.3) we easily obtain $u(x) = \int_Y u_0(x, y) \, dy$ (u is the mean value of u_0). It follows that u_0 is (uniquely) expressible in the form

$$u_0(x, y) = u(x) + \bar{u}_0(x, y) \quad \text{with} \int_Y \bar{u}_0(x, y) \, dy = 0.$$

So assume there is a subsequence from (u_ε) that converges strongly in $L^2(\Omega)$ as $\varepsilon \downarrow 0$. Then an easy computation yields $\bar{u}_0 = 0$; that is, the leading term u_0 in (1.2) does not depend on the local variables y. In other words, if the leading term depends on y, i.e., $\bar{u}_0 \neq 0$, then (u_ε) never contains a strongly convergent subsequence (see § 1).

5. The next-order approximation. A convergence theorem.

5.1. Notation and preliminaries. We denote by C_p^∞ the subspace of C_p formed of C^∞ functions, H_p^1 the subspace of L_p^2 formed of functions w such that $\partial w/\partial y_i \in L_p^2$ for $i = 1, \cdots, N$ (the derivatives obviously being taken in the distribution sense).

We provide H_p^1 with the norm

$$\|w\|_{H^1(Y)} = \left(\|w\|^2_{L^2(Y)} + \sum_{i=1}^N \left\| \frac{\partial w}{\partial y_i} \right\|^2_{L^2(Y)} \right)^{1/2},$$

which makes it a Hilbert space.

Sometimes it is more convenient to consider, instead of H_p^1, its closed subspace

$$\frac{H_p^1}{\mathbb{R}} = \left\{ w \in H_p^1; \int_Y w \, dy = 0 \right\}$$

on which the norm

$$\|w\|_{H^1(Y)/\mathbb{R}} = \left(\sum_{i=1}^N \left\| \frac{\partial w}{\partial y_i} \right\|^2_{L^2(Y)} \right)^{1/2}$$

is equivalent to the above H_p^1-norm.

We will need the following lemma.

LEMMA 4. *Let $f = (f_i), f_i \in L_p^2 (1 \leqq i \leqq N)$. Assume that $\sum_{i=1}^N \int_Y f_i w_i \, dy = 0$ for all $w = (w_i)$ in $(C_p^\infty)^N$ such that* div $w = 0$ *(where* div $w = \sum_{i=1}^N \partial w_i/\partial y_i$*). Then there exists a unique function $q \in H_p^1/\mathbb{R}$ such that $f_i = \partial q/\partial y_i$ for $i = 1, \cdots, N$.* □

Lemma 4 is the "periodic version" of the well-known result concerning the solvability of the equation grad $q = f$ for f given in $(L^2_{\text{loc}})^N$ (see, e.g., [10]). See, e.g., [6, Appendix] for the proof.

5.2. A convergence theorem (next-order approximation). We are now in a position to prove the main result in this section. In what follows, Ω denotes a smooth bounded open set in $\mathbb{R}^N$ (Ω independent of ε). As in the preceding sections, ε ($\varepsilon > 0$) denotes a sequence tending to zero.

THEOREM 3. *Let $u_\varepsilon \in H^1(\Omega)$. Suppose that there exists a constant $c > 0$ such that*

$$\|u_\varepsilon\|_{H^1(\Omega)} \leqq c \quad \forall \varepsilon. \tag{5.1}$$

Then a subsequence (still denoted by ε) can be extracted from ε such that, as $\varepsilon \downarrow 0$,

$$u_\varepsilon \to u \text{ in } H^1(\Omega)\text{-weak}, \tag{5.2}$$

$$\int_\Omega \frac{\partial u_\varepsilon}{\partial x_i} \Psi^\varepsilon v \, dx \to \int_{\Omega \times Y} \left[\frac{\partial u}{\partial x_i}(x) + \frac{\partial u_1}{\partial y_i}(x, y) \right] \Psi(y) v(x) \, dx \, dy, \tag{5.3}$$

$i = 1, \cdots, N$; for all Ψ in L_p^2 and all v in $\mathscr{K}(\bar{\Omega})$, where $u_1 \in L^2(\Omega; H_p^1/\mathbb{R})$.

Proof. By virtue of (5.1) we can extract a subsequence such that (5.2) holds. Moreover, by Theorem 2 there exists $z_i \in L^2(\Omega; L_p^2)$, $1 \leqq i \leqq N$, such that

$$\int_\Omega \frac{\partial u_\varepsilon}{\partial x_i} \Psi^\varepsilon v \, dx \to \int_{\Omega \times Y} z_i(x, y) \Psi(y) v(x) \, dx \, dy \quad \text{as } \varepsilon \downarrow 0 \tag{5.4}$$

for all Ψ in L_p^2 and all v in $\mathscr{K}(\bar{\Omega})$.

It remains to show that there exists $u_1 \in L^2(\Omega; H^1_p/\mathbb{R})$ such that

$$z_i(x, y) = \frac{\partial u}{\partial x_i}(x) + \frac{\partial u_1}{\partial y_i}(x, y) \quad \text{for } i = 1, \cdots, N.$$

So let $\Psi = (\Psi_i)$ be a vector function in $(C^\infty_p)^N$ satisfying $\operatorname{div} \Psi = 0$. Then for v in $\mathcal{D}(\Omega)$ we have

$$\sum_{i=1}^N \int_\Omega \frac{\partial u_\varepsilon}{\partial x_i} \Psi_i^\varepsilon v \, dx = -\sum_{i=1}^N \int_\Omega u_\varepsilon \frac{\partial}{\partial x_i}(\Psi_i^\varepsilon v) \, dx.$$

By Leibniz's formula and the fact that $\operatorname{div} \Psi = 0$ (note that $\sum_{i=1}^N \partial \Psi_i^\varepsilon / \partial x_i = 1/\varepsilon (\operatorname{div} \Psi)^\varepsilon$) it follows that

$$\sum_{i=1}^N \int_\Omega \frac{\partial u_\varepsilon}{\partial x_i} \Psi_i^\varepsilon v \, dx = -\sum_{i=1}^N \int_\Omega u_\varepsilon \Psi_i^\varepsilon \frac{\partial v}{\partial x_i} \, dx.$$

By the Rellich theorem we may assume that the above subsequence ε satisfies the further property

$$u_\varepsilon \to u \quad \text{in } L^2(\Omega)\text{-strong},$$

so that, letting $\varepsilon \downarrow 0$ and recalling (5.4), we obtain

$$\sum_{i=1}^N \int_{\Omega \times Y} \left[z_i(x, y) - \frac{\partial u}{\partial x_i}(x) \right] \Psi_i(y) v(x) \, dx \, dy = 0$$

for all $\Psi \in (C^\infty_p)^N$, $\operatorname{div} \Psi = 0$, and all $v \in \mathcal{D}(\Omega)$. Hence we have for almost all $x \in \Omega$

$$\sum_{i=1}^N \int_Y \left[z_i(x, y) - \frac{\partial u}{\partial x_i}(x) \right] \Psi_i(y) \, dy = 0 \quad \text{for } \Psi \in (C^\infty_p)^N, \operatorname{div} \Psi = 0.$$

It follows by Lemma 4 that there exists a function u_1 from Ω to $H^1_p/\mathbb{R}$ such that

$$z_i(x, \cdot) - \frac{\partial u}{\partial x_i}(x) = \frac{\partial u_1(x)}{\partial y_i} \quad \text{a.e. in } \Omega (i = 1, \cdots, N). \tag{5.5}$$

Finally, from (5.5) we can easily show (e.g., by Lusin's characterization [3]) that u_1 is a measurable function from Ω to $H^1_p/\mathbb{R}$ (obtained from appropriate norm defined in § 5.1). Furthermore, again by (5.5) we have

$$\int_\Omega \|u_1(x)\|^2_{H^1(Y)/\mathbb{R}} \, dx < \infty$$

and the conclusion follows. □

6. A new approach in the theory of homogenization. Classically, the mathematical analysis of homogenization problems proceeds in two steps [1]. The first step, which is formal, derives, for example, from two-scale asymptotic expansions of the form

$$\begin{aligned} &u_\varepsilon(x) = u_0(x, y) + \varepsilon u_1(x, y) + \cdots, \quad y = \frac{x}{\varepsilon}, \\ &u_0, u_1, \cdots, \quad Y\text{-periodic in } y. \end{aligned} \tag{6.1}$$

More precisely, we postulate that the solution u_ε of a given problem (associated with a partial differential equation with coefficients ε-periodic) is similar to (6.1). Next, introducing (6.1) into the given problem yields a sequence of problems that determine $u_0, u_1, \cdots$.

The second step consists of rigorously proving the convergence of the preceding homogenization process, i.e., we must find some suitable topology in order that $\lim u_\varepsilon = u_0$ as $\varepsilon \to 0$. This validates the above formal calculations.

In this last section we propose an alternative approach. More precisely, we introduce a new asymptotic method for the mathematical analysis of homogenization problems. The method is quite straightforward. There is no need to postulate the existence of the functions u_0, u_1 in (6.1), since by Theorems 2 (or 1) and 3 such functions are available for a suitable subsequence from ε.

Our approach is illustrated by a regular homogenization problem. Nevertheless, the basic ideas can easily be extended to problems of the singular type.

6.1. Setting of the problem. In all that follows, unless otherwise specified, the summation convention is used.

Let Ω be a smooth bounded open set in $\mathbb{R}^N$ (the space of the variables $x_1, \cdots, x_N$) with boundary $\partial\Omega$. Let a_{ij} $(1 \leqq i, j \leqq N)$ be given functions defined on $\mathbb{R}^N$ (the space of the variables $y_1, \cdots, y_N$) and subject to the following conditions:

$$a_{ij} \in L^\infty, \quad a_{ij} \ Y\text{-periodic}, \quad a_{ij} = a_{ji}. \tag{6.2}$$

There exists $\alpha > 0$ such that the following holds for almost all y:

$$a_{ij}(y)\xi_i\xi_j \geqq \alpha|\xi|^2 \quad \forall \xi = (\xi_i) \in \mathbb{R}^N \tag{6.3}$$

(where the summation convention is utilized) with $|\xi|^2 = \sum_{i=1}^N \xi_i^2$.

Finally, let $f \in L^2(\Omega)$, and for each $\varepsilon > 0$ let u_ε be defined by

$$\begin{aligned} &u_\varepsilon \in H^1(\Omega), \\ &-\frac{\partial}{\partial x_i}\left(a_{ij}^\varepsilon \frac{\partial u_\varepsilon}{\partial x_j}\right) = f \quad \text{in } \Omega, \\ &u_\varepsilon = 0 \quad \text{on } \partial\Omega \end{aligned} \tag{6.4}$$

where $a_{ij}^\varepsilon(x) = a_{ij}(x/\varepsilon)$ (see (3.6)).

Clearly, from (6.2) (the first assumption) and (6.3), we see (6.4) uniquely determines u_ε.

Our aim is to find $\lim u_\varepsilon$ as $\varepsilon \downarrow 0$. In other words, we must study the homogenization problem associated with (6.4). Note that this problem has been solved in [1], where the results of the formal analysis were made rigorous by applying the Energy Method. As mentioned in § 1, we propose an alternative approach that should be more flexible and thus more adaptable for the study of unusual problems.

6.2. Description of the method. First, observe that u_ε, the solution of (6.4), satisfies

$$\begin{aligned} &u_\varepsilon \in H_0^1(\Omega), \\ &\int_\Omega a_{ij}^\varepsilon \frac{\partial u_\varepsilon}{\partial x_j}\frac{\partial v}{\partial x_i}\,dx = \int_\Omega fv\,dx \quad \forall v \in H_0^1(\Omega). \end{aligned} \tag{6.5}$$

Next we estimate $\|u_\varepsilon\|_{H_0^1(\Omega)}$. Taking the particular test function $v = u_\varepsilon$ and using the boundedness and the coerciveness (from (6.3)) of the bilinear form in (6.5), we obtain

$$\|u_\varepsilon\|_{H^1(\Omega)} \leqq c \ (c > 0) \quad \forall \varepsilon.$$

Hence, the hypotheses of Theorem 3 are fulfilled. We can extract a subsequence still denoted by ε for simplicity such that

$$u_\varepsilon \to u \quad \text{in } H_0^1(\Omega)\text{-weak} \quad \text{as } \varepsilon \downarrow 0 \tag{6.6}$$

and, for all $\Psi \in L_p^2$, $v \in \mathscr{K}(\bar{\Omega})$,

$$\int_\Omega \frac{\partial u_\varepsilon}{\partial x_j} \Psi^\varepsilon v \, dx \to \int_{\Omega \times Y} \left[\frac{\partial u}{\partial x_j}(x) + \frac{\partial u_1}{\partial y_j}(x, y) \right] \Psi(y) v(x) \, dx \, dy, \quad j = 1, \cdots, N, \tag{6.7}$$

where $u_1 \in L^2(\Omega; H_p^1/\mathbb{R})$.

Derivation of the local problem. In (6.5) we take test functions of the form $v = \varepsilon w^\varepsilon \phi$ with $w \in H_p^1$, $\phi \in \mathscr{D}(\Omega)$. Then, noting that $\partial w^\varepsilon / \partial x_i = 1/\varepsilon (\partial w / \partial y_i)^\varepsilon$, where of course $(\partial w / \partial y_i)^\varepsilon(x) = \partial w / \partial y_i (x/\varepsilon)$, we are led to

$$\int_\Omega a_{ij}^\varepsilon \frac{\partial u_\varepsilon}{\partial x_j} \left(\frac{\partial w}{\partial y_i} \right)^\varepsilon \phi \, dx + \varepsilon \int_\Omega a_{ij}^\varepsilon \frac{\partial u_\varepsilon}{\partial x_j} w^\varepsilon \frac{\partial \phi}{\partial x_i} \, dx = \varepsilon \int_\Omega f w^\varepsilon \phi \, dx.$$

Now we propose passing to the limit as $\varepsilon \downarrow 0$. It is easy to check that both the second term on the left and the term on the right tend to zero. Hence,

$$\int_\Omega a_{ij}^\varepsilon \frac{\partial u_\varepsilon}{\partial x_j} \left(\frac{\partial w}{\partial y_i} \right)^\varepsilon \phi \, dx \to 0.$$

On the other hand, choose in (6.7) $\Psi = a_{ij}(\partial w / \partial y_i)$ (summation) with $w \in H_p^1$. By the above result we are finally led to

$$\int_{\Omega \times Y} a_{ij}(y) \left[\frac{\partial u}{\partial x_j}(x) + \frac{\partial u_1}{\partial y_j}(x, y) \right] \frac{\partial w}{\partial y_i}(y) \phi(x) \, dx \, dy = 0$$

for all $w \in H_p^1$ and all $\phi \in \mathscr{D}(\Omega)$. Hence the following holds for almost every x in Ω:

$$\int_Y a_{ij}(y) \left[\frac{\partial u}{\partial x_j}(x) + \frac{\partial u_1}{\partial y_j}(x, y) \right] \frac{\partial w}{\partial y_i}(y) \, dy = 0 \quad \forall w \in H_p^1. \tag{6.8}$$

Equation (6.8) is exactly that obtained by the formal method using multiple-scale asymptotic expansions (see [1]). It associates with the relation $u_1(x, \cdot) \in H_p^1/\mathbb{R}$ to give the so-called local problem, which permits us to express u_1 in terms of u. Evidently u_1 satisfies, for fixed x,

$$\begin{aligned} &u_1(x, \cdot) \in \frac{H_p^1}{\mathbb{R}}, \\ &\int_Y a_{ij} \frac{\partial u_1}{\partial y_j}(x, \cdot) \frac{\partial w}{\partial y_i} \, dy = -\frac{\partial u}{\partial x_j}(x) \int_Y a_{ij} \frac{\partial w}{\partial y_i} \, dy \quad \forall w \in \frac{H_p^1}{\mathbb{R}}, \end{aligned} \tag{6.9}$$

which is an elliptic variational problem for $u_1(x, \cdot)$, admitting one and only one solution.

We should stress that, contrary to the classical method, the resolution of the above problem does not concern us since u_1 has been constructed in Theorem 3. We only observe that u_1 is unique (i.e., independent of the subsequence extracted above) as soon as u is well determined.

Now we calculate u_1 in terms of u. Following [1], let χ^j $(j=1,\cdots,N)$ be defined by

$$\begin{aligned} &\chi^j \in \frac{H^1_p}{\mathbb{R}}, \\ &\int_Y a_{kh}\frac{\partial \chi^j}{\partial y_h}\frac{\partial w}{\partial y_k}\,dy = \int_Y a_{kj}\frac{\partial w}{\partial y_k}\,dy \quad \forall w \in \frac{H^1_p}{\mathbb{R}}. \end{aligned} \tag{6.10}$$

Then, from the preceding remarks, we see that u_1 is given by

$$u_1(x,y) = -\frac{\partial u}{\partial x_j}(x)\chi^j(y). \tag{6.11}$$

Indeed, the function on the right-hand side is the solution of (6.9).

Remark 6. It is not difficult to verify that the equation in (6.10) can be written under the form

$$a(\chi^j - y_j, w) = 0 \quad \forall w \in H^1_p/\mathbb{R} \tag{6.12}$$

where $a(\cdot,\cdot)$ is the bilinear form that figures in (6.10), and $y_j (1 \leqq j \leqq N)$ are the coordinate functions. □

Derivation of the global (or limit) problem. The point now is to derive the boundary value problem satisfied by the global limit u. This is straightforward. Choose in (6.7) the particular function $\Psi = a_{ij}$, and in place of the v's consider the derivatives $\partial v/\partial x_i$, with $v \in \mathcal{D}(\Omega)$. Hence, summing over i,j on both sides of (6.7) and using (6.5) yields

$$\int_{\Omega\times Y} a_{ij}(y)\left[\frac{\partial u}{\partial x_j}(x) + \frac{\partial u_1}{\partial y_j}(x,y)\right]\frac{\partial v}{\partial x_i}(x)\,dx\,dy = \int_\Omega fv\,dx,$$

which by (6.11) becomes

$$\int_\Omega \left(\tilde{a}_{ij} - \int_Y a_{ih}\frac{\partial \chi^j}{\partial y_h}\,dy\right)\frac{\partial u}{\partial x_j}\frac{\partial v}{\partial x_i}\,dx = \int_\Omega fv\,dx$$

where $\tilde{a}_{ij} = \int_Y a_{ij}(y)\,dy$. But it is easy to check that

$$\tilde{a}_{ij} - \int_Y a_{ih}\frac{\partial \chi^j}{\partial y_h}\,dy = -a(y_i, \chi^j - y_j).$$

On the other hand, by (6.12) we have easily that $-a(y_i, \chi^j - y_j) = a(\chi^i - y_i, \chi^j - y_j)$ (note that the form $a(\cdot,\cdot)$ is symmetric). From all that we deduce the problem for u:

$$\begin{aligned} &u \in H^1_0(\Omega), \\ &\int_\Omega q_{ij}\frac{\partial u}{\partial x_j}\frac{\partial v}{\partial x_i}\,dx = \int_\Omega fv\,dx \quad \forall v \in H^1_0(\Omega), \end{aligned} \tag{6.13}$$

where

$$q_{ij} = a(\chi^i - y_i, \chi^j - y_j). \tag{6.14}$$

The constants q_{ij} are the so-called *homogenized coefficients.* They satisfy the ellipticity condition

$$q_{ij}\xi_i\xi_j \geqq c|\xi|^2 (c>0) \quad \forall \xi \in \mathbb{R}^N \quad \text{(see [1])}$$

so that u is uniquely determined by (6.13). Consequently, the subsequence ε in (6.6) and (6.7) may be replaced by the whole sequence from which it was extracted.

Thus, we have proved the following homogenization theorem.

THEOREM 4. *For each $\varepsilon > 0$ let u_ε be the solution of the boundary value problem* (6.4). *Then, as $\varepsilon \downarrow 0$,*

$$
\begin{aligned}
&u_\varepsilon \to u \quad \text{in } H_0^1(\Omega)\text{-weak},\\
&\int_\Omega \frac{\partial u_\varepsilon}{\partial x_j} \Psi^\varepsilon v \, dx \to \left(\int_\Omega \frac{\partial u}{\partial x_k} v \, dx \right) \int_Y \Psi \frac{\partial}{\partial y_j} (y_k - \chi^k) \, dy,
\end{aligned} \tag{6.15}
$$

$j = 1, \cdots, N$, for all $\Psi \in L_p^2$ and all $v \in \mathscr{K}(\bar{\Omega})$, where u is the solution of the boundary value problem

$$
\begin{aligned}
-\frac{\partial}{\partial x_i}\left(q_{ij} \frac{\partial u}{\partial x_j} \right) &= f \quad \text{in } \Omega\\
u &= 0 \quad \text{on } \partial\Omega,
\end{aligned}
$$

q_{ij} given by (6.14), *and $\chi^k (k = 1, \cdots, N)$ given by* (6.10).

Remark 7. The usual homogenization theorem [1], [9] does not involve (6.15). This property obviously follows from (6.7) and (6.11).

6.3. Concluding remarks. We have just proposed a new asymptotic method for the mathematical analysis of homogenization problems. The method is straightforward and quite natural. Note that, although we have chosen a problem of the regular type for a detailed analysis, our approach is essentially based on Theorem 1, which requires only the weaker assumption that u_ε remains bounded in L^2. So it is reasonable to assume the above idea can be successfully extended to a more general situation involving problems of the singular type.

Acknowledgment. The author thanks the referees for their kind advice.

A NONABELIAN VERSION OF THE SHANNON SAMPLING THEOREM*

A. H. DOOLEY†

Abstract. Using techniques from the theory of contraction of Lie groups, a version of the Shannon sampling theorem appropriate to Cartan motion groups is proved. This work has possible applications in digital signal analysis.

Key words. contractions, sampling theorems, Hankel transform

AMS(MOS) subject classifications. 22E46, 42C99

1. Introduction. The Shannon sampling theorem for the real line R may be stated as follows.

THEOREM A. *Let $f \in L^2(R)$ have Fourier transform $\hat{f}(\nu) = 1/2\pi \int f(x)\, e^{-i\nu x}\, dx$, and suppose that $\hat{f}$ is supported in $[-S, S]$. Then*

$$f(x) = \sum_{n=-\infty}^{\infty} d_n(x) f\left(\frac{n}{2S}\right),$$

where $d_n(x) = k_S(x-(n/2S)) = 1/2S \int_{-S}^{S} e^{i(x-(n/2S))\nu}\, d\nu$.

Thus, knowledge of f at the points $n/2S$, $n = 0, \pm 1, \cdots$, allows reconstruction of f everywhere, by use of the kernels k_S.

The obvious generalization of this theorem to $L^2(R^2)$ holds, where the two-dimensional Fourier transform is considered. However, we do not wish to pursue this line here. Rather, we want to discuss a version of the sampling theorem appropriate to the Fourier-Bessel transform of $f \in L^2(R^2)$, which is given by considering f as a linear combination of $F_n(re^{i\alpha}) = \phi_n(r)\, e^{in\alpha}$. The Fourier-Bessel transform of F_n is given by

$$\hat{F}_n(\mathrm{Re}^{i\psi}) = 2\pi i^n\, e^{in\psi} \Phi_n(R),$$

where

$$\Phi_n(R) = \int_0^{\infty} \phi_n(r) J_n(Rr) r\, dr.$$

(Here, J_n denotes the nth Bessel function.)

The following theorem is due to Kramer [9].

THEOREM B. *Suppose $f \in L^2(R^2)$. If $\int_0^{2\pi} f(re^{i\phi})\, e^{ik\phi}\, d\phi = 0$ for $|k| \geqq M$ and if there is $R_0 > 0$ such that for all k, $\Phi_k(R) = 0$ whenever $R > R_0$, then*

$$f(re^{i\phi}) = \sum_{k=-M}^{M} e^{ik\phi} \sum_{n=1}^{\infty} f_k(t_{k,n}) S_{k,n}(r)$$

where $S_{k,n}(r) = 2t_{k,n} J_k(r)/((t_{k,n}^2 - r^2) J_{k+1}(t_{k,n}))$. In these expressions, $(t_{k,n})_{n=1}^{\infty}$ are the zeros of the Bessel function J_k.

Kramer's theorem applies not only to expansions in Bessel functions, but also to a number of other special function expansions—see Jerri [6, § 3] for a full discussion of these generalizations. Analogues of Theorem B may be obtained for these expansions, but the above version will suffice to explain the background to the present paper.

* Received by the editors February 24, 1987; accepted for publication (in revised form) July 5, 1988. This research was supported by the Australian Research Grants Scheme.

Theorem B is somewhat unsatisfactory in certain respects. First, from a practical point of view, the data are rarely presented at the zeros of the Bessel functions—these are hard to locate, too. Secondly, the sampling must be at zeros of different Bessel functions for each component f_k of f. Thirdly, the comparatively neat form of the kernel $S_n(r)$ is obtained by using rather particular properties of J_k not shared for other special functions; the kernels obtained by Jerri [7] are much more complicated.

I would like to propose here an alternative theorem based on the Fourier-Bessel transform in R^2 (and more generally on the Radon transform in R^n) but in which the sample points are spaced equally. Of course, we can no longer expect to match f exactly—it is known that the classical Shannon sampling is the only way to do that. However, the L^2 difference between the reconstructed function and f can be estimated uniformly in the spacing.

Our general theorem applies to the Fourier transform on a motion group (Theorem 2.1). A corollary (Theorem 4.2) deals with the Radon transform on the tangent space of a symmetric space. For the purposes of comparison, we present here the simple case of R^2 considered relative to the rotation action of $S0(2)$. This is a direct analogue of Theorem B where the sampling is done at equally spaced points (grid $1/\lambda$) and f is reconstructed to within $0(1/\lambda)$.

THEOREM C. *Let f satisfy the conditions of Theorem B. Then*

$$f(re^{i\psi}) = \sum_{k=-m}^{m} e^{ik\psi} \sum_{n=1}^{\infty} (2n+1) h_\lambda^k\left(r, \frac{n}{\lambda}\right) \Phi_k\left(\frac{n}{\lambda}\right) + 0\left(\frac{1}{\lambda}\right)$$

where

$$h_\lambda^k\left(r, \frac{n}{\lambda}\right) = \frac{1}{\lambda^2} \int_0^\lambda J(Sr) J\left(S\frac{n}{\lambda}\right) S\, dS, \text{ and } \left\| 0\left(\frac{1}{\lambda}\right) \right\|_2 \leqq \frac{K}{\lambda}.$$

The final section of this paper details some applications of these abstract theorems to the theory of signal processing.

2. Preliminaries. Let (G, K) be a Riemannian symmetric pair of the compact type. (We will recover Theorem C in the case $G = S0(3)$, $K = S0(2)$.) Then [4] we may write $\mathbf{g} = \mathbf{k} + V$, where V is a vector space complement for $\mathbf{k}$ in $\mathbf{g}$, and we may form the Cartan motion group associated with (G, K). This is the semidirect product $V \rtimes K$ of V by the adjoint action of K. Of particular interest will be sampling for functions on $V \rtimes K$ which are bi-K-invariant—these are in bijective correspondence with functions on V which are K-invariant. In the special case of $(G, K) = (S0(n+1), S0(n))$, this will amount to an approximate sampling theorem for rotationally invariant functions on R^n, i.e., for the n-Hankel transform on R^+.

Central to our analysis will be techniques from [2], where an approximation theorem for matrix coefficients was obtained [2, Thm. 2]. The map $\pi_\lambda : V \rtimes K \to G$ defined by $\pi_\lambda(v, k) = \exp_G{}^{v/\lambda} \cdot k$ generalizes the map $R \to T : r \to e^{ir/\lambda}$, and gives the structural link between the groups which enables us to "transfer" harmonic analysis.

I can now explain the idea behind the proof of Theorem 1. Consider the following proof of Theorem A, which has been attributed to Kolmogorov.

Let $f \in L^1 \cap L^2(R)$ and suppose that $\operatorname{supp} \hat{f} \subseteq [-S, S]$. Then $f(x) = \int_{-S}^{S} \hat{f}(w)\, e^{iwx}\, dw$. For each x we may expand $w \to e^{iwx}$ in a Fourier series on $[-S, S]$, obtaining

$$e^{iwx} = \sum_{n=-\infty}^{\infty} d_n(x)\, e^{i(n/2S)w},$$

where $d_n(x)$ is as in Theorem A of the Introduction. Substituting back in, we have

$$f(x)=\sum_{n=-\infty}^{\infty} d_n(x)\int \hat{f}(w)\,e^{i(n/2S)w}\,dw=\sum_{n=-\infty}^{\infty} d_n(x)f\left(\frac{n}{2S}\right).$$

The idea is to generalize the above proof, replacing R by $V\rtimes K$ and $[-S, S]$ by the group G, via the contraction map π_λ.

A set of irreducible representations of $V\rtimes K$ of full Plancherel measure may be described as follows (cf. [1], [8]). Choose a maximal Abelian subalgebra $\mathbf{a}$ of V, and let M be the stabilizer of $\mathbf{a}$ in K. Given $\psi\in\mathbf{a}^{*+}$ and $\mu\in\hat{M}$ acting in $\underset{\sim}{H}_\mu$ we have a representation $\rho_{\mu,\psi}$ acting in

$$\underset{\sim}{K}_\mu=\{h\in L^2(K,\underset{\sim}{H}_\mu)\colon \mu(m)h(km)=h(k),\ \forall\, m\in M,\ \forall k\in K\}$$

by $(\rho_{\mu,\psi}(v,k)h)(k_0)=e^{i\psi(Ad(k_0^{-1})v)}h(k^{-1}k_0)$.

For $f\in L^1(V\rtimes K)$, we define $\hat{f}(\rho_{\mu,\psi})\in B(\underset{\sim}{H}_{\mu,\psi})$ by

$$(\hat{f}(\rho_{\mu,\psi})h)(k_0)=\int_V\int_K e^{i\psi(Adk_0^{-1}V)}\,h(k^{-1}k_0)f(v,k)\,du\,dk.$$

The Plancherel formula for $V\rtimes K$ (cf. [7]) then states that for $f\in C_c^\infty(V\rtimes K)$

$$f(x)=\sum_{\mu\in\hat{M}} d_\mu\int_{(\mathbf{a}^*)^+}\operatorname{Tr}\left(\hat{f}(\rho_{\mu,\phi})\rho_{\mu,\phi}(x)\right)\prod_{\alpha\in P_+}\phi(H_\alpha)\,d\phi,$$

where P_+ denotes a set of reduced roots for G on $\mathbf{a}$.

Given $\mu\in\hat{M}$, we set

$$f_\mu(x)=\int_{(\mathbf{a}^*)^+}\operatorname{Tr}\left(\hat{f}(\rho_{\mu,\phi})\rho_{\mu,\phi}(x)\right)\prod_{\alpha\in P_+}\phi(M_\alpha)\,d\phi.$$

(The f_μ are the analogues of the F_n in § 1.)

Let P denote the set of K-class one weights of $\mathbf{a}$ in $\mathbf{a}^*$. We may now state our version of the sampling theorem.

THEOREM 2.1. *Let $f\in L^1(V\rtimes K)$ and suppose that*

(i) $\operatorname{supp}\hat{f}\subseteq\{\rho_{\mu,\phi}\colon |\phi|\leqq R\}$

(ii) *$\hat{f}(\rho_{\mu,\phi})$ has finite rank as an operator on $\underset{\sim}{H}_{\mu,\phi}$.*

Then $f=\sum_{\mu\in\hat{M}} d_\mu f_\mu$, and each f_μ may be approximately reconstructed by, for $v=k_0\eta\in V$,

$$f_\mu(v,k)=\sum_{\beta\in P} d_{\mu,\beta}\sum_{r,s,t,\ell=0}^{M} K^{r,s,t,\ell}\left(\eta,\frac{\beta}{\lambda}\right)f_{s,r,\ell,t}\left(k_0\frac{\beta}{\lambda},k\right)+0\left(\frac{1}{\lambda}\right).$$

Here, for a suitable choice of basis for $\underset{\sim}{K}_\mu$ (specified below),

$$K^{r,s,t,\ell}_{\mu,\lambda}\left(\phi,\frac{\beta}{\lambda}\right)=\lambda^{\dim V}\int_{B_\lambda}(\rho_{\mu,\phi}(x))_{r,s}\,\overline{(\rho_{\mu,\,i\beta/\lambda}(x))_{t,\ell}}\,dx$$

and

$$f_{s,r,\ell,t}(x)=\int_{|\phi|\leqq R}\hat{f}(\rho_{\mu,\phi})_{s,r}(\rho_{\mu,\phi}(x))_{\ell,t}\prod_{\alpha\in P_+}\phi(H_\alpha)\,d\phi.$$

The $0(1/\lambda)$ is uniform on compact subsets of $V\rtimes K$.

This theorem will be proved in the next section.

3. Proof of the theorem. Before giving the proof, we will need some lemmas. Let $f \in L^1 \cap L^2(V \rtimes K)$ and suppose $\operatorname{supp} \hat{f} \subseteq \{\rho_{\mu,\phi}: |\phi| \leqq R\} = S_{\mu,R}$. We then have

$$f_\mu(x) = \int_{\{\phi: |\phi| \leqq R\}} \operatorname{Tr}(\hat{f}(\rho_{\mu,\phi})\rho_{\mu,\phi}(x)) \prod_{\alpha \in P_+} \phi(H_\alpha)\, d\phi.$$

We may write $x \in V \rtimes K$ as $x = (v, k)(v \in V, k \in K)$ and using the fact ([3]) that each K-orbit in V intersects $\mathbf{a}^+$ in just one point, we may write $v = k_0\beta$, $\beta \in \mathbf{a}^+$, and $k_0 \in K$. Our first lemma enables us to "pass β from the group to its dual." We identify $\mathbf{a}$ and $\mathbf{a}^*$ by the Killing form $\langle , \rangle$.

LEMMA 3.1. *Let $\phi \in \mathbf{a}$, $\beta \in \mathbf{a}^*$, $\mu \in \hat{M}$, $k, k_0 \in K$. Then*

$$\rho_{\mu,\phi}(k_0\beta, k) = \rho_{\mu,\beta}(k_0\phi, k).$$

Proof. This is simply a matter of looking at the definition of $\rho_{\mu,\phi}$. □

Using this lemma, we may write

$$f_\mu(k_0\beta, k) = \int_{|\phi| \leqq R} \operatorname{Tr}(\hat{f}(\rho_{\mu,\phi})\rho_{\mu,\beta}(k_0\phi, k)) \prod_{\alpha \in \Phi_+} \phi(H_\alpha)\, d\phi. \tag{1}$$

In order to analyse the trace, we choose an orthonormal basis for $\underset{\sim}{K}_\mu$ as follows (cf. [1, § 4]). Take a sequence $\beta_1, \beta_2 \cdots$ of vectors in the lattice P of K-class one vectors in $\mathbf{a}^{*+}$ such that

$$\left|\beta - \frac{1}{n}\sum_{j=1}^{n} \beta_j\right| = 0\left(\frac{1}{n}\right).$$

The vectors $\mu + \psi_n = \mu + \sum_{j=1}^{n} \beta_j \in \mathbf{t}^*$ define integral weights and hence representations σ_{μ,ψ_n} of G acting in

$$\underset{\sim}{H}_{\mu,\psi_n} = \{f \in C^\infty(G): \text{(i) } f(gt) = e^{i(\psi_n, t)} f(g); \text{(ii) } Xf = 0\ \forall X \in \eta_+\}.$$

(Here $\eta_+ = \bigoplus_{\alpha \in P_+} \mathbf{g}_\alpha$.)

The images $\underset{\sim}{H}_{\mu,\psi_n}|_K$ form an ascending union of subspaces that are dense in $\underset{\sim}{K}_\mu$; we denote by $R = R_{\mu,n}$ the restriction map $f \to f|_K$. We choose an orthonormal basis $\{u_i\}$ for K_μ, which is compatible with this structure in the sense that there exists a sequence $i(1), i(2) \cdots$ such that $u_{i(j)}, u_{i(j)}, \cdots, u_{i(j+1)-1}$ is an orthonormal basis for $\underset{\sim}{H}_{\mu,\psi_0}|_K$.

For $A \in B(\underset{\sim}{H}_\mu)$, we will denote by $A_{r,s}$ the components of A with respect to this basis, i.e.,

$$A_{r,s} = (Au_r, u_s)_{L^2(K)}.$$

The assumption that $\hat{f}(\rho_{\mu,\phi})$ has finite rank implies that there exists $M \in N$ such that for all ϕ,

$$\hat{f}(\rho_{\mu,\phi})_{r,s} = 0 \quad \forall\ r, s \geqq M.$$

Thus

$$\operatorname{Tr}(\hat{f}(\rho_{\mu,\phi})\rho_{\mu,i\beta}(k_0\phi, k)) = \sum_{r,s=1}^{M} (\rho_{\mu,\phi})_{r,s}(\rho_{\mu,i\beta}(k_0\phi, k))_{s,r}. \tag{2}$$

In order to demonstrate our estimate, we need an approximate identity on $V \rtimes K$.

LEMMA 3.2. *For each $\delta > 0$, there is a nonnegative function $\kappa_\delta \in C^\infty(G)$ with the following properties*

i) $\operatorname{supp} \kappa_\delta \subseteq \pi_1(V \rtimes K)$

ii) $\hat{\kappa}_\delta$ *is rapidly decreasing on* G

iii) $\kappa_{\delta,\lambda} = \lambda^{\dim V}(\kappa_\delta \otimes \pi_\lambda)$ *is an approximate identity for* $L^2(V \rtimes K)$ *as* $\delta \to 0$ *and* $\lambda \to \infty$

iv) *For all* μ *and for all* $\varepsilon > 0$, *there exists* $\delta_0 > 0$ *such that whenever* $\delta < \delta_0$, $|\kappa^*_{\delta,\lambda}(\rho_{\mu,\eta})_{r,s}(v,k) - (\rho_{\mu,\eta})_{r,s}(v,k)| < 0(1/\lambda) + \varepsilon$ *(as* $\lambda \to \infty$*) for all* $r, s = 1, \cdots, M$ *for all* η *and for all* v.

Proof. Let $B \subseteq V$ be an $Ad(K)$-invariant set such that $\exp_G$ is one-to-one on B. Choose a nonnegative (and nonzero) C^∞ function $\tilde{\tilde{\kappa}}$ on V which is $Ad(K)$-invariant and supported inside B. Let $(h_\delta)_{\delta \to 0}$ be a nonnegative approximate identity for K (see [5], 25.47).

Set $\tilde{\kappa} = \tilde{\tilde{\kappa}} \circ \log_G$ and let κ_δ be defined by $\kappa_\delta(g) = (\tilde{\kappa} \otimes h_g)(\pi_1^{-1}(g))$. (Note that π_1 is one-to-one on $B \times K$, cf. [2, § 3].) Here, I denote by $\tilde{\kappa} \otimes h_\delta$ the function $(v,k) \to \tilde{\kappa}(v)h_\delta(k)$.

Since $\kappa_\delta \in C_c^\infty$, its Fourier transform is rapidly decreasing. An easy calculation shows that

$$\lambda^{\dim V}(\kappa_\delta \circ \pi_\lambda)(v,k) = \lambda^{\dim V}\tilde{\kappa}\left(\frac{v}{\lambda}\right)h_\delta(k).$$

The latter is clearly an approximate identity for $L^2(V \rtimes K)$; in fact, letting $\tilde{\kappa}_\lambda(v) = \lambda^{\dim V}\tilde{\kappa}(v/\lambda)$, we have

$$((\tilde{\kappa}_\lambda \otimes h_\delta) * f)(v,k) = \int\int \tilde{\kappa}_\lambda(v - v_1)h_\delta(k_1^{-1}k)f(v_1, k_1)\, dv_1\, dk_1.$$

To prove (iv), we calculate in the same manner that

$$(\kappa_{\delta,\lambda} * \rho_{\mu,\eta})_{r,s}(v,k) = \langle \tilde{\kappa}_\lambda * e^{i\eta k_0^{-1}(\cdot)}(v)h_\delta * u_r(k^{-1}k_0), u_s(k_0)\rangle H_\mu.$$

By a suitable choice of δ, we have $h_\delta * u_r$ arbitrarily close to u_r in $\underset{\sim}{K}_\mu$. On the other hand, $\tilde{\kappa}_\lambda * e^{i\eta k_0^{-1}(\cdot)}(v) = \tilde{\kappa}_\lambda * e^{i\eta(\cdot)}(k_0 v)$, and we calculate that $\tilde{\kappa}_\lambda * e^{i\eta(\cdot)}(v) = e^{i\eta v}\int_V \tilde{\kappa}(v_1)\, e^{-i\eta v_1 \lambda}\, dv_1$.

Since we are integrating over a bounded set B, we see that $|\kappa_\lambda * e^{i\eta(\cdot)}(v) - e^{i\eta v}| \leqq 0(1/\lambda)$. This gives (iv). □

LEMMA 3.3. *For all* $g \in G$, $\mu \in \hat{M}$, $\phi \in \mathfrak{a}^{*+}$ *and* $1 \leqq s, r \leqq M$,

$$\kappa_\delta * (\rho_{\mu,\phi} \otimes \pi_\lambda^{-1})_{s,r}(g) = \sum_{\sigma \in \hat{G}} d_\sigma \operatorname{Tr}(\hat{\kappa}_\delta(\sigma)(\rho_{\mu,\phi} \otimes \pi_\lambda^{-1})_{s,r})\hat{}(\sigma)\sigma(g).$$

Proof. This holds since $\kappa_\delta \in C^\infty(G)$. □

We next summarize, in a form convenient to the present article, some results from [1] and [2].

LEMMA 3.4. *Let* $\sigma \in \hat{G}$, $\sigma = \sigma_{\alpha+\beta}$ *where* $\alpha \in P_-$ *and* $\beta \in P_+$. *Then for all* $\phi \in \mathfrak{a}^*$

$$(\rho_{\mu,i\phi} \otimes \pi_\lambda^{-1})^\wedge_{r,s}(\sigma) = 0 \quad \textit{unless } \alpha = \mu.$$

Proof. Let T_1 be a maximal torus in M. Then $(\rho_{\mu,i\phi} \otimes \pi_\lambda^{-1})_{r,s}$ transforms as χ_μ under the left action of T_1. On the other hand, $\sigma_{p,q}(g)$ transforms as χ_α under left action of T_1. Thus unless $\alpha = \mu$ we have orthogonality. □

LEMMA 3.5. *There is a constant* $M = M(A, R)$ *such that whenever* $|\beta/\lambda - \phi| < A/\lambda (\beta \in P, \phi \in \mathfrak{a}^{*+})$ *and* $(v,k) \in B_R$,

$$\|R\sigma_{\mu,\beta}(\pi_\lambda(v,k))R^{-1}u - \rho_{\mu,\phi}(v,k)u\|_{H_\mu} \leqq \frac{M}{\lambda}.$$

Proof. This follows immediately from [2, Thm. 3]. □

Hence

$$|\phi_{\mu,\beta}(\pi_\lambda(v,k))_{t,\ell} - \rho_{\mu,\phi}(v,k)_{t,\ell}| < \frac{M}{\lambda}. \tag{3}$$

If we take into account the definition of $K_{\mu,\lambda}^{r,s,t,\ell}$ (see Theorem 2.1), Lemma 3.6 follows immediately from (3).

LEMMA 3.6. *For* $1 \leqq \ell, s, r, t \leqq M$,

$$\left| ((\rho_{\mu,\phi} \circ \pi_\lambda^{-1})^\wedge_{s,r}(\sigma_{\mu,\beta}))_{t,\ell} - K_\mu^{r,s,t,\ell}\left(\sigma, \frac{\beta}{\lambda}\right) \right| < 0\left(\frac{1}{\lambda}\right)$$

where "0" *depends on R and M.*

Now

$$(\rho_{\mu,\phi} \circ \pi_\lambda^{-1})^\wedge_{s,r}(\sigma_{\mu,\beta})_{t,\ell} = \int_G (\rho_{\mu,\phi}(\pi_\lambda^{-1}(g)))_{s,r} \overline{(\sigma_{\mu,\beta}(g))_{t,\ell}}\, dg$$

and by [1] Lemma 3.3, this is equal to

$$\frac{1}{\lambda^{\dim V}} \int_{B_\lambda} (\rho_{\mu,\phi}(x))_{s,r} (\sigma_{\mu,\beta}(\pi_\lambda(x))_{t,\ell} dx + 0\left(\frac{1}{\lambda^{2+\dim V}}\right)$$

where $B_\lambda = \{(v,k) \in V \rtimes K : |v| \leqq \lambda\}$.

Now according to (3), the latter expression is, to within $0(1/\lambda)$, equal to

$$\frac{1}{\lambda^{\dim V}} \int_{B_\lambda} (\rho_{\mu,\phi}(x))_{s,r} (\rho_{\mu,\beta/\lambda}(x))_{t,\ell}\, dx$$

which is by definition $K_{\mu,\lambda}^{s,r,t,\ell}(\phi, B/\lambda)$. □

We may now prove Theorem 2.1.

Proof of the theorem. By (1) and (2), we have

$$f_\mu(x) = \sum_{r,s=1}^{M} \int_{|\phi| \leqq R} \hat{f}(\rho_{\mu,\phi})_{r,s} [\rho_{\mu,\eta}(k_0\phi, k)]_{s,r} \prod_{\alpha \in P_+} \phi(H_\alpha)\, d\phi. \tag{3}$$

Using Lemma 3.2 (iv), we have

$$|\lambda^{\dim V}(\kappa_\delta \circ \pi_\lambda) * (\rho_{\mu,\eta})_{r,s}(k_0\phi, k) - (\rho_{\mu,\eta})_{r,s}(k_0\phi, k)| < 0\left(\frac{1}{\lambda}\right) + \varepsilon \text{ as } \lambda \to \infty.$$

Furthermore, by Lemma 3.3 of [2]

$$|\lambda^{\dim V}((\kappa_\delta \circ \pi_\lambda) * (\rho_{\mu,\eta})_{r,s})(k_0\phi, k) - (\kappa_\delta * [(\rho_{\mu,\eta})_{r,s} \circ \pi_\lambda^{-1}])(\pi_\lambda(k_0\phi, k))| < 0\left(\frac{1}{\lambda}\right). \tag{4}$$

(Note that the first convolution in (3) is in $V \rtimes K$ whereas the second is in G.) Equation (4) holds uniformly for $|\phi| < R$.

From (3) and (4) we deduce

$$|\rho_{\mu,\eta}(k_0\phi, k)_{r,s} - (\kappa_\delta * (\rho_{\mu,\eta})_{r,s} \circ \pi_\lambda^{-1})(\pi_\lambda(k_0\phi, k))| < 0\left(\frac{1}{\lambda}\right). \tag{5}$$

Now Lemmas 3.3 and 3.4 give

$$\begin{aligned}
&(\kappa_\delta * (\rho_{\mu,\eta})_{r,s} \circ \pi_\lambda^{-1})(\pi_\lambda(k_0\phi, k)) \\
&\quad = \sum_{\sigma \in \hat{G}} d_\sigma \operatorname{Tr}\{\hat{\kappa}_\delta(\sigma)((\rho_{\mu,\eta})_{r,s} \circ \pi_\lambda^{-1})^\wedge(\sigma)\sigma(\pi_\lambda(k_0\phi, k))\} \\
&\quad = \sum_{\beta \in P} d_{\mu,\beta} \sum_{t,\ell=0}^{\min(M, d_{\mu,\beta})} (\hat{\kappa}_\delta(\sigma_{\mu,\beta})((\rho_{\mu,\eta})_{r,s} \circ \pi_\lambda^{-1})^\wedge(\sigma_{\mu,\beta}))_{t,\ell} \sigma_{\mu,\beta}(\pi_\lambda(k_0\phi, k))_{\ell,t}.
\end{aligned}$$

By (3.2)(iii), for each $\varepsilon > 0$ we may choose a finite subset P_0 of P, independent of λ, such that

$$\begin{aligned}(6)\qquad &\left|(\kappa_\delta * (\rho_{\mu,\eta})_{r,s} \circ \pi_\lambda^{-1})(\pi_\lambda(k_0\phi, k))\right. \\ &\left. - \sum_{\beta\in P} d_{\mu,\beta} \sum_{t,\ell} (\hat{\kappa}_\delta(\sigma_{\mu,\beta})((\rho_{\mu,\eta})_{r,s} \circ \pi_\lambda^{-1})\hat{}\,(\sigma_{\mu,\beta}))(\pi_\lambda(k_0\phi, k))_{\ell,t}\right| < \varepsilon.\end{aligned}$$

Now, Lemmas 3.5 and 3.6 allow us to approximate $((\rho_{\mu,\eta})_{r,s} \circ \pi_\lambda^{-1})\hat{}\,(\sigma_{\mu,\beta})_{t,\ell}$ to within $0(1/\lambda)$, uniformly for $\beta \in P_0$, by

$$(7)\qquad K_{\mu,\lambda}^{r,s,t,\ell}\left(\eta, \frac{\beta}{\lambda}\right),$$

and $\sigma_{\mu,\beta}(\pi_\lambda(k_0\phi, k))_{\ell,t}$ to within $0(1/\lambda)$, uniformly for $\beta \in P_0$, by

$$(8)\qquad (\rho_{\mu,\beta/\lambda}(k_0\phi, R))_{\ell,t}.$$

Finally, from [1, (3.3)] and Lemma 3.5,

$$(9)\qquad |\hat{\kappa}_\delta(\sigma_{\mu,\beta})_{t,u} - \lambda^{\dim V}(\kappa \circ \pi_\lambda^{-1})\hat{}\,(\rho_{\mu,\beta/\lambda})_{t,u}| < 0\left(\frac{1}{\lambda}\right)$$

for $1 \leqq t, u \leqq M$.

Combining (6) with (5), (7), (8), and (9), we have

$$\begin{aligned}(10)\qquad &\left|(\rho_{\mu,\eta})_{r,s}(k_0\phi, k) - \sum_{\beta\in P_0} d_{\mu,\beta} \sum_{u,t,\ell=0}^{\min(M,d_{\mu,\beta})} \lambda^{\dim V}(\kappa \circ \pi_\lambda^{-1})\hat{}\,(\rho_{\mu,\beta/\lambda})_{t,u}\right. \\ &\left. \cdot K^{r,s,u,\ell}\left(\eta, \frac{\beta}{\lambda}\right)(\rho_{\mu,\eta})_{\ell,t}(k_0\phi, k)\right| < 0\left(\frac{1}{\lambda}\right) + \varepsilon.\end{aligned}$$

By (3.2)(iv), we also have

$$|\lambda^{\dim V}(\kappa \circ \pi_\lambda^{-1})\hat{}\,(\rho_{\mu,\beta/\lambda})_{t,u}| = 0\left(\frac{1}{\lambda}\right).$$

This fact, together with (3) and (10) gives

$$\left|f_\mu(x) - \sum_{\beta\in P_0} d_{\mu,\beta} \sum_{r,s,t,\ell=0}^{\min(M,d_{\mu,\beta})} K^{r,s,t,\ell}\left(\eta, \frac{\beta}{\lambda}\right) \int \hat{f}_{s,r}(\rho_{\mu,\phi})(\rho_{\mu,\phi})_{\ell,t}\left(k_0\frac{\beta}{\lambda}, k\right)\right| < 0\left(\frac{1}{\lambda}\right) + \varepsilon.$$

So, given $\varepsilon > 0$ we may choose λ_0 such that $\lambda > \lambda_0$

$$\left|f_\mu(x) - \sum_{\beta\in P_0} d_{\mu,\beta} \sum_{r,s,t,\ell=0}^{\min(M,d_{\mu,\beta})} K^{r,s,t,\ell}\left(\eta, \frac{\beta}{\lambda}\right) f_{s,r,\ell,t}\left(k_0\frac{\beta}{\lambda}, k\right)\right| < \varepsilon + 0\left(\frac{1}{\lambda}\right).$$

The assumptions on f guarantee that f is rapidly decreasing. Hence for each s, r, t, and ℓ the sum

$$\sum_{\beta\in P} d_{\mu,\beta} K^{r,s,t,\ell}\left(\eta, \frac{\beta}{\lambda}\right) f_{s,r,\ell,t}\left(k_0\frac{\beta}{\lambda}, k\right)$$

is finite. From this it follows, since ε is arbitrary, that

$$\left|f_\mu(x) - \sum_{\beta\in P} d_{\mu,\beta} \sum_{r,s,t,\ell=0}^{\min(M,d_{\mu,\beta})} K^{r,s,t,\ell}\left(\eta, \frac{\beta}{\lambda}\right) f_{s,r,\ell,t}\left(k_0\frac{\beta}{\lambda}, k\right)\right| < 0\left(\frac{1}{\lambda}\right). \qquad \square$$

4. Corollaries and complements. To obtain a more precise analogue of the sampling theorem, we would need also

$$K_{\mu,\lambda}^{r,s,t,\ell}\left(\eta, \frac{\beta}{\lambda}\right) = K_{\mu,\lambda}\left(\eta, \frac{\beta}{\lambda}\right)\delta_{r,t}\delta_{s,\ell} + 0\left(\frac{1}{\lambda}\right),$$

where $K_{\mu,\lambda}$ is independent of r, s, t, and ℓ, and δ denotes the Dirac delta. This would yield (for $x = (k_0\eta, k)$)

$$f_\mu(x) = \sum_{\beta \in P_+} d_{\mu,\beta} K_\mu\left(\eta, \frac{\beta}{\lambda}\right) f_\mu\left(k_0 \frac{\beta}{\lambda}, k\right).$$

Unfortunately, such a condition does not hold for $K^{r,s,t,\ell}$. Nevertheless, $K^{r,s,t,\ell}$ is "approximately" diagonal. Consider the right action of K on $(\rho_{\mu,\phi})_{r,s}$. We have

$$\begin{aligned}(\rho_{\mu,\phi})_{r,s}(xk) &= (\rho_{\mu,\phi}(xk)u_r, u_s)\\ &= (\rho_{\mu,\phi}(x)u_r(k^{-1}\cdot), u_s(\cdot)).\end{aligned}$$

It follows that $K^{r,s,t,\ell} = 0$ unless u_r and u_t have the same K-type. It is similar for u_s and u_ℓ. Our choice of basis thus implies that there is $n(i)$ such that r and t (respectively, s and ℓ) both lie between $n(i)+1$ and $n(i+1)$.

In the special case $(G, K) = (SO(3)), SO(2))$, we have $n(i) = i$, and thus K_μ is diagonal.

COROLLARY 4.1. *For the Euclidean motion group $M(2)$, the sampling theorem takes the form*

$$f(x) = \sum_{n \in N} (2n+1) \sum_{r=1}^{M} K^r\left(\eta, \frac{n}{\lambda}\right) f_+\left(k_0 \frac{n}{\lambda}, k\right) + 0\left(\frac{1}{\lambda}\right)$$

where

$$f_r(x) = \int_0^R (\hat{f}(S)\rho_S(x))_{r,r} S\, dS$$

and

$$K^r(\eta, \phi) = \frac{1}{\lambda^2}\int_0^\lambda J_r(S\eta)J_r(S\phi)S\, dS.$$

(*As usual, the J's denote Bessel functions.*)

By making certain restrictions on the function f we may also obtain simpler forms of the sampling theorem. In particular, if f is bi-K-invariant $\hat{f}$ has rank one: we may suppose that $\hat{f}(\rho)_{r,s} = 0$ unless $r = s = 0$. For this case $u_r = u_s = 1$, the identity on K;

$$\rho_{\mu,\phi}(v, k)_{00} = \int e^{i\phi(k^{-1}v)}\, dk = J_\phi(\eta), \quad \text{where } v = k_0\eta.$$

The argument on K-types given above shows that $K_{\mu,\lambda}^{r,s,t,\ell} = 0$ unless $\mu = 1$ and $r = s = t = \ell = 0$. Thus we see that

$$K_\lambda = K_\lambda^{00} = \lambda^{\dim V}\int_{\beta_\lambda} J_0(\eta)\overline{J_0\left(\frac{\beta}{\lambda}\right)} \prod_{\alpha \in P_+} \phi(H_\alpha)\, d\phi.$$

THEOREM 4.2. *Let f be bi-K-invariant on G. Then*

$$\left| f(x) - \sum_{\beta \in P_+} d_{1,\beta} K_\lambda\left(\eta, \frac{\beta}{\lambda}\right) f\left(k_0 \frac{\beta}{\lambda}, k\right)\right| < 0\left(\frac{1}{\lambda}\right).$$

COROLLARY 4.3. *Let f be a K-invariant function on V. Then*

$$\left| f(\eta) - \sum_{\beta \in P_+} d_\beta K_\lambda\left(\eta, \frac{\beta}{\lambda}\right) f\left(\frac{\beta}{\lambda}\right) \right| < 0\left(\frac{1}{\lambda}\right).$$

With this corollary, taking $(G, K) = (SO(n+1), SO(n))$, we recover the case of even spacing for the n-Hankel transform on R.

5. Applications. In this section we should like to mention two possible applications of the above theorems in the area of image processing and signal analysis. We will restrict ourselves to exploitation of Corollaries 4.1 and 4.3, although it is clear that the method would work more generally. Even in these special cases, work remains to be done to implement the sampling in any practical situation. However, we believe they indicate the relevance of the theory presented here to the real world.

Example 5.1. Image reconstruction in the plane. In many applications, there is interest in reconstructing a two-dimensional picture from a two-dimensional set of data points that are equally spaced along radial lines at angles $\theta_1 \cdot \theta_2 \cdots, \sigma_k$, for instance. As examples, we mention problems in geophysics [10], in radiology (the fan beam problem—see [3]) and in radar (see [11]).

Corollary 4.3 may be applied in this context to give an approximate reconstruction technique: if the points are spaced at distance $1/\lambda$ apart, and if the function f is Fourier-Bessel band limited, then in polar coordinates, we have

$$f(\eta, \theta) = \sum_{n \in N} (2n+1) \sum_{|r| \leqq M} K^r\left(\eta, \frac{n}{\lambda}\right) f_r\left(\frac{n}{\lambda}, \theta\right) + 0\left(\frac{1}{\lambda}\right),$$

where $f_r(\eta, \theta) = \int f(\eta, \phi)\, e^{-ir\phi}\, d\phi \cdot e^{ir\sigma}$, and K^r is as in (4.1). Standard Shannon sampling may then be applied in the angular variables, giving

$$f(\eta, \theta) = \sum_{n \in N} \sum_{k} (2n+1) \sum_{|r| \leqq M} K^r\left(\eta, \frac{n}{\lambda}\right) e^{-i(\theta - \theta_k)} f_r\left(\frac{n}{\lambda}, \theta_k\right) + 0\left(\frac{1}{\lambda}\right).$$

This represents approximate reconstruction of f from its values at the points $(n/\lambda, \theta_k)$.

Example 5.2. Digital signal processing. Another scenario in which our results may be applied is that of a one-dimensional signal of which the n-Hankel transform is known to be band limited, and which is being sampled at equally spaced time intervals. This typically arises when signal sampling is done by a digital processor. Corollary 4.3 then enables us to write

$$f(x) = \sum_{k=0}^{\infty} d_k K_\lambda\left(x, \frac{k}{\lambda}\right) f\left(\frac{k}{\lambda}\right) + 0\left(\frac{1}{\lambda}\right),$$

where $d_k = (2k+n-2)(n+k-3)!/(n-2)!k!$ is the dimension of the space of harmonic polynomials of degree k in R^n and where K_λ is as in Corollary 4.3. Again, this shows how to recover f to within $0(1/\lambda)$ from evenly spaced data points.

Acknowledgment. The idea for this paper occurred to me during a seminar given by I. Kluvánek. I gratefully acknowledge this source of my inspiration.

ON SOME CONJECTURES OF TURCOTTE, SPENCE, BAU, AND HOLMES*

S. P. HASTINGS† AND W. C. TROY†

Abstract. Turcotte, Spence, and Bau [*Internat. J. Heat Mass Transfer*, 25 (1982), pp. 699-706] contains conjectures concerning the equation

$$V'' = (V^2 - A(1-X^2))/2$$

with boundary conditions $V(-1) = V(1) = 0$, where A is a nonnegative parameter. For large A an appropriate asymptotic expansion results in a version of the first Painlevé transcendent, namely $Y'' = (Y^2 - s)/2$ seeking a solution such that $Y(0) = 0$, $Y(s) \sim \sqrt{s}$ as $s \to \infty$. This was studied extensively by Holmes and Spence, who conjectured that there are only two solutions. In this paper proofs of these conjectures are provided. During one of these proofs it is shown how a computer language for symbol manipulation, such as MACSYMA, can be used in a mathematically rigorous analysis.

Key words. boundary value problems, MACSYMA

AMS(MOS) subject classification. 34B15

1. Introduction and statement of results. In [2] Turcotte, Spence, and Bau have studied the problem of vertical flow of an internally heated Boussinesq fluid with viscous dissipation and pressure work. For the steady state flow under appropriate assumptions they have obtained the following boundary value problem for the velocity V as a function of the scaled position x, where the walls of the vertical channel are at $x = \pm 1$:

$$V''(x) = (V(x)^2 - A(1-x^2))/2, \tag{1}$$

$$V(1) = V(-1) = 0. \tag{2}$$

Here A is a nonnegative parameter. They have studied separately the cases $A = 0$, A small, A intermediate, and A large. In the latter cases their numerical observations have led them to conjecture that as A increases the number of solutions of (1)-(2) increases without bound.

In studying the case A large, they have found it necessary to match an inner expansion near the walls $x = \pm 1$ with an outer solution valid in the interior. (The outer solution is simply $V = \pm\sqrt{A(1-x^2)}$.) They have found the appropriate inner variables near $x = -1$ to be

$$s = (1+x)/\varepsilon, \qquad Y = \varepsilon^2 V$$

where $\varepsilon = (2A)^{-1/5}$. In terms of these variables the lowest-order terms of the inner expansion have been found to satisfy the equation

$$Y'' = (Y^2 - s)/2 \tag{3}$$

with boundary conditions

$$Y(0) = 0, \qquad Y(s) \sim \sqrt{s} \quad \text{as } s \to \infty. \tag{4}$$

This problem has been, in turn, studied extensively by Holmes and Spence [1]. They have obtained several interesting results, which are summarized in § 3. However,

they left unanswered a key question that we address in this paper, namely, the number of solutions of (3)-(4) that match the outer solution $Y=+\sqrt{s}$ at $+\infty$. We show that there are exactly two such solutions. This had been conjectured by Holmes and Spence on the basis of extensive numerical calculations. We give two proofs of this result. One relies on detailed (four decimal place) estimates of the solution while the other uses a symbolic manipulator (MACSYMA) to determine the number of zeros of certain comparison polynomials and thereby implement the previous method with less effort. The steps using MACSYMA are discussed throughout the more standard proof. Note that the result using MACSYMA is rigorous, because all computations using rational arithmetic are exact. We make crucial use of Sturm's theorem on the number of roots of a polynomial in a given interval [3]. We also investigate the behavior of solutions of the original problem (1)-(2). In Theorem 1 we prove the conjecture made by Turcotte, Spence, and Bau.

Our results are the following theorems.

THEOREM 1. *Let $N(A)$ denote the number of solutions of* (1)-(2). *Then $N(A)\to\infty$ as $A\to\infty$.*

THEOREM 2. *The differential equation* (3) *has exactly two solutions such that $Y(0)=0$ and $Y(s)\sim\sqrt{s}$ as $s\to\infty$. For one of these solutions, say Y_+, $Y'(0)>0$, while for the other, say Y_-, $Y'(0)<0$.*

See [1] and [2] for the implications of these results.

2. Proof of Theorem 1. This is by far the easier of the two results to prove. We will show, in fact, that there are, for large A, many solutions of (1) that are even ($V'(0)=0$). The proof begins by describing the behavior of a particular solution of (1). Let $\hat{V}$ denote the unique solution of (1) such that $V'(0)=0$ and $V(0)=-\sqrt{A}$.

LEMMA 1. *The solution $\hat{V}$ increases monotonically to infinity at a finite blowup point $x_A>1$. Further, $\hat{V}''>0$ on $(0, x_A)$.*

Proof. We consider the energy functional

$$E(x)=\frac{(\hat{V}''')^2}{2}-\frac{\hat{V}(\hat{V}'')^2}{2}-\hat{V}''(\hat{V}')^2-A\hat{V}''$$

so that

$$E'(x)=-\frac{5\hat{V}'(\hat{V}'')^2}{2}$$

and E decreases as long as $\hat{V}'$ is positive. Note that $E(0)=0$. If there is a first point where $\hat{V}''=0$, then at that point E is positive, which is a contradiction. The rest of the conclusions follow readily.

We now use a "shooting" method to obtain solutions of (1)-(2). It seems best to "shoot" backward from $x=1$. Therefore let V_β denote the unique solution of (1) such that $V(1)=0$ and $V'(1)=\beta$. We will show that for large A there are many values of β such that $V'_\beta(0)=0$, which will prove Theorem 1.

LEMMA 2. *If $\beta=0$, then V_β is negative on* $[0, 1)$.

Proof. In this proof, V denotes V_0. By differentiating (1) it is seen that $V'''(1)=A>0$, so that in some interval to the left of 1, $V<0$. Suppose that there is a first positive x_1 to the left of 1 where $V=0$. Let F be the energy function defined by

$$F=(V')^2-\frac{V^3}{3}+AV-Ax^2V.$$

Then

$$F' = -2AxV$$

so that as x decreases from 1, F decreases from zero as long as V is negative. However, at x_1, $F \geqq 0$, which is the desired contradiction.

Now let $U(x) = \hat{V}(x) - V_0(x)$. Then

$$U''(x) = \tfrac{1}{2}(\hat{V} + V_0)U(x)$$

so that U oscillates frequently when $\hat{V} + V_0$ is large and negative. It follows from Lemma 1 that $\hat{V} \leqq -\sqrt{A(1-x^2)}$ on $[0, 1]$. Thus, on $[0, \frac{1}{2}]$, say, $V_0 + \hat{V}$ is large and negative for large A. Hence U must vanish many times in this interval, for large A.

On the other hand, it is easy to show that if β is large (for fixed A), then $\hat{V} - V_\beta$ vanishes only once in $[0, 1)$, at a point close to $x = 1$. The graph of V_β cannot be tangent to the graph of $\hat{V}$, and it is then seen that the zeros of $\hat{V} - V_\beta$ that exist when $\beta = 0$ must leave the interval $[0, 1)$ by crossing to the left across $x = 0$. As successive zeros cross $x = 0$, $V'_\beta(0)$ must alternate in sign, since $\hat{V}'(0) = 0$. Therefore, between values of β such that $V_\beta(0) = 0$ there must be values of β such that $V'_\beta(0) = 0$, and these correspond to solutions of (1)-(2). This proves Theorem 1.

3. Proof of Theorem 2. (i) It is convenient to rescale the equation, setting $y(x) = aY(bx)$, with $a = 4^{1/5}$ and $b = a^2/2$. This leads to the equation

$$y'' = y^2 - x. \tag{5}$$

We want a solution such that

$$y(0) = 0, \qquad y \sim \sqrt{x} \quad \text{as } x \to \infty. \tag{6}$$

As before, we use a shooting method. Let y_γ denote the solution of (5) such that

$$y(0) = 0, \qquad y'(0) = \gamma.$$

Holmes and Spence [1] have proved a unique positive γ exists such that y_γ satisfies (5)-(6), and there is at least one such value of γ that is negative. They show that the solution with $\gamma = 0$ does not satisfy (3). They have conjectured that there is only one possible negative γ. Holmes and Spence have further proved that for each negative γ, there is a first $x = x_\gamma > 0$ where $y'_\gamma(x) = 0$. Finally, they have proved the following important result.

LEMMA 3. *Suppose that in some interval $\gamma_1 < \gamma \leqq \gamma_2 < 0$, x_γ is a strictly decreasing function of γ, and also that $y_\gamma(x_\gamma)$ is decreasing in γ. Then there is at most one value of γ in this interval such that y_γ satisfies* (6).

Recall that Holmes and Spence have shown at least one γ^* exists such that (6) is satisfied if $\gamma = \gamma^*$. We prove Theorem 2 with the following two additional lemmas.

LEMMA 4. *Any possible γ^* is less than -2.3.*

LEMMA 5. *The hypotheses of Lemma 3 hold with $\gamma_1 = -\infty$ and $\gamma_2 = -2.3$.*

Proof of Lemma 4. We use the functional

$$Q = \frac{y^3}{3} - xy - \frac{(y')^2}{2},$$

where $y(x)$ is a solution of (5)-(6). Thus, $Q(0) = -\gamma^2/2$ and

$$Q' = -y. \tag{7}$$

Note that, on some interval $(0, \varepsilon)$, $Q < 0$ and $y < 0$. The following useful result is easy to prove.

LEMMA 6. *If $Q>0$ before $y>0$, then y cannot satisfy* (6).

Proof. If (6) holds then there is a first x_1 with $y(x_1)=0$. From (7) we see that $Q(x_1)>0$. However, the definition of Q shows that $Q(x_1)\leqq 0$. This proves Lemma 6.

Continuing with the proof of Lemma 4, our method requires step-by-step estimates of the solution, via a sequence of further lemmas.

LEMMA 7. *For $0<x<.6$, as long as $y'<0$, y'' has at most one zero.*

Proof of Lemma 7. Consider the functional

$$H=(y''')^2/2-y(y'')^2-2y''(y')^2.$$

Then $H(0)=\frac{1}{2}$ and

$$H'=-5y'(y'')^2. \tag{8}$$

If there are at least two numbers $b>a>0$ in $(0, .6)$ where $y''=0$, and $y'<0$ in $[0, b)$, then (8) implies that $H\geqq\frac{1}{2}$ in $[0, b]$. Therefore, from the definition of H, $y'''\neq 0$ at $x=a$ and $x=b$. We may therefore assume that $y''<0$ on $(0, a)$ and $y''>0$ on (a, b). From (8) and the definition of H we conclude that

$$y'''(a)\geqq 1, \tag{9}$$

$$y'''(b)\leqq -1. \tag{10}$$

Differentiating (5), we obtain

$$y''''=2yy''+2(y')^2\geqq 2y^3.$$

On (a, b), $|y|<\sqrt{b}$, so $y''''\geqq -2(.6)^{3/2}$. Integrating this and using (9) gives a contradiction to (10). This proves Lemma 7.

Continuing with the proof of Lemma 4, we need Lemma 8.

LEMMA 8. *Suppose that $\gamma<0$. If y'' has two zeros on $(0, x_\gamma]$, where x_γ is the first zero of y', then y cannot satisfy* (6).

Proof. Again let a and b be the first two zeros of y'', and assume that $y'<0$ in $[0, b)$. From the previous lemma we see that $b>.6$. Also, as before, $y'''(a)>1$, $y'''(b)<-1$, and $y''>0$ on (a, b). It follows that $y(b)=-\sqrt{b}$ and $y'(b)\geqq-\frac{1}{2}\sqrt{b}$. Therefore, $Q(b)\geqq 2b^{2/3}/3-1/(8b)>0$ and Lemma 6 implies the result.

As we continue the proof of Lemma 4 with the use of Lemma 6, we introduce a key method of polynomial estimates of the solution. This method can be implemented with MACSYMA. It is convenient to introduce operators on the space of polynomials as follows:

$$I(p)(x)=\int_0^x p(s)\,ds,$$

$$J(p)(x)=\gamma+I(p)(x), \qquad K(p)(x)=(p(x))^2-x,$$

$$M(p)=IJK(p)=\gamma x+\int_0^x\int_0^t (p^2(t)-t)\,dt\,dx.$$

We then define a sequence of polynomials $y_0(x)=0$, $y_{i+1}=M(y_i)$. As long as $y_2(x)$ is negative, we have

$$0>y_{2j}(x)>y_{2j+2}(x)>y(x)>y_{2j+1}(x)>y_{2j-1}(x), \tag{11a}$$

$$0>y'_{2j}(x)>y'_{2j+2}(x)>y'(x)>y'_{2j+1}(x)>y'_{2j-1}(x) \tag{11b}$$

for $j=1, 2, 3, \cdots$. The repeated use of these inequalities will give our result.

The "hand" computation first uses y_2. Easy estimates show that $y_2(x)<0$ for $0<x\leqq 1.75$ and $-2.3\leqq\gamma<0$. At this point, the "hand" computation requires that we break up the interval $[-2.3, 0)$ into $[-2.3, -2.1)$ and $[-2.1, 0)$. Using y_2 and (7), we

show that $Q(1.75)>0$ if $-2.1\leqq\gamma<0$. In the range $-2.3\leqq\gamma\leqq-2.1$, the estimate using y_2 is inadequate. However, it is difficult to work with y_4, since it involves terms as high as x^{38}. Instead, we observe that y_2 can be truncated. We find that the inequalities $y<y_2\leqq 0$ imply

$$y\leqq\bar{y}_2=\frac{\gamma^2x^4}{12}+\frac{89}{90}\gamma x-.166x^3<0. \tag{12}$$

From this we have

$$y'>JK(\bar{y}_2)$$

and

$$y>M(\bar{y}_2). \tag{13}$$

We substitute $x=1$ in these inequalities to obtain

$$y(1)\geqq-2.062,\qquad y'(1)\geqq-1.28 \tag{14}$$

if $-2.3\leqq\gamma\leqq-2.1$ and $y_2\leqq 0$ on $(0,1)$.

Next, truncating (13) gives

$$y(x)>\bar{y}_3(x)=.07\gamma^2x^4-x^3/6+\gamma x$$

for x in $[0,1]$ and γ in $[-2.5,-2.1]$. From this,

$$y\leqq M(\bar{y}_3)$$

and this inequality implies that

$$y(1)\leqq-1.9,\qquad y'(1)\leqq-1.1. \tag{15}$$

Finally, using (13) and the fact that $Q'=-y$, we obtain that

$$Q(1)\geqq-1.55 \tag{16}$$

for γ in $[-2.3,-2.1]$. Again, all of this derives from the observation that $y_2<0$ on $[0,1)$.

By this point the reader will have a clear idea of our method—repeated application of the inequalities (11) with appropriate truncations to make the calculations tractable. Our goal is still to prove that Q becomes positive before y, if $\gamma\geqq-2.3$. Continuing on from $x=1$, with (14)-(16) as starting values, accomplishes this. At the same time, it can be verified that $y_2<0$ as long as necessary. At this point, however, we turn to a proof using MACSYMA.

4. Proof of Lemma 4 using MACSYMA. We can, of course, simply use MACSYMA to check the various steps of the earlier proof, and indeed, this has been done. However, we can better illustrate the utility of symbolic manipulation as a tool for this sort of proof by an application that does not need the nontrivial truncation that obtaining (12) required. In fact, it turns out that Lemma 4 can be strengthened, and this improvement helps give a complete MACSYMA proof of Theorem 2.

LEMMA 4M. *If* $-2.4\leqq\gamma<0$, *then* $Q=0$ *before* $y=0$, *so that* (6) *cannot hold.*

Proof. We use Sturm's theorem [3]: Let p be a polynomial of degree n. Define polynomials $p_0, p_1, \cdots, p_r$ as follows: $p_0=p$, $p_1=p'$, $p_i=q_ip_{i+1}-p_{i+2}$ where the q_i are polynomials, $\deg(p_{i+2})<\deg(p_{i+1})$, and $p_r\neq 0$, $p_{r+1}=0$ (Euclidean algorithm). Then the number of roots of p in an interval $(x_1,x_2]$, not counting multiplicity, is $j-k$, where j is the number of sign changes (ignoring zeros) in the sequence $\{p_0(x_1),p_1(x_1),\cdots,p_r(x_1)\}$ and k is the number of sign changes when the p_i are evaluated at x_2.

It is now clear how, in principle, MACSYMA can be used to give rigorously the number of roots of a polynomial p with rational coefficients in an interval with rational

endpoints, since MACSYMA calculations with rational numbers are exact. However, limitations of machine time and memory mean that all is not completely straightforward. With the VAX 8600, polynomials of degree 15 or 16 can generally be handled within 10 minutes of CPU time (although this depends on how many digits are required to give the coefficients as fractions), but machine time and space requirements quickly become a problem for polynomials of higher degree.

Further, this theorem is for a polynomial in one variable, and our comparison polynomials y_j depend on x and γ. Therefore some investigation is necessary. The hand calculations made earlier facilitate this. We first prove Lemma 9.

LEMMA 9. *If* $0 \leqq x \leqq 1.8$ *and* $-2.4 \leqq \gamma \leqq 0$, *then* $y < 0$.

Proof. We use a series of intermediate results.

LEMMA 10. *If* $-2 \leqq \gamma \leqq 0$ *and* $0 \leqq x \leqq 1.8$, *then* $y_2 < 0$.

Proof. Since y_2 is of degree 8 in x, this can be checked with Sturm's theorem (computations done with MACSYMA) for $\gamma = 0$ and $\gamma = -2$. Since $d^2y_2/d\gamma^2$ is positive, y_2 must also be negative for the intermediate values of γ.

Now let I and J denote the intervals $(1.7, 1.8]$ and $[-2.4, -2]$, respectively.

LEMMA 11. $y_2' > 0$ *in* $I \times J$.

Proof. $y_2'(1.7, \gamma)$ is a quadratic polynomial in γ and it is easy to check that it is positive for $\gamma \in J$. Also, $y_2'' = y_1^2 - x$. But $y_1'' = -x < 0$, while $d^2/dx^2(-\sqrt{x}) > 0$. Again, we easily check that $(y_1^2 - x) > 0$ in $I \times J$.

LEMMA 12. $y_3' < 0$ *in* $I \times J$.

Proof. $y_3'(1.7, \gamma)$ is of degree 4 in γ. With MACSYMA this is easily found to be negative for γ in J. Also, $y_3'' = y_2^2 - x$. Further use of Sturm's theorem shows that for γ in I, $|y_2(x, \gamma)|^2 < 1.8$ for $x = 1.7$ and $x = 1.8$. Hence, from Lemma 11, $y_3'' < 0$ in $I \times J$. This implies Lemma 12.

LEMMA 13. $y_3^2 > x$ *in* $I \times J$.

Proof. The polynomial $y_3^2(1.7, \gamma)$ is of degree 8 in γ, so Sturm's theorem can be used to show that $y_3^2(1.7, \gamma) > 1.8$. Now Lemma 13 follows from Lemma 12.

LEMMA 14. $y_4' > 0$ *in* $I \times J$.

Proof. Similarly, $y_4'(1.7, \gamma)$ is of degree 8 in γ, and, using MACSYMA, we easily show it is positive. Lemma 14 therefore follows from Lemma 13.

To prove Lemma 9, we first use MACSYMA to check that y_2 is negative for x in $(0, 1.7)$ and γ in $[-2.4, 0]$. Hence, by (11), $y < y_4 < y_2 < 0$ in this region. If $-2 \leqq \gamma \leqq 0$, then these inequalities hold up to $x = 1.8$. For γ in J, we observe that $y < y_4$ as long as $y_4^2 > y_2^2$. Since y_2 is increasing in I, the last inequality can only fail if, at some x in I, $y_4 + y_2 = 0$. As a result of Lemmas 11 and 14, to prove Lemma 9 we need only check that $y_4 + y_2 \leqq 0$ at $x = 1.8$, γ in J. This polynomial, of degree 8 in γ, is again easily checked. This completes the proof of Lemma 9.

Lemma 4M is a consequence of Lemmas 6 and 9 and the following lemma.

LEMMA 15. *If* $0 < -\gamma \leqq 2.4$, *then* $Q(1.8) > 0$.

Proof. From (11) and (7),

$$Q(x) \geqq -\frac{\gamma^2}{2} - \int_0^x y_4(s)\, ds$$

for (x, γ) in the region described in Lemma 9.

Setting $x = \frac{9}{5}$ and using Sturm's lemma on $-\frac{12}{5} < \gamma \leqq 0$ gives the result.

5. Proof of Theorem 2. (ii) The idea here is to use the variational equation for (5). This is

$$w'' = 2yw. \tag{17}$$

To show that the hypotheses of Lemma 3 are satisfied in $(-\infty, -2.3)$, which is necessary for the "hand" proof, we must show that x_γ, the first zero of y'_γ, and $y_\gamma(x_\gamma)$ are strictly increasing functions of x_γ in an appropriate interval.

It is convenient to use the notation $y_\gamma(x) = y(x, \gamma)$ in this section. Recall that γ^* denotes some value of γ such that (6) is satisfied. We show first that $y(x_\gamma, \gamma)$ is strictly increasing in $(-\infty, \gamma^*)$.

Note that from the definition of x_γ,

$$\frac{d}{d\gamma}[y(x_\gamma, \gamma)] = \frac{\partial y(x, \gamma)}{\partial \gamma}\bigg|_{x=x_\gamma} = w(x_\gamma, \gamma),$$

where $w(x, \gamma)$ is the solution of (17) with $y = y(x, \gamma)$ and $w(0) = 0$, $w'(0) = 1$. The Sturm Oscillation Theorem implies that $w(x, \gamma) > 0$ for $0 < x \leqq x_\gamma$ if

$$-2x_\gamma^2 y(x_\gamma, \gamma) < \pi^2. \tag{18}$$

The "hand" proof of (18) begins with the relations

$$\bar{y}_3(x) = .07\gamma^2 x^4 - \frac{x^3}{6} + \gamma x < y < \bar{y}_2 = \frac{\gamma^2 x^4}{12} + \frac{89\gamma x}{90} - (.166)x^3, \tag{19}$$

which hold as long as $\bar{y}_2 < 0$.

The key step is to find upper and lower bounds in terms of γ for x_γ. Numerical and asymptotic calculations suggest that these bounds should each be of the form $-k/\gamma^{1/3}$ for some k, and numerical experimentation suggests the values 1.32 and 1.85 for k. Therefore we define an initial value $x_0 = -1.32/\gamma^{1/3}$, and set $x_1 = -1.85/\gamma^{1/3}$. Substituting x_0 into (19) and truncating appropriately, we obtain the relations

$$(.3863)\gamma - \frac{.64}{\gamma^{2/3}} - \frac{.0274}{\gamma^{7/3}} \leqq y'(x_0) \leqq (.34)\gamma - \frac{.63}{\gamma^{2/3}} - \frac{.028}{\gamma^{2/3}} \tag{20}$$

and

$$-(1.099)\gamma^{2/3} + \frac{.331}{\gamma} + \frac{.0045}{\gamma^{8/3}} \leqq y(x_0) \leqq -(1.0894)\gamma^{2/3} + \frac{.327}{\gamma}. \tag{21}$$

We also see that $\bar{y}_2(x_1) < 0$.

To prove (18), we first show that $y'' > 0$ on (x_0, x_γ). This implies that

$$y(x_\gamma) > y(x_0) + y'(x_0)(x_1 - x_0),$$

and substitution of the estimates for x_1 and x_0 into $x_\gamma^2 y(x_\gamma)$ yields (18).

6. Proof of (18) using MACSYMA. Our goal is again to prove (18), and the technique is the same as before; that is, we find upper and lower bounds for x_γ, the first zero of y', and then use the comparison polynomials to estimate $x^2 y(x)$ at x_γ.

A minor complication in this section is the need to consider all $\gamma \leqq -2.4$ (from Lemma 4M). Sturm's lemma requires consideration of polynomials in γ over a finite interval. However, we can circumvent this by using MACSYMA to prove the following lemma.

LEMMA 16. *If $\gamma \leqq -100$, then y cannot satisfy* (6).

Proof. We can readily see, even by hand, that $y_3(1) > 0$ if $\gamma < -100$. Thus the first zero of y must come before $x = 1$. It is easy to show, further, that $\min_{0 \leqq x \leqq 1} y(x) \to -\infty$ as $\gamma \to -\infty$. From this we quickly see that $y'(x_1) \to \infty$, and the result follows.

Nevertheless, implementing Sturm's lemma was a little harder than expected and proved to be a valuable lesson in using these techniques. By Lemmas 4M and 16, we must obtain the desired estimate for $-100 \leqq \gamma \leqq -2.4$. It turns out that if we could

obtain the estimate at $\gamma = -2.4$, then using Sturm's lemma gives the same estimate in $-100 < \gamma \leqq -12/5$.

Initially, then, we tried to demonstrate (18) for $\gamma = \gamma_0 = -12/5$. Using y_2' we first obtain a lower bound on x_{γ_0}. As before, we look for this estimate in the form $-k/\delta_0$, where $\delta_0 = \gamma_0^{1/3}$. From y_2' we find that $k = 7/5$ is sufficient. That is, y_2', and hence y', are negative at $x = -7/(5\delta)$ if $-100^{1/3} < \delta \leqq \delta_0$. Also, $y_3'' > 0$ for $x > -7/(5\delta)$, which implies that $y'' > 0$ as long after $-7/(5\delta)$ as $y_2 < 0$.

To obtain an upper bound for x_γ, we must use y_3', looking for k_1 such that $y_2(-k_1/\delta) < 0$ and $y_3'(-k_1/\delta) > 0$, if $\delta \leqq \delta_0$. We found that $k_1 = 191/100$ satisfied these conditions. Unfortunately, these estimates are insufficient. We find that if $x_0 = -7/(5\delta_0)$ and $x_1 = -191/(100\delta_0)$, then

$$-x_0^2(y_3(x_0) + y_3'(x_0)(x_1 - x_0)) > \pi^2/2. \tag{22}$$

In other words, the estimates based on y_2 and y_3 are insufficient, and we must use the 38th-degree polynomial y_4. In principle, this is not difficult, because we need to use y_4 only to improve the estimate of x_0, and we can easily show that $y_2(x_1) < 0$. In practice, however, it seemed we would be unable to implement the method because to verify (18) on an interval (γ_1, γ_0), we would need to apply the Euclidean algorithm to the polynomial $P(\delta) = -\delta^{37} y_4'(-k/\delta)$, where k is chosen so that y_4', and hence y', is negative at $-k/\delta_0$. This polynomial is of degree 40, and in general, as observed earlier, it seemed that exactly implementing the Euclidian algorithm with rational arithmetic would exceed time and space limitations on the computer. Fortunately, however, the polynomial P, while of high degree, only contains nine terms, and the computation does succeed in a reasonable time. We find that $y_4'(-8/(5\delta))$ is negative for $-100^{1/3} < \delta \leqq \bar{\delta}_0$, where $\bar{\delta}_0 = -1{,}338/1{,}000$ is an upper bound for δ_0. Using $x_0 = -8/(5\delta)$ and $x_1 = -191/(100\delta)$ in (22) yields the required reverse inequality for $-100^{1/3} < \delta \leqq \bar{\delta}_0$.

7. Continuation of proof of Lemma 5. We have only to show that x_γ is increasing in γ for $\gamma \leqq \gamma^*$. One technical difficulty is the possibility that there are values $\gamma_2 < \gamma^*$ such that $y(x, \gamma_2)$ attains both a relative minimum and relative maximum in the interval $0 < x < x_\gamma^*$.

LEMMA 17. *Suppose that $\gamma < \gamma^*$ and as before let x_γ denote the first positive zero of $y'(x, \gamma)$. If $0 < x_\gamma < x_\gamma^*$, then $y''(x_\gamma, \gamma) > 0$. If $y'(a, \gamma) = 0$ at some first a in (x_γ, x_γ^*), then $y(a, \gamma) > y(a, \gamma^*)$.*

Proof. First, we determine some crucial properties of $y(x, \gamma^*)$. It easily follows from (5) that the first zero of $y''(x, \gamma^*)$ lies in the interval $(0, 1/\gamma^{*2}) \subseteq (0, \frac{1}{2})$. Furthermore, Lemma 8 implies that $y''(x, \gamma^*)$ cannot have a second zero on $(0, x_\gamma^*)$. By hypothesis, $y'(x_\gamma, \gamma) = 0$ and $0 < x_\gamma < x_\gamma^*$. The definition of x_γ implies that $y''(x_\gamma, \gamma) \geqq 0$. Suppose that $y''(x_\gamma, \gamma) = 0$. Then x_γ must be at least the second zero of $y''(x, \gamma)$, and Lemma 8 implies that $x_\gamma \geqq .6$. Furthermore, (18) guarantees that if $y(x_\gamma, \gamma) \geqq y(x_\gamma^*, \gamma^*)$, then $y(x_\gamma, \gamma) < y(x_\gamma, \gamma^*)$. But then $y''(x_\gamma, \gamma^*) < 0$, a contradiction. Therefore, $y''(x_\gamma, \gamma) > 0$.

We assume, for the sake of contradiction, that $y'(b, \gamma) = 0$ for some first b in (x_γ, x_γ^*) and that $y(x_\gamma, \gamma) \geqq y(b, \gamma^*)$. Then $y''(b, \gamma^*) \leqq 0$, a contradiction, which proves Lemma 12.

LEMMA 18. *Let $\gamma_2 < \gamma_1 \leqq \gamma^*$. Then $x_{\gamma_2} < x_{\gamma_1}$.*

Proof. Suppose, on the contrary, that there exist $\gamma_2 < \gamma_1 \leqq \gamma^*$ with $x_{\gamma_2} \geqq x_{\gamma_1}$. This and (18) imply that $y(x, \gamma_2) < y(x, \gamma_1) < 0$ for all x in $(0, x_{\gamma_1})$. Therefore $y(x_{\gamma_1}, \gamma_2) \leqq y(x_{\gamma_1}, \gamma_1)$ and

$$y'(x_{\gamma_1}, \gamma_2) \leqq 0. \tag{23}$$

Let $\tau = y(x, \gamma_2)y'(x, \gamma_1) - y(x, \gamma_1)y'(x, \gamma_2)$. Then

$$\tau' = (x + y(x, \gamma_2)y(x, \gamma_1))(y(x, \gamma_1) - y(x, \gamma_2)) > 0$$

for all x in $(0, x_{\gamma_1})$. Since $\tau(0) = 0$, this implies that

$$\tau(x_{\gamma_1}) > 0. \tag{24}$$

However, (23) and the definition of τ lead to

$$\tau(x_{\gamma_1}) = -y(x_{\gamma_1})y'(x_{\gamma_1}, \gamma_1) \leqq 0,$$

contradicting (24). This proves Lemma 18.

From (18) and the variational equations (17) it follows that $d/d\gamma[y(x_\gamma, \gamma)] > 0$ for all $\gamma < \gamma^*$. Therefore if $\gamma_2 < \gamma_1 < \gamma^*$ then $y(x_{\gamma_2}, \gamma_2) < y(x_{\gamma_1}, \gamma_1)$. This completes the proof of Lemma 4 and Theorem 2.

EQUILIBRIUM OF AN ELASTIC SPHERICAL CAP PULLED AT THE RIM*

P. PODIO-GUIDUGLI†, M. ROSATI‡, A. SCHIAFFINO§, AND V. VALENTE‡

Abstract. For thin and shallow caps the title problem is carefully formulated. The outcome is a nonlinear system of two ordinary differential equations of second order; this system is amenable to a variational format through reduction to a single functional equation, which turns out to be the Euler-Lagrange equation of a suitable energy integral depending on a load parameter π_0 and a thickness parameter κ_0.

It is shown that, for all admissible values of the parameters, a global minimizer exists that is unique for sufficiently large outward tractions; moreover, no matter what the cap's thickness, such a global minimizer tends to a flat pseudoconfiguration when $\pi_0 \to +\infty$. It is also shown that, for $\pi_0 = 0$, in addition to the unstressed reference configuration, a κ_0-sequence of local minimizers exists, interpretable as everted stressed configurations of the cap; this sequence, for $\kappa_0 \to +\infty$, tends to a pseudoconfiguration that is the reflection with respect to the horizontal plane of the middle surface of the cap in its reference configuration.

Key words. nonlinear shells, minimum problems, equilibrium stability

AMS(MOS) subject classifications. 34B15, 73H05, 73L99

1. Introduction. It is common for a thin and shallow elastic cap to be made to snap from a load-free and stress-free reference configuration into another equilibrium configuration, still load-free but no more stress-free, characterized by a macroscopic change in sign of the surface curvature.

A process through which such change in equilibrium configurations takes place is called an *eversion*, and the resulting configuration is called an *everted* equilibrium configuration. Indeed, the possibility of eversion of spherical shells, tubes, etc. is one of the mundane facts that best demonstrate the lack of uniqueness inherent in static problems of finite elasticity (cf. the discussion with illustrations given by Truesdell in [1]; the eversion into a spherical form of thick spherical shells has been considered by Antman in [2]).

Common experience shows how rather small disturbances induce the cap to snap back from the everted to the reference configuration; this suggests that the energy functional should attain a local minimum at the everted configuration.

Our paper is organized as follows. Section 2 is devoted to constructing the model of a spherical cap uniformly pulled along its rim by outward horizontal tractions. Section 3 covers the mathematical analysis of the resulting variational problem.

Care must be exercised in formulating this problem at a tractable level of generality, especially if we want to specify which simplifying hypotheses (among the many which shell theory practitioners use in a scattered and sometimes contradictory way) are going to be accepted, and under which form. Our formulation opens the way to tackle also other similar equilibrium problems, as it allows for a variety of meaningful loading and boundary conditions, in addition to those covered here. This is not the case for other related studies, where rather artificial boundary conditions appear to be essential for successful mathematical analysis.

A spherical cap has two aspect ratios, *thickness* and *shallowness*, defined by (2.1) and (2.2) below. In § 2.1, we give a succinct account of the kinematics of axially symmetric deformations of spherical caps of arbitrary thickness and shallowness. In

§ Dipartimento di Matematica, Università di Roma 2, Via O. Raimondo, 00173 Roma, Italy.

§ 2.2, we carefully state the hypotheses underlying the notion of a *thin* cap. Roughly speaking, our thinness hypotheses, in the spirit of the semiinverse method, seek equilibrium displacements that have a particularly simple representation and that, in addition, give rise to strain states such that material fibers only suffer moderate stretching at the middle surface. In § 2.3 we stipulate that our cap is made of a homogeneous elastic material of the Saint-Venant & Kirchhoff type: this constitutive law, featuring a linear relationship between nonlinear measures of strain and stress, has the merit of simplicity (it also has drawbacks; cf. [3]). Integrating over the latitude and the thickness coordinates, we obtain the total energy functional as the sum of a stored energy functional and a loading potential; then, in §§ 2.4 and 2.5, respectively, we derive the relative field and boundary equations. Finally, in § 2.6, we give these equations the simplified form appropriate to *shallow* caps and arrive at Problem $\mathscr{P}$, i.e., a semilinear system of two ordinary differential equations of the second order, with linear boundary conditions, depending on two parameters: a parameter π_0, which is directly proportional to the applied load, and a parameter κ_0, which is inversely proportional to the cap's thickness.

In §§ 3.1–3.3 we select suitable weighted function spaces for Problem $\mathscr{P}$, introduce a pair of Green operators associated with the principal part operators in that problem, and end up reformulating it as a single functional equation whose solutions are the stationary points of a functional Γ depending parametrically on π_0 and κ_0. We then look for global (§ 3.3) and local (§ 3.4) minimizers of this functional. Our main findings may be summarized as follows.

For all values of π_0, that is, no matter whether the cap's rim is pulled or pushed, and for all possible values of the thickness parameter κ_0, there exists at least a global minimizer of Γ.

When the applied load is a sufficiently large outward traction, the global minimizer is unique (cf. Theorem 3(i)-(iv), and Theorem 4, § 3.3); moreover, for every $\kappa_0 > 0$ fixed, when $\pi_0 \to +\infty$ such global minimizer tends uniformly to a pseudoconfiguration of the cap that is not an equilibrium solution, but rather would correspond to "flattening" the cap into a disk under extremely high loads (cf. Thm. 5, § 3.3).

When the value of π_0 falls into the range of possible nonuniqueness for global minimizers and, in addition, κ_0 is greater than a positive number depending on π_0, the functional Γ is not convex (cf. Theorem 3(v)). In particular, Γ is not convex when $\pi_0 = 0$. In this situation, we find that for sufficiently thin caps there exists a sequence of local minimizers. This sequence, when $\kappa_0 \to +\infty$, tends to another pseudoconfiguration of the cap that is not an equilibrium solution, but may be described as the result of everting the reference configuration of an extremely thin cap with no bending resistance (in fact, a membrane) into its reflected image with respect to a horizontal support plane.

Thus, although we are unable to produce everted solutions explicitly, we believe we have sufficient grounds to claim that, at zero load, our model indeed accounts for eversion of sufficiently thin caps. This claim is substantiated by numerical computations presented in [4]; in particular, the everted shapes of Fig. 2 exhibit not only the overall change in curvature alluded to above, but also the expected flaring in the proximities of the cap's rim.

2. Formulation. Let $\{\mathbf{O}; \mathbf{i}, \mathbf{j}, \mathbf{k}\}$ be an orthonormal Cartesian frame, and let $\{R, \Theta, \Phi\}$ be a system of spherical coordinates centered at $\mathbf{O}$ (see Fig. 1).

Given three positive numbers R_0, ρ_0, and Θ_0, set

$$\varepsilon := \frac{\rho_0}{R_0} \tag{2.1}$$

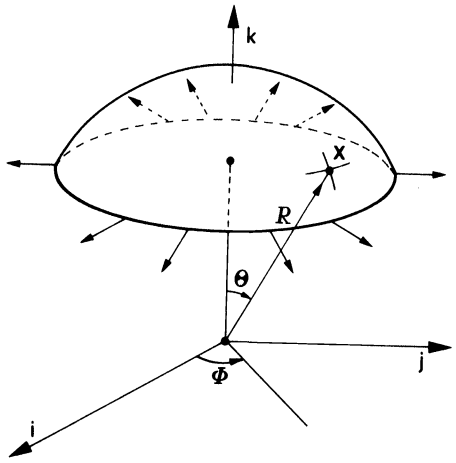

FIG. 1

and

$$\eta := \frac{1-\cos\Theta_0}{\sin\Theta_0}, \tag{2.2}$$

and consider the region $\mathscr{C}$

$$R \in]R_0-\rho_0, R_0+\rho_0[, \quad \Theta \in [0, \Theta_0[, \quad \Phi \in [0, 2\pi[, \tag{2.3}$$

of *thickness* 2ε and *shallowness* 2η. We will interpret $\mathscr{C}$ as the reference configuration of a spherical cap comprised of an elastic material of Saint-Venant & Kirchhoff type.

2.1. Kinematics. A displacement of $\mathscr{C}$ is a smooth vector field $\mathbf{u}$ over $\mathscr{C}$ such that the deformation

$$\mathbf{X} \mapsto \mathbf{x} = \mathbf{f}(\mathbf{X}) := \mathbf{X} + \mathbf{u}(\mathbf{X}) \tag{2.4}$$

is smooth, orientation preserving, and one to one;

$$\mathbf{F} := \nabla \mathbf{f} \quad \text{and} \quad \mathbf{H} := \nabla \mathbf{u} = \mathbf{F} - \mathbf{I}, \tag{2.5}$$

with $\mathbf{I}$ the gradient of the identity mapping, are the deformation and the displacement gradient, respectively. The linear and nonlinear deformation measures $\mathbf{E}$ and $\mathbf{D}$ are based on $\mathbf{H}$ and $\mathbf{F}$:

$$\mathbf{E} := \tfrac{1}{2}(\mathbf{H}+\mathbf{H}^T), \qquad \mathbf{D} := \tfrac{1}{2}(\mathbf{F}^T\mathbf{F}-\mathbf{I}) = \mathbf{E} + \tfrac{1}{2}\mathbf{H}^T\mathbf{H}. \tag{2.6}$$

Let $\mathbf{X} = X^1\mathbf{i} + X^2\mathbf{j} + X^3\mathbf{k}$ be a typical point of $\mathscr{C}$, having spherical coordinates

$$Z^1 = R, \quad Z^2 = \Theta, \quad Z^3 = \Phi. \tag{2.7}$$

At $\mathbf{X}$, the covariant basis is

$$\mathbf{E}_A := \partial_{Z^A}\mathbf{X}, \quad \text{for } A = 1, 2, 3; \tag{2.8}$$

as we will deal only with the so-called "physical" components of tensorial quantities throughout this paper, we introduce the associated orthonormal basis

$$\begin{gathered} \tilde{\mathbf{E}}_R := \mathbf{E}_R = \sin\Theta\mathbf{e} + \cos\Theta\mathbf{k}, \qquad \tilde{\mathbf{E}}_\Theta := R^{-1}\mathbf{E}_\Theta = \cos\Theta\mathbf{e} - \sin\Theta\mathbf{k}, \\ \tilde{\mathbf{E}}_\Phi := (R\sin\Theta)^{-1}\mathbf{E}_\Phi = \mathbf{e}^\perp, \end{gathered} \tag{2.9}$$

where the unit vectors $\mathbf{e}$ and $\mathbf{e}^\perp$ are defined to be

$$\mathbf{e} := \cos\Phi\mathbf{i} + \sin\Phi\mathbf{j}, \qquad \mathbf{e}^\perp := -\sin\Phi\mathbf{i} + \cos\Phi\mathbf{j}. \tag{2.10}$$

We here restrict attention to *axially symmetric* deformations. Accordingly, the displacement vector $\mathbf{u}$ has components

$$u_R := \mathbf{u} \cdot \tilde{\mathbf{E}}_R = u_R(R, \Theta), \qquad u_\Theta := \mathbf{u} \cdot \tilde{\mathbf{E}}_\Theta = u_\Theta(R, \Theta), \tag{2.11}$$
$$u_\Phi := \mathbf{u} \cdot \tilde{\mathbf{E}}_\Phi \equiv 0;$$

the displacement gradient $\mathbf{H}$ and the linear strain measure $\mathbf{E}$ have nonvanishing components

$$H_{RR} = u_{R,R}, \quad H_{\Theta\Theta} = \frac{1}{R}(u_{\Theta,\Theta} + u_R), \quad H_{\Phi\Phi} = \frac{1}{R}(u_R + \cot\Theta u_\Theta), \tag{2.12}$$
$$H_{R\Theta} = \frac{1}{R}(u_{R,\vartheta} - u_\Theta), \qquad H_{\Theta R} = u_{\Theta,R},$$

and

$$E_{RR} = H_{RR}, \quad E_{\Theta\Theta} = H_{\Theta\Theta}, \quad E_{\Phi\Phi} = H_{\Phi\Phi}, \tag{2.13}$$
$$E_{R\Theta} = \frac{1}{2}(H_{R\Theta} + H_{\Theta R}) = \frac{1}{2R}(u_{R,\Theta} + Ru_{\Theta,R} - u_\Theta),$$

respectively. The nonlinear strain measure $\mathbf{D}$ has nonvanishing components

$$D_{RR} = H_{RR} + \tfrac{1}{2}(H_{RR}^2 + H_{\Theta R}^2), \qquad D_{\Theta\Theta} = H_{\Theta\Theta} + \tfrac{1}{2}(H_{\Theta\Theta}^2 + H_{R\Theta}^2), \tag{2.14}$$
$$D_{\Phi\Phi} = H_{\Phi\Phi} + \tfrac{1}{2}H_{\Phi\Phi}^2, \qquad D_{R\Theta} = \tfrac{1}{2}(H_{R\Theta} + H_{\Theta R}) + \tfrac{1}{2}(H_{RR}H_{R\Theta} + H_{\Theta\Theta}H_{\Theta R}).$$

For axially symmetric deformations, it is easy to believe that $u_R(R, \cdot)$ and $u_\Theta(R, \cdot)$, provided their common domain of definition is extended in the obvious way, must be even and odd functions of Θ, respectively, for every fixed $R \in]R_0 - \rho_0, R_0 + \rho_0[$. Thus, in particular, all of $u_{R'}(R, \cdot)$, $u_\Theta(R, \cdot)$ and $H_{R\Theta}(R, \cdot)$ vanish at $\Theta = 0$.

2.2. Thin caps. To motivate some simplifying hypotheses that will prove crucial to our further developments, we now lay down counterparts adapted to the present context of the classical hypotheses of Kirchhoff's thin plate theory [5]-[9]. Our hypotheses are, for $R = R_0$,

$$D_{R\Theta} = D_{R\Phi} = 0, \tag{2.15}$$

$$D_{RR} = 0, \tag{2.16}$$

$$D_{\Theta\Theta} = D_{\Phi\Phi} = D_{\Theta\Phi} = 0. \tag{2.17}$$

As is well known, (2.15) and (2.16) express, respectively, the requirement that a radial material fiber remains, at the point where it crosses the middle surface, both orthogonal to the middle surface itself and unstretched. Equation (2.17) expresses the requirement that the material comprising the middle surface suffers no stretching in any conceivable deformation of the cap.

Note that for axially symmetric deformations, $(2.15)_2$ and $(2.17)_3$ are identically satisfied. In view of (2.14), the remaining equations can be written as

$$H_{R\Theta}^0(1 + H_{RR}^0) + H_{\Theta R}^0(1 + H_{\Theta\Theta}^0) = 0, \tag{2.18}$$

$$(1 + H_{RR}^0)^2 + (H_{\Theta R}^0)^2 = 1, \tag{2.19}$$

$$(1 + H_{\Theta\Theta}^0)^2 + (H_{R\Theta}^0)^2 = 1, \tag{2.20}$$

$$(1 + H_{\Phi\Phi}^0)^2 = 1. \tag{2.21}$$

(Here the superscript denotes evaluation at $R = R_0$.) This suggests that we look at situations when

$$|H^0_{RR}| \ll 1, \quad |H^0_{\Theta\Theta}| \ll 1, \quad |H^0_{\Phi\Phi}| \ll 1. \tag{2.22}$$

It follows from (2.22) that all of the above conditions of Kirchhoff's type are satisfied, except for (2.18), which reduces to

$$H^0_{R\Theta} + H^0_{\Theta R} \approx 0, \tag{2.23}$$

and the consistency condition

$$(H^0_{R\Theta})^2 \ll 1. \tag{2.24}$$

On adapting a procedure that has proved to be expedient in the case of plates ([8]), we look for solutions of (2.18)–(2.21) having the following form:

$$\begin{aligned} u_R(R, \Theta) &= u^0_R(\Theta) + \zeta(R) w(\Theta), \\ u_\Theta(R, \Theta) &= u^0_\Theta(\Theta) + \zeta(R) u(\Theta), \end{aligned} \qquad \zeta(R) := \frac{R - R_0}{R_0}, \tag{2.25}$$

implicitly restricting attention to *thin* caps.

We find that hypotheses (2.22) can be equivalently written as

$$\frac{1}{R_0}|w| \ll 1, \quad \frac{1}{R_0}|u^0_R + u^0_{\Theta,\Theta}| \ll 1, \quad \frac{1}{R_0}|u^0_R + \cot\Theta u^0_\Theta| \ll 1, \tag{2.26}$$

whereas (2.23) is satisfied if

$$u = u^0_\Theta - u^0_{R,\Theta}. \tag{2.27}$$

Accordingly, we write (2.25) as

$$u_R(R, \Theta) = u^0_R(\Theta), \qquad u_\Theta(R, \Theta) = u^0_\Theta(\Theta) + \zeta(R)(u^0_\Theta(\Theta) - u^0_{R,\Theta}(\Theta)). \tag{2.28}$$

Note that the parity properties requested for $u_R(R, \cdot)$ and $u_\Theta(R, \cdot)$ are guaranteed if we assume that

$$u^0_R(\cdot) \text{ is even and } u^0_\Theta(\cdot) \text{ is odd.} \tag{2.29}$$

From $(2.12)_{4,5}$ we obtain that

$$H_{\Theta R} = \frac{1}{R_0}(u^0_\Theta - u^0_{R,\Theta}) = H^0_{\Theta R} = -H^0_{R\Theta} = -H_{R\Theta}; \tag{2.30}_1$$

likewise, from $(2.12)_{1,2,3}$ it follows that

$$H_{RR} \approx 0, \tag{2.30}_2$$

$$H_{\Phi\Phi} \approx H^0_{\Phi\Phi} + \zeta \dot{H}^0_{\Phi\Phi} \quad \text{with } \dot{H}^0_{\Phi\Phi} = -\cot\Theta H^0_{R\Theta}, \tag{2.30}_3$$

$$H_{\Theta\Theta} \approx H^0_{\Theta\Theta} + \zeta \dot{H}^0_{\Theta\Theta} \quad \text{with } \dot{H}^0_{\Theta\Theta} = -H^0_{R\Theta,\Theta}. \tag{2.30}_4$$

We are now in a position to use (2.14) and (2.30) to evaluate the nonvanishing components of the nonlinear strain measure **D**. These are:

$$D_{\Theta\Theta} \approx D^0_{\Theta\Theta} + \zeta \dot{D}^0_{\Theta\Theta}, \qquad D_{\Phi\Phi} \approx D^0_{\Phi\Phi} + \zeta \dot{D}^0_{\Phi\Phi}, \tag{2.31}$$

with

$$\begin{aligned} D^0_{\Theta\Theta} &\approx H^0_{\Theta\Theta} + \frac{1}{2}(H^0_{R\Theta})^2 = \frac{1}{R_0}(u^0_R + u^0_{\Theta,\Theta}) + \frac{1}{2R_0^2}(u^0_\Theta - u^0_{R,\Theta})^2, \\ D^0_{\Phi\Phi} &\approx H^0_{\Phi\Phi} = \frac{1}{R_0}(u^0_R + \cot\Theta u^0_\Theta), \end{aligned} \tag{2.32}$$

and

$$\dot{D}^0_{\Theta\Theta} = \dot{H}^0_{\Theta\Theta} + (H^0_{\Theta\Theta} + H^0_{R\Theta})(\dot{H}^0_{\Theta\Theta} + \dot{H}^0_{R\Theta})$$

$$\approx \dot{H}^0_{\Theta\Theta} = \frac{1}{R_0}(u^0_\Theta - u^0_{R,\Theta})_{,\Theta}, \tag{2.33}$$

$$\dot{D}^0_{\Phi\Phi} = (1 + H^0_{\Phi\Phi})\dot{H}^0_{\Phi\Phi} \approx \dot{H}^0_{\Phi\Phi} = \frac{\cot\Theta}{R_0}(u^0_\Theta - u^0_{R,\Theta}).$$

2.3. Energy functional. For a Saint-Venant & Kirchhoff material, the stored energy density is

$$\sigma := \mu|\mathbf{D}|^2 + \tfrac{1}{2}\lambda(\operatorname{trace}(\mathbf{D}))^2, \tag{2.34}$$

with μ and λ two constant material moduli;

$$\Sigma := \int_{\mathscr{C}} \sigma \tag{2.35}$$

is the associated stored energy functional. The following constitutive law:

$$\mathbf{S} := \partial_{\mathbf{D}}\sigma = 2\mu\mathbf{D} + \lambda \operatorname{trace}(\mathbf{D})I \tag{2.36}$$

delivers the stress accompanying $\mathbf{D}$.

In view of (2.31)-(2.33), the integrand in (2.35) can be written as follows:

$$\sigma(R, \Theta) \approx \sigma^0(\Theta) + \zeta(R)\dot{\sigma}^0(\Theta) + \tfrac{1}{2}\zeta^2(R)\ddot{\sigma}^0(\Theta), \tag{2.37}$$

where

$$\begin{aligned}
\sigma^0 &= \tfrac{1}{2}(2\mu+\lambda)((D^0_{\Theta\Theta})^2 + (D^0_{\Phi\Phi})^2) + \lambda D^0_{\Theta\Theta}D^0_{\Phi\Phi},\\
\dot{\sigma}^0 &= (2\mu+\lambda)(D^0_{\Theta\Theta}\dot{D}^0_{\Theta\Theta} + D^0_{\Phi\Phi}\dot{D}^0_{\Phi\Phi}) + \lambda(D^0_{\Theta\Theta}\dot{D}^0_{\Phi\Phi} + D^0_{\Phi\Phi}\dot{D}^0_{\Theta\Theta}),\\
\ddot{\sigma}^0 &= (2\mu+\lambda)((\dot{D}^0_{\Theta\Theta})^2 + (\dot{D}^0_{\Phi\Phi})^2) + 2\lambda\dot{D}^0_{\Theta\Theta}\dot{D}^0_{\Phi\Phi}.
\end{aligned} \tag{2.38}$$

Integrating over the latitude and the thickness, we obtain

$$\begin{aligned}
\Sigma = \frac{4\pi}{3}R_0^3\Bigg(&\varepsilon(3+\varepsilon^2)\int_0^{\Theta_0}\sigma^0\sin\Theta\,d\Theta + 2\varepsilon^3\int_0^{\Theta_0}\dot{\sigma}^0\sin\Theta\,d\Theta\\
&+\frac{1}{2}\varepsilon^3\left(1+\frac{3}{5}\varepsilon^2\right)\int_0^{\Theta_0}\ddot{\sigma}^0\sin\Theta\,d\Theta\Bigg),
\end{aligned} \tag{2.39}$$

where ε is the thickness parameter (2.1). Adhering to a common practice (cf., e.g., [10]), we take

$$\Sigma \approx \frac{4\pi}{3}R_0^3\left(3\varepsilon\int_0^{\Theta_0}\sigma^0\sin\Theta\,d\Theta + \frac{1}{2}\varepsilon^3\int_0^{\Theta_0}\ddot{\sigma}^0\sin\Theta\,d\Theta\right). \tag{2.40}$$

We stipulate that the cap is pulled along its rim $\mathscr{R} := \{\mathbf{X}\in\partial\mathscr{C}\,|\,\Theta = \Theta_0\}$ by a horizontal outward traction $\mathbf{p}$, of constant magnitude p per unit area,

$$\mathbf{p} = p\mathbf{e}, \tag{2.41}$$

with $\mathbf{e}$ defined by $(2.10)_1$. The associated loading potential is

$$\Pi := \int_{\mathscr{R}} \mathbf{p}\cdot\mathbf{u}; \tag{2.42}$$

by use of (2.11) and (2.28), integrating again over the latitude and the thickness, we arrive at

$$\Pi = p\frac{4\pi}{3} R_0^2 \sin\Theta_0 (3\varepsilon(\sin\Theta_0 u_R^0(\Theta_0) + \cos\Theta_0 u_\Theta^0(\Theta_0)) + \varepsilon^3 \cos\Theta_0 (u_\Theta^0(\Theta_0) - u_{R,\Theta}^0(\Theta_0))). \tag{2.43}$$

Suppose now that we would be willing to stipulate that the vertical component of the displacement vector vanish along the cap's rim:

$$\mathbf{u}\cdot\mathbf{k} = 0 \quad \text{for all points of } \mathscr{R}. \tag{2.44}$$

This assumption would imply that

$$\cos\Theta_0 u_R^0(\Theta_0) - \sin\Theta_0 u_\Theta^0(\Theta_0) = 0, \qquad \sin\Theta_0 (u_\Theta^0(\Theta_0) - u_{R,\Theta}^0(\Theta_0)) = 0. \tag{2.45}$$

On recalling $(2.30)_1$ we note that, as $\sin\Theta_0 \neq 0$, the geometric condition $(2.45)_2$ is equivalent to

$$H_{\Theta R}^0(\Theta_0) = 0. \tag{2.46}$$

Motivated by the above argument, we choose to reduce the loading potential (2.43) to

$$\Pi = p 4\pi R_0^2 \varepsilon \sin\Theta_0 (\sin\Theta_0 u_R^0(\Theta_0) + \cos\Theta_0 u_\Theta^0(\Theta_0)), \tag{2.47}$$

stipulate that $(2.45)_1$ holds, and dispense with $(2.45)_2$.

In conclusion, we will request that the energy functional

$$I\{u_R^0, u_\Theta^0\} := \Sigma\{u_R^0, u_\Theta^0\} - \Pi\{u_R^0, u_\Theta^0\}, \tag{2.48}$$

with Σ and Π given by (2.40) and (2.47), respectively, be stationary over the class of variations (v_R, v_Θ) obeying the geometric condition $(2.45)_1$:

$$\cos\Theta_0 v_R(\Theta_0) - \sin\Theta_0 v_\Theta(\Theta_0) = 0. \tag{2.49}$$

Condition (2.49) guarantees that the variation vector

$$\mathbf{v} := v_R \mathbf{E}_R + v_\Theta \mathbf{E}_\Theta$$

has null vertical component at the rim. We will also stipulate that $v_R(\cdot)$, like $u_R(R, \cdot)$, is an even function, and that $v_\Theta(\cdot)$, like $u_\Theta(R, \cdot)$ is an odd function of Θ.

2.4. Euler–Lagrange equations. After some manipulations the following system of differential equations in $]0, \Theta_0[$ is arrived at:

$$\begin{aligned} &(\sin\Theta M' + \cos\Theta(M-N) - \sin\Theta H_{\Theta R}^0 S)' - \sin\Theta(S+T) = 0, \\ &\sin\Theta M' + \cos\Theta(M-N) - \sin\Theta H_{\Theta R}^0 S - \cos\Theta T + (\sin\Theta S)' = 0, \end{aligned} \tag{2.50}$$

where for convenience we have denoted differentiation with respect to Θ by an apostrophe and we have set

$$\begin{aligned} &S := D_{\Theta\Theta}^0 + \frac{\lambda}{2\mu}(D_{\Theta\Theta}^0 + D_{\Phi\Phi}^0), \qquad T := D_{\Phi\Phi}^0 + \frac{\lambda}{2\mu}(D_{\Theta\Theta}^0 + D_{\Phi\Phi}^0), \\ &\frac{3}{\varepsilon^2} M := \dot{D}_{\Theta\Theta}^0 + \frac{\lambda}{2\mu}(\dot{D}_{\Theta\Theta}^0 + \dot{D}_{\Phi\Phi}^0), \qquad \frac{3}{\varepsilon^2} N := \dot{D}_{\Phi\Phi}^0 + \frac{\lambda}{2\mu}(\dot{D}_{\Theta\Theta}^0 + \dot{D}_{\Phi\Phi}^0). \end{aligned} \tag{2.51}$$

To give (2.50) a more tractable form we need some preliminary results. First, from (2.32) and $(2.51)_{1,2}$ we obtain that

(2.52)
$$\sin\Theta T'+\cos\Theta(T-S)-\frac{\lambda}{2(\lambda+\mu)}\sin\Theta(T+S)'=-\cos\Theta H^0_{\Theta R}\left(\frac{1}{2}H^0_{\Theta R}+\tan\Theta\right).$$

Second, in view of (2.33) and $(2.51)_{3,4}$, we have that

(2.53)
$$\sin\Theta M'+\cos\Theta(M-N)=\frac{\varepsilon^2}{3}\sin\Theta\Big(H^{0\prime\prime}_{\Theta R}+\cot\Theta(H^{0\prime}_{\Theta R}-\cot\Theta H^0_{\Theta R})+\frac{\lambda}{2\mu}(H^{0\prime}_{\Theta R}+\cot\Theta H^0_{\Theta R})'\Big).$$

Third, solving $(2.50)_2$ for T, we get

$$T=S+\tan\Theta S'+\frac{1}{\cos\Theta}(\sin\Theta M'+\cos\Theta(M-N)-\sin\Theta H^0_{\Theta R}S), \tag{2.54}$$

and substituting (2.54) into $(2.50)_1$ yields

$$(\sin^2\Theta S)'=(\cos\Theta(\sin\Theta M'-\cos\Theta(M-N)-\sin\Theta H^0_{\Theta R}S))'. \tag{2.55}$$

Integrating (2.55) over $[0,\Theta]$, we obtain

$$\tan^2\Theta S=\frac{1}{\cos\Theta}(\sin\Theta M'+\cos\Theta(M-N)-\sin\Theta H^0_{\Theta R}S) \tag{2.56}$$

(here we have made use of (2.61) below); but, (2.54) and (2.56) together imply that

$$T=(\tan\Theta S)'. \tag{2.57}$$

Now, from (2.52) and (2.57), we deduce

$(2.58)_1$
$$-\tan\Theta\left(\frac{\lambda+2\mu}{2(\lambda+\mu)}(\tan\Theta S)''-\frac{\lambda}{2(\lambda+\mu)}S'\right)+(S-(\tan\Theta S)')=H^0_{\Theta R}\left(\frac{1}{2}H^0_{\Theta R}+\tan\Theta\right);$$

from $(2.50)_2$, (2.53), and (2.57), we have

$(2.58)_2$
$$\frac{\varepsilon^2}{3}\left(H^{0\prime\prime}_{\Theta R}+\cot\Theta(H^{0\prime}_{\Theta R}-\cot\Theta H^0_{\Theta R})+\frac{\lambda}{2\mu}(H^{0\prime}_{\Theta R}+\cot\Theta H^0_{\Theta R})'\right)=(H^0_{\Theta R}+\tan\Theta)S.$$

The ordinary second-order equations $(2.58)_{1,2}$ compose a system for the unknowns S and $H^0_{\Theta R}$, expressing the equilibrium of the cap under study.

2.5. Boundary conditions. In order that the first variation of the energy functional (2.48) vanish identically, we must require that the following condition be satisfied at the boundary:

$$[\sin\Theta S v_\Theta-\sin\Theta H^0_{\Theta R}Sv_R+\sin\Theta M(v_\Theta-v_{R'})+(\sin\Theta M'+\cos\Theta(M-N))v_R]_0^{\Theta_0}$$
$$-\tilde{\pi}_0\sin\Theta_0(\sin\Theta_0 v_R(\Theta_0)+\cos\Theta_0 v_\Theta(\Theta_0))=0 \tag{2.59}$$

for all admissible variations v_R and v_Θ, and for

$$\tilde{\pi}_0:=\frac{p}{2\mu},\qquad \mu>0. \tag{2.60}$$

On evaluating at $\Theta = 0$ the term between square brackets in (2.59), we see that it vanishes if and only if

$$M(0) - N(0) = 0. \tag{2.61}$$

As

$$M(\Theta) - N(\Theta) = \dot{D}^0_{\Theta\Theta}(\Theta) - \dot{D}^0_{\Phi\Phi}(\Theta) = -\frac{(\sin\Theta H^0_{\Theta R})'}{\sin\Theta},$$

the parity properties of axially symmetric solutions imply that indeed

$$\lim_{\Theta\to 0}(M(\Theta) - N(\Theta)) = 0.$$

Taking (2.49) and (2.61) into account, we have that (2.59) yields the two natural boundary conditions that prevail at the rim; these are

$$M(\Theta_0) = 0 \quad \text{and} \quad \sin\Theta_0 Q(\Theta_0) + \cos\Theta_0 S(\Theta_0) - \tilde{\pi}_0 = 0, \tag{2.62}$$

and involve the "bending moment" M and the "shear force" Q, the latter being defined by

$$\sin\Theta Q := \sin\Theta M' + \cos\Theta(M - N) - \sin\Theta H^0_{\Theta R} S. \tag{2.63}$$

In view of (2.33) and $(2.51)_3$, $(2.62)_1$ can be written as follows:

$$H^{0\prime}_{\Theta R}(\Theta_0) + \frac{\lambda}{\lambda + 2\mu}\cot\Theta_0 H^0_{\Theta R}(\Theta_0) = 0; \tag{2.64}_1$$

likewise, as (2.56) and (2.63) imply that

$$Q = \tan\Theta S \tag{2.65}$$

at equilibrium, $(2.62)_2$ can be written as follows:

$$S(\Theta_0) - \tilde{\pi}_0\cos\Theta_0 = 0. \tag{2.64}_2$$

The boundary conditions prevailing at $\Theta = 0$ are dictated by the often-recalled parity properties of axially symmetric deformations, as they are reflected in such constructs as S and $H^0_{\Theta R}$. Indeed, it is easy to see from the relevant definitions that S and $H^0_{\Theta R}$ must be even and odd functions of Θ, respectively. Therefore, we insist that

$$S'(0) = 0 \quad \text{and} \quad H^0_{\Theta R}(0) = 0. \tag{2.66}$$

2.6. Shallow caps. The differential equations (2.58), supplemented by the boundary conditions (2.64) and (2.66), regulate the equilibrium of a thin spherical cap uniformly pulled at its rim. The corresponding equations for the case of *shallow* caps, i.e., when $2\eta \approx \Theta_0$, are obtained by simply replacing throughout $\tan\Theta$ with Θ, etc. The resulting differential system is

$$\begin{aligned} F'' + \frac{3}{\Theta}F' &= \kappa_0(1+F)G + 2\pi_0\kappa_0^2(1+F), \\ G'' + \frac{3}{\Theta}G' &= -\kappa_0(2+F)F, \end{aligned} \tag{2.67}$$

where for convenience we have set

$$\begin{aligned} &\Theta F := H^0_{\Theta R}, \qquad G := \frac{2\kappa_0}{1+\nu}(S - \tilde{\pi}_0), \\ &2\kappa_0^2 := \frac{3}{\varepsilon^2}(1-\nu^2), \qquad \pi_0 := \frac{\tilde{\pi}_0}{1+\nu} \quad \text{with } \nu := \frac{\lambda}{\lambda+2\mu}. \end{aligned} \tag{2.68}$$

The boundary conditions are

$$F'(0)=0, \qquad \Theta_0 F'(\Theta_0)+(1+\nu)F(\Theta_0)=0,$$
$$G'(0)=0, \qquad G(\Theta_0)=0, \tag{2.69}$$

where $(2.69)_1$ efficiently replaces $(2.66)_2$, a condition which is rendered empty by the change of variable $(2.68)_1$.

3. Analysis. We will refer to the boundary value problem (2.67), (2.69) as to Problem $\mathcal{P}$. We remark that ν is the only material parameter of importance in this problem. For Saint-Venant & Kirchhoff materials, ν is the direct counterpart of Poisson's modulus for isotropic, linearly elastic materials. For reasons of physical plausibility we assume that

$$\nu \in]-1, \tfrac{1}{2}[; \tag{3.1}$$

hence, definitions $(2.68)_{2,3,4}$ make sense, and we may regard the thickness parameter in Problem $\mathcal{P}$ as positive:

$$\kappa_0 > 0. \tag{3.2}$$

On the other hand, the sign of π_0, the applied force parameter, tells us whether the cap is pulled ($\pi_0 > 0$) or pushed ($\pi_0 < 0$) at its rim.

In this section we will study existence, multiplicity, and stability of solutions to Problem $\mathcal{P}$, for ν fixed, and for the parameters κ_0, π_0 varying over their admissible ranges. We will devote special attention to the case of zero load ($\pi_0 = 0$), when eversion is in order.

3.1. Function spaces. To motivate our choice of function spaces, consider first, in an informal way, the linear differential operator that composes the principal part of both equations (2.67):

$$-L[\,\cdot\,] := [\,\cdot\,]'' + 3\Theta^{-1}[\,\cdot\,]' = \Theta^{-3}[\Theta^3[\,\cdot\,]']'. \tag{3.3}$$

For h some "test" function vanishing in a neighborhood of zero, the weak version of the equation

$$L[f] = g \tag{3.4}$$

is

$$-[\Theta^3 f' h]_0^{\Theta_0} + \int_0^{\Theta_0} \Theta^3 f' h' \, d\Theta = \int_0^{\Theta_0} \Theta^3 g h \, d\Theta, \tag{3.5}$$

or rather, taking the boundary condition $(2.69)_2$ into account,

$$(1+\nu)\Theta_0^2 f(\Theta_0) h(\Theta_0) + \int_0^{\Theta_0} \Theta^3 f' h' \, d\Theta = \int_0^{\Theta_0} \Theta^3 g h \, d\Theta. \tag{3.6}$$

In the light of the above, we introduce the following weighted Hilbert spaces:

K = the space of all functions on $]0, \Theta_0[$ that are square integrable with respect to the weight Θ^3,

K^1 = the space of all functions on $]0, \Theta_0]$ whose first derivatives are elements of K,

K_0^1 = the space of all functions of K^1 vanishing at Θ_0,

with scalar product and norm

$$(f_1, f_2)_0 := \int_0^{\Theta_0} \Theta^3 f_1(\Theta) f_2(\Theta) \, d\Theta, \quad \|f\|_0^2 := (f,f)_0 \quad \text{in } K, \tag{3.7}$$

$$(f_1, f_2)_1 := (f_1', f_2')_0 + (1+\nu)\Theta_0^2 f_1(\Theta_0) f_2(\Theta_0), \qquad \|f\|_1^2 := (f,f)_1 \text{ in } K^1. \tag{3.8}$$

We point out that K_0^1 turns out to be the orthogonal complement in K^1 of the subspace of all constants; thus, our choice of function spaces nicely accommodates the boundary conditions $(2.69)_{3,4}$.

LEMMA 1. *Let $f \in K^1$. Then, there exist two positive constants γ_1 and γ_2 such that*

(i) $\int_0^{\Theta_0} \Theta f^2(\Theta)\, d\Theta \leqq \gamma_1 \|f\|_1^2$;

(ii) $\int_0^{\Theta_0} \Theta^3 f^4(\Theta)\, d\Theta \leqq \gamma_2 \|f\|_1^4$.

Moreover,

(iii) *K^1 is compactly embedded into K.*

Proof. Preliminarily, note that both (i) and (ii) trivially hold true if f has constant value. Hence, it is sufficient to consider the case when $f \in K_0^1$. In this case, we have that

$$f^2(\Theta) = -2 \int_\Theta^{\Theta_0} f(\Phi) f'(\Phi)\, d\Phi,$$

and

$$f^4(\Theta) \leqq 4 \left(\int_\Theta^{\Theta_0} f^2(\Phi)\, d\Phi \right) \left(\int_\Theta^{\Theta_0} f'^2(\Phi)\, d\Phi \right).$$

Consequently,

$$\Theta f^2(\Theta) \leqq 2 \int_\Theta^{\Theta_0} \Phi |f(\Phi) f'(\Phi)|\, d\Phi \tag{3.9}_1$$

and

$$\Theta^3 f^4(\Theta) \leqq 4 \left(\int_\Theta^{\Theta_0} f^2(\Phi)\, d\Phi \right) \left(\int_\Theta^{\Theta_0} \Phi^3 f'^2(\Phi)\, d\Phi \right) \leqq 4 \|f\|_1^2 \int_\Theta^{\Theta_0} f^2(\Phi)\, d\Phi. \tag{3.9}_2$$

Consider now the identity

$$\int_0^{\Theta_0} \Theta f(\Theta)\, d\Theta = \int_0^{\Theta_0} d\Theta \int_\Theta^{\Theta_0} f(\Phi)\, d\Phi, \tag{3.10}$$

that holds whenever the mapping $\Theta \mapsto \Theta f(\Theta)$ is integrable over $]0, \Theta_0[$. In view of (3.10), $(3.9)_1$ yields

$$\begin{aligned} \int_0^{\Theta_0} \Theta f^2(\Theta)\, d\Theta &\leqq 2 \int_0^{\Theta_0} \Theta^2 |f(\Theta) f'(\Theta)|\, d\Theta \\ &\leqq 2 \left(\int_0^{\Theta_0} \Theta f^2(\Theta)\, d\Theta \right)^{1/2} \left(\int_0^{\Theta_0} \Theta^3 f'^2(\Theta)\, d\Theta \right)^{1/2} \end{aligned}$$

which is (i). Item (ii) is proved in a completely analogous way, using the last formula above and $(3.9)_2$.

To establish (iii), consider a bounded sequence $\{f_n\} \subset K^1$. As all functions f_n are equicontinuous over every subinterval $[\varepsilon, \Theta_0]$ with $\varepsilon > 0$, we can always find a subsequence converging uniformly in any one of those subintervals. The desired result then follows from the estimate under (i). □

3.2. Green operators. As a consequence of Lemma 1(i) $f \mapsto f^2$ is a continuous mapping from K^1 into K. Therefore, in Problem $\mathcal{P}$, the right-hand sides of equations (2.67) belong to K if both G and F belong to K^1.

Then pick $g \in K$, and consider the following two problems associated with (equation (3.4) and) Problem $\mathscr{P}$:

($\mathscr{P}_0$) Find $f \in K_0^1$ such that $(f, h)_1 = (g, h)_0$ for all $h \in K_0^1$.

($\mathscr{P}_1$) Find $f \in K^1$ such that $(f, h)_1 = (g, h)_0$ for all $h \in K^1$.

On appealing to standard results from the Hilbertian theory for boundary value problems, we see that Problem $\mathscr{P}_\alpha$ ($\alpha = 0, 1$) has a unique solution f_α that solves (3.4); for almost every $\Theta \in]0, \Theta_0[$, satisfies the boundary condition in Θ_0 (i.e., either $f_0(\Theta_0) = 0$ for $\alpha = 0$ or $\Theta_0 f_1'(\Theta_0) + (1+\nu) f_1(\Theta_0) = 0$ for $\alpha = 1$), and satisfies the boundary condition in 0 in a weak sense (i.e., $f_\alpha' \in K$). Accordingly, the mappings $g \mapsto f_\alpha$ ($\alpha = 0, 1$) define two (linear and bounded) Green operators G_α from K into, respectively, K_0^1 for $\alpha = 0$ and K^1 for $\alpha = 1$; we have also that, for all functions $h \in K_0^1$ for $\alpha = 0$ and all functions $h \in K^1$ for $\alpha = 1$,

$$(G_\alpha[g], h)_1 = (g, h)_0. \tag{3.11}$$

LEMMA 2. *Let G_α be either one of the Green operators defined just above, and let g, f_α ($\alpha = 0, 1$) be such that $f_\alpha = G_\alpha[g]$. Then, for $\Theta \in]0, \Theta_0]$, the following inequalities hold true*:

(i) $|f_\alpha'(\Theta)|^2 \leqq \frac{1}{6} \int_0^\Theta \Theta |g(\Theta)|^2 \, d\Theta$;

(ii) $|f_\alpha(\Theta_0) - f_\alpha(\Theta)| \leqq \frac{1}{2} \|g\|_0 \ln(\Theta_0/\Theta)$.

Moreover,

(iii) *G_α maps compactly K into K^1;*

(iv) *G_α can be seen as a self-adjoint operator of K into itself;*

(v) *G_α is a positive operator, i.e., $g > 0 \Rightarrow G_\alpha[g] = f_\alpha > 0$;*

(vi) *G_α maps continuously $C^0[0, \Theta_0]$ into $C^2[0, \Theta_0]$.*

Proof. Preliminarily, we observe that it follows from the strong integrability requirement necessary for the right-hand side of (i) to be finite that the boundary condition at zero is satisfied in classical sense, i.e.,

$$\lim_{\Theta \to 0+} f_\alpha'(\Theta) = 0.$$

Under the current hypotheses,

$$(G_\alpha[g](\Theta))' = f_\alpha'(\Theta) = -\Theta^{-3} \int_0^\Theta \Phi^3 g(\Phi) \, d\Phi. \tag{3.12}$$

To see this, first take $g(\Theta) \equiv 0$ in an arbitrarily small right neighborhood of zero; as $f_\alpha(\Theta)$ has constant value in such a neighborhood, (3.12) holds; a straightforward density argument then shows that this conclusion continues to hold for an arbitrary $g \in K$.

By integrating $(3.12)_2$ over $[\Theta, \Theta_0]$, we obtain

$$f_\alpha(\Theta) = f_\alpha(\Theta_0) - \frac{1}{2}\Theta_0^{-2} \int_0^{\Theta_0} \Phi^3 g(\Phi) \, d\Phi + \frac{1}{2}\Theta^{-2} \int_0^\Theta \Phi^3 g(\Phi) \, d\Phi + \frac{1}{2} \int_\Theta^{\Theta_0} \Phi g(\Phi) \, d\Phi. \tag{3.13}$$

Now, for $\alpha = 0$, $f_0(\Theta_0) = 0$ and (3.13) yields

$$f_0(\Theta) = \frac{1}{2} \int_0^\Theta \Phi^3 (\Theta^{-2} - \Theta_0^{-2}) g(\Phi) \, d\Phi + \frac{1}{2} \int_\Theta^{\Theta_0} \Phi^3 (\Phi^{-2} - \Theta_0^{-2}) g(\Phi) \, d\Phi; \tag{3.14}$$

for $\alpha = 1$, again $(3.12)_2$ implies that

$$\int_0^{\Theta_0} \Phi^3 g(\Phi)\, d\Phi = -\Theta_0^3 f_1'(\Theta_0) = \Theta_0^2(1+\nu) f_1(\Theta_0), \tag{3.15}$$

so that (3.13) this time yields

$$f_1(\Theta) = f_0(\Theta) + (1+\nu)^{-1}\Theta_0^{-2} \int_0^{\Theta_0} \Phi^3 g(\Phi)\, d\Phi. \tag{3.16}$$

From $(3.12)_2$, (i) follows by splitting $\Theta^3 g(\Theta)$ as $\Theta^{5/2} \times \Theta^{1/2} g(\Theta)$ and using the Schwartz inequality. Next, by integrating $(3.12)_2$ over $[\Theta, \Theta_0]$ and using the Schwartz inequality again, we get (ii).

The proofs of statements (iii) and (iv) are almost trivial, and we omit them. The proof of statement (v) easily follows from either a glance to (3.14) and (3.16) or a direct application of the Maximum Principle.

Finally, assume that g is continuous at zero. To show that statement (vi) holds true, it is sufficient to divide both sides of $(3.12)_2$ by Θ, and then pass to the limit for $\Theta \to 0$, to get

$$f_\alpha''(0) = \tfrac{1}{4} g(0). \qquad \square$$

We are now in a position to write Problem $\mathscr{P}$ in the following form:

$$(\mathscr{P}') \qquad \begin{aligned} F &= -\kappa_0 G_1[(1+F)G + 2\pi_0\kappa_0(1+F)], \\ G &= \kappa_0 G_0[(2+F)F]. \end{aligned}$$

We remark that the inequalities under Lemma 2(i) and (ii) ensure us that every solution of Problem $\mathscr{P}'$ is in fact a classical solution of Problem $\mathscr{P}$.

3.3. Global minimizers. We begin by noting that Problem $\mathscr{P}'$ can be written under the form of a single equation for the unknown F, namely,

$$F + \kappa_0^2 G_1[(1+F)G_0[(2+F)F] + 2\pi_0(1+F)] = 0. \tag{3.17}$$

On recalling (3.11), $(3.12)_1$, and Lemma 2(iv), it can be shown that the left-hand side of (3.17) is the Fréchet derivative of the functional

$$\Gamma(F) := \frac{1}{2}\|F\|_1^2 + \frac{\kappa_0^2}{4}\|G_0[(2+F)F]\|_1^2 + \pi_0\kappa_0^2(2+F, F)_0; \tag{3.18}$$

consequently, the solutions of (3.17) are the stationary points of Γ. Moreover, the second differential of Γ at F turns out to be the quadratic form

$$\Gamma''(F; h) := \|h\|_1^2 + 2\kappa_0^2\|G_0[(1+F)h]\|_1^2 + \kappa_0^2(G_0[(2+F)F], h^2)_0 + 2\pi_0\kappa_0^2\|h\|_0^2. \tag{3.19}$$

THEOREM 3. *The functional* Γ *over* K^1 *defined by* (3.18) *has the following properties*:

(i) Γ *is lower semicontinuous with respect to the weak topology of* K^1;

(ii) Γ *is coercive, i.e.,* $\Gamma(F) \to +\infty$ *as* $\|F\|_1 \to +\infty$;

(iii) Γ *is strictly convex for* $\pi_0 \geqq \Theta_0^2/16$;

(iv) *for every* $\pi_0 < \Theta_0^2/16$ *there exists a positive number* κ_{π_0} *such that* Γ *is not convex for* $\kappa_0 > \kappa_{\pi_0}$.

Proof. Statement (i) is an easy consequence of (iii) in Lemma 2.

Statement (ii) is proved by contradiction. Indeed, let $\{f_n\} \subset K^1$, with $\|f_n\| \to +\infty$, and assume that there exists some constant γ such that

$$\Gamma(f_n) \leqq \gamma. \tag{3.20}$$

From (3.18) we then have that

$$\lim_{n\to\infty} \|f_n\|^{-4}\Gamma(f_n) = \lim_{n\to\infty} \left\| G_0\left[\frac{f_n^2}{\|f_n\|_1^2}\right]\right\|_1^2 = 0. \tag{3.21}$$

As zero is not a proper value of G_0, it follows from $(3.21)_2$ that

$$\frac{\|f_n^2\|_0}{\|f_n\|_1^2} \to 0.$$

Consequently,

$$\liminf_{n\to\infty} \Gamma(f_n) \geqq \tfrac{1}{2} \liminf_{n\to\infty} \|f_n\|_1^2 = +\infty,$$

an inequality incompatible with (3.20).

To prove items (iii) and (iv), we begin by observing that

$$\Gamma''(F; h) - \Gamma''(-1; h) = 2\kappa_0^2 \|G_0[(1+F)h]\|_1^2 + \kappa_0^2 (G_0[(1+F)^2], h^2)_0 \geqq 0, \tag{3.22}$$

where the last inequality follows from Lemma 2(v). In addition, we observe that

$$\Gamma''(-1; h) = \|h\|_1^2 + 2\pi_0\kappa_0^2 \|h\|_0^2 - \kappa_0^2 (G_0[1], h^2)_0, \tag{3.23}$$

and that

$$G_0[1] = \frac{\Theta_0^2 - \Theta^2}{8}. \tag{3.24}$$

But, (3.22)-(3.24) together imply that

$$\Gamma''(F; h) \geqq \|h\|_1^2 + \kappa_0^2 \int_0^{\Theta_0} \Theta^3 \left(2\pi_0 - \frac{\Theta_0^2 - \Theta^2}{8}\right) h^2(\Theta)\, d\Theta; \tag{3.25}$$

from (3.25), the desired conclusions easily follow. □

As a straightforward corollary of Theorem 3 we have the following theorem.

THEOREM 4. *For all admissible values of the parameters, i.e., for all* $\pi_0 \in \mathbb{R}$ *and* $\kappa_0 > 0$, *a global minimizer exists in* K^1 *for the functional* Γ; *moreover, if* $\pi_0 \geqq \Theta_0^2/16$, *such a minimizer is unique.*

Thus, the equilibrium problem under study has at least a solution of minimum energy, which is the only solution when sufficiently large outward tractions are applied along the cap's rim.

Our next theorem gives qualitative information concerning the nature of global minimizers.

THEOREM 5. *Let* $\kappa_0 > 0$ *be fixed*; *moreover, for every choice of* $\pi_0 \geqq \Theta_0^2/16$, *let* F_{π_0} *denote the global minimizer of* Γ *associated with* (κ_0 *and*) π_0. *Then, as* $\pi_0 \to +\infty$, $(F_{\pi_0}(\Theta) + 1) \to 0$ *uniformly in* $[0, \Theta_0]$.

Proof. Set $H_{\pi_0} := F_{\pi_0} + 1$. Then, from the second equation in Problem $\mathscr{P}'$, we get that

$$G_{\pi_0} = \kappa_0 G_0[H_{\pi_0}^2] - \kappa_0 G_0[1]; \tag{3.26}$$

in turn, in view of Lemma 2(v), (3.24), and the present hypothesis on the parameter π_0, (3.26) implies that

$$G_{\pi_0} + 2\pi_0\kappa_0 > 0. \tag{3.27}$$

With this, from $(2.67)_1$ we obtain

$$-M[F_{\pi_0}] := -(L + \kappa_0(G_{\pi_0} + 2\pi_0\kappa_0)I)[F_{\pi_0}] = \kappa_0(G_{\pi_0} + 2\pi_0\kappa_0) \geqq 0, \tag{3.28}$$

where we have denoted by I the identity operator. Now, by the Maximum Principle,

$$F_{\pi_0}(\Theta) \leqq 0. \tag{3.29}$$

On the other hand, as

$$L[H_{\pi_0}] \geqq 0,$$

and as

$$H'_{\pi_0}(0) = 0, \qquad \Theta_0 H'_{\pi_0}(\Theta_0) + (1+\tilde{\nu}) H_{\pi_0}(\Theta_0) > 0,$$

by the Maximum Principle the global minimizer F_{π_0} must be such that $F_{\pi_0}(\Theta) \geqq -1$. We then conclude, with the aid of (3.29), that

$$-1 \leqq F_{\pi_0}(\Theta) \leqq 0. \tag{3.30}$$

Suppose now that there exists a sequence $\{\pi_{0,n}\} \to +\infty$ such that

$$\max_{[0,\Theta_0]} F_{\pi_{0,n}}(\Theta) \geqq \alpha > -1. \tag{3.31}$$

We may safely assume, in addition, that

$$\pi_{0,n+1} - \pi_{0,n} \geqq \Theta_0^2/16.$$

Therefore, repeating the argument leading to (3.29), we have that the sequence $\{F_{\pi_{0,n}}\}$ decreases pointwise to some function F_∞; we also have that, in the topologies of K and K^1, respectively,

$$\{(2+F_{\pi_{0,n}})F_{\pi_{0,n}}\} \to (2+F_\infty)F_\infty, \qquad \{G_{\pi_{0,n}}\} \to \kappa_0 G_0[(2+F_\infty)F_\infty].$$

In view of this, dividing the first equation in Problem $\mathscr{P}'$ by $\pi_{0,n}$ and taking the limit for $n \to \infty$, it follows that $G_1[F_\infty + 1] = 0$, which in turn implies that $F_\infty + 1 = 0$. But then, by Dini's Theorem, $F_{\pi_{0,n}}(\Theta) \to -1$ uniformly; this contradicts (3.31). □

Obviously, as $F \equiv -1$ does not solve (3.17) for any finite π_0, it cannot be interpreted as a possible equilibrium configuration of our cap. However, $F \equiv -1$ does correspond to a "flat" pseudoconfiguration, in a sense that we will now make precise.

We begin by noting that, for $F \equiv -1$, we have from (2.30) and $(2.68)_1$ that

$$u^0_\Theta(\Theta) - u^{0\prime}_R(\Theta) = -R_0\Theta. \tag{3.32}$$

We also have from the second equation in Problem $\mathscr{P}'$ together with $(2.68)_2$ and (3.24) that

$$S(\Theta) = \pi_0 - \frac{\Theta_0^2 - \Theta^2}{16}. \tag{3.33}$$

On the other hand, it is not difficult to see that, from a purely kinematic point of view, an axisymmetric flattening displacement of the spherical surface coinciding with the middle surface of the cap in the reference configuration has to have the following form:

$$\begin{aligned} u^0_R(\Theta) &= -R_0(1 - \cos\Theta_0 \cos\Theta) + \sin\Theta v(\Theta), \\ u^0_\Theta(\Theta) &= -R_0 \cos\Theta_0 \sin\Theta + \cos\Theta v(\Theta), \end{aligned} \tag{3.34}$$

where v is an arbitrary (smooth and) odd function. Equivalently, (3.34) can be written as follows:

$$u^0_\Theta(\Theta) - u^{0\prime}_R(\Theta) = -\sin\Theta v'(\Theta), \qquad u^0_R(\Theta) + \cot\Theta u^0_\Theta = -R_0 + \frac{v(\Theta)}{\sin\Theta}, \tag{3.35}$$

or rather, with the use of the shallow cap approximation introduced in § 2.6:

$$u^0_\Theta(\Theta)-u^{0\prime}_R(\Theta)=-\Theta v'(0),\qquad \Theta u^0_R(\Theta)+u^0_\Theta(\Theta)=\Theta(-R_0+v'(0)). \tag{3.36}$$

Comparison of (3.32) and $(3.36)_1$ suggests that we exploit the arbitrariness in the choice of v by taking $v'(0)=R_0$, so that (3.32) is satisfied and $(3.36)_2$ becomes

$$\Theta u^0_R(\Theta)+u^0_\Theta(\Theta)=0. \tag{3.37}$$

But, it follows from (2.32), $(2.51)_{1,2}$, and (2.57) that

$$\frac{1}{R_0}(u^0_R+\cot\Theta u^0_\Theta)=\frac{1}{R_0}(u^0_R+u^{0\prime}_\Theta)+\frac{1}{2R_0^2}(u^0_\Theta-u^{0\prime}_R)^2+(\tan\Theta S)'-S. \tag{3.38}$$

In the shallow cap approximation, (3.37) results from (3.38) by the use of (3.32) and (3.33). We then have reason to say that $F\equiv -1$ corresponds to "flattening" a spherical cap of small, but nonnegligible thickness into a circular disk by means of extremely high outward peripheral tractions.

3.4. Local minimizers. We begin with a lemma that will allow us to define the Leray-Schauder degree of Γ', the Fréchet derivative of the energy functional.

LEMMA 6. *Let* $\{\kappa_{0,n}\}$ *with* $\inf\kappa_{0,n}>0$, *and* $\{\pi_{0,n}\}$ *be two bounded sequences in* $\mathbb{R}$; *moreover, for* $\{f_n\}$ *a sequence in* K^1, *let*

$$\Gamma'(f_n):=f_n+\kappa^2_{0,n}G_1[(1+f_n)G_0[(2+f_n)f_n]+2\pi_{0,n}(1+f_n)]. \tag{3.39}$$

Then, if the sequence $\{\Gamma'(f_n)\}$ *is bounded, the sequence* $\{f_n\}$ *is also bounded in the* K^1*-norm.*

Proof. With a view toward coming up with a contradiction, and with no loss of generality, we suppose that $\|f_n\|_1\to+\infty$. We may also suppose that

$$\frac{1+f_n}{\|1+f_n\|_1}\to h$$

weakly in K^1, and therefore strongly in K. Now, by (3.39) and the definitions of the scalar products for K^1 and K, we have that

$$(\Gamma'(f_n),1+f_n)_1=(f_n,1+f_n)_1+\kappa^2_{0,n}(2\pi_{0,n}+G_0[(2+f_n)f_n],(1+f_n)^2)_0. \tag{3.40}$$

Dividing (3.40) by $\|1+f_n\|_1^4$ and taking the limit for $n\to\infty$, it follows that $(G_0[h^2],h^2)_0=0$, thereby implying that $h=0$, or rather,

$$\frac{\|1+f_n\|_0}{\|1+f_n\|_1}\to 0.$$

From (3.40) we have that

$$(\Gamma'(f_n),1+f_n)_1\geqq(f_n,1+f_n)_1+2\pi_{0,n}\kappa^2_{0,n}(1,(1+f_n)^2)_0-\kappa^2_{0,n}(G_0[1],(1+f_n)^2)_0,$$

and hence

$$\liminf_{n\to\infty}\frac{(\Gamma'(f_n),1+f_n)_1}{\|1+f_n\|_1}\geqq\lim_{n\to\infty}\|1+f_n\|_1=+\infty,$$

a result incompatible with the hypothesis that the sequence $\{\Gamma'(f_n)\}$ is bounded. □

In view of the preceding lemma we have that the Leray-Schauder degree δ of Γ' is well defined and independent of the values of parameters π_0 and κ_0. Due to the convexity of Γ for π_0 large, we also have that $\delta=1$.

We remark that each extremal F of Γ must be such that $F(\Theta_0) \neq -1$. Indeed, consider the flat manifold

$$\mathcal{M} := \{F \in K^1 \,|\, F(\Theta_0) = -1\}$$

and let

$$F \mapsto \tilde{F} := -2 - F$$

be the symmetry mapping of K^1 onto itself about the point $F_0 \equiv -1$. By direct inspection of the definition (3.18) of Γ, we see that $\Gamma|_{\mathcal{M}}$, the restriction of Γ to $\mathcal{M}$, attains its absolute minimum at F_0 and, moreover, for each $F \in \mathcal{M}$, $\Gamma|_{\mathcal{M}}(F) = \Gamma|_{\mathcal{M}}(\tilde{F})$. Suppose absurdly that $F \neq F_0$, and therefore also that $\tilde{F}$ were an extremal of $\Gamma|_{\mathcal{M}}$. Then, the fourth-order polynomial

$$\tau \mapsto \Gamma|_{\mathcal{M}}(-1 + \tau(1+F))$$

would need to have extremals at $\tau = \pm 1$, absolute minimum at $\tau = 0$, and would have to grow to $+\infty$ for $\tau \to \pm\infty$, which is manifestly impossible.

If we denote by $\Omega^+(\Omega^-)$ the collection of all functions $\hat{F}$ in K^1 such that $\hat{F}(\Theta_0) > -1 (\hat{F}(\Theta_0) < -1)$, and with δ^+ and, respectively, δ^- the corresponding degrees, we deduce from the above that both $\delta^+ = 1$ and $\delta^- = 0$.

We now turn to investigating the behavior of local minimizers for the thickness parameter tending to infinity, i.e., when the cap is made thinner and thinner.

For π_0 fixed, let $\{\kappa_{0,n}\}$ be a sequence in $\mathbb{R}$ such that $\{\kappa_{0,n}\} \to +\infty$, and let $\{\hat{F}_n\}$ be a sequence in K^1 whose typical element $\hat{F}_n$ is the extremal of Γ corresponding to (π_0 and) $\kappa_{0,n}$. We will call such a sequence a κ_0-sequence of extremals.

LEMMA 7. *For π_0 fixed, let $\{\hat{F}_n\}$ be a bounded κ_0-sequence of extremals. Then, we have the following*:

(i) *For $\pi_0 \neq 0$, $\{\hat{F}_n\} \to -1$ weakly*;

(ii) *For $\pi_0 = 0$, every weakly convergent subsequence of $\{\hat{F}_n\}$ tends to -2, -1, or zero.*

Proof. Let $\{\hat{F}_n\} \to \hat{F} \in K^1$ weakly. From (3.17), in the limit for $n \to \infty$, we get

$$G_1[(1+\hat{F})G_0[(2+\hat{F})\hat{F}] + 2\pi_0(1+\hat{F})] = 0,$$

and hence

$$(1+\hat{F})(G_0[(2+\hat{F})\hat{F}] + 2\pi_0) = 0. \tag{3.41}$$

On setting

$$\hat{G} := G_0[(2+\hat{F})\hat{F}], \tag{3.42}$$

we obtain from (3.41) and (3.42) that

$$(1+\hat{F})(\hat{G} + 2\pi_0) = 0 \quad \text{and} \quad L[\hat{G}] = (2+\hat{F})\hat{F}. \tag{3.43}$$

Let J denote any connected component of the set $\{\Theta \in]0, \Theta_0[\,|\, \hat{F}(\Theta) \neq -1\}$. As the function $(\hat{G} + 2\pi_0)$ vanishes identically over J, so does the function $(2+\hat{F})\hat{F}$ and, by (3.42), so does also $\hat{G}$. The two assertions under (i) and (ii) easily follow. □

It is interesting to note that the "flat" pseudoconfiguration corresponding to $\hat{F} \equiv -1$ is the common limit of situations when either κ_0 is fixed and the applied load is made to tend to $+\infty$ (Theorem 5) or π_0 is fixed and the thickness is made to tend to zero. For $\pi_0 = 0$, the two other possible weak limits of bounded κ_0-sequences of extremals are the reference configuration, which obtains for $\hat{F} \equiv 0$, and an "everted" pseudoconfiguration corresponding to $\hat{F} \equiv -2$.

To explain the terminology alluding to eversion, we first observe that, for $\hat{F} \equiv -2$, (3.32) and (3.33) are replaced, respectively, by

$$u^0_\Theta - u^{0\prime}_R = -2R_0\Theta \tag{3.44}$$

and

$$S \equiv 0. \tag{3.45}$$

Second, it follows from (2.32), $(2.51)_{1,2}$, (2.57), and (3.1) that

$$u^0_R + \cot\Theta u^0_\Theta = \frac{R_0}{1+\nu}((\tan\Theta S)' - \nu S), \tag{3.46}$$

so that, in view of (3.45), we have that

$$u^0_R + \cot\Theta u^0_\Theta = 0. \tag{3.47}$$

Third, we note the form that a reflection with respect to the horizontal plane of the surface coinciding with the middle surface of the cap in the reference configuration must have

$$u^0_R(\Theta) = -2R_0\cos\Theta(\cos\Theta - \cos\Theta_0), \qquad u^0_\Theta(\Theta) = 2R_0\sin\Theta(\cos\Theta - \cos\Theta_0). \tag{3.48}$$

Equivalently, in such a reflection, (3.47) and

$$u^0_\Theta - u^{0\prime}_R = -2R_0\sin\Theta\cos\Theta$$

have to prevail. In the shallow cap limit we are then entitled to interpret $F \equiv -2$ as the limit situation corresponding to perform an eversion process, at zero loads, of thinner and thinner caps.

We remark that, for $\pi_0 < \Theta_0^2/16$ and κ_0 large, there exists a neighborhood of -1 in K^1 (independent of κ_0) where Γ'' is not semidefinite; therefore, a sequence of local minimizers cannot converge to -1. Thus, in view of Lemma 7, if $\pi_0 = 0$, a κ_0-sequence of local minimizers breaks down into subsequences converging weakly to $\hat{F} \equiv 0$ or $\hat{F} \equiv -2$, or else diverging in the K^1-norm; if $\pi_0 \neq 0$, a κ_0-sequence of local minimizers has to diverge.

To put the last remark into perspective, we observe that

$$\Gamma(F_n) \leqq \Gamma(0) = 0$$

for $\{F_n\}$ any sequence of global minimizers. With a glance to (3.18) we see that, for $\pi_0 > 0$, we must have

$$(2 + F_n, F_n)_0 \leqq 0,$$

or rather

$$\|1 + F_n\|_0^2 < \|1\|_0^2.$$

Thus, when $\pi_0 > 0$, a sequence of global minimizers cannot diverge in the K-norm.

We now show that local minimizers do exist in Ω^-.

THEOREM 8. *Let $\pi_0 = 0$. Then, there exists $\bar{\kappa}_0 > 0$ such that, for all $\kappa_0 > \bar{\kappa}_0$, the energy functional Γ has a local minimizer $\hat{F}_{\kappa_0}$ belonging to Ω^-. Moreover, a κ_0-sequence of such local minimizers tends to $F \equiv -2$.*

Proof. Choose $\gamma_1 > \|-2\|_1$ and $\gamma_2 \in]-2, -1[$, and define

$$\Delta := \{f \in K^1 \mid \|f\|_1 \leqq \gamma_1, f(\Theta_0) \leqq \gamma_2\},$$

with $\partial\Delta$, the boundary of Δ, such that

$$\partial\Delta = \partial_1\Delta \cup \partial_2\Delta \quad \text{with} \quad \begin{aligned} \partial_1\Delta &:= \{f \in \partial\Delta \,|\, \|f\| = \gamma_1\}, \\ \partial_2\Delta &:= \{f \in \partial\Delta \,|\, f(\Theta_0) = \gamma_2\}. \end{aligned}$$

As Δ is a closed and convex set, Γ must attain an absolute minimum on Δ; on the other hand, $F \equiv -2$ is an interior point of Δ itself. We will now establish the first statement of the theorem by proving that there exists $\bar{\kappa}_0(\gamma_1, \gamma_2)$ such that

$$\inf_{F \in \partial\Delta} \Gamma(F) > \Gamma(-2) \quad \text{for } \kappa_0 > \bar{\kappa}_0(\gamma_1, \gamma_2). \tag{3.49}$$

Indeed, for $F \in \partial_1\Delta$,

$$\Gamma(F) \geqq \tfrac{1}{2}\gamma_1^2 > \Gamma(-2).$$

Furthermore, for $F \in \partial_2\Delta$, let

$$\gamma_3 := \min_{F \in \partial_2\Delta} \|G_0[(2+F)F]\|_1^2 > 0$$

(as $\partial_2\Delta$ is a closed and convex set, this definition makes sense). Then, it is always possible to choose $\bar{\kappa}_0(\gamma_1, \gamma_2)$ such that, for $\bar{\kappa}_0 < \kappa_0$,

$$\Gamma(F) \geqq \frac{\kappa_0^2}{4}\gamma_3 > \Gamma(-2).$$

Finally, the second statement of the theorem follows from the fact that the Δ sets form a neighborhood base for $F \equiv -2$. □

In the light of this theorem, among the three weak limits possible for bounded κ_0-sequences of extremals according to Lemma 7 when $\pi_0 = 0$, the "everted" pseudoconfiguration $\hat{F} \equiv -2$ is the only one that is a local minimizer.

In Fig. 2, for $\pi_0 = 0$, $\nu = 0.3$, and $\Theta_0 = 0.4$ rad, the everted configurations have been graphed that are obtained by solving system (2.67) with the boundary conditions (2.69) for various values of the thickness parameter κ_0.

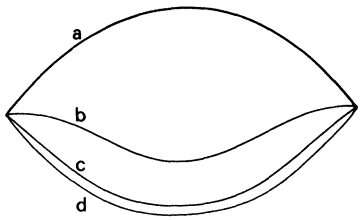

FIG. 2. *Reference configuration* (a) *and everted shapes for* $\pi_0 = 0$, $\Theta_0 = 0.4$, $\nu = 0.3$, *and* $\kappa_0 = 133$ (b), 313 (c), 1875 (d).

For relatively small κ_0 (a relatively thick cap), an edge flaring effect is evident. We can also see that the everted shape increasingly resembles the reflected shape of the reference configuration as κ_0 increases. For completeness, the (rescaled) bending moment M and stress S corresponding to case b of Fig. 2 are graphed in Fig. 3.

We remark that, as the degree of Γ' in Ω^- is null and as a local minimizer exists, another extremal of Γ must be found in Ω^-. We have been unable to spot this other extremal, either analytically or numerically.

Finally, we remark that, as inequality (3.49) holds true also for small values of π_0, Theorem 8 can be established also under the weaker hypothesis that $|\pi_0| \ll 1$.

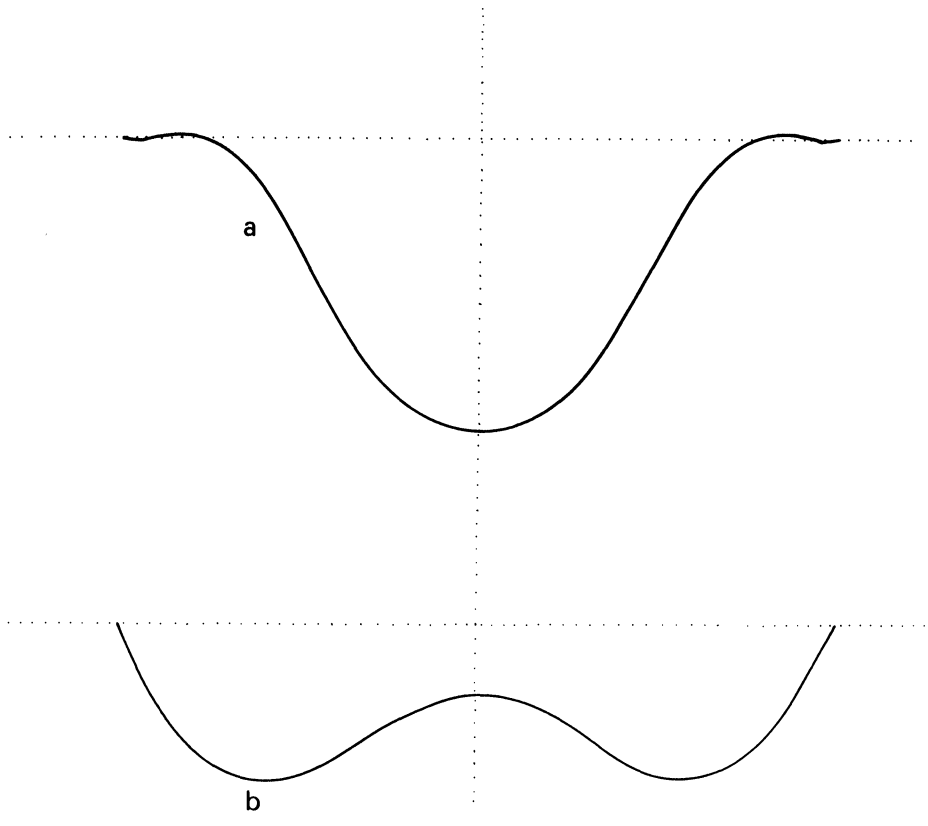

FIG. 3. *Moment* (a, $10^{-1} \times M$) *and stress* (b, $50 \times S$) *for the everted configuration* b *of Fig.* 2.

$M(\lambda)$ THEORY FOR SINGULAR HAMILTONIAN SYSTEMS WITH ONE SINGULAR POINT*

ALLAN M. KRALL†

Abstract. The theory of singular Hamiltonian systems is developed. Square integrable solutions are exhibited and used to define Green's function. Using a singular Green's formula, other self-adjoint boundary value problems are generated in which regular and singular boundary conditions are mixed together. Finally the spectral measure, the generalized Fourier transform of an arbitrary function, and the inverse transform for problems with separated boundary conditions are derived.

Key words. singular boundary value problems, Sturm–Liouville problem, spectral resolution

AMS(MOS) subject classifications. 34B05, 34B20, 34B25

1. Introduction. The solution of linear boundary value problems has a long and honored history. Rising from attacks on such problems as the solution of the heat, wave, and Laplace equation as well as others from mathematical physics, linear boundary value problems have played an important part in mathematics for over two centuries.

The problems fall into two classifications. First, those defined over finite intervals with well-behaved coefficients are called regular. They have a discrete set of eigenvalue, eigenfunction pairs, which are used as building blocks in the solution of the partial differential equations from mathematical physics. The solution of such problems is classical and may be found in many books, such as [3].

Problems that are not regular are singular. These are considerably more difficult to discuss, and as a result have only been examined closely during this century. The work was begun by Weyl [32] in 1910. He was followed by Titchmarsh [30] and many others. From 1910 until 1945 these mathematicians developed and polished the theory of self-adjoint differential operators of second order to a high degree.

Their work was continued by Kodaira [21], Coddington and Levinson [3], and Hartman and Wintner (see [4]) in the late 1940s and 1950s. Not only were additional results found for operators of second order, but operators of higher order were also examined. At the same time the Russian school, led by Krein, Naimark, Akhiezer, and Glazman, also made major contributions.

For a far more comprehensive survey of this work, we recommend the second volume of Dunford and Schwartz [4]. They provide an excellent summary of the numerous contributions made by many mathematicians.

Further study continued in the 1960s and 1970s with the work of Atkinson [1] on regular Hamiltonian systems and Everitt [5]–[11] on higher-order scalar problems. The work of this period is summarized by Atkinson [1], Everitt and Kumar [12] and by Kogan and Rofe-Beketov [22] of the Russian school. Again, there were many other contributors. One contribution, perhaps, deserves special mention. Walker [31] showed that any scalar self-adjoint problem of an arbitrary order can be reformulated as an equivalent self-adjoint Hamiltonian system. This removed the need to discuss scalar problems and systems separately.

Most recently in the 1980s Hinton and Shaw [13]-[20] have made great progress by considering singular problems in the Hamiltonian system format, following the lead of Atkinson [1]. Many of the results of the past, including the development of $M(\lambda)$ theory, the derivation of the Green's function, and singular boundary conditions, were substantially improved.

We will follow in the footsteps of Atkinson, Hinton, and Shaw by considering the $2n$-dimensional linear Hamiltonian system $JY' = (\lambda A + B)Y$, over an interval $[a, b)$. The procedure we will follow is to first examine the differential equation over a subinterval $[a, b']$, $a < b' < b$, on which the problem is regular. We then allow b' to approach b.

The first problem to be encountered concerns the number of solutions that lie in the underlying Hilbert space $L^2_A(a, b)$, generated by the inner product

$$\langle Y, Z\rangle = \int_a^b Z^* A Y \, dt.$$

For $\operatorname{Im} \lambda \neq 0$ it is possible to show that there exist m solutions in $L^2_A(a, b)$, $n \leqq m \leqq 2n$. Since, in order to exhibit a Green's function, only n are needed, the problem is to determine which to choose.

There are two easier to handle situations. If the number is n, then there is no freedom. Everything is determined. If the number is $2n$, then there are automatically a number of required limits. But a number of problems exist in the situations involving m solutions in $L^2_A(a, b)$, $n < m < 2n$. These are handled by the use of singular boundary conditions. One main purpose of this paper is to show how this is done.

Another problem arises if we attempt to impose boundary conditions arbitrarily. When is a problem self-adjoint? We will show how to use Green's formula to determine all self-adjoint problems. We will do so in a manner that considerably simplifies previously used approaches [4].

Finally, as we allow b' to approach b, the generalized eigenfunction expansion over $[a, b']$ is shown to converge into the general spectral resolution traditionally associated with self-adjoint operators. The generalized Fourier transform and inverse transform will be explicitly exhibited.

2. Notation and definition. We consider over the interval $[a, b)$ the differential expression

$$(*) \qquad JY' = (\lambda A + B)Y,$$

where Y is of dimension $2n$ (a $2n \times 1$ matrix).

$$J = \begin{pmatrix} 0 & -I_n \\ I_n & 0 \end{pmatrix}, \qquad A = \begin{pmatrix} A_{11}(x) & A_{12}(x) \\ A_{21}(x) & A_{22}(x) \end{pmatrix}, \qquad B = \begin{pmatrix} B_{11}(x) & B_{12}(x) \\ B_{21}(x) & B_{22}(x) \end{pmatrix}$$

are locally integrable $2n \times 2n$ matrices, $A = A^* \geqq 0$ and $B = B^*$. We assume that a is a regular point, while b is singular. That is, a is finite; A and B are integrable in a neighborhood of a. b may be finite or infinite; A and B may not be integrable in a neighborhood of b. The word singular is used to denote difficulties with infinity or with nonintegrability.

Our setting is $L^2_A(a, b)$, the Hilbert space generated by the inner product

$$\langle Y, Z\rangle = \int_a^b Z^* A Y \, dt.$$

To ensure that elements in the domain of the maximal operator, to be defined, are dense in $L_A^2(a, b)$, we assume that if $JY' - BY = AF$ and $AY = 0$, then $Y = 0$. Most of what follows proceeds without this assumption, but without it some expansions must be restricted to subspaces instead of holding on all of $L_A^2(a, b)$. Earlier works ([1], [13]-[29]) made this assumption with $F = 0$.

We impose a regular, self-adjoint boundary condition at a,

$$(\alpha_1, \alpha_2)\, Y(a) = 0,$$

where α_1, α_2 are $n \times n$ matrices satisfying rank $(\alpha_1, \alpha_2) = n$ and

$$\alpha_1 \alpha_1^* + \alpha_2 \alpha_2^* = I, \qquad \alpha_1 \alpha_2^* - \alpha_2 \alpha_1^* = 0.$$

Self-adjointness is assured, since when written as $MY(a) = 0$, where

$$M = \begin{pmatrix} \alpha_1 & \alpha_2 \\ 0 & 0 \end{pmatrix},$$

$$MJM^* = \begin{pmatrix} \alpha_1 & \alpha_2 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 0 & -I_n \\ I_n & 0 \end{pmatrix} \begin{pmatrix} \alpha_1^* & 0 \\ \alpha_2^* & 0 \end{pmatrix} = 0,$$

the requirement for self-adjointness under separated conditions [3, p. 291].

It is no imposition to assure that $\alpha_1 \alpha_1^* + \alpha_2 \alpha_2^* = I_n$, for if the rank $(\alpha_1, \alpha_2) = n$, then

$$\operatorname{rank} \begin{pmatrix} \alpha_1^* \\ \alpha_2^* \end{pmatrix} = n,$$

and the rank of

$$\alpha_1 \alpha_1^* + \alpha_2 \alpha_2^* = (\alpha_1 \alpha_2) \begin{pmatrix} \alpha_1^* \\ \alpha_2^* \end{pmatrix}$$

is n. It is nonsingular and positive. Hence if the sum does not equal I_n, replace α_1 and α_2 by $(\alpha_1 \alpha_1^* + \alpha_2 \alpha_2^*)^{1/2} \alpha_1$ and $(\alpha_1 \alpha_1^* + \alpha_2 \alpha_2^*)^{1/2} \alpha_2$.

Next let b' be in (a, b) and impose the regular, self-adjoint boundary condition

$$(\beta_1, \beta_2)\, Y(b') = 0,$$

where

$$\beta_1 \beta_1^* + \beta_2 \beta_2^* = I_n, \qquad \beta_1 \beta_2^* + \beta_2 \beta_1^* = 0.$$

If the boundary condition is written as $NY(b') = 0$, where

$$N = \begin{pmatrix} 0 & 0 \\ \beta_1 & \beta_2 \end{pmatrix},$$

then

$$NJN^* = \begin{pmatrix} 0 & 0 \\ \beta_1 & \beta_2 \end{pmatrix} \begin{pmatrix} 0 & -I_n \\ I_n & 0 \end{pmatrix} \begin{pmatrix} 0 & \beta_1^* \\ 0 & \beta_2^* \end{pmatrix} = 0.$$

Again the requirement for self-adjointness is under separated conditions.

Problem (*), together with the two boundary conditions, defines a regular, self-adjoint Sturm-Liouville problem.

Finally, let

$$E = \begin{pmatrix} \alpha_1^* & -\alpha_2^* \\ \alpha_2^* & \alpha_1^* \end{pmatrix}$$

and let $\mathcal{Y}$ be the fundamental matrix for (*) satisfying $\mathcal{Y}(a) = E$.

If $\mathcal{Y}$ is partitioned into

$$\mathcal{Y} = (\theta, \phi) = \begin{pmatrix} \theta_1 & \phi_1 \\ \theta_2 & \phi_2 \end{pmatrix},$$

then at $x = a$, $(\alpha_1, \alpha_2)\theta(a) = I_n$, and $(\alpha_1, \alpha_2)\phi(a) = 0$. $\phi = \binom{\phi_1}{\phi_2}$ satisfies the boundary condition at a.

3. The $M(\lambda)$ matrix. The following definition and characterization of the matrix $M(\lambda)$ is a generalization of the Weyl-Titchmarsh $m(\lambda)$ function [30], [31]. What immediately follows is closely patterned on the work of Hinton and Shaw [13]-[20]. It is essential in providing the building blocks needed throughout the remainder of the paper: the square integrable solutions of (*).

THEOREM 3.1. *Let β_1, β_2 satisfy*

$$\beta_1\beta_1^* + \beta_2\beta_2^* = I_n, \qquad \beta_1\beta_2^* - \beta_2\beta_1^* = 0.$$

Let

$$\chi_{b'} = \mathcal{Y}\begin{pmatrix} I_n \\ M(b') \end{pmatrix},$$

and suppose $(\beta_1, \beta_2)\chi_{b'}(b') = 0$. Then

$$M(b') = -(\beta_1\phi_1(b') + \beta_2\phi_2(b'))^{-1}(\beta_1\theta_1(b') + \beta_2\theta_2(b'))$$

and $\chi_{b'}^*(b')J\chi_{b'}(b') = 0$.

Conversely, if for some M,

$$\chi_{b'} = \mathcal{Y}\begin{pmatrix} I_n \\ M \end{pmatrix}$$

satisfies $\chi_{b'}^*(b')J\chi_{b'}(b') = 0$, then there exist β_1, β_2 satisfying

$$\beta_1\beta_1^* + \beta_2\beta_2^* = I_n, \qquad \beta_1\beta_2^* - \beta_2\beta_1^* = 0$$

such that $(\beta_1, \beta_2)\chi_{b'}(b') = 0$ and

$$M = -(\beta_1\phi_1(b') + \beta_2\phi_2(b'))^{-1}(\beta_1\theta_1(b') + \beta_2\theta_2(b')).$$

Proof. Let $\operatorname{Im}\lambda \neq 0$, and impose on

$$\chi_{b'} = \mathcal{Y}\begin{pmatrix} I_n \\ M(b') \end{pmatrix}$$

the boundary condition $(\beta_1, \beta_2)\chi_{b'}(b') = 0$. Hence, with $x = b'$,

$$(\beta_1, \beta_2)\begin{pmatrix} \theta_1 & \phi_1 \\ \theta_2 & \phi_2 \end{pmatrix}\begin{pmatrix} I_n \\ M(b') \end{pmatrix} = 0.$$

This yields

$$(\beta_1\theta_1(b') + \beta_2\theta_2(b')) + (\beta_1\phi_1(b') + \beta_2\phi_2(b'))M(b') = 0$$

and

$$M(b') = -(\beta_1\phi_1(b') + \beta_2\phi_2(b'))^{-1}(\beta_1\theta_1(b') + \beta_2\theta_2(b')).$$

The inverse must exist. Otherwise λ, which is complex, would be an eigenvalue of the self-adjoint boundary value problem on $[a, b']$.

Since $(\beta_1, \beta_2)\chi_{b'}(b') = 0$,

$$\chi(b') = \begin{pmatrix} 0 & -I_n \\ I_n & 0 \end{pmatrix} \begin{pmatrix} \beta_1^* \\ \beta_2^* \end{pmatrix} C,$$

for

$$(\beta_1, \beta_2) \begin{pmatrix} 0 & -I_n \\ I_n & 0 \end{pmatrix} \begin{pmatrix} \beta_1^* \\ \beta_2^* \end{pmatrix} C = 0.$$

This in turn implies that $\chi_{b'}^*(b') J \chi_{b'}(b') = 0$, or

$$(I_n, M(b')^*) \mathcal{Y}(b')^* J \mathcal{Y}(b') \begin{pmatrix} I_n \\ M(b') \end{pmatrix} = 0.$$

Conversely, if for some M,

$$(I_n, M^*) \mathcal{Y}(b')^* J \mathcal{Y}(b') \begin{pmatrix} I_n \\ M \end{pmatrix} = 0,$$

define $(\beta_1, \beta_2) = (I_n, M^*) \mathcal{Y}(b')^* J$. Then rank $(\beta_1, \beta_2) = n$,

$$(\beta_1, \beta_2) \mathcal{Y}(b') \begin{pmatrix} I_n \\ M \end{pmatrix} = 0,$$

and

$$-\beta_1 \beta_2^* + \beta_2 \beta_1^* = (\beta_1, \beta_2) \begin{pmatrix} 0 & -I_n \\ I_n & 0 \end{pmatrix} \begin{pmatrix} \beta_1 \\ \beta_2 \end{pmatrix} = (I, M^*) \mathcal{Y}(b')^* J^3 \mathcal{Y}(b') \begin{pmatrix} I \\ M \end{pmatrix} = 0.$$

Further $M = -(\beta_1 \phi_1(b') + \beta_2 \phi_2(b'))^{-1} (\beta_1 \theta_1(b') + \beta_2 \phi_2(b'))$, and

$$\beta_1 \beta_1^* + \beta_2 \beta_2^* = (\beta_1, \beta_2) \begin{pmatrix} \beta_1^* \\ \beta_2^* \end{pmatrix} = (I_n, M^*) \mathcal{Y}(b')^* \mathcal{Y}(b') \begin{pmatrix} I_n \\ M \end{pmatrix} > 0,$$

and so with minor adjustments like those of the previous section, we can have $\beta_1 \beta_1^* + \beta_2 \beta_2^* = I_n$.

4. M circles. The M circle equation is

$$\pm (I_n, M^*) \mathcal{Y}(b')^* (J/i) \mathcal{Y}(b') \begin{pmatrix} I_n \\ M \end{pmatrix} = 0$$

where for convenience, we have divided by i, and $(+)$ holds when $\operatorname{Im} \lambda > 0$, $(-)$ holds when $\operatorname{Im} \lambda < 0$.

Let

$$\begin{pmatrix} \mathcal{A} & \mathcal{B}^* \\ \mathcal{B} & \mathcal{D} \end{pmatrix} = \begin{cases} \mathcal{Y}(b')^* (J/i) \mathcal{Y}(b'), & \operatorname{Im} \lambda > 0, \\ -\mathcal{Y}(b')^* (J/i) \mathcal{Y}(b'), & \operatorname{Im} \lambda < 0, \end{cases}$$

and let

$$E(M) = (I_n, M^*) \begin{pmatrix} \mathcal{A} & \mathcal{B}^* \\ \mathcal{B} & \mathcal{D} \end{pmatrix} \begin{pmatrix} I_n \\ M \end{pmatrix}.$$

THEOREM 4.1. *The expression $E(M) = 0$ if and only if $M = M_\beta$ for some $\beta = (\beta_1, \beta_2)$, where*

$$M_\beta = -(\beta_1 \phi_1(b') + \beta_2 \phi_2(b'))^{-1} (\beta_1 \theta_1(b') + \beta_2 \theta_2(b')).$$

This is a restatement of Theorem 3.1.

Expanding, we find

$$\begin{aligned} E(M) &= (M+\mathscr{D}^{-1}\mathscr{B})^*\mathscr{D}(M+\mathscr{D}^{-1}\mathscr{B})+\mathscr{A}-\mathscr{B}^*\mathscr{D}^{-1}\mathscr{B} \\ &= (M-C)^*R_1^{-2}(M-C)-R_2^2 \\ &= 0, \end{aligned}$$

where $C=-\mathscr{D}^{-1}\mathscr{B}$, $R_1=\mathscr{D}^{-1/2}$, $R_2=(\mathscr{B}^*\mathscr{D}^{-1}\mathscr{B}-\mathscr{A})^{1/2}$.

LEMMA 4.2. *The matrix* $\mathscr{D}>0$.

Proof.

$$\begin{pmatrix} \mathscr{A} & \mathscr{B}^* \\ \mathscr{B} & \mathscr{D} \end{pmatrix} = \pm \begin{pmatrix} \theta_1^* & \theta_2^* \\ \phi_1^* & \phi_2^* \end{pmatrix} \begin{pmatrix} 0 & iI_n \\ -iI_n & 0 \end{pmatrix} \begin{pmatrix} \theta_1 & \phi_1 \\ \theta_2 & \phi_2 \end{pmatrix} = \pm \begin{pmatrix} -i\theta^*J\theta & -i\theta^*J\phi \\ -i\phi^*J\theta & -i\phi^*J\phi \end{pmatrix}$$

where

$$\phi = \begin{pmatrix} \theta_1 \\ \theta_2 \end{pmatrix}, \qquad \phi = \begin{pmatrix} \phi_1 \\ \phi_2 \end{pmatrix}.$$

So $\mathscr{D}=\pm\phi^*(b')(J/i)\phi(b')$. Now manipulation of the differential equation $J\phi'=(\lambda A+B)\phi$ yields

$$\phi^*(J/i)\phi|_a^{b'} = 2 \operatorname{Im}\lambda \int_a^{b'} \phi^* A\phi \, dt.$$

The limit at $x=a$ is 0. Hence $\phi(b')^*(J/i)\phi(b')>0$ when $\operatorname{Im}\lambda>0$, and $\phi(b')^*(J/i)\phi(b')<0$ when $\operatorname{Im}\lambda<0$. In either case $\mathscr{D}>0$.

LEMMA 4.3. *The matrix* $\mathscr{B}^*\mathscr{D}\mathscr{B}-\mathscr{A}=\tilde{\mathscr{D}}^{-1}$, *where* $\tilde{\mathscr{D}}^{-1}=\mathscr{D}^{-1}(\bar{\lambda})$.

Proof. Note that for λ and $\bar{\lambda}$, $\mathscr{Y}(x,\bar{\lambda})^*J\mathscr{Y}(x,\lambda)=J$ for all x. Hence $-J\mathscr{Y}(x,\bar{\lambda})^*J\mathscr{Y}(x,\lambda)=I$ and $(J\mathscr{Y}(x,\lambda))(-J\mathscr{Y}(x,\bar{\lambda})^*)=I$ as well. Multiplying by J yields $\mathscr{Y}(x,\lambda)J\mathscr{Y}(x,\bar{\lambda})^*=J$ for all x. As a result

$$\begin{aligned} J &= \mathscr{Y}(x,\lambda)^*J\mathscr{Y}(x,\bar{\lambda}) \\ &= \mathscr{Y}(x,\lambda)^*[-J\mathscr{Y}(x,\lambda)J\mathscr{Y}(x,\bar{\lambda})^*J]\mathscr{Y}(x,\bar{\lambda}) \\ &= -[\mathscr{Y}(x,\lambda)^*(J/i)\mathscr{Y}(x,\lambda)]J[-\mathscr{Y}(x,\bar{\lambda})^*(J/i)\mathscr{Y}(x,\bar{\lambda})]. \end{aligned}$$

Or

$$\begin{pmatrix} 0 & -I_n \\ I_n & 0 \end{pmatrix} = -\begin{pmatrix} \mathscr{A} & \mathscr{B}^* \\ \mathscr{B} & \mathscr{D} \end{pmatrix} \begin{pmatrix} 0 & -I_n \\ I_n & 0 \end{pmatrix} \begin{pmatrix} \tilde{\mathscr{A}} & \tilde{\mathscr{B}}^* \\ \tilde{\mathscr{B}} & \tilde{\mathscr{D}} \end{pmatrix}$$

where $\tilde{}$ indicates $\bar{\lambda}$ replaces λ. (Remember that there is a sign change in the matrix when λ replaces $\bar{\lambda}$.) Hence

$$0=\mathscr{A}\tilde{\mathscr{B}}-\mathscr{B}^*\tilde{\mathscr{A}}, \qquad -I_n=\mathscr{A}\tilde{\mathscr{D}}-\mathscr{B}^*\tilde{\mathscr{B}},$$

$$I_n=\mathscr{B}\tilde{\mathscr{B}}-\mathscr{D}\tilde{\mathscr{A}}, \qquad 0=\mathscr{B}\tilde{\mathscr{D}}-\mathscr{D}\tilde{\mathscr{B}}^*.$$

The last yields $\tilde{\mathscr{B}}^*\tilde{\mathscr{D}}^{-1}=\mathscr{D}^{-1}\mathscr{B}$. The second shows

$$\begin{aligned} \tilde{\mathscr{D}}^{-1} &= -\mathscr{A}+\mathscr{B}^*[\tilde{\mathscr{B}}^*\tilde{\mathscr{D}}^{-1}] \\ &= -\mathscr{A}+\mathscr{B}^*\mathscr{D}^{-1}\mathscr{B}. \end{aligned}$$

COROLLARY 4.4. *The matrices* R_1 *and* R_2 *satisfy* $R_2=\tilde{R}_1$.

Note that if the coefficient matrices A and B are real, then $\mathcal{Y}(x, \bar{\lambda}) = \overline{\mathcal{Y}(x, \lambda)}$ and so also for $\mathcal{A}, \mathcal{B}, \mathcal{D}$. In this case, $R_2 = \bar{R}_1$.

THEOREM 4.5. *As b' increases, $\mathcal{D}$ increases, R_1 decreases, and R_2 decreases.*

Proof. Note that

$$\mathcal{D} = 2|\operatorname{Im} \lambda| \int_a^{b'} \phi^* A \phi \, dt.$$

The results are then immediate.

THEOREM 4.6. $\lim_{b' \to b} R_1(b', \lambda) = R_0(\lambda)$, $\lim_{b' \to b} R_2(b', \lambda) = R_0(\bar{\lambda}) = \tilde{R}_0$ *exist.* $R_0 \geqq 0$, $\tilde{R}_0 \geqq 0$.

THEOREM 4.7. *As b' approaches b, the circles $E(M) = 0$ are nested.* $\lim_{b' \to b} C(b', \lambda) = C_0$ *exists.*

Proof. The interior of the circle $E(M) = 0$ is given by $E(M) \leqq 0$, or by

$$\pm(I_n, M^*) \mathcal{Y}(b')^* (J/i) \mathcal{Y}(b') \begin{pmatrix} I_n \\ M \end{pmatrix} \leqq 0.$$

Using the differential equation (*), we find

$$E(M) = 2|\operatorname{Im} \lambda| \int_a^{b'} \chi_{b'}^* A \chi_{b'} \, dt \pm (M^* - M)/i.$$

Now if M is in the circle at $b'' > b'$, then $E(M) \leqq 0$ at b''. At b', $E(M)$ is certainly smaller, and so M is in the circle at b' as well. The circles are nested.

To show that the centers converge, we need to solve the circle equation

$$(M - C)^* R_1^{-2} (M - C) = \tilde{R}_1^2.$$

(Recall that $\mathcal{D}$, R_1, and $\tilde{R}_1$ are self-adjoint matrices.) This is equivalent to

$$[R_1^{-1}(M - C)\tilde{R}_1^{-1}]^* [R_1^{-1}(M - C)\tilde{R}_1^{-1}] = I_n.$$

Therefore the bracketed term

$$R_1^{-1}(M - C)\tilde{R}_1^{-1} = U,$$

a unitary matrix, and

$$M = C + R_1 U \tilde{R}_1.$$

As U varies over the $n \times n$ unit sphere, M varies over a "circle" with center C. We will have more to say about the range of M shortly.

Now let C_1 be the center at b', and C_2 be the center at b''. If

$$M_1 = C_1 + R_1(b') U_1 \tilde{R}_1(b')$$

and

$$M_2 = C_2 + R_1(b'') U_2 \tilde{R}_2(b''),$$

then M_2 lies in the b' circle as well, and

$$M_2 = C_1 + R_1(b') V_1 \tilde{R}_1(b')$$

where V_1 is a contraction. Thus

$$C_1 - C_2 = R_1(b'') U_2 \tilde{R}_1(b'') - R_1(b') V_1 \tilde{R}_1(b').$$

Consider the mapping defined by the equations for M_2 above, defining V_1 in terms of U_2: $V_1 = F(U_2)$. It is a continuous transformation of the unit sphere into itself and therefore has a unique fixed point U. Letting U_2 and V_1 be replaced by U, we find

$$\begin{aligned}\|C_1 - C_2\| &= \|R_1(b'')U\tilde{R}_1(b'') - R_1(b')U\tilde{R}_1(b')\| \\ &\leqq \|R_1(b'')U\tilde{R}_1(b'') - R_1(b'')U\tilde{R}_1(b')\| \\ &\quad + \|R_1(b'')U\tilde{R}_1(b') - R_1(b')U\tilde{R}_1(b')\| \\ &\leqq \|R_1(b'')\|\,\|\tilde{R}_1(b'') - \tilde{R}_1(b')\| + \|R_1(b'') - R_1(b')\|\,\|\tilde{R}_1(b')\|.\end{aligned}$$

As b' and b'' approach b, R_1 and $\tilde{R}_1$ have limits. The centers then form a Cauchy sequence and converge.

A computation shows

$$\mathscr{B} = \pm\left[2\,\mathrm{Im}\,\lambda \int_a^{b'} \phi^* A\theta\, dt - iI_n\right].$$

So at b', the center

$$C = -\mathscr{D}^{-1}\mathscr{B} = -\left[2\,\mathrm{Im}\,\lambda \int_a^{b'} \phi^* A\phi\, dt\right]^{-1}\left[2\,\mathrm{Im}\,\lambda \int_a^{b'} \phi^* A\theta\, dt - iI_n\right].$$

As we have seen, as b' approaches b, this has a limit C_0.

The limiting "circle" equation may not exist because both R_0 and $\tilde{R}_0$ may have rank less than n and may be singular. Nonetheless

$$M = C_0 + R_0 U\tilde{R}_0$$

is perfectly well defined. As U varies over the unit circle in $n \times n$ space, the limit "circle" or "point" $E_0(M)$ is covered.

5. Square integrable solutions. As a consequence of the previous section we have the following theorem.

THEOREM 5.1. *Let M be a point inside $E_0(M) \leqq 0$. Let $\chi = \theta + \phi M$; then χ is in $L_A^2(a, b)$.*

Proof.

$$2|\mathrm{Im}\,\lambda| \int_a^{b'} \chi^* A\chi\, dt \pm [M^* - M]/i = E(M) \leqq 0.$$

As a result,

$$0 \leqq \int_a^{b'} \chi^* A\chi\, dt \leqq [M - M^*]/2i|\mathrm{Im}\,\lambda|.$$

The upper bound is fixed, so let $b' \to b$. Remember that

$$M = C_0 + R_0 U\tilde{R}_0$$

where R_0 and $\tilde{R}_0$ are decreasing matrices and U is either unitary or a contraction.

THEOREM 5.2. *Let* rank $R_0 = r$, rank $\tilde{R}_0 = \tilde{r}$; *let $S(U) = R_0 U\tilde{R}_0$ where U is unitary. Then* rank $S(U) \leqq \min(r, \tilde{r})$.

Proof. That the rank of a product of matrices is less than or equal to the ranks of the components may be found in virtually any linear algebra text.

THEOREM 5.3. *Under the conditions of Theorem* 5.2, $\sup_U$ rank $S(U) = \min(r, \tilde{r})$.

Proof. Let $r \geqq \tilde{r}$. Otherwise consider the transpose $\tilde{R}_0^T U^T R_0^T$. The rank of $S(U)$ is the dimension of the image of $R_0 U\tilde{R}_0$ acting on C^n. Let $\tilde{R}_0$ acting on C^n be the

subspace W of dimension $\tilde{r} = \text{rank } \tilde{R}_0$. Further note that there is a subspace X of C^n such that $\dim R_0 X = \text{rank } R_0 = r$. Since $\dim X \geqq \dim W$, there is a unitary matrix $U: W \to X$, injectively. Then $U(W)$ is a subspace of X of dimension $\tilde{r}$, and $\dim (R_0 U(W)) = \dim W = \tilde{r}$.

THEOREM 5.4. *Let $m = n + \min(r, \tilde{r})$; let $\text{Im } \lambda \neq 0$. Then there exist m solutions of (*) in $L_A^2(a, b)$, $n \leqq m \leqq 2n$.*

Proof. $\vec{\theta} + \vec{\phi} C_0$ is made up of n solutions in $L_A^2(a, b)$. As U varies, $\phi(R_0 U \tilde{R}_0)$ gives an additional $m - n$ solutions, which are independent of the others. This does not say the deficiency indices for (*) are equal. It says merely that there are at least m solutions in $L_A^2(a, b)$. For λ or $\bar{\lambda}$ there may be more.

By way of example consider Table 1. These cases actually occur in practice for scalar problems. It is also possible for rank $R_0 \neq$ rank $\tilde{R}_0$. McLeod [33] has found a very interesting example.

TABLE 1

n	rank R_0	rank $\tilde{R}_0$	m	Case name
1	1	1	2	limit circle
1	0	0	1	limit point
2	2	2	4	limit circle
2	1	1	3	intermediate
2	0	0	2	limit point
3	3	3	6	limit circle
3	2	2	5	intermediate
3	1	1	4	intermediate
3	0	0	3	limit point
