In closing this section we include a rather interesting theorem concerning the eigenvalues of $\mathcal{D}(b', \lambda)$ as b' approaches b. It generalizes a theorem of Hinton and Shaw [20, Lemma 2.1].

THEOREM 5.5. *Let $\mu_1(b') \leqq \cdots \leqq \mu_n(b')$ be the eigenvalues of $\mathcal{D}(b', \lambda)$. Let there be m, $n \leqq m \leqq 2n$ solutions of $JY' = (\lambda A + B)Y$, $\text{Im } \lambda \neq 0$, in $L_A^2(a, b)$. Then $\mu_1(b'), \cdots, \mu_{m-n}(b')$ remain finite and $\mu_{m-n+1}(b'), \cdots, \mu_{2n}(b')$ approach ∞ as b' approaches b.*

Proof. Suppose $\mu(b') < B$ for all b'. Let $v_{b'}$ be a unit eigenvector of $\mathcal{D}(b', \lambda)$. Setting $\chi_{b'} = \phi v_{b'}$, we get

$$2i \text{ Im } \lambda \int_a^{b'} \chi_{b'}^* A \chi_{b'} \, dx = v_{b'}^* \phi^* J \phi v_{b'} \Big|_a^{b'} = i \text{ sgn } (\text{Im } \lambda) \cdot \mu(b').$$

Thus

$$\int_a^{b'} \chi_{b'}^* A \chi_{b'} \, dx \leqq \mu(b')/|\text{Im } \lambda| \leqq B/|\text{Im } \lambda|.$$

Choosing a subsequence of $(v_{b'})$'s that converge, we find a solution $\chi = \phi v$ in $L_A^2(a, b)$. Since there are only mL_A^2-solutions and $\chi = \theta + \phi M$ comprises n of these, there can only be $m - n$ such χ's and only $m - n$ finite μ's.

Niessen [27] has a very similar theorem for proving the existence of square integrable solutions. His theorem depends upon the eigenvalues of

$$\begin{pmatrix} \mathscr{A} & \mathscr{B}^* \\ \mathscr{B} & \mathscr{D} \end{pmatrix}$$

instead of those of $\mathscr{D}$.

6. Singular boundary conditions. Unlike regular boundary points, such as b', where a regular boundary condition $(\beta_1, \beta_2)Y(b') = 0$ is imposed, singular boundary points, such as b, require a more careful approach. We define a singular boundary value that is valid on the domain of the maximal operator.

DEFINITION 6.1. We denote by D_M those elements Y in $L_A^2(a, b)$ satisfying

$$lY = JY' - BY = AF \tag{1}$$

exists almost everywhere for some F in $L_A^2(a, b)$.

DEFINITION 6.2. We define the maximal operator L_M by setting $L_M Y = F$ for all Y in D_M.

THEOREM 6.3. *Let Y_j be a solution of $JY_j' = (\bar{\lambda}A + B)Y_j$, $\operatorname{Im}\lambda \neq 0$. Then for all Y in D_M,*

$$B_{bj}(Y) = \lim_{x \to b} Y_j^* JY$$

exists if and only if Y_j is in $L_A^2(a, b)$.

Proof. Manipulation of

$$JY' - BY = AF$$

and

$$JY_j' - BY_j = \bar{\lambda} A Y_j$$

yields

$$(Y_j^* JY)' = Y_j^* A[F - \lambda Y].$$

Integrating, we get

$$(Y_j^* JY)(x) = Y_j^* JY(a) + \int_a^x Y_j^* A[F - \lambda Y]\, dx.$$

If Y_j is in $L_A^2(a, b)$, then as x approaches b, the integral on the right converges, and $\lim_{x \to b} Y_j^* JY(x)$ exists.

Conversely, if the integral on the right converges for all Y, F in $L_A^2(a, b)$, the Hahn-Banach theorem states that it generates a bounded operator. The Riesz Representation Theorem then affirms that Y_j is in $L_A^2(a, b)$.

DEFINITION 6.4. Let $\operatorname{Im}\lambda \neq 0$. Let $M(\bar{\lambda}) = \tilde{C}_0 + \tilde{R}_0 U R_0$ be on the limit circle. Let $\chi(x, \bar{\lambda}) = \theta(x, \bar{\lambda}) + \phi(x, \bar{\lambda})M(\bar{\lambda})$ satisfy (*) with λ replaced by $\bar{\lambda}$ and be in $L_A^2(a, b)$. We define the boundary value $B_\lambda(Y)$ by setting

$$B_\lambda(Y) = \lim_{x \to b} \chi(x, \bar{\lambda})^* JY(x)$$

for all Y in D_M.

Note that $B_\lambda(Y)$ is explicitly written as

$$B_\lambda(Y) = \lim_{x \to b} (I_n, M(\bar{\lambda})^*)\mathscr{Y}(x, \bar{\lambda})^* JY(x).$$

Note also that $\bar{\lambda}$ is used in the definition of $B_\lambda(Y)$. This is a convenience only. We shall remove the requirement later.

7. The differential operator L. We assume that the number of solutions of (*) in $L^2_A(a, b)$ in either half plane $\operatorname{Im}\lambda > 0$ and $\operatorname{Im}\lambda < 0$ is the same, m, as given by Theorems 5.4 and 5.5. This is certainly true if A and B are real. Using boundary conditions at both a and b, we can now define a self-adjoint differential operator on $L^2_A(a, b)$.

DEFINITION 7.1. We denote by D those elements Y in $L^2_A(a, b)$ satisfying

$$lY = JY' - BY = AF \tag{2}$$

exists almost everywhere for some F in $L^2_A(a, b)$,

$$(\alpha_1, \alpha_2)\, Y(a) = 0, \tag{3}$$

$$B_\lambda(Y) = 0. \tag{4}$$

DEFINITION 7.2. We define the operator L by setting $LY = F$ for all Y in D.

The inverse of $L - \lambda I$ can now be calculated easily. If we solve

$$JY' = (\lambda A + B)\, Y + AF$$

by variation of parameters, the substitution of $Y = \mathcal{Y}C$, where $\mathcal{Y}$ is the fundamental matrix, yields $J\mathcal{Y}C' = AF$, so $C' = -J\mathcal{Y}^t AF$ where we have written $\mathcal{Y}^t(x, \lambda)$ for $\mathcal{Y}(x, \bar{\lambda})^*$, since if the matrix coefficients A and B are real, $\mathcal{Y}^t = \mathcal{Y}^T$, the transpose. Integrating, we find

$$Y = -\mathcal{Y}(x, \lambda) \int_a^x J\mathcal{Y}^t(\xi, \lambda) A(\xi x) F(\xi)\, d\xi + \mathcal{Y}(x, \lambda) K$$

where K is constant.

Since

$$\begin{pmatrix} \alpha_1 & \alpha_2 \\ 0 & 0 \end{pmatrix} Y(a) = 0,$$

$$0 + \begin{pmatrix} \alpha_1 & \alpha_2 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} \alpha_1^* & -\alpha_2^* \\ \alpha_2^* & \alpha_1^* \end{pmatrix} K = 0,$$

or

$$\begin{pmatrix} I_n & 0 \\ 0 & 0 \end{pmatrix} K = 0.$$

Further,

$$\begin{pmatrix} 0 & 0 \\ I_n & M^t \end{pmatrix} \mathcal{Y}^t(x, \lambda) JY(x) = -\begin{pmatrix} 0 & 0 \\ I_n & M^t \end{pmatrix} \mathcal{Y}^t(x, \lambda) J\mathcal{Y}(x, \lambda) \int_a^x J\mathcal{Y}^t(\xi, \lambda) A(\xi) F(\xi)\, d\xi$$
$$+ \begin{pmatrix} 0 & 0 \\ I_n & M^t \end{pmatrix} \mathcal{Y}^t(x, \lambda) J\mathcal{Y}(x, \lambda) K.$$

Since $\mathcal{Y}^t(x, \lambda) J\mathcal{Y}(x, \lambda) \equiv J$ for all x,

$$\begin{pmatrix} 0 & 0 \\ I_n & M^t \end{pmatrix} \mathcal{Y}^t(x, \lambda) J\mathcal{Y}(x) = \begin{pmatrix} 0 & 0 \\ I_n & M^t \end{pmatrix} \int_a^x \mathcal{Y}^t(\xi, \lambda) A(t) F(t)\, dt$$
$$+ \begin{pmatrix} 0 & 0 \\ I_n & M^t \end{pmatrix} \begin{pmatrix} 0 & -I_n \\ I_n & 0 \end{pmatrix} K.$$

Letting $x \to b$,

$$0 = \int_a^b \begin{pmatrix} 0 & 0 \\ I_n & M^t \end{pmatrix} \mathcal{Y}^t(\xi, \lambda) A(\xi) F(\xi)\, d\xi + \begin{pmatrix} 0 & 0 \\ M^t & -I_n \end{pmatrix} K.$$

Adding

$$0 = \begin{pmatrix} I_n & 0 \\ 0 & 0 \end{pmatrix} K$$

to this, we have

$$0 = \int_a^b \begin{pmatrix} 0 & 0 \\ I_n & M^t \end{pmatrix} \mathcal{Y}^t(\xi, \lambda) A(\xi) F(\xi)\, d\xi + \begin{pmatrix} I_n & 0 \\ M^t & -I_n \end{pmatrix} K.$$

The coefficient of K is its own inverse. Hence

$$K = \int_a^b \begin{pmatrix} 0 & 0 \\ I_n & M^t \end{pmatrix} \mathcal{Y}^t(\xi, \lambda) A(\xi) F(\xi)\, d\xi,$$

and

$$Y = \mathcal{Y}(x, \lambda) \int_a^x \begin{pmatrix} 0 & I_n \\ 0 & M^t \end{pmatrix} \mathcal{Y}^t(\xi, \lambda) A(\xi) F(\xi)\, d\xi + \mathcal{Y}(x, \lambda) \int_x^b \begin{pmatrix} 0 & 0 \\ I_n & M^t \end{pmatrix} \mathcal{Y}^t(\xi, \lambda) A(\xi) F(\xi)\, d\xi.$$

At this point we note that the Green's function, the kernel of the integral operator, is the limit of Green's functions of regular Sturm–Liouville problems. Since regular problems satisfy

$$G(\lambda, x, \xi) = G^*(\bar{\lambda}, \xi, x),$$

so does the present Green's function. Comparison of the two sides gives a definition of $M(\lambda)$ in terms of $M(\bar{\lambda})$,

$$M(\lambda) = M^t = M^*(\bar{\lambda}),$$

and $\chi(x, \lambda) = \theta(x, \lambda) + \phi(x, \lambda) M(\lambda)$ is in $L_A^2(a, b)$. Now from the first integral, the terms

$$\mathcal{Y}(x, \lambda) \begin{pmatrix} 0 & I_n \\ 0 & M^t \end{pmatrix} \mathcal{Y}^*(\xi, \lambda) = \chi(x, \lambda) \phi^t(\xi, \lambda).$$

From the second, recalling that $M^t = M$,

$$\mathcal{Y}(x, \lambda) \begin{pmatrix} 0 & 0 \\ I_n & M^t \end{pmatrix} \mathcal{Y}^t(\xi, \lambda) = \phi(x, \lambda) \chi^t(\xi, \lambda).$$

Therefore

$$Y(x) = \chi(x, \lambda) \int_a^x \phi(\xi, \bar{\lambda})^* A(\xi) F(\xi)\, d\xi + \phi(x, \lambda) \int_x^b \chi(\xi, \bar{\lambda})^* A(\xi) F(\xi)\, d\xi,$$

or

$$Y = \int_a^b G(\lambda, x, \xi) A(\xi) F(\xi)\, d\xi,$$

where

$$(**)\qquad \begin{aligned} G(\lambda, x, \xi) &= \chi(x, \lambda)\phi(\xi, \bar{\lambda})^*, \qquad a \leqq \xi \leqq x \leqq b \\ &= \phi(x, \lambda)\chi(\xi, \bar{\lambda})^*, \qquad a \leqq x \leqq \xi \leqq b. \end{aligned}$$

THEOREM 7.3. *The parameter λ, used in defining the boundary condition B_λ, is in the resolvent of L,*

$$(L-\lambda I)^{-1}(F(x)) = \int_0^b G(\lambda, x, \xi)A(\xi)F(\xi)\, d\xi,$$

where G is given by (**).

THEOREM 7.4. *The operator L is self-adjoint.*

Proof. Let $(L-\lambda I)Y = F$, $(L^*-\bar{\lambda}I)Z = G$. Then

$$\begin{aligned} \langle (L-\lambda I)^{-1}F, G\rangle &= \int_a^b G^*(x)A(x) \int_a^b G(\lambda, x, \xi)A(\xi)F(\xi)\, d\xi\, dx \\ &= \int_a^b \left[\int_a^b G^*(\lambda, x, \xi)A(x)G(x)\, dx\right]^* A(\xi)F(\xi)\, d\xi \\ &= \int_a^b [G^*(\lambda, \xi, x)A(\xi)G(\xi)\, d\xi]^* A(x)F(x)\, dx \\ &= \int_a^b \left[\int_a^b G(\bar{\lambda}, x, \xi)A(\xi)G(\xi)\, d\xi\right]^* A(x)F(x)\, dx \\ &= \langle F, (L-\bar{\lambda}I)^{-1}G\rangle \end{aligned}$$

since $G(\lambda, x, \xi) = G(\bar{\lambda}, \xi, x)^*$. But

$$\langle (L-\lambda)^{-1}F, G\rangle = \langle F, (L^*-\bar{\lambda}I)G\rangle,$$

so $(L-\bar{\lambda}I)^{-1} = (L^*-\bar{\lambda}I)^{-1}$. Taking inverses, $L-\bar{\lambda}I = L^*-\bar{\lambda}I$. Canceling $\bar{\lambda}I$, $L = L^*$.

We remark that when $M(\bar{\lambda})$ is on the limit circle, then $\lim_{x\to b}\chi(x, \bar{\lambda})^*J\chi(x, \bar{\lambda}) = 0$. This is a test for self-adjointness of the singular boundary condition $B_\lambda(Y)$. It is the limiting form of $(\beta_1, \beta_2)J(\beta_1, \beta_2)^* = 0$, required in the regular case.

THEOREM 7.5. *The operator $(L-\lambda I)^{-1}$ is a bounded operator.*

$$\|(L-\lambda I)^{-1}\| \leqq 1/|\operatorname{Im}\lambda|.$$

Proof. Let $(L-\lambda I)Y = F$. Then

$$\langle Y, F\rangle - \langle F, Y\rangle = \langle Y, (L-\lambda I)Y\rangle - \langle (L-\lambda I)Y, Y\rangle = (\lambda-\bar{\lambda})\langle Y, Y\rangle.$$

Applying Schwarz's inequality to the left,

$$2|\operatorname{Im}\lambda|\, \|Y\|^2 \leqq 2\|Y\|\, \|F\|.$$

Canceling $\|Y\|$ yields the result. (This may be found in [1] as well.)

THEOREM 7.6. *If $JY' - BY = AF$, $AY = 0$ implies $Y = 0$, then D is dense in $L^2_A(a, b)$.*

Proof. If D is not dense, then there is a G orthogonal to D. Let Y be in D, and let Z satisfy $Z \in D$, $JZ' - BZ = \bar{\lambda}AZ + AG$ for $\operatorname{Im}\lambda \neq 0$. Then

$$\begin{aligned} 0 = \langle Y, G\rangle &= \int_a^b G^*AY\, dx = \int_a^b [JZ' - BZ - \bar{\lambda}AZ]^* Y\, dx \\ &= \int_a^b Z^*[JY' - BY - \lambda AY]\, dx. \end{aligned}$$

Let $JY' - BY - \lambda AY = AF$. Then

$$0 = \langle F, Z \rangle = \int_a^b Z^* AF \, dx.$$

Now F is arbitrary, so let $F = Z$. Thus $\int_a^b Z^* AZ \, dx = 0$ and $AZ = 0$. Thus $JZ' - BZ = AG$, and $Z = 0$. Since $Z = 0$, $AG = 0$, and $G = 0$ in $L_A^2(a, b)$.

8. Extension of the boundary conditions. We have chosen $\bar{\lambda}$ to be fixed in generating the boundary condition at $x = b$. We would like to show now that, properly extended, $\chi(x, \lambda) = \theta(x, \lambda) + \phi(x, \lambda)M(\lambda)$ remains in $L_A^2(a, b)$ and that if $\lim_{x \to b} \chi(x, \bar{\lambda})^* JY(x) = 0$, then for all λ, $\operatorname{Im} \lambda \neq 0$, $\lim_{x \to b} \chi(x, \bar{\lambda})^* JY(x) = 0$. In a sense, the boundary condition is independent of λ.

In the course of deriving the Green's function, we show that $M(\lambda) = M(\bar{\lambda})^*$. As a consequence we find the following theorem holds.

THEOREM 8.1. *If* $\chi(x, \lambda) = \theta(x, \lambda) + \phi(x, \lambda)M(\lambda)$, *then* $\lim_{x \to b} \chi(x, \bar{\lambda})^* \cdot J\chi(x, \lambda) = 0$.

Proof.

$$\begin{aligned} \chi(x, \bar{\lambda})^* J \chi(x, \lambda) &= (I_n, M(\bar{\lambda})^*) \mathcal{Y}(x, \bar{\lambda})^* J \mathcal{Y}(x, \lambda) \begin{pmatrix} I_n \\ M(\lambda) \end{pmatrix} \\ &= (I_n, M(\bar{\lambda})^*) J \begin{pmatrix} I_n \\ M(\lambda) \end{pmatrix} \\ &= 0, \end{aligned}$$

so the limit is zero also.

COROLLARY 8.2. *Let the columns of* $\chi(x, \lambda)$ *be modified smoothly so that they vanish near* $x = a$. *Then, so modified, the columns of* $\chi(x, \lambda)$ *are in* D.

THEOREM 8.3. *If* Y *is in* D, *then* $\lim_{x \to b} \chi(x, \lambda)^* JY(x) = 0$.

Proof. Since each column of $\chi(x, \lambda)$, appropriately modified, is in D, an application of Green's formula shows the limit is zero.

DEFINITION 8.4. We extend the definition of $\chi(x, \bar{\lambda})$ to other values $\bar{\mu}$ in the same half plane as $\bar{\lambda}$, by

$$\chi(x, \bar{\mu}) = \chi(x, \bar{\lambda}) + (\bar{\mu} - \bar{\lambda}) \int_a^b G(\bar{\lambda}, x, \xi) A(\xi) \chi(\xi, \mu) \, d\xi.$$

It is well known that if $|\bar{\mu} - \bar{\lambda}| < |1/\operatorname{Im} \lambda|$, then with initial estimate $\chi(x, \bar{\lambda})$, a Neumann series may be used to show that the integral equation has a unique solution, analytic in $\bar{\mu}$ and in $L_A^2(a, b)$. Further, this solution can be extended analytically through the entire half plane containing $\bar{\lambda}$. It is also easy to show that $(L - \bar{\mu})\chi(x, \bar{\mu}) = 0$.

A simple calculation shows that $\chi(x, \bar{\mu}) = \theta(x, \bar{\mu}) + \phi(x, \bar{\mu})M(\bar{\mu})$, where

$$M(\bar{\mu}) = M(\bar{\lambda}) + (\bar{\mu} - \bar{\lambda}) \int_a^b \chi(x, \bar{\lambda})^* A(\xi) \chi(\xi, \bar{\mu}) \, d\xi,$$

thus extending $M(\bar{\mu})$ as well.

THEOREM 8.5. *For different parameters* $\bar{\lambda}$ *and* $\bar{\mu}$, $\lim_{x \to b} \chi(x, \bar{\lambda})^* J \chi(x, \bar{\mu}) = 0$.

Proof. If $\lim_{x \to b} \chi(x, \bar{\lambda})^* J$ is applied to the integral equation, both terms on the right-hand side have limit zero. Extended analytically in $\bar{\mu}$, this remains zero.

COROLLARY 8.6. *Let the columns of* $\chi(x, \bar{\mu})$ *be modified smoothly so that they vanish near* $x = a$. *Then, so modified, the columns of* $\chi(x, \bar{\mu})$ *are in* D.

THEOREM 8.7. *If* Y *is in* D, *then* $\lim_{x \to b} \chi(x, \bar{\mu})^* JY(x) = 0$.

DEFINITION 8.8. We extend the definition of $\chi(x, \mu)$ to other values μ in the same half plane as λ by

$$\chi(x, \mu) = \chi(x, \lambda) + (\mu - \lambda) \int_a^b G(\lambda, x, \xi) A(\xi) \chi(\xi, \mu)\, d\xi.$$

The comments made after Definition 8.4 apply here as well with the conjugate signs removed.

THEOREM 8.9. *For different parameters λ and μ, $\lim_{x \to b} \chi(x, \lambda)^* J \chi(x, \mu) = 0$.*

COROLLARY 8.10. *Let the columns of $\chi(x, \mu)$ be modified smoothly so that they vanish near $x = a$. Then, so modified, the columns of $\chi(x, \mu)$ are in D.*

Proof. Clearly the columns are in D, associated with λ. But D, defined by $B_\lambda(Y)$, and D, defined by $B_{\bar\lambda}(Y)$, are the same.

THEOREM 8.11. *If Y is in D, then $\lim_{x \to b} \chi(x, \mu) J Y(x) = 0$.*

In summary, we state the following theorem.

THEOREM 8.12. *Let Y be in D. Then, for all λ, $\operatorname{Im} \lambda \neq 0$, $B_\lambda(Y) = 0$.*

THEOREM 8.13. *For all λ, $\operatorname{Im} \lambda \neq 0$, $(L - \lambda I)^{-1}$ exists and is given by (**).*

$$\|(L - \lambda I)^{-1}\| \leqq 1/|\operatorname{Im} \lambda|.$$

Proof. The previous calculation holds no matter what λ.

Finally we comment that for all μ, $\operatorname{Im} \mu \neq 0$, $\chi(x, \mu) = \theta(x, \mu) + \phi(x, \mu) M(\mu)$ satisfies $\lim_{x \to b} \chi(x, \mu)^* J \chi(x, \mu) = 0$. This implies that $M(\mu)$ is on the μ limit circle; however, its exact relation to the sequence (β_1, β_2) and U, used to define $M(\bar\lambda)$ on the original limit circle, is not clear.

9. The Lagrange bilinear form. Just as L is a restriction of the maximal operator L_M, all other self-adjoint operators involving the differential equation (*) are also generated by examining other restrictions of L_M. This can be done by examining Green's formula, a major component of which is the Lagrange bilinear form $Z^* J Y$. This must be expressed properly in order to identify those which are self-adjoint. If Y and Z are in D_M, then a preliminary form of Green's formula is

$$\int_a^b [Z^*(JY' - BY) - (JZ' - BZ)^* Y]\, dx = Z^* J Y|_a^b.$$

Since Y and Z are in D_M, they satisfy

$$JY' - (\lambda A + B) Y = AF, \qquad JZ' - (\bar\lambda A + B) Z = AG,$$

where $\operatorname{Im} \lambda > 0$ and F and G are in $L_A^2(a, b)$. Using the Green's function for L we can write

$$Y(x) = \int_a^b G(\lambda, x, \xi) A(\xi) F(\xi)\, d\xi + \chi_b(x, \lambda) C_1 + \phi(x, \lambda) C_2,$$

$$Z(x) = \int_a^b G(\bar\lambda, x, \xi) A(\xi) G(\xi)\, d\xi + \chi_b(x, \bar\lambda) D_1 + \phi(x, \bar\lambda) D_2,$$

where C_2 and D_2 are chosen so that $\phi(x, \lambda) C_2$ and $\phi(x, \bar\lambda) D_2$ consists only of $L_A^2(a, b)$ solutions.

We can solve for C_1, C_2, D_1, D_2. Since the integral in the formula for Y, as well as the term $\chi_b(x, \lambda) C_1$ satisfy the limit boundary condition, and $\lim_{x \to b} \chi_b(x, \bar\lambda) J \phi(x, \lambda) = -I$,

$$\lim_{x \to b} \chi_b(x, \bar\lambda)^* J Y(x) = -C_2.$$

Further

$$\lim_{x\to b} D_2^*\phi(x,\bar\lambda)^*JY = \lim_{x\to b} D_2^*\phi(x,\bar\lambda)^*JR_Y(x) + D_2^*C_1,$$

where

$$R_Y(x) = \int_a^b G(\lambda, x, \xi)A(\xi)F(\xi)\,d\xi.$$

Likewise

$$\lim_{x\to b} Z(x)^*J\chi_b(x,\lambda) = D_2^*$$

and

$$\lim_{x\to b} Z(x)^*J\phi(x,\lambda)C_2 = \lim_{x\to b} R_Z(x)^*J\phi(x,\lambda)C_2 - D_1^*C_2,$$

where

$$R_Z(x) = \int_a^b G(\bar\lambda, x, \xi)A(\xi)G(\xi)\,d\xi.$$

We then compute

$$\lim_{x\to b} Z^*(x)JY(x) = \lim_{x\to b} R_Z(x)^*J\phi(x,\lambda)C_2 + \lim_{x\to b} D_2^*\phi(x,\bar\lambda)^*JR_Y(x) - D_1^*C_2 + D_2^*C_1,$$

the other terms cancelling because they satisfy the χ boundary condition at b.

Eliminating the terms $D_1^*C_2$ and $D_2^*C_1$ by substitution, we obtain

$$\lim_{x\to b} Z(x)^*JY(x) = \lim_{x\to b} Z(x)^*J\phi(x,\lambda)C_2 + \lim_{x\to b} D_2^*\phi(x,\bar\lambda)^*JY(x).$$

Now the term

$$\phi(x,\lambda)C_2 = -\phi(x,\lambda)\left[\lim_{x\to b}\chi_b(x,\bar\lambda)^*JY(x)\right].$$

Let $\phi(x,\lambda) = (\phi_1, \phi_2)(x)E_b$, where $\phi_1(x,\lambda)$ consists of those $m-n$ solutions of $(*)$ in $L_A^2(a,b)$, and $\phi_2(x,\lambda)$ are those not in $L_A^2(a,b)$. Let

$$\chi_b(x,\bar\lambda)E_b^* = (\chi_1, \chi_2)(x,\bar\lambda),$$

where χ_1 contains $m-n$ components as well. Then

$$\phi(x,\lambda)C_2 = -\phi_1(x,\lambda)\left[\lim_{x\to b}\chi_1(x,\bar\lambda)^*JY(x)\right].$$

Likewise, the term

$$D_2^*\phi(x,\bar\lambda)^* = \left[\lim_{x\to b} Z(x)^*J\chi_b(x,\lambda)\right]\phi(x,\bar\lambda)^*$$

$$= \left[\lim_{x\to b} Z(x)^*J\chi_1(x,\lambda)\right]\phi_1(x,\bar\lambda)^*$$

where $\phi_1(x,\bar\lambda)$ contains $m-n$ components. The terms

$$-\phi_2(x,\phi)\left[\lim_{x\to b}\chi_2(x,\bar\lambda)^*JY(x)\right]$$

and

$$\left[\lim_{x\to b} Z(x)^*J\chi_2(x,\lambda)\right]\phi_2(x,\bar\lambda)^*$$

are not present because $\phi(x,\lambda)C_2$ and $\phi(x,\bar{\lambda})D_2$ contain only solutions in $L^2_A(a,b)$. Therefore, we have the following theorem.

THEOREM 9.1. *Let* $\phi(x,\lambda)=(\phi_1,\phi_2)(x,\lambda)E_b$, *where* ϕ_1 *consists of all of the* $\phi - L^2_A(a,b)$ *solutions of* $(*)$. *Let* $\phi(x,\bar{\lambda})=(\phi_1,\phi_2)(x,\bar{\lambda})\tilde{E}_b$, *where* ϕ_1 *consists of all of the* $\phi - L^2_A(a,b)$ *solutions of* $(*)$ *with* λ *replaced by* $\bar{\lambda}$. *Let* $(\chi_1,\chi_2)(x,\bar{\lambda})=\chi_b(x,\bar{\lambda})E^*_b$, *and let* $(\chi_1,\chi_2)(x,\lambda)=\chi_b(x,\lambda)\tilde{E}^*_b$. *Then for all* Y *and* Z *in* D_M

$$\lim_{x\to b}\chi_2(x,\bar{\lambda})^*JY(x)=0, \qquad \lim_{x\to b}\chi_2(x,\lambda)^*JZ(x)=0.$$

Proof. This is the only way to ensure that $\phi_2(x,\lambda)$ and $\phi_2(x,\bar{\lambda})$ are not present.

The possibility of this occurring was reported to the author by D. B. Hinton several years ago.

Theorem 9.1 explains an apparent discrepancy. It appears that by imposing the conditions $\lim_{x\to b}\chi(x,\bar{\lambda})^*JY(x)=0$ and $(\alpha_1,\alpha_2)Y(a)=0$, that $2n$ boundary conditions are being required. However, since the deficiency indices at $x=b$ are (m,m), only $n+m$ should be imposed.

Theorem 9.1 shows that in fact when $m-n$ ϕ combinations are in $L^2_A(a,b)$, $2n-m$ combinations are not, and so there are $2n-m$ χ_2 automatically zero conditions. As a result χ imposes only $n-(2n-m)=m$ constraints. With n constraints at $x=a$, the total is $n+m$, not $2n$.

Returning to $\lim_{x\to b}Z(x)^*JY(x)$, we find

$$\lim_{x\to b}Z(x)^*JY(x)=\left[\lim_{x\to b}\phi_1(x,\lambda)^*JZ(x)\right]^*\left[\lim_{x\to b}\chi_1(x,\bar{\lambda})^*JY(x)\right]$$
$$-\left[\lim_{x\to b}\chi_1(x,\lambda)^*JZ(x)\right]^*\left[\lim_{x\to b}\phi_1(x,\bar{\lambda})^*JY(x)\right].$$

THEOREM 9.2. *Under the conditions of Theorem* 9.1, *let*

$$B_b(Y)=\begin{pmatrix}\lim_{x\to b}\chi_1(x,\bar{\lambda})^*JY(x)\\ \lim_{x\to b}\phi_1(x,\bar{\lambda})^*JY(x)\end{pmatrix},$$

$$\tilde{B}_b(Z)=\begin{pmatrix}\lim_{x\to b}\chi_1(x,\lambda)^*JZ(x)\\ \lim_{x\to b}\phi_1(x,\lambda)^*JZ(x)\end{pmatrix},$$

$$J_b=\begin{pmatrix}0 & -I_{m-n}\\ I_{m-n} & 0\end{pmatrix},$$

where (m,m) *are the defect indices of* $(*)$ *at* b; *then*

$$\lim_{x\to b}Z(x)^*JY(x)=\tilde{B}_b(Z)^*J_bB_b(Y).$$

The symbol $\tilde{}$ indicates λ is used instead of $\bar{\lambda}$.

If the end $x=a$ is regular, the computation is a bit easier. Note that

$$[\chi_b(x,\lambda),\phi(x,\lambda)]J[\chi_b(x,\bar{\lambda}),\phi(x,\bar{\lambda})]^*=J.$$

Therefore

$$Z^*(a)JY(a)=-Z^*(a)J[\chi_b(a,\lambda),\phi(a,\lambda)]J[\chi_b(a,\bar{\lambda}),\phi(a,\bar{\lambda})]^*JY(a).$$

THEOREM 9.3. *Let*

$$B_a(Y)=\begin{pmatrix}\chi_b(a,\bar{\lambda})^*JY(a)\\ \phi_b(a,\bar{\lambda})^*JY(a)\end{pmatrix},$$

$$\tilde{B}_a(Z)=\begin{pmatrix}\chi_b(a,\lambda)^*JZ(a)\\ \phi_b(a,\lambda)^*JZ(a)\end{pmatrix},$$

$$J=\begin{pmatrix}0 & -I_n\\ I_n & 0\end{pmatrix};$$

then

$$Z^*(a)JY(a)=\tilde{B}_a(Z)^*JB_a(Y).$$

The terms $\phi_b(a,\bar{\lambda})JY(a)$ and $\phi_b(a,\lambda)JZ(a)$ are simply $(\alpha_1,\alpha_2)Y(a)$ and $(\alpha_1,\alpha_2)Z(a)$. The terms $\chi_b(a,\bar{\lambda})^*JY(a)$ and $\chi_b(a,\lambda)^*JZ(a)$ may be replaced by $\theta(a,\bar{\lambda})^*JY(a)$ and $\theta(a,\lambda)^*JZ(a)$, and the formula for $Z(a)^*JY(a)$ still holds. $\theta(a,\bar{\lambda})^*JY(a)=(-\alpha_2,\alpha_1)Y(a)$; $\theta(a,\bar{\lambda})^*JZ(a)=(-\alpha_2,\alpha_1)Z(a)$ as well. These are complimentary boundary forms.

10. Green's formula. If the pieces from the previous section are assembled together, we have the following theorem.

THEOREM 10.1. *Let Y and Z be in D_M. Then*

$$\int_a^b\{Z^*[JY'-BY]-[JZ'-BZ]^*Y\}\,dx=-\tilde{B}_a(Z)^*JB_a(Y)+\tilde{B}_b(Z)^*J_bB_b(Y)$$

$$=(\tilde{B}_a(Z)^*,\tilde{B}_b(Z)^*)\begin{pmatrix}-J & 0\\ 0 & J_b\end{pmatrix}\begin{pmatrix}B_a(Y)\\ B_b(Y)\end{pmatrix}.$$

Let M and N be $r\times 2n$ and $r\times(2m-2n)$ matrices, respectively, where (m,m) are the defect indices of $(*)$ at b, with rank $(MN)=r$, $0\leqq r\leqq 2m$. Further, let P and Q be $(2m-r)\times 2n$ and $(2m-r)\times(2m-2n)$ matrices such that

$$\begin{pmatrix}M & N\\ P & Q\end{pmatrix}$$

is nonsingular. If $\tilde{M},\tilde{N},\tilde{P},\tilde{Q}$ are $r\times 2n$, $r\times(2m-2n)$, $(2m-r)\times 2n$, $(2m-r)\times(2m-2n)$ matrices such that

$$\begin{pmatrix}\tilde{M}^* & \tilde{P}^*\\ \tilde{N}^* & \tilde{Q}^*\end{pmatrix}\begin{pmatrix}M & N\\ P & Q\end{pmatrix}=\begin{pmatrix}-J & 0\\ 0 & J_b\end{pmatrix},$$

then inserting this in Green's formula gives it its final form.

THEOREM 10.2. (Green's formula.) *Let Y and Z be in D_M. Then*

$$\int_a^b\{Z^*[JY'-BY]-[JZ'-BZ]^*Y\}\,dx$$

$$=[\tilde{M}\tilde{B}_a(Z)+\tilde{N}\tilde{B}_b(Z)]^*[MB_a(Y)+NB_b(Y)]$$

$$+[\tilde{P}\tilde{B}_a(Z)+\tilde{Q}\tilde{B}_b(Z)]^*[PB_a(Y)+QB_a(Y)].$$

DEFINITION 10.3. We denote by $\tilde{D}$ those elements Y in $L_A^2(a, b)$ satisfying
(1) Y is in D_M;
(2) $MB_a(Y)+NB_b(Y)=0$.

DEFINITION 10.4. We denote by $\tilde{L}$ the operator defined by setting $\tilde{L}Y=F$ whenever $JY'-BY=AF$ and Y is in $\tilde{D}$.

DEFINITION 10.5. We denote by $\tilde{D}^*$ those elements Z in $L_A^2(a, b)$ satisfying
(1) Z is in D_M;
(2) $\tilde{P}\tilde{B}_a(Z)+\tilde{Q}\tilde{B}_b(Z)=0$.

DEFINITION 10.6. We denote by $\tilde{L}^*$ the operator defined by setting $\tilde{L}^*Z=G$ whenever $JZ'-BZ=AG$ and Z is in $\tilde{D}^*$.

THEOREM 10.7. *The abuse of notation above is correct. The adjoint of $\tilde{L}$ in $L_A^2(a, b)$ is $\tilde{L}^*$. The adjoint of $\tilde{L}^*$ in $L_A^2(a, b)$ is $\tilde{L}$.*

Proof. The form of the adjoint of $\tilde{L}$ is well known to be the same as that of $\tilde{L}^*$. From Green's formula it is clear that $\tilde{D}^*$ is included in domain of the adjoint.

Conversely, again from Green's formula, since $PB_a(Y)+QB_b(Y)$ is arbitrary, any element in the adjoint's domain must be in $\tilde{D}^*$.

There are parametric boundary conditions as well. Set

$$MB_a(Y)+NB_b(Y)=0, \qquad PB_a(Y)+QB_b(Y)=\Gamma,$$

where Γ is arbitrary. Multiply

$$\begin{pmatrix} M & N \\ P & Q \end{pmatrix}\begin{pmatrix} B_a(Y) \\ B_b(Y) \end{pmatrix}=\begin{pmatrix} 0 \\ \Gamma \end{pmatrix}$$

by

$$\begin{pmatrix} J & 0 \\ 0 & -J_{m-n} \end{pmatrix}\begin{pmatrix} \tilde{M}^* & \tilde{P}^* \\ \tilde{N}^* & \tilde{Q}^* \end{pmatrix}.$$

The result is

$$B_a(Y)=J\tilde{P}^*\Gamma, \qquad B_b(Y)=-J_b\tilde{Q}^*\Gamma.$$

Likewise, if

$$\tilde{M}\tilde{B}_a(Z)+\tilde{N}\tilde{B}_b(Z)=\Delta, \qquad \tilde{P}\tilde{B}_a(Z)+\tilde{Q}\tilde{B}_b(Z)=0,$$

then post-multiply

$$(\tilde{B}_a(Z)^*, \tilde{B}_b^*(Z))\begin{pmatrix} \tilde{M}^* & \tilde{P}^* \\ \tilde{N}^* & \tilde{Q}^* \end{pmatrix}=(\Delta^*, 0)$$

by

$$\begin{pmatrix} M & N \\ P & Q \end{pmatrix}\begin{pmatrix} J & 0 \\ 0 & -J_b \end{pmatrix}.$$

The result is

$$\tilde{B}_a(Z)=-JM^*\Delta, \qquad \tilde{B}_b(Z)=J_bN^*\Delta.$$

THEOREM 10.8. *The parametric boundary conditions are fully equivalent to the original boundary conditions.*

11. Equivalent boundary conditions. The evaluation of $\lim_{x\to b} Z(x)^*JY(x)$, found in the proof of Theorem 9.1, enables us to establish a number of interesting relationships.

First think of it as defining a boundary condition on Y:

$$B_Z(Y) = \lim_{x\to b} Z(x)^* JY(x)$$

$$= \left[\lim_{x\to b} \phi_1(x,\lambda)^* JZ(x)\right]^* \left[\lim_{x\to b} \chi_1(x,\bar{\lambda})^* JY(x)\right]$$

$$- \left[\lim_{x\to b} \chi_1(x,\lambda) JZ(x)\right]^* \left[\lim_{x\to b} \phi_1(x,\bar{\lambda}) JY(x)\right].$$

If we let

$$C = \left[\left\{\lim_{x\to b} \phi_1(x,\lambda) JZ(x)\right\}^*, \left\{-\lim_{x\to b} \chi_1(x,\lambda)^* JZ(x)\right\}^*\right]$$

we have the following theorem.

THEOREM 11.1. *Let Z be in D_M; then*

$$B_Z(Y) = CB_b(Y).$$

Since Glazman showed that all self-adjoint boundary conditions can be generated by using appropriate elements from D_M, this shows that our solution-generated boundary conditions also suffice.

As a special case, let $Z = \chi_1(x,\lambda)$.

THEOREM 11.2. *Let $\tilde{V}_{11} = [\lim_{x\to b} \phi_1(x,\lambda)^* J\chi_1(x,\lambda)]^*$; then*

$$\left[\lim_{x\to b} \chi_1(x,\lambda)^* JY(x)\right] = \tilde{V}_{11}\left[\lim_{x\to b} \chi_1(x,\bar{\lambda})^* JY(x)\right].$$

The coefficient

$$\tilde{V}_{12} = \left[\lim_{x\to b} \chi_1(x,\lambda)^* J\chi_1(x,\lambda)]^*\right]$$

is zero.

Likewise, let $Z = \phi_1(x,\lambda)$.

THEOREM 11.3. *Let*

$$\tilde{V}_{21} = \left[\lim_{x\to b} \phi_1(x,\lambda)^* J\phi_1(x,\lambda)\right]^*,$$

$$\tilde{V}_{22} = \left[\lim_{x\to b} \chi_1(x,\lambda)^* J\phi_1(x,\lambda)\right]^*,$$

and $\tilde{V} = (\tilde{V}_{ij})$; then

$$\tilde{B}_b(Y) = \tilde{V}B_b(Y).$$

COROLLARY 11.4. *There exists a matrix V such that*

$$B_b(Y) = V\tilde{B}_b(Y).$$

Note that if λ can be chosen to be real, which is frequently the case, then $V = \tilde{V} = I$.

12. Self-adjointness.

THEOREM 12.1. *$\tilde{L}$ is self-adjoint if and only if $r = m$ and*

$$MJM^* = NVJ_bN^*.$$

Proof. Suppose $\tilde{L}$ is self-adjoint. Then Y in $\tilde{D}$ satisfies

$$MB_a(Y)+NB_b(Y)=0$$

and

$$\tilde{P}\tilde{B}_a(Y)+\tilde{Q}\tilde{B}_b(Y)=0.$$

Since the boundary evaluations at each end must be the same, and $B_a(Y)=\tilde{B}_a(Y)$, we find $B_b(Y)=V\tilde{B}_b(Y)$ for all Y in $\tilde{D}$.

Then

$$\tilde{B}_a(Y)=B_a(Y)=-JM^*\Delta, \qquad \tilde{B}_b(Y)=V^{-1}B_b(Y)=J_bN^*\Delta.$$

We have

$$M(-JM^*\Delta)+N(VJ_bN^*\Delta)=0, \qquad \text{or} \qquad [-MJM^*+NVJ_bN^*]\Delta=0.$$

Since Δ may be arbitrary,

$$MJM^*=NVJ_bN^*.$$

Conversely, if

$$MJM^*=NVJ_bN^*,$$

then

$$(M,N)\begin{pmatrix}-JM\\VJ_bN^*\end{pmatrix}=0, \qquad (M,N)\begin{pmatrix}B_a(Y)\\B_b(Y)\end{pmatrix}=0.$$

Thus there must exist a nonsingular Δ such that

$$\begin{pmatrix}-JM^*\\VJ_bN^*\end{pmatrix}\Delta=\begin{pmatrix}B_a(Y)\\B_b(Y)\end{pmatrix}$$

and $B_a(Y)=-JM^*\Delta$, $B_b(Y)=VJ_bN^*\Delta$. Hence $\tilde{B}_a(Y)=-JM^*\Delta$, $\tilde{B}_b(Y)=J_bN^*\Delta$. This implies

$$\tilde{P}\tilde{B}_a(Y)+\tilde{Q}\tilde{B}_b(Y)=0,$$

and so Y is in $\tilde{D}^*$. A symmetric argument then shows $\tilde{D}=\tilde{D}^*$, and $\tilde{L}$ is self-adjoint.

13. The spectral resolution of L. This section closely follows the lead of Coddington and Levinson [3, Chap. 9].

If we consider the regular boundary value problem on $[a, b']$,

$$JY'(\lambda A+B)Y,$$

$$(\alpha_1\alpha_2)Y(a)=0, \qquad (\beta_1\beta_2)Y(b')=0,$$

we recall that ϕ satisfies the boundary condition at a, while for $\operatorname{Im}\lambda\neq 0$, $\chi_{b'}=\theta+\phi M_{b'}$ satisfies the boundary condition at b provided

$$M_{b'}=-[(\beta_1\beta_2)\phi(b',b)]^{-1}[(\beta_1\beta_2)\theta(b',\lambda)].$$

For all λ, $M_{b'}$ is analytic in λ except for real poles, which are eigenvalues for the regular problem on $[a, b']$. We denote these eigenvalues by $\{\lambda_k\}_{k=1}^{\infty}$. Their corresponding eigenfunctions are $\{V_k\}_{k=1}^{\infty}$. For each λ_k,

$$V_k=\phi(x,\lambda_k)K_k,$$

where K_k is an $n \times 1$ matrix. We assume that at multiple eigenvalues, the corresponding eigenfunctions have been made orthogonal.

THEOREM 13.1. *Let $F(x)$ be an arbitrary element in $L_A^2(a, b')$. Then*

$$F(x) = \sum_{k=1}^{\infty} \phi_k(x) C_k,$$

where $\phi_k(x) = \phi(x, \lambda_k)$ and

$$C_k = \left[\int_a^{b'} \phi_k^* A \phi_k \, d\xi \right]^{-1} \int_a^{b'} \phi_k A F \, d\xi.$$

This is, of course, just the standard eigenfunction expansion. Note that C_k is an $n \times 1$ matrix.

THEOREM 13.2. *Let $F(x)$ be an arbitrary element in $L_A^2(a, b')$. Then*

$$\int_a^{b'} F^* A F \, d\xi = \sum_{k=1}^{\infty} \left[\int_a^{b'} F^* A \phi_k \, d\xi \right] \left[\int_a^{b'} \phi_k^* A \phi_k \, d\xi \right]^{-1} \left[\int_a^{b} \phi_k^* A F \, d\xi \right].$$

This is Parseval's equality.

DEFINITION 13.3. Let R_k^2 denote the $n \times n$ matrix $[\int_a^{b'} \phi_k^* A \phi_k \, d\xi]^{-1}$.

DEFINITION 13.4. Let

$$G(\lambda) = \int_a^{b'} \phi(\xi, \lambda)^* A(\xi) F(\xi) \, d\xi.$$

DEFINITION 13.5. Let $P_{b'}(\lambda)$ be an $n \times n$ matrix valued function satisfying

(1) $P_{b'}(0+) = 0$;

(2) $P_{b'}(\lambda)$ is increasing, jumping R_k^2 at $\lambda = \lambda_k$, but otherwise constant, continuous from above.

Thus

$$P_{b'}(\lambda) = \sum_{0 < \lambda_k \leqq \lambda} R_k^2, \qquad \lambda \geqq 0,$$

$$P_{b'}(\lambda) = -\sum_{\lambda < \lambda_k \leqq 0} R_k^2, \qquad \lambda < 0.$$

THEOREM 13.6. (Parseval's equality.) *Let F be an arbitrary element of $L_A^2(a, b')$. Then*

$$\int_a^{b'} F^* A F \, d\xi = \int_{-\infty}^{\infty} G^*(\lambda) \, dP_{b'}(\lambda) G(\lambda).$$

This can be extended by the polarization identities to inner products.

COROLLARY 13.7. *Let F_1, F_2 be arbitrary elements in $L_A^2(a, b')$. Let $G_1(\lambda)$ and $G_2(\lambda)$ correspond to them according to Definition* 13.4. *Then*

$$\int_a^{b'} F_2^* A F_1 \, d\xi = \int_{-\infty}^{\infty} G_2^*(\lambda) \, dP_{b'}(\lambda) G_1(\lambda).$$

We will need this in the theorem that follows.

THEOREM 13.8. *There exists a nondecreasing $n \times n$ matrix valued function $P(\lambda)$, defined on $(-\infty, \infty)$, such that*

(1) $P(0+) = 0$,

(2) $P(\lambda) - P(\mu) = \lim_{b' \to b} [P_{b'}(\lambda) - P_{b'}(\mu)]$, $\lambda > \mu$.

Proof. Let $M_{b'}$ be on the circle $E(M)$, defined by setting $\chi_{b'}^*(b', \lambda)(J/i)\chi_b(b', \lambda) = 0$. Set λ equal to λ_0, and $\chi_{b'}(x, \lambda_0) = \theta(x, \lambda_0) + \phi(x, \lambda_0)M_{b'}(\lambda_0)$. Then $J\chi_{b'}' = (\lambda_0 A + B)\chi_{b'}$. Apply Parseval's equality to $\chi_{b'}$.

$$\int_a^{b'} \chi_{b'}^* A \chi_{b'}\, d\xi = \int_{-\infty}^{\infty} G(\lambda)^*\, dP_{b'}(\lambda) G(\lambda)$$

where

$$G(\lambda) = \int_a^{b'} \phi^*(\xi, \lambda) A(\xi) \chi_{b'}(\xi, \lambda_0)\, d\xi.$$

Now $J\chi_b' = (\lambda_0 A + B)\chi_{b'}$ and $J\phi_k' = (\lambda_k A + B)\phi_k$ imply

$$\phi_k^* J \chi_{b'}\Big|_a^{b'} = (\lambda_0 - \lambda_k) \int_a^{b'} \phi_k^* A \chi_{b'}\, d\xi.$$

At b' both ϕ_k and $\chi_{b'}$ satisfy $(\beta_1, \beta_2)\, Y(b') = 0$, so the upper limit on the left is 0. At $x = a$,

$$\phi_k^* J \chi_{b'}(a) = (-\alpha_2, \alpha_1) \begin{pmatrix} 0 & -I_n \\ I_n & 0 \end{pmatrix} \begin{pmatrix} \alpha_1^* & -\alpha_2^* \\ \alpha_2^* & \alpha_1 \end{pmatrix} \begin{pmatrix} I_n \\ M_{b'} \end{pmatrix} = I_n.$$

So

$$G(\lambda_k) = \int_a^{b'} \phi_k^* A \chi_{b'}\, d\xi = (\lambda_k - \lambda_0)^{-1} I_n.$$

Parseval's equality becomes

$$\int_a^{b'} \chi_{b'}^* A \chi_{b'}\, d\xi = \int_{-\infty}^{\infty} |\lambda - \lambda_0|^{-2}\, dP_{b'}(\lambda).$$

An easy calculation using the differential equation for $\chi_{b'}$ shows

$$\int_a^{b'} \chi_{b'}^* A \chi_{b'}\, d\xi = [M_{b'} - M_{b'}^*]/(2i \operatorname{Im} \lambda_0).$$

If $\lambda_0 = i = \sqrt{-1}$, then

$$\int_{-\infty}^{\infty} |i - \lambda|^{-2}\, dP_{b'}(\lambda) = [M_{b'}(i) - M_{b'}^*(i)]/(2i).$$

Since $|i - \lambda|^2 = \lambda^2 + 1$, we see there is a $K > 0$ such that

$$\int_{-\infty}^{\infty} (\lambda^2 + 1)^{-1}\, dP_{b'}(\lambda) < K.$$

This implies for $\mu > 0$ that

$$\int_{-\mu}^{\mu} dP_{b'}(\lambda) < K[1 + \mu^2].$$

This implies since $P_{b'}$ is increasing, and $0 \leqq P_{b'}(\mu) < K[1 + \mu^2]$, then $0 \leqq -P_{b'}(-\mu) < K[1 + \mu^2]$ for all $\mu \geqq 0$. Therefore $P_{b'}(\lambda)$ is uniformly bounded on compact subintervals of the real line. Helly's first theorem [23] shows there is a subsequence that converges "weakly" to $P(\lambda)$ with the properties stated.

THEOREM 13.9. *If F is in $L_A^2(a, b)$, there is a function $G(\lambda)$ in $L_p^2(-\infty, \infty)$, with inner product*

$$(G, H)_p = \int_{-\infty}^{\infty} H^* \, dPG,$$

such that if

$$E(\lambda) = G(\lambda) - \int_a^{b'} \phi^*(\xi, \lambda) A(\xi) F(\xi) \, d\xi,$$

then

$$\lim_{b' \to b} \int_{-\infty}^{\infty} E(\lambda)^* \, dP(\lambda) E(\lambda) = 0,$$

and

$$\int_a^b F(\xi)^* A(\xi) F(\xi) \, d\xi = \int_{-\infty}^{\infty} G(\lambda)^* \, dP(\lambda) G(\lambda).$$

Proof. (1) Let F be in $C_0^1(a, b)$. Then F is in D.
If b' is large enough,

$$\int_a^{b'} (LF)^* A(LF) = \int_a^{b'} H^* AH \, d\xi = \sum_{k=1}^{\infty} \left(\int_a^b \phi_k^* AH \, d\xi \right)^* R_k^2 \left(\int_a^b \phi_k^* AH \, d\xi \right).$$

But

$$\int_a^b \phi_k^* AH \, d\xi = \int_a^{b'} \phi_k^* [JF' - BF] \, d\xi = \int_a^{b'} [J\phi_k' - B\phi_k]^* F \, d\xi$$

$$= \lambda_k \int_a^{b'} \phi_k^* AF \, d\xi = \lambda_k G(\lambda_k).$$

Thus

$$\int_a^b (LF)^* A(LF) \, d\xi = \int_{-\infty}^{\infty} \lambda^2 G(\lambda)^* \, dP_{b'}(\lambda) G(\lambda).$$

Let $N > 0$. Then

$$\left(\int_{-\infty}^{-N} + \int_N^{\infty} \right) G^* \, dP_{b'} G \leqq \frac{1}{N^2} \left(\int_{-\infty}^{-N} + \int_N^{\infty} \right) \lambda^2 G^* \, dP_{b'} G$$

$$\leqq \frac{1}{N^2} \int_{-\infty}^{\infty} \lambda^2 G^* \, dP_{b'} G \leqq \frac{1}{N^2} \int_a^b (LF)^* A(LF) \, d\xi.$$

So, since

$$\int_a^b F^* AF \, d\xi = \left(\int_{-\infty}^{-N} + \int_{-N}^{N} + \int_N^{\infty} \right) G^* \, dP_{b'} G,$$

$$\left| \int_a^b F^* AF \, d\xi - \int_{-N}^{N} G^* \, dP_{b'} G \right| = \left(\int_{-\infty}^{-N} + \int_N^{\infty} \right) G^* \, dP_{b'} G$$

$$\leqq \frac{1}{N^2} \int_a^b (LF)^* A(LF) \, d\xi.$$

Let b' approach b. Helly's second theorem [23] implies

$$\left| \int_a^b F^* AF\, d\xi - \int_{-N}^{N} G^*\, dPg \right| \leqq \frac{1}{N^2} \int_a^b (LF)^* A(LF)\, d\xi.$$

Let N approach ∞.

$$\int_a^b F^* AF\, d\xi = \int_{-\infty}^{\infty} G^*\, dPG,$$

provided F is in $C_0^1(a, b)$.

(2) Let F vanish near b but otherwise be arbitrary in $L_A^2(a, b)$. Choose $\{F_j\}_{j=1}^{\infty}$ in $C_0^1(a, b)$ such that

$$\lim_{j\to\infty} \int_a^b (F_j - F)^* A(F_j - F)\, d\xi = 0.$$

Apply Parseval's equality to $F_j - F_k$,

$$\int_a^b (F_j - F_k)^* A(F_j - F_k)\, d\xi = \int_{-\infty}^{\infty} (G_j - G_k)^*\, dP(G_j - G_k),$$

where

$$G_j = \int_a^b \phi^* AF_j\, d\xi, \qquad G_k = \int_a^b \phi^* AF_k\, d\xi.$$

Since $\lim_{j\to\infty} F_j = F$, $\{G_j\}_{j=1}^{\infty}$ is also a Cauchy sequence in $L_p^2(-\infty, \infty)$. Thus there is a G in $L_p^2(-\infty, \infty)$ such that $\lim_{j\to\infty} G_j = G$. Since

$$\left| G_j - \int_a^{b'} \phi^*\, AF\, d\xi \right| = \left| \int_a^{b'} \phi^* A(F_j - F)\, d\xi \right|$$

$$\leqq \left(\int_a^{b'} \phi^* A\phi\, d\xi \right)^{1/2} \left(\int_a^{b'} [F_j - F]^* A[F_j - F]\, d\xi \right)^{1/2}$$

implies $\lim_{j\to\infty} G_j = \int_a^{b'} \phi^* AF\, d\xi$, which is continuous, we find $G = \int_a^b \phi^* AF\, d\xi$, almost everywhere. Thus if F vanishes near $x = b$,

$$\int_a^b F^* AF\, d\xi = \lim_{j\to\infty} \int_a^b F_j^* AF_j\, d\xi = \lim_{j\to\infty} \int_{-\infty}^{\infty} G_j^*\, dPG_j = \int_{-\infty}^{\infty} G^*\, dPG.$$

(3) Finally, if F is arbitrary in $L_A^2(a, b)$, let

$$F_{b'} = F, \qquad x \leqq b',$$

$$F_{b'} = 0, \qquad x > b'.$$

Let

$$G_{b'} = \int_a^b \phi^* AF_{b'}\, d\xi = \int_a^{b'} \phi^* AF\, d\xi.$$

Since

$$\int_{-\infty}^{\infty} (G_c - G_d)^*\, dP(G_c - G_d) = \int_c^d F^* AF\, d\xi,$$

$\{G_{b'}\}$ is a Cauchy sequence as b' approaches b. Let $\lim_{b'\to b} G_{b'} = G$ in $L_p^2(-\infty, \infty)$. Letting b' approach b in the previous result, we get

$$\int_a^b F^*AF\,d\xi = \int_{-\infty}^{\infty} G^*\,dPG.$$

(4) Since $G_{b'}$ approaches G in $L_p^2(-\infty, \infty)$,

$$\lim_{b'\to b} \int_{-\infty}^{\infty} \left[G(\lambda) - \int_a^{b'} \phi^*AF\,d\xi\right]^* dP(\lambda) \left[G(\lambda) - \int_a^{b'} \phi^*AF\,d\xi\right] = 0.$$

We remark that if the condition $JY' - BY = AF$, $AY = 0$ implies $Y = 0$ fails to hold, then the approximation used in the proof of this theorem may hold only on a subspace of $L_A^2(a, b)$. The subspace may be as small as only one dimension. We will give examples later.

THEOREM 13.10. *If $G(\lambda)$ is the limit of $\int_a^{b'} \phi(\xi, \lambda)^*A(\xi)F(\xi)\,d\xi$ in $L_p^2(-\infty, \infty)$, then*

$$\int_{-\infty}^{\infty} \phi(x, \lambda)\,dP(\lambda)G(\lambda) = F(x)$$

in $L_A^2(a, b)$; that is,

$$\lim_{I\to(-\infty,\infty)} \int_a^b \left[F - \int_I \phi\,dPG\right]^* A \left[F - \int_I \phi\,dPG\right] d\xi = 0.$$

Proof. Let $I = (\mu, \nu)$, and

$$F_I(x) = \int_I \phi(x, \lambda)\,dP(\lambda)G(\lambda).$$

If b' is in $[a, b)$, then

$$\int_a^{b'} [F - F_I]^*AF_I\,d\xi = \int_a^{b'} [F - F_I]^*A\left[\int_I \phi\,dPG\right] d\xi$$
$$= \int_I \left[\int_a^{b'} [F - F_I]^*A\phi\,d\xi\right] dPG.$$

Likewise, we have

$$\int_a^{b'} [F - F_I]^*AF\,d\xi = \int_{-\infty}^{\infty} \left[\int_a^{b'} [F - F_I]^*A\phi\,d\xi\right] dPG.$$

Subtracting, we obtain

$$\int_a^{b'} [F - F_I]^*A[F - F_I]\,d\xi = \int_{(-\infty,\infty)-I} \left[\int_a^{b'} [F - F_I]^*A\phi\,d\xi\right] dPG.$$

Now $\int_a^{b'} \phi^*A[F - F_I]\,d\xi$ is the transform of a function in $L_A^2(a, b)$, which vanishes on (b', b). Consequently the integral from a to b' in brackets is in $L_p^2(-\infty, \infty)$. Applying Schwarz's inequality,

$$\left(\int_a^{b'} [F - F_I]^*A[F - F_I]\,d\xi\right)^2$$
$$\leqq \left(\int_{(-\infty,\infty)-I} \left[\int_a^{b'} \phi^*A[F - F_I]\,d\xi\right]^* dP \left[\int_a^{b'} \phi^*A[F - F_I]\,d\xi\right]\right)$$
$$\times \left(\int_{(-\infty,\infty)-I} G^*\,dPG\right).$$

The first integral on the right is less than or equal to

$$\int_a^{b'} [F-F_I]^* A[F-F_I]\, d\xi.$$

If this is inserted and canceled,

$$\int_a^{b'} [F-F_I]A[F-F_I]\, d\xi \leqq \int_{(-\infty,\infty)-I} G^*\, dPG.$$

Let b' approach b. Then let I approach $(-\infty, \infty)$. The result is that $F = \lim_{I\to(-\infty,\infty)} F_I$, or

$$F(x) = \lim_{(\mu,\nu)\to(-\infty,\infty)} \int_\mu^\nu \phi(x,\lambda)\, dP(\lambda)G(\lambda)$$

in $L_A^2(a, b)$.

Theorem 13.9 may be extended to involve inner products by use of the polarization identity. The inner product form of Parseval's equality is

$$\int_a^b F_2(\xi)^* A(\xi)F_1(\xi)\, d\xi = \int_{-\infty}^{\infty} G_2(\lambda)^*\, dP(\lambda)G_1(\lambda),$$

where

$$G_j(\lambda) = \int_a^b \phi(\xi,\lambda)^* A(\xi)F_j(\xi)\, d\xi, \qquad j = 1, 2.$$

Theorems 13.9 and 13.10 may be extended to represent the resolvent operator $(L-\lambda_0 I)^{-1}$ when λ_0 is not in the support of $dP(\lambda)$. Parseval's equality is

$$\int_a^b [(L-\lambda_0 I)^{-1}F(\xi)]^* A(\xi)[(L-\lambda_0 I)^{-1}F(\xi)]\, d\xi = \int_{-\infty}^{\infty} \frac{G(\lambda)^*\, dP(\lambda)G(\lambda)}{|\lambda-\lambda_0|^2}.$$

The resolvent expansion is

$$(L-\lambda_0 I)^{-1}F(x) = \int_{-\infty}^{\infty} \phi(x,\lambda)\, dP(\lambda)\frac{G(\lambda)}{\lambda-\lambda_0}.$$

14. The converse problem. Again, this section follows closely the lead of Coddington and Levinson [3, Chap. 9].

The preceding section began with choosing an F in $L_A^2(a, b)$, producing G in $L_p^2(-\infty, \infty)$, and then showing that F could be recovered from G. In this section we begin with G, produce F, and then recover G.

Without the assumption that $JY' - BY = 0$, $AY = 0$ implies $Y = 0$, $L_p^2(-\infty, \infty)$ may be too large in the sense that $G \to F \to \tilde{G}$, but $\tilde{G}$ may not equal G. $\tilde{G}$ may be only in a subspace of $L_p^2(-\infty, \infty)$.

With the assumption made in the Introduction (let $F = 0$), there is no difficulty.

LEMMA 14.1. *Let $G(\lambda)$ be in $L_p^2(-\infty, \infty)$. Let*

$$F_I(x) = \int_I \phi(x,\lambda)\, dP(\lambda)G(\lambda).$$

Then $\lim_{I\to(-\infty,\infty)} F_I(x)$ exists in $L_A^2(a, b)$.

Proof. Let $I_1 \subset I_2$. Then

$$F_{I_2} - F_{I_1} = \int_{I_2-I_1} \phi(x,\lambda)\, dP(\lambda)G(\lambda) = \int_{-\infty}^{\infty} \phi(x,\lambda)\, dP(\lambda)K_{I_2-I_1}(\lambda)G(\lambda)$$

where

$$K_{I_2-I_1}(\lambda)=1, \qquad \lambda\in I_2-I_1,$$
$$K_{I_2-I_1}(\lambda)=0, \qquad \lambda\notin I_2-I_1.$$

Let F be an arbitrary element of $L_A^2(a,b)$, which vanishes near b. Then

$$\int_a^b R^*A[F_{I_2}-F_{I_1}]\,d\xi=\int_a^b R^*A\left[\int_{I_2-I_1}\phi\,dPG\right]d\xi$$
$$=\int_{I_2-I_1}\left[\int_a^b \phi^*AR\,d\xi\right]^*dPG=\int_{I_2-I_1}S^*\,dPG,$$

where S is the transform of R: $S=\int_a^b \phi^*AR\,d\xi$. We now let $R=F_{I_2}-F_{I_1}$ on $[a,b')$, but set $R=0$ near b. Then

$$\int_a^b [F_{I_2}-F_{I_1}]^*A[F_{I_2}-F_{I_1}]\,d\xi=\int_{I_2-I_1}S^*\,dPG$$
$$\leqq\left(\int_{I_2-I_1}S^*\,dPS\right)^{1/2}\left(\int_{I_2-I_1}G^*\,dPG\right)^{1/2}$$
$$\leqq\left(\int_{-\infty}^{\infty}S^*\,dPS\right)^{1/2}\left(\int_{I_2-I_1}G^*\,dPG\right)^{1/2}.$$

But by Parseval's equality

$$\int_a^b [F_{I_2}-F_{I_1}]^*A[F_{I_2}-F_{I_1}]\,d\xi=\int_{-\infty}^{\infty}S^*\,dPS.$$

Take the square root, cancel with the inequality above, and then square.

$$\int_a^b [F_{I_2}-F_{I_1}]^*A[F_{I_2}-F_{I_1}]\,d\xi\leqq\int_{I_2-I_1}G^*\,dPG.$$

Since the right-hand side is independent of b', let b' approach b. Then $F_{I_2}-F_{I_1}$ is in $L_A^2(a,b)$. As I approaches $(-\infty,\infty)$, the inequality also shows that $\{F_I\}$ forms a Cauchy sequence in $L_A^2(a,b)$, and therefore $\lim_{I\to(-\infty,\infty)}F_I=F$ in $L_A^2(a,b)$.

LEMMA 14.2. *Let $G(\lambda)$ be in $L_P^2(-\infty,\infty)$. Let*

$$F_I(x)=\int_I\phi(x,\lambda)\,dP(\lambda)G(\lambda),$$

$$F(x)=\lim_{I\to(-\infty,\infty)}\int_I\phi(x,\lambda)\,dP(\lambda)G(\lambda).$$

Let

$$\tilde{G}(\lambda)=\int_a^b\phi^*(\xi,\lambda)A(\xi)F(\xi)\,d\xi,$$

and let

$$\tilde{F}_I(x)=\int_I\phi(x,\lambda)\,dP(\lambda)\tilde{G}(\lambda).$$

Then

$$\lim_{I\to(-\infty,\infty)}\int_a^b[F_I-\tilde{F}_I]^*A[F_I-\tilde{F}_I]\,d\xi=0.$$

Proof. From Theorem 13.10, $F(x) = \lim_{I\to(-\infty,\infty)} \tilde{F}_I(x)$ in $L^2_A(a, b)$. But by definition, $F(x) = \lim_{I\to(-\infty,\infty)} F_I(x)$. The triangle inequality

$$\|F_I - \tilde{F}_I\|_A \leqq \|F_I - F\|_A + \|F - \tilde{F}_I\|_A$$

shows that as I approaches $(-\infty, \infty)$, $\|F_I - \tilde{F}_I\|_A$ approaches zero.

At this point we have, given G, that an F exists. F yields $\tilde{G}$ which again yields F. And so the process stops. We continue to show G and $\tilde{G}$ coincide.

LEMMA 14.3. *Let λ_0 be a complex number with positive imaginary part, and let*

$$H_I(x, \lambda_0) = \int_I \phi(x, \lambda)\, dP(\lambda) \left[\frac{G(\lambda) - \tilde{G}(\lambda)}{\lambda - \lambda_0}\right].$$

Then for all fixed λ_0, $\lim_{I\to(-\infty,\infty)} H_I(x, \lambda_0) = 0$.

Proof. H_I satisfies

$$JH_I' - [\lambda_0 A + B]H_I = A(x) \int_I [\phi(x, \lambda)\, dP(\lambda)][G(\lambda) - \tilde{G}(\lambda)].$$

Further, H_I satisfies the boundary condition $(\alpha_1, \alpha_2)H_I(a, \lambda_0) = 0$. Thus

$$H_I(x) = \int_a^b G(\lambda_0, x, \xi)A(\xi)[F_I(\xi) - \tilde{F}_I(\xi)]\, d\xi + \phi(x, \lambda_0)C,$$

where here $G(\lambda_0, x, \xi)$ is the Green's function for the singular boundary value problem. As I approaches $(-\infty, \infty)$, the integral approaches zero. So

$$H(x, \lambda_0) = \lim_{I\to(-\infty,\infty)} H_I(x, \lambda_0) = \phi(x, \lambda_0)C.$$

But $\lim_{x\to b} \chi(x, \bar{\lambda}_0)^* JH(x, \lambda_0) = 0$ because, since H_I satisfies the boundary condition as x approaches b, H must satisfy the singular boundary condition as x approaches b as well. Since $\lim_{x\to b} \chi(x, \bar{\lambda}_0)^* J\phi(x, \lambda_0) = M(\lambda)$, which is nonsingular, $C = 0$.

LEMMA 14.4. *$G(\lambda) = \tilde{G}(\lambda)$ in $L^2_p(-\infty, \infty)$.*

Proof. Let K be a constant $2n \times 1$ matrix; let

$$Y_s(\lambda) = \int_a^s \phi(\xi, \lambda)^* A(\xi) K\, d\xi.$$

Then $Y_s(\lambda)$ is in $L^2_p(-\infty, \infty)$, since it is the transform of a function that vanishes near b. Then

$$\int_a^s K^* A(\xi) H_I(\xi, \lambda_0)\, d\xi = \int_I Y_s(\lambda)^*\, dP(\lambda) \left[\frac{G(\lambda) - \tilde{G}(\lambda)}{\lambda - \lambda_0}\right].$$

Let I approach $(-\infty, \infty)$. Then

$$0 = \int_{-\infty}^{\infty} Y_s(\lambda)^*\, dP(\lambda) \left[\frac{G(\lambda) - \tilde{G}(\lambda)}{\lambda - \lambda_0}\right].$$

By varying μ_0 and ν_0 ($\lambda_0 = \mu_0 + i\nu_0$) independently, we see that

$$0 = \int_{-\infty}^{\infty} Y_s(\lambda)^*\, dP(\lambda)[G(\lambda) - \tilde{G}(\lambda)] \left[\frac{\nu_0}{(\lambda - \mu_0)^2 + \nu_0^2}\right].$$

If we integrate with respect to μ_0 from α to β, reversing the order of integration, we have

$$0 = \int_{-\infty}^{\infty} Y_s(\lambda)^*\, dP(\lambda)[G(\lambda) - \tilde{G}(\lambda)] \left[\tan^{-1}\left(\frac{\beta - \lambda}{\nu_0}\right) - \tan^{-1}\left(\frac{\alpha - \lambda}{\nu_0}\right)\right].$$

Letting ν_0 approach zero, we get

$$0=\int_\alpha^\beta Y_s(\lambda)^*\, dP(\lambda)[G(\lambda)-\tilde{G}(\lambda)],$$

or

$$0=\int_a^s\left[\int_\alpha^\beta K^*A(\xi)\phi(\xi,\lambda)\, dP(\lambda)[G(\lambda)-\tilde{G}(\lambda)]\right]d\xi.$$

Differentiate with respect to s:

$$0=\int_\alpha^\beta K^*A(x)\phi(x,\lambda)\, dP(\lambda)[G(\lambda)-\tilde{G}(\lambda)].$$

Now apply an extension of the Mean Value Theorem, remembering that the expression is 1×1 and ϕ is analytic in λ. We find for some λ_0 in $[\alpha,\beta]$

$$K^*A(x)\phi(x,\lambda_0)\int_\alpha^\beta dP(\lambda)[G(\lambda)-\tilde{G}(\lambda)]=0.$$

Since $A(x)\phi(x,\lambda_0)v$ is only zero for all x when $v=0$, we can choose K appropriately to conclude that

$$\int_\alpha^\beta dP(\lambda)[G(\lambda)-\tilde{G}(\lambda)]=0$$

for all α,β. We use this to build up integrals involving step functions, dense in $L_p^2(-\infty,\infty)$, which have as their limit

$$\int_{-\infty}^{\infty}[G(\lambda)-\tilde{G}(\lambda)]^*\, dP(\lambda)[G(\lambda)-\tilde{G}(\lambda)]=0.$$

Hence $G=\tilde{G}$ in $L_p^2(-\infty,\infty)$.

We summarize in the following theorem.

THEOREM 14.5. *If $G(\lambda)$ is in $L_p^2(-\infty,\infty)$, there is a unique $F(x)$ in $L_p^2(a,b)$ such that*

$$F(x)=\int_{-\infty}^{\infty}\phi(x,\lambda)\, dP(\lambda)G(\lambda)$$

and

$$G(\lambda)=\int_a^b\phi(\xi,\lambda)^*A(\xi)F(\xi)\, d\xi.$$

15. The relation between $M(\lambda)$ and $P(\lambda)$. The matrix $M(\lambda)$ can frequently be determined by careful inspection of the solutions of (*) to determine appropriate solutions in $L_A^2(a,b)$. More difficult is the determination of the spectral measure $P(\lambda)$, since its existence follows from Helly's selection theorems. Fortunately, they are intimately connected. Recall the following theorems.

THEOREM 15.1. *Let $M(\lambda)$ be on the limit circle; let $\chi(x,\lambda)=\theta(x,\lambda)+\phi(x,\lambda)M(\lambda)$ for $\lambda=\mu+i\nu$, $\nu\neq 0$. Then*

$$\int_a^b\chi(\xi,\lambda)^*A(\xi)\chi(\xi,\lambda)\, d\xi=[M(\lambda)-M(\lambda)^*]/(2i\ \mathrm{Im}\,\lambda).$$

THEOREM 15.2. *Let* $\lambda_0 = \mu + i\nu$, $\nu \neq 0$. *Then*

$$\int_a^b \chi(\xi, \lambda_0)^* A(\xi)\chi(\xi, \lambda_0)\, d\xi = \int_{-\infty}^{\infty} |\lambda - \lambda_0|^{-2}\, dP(\lambda).$$

Proof. The theorem is true if b is replaced by b'. Let b' approach b.

THEOREM 15.3. *If* λ_1 *and* λ_2 *are real, then*

$$P(\lambda_2) - P(\lambda_1) = \lim_{\nu \to 0+} \frac{1}{\pi} \int_{\lambda_1}^{\lambda_2} \operatorname{Im} M(\mu + i\nu)\, d\mu.$$

Further, if λ_1 *and* λ_2 *have nonzero imaginary parts, then*

$$M(\lambda_2) - M(\lambda_1) = \int_{-\infty}^{\infty} [(\lambda - \lambda_2)^{-1} - (\lambda - \lambda_1)^{-1}]\, dP(\lambda).$$

Proof. We have $\int_{-\infty}^{\infty} |\lambda - \lambda_0|^{-2}\, dP(\lambda) = [M(\lambda_0) - M(\lambda_0)^*]/2i$ satisfies

$$\operatorname{Im} M(\mu + i\nu) = \int_{-\infty}^{\infty} \frac{\nu\, dP(\lambda)}{(\lambda - \mu)^2 + \nu^2}.$$

Integrate both sides from λ_1 to λ_2 with respect to μ.

$$\int_{\lambda_1}^{\lambda_2} \operatorname{Im} M(\mu + i\nu)\, d\mu = \int_{\lambda_1}^{\lambda_2} \int_{-\infty}^{\infty} \frac{\nu\, dP(\lambda)}{(\lambda - \mu)^2 + \nu^2}\, d\mu$$

$$= \int_{-\infty}^{\infty} \left[\tan^{-1}\left(\frac{\lambda_2 - \lambda}{\nu}\right) - \tan^{-1}\left(\frac{\lambda_1 - \lambda}{\nu}\right) \right] dP(\lambda).$$

Let ν approach 0 from above, we obtain

$$\lim_{\nu \to 0+} \int_{\lambda_1}^{\lambda_2} \operatorname{Im} M(\mu + i\nu)\, d\mu = \pi \int_{\lambda_1}^{\lambda_2} dP(\lambda) = \pi[P(\lambda_2) - P(\lambda_1)].$$

To validate the second part, note

$$\operatorname{Im}[M(\lambda_0) - M(\lambda_1)] = \int_{-\infty}^{\infty} \left[\frac{\nu_2}{|\lambda - \lambda_2|^2} - \frac{\nu_1}{|\lambda - \lambda_1|^2} \right] dP(\lambda)$$

$$= \operatorname{Im} \int_{-\infty}^{\infty} \left[\frac{(\lambda - \lambda_2)^*}{|\lambda - \lambda_2|^2} - \frac{(\lambda - \lambda_1)^*}{|\lambda - \lambda_1|^2} \right] dP(\lambda)$$

$$= \operatorname{Im} \int_{-\infty}^{\infty} [(\lambda - \lambda_2)^{-1} - (\lambda - \lambda_1)^{-1}]\, dP(\lambda).$$

We therefore have two functions, analytic in λ_1 and λ_2, whose imaginary parts are equal. The real parts can only differ by a constant. Letting $\lambda_2 = \lambda_1$ shows this constant to be zero.

16. The spectral resolution. We connect the result of the preceding sections to the representation of the identity as an integral generated by a projection valued measure E_λ. Given

$$F(x) = \int_{-\infty}^{\infty} \phi(x, \lambda)\, dP(\lambda) G(\lambda)$$

where

$$G(\lambda) = \int_a^b \phi^*(\xi, \lambda) A(\xi) F(\xi)\, d\xi,$$

we define

$$E_\lambda F(x) = \int_{-\infty}^{\lambda_+} \phi(x, \lambda)\, dP(\lambda) G(\lambda).$$

Considered the limit of eigenfunction expansions, E_λ can easily be shown to be a projection. It is continuous from above and satisfies $E_{\lambda_1} E_{\lambda_2} = E_{\lambda_1}$ when $\lambda_1 \leqq \lambda_2$, as well as $E_{-\infty} = O$, $E_\infty = I$. If we let $\{\lambda_j\}_{j=-\infty}^{\infty}$ be a partition of $(-\infty, \infty)$, $\lambda_i < \lambda_j$ if $i < j$, and

$$\Delta_j E F(x) = \int_{\lambda_j}^{\lambda_{j+1}} \phi(x, \lambda)\, dP(\lambda) G(\lambda),$$

then $F(x) = \sum_{j=-\infty}^{\infty} \Delta_j E F(x)$. As the mesh $\{\lambda_j\}_{j=-\infty}^{\infty}$ becomes finer, we may write

$$F(x) = \int_{-\infty}^{\infty} dE_\lambda F(x)$$

as the limit of the decomposition above.

If Y is in D, it has the representation

$$Y(x) = \int_{-\infty}^{\infty} \phi(x, \lambda)\, dP(\lambda) G(\lambda)$$

where

$$G(\lambda) = \int_a^b \phi^*(\xi, \lambda) A(\xi) Y(\xi)\, d\xi.$$

Then

$$LY(x) = \int_{-\infty}^{\infty} \lambda \phi(x, \lambda)\, dP(\lambda) G(\lambda).$$

This translates into

$$LY(x) = \int_{-\infty}^{\infty} \lambda\, dE_\lambda Y(x).$$

The resolvent operator also has the standard representation. If λ_0 is complex,

$$(L - \lambda_0 I)^{-1} F(x) = \int_{-\infty}^{\infty} \frac{1}{\lambda - \lambda_0}\, dE_\lambda F(x).$$

It is apparent that λ_0 is in the spectrum of L if and only if it is in the support of dE_λ or $dP(\lambda)$.

17. Examples. (1) Consider the two-dimensional system

$$\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}' = \left[\lambda \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 \\ 0 & (x^2 - 1)^{-1} \end{pmatrix} \right] \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}$$

on the interval $[0, 1)$, together with boundary conditions

$$O: \quad (1, 0) \begin{pmatrix} y_1(0) \\ y_2(0) \end{pmatrix} = 0$$

or

$$E: \quad (0, 1) \begin{pmatrix} y_1(0) \\ y_2(0) \end{pmatrix} = 0$$

at $x=0$, and

$$\lim_{x\to 1}(1,0)\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}\begin{pmatrix}y_1(x)\\ y_2(x)\end{pmatrix}=0$$

at $x=1$.

The differential system is equivalent to the Legendre differential equation. With the O boundary condition, the odd polynomial boundary value problem is generated. With the E boundary condition, the even polynomial boundary value problem arises. The boundary condition at $x=1$ is the one satisfied by the Legendre polynomials. $x=1$ is limit circle.

(2) Consider the four-dimensional system

$$\begin{pmatrix}0&0&-1&0\\0&0&0&-1\\1&0&0&0\\0&1&0&0\end{pmatrix}\begin{pmatrix}y_1\\y_2\\y_3\\y_4\end{pmatrix}'=\left[\lambda\begin{pmatrix}1&0&0&0\\0&0&0&0\\0&0&0&0\\0&0&0&0\end{pmatrix}+\begin{pmatrix}0&0&0&0\\0&-2(1-x^2)&1&0\\0&0&0&0\\0&0&0&(1-x^2)^{-2}\end{pmatrix}\right]\begin{pmatrix}y_1\\y_2\\y_3\\y_4\end{pmatrix}$$

on the interval $[0,1)$, together with boundary conditions

$$O:\quad (1,0,0,0)\begin{pmatrix}y_1(0)\\y_2(0)\\y_3(0)\\y_4(0)\end{pmatrix}=0,\qquad (0,0,0,1)\begin{pmatrix}y_1(0)\\y_2(0)\\y_3(0)\\y_4(0)\end{pmatrix}=0$$

or

$$E:\quad (0,1,0,0)\begin{pmatrix}y_1(0)\\y_2(0)\\y_3(0)\\y_4(0)\end{pmatrix}=0,\qquad (0,0,1,0)\begin{pmatrix}y_1(0)\\y_2(0)\\y_3(0)\\y_4(0)\end{pmatrix}=0$$

at $x=0$, and

$$\lim_{x\to 1}(\ln(1+x),(1+x)^{-1},0,-(1-x)^2)\begin{pmatrix}0&0&-1&0\\0&0&0&-1\\1&0&0&0\\0&1&0&0\end{pmatrix}\begin{pmatrix}y_1\\y_2\\y_3\\y_4\end{pmatrix}=0,$$

$$\lim_{x\to 1}(1,0,0,0)\begin{pmatrix}0&0&-1&0\\0&0&0&-1\\1&0&0&0\\0&1&0&0\end{pmatrix}\begin{pmatrix}y_1\\y_2\\y_3\\y_4\end{pmatrix}=0$$

where, at $x=1$, the limit-4 case holds, and for $\lambda=0$, $(1,0,0,0)^T$, and $(\ln(1+x),(1+x)^{-1},0,-(1-x)^2)^T$ are L^2 solutions. The problem with O boundary conditions is again the odd-degree Legendre polynomial boundary value problem. With E boundary conditions, the even-degree Legendre polynomial value problem is the result.

(3) Consider the fourth-order scalar problem $(y'')''=\lambda y$ on $[0,\infty)$, together with boundary conditions $y(0)=0$, $y'''(0)=0$. ∞ is limit point, so no boundary condition at ∞ is required.

Let $y_1 = y$, $y_2 = y'$, $y_3 = -y'''$, $y_4 = y''$; then the problem is equivalent to

$$\begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{pmatrix}' = \left[\lambda \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \right] \begin{pmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{pmatrix},$$

with boundary condition

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{pmatrix} (0) = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}.$$

The initial condition for the fundamental matrix is

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}.$$

The components of the four 4×1 matrices that makes its columns are combinations of $\sinh z_0 x$, $\cosh z_0 x$, and $\cos z_0 x$, where $z_0 = \lambda^{1/4}$. Multiplying the fundamental matrix by

$$\begin{pmatrix} I_2 \\ M \end{pmatrix}$$

and requiring the result to be in $L_A^2(0, \infty)$ shows that

$$M = \begin{pmatrix} z_0^3(1+i)/2 & z_0(1-i)/2 \\ z_0(-i+1)/2 & (1+i)/2z_0 \end{pmatrix}.$$

As $\lambda = z_0^4$ approaches the positive real axis,

$$\operatorname{Im} M \to \begin{pmatrix} \lambda^{3/4}/2 & -\lambda^{1/4}/2 \\ -\lambda^{1/4}/2 & 1/2\lambda^{1/4} \end{pmatrix}.$$

As λ approaches the negative real axis, $\operatorname{Im} M \to 0$. Consequently,

$$dP(\lambda) = \frac{1}{\pi} \begin{pmatrix} \lambda^{3/4}/2 & \lambda^{1/4}/2 \\ -\lambda^{1/4}/2 & 1/2\lambda^{1/4} \end{pmatrix} d\lambda, \qquad \lambda \geqq 0.$$

Elements in $L_A^2(0, \infty)$ are dependent only on their first component, so $F = (f(x), 0, 0, 0)^T$. Then

$$G(\lambda) = \frac{1}{2\lambda^{3/4}} \int_0^\infty \begin{pmatrix} \sin \lambda^{1/4} \xi \\ -\lambda^{1/2} \sin \lambda^{1/4} \xi \end{pmatrix} f(\xi)\, d\xi,$$

$$F(x) = \begin{pmatrix} \dfrac{2}{\pi} \displaystyle\int_0^\infty \sin \mu x \left[\int_0^\infty \sin \mu \xi f(\xi)\, d\xi \right] d\mu \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

where we have replaced λ by μ^4. This is the Fourier sine expansion.

18. Subspace expansions. At the beginning the assumption $JY' - BY = AF$, $AY = 0$ implies $Y = 0$ was made. We would like to briefly comment on what occurs if the assumption fails to hold.

First A must be singular. Thus if F is in the maximal domain: $JF' - BF = AH$, the dimension of AH is less than $2n$. If function $\gamma_1, \cdots, \gamma_{2n}$ is chosen so that

$$(\gamma_1, \cdots, \gamma_{2n})A = 0,$$

then

$$(\gamma_1, \cdots, \gamma_{2n})(JF' - BF) = 0.$$

Letting $(\gamma_1, \cdots, \gamma_{2n})J = K$, $(\gamma_1, \cdots, \gamma_{2n})B = L$, we have $K_jF_j' - L_jF_j = 0, j = 1, \cdots, 2n$.

Three possibilities occur:

(1) If $K_j \neq 0$, $F_j = c_j \exp \int_a^x (L_j/K_j)\, d\xi$.

(2) If $K_j = 0$, $L_j = 0$, F_j is arbitrary.

(3) If $K_j = 0$, $L_j \neq 0$, $F_j = 0$.

Since not all $K_j = 0$, F_j is restricted and may not be dense in $L_A^2(a, b)$.

We provide two examples to illustrate. First consider

$$\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} y_1 \\ y_2 \end{pmatrix}' = \lambda \begin{pmatrix} 4 & -1 \\ -1 & 1/4 \end{pmatrix}\begin{pmatrix} y_1 \\ y_2 \end{pmatrix} + \begin{pmatrix} 4 & -1 \\ -1 & 1/4 \end{pmatrix}\begin{pmatrix} f_1 \\ f_2 \end{pmatrix}.$$

The fundamental matrix is

$$Y(x, \lambda) = \begin{pmatrix} 1 - \lambda x & 1/4\lambda x \\ -4\lambda x & 1 + \lambda x \end{pmatrix}.$$

Elements in $L_A^2(0, 1)$ have an inner product

$$\left\langle \begin{pmatrix} f_1 \\ f_2 \end{pmatrix}, \begin{pmatrix} g_1 \\ g_2 \end{pmatrix} \right\rangle = \int_0^1 (\bar{g}_1, \bar{g}_2)\begin{pmatrix} 4 & -1 \\ -1 & 1/4 \end{pmatrix}\begin{pmatrix} f_1 \\ f_2 \end{pmatrix} d\xi;$$

an element is zero if $2f_1 = \frac{1}{2}f_2$.

If boundary conditions

$$(1, 0)\begin{pmatrix} y_1 \\ y_2 \end{pmatrix}(0) = 0, \qquad (0, 1)\begin{pmatrix} y_1 \\ y_2 \end{pmatrix}(1) = 0$$

are imposed, there is only one eigenvalue $\lambda = -1$ and one eigenfunction

$$\begin{pmatrix} y_1 \\ y_2 \end{pmatrix} = \begin{pmatrix} -(1/4)x \\ 1 - x \end{pmatrix}.$$

The solution ϕ is

$$\begin{pmatrix} (1/4)\lambda x \\ 1 + \lambda x \end{pmatrix},$$

so for $F = \binom{f_1}{f_2}$,

$$G(\lambda) = \int_0^1 \left(-f_1 + \frac{1}{4} f_2 \right) d\xi.$$

dP is zero unless $\lambda = -1$. $dP(-1) = 4$. So

$$F(x) = \begin{pmatrix} -(1/4)x \\ 1 - x \end{pmatrix} \cdot 4 \cdot \int_0^1 \left(-f_1 + \frac{1}{4} f_2 \right) d\xi.$$

Clearly this is one-dimensional. In fact, elements in the maximal domain are of the form $\binom{c}{0}$, where c is constant. Such elements are equivalent to the eigenfunction

$$\begin{pmatrix} -(1/4)x \\ 1-x \end{pmatrix}.$$

Only these can be expanded.

Second, consider

$$\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} y_1 \\ y_2 \end{pmatrix}' = \left[\lambda\begin{pmatrix} e^{-x} & -1 \\ -1 & e^{x} \end{pmatrix}\right]\begin{pmatrix} y_1 \\ y_2 \end{pmatrix} + \begin{pmatrix} e^{-x} & -1 \\ -1 & e^{x} \end{pmatrix}\begin{pmatrix} f_1 \\ f_2 \end{pmatrix},$$

$$(1,0)\begin{pmatrix} y_1 \\ y_2 \end{pmatrix}(0) = 0, \qquad (0,1)\begin{pmatrix} y_1 \\ y_2 \end{pmatrix}(1) = 0.$$

The only eigenvalue is at $\lambda = (1-e)^{-1}$. Its eigenvector is

$$\begin{pmatrix} [e^{x}-1]/[1-e] \\ [1-ee^{-x}]/[1-e] \end{pmatrix}.$$

If

$$\begin{pmatrix} f_1 \\ f_2 \end{pmatrix}$$

is an element of $L_A^2(0,1)$, then

$$G(\lambda) = \int_0^1 (-e^{-\xi}f_1 + f_2)\, d\xi.$$

dP is zero except at $\lambda = (1-e)^{-1}$, where it is $e/(1-e)$. Thus if

$$F(x) = \begin{pmatrix} f_1 \\ f_2 \end{pmatrix}$$

is in the maximal domain, D_M,

$$F(x) = \begin{pmatrix} [(e^{x}-1]/[1-e] \\ [1-ee^{x}]/[1-e] \end{pmatrix}\begin{pmatrix} e \\ 1-e \end{pmatrix}\int_0^1 (-e^{-\xi}f_1 + f_2)\, d\xi.$$

A quick calculation shows that elements in D_M have the form $\binom{c}{0}$, where c is constant. Arbitrary elements in $L_A^2(0,1)$ have the form

$$\begin{pmatrix} f_1 - e^{x}f_2 \\ 0 \end{pmatrix},$$

so D_M is not dense.

$M(\lambda)$ THEORY FOR SINGULAR HAMILTONIAN SYSTEMS WITH TWO SINGULAR POINTS*

ALLAN M. KRALL†

Abstract. The $2n$-dimensional Hamiltonian system $JY' = (\lambda A + B)Y$ on an interval (a, b) is considered, where both a and b are singular points. A Green's function is derived using separated singular boundary conditions, and it is used to show that the singular boundary value problem consisting of the differential equation and boundary conditions is self-adjoint. Then a doubly singular version of Green's formula is derived and all self-adjoint boundary value problems arising from the differential equation are characterized. Finally, the spectral measure, generalized Fourier transform of an arbitrary function and its inverse transform for the original boundary value problem with separated boundary conditions are derived.

Key words. single boundary value problem, Sturm-Liouville problem, spectral resolution

AMS(MOS) subject classifications. 34B05, 34B20, 34B25

1. Introduction. The present paper follows up on our earlier work [11], which discussed linear Hamiltonian boundary value problems with one singular point. Our purpose here is to state the results for doubly singular problems and to give proofs where necessary. But where verifications closely parallel the single singular point development, we will merely refer to the proofs given in [11].

We refer to [11] or to [4] for a lengthy development of the history of the problem. We would be remiss, however, if we did not mention those works that had the most direct impact on what follows. Kodaira (see [3]) and Coddington and Levinson [3], [10] developed the theory of singular scalar differential operators of nth order. Many further details, as well as other results, were worked out by Everitt (see [11]). The notation and general techniques for systems were developed by Atkinson [1]. Following Atkinson's lead, Hinton and Shaw [6]-[8] made major advances. The present work uses the results of these authors extensively throughout. It is virtually impossible to give full credit to them where warranted, because their influence is so widespread. We are sure, however, that those who read on will recognize where their contributions appear. Without them this current version could not have been written.

We follow the footsteps of Atkinson [1] and Hinton and Shaw [6]-[8] by considering the $2n$-dimensional system $JY' = (\lambda A + B)Y$ over an interval (a, b) where both a and b are singular points. Our procedure is to first consider a problem on $[a', b']$ where $a < a' < b' < b$, then permit a' to approach a, b' to approach b.

The first problem we encounter is the verification of the existence of solutions that are in $L_A^2(a, c)$ and $L_A^2(c, b)$, $a < c < b$, where the Hilbert spaces L_A^2 are generated by

$$\langle Y, Z\rangle = \int Z^* A Y \, dt.$$

For $\operatorname{Im}\lambda \neq 0$ it can be shown that there exist at least n L_A^2-solutions toward a and toward b. By using these solutions appropriately, we can construct a Green's function

* Received by the editors May 18, 1987; accepted for publication (in revised form) August 9, 1988. This work was supported by the Applied Mathematical Sciences subprogram of the Office of Energy Research, U.S. Department of Energy, under contract W-31-109-Eng-38.

† Department of Mathematics, McAllister Building, Pennsylvania State University, University Park, Pennsylvania 16802.

with which we can develop a second problem to determine the self-adjointness of a differential operator related to $JY' - BY$ in $L_A^2(a, b)$.

Using the Green's function appropriately enables us to develop a singular Green's formula. This in turn permits us to determine other problems, possibly with mixed boundary conditions, that are self-adjoint in $L_A^2(a, b)$. Finally, employing the regular eigenfunction expansion over an interval $[a', b']$, we follow the lead of Coddington and Levinson [3] to develop the spectral resolution for a doubly singular problem with separated boundary conditions. Brauer [2] has developed the broader theory for mixed boundary problems.

2. Notation and definitions. We consider over an interval (a, b) the differential expression

$$(*) \qquad JY' = (\lambda A + B)Y,$$

where Y is of dimension $2n$ (a $2n \times 1$ matrix),

$$J = \begin{Bmatrix} 0 & -I_n \\ I_n & 0 \end{Bmatrix}, \qquad A = \begin{Bmatrix} A_{11}(x) & A_{12}(x) \\ A_{21}(x) & A_{22}(x) \end{Bmatrix}, \qquad B = \begin{Bmatrix} B_{11}(x) & B_{12}(x) \\ B_{21}(x) & B_{22}(x) \end{Bmatrix}$$

are locally integrable $2n \times 2n$ matrices, $A = A^* \geqq 0$, $B = B^*$. We will assume that both a and b are singular points; that is, either or both a and b may be infinite. Neither A nor B is necessarily integrable in a neighborhood of a or b. Our setting is $L_A^2(a, b)$, the Hilbert space generated by the inner product

$$\langle Y, Z \rangle = \int_a^b Z^* A Y \, dt.$$

To ensure that elements of the maximal operator are dense in $L_A^2(a, b)$, we assume that if $JY' - BY = AF$ and $AY = 0$, then $Y = 0$.

As a preliminary step we consider $(*)$ over a subinterval $[a', b']$, $a < a' < b' < b$, and impose at a' and b' the separated regular self-adjoint boundary conditions

$$(\alpha_1, \alpha_2) Y(a') = 0, \qquad (\beta_1, \beta_2) Y(b') = 0,$$

where $\alpha_1, \alpha_2, \beta_1, \beta_2$ are $n \times n$ matrices satisfying

$$\begin{aligned} &\operatorname{rank}(\alpha_1, \alpha_2) = n, && \operatorname{rank}(\beta_1, \beta_2) = n, \\ &\alpha_1 \alpha_1^* + \alpha_2 \alpha_2^* = I_n, && \beta_1 \beta_1^* + \beta_2 \beta_2^* = I_n, \\ &\alpha_1 \alpha_2^* - \alpha_2 \alpha_1^* = 0, && \beta_1 \beta_2^* - \beta_2 \beta_1^* = 0. \end{aligned}$$

Equation $(*)$, together with these boundary conditions, defines a regular self-adjoint boundary value problem over $[a', b']$.

Finally, let c be in $[a', b']$, and let $\mathcal{Y}(x, \lambda)$ be a fundamental matrix for $(*)$ satisfying $\mathcal{Y}(c, \lambda) = I_{2n}$. We decompose into $2n \times n$ matrices θ and ϕ such that $\mathcal{Y}(x, \lambda) = (\theta(x, \lambda), \phi(x, \lambda))$.

3. $M(\lambda)$ functions, limit circles, L^2 solutions. If $\operatorname{Im} \lambda \neq 0$, we attempt to satisfy the b' boundary condition by $\chi_{b'}(x, \lambda) = \theta(x, \lambda) + \phi(x, \lambda) M_{b'}(\lambda)$. Insertion into $(\beta_1, \beta_2) Y(b') = 0$ shows that

$$M_{b'}(\lambda) = -[(\beta_1, \beta_2)\phi(b', \lambda)]^{-1}[(\beta_1, \beta_2)\theta(b', \lambda)].$$

The inverse must exist, for otherwise the boundary value problem of $(*)$, the b' boundary condition, and the c boundary condition $(I_n, 0) Y(c) = 0$ would be self-adjoint, but would have a complex eigenvalue.

The circle equation, satisfied by $M_{b'}$, is $\pm\chi_{b'}(b',\lambda)^*(J/i)\chi_{b'}(b',\lambda)=0$. If at b', we let

$$\begin{pmatrix}\mathscr{A} & \mathscr{B}^*\\ \mathscr{B} & \mathscr{D}\end{pmatrix}=\begin{matrix}\mathscr{Y}^*(J/i)\mathscr{Y}, & \operatorname{Im}\lambda>0,\\ -\mathscr{Y}^*(J/i)\mathscr{Y}, & \operatorname{Im}\lambda<0,\end{matrix}$$

the circle equation can be written as

$$(I_n, M_{b'}^*)\begin{pmatrix}\mathscr{A} & \mathscr{B}^*\\ \mathscr{B} & \mathscr{D}\end{pmatrix}\begin{pmatrix}I_n\\ M_{b'}\end{pmatrix}=0.$$

Expanded, this is

$$M_{b'}^*\mathscr{D}M_{b'}+M_{b'}^*\mathscr{B}+\mathscr{B}^*M_{b'}+\mathscr{A}=0.$$

It is possible to show that

$$\mathscr{A}=\pm\theta^*(b')(J/i)\theta(b'),$$

$$\mathscr{B}=\pm\phi^*(b')(J/i)\theta(b')=\pm\left[2\operatorname{Im}\lambda\int_c^{b'}\phi^*A\theta\,dt-iI_n\right],$$

$$\mathscr{D}=\pm\phi^*(b')(J/i)\phi(b')=\pm\left[2\operatorname{Im}\lambda\int_c^{b'}\phi^*A\phi\,dt\right].$$

If $R_1=\mathscr{D}^{-1/2}$, $R_2=R_1(\bar\lambda)$, and $C=-\mathscr{D}^{-1}\mathscr{B}$, then $M_{b'}=C+R_1U_bR_2$, where U_b is any unitary matrix. As b' approaches b, C, R_1, and R_2 have limits C_b, R_b, $\tilde R_b$, giving M_b.

It is shown in [11] that as b' approaches b, $M_{b'}$ can be made to approach $M_b=C_b+R_bU_b\tilde R_b$, where

$$C_b=\lim_{b'\to b}\left[2\operatorname{Im}\lambda\int_c^{b'}\phi^*A\phi\,dt\right]^{-1}\left[2\operatorname{Im}\lambda\int_c^{b'}\phi^*A\theta\,dt-iI_n\right],$$

$$R_b=\lim_{b'\to b}\left[2\,|\operatorname{Im}\lambda|\int_c^{b}\phi^*A\phi\,dt\right]^{-1/2},\qquad \tilde R_b(\lambda)=R_b(\bar\lambda),$$

and $U_b(\lambda)$ is a unitary matrix.

It is further shown that if $\chi_b(x,\lambda)=\theta(x,\lambda)+\phi(x,\lambda)M_b(\lambda)$, then

$$\int_c^b\chi_b^*A\chi_b\,dt\leqq[M_b-M_b^*]/2\operatorname{Im}\lambda.$$

For $\chi_b(x,\lambda)$ and $\chi_b(x,\mu)$, $\operatorname{Im}\lambda\neq0$, $\operatorname{Im}\mu\neq0$, we have

$$\lim_{x\to b}\chi_b(x,\mu)^*J\chi_b(x,\lambda)=0.$$

Note that for all λ, $\operatorname{Im}\lambda\neq0$,

$$\frac{\operatorname{Im}M_b}{\operatorname{Im}\lambda}=\frac{M_b-M_b^*}{2i\operatorname{Im}\lambda}>0.$$

Similarly, we attempt to satisfy the a' boundary conditions by $\chi_{a'}(x,\lambda)=\theta(x,\lambda)+\phi(x,\lambda)M_{a'}(\lambda)$. Insertion into $(\alpha_1,\alpha_2)Y(a')=0$ shows that

$$M_{a'}=-[(\alpha_1,\alpha_2)\phi(a')]^{-1}[(\alpha_1,\alpha_2)\theta(a')],$$

where, again, the inverse must exist.

The circle equation, satisfied by $M_{a'}$, is $\pm\chi_{a'}(a',\lambda)^*(J/i)\chi_{a'}(a',\lambda)=0$. If at a', we let

$$\begin{pmatrix}\mathscr{A} & \mathscr{B}^*\\ \mathscr{B} & \mathscr{D}\end{pmatrix}=\begin{matrix}-\mathscr{Y}^*(J/i)\mathscr{Y}, & \operatorname{Im}\lambda>0,\\ \mathscr{Y}^*(J/i)\mathscr{Y}, & \operatorname{Im}\lambda<0,\end{matrix}$$

the circle equation can be rewritten as

$$(I_n, M_{a'}^*)\begin{pmatrix}\mathscr{A} & \mathscr{B}\\ \mathscr{B} & \mathscr{D}\end{pmatrix}\begin{pmatrix}I_n\\ M_{a'}\end{pmatrix}=0.$$

Expanded, this is again

$$M_{a'}^*\mathscr{D}M_{a'}+M_{a'}^*\mathscr{B}+\mathscr{B}^*M_{a'}+\mathscr{A}=0.$$

It is possible to show that

$$\mathscr{A}=\pm\theta^*(a')(J/i)\theta(a'),$$

$$\mathscr{B}=\pm\phi^*(a')(J(i)\theta(a'))=\pm\left[2\operatorname{Im}\lambda\int_{a'}^{c}\phi^*A\theta\,dt+iI_n\right],$$

$$\mathscr{D}=\pm\phi^*(a')(J(i)\phi(a'))=\pm\left[2\operatorname{Im}\lambda\int_{a'}^{c}\phi^*A\phi\,dt\right].$$

If $R_1=\mathscr{D}^{1/2}$, $R_2=R_1(\bar\lambda)$ and $C=-\mathscr{D}^{-1}\mathscr{B}$, then $M_{a'}=C+R_1U_aR_2$, where U_a is any unitary matrix. As a' approaches a, C, R_1 and R_2 have limits C_a, R_a, $\tilde R_a$, giving M_a.

As a' approaches a, $M_{a'}$ can be made to approach $M_a=C_a+R_aU_a\tilde R_a$ where

$$C_a=\lim_{a'\to a}-\left[2\operatorname{Im}\lambda\int_a^c\phi^*A\phi\,dt\right]^{-1}\left[2\operatorname{Im}\lambda\int_{a'}^{c}\phi^*A\theta\,dt+iI_n\right],$$

$$R_a=\lim_{a'\to a}\left[2|\operatorname{Im}\lambda|\int_{a'}^{c}\phi^*A\phi\,dt\right]^{-1/2},\qquad \tilde R_a=R_a(\bar\lambda),$$

and U_a is a perhaps different, unitary matrix.

With $\chi_a(x,\lambda)=\theta(x,\lambda)+\phi(x,\lambda)M_a(\lambda)$, it is also true that

$$\int_a^c\chi_a^*A\chi_a\,dt\leqq[M_a^*-M_a]/2i\operatorname{Im}\lambda.$$

For $\chi_a(x,\lambda)$ and $\chi_a(x,\mu)$, $\operatorname{Im}\lambda\neq0$, $\operatorname{Im}\mu\neq0$, we have

$$\lim_{x\to a}\chi_a(x,\mu)^*J\chi_a(x,\lambda)=0.$$

Note that

$$\frac{\operatorname{Im}M_a}{\operatorname{Im}\lambda}=\frac{M_a-M_a^*}{2i\operatorname{Im}\lambda}<0.$$

We will require some facts concerning $M_a(\lambda)$ and $M_b(\lambda)$.

THEOREM 3.1. *For all* λ, $\operatorname{Im}\lambda\neq0$,

(a) $M_a(\lambda)\neq M_b(\lambda)$, $[\operatorname{Im}\lambda][M_a(\lambda)-M_b(\lambda)]<0$;

(b) $M_a(\lambda)=M_a(\bar\lambda)^*$, $M_b(\lambda)=M_b(\bar\lambda)^*$;

(c) $M_b(\lambda)$, $M_b(\lambda)$, $M_a(\lambda)-M_b(\lambda)$ *are all invertible*;

(d) $M_0(\lambda)[M_a(\lambda)-M_b(\lambda)]^{-1}M_a(\lambda)=M_a(\lambda)[M_a(\lambda)-M_b(\lambda)]^{-1}M_b(\lambda)$.

Proof. The second part follows from the statements

$$\lim_{x\to a}\chi_a(x,\mu)^*J\chi_a(x,\lambda)=0,$$

$$\lim_{x\to b}\chi_b(x,\mu)^*J\chi_b(x,\lambda)=0,$$

letting $\mu = \bar{\lambda}$. The third follows from noting that for any matrices $M = A + iB$, with $M^* = A - iB$, we have $A = (M + M^*)/2$ and $B = (M - M)^*/2i$. If $B > 0$ or $B < 0$, then M is nonsingular. Suppose M is singular. Then there exists an eigenvector v such that $Mv = 0$. This implies $0 = v^*Mv = v^*Av + iv^*Bv$. Since $B > 0$ or $B < 0$, iv^*Bv is imaginary, while v^*Av is real. This is impossible.

The fourth is an easy computation.

4. The differential operator. From an extension of a theorem of Everitt [5], we know that the number of solutions of (*) in $L^2_A(a, b)$ is invariant provided $\operatorname{Im} \lambda > 0$ or $\operatorname{Im} \lambda < 0$. It is possible, however, for the deficiency indices to be unequal. Only when both ends a and b are limit circle (all solutions in $L^2_A(a, b)$ for all λ), or when A and B are real, are they guaranteed to be equal. Here we must assume the deficiency indices are equal.

DEFINITION 4.1. We denote by D_M those elements Y in $L^2_A(a, b)$ satisfying

$$lY = JY' - BY = AF \tag{1}$$

exists almost everywhere for some F in $L^2_A(a, b)$.

DEFINITION 4.2. We define the maximal operator L_M by setting $L_M Y = F$ for all Y in D_M.

THEOREM 4.3. *Let Y_j be a solution of*

$$JY_j' = (\bar{\lambda}A + B)Y_j, \qquad \operatorname{Im} \lambda \neq 0.$$

Then for all Y in D_M,

$$B_{a_j}(Y) = \lim_{x \to a} Y_j^* JY$$

exists if and only if Y_j is in $L^2_A(a, c)$,

$$B_{b_j}(Y) = \lim_{x \to b} Y_j^* JY$$

exists if and only if Y_j is in $L^2_A(c, b)$.

DEFINITION 4.4. Let $\operatorname{Im} \lambda \neq 0$. Let $M_a(\bar{\lambda}) = \tilde{C}_a + \tilde{R}_a U_a R_a$ be on the limit circle at a. Let $\chi_a(x, \bar{\lambda}) = \theta(x, \bar{\lambda}) + \phi(x, \bar{\lambda}) M_a(\bar{\lambda})$ satisfy (*) with λ replaced by $\bar{\lambda}$ and be in $L^2_A(a, c)$. Let $M_b(\bar{\lambda}) = \tilde{C}_b + \tilde{R}_b U_b R_b$ be on the limit circle at b. Let $\chi_b(x, \bar{\lambda}) = \theta(x, \bar{\lambda}) + \phi(x, \bar{\lambda}) M_b(\bar{\lambda})$ satisfy (*) with λ replaced by $\bar{\lambda}$ and be in $L^2_A(c, b)$. We define the boundary values $B_a(Y)$ and $B_b(Y)$ by setting

$$B_a(Y) = \lim_{x \to a} \chi_a(x, \bar{\lambda})^* JY(x),$$

$$B_b(Y) = \lim_{x \to b} \chi_b(x, \bar{\lambda})^* JY(x),$$

for all Y in D_M.

Note that $\bar{\lambda}$ is used in the definition. This is for convenience only and will be removed later.

DEFINITION 4.5. We denote by D those elements Y in $L^2_A(a, b)$ satisfying (1) $l(Y) = JY' - BY = AF$ exists almost everywhere for some F in $L^2_A(a, b)$; (2) $B_a(Y) = 0$; (3) $B_b(Y) = 0$, for some fixed λ, $\operatorname{Im} \lambda \neq 0$.

DEFINITION 4.6. We define the operator L by setting $LY = F$ for all Y in D.

5. The resolvent, the Green's function. The inverse of $(L - \lambda I)$ can be calculated with ease. We solve (*) together with the two boundary conditions. If we set $Y = \mathcal{Y}C$, variation of parameters shows $C' = -J\mathcal{Y}^* AF$, where $\mathcal{Y}'(x, \lambda) = \mathcal{Y}(x, \bar{\lambda})^*$. Thus

$$Y(x) = -\mathcal{Y}(x, \lambda) \int_c^x J\mathcal{Y}'(\xi, \lambda) A(\xi) F(\xi)\, d\xi + \mathcal{Y}(x, \lambda) K.$$

We multiply by

$$\begin{pmatrix} \chi_b^t \\ 0 \end{pmatrix} J,$$

so

$$\begin{pmatrix} \chi_b^t \\ 0 \end{pmatrix} JY(x) = -\begin{pmatrix} \chi_b^t \\ 0 \end{pmatrix} JY \int_c^x JY^t AF\, d\xi + \begin{pmatrix} \chi_b^t \\ 0 \end{pmatrix} JYK.$$

Now

$$\begin{pmatrix} \chi_b^t \\ 0 \end{pmatrix} JY$$

is constant. At $x = c$,

$$\begin{pmatrix} \chi_b^t \\ 0 \end{pmatrix} JY = \begin{pmatrix} M_b^t & -I_n \\ 0 & 0 \end{pmatrix}.$$

Thus

$$\begin{pmatrix} \chi_b^t \\ 0 \end{pmatrix} JY(x) = \int_c^x \begin{pmatrix} \chi_b^t \\ 0 \end{pmatrix} AF\, d\xi + \begin{pmatrix} M_b^t & -I_n \\ 0 & 0 \end{pmatrix} K.$$

Letting $x \to b$, we get

$$0 = \int_c^b \begin{pmatrix} \chi_b^t \\ 0 \end{pmatrix} AF\, d\xi + \begin{pmatrix} M_b & -I_n \\ 0 & 0 \end{pmatrix} K.$$

Note that the integral exists since χ_b is in $L_A^2(c, b)$.

Now return to Y and multiply by

$$\begin{pmatrix} 0 \\ \chi_a^t \end{pmatrix} J.$$

Then

$$\begin{pmatrix} 0 \\ \chi_a^t \end{pmatrix} JY(x) = \begin{pmatrix} 0 \\ \chi_a^t \end{pmatrix} J\mathcal{Y} \int_x^c J\mathcal{Y}^t AF\, d\xi + \begin{pmatrix} 0 \\ \chi_a^t \end{pmatrix} J\mathcal{Y}K.$$

Now

$$\begin{pmatrix} 0 \\ \chi_a^t \end{pmatrix} J\mathcal{Y}$$

is constant. At $x = c$

$$\begin{pmatrix} 0 \\ \chi_a^t \end{pmatrix} J\mathcal{Y} = \begin{pmatrix} 0 & 0 \\ M_a^t & -I_n \end{pmatrix}.$$

Thus

$$\begin{pmatrix} 0 \\ \chi_a^t \end{pmatrix} JY(x) = -\int_x^c \begin{pmatrix} 0 \\ \chi_a^t \end{pmatrix} AF\, d\xi + \begin{pmatrix} 0 & 0 \\ M_a^t & -I_n \end{pmatrix} K.$$

Letting $x \to a$, we get

$$0 = -\int_a^c \begin{pmatrix} 0 \\ \chi_a^t \end{pmatrix} AF\, d\xi + \begin{pmatrix} 0 & 0 \\ M_a^t & -I_n \end{pmatrix} K.$$

Again the integral exists since χ_a is in $L_A^2(a, c)$.

Add the two limit equations together to get

$$0=\int_c^b \begin{pmatrix} \chi_b^t \\ 0 \end{pmatrix} AF\,d\xi - \int_a^c \begin{pmatrix} 0 \\ \chi_a^t \end{pmatrix} AF\,d\xi + \begin{bmatrix} M_b^t & -I_n \\ M_a^t & -I_n \end{bmatrix} K.$$

The coefficient of K is nonsingular, yielding

$$K=\begin{bmatrix} (M_a-M_b)^{-1} & -(M_a-M_b)^{-1} \\ M_a(M_a-M_b)^{-1} & -M_b(M_a-M_b)^{-1} \end{bmatrix} \int_c^{b'} \begin{bmatrix} I_n & M_b^t \\ 0 & 0 \end{bmatrix} \mathcal{Y}^t AF\,d\xi$$
$$-\begin{bmatrix} (M_a-M_b)^{-1} & -(M_a-M_b)^{-1} \\ M_a(M_a-M_b)^{-1} & -M_b(M_a-M_b)^{-1} \end{bmatrix} \int_a^c \begin{pmatrix} 0 & 0 \\ I_n & M_a^t \end{pmatrix} \mathcal{Y}^t AF\,d\xi.$$

Inserting this in Y, we obtain

$$Y(x)=\mathcal{Y}\begin{pmatrix} I_n & 0 \\ M_b & 0 \end{pmatrix}\begin{pmatrix} 0 & (M_a-M_b)^{-1} \\ (M_a-M_b)^{-1} & 0 \end{pmatrix} \int_a^x \begin{pmatrix} 0 & 0 \\ I_n & M_a^t \end{pmatrix} \mathcal{Y}^t AF\,d\xi$$
$$+\mathcal{Y}\begin{pmatrix} 0 & I_n \\ 0 & M_a \end{pmatrix}\begin{pmatrix} 0 & (M_a-M_b)^{-1} \\ (M_a-M_b)^{-1} & 0 \end{pmatrix} \int_x^b \begin{pmatrix} I_n & M_b^t \\ 0 & 0 \end{pmatrix} \mathcal{Y}^t AF\,d\xi.$$

Further computation shows this can be written as

$$Y(x)=\chi_b(x,\lambda)(M_a(\lambda)-M_b(\lambda))^{-1}\int_a^x \chi_a(\xi,\bar{\lambda})^* A(\xi)F(\xi)\,d\xi$$
$$+\chi_a(x,\lambda)(M_a(\lambda)-M_b(\lambda))^{-1}\int_x^b \chi_b(\xi,\bar{\lambda})^* A(\xi)F(\xi)\,d\xi.$$

THEOREM 5.1. *$(L-\lambda I)^{-1}$ is given by*

$$(L-\lambda I)^{-1}F(x)=\int_a^b G(\lambda,x,\xi)A(\xi)F(\xi)\,d\xi,$$

where

$$G(\lambda,x,\xi)=\chi_b(x,\lambda)(M_a(\lambda)-M_b(\lambda))^{-1}\chi_a(\xi,\bar{\lambda})^*, \qquad a<\xi<x<b,$$
$$G(\lambda,x,\xi)=\chi_a(x,\lambda)(M_a(\lambda)-M_b(\lambda))^{-1}\chi_b(\xi,\bar{\lambda})^*, \qquad a<x<\xi<b.$$

THEOREM 5.2. *G is symmetric*

$$G(\lambda,x,\xi)=G(\bar{\lambda},\xi,x)^*.$$

THEOREM 5.3. *$(L-\lambda I)^{-1}$ is bounded*

$$\|(L-\lambda I)^{-1}\|\leqq 1/|\operatorname{Im}\lambda|.$$

THEOREM 5.4. *L is self-adjoint.*

6. Parameter independence of the domain. It appears that D is dependent on the parameter λ used in the boundary conditions. Indeed, the Green's function was only calculated for λ. As shown in [11], however, we can demonstrate that λ may vary with impunity so long as $\operatorname{Im}\lambda\neq 0$.

THEOREM 6.1. *Let Y be in D. Then for all λ, $\operatorname{Im}\lambda\neq 0$, $B_a(Y)=0$, $B_b(Y)=0$.*

THEOREM 6.2. *For all λ, $\operatorname{Im}\lambda\neq 0$, $(L-\lambda I)^{-1}$ exists and is given by* (**)

$$\|(L-\lambda)^{-1}\|\leqq 1/|\operatorname{Im}\lambda|.$$

7. Green's formula. Only minor modifications in the technique used in [11] are needed to express the Lagrange bilinear form Z^*JY properly for insertion into Green's formula. Using the Green's function for the doubly singular problem, we get

$$G(\lambda, x, \xi) = \chi_b(x, \lambda)[M_a(\lambda) - M_b(\lambda)]^{-1}\chi_a(\xi, \bar{\lambda})^*, \qquad a \leqq \xi < x \leqq b,$$

$$G(\lambda, x, \xi) = \chi_a(x, \lambda)[M_a(\lambda) - M_b(\lambda)]^{-1}\chi_b(\xi, \bar{\lambda})^*, \qquad a \leqq x < \xi \leqq b;$$

instead of the one for the previous problem [11]. We set

$$R_Y(x) = \int_a^b G(\lambda x, \xi)A(\xi)F(\xi)\, d\xi.$$

The previous calculation [11] then goes through without change.

Assume that for $\operatorname{Im}\lambda \neq 0$ there are m solutions of $(*)$ in $L_A^2(c, b)$, $a < c < b$. Since n of these are represented by χ_b, the other $m-n$ are linear combinations of columns of ϕ.

THEOREM 7.1. *Let $\phi(x, \lambda) = (\phi_1, \phi_2)(x, \lambda)E_b$, where ϕ_1 consists of all of the $\phi - L_A^2(c, b)$ solutions of $(*)$. Let $\phi(x, \bar{\lambda}) = (\phi_1, \phi_2)(x, \bar{\lambda})\tilde{E}_b$, where ϕ_1 consists of all of the $\phi - L_A^2(c, b)$ solutions of $(*)$ with λ replaced by $\bar{\lambda}$. Let $(\chi_1, \chi_2)(x, \bar{\lambda}) = \chi_b(x, \bar{\lambda})E_b^*$ and let $(\chi_1, \chi_2)(x, \lambda) = \chi_b(x, \lambda)\tilde{E}_b^*$. Then for all Y and Z in D_M,*

$$\lim_{x\to b} \chi_2(x, \bar{\lambda})^*JY(x) = 0, \qquad \lim_{x\to b} \chi_2(x, \lambda)^*JZ(x) = 0.$$

Returning to $\lim_{x\to b} Z(x)^*JY(x)$, we find

$$\lim_{x\to b} Z(x)^*JY(x) = [\lim_{x\to b} \phi_1(x, \lambda)^*JZ(x)]^*[\lim_{x\to b} \chi_1(x, \bar{\lambda})^*JY(x)]$$

$$-[\lim_{x\to b} \chi_1(x, \lambda)^*JZ(x)]^*[\lim_{x\to b} \phi_1(x, \bar{\lambda})^*JY(x)].$$

Hence we formulate the following theorem.

THEOREM 7.2. *Under the conditions of Theorem* 7.1, *let*

$$B_b(Y) = \begin{pmatrix} \lim_{x\to b} \chi_1(x, \bar{\lambda})^*JY(x) \\ \lim_{x\to b} \phi_1(x, \bar{\lambda})^*JY(x) \end{pmatrix},$$

$$\tilde{B}_b(Z) = \begin{pmatrix} \lim_{x\to b} \chi_1(x, \lambda)^*JZ(x), \\ \lim_{x\to b} \phi_1(x, \lambda)^*JZ(x) \end{pmatrix},$$

$$J_b = \begin{pmatrix} 0 & -I_{m-n} \\ I_{m-n} & 0 \end{pmatrix},$$

where (m, m) are the defect indices of $(*)$ at b. Then

$$\lim_{x\to b} Z(x)^*JY(x) = \tilde{B}_b(Z)^*J_bB_b(Y).$$

The symbol $\tilde{}$ indicates λ is used instead of $\bar{\lambda}$.

Assume that for $\operatorname{Im}\lambda \neq 0$, there are p solutions of $(*)$ in $L_A^2(a, c)$, $a < c < b$. Since n of these are represented by χ_a, the other $p-n$ are linear combinations of ϕ.

THEOREM 7.3. *Let* $\phi(x,\lambda)=(\phi_1,\phi_2)(x,\lambda)E_a$, *where* ϕ_1 *consists of all of the* $\phi - L^2_A(a,c)$ *solutions of* $(*)$. *Let* $\phi(x,\bar\lambda)=(\phi_1,\phi_2)(x,\lambda)\tilde E_a$, *where* ϕ_1 *consists of all the* $\phi - L^2_A(a,c)$ *solutions of* $(*)$ *with* λ *replaced by* $\bar\lambda$. *Let* $(\chi_1,\chi_2)(x,\bar\lambda)=\chi_a(x,\bar\lambda)E_a^*$, *and let* $(\chi_1,\chi_2)(x,\lambda)=\chi_a(x,\lambda)\tilde E_a^*$. *Then for all* Y *and* Z *in* D_M,

$$\lim_{x\to a}\chi_2(x,\bar\lambda)^*JY(x)=0, \qquad \lim_{x\to a}\chi_2(x,\lambda)^*JZ(x)=0.$$

THEOREM 7.4. *Under the conditions of Theorem* 7.3, *let*

$$B_a(Y)=\begin{pmatrix}\lim_{x\to a}\chi_1(x,\bar\lambda)^*JY(x)\\ \lim_{x\to a}\phi_1(x,\bar\lambda)^*JY(x)\end{pmatrix},$$

$$\tilde B_a(Z)=\begin{pmatrix}\lim_{x\to a}\chi_1(x,\lambda)^*JZ(x)\\ \lim_{x\to a}\phi_1(x,\lambda)^*JZ(x)\end{pmatrix},$$

$$J_a=\begin{pmatrix}0 & -I_{p-n}\\ I_{p-n} & 0\end{pmatrix},$$

where (p,p) *are the defect indices of* $(*)$ *at* a; *then*

$$\lim_{x\to a}Z^*(x)JY(x)=\tilde B_a(Z)^*J_aB_a^*(Y).$$

Again the symbol $\tilde{}$ indicates λ is used instead of $\bar\lambda$.

The pieces now can be put together to yield

$$\int_a^b\{Z^*[JY'-BY]-[JZ'-BZ]^*Y\}\,dx=(\tilde B_a(Z)^*,\tilde B_b(Z)^*)\begin{pmatrix}-J_a & 0\\ 0 & J_b\end{pmatrix}\begin{pmatrix}B_a(Y)\\ B_b(Y)\end{pmatrix}.$$

If M, N, P, Q are $r\times(2p-2n)$, $r\times(2m-2n)$, $(2m+2p-4n-r)\times(2p-2n)$, and $(2m+2p-4n-r)\times(2m-2n)$ matrices, $0\leqq r\leqq 2m+2p$, and $\tilde M$, $\tilde N$, $\tilde P$, $\tilde Q$ are chosen so that

$$\begin{pmatrix}\tilde M^* & \tilde P^*\\ \tilde N^* & \tilde Q^*\end{pmatrix}\begin{pmatrix}M & N\\ P & Q\end{pmatrix}=\begin{pmatrix}-J_a & 0\\ 0 & J_b\end{pmatrix}.$$

We finally have the following theorem.

THEOREM 7.5 (Green's formula). *Let* Y *and* Z *be in* D_M. *Then*

$$\begin{aligned}\int_a^b&\{Z^*[JY'-BY]-[JZ'-BZ]^*Y\}\,dx\\ &=[\tilde M\tilde B_a(Z)+\tilde NB_b(Z)]^*[MB_a(Y)+NB_b(Y)]\\ &\quad+[\tilde P\tilde B_a(Z)+\tilde QB_b(Z)]^*[PB_a(Y)+QB_b(Y)].\end{aligned}$$

DEFINITION 7.6. We denote by $\tilde D$ those elements Y in $L^2_A(a,b)$ satisfying

(1) Y is in D_M;

(2) $MB_a(Y)+NB_b(Y)=0$.

DEFINITION 7.7. We denote by $\tilde L$ the operator defined by setting $\tilde LY=F$ whenever $JY'-BY=AF$ and Y is in $\tilde D$.

DEFINITION 7.8. We denote by $\tilde D^*$ those elements Z in $L^2_A(a,b)$ satisfying

(1) Z is in D_M;

(2) $\tilde P\tilde B_a(Z)+\tilde Q\tilde B_b(Z)=0$.

DEFINITION 7.9. We denote by $\tilde L^*$ the operator defined by setting $\tilde L^*Z=G$ whenever $JZ'-BZ=AG$ and Z is in $\tilde D^*$.

THEOREM 7.10. *The abuse of notation above is correct. The adjoint of* $\tilde{L}$ *in* $L_A^2(a, b)$ *is* $\tilde{L}^*$. *The adjoint of* $\tilde{L}^*$ *in* $L_A^2(a, b)$ *is* $\tilde{L}$.

The proof is almost the same as that with only one singular point.

8. Self-adjoint problems. In [11] it was shown that every boundary condition at b can be written as a linear combination of terms from

$$B_b(Y) = \begin{bmatrix} \lim_{x\to b} \chi_1(x, \bar{\lambda})^* JY(x) \\ \lim_{x\to b} \phi_1(x, \bar{\lambda})^* JY(x) \end{bmatrix}.$$

In particular $\tilde{B}_b(Y)$ has the representation

$$B_b(Y) = V\tilde{B}_b(Y),$$

where

$$V_b = \begin{pmatrix} V_{11} & 0 \\ V_{21} & V_{22} \end{pmatrix}$$

is nonsingular. If λ can be made real, then $V_b = I$.

This same sort of representation also holds at a:

$$B_a(Y) = V_a\tilde{B}_a(Y).$$

As an immediate consequence, we find the following theorem holds.

THEOREM 8.1. $\tilde{L}$ *is self-adjoint if and only if* $r = m + p - 2n$ *and*

$$MV_aJ_aM^* = NV_bJ_bN^*.$$

9. The spectral resolution of L. The operator L was defined in § 4. Restricted to a finite regular subinterval (a', b'), the resulting operator has a well-known spectral resolution that is an eigenfunction expansions: if $\{\lambda_k\}_{k=1}^{\infty}$ are the eigenvalues with $\chi_k = \theta(x, \lambda_k)S_k + \phi(x, \lambda_k)T_k$, $k = 1, \cdots$, the associated normalized eigenfunctions, then

$$\chi_k = \mathcal{Y}(x, \lambda_k)\begin{pmatrix} S_k \\ T_k \end{pmatrix},$$

and we have the following theorem.

THEOREM 9.1. *For all* F *in* $L_A^2(a', b')$,

$$F(x) = \sum_{k=1}^{\infty} \mathcal{Y}(x, \lambda_k)\begin{pmatrix} S_k \\ T_k \end{pmatrix}(S_k^*, T_k^*)\int_{a'}^{b'} \mathcal{Y}(\xi, \lambda_k)^* A(\xi)F(\xi)\, d\xi.$$

Parseval's equality also holds.

THEOREM 9.2. *For all* F *in* $L_A^2(a', b')$,

$$\int_{a'}^{b'} F^*AF\, d\xi = \left[\int_{a'}^{b'} \mathcal{Y}(\xi, \lambda_k)^* AF\, d\xi\right]^* \begin{pmatrix} S_kS_k^* & S_kT_k^* \\ T_kS_k^* & T_kT_k^* \end{pmatrix}\left[\int_{a'}^{b'} \mathcal{Y}(\xi, \lambda_k)^* AF\, d\xi\right].$$

DEFINITION 9.3. Let R_k^2 denote the $2n \times 2n$ matrix

$$\begin{pmatrix} S_kS_k^* & S_kT_k^* \\ T_kS_k^* & T_kT_k^* \end{pmatrix}.$$

DEFINITION 9.4. Let

$$G_I(\lambda) = \int_{a'}^{b'} \mathcal{Y}(\xi, \lambda)^* AF\, d\xi,$$

$$= \int_{a'}^{b'} \begin{pmatrix} \theta(\xi, \lambda)^* \\ \phi(\xi, \lambda)^* \end{pmatrix} AF\, d\xi.$$

DEFINITION 9.5. Let $P_I(\lambda)$ be a $2n \times 2n$ matrix-valued function satisfying

(1) $P_I(0+) = 0$;

(2) $P_I(\lambda)$ is increasing, jumping R_k^2 at $\lambda = \lambda_k$, but otherwise constant, continuous from above.

Thus

$$P_I(\lambda) = \sum_{0<\lambda\leqq\lambda} R_k^2, \qquad \lambda \geqq 0,$$

$$P_I(\lambda) = -\sum_{\lambda<\lambda\leqq 0} R_k^2, \qquad \lambda < 0.$$

THEOREM 9.6 (Parseval's equality). *Let F be an arbitrary element in $L_A^2(a', b')$. Then*

$$\int_{a'}^{b'} F^* A F \, d\xi = \int_{-\infty}^{\infty} G_I^*(\lambda) \, dP_I(\lambda) G_I(\lambda).$$

This can be extended by the polarization identities.

COROLLARY 9.7. *Let F_1, F_2 be arbitrary elements in $L_A^2(a', b')$. Let G_{I1}, G_{I2} correspond to them according to Definition 9.4. Then*

$$\int_{a'}^{b'} F_2^* A F_1 \, d\xi = \int_{-\infty}^{\infty} G_{12}(\lambda)^* \, dP_I(\lambda) G_{I1}(\lambda).$$

THEOREM 9.8. *There exists a nondecreasing $2n \times 2n$ matrix-valued function $P(\lambda)$, defined on $(-\infty, \infty)$ satisfying*

(1) $P(0+) = 0$;

(2) $P(\lambda) - P(\mu) = \lim_{I \to (a,b)} [P_I(\lambda) - P_I(\mu)]$, $\lambda > \mu$.

The proof consists of showing that if

$$H(x) = \chi_{b'}(x, \lambda)[M_{a'} - M_{b'}]^{-1} \chi_{a'}(c, \bar{\lambda})^*, \qquad c < x,$$

$$H(x) = \chi_{a'}(x, \lambda)[M_{a'} - M_{b'}]^{-1} \chi_{b'}(c, \bar{\lambda})^*, \qquad c > x.$$

Then $\int_{a'}^{b'} H^* A H \, dx < K$. This ultimately yields

$$\int_{-\mu}^{\mu} dP_I(\lambda) < K(1 + \mu^2).$$

Helly's first convergence theorem can then be applied. See [10].

THEOREM 9.9. *If F is in $L_A^2(a, b)$ there is a function $G(\lambda)$ in $L_p^2(-\infty, \infty)$, with inner product*

$$(G, H)_p = \int_{-\infty}^{\infty} H^* \, dP \, G,$$

such that if

$$E(\lambda) = G(\lambda) - \int_{a'}^{b'} \mathcal{Y}(\xi, \lambda)^* A(\xi) F(\xi) \, d\xi,$$

then

$$\lim_{(a',b') \to (a,b)} \int_{-\infty}^{\infty} E(\lambda)^* \, dP(\lambda) E(\lambda) = 0$$

and

$$\int_a^b F(\xi)^* A(\xi) F(\xi) \, d\xi = \int_{-\infty}^{\infty} G(\lambda)^* \, dP(\lambda) G(\lambda).$$

THEOREM 9.10. *If $G(\lambda)$ is the limit of $\int_{a'}^{b'} \mathcal{Y}(\xi,\lambda)^* A(\xi)F(\xi)\,d\xi$ in $L_p^2(-\infty,\infty)$, then*

$$\int_{-\infty}^{\infty} \mathcal{Y}(x,\lambda)\,dP(\lambda)G(\lambda) = F(x)$$

in $L_A^2(a,b)$, that is,

$$\lim_{I\to(-\infty,\infty)} \int_a^b \left[F - \int_I \mathcal{Y}\,dP\,G\right]^* A\left[F - \int_I \mathcal{Y}\,dP\,G\right] d\xi = 0.$$

Theorem 9.9 may be extended to involve inner products by use of the polarization identity. The inner product form of Parseval's equality is

$$\int_a^b F_2(\xi)^* A(\xi)F_1(\xi)\,d\xi = \int_{-\infty}^{\infty} G_2(\lambda)^*\,dP(\lambda)G_1(\lambda),$$

where

$$G_j(\lambda) = \int_a^b \mathcal{Y}(\xi,\lambda)^* A(\xi)F_j(\xi)\,d\xi, \qquad j = 1, 2.$$

Theorems 9.9 and 9.10 may be extended to represent the resolvent operator $(L-\lambda_0 I)^{-1}$ when λ_0 is not in the support of $dP(\lambda)$. Parseval's equality is

$$\int_a^b [(L-\lambda_0 I)^{-1}F(\xi)]^* A(\xi)[(L-\lambda_0 I)^{-1}F(\xi)]\,d\xi = \int_{-\infty}^{\infty} \frac{G(\lambda)^*\,dP(\lambda)G(\lambda)}{|\lambda-\lambda_0|^2}.$$

The resolvent expansion is

$$(L-\lambda_0 I)^{-1}F(x) = \int_{-\infty}^{\infty} \mathcal{Y}(x,\lambda)\,dP(\lambda)\frac{G(\lambda)}{\lambda-\lambda_0}.$$

10. The converse problem. The preceding section began with choosing an F in $L_A^2(a,b)$, producing a G in $L_p^2(-\infty,\infty)$, and then showing that F could be recovered from G. In this section we begin with G, produce F, and then recover G.

Without the assumption that $JY' - BY = 0$, $AY = 0$ implies $Y = 0$, $L_p^2(-\infty,\infty)$ may be too large in the sense that $G \to F \to \tilde{G}$, but $\tilde{G}$ may not equal G. $\tilde{G}$ may be only in a subspace of $L_p^2(-\infty,\infty)$.

With the assumption made in the Introduction (i.e., let $F = 0$), there is no such difficulty.

THEOREM 10.1. *If $G(\lambda)$ is in $L_p^2(-\infty,\infty)$, there is a unique $F(x)$ in $L_A^2(a,b)$ such that*

$$F(x) = \int_{-\infty}^{\infty} \mathcal{Y}(x,\lambda)\,dP(\lambda)G(\lambda)$$

and

$$G(\lambda) = \int_a^b \mathcal{Y}(\xi,\lambda)^* A(\xi)F(\xi)\,d\xi.$$

11. The relation between M_a, M_b, and $P(\lambda)$. The matrices M_a and M_b can frequently be determined by a careful inspection of the solutions of (*) to determine appropriate L_A^2 solutions. More difficult is the determination of the spectral matrix $P(\lambda)$, since its existence follows from Helly's selection theorems. Fortunately, they are intimately connected.

THEOREM 11.1. *Let*

$$M=\begin{pmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{pmatrix},$$

where

$$M_{11}=(M_a-M_b)^{-1}-(M_a^*-M_b^*)^{-1}=2i\ \mathrm{Im}\,(M_a-M_b)^{-1},$$

$$M_{12}=\tfrac{1}{2}(M_a-M_b)^{-1}(M_a+M_b)-\tfrac{1}{2}(M_a^*-M_b^*)^{-1}(M_a^*+M_b^*),$$

$$M_{21}=-\tfrac{1}{2}(M_a+M_b)(M_a-M_b)^{-1}+\tfrac{1}{2}(M_a^*+M_b^*)(M_a^*-M_b^*)^{-1}=-M_{12}^*,$$

$$M_{22}=M_a(M_a-M_b)^{-1}M_b-M_b^*(M_a^*-M_b^*)^{-1}M_a^*=2i\ \mathrm{Im}\ M_a(M_a-M_b)^{-1}M_b.$$

If λ_1 *and* λ_2 *are real, then*

$$P(\lambda_2)-P(\lambda_1)=\lim_{v\to 0+}\frac{1}{2\pi i}\int_{\lambda_1}^{\lambda_2} M(\mu+iv)\,d\mu.$$

12. The spectral resolution. We connect these results to the classic representation of the identity as an integral generated by a projection valued measure E_λ. Given

$$F(x)=\int_{-\infty}^{\infty}\mathcal{Y}(x,\lambda)\,dP(\lambda)G(\lambda),$$

where

$$G(\lambda)=\int_a^b \mathcal{Y}^*(\xi,\lambda)A(\xi)F(\xi)\,d\xi,$$

we define

$$E_\lambda F(x)=\int_{-\infty}^{\lambda+}\mathcal{Y}(x,\lambda)\,dP(\lambda)G(\lambda).$$

Considered as the limit of eigenfunction expansions, E_λ can easily be shown to be a projection that is continuous from above and satisfies $E_{\lambda_1}E_{\lambda_2}=E_{\lambda_1}$ when $\lambda_1\leqq\lambda_2$, as well as $E_{-\infty}=0$, $E_\infty=I$. If we let $\{\lambda_j\}_{j=-\infty}^{\infty}$ be a partition of $(-\infty,\infty)$, $\lambda_i<\lambda_j$ if $i<j$, and

$$\Delta_j EF(x)=\int_{\lambda_j}^{\lambda_{j+1}}\mathcal{Y}(x,\lambda)\,dP(\lambda)G(\lambda),$$

then $F(x)=\sum_{j=-\infty}^{\infty}\Delta_j EF(x)$. As $\{\lambda_j\}_{j=-\infty}^{\infty}$ becomes finer, we may write

$$F(x)=\int_{-\infty}^{\infty} dE_\lambda\,F(x)$$

as the limit of the decomposition above.

If Y is in D, it has the representation

$$Y(x)=\int_{-\infty}^{\infty}\mathcal{Y}(x,\lambda)\,dP(\lambda)G(\lambda),$$

where

$$G(\lambda)=\int_a^b \mathcal{Y}^*(\xi,\lambda)A(\xi)Y(\xi)\,d\xi.$$

Then

$$LY = \int_{-\infty}^{\infty} \lambda \mathcal{Y}(x, \lambda)\, dP(\lambda) G(\lambda),$$

which is equivalent to

$$LY(x) = \int_{-\infty}^{\infty} \lambda\, dE_\lambda\, Y(x).$$

The resolvent operator also has the standard representation. If λ_0 is complex,

$$(L-\lambda_0 I)^{-1} F(x) = \int_{-\infty}^{\infty} \frac{1}{\lambda-\lambda_0}\, dE_\lambda\, F(x).$$

It is apparent that λ_0 is in the spectrum of L if and only if it is in the support of dE_λ or $dP(\lambda)$.

Example. (The Legendre Squared Problem.) The square of the Legendre operator is

$$Ly = [(1-x^2)^2 y'']'' - 2[(1-x^2)y']'.$$

We put this in system format by setting $y_1 = y$, $y_2 = y'$, $y_3 = -((1-x^2)^2 y'')' - 2(1-x^2)y'$, $y_4 = (1-x^2)y''$. Then $(L-\lambda)y = 0$ becomes

$$\begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{pmatrix}' = \left[\lambda \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 2(1-x^2) & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1/(1-x^2)^2 \end{pmatrix} \right] \begin{pmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{pmatrix}.$$

With $\lambda = 0$ there are four solutions, all of which are square integrable over $(-1, 1)$. They are

$$Y_1 = \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \quad Y_2 = \begin{pmatrix} \ln(1+x) \\ (1+x)^{-1} \\ 0 \\ -(1-x)^{-2} \end{pmatrix}, \quad Y_3 = \begin{pmatrix} \ln(1-x) \\ -(1-x)^{-1} \\ 0 \\ -(1+x)^{-2} \end{pmatrix}$$

and Y_4, whose initial component is

$$y_1 = \int^x (1-t)^{-1} \int^t [\ln(1-s)/(1+s)^2]\, ds\, dt,$$

but nonetheless is square integrable. Each generates boundary conditions at ± 1. We content ourselves with displaying those satisfied by the Legendre polynomials. They are in terms of scalar y,

$$\lim_{x\to -1} [(1-x^2)^2 y''' - 4x(1-x^2)y'' - 2(1-x^2)y'] = 0,$$

$$\lim_{x\to -1} (1+x)^2(-y' + (1-x)y'') = 0,$$

$$\lim_{x\to 1} [-(1-x^2)^2 y''' + 4x(1-x^2)y'' + 2(1-x^2)y'] = 0,$$

$$\lim_{x\to 1} (1-x)^2(y' + (1+x)y'') = 0.$$

For system Y, they are, of course, $\lim Y_j^* J Y$, where $j = 1, 2$ as $x \to 1$, $j = 1, 3$ as $x \to -1$.

EXISTENCE AND UNIQUENESS THEOREMS FOR THREE-POINT BOUNDARY VALUE PROBLEMS*

A. R. AFTABIZADEH,† CHAITAN P. GUPTA,‡ AND JIAN-MING XU†

Abstract. Existence and uniqueness theorems for third-order boundary value problems are studied. The methods used are the Leray-Schauder continuation theorem and Wirtinger-type inequalities.

Key words. third-order boundary value problems, Leray-Schauder continuation theorem, Wirtinger-type inequalities, sandwich beam

AMS(MOS) subject classifications. 34B10, 34B15

1. Introduction.

The existence and uniqueness of third-order boundary value problems deserve a good deal of attention, since they occur in a wide variety of applications. For example, a three-layer beam is formed by parallel layers of different materials. For an equally loaded beam of this type, Krajcinovic [6] has shown that the deflection ψ is governed by an ordinary third-order linear differential equation

$$\psi''' - K^2\psi' + a = 0,$$

where K^2 and a are physical parameters depending on the elasticity of the layers. The condition of zero moment at the free ends implies the boundary conditions,

$$\psi'(0) = \psi'(1) = 0,$$

and symmetry yields the third boundary condition

$$\psi(1/2) = 0.$$

For recent results concerning third-order boundary value problems, we refer the readers to [1]-[5], [8]-[10].

The purpose of this paper is to study existence and uniqueness results for nonlinear third-order boundary value problems

$$u''' + f(u')u'' = g(x, u, u', u'') + e(x) \tag{1.1}$$

$$u'(0) = u'(1) = u(\eta) = 0, \quad 0 \le \eta \le 1, \tag{1.2}$$

and

$$u''' = g(x, u, u', u'') + e(x) \tag{1.3}$$

$$u'(0) = u''(1) = u(\eta) = 0, \quad 0 \le \eta \le 1, \tag{1.4}$$

where $f \in C(R, R)$ and $g : [0,1] \times R^3 \to R$ satisfies Carathéodory's conditions, that is

(1) for almost everywhere $x \in [0,1]$, the function $u \in R^3 \to g(x,u) \in R$ is continuous;

(2) for every $u \in R^3$, the function $x \in [0,1] \to g(x,u) \in R$ is measurable;

(3) for every $r > 0$, there is a real valued function $g_r(x) \in L^1[0,1]$ such that for almost everywhere $x \in [0,1]$, $|g(x,u)| \le g_r(x)$ wherever $\|u\| \le r$.

The boundary value problems (1.1), (1.2) and (1.3), (1.4) are in the form of operator equations

$$Lu + Nu = w, \quad \text{where} \quad L : D(L) \subset X \to Y$$

is a linear operator, $N : X \to Y$ is a nonlinear operator and X, Y are suitably Banach spaces in duality (denoted by $(\ ,\ )$). Clearly the linear operator L in (1.1), (1.2) or (1.3), (1.4) is given by

$$Lu = u''',$$

where the boundary conditions (1.2) or (1.3) are used to define the domain, $D(L)$, of L. Our study is motivated by the observation that although it is not possible to obtain necessary a priori estimates to use Leray-Schauder continuation theorem using (Lu, u), it is possible to obtain the necessary a priori estimates using (Lu, u'). In fact, we use (Lu, u') and Wirtinger-type inequalities to obtain the needed a priori estimates to apply Leray-Schauder continuation theorem. Accordingly, we believe that our methods to study the boundary value problems (1.1), (1.2) and (1.3), (1.4) are natural and different than those used in [1]-[5], [8]-[10].

In §§2 and 3 we present some existence and uniqueness results for problems (1.1), (1.2) and (1.3), (1.4), and in §4 we compare our results with the results given in [3], [10]. First we present some results, which help to simplify the proofs of our main results. Let us define

$$\|u\|_\infty = \sup_{0 \le x \le 1} |u(x)|, \quad \text{and} \quad \|u\|_2^2 = \int_0^1 u^2(x)\,dx.$$

LEMMA 1.1. *If* $u(x) \in C^1[0,1]$ *and* $u(0) = 0$, *then* $\|u\|_2^2 \le (4/\pi^2)\|u'\|_2^2$.

LEMMA 1.2. *If* $u(x) \in C^1[0,1]$ *and* $u(0) = u(1) = 0$, *then* $\|u\|_2^2 \le (1/\pi^2)\|u'\|_2^2$.

LEMMA 1.3. *Let* $M_\eta = \max\{\eta, 1-\eta\}$, $0 \le \eta \le 1$. *If* $u(\eta) = 0$, *then*

$$\|u\|_2^2 \le \frac{4}{\pi^2} M_\eta^2 \|u'\|_2^2.$$

Proof. Since $u(\eta) = 0$, then by Lemma 1.1,

$$\int_0^\eta u^2(x)\,dx \le \frac{4}{\pi^2}\eta^2 \int_0^\eta [u'(x)]^2\,dx$$

and

$$\int_\eta^1 u^2(x)\,dx \le \frac{4}{\pi^2}(1-\eta)^2 \int_\eta^1 [u'(x)]^2\,dx.$$

Thus

$$\int_0^1 u^2(x)\,dx \le \frac{4}{\pi^2}\eta^2 \int_0^\eta [u'(x)]^2\,dx + \frac{4}{\pi^2}(1-\eta)^2 \int_\eta^1 [u'(x)]^2\,dx,$$

or

$$\|u\|_2^2 \leq \frac{4}{\pi^2} M_\eta^2 \|u'\|_2^2.$$

LEMMA 1.4. *If* $u(0) = u(1) = 0$, *then*

$$\|u\|_\infty \leq \frac{1}{2} \int_0^1 |u'(x)|\, dx.$$

Let us define the space $H^3(0,1)$ by

$$H^3(0,1) = \left\{ u \in [[0,1], R] \ : \ \frac{d^j u}{dx^j} \ \text{is absolutely continuous on } [0,1] \ \text{for } j = 0,1,2, \text{ and } \frac{d^3 u}{dx^3} \in L^2([0,1]) \right\}.$$

with the usual inner product and the corresponding norm $|\cdot|_{H^3}$. We define a linear operator

$$L \ : \ D(L) \subset C^2[0,1] \to L^1[0,1]$$

by setting

$$D(L) = \{u \in H^3(0,1) \ : \ u \quad \text{satisfies (1.2) or (1.4)}\}$$

and for $u \in D(L)$,

$$Lu = \frac{d^3 u}{dx^3}.$$

LEMMA 1.5. *ker* $L = \{0\}$.

2. Existence results. In this section we apply the results of §1 and the version of Leray-Schauder continuation theorem given by Mawhin in Corollary IV.7 [7] to obtain the existence of a solution for the boundary value problems (1.1), (1.2) and (1.3), (1.4).

THEOREM 2.1. *Let* $g : [0,1] \times R^3 \to R$ *satisfy Carathéodory's conditions, and* $f \in C(R,R)$. *Assume that*

(i) *There exist functions* $a(x) \in C^1[0,1], b(x), c(x) \in C[0,1]$, $d(x) \in L^1[0,1]$, *and real numbers* a_0, b_0, $c_0 \in R$ *such that*

$$a'(x) \leq a_0, \quad b(x) \geq -b_0, \quad c(x) \geq -c_0 \quad \text{for a.e. } x \in [0,1],$$

and for every u, v, $w \in R$, *a.e.* $x \in [0,1]$

$$g(x,u,v,w)v \geq a(x)vw + b(x)v^2 + c(x)|uv| + d(x)|v|;$$

(ii) *There exist* $\alpha \in C\big[[0,1] \times R^2, R\big]$ *and* $\beta \in L^1[0,1]$ *such that*

$$\big|g(x,u,v,w)\big| \leq \big|\alpha(x,u,v)\big||w|^2 + \beta(x)$$

for every $u, v, w \in R$, *and a.e.* $x \in [0,1]$.
Then for every $e(x) \in L^1[0,1]$, *the problem* (1.1) *with* (1.2) *has at least one solution if*

$$(a_0 + 2b_0)\pi + 4M_\eta c_0 < 2\pi^3,$$

where $M_\eta = \max(\eta, 1-\eta)$.

Proof. Let X denote the Banach space $C^2[0,1]$ and Y denote the Banach space $L^1[0,1]$ with its usual norm. Also for $u \in X$, $v \in L^1[0,1]$ let

$$(u,v) = \int_0^1 u(x)v(x)\,dx,$$

denote the duality pairing. We define a linear mapping $L : D(L) \subset X \to Y$ by setting

$$D(L) = \left\{ \begin{array}{l} u \in X \mid u'' \text{ absolutely continuous on } [0,1], \\ \qquad\qquad \text{and } u'(0) = u'(1) = u(\eta) = 0 \end{array} \right\},$$

and for $u \in D(L)$,

$$Lu = u'''.$$

We also define a nonlinear mapping $N : X \to Y$ by setting

$$(Nu)(x) = f(u'(x))u''(x) - g\big(x, u(x), u'(x), u''(x)\big).$$

We note that N is a bounded, continuous mapping. Next, it is easy to see that the linear mapping $L : D(L) \subset X \to Y$, defined above, is a one-to-one mapping. Also the linear mapping $K : Y \to X$, defined, for $y \in Y$, by

$$(Ky)(x) = \int_\eta^x \int_0^t \int_0^s y(\tau)\,d\tau\,ds\,dt + \frac{(\eta^2 - x^2)}{2} \int_0^1 \int_0^t y(\tau)\,d\tau\,dt$$

is such that for $y \in Y$, $Ky \in D(L)$ and $LKy = y$ and for $u \in D(L)$, $KLu = u$. Furthermore, it follows easily by using the Arzela–Ascoli theorem that K maps a bounded subset of Y into relatively compact subsets of X. Hence, $KN : X \to X$ is a compact mapping.

We next note that $u \in C^2[0,1]$ is a solution of the boundary value problem (1.1), (1.2) if and only if u is a solution of the operator equation

$$Lu + Nu = e.$$

Now, the operator equation $Lu + Nu = e$ is equivalent to the equation

$$u + KNu = Ke.$$

We now apply the Leray-Schauder continuation theorem (see, e.g., [7, Cor. IV.7]) to obtain the existence of a solution for $u + KNu = Ke$ or equivalently to the boundary value problem (1.1) and (1.2).

To do this it is suffices to verify that the set of all possible solutions of the family of equations

$$(2.1) \qquad \left\{ \begin{array}{ll} u''' + \lambda f(u')u'' = \lambda g(x,u,u',u'') + \lambda e(x), & x \in (0,1) \\ u(\eta) = u'(0) = u'(1) = 0, & 0 \le \eta \le 1, \end{array} \right.$$

is, a priori, bounded in $C^2[0,1]$ by a constant independent of $\lambda \in [0,1]$.

Let $u(x)$ be a possible solution of (2.1) for some $\lambda \in [0,1]$. Since $u'(0) = u'(1) = 0$, then by Lemma 1.2,

$$\|u'\|_2^2 \leq \frac{1}{\pi^2}\|u''\|_2^2,$$

and from Lemma 1.4

$$\|u'\|_\infty \leq \frac{1}{2}\|u''\|_2.$$

From $u(\eta) = 0$ and Lemma 1.3, we have

$$\|u\|_2^2 \leq \frac{4}{\pi^2}M_\eta^2\|u'\|_2^2 \leq \frac{4}{\pi^4}M_\eta^2\|u''\|_2^2.$$

On multiplying the equation (2.1) by u' and integrating from zero to 1, we have

$$\int_0^1 u'u'''\,dx + \lambda\int_0^1 f(u')u'u''\,dx = \lambda\int_0^1 g(x,u,u',u'')u'\,dx + \lambda\int_0^1 e(x)u'\,dx.$$

Since $u'(0) = u'(1) = 0$, it follows that

$$\int_0^1 f(u')u'u''\,dx = 0,$$

and then from the condition (i), we have

$$-\int_0^1 [u''(x)]^2\,dx \geq \lambda\int_0^1 a(x)u'u''\,dx + \lambda\int_0^1 b(x)[u'(x)]^2\,dx + \lambda\int_0^1 c(x)|uu'|\,dx + \lambda\int_0^1 d(x)|u'|\,dx + \lambda\int_0^1 e(x)u'\,dx$$

$$-\int_0^1 [u''(x)]^2\,dx \geq -\frac{\lambda}{2}\int_0^1 a'(x)[u'(x)]^2\,dx + \lambda\int_0^1 b(x)[u'(x)]^2\,dx + \lambda\int_0^1 c(x)|uu'|\,dx + \lambda\int_0^1 d(x)|u'|\,dx + \lambda\int_0^1 e(x)u'\,dx$$

or

$$\|u''\|_2^2 \leq \lambda\Big[\Big(\frac{a_0}{2} + b_0\Big)\|u'\|_2^2 + c_0\|u\|_2\|u'\|_2 + \|d\|_1\|u'\|_\infty + \|e\|_1\|u'\|_\infty\Big].$$

Hence from the estimates following (2.1), we obtain

$$\|u''\|_2 \leq \frac{\pi^3\big(\|d\|_1 + \|e\|_1\big)}{2\pi^3 - \pi(a_0 + 2b_0) - 4M_\eta c_0} = \rho.$$

Thus

$$\|u'\|_\infty \leq \rho \quad \text{and} \quad \|u\|_\infty \leq \rho.$$

Now, let us assume that

$$M_\rho = \max\big|f(v)\big|, \quad v \in [-\rho, \rho],$$

then

$$|u'''| \leq |f(u')||u''| + |g(x, u, u', u'')| + |e(x)|,$$

and using condition (ii) we have

$$\begin{aligned}\|u'''\|_1 &\leq M_\rho \|u''\|_2 + \int_0^1 |g(x, u, u', u'')|\, dx + \|e\|_1 \\ &\leq M_\rho \rho + \int_0^1 |\alpha(x, u, u')||u''|^2\, dx + \|\beta\|_1 + \|e\|_1 \\ &\leq \rho M_\rho + \rho^2 K_\rho + \|\beta\|_1 + \|e\|_1 \quad = \rho_1,\end{aligned}$$

where

$$K_\rho = \max |\alpha(x, u, v)| \quad \text{on} \quad [0,1] \times [-\rho, \rho] \times [-\rho, \rho].$$

Further, since $u'(0) = u'(1) = 0$, there is an $\xi \in [0,1]$ such that $u''(\xi) = 0$ and $u''(x) = \int_\xi^x u'''(t)\, dt$, for $x \in [0,1]$. It follows that

$$\|u''\|_\infty \leq \|u'''\|_1 \leq \rho_1.$$

All of these considerations imply that there is a constant C, independent of $\lambda \in [0,1]$ such that

$$\|u\|_{C^2[0,1]} \leq C.$$

This completes the proof of this theorem. □

Essentially the same reasoning establishes Theorem 2.2.

THEOREM 2.2. *Suppose all conditions of Theorem* 2.1 *hold true, except in condition* (i) *we assume that* $a(x) \in C[0,1]$ *and* $a(x) \geq -a_0$, *and*

$$v.g(x, u, v, w) \geq a(x)|vw| + b(x)v^2 + c(x)|uv| + d(x)|v|,$$

then problem (1.1), (1.2) *has at least one solution provided*

$$a_0\pi^2 + b_0\pi + 2c_0 M_\eta < \pi^3$$

Remark 2.1. Theorems 2.1 and 2.2 give the solvability of problem (1.1), (1.2) for every given $e(x)$ in $L^1[0,1]$, it is obvious that Theorem 2.1 also gives the solvability of the equation (1.1) with inhomogeneous boundary conditions

$$u'(0) = A_1, \quad u'(1) = A_2, \quad u(\eta) = A_3.$$

COROLLARY 2.1. *Let* $g : [0,1] \times R^3 \to R$ *satisfy Carathéodory's conditions,* $f : R \to R$ *be continuous and assume that for almost everywhere* $x \in [0,1]$, *the function* $g(x, u, v, w)$ *is continuously differentiable with respect to* u, v, *and* w. *Suppose that there exist real numbers* a_0, b_0, *and* c_0 *with* $a_0\pi^2 + b_0\pi + 2c_0 M_\eta < \pi^3$ *such that*

$$\frac{\partial g}{\partial u}(x, u, v, w) \geq -c_0, \quad \frac{\partial g}{\partial v}(x, 0, v, w) \geq -b_0 \quad \left|\frac{\partial g}{\partial w}(x, 0, 0, w)\right| \leq a_0, \tag{2.2}$$

for almost everywhere $x \in [0,1]$ *and all* u, v, $w \in R$. *Suppose further that there exists a continuous function* $\alpha : [0,1] \times R^2 \to R$ *and* $\beta(x) \in L^1[0,1]$ *such that*

$$|g(x,u,v,w)| \leq |\alpha(x,u,v)||w|^2 + \beta(x), \tag{2.3}$$

for every u, v, $w \in R$ *and for almost everywhere* $x \in [0,1]$.

Then for every given $e(x) \in L^1[0,1]$ *the boundary value problem* (1.1), (1.2) *has a solution.*

We can use the same method as in Theorem 2.1 to prove the following theorem for the boundary value problem (1.3), (1.4).

THEOREM 2.3. *Let* $g : [0,1] \times R^3 \to R$ *satisfy Carathéodory's conditions. Assume that*

(i) *There exist functions* $a(x)$, $b(x)$, *and* $c(x) \in C[0,1]$, $d(x) \in L^1[0,1]$, *and real numbers* $a_0, b_0, c_0 \in R$ *such that for every* $x \in [0,1]$

$$a(x) \geq -a_0, \quad b(x) \geq -b_0, \quad c(x) \geq -c_0$$

and for every u, v, $w \in R$, *almost everywhere* $x \in [0,1]$

$$g(x,u,v,w)v \geq a(x)|vw| + b(x)v^2 + c(x)|uv| + d(x)|v|;$$

(ii) *There exist* $\alpha \in C[[0,1] \times R^2, R]$ *and* $\beta \in L^1[0,1]$ *such that*

$$|g(x,u,v,w)| \leq |\alpha(x,u,v)||w|^2 + \beta(x)$$

for every u, v, $w \in R$, *almost everywhere* $x \in [0,1]$.
Then for every $e(x) \in L^1[0,1]$, *problem* (1.3)-(1.4) *has at least one solution if*

$$2\pi^2 a_0 + 4\pi b_0 + 8M_\eta c_0 < \pi^3,$$

where $M_\eta = \max(\eta, 1-\eta)$.

COROLLARY 2.2. *Suppose that all conditions of Corollary* 2.1 *hold true, except that the condition* $a_0\pi^2 + b_0\pi + 2c_0M_\eta < \pi^3$ *is replaced by*

$$2\pi^2 a_0 + 4\pi b_0 + 8M_\eta c_0 < \pi^3,$$

then boundary value problem (1.3), (1.4) *has a solution.*

3. Uniqueness results. In this section we discuss existence of a unique solution for the boundary value problems

$$u''' + Au'' = g(x,u,u',u'') + e(x) \tag{3.1}$$

$$u(\eta) = u'(0) = u'(1) = 0, \tag{3.2}$$

and

$$u''' = g(x,u,u',u'') + e(x) \tag{3.3}$$

$$u(\eta) = u'(0) = u''(1) = 0, \tag{3.4}$$

where A is a constant and $g(x, u, v.w)$ satisfies Carathéodory's conditions, and $e(x) \in L^1[0,1]$.

THEOREM 3.1. *Let $g : [0,1] \times R^3 \to R$ satisfy Carathéodory's conditions, and A be a constant. Assume there exist functions $a(x) \in C^1[0,1]$, $b(x)$, $c(x) \in C[0,1]$, and constants a_0, b_0, $c_0 \in R$ such that for almost everywhere $x \in [0,1]$*

$$a'(x) \le a_0,\ b(x) \ge -b_0,\ c(x) \ge -c_0$$

and for every u_i, v_i, $w_i \in R$, $i = 1, 2$, and almost everywhere $x \in [0,1]$

$$\begin{aligned}\big(g(x,u_1,v_1,w_1) - g(x,u_2,v_2,w_2)\big)(v_1 - v_2) \ge & a(x)(w_1 - w_2)(v_1 - v_2) \\ & + b(x)(v_1 - v_2)^2 + c(x)|u_1 - u_2||v_1 - v_2|.\end{aligned}$$

Then for every $e(x) \in L^1[0,1]$, problem (3.1), (3.2) has a unique solution provided

$$(a_0 + 2b_0)\pi + 4c_0 M_\eta < 2\pi^3.$$

Proof. Let us assume that u_1 and u_2 are two solutions of (3.1)-(3.2), then

$$(u_1 - u_2)''' + A(u_1 - u_2)'' = g(x, u_1, u_1', u_1'') - g(x, u_2, u_2', u_2'') \tag{3.5}$$

and

$$(u_1 - u_2)(\eta) = 0,\ (u_1 - u_2)'(0) = 0,\ (u_1 - u_2)'(1) = 0. \tag{3.6}$$

On multiplying (3.5) by $(u_1 - u_2)'$ and integrating for 0 to 1, we have

$$-\int_0^1 \big[(u_1 - u_2)''\big]^2\,dx = \int_0^1 \big[g(x, u_1, u_1', u_1'') - g(x, u_2, u_2', u_2'')\big](u_1 - u_2)'\,dx.$$

Let $y = u_1 - u_2$, then from the condition (i)

$$\begin{aligned}-\int_0^1 [y'']^2\,dx &\ge \int_0^1 a(x)y''y'\,dx + \int_0^1 b(x)[y']^2\,dx + \int_0^1 c(x)|y||y'|\,dx \\ &\ge -\frac{1}{2}\int_0^1 a'(x)(y')^2\,dx + \int_0^1 b(x)(y')^2\,dx + \int_0^1 c(x)|y||y'|\,dx\end{aligned}$$

or

$$\begin{aligned}\int_0^1 (y'')^2\,dx &\le \Big(\frac{1}{2}a_0 + b_0\Big)\int_0^1 (y')2\,dx + c_0\Big[\int_0^1 y^2\,dx\Big]^{1/2}\Big[\int_0^1 (y')^2\,dx\Big]^{1/2} \\ &\le \frac{a_0/2 + b_0}{\pi^2}\int_0^1 (y'')^2\,dx + \frac{2M_\eta c_0}{\pi^3}\int_0^1 (y'')^2\,dx\end{aligned}$$

or $\|y''\|_2{}^2 \le 0$. From Lemma 1.2, it follows that $\|y'\|_2^2 \le 0$. Since

$$\|y\|_\infty \le \|y'\|_2 \le 0,$$

then $y(x) = 0$, and hence $u_1(x) = u_2(x)$ for almost everywhere $x \in [0,1]$. But $H^3(0,1) \subset C^2[0,1]$, which implies $u_1(x) = u_2(x)$ for every $x \in [0,1]$. The proof is complete. □

THEOREM 3.2. *Let $g : [0,1] \times R \to R$ satisfy Carathéodory's conditions, and A be a constant. Assume there exist functions $a(x)$, $b(x)$, $c(x) \in C[0,1]$, and constants a_0, b_0, $c_0, \in R$ such that for almost everywhere $x \in [0,1]$*

$$a(x) \geq -a_0, \quad b(x) \geq -b_0, \quad c(x) \geq -c_0$$

and for every u_i, v_i, $w_i \in R$, $i = 1,2$ and almost everywhere $x \in [0,1]$

$$\Big(g(x,u_1,v_1,w_1) - g(x,u_2,v_2,w_2)\Big)(v_1 - v_2) \geq a(x)|w_1 - w_2||v_1 - v_2| + b(x)(v_1 - v_2)^2 + c(x)|u_1 - u_2|\,|v_1 - v_2|.$$

Then for every $e(x) \in L^1[0,1]$, the problem (3.1), (3.2) *has a unique solution provided*

$$a_0\pi^2 + b_0\pi + 2c_0M_\eta < \pi^3.$$

THEOREM 3.3. *Let $g : [0,1] \times R^3 \to R$ satisfies Carathéodory's conditions. Assume there exist functions $a(x)$, $b(x)$, $c(x) \in C[0,1]$ and constants a_0, b_0, $c_0 \in R$ such that for almost everywhere $x \in [0,1]$*

$$a(x) \geq -a_0, \quad b(x) \geq -b_0, \quad |c(x)| \leq c_0$$

and for every u_i, v_i, $w_i \in R$, i=1,2, and almost everywhere $x \in [0,1]$,

$$\big(g(x,u_1,v_1,w_1) - g(x,u_2,v_2,w_2)\big)(v_1 - v_2) \geq a(x)|w_1 - w_2|v_1 - v_2| + b(x)(v_1 - v_2)^2 + c(x)|u_1 - u_2||v_1 - v_2|.$$

Then for every $e(x) \in L^1[0,1]$ the problem (3.3), (3.4) *has a unique solution if*

$$2\pi^2a_0 + 4\pi b_0 + 8M_\eta c_0 < \pi^3.$$

Remark 3.1. We remark that Theorems 3.1–3.3 give uniqueness results for the boundary value problems (3.1), (3.2) and (3.3), (3.4). To obtain existence and uniqueness results for (3.1), (3.2) and (3.3), (3.4) we only need to combine the theorems of §§2 and 3.

4. Examples and comparisons. From Theorem 2.2 it is easy to prove the following corollary.

COROLLARY 4.1. *Suppose all conditions of Theorem* 2.2 *hold true except condition* (ii) *which we replace by*

(ii)′ *There exist $\alpha \in C\big[[0,1] \times R^2, R\big]$, $\gamma \in C\big[[0,1] \times R^3, R\big]$, and $\beta \in L^1[0,1]$ such that*

$$\big|g(x,u,v,w)\big| \leq \alpha(x,u,v)|w|^2 + \gamma(x,u,v,w) + \beta(x)$$

for every u, v, $w \in R$ *and almost everywhere* $x \in [0,1]$, *where* $\gamma(x,u,v,w)$ *is bounded when* (x,u,v) *varies in a bounded set in* $[0,1] \times R^2$. *Then the problem* (1.1), (1.2) *has a solution provided*

$$a_0\pi^2 + b_0\pi + 2c_0M_\eta < \pi^3 .$$

Aftabizadeh and Wiener [1] studied problem (1.1), (1.2) when $f \equiv 0$ and $\eta = 0$. Granas, Guenther, and Lee [3] discussed the existence of solutions of boundary value problem (1.3) ((1.2), or (1.4)) where $g = \varphi + \psi$, they proved the following [3].

The boundary value problem

$$u''' = \varphi(x,u,u',u'') + \psi(x,u,u',u''), \quad u(0) = u'(0) = u'(1) = 0$$

has at least one solution provided the functions φ and ψ are continuous and

(a) $\varphi \cdot v \geq 0$ on $[0,1] \times R^3$

(b) $|\psi| \leq B\big(1 + |u|^\alpha + |v|^\beta + |w|^\gamma\big)$, where $B < \infty$, $0 \leq \alpha, \beta, \gamma < 1$.

(c) $\varphi(x,u,v,w)$ is bounded when (x,u,v) in a bounded set $[0,1] \times R^2$.

Corollary 4.1 covers this results. Indeed it is clear that (b) implies there exists $B' < \infty$, such that for every u, v, $w \in R$, $x \in [0,1]$

$$|\psi(x,u,v,w)| \leq |u| + |v| + |w| + B. \tag{4.1}$$

Then from (a) we have

$$(\varphi + \psi).v \geq \psi.v \geq -|\psi|.|v| \geq -|uv| - v^2 - |vw| - B'|v|. \tag{4.2}$$

Also from (4.1) we have

$$|\varphi + \psi| \leq |\varphi| + |\psi| \leq |w|^2 + \big[|\varphi| + |u| + |v| + B' + 1\big].$$

Hence, if we take $f \equiv 0$, $e \equiv 0$ and $g = \varphi + \psi$ in Corollary 4.1 with $\eta = 0$, then the result of [3] follows.

O'Regan [10] proved the following theorem.

THEOREM O. *Let* $g : [0,1] \times R^3 \to R$ *be continuous.*

(a) *Suppose there is a constant* $M \geq 0$ *such that*

$$pg(x,u,p,0) \geq 0 \quad \textit{for} \quad |p| > M \quad \textit{and} \quad (x,u) \in [0,1] \times R.$$

(b) *Suppose that*

$$|g(x,u,p,q)| \leq A(x,u,p)q^2 + B(x,u,p)$$

where $A(x,u,p), B(x,u,p) \geq 0$ *are functions bounded on bounded* (x,u,p) *sets. Then the boundary value problem*

$$u''' = g(x,u,u',u''), \quad u(\eta) = u'(0) = u'(1) = 0, \quad x \in [0,1],$$

has at least one solution in $C^3[0,1]$.

In general this theorem covers more class of differential equations than our Theorem 2.1 if $f \equiv 0$. Condition (a) is weaker than condition (i) of Theorem 2.1. If

the function $g(x,u,v,w)$ is independent of w, then our results are stronger, as the following example shows.

Example. (Sandwich beam). Consider the differential equation

$$\psi''' = k^2(x,\psi)\psi' - a(x,\psi), \qquad x \in [0,1],$$

with the boundary conditions

$$\psi'(0) = \psi'(1) = \psi(1/2) = 0.$$

O'Regan [10] assumed that $k^2(x,\psi)$ and $a(x,\psi)$ are continuous functions on $[0,1]\times R$. In addition, suppose there exists a constant $L < \infty$ such that

$$\left|\frac{a(x,\psi)}{k^2(x,\psi)}\right| \le L \qquad \text{for } (x,\psi) \in [0,1]\times R.$$

Then $\psi' g(x,\psi,\psi) = \psi'(k^2\psi' - a) > 0$ for $|\psi'| > L$ and $(x,\psi) \in [0,1]\times R$, and so Theorem O implies that the boundary value problem has at least one solution in $C^3[0,1]$.

Now we make the following assumptions on k and a.

Suppose $k^2(x,\psi) \equiv 1$ and $a(x,\psi) = a(x)\psi + b(x)$ then Theorem O does not guarantee this problem has a solution while Theorem 2.1 implies the boundary value problem has a solution. More generally, if we suppose that k, $a \in C\big[[0,1]\times R, R\big]$ and there exists functions $c(x) \in C[0,1]$, $d(x) \in L^1[0,1]$ such that $c(x) > -\pi^3$ and

$$\psi' \,.\, a(x,\psi) \le c(x)|\psi.\psi'| + d(x)|\psi'|,$$

then Theorem 2.1 guarantees this boundary value problem has at least one solution in $C^3[0,1]$.

QUADRATIC BIRTH AND DEATH PROCESSES AND ASSOCIATED CONTINUOUS DUAL HAHN POLYNOMIALS*

MOURAD E. H. ISMAIL†, JEAN LETESSIER,‡ AND GALLIANO VALENT‡

Abstract. Birth and death process polynomials with symmetric quadratic rates are studied. They provide two generalizations of the continuous dual Hahn polynomials. Generating functions and explicit representations are derived. The asymptotic behavior and weight functions of the polynomials under consideration are also determined.

Key words. continuous dual Hahn polynomials, birth and death processes, generating functions

AMS(MOS) subject classifications. 33A65, 42C05, 60K25

1. Introduction. A birth and death process with birth rates $\{\lambda_n\}$ and death rates $\{\mu_n\}$ gives rise to a set of polynomials $\{p_n(x)\}$ defined recursively by

$$p_0(x)=1,\ p_1(x)=(\lambda_0+\mu_0-x)/\mu_1, \tag{1.1}$$

$$-xp_n(x)=\mu_{n+1}p_{n+1}(x)+\lambda_{n-1}p_{n-1}(x)-(\lambda_n+\mu_n)p_n(x). \tag{1.2}$$

It is assumed that

$$\lambda_n>0,\quad \mu_{n+1}>0,\quad n\geqq 0,\quad \mu_0\geqq 0. \tag{1.3}$$

The p_n's are orthogonal with respect to a probability measure $d\psi$ with finite moments. The orthogonality relation is

$$\int_0^\infty p_m(x)\,p_n(x)\,d\psi(x)=\pi_n\delta_{m,n}, \tag{1.4}$$

where

$$\pi_0=1,\quad \pi_n=\lambda_0\lambda_1,\cdots,\lambda_{n-1}/\mu_1\mu_2,\cdots,\mu_n,\quad n>0. \tag{1.5}$$

Karlin and McGregor [8], [9] proved that the transition probability $p_{mn}(t)$, the probability that the system moves from state m to state n in time t, is given by

$$\pi_n p_{mn}(t)=\int_0^\infty e^{-xt}p_m(x)\,p_n(x)\,d\psi(x).$$

Such a measure $d\psi$ is called a spectral measure of the birth and death process.

Birth and death processes with polynomial rates $\{\lambda_n\}$, $\{\mu_n\}$ arise in many fields [5], but there seem to be very few cases known where the polynomials and the spectral measures are known explicitly. A complete analysis of the cases when both λ_n and μ_{n+1}, $n\geqq 0$ are linear in n was completed only recently [4], [7], [20]. The polynomials are associated Laguerre and associated Meixner polynomials.

We will study symmetric birth and death process polynomials with quadratic rates

$$\lambda_n=(n+a)(n+b),\quad n\geqq 0,\quad \mu_n=(n+\alpha)(n+\beta),\quad n>0,\quad \mu_0=0 \text{ or } \mu_0=\alpha\beta. \tag{1.6}$$

When α or $\beta = 0$ the polynomials reduce to the dual Hahn polynomials in Askey's tableaux; see [1], [3], and [10]. This case has also been treated in [11]. The cases $ab = 0$ are in [12]. We will call these polynomials the associated continuous dual Hahn polynomials. In § 2 we find generating functions for the polynomials and for the numerator polynomials of the corresponding J fraction. We also apply Darboux's asymptotic method to these generating functions and determine the main term in the asymptotic expansion of the polynomials under consideration. In § 3 we find the continued fraction whose denominators are the associated continuous dual Hahn polynomials. The spectral measure in this case turns out to be unique, so the continued fraction is the Stieltjes transform of the spectral measure. The Stieltjes transform is then inverted and the spectral measure is found. In § 4 we obtain explicit representations for our polynomials and use the symmetry of the polynomials in the parameters α, β to obtain transformation formulas involving double sums.

We follow the notation, terminology, and methodology in [2] and [14]. In particular, if a sequence of orthogonal polynomials $\{r_n(x)\}$ satisfies a three-term recurrence relation

$$r_{n+1}(x) = (a_n x + b_n) r_n(x) - d_n r_{n-1}(x),$$

then the associated polynomials $\{r_n(x; c)\}$ are given initially by

$$r_0(x; c) = 1, \; r_1(x; c) = a_c x + b_c$$

and are defined recursively by

$$r_{n+1}(x; c) = (a_{n+c} x + b_{n+c}) r_n(x; c) - d_{n+c} r_n(x; c), \qquad n > 0,$$

provided that the coefficients a_{n+c}, b_{n+c}, d_{n+c} are well defined and $r_n(x; c)$ has precise degree n. The interesting cases arise when c is not a positive integer. For references on associated polynomials, see [2] and [4]. Recently Wimp [19] made a detailed study of the associated Jacobi polynomials, applying the approach used in [4].

We will follow the standard hypergeometric function notation as in [6], [15], and [17] and the terminology of asymptotic analysis as in Olver [13].

2. Generating functions. We will treat two distinct cases according to whether or not μ_0 vanishes. For convenience we introduce an auxiliary parameter η in the following way.

$$\text{Case I: } \eta = 0 \text{ and } \mu_0 = 0 \qquad \text{Case II: } \eta = 1 \text{ and } \mu_0 = \alpha\beta.$$

Let $\{P_n(x)\}$ (or $\{P_n(x; a, b, \alpha, \beta, \eta)\}$) be the corresponding orthogonal polynomials and set

$$G(x, w) = \sum_0^\infty P_n(x) w^n. \tag{2.1}$$

Multiplying the recurrence relation (1.2) by w^{n+1} and applying the initial conditions (1.1), we derive the differential equation

$$\begin{aligned} w(1-w)^2 G'' + (1-w)[1+\alpha+\beta-(a+b+1)w]G' \\ + [x + (w-1)(ab - \alpha\beta/w)]G = \alpha\beta(1-w)^\eta / w, \end{aligned} \tag{2.2}$$

where $'$ denotes differentiation with respect to w. We then observe that the singularities of the above differential equation are $w = 0, 1, \infty$ and that all three are regular singular points. This means that if H is a solution of the homogeneous equation corresponding

to (2.2) then we can find parameters μ and ν such that the function $F(w) = w^{-\mu}(1-w)^{-\nu}H(w)$ satisfies the hypergeometric differential equation

$$w(1-w)F'' + [C-(1+A+B)w]F' - ABF = 0. \tag{2.3}$$

We make the choices

$$\mu = -\beta, \qquad \nu = \gamma - (\gamma^2 - x)^{1/2} \quad \text{where } \gamma = (1+\alpha+\beta-a-b)/2, \tag{2.4}$$

and find

$$A = -(\gamma^2-x)^{1/2} + (1+\alpha-\beta+b-a)/2, \qquad B = A+a-b, \qquad C = 1+\alpha-\beta. \tag{2.5}$$

At this stage the square root appearing in ν in (2.4) has no particular branch associated with it. Later we will choose the branch that makes $\operatorname{Re}(\gamma^2-x)^{1/2} > 0$. Two linearly independent solutions of the homogeneous differential equation corresponding to (2.2) are given by the functions G_1 and G_2 defined below.

$$G_1^{\alpha,\beta}(w) = w^{-\beta}(1-w)^{\gamma-(\gamma^2-x)^{1/2}} \qquad {}_2F_1(A, B; C; w)$$

$$G_2^{\alpha,\beta}(w) = G_1^{\beta,\alpha}(w).$$

The Wronskian of G_1 and G_2 is $C_1 w^{-\alpha-\beta-1}(1-w)^{\alpha+\beta-a-b}$, C_1 being a constant. Therefore the solution of (2.2), which is analytic at $w=0$ and $G(x,0)=1$, is given by

$$\begin{aligned} G(x, w) = \frac{\alpha\beta}{\alpha-\beta}\int_0^w u^{\alpha+\beta-1}(1-u)^{\eta-2\gamma-1}[G_1^{\alpha,\beta}(w)G_2^{\alpha,\beta}(u) \\ - G_1^{\alpha,\beta}(u)G_2^{\alpha,\beta}(w)]\,du. \end{aligned} \tag{2.6}$$

We next determine the main term in the asymptotic development of $P_n(x)$ using the asymptotic method of Darboux which states that if

$$f(z) = \sum_0^\infty f_n z^n \text{ and } g(z) = \sum_0^\infty g_n z^n$$

are analytic in $|z| < r$, and $f(z) - g(z)$ is continuous on $|z| = r$ then $f_n = g_n + o(r^{-n})$ as $n \to \infty$. Thus the asymptotics of the coefficients in the Taylor series expansion of a function $f(z)$ analytic in a neighborhood of $z=0$ are determined by the main term in the singular part of $f(z)$ at the closest singularities to the origin. For details see Olver [13] and Szegö [18]. It is clear that the ${}_2F_1$'s appearing in (2.6) are defined when their argument equals unity if $\operatorname{Re}\{(\gamma^2-x)^{1/2}\} > 0$. Therefore in this case

$$(1-w)^{-\gamma+\sqrt{\gamma^2-x}}G(x, w)$$

is an analytic function of w in $|w| \leqq 1$. Let $\mathscr{A}$ denote the limit of the above function as $w \to 1$. The smallest exponent of $1-w$ in the expansion of $G(x, w)$ around $w=1$ is $\gamma - (\gamma^2-x)^{1/2}$. We now apply Darboux's asymptotic method. Thus the dominant term in the asymptotic expansion of $P_n(x)$ equals the coefficient of w^n in $\mathscr{A}(1-w)^{\gamma-\sqrt{\gamma^2-x}}$. We then use the binomial theorem to find the latter coefficient to be

$$\mathscr{A}\frac{\Gamma(n-\gamma+\sqrt{\gamma^2-x})}{\Gamma(\sqrt{\gamma^2-x}-\gamma)\Gamma(n+1)}$$

which is asymptotic to $n^{-\gamma-1+\sqrt{\gamma^2-x}}/\Gamma(-\gamma+\sqrt{\gamma^2-x})$. This establishes the asymptotic

formula

$$P_n(x)\approx\frac{\alpha\beta n^{-1-\gamma-(\gamma^2-x)^{1/2}}}{(\beta-\alpha)\Gamma\{(\gamma^2-x)^{1/2}-\gamma\}}\int_0^1(1-u)^{\eta-\gamma-1-\sqrt{\gamma^2-x}}$$
$$\cdot\left[u^{\alpha-1}\frac{\Gamma(1+\beta-\alpha)\Gamma(2(\gamma^2-x)^{1/2})}{\Gamma(1-A)\Gamma(1-B)}{}_2F_1\left(\begin{matrix}A+\beta-\alpha, B+\beta-\alpha\\ 1+\alpha-\beta\end{matrix}\middle| u\right)\right.$$
$$\left.-\text{a similar term with } \alpha \text{ and } \beta \text{ interchanged}\right]du,$$

when $x\notin R$. The integrand in the above asymptotic formula can be greatly simplified by using the connection relation [6, § 2.9, (33)]

$$(1-z)^{h-f-g}{}_2F_1\left(\begin{matrix}h-f, h-g\\ 1+h-f-g\end{matrix}\middle| 1-z\right)$$
$$=\frac{\Gamma(1+h-f-g)\Gamma(1-h)}{\Gamma(1-f)\Gamma(1-g)}{}_2F_1\left(\begin{matrix}f, g\\ h\end{matrix}\middle| z\right)$$
$$+\frac{\Gamma(1+h-f-g)\Gamma(h-1)}{\Gamma(h-f)\Gamma(h-g)}z^{1-h}{}_2F_1\left(\begin{matrix}1+f-h, 1+g-h\\ 2-h\end{matrix}\middle| z\right).$$

The result is

$$P_n(x)\approx\frac{\alpha\beta n^{-1-\gamma-(\gamma^2-x)^{1/2}}}{2(\gamma^2-x)^{1/2}\Gamma\{(\gamma^2-x)^{1/2}-\gamma\}}\int_0^1 u^{\beta-1}(1-u)^{\eta-1-\gamma+\sqrt{\gamma^2-x}}$$
$$\cdot{}_2F_1\left(\begin{matrix}1-A, 1-B\\ 1+2(\gamma^2-x)^{1/2}\end{matrix}\middle| 1-u\right)du,$$

valid for nonreal x. We now apply the Euler type integral representation [15, § 49]

$$(2.7)\quad {}_3F_2\left(\begin{matrix}a_1, a_2, a_3\\ b_1, b_2\end{matrix}\middle| z\right)=\frac{\Gamma(b_2)}{\Gamma(b_2-a_3)\Gamma(a_3)}\int_0^1 t^{a_3-1}(1-t)^{b_2-a_3-1}{}_2F_1\left(\begin{matrix}a_1, a_2\\ b_1\end{matrix}\middle| zt\right)dt$$

and obtain the asymptotic relationship

$$(2.8)\quad P_n(x)\approx\frac{\alpha\beta n^{\sqrt{\gamma^2-x}-1-\gamma}\Gamma(\beta)\Gamma(\eta-\gamma+\sqrt{\gamma^2-x})}{2\sqrt{\gamma^2-x}\Gamma(\sqrt{\gamma^2-x}-\gamma)\Gamma[\eta+\sqrt{\gamma^2-x}+(a+b+\beta-\alpha-1)/2]}$$
$$\cdot{}_3F_2\left(\begin{matrix}a_1, a_2, a_3\\ b_1, b_2\end{matrix}\middle| 1\right)$$

where

$$a_1=(1+a-b+\beta-\alpha)/2+\sqrt{\gamma^2-x},$$
$$a_2=\sqrt{\gamma^2-x}+(1+b-a+\beta-\alpha)/2,$$
$$a_3=\sqrt{\gamma^2-x}+\eta+(a+b-\alpha-\beta-1)/2,$$
$$b_1=1+2\sqrt{\gamma^2-x},$$
$$b_2=\sqrt{\gamma^2-x}+\eta+(a+b+\beta-\alpha-1)/2,$$

as $n\to\infty$ and fixed x with $\operatorname{Im}\{x\}\neq 0$.

3. The spectral measures. The orthonormal polynomials $\{\omega_n(x)\}$ are given by

$$\omega_n(x)=[\mu_1\mu_2,\cdots,\mu_n/\lambda_0\lambda_1,\cdots,\lambda_{n-1}]^{1/2}P_n(x).$$

Therefore

$$\omega_n(x)\approx[\Gamma(a)\Gamma(b)/\Gamma(\alpha+1)\Gamma(\beta+1)]n^{\alpha+\beta+2-a-b}P_n(x),\quad \text{as } n\to\infty.$$

It easily follows from (2.8) and the above asymptotic relationship that the series

$$\sum_0^\infty|\omega_n(x)|^2$$

diverges for some complex x. Now Theorem 2.9 [16, p. 50] implies that the corresponding moment problem is determined, i.e., the spectral measure is unique.

The numerators $\{q_n(x)\}$ of the continued fraction whose partial denominators are the p_n's (of (1.1) and (1.2)) satisfy the recursion (1.2) and the initial conditions

$$q_0(x)=0,\qquad q_1(x)=-1/\mu_1. \tag{3.1}$$

Clearly, $q_n(x)$ is a polynomial of degree $n-1$. Let σ denote the support of the spectral measure $d\psi$. The determinacy of the moment problem ensures the uniform convergence of $q_n(x)/p_n(x)$ to $\int_\sigma(x-t)^{-1}\,d\psi(x)$ on compact subsets of the complex x-plane cut along σ [16, Thm. 2.9, p. 50]. At this stage we need to exhibit the dependence of the polynomials on the parameters involved, so we will use $P_n(x;a,b,\alpha,\beta,\eta)$ instead of just $P_n(x)$ to denote our polynomials and will use a similar notation for the q_n's. We can easily see that

$$\begin{aligned}q_n(x;a,b,\alpha,\beta,\eta)&=[-(\alpha+1)(\beta+1)]^{-1}\\&\quad\cdot P_{n-1}(x;a+1,b+1,\alpha+1,\beta+1,0),\qquad \eta=0,1,\end{aligned} \tag{3.2}$$

follows from (1.1), (1.2), and (3.1). Set

$$X_\eta(x)=\lim_{n\to\infty}q_n(x;a,b,\alpha,\beta,\eta)/P_n(x;a,b,\alpha,\beta,\eta). \tag{3.3}$$

We are now in a position to prove the following theorem.

THEOREM 1. *The functions $X_\eta(x)$ are given by*

$$X_\eta(x)=\frac{\alpha^{-1}{}_3F_2\left(\begin{matrix}1-A,\,1-B,\,\sqrt{\gamma^2-x}-\gamma\\1+2\sqrt{\gamma^2-x},\,b-A+1\end{matrix}\,\middle|\,1\right)}{[\gamma-\sqrt{\gamma^2-x}+\beta(\eta-1)]_3F_2\left(\begin{matrix}1-A,\,1-B,\,\sqrt{\gamma^2-x}-\gamma+\eta\\1+2\sqrt{\gamma^2-x},\,b-A+\eta\end{matrix}\,\middle|\,1\right)},\quad \eta=0,1. \tag{3.4}$$

Proof. The theorem follows from (3.2), (3.3), and (2.8). □

The next step is to invert the Stieltjes transforms $X_\eta(x)$ and find the measures $d\psi$ explicitly via the following inversion formula, which holds when the support of $d\psi$ is contained in a half line

$$\begin{aligned}&\int_{-\infty}^{\infty}\frac{d\psi(t)}{x-t}=F(x),\qquad x\notin\operatorname{supp}\{d\psi\}\\&\text{iff }\psi(t_2)-\psi(t_1)=\lim_{\varepsilon\to0^+}\int_{t_1}^{t_2}\frac{F(t-i\varepsilon)-F(t+i\varepsilon)}{2\pi i}\,dt.\end{aligned} \tag{3.5}$$

The inversion formula (3.5) is usually referred to as the Perron-Stieltjes inversion formula. We now state a technical lemma needed in the inversion of the Stieltjes transforms of the measures $d\psi(x)$.

LEMMA 2. *Assume that* $\operatorname{Re}\{d-a-b\}>0$ *and* $\operatorname{Re}\{a+b+c-d-e\}>0$. *Then*

$$\lim_{z\to 1^-}(1-z)^{a+b+c-d-e}\,{}_3F_2\left(\begin{matrix}a, b, c\\ d, e\end{matrix}\,\middle|\, z\right)=\frac{\Gamma(d)\Gamma(e)\Gamma(a+b+c-d-e)}{\Gamma(a)\Gamma(b)\Gamma(c)} \tag{3.6}$$

Proof. Applying the Pfaff-Kummer transformation [15]

$${}_2F_1(a, b; c; z)=(1-z)^{-a}\,{}_2F_1(a, c-b; c; z/(z-1)) \tag{3.7}$$

to the ${}_2F_1$ in (2.7), then replacing t by $1-t$ we get

$$\begin{aligned}{}_3F_2\left(\begin{matrix}a, b, c\\ d, e\end{matrix}\,\middle|\, z\right)&=\frac{\Gamma(e)(1-z)^{d-a-b}}{\Gamma(c)\Gamma(e-c)}\int_0^1 t^{e-c-1}(1-t)^{c-1}\\ &\quad\cdot\left\{1-\frac{zt}{z-1}\right\}^{d-a-b}{}_2F_1\left(\begin{matrix}d-a, d-b\\ d\end{matrix}\,\middle|\, z(1-t)\right)dt\\ &=\frac{\Gamma(e)(1-z)^{d-a-b}}{\Gamma(c)\Gamma(e-c)}\sum_0^\infty\frac{(d-a)_n(d-b)_n}{n!(d)_n}z^n\int_0^1 t^{e-c-1}(1-t)^{n+c-1}\\ &\quad\cdot\left(1-\frac{zt}{z-1}\right)^{d-a-b}dt\\ &=\frac{\Gamma(e)(1-z)^{d-a-b}}{\Gamma(c)\Gamma(e-c)}\sum_0^\infty\frac{(d-a)_n(d-b)_n}{n!(d)_n}z^n\,{}_2F_1\left(\begin{matrix}e-c, a+b-d\\ e+n\end{matrix}\,\middle|\,\frac{z}{z-1}\right).\end{aligned}$$

In the last step we also used the Euler integral representation for a ${}_2F_1$, i.e., (2.7) with a_1 equal to b_1. Next apply the transformation (3.7) to the ${}_2F_1$ in the last sum to obtain

$$\begin{aligned}(1-z)^{a+b+c-d-e}\,{}_3F_2\left(\begin{matrix}a, b, c\\ d, e\end{matrix}\,\middle|\, z\right)&=\frac{\Gamma(e)}{\Gamma(c)}\sum_0^\infty\frac{(d-a)_n(d-b)_n\Gamma(n+c)}{n!(d)_n\Gamma(e+n)}\\ &\quad\cdot{}_2F_1\left(\begin{matrix}e-c, n+d+e-a-b\\ e+n\end{matrix}\,\middle|\, z\right).\end{aligned} \tag{3.8}$$

We then let $z\to 1^-$ in (3.8) and use Gauss's theorem [15]

$${}_2F_1(\alpha, \beta; \gamma; 1)=\Gamma(\gamma)\Gamma(\gamma-\alpha-\beta)/\{\Gamma(\gamma-\alpha)\Gamma(\gamma-\beta)\},\quad \operatorname{Re}(\gamma-\alpha-\beta)>0.$$

It is easy to justify interchanging the limiting and summation processes. The result is that the right-hand side of (3.8) reduces to

$$\frac{\Gamma(e)}{\Gamma(c)}\sum_0^\infty\frac{(d-a)_n(d-b)_n\Gamma(a+b+c-d-e)}{n!(d)_n\Gamma(a+b-d)}$$

which can be summed by Gauss's theorem. This completes the proof of the lemma. □

We now discuss the inversion of the Stieltjes transforms $X_\eta(x)$, $\eta=0, 1$, and find the measures with respect to which our polynomials are orthogonal. Let

$$X_\eta(x)=\int_0^\infty (x-t)^{-1}\,d\psi(t; \eta). \tag{3.9}$$

We can easily see from (3.5) that

$$2\pi i\psi'(t; \eta)=X_\eta(t-i0^+)-X_\eta(t+i0^+). \tag{3.10}$$

It readily follows from (3.10) that ψ' vanishes identically on $(-\infty, \gamma^2)$ because $X_\eta(x)$ is single-valued in the complex plane cut along $(-\infty, \gamma^2)$. Clearly,

$$\sqrt{\gamma^2-t\pm i0^+}=\pm i\sqrt{t-\gamma^2},\quad t\in[\gamma^2, \infty). \tag{3.11}$$

Define

$$D=-i\sqrt{t-\gamma^2}+\tfrac{1}{2}(1+a+b+\beta-\alpha), \qquad E=i\sqrt{t-\gamma^2}+\tfrac{1}{2}(1+a+b+\beta-\alpha). \tag{3.12}$$

It is easy to see from (3.4), (3.11), and (3.12) that

$$X_0(t-i0)-X_0(t+i0)$$

$$=\frac{{}_3F_2\left(\begin{matrix}D-a, D-b, D-\alpha-1\\ 1-2i\sqrt{t-\gamma^2}, D\end{matrix}\middle|1\right)}{\alpha(D-1){}_3F_2\left(\begin{matrix}D-a, D-b, D-\alpha-1\\ 1-2i\sqrt{t-\gamma^2}, D-1\end{matrix}\middle|1\right)}-\text{complex conjugate}. \tag{3.13}$$

We then apply (4.4.3) in Slater [17] and obtain

$$\alpha[t-\gamma^2+\{(a+b+\beta-\alpha-1)/2\}^2]\{t-\gamma^2\}^{-1/2}\{X_0(t-i0)-X_0(t+i0)\}$$

$$=\lim_{z\to 1^-}\frac{(1-z)^{a+b+\beta+1-D-E}{}_3F_2\left(\begin{matrix}a, b, \beta+1\\ D, E\end{matrix}\middle|z\right)}{\left|{}_3F_2\left(\begin{matrix}D-a, D-b, D-\alpha-1\\ 1-2i\sqrt{t-\gamma^2}, D-1\end{matrix}\middle|z\right)\right|^2}.$$

Lemma 2 shows that the limit of the numerator on the right-hand side of the above formula is $\Gamma(E)\Gamma(D)\Gamma(a+b+\beta+1-D-E)/\{\Gamma(1+\beta)\Gamma(a)\Gamma(b)\}$. This fact, when combined with (3.10) establishes, after some simplification, the following result.

THEOREM 3. *The weight function $\psi'(t;0)$ is supported on $[\gamma^2,\infty)$ where it is given by*

$$\psi'(t;0)=\frac{\Gamma(\alpha)\sqrt{t-\gamma^2}}{\pi\alpha\Gamma(a)\Gamma(b)\Gamma(\beta+1)} \tag{3.14}$$

$$\cdot\left|\frac{\Gamma(i\sqrt{t-\gamma^2}+\frac{1}{2}(a+b-1+\beta-\alpha))}{{}_3F_2\left(\begin{matrix}i\sqrt{t-\gamma^2}+\frac{1}{2}(a-b+1+\beta-\alpha), i\sqrt{t-\gamma^2}+\frac{1}{2}(b-a+1+\beta-\alpha), i\sqrt{t-\gamma^2}+\frac{1}{2}(a+b-1-\alpha-\beta),\\ 1+2i\sqrt{t-\gamma^2}, i\sqrt{t-\gamma^2}+\frac{1}{2}(a+b+\beta-\alpha-1)\end{matrix}\middle|1\right)}\right|^2\cdot$$

It is clear from (1.1), (1.2), and (1.6) that the dual Hahn polynomials remain invariant if we interchange a and b, or interchange α and β. Therefore $\psi'(t,\eta)$ must also be invariant under the same operations. The right-hand side of formula (3.14) is symmetric in a and b but does not exhibit the symmetry of $\psi'(t;0)$ in α and β. The more symmetric form

$$\pi\Gamma(a)\Gamma(b)\Gamma(\alpha+1)\Gamma(\beta+1)\psi'(t;0)$$

$$=\sqrt{t-\gamma^2}\left|\frac{\Gamma\{\frac{1}{2}(3+\alpha+\beta-a-b)+i\sqrt{t-\gamma^2}\}\Gamma\{\frac{1}{2}(a+b+\beta-\alpha-1)+i\sqrt{t-\gamma^2}\}}{\Gamma(1+2i\sqrt{t-\gamma^2})}\right|^2 \tag{3.15}$$

$$\cdot\left|{}_3F_2\left(\begin{matrix}a-1, & b-1, & \frac{1}{2}(1+\alpha+\beta-a-b)+i\sqrt{t-\gamma}\\ \frac{1}{2}(a+b+\alpha-\beta-1)+i\sqrt{t-\gamma^2}, & \frac{1}{2}(a+b+\beta-\alpha-1)+i\sqrt{t-\gamma^2}\end{matrix}\middle|1\right)\right|^2,$$

for $t\in[\gamma^2,\infty)$ can be obtained from the transformation

$${}_3F_2\left(\begin{matrix}\mathbf{A}, \mathbf{B}, \mathbf{C}\\ \mathbf{D}, \mathbf{E}\end{matrix}\middle|1\right)=\frac{\Gamma(\mathbf{E})\Gamma(\mathbf{S})}{\Gamma(\mathbf{E}-\mathbf{C})\Gamma(\mathbf{S}+\mathbf{C})}{}_3F_2\left(\begin{matrix}\mathbf{D}-\mathbf{A}, \mathbf{D}-\mathbf{B}, \mathbf{C}\\ \mathbf{D}, \mathbf{S}+\mathbf{C}\end{matrix}\middle|1\right),$$

with $\mathbf{S}=\mathbf{D}+\mathbf{E}-\mathbf{A}-\mathbf{B}-\mathbf{C}$.

One can treat the case $\eta=1$ similarly, that is $\mu_0=0$. In this case we need the following lemma.

LEMMA 4. *The ${}_3F_2$'s satisfy the contiguous relation*

$$Z\,{}_3F_2\left(\begin{matrix}X, Y, Z+1\\ U, V\end{matrix}\middle|1\right)=(V-1)\,{}_3F_2\left(\begin{matrix}X, Y, Z\\ U, V-1\end{matrix}\middle|1\right)+(1+Z-V)\,{}_3F_2\left(\begin{matrix}X, Y, Z\\ U, V\end{matrix}\middle|1\right). \tag{3.16}$$

Proof. This lemma follows from

$$Z(Z+1)_n=(Z)_n(Z+n)=(Z)_n\{(Z-V+1)+(V+n-1)\}. \qquad \square$$

Remark. Lemma 4 is known but is not easily accessible.

Using the notation

$$X=\tfrac{1}{2}(a-b+\beta-\alpha+1)-i\sqrt{t-\gamma^2}, \qquad Y=\tfrac{1}{2}(1+b-a+\beta-\alpha)-i\sqrt{t-\gamma^2},$$

$$U=1-2i\sqrt{t-\gamma^2},$$

$$V=\tfrac{1}{2}(1+a+b-\beta-\alpha)-i\sqrt{t-\gamma^2}, \qquad Z=\tfrac{1}{2}(a+b-1-\beta-\alpha)-i\sqrt{t-\gamma^2},$$

together with (3.4), (3.9), and (3.10) we find

$$\begin{aligned}
&\alpha\left|\gamma-i\sqrt{t-\gamma^2}\right|^2\{X_1(t+i0)-X_1(t-i0)\}\left|{}_3F_2\left(\begin{matrix}X, Y, Z+1\\ U, V\end{matrix}\middle|1\right)\right|^2\\
&\quad=Z\,{}_3F_2\left(\begin{matrix}X, Y, Z+1\\ U, V\end{matrix}\middle|1\right){}_3F_2\left(\begin{matrix}\bar X, \bar Y, \bar Z\\ \bar U, \bar V\end{matrix}\middle|1\right)-\text{complex conjugate}\\
&\quad=(V-1)\,{}_3F_2\left(\begin{matrix}X, Y, Z\\ U, V-1\end{matrix}\middle|1\right){}_3F_2\left(\begin{matrix}\bar X, \bar Y, \bar Z\\ \bar U, \bar V\end{matrix}\middle|1\right)\\
&\qquad+(1+Z-V)\left|{}_3F_2\left(\begin{matrix}X, Y, Z\\ U, V\end{matrix}\middle|1\right)\right|^2-\text{complex conjugate},
\end{aligned}$$

which, since $1+Z-V$ is real, simplifies to

$$(V-1)\,{}_3F_2\left(\begin{matrix}X, Y, Z\\ U, V-1\end{matrix}\middle|1\right){}_3F_2\left(\begin{matrix}\bar X, \bar Y, \bar Z\\ \bar U, \bar V\end{matrix}\middle|1\right)-\text{complex conjugate}.$$

The above quantity appeared earlier in the inversion of $X_0(x)$ and was simplified using (4.4.3) in Slater [15]. This enables us to find the absolutely continuous component of the measure $d\psi(t;1)$. When we combine this result with (3.14) we obtain the following theorem.

THEOREM 5. *Let $\gamma=(1+\alpha+\beta-a-b)/2$ (as in (2.4)). The weight functions $\psi'(t;\eta)$ when $\eta=0,1$, are given by*

$$\begin{aligned}
\psi'(t;\eta)=&\frac{t^{-\eta}\sqrt{t-\gamma^2}\left|\Gamma\{1-\eta+\gamma+i\sqrt{t-\gamma^2}\}\right|^2}{\pi\Gamma(a)\Gamma(b)\Gamma(\alpha+1)\Gamma(\beta+1)\left|\Gamma\{1+2i\sqrt{t-\gamma^2}\}\right|^2}\\
&\cdot\left|\frac{\Gamma\{\eta+\alpha-\gamma-i\sqrt{t-\gamma^2}\}\Gamma\{\eta+\beta-\gamma+i\sqrt{t-\gamma^2}\}}{{}_3F_2\left(\begin{matrix}a+\eta-1, b+\eta-1, \eta-\gamma+i\sqrt{t-\gamma^2}\\ \eta+\alpha-\gamma+i\sqrt{t-\gamma^2}, \eta+\beta-\gamma+i\sqrt{t-\gamma^2}\end{matrix}\middle|1\right)}\right|^2
\end{aligned} \tag{3.17}$$

valid for $t\in(\gamma^2,\infty)$.

The isolated jumps of ψ coincide with poles of its Stieltjes transform. We believe, but have been unable to prove, that the functions appearing in the denominators of $X_\eta(x)$, $\eta=0,1$ do not vanish for real values of x if α and β are positive when $\mu_0=\alpha\beta$, or $\alpha>-1$ and $\beta>-1$ when $\mu_0=0$.

4. Explicit and transformation formulas. We first derive the explicit formula

$$P_n(x;a,b,\alpha,\beta,\eta)=\sum_{j=0}^{n}\frac{(\gamma+a-i\sqrt{x-\gamma^2})_j(\gamma+b-i\sqrt{x-\gamma^2})_j(-\gamma+i\sqrt{x-\gamma^2})_{n-j}}{(n-j)!(\alpha+1)_j(\beta+1)_j}$$

$$\cdot\,{}_3F_2\left(\begin{matrix}\alpha,\ \beta,\ \gamma-\eta-i\sqrt{x-\gamma^2}\\ \gamma+a-i\sqrt{x-\gamma^2},\ \gamma+b-i\sqrt{x-\gamma^2}\end{matrix}\middle|1\right). \tag{4.1}$$

Proof of (4.1). We make the substitution

$$G(x,w)=w^{-\beta}(1-w)^{\gamma-i\sqrt{x-\gamma^2}}F(x,w) \tag{4.2}$$

in (2.2) and find that the function $F(x,w)$ satisfies the differential equation

$$w(1-w)F''+[C-(1+A+B)w]F'-ABF=\alpha\beta w^{\beta-1}(1-w)^{\eta-\gamma+i\sqrt{x-\gamma^2}}, \tag{4.3}$$

where $'$ denotes differentiation with respect to w. We then solve (4.3) using the Frobenius method. Clearly,

$$F(x,w)=\sum_{0}^{\infty}c_n w^{n+\beta},$$

with $c_0=1$. Equating coefficients of various powers of w leads to the two-term recurrence relations

$$(\alpha+n+1)(\beta+n+1)c_{n+1}-(n+a+\gamma-i\sqrt{x-\gamma^2})$$

$$\cdot\,(n+b+\gamma-i\sqrt{x-\gamma^2})c_n=\frac{\alpha\beta(\gamma-\eta-i\sqrt{x-\gamma^2})_{n+1}}{(n+1)!}$$

whose solution, subject to the initial condition $c_o=1$, is

$$c_n=\frac{(a+\gamma-i\sqrt{x-\gamma^2})_n(b+\gamma-i\sqrt{x-\gamma^2})_n}{(\alpha+1)_n(\beta+1)_n}\sum_{k=0}^{n}\frac{(\alpha)_k(\beta)_k(\gamma-\eta-i\sqrt{x-\gamma^2})_k}{k!(a+\gamma-i\sqrt{x-\gamma^2})_k(b+\gamma-i\sqrt{x-\gamma^2})_k}.$$

This and (4.2) establish (4.1) and the proof is complete. □

Observe that when α or β vanishes our polynomials reduce to the continuous dual Hahn polynomials and (4.1) provides a representation of continuous dual Hahn polynomials as multiples of ${}_3F_2$'s. Note also that (4.1) remains valid if we reverse the signs of all square roots involved because the left-hand side is a real polynomial in x.

An interesting representation of the associated continuous dual Hahn polynomials is discovered if we change variables in (2.2) as follows. Set

$$G(x,w)=w^{-\beta}(1-w)^{\beta-a}P(x,z), \qquad \text{with } w=z/(1+z). \tag{4.4}$$

It is readily seen that $P(x,z)$ satisfies the differential equation

$$z(1+z)\frac{\partial^2 P}{\partial z^2}+[1+\alpha-\beta+(2+a-b+\alpha-\beta)z]\frac{\partial P}{\partial z}$$

$$+[(a-\beta)(a-b+1)+x]P=\alpha\beta z^{\beta-1}(1+z)^{1-\alpha-\eta}.$$

We again apply the Frobenius method and let

$$P(x,z)=\sum_{n=0}^{\infty}h_n z^{n+\beta}.$$

We then find that the h_n's satisfy the two-term recurrence relation

$$(n+\beta+1)(n+\alpha+1)h_{n+1}$$

$$+\{(n+\beta)(n+a-b+\alpha+1)+(a-\beta)(\alpha-b+1)+x\}h_n=\alpha\beta(-1)^{n+1}\frac{(a+\eta-1)_{n+1}}{(n+1)!},$$

whose solution subject to $h_0=1$ is

$$h_n=(-1)^n\frac{(a+\gamma+i\sqrt{x-\gamma^2})_n(a+\gamma-i\sqrt{x-\gamma^2})_n}{(\alpha+1)_n(\beta+1)_n}$$

$$\cdot\sum_{k=0}^{n}\frac{(\alpha)_k(\beta)_k(a+\eta-1)_k}{k!(a+\gamma+i\sqrt{x-\gamma^2})_k(a+\gamma-i\sqrt{x-\gamma^2})_k}.$$

Thus we have

$$G(x,w)=(1-w)^{-a}\sum_{k=0}^{\infty}h_k\left(\frac{w}{1-w}\right)^k=\sum_{j,k=0}^{\infty}\frac{(a+k)_j}{j!}h_kw^{k+j}.$$

Replacing $(a+k)_j$ by $(a)_{k+j}/(a)_k$ leads to the explicit formula

$$P_n(x;a,b,\alpha,\beta,\eta)=\frac{(a)_n}{n!}\sum_{k=0}^{n}\frac{(-n)_k(a+\gamma+i\sqrt{x-\gamma^2})_k(a+\gamma-i\sqrt{x-\gamma^2})_k}{(a)_k(\alpha+1)_k(\beta+1)_k}$$

$$\cdot\sum_{j=0}^{k}\frac{(\alpha)_j(\beta)_j(a+\eta-1)_j}{j!(a+\gamma+i\sqrt{x-\gamma^2})_j(a+\gamma-i\sqrt{x-\gamma^2})_j}. \tag{4.5}$$

When α or β vanishes, the right-hand side of (4.5) reduces to the familiar ${}_3F_2$ representation of continuous dual Hahn polynomials.

Observe that the right-hand side of (4.5) is obviously invariant under interchanging α and β. On the other hand, the λ_n's and μ_n's in (1.1) and (1.2) are symmetric in a and b (see (1.6)). Therefore the polynomials P_n must also be symmetric in a and b.

THEOREM 6. *The right-hand side of* (4.5) *is a symmetric function of a and b where* γ *is as in* (2.4).

Theorem 6 is a generalization of the Whipple transformation [17] to a double series.

Acknowledgment. We thank the referees for their help in improving the presentation of some of our results, for correcting several typographical errors, and for pointing out a minor error in the original version of this paper.

ON THE ZEROS OF POLYNOMIALS ORTHOGONAL ON THE SEMICIRCLE*

WALTER GAUTSCHI†

Abstract. It is shown that the polynomials $\pi_n(\cdot; w)$ orthogonal in the sense of [W. Gautschi, H. J. Landau, and G. V. Milovanović, *Constr. Approx.*, 3 (1987), pp. 389-404] on the unit upper semicircle need not necessarily have all their zeros in the interior of the unit upper semidisc, not even for weight functions w that are symmetric, $w(-z)=w(z)$. A symmetric weight function w_a (depending on a parameter a) is exhibited, which has the property that $\pi_n(\cdot; w_a)$ for any fixed even n has a zero on the imaginary axis with imaginary part greater than one, provided a is large enough. Similarly, a weight function w^a is constructed for which the analogous property holds for $\pi_n(\cdot; w^a)$, n odd.

Key words. complex orthogonal polynomials, indefinite inner product, zeros

AMS(MOS) subject classifications. 30C10, 30C15, 33A65

1. In [3], [4] we introduced polynomials that are orthogonal on the semicircle with respect to the (non-Hermitian) inner product

$$(p, q)=\int_0^{\pi} p(e^{i\theta})q(e^{i\theta})w(e^{i\theta})\,d\theta. \tag{1.1}$$

Here, w is a "weight function" analytic on the semidisc $D_+=\{z\in\mathbb{C}: |z|<1, \operatorname{Im} z>0\}$, nonnegative on $(-1, 1)$ and integrable over ∂D_+. We have shown that under the assumption

$$\operatorname{Re}\int_0^{\pi} w(e^{i\theta})\,d\theta\neq 0 \tag{1.2}$$

there exists a unique system $\{\pi_n\}_{n=0}^{\infty}$ of monic polynomials $\pi_n(\cdot)=\pi_n(\cdot; w)$ such that

$$\deg \pi_n=n, \quad n=0, 1, 2, \cdots, \qquad (\pi_k, \pi_l)\begin{cases}=0, & k\neq l,\\ \neq 0, & k=l.\end{cases} \tag{1.3}$$

They possess many of the properties familiar from orthogonal polynomials on the real line, such as satisfying a three-term recurrence relation and a second-order linear differential equation (for special weight functions), and in fact can be expressed as (complex) linear combinations of two successive polynomials orthogonal on the interval $(-1, 1)$ with respect to the same weight function w. They give rise to Gauss-type quadrature rules for integration over the semicircle and to new, possibly more stable, quadrature formulae for evaluating Cauchy principal value integrals (see [3, §§ 7, 8]). Since the nodes of these quadrature rules involve the zeros of the polynomials π_n in (1.3), a study of the qualitative properties of these zeros is of interest.

In [4] we have shown that for weight functions analytic in $D=\{z\in\mathbb{C}: |z|<1\}$, symmetric in the sense

$$w(-z)=w(z) \quad \text{for all } z\in D, \tag{1.4}$$

and satisfying

$$w(x)\geqq 0 \quad \text{on } (-1, 1), \quad w(0)>0, \tag{1.5}$$

* Received by the editors December 8, 1987; accepted for publication (in revised form) August 1, 1988. This research was supported in part by National Science Foundation grant CCR-8704404.

† Department of Computer Sciences, Purdue University, West Lafayette, Indiana 47907.

all zeros of π_n are contained in D_+ with the possible exception of a single (simple) zero iy, $y \geqq 1$. For the Gegenbauer weight $w(z) = (1-z^2)^{\lambda-1/2}$, the exceptional case can only arise if $n = 1$ and $-\frac{1}{2} < \lambda \leqq 0$. Likewise, no exceptional cases seem to occur for Jacobi weights $w(z) = (1-z)^\alpha (1+z)^\beta$, $\alpha > -1$, $\beta > -1$, if $n \geqq 2$, as was observed by numerical computation. We might be led to believe that this absence of exceptional cases prevails for arbitrary weight functions w. In this note we show, however, that this is not so, not even for symmetric weight functions. We exhibit symmetric functions w for which $\pi_n(\cdot; w)$, for arbitrary fixed n, has a zero iy with $y \geqq 1$.

2. Let $b_k = b_k(w)$, $k = 1, 2, 3, \cdots$, be the coefficients in the recurrence formula

$$y_{k+1} = xy_k - b_k y_{k-1}, \quad k = 0, 1, 2, \cdots, \qquad y_{-1} = 0, \quad y_0 = 1 \tag{2.1}$$

satisfied by the polynomials $p_n(x; w)$ orthogonal on the interval $(-1, 1)$ relative to the symmetric weight function w. We recall from the proof of Theorem 6.5 and equations (5.2), (5.4) of [4] that iy is a zero of $\pi_n(\cdot; w)$ if and only if

$$\omega_n(y) - \theta_{n-1} = 0, \tag{2.2}$$

where

$$\omega_1(y) = y, \quad \omega_k(y) = y + \frac{b_{k-1}}{\omega_{k-1}(y)}, \quad k = 2, 3, \cdots, \tag{2.3}$$

$$\theta_{n-1} = \begin{cases} \dfrac{b_1 b_3 \cdots b_{n-1}}{b_2 b_4 \cdots b_{n-2}} \dfrac{\pi}{m_0}, & n \text{ even}, \\ \dfrac{b_2 b_4 \cdots b_{n-1}}{b_1 b_3 \cdots b_{n-2}} \dfrac{m_0}{\pi}, & n \text{ odd}, \end{cases} \tag{2.4}$$

and

$$m_0 = \int_{-1}^{1} w(x)\, dx = 2\int_0^1 w(x)\, dx, \tag{2.5}$$

the weight function w having been normalized to satisfy

$$w(0) = 1. \tag{2.6}$$

If $n = 1$ or $n = 2$, empty products in (2.4) are assumed to be one. Equation (2.2) holds for some $y \geqq 1$ if and only if

$$\omega_n(1) - \theta_{n-1} \leqq 0. \tag{2.7}$$

Indeed, since $\omega_n(y) \to \infty$ as $y \to \infty$, inequality (2.7) trivially implies (2.2) for some $y \geqq 1$. Conversely, if (2.2) holds for some $y \geqq 1$, but (2.7) (if $n \geqq 2$) does not, the left-hand side of (2.2), hence $\pi_n(iy)$, would have either two distinct zeros >1, or a double zero >1, which is impossible by Theorem 6.2 of [4]. By (2.3), we can write (2.7) in the form

$$1 + \frac{b_{n-1}}{1+}\,\frac{b_{n-2}}{1+} \cdots \frac{b_1}{1} \leqq \theta_{n-1}. \tag{2.8}$$

We now show that (2.8), for any fixed $n \geqq 1$, can always be achieved for some suitable weight function w.

3. It is necessary to distinguish the cases n even and n odd. In the former case, (2.8) becomes

$$1 + \frac{b_{n-1}}{1+}\,\frac{b_{n-2}}{1+} \cdots \frac{b_1}{1} \leqq \frac{b_1 b_3 \cdots b_{n-1}}{b_2 b_4 \cdots b_{n-2}} \frac{\pi}{m_0}. \tag{3.1}$$

It is clear that we can enforce (3.1) to hold if we can find a family of weight functions w for which m_0 tends to zero and the b_k remain bounded and bounded away from zero. Such a family of weight functions (keeping in mind that they should be analytic in D, satisfy (1.4), and be normalized by (2.6)) is given by

$$w(z) = w_a(z) = \frac{1+\sqrt{a/\pi}\, e^{-az^2}}{1+\sqrt{a/\pi}}, \qquad a>0. \tag{3.2}$$

The fact that w_a also satisfies (1.2) follows from Theorem 5.1 of [4]. We note that the second term in the numerator of (3.2), for real $z=x$, is an approximation to the Dirac delta function $\delta(x)$, to which it converges as $a\to\infty$. It follows that, for any polynomial p,

$$\begin{aligned}\left(1+\sqrt{\frac{a}{\pi}}\right)\int_{-1}^{1} w_a(x)p(x)\,dx &\to \int_{-1}^{1}[1+\delta(x)]p(x)\,dx \\ &= \int_{-1}^{1} p(x)\,dx + p(0) \quad \text{as } a\to\infty.\end{aligned} \tag{3.3}$$

In particular, putting $p(x)\equiv 1$,

$$m_0 \sim 3\sqrt{\pi/a}, \qquad a\to\infty. \tag{3.4}$$

Furthermore,

$$\lim_{a\to\infty} b_k(w_a) = b_{k,\infty} > 0, \quad \cdot\ k=1,2,3,\cdots, \tag{3.5}$$

where $b_{k,\infty}$ are the recursion coefficients of the monic polynomials orthogonal with respect to the weight function $1+\delta(x)$ on $[-1,1]$ (Legendre weight plus Dirac function centered at the origin). It follows from (3.4) and (3.5) that for a sufficiently large, (3.1) will be true (even with strict inequality). The proof of (3.5) is deferred to § 4.

Assume next that n is odd. Then, (2.8) becomes

$$1+\frac{b_{n-1}}{1+}\,\frac{b_{n-2}}{1+}\cdots\frac{b_1}{1} \leqq \frac{b_2b_4\cdots b_{n-1}}{b_1b_3\cdots b_{n-2}}\,\frac{m_0}{\pi}. \tag{3.6}$$

We now want m_0 to be large and may choose, for example,

$$w(z) = w^a(z) = 1+az^2, \qquad a>0. \tag{3.7}$$

Then

$$m_0 = \tfrac{2}{3}a+2 \tag{3.8}$$

and

$$\lim_{a\to\infty} b_k(w^a) = b_k^{\infty} > 0, \qquad k=1,2,3,\cdots, \tag{3.9}$$

where b_k^{∞} are the recursion coefficients of the monic polynomials orthogonal with respect to the weight function x^2 on $[-1,1]$. Again, from (3.8) and (3.9) it follows that (3.6) will be true for a sufficiently large. It remains to prove (3.5) and (3.9).

4. We denote the moments of w by m_k,

$$m_{2r+1} = 0, \qquad m_{2r} = 2\int_0^1 x^{2r}w(x)\,dx > 0. \tag{4.1}$$

The recursion coefficients $b_k(w)$ can be expressed in terms of Hankel determinants:

$$\Delta_n(m) = \det\,(m_{i+j})_{\substack{i=0,1,\cdots,n-1\\ j=0,1,\cdots,n-1}}, \qquad \Delta_0 = 1, \tag{4.2}$$

by means of [1, p. 19]

$$b_k(w)=\frac{\Delta_{k-1}(m)\Delta_{k+1}(m)}{[\Delta_k(m)]^2}, \qquad k=1,2,3,\cdots. \tag{4.3}$$

In the case of $w(x)=w_a(x)$ [cf. (3.2)], we have by (3.3)

$$m_r\sim\sqrt{\pi/a}\,m_{r,\infty}, \qquad a\to\infty, \quad r=0,1,2,\cdots, \tag{4.4}$$

where $m_{r,\infty}$ are the moments of the weight function $1+\delta(x)$ on $[-1,1]$. Therefore,

$$\Delta_n(m)\sim\left(\frac{\pi}{a}\right)^{n/2}\Delta_n(m_\infty), \qquad a\to\infty,$$

and, consequently, by (4.3),

$$b_k(w_a)\sim\frac{\Delta_{k-1}(m_\infty)\Delta_{k+1}(m_\infty)}{[\Delta_k(m_\infty)]^2}, \qquad a\to\infty,$$

that is,

$$b_k(w_a)\to b_{k,\infty} \quad \text{as } a\to\infty. \tag{4.5}$$

Likewise, for $w(x)=w^a(x)$ [cf. (3.7)],

$$m_r\sim am_r^\infty, \quad a\to\infty, \quad r=0,1,2,\cdots,$$

where m_r^∞ are the moments of the weight function x^2 on $[-1,1]$, and thus,

$$\Delta_n(m)\sim a^n\Delta_n(m^\infty), \qquad a\to\infty,$$

giving

$$b_k(w^a)\to b_k^\infty \quad \text{as } a\to\infty. \tag{4.6}$$

This proves the assertions in (3.5) and (3.9).

We remark that instead of one in (2.7) we could have selected any number larger than one, which means that the zeros of $\pi_n(\cdot\,;w_a)$ and $\pi_n(\cdot\,;w^a)$ on the imaginary axis can be made to have arbitrarily large imaginary parts by choosing a sufficiently large.

5. We now confirm the validity of the construction in § 3 numerically by computing the zeros of $\pi_n(\cdot\,;w_a)$, n even, and of $\pi_n(\cdot\,;w^a)$, n odd, for the critical value $a=a_n^*$ (which should yield a zero at i) and a few selected values $a>a_n^*$. We compute these zeros in terms of eigenvalues of a real tridiagonal (nonsymmetric) matrix, as indicated in [4, § 6.1], the coefficients $b_k(w_a)$ and $b_k(w^a)$ being generated by the "discretized Stieltjes procedure" (cf. [2, § 2.2]).

Table 5.1 shows the values of a_n^* for $n=2(1)10$ obtained to eight significant decimal digits by using the bisection method on (2.2) where $y=1$. The zeros of $\pi_n(\cdot\,;w_a)$

and $\pi_n(\cdot; w^a)$ for $n = 2(2)10$ and $n = 3(2)9$, respectively, where $a = (1+\kappa)a_n^*$, $\kappa = 0$, $\frac{1}{2}$, 1, ∞, are listed in Tables 5.2 and 5.3. Although they were computed to eight significant digits, only three-digit values are shown because of space considerations. If $a \to \infty$ (i.e., $\kappa \to \infty$), it follows from $\pi_n = p_n - i\theta_{n-1}p_{n-1}$ (cf. [4, eq. (2.9)]) and $\theta_{n-1} \to \infty$ that the (finite) zeros of π_n tend to those of p_{n-1}, the orthogonal polynomial of degree $n-1$ relative to the limiting weight function $w_\infty(x) = 1 + \delta(x)$ and $w^\infty(x) = x^2$, for n even and odd, respectively. These limiting weights are not as unrelated as we might think at first. We have, in fact,

$$p_{n-1}(x; w_\infty) = xp_{n-2}(x; w^\infty), \qquad n(\text{even}) \geqq 2,$$

since each side is easily seen to be orthogonal on $[-1, 1]$ to all powers of degree $\leqq n-2$ with respect to the constant weight function $w \equiv 1$, and hence equal to the monic Legendre polynomial of degree $n-1$. This is why the limiting zeros for $\kappa = \infty$ in Table 5.2 and Table 5.3 are the same.

It can be seen that for n even, there are two zeros on the imaginary axis moving in opposite directions as a increases from a_n^* to ∞, one up from i to $i\infty$ (cf. the remark at the end of § 4), the other down from some iy_n^*, $0 < y_n^* < 1$, to zero. For n odd, there is one zero on the imaginary axis moving up from i to $i\infty$.

It is also easy to compute the coefficients $b_{k,\infty}$ and b_k^∞ and to observe numerically the convergence in (3.5) and (3.9).

UNIFORM ASYMPTOTIC EXPANSIONS FOR WHITTAKER'S CONFLUENT HYPERGEOMETRIC FUNCTIONS*

T. M. DUNSTER†

Abstract. The asymptotic behavior, as $\kappa \to \infty$, of the Whittaker confluent hypergeometric functions $M_{\kappa,\mu}(z)$ and $W_{\kappa,\mu}(z)$ is examined. Asymptotic expansions are derived in terms of Bessel and Airy functions, the results being uniformly valid for real values of κ and μ such that $0 \leqq \mu/\kappa \leqq A < 1$ (A an arbitrary constant), and for all complex values of the argument z. Explicit error bounds are available for all the approximations.

Key words. confluent hypergeometric functions, asymptotic expansions

AMS(MOS) subject classifications. 33A30, 34E05

1. Introduction. In this paper we aim to derive asymptotic expansions for solutions of Whittaker's equation

$$\frac{d^2w}{dz^2} = \left\{\frac{1}{4} - \frac{\kappa}{z} + \frac{\mu^2 - \frac{1}{4}}{z^2}\right\} w, \tag{1.1}$$

this being a form of the confluent hypergeometric equation (see, for example, Olver [5, p. 260]).

We consider the case where the parameters κ and μ are real, with κ large and μ either large or small, and the independent variable z complex with unbounded absolute value.

Previously there have been a large number of investigations into the asymptotic behavior of solutions of Whittaker's equation, and for a comprehensive survey of the results prior to 1975 the reader is referred to Olver [6, pp. 127-132]. In this survey Olver remarks that there are several outstanding problems to be tackled. One of these is the case of $|\mu| \to \infty$ with $1 - \delta \leqq \kappa/\mu \leqq 1 + \delta$; (here and throughout δ is used generically as an arbitrary small positive constant). This problem has since been successfully treated by Olver [8] who has derived asymptotic solutions in terms of parabolic cylinder functions. The results are uniformly valid for κ, μ, and z either all real or all purely imaginary, and are furnished with explicit error bounds. The asymptotic solutions were derived by an application of the asymptotic theory of second-order differential equations having coalescing turning points (Olver [7]).

A second outstanding problem is the case where $\kappa \to \infty$ with $-1 + \delta \leqq \mu/\kappa \leqq 1 - \delta$, and this is the problem that we address in the present paper. To get a better insight into this particular case let us reformulate (1.1) into the form

$$\frac{d^2w}{d\xi^2} = \left\{\frac{\kappa^2(\xi - \xi_1(\alpha^2))(\xi - \xi_2(\alpha^2))}{4\xi^2} - \frac{1}{4\xi^2}\right\} w, \tag{1.2}$$

where for convenience we write

$$\xi = z/\kappa, \tag{1.3}$$

$$\alpha = 2\mu/\kappa, \tag{1.4}$$

* Received by the editors January 27, 1988; accepted for publication (in revised form) July 1, 1988.

and

$$\xi_1 = 2-(4-\alpha^2)^{1/2}, \tag{1.5a}$$

$$\xi_2 = 2+(4-\alpha^2)^{1/2}. \tag{1.5b}$$

When κ is large, (1.2) is characterized by having a regular singularity at $\xi=0$, an irregular singularity at infinity, and turning points at $\xi=\xi_1(\alpha^2)$ and $\xi=\xi_2(\alpha^2)$. The position of these turning points depends on the value of α^2. When κ and μ are real we have the following four cases:

(i) $\alpha^2=0$; ξ_1 coalesces with the singularity $\xi=0$, and $\xi_2=4$.

(ii) $0<\alpha^2<4$; ξ_1 lies in the interval $(0,2)$, and ξ_2 lies in the interval $(2,4)$.

(iii) $\alpha^2=4$; ξ_1 and ξ_2 coalesce at the point $\xi=2$.

(iv) $4<\alpha^2<\infty$; ξ_1 and ξ_2 no longer lie on the real axis, and are complex conjugates.

Our results then will be uniformly valid for $0\leqq\alpha^2\leqq 4-\delta$, or in other words for ξ_1 either coalescing with the pole at the origin or taking positive real values. As $\alpha^2\to 4$ the turning points coalesce and the results of Olver [8] are applicable; our results can be regarded as complementary to Olver's.

The plan of the paper is as follows. In § 2 we present definitions and relevant properties of the Whittaker functions that are to be approximated. Also, we record connection formulae that will be used relating to these functions.

In §§ 3 and 4 we transform Whittaker's equation (1.2) into two different forms. In the first of these new equations the coefficient of κ^2 has a double pole and a simple zero which coalesces with the pole as $\alpha\to 0$. The coefficient of κ^2 in the second equation has only one transition point, a simple zero.

In § 5 we apply the general theory of a coalescing turning point and singularity (Boyd and Dunster [2]). This general theory is applicable to the first of the transformed equations, and provides asymptotic expansions for its solutions in terms of Bessel functions. These approximations for Whittaker functions are uniformly valid in certain regions of the complex ξ plane which include both $\xi=0$ and $\xi=\xi_1$, but not $\xi=\xi_2$.

We then apply the general theory of a simple turning point in the complex plane to the second of the transformed equations. This theory is given in Olver [5, Chap. 11]. The resulting asymptotic expansions involve Airy functions and are uniformly valid in certain regions of the complex ξ plane that include $\xi=\xi_2$, but not $\xi=\xi_1$. The domains of validity for the Bessel function and Airy function expansions overlap and together cover the entire complex ξ plane. The principal results are summarized in § 6.

Of the previous investigations into Whittaker functions with $|\kappa|$ large we mention two special cases of our results. The first is the work of Erdélyi and Swanson [3] who construct asymptotic approximations for $M_{\kappa,\mu}(\kappa\xi)$ and $W_{\kappa,\mu}(\kappa\xi)$ in terms of Bessel and Airy functions. These results are valid for *fixed* nonnegative μ, i.e., $\alpha=O(\kappa^{-1})$. Accordingly, the investigation is that of the case of a simple pole and one fixed turning point. The resulting approximations are uniformly valid for $|\kappa|$ large (real or complex) and ξ real with $0\leqq\xi<\infty$. Skovgaard [9] has extended these results to asymptotic expansions with ξ complex.

Neither Erdélyi and Swanson, nor Skovgaard, supply error bounds for their approximations; however, for the real variable case, Olver [5, pp. 412-413, 446-447] provides error bounds for both the Airy and Bessel function expansions.

More recently, Baumgartner [1] has investigated the Whittaker function $M_{\kappa,\mu}(\kappa\xi)$ in great detail, and has derived a uniform approximation in terms of the Bessel function $J_\nu(z)$, which is uniformly valid for positive μ and κ with $0\leqq\mu/\kappa\leqq 1-\delta$, and for ξ lying in the finite interval $0\leqq\xi\leqq\xi_2-\delta$. A very thorough error analysis is given and explicit error bounds are derived. Our results are considerably more general than those

of Baumgartner: we derive full expansions rather than the leading term; we approximate in turn the Whittaker functions $M_{\kappa,\mu}(\kappa\xi)$, $W_{\kappa,\mu}(\kappa\xi)$, $W_{-\kappa,\mu}(\kappa\xi e^{-\pi i})$, and $W_{-\kappa,\mu}(\kappa\xi e^{\pi i})$; and the results are uniformly valid in domains that cover the entire complex ξ plane. These expansions are uniformly valid for real nonnegative values of μ and κ such that $0\leqq\mu/\kappa\leqq 1-\delta$, and are readily extended to negative values of μ and κ by means of appropriate connection formulae.

2. Whittaker functions: Definitions, characteristic properties and connection formulae.

2.1. Standard solutions. The Whittaker functions we approximate are $M_{\kappa,\mu}(z)$, $W_{\kappa,\mu}(z)$, $W_{-\kappa,\mu}(z e^{\pi i})$, and $W_{-\kappa,\mu}(z e^{-\pi i})$, each being a solution of (1.1). These functions are defined by

$$M_{\kappa,\mu}(z)=e^{-z/2}z^{1/2+\mu}\,{}_1F_1(\tfrac{1}{2}+\mu-\kappa;\,1+2\mu;\,z), \tag{2.1}$$

and

$$W_{\kappa,\mu}(z)=\frac{\Gamma(-2\mu)}{\Gamma(\frac{1}{2}-\mu-\kappa)}M_{\kappa,\mu}(z)+\frac{\Gamma(2\mu)}{\Gamma(\frac{1}{2}+\mu-\kappa)}M_{\kappa,-\mu}(z), \tag{2.2}$$

where ${}_1F_1$ denotes the confluent hypergeometric function. The limiting form of (2.2) is taken when 2μ is an integer. The four solutions are linearly independent of one another for all nonnegative values of μ and κ, the only exception being that $M_{\kappa,\mu}(z)$ and $W_{k,\mu}(z)$ are multiples of one another when $\kappa-\mu-\frac{1}{2}$ is a nonnegative integer.

2.2. Behavior at singular points. Whittaker's equation has a regular singularity at $z=0$ and an irregular singularity at infinity. The behavior of the four solutions at these singular points is given as follows (with κ and μ assumed fixed):

$$M_{\kappa,\mu}(z)=z^{\mu+1/2}\{1+O(z)\}\quad\text{as } z\to 0, \tag{2.3}$$

$$\begin{aligned}W_{\kappa,\mu}(z)=&\frac{\Gamma(-2\mu)}{\Gamma(\frac{1}{2}-\mu-\kappa)}z^{\mu+1/2}\{1+O(z)\}\\&+\frac{\Gamma(2\mu)}{\Gamma(\frac{1}{2}+\mu-\kappa)}z^{-\mu+1/2}\{1+O(z)\}\quad\text{as } z\to 0,\end{aligned} \tag{2.4}$$

$$\begin{aligned}M_{\kappa,\mu}(z)=&\frac{\Gamma(2\mu+1)}{\Gamma(\mu+\kappa+\frac{1}{2})}e^{(\mu-\kappa+1/2)\pi i}z^{\kappa}e^{-z/2}\{1+O(z^{-1})\}\\&+\frac{\Gamma(2\mu+1)}{\Gamma(\mu-\kappa+\frac{1}{2})}z^{-\kappa}e^{z/2}\{1+O(z^{-1})\}\\&\qquad\text{as } z\to\infty,\quad -\pi/2<\arg z<3\pi/2,\end{aligned} \tag{2.5}$$

$$W_{\kappa,\mu}(z)=z^{\kappa}e^{-z/2}\{1+O(z^{-1})\}\quad\text{as } z\to\infty,\quad -3\pi/2<\arg z<3\pi/2, \tag{2.6}$$

$$W_{-\kappa,\mu}(z e^{\pi i})=e^{-\kappa\pi i}z^{-\kappa}e^{z/2}\{1+O(z^{-1})\}\quad\text{as } z\to\infty,\quad -5\pi/2<\arg z<\pi/2, \tag{2.7}$$

$$W_{-\kappa,\mu}(z e^{-\pi i})=e^{\kappa\pi i}z^{-\kappa}e^{z/2}\{1+O(z^{-1})\}\quad\text{as } z\to\infty,\quad -\pi/2<\arg z<5\pi/2. \tag{2.8}$$

From (2.3), (2.6), (2.7), and (2.8) we perceive that the characterizing properties of the four functions are that, for nonnegative μ, $M_{\kappa,\mu}(z)$ is recessive at the origin, and that for all values of μ and κ the functions $W_{\kappa,\mu}(z)$, $W_{-\kappa,\mu}(z e^{\pi i})$, and $W_{-\kappa,\mu}(z e^{-\pi i})$ are recessive at infinity in the sectors $-\pi/2<\arg z<\pi/2$, $-3\pi/2<\arg z<-\pi/2$, and $\pi/2<\arg z<3\pi/2$, respectively.

2.3. Connection formulae. We will require the following connection formulae:

$$W_{\kappa,\mu}(z)=\frac{1}{2\pi}\Gamma\left(\kappa+\mu+\frac{1}{2}\right)\Gamma\left(\kappa-\mu+\frac{1}{2}\right)\cdot[e^{(\kappa-1/2)\pi i}W_{-\kappa,\mu}(z\,e^{\pi i})+e^{-(\kappa-1/2)\pi i}W_{-\kappa,\mu}(z\,e^{-\pi i})], \tag{2.9}$$

$$M_{\kappa,\mu}(z)=\frac{1}{2\pi}\Gamma(2\mu+1)\Gamma\left(\kappa-\mu+\frac{1}{2}\right)[e^{\mu\pi i}W_{-\kappa,\mu}(z\,e^{\pi i})+e^{-\mu\pi i}W_{-\kappa,\mu}(z\,e^{-\pi i})]. \tag{2.10}$$

Our results are valid for $\mu\geqq 0$ and $\kappa>0$. We can extend these parameters to negative values using (2.2) and the following relations:

$$M_{-\kappa,\mu}(z\,e^{\pm\pi i})=e^{\pm(\mu+1/2)\pi i}M_{\kappa,\mu}(z), \tag{2.11}$$

$$W_{\kappa,-\mu}(z)=W_{\kappa,\mu}(z). \tag{2.12}$$

3. Domains containing the transition points $\xi=0$ and $\xi=\xi_1$: Preliminary transformations. In §§ 3 and 4 our purpose is to transform Whittaker's equation (1.1) to two new forms. The first, given here, resembles Bessel's equation and has a finite regular singularity. The second, given in § 4, resembles Airy's equation. Both have simple turning points. Having made these transformations, we can derive asymptotic solutions and then identify them with standard Whittaker functions.

Then, using a Liouville transformation that transforms both the dependent and independent variables, we transform (1.1) to the Bessel equation form. Following [2, eq. (2.1)], we define a new independent variable $\zeta(\xi)$ and dependent variable $W(\zeta)$ by

$$\frac{d\zeta}{d\xi}=\frac{\zeta}{\xi}\left(\frac{\xi_1-\xi}{\alpha^2-\zeta}\right)^{1/2}(\xi_2-\xi)^{1/2}, \tag{3.1}$$

$$W(\zeta)=\left(\frac{d\zeta}{d\xi}\right)^{1/2}w(\xi), \tag{3.2}$$

where the branches of the fractional powers will be specified shortly. With these transformations, Whittaker's equation (1.1) is transformed to the equation

$$\frac{d^2W}{d\zeta^2}=\left\{\kappa^2\left[\frac{\alpha^2}{4\zeta^2}-\frac{1}{4\zeta}-\frac{1}{4\zeta^2}\right]+\frac{\psi(\alpha,\zeta)}{\zeta}\right\}W, \tag{3.3}$$

where

$$\frac{\psi(\alpha,\zeta)}{\zeta}=\xi'^{1/2}\frac{d^2}{d\zeta^2}(\xi'^{-1/2})-\frac{\xi'^2}{4\xi^2}+\frac{1}{4\zeta^2}; \tag{3.4}$$

primes ($'$) denote differentiation with respect to ζ. An explicit expression for ψ can be obtained by using (3.2); a straightforward calculation yields

$$\psi(\alpha,\zeta)=\frac{1}{16(\alpha^2-\zeta)^2}\left[\zeta+4\alpha^2-\frac{4(\alpha^2-\zeta)^3}{[(\xi_1-\xi)(\xi_2-\xi)]^3}\left(\frac{\xi}{\zeta}\right)(\xi^3-16\xi^2+4(1-\alpha^3)\xi+4\alpha^2)\right]. \tag{3.5}$$

We now examine the $\xi-\zeta$ transformation in more detail. First, integration of (3.1) gives the relationship

$$\int_{\alpha^2}^{\zeta}\frac{(\alpha^2-t)^{1/2}}{2t}\,dt=\int_{\xi_1}^{\xi}\frac{(\xi_1-t)^{1/2}(\xi_2-t)^{1/2}}{2t}\,dt. \tag{3.6}$$

The lower integration limits are chosen so that the turning point $\xi = \xi_1$ of the original equation (1.1) is mapped to the turning point $\zeta = \alpha^2$ of the transformed equation (3.3). Note also that both integrands have a singularity at the origin, and as a consequence the pole $\xi = 0$ of (1.1) corresponds to the pole $\zeta = 0$ of (3.3).

The relationship (3.6) as it stands is not well defined as there are branch points at the transition points $\xi = 0$, ξ_1, ξ_2, and $\zeta = 0$ and α^2. We therefore introduce branches as follows. First, with regard to the poles at the origin, we temporarily introduce a branch cut along the negative real axis in both cases, and assign the principal values of the arguments for both ξ and ζ. Throughout this paper we assume that ξ (and ζ) take their principal values; appropriate connection formulae can be used to extend all subsequent results to other ranges of arg ξ.

The branches of the fractional powers are chosen as follows. The integrand on the left-hand side of (3.6) is assumed to be negative imaginary just above the semi-infinite interval (α^2, ∞), positive imaginary below the same interval, and continuous elsewhere. The integrand on the right-hand side is assumed to be negative imaginary just above the interval (ξ_1, ξ_2), positive imaginary below the interval, and continuous elsewhere.

The integrals in (3.6) can be evaluated explicitly (see, for example, Gradshteyn and Ryzhik, [4, pp. 83, 84]). We obtain

$$
\begin{aligned}
&(\alpha^2-\zeta)^{1/2}-\frac{\alpha}{2}\ln\left\{\frac{\alpha+(\alpha^2-\zeta)^{1/2}}{\alpha-(\alpha^2-\zeta)^{1/2}}\right\}\\
&\quad=\frac{1}{2}(\xi_1-\xi)^{1/2}(\xi_2-\xi)^{1/2}+\frac{\alpha}{2}\ln\left\{\frac{\xi}{\xi_1}\,\frac{\alpha^2-2\xi_1}{\alpha^2-2\xi+\alpha(\xi_1-\xi)^{1/2}(\xi_2-\xi)^{1/2}}\right\}\\
&\qquad+\ln\left\{\frac{2-\xi_1}{2-\xi-(\xi_1-\xi)^{1/2}(\xi_2-\xi)^{1/2}}\right\}.
\end{aligned}
\tag{3.7}
$$

Let $\underline{\Delta}$ denote the ζ domain given by $|\arg \zeta| < \pi$ with all points on the interval $[\zeta_2, \infty)$ excluded (ζ_2 denoting $\zeta(\xi_2)$). We will confine our attention to $\underline{\Delta}$ and the corresponding ξ domain Δ: both Δ and $\underline{\Delta}$, together with corresponding points, are illustrated in Figs. 1(a) and 1(b). The curves CD, CD' are given by

$$
\operatorname{Re}\int_{\xi_2}^{\xi}\frac{(\xi_1-t)^{1/2}(\xi_2-t)^{1/2}\,dt}{2t}=0,
$$

and are asymptotic to a line parallel to the imaginary axis.

The mapping $\zeta(\xi)$ is conformal within Δ and hence the inverse $\xi(\zeta)$ is conformal within $\underline{\Delta}$. It follows that $\psi(\alpha, \zeta)$ is holomorphic in $\underline{\Delta}$, and that, moreover, it is uniformly

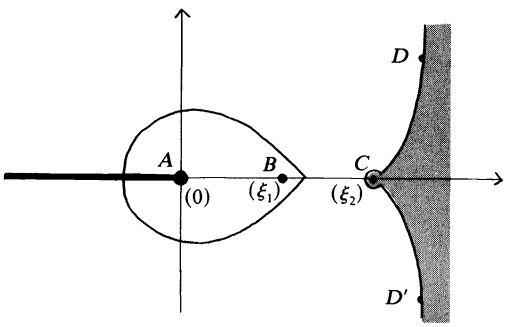

FIG. 1(a). *Domain Δ in ξ plane.*

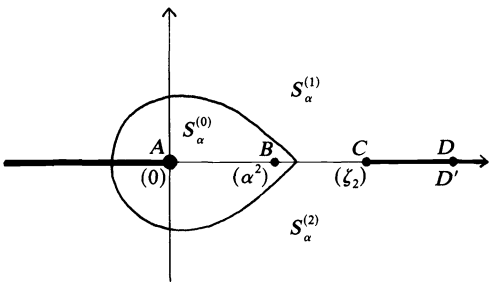

FIG. 1(b). *Domain $\underline{\Delta}$ in ζ plane.*

continuous for $\zeta \in \underline{\Delta}$ and $\alpha \in [0, 2-\delta]$; (see [2, eq. (2.6) and the paragraph after Lemma 1]).

To identify solutions of the transformed equation (3.3) with standard Whittaker functions we will need to know the asymptotic behavior of $\zeta(\xi)$ as $\xi \to 0$, and also as $\xi \to -\infty \pm i0$. (Here and throughout $\pm i0$ indicates a complex number being above or below a cut.)

First, we find from (3.7) that $\zeta \to 0$ as $\xi \to 0$, and more specifically

$$\alpha - \alpha \ln 2\alpha + \frac{\alpha}{2} \ln \zeta + O(\zeta) = \frac{\alpha}{2} + \frac{\alpha}{2} \ln \left\{ \frac{\alpha^2 - 2\xi_1}{2\alpha^2 \xi_1} \right\} + \ln \left\{ \frac{2-\xi_1}{2-\alpha} \right\} + \frac{\alpha}{2} \ln \xi + O(\xi). \tag{3.8}$$

On collecting terms and exponentiating we arrive at

$$\zeta = c(\alpha)\xi + O(\xi^2) \quad \text{as } \xi \to 0, \tag{3.9}$$

where

$$c(\alpha) = \frac{2}{e} \left(\frac{\alpha^2 - 2\xi_1}{\xi_1} \right) \left(\frac{2-\xi_1}{2-\alpha} \right)^{2/\alpha}. \tag{3.10}$$

We remark that (3.9), (3.10) is uniformly valid for $\alpha \in [0, 2-\delta]$; (see [5, eqs. (A3), (A4)]). In particular when $\alpha = 0$ the limiting form of (3.9) applies:

$$\zeta \sim 4\xi \quad \text{as } \xi \to 0. \tag{3.11}$$

Next we examine $\zeta(\xi)$ as $\xi \to -\infty \pm i0$. We find from (3.7) that $\zeta \to -\infty \pm i0$, such that

$$(-\zeta)^{1/2} + O\left(\frac{1}{\zeta}\right) = \frac{1}{2}(-\xi) + \frac{\alpha}{2} \ln \left\{ \frac{\alpha^2 - 2\xi_1}{\xi_1(2+\alpha)} \right\} + \ln \left\{ \frac{2(2-\xi_1)}{4-\alpha^2} \right\} + \ln(-\xi) + O\left(\frac{1}{\xi}\right), \tag{3.12}$$

the result being uniformly valid for $\alpha \in [0, 2-\delta]$.

Finally we must examine the asymptotic behavior of $\psi(\alpha, \zeta)$ and its derivatives as $\zeta \to \infty$ in $\underline{\Delta}$. From (3.7) we have

$$(-\zeta)^{1/2} \sim \tfrac{1}{2}\xi + O(\ln \xi) \quad \text{as } \xi \to \infty \text{ in } \Delta,$$

and hence from (3.5) we have

$$\psi(\alpha, \zeta) \sim \frac{1}{8(-\zeta)^{3/2}} \quad \text{as } \zeta \to \infty \text{ in } \underline{\Delta}, \tag{3.13}$$

uniformly for $\alpha \in [0, 2-\delta]$.

Also, on differentiating (3.5) s times, we find that the sth derivative of ψ

$$\psi^{(s)}(\alpha, \zeta) = O(\zeta^{-3/2-s}) \quad \text{as } \zeta \to \infty \text{ in } \underline{\Delta}, \tag{3.14}$$

uniformly for $\alpha \in [0, 2-\delta]$.

4. Domains containing the transition point $\xi = \xi_2$: Preliminary transformations. In the previous section Whittaker's equation was transformed, via a Liouville transformation, to a new differential equation from which asymptotic solutions are to be obtained. As we have remarked, the transformation is not regular at $\xi = \xi_2$, and the asymptotic solutions that we obtain are not uniformly valid in a neighborhood of $\xi = \xi_2$. The purpose of this section is to use the general theory of [5] to transform Whittaker's equation, via a different Liouville transformation, to a differential equation from which we can obtain asymptotic solutions that are uniformly valid in a neighborhood of $\xi = \xi_2$.

We use the notation of [5] except that each term here is written with a circumflex (^) to avoid a clash of notation with § 3.

The appropriate Liouville transformation is given by the following (see [5, (3.02)]):

$$\frac{d\hat{\zeta}}{d\xi}=\left(\frac{(\xi-\xi_1)(\xi-\xi_2)}{\hat{\zeta}}\right)^{1/2}\frac{1}{2\xi}, \tag{4.1}$$

$$\hat{W}(\hat{\zeta})=\left(\frac{d\hat{\zeta}}{d\xi}\right)^{1/2}w(\xi). \tag{4.2}$$

The effect of the above transformations is to transform (1.1) into

$$\frac{d^2\hat{W}}{d\hat{\zeta}^2}=\{\kappa^2\hat{\zeta}+\hat{\psi}(\alpha,\hat{\zeta})\}\hat{W}, \tag{4.3}$$

where

$$\hat{\psi}(\alpha,\hat{\zeta})=\frac{5}{16\hat{\zeta}^2}-\frac{\hat{\zeta}\xi}{(\xi-\xi_1)^3(\xi-\xi_2)^3}[\xi^3-16\xi^2+4(1-\alpha^2)\xi+4\alpha^2]. \tag{4.4}$$

For the $\xi-\hat{\zeta}$ map to be regular at the transition point $\xi=\xi_2$, this point must correspond to the turning point $\hat{\zeta}=0$ of the transformed equation (4.3). Thus integration of (4.1) yields

$$\frac{2}{3}\hat{\zeta}^{3/2}=\int_{\xi_2}^{\xi}\frac{[(t-\xi_1)(t-\xi_2)]^{1/2}}{2t}\,dt. \tag{4.5}$$

With regard to the logarithmic singularity at $\xi=0$ we introduce a branch cut along the negative real axis and restrict our attention to $|\arg\xi|<\pi$. We also introduce a cut along the negative real $\hat{\zeta}$ axis and a cut along the real ξ axis from ξ_1 to ξ_2; with these cuts both sides of (4.5) are assumed to be positive for $\hat{\zeta}\in(0,\infty)$ and $\xi\in(\xi_2,\infty)$ and to be continuous elsewhere in the cut plane.

The integral in (4.5) is expressible in terms of elementary functions: we obtain the relationship (cf. (3.7))

$$\begin{aligned}\frac{2}{3}\hat{\zeta}^{3/2}=&\frac{1}{2}(\xi-\xi_1)^{1/2}(\xi-\xi_2)^{1/2}+\frac{\alpha}{2}\ln\frac{\xi}{\xi_2}\left\{\frac{2\xi_2-\alpha^2}{2\xi-\alpha^2-\alpha(\xi-\xi_1)^{1/2}(\xi-\xi_2)^{1/2}}\right\}\\&+\ln\left\{\frac{\xi_2-2}{\xi-2+(\xi-\xi_1)^{1/2}(\xi-\xi_2)^{1/2}}\right\}.\end{aligned} \tag{4.6}$$

The map of the half space $0\leqq\arg\xi<\pi$ is shown in Figs. 2(a) and 2(b) for $\alpha\neq 0$. The map of the half space $-\pi<\arg\xi\leqq 0$ is the conjugate of the $\hat{\zeta}$ domain indicated in Fig. 2(b).

It is possible to obtain asymptotic solutions of (4.3) that are uniformly valid as $\hat{\zeta}\to\infty$ with $\arg\hat{\zeta}=\pm 4\pi/3$, or equivalently as $\xi\to 0\pm i0$. However, these solutions would not hold uniformly at $\xi=0$ when $\alpha\to 0$.

On the other hand, the asymptotic solutions of (3.3) *are* uniformly valid in a neighborhood of $\xi=0$ for $\alpha\in[0,2-\delta]$. Therefore for simplicity we will restrict our attention to a ξ domain that includes $\xi=\xi_2$, but excludes both $\xi=0$ and $\xi=\xi_1$.

To this end we define $\hat{\Delta}$ to be the ξ domain $|\arg\xi|<\pi$ lying outside the pear-shaped region BCB', with a neighborhood of $\xi=\xi_1$ excluded. When $\alpha=0$ $\hat{\Delta}$ is the ξ domain $|\arg\xi|<\pi$ with a neighborhood of $\xi=0$ excluded. The domain $\hat{\Delta}$ and the corresponding $\hat{\zeta}$ domain $\hat{\underline{\Delta}}$, are shown in Figs. 3(a) and 3(b).

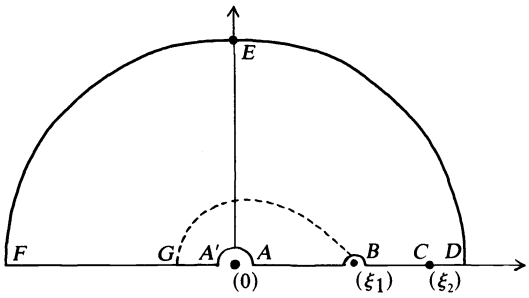

FIG. 2(a). *ξ plane.*

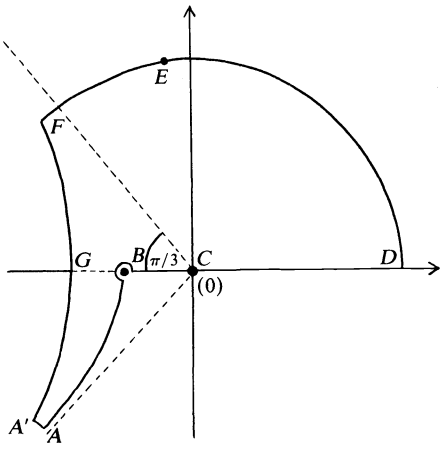

FIG. 2(b). *ζ̂ plane.*

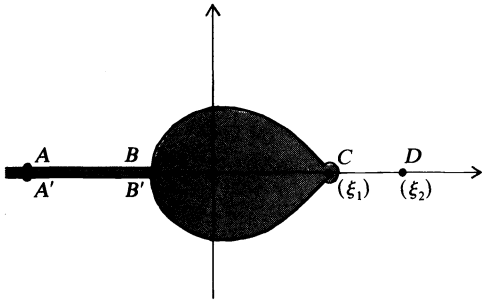

FIG 3(a). *Domain* $\hat{\Delta}$ *in* ξ *plane.*

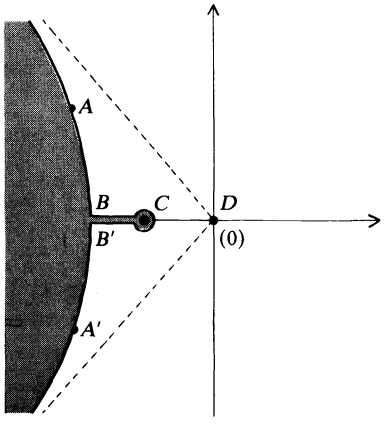

FIG. 3(b). *Domain* $\hat{\underline{\Delta}}$ *in* $\hat{\zeta}$ *plane.*

Since both $\xi = 0$ and $\xi = \xi_1$ do not lie in $\hat{\Delta}$, it follows that $\hat{\zeta}(\xi)$ is holomorphic within $\hat{\Delta}$. Furthermore, since $d\hat{\zeta}/d\xi$ does not vanish in this domain the inverse mapping $\xi(\hat{\zeta})$ is holomorphic within $\hat{\underline{\Delta}}$. We also note that $\hat{\psi}(\alpha, \hat{\zeta})$ is holomorphic within $\hat{\underline{\Delta}}$, as well as being uniformly continuous for $\hat{\zeta} \in \hat{\underline{\Delta}}$ and $\alpha \in [0, 2-\delta]$.

We now record the asymptotic behavior of $\hat{\zeta}(\xi)$ as $\xi \to \infty$. From (4.6) we find that

$$\frac{2}{3}\hat{\zeta}^{3/2} = \frac{1}{2}\xi - \ln \xi + \frac{\alpha}{2}\ln\left\{\frac{2\xi_2 - \alpha^2}{\xi_2(2-\alpha)}\right\} + \ln\left(\frac{1}{2}\xi_2 - 1\right) + O(\xi^{-1}), \qquad |\arg \hat{\zeta}| \leqq \frac{2\pi}{3}. \tag{4.7}$$

In general,

$$\frac{2}{3}\hat{\zeta}^{3/2} = \frac{1}{2}\xi + O(\ln \xi) \quad \text{as } \xi \to \infty \text{ in } \hat{\Delta}, \tag{4.8}$$

and therefore from (4.4) we deduce that

$$\hat{\psi}(\alpha, \hat{\zeta}) \sim -\frac{1}{4\hat{\zeta}^2}, \tag{4.9}$$

and

$$\hat{\psi}^{(s)}(\alpha, \hat{\zeta}) = O(\hat{\zeta}^{-2-s}) \quad \text{as } \hat{\zeta} \to \infty \text{ in } \hat{\underline{\Delta}}. \tag{4.10}$$

5. Asymptotic expansions for Whittaker functions. Having made the preliminary transformations, we now apply the general theories of [2] and [5] to obtain asymptotic solutions of the transformed equations (3.3) and (4.3).

First let us apply the theory of § 5 of [2] to the differential equation (3.3). From Theorem 3 we deduce that, for each value of κ and α and nonnegative integer n, the following solutions of (3.3) exist that are holomorphic in $\underline{\Delta}$:

$$W^{(j)}_{2n+1}(k,\alpha,\zeta)=\zeta^{1/2}\mathscr{C}^{(j)}_{\kappa\alpha}(\kappa\zeta^{1/2})\sum_{s=0}^{n}\frac{A_s(\alpha,\zeta)}{\kappa^{2s}} + \frac{\zeta}{\kappa}\,\mathscr{C}^{(j)'}_{\kappa\alpha}(\kappa\zeta^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\alpha,\zeta)}{\kappa^{2s}}+\varepsilon^{(j)}_{2n+1}(\kappa,\alpha,\zeta) \tag{5.1}$$

$$(j=0,1,2),$$

with $\mathscr{C}^{(j)}_{\nu}(z)$ denoting the Bessel function $2J_\nu(z)$, $H^{(1)}_\nu(z)$, $H^{(2)}_\nu(z)$ for $j=0,1,2$, respectively. The coefficients A_s and B_s are given recursively by the integral equations

$$B_s(\alpha,\zeta)=(\alpha^2-\zeta)^{-1/2}\int_{\zeta}^{\alpha^2}(\alpha^2-t)^{-1/2}(tA''_s(\alpha,t)+A'_s(\alpha,t)-\psi(\alpha,t)A_s(\alpha,t))\,dt \tag{5.2}$$

$$(s=0,1,2,\cdots),$$

$$A_s(\alpha,\zeta)=-\zeta B'_{s-1}+\int^{\zeta}\psi(\alpha,t)B_{s-1}(\alpha,t)\,dt+\lambda_s \qquad (s=1,2,\cdots), \tag{5.3a}$$

$$A_0(\alpha,\zeta)=\lambda_0. \tag{5.3b}$$

The numbers λ_s $(s=0,1,2,\cdots)$ are arbitrary constants of integration, and the branches in (5.2) are defined as in § 3. Each of the coefficients is holomorphic in $\underline{\Delta}$, and furthermore they are uniformly continuous for $\zeta\in\underline{\Delta}$ and $\alpha\in[0,2-\delta]$ (provided of course that each constant λ_s is taken to be a continuous function of α).

Before assigning values to the constants λ_s we must record the asymptotic behavior of $A_s(\alpha,\zeta)$ and $B_s(\alpha,\zeta)$ as $\zeta\to\infty$ in $\underline{\Delta}$. From (3.13), (3.14), and Ritt's theorem (see, for example, Olver ([5, pp. 9, 10)]) we can easily establish by induction from (5.2), (5.3a, b) that

$$A_s(\alpha,\zeta)=a_s+O(\zeta^{-1/2}) \qquad (s=1,2,\cdots), \tag{5.4a}$$

$$B_s(\alpha,\zeta)=b_s(-\zeta)^{-1/2}+O(\zeta^{-3/2}) \qquad (s=0,1,2,\cdots), \tag{5.4b}$$

as $\zeta\to\infty$ with $|\arg(-\zeta)|\leqq\pi-\delta$. Here a_s and b_s are numbers independent of ζ. Similarly, we can prove the important result that the variations $\mathscr{V}\{(\zeta-\alpha^2)^{1/2}B_s(\zeta)\}$ converge as $\zeta\to\infty$ with $|\arg(-\zeta)|\leqq\pi-\delta$.

We choose two different sets of values for the constants as follows. For the solutions $W^{(1)}_{2n+1}$ and $W^{(2)}_{2n+1}$ we assign λ_0 (and hence A_0) the value 1, and each of the subsequent constants λ_s so that

$$a_s=0 \qquad (s=1,2,\cdots). \tag{5.5}$$

For each solution $W^{(0)}_{2n+1}$ we again choose $A_0=1$, but now choose each λ_s in turn so that

$$A_s(\alpha,0)=0 \qquad (s=1,2,\cdots). \tag{5.6}$$

Bounds for the error terms $\varepsilon^{(j)}_{2n+1}$ are furnished by Theorem 3 of [2] with u replaced by κ. For the bounds to be meaningful a reference point $\zeta^{(j)}$ in $\underline{\Delta}$ must be assigned for each of the three functions $\varepsilon^{(j)}_{2n+1}$. We take $\zeta^{(0)}=0$, $\zeta^{(1)}=-\infty+i0$, and $\zeta^{(2)}=-\infty-i0$.

Given these reference points we define domains $\underline{\Delta}^{(j)}$, $(j=0, 1, 2)$, to be the set of points in $\underline{\Delta}$ that can be linked to $\zeta^{(j)}$ by a progressive path $\mathscr{P}^{(j)}$ (see [2, p. 439]). Under these circumstances $\underline{\Delta}^{(1)}=\underline{\Delta}^{(2)}=\underline{\Delta}$, and $\underline{\Delta}^{(0)}$ consists of all points in $\underline{\Delta}$ except those lying on the cut on the real axis from $\zeta=\zeta_2$ to $\zeta=\infty$.

The regions $S_\alpha^{(j)}$, $(j=0, 1, 2)$, which are defined in [2], § 5, are illustrated in Fig. 1(b). Each of the solutions $W_{2n+1}^{(j)}$ is characteristically recessive within $S_\alpha^{(j)}$ and dominant elsewhere in $\underline{\Delta}^{(j)}$.

The bounds for $\varepsilon_{2n+1}^{(j)}$ given in Theorem 3 of [2] imply, for each $j=0$, 1, 2, that the ratio $\varepsilon_{2n+1}^{(j)}(\kappa, \alpha, \zeta)[\zeta^{1/2}\mathscr{C}_{\kappa\alpha}^{(j)}(\kappa\zeta^{1/2})]^{-1}$ is $O(\kappa^{-2n-1})$ uniformly for $\alpha\in[0, 2-\delta]$, and for all points ζ in $\underline{\Delta}^{(j)}$ except those near the zeros of the denominator. Furthermore, the same ratio vanishes as $\zeta\to\zeta^{(j)}$. These two important observations are deduced from the properties of the auxiliary functions E and M given in § 5 of [2].

Let us now identify the standard Whittaker functions with the asymptotic solutions (5.1). First we note that $(d\zeta/d\xi)^{1/2}M_{\kappa,\mu}(\kappa\xi)$, regarded as a function of ζ, and $W_{2n+1}^{(0)}(\kappa, \alpha, \zeta)$ are solutions of (3.3) that are recessive at the origin. It follows that, to within a multiplicative constant, the two solutions must be identical. Therefore there exists a constant $c_{2n+1}^{(0)}$ such that

$$M_{\kappa,\mu}(\kappa\xi)=c_{2n+1}^{(0)}\left(\frac{\alpha^2-\zeta}{\xi_1-\xi}\right)^{1/4}(\xi_2-\xi)^{-1/4}\left(\frac{\xi}{\zeta}\right)^{1/2}W_{2n+1}^{(0)}(\kappa, \alpha, \zeta). \tag{5.7}$$

The constant can be determined by comparing both sides of (5.7) at some particular value of ζ. It is convenient to do so at $\zeta=0$ because, as noted above, the ratio $\varepsilon_{2n+1}^{(0)}(\kappa, \alpha, \zeta)[\zeta^{1/2}2J_{\kappa\alpha}(\kappa\zeta^{1/2})]^{-1}$ vanishes as $\zeta\to 0$.

From (2.3) and (3.9) we find that the left-hand side of (5.7) is equal to

$$(\kappa/c(\alpha))^{\mu+1/2}\zeta^{\mu+1/2}(1+O(\zeta)) \quad \text{as } \zeta\to 0, \tag{5.8}$$

where, for the moment, α and κ are assumed to be nonzero and held fixed.

Next, on using the known behavior of $J_\nu(z)$ and $J_\nu'(z)$ near $z=0$ (see Olver [5, p. 436]), and on referring to (3.9), (5.1), and (5.6) we find that the right-hand side of (5.7) is equal to

$$c_{2n+1}^{(0)}\left(\frac{\alpha^2}{\xi_1}\right)^{1/4}\xi_2^{-1/4}c(\alpha)^{-1/2}\frac{2(\kappa/2)^{\kappa\alpha}}{\Gamma(\kappa\alpha+1)}\left\{1+\alpha\sum_{s=0}^{n-1}\frac{B_s(\alpha, 0)}{\kappa^{2s+1}}\right\}\zeta^{(\kappa\alpha+1)/2}(1+O(\zeta)) \tag{5.9}$$

as $\zeta\to 0$.

On equating (5.8) and (5.9), and invoking (1.4) and (3.10), we arrive at the desired relation:

$$c_{2n+1}^{(0)}=\frac{\kappa^{1/2}}{2}\Gamma(\kappa\alpha+1)\left(\frac{2\xi_1 e}{\kappa(\alpha^2-2\xi_1)}\right)^{\kappa\alpha/2}\left(\frac{2-\alpha}{2-\xi_1}\right)^{\kappa}\left\{1+\alpha\sum_{s=0}^{n-1}\frac{B_s(\alpha, 0)}{\kappa^{2s+1}}\right\}^{-1}. \tag{5.10}$$

The assumption that κ and α be held fixed can now be relaxed, and an asymptotic expansion for $M_{\kappa,\mu}(\kappa\xi)$, uniformly valid for $\zeta\in\underline{\Delta}^{(0)}$ and $\alpha\in[0, 2-\delta]$, is now given by (5.7) and (5.10). This and all subsequent expansions will be expressed again in terms of the original variables in § 6.

Next, consider the asymptotic solution $W_{2n+1}^{(1)}(\kappa, \alpha, \zeta)$. This function shares the property with the Whittaker function $(d\zeta/d\xi)^{1/2}W_{-\kappa,\mu}(\kappa\xi e^{-\pi i})$ of being a solution of (3.3) that is recessive as $\zeta\to-\infty+i0$. It therefore follows that a constant $c_{2n+1}^{(1)}$ exists such that

$$W_{-\kappa,\mu}(\kappa\xi e^{-\pi i})=c_{2n+1}^{(1)}\left(\frac{\alpha^2-\zeta}{\xi_1-\xi}\right)^{1/4}(\xi_2-\xi)^{-1/4}\left(\frac{\xi}{\zeta}\right)^{1/2}W_{2n+1}^{(1)}(\kappa, \alpha, \zeta). \tag{5.11}$$

The value of the constant is established similarly to the foregoing analysis, namely when we compare the ratio of both sides of the equation at a convenient value of ζ. In this case we compare both sides of the equation as $\zeta \to -\infty + i0$. Thus we have

$$c_{2n+1}^{(1)} = \lim_{\zeta \to -\infty + i0} \left(\frac{\xi_1 - \xi}{\alpha^2 - \zeta}\right)^{1/4} \left[(\xi_2 - \xi)^{1/4} \left(\frac{\zeta}{\xi}\right)^{1/2} \frac{W_{-\kappa,\mu}(\kappa \xi e^{-\pi i})}{W_{2n+1}^{(1)}(\kappa, \alpha, \zeta)} \right]. \tag{5.12}$$

On employing (2.8), (3.12), (5.1), (5.4a, b), (5.5), together with the known asymptotic behavior of $H_\nu^{(1)}(z)$ and $H_\nu^{(1)'}(z)$ at infinity (see Olver [5, p. 238]), we can evaluate the above limit. After some straightforward calculation we find that

$$c_{2n+1}^{(1)} = -\left(\frac{\pi\kappa}{2}\right)^{1/2} e^{i\kappa\alpha\pi/2} \left(\frac{2(2-\xi_1)}{\kappa(4-\alpha^2)}\right)^{\kappa} \left(\frac{\alpha^2 - 2\xi_1}{\xi_1(2+\alpha)}\right)^{\kappa\alpha/2} \left\{1 - \sum_{s=0}^{n-1} \frac{b_s}{\kappa^{2s+1}}\right\}^{-1}. \tag{5.13}$$

This expression together with (5.11) gives an asymptotic expansion for $W_{-\kappa,\mu}(\kappa\xi e^{-\pi i})$ that is uniformly valid for $\zeta \in \underline{\Delta}$ and $\alpha \in [0, 2-\delta]$. The identification of $W_{2n+1}^{(2)}$ is similar. Both this function and the Whittaker function $(d\zeta/d\xi)^{1/2} W_{-\kappa,\mu}(\kappa\xi e^{\pi i})$ are solutions of (3.3) that are recessive in $S_\alpha^{(2)}$. We deduce the existence of a constant $c_{2n+1}^{(2)}$ such that

$$W_{-\kappa,\mu}(\kappa\xi e^{\pi i}) = c_{2n+1}^{(2)} \left(\frac{\alpha^2 - \zeta}{\xi_1 - \xi}\right)^{1/4} (\xi_2 - \xi)^{-1/4} \left(\frac{\xi}{\zeta}\right)^{1/2} W_{2n+1}^{(2)}(\kappa, \alpha, \zeta), \tag{5.14}$$

the value of the constant being found, similarly to (5.13), to be

$$c_{2n+1}^{(2)} = e^{-i\kappa\alpha\pi} c_{2n+1}^{(1)}. \tag{5.15}$$

Again, these results are uniformly valid for $\zeta \in \underline{\Delta}$, $\alpha \in [0, 2-\delta]$.

Now consider the $\hat{\zeta}$ domain $\hat{\underline{\Delta}}$. Applying Theorem 9.1 of [5] to the transformed equation (4.3) yields asymptotic solutions that are uniformly valid in this region. We obtain the three solutions

$$\hat{W}_{2n+1,j}(\kappa, \hat{\zeta}) = Ai_j(\kappa^{2/3}\hat{\zeta}) \sum_{s=0}^{n} \frac{\hat{A}_s(\hat{\zeta})}{\kappa^{2s}} + \frac{Ai_j'(\kappa^{2/3}\hat{\zeta})}{\kappa^{4/3}} \sum_{s=0}^{n-1} \frac{\hat{B}_s(\hat{\zeta})}{\kappa^{2s}} + \hat{\varepsilon}_{2n+1}(\kappa, \hat{\zeta}) \tag{5.16}$$

$$(j = 0, 1, -1),$$

where $\mathrm{Ai}_j(z)$ denotes the Airy function of complex argument $\mathrm{Ai}(z e^{-2\pi i j/3})$. The coefficients $\hat{A}_s$ and $\hat{B}_s$ are defined recursively by $\hat{A}_0(\hat{\zeta}) = 1$,

$$\hat{B}_s(\hat{\zeta}) = \frac{1}{2} \hat{\zeta}^{-1/2} \int_0^{\hat{\zeta}} \{\hat{\psi}(t)\hat{A}_s''(t) - \hat{A}_s''(t)\} t^{-1/2}\, dt, \tag{5.17}$$

and

$$\hat{A}_{s+1}(\hat{\zeta}) = -\frac{1}{2} \hat{B}_s(\hat{\zeta}) + \int_0^{\hat{\zeta}} \hat{\psi}(t)\hat{B}(t)\, dt + \hat{\lambda}_{s+1} \qquad (s = 0, 1, 2, \cdots). \tag{5.18}$$

Each $\hat{\lambda}_s$ $(s = 1, 2, \cdots)$ is an arbitrary integration constant for which a value will be assigned shortly.

The explicit error bounds given by (9.03) of [5] are meaningful—provided a reference point $\hat{\zeta} = \hat{\alpha}_j$ in $\hat{\underline{\Delta}}$ is assigned for each of the solutions $\hat{W}_{2n+1,j}$ $(j = 0, \pm 1)$. Before we do so we observe that

$$\hat{A}_s(\hat{\zeta}) = \hat{a}_s + O(\hat{\zeta}^{-3/2}), \tag{5.19}$$

$$\hat{B}_s(\hat{\zeta}) = \hat{b}_s \hat{\zeta}^{-1/2} + O(\hat{\zeta}^{-2}), \tag{5.20}$$

as $\hat{\zeta} \to \infty$ in $\hat{\underline{\Delta}}$, where each $\hat{a}_s$ and $\hat{b}_s$ is a constant. Also, we can prove that the variations $\mathcal{V}(\hat{\zeta}^{1/2}\hat{B}_s(\hat{\zeta}))$ converge as $\hat{\zeta} \to \infty$ in $\hat{\underline{\Delta}}$. These results follow from (4.9), (4.10), (5.17),

(5.18), and Ritt's theorem. It is justifiable then to choose the reference points at infinity: we take $\hat{\alpha}_0=\infty$, $\hat{\alpha}_1=\infty\, e^{2\pi i/3}$, and $\hat{\alpha}_{-1}=\infty\, e^{-2\pi i/3}$. With these choices it follows from the error bounds that for each $j(0,\pm 1)$ the ratio $\hat{\varepsilon}_{2n+1,j}(\kappa,\hat{\zeta})/\mathrm{Ai}_j(\kappa^{2/3}\hat{\zeta})$ is $O(\kappa^{-2n-1})$ uniformly for $\hat{\zeta}\in\hat{\underline{\Delta}}$, except near the zeros of the denominator and near the cut interval BCB'. Moreover, the same ratio vanishes as $\hat{\zeta}\to\hat{\alpha}_j$.

For convenience we take the constants $\hat{\lambda}_s$ $(s=1,2,\cdots)$ to be the same set for each solution $\hat{W}_{2n+1,j}$ $(j=0,\pm 1)$, defining them recursively such that

$$\hat{a}_s=0 \qquad (s=1,2,\cdots). \tag{5.21}$$

The three solutions $\hat{W}_{2n+1,0}$, $\hat{W}_{2n+1,1}$, and $\hat{W}_{2n+1,-1}$ have the characteristic property of being recessive in the sectors $|\arg\hat{\zeta}|<\pi/3$, $\pi/3<\arg\hat{\zeta}<\pi$, and $-\pi<\arg\hat{\zeta}<-\pi/3$, respectively. Thus, we can identify them directly with standard Whittaker functions.

Beginning with $\hat{W}_{2n+1,0}(\kappa,\hat{\zeta})$, we identify this with the Whittaker function $(d\hat{\zeta}/d\xi)^{1/2}W_{\kappa,\mu}(\kappa\xi)$, since this too is a solution of (4.3) that is recessive in the sector $|\arg\hat{\zeta}|<\pi/3$. We have then the following identification:

$$W_{\kappa,\mu}(\kappa\xi)=\hat{c}_{2n+1,0}\left[\frac{(2\xi)^{1/2}\hat{\zeta}^{1/4}}{[(\xi-\xi_1)(\xi-\xi_2)]^{1/4}}\right]\hat{W}_{2n+1,0}(\kappa,\hat{\zeta}), \tag{5.22}$$

where $\hat{c}_{2n+1,0}$ is a constant of proportionality. We can determine the constant by comparing both sides of (5.22) as $\xi\to+\infty$ $(\hat{\zeta}\to\hat{\alpha}_0)$. On employing (4.7), (5.16), (5.20), and (5.21), as well as the asymptotic forms for $\mathrm{Ai}(z)$ and $\mathrm{Ai}'(z)$ with large argument (see [5, p. 392]), we find that the right-hand side of (5.22) is asymptotically equal to

$$\hat{c}_{2n+1,0}(2\pi)^{-1/2}\kappa^{-1/6}(2\xi)^{\kappa}\,e^{-\kappa\xi/2}\left(\frac{\xi_2(2-\alpha)}{2\xi_2-\alpha^2}\right)^{\kappa\alpha/2}(\xi_2-2)^{-\kappa}\left\{1-\sum_{s=0}^{n-1}\frac{\hat{b}_s}{\kappa^{2s+1}}\right\}. \tag{5.23}$$

This must be equal to the asymptotic form of $W_{\kappa,\mu}(\kappa\xi)$ as $\xi\to\infty$ (see (2.6)), and so we conclude that

$$\hat{c}_{2n+1,0}=(2\pi)^{1/2}\kappa^{1/6}\left(\frac{2\xi_2-\alpha^2}{\xi_2(2-\alpha)}\right)^{\kappa\alpha/2}\left(\kappa\left(\frac{\xi_2}{2}-1\right)\right)^{\kappa}\left\{1-\sum_{s=0}^{n-1}\frac{\hat{b}_s}{\kappa^{2s+1}}\right\}^{-1}. \tag{5.24}$$

Equation (5.22), with $\hat{W}_{2n+1,0}$ and $\hat{c}_{2n+1,0}$ given by (5.16) and (5.24), respectively, gives an asymptotic expansion for $W_{\kappa,\mu}(\kappa\xi)$ that is uniformly valid for $\hat{\zeta}\in\hat{\underline{\Delta}}^{(0)}$ and $\alpha\in[0,2-\delta]$, where $\hat{\underline{\Delta}}^{(0)}$ is the domain consisting of all points in $\hat{\underline{\Delta}}$ except those lying on either side of the cut interval BCB' (see Fig. 3(b)).

An asymptotic expansion for $W_{\kappa,\mu}(\kappa\xi)$ that is uniformly valid in the complementary ξ domain Δ can be obtained by replacing the functions $W_{-\kappa,\mu}(\kappa\xi\, e^{\pm\pi i})$ by their asymptotic forms (5.11) and (5.14) in the connection formula (2.9). For the result (stated in terms of the original parameters), see (6.8) in § 6.

The identification of the other two solutions in (5.16) is similarly achieved. For $j=1$ we have the identity

$$W_{-\kappa,\mu}(\kappa\xi\, e^{-\pi i})=\hat{c}_{2n+1,1}\left[\frac{(2\xi)^{1/2}\hat{\zeta}^{1/4}}{[(\xi-\xi_1)(\xi-\xi_2)]^{1/4}}\right]\hat{W}_{2n+1,1}(\kappa,\hat{\zeta}), \tag{5.25}$$

since both sides share the same recessive property in the sector $\pi/3<\arg\hat{\zeta}\leqq\pi$. By comparing both sides as $\zeta\to\hat{\alpha}_1$, $\xi\to-\infty+i0$ (see (4.7)), we obtain the following expression for the constant of proportionality:

$$\begin{aligned}\hat{c}_{2n+1,1}=(2\pi)^{1/2}\kappa^{1/6}\,e^{(\kappa-1/6)\pi i}&\left(\frac{\xi_2(2-\alpha)}{2\xi_2-\alpha^2}\right)^{\kappa\alpha/2}\\ &\cdot\left(\kappa\left(\frac{\xi_2}{2}-1\right)\right)^{-\kappa}\left\{1-e^{-\pi i/3}\sum_{s=0}^{n-1}\frac{\hat{b}_s}{\kappa^{2s+1}}\right\}^{-1}.\end{aligned} \tag{5.26}$$

This asymptotic expansion is uniformly valid for $\hat{\zeta} \in \hat{\underline{\Delta}}^{(1)}$ and $\alpha \in [0, 2-\delta]$, where $\hat{\underline{\Delta}}^{(1)}$ is the domain consisting of all points in $\hat{\underline{\Delta}}$ except those lying on the lower part of the cut interval BCB'.

Likewise, we can show that the following asymptotic expansion:

$$W_{-\kappa,\mu}(\kappa\xi e^{\pi i}) = \hat{c}_{2n+1,-1}\left[\frac{(2\xi)^{1/2}\hat{\zeta}^{1/4}}{[(\xi-\xi_1)(\xi-\xi_2)]^{1/4}}\right]\hat{W}_{2n+1,-1}(\kappa, \hat{\zeta}), \tag{5.27}$$

where

$$\hat{c}_{2n+1,-1} = (2\pi)^{1/2}\kappa^{1/6}\, e^{-(\kappa-1/6)\pi i}\left(\frac{\xi_2(2-\alpha)}{2\xi_2-\alpha^2}\right)^{\kappa\alpha/2} \cdot\left(\kappa\left(\frac{\xi_2}{2}-1\right)\right)^{-\kappa}\left\{1-e^{\pi i/3}\sum_{s=0}^{n-1}\frac{\hat{b}_s}{\kappa^{2s+1}}\right\}^{-1}, \tag{5.28}$$

is uniformly valid for $\hat{\zeta} \in \hat{\underline{\Delta}}^{(-1)}$ and $\alpha \in [0, 2-\delta]$, where $\hat{\underline{\Delta}}^{(-1)}$ is the domain consisting of all points in $\hat{\underline{\Delta}}$ except those lying on the upper part of the cut interval BCB'.

From (2.10), (5.25), and (5.27) we can obtain a uniform asymptotic expansion for $M_{\kappa,\mu}(\kappa\xi)$, uniformly valid for $\hat{\zeta} \in \hat{\underline{\Delta}}^{(0)}$, $\alpha \in [0, 2-\delta]$. The result, stated in terms of the original variables, is given in § 6, eq. (6.16).

6. Summary. For reference we now present the principal results of this paper, and in doing so we express them in terms of the original parameters κ and μ. We present asymptotic expansions as $\kappa \to \infty$ for the Whittaker functions $W_{\kappa,\mu}(z)$ and $M_{\kappa,\mu}(z)$. These expansions are uniformly valid for all real values of κ and μ such that

$$0 \leqq \mu/\kappa \leqq 1-\delta, \qquad \kappa > 0, \tag{6.1}$$

where δ is an arbitrarily small positive constant. Moreover the expansions, which either involve Airy functions or Bessel functions, are uniformly valid in certain complex z domains. These domains overlap and taken together cover the entire complex z plane. Thus an asymptotic expansion is available for both of the Whittaker functions for any value of z such that $|\arg z| \leqq \pi$. For other ranges of $\arg z$ we can use appropriate connection formulae (see, for example, Olver [5, p. 262]).

We also present expansions for the solutions of Whittaker's equation $W_{-\kappa,\mu}(z e^{-\pi i})$ and $W_{-\kappa,\mu}(z e^{\pi i})$. A separate identification for these functions is necessary because they are recessive in the second and third quadrants respectively of the complex z plane. Asymptotic expansions for the Whittaker function $M_{\kappa,\mu}(z)$ for negative values of κ are easily obtained from the ensuing results (where κ is positive) and the connection formula (2.11). Also, we can extend the following expansions to negative values of μ on using (2.2) and (2.12).

We first introduce two transformed variables ζ and $\hat{\zeta}$ that are related to the parameters κ, μ, and the independent variable z, with $-\pi < \arg z \leqq \pi$, by the following equations:

$$(4\mu^2-\kappa\zeta)^{1/2} - \mu \ln\left\{\frac{2\mu+(4\mu^2-\kappa\zeta)^{1/2}}{2\mu-(4\mu^2-\kappa\zeta)^{1/2}}\right\} = -\frac{1}{2}Z + \mu\ln\left\{\frac{z(\mu^2-\kappa^2+\kappa(\kappa^2-\mu^2)^{1/2})}{(\kappa-(\kappa^2-\mu^2)^{1/2})(2\mu^2-\kappa z-\mu Z)}\right\} + \kappa\ln\left\{\frac{2(\kappa^2-\mu^2)^{1/2}}{2\kappa-z+Z}\right\}, \tag{6.2}$$

$$\frac{2}{3}\kappa\hat{\zeta}^{3/2} = \frac{1}{2}Z + \mu\ln\left\{\frac{z(\kappa^2-\mu^2+\kappa(\kappa^2-\mu^2)^{1/2})}{(\kappa+(\kappa^2-\mu^2)^{1/2})(\kappa z-2\mu^2-\mu Z)}\right\} + \kappa\ln\left\{\frac{2(\kappa^2-\mu^2)^{1/2}}{z-2\kappa+Z}\right\}, \tag{6.3}$$

where

$$Z = (z^2-4\kappa z+4\mu^2)^{1/2}. \tag{6.4}$$

The fractional powers on the left side of (6.2) and (6.3) are assumed to take their principal values, with

$$-\pi<\arg\zeta\leqq\pi, \qquad -\pi<\arg\hat{\zeta}\leqq\pi.$$

Let $z=z_1$, z_2 denote the zeros $2\kappa-2(\kappa^2-\mu^2)^{1/2}$, $2\kappa+2(\kappa^2-\mu^2)^{1/2}$, respectively, of the function Z; we take the root of (6.4) such that Z is positive imaginary above the interval (z_1, z_2), negative imaginary below the same interval, and continuous elsewhere in the complex z plane.

For convenience we introduce the following functions:

$$\Phi(\kappa,\mu,z)=\left(\frac{4\mu^2-\kappa^2\zeta}{z_1-z}\right)^{1/4}(z_2-z)^{-1/4}\left(\frac{z}{\kappa}\right)^{1/2}, \tag{6.5}$$

$$\hat{\Phi}(\kappa,\mu,z)=\left(\frac{\hat{\zeta}}{z-z_2}\right)^{1/4}\frac{(2z)^{1/2}}{(z-z_1)^{1/4}}, \tag{6.6}$$

where again principal values are to be taken.

The following asymptotic expansions are uniformly valid for $0\leqq\mu/\kappa\leqq 1-\delta$, $\kappa>0$, and for z and ζ lying in the specified complex domains.

$$M_{\kappa,\mu}(z)=\kappa^{1/2}\Gamma(2\mu+1)\left(\frac{e^2}{\kappa^2-\mu^2}\right)^{\mu/2}\left(\frac{\kappa-\mu}{\kappa+\mu}\right)^{\kappa/2}\left\{1+2\mu\sum_{s=0}^{n-1}\frac{B_s(\alpha,0)}{\kappa^{2s+2}}\right\}^{-1}$$

$$\cdot\Phi(\kappa,\mu,z)\left[J_{2\mu}(\kappa\zeta^{1/2})\sum_{s=0}^{n}\frac{A_s(\zeta)}{\kappa^{2s}}+\frac{\zeta^{1/2}}{\kappa}J'_{2\mu}(\kappa\zeta^{1/2})\right. \tag{6.7}$$

$$\left.\cdot\sum_{s=0}^{n-1}\frac{B_s(\zeta)}{\kappa^{2s}}+\frac{1}{2}\zeta^{-1/2}\varepsilon^{(0)}_{2n+1}(\zeta)\right], \qquad \frac{z}{\kappa}\in\Delta^{(0)}, \quad \zeta\in\underline{\Delta}^{(0)};$$

$$W_{\kappa,\mu}(z)=\frac{1}{\pi}\Gamma\left(\kappa+\mu+\frac{1}{2}\right)\Gamma\left(\kappa-\mu+\frac{1}{2}\right)e^{-\mu\pi i}c^{(1)}_{2n+1}\Phi(\kappa,\mu,z)$$

$$\cdot\left[\{J_{2\mu}(\kappa\zeta^{1/2})\sin(\kappa-\mu)\pi-Y_{2\mu}(\kappa\zeta^{1/2})\cos(\kappa-\mu)\pi\}\sum_{s=0}^{n}\frac{A_s(\zeta)}{\kappa^{2s}}\right.$$

$$+\frac{\zeta^{1/2}}{\kappa}\{J'_{2\mu}(\kappa\zeta^{1/2})\sin(\kappa-\mu)\pi-Y'_{2\mu}(\kappa\zeta^{1/2})\cos(\kappa-\mu)\pi\}\sum_{s=0}^{n-1}\frac{B_s(\zeta)}{\kappa^{2s}} \tag{6.8}$$

$$\left.+\frac{i}{2}\zeta^{-1/2}\{e^{-(\kappa-\mu)\pi i}\varepsilon^{(1)}_{2n+1}(\zeta)-e^{(\kappa-\mu)\pi i}\varepsilon^{(2)}_{2n+1}(\zeta)\}\right],$$

$$\frac{z}{\kappa}\in\Delta, \quad \zeta\in\underline{\Delta},$$

$$W_{-\kappa,\mu}(z\,e^{-\pi i})=c^{(1)}_{2n+1}\Phi(\kappa,\mu,z)\left[H^{(1)}_{2\mu}(\kappa\zeta^{1/2})\sum_{s=0}^{n}\frac{A_s(\zeta)}{\kappa^{2s}}\right.$$

$$\left.+\frac{\zeta^{1/2}}{\kappa}H^{(1)'}_{2\mu}(\kappa\zeta^{1/2})\sum_{s=0}^{n-1}\frac{B_s(\zeta)}{\kappa^{2s}}+\zeta^{-1/2}\varepsilon^{(1)}_{2n+1}(\zeta)\right], \tag{6.9}$$

$$\frac{z}{\kappa}\in\Delta, \quad \zeta\in\underline{\Delta},$$

$$W_{-\kappa,\mu}(z\,e^{\pi i}) = c_{2n+1}^{(1)}\, e^{-2\mu\pi i}\Phi(\kappa,\mu,z)\Bigg[H_{2\mu}^{(2)}(\kappa\zeta^{1/2}) \sum_{s=0}^{n} \frac{A_s(\zeta)}{\kappa^{2s}}$$

$$+\frac{\zeta}{\kappa} H_{2\mu}^{(2)'}(\kappa\zeta^{1/2}) \sum_{s=0}^{n-1} \frac{B_s(\zeta)}{\kappa^{2s}} + \zeta^{-1/2}\varepsilon_{2n+1}^{(2)}(\zeta)\Bigg], \tag{6.10}$$

$$\frac{z}{\kappa}\in\Delta, \quad \zeta\in\underline{\Delta}.$$

The coefficient $c_{2n+1}^{(1)}$ is given by

$$c_{2n+1}^{(1)} = -e^{\mu\pi i}\left(\frac{\pi\kappa}{2}\right)^{1/2}\left(\frac{\kappa-\mu}{\kappa+\mu}\right)^{\mu/2}(\kappa^2-\mu^2)^{-\kappa/2}\left\{1-\sum_{s=0}^{n-1}\frac{b_s}{\kappa^{2s+1}}\right\}^{-1}. \tag{6.11}$$

The z domain of validity Δ, and the corresponding ζ domain $\underline{\Delta}$, are illustrated in Figs 1(a) and 1(b). The domain $\Delta^{(0)}$ ($\underline{\Delta}^{(0)}$) consists of all points in Δ ($\underline{\Delta}$) except those lying on the lines CD, CD'. The coefficients $A_s(\zeta)$ and $B_s(\zeta)$ are defined recursively by (5.2) and (5.3a, b), with (5.6) applying to (6.7), and (5.5) applying to (6.8), (6.9), and (6.10). In (5.2) the function ψ is given by (3.5) together with (1.3) and (1.4).

The error terms $\varepsilon_{2n+1}^{(0)}$, $\varepsilon_{2n+1}^{(1)}$, and $\varepsilon_{2n+1}^{(2)}$ have explicit upper bounds available (see [2, eq. (5.16)]). From these bounds the following asymptotic properties as $\kappa\to\infty$ can be deduced:

$$\zeta^{-1/2}\varepsilon_{2n+1}^{(j)}(\zeta) = \mathscr{C}_{2\mu}^{(j)}(\kappa\zeta^{1/2})O(\kappa^{-2n-1}) + \frac{\zeta^{1/2}}{\kappa}\mathscr{C}_{2\mu}^{(j)'}(\kappa\zeta^{1/2})O(\kappa^{-2n+1}) \quad (j=0,1,2), \tag{6.12}$$

where $\mathscr{C}_\nu^{(j)} = 2J_\nu$, $H_\nu^{(1)}$, $H_\nu^{(2)}$ for $j=0,1,2$, respectively. The O-terms are uniform for $0\leqq\mu/\kappa\leqq 1-\delta$, $\kappa>0$, and ζ lying in the respective domain of validity.

The error terms also satisfy the following boundary conditions:

$$\lim_{\zeta\to 0}\{\varepsilon_{2n+1}^{(0)}(\zeta)/J_{2\mu}(\kappa\zeta^{1/2})\} = 0, \tag{6.13}$$

$$\lim_{\zeta\to -\infty+i0}\{\varepsilon_{2n+1}^{(1)}(\zeta)/H_{2\mu}^{(1)}(\kappa\zeta^{1/2})\} = 0, \tag{6.14}$$

$$\lim_{\zeta\to -\infty-i0}\{\varepsilon_{2n+1}^{(2)}(\zeta)/H_{2\mu}^{(2)}(\kappa\zeta^{1/2})\} = 0. \tag{6.15}$$

The following asymptotic expansions are uniformly valid for $0\leqq\mu/\kappa\leqq 1-\delta$, $\kappa>0$, and for z and $\hat{\zeta}$ lying in the specified complex domains:

$$M_{\kappa,\mu}(z) = \frac{\hat{c}}{2\pi}\Gamma(2\mu+1)\Gamma\left(\kappa-\mu+\frac{1}{2}\right)\left(1+\hat{\phi}_n^2-\frac{1}{2}\hat{\phi}_n\right)^{-1}\hat{\Phi}(\kappa,\mu,z)$$

$$\cdot\Bigg[\left\{Ai(\kappa^{2/3}\hat{\zeta})\left(\sin(\kappa-\mu)\pi-\hat{\phi}_n\sin\left(\kappa-\mu+\frac{1}{3}\right)\pi\right)\right.$$

$$\left.+Bi(\kappa^{2/3}\hat{\zeta})\left(\cos(\kappa-\mu)\pi-\hat{\phi}_n\cos\left(\kappa-\mu+\frac{1}{3}\right)\pi\right)\right\}\sum_{s=0}^{n}\frac{\hat{A}_s(\hat{\zeta})}{\kappa^{2s}}$$

$$-\kappa^{-4/3}\left\{Ai'(\kappa^{2/3}\hat{\zeta})\left(\sin\left(\kappa-\mu-\frac{1}{3}\right)\pi-\hat{\phi}_n\sin(\kappa-\mu)\pi\right)\right. \tag{6.16}$$

$$\left.+Bi'(\kappa^{2/3}\hat{\zeta})\left(\cos\left(\kappa-\mu-\frac{1}{3}\right)\pi-\hat{\phi}_n\cos(\kappa-\mu)\pi\right)\right\}\sum_{s=0}^{n-1}\frac{\hat{B}_s(\hat{\zeta})}{\kappa^{2s}}$$

$$+\{e^{(\kappa-\mu-1/6)\pi i}(1-e^{\pi i/3}\hat{\phi}_n)\hat{\varepsilon}_{2n+1,1}(\hat{\zeta}) + e^{-(\kappa-\mu-1/6)\pi i}(1-e^{-\pi i/3}\hat{\phi}_n)\hat{\varepsilon}_{2n+1,-1}(\hat{\zeta})\}\Big],$$

$$\frac{z}{\kappa}\in\hat{\Delta}^{(0)}, \quad \hat{\zeta}\in\hat{\underline{\Delta}}^{(0)},$$

$$W_{\kappa,\mu}(z)=(2\pi)^{1/2}\kappa^{1/6}\left(\frac{\kappa+\mu}{\kappa-\mu}\right)^{\mu/2}(4(\kappa^2-\mu^2))^{\kappa/2}(1-\hat{\phi}_n)^{-1}\hat{\Phi}(\kappa,\mu,z)$$

$$\cdot\Big[\mathrm{Ai}\,(\kappa^{2/3}\hat{\zeta})\sum_{s=0}^{n}\frac{\hat{A}_s(\hat{\zeta})}{\kappa^{2s}}+\frac{\mathrm{Ai}'\,(\kappa^{2/3}\hat{\zeta})}{\kappa^{4/3}}\sum_{s=0}^{n-1}\frac{\hat{B}_s(\hat{\zeta})}{\kappa^{2s}}+\hat{\varepsilon}_{2n+1,0}(\hat{\zeta})\Big], \tag{6.17}$$

$$\frac{z}{\kappa}\in\hat{\Delta}^{(0)}, \quad \hat{\zeta}\in\hat{\underline{\Delta}}^{(0)};$$

$$W_{-\kappa,\mu}(z\,e^{-\pi i})=\hat{c}\,e^{(\kappa-1/6)\pi i}(1-e^{-\pi i/3}\hat{\phi}_n)^{-1}\hat{\Phi}(\kappa,\mu,z)$$

$$\cdot\Big[\mathrm{Ai}\,(\kappa^{2/3}\hat{\zeta}\,e^{-2\pi i/3})\sum_{s=0}^{n}\frac{\hat{A}_s(\hat{\zeta})}{\kappa^{2s}} +\frac{\mathrm{Ai}'\,(\kappa^{2/3}\hat{\zeta}\,e^{-2\pi i/3})}{\kappa^{4/3}}\sum_{s=0}^{n-1}\frac{\hat{B}_s(\hat{\zeta})}{\kappa^{2s}}+\hat{\varepsilon}_{2n+1,1}(\hat{\zeta})\Big], \tag{6.18}$$

$$\frac{z}{\kappa}\in\hat{\Delta}^{(1)}, \quad \hat{\zeta}\in\hat{\underline{\Delta}}^{(1)},$$

$$W_{-\kappa,\mu}(z\,e^{\pi i})=\hat{c}\,e^{-(\kappa-1/6)\pi i}(1-e^{\pi i/3}\hat{\phi}_n)^{-1}\hat{\Phi}(\kappa,\mu,z)$$

$$\cdot\Big[\mathrm{Ai}\,(\kappa^{2/3}\hat{\zeta}\,e^{2\pi i/3})\sum_{s=0}^{n}\frac{\hat{A}_s(\hat{\zeta})}{\kappa^{2s}} +\frac{\mathrm{Ai}'\,(\kappa^{2/3}\hat{\zeta}\,e^{2\pi i/3})}{\kappa^{4/3}}\sum_{s=0}^{n-1}\frac{\hat{B}_s(\hat{\zeta})}{\kappa^{2s}}+\hat{\varepsilon}_{2n+1,-1}(\hat{\zeta})\Big] \tag{6.19}$$

$$\frac{z}{\kappa}\in\hat{\Delta}^{(-1)}, \quad \hat{\zeta}\in\hat{\underline{\Delta}}^{(-1)}.$$

The coefficient $\hat{c}$ is given by

$$\hat{c}=(2\pi)^{1/2}\kappa^{1/6}\left(\frac{\kappa-\mu}{\kappa+\mu}\right)^{\mu/2}(4(\kappa^2-\mu^2))^{-\kappa/2}, \tag{6.20}$$

and $\hat{\phi}_n$ is defined by

$$\hat{\phi}_n=\sum_{s=0}^{n-1}\frac{\hat{b}_s}{\kappa^{2s+1}}. \tag{6.21}$$

The z domain $\hat{\Delta}$ and the corresponding $\hat{\zeta}$ domain $\hat{\underline{\Delta}}$ are illustrated in Figs. 3(a) and 3(b). The $\hat{\zeta}$ domains of validity $\hat{\underline{\Delta}}^{(1)}$ and $\hat{\underline{\Delta}}^{(-1)}$ consist of all points in $\hat{\underline{\Delta}}$ except those lying, respectively, on the lower and upper parts of the cut interval BCB'. $\hat{\underline{\Delta}}^{(0)}$ is the intersection of $\hat{\underline{\Delta}}^{(1)}$ and $\hat{\underline{\Delta}}^{(-1)}$.

The coefficients $\hat{A}_s(\hat{\zeta})$ and $\hat{B}_s(\hat{\zeta})$ are defined recursively by (5.17), (5.18), with (4.4) and (5.21). Bounds for the error functions $\hat{\varepsilon}_{2n+1}$, $\hat{\varepsilon}_{2n+1,1}$, $\hat{\varepsilon}_{2n+1,-1}$, are supplied in [5, p. 418]. These functions satisfy the following boundary conditions:

$$\lim_{\hat{\zeta}\to\infty e^{2\pi ij/3}}\{\hat{\varepsilon}_{2n+1,j}(\hat{\zeta})/\mathrm{Ai}\,(\kappa^{2/3}\hat{\zeta}\,e^{-2\pi ij/3})\}=0 \qquad (j=0,\pm1). \tag{6.22}$$

Finally, we remark that (6.8) and (6.16) should not be used when $\kappa-\mu-\frac{1}{2}$ is equal to a nonnegative integer. In this case the asymptotic formulae (6.7) and (6.17) should be used, together with the relation

$$W_{\kappa,\mu}(z)=\frac{\Gamma(-2\mu)}{\Gamma(\frac{1}{2}-\mu-\kappa)}M_{\kappa,\mu}(z). \tag{6.23}$$

ERRATUM:

Study of a Doubly Nonlinear Heat Equation with No Growth Assumptions on the Parabolic Term*

D. BLANCHARD† AND G. A. FRANCFORT†

Inequalities (64) and (101) of [1] are not satisfied under the assumptions on Φ listed in (5) of that paper. Rather, they immediately result from the following implicitly (*but not explicitly*) assumed almost pointwise inequality:

$$(I) \qquad (D\Phi(w)(x) - D\Phi(w')(x),\, w(x) - w'(x))_{\mathbb{R}^N} \geqq 0,$$

for any w and w' in $[L_q(\Omega)]^N$.

Counterexamples of functionals Φ that satisfy (5) of [1] and for which (I) is violated are easily obtained. In the usually considered case where Φ is a C^1, convex, coercive, *local* functional (cf. definition below), (I) is trivially satisfied and inequalities (64), (101) hold true.

DEFINITION. The functional Φ defined on $[L_q(\Omega)]^N$, $q > 1$, is a C^1, convex, coercive, local functional if there exists a convex normal integrand $f(x, \xi)$ on $\Omega \times \mathbb{R}^N$, C^1 in ξ for almost every x in Ω with the following properties:

There exist an element $a(x)$ of $L_1(\Omega)$, two strictly positive constants α and β such that, for almost every x of Ω and every ξ of $\mathbb{R}^N$,

$$\alpha|\xi|^q \leqq f(x, \xi) \leqq a(x) + \beta|\xi|^q,$$

For every w in $[L_q(\Omega)]^N$,

$$\Phi(w) = \int_\Omega f(x, w(x))\, dx.$$

Remark. If Φ is a C^1, convex, coercive, local functional and if $\Phi(0) = 0$, $D\Phi$ is bounded on the bounded sets of $[L_q(\Omega)]^N$ and Φ satisfies (5) of [1] with a coercivity exponent r equal to q.

To ensure the validity of the results of our paper, it is then tempting to impose (I) as an additional hypothesis to (5) and to investigate the nonlocal functionals that satisfy (5) and (I). In fact there are *no* such functionals and the following theorem can be deduced from the work of Buttazzo and Dal Maso concerning integral representations of local functionals (the proof uses [2, Thm. 1.4 and Cors. 1.5, 1.7]).

THEOREM. *If Φ satisfies* (5) *and* (I), *Φ is a C^1, convex, coercive, local functional on $[L_q(\Omega)]^N$.*

Conclusion. If Φ is a C^1, convex, coercive, local functional on $[L_q(\Omega)]^N$ in the sense of the above definition (and if $\Phi(0) = 0$), Theorems 1 and 2 of [1] hold true as stated. In fact, Theorems 1 and 2 hold true (*except for the comparison results*) even when (I) is not satisfied, as can be shown by the method developed for the proof of Theorem 2, but such considerations are beyond the scope of an erratum.

REGULARITY OF THE SOLUTION OF ELLIPTIC PROBLEMS WITH PIECEWISE ANALYTIC DATA, II: THE TRACE SPACES AND APPLICATION TO THE BOUNDARY VALUE PROBLEMS WITH NONHOMOGENEOUS BOUNDARY CONDITIONS*

I. BABUŠKA† AND B. Q. GUO‡

Abstract. This paper analyzes the trace spaces of the weighted space $\mathfrak{B}^2_\beta(\Omega)$ introduced by Babuška and Guo [*SIAM J. Math. Anal.*, 19 (1988), pp. 172-203].

Key words. elliptic equation with piecewise analytic data, Dirichlet problem, corner singularities

AMS(MOS) subject classifications. 35B65, 35D10, 35G15, 35J05

1. Introduction. Elliptic boundary value problems with piecewise analytic data are typical in many fields of applications, for example, in structural mechanics. These problems are then numerically analyzed in engineering by the finite-element method. The design and performance of a numerical method directly depends on the class of problems to which it is oriented. The smaller the class is, the more effective the numerical method can be. Hence, it is important to characterize mathematically a (minimal) class that encompasses virtually all practical problems in a field of applications. The space $\mathfrak{B}^2_\beta(\Omega)$ is such a class. In [4], [5a], and [5b] it has been shown that if the solution belongs to the space $\mathfrak{B}^2_\beta(\Omega)$, then the *h-p* version of the finite-element method has an exponential rate of convergence. The *h-p* version uses properly refined mesh and a high degree of elements in contrast to the usual *h*-version that uses only low-degree elements. For the survey of various theoretical and practical aspects of the *h-p* version we refer the reader to [1] and the references given therein.

In [3] the spaces $\mathfrak{B}^2_\beta(\Omega)$ have been analyzed. It has been shown that the solution of the elliptic boundary value problems with piecewise analytic data belongs to these spaces.

The present paper elaborates in detail on the structure of the traces of functions of $\mathfrak{B}^2_\beta(\Omega)$. The results give easy characterization of the case when the solution belongs to $\mathfrak{B}^2_\beta(\Omega)$. In § 2 we give the preliminaries and basic definitions. Section 3 defines the model problem of second-order elliptic partial differential equations. Section 4 introduces the space of traces of $u \in \mathfrak{B}^2_\beta(\Omega)$ on the boundary $\partial\Omega$. It is also shown that these traces can be extended into $\mathfrak{B}^2_\beta(\Omega)$.

2. Preliminaries. Let $\Omega \subset \mathbb{R}^2$, $(x_1, x_2) = x$ be a simply-connected, bounded domain with the boundary $\partial\Omega = \Gamma = \cup_{i=1}^M \bar{\Gamma}_i$. Γ_i are analytic simple arcs called *edges*,

$$\bar{\Gamma}_i \in \{(\varphi_i(\xi), \psi_i(\xi)) \,|\, \xi \in \bar{I} = [-1, 1]\},$$

where $\varphi_i(\xi)$, $\psi_i(\xi)$ are *analytic functions* on $\bar{I}$ and $|\varphi_i'(\xi)|^2 + |\psi_i'(\xi)|^2 \geqq \alpha_i > 0$. By Γ_i we denote the open arc, i.e., the image of $I = (-1, 1)$. Let A_i, $i = 1, \cdots, M$, be the vertices

of Ω and $\Gamma_i = A_iA_{i+1}$, i.e., the edge Γ_i is linking the vertices A_i and A_{i+1}. For simplicity we will also write $A_1 = A_{M+1}$. An example of the domain Ω under consideration is given in Fig. 2.1. By ω_i, $i = 1, \cdots, M$, we denote the internal angles of Ω at A_i. We will assume that $0 < \omega_i \leqq 2\pi$. We will also consider the case when two edges coincide. Then we understand them in a "two-sided" sense. If all edges are straight lines then we call the domain Ω a *straight polygon.* Otherwise we speak about a *curvilinear polygon.* If $0 < \omega_i < 2\pi$, $i = 1, \cdots, M$, we speak about a Lipschitzian domain. Let us assume that $\Gamma = \Gamma^{(0)} \cup \Gamma^{(1)}$ where $\Gamma^{(0)} = \cup_{i \in Q} \bar{\Gamma}_i$, $\Gamma^{(1)} = \Gamma - \Gamma^{(0)}$, $\bar{\Gamma}^{(1)} = \cup_{i \in Q'} \bar{\Gamma}_{i'}$, where Q is some subset of the set $\{1, 2, \cdots, M\} = \mathcal{M}$ and $Q' = \mathcal{M} - Q$.

We assume for simplicity that Ω is a simply-connected domain. The results we present here are also valid when Ω is an n-connected, bounded domain and its boundary is composed of n-curves.

Denote $I = \{x \mid -1 < x < 1\}$; we also write $I = \{x_1, x_2 \mid -1 < x_1 < 1, x_2 = 0\} \subset \mathbb{R}_2$ when no misunderstanding can occur.

By $L_2(\Omega)$, $L_p(\Omega)$, $L_2(I)$, $L_p(I)$, the usual spaces of p-integrable, $1 < p < \infty$, functions on Ω or I are denoted. By $H^m(\Omega)$, $H^m(I)$, $m \geqq 0$ integer, we denote the usual Sobolev space of functions with square integrable derivatives of order less than or equal to m on Ω (respectively, I). The space $H^m(\Omega)$ is furnished with the usual norm

$$\|u\|^2_{H^m(\Omega)} = \sum_{0 \leqq |\alpha| \leqq m} \|D^\alpha u\|^2_{L_2(\Omega)}$$

where $\alpha = (\alpha_1, \alpha_2)$, $\alpha_i \geqq 0$ integer, $i = 1, 2$, $|\alpha| = \alpha_1 + \alpha_2$, and

$$D^\alpha u = \frac{\partial^\alpha u}{\partial x_1^{\alpha_1} \partial x_2^{\alpha_2}} = u_{x_1^{\alpha_1} x_2^{\alpha_2}}.$$

Furthermore, we let

$$|u|_{H^m(\Omega)} = \| |D^m u| \|_{L_2(\Omega)}, \qquad |D^m u|^2 = \sum_{|\alpha| = m} |D^\alpha u|^2.$$

As usual, we write $H^0(\Omega) = L_2(\Omega)$,

$$H^1_0(\Omega) = \{u \in H^1(\Omega) \mid u = 0 \text{ on } \Gamma^{(0)}\}.$$

In an analogous way we define $H^m(I)$ by $D^k u = u^{(k)} = d^k u / dx^k$.

By $r_j(x) = \text{dist}\,(x, A_j) = |x - A_j|$, $x \in \Omega$, $j \in \mathcal{M}$, we denote the Euclidean distance between the point x and the vertex A_j, $\hat{r}_1(x) = x + 1$, $\hat{r}_2(x) = x - 1$, $x \in I$. Let $\beta = (\beta_1, \cdots, \beta_M)$ (respectively, $\beta = (\beta_1, \beta_2)$) be an M-tuple of real numbers $0 < \beta_i < 1$,

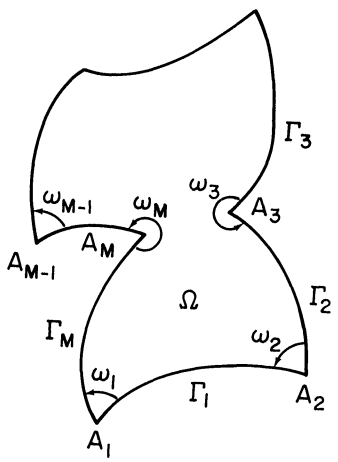

FIG. 2.1. *The scheme of the domain.*

$i=1,\cdots,M$. We write $\alpha_1<\beta<\alpha_2$ (respectively, $\bar{\beta}<\beta$) if $\alpha_1<\beta_i<\alpha_2$ (respectively, $\bar{\beta}_i<\beta_i$), $i=1,\cdots,M$. For any integer β, we write $\beta+k=\{\beta_1+k,\cdots,\beta_M+k\}$ such that

$$\Phi_{\beta+k}(x)=\prod_{i=1}^{M}|r_i(x)|^{\beta_i+k},\qquad x\in\Omega$$

and

$$\hat{\Phi}_{\beta+k}(x)=\prod_{i=1}^{2}|\hat{r}_i(x)|^{\beta_i+k},\qquad x\in I.$$

By $C^j(\Omega)$, $C^j(\bar{\Omega})$, $C^j(I)$, $C^j(\bar{I})$, $j\geqq 0$ integer we will denote the set of all functions with continuous j-derivatives on Ω, $\bar{\Omega}$, I, $\bar{I}$, furnished with the usual norm $\|\cdot\|_{C^j(\Omega)}$, $\|\cdot\|_{C^j(I)}$. Let $H_\beta^{m,l}(\Omega)$, $m\geqq l\geqq 0$ integers, be the completion of the set of all infinitely differentiable functions under the norm

$$\|u\|^2_{H_\beta^{m,l}(\Omega)}=\|u\|^2_{H^{l-1}(\Omega)}+\sum_{\substack{|\alpha|=k\\ k=l}}^{k=m}\|\Phi_{\beta+k-l}|D^\alpha u|\,\|^2_{L_2(\Omega)}\quad\text{for } l\geqq 1,$$

$$\|u\|^2_{H_\beta^{m,0}(\Omega)}=\sum_{\substack{|\alpha|=k\\ k=0}}^{k=m}\|\Phi_{\beta+k}|D^\alpha u|\,\|^2_{L_2(\Omega)}.$$

If $m=l=0$ we will write $H_\beta^{0,0}=L_\beta(\Omega)$. Analogously as before we define

$$|u|^2_{H_\beta^{l,l}(\Omega)}=\sum_{|\alpha|=l}\|\Phi_\beta|D^\alpha u|\,\|^2_{L_2(\Omega)}.$$

In a similar way $H_\beta^{m,l}(I)$ is defined

$$\|u\|^2_{H_\beta^{m,l}(I)}=\|u\|^2_{H^{l-1}(I)}+\sum_{k=l}^{k=m}\|\hat{\Phi}_{\beta+k-l}|D^k u|\,\|^2_{L_2(I)}\quad\text{for } l\geqq 1,$$

$$\|u\|^2_{H_\beta^{m,0}(I)}=\sum_{k=0}^{k=m}\|\hat{\Phi}_{\beta+k}|D^k u|\,\|^2_{L_2(I)}.$$

Furthermore we introduce the space $\mathfrak{B}_\beta^l(\Omega)$, $l\geqq 0$ integer that will play an important role in this paper:

$$\mathfrak{B}_\beta^l(\Omega)=\{u\,|\,u\in H_\beta^{k,l}(\Omega),\text{ for any } k\geqq l,\ \|\Phi_{\beta+k-l}|D^\alpha u|\,\|_{L_2(\Omega)}\leqq Cd^{k-l}(k-l)!,\ |\alpha|=k,\ C>0,\ d\geqq 1 \text{ independent of } k\},$$

where C and d may depend on u. If we wish to emphasize the dependence on d we will write $\mathfrak{B}_{\beta,d}^l(\Omega)$. Analogously for $l\geqq 0$ integer

$$\mathfrak{B}_\beta^l(I)=\{u\,|\,u\in H_\beta^{k,l}(I),\text{ for any } k\geqq l,\ \|\hat{\Phi}_{\beta+k-l}u^{(k)}\|_{L_2(I)}\leqq Cd^{k-l}(k-l)!,\ C>0,\ d\geqq 1 \text{ independent of } k\}.$$

Furthermore, for $j=1,2$,

$$\mathfrak{C}_\beta^j(\Omega)=\{u\in H_\beta^{j,j}(\Omega)\,|\,|D^\alpha u(x)|\leqq Cd^k k!|\Phi_{k+\beta-j+1}(x)|^{-1},\ |\alpha|=k=j-1,j,\cdots,\ C>0,\ d\geqq 1 \text{ independent of } k\},$$

$$\mathfrak{C}_\beta^j(I)=\{u\in H_\beta^{j,j}(I)\,|\,|u^{(k)}(x)|\leqq C|\hat{\Phi}_{k+\beta-j+1/2}(x)|^{-1}d^k k!,\ k=j-1,j,\cdots,\ C>0,\ d\geqq 1 \text{ independent of } k\}.$$

Let $\gamma = \cup_{i \in \rho \subset \mathcal{M}} \bar{\Gamma}_i$. Then we define $H^{k-1/2}(\gamma)$, $k \geqq 1$ (respectively, $H_\beta^{k-1/2,l-1/2}(\gamma)$, $k \geqq l \geqq 1$) integers as follows: for any $\varphi \in H^{k-1/2}(\gamma)$ (respectively, $H_\beta^{k-1/2,l-1/2}(\gamma)$) there exists $f \in H^k(\Omega)$ (respectively, $H_\beta^{k,l}(\Omega)$) such that $f|_\gamma = \varphi$. We define then

$$\|\varphi\|_{H^{k-1/2}(\Gamma)} \quad \text{(respectively, } \|\varphi\|_{H_\beta^{k-1/2,l-1/2}(\gamma)})$$
$$= \inf_{f|_\gamma = \varphi} \|f\|_{H^k(\Omega)} \quad \text{(respectively, } \|f\|_{H_\beta^{k,l}(\Omega)}).$$

By $\mathfrak{B}_\beta^{l-1/2}(\gamma)$, $l \geqq 1$, we will denote the set of the traces on γ of functions from the space $\mathfrak{B}_\beta^l(\Omega)$.

Let Γ_i be an edge of Ω; then by the assumption there exists a one-to-one mapping m_i of I onto Γ_i which is analytic. If Γ_i is a straight line, then we will assume that m_i is the linear mapping. Let u be defined on Γ_i, $U(x) = u(m_i(x))$ be defined on I. Then we define

$$H^m(\Gamma_i) = \{u \mid U \in H^m(I)\}, \qquad \|u\|_{H^m(\Gamma_i)} = \|U\|_{H^m(I)}.$$

In the same way we define the spaces $H_\beta^{m,l}(\Gamma_i)$, $\mathfrak{B}_\beta^l(\Gamma_i)$, $\mathfrak{C}_\beta^l(\Gamma_i)$. Let us remark that, as we defined it, $\|\cdot\|_{H^m(\Gamma_i)}$ depends on the mapping m_i, i.e., it depends on the parameterization of the arc Γ_i. Nevertheless the space $H_\beta^{m,l}(\Gamma_i)$ does not do as well as $\mathfrak{C}_\beta^l(\Gamma_i)$ (see Lemma 4.6) but $\mathfrak{B}_\beta^l(\Gamma_i)$ could be dependent on m_i. Let us now state some lemmas that will be used later.

LEMMA 2.1. *We have*

$$H_\beta^{2,2}(\Omega) \subset C^0(\bar{\Omega})$$

with the continuous injection.

See Lemma 7 of [2].

LEMMA 2.2. *Let* $u \in H_\beta^{2,2}(\Omega)$. *Then*

(i)

$$\| |D^1 u| \Phi_{\beta-1} \|_{L_2(\Omega)} \leqq C \|u\|_{H_\beta^{2,2}(\Omega)}. \tag{2.1}$$

(ii) *Let* $u(A_i) = 0$, $i = 1, \cdots, M$. *Then*

$$\|u \Phi_{\beta-2}\|_{L_2(\Omega)} \leqq C \|u\|_{H_\beta^{2,2}(\Omega)}. \tag{2.2}$$

See Lemma 8 of [2].

LEMMA 2.3. $\mathfrak{B}_\beta^2(\Omega) \subset \mathfrak{C}_\beta^2(\Omega)$ *and* $\mathfrak{C}_\beta^2(\Omega) \subset \mathfrak{B}_{\beta+\varepsilon}^2(\Omega)$, $0 < \beta + \varepsilon < 1$, $\varepsilon > 0$ *arbitrary.*

See Theorems 2.2 and 2.3 of [4].

LEMMA 2.4. *Let* $u \in \mathfrak{B}_\beta^j(\Omega)$, $j \geqq 0$; *then* u *is analytic on* $\bar{\Omega} - \cup_{i=1}^M A_i$.

LEMMA 2.5. *Let* $r \neq 1$ *and* $F(x)$, $0 < x < \infty$ *is defined by*

$$F(x) = \int_0^x f(t)\, dt \quad \text{for } r > 1,$$

$$F(x) = \int_x^\infty f(t)\, dt \quad \text{for } r < 1.$$

Then

$$\int_0^\infty x^{-r} F^2(x)\, dx \leqq \left(\frac{2}{|r-1|}\right)^2 \int_0^\infty x^{-r} (xf)^2\, dx.$$

See Theorem 330 of [7].

3. The model problem and its properties. Let Ω be the curvilinear or straight polygon and let L be a strongly elliptic operator

$$L(u) = -\sum_{i,j=1}^{2} (a_{i,j}(x)u_{x_i})_{x_j} + \sum_{i=1}^{2} b_i(x)u_{x_i} + c(x)u$$

where $a_{i,j}(x) = a_{j,i}(x)$, $b_i(x)$, $c(x)$ are analytic functions on $\bar{\Omega}$ and for any $\xi_1, \xi_2 \in \mathbb{R}$ and any $x \in \Omega$ let

$$\sum_{i,j=1}^{2} a_{i,j}\xi_i\xi_j \geqq \mu_0(\xi_1^2 + \xi_2^2)$$

with $\mu_0 > 0$.

Let $B(u, v)$ be a continuous bilinear form on $H_0^1(\Omega) \times H_0^1(\Omega)$:

$$B(u, v) = \int_\Omega \left(\sum_{i,j=1}^{2} a_{i,j}u_{x_i}v_{x_j} + \sum_{i=1} b_i u_{x_i}v + cuv \right) dx.$$

We assume that

$$\inf_{\substack{\|u\|_{H^1(\Omega)}=1 \\ u \in H_0^1(\Omega)}} \sup_{\substack{\|v\|_{H^1(\Omega)}=1 \\ v \in H_0^1(\Omega)}} |B(u, v)| \geqq \mu_1 > 0$$

and for any $v \in H_0^1(\Omega)$, $v \neq 0$

$$\sup_{\substack{\|u\|_{H^1(\Omega)}=1 \\ u \in H_0^1(\Omega)}} |B(u, v)| > 0.$$

Assume now that $g^{[l]} \in \mathfrak{B}_\beta^{3/2-l}(\Gamma^{(l)})$, $l = 0, 1$, $f \in \mathfrak{B}_\beta^0(\Omega)$ and consider the boundary value problem

$$Lu = f \quad \text{on } \Omega, \tag{3.1a}$$

$$u = g^{[0]} \quad \text{on } \Gamma^{(0)}, \tag{3.1b}$$

$$\frac{\partial u}{\partial n_c} = g^{[1]} \quad \text{on } \Gamma^{(1)} \tag{3.1c}$$

where we denoted by n_c the conormal in the usual sense. The solution of our problem is understood in the usual sense. Then we have Theorem 3.1.

THEOREM 3.1. *There exists unique solution* $u_0 \in H^1(\Omega)$ *of the problem* (3.1). *See Lemma* 3.1 *of* [3].

Let us mention some theorems addressing regularity of the solution u_0.

THEOREM 3.2. *There exists* $0 \leqq \bar{\beta}_i < 1$, $i = 1, \cdots, M$, *depending on the problem* (*i.e., operator L,* ω_i, *etc.*), *such that if* $f \in \mathfrak{B}_\beta^0(\Omega)$, $g^{[l]} \in \mathfrak{B}_\beta^{3/2-l}(\Gamma^{(l)})$, $l = 0, 1$, $\bar{\beta} < \beta < 1$, *then* $u_0 \in \mathfrak{B}_\beta^2(\Omega)$.

Proof is given in [3].

THEOREM 3.3. *Let* Ω *be a* (*curvilinear*) *polygon* (*instead of straight polygon as in Theorem* 3.2) *and let the assumptions of Theorem* 3.2 *hold. Then* $u_0 \in \mathfrak{C}_\beta^2(\Omega)$.

Proof of the theorem is given in [4].

We have seen in [4], [5a], and [5b] that when the solution u of the problem (3.1a)-(3.1c) belongs to the class $\mathfrak{B}_\beta^2(\Omega)$ then the *h-p* version of the finite-element method converges exponentially.

Theorems 3.1 and 3.2 show that it is important to develop practical characterizations of spaces $\mathfrak{B}_\beta^{3/2-l}(\Gamma)$, $l = 0, 1$, which can be easily used in concrete cases to verify whether the input data, i.e., $g^{[l]}$ belong to the desired space. We will elaborate on this in the next section.

4. Traces and extensions of weighted Sobolev spaces. Characterization of the spaces $\mathfrak{B}_\beta^{3/2-l}(\Gamma)$. In this section we will elaborate on the characterization of the space $\mathfrak{B}_\beta^{3/2-l}(\Gamma)$, $l=0,1$, which leads to an easy verification in the concrete cases of applications.

LEMMA 4.1. *Let $\beta=(\beta_1,\beta_2)$, $0<\beta<\frac{1}{2}$ and $g\in H_\beta^{1,1}(I)$. Then*

(i) $g\in C^0(\bar I)$ *and* $\|g\|_{C^0(\bar I)}\leqq C\|g\|_{H_\beta^{1,1}(I)}$;

(ii) $|g(x)-g(-1)|\leqq C\hat\Phi_{1/2-\beta}(x)\|g\|_{H_\beta^{1,1}(I)}$,

$|g(x)-g(1)|\leqq C\hat\Phi_{1/2-\beta}(x)\|g\|_{H_\beta^{1,1}(I)}$,

where C is a constant independent of $g(x)$ (but depends on β).

Proof. Obviously,

$$
\begin{aligned}
|g(x)-g(t)| &\leqq \left|\int_t^x g'(\tau)\,d\tau\right| \\
&\leqq \left[\int_t^x g'^2(\tau)\hat\Phi_\beta^2(\tau)\,d\tau\right]^{1/2}\left[\int_t^x (\hat\Phi_\beta(\tau))^{-2}\,d\tau\right]^{1/2} \qquad (4.1)\\
&\leqq \|g\|_{H_\beta^{1,1}(I)}\left[\int_t^x (\hat\Phi_\beta(\tau))^{-2}\,d\tau\right]^{1/2},
\end{aligned}
$$

which shows that g is continuous on $\bar I$. Using the imbedding theorem on $(-\frac{1}{2},\frac{1}{2})=I'$, we have

$$
|g(0)|\leqq C\|g\|_{H^1(I')}\leqq C\|g\|_{H_\beta^{1,1}(I)} \qquad (4.2)
$$

and we get immediately

$$
\|g\|_{C^0(I)}\leqq C\|g\|_{H_\beta^{1,1}(I)}.
$$

Further, (4.1) immediately leads to (ii). □

LEMMA 4.2. *Let $\beta=(\beta_1,\beta_2)$, $\frac{1}{2}<\beta<1$ and $g\in H_\beta^{2,2}(I)$. Then*

(i) $g\in C^0(I)$ *and* $\|g\|_{C^0(I)}\leqq C\|g\|_{H_\beta^{2,2}(I)}$;

(ii) $|g(x)-g(-1)|\leqq C\hat\Phi_{3/2-\beta}(x)\|g\|_{H_\beta^{2,2}(I)}$,

$|g(x)-g(1)|\leqq C\hat\Phi_{3/2-\beta}(x)\|g\|_{H_\beta^{2,2}(I)}$,

where C is a constant independent of $g(x)$.

Proof. Using (4.1), we get

$$
\begin{aligned}
|g(x)-g(t)| &= \left|\int_t^x g'(\tau)\,d\tau\right| \\
&\leqq \left[\int_t^x g'^2(\tau)\hat\Phi_{1-\beta}^{-2}\,d\tau\right]^{1/2}\left[\int_t^x \hat\Phi_{1-\beta}^2(\tau)\,d\tau\right]^{1/2} \\
&\leqq \|g'\hat\Phi_{1-\beta}^{-1}\|_{L_2(I)}\left[\int_t^x \hat\Phi_{1-\beta}^2(\tau)\,d\tau\right]^{1/2}
\end{aligned}
$$

and

$$
\begin{aligned}
\|g'\hat\Phi_{1-\beta}^{-1}\|_{L_2(I)} &\leqq \|(g'-g'(0))\hat\Phi_{1-\beta}^{-1}\|_{L_2(I)}+|g'(0)|\,\|\hat\Phi_{1-\beta}^{-1}\|_{L_2(I)} \\
&\leqq C[|g'(0)|+\|g''\hat\Phi_\beta\|_{L_2(I)}] \\
&\leqq C\|g\|_{H_\beta^{2,2}(I)}.
\end{aligned}
$$

In the last inequality we used Lemma 2.5 and the fact that $\frac{1}{2}<\beta<1$. The lemma now follows immediately. □

LEMMA 4.3. *Let* $g \in \mathfrak{B}^1_{\beta,d}(I)$, $0<\beta<1$. *Then for* $k \geqq 1$

$$|g^{(k)}(x)| \leqq C(\hat{\Phi}_{k-1/2+\beta}(x))^{-1}(d_1)^k k!$$

where $d_1 = \gamma d$, $\gamma > 1$ *is independent of* g, k, d, *and* C *depends on* β, *but is independent of* g, k.

Proof. Let $I' = (-\frac{1}{2}, \frac{1}{2})$. *Then for any* $k \geqq 1$ we have

$$\|g^{(k)}\|_{H^1(I')} \leqq C(\hat{\Phi}(\tfrac{1}{2}))^{-k-\bar{\beta}} k! d^k$$

where $\bar{\beta} = \max(\beta_1, \beta_2)$. Hence by the imbedding theorem, we have

$$|g^{(k)}(0)| \leqq C d_1^k k!$$

where $d_1 \geqq \gamma d$, $\gamma > \hat{\Phi}^{-1}(\frac{1}{2}) > 1$. Further, for $k \geqq 1$, we have that

$$\begin{aligned}
|g^{(k)}(x)| &\leqq |g^{(k)}(0)| + \left| \int_0^x g^{(k+1)}(t)\, dt \right| \\
&\leqq |g^{(k)}(0)| + \left[\int_0^x (g^{(k+1)}(t))^2 \hat{\Phi}^2_{\beta+k}(t)\, dt \right]^{1/2} \left[\int_0^x \hat{\Phi}^{-2}_{\beta+k}(t)\, dt \right]^{1/2} \\
&\leqq C d_1^k k! [1 + \hat{\Phi}^{-1}_{\beta+k-1/2}(x)] \\
&\leqq C d_1^k k! (\hat{\Phi}_{k-1/2+\beta}(x))^{-1}.
\end{aligned}$$

□

COROLLARY 4.4. *Let* $g \in \mathfrak{B}^1_\beta(I)$, $0<\beta<1$. *Then* $g \in \mathfrak{C}^1_\beta(I)$.

COROLLARY 4.5. *Let* $g \in \mathfrak{B}^2_\beta(I)$, $0<\beta<1$. *Then for* $k \geqq 2$

$$|g^{(k)}(x)| \leqq C(\hat{\Phi}_{k-3/2+\beta}(x))^{-1} d_1^k k!$$

and $g \in \mathfrak{C}^2_\beta(I)$.

LEMMA 4.6. *Let* $\xi = m(x)$ *be a one-to-one map of* $\bar{I}$ *onto* $\bar{I}$, *let* $m(x)$ *be analytic on* $\bar{I}$, *and let* $|m'(x)| > 0$, $x \in \bar{I}$. *Assume that* $g \in \mathfrak{C}^j_\beta(I)$, $j = 1, 2$, *and define* $v(x) = g(m(x))$. *Then* $v \in \mathfrak{C}^j_\beta(I)$, $j = 1, 2$.

Proof. Because $m(x)$ is analytic on $\bar{I}$ it can be extended into the complex plane $\mathbb{C}$ on $I_\delta = \{z = x+iy \mid -1-\delta < x < 1+\delta, |y| < \delta\}$, $\delta > 0$, $m(z)$ is a one-to-one mapping of $\bar{I}_\delta$ onto $\bar{I}^*_\delta \supset I_{\delta'}$, $\delta' > 0$ and $|m'(z)| > \alpha_0 > 0$, $z \in \bar{I}_\delta$. Now let $j = 1$ and $x_0 \in I$. Then for $k \geqq 1$

$$|g^{(k)}(x_0)| \leqq C(\hat{\Phi}_{k-1/2+\beta}(x_0))^{-1} d_1^k k!$$

and the series

$$g'(x) = \sum_{k=0}^{\infty} g^{(k+1)}(x_0)(x-x_0)^k \frac{1}{k!}$$

is absolutely convergent for $|x - x_0| \leqq \alpha(\hat{\Phi}(x_0)/d_1)$, $\alpha < 1$. Hence also

$$g'(z) = \sum_{k=0}^{\infty} g^{(k+1)}(x_0)(z-x_0)^k \frac{1}{k}!$$

converges and $|g'(z)| \leqq C\hat{\Phi}^{-1}_{\beta+1/2}(x_0)$ for $|z - x_0| \leqq \alpha(\hat{\Phi}(x_0)/d_1)$ where C is independent of x_0. Hence $g(z)$ is a holomorphic function and $v(z) = g(m(z))$ is holomorphic, too. Using Cauchy's theorem we get immediately that for $k \geqq 1$

$$|v^{(k)}(x)| \leqq C d_2^k \hat{\Phi}^{-1}_{k-1/2+\beta}(x) k!.$$

Obviously, $v(x) \in H^{1,1}_\beta(I)$. In quite a similar way we prove the statement for $j = 2$. □

Remark 4.1. Lemma 4.6 shows that the space $\mathfrak{C}^j_\beta(I)$ is invariant with respect to an analytic mapping. Using the formula of the nth derivative of a composite function (see formula 0.430 of [8]) we can also show that $\mathfrak{B}^j_\beta(I)$ is an invariant space with respect to an analytic mapping $m(x)$ as in Lemma 4.6.

Let Γ be an analytic arc. Then we could define the spaces $\mathfrak{C}^j_\beta(\Gamma)$ and $\mathfrak{B}^j_\beta(\Gamma)$ with respect to the length instead as we did in § 2 by using a specific mapping. These two definitions are then equivalent by Lemma 4.6 and Remark 4.1.

LEMMA 4.7. *Let $M(x)$, $x\in\mathbb{R}^2$, $M(x)=(M_1(x), M_2(x))$ be a one-to-one mapping of $\bar\Omega$ onto $\bar{\tilde\Omega}$ and $|J^{-1}|\leqq\mu$ on $\bar\Omega$, where J is the Jacobian of the mapping. Assume that $M(x)$ can be analytically extended on $\bar\Omega_\delta=\{x\in\mathbb{R}^2 \mid \operatorname{dist}(x,\Omega)\leqq\delta\}$ so that it is a one-to-one mapping of $\bar\Omega_\delta$ onto $\bar\Omega^*$, $\Omega^*\supset\bar\Omega$. Let $u\in\mathfrak{C}^j_\beta(\Omega)$, $j=1,2$, $v(M(x))=u(x)$. Then $v\in\mathfrak{C}^j_\beta(\tilde\Omega)$.*

The proof is analogous to that of Lemma 4.6, however, we must apply the theory of two complex variables.

LEMMA 4.8. *Let $g\in\mathfrak{C}^j_\beta(I)$, $0<\beta<1$, $j=1,2$. Then*

$$g\in\mathfrak{B}^j_{\bar\beta}(I),\qquad 0<\bar\beta<1,$$

$$\bar\beta=\beta+\varepsilon,\quad \varepsilon>0 \quad \textit{arbitrary.}$$

Proof. Let us consider only the case $j=1$. The case $j=2$ is analogous. Because for $k\geqq 1$

$$|g^{(k)}(x)|\leqq Cd^k k!(\hat\Phi_{k+\beta-1/2}(x))^{-1}$$

we get

$$\int_{-1}^{1}(g^{(k)}(x))^2\hat\Phi^2_{k+\bar\beta-1}(x)\,dx\leqq Cd^{2k}(k!)^2\int_{-1}^{1}\hat\Phi^2_{\bar\beta-\beta-1/2}(x)\,dx$$

$$\leqq C(\varepsilon)d^{2k}(k!)^2. \qquad \square$$

We see that Lemma 2.3 has a completely analogous version for the relation between $\mathfrak{B}^2_\beta(I)$ and $\mathfrak{C}^2_\beta(I)$.

THEOREM 4.1. *Let $u\in H^{k+2,2}_\beta(\Omega)$, $k\geqq 0$, and Γ_i be a straight line edge of Ω and $u|_{\Gamma_i}=g_i$. Then we have the following*:

(i) *For $\frac12<\beta_i,\ \beta_{i+1}<1$ and $k\geqq 0$*

$$g_i\in H^{k+1,1}_{\hat\beta_i}(\Gamma_i),\qquad \hat\beta_i=(\hat\beta_{i,1},\hat\beta_{i,2}),$$

$$\hat\beta_{i,j}>0,\quad \hat\beta_{i,j}\in(\beta_{i+j-1}-\tfrac12,1),\quad j=1,2$$

and

$$\|g_i\|_{H^{k+1,1}_{\hat\beta_i}(\Gamma_i)}\leqq Cd^k\|u\|_{H^{k+2,2}_\beta(\Omega)}$$

with C independent of k and $d\geqq 1$.

(ii) *For $0<\beta_i,\ \beta_{i+1}<\frac12$, $k\geqq 1$*

$$g_i\in H^1(\Gamma_i),$$

$$g_i\in H^{k+1,2}_{\hat\beta_i}(\Gamma_i),\quad \hat\beta_{i,j}\in(\beta_{i+j-1}+\tfrac12,1),\quad j=1,2,$$

$$\|g_i\|_{H^1(\Gamma_i)}\leqq C\|u\|_{H^{2,2}_\beta(\Omega)},$$

$$\|g_i\|_{H^{k+1,2}_{\hat\beta_i}(\Gamma_i)}\leqq Cd^k\|u\|_{H^{k+2,2}_\beta(\Omega)}.$$

(iii) *If $u\in\mathfrak{B}^2_\beta(\Omega)$ and $\frac12<\beta_i,\ \beta_{i+1}<1$, then $g_i\in\mathfrak{B}^1_{\hat\beta_i}(\Gamma_i)$, $\hat\beta_{i,j}\in(\beta_{i+j-1}-\frac12,\frac12)$, $j=1,2$. If $0<\beta_i,\ \beta_{i+1}<\frac12$, then $g_i\in\mathfrak{B}^2_{\hat\beta_i}(\Gamma_i)$, $\hat\beta_{i,j}\in(\beta_{i+j-1}+\frac12,1)$.*

Proof. Without any loss of generality we can assume that $\Gamma_i = \Gamma_1$ and

$$\Gamma_1 = \{x_1, x_2 | x_1 \in I, x_2 = 0\}, \quad A_1 = (-1, 0), \quad A_2 = (1, 0), \quad \tilde{\beta} = (\beta_1, \beta_2).$$

Let $k \geqq 0$ and $v_k = (\partial^k u / \partial x_1^k)\Phi_{k+\beta}$. Then for $k \geqq 2$,

$$\begin{aligned}\|v_k\|_{H^2(\Omega)} &\leqq C\left[\left\|\left(D^2 \frac{\partial^k u}{\partial x_1^k}\right)\Phi_{k+\beta}\right\|_{L_2(\Omega)} + k\left\|\left(D^1 \frac{\partial^k u}{\partial x_1^k}\right)\Phi_{k+\beta-1}\right\|_{L_2(\Omega)}\right. \\ &\quad \left. + k^2\left\|\left(\frac{\partial^k u}{\partial x_1^k}\right)\Phi_{k+\beta-2}\right\|_{L_2(\Omega)}\right] \\ &\leqq Ck^2\|u\|_{H_\beta^{k+2,2}(\Omega)}.\end{aligned}$$

Using Lemma 2.2, we get for $k = 1$

$$|v_1|_{H^2(\Omega)} \leqq C\|u\|_{H_\beta^{3,2}(\Omega)}.$$

Because of Lemma 2.1 $u \in C^0(\bar{\Omega})$, and hence $v_0(A_i) = 0$, $i = 1, 2$. Hence, using Lemma 2.2, we get

$$|v_0|_{H^2(\Omega)} \leqq C\|u\|_{H_\beta^{2,2}(\Omega)},$$

and hence for all $k \geqq 0$

$$\|v_k\|_{H^2(\Omega)} \leqq C(k+1)^2\|u\|_{H_\beta^{k+2,2}(\Omega)} \tag{4.3}$$

where C is independent of k. Therefore by the imbedding theorem

$$v_k \in C^0(\bar{\Omega}), \qquad k \geqq 1.$$

Let us now show that $v_k(A_i) = 0$, $i = 1, 2$, $k \geqq 1$. Assume on the contrary that $v_k^2(A_1) > 0$. Then because $v_k \in C^0(\bar{\Omega})$ we have

$$v_k^2(x) > \varepsilon > 0 \quad \text{for } |x - A_1| < \delta, \quad \delta > 0.$$

Hence for $k \geqq 2$

$$\begin{aligned}\infty > \int_\Omega \Phi_{k+\beta-2}^2 \left(\frac{\partial^k u}{\partial x_1^k}\right)^2 dx &= \int_\Omega \Phi_{-2}^2 v_k^2 \, dx \\ &\geqq \varepsilon^2 \int_{\Omega_\delta'} \Phi_{-2}^2 \, dx = \infty\end{aligned}$$

where

$$\Omega_\delta' = \Omega \cap \{x \,|\, |x - A_1| < \delta\}$$

and we have the desired contradiction. For $k = 1$ we use Lemma 2.2 and get

$$\infty > \int_\Omega \left(\frac{\partial u}{\partial x_1}\right)^2 \Phi_{\beta-1}^2 \, dx > \varepsilon^2 \int_{\Omega_\delta'} \Phi_{-2}^2 \, dx = \infty.$$

If $u \in \mathfrak{B}_\beta^2(\Omega)$ then we get from (4.3) for $k \geqq 0$

$$\|v_k\|_{H^2(\Omega)} \leqq Cd_1^k k!.$$

We have $g_1^{(k)}(x_1) = \partial^k u / \partial x_1^k|_{\Gamma_1}$, $k \geqq 0$. Then $g_1^{(k)}(x_1) = \Phi_{k+\beta}^{-1}(x)v_k(x)|_{\Gamma_1} = \Phi_{k+\beta}^{-1}(x_1)v_k(x_1)$ where we wrote $\Phi_{k+\beta}^{-1}(x_1)$ and $v_k(x_1)$ instead of $\Phi_{k+\beta}^{-1}(x_1, 0)$ and $v_k(x_1, 0)$. Assume first that $\frac{1}{2} < \beta_1, \beta_2 < 1$. Let $d_0 = \{\min_{j=3,\cdots,M} \operatorname{dist}(A_j, \Gamma_1)\}^{M-2}$. Then we have for $x \in \Gamma_1$, $\hat{\Phi}(x_1) \leqq \Phi(x_1)d_0^{-1}$, and hence for $j = 1, 2, \cdots, k+1$,

$$\begin{aligned}\int_{\Gamma_1} \hat{\Phi}_{j-1+\hat{\beta}_1}^2 |g_1^{(j)}(x_1)|^2 \, dx_1 &\leqq Cj^2\left\{\int_{-1}^1 \hat{\Phi}_{j-1+\hat{\beta}_1}^2 [|v_{j-1}'|^2 \Phi_{\beta+j-1}^{-2} + \Phi_{j+\beta}^{-2}|v_{j-1}|^2] \, dx_1\right\} \\ &\leqq Cd_0^{-2j}j^2\left\{\int_{-1}^1 [|v_{j-1}'|^2 \hat{\Phi}_{\hat{\beta}_1-\tilde{\beta}}^2 + |v_{j-1}|^2 \hat{\Phi}_{-1+\hat{\beta}_1-\tilde{\beta}}^2] \, dx_1\right\}.\end{aligned}$$

Using Lemma 2.5, the fact that $j=1,\cdots,k+1$, $v_{j-1}(A_i)=0$, $i=1,2$ and that $\tilde{\beta}-\hat{\beta}_1+1>\frac{1}{2}$, we get for some $d_1<1$

$$\int_{\Gamma_1}\hat{\Phi}^2_{j-1+\hat{\beta}}|g_1^{(j)}(x_1)|^2\,dx_1\leqq Cd_1^{-2j}\int_{-1}^{1}|v'_{j-1}|^2\hat{\Phi}^2_{\hat{\beta}_1-\tilde{\beta}}\,dx_1.$$

By (4.3) and the imbedding theorem we have for $1<p<\infty$ and $j=1,\cdots,k+1$

$$\|v'_{j-1}\|_{L_p(I)}\leqq C(p)\|v_{j-1}\|_{H^2(\Omega)}\leqq Cj^2\|u\|_{H^{j+1,2}_{\beta}(\Omega)}.$$

Hence for $j=1,\cdots,k+1$, because $\hat{\beta}_1-\tilde{\beta}>-\frac{1}{2}$, we get

$$\begin{aligned}\int_{-1}^{1}\hat{\Phi}^2_{j-1+\hat{\beta}_1}|g^{(j)}(x_1)|^2\,dx&\leqq Cd_1^{-2k}\left(\int_{-1}^{1}(\Phi^2_{\hat{\beta}_1-\tilde{\beta}})^p\,dx\right)^{1/p}\|v'_{j-1}\|^2_{L_{2q}(I)}\\&\leqq Cd_1^{-2k}\|v_{j-1}\|^2_{H^2(\Omega)}\\&\leqq Cd_2^{-2k}\|u\|^2_{H^{k+2,2}_{\beta}(\Omega)}.\end{aligned}$$

Because by Lemma 2.1

$$\|u\|_{C^0(\bar{\Omega})}\leqq C\|u\|_{H^{2,2}_{\tilde{\beta}}(\Omega)},$$

we get

$$\|g\|_{L_2(\Gamma_1)}\leqq C\|u\|_{H^{2,2}_{\tilde{\beta}}(\Omega)}.$$

Hence we have proven (i) and (iii) for $\frac{1}{2}<\beta_i,\beta_{i+1}<1$ and $k\geqq 0$. Assume now that $0<\beta_1,\beta_2<\frac{1}{2}$. We will proceed analogously as before. For $j\geqq 2$, we have

$$\begin{aligned}\int_{\Gamma_1}\hat{\Phi}^2_{j-2+\hat{\beta}_1}|g^{(j)}(x_1)|^2\,dx_1&\leqq Cj^2\int_{-1}^{1}\hat{\Phi}^2_{j-2+\hat{\beta}_1}[|v'_{j-1}|^2\Phi^{-2}_{\beta+j-1}+\Phi^{-2}_{j+\beta}|v_{j-1}|^2]\,dx_1\\&\leqq Cd_1^{-2j}\int_{-1}^{1}\hat{\Phi}^2_{-1+\hat{\beta}_1-\tilde{\beta}}(v'_{j-1}(x_1))^2\,dx_1\end{aligned}$$

where we once used Lemma 2.5 and the fact that $-1+\hat{\beta}_1-\tilde{\beta}>-\frac{1}{2}$. Hence, using (4.3) and realizing that $-1+\hat{\beta}_1-\tilde{\beta}>-\frac{1}{2}$, we get analogously as before for $j=2,\cdots,k+1$

$$\int_{\Gamma_1}\hat{\Phi}^2_{j-2+\hat{\beta}_1}|g^{(j)}(x_1)|^2\,dx_1\leqq Cd_2^{2k}\|u\|^2_{H_2^{k+2,2}(\Omega)}.$$

Let us prove now that

$$\|g\|_{H^1(\Gamma_i)}\leqq C\|u\|_{H^{k+2,2}_{\beta}(\Omega)},\qquad k\geqq 1.$$

We have $v_0(A_1)=v_0(A_2)=0$, and hence

$$\int_{-1}^{1}g'^2\,dx\leqq Cd_0^{-2}\int_{-1}^{1}[\hat{\Phi}^{-2}_{\tilde{\beta}}|v'_0|^2+|v_0|^2\hat{\Phi}^{-2}_{\tilde{\beta}+1}]\,dx\leqq\tilde{C}d_0^{-2}\int_{-1}^{1}\hat{\Phi}^{-2}_{\tilde{\beta}}|v'_0|^2\,dx$$

where we have again used Lemma 2.5. Because $0<\tilde{\beta}<\frac{1}{2}$ and

$$\|v'_0\|_{L_p(I)}\leqq C(p)\|v_0\|_{H^2(\Omega)}\leqq C\|u\|_{H^{2,2}_{\tilde{\beta}}(\Omega)},$$

we proceed as before and (ii) and (iii) follow easily. □

Remark 4.2. In the proof of Theorem 4.1 it has been assumed that $\hat{\beta}_{i,j}\in(\beta_{i+j-1}-\frac{1}{2},1)$, respectively, $\hat{\beta}_{i,j}\in(\beta_{i+j-1}+\frac{1}{2},1)$, i.e., of the open interval. The proof does not hold for the closed interval. It has been assumed in Lemma 4.9 that the edge Γ_i of the domain was straight. Let us now assume that $\Gamma_i=m(\bar{I})$ where $m=(\varphi,\psi)$ are analytic functions on I as given in § 2. Then we have Lemma 4.9.

LEMMA 4.9. *Let the edge Γ_i of the domain be analytic. Then part* (iii) *of Theorem* 4.1 *holds.*

Proof. By Lemma 2.3, $u \in \mathfrak{C}^2_\beta(\Omega)$. Let $M(\xi) = (\varphi(\xi), \psi(\xi))$, $\xi \in I$, be the mapping of I onto Γ_1. Then we define

$$M_1(\xi, \eta) = \varphi(\xi) - \eta\psi'(\xi), \qquad M_2(\xi, \eta) = \psi(\xi) + \xi\varphi'(\xi).$$

Then the mapping $M(\xi, \eta) = (M_1(\xi, \eta), M_2(\xi, \eta))$ is analytic on $I_\delta = \{\xi, \eta \,|\, -1-\delta < \xi < 1+\delta, |\eta| < \delta\}$, $\delta > 0$, $|J| < \alpha$, $|J^{-1}| < \alpha$ on I_δ (where J is the Jacobian of the mapping) and maps I_δ onto the (open) neighborhood S^* of Γ_i. Denoting $\Omega^* = \Omega \cap S^*$, $T = M^{-1}(\Omega^*)$, we see that $v(x) = u(M^{-1}(x))$ is defined on T, and $v \in \mathfrak{C}^2_\beta(T)$ by using Lemma 4.7. Hence $v \in \mathfrak{B}^2_{\beta+\varepsilon}(T)$, $\varepsilon > 0$ arbitrary, by Lemma 2.3. Hence for $\frac{1}{2} < \beta_i, \beta_{i+1} < 1$ we get by Theorem 4.1(iii)

$$g_i(\xi) = v(\xi, 0) \in \mathfrak{B}^1_{\hat\beta_i}(I_i), \quad \hat\beta_{i,j} \in (\beta_{i+j-1} + \varepsilon - \tfrac{1}{2}, \tfrac{1}{2}), \quad j = 1, 2.$$

Because $\varepsilon > 0$ is arbitrary, $\hat\beta_{i,j} \in (\beta_{i+j-1} - \frac{1}{2}, \frac{1}{2})$. Analogously for $0 < \beta_i, \beta_{i+1} < \frac{1}{2}$, $g_i(\xi) \in \mathfrak{B}^2_{\hat\beta_i}(I)$, $\hat\beta_{i,j} \in (\beta_{i+j-1} + \frac{1}{2}, 1)$. □

LEMMA 4.10. *Let $g_1 \in \mathfrak{B}^1_\beta(I)$, $0 < \hat\beta_1 < \frac{1}{2}$, $0 < \hat\beta_2 < 1$, $g_2 \in \mathfrak{B}^2_{\hat\beta}(I)$, $\frac{1}{2} < \hat\beta_1 < 1$, $0 < \hat\beta_2 < 1$. Let $S = \{r, \theta \,|\, 0 < \theta < 2\pi, 0 < r < 1\}$ where (r, θ) are polar coordinates with respect to $(-1, 0)$ and $\Phi(r) = r$. Define*

$$U_i(r, \theta) = g_i(-1 + r), \qquad V_i(r, \theta) = \theta[g_i(-1 + r) - g_i(-1)]$$

(by Theorems 3.1, 3.2, *$g_i \in C^0(\bar I)$, $i = 1, 2$, and hence $g_i(-1)$ is well defined). Then*

$$U_1, V_1 \in \mathfrak{B}^2_\beta(S), \qquad \beta = \hat\beta_1 + \tfrac{1}{2},$$

$$U_2, V_2 \in \mathfrak{B}^2_\beta(S), \qquad \beta = \tilde\beta_1 - \tfrac{1}{2}.$$

Proof. Assume first that $0 < \hat\beta_1 < \frac{1}{2}$ and $g_1 \in \mathfrak{B}^1_\beta(I)$. Set $\beta = \hat\beta_1 + \frac{1}{2}$ and $U_1 = g_1(-1 + r)$. Then for $k \geqq 2$

$$\int_S \left(\frac{\partial^k U_1}{\partial r^k}\right)^2 (r^{k-2+\beta})^2 \, r \, dr \, d\theta \leqq Cd^{2k} \|g_1^{(k)} \hat\Phi_{k-1+\hat\beta}\|^2_{L_2(I)}$$

$$\leqq Cd_1^{2k}(k!)^2.$$

Hence by Theorem 1.1 of [4] we have for $k \geqq 2$, $|\alpha| = k$

$$\| |D^\alpha U_1| \phi_{\beta+k-2} \|_{L_2(S)} \leqq Cd_2^k k! \, .$$

Furthermore,

$$\| U_1 \|_{H^1(S)} \leqq C \| g_1^{(1)} \Phi_{1/2} \|_{L_2(I)}$$

$$\leqq C \| g_1^{(1)} \hat\Phi_{\hat\beta_1} \|_{L_2(I)}.$$

Hence, $U_1 \in \mathfrak{B}^2_\beta(S)$. Now let $\frac{1}{2} < \tilde\beta_1 < 1$. Set $\beta = \tilde\beta_1 - \frac{1}{2}$. As before, we have for $k \geqq 2$

$$\int_S \left(\frac{\partial^k U_2}{\partial r^k}\right)^2 (r^{k-2+\beta})^2 r \, dr \, d\theta \leqq Cd_1^{2k}(k!)^2$$

and we get $\| U_2 \|_{H^1(S)} < \infty$. Hence, $U_2 \in \mathfrak{B}^2_\beta(S)$. Let us now consider the function $V_1(r, \theta)$. Then as before

$$\int_S \left(\frac{\partial^k V_1}{\partial r^k}\right)^2 (r^{k-2+\beta})^2 r \, dr \, d\theta \leqq Cd_1^{2k}(k!)^2.$$

Furthermore, using Lemma 2.5 and $k \geqq 2$, we get

$$\begin{aligned}\int_S \left(\frac{\partial^k V_1}{\partial r^{k-1}\,\partial\theta}\right)^2 r^{-2}(r^{k-2+\beta})^2 r\,dr\,d\theta &= \int_S \left(\frac{\partial^{k-1} g_1}{\partial r^{k-1}}\right)^2 r^{-2}(r^{k-2+\beta})^2 r\,dr\,d\theta \\ &\leqq Cd_1^{2k}\|g_1^{(k-1)}\hat{\Phi}_{k-2+\hat{\beta}_1}\|^2_{L_2(I)} \\ &\leqq Cd^{2k}[\|(g_1^{(k-1)} - g_1^{(k-1)}(0))\hat{\Phi}_{k-2+\hat{\beta}_1}\|^2_{L_2(I)} \\ &\qquad + (g_1^{(k-1)}(0))^2\|\hat{\Phi}_{k-2+\hat{\beta}_1}\|^2_{L_2(I)}] \\ &\leqq Cd_2^{2k}[(g_1^{(k-1)}(0))^2 + \|g_1^{(k)}\hat{\Phi}_{k-1+\hat{\beta}_1}\|^2_{L_2(I)}] \\ &\leqq Cd_3^{2k}(k!)^2.\end{aligned}$$

In the last inequality we used the fact that

$$|g^{(k-1)}(0)| \leqq Cd_4^k(k!)$$

and realizing that $\partial^k V_1/(\partial r^{k-j}\,d\theta^j) = 0$ for $k \geqq j \geqq 2$ we have for $|\alpha| = k \geqq 2$

$$\|\,|D^\alpha V_1|\Phi_{\beta+k-2}\|_{L_2(S)} \leqq Cd^k k!\,.$$

Furthermore for $0 < \hat{\beta}_1 < \frac{1}{2}$ and $I^* = (-1, 0)$ we have

$$\begin{aligned}\|V_1\|^2_{H^1(S)} &\leqq C[\|g_1^{(1)}\hat{\Phi}_{1/2}\|^2_{L_2(I^*)} + \|(g_1(x) - g_1(-1))\hat{\Phi}_{-1/2}\|^2_{L_2(I^*)}] \\ &\leqq C[\|g_1^{(1)}\hat{\Phi}_{\hat{\beta}_1}\|^2_{L_2(I^*)} + \|(g_1(x) - g_1(-1))\hat{\Phi}_{-1+\hat{\beta}_1}\|^2_{L_2(I^*)}] \\ &\leqq C[\|g_1^{(1)}\hat{\Phi}_{\hat{\beta}_1}\|^2_{L_2(I^*)} + \|g_1^{(1)}\hat{\Phi}_{\hat{\beta}_1}\|^2_{L_2(I)}] \\ &\leqq C\|g_1\|^2_{H^{1,1}_{\hat{\beta}}(I)}.\end{aligned}$$

In the last inequality we have used once more Lemma 2.5 and the fact that $\hat{\beta}_1 < \frac{1}{2}$. Quite analogously we prove that $V_2 \in \mathfrak{B}^2_\beta(S)$. □

LEMMA 4.11. *Let* $g \in \mathfrak{B}^1_{\hat{\beta}}(I)$, $0 < \hat{\beta} < \frac{1}{2}$, $g(\pm 1) = 0$. *Then for* $0 < \gamma < \frac{1}{2}$, $v = g\hat{\Phi}_{-\gamma} \in \mathfrak{B}^1_{\hat{\beta}+\gamma}(I)$.

Proof. For $k \geqq 1$,

$$\begin{aligned}&\int_{-1}^1 ((v^{(k)})^2\hat{\Phi}^2_{k-1+\hat{\beta}+\gamma})\,dx \\ &\quad\leqq \int_{-1}^1 \left(\sum_{l=0}^k \binom{k}{l} g^{(l)}(\hat{\Phi}_{-\gamma})^{(k-l)}\right)^2 \hat{\Phi}^2_{k-1+\hat{\beta}+\gamma}\,dx \\ &\quad\leqq Cd^{2k}\sum_{l=0}^k \int_{-1}^1 (g^{(l)})^2((k-l)!)^2\hat{\Phi}^2_{-\gamma-(k-l)}\hat{\Phi}^2_{k-1+\hat{\beta}+\gamma}\,dx \\ &\quad\leqq Cd^{2k}\left[\sum_{l=1}^k \int_{-1}^1 (g^{(l)})^2\hat{\Phi}^2_{\hat{\beta}+l-1}((k-l)!)^2\,dx + \int_{-1}^1 (g)^2\hat{\Phi}^2_{\hat{\beta}-1}(k!)^2\,dx\right] \\ &\quad\leqq Cd^{2k}\left[\sum_{l=1}^k \int_{-1}^1 (g^{(l)})^2\hat{\Phi}_{\hat{\beta}+l-1}((k-l)!)^2\,dx + \int_{-1}^1 (g')^2\hat{\Phi}^2_{\hat{\beta}}(k!)^2\,dx\right] \leqq Cd_1^{2k}(k!)^2\end{aligned}$$

where we have used Lemma 2.5 in the above inequality. Furthermore,

$$\int_{-1}^1 v^2\,dx = \int_{-1}^1 g^2\Phi^2_{-\gamma}\,dx \leqq C\|g\|^2_{H^{1,1}_{\hat{\beta}}(I)}$$

by Lemma 4.1. □

LEMMA 4.12. *Let* $g \in \mathfrak{B}^2_{\hat\beta}(I)$, $g(\pm 1)=0, \frac{1}{2}<\hat\beta<1$, $0<\gamma<\frac{1}{2}$, $v=g\hat\Phi_{-\gamma}$. *Then for* $\hat\beta+\gamma>1$, $v\in\mathfrak{B}^1_{\hat\beta+\gamma-1}(I)$ *and for* $\hat\beta+\gamma<1$, $v\in\mathfrak{B}^2_{\hat\beta+\gamma}(I)$.

Proof. (a) Assume first that $\hat\beta+\gamma>1$. Then for $k\geqq 2$

$$\int_{-1}^{1}(v^{(k)})^2\hat\Phi^2_{k+\hat\beta+\gamma-2}\,dx \leqq Cd^{2k}\Bigg[\sum_{l=2}^{k}\int_{-1}^{1}(g^{(l)})^2\hat\Phi^2_{-\gamma-(k-l)+k+\hat\beta+\gamma-2}((k-l)!)^2\,dx + (k!)^2\int_{-1}^{1}g^2\hat\Phi^2_{\hat\beta-2}\,dx+((k-1)!)^2\int_{-1}^{1}g'^2\hat\Phi^2_{\hat\beta-1}\,dx\Bigg]$$

$$\leqq Cd^{2k}\Bigg[\sum_{l=2}^{k}\int_{-1}^{1}(g^{(l)})^2\hat\Phi^2_{\hat\beta+l-2}((k-l)!)^2\,dx + (k!)^2\int_{-1}^{1}g'^2\hat\Phi^2_{\hat\beta-1}\,dx\Bigg].$$

In the last inequality, Lemma 2.5 has been used. Because by the imbedding theorem $|g'(0)|\leqq C\|g\|_{H^{2,2}_{\hat\beta}(I)}$ and using Lemma 2.5 once more yields $\hat\beta-1>-\frac{1}{2}$, we get

$$\int_{-1}^{1}g'^2\hat\Phi^2_{\hat\beta-1}\,dx\leqq C\Bigg[\int_{-1}^{1}g''^2\hat\Phi^2_{\hat\beta}\,dx+|g'(0)|^2\Bigg]\leqq C\|g\|^2_{H^{2,2}_{\hat\beta}(I)}<\infty.$$

Hence,

$$\int_{-1}^{1}(v^{(k)})^2\hat\Phi_{k+\hat\beta+\gamma-2}\,dx\leqq Cd_1^{2k}(k!)^2.$$

Furthermore, as before

$$\int_{-1}^{1}v'^2\hat\Phi^2_{\hat\beta+\gamma-1}\,dx\leqq C\int_{-1}^{1}g'^2\hat\Phi^2_{\hat\beta-1}\,dx\leqq C\|g\|^2_{H^{2,2}_{\hat\beta}(I)}<\infty.$$

Because $g\in C^0(\bar I)$, $v\in L_2(I)$.

(b) Now assume that $\hat\beta+\gamma<1$. Then for $k\geqq 2$ we get exactly as before that

$$\int_{-1}^{1}(v^{(k)})^2\hat\Phi^2_{k+\hat\beta+\gamma-2}\,dx\leqq Cd_1^{2k}(k!)^2.$$

Furthermore,

$$\int_{-1}^{1}v'^2\,dx\leqq C\Bigg[\int_{-1}^{1}g^2\hat\Phi^2_{-\gamma-1}\,dx+\int_{-1}^{1}g'^2\hat\Phi^2_{-\gamma}\,dx\Bigg]$$

$$\leqq C\Bigg[\int_{-1}^{1}g''^2\hat\Phi^2_{-\gamma+1}\,dx+|g'(0)|^2\Bigg].$$

Because $-\gamma+1>\hat\beta$ by our assumption we see that

$$\int_{-1}^{1}v'^2\,dx\leqq C\|g\|^2_{H^{2,2}_{\hat\beta}(I)}.$$

Using Lemma 4.2, we also get $\|v\|_{L_2(I)}\leqq C\|g\|_{H^{2,2}_{\hat\beta}(I)}$. □

LEMMA 4.13. *Let* Ω *be a curvilinear polygon with the vertices* A_i, $i=1,\cdots,M$. *Let* $u\in\mathfrak{B}^2_\beta(\Omega)$ *and* w *be such that*

$$|D^\alpha w|\leqq C\Phi_{-|\alpha|+\gamma}|\alpha|!d^{|\alpha|},$$

$$\gamma=(\gamma_1,\cdots,\gamma_M),\quad |\alpha|\geqq 0,\quad \beta_i-\gamma_i>0,\quad \gamma_i\geqq 0.$$

Then $v=wu\in\mathfrak{B}^2_{\bar\beta}(\Omega)$ *where* $\bar\beta_i=\beta_i-\gamma_i$.

Proof. For $k \geqq 2$, $|\alpha| = k$, we have

$$\int_\Omega |D^{|\alpha|}v|^2 \Phi^2_{|\alpha|-2+\bar\beta}\, dx \leqq Cd^{2k}\left(\sum_{l=0}^{k}\int_\Omega |D^{k-l}u||D^l w|\right)^2 \Phi^2_{k-2+\bar\beta}\, dx$$

$$\leqq Cd_1^{2k}\sum_{l=0}^{k}((l+1)!)^2\int_\Omega |D^{k-l}u|^2\Phi^2_{k-2-l+\beta}\, dx$$

$$\leqq Cd_1^{2k}\sum_{l=0}^{k}((l+1)!)^2((k-1+l)!)^2 \leqq Cd_2^{2k-2}((k-2)!)^2.$$

Furthermore,

$$\int_\Omega |D^1 v|^2\, dx \leqq C\left[\int_\Omega |D^1 u|^2|w|^2\, dx + \int_\Omega |u|^2|D^1 w|^2\, dx\right] < \infty$$

because by Lemma 2.1 $u \in C^0(\bar\Omega)$. □

It is very easy to prove the following lemma.

LEMMA 4.14. *Let* $g \in \mathfrak{B}^0_{\hat\beta}(I)$, $0 < \hat\beta < \frac{1}{2}$. *Then* $v = g\hat\Phi \in \mathfrak{B}^1_{\hat\beta}(I)$ *and* $v(\pm 1) = 0$. *Let* $g \in \mathfrak{B}^1_{\hat\beta}(I)$, $\frac{1}{2} < \hat\beta < 1$; *then* $v = g\hat\Phi \in \mathfrak{B}^2_{\hat\beta}(I)$ *and* $v(\pm 1) = 0$.

Proof. The statement that $v \in \mathfrak{B}^1_{\hat\beta}(I)$ can be directly verified. By Lemma 4.1 v is continuous on $\bar I$. If $v(-1) \neq 0$, then $v^2(x) > \varepsilon > 0$ for all $|x+1| < \delta$. Hence, $g^2 = (v\hat\Phi^{-1})^2 \geqq \varepsilon\hat\Phi^2_{-1}$, which contradicts the assumption that $g \in \mathfrak{B}^0_{\hat\beta}(I)$, $0 < \hat\beta < \frac{1}{2}$. The proof of the second part of the lemma is analogous. □

LEMMA 4.15. *Let* $u \in \mathfrak{B}^2_\beta(\Omega)$, $0 < \beta < 1$ *and* $u = 0$ *at* A_i. *Then* $u\Phi^{-1} \in \mathfrak{B}^1_\beta(\Omega)$.

The proof follows easily using Lemma 2.2.

THEOREM 4.2. *Let* Ω *be a straight polygon with the edges* Γ_i, $i = 1, \cdots, M$, *and let* $g \in \mathfrak{B}^1_{\hat\beta}(\Gamma_1)$, $0 < \hat\beta_i < \frac{1}{2}$, $\beta_i = \hat\beta_i + \frac{1}{2}$, $i = 1, 2$ (*respectively,* $g \in \mathfrak{B}^2_{\hat\beta}(\Gamma_1)$, $\frac{1}{2} < \hat\beta_i < 1$, $\beta_i = \hat\beta_i - \frac{1}{2}$, $i = 1, 2$) *and* $g(A_i) = 0$, $i = 1, 2$. *Then there is* u *such that*

(i) $u \in \mathfrak{B}^2_\beta(\Omega)$, *with* $0 < \beta_j < 1$, $j = 3, \cdots, M$, *arbitrary*;

(ii) $u|_{\Gamma_1} = g$ *and* $u|_{\Gamma_j} = 0$ *for* $j = 2, \cdots, M$.

Proof. Let $\psi = \prod_{i=3}^{M}|x - A_i|^2$, $x \in \Omega$. Denote $\tilde g = g/\psi$. Then obviously $\tilde g \in \mathfrak{B}^1_{\hat\beta}(\Gamma_1)$ (respectively, $\tilde g \in \mathfrak{B}^2_{\hat\beta}(\Gamma_1)$). Now select $0 < \gamma_i < \frac{1}{2}$ such that $0 < \hat\beta + \gamma_i < \frac{1}{2}$ (respectively, $0 < \hat\beta + \gamma_i - 1 < \frac{1}{2}$). Denote $\hat g = \tilde g \prod_{i=1}^{2}|x - A_i|^{-\gamma_i} = \tilde g\Phi_{-\gamma}$ where $\gamma = (\gamma_1, \gamma_2, 0, \cdots, 0)$. By Lemmas 4.1 and 4.2 $\hat g(A_i) = 0$, $i = 1, 2$. Using Lemma 4.11 (and 4.12) we see that $\hat g \in \mathfrak{B}^1_{\hat\beta+\gamma}(I)$ (respectively, $\hat g \in \mathfrak{B}^1_{\hat\beta+\gamma-1}(I)$).

Let $U \in H^1(\Omega)$, $\Delta U = 0$ and $U = \hat g$ on Γ_1 and $U = 0$ on Γ_j, $j = 2, \cdots, M$. Function U exists and is uniquely determined. To see this consider $\varphi(x)$, $x \in \Gamma_1$, $\varphi \in C^\infty(\Gamma_1)$, $\varphi(x) = 1$ for $|x - A_i| \leqq \varepsilon/2$, $i = 1, 2$ and $\varphi(x) = 0$ for $|x - A_i| > \varepsilon$, $i = 1, 2$ with ε sufficiently small. We define

$$U = U_1 + U_2$$

where $\Delta U_i = 0$, $U_i \in H^1(\Omega)$, $i = 1, 2$, $U_1|_{\Gamma_1} = \hat g(1 - \varphi)$, $U_2|_{\Gamma_1} = \hat g\varphi$ and $U_i = 0$ on Γ_j, $j = 2, \cdots, M$. Because $h_1 = \hat g(1 - \varphi) \in C^\infty(\Gamma_1)$ and $h_1(x) = 0$ for $|x - A_i| \leqq \varepsilon/2$, U_1 obviously exists.

By Lemma 4.10 there exists $W \in H^1(\Omega)$ such that $W|_{\Gamma_1} = h_2 = \hat g\varphi$, and $W|_{\Gamma_j} = 0$, $j = 2, \cdots, M$. Hence, U_2 exists too. Function U has the following properties:

(i) $\Delta U = 0$.

(ii) $U|_{\Gamma_1} = \hat g$, $U|_{\Gamma_j} = 0$, $j = 2, \cdots, M$.

(iii) $\hat g$ is analytic on Γ_1 (not on $\bar\Gamma_1$).

(iv) In $\Omega_{i,\delta} = \Omega \cap \{x \,|\, |x - A_i| < \delta\}$, $i = 1, 2$, with δ sufficiently small, there is W_i such that $W_i \in \mathfrak{B}^2_{\bar\beta}(\Omega_{i,\delta})$, where $\bar\beta = \hat\beta + \gamma + \frac{1}{2}$ (respectively, $\bar\beta = \hat\beta + \gamma - 1 + \frac{1}{2}$) and $W_i|_{\Gamma_i \cap \bar\Omega_{i,\delta}} = \hat g$. (This follows from Lemma 4.10.)

By the selection of γ_i we have $\bar{\beta}_i > \frac{1}{2}$, $i = 1, 2$. Now using the same arguments as in the proof of Theorem 2.1 in [4], we conclude that $U \in \mathfrak{B}^2_{\bar{\beta}}(\Omega)$, where $\bar{\beta}_i = \hat{\beta}_i + \gamma_i + \frac{1}{2}$ (respectively, $\bar{\beta}_i = \hat{\beta}_1 + \gamma_i - \frac{1}{2}$), $i = 1, 2$, and $1 > \bar{\beta}_j > \frac{1}{2}$.

By Lemma 4.13 we see that $u = \psi \Phi_\gamma U \in \mathfrak{B}^2_\beta(\Omega)$ where $\beta_i = \hat{\beta}_i + \frac{1}{2}$ (respectively, $\beta_i = \hat{\beta}_i - \frac{1}{2}$), $i = 1, 2$ and $0 < \beta_j < 1$ arbitrary for $j = 3, \cdots, M$. In addition, $u|_{\Gamma_1} = g$ and $u|_{\Gamma_j} = 0$, $j = 2, \cdots, M$.

Let us outline the main idea of the assertion that $U \in \mathfrak{B}^2_{\bar{\beta}}(\Omega)$. Let $S_{i,\delta_i} = \{r_i, \theta_i | 0 < r_i < \delta_i, 0 < \theta_i < \omega_i\} \cap \Omega$ where (r_i, θ_i) are the polar coordinates with the origin in A_i. We select $\delta_i < 1$ such that $S_{i,2\delta_i} \cap S_{j,2\delta_j} = \varnothing$ for $i \neqq j$. Using Theorems 5.7.1, 5.7.1′, and 6.6.1 of [8], we conclude similarly, as in the proof of Theorem 2.1 of [3], that $U \in \mathfrak{B}^2_{\bar{\beta}}(\Omega - \bigcup_{i=1}^M S_{i,\delta_i/4})$ due to the analyticity of $\hat{g}$ on $\Gamma - \bigcup_{i=1}^M S_{i,\delta_i/4}$. Hence we have to prove only that $U \in \mathfrak{B}^2_{\bar{\beta}}(S_{i,\delta_i/4})$.

Let

$$\varphi_0 \in C^\infty(\mathbb{R}^+),$$

$$\varphi_0(r) = 1 \quad \text{for } 0 \leqq r \leqq \tfrac{1}{2},$$

$$\varphi_0(r) = 0 \quad \text{for } x \geqq 1,$$

$$\varphi_{\delta_i}(r) = \varphi_0(r/2\delta_i) = \varphi(r).$$

Denote $v = \varphi U$. Then v can be understood to be defined on the infinite sector $Q^{(i)}_{w_i} = \{(r_i, \theta_i) | 0 < r_i < \infty, 0 < \theta_i < \omega_i\}$ when extended by zero outside of S_{i,δ_i} and we have $v \in H^1(Q^{(i)}_{\omega_i})$. □

Now we prove that $v \in \mathfrak{B}^2_\beta(S_{i,\delta_i/2})$ as in [3].

Remark 4.3. We have assumed that either $g \in \mathfrak{B}^1_{\hat{\beta}}(\Gamma_1)$, $0 < \hat{\beta} < \frac{1}{2}$ or $g \in \mathfrak{B}^2_{\hat{\beta}}(\Gamma_1)$, $\frac{1}{2} < \hat{\beta} < 1$. Obviously Theorem 4.2 is correct if $g \in \mathfrak{B}^1_{\hat{\beta}}(\Gamma_1)$ only in the neighborhood of A_1 and $g \in \mathfrak{B}^2_{\hat{\beta}}(\Gamma_1)$ in the neighborhood of A_2. Theorem 4.1 leads easily to the next theorem.

THEOREM 4.3. *Let Ω be a straight polygon with the edges Γ_i, $i = 1, \cdots, M$ and let*

$$g \in \mathfrak{B}^1_{\bar{\beta}_i}(\Gamma_i), \quad \hat{\beta}_i = (\hat{\beta}_{i,1}, \hat{\beta}_{i,2}), \quad 0 < \hat{\beta}_{i,1}, \hat{\beta}_{i,2} < \tfrac{1}{2},$$
$$\bar{\beta}_{i,1} = \hat{\beta}_{i,1} + \tfrac{1}{2}, \quad \bar{\beta}_{i,2} = \hat{\beta}_{i,2} + \tfrac{1}{2}, \quad i \in Q \subset \{1, \cdots, M\}$$

or

$$g \in \mathfrak{B}^2_{\bar{\beta}_i}(\Gamma_i), \quad \hat{\beta}_i = (\hat{\beta}_{i,1}, \hat{\beta}_{i,2}), \quad \tfrac{1}{2} < \hat{\beta}_{i,1}, \hat{\beta}_{i,2} < 1,$$
$$\bar{\beta}_{i,1} = \hat{\beta}_{i,1} - \tfrac{1}{2}, \quad \bar{\beta}_{i,2} = \hat{\beta}_{i,2} - \tfrac{1}{2}, \quad i \in Q \subset \{1, \cdots, M\}.$$

Further, let g be continuous on $\gamma = \bigcup_{i \in Q} \bar{\Gamma}_i$. Then $g \in \mathfrak{B}^{3/2}_{\bar{\beta}}(\gamma)$ where $\bar{\beta}_i = \max(\bar{\beta}_{i-1,2}, \bar{\beta}_{i,1})$, for $A_i \in \gamma$ (if $i - 1 \notin Q$ or $i \notin Q$ then we define $\bar{\beta}_{i-1,2} = 0$, respectively, $\bar{\beta}_{i,1} = 0$) and $0 < \bar{\beta}_i < 1$ arbitrarily for $A_i \notin \gamma$.

Proof. Because g is continuous on γ we can construct a polynomial P on Ω such that $g - P = 0$ at A_i. Then we can apply Theorem 4.2. □

Remark 4.4. It is obvious how the theorem may be modified when $g \in \mathfrak{B}^1_\beta(\Gamma_i)$, respectively, $g \in \mathfrak{B}^2_\beta(\Gamma_i)$ in the neighborhood of A_i only. See also Remark 4.3.

Remark 4.5. Theorems 4.1 and 4.3 are complementary, which is analogous to the theorems of trace and extension in usual Sobolev spaces on smooth domain. Namely, if $g \in \mathfrak{B}^1_{\hat{\beta}_i}(\Gamma_i)$, $0 < \hat{\beta}_{i,j} < \frac{1}{2}$ (respectively, $g \in \mathfrak{B}^2_{\hat{\beta}_i}(\Gamma)$, $\frac{1}{2} < \hat{\beta}_{i,j} < 1$) $j = 1, 2$, then we have an extension by function $G \in \mathfrak{B}^2_\beta(\Omega)$, $\beta_i = \hat{\beta}_{i,1} + \frac{1}{2}$, $\beta_{i+1} = \hat{\beta}_{i,2} + \frac{1}{2}$ (respectively, $\beta_i = \hat{\beta}_{i,1} - \frac{1}{2}$, $\beta_{i+1} = \hat{\beta}_{i,2} - \frac{1}{2}$), and if $G \in \mathfrak{B}^2_\beta(\Omega)$ then $G|_{\Gamma_i} = g \in \mathfrak{B}^1_{\hat{\beta}_i + \varepsilon}(\Gamma_i)$, $\hat{\beta}_{i,1} = \beta_i - \frac{1}{2}$, $\hat{\beta}_{i,2} = \beta_{i+1} - \frac{1}{2}$ for $\frac{1}{2} < \beta_i, \beta_{i+1} < 1$ (respectively, $g \in \mathfrak{B}^2_{\hat{\beta}_i + \varepsilon}(\Gamma_i)$, $\hat{\beta}_{i,1} = \beta_i + \frac{1}{2}$, $\hat{\beta}_{i,2} = \beta_{i+1} + \frac{1}{2}$ for $0 < \beta_i, \beta_{i+1} < \frac{1}{2}$), $\varepsilon > 0$ arbitrary.

THEOREM 4.4. *Let Ω be a straight polygon with the edges Γ_i, $i=1,\cdots,M$, and let $g\in\mathfrak{B}^0_{\hat\beta}(\Gamma_1)$, $0<\hat\beta_i<\frac12$, $i=1,2$, $\beta_i=\hat\beta_i+\frac12$, $i=1,2$ (respectively, $g\in\mathfrak{B}^1_{\hat\beta}(\Gamma_1)$, $\frac12<\hat\beta_i<1$, $\beta_i=\hat\beta_i-\frac12$, $i=1,2$). Then there is u such that we have the following:*

(i) *$u\in\mathfrak{B}^1_\beta(\Omega)$ with $0<\beta_j<1$, $j=3,\cdots,M$ arbitrary.*

(ii) *$u|_{\Gamma_i}=g$ and $u|_{\Gamma_j}=0$, $j=2,\cdots,M$.*

Proof. By Lemma 4.14, $\tilde g=g\hat\Phi\in\mathfrak{B}^1_{\hat\beta}(\Gamma_1)$, respectively, $\mathfrak{B}^2_{\hat\beta}(\Gamma_1)$ and $\tilde g(A_i)=0$, $i=2,3$, and hence by Theorem 4.2 there is $v\in\mathfrak{B}^2_\beta(\Omega)$ such that $v=\tilde g$ on Γ_1 and $v=0$ on Γ_j, $j=2,\cdots,M$. By Lemma 4.15 the function $v\Phi^{-1}$ has the desired properties. □

Theorem 4.4 leads immediately to Theorem 4.5.

THEOREM 4.5. *Let Ω be a straight polygon with the edges Γ_i, $i=1,\cdots,M$, and let*

$$g\in\mathfrak{B}^0_{\hat\beta_i}(\Gamma_i),\quad \hat\beta_i=(\hat\beta_{i,1},\hat\beta_{i,2}),\quad 0<\hat\beta_{i,1},\hat\beta_{i,2}<\tfrac12,$$

$$\bar\beta_{i,1}=\hat\beta_{i,1}+\tfrac12,\quad \bar\beta_{i,2}=\hat\beta_{i,2}+\tfrac12,\quad i\in Q\subset\{1,\cdots,M\}$$

or

$$g\in\mathfrak{B}^1_{\hat\beta_i}(\Gamma_i),\quad \hat\beta_i=(\hat\beta_{i,1},\hat\beta_{i,2}),\quad \tfrac12<\hat\beta_{i,1},\hat\beta_{i,2}<1,$$

$$\bar\beta_{i,1}=\hat\beta_{i,1}-\tfrac12,\quad \bar\beta_{i,2}=\hat\beta_{i,2}-\tfrac12,\quad i\in Q\subset\{1,\cdots,M\}.$$

Let $\gamma=\bigcup_{i\in Q}\bar\Gamma_i$. Then $g\in\mathfrak{B}^{1/2}_\beta(\gamma)$ where $\bar\beta_i=\max(\bar\beta_{i-1,2},\bar\beta_{i,1})$, $A_i\in\gamma$ (if $i-1\notin Q$ or $i\notin Q$ when we define $\hat\beta_{i-1,2}=0$, respectively, $\bar\beta_{i,1}=0$) and $0<\bar\beta_i<1$ arbitrarily for $A_i\notin\gamma$.

Remark 4.6. It is obvious how Theorem 4.4 has to be modified when $g\in\mathfrak{B}^1_{\hat\beta}(\Gamma_i)$, respectively, $g\in\mathfrak{B}^2_{\hat\beta}(\Gamma_i)$ in the neighborhood of A_i only. See Remark 4.3.

Theorems 4.3 and 4.5 give the characterization of the boundary conditions that guarantees that the solution of an elliptic partial differential equation of second order with analytic coefficients on a domain Ω with piecewise analytic boundary belongs to $\mathfrak{B}^2_\beta(\Omega)$ or $\mathfrak{C}^2_\beta(\Omega)$ (see Theorems 3.2 and 3.3).

In the concrete cases these conditions are usually very easy to check. Let us state a useful lemma that characterizes the space $\mathfrak{B}^1_{\hat\beta}(I)$ (respectively, $\mathfrak{B}^2_{\hat\beta}(I)$).

LEMMA 4.16. *Let*

$$\Omega_\alpha=\{z=x+iy\,|\,x\in I,\ |y|\leqq\alpha\hat\Phi(x),\ \alpha>0\}$$

and $G(z)$ be a holomorphic function on Ω_α such that for $\nu=(\nu_1,\nu_2)$

$$|G(z)|\leqq C\hat\Phi_\nu(\operatorname{Re} z).$$

Let $g(x)=\operatorname{Re} G(z)|_I$ or $\operatorname{Im} G(z)|_I$. Then for $\nu_i>-\frac12+(j-1)$, $\hat\beta_i+\nu_i>\frac12+(j-1)$, $0<\hat\beta_i<1$, $i=1,2$, $j=0,1,2$

$$g(x)\in\mathfrak{B}^j_{\hat\beta}(I).$$

Proof. By the Cauchy formula we have for $k>0$

$$|g^{(k)}(x)|\leqq C\hat\Phi_\nu(x)(\hat\Phi(x))^{-k}k!\alpha^{-k}.$$

Hence,

$$\int_{-1}^1\Phi^2_{k-1+\hat\beta}|g^{(k)}(x)|^2\,dx\leqq(Ck!\alpha^{-k})^2\int_{-1}^1\Phi^2_{\nu+\hat\beta-1}\,dx\leqq(C_1d^kk!)^2$$

provided that $\nu_i+\hat\beta_i>\frac12$. Furthermore, for $k=0$

$$|g(x)|\leqq C\Phi_\nu(x),$$

and hence for $\nu_i > -\frac{1}{2}$, $g \in H^0(I)$. The lemma is proved for $j=1$. The proof of the case $j=0$ is analogous. Let us consider now the case $j=2$. We see that for $\nu_i + \hat{\beta}_i > \frac{3}{2}$ and $k \geqq 2$

$$\int_{-1}^{1} \Phi^2_{k-2+\hat{\beta}} |g^{(k)}(x)|^2 \, dx \leqq (Ck!\alpha^{-k})^2 \int_{-1}^{1} \Phi^2_{\nu-k+k-2+\hat{\beta}} \, dx \leqq (C_1 d^k k!)^2.$$

Furthermore, if $\nu_i > \frac{1}{2}$, then also $g \in H^1(I)$. □

Instead of $|G(z)| \leqq C\hat{\Phi}_\nu(\operatorname{Re} z)$ we can assume that $|G(z) - P(z)| \leqq C\hat{\Phi}_\nu(\operatorname{Re} z)$ where $P(z)$ is a polynomial.

Lemma 4.16 is very useful in practice. For example, if g is analytic on $\bar{\Gamma}_i$ then $g(x)$ can be extended into some neighborhood of $\bar{\Gamma}_i$ and therefore $g \in \mathfrak{B}^1_\beta(I)$. Lemma 4.16 characterizes very well the structure of the spaces $\mathfrak{B}^1_\beta(I)$ (respectively, $\mathfrak{B}^2_\beta(I)$).

LEMMA 4.17. *Let $g \in \mathfrak{B}^1_{\hat{\beta}}(I)$, $0 < \hat{\beta}_i < \frac{1}{2}$. Then there exists $\alpha > 0$ such that g can be analytically extended onto Ω_α and*

$$\left| G(z) - g(-1)\frac{(1-x)}{2} - g(1)\frac{(x+1)}{2} \right| \leqq C\hat{\Phi}_{1/2-\hat{\beta}}(\operatorname{Re} x)$$

($g \in C^0(\bar{I})$ by Theorem 3.1).

Proof. Since $g \in \mathfrak{B}^1_{\hat{\beta}}(I)$ we have by Lemma 4.3 for $k \geqq 1$

$$|g^{(k)}(x)| \leqq C(\Phi_{k-1/2+\hat{\beta}}(x))^{-1} d^k k!.$$

Hence the series

$$g'(x) = \sum_{k=0}^{\infty} g^{(k+1)}(x_0)(x-x_0)^k \frac{1}{k!}, \qquad x_0 \in I$$

is absolutely convergent for $|x - x_0| \leqq \frac{1}{2}(\Phi(x_0)/d)$, and hence also

$$G'(z) = \sum_{k=0}^{\infty} g^{(k+1)}(x_0)(z-x_0)^k \frac{1}{k!}$$

converges for $|z - x_0| \leqq \frac{1}{2}(\Phi(x_0)/d)$ and $|G'(z)| \leqq C\hat{\Phi}^{-1}_{\hat{\beta}+1/2}(x_0)$, $x_0 = \operatorname{Re}(z)$, and C is independent of x_0, which yields the lemma. □

So far we have assumed that Ω is a straight polygon. We did not exclude the case where the internal angle is 2π; i.e., we did not exclude the slit domain. Let us now consider the curvilinear polygon and assume that it is a Lipschitzian domain. Let us prove first Lemma 4.18.

LEMMA 4.18. *Let* $\Omega = \{x_1, x_2 | -1 < x_1 < 1, 0 < x_2 < h(x_1), h(x_1) > \alpha(x_1+1), h(-1) = 0, \alpha > 0\}$. *Assume that $\psi(x_1, x_2)$ is an analytic function on* $S = \{x_1, x_2 | (x_1+1)^2 + x_2^2 \leqq 4\}$ *such that we have the following*:

(i) $\psi(x_1, h(x_1)) = 0$;

(ii) $\partial\psi/\partial x_1(x_1, 0) > \alpha > 0$, $-1 \leqq x_1 \leqq 1$.

Define

$$\Gamma_1 = \{x_1, x_2 | -1 < x_1 < 1, x_2 = 0\},$$

$$\Gamma_2 = \{x_1, x_2 | -1 < x_1 < 1, x_2 = h(x_1)\},$$

and let $T = \Omega \cap S_1$ where $S_1 = \{r, \theta | 0 < \theta < 2\pi, 0 < r < 1\}$ where (r, θ) are polar coordinates with respect to $(-1, 0)$ and $T^* = S_1 - T$. Let $g_1 \in \mathfrak{B}^1_{\hat{\beta}}(\Gamma_1)$, $0 < \hat{\beta}_i < \frac{1}{2}$, $\hat{\beta}_1 = \hat{\beta}_2$ (respectively, $g_2 = \mathfrak{B}^2_{\hat{\beta}}(\Gamma_1)$, $\frac{1}{2} < \hat{\beta}_i < 1$, $\hat{\beta}_1 = \hat{\beta}_2$), $g_i(-1) = 0$, $i = 1, 2$ and $\Phi = r$.

Then there exists

$$V_1 \in \mathfrak{B}^2_{\bar{\beta}}(T), \quad V_1^* \in \mathfrak{B}^2_{\bar{\beta}}(T^*), \quad \bar{\beta} = \hat{\beta} + \tfrac{1}{2}$$

(respectively, $V_2 \in \mathfrak{B}^2_{\bar\beta}(T)$, $V_2^* \in \mathfrak{B}^2_{\bar\beta}(T^*)$, $\bar\beta = \hat\beta - \frac{1}{2}$*) such that* $V_i = g_i$ *and* $V_i^* = g_i$ *on* $\Gamma_1 \cap \bar T$ *and* V_i, $V_i^* = 0$ *on* $\Gamma_2 \cap \bar T$.

Proof. Let $\varphi(r, \theta) = \psi(r, \theta)/r$. Then $\varphi(r, 0) = \varphi(x_1)$ is analytic on $\bar\Gamma_1$ and $\varphi(x_1) > \bar\alpha > 0$; hence $\varphi^{-1}(x_1)$ is analytic on $\bar\Gamma_1$ too. In addition, $\varphi = 0$ on Γ_2. Furthermore, $|D^\alpha \varphi(x_1, x_2)| \leqq C|\alpha|!\Phi^{-|\alpha|} d^{|\alpha|}$ by Cauchy's theorem on the theory of two complex variables. Define $\tilde g_1 = g_1 \varphi^{-1}(x_1)$. Then $\tilde g_1 \in \mathfrak{B}^1_{\hat\beta}(\Gamma_1)$ and by Lemma 4.11 there exists U_1 on S_1 such that $U_1 \in \mathfrak{B}^2_{\bar\beta}(S_1)$, $\bar\beta = \hat\beta + \frac{1}{2}$ and $U_1|_{\Gamma_1} = \tilde g_1$. Now define $V_1 = U_1 \varphi$. Using Lemma 4.13, we conclude that $V_1 \in \mathfrak{B}^2_{\bar\beta}(T)$ (respectively, $\mathfrak{B}^2_{\bar\beta}(T^*)$), $V_1|_{\Gamma_1} = g_1$ and $V_1|_{\Gamma_2} = 0$. The proof that V_2 has desired properties is analogous. □

LEMMA 4.19. *Let* $\Omega = \{x_1, x_2 | -1 < x_1 < 1, h_1(x_1) < x_2 < h_2(x_1), h_1(x_1) < -\alpha(x_1 + 1), h_2(x_1) > \alpha(x_1 + 1), \alpha > 0, h_i(-1) = 0, h_i(x_1)$ *analytic functions on* $\bar I, i = 1, 2\}$ *and*

$$\Gamma_i = \{x_1, x_2 | -1 < x_1 < 1, x_2 = h_i(x_1)\},$$

$$\Omega_\eta = \Omega \cap S_\eta, \quad S_\eta = \{r, \theta | 0 < \theta \leqq 2\pi, 0 < r < \eta, \eta > 0\}, \quad \Omega_\eta^* = S_\eta - \Omega_\eta,$$

where (r, θ) *are polar coordinates with the origin at* $(-1, 0)$. *Let* $g_1 \in \mathfrak{B}^1_{\hat\beta}(\Gamma_1)$, $0 < \hat\beta < \frac{1}{2}$ *(respectively,* $g_2 \in \mathfrak{B}^2_{\hat\beta}(\Gamma_1)$, $\frac{1}{2} < \hat\beta_i < 1$*),* $\beta_1 = \beta_2$, $g_i(-1) = 0$ *and let* $\Phi = r$. *Then there exist* $\eta > 0$ *and* $V_1 \in \mathfrak{B}^2_{\bar\beta}(\Omega_\eta)$, $V_1^* \in \mathfrak{B}^2_{\bar\beta}(\Omega_\eta^*)$, $\bar\beta = \hat\beta + \frac{1}{2} + \varepsilon$, $\varepsilon > 0$ *arbitrary (respectively,* $V_2 \in \mathfrak{B}^2_{\bar\beta}(\Omega_\eta)$, $V_2 \in \mathfrak{B}^2_{\bar\beta}(\Omega_\eta^*)$, $\bar\beta = \hat\beta - \frac{1}{2} + \varepsilon$*) such that* $V_i|_{\Gamma_1 \cap \bar\Omega_\eta} = g_i$ *and* $V_i|_{\Gamma_2 \cap \bar\Omega_\eta} = 0$.

Proof. Because $h_1(x_1)$ is analytic on $\bar I$ it can be analytically extended onto $\tilde I_\delta = \{-1 - \delta < x_1 < 1 + \delta\}$. Then the mapping $M: (x_1, x_2) \to (y_1, y_2)$, $y_1 = x_1$, $y_2 = x_2 - h_1(x_1)$ is analytic on Ω_η, $\eta = \delta/2$ and $M(\Omega_\eta) = \tilde\Omega_\eta$. For η_1 sufficiently small we have $\partial\tilde\Omega_\eta \cap S_{\eta_1} = \Gamma_1^* \cup \Gamma_2^*$ where

$$\Gamma_1^* = \{y_1, y_2 | -1 < y_1 < -1 + \eta, y_2 = 0\},$$

$$\Gamma_2^* = \{y_1, y_2 | -1 < y_1 < -1 + \bar\eta_1, y_2 = h_2^*(y_1) = h_2(y_1) - h_1(y_1)\},$$

and $h_2(y_1) > \alpha_1(y_1 + 1)$. In addition, it is easy to see that $|J|$, $|J^{-1}| < \mu < \alpha$, where J is the Jacobian of the mapping M. Because $h_2^*(y_1)$ is analytic on $-1 \leqq y_1 \leqq -1 + \bar\eta_1$ we define $\psi(y_1, y_2) = -y_2 + h_2^*(y_1)$ and $\psi(y_1, y_2)$ has the properties in Lemma 4.18. Now using Corollaries 4.4, 4.5, $g_1 \in \mathfrak{C}^1_{\hat\beta}(\Gamma_1)$, $g_2 \in \mathfrak{C}^2_{\hat\beta}(\Gamma_1)$, and hence using Lemma 4.6, $g_1(M^{-1}(y))|_{y_2=0} \in \mathfrak{C}^1_{\hat\beta}(\Gamma_1^*)$, $g_2(M^{-1}(y))|_{y_2=0} \in \mathfrak{C}^2_{\hat\beta}(\Gamma_1^*)$. Using Lemmas 4.8 and 4.18, we obtain functions V_1 and V_1^* (respectively, V_2 and V_2^*) on $\tilde\Omega_\eta \cap S_{\eta_2}$ (respectively, $\tilde\Omega_\eta^* \cap S_{\eta_2}$), which belong to $\mathfrak{B}^2_{\bar\beta+\varepsilon/2}(\Omega_\eta \cap S_{\eta_2})$ (respectively, $\mathfrak{B}^2_{\bar\beta+\varepsilon/2}(\tilde\Omega_\eta^* \cap S_{\eta_2})$). Now when we use Lemmas 4.7 and 2.3, our lemma follows. □

The lemma leads to the following theorem.

THEOREM 4.6. *Theorems* 4.3 *and* 4.5 *hold also for a Lipschitzian curvilinear polygon when* $\bar\beta_i$ *are replaced by* $\bar\beta_i + \varepsilon$, $\varepsilon > 0$ *arbitrary.*

Proof. Because the edges are analytic curves and g are analytic on Γ_i (but not on $\bar\Gamma_i$) we show similarly (as in the proof of Theorem 4.1) that the solution u of the Laplace equation belongs to $\mathfrak{B}^2_{\bar\beta+\varepsilon}(\Omega)$. This can be done identically as in the proofs of Theorems 3.3 and 3.4 of [6], showing that $u \in \mathfrak{C}^2_{\bar\beta+\varepsilon}(\Omega)$. □

Remark 4.7. Comparing the respective theorems for straight and curvilinear polygons, we see that in the latter case we lose slightly in the regularity. It is not known whether this loss can be removed.

DECAY ESTIMATES FOR A CLASS OF NONLINEAR BOUNDARY VALUE PROBLEMS IN TWO DIMENSIONS*

C. O. HORGAN† AND L. E. PAYNE‡

Abstract. This paper is concerned with second-order quasilinear partial differential equations in two independent variables of the form $\operatorname{div}[\rho(\mathbf{x}, u, \operatorname{grad} u)\operatorname{grad} u] = 0$. Previous work of the authors, establishing exponential decay estimates for Dirichlet problems on a semi-infinite strip subject to nonzero data on the finite end, is extended to include regions of arbitrary shape, and, in the case of unbounded regions, the a priori assumption that solutions must decay to zero as $|\mathbf{x}| \to \infty$ is removed. The results have application to Saint-Venant principles for nonlinear elasticity as well as to theorems of Phragmén-Lindelöf type.

Key words. second-order quasilinear partial differential equations, two independent variables, decay estimates, Dirichlet problems, Saint-Venant principles, Phragmén-Lindelöf type theorems

AMS(MOS) subject classifications. 35B40, 35J60, 73C10

1. Introduction. In a recent paper [3] the authors derived exponential decay estimates for a certain class of nonlinear boundary-value problems in the plane. Specifically, they treated a class of second-order quasilinear equations (not necessarily elliptic) defined in a semi-infinite strip with nonzero boundary data at the finite end. Assuming boundedness of certain functionals on the strip, the authors derived exponential decay estimates in various norms. In a subsequent paper [4] these results were extended to $\mathbb{R}^3$.

In this paper we remove the requirement that the region be a strip domain (i.e., of constant cross section) and in the case of unbounded regions we eliminate the a priori assumption that solutions must decay to zero uniformly as $|\mathbf{x}| \to \infty$, where $|\mathbf{x}| = (x_1^2 + x_2^2)^{1/2}$.

The spatial decay estimates of concern in [3], [4] and in the present paper are of interest in connection with studies on Saint-Venant's principle in elasticity theory. (See [2] for a review of results on Saint-Venant's principle.) The results may also be viewed as giving rise to theorems of Phragmén-Lindelöf type (see, e.g., the references cited in [3]).

Let Ω be a bounded (or unbounded) simply-connected region with Lipschitz boundary $\partial\Omega$, lying in the half plane $x_2 > 0$, and let $u(x_1, x_2)$ be a classical solution of the equation

$$[\rho(\mathbf{x}, u, \operatorname{grad} u)u_{,j}]_{,j} = 0 \qquad (j = 1, 2) \tag{1.1}$$

in Ω. Here we have adopted the convention of summing over repeated indices and a comma denotes partial differentiation. The boundary $\partial\Omega$ is composed of a small arc Σ on which no data are prescribed and the remainder $\partial\Omega/\Sigma$ on which u is assumed to vanish. When Ω is unbounded it is assumed that no data are prescribed on Σ and that u vanishes on the finite portion of the remainder of $\partial\Omega$. For the moment no a priori assumption is made about the behavior of u as $|\mathbf{x}| \to \infty$ in Ω, where $|\mathbf{x}| = (x_1^2 + x_2^2)^{1/2}$.

Although we assume existence of a classical solution throughout, it will be clear that the same decay results would hold for appropriately defined weak solutions.

Consider then the solution u of (1.1) subject to the condition

$$u = 0 \quad \text{on } \partial\Omega/\Sigma. \tag{1.2}$$

We wish to derive a bound for a suitable norm of the solution that decays as some function of the distance from Σ. The assumptions on the form of ρ are as follows. We have either Case 1 or Case 2 as follows.

Case 1.

$$0 < m_1 \leqq \rho \leqq M_1 + K_1 \rho q^2. \tag{1.3}$$

Case 2.

$$0 < m_2 \leqq \rho^{-1} \leqq M_2 + K_2 \rho q^2 \quad \text{in } \Omega. \tag{1.4}$$

Here we have used the notation $q^2 = |\text{grad } u|^2$. These are the same assumptions made in [3]. It will be clear that M_1 and M_2 could be allowed to depend on x_1 and x_2, but in this paper we assume that the m_i and M_i are positive constants and that the K_i are nonnegative constants. We recall the discussion in [3] concerning assumptions (1.3), (1.4). If, for instance, ρ were a bounded function of its arguments, then K_1 in (1.3) could be taken to be zero. Roughly speaking, the first term on the right in (1.3) provides a bound on ρ as $q \to 0$, while the second term gives a bounding function for ρ as $q \to \infty$. A function ρ for which (1.3) holds is $\rho = 1 + q^2$, in which case we may take $m_1 = 1$, $M_1 = 1$, and $K_1 = 1$. If $\rho = (1+q^2)^{-1/2}$, in which case (1.1) is the minimal surface equation, then (1.4) is satisfied with $m_2 = 1$, $M_2 = 1$, and $K_2 = 1$.

Let us now introduce a family of curves $f(x_1, x_2) = \alpha$, $\alpha > \alpha_0$. For $\alpha_0 < \alpha < \alpha_1$ the curve $f = \alpha$ is assumed to intersect Ω and form a region Ω_α defined as

$$\Omega_\alpha = \Omega \cap \{x_1, x_2; f(x_1, x_2) > \alpha\}. \tag{1.5}$$

It is further assumed that through each point of Ω one and only one curve of the family passes and that the following properties hold:

(i) $\beta \leqq \delta \Rightarrow \Omega_\beta \supset \Omega_\delta$;

(ii) $\partial\Omega_{\alpha_0}$ contains no points of Σ;

(iii) $|\text{grad } f| \leqq \gamma$ in Ω_{α_0}.

We will also investigate the case in which Ω is unbounded and α_1 is infinity. In the previous paper [3] the region Ω was assumed to be the semi-infinite strip $\{x_1 > 0, 0 < x_2 < h\}$, and $f(x_1, x_2)$ was chosen to be the coordinate x_1. For certain geometries this same choice of f can be made for the class of problems considered in this paper.

2. Decay estimates in the first case. The method of proof will differ somewhat from that used in [3]. Furthermore, for the case of unbounded Ω we make no a priori assumption on the decay of u as $|\mathbf{x}| \to \infty$ in Ω. The method itself will provide an appropriate alternative.

Let us first introduce some additional notation, i.e.,

$$\begin{aligned} S_\alpha &:= \{f(x_1, x_2) = \alpha\} \cap \Omega, \\ l(\alpha) &= \text{length of } S_\alpha, \\ B(\alpha) &= \int_{S_\alpha} \rho |\text{grad } f| \, ds, \\ \mathscr{B}(\alpha) &= \int_{S_\alpha} \rho^{-1} |\text{grad } f| \, ds. \end{aligned} \tag{2.1}$$

We wish to consider the behavior of the functional

$$F(\alpha)=\int_{S_\alpha}\frac{\rho u u_{,i} f_{,i}}{|\operatorname{grad} f|}\,ds, \qquad \alpha_0<\alpha<\alpha_1 \tag{2.2}$$

as a function of α. It is understood throughout that $\rho \equiv \rho(\mathbf{x}, u, \operatorname{grad} u)$.

Now, $F(\alpha)$ may be rewritten as either

$$F(\alpha)=-\int_{\Omega_\alpha}\rho q^2\,dx \quad \text{if } \Omega \text{ is bounded,} \tag{2.3}$$

or

$$F(\alpha)=F(\alpha_0)+\int_{\alpha_0}^{\alpha}\int_{S_\eta}\frac{\rho q^2}{|\operatorname{grad} f|}\,ds\,d\eta \quad \text{if } \Omega \text{ is unbounded.} \tag{2.4}$$

We could, of course, use the second representation in either case. Both representations follow directly from the divergence theorem. The weighted Dirichlet integrals (2.3), (2.4) provide a measure for the "energy" associated with solutions of (1.1), (1.2). It follows that

$$F'(\alpha)=\int_{S_\alpha}\frac{\rho q^2}{|\operatorname{grad} f|}\,ds, \tag{2.5}$$

where the prime denotes differentiation with respect to α. Our first objective is to derive an explicit inequality of the form

$$|F(\alpha)|\leqq k^{-1}(\alpha)F'(\alpha). \tag{2.6}$$

This will lead to the following two first-order differential inequalities:

$$F'(\alpha)\geqq k(\alpha)F(\alpha), \tag{2.7}$$

$$F'(\alpha)\geqq -k(\alpha)F(\alpha). \tag{2.8}$$

One of these inequalities will be superfluous if Ω is bounded, but it will permit us to derive an alternative result if Ω is unbounded. We now proceed to establish (2.6).

By Schwarz's inequality,

$$F^2(\alpha)\leqq\int_{S_\alpha}\frac{\rho(\partial u/\partial n)^2}{|\operatorname{grad} f|}\,ds\int_{S_\alpha}\rho u^2|\operatorname{grad} f|\,ds. \tag{2.9}$$

Regarding ρ as a function of the variables (x_1, x_2) and introducing the variable

$$\sigma=\int_0^s \rho|\operatorname{grad} f|\,ds, \tag{2.10}$$

we have

$$\int_{S_\alpha}\rho u^2|\operatorname{grad} f|\,ds=\int_0^{B(\alpha)}u^2\,d\sigma\leqq\frac{[B(\alpha)]^2}{\pi^2}\int_0^{B(\alpha)}\left(\frac{\partial u}{\partial\sigma}\right)^2 d\sigma, \tag{2.11}$$

where $B(\alpha)$ is as defined in (2.1). The boundary condition (1.2) and a well-known inequality of Wirtinger type (see e.g., [1, p. 185]) have been used in obtaining the last inequality. Reverting to the original coordinates, we have

$$\begin{aligned}\int_{S_\alpha}\rho u^2|\operatorname{grad} f|\,ds&\leqq\frac{[B(\alpha)]^2}{\pi^2}\int_{S_\alpha}\rho^{-1}\left(\frac{\partial u}{\partial s}\right)^2|\operatorname{grad} f|^{-1}\,ds\\&\leqq\frac{[B(\alpha)]^2}{m_1^2\pi^2}\int_{S_\alpha}\frac{\rho}{|\operatorname{grad} f|}\left(\frac{\partial u}{\partial s}\right)^2 ds,\end{aligned} \tag{2.12}$$

where the left-hand inequality of (1.3) has been used in the last step. Insertion of the above into (2.9) leads to

$$
\begin{aligned}
|F(\alpha)| &\leqq \frac{B(\alpha)}{m_1\pi}\left\{\int_{S_\alpha}\frac{\rho}{|\operatorname{grad} f|}\left(\frac{\partial u}{\partial n}\right)^2 ds \int_{S_\alpha}\frac{\rho}{|\operatorname{grad} f|}\left(\frac{\partial u}{\partial s}\right)^2 ds\right\}^{1/2} \\
&\leqq \frac{B(\alpha)}{2m_1\pi}F'(\alpha).
\end{aligned} \tag{2.13}
$$

We have thus established (2.6) with $k(\alpha)=2m_1\pi/B(\alpha)$.

An integration of (2.7) with the above value for $k(\alpha)$ leads to

$$
F(\alpha)\geqq F(\tilde{\alpha})\exp\left\{2m_1\pi\int_{\tilde{\alpha}}^{\alpha}[B(\eta)]^{-1}\,d\eta\right\} \tag{2.14}
$$

for $\alpha\geqq\tilde{\alpha}>\alpha_0$. This inequality shows that if $F(\alpha)>0$ for any α (say $\tilde{\alpha}$), then $F(\alpha)>0$ for $\alpha>\tilde{\alpha}$, and hence if Ω is bounded then $F(\alpha_1)$ cannot be zero. Thus in this case $F(\alpha)<0$, for all α. It is, of course, obvious from (2.3) that, for bounded Ω, $F(\alpha)$ can never be positive. Thus for Ω bounded we have from (2.8)

$$
-F(\alpha)\leqq -F(\alpha_0)\exp\left\{-2m_1\pi\int_{\alpha_0}^{\alpha}[B(\eta)]^{-1}\,d\eta\right\}, \tag{2.15}
$$

which we write as

$$
\int_{\Omega_\alpha}\rho q^2\,dx\leqq\int_{\Omega_{\alpha_0}}\rho q^2\,dx\exp\left\{-2m_1\pi\int_{\alpha_0}^{\alpha}[B(\eta)]^{-1}\,d\eta\right\}. \tag{2.16}
$$

The exponential will now be bounded in a manner somewhat different from that used in [3]. We note that

$$
\begin{aligned}
\int_{\alpha_0}^{\alpha}[B(\eta)]^{-1}\,d\eta &\geqq \int_{\alpha_0}^{\alpha}d\eta\Big/\left[\int_{S_\eta}\{M_1+K_1\rho q^2\}|\operatorname{grad} f|\,ds\right] \\
&\geqq \frac{1}{M_1\gamma}\int_{\alpha_0}^{\alpha}d\eta\Big/ l(\eta)\left\{1+\frac{K_1\gamma}{M_1 l(\eta)}\int_{S_\eta}\frac{\rho q^2}{|\operatorname{grad} f|}\,ds\right\},
\end{aligned} \tag{2.17}
$$

where we recall from (2.1) that $l(\eta)$ is the length of S_η. Thus

$$
\begin{aligned}
\int_{\alpha_0}^{\alpha}[B(\eta)]^{-1}\,d\eta &\geqq \frac{1}{M_1\gamma}\int_{\alpha_0}^{\alpha}\frac{d\eta}{l(\eta)}-\frac{K_1}{M_1^2}\int_{\alpha_0}^{\alpha}\left(\int_{S_\eta}\frac{\rho q^2}{l^2(\eta)|\operatorname{grad} f|}\,ds\right)d\eta \\
&\geqq \frac{1}{M_1\gamma}\int_{\alpha_0}^{\alpha}\frac{d\eta}{l(\eta)}-\frac{K_1}{M_1^2 l_\alpha^2}\int_{\Omega_{\alpha_0}}\rho q^2\,dx
\end{aligned} \tag{2.18}
$$

where l_α denotes $\inf_{\eta\in[\alpha_0,\alpha]} l(\eta)$. We are thus led, for bounded Ω, to the inequality

$$
\int_{\Omega_\alpha}\rho q^2\,dx\leqq\int_{\Omega_{\alpha_0}}\rho q^2\,dx\exp\left\{\frac{2m_1K_1\pi}{M_1^2l_\alpha^2}\int_{\Omega_{\alpha_0}}\rho q^2\,dx\right\}\exp\left\{\frac{-2m_1\pi}{M_1\gamma}\int_{\alpha_0}^{\alpha}\frac{d\eta}{l(\eta)}\right\}, \tag{2.19}
$$

which is the desired decay result. Thus we have established Theorem 1.

THEOREM 1. *If Ω is bounded, then the decay estimate* (2.19) *holds for $\alpha_0<\alpha<\alpha_1$.*

To make the inequality explicit we of course need a bound for $\int_{\Omega_{\alpha_0}}\rho q^2\,dx$. Techniques for finding such bounds have been indicated in [3].

We now consider the case in which Ω is unbounded. From (2.14) we again conclude that if $F(\alpha)$ is positive for some $\tilde{\alpha}$ then it must be positive for all $\alpha > \tilde{\alpha}$. Let us suppose now that $F(\tilde{\alpha}) > 0$ and that

$$l(\eta) \leqq L < \infty. \tag{2.20}$$

Then if

$$\liminf_{\alpha \to \infty} \frac{\int_{S_\alpha} (\rho q^2/|\operatorname{grad} f|)\, ds}{\alpha} = 0 \tag{2.21}$$

we will show that we are led to a contradiction, i.e., it must follow that $F(\alpha) \leqq 0$, for all $\alpha \in (\alpha_0, \infty)$. This can be deduced from the fact that, if $F(\tilde{\alpha}) > 0$, then for $\alpha > \tilde{\alpha}$, (2.7), (2.5), and (2.14) lead to

$$\begin{aligned} \alpha^{-1} \int_{S_\alpha} \frac{\rho q^2}{|\operatorname{grad} f|}\, ds &\geqq \frac{2m_1 \pi F(\tilde{\alpha})}{\alpha\gamma[M_1 l(\alpha) + K_1 \gamma \int_{S_\alpha} (\rho q^2\, ds/|\operatorname{grad} f|)]} \\ &\quad \cdot \exp\left\{ \int_{\tilde{\alpha}}^{\alpha} \frac{2m_1 \pi\, d\eta}{\gamma[M_1 l(\eta) + K_1 \gamma \int_{S_\eta} (\rho q^2\, ds/|\operatorname{grad} f|)]} \right\}. \end{aligned} \tag{2.22}$$

But given any $\varepsilon > 0$ it follows from assumption (2.21) that for sufficiently large α

$$\int_{S_\alpha} \frac{\rho q^2}{|\operatorname{grad} f|}\, ds \leqq \varepsilon\alpha. \tag{2.23}$$

Thus for sufficiently large α

$$\begin{aligned} \varepsilon \geqq \alpha^{-1} \int_{S_\alpha} \frac{\rho q^2}{|\operatorname{grad} f|}\, ds &\geqq \frac{2m_1 \pi F(\tilde{\alpha})}{\alpha\gamma[M_1 L + \gamma K_1 \varepsilon\alpha]} \left[\frac{M_1 L + \gamma K_1 \varepsilon\alpha}{M_1 L + \gamma K_1 \varepsilon\tilde{\alpha}} \right]^{2m_1 \pi / K_1 \gamma^2 \varepsilon} \\ &\geqq 2m_1 K_1 \varepsilon \pi F(\tilde{\alpha}) [M_1 L + \gamma K_1 \varepsilon\alpha]^{[(2m_1 \pi / K_1 \gamma^2 \varepsilon) - 2]} [M_1 L + \gamma K_1 \varepsilon\tilde{\alpha}]^{-2m_1 \pi / K_1 \gamma^2 \varepsilon}. \end{aligned} \tag{2.24}$$

Letting $\alpha \to \infty$ we observe that for ε sufficiently small the right-hand side tends to infinity. Thus we have established Theorem 2.

THEOREM 2. *If Ω is unbounded and $l(\alpha)$ is bounded for all α, then either* $\liminf_{\alpha \to \infty} [\alpha^{-1} \int_{S_\alpha} (\rho q^2/|\operatorname{grad} f|)\, ds] > K > 0$ *or* $F(\alpha) \leqq 0$ *for all* $\alpha \in (\alpha_0, \infty)$.

If $l(\alpha) \to \infty$ as $\alpha \to \infty$, then similar alternative theorems can be derived depending on the order of $l(\alpha)$ as $\alpha \to \infty$. For instance, if the family of curves $x_1 = \alpha$ is used and $l(\alpha) \leqq C\alpha$ for some positive constant C then $\gamma \equiv 1$, and in (2.22) the exponential term is bounded by

$$\begin{aligned} &\exp\left\{ 2m_1 \pi \int_{\tilde{\alpha}}^{\alpha} \frac{d\eta}{[M_1 l(\eta) + K_1 \int_{S_\eta} (\rho q^2\, ds/|\operatorname{grad} f|)]} \right\} \\ &\qquad \leqq \left[\frac{\alpha}{\tilde{\alpha}} \right]^{2m_1 \pi / [M_1 C + K_1 \varepsilon]}. \end{aligned} \tag{2.25}$$

Thus (2.22), (2.23) imply in this case

$$\begin{aligned} \varepsilon &\geqq \alpha^{-1} \int_{S_\alpha} \rho q^2\, ds \\ &\geqq \frac{2m_1 \pi F(\tilde{\alpha})}{[M_1 C + K_1 \varepsilon]} [\tilde{\alpha}]^{-2m_1 \pi / (M_1 C + K_1 \varepsilon)} [\alpha]^{2[m_1 \pi / (M_1 C + K_1 \varepsilon) - 1]}. \end{aligned} \tag{2.26}$$

We observe that if

$$m_1 \pi / M_1 C > 1, \tag{2.27}$$

then we may choose ε so small that the exponent of α is positive. Then, letting $\alpha \to \infty$, we would again be led to a contradiction. We see, therefore, that if $l(\alpha) \leqq C\alpha$ then either $\liminf_{\alpha\to\infty}[\alpha^{-1}\int_{S_\alpha} \rho q^2\, ds] > K > 0$ or $F(\alpha) \leqq 0$ for all $\alpha \in (\alpha_0, \infty)$ provided (2.27) is satisfied.

Alternatively we could have chosen the family $|\mathbf{x}| = \alpha$, in which case the assumption $l(\alpha) \leqq C\alpha$ would have led to the same result. We could also have shown by similar arguments that if $m_1\pi/M_1C > 2$ then either $\liminf_{\alpha\to\infty}\{\alpha^{-2}\int_{S_\alpha} \rho q^2\, ds\} > K > 0$ or $F(\alpha) \leqq 0$ for all $\alpha \in (\alpha_0, \infty)$.

We assume henceforth that conditions as $\alpha \to \infty$ imply that $F(\alpha) \leqq 0$ for all $\alpha > \alpha_0$. It follows then from (2.16) that

$$\int_{\Omega_\alpha} \rho q^2\, dx \leqq \int_{\Omega_{\alpha_0}} \rho q^2\, dx \exp\left\{-2m_1\pi \int_{\alpha_0}^{\alpha} [B(\eta)]^{-1}\, d\eta\right\}, \tag{2.28}$$

and we conclude as before that the decay estimate (2.19) holds now for unbounded Ω.

Suppose that Ω is a wedge of angle 2δ. Then by using $f(x_1, x_2) = |\mathbf{x}|$ in (2.19), we find that, as $\alpha \to \infty$, the energy term $\int_{\Omega_\alpha} \rho q^2\, dx$ tends to zero like $(x_1^2 + x_2^2)^{-\beta}$. The constant β is given by

$$\beta = m_1\pi/2M_1\delta. \tag{2.29}$$

(Note that when $f = |\mathbf{x}|$, γ may be taken to be 1.) It follows that if $m_1 = M_1$, the estimated decay rate β will be the same as the optimal decay rate for harmonic functions (see, e.g., [2], [5], [6]). Since (1.3) yields $m_1 \leqq M_1$, the estimated decay rate (2.29) is always less than or equal to the actual decay rate for harmonic functions.

For the wedge we have $l(\alpha) = 2\delta\alpha$, and if $m_1 = M_1$, condition (2.27) implies that the alternative holds for $\delta < \pi/2$. For angles $\pi/2 < \delta < \pi$ we must replace the condition

$$\liminf_{\alpha\to\infty}\left[\alpha^{-1}\int_{S_\alpha} \frac{\rho q^2\, ds}{|\operatorname{grad} f|}\right] = 0 \quad \text{by} \quad \liminf_{\alpha\to\infty}\left[\alpha^{-p}\int_{S_\alpha} \frac{\rho q^2\, ds}{|\operatorname{grad} f|}\right] = 0$$

for an appropriately chosen $p \in (0, 1)$.

When Ω is a semi-infinite strip, we may take $f(x_1, x_2) = x_1$ and recover from (2.19) the *exponential* decay estimate (2.1) of [3].

3. Decay estimates in the second case. Again in this case we define $F(\alpha)$ as in (2.2) and seek to determine a $k(\alpha)$ such that (2.6) is satisfied. To bound the second integral on the right-hand side of (2.9) we now note that, on using the left-hand inequality in (1.4), we have

$$\int_{S_\alpha} \rho u^2 |\operatorname{grad} f|\, ds \leqq \frac{1}{m_2^2}\int_{S_\alpha} \rho^{-1} u^2 |\operatorname{grad} f|\, ds. \tag{3.1}$$

Thus, on setting

$$\tau = \int_0^s \rho^{-1}|\operatorname{grad} f|\, ds, \qquad \mathscr{B}(\alpha) = \int_{S_\alpha} \rho^{-1}|\operatorname{grad} f|\, ds \tag{3.2}$$

we are now led to

$$\int_{S_\alpha} \rho u^2 |\operatorname{grad} f|\, ds \leqq \frac{\mathscr{B}^2(\alpha)}{\pi^2 m_2^2}\int_{S_\alpha} \frac{\rho}{|\operatorname{grad} f|}\left(\frac{\partial u}{\partial s}\right)^2 ds \tag{3.3}$$

which, together with (2.9), (2.5) yields

$$|F(\alpha)| \leqq \frac{\mathscr{B}(\alpha)}{2m_2\pi} F'(\alpha). \tag{3.4}$$

It is clear now that the arguments following (2.13) carry through and that we obtain (2.19) with m_1, M_1, and K_1 replaced by m_2, M_2, and K_2, respectively, provided either that Ω is bounded or that the appropriate behavior at infinity is assumed.

In [3] decay estimates for other norms of the solution have been given. Similar estimates are obtainable for solutions of the problems considered in this paper.

As has been pointed out in the Introduction, for the case of the minimal surface equation we have $m_2 = M_2 = K_2 = 1$, in which case the bound for the decay rate is given according to (2.19) as $\exp\{-2\pi\gamma^{-1}\int_{\alpha_0}^{\alpha} d\eta/l(\eta)\}$, which for a wedge and for a semi-infinite strip agrees with the optimal decay rate for harmonic functions. (We choose $f = |\mathbf{x}|$, $\gamma = 1$ for a wedge; $f = x_1$, $\gamma = 1$ for a semi-infinite strip.)

Acknowledgments. We are grateful to the referees for their comments on an earlier version of this paper.

DECAY ESTIMATES IN STEADY PIPE FLOW*

K. A. AMES† AND L. E. PAYNE‡

Abstract. In this paper St. Venant type results are derived for the flow of viscous fluid in a pipe of arbitrary cross section. In the spirit of earlier work of Horgan and Wheeler [*SIAM J. Appl. Math.*, 35 (1978), pp. 97-116], the decay to fully developed flow as a function of distance from the entry section is investigated. Here, it is not assumed that the flow is fully developed at the exit section. Weighted energy inequalities are derived that lead to estimates for the "energy" associated with the velocity field represented by the difference between the entrance flow and the fully developed flow in a portion of the pipe near the exit section. The analysis is based on a variety of differential inequality techniques and Payne's investigation of uniqueness criteria for steady-state solutions of the Navier-Stokes equations [*Simpos. Internaz. Appl. Fis. Mat.*, 1965, pp. 130-153].

1. Introduction.

Consider the problem of steady flow of a viscous fluid in a pipe of arbitrary smooth cross section. The flow is governed by the Navier-Stokes equations together with the assumption of adherence at the pipe boundary. If the Reynolds number is sufficiently small we expect that, irrespective of the entrance velocity profile, the flow will approach the fully developed flow near the pipe exit if the pipe is sufficiently long. In a recent paper of Horgan and Wheeler [7] the goal of the authors was to show that under certain assumptions this decay to fully developed flow (in the appropriate measure) was exponential. Their results were based on differential inequality techniques developed by Knowles [8] and Toupin [17] in their investigations of St. Venant's Principle in classical elasticity theory (see also Horgan and Knowles [5]).

In the present paper we again address this flow problem with an analysis that has many features in common with that used by Horgan and Wheeler and thus relies heavily on differential inequality techniques. However, our formulation of the problem and methodology differ somewhat from theirs with the consequence that we have obtained slightly better, more explicit estimates for a weighted energy integral associated with the flow.

One of the assumptions that Horgan and Wheeler made in their work was that the entrance flow had already evolved completely into the fully developed flow at the exit end of the pipe and thus that the tangential components of the velocity in the outlet cross section were both zero. This is a somewhat unrealistic assumption since we cannot expect complete evolution in a pipe of finite length. In this paper we relax that assumption, supposing instead that the tangential velocities and their derivatives in the exit section are small. Our assumption has the effect of making the problem considerably more complicated, and we find it convenient to compare the entrance flow to the fully developed flow indirectly through the introduction of a linearized Stokes flow that enters the pipe with a velocity field equivalent to the fully developed one. Such an approach has necessitated the introduction of some additional restrictions on the boundary data for us to obtain our estimates.

Our main result is an explicit inequality that gives an indication of the spatial development of the entrance flow as it moves through the pipe. If the data and ν are suitably restricted, the inequality we derive establishes a decay estimate for a weighted functional defined on the difference between the entrance velocity field and the Stokes flow. Combining this result with estimates on this functional defined on the difference between the Stokes and fully developed flows, we obtain the desired inequality comparing the entrance and fully developed velocity fields. In fact we show that a certain weighted energy functional of this difference is bounded by the sum of two terms—one a decaying exponential and the other a function of difference in exit data.

In the course of our analysis, it becomes necessary for us to find bounds for the energy of the corresponding linearized Stokes problem. The arguments we used to accomplish this are patterned after those used by Payne [11] in his investigation of uniqueness criteria for steady state solutions of the Navier-Stokes equations. As we will see, our estimates are explicit in the sense that they depend only on ν, the boundary data, and the geometry of the domain.

It should be pointed out that questions related to those discussed in this paper have also been considered by Amick [1], [2], Yosifian [19], [20], and Oleinik [10]. In these latter papers the authors have considered domains with boundaries extending to infinity, concentrating primarily on questions of existence, uniqueness, and regularity. Yosifian [19] has established an energy decay result for the Stokes system (which is of precisely the same form as the equations of incompressible linear elasticity), and Amick [2] has established exponential energy decay rates, but for general cross sections these were not explicitly expressed in terms of the data and geometry.

In the next section, we will formulate the boundary value problem that serves as the basis for our analysis. Section 3 is devoted to a summary of the inequalities and auxiliary results that we will utilize to generate our estimates. We then compare the entrance flow to a Stokes flow whose boundary data on the inlet cross section coincide with that of the fully developed flow. Our main differential inequality is established in § 4 and bounds for the Stokes flow are derived in §§ 5 and 6. Comparison of the entrance and fully developed flows and a discussion of our results, in particular the criteria that ensure decay, are the subjects of § 7. In this section, we also obtain an upper bound for the maximum speed of the fully developed flow in terms of the prescribed net inflow and the domain geometry by taking advantage of results for the analogous Saint-Venant torsion problem. The section also contains some remarks about the constants appearing in our estimates. Finally, part of § 7 is devoted to a brief description of how bounds for the total weighted energy in terms of data and geometry can be derived. We note that because of the tedious nature of the analysis used in this problem, we have relegated some of the details to three appendices.

2. Formulation of problem. In this section we formulate the boundary value problem that provides the framework for our investigation of the flow development of an incompressible viscous fluid in a pipe. Much of our notation coincides with that used by Horgan and Wheeler [7]. We let R denote the interior of a three-dimensional cylindrical pipe of length l and ∂R its boundary. A plane cross section of the pipe with Cartesian coordinates (x_1, x_2, z), $z \in [0, l]$ fixed, will be denoted by S_z and its boundary by ∂S_z. In particular, S_0 represents the inlet cross section and S_l the outlet cross section of the pipe.

The velocity field $u_i(x_1, x_2, x_3)$ $(i = 1, 2, 3)$ and the pressure $p(x_1, x_2, x_3)$ of the fluid are assumed to be classical solutions of the following boundary value problem:

$$\nu \Delta u_i = p_{,i} + u_j u_{i,j} \quad \text{in } R, \tag{2.1}$$

$$u_{i,i} = 0 \quad \text{in } R, \tag{2.2}$$

$$u_i = 0 \quad \text{on } \partial R \backslash (S_0 \cup S_l), \tag{2.3}$$

$$u_i = f_i(x_1, x_2) \quad \text{on } S_0, \tag{2.4}$$

$$u_i = g_i(x_1, x_2) \quad \text{on } S_l. \tag{2.5}$$

Here Δ denotes the Laplace operator and ν is the constant kinematic viscosity. The prescribed entrance profile $f_i(x_1, x_2)$ and exit velocity $g_i(x_1, x_2)$ are assumed to be zero on ∂S_0 and ∂S_l, respectively. The vector field $v_i(x_1, x_2, x_3)$ is the solution of the Stokes problem

$$\nu \Delta v_i = q_{,i} \quad \text{in } R, \tag{2.6}$$

$$v_{i,i} = 0 \quad \text{in } R, \tag{2.7}$$

$$v_i = 0 \quad \text{on } \partial R \backslash (S_0 \cup S_l), \tag{2.8}$$

$$v_i = V\delta_{3i} \quad \text{on } S_0, \tag{2.9}$$

$$v_i = u_i \quad \text{on } S_l. \tag{2.10}$$

Here $(0, 0, V(x_1, x_2))$ represents the fully developed velocity field corresponding to the net inflow

$$\int_{S_0} f_3 \, dx = Q \tag{2.11}$$

and can thus be characterized as the solution of the boundary value problem

$$\nu V_{,\alpha\alpha} = \tilde{p}_{,3} \quad \text{in } S_z, \tag{2.12}$$

$$V = 0 \quad \text{on } \partial S_z, \tag{2.13}$$

$$\int_{S_z} V \, dx = Q. \tag{2.14}$$

The gradient of the pressure $\tilde{p}$ in (2.12) has the form $\tilde{p}_{,i} = -P\delta_{3i}$ where P is a positive constant.

If the velocity vector $g_i(x_1, x_2)$ at the exit end of the pipe is close to that of fully developed flow then the data $g_i - V\delta_{3i}$ may be expected to be small as elements of $W_2^1(S_l)$. We shall have more to say about this later.

In the previous equations as well as the subsequent analysis, we adopt the summation convention and denote differentiation by a comma. Latin subscripts will range from 1-3 while Greek subscripts will range only from 1-2.

Recall that our goal is to compare the entrance flow u_i to the fully developed flow V. To do so we introduce a Stokes flow v_i that coincides with V on the inlet cross section of the pipe and with u_i on the outlet section. We shall first compare u_i and v_i and then v_i and $V\delta_{3i}$. These separate comparisons will lead to estimates for the energy of the difference between the entrance and fully developed flows. As mentioned in the Introduction, our reason for taking this approach rather than comparing u_i and $V\delta_{3i}$ directly as Horgan and Wheeler did, is motivated by the fact that we do not expect the entrance velocity field to evolve completely into the fully developed field in a pipe of finite length. The present approach allows us to avoid making the assumption that $u_\alpha = 0$ and $u_3 = V$ on S_l.

To relate the solution u_i of (2.1)-(2.5) to the solution v_i of (2.6)-(2.10), we define $w_i = u_i - v_i$ and $s = p - q$. Then the boundary value problem governing the difference fields is

$$\nu \Delta w_i = s_{,i} + (w_j + v_j)(w_{i,j} + v_{i,j}) \quad \text{in } R, \tag{2.15}$$

$$w_{i,i} = 0 \quad \text{in } R, \tag{2.16}$$

$$w_i = 0 \quad \text{on } \partial R \backslash S_0, \tag{2.17}$$

$$w_i = f_i - V\delta_{3i} \quad \text{on } S_0. \tag{2.18}$$

In view of (2.11) and (2.14), we have $\int_{S_0} w_3 \, dx = 0$. From this fact as well as equations (2.16)-(2.18) and the divergence theorem, we readily obtain the condition of zero net axial flow, i.e.,

$$\int_{S_z} w_3 \, dx = 0 \quad \text{for } 0 \leqq z \leqq l. \tag{2.19}$$

As pointed out in [7], an analogy between this condition and one that arises in Saint-Venant's Principle of elasticity theory can be made.

3. Auxiliary results. To establish the main estimate of this paper, we have relied on a number of standard inequalities that we summarize in this section.

Let S be a plane domain with boundary ∂S. If $w = 0$ on ∂S, then we have the Poincaré inequality

$$\lambda_1 \int_S w^2 \, dx \leqq \int_S w_{,\alpha} w_{,\alpha} \, dx \tag{3.1}$$

where λ_1 is the smallest positive eigenvalue of

$$\Delta \varphi + \lambda \varphi = 0 \quad \text{in } S, \qquad \varphi = 0 \quad \text{on } \partial S.$$

If, however, $w = 0$ on ∂S and $\int_S w \, dx = 0$, then

$$\lambda_2 \int_S w^2 \, dx \leqq \int_S w_{,\alpha} w_{,\alpha} \, dx \tag{3.2}$$

where λ_2 is the smallest positive eigenvalue of the problem

$$\Delta \varphi + \lambda \varphi = \hat{k} \quad \text{in } S, \qquad \varphi = 0 \quad \text{on } \partial S,$$

$$\int_S \varphi \, dx = 0$$

for a constant $\hat{k}$. It is easily seen that $\lambda_1 \leqq \lambda_2$. In fact, as indicated in § 5, a sharper lower bound for λ_2 can be found.

In addition to inequalities (3.1) and (3.2), we will make use of the following two Sobolev inequalities that hold for any sufficiently smooth function w with compact support in either $\mathbb{R}^2$ or $\mathbb{R}^3$:

$$\text{(i)} \quad \int\int_{-\infty}^{\infty} w^4 \, dx \leqq \frac{1}{2} \left(\int\int_{-\infty}^{\infty} w^2 \, dx \right) \left(\int\int_{-\infty}^{\infty} w_{,\alpha} w_{,\alpha} \, dx \right), \tag{3.3}$$

$$\text{(ii)} \quad \int\int\int_{-\infty}^{\infty} w^6 \, dx \leqq \Omega \left(\int\int\int_{-\infty}^{\infty} w_{,j} w_{,j} \, dx \right)^3. \tag{3.4}$$

In a number of papers [9], [16], the best constant in (3.4) has been computed to have the value $\Omega = (1/27)(2/\pi)^4$.

An important result that will be needed in deriving our estimates is contained in the following theorem that is given in Babuška and Aziz [3] under less stringent smoothness hypotheses.

THEOREM A. *Let S be a plane Lipschitz domain and let w be a function that is continuously differentiable on $\bar{S}$ and satisfies $\int_S w\,dx = 0$. Then there exists a vector function ψ_α such that*

$$\psi_{\alpha,\alpha} = w \quad \text{in } S, \qquad \psi_\alpha = 0 \quad \text{on } \partial S \tag{3.5}$$

and a positive constant C depending only on the geometry of S such that

$$\int_S \psi_{\alpha,\beta}\psi_{\alpha,\beta}\,dx \leqq C \int_S (\psi_{\alpha,\alpha})^2\,dx. \tag{3.6}$$

This theorem asserts the existence of such a function ψ_α, which clearly is not unique. In fact, in our applications we will not be interested in the function ψ_α itself (we require only the existence of such a function) but rather in the constant C. More specifically, for a given domain S we would like to find the smallest possible value of C or, barring this, a close upper bound for this optimal C. Since the optimal C does not depend on the size of S but only on its shape (it can be thought of as a dimensionless eigenvalue defined by (3.6)), it can easily be seen that the optimal constant for a circle of arbitrary radius is $C = 1$. In [6] it has been shown how this optimal constant is related to an optimal Korn's constant and to an optimal Friedrich's constant. In this latter paper an explicit upper bound for the optimal C for a star-shaped region is given. Not only will inequality (3.6) be useful in establishing the final estimate but this result will enable us to eliminate the pressure difference s via the introduction of an auxiliary function ψ_α, the existence of which is ensured by the theorem since w_3 satisfies its hypotheses.

4. Comparison of u_i and v_i. We will divide our analysis into two parts. In the first part, we derive a first-order inequality for a weighted energy integral that is defined for solutions of (2.15)-(2.18). Integration of this inequality results in the desired estimates. In the course of this derivation, we shall need some inequalities for the energy associated with the linearized Stokes problem that corresponds to (2.15)-(2.18). Section 5 will be devoted to establishing these inequalities.

We define a weighted energy integral by

$$\Phi(z) = \frac{1}{3}\int_z^l \int_{S_\xi} (\xi - z)^3 w_{i,j} w_{i,j}\,dx\,d\xi \tag{4.1}$$

for solutions w_i of the problem (2.15)-(2.18). In this section, we show that $\Phi(z)$ satisfies a first-order differential inequality of the form

$$K\frac{d\Phi}{dz} + M\Phi \leqq M_2 l^3 Q_0 \tag{4.2}$$

where K, M, and M_2 are positive constants and Q_0 is a data term. Integration of this inequality with the appropriate data assumptions leads to a result of the form

$$\Phi(z) \leqq \Phi(0)e^{-\kappa_1 z} + \kappa_2 l^3 Q_0(1 - e^{-\kappa_1 z}) \tag{4.3}$$

for $0 \leqq z \leqq l$. Here $\kappa_1 = M/K$ and $\kappa_2 = M_2/M$.

To obtain (4.2), we first observe that the function $\Phi(z)$ can be rewritten after an integration by parts and substitution of the differential equations for w_i as

$$\begin{aligned}\Phi(z) = &-\int_z^l \int_{S_\xi} (\xi - z)^2 w_i w_{i,3}\, dx\, d\xi + \frac{1}{\nu}\int_z^l \int_{S_\xi} (\xi - z)^2 w_3 s\, dx\, d\xi \\ &+\frac{1}{2\nu}\int_z^l \int_{S_\xi} (\xi - z)^2 w_i w_i v_3\, dx\, d\xi \\ &-\frac{1}{3\nu}\int_z^l \int_{S_\xi} (\xi - z)^3 w_i [w_j w_{i,j} + (w_j + v_j) v_{i,j}]\, dx\, d\xi.\end{aligned} \tag{4.4}$$

From the definition of $\Phi(z)$ in (4.1), we also have

$$\frac{d\Phi}{dz} = -\int_z^l \int_{S_\xi} (\xi - z)^2 w_{i,j} w_{i,j}\, dx\, d\xi. \tag{4.5}$$

To derive the desired differential inequality, we need to eliminate the pressure term s from the expression (4.4) for $\Phi(z)$. This can be accomplished with the aid of Theorem A from § 3. We thus introduce the vector function ψ_α that satisfies

$$\psi_{\alpha,\alpha} = w_3 \quad \text{in } S_z, \tag{4.6}$$

$$\psi_\alpha = 0 \quad \text{on } \partial S_z \tag{4.7}$$

for $z \in [0, l]$. The existence of such a function is guaranteed by Theorem A since $\int_{S_z} w_3\, dx = 0$ for $0 \leqq z \leqq l$. If we now multiply the first two of equations (2.14) by $(\xi - z)^2 \psi_\alpha$ and integrate over the domain, we obtain (following Horgan and Wheeler [7])

$$\begin{aligned}&\int_z^l \int_{S_\xi} (\xi - z)^2 s w_3\, dx\, d\xi \\ &\quad = \int_z^l \int_{S_\xi} (\xi - z)^2 [\psi_\alpha (w_j + v_j)(w_{\alpha,j} + v_{\alpha,j}) + \nu \psi_{\alpha,j} w_{\alpha,j} - \nu(\psi_\alpha w_{\alpha,3})_{,3}]\, dx\, d\xi.\end{aligned} \tag{4.8}$$

Substitution of this expression into (4.4) leads to

$$\begin{aligned}\Phi(z) = &-\int_z^l \int_{S_\xi} (\xi - z)^2 w_i w_{i,3}\, dx\, d\xi - \int_z^l \int_{S_\xi} (\xi - z)^2 (\psi_\alpha w_{\alpha,3})_{,3}\, dx\, d\xi \\ &+\int_z^l \int_{S_\xi} (\xi - z)^2 \psi_{\alpha,j} w_{\alpha,j}\, dx\, d\xi + \frac{1}{\nu}\int_z^l \int_{S_\xi} (\xi - z)^2 \psi_\alpha (w_j + v_j)(w_{\alpha,j} + v_{\alpha,j})\, dx\, d\xi \\ &+\frac{1}{2\nu}\int_z^l \int_{S_\xi} (\xi - z)^2 w_i w_i v_3\, dx\, d\xi - \frac{1}{3\nu}\int_z^l \int_{S_\xi} (\xi - z)^2 w_i (w_j + v_j) v_{i,j}\, dx\, d\xi \\ &-\frac{1}{3\nu}\int_z^l \int_{S_\xi} (\xi - z)^3 w_i w_j w_{i,j}\, dx\, d\xi.\end{aligned} \tag{4.9}$$

We have thus written $\Phi(z)$ as the sum of eleven integrals Φ_k each of which we must now bound in terms of Φ and $d\Phi/dz$. We indicate here how this can be done for four representative Φ_k; the remaining seven integrals are treated in Appendix I. We note that all but Φ_9 and Φ_{10} can be bounded in terms of $d\Phi/dz$ alone. As we shall see, the bounds on Φ_9 and Φ_{10} will generate a decay criterion.

Consider first

$$\Phi_3 = \int_z^l \int_{S_\xi} (\xi - z)^2 \psi_{\alpha,j} w_{\alpha,j}\, dx\, d\xi$$
$$= \int_z^l \int_{S_\xi} (\xi - z)^2 \psi_{\alpha,\beta} w_{\alpha,\beta}\, dx\, d\xi + \int_z^l \int_{S_\xi} (\xi - z)^2 \psi_{\alpha,3} w_{\alpha,3}\, dx\, d\xi.$$

Using Schwarz's inequality and inequalities (3.1), (3.2) and (3.6), we have

$$\Phi_3 \leqq \left(\frac{C}{\lambda_2}\right)^{1/2} \left(\int_z^l \int_{S_\xi} (\xi - z)^2 w_{3,\beta} w_{3,\beta}\, dx\, d\xi \right)^{1/2} \left(\int_z^l \int_{S_\xi} (\xi - z)^2 w_{\alpha,\beta} w_{\alpha,\beta}\, dx\, d\xi \right)^{1/2}$$
$$+ \left(\int_z^l \int_{S_\xi} (\xi - z)^2 w_{\alpha,3} w_{\alpha,3}\, dx\, d\xi \right)^{1/2} \left(\int_z^l \int_{S_\xi} (\xi - z)^2 \psi_{\alpha,3} \psi_{\alpha,3}\, dx\, d\xi \right)^{1/2}. \tag{4.10}$$

Since $\psi_\alpha = 0$ on ∂S_z, we have $\psi_{\alpha,3} = 0$ on ∂S_z and thus

$$\int_z^l \int_{S_\xi} (\xi - z)^2 \psi_{\alpha,3} \psi_{\alpha,3}\, dx\, d\xi \leqq \frac{1}{\lambda_1} \int_z^l \int_{S_\xi} (\xi - z)^2 \psi_{\alpha,\beta 3} \psi_{\alpha,\beta 3}\, dx\, d\xi$$
$$\leqq \frac{C}{\lambda_1} \int_z^l \int_{S_\xi} (\xi - z)^2 (\psi_{\alpha,\alpha 3})^2\, dx\, d\xi$$
$$= \frac{C}{\lambda_1} \int_z^l \int_{S_\xi} (\xi - z)^2 w_{3,3}^2\, dx\, d\xi$$

after application of inequalities (3.1) and (3.6). From the arithmetic-geometric mean inequality, we then obtain the bound

$$\Phi_3 \leqq -\frac{1}{2} \sqrt{\frac{C}{\lambda_1}} \frac{d\Phi}{dz}. \tag{4.11}$$

To bound $\Phi_5 = 1/\nu \int_z^l \int_{S_\xi} (\xi - z)^2 \psi_\alpha v_j w_{\alpha,j}\, dx\, d\xi$, we first rewrite the integral as

$$\Phi_5 = \frac{1}{\nu} \int_z^l \int_{S_\xi} (\xi - z)^2 \psi_\alpha w_{\alpha,3} V\, dx\, d\xi + \frac{1}{\nu} \int_z^l \int_{S_\xi} (\xi - z)^2 \psi_\alpha w_{\alpha,j} \zeta_j\, dx\, d\xi = I_1 + I_2$$

where $\zeta_j = v_j - V\delta_{3j}$. The first integral is bounded by applying the Schwarz and Poincaré inequalities. We have

$$I_1 \leqq \frac{v_s}{\nu \sqrt{\lambda_1}} \left(\int_z^l \int_{S_\xi} (\xi - z)^2 w_{\alpha,3} w_{\alpha,3}\, dx\, d\xi \right)^{1/2} \left(\int_z^l \int_{S_\xi} (\xi - z)^2 \psi_{\alpha,\beta} \psi_{\alpha,\beta}\, dx\, d\xi \right)^{1/2}$$

where $v_s = \max_{S_z} |V(x_1, x_2)|$. It then follows from (3.6), (3.2), and the arithmetic-geometric mean inequality that

$$I_1 \leqq -\frac{v_s}{2\nu} \sqrt{\frac{C}{\lambda_1 \lambda_2}} \frac{d\Phi}{dz}. \tag{4.12}$$

A bound for I_2 is established through the use of Schwarz's inequality and the inequalities (3.1)-(3.3) as well as (3.6). We obtain

$$I_2 \leqq \frac{1}{2\nu} \sqrt{\frac{C}{\lambda_2}} \left(\frac{1}{2\lambda_1}\right)^{1/4} \max_z \left(\int_{S_z} (\zeta_i \zeta_i)^2\, dx \right)^{1/4}$$
$$\cdot \left[\int_z^l \int_{S_\xi} (\xi - z)^2 w_{3,\beta} w_{3,\beta}\, dx\, d\xi + \int_z^l \int_{S_\xi} (\xi - z)^2 w_{\alpha,j} w_{\alpha,j}\, dx\, d\xi \right].$$

Consequently, we conclude that

$$\Phi_5 \leqq -\frac{v_s}{2\nu}\sqrt{\frac{C}{\lambda_1\lambda_2}}\frac{d\Phi}{dz} - \frac{1}{2\nu}\sqrt{\frac{C}{\lambda_2}}\left(\frac{1}{2\lambda_1}\right)^{1/4}\max_z\left(\int_{S_z}(\zeta_i\zeta_i)^2\,dx\right)^{1/4}\frac{d\Phi}{dz}. \tag{4.13}$$

Consider now

$$\Phi_9 = -\frac{1}{3\nu}\int_z^l\int_{S_\xi}(\xi-z)^3 w_3 w_\alpha V_{,\alpha}\,dx\,d\xi - \frac{1}{3\nu}\int_z^l\int_{S_\xi}(\xi-z)^3 w_i w_j \zeta_{i,j}\,dx\,d\xi = J_1 + J_2$$

with ζ_i defined as before. Integration of the first integral leads to

$$J_1 = \frac{1}{3\nu}\int_z^l\int_{S_\xi}(\xi-z)^3 w_\alpha w_{3,\alpha} V\,dx\,d\xi + \frac{1}{2\nu}\int_z^l\int_{S_\xi}(\xi-z)^2 w_3^2 V\,dx\,d\xi.$$

From Schwarz's inequality, (3.1), (3.2), and the arithmetic-geometric mean inequality, we obtain the bound

$$J_1 \leqq \frac{1}{3}\left(\frac{v_s}{2\nu\sqrt{\lambda_1}}\right)\left[\int_z^l\int_{S_\xi}(\xi-z)^3 w_{3,\alpha}w_{3,\alpha}\,dx\,d\xi + \int_z^l\int_{S_\xi}(\xi-z)^3 w_{\alpha,\beta}w_{\alpha,\beta}\,dx\,d\xi\right]$$
$$+\frac{v_s}{2\nu\lambda_2}\int_z^l\int_{S_\xi}(\xi-z)^2 w_{3,\beta}w_{3,\beta}\,dx\,d\xi.$$

Thus,

$$J_1 \leqq \frac{v_s}{2\nu\sqrt{\lambda_1}}\Phi - \frac{v_s}{2\nu\lambda_2}\frac{d\Phi}{dz}. \tag{4.14}$$

Turning to J_2, we observe that it may be rewritten as

$$J_2 = \frac{1}{3\nu}\int_z^l\int_{S_\xi}(\xi-z)^3 w_{i,j}w_j\zeta_i\,dx\,d\xi + \frac{1}{\nu}\int_z^l\int_{S_\xi}(\xi-z)^2 w_i w_3\zeta_i\,dx\,d\xi.$$

It then follows by applying Schwarz's inequality, (3.1)-(3.3), and the arithmetic-geometric mean inequality in the proper sequence that

$$J_2 \leqq \frac{1}{3\nu}\left(\frac{1}{2\lambda_1}\right)^{1/4}\max_z\left(\int_{S_z}(\zeta_i\zeta_i)^2\,dx\right)^{1/4}\int_z^l\int_{S_\xi}(\xi-z)^3 w_{i,j}w_{i,j}\,dx\,d\xi$$
$$+\frac{1}{2\nu\sqrt{\lambda_2}}\left(\frac{1}{2\lambda_1}\right)^{1/4}\max_z\left(\int_{S_z}(\zeta_i\zeta_i)^2\,dx\right)^{1/4}$$
$$\cdot\left[\int_z^l\int_{S_\xi}(\xi-z)^2 w_{i,\beta}w_{i,\beta}\,dx\,d\xi + \int_z^l\int_{S_\xi}(\xi-z)^2 w_{3,\beta}w_{3,\beta}\,dx\,d\xi\right].$$

Hence, we see that

$$J_2 \leqq \frac{1}{\nu}\left(\frac{1}{2\lambda_1}\right)^{1/4}\max_z\left(\int_{S_z}(\zeta_i\zeta_i)^2\,dx\right)^{1/4}\Phi - \frac{1}{\nu\sqrt{\lambda_2}}\left(\frac{1}{2\lambda_1}\right)^{1/4}\max_z\left(\int_{S_z}(\zeta_i\zeta_i)^2\,dx\right)^{1/4}\frac{d\Phi}{dz}. \tag{4.15}$$

Combining (4.14) and (4.15), we have a bound for Φ_9 in terms of Φ and $d\Phi/dz$.

Finally let us consider Φ_{10}, which we rewrite as the sum of three integrals:

$$\Phi_{10} = -\frac{1}{3\nu}\int_z^l\int_{S_\xi}(\xi-z)^3 w_i\zeta_i\zeta_{i,j}\,dx\,d\xi - \frac{1}{3\nu}\int_z^l\int_{S_\xi}(\xi-z)^3 w_i\zeta_{i,3}V\,dx\,d\xi$$
$$-\frac{1}{3\nu}\int_z^l\int_{S_\xi}(\xi-z)^3 w_3\zeta_\alpha V_{,\alpha}\,dx\,d\xi$$
$$= K_1 + K_2 + K_3.$$

We see that

$$K_1+K_2\leqq\frac{1}{3\nu}\int_z^l(\xi-z)^3\left(\int_{S_\xi}(\zeta_i\zeta_i)^2\,dx\right)^{1/4}\left(\int_{S_\xi}(w_iw_i)^2\,dx\right)^{1/4}\left(\int_{S_\xi}\zeta_{i,j}\zeta_{i,j}\,dx\right)^{1/2}d\xi$$
$$+\frac{v_s}{3\nu}\int_z^l(\xi-z)^3\left(\int_{S_\xi}w_iw_i\,dx\right)^{1/2}\left(\int_{S_\xi}\zeta_{i,3}\zeta_{i,3}\,dx\right)^{1/2}d\xi$$

from which, after applying the appropriate inequalities, it follows that

$$K_1+K_2\leqq\frac{1}{3\nu}\frac{1}{2}\left(\frac{1}{2\lambda_1}\right)^{1/4}\max_z\left(\int_{S_z}(\zeta_i\zeta_i)^2\,dx\right)^{1/4}$$
$$\cdot\left[a_1\int_z^l\int_{S_\xi}(\xi-z)^3w_{i,\beta}w_{i,\beta}\,dx\,d\xi+\frac{1}{a_1}\int_z^l\int_{S_\xi}(\xi-z)^3\zeta_{i,j}\zeta_{i,j}\,dx\,d\xi\right] \tag{4.16}$$
$$+\frac{1}{3}\frac{v_s}{2\nu\sqrt{\lambda_1}}\left[a_2\int_z^l\int_{S_\xi}(\xi-z)^3w_{i,\beta}w_{i,\beta}\,dx\,d\xi+\frac{1}{a_2}\int_z^l\int_{S_\xi}(\xi-z)^3\zeta_{i,3}\zeta_{i,3}\,dx\,d\xi\right]$$

where a_1 and a_2 are arbitrary positive constants. We now observe that integration, the fact that $\int_{S_z}\zeta_3\,dx=0$, and the divergence free condition allow us to express K_3 as

$$K_3=\frac{1}{3\nu}\int_z^l\int_{S_\xi}(\xi-z)^3w_{3,j}\zeta_jV\,dx\,d\xi+\frac{1}{\nu}\int_z^l\int_{S_\xi}(\xi-z)^3w_3\zeta_3V\,dx\,d\xi$$
$$\leqq\frac{1}{3}\frac{v_s}{2\nu\sqrt{\lambda_1}}\left[a_2\int_z^l\int_{S_\xi}(\xi-z)^3w_{3,j}w_{3,j}\,dx\,d\xi+\frac{1}{a_2}\int_z^l\int_{S_\xi}(\xi-z)^3\zeta_{j,\beta}\zeta_{j,\beta}\,dx\,d\xi\right] \tag{4.17}$$
$$+\frac{v_s}{2\nu\lambda_2}\left[\int_z^l\int_{S_\xi}(\xi-z)^2w_{3,\beta}w_{3,\beta}\,dx\,d\xi+\int_z^l\int_{S_\xi}(\xi-z)^2\zeta_{3,\beta}\zeta_{3,\beta}\,dx\,d\xi\right].$$

From (4.16) and (4.17), we thus conclude that

$$\Phi_{10}\leqq\left\{\frac{a_1}{2\nu}\left(\frac{1}{2\lambda_1}\right)^{1/4}\max_z\left(\int_{S_z}(\zeta_i\zeta_i)^2\,dx\right)^{1/4}+\frac{a_2v_s}{\nu\sqrt{\lambda_1}}\right\}\Phi$$
$$+\frac{v_s}{2\nu\lambda_2}\left[-\frac{d\Phi}{dz}+\int_z^l\int_{S_\xi}(\xi-z)^2\zeta_{i,j}\zeta_{i,j}\,dx\,d\xi\right] \tag{4.18}$$
$$+\left\{\frac{1}{6\nu a_1}\left(\frac{1}{2\lambda_1}\right)^{1/4}\max_z\left(\int_{S_z}(\zeta_i\zeta_i)^2\,dx\right)^{1/4}+\frac{v_s}{3\nu a_2\sqrt{\lambda_1}}\right\}$$
$$\cdot\int_z^l\int_{S_\xi}(\xi-z)^3\zeta_{i,j}\zeta_{i,j}\,dx\,d\xi.$$

In Appendix I, we derive the following inequalities:

$$\Phi_1\leqq\frac{-1}{2\sqrt{\lambda_1}}\frac{d\Phi}{dz}, \tag{4.19}$$

$$\Phi_2\leqq-2\sqrt{\frac{C}{\lambda_1}}\frac{d\Phi}{dz}, \tag{4.20}$$

$$\Phi_4\leqq-\frac{2}{\nu}\sqrt{\frac{C}{\lambda_1}}\left(\frac{1}{2\lambda_1}\right)^{1/4}\max_z\left(\int_{S_z}(w_\alpha w_\alpha)^2\,dx\right)^{1/4}\frac{d\Phi}{dz}, \tag{4.21}$$

$$\Phi_6\leqq-\frac{\sqrt{C}}{2\nu}\max_z\left(\int_{S_z}(\zeta_\alpha\zeta_\alpha)^2\,dx\right)^{1/4}\left[\frac{1}{\sqrt{\lambda_2}}\left(\frac{1}{2\lambda_1}\right)^{1/4}+\frac{5}{\sqrt{\lambda_1}}\left(\frac{1}{2\lambda_2}\right)^{1/4}\right]\frac{d\Phi}{dz}, \tag{4.22}$$

$$\Phi_7 \leqq \frac{1}{2\nu}\sqrt{\frac{C}{\lambda_2}}\left\{\left(\frac{1}{2\lambda_1}\right)^{1/4}\max_z\left(\int_{S_z}(\zeta_i\zeta_i)^2\,dx\right)^{1/4}+\frac{v_s}{\sqrt{\lambda_1}}\right\}$$
$$\cdot\left[-\frac{d\Phi}{dz}+\int_z^l\int_{S_\xi}(\xi-z)^2\zeta_{i,j}\zeta_{i,j}\,dx\,d\xi\right], \tag{4.23}$$

$$\Phi_8 \leqq -\frac{1}{2\nu}\left[\frac{1}{2\sqrt{\lambda_1}}\max_z\left(\int_{S_z}\zeta_3^2\,dx\right)^{1/2}+\frac{v_s}{\lambda_1}\right]\frac{d\Phi}{dz}, \tag{4.24}$$

$$\Phi_{11} \leqq -\frac{1}{2\nu\sqrt{2\lambda_1}}\max_z\left(\int_{S_z}w_3^2\,dx\right)^{1/2}\frac{d\Phi}{dz}. \tag{4.25}$$

Combining the relevant inequalities, we obtain the result

$$\Phi \leqq M_1\Phi - K\frac{d\Phi}{dz}+N \tag{4.26}$$

where

$$M_1=\frac{v_s}{2\nu\sqrt{\lambda_1}}(1+2a_2)+\frac{1}{\nu}\left(\frac{1}{2\lambda_1}\right)^{1/4}\max_z\left(\int_{S_z}(\zeta_i\zeta_i)^2\,dx\right)^{1/4}\left(1+\frac{a_1}{2}\right), \tag{4.27}$$

$$N=\left\{\frac{1}{6\nu a_1}\left(\frac{1}{2\lambda_1}\right)^{1/4}\max_z\left(\int_{S_z}(\zeta_i\zeta_i)^2\,dx\right)^{1/4}+\frac{v_s}{3\nu a_2\sqrt{\lambda_1}}\right\}\int_z^l\int_{S_\xi}(\xi-z)^3\zeta_{i,j}\zeta_{i,j}\,dx\,d\xi$$
$$+\left\{\frac{v_s}{2\nu\lambda_2}+\frac{1}{2\nu}\frac{\sqrt{C}}{\sqrt{\lambda_2}}\left[\left(\frac{1}{2\lambda_1}\right)^{1/4}\max_z\left(\int_{S_z}(\zeta_i\zeta_i)^2\,dx\right)^{1/4}+\frac{v_s}{\sqrt{\lambda_1}}\right]\right\} \tag{4.28}$$
$$\cdot\int_z^l\int_{S_\xi}(\xi-z)^2\zeta_{i,j}\zeta_{i,j}\,dx\,d\xi,$$

and

$$K=\frac{1}{2\sqrt{\lambda_1}}(1+5\sqrt{C})+\frac{v_s}{\nu}\left(\sqrt{\frac{C}{\lambda_1\lambda_2}}+\frac{1}{\lambda_2}+\frac{1}{2\lambda_1}\right)$$
$$+\frac{1}{2\nu\sqrt{2\lambda_1}}\left[\max_z\left(\int_{S_z}w_3^2\,dx\right)^{1/2}+\max_z\left(\int_{S_z}\zeta_3^2\,dx\right)^{1/2}\right]$$
$$+\frac{2}{\nu}\sqrt{\frac{C}{\lambda_2}}\left(\frac{1}{2\lambda_1}\right)^{1/4}\max_z\left(\int_{S_z}(w_\alpha w_\alpha)^2\,dx\right)^{1/4} \tag{4.29}$$
$$+\frac{\sqrt{C}}{2\nu}\left[\frac{1}{\sqrt{\lambda_2}}\left(\frac{1}{2\lambda_1}\right)^{1/4}+\frac{5}{\sqrt{\lambda_1}}\left(\frac{1}{2\lambda_2}\right)^{1/4}\right]\max_z\left(\int_{S_z}(\zeta_\alpha\zeta_\alpha)^2\,dx\right)^{1/4}$$
$$+\frac{1}{\nu\sqrt{\lambda_2}}\left(\frac{1}{2\lambda_1}\right)^{1/4}\left(1+\frac{3}{2}\sqrt{C}\right)\max_z\left(\int_{S_z}(\zeta_i\zeta_i)^2\,dx\right)^{1/4}.$$

We thus have the inequality

$$K\frac{d\Phi}{dz}+(1-M_1)\Phi \leqq N.$$

To ensure decay, we require

$$M \equiv 1-M_1 > 0. \tag{4.30}$$

This condition yields a restriction on the flow. We shall subsequently require a somewhat stronger hypothesis if decay is to occur. We shall consider these restrictions more thoroughly in § 7.

5. Bounds in the Stokes flow problem. The definitions of the constants M_1 and K involve the quantities $\max_z (\int_{S_z} w_3^2\,dx)^{1/2}$, $\max_z (\int_{S_z} (w_\alpha w_\alpha)^2\,dx)^{1/4}$, $\max_z (\int_{S_z} \zeta_3^2\,dx)^{1/2}$, and $\max_z (\int_{S_z} (\zeta_i\zeta_i)^2\,dx)^{1/4}$. In addition, we see that N is expressed in terms of the integrals $\int_z^l \int_{S_\xi} (\xi - z)^n \zeta_{i,j}\zeta_{i,j}\,dx\,d\xi$ $(n = 2, 3)$. Since we would like our estimate to depend only on the parameter ν, the boundary data, and the geometry of the domain, we need to obtain bounds for the aforementioned expressions in terms of these quantities. The task of obtaining such estimates ultimately reduces to one of deriving bounds in terms of the geometry and the data for the linearized Stokes problem. This section will be devoted to finding these bounds. We note that our analysis is modeled on that used by Payne [11] in his investigation of uniqueness criteria for steady state solutions of the Navier-Stokes equations. In § 6 we shall address the problem of deriving bounds for the energy associated with the velocity field $\zeta_i = v_i - V\delta_{3i}$.

5.1. Estimates for $\mathscr{L}_2$ and energy integrals. We first observe that since $w_{i,i} = 0$,

$$\int_{S_z} w_3^2\,dx = -2\int_z^l \int_{S_\xi} w_3 w_{3,3}\,dx\,d\xi$$

$$= -(2-a)\int_z^l \int_{S_\xi} w_3 w_{3,3}\,dx\,d\xi - a\int_z^l \int_{S_\xi} w_\alpha w_{3,\alpha}\,dx\,d\xi$$

for any constant a. Application of Schwarz's inequality, (3.1), (3.2), and the arithmetic-geometric mean inequality then lead for $0 < a < 2$ to

$$\int_{S_z} w_3^2\,dx \leqq \frac{ac}{2\sqrt{\lambda_1}}\int_z^l \int_{S_\xi} w_{\alpha,\beta} w_{\alpha,\beta}\,dx\,d\xi + \frac{(2-a)b}{2\sqrt{\lambda_2}}\int_z^l \int_{S_\xi} w_{3,3}^2\,dx\,d\xi$$

$$+\left(\frac{2-a}{2b\sqrt{\lambda_2}} + \frac{a}{2c\sqrt{\lambda_1}}\right)\int_z^l \int_{S_\xi} w_{3,\beta} w_{3,\beta}\,dx\,d\xi \tag{5.1}$$

where b and c are positive constants that we choose so that the coefficients of the three integrals in (5.1) are equal. Then,

$$\int_{S_z} w_3^2\,dx \leqq \frac{\sqrt{\lambda_1(2-a)^2 + \lambda_2 a^2}}{2\sqrt{\lambda_1\lambda_2}}\int_z^l \int_{S_\xi} w_{i,j} w_{i,j}\,dx\,d\xi.$$

The optimal choice $a = 2\lambda_1/(\lambda_1 + \lambda_2)$ leads to the result

$$\int_{S_z} w_3^2\,dx \leqq \frac{1}{\sqrt{\lambda_1} + \sqrt{\lambda_2}}\int_z^l \int_{S_\xi} w_{i,j} w_{i,j}\,dx\,d\xi. \tag{5.2}$$

A bound on $\max_z (\int_{S_z} w_3^2\,dx)^{1/2}$ in terms of $\int_0^l \int_S w_{i,j} w_{i,j}\,dx\,dz$ where S is a generic cross section easily follows from (5.2).

We can also bound $\max_z (\int_{S_z} (w_\alpha w_\alpha)^2\,dx)^{1/4}$ in terms of $\int_0^l \int_S w_{i,j} w_{i,j}\,dx\,dz$ since

$$\int_{S_z} (w_\alpha w_\alpha)^2\,dx = -4\int_z^l \int_{S_\xi} w_\alpha w_{\alpha,3} w_\beta w_\beta\,dx\,d\xi$$

$$\leqq 4\left(\int_z^l \int_{S_\xi} w_{\alpha,3} w_{\alpha,3}\,dx\,d\xi\right)^{1/2}\left(\int_z^l \int_{S_\xi} (w_\alpha w_\alpha)^3\,dx\,d\xi\right)^{1/2}$$

by Schwarz's inequality. Applying the Sobolev inequality (3.4),[1] we obtain

$$\int_{S_z} (w_\alpha w_\alpha)^2 \, dx \leqq 8\Omega^{1/2}\left(\int_0^l \int_{S_\xi} w_{i,j} w_{i,j} \, dx \, dz\right)^2. \tag{5.3}$$

This inequality then leads to the desired bound.

In view of these expressions, we must now obtain a bound for $\int_0^l \int_S w_{i,j} w_{i,j} \, dx \, dz$. To accomplish this, we introduce an auxiliary vector field F_i that satisfies the Stokes problem

$$\begin{aligned} &\nu \Delta F_i = \tilde{q}_{,i} \quad \text{in } R = S \times [0, l], \\ &F_{i,i} = 0 \quad \text{in } R, \\ &F_i = w_i \quad \text{on } \partial R. \end{aligned} \tag{5.4}$$

Our task is now twofold. We shall first compare the energy $\int_0^l \int_S w_{i,j} w_{i,j} \, dx \, dz$ to the energy $\int_0^l \int_S F_{i,j} F_{i,j} \, dx \, dz$ associated with (5.4). Second, we shall obtain a bound on the energy of the Stokes problem in terms of the geometry and boundary data (which are just the data for w_i). In this way, we are led to the desired bound on $\int_0^l \int_S w_{i,j} w_{i,j} \, dx \, dz$ in terms of its data and the geometry of the domain.

Let us begin by noting that since both w_i and F_i are divergence free and $w_i - F_i$ vanishes on ∂R, we have

$$\int_0^l \int_S w_{i,j} w_{i,j} \, dx \, dz - \int_0^l \int_S F_{i,j} F_{i,j} \, dx \, dz = \int_0^l \int_S (w_i - F_i)_{,j} (w_i - F_i)_{,j} \, dx \, dz. \tag{5.5}$$

Applying the divergence theorem to the integral on the right side of (5.5), making use of the governing equations, and adding in the term $(1/\nu) \int_0^l \int_S (w_i - F_i)(w_i - F_i)_{,j} u_j \, dx \, dz$, which clearly gives no contribution, we find that

$$I = \int_0^l \int_S (w_i - F_i)_{,j} (w_i - F_i)_{,j} \, dx \, dz = \frac{1}{\nu} \int_0^l \int_S (w_i - F_i)_{,j} (w_j + v_j)(v_i + F_i) \, dx \, dz.$$

Adding and subtracting the term $(1/\nu) \int_0^l \int_S (w_i - F_i)_{,j} v_i F_j \, dx \, dz$ and introducing $\zeta_i = v_i - V\delta_{3i}$, we obtain I as the sum of nine integrals I_k,

$$\begin{aligned} I = {} & \frac{1}{\nu} \int_0^l \int_S (w_i - F_i)_{,j} (w_j - F_j) \zeta_i \, dx \, dz + \frac{1}{\nu} \int_0^l \int_S (w_i - F_i)_{,j} (w_j - F_j) V\delta_{3i} \, dx \, dz \\ & + \frac{1}{\nu} \int_0^l \int_S (w_i - F_i)_{,j} w_j F_i \, dx \, dz + \frac{1}{\nu} \int_0^l \int_S (w_i - F_i)_{,j} (\zeta_i F_j + \zeta_j F_i) \, dx \, dz \\ & + \frac{1}{\nu} \int_0^l \int_S (w_i - F_i)_{,j} (F_j V\delta_{3i} + F_i V\delta_{3j}) \, dx \, dz \\ & + \frac{1}{\nu} \int_0^l \int_S (w_i - F_i)_{,j} \zeta_i \zeta_j \, dx \, dz + \frac{1}{\nu} \int_0^l \int_S (w_3 - F_3)_{,\alpha} \zeta_\alpha V \, dx \, dz \\ & - \frac{1}{\nu} \int_0^l \int_S (w_3 - F_3) \zeta_{3,3} V \, dx \, dz + \frac{1}{\nu} \int_0^l \int_S (w_i - F_i)_{,3} \zeta_i V \, dx \, dz. \end{aligned} \tag{5.6}$$

Each of the I_k can be bounded in terms of I, $\int_0^l \int_S w_{i,j} w_{i,j} \, dx \, dz$, $\int_0^l \int_S F_{i,j} F_{i,j} \, dx \, dz$ and $\int_0^l \int_S \zeta_{i,j} \zeta_{i,j} \, dx \, dz$. Using these bounds and (5.5), we can obtain a bound for

[1] To apply (3.4) we have extended w_i as an even function across $z = 0$.

$\int_0^l \int_S w_{i,j} w_{i,j}\, dx\, dz$. In Appendix II, we outline how the proper use of inequalities and (5.5) leads us to the inequality

$$\begin{aligned}&\{1-k_1 v_s - k_2 \mathscr{F}^{1/2} - k_3 \mathscr{H}^{1/2}\} \int_0^l \int_S w_{i,j} w_{i,j}\, dx\, dz \\ &\leqq \left\{1 - k_4 v_s - \frac{k_2}{2} \mathscr{F}^{1/2} - k_5 \mathscr{H}^{1/2}\right\} \mathscr{F} + \{k_6 v_s + k_7 \mathscr{H}^{1/2}\} \mathscr{H}\end{aligned} \tag{5.7}$$

where

$$\mathscr{F} = \int_0^l \int_S F_{i,j} F_{i,j}\, dx\, dz \quad \text{and} \quad \mathscr{H} = \int_0^l \int_S \zeta_{i,j} \zeta_{i,j}\, dx\, dz.$$

Here the k_i are positive constants defined by

$$\begin{aligned} k_1 &= \frac{1}{2\nu\sqrt{\lambda_1}} [\sqrt{(\lambda_1+\lambda_2)/\lambda_2}\,(1+\varepsilon_1) + \hat{c}], \\ k_2 &= \frac{1}{\nu}\left(\frac{4}{\lambda_1}\right)^{1/4} \Omega^{1/8}, \qquad k_3 = k_2(1+\delta), \\ k_4 &= k_1 - \frac{2}{\hat{c}\nu\sqrt{\lambda_1}}, \qquad k_5 = k_3 - \frac{2}{\delta} k_2, \\ k_6 &= \frac{1}{\varepsilon_1 \nu\sqrt{\lambda_1}} \sqrt{(\lambda_1+\lambda_2)/\lambda_2}, \qquad k_7 = \frac{1}{2\delta} k_2 \end{aligned} \tag{5.8}$$

where $0 < \varepsilon_1 \ll 1$, $0 < \delta \ll 1$, and $\hat{c}$ is an arbitrary positive constant. Inequality (5.7) is the desired bound on $\int_0^l \int_S w_{i,j} w_{i,j}\, dx\, dz$ provided

$$1 - k_1 v_s - k_2 \mathscr{F}^{1/2} - k_3 \mathscr{H}^{1/2} > 0. \tag{5.9}$$

As we discuss in § 7, this condition generates another restriction on the flow if energy decay is to occur.

5.2. Estimates for the Stokes flow. We now turn to the task of finding a bound for $\int_0^l \int_S F_{i,j} F_{i,j}\, dx\, dz$ in terms of the boundary data and geometry. Here we shall assume in order to make our results explicit that the region $R = S \times [0, l]$ is star-shaped. With a little more effort a bound for the Stokes flow energy can be found for regions that are not star-shaped (see Payne [11]), but we will not pursue this topic in the present paper.

We first observe that

$$\int_R F_{i,j} F_{i,j}\, d\mathscr{V} = \int_R F_{i,j}(F_{i,j} - F_{j,i})\, d\mathscr{V} - \int_{S_0} (F_{3,\alpha} F_\alpha - F_{\alpha,\alpha} F_3)\, dx, \tag{5.10}$$

since F_i is divergence free and vanishes everywhere on ∂R except on S_0. Consequently, to obtain the desired bound we need to estimate the first integral on the right side of (5.10). Let $y_k = x_k + d\delta_{k3}$ where $d = \min_{\partial R \setminus S_0 \cup S_l} x_\alpha n_\alpha$ and consider the identity

$$\begin{aligned} 0 &= \frac{1}{\nu} \int_R y_k F_{i,k} (\nu \Delta F_i - \tilde{q}_{,i})\, d\mathscr{V} \\ &= -\frac{1}{\nu} \int_{\partial R} \tilde{q} y_k F_{i,k} n_i\, d\mathscr{S} + \int_{\partial R} y_k F_{i,k}(F_{i,j} - F_{j,i}) n_j\, d\mathscr{S} \\ &\quad + \frac{1}{2} \int_R F_{i,j}(F_{i,j} - F_{j,i})\, d\mathscr{V} - \frac{1}{2} \int_{\partial R} y_k n_k F_{i,j}(F_{i,j} - F_{j,i})\, d\mathscr{S}. \end{aligned} \tag{5.11}$$

Rewriting (5.11), we have

$$\frac{1}{2}\int_R F_{i,j}(F_{i,j}-F_{j,i})\,d\mathcal{V}=\frac{1}{\nu}\int_{S_0}\tilde{q}y_k(F_{i,k}n_i-F_{i,i}n_k)\,dx$$
$$-\int_{\partial R}y_k(n_jF_{i,k}-n_kF_{i,j})(F_{i,j}-F_{j,i})\,d\mathcal{S} \tag{5.12}$$
$$-\frac{1}{2}\int_{\partial R}y_kn_kF_{i,j}(F_{i,j}-F_{j,i})\,d\mathcal{S}.$$

It follows from Schwarz's inequality and the arithmetic-geometric mean inequality that

$$\frac{1}{2}\int_R F_{i,j}(F_{i,j}-F_{j,i})\,d\mathcal{V}$$
$$\leqq\left(\frac{a}{2}-\frac{1}{4}\right)\int_{\partial R}y_kn_k(F_{i,j}-F_{j,i})(F_{i,j}-F_{j,i})\,d\mathcal{S} \tag{5.13}$$
$$+\frac{1}{2a}\int_{S_0}\frac{y_sy_s}{y_ln_l}(n_jF_{i,k}-n_kF_{i,j})(n_jF_{i,k}-n_kF_{i,j})\,dx$$
$$+\frac{1}{2b}\int_{S_0}(y_\alpha F_{3,\alpha}-y_3F_{\alpha,\alpha})(y_\beta F_{3,\beta}-y_3F_{\beta,\beta})\,dx+\frac{b}{2\nu^2}\int_{S_0}\tilde{q}^2\,dx$$

for positive constants a and b, $a<\frac{1}{2}$. In Appendix III, we derive a bound for the last term of (5.13) of the form

$$\int_{S_0}\tilde{q}^2\,dx\leqq\frac{\nu^2\alpha_1}{4}\int_{\partial R}(F_{i,j}-F_{j,i})(F_{i,j}-F_{j,i})\,d\mathcal{S} \tag{5.14}$$

with an explicit constant α_1. Substituting (5.14) for the pressure term in (5.13), we obtain the result

$$\frac{1}{2}\int_R F_{i,j}(F_{i,j}-F_{j,i})\,d\mathcal{V}$$
$$\leqq\left[\left(\frac{a}{2}-\frac{1}{4}\right)d+\frac{b\alpha_1}{8}\right]\int_{\partial R}(F_{i,j}-F_{j,i})(F_{i,j}-F_{j,i})\,d\mathcal{S} \tag{5.15}$$
$$+\frac{1}{2a}\left(\frac{r_M^2+d^2}{d}\right)\int_{S_0}(n_jF_{i,k}-n_kF_{i,j})(n_jF_{i,k}-n_kF_{i,j})\,dx$$
$$+\frac{1}{2b}\int_{S_0}(y_\alpha F_{3,\alpha}-y_3F_{\alpha,\alpha})(y_\beta F_{3,\beta}-y_3F_{\beta,\beta})\,dx$$

where $r_M^2=\max_{S_0}x_\alpha x_\alpha$. We now choose a and b in such a way that $(a/2-\frac{1}{4})d+b\alpha_1/8=0$ and thus obtain from (5.15) a bound for $\int_R F_{i,j}(F_{i,j}-F_{j,i})\,d\mathcal{V}$ in terms of the given data and geometry. From (5.10) we then have the bound

$$\int_R F_{i,j}F_{i,j}\,d\mathcal{V}\leqq\frac{1}{a}\left(\frac{r_M^2+d^2}{d}\right)\int_{S_0}(n_jF_{i,k}-n_kF_{i,j})(n_jF_{i,k}-n_kF_{i,j})\,dx$$
$$+\frac{1}{b}\int_{S_0}(y_\alpha F_{3,\alpha}-y_3F_{\alpha,\alpha})(y_\beta F_{3,\beta}-y_3F_{\beta,\beta})\,dx \tag{5.16}$$
$$-\int_{S_0}(F_{3,\alpha}F_\alpha-F_{\alpha,\alpha}F_3)\,dx.$$

Using Schwarz's inequality and the arithmetic-geometric mean inequality leads to the result

$$\int_R F_{i,j}F_{i,j}\,d\mathcal{V} \leqq \gamma_1 \int_{S_0} F_iF_i\,dx + \gamma_2 \int_{S_0} F_{i,\alpha}F_{i,\alpha}\,dx \tag{5.17}$$

where the positive constants γ_1 and γ_2 can be explicitly computed and depend only on the geometry of the domain.

6. The Stokes flow problem for ζ_i. The purpose of this section is to briefly discuss the bounds for the flow associated with the velocity field ζ_i that are needed to complete our analysis. We first observe that the ζ_i satisfy

$$\begin{aligned} &\nu\Delta\zeta_i = \tilde{s}_{,i} \quad \text{in } R,\\ &\zeta_{i,i} = 0 \quad \text{in } R,\\ &\zeta_i = 0 \quad \text{on } \partial R\backslash S_l,\\ &\zeta_i = g_i - V\delta_{3i} \quad \text{on } S_l. \end{aligned} \tag{6.1}$$

This problem is just the Stokes problem (5.4) except that here the data are nonzero on S_l instead of S_0. Consequently, the bounds we need for this flow can be derived in much the same manner as those for (5.4) with some modifications.

Recall that we require estimates for $\max_z (\int_{S_z} \zeta_3^2\,dx)^{1/2}$, $\max_z (\int_{S_z} (\zeta_i\zeta_i)^2\,dx)^{1/4}$, and $\int_z^l \int_{S_\xi} (\xi - z)^n \zeta_{i,j}\zeta_{i,j}\,dx\,d\xi$ to make our decay inequality explicit. The first two quantities can be bounded using the methods of § 5.1 with the result that

$$\int_{S_z} \zeta_3^2\,dx \leqq \frac{1}{\sqrt{\lambda_1+\lambda_2}} \int_0^z \int_{S_\xi} \zeta_{i,j}\zeta_{i,j}\,dx\,d\xi \tag{6.2}$$

and

$$\int_{S_z} (\zeta_i\zeta_i)^2\,dx \leqq 8\Omega^{1/2}\left(\int_0^l \int_{S_\xi} \zeta_{i,j}\zeta_{i,j}\,dx\,dz\right)^2. \tag{6.3}$$

In addition, we observe that

$$J_n(z) = \int_z^l \int_{S_\xi} (\xi - z)^n \zeta_{i,j}\zeta_{i,j}\,dx\,d\xi \leqq l^n \int_0^l \int_S \zeta_{i,j}\zeta_{i,j}\,dx\,dz. \tag{6.4}$$

Thus, we again need to find an upper bound for the energy of a Stokes flow problem in terms of the data on S_l and geometry of the domain.

We will not go into the details of finding this bound but indicate where our previous analysis requires modification. Since the data are nonzero on S_l, we have upon integration and application of Schwarz's inequality

$$\begin{aligned} \int_R \zeta_{i,j}\zeta_{i,j}\,d\mathcal{V} &= \int_{S_l} \zeta_i(\zeta_{i,3} - \zeta_{3,i})\,dx + \int_{S_l} \zeta_i\zeta_{3,i}\,dx - \frac{1}{\nu}\int_{S_l} \zeta_3\tilde{s}\,dx\\ &\leqq \left(\int_{S_l} \zeta_i\zeta_i\,dx\right)^{1/2}\left(\int_{\partial R} (\zeta_{i,j} - \zeta_{j,i})(\zeta_{i,j} - \zeta_{j,i})\,d\mathcal{S}\right)^{1/2}\\ &\quad + \left(\int_{S_l} \zeta_3^2\,dx\right)^{1/2}\left(\int_{S_l} \tilde{s}^2\,dx\right)^{1/2} + \int_{S_l} [\zeta_\alpha\zeta_{3,\alpha} - \zeta_3\zeta_{\alpha,\alpha}]\,dx. \end{aligned}$$

The bound on $\int_{S_l} \tilde{s}^2\,dx$ can be found using the analysis of Appendix III with the obvious modification that $\partial G/\partial n = \tilde{s}$ on S_l and is zero elsewhere. To bound $\int_{\partial R} (\zeta_{i,j}-\zeta_{j,i})(\zeta_{i,j}-\zeta_{j,i})\,d\mathscr{S}$, we integrate, instead of (5.11), the identity

$$0 = \int_R [x_k - (l-d)\delta_{k3}]\zeta_{i,k}(\nu\Delta\zeta_i - \tilde{s}_{,i})\,d\mathscr{V}$$

where d is given following (5.10).

The final result is that we can compute explicit constants β_1, β_2 that depend only on the geometry of the domain such that

$$\int_0^l \int_S \zeta_{i,j}\zeta_{i,j}\,dx\,dz \leqq \beta_1 \int_{S_l} \zeta_i\zeta_i\,dx + \beta_2 \int_{S_l} \zeta_{i,\alpha}\zeta_{i,\alpha}\,dx. \tag{6.5}$$

We thus have bounds for the quantities that appear in M_1 and K as well as $J_n(z)$ $(n=2,3)$ in terms of the geometry and data of the problem.

For future use let us write

$$J_3(z) \leqq \kappa_3 l^3 Q_0 \tag{6.6}$$

where Q_0 is the data term in (6.5).

7. Discussion of results.

7.1. Comparison of entrance and fully-developed flows. In the last few sections, we have shown that provided certain conditions hold, $\Phi(z)$ satisfies an inequality of the form (4.2) where the constants K and M depend on v_s, ν, the boundary data, and the geometry. The data term N also depends on these quantities and in view of (6.4) and (6.5) is of order l^3. From (4.2), we can thus obtain the estimate (4.3) that we shall now use to compare u_i and $V\delta_{3i}$. Since $\omega_i = u_i - V\delta_{3i} = w_i + \zeta_i$, we see that

$$\begin{aligned}\left(\int_z^l \int_{S_\xi} (\xi-z)^3\omega_{i,j}\omega_{i,j}\,dx\,d\xi\right)^{1/2} &\leqq \left(\int_z^l \int_{S_\xi} (\xi-z)^3 w_{i,j}w_{i,j}\,dx\,d\xi\right)^{1/2} \\ &\quad + \left(\int_z^l \int_{S_\xi} (\xi-z)^3\zeta_{i,j}\zeta_{i,j}\,dx\,d\xi\right)^{1/2}.\end{aligned} \tag{7.1}$$

The first integral on the right of (7.1) is just a multiple of $\Phi(z)$ while the second is $\sqrt{J_3(z)}$. It then follows that

$$E(\omega_i) \equiv \frac{1}{3}\int_z^l \int_{S_\xi} (\xi-z)^3\omega_{i,j}\omega_{i,j}\,dx\,d\xi \leqq \left(1+\frac{\sqrt{\kappa_3}}{\sqrt{\kappa_2}}\right)\Phi(0)\,e^{-\kappa_1 z} + (\sqrt{\kappa_2}+\sqrt{\kappa_3})^2 l^3 Q_0 \tag{7.2}$$

where κ_2 and κ_3 are given by (4.3) and (6.6). Inequality (7.2) provides an upper bound for the weighted energy associated with the difference of velocities between the entrance flow and the fully developed flow measured over the portion of the pipe between S_z and S_l. If (7.2) is to be meaningful when l is large, then we need to assume that

$$\begin{aligned} Q_0 &\equiv \beta_1 \int_{S_l} \zeta_i\zeta_i\,dx + \beta_2 \int_{S_l} \zeta_{i,\alpha}\zeta_{i,\alpha}\,dx \\ &\equiv \beta_1 \int_{S_l} (g_i - V\delta_{3i})(g_i - V\delta_{3i})\,dx + \beta_2 \int_{S_l} (g_i - V\delta_{3i})_{,\alpha}(g_i - V\delta_{3i})_{,\alpha}\,dx \\ &\leqq \frac{\varepsilon^2}{l^3}\end{aligned} \tag{7.3}$$

for some $\varepsilon \ll 1$. In that case $E(\omega_i)$ will be bounded by a term that decays exponentially in z plus a term that is $O(\varepsilon^2)$.

7.2. Decay criteria. In the course of our analysis, we have imposed two restrictions on the flow to ensure that the first term in (7.2) decays. Let us examine these conditions more closely. We have from (4.30) and (5.9) the following conditions:

(1) $1-(v_s/2\nu\sqrt{\lambda_1})(1+2a_2)-k_2(1+a_1/2)\mathscr{H}^{1/2}>0$,

(2) $1-k_1v_s-k_2\mathscr{F}^{1/2}-k_3\mathscr{H}^{1/2}>0$

where the k_i, $\mathscr{H}$, and $\mathscr{F}$ are as defined in § 5 and a_1, a_2 are positive arbitrary constants, chosen so that condition (1) holds. Both of these conditions yield two pieces of information: (i) a restriction on ν and (ii) a restriction on the boundary data. From (1) we obtain

$$\beta_1\int_{S_l}\zeta_i\zeta_i\,dx+\beta_2\int_{S_l}\zeta_{i,\alpha}\zeta_{i,\alpha}\,dx\leqq\left\{\left[\frac{1}{k_2(1+a_1/2)}\right]\left[1-\frac{v_s}{2\nu\sqrt{\lambda_1}}(1+2a_2)\right]\right\}^2 \tag{7.4}$$

provided $1-(v_s/2\nu\sqrt{\lambda_1})(1+2a_2)>0$, or choosing $a_2=\varepsilon_2/2\ll 1$

$$\nu>\frac{v_s}{2\sqrt{\lambda_1}}(1+\varepsilon_2). \tag{7.5}$$

Condition (2) yields

$$\begin{aligned}&k_2\left(\gamma_1\int_{S_0}w_iw_i\,dx+\gamma_2\int_{S_0}w_{i,\alpha}w_{i,\alpha}\,dx\right)^{1/2}\\&\quad+k_3\left(\beta_1\int_{S_l}\zeta_i\zeta_i\,dx+\beta_2\int_{S_l}\zeta_{i,\alpha}\zeta_{i,\alpha}\,dx\right)^{1/2}\leqq 1-k_1v_s.\end{aligned} \tag{7.6}$$

We thus require $1-k_1v_s>0$ which, in view of our definition of k_1 translates into the viscosity restriction

$$\nu>\frac{v_s}{2\sqrt{\lambda_1}}\left[\frac{\sqrt{\lambda_1+\lambda_2}}{\sqrt{\lambda_2}}(1+\varepsilon_1)+\hat{c}\right]. \tag{7.7}$$

We are at liberty to choose $\hat{c}\ll 1$, but in any case if (7.7) is satisfied then so is (7.5). We thus see that condition (1) is actually contained in (2).

The two conditions (7.7) and (7.6) indicate that our inequality is valid only for flows with sufficiently large viscosity coefficients (or, with the proper definition, small Reynolds' numbers), and for flows whose data are suitably restricted.

7.3. Bounds for v_s and λ_2. To make our inequalities more explicit, we shall now demonstrate how an upper bound for v_s in terms of the geometry of the domain and the prescribed data can be obtained. We make use here of some results for the Saint-Venant torsion problem in a simply connected plane domain S. The torsion function Ψ satisfies

$$\Delta\Psi=-2 \quad \text{in } S, \qquad \Psi=0 \quad \text{on } \partial S.$$

In view of (2.11)-(2.13) and the relation $\tilde{p}_{,i}=-P\delta_{3i}$, we may express V in terms of the torsion function, the torsional rigidity $T\equiv 2\int_S\Psi\,dx$, and the net inflow Q. We have (see, e.g., [7])

$$V=\frac{2Q}{T}\Psi$$

and thus

$$v_s \leqq 2Q\frac{\Psi_M}{T}$$

where Ψ_M is the maximum value of the torsion function on S. We now need an upper bound on Ψ_M/T. For a simply connected domain, we have the isoperimetric inequality (see [12]),

$$2\pi\Psi_M^2 \leqq T.$$

Using this inequality, we see that

$$v_s \leqq Q\sqrt{\frac{2}{\pi T}}. \tag{7.8}$$

The desired upper bound can be obtained from (7.8) once we find a lower bound for the torsional rigidity. Such bounds for various domains are available in the literature or can be derived using monotony arguments [12], [15]. We mention here two results: (1) the inequality of Pólya and Szegö [15] for a star-shaped domain

$$T \geqq A^2R^{-1}$$

where A is the area of S and $R = \int_{\partial S}(xn_x + yn_y)^{-1}\,ds$, and (2) the bound obtained by Payne and Weinberger [14] for convex domains

$$T \geqq \frac{A^2}{2\pi}[1 - 2D^2(1-D^2)^{-1} - 4D^4(1-D^2)^{-2}\log D]$$

where $D^2 = 1 - 4\pi AL^{-2}$, A is the area of S, and L is the length of the perimeter.

Recall from § 3 that $\lambda_2 \geqq \lambda_1$. We can actually get a sharper bound for λ_2 in terms of the first two positive eigenvalues μ_1 $(=\lambda_1)$ and μ_2 of the fixed membrane problem using Weinstein's method [18] and the Payne-Rayner inequality [13]. We shall not go into the details of this derivation but merely record the lower bound that can be obtained. We find that

$$\lambda_2 \geqq \mu_1 + \left(\frac{\mu_2 - \mu_1}{A\mu_1}\right)4\pi$$

where A is the cross-sectional area.

7.4. Bound for $\Phi(0)$. Finally, we shall briefly indicate how an upper bound for $\Phi(0)$ can be derived. Using (4.9) with z replaced by zero, we may write $\Phi(0)$ as the sum of eleven integrals, each of which may be bounded in terms of $\Phi(0)$, $\int_0^l \int_S w_{i,j}w_{i,j}\,dx\,dz$, and $\int_0^l \int_S \zeta_{i,j}\zeta_{i,j}\,dx\,dz$. These bounds are generated in much the same way as those for the $\Phi_k(z)$ by making use of the appropriate integral inequalities. The major difference here is that it is necessary to use Hölder's inequality and Young's inequality in place of the Schwarz and arithmetic-geometric mean inequalities, respectively. We omit the derivation of these estimates since we assume by now the reader is familiar with the general procedure. The result is an inequality of the form

$$\mathcal{D}\Phi(0) \leqq \gamma_3 \int_0^l \int_S w_{i,j}w_{i,j}\,dx\,dz + \gamma_4 \int_0^l \int_S \zeta_{i,j}\zeta_{i,j}\,dx\,dz \tag{7.9}$$

where γ_3 and γ_4 are positive constants,

$$\mathcal{D} = 1 - k_1 v_s - k_3\mathcal{H}^{1/2} - \delta_1$$

and $0<\delta_1\ll 1$. Provided $\mathscr{D}>0$ and in view of the results of §§ 5 and 6, (7.9) yields an upper bound for $\Phi(0)$ in terms of the geometry and data. Note that we are guaranteed that $\mathscr{D}>0$ once we impose (5.9).

We conclude here by remarking that, in view of the results of this section, the constants in our estimates depend only on ν, the geometry of the domain, and the prescribed boundary data.

8. Concluding remarks. We note here that if we were to assume that v_i and the fully developed flow are identical, then we would recover Horgan and Wheeler's results with a slightly better decay constant. In fact, we would obtain instead of (4.2) the inequality

$$K\frac{d\Phi}{dz}+M\Phi\leqq 0$$

where $M=1-v_s/2\nu\sqrt{\lambda_1}$. Consequently, we may conclude that our methodology, although it bears much resemblance to that of the aforementioned authors, yields a slightly sharper decay rate.

We also observe that our estimate for $\Phi(z)$ can be used to obtain bounds on other integral quantities associated with the difference flow w_i. For example, we could find upper bounds for a weighted $\mathscr{L}_2$ integral of w_i or the ordinary $\mathscr{L}_2$ integral over a subdomain.

The case of a semi-infinite pipe is of some interest. In this case our results are still valid for $0\leqq z\leqq l$, where now we may think of Q_0 not as data but as the value of the combination of the "unknown" indicated integrals over that section. It becomes clear then from (7.2) and the arguments leading to (7.9) that if (5.9) is satisfied, and provided

$$\lim_{z\to\infty}\left[\beta_1\int_{S_z}\zeta_i\zeta_i\,dx+\beta_2\int_{S_z}\zeta_{i,\alpha}\zeta_{i,\alpha}\,dx\right]z^3=0,$$

we may conclude that

$$\int_z^\infty\int_{S_\xi}(\xi-z)^3w_{i,j}w_{i,j}\,dx\,d\xi\leqq\left[\int_0^\infty\int_{S_\xi}\xi^3w_{i,j}w_{i,j}\,dx\,d\xi\right]e^{-\kappa_1 z},$$

an inequality reminiscent of the exponential decay exhibited by the St. Venant Principle of classical elasticity.

Appendix I. In this Appendix, we derive the upper bounds given in (4.19)-(4.25) of the main text. We begin by considering

$$\Phi_1=-\int_z^l\int_{S_\xi}(\xi-z)^2w_iw_{i,3}\,dx\,d\xi.$$

Schwarz's inequality, (3.1), and the arithmetic-geometric mean inequality then yield

$$\Phi_1\leqq\frac{1}{2}\frac{1}{\sqrt{\lambda_1}}\int_z^l\int_{S_\xi}(\xi-z)^2w_{i,j}w_{i,j}\,dx\,d\xi$$

from which (4.19) follows. For Φ_2, we see that

$$\begin{aligned}\Phi_2&=-\int_z^l\int_{S_\xi}(\xi-z)^2(\psi_\alpha w_{\alpha,3})_{,3}\,dx\,d\xi=2\int_z^l\int_{S_\xi}(\xi-z)\psi_\alpha w_{\alpha,3}\,dx\,d\xi\\&\leqq 2\left(\int_z^l\int_{S_\xi}(\xi-z)^2w_{\alpha,3}w_{\alpha,3}\,dx\,d\xi\right)^{1/2}\left(\int_z^l\int_{S_\xi}\psi_\alpha\psi_\alpha\,dx\,d\xi\right)^{1/2}.\end{aligned}\tag{I.1}$$

Now

$$\int_z^l \int_{S_\xi} \psi_\alpha \psi_\alpha \, dx \, d\xi = -2 \int_z^l \int_{S_\xi} (\xi - z) \psi_{\alpha,3} \psi_\alpha \, dx \, d\xi$$

$$\leqq 2 \left(\int_z^l \int_{S_\xi} \psi_\alpha \psi_\alpha \, dx \, d\xi \right)^{1/2} \left(\int_z^l \int_{S_\xi} (\xi - z)^2 \psi_{\alpha,3} \psi_{\alpha,3} \, dx \, d\xi \right)^{1/2}.$$

Thus, we find that

$$\left(\int_z^l \int_{S_\xi} \psi_\alpha \psi_\alpha \, dx \, d\xi \right)^{1/2} \leqq 2 \left(\int_z^l \int_{S_\xi} (\xi - z)^2 \psi_{\alpha,3} \psi_{\alpha,3} \, dx \, d\xi \right)^{1/2}$$

and, recalling that $\psi_{\alpha,3} = 0$ on ∂S_z, we have from (3.1) and (3.7) the bound

$$\left(\int_z^l \int_{S_\xi} \psi_\alpha \psi_\alpha \, dx \, d\xi \right)^{1/2} \leqq 2 \sqrt{\frac{C}{\lambda_1}} \left(\int_z^l \int_{S_\xi} (\xi - z)^2 w_{3,3}^2 \, dx \, d\xi \right)^{1/2}. \tag{I.2}$$

Substituting this result in (I.1) and applying the arithmetic-geometric mean inequality results in the estimate (4.20).

To bound Φ_4, we first integrate by parts and write it as the sum of three integrals:

$$\Phi_4 = \frac{1}{\nu} \int_z^l \int_{S_\xi} (\xi - z)^2 \psi_\alpha w_{\alpha,j} w_j \, dx \, d\xi = \sum_{i=1}^{3} \Phi_4^i$$

$$= \frac{1}{\nu} \int_z^l \int_{S_\xi} (\xi - z)^2 \psi_{\alpha,\beta} w_\beta w_\alpha \, dx \, d\xi - \frac{1}{\nu} \int_z^l \int_{S_\xi} (\xi - z)^2 \psi_{\alpha,3} w_3 w_\alpha \, dx \, d\xi$$

$$- \frac{2}{\nu} \int_z^l \int_{S_\xi} (\xi - z) \psi_\alpha w_\alpha w_3 \, dx \, d\xi.$$

Each of these three integrals can now be bounded using Schwarz's inequality, (3.1)-(3.3), (3.6), and the arithmetic-geometric mean inequality. We have

$$\Phi_4^1 \leqq \frac{1}{\nu} \int_z^l (\xi - z)^2 \left(\int_{S_\xi} (w_\alpha w_\alpha)^2 \, dx \right)^{1/4} \left(\int_{S_\xi} (w_\beta w_\beta)^2 \, dx \right)^{1/4} \left(\int_{S_\xi} \psi_{\alpha,\beta} \psi_{\alpha,\beta} \, dx \right)^{1/2} d\xi$$

$$\leqq \frac{\sqrt{C}}{\nu} \max_z \left(\int_{S_z} (w_\alpha w_\alpha)^2 \, dx \right)^{1/4}$$

$$\cdot \int_z^l (\xi - z)^2 \left(\int_{S_\xi} w_3^2 \, dx \right)^{1/2} \left[\frac{1}{2} \left(\int_{S_\xi} w_\alpha w_\alpha \, dx \right) \left(\int_{S_\xi} w_{\alpha,\beta} w_{\alpha,\beta} \, dx \right) \right]^{1/4} d\xi \tag{I.3}$$

$$\leqq \frac{1}{2\nu} \left(\frac{1}{2\lambda_1} \right)^{1/4} \sqrt{\frac{C}{\lambda_2}} \max_z \left(\int_{S_z} (w_\alpha w_\alpha)^2 \, dx \right)^{1/4}$$

$$\cdot \left\{ \int_z^l \int_{S_\xi} (\xi - z)^2 w_{3,\beta} w_{3,\beta} \, dx \, d\xi + \int_z^l \int_{S_\xi} (\xi - z)^2 w_{\alpha,\beta} w_{\alpha,\beta} \, dx \, d\xi \right\}.$$

An analogous process leads to the bound

$$\Phi_4^2 \leqq \frac{1}{2\nu} \left(\frac{1}{2\lambda_1} \right)^{1/4} \sqrt{\frac{C}{\lambda_2}} \max_z \left(\int_{S_z} (w_\alpha w_\alpha)^2 \, dx \right)^{1/4}$$

$$\cdot \left\{ \int_z^l \int_{S_\xi} (\xi - z)^2 w_{3,3}^2 \, dx \, d\xi + \int_z^l \int_{S_\xi} (\xi - z)^2 w_{3,\beta} w_{3,\beta} \, dx \, d\xi \right\}. \tag{I.4}$$

Finally, it follows from (3.3), (3.1), and (3.6) that

$$\int_{S_z}(\psi_\alpha\psi_\alpha)^2\,dx \leqq \frac{1}{2}\left(\int_{S_z}\psi_\alpha\psi_\alpha\,dx\right)\left(\int_{S_z}\psi_{\alpha,\beta}\psi_{\alpha,\beta}\,dx\right) \leqq \frac{1}{2\lambda_1}\left(\int_{S_z}\psi_{\alpha,\beta}\psi_{\alpha,\beta}\,dx\right)^2$$
$$\leqq \frac{C^2}{2\lambda_1}\left(\int_{S_z} w_3^2\,dx\right)^2$$

and therefore

$$\Phi_4^3 \leqq \frac{2}{\nu}\int_z^l (\xi - z)\left(\int_{S_\xi}(\psi_\alpha\psi_\alpha)^2\,dx\right)^{1/4}\left(\int_{S_\xi}(w_\alpha w_\alpha)^2\,dx\right)^{1/4}\left(\int_{S_\xi} w_3^2\,dx\right)^{1/2} d\xi$$
$$\leqq \frac{2}{\nu}\left(\frac{C^2}{2\lambda_1}\right)^{1/4}\max_z\left(\int_{S_z}(w_\alpha w_\alpha)^2\,dx\right)^{1/4}\int_z^l\int_{S_\xi}(\xi - z)w_3^2\,dx\,d\xi.$$

Now, since $\int_z^l\int_{S_\xi}(\xi - z)w_3^2\,dx\,d\xi = -\int_z^l\int_{S_\xi}(\xi - z)w_3 w_{3,3}\,dx\,d\xi$, we find after application of (3.2) and the arithmetic-geometric mean inequality that

$$\Phi_4^3 \leqq \frac{1}{\nu}\left(\frac{1}{2\lambda_1}\right)^{1/4}\sqrt{\frac{C}{\lambda_2}}\max_z\left(\int_{S_z}(w_\alpha w_\alpha)^2\,dx\right)^{1/4}$$
$$\cdot\left\{\int_z^l\int_{S_\xi}(\xi - z)^2 w_{3,\beta}w_{3,\beta}\,dx\,d\xi + \int_z^l\int_{S_\xi}(\xi - z)^2 w_{3,3}^2\,dx\,d\xi\right\}. \tag{I.5}$$

Combining (I.3)-(I.5), we then obtain (4.21).

Turning now to Φ_6, we write

$$\Phi_6 = \frac{1}{\nu}\int_z^l\int_{S_\xi}(\xi - z)^2\psi_\alpha w_j v_{\alpha,j}\,dx\,d\xi = -\frac{1}{\nu}\int_z^l\int_{S_\xi}(\xi - z)^2\psi_{\alpha,\beta}w_\beta\zeta_\alpha\,dx\,d\xi$$
$$-\frac{1}{\nu}\int_z^l\int_{S_\xi}(\xi - z)^2\psi_{\alpha,3}w_3\zeta_\alpha\,dx\,d\xi - \frac{2}{\nu}\int_z^l\int_{S_\xi}(\xi - z)\psi_\alpha w_3\zeta_\alpha\,dx\,d\xi$$

where $\zeta_i = v_i - V\delta_{3i}$.

Again, the appropriate inequalities applied to each of the three integrals in this expression for Φ_6 will lead to the bound

$$\Phi_6 \leqq \frac{1}{2\nu}\left(\frac{1}{2\lambda_1}\right)^{1/4}\sqrt{\frac{C}{\lambda_2}}\max_z\left(\int_{S_z}(\zeta_\alpha\zeta_\alpha)^2\right)^{1/4}$$
$$\cdot\left[\int_z^l\int_{S_\xi}(\xi - z)^2 w_{3,\beta}w_{3,\beta}\,dx\,d\xi + \int_z^l\int_{S_\xi}(\xi - z)^2 w_{\alpha,\beta}w_{\alpha,\beta}\,dx\,d\xi\right]$$
$$+\frac{5}{2\nu}\left(\frac{1}{2\lambda_2}\right)^{1/4}\sqrt{\frac{C}{\lambda_1}}\max_z\left(\int_{S_z}(\zeta_\alpha\zeta_\alpha)^2\right)^{1/4}$$
$$\cdot\left[\int_z^l\int_{S_\xi}(\xi - z)^2 w_{3,\beta}w_{3,\beta}\,dx\,d\xi + \int_z^l\int_{S_\xi}(\xi - z)^2 w_{3,3}^2\,dx\,d\xi\right]$$

from which (4.22) easily follows.

Consider now

$$\Phi_7 = \frac{1}{\nu}\int_z^l\int_{S_\xi}(\xi - z)^2\psi_\alpha v_j v_{\alpha,j}\,dx\,d\xi$$
$$= \frac{1}{\nu}\int_z^l\int_{S_\xi}(\xi - z)^2\psi_\alpha\zeta_j\zeta_{\alpha,j}\,dx\,d\xi + \frac{1}{\nu}\int_z^l\int_{S_\xi}(\xi - z)^2\psi_\alpha V\zeta_{\alpha,3}\,dx\,d\xi$$
$$\leqq \frac{1}{\nu}\int_z^l(\xi - z)^2\left(\int_{S_\xi}(\psi_\alpha\psi_\alpha)^2\,dx\right)^{1/4}\left(\int_{S_\xi}(\zeta_i\zeta_i)^2\,dx\right)^{1/4}\left(\int_{S_\xi}(\zeta_{\alpha,j}\zeta_{\alpha,j})^2\,dx\right)^{1/2} d\xi$$

$$(I.6)\qquad +\frac{v_s}{\nu}\int_z^l (\xi-z)^2\left(\int_{S_\xi}(\psi_\alpha\psi_\alpha)^2\,dx\right)^{1/2}\left(\int_{S_\xi}\zeta_{\alpha,3}\zeta_{\alpha,3}\,dx\right)^{1/2}d\xi$$

$$\leqq\frac{1}{2\nu}\left(\frac{1}{2\lambda_1}\right)^{1/4}\sqrt{\frac{C}{\lambda_2}}\max_z\left(\int_{S_z}(\zeta_i\zeta_i)^2\,dx\right)^{1/4}$$

$$\cdot\left[\int_z^l\int_{S_\xi}(\xi-z)^2w_{3,\beta}w_{3,\beta}\,dx\,d\xi+\int_z^l\int_{S_\xi}(\xi-z)^2\zeta_{\alpha,j}\zeta_{\alpha,j}\,dx\,d\xi\right]$$

$$+\frac{v_s}{2\nu\sqrt{\lambda_1}}\sqrt{\frac{C}{\lambda_2}}\left[\int_z^l\int_{S_\xi}(\xi-z)^2w_{3,\beta}w_{3,\beta}\,dx\,d\xi+\int_z^l\int_{S_\xi}(\xi-z)^2\zeta_{\alpha,3}\zeta_{\alpha,3}\,dx\,d\xi\right].$$

Inequality (4.23) then follows directly from (I.6).

Finally, bounds for Φ_8 and Φ_{11} are easily derivable using the same procedure. We find

$$\Phi_8=\frac{1}{2\nu}\int_z^l\int_{S_\xi}(\xi-z)^2w_iw_iv_3\,dx\,d\xi$$

$$=\frac{1}{2\nu}\int_z^l\int_{S_\xi}(\xi-z)^2w_iw_i\zeta_3\,dx\,d\xi+\frac{1}{2\nu}\int_z^l\int_{S_\xi}(\xi-z)^2w_iw_iV\,dx\,d\xi$$

$$\leqq\left[\frac{1}{2\nu}\frac{1}{\sqrt{2\lambda_1}}\max_z\left(\int_{S_z}\zeta_3^2\,dx\right)^{1/2}+\frac{v_s}{2\nu\lambda_1}\right]\int_z^l\int_{S_\xi}(\xi-z)^2w_{i,\beta}w_{i,\beta}\,dx\,d\xi$$

and

$$\Phi_{11}=\frac{1}{2\nu}\int_z^l\int_{S_\xi}(\xi-z)^2w_3w_iw_i\,dx\,d\xi$$

$$\leqq\frac{1}{2\nu\sqrt{2\lambda_1}}\max_z\left(\int_{S_z}w_3^2\,dx\right)^{1/2}\int_z^l\int_{S_\xi}(\xi-z)^2w_{i,\beta}w_{i,\beta}\,dx\,d\xi.$$

Appendix II. We will briefly indicate here how the inequality (5.7) is obtained from (5.5) and (5.6). The basic idea is to bound each of the integrals I_K in (5.6) in terms of I, $\int_0^l\int_S w_{i,j}w_{i,j}\,dx\,dz$, $\int_0^l\int_S F_{i,j}F_{i,j}\,dx\,dz$, and $\int_0^l\int_S\zeta_{i,j}\zeta_{i,j}\,dx\,dz$. Such bounds are derived by appropriately utilizing Schwarz's inequality, (3.1)–(3.3), and the arithmetic-geometric mean inequality. Since this is a somewhat tedious task, we will illustrate the methodology for only one integral and summarize the bounds for the other eight.

Let us consider I_3. We have

$$I_3=\frac{1}{\nu}\int_0^l\int_S(w_i-F_i)_{,j}w_jF_i\,dx\,dz$$

$$\leqq\frac{1}{\nu}\max_z\left(\int_S(F_iF_i)^2\,dx\right)^{1/4}\left(\int_0^l\int_S(w_i-F_i)_{,j}(w_i-F_i)_{,j}\,dx\,dz\right)^{1/2}$$

$$\cdot\left(\int_0^l\int_S(w_jw_j)^2\,dx\,dz\right)^{1/4}$$

$$\leqq\frac{1}{2\nu}\left(\frac{1}{2\lambda_1}\right)^{1/4}\max_z\left(\int_S(F_iF_i)^2\,dx\right)^{1/4}$$

$$\cdot\left[a_1\int_0^l\int_S(w_i-F_i)_{,j}(w_i-F_i)_{,j}\,dx\,dz+\frac{1}{a_1}\int_0^l\int_S w_{i,\beta}w_{i,\beta}\,dx\,dz\right]$$

after applying Schwarz's inequality twice and then using the Sobolev inequality (3.3) and arithmetic-geometric mean inequality.

We observe that the bounds for I_2, I_7, I_8, and I_9 can be combined in such a way that the constants arising from the arithmetic-geometric mean inequality can be chosen so as to optimize the coefficient of $\int_0^l \int_S (w_i - F_i)_{,j}(w_i - F_i)_{,j}\, dx\, dz$. In fact, we find that

$$I_2 + I_7 + I_8 + I_9 \leqq \frac{v_s}{2\nu\sqrt{\lambda_1}} \sqrt{\frac{\lambda_1+\lambda_2}{\lambda_2}} (1+\varepsilon_1) \int_0^l \int_S (w_i - F_i)_{,j}(w_i - F_i)_{,j}\, dx\, dz$$
$$+ \frac{v_s}{\varepsilon_1 \nu\sqrt{\lambda_1}} \sqrt{\frac{\lambda_1+\lambda_2}{\lambda_2}} \int_0^l \int_S \zeta_{i,j}\zeta_{i,j}\, dx\, dz$$

where $0 < \varepsilon_1 \ll 1$.

Combining our bounds, we have

$$\begin{aligned} I = &\int_0^l \int_S (w_i - F_i)_{,j}(w_i - F_i)_{,j}\, dx\, dz \\ \leqq &\left\{ \frac{v_s}{2\nu\sqrt{\lambda_1}} \sqrt{\frac{\lambda_1+\lambda_2}{\lambda_2}} (1+\varepsilon_1) + \hat{c} + \frac{b_2}{2\nu} \left(\frac{1}{2\lambda_1}\right)^{1/4} \max_z \left(\int_S (F_i F_i)^2\, dx \right)^{1/4} \right. \\ &\left. + \frac{1}{\nu} \left(\frac{1}{2\lambda_1}\right)^{1/4} \left(1 + a_1 + \frac{b_1}{2}\right) \max_z \left(\int_S (\zeta_i \zeta_i)^2\, dx \right)^{1/4} \right\} I \\ &+ \frac{1}{2b_2\nu} \left(\frac{1}{2\lambda_1}\right)^{1/4} \max_z \left(\int_S (F_i F_i)^2\, dx \right)^{1/4} \int_0^l \int_S w_{i,j} w_{i,j}\, dx\, dz \\ &+ \left\{ \frac{2v_s}{\hat{c}\nu\sqrt{\lambda_1}} + \frac{1}{a_1\nu} \left(\frac{1}{2\lambda_1}\right)^{1/4} \max_z \left(\int_S (\zeta_i \zeta_i)^2\, dx \right)^{1/4} \right\} \int_0^l \int_S F_{i,j} F_{i,j}\, dx\, dz \\ &+ \left\{ \frac{v_s}{\nu\varepsilon_1\sqrt{\lambda_1}} \sqrt{\frac{\lambda_1+\lambda_2}{\lambda_2}} + \frac{1}{2b_1\nu} \left(\frac{1}{\lambda_1}\right)^{1/4} \max_z \left(\int_S (\zeta_i \zeta_i)^2\, dx \right)^{1/4} \right\} \int_0^l \int_S \zeta_{i,j}\zeta_{i,j}\, dx\, dz \end{aligned}$$

where a_i, b_i $(i = 1, 2)$ and $\hat{c}$ are arbitrary positive constants. If we now make use of the identity (5.5), choose $b_2 = 1$, and rearrange the preceding inequality, we obtain

$$\begin{aligned} &\left\{ 1 - k_1 v_s - \frac{1}{\nu} \left(\frac{1}{2\lambda_1}\right)^{1/4} \left(1 + a_1 + \frac{b_1}{2}\right) \mathcal{M}_1 - \frac{1}{\nu} \left(\frac{1}{2\lambda_1}\right)^{1/4} \mathcal{M}_2 \right\} \int_0^l \int_S w_{i,j} w_{i,j}\, dx\, dz \\ &\quad \leqq \left\{ \frac{v_s}{\varepsilon\nu\sqrt{\lambda_1}} \sqrt{\frac{\lambda_1+\lambda_2}{\lambda_2}} + \frac{1}{2b_1\nu} \left(\frac{1}{2\lambda_1}\right)^{1/4} \mathcal{M}_1 \right\} \int_0^l \int_S \zeta_{i,j}\zeta_{i,j}\, dx\, dz \\ &\quad + \left\{ 1 - k_1 v_s + \frac{2v_s}{\hat{c}\nu\sqrt{\lambda_1}} - \frac{1}{\nu} \left(\frac{1}{2\lambda_1}\right)^{1/4} \left(1 + a_1 + \frac{b_1}{2} - \frac{1}{a_1}\right) \mathcal{M}_1 - \frac{1}{2\nu} \left(\frac{1}{2\lambda_1}\right)^{1/4} \mathcal{M}_2 \right\} \\ &\quad \cdot \int_0^l \int_S F_{i,j} F_{i,j}\, dx\, dz \end{aligned} \tag{II.1}$$

where

$$k_1 = \frac{1}{2\nu\sqrt{\lambda_1}} \sqrt{\frac{\lambda_1+\lambda_2}{\lambda_2}} (1+\varepsilon_1)$$

and

$$\mathcal{M}_1 = \max_z \left(\int_S (\zeta_i \zeta_i)^2\, dx \right)^{1/4}, \qquad \mathcal{M}_2 = \max_z \left(\int_S (F_i F_i)^2\, dx \right)^{1/4}.$$

It now remains to find bounds for $\mathcal{M}_1$ and $\mathcal{M}_2$. We observe that since $\zeta_i = 0$ on S_0

$$\begin{aligned}\int_S (\zeta_i\zeta_i)^2\,dx &= 4\int_0^z\int_{S_\xi} \zeta_i\zeta_i\zeta_j\zeta_{j,3}\,dx\,d\xi \\ &\leqq 4\left(\int_0^z\int_{S_\xi}(\zeta_i\zeta_i)^3\,dx\,d\xi\right)^{1/2}\left(\int_0^z\int_{S_\xi}\zeta_{j,3}\zeta_{j,3}\,dx\,d\xi\right)^{1/2} \\ &\leqq 8\Omega^{1/2}\left(\int_0^l\int_{S_\xi}\zeta_{i,j}\zeta_{i,j}\,dx\,dz\right)^2\end{aligned} \tag{II.2}$$

where we have used (3.4) to obtain (II.2). Consequently,

$$\mathcal{M}_1 \leqq 2^{3/4}\,\Omega^{1/8}\left(\int_0^l\int_S \zeta_{i,j}\zeta_{i,j}\,dx\,dz\right)^{1/2}. \tag{II.3}$$

Similarly, since $F_i = 0$ on S_l, we find that

$$\mathcal{M}_2 \leqq 2^{3/4}\,\Omega^{1/8}\left(\int_0^l\int_S F_{i,j}F_{i,j}\,dx\,dz\right)^{1/2}. \tag{II.4}$$

Substituting (II.3) and (II.4) into (II.1) and choosing $b_1 = 2a_1 = \delta$ for $0 < \delta \ll 1$, we obtain the results (5.7) and (5.8).

Appendix III. To derive the bound (5.15) for the pressure term in the Stokes flow problem, we first observe that $\tilde{q}$ is defined only up to an arbitrary constant and then fix it by requiring $\int_{S_0}\tilde{q}\,dx = 0$. Let us now introduce an auxiliary function G such that

$$\begin{aligned}&\Delta G = 0 \quad \text{in } R = S\times[0,l], \\ &\frac{\partial G}{\partial n} = 0 \quad \text{on } \partial R\backslash S_0, \\ &\frac{\partial G}{\partial n} = \tilde{q} \quad \text{on } S_0.\end{aligned} \tag{III.1}$$

We have

$$\int_{S_0}\tilde{q}^2\,dx = \int_{\partial R}\tilde{q}\frac{\partial G}{\partial n}\,d\mathcal{S} = \int_R \tilde{q}_{,i}G_{,i}\,d\mathcal{V} = \nu\int_R G_{,i}(F_{i,j}-F_{j,i})_{,j}\,d\mathcal{V}$$

and thus

$$\int_{S_0}\tilde{q}^2\,dx = \frac{\nu}{2}\int_{\partial R}(G_{,i}n_j - G_{,j}n_i)(F_{i,j}-F_{j,i})\,d\mathcal{S}.$$

An application of Schwarz's inequality yields the bound

$$\begin{aligned}\int_{S_0}\tilde{q}^2\,dx \leqq \frac{\nu}{2}&\left(\int_{\partial R}(F_{i,j}-F_{j,i})(F_{i,j}-F_{j,i})\,d\mathcal{S}\right)^{1/2} \\ &\cdot\left(\int_{\partial R}(G_{,i}n_j - G_{,j}n_i)(G_{,i}n_j - G_{,j}n_i)\,d\mathcal{S}\right)^{1/2}.\end{aligned} \tag{III.2}$$

We now need to bound the second integral on the right in terms of $\int_{S_0}(\partial G/\partial n)^2\,dx$.

For a region whose boundary is star-shaped with respect to the origin (which we take at the center of the section $z = l/2$), we have the following two identities:

$$\begin{aligned} 0 &= \int_0^l \int_S \left(\xi - \frac{l}{2}\right) G_{,\xi} \Delta G \, dx \, d\xi \\ &= \frac{1}{2}\int_0^l \int_S [G_{,\alpha}G_{,\alpha} - G_{,3}^2] \, dx \, d\xi - \frac{l}{4}\int_{S_0 \cup S_l} G_{,\alpha}G_{,\alpha} \, dx + \frac{l}{4}\int_{S_0} \tilde{q}^2 \, dx, \end{aligned} \tag{III.3}$$

$$\begin{aligned} 0 &= \int_0^l \int_S x_\alpha G_{,\alpha} \Delta G \, dx \, d\xi \\ &= \int_0^l \int_S G_{,3}^2 \, dx \, d\xi - \frac{1}{2}\int_{\partial S \times [0,l]} x_\alpha n_\alpha G_{,j} G_{,j} \, d\mathcal{S} + \int_{S_0} x_\alpha G_{,\alpha} \tilde{q} \, dx. \end{aligned} \tag{III.4}$$

Upon rewriting (III.3) and (III.4), we see that

(III.5)

$$\int_{S_0 \cup S_l} G_{,\alpha}G_{,\alpha} \, dx = \int_{S_0 \cup S_l} |\text{grad}_s \, G|^2 \, dx = \frac{2}{l}\int_0^l \int_S [G_{,\alpha}G_{,\alpha} - G_{,3}^2] \, dx \, d\xi + \int_{S_0} \tilde{q}^2 \, dx$$

and

$$\frac{1}{2}\int_{\partial S \times [0,l]} x_\alpha n_\alpha |\text{grad}_s \, G|^2 \, d\mathcal{S} = \int_{S_0} x_\alpha G_{,\alpha} \tilde{q} \, dx + \int_0^l \int_S G_{,3}^2 \, dx \, d\xi \tag{III.6}$$

where $|\text{grad}_s \, G|^2$ denotes the tangential derivatives, i.e.,

$$|\text{grad}_s \, G|^2 = \tfrac{1}{2}(n_k G_{,j} - n_j G_{,k})(n_k G_{,j} - n_j G_{,k}).$$

An application of Schwarz's inequality and the arithmetic-geometric mean inequality in (III.6) leads to the inequality

$$\int_{\partial S \times [0,l]} |\text{grad}_s \, G|^2 \, d\mathcal{S} \leqq \sigma \frac{r_M^2}{h}\int_{S_0} \tilde{q}^2 \, dx + \frac{1}{\sigma h}\int_{S_0} G_{,\alpha}G_{,\alpha} \, dx + \frac{2}{h}\int_0^l \int_S G_{,3}^2 \, dx \, d\xi \tag{III.7}$$

where $r_M^2 = \max_{S_0} x_\alpha x_\alpha$, $h = \min_{\partial S} x_\alpha n_\alpha$, and σ is a positive constant. If we now add (III.5) and (III.7) and choose $\sigma = 1/r_M$, we obtain

$$\int_{\partial R} |\text{grad}_s \, G|^2 \, d\mathcal{S} \leqq \left(1 + \frac{2r_M}{h}\right)\int_{S_0} \tilde{q}^2 \, dx + K \int_0^l \int_S G_{,j}G_{,j} \, dx \, d\xi \tag{III.8}$$

where

$$K = \max\left[\frac{2}{l}\left(1 + \frac{r_M}{h}\right), \frac{2}{h} - \frac{2}{l}\left(1 + \frac{r_M}{h}\right)\right].$$

Let us now consider $\int_0^l \int_S G_{,j}G_{,j} \, dx \, d\xi = J$. Since

$$J = \int_{S_0} G\tilde{q} \, dx \leqq \left(\int_{S_0} G^2 \, dx\right)^{1/2}\left(\int_{S_0} \tilde{q}^2 \, dx\right)^{1/2}$$

it follows that

$$J^2 \leqq \frac{1}{\mu_2}\left(\int_{S_0} G_{,\alpha}G_{,\alpha} \, dx\right)\left(\int_{S_0} \tilde{q}^2 \, dx\right)$$

where μ_2 is the first positive eigenvalue of the free membrane problem. In view of (III.5), we have

$$\mu_2 J^2 \leqq M^2 + \frac{2}{l} MJ$$

where $M = \int_{S_0} \tilde{q}^2 \, dx$. Solving this inequality, we conclude that

$$\text{(III.9)} \qquad \int_0^l \int_S G_{,j} G_{,j} \, dx \, d\xi \leqq \frac{1}{\mu_2 l} (1 + \sqrt{1 + \mu_2^2 l^2}) \int_{S_0} \tilde{q}^2 \, dx.$$

Inserting this inequality into (III.8), we then obtain the bound

$$\int_{\partial R} |\text{grad}_S \, G|^2 \, d\mathcal{S} \leqq \alpha_1 \int_{S_0} \tilde{q}^2 \, dx$$

where

$$\alpha_1 = \left(1 + \frac{2r_M}{h}\right) + \frac{K}{\mu_2 l} (1 + \sqrt{1 + \mu_2^2 l^2}).$$

From (III.2), it follows that

$$\int_{S_0} \tilde{q}^2 \, dx \leqq \frac{\alpha_1 \nu^2}{4} \int_{\partial R} (F_{i,j} - F_{j,i})(F_{i,j} - F_{j,i}) \, d\mathcal{S}.$$

FINITE-DIMENSIONAL ATTRACTORS ASSOCIATED WITH PARTLY DISSIPATIVE REACTION-DIFFUSION SYSTEMS*

MARTINE MARION†

Résumé. L'objet de cet article est d'étudier le comportement quand le temps tend vers l'infini des solutions de certains systèmes de réaction-diffusion partiellement dissipatifs. On considère deux types de problèmes: des systèmes avec des nonlinéarités polynomiales et des systèmes possédant une région positivement invariante. L'article démontre que le comportement à t infini peut être décrit par un attracteur universel, et des majorations des dimensions Hausdorff et fractale de cet attracteur sont établis. Ces résultats sont appliqués à plusieurs systèmes classiques issus de la biologie, de la physique et de la chimie.

Abstract. The long-time behavior of the solutions of some partly dissipative reaction-diffusion systems is studied. Two types of problems are considered: systems with a polynomial growth nonlinearity, and systems admitting a positively invariant region. It is shown that the long-time behavior can be described by a universal attractor, and bounds of the Hausdorff and fractal dimensions of this attractor are derived. The results are applied to several classical systems borrowed from mathematical biology, physics and chemistry.

Key words. attractors, reaction-diffusion equations, partly dissipative systems, fractal dimension

AMS(MOS) subject classifications. 35B40, 35K57, 35Q20

0. Introduction. It is now well known that many parabolic dissipative evolutionary equations possess a universal attractor that has finite Hausdorff and fractal dimensions. All trajectories converge to this attractor as time goes to infinity so that the long-time behavior of solutions depends actually on a finite number of degrees of freedom (see Temam [26] for an extensive review on the subject). In particular, in the case of reaction-diffusion equations, such questions have been investigated by Babin and Vishik [1], [2], Kopell and Ruelle [15], and Marion [18]. However, in these works, a strong dissipation assumption is required; namely, all diffusion coefficients are assumed to be positive.

The aim of this article is to derive the existence of finite-dimensional attractors for reaction-diffusion systems with vanishing diffusion coefficients. The mathematical study differs from the ones in [1], [2], [15], [18], mainly for two reasons:

(1) The semigroup associated with the problem is no longer compact.

(2) The methods used in [1], [2], [15], [18] to prove the finite dimensionality fail; the upper bound on the dimension of the attractor derived there goes to $+\infty$ as the diffusion tends to zero.

We will investigate two types of systems: those with a polynomial growth nonlinearity, and those admitting a positively invariant region.

We first study systems with a polynomial growth nonlinearity. A typical sample of systems we consider is

$$\frac{\partial u}{\partial t} - d\Delta u + h(u) + \sigma v = 0, \qquad \frac{\partial v}{\partial t} + \delta v + \gamma u = 0, \tag{0.1}$$

where $\delta > 0$, $\sigma, \gamma \in \mathbb{R}$, and h is a polynomial of odd degree with a positive leading coefficient. The precise assumptions on the equations are stated in § 1. In § 2, we derive the existence of a universal attractor by applying a general criterion of existence of

attractors used by Ghidaglia and Temam [10] for abstract nonlinear wave equations (see also the review of Hale [27] and the presentation in Temam [26]). We then prove an important regularity property of the attractor. Section 3 contains the estimates of the Hausdorff and fractal dimensions of the attractor; these estimates rely on the general method of Constantin, Foias and Temam [6] and on generalizations of the Sobolev-Lieb-Thirring inequalities proved in Ghidaglia, Marion, and Temam [11]. We conclude the section by applying our results to problem (0.1).

We then consider systems of reaction-diffusion equations admitting a positively invariant region as described by Chueh, Conley, and Smoller [3]. Section 4 contains the description of the equations; we assume in particular that the equations take the form

$$\frac{\partial u}{\partial t} - D\Delta u + f(x, u, v) = 0, \qquad \frac{\partial v}{\partial t} + G(x, u)v + g(x, u) = 0,$$

where u (respectively, v) takes its values in $\mathbb{R}^{m_1}$ (respectively, $\mathbb{R}^{m_2}$) and $G(x, u)$ is a square matrix of order m_2 with definite positive symmetric part. The existence of a universal attractor is proved in § 5. We also derive there the estimates of the Hausdorff and fractal dimensions of the attractor. In § 6 we apply our results to several classical systems, namely the nerve equations (Hodgkin-Huxley equations and FitzHugh-Nagumo equations), some equations related to solid combustion, and the Feld-Noyes equations arising in chemical kinetics.

The results presented here were announced in [28].

A few words about notation follow. Let Ω be an open bounded set of $\mathbb{R}^n$ with boundary Γ. For $p \in [1, +\infty]$, we denote by $L^p(\Omega)$ the space of measurable scalar functions on Ω for which

$$|u|_{L^p(\Omega)} = \left(\int_\Omega |u(x)|^p \, dx \right)^{1/p} < +\infty \quad \text{for } 1 \leqq p < \infty,$$

$$|u|_{L^\infty(\Omega)} = \operatorname*{ess\,sup}_{x \in \Omega} |u(x)| < +\infty \quad \text{for } p = +\infty.$$

We denote by $H^k(\Omega)$ the Sobolev space of scalar functions that are in $L^2(\Omega)$ together with their weak derivatives of order less than or equal to $k \in \mathbb{N}^*$. $H_0^1(\Omega)$ is the Hilbert subspace of $H^1(\Omega)$ made of functions vanishing on Γ.

We will also consider vector-valued functions and use the notation $\mathbb{L}^2(\Omega) = (L^2(\Omega))^m$, $\mathbb{H}^k(\Omega) = (H^k(\Omega))^m$, $\mathbb{H}_0^1(\Omega) = (H_0^1(\Omega))^m$. We denote by $(\cdot, \cdot)$ the scalar product on $\mathbb{L}^2(\Omega)$ and we equip $\mathbb{H}_0^1(\Omega)$ with the norm

$$\|u\| = \left(\sum_{i=1}^n \left| \frac{\partial u}{\partial x_1} \right|^2 \right)^{1/2}.$$

Let I be a bounded interval of $\mathbb{R}$ and let X be a Banach space. We denote by $L^p(I; X)$, $1 \leqq p \leqq +\infty$, the space of measurable functions f from I into X such that $\|f\|_X \in L^p(I)$. This is a Banach space for the norm

$$\|f\|_{L^p(I;X)} = \big| \|f\|_X \big|_{L^p(I)}.$$

Part I. Systems with a Polynomial Growth Nonlinearity

1. The equations and the semigroup. Let Ω denote an open bounded set of $\mathbb{R}^n$ with boundary Γ. We consider the following initial-boundary value problem involving a

vector function (u, v) from $\Omega\times\mathbb{R}^+$ into $\mathbb{R}^2$; (u, v) satisfies

$$\begin{aligned}&\frac{\partial u}{\partial t}-d\Delta u+h(x,u)+f(x,u,v)=0 \quad \text{in } \Omega\times\mathbb{R}^+,\\ &\frac{\partial v}{\partial t}+\sigma(x)v+g(x,u)=0 \quad \text{in } \Omega\times\mathbb{R}^+,\end{aligned} \tag{1.1}$$

together with the initial conditions

$$u(x,0)=u_0(x), \qquad v(x,0)=v_0(x), \tag{1.2}$$

and a boundary condition of either Dirichlet type

$$u=0 \quad \text{on } \Gamma, \tag{1.3}_1$$

or of Neumann type

$$\frac{\partial u}{\partial \nu}=0 \quad \text{on } \Gamma, \tag{1.3}_2$$

or of periodicity type

$$\Omega=(0,L)^n \quad u \text{ is } \Omega\text{-periodic.} \tag{1.3}_3$$

Here, the diffusion coefficient d is positive. Also, the functions h, f, σ and g are assumed to be twice continuously differentiable in all variables and to satisfy

$$\delta_1|u|^p-\delta_3\leqq h(x,u)u\leqq\delta_2|u|^p+\delta_3, \qquad p>2, \tag{1.4}$$

$$|f(x,u,v)|\leqq\delta_4(1+|u|^{p_1}+|v|), \qquad 0<p_1<p-1, \tag{1.5}$$

$$\sigma(x)\geqq\delta>0, \tag{1.6}$$

$$|g'_u(x,u)|\leqq\delta_5, \quad |g'_{x_i}(x,u)|\leqq\delta_5(1+|u|), \quad i=1,\cdots,n, \tag{1.7}$$

where the δ_i's are positive constants. We finally require the monotonicity assumption

$$(h'_u(x,u)+f'_u(x,u,v))\xi_1^2+f'_v(x,u,v)\xi_1\xi_2\geqq-\delta_6(\xi_1^2+\xi_2^2) \quad \forall(\xi_1,\xi_2)\in\mathbb{R}^2, \tag{1.8}$$

with $\delta_6\geqq 0$.

For the mathematical setting of problem (1.1)-$(1.3)_\alpha$ we introduce the functional spaces

$$H=\mathbb{L}^2(\Omega)=L^2(\Omega)^2, \qquad V=V_1\times L^2(\Omega),$$

where

$$V_1=\begin{cases}H_0^1(\Omega) & \text{for } \alpha=1,\\ H^1(\Omega) & \text{for } \alpha=2,\\ H_p^1(\Omega) & \text{for } \alpha=3,\end{cases}$$

where $H_p^k(\Omega)$, $k\in\mathbb{N}$, $\Omega=(0,L)^n$ denotes the space of functions that are locally in $H^k(\mathbb{R}^n)$ and are periodic with period L in each direction.[1]

With the above assumptions and using classical methods (see, for instance, Lions [16]), we can prove the following existence and uniqueness result.

[1] $u(x+Le_i)=u(x)$, where $(e_1,\cdots,e_n)$ denotes the canonical basis of $\mathbb{R}^n$.

PROPOSITION 1.1. *For (u_0, v_0) given in H, there exists a unique solution (u, v) of (1.1)-(1.3)$_\alpha$ satisfying*

$$(u, v) \in \mathscr{C}(\mathbb{R}^+, H),$$

$$u \in L^2(0, T; V_1) \cap L^p(Q_T), \quad Q_T = \Omega \times]0, T[\quad \text{for all } T > 0.$$

The mapping $(u_0, v_0) \to (u(t), v(t))$ is continuous on H.

2. The universal attractor. This section is devoted to the existence and to some properties of the universal attractor associated with (1.1)-(1.3)$_\alpha$. We first give in § 2.1, general definitions and results. We then prove in § 2.2 the existence of a universal attractor. Finally we conclude the section by deriving a regularity property of the universal attractor.

2.1. A general result on the existence of attractors. Let H be a subset of a Banach space $(E, |\ |)$ and let $S(t)$, $t \geqq 0$, be a semigroup of operators from H into itself. We recall that the *ω-limit set* of a subset $\mathscr{C}$ of H is defined by

$$\omega(\mathscr{C}) = \bigcap_{s \geqq 0} \overline{\bigcup_{t \geqq s} S(t)\mathscr{C}}^H.$$

A *functional invariant set* for the semigroup $S(t)$ is a set $\mathscr{X} \subset H$ such that

$$S(t)\mathscr{X} = \mathscr{X} \quad \forall t > 0.$$

If an invariant set $\mathscr{A}$, compact in H, possesses an open neighborhood $\mathscr{U}$ such that the image by $S(t)$ of any bounded subset of $\mathscr{U}$ converges to $\mathscr{A}$ as $t \to +\infty$, then $\mathscr{A}$ is called an *attractor* and the largest open set that contains $\mathscr{A}$ and that enjoys the same property as $\mathscr{U}$ is called the *basin of attraction* of $\mathscr{A}$. The *universal attractor*, if it exists, is the only attractor that admits H for basin of attraction, i.e., the image by $S(t)$ of any bounded set in H converges to $\mathscr{A}$ when $t \to +\infty$.

A set $\mathscr{B} \subset H$ is said to be *absorbing* for the semigroup $S(t)$ if, for every bounded set $\mathscr{B}_0$ of H, there exists $T = T(\mathscr{B}_0)$ such that $S(t)\mathscr{B}_0 \subset \mathscr{B}$, for all $t \geqq T(\mathscr{B}_0)$.

The following assumptions are made on the semigroup $S(t)$. First:

(2.1) $S(t)$ is continuous from H into itself, for all $t > 0$.

We also require that, for every t, $S(t) = S_1(t) + S_2(t)$, where the operators S_1, S_2 map H into E and satisfy the following:

(2.2) The operators $S_1(t)$ are uniformly compact in the following sense: for every bounded set $\mathscr{B}$ in H, there exists $t_0 \geqq 0$, such that $\bigcup_{t \geqq t_0} S_1(t)\mathscr{B}$ is relatively compact in E.

(2.3) For every bounded set $\mathscr{B} \subset H$, $r_{\mathscr{B}}(t) = \sup_{\varphi \in \mathscr{B}} |S_2(t)\varphi| \to 0$ as $t \to +\infty$.

We now recall a general result ensuring the existence of a universal attractor.

THEOREM 2.1. *We assume that (2.1)-(2.3) are satisfied and that there exists a bounded absorbing set $\mathscr{B}$. Then, the ω-limit set of $\mathscr{B}$, $\mathscr{A} = \omega(\mathscr{B})$, is the universal attractor for $S(t)$ in H. Furthermore, if H is convex, then $\mathscr{A}$ is connected.*

We conclude the section by a remark that will be useful in the sequel. Under the assumptions of Theorem 2.1, the universal attractor $\mathscr{A}$ is also the ω-limit set of $\mathscr{B}$ for the family of operators S_1, i.e.,

$$\mathscr{A} = \bigcap_{s \geqq 0} \overline{\bigcup_{t \geqq s} S_1(t)\mathscr{B}}^E.$$

Hence, $u \in \mathscr{A}$ if and only if there exist a sequence $u_l \in \mathscr{B}$ and a sequence $t_l \to +\infty$ such that

$$S_1(t_l)u_l \to u \quad \text{as } l \to +\infty. \tag{2.4}$$

The reader is referred to Temam [26] for more details and in particular for the proof of Theorem 2.1.

2.2. Existence of a universal attractor. We apply here the concepts and the results of § 2.1 to the semigroup associated with (1.1)-(1.3)$_\alpha$.

THEOREM 2.2. *Under assumptions* (1.4)-(1.8), *the semigroup* $\{S(t)\}_{t\in\mathbb{R}_+}$ *associated with* (1.1)-(1.3)$_\alpha$ *possesses a universal attractor* $\mathscr{A}$ *that is connected in H.*

Proof of Theorem 2.2.

(a) *Energy estimates and the existence of an absorbing set.* We multiply the first equation (1.1) by u and the second one by v and integrate over Ω. Using the Green formula and (1.3)$_\alpha$, we obtain

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}(|u|^2+|v|^2)+d\|u\|^2+\int_\Omega \sigma(x)v^2\,dx+\int_\Omega h(x,u)u\,dx \\ &\quad+\int_\Omega (f(x,u,v)u+g(x,u)v)\,dx=0. \end{aligned} \tag{2.5}$$

Due to (1.7), there exists a constant $\delta_7>0$ such that

$$|g(x,\xi)| \leqq \delta_7(1+|\xi|) \quad \forall \xi\in\mathbb{R}, \quad \forall x\in\Omega. \tag{2.6}$$

Using also (1.4)-(1.6), we deduce from (2.5) that

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}(|u|^2+|v|^2)+d\|u\|^2+\delta|v|^2+\delta_1\int_\Omega |u|^p\,dx \\ &\quad\leqq \delta_3|\Omega|+c_1\int_\Omega (|u|+|u|^{p_1+1})\,dx+c_1\int_\Omega |v|(1+|u|)\,dx, \end{aligned} \tag{2.7}$$

with $c_1=\delta_4+\delta_7$. The last integral in (2.7) is then majorized as follows:

$$c_1\int_\Omega |v|(1+|u|)\,dx \leqq \frac{\delta}{2}\int_\Omega |v|^2\,dx+\frac{c_1^2}{2\delta}\int_\Omega (|u|+1)^2\,dx.$$

Also, when we set $q=\max(p_1+1,2)$, there exists a constant $c_2>0$ such that

$$c_1\left(|\xi|+|\xi|^{p_1+1}+\frac{c_1^2}{2\delta}(1+|\xi|)^2\right) \leqq c_2(|\xi|^q+1) \quad \forall \xi\in\mathbb{R}.$$

Hence

$$\begin{aligned} c_1\int_\Omega \left(|u|+|u|^{p_1+1}+\frac{c_1^2}{2\delta}(|u|+1)^2\right)dx &\leqq c_2\int_\Omega |u|^q\,dx+c_2|\Omega| \\ &\leqq \frac{\delta_1}{4}\int_\Omega |u|^p\,dx+c_3 \quad \text{(using Young's inequality).} \end{aligned}$$

Combining the above inequalities, we infer from (2.7) that

$$\frac{1}{2}\frac{d}{dt}(|u|^2+|v|^2)+d\|u\|^2+\frac{\delta}{2}|v|^2+\frac{3\delta_1}{4}\int_\Omega |u|^p\,dx \leqq \delta_3|\Omega|+c_3. \tag{2.8}$$

Again using Young's inequality, we have

$$\frac{\delta}{2}\int_\Omega |u|^2\,dx \leqq \frac{\delta_1}{4}\int_\Omega |u|^p\,dx + c_4.$$

Hence (2.8) implies

$$\frac{d}{dt}(|u|^2+|v|^2)+2d\|u\|^2+\delta(|u|^2+|v|^2)+\delta_1\int_\Omega |u|^p\,dx \leqq c_5, \tag{2.9}$$

where $c_5 = 2(\delta_3|\Omega| + c_3 + c_4)$; (2.9) gives in particular

$$\frac{d}{dt}(|u|^2+|v|^2)+\delta(|u|^2+|v|^2) \leqq c_5,$$

which yields, using Gronwall's lemma,

$$|u(t)|^2+|v(t)|^2 \leqq (|u_0|^2+|v_0|^2)\exp(-\delta t)+\frac{c_5}{\delta}(1-\exp(-\delta t)). \tag{2.10}$$

We deduce from (2.10) that any ball of H centered at zero and of radius $\rho_2 > \rho_1 = (c_5/\delta)^{1/2}$ is an absorbing set. Indeed, if $\mathcal{B}$ is a bounded set of H, included in a ball $B(0, R)$ of H centered at zero and of radius R, then $S(t)\mathcal{B} \subset B(0, \rho_2)$ for $t \geqq T_0 = T_0(\mathcal{B}, \rho_2)$

$$T_0 = \frac{1}{\delta}\log\frac{R^2}{\rho_2^2-\rho_1^2}.$$

Let $\rho_2 > \rho_1$ and $r > 0$ be fixed. We infer from (2.9) after integrating in t that

$$2d\int_t^{t+r}\|u\|^2\,ds+\delta_1\int_t^{t+r}\int_\Omega |u|^p\,dx\,ds \leqq rc_5+|u(t)|^2+|v(t)|^2 \quad \forall t \geqq 0. \tag{2.11}$$

Hence, for $(u_0, v_0) \in \mathcal{B} \subset B(0, R)$ and $t \geqq T_0$,

$$2d\int_t^{t+r}\|u\|^2\,ds+\delta_1\int_t^{t+r}\int_\Omega |u|^p\,dx\,ds \leqq rc_5+\rho_2^2. \tag{2.12}$$

Again integrating (2.9) in t, we also get for $(u_0, v_0) \in \mathcal{B} \subset B(0, R)$,

$$\int_0^t \|u\|^2\,ds \leqq \frac{1}{2d}(c_5 t + R^2) \quad \forall t \geqq 0. \tag{2.13}$$

(b) The solution v of (1.1) can be written $v(t) = v_1(t) + v_2(t)$ with

$$\begin{aligned} v_1(x, t) &= -\int_0^t g(x, u(x, s))\, e^{-\sigma(x)(t-s)}\,ds, \\ v_2(x, t) &= v_0(x)\exp(-\sigma(x)t), \end{aligned} \tag{2.14}$$

and we define two families S_1, S_2 of operators from H into H by setting

$$\begin{aligned} S_1(t) &: (u_0, v_0) \to (u(t), v_1(t)), \\ S_2(t) &: (u_0, v_0) \to (0, v_2(t)). \end{aligned} \tag{2.15}$$

It is straightforward that $S_2(t)$ satisfies (2.3); indeed, for every bounded set $\mathcal{B} \subset H$,

$$r_{\mathcal{B}}(t) \leqq \exp(-\delta t)\sup_{\varphi\in\mathcal{B}}|\varphi|.$$

Our aim now is to check the uniform compactness of the operators $S_1(t)$ by using uniform in time a priori estimates on $u(t)$ and $v_1(t)$.

We multiply the first equation in (1.1) by $-\Delta u$ and integrate over Ω. Thanks to $(1.3)_\alpha$ and the Green formula, this gives the energy-type relation

$$\frac{1}{2}\frac{d}{dt}\|u\|^2+d|\Delta u|^2=\int_\Omega h(x,u)\,\Delta u\,dx+\int_\Omega f(x,u,v)\,\Delta u\,dx.$$

Due to (1.4), there exists a constant $\delta_8>0$ such that

$$|h(x,\xi)|\leqq\delta_8(1+|\xi|^{p-1})\quad\forall\xi\in\mathbb{R},\quad\forall x\in\Omega.$$

Hence, using also (1.5), we get, setting $c_6=\max(\delta_8,\delta_4)$,

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\|u\|^2+d|\Delta u|^2&\leqq c_6\int_\Omega(2+|u|^{p_1}+|u|^{p-1}+|v|)|\Delta u|\,dx\\&\leqq\frac{d}{2}|\Delta u|^2+\frac{c_6^2}{2d}\int_\Omega(2+|u|^{p_1}+|u|^{p-1}+|v|)^2\,dx.\end{aligned}$$

Thus

$$\begin{aligned}\frac{d}{dt}\|u\|^2&\leqq\frac{4c_6^2}{d}\int_\Omega(4+|u|^{2p_1}+|u|^{2p-2}+|v|^2)\,dx\\&\leqq c_7\int_\Omega(1+|u|^{2p-2}+|v|^2)\,dx\quad(\text{since } p_1<p-1).\end{aligned}\tag{2.16}$$

□

We then apply the uniform Gronwall lemma, which we recall.

LEMMA 2.3. *Let g, h, y be three locally integrable scalar functions on $]t_0,\infty[$ satisfying*

$$\frac{dy}{dt}\in L^1_{\mathrm{loc}}(]t_0,+\infty[)\quad\text{and}\quad\frac{dy}{dt}\leqq gy+h\quad\text{for } t\geqq t_0,$$

$$\int_t^{t+r}g(s)\,ds\leqq a_1,\quad\int_t^{t+r}h(s)\,ds\leqq a_2,\quad\int_t^{t+r}y(s)\,ds\leqq a_3\quad\text{for } t\geqq t_0,$$

where r, a_1, a_2, a_3 are positive constants. Then

$$y(t+r)\leqq\left(\frac{a_3}{r}+a_2\right)\exp(a_1)\quad\forall t\geqq t_0.\tag{2.17}$$

The proof of this lemma can be found for instance in Foias, Manley, and Temam [9]. Thanks to the techniques of Lemma 2.5 below for $k=1$ and (2.12), we can check the existence of a constant c_8 such that for $(u_0,v_0)\in\mathcal{B}$ and $t\geqq T_0+r$

$$\int_t^{t+r}\int_\Omega|u|^{2p-2}\,dx\,ds\leqq c_8.$$

Hence, again using (2.12) and the existence of the absorbing set $B(0,\rho_2)$, we conclude that we can apply the uniform Gronwall lemma to (2.16) and we infer from (2.17) that

$$\begin{aligned}&\|u(t)\|^2\leqq c_9\quad\forall t\geqq T_0+2r,\\&c_9=\frac{1}{2dr}(rc_5+\rho_2^2)+c_7(r|\Omega|+c_8+r\rho_2^2).\end{aligned}\tag{2.18}$$

We now derive a time-uniform estimate of $v_1(t)$ in $H^1(\Omega)$. First, it is easy to deduce from (2.14) and (2.10) that there exists a constant $c_{10}=c_{10}(R)$ such that, for $(u_0, v_0)\in\mathcal{B}\subset B(0, R)$,

$$|v_1(t)|^2\leqq c_{10}(R)\quad \forall t\geqq 0. \tag{2.19}$$

We then set $w_j=\partial v_1/\partial x_j$, $j=1,\cdots,n$; w_j satisfies

$$\begin{aligned}&\frac{\partial w_j}{\partial t}+\sigma(x)w_j=-\sigma'_{x_j}(x)v_1-g'_{x_j}(x,u)-g'_u(x,u)\frac{\partial u}{\partial x_j},\\ &w_j(0)=0.\end{aligned} \tag{2.20}$$

The right-hand side of (2.20) satisfies the pointwise inequality (see (1.7))

$$\left|\sigma'_{x_j}(x)v_1+g'_{x_j}(x,u)+g'_u(x,u)\frac{\partial u}{\partial x_j}\right|\leqq(c_{11}+\delta_5)(1+|u|+|v_1|)+\delta_5\left|\frac{\partial u}{\partial x_j}\right|,$$

where $c_{11}=\max_{1\leqq j\leqq n}\max_{x\in\bar{\Omega}}|\sigma'_{x_j}(x)|$. Hence, by multiplying (2.20) by w_j and integrating over Ω, we find

$$\frac{1}{2}\frac{d}{dt}|w_j|^2+\delta|w_j|^2\leqq\frac{\delta}{2}|w_j|^2+\frac{1}{2\delta}\int_\Omega\left\{(c_{11}+\delta_5)(1+|u|+|v_1|)+\delta_5\left|\frac{\partial u}{\partial x_j}\right|\right\}^2 dx,$$

$$\frac{d}{dt}|w_j|^2+\delta|w_j|^2\leqq\frac{2}{\delta}(c_{11}+\delta_5)^2\int_\Omega(1+|u|+|v_1|)^2\,dx+\frac{2\delta_5^2}{\delta}\int_\Omega\left|\frac{\partial u}{\partial x_j}\right|^2 dx,$$

which, thanks to (2.19) and (2.10), for $(u_0, v_0)\in\mathcal{B}\subset B(0, R)$, gives

$$\begin{aligned}&\frac{d}{dt}|w_j|^2+\delta|w_j|^2\leqq c_{12}+\frac{2\delta_5^2}{\delta}\int_\Omega\left|\frac{\partial u}{\partial x_j}\right|^2 dx,\\ &c_{12}=c_{12}(R)=\frac{8}{\delta}(c_{11}+\delta_5)^2\left(|\Omega|+R^2+\frac{c_5}{\delta}+c_{10}\right).\end{aligned} \tag{2.21}$$

Summing (2.21) from $j=1$ to $j=n$, we finally obtain, for $(u_0, v_0)\in\mathcal{B}\subset B(0, R)$,

$$\frac{d}{dt}\|v_1\|^2+\delta\|v_1\|^2\leqq nc_{12}+\frac{2\delta_5^2}{\delta}\|u\|^2. \tag{2.22}$$

We then integrate this inequality; this gives, since $v_1(0)=0$,

$$\begin{aligned}\|v_1(t)\|^2&\leqq\frac{nc_{12}}{\delta}+\frac{2\delta_5^2}{\delta}\int_0^t\|u(s)\|^2\exp(\delta(s-t))\,ds\quad\forall t\geqq 0\\ &\leqq\frac{nc_{12}}{\delta}+\frac{2\delta_5^2}{\delta}\int_0^{T_0+2r}\|u(s)\|^2\exp(\delta(s-t))\,ds\\ &\quad+\frac{2\delta_5^2}{\delta}\int_{T_0+2r}^t\|u(s)\|^2\exp(\delta(s-t))\,ds\\ &\leqq\frac{nc_{12}}{\delta}+\frac{\delta_5^2}{\delta d}\{c_5(T_0+2r)+R^2\}+\frac{2\delta_5^2c_9}{\delta^2}\quad\forall t\geqq 0\end{aligned} \tag{2.23}$$

(using (2.13) and (2.18)).

The estimates (2.23), (2.19), (2.18), and (2.10) provide the uniform compactness of the operators S_1. Indeed, if $(u_0, v_0) \in \mathcal{B} \subset B(0, R)$ and $t \geqq T_0 + 2r$, then $S_1(t) \cdot (u_0, v_0)$ belongs to a set bounded in $\mathbb{H}^1(\Omega)$ independently of t and relatively compact in H.

In conclusion, the assumptions (2.1)-(2.3) are satisfied and we have proved the existence of a bounded absorbing set. Hence, Theorem 2.1 applies and gives Theorem 2.2. □

2.3. A regularity property of the attractor. The goal of this section is to prove the following regularity result.

THEOREM 2.4. *Under assumptions* (1.4)-(1.8), *the universal attractor* $\mathcal{A}$ *defined in Theorem* 2.2 *is bounded in* $\mathbb{L}^\infty(\Omega)$.

We start by proving the following weaker result.

LEMMA 2.5. *The attractor* $\mathcal{A}$ *defined in Theorem* 2.2 *is bounded in* $\mathbb{L}^q(\Omega)$, *for all* $q \in [1, +\infty[$.

Proof. Let $\alpha(k) = k(p-2)+2$. Since $\alpha(k) \to +\infty$, as $k \to +\infty$, it suffices to prove that $\mathcal{A}$ is bounded in $\mathbb{L}^{\alpha(k)}(\Omega)$, for all $k \in \mathbb{N}$. Let $r > 0$ be fixed; we shall prove by induction on k that

$$(2.24)_k \qquad \mathcal{A} \text{ is bounded in } \mathbb{L}^{\alpha(k)}(\Omega),$$

$$(2.25)_k \qquad \sup_{(u_0, v_0) \in \mathcal{A}} \int_t^{t+r} \int_\Omega |u|^{\alpha(k+1)}\, dx\, ds \leqq K \quad \forall t \geqq 0,$$

where (u, v) is the solution of (1.1)-$(1.3)_\alpha$; hereafter, we denote by K any constant that depends on the data and on k.

(a) $k = 0$; $\alpha(0) = 2$, and $\alpha(1) = p$; $(2.24)_0$ has been proved in Theorem 2.2. Let $(u_0, v_0) \in \mathcal{A}$; we infer from (2.11) that

$$\delta_1 \int_t^{t+r} \int_\Omega |u|^p\, dx\, ds \leqq rc_5 + |u(t)|^2 + |v(t)|^2 \quad \forall t \geqq 0$$

$$\leqq K \quad \text{(thanks to } (2.24)_0\text{)};$$

hence we have $(2.25)_0$.

(b) We now assume that $(2.24)_{k-1}$ and $(2.25)_{k-1}$ hold for $k \geqq 1$. In particular, there exists a constant $K > 0$ such that

$$(2.26) \qquad \int_\Omega |\tilde{v}|^{\alpha(k-1)}\, dx \leqq K \quad \forall (\tilde{u}, \tilde{v}) \in \mathcal{A}.$$

Let $(u_0, v_0) \in \mathcal{A}$. By multiplying the first equation in (1.1) by $|u|^{\alpha(k)-2}u$ and integrating over Ω, we obtain

$$(2.27) \qquad \begin{aligned} &\frac{1}{\alpha(k)} \frac{d}{dt} \int_\Omega |u|^{\alpha(k)}\, dx - d \int_\Omega \Delta u |u|^{\alpha(k)-2} u\, dx \\ &\quad + \int_\Omega h(x, u) |u|^{\alpha(k)-2} u\, dx + \int_\Omega f(x, u, v) |u|^{\alpha(k)-2} u\, dx = 0. \end{aligned}$$

Thanks to the Green formula and $(1.3)_\alpha$, we have

$$-\int_\Omega \Delta u |u|^{\alpha(k)-2} u\, dx = (\alpha(k)-1) \int_\Omega |\nabla u|^2 |u|^{\alpha(k)-2}\, dx \geqq 0.$$

Hence, using also (1.4) and (1.5), we deduce from (2.27)

$$\frac{1}{\alpha(k)}\frac{d}{dt}\int_\Omega |u|^{\alpha(k)}\,dx+\delta_1\int_\Omega |u|^{\alpha(k+1)}\,dx$$

$$\leqq \int_\Omega (\delta_3|u|^{\alpha(k)-2}+\delta_4|u|^{\alpha(k)-1}+\delta_4|u|^{p_1+\alpha(k)-1})\,dx$$

$$+\delta_4\int_\Omega |v|\,|u|^{\alpha(k)-1}\,dx$$

(since $p_1+\alpha(k)-1<\alpha(k+1)$),

$$\leqq \frac{\delta_1}{4}\int_\Omega |u|^{\alpha(k+1)}\,dx+K+\delta_4\int_\Omega |v|\,|u|^{\alpha(k)-1}\,dx, \tag{2.28}$$

$$\frac{1}{\alpha(k)}\frac{d}{dt}\int_\Omega |u|^{\alpha(k)}\,dx+\delta_1\frac{3}{4}\int_\Omega |u|^{\alpha(k+1)}\,dx$$

$$\leqq \delta_4\int_\Omega |v|\,|u|^{\alpha(k)-1}\,dx+K.$$

Let $\bar{p}=\alpha(k+1)/(\alpha(k)-1)$ and let $\bar{q}$ be such that $1/\bar{p}+1/\bar{q}=1$. With the Young inequality, the last integral in (2.28) is majorized as follows:

$$\delta_4\int_\Omega |v|\,|u|^{\alpha(k)-1}\,dx\leqq\frac{\delta_1}{4}\int_\Omega |u|^{\alpha(k+1)}\,dx+c_k'\int_\Omega |v|^{\bar{q}}\,dx.$$

Since $\bar{q}\leqq\alpha(k-1)$, using the Hölder inequality, we also have

$$\int_\Omega |v|^{\bar{q}}\,dx\leqq|\Omega|^{1-(\bar{q}/\alpha(k-1))}\left(\int_\Omega |v|^{\alpha(k-1)}\right)^{\bar{q}/\alpha(k-1)}$$

$$\leqq K \quad \text{(by (2.26))}.$$

Combining the above inequalities, we finally obtain

$$\frac{1}{\alpha(k)}\frac{d}{dt}\int_\Omega |u|^{\alpha(k)}\,dx+\frac{\delta_1}{2}\int_\Omega |u|^{\alpha(k+1)}\,dx\leqq K. \tag{2.29}$$

Thanks to the induction assumption $(2.25)_{k-1}$, we can apply the uniform Gronwall lemma to (2.29) and we conclude from (2.17) that there exists a constant K such that

$$\int_\Omega |u|^{\alpha(k)}\,dx\leqq K\quad\forall t\geqq r.$$

Since $S(r)\mathscr{A}=\mathscr{A}$, this implies

$$\int_\Omega |\tilde{u}|^{\alpha(k)}\,dx\leqq K\quad\forall(\tilde{u},\tilde{v})\in\mathscr{A}. \tag{2.30}$$

Then integrating (2.29) between t and $t+r$ and using (2.30), we find

$$\sup_{(u_0,v_0)\in\mathscr{A}}\int_t^{t+r}\int_\Omega |u|^{\alpha(k+1)}\,dx\,ds\leqq K\quad\forall t\geqq 0,$$

i.e., $(2.25)_k$.

It remains to check that

$$\int_\Omega |\tilde{v}|^{\alpha(k)}\,dx \leqq K \quad \forall (\tilde{u},\tilde{v}) \in \mathscr{A}. \tag{2.31}$$

Let $(\tilde{u},\tilde{v}) \in \mathscr{A}$. We claim that there exists a sequence $(u_{0l}, v_{0l}) \in \mathscr{A}$ and a sequence $t_l \to +\infty$ such that

$$S_1(t_l)\cdot(u_{0l}, v_{0l}) \to (\tilde{u},\tilde{v}) \quad \text{in } H \quad \text{as } l \to +\infty,$$

where $S_1(t)$ is given by (2.15). Indeed this follows from the functional invariance of $\mathscr{A}$ and the property (2.3) for $S_2(t) = S(t) - S_1(t)$.

Then, by (2.14),

$$\begin{aligned} |v_{1l}(t)|_{L^{\alpha(k)}(\Omega)} &\leqq \int_0^t |g(x,u_l)|_{L^{\alpha(k)}(\Omega)}\, e^{-\delta(t-s)}\,ds \quad (\delta \text{ given by (1.6)}) \\ &\leqq \delta_7 \int_0^t |1+|u_l||_{L^{\alpha(k)}(\Omega)}\, e^{-\delta(t-s)}\,ds \quad \text{(with (2.6))} \\ &\leqq \delta_7 K \frac{1}{\delta} \quad \forall t \geqq 0 \quad \text{(thanks to (2.30))}, \end{aligned} \tag{2.32}$$

which implies (2.31), since there exists a subsequence l_m such that

$$|\tilde{v}|_{L^{\alpha(k)}} \leqq \liminf_{m\to+\infty} |v_{1l_m}(t_{l_m})|_{L^{\alpha(k)}}.$$

The proof of Lemma 2.5 is therefore complete. □

Conclusion of the proof of Theorem 2.4. We now show that the attractor $\mathscr{A}$ is bounded in $\mathbb{L}^\infty(\Omega)$. Let $(\tilde{u},\tilde{v}) \in \mathscr{A}$ and let $\tilde{t} > 0$. Since $\mathscr{A}$ is a functional invariant set, there exists a solution (u, v) of (1.1)-(1.3)$_\alpha$ satisfying $(u_0, v_0) \in \mathscr{A}$ and $(u(\tilde{t}), v(\tilde{t})) = (\tilde{u},\tilde{v})$. Introducing the semigroup $\Sigma(t)$ associated with the linear operator $\partial/\partial t - d\Delta + I$ and with the boundary condition (1.3)$_\alpha$, it is classical that u can be written as

$$u(t) = \Sigma(t)u_0 + \int_0^t \Sigma(t-s)\{-h(x,u(s)) - f(x,u(s),v(s)) + u(s)\}\,ds \quad \text{for } t \geqq 0. \tag{2.33}$$

The semigroup $\Sigma(t)$ satisfies the regularity property (see Rothe [22])

$$|\Sigma(t)\varphi|_{L^\infty(\Omega)} \leqq cm(t)^{-1/2}\, e^{-\lambda t}|\varphi|_{L^n(\Omega)},$$

where $m(t) = \min(1, t)$, λ is the smallest eigenvalue of the operator $-d\Delta + I$ associated with the boundary condition (1.3)$_\alpha$, and c is a positive constant. Also, by Lemma 2.5, there exists a constant $K > 0$ such that

$$|u|_{L^n(\Omega)},\ |-h(x,u) - f(x,u,v) + u|_{L^n(\Omega)} \leqq K.$$

Hence, we deduce from (2.33) that

$$\begin{aligned} |u(t)|_{L^\infty(\Omega)} &\leqq cK\left\{ e^{-\lambda t}m(t)^{-1/2} + \int_0^t e^{-\lambda(t-s)}m(t-s)^{-1/2}\,ds \right\} \quad \forall t \geqq 0 \\ &\leqq cK\left\{ m\left(\frac{\tilde{t}}{2}\right)^{-1/2} + 2 + \frac{1}{\lambda} \right\} \quad \forall t \geqq \frac{\tilde{t}}{2}. \end{aligned}$$

In particular, $\tilde{u} = u(\tilde{t})$ satisfies

$$|\tilde{u}|_{L^\infty(\Omega)} \leqq cK\left\{m\left(\frac{\tilde{t}}{2}\right)^{-1/2} + 2 + \frac{1}{\lambda}\right\} \quad \forall (\tilde{u}, \tilde{v}) \in \mathscr{A}.$$

Finally, the bound on $|\tilde{v}|_{L^\infty(\Omega)}$ follows from the one on $|\tilde{u}|_{L^\infty(\Omega)}$ as in Lemma 2.5 above. This concludes the proof of Theorem 2.4. □

3. Dimension of the universal attractor. Our aim is now to prove the finite dimensionality of the attractor introduced before. We start by giving a few results borrowed from Constantin, Foias, and Temam [6] and Ghidaglia and Temam [10] (§ 3.1). We then derive in § 3.2 estimates of the Hausdorff and fractal dimensions of the attractor. Finally, we conclude the section by applying our results to an example (§ 3.3).

3.1. Some general results on the dimension of functional invariant sets. Let E be a Hilbert space (norm $|\cdot|$) and let $\mathscr{X}$ be a compact functional invariant set for a semigroup $\{S(t)\}_{t \geqq 0}$. We assume the following for all $t \geqq 0$:

(3.1) $S(t)$ is uniformly differentiable in $\mathscr{X}$, which means that for every $u \in \mathscr{X}$ there exists a linear operator $L = L(t, u) \in \mathscr{L}(E)$ such that

$$\sup_{\substack{u, v \in \mathscr{X} \\ 0 < |v-u| \leqq \varepsilon}} \frac{|S(t)v - S(t)u - L(t, u) \cdot (v-u)|}{|v-u|} \to 0 \quad \text{as } \varepsilon \to 0,$$

(3.2)
$$\sup_{u \in \mathscr{X}} |L(t, u)|_{\mathscr{L}(E)} < +\infty.$$

For $L \in \mathscr{L}(E)$ and $N \in \mathbb{N}^*$, we denote by $\omega_N(L)$ the norm of the exterior product $\Lambda^N L$ in $\Lambda^N E$:

$$\omega_N(L) = \sup_{\substack{\xi^1, \cdots, \xi^N \in E \\ |\xi^j| \leqq 1}} |L\xi^1 \wedge \cdots \wedge L\xi^N|.$$

We then introduce for $N \in \mathbb{N}^*$

$$\bar{\omega}_N(t) = \sup_{u_0 \in \mathscr{X}} \omega_N(L(t, u_0)), \qquad t \geqq 0,$$

$$\Pi_N = \lim_{t \to +\infty} \bar{\omega}_N(t)^{1/t}$$

and we define the uniform Lyapunov numbers μ_N by

$$\mu_1 = \log \Pi_1, \quad \mu_N = \log \Pi_N - \log \Pi_{N-1}, \quad N \geqq 2.$$

A general result on the Hausdorff and fractal dimensions of functional invariant sets states the following.

THEOREM 3.1. *Under assumptions* (3.1), (3.2), *if, for some integer* $N \geqq 1$, $\mu_1 + \cdots + \mu_N < 0$, *then the Hausdorff dimension of* $\mathscr{X}$ *is less than or equal to* N *and the fractal dimension of* $\mathscr{X}$ *is less than or equal to*

$$N \cdot \max_{1 \leqq l \leqq N-1} \left(1 + \frac{(\mu_1 + \cdots + \mu_l)_+}{|\mu_1 + \cdots + \mu_N|}\right).$$

The reader is referred to Constantin, Foias and Temam [6] for the proof of this result when the linear operators $L(t, u)$ are assumed to be compact and to Ghidaglia and Temam [10] for the extension to the noncompact case that we use here. We conclude this section by recalling the definitions of the Hausdorff and fractal dimensions

(Federer [7], Mandelbrot [17]). The d-dimensional Hausdorff measure of $\mathscr{X}$ is the number

$$\mu_H(\mathscr{X}, d) = \lim_{\varepsilon \to 0} \mu_H(\mathscr{X}, d, \varepsilon)$$

where

$$\mu_H(\mathscr{X}, d, \varepsilon) = \inf \sum_i r_1^d,$$

the infimum being taken for all the coverings of $\mathscr{X}$ by balls of radii $r_1 \leqq \varepsilon$. There exists $d = d_H(\mathscr{X}) \in [0, +\infty]$ such that $\mu_H(\mathscr{X}, d) = 0$ for $d > d_H(\mathscr{X})$ and is equal to ∞ for $d < d_H(\mathscr{X})$; $d_H(\mathscr{X})$ is the Hausdorff dimension of $\mathscr{X}$.

The fractal dimension of $\mathscr{X}$ is

$$d_F(\mathscr{X}) = \inf \{d > 0, \mu_F(\mathscr{X}, d) = 0\}$$

where

$$\mu_F(\mathscr{X}, d) = \limsup_{\varepsilon \to 0} \varepsilon^d n_{\mathscr{X}}(\varepsilon),$$

and $n_{\mathscr{X}}(\varepsilon)$ is the minimum number of balls of radii ε necessary to cover $\mathscr{X}$. Since $\mu_F(\mathscr{X}, d) \geqq \mu_H(\mathscr{X}, d)$, it is clear that the fractal dimension of a set is larger than or equal to its Hausdorff dimension, the converse being false in general.

3.2. Estimate of the dimension of the attractor. We now return to the universal attractor $\mathscr{A}$ defined in Theorem 2.2. According to Theorem 2.4, there exists a constant $\alpha > 0$ such that

$$|\tilde{u}|_{L^\infty(\Omega)}, |\tilde{v}|_{L^\infty(\Omega)} \leqq \alpha \quad \forall (\tilde{u}, \tilde{v}) \in \mathscr{A}$$

and we introduce

$$c_3 = \inf_{\substack{x \in \bar{\Omega} \\ |u| \leqq \alpha, |v| \leqq \alpha}} (h'_u(x, u) + f'_u(x, u, v)), \tag{3.3}$$

$$c_4 = \sup_{\substack{x \in \bar{\Omega} \\ |u| \leqq \alpha, |v| \leqq \alpha}} |f'_v(x, u, v) + g'_u(x, u)|. \tag{3.4}$$

(Note that $c_3 \geqq -\delta_6$ given by (1.8).) The aim of this section is to prove Theorem 3.2.

THEOREM 3.2. *Under assumptions* (1.4)-(1.8), *the Hausdorff and fractal dimensions of the universal attractor* $\mathscr{A}$ *defined in Theorem* 2.2 *are finite. Moreover, they are both bounded by*

$$c\left\{1 + \frac{d}{\delta |\Omega|^{2/n}} + \frac{|\Omega|}{d^{n/2}}\left(\delta^{n/2} + \frac{1}{\delta}(c_3^-)^{n_1} + \frac{1}{\delta^{n_1+1}} c_4^{2n_1}\right)\right\} \tag{3.5}$$

where c *denotes a constant depending on* n *and the shape of* Ω;[2] $n_1 = 1 + n/2$, $c_3^- = \max(0, -c_3)$, *and* δ, c_3, c_4 *are given by* (1.6), (3.3), *and* (3.4), *respectively.*

Remark 3.3. In the course of the proof of Theorem 3.2 below, we derive the following sharper bound of the Hausdorff and fractal dimensions:

$$c\left\{1 + \frac{d}{\delta |\Omega|^{2/n}} + \frac{\delta^{n/2}|\Omega|}{d^{n/2}} + \frac{c_5}{\delta\, d^{n/2}}\right\},$$

[2] This means that the constant is invariant by homothety and translation of Ω.

where

$$c_5 = \liminf_{t\to+\infty} \sup_{(u_0,v_0)\in\mathscr{A}} \left\{ \frac{1}{t}\int_0^t \int_\Omega \left\{ ((h'_u(x,u)+f'_u(x,u,v))^-)^{n_1} + \frac{|f'_v(x,u,v)+g'_u(x,u)|^{2n_1}}{\delta^{n_1}} \right\} dx\, ds \right\}, \tag{3.6}$$

and c is as in Theorem 3.2.

Theorem 3.2 is proved by using the general result recalled in § 3.1. We start by checking the assumptions (3.1) and (3.2) for the semigroup $S(t)$ associated with (1.1)-$(1.3)_\alpha$.

LEMMA 3.4. *For every $t_0>0$, $s(t_0)$ is uniformly differentiable on $\mathscr{A}$. Its differential at (u_0, v_0) is the linear operator on $H: (\xi,\eta)\to L(t_0,u_0,v_0)$. $(\xi,\eta)=(U(t_0), V(t_0))$, where $(U(t_0), V(t_0))$ is the value at time t_0 of the solution $(U(t), V(t))$ of the linearized problem*

$$\frac{\partial U}{\partial t} - d\Delta U + [h'_u(x,u)+f'_u(x,u,v)]U + f'_v(x,u,v)V = 0, \tag{3.7}$$

$$\frac{\partial V}{\partial t} + \sigma(x)V + g'_u(x,u)U = 0,$$

$$U(0)=\xi, \qquad V(0)=\eta, \tag{3.8}$$

$$U \text{ satisfies } (1.3)_\alpha,$$

where (u, v) is the solution of (1.1)-$(1.3)_\alpha$. Furthermore, we have

$$\sup_{(u_0,v_0)\in\mathscr{A}} |L(t_0,u_0,v_0)|_{\mathscr{L}(H)} < +\infty.$$

Proof of Lemma 3.4. The proof of this technical result is left to the reader. We only note here that it relies essentially on Theorem 2.4. □

For $(u_0, v_0)\in\mathscr{A}$, let us denote by $\mathfrak{A}(u, v)$ the linear operator from $H^2(\Omega)\times L^2(\Omega)$ into H occurring in (3.7), (3.8), i.e.,

$$\mathfrak{A}(u,v)\cdot(U,V) = (-d\Delta U + (h'_u+f'_u)U + f'_v V,\ \sigma V + g'_u U).$$

For $N\geqq 1$, we introduce

$$q_N = \limsup_{t\to+\infty} \left(\inf_{(u_0,v_0)\in\mathscr{A}} \frac{1}{t}\int_0^t \inf_{\text{rank } Q=N} \operatorname{Tr}(\mathfrak{A}(u,v)\circ Q)\, ds \right), \tag{3.9}$$

where Q denotes any orthogonal projector in H of rank N such that $QH\subset W$ with

$$W = \{(U,V)\in H^2(\Omega)\times L^2(\Omega),\ U \text{ satisfies } (1.3)_\alpha\}.$$

Returning to the definitions of § 3.1, it can be shown exactly as in [6] that

$$\mu_1+\cdots+\mu_N \leqq -q_N, \qquad N\geqq 1.$$

Thus, we infer from Theorem 3.1 that, if $q_N>0$ for some N, then the Hausdorff dimension of $\mathscr{A}$ is less than or equal to N and its fractal dimension is majorized by

$$N\cdot \max_{1\leqq l\leqq N-1} \left(1+\frac{(-q_l)_+}{q_N}\right). \tag{3.10}$$

We next estimate the q_N's. Let Q be an orthogonal projector in H of rank N such that $QH \subset W$ and let $\{(\varphi^j, \psi^j)\}_{j\in\mathbb{N}}$ be an orthonormal basis of H such that $(\varphi^1, \psi^1), \cdots, (\varphi^N, \psi^N)$ is a basis of QH. Then

$$
\begin{aligned}
\operatorname{Tr} \mathfrak{A}(u, v) \circ Q &= \sum_{j=1}^{N} (\mathfrak{A}(u, v) \cdot (\varphi^j, \psi^j), (\varphi^j, \psi^j)) \\
&= \sum_{j=1}^{N} \Big(d\|\varphi^j\|^2 + \int_\Omega \sigma(x)\psi^{j^2}\, dx \\
&\qquad + \int_\Omega (h'_u(x, u) + f'_u(x, u, v))\varphi^{j^2}\, dx \\
&\qquad + \int_\Omega (f'_v(x, u, v) + g'_u(x, u))\varphi^j\psi^j\, dx \Big) \\
&\geqq d \sum_{j=1}^{N} \|\varphi^j\|^2 + \delta \sum_{j=1}^{N} |\psi^j|^2 - \int_\Omega (h'_u + f'_u)^- \rho(x)\, dx \\
&\qquad + \sum_{j=1}^{N} \int_\Omega (f'_v + g'_u)\varphi^j\psi^j\, dx \quad \text{(by (1.6))},
\end{aligned}
\tag{3.11}
$$

where we have set

$$
\rho(x) = \sum_{j=1}^{N} (\varphi^j(x))^2.
$$

After majorizing the last integral as follows:

$$
\left| \sum_{j=1}^{N} \int_\Omega (f'_v + g'_u)\varphi^j\psi^j\, dx \right| \leqq \frac{\delta}{2} \sum_{j=1}^{N} \int_\Omega |\psi^j|^2\, dx + \frac{1}{2\delta} \int_\Omega (f'_v + g'_u)^2 \rho(x)\, dx,
$$

we have that (3.11) gives

$$
\operatorname{Tr} \mathfrak{A}(u, v) \circ Q \geqq d \sum_{j=1}^{N} \|\varphi^j\|^2 + \frac{\delta}{2} \sum_{j=1}^{N} |\psi^j|^2 - \int_\Omega \alpha_1(x, t)\rho(x)\, dx \tag{3.12}
$$

where

$$
\alpha_1(x, t) = (h'_u + f'_u)^- + \frac{1}{2\delta}(f'_v + g'_u)^2. \tag{3.13}
$$

We next apply the generalized Lieb-Thirring inequalities (see Ghidaglia, Marion, and Temam [11] to the suborthonormal[3] family $(\varphi^j)_{1\leqq j\leqq N}$: there exist two constants K_1 and K_2 depending on n and the shape of Ω such that

$$
\sum_{j=1}^{N} \|\varphi^j\|^2 \geqq K_1 \int_\Omega \rho(x)^{1+(2/n)}\, dx - \frac{K_2}{L^2} \int_\Omega \rho(x)\, dx, \tag{3.14}
$$

where L denotes the diameter of Ω. Thus, we infer from (3.12) that

$$
\begin{aligned}
\operatorname{Tr} \mathfrak{A}(u, v) \circ Q &\geqq \frac{\delta}{2} \sum_{j=1}^{N} (|\varphi^j|^2 + |\psi^j|^2) \\
&\qquad + dK_1 \int_\Omega \rho(x)^{1+(2/n)}\, dx - \int_\Omega \left(\frac{\delta}{2} + \frac{dK_2}{L^2} + \alpha_1(x, t) \right) \rho(x)\, dx.
\end{aligned}
\tag{3.15}
$$

[3] We say (cf. [11]) that the family $\varphi^j \in L^2(\Omega)$, $1 \leqq j \leqq N$, is suborthonormal if $\sum_{i,j=1}^{N} \xi_i\xi_j \int_\Omega \varphi^i\varphi^j\, dx \leqq \sum_{k=1}^{N} \xi_k^2$, for all $\xi \in \mathbb{R}^N$.

Since the family (φ^j, ψ^j) is orthonormal, we then have

$$\sum_{j=1}^{N} (|\varphi^j|^2 + |\psi^j|^2) = N.$$

Also, with the Young inequality, the last integral in (3.15) can be majorized as follows:

$$\int_\Omega \left(\frac{\delta}{2} + \frac{dK_2}{L^2} + \alpha_1(x,t)\right)\rho(x)\,dx \leqq \frac{dK_1}{2}\int_\Omega \rho(x)^{1+(2/n)}\,dx + \alpha_2(t),$$

(3.16)

$$\alpha_2(t) = \frac{2}{n+2}\left(\frac{4n}{(n+2)\,dK_1}\right)^{n/2}\int_\Omega \left(\frac{\delta}{2} + \frac{dK_2}{L^2} + \alpha_1(x,t)\right)^{n_1} dx, \qquad n_1 = 1 + \frac{n}{2}.$$

Combining these inequalities, we finally obtain

$$\operatorname{Tr}\mathfrak{A}(u,v)\circ Q \geqq \frac{\delta}{2}N + \frac{dK_1}{2}\int_\Omega \rho(x)^{1+(2/n)}\,dx - \alpha_2(t)$$

(3.17)

$$\geqq \frac{\delta}{2}N - \alpha_2(t).$$

Hence, we conclude from (3.17) and definition (3.9) that

$$q_N \geqq \frac{\delta}{2}N - \alpha, \tag{3.18}$$

where

$$\alpha = \liminf_{t\to+\infty} \sup_{(u_0,v_0)\in\mathscr{A}} \frac{1}{t}\int_0^t \alpha_2(t)\,dt. \tag{3.19}$$

Let now $\bar{N}$ be the integer such that

$$\frac{\delta}{2}(\bar{N}-1) \leqq 2\alpha < \frac{\delta}{2}\bar{N}. \tag{3.20}$$

Then $q_{\bar{N}} > 0$. As observed before, the Hausdorff dimension is majorized by $\bar{N}$ and, by (3.10) and (3.18),

$$d_F(\mathscr{A}) \leqq \bar{N} \max_{1\leqq l\leqq \bar{N}-1}\left(1 + \frac{\alpha}{\alpha}\right) = 2\bar{N}.$$

To conclude, we express the bound on $\bar{N}$ given by (3.20). We find

$$\bar{N} \leqq 1 + \frac{4\alpha}{\delta}$$

$$\leqq c\left(1 + \frac{d}{\delta|\Omega|^{2/n}} + \frac{\delta^{n/2}|\Omega|}{d^{n/2}} + \frac{c_5}{\delta\, d^{n/2}}\right) \quad \text{(by (3.19), (3.16), and (3.13))},$$

where c_5 is given by (3.6), and c depends on n and the shape of Ω. This gives (3.5) by using the constants c_3 and c_4 given by (3.3) and (3.4). The proof of Theorem 3.2 is therefore complete. □

3.3. An example. Here we apply our results to the system

$$\frac{\partial u}{\partial t} - d\Delta u + h(u) + \sigma v = 0, \qquad \frac{\partial v}{\partial t} + \delta v + \gamma u = 0, \tag{3.21}$$

where $\delta > 0$, $\delta, \gamma \in \mathbb{R}$, and h is a polynomial of odd degree greater than 1 with a positive leading coefficient.

Assumptions (1.5)-(1.8) are satisfied. Theorems 2.2 and 3.2 apply and give the existence of a universal attractor that describes the long-time behavior of the solutions of (3.21) (the boundary condition is either the Dirichlet or the Neumann or the periodic boundary condition). This attractor has finite Hausdorff and fractal dimensions and these dimensions moreover are bounded by

$$c\left[1+\frac{d}{\delta|\Omega|^{2/n}}+\frac{|\Omega|}{d^{n/2}}\left\{\delta^{n/2}+\frac{1}{\delta}(c_3^-)^{n_1}+\frac{1}{\delta^{n_1+1}}|\sigma+\gamma|^{2n_1}\right\}\right],$$

where c denotes a constant depending on n and the shape of Ω, $n_1=1+n/2$, and

$$c_3^-=\max(0,-c_3), \qquad c_3=\min_{u\in\mathbb{R}} h'(u).$$

Part II. Systems with an Invariant Region.

In the second part of this work we consider partly dissipative systems of reaction-diffusion equations admitting a positively invariant region. The precise assumptions on the equations are stated in § 4. Then, in § 5, we prove the existence of a universal attractor and we derive an estimate of the dimension of the attractor. Finally, in § 5, we apply our results to several classical equations borrowed from mathematical biology, physics and chemistry.

4. The equations and the semigroup. We denote again by Ω an open bounded set of $\mathbb{R}^n$ with boundary Γ. Let $m=m_1+m_2$ and let D be a positive diagonal matrix of diffusion coefficients

$$D=\operatorname{diag}(d_1,\cdots,d_{m_1}), \qquad d_i>0.$$

The system of ordinary differential equations coupled with partial differential equations to be considered involves a vector function (u, v) from $\Omega\times\mathbb{R}_+$ into $\mathbb{R}^{m_1}\times\mathbb{R}^{m_2}$ and takes the form

$$\begin{aligned}&\frac{\partial u}{\partial t}-D\Delta u+f(x,u,v)=0,\\ &\frac{\partial v}{\partial t}+G(x,u)v+g(x,u)=0,\end{aligned} \tag{4.1}$$

where $f=(f_1,\cdots,f_{m_1})$ is a function of class $\mathscr{C}^2$ on $\bar{\Omega}\times\mathbb{R}^m$, $g=(g_1,\cdots,g_{m_2})$ is a function of class $\mathscr{C}^2$ on $\bar{\Omega}\times\mathbb{R}^{m_1}$, and $G=(g_{kl})$ is a square matrix of order m_2 whose coefficients are functions of class $\mathscr{C}^2$ on $\bar{\Omega}\times\mathbb{R}^{m_1}$. We supplement (4.1) with the initial conditions

$$u(x,0)=u_0(x), \qquad v(x,0)=v_0(x) \quad \text{in } \Omega, \tag{4.2}$$

and a boundary condition of either Dirichlet type

$$u=0 \quad \text{on } \Gamma, \tag{4.3}_1$$

of Neumann type

$$\frac{\partial u}{\partial \nu}=0 \quad \text{on } \Gamma, \tag{4.3}_2$$

or of periodicity type

$$\Omega=]0,L[^n, \quad u \text{ is } \Omega\text{-periodic.} \tag{4.3}_3$$

The following assumptions are made on the initial boundary value problem (4.1)-(4.3)$_\alpha$. First:

(4.4) There exists a closed convex region $\mathscr{D} \subset \mathbb{R}^m$ that is positively invariant. Moreover, $\mathscr{D}$ is compact for $\alpha = 2, 3$.

This means that any solution (u, v), with boundary data and initial data $(u_0(x), v_0(x))$ in $\mathscr{D}$ for every (or almost every) x in Ω, satisfies $(u(x, t), v(x, t)) \in \mathscr{D}$ for all $t > 0$ for which the solution exists. We refer to Chueh, Conley, and Smoller [3] for the derivation of sufficient and of necessary and sufficient conditions that guarantee the existence of a positively invariant region (see also Tartar [25], Sermange [23]).

For the mathematical setting of the problem, we introduce the functional spaces

$$H = L^2(\Omega, \mathscr{D}) = \{(u, v) \in \mathbb{L}^2(\Omega), (u(x), v(x)) \in \mathscr{D} \text{ for a.e. } x \in \Omega\},$$
$$V = V_1 \times (L^2(\Omega))^{m_2},$$

where

$$V_1 = \begin{cases} H_0^1(\Omega)^{m_1} & \text{if } \alpha = 1, \\ H^1(\Omega)^{m_1} & \text{if } \alpha = 2, \\ H_p^1(\Omega)^{m_1} & \text{if } \alpha = 3. \end{cases}$$

We assume that (4.1)-(4.3)$_\alpha$ is well posed, for (u_0, v_0) in H, in the following sense:

(4.5) For $(u_0, v_0) \in H$, (4.1)-(4.3)$_\alpha$ possesses a unique solution (u, v) for all time, $(u(t), v(t)) \in H$, for all t, $(u, v) \in L^2(0, T; V)$, for all $T > 0$. The mapping $(u_0, v_0) \to (u(t), v(t))$ is continuous in H. Moreover, if $(u_0, v_0) \in V$, then $u \in L^2(0, T; H^2(\Omega)^{m_1})$, for all $T > 0$.

Finally, we assume the following:

(4.6) There exists $\delta > 0$ such that, for all $(x, u, v) \in \bar{\Omega} \times \mathscr{D}$,

$$\sum_{k,l=1}^{m_2} g_{kl}(x, u)\xi_k \xi_l \geqq \delta \sum_{k=1}^{m_2} \xi_k^2 \quad \forall \xi \in \mathbb{R}^{m_2}.$$

(4.7) f, g and the partial derivatives of order one and two of f, g and G are bounded on $\bar{\Omega} \times \mathscr{D}$.

We also set

$$c_1 = \sup_{(x,u,v) \in \bar{\Omega} \times \mathscr{D}} |f(x, u, v)|, \tag{4.8}$$

$$c_2 = \sup_{(x,u,v) \in \bar{\Omega} \times \mathscr{D}} |g(x, u)|. \tag{4.9}$$

5. The universal attractor.

5.1. Existence of a universal attractor. Our goal in this section is to prove Theorem 5.1.

THEOREM 5.1. *Under assumptions* (4.4)-(4.7), *the semigroup* $S(t)$ *associated with* (4.1)-(4.3)$_\alpha$ *possesses a universal attractor* $\mathscr{A}$ *that is connected in* H.

Proof of Theorem 5.1. The proof relies on technical a priori estimates and on the general results given in § 2.1.

We first note that when the positively invariant region $\mathscr{D}$ is compact (Neumann and periodic boundary conditions), the existence of an absorbing set is straightforward and Theorem 5.1 then follows by using the same arguments as in step (b) below for the Dirichlet case. So, in the sequel, we restrict ourselves to the Dirichlet boundary condition.

(a) *Existence of an absorbing set.* We multiply the first equation (4.1) by u and integrate over Ω. Using the Green formula and $(4.3)_\alpha$, we obtain

$$\frac{1}{2}\frac{d}{dt}|u|^2+\sum_{i=1}^{m_1} d_i\|u_i\|^2+\int_\Omega f(x,u,v)\cdot u\,dx=0.$$

Introducing the constant

$$d_0=\min_{1\leqq i\leqq m_1} d_i, \tag{5.1}$$

and using the constant c_1 defined in (4.8), we get

$$\frac{1}{2}\frac{d}{dt}|u|^2+d_0\|u\|^2\leqq c_1|\Omega|^{1/2}|u|. \tag{5.2}$$

Thanks to the Poincaré inequality, there exists a constant $c_3>0$ such that $|u|\leqq c_3\|u\|$ for all $u\in V_1$. Hence, we infer from (5.2) that

$$\frac{1}{2}\frac{d}{dt}|u|^2+\frac{d_0}{c_3^2}|u|^2\leqq c_1|\Omega|^{1/2}|u|\leqq\frac{1}{2}\frac{d_0}{c_3^2}|u|^2+\frac{c_1^2c_3^2|\Omega|}{2d_0},$$

$$\frac{d}{dt}|u|^2+\frac{d_0}{c_3^2}|u|^2\leqq\frac{c_1^2c_3^2|\Omega|}{d_0},$$

which gives, by integration,

$$|u(t)|^2\leqq|u_0|^2\exp\left(-\frac{d_0}{c_3^2}t\right)+\frac{c_1^2c_3^4|\Omega|}{d_0^2}\left(1-\exp\left(-\frac{d_0}{c_3^2}t\right)\right)\quad\forall t\geqq 0. \tag{5.3}$$

Let $\rho_2>\rho_1=c_1c_3^2|\Omega|^{1/2}/d_0$ be fixed and let $\mathcal{B}$ be any bounded set of H included in a ball $B(0,R)$ of H centered at zero and of radius R. We deduce from (5.3) that, if $(u_0,v_0)\in\mathcal{B}$, then

$$|u(t)|\leqq\rho_2\quad\forall t\geqq T_1(\mathcal{B},\rho_2), \tag{5.4}$$

where

$$T_1=\frac{c_3^2}{d_0}\log\frac{R^2}{\rho_2^2-\rho_1^2}.$$

Also, by integrating (5.2) between t and $t+r$, $r>0$ fixed, we have

$$\int_t^{t+r}\|u\|^2\,ds\leqq\frac{c_1|\Omega|^{1/2}}{d_0}\int_t^{t+r}|u|\,ds+\frac{|u(t)|^2}{2d_0},$$

and, if $(u_0,v_0)\in\mathcal{B}\subset B(0,R)$ and $t\geqq T_1(\mathcal{B},\rho_2)$,

$$\int_t^{t+r}\|u\|^2\,ds\leqq c_4,\qquad c_4=\frac{1}{d_0}rc_1|\Omega|^{1/2}\rho_2+\frac{\rho_2^2}{2d_0}. \tag{5.5}$$

Integrating again (5.2) between zero and t and using (5.3), we get furthermore that, if $(u_0,v_0)\in\mathcal{B}\subset B(0,R)$,

$$\int_0^t\|u\|^2\,ds\leqq\frac{1}{d_0}c_1|\Omega|^{1/2}\sqrt{R^2+\rho_1^2}\,t+\frac{R^2}{2d_0}\quad\forall t\geqq 0. \tag{5.6}$$

Now, multiplying the second equation in (4.1) by v and integrating over Ω, we obtain

$$\frac{1}{2}\frac{d}{dt}|v|^2+\int_\Omega G(x,u)v\cdot v\,dx+\int_\Omega g(x,u)\cdot v\,dx=0.$$

Hence, using the constant δ defined in (4.6), we have

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}|v|^2+\delta|v|^2&\leqq-\int_\Omega g(x,u)\cdot v\,dx\\&\leqq c_2|\Omega|^{1/2}|v|\quad(c_2\text{ given by (4.9)})\\&\leqq\frac{\delta}{2}|v|^2+\frac{c_2^2|\Omega|}{2\delta},\\\frac{d}{dt}|v|^2+\delta|v|^2&\leqq\frac{c_2^2|\Omega|}{\delta},\end{aligned}$$

which gives

$$|v(t)|^2\leqq|v_0|^2\exp(-\delta t)+\frac{c_2^2|\Omega|}{\delta^2}(1-\exp(-\delta t))\quad\forall t\geqq0. \tag{5.7}$$

Let $\rho_4>\rho_3=c_2|\Omega|^{1/2}/\delta$ be fixed. It follows from (5.7) that if $(u_0,v_0)\in\mathcal{B}\subset B(0,R)$ then

$$|v(t)|\leqq\rho_4\quad\forall t\geqq T_2(\mathcal{B}_0,\rho_4), \tag{5.8}$$

where

$$T_2(\mathcal{B}_0,\rho_4)=\frac{1}{\delta}\log\frac{R^2}{\rho_4^2-\rho_3^2}.$$

We conclude immediately from (5.4) and (5.8) that the ball of H of radius $\{\rho_2^2+\rho_4^2\}^{1/2}$ and of center zero is absorbing in H.

(b) We now write $v(t)=v_1(t)+v_2(t)$, where $v_1(t)$ is the unique solution of

$$\frac{\partial v_1}{\partial t}+G(x,u)v_1+g(x,u)=0, \tag{5.9}$$

$$v_1(0)=0, \tag{5.10}$$

and $v_2(t)$ is the unique solution of

$$\frac{\partial v_2}{\partial t}+G(x,u)v_2=0, \tag{5.11}$$

$$v_2(0)=v_0. \tag{5.12}$$

We define two families S_1, S_2 of nonlinear operators from H into $E=\mathbb{L}^2(\Omega)$ by setting

$$S_1(t):(u_0,v_0)\to(u(t),v_1(t)),\qquad S_2(t):(u_0,v_0)\to(0,v_2(t)).$$

Our aim is to derive properties (2.2) and (2.3) for this decomposition. It is easy to check (2.3). Indeed, multiplying (5.11) by v_2 and integrating over Ω, we get

$$\frac{1}{2}\frac{d}{dt}|v_2|^2+\int_\Omega G(x,u)v_2\cdot v_2\,dx=0.$$

Hence, by (4.6),

$$\frac{1}{2}\frac{d}{dt}|v_2|^2+\delta|v_2|^2\leqq 0,$$

which yields

$$|v_2(t)|^2\leqq \exp(-2\delta t)|v_0|^2.$$

This implies immediately (2.3).

Next, we multiply (4.1) by $-\Delta u$ and integrate over Ω. We obtain

$$\frac{1}{2}\frac{d}{dt}\|u(t)\|^2+(D\Delta u,\Delta u)=\int_\Omega f(x,u,v)\cdot\Delta u\,dx.$$

Thus, using the constants d_0 and c_1 defined in (5.1) and (4.8), we have

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\|u(t)\|^2+d_0|\Delta u|^2&\leqq c_1|\Omega|^{1/2}|\Delta u|\\ &\leqq \frac{d_0}{2}|\Delta u|^2+\frac{c_1^2|\Omega|}{2d_0},\end{aligned}\tag{5.13}$$

$$\frac{d}{dt}\|u(t)\|^2+d_0|\Delta u|^2\leqq\frac{c_1^2|\Omega|}{d_0}.$$

Thanks to (5.5), we can apply the uniform Gronwall lemma to (5.13). We conclude from (2.17) that if $(u_0,v_0)\in\mathcal{B}\subset B(0,R)$, then

$$\|u(t)\|^2\leqq\frac{c_4}{r}+\frac{rc_1^2|\Omega|}{d_0}\quad\text{for } t\geqq T_1+r.\tag{5.14}$$

Now we aim to establish time uniform estimates for $v_1(t)$. We first claim that

$$|v_1(t)|_{\mathbb{L}^\infty(\Omega)}\leqq\frac{2c_2}{\delta}\quad\forall t\geqq 0,\tag{5.15}$$

where δ and c_2 are given by (4.6) and (4.9). Indeed, for any given $q>2$, let us multiply (5.19) by $|v_1|^{q-2}v_1$ and integrate over Ω. We get

$$\frac{1}{q}\frac{d}{dt}\int_\Omega|v_1|^q\,dx+\int_\Omega|v_1|^{q-2}G(x,u)v_1\cdot v_1\,dx=-\int_\Omega|v_1|^{q-2}g(x,u)\cdot v_1\,dx.\tag{5.16}$$

Due to (4.6), we have

$$\int_\Omega|v_1|^{q-2}G(x,u)v_1\cdot v_1\,dx\geqq\delta\int_\Omega|v_1|^q\,dx.\tag{5.17}$$

Also, by (4.9),

$$\begin{aligned}\left|\int_\Omega|v_1|^{q-2}g(x,u)\cdot v_1\,dx\right|&\leqq c_2\int_\Omega|v_1|^{q-1}\,dx\\ &\leqq\frac{\delta}{2}\int_\Omega|v_1|^q\,dx+c_5(q)\quad\text{(by Young's inequality),}\end{aligned}\tag{5.18}$$

where

$$c_5(q)=\frac{1}{q}\,c_2^q|\Omega|\left(\frac{2(q-1)}{\delta q}\right)^{q-1}.$$

Hence, combining (5.16)-(5.18), we obtain

$$\frac{1}{q}\frac{d}{dt}\int_\Omega |v_1|^q\,dx+\frac{\delta}{2}\int_\Omega |v_1|^q\,dx\leqq c_5(q).$$

This implies by integrating, since $v_1(0)=0$,

$$|v_1(t)|_{\mathbb{L}^q(\Omega)}\leqq\left(\frac{2c_5(q)}{\delta}\right)^{1/q}\quad\forall t\geqq 0,$$

which yields (5.15) by taking the limit $q\to+\infty$.

We now derive an estimate of $\|v_1(t)\|$. For $j=1,\cdots,n$, we set $w_j=\partial v_1/\partial x_j$; w_j satisfies

$$\frac{\partial w_j}{\partial t}+G(x,u)w_j+\frac{\partial G}{\partial x_j}v_1+\sum_{i=1}^{m_1}\frac{\partial u_i}{\partial x_j}\frac{\partial G}{\partial u_i}v_1+\frac{\partial g}{\partial x_j}+\sum_{i=1}^{m_1}\frac{\partial u_i}{\partial x_j}\frac{\partial g}{\partial u_i}=0. \tag{5.19}$$

Thanks to the assumption (4.7) and to (5.15), it is easy to see that the vector functions

$$\frac{\partial G}{\partial x_j}v_1,\ \frac{\partial G}{\partial u_i}v_1,\ \frac{\partial g}{\partial x_j},\ \frac{\partial g}{\partial u_i},\quad j=1,\cdots,n,\quad i=1,\cdots,m_1,$$

are bounded in $\mathbb{L}^\infty((0,+\infty)\times\Omega)$. Hence, if we multiply (5.19) by w_j and integrate over Ω, we find

$$\frac{1}{2}\frac{d}{dt}|w_j|^2+\int_\Omega G(x,u)w_j\cdot w_j\,dx\leqq c_6\int_\Omega |w_j|\left(\left|\frac{\partial u}{\partial x_j}\right|+1\right)dx,$$

where c_6 denotes a constant depending only on the data. Using (4.6), we then have

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}|w_j|^2+\delta|w_j|^2&\leqq c_6\int_\Omega |w_j|\left(\left|\frac{\partial u}{\partial x_j}\right|+1\right)dx\\&\leqq\frac{\delta}{2}|w_j|^2+\frac{c_6^2}{\delta}\left\{|\Omega|+\left|\frac{\partial u}{\partial x_j}\right|^2\right\},\\\frac{d}{dt}|w_j|^2+\delta|w_j|^2&\leqq\frac{2c_6^2}{\delta}\left\{|\Omega|+\left|\frac{\partial u}{\partial x_j}\right|^2\right\}.\end{aligned}$$

Summing these inequalities from $j=1$ up to $j=n$, we finally obtain

$$\frac{d}{dt}\|v_1\|^2+\delta\|v_1\|^2\leqq\frac{2nc_6^2|\Omega|}{\delta}+\frac{2c_6^2}{\delta}\|u\|^2. \tag{5.20}$$

This inequality is similar to (2.22) and, as in the proof of Theorem 2.2, we can infer from (5.6), (5.14), and (5.20) that there exists a constant $c_7=c_7(R)$ such that, if $(u_0,v_0)\in\mathcal{B}\subset B(0,R)$,

$$\|v_1(t)\|\leqq c_7\quad\forall t\geqq 0. \tag{5.21}$$

It is now easy to conclude the proof of Theorem 5.1. It follows from (5.21), (5.15), (5.14) and (5.3) that the operators S_1 are uniformly compact. Hence, the assumptions (2.1)-(2.3) are satisfied and there exists a bounded absorbing set in H. Theorem 2.1 applies and yields Theorem 5.1. □

Remark 5.2. The proof of Theorem 5.1 actually shows that

$$|v|_{\mathbb{L}^\infty(\Omega)} \leqq \frac{2c_2}{\delta} \quad \forall (u, v) \in \mathscr{A}. \tag{5.22}$$

This result, which follows from (5.15) and (2.4), will be useful in the next section.

5.2. Estimate of the dimension of the attractor. We introduce the following constants:

$$c_3 = \sup_{(x,u,v)\in\bar{\Omega}\times\mathscr{D}} \left\{ \sum_{i=1}^{m_1} \left| \frac{\partial f}{\partial u_i} \right|^2 \right\}^{1/2}, \tag{5.23}$$

$$c_4 = \sup_{(x,u,v)\in\bar{\Omega}\times\mathscr{D}} \left\{ \sum_{l=1}^{m_2} \left| \frac{\partial f}{\partial v_l} \right|^2 + \sum_{i=1}^{m_1} \left(\left| \frac{\partial g}{\partial u_i} \right|^2 + \frac{c_2^2}{\delta^2} \left| \frac{\partial G}{\partial u_i} \right|^2 \right) \right\}^{1/2}, \tag{5.24}$$

where δ and c_2 are given by (4.6) and (4.9). Our aim is to prove Theorem 5.3.

THEOREM 5.3. *Under assumptions* (4.4)-(4.7), *the universal attractor* $\mathscr{A}$ *defined in Theorem* 5.1 *has finite Hausdorff and fractal dimensions. Moreover, both dimensions are bounded by*

$$c\left\{ 1 + \frac{d_0}{\delta |\Omega|^{2/n}} + \frac{|\Omega|}{d_0^{n/2}} \left(\delta^{n/2} + \frac{1}{\delta} c_3^{n_1} + \frac{1}{\delta^{n_1+1}} c_4^{2n_1} \right) \right\}, \tag{5.25}$$

where c *denotes a constant depending on* n, m_1 *and the shape of* Ω; $n_1 = 1 + n/2$ *and* δ, d_0, c_3, c_4 *are, respectively, given by* (4.6), (5.1), (5.23), *and* (5.24).

Remarks 5.4. (1) A remark similar to Remark 3.3 could be made here; the details are left to the reader.

(2) In all the examples of § 6 below, the positively invariant region $\mathscr{D}$ is bounded in the v direction; i.e., there exists $\alpha > 0$ such that $|v| \leqq \alpha$, for all $(u, v) \in \mathscr{D}$. It follows that the universal attractor $\mathscr{A}$ satisfies

$$|v|_{\mathbb{L}^\infty(\Omega)} \leqq \alpha \quad \forall (u, v) \in \mathscr{A}.$$

Using this bound (instead of (5.22)) and the same arguments as in the proof of Theorem 5.3, we can derive another estimate of the Hausdorff and fractal dimensions of the attractor:

$$c\left\{ 1 + \frac{d_0}{\delta |\Omega|^{2/n}} + \frac{|\Omega|}{d_0^{n/2}} \left(\delta^{n/2} + \frac{1}{\delta} c_3^{n_1} + \frac{1}{\delta^{n_1+1}} c_4'^{2n_1} \right) \right\}, \tag{5.25}'$$

where

$$c_4' = \sup_{(x,u,v)\in\bar{\Omega}\times\mathscr{D}} \left\{ \sum_{l=1}^{m_2} \left| \frac{\partial f}{\partial v_l} \right|^2 + \sum_{i=1}^{m_1} \left(\left| \frac{\partial g}{\partial u_i} \right|^2 + \alpha^2 \left| \frac{\partial G}{\partial u_i} \right|^2 \right) \right\}^{1/2}.$$

We shall use the estimate (5.25)′ in all the examples of § 6.

Proof of Theorem 5.3. The proof follows the same steps as for Theorem 3.2 and most of the computations in the proof of Theorem 3.2 will be adapted here. For $(u_0, v_0) \in \mathscr{A}$, let us denote by $\mathfrak{A}(u, v)$ the linear operator from $(H^2(\Omega))^{m_1} \times (L^2(\Omega))^{m_2}$ into $E = \mathbb{L}^2(\Omega)$ defined by

$$\mathfrak{A}(u, v) \cdot (U, V) = (\mathfrak{A}_1(u, v) \cdot (U, V), \mathfrak{A}_2(u, v) \cdot (U, V)),$$

$$\mathfrak{A}_1(u, v) \cdot (U, V) = -D\Delta U + \sum_{i=1}^{m_1} \frac{\partial f}{\partial u_i}(x, u, v) U_i + \sum_{l=1}^{m_2} \frac{\partial f}{\partial v_l}(x, u, v) V_l,$$

$$\mathfrak{A}_2(u, v) \cdot (U, V) = G(x, u) V + \sum_{i=1}^{m_1} \frac{\partial G}{\partial u_i}(x, u) v U_i + \sum_{i=1}^{m_1} \frac{\partial g}{\partial u_i}(x, u) U_i,$$

where (u, v) is the solution of (4.1)-$(4.3)_\alpha$.

We first show that, for every $t_0 > 0$, $S(t_0)$ is uniformly differentiable on $\mathscr{A}$. Its differential at (u_0, v_0) is the linear operator on $E: (\xi, \eta) \to L(t_0, u_0, v_0) \cdot (\xi, \eta) = (U(t_0), V(t_0))$, where $(U(t_0), V(t_0))$ is the value at time t_0 of the solution $(U(t), V(t))$ of the following linearized problem:

$$\dot{U} + \mathfrak{A}_1(u, v) \cdot (U, V) = 0, \qquad \dot{V} + \mathfrak{A}_2(u, v) \cdot (U, V) = 0,$$
$$U(0) = \xi, \qquad V(0) = \eta,$$
$$U \text{ satisfies } (4.3)_\alpha$$

(we omit the details).

We then define

$$q_N = \limsup_{t \to +\infty} \left(\inf_{(u_0, v_0) \in \mathscr{A}} \frac{1}{t} \int_0^t \inf_{\text{rank } Q = N} \operatorname{Tr} (\mathfrak{A}(u, v) \circ Q)\, ds \right),$$

where Q denotes any orthogonal projector of rank N in E such that

$$QE \subset \{(U, V) \in (H^2(\Omega))^{m_1} \times (L^2(\Omega))^{m_2},\ U \text{ satisfies the boundary condition } (4.3)_\alpha\}.$$

As in Theorem 3.2, if $q_N > 0$ for some integer N, then the Hausdorff dimension of $\mathscr{A}$ is majorized by N and its fractal dimension is bounded by (3.10).

To estimate the q_N's, let Q be an orthogonal projector satisfying the above conditions and let $\{(\varphi^j, \psi^j)\}_{j \in \mathbb{N}}$ be an orthonormal basis of E such that $(\varphi^1, \psi^1), \cdots, (\varphi^N, \psi^N)$ is a basis of the image of Q. Then

$$\begin{aligned} \operatorname{Tr} \mathfrak{A}(u, v) \circ Q &= \sum_{j=1}^N (\mathfrak{A}(u, v)(\varphi^j, \psi^j), (\varphi^j, \psi^j)) \\ &= \sum_{j=1}^N \left(\sum_{i=1}^{m_1} d_i \|\varphi_i^j\|^2 + \int_\Omega G\psi^j \cdot \psi^j\, dx + \sum_{i,k=1}^{m_1} \int_\Omega \frac{\partial f_k}{\partial u_i} \varphi_i^j \varphi_k^j\, dx \right) \\ &\quad + \sum_{j=1}^N \sum_{i=1}^{m_1} \sum_{l=1}^{m_2} \int_\Omega \left(\frac{\partial f_i}{\partial v_l} + \left(\frac{\partial G}{\partial u_i} v \right)_l + \frac{\partial g_l}{\partial u_i} \right) \varphi_i^j \psi_l^j\, dx. \end{aligned} \tag{5.26}$$

Using the constants d_0 and δ defined in (5.1) and (4.6), we have

$$\sum_{j=1}^N \left(\sum_{i=1}^{m_1} d_i \|\varphi_i^j\|^2 + \int_\Omega G\psi^j \cdot \psi^j\, dx \right) \geqq d_0 \sum_{j=1}^N \|\varphi^j\|^2 + \delta \sum_{j=1}^N |\psi^j|^2.$$

Also

$$\left| \sum_{j=1}^N \sum_{i,k=1}^{m_1} \int_\Omega \frac{\partial f_k}{\partial u_i} \varphi_i^j \varphi_k^j\, dx \right| \leqq c_3 \int_\Omega \rho(x)\, dx \quad (c_3 \text{ given by (5.23)}),$$

where we have set

$$\rho(x) = \sum_{j=1}^N |\varphi^j(x)|^2.$$

Using (5.22) and the constant c_4 defined in (5.24), we have that the last integral in (5.26) is majorized as follows:

$$\begin{aligned} &\left| \sum_{j=1}^N \sum_{i=1}^{m_1} \sum_{l=1}^{m_2} \int_\Omega \left(\frac{\partial f_i}{\partial v_l} + \left(\frac{\partial G}{\partial u_i} v \right)_l + \frac{\partial g_l}{\partial u_i} \right) \varphi_i^j \psi_l^j\, dx \right| \\ &\quad \leqq c_5 c_4 \sum_{j=1}^N |\varphi^j|\, |\psi^j| \quad (c_5 \text{ is a universal constant}) \\ &\quad \leqq \frac{\delta}{2} \sum_{j=1}^N |\varphi^j|^2 + \frac{c_5^2 c_4^2}{2\delta} \int_\Omega \rho(x)\, dx. \end{aligned}$$

Combining the above inequalities, from (5.26) we infer that

$$\operatorname{Tr} \mathfrak{A}(u, v) \circ Q \geqq d_0 \sum_{j=1}^{N} \|\varphi^j\|^2 + \frac{\delta}{2} \sum_{j=1}^{N} \|\psi^j|^2 - \left(c_3 + \frac{c_5^2 c_4^2}{2\delta}\right) \int_\Omega \rho(x)\, dx.$$

This estimate is analogous to (3.12). Moreover, the generalized Lieb-Thirring inequalities for the vector functions $(\varphi^j)_{1 \leqq j \leqq N}$ read like the ones (see (3.14)) for the scalar functions with constants K_1, K_2 that depend on n, m_1, and the shape of Ω. Hence, we can conclude the proof of Theorem 5.3 thanks to computations similar to the ones from (3.12) in the proof of Theorem 3.2; the details are left to the reader. □

6. Examples. We describe some examples of reaction-diffusion systems satisfying the hypotheses (4.4)-(4.7).

Example 6.1. *Hodgkin-Huxley equations.* This system, proposed by Hodgkin and Huxley [13], describes the nerve impulse transmission. Here $n = 1$, $\Omega = (0, L)$ and the system is of the form (4.1) with $m_1 = 1$, $m_2 = 3$:

$$\begin{aligned} \frac{\partial u}{\partial t} &= d \frac{\partial^2 u}{\partial x^2} - f(u, v_1, v_2, v_3), \\ \frac{\partial v_1}{\partial t} &= k_1(u)(h_1(u) - v_1), \\ \frac{\partial v_2}{\partial t} &= k_2(u)(h_2(u) - v_2), \\ \frac{\partial v_3}{\partial t} &= k_3(u)(h_3(u) - v_3). \end{aligned} \tag{6.1}$$

We have

$$f(u, v) = -\gamma_1 v_1^2 v_2 (\sigma_1 - u) - \gamma_2 v_3^4 (\sigma_2 - u) - \gamma_3 (\sigma_3 - u),$$

with $\gamma_i > 0$, $\sigma_1 > \sigma_3 > 0 > \sigma_2$. Furthermore, $d > 0$, k_i, h_i are $\mathscr{C}^\infty$ functions and satisfy $k_i > 0$, $1 > h_i > 0$, $i = 1, 2, 3$; u represents the electrical potential in the nerve, while v_1, v_2, v_3 represent chemical concentrations and vary thus between zero and one.

It is proved in Chueh, Conley, and Smoller [3] and Sermange [23] that any rectangle

$$\mathscr{D} = \{(u, v_1, v_2, v_3),\ \alpha_0 \leqq u \leqq \alpha_1,\ 0 \leqq v_i \leqq 1,\ i = 1, 2, 3\}$$

is an invariant region provided $\alpha_1 \geqq \delta_1$ (> 0), $\alpha_0 \leqq \delta_2$ (< 0). Assumptions (4.6) and (4.7) are obviously satisfied and (4.5) follows from the existence of the compact invariant region $\mathscr{D}$ (see [18] for more details).

Theorems 5.1 and 5.3 apply and give the existence of a universal attractor $\mathscr{A}$ whose Hausdorff and fractal dimensions are finite (the boundary condition is the Dirichlet, the Neumann, or the periodic boundary condition). This attractor describes the long-time behavior of the impulse transmission in the nerve. Its Hausdorff and fractal dimensions are more precisely bounded by

$$c\left(1 + \frac{1}{\delta L^2} d + \frac{1}{d^{1/2}} L\left(\delta^{1/2} + \frac{1}{\delta} c_3^{3/2} + \frac{1}{\delta^{5/2}} c_4^3\right)\right),$$

where c is a universal constant and

$$\delta = \min_{1 \leqq i \leqq 3} \min_{\alpha_0 \leqq u \leqq \alpha_1} k_i(u),$$

$$c_3 = \max_{(u, v) \in \mathscr{D}} \left|\frac{\partial f}{\partial u}(u, v)\right|,$$

$$c_4 = \max_{(u,v)\in\mathscr{D}} \left(\sum_{i=1}^{3} \left(\left| \frac{\partial f}{\partial v_i}(u,v) \right|^2 + |k_i(u)h_i'(u)|^2 + |k_i'(u)|^2 \right) \right)^{1/2}.$$

Example 6.2. *FitzHugh-Nagumo equations.* These equations introduced by FitzHugh [8] and Nagumo, Arimoto, and Yosimzawa [21] are also intended to describe the signal transmission across axons; they read as follows:

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + h(u) - v, \qquad \frac{\partial v}{\partial t} = \sigma u - \delta v.$$

Here $n = 1$, $\Omega = (0, L)$, $m_1 = m_2 = 1$, $\sigma > 0$, $\delta > 0$ and

$$h(u) = -u(u-\beta)(u-1), \qquad 0 < \beta < \tfrac{1}{2}.$$

As in (6.1), u represents the electrical potential in the axon, but v has a more complicated interpretation.

It is proved in Chueh, Conley, and Smoller [3] that any rectangle

$$\mathscr{D} = \{(u, v), -\alpha_1 \leqq u \leqq \alpha_2, -\alpha_3 \leqq v \leqq \alpha_4\}$$

is an invariant region provided the edges $v = \alpha_4$ and $v = -\alpha_3$ of $\mathscr{D}$ are, respectively, included in the half spaces $\sigma u - \delta v < 0$ and $\sigma u - \delta v > 0$ and the edges $u = \alpha_2$ and $u = -\alpha_1$ are on both sides of the zero set of $h(u) - v$. Assumptions (4.6) and (4.7) are obviously satisfied and (4.5) is proved as in Example 6.1 above.

Theorem 5.1 and 5.3 apply and give the existence of a universal attractor having finite Hausdorff and fractal dimensions (the boundary condition is either the Dirichlet or the Neumann or the periodic boundary condition). Moreover, both dimensions are bounded by

$$c\left(1 + \frac{1}{\delta L^2} + L\left(\delta^{1/2} + \frac{1}{\delta} c_3^{3/2} + \frac{1}{\delta^{5/2}} c_4^3\right)\right),$$

where c is a universal constant and

$$c_3 = \max_{-\alpha_1 \leqq u \leqq \alpha_2} |h'(u)|, \qquad c_4 = \{1 + \sigma^2\}^{1/2}.$$

Example 6.3. *A system of solid combustion type.* In the theory of combustion of solids, there arises the following system:

$$\frac{\partial u}{\partial t} = \Delta u + \sigma v h(u), \qquad \frac{\partial v}{\partial t} = -\sigma v h(u) + k(x).$$

Here $n \geqq 1$, $m_1 = m_2 = 1$; $\sigma > 0$, $k(x)$ is a $\mathscr{C}^2$ function on $\bar{\Omega}$ with $k \geqq 0$ and we have

$$h(u) = \exp\left(-\frac{\beta(1-u)}{1+\gamma(u-1)}\right),$$

where $\beta > 0$, $\gamma \in]0, 1[$; u represents the temperature while v represents the concentration of the solid reactant. The original model where $k = 0$ (see Matkowsky and Sivashinsky [20]) leads to a trivial attractor; here we introduce a source term of reactant $k \neq 0$. From a physical point of view, a useful variant of the model consists in assuming a constant flux of reactant across the boundary (Clavin et al. [4], Clavin [5]); the corresponding problem, which requires some modifications of the above framework, will be studied in another paper [19].

Using the classical truncation method, we can show that the rectangle

$$\mathscr{D} = \{(u, v), u \geqq 0, 0 \leqq v \leqq \alpha\}, \qquad \alpha = \frac{1}{\sigma} \exp\left(\frac{\beta}{1-\gamma}\right) \sup_{x\in\bar{\Omega}} |k(x)|$$

is a positively invariant region. Also, assumptions (4.6) and (4.7) are satisfied and (4.5) is proved thanks to an estimate of $|u(t)|_{L^\infty(\Omega)}$.

Theorems 5.1 and 5.3 apply and give the existence of a universal attractor with finite Hausdorff and fractal dimensions (for a Dirichlet boundary condition). These dimensions are majorized by

$$c\left(1+\frac{1}{\delta|\Omega|^{2/n}}+|\Omega|\left(\delta^{n/2}+\frac{1}{\delta}c_3^{n_1}+\frac{1}{\delta^{n_1+1}}c_4^{2n_1}\right)\right),$$

where c depends on n and the shape of Ω, $n_1=1+n/2$, and

$$\delta=\sigma\exp\left(-\frac{\beta}{1-\gamma}\right),\qquad c_3=\frac{\gamma^2}{\beta}\exp\left(\frac{\beta}{\gamma(1-\gamma)}\right)\sup_{x\in\bar{\Omega}}|k(x)|,$$

$$c_4=\left(\sigma^2\exp\left(\frac{2\beta}{\gamma}\right)+c_3^2\right)^{1/2}.$$

Example 6.4. *Feld-Noyes equations.* The equations of this last example serve as a model for the Belousov-Zhabotinskii reactions in chemical kinetics (cf. Howard and Kopell [14], Hastings and Murray [12]). Here, $n\geqq 1$, $m_1=1$, $m_2=2$ and (u, v_1, v_2) satisfy

$$\begin{aligned}\frac{\partial u}{\partial t}&=d\Delta u+\alpha(v_1-uv_1+u-\beta u^2),\\ \frac{\partial v_1}{\partial t}&=\frac{1}{\alpha}(\gamma v_2-v_1-uv_1),\\ \frac{\partial v_2}{\partial t}&=\sigma(u-v_2),\end{aligned}\tag{6.2}$$

where α, β, γ, σ are positive constants. The constant d can usually be greater than or equal to zero, but we impose $d>0$; u, v_1, v_2 represent chemical concentrations.

For convenience, we introduce the new unknowns $w_1=v_1$, $w_2=\xi v_2$, where $\xi>0$ will be chosen later. Then the system (6.2) becomes

$$\begin{aligned}\frac{\partial u}{\partial t}&=d\Delta u+\alpha(w_1-uw_1+u-\beta u^2),\\ \frac{\partial w_1}{\partial t}&=\frac{1}{\alpha}\left(\frac{\gamma}{\xi}w_2-w_1-uw_1\right),\\ \frac{\partial w_2}{\partial t}&=\sigma(\xi u-w_2).\end{aligned}$$

It is proved by Chueh, Conley, and Smoller [3] that

$$\mathcal{D}=\{(u, w_1, w_2), 0\leqq u\leqq a, 0\leqq w_1\leqq b, 0\leqq w_2\leqq \xi c\}$$

is invariant provided $a>\max(1, \beta^{-1})$, $c>a$, $b>\gamma c$. Assumption (4.7) is obvious and (4.5) is proved as in Example 6.1; (4.6) is satisfied provided $\gamma^2<4\sigma\alpha\xi^2$ and we choose $\xi=\gamma/(2\sigma\alpha)^{1/2}$.

Theorems 5.1 and 5.3 apply and give the existence of a universal attractor whose Hausdorff and fractal dimensions are bounded by

$$c\left(1+\frac{1}{\delta|\Omega|^{2/n}}+\frac{|\Omega|}{d^{n/2}}\left(\delta^{n/2}+\frac{1}{\delta}c_3^{n_1}+\frac{1}{\delta^{n_1+1}}c_4^{2n_1}\right)\right)$$

where c depends on n and the shape of Ω, $n_1 = 1 + n/2$, and

$$\delta = \min_{u \in [0,a]} \frac{1}{2}\left(\frac{1+u}{\alpha} + \sigma - \left(\left(\frac{1+u}{\alpha} - \sigma\right)^2 + \frac{2\sigma}{\alpha}\right)^{1/2}\right),$$

$$c_3 = \alpha(b + 1 + \beta a),$$

$$c_4 = \left(\alpha^2(1+a)^2 + \sigma^2 + \frac{1}{\alpha^2}\left(b^2 + \frac{\gamma^2 c^2}{\sigma\alpha}\right)\right)^{1/2}.$$

LOCALIZED CLUSTER SOLUTIONS OF NONLINEAR DEGENERATE DIFFUSION EQUATIONS ARISING IN POPULATION DYNAMICS*

YUZO HOSONO† AND MASAYASU MIMURA‡

Abstract. The stationary problem of a nonlinear degenerate diffusion equation with nonlocal advection term including the aggregative mechanism is investigated. The spatially clustering phenomena of individuals in population dynamics is modeled. The existence of two kinds of stationary solutions with connected compact support—a large as well as a small cluster solution—is proved by the matched asymptotic expansion method and the geometric singular perturbation method, respectively.

Key words. nonlinear degenerate diffusion, nonlocal advection, aggregation, clustering, singular perturbation

AMS(MOS) subject classifications. 35K65, 34E15, 92A15

1. Introduction. In this paper, we will study stationary patterns of a one-dimensional phenomenological population model that describes the spatially clustering phenomena of individuals:

$$u_t = \varepsilon^2 (u^m)_{xx} - \varepsilon (K[u]u)_x + f(u), \qquad (x, t) \in R \times (0, \infty), \tag{1.1}$$

where $u(x, t)$ denotes the population density at position x and time t and the constants m and ε satisfy that $m > 1$ and $\varepsilon > 0$. Here, $K[u]$ is given by

$$K[u](x, t) = \lambda \left[\int_x^{x+r} u(y, t)\, dy - \int_{x-r}^{x} u(y, t)\, dy \right] \tag{1.2}$$

with parameters $\lambda > 0$ and r $(0 \leqq r \leqq \infty)$, and f is assumed to be a cubic-like function.

First, we briefly give the ecological interpretation on the model equation (1.1) with (1.2). The dispersal of individuals involves two processes. One is the density-dependent random movement that possesses "population pressure effect" (see Gurney and Nisbet [8], for instance). The other is the directed movement to cluster for oneself; that is, if the total population in the interval $(x-r, x)$ is less than that in $(x, x+r)$, that is, $\int_{x-r}^{x} u(y, t)\, dy < \int_x^{x+r} u(y, t)\, dy$, the individuals at position x move to the right and to the left if the inequality is reversed. Hence, (1.2) includes the aggregative mechanism of individuals through nonlocal interactions. $f(u)$ means the growth term of individuals. Let us show one specific form of $f(u)$ often used in mathematical ecology:

$$f_p(u) = \left(\alpha - \frac{u}{K} \right) u - \frac{ku}{1+u} P,$$

where α is the intrinsic growth rate of the individual. K is the carrying capacity, $ku/(1+u)$ is the predation rate of a predator with the maximum rate k, and P is the population density of the predator. If P remains constant and takes a suitable value, $f_p(u) = 0$ has three solutions, say O, A, and I as in Fig. 1. In this paper, we specify $f(u)$ as

$$f(u) = u(1-u)(u-a) \tag{1.3}$$

with a parameter a $(0 < a < 1)$, because it is a quite simple but suggestive nonlinearity.

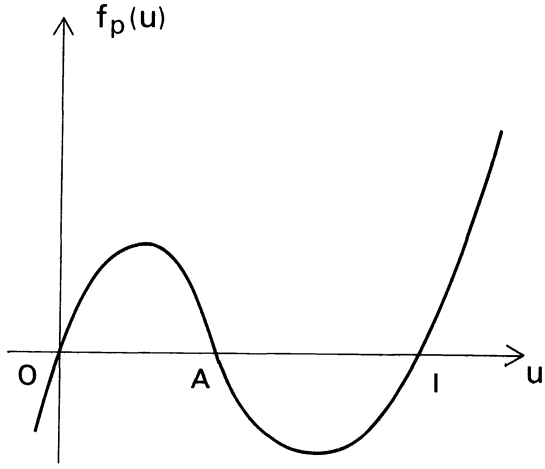

FIG. 1. *Functional form of* $f_p(u)$.

This kind of model has been discussed recently by several authors. For $f \equiv 0$ and $m > 1$, Nagai and Mimura [14]-[16] have fully discussed the case $r = \infty$ and have shown the existence of stationary solutions localized in a finite interval and their stability, and Ikeda [11] and Ikeda and Nagai [12] have investigated the case $r < +\infty$. See also Alt [1] for chemotactic models.

If $\lambda = 0$, that is, if there exists no aggregative effect, then (1.1) is reduced to the nonlinear degenerate diffusion equation with bistable kinetics (1.3):

$$u_t = \varepsilon^2 (u^m)_{xx} + f(u), \qquad (x, t) \in R \times (0, \infty). \tag{1.4}$$

Suppose that the initial data have compact support. Then, if $S(a, m) \equiv \int_0^1 f(u) u^{m-1}\, du < 0$, the solution $u(x, t)$ of (1.4) tends to zero uniformly in $x \in R$, while if $S(a, m) > 0$ and $u(x, 0) > a$ for all $x \in (-L, L)$ with sufficiently large positive L, $u(x, t)$ tends to 1 uniformly on any compact subset of R. Moreover, the support of solutions is compact for each $t > 0$ and monotone nondecreasing, that is, $\operatorname{supp}[u(\cdot, t_1)] \subset \operatorname{supp}[u(\cdot, t_2)]$ for any $0 \leqq t_1 < t_2$ (see Hosono [9]). This compactness property of support is one of the main features of nonlinear degenerate diffusion equations such as the porous media equation (see, for example, Aronson [2]).

The linear diffusion case (1.1) for $m = 1$ and $r = \infty$ has already been studied by Mimura, Terman, and Tsujikawa [13] for the case of bistable kinetics (1.3). The above results motivate us to consider (1.1) for $m > 1$ and $r < +\infty$, and show the existence of localized cluster solutions due to nonlocal advection (1.2).

In this paper, we assume that ε is sufficiently small, namely, the dispersal rate is much slower than the rate of dynamics, and consider the stationary problem of (1.1):

$$\begin{aligned} &\varepsilon^2 (u^m)_{xx} - \varepsilon (K[u]u)_x + f(u) = 0, \qquad x \in R, \\ &u(\pm\infty) = 0. \end{aligned} \tag{1.5}$$

We show that two types of solutions with compact connected support exist, depending on r and a: a large single cluster solution that has $O(1)$-length support and a small one that has $O(\varepsilon)$-length support (see Fig. 4). The numerical simulations suggest that the former is *stable* while the latter is *unstable*. Here, it should be noted that the degeneracy of diffusion at $u = 0$ requires the weak definition of solutions. A solution

of (1.5) is defined by a nonnegative function u on R satisfying the following: (i) u is bounded and continuous; (ii) u^m satisfies the integral identity

$$\int_{-\infty}^{+\infty} \{-[\varepsilon^2(u^m)_x - \varepsilon K[u]u]\varphi_x + f\varphi\}\, dx = 0$$

for all $\varphi \in C^1(R)$ such that $\varphi \geqq 0$ and vanishes for large values of $|x|$. To prove the existence of single cluster solutions, we employ two different approaches by exploiting the smallness of ε, that is, the singular perturbation method (the matched asymptotic expansion technique) for a large one and the shooting method used in [6] for a small one. In both cases, the degenerate character of the problem makes the proofs more complicated than for linear diffusion cases.

Due to the compact support of the stationary solutions, there also exist *multiple* cluster solutions. Figure 2a-f shows several cluster solutions; the number of clusters depends on the magnitude of the initial function in an appropriate sense. Such phenomena are drastically different from the linear version ($m = 1$).

2. Formulation of the problem and the main results. We consider a symmetric solution $u(x)$ at $x = 0$, with connected compact support, that is, it satisfies $u(x) = u(-x)$ for all $x \in R$ and $\operatorname{supp}[u] = [-\omega, \omega]$ with some $\omega > 0$. Then our problem is to find a solution $u(x; \varepsilon, \omega)$ of

$$\varepsilon^2(u^m)_{xx} - \varepsilon(K[u]u)_x + f(u) = 0, \qquad x \in I_\omega = (-\omega, \omega), \tag{2.1}$$

$$u = 0, \quad (u^m)_x = 0 \quad \text{at } x = I_{\pm\omega},$$

$$u(x) = u(-x) > 0 \quad \text{for } x \in I_\omega, \tag{2.2}$$

$$u(x) = 0 \quad \text{for } x \in R \setminus I_\omega,$$

where ω is a parameter to be determined. We note that solutions of (2.1), (2.2) become a solution of (1.5).

We will first construct a formal approximation to a large cluster solution of (2.1), (2.2). Set $\varepsilon = 0$ in (2.1). Then we have $f(u) = 0$, and define U_o by

$$U_o(x, \beta) = \begin{cases} 1, & 0 \leqq |x| < \beta, \\ 0, & |x| \geqq \beta, \end{cases} \tag{2.3}$$

for any fixed $\beta \in (0, \infty)$. We discuss the jump discontinuity of U_o only at $x = \beta$. Let us introduce the stretched variable $\xi = (x - \beta)/\varepsilon$. Then the equation in (2.1) is

$$(u^m)_{\xi\xi} - (K[u]u)_\xi + f(u) = 0,$$

where

$$K[u] = \lambda\left[\int_{\varepsilon\xi+\beta}^{\varepsilon\xi+\beta+r} u(y)\, dy - \int_{\varepsilon\xi+\beta-r}^{\varepsilon\xi+\beta} u(y)\, dy\right].$$

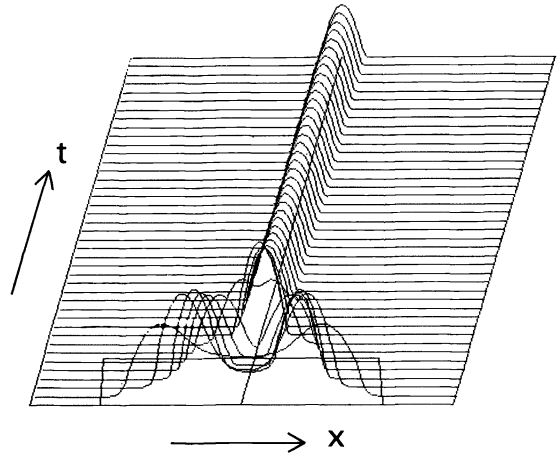
We may expect that the solution u is given by $U_o(x, \omega) + o(1)$ for $|x| \leqq \beta - \kappa(\varepsilon)$ and $|x| \geqq \beta + \kappa(\varepsilon)$ with some positive $\kappa(\varepsilon) = o(1)$, so that

$$K[u] = \lambda\left[\int_{\beta}^{\beta+r} U_o(y, \beta)\, dy - \int_{\beta-r}^{\beta} U_o(y, \beta)\, dy\right] + o(1) = -\lambda \min(r, 2\beta) + o(1).$$

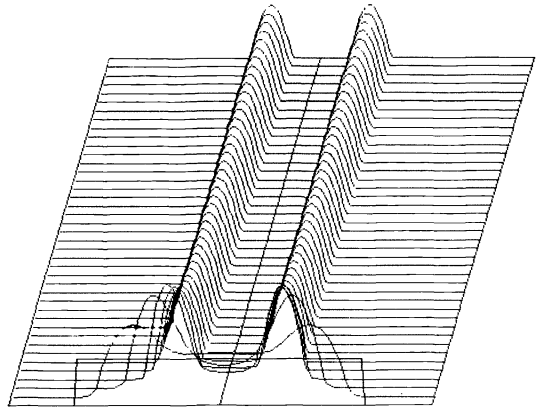
Setting $\varepsilon = 0$ and $k = \min(r, 2\beta)$, we have the inner problem:

$$(u^m)_{\xi\xi} + \lambda k u_\xi + f(u) = 0, \qquad \xi \in R, \tag{2.4}$$

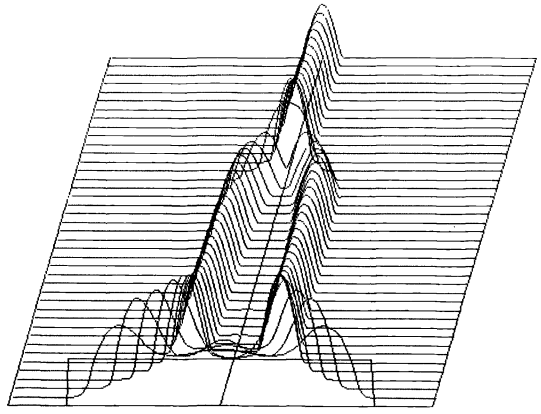
$$u(-\infty) = 1, \quad u(\beta_1) = (u^m)_x(\beta_1) = 0, \quad u(0) = \alpha \in [0, 1),$$



(a) $L = 10$.

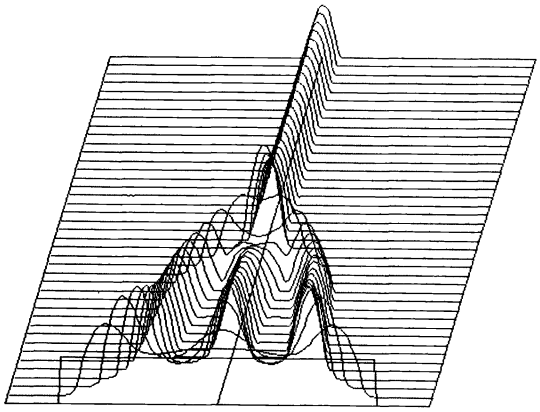


(b) $L = 11$.

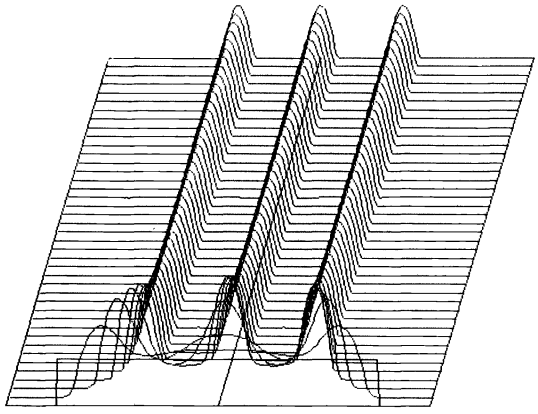


(c) $L = 13$.

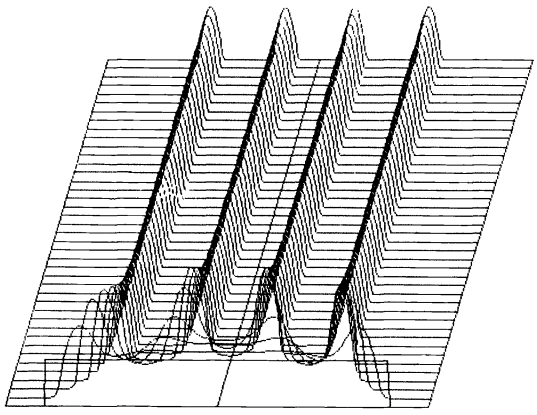
FIG. 2. *Time development of initial functions into multiple cluster solutions for the initial data* $u_0(x) = 1$ *for* $|x| \leqq L$ *and* $u_0(x) = 0$ *for* $|x| > L$, *where* $\varepsilon = \lambda = 1.0$, $a = 0.2$, $m = 2$, *and* $r = 5.0$.



(d) $L = 15$.



(e) $L = 16$.



(f) $L = 2$.

FIG. 2—continued

where the last condition is imposed to fix the translation invariance and β_1 is an unknown to be determined. For this problem, it is shown in [7] that there exist a unique $c^*(a)$ and a unique positive ω_1 such that (2.4) has a unique monotone decreasing solution $U_i(\xi, \beta_1)$ in the weak sense if and only if $k = c^*(a)/\lambda$ and $\beta_1 = \omega_1$. Moreover, $c^*(a)$ is a strictly monotone decreasing function of $a \in (0, 1)$ satisfying $c^*(a) = 0$ for $a = a^* = (m+1)/(m+3)$ and $c^*(a) \gtreqless 0$ according to $S(a, m) \gtreqless 0$ (see [7]). Therefore,

if $a \in (0, a^*)$ and r satisfies $r \geqq 2\omega_0$ with $\omega_0 = c^*(a)/2\lambda > 0$, we can choose β as $\beta = \omega_0$ so that $k = \min(r, 2\beta)$ attains the value $c^*(a)/\lambda$. Thus, we have obtained the lowest-order outer and inner solutions as $U_o(x, \omega_0)$ and $U_i(\xi, \omega_1) = U_i((x-\omega_0)/\varepsilon, \omega_1)$, respectively.

Next, we consider a small cluster solution. Taking its outer solution as identically zero, we may construct only the inner solution. Put $\omega = \varepsilon\sigma$ and $\eta = x/\varepsilon$, and rewrite (2.1) as follows:

$$(u^m)_{\eta\eta} - \varepsilon(\tilde{K}[u]u)_\eta + f(u) = 0, \qquad \eta \in J = (-\sigma, \sigma), \tag{2.5}$$

$$u = (u^m)_\eta = 0 \quad \text{at } \eta = \pm\sigma,$$

$$u(\eta) = u(-\eta) > 0 \quad \text{for } \eta \in J, \tag{2.6}$$

$$u(\eta) \equiv 0 \quad \text{for } \eta \in R \backslash J,$$

where

$$\tilde{K}[u] = \lambda\left[\int_\eta^{\eta+r/\varepsilon} u(\eta')\,d\eta' - \int_{\eta-r/\varepsilon}^{\eta} u(\eta')\,d\eta'\right].$$

Setting $\varepsilon = 0$ in (2.5), we have

$$(u^m)_{\eta\eta} + f(u) = 0, \qquad \eta \in J, \tag{2.7}$$

which can be solved under the conditions (2.6) (see Lemma 4.1 and its remark). We see that, for each $a \in (0, a^*)$, there is a unique $\sigma_0 > 0$ such that a solution $u_i(\eta, \sigma_0)$ of (2.7) uniquely exists for $\sigma = \sigma_0$ and is monotone decreasing for $\eta \geqq 0$. Moreover, σ_0 is a strictly monotone increasing function of a satisfying $\lim_{a\to a^*} \sigma_0 = +\infty$ and $\lim_{a\to 0} \sigma_0 = 0$. This is the lowest-order approximation to a small solution. Now we state our theorem.

THEOREM 2.1 (Existence of single cluster solutions). *Assume that $0 < a < a^*$ and let δ be any small positive constant. Then, we have the following*:

(A) *For each fixed $r \geqq 2\omega_0 + \delta$, there exists an $\varepsilon_0 > 0$ such that for any $\varepsilon \in (0, \varepsilon_0)$, (2.1), (2.2) has a large single (symmetric) cluster solution $U_l(x, \varepsilon)$ satisfying that for any small $\kappa > 0$,*

$$\lim_{\varepsilon\to 0} U_l(x, \varepsilon) = 1 \quad \textit{uniformly in } x \in (-\omega_0 + \kappa, \omega_0 - \kappa) \tag{2.8}$$

and

$$\operatorname{supp}[U_l] = [-\omega_0 - \tilde{\omega}_1(\varepsilon), \omega_0 + \tilde{\omega}_1(\varepsilon)], \tag{2.9}$$

where $\tilde{\omega}_1(\varepsilon)$ is a positive function of ε satisfying $\lim_{\varepsilon\to 0} \tilde{\omega}_1(\varepsilon) = 0$.

(B) *For each fixed $r \geqq \delta > 0$, there exists an $\varepsilon_1 > 0$ such that for any $\varepsilon \in (0, \varepsilon_1)$, (2.1), (2.2) has a small single (symmetric) cluster solution $U_s(x, \varepsilon)$ satisfying*

$$\lim_{\varepsilon\to 0} U_s(\varepsilon\eta, \varepsilon) = u_i(\eta; \sigma_0) \quad \textit{uniformly in } \eta = \frac{x}{\varepsilon} \in R \tag{2.10}$$

and

$$\operatorname{supp}[U_s] = [-\varepsilon\sigma_\varepsilon, \varepsilon\sigma_\varepsilon], \tag{2.11}$$

where σ_ε is some positive function of ε satisfying $\lim_{\varepsilon\to 0} \sigma_\varepsilon = \sigma_0$.

Let u_1 and u_2 be any two solutions of (1.5) satisfying that the distance between $\operatorname{supp}[u_1]$ and $\operatorname{supp}[u_2]$ is not less than r; that is, $\operatorname{dist}(\operatorname{supp}[u_1], \operatorname{supp}[u_2]) \geqq r$. Then, it is easily seen that $u_1 + u_2$ becomes a solution of (1.5), so that our theorem directly gives the following corollary.

COROLLARY (Existence of multiple cluster solutions). *Let* $\{x_i\}_{i\in\Lambda}$ (Λ: *an index set*) *be a finite or countable sequence of real numbers and* Λ_1, Λ_2 *be index sets satisfying* $\Lambda=\Lambda_1\cup\Lambda_2$, $\Lambda_1\cap\Lambda_2=\phi$, *and denote* $U_i=U_l(x-x_i,\varepsilon)$ *for* $i\in\Lambda_1$ *and* $u_j=U_s(x-x_j,\varepsilon)$ *for* $j\in\Lambda_2$. *If* $\operatorname{dist}(\operatorname{supp}[u],\operatorname{supp}[\tilde{u}])\geqq r$ *for any* $u,\hat{u}\in\{U_i\}_{i\in\Lambda_1}\cup\{u_j\}_{j\in\Lambda_2}$ *such that* $u\neq\tilde{u}$, *then* (1.5) *has also a solution* $u(x,\varepsilon)$ *represented by*

$$u(x,\varepsilon)=\sum_{i\in\Lambda_1}U_i+\sum_{j\in\Lambda_2}u_j \tag{2.12}$$

(*see Fig.* 2).

Remark 1. If $a\geqq a^*$, then $c^*(a)\leqq 0$, so that there exists no solution for (2.4) since $k=\min(r,2\beta)>0$. Also (2.7) and (2.6) have no solution for $a\geqq a^*$. By this result and the complementary numerical simulations, we may conjecture that (2.1) and (2.2) have no spatially heterogeneous steady state solution when $a\geqq a^*$.

Remark 2. Let r be fixed in $(0,2\omega_0^*)$ with $\omega_0^*\equiv\lim_{a\to 0}c^*(a)/2\lambda$ and define a_r^* by the relation $r=c^*(a_r^*)/\lambda$. Then $k\leqq r<2\omega_0^*$ for all $\beta>0$, which implies that there exists no solution of (2.4) for $a\in[0,a_r^*]$. Hence, for small $\varepsilon>0$, we can expect that there is some $a_r(\varepsilon)$ satisfying $\lim_{\varepsilon\to 0}a_r(\varepsilon)=a_r^*$ such that for $0\leqq a\leqq a_r(\varepsilon)$ there exists no large cluster solution and any solution expands into R, as in Fig. 3, or decays to zero when initial data have compact support.

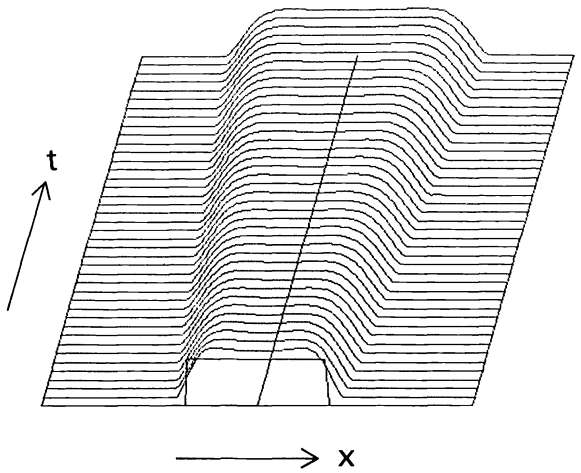


FIG. 3. *An expanding wave solution for* $r=1.5<2\omega_0$, $\varepsilon=\lambda=1.0$, $a=0.1$, *and* $m=2$.

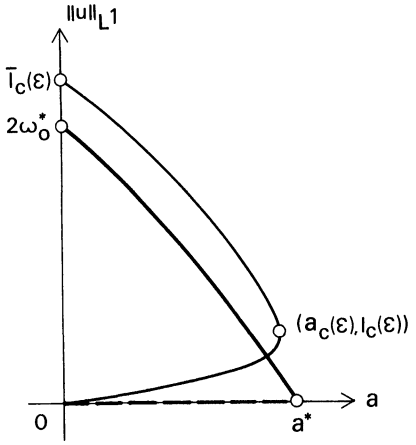
These results suggest the global branch of single cluster solutions in $(a,\|u\|_{L^1})$-space as $\varepsilon\to 0$, where $\|u\|_{L^1}$ denotes the L^1-norm of a solution u. For each fixed $r\geqq 0$, we consider the branch $\|u\|_{L^1}$ as a function of a. For $r\geqq 2\omega_0^*$, the solution branch is as in Fig. 4(a) where there are large (bold line) as well as small (bold broken line) singular solutions (as $\varepsilon\to 0$ for $0<a<a^*$), and for $0<r<2\omega_0^*$, the branch is as in Fig. 4(b), where there is a large singular solution only for $a_r^*<a<a^*$. For $r=0$, there is only a small singular solution branch for $0<a<a^*$. From the result of the singular case, we may conjecture the following global structure of single cluster solutions for $\varepsilon>0$. We first note that there are two numbers $r_1(\varepsilon)$ and $r_2(\varepsilon)$ satisfying $\lim_{\varepsilon\to 0}r_1(\varepsilon)=0$ and $\lim_{\varepsilon\to 0}r_2(\varepsilon)=2\omega_0^*$, such that for each fixed $r\geqq r_2(\varepsilon)$, the (unstable) small solution branch starting from the origin goes right up to a limit point, say $(a_c(\varepsilon),l_c(\varepsilon))$ and through this point, it goes back to the left with the recovery of stability. Then it arrives at a point on $a=0$, say $(0,\bar{l}_c(\varepsilon))$. Here it should be noted that $a_c(\varepsilon)\to a^*$, $l_c(\varepsilon)\to 0$, and $\bar{l}_c(\varepsilon)\to 2\omega_0^*$ as $\varepsilon\to 0$. For a fixed $r\in(r_1(\varepsilon),r_2(\varepsilon))$, there

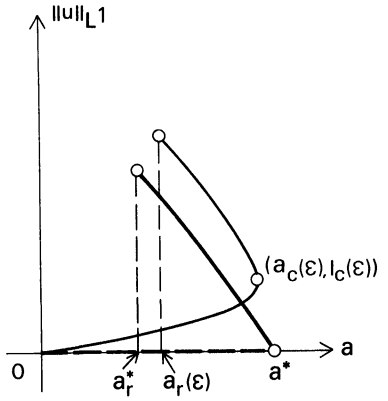
is a large solution only for $a_r(\varepsilon) < a < a_c(\varepsilon)$, and for $r \in (0, r_1^*(\varepsilon))$ there exists no large cluster solution. The cases when $\varepsilon > 0$ are depicted in Fig. 4a-c by solid lines.

We devote the remaining part of this paper to the proof of our theorem.

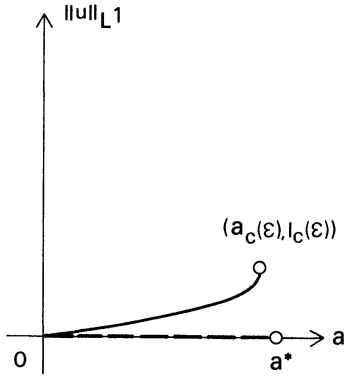
3. Existence of a large single cluster solution. Set $v(x) = \int_0^x u(y)\,dy$ and assume $r \geqq 2\omega$. This implies that $v(x+r) = -v(x-r) = \int_0^\omega u(y)\,dy$ for $|x| \leqq \omega$ and $u(x) \equiv 0$ for $|x| > \omega$, so that we see $K[u]u = -\lambda 2vu$. Here, we introduce the new variable $q = u^{m-1}$.



(a) $r \geqq 2\omega_0$.



(b) $\delta < r < 2\omega_0$.



(c) $r = O(\varepsilon)$ *and* $r \geqq \varepsilon\sigma_0$.

FIG. 4. *The global solution branch in* $(a, \|u\|_{L^1})$*-space for* $\varepsilon = 0$ *and* $\varepsilon > 0$.

Then our problem is to find a solution (q, v) and ω of

$$N(q, v) \equiv \begin{pmatrix} \varepsilon^2 q q_{xx} + \varepsilon^2 \mu q_x^2 + 2\varepsilon \dfrac{\lambda}{m} v q_x + F_\varepsilon(q) \\ v_x - q^\mu \end{pmatrix} = 0 \quad \text{for } x \in I_\omega = (0, \omega) \tag{3.1}$$

and

$$\begin{aligned} &q_x(0) = q(\omega) = (q^{\mu m})_x(\omega) = 0, \\ &q(x) > 0 \quad \text{for } x \in I_\omega, \qquad q(x) = 0 \quad \text{for } \bar{R}_\omega = [\omega, +\infty), \\ &v(0) = 0, \end{aligned} \tag{3.2}$$

where $\mu = 1/(m-1)$ and $F_\varepsilon(q) = (1/m\mu)[q^{1-\mu} f(q^\mu) + 2\varepsilon\lambda q^{1+\mu}]$. To solve this problem, we employ the singular perturbation method with the patching argument (see, for example, [7]). Hence, we split it into the following two problems. Let α be a fixed constant satisfying $a^{m-1} < \alpha < 1$, and let β and γ be parameters in some neighborhood $J_\delta = (\omega_0 - \delta, \omega_0 + \delta)$ of ω_0 with a small $\delta > 0$. The first problem is to find a solution $(\tilde{q}, \tilde{v})$ of

$$\begin{aligned} &N(q, v) = 0, \qquad x \in I_\beta = (0, \beta), \\ &q_x(0) = 0, \quad q(\beta) = \alpha, \quad v(0) = 0. \end{aligned} \tag{3.3}$$

The second is to find a solution $(\hat{q}, \hat{v})$ and ω of

$$\begin{aligned} &N(q, v) = 0, \qquad x \in R_\beta = (\beta, +\infty), \\ &q(\beta) = \alpha, \quad q(\omega) = (q^{m\mu})_x(\omega) = 0, \quad q(x) > 0 \quad \text{for } x \in [\beta, \omega), \\ &v(\beta) = \gamma, \end{aligned} \tag{3.4}$$

which has the degenerate character passed from (3.1), (3.2). We first discuss (3.4) and later (3.3).

Throughout this paper, we will use the following Banach spaces: For $I = (0, 1)$ and $J = R_+ = (0, +\infty)$:

$$C_0^1(I) = \left\{ u \middle| u \in C^1(I), \sup_{x \in I} \left(|u(x)| + \left| \frac{du}{dx}(x) \right| \right) < +\infty, u(0) = 0 \right\},$$

$$C_{\varepsilon,0}^2(I) = \left\{ u \middle| u \in C^2(I), \sup_{x \in I} \sum_{i=0}^{2} \left| \left(\varepsilon \frac{d}{dx} \right)^i u(x) \right| < +\infty, u_x(0) = u(1) = 0 \right\},$$

$$X_\rho^p(J) = \left\{ u \middle| u \in C^p(J), \sup_{x \in J} e^{\rho x} \sum_{i=0}^{p} \left| \left(\frac{d}{dx} \right)^i u(x) \right| < +\infty \right\},$$

$$X_{\rho,0}^p(J) = \{ u | u \in X_\rho^p(J), u(0) = 0 \},$$

$$X_{,\rho}^1(J) = \{ u | u \in X_{0,0}^0(J), u_x \in X_\rho^0(J) \},$$

$$X^0(J) = X_0^0(J).$$

We often write $C_0^1(I)$ as simply C_0^1, and do other spaces in a similar way. C_j $(j = 0, 1, 2, \cdots)$ always denote positive constants independent of ε.

3.1. Construction of solutions of the degenerate problem. Set $\xi = (x - \beta)/\varepsilon$ and $p = q_\xi$, and introduce the new independent variable ζ by

$$\frac{d\xi}{d\zeta} = q, \qquad \xi(0) = 0. \tag{3.5}$$

Then, (3.4) is written as

$$(3.6)_\varepsilon \qquad \begin{aligned} q_\zeta &= pq, \\ p_\zeta &= -\mu p^2 - \frac{2\lambda}{m} vp - F_\varepsilon(q), \qquad \zeta \in R_+ = (0, +\infty), \\ v_\zeta &= \varepsilon q^{1+\mu}, \end{aligned}$$

and

$$(3.7) \qquad \begin{aligned} &q(0) = \alpha, \quad q(+\infty) = 0, \quad p(\zeta) < 0 \quad \text{for } \zeta \in R_+, \\ &v(0) = \gamma. \end{aligned}$$

For $\varepsilon = 0$, assuming that δ is sufficiently small, we already have the result that for $\gamma \in J_\delta$, there exists a unique solution $y_0(\zeta; \gamma) = (q_0(\zeta: \gamma), p_0(\zeta; \gamma), v_0(\zeta; \gamma))$ of $(3.6)_\varepsilon$, (3.7) which satisfies that $q_0, p_0 + 2\lambda\gamma/m\mu \in X^1_{-\rho_-}(R_+)$ with $\rho_- = -2\lambda\gamma/m\mu$, $v_0(\zeta; \gamma) \equiv \gamma$, and $p_0(0, \gamma)$ is monotone decreasing with respect to γ (see [10, Lemma 5.6]). For $(3.6)_\varepsilon$, (3.7) with a small $\varepsilon > 0$, we will look for a solution $\hat{y}$ of $(3.6)_\varepsilon$, (3.7) in the form $\hat{y} = y_0 + y$, where $y = {}^t(q_1, p_1, v_1)$. Let $y_1 = {}^t(q_1, p_1)$. Then, $(3.6)_\varepsilon$ is written as

$$(3.8) \qquad G(y, \varepsilon) = \begin{pmatrix} Q_1 y_1 - g_1(y, \varepsilon) \\ \dfrac{d}{d\zeta} v_1 - g_2(q_1, \varepsilon) \end{pmatrix} = 0,$$

where

$$Q_1 = \frac{d}{d\zeta} - B(\zeta), \qquad B(\zeta) = \begin{pmatrix} p_0 & q_0 \\ -F_0'(q_0) & -2(\mu p_0 + \lambda\gamma/m) \end{pmatrix}$$

with $F_0(q) = q^{1-\mu} f(q^\mu)/m\mu$,

$$g_1(y, \varepsilon) = \begin{pmatrix} p_1 q_1 \\ -[F_0(q_0 + q_1) - F_0(q_0) - F_0'(q_0) q_1] - \mu p_1^2 - \dfrac{2\lambda}{m}(p_0 + p_1) r - \dfrac{2\lambda\varepsilon}{m\mu}(q_0 + q_1)^{1+\mu} \end{pmatrix}$$

and $g_2(q_1, \varepsilon) = \varepsilon(q_0 + q_1)^{1+\mu}$. The boundary condition is

$$(3.9) \qquad q_1(0) = q_1(+\infty) = 0, \qquad v_1(0) = 0.$$

From (3.8), (3.9), for a small $\varepsilon_0 > 0$ and some $\rho \in (0, \rho_\delta]$ with $\rho_\delta = -\rho_- - \delta$ $(\delta > 0)$, we define a nonlinear mapping

$$G(y, \varepsilon): Z^1_{\rho,0} \times [0, \varepsilon_0) \equiv X^1_{\rho,0} \times X^1_0 \times X^1_{,\rho} \times [0, \varepsilon_0) \to Z^0_\rho \equiv X^0_\rho \times X^0 \times X^0.$$

Then our problem is to find a solution $y(\varepsilon) \in Z^1_{\rho,0}$ of $G(y, \varepsilon) = 0$. Let us further rewrite this as follows. Integrating the second equation in (3.8), we see that if $q_1 \in X^0_{\rho,0}$, then

$$(3.10) \qquad v_1(\zeta) = \varepsilon \int_0^\zeta [q_0(\zeta') + q_1(\zeta')]^{1+\mu} \, d\zeta' = \varepsilon R_1(q_1) \in X^1_{\rho,0}$$

for any $\rho \in (0, \rho_\delta]$. Therefore, (3.8), (3.9) is reduced to

$$(3.11) \qquad Q_1 y_1 = g_1(y_1, \varepsilon R(q_1), \varepsilon) = h_1(y_1) + \varepsilon h_2(y_1),$$

where

$$h_1(y_1) = \begin{pmatrix} h_{11}(y_1) \\ h_{12}(y_1) \end{pmatrix} = \begin{pmatrix} p_1 q_1 \\ -[F_0(q_0 + q_1) - F_0(q_0) - F_0'(q_0) q_1] - \mu p_1^2 \end{pmatrix}$$

and

$$h_2(y_1)=\begin{pmatrix}0\\ h_{22}(y_1)\end{pmatrix}$$

$$=\begin{pmatrix}0\\ -\dfrac{2\lambda}{m}(p_0+p_1)R(q_1)-\dfrac{2\lambda}{m\mu}(q_0+q_1)^{1+\mu}\end{pmatrix}.$$

For the linear mapping Q_1, we have Lemma 3.1.

LEMMA 3.1. *Let δ be sufficiently small. Then for each $\rho\in(0,\rho_\delta]$, the map Q_1: $Y_\rho^1\equiv X_{\rho,0}^1\times X_0^1\to Y_\rho\equiv X_\rho^0\times X^0$ has a bounded inverse Q_1^{-1}.*

Proof. See the Appendix for the proof.

Applying Q_1^{-1} to (3.11), we have the equation

$$y_1=Q^{-1}g_1(y_1,2R(q_1),\varepsilon)\equiv\mathcal{F}(y_1,\varepsilon). \tag{3.12}$$

The nonlinear operator $\mathcal{F}$: $Y_\rho\times[0,\varepsilon_0)\to Y_\rho^1\subset Y_\rho$ satisfies the following lemma.

LEMMA 3.2. *Let ρ be fixed in $(0,\rho_\delta]$ and $\gamma\in J_\delta$. Then there exist a small closed ball $B_\kappa(0)=\{y_1\,|\,\|y_1\|_{Y_\rho}\leqq\kappa\}$ and a small constant $\varepsilon_0>0$ such that $\mathcal{F}$ is a uniform contraction on $B_\kappa(0)$ and continuous from $B_\kappa(0)\times[0,\varepsilon_0)$ into $B_\kappa(0)$.*

Proof. See the Appendix for the proof.

Thus, we can apply the uniform contraction principle [4, Thm. 2.2] to (3.12) and obtain a solution $y_1(\varepsilon)=(q_1(\zeta;\varepsilon,\gamma),\ p_1(\zeta;\varepsilon,\gamma))\in Y_\rho$ satisfying $y_1(0)=0$. Moreover, (3.10), (3.12) shows that $y(\zeta;\varepsilon,\gamma)=(q_1(\zeta;\varepsilon,\gamma),\ p_1(\zeta;\varepsilon,\gamma),\ v_1(\zeta;\varepsilon,\gamma))\in Z_\rho^1$ with $v_1(\zeta;\varepsilon,\gamma)=\varepsilon R_1(q_1(\zeta;\varepsilon,\gamma))$ and it satisfies $\lim_{\varepsilon\to0}\|y(\zeta;\varepsilon,\gamma)\|_{Z_\rho^1}=0$. Hence we have a solution $y_0(\zeta;\gamma)+y(\zeta;\varepsilon,\gamma)$ of $(3.6)_\varepsilon$, (3.7). Note that the above argument is valid uniformly in $\gamma\in J_\delta$ for a small $\delta>0$, so that y is uniformly continuous in ε and γ.

Next, we examine relation (3.5). Let $\phi_0(\zeta)=\int_0^\zeta q_0(\zeta';\gamma)\,d\zeta'$ and $\phi_\varepsilon(\zeta)=\int_0^\zeta[q_0(\zeta';\gamma)+q_1(\zeta';\varepsilon,\gamma)]\,d\zeta'$. Then

$$\sup_{\zeta\in R_+}|\phi_\varepsilon(\zeta)-\phi_0(\zeta)|\leqq\sup_{\zeta\in R_+}\int_0^\zeta|q_1(\zeta';\varepsilon,\gamma)|\,d\zeta'\leqq\|q_1\|_{X_\rho^0}\int_0^\infty e^{-\rho\zeta'}\,d\zeta'\to0$$

as $\varepsilon\to0$ uniformly in $\gamma\in I_\delta$. Set $\lim_{\zeta\to\infty}\phi_\varepsilon(\zeta)=\omega_\varepsilon(\gamma)<+\infty$ for $\varepsilon\in[0,\varepsilon_0)$. Since $d\phi_\varepsilon/d\zeta>0$ for $\zeta\in[0,\infty)$, ϕ_ε is a diffeomorphism from $[0,\infty)$ onto $[0,\omega_0)$, so that we have an inverse function ϕ_ε^{-1} of ϕ_ε. Using this, we define a pair of functions $(\hat q,\hat v)$ by

$$\hat q(\xi;\varepsilon,\gamma)=\begin{cases}\hat q_0(\xi;\gamma)+q_1(\phi_\varepsilon^{-1}(\xi);\varepsilon,\gamma), & 0<\xi<\omega_\varepsilon,\\ 0, & \omega_\varepsilon\leqq\xi<+\infty,\end{cases}$$

$$\hat v(\xi;\varepsilon,\gamma)=\gamma+\varepsilon\int_0^\xi[\hat q(\xi';\varepsilon,\gamma)]^\mu\,d\xi'$$

with $\xi=(x-\beta)/\varepsilon$, where $\hat q_0(\xi;\gamma)=q_0(\phi_\varepsilon^{-1}(\xi);\gamma)$. This is a solution of (3.4). Thus we have Theorem 3.1.

THEOREM 3.1. *Let $\delta>0$ be sufficiently small. Then, for $\gamma\in I_\delta$ there exists a small $\varepsilon_0>0$ such that for $\varepsilon\in(0,\varepsilon_0)$, (3.4) has a solution $(\hat q(\xi;\varepsilon,\gamma),\ \hat v(\xi;\varepsilon,\gamma))$ with $\xi=(x-\beta)/\varepsilon$ satisfying $\hat q>0$ for $0\leqq\xi<\omega_\varepsilon(\gamma)<+\infty$, $\hat q=0$ for $\xi\geqq\omega_\varepsilon(\gamma)$, and $\lim_{\varepsilon\to0}(d/d\xi)\hat q(0;\varepsilon,\gamma)=(d/d\xi)\hat q_0(0;\gamma)$ uniformly in γ. Moreover, $(\hat q,\hat v)$ is uniformly continuous in ε and γ relative to the norm of $C^2(I_{\kappa'})\times C^2(I_{\kappa'})$ with $I_{\kappa'}=[0,\omega_0-\kappa']$ for any $\kappa'>0$ and $(d/d\xi)\hat q_0(0;\gamma)$ is strictly monotone decreasing with respect to γ.*

Remark 3.1. $\hat{q}_0(\xi;\gamma)$ is a unique monotone solution of

$$
\begin{aligned}
&qq_{\xi\xi}+\mu q_\xi^2+2\frac{\lambda\gamma}{m}q_\xi+F_0(q)=0, \qquad \xi\in(0,\omega_0),\\
&q(0)=\alpha, \qquad q(\omega_0)=0.
\end{aligned}
\tag{3.13}
$$

3.2. Construction of solutions of the nondegenerate problem. To make the parameter dependency of solutions clear, we normalize the interval by $z=x/\beta$ and set $\sigma=\varepsilon/\beta$. Then, (3.3) is

$$
\begin{aligned}
&\tilde{N}(q,v)\equiv\begin{pmatrix}\sigma^2qq_{zz}+\sigma^2\mu q_z^2+2\sigma\dfrac{\lambda}{m}vq_z+F_\sigma(q)\\ v_z-\beta q^\mu\end{pmatrix}=0,\\
&q_z(0)=0, \quad q(1)=\alpha, \quad v(0)=0,
\end{aligned}
\qquad z\in I=(0,1),
\tag{3.14}
$$

where $F_\sigma(q)=[q^{1-\mu}f(q^\mu)+2\lambda\sigma\beta q^{1+\mu}]/m\mu$. For sufficiently small $\sigma>0$, the standard singular perturbation method gives the lowest-order approximation as

$$
\tilde{q}_0(z;\sigma,\beta)=1+\theta(z-1)[q_0(\eta;\beta)-1],
$$

$$
\tilde{v}_0(z;\sigma,\beta)=\beta\int_0^z\tilde{q}_0(z';\sigma,\beta)^\mu\,dz',
$$

where $\eta=(z-1)/\sigma$ and $q_0(\eta,\beta)$ is a unique monotone decreasing solution of

$$
\begin{aligned}
&qq_{\eta\eta}+\mu q_\eta^2+2\frac{\lambda\beta}{m}q_\eta+F_0(q)=0, \qquad \eta\in R_-=(-\infty,0),\\
&q(-\infty)=1, \qquad q(0)=\alpha\in(0,1),
\end{aligned}
\tag{3.15}
$$

and $\theta(z)$ is a C^∞ cutoff function such that $0\leqq\theta(z)\leqq1$, $\theta(z)=1$ for $|z|\leqq\frac{1}{4}$ and $\theta(z)=0$ for $|z|\geqq\frac{1}{2}$. Note here that $|q_0(\eta;\beta)-1|$ decays exponentially with exponent $[-\lambda\beta+((\lambda\beta)^2-F_0'(1))^{1/2}]/m$ and $(d/d\eta)q_0(0;\beta)$ is strictly monotone increasing with respect to β. Using this approximation, we seek a solution in the form $(q,v)=(\tilde{q}_0,\tilde{v}_0)+(q_1,v_1)$.

For small positive σ_0 and δ, let us define a nonlinear mapping

$$
S(t,\sigma,\beta)=\tilde{N}(\tilde{q}_0+q_1,\tilde{v}_0+v_1)\colon Y_\sigma^2\times(0,\sigma_0)\times J_\delta\to Y^0,
$$

where $t=(q_1,v_1)$, $Y_\sigma^2=C_{\sigma,0}^2\times C_0^1$, and $Y^0=C^0\times C^0$. The Fréchet derivative of S,

$$
S_t(t,\sigma,\beta)=\begin{pmatrix}S_{11}&S_{12}\\S_{21}&S_{22}\end{pmatrix}
$$

is given by

$$
S_{11}(t,\sigma,\beta)=\sigma^2q\left(\frac{d}{dz}\right)^2+2\sigma\left(\mu\sigma q_z+\frac{\lambda}{m}v\right)\frac{d}{dz}+[\sigma^2q_{zz}+F'(q)],
$$

$$
S_{12}(t,\sigma,\beta)=2\sigma\frac{\lambda}{m}q_z, \quad S_{21}(t,\sigma,\beta)=-\mu\beta q^{\mu-1}, \quad S_{22}=\frac{d}{dz}.
$$

Let $B_\kappa(0)=\{t\,|\,\|t\|_{Y_\rho^2}\leqq\kappa\}$. It follows from this expression that

$$
\|S_t(t_1,\alpha,\beta)-S_t(t_2,\alpha,\beta)\|_{Y_\sigma^2\to Y^0}\leqq K_1\|t_1-t_2\|_{Y_\sigma^2}
$$

for $t_1,t_2\in B_\kappa(0)$, $\sigma\in(0,\sigma_0)$, and $\beta\in J_\delta$, where K_1 is some constant. We show the uniform invertibility of S_t.

LEMMA 3.3. *There exist small positive σ_0 and δ such that for any $\sigma \in (0, \sigma_0)$, $\alpha \in (1-\delta, 1)$, and $\beta \in J_\delta$, $S_t(0; \sigma, \beta)$ has an inverse S_t^{-1} satisfying $\|S_t^{-1}\|_{Y^0 \to Y^2_\sigma} \leqq K_s$, where K_s is a positive constant independent of σ and β.*

Proof. We first consider

$$S_{11}(0, \sigma, \beta) = \sigma^2 a_0 \left(\frac{d}{dz}\right)^2 + \sigma a_1 \frac{d}{dz} + a_2 : C^2_{\sigma,0} \to C^0,$$

where $a_0 = \tilde{q}_0$, $a_1 = 2(\mu \tilde{q}_{0z} + (\lambda/m)\tilde{v}_0)$, and $a_2 = \sigma^2 \tilde{q}_{0zz} + F'_\sigma(\tilde{q}_0)$. Since $\tilde{q}_0$ satisfies $\sup_{z \in I} |(\sigma(d/dz))^i [\tilde{q}_0 - 1]| \leqq C_i(1-\alpha)$ $(i = 0, 1, 2)$ with $C_0 = 1$, we easily find that $a_0 \geqq \alpha > 0$ and $a_2 \leqq C_2(1-\alpha) + F'_0(1) + F'_0(\tilde{q}_0) - F'_0(1) + 2\sigma\beta(\lambda/m)\mu \tilde{q}_0^{\mu-1} < 0$ for $\alpha \in (1-\delta, 1)$, $\beta \in J_\delta$, $\sigma \in (0, \sigma_0)$ if we choose δ and σ_0 sufficiently small. Therefore, the maximum principle for usual two-point boundary value problems shows that S_{11} has a uniformly bounded inverse $S_{11}^{-1}: C^0 \to C^2_{\sigma,0}$ satisfying $\|S_{11}^{-1}\| \leqq K_1$, where K_1 denotes a positive constant independent of σ, α, and β. It is obvious that $S_{22}(0, \sigma, \beta): C^1_0 \to C^0$ has an inverse S_{22}^{-1} satisfying $\|S_{22}^{-1}\|_{C^0 \to C^1_0} = 2$. S_{12} and S_{21} are multiplication operators satisfying

$$|S_{12}(0, \sigma, \beta)| \leqq \sup_{z \in I} \left| \frac{2\lambda}{m} \sigma \frac{d}{dz} \tilde{q}_0 \right| < \frac{2\lambda}{m} C_1(1-\alpha)$$

and

$$|S_{21}(0, \sigma, \beta)| \leqq \sup_{z \in I} |\mu\beta \tilde{q}_0^{\mu-1}| \leqq \mu\beta \max(1, (1-\alpha)^{\mu-1}) < C_3.$$

These estimates assure the uniform invertibility of S_t. Actually, consider $S_t(0, \sigma, \beta)t = k$ for $k = (k_1, k_2) \in Y^0$. Then we can easily rewrite it as follows:

$$q_1 = S_{11}^{-1}(k_1 - S_{12}S_{22}^{-1}k_2) - S_{11}^{-1}S_{12}S_{22}^{-1}S_{21}q_1,$$
$$v_1 = S_{22}^{-1}k_2 - S_{22}^{-1}S_{21}q_1.$$

Since $\|S_{11}^{-1}S_{12}S_{22}^{-1}S_{21}\|_{C^2_{\sigma,0} \to C^2_{\sigma,0}} \leqq (4\lambda/m)C_1C_3K_1(1-\alpha) \leqq \frac{1}{2}$ if we choose α as $\alpha \geqq 1 - m/8\lambda C_1C_3K_1$, it follows from the above equations that $\|q_1\|_{C^2_{\sigma,0}} \leqq C_4\|k\|_{Y^0}$ and $\|v_1\|_{C^1_0} \leqq C_5\|k\|_{Y^0}$. Here all constants C_i are independent of σ, α, and β. This completes the proof.

LEMMA 3.4. $\lim_{\sigma \to 0} \|S(0, \sigma, \beta)\|_{Y^0} = 0$ *uniformly in $\beta \in J_\delta$ for small $\delta > 0$.*

Proof. This lemma can be proved by the standard matched asymptotic technique (see, for example, [10]), so we omit the proof.

Now Lemmas 3.2 and 3.3 enable us to apply the implicit function theorem to $S(t, \sigma, \beta) = 0$. Then we see that there exists a solution $t(\sigma, \beta) = (q_1(z; \sigma, \beta), v_1(z; \sigma, \beta))$ of $S(t(\sigma, \beta), \sigma, \beta) = 0$ satisfying that $\lim_{\sigma \to 0} \|t(\sigma, \beta)\|_{C^2_{\sigma,0}} = 0$ uniformly in $\beta \in I_\delta$ and $t(\sigma, \beta)$ is uniformly continuous in σ and β relative to the norm of $C^2_{\sigma,0}$. Thus we obtain a solution $(\tilde{q}_0(z; \sigma, \beta) + q_1(z; \sigma, \beta), \tilde{v}_0(z; \sigma, \beta) + v_1(z; \sigma, \beta))$ with $z = x/\beta$ and $\sigma = \varepsilon/\beta$.

THEOREM 3.2. *There exist small positive constants ε_0 and δ such that for any $\varepsilon \in (0, \varepsilon_0)$, $\alpha \in (1-\delta, 1)$, and $\beta \in J_\delta$, (3.3) has a solution $(\tilde{q}(x; \varepsilon, \beta), \tilde{v}(x; \varepsilon, \beta))$ satisfying $\lim_{\varepsilon \to 0} \|\tilde{q}(x; \varepsilon, \beta) - 1\|_{C^2(I_\kappa)} = 0$ with $I_\kappa = [0, \beta - \kappa]$ for any small $\kappa > 0$ and $\lim_{\varepsilon \to 0} \varepsilon(d/dx)\tilde{q}(\beta; \varepsilon, \beta) = (d/d\eta)q_0(0; \beta)$ uniformly in β. Moreover, $(\tilde{q}, \tilde{v})$ is uniformly continuous in ε and β relative to the norm of $C^2_{\sigma,0}$ and $(d/d\eta)q_0(0; \beta)$ is strictly monotone increasing with respect to β.*

3.3. Patching of solutions. We proceed to construct a solution of (3.1), (3.2) by patching two solutions $(\tilde{q}, \tilde{v})$ and $(\hat{q}, \hat{v})$ as

$$(q(x; \varepsilon, \beta, \gamma), v(x; \varepsilon, \beta, \gamma)) = \begin{cases} (\tilde{q}(x; \varepsilon, \beta), \tilde{v}(x; \varepsilon, \beta)), & x \in I_\beta, \\ (\hat{q}(\xi; \varepsilon, \gamma), \hat{v}(\xi; \varepsilon, \gamma)), & \xi = (x-\beta)/\varepsilon \in R_\beta. \end{cases}$$

To do this, it is sufficient to show that at $x=\beta$, v is continuous and q is C^1-continuous. We first choose $\gamma=\gamma_\varepsilon(\beta)\equiv\tilde{v}(\beta;\varepsilon,\beta)=\beta+O(\varepsilon)$ to assure the continuity of v. Next consider $\Phi(\varepsilon,\beta)\equiv\varepsilon(d/dx)\tilde{q}(\beta;\varepsilon,\beta)-\varepsilon(d/dx)\hat{q}(0;\varepsilon,\gamma_\varepsilon(\beta))$. It follows immediately from Theorems 3.1 and 3.2 that $\Phi(\varepsilon,\beta)$ is uniformly continuous in $\varepsilon\in(0,\varepsilon_0)$ and $\beta\in I_\delta$ and

$$\Phi(0,\beta)\equiv\lim_{\varepsilon\to 0}\Phi(\varepsilon,\beta)=\frac{d}{d\eta}q_0(0;\beta)-\frac{d}{d\xi}\hat{q}_0(0,\beta).$$

Note (3.13), (3.14) and choose $\beta=\omega_0$ $(=c^*(a)/2\lambda)$. Then the unique existence of solutions (2.4) proves $\Phi(0,\omega_0)=0$. $\Phi(0,\beta)$ is strictly monotone increasing with respect to β since $(d/d\eta)q_0(0,\beta)$ and $(d/d\xi)\hat{q}_0(0,\beta)$ are strictly monotone increasing and decreasing, respectively. Therefore, it is easy to see that there exists a function $\beta=\beta(\varepsilon)$ defined for $\varepsilon\in(0,\varepsilon_0)$ for sufficiently small $\varepsilon_0>0$ that satisfies $\Phi(\varepsilon,\beta(\varepsilon))\equiv 0$ and $\lim_{\varepsilon\to 0}\beta(\varepsilon)=\omega_0$. For this $\beta(\varepsilon)$, $(q(x;\varepsilon,\beta(\varepsilon),\gamma_\varepsilon(\beta(\varepsilon))),\ v(x;\varepsilon,\beta(\varepsilon),\gamma_\varepsilon(\beta(\varepsilon))))$ is a solution of (3.1), (3.2) satisfying $\operatorname{supp}[q]=[0,\beta(\varepsilon)+\varepsilon\omega_\varepsilon(\gamma_\varepsilon(\beta(\varepsilon)))]\to[0,\omega_0]$ as $\varepsilon\to 0$. Thus, we have obtained a large solution $U(x,\varepsilon)=q(x;\varepsilon,\beta(\varepsilon),\gamma_\varepsilon(\beta(\varepsilon)))^\mu$ of (2.1), (2.2) satisfying all properties required in the theorem of § 2. This completes the first half of our theorem.

4. Existence of a small single cluster solution. For a small solution, we assume that $r\geqq 2\omega=2\varepsilon\sigma$ and set $\tilde{v}(\eta)=\int_0^\eta u(\eta')\,d\eta'$. Then, as in § 3, our problem (2.5), (2.6) is to find solutions (u,v) and σ of

$$\begin{aligned}&(u^m)_{\eta\eta}+2\varepsilon\lambda(\tilde{v}u)_\eta+f(u)=0,\\&\tilde{v}_\eta-u=0,\end{aligned}\qquad \eta\in J_\sigma=[0,\sigma),\tag{4.1}$$

with

$$\begin{aligned}&u_\eta(0)=0,\quad u(\sigma)=(u^m)_\eta(\sigma)=0,\quad u(\eta)>0\quad\text{for }\eta\in J_\sigma,\\&v(0)=0.\end{aligned}\tag{4.2}$$

In a slightly different manner from that of § 3, we introduce the new dependent variable (U,V,W) and the independent variable τ by

$$\begin{aligned}&U=u^{m-1},\quad V=\tilde{v},\quad W=(u^{m-1})_\eta+2\varepsilon\nu\tilde{v}=U_\eta+2\varepsilon\nu V,\\&\frac{d\eta}{d\tau}=U\quad\text{with }\tau|_{\eta=0}=0,\end{aligned}\tag{4.3}$$

where $\nu=\lambda(m-1)/m$. Now we rewrite (4.1), (4.2) as the first-order system

$$\begin{aligned}&U_\tau=U(W-2\varepsilon\nu V),\\&V_\tau=U^{1+\mu},\qquad\qquad\tau\in R_+=(0,\infty),\\&W_\tau=-\mu W(W-2\varepsilon\nu V)-F_0(U),\end{aligned}\tag{4.4}$$

with the conditions

$$\begin{aligned}&V(0)=W(0)=0,\qquad U(+\infty)=W(+\infty)=0,\\&W(\tau)<0\quad\text{for all }\tau>0,\end{aligned}\tag{4.5}$$

where $\mu=1/(m-1)$ and $F_0(U)=1/(1+\mu)U^{1-\mu}f(U^\mu)$. We should note that $(4.4)_\varepsilon$ has the one-dimensional critical manifold $\Omega_c\equiv\{(U,V,W)\,|\,U=0,\ W=0\}$ in the half-space $\{(U,V,W)\,|\,W\leqq 0\}$. In the following, we use vector notation for convenience. Let us write $(4.4)_\varepsilon$ as $y_\tau=f_\varepsilon(y)$ with $y=(U,V,W)$ and let $y_\varepsilon(\tau;\xi)$ denote the solution

of $(4.4)_\varepsilon$ satisfying $y_\varepsilon(0;\xi)=\xi$. We simplify this further by writing $\xi\cdot\tau=y_\varepsilon(\tau;\xi)$ and $\xi\cdot S=\{y\,|\,y=\xi\cdot\tau,\ \tau\in S\}$.

We first discuss the problem for $(4.4)_0$, namely,

$$(4.4)_0\qquad \begin{aligned} U_\tau &= UW,\\ V_\tau &= U^{1+\mu}, \qquad\qquad \tau\in R_+,\\ W_\tau &= -\mu W^2 - F_0(U), \end{aligned}$$

with (4.5). This is easily solved by phase plane analysis. Let γ_0 be a unique positive number satisfying

$$\int_0^{\gamma_0} U^\mu f(U^\mu)\,dU=\frac{1}{\mu}\int_0^{(\gamma_0)^\mu} u^{m-1}f(u)\,du=0$$

for each $a\in(0,a^*)$. Let $y_0(\tau;\gamma)=(U_0(\tau;\gamma),V_0(\tau;\gamma),W_0(\tau;\gamma))$ be a solution of $(4.4)_0$ satisfying $y_0(0;\gamma)=\xi_0$ with $\xi_0=(\gamma,0,0)$. Also, set $D=\{(U,V,W)\,|\,0<U<1,\ V>0,\ W<0\}$ and $E_0^-=\{(U,V,W)\,|\,0<U<a_0,\ V\geqq 0,\ W=0\}$. Then we have Lemma 4.1.

LEMMA 4.1. *For each $a\in(0,a^*)$, $y_0(\tau;\gamma_0)$ is a unique solution of $(4.4)_0$, (4.5) such that $U_0(\tau,\gamma_0)=O(\tau^{-2})$ and $W_0(\tau,\gamma_0)=O(\tau^{-1})$ as $\tau\to+\infty$, $\lim_{\tau\to\infty}V_0(\tau;\gamma_0)=V_0^*<+\infty$. Moreover, if $\gamma_0<\gamma<1$, $\lim_{\tau\to\infty}y_0(\tau;\gamma)=(0,V_0^\infty,-\infty)$ holds with some $V_0^\infty<+\infty$, while if $a_0<\gamma<\gamma_0$, there exists a unique finite $\tau(\gamma)>0$ such that $y_0(\tau;\gamma)\in D$ for $\tau\in(0,\tau(\gamma))$ and $y_0(\tau(\gamma);\gamma)\in E_0^-$.*

Proof. We can prove this lemma by the standard technique. In fact, the first and third equations of $(4.4)_0$ give the relation

$$\frac{1}{2}\frac{d}{d\tau}(U^\mu W)^2=\mu U^{2\mu-1}W^2U_\tau+U^{2\mu}WW_\tau=-U^{2\mu-1}F_0(U)U_\tau. \tag{4.6}$$

When we assume that there exists a monotone solution U, we can integrate this over $(0,\tau)$ as

$$\frac{1}{2}(U^\mu W)^2+\frac{1}{1+\mu}\int_\gamma^U S^\mu f(S^\mu)\,ds=0, \tag{4.7}$$

since $U(0)=\gamma$, $W(0)=0$. The condition $U(+\infty)=W(+\infty)=0$ requires $\gamma=\gamma_0$, so we have

$$\frac{dU}{d\tau}=-U^{1-\mu}\left[\frac{2}{1+\mu}\int_U^{\gamma_0}s^\mu f(s^\mu)\,ds\right]^{1/2}\equiv-\Phi(U;\gamma_0). \tag{4.8}$$

Integrating (4.8) with $U(0)=\gamma_0$, we see that $U(\tau)$ satisfies $\tau=\int_U^{\gamma_0}\Phi(s;\gamma_0)^{-1}\,ds$. There exists a unique function $U_0(\tau;\gamma_0)$ satisfying this relationship. Conversely, such a function gives a solution of $(4.4)_0$, (4.5). To see the decay rate of U_0, it suffices to examine (4.8) near $U=0$ as

$$\begin{aligned}\frac{dU}{d\tau}&=-U^{1-\mu}\left[-\frac{2}{1+\mu}\int_0^U s^\mu f(s^\mu)\,ds\right]^{1/2}\\ &=-\sqrt{\frac{a}{\mu(1+\mu)}}\,U^{3/2}(1+O(U^\mu)).\end{aligned} \tag{4.9}$$

Integrating this proves the estimate $U_0(\tau;\gamma_0)=O(\tau^{-2})$ as $\tau\to+\infty$, which also assures $W_0(\tau;\gamma_0)=O(\tau^{-1})$ as $\tau\to+\infty$.

The behavior of solutions $y_0(\tau;\gamma)$ is easily derived by examining relation (4.7) in a way similar to the above. This completes the proof.

Remark 4.1. We see $U_0 \in L^1(R_+)$ since U_0 satisfies $0 < U_0 \leqq \gamma$ for $\tau \in R_+$ and $U_0 = O(\tau^{-2})$ as $\tau \to +\infty$. Hence, $\eta = \phi_0(\tau) \equiv \int_0^\tau U_0(\tau'; \gamma_0)\, d\tau'$ is monotone increasing and $\lim_{\tau\to\infty} \eta(\tau) = \sigma_0 < +\infty$, so that the inverse function $\tau = \phi_0^{-1}(\eta)$ is defined on $[0, \sigma_0)$ and satisfies $\phi_0^{-1}(0) = 0$ and $\lim_{\eta\to\sigma_0} \phi_0^{-1}(\eta) = +\infty$. Set $u_i(\eta; \sigma_0) = U_0(\phi_0^{-1}(\eta); \gamma_0)^\mu$. Then it is a unique solution of (2.7), (2.6) since

$$(u_i^m)_\eta(\eta)\big|_{\eta=\sigma_0} = (U_0^{1+\mu})_\tau \frac{d\tau}{d\eta}\bigg|_{\tau=+\infty} = (1+\mu) U_0^\mu W_0|_{\tau=+\infty} = 0.$$

Next we will prove the existence of solutions of $(4.4)_\varepsilon$, (4.5) for $\varepsilon > 0$. To do this, we apply the variant of the Wazewski theorem formulated by Dunbar in [6]. We begin by constructing a Wazewski set $\Omega \subset R^3$. For small $\delta_1 > 0$, define $H(U)$ by

$$H(U) = \begin{cases} -\delta_1 U & (0 \leqq U \leqq a_0/2), \\ \delta_1(U - a_0) & (a_0/2 < U \leqq a_0), \\ 0 & (a_0 < U \leqq 1). \end{cases}$$

For a sufficiently small positive δ_2 (<1) and a large C, define the set Ω bounded by

$$\Omega_1^+ = \{(U, V, W) \mid 0 < U \leqq 1,\ V = 0,\ -\sqrt{U/\delta_2} < W < H(U)\},$$
$$\Omega_2^+ = \{(U, V, W) \mid a_0 < U \leqq 1,\ 0 \leqq \varepsilon V \leqq C + \varepsilon(1-U),\ W = 0\},$$
$$\Omega_3^+ = \{(U, V, W) \mid U = 1,\ 0 \leqq \varepsilon V \leqq C,\ -1/\sqrt{\delta_2} < W \leqq 0\},$$
$$\Omega_4^+ = \{(U, V, W) \mid 0 < U < 1,\ \varepsilon V = C + \varepsilon(1-U),\ -\sqrt{U/\delta_2} < W < H(U)\},$$
$$\Omega_1^- = \{(U, V, W) \mid 0 < U \leqq a_0,\ 0 \leqq \varepsilon V \leqq C + \varepsilon(1-U),\ W = H(U)\},$$
$$\Omega_2^- = \{(U, V, W) \mid U = \delta_2 W^2,\ 0 \leqq \varepsilon V \leqq C + \varepsilon(1-U),\ -1/\sqrt{\delta_2} \leqq W < 0\},$$
$$\Omega_0 = \{(U, V, W) \mid U = W = 0,\ 0 \leqq \varepsilon V \leqq C + \varepsilon\},$$

where δ_i $(i = 1, 2)$ and C will be specified later so that Ω becomes a Wazewski set (see Fig. 5). The boundary $\partial\Omega$ of Ω is represented by $\partial\Omega = \Omega_0 \cup \Omega^+ \cup \Omega_1^- \cup \Omega_2^-$, where $\Omega^+ = \cup_{i=1}^4 \Omega_i^+$. Note that Ω_1^- and Ω_2^- are disjoint. Let Ω^- be the immediate exit set of Ω, that is, for all $y_0 \in \Omega^-$, $y_0 \cdot [0, \tau) \not\subset \Omega$ for any $\tau > 0$. Then, we have the following lemma.

LEMMA 4.2. *Let δ_i $(i = 1, 2)$ be sufficiently small, and let C be sufficiently large. Then, $\Omega^- = \Omega_1^- \cup \Omega_2^-$.*

Proof. Set $(\Omega^-)^c = \partial\Omega \backslash \Omega^-$. It is obvious that $\Omega_i^+ \subset (\Omega^-)^c$ for $i = 1, 2, 3$. We have that $\Omega_0 \subset (\Omega^-)^c$ since any point in Ω_0 is a critical point of $(4.4)_\varepsilon$. Therefore, we may only consider Ω_4^+, Ω_1^-, and Ω_2^-. First consider Ω_4^+. $n_4 = (1, 1, 0)$ is an outward normal for Ω at $y \in \Omega_4^+$. For $y \in \Omega_4^+$, $0 < U < 1$, $W < 0$, and $\varepsilon V = C + \varepsilon(1-U) > C$, so that the inner product $n_4 \cdot f_\varepsilon(y)$ is estimated as

$$n_4 \cdot f_\varepsilon(y) = U(W - 2\varepsilon\nu V) + U^{1+\mu} < (1 - 2\nu C) U < 0,$$

if we choose $C > 1/(2\nu)$. This implies $\Omega_4^+ \subset (\Omega^-)^c$ for any $C > 1/(2\nu)$.

The outward normal at $y \in \Omega_2^-$ is given by $n_2 = (-1, 0, 2\delta_2 W)$. For $y \in \Omega_2^-$, $V \geqq 0$, $W < 0$, $0 < U \leqq 1$, and $U = \delta_2 W^2$. Hence, we have

$$\begin{aligned} n_2 \cdot f_\varepsilon(y) &= -U(W - 2\varepsilon\nu V) - 2\delta_2 W^2(W - 2\varepsilon\nu V) - 2\delta_2 W F_0(U) \\ &= -(1+2\mu)\delta_2 W^2(W - 2\varepsilon\nu V) - 2\delta_2 W F_0(\delta_2 W^2) \\ &> -(1+2\mu)\delta_2 W^3 + 2\delta_2^2 W^3 k_0 \\ &= \delta_2 W^3[2\delta_2 k_0 - (1+2\mu)], \end{aligned}$$

where $k_0 = -\inf_{0<U\leqq 1}(F_0(U)/U)$ $(= a/(1+\mu))$. If we choose $\delta_2 < (1+2\mu)/2k_0$, $n_2 \cdot f_\varepsilon(y) > 0$, which proves $\Omega_2^- \subset \Omega^-$. Consider Ω_1^- and define $E_\pm$ by $E_+ = \{(U, V, W) \in \Omega_1^- \mid 0 < U < a_0/2\}$ and $E_- = \{(U, V, W) \in \Omega_1^- \mid a_0/2 \leqq U \leqq a_0\}$. The outward

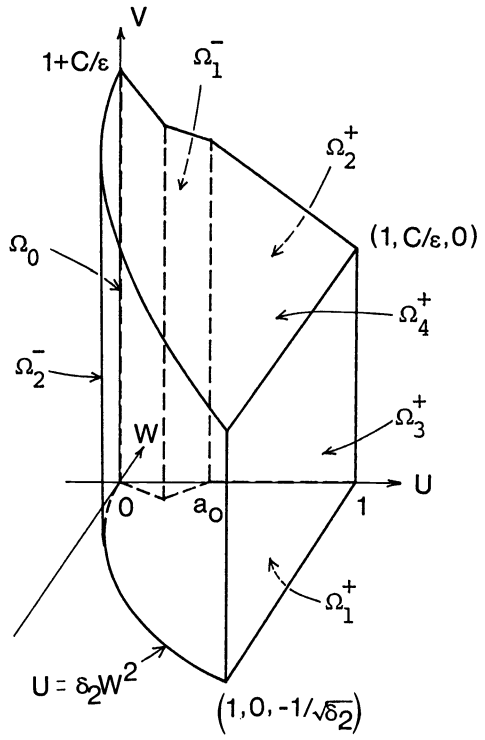


FIG. 5. *The Wazewski set for a small cluster solution.*

normals for Ω at $y \in E_\pm$ are $n_\pm = (\pm\delta_1, 0, 1)$, respectively. For $y \in E_+$, $W = -\delta_1 U$, $0 < U < a_0/2$, and $\varepsilon V < C + \varepsilon < C + 1$, so that

$$\begin{aligned} n_+ \cdot f_\varepsilon(y) &= \delta_1 U(W - 2\varepsilon\nu V) - \mu W(W - 2\varepsilon\nu V) - F_0(U) \\ &> -\delta_1(1+\mu)U\{\delta_1 U + 2V(C+1)\} + k_1 U > 0 \end{aligned}$$

with $k_1 = \inf_{0<U<a_0/2}(-F_0(U)/U)$, if we choose $\delta_1 < k_1/(1+\mu)\{1+2\nu(C+1)\}$. Analogously, for $y \in E_-$ we have

$$\begin{aligned} n_- \cdot f_\varepsilon(y) &= -\delta_1 U(W - 2\varepsilon\nu V) - \mu W(W - 2\varepsilon\nu V) - F_0(U) \\ &> -\mu\delta_1(a_0 - U)\{\delta_1(a_0 - U) + 2\nu(C+1)\} + k_2(a_0 - U) > 0, \end{aligned}$$

with $k_2 = \inf_{a_0/2<U<a_0}(-F_0(U)/(a_0 - U))$, if we choose $\delta_1 < k_2/\mu\{1+2\nu(C+1)\}$. Hence, we have $\Omega_1^- = E_+ \cup E_- \subset \Omega^-$. This completes the proof.

Let δ_0 be a small positive constant satisfying $\Sigma_U \equiv [\gamma_0 - \delta_0, \gamma_0 + \delta_0] \subset (a_0, 1)$, and set $\Sigma \equiv \{(U, V, W) \mid U \in \Sigma_U,\ V = W = 0\}$. Let $\Sigma^0 = \{\xi_0 \in \Sigma \mid$ with a $\tau_0 = \tau_0(\xi_0)$ such that $\xi_0 \cdot \tau_0 \in \Omega\}$. For $\xi_0 \in \Sigma^0$, define $T(\xi_0) = \sup\{\tau \mid \xi_0 \cdot [0, \tau] \subseteq \Omega\}$. Suppose $\xi_0 \in \Sigma$ and $\xi_0 \cdot [0, \tau] \subseteq \text{cl}(\Omega)$, where cl (Ω) denotes the closure of Ω. Then $\xi_0 \cdot [0, \tau] \subset \Omega$ since Ω is closed. Suppose $\xi_0 \in \Sigma$, $\tau < T(\xi_0)$, $y_\varepsilon(\tau; \xi_0) \notin \Omega^-$. Then, $y_\varepsilon(\tau; \xi_0) \in \text{int}\,\Omega \cup \Omega_0 \cup \Omega^+$. Here, Ω_0 consists only of critical points, so $y_\varepsilon(\tau; \xi_0) \notin \Omega_0$. After some calculation, we can show that for any $\xi \in \Omega^+$, there exists $\tau_0 > 0$ such that $\xi \cdot \tau' \in \Omega$ for all $\tau' \in [-\tau_0, 0)$, which proves $y_\varepsilon(\tau; \xi_0) \notin \Omega^+$. Hence, we have $y_\varepsilon(\tau; \xi_0) \in \text{int}\,\Omega$. This implies that there is an open set S_τ about $\xi_0 \cdot \tau$ disjoint from Ω^-. Thus, it turns out that Ω is a Wazewski set.

Next, consider the mapping $\mathcal{T}(\xi_0) = \xi_0 \cdot T(\xi_0)$ from Σ^0 into Ω^-. For given γ_1, γ_2 satisfying $a_0 < \gamma_1 < \gamma_0 < \gamma_2 < 1$, set $\xi_i = (\gamma_i, 0, 0)$ $(i = 1, 2)$. Then from Lemma 4.1 and

the continuous dependence of a parameter ε, it follows that there exists a small $\varepsilon_0 > 0$ such that for each $\varepsilon \in [0, \varepsilon_0)$, $y_\varepsilon(\tau; \xi_1)$ and $y_\varepsilon(\tau; \xi_2)$ intersect Ω_1^- and Ω_2^- in finite time, respectively, that is, $\mathcal{T}(\xi_1) \in \Omega_1^-$ and $\mathcal{T}(\xi_2) \in \Omega_2^-$. Note that Σ is compact and intersects a trajectory of $(4.4)_\varepsilon$ only once in Ω. Then, if $\Sigma = \Sigma^0$, Proposition 1 of [6] proves that $\mathcal{T}$ is a homeomorphism of the connected set Σ to its image in the disconnected set Ω^-. This is a contradiction, so that $\Sigma \neq \Sigma^0$. Therefore, there is a $\xi_\varepsilon = (\gamma_\varepsilon, 0, 0) \in \Sigma$ such that the solution $y_\varepsilon(\tau; \xi_0)$ of $(4.4)_\varepsilon$ remains in Ω for all $\tau \geqq 0$.

LEMMA 4.3. *There is a small $\varepsilon_0 > 0$ such that for any $\varepsilon \in (0, \varepsilon_0)$, $(4.4)_\varepsilon$, (4.5) has a solution $y_\varepsilon(\tau; \xi_\varepsilon) = (U_\varepsilon(\tau; \gamma_\varepsilon), V_\varepsilon(\tau; \gamma_\varepsilon), W_\varepsilon(\tau; \gamma_\varepsilon))$ satisfying*

$$\lim_{\tau \to \infty} y_\varepsilon(\tau; \xi_\varepsilon) = (0, V^*, 0), \tag{4.10}$$

where V^* satisfies $0 < C_1 < V^* < C_2$. Moreover, $v_\varepsilon(\tau; \xi_\varepsilon)$ satisfies

$$\lim_{\tau \to \infty} U_\varepsilon(\tau; \gamma_\varepsilon) / W_\varepsilon(\tau; \gamma_\varepsilon) = \frac{2(1+\mu)\nu V^*}{F_0'(0)} \varepsilon. \tag{4.11}$$

Proof. It suffices for us to show (4.10) and (4.11). Any point $y \in \Omega \backslash \Omega_0$ is an ordinary point of $(4.4)_\varepsilon$, where $U_\tau < 0$ and $V_\tau > 0$, so that $y_\varepsilon(\tau; \xi_\varepsilon)$ must approach some point $(0, V^*, 0) \in \Omega_0$ as $\tau \to \infty$. This implies that for any small ε there exists some $\tau_\varepsilon > 0$ satisfying $U_\varepsilon(\tau_\varepsilon) = a_0/2$ and $0 < \tau_1 < \tau_\varepsilon < \tau_2$ with some constants τ_1, τ_2 independent of ε. Since $W_\varepsilon < -\delta_1 U_\varepsilon$ for $\tau \geqq \tau_\varepsilon$, it follows from the first equation $(4.4)_\varepsilon$ that

$$\frac{dU_\varepsilon}{d\tau} = U_\varepsilon(W_\varepsilon - 2\varepsilon\nu V_\varepsilon) \leqq U_\varepsilon W_\varepsilon \leqq -\delta_1 U_\varepsilon^2.$$

Integrating this over (τ_ε, τ), we have

$$U_\varepsilon(\tau) \leqq \frac{a_0}{2 + a_0\delta_1(\tau - \tau_\varepsilon)}, \tag{4.12}$$

where $U_\varepsilon(\tau)$ simply denotes $U_\varepsilon(\tau; \gamma_\varepsilon)$. Then the second equation of $(4.4)_\varepsilon$ shows

$$\begin{aligned} V_\varepsilon(\tau) &= \int_0^{\tau_\varepsilon} U_\varepsilon(\tau')^{1+\mu}\, d\tau' + \int_{\tau_\varepsilon}^{\tau} U_\varepsilon(\tau')^{1+\mu}\, d\tau' \\ &\leqq \tau_\varepsilon + \frac{a_0^\mu}{\delta_1 \mu} \frac{1}{[2 + a_0\delta_1(\tau - \tau_\varepsilon)]^\mu} \leqq C_2 \end{aligned}$$

with some positive constant C_1 independent of ε. It is obvious that there is $C_1 > 0$ independent of ε such that $V_\varepsilon(\tau_\varepsilon) \geqq C_1$. Since $V_\varepsilon(\tau)$ is monotone increasing, $V_\varepsilon(\tau)$ has a unique limit V^* satisfying $C_1 \leqq V^* \leqq C_2$ as $\tau \to \infty$.

Let us prove (4.11). We first note that for any $\delta > 0$, there exists a large τ_0 such that $V^* - \delta \leqq V_\varepsilon(\tau) < V^*$ for all $\tau \geqq \tau_0$. The first and third equations of $(4.4)_\varepsilon$ are written as follows:

$$\begin{aligned} U_\tau &= -2\varepsilon\nu V^* U + g_1, \\ W_\tau &= 2\varepsilon\mu\nu V^* W - F_0'(0) U + g_2, \end{aligned}$$

where $g_1 = UW - 2\varepsilon\nu(V - V^*)U$ and $g_2 = -\mu W^2 + 2\varepsilon\nu\mu(V - V^*)W - \{F_0(U) - F_0'(0)U\}$. Set $Z = {}^t(U, W)$ and $G(Z, V) = {}^t(g_1, g_2)$. By the linear transformation $Z = P\tilde{Z}$ with

$$P = \begin{pmatrix} 1 & 0 \\ F_0'(0)/2\varepsilon\nu V^*(1+\mu) & 1 \end{pmatrix},$$

we have the equation for $\tilde{Z}$:

$$\frac{d\tilde{Z}}{d\tau} = \begin{pmatrix} -2\varepsilon\nu V^* & 0 \\ 0 & 2\varepsilon\mu\nu V^* \end{pmatrix} \tilde{Z} + \tilde{G}(\tilde{Z}, \tau),$$

where $\tilde{G}(\tilde{Z}, \tau) = P^{-1}G(P\tilde{Z}, V(\tau))$. By applying the result in Theorems 4.1 and 4.2 of [5] to this equation, we can prove (4.11), which completes the proof.

Now we can show the properties of a small solution stated in Theorem 2.1. To do so, we need further information on the solution. Consider the plane $E_1 = \{(U, V, W) \mid 0 < U \leqq \varepsilon^2,\ 0 \leqq V \leqq C_2,\ W = -\delta_2 U/\varepsilon$ having the normal vector $m_1 = (\delta_2, 0, \varepsilon)$ with $\delta_2 \in (0, 1)$. Then the inner product $m_1 \cdot f_\varepsilon$ is estimated as

$$\begin{aligned} m_1 \cdot f_\varepsilon &= \delta_2 U(W - 2\varepsilon\nu V) - \varepsilon\mu W(W - 2\varepsilon\nu V) - \varepsilon F_0(U) \\ &= U\{\delta_2(1+\mu)(W - 2\varepsilon\nu V) + \varepsilon(-F_0(U)/U)\} \\ &> U_\varepsilon\{k_1 - \delta_2(1+\mu)(\delta_2 + 2\varepsilon\nu C_2)\} > 0, \end{aligned}$$

if we choose $\delta_2 < k_1/(1+\mu)(1+2\nu C_2)$. Also, consider the surface $E_2 = \{(U, V, W) \mid \varepsilon_2 < U \leqq a_0/2,\ 0 \leqq V \leqq C_2,\ W^2 = \delta_2^2 U,\ W < 0\}$ having the normal vector $m_2 = (\delta_2^2, 0, -2W)$. Then for E_2,

$$\begin{aligned} m_2 \cdot f_\varepsilon &= \delta_2^2 U(W - 2\varepsilon\nu V) + 2\mu W^2(W - 2\varepsilon\nu V) + 2WF_0(U) \\ &\geqq U[(1+2\mu)\delta_2^2(W - 2\varepsilon\nu C_2) - 2Wk_1] \\ &\geqq U[\{(1+2\mu)\delta_2^2 - k_1\}W - \delta_2\varepsilon\{2(1+2\mu)\nu C_2\delta_2 - k_1\}] \\ &> 0 \end{aligned}$$

for sufficiently small positive δ_2. Here we have used the estimate $V \leqq C_2$. Together with (4.11), these two estimates prove that the orbit $y_\varepsilon(\tau; \xi_\varepsilon)$ cannot intersect $E_1 \cup E_2$. That is, we choose U as the independent variable in place of τ through $U = U_\varepsilon(\tau; \gamma_\varepsilon) \equiv \psi_\varepsilon(\tau)$ and denote the solution orbit as S_ε: $(U, V_\varepsilon(U), W_\varepsilon(U)) = (U, V_\varepsilon(\psi_\varepsilon^{-1}(U); \gamma_\varepsilon), W_\varepsilon(\psi_\varepsilon^{-1}(U); \gamma_\varepsilon))$ defined for $U \in (0, \gamma_\varepsilon)$, where ψ_ε^{-1} is the inverse function of ψ_ε. Then $W_\varepsilon(U) < -\delta_2 U/\varepsilon$ for $0 < U \leqq \varepsilon^2$ and $W_\varepsilon(U) < -\delta_2\sqrt{U}$ for $\varepsilon^2 \leqq U \leqq a_0/2$. Also, we denote the solution orbit of $y_0(\tau; \gamma_0)$ as S_0: $(U, V_0(U), W_0(U)) = (U, V_0(\psi_0^{-1}(U); \gamma_0), W_0(\psi_0^{-1}(U); \gamma_0))$ for $U \in (0, \gamma_0)$, where $U = U_0(\tau, \gamma_0) \equiv \psi_0(\tau)$ and its inverse is ψ_0^{-1}.

Let us study the ε-dependence of S_ε. It follows from $(4.4)_\varepsilon$ that for $U \in (0, \underline{\gamma})$ with $\underline{\gamma} = \min(\gamma_0, \gamma_\varepsilon)$,

$$\frac{1}{2}(U^\mu W_\varepsilon)^2 - \frac{1}{2}(U^\mu W_0)^2 = -\frac{2\varepsilon\nu}{1+\mu}\int_0^U s^{\mu+1} f(s^\mu) V_\varepsilon(s)\left(\frac{dU_\varepsilon}{d\tau}(s)\right)^{-1} ds \tag{4.13}$$

(see (4.6) and (4.7)). Note that for small $\delta > 0$ there is a large τ_0 such that $V_\varepsilon \geqq V^* - \delta \equiv V_\delta$ for $\tau \geqq \tau_0$ and $0 < \inf_{0<\varepsilon<\varepsilon_0} U_\varepsilon(\tau_0) \equiv U_1 < a_0/2$ with small $\varepsilon_0 > 0$. Then $|dU_\varepsilon/d\tau(U)| = |U(W_\varepsilon - 2\varepsilon\nu V_\varepsilon)| \geqq U(\delta_2 U/\varepsilon + 2\varepsilon\nu V_\delta)$ for $0 < U \leqq \varepsilon^2$ and $|dU_\varepsilon/d\tau(U)| \geqq \delta_2 U^{3/2}$ for $\varepsilon^2 \leqq U \leqq U_1$, so that for $0 < U \leqq \varepsilon^2$,

$$\begin{aligned} I_f &\equiv \left| \int_0^U s^{\mu+1} f(s^\mu) V_\varepsilon\left(\frac{dU_\varepsilon}{d\tau}\right)^{-1} d\tau \right| \leqq \frac{V^* K_1}{\delta_2}\int_0^U \frac{\varepsilon s^{2\mu+1}\, ds}{s(s+\varepsilon^2 a)} \\ &\leqq \frac{V^* K_1}{\delta_2} U^{2\mu}\varepsilon \log\left(1 + \frac{U}{\varepsilon^2 a}\right) \leqq C_3\varepsilon U^{2\mu}, \end{aligned}$$

with $K_1 = \sup_{0<u<1} |f'(U)|$ and $a = 2\nu V_\delta/\delta_2$. For $\varepsilon^2 < U \leqq U_1$, we know

$$\begin{aligned} I_f &\leqq C_3\varepsilon(\varepsilon^2)^{2\mu} + V^* K_1 \int_{\varepsilon^2}^U \frac{s^{2\mu}\, ds}{\delta_2\sqrt{s} + 2\varepsilon\nu V_\delta} \\ &\leqq \left(C_3\varepsilon + \frac{V^* K_1}{2\delta_2}\sqrt{U}\right) U^{2\mu} \leqq C_4 U^{2\mu}. \end{aligned}$$

Furthermore, we easily see that for small $\delta'>0$, $|dU_\varepsilon/d\tau(U)^{-1}|\leqq C_5$ for $U\in[U_1, \gamma_\varepsilon-\delta']$ and $|dU_\varepsilon/d\tau(U)^{-1}|\leqq C_6/\sqrt{\gamma_\varepsilon-U}$ for $U\in[\gamma_\varepsilon-\delta', \gamma_\varepsilon)$. Applying all these estimates to I_f, we have $|W_\varepsilon(U)^2-W_0(U)^2|\leqq C_7\varepsilon$ for all $U\in(0, \underline{\gamma})$, so that

$$\sup_{0<U<\underline{\gamma}}|W_\varepsilon(U)-W_0(U)|\leqq C_8\sqrt{\varepsilon}. \tag{4.14}$$

At the same time, this proves $\lim_{\varepsilon\to 0}\gamma_\varepsilon=\gamma_0$. Since $U_\varepsilon(0;\gamma_\varepsilon)=\gamma_\varepsilon\to U_0(0;\gamma_0)=\gamma_0$ as $\varepsilon\to 0$ and $V_\varepsilon(0;\gamma_\varepsilon)=V_0(0;\gamma_0)=W_\varepsilon(0;\gamma_\varepsilon)=W_0(0;\gamma_0)=0$, the continuous dependence of solutions on initial values and parameters shows that $(U_\varepsilon(\tau;\gamma_\varepsilon), V_\varepsilon(\tau;\gamma_\varepsilon), W_\varepsilon(\tau;\gamma_\varepsilon))\to(U_0(\tau;\gamma_0), V_0(\tau;\gamma_0), W_0(\tau;\gamma_0))$ uniformly on any compact subset of R_+ as $\varepsilon\to 0$. Also note that (4.12) and Lemma 4.1 show $|U_\varepsilon(\tau;\gamma_\varepsilon)|, |U_0(\tau;\gamma_0)|\leqq C_9/\tau$ as $\tau\to\infty$. Therefore, we have

$$\lim_{\varepsilon\to 0}\sup_{\tau\in R_+}|U_\varepsilon(\tau;\gamma_\varepsilon)-U_0(\tau;\gamma_0)|=0. \tag{4.15}$$

To prove the compactness of support, let us consider the difference between $\eta_\varepsilon=\phi_\varepsilon(\tau)=\int_0^\tau U_\varepsilon(\tau';\gamma_\varepsilon)\,d\tau'$ and $\eta=\phi_0(\tau)=\int_0^\tau U_0(\tau';\gamma_0)\,d\tau'$, which is written as follows:

$$\begin{aligned}\phi_\varepsilon(\tau)-\phi_0(\tau)&=\int_0^{\tau_0}[U_\varepsilon(\tau';\gamma_\varepsilon)-U_0(\tau';\gamma_0)]\,d\tau'+\int_{U_\varepsilon(\tau_0)}^{U_0(\tau_0)}\frac{dU}{W_\varepsilon(U)-2\varepsilon\nu V_\varepsilon(U)}\\&\quad+\int_{U_0(\tau_0)}^{U_\varepsilon(\tau)}\left[\frac{1}{W_\varepsilon(U)-2\varepsilon\nu V_\varepsilon(U)}-\frac{1}{W_0(U)}\right]dU-\int_{U_\varepsilon(\tau)}^{U_0(\tau)}\frac{dU}{W_0(U)}\\&\equiv I_1+I_2+I_3+I_4,\end{aligned}$$

for sufficiently large τ_0. For any finite τ_0 fixed, I_1 and I_2 obviously tend to zero as $\varepsilon\to 0$. I_3 is evaluated as follows:

$$|I_3|\leqq\left(\sup_{0<U<U_0(\tau_0)}|W_\varepsilon(U)-W_0(U)|+2\varepsilon\nu V^*\right)\int_0^{U_0(\tau_0)}\frac{dU}{W_0(U)[W_\varepsilon(U)-2\varepsilon\nu V_\delta]}.$$

Since (4.9) assures us that $W_0\leqq-\delta_3\sqrt{U}$ for $U\in(0, U_0(\tau_0))$ with small $\delta_3>0$, elementary calculus shows that

$$\begin{aligned}\int_0^{U_0(\tau_0)}\frac{dU}{W_0(W_\varepsilon-2\varepsilon\nu V_\delta)}&\leqq\int_0^{\varepsilon_2}\frac{\varepsilon\,dU}{\delta_2\delta_3\sqrt{U}(U+\varepsilon^2 b)}+\int_{\varepsilon^2}^{U_0(\tau_0)}\frac{dU}{\delta_2\delta_3\sqrt{U}(\sqrt{U}+\varepsilon b)}\\&=\frac{2}{\delta_2\delta_3\sqrt{b}}\tan^{-1}\frac{1}{\sqrt{b}}+\frac{2}{\delta_2\delta_3}\log\frac{\sqrt{U_0(\tau_0)}+\varepsilon b}{(1+b)\varepsilon},\end{aligned}$$

where $b=2\nu V_\delta/\delta_2$. Together with (4.14), this proves $|I_3|\leqq C_{10}\sqrt{\varepsilon}\,|\log\varepsilon|\to 0$ as $\varepsilon\to 0$. It follows from (4.15) that

$$|I_4|\leqq\frac{1}{\delta_3}\left|\int_{U_\varepsilon(\tau)}^{U_0(\tau_0)}dU/\sqrt{U}\right|=|\sqrt{U_0(\tau)}-\sqrt{U_\varepsilon(\tau)}|/\delta_3\to 0$$

uniformly in $\tau\in R_+$ as $\varepsilon\to 0$. Finally, we have

$$\lim_{\varepsilon\to 0}\sup_{\tau\in R_+}|\phi_\varepsilon(\tau)-\phi_0(\tau)|=0, \tag{4.16}$$

which means, in particular, that $|\sigma_\varepsilon-\sigma_0|\equiv|\phi_\varepsilon(+\infty)-\phi_0(+\infty)|\to 0$ as $\varepsilon\to 0$.

Next, let us show (2.10). Let $\tau=\phi_\varepsilon^{-1}(\eta)$ be the inverse function of $\eta=\phi_\varepsilon(\tau)$ defined on $[0, \sigma_\varepsilon)$, and let $U_\varepsilon(\eta)$ be $U_\varepsilon(\phi_\varepsilon^{-1}(\eta);\gamma_\varepsilon)$. It is obvious that

$$u=\begin{cases}U_\varepsilon(\eta)^\mu & (0\leqq\eta<\sigma_\varepsilon),\\ 0 & (\eta\geqq\sigma_\varepsilon)\end{cases}$$

is a solution of (4.1), (4.2). Set $\varrho = \min(\sigma_\varepsilon, \sigma_0)$ and consider $U_\varepsilon(\eta) - U_0(\eta)$ for $\eta \in [0, \varrho)$, which is represented as

$$\begin{aligned} U_\varepsilon(\eta) - U_0(\eta) &= U_\varepsilon(\phi_\varepsilon^{-1}(\eta); \gamma_\varepsilon) - U_0(\phi_0^{-1}(\eta); \gamma_0) \\ &= U_\varepsilon(\phi_0^{-1}(\eta); \gamma_\varepsilon) - U_0(\phi_0^{-1}(\eta); \gamma_0) + U_\varepsilon(\phi_\varepsilon^{-1}(\eta); \gamma_\varepsilon) \\ &\quad - U_\varepsilon(\phi_0^{-1}(\eta); \gamma_\varepsilon). \end{aligned}$$

The first difference on the right-hand side tends to zero uniformly in $\tau = \phi_0^{-1}(\eta) \in R_+$ as $\varepsilon \to 0$, so that we only consider the second difference as follows:

$$\begin{aligned} \Delta &= U_\varepsilon(\phi_\varepsilon^{-1}(\eta); \gamma_\varepsilon) - U_\varepsilon(\phi_0^{-1}(\eta); \gamma_\varepsilon) = U(\phi_\varepsilon^{-1}(\phi_0(\tau)); \gamma_\varepsilon) - U_\varepsilon(\tau; \gamma_\varepsilon) \\ &= U_\varepsilon(\phi_\varepsilon^{-1}(\eta); \gamma_\varepsilon) - U_\varepsilon(\phi_\varepsilon^{-1}(\eta_\varepsilon); \gamma_\varepsilon) \end{aligned}$$

with $\eta_\varepsilon = \phi_\varepsilon(\tau)$. Hence, noting $d\phi_\varepsilon^{-1}/d\eta(\eta) = [(d\phi_\varepsilon/d\tau)(\tau_\varepsilon)]^{-1} = U_\varepsilon(\tau_\varepsilon; \gamma_\varepsilon)^{-1}$ with $\tau_\varepsilon = \phi_\varepsilon^{-1}(\eta)$, we easily have

$$\begin{aligned} |\Delta| &= \left| \frac{dU_\varepsilon}{d\tau}(\bar{\tau}_\varepsilon, \gamma_\varepsilon) \frac{d\phi_\varepsilon^{-1}}{d\eta}(\bar{\eta})(\eta - \eta_\varepsilon) \right| \leqq C_{11} |\phi_\varepsilon(\tau) - \phi_0(\tau)| \\ &\to 0 \quad \text{uniformly in } \tau \in R_+ \quad \text{as } \varepsilon \to 0, \end{aligned}$$

where $\bar{\eta} = \phi_\varepsilon(\bar{\tau}_\varepsilon)$ is an intermediate value between η and η_ε. Thus, we have $\lim_{\varepsilon \to 0} \sup_{0 < \eta < \varrho} |U_\varepsilon(\eta) - U_0(\eta)| = 0$. This completes the proof of Theorem 2.1.

5. Appendix.

5.1. Proof of Lemma 3.1. Let $(q_{0\zeta}, p_{0\zeta}) = (\varphi_1, \varphi_2)$. Differentiating $(3.6)_\varepsilon$ with respect to ζ, we see that $\varphi = {}^t(\varphi_1, \varphi_2)$ satisfies the linearized equations of $(3.6)_0$, that is, $Q_1 \varphi = 0$. Since $\varphi_1(\zeta) < 0$ for all $\zeta \geqq 0$, by reducing the order of the system, we have the linearly independent solution $\psi = {}^t(\psi_1, \psi_2)$ of $Q_1 \psi = 0$ as

$$\begin{aligned} &\psi_1(\zeta) = \varphi_1(\zeta)\chi(\zeta), \\ &\psi_2(\zeta) = \varphi_2(\zeta)\chi(\zeta) + \exp\left(- \int_0^\zeta A(\zeta')\, d\zeta' \right), \end{aligned} \tag{5.1}$$

where

$$A(\zeta) = \frac{\varphi_2(\zeta)}{\varphi_1(\zeta)} q_0(\zeta) + 2\mu \left(p_0(\zeta) + \frac{\lambda\gamma}{m\mu} \right)$$

and

$$\chi(\zeta) = \int_0^\zeta \left[\frac{q_0(\zeta')}{\varphi_1(\zeta')} \exp\left(- \int_0^{\zeta'} A(\zeta'')\, d\zeta'' \right) \right] d\zeta'.$$

As $\zeta \to +\infty$,

$$B(+\infty) = \begin{pmatrix} -2\lambda\gamma/m\mu & 0 \\ -F_0'(0) & 2\lambda\gamma/m \end{pmatrix},$$

so that its eigenvalues are $\rho_+ = 2\lambda\gamma/m$ and $\rho_- = -2\lambda\gamma/m\mu$, and the corresponding eigenvectors are ${}^t(0, 1)$ and ${}^t(2\lambda\gamma, F_0'(0))$, respectively. By the standard argument in the theory of ordinary differential equations, noting $F_0(q) \in C^{1,\mu}$, where $C^{1,\mu}$ is the set of functions whose first derivative is Hölder continuous with the exponent μ, we see that q_0 and $p_0 + (2\lambda\gamma/m\mu)$ belong to the class $X^2_{-\rho_-}(R_+)$, which means $\varphi_1, \varphi_2 \in X^1_{-\rho_-}(R_+)$. Knowing this, we have Proposition 5.1.

PROPOSITION 5.1. $|\psi_2(\zeta)|, |(d/d\zeta)\psi_2(\zeta)| = O(\exp \rho_+\zeta)$ *and* $|\psi_1(\zeta)|, |(d/d\zeta)\psi_1(\zeta)| = O(\exp(\rho_+ + \rho_-)\zeta)$ *as* $\zeta \to +\infty$.

Proof. Noting $\varphi_1 = dq_0/d\zeta$ and $\varphi_2 = dp_0/d\zeta$, we see that

$$\frac{\varphi_2(\zeta)}{\varphi_1(\zeta)} = \frac{dp_0}{dq_0} = \frac{1}{2\lambda\gamma} F_0'(0)(1+\gamma_1(q_0)) \quad \text{as } \zeta \to +\infty.$$

Hereafter, $\gamma_i(q_0)$ $(i = 1, 2, \cdots)$ denote some appropriate functions satisfying $\gamma_i(q_0) = O(|q_0|^{\min(\mu,1)})$. Also, we see that

$$2\mu\left(p_0(\zeta) + \frac{\lambda\gamma}{\mu m}\right) = 2\mu\left[\left(p_0(\zeta) + \frac{2\lambda\gamma}{\mu m}\right) \Big/ q_0(\zeta)\right] q_0(\zeta) - \frac{2\lambda\gamma}{m}$$

$$= \frac{\mu}{\lambda\gamma} F_0'(0)(1+\gamma_2(q_0))q_0 - \frac{2\lambda\gamma}{m}.$$

Thus, we have

$$A(\zeta) = \frac{m+1}{2\lambda\gamma\mu} F_0'(0)(1+\gamma_3(q_0))q_0 - \frac{2\lambda\gamma}{m}.$$

Integration of this gives

$$\int_0^\zeta A(\zeta')\, d\zeta' = \frac{m+1}{2\lambda\gamma\mu} F_0'(0) \int_0^\zeta [1+\gamma_3(q_0)]q_0\, d\zeta' - \frac{2\lambda\gamma}{m}\zeta$$

$$= O(1) - \frac{2\lambda\gamma}{m}\zeta$$

so that we have

$$\exp\left(-\int_0^\zeta A(\zeta')\, d\zeta'\right) = O(\exp \rho_+\zeta).$$

Since $\varphi_1 = dq_0/d\zeta = q_0 p_0$ and $p_0 = O(1)$ for $\zeta \geqq 0$, we have

$$\chi(\zeta) = \int_0^\zeta \frac{1}{p_0(\zeta')} \exp\left(-\int_0^{\zeta'} A(\zeta'')\, d\zeta''\right) d\zeta'' = O(\exp \rho_+\zeta).$$

By using these estimates, elementary calculation proves $\psi_1(\zeta) = O(\exp(\rho_+ + \rho_-)\zeta)$ and $\psi_2(\zeta) = O(\exp \rho_+\zeta)$. Differentiating (5.1) with respect to ζ and applying the estimate that $d\varphi_1/d\zeta$, $d\varphi_2/d\zeta = O(\exp \rho_-\zeta)$, we also have $d\psi_1/d\zeta = O(\exp(\rho_+ + \rho_-)\zeta)$ and $d\psi_2/d\zeta = O(\exp \rho_+\zeta)$. This completes the proof.

Using these solutions, we can write the general solution of $(d/d\zeta - B(\zeta))y = k$ with $y = {}^t(y_1, y_2)$ and $k = {}^t(k_1, k_2)$ as

$$\begin{aligned} y(\zeta) = &\left(c_1 + \int_0^\zeta D(\zeta')[\psi_2(\zeta')k_1(\zeta') - \psi_1(\zeta')k_2(\zeta')]\, d\zeta'\right)\varphi(\zeta) \\ &+ \left(c_2 + \int_0^\zeta D(\zeta')[-\varphi_2(\zeta')k_1(\zeta') + \varphi_1(\zeta')k_2(\zeta')]\, d\zeta'\right)\psi(\zeta), \end{aligned} \tag{5.2}$$

where $D(\zeta) = [\det(\varphi(\zeta), \psi(\zeta))]^{-1}$ and c_1, c_2 are arbitrary constants. Since $D(\zeta)^{-1} = \varphi_1\psi_2 - \varphi_2\psi_1 = \varphi_1(\zeta) \exp(-\int_0^\zeta A(\zeta')\, d\zeta') = O(\exp(\rho_- + \rho_+)\zeta)$, it follows from Proposition 5.1 that

$$D(\zeta)\begin{pmatrix} \psi_2(\zeta) & -\psi_1(\zeta) \\ -\varphi_2(\zeta) & \varphi_1(\zeta) \end{pmatrix} = \begin{pmatrix} O(\exp -\rho_-\zeta) & O(1) \\ O(\exp -\rho_+\zeta) & O(\exp -\rho_+\zeta) \end{pmatrix}. \tag{5.3}$$

The boundary condition on $y_1(0)$ determines $c_1 = 0$. Using (5.3), we consider the behavior of y as $\zeta \to +\infty$ for $k \in X^0_\rho \times X^0$ with $\rho = -\rho_- - \delta \geqq 0$ ($\delta > 0$) as follows:

$$\left|\varphi(\zeta)\int_0^\zeta D[\psi_2 k_1 - \psi_1 k_2]\,d\zeta'\right| \leqq \left(C_1\int_0^\zeta e^{-\rho_-\zeta'}\,e^{-\rho\zeta'}|e^{\rho\zeta'}k_1(\zeta')|\,d\zeta' + C_2\int_0^\zeta |k_2(\zeta')|\,d\zeta'\right)e^{\rho_-\zeta}$$

$$\leqq \left[\frac{C_1}{\delta}(e^{\delta\zeta}-1)\|k_1\|_{X^0_\rho} + C_2\zeta\|k_2\|_{X^0}\right]e^{\rho_-\zeta}$$

$$\leqq C_3(\|k_1\|_{X^0_\rho} + \|k_2\|_{X^0})\,e^{-\rho\zeta}.$$

Similarly, we have

$$\left|\int_0^\zeta D[-\varphi_2 k_1 + \varphi_1 k_2]\,d\zeta'\right| \leqq C_4\int_0^\zeta e^{-\rho_+\zeta'}\,e^{-\rho\zeta'}|\,e^{\rho\zeta'}k_1(\zeta')|\,d\zeta' + C_5\int_0^\zeta e^{-\rho_+\zeta'}|k_2(\zeta')|\,d\zeta'$$

$$\leqq C_6(\|k_1\|_{X^0_\rho} + \|k_2\|_{X^0}).$$

These two inequalities show that the uniform boundedness of a solution requires

$$c_2 + \int_0^\infty D(\zeta')[-\varphi_2(\zeta')k_1(\zeta') + \varphi_1(\zeta')k_2(\zeta')]\,d\zeta' = 0. \tag{5.4}$$

Conversely, if (5.4) holds, then the second term in the right-hand side of (5.2) is evaluated as

$$\left|\psi_1(\zeta)\int_\zeta^{+\infty} D[-\varphi_2 k_1 + \varphi_1 k_2]\,d\zeta'\right|$$

$$\leqq C_7\left(\frac{1}{\rho_+ + \rho}\,e^{-(\rho+\rho_+)\zeta}\|k_1\|_{X^0_\rho} + \frac{1}{\rho_+}\,e^{-\rho_+\zeta}\|k_2\|_{X^0}\right)e^{(\rho_+ + \rho_-)\zeta}$$

$$\leqq C_8(\|k_1\|_{X^0_\rho} + \|k_2\|_{X^0})\,e^{-\rho\zeta},$$

$$\left|\psi_2(\zeta)\int_\zeta^{+\infty} D[-\varphi_2 k_1 + \varphi_1 k_2]\,d\zeta'\right| \leqq C_9(\|k_1\|_{X^0_\rho} + \|k_2\|_{X^0}).$$

Hence, (5.4) is sufficient to assure $y \in X^0_\rho \times X^0$, so that we have a unique solution $y(\zeta) \in X^0_{\rho,0} \times X^0$ given by

$$y = \varphi\int_0^\zeta D[\psi_2 k_1 - \psi_1 k_2]\,d\zeta' + \psi\int_\zeta^{+\infty} D[-\varphi_2 k_1 + \varphi_1 k_2]\,d\zeta'.$$

Differentiating this, we easily see that $y \in X^1_{\rho,0} \times X^1$. Thus we have proved Lemma 3.1.

5.2. Proof of Lemma 3.2. We first show that for small $\kappa \in (0, 1)$ and $\varepsilon \geqq 0$, $\mathcal{F} = Q^{-1}g_1$ maps $B_\kappa(0)$ into $B_\kappa(0)$. To see this, we evaluate $g_1(y_1, \varepsilon R_1(q_1), \varepsilon)$ for $y = {}^t(q_1, p_1) \in B_\kappa(0)$ as follows:

$$\|h_{11}(y_1)\|_{X^0_\rho} = \sup_{\zeta \in R_+} |e^{\rho\zeta}p_1(\zeta)q_1(\zeta)| \leqq \|p_1\|_{X^0}\|q_1\|_{X^0_\rho} \leqq \|y\|^2_{Y_\rho},$$

$$\|h_{12}(y_1)\|_{X^0} \leqq \|F_0(q_0+q_1) - F_0(q_0) - F_0'(q_0)q_1\|_{X^0} + \|\mu p_1^2\|_{X^0}$$

$$\leqq C_1\|q_1^{1+\mu'}\|_{X^0} + \mu\|p_1\|^2_{X^0} \leqq C_2\|y_1\|^{1+\mu'}_{Y_\rho},$$

$$|R(q_1)| \leqq \left| \int_0^\zeta (q_0+q_1)^{1+\mu}\zeta' \right| \leqq \int_0^\zeta e^{-\rho(1+\mu)\zeta'}[e^{\rho\zeta'}(q_0+q_1)]^{1+\mu}\, d\zeta'$$
$$\leqq C_3\|q_0+q_1\|_{X_\rho^0}^{1+\mu} \leqq C_4(1+\|y\|_{Y_\rho})^{1+\mu},$$
$$\|h_2(y_1)\|_{X^0} \leqq \left\| \frac{2\lambda}{m}(p_0+p_1)R(q_1) \right\|_{X^0} + \left\| \frac{2\lambda}{m\mu}(q_0+q_1)^{1+\mu} \right\|_{X^0}$$
$$\leqq C_5(1+\|y\|_{Y_\rho})^{2(1+\mu)} + C_6(1+\|y\|_{Y_\rho})^{1+\mu}.$$

Combining these estimates, we have

$$\|Q_1^{-1}g_1\|_{Y_\rho} \leqq K_1[\|y\|_{Y_\rho}^2 + C_2\|y_1\|_{Y_\rho}^{1+\mu'} + \varepsilon C_7(1+\|y\|_{Y_\rho})^{2(1+\mu)}]$$
$$\leqq K_1[\kappa^2 + C_2\kappa^{1+\mu'} + \varepsilon C_7(1+\kappa)^{2(1+\mu)}],$$

where $K_1 = \|Q_1^{-1}\|_{Y_\rho \to Y_\rho}$.

Thus, we choose κ and $\varepsilon_0(\kappa)$ as $\kappa^{\mu'} \leqq \kappa_1 = 1/2K_1(1+C_2)$ and $\varepsilon_1 = \kappa/2^{3+2\mu}K_1C_7$, so that $\|\mathcal{F}\|_{Y_\rho} \leqq \kappa$ for all $\varepsilon \in [0, \varepsilon_1]$.

Next we consider the contracting property. We easily have

$$\|\mathcal{F}(y_1, \varepsilon) - \mathcal{F}(y_2, \varepsilon)\|_{Y^\rho} \leqq K_1(\|h_{11}(y_1) - h_{11}(y_2)\|_{X_\rho^0} + \|(h_{12}(y_1) - h_{12}(y_2)\|_{X^0})$$
$$+ \varepsilon K_1\|h_{22}(y_1) - h_{22}(y_2)\|_{X^0},$$

where $y_i = {}^t(q_i, p_i)$ for $i = 1, 2$. The right-hand side is estimated as follows:

$$\|h_{11}(y_1) - h_{11}(y_2)\|_{X_\rho^0} \leqq \|(p_1-p_2)q_1\|_{X_\rho^0} + \|p_2(q_1-q_2)\|_{X_\rho^0}$$
$$\leqq \|q_1\|_{X_\rho^0}\|p_1-p_2\|_{X^0} + \|p_2\|_{X^0}\|q_1-q_2\|_{X_\rho^0}$$
$$\leqq \kappa\|y_1-y_2\|_{Y^\rho},$$

$$\|h_{12}(y_1) - h_{12}(y_2)\|_{X^0}$$
$$\leqq \|F_2(q_0+q_1) - F_0(q_0+q_2) - F_0'(q_0)(q_1-q_2)\|_{X^0} + \mu\|p_1^2 - p_2^2\|_{X^0}$$
$$\leqq \|F_0'(q_0+q_1+\theta(q_2-q_1)) - F_0'(q_0)\|_{X^0}\|q_1-q_2\|_{X_\rho^0} + 2\mu\kappa\|p_1-p_2\|_{X^0}$$
$$\leqq (C_8(2\kappa)^{\mu'} + 2\mu\kappa)\|y_1-y_2\|_{Y_\rho},$$

where θ is an appropriate value in $(0, 1)$ and C_8 is the Hölder constant of the first derivative of F_0. Since

$$|R(q_1) - R(q_2)| = \int_0^\zeta |(q_0+q_1)^{1+\mu} - (q_0+q_2)^{1+\mu}|\, d\zeta'$$
$$\leqq (1+\mu)\int_0^\zeta |q_0+q_1+\theta(q_2-q_1)|^\mu\, e^{-\rho\zeta'}\, e^{\rho\zeta'}|q_1-q_2|\, d\zeta'$$
$$\leqq C_9\|q_1-q_2\|_{X_\rho^0},$$

we have

$$\|h_{22}(y_1) - h_{22}(y_2)\|_{X^0}$$
$$\leqq C_{10}(\|R(q_1) - R(q_2)\|_{X^0} + \|p_1R(q_1) - p_2R(q_2)\|_{X^0}$$
$$+ \|(q_0+q_1)^{1+\mu} - (q_0+q_2)^{1+\mu}\|_{X^0})$$
$$\leqq C_{11}(\|q_1-q_2\|_{X_\rho^0} + \|p_1-p_2\|_{X^0}) = C_{11}\|y_1-y_2\|_{Y_\rho^0}.$$

It follows from these estimates that

$$\|\mathcal{F}(y_1, \varepsilon) - \mathcal{F}(y_2, \varepsilon)\|_{Y_\rho^0} \leqq (C_{12}\kappa^{\mu'} + C_{11}K_1\varepsilon)\|y_1-y_2\|_{Y_\rho^0}. \tag{5.5}$$

Hence for $\kappa^{\mu'} = \min(\kappa_1, 1/4C_{12})$ we choose $\varepsilon_0(\kappa) = \min(\varepsilon_1, 1/4C_{11}K_1)$. Then for all $\varepsilon \in [0, \varepsilon_0(\kappa)]$, $\mathcal{F}$ is a contracting mapping. Inequality (5.5) also ensures the uniform continuity of $\mathcal{F}(y_1, \varepsilon)$ with respect to y_1 in $(y_1, \varepsilon) \in B_\kappa(0) \times [0, \varepsilon_0(\kappa)]$. The form of $\mathcal{F}(y_1, \varepsilon)$ directly proves its uniform continuity with respect to ε. This completes the proof.

SMALL PARAMETERS IN STRUCTURED POPULATION MODELS AND THE TROTTER–KATO THEOREM*

H. J. A. M. HEIJMANS† AND J. A. J. METZ‡

Abstract. The justification of some (often implicit) limit arguments used in the development of structured population models is discussed via two examples. The first example shows how a pair of sink-source terms may transform into a side condition relating the appearance of individuals in the interior of the individual state space to the outflow of individuals at its boundary. The second example considers the usual equation for size-dependent population growth in which it is implicitly assumed that discrete finitely-sized young are produced from infinitesimal contributions by all potential parents. The main mathematical tool for dealing with these examples is the Trotter–Kato theorem for one-parameter semigroups of bounded linear operators.

Key words. structured population, limit transition, C_0-semigroup, Trotter–Kato theorem

1. Introduction.

1.1. Biological motivation: structured populations, semigroups of operators, and the need for model simplifications. The tenet of the *physiologically structured* approach to the modeling of the dynamics of populations as set out in Metz and Diekmann (1986) is that, provided all individuals experience the same environmental inputs such as food availability or chance of running into a predator, we may (and should) represent a population as a frequency distribution over a space Ω of potential states of the individuals comprising the population. (As we frequently need corresponding concepts on the individual and population levels we will, where necessary, use the prefixes *i*- and *p*- to distinguish the corresponding terms, for example *i*-state versus *p*-state, where the latter refers to the frequency distribution.) The main effort in model construction is the determination of an appropriate state representation of *i*-behavior, where the *i*-behavior consists of (i) any contributions to population change such as giving birth or dying, and (ii) any quantities relevant to the calculation of the output from the population model, such as the rate at which the individual consumes food. If we make the assumption that the number of individuals is sufficiently large, then for any given course of the environment the present *p*-state should determine the future *p*-states in a deterministic and linear fashion. For a constant environment the maps relating subsequent *p*-states should form a linear semigroup.

The transition from *i*-model to *p*-model is made through their differential generators. It is here that we leave biology and start doing mathematics: did we really write down a genuine differential generator, and what can be said about the properties of the semigroup so generated?

Until now the attention has been mostly restricted to models where the *i*-state space Ω is a subset of $\mathbb{R}^k$, and where the individuals move through Ω according to the solution of an ordinary differential equation (ODE), possibly alternating with (usually randomly occurring) state jumps, for example, due to an individual losing weight when it splits off a daughter. The reasons for this restriction are twofold. First, models allowing continuous random *i*-state movements contain many more coefficient functions, which are difficult to specify on a mechanistic basis starting from known

underlying biology. Second, it is generally easier to obtain biological information from less complex models. After all, the goal of the whole exercise is gaining, preferably quantitative, insight into the relation between concrete, though possibly idealized, mechanisms operating in the individuals and consequent population dynamical phenomena. In fact random state jumps are already a bit of a nuisance in that they preclude the sort of simple calculations that a practicing biologist can perform all by himself.

In the present paper we will consider the systematic simplification of two models that both contain random i-state jumps. In the first model, which derives from cell kinetics, we will remove the random character of the jumps by concentrating the takeoffs at one place in Ω only. In the second model, which derives from the population dynamics of ectothermic animals (compare Sinko and Streifer (1967); Streifer (1974); Murphy (1983); Metz, de Roos, and van den Bosch (1988); and in particular Metz and Diekmann (1986)) and also from the dynamics of fungal pellet cultures (compare Edelstein and Hadar (1983); and Chipot and Edelstein (1983)), we will let the size of the jumps become infinitesimally small, while at the same time increasing their occurrence rate. The mathematical tools we use to justify the limit transitions are derived from the theory of one-parameter semigroups of operators (see Pazy (1983)). Particularly important is the Trotter-Kato theorem, which relates the convergence of a sequence of infinitesimal generators (respectively, their resolvents) to the convergence of the associated semigroups. The resulting limit models both allow simple alternative representations in the form of renewal equations for the rates at which newborns appear into the population with kernels, which can easily be calculated in terms of the model ingredients, making possible the routine calculation of biologically relevant quantities such as the asymptotic rate of population increase. Moreover, the limit models contain a smaller number of coefficient functions, making it easier to calibrate them against experimental data.

1.2. Simplification procedures in two special models. In both models considered in this paper the i-state variable of interest will be size; the growth rate of an individual of size x will be denoted as $g(x)$, and Ω will be an interval of $\mathbb{R}_+$. The rate at which individuals of size x die will be denoted as $\mu(x)$.

In the first family of models we consider cells that divide into two at a rate $b_\varepsilon(x)$, where $\varepsilon > 0$ is a small parameter. It is assumed that cells that have passed size one are no longer capable of dividing, but either differentiate or die, i.e., $b_\varepsilon(x) = 0$ for $x > 1$. We will moreover assume that $b_\varepsilon(x) = 0$ for $x < 1 - \varepsilon$. The two daughter cells may differ in size, but the distribution of their relative sizes is constant. This distribution is represented by the probability density $d(p)$, $d : (0, 1) \to \mathbb{R}_+$, where p is the fractional size of the daughter relative to that of its mother. As the sizes of the two daughters add up to the size of the mother, d is symmetric around $\frac{1}{2}$. We will moreover assume that $d(p) = 0$ outside $(\frac{1}{2} - \Delta, \frac{1}{2} + \Delta)$. Finally we assume that ε is so small that the size of the largest newborn daughter is less than the size of the smallest mother, i.e., $\frac{1}{2} + \Delta < 1 - \varepsilon$. Then the size of the smallest daughter, $x_{\min}$, satisfies

$$x_{\min} = (1 - \varepsilon)(\tfrac{1}{2} - \Delta) > (\tfrac{1}{2} + \Delta)(\tfrac{1}{2} - \Delta) =: \alpha.$$

This allows us to choose Ω to be $[\alpha, 1]$ independent of ε. The growth rate g is assumed to be positive and continuous on Ω. Let $n(t, \cdot)$ denote the density function of the cell sizes present at time t; then

$$\text{(1.1a)} \quad \frac{\partial}{\partial t} n(t, x) = -\frac{\partial}{\partial x}(g(x) n(t, x)) - b_\varepsilon(x) n(t, x) + 2 \int_0^1 \frac{d(p)}{p} b_\varepsilon\left(\frac{x}{p}\right) n\left(t, \frac{x}{p}\right) dp,$$

$$\text{(1.1b)} \quad n(t, \alpha) = 0.$$

Now assume that when we let $\varepsilon \downarrow 0$, the quantity

$$\int_{1-\varepsilon}^{1} \frac{b_\varepsilon(y)}{g(y)}\,dy$$

converges to a number larger than zero. This means that the probability that a newborn cell is eventually going to divide

$$\pi_\varepsilon = 1 - \exp\left(-\int_{1-\varepsilon}^{1} \frac{b_\varepsilon(y)}{g(y)}\,dy\right) \tag{1.2}$$

converges to a value $\pi_0 > 0$. In the limit cells will only divide on reaching $x = 1$, and they do so with probability π_0. The corresponding population equation is

$$\frac{\partial}{\partial t} n(t, x) = -\frac{\partial}{\partial x}(g(x)n(t, x)) + 2d(x)\pi_0 g(1)n(t, 1), \tag{1.3a}$$

$$n(t, \alpha) = 0. \tag{1.3b}$$

This limit model may be used as a convenient approximation when cell division occurs only in a narrow size window.

In § 2 we show that under suitable assumptions on the functions g, d, and b_ε, the solutions of (1.1) on the space $L^1[\alpha, 1]$ indeed converge to the solutions of (1.3).

In the second family of models we consider individuals that reproduce at a rate $\beta_\varepsilon(x)$ by splitting off young with size ε, ε small, while concurrently their size is decreased by the same amount. We assume that newborns have viability ρ_ε due to the necessity to survive an infinitesimally short larval stage. The corresponding population equation reads as follows:

$$\frac{\partial n}{\partial t}(t, x) + \frac{\partial}{\partial x}(g(x)n(t, x)) = -\beta_\varepsilon(x)n(t, x) + \beta_\varepsilon(x+\varepsilon)n(t, x+\varepsilon) - \mu(x)n(t, x), \tag{1.4a}$$

$$g(\varepsilon+)n(t, \varepsilon+) - g(\varepsilon-)n(t, \varepsilon-) = \rho_\varepsilon \int_0^1 \beta_\varepsilon(x)n(t, x)\,dx, \tag{1.4b}$$

$$g(0)n(t, 0) = 0, \tag{1.4c}$$

$$n(0, x) = \psi(x). \tag{1.4d}$$

In (1.4b),

$$g(\varepsilon+)n(t, \varepsilon+) - g(\varepsilon-)n(t, \varepsilon-) = \lim_{h \downarrow 0} [g(\varepsilon+h)n(t, \varepsilon+h) - g(\varepsilon-h)n(t, \varepsilon-h)].$$

It is assumed that growth stops at $x = 1$, i.e., $g(1) = 0$, and that g is positive for all smaller sizes including zero. Although the model structure is still compatible with representing the population state as a density function $n(t, \cdot)$, the *jump condition* (1.4b) makes the problem technically troublesome. A natural way out of this dilemma is provided by the observation that the only interesting quantities to be derived from a structured population model are population averages such as total population size, total biomass, or population feeding rate, i.e., linear functionals of $n(t, \cdot)$. This brings us to consider the so-called backward equation

$$\begin{aligned}\frac{\partial m}{\partial t}(t, x) - g(x)\frac{\partial m}{\partial x}(t, x) \\ = -\beta_\varepsilon(x)m(t, x) + \beta_\varepsilon(x)m(t, x-\varepsilon) + \rho_\varepsilon\beta_\varepsilon(x)m(t, \varepsilon) - \mu(x)m(t, x),\end{aligned} \tag{1.5a}$$

$$m(0, x) = \phi(x), \tag{1.5b}$$

satisfied by the clan averages

$$m(t,x)=\int_0^1 \phi(\xi)N_x(t,d\xi), \tag{1.6}$$

where the Borel measure $N_x(t,\cdot)$ represents the expected state at time t of a clan descending from an ancestral individual sized x at time zero. If $m_\varepsilon(t,x;\phi)$ is the solution of (1.5), then every p-output is of the form $\int_0^1 m_\varepsilon(t,x;\phi)\psi(dx)$, where ψ is the initial condition in (1.4d). In § 3.3 we give a precise description of the duality relation between solutions of the forward and backward equations in terms of semigroups and generators (also see Heijmans (1984) and Clement et al. (1987)).

In nature usually roughly the same amount of energy is available for reproduction, which, depending on the species, may be spent on producing a few large or many small young. Therefore we set

$$\beta_\varepsilon(x)=\varepsilon^{-1}b(x). \tag{1.7}$$

Moreover, in species with many small young, infant mortality is generally much higher than when the young are large. If recruitment is to stay bounded when we let ε go to zero we have to put

$$\rho_\varepsilon=\varepsilon r. \tag{1.8}$$

Inserting (1.7) and (1.8) into (1.5a) and letting $\varepsilon\downarrow 0$, we obtain

$$\frac{\partial m}{\partial t}(t,x)-(g(x)-b(x))\frac{\partial m}{\partial x}(t,x)=rb(x)m(t,0)-\mu(x)m(t,x), \tag{1.9}$$

which corresponds to the forward equation

$$\begin{aligned}&\frac{\partial}{\partial t}n(t,x)=-\frac{\partial}{\partial x}(\gamma(x)n(t,x))-\mu(x)n(t,x),\\ &\gamma(x_0)n(t,x_0)=\int rb(y)n(t,y)\,dy,\end{aligned} \tag{1.10}$$

with

$$\gamma(x)=g(x)-b(x) \tag{1.11}$$

and $x_0=0$. Instead of being set back in size at each discrete reproductive event the individual's growth rate is reduced by an amount related to the energy spent in reproduction. Note that in contrast to g the reduced growth rate γ is no longer positive on $[0,1)$, in particular $\gamma(1)=-b(1)<0$.

In § 3.2 we show that under suitable assumptions on the functions g, b, and μ, the semigroup generated by (1.5) indeed converges to the semigroup generated by (1.9). In that section we will also discuss in somewhat more detail the relation between the forward and backward equations.

Equation (1.10) is the equation usually encountered in the population dynamical literature; only x_0 is generally assumed to be positive. Biologically this amounts to the assumption that either parents can time and again produce instantaneously additional masses x_0, notwithstanding the fact that they can add to their own body mass only in a continuous fashion, or else that live newborns are created by magic out of the added infinitesimal contributions by all parents together. Both assumptions go against the grain. Our limiting procedure provides a possible justification, provided x_0 is vanishingly small.

Note for the biological reader. There remains the seemingly awkward assumption that $g(0)>0$. However, the most often encountered biological growth law, the Von Bertalanffy equation, has precisely this property. Note that the Von Bertalanffy Ansatz does not allow individuals to spontaneously spring into being by growing away from size zero. What matters is that $\lim_{x\downarrow 0} g(x)>0$. Individuals of size zero never exist, only individuals that are very small.

Remark. Another way to guarantee that recruitment stays bounded for $\varepsilon\downarrow 0$ is to keep ρ_ε constant and to replace the usual integrability assumption on μ by the assumption that

$$\frac{\mu(x)}{g(x)}=\frac{1}{x}+f(x)$$

with f an L^1 function. To see that this has indeed the intended effect, observe that the probability that a recruited individual survives until it reaches size $x>\varepsilon$ equals

$$\exp\left(-\int_\varepsilon^x \frac{\mu(y)}{g(y)}\,dy\right).$$

(Note that any other choice for the behavior of $\mu(x)$ near $x=0$ does not for $\varepsilon\downarrow 0$ yield the needed survival proportional to ε during the first moments after recruitment!)

2. From distributed to concentrated division.

2.1. The equation and the associated semigroup. In this section we make a thorough mathematical study of (1.1) describing a size-structured cell population reproducing by division. For the sake of convenience we recall the following equation:

$$\text{(2.1a)}\quad \frac{\partial n}{\partial t}(t,x)+\frac{\partial}{\partial x}(g(x)n(t,x))=-b_\varepsilon(x)n(t,x)+2\int_0^1 \frac{d(p)}{p}b_\varepsilon\left(\frac{x}{p}\right)n\left(t,\frac{x}{p}\right)dp,$$

$$\text{(2.1b)}\quad n(t,\alpha)=0,$$

$$\text{(2.1c)}\quad n(0,x)=\phi(x).$$

We will prove that under the right set of assumptions solutions of this problem converge for $\varepsilon\downarrow 0$ to solutions of the limit equation (1.3), i.e.,

$$\text{(2.2a)}\quad \frac{\partial n}{\partial t}(t,x)+\frac{\partial}{\partial x}(g(x)n(t,x))=2\pi_0 d(x)g(1)n(t,1),$$

$$\text{(2.2b)}\quad n(t,a)=0,$$

$$\text{(2.2c)}\quad n(0,x)=\phi(x).$$

We refer to § 1.2 for the interpretation of ε, g, b_ε, d, α, and π_0. As the underlying population state space we choose $X=L^1[\alpha,1]$. We make the following assumptions.

Assumption 2.1. (a) $g\in C[\alpha,1]$; $g(x)>0$, $x\in[\alpha,1]$.

(b) $d\in C[0,1]$; $d(p)>0$ if and only if $|p-\frac{1}{2}|<\Delta$; d is symmetric around $p=\frac{1}{2}$, and $\int_{1/2-\Delta}^{1/2+\Delta} d(p)\,dp=1$.

(c) $b_\varepsilon\in C[\alpha,1]$; $b_\varepsilon(x)=0$, $x\in[\alpha,1-\varepsilon]$; $b_\varepsilon(x)>0$, $x\in(1-\varepsilon,1]$.

We can write (2.1) with initial condition $\phi\in X$ as the abstract Cauchy problem

$$\text{(2.3)}\quad \frac{dn}{dt}(t)=A_\varepsilon n(t),\qquad n(0)=\phi,$$

where the closed operator A_ε on X is given by

$$\text{(2.4)}\quad (A_\varepsilon\phi)(x)=-\frac{d}{dx}(g(x)\phi(x))-b_\varepsilon(x)\phi(x)+2\int_{1/2-\Delta}^{1/2+\Delta}\frac{d(p)}{p}b_\varepsilon\left(\frac{x}{p}\right)\phi\left(\frac{x}{p}\right)dp,$$

for any ϕ in its domain

$$D(A_\varepsilon)=\{\phi\in X:\ g\phi\in W^{1,1}[\alpha,1] \text{ and } \phi(\alpha)=0\}. \tag{2.5}$$

Using a standard perturbation result for C_0-semigroups (Pazy (1983, § 3.1)) we easily show that A_ε is the infinitesimal generator of a strongly continuous semigroup $\{T_\varepsilon(t)\}_{t\geqq 0}$.

Let A be a closed linear operator on the Banach space X and let $M\geqq 0$, $\omega\in\mathbb{R}$. We say that $A\in G(M,\omega)$ if A is the infinitesimal generator of a C_0-semigroup $\{T(t)\}_{t\geqq 0}$ of bounded linear operators satisfying

$$\|T(t)\|\leqq M e^{\omega t},\qquad t\geqq 0$$

(e.g., Pazy (1983, § 3.4)). The next proposition states, among other things, that there exists a semigroup solution to (2.1).

THEOREM 2.2. *There exist constants $\omega\in\mathbb{R}$ and $M\geqq 1$ (which do not depend on ε), such that $A_\varepsilon\in G(M,\omega)$.*

Proof. Let $\|\cdot\|$ be the L^1-norm. Then the norm $\|\cdot\|$ is equivalent to the norm $\|\cdot\|'$ given by

$$\|\phi\|'=\int_\alpha^1 x|\phi(x)|\,dx,\qquad \phi\in X.$$

Let, for $t\geqq 0$,

$$\|T_\varepsilon(t)\|'=\sup\{\|T_\varepsilon(t)\phi\|'/\|\phi\|':\ \phi\in X,\ \phi\neq 0\}.$$

Since $T_\varepsilon(t)$ is a positive operator, we have

$$\|T_\varepsilon(t)\|'=\{\|T_\varepsilon(t)\phi\|'/\|\phi\|':\ \phi\in X_+,\ \phi\neq 0\},$$

where X_+ is the cone of positive elements. If $\phi\in X_+$, then $\|T_\varepsilon(t)\phi\|'=\int_\alpha^1 xn(t,x)\,dx$, where $n(t,x)$ is the solution of (2.1). If, in addition, $\phi\in D(A_\varepsilon)$, then

$$\frac{d}{dt}\int_\alpha^1 xn(t,x)\,dx\leqq\int_\alpha^1 g(x)n(t,x)\,dx\leqq\omega\int_\alpha^1 xn(t,x)\,dx,$$

where $\omega>0$ is taken so large that $g(x)\leqq\omega x$, $x\in[\alpha,1]$. So for $\phi\in D(A_\varepsilon)\cap X_+$ we find that

$$\|T_\varepsilon(t)\phi\|'=\int_\alpha^1 xn(t,x)\,dx\leqq e^{\omega t}\int_\alpha^1 x\phi(x)\,dx=e^{\omega t}\|\phi\|'.$$

Since $D(A_\varepsilon)\cap X_+$ is norm-dense in X_+, this holds for any $\phi\in X_+$, and we find that

$$\|T_\varepsilon(t)\|'\leqq e^{\omega t},\qquad t\geqq 0.$$

Since $\|\cdot\|'$ and $\|\cdot\|$ are equivalent norms, there exists a constant $M>0$ such that

$$\|T_\varepsilon(t)\|\leqq M e^{\omega t},\qquad t\geqq 0,$$

and the result is proved. □

2.2. Justification of the limit transition. In this section we give a formal mathematical justification of the limit transition $\varepsilon\downarrow 0$ which amounts to (2.2). That is to say, we prove that the solution of (2.1) given by $n(t,\cdot)=T_\varepsilon(t)\phi$ converges to the solution of (2.2) as $\varepsilon\downarrow 0$. For this purpose, we use the Trotter–Kato theorem. Besides Assumptions 2.1(a)–(c) we only assume there exists a $\pi_0\in[0,1)$ such that $\lim_{\varepsilon\downarrow 0}\pi_\varepsilon=\pi_0$.

We rewrite (2.2) as the abstract Cauchy problem

$$\frac{dn}{dt}(t) = An(t), \qquad n(0) = \phi, \tag{2.6}$$

where A is the closed operator

$$(A\phi)(x) = -\frac{d}{dx}(g(x)\phi(x)) + 2\pi_0 d(x) g(1)\phi(1) \tag{2.7}$$

with dense domain

$$D(A) = \{\phi \in X: g\phi \in W^{1,1}[\alpha, 1] \text{ and } \phi(\alpha) = 0\}. \tag{2.8}$$

THEOREM 2.3. *For $\lambda \in \mathbb{R}$ large enough we have*

$$R(\lambda, A_\varepsilon)\phi \to R(\lambda, A)\phi, \qquad \varepsilon \downarrow 0,$$

for every $\phi \in X$.

Proof. The proof consists of four steps.

(1) Let the isomorphism $U_\varepsilon: X \to X$ be given by

$$(U_\varepsilon \phi)(x) = \frac{E_\varepsilon(x)}{g(x)}\phi(x),$$

where $E_\varepsilon(x) = \exp\left(-\int_\alpha^x (b_\varepsilon(y)/g(y))\, dy\right)$. Let

$$D = D(A) = D(A_\varepsilon) = \{\phi \in X: g\phi \in W^{1,1}[\alpha, 1] \text{ and } \phi(\alpha) = 0\},$$

and

$$\tilde{D} = U_\varepsilon^{-1} D = \{\phi \in X: \phi \in W^{1,1}[\alpha, 1] \text{ and } \phi(\alpha) = 0\}.$$

Let $\tilde{A}_\varepsilon$ be the closed operator $U_\varepsilon^{-1} A_\varepsilon U_\varepsilon$ with domain $D(\tilde{A}_\varepsilon) = \tilde{D}$. Then $\tilde{A}_\varepsilon$ is given by

$$(\tilde{A}_\varepsilon \phi)(x) = -g(x)\frac{d\phi}{dx}(x) + 2\frac{g(x)}{E_\varepsilon(x)} \int_{1/2-\Delta}^{1/2+\Delta} \frac{d(p)}{p} r_\varepsilon\left(\frac{x}{p}\right)\phi\left(\frac{x}{p}\right) dp,$$

where $r_\varepsilon(x) = (b_\varepsilon(x)/g(x))E_\varepsilon(x)$ for $x \in [\alpha, 1]$. We define the isomorphism $U: X \to X$ by

$$(U\phi)(x) = \frac{\phi(x)}{g(x)}.$$

Let $\tilde{A}$ be the closed operator $U^{-1}AU$ with domain $D(\tilde{A}) = U^{-1}D = \tilde{D}$. For $\phi \in D(\tilde{A})$ we have

$$(\tilde{A}\phi)(x) = -g(x)\frac{d\phi}{dx}(x) + 2\pi_0\, d(x) g(x)\phi(1).$$

(2) We show that for every $\phi \in \tilde{D}$,

$$\tilde{A}_\varepsilon \phi \to \tilde{A}\phi \quad \text{as } \varepsilon \downarrow 0.$$

Let $\phi \in \tilde{D}$, then

$$(\tilde{A}_\varepsilon \phi)(x) - (\tilde{A}\phi)(x) = 2\frac{g(x)}{E_\varepsilon(x)} \int_{1/2-\Delta}^{1/2+\Delta} \frac{d(p)}{p} r_\varepsilon\left(\frac{x}{p}\right)\phi\left(\frac{x}{r}\right) dp - 2\pi_0\, d(x) g(x)\phi(1).$$

We define $\bar{g} = \max_{x\in[\alpha,1]} g(x)$, $\bar{d} = \max_{p\in[1/2-\Delta,1/2+\Delta]} d(p)$. Now

$$\|\tilde{A}_\varepsilon\phi - \tilde{A}\phi\| = \int_\alpha^1 \left| \frac{2g(x)}{E_\varepsilon(x)} \int_{1/2-\Delta}^{1/2+\Delta} \frac{d(p)}{p} r_\varepsilon\left(\frac{x}{p}\right)\phi\left(\frac{x}{p}\right) dp - 2\pi_0\, d(x)g(x)\phi(1) \right| dx$$

$$= \int_{(1/2-\Delta)(1-\varepsilon)}^{1/2+\Delta} \left| 2g(x) \int_{1/2-\Delta}^{1/2+\Delta} \frac{d(p)}{p} r_\varepsilon\left(\frac{x}{p}\phi\left(\frac{x}{p}\right)\right) dp - 2\pi_0\, d(x)g(x)\phi(1) \right| dx$$

$$\leqq 2\bar{g} \int_{(1/2-\Delta)(1-\varepsilon)}^{1/2+\Delta} \left| \int_{1/2-\Delta}^{1/2+\Delta} \frac{d(p)}{p} r_\varepsilon\left(\frac{x}{p}\right)\phi\left(\frac{x}{p}\right) dp - \pi_\varepsilon\, d(x)\phi(1) \right| dx$$

$$+ 2\bar{g}\,|\pi_\varepsilon - \pi_0| \cdot |\phi(1)|.$$

This second expression at the right-hand side can easily be estimated. We write the first expression as the sum of three integrals:

$$\int_{(1/2-\Delta)(1-\varepsilon)}^{1/2+\Delta} = \int_{(1/2-\Delta)(1-\varepsilon)}^{1/2-\Delta} + \int_{1/2-\Delta}^{(1/2+\Delta)(1-\varepsilon)} + \int_{(1/2+\Delta)(1-\varepsilon)}^{1/2+\Delta}.$$

It is the middle integral that causes the most trouble, and we restrict our attention to this term. Let $\delta > 0$:

$$2\bar{g} \int_{1/2-\Delta}^{(1/2+\Delta)(1-\varepsilon)} \left| \int_{1/2-\Delta}^{1/2+\Delta} \frac{d(p)}{p} r_\varepsilon\left(\frac{x}{p}\right)\phi\left(\frac{x}{p}\right) dp - \pi_\varepsilon\, d(x)\phi(1) \right| dx$$

$$= 2\bar{g} \int_{1/2-\Delta}^{(1/2+\Delta)(1-\varepsilon)} \left| \int_{x/(1/2+\Delta)}^{x/(1/2-\Delta)} \frac{1}{y} d\left(\frac{x}{y}\right) r_\varepsilon(y)\phi(y)\, dy - \pi_\varepsilon\, d(x)\phi(1) \right| dx$$

$$= 2\bar{g} \int_{1/2-\Delta}^{(1/2+\Delta)(1-\varepsilon)} \left| \int_{1-\varepsilon}^{1} \frac{1}{y} d\left(\frac{x}{y}\right) r_\varepsilon(y)\phi(y)\, dy - \int_{1-\varepsilon}^{1} d(x) r_\varepsilon(y)\phi(1)\, dy \right| dx$$

$$= 2\bar{g} \int_{1/2-\Delta}^{(1/2+\Delta)(1-\varepsilon)} \left| \int_{1-\varepsilon}^{1} \left\{ \frac{1}{y} d\left(\frac{x}{y}\right)\phi(y) - \frac{1}{1} d\left(\frac{x}{1}\right)\phi(1) \right\} r_\varepsilon(y)\, dy \right| dx$$

$$\leqq 2\bar{g} \int_{1/2-\Delta}^{(1/2+\Delta)(1-\varepsilon)} \left\{ \int_{1-\varepsilon}^{1} \delta r_\varepsilon(y)\, dy \right\} dx \leqq 2\bar{g} \cdot 2\Delta \cdot \delta.$$

Here we have chosen $\varepsilon > 0$ so small that

$$\left| \frac{1}{y} d\left(\frac{x}{y}\right)\phi(y) - \frac{1}{1} d\left(\frac{x}{1}\right)\phi(1) \right| < \delta,$$

for every $x \in [\frac{1}{2}-\Delta, (\frac{1}{2}+\Delta)(1-\varepsilon)]$ and $y \in [1-\varepsilon, 1]$, and we used that $\int_{1-\varepsilon}^{1} r_\varepsilon(y)\, dy = \pi_\varepsilon \leqq 1$. This shows that $\tilde{A}_\varepsilon\phi \to \tilde{A}\phi$ as $\varepsilon \downarrow 0$, for $\phi \in \tilde{D}$.

(3) We show that for $\lambda \in \mathbb{R}$ large enough (in particular $\lambda > \omega$; see Theorem 2.2)

$$R(\lambda, \tilde{A}_\varepsilon)\phi \to R(\lambda, \tilde{A})\phi \quad \text{as } \varepsilon \downarrow 0,$$

for every $\phi \in X$. Choose $\lambda > \omega$ so large that $\lambda \in \rho(A) = \rho(\tilde{A})$. Let $\phi \in X$, and define $\psi \in \tilde{D}$ as $\psi = R(\lambda, \tilde{A})\phi$. For $\varepsilon > 0$, let $\phi_\varepsilon = (\lambda - \tilde{A}_\varepsilon)\psi$. From

$$\tilde{A}_\varepsilon\psi \to \tilde{A}\psi \quad \text{as } \varepsilon \downarrow 0$$

we get $\phi_\varepsilon \to \phi$ as $\varepsilon \downarrow 0$. Since $R(\lambda, \tilde{A}_\varepsilon) = U_\varepsilon^{-1} R(\lambda, A_\varepsilon) U_\varepsilon$, we deduce from Theorem 2.2 that

$$\|R(\lambda, \tilde{A}_\varepsilon)\| \leqq \frac{\tilde{M}}{\lambda - \omega}, \qquad \varepsilon > 0.$$

Here we have used explicitly that $\pi_0 < 1$. Now

$$\lim_{\varepsilon \downarrow 0} R(\lambda, \tilde{A}_\varepsilon)\phi = \lim_{\varepsilon \downarrow 0} [R(\lambda, \tilde{A}_\varepsilon)(\phi - \phi_\varepsilon) + \psi] = \psi = R(\lambda, \tilde{A})\phi.$$

(4) We finally show that for $\lambda \in \mathbb{R}$ large enough,

$$R(\lambda, A_\varepsilon)\phi \to R(\lambda, A)\phi \quad \text{as } \varepsilon \downarrow 0,$$

for every $\phi \in X$. It is easily checked that

$$U_\varepsilon \phi \to U\phi, \quad \varepsilon \downarrow 0 \quad \text{and} \quad U_\varepsilon^{-1}\phi \to U^{-1}\phi, \quad \varepsilon \downarrow 0,$$

for every $\phi \in X$, and that there exists a constant $L > 0$ such that $\|U_\varepsilon\|$, $\|U\|$, $\|U_\varepsilon^{-1}\|$, $\|U^{-1}\| \leqq L$, $\varepsilon > 0$. For every $\phi \in X$ we have

$$\begin{aligned}
\|R(\lambda, A_\varepsilon)\phi - R(\lambda, A)\phi\| &= \|U_\varepsilon R(\lambda, \tilde{A}_\varepsilon) U_\varepsilon^{-1}\phi - UR(\lambda, A)U^{-1}\phi\| \\
&= \|(U_\varepsilon - U)(R(\lambda, \tilde{A}_\varepsilon)U_\varepsilon^{-1} - R(\lambda, \tilde{A}_\varepsilon)U^{-1} + R(\lambda, \tilde{A}_\varepsilon)U^{-1} \\
&\quad - R(\lambda, \tilde{A})U^{-1} + R(\lambda, \tilde{A})U^{-1})\phi \\
&\quad + U(R(\lambda, \tilde{A}_\varepsilon) - R(\lambda, \tilde{A}))(U_\varepsilon^{-1} - U^{-1} + U^{-1})\phi \\
&\quad + UR(\lambda, \tilde{A})(U_\varepsilon^{-1} - U^{-1})\phi\| \\
&\leqq \|U_\varepsilon - U\| \, \|R(\lambda, \tilde{A}_\varepsilon)\| \, \|U_\varepsilon^{-1}\phi - U^{-1}\phi\| \\
&\quad + \|U_\varepsilon - U\| \, \|R(\lambda, \tilde{A}_\varepsilon)U^{-1}\phi - R(\lambda, \tilde{A})U^{-1}\phi\| \\
&\quad + \|(U_\varepsilon - U)R(\lambda, \tilde{A})U^{-1}\phi\| \\
&\quad + \|U\| \, \|R(\lambda, \tilde{A}_\varepsilon) - R(\lambda, \tilde{A})\| \, \|U_\varepsilon^{-1}\phi - U^{-1}\phi\| \\
&\quad + \|U\| \, \|(R(\lambda, \tilde{A}_\varepsilon) - R(\lambda, \tilde{A}))U^{-1}\phi\| \\
&\quad + \|U\| \, \|R(\lambda, \tilde{A})\| \, \|U_\varepsilon^{-1}\phi - U^{-1}\phi\|,
\end{aligned}$$

and all these terms go to zero as $\varepsilon \downarrow 0$. □

We can now apply the Trotter-Kato theorem (Pazy (1983, § 3.4)), which yields that (i) A is the infinitesimal generator of a C_0-semigroup (in particular this means that (2.2) is well posed) and that (ii) the solution of (2.1) converges to the solution of (2.2) as $\varepsilon \downarrow 0$.

THEOREM 2.4. *$A \in G(M, \omega)$, and if $\{T(t)\}_{t \geqq 0}$ is the semigroup generated by A, then for every $\phi \in X$, $t \geqq 0$,*

$$T_\varepsilon(t)\phi \to T(t)\phi \quad \text{as } \varepsilon \downarrow 0.$$

Moreover, the convergence is uniform with respect to t in bounded subsets of $(0, \infty)$.

3. From size jumps to reduced growth.

3.1. The semigroup solution to the backward equation. In this section we show that under some reasonable assumptions we can associate a C_0-semigroup of bounded linear operators on $X = C[0, 1]$ with the backward equation (1.5), which we recall below for convenience. Throughout this section we will assume that the death rate μ

is identically zero. However, all the results obtained here remain valid for nonzero death rates. The backward equation reads as follows:

$$\frac{\partial m}{\partial t}(t,x)-g(x)\frac{\partial m}{\partial x}(t,x)=-\beta_\varepsilon(x)n(t,x)+\beta_\varepsilon(x)m(t,x-\varepsilon)+\rho_\varepsilon\beta_\varepsilon(x)m(t,\varepsilon), \tag{3.1a}$$

$$m(0,x)=\phi(x). \tag{3.1b}$$

Assumption 3.1. (a) g is Lipschitz continuous on $[0,1]$; $g(x)>0$, $x\in[0,1)$; $g(1)=0$.

(b) β_ε is Lipschitz continuous on $[0,1]$; there is an $a>\varepsilon$ such that $\beta_\varepsilon(x)=0$, $x\in[0,a]$ and $\beta_\varepsilon(x)>0$, $x\in(a,1]$.

Here a denotes the minimum size at which an individual can reproduce. We can write (3.1) as the abstract Cauchy problem:

$$\frac{dm}{dt}(t)=A_\varepsilon m(t), \tag{3.2a}$$

$$m(0)=\phi\in X, \tag{3.2b}$$

where the closed unbounded operator A_ε with domain

$$D(A_\varepsilon)=\{\phi\in X\cap W^{1,1}_{\mathrm{loc}}[0,1]\colon g\phi'\in X\},$$

is given by

$$(A_\varepsilon\phi)(x)=g(x)\frac{d\phi}{dx}(x)-\beta_\varepsilon(x)\phi(x)+\beta_\varepsilon(x)\phi(x-\varepsilon)+\rho_\varepsilon\beta_\varepsilon(x)\phi(\varepsilon).$$

We write A_ε as the sum of two operators:

$$A_\varepsilon=A_0+B_\varepsilon, \tag{3.3}$$

where the closed unbounded operator A_0 has the same domain as A_ε and is given by

$$(A_0\phi)(x)=g(x)\frac{d\phi}{dx}(x),$$

and where B_ε is a bounded operator given by

$$(B_\varepsilon\phi)(x)=-\beta_\varepsilon(x)\phi(x)+\beta_\varepsilon(x)\phi(x-\varepsilon)+\rho_\varepsilon\beta_\varepsilon(x)\phi(\varepsilon).$$

It is quite easy to show that A_0 generates a strongly continuous semigroup $\{T_0(t)\}_{t\geqq 0}$, and therefore A_ε, being a bounded perturbation of A_0, also generates a strongly continuous semigroup $\{T_\varepsilon(t)\}_{t\geqq 0}$ (see Pazy (1983, § 3.1)).

Both $\{T_0(t)\}_{t\geqq 0}$ and $\{T_\varepsilon(t)\}_{t\geqq 0}$ are positive semigroups, which is intuitively clear from the biological interpretation, but can also be shown rigorously (see Heijmans (1986)). Let $\mathbf{1}$ be the element of X that is identically one on $[0,1]$. Then

$$A_\varepsilon\mathbf{1}=\rho_\varepsilon\beta_\varepsilon.$$

Define the positive scalar ω_ε by

$$\omega_\varepsilon=\sup\{\rho_\varepsilon\beta_\varepsilon(x)\colon x\in[0,1]\}. \tag{3.4}$$

We see immediately that

$$0\leqq A_\varepsilon\mathbf{1}\leqq\omega_\varepsilon\mathbf{1}.$$

We show that $A_\varepsilon \in G(1, \omega_\varepsilon)$. First suppose that $\omega_\varepsilon < s(A_\varepsilon)$, where $s(A_\varepsilon)$ is the spectral bound of A_ε, i.e., $s(A_\varepsilon) = \sup\{\mathrm{Re}\,\lambda : \lambda \in \sigma(A_\varepsilon)\}$. Since $\{T_\varepsilon(t)\}_{t\geqq 0}$ is a positive semigroup, $s(A_\varepsilon) \in \sigma(A_\varepsilon)$ if $\sigma(A_\varepsilon) \neq \emptyset$, and $R(\lambda, A_\varepsilon)$ is a positive operator if $\lambda > s(A_\varepsilon)$ (see Nagel (1986)). Choose $\lambda > s(A_\varepsilon)$. Since $R(\lambda, A_\varepsilon)$ is a positive operator we get that

$$0 \leqq R(\lambda, A_\varepsilon)\mathbf{1} \leqq \frac{1}{\lambda - \omega_\varepsilon}\mathbf{1};$$

hence $\|R(\lambda, A_\varepsilon)\| = \|R(\lambda, A_\varepsilon)\mathbf{1}\| \leqq 1/(\lambda - \omega_\varepsilon)$, and we find that $\|R(\lambda, A_\varepsilon)\|$ remains bounded if $\lambda \downarrow s(A_\varepsilon)$, which is in contradiction with

$$s(A_\varepsilon) \in \sigma(A_\varepsilon).$$

Therefore $\omega_\varepsilon \geqq s(A_\varepsilon)$. Using the same arguments as above, we find that for $\lambda > \omega_\varepsilon$,

$$\|R(\lambda, A_\varepsilon)\| \leqq \frac{1}{\lambda - \omega_\varepsilon},$$

which yields that for $n = 1, 2, \cdots$

$$\|R(\lambda, A_\varepsilon)^n\| \leqq \frac{1}{(\lambda - \omega_\varepsilon)^n},$$

and it follows from the Hille-Yosida theorem that $A_\varepsilon \in G(1, \omega_\varepsilon)$. In particular this implies that A_ε is the generator of a C_0-semigroup $\{T_\varepsilon(t)\}_{t\geqq 0}$ on X.

3.2. The limit transition justified. Assuming (1.7) and (1.8), i.e., $\beta_\varepsilon(x) = \varepsilon^{-1}b(x)$ and $\rho_\varepsilon = \varepsilon r$, we find the limiting equation

$$\frac{\partial m}{\partial t}(t, x) - \gamma(x)\frac{\partial m}{\partial x}(t, x) = rb(x)m(t, 0), \tag{3.5a}$$

$$m(0, x) = \phi(x), \tag{3.5b}$$

where γ is the *reduced growth rate*

$$\gamma(x) = g(x) - b(x). \tag{3.6}$$

Note that it follows from Assumption 3.1 that (i) b is Lipschitz continuous on $[0, 1]$, $b(x) = 0$ for $x \leqq a$ and $b(x) > 0$ for $a < x \leqq 1$, and that (ii) γ is *not* positive on the whole interval $[0, 1]$, in particular $\gamma(1) = -b(1) < 0$.

In the rest of this section we will show how the Trotter-Kato theorem can be used to justify the formal transition from (3.1)-(3.5). In the next section we interpret these results in terms of the forward equations (1.4) and (1.10) (with $x_0 = 0$).

First we reformulate (3.5a) supplied with initial condition (3.5b) as an abstract Cauchy problem:

$$\frac{dm}{dt}(t) = Am(t), \qquad m(0) = \phi \in X, \tag{3.7}$$

where the closed operator A is given by

$$(A\phi)(x) = \gamma(x)\frac{d\phi}{dx}(x) + rb(x)\phi(0)$$

for every ϕ in its domain

$$D(A) = \{\phi \in X \cap W^{1,1}_{\mathrm{loc}}[0, 1] : \gamma\phi' \in X\}.$$

It is not difficult to show that A generates a strongly continuous positive semigroup: this, however, will also follow from the forthcoming analysis. Let

$$\omega := \{rb(x): 0 \leqq x \leqq 1\}. \tag{3.8}$$

Obviously, $\omega_\varepsilon = \omega$ and from the results of § 3.1 it follows that

$$A_\varepsilon \in G(1, \omega). \tag{3.9}$$

Assumption 3.2. There exists a unique $\hat{x} \in (0, 1)$ such that $g(\hat{x}) = b(\hat{x})$.

In combination with the other assumptions of this section this means that

$$\gamma(x) > 0, \qquad 0 \leqq x < \hat{x},$$
$$\gamma(x) < 0, \qquad \hat{x} < x \leqq 1.$$

Now let $D = C^1[0, 1]$, i.e., the subspace of X containing all continuously differentiable functions on $[0, 1]$. Clearly

$$D(A_\varepsilon) \subseteq D, \qquad D(A) \subseteq D.$$

PROPOSITION 3.3. *$(\lambda - A)D$ is dense in X for $\lambda \in \mathbb{R}$ sufficiently large.*

Proof. Consider for $F \in X$ the inhomogeneous equation

$$\lambda\phi(x) - \gamma(x)\phi'(x) = F(x),$$

where $\lambda \in \mathbb{R}$ is sufficiently large ($\lambda > \omega$). The solution of this equation for $0 \leqq x < \hat{x}$ is given by

$$\phi(x) = \int_x^{\hat{x}} \frac{F(y)}{\gamma(y)} \exp\left\{-\lambda \int_x^y \frac{d\xi}{\gamma(\xi)}\right\} dy, \tag{*}$$

and a similar expression can be found for $\phi(x)$, if x is greater than $\hat{x}$. It is easy to check that $\phi \in D$ if $F \in D$. Now, for $f \in X$, the solution of

$$\lambda\phi - A\phi = f, \tag{**}$$

on $(0, \hat{x})$ is given by (*), with $F(x) = f(x) + r\phi(0)b(x)$ substituted. Hence $\phi \in D$ if $F \in D$. Let $f \in X$ and let ϕ be the solution of (**); then

$$\phi(0) = \int_0^{\hat{x}} \frac{f(y) + r\phi(0)b(y)}{\gamma(y)} \exp\left\{-\lambda \int_0^y \frac{d\xi}{\gamma(\xi)}\right\} dy.$$

We assume that $\lambda \in \mathbb{R}$ is so large that

$$\alpha_\lambda := \int_0^{\hat{x}} \frac{b(y)}{\gamma(y)} \exp\left\{-\lambda \int_0^y \frac{d\xi}{\gamma(\xi)}\right\} dy < \frac{1}{r},$$

and for $f \in X$ we define

$$H_\lambda(f) := \frac{r}{1 - \alpha_\lambda r} \int_0^{\hat{x}} \frac{f(y)}{\gamma(y)} \exp\left\{-\lambda \int_0^y \frac{d\xi}{\gamma(\xi)}\right\} dy.$$

Then the solution ϕ of (**) satisfies

$$r\phi(0) = H_\lambda(f).$$

So we get that $\phi \in D$ if $f + H_\lambda(f)b \in D$. We define $V \subseteq X$ as

$$V = \{f \in X: f + H_\lambda(f)b \in D\}.$$

Then $V \subseteq (\lambda - A)D$, and it suffices to show that V is a dense subset of X. Let $f \in X$ and define $g \in X$ as

$$g = f + H_\lambda(f)b.$$

Let $\{g_n\}$ be a sequence in D converging to g as $n \to \infty$. The solution of

$$g_n = f_n + H_\lambda(f_n)b$$

is given by

$$f_n = g_n - \frac{H_\lambda(g_n)}{1+H_\lambda(b)}\, b.$$

Now $f_n \in V$ and

$$f_n \to g - \frac{H_\lambda(g)}{1+H_\lambda(b)} \cdot b = f,\ n \to \infty.$$

Therefore $\bar{V} = X$. □

PROPOSITION 3.4. *$A_\varepsilon\phi \to A\phi$ as $\varepsilon \downarrow 0$, for every $\phi \in D$.*

Proof. Let $\phi \in D$. Then

$$|(A_\varepsilon\phi)(x) - (A\phi)(x)| \leqq |b(x)| \cdot \left|\frac{1}{\varepsilon}(\phi(x) - \phi(x-\varepsilon)) - \phi'(x)\right| + r|b(x)| \cdot |\phi(\varepsilon) - \phi(0)|,$$

for every $x \in [0, 1]$, and thus

$$\|A_\varepsilon\phi - A\phi\| = \sup_{x\in[0,1]} |(A_\varepsilon\phi)(x) - (A\phi)(x)| \to 0, \qquad \varepsilon \downarrow 0. \qquad \square$$

We are now ready to apply the Trotter-Kato theorem which gives us the following theorem.

THEOREM 3.5. *$A \in G(1, \omega)$, and if $\{T(t)\}_{t\geqq 0}$ is the semigroup generated by A, then*

$$T_\varepsilon(t)\phi \to T(t)\phi, \qquad \varepsilon \downarrow 0,$$

for every $\phi \in X$, where the convergence is uniform for t in bounded subsets of $(0, \infty)$.

This theorem tells us that a solution of the limit equation (3.8) is indeed an approximation of solutions of equation (3.2a), presupposed that their initial condition ϕ is the same.

We can give a very precise description of the relation between the backward and the forward equations and their respective solutions in semigroup terms. It is the backward equation that can be derived rigorously and that is to be solved on the space of continuous functions. Let A_ε be the differential operator on X associated with the backward problem (see (3.2)). Then, by definition, the abstract forward equation is

$$\frac{dn}{dt}(t) = A_\varepsilon^* n(t), \qquad n(0) = \psi \in X^*, \tag{3.10}$$

where A_ε^*, the dual operator of A_ε, is defined on the dual space $X^* = M[0, 1]$, the space of regular Borel measures on $[0, 1]$. The solutions of (3.10) are given by $n_\varepsilon(t, \cdot\,; \psi) = T_\varepsilon^*(t)\psi$. Here the notion of solution must be understood in terms of the weak* topology on X^*. The dual semigroup $\{T_\varepsilon^*(t)\}_{t\geqq 0}$ is a weakly* continuous semigroup with weak* generator A_ε^* (see Butzer and Berens (1967)). There exists the following duality relation between solutions of the forward and the backward equations. For $\phi \in X$ we have

$$\begin{aligned} \int_0^1 \phi(x) n_\varepsilon(t, dx; \psi) &= \langle \phi, n_\varepsilon(t, \cdot\,; \psi)\rangle = \langle \phi, T_\varepsilon^*(t)\psi\rangle \\ &= \langle T_\varepsilon(t)\phi, \psi\rangle = \langle m_\varepsilon(t, \cdot\,; \phi), \psi\rangle = \int_0^1 m_\varepsilon(t, x; \phi)\psi(dx), \end{aligned} \tag{3.11}$$

where $\langle \cdot, \cdot \rangle$ denotes the duality pairing between X and X^*, and where $m_\varepsilon(t, \cdot\,; \phi)$ is the solution of the backward problem (3.1).

Let $X^{\odot}$ be the closed subspace of X^* where $\{T_\varepsilon^*(t)\}_{t\geq 0}$ is strongly continuous. Then $X^{\odot} = \overline{D(A_\varepsilon^*)}$ (see Butzer and Berens (1967)). It can be shown (compare the remark below) that in the present situation $X^{\odot} = L^1[0, 1]$ (e.g., Clément et al. (1987); (Clément, Heijmans et al. (1987)). Obviously, $X^{\odot}$ is invariant under $\{T_\varepsilon^*(t)\}_{t\geq 0}$, and the restriction $\{T_\varepsilon^{\odot}(t)\}_{t\geq 0}$ is a strongly continuous semigroup. If we denote its generator by $A_\varepsilon^{\odot}$, then

$$\frac{dn}{dt}(t) = A_\varepsilon^{\odot} n(t), \qquad n(0) = \psi \in X^{\odot},$$

is the abstract formulation of (1.4) and with this observation the circle is closed.

Remark. To prove the latter statement, we have to calculate A_ε^* and its domain $D(A_\varepsilon^*)$ from A_ε and $D(A_\varepsilon)$. This calculation involves the following steps (e.g., Heijmans (1984)):

(i) compute the resolvent operator $R(\lambda, A_\varepsilon)$

(ii) compute its dual $R(\lambda, A_\varepsilon^*) = R(\lambda, A_\varepsilon)^*$

(iii) find the domain $D(A_\varepsilon^*)$ from the relation

$$D(A_\varepsilon^*) = \text{Ran}\,(R(\lambda, A_\varepsilon^*)),$$

Ran$(\cdot)$ denoting the range

(iv) calculate $A_\varepsilon^* \psi$, where $\psi \in D(A_\varepsilon^*)$, from the relation

$$\langle \phi, A_\varepsilon^* \psi \rangle = \langle A_\varepsilon \phi, \psi \rangle \quad \text{for } \phi \in D(A_\varepsilon)$$

(v) $X^{\odot} = \overline{D(A_\varepsilon^*)}$ and $A_\varepsilon^{\odot}$ is the part of A_ε^* in $X^{\odot}$ (e.g., Butzer and Berens (1967)).

Our main result of this section, Theorem 3.5, can be restated in terms of solutions of the forward equation by using the duality relation (3.11). We find that for any $\psi \in M[0, 1]$,

$$n_\varepsilon(t, \cdot\,; \psi) \to n(t, \cdot\,; \psi) \quad \text{as } \varepsilon \downarrow 0$$

where convergence holds with respect to the weak* topology of $X^* = M[0, 1]$, and is uniform for t in bounded intervals of $(0, \infty)$.

4. Discussion. In the previous two sections we have proved the essential correctness of two limit arguments initially derived in a heuristic manner. We expect these cases to be exemplary for a general procedure: (i) start imagining how any model simplification works on the level of the individual, (ii) take good care that birth rates keep behaving, (iii) translate individual behavior into a structured population model, both before and after the simplification, (iv) use the Trotter–Kato theorem to connect the two. The upshot from the examples discussed in this paper is that our intuition derived from the individual level appears to be essentially correct when applied to the population level, at least when we are careful. To emphasize the latter point we finish with three cautionary notes.

(i) From a biological point of view the models from which we started in our examples were already fairly metaphorical. In deriving them we made a great number of simplifying assumptions about the underlying biology, comparable to the ones we spelled out in our limit arguments. The nice thing about apparently being able to make our simplifications with impunity already at the level of the individual, is that usually for the more complicated pictures of individual behavior that lie at the start of our considerations we do not even know how to formulate a full population model. Yet, it is of great importance not to be too naive about our simplifications. A thorough analysis of some metaphorical examples such as those we consider in this paper should

help to clarify the issues. In this context we may point to the work of Chipot and Edelstein (1983) on the dynamics of fungal pellet cultures. Their heuristic model formulation basically seems comparable to the formulation that we chose in our second example. Therefore we feel that the limit model embodied in (1.10) also should be the correct model formulation for that particular class of biological systems, and we fail to understand the rationale that led these authors to a different type of equation.

(ii) The Trotter–Kato theorem only gives information about what happens in finite time intervals. Often our main interest is in the long-term behavior of the population model under consideration. Whether the limit argument extends to such properties has to be ascertained in a separate manner. As an example we may refer to Heijmans (1984) who considers both the transient behavior and some properties of the stable i-state distribution (the dominant eigenfunction of the forward equation), as well as the eventual convergence of the p-state towards this distribution, for a model of satiation dependent predatory behavior.

(iii) The proofs in this paper only apply to the linear time-invariant case, i.e., we did not allow any direct or indirect interactions between the individuals. Ultimately, we will wish to extend the limit theorems to the nonlinear case as well. After all, the greatest strength of the structured population methodology is that it allows us for the first time to incorporate various biologically realistic mechanisms for density dependent population regulation, such as a feedback through the limiting of individual growth by food shortage, into analytically formulated population models. Two approaches are possible. Either we could take recourse to direct nonlinear extensions of the Trotter–Kato theorem (compare, e.g., Clément, Heijmans et al. (1987, § 2.3)), or we could try to fall back on the specific mathematical structure of the equations of structured populations, whose main property is that for a given course of the environment the equations are linear (but time-inhomogeneous). Abstractly, such equations take the form

$$\frac{dn}{dt}(t) = A_\varepsilon(E(t))n(t), \qquad n(0) = \phi \in X. \tag{4.1}$$

Here the vector $E(t)$ describes the environment at time t, and can be calculated as the p-output

$$E(t) = \langle n(t), \xi \rangle$$

for some $\xi \in X^*$. Assuming that, for a given input $E(\cdot)$, the linear time-inhomogeneous equation (4.1) has a solution $n(\cdot)$ we can compute the p-output

$$\tilde{E}(t) = \langle n(t), \xi \rangle.$$

Solving (4.1) amounts to solving the fixed-point equation

$$\tilde{E}(\cdot) = E(\cdot).$$

This fixed-point equation still depends on the parameter ε. If this dependence is continuous (in a sense to be specified) then we might expect that the same is true for its solution.

However, all this is music of a distant future as only the first hesitant steps toward a proof of existence and uniqueness theorems for somewhat more general structured population models of the form (4.1) are being taken at this very moment. Therefore the present paper should only be considered as an introduction to the fascinating problem of putting a more rigorous basis under the structured population methodology.

SOME BLOWUP RESULTS FOR A NONLINEAR PARABOLIC EQUATION WITH A GRADIENT TERM*

M. CHIPOT† AND F. B. WEISSLER‡

Abstract. Under some conditions, a blowup result is proved for the solution u of:

$$u_t = \Delta u - |\nabla u|^q + |u|^{p-1}u, \quad t>0, \quad x\in\Omega,$$
$$u(t,x) = 0, \quad t>0, \quad x\in\Gamma,$$
$$u(0,x) = \varphi(x), \quad x\in\Omega.$$

The associated elliptic problem is also studied.

Key words. blowup, nonlinear parabolic equations

AMS(MOS) subject classifications. 35K60, 35B35, 35B60

1. Introduction. In this paper we study the solution of the following semilinear parabolic problem:

$$\begin{aligned} &u_t = \Delta u - |\nabla u|^q + |u|^{p-1}u, && t>0, \quad x\in\Omega, \\ &u(t,y) = 0, && t>0, \quad y\in\Gamma, \\ &u(0,x) = \phi(x), && x\in\Omega. \end{aligned} \tag{1.1}$$

Here $\Omega\subset\mathbf{R}^N$ is a bounded domain with smooth boundary Γ, $u=u(t,x)$, Δ and ∇ apply only to the spatial variables, and $p>1$ and $q>1$ are fixed (finite) parameters. Our main goal is to show that under appropriate conditions on q, p, and n, there exists a suitable initial value ϕ so that the corresponding solution of (1.1) blows up in a finite time.

In the case where there is no gradient term, i.e.,

$$\begin{aligned} &u_t = \Delta u + |u|^{p-1}u, && t>0, \quad x\in\Omega, \\ &u(t,y) = 0, && t>0, \quad y\in\Gamma, \\ &u(0,x) = \phi(x), && x\in\Omega, \end{aligned} \tag{1.2}$$

the following result due to Levine [35] has been known for some time (see also Ball [2]).

THEOREM 1.1. *Let $p>1$ and let $\phi:\bar{\Omega}\to R$ be sufficiently smooth (e.g., C^2) with $\phi|_\Gamma\equiv 0$. If ϕ is large enough in the sense that its "energy,"*

$$E(\phi) = \frac{1}{2}\|\nabla\phi\|_2^2 - \frac{1}{p+1}\|\phi\|_{p+1}^{p+1}, \tag{1.3}$$

is negative, then the corresponding solution of (1.2) *blows up in finite time.*

We remark that local existence of solutions for (1.2) follows by standard iteration methods (see, for example, Segal [28]) on the Banach space $C_0(\Omega)$. Thus, if the existence time T of the maximal solution to (1.2) is finite, i.e., if the solution blows up in finite time T, then $\lim_{t\to T}\|u(t,\cdot)\|_\infty = \infty$.

In the past few years, a great deal of work has been done to study the precise behavior of solutions to (1.2) as t approaches the finite blowup time (see [3], [12], [14]-[16], [24], [25], [29], [32], [33]). A corresponding theory is also being developed in the case where $|u|^{p-1}u$ in (1.2) is replaced by λe^u (see [4]-[8], [12], [22], [23], [30]).

We are naturally led to consider more general parabolic problems of the form

$$u_t = \Delta u + f(u, \nabla u). \tag{1.4}$$

To our knowledge, there has not been much study of solutions to equations of the form (1.4) that blow up in finite time. (For an example, see [11].) Moreover, we are not aware of any finite-time blowup results that would apply to (1.1). Furthermore, the gradient term in (1.1) has a damping effect, working against blowup; and so it is not clear if problem (1.1) has solutions that blow up in finite time. Our goal is therefore somewhat modest: to find an analogue of Theorem 1.1 for problem (1.1).

THEOREM 1.2. *Let* $1 < q \leqq 2p/(p+1)$ *and let* $\phi \in W^{3,s}(\Omega)$ *for* s *sufficiently large,* ϕ *not identically zero. In addition suppose the following*:

(i) $\phi = 0$ *on* Γ;
(ii) $\Delta\phi - |\nabla\phi|^q + |\phi|^{p-1}\phi = 0$ *on* Γ;
(iii) $\phi \geqq 0$ *in* Ω;
(iv) $\Delta\phi - |\nabla\phi|^q + \phi^p \geqq 0$ *in* Ω;
(v) $E(\phi) \leqq 0$;
(vi) *If* $q < 2p/(p+1)$, *then* $\|\phi\|_{p+1}$ *is sufficiently large*;
(vii) *If* $q = 2p/(p+1)$, *then* p *is sufficiently large.*

Then the corresponding solution of (1.1) *blows up in finite time, in the* L^∞ *norm.*

The obvious difficulty with this result is that it is not at all clear if such a ϕ exists. A natural candidate for ϕ is a regular solution of the following elliptic problem:

$$\begin{aligned} &\Delta\phi - |\nabla\phi|^q + \lambda\phi^p = 0 \quad \text{in } \Omega, \\ &\phi > 0 \quad \text{in } \Omega, \\ &\phi = 0 \quad \text{on } \Gamma, \end{aligned} \tag{1.5}$$

where $\lambda > 0$ is sufficiently small.

THEOREM 1.3. *Let* $\Omega = B_R = \{x \in \mathbf{R}^n : |x| < R\}$. *Suppose* $1 < q < 2p/(p+1)$ *and (if* $n \geqq 3$), $p < (n+2)/(n-2)$. *Then for all* $\lambda > 0$ *there exists a regular solution* ϕ *of* (1.5). *If* λ *is sufficiently small, then* ϕ *satisfies conditions* (i)-(vi) *in Theorem* 1.2.

Suppose $n = 1$ *and* $q = 2p/(p+1)$. *Then for all* $\lambda > \lambda_p$, *where*

$$\lambda_p = \frac{(2p)^p}{(p+1)^{2p+1}}, \tag{1.6}$$

there exists a regular solution ϕ *of* (1.5). *If in addition* $\lambda \leqq 2/(p+1)$, *then* ϕ *satisfies conditions* (i)-(v) *in Theorem* 1.2. ("*Regular*" *above means regular enough to apply Theorem* 1.2.)

The paper is organized as follows. In § 2 we prove local existence and uniqueness, and regularity for problem (1.1) with initial values in an appropriate Sobolev space. Moreover, we indicate precisely the conditions on s required for Theorem 1.2 and prove that conditions (i)-(iv) on ϕ imply $u(t, \cdot) \geqq 0$ and $u_t(t, \cdot) \geqq 0$ throughout the trajectory. In § 3 we prove Theorem 1.2, using energy arguments based on the methods found in Ball [2]. We have attempted to write § 3 so that it is, at least formally, independent of the technicalities of § 2. In § 4 we begin the study of (1.5) and prove Theorem 1.3. Finally, in § 5 we present some additional results concerning (1.5). In particular, we show that the value of λ_p claimed in Theorem 1.3 is in fact sharp.

We remark that the value $q=2p/(p+1)$ is "critical" in many respects. The condition $q \leqq 2p/(p+1)$ arises naturally in the energy arguments. When $q=2p/(p+1)$, both (1.1) and (1.5) have the same scaling properties as the same equations without the gradient term; and the character of solutions to (1.5) changes considerably as q is smaller than, equal to, or bigger than $2p/(p+1)$.

2. Local existence and regularity for the evolution equation. In this section $\Omega \subset \mathbf{R}^n$ is a bounded domain with smooth boundary $\Gamma = \partial\Omega$. Also, p and q are fixed real numbers, strictly larger than 1. Our goal is to construct a local theory for the parabolic problem (1.1). The first step is to write the corresponding variation of parameters integral equation

$$u(t) = e^{t\Delta}\phi + \int_0^t e^{(t-s)\Delta} J(u(s))\, ds, \tag{2.1}$$

where $u(t) = u(t, \cdot)$ and $J = J_1 + J_2$ with

$$J_1(u) = -|\nabla u|^q, \qquad J_2(u) = |u|^{p-1}u.$$

Also, $e^{t\Delta}$ denotes the heat semigroup on Ω with Dirichlet boundary conditions. Recall that for $1 < s < \infty$, $e^{t\Delta}$ is an analytic, contraction, C_0 semigroup on $L^s = L^s(\Omega)$. Furthermore, the domain of its generator in L^s is

$$D_s(\Delta) = W^{2,s}(\Omega) \cap W_0^{1,s}(\Omega).$$

Moreover, it is known [10] that $e^{t\Delta}$ restricts to a C_0 semigroup on $W_0^{1,s}(\Omega)$, $1 < s < \infty$.

We will construct a local theory for the integral equation (2.1) in the Banach space $W_0^{1,s} = W_0^{1,s}(\Omega)$, s sufficiently large, using the framework developed in [31]. Note that for suitable $r_1, r_2 \geqq 1$,

$$J_1 : W_0^{1,s} \to L^{r_1}, \qquad J_2 : W_0^{1,s} \to L^{r_2}$$

are continuously Fréchet differentiable maps, Lipschitz on bounded sets in $W_0^{1,s}$. Indeed, r_1 can clearly be chosen s/q, provided $s \geqq q$, and allowable values for r_2 can easily be computed by first determining when $W_0^{1,s}$ is embedded in $L^{r_2 p}$. Moreover, if $1 \leqq r \leqq s < \infty$, then for $t > 0$

$$e^{t\Delta} : L^r \to W_0^{1,s}$$

is bounded with norm bounded by $Ct^{-\alpha}$, where

$$\alpha = \frac{n}{2}\left(\frac{1}{r} - \frac{1}{s}\right) + \frac{1}{2}$$

and C can be chosen uniformly up to any finite time. (See [31, Lemma 4.1] and [1, Thm. 4.17].) Therefore, for each $t > 0$, the map $K_t \equiv e^{t\Delta}J$ is a continuously Fréchet differentiable mapping of $W_0^{1,s}$ into itself, Lipschitz on bounded sets. To apply the results in [31], it suffices to choose s so that $\alpha < 1$ with both $r = r_1 \geqq 1$ and $r = r_2 \geqq 1$. Routine calculations (albeit somewhat tedious) show that this can be done if

$$\begin{aligned} &s \geqq q, \qquad s > n(q-1), \\ &s \geqq np/(n+p), \qquad s > n(p-1)/(p+1). \end{aligned} \tag{2.2}$$

(The conditions on the left side of (2.2) come from the requirement that $r_1, r_2 \geqq 1$; the conditions on the right side come from the requirement that $\alpha < 1$ for both r_1 and r_2.) From now on we assume that s satisfies (2.2). (Later we will need an additional assumption on s.) Thus, by Theorem 1 of [31], for every $\phi \in W_0^{1,s}$, there is a unique

maximal solution $u \in C([0, T_\phi); W_0^{1,s})$ to the integral equation (2.1). T_ϕ is the existence time of the solution starting at ϕ; and if $T_\phi < \infty$, then $\|u(t)\|_{W_0^{1,s}} \to \infty$ as $t \to T_\phi$.

We remark that if $q < 2$, then a local theory for the integral equation (2.1) can be constructed in $L^r(\Omega)$, using the framework developed in [34]. In fact, Theorem 2 of [34] needs to be modified slightly to handle a nonlinearity of the form $J = J_1 + J_2$. (Two spaces E_{J_1} and E_{J_2} are needed instead of just E_J.) We omit the details and simply indicate that if

$$\begin{aligned} &r > n(p-1)/2, \\ &r > n(q-1)/(2-q), \qquad q < 2, \end{aligned} \tag{2.2a}$$

then we have local existence and uniqueness for (2.1) in L^r. In particular, if the existence time T_ϕ is finite, then $\|u(t, \cdot)\|_r \to \infty$ as $t \to T_\phi$. It follows, of course, that $\|u(t, \cdot)\|_\infty \to \infty$ as $t \to T_\phi$. Since $q \leqq 2p/(p+1)$ implies $q < 2$, this is the case under the hypotheses of Theorem 1.2.

We would like to show that if ϕ is sufficiently regular, then the resulting solution of (2.1) is also a solution of the original problem (1.1) and has some additional regularity properties. Recall that the integral equation (2.1) gives rise to a "semiflow" W_t on $W_0^{1,s}$, i.e., W_t takes $\phi \in W_0^{1,s}$ to its value at time t under the action of (2.1). In other words, $W_t\phi = u(t)$, where $u(t)$ is the maximal solution in $W_0^{1,s}$ of (2.1) with initial value ϕ. In particular, $W_t\phi$ is defined precisely for $t \in [0, T_\phi)$. The generator of the semiflow W_t is

$$B\phi = \lim_{t \to 0^+} \frac{W_t\phi - \phi}{t}, \tag{2.3}$$

where the limit is taken in $W_0^{1,s}$. The domain of B, i.e., $D(B)$, is simply the set of $\phi \in W_0^{1,s}$ for which the limit (2.3) exists. Formally, $B = \Delta + J$, i.e.,

$$B\phi = \Delta\phi - |\nabla\phi|^q + |\phi|^{p-1}\phi. \tag{2.4}$$

However, the characterization of B and $D(B)$ in Theorem 3.1 of [31] is somewhat abstract, and some care is needed to describe B and $D(B)$ in the present context. For technical convenience, we make the following additional restrictions on s:

$$s \geqq 2q, \qquad s > nq. \tag{2.5}$$

PROPOSITION 2.1. *Suppose $s \in \mathbf{R}$ satisfies* (2.2) *and* (2.5). *Let W_t be the semiflow on $W_0^{1,s}$ resulting from the integral equation* (2.1), *with generator B and domain $D(B)$. Then $D(B)$ is the set of all $\phi \in W^{3,s} \cap W_0^{1,s}$ such that*

$$\Delta\phi - |\nabla\phi|^q + |\phi|^{p-1}\phi \in W_0^{1,s}. \tag{2.6}$$

For $\phi \in D(B)$, $B\phi$ is given by (2.4).

Proof. First suppose $\phi \in D(B)$. By Theorem 3.1(iv) in [31], it follows that

$$\Delta e^{t\Delta}\phi + e^{t\Delta}(-|\nabla\phi|^q + |\phi|^{p-1}\phi) \tag{2.7}$$

converges strongly in $W_0^{1,s}$ to $B\phi$ as $t \to 0^+$. Now certainly $|\nabla\phi|^q \in L^{s/q}$ and, thanks to (2.5), $|\phi|^{p-1}\phi \in W_0^{1,s} \subset L^{s/q}$. Thus, the second term in (2.7) converges in $L^{s/q}$ as $t \to 0^+$ to $(-|\nabla\phi|^q + |\phi|^{p-1}\phi)$. Furthermore, again by (2.5), $\phi \in W_0^{1,s} \subset H_0^1(\Omega)$; and so $\Delta e^{t\Delta}\phi \to \Delta\phi$ in $H^{-1}(\Omega)$ as $t \to 0^+$. Thus, the distributional limit of (2.7) as $t \to 0^+$ is the desired expression

$$\Delta\phi - |\nabla\phi|^q + |\phi|^{p-1}\phi.$$

This must be the same as the $W_0^{1,s}$ limit, which proves (2.6) and (2.4).

To prove that $\phi \in W^{3,s}$, note first that $B\phi \in W_0^{1,s} \subset L^{s/q}$ and $-|\nabla\phi|^q + |\phi|^{p-1}\phi \in L^{s/q}$. Hence $\Delta\phi \in L^{s/q}$. Since $\phi \in W_0^{1,s/q}$, elliptic regularity gives us that $\phi \in W^{2,s/q}$. Therefore $\nabla\phi \in W^{1,s/q}$. Again by (2.5), $W^{1,s} \subset W^{1,s/q} \subset L^\infty$. Thus $|\nabla\phi|^q$ and $|\phi|^{p-1}\phi$ are both in L^∞. Since $B\phi \in W_0^{1,s} \subset L^\infty$, it follows that $\Delta\phi \in L^\infty$. Thus $\phi \in W^{2,r}(\Omega)$ for every finite r. Therefore $|\nabla\phi|^q$ and $|\phi|^{p-1}\phi$ are both in $W^{1,s}$; and since $B\phi \in W^{1,s}$, we get that $\Delta\phi \in W^{1,s}$. By higher-order elliptic regularity (see, for example, [9, Thm. IX.32]), it follows that $\phi \in W^{3,s}$.

On the other hand, suppose $\phi \in W^{3,s} \cap W_0^{1,s}$ satisfies (2.6). To show that $\phi \in D(B)$, we must show, by Theorem 3.1(iv) in [31], that for all $t > 0$, $e^{t\Delta}\phi$ is in the domain of Δ as a semigroup generator in $W_0^{1,s}$ and that (2.7) has a limit in $W_0^{1,s}$ as $t \to 0^+$. Now $e^{t\Delta}$ is an analytic semigroup on L^s. Thus, $e^{t\Delta}$ restricts us to an analytic semigroup on $D_s(\Delta)$, considered as a Banach space with its graph norm. Since $\phi \in D_s(\Delta) = W^{2,s} \cap W_0^{1,s}$, it follows that for all $t > 0$, $e^{t\Delta}\phi$ is in the domain of Δ as a semigroup generator in $D_s(\Delta)$. Since $D_s(\Delta)$ is continuously embedded in $W_0^{1,s}$, $e^{t\Delta}\phi$ is in the domain of Δ as a semigroup generator in $W_0^{1,s}$. Finally, again since $\phi \in D_s(\Delta)$, $\Delta e^{t\Delta}\phi = e^{t\Delta}\Delta\phi$, where both expressions make sense in L^s. Consequently, (2.7) equals

$$e^{t\Delta}(\Delta\phi - |\nabla\phi|^q + |\phi|^{p-1}\phi),$$

which clearly has a limit in $W_0^{1,s}$ as $t \to 0^+$ because of (2.6).

Remark. The proof above shows that Proposition 2.1 remains correct if $W^{3,s}$ is replaced by $W^{2,s}$. Higher-order elliptic regularity allowed us to conclude $\phi \in W^{3,s}$.

PROPOSITION 2.2. *Under the same conditions as in Proposition* 2.1, *let* $\phi \in D(B)$ *and* $u(t) = W_t\phi$; *i.e.*, $u(t)$ *is the maximal solution of* (2.1). *Then we have the following*:

(i) $u \in C^1([0, T_\phi); W_0^{1,s})$ *and*

$$u'(t) = \Delta u(t) - |\nabla u(t)|^q + |u(t)|^{p-1}u(t), \tag{2.8}$$

where each term on the right side of (2.8) *is in* $C([0, T_\phi); L^{s/q})$;

(ii) $u \in C([0, T_\phi); W^{2,s/q})$;

(iii) $\|u(t)\|_\infty$ *and* $\|\nabla u(t)\|_\infty$ *are bounded on any interval* $[0, T]$ *with* $T < T_\phi$.

Proof. By Theorem 2.2 in [31], $u \in C^1([0, T_\phi); W_0^{1,s})$, $u(t) \in D(B)$ for all $t \in [0, T_\phi)$, and $u'(t) = Bu(t)$. The previous proposition now implies (2.8). Furthermore, $|\nabla u(t)|^q$ and $|u(t)|^{p-1}u(t)$ are clearly continuous into $L^{s/q}$ (again using (2.5)), and since $Bu(t)$ is continuous into $W_0^{1,s}$, it follows that $\Delta u(t)$ is continuous into $L^{s/q}$. This proves (i).

Since $u(t) \in D(B)$, the previous proposition implies $u(t) \in W^{2,s/q} \cap W_0^{1,s/q}$. Also $u(t)$ and $\Delta u(t)$ are both continuous in $L^{s/q}$. Since the graph norm for Δ on $W^{2,s/q} \cap W_0^{1,s/q}$ is equivalent to the $W^{2,s/q}$ norm, it follows that $u(t)$ is continuous into $W^{2,s/q}$, which proves (ii).

Finally, (iii) follows easily since $W^{1,s/q}$ is continuously embedded in L^∞, thanks to assumption (2.5).

PROPOSITION 2.3. *Under the same conditions as in Proposition* 2.1, *let* $\phi \in W_0^{1,s}$ *with* $\phi \geqq 0$ *almost everywhere in* Ω. *Then* $u(t) = W_t\phi \geqq 0$ *for all* $t \in [0, T_\phi)$.

Proof. Any $\phi \geqq 0$ in $W_0^{1,s}$ can be approximated in $W_0^{1,s}$ by nonnegative C^∞ functions with compact support in Ω, in particular by nonnegative functions in $D(B)$. By the continuity properties of the semiflow W_t (see [31, Thm. 1]), we may therefore assume $\phi \geqq 0$ is in $D(B)$. (In fact, we only need the result for $\phi \in D(B)$.)

Multiplying (2.8) by

$$u(t)^- \equiv \frac{|u(t)| - u(t)}{2}$$

and integrating over Ω yields

$$\int u'u^- = \int (\Delta u)u^- - \int |\nabla u|^q u^- + \int |u|^{p-1}uu^-,$$

where we have suppressed the dependence on t. By the previous proposition, we clearly have $u \in C^1((0, T_\phi); L^2)$ and $u \in C((0, T_\phi); H_0^1)$. Thus

$$\int u'u^- = -\frac{1}{2}\frac{d}{dt}\int (u^-)^2$$

and

$$\int (\Delta u)u^- = \int |\nabla u^-|^2.$$

The first formula above follows from the definition of u^- (multiply out $(u^-)^2$) and the second formula from well-known facts about ∇u^- [17, § 7.4]. We now restrict ourselves to $t \in [0, T]$ for a fixed $T < T_\phi$. By part (iii) of the previous proposition, there is a constant $C = C(T)$ such that

$$\int |u|^p |u^-| \leqq C \int |u^-|^2$$

and

$$\begin{aligned}\int |\nabla u|^q |u^-| &\leqq C \int |\nabla u^-||u^-| \\ &\leqq \varepsilon C \int |\nabla u^-|^2 + C_\varepsilon C \int |u^-|^2,\end{aligned}$$

where $\varepsilon > 0$ is arbitrary, but C_ε depends on the choice of ε. Putting all this together, and choosing $\varepsilon > 0$ so that $\varepsilon C \leqq 1$, we get that for $t \in (0, T]$,

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int |u^-|^2 &\leqq -\int |\nabla u^-|^2 + \varepsilon C \int |\nabla u^-|^2 + C_\varepsilon C \int |u^-|^2 \\ &\leqq C_\varepsilon C \int |u^-|^2.\end{aligned}$$

Since $u^- \in C([0, T]; L^2)$ and $u(0)^- = \phi^- = 0$, Gronwall's lemma now implies $\int |u^-|^2 = 0$ for all $t \in [0, T]$. Since $T < T_\phi$ is arbitrary, we see that $u(t)^- = 0$ for all $t \in [0, T_\phi)$.

For the energy arguments in the next section we need not only $u(t) \geqq 0$, but also $u'(t) \geqq 0$, throughout the trajectory. To prove this with the weak maximum principle methods of previous proof, we need some higher-order regularity in t. We begin with the following lemma. Its proof is modeled on the proof of Theorem 3 in [20]. (See also [31, Prop. 1.2].)

LEMMA 2.4. *Under the same conditions as in Proposition* 2.1, *let* $\phi \in D(B)$ *and* $u(t) = W_t\phi \in C^1([0, T_\phi); W_0^{1,s})$. *Denote* $v(t) = u'(t)$, *so* $v \in C([0, T_\phi); W_0^{1,s})$. *Then for any compact subinterval* $[\varepsilon, T] \subset (0, T_\phi)$, $v : [\varepsilon, T] \to W_0^{1,s}$ *is Hölder continuous.*

Proof. By Theorem 2.2 of [31], $v(t)$ satisfies the following integral equation:

$$\begin{aligned}v(t) = e^{t\Delta}(B\phi) - q\int_0^t e^{(t-s)\Delta}(|\nabla u(s)|^{q-2}\nabla u(s)\cdot\nabla v(s))\,ds \\ + p\int_0^t e^{(t-s)\Delta}|u(s)|^{p-1}v(s)\,ds.\end{aligned} \tag{2.9}$$

Since $B\phi \in W_0^{1,s} \subset L^s$ and $e^{t\Delta}$ is an analytic semigroup on L^s, it follows that $e^{t\Delta}(B\phi)$ is in $C^1((0,\infty); D_s(\Delta))$ and thus is certainly Hölder continuous in $W_0^{1,s}$ on $[\varepsilon, T]$. Thus, it suffices to show that the two integral terms are Hölder continuous on $[\varepsilon, T]$. We consider only the first one, the second one being easier to handle.

By Proposition 2.2(ii) and the fact that $W^{1,s/q} \subset L^\infty$ by (2.5), we have that ∇u, and hence $|\nabla u|^{q-2}\nabla u$ must be in $C([0, T]; L^\infty)$. (Obviously, we mean that $|\nabla u|^{q-2}\nabla u = 0$ in the case where $|\nabla u| = 0$. This presents no problem since $q > 1$.) Moreover, ∇v is clearly in $C([0, T]; L^s)$. Therefore

$$w(t) \equiv |\nabla u(t)|^{q-2}\nabla u(t) \cdot \nabla v(t) \tag{2.10}$$

is in $C([0, T]; L^s)$. Let

$$z(t) = \int_0^t e^{(t-s)\Delta} w(s)\, ds.$$

Since $W_0^{1,s} = D_s(\sqrt{-\Delta})$, the domain of $\sqrt{-\Delta}$ in L^s (see [26], [27]), to show that $z(t)$ is Hölder continuous in $W_0^{1,s}$ it suffices to show $\sqrt{-\Delta}\, z(t)$ Hölder continuous in L^s. For $0 \leqq t < t+\tau \leqq T$, we have

$$\begin{aligned}
\sqrt{-\Delta}\,(z(t+\tau)-z(t)) &= \sqrt{-\Delta}\,(e^{\tau\Delta}-I)\int_0^t e^{(t-s)\Delta} w(s)\, ds \\
&\quad + \sqrt{-\Delta}\int_0^\tau e^{s\Delta} w(t+\tau-s)\, ds \\
&= (e^{\tau\Delta}-I)(-\Delta)^{-\alpha}\int (-\Delta)^{\alpha+1/2} e^{(t-s)\Delta} w(s)\, ds \\
&\quad + \int_0^\tau (-\Delta)^{1/2} e^{s\Delta} w(t+\tau-s)\, ds,
\end{aligned}$$

where $0 < \alpha < \frac{1}{2}$. Using the facts [21, Thms. 11.3, 12.1] that for $t \in (0, T]$ and $0 < \nu < 1$

$$\|(-\Delta)^\nu e^{t\Delta}\|_s \leqq Ct^{-\nu}, \qquad \|(e^{t\Delta}-I)(-\Delta)^{-\nu}\|_s \leqq Ct^{\nu},$$

we deduce that

$$\begin{aligned}
\|\sqrt{-\Delta}\,(z(t+\tau)-z(t))\|_s &\leqq C\tau^\alpha \int_0^t (t-s)^{-\alpha-1/2}\, ds \sup_{[0,T]} \|w(t)\|_s \\
&\quad + C\int_0^\tau s^{-1/2}\, ds \sup_{[0,T]} \|w(t)\|_s.
\end{aligned}$$

This proves the Hölder continuity of $\sqrt{-\Delta}\, z(t)$ in L^s and thereby completes the proof of the lemma.

Remark. For the above result we do not need the rather strong result that $W_0^{1,s} = D_s(\sqrt{-\Delta})$. The easier result that $D_s((-\Delta)^\nu)$ is continuously embedded in $W_0^{1,s}$ [21, Thm. 9.2] can be used with only a slight modification of the proof.

PROPOSITION 2.5. *Under the same conditions and with the same notation of Lemma* 2.4, *we have that* $v \in C^1((0, T_\phi); L^{s/q})$ *and*

$$v'(t) = \Delta v(t) - q|\nabla u(t)|^{q-2}\nabla u(t) \cdot \nabla v(t) + p|u(t)|^{p-1} v(t). \tag{2.11}$$

Proof. Since $\phi \in D(B)$, $u \in C^1[(0, T_\phi); W_0^{1,s})$, and so $\nabla u \in C^1([0, T_\phi); L^s)$. Furthermore, by the previous lemma ∇v is Hölder continuous in L^s on $[\varepsilon, T]$. It follows that $w(t)$ given by (2.10) is Hölder continuous in $L^{s/q}$ on $[\varepsilon, T]$. Similarly, $|u|^{p-1}v$ is Hölder continuous in $L^{s/q}$ on $[\varepsilon, T]$.

We now consider the integral equation (2.9) as an equation in $L^{s/q}$. The semigroup is analytic in $L^{s/q}$ and the two integrands (not including $e^{(t-s)\Delta}$) are both Hölder continuous functions into $L^{s/q}$ on any compact subinterval $[\varepsilon, T] \subset (0, T_\phi)$. The result now follows from well-known properties of analytic semigroups. (See, for example, [19, Thm. 1.27, Chap. IX]).

We are now able to prove the desired positivity of $u'(t)$.

PROPOSITION 2.6. *Suppose $s \in \mathbf{R}$ satisfies (2.2) and (2.5) and that ϕ is in $D(B)$. Let $u(t) = W_t\phi$ and $v(t) = u'(t)$, and suppose further that $v(0) = u'(0) = B\phi \geqq 0$. Then $u'(t) \geqq 0$ for all $t \in [0, T_\phi)$.*

Proof. We know that $v \in C([0, T_\phi); W_0^{1,s}) \subset C([0, T_\phi); H_0^1)$ and that $v \in C^1((0, T_\phi); L^{s/q}) \subset C^1((0, T_\phi); L^2)$. Thus, multiplying (2.11) by $v(t)^-$ and integrating over Ω yields

$$\frac{1}{2}\frac{d}{dt}\int |v^-|^2 = -\int |\nabla v^-|^2 + q\int |\nabla u|^{q-2}\nabla u \cdot \nabla v(v^-) - p\int |u|^{p-1}vv^-$$

$$\leqq -\int |\nabla v^-|^2 + C\int |\nabla v^-||v^-| + C\int |v^-|^2,$$

where we use Proposition 2.2(iii) to estimate ∇u and u, and C can be chosen uniformly for $t \in (0, T]$, $T < T_\phi$. The proof is completed exactly as in the proof of Proposition 2.3.

3. Energy arguments. In this section we prove Theorem 1.2. Throughout this section, Ω, Γ, p, and q are as in the Introduction, and we assume $s \in \mathbf{R}$ satisfies (2.2) and (2.5). Also, we take $\phi \in W^{3,s}$, not identically zero, satisfying hypotheses (i)-(iv) of Theorem 1.2. In the language of § 2, that means $\phi \in D(B) \subset W_0^{1,s}$ with $\phi \geqq 0$ and $B\phi \geqq 0$. T_ϕ is the existence time of the maximal solution $u(t)$ of the integral equation (2.1). By Propositions 2.2, 2.3, and 2.6, $u \in C^1([0, T_\phi); W_0^{1,s})$, satisfying equation (2.8), with $u(t) \geqq 0$ and $u'(t) \geqq 0$ for all $t \in [0, T_\phi)$.

LEMMA 3.1. *The energy of the solution $u(t)$,*

$$E(u(t)) = \frac{1}{2}\|\nabla u(t)\|_2^2 - \frac{1}{p+1}\|u(t)\|_{p+1}^{p+1},$$

is a nonincreasing function of $t \in [0, T_\phi)$.

Proof. Since $u \in C^1([0, T_\phi); W_0^{1,s})$ and, by (2.5), $W_0^{1,s} \subset H_0^1$ and $W_0^{1,s} \subset L^\infty$, it follows that $E(u(t))$ is a C^1 function of $t \in [0, T_\phi)$. We easily calculate from (2.8) that

$$\frac{d}{dt}E(u(t)) = \langle -\Delta u(t), u'(t)\rangle - \langle u(t)^p, u'(t)\rangle$$

$$= -\langle u'(t) + |\nabla u(t)|^q, u'(t)\rangle$$

$$\leqq 0.$$

LEMMA 3.2. *Suppose $E(\phi) = E(u(0)) \leqq 0$ and that $q \leqq 2p/(p+1)$. Then for all $t \in [0, T_\phi)$*

$$|\langle u(t), |\nabla u(t)|^q\rangle| \leqq \left(\frac{2}{p+1}\right)^{q/2} C(p, q)\|u(t)\|_{p+1}^{p+1-\alpha}$$

where

$$\alpha = p - \frac{q(p+1)}{2} \geqq 0$$

and $C(p, q) = 1$ in case $q = 2p/(p+1)$.

Proof. From Hölder's inequality, it follows that

$$|\langle u, |\nabla u|^q\rangle| \leqq \|u\|_{p+1} \| |\nabla u|^q \|_{(p+1)/p}$$
$$= \|u\|_{p+1} \|\nabla u\|^q_{q(p+1)/p}.$$

Since $q \leqq 2p/(p+1)$, we have $q(p+1)/p \leqq 2$; and so

$$|\langle u, |\nabla u|^q\rangle| \leqq C(p,q)\|u\|_{p+1}\|\nabla u\|_2^q,$$

where $C(p,q)=1$ if $q=2p/(p+1)$.

By the previous lemma $E(u(t)) \leqq 0$ for all $t \in [0, T_\phi)$, or

$$\|\nabla u\|_2^q \leqq \left(\frac{2}{p+1}\right)^{q/2} \|u\|_{p+1}^{q(p+1)/2}.$$

The result follows by combining the last two inequalities.

Proof of Theorem 1.2. Suppose to the contrary that $T_\phi = \infty$. Let $F(t) = \|u(t)\|_2^2$. Then $F \in C^1([0,\infty))$, $F(0) = \|\phi\|_2^2 > 0$, and

$$F'(t) = 2\langle u(t), u'(t)\rangle$$
$$= -2\|\nabla u(t)\|_2^2 - 2\langle u(t), |\nabla u(t)|^q\rangle + 2\|u(t)\|_{p+1}^{p+1}$$
$$= -4E(t) + 2\left(\frac{p-1}{p+1}\right)\|u(t)\|_{p+1}^{p+1} - 2\langle u, |\nabla u|^q\rangle$$
$$\geqq 2\left(\frac{p-1}{p+1}\right)\|u(t)\|_{p+1}^{p+1} - 2\left(\frac{2}{p+1}\right)^{q/2} C(p,q)\|u(t)\|_{p+1}^{p+1-\alpha},$$

where we have used Lemma 3.1 ($E(u(t)) \leqq E(\phi) \leqq 0$) and Lemma 3.2. Continuing the calculation, we have

$$F'(t) \geqq 2\|u(t)\|_{p+1}^{p+1}\left[\left(\frac{p-1}{p+1}\right) - \left(\frac{2}{p+1}\right)^{q/2} C(p,q)\|u(t)\|_{p+1}^{-\alpha}\right]$$
$$\geqq CF(t)^{(p+1)/2}\left[\left(\frac{p-1}{p+1}\right) - \left(\frac{2}{p+1}\right)^{q/2} C(p,q)\|u(t)\|_{p+1}^{-\alpha}\right].$$

Suppose first $q < 2p/(p+1)$ and that $\|\phi\|_{p+1}$ is sufficiently large so that

$$\left(\frac{p-1}{p+1}\right) - \left(\frac{2}{p+1}\right)^{q/2} C(p,q)\|\phi\|_{p+1}^{-\alpha} \equiv k > 0.$$

Then since $u'(t) \geqq 0$, it follows that

$$F'(t) \geqq kCF(t)^{(p+1)/2}$$

for all $t \in [0,\infty)$. Since $(p+1)/2 > 1$, this is impossible for a function $F \in C^1([0,\infty))$ with $F(0) > 0$. This contradiction shows $T_\phi < \infty$.

Now suppose $q = 2p/(p+1)$. Then $C(p,q) = 1$ and $\alpha = 0$, so

$$F'(t) \geqq CF(t)^{(p+1)/2}\left[\left(\frac{p-1}{p+1}\right) - \left(\frac{2}{p+1}\right)^{p/(p+1)}\right].$$

This again yields a contradiction if p is large enough that the coefficient above is positive.

Remark. The expression

$$\left(\frac{p-1}{p+1}\right) - \left(\frac{2}{p+1}\right)^{p/(p+1)}$$

is increasing in p for $1<p<\infty$ with limit 1 as $p\to\infty$. Thus, if we let p_* be its unique zero in this range, then the above argument works for all $p>p_*$. An easy computation shows $3.3<p_*<3.4$.

4. The elliptic problem. For the moment, Ω, Γ, p, and q are as in the Introduction. Also, λ is always positive. Our goal is first to show the connection between the elliptic problem (1.5) and the hypotheses of Theorem 1.2. Then for $\Omega=B_R$ we will study the existence of solutions to (1.5). Together, this will prove Theorem 1.3.

PROPOSITION 4.1. *Let $2\leqq s<\infty$ and suppose $\phi\in W^{2,s}(\Omega)$ is a solution of* (1.5) *with $\lambda\leqq 2/(p+1)$. Then ϕ satisfies hypotheses* (i)-(v) *of Theorem* 1.2. *If in addition s satisfies* (2.5), *then $\phi\in W^{3,s}$.*

Proof. Hypotheses (i) and (iii) are stated in (1.5), and so there is nothing to prove. Now

$$\Delta\phi-|\nabla\phi|^q+\phi^p=(1-\lambda)\phi^p,$$

which immediately gives (ii) and (iv). Finally, since $\phi=0$ on Γ implies $\phi\in W_0^{1,s}$,

$$\begin{aligned}E(\phi)&=\frac{1}{2}\|\Delta\phi\|_2^2-\frac{1}{p+1}\|\phi\|_{p+1}^{p+1}\\&=-\frac{1}{2}\int_\Omega\phi\,\Delta\phi-\frac{1}{p+1}\int_\Omega\phi^{p+1}\\&=-\frac{1}{2}\int_\Omega\phi|\nabla\phi|^q-\left(\frac{1}{p+1}-\frac{\lambda}{2}\right)\int_\Omega\phi^{p+1}.\end{aligned}$$

Thus $E(\phi)\leqq 0$ because $\lambda\leqq 2/(p+1)$. The regularity of ϕ follows exactly as in the proof of Proposition 2.1. Simply note at the start that, thanks to (2.5), $\phi^p\in W_0^{1,s}$ and so

$$B\phi=(1-\lambda)\phi^p\in W_0^{1,s}.$$

PROPOSITION 4.2. *Assume that $p\leqq(n+2)/(n-2)$. (If $n=1$ or 2, this condition is vacuous.) Suppose that $\phi_k\in H_0^1$, $k=1,2,3,\cdots$, satisfy*

$$\Delta\phi_k+\lambda_k\phi_k^p\geqq 0,\quad \phi_k\geqq 0,\quad \phi_k\not\equiv 0, \tag{4.1}$$

where $\lambda_k>0$ and $\lambda_k\to 0$ as $k\to\infty$. Then $\|\phi_k\|_{p+1}\to\infty$ as $k\to\infty$.

Proof. Suppose not. Then, by passing to a subsequence, we may assume $\|\phi_k\|_{p+1}\leqq M$ independent of k. Let $\|\phi_k\|_{p+1}=N_k$ and

$$\psi_k=\phi_k/N_k.$$

Obviously $\|\psi_k\|_{p+1}=1$. ($N_k\neq 0$ since $\phi_k\not\equiv 0$.) Moreover, multiplying the inequality in (4.1) by ϕ_k and integrating over Ω, we have that

$$\|\nabla\phi_k\|_2^2\leqq\lambda_k\|\phi_k\|_{p+1}^{p+1},$$

or

$$\|\nabla\psi_k\|_2^2\leqq\lambda_k N_k^{p-1}\|\psi_k\|_{p+1}^{p+1}.$$

Since $\|\psi_k\|_{p+1}=1$, $N_k\leqq M$, and $\lambda_k\to 0$, it follows that $\|\nabla\psi_k\|_2\to 0$ as $k\to\infty$, i.e., $\psi_k\to 0$ in $H_0^1(\Omega)$ as $k\to\infty$. However, the condition on p implies that $H_0^1(\Omega)$ is embedded in L^{p+1}, and so $\psi_k\to 0$ in L^{p+1}. This contradicts the fact that $\|\psi_k\|_{p+1}=1$, thereby proving the proposition.

The following corollary to the above two propositions states explicitly how solutions of (1.5) yield solutions of (1.1) that blow up in finite time.

COROLLARY 4.3. *Assume* $s \in \mathbf{R}$ *satisfies* (2.2) *and* (2.5). *Suppose first that* $1 < q < 2p/(p+1)$ *and that* $1 < p < (n+2)/(n-2)$ ($1 < p < \infty$ *if* $n = 1$ *or* 2). *If* $\phi \in W^{2,s}$ *is a solution of* (1.5) *with* λ *sufficiently small, then* ϕ *satisfies all the hypotheses of Theorem* 1.2; *and so the solution of* (1.1) *with initial value* ϕ *blows up in finite time.*

Suppose next that $q = 2p/(p+1)$ *with* $p > p_*$. (*See the remark at the end of* § 3.) *If* $\phi \in W^{2,s}$ *is a solution of* (1.5) *with* $\lambda \leqq 2/(p+1)$, *then* ϕ *satisfies all the hypotheses of Theorem* 1.2; *and so the solution of* (1.1) *with initial value* ϕ *blows up in finite time.*

Now we let $\Omega = B_R = \{x \in \mathbf{R}^n : |x| < R\}$, and we look for solutions of (1.5) on B_R. In fact we are going to look for radially symmetric solutions of (1.5). This is not a genuine restriction, because the techniques of [13] can be used to show that any solution of (1.5) in B_R must be radially symmetric. We are therefore led to consider the following initial value problem:

$$\begin{aligned} &u''(r) + \frac{n-1}{r} u'(r) - |u'(r)|^q + \lambda |u(r)|^p = 0, \qquad r > 0, \\ &u(0) = a > 0, \qquad u'(0) = 0. \end{aligned} \tag{4.2}$$

If $u \in C^2([0, R])$ is a solution of (4.2) with $u(r) > 0$ for $0 \leqq r < R$ and $u(R) = 0$, then $\phi(x) = u(|x|)$ is the desired solution of (1.5). (Note that, for the rest of the paper, we will no longer be directly concerned with problem (1.1). Thus, the letter "u" will henceforth be used to denote solutions of (4.2).)

PROPOSITION 4.4. *Fix* $\lambda > 0$. *For every* $a > 0$ *there exists a* (*unique*) *maximal solution* $u \in C^2([0, R_a))$ *of* (4.2). *Furthermore, we have the following*:

(i) $u'(r) < 0$ *for all* r, $0 < r < R_a$;

(ii) *The function*

$$H(r) = \frac{1}{2} u'(r)^2 + \frac{\lambda}{p+1} |u(r)|^p u(r)$$

is decreasing on $[0, R_a)$;

(iii) *If* $u(r) > 0$ *for all* $0 \leqq r < R_a$, *then* $R_a = \infty$ *and*

$$\lim_{r \to \infty} u(r) = 0, \quad \lim_{r \to \infty} u'(r) = 0, \quad \lim_{r \to \infty} u''(r) = 0.$$

Proof. We first prove the existence of a unique solution to (4.2) on some interval $[0, \varepsilon]$. Consider the system

$$\begin{aligned} u(r) &= a + \int_0^r v(s)\, ds, \\ v(r) &= r^{-(n-1)} \int_0^r s^{n-1} (|v(s)|^q - \lambda |u(s)|^p)\, ds. \end{aligned} \tag{4.3}$$

It is easy to see that a solution of (4.2) is also a solution of (4.3) with $v = u'$. Indeed, simply multiply the equation in (4.2) by r^{n-1} and integrate. On the other hand, by standard iteration techniques, there is certainly a unique solution $u, v \in C([0, \varepsilon])$ to (4.3) for some $\varepsilon > 0$. Clearly, $u \in C^1([0, \varepsilon])$ with $u'(r) = v(r)$. In particular, $u'(0) = 0$. Moreover, v is immediately seen to be in $C^1((0, \varepsilon])$ and so $u \in C^2((0, \varepsilon])$ and satisfies (4.2). It remains to show that u is C^2 at $r = 0$, i.e., that v is C^1 at $r = 0$. From (4.3), l'Hôpital's rule easily gives

$$v'(0) = \lim_{r \to 0} \frac{v(r)}{r} = -\frac{\lambda a^p}{n}.$$

On the other hand, from (4.2)

$$\lim_{r\to 0} v'(r) = \lim_{r\to 0} u''(r) = \frac{(n-1)\lambda a^p}{n} - \lambda a^p = -\frac{\lambda a^p}{n}.$$

Thus, $u \in C^2([0, \varepsilon])$.

Since for $r > 0$, there are no singularities in (4.2), the solution on $[0, \varepsilon]$ can be locally continued to a maximal solution $u \in C^2([0, R_a))$. Since the continuation procedure treats (4.2) as a system $(u(r), v(r))$ with $u'(r) = v(r)$, it follows that if $R_a < \infty$ then either $|u(r)| \to \infty$ or $|u'(r)| \to \infty$ as $r \to R_a$.

To prove (i), note first that $u'(0) = 0$ and $u''(0) < 0$. Hence $u'(r) < 0$ on some interval $(0, \delta)$. Let r_0 be the first positive zero of u'. Then $u(r_0) \neq 0$ since, if $u(r_0) = u'(r_0) = 0$, it follows by uniqueness that $u(r) \equiv 0$. Consequently, from the equation in (4.2)

$$u''(r_0) = -\lambda |u(r_0)|^p < 0,$$

which implies that $u'(r) > 0$ for r in some interval $(r_0 - \varepsilon, r_0)$. This contradicts the choice of r_0, and thereby proves (i).

Next, we compute easily that for $r > 0$

$$\begin{aligned} H'(r) &= u'(r)u''(r) + \lambda |u(r)|^p u'(r) \\ &= u'(r)\left[-\left(\frac{n-1}{r}\right) u'(r) + |u'(r)|^q \right] \\ &< 0. \end{aligned}$$

This proves (ii).

Finally, if $u(r) > 0$ for all $r \in [0, R_a)$, then $0 < H(r) \leqq H(0)$ for all $r \in [0, R_a)$. Thus, $u(r)$ and $u'(r)$ are a priori bounded and so $R_a = \infty$. Now $u'(r) < 0$ and $u(r) > 0$. Hence,

$$\lim_{r\to\infty} u(r) = u_\infty \quad \text{(finite)}$$

exists. Likewise, $H(r)$ has a finite limit as $r \to \infty$. It follows therefore that

$$\lim_{r\to\infty} u'(r) = v_\infty$$

exists. In fact we must have $v_\infty = 0$ for $\lim_{r\to\infty} u(r)$ to exist. Finally, from (4.2) we now deduce that

$$\lim_{r\to\infty} u''(r) = -\lambda |u_\infty|^p.$$

Thus, the only way we can have $\lim_{r\to\infty} u'(r) = 0$ is if $u_\infty = 0$. This completes the proof of (iii).

For a fixed $\lambda > 0$, we denote the first zero of the solution to (4.2) by $z(a)$. We set the convention that $z(a) = \infty$ in case $u(r) > 0$ for all $r \geqq 0$. Thus, the solution $u(r)$ of (4.2) yields the desired solution of (1.5) precisely if $z(a) = R$. This certainly motivates studying the function $z(a)$.

PROPOSITION 4.5. *$\{a > 0: z(a) < \infty\}$ is open and $z(\cdot)$ is continuous on this set. Moreover,*

$$\lim_{a\to 0} z(a) = \infty. \tag{4.4}$$

Also, if $z(a_0) = \infty$ for some $a_0 \in \mathbf{R}$, then $\lim_{a\to a_0} z(a) = \infty$.

Proof. If $z(a) < \infty$, then $u(r) < 0$ for r slightly larger than $z(a)$. By continuous dependence on the data, if we change a by only a little bit, $u(r)$ must still be negative

somewhere, and must therefore have a zero. Continuity of $z(\cdot)$ follows from continuous dependence of $u(r)$ on a and the fact that u can have at most one zero since $u'(r)<0$ for $r>0$.

To prove (4.4), we note that since $H(r)$ is decreasing, it follows that

$$\frac{1}{2}u'(r)^2 \leqq H(r) \leqq H(0) = \frac{\lambda a^{p+1}}{p+1}$$

or

$$|u'(r)| \leqq \sqrt{2\lambda/(p+1)}\, a^{(p+1)/2}. \tag{4.5}$$

Consequently,

$$\begin{aligned} a &= u(0) - u(z(a)) \\ &= -\int_0^{z(a)} u'(s)\, ds \\ &\leqq z(a) a^{(p+1)/2} \sqrt{2\lambda/(p+1)}, \end{aligned}$$

or

$$z(a) \geqq \frac{a^{-(p-1)/2}}{\sqrt{2\lambda/(p+1)}}. \tag{4.6}$$

This proves (4.4).

For the last statement, we show that given $M>0$, then $z(a)>M$ if a is sufficiently close to a_0. Now for $a=a_0$, $u(r)>0$ for all $r>0$; hence $u(r)\geqq\delta>0$ on $[0, M]$. By continuous dependence on the data, if a is sufficiently close to a_0 then $u(r)\geqq\delta/2$ on $[0, M]$. Hence $z(a)>M$ for such a.

Next we would like to study the behavior of $z(a)$ as $a\to\infty$. We first consider the case $q<2p/(p+1)$.

PROPOSITION 4.6. *Assume that* $q<2p/(p+1)$ *and (in the case where* $n\geqq 3$*)* $p<(n+2)/(n-2)$. *Then, for all* $\lambda>0$, *we have*

$$\limsup_{a\to\infty} a^{(p-1)/2} z(a) < \infty, \tag{4.7}$$

$$\lim_{a\to\infty} z(a) = 0. \tag{4.8}$$

Proof. Fix $\lambda>0$. Denote by $u(\cdot\,; a)$ the solution of (4.2) with initial value a; and for all $a>0$, set

$$V_a(r) = a^{-1} u(r a^{-(p-1)/2}; a).$$

Then v_a is easily seen to satisfy

$$\begin{aligned} &v_a'' + \frac{n-1}{r} v_a' - a^{q(p+1)/2-p} |v_a'| + \lambda |v_a|^p = 0, \\ &v_a(0) = 1, \qquad v_a'(0) = 0. \end{aligned} \tag{4.9}$$

Also, $v_a'(r)<0$ for $r>0$ and $v_a(r)>0$ for $0\leqq r< a^{(p-1)/2} z(a)$. Hence

$$0 \leqq v_a(r) \leqq 1, \qquad 0 \leqq r \leqq a^{(p-1)/2} z(a). \tag{4.10}$$

Moreover, (4.5) translates into

$$|v_a'(r)| \leqq \sqrt{2\lambda/(p+1)}, \qquad r \geqq 0. \tag{4.11}$$

Now suppose there exists a sequence $a_m \to \infty$ such that $a_m^{(p-1)/2} z(a_m) \to \infty$ as $m \to \infty$. By the Arzelà-Ascoli theorem and a standard diagonal argument, there is a subsequence, which we still denote a_m, and a continuous function $v:[0,\infty)\to[0,1]$ such that $v_{a_m} \to v$ uniformly on all compact subsets $[0, M] \subset [0,\infty)$. In particular, $v(0)=1$, v is nonincreasing on $[0,\infty)$, and v is Lipschitz continuous with a Lipschitz constant no greater than $\sqrt{2\lambda/(p+1)}$. (Each v_a has these properties.) Finally, since $q < 2p/(p+1)$ and $|v_a'|$ is bounded independent of r and a, it follows from (4.9) that

$$v'' + \frac{n-1}{r} v' + \lambda v^p = 0 \tag{4.12}$$

in the sense of distributions on $(0,\infty)$.

It is well known that since $p < (n+2)/(n-2)$, such a v cannot exist. This is proved on pp. 293-294 of [33] in the case $\lambda = 1$. (See also [18, Prop. 3.9].) The same arguments work for any $\lambda > 0$, or else λ can be scaled away by multiplying v by a suitable factor. This proves (4.7), and hence (4.8).

We now turn to the case $q = 2p/(p+1)$. This will be quite different since the scaled solution v_a satisfies the same equation as u.

LEMMA 4.7. *If $q = 2p/(p+1)$, then for all $a > 0$,*

$$z(a) = a^{-(p-1)/2} z(1). \tag{4.13}$$

Proof. By (4.9), we see that $v_a = u(\cdot\,; 1)$ for all $a > 0$. Hence the first zero of v_a is $z(1)$. However, by the definition of v_a, its first zero is $a^{(p-1)/2} z(a)$. This proves (4.13).

In other words, whether or not $z(a)$ is finite depends entirely on whether or not $z(1)$ is finite. This in turn depends on λ.

LEMMA 4.8. *Let $r_0 \geqq 0$, $\lambda > 0$, $q = 2p/(p+1)$, and suppose $u:(r_0,\infty)\to\mathbf{R}$ is C^2 and satisfies*

(i) $u(r) > 0$, $r > r_0$, *and* $\lim_{r\to\infty} u(r) = 0$;
(ii) $u'(r) < 0$, $r > r_0$, *and* $\lim_{r\to\infty} u'(r) = 0$;
(iii) $u''(r) - |u'(r)|^q + \lambda u(r)^p = 0$, $r > r_0$.

If in addition $u(r)$ satisfies

$$u''(r) \leqq k|u'(r)|^q, \qquad r > r_0, \tag{4.14}$$

where $k > 0$ is a fixed constant, then u must also satisfy

$$u''(r) \leqq \left[1 - \lambda\left(\frac{p+1}{2k}\right)^p\right] |u'(r)|^q, \qquad r > r_0. \tag{4.15}$$

Proof. Since $u'(r) < 0$, inequality (4.14) can be rewritten:

$$(-u'(r))^{-(q-1)} u''(r) \leqq -ku'(r).$$

Integrating this from r to ∞, we get

$$\frac{(-u'(r))^{2-q}}{2-q} \leqq ku(r),$$

or

$$u(r) \geqq \frac{p+1}{2k} (-u'(r))^{2/(p+1)}.$$

(Recall that $q = 2p/(p+1) < 2$.) Hence

$$\begin{aligned} u''(r) &= (-u'(r))^q - \lambda u(r)^p \\ &\leqq \left[1 - \lambda\left(\frac{p+1}{2k}\right)^p\right](-u'(r))^q. \end{aligned}$$

PROPOSITION 4.9. *Suppose* $n=1$ *and* $q=2p/(p+1)$. *If* $\lambda \geqq (2/(p+1))^p$, *then* $z(a)<\infty$ *for all solutions* $u(r)$ *of* (4.2).

Proof. If $z(a)=\infty$, then $u(r)>0$ for all $r>0$. By Proposition 4.4, and the fact that $n=1$, $u(r)$ satisfies conditions (i)-(iii) of Lemma 4.8 with $r_0=0$. Furthermore, by (4.2) with $n=1$, we have that (4.14) holds with $k=1$. Thus (4.15) holds with $k=1$. Since $\lambda \geqq [2/(p+1)]^p$, it follows that $u''(r)\leqq 0$ for $r>0$. This is impossible because $u'(r)<0$ and $u(r)>0$ for $r>0$.

The result in Proposition 4.9 is already enough to give us a solution of (1.5) with $\lambda \leqq 2/(p+1)$. Indeed, $[2/(p+1)]^p < 2/(p+1)$. However, this result can be improved.

LEMMA 4.10. *Suppose* $\lambda > \lambda_p$, *given by* (1.6). *Define the following sequence inductively*:

$$k_0=1, \qquad k_m = 1-\lambda\left(\frac{p+1}{2k_{m-1}}\right)^p,$$

as long as $k_{m-1}>0$. *Then either* k_m *is eventually nonpositive or* $\lim_{m\to\infty} k_m = 0$.

Proof. It is easy to verify by induction that the sequence k_m is decreasing as long as it is defined. Consequently, if the conclusion is false, then

$$\lim_{m\to\infty} k_m = k > 0,$$

and k must satisfy

$$k = 1-\lambda\left(\frac{p+1}{2k}\right)^p.$$

In other words, k is a positive solution to

$$f(x) = x^{p+1}-x^p = -\lambda\left(\frac{p+1}{2}\right)^p.$$

However, the minimum value of $f(x)$ for $x>0$ is easily computed to be

$$-\frac{1}{p+1}\cdot\left(\frac{p}{p+1}\right)^p.$$

Hence we must have

$$\lambda \leqq \left(\frac{2}{p+1}\right)^p \cdot \frac{1}{p+1}\left(\frac{p}{p+1}\right)^p = \lambda_p.$$

Therefore, if $\lambda > \lambda_p$, the conclusion holds.

PROPOSITION 4.11. *Suppose* $n=1$ *and* $q=2p/(p+1)$. *If* $\lambda > \lambda_p$, *then* $z(a)<\infty$ *for all solutions of* (4.2).

Proof. If $z(a)=\infty$, then $u(r)>0$ for all $r>0$. By Proposition 4.4 and the fact that $n=1$, $u(r)$ satisfies conditions (i)-(iii) of Lemma 4.8 with $r_0=0$. Furthermore, by (4.2) with $n=1$, we have that (4.14) holds with $k=1$. Hence by Lemma 4.8, (4.14) and therefore (4.15) hold with all values $k=k_m$ defined in Lemma 4.10. Thus, by Lemma 4.10, $u''(r)\leqq 0$ for all $r>0$. This is impossible since $u'(r)<0$ and $u(r)>0$ for $r>0$.

Proof of Theorem 1.3. Suppose first that $1<q<2p/(p+1)$ and (if $n\geqq 3$) $p<(n+2)/(n-2)$. By Propositions 4.5 and 4.6, for all $\lambda>0$ and $R>0$, there exists $a>0$ such that $z(a)=R$. In other words, if $u(r)$ is the solution to (4.2) with this initial value a, then $u(r)>0$ for $0\leqq r<R$ and $u(R)=0$. Then $\phi(x)=u(|x|)$, $|x|\leqq R$, is the desired solution of (1.5). The other properties of ϕ follow from Corollary 4.3.

Now suppose that $n=1$, $q=2p/(p+1)$, and $\lambda>\lambda_p$. Then by Proposition 4.11 and Lemma 4.7, there exists (a unique) $a>0$ such that $z(a)=R$. The rest of the proof is as in the previous case.

5. Further results on the elliptic problem. In this section we continue in the same context and with the same notation established in the previous section. In particular, for a fixed $\lambda>0$, $z(a)$ is the first zero of the solution to the initial value problem (4.2), with the convention that $z(a)=\infty$ in case the solution always remains positive. Our goal is to study more completely the problem (4.2), i.e., the elliptic problem (1.5) in B_R. We first gather as much information as we can in the general case, and then specialize to dimension $n=1$. The following result is a variation on the estimate (4.6).

LEMMA 5.1. *Let $\lambda>0$ and $u(r)$ be the solution of* (4.2), *with $z(a)$ the first zero of $u(r)$. Then*

$$z(a)\geqq\lambda^{-1/q}a^{1-(p/q)}. \tag{5.1}$$

Proof. We may certainly assume $z(a)<\infty$. We claim first that the maximum value of $-u'(r)$ on $[0, z(a)]$ is achieved in the interior. Indeed,

$$-u''(0)=\frac{\lambda a^p}{n}>0,$$

$$-u''(z(a))=\left(\frac{n-1}{z(a)}\right)u'(z(a))-|u'(z(a))|^q<0.$$

So if r_0 is such that $-u'(r_0)$ is a maximum on $[0, z(a)]$, then $u''(r_0)=0$, i.e.,

$$-(-u'(r_0))^q+\lambda u(r_0)^p=-\frac{n-1}{r_0}u'(r_0)\geqq 0$$

or

$$(-u'(r_0))^q\leqq\lambda u(r_0)^p\leqq\lambda a^p.$$

This implies that for $0\leqq r\leqq z(a)$,

$$-u'(r)\leqq\lambda^{1/q}a^{p/q}.$$

Hence,

$$\begin{aligned}a&=u(0)-u(z(a))\\&=-\int_0^{z(a)}u'(s)\,ds\\&\leqq z(a)\lambda^{1/q}a^{p/q},\end{aligned}$$

which proves (5.1).

LEMMA 5.2. *Let $q>2p/(p+1)$ and (in case $n\geqq 3$) $p<(n+2)/(n-2)$. Then, for all $\lambda>0$, we have*

$$\limsup_{a\to 0}a^{(p-1)/2}z(a)<\infty.$$

In particular, for all sufficiently small a, $z(a)<\infty$ and

$$z(a)\leqq Ca^{-(p-1)/2}. \tag{5.2}$$

Proof. This is an obvious modification to the proof of Proposition 4.6.

Let us consider for a moment whether or not a regular (i.e., C^2) solution of the elliptic problem (1.5) exists on $\Omega = B_R$. As noted in § 4, the methods of [13] can be used to prove that such a solution $\phi(x)$ must be radially symmetric. In other words, $\phi(x) = u(|x|)$, where $u(r)$ is a solution of (4.2) with $z(a) = R$. Therefore, for a fixed $\lambda > 0$, the number of solutions to (1.5) on B_R is precisely the cardinality of the set $z^{-1}(R)$. For each $\lambda > 0$, we define

$$R(\lambda) = \inf_{a>0} z(a). \tag{5.3}$$

Note that if $R(\lambda) < \infty$, then by Proposition 4.5, $z(a) = R$ has at least one solution whenever $R(\lambda) < R < \infty$.

PROPOSITION 5.3. (i) *If $q \geqq p$ then $R(\lambda) > 0$.*

(ii) *If $q > 2p/(p+1)$ and (in case $n \geqq 3$) $p < (n+2)/(n-2)$, then $R(\lambda) < \infty$.*

(iii) *If $q > p$ and (in case $n \geqq 3$) $p < (n+2)/(n-2)$, then $z(a) = R(\lambda) < \infty$ for some $a > 0$, and $z(a) = R$ has at least <u>two</u> solutions $a > 0$ for each $R > R(\lambda)$.*

Proof. Statement (i) follows from the lower estimates for $z(a)$ given by (4.6) and (5.1). Statement (ii) follows from Lemma 5.2. For statement (iii) note that (4.6) and (5.1) imply $\lim_{a\to 0} z(a) = \infty$ and $\lim_{a\to\infty} z(a) = \infty$. Moreover, by Lemma 5.2, $z(a)$ is finite for some values of a, and hence, by Proposition 4.5, assumes its (positive) minimum $R(\lambda)$ at some a_m, $0 < a_m < \infty$. Clearly, then for each $R > R(\lambda)$, there exist a_1 and a_2 with $0 < a_1 < a_m < a_2 < \infty$ such that $z(a_1) = z(a_2) = R$.

COROLLARY 5.4. (i) *If $q \geqq p$ and $0 < R < R(\lambda)$, then there is no regular solution of* (1.5) *on B_R.*

(ii) *If $q > 2p/(p+1)$ and (in case $n \geqq 3$) $p < (n+2)/(n-2)$, then for $R > R(\lambda)$, there is at least one regular solution of* (1.5) *on B_R.*

(iii) *If $q > p$ and (in case $n \geqq 3$) $p < (n+2)/(n-2)$, then for $R = R(\lambda)$, there is at least one regular solution of* (1.5) *on B_R; and for $R > R(\lambda)$, there are at least <u>two</u> regular solutions of* (1.5) *on B_R.*

We next focus our attention on the case $q = 2p/(p+1)$. This is particularly interesting since it is the critical value for both the energy arguments in § 3 and the scaling argument in (the proof of) Proposition 4.6.

PROPOSITION 5.5. *Let $q = 2p/(p+1)$ and $\lambda > 0$. Suppose first $n = 1, 2$ or $n \geqq 3$ and $p < n/(n-2)$. Then there exists a positive constant k such that*

$$U(r) = kr^{-2/(p-1)} \tag{5.4}$$

satisfies

$$u''(r) + \frac{n-1}{r} u'(r) - |u'(r)|^q + \lambda u(r)^p = 0 \tag{5.5}$$

if and only if $\lambda \leqq \lambda_{p,n}$, where

$$\lambda_{p,n} = \frac{1}{p+1}\left[\frac{2p}{(p+1)(2p-np+n)}\right]^p.$$

On the other hand, if $n \geqq 3$ and $p \geqq n/(n-2)$, then such a solution exists for all $\lambda > 0$.

Proof. By direct calculation, we see that $U(r)$, given by (5.4), satisfies (5.5) precisely when

$$\lambda k^{p-1} - \left(\frac{2}{p-1}\right)^q k^{q-1} = -\frac{2}{p-1}\left(\frac{2p}{p-1} - n\right). \tag{5.6}$$

If $n \geqq 3$ and $p \geqq n/(n-2)$, then the right-hand side of (5.6) is nonnegative. In this case, since $q = 2p/(p+1) < p$, a positive solution k to (5.6) can always be found.

Suppose instead either $n=1,2$ or in the case where $n\geqq 3$, $p<n/(n-2)$, so the right-hand side of (5.6) is negative. Then a positive solution k of (5.6) can be found precisely when

$$\inf_{x>0} f(x) \leqq -\frac{2}{p-1}\left(\frac{2p}{p-1}-n\right), \tag{5.7}$$

where $f(x)=\lambda x^{p-1}-[2/(p-1)]^q x^{q-1}$. Using elementary calculus, and not forgetting that $q=2p/(p+1)$, we can verify that (5.7) holds if and only if $\lambda \leqq \lambda_{p,n}$.

Remark. Note that $\lambda_{p,1}=\lambda_p$, defined by (1.6). Also, $\lambda_{p,n}$ is increasing as a function of n.

PROPOSITION 5.6. *Assume* $q=2p/(p+1)$ *and* $\lambda \leqq \lambda_p=\lambda_{p,1}$. *Then* $z(a)=\infty$ *for all* $a>0$. *In other words, there is no regular solution of* (1.5) *on* B_R, *for any* $R>0$.

Proof. In dimension $n=1$ there is a particularly easy and elegant proof, which we present first. Suppose a C^2 solution ϕ of (1.5) exists in dimension $n=1$. Let $U(r)$ be the solution of (5.5) given by (5.4) with $n=1$. (Recall $\lambda \leqq \lambda_{p,1}$.) Set

$$\bar{\rho}=\sup\{\rho\in\mathbf{R}\text{: the graph of } \phi(r-\rho) \text{ does not touch the graph of } U(r)\}.$$

Clearly, $\bar{\rho}\in\mathbf{R}$. Also, the graphs of $\phi(r-\bar{\rho})$ and $U(r)$ touch at some point r_0, i.e., $\phi(r_0-\bar{\rho})=U(r_0)>0$; and by the definition of $\bar{\rho}$, we must also have $\phi'(r_0-\bar{\rho})=U'(r_0)$. However, both $\phi(r-\bar{\rho})$ and $U(r)$ satisfy (5.5) with the same Cauchy data at r_0. Hence $\phi(r-\bar{\rho})=U(r)$ wherever both functions are defined. In particular, ϕ cannot be $C^2([-R,R])$ with $\phi(\pm R)=0$.

For the case $n\geqq 2$, we assume that $z(a)<\infty$ for some $a>0$. For any fixed $\gamma>0$, let

$$G(r)=\frac{u'(r)^2}{2}-\gamma|u(r)|^p u(r).$$

Then $G(0)<0$ and $G(z(a))>0$. ($u'(z(a))=0$ by local existence and uniqueness.) Thus, the first zero of $G(r)$ is between zero and $z(a)$; call it r_0. Clearly, $G(r_0)=0$ and $G'(r_0)\geqq 0$. However, since $G(r_0)=0$, we have

$$|u'(r_0)|=\sqrt{2\gamma}\,u(r_0)^{(p+1)/2}.$$

Therefore, at $r=r_0$

$$\begin{aligned} G' &= u'u''-\gamma(p+1)u^p u' \\ &= u'\left(-\frac{n-1}{r_0}u'+|u'|^q-\lambda u^p-\gamma(p+1)u^p\right) \\ &< u'(|u'|^q-(\lambda+\gamma(p+1))u^p) \\ &= u'((2\gamma)^{q/2}u^{(p+1)q/2}-(\lambda+\gamma(p+1))u^p) \\ &= u'u^p f(\gamma), \end{aligned}$$

where

$$f(\gamma)=(2\gamma)^{p/(p+1)}-\gamma(p+1)-\lambda.$$

(We have used the fact that $(p+1)q/2=p$.) Now $G'(r_0)\geqq 0$, $u'(r_0)<0$, and $u(r_0)>0$. Consequently, we must have $f(\gamma)<0$. Since $\gamma>0$ was arbitrary, this must be true for all $\gamma>0$. A straightforward calculation of the extreme points for $f(\gamma)$ shows that we must have $\lambda>\lambda_{p,1}$. This proves the proposition.

Remarks. The estimate for $G'(r_0)$ depends on the fact that $n \geqq 2$ in order to get strict inequality. Thus, it seems that for $n=1$, the second argument misses the case $\lambda = \lambda_{p,1}$. However, since for a fixed value of a, the set of $\lambda > 0$ for which $z(a) < \infty$ is clearly open, we recover the case $\lambda = \lambda_{p,1}$ when $n = 1$.

Also, in the case $n=1$, Proposition 5.6 and Theorem 1.3 give a complete description of when there are solutions of (1.5) on B_R with $q = 2p/(p+1)$. There exists a solution if and only if $\lambda > \lambda_p$. It is natural to conjecture an analogous result for higher dimensions. We wonder what the sharp cutoff value would be, in particular if it is $\lambda_{p,n}$.

A variation on the proof of Proposition 5.6 yields the following result.

PROPOSITION 5.7. *Assume $q < 2p/(p+1)$ and fix $\lambda > 0$. Then there exists $a_* > 0$ such that $z(a) = \infty$ for $a \leqq a_*$.*

Proof. Suppose $z(a) < \infty$. Let $u(r)$ be the corresponding solution of (4.2) and set

$$G(r) = \frac{u'(r)^2}{2} - \lambda |u(r)|^p u(r).$$

Then $G(0) < 0$ and $G(z(a)) > 0$. Let r_0 be the first zero of G; so $G(r_0) = 0$ and $G'(r_0) \geqq 0$. Reasoning as in the proof of Proposition 5.6 (with $\gamma = \lambda$), we see that at $r = r_0$

$$\begin{aligned} G' &\leqq u'((2\lambda)^{q/2} u^{(p+1)q/2} - \lambda(p+2)u^p) \\ &\leqq u' u^{(p+1)q/2}((2\lambda)^{q/2} - \lambda(p+2)a^{p-[(p+1)q/2]}). \end{aligned}$$

Since $p > (p+1)q/2$, it follows that for a sufficiently small, $G'(r_0) < 0$. This contradicts the earlier observation that $G'(r_0) \geqq 0$.

Hence $z(a) = \infty$ for $a > 0$ sufficiently small.

We now restrict ourselves to the special case $n = 1$. The problem (4.2) becomes the autonomous problem

$$\begin{aligned} &u''(r) - |u'(r)|^q + \lambda |u(r)|^p = 0, \\ &u(0) = a > 0, \qquad u'(0) = 0. \end{aligned} \tag{5.8}$$

Problem (1.5) becomes

$$\begin{aligned} &\phi'' - |\phi'|^q + \lambda \phi^p = 0 \quad \text{in } (-R, R), \\ &\phi > 0 \quad \text{in } (-R, R), \\ &\phi(\pm R) = 0, \end{aligned} \tag{5.9}$$

where $\phi \in C^2([-R, R])$.

Consider the case $q < 2p/(p+1)$. By Propositions 4.5 and 4.6, i.e., the first part of Theorem 1.3, for all $\lambda > 0$ and $R > 0$, there is a solution to problem (5.9). We will show it to be unique. (Note that in the case $q = 2p/(p+1)$ the solution of (5.9) is unique when it exists because of formula (4.13). If $q > p$, we know it is not unique for R large enough.)

LEMMA 5.8. *Let $v(r)$ be the maximal solution (as in Proposition 4.4) to the problem*

$$\begin{aligned} &v''(r) - b|v'(r)|^q + \lambda |v(r)|^p = 0, \\ &v(0) = v_0 > 0, \qquad v'(0) = 0, \end{aligned} \tag{5.10}$$

where $b > 0$ and $\lambda > 0$ are parameters. Then $v(r)$ is an increasing function of b.

Proof. The existence and uniqueness of $v(r)$ follow exactly as in the proof of Proposition 4.1. In particular, $v'(r) < 0$ for $r < 0$. It is clear from the integral equation corresponding to (5.10) that v is a C^1 function jointly in r and b. We denote $v_r = \partial v/\partial r$

and $v_b = \partial v/\partial b$. Then considering v_r and v_b as functions of r, and using $'$ to denote d/dr, we have

$$v_r'' + bq|v'|^{q-1}v_r' + \lambda p|v|^{p-1}v_r = 0,$$
$$v_b'' + bq|v'|^{q-1}v_b' + \lambda p|v|^{p-1}v_r = (-v')^q.$$

Hence, setting $w = v_b'v_r - v_r'v_b$, it follows that

$$w' + qb(-v')^{q-1}w = (-v')^q v' < 0,$$

or, if f denotes a primitive of $qb(-v')^{q-1}$, that

$$(e^f w)' < 0. \tag{5.11}$$

Since $v_b(0) = v_r(0) = 0$, we have $w(0) = 0$. Hence by (5.11), $w(r) < 0$ for $r > 0$. This implies $(v_b/v_r)' < 0$ for $r > 0$. Moreover,

$$\lim_{r\to 0} \frac{v_b(r)}{v_r(r)} = \lim_{r\to 0} \frac{v_b'(r)}{v_r'(r)} = \frac{0}{v''(0)} = 0,$$

and so $v_b/v_r < 0$ for all $r > 0$, i.e., $v_b(r) > 0$ for $r > 0$.

PROPOSITION 5.9. *Let $q < 2p/(p+1)$ and $n = 1$. Then, for all $\lambda > 0$, $a^{(p-1)/2}z(a)$ is a decreasing function of a. In particular, $z(a)$ is decreasing.*

If $q > 2p/(p+1)$ and $n = 1$, then for all $\lambda > 0$, $a^{(p-1)/2}z(a)$ is an increasing function of a.

Proof. By the previous lemma, if $n = 1$ and $q < 2p/(p+1)$, then $v_a(r)$ defined by (4.9) is a decreasing function of a. Consequently, the first zero of v_a, i.e., $a^{(p-1)/2}z(a)$, is a decreasing function of a. More precisely, $a^{(p-1)/2}z(a)$ is nonincreasing for all $a > 0$ and strictly decreasing where it is finite.

An analogous argument works for $q > 2p/(p+1)$.

COROLLARY 5.10. *Let $q < 2p/(p+1)$ and $n = 1$. Then for every $\lambda > 0$ and $R > 0$, the C^2 solution of (5.9) is unique.*

Finally, we have a result that further contrasts the cases $q < 2p/(p+1)$ and $q > 2p/(p+1)$.

PROPOSITION 5.11. *Suppose $q > 2p/(p+1)$ and $n = 1$. Let $\lambda > 0$ be arbitrary. Then $z(a) < \infty$ for all $a > 0$ and $\lim_{a\to 0} z(a) = \infty$.*

Proof. By Lemma 5.2 and Proposition 4.5 we already know that $z(a) < \infty$ for small $a > 0$ and $\lim_{a\to 0} z(a) = \infty$. Suppose $z(a) = \infty$ for some $a > 0$, and let $u(r)$ be the corresponding solution of (5.8). Let $v(r)$ be a solution to (5.8) with a smaller initial value a such that $z(a) < \infty$. Let

$$\bar{\rho} = \sup\{\rho \in \mathbf{R}: \text{the graph of } v(r-\rho) \text{ does not touch the graph of } u(r)\}.$$

As in the proof of Proposition 5.6, it is clear that $\bar{\rho} \in R$ and that $u(r)$ and $v(r-\bar{\rho})$ would have to coincide, which is impossible.

Remarks. We can make a few more observations in the case $n = 1$. First, if $q < 2p/(p+1)$, then by Propositions 4.6, 5.7, and 5.9 there exists $a_* > 0$ such that $z(a) = \infty$ for $a \leqq a_*$ and $z(a) < \infty$ for $a > a_*$. Next, in the case $q > 2p/(p+1)$, if ϕ_1 and ϕ_2 are two different solutions of (5.9), then $\phi_1(x) \neq \phi_2(x)$ for all x in $(-R, R)$. This follows from a translation argument similar to the proofs of Propositions 5.6 and 5.11. We mention without proof that if $q > 2p/(p+1)$, there can exist singular solutions of (5.9), i.e., solutions in $C^2([-R, R]\backslash\{0\})$ with $\lim_{x\to 0} \phi(x) = \infty$.

Clearly, solutions of (1.5) exhibit radically different behavior depending on the relationship between p and q. However, the picture is certainly not complete.

Note added in proof. After we completed this paper, we learned that B. Kawohl and L. Peletier obtained, among other interesting results, blowup in the case $q = 2$. (See B. Kawohl and L. Peletier [36].)

Acknowledgments. While at the Institute for Mathematics and Its Applications (IMA), the University of Minnesota, the authors were fortunate to be able to discuss this work with S. Hastings, R. Pego, and P. Souganidis. We thank them for their ideas and suggestions, and we are grateful to the IMA for its support.

THE RIEMANN PROBLEM FOR MULTICOMPONENT POLYMER FLOODING*

THORMOD JOHANSEN† AND RAGNAR WINTHER‡

Abstract. The global Riemann problem for a nonstrictly hyperbolic system of conservation laws modeling multicomponent polymer flooding is solved. The solution is constructed by first generating the Riemann solution of an associated one-phase problem.

Key words. Riemann problems, polymer flooding, adsorption

AMS(MOS) subject classifications. 35L65, 76S05

1. Introduction. In this paper we construct the global solution of the Riemann problem for a nonstrictly hyperbolic system of conservation laws of the following form:

$$\begin{aligned} &s_t + f(s, c_1, \cdots, c_n)_x = 0, \\ &[sc_i + a_i(c_i)]_t + [c_i f(s, c_1, \cdots, c_n)]_x = 0, \qquad i = 1, 2, \cdots, n, \end{aligned} \tag{1.1}$$

where the unknown state vector $(s, c_1, \cdots, c_n) = (s, c) \in \mathbb{I}^{n+1}$ and $f: \mathbb{I}^{n+1} \to \mathbb{R}$ and $a_i: \mathbb{I} \to \mathbb{R}$ are given smooth functions. Here $\mathbb{I}$ denotes the unit interval $\mathbb{I} = [0, 1]$.

The results presented here generalize the results of Johansen and Winther [9] where the general Riemann problem for the model (1.1) is solved for $n = 1$.

The main purpose of this paper is to extend this solution to the case where $n > 1$. We show that a certain "projection principle" makes it possible to construct the Riemann solution in this case from a coupled sequence of Riemann problems of the form studied in [9]. This construction is the main result of the paper.

The system (1.1) models simultaneous one-dimensional flow of two immiscible phases (the aqueous phase and the oilic phase) in a homogeneous porous medium. It is further assumed that n chemical components are dissolved in the aqueous phase. These components could, for example, be different polymers that all have different influence on the flow properties. The equations are derived from conservation of mass of the two phases and of the n chemical components. The variable s denotes the saturation of the aqueous phase. The term a_i in (1.1) models the adsorption of component i on the porous medium. It is assumed throughout the paper that a_i is a given function of concentration that depends only on the variable c_i; i.e., $a_i = a_i(c_i)$. As in [9] we will assume that each of the adsorption functions a_i are of Langmuir type; i.e., a_i is a concave, increasing function such that $a_i(0) = 0$. No relation between the different adsorption functions will be assumed. The function $f = f(s, c_1, \cdots, c_n)$ is the fractional flow function of the aqueous phase. We will assume that this function is a decreasing function with respect to each of the variables c_i. This corresponds, for example, to the effect that the viscosity of the aqueous phase is increasing with respect to the concentration c_i. For any fixed concentration vector c the function f is assumed to be an increasing function of s with one inflection point. For more details on the physical derivation of the model (1.1) we refer to [9] and references given therein.

A model, where the effects of polymer and surfactants are modeled as described above, is for example proposed by Lake and Helfferich [11]. A more realistic description of the adsorption effects would be that the different components compete for the vacant adsorption sites. In [13], Rhee, Aris, and Amundson solve the Riemann problem for such a model in a one-phase situation. They assume that the adsorption effects are of generalized Langmuir type; i.e., the adsorption functions a_i are of the form

$$a_i = a_i(c_1, c_2, \cdots, c_n) = K_i c_i \Big/ \left(1 + \sum_{j=1}^{n} K_j c_j\right) \tag{1.2}$$

for $i = 1, 2, \cdots, n$, where $K_1 < K_2 < \cdots < K_n$ are given positive constants. The techniques developed in this paper can also be used to construct the Riemann solution for a two-phase model of the form (1.1), but where the functions $a_i(c_i)$ are replaced by adsorption functions of the form (1.2). This construction will be discussed in a forthcoming paper.

The model (1.1) is an example of a system of hyperbolic conservation laws. However, under the present assumptions on the fractional flow function f, the system is not strictly hyperbolic; i.e., there exist regions in the state space where the eigenvalues of the appropriate Jacobian matrix are not distinct.

The Riemann problem for the model (1.1) consists of constructing a weak solution of the pure initial value problem for (1.1) with initial condition

$$(s, c)(x, 0) = \begin{cases} (s^L, c^L) & \text{if } x < 0, \\ (s^R, c^R) & \text{if } x > 0, \end{cases} \tag{1.3}$$

where the left and right states (s^L, c^L) and (s^R, c^R) in I^{n+1} are arbitrary. To distinguish the physically meaningful weak solutions we will also require that any discontinuity of the solution satisfies an "entropy condition" obtained from traveling wave analysis. As in [9] the entropy condition will allow overcompressive shocks. In particular, this condition will guarantee the uniqueness of the solution of the Riemann problem.

The interest in Riemann problems is partly motivated from their potential application as building blocks in the construction of numerical methods. Examples of such methods are the Random Choice Method [1]-[3], Godunov-type methods [6] and front-tracking techniques [4], [5]. It is therefore of interest to develop a computer program that computes the desired solution of the Riemann problem. Such a program has been implemented from the constructive existence proof given in this paper. In a forthcoming paper we will discuss this implementation and also present some examples of solutions.

If $n = 1$ and if the adsorption term $a_i(c_i)$ is neglected, the model (1.1) corresponds to a 2×2 system of conservation laws analyzed by Keyfitz and Kranzer [10] and Isaacson [7]. In [9] the adsorption term is included. The effect of this term is that the linearly degenerate characteristic field appearing in the analysis of [7] and [10] is replaced by a nondegenerate field. A further consequence of the adsorption term is that the state-space solution of the Riemann problem becomes unique. A multicomponent version of the nonadsorption model of [7] and [10] is studied by Isaacson and Temple [8]. In the present paper the model (1.1), with adsorption terms included, is analyzed in the case when $n > 1$. The results depend heavily on the results of [9] and on the fact that the Riemann problem decouples according to a "projection principle." As a consequence of this principle the Riemann problem for (1.1) can be constructed by first solving the Riemann problem for an associated one-phase problem. Thereafter, the solution for (1.1) can be obtained from a finite sequence of coupled 2×2 Riemann problems.

The precise assumptions on the system (1.1) are stated in § 2. In § 3 the properties of the elementary waves (rarefactions and shocks) are described. The "projection principle" is discussed in § 4, while the complete construction of the Riemann solution is performed in § 5. The main conclusions obtained from this paper are given in § 6.

2. A precise formulation of the model. The model (1.1) is a system of $n+1$ hyperbolic conservation laws with $n+1$ unknowns $s, c_1, \cdots, c_n$. We frequently let c denote the n-vector $(c_1, c_2, \cdots, c_n)$. For the partial derivatives of the flux function $f=f(s, c)=f(s, c_1, \cdots, c_n)$ we use the notation

$$f_s=\frac{\partial f}{\partial s} \quad \text{and} \quad f_i=\frac{\partial f}{\partial c_i} \quad \text{for } i=1, 2, \cdots, n.$$

Furthermore, f_c denotes the row vector $f_c=(f_1, f_2, \cdots, f_n)$.

The derivatives of the adsorption functions $a_i=a_i(c_i)$ are denoted by $h_i=da_i/dc_i$, and $H(c)$ is the $n\times n$ matrix

$$H(c)=\operatorname{diag}(h_1(c_1), \cdots, h_n(c_n)).$$

The assumptions on the functions f and a_i are similar to those made in [9]. In particular, the adsorption functions a_i are assumed to be smooth, strictly increasing, strictly concave functions of c_i such that $a_i(0)=0$ (cf. Fig. 2.1); i.e.,

$$h_i(c_i)>0 \quad \text{and} \quad \frac{dh_i}{dc_i}(c_i)<0 \quad \text{for } c_i\in\mathbb{I}. \tag{2.1}$$

The flux function f is assumed to be a smooth function such that (cf. Fig. 2.2):

(2.2a) $f(0, c)\equiv 0, \quad f(1, c)\equiv 1,$

(2.2b) $f_s(s, c)>0$ for $0<s<1$, $c\in\mathbb{I}^n$,

(2.2c) $f_i(s, c)<0$ for $0<s<1$, $c\in\mathbb{I}^n$,

(2.2d) for each $c\in\mathbb{I}^n$, $f(\cdot, c)$ has a unique point of inflection $s^I=s^I(c)\in\mathbb{I}$ such that $f_{ss}(s, c)>0$ for $s\in(0, s^I)$, $f_{ss}(s, c)<0$ for $s\in(s^I, 1)$.

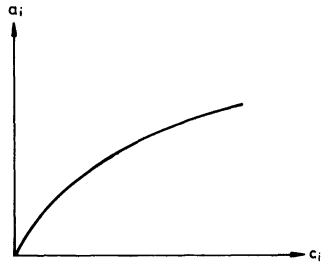

FIG. 2.1

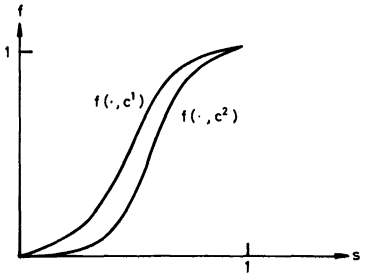

FIG. 2.2. $c_j^1=c_j^2$ *for* $j\neq i$, $c_i^1<c_i^2$.

Let $u \in \mathbb{R}^{n+1}$ denote the state vector $u = (s, c)$. If the solution of the system (1.1) is smooth, then the system can be rewritten in the form

$$u_t + A(u)u_x = 0,$$

where $A(u)$ is the $(n+1)\times(n+1)$ matrix

$$A(u) = \begin{pmatrix} f_s(s, c) & f_c(s, c) \\ 0 & f(s, c)(sI + H(c))^{-1} \end{pmatrix}.$$

Here I denotes the $n \times n$ identity matrix. The eigenvalues of A are $\lambda_s = f_s$ and $\lambda_i = f/(s + h_i)$. In general these eigenvalues are not distinct.

For a given $c \in \mathbb{I}^n$ there is at most one value of $s > 0$ such that $\lambda_s = \lambda_i$ (cf. Fig. 2.3). In particular, for constant values of c_j, for $j \neq i$, the set $\{(s, c) \mid \lambda_s(s, c) = \lambda_i(s, c), s > 0\}$ defines a curve in (s, c_i)-space similar to the transition curve T appearing in the analysis of [9]. We impose the same regularity requirements on all of these curves as we did on the corresponding curve in [9]; i.e., for arbitrary constant values of c_j, for $j \neq i$, there is a unique value c_i^T such that the curve $\lambda_i = \lambda_s$ exists for $0 \leqq c_i \leqq c_i^T$ (cf. Fig. 2.4).

Furthermore, the relation $\lambda_i = \lambda_j$ defines an n-dimensional surface in state space given by

$$h_j(c_j) = h_i(c_i) \quad \text{or} \quad c_j = h_j^{-1}(h_i(c_i)) \equiv g_{i,j}(c_i).$$

We observe that it follows from the assumptions on the functions h_i that the functions $g_{i,j}$ are increasing functions of c_i (cf. Fig. 2.5).

3. Elementary waves. In this section we determine all the elementary waves of the model (1.1); i.e., we determine the rarefaction waves and the shock waves. The

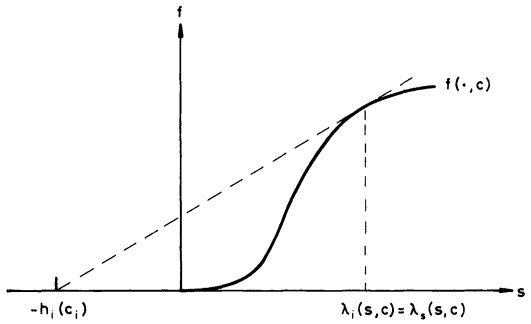

FIG. 2.3. $\lambda_i = \lambda_s$.

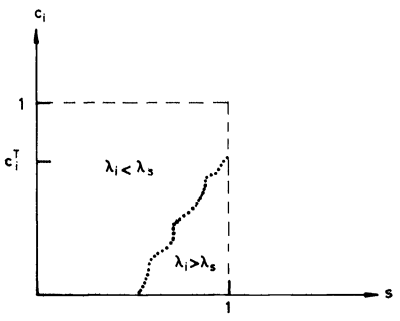

FIG. 2.4

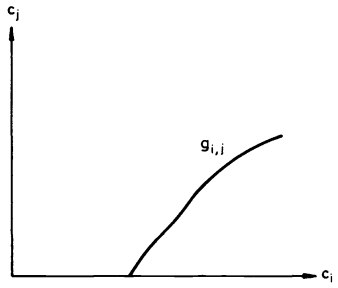

FIG. 2.5

construction of the solution of the general Riemann problem will thereafter be performed by composing different elementary waves and constant states.

Any weak solution of the pure initial value problem for (1.1), with initial conditions of the form (1.3), depends only on the variable x/t. The rarefaction waves are the possible smooth solutions. Let $u(x, t) = (s, c)(x, t) = v(x/t)$ be a smooth solution of (1.1), (1.2). It is well known that the values of v must lie on an integral curve of one of the (right) eigenvectors of the matrix $A(v)$, while $\xi = x/t$ is the corresponding eigenvalue $\lambda(v)$. Thus $\lambda(v(\xi))$ must increase monotonically with ξ. The requirement gives a direction, corresponding to increasing values of $\xi = x/t$, associated with the integral curves. These directed integral curves are called *rarefaction curves.*

To determine the rarefaction curves we have to find the eigenvectors of the matrix $A(v)$. If the eigenvalue $\lambda = \lambda_s = f_s$ then the corresponding eigenvector r is given by $r = (1, 0)$ (i.e., $c_i = 0$ for $i = 1, 2, \cdots, n$). Hence, the associated integral curves are the curves c-constant. The associated rarefaction waves correspond to rarefaction waves of the single Buckley–Leverett equation

$$s_t + f(s)_x = 0, \tag{3.1}$$

where $f(s) = f(s, c)$, $c =$ constant. These waves are referred to as *s-rarefactions.*

If $\lambda = \lambda_i$ for some i then the vector c will be nonconstant along the associated integral curves. These rarefaction waves will therefore be referred to as *c-rarefactions.* An eigenvector corresponding to $\lambda = \lambda_i$ is given by

$$r_i = f_i(1, 0) + (\lambda_i - \lambda_s)(0, e_i), \tag{3.2}$$

where e_i denotes the ith unit vector in $\mathbb{R}^n$ and $(1, 0)$ is the first unit vector in $\mathbb{R}^{n+1}$.

Hence, the associated integral curves are determined by

$$f_i \frac{dc_i}{ds} = \lambda_i - \lambda_s, \qquad c_j = \text{constant for } j \neq i, \tag{3.3}$$

where $c_i = c_i(s)$. Since $f_i(s, c) < 0$ for $0 < s < 1$ this implies that $dc_i/ds > 0$ when $\lambda_s > \lambda_i$ and that $dc_i/ds < 0$ when $\lambda_s < \lambda_i$. Furthermore, a straightforward calculation shows that

$$\frac{d\lambda_i}{ds} = -\frac{\lambda_i}{s + h_i} \frac{dh_i}{dc_i} \frac{dc_i}{ds}$$

along the integral curves. Since $dh_i/dc_i < 0$, this implies that the rarefaction curves are directed toward increasing values of c_i (cf. Fig. 3.1). If $\lambda = \lambda_i = \lambda_j$ for $i \neq j$ then any linear combination of the eigenvectors r_i and r_j given by (3.2) corresponds to an eigenvector associated with this eigenvalue. Furthermore, if such an eigenvector is

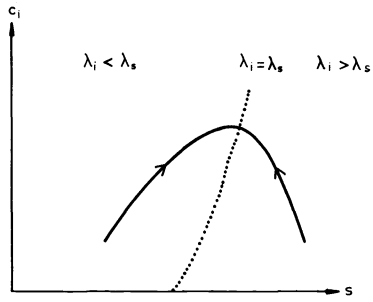

FIG. 3.1

tangential to the surface $\lambda_i = \lambda_j$, the corresponding integral curve is a curve on the surface $\lambda_i = \lambda_j$. Hence, if we choose

$$r = \left(f_i + f_j \frac{dg_{i,j}}{dc_i}\right)(1, 0) + (\lambda - \lambda_s)\left[(0, e_i) + \frac{dg_{i,j}}{dc_i}(0, e_j)\right]$$

we obtain the integral curve

$$\begin{aligned} &\left(f_i + f_j \frac{dg_{i,j}}{dc_i}\right)\frac{dc_i}{ds} = \lambda - \lambda_s, \\ &c_j = g_{i,j}(c_i), \\ &c_k = \text{constant for } k \neq i, j, \end{aligned} \tag{3.4}$$

where $c_i = c_i(s)$. This is a curve on the surface $\lambda_i = \lambda_j$. Since $f_i + f_j(dg_{i,j}/dc_i) < 0$ for $0 < s < 1$, the same analysis as above shows that the projection of the integral curves into (s, c_i)-space have the form illustrated in Fig. 3.1. In particular, the variable c_i is increasing in the direction of the rarefaction curves.

The rarefaction curves generated by (3.4), where $\lambda_i = \lambda_j$, will be referred to as c-rarefactions of multiplicity two. The analysis above can easily be generalized to *c-rarefactions of multiplicity $m+1$* on the surface $\lambda_i = \lambda_{j_1} = \lambda_{j_2} = \cdots = \lambda_{j_m}$. These curves are determined by the system

$$\begin{aligned} &\left(f_i + \sum_{j \in J} f_j \frac{dg_{i,j}}{dc_i}\right)\frac{dc_i}{ds} = \lambda - \lambda_s, \\ &c_j = g_{i,j}(c_i) \quad \text{for } j \in J, \\ &c_k = \text{constant} \quad \text{for } k \neq i \text{ and } k \notin J, \end{aligned}$$

where J denotes the index set $J = \{j_1, j_2, \cdots, j_m\}$. As above these rarefaction curves are directed toward increasing values of c_i (and $c_{j_1}, \cdots, c_{j_m}$), and the projection of the curves into (s, c_i)-space have the form illustrated by Fig. 3.1.

We next determine the shock waves of the model (1.1); i.e., for given states $u^L, u^R \in \mathbb{I}^{n+1}$ we derive possible weak solutions of (1.1) of the form

$$u(x, t) = \begin{cases} u^L & \text{if } x/t < \sigma, \\ u^R & \text{if } x/t > \sigma, \end{cases} \tag{3.5}$$

where σ is the shock speed. We will also require that the shock waves satisfy an "entropy condition."

Any weak solution of (1.1) of the form (3.5) must satisfy the Rankine-Hugoniot condition given by

$$
\begin{aligned}
&f(s^R, c^R) - f(s^L, c^L) = \sigma(s^R - s^L),\\
&c_i^R f(s^R, c^R) - c_i^L f(s^L, c^L) = \sigma[s^R c_i^R + a_i(c_i^R) - s^L c_i^L - a_i(c_i^L)]\\
&\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{for } i = 1, 2, \cdots, n.
\end{aligned} \tag{3.6}
$$

If $c^R = c^L$ (i.e., $c_i^R = c_i^L$ for $i = 1, 2, \cdots, n$), then (3.6) reduces to the single equation

$$f(s^R, c) - f(s^L, c) = \sigma(s^R - s^L), \tag{3.7}$$

where $c = c^R = c^L$. This corresponds to the Rankine-Hugoniot condition for the single Buckley-Leverett equation (3.1). Corresponding to the theory for scalar conservation laws, shock waves of this form satisfy an entropy condition if and only if

$$[f(s, c) - f(s^L, c) - \sigma(s - s^L)] \operatorname{sign}(s - s^L) \geqq 0 \tag{3.8}$$

for any s between s^L and s^R (cf. [9], [12], [15] and references given therein). These shocks, with $c = c^R = c^L$ and which satisfy (3.7) and (3.8), are referred to as *s-shocks.*

Consider the Rankine-Hugoniot relations (3.6) when $c^L \neq c^R$. Shock waves of this form will be referred to as *c-shocks.* If $c_i^L \neq c_i^R$ for some i, and $c_j^L = c_j^R$ for $j \neq i$, the relations (3.6) can be written in the following form (cf. [9]):

$$\frac{f(s^R, c^R)}{s^R + h_i^L(c_i^R)} = \frac{f(s^L, c^L)}{s^L + h_i^L(c_i^R)} = \sigma, \tag{3.9}$$

where $h_i^L(c_i)$ is defined by

$$h_i^L(c_i) = \begin{cases} (a_i(c_i) - a_i(c_i^L))/(c_i - c_i^L) & \text{if } c_i \neq c_i^L, \\ h_i(c_i) & \text{if } c_i = c_i^L. \end{cases}$$

We observe that the value $h_i^L(c_i^R)$ is determined from the values of c_i^L and c_i^R and that, if s^L, c^L, and c^R are given, there are at most two values of s^R that satisfy the relation (3.9) (cf. Fig. 3.2).

In [9] the entropy conditions for the c-shocks have been derived from a traveling wave analysis. Here, it suffices to simply state the result of a corresponding analysis. For the c-shocks, with $c_i^L \neq c_i^R$ and $c_j^L = c_j^R$ for $j \neq i$, the entropy conditions are

$$c_i^L > c_i^R \tag{3.10}$$

and

$$\lambda_s(u^R) < \sigma \quad \text{or} \quad \lambda_s(u^L), \lambda_s(u^R) \geqq \sigma. \tag{3.11}$$

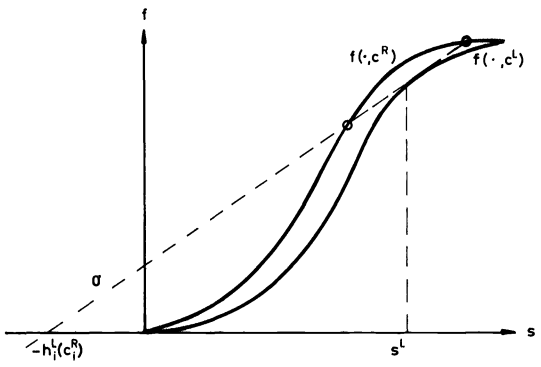

FIG. 3.2

Since the function h_i is strictly decreasing, relation (3.9) implies that (3.10) is equivalent to the eigenvalue/shock speed relation

$$\lambda_i(u^L) > \sigma > \lambda_i(u^R).$$

Hence, if in addition

$$\lambda_s(u^L) \geqq \sigma > \lambda_s(u^R),$$

then we do allow overcompressive shocks where both characteristics on both sides of the shock enter the shock (cf. Schaeffer and Schearer [14]). An example of such a shock wave is illustrated in Fig. 3.3.

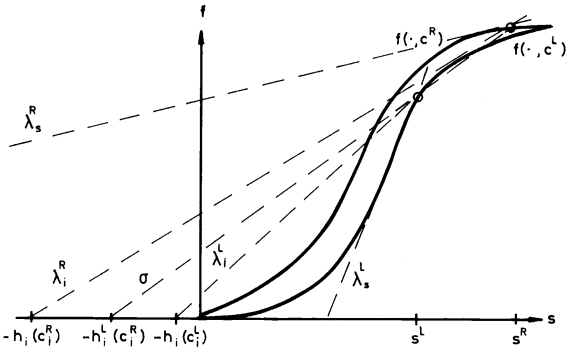

FIG. 3.3. *Overcompressive shock.*

We recall from [9] that when $n = 1$ an overcompressive shock can never be joined to another wave in a Riemann solution. As we will see below, this will not be the case when $n > 1$.

The c-shocks described above, with $c_i^L \neq c_i^R$, $c_j^L = c_j^R$ for $j \neq i$ and that satisfy (3.9), (3.10), and (3.11) will be referred to as c-shocks with multiplicity one. Shock waves where $c_i^L \neq c_i^R$, $c_{j_1}^L \neq c_{j_2}^R, \cdots, c_{j_m}^L \neq c_{j_m}^R$, and $c_k^L = c_k^R$ for $k \neq i, j_1, \cdots, j_m$ will be referred to as c-shocks with multiplicity $m+1$. In this case we obtain from (3.6) that (3.9) must hold for the index i and for any $j \in J$, where $J = \{j_1, j_2, \cdots, j_m\}$. Hence, in this case the Rankine–Hugoniot condition can be written as

$$\frac{f(s^R, c^R)}{s^R + h} = \frac{f(s^L, c^L)}{s^L + h} = \sigma, \tag{3.12}$$

where

$$h_j^L(c_j^R) = h_i^L(c_i) \equiv h \quad \text{for } j \in J. \tag{3.13}$$

We therefore observe that the structure of a shock with multiplicity $m+1$ is similar to the structure of a c-shock with multiplicity one, with the additional requirement that the relation (3.13) holds. The entropy condition for a shock with multiplicity $m+1$ is similar to (3.10) and (3.11) above, but where (3.10) is replaced by

$$c_i^L > c_i^R, \qquad c_j^L > c_j^R \quad \text{for } j \in J.$$

Finally in this section, let us consider the possible c-waves when $s = 0$ or $s = 1$. If $s = 0$ the i-rarefaction curves will simply be the lines $s = 0$, $c_j = \text{constant}$ for $j \neq i$. Furthermore, along these lines the eigenvalue λ_i is identically equal to zero. Similarly, if $s^L = s^R = 0$ the Rankine–Hugoniot condition (3.9) is satisfied with $\sigma = 0$. Hence, the

curves $s=0$, $c_j=$ constant for $j\neq i$, correspond to contact discontinuities with $\sigma=0$ and with two allowed directions. If $s=1$ the i-rarefaction curves are the lines $s=1$, $c_j=$ constant for $j\neq i$, but now the eigenvalue λ_i is given by

$$\lambda_i=\frac{1}{1+h_i(c_i)}.$$

Hence, λ_i is an increasing function of c_i along the rarefaction curves. Similarly, for given values of c^L and c^R, where $c_i^L\neq c_i^R$ and $c_j^L=c_j^R$ for $j\neq i$, the states $(1, c^L)$ and $(1, c^R)$ correspond to a c-shock with speed $1/(1+h_i^L(c_i^R))$ if and only if $c_i^L>c_i^R$. The generalization of this description to c-waves of higher multiplicity is straightforward.

4. The projection principle. A solution of a Riemann problem for the model (1.1) consists of a sequence of elementary waves that connects the left state u^L and the right state u^R. We will adopt the notation that $u^1\to u^2$ means that the left state u^1 can be connected to the right state u^2 by an elementary wave. Two elementary waves $u^1\xrightarrow{a}u^2$ and $u^2\xrightarrow{b}u^3$ are said to be *compatible* if they can be composed to solve the Riemann problem with left state u^1 and right state u^3. Hence, the two waves are compatible if and only if the final speed of the a-wave is less than or equal to the initial speed of the b-wave. Furthermore, we require a strict inequality if both waves are shock waves.

Any compatible composition of s-rarefactions and s-shocks that corresponds to a solution of the Buckley–Leverett equation (3.1) with $f=f(\cdot, c)$ for some $c\in I^n$ is referred to as an *s-wave*. We recall from the theory of the Buckley–Leverett equation that for a given left state $u^1=(s^1, c^1)$ and a given right state $u^2=(s^2, c^2)$, where $c^1=c^2=c$, there always exists a unique s-wave that connects u^1 and u^2. Furthermore, this s-wave can be constructed from a lower convex or an upper concave envelope of the function $f=f(\cdot, c)$ (cf. [9] and references given therein). This s-wave will simply be denoted by $u^1\xrightarrow{s}u^2$. A c-wave is either a c-rarefaction or a c-shock. A c-wave that connects the left state u^1 with the right state u^2 is denoted by $u^1\xrightarrow{c}u^2$.

Associated with the two-phase problem (1.1) we consider the one-phase problem given by

$$(c_i+a_i(c_i))_t+(c_i)_x=0,\qquad i=1, 2, \cdots, n. \tag{4.1}$$

This model, which is an $n\times n$ system of conservation laws, describes a one-phase flow including the same n components as the model (1.1). We observe that the n equations of (4.1) are completely decoupled. Therefore, the rarefaction waves and the shock waves of (4.1) are determined by n scalar equations. In particular, the rarefaction waves are of the form

$$c_i^L<c_i^R,\qquad \xi\equiv\frac{x}{t}=\frac{1}{1+h_i(c_i)} \tag{4.2}$$

and the shock waves of the form

$$c_i^L>c_i^R,\qquad \xi\equiv\frac{x}{t}=\frac{1}{1+h_i^L(c_i^R)}. \tag{4.3}$$

The system (4.1) is in general not strictly hyperbolic, since it might occur that $h_i(c_i)=h_j(c_j)$ for $i\neq j$. Also observe that, for any c-wave of the system (1.1), we obtain an elementary wave of (4.1) by projecting the wave curve into c-space and by letting the speed $\xi=x/t$ be given by (4.2) or (4.3). Hence, if

$$(s^1, c^1)\xrightarrow{c}(s^2, c^2)$$

is a c-wave for (1.1), we obtain a projected elementary wave for the associated system (4.1). This wave will be denoted by $c^1 \xrightarrow{P(c)} c^2$.

The following lemma explains the importance of the system (4.1) for the construction of the solution of the Riemann problem for the system (1.1).

LEMMA 4.1. *Assume that the three waves*

$$(s^L, c^L) \xrightarrow{c_1} (s^1, c) \xrightarrow{s} (s^2, c) \xrightarrow{c_2} (s^R, c^R)$$

are compatible for the system (1.1). *Then the two waves*

$$c^L \xrightarrow{P(c_1)} c \xrightarrow{P(c_2)} c^R$$

are compatible for the corresponding system (4.1).

Proof. Let $h_1, h_2 > 0$ be such that the final speed of the c_1-wave, v_1^f, and the initial speed of the c_2-wave , v_2^i, are given by

$$v_1^f = \frac{f(s^1, c)}{s^1 + h_1} \quad \text{and} \quad v_2^i = \frac{f(s^2, c)}{s^2 + h_2}.$$

By exactly the same argument as was used in the proof of Lemma 5.1 of [9], we then deduce that $h_1 \geqq h_2$ or

$$\frac{1}{1+h_1} \leqq \frac{1}{1+h_2}.$$

Hence, the final speed of $P(c_1)$ is less than or equal to the initial speed of $P(c_2)$. □

A consequence of the lemma above is that, if a solution of the Riemann problem for (1.1) with left state (s^L, c^L) and right state (s^R, c^R) is given, then the projection of the wave curves into c-space corresponds to a solution of the Riemann problem for the associated system (4.1) with data c^L and c^R. Furthermore, since (4.1) is a decoupled system, the Riemann problem for (4.1) has a unique solution for any values of c^L and c^R in $\mathbb{I}^n$. In each component the solution either consists of a single rarefaction wave or a single shock wave. The solution for the complete system is therefore obtained by superimposing the x, t-diagrams corresponding to each component (cf. Fig. 4.1). In particular we observe that the wave cones corresponding to the different components may overlap.

We have therefore seen that for any given Riemann problem for (1.1), the only possible projection of the wave curves of the solution into c-space can be determined by solving n scalar Riemann problems (cf. Figs. 4.1 and 4.2).

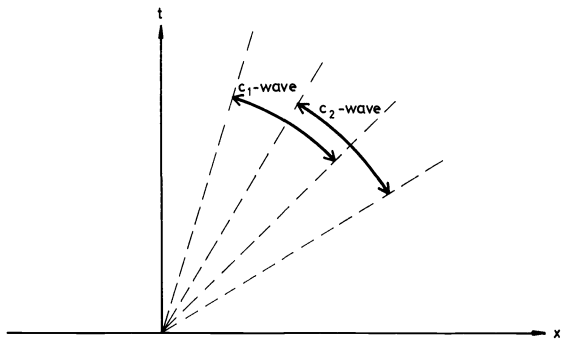

FIG. 4.1. *Component wave cones.*

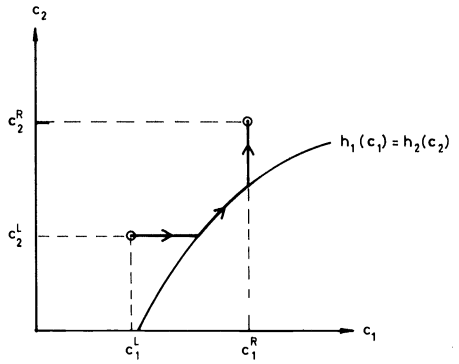

FIG. 4.2. *Projection of wave curves.*

In our construction of the solution of the Riemann problem for (1.1) we will utilize the fact that the projection of the wave curves of the solution into c-space can be easily determined. Our strategy will be first to compute the solution of the associated Riemann problem for (4.1) and thereafter the complete Riemann solution for (1.1) will be constructed from the computed sequence of projected wave curves.

5. The solution of the Riemann problem. The purpose of this section is to present the construction of the solution of the Riemann problem for the model (1.1) for arbitrary left and right states in $\mathbb{I}^{n+1}$. As above, we let $u^L = (s^L, c^L)$ and $u^R = (s^R, c^R)$ denote the left and right states, respectively. We already know from Lemma 4.1 that if a solution of the Riemann problem for (1.1) exists, then the projection of the wave curves into c-space must correspond to the wave curves of the unique solution of a Riemann problem for the corresponding model (4.1). Hence, the projection of the wave curves into c-space will form a path in c-space. This path will be referred to as the *composition path* or simply the *c-path.*

Since the c-path can easily be derived by solving n scalar Riemann problems, we will assume throughout this section that this path is given. In particular this means that c^L and c^R are fixed and that the data of the Riemann problem only varies with s^L and s^R.

In most of the discussion below we will also assume that the wave cones in x, t-space, corresponding to the Riemann solutions of the different components of (4.1), do not overlap. Hence, if the c-components are ordered with respect to increasing wave speed, we assume that

$$v_1^i \leqq v_1^f \leqq v_2^i \leqq \cdots \leqq v_n^i \leqq v_n^f, \tag{5.1}$$

where v_j^i and v_j^f denote the initial and final speed of the wave which solves the Riemann problem for the jth component of (4.1) (cf. Fig. 5.1). The assumption will be removed at the end of this section.

A consequence of (5.1) is that no c-wave occurring in the Riemann solution of (1.1) has multiplicity greater than one, i.e., no $(i, j_1, \cdots, j_m)$ wave with $m > 0$ is included in the solution. In particular, the c-path consists of n straight lines parallel to the axis. The solution of the Riemann problem for (1.1) will therefore be located in a region of (s, c)-space which can be considered as n strips in $\mathbb{R}^2$ as illustrated in Fig. 5.2, where the line $c_i = c_i^R$ is identified with the line $c_{i+1} = c_{i+1}^L$. This region will be referred to as the state space associated to the given c-path. Each state (s, c_i) in the ith strip of this region can be joined to other states by either an s-wave (i.e., $c_i = \text{const.}$) or a

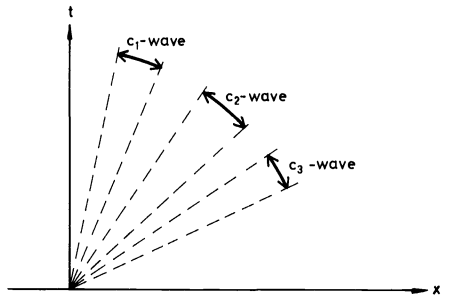

FIG. 5.1. $n=3$.

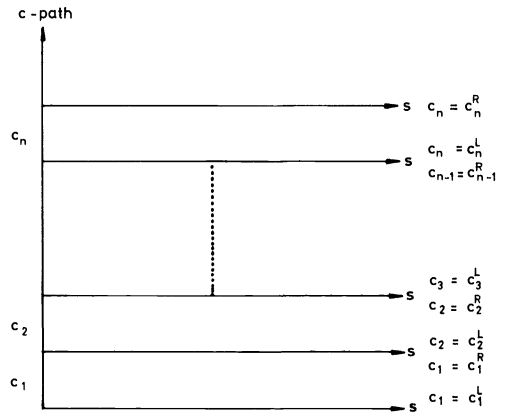

FIG. 5.2. *The state space associated with c-path.*

c-wave. The admissible c-waves are all directed upwards on Fig. 5.2. The c-waves in the ith strip are i-rarefaction if $c_i^L < c_i^R$ and i-shocks if $c_i^L > c_i^R$.

For each strip of the state space we can associate a transition curve T_i. First, for any c_i between c_i^L and c_i^R we define the associated wave speed by

$$\sigma_i(s, c_i) = \begin{cases} \dfrac{f(s, c_i)}{s + h_i(c_i)} & \text{if } c_i^L < c_i^R, \\ \dfrac{f(s, c_i)}{s + h_i^L(c_i^R)} & \text{if } c_i^L > c_i^R, \end{cases}$$

where here and below $f(s, c_i)$ denotes the value $f(s, c_1^R, \cdots, c_{i-1}^R, c_i, c_{i+1}^L, \cdots, c_n^L)$. The transition curve T_i in the ith strip is defined from the relation

$$\sigma_i(s, c_i) = f_s(s, c_i); \tag{5.2}$$

i.e., $(s, c_i) \in T_i$ if and only if $s > 0$ and (5.2) holds. For each value of c_i there is at most one value of s, called $s_i^T(c_i)$, such that $(s_i^T, c_i) \in T_i$. If no such value of s exists, we let $s_i^T(c_i) = +\infty$. We note that if $c_i^L < c_i^R$, i.e., the i-waves are rarefaction waves, the transition curve T_i corresponds exactly to the curve where $\lambda_i = \lambda_s$ (cf. § 2). On the lines $c_i = c_i^R$ or $c_{i+1} = c_{i+1}^L$ there are two possible values of s^T, $s_i^T(c_i^R)$ and $s_{i+1}^T(c_{i+1}^L)$, corresponding to the strip below and above this line. Assumption (5.1) implies that

$$s_i^T(c_i^R) \geqq s_{i+1}^T(c_{i+1}^L). \tag{5.3}$$

The transition curves T_i, in the n strips of the state space associated to the given c-path, are therefore located as illustrated in Fig. 5.3.

To construct the solution of the global Riemann problem we have to characterize the possible compatible compositions of elementary waves. In each strip of the state space this analysis corresponds to the analysis given in [9] for the case $n = 1$. To state the desired results from [9] we need some notation. For each state (s, c_i) in the ith strip of the state space we define the associated critical value $s_i^K(s, c_i)$ from the relation

$$\sigma_i(s_i^K, c_i) = \sigma_i(s, c_i). \tag{5.4}$$

If $s \geqq s_i^T(c_i)$, s_i^K is the unique value such that $s_i^K \leqq s_i^T(c_i)$ and such that (5.4) holds (cf. Fig. 5.4). If $s \leqq s_i^T(c_i)$, s_i^K is either the unique value greater than or equal to $s_i^T(c_i)$ such that (5.4) holds, or, if no such s_i^K exists, we let $s_i^K = +\infty$.

Now consider possible compositions of pairs of waves of the forms

$$(s^1, c_i^1) \xrightarrow{c} (s^M, c_i^2) \xrightarrow{s} (s^2, c_i^2) \tag{5.5}$$

and

$$(s^1, c_i^1) \xrightarrow{s} (s^M, c_i^1) \xrightarrow{c} (s^2, c_i^2) \tag{5.6}$$

in the ith strip of state space. Necessary and sufficient conditions for the compatibility of these compositions can be obtained directly from the analysis given in [9]. However,

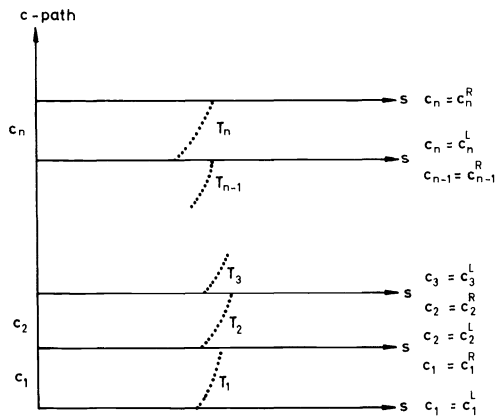

FIG. 5.3

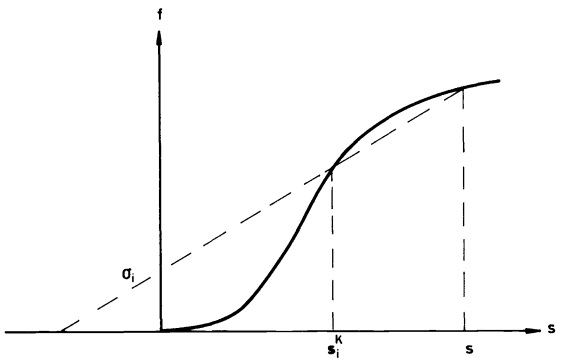

FIG. 5.4

to make these conditions as simple as possible, we will make a minor change in terminology with respect to the overcompressive c-shocks.

The admissible overcompressive shocks have the property that

$$\lambda_i^L > \sigma > \lambda_i^R \quad \text{and} \quad \lambda_s^L \geqq \sigma > \lambda_s^R,$$

where λ^L and λ^R denote eigenvalues to the left and to the right of the shock, respectively. They are illustrated in Fig. 3.3. These shocks may be thought of as a composition of a c-shock and an s-shock with the same speed. Usually such compositions are not allowed. However, in the analysis below, statements about the compatibility of compositions of elementary waves will simplify if we do allow compositions of two shocks with the same speed starting with a c-shock and do not allow the overcompressive c-shocks. With this change in terminology the overcompressive c-shocks are described as a composition of the form (5.5). Furthermore, the entropy condition for the allowed c-shock takes the form

$$\lambda_i^L > \sigma > \lambda_i^R \quad \text{and} \quad \lambda_s^L, \lambda_s^R \geqq \sigma \quad \text{or} \quad \lambda_s^L, \lambda_s^R < \sigma.$$

This change of terminology is used in all the lemmas below. The following result is now a direct consequence of Lemmas 6.1 and 7.1 of [9].

LEMMA 5.1. *Consider a composition of a c-wave and an s-wave in the ith strip of state space.*

(i) *The composition* (5.5) *is compatible if and only if*

$$s^M \leqq s_i^T(c_i^2) \quad \textit{and} \quad 0 \leqq s^2 \leqq s_i^K(s^M, c_i^2).$$

(ii) *The composition* (5.6) *is compatible if and only if*

$$s^M \geqq s_i^T(c_i^1) \quad \textit{and} \quad s_i^K(s^M, c_i^1) \leqq s^1 \leqq 1.$$

Remark. If we had not changed the terminology as described above, the statements of the lemma above would only be correct if the admissible c-waves in the ith strip were rarefaction waves. If the c-wave is a shock the proper condition for composition (5.5) is

$$s^M \leqq s_i^T(c_i^2) \quad \text{and} \quad 0 \leqq s^2 < s_i^K(s^M, c_i^2),$$

while the case $s^2 = s_i^K(s^M, c_i^2)$ corresponds to an overcompressive shock from (s^1, c_i^1) to (s^2, c_i^2). Similarly, the proper condition for (5.6) is

$$s^M \geqq s_i^T(c_i^1) \quad \text{and} \quad s_i^K(s^M, c_i^1) < s^1 \leqq 1.$$

We also note that when the c-wave is a shock, the compositions (5.5) and (5.6) only occur when $c_i^1 = c_i^L$ and $c_i^2 = c_i^R$.

Consider next the composition of three waves of the form

$$\xrightarrow{c} (s^1, c_i^M) \xrightarrow{s} (s^2, c_i^M) \xrightarrow{c}$$

on the ith strip, where we assume that $c_i^L < c_i^R$ such that the c-waves are rarefactions. If $c_i^L < c_i^M < c_i^R$ it follows from Lemma 5.1 that this composition is compatible if and only if

$$s^1 \leqq s_i^T(c_i^M), \quad s^2 \geqq s_i^T(c_i^M), \quad s^2 = s_i^K(s^1, c_i^M).$$

However, at the intersections of two strips, where the transition curve is discontinuous, there are more possibilities. Consider a composition of the form

$$\xrightarrow{c} (s^1, c_i^R) \xrightarrow{s} (s^2, c_{i+1}^L) \xrightarrow{c}. \tag{5.7}$$

The precise conditions for the compatibility of (5.7) can be derived by combining statements (i) and (ii) of Lemma 5.1. We summarize this result in the following lemma.

LEMMA 5.2. *The composition* (5.7) *is compatible if and only if either*

$$s^1 \leqq s_{i+1}^T(c_{i+1}^L) \quad \textit{and} \quad s^2 \in [s_{i+1}^K(s^1, c_{i+1}^L), s_i^K(s^1, c_i^R)]$$

or

$$s^1 \in [s_{i+1}^T(c_{i+1}^L), s_i^T(c_i^R)] \quad \textit{and} \quad s^2 \in [s_{i+1}^T(c_{i+1}^L), s_i^K(s^1, c_i^R)].$$

The two cases of the lemma are illustrated in Figs. 5.5 and 5.6.

Before we proceed to construct the solution of the Riemann problem for (1.1) we will first review the main structure of the solution in the case when $n = 1$. For a more precise description of this solution we refer to [9]. Consider first the case when $c_1^L < c_1^R$, i.e., when the c-waves are rarefactions. We divide this case further into two subcases.

First, assume that $s^L < s_1^T(c_1^L)$ and that the rarefaction curve through the point (s^L, c_1^L) intersects the line $c_1 = c_1^R$ at a point $(\hat{s}, c_1^R)$, where $\hat{s} \leqq s_1^T(c_1^R)$. Typical solutions of the Riemann problem, depending on the location of s^R, are illustrated in Fig. 5.7, where $\hat{s}^K = s_1^K(\hat{s}, c_1^R)$. In particular, the Riemann solution terminates with a c-wave if and only if $s^R = \hat{s}$ and $s^R > \hat{s}^K$.

The second subcase occurs when either $s^L > s_1^T(c_1^L)$ or $s^L \leqq s_1^T(c_1^L)$, but the rarefaction curve through (s^L, c_1^L) intersects the transition curve at $c_1 = c_1^*$, where $c_1^* < c_1^R$. Examples of Riemann solutions in this case are illustrated in Figs. 5.8(a) and 5.8(b). In particular, the solution terminates with a c-wave if and only if $s^R \geqq s_1^T(c_1^R)$. Hence, if we let $\hat{s} = \hat{s}^K = s_1^T(c_1^R)$ in this latter case, we conclude that, if the c-waves are rarefaction waves, the unique solution of the Riemann problem terminates with a c-wave if and only if $s^R = \hat{s}$ or $s^R > \hat{s}^K$.

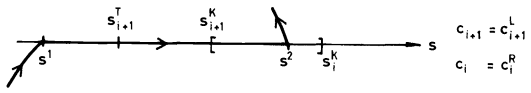

FIG. 5.5. $s^1 \leqq s_{i+1}^T(c_{i+1}^L)$.

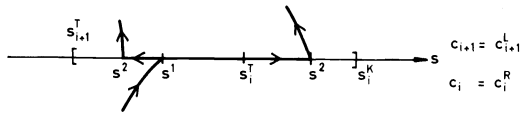

FIG. 5.6. $s_{i+1}^T < s^1 < s_i^T$.

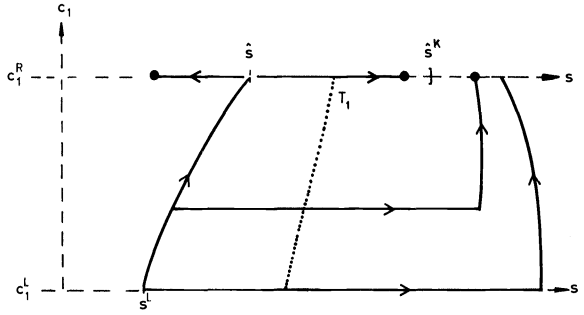

FIG. 5.7

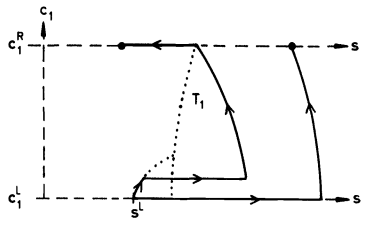

FIG. 5.8(a). $s^L \leqq s_1^T(c_1^L)$.

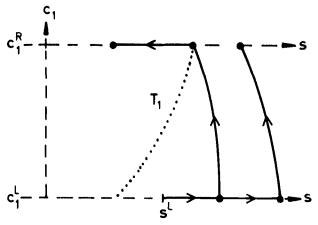

FIG. 5.8(b). $s^L > s_1^T(c_1^L)$.

Consider next the case when $n=1$ and $c_1^L > c_1^R$. Again this case is divided into two subcases. If $s^L \leqq s_1^T(c_1^L)$ there is always a unique value $\hat{s}$ such that $\hat{s} \in s_1^T(c_1^R)$ and such that

$$(s^L, c_1^L) \xrightarrow{c} (\hat{s}, c_1^R)$$

is a c-shock. Let $\hat{s}^K = s_1^K(\hat{s}, c_1^R)$. The different Riemann solutions in this case are illustrated in Fig. 5.9.

Finally, if $s^L > s_1^T(c_1^L)$ let s_1^- be the unique value $s_1^- < s_1^T(c_1^R)$ such that

$$(s_1^T(c_1^L), c_1^L) \xrightarrow{c} (s_1^-, c_1^R)$$

is a c-shock. Furthermore, let $s_1^+ = s_1^K(s_1^-, c_1^R)$. The different possible Riemann solutions are illustrated in Fig. 5.10.

Hence, if we let $\hat{s} = s_1^-$ and $\hat{s}^K = s_1^+$ in this latter case, the structure of Riemann solutions in the shock case has the property that it terminates with a c-shock if and only if $s^R = \hat{s}$ or $s^R > \hat{s}^K$. We have therefore seen that this property of the Riemann solution is shared both by the rarefaction case and the shock case.

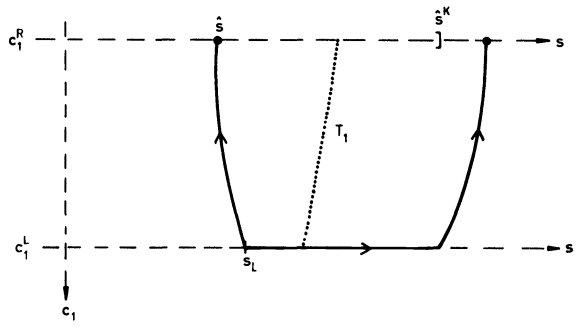

FIG. 5.9

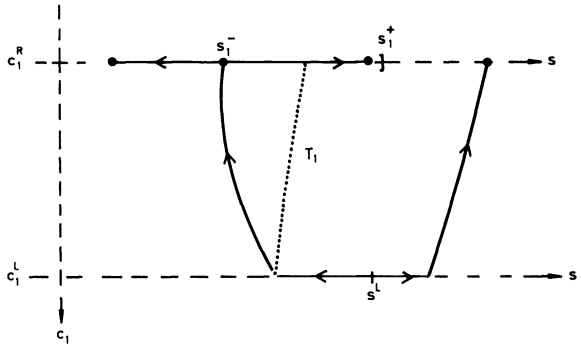

FIG. 5.10

(We remark again that the correctness of this description of the Riemann solution depends on the change of terminology introduced at the beginning of this section. A more correct description of the solution in the shock case is that it terminates with a c-shock if and only if $s^R = \hat{s}$ or $s^R \geqq \hat{s}^K$.)

Let us return to the case when $n > 1$. Motivated by the structure of the Riemann solution above, we introduce some extra notation. If the i-waves are shocks, we define s_i^- as the unique value satisfying

$$s_i^- < s_i^T(c_i^R) \text{ and such that } (s_i^T(c_i^L), c_i^L) \xrightarrow{c} (s_i^-, c_i^R)$$

corresponds to a c-shock. Furthermore, we let $s_i^+ = s_i^K(s_i^-, c_i^R)$. The location of these points on the line $c_i = c_i^R$ and $c_{i+1} = c_{i+1}^L$ are illustrated in Fig. 5.11. The two s_i^--points indicate that s_i^- can be located on any side of T_{i+1}, but always to the left of T_i. In particular,

$$s_i^+ \geqq s_i^T(c_i^R) \geqq s_{i+1}^T(c_{i+1}^L),$$

while s_i^- can be greater than or less than $s_{i+1}^T(c_{i+1}^L)$. If the i-waves are rarefactions we let $s_i^- = s_i^+ = s_i^T(c_i^R)$.

We are now in a position to construct the general solution of the Riemann problem for (1.1).

We recall again that since c^L and c^R are considered fixed, the data of the Riemann problem only varies with s^L and s^R.

LEMMA 5.3. *Assume that the associated Riemann solution of* (4.1) *satisfies condition* (5.1). *The Riemann problem for* (1.1) *has a unique solution for arbitrary* s^L *and* s^R. *Furthermore, for any given* s^L *there exist values* $\hat{s}$ *and* $\hat{s}^K$, *with* $\hat{s} \leqq s_n^-$ *and* $\hat{s}^K \geqq s_n^+$, *such that the Riemann solution terminates with c-wave if and only if*

$$s^R = \hat{s} \quad \text{or} \quad s^R > \hat{s}^K.$$

Here $\hat{s}$ *and* $\hat{s}^K$ *are related by* $\hat{s}^K = s_n^K(\hat{s}, c_n^R)$.

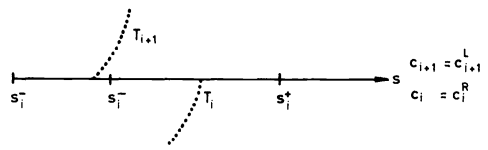

FIG. 5.11

Proof. The proof uses induction on n. We have already seen in the discussion above that the result holds for $n=1$. Assume that the result holds for $n-1$; i.e., any states (s^L, c_1^L) and (s^R, c_{n-1}^R) can be connected by a unique composition of compatible elementary waves.

Throughout the rest of the proof we consider s^L as fixed. By the induction hypothesis there exist values $\hat{s}_{n-1}$ and $\hat{s}_{n-1}^K$, where $\hat{s}_{n-1} \leqq s_{n-1}^-$ and $\hat{s}_{n-1}^K = s_{n-1}^K(\hat{s}_{n-1}, c_{n-1}^R)$, such that a Riemann solution that connects (s^L, c_2^L) to (s^R, c_{n-1}^R) terminates with a c-wave if and only if $s^R = \hat{s}_{n-1}$ or $s^R > \hat{s}_{n-1}^K$.

To show that the desired result holds for n, we have to construct the Riemann solution for any right state (s^R, c_n^R) and to show that this solution is unique. In the analysis below we will concentrate our effort on the construction of a solution. The uniqueness of this solution can easily be established in all cases by applying the results of Lemmas 5.1 and 5.2. We will start the construction by identifying the desired values $\hat{s}$ and $\hat{s}^K$.

Assume first that the n-waves are rarefactions; i.e., assume that $c_n^L < c_n^R$. If $\hat{s}_{n-1} < s_n^T(c_n^L)$ and if the rarefaction curve through $(\hat{s}_{n-1}, c_n^L)$ intersects the line $c_n = c_n^R$, we let $\hat{s}$ be the unique value less than or equal to $s_n^T(c_n^R)$ such that the rarefaction curve intersects the line $c_n = c_n^R$ at $(\hat{s}, c_n^R)$. In this case the composition

$$(s^L, c_1^L) \Rightarrow (\hat{s}_{n-1}, c_{n-1}^R) \xrightarrow{c} (\hat{s}, c_n^R),$$

where here and below $\Rightarrow$ denotes the unique Riemann solution from the induction hypothesis, is a Riemann solution that terminates with a c-wave. If $\hat{s}_{n-1} \geqq s_n^T(c_n^L)$ or if no rarefaction curve connects $(\hat{s}_{n-1}, c_n^L)$ to the line $c_n = c_n^R$, we let $\hat{s} = s_n^T(c_n^R)$. To see that the Riemann solution with $s^R = \hat{s}$ terminates with a c-wave, in this case we let s_{n-1} be the unique value such that $s_{n-1} > s_n^T(c_n^L)$ and such that (s_{n-1}, c_n^L) and $(\hat{s}, c_n^R)$ are connected by a rarefaction curve (cf. Fig. 5.12).

If $s_{n-1} > \hat{s}_{n-1}^K$ it follows from the induction hypothesis that the solution

$$(s^L, c_1^L) \Rightarrow (s_{n-1}, c_{n-1}^R)$$

terminates with a c-wave. Therefore, the composition

$$(s^L, c_1^L) \Rightarrow (s_{n-1}, c_n^L) \xrightarrow{c} (s_n, c_n^R)$$

is compatible and terminates with a c-wave. If $s_{n-1} \leqq \hat{s}_{n-1}^K$ it follows from the result for $n=1$ that the unique compatible composition that connects $(\hat{s}_{n-1}, c_n^L)$ and $(\hat{s}, c_n^R)$ either starts and terminates with a c-wave or is of the form

$$(\hat{s}_{n-1}, c_n^L) \xrightarrow{s} (s_{n-1}, c_n^L) \xrightarrow{c} (\hat{s}, c_n^R). \tag{5.8}$$

In particular, the states are connected by waves of the form (5.8) only if $\hat{s}_{n-1} \geqq s_n^T(c_n^L)$ or if $s_{n-1} \in [s_n^K(\hat{s}_{n-1}, c_n^L), \hat{s}_{n-1}^K]$. But in these cases it follows from Lemma 5.2 and the

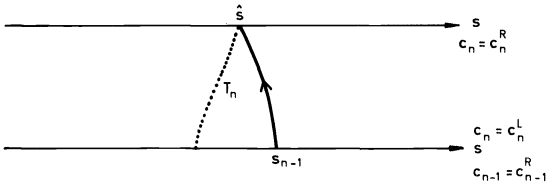

FIG. 5.12

induction hypothesis that the complete composition

$$(s^L, c_1^L) \Rightarrow (\hat{s}_{n-1}, c_n^L) \xrightarrow{s} (s_{n-1}, c_n^L) \xrightarrow{c} (\hat{s}, c_n^R)$$

is compatible (cf. Figs. 5.13 a,b). We have therefore seen that if the n-waves are rarefactions, then in all possible cases a value $\hat{s} \leqq s_n^T(c_n^R)$ can be constructed such that if $s^R = \hat{s}$ the Riemann solution terminates with a c-wave.

Consider next the case where the n-waves are shocks. If $\hat{s}_{n-1} \leqq s_n^T(c_n^L)$, we simply let $\hat{s}$ be the unique value such that $\hat{s} \leqq s_n^-$ and such that

$$(\hat{s}_{n-1}, c_n^L) \xrightarrow{c} (\hat{s}_n, c_n^R)$$

is a c-shock. If $\hat{s}_{n-1} > s_n^T(c_n^L)$, we let $\hat{s} = s_n^-$. Since it follows from Lemma 5.2 and the induction hypothesis that the composition

$$(s^L, c_1^L) \Rightarrow (\hat{s}_{n-1}, c_n^L) \xrightarrow{s} (s_n^T(c_n^L), c_n^L) \xrightarrow{c} (\hat{s}, c_n^R)$$

(cf. Fig. 5.14) is compatible, we have, in all cases where the n-waves are shocks, generated $\hat{s} \leqq s_n^-$ such that the Riemann solution with $s^R = \hat{s}$ terminates with a c-wave. Hence, we have completed the construction of the values $\hat{s}$ and $\hat{s}^K \equiv s_n^K(\hat{s}, c_n^R)$.

Furthermore, it follows from Lemma 5.1 that if the solution that connects (s^L, c_1^L) and $(\hat{s}, c_n^R)$ is extended by an s-wave of the form

$$(\hat{s}, c_n^R) \xrightarrow{s} (s^R, c_n^R),$$

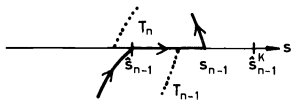

FIG. 5.13(a). $\hat{s}_{n-1} \geqq s_n^T(c_n^L)$.

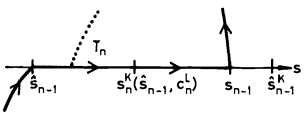

FIG. 5.13(b). $s_{n-1} \in [s_n^K(\hat{s}_{n-1}, c_n^L), \hat{s}_{n-1}^K]$.

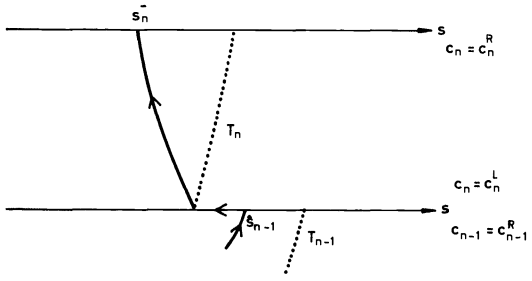

FIG. 5.14

then the complete composition is compatible as long as $s^R \leqq \hat{s}^K$. Hence, to complete the proof of the lemma, we have to construct a Riemann solution that terminates with a c-wave when $s^R > \hat{s}^K$. If $s^R > \hat{s}^K \geqq s_n^+$ there exists a unique value $s_{n-1} > s_n^T(c_n^L)$ such that

$$(s_{n-1}, c_n^L) \xrightarrow{c} (s^R, c_n^R)$$

is a c-wave (shock or rarefaction). If $s_{n-1} > \hat{s}_{n-1}^K$ the induction hypothesis implies that the Riemann solution is given by

$$(s^L, c_1^L) \Rightarrow (s_{n-1}, c_n^L) \xrightarrow{c} (s^R, c_n^R).$$

Otherwise, if $s_{n-1} \leqq s_{n-1}^K$ we first consider the compatible composition that connects $(\hat{s}_{n-1}, c_n^L)$ and (s^R, c_n^R). This composition either starts and terminates with a c-wave (this is only possible if $\hat{s}_{n-1} < s_n^T(c_n^L)$ and the n-waves are rarefactions) or it is of the form

$$(\hat{s}_{n-1}, c_n^L) \xrightarrow{s} (s_{n-1}, c_n^L) \xrightarrow{c} (s^R, c_n^R). \tag{5.9}$$

As above, the composition is of the form (5.9) only if $\hat{s}_{n-1} \geqq s_n^T(c_n^L)$ or if $s_{n-1} \in [s_n^K(\hat{s}_{n-1}, c_n^L), \hat{s}_{n-1}^K]$. Hence, Lemma 5.2 and the induction hypothesis imply that

$$(s^L, c_1^L) \Rightarrow (\hat{s}_{n-1}, c_n^L) \xrightarrow{s} (s_{n-1}, c_n^L) \xrightarrow{c} (s^R, c_n^R)$$

is a compatible composition of waves. We have therefore seen that the Riemann solution always terminates with a c-wave when $s^R > \hat{s}^K$. This completes the induction argument and therefore the proof of the lemma. □

The construction of the Riemann solution given above can be thought of as a "factorization" of the general Riemann problem associated with a given c-path. First, the values $\hat{s}_i$ and $\hat{s}_i^K$, for $i = 1, 2, \cdots, n$, are constructed from s^L and the given c-path. Thereafter, the Riemann solution is constructed from s^R and all the values $\hat{s}_i$ and $\hat{s}_i^K$. This interpretation of the proof makes a computer implementation of the construction rather attractive.

The proof of Lemma 5.3 above completes the discussion of the Riemann problem for (1.1) under the additional assumption (5.1). To remove this assumption, we finally do allow the wave cones, corresponding to the different components of the system (4.1), to overlap. Hence, c-waves of multiplicity greater than one may occur in the Riemann solution of (1.1). However, since the structure of such c-waves is similar to the structure of simple waves, their occurrence will not change the logical structure of the construction of the Riemann solution. The occurrence of c-waves of multiplicity greater than one will only increase the possible number of strips of the state space along the given c-path. For example, if $n = 2$ and the two wave cones intersect, the state space along the c-path will consist of three strips as illustrated in Figs. 5.15 and 5.16. Hence, by possibly increasing the number of strips to at most $2n - 1$, the construction given in the proof of Lemma 5.3 also applies when assumption (5.1) is removed. We have therefore established the main result of this paper.

THEOREM 5.1. *For arbitrary states* $u^L = (s^L, c^L) \in \mathbb{I}^{n+1}$ *and* $u^R = (s^R, c^R) \in \mathbb{I}^{n+1}$ *there exists a unique solution of the Riemann problem for the system* (1.1) *with left state* u^L *and right state* u^R.

Before we end this section we would like to point out one property of the Riemann solution constructed above. We recall from [9] that in the case when $n = 1$ an overcompressive shock can never join any other wave in a Riemann solution. However, it can

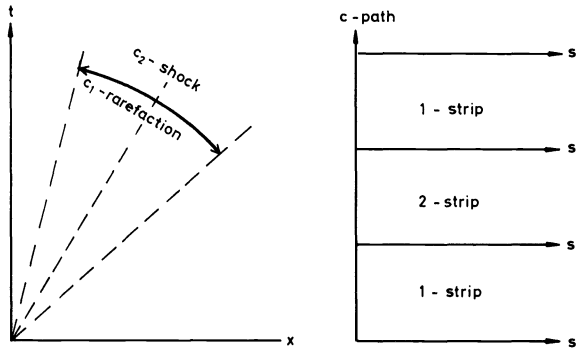

FIG. 5.15

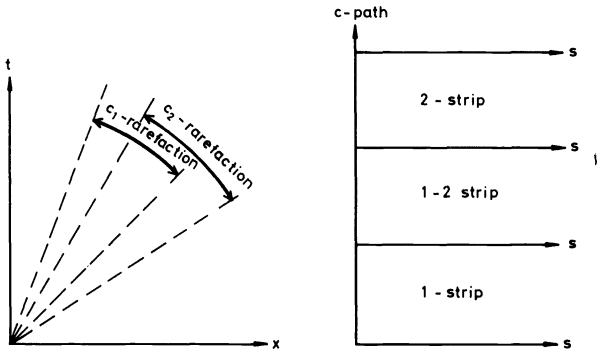

FIG. 5.16

be seen from the construction above that this property does not hold when $n > 1$. An example of a Riemann solution of the form

$$(s^L, c_1^L, c_2^L) \xrightarrow{c} (\bar{s}, c_1^R, c_2^L) \xrightarrow{c} (s^R, c_1^R, c_2^R),$$

where both c-waves are shocks and where the first shock is overcompressive, is illustrated in Fig. 5.17.

6. Conclusion. The solution of the general $(n+1)\times(n+1)$ Riemann problem for the model (1.1) has been constructed. The construction is based on the fact that a projection principle, described in § 4, decouples the Riemann problem into a finite sequence of coupled 2×2 Riemann problems. This sequence of coupled Riemann problems is then solved in § 5. The construction done in § 5 establishes a factorization algorithm for the coupled sequence of Riemann problems. In a forthcoming paper we will discuss further the practical implementation of this algorithm and also present examples of numerical results.

The projection principle described in § 4 is valid independent of the structure of the adsorption functions a_i. Hence, if for example the functions $a_i(c_i)$ in (1.1) are replaced by a family of generalized Langmuir adsorption functions of the form (1.2), the general Riemann solution can still be found from a construction of the form studied in § 5. The only difference would be that the corresponding one-phase problem would be changed. Hence, a different procedure for the construction of the desired composition path would be required. In a forthcoming paper we will discuss how the techniques

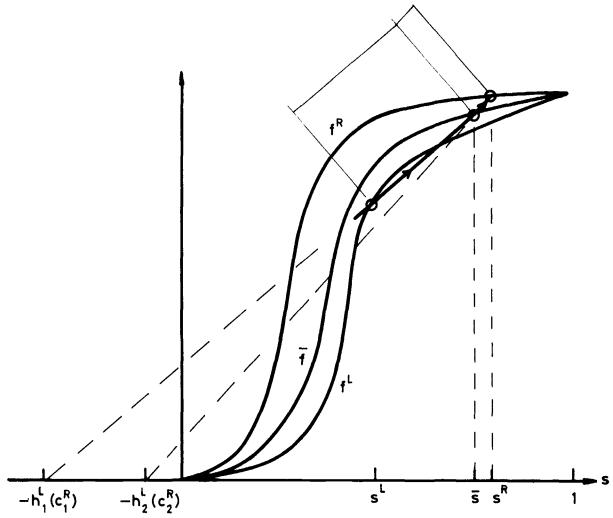

FIG. 5.17. $f^L = f(\cdot, c_1^L, c_2^L)$, $\bar{f} = f(\cdot, c_1^R, c_2^L)$, $f^R = f(\cdot, c_1^R, c_2^R)$.

developed in this paper can be combined with the results of [13] to obtain the Riemann solution of a two-phase model of the form (1.1), but where the functions $a_i(c_i)$ are replaced by a family of generalized Langmuir adsorption functions.

PERSISTENCE IN DISCRETE SEMIDYNAMICAL SYSTEMS*

H. I. FREEDMAN† AND JOSEPH W.-H. SO‡

Abstract. Conditions are established for the persistence of a discrete semidynamical system formulated in terms of the global attractor of the boundary semiflow and its stable set. An application to an ecological model of a predator-prey system is given.

Key words. semidynamical systems, persistence, dissipative, isolated invariant set, stable and unstable sets, acyclic covering, predator-prey

AMS(MOS) subject classification. 92A17

1. Introduction. Let X be a metric space with metric d. A map $f: X \to X$ defines a discrete semidynamical system $T: \mathbb{Z}_+ \times X \to X$ by $T(n, x) = f^n(x)$, where $\mathbb{Z}_+$ denotes the set of nonnegative integers and $f^n(x)$ denotes the nth iterate of x under f, i.e., $f^n(x) = f \circ f \circ \cdots \circ f(x)$ (n times). Such discrete semidynamical systems are frequently used in the modeling of ecological systems where X is the set of all possible states of the populations in the ecosystem (for example, $X = \mathbb{R}^n_+$, the nonnegative cone in $\mathbb{R}^n$) and f describes what happens to each state after a fixed period of time (for example, a year or a generation).

Let Y be a subspace of X. We say that f is persistent (with respect to Y) if for all $x \in X \setminus Y$, $\liminf_{n\to\infty} d(f^n(x), Y) > 0$. This means that Y is in some sense a repeller (or is ejective). Stronger or weaker forms than the above notion of persistence have also been introduced (Butler, Freedman, and Waltman [1]). In the context of ecological modeling, Y could be the set of extinction states in X (for example, $Y = \partial(\mathbb{R}^n_+)$, the boundary of $\mathbb{R}^n_+$ in $\mathbb{R}^n$). In that case, persistence captures the idea of nonextinction or coexistence.

The object of this paper is to obtain criteria for persistence that are testable at least in some elementary applications. Roughly speaking, these criteria are conditions imposed on the global attractor of $f|_Y$, the restriction of f on Y. More specifically, we will derive the discrete semidynamical systems analogue of the results given in Butler and Waltman [2].

Recently, Fonda [4] has derived criteria for persistence in discrete semidynamical systems of ecological models. His criteria involve establishing the existence of a certain persistence function. However, the question of how to construct such a persistence function for a given model remains open. We emphasize that our technique is a testable one in that the criteria can be checked provided only that the boundary dynamics can be analyzed.

This paper utilizes the notation and theory of dynamical systems (see [13]), as modified to discrete semidynamical systems (see [12]). The required modified definitions are stated in § 2 for completeness.

The rest of the paper is organized as follows. In § 2, we introduce some basic notation and definitions in the theory of discrete semidynamical systems. We prove in Propositions 2.2 and 3.2 that an acyclic covering gives rise to a Morse decomposition. Our main results on persistence of discrete semidynamical systems (Theorem 3.3) are presented in § 3. We also prove a Butler-McGehee type lemma for discrete semidynamical systems (Theorem 3.1) in this section. Section 4 consists of an application of this theory to an ecological model of a predator-prey system. Finally, a brief discussion and concluding remarks are given in § 5.

2. Preliminaries. Let $Y \subset X$ and let $f: X \to X$. Let $f^n(x)$ denote the nth iterate of x under f.

DEFINITION 2.1. f is said to be *persistent* (with respect to Y) if for all $x \in X \setminus Y$, $\liminf_{n\to\infty} d(f^n(x), Y) > 0$.

The main objective of this paper is to answer the following question.

PERSISTENCE QUESTION. When do we have persistence (with respect to Y)?

In [2] Butler and Waltman study the Persistence Question for a continuous dynamical system. Our aim here is to carry out the same program as in the above paper for the discrete semidynamical system defined by f. As we shall see, the results we obtain are similar. However, the noninvertibility of f makes the proofs more difficult.

In the applications we have in mind $X = \mathbb{R}^n_+$, the nonnegative cone in $\mathbb{R}^n$. It is the set of all possible states of the populations in an ecosystem. $Y = \partial(\mathbb{R}^n_+)$, the boundary of $\mathbb{R}^n_+$ in $\mathbb{R}^n$, is the set of "extinction" states of the populations in the ecosystem. f is a map that describes what happens to a state of populations after a certain fixed period of time, such as after one year or one generation. Note that f is autonomous, in the sense that its action is the same independent of year or generation.

Based on the above discussion, we will make the following assumptions.

(A1) X is a metric space with metric d.

(A2) Y is a closed subset of X.

(A3) $f: X \to X$ is continuous.

(A4) $f(Y) \subset Y$.

(A5) $f(X \setminus Y) \subset X \setminus Y$.

Under these assumptions, $f|_Y : Y \to Y$ is continuous.

DEFINITION 2.2. Let $x \in X$. Let $\mathbb{Z}$ denote the set of integers and let $\mathbb{Z}_+$ denote the set of nonnegative integers.

(i) A sequence $\{x_n\}_{n\in\mathbb{Z}_+}$ of points in X is called a *positive orbit* through x if $x_0 = x$ and $f(x_n) = x_{n+1}$ for all $n \in \mathbb{Z}_+$.

(ii) A sequence $\{x_{-n}\}_{n\in\mathbb{Z}_+}$ of points in X is called a *negative orbit* through x if $x_0 = x$ and $f(x_{-n-1}) = x_{-n}$ for all $n \in \mathbb{Z}_+$.

(iii) A sequence $\{x_n\}_{n\in\mathbb{Z}}$ of points in X is called an *orbit* through x if $x_0 = x$ and $f(x_n) = x_{n+1}$ for all $n \in \mathbb{Z}$.

The positive orbit through x always exists and is unique. In fact, it is the sequence $O^+(x) = \{x, f(x), f^2(x), \cdots\}$. The negative orbit and the orbit through x may not exist, and even when they exist, they may not be unique.

DEFINITION 2.3. A positive orbit $\{x_n\}_{n\in\mathbb{Z}_+}$ (respectively, a negative orbit $\{x_{-n}\}_{n\in\mathbb{Z}_+}$) through x is said to be *compact* if, when considered as a subset of X, it is precompact.

(A6) For all $x \in X$, $O^+(x)$ is a compact positive orbit.

DEFINITION 2.4. (i) Let $\{x_n\}_{n\in\mathbb{Z}_+}$ be a positive orbit. The *omega limit set* of $\{x_n\}_{n\in\mathbb{Z}_+}$ is the set $\Lambda^+(\{x_n\}_{n\in\mathbb{Z}_+}) = \{y \in X : y = \lim_{n\to\infty} x_{i_n}$ for some subsequence $\{x_{i_n}\}_{n\in\mathbb{Z}_+}$ of $\{x_n\}_{n\in\mathbb{Z}_+}\}$.

(ii) Let $\{x_{-n}\}_{n\in\mathbb{Z}_+}$ be a negative orbit. The *alpha limit set* of $\{x_{-n}\}_{n\in\mathbb{Z}_+}$ is the set $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+}) = \{y \in X : y = \lim_{n\to\infty} x_{-i_n}$ for some subsequence $\{x_{-i_n}\}_{n\in\mathbb{Z}_+}$ of $\{x_{-n}\}_{n\in\mathbb{Z}_+}\}$.

The omega limit set (respectively, alpha limit set) of a positive orbit (respectively negative orbit) is the set of all limit points of the positive orbit (respectively, negative orbit) when considered as a sequence. We also denote the omega limit set of the positive orbit through x by $\Lambda^+(x)$.

DEFINITION 2.5. Let $M \subset X$. M is *positively invariant* (respectively, *negatively invariant, invariant*) if $f(M) \subset M$ (respectively, $M \subset f(M)$, $f(M) = M$).

The union of invariant sets is invariant. For a continuous f, the closure of a positively invariant set is positively invariant, the closure of a precompact negative invariant set is negatively invariant, and the closure of a precompact invariant set is invariant.

DEFINITION 2.6. Let $M \subset X$ be invariant. M is said to be *compactly invariantly connected* if whenever $M \subset M_1 \cup M_2$, where M_1 and M_2 are disjoint nonempty, compact, invariant sets, then either $M \cap M_1 = \emptyset$ or $M \cap M_2 = \emptyset$.

PROPOSITION 2.1. (i) *If $\{x_n\}_{n\in\mathbb{Z}_+}$ is a compact positive orbit, then $\Lambda^+(\{x_n\}_{n\in\mathbb{Z}_+})$ is nonempty, compact, invariant, and compactly invariantly connected, and* $\lim_{k\to\infty} d(x_k, \Lambda^+(\{x_n\}_{n\in\mathbb{Z}_+})) = 0$.

(ii) *If $\{x_{-n}\}_{n\in\mathbb{Z}_+}$ is a compact negative orbit, then $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})$ is nonempty, compact, invariant, and compactly invariantly connected, and* $\lim_{k\to\infty} d(x_{-k}, \Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})) = 0$.

Proof. (i) See Theorem 1.5.2 of [12].

(ii) Since $\{x_{-n}\}_{n\in\mathbb{Z}_+}$ is a sequence in a compact set, it has a convergent subsequence. Therefore, $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})$ is nonempty. Since the set of all limit points of a sequence is closed, therefore $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})$ is closed and hence it is compact. Let $y \in \Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})$. Then $y = \lim_{n\to\infty} x_{-i_n}$ for some subsequence $\{x_{-i_n}\}_{n\in\mathbb{Z}_+}$ of $\{x_{-n}\}_{n\in\mathbb{Z}_+}$. Clearly, $f(y) = \lim_{n\to\infty} x_{-i_n+1} \in \Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})$. On the other hand, if z is the limit of any convergent subsequence of $\{x_{-i_n-1}\}_{n\in\mathbb{Z}_+}$ then $z \in \Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})$ and $f(z) = y$. Thus, $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})$ is invariant.

To show that $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})$ is compactly invariantly connected, let M_1 and M_2 be two disjoint nonempty, compact, invariant sets such that $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+}) \subset M_1 \cup M_2$. Then $\varepsilon = d(M_1, M_2) > 0$. Let $U_i = B_{\varepsilon/3}(M_i)$, the $\varepsilon/3$-ball about M_i. Then $M_i \subset U_i$ $(i = 1, 2)$ and $U_1 \cap U_2 = \emptyset$. For all $x \in M_1, f(x) \in M_1 \subset U_1$. Therefore, there exists $\delta_x > 0$ such that $\mathrm{cl}\,(B_{\delta_x}(x)) \subset U_1$ and $f(\mathrm{cl}\,(B_{\delta_x}(x))) \subset U_1$. Since M_1 is compact, there exist $x_1, \cdots, x_K \in M_1$ such that $M_1 \subset V_1$, $\mathrm{cl}\,(V_1) \subset U_1$, and $f(\mathrm{cl}\,(V_1)) \subset U_1$, where $V_1 = \cup_{i=1}^K B_{\delta_{x_i}}(x_i)$. Suppose that $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+}) \cap M_i \neq \emptyset$ for $i = 1, 2$. Then $\{x_{-n}\}_{n\in\mathbb{Z}_+}$ intersects both V_1 and U_2 an infinite number of times. This implies the existence of subsequences $\{x_{-1_n}\}_{n\in\mathbb{Z}_+}$, $\{x_{-2_n}\}_{n\in\mathbb{Z}_+}$ of $\{x_{-n}\}_{n\in\mathbb{Z}_+}$ such that $x_{-1_n} \in V_1$ and $x_{-2_n} \in U_2$. Define the subsequence $\{x_{-3_n}\}_{n\in\mathbb{Z}_+}$ of $\{x_{-n}\}_{n\in\mathbb{Z}_+}$ by the following properties: $-1_n \leqq -3_n < -2_n$, $x_k \in V_1$ for all k, $-1_n \leqq k \leqq -3_n$ and $x_{-3_n+1} \notin V_1$ for all $n \in \mathbb{Z}_+$. Since $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})$ is compact, by going to subsequences if necessary, we can assume that $\{x_{-3_n}\}_{n\in\mathbb{Z}_+}$ converges. Let $p = \lim_{n\to\infty} x_{-3_n+1} = \lim_{n\to\infty} f(x_{-3_n})$. Since $x_{-3_n+1} \in U_1 \setminus V_1$ for all $n \in \mathbb{Z}_+$, $p \in \bar{U}_1 \setminus V_1$. Thus, $p \in \Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})$ is neither in V_1 nor U_2. This contradicts $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+}) \subset V_1 \cup U_2$.

Suppose $\limsup_{k\to\infty} d(x_{-k}, \Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})) > 0$. Then there exists $\eta > 0$ and a subsequence $\{x_{-i_k}\}_{k\in\mathbb{Z}_+}$ of $\{x_{-k}\}_{k\in\mathbb{Z}_+}$ such that $d(x_{-i_k}, \Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})) \geqq \eta$. Since $\{x_{-i_k}\}_{k\in\mathbb{Z}_+}$ contains a convergent subsequence whose limit is in $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})$, this is a contradiction. □

Under assumptions (A2), (A3), and (A6), f is not persistent if and only if there exists $x \in X \setminus Y$ such that $\Lambda^+(x) \cap Y \neq \emptyset$ (that is, $d(\Lambda^+(x), Y) = 0$).

DEFINITION 2.7. f is said to be dissipative if the set $\Omega(f) = \cup \{\Lambda^+(x): x \in X\}$ is precompact.

Under assumptions (A3) and (A6), if f is dissipative then $\Omega(f)$ is invariant and so is its closure, $\bar{\Omega}(f)$.

DEFINITION 2.8. A nonempty, closed invariant subset M of X is an *isolated invariant set* if it is the maximal (under the order of inclusion) invariant set in some neighbourhood of itself. A subset N of X is an *isolating neighbourhood* if the maximal invariant set in N is nonempty, closed, and contained in int (N), the interior of N.

Let M be an isolated invariant set and let $x \in X \setminus M$. Then there exists a closed isolating neighbourhood N of M such that $x \in X \setminus N$.

DEFINITION 2.9. Let $M \subset X$ be an isolated invariant set.

(i) A compact positive orbit $\{x_n\}_{n\in\mathbb{Z}_+}$ is said to be in the *stable set* of M (under f) (in notation, $\{x_n\}_{n\in\mathbb{Z}_+} \in W^+(M)$) if $\Lambda^+(\{x_n\}_{n\in\mathbb{Z}_+}) \subset M$.

(ii) A compact negative orbit $\{x_{-n}\}_{n\in\mathbb{Z}_+}$ is said to be in the *unstable set* of M (under f) (in notation, $\{x_{-n}\}_{n\in\mathbb{Z}_+} \in W^-(M)$) if $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+}) \subset M$.

(iii) A compact positive orbit $\{x_n\}_{n\in\mathbb{Z}_+}$ is said to be in the *weakly stable set* of M (under f) (in notation, $\{x_n\}_{n\in\mathbb{Z}_+} \in W_w^+(M)$) if $\Lambda^+(\{x_{-n}\}_{n\in\mathbb{Z}_+}) \cap M \neq \emptyset$.

(iv) A compact negative orbit $\{x_{-n}\}_{n\in\mathbb{Z}_+}$ is said to be in the *weakly unstable set* of M (under f) (in notation, $\{x_{-n}\}_{n\in\mathbb{Z}_+} \in W_w^-(M)$) if $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+}) \cap M \neq \emptyset$.

Under (A4), $f|_Y : Y \to Y$ defines a discrete semidynamical system. We will have occasion to consider the dynamics of $f|_Y$. To distinguish the notions of stable sets, etc., in this case with those defined previously for f, we will employ the notation $W^+(M; f|_Y)$, etc. when we refer to $f|_Y$.

DEFINITION 2.10. Let M_1 and M_2 be two isolated invariant sets. We say that M_1 is *chained to* M_2 if there exists an orbit $\{x_n\}_{n\in\mathbb{Z}}$ with $x_k \notin M_1 \cup M_2$ for some $k \in \mathbb{Z}$ such that $\{x_{-n}\}_{n\in\mathbb{Z}_+} \in W^-(M_1)$ and $\{x_n\}_{n\in\mathbb{Z}_+} \in W^+(M_2)$.

DEFINITION 2.11. A finite sequence $M_1, M_2, \cdots, M_k$ of isolated invariant sets will be called a *chain* if $M_1 \to M_2 \to \cdots \to M_k$. A chain is called a *cycle* if $M_k = M_1$.

In the following definitions, we will assume that (A3)-(A5) hold.

DEFINITION 2.12. A covering $\Pi = \{M_1, M_2, \cdots, M_k\}$ of $\bar{\Omega}(f|_Y)$ is called an *isolated covering* of $f|_Y$ if $M_1, M_2, \cdots, M_k$ are pairwise disjoint, compact and isolated invariant.

Note that each $M_i \subset Y$ $(i = 1, \cdots, k)$ is required to be an isolated invariant set in X under f and that $\bar{\Omega}(f|_Y) \subset \cup_{i=1}^k M_i$.

DEFINITION 2.13. An isolated covering $\Pi = \{M_1, \cdots, M_k\}$ of $f|_Y$ is called an *acyclic covering* of $f|_Y$ if no subsets of Π form a cycle for $f|_Y$ in Y.

Note that the "acyclic" condition is a requirement on an isolated covering of $f|_Y$ but not on $f|_Y$ itself.

In the statements of our main results on persistence in the next section, we always assume (A1)-(A6) and the following hypotheses:

(H1) $f|_Y$ is dissipative.

(H2) $f|_Y$ has an acyclic covering $\Pi = \{M_1, M_2, \cdots, M_k\}$.

PROPOSITION 2.2. *Let* (A1)-(A6) *and* (H1), (H2) *hold. Then for any positive orbit* $\{x_n\}_{n\in\mathbb{Z}_+}$ *in* Y, *there exists one and only one* i *such that* $\{x_n\}_{n\in\mathbb{Z}_+} \in W^+(M_i; f|_Y)$.

Proof. Since the positive orbit $\{x_n\}_{n\in\mathbb{Z}_+}$ is compact, by Proposition 2.1, $\Lambda^+(\{x_n\}_{n\in\mathbb{Z}_+})$ is compactly invariantly connected. On the other hand, $\Lambda^+(\{x_n\}_{n\in\mathbb{Z}_+}) \subset \Omega(f|_Y) \subset \cup_{i=1}^k M_i$. Thus, $\Lambda^+(\{x_n\}_{n\in\mathbb{Z}_+}) \subset M_i$ for some i and $\{x_n\}_{n\in\mathbb{Z}_+} \in W^+(M_i)$. □

3. Persistence. Various forms of the following theorem have been referred to as the Butler-McGehee lemma. In the original form (Freedman and Waltman [7, App. A, Lemma 1]), the setting is for a hyperbolic restpoint of an autonomous ordinary differential equation. Since then it has been extended to an isolated invariant set for a continuous flow on a locally compact metric space by Butler and Waltman [2] and for continuous semiflows by Dunbar, Rybakowski, and Schmitt [3]. Our version here is similar to that in [2] except that now we have a discrete semiflow.

THEOREM 3.1. *Let X be a metric space with metric d. Let $f: X \to X$ be continuous and let M be an isolated invariant set in X.*

(I) *If $\{x_n\}_{n\in\mathbb{Z}^+}$ is a compact positive orbit and $\{x_n\}_{n\in\mathbb{Z}^+} \in W_w^+(M)\setminus W^+(M)$, then*
  (a) *There exists a positive orbit $\{y_n\}_{n\in\mathbb{Z}^+}$ in $\Lambda^+(\{x_n\}_{n\in\mathbb{Z}^+})$ such that $y_0 \notin M$ and $\{y_n\}_{n\in\mathbb{Z}^+} \in W^+(M)$, and*
  (b) *There exists a negative orbit $\{z_{-n}\}_{n\in\mathbb{Z}^+}$ in $\Lambda^+(\{x_n\}_{n\in\mathbb{Z}^+})$ such that $z_0 \notin M$ and $\{z_{-n}\}_{n\in\mathbb{Z}^+} \in W^-(M)$.*

(II) *If $\{x_{-n}\}_{n\in\mathbb{Z}^+}$ is a compact negative orbit and $\{x_{-n}\}_{n\in\mathbb{Z}^+} \in W_w^-(M)\setminus W^-(M)$, then*
  (a) *There exists a positive orbit $\{y_n\}_{n\in\mathbb{Z}^+}$ in $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}^+})$ such that $y_0 \notin M$ and $\{y_n\}_{n\in\mathbb{Z}^+} \in W^+(M)$, and*
  (b) *There exists a negative orbit $\{z_{-n}\}_{n\in\mathbb{Z}^+}$ in $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}^+})$ such that $z_0 \notin M$ and $\{z_{-n}\}_{n\in\mathbb{Z}^+} \in W^-(M)$.*

Proof. (I)(a). It suffices to show that there exists a positive orbit $\{y_n\}_{n\in\mathbb{Z}^+}$ in $\Lambda^+(\{x_n\}_{n\in\mathbb{Z}^+})$ such that $y_0 \notin M$ and $y_n \in N$ for all $n \in \mathbb{Z}_+$ sufficiently large, where N is any closed isolating neighbourhood of M. (Since then $\Lambda^+(\{y_n\}_{n\in\mathbb{Z}^+}) \subset N$ and $\Lambda^+(\{y_n\}_{n\in\mathbb{Z}^+})$ is invariant, this implies $\Lambda^+(\{y_n\}_{n\in\mathbb{Z}^+}) \subset M$ and hence $\{y_n\}_{n\in\mathbb{Z}^+} \in W^+(M)$.) Since $\{x_n\}_{n\in\mathbb{Z}^+} \in W_w^+(M)\setminus W^+(M)$, there exist $p_1, p_2 \in \Lambda^+(\{x_n\}_{n\in\mathbb{Z}^+})$ such that $p_1 \in M$ and $p_2 \notin M$. Let N be a closed isolating neighbourhood of M such that $p_2 \notin N$. Let $\{x_{1_n}\}_{n\in\mathbb{Z}^+}$ and $\{x_{2_n}\}_{n\in\mathbb{Z}^+}$ be two (convergent) subsequences of $\{x_n\}_{n\in\mathbb{Z}^+}$ such that $\lim_{n\to\infty} x_{1_n} = p_1$ and $\lim_{n\to\infty} x_{2_n} = p_2$. By going to subsequences if necessary, we can assume that $x_{1_n} \in \operatorname{int}(N)$, $x_{2_n} \notin N$, and $2_n < 1_n < 2_{n+1}$ for all $n \in \mathbb{Z}_+$. Define a subsequence $\{x_{3_n}\}_{n\in\mathbb{Z}^+}$ of $\{x_n\}_{n\in\mathbb{Z}^+}$ by the properties: (i) $2_n < 3_n \leqq 1_n$, (ii) $x_{3_n-1} \notin N$, and (iii) $x_k \in N$ for all k, $3_n \leqq k \leqq 1_n$. Again by going to subsequences if necessary, we can assume that $\lim_{n\to\infty} x_{3_n-1} = y_0$ exists. Then $\lim_{n\to\infty} x_{3_n} = y_1$ also exists. Moreover, $y_0 \notin \operatorname{int}(N)$ (and hence $\notin M$), $y_1 \in N$, and $y_1 = f(y_0)$. Let $\{y_n\}_{n\in\mathbb{Z}^+}$ be the positive orbit through y_0. Then $\{y_n\}_{n\in\mathbb{Z}^+} \subset \Lambda^+(\{x_n\}_{n\in\mathbb{Z}^+})$. There are two cases to consider.

Case 1. $\{1_n - 3_n\}_{n\in\mathbb{Z}_+}$ is unbounded. By going to subsequences if necessary, we can assume that $\{1_n - 3_n\}_{n\in\mathbb{Z}_+} \uparrow \infty$. Fix any $k \in \mathbb{Z}_+$, $k \geqq 1$. Since $y_k = \lim_{n\to\infty} x_{3_n+k-1}$ and $3_n \leqq 3_n + k - 1 \leqq 1_n$ for $n \in \mathbb{Z}_+$ sufficiently large, we have $y_k \in N$. Thus, $\Lambda^+(\{y_n\}_{n\in\mathbb{Z}^+}) \subset N$ and $\{y_n\}_{n\in\mathbb{Z}^+} \in W^+(M)$.

Case 2. $\{1_n - 3_n\}_{n\in\mathbb{Z}_+}$ is bounded. By going to subsequences if necessary, we can assume that $1_n - 3_n = m$ for some $m \in \mathbb{Z}_+$. Therefore, $y_{m+1} = \lim_{n\to\infty} x_{3_n+m+1-1} = \lim_{n\to\infty} x_{1_n} = p_1 \in M$. Since M is invariant, $y_n \in M$ for $n \in \mathbb{Z}_+$, $n > m$. Thus, again $\{y_n\}_{n\in\mathbb{Z}^+} \in W^+(M)$.

(I)(b). It suffices to show that there exists a negative orbit $\{z_{-n}\}_{n\in\mathbb{Z}^+}$ in $\Lambda^+(\{x_n\}_{n\in\mathbb{Z}^+})$ such that z_0 is not in M and $z_{-n} \in N$ for all $n \in Z_+$ sufficiently large, where N is any closed isolating neighbourhood of M. (Since then $\Lambda^-(\{z_{-n}\}_{n\in\mathbb{Z}^+}) \subset N$ and $\Lambda^-(\{z_{-n}\}_{n\in\mathbb{Z}^+})$ is invariant, this implies $\Lambda^-(\{z_{-n}\}_{n\in\mathbb{Z}^+}) \subset M$ and hence $\{z_{-n}\}_{n\in\mathbb{Z}^+} \in W^-(M)$.) Since $\{x_n\}_{n\in\mathbb{Z}^+} \in W_w^+(M)\setminus W^+(M)$, there exist $p_1, p_2 \in \Lambda^+(\{x_n\}_{n\in\mathbb{Z}^+})$ such that $p_1 \in M$ and $p_2 \notin M$. Let N be a closed isolating neighbourhood of M such that $p_2 \notin N$. Let $\{x_{1_n}\}_{n\in\mathbb{Z}^+}$ and $\{x_{2_n}\}_{n\in\mathbb{Z}^+}$ be two subsequences of $\{x_n\}_{n\in\mathbb{Z}^+}$ such that $\lim_{n\to\infty} x_{1_n} = p_1$ and $\lim_{n\to\infty} x_{2_n} = p_2$. By going to subsequences if necessary, we can assume that $x_{1_n} \in \operatorname{int}(N)$, $x_{2_n} \notin N$, and $1_n < 2_n < 1_{n+1}$ for all $n \in \mathbb{Z}_+$. Define a subsequence $\{x_{3_n}\}_{n\in\mathbb{Z}^+}$ of $\{x_n\}_{n\in\mathbb{Z}^+}$

by the following properties: (i) $1_n \leqq 3_n < 2_n$; (ii) $x_{3_n+1} \notin N$; and (iii) $x_k \in N$ for all k, $1_n \leqq k \leqq 3_n$. Again by going to subsequences if necessary, we can assume that $\lim_{n\to\infty} x_{3_n} = z_{-1}$ exists. Then $\lim_{n\to\infty} x_{3_n+1} = z_0$ also exists. Moreover, $z_0 \notin \text{int}(N)$ (and hence $\notin M$), $z_{-1} \in N$, and $z_0 = f(z_{-1})$. We construct a negative orbit $\{z_{-n}\}_{n\in\mathbb{Z}^+}$ through z_0 in $\Lambda^+(\{x_n\}_{n\in\mathbb{Z}^+})$ as follows. z_{-2} is the limit of any convergent subsequence $\{x_{(-2)_n}\}_{n\in\mathbb{Z}^+}$ of $\{x_{3_n-1}\}_{n\in\mathbb{Z}^+}$, z_{-3} is the limit of any convergent subsequence $\{x_{(-3)_n}\}_{n\in\mathbb{Z}^+}$ of $\{x_{(-2)_n-1}\}_{n\in\mathbb{Z}^+}$, etc. There are two cases to consider.

Case 1. $\{3_n - 1_n\}_{n\in\mathbb{Z}_+}$ is unbounded. By going to subsequences if necessary, we can assume that $\{3_n - 1_n\}_{n\in\mathbb{Z}_+} \uparrow \infty$. We will show that $z_{-k} \in N$ for all $k \in \mathbb{Z}_+$, $k \geqq 1$. Fix any $k \in \mathbb{Z}_+$, $k \geqq 1$. Recall that $z_{-k} = \lim_{n\to\infty} x_{(-k)_n}$. Since $\{(-k)_n\}_{n\in\mathbb{Z}_+}$ is a subsequence of $\{3_n - k + 1\}_{n\in\mathbb{Z}_+}$ and $1_n \leqq 3_n - k + 1 \leqq 3_n$ for $n \in \mathbb{Z}_+$ sufficiently large, therefore $x_{(-k)_n} \in N$ for $n \in \mathbb{Z}_+$ sufficiently large. Thus $z_{-k} \in N$. Hence, $\Lambda^-(\{z_{-n}\}_{n\in\mathbb{Z}^+}) \subset N$ and $\{z_{-n}\}_{n\in\mathbb{Z}^+} \in W^-(M)$.

Case 2. $\{1_n - 3_n\}_{n\in\mathbb{Z}_+}$ is bounded. By going to subsequences if necessary, we can assume that $3_n - 1_n = m$ for some $m \in \mathbb{Z}_+$. Now, $z_0 = \lim_{n\to\infty} x_{3_n+1} = \lim_{n\to\infty} x_{1_n+m+1} = f^{m+1}(p_1) \in M$, since $p_1 \in M$ and M is invariant, which is a contradiction. This shows that $\{1_n - 3_n\}_{n\in\mathbb{Z}_+}$ must be unbounded.

The proofs of (II)(a) and (II)(b) are similar to (I)(a) and (I)(b). □

The following proposition together with Proposition 2.2 shows that an acyclic covering of $f|_Y$ is a Morse decomposition for $\Omega(f|_Y)$.

PROPOSITION 3.2. *Let* (A1)-(A6) *and* (H1), (H2) *hold. Then for any compact negative orbit* $\{x_{-n}\}_{n\in\mathbb{Z}_+}$ *in* Y, *there exists one and only one* i *such that* $\{x_{-n}\}_{n\in\mathbb{Z}_+} \in W^-(M_i; f|_Y)$.

Proof. Note that we are only interested in $f|_Y$ and not f here. Suppose $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+}) \not\subset M_i$ for all i. Let $y \in \Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})$. Since $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})$ is invariant, by (A4) and (A5), there exists an orbit $\{y_n\}_{n\in\mathbb{Z}}$ through y such that $\{y_n\}_{n\in\mathbb{Z}}$ is in Y and $\{y_n\}_{n\in\mathbb{Z}} \subset \Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})$. Thus, $\emptyset \neq \Lambda^+(\{y_n\}_{n\in\mathbb{Z}_+}) \subset \Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})$. Moreover, $\Lambda^+(\{y_n\}_{n\in\mathbb{Z}_+}) \subset M_{i_1}$ for some i_1, by Proposition 2.2. Thus, $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+}) \cap M_{i_1} \neq \emptyset$, that is, $\{x_{-n}\}_{n\in\mathbb{Z}_+} \in W_w^-(M_{i_1}; f|_Y)$. Since $\{x_{-n}\}_{n\in\mathbb{Z}_+} \notin W^-(M_{i_1}; f|_Y)$ by assumption, by Theorem 3.1 there exists a negative orbit $\{z_{-n}\}_{n\in\mathbb{Z}^+} \subset \Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})$ such that $z_0 \notin M_{i_1}$ and $\{z_{-n}\}_{n\in\mathbb{Z}^+} \in W^-(M_{i_1}; f|_Y)$. Let $\{z_n\}_{n\in\mathbb{Z}}$ be the (full) orbit extending $\{z_{-n}\}_{n\in\mathbb{Z}^+}$. By Proposition 2.2 again, there exists i_2 such that $\{z_n\}_{n\in\mathbb{Z}^+} \in W^+(M_{i_2}; f|_Y)$. Clearly, there exists n such that $z_n \notin M_{i_2}$. Therefore $M_{i_1} \to M_{i_2}$. Since $\emptyset \neq \Lambda^+(\{z_n\}_{n\in\mathbb{Z}_+}) \subset \Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+})$ and $\Lambda^+(\{z_n\}_{n\in\mathbb{Z}_+}) \subset M_{i_2}$, $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+}) \cap M_{i_2} \neq \emptyset$, that is, $\Lambda^-(\{x_{-n}\}_{n\in\mathbb{Z}_+}) \in W_w^-(M_{i_2}; f|_Y)$. Since $\{x_{-n}\}_{n\in\mathbb{Z}_+} \notin W^-(M_{i_2}; f|_Y)$, we can repeat the above argument to get an i_3 such that $M_{i_2} \to M_{i_3}$. Since there are only a finite number of M_i's, we will eventually arrive at a cycle. This contradicts (H2). □

THEOREM 3.3. *Under assumptions* (A1)-(A6) *and hypotheses* (H1) *and* (H2), f *is persistent* (*with respect to* Y) *if and only if we have the following*:

(H3) *There is no positive orbit* $\{x_n\}_{n\in\mathbb{Z}_+}$ *in* $X \setminus Y$ *such that* $\{x_n\}_{n\in\mathbb{Z}_+} \in W^+(M_i)$ *for some* i (*in notation, we write* $W^+(M_i) \cap X \setminus Y = \emptyset$ *for all* $i = 1, 2, \cdots, k$).

Proof. (→ part.) If (H3) fails to hold, then there exists a positive orbit $\{x_n\}_{n\in\mathbb{Z}_+}$ in $X \setminus Y$ such that $\{x_n\}_{n\in\mathbb{Z}_+} \in W^+(M_i)$ for some i. Then $\lim_{n\to\infty} d(x_n, M_i) = 0$ and $\limsup_{n\to\infty} d(f^n(x), Y) = 0$, where $x = x_0$. Thus, f is not weakly persistent (with respect to Y) and hence not persistent (with respect to Y).

(← part.) Suppose f is not persistent (with respect to Y). Then there exists a positive orbit $\{x_n\}_{n\in\mathbb{Z}_+} \subset X \setminus Y$ such that $\Lambda^+(\{x_n\}_{n\in\mathbb{Z}_+}) \cap Y \neq \emptyset$. Let $y \in \Lambda^+(\{x_n\}_{n\in\mathbb{Z}_+}) \cap Y$ and denote the positive orbit through y by $\{y_n\}_{n\in\mathbb{Z}_+}$. Then $\{y_n\}_{n\in\mathbb{Z}_+} \subset Y$ and $\emptyset \neq \Lambda^+(\{y_n\}_{n\in\mathbb{Z}_+}) \subset \Lambda^+(\{x_n\}_{n\in\mathbb{Z}_+}) \cap Y$. By Proposition 3.2, there exists i_1 such that

$\Lambda^+(\{y_n\}_{n\in\mathbb{Z}_+}) \subset M_{i_1}$. Thus, $\Lambda^+(\{x_n\}_{n\in\mathbb{Z}_+}) \cap M_{i_1} \neq \emptyset$, that is, $\{x_n\}_{n\in\mathbb{Z}_+} \in W_w^+(M_{i_1})$. Since, by (H3), $\{x_n\}_{n\in\mathbb{Z}_+} \notin W^+(M_{i_1})$, we can apply Theorem 3.1 to get a positive orbit $\{z_n\}_{n\in\mathbb{Z}_+} \subset \Lambda^+(\{x_n\}_{n\in\mathbb{Z}_+})$ such that $z_0 \notin M_{i_1}$ and $\{z_n\}_{n\in\mathbb{Z}_+} \in W^+(M_{i_1})$. By (H3), $\{z_n\}_{n\in\mathbb{Z}_+} \subset Y$. Clearly $z_0 \notin M_i$ for all i. Let $\{z_n\}_{n\in\mathbb{Z}}$ be an orbit through z_0. It exists because $z_0 \in \Lambda^+(\{x_n\}_{n\in\mathbb{Z}_+})$ and $\Lambda^+(\{x_n\}_{n\in\mathbb{Z}_+})$ is invariant. Clearly, $\{z_n\}_{n\in\mathbb{Z}} \subset Y$ and $\{z_n\}_{n\in\mathbb{Z}} \subset \Lambda^+(\{x_n\}_{n\in\mathbb{Z}_+})$. Since $\{z_{-n}\}_{n\in\mathbb{Z}_+}$ is a compact negative orbit, by Proposition 3.2, $\{z_{-n}\}_{n\in\mathbb{Z}_+} \in W^-(M_{i_2})$ for some i_2. Therefore, $M_{i_2} \to M_{i_1}$. Clearly, $\{x_n\}_{n\in\mathbb{Z}_+} \in W_w^+(M_{i_2})$ and we can repeat the above argument to get an i_3 such that $M_{i_3} \to M_{i_2}$. Since there are only a finite number of M_i's, we will eventually arrive at a cycle. This contradicts (H2). □

4. Application to a predator-prey model. It has been shown that models of arthropod parisitoid-host systems [8] and models of predator-prey systems when population numbers are small [5] can be best described by a discrete semidynamical system. In this section we describe such a system, which includes models considered in [9]-[11] as special cases.

Let x_n be the prey or host population numbers in the nth generation and let y_n be the predator or parasitoid population. Then the model takes the form

$$\begin{aligned} x_{n+1} &= x_n F(x_n, y_n), & x_0 &\geqq 0, \\ y_{n+1} &= x_n y_n G(x_n, y_n), & y_0 &\geqq 0. \end{aligned} \tag{4.1}$$

In this case, $X = \mathbb{R}_+^2 = \{(x, y): x \geqq 0, y \geqq 0\}$ and $Y = \{(x, 0): x \geqq 0\} \cup \{(0, y): y \geqq 0\}$, the nonnegative x and y axes. Moreover, persistence is synonymous with the survival of both populations over all time.

The mathematical assumptions and their biological interpretations, where appropriate, are as follows:

(PP1) $F, G \in \mathscr{C}([0, \infty) \times [0, \infty))$. Small changes in population numbers in any generation result in small changes in the succeeding generation.

(PP2) $F(0, 0) > 1$. In the absence of predators, the prey population will grow if its numbers are small.

(PP3) $F(x, y) \geqq 0$, $G(x, y) \geqq 0$ if $x \geqq 0$, $y \geqq 0$; $F(x, y) > 0$, $G(x, y) > 0$ if $x > 0$, $y > 0$. In general there cannot be a negative number of populations. Further, if both populations are present, extinction of either population cannot occur in finite time.

(PP4) $F(x, y)$ is monotonically decreasing in y. Further, $\lim_{y\to\infty} F(x, y) = 0$. The larger the number of predators, the smaller the growth rate of the prey. For a very large number of predators, the prey population is driven to near extinction.

(PP5) There exists $x_K > 0$ such that $F(x_K, 0) = 1$ and $F(x, 0) < 1$ for all $x > x_K$. There is a carrying capacity of the environment beyond which the prey population cannot be sustained, even in the absence of predators.

(PP6) $xG(x, y)$ is a strictly increasing function of x with $x_K G(x_K, 0) > 1$. The more food for the predator, the higher will be its growth rate. Further, at some prey value prior to carrying capacity, and thereafter, the predator population can sustain itself on the prey population.

(PP7) $G(x, y)$ is monotonically decreasing in y. The per capita growth rate of the predator is diminished for larger values of its population due to intraspecific competition for its food.

Before stating the final hypothesis for model (4.1), we need to study the single-species dynamics of the prey in the absence of predators. This dynamics is given by the equation

$$x_{n+1} = x_n F(x_n, 0), \qquad x_0 \geqq 0. \tag{4.2}$$

The dynamics of system (4.2) is discussed in [6]. Let $\tilde{x} = \sup_{0 \leqq x \leqq x_K} xF(x, 0)$. Then $\tilde{x} \geqq x_K$ and if $\{x_n\}_{n \in \mathbb{Z}_+}$ is a positive orbit of (4.2), then $\limsup_{n \to \infty} x_n \leqq \tilde{x}$.

Further, assuming (PP1), (PP2), (PP5), it is shown in [6] that there exists $\eta > 0$, η computable, such that for $x_0 > 0$, $\Lambda^+(\{x_n\}_{n \in \mathbb{Z}_+}) \subset [\eta, \tilde{x}]$.

The final hypothesis is the following.

(PP8) $\eta G(\eta, 0) > 1$.

By (PP6), (PP8) implies $xG(x, 0) > 1$ for all $x \geqq \eta$, which in turn implies the semi-axis $\{(x, 0) \in \mathbb{R}^2_+ : x \geqq \eta\}$ repels in the y direction.

To show that system (4.1) is persistent under assumptions (PP1)-(PP8), we need to check that (A1)-(A6) and (H1)-(H3) are satisfied.

Clearly (A1)-(A5) are satisfied. To show (A6) and (H1), let $\{(x_n, y_n)\}_{n \in \mathbb{Z}_+}$ be a positive orbit of (4.1) in $\mathbb{R}^2_+$. Then since $F(x, y) \leqq F(x, 0)$, $\limsup_{n \to \infty} x_n \leqq \tilde{x}$. For the purpose of the following discussion we can assume that $x_n \leqq \bar{x}$ for all n, where $\bar{x} \equiv \tilde{x} + 1$.

Let $\phi(y) = \sup_{0 \leqq x \leqq \bar{x}} xF(x, y)$. By (PP4), $\phi(y)$ is a decreasing function of y and $\lim_{y \to \infty} \phi(y) = 0$. Let $\delta > 0$ be such that

$$\delta \bar{x} G(\bar{x}, 0) G(\delta, 0) = 1 \tag{4.3}$$

which exists by (PP6) since $\bar{x}G(\bar{x}, 0) > 1$. Further, choose $\tilde{y}$ so large that $\phi(y) < \delta$ for all $y \geqq \tilde{y}$ and define $\hat{y} = \bar{x}\tilde{y}G(\bar{x}, 0)$. Clearly $\hat{y} > \tilde{y}$. Moreover, $x_{n+1} = x_n F(x_n, y_n) \leqq \phi(y_n)$.

Let us make the following observations.

Observation 1. Suppose y_n is such that $0 < y_n \leqq \tilde{y}$. Then $y_{n+1} = x_n y_n G(x_n, y_n) \leqq \bar{x}G(\bar{x}, 0) y_n \leqq \bar{x}G(\bar{x}, 0)\tilde{y} = \hat{y}$.

Observation 2. If y_n is such that $y_n > \tilde{y}$, then $x_{n+1} \leqq \phi(y_n) < \delta$ and $y_{n+2} = x_{n+1} y_{n+1} G(x_{n+1}, y_{n+1}) = x_{n+1} x_n y_n G(x_n, y_n) G(x_{n+1}, y_{n+1}) < \delta \bar{x} G(\bar{x}, 0) G(\delta, 0) y_n = y_n$, by (4.3).

We now consider two cases.

Case 1. $y_n > \hat{y}$ for all n. In this case, by Observation 2, $y_0 > y_2 > y_4 > \cdots$. Let $y_* = \lim_{k \to \infty} y_{2k}$. Since $y_{2k+1} \leqq \bar{x}G(\bar{x}, 0) y_{2k}$, $\limsup_{n \to \infty} y_n \leqq y_* \bar{x} G(\bar{x}, 0)$. Claim: $y_* = \hat{y}$. Suppose not, that is, suppose $y_* > \hat{y}$. Let $\{x_{2k_j}\}$ be a convergent subsequence of $\{x_{2k}\}$ and denote its limit by x_*. Also denote the map on the right-hand side of (4.1) by f. Then $f^2(x_*, y_*) = f^2(\lim_{j \to \infty} x_{2k_j}, \lim_{j \to \infty} y_{2k_j})$ so that the second component of $f^2(x_*, y_*)$ is $\lim_{j \to \infty} y_{2k_j+2} = y_*$. This contradicts Observation 2 since $y_* > \hat{y} > \tilde{y}$. Hence, we have shown that $\limsup_{n \to \infty} y_n \geqq \hat{y}\bar{x}G(\bar{x}, 0)$.

Case 2. There exists n_0 such that $y_{n_0} \leqq \hat{y}$. If $y_{n_0} \leqq \tilde{y}$, by Observation 1, $y_{n_0+1} \leqq \hat{y}$. If $\tilde{y} < y_{n_0} \leqq \hat{y}$, then $y_{n_0+1} \leqq \hat{y}\bar{x}G(\bar{x}, 0)$ and, by Observation 2, $y_{n_0+2} \leqq y_{n_0} \leqq \hat{y}$. Proceeding inductively, we can easily show $y_n \leqq \hat{y}\bar{x}G(\bar{x}, 0)$ for all $n \geqq n_0$ and thus $\limsup_{n \to \infty} y_n \leqq \hat{y}\bar{x}G(\bar{x}, 0)$.

This shows that $\Omega(f) \subset [0, \bar{x}] \times [0, \hat{y}\bar{x}G(\bar{x}, 0)]$ and hence (A6) and (H1) are satisfied.

To show (H2) is satisfied we note that $\{M_1, M_2\}$ is an isolated covering of $f|_Y$, where $M_1 = \{(0, 0)\}$ and M_2 is the maximal invariant set in $\{(x, 0) : \eta \leqq x \leqq \tilde{x}\}$, and that this covering is acyclic.

Finally, we show (H3). We first show that $W^+(M_1) \cap \operatorname{int}(\mathbb{R}^2_+) = \varnothing$. Suppose not. Let $\{(x_n, y_n)\}_{n \in \mathbb{Z}_+}$ be a positive orbit in $\operatorname{int}(\mathbb{R}^2_+)$ such that $\lim_{n \to \infty} (x_n, y_n) = (0, 0)$. Since $F(0, 0) > 1$, $F(x, y) > 1$ for (x, y) near $(0, 0)$. Thus for sufficiently large n, $x_{n+1} =$

$x_nF(x_n, y_n) > x_n$, contradicting $\lim_{n\to\infty} x_n = 0$. Next, we show that $W^+(M_2) \cap \text{int}(\mathbb{R}^2_+) = \varnothing$. Again, suppose not. Let $\{(x_n, y_n)\}_{n\in\mathbb{Z}_+}$ be a positive orbit in $\text{int}(\mathbb{R}^2_+)$ such that $\lim_{n\to\infty} d((x_n, y_n), M_2) = 0$. Then $\liminf_{n\to\infty} x_n \geqq \eta$, $\limsup_{n\to\infty} x_n \leqq \tilde{x}$, and $\lim_{n\to\infty} y_n = 0$. Since by (PP8) $\eta G(\eta, 0) > 1$, let $\varepsilon > 0$ be such that $(1-\varepsilon)\eta G(\eta, 0) > 1$. Since G is continuous, for sufficiently large n, we have $G(x, y_n) \geqq (1-\varepsilon)G(x, 0)$ for all $0 \leqq x \leqq \tilde{x}+1$. Thus, $y_{n+1} = x_n y_n G(x_n, y_n) \geqq (1-\varepsilon)x_n G(x_n, 0)y_n > y_n$ for sufficiently large n, contradicting $\lim_{n\to\infty} y_n = 0$.

Hence all the hypotheses for Theorem 3.3 are satisfied and model (4.1) exhibits persistence.

5. Discussion. The notion of persistence, originating in the theory of dynamical systems in locally compact metric spaces [1], [2], has been extended in various manners in recent work. In this paper we have extended the notion of persistence to discrete semidynamical systems. To obtain testable persistence criteria, we have proved a Butler-McGehee type lemma for such systems.

In [6], we have obtained testable uniform persistence criteria for one-dimensional maps. Here, we extend that work to obtain testable criteria for persistence in higher-dimensional systems.

We have applied our results to a class of discrete predator-prey models, which have been discussed in the literature as to their relevance, but not as to persistence and extinction of the modeled populations. In particular, a feature of these models is that all solutions initiating on the y-axis map to the origin in one iteration (in the absence of food, all predators die). By continuity, solutions initiating close to the y-axis are mapped to a neighbourhood of the origin. Hence, it is not obvious that the omega limit set of such an orbit is bounded away from the axes (persistence). Here we give criteria, with reasonable biological interpretations, for persistence to occur.

OSCILLATION AND NONOSCILLATION FOR SYSTEMS OF SELF-ADJOINT SECOND-ORDER DIFFERENCE EQUATIONS*

SHAOZHU CHEN† AND LYNN H. ERBE‡

Abstract. The self-adjoint second-order difference system (1) $\Delta(R_n\Delta Y_n)+P_nY_{n+1}=0$, $n\geqq 0$, where $\Delta Y_n = Y_{n+1}-Y_n$, $\{R_n\}_{n=0}^{\infty}$, $\{P_n\}_{n=0}^{\infty}$ are sequences of $d\times d$ Hermitian matrices with $R_n>0$ (positive definite) are considered. Oscillation and nonoscillation criteria for solutions of (1) are obtained by Riccati and averaging techniques.

Key words. difference equation, oscillation, nonoscillation, Riccati, averaging

AMS(MOS) subject classification. 39A10

1. Introduction.

Consider the self-adjoint second-order difference system

$$\Delta(R_n\Delta Y_n)+P_nY_{n+1}=0, \qquad n\geqq 0, \tag{1.1}$$

where Δ is the forward difference operator $\Delta Y_n = Y_{n+1}-Y_n$, and $R=\{R_n\}_{n=0}^{\infty}$, $P=\{P_n\}_{n=0}^{\infty}$ are sequences of $d\times d$ Hermitian matrices with $R_n>0$. We remark that Hermitian matrix inequalities $A>0$ ($\geqq 0$) are in the sense of positive (nonnegative) definiteness. In this paper we are interested in establishing oscillation and nonoscillation properties of solutions of (1.1) that may be considered as discrete versions of results for the second-order linear differential system

$$(R(t)Y'(t))'+P(t)Y(t)=0, \tag{1.2}$$

where $R(t)$, $P(t)$ are continuous Hermitian-matrix valued functions defined on $[0,+\infty)$ with $R(t)>0$. This problem has attracted substantial interest recently (we refer to [1]-[4], [8] for a careful discussion of disconjugacy and related properties of (1.1) and its relation to the continuous case (1.2)). We refer to [5]-[7] and [9] for additional results in the scalar case. In particular, in [5] the authors used Riccati and averaging techniques for the scalar case of (1.1) (R_n, P_n real numbers) to obtain a number of oscillation results. These, in turn, may be considered analogues (and, in some cases, a strengthening) of criteria in the scalar case of (1.2).

The results involve "averaging" methods that have previously been used in scalar differential and difference equations which allow us to obtain more sensitive tests for oscillation. As a corollary we obtain the discrete analogue of a recent test for oscillation of matrix differential equations obtained in [4] and [8] (cf. Corollary 2.16) which has generated considerable activity. To be specific, if $R_n=I$ (the $d\times d$ identity matrix) for all n, and if $\lim_{n\to\infty}\sum_{j=0}^{n}P_j$ does not exist (finite), then

$$\Delta^2 Y_n+P_nY_{n+1}=0$$

is oscillatory. The same conclusion holds if

$$\limsup_{n\to\infty}\lambda_1\left(\sum_{j=0}^{n}P_j\right)=+\infty,$$

where $\lambda_1(\cdot)$ denotes the largest eigenvalue. (This is the extension of the result of [4] and [8] referred to above.)

Let $U=\{U_n\}$, $V=\{V_n\}$ be two sequences of $d\times d$ matrices. We define the "bracket function" by

$$\{U, V\}_n = U_n^* R_n \Delta V_n - (R_n \Delta U_n)^* V_n, \qquad n \geqq 0, \tag{1.3}$$

where * denotes the conjugate transpose. It is straightforward to establish that

$$\{U, V\}_n = -\{V, U\}_n^* \tag{1.4}$$

and if U, V are solutions of (1.1), then

$$\Delta\{U, V\}_n = 0, \tag{1.5}$$

so that $\{U, V\}_n \equiv C$ (a constant matrix).

We say that a solution Y of (1.1) is *prepared* in case $\{Y, Y\}_n = 0$, $n \geqq 0$. We refer to [1] and [2] for an additional discussion of this and remark only that the analogue of the "preparedness" for (1.2) is $Y^*(t)R(t)Y'(t) \equiv Y^{*\prime}(t)R(t)Y(t)$, $t \geqq 0$. It is easy to establish that a solution Y of (1.1) is prepared if and only if $Y_{n+1}^* R_n Y_n$ is Hermitian for each $n \geqq 0$. We also have the following result whose proof is omitted.

LEMMA 1.1. *Let Y be a prepared solution of* (1.1) *and assume* $\det Y_n \neq 0$ *for $n \geqq N$ for some $N \geqq 0$. Then $R_n Y_{n+1} Y_n^{-1}$ is Hermitian for each $n \geqq N$.*

We say that a prepared solution Y of (1.1) is *nonoscillatory* if there exists an $N \geqq 0$ such that

$$Y_{n+1}^* R_n Y_n > 0 \quad \text{for } n \geqq N; \tag{1.6}$$

and Y is said to be *oscillatory* otherwise.

The next result gives a simple characterization of nonoscillatory solutions of (1.1).

LEMMA 1.2. *Suppose that Y is a prepared solution of* (1.1). *Then Y is nonoscillatory if and only if there exists an $N \geqq 0$ such that*

$$R_n Y_{n+1} Y_n^{-1} > 0 \quad \textit{for } n \geqq N. \tag{1.7}$$

Proof. Suppose that Y is nonoscillatory. Then $Y_n^* R_n Y_{n+1} = Y_{n+1}^* R_n Y_n$ for $n \geqq N$ and hence

$$R_n Y_{n+1} Y_n^{-1} = (Y_n^{-1})^* (Y_n^* R_n Y_{n+1}) Y_n^{-1} > 0 \quad \text{for } n \geqq N.$$

Conversely, if $R_n Y_{n+1} Y_n^{-1} > 0$ for $n \geqq N$, then

$$Y_{n+1}^* R_n Y_n = Y_n^* R_n Y_{n+1} = Y_n^* (R_n Y_{n+1} Y_n^{-1}) Y_n > 0 \quad \text{for } n \geqq N.$$

Hence Y is nonoscillatory.

Remark. It is easy to see that (1.7) is also equivalent to $R_n Y_n Y_{n+1}^{-1} > 0$ for $n \geqq N$. We also remark that by a Sturm-type separation theorem for (1.1), it follows that either all nontrivial prepared solutions of (1.1) are nonoscillatory or none of them are. To be specific, if in our notation, $D_n \equiv R_n + R_{n+1} - P_n > 0$ holds for all large n, the separation theorem is given in [1]. Moreover, if there exists a sequence $n_k \to \infty$ such that D_{n_k} is not positive definite, then it follows from Lemma 1.2 and some manipulation that there does not exist a prepared nonoscillatory solution of (1.1). We also remark that the fact that nonoscillation implies that D_n is eventually positive definite follows immediately from Corollary 3.1 of [2]. Furthermore, to avoid complications in applying the Sturm theory, it is necessary to restrict attention in this paper to solutions of (1.1) for which the $2d \times d$ partitioned matrix

$$\begin{pmatrix} Y_{n+1} \\ R_n \Delta Y_n \end{pmatrix}$$

has full rank (for some and hence all values of n).

Suppose that (1.1) is nonoscillatory and let Y be a solution with $R_n Y_{n+1} Y_n^{-1} > 0$ for $n \geqq N$ (Lemma 1.2). We define the Riccati difference operator by

$$Z_n = (R_n \Delta Y_n) Y_n^{-1}, \qquad n \geqq N. \tag{1.8}$$

Then since $Z_n = R_n Y_{n+1} Y_n^{-1} - R_n$, it follows by Lemmas 1.1 and 1.2 that Z_n is Hermitian and $Z_n > -R_n$ for $n \geqq N$. A simple computation gives

$$\Delta Z_n + Z_n (Z_n + R_n)^{-1} Z_n + P_n = 0, \qquad n \geqq N. \tag{1.9}$$

Equation (1.9) is called the *Riccati difference equation* associated with (1.1).

2. Oscillation and nonoscillation results. We shall assume henceforth in this paper that $D_n > 0$ holds for all large n. For any Hermitian matrix A, we will assume its eigenvalues $\lambda_k(A)$, $1 \leqq k \leqq d$, are ordered so that

$$\lambda_1(A) \geqq \cdots \geqq \lambda_d(A)$$

and as usual

$$\operatorname{tr} A = \sum_{i=1}^{d} \lambda_i(A), \qquad \|A\| = (\lambda_1(A^* A))^{1/2}.$$

THEOREM 2.1. *Equation* (1.1) *is nonoscillatory if and only if there exists a sequence* Z *of* $d \times d$ *Hermitian matrices with* $Z_n > -R_n$ *for* $n \geqq N$ *for some* $N \geqq 0$ *satisfying* (1.9).

Proof. We need only to prove the sufficiency. Let Z be the solution of (1.9) with $Z_n > -R_n$ for $n \geqq N$. Define Y by $Y_N = I$, the $d \times d$ identity matrix, and for $n \geqq N+1$

$$Y_n = \prod_{j=N}^{n-1} (R_j^{-1} Z_j + I) = (R_{n-1}^{-1} Z_{n-1} + I) \cdots (R_N^{-1} Z_N + I). \tag{2.1}$$

Then Y is a solution of (1.1) for $n \geqq N$ and moreover the matrix

$$Y_{n+1}^* R_n Y_n = Y_n^* (Z_n R_n^{-1} + I) R_n Y_n = Y_n^* (Z_n + R_n) Y_n$$

is Hermitian for all $n \geqq N$ and hence Y is a prepared solution of (1.1). Since $R_n Y_{n+1} Y_n^{-1} = R_n (R_n^{-1} Z_n + I) = Z_n + R_n > 0$ for $n \geqq N$, it follows by Lemma 1.2 that (1.1) is nonoscillatory. This completes the proof.

Next suppose that (1.1) is nonoscillatory and let Z be a Hermitian solution of (1.9). Then by Lemma 1.2 we have

$$\begin{aligned} Z_N - Z_N (Z_N + R_N)^{-1} Z_N &= Z_N (Z_N + R_N)^{-1} R_N = Z_N Y_N Y_{N+1}^{-1} \\ &= R_N - R_N Y_N Y_{N+1}^{-1} < R_N. \end{aligned}$$

Hence, from (1.9) for all $n \geqq N+1$ we have

$$\begin{aligned} \sum_{j=N}^{n-1} P_j &= Z_N - \sum_{j=N}^{n-1} Z_j (Z_j + R_j)^{-1} Z_j - Z_n \\ &< Z_N - Z_N (Z_N + R_N)^{-1} Z_N + R_n \\ &< R_N + R_n. \end{aligned} \tag{2.2}$$

In particular, letting $n = N+1$ and replacing N by n, we have

$$P_n < R_n + R_{n+1} \quad \text{for } n \geqq N, \tag{2.3}$$

which is the condition $D_n > 0$ (see the remark following Lemma 1.2). Actually, that (2.2), a generalization of (2.3), holds for all large N and $n \geqq N+1$ is a necessary condition for (1.1) to be nonoscillatory. This establishes Theorem 2.2.

THEOREM 2.2. *If there exist two sequences of integers* $\{N_k\}$ *and* $\{n_k\}$ *with* $n_k \geqq N_k + 1$, $N_k \to \infty$ *as* $k \to \infty$ *such that*

$$\lambda_d \left(R_{n_k} + R_{N_k} - \sum_{j=N_k}^{n_k-1} P_j \right) \leqq 0, \qquad k = 1, 2, \cdots, \tag{2.4}$$

then (1.1) *is oscillatory.*

From this we may easily obtain Corollary 2.3.

COROLLARY 2.3. *If there exist three sequences of integers* $\{N_k\}$, $\{M_k\}$, $\{n_k\}$ *with* $n_k \geqq M_k + 1$, $M_k \geqq N_k + 1$, $N_k \to \infty$ *as* $k \to \infty$ *such that*

$$\sum_{j=N_k}^{M_k-1} P_j \geqq R_{N_k} \tag{2.5}$$

and

$$\lambda_d \left(R_{n_k} - \sum_{j=M_k}^{n_k-1} P_j \right) \leqq 0, \qquad k = 1, 2, \cdots, \tag{2.6}$$

then (1.1) *is oscillatory.*

Proof. We have

$$\begin{aligned} \lambda_d \left(R_{n_k} + R_{N_k} - \sum_{j=N_k}^{n_k-1} P_j \right) &= \lambda_d \left\{ R_{n_k} - \sum_{j=M_k}^{n_k-1} P_j + \left(R_{N_k} - \sum_{j=N_k}^{M_k-1} P_j \right) \right\} \\ &\leqq \lambda_d \left\{ R_{n_k} - \sum_{j=M_k}^{n_k-1} P_j \right\} \leqq 0, \qquad k = 1, 2, \cdots \end{aligned}$$

so that (1.1) is oscillatory by Theorem 2.2.

From Corollary 2.3, more particularly, we have Corollary 2.4.

COROLLARY 2.4. *If for any* N *there exists an* $n \geqq N + 1$ *such that*

$$\lambda_d \left(R_n - \sum_{j=N}^{n-1} P_j \right) \leqq 0 \tag{2.7}$$

and

$$\lim_{n \to \infty} \lambda_d \left(\sum_{j=0}^{n} P_j \right) = \infty, \tag{2.8}$$

then (1.1) *is oscillatory.*

Proof. For any integer N_k by (2.8) we can find an $M_k \geqq N_k + 1$ so that (2.5) holds. Then it follows from (2.7) that there is an $n_k \geqq M_k + 1$ so that (2.6) holds. Therefore, (1.1) is oscillatory by Corollary 2.3.

Remark. In the scalar case, Theorem 2.2 and Corollary 2.4 become Theorem 2.9 in [5] and Lemma 3.5 in [9], respectively.

Example 1. Let $d = 2$. For any integer $k \geqq 3$, we let $R_{k^2} = R_{k^2+9} = I$ (2×2 identity matrix), let $P_n = \operatorname{diag}(p_n, q_n)$ with $p_n = \frac{1}{4}$ and q_n arbitrary real numbers for $n = k^2, \cdots, k^2 + 8$, and let R_n, P_n be arbitrary otherwise. Then (1.1) is oscillatory since condition (2.4) in Theorem 2.2 holds for $N = k^2$, $n = k^2 + 9$. Note that (2.8) may not hold if we define P_n appropriately for $k^2 + 9 \leqq n \leqq (k+1)^2 - 1$.

We will denote by $\mathscr{C}$ the set of all Hermitian matrix sequences $f = \{f_n\}_{n=0}^{\infty}$ with the property that

$$\lim_{n \to \infty} \sum_{j=0}^{n} f_j = \sum_{j=0}^{\infty} f_j \quad \text{exists (finite).}$$

Clearly, if $f \in \mathscr{C}$ then $F_n = \sum_{j=n}^{\infty} f_j$ is Hermitian for all $n \geqq 0$. If f is a sequence of Hermitian matrices with $f_n \geqq 0$, $n \geqq 0$, then

$$f \in \mathscr{C} \Leftrightarrow \sum_{n=0}^{\infty} \operatorname{tr} f_n < \infty \Leftrightarrow \sum_{n=0}^{\infty} \|f_n\| < \infty. \tag{2.9}$$

Set $a_n = \lambda_d(R_n)$, $A_n = \lambda_1(R_n)$, $n \geqq 0$. Then

$$0 < a_n I \leqq R_n \leqq A_n I, \qquad 0 < A_n^{-1} I \leqq R_n^{-1} \leqq a_n^{-1} I. \tag{2.10}$$

We will also denote by $\mathscr{F}$ the set of all sequences of real numbers $b = \{b_n\}_{n=0}^{\infty}$ with $0 \leqq b_n \leqq 1$ and

$$\sum_{n=0}^{+\infty} b_n = +\infty. \tag{2.11}$$

It will be convenient to set

$$B_n = \sum_{j=0}^{n} b_j, \qquad B_{n,m} = \sum_{j=m}^{n} b_j.$$

Whenever we write $(B_{n,m})^{-1}$, we will take $n \geqq m$ sufficiently large so that $B_{n,m} > 0$. Obviously, we have

$$\lim_{n\to\infty} B_n^{-1} B_{n,N} = 1 \quad \text{for any fixed } N \geqq 0. \tag{2.12}$$

We also have the following lemma.

LEMMA 2.5. *Let $f = \{f_n\}_{n=0}^{\infty}$ be a sequence either of real numbers or of $d \times d$ matrices. If $\lim_{n\to\infty} f_n = C$ (where C is either a real number (or $\pm\infty$) or a $d \times d$ matrix), then*

$$\lim_{n\to\infty} (B_{n,N})^{-1} \sum_{k=N}^{n} b_k f_k = C \quad \text{for } N \geqq 0. \tag{2.13}$$

In the latter case, if C is a $d \times d$ matrix, then (2.13) *is to be interpreted componentwise.*

That is, "averaging" with respect to the class $\mathscr{F}$ preserves limits.

We introduce the following conditions, which will be needed in the results to follow:

(A1) The sequence A/a is bounded, i.e., there is a $K > 0$ such that $A_n/a_n \leqq K$, $n \geqq 0$, and there exist $b \in \mathscr{F}$ and $M > 0$ such that

$$B_n^{-3/2} \sum_{j=0}^{n} b_j A_{j+1} \leqq M \quad \text{for all large } n.$$

(A2) The sequence A/a is bounded and there exist $b \in \mathscr{F}$ and $M > 0$ such that

$$B_n^{-1} \sum_{j=0}^{n} b_j A_{j+1} \leqq M \quad \text{for all large } n.$$

(A3) The sequences A/a and A are bounded.

Clearly, we have (A3)$\Rightarrow$(A2)$\Rightarrow$(A1).

THEOREM 2.6. *If R satisfies* (A1) *and equation* (1.1) *is nonoscillatory, then the following are equivalent*:

(i) $$\lim_{n\to\infty} B_n^{-1} \sum_{k=0}^{n} b_k \sum_{j=0}^{k} P_j = C, \tag{2.14}$$

where C is a constant Hermitian matrix and may depend on $b \in \mathscr{F}$;

(ii) $$\liminf_{n\to\infty} B_n^{-1} \sum_{k=0}^{n} b_k \sum_{j=0}^{k} \operatorname{tr} P_j > -\infty; \tag{2.15}$$

(iii) *For any prepared solution* Y *of* (1.1) *with* $Y_{n+1}^* R_n Y_n > 0$ *for* $n \geqq N$ *for some* $N \geqq 0$, *the sequence*

$$Z(Z+R)^{-1}Z \in \mathscr{C}, \tag{2.16}$$

where Z *is given by* (1.8).

Proof. Obviously (i)$\Rightarrow$(ii).

(ii)$\Rightarrow$(iii). Suppose not, and let $\rho_n \equiv Z_n(Z_n+R_n)^{-1}Z_n$. Then since $\rho_n \geqq 0$ we have

$$\sum_{n=N}^{\infty} \operatorname{tr} \rho_n = +\infty. \tag{2.17}$$

From (1.9) we have

$$-Z_{n+1} = \sum_{j=N}^{n} Z_j(Z_j+R_j)^{-1}Z_j + \sum_{j=N}^{n} P_j - Z_N \tag{2.18}$$

and hence

$$\begin{aligned}(B_{n,N})^{-1} \sum_{k=N}^{n} b_k \sum_{j=N}^{k} \operatorname{tr} \rho_j + (B_{n,N})^{-1} \sum_{k=N}^{n} b_k \sum_{j=N}^{k} \operatorname{tr} P_j - \operatorname{tr} Z_N \\ = (B_{n,N})^{-1} \sum_{k=N}^{n} b_k \operatorname{tr}(-Z_{k+1}).\end{aligned} \tag{2.19}$$

Now by Lemma 2.5, (2.17) implies that the first term on the left side of (2.19) $\to \infty$ as $n \to \infty$. It follows from (ii) and (2.19) that

$$\lim_{n\to\infty} (B_{n,N})^{-1} \sum_{k=N}^{n} b_k \operatorname{tr}(-Z_{k+1}) = +\infty$$

and hence

$$\lim_{n\to\infty} (B_{n,N})^{-1} \sum_{k=N}^{n} b_k \|Z_{k+1}\| = +\infty. \tag{2.20}$$

Dividing (2.19) by $(B_{n,N})^{1/2}$, in view of (ii), condition (A1), and the fact that $-Z_{k+1} < R_{k+1}$, we have for all large n

$$(B_{n,N})^{-3/2} \sum_{k=N}^{n} b_k \sum_{j=N}^{k} \operatorname{tr} \rho_j \leqq M_1 < \infty.$$

For any fixed $n \geqq N+1$, choose $m > n$ so that $B_{n,N} \leqq (B_m - B_n) \leqq 2B_{n,N}$ and hence $B_{m,N} \leqq 3B_{n,N}$. Then we have

$$\begin{aligned}(B_{n,N})^{-1/2} \sum_{j=N}^{n} \operatorname{tr} \rho_j &\leqq (B_{n,N})^{-3/2}(B_m - B_n) \sum_{j=N}^{n} \operatorname{tr} \rho_j \\ &\leqq (B_{n,N})^{-3/2} \sum_{k=N}^{m} \left(b_k \sum_{j=N}^{k} \operatorname{tr} \rho_j \right) \\ &\leqq 3^{3/2}(B_{m,N})^{-3/2} \sum_{k=N}^{m} \left(b_k \sum_{j=N}^{k} \operatorname{tr} \rho_j \right) \leqq 3^{3/2} M_1 < \infty.\end{aligned} \tag{2.21}$$

On the other hand, since

$$\begin{aligned}\rho_n &= Z_n(Z_n+R_n)^{-1}Z_n = Z_n(R_n^{-1}Z_n + I)^{-1}R_n^{-1}Z_n \\ &= Z_n R_n^{-1} Z_n (I + R_n^{-1}Z_n)^{-1}\end{aligned}$$

and $A_n^{-1}Z_n^2 \leqq Z_n R_n^{-1} Z_n = \rho_n(I + R_n^{-1}Z_n)$, we have

$$\begin{aligned}\|Z_n\|^2 = \|Z_n^2\| &\leqq A_n \|\rho_n\| + \frac{A_n}{a_n}\|\rho_n\|\,\|Z_n\| \\ &= \frac{A_n}{a_n}\|\rho_n\|(a_n + \|Z_N\|) \\ &\leqq \frac{2A_n}{a_n}\|\rho_n\| \max(a_n, \|Z_n\|)\end{aligned}$$

and hence

$$\begin{aligned}\|Z_n\| &\leqq \max\left(\frac{2A_n}{a_n}\|\rho_n\|, (2\|\rho_n\|A_n)^{1/2}\right) \\ &\leqq 2K\|\rho_n\| + (2\|\rho_n\|A_n)^{1/2}.\end{aligned} \tag{2.22}$$

By the Schwarz inequality we obtain

$$\begin{aligned}(B_{n,N})^{-1}\sum_{k=N}^{n} b_k\|Z_{k+1}\| &\leqq 2K(B_{n,N})^{-1}\sum_{k=N}^{n} b_k\|\rho_{k+1}\| \\ &\quad + \sqrt{2}\,(B_{n,N})^{-1}\sum_{k=N}^{n} b_k(\|\rho_{k+1}\|A_{k+1})^{1/2} \\ &\leqq 2K(B_{n,N})^{-1}\sum_{k=N}^{n}\|\rho_{k+1}\| \\ &\quad + \sqrt{2}\,(B_{n,N})^{-1}\left(\sum_{k=N}^{n}\|\rho_{k+1}\|\right)^{1/2}\left(\sum_{k=N}^{n} b_k A_{k+1}\right)^{1/2}.\end{aligned} \tag{2.23}$$

Now from (2.23), (2.21), and (A1) we see that

$$(B_{n,N})^{-1}\sum_{k=N}^{n} b_k\|Z_{k+1}\|$$

is bounded above, which contradicts (2.20). This shows that (ii)$\Rightarrow$(iii).

(iii)$\Rightarrow$(i). From condition (iii) we have

$$\sum_{k=N}^{\infty}\|\rho_{k+1}\| < \infty. \tag{2.24}$$

Hence, from (2.23), (2.24), and (A1) it follows that

$$\lim_{n\to\infty}(B_{n,N})^{-1}\sum_{k=N}^{n} b_k\|Z_{k+1}\| = 0. \tag{2.25}$$

Since

$$(B_{n,N})^{-1}\sum_{k=N}^{n} b_k\sum_{j=N}^{k} P_j = Z_n + (B_{n,N})^{-1}\sum_{k=N}^{n} b_k(-Z_{k+1}) - (B_{n,N})^{-1}\sum_{k=N}^{n} b_k\sum_{j=N}^{k}\rho_j \tag{2.26}$$

and each term on the right side of (2.26) is convergent as $n\to\infty$, we obtain (i) by letting $n\to\infty$ in (2.26). This completes the proof of the theorem.

COROLLARY 2.7. *Suppose that R satisfies* (A1) *and that P satisfies condition* (2.15). *If*

$$\lim_{n\to\infty} B_n^{-1} \sum_{k=0}^{n} b_k \sum_{j=0}^{k} P_j \quad \textit{does not exist (finite)}, \tag{2.27}$$

then (1.1) *is oscillatory.*

Remark. Thus, if there exists $b \in \mathcal{F}$ such that conditions (A1), (2.15), and (2.27) are satisfied, then we conclude that (1.1) is oscillatory. It is easy to give conditions under which the limit in (2.27) does not exist. For example, under the assumption that (A1) and (2.15) hold, (1.1) is oscillatory if either of the following conditions holds:

$$\limsup_{n\to\infty} B_n^{-1} \sum_{k=0}^{n} b_k \sum_{j=0}^{k} \operatorname{tr} P_j = +\infty \tag{2.28}$$

or

$$\liminf_{n\to\infty} B_n^{-1} \sum_{k=0}^{n} b_k \sum_{j=0}^{k} \operatorname{tr} P_j < \limsup_{n\to\infty} B_n^{-1} \sum_{k=0}^{n} b_k \sum_{j=0}^{k} \operatorname{tr} P_j. \tag{2.29}$$

We next introduce a Riccati summation equation. Suppose that (A1) and condition (2.15) hold and that (1.1) is nonoscillatory. Since

$$B_n^{-1} \sum_{k=0}^{n} b_k \sum_{j=0}^{k} P_j = B_n^{-1} \sum_{k=0}^{N-1} b_k \sum_{j=0}^{k} P_j + B_n^{-1} B_{n,N} \left(\sum_{j=0}^{N-1} P_j \right) + (B_n^{-1} B_{n,N}) B_{n,N}^{-1} \sum_{k=N}^{n} b_k \sum_{j=N}^{k} P_j$$

for $n > N \geqq 0$, we have after some computation

$$\lim_{n\to\infty} B_{n,N}^{-1} \sum_{k=N}^{n} b_k \sum_{j=N}^{k} P_j = C - \sum_{j=0}^{N-1} P_j \tag{2.30}$$

(using $B_n^{-1} B_{n,N} \to 1$ as $n \to \infty$), where C is defined as in (2.14).

THEOREM 2.8. *Let* (A1) *and condition* (2.15) *hold for some* $b \in \mathcal{F}$. *Then* (1.1) *is nonoscillatory if and only if there exists a sequence Z of Hermitian matrices with* $Z_n > -R_n$ *for* $n \geqq N$ *for some* $N \geqq 0$ *satisfying*

$$Z_n = C - \sum_{j=0}^{n-1} P_j + \sum_{j=n}^{\infty} Z_j (Z_j + R_j)^{-1} Z_j, \qquad n \geqq N, \tag{2.31}$$

where C is defined in (2.14) *and may depend on b.*

Proof. Suppose first that (1.1) is nonoscillatory. By Theorem 2.6 there exists a sequence Z of Hermitian matrices with $Z_n > -R_n$ for $n \geqq N$ satisfying (2.26). Letting $n \to \infty$ in (2.26), using (2.30), and replacing N by n, we obtain (2.31). Conversely, suppose that Z is the Hermitian matrix sequence in the theorem. From (2.31) we have

$$\Delta Z_n = -P_n - Z_n (Z_n + R_n)^{-1} Z_n$$

and so (1.1) is nonoscillatory by Theorem 2.1.

THEOREM 2.9. *Let* (A2) *hold for some* $b \in \mathcal{F}$. *If* (1.1) *is nonoscillatory then the following statements are equivalent*:

(i) $\lim_{n\to\infty} B_n^{-1} \sum_{k=0}^{n} b_k \sum_{j=0}^{k} \operatorname{tr} P_j = -\infty$;

(ii) $\liminf_{n\to\infty} B_n^{-1} \sum_{k=0}^{n} b_k \sum_{j=0}^{k} \operatorname{tr} P_j = -\infty$;

(iii) *There exists a nonoscillatory solution Y of* (1.1) *with* $Y_{n+1}^* R_n Y_N > 0$ *for* $n \geqq N$ *for some* $N \geqq 0$ *such that the sequence* $Z_n = R_n (\Delta Y_n) Y_n^{-1}$, $n \geqq N$, *satisfies*

$$\sum_{j=N}^{\infty} \operatorname{tr} (Z_j (Z_j + R_j)^{-1} Z_j) = +\infty.$$

Proof. Since (A2)$\Rightarrow$(A1), (ii) and (iii) are equivalent by virtue of Theorem 2.6. Since (i) clearly implies (ii) we need only show that (ii) and (iii)$\Rightarrow$(i). From (2.19)

we have

$$(B_{n,N})^{-1}\sum_{k=N}^{n} b_k \sum_{j=N}^{k} \operatorname{tr} P_j \leqq \operatorname{tr} Z_n + (B_{n,N})^{-1}\sum_{k=N}^{n} b_k \operatorname{tr} R_{k+1} - (B_{n,N})^{-1}\sum_{k=N}^{n} b_k \sum_{j=N}^{k} \operatorname{tr} \rho_j. \tag{2.32}$$

Since the right side of (2.32) tends to $-\infty$ as $n\to\infty$, it follows that (i) holds. This completes the proof.

COROLLARY 2.10. *If* (A2) *holds for some* $b\in\mathscr{F}$ *and*

$$-\infty = \liminf_{n\to\infty} B_n^{-1}\sum_{k=0}^{n} b_k \sum_{j=0}^{k} \operatorname{tr} P_j < \limsup_{n\to\infty} B_n^{-1}\sum_{k=0}^{n} b_k \sum_{j=0}^{k} \operatorname{tr} P_j,$$

then (1.1) *is oscillatory.*

THEOREM 2.11. *Let* (A3) *hold. If* (1.1) *is nonoscillatory, then the following statements are equivalent*:

(i) $P\in\mathscr{C}$;

(ii) $\lim_{n\to\infty} B_n^{-1}\sum_{k=0}^{n} b_k \sum_{j=0}^{k} P_j = C$ *for some* $b\in\mathscr{F}$, *where* C *is a constant matrix*;

(iii) *The sequence* P *satisfies condition* (2.15) *for some* $b\in\mathscr{F}$;

(iv) *For any nonoscillatory solution* Y *of* (1.1) *with* $Y_{n+1}^{*}R_nY_n>0$ *for* $n\geqq N$ *for some* $N\geqq 0$ *the sequence* $Z_n = R_n(\Delta Y_n)Y_n^{-1}$, $n\geqq N$, *satisfies* $Z(Z+R)^{-1}Z\in\mathscr{C}$.

Proof. Since (A3)$\Rightarrow$(A1), (iii) and (iv) are equivalent by Theorem 2.6. Obviously (i)$\Rightarrow$(ii)$\Rightarrow$(iii). We need only show that (iii) and (iv)$\Rightarrow$(i). Now from (2.18) it is sufficient to show that $Z_n\to 0$ as $n\to\infty$. But this is immediate from (2.22) because of the boundedness of the sequence $\{A_n\}$. This completes the proof.

We observe that if $P\in\mathscr{C}$, then the limit C in (ii) of Theorem 2.11 is independent of $b\in\mathscr{F}$ and $C=\sum_{j=0}^{\infty} P_j$. If we let

$$Q_n = \sum_{j=n}^{\infty} P_j,$$

then we can get an analogue of Theorem 2.8 under the assumption (A3) instead of (A1) as follows.

THEOREM 2.12. *Let* (A3) *and condition* (2.15) *hold for some* $b\in\mathscr{F}$. *Then* (1.1) *is nonoscillatory if and only if* $P\in\mathscr{C}$ *and there exists a sequence* Z *of Hermitian matrices with* $Z_n>-R_n$ *for* $n\geqq N$ *for some* $N\geqq 0$ *satisfying*

$$Z_n = Q_n + \sum_{j=n}^{\infty} Z_j(Z_j+R_j)^{-1}Z_j, \qquad n\geqq N. \tag{2.33}$$

We can also obtain a counterpart to Theorem 2.11.

THEOREM 2.13. *Let* (A3) *hold. If* (1.1) *is nonoscillatory then the following statements are equivalent*:

(i) $\lim_{n\to\infty}\lambda_d(\sum_{j=0}^{n} P_j)=-\infty$, $\limsup_{n\to\infty}\lambda_1(\sum_{j=0}^{n} P_j)<\infty$;

(ii) $\lim_{n\to\infty}\operatorname{tr}(\sum_{j=0}^{n} P_j)=-\infty$;

(iii) $\liminf_{n\to\infty} B_n^{-1}\sum_{k=0}^{n} b_k\sum_{j=0}^{k}\operatorname{tr} P_j=-\infty$ *for some* $b\in\mathscr{F}$;

(iv) *There exists a prepared solution* Y *of* (1.1) *with* $Y_{n+1}^{*}R_nY_n>0$ *for* $n\geqq N$ *for some* $N\geqq 0$ *such that*

$$\sum_{j=N}^{\infty}\operatorname{tr}(Z_j(Z_j+R_j)^{-1}Z_j)=\infty,$$

where $Z_n = R_n(\Delta Y_n)Y_n^{-1}>-R_n$ *for* $n\geqq N$.

Proof. Obviously (i)⇒(ii)⇒(iii). By Theorem 2.11 it follows that (iii) and (iv) are equivalent. If Z is the sequence in (iv), then for all $n \geqq N$ we have

$$\sum_{j=N}^{n} P_j = Z_N - Z_{n+1} - \sum_{j=N}^{n} Z_j(Z_j + R_j)^{-1} Z_j$$

$$< Z_N + R_{n+1} - \sum_{j=N}^{n} Z_j(Z_j + R_j)^{-1} Z_j.$$

Hence

$$\operatorname{tr}\left(\sum_{j=N}^{n} P_j\right) \leqq \operatorname{tr} Z_N + M_1 - \sum_{j=N}^{n} \operatorname{tr}\left(Z_j(Z_j + R_j)^{-1} Z_j\right) \to -\infty$$

as $n \to \infty$, i.e., (iv)⇒(ii). By the convexity of the functional $\lambda_1(\cdot)$, we also have

$$\lambda_1\left(\sum_{j=N}^{n} P_j\right) \leqq \lambda_1(Z_N) + \lambda_1(R_{n+1}) + \lambda_1\left(-\sum_{j=N}^{n} Z_j(Z_j + R_j)^{-1} Z_j\right) \leqq \lambda_1(Z_N) + M_1,$$

i.e., (iv) and (ii)⇒(i). This proves the theorem.

Remark. Theorems 2.11 and 2.13 show the significant dependence of the oscillation of (1.1) on the divergence of the sequence P under (A3). The analogue of Theorem 2.11 for the differential equation (1.2) is only partially true. For example, if we let $R(t) = I$ and assume

$$\liminf_{t\to\infty} \frac{1}{t} \int_0^t \int_0^s \operatorname{tr} P(r)\, dr\, ds > -\infty,$$

then the nonoscillation of (1.2) does not imply the convergence of $\int_0^\infty P(t)\, dt$.

The following oscillation criteria are immediate from Theorems 2.11 and 2.13.

COROLLARY 2.14. *Let* (A3) *hold and assume that P satisfies* (2.15) *for some* $b \in \mathcal{F}$. *If* $P \notin \mathcal{C}$, *then* (1.1) *is oscillatory. In particular,* (1.1) *is oscillatory in case either*

$$\limsup_{n\to\infty} \lambda_1\left(\sum_{j=0}^{n} P_j\right) = +\infty, \tag{2.34}$$

or

$$\liminf_{n\to\infty} \lambda_k\left(\sum_{j=0}^{n} P_j\right) < \limsup_{n\to\infty} \lambda_k\left(\sum_{j=0}^{n} P_j\right) \quad \text{for some } 1 \leqq k \leqq d. \tag{2.35}$$

COROLLARY 2.15. *Let* (A3) *hold. If for some* $b \in \mathcal{F}$

$$\liminf_{n\to\infty} B_n^{-1} \sum_{k=0}^{n} b_k \sum_{j=0}^{k} \operatorname{tr} P_j = -\infty,$$

then (1.1) *is oscillatory in case either* (2.34) *holds or*

$$\limsup_{n\to\infty} \sum_{j=0}^{n} \operatorname{tr} P_j > -\infty. \tag{2.36}$$

Combining Corollaries 2.14 and 2.15, we obtain Corollary 2.16.

COROLLARY 2.16. *If* (A3) *and* (2.34) *hold, then* (1.1) *is oscillatory.*

Remark. Corollary 2.16 shows that the discrete matrix analogue of a recent result of Kaper and Kwong [8] and of Byers, Harris, and Kwong [4] for the continuous case (eq. (1.2)) is valid. The criteria in Corollaries 2.14 and 2.15 may also be considered analogues of some of the results of [3] for (1.2).

Example 2. Let $d=2$, $R_n=I$ and let $P_n=\operatorname{diag}(p_n, q_n)$ with $p_n+q_n=0$, $p_n, q_n<2$ for all n, and

$$\liminf_{n\to\infty}\sum_{j=0}^{n} p_j<\limsup_{n\to\infty}\sum_{j=0}^{n} p_j.$$

Then (1.1) is oscillatory by Corollary 2.14.

Example 3. Let $d=2$, $R_n=I$, and $P_n=\operatorname{diag}(p_n, q_n)$ with $p_n=1/n$ if n is prime and $p_n=0$ otherwise. If

$$\limsup_{n\to\infty}\sum_{j=0}^{n}(p_j+q_j)>-\infty,$$

then (1.1) is oscillatory from the following result.

COROLLARY 2.17. *Let* (A3) *hold. If* $P\notin\mathscr{C}$ *and* (2.36) *holds, then* (1.1) *is oscillatory.*

Proof. From (2.36) we can find a sequence of integers n_r with $n_r\to\infty$ as $r\to\infty$ such that

$$\lim_{r\to\infty}\sum_{j=0}^{n_r}\operatorname{tr} P_j=C>-\infty.$$

Let $b_n=1$ if $n=n_r$, $r=1,2,\cdots$ and $b_n=0$ otherwise. Then

$$B_{n_r}^{-1}\sum_{k=0}^{n_r} b_k\sum_{j=0}^{k}\operatorname{tr} P_j=\frac{1}{r}\sum_{k=1}^{r}\sum_{j=0}^{n_k}\operatorname{tr} P_j\to C\quad\text{as } r\to\infty.$$

Thus, (2.15) is satisfied and the oscillation of (1,1) follows from Corollary 2.14.

More sophisticated examples may also be given. We leave this to the interested reader.

Acknowledgment. The authors are indebted to the referees for their detailed comments.

CONDITIONAL ANALYTIC FEYNMAN INTEGRALS AND A RELATED SCHRÖDINGER INTEGRAL EQUATION*

DONG MYUNG CHUNG† AND DAVID SKOUG‡

Abstract. The concept of a conditional Feynman integral of a function F given a function X is introduced, and its existence is established for various functions. Then the conditional Feynman integral is used to derive an integral equation that is formally equivalent to the Schrödinger equation.

Key words. Wiener integral, conditional Wiener integral, Feynman integral, conditional Feynman integral

AMS(MOS) subject classification. 28C20

1. Introduction. In this paper we define the concept of a conditional analytic Feynman integral of a function F on Wiener space given a function X. In particular, for a certain choice of X we establish the existence of the conditional Feynman integral for all functions F in the Banach algebra S introduced by Cameron and Storvick [3]. In [15] Johnson has shown that S is isometrically isomorphic to the class $\mathscr{F}(H)$ of Fresnel integrable functions as given by Albeverio and Høegh-Krohn [1]. The Banach algebras $\mathscr{F}(H)$ and S and related theories have been studied quite extensively; references include [3]-[7], [9]-[11], [14], [15], [17]-[21].

To define the conditional analytic Feynman integral we use the conditional Wiener integral as given by Yeh in [23], [24] and studied further in [8], [13], [22], [25]. In [24] Yeh used the conditional Wiener integral to derive the Kac-Feynman formula. Here we use the conditional Feynman integral to derive an integral equation formally equivalent to the Schrödinger equation. We also use the conditional Feynman integral to provide a fundamental solution to the Schrödinger equation.

2. Definitions and preliminaries. Let ν be a positive integer and let $C_0^\nu[0, t]$ denote ν-dimensional Wiener space, that is the space of $\mathbb{R}^\nu$-valued continuous functions $\vec{x}$ on $[0, t]$ such that $\vec{x}(0) = \vec{0}$. Let $\mathscr{M}^\nu$ denote the class of all Wiener measurable subsets of $C_0^\nu[0, t]$ and let m^ν denote ν-dimensional Wiener measure. $(C_0^\nu[0, t], \mathscr{M}^\nu, m^\nu)$ is a complete measure space. In case $\nu = 1$, we delete the one and simply write $(C_0[0, t], \mathscr{M}, m)$. Of course, $C_0^\nu[0, t] = C_0[0, t] \times \cdots \times C_0[0, t]$ (ν times). We denote the Wiener integral of a function F by

$$\int_{C_0^\nu[0,t]} F(\vec{x})\, dm^\nu(\vec{x}).$$

A subset E of $C_0^\nu[0, t]$ is said to be scale-invariant measurable [12], [16] provided ρE is Wiener measurable for each $\rho > 0$, and a scale-invariant measurable set N is said to be scale-invariant null provided $m^\nu(\rho N) = 0$ for each $\rho > 0$. A property that holds except on a scale-invariant null set is said to hold scale-invariant almost everywhere (s-a.e.).

Next we give Yeh's definition of the conditional Wiener integral from [24].

DEFINITION 1. Let X be an $\mathbb{R}^\nu$-valued Wiener measurable function on $C_0^\nu[0, t]$ and let F be a complex-valued Wiener integrable function on $C_0^\nu[0, t]$. Let P_X be the probability distribution of X, i.e., for all $B \in \mathcal{B}^\nu$, the Borel sets in $\mathbb{R}^\nu$, $P_X(B) = m^\nu(X^{-1}(B))$. The conditional Wiener integral of F given X is by definition the equivalence class of Borel measurable and P_X-integrable functions ψ on $\mathbb{R}^\nu$, modulo null functions on $(\mathbb{R}^\nu, \mathcal{B}^\nu, P_X)$, such that for all $B \in \mathcal{B}^\nu$,

$$\int_{X^{-1}(B)} F(\vec{x})\, dm^\nu(\vec{x}) = \int_B \psi(\vec{\eta})\, dP_X(\vec{\eta}).$$

By the Radon-Nikodym theorem such a function ψ exists and is determined up to a null function on $(\mathbb{R}^\nu, \mathcal{B}^\nu, P_X)$. We let $E(F|X)$ denote a representative of the equivalence class and so for all $B \in \mathcal{B}^\nu$,

$$\int_{X^{-1}(B)} F(\vec{x})\, dm^\nu(\vec{x}) = \int_B E(F|X)(\vec{\eta})\, dP_X(\vec{\eta}).$$

We are now ready to define the conditional analytic Feynman integral of a function F given X.

DEFINITION 2. Let X be an $\mathbb{R}^\nu$-valued scale-invariant measurable function on $C_0^\nu[0, t]$ and let F be a scale-invariant measurable function on $C_0^\nu[0, t]$ such that the Wiener integral

$$\int_{C_0^\nu[0,t]} F(\lambda^{-1/2}\vec{x})\, dm^\nu(\vec{x})$$

exists as a finite number for all $\lambda > 0$. For $\lambda > 0$ let

$$J_\lambda(\vec{\eta}) = E(F(\lambda^{-1/2}\cdot)|X(\lambda^{-1/2}\cdot))(\vec{\eta})$$

denote the conditional Wiener integral of $F(\lambda^{-1/2}\cdot)$ given $X(\lambda^{-1/2}\cdot)$. If for almost every $\vec{\eta} \in \mathbb{R}^\nu$, there exists a function $J_\lambda^*(\vec{\eta})$, analytic in λ on $\mathbb{C}^+ \equiv \{\lambda \in \mathbb{C}: \operatorname{Re} \lambda > 0\}$ such that $J_\lambda^*(\vec{\eta}) = J_\lambda(\vec{\eta})$ for all $\lambda > 0$, then J_λ^* is defined to be the conditional analytic Wiener integral of F given X with parameter λ and for $\lambda \in \mathbb{C}^+$ we write

$$E^{\mathrm{anw}_\lambda}(F|X)(\vec{\eta}) = J_\lambda^*(\vec{\eta}).$$

If for fixed real $q \neq 0$, the limit

$$\lim_{\lambda \to -iq} E^{\mathrm{anw}_\lambda}(F|X)(\vec{\eta})$$

exists for almost every $\vec{\eta} \in \mathbb{R}^\nu$ where λ approaches $-iq$ through $\mathbb{C}^+$, we will denote the value of this limit by $E^{\mathrm{anf}_q}(F|X)$ and call it the conditional analytic Feynman integral of F given X with parameter q.

Remark 1. The notation $E^{\mathrm{anw}_\lambda}(F|X)$ does not mean "conditional expectation with respect to a probability measure" but rather an extension of such a conditional expectation.

Remark 2. In [24] Yeh (in this paper he worked with $\nu = 1$ but clearly his results in § 3 hold for general ν) always chose X to be the function $X(\vec{x}) = \vec{x}(t)$ and in that case

$$\frac{dP_X(\vec{\eta})}{d\vec{\eta}} = (2\pi t)^{-\nu/2} \exp\left\{-\frac{\|\vec{\eta}\|^2}{2t}\right\}.$$

In addition, when we use his inversion formulas [23, Thm. 2] and [24, Thm. 3], a version of $E(F|X)(\vec{\eta})$ is given for all $\vec{\eta} \in \mathbb{R}^\nu$ by the formula

$$(1)\quad E(F|X)(\vec{\eta}) = \left(\frac{dP_X(\vec{\eta})}{d\vec{\eta}}\right)^{-1} (2\pi)^{-\nu} \int_{\mathbb{R}^\nu} e^{-i\langle \vec{U}, \vec{\eta}\rangle} \int_{C_0^\nu[0,t]} e^{i\langle \vec{U}, \vec{x}(t)\rangle} F(\vec{x})\, dm^\nu(\vec{x})\, d\vec{U}$$

provided that the Wiener integral

$$\int_{C_0^\nu[0,t]} e^{i\langle \vec{U}, \vec{x}(t)\rangle} F(\vec{x})\, dm^\nu(\vec{x}) \tag{2}$$

is an integrable function of $\vec{U}$ on $\mathbb{R}^\nu$.

Remark 3. In [22], Park and Skoug have shown that if F is Borel measurable and Wiener integrable and if $X(\vec{x}) = \vec{x}(t)$, then the conditional Wiener integral $E(F|X)$ is given in terms of an ordinary Wiener integral by the formula

$$E(F|X)(\vec{\eta}) = \int_{C_0^\nu[0,t]} F\left(\vec{x}(\cdot) - \frac{\cdot}{t}\vec{x}(t) + \frac{\cdot}{t}\vec{\eta}\right) dm^\nu(\vec{x}). \tag{3}$$

Since all the functions F we consider in this paper are Borel measurable we can use either (1) or (3) to compute $E(F|X)$; one advantage of using (3) is that we do not need to show first that the expression in (2) is an integrable function of $\vec{U}$ on $\mathbb{R}^\nu$. It has also been pointed out in [22] that if F is only Wiener measurable rather than Borel measurable then the expression on the right-hand side of (3) is not necessarily a Borel measurable function of $\vec{\eta}$; however, in that case we can still choose a version of $E(F|X)$ that is equal almost everywhere to the right-hand side of (3).

We finish this section by stating the definitions [3] of the analytic Feynman integral and the Banach algebra $S(\nu)$.

Let F be a $\mathbb{C}$-valued scale-invariant measurable function on $C_0^\nu[0, t]$ such that the Wiener integral

$$J(\lambda) = \int_{C_0^\nu[0,t]} F(\lambda^{-1/2}\vec{x})\, dm^\nu(\vec{x})$$

exists as a finite number for all $\lambda > 0$. If there exists a function $J^*(\lambda)$ analytic in $\mathbb{C}^+$ such that $J^*(\lambda) = J(\lambda)$ for all $\lambda > 0$, then $J^*(\lambda)$ is defined to be the analytic Wiener integral of F over $C_0^\nu[0, t]$ with parameter λ, and for $\lambda \in \mathbb{C}^+$ we write

$$E^{\mathrm{anw}_\lambda}(F) = J^*(\lambda).$$

Let $q \neq 0$ be a real number and let F be a function such that $E^{\mathrm{anw}_\lambda}(F)$ exists for all $\lambda \in \mathbb{C}^+$. If the following limit exists, we call it the analytic Feynman integral of F with parameter q and we write

$$E^{\mathrm{anf}_q}(F) = \lim_{\lambda \to -iq} E^{\mathrm{anw}_\lambda}(F)$$

where λ approaches $-iq$ through $\mathbb{C}^+$.

The Banach algebra $S(\nu)$ consists of functions on $C_0^\nu[0, t]$ expressible in the form

$$F(\vec{x}) = \int_{L_2^\nu[0,t]} \exp\left\{ i \sum_{j=1}^{\nu} \int_0^t v_j(s)\, \tilde{d}x_j(s) \right\} d\sigma(\vec{V}) \tag{4}$$

for s-a.e. $\vec{x} = (x_1, \cdots, x_\nu)$ in $C_0^\nu[0, t]$ where σ is an element of $M(L_2^\nu[0, t])$, the space of $\mathbb{C}$-valued, countably additive Borel measures on $L_2^\nu[0, t]$, and the integrals $\int_0^t v_j(s)\, \tilde{d}x_j(s)$ are Paley-Wiener-Zygmund (PWZ) integrals. In addition, Cameron and Storvick [3, Thm. 5.1] show that for F given by (4)

$$E^{\mathrm{anw}_\lambda}(F) = \int_{L_2^\nu[0,t]} \exp\left\{ -\frac{1}{2\lambda} \sum_{j=1}^{\nu} \|v_j\|^2 \right\} d\sigma(\vec{V}), \qquad \lambda \in \mathbb{C}^+$$

and

$$E^{\mathrm{anf}_q}(F) = \int_{L_2^\nu[0,t]} \exp\left\{ -\frac{i}{2q} \sum_{j=1}^{\nu} \|v_j\|^2 \right\} d\sigma(\vec{V}) \tag{5}$$

for each real $q \neq 0$.

Finally we state the following well-known integration formula:

$$\int_{\mathbb{R}^\nu} \exp\left\{-\frac{b}{2}\|\vec{\eta}\|^2 + i\langle\vec{\eta},\vec{\xi}\rangle\right\} d\vec{\eta} = \left(\frac{2\pi}{b}\right)^{\nu/2} \exp\left\{-\frac{1}{2b}\|\vec{\xi}\|^2\right\}, \qquad \text{Re } b > 0,$$

which we use several times in this paper.

3. Conditional analytic Feynman integrals.

THEOREM 1. *Let $F \in S(\nu)$ be given by* (4) *and let $X(\vec{x}) = \vec{x}(t)$. Then for all $\lambda \in \mathbb{C}^+$, the conditional analytic Wiener integral $E^{\text{anw}_\lambda}(F|X)$ exists and for all $\vec{\eta} \in \mathbb{R}^\nu$ is given by the formula*

$$E^{\text{anw}_\lambda}(F|X)(\vec{\eta}) = \int_{L_2^\nu[0,t]} \exp\left\{-\frac{1}{2\lambda t}\sum_{j=1}^{\nu}[t\|v_j\|^2 - b_j^2] + \frac{i}{t}\langle\vec{\eta},\vec{B}\rangle\right\} d\sigma(\vec{V}) \tag{6}$$

where $\vec{B} = (b_1, \cdots, b_\nu) = (\int_0^t v_1(s)\,ds, \cdots, \int_0^t v_\nu(s)\,ds)$. Furthermore, the conditional analytic Feynman integral $E^{\text{anf}_q}(F|X)$ exists for all real $q \neq 0$ and for all $\vec{\eta} \in \mathbb{R}^\nu$ is given by the formula

$$E^{\text{anf}_q}(F|X)(\vec{\eta}) = \int_{L_2^\nu[0,t]} \exp\left\{-\frac{i}{2qt}\sum_{j=1}^{\nu}[t\|v_j\|^2 - b_j^2] + \frac{i}{t}\langle\vec{\eta},\vec{B}\rangle\right\} d\sigma(\vec{V}). \tag{7}$$

Proof. Using (3), the Fubini theorem, and a fundamental Wiener integration formula involving PWZ integrals, we obtain that for $\lambda > 0$ and all $\vec{\eta} \in \mathbb{R}^\nu$

$$\begin{aligned}
&E(F(\lambda^{-1/2}\cdot)|X(\lambda^{-1/2}\cdot))(\vec{\eta}) \\
&= \int_{C_0^\nu[0,t]} \int_{L_2^\nu[0,t]} \exp\left\{i\sum_{j=1}^{\nu}\int_0^t v_j(s)\,\tilde{d}\left[\lambda^{-1/2}x_j(s) - \lambda^{-1/2}\frac{s}{t}x_j(t) + \frac{s}{t}\eta_j\right]\right\} d\sigma(\vec{V})\,dm^\nu(\vec{x}) \\
&= \int_{L_2^\nu[0,t]} \int_{C_0^\nu[0,t]} \exp\left\{\frac{i}{\sqrt{\lambda}}\sum_{j=1}^{\nu}\left[\int_0^t v_j(s)\,\tilde{d}x_j(s) - \frac{x_j(t)}{t}\int_0^t v_j(s)\,ds\right] + \frac{i}{t}\sum_{j=1}^{\nu}\eta_j\int_0^t v_j(s)\,ds\right\} dm^\nu(\vec{x})\,d\sigma(\vec{V}) \qquad (8) \\
&= \int_{L_2^\nu[0,t]} \exp\left\{\frac{i}{t}\langle\vec{\eta},\vec{B}\rangle\right\} \int_{C_0^\nu[0,t]} \cdot \exp\left\{\frac{i}{\sqrt{\lambda}}\sum_{j=1}^{\nu}\int_0^t\left[v_j(s) - \frac{b_j}{t}\right]\tilde{d}x_j(s)\right\} dm^\nu(\vec{x})\,d\sigma(\vec{V}) \\
&= \int_{L_2^\nu[0,t]} \exp\left\{\frac{i}{t}\langle\vec{\eta},\vec{B}\rangle\right\} \exp\left\{-\frac{1}{2\lambda}\sum_{j=1}^{\nu}\int_0^t\left[v_j(s) - \frac{b_j}{t}\right]^2 ds\right\} d\sigma(\vec{V}) \\
&= \int_{L_2^\nu[0,t]} \exp\left\{-\frac{1}{2\lambda t}\sum_{j=1}^{\nu}\left[t\|v_j\|^2 - b_j^2\right] + \frac{i}{t}\langle\vec{\eta},\vec{B}\rangle\right\} d\sigma(\vec{V}).
\end{aligned}$$

But by the Cauchy-Schwarz inequality it follows that

$$b_j^2 = \left[\int_0^t v_j(s)\,ds\right]^2 \leqq \int_0^t 1^2\,ds \int_0^t v_j^2(s)\,ds = t\|v_j\|^2. \tag{9}$$

Hence, since $\sigma \in M(L_2^\nu[0,t])$, we see that the last expression on the right-hand side of (8) is an analytic function of λ throughout $\mathbb{C}^+$ and is a continuous function of λ for $\text{Re } \lambda \geqq 0$, $\lambda \neq 0$. Thus (see Definition 2 above) (6) and (7) are established, which concludes the proof of Theorem 1.

In our next theorem we show that if we multiply $E^{\text{anf}_q}(F|X)(\vec{\eta})$ by $(q/2\pi it)^{\nu/2}\exp\{(iq/2t)\|\vec{\eta}\|^2\}$, the analytic extension of the Radon-Nikodym derivative evaluated at $\lambda=-iq$, and then integrate over $\mathbb{R}^\nu$ we obtain the Feynman integral $E^{\text{anf}_q}(F)$. However, to do so we need a summation procedure; we will use the same one as in [19, p. 340]. Let

$$\overline{\int}_{\mathbb{R}^\nu} f(\vec{\eta})\,d\vec{\eta}=\lim_{A\to+\infty}\int_{\mathbb{R}^\nu} f(\vec{\eta})\exp\left\{-\frac{\|\vec{\eta}\|^2}{2A}\right\}d\vec{\eta} \tag{10}$$

whenever the expression on the right exists. Of course, if $f\in L_1(\mathbb{R}^\nu)$, it is clear using the Dominated Convergence Theorem that

$$\overline{\int}_{\mathbb{R}^\nu} f(\vec{\eta})\,d\vec{\eta}=\int_{\mathbb{R}^\nu} f(\vec{\eta})\,d\vec{\eta}.$$

THEOREM 2. *Let $F\in S(\nu)$ be given by* (4) *and let $X(\vec{x})=\vec{x}(t)$. Then for all $\lambda\in\mathbb{C}^+$*

$$\int_{\mathbb{R}^\nu}\left(\frac{\lambda}{2\pi t}\right)^{\nu/2}\exp\left\{-\frac{\lambda}{2t}|\vec{\eta}\|^2\right\}E^{\text{anw}_\lambda}(F|X)(\vec{\eta})\,d\vec{\eta}=E^{\text{anw}_\lambda}(F) \tag{11}$$

and for all real $q\neq 0$,

$$\overline{\int}_{\mathbb{R}^\nu}\left(\frac{q}{2\pi it}\right)^{\nu/2}\exp\left\{\frac{iq}{2t}\|\vec{\eta}\|^2\right\}E^{\text{anf}_q}(F|X)(\vec{\eta})\,d\vec{\eta}=E^{\text{anf}_q}(F). \tag{12}$$

Proof. We will establish (12); the proof of (11) is similar, but easier since the summation procedure is not needed. Let $q\neq 0$ be given. Then using (10), (7), the Fubini theorem, and (5), we obtain

$$\begin{aligned}
&\overline{\int}_{\mathbb{R}^\nu}\left(\frac{q}{2\pi it}\right)^{\nu/2}\exp\left\{\frac{iq}{2t}\|\vec{\eta}\|^2\right\}E^{\text{anf}_q}(F|X)(\vec{\eta})\,d\vec{\eta}\\
&\quad=\lim_{A\to+\infty}\int_{\mathbb{R}^\nu}\left(\frac{q}{2\pi it}\right)^{\nu/2}\exp\left\{\frac{1}{2}\left(\frac{iq}{t}-\frac{1}{A}\right)\|\vec{\eta}\|^2\right\}\\
&\qquad\cdot\int_{L_2^\nu[0,t]}\exp\left\{-\frac{i}{2qt}\sum_{j=1}^{\nu}[t\|v_j\|^2-b_j^2]+\frac{i}{t}\langle\vec{\eta},\vec{B}\rangle\right\}d\sigma(\vec{V})\,d\vec{\eta}\\
&\quad=\lim_{A\to+\infty}\int_{L_2^\nu[0,t]}\exp\left\{-\frac{i}{2qt}\sum_{j=1}^{\nu}[t\|v_j\|^2-b_j^2]\right\}\left(\frac{q}{2\pi it}\right)^{\nu/2}\\
&\qquad\cdot\int_{\mathbb{R}^\nu}\exp\left\{-\frac{1}{2}\left(\frac{t-Aiq}{At}\right)\|\vec{\eta}\|^2+i\left\langle\vec{\eta},\frac{\vec{B}}{t}\right\rangle\right\}d\vec{\eta}\,d\sigma(\vec{V})\\
&\quad=\lim_{A\to+\infty}\int_{L_2^\nu[0,t]}\exp\left\{-\frac{i}{2qt}\sum_{j=1}^{\nu}[t\|v_j\|^2-b_j^2]\right\}\left(\frac{q}{2\pi it}\right)^{\nu/2}\\
&\qquad\cdot\left(\frac{2\pi At}{t-Aiq}\right)^{\nu/2}\exp\left\{-\frac{A}{2(t-Aiq)t}\|\vec{B}\|^2\right\}d\sigma(\vec{V})\\
&\quad=\int_{L_2^\nu[0,t]}\exp\left\{-\frac{i}{2q}\sum_{j=1}^{\nu}\|v_j\|^2+\frac{i}{2qt}\|\vec{B}\|^2\right\}\exp\left\{-\frac{i}{2qt}\|\vec{B}\|^2\right\}d\sigma(\vec{V})\\
&\quad=\int_{L_2^\nu[0,t]}\exp\left\{-\frac{i}{2q}\sum_{j=1}^{\nu}\|v_j\|^2\right\}d\sigma(\vec{V})\\
&\quad=E^{\text{anf}_q}(F).
\end{aligned}$$

In our next theorem we obtain the existence of the conditional analytic Feynman integral for a class of functions that are not necessarily in $S(\nu)$.

THEOREM 3. *Let $\psi:\mathbb{R}^\nu \to \mathbb{C}$ be a Borel measurable function such that*

$$\int_{\mathbb{R}^\nu} |\psi(\vec{\eta})| \exp\{-a\|\vec{\eta}\|^2\}\, d\vec{\eta} < \infty$$

for all $a>0$. Let $F \in S(\nu)$ be given by (4). *Let $G(\vec{x}) = F(\vec{x})\psi(\vec{x}(t))$ and let $X(\vec{x}) = \vec{x}(t)$. Then $E^{\text{anf}_q}(G|X)$ exists for all real $q \neq 0$ and*

$$E^{\text{anf}_q}(G|X)(\vec{\eta}) = \psi(\vec{\eta}) E^{\text{anf}_q}(F|X)(\vec{\eta}) \tag{13}$$

for almost all $\vec{\eta} \in \mathbb{R}^\nu$.

Proof. We first note that

$$\int_{C^\nu[0,t]} |G(\lambda^{-1/2}\vec{x})|\, dm^\nu(\vec{x}) < \infty$$

for all $\lambda > 0$ since F is bounded. The existence of $E^{\text{anf}_q}(G|X)$ and (13) now follows from (3) (with F replaced by G) and Theorem 1.

Remark 4. Note that G is not necessarily in $S(\nu)$ since ψ may be unbounded.

4. The integral equation. Let $\mathcal{G}$ be the set of all $\mathbb{C}$-valued functions on $[0,\infty)\times\mathbb{R}^\nu$ of the form

$$\theta(s, \vec{U}) = \int_{\mathbb{R}^\nu} \exp\{i\langle \vec{U}, \vec{V}\rangle\}\, d\mu_s(\vec{V}) \tag{14}$$

where $\{\mu_S: 0 \leqq s < \infty\}$ is a family from $M(\mathbb{R}^\nu)$ satisfying the following two conditions:

(i) For every $B \in \mathcal{B}(\mathbb{R}^\nu)$, $\mu_S(B)$ is Borel measurable in s.

(ii) $\|\mu_S\| \in L_1[0, t]$ for all $t > 0$.

In [19], it is noted that $\theta(s, \vec{U})$ and $\theta(s, \vec{x}(s))$ are Borel measurable and that $F(\vec{x}) = \exp\{\int_0^t \theta(s, \vec{x}(s))\, ds\}$ is in $S(\nu)$.

Remark 5. Note that $S(\nu)$ actually depends on t and so we could write $S(\nu) = S_t(\nu)$. But for $0 < s \leqq t$, $F \in S_S(\nu) \Rightarrow F \in S_t(\nu)$. So we will usually delete the subscript unless the meaning is unclear without it.

THEOREM 4. *Let $\theta \in \mathcal{G}$ be given by* (14), *let*

$$F(\vec{x}) = F_t(\vec{x}) = \exp\left\{\int_0^t \theta(s, \vec{x}(s))\, ds\right\},$$

and let $X(\vec{x}) = X_t(\vec{x}) = \vec{x}(t)$. For $(t, \vec{\eta}, \lambda) \in (0,\infty)\times\mathbb{R}^\nu\times(0,\infty)$ let

$$H(t, \vec{\eta}, \lambda) = \left(\frac{\lambda}{2\pi t}\right)^{\nu/2} \exp\left\{-\frac{\lambda}{2t}\|\vec{\eta}\|^2\right\} E(F(\lambda^{-1/2}\cdot)|X(\lambda^{-1/2}\cdot))(\vec{\eta}). \tag{15}$$

Then for $(t, \vec{\eta}, \lambda) \in (0,\infty)\times\mathbb{R}^\nu\times(0,\infty)$, $H(t, \vec{\eta}, \lambda)$ satisfies the integral equation

$$\begin{aligned} H(t, \vec{\eta}, \lambda) &= \left(\frac{\lambda}{2\pi t}\right)^{\nu/2} \exp\left\{-\frac{\lambda}{2t}\|\vec{\eta}\|^2\right\} \\ &\quad + \int_0^t \left(\frac{\lambda}{2\pi(t-s)}\right)^{\nu/2} \int_{\mathbb{R}^\nu} \theta(s, \vec{\xi}) H(s, \vec{\xi}, \lambda) \\ &\quad \cdot \exp\left\{-\frac{\lambda}{2(t-s)}\|\vec{\eta}-\vec{\xi}\|^2\right\} d\vec{\xi}\, ds. \end{aligned} \tag{16}$$

Proof. Let $(t, \vec{\eta}, \lambda) \in (0, \infty) \times \mathbb{R}^\nu \times (0, \infty)$ be given. Then by differentiating the function $\exp\{\int_0^s \theta(u, \lambda^{-1/2}\vec{x}(u))\, du\}$ with respect to s and then integrating the derivative on $[0, t]$ we obtain the formula

$$\exp\left\{\int_0^t \theta(s, \lambda^{-1/2}\vec{x}(s))\, ds\right\} = 1 + \int_0^t \theta(s, \lambda^{-1/2}\vec{x}(s)) \exp\left\{\int_0^s \theta(u, \lambda^{-1/2}\vec{x}(u))\, du\right\} ds.$$

Hence, taking conditional expectations, using (3) and the Fubini theorem, we obtain

$$\begin{aligned}
&E(F(\lambda^{-1/2}\cdot)|X(\lambda^{-1/2}\cdot))(\vec{\eta}) \\
&\quad = 1 + E\left(\int_0^t \theta(s, \lambda^{-1/2}\vec{x}(s)) \exp\left\{\int_0^s \theta(u, \lambda^{-1/2}\vec{x}(u))\, du\right\} ds | \lambda^{-1/2}\vec{x}(t) = \vec{\eta}\right) \\
&\quad = 1 + \int_{C_0^\nu[0,t]} \int_0^t \theta\left(s, \lambda^{-1/2}\left[\vec{x}(s) - \frac{s}{t}\vec{x}(t)\right] + \frac{s}{t}\vec{\eta}\right) \\
&\qquad \cdot \exp\left\{\int_0^s \theta\left(u, \lambda^{-1/2}\left[\vec{x}(u) - \frac{u}{s}\vec{x}(s)\right]\right.\right. \\
&\qquad\qquad \left.\left. + \frac{u}{s}\left[\lambda^{-1/2}\left(\vec{x}(s) - \frac{s}{t}\vec{x}(t)\right) + \frac{s}{t}\vec{\eta}\right]\right) du\right\} ds\, dm^\nu(\vec{x}) \\
&\quad = 1 + \int_0^t \int_{C_0^\nu[0,t]} \theta\left(s, \lambda^{-1/2}\left[\vec{x}(s) - \frac{s}{t}\vec{x}(t)\right] + \frac{s}{t}\vec{\eta}\right) \\
&\qquad \cdot \exp\left\{\int_0^s \theta\left(u, \lambda^{-1/2}\left[\vec{x}(u) - \frac{u}{s}\vec{x}(s)\right]\right.\right. \\
&\qquad\qquad \left.\left. + \frac{u}{s}\left[\lambda^{-1/2}\left(\vec{x}(s) - \frac{s}{t}\vec{x}(t)\right) + \frac{s}{t}\vec{\eta}\right]\right) du\right\} dm^\nu(\vec{x})\, ds.
\end{aligned}$$

But $\lambda^{-1/2}[\vec{x}(s) - (s/t)\vec{x}(t)] + (s/t)\vec{\eta}$ is a Gaussian random variable with mean $(s/t)\vec{\eta}$ and variance $s(t-s)/\lambda t$ for $0 \leqq s < t$. Also it is independent of the random variable $\vec{x}(u) - (u/s)\vec{x}(s)$ for $0 < u < s < t$. But Brownian motion $\vec{x}(u)$ has stationary increments and so using (15) we obtain

$$\begin{aligned}
H(t, \vec{\eta}, \lambda) &= \left(\frac{\lambda}{2\pi t}\right)^{\nu/2} \exp\left\{-\frac{\lambda}{2t}\|\vec{\eta}\|^2\right\} \\
&\quad + \int_0^t \left(\frac{\lambda}{2\pi(t-s)}\right)^{\nu/2} \int_{\mathbb{R}^\nu} \theta(s, \vec{\xi}) \exp\left\{-\frac{\lambda}{2(t-s)}\|\vec{\eta} - \vec{\xi}\|^2\right\} \\
&\quad \cdot \left(\frac{\lambda}{2\pi s}\right)^{\nu/2} \exp\left\{-\frac{\lambda}{2s}\|\vec{\xi}\|^2\right\} E(F_s(\lambda^{-1/2}\cdot)|X(\lambda^{-1/2}\cdot))(\vec{\xi})\, d\vec{\xi}\, ds \\
&= \left(\frac{\lambda}{2\pi t}\right)^{\nu/2} \exp\left\{-\frac{\lambda}{2t}\|\vec{\eta}\|^2\right\} \\
&\quad + \int_0^t \left(\frac{\lambda}{2\pi(t-s)}\right)^{\nu/2} \int_{\mathbb{R}^\nu} \theta(s, \vec{\xi}) H(s, \xi, \lambda) \\
&\quad \cdot \exp\left\{-\frac{\lambda}{2(t-s)}\|\vec{\eta} - \vec{\xi}\|^2\right\} d\vec{\xi}\, ds,
\end{aligned}$$

which concludes the proof of Theorem 4.

THEOREM 5. *Let F and X be as in Theorem 4. Then for $(t, \vec{\eta}, \lambda) \in (0, \infty) \times \mathbb{R}^\nu \times \mathbb{C}^+$ the function*

$$H(t, \vec{\eta}, \lambda) = \left(\frac{\lambda}{2\pi t}\right)^{\nu/2} \exp\left\{-\frac{\lambda}{2t}\|\vec{\eta}\|^2\right\} E^{\mathrm{anw}_\lambda}(F|X)(\vec{\eta}) \tag{17}$$

satisfies the integral equation (16).

Proof. By Theorem 4 we know that $H(t, \vec{\eta}, \lambda)$ given by (17) satisfies the integral equation for $\lambda > 0$. Thus it suffices to show that both sides of (16) are analytic functions of λ throughout $\mathbb{C}^+$. But by Theorem 1, $H(t, \vec{\eta}, \lambda)$ exists and is analytic throughout $\mathbb{C}^+$. Thus it suffices to show that the second term on the right-hand side of (16), which we will denote by $h(\lambda)$, is an analytic function of λ on $\mathbb{C}^+$. We will use Morera's theorem to show that $h(\lambda)$ is analytic. First an application of the Dominated Convergence Theorem shows that $h(\lambda)$ is continuous on $\mathbb{C}^+$; an appropriate dominating function is obtained almost exactly as in the following argument and so will be omitted here. Now let Δ be a triangular path in $\mathbb{C}^+$. We need only show that $\int_\Delta h(\lambda)\, d\lambda = 0$. But this will clearly follow from the Cauchy Integral Theorem if we can justify moving the integral with respect to λ inside the other two integrals. Let $D = \sup\{|\lambda|: \lambda \in \Delta\}$ and $E = \inf\{\mathrm{Re}\,\lambda: \lambda \in \Delta\}$. Then

$$\left(\frac{D}{E}\right)^{\nu/2} \left(\frac{E}{2\pi(t-s)}\right)^{\nu/2} \|\mu_s\| \left(\frac{D}{2\pi t}\right)^{\nu/2} \exp\left\{-\frac{E}{2t}\|\vec{\eta}\|^2\right\} \|\sigma\| \exp\left\{-\frac{E}{2(t-s)}\|\vec{\eta} - \vec{\xi}\|^2\right\}$$

is a dominating function that is integrable with respect to $(s, \vec{\xi}, \lambda)$ on $[0, t] \times \mathbb{R}^\nu \times \Delta$.

THEOREM 6. *Let F and X be as in Theorem 4. Then for $(t, \vec{\eta}, q) \in (0, \infty) \times \mathbb{R}^\nu \times (\mathbb{R} - \{0\})$ the function*

$$H(t, \vec{\eta}, -qi) = \left(\frac{q}{2\pi i t}\right)^{\nu/2} \exp\left\{\frac{qi}{2t}\|\vec{\eta}\|^2\right\} E^{\mathrm{anf}_q}(F|X)(\vec{\eta}) \tag{18}$$

satisfies the Schrödinger integral equation

$$\begin{aligned} H(t, \vec{\eta}, -qi) &= \left(\frac{q}{2\pi i t}\right)^{\nu/2} \exp\left\{\frac{qi}{2t}\|\vec{\eta}\|^2\right\} \\ &\quad + \int_0^t \left(\frac{q}{2\pi i(t-s)}\right)^{\nu/2} \int_{\mathbb{R}^\nu} \theta(s, \vec{\xi}) H(s, \vec{\xi}, -qi) \\ &\quad \cdot \exp\left\{\frac{qi}{2(t-s)}\|\vec{\eta} - \vec{\xi}\|^2\right\} d\vec{\xi}\, ds. \end{aligned} \tag{19}$$

Proof. We first note that the techniques used in Theorem 5 will not work here since $\lim_{\lambda \to -qi} (|\lambda|/\mathrm{Re}\,\lambda) = +\infty$ and so it is not possible to find an integrable dominating function. Next note that by Theorem 1,

$$\lim_{\lambda \to -qi} H(t, \vec{\eta}, \lambda) = H(t, \vec{\eta}, -qi). \tag{20}$$

Next let

$$G(s, \vec{\xi}, \lambda) = \left(\frac{\lambda}{2\pi(t-s)}\right)^{\nu/2} \theta(s, \vec{\xi}) H(s, \vec{\xi}, \lambda) \exp\left\{-\frac{\lambda}{2(t-s)}\|\vec{\eta} - \vec{\xi}\|^2\right\}$$

for $s \in (0, t)$, $\vec{\xi} \in \mathbb{R}^\nu$ and $\lambda \neq 0$ such that $\mathrm{Re}\,\lambda \geqq 0$. Because the integral equation (16)

holds for all $\lambda \in \mathbb{C}^+$ it suffices in view of (20) to show that

$$\lim_{\lambda \to -qi} \int_0^t \int_{\mathbb{R}^\nu} G(s, \vec{\xi}, \lambda)\, d\vec{\xi}\, ds = \int_0^t \overline{\int_{\mathbb{R}^\nu}} G(s, \vec{\xi}, -qi)\, d\vec{\xi}\, ds. \tag{21}$$

But this follows from the following calculations provided that the use of the Dominated Convergence Theorem can be justified in steps 3, 4, and 6 below:

$$\begin{aligned}
\int_0^t \overline{\int_{\mathbb{R}^\nu}} G(s, \vec{\xi}, -iq)\, d\vec{\xi}\, ds &= \int_0^t \lim_{A\to\infty} \int_{\mathbb{R}^\nu} G(s, \vec{\xi}, -iq) \exp\left\{-\frac{\|\vec{\xi}\|^2}{2A}\right\} d\vec{\xi}\, ds \\
&= \int_0^t \lim_{A\to\infty} \int_{\mathbb{R}^\nu} \lim_{\lambda\to -iq} G(s, \vec{\xi}, \lambda) \exp\left\{-\frac{\|\vec{\xi}\|^2}{2A}\right\} d\vec{\xi}\, ds \\
&= \int_0^t \lim_{A\to\infty} \lim_{\lambda\to -iq} \int_{\mathbb{R}^\nu} G(s, \vec{\xi}, \lambda) \exp\left\{-\frac{\|\vec{\xi}\|^2}{2A}\right\} d\vec{\xi}\, ds \\
&= \int_0^t \lim_{\lambda\to -iq} \lim_{A\to\infty} \int_{\mathbb{R}^\nu} G(s, \vec{\xi}, \lambda) \exp\left\{-\frac{\|\vec{\xi}\|^2}{2A}\right\} d\vec{\xi}\, ds \\
&= \int_0^t \lim_{\lambda\to -iq} \int_{\mathbb{R}^\nu} G(s, \vec{\xi}, \lambda)\, d\vec{\xi}\, ds \\
&= \lim_{\lambda\to -iq} \int_0^t \int_{\mathbb{R}^\nu} G(s, \vec{\xi}, \lambda)\, d\vec{\xi}\, ds.
\end{aligned}$$

To show that we can apply the Dominated Convergence Theorem we will find a function that dominates the function

$$L(s) = \int_{\mathbb{R}^\nu} G(s, \vec{\xi}, \lambda) \exp\left\{-\frac{\|\vec{\xi}\|^2}{2A}\right\} d\vec{\xi}$$

for all A sufficiently large, for all $\lambda \in \mathbb{C}^+$ sufficiently close to $-qi$, and that is in $L_1[0, t]$ as a function of s. Actually we will find a dominating function that is independent of A and dominates for all $\lambda \neq 0$ such that $\operatorname{Re} \lambda \geqq 0$ and $|\lambda| \leqq \lambda_0 = 2|q| + 1$. Also it suffices to take the limit as $\lambda \to -qi$ along a horizontal line since we know that the limit in (21) exists.

First using the definitions of $L(s)$ and $G(s, \vec{\xi}, \lambda)$, and then (14) and (17), we obtain

$$\begin{aligned}
L(s) = \left(\frac{\lambda}{2\pi(t-s)}\right)^{\nu/2} \left(\frac{\lambda}{2\pi s}\right)^{\nu/2} \int_{\mathbb{R}^\nu} \left[\int_{\mathbb{R}^\nu} e^{i\langle \vec{\xi}, \vec{W}\rangle}\, d\mu_s(\vec{W})\right] \\
\cdot \exp\left\{-\frac{\lambda}{2(t-s)} \|\vec{\eta} - \vec{\xi}\|^2\right\} \exp\left\{-\frac{(s + A\lambda)}{2As} \|\vec{\xi}\|^2\right\} \\
\cdot \int_{L_2^\nu[0,s]} \exp\left\{-\frac{1}{2\lambda s} \sum_{j=1}^{\nu} [s\|v_j\|^2 - b_j^2] + \frac{i}{s}\langle \vec{\xi}, \vec{B}\rangle\right\} d\sigma_s(\vec{V})\, d\vec{\xi}
\end{aligned}$$

where $b_j = \int_0^s v_j(\tau)\, d\tau$, $\vec{B} = (b_1, \cdots, b_\nu)$ and $\sigma_s \in M(L_2^\nu[0, s])$ is such that

$$\exp\left\{\int_0^s \theta(\tau, \vec{x}(\tau))\, d\tau\right\} = \int_{L_2^\nu[0,s]} \exp\left\{i \sum_{j=1}^{\nu} \int_0^s v_j(\tau)\, d\tilde{x}_j(\tau)\right\} d\sigma_s(\vec{V}).$$

Next we use the Fubini theorem, then carry out the integration with respect to $\vec{\xi}$, simplify, and obtain

$$L(s)=\left(\frac{\lambda}{2\pi t}\right)^{\nu/2}\left(\frac{A\lambda t}{s(t-s)+A\lambda t}\right)^{\nu/2}\int_{\mathbb{R}^\nu}\int_{L_2^\nu[0,t]}\exp\left\{-\frac{1}{2\lambda s}\sum_{j=1}^{\nu}[s\|v_j\|^2-b_j^2]\right\}$$
$$\cdot\exp\left\{-\frac{\lambda}{2(t-s)}\|\vec{\eta}\|^2-\frac{As(t-s)}{2[s(t-s)+A\lambda t]}\left\|\vec{W}+\frac{\vec{B}}{s}-\frac{i\lambda\vec{\eta}}{t-s}\right\|^2\right\}d\sigma_s(\vec{V})\,d\mu_s(\vec{W}).$$

Now we claim that for all $A>0$ and all $\lambda\neq 0$ such that $\operatorname{Re}\lambda\geqq 0$ and $|\lambda|\leqq\lambda_0=2|q|+1$,

$$|L(s)|\leqq\left(\frac{\lambda_0}{2\pi t}\right)^{\nu/2}\|\sigma_s\|\,\|\mu_s\|\leqq\left(\frac{\lambda_0}{2\pi t}\right)^{\nu/2}\|\sigma\|\,\|\mu_s\|. \tag{22}$$

Once this claim is established, the proof is complete because the expression on the right-hand side of (22) is in $L_1[0,t]$ as a function of s.

(i) Clearly, $|A\lambda t/(s(t-s)+A\lambda t)|\leqq 1$ for all $A>0$ and $\operatorname{Re}\lambda\geqq 0$.

(ii) $|\exp\{-(1/2\lambda s)\sum_{j=1}^{\nu}[s\|v_j\|^2-b_j^2]\}|\leqq 1$ by the Cauchy-Schwarz inequality since $\operatorname{Re}(-1/2\lambda s)\leqq 0$.

(iii) Formula (22) will follow once we show that

$$\left|\exp\left\{-\frac{\lambda}{2(t-s)}\|\vec{\eta}\|^2-\frac{As(t-s)}{2[s(t-s)+A\lambda t]}\left\|\vec{W}+\frac{\vec{B}}{s}-\frac{i\lambda\vec{\eta}}{t-s}\right\|^2\right\}\right|\leqq 1$$

for all appropriate values of the variables involved. It suffices to consider one coordinate at a time and show that the real part of the exponent is nonpositive. We will work with the jth coordinate and to simplify notation we let $\eta_j=\eta$, $b_j=b$, and $w_j=w$. Then, recalling that $\lambda=p-qi$ and letting $y=w+b/s-q\eta/(t-s)$, we obtain

$$\operatorname{Re}\left\{-\frac{\lambda\eta^2}{2(t-s)}-\frac{As(t-s)}{2[s(t-s)+A\lambda t]}\left(w+\frac{b}{s}-\frac{i\lambda\eta}{t-s}\right)^2\right\}$$
$$=-\frac{As(t-s)[s(t-s)+Apt]}{2[(Apt+s(t-s))^2+(Aqt)^2]}\left[y+\frac{p\eta Aqt}{(t-s)[Apt+s(t-s)]}\right]^2$$
$$-\frac{p\eta^2}{2(t-s)}\left\{1-\frac{A^3spq^2t^2+Asp[Apt+s(t-s)]}{[(Apt+s(t-s))^2+(Atq)^2][Apt+s(t-s)]}\right\},$$

which is nonpositive since for $p\geqq 0$ and $0\leqq s\leqq t$,

$$A^3spq^2t^2+Asp[s(t-s)+Apt]^2\leqq[s(t-s)+Apt][(Apt+s(t-s))^2+(Atq)^2].$$

As a consequence of our next theorem we will see that $H(t,-\vec{\eta},-qi)$ is a fundamental solution to the Schrödinger partial differential equation.

THEOREM 7. *Let F and X be as in Theorem* 1. *Let $\psi\in\hat{M}(\mathbb{R}^\nu)$; that is to say*

$$\psi(\vec{\eta})=\int_{\mathbb{R}^\nu}\exp\{i\langle\vec{\eta},\vec{U}\rangle\}\,d\phi(\vec{U}) \tag{23}$$

for some $\phi\in M(\mathbb{R}^\nu)$. For $(t,\vec{\eta})\in(0,\infty)\times\mathbb{R}^\nu$, let

$$G(\vec{x})\equiv G_{t,\vec{\eta}}(\vec{x})=F(\vec{x})\psi(\vec{x}(t)+\vec{\eta}).$$

Then for all real $q\neq 0$ we have that

$$\Gamma(t,\vec{\eta},q)\equiv E^{\mathrm{anf}_q}(G)$$
$$=\int_{L_2^\nu[0,t]}\left[\exp\left\{-\frac{i}{2qt}\sum_{j=1}^{\nu}(t\|v_j\|^2-b_j^2)\right\}\right. \tag{24}$$

$$\cdot \int_{\mathbb{R}^\nu} \exp\left\{ i\langle \vec{\eta}, \vec{U}\rangle - \frac{i}{2qt}\|\vec{B}+t\vec{U}\|^2 \right\} d\phi(\vec{U}) \Big] d\sigma(\vec{V}).$$

In addition, we have the alternative expression

$$E^{\mathrm{anf}_q}(G) = \overline{\int_{\mathbb{R}^\nu}} E^{\mathrm{anf}_q}(F|X)(\vec{\xi}-\vec{\eta}) \left(\frac{q}{2\pi it}\right)^{\nu/2} \exp\left\{ \frac{iq\|\vec{\xi}-\vec{\eta}\|^2}{2t} \right\} \psi(\vec{\xi})\, d\vec{\xi} \tag{25}$$

where $E^{\mathrm{anf}_q}(F|X)(\cdot)$ *is given by* (7).

Proof. Since $P_{X(\cdot)+\vec{\eta}}(d\vec{\xi}) = (2\pi t)^{-\nu/2} \exp\{-\|\vec{\xi}-\vec{\eta}\|^2/2t\}\, d\vec{\xi}$, by Lemma 1 of [24] it follows that

$$\begin{aligned} J(\lambda) &= \int_{C_0^\nu[0,t]} G(\lambda^{-1/2}\vec{x})\, dm^\nu(\vec{x}) \\ &= \int_{C_0^\nu[0,t]} F(\lambda^{-1/2}\vec{x})\psi(X(\lambda^{-1/2}\vec{x})+\vec{\eta})\, dm^\nu(\vec{x}) \\ &= \int_{\mathbb{R}^\nu} E(F(\lambda^{-1/2}\cdot)|X(\lambda^{-1/2}\cdot)+\vec{\eta})(\vec{\xi})\psi(\vec{\xi}) \left(\frac{\lambda}{2\pi t}\right)^{\nu/2} \exp\left\{ -\frac{\lambda\|\vec{\xi}-\vec{\eta}\|^2}{2t} \right\} d\vec{\xi} \\ &= \int_{\mathbb{R}^\nu} E(F(\lambda^{-1/2}\cdot)|X(\lambda^{-1/2}\cdot))(\vec{\xi}-\vec{\eta})\psi(\vec{\xi}) \left(\frac{\lambda}{2\pi t}\right)^{\nu/2} \exp\left\{ -\frac{\lambda\|\vec{\xi}-\vec{\eta}\|^2}{2t} \right\} d\vec{\xi} \end{aligned}$$

for all $\lambda > 0$. Then, using Theorem 1 and Morera's theorem, we obtain

$$E^{\mathrm{anw}_\lambda}(G) = \int_{\mathbb{R}^\nu} E^{\mathrm{anw}_\lambda}(F|X)(\vec{\xi}-\vec{\eta}) \left(\frac{\lambda}{2\pi t}\right)^{\nu/2} \exp\left\{ -\frac{\lambda\|\vec{\xi}-\vec{\eta}\|^2}{2t} \right\} \psi(\vec{\xi})\, d\vec{\xi} \tag{26}$$

for all $\lambda \in \mathbb{C}^+$. Next we substitute for $E^{\mathrm{anw}_\lambda}(F|X)(\vec{\xi}-\vec{\eta})$ and $\psi(\vec{\xi})$ in (26) using (7) and (23), use the Fubini theorem, and then carry out the integration with respect to $\vec{\xi}$ and obtain the formula

$$\begin{aligned} E^{\mathrm{anw}_\lambda}(G) = \int_{L_2^\nu[0,t]} \Bigg[&\exp\left\{ -\frac{1}{2\lambda t} \sum_{j=1}^{\nu} (t\|v_j\|^2 - b_j^2) \right\} \\ &\cdot \int_{\mathbb{R}^\nu} \exp\left\{ i\langle \vec{\eta}, \vec{U}\rangle - \frac{1}{2\lambda t}\|\vec{B}+t\vec{U}\|^2 \right\} d\phi(\vec{U}) \Bigg] d\sigma(\vec{V}) \end{aligned} \tag{27}$$

for all $\lambda \in \mathbb{C}^+$. Next we note that the right-hand side of (27) is continuous in λ for $\mathrm{Re}\,\lambda \geqq 0$, $\lambda \neq 0$, and hence $E^{\mathrm{anf}_q}(G)$ exists and is given by (24).

To obtain the alternative expression (25), we use (10), (7), the Dominated Convergence Theorem, and (24):

$$\begin{aligned} &\overline{\int_{\mathbb{R}^\nu}} E^{\mathrm{anf}_q}(F|X)(\vec{\xi}-\vec{\eta}) \left(\frac{q}{2\pi it}\right)^{\nu/2} \exp\left\{ \frac{iq}{2t}\|\vec{\xi}-\vec{\eta}\|^2 \right\} \psi(\vec{\xi})\, d\vec{\xi} \\ &= \lim_{A\to+\infty} \int_{\mathbb{R}^\nu} E^{\mathrm{anf}_q}(F|X)(\vec{\xi}-\vec{\eta}) \left(\frac{q}{2\pi it}\right)^{\nu/2} \exp\left\{ \frac{iq}{2t}\|\vec{\xi}-\vec{\eta}\|^2 - \frac{1}{2A}\|\vec{\xi}\|^2 \right\} \psi(\vec{\xi})\, d\vec{\xi} \\ &= \lim_{A\to+\infty} \int_{\mathbb{R}^\nu} \Bigg[\int_{L_2^\nu[0,t]} \exp\left\{ -\frac{i}{2qt} \sum_{j=1}^{\nu} (t\|v_j\|^2 - b_j^2) + \frac{i}{t}\langle \vec{\xi}-\vec{\eta}, \vec{B}\rangle \right\} d\sigma(\vec{V}) \\ &\qquad \cdot \left(\frac{q}{2\pi it}\right)^{\nu/2} \exp\left\{ \frac{iq}{2t}\|\vec{\xi}-\vec{\eta}\|^2 - \frac{1}{2A}\|\vec{\xi}\|^2 \right\} \int_{\mathbb{R}^\nu} \exp\{i\langle \vec{\xi}, \vec{U}\rangle\}\, d\phi(\vec{U}) \Bigg] d\vec{\xi} \end{aligned}$$

$$= \lim_{A\to+\infty} \int_{L_2^\nu[0,t]} \left[\int_{\mathbb{R}^\nu} \exp\left\{ -\frac{i}{2qt} \sum_{j=1}^{\nu} (t\|v_j\|^2 - b_j^2) - \frac{i}{t}\langle \vec{\eta}, \vec{B}\rangle \right\} \left(\frac{q}{2\pi i t}\right)^{\nu/2} \right.$$

$$\left. \cdot \left[\int_{\mathbb{R}^\nu} \exp\left\{ \frac{i}{t}\langle \vec{\xi}, \vec{B}\rangle + \frac{iq}{2t}\|\vec{\xi} - \vec{\eta}\|^2 - \frac{1}{2A}\|\vec{\xi}\|^2 + i\langle \vec{\xi}, \vec{U}\rangle \right\} d\vec{\xi} \right] d\phi(\vec{U}) \right] d\sigma(\vec{V})$$

$$= \lim_{A\to+\infty} \int_{L_2^\nu[0,t]} \left[\int_{\mathbb{R}^\nu} \exp\left\{ -\frac{i}{2qt} \sum_{j=1}^{\nu} (t\|v_j\|^2 - b_j^2) - \frac{i}{t}\langle \vec{\eta}, \vec{B}\rangle + \frac{iq}{2t}\|\vec{\eta}\|^2 \right\} \left(\frac{q}{2\pi i t}\right)^{\nu/2} \right.$$

$$\left. \cdot \left[\int_{\mathbb{R}^\nu} \exp\left\{ -\frac{(t - Aiq)}{2At}\|\vec{\xi}\|^2 + \frac{i}{t}\langle \vec{\xi}, \vec{B} - q\vec{\eta} + t\vec{U}\rangle \right\} d\vec{\xi} \right] d\phi(\vec{U}) \right] d\sigma(\vec{V})$$

$$= \lim_{A\to+\infty} \int_{L_2^\nu[0,t]} \left[\exp\left\{ -\frac{i}{2qt} \sum_{j=1}^{\nu} (t\|v_j\|^2 - b_j^2) - \frac{i}{t}\langle \vec{\eta}, \vec{B}\rangle + \frac{iq}{2t}\|\vec{\eta}\|^2 \right\} \right.$$

$$\left. \cdot \left(\frac{q}{2\pi i t}\right)^{\nu/2} \left(\frac{2\pi At}{t - Aiq}\right)^{\nu/2} \int_{\mathbb{R}^\nu} \exp\left\{ -\frac{A}{2t(t - Aiq)}\|\vec{B} - q\vec{\eta} + t\vec{U}\|^2 \right\} d\phi(\vec{U}) \right] d\sigma(\vec{V})$$

$$= \int_{L_2^\nu[0,t]} \left[\exp\left\{ -\frac{i}{2qt} \sum_{j=1}^{\nu} (t\|v_j\|^2 - b_j^2) \right\} \right.$$

$$\left. \cdot \int_{\mathbb{R}^\nu} \exp\left\{ i\langle \vec{\eta}, \vec{U}\rangle - \frac{i}{2qt}\|\vec{B} + t\vec{U}\|^2 \right\} d\phi(\vec{U}) \right] d\sigma(\vec{V})$$

$$= E^{\mathrm{anf}_q}(G).$$

Remark 6. Note that (25) can be written as $\Gamma(t, \vec{\eta}, q) = H(t, -(\cdot), -qi) * \psi(\vec{\eta})$ where * denotes convolution and $H(t, \vec{\eta}, -qi)$ is given by (18). Next consider the Schrödinger partial differential equation:

$$i\hbar \frac{\partial \Gamma}{\partial t} = -\frac{\hbar^2}{2m}\Delta\Gamma + \theta(t, \vec{\eta})\Gamma, \qquad \Gamma(0, \vec{\eta}) = \psi(\vec{\eta}) \tag{28}$$

where Δ is the Laplacian on $\mathbb{R}^\nu$, $\hbar = h/2\pi$ where h is Planck's constant and $\theta(s, \cdot)$ is a time-dependent potential.

If $\theta(s, \cdot) = \theta(\cdot)$ is a time-independent and an $\mathbb{R}$-valued potential in $\hat{M}(\mathbb{R}^\nu)$, and ψ is in $\hat{M}(\mathbb{R}^\nu) \cap L_2(\mathbb{R}^\nu)$, then by the results of [15], [20] combined with the results of [1, Thm. 3.1], it follows that $E^{\mathrm{anf}_q}(F(\vec{x})\psi(\vec{x}(t) + \vec{\eta}))$ (with $q = m/\hbar$) for some F in $S(\nu)$ is a (weak) solution of the Schrödinger equation (28). Hence, (25) shows that $H(t, -\vec{\eta}, -qi)$ is a fundamental solution to the Schrödinger equation (28).

If $\theta(s, \vec{\eta})$ is the time-dependent potential given by (14), then by [19, Thm. 7.1] $\Gamma(t, \vec{\eta}, q)$ is a solution of the following integral equation that is formally equivalent to the Schrödinger equation (28) (with $q = m/\hbar$):

$$\Gamma(t, \vec{\eta}, q) = \left(\frac{q}{2\pi i t}\right)^{\nu/2} \int_{\mathbb{R}^\nu} \psi(\vec{U}) \exp\left\{ \frac{iq\|\vec{\eta} - \vec{U}\|^2}{2t} \right\} d\vec{U}$$

$$+ \int_0^t \left[\frac{q}{2\pi i(t - s)} \right]^{\nu/2} \int_{\mathbb{R}^\nu} \theta(s, \vec{U})\Gamma(s, \vec{U}, q) \exp\left\{ \frac{iq\|\vec{\eta} - \vec{U}\|^2}{2(t - s)} \right\} d\vec{U}\, ds.$$

Theorem 6 shows that the solution $\Gamma(t, \vec{\eta}, q)$ of this integral equation can be obtained by use of (25).

5. More general conditioning functions. In this section with $\nu = 1$ we obtain results corresponding to those in § 3 but for conditioning functions of the form $X(x) = (x(t_1), \cdots, x(t_n))$.

Let n be a positive integer and let $0 = t_0 < t_1 < \cdots < t_n = t$ be a partition of $[0, t]$. For each $x \in C_0[0, t]$, define the polygonal function $[x]$ on $[0, t]$ by

$$[x](s) = x(t_{k-1}) + \frac{s - t_{k-1}}{t_k - t_{k-1}}(x(t_k) - x(t_{k-1})), \quad t_{k-1} \leqq s \leqq t_k, \quad k = 1, \cdots, n.$$

Similarly, for each $\vec{\eta} = (\eta_1, \cdots, \eta_n) \in \mathbb{R}^n$, define the polygonal function $[\vec{\eta}]$ of $\vec{\eta}$ on $[0, t]$ by

$$[\vec{\eta}](s) = \eta_{k-1} + \frac{s - t_{k-1}}{t_k - t_{k-1}}(\eta_k - \eta_{k-1}), \quad t_{k-1} \leqq s \leqq t_k, \quad k = 1, \cdots, n.$$

As noted in [22], $\{x(s) - [x](s), t_{k-1} \leqq s \leqq t_k\}$, $k = 1, \cdots, n$ are independent Brownian bridge processes. Furthermore, the processes $\{x(s) - [x](s), 0 \leqq s \leqq t\}$ and $X(x) = (x(t_1), \cdots, x(t_n))$ are stochastically independent.

In [22] Park and Skoug have shown that if F is Borel measurable and Wiener integrable then the conditional Wiener integral $E(F(x)|X(x) \equiv (x(t_1), \cdots, x(t_n)))(\vec{\eta})$ can be expressed in terms of an ordinary Wiener integral by the formula

$$(29) \quad E(F(x)|X(x)) \equiv (x(t_1), \cdots, x(t_n))(\vec{\eta}) = \int_{C_0[0,t]} F(x - [x] + [\vec{\eta}])\, dm(x).$$

DEFINITION 3. Let $0 = t_0 < t_1 < \cdots < t_n = t$ be a partition of $[0, t]$. Then for each function $v \in L_2[0, t]$ we define the sectional average of v by letting

$$\bar{v}(s) = \frac{1}{t_k - t_{k-1}} \int_{t_{k-1}}^{t_k} v(u)\, du$$

on each subinterval $(t_{k-1}, t_k]$ and by letting $\bar{v}(0) = 0$.

Note that $\bar{v}$ is a step function of bounded variation on $[0, t]$. The following theorem gives a relationship involving $\bar{v}$ and $[x]$ that is very useful in computing conditional expectations.

THEOREM 8. *Let $v \in L_2[0, t]$. Then*

$$(30) \quad \int_0^t v(s)\bar{v}(s)\, ds = \int_0^t \bar{v}^2(s)\, ds,$$

$$(31) \quad \|v - \bar{v}\|_2^2 = \|v\|_2^2 - \|\bar{v}\|_2^2 \geqq 0, \quad \textit{and}$$

$$(32) \quad \int_0^t v(s)\, d[x](s) = \int_0^t \bar{v}(s)\, dx(s) = \int_0^t \bar{v}(s)\, d[x](s) \quad \textit{for each } x \in C_0[0, t].$$

Proof. Equation (30) follows easily from the definition of $\bar{v}$ while (31) follows from (30). To obtain (32) note that for each $k = 1, \cdots, n$,

$$\int_{t_{k-1}}^{t_k} v(s)\, d[x](s) = \frac{x(t_k) - x(t_{k-1})}{t_k - t_{k-1}} \int_{t_{k-1}}^{t_k} v(s)\, ds$$

$$= \bar{v}(t_k)(x(t_k) - x(t_{k-1})) = \int_{t_{k-1}}^{t_k} \bar{v}(s)\, dx(s).$$

THEOREM 9. *Let* $F(x)=\int_{L_2[0,t]}\exp\{i\int_0^t v(s)\,\tilde{d}x(s)\}\,d\sigma(v)$ *be an element of* $S(1)$ *and let* $X(x)=(x(t_1),\cdots,x(t_n))$. *Then for all* $\lambda\in\mathbb{C}^+$ *and each* $\vec{\eta}=(\eta_1,\cdots,\eta_n)\in\mathbb{R}^n$

$$E^{\mathrm{anw}_\lambda}(F|X)(\vec{\eta})=\int_{L_2[0,t]}\exp\left\{i\int_0^t v(s)\,d[\vec{\eta}](s)-\frac{1}{2\lambda}\int_0^t(v(s)-\bar{v}(s))^2\,ds\right\}d\sigma(v), \tag{33}$$

and for all real $q\neq 0$,

$$E^{\mathrm{anf}_q}(F|X)(\vec{\eta})=\int_{L_2[0,t]}\exp\left\{i\int_0^t v(s)\,d[\vec{\eta}](s)-\frac{i}{2q}\int_0^t(v(s)-\bar{v}(s))^2\,ds\right\}d\sigma(v). \tag{34}$$

Proof. Using (29), the Fubini theorem, and Theorem 8, we see that for each $\lambda>0$ and each $\vec{\eta}\in\mathbb{R}^n$,

$$\begin{aligned}
&E(F(\lambda^{-1/2}\cdot)|X(\lambda^{-1/2}\cdot))(\vec{\eta})\\
&\quad=\int_{C_0[0,t]}\int_{L_2[0,t]}\exp\left\{i\int_0^t v(s)\,\tilde{d}(\lambda^{-1/2}x(s)-\lambda^{-1/2}[x](s)\right.\\
&\qquad\qquad\left.+[\vec{\eta}](s))\right\}d\sigma(v)\,dm(x)\\
&\quad=\int_{L_2[0,t]}\exp\left\{i\int_0^t v(s)\,d[\vec{\eta}](s)\right\}\int_{C_0[0,t]}\\
&\qquad\cdot\exp\left\{i\lambda^{-1/2}\int_0^t(v(s)-\bar{v}(s))\,\tilde{d}x(s)\right\}dm(x)\,d\sigma(v) \qquad (35)\\
&\quad=\int_{L_2[0,t]}\exp\left\{i\int_0^t v(s)\,d[\vec{\eta}](s)\right\}\\
&\qquad\cdot(2\pi)^{-1/2}\int_{\mathbb{R}}\exp\{iu\lambda^{-1/2}\|v-\bar{v}\|-u^2/2\}\,du\,d\sigma(v)\\
&\quad=\int_{L_2[0,t]}\exp\left\{i\int_0^t v(s)\,d[\vec{\eta}](s)-\frac{1}{2\lambda}\int_0^t(v(s)-\bar{v}(s))^2\,ds\right\}d\sigma(v).
\end{aligned}$$

But since $\sigma\in M(L_2[0,t])$, it is not hard to see that the right-hand side of (35) above is an analytic function of λ throughout $\mathbb{C}^+$ and is a continuous function of λ for $\mathrm{Re}\,\lambda\geqq 0$, $\lambda\neq 0$.

THEOREM 10. *Let* F *and* X *be as in Theorem* 9. *Then for all* $\lambda\in\mathbb{C}^+$,

$$\begin{aligned}
&\int_{\mathbb{R}^n}\prod_{k=1}^n\left(\frac{\lambda}{2\pi(t_k-t_{k-1})}\right)^{1/2}\exp\left\{-\frac{\lambda}{2}\sum_{k=1}^n\frac{(\eta_k-\eta_{k-1})^2}{t_k-t_{k-1}}\right\}E^{\mathrm{anw}_\lambda}(F|X)(\vec{\eta})\,d\vec{\eta}\\
&\quad=\int_{L_2[0,t]}\exp\left\{-\frac{1}{2\lambda}\|v\|^2\right\}d\sigma(v)=E^{\mathrm{anw}_\lambda}(F)
\end{aligned} \tag{36}$$

and for all real $q\neq 0$,

$$\begin{aligned}
&\int_{\mathbb{R}^n}\prod_{k=1}^n\left(\frac{q}{2\pi i(t_k-t_{k-1})}\right)^{1/2}\exp\left\{\frac{iq}{2}\sum_{k=1}^n\frac{(\eta_k-\eta_{k-1})^2}{t_k-t_{k-1}}\right\}E^{\mathrm{anf}_q}(F|X)(\vec{\eta})\,d\vec{\eta}\\
&\quad=\int_{L_2[0,t]}\exp\left\{-\frac{i}{2q}\|v\|^2\right\}d\sigma(v)=E^{\mathrm{anf}_q}(F)
\end{aligned} \tag{37}$$

where $E^{\mathrm{anw}_\lambda}(F|X)$ *and* $E^{\mathrm{anf}_q}(F|X)$ *are given by* (33) *and* (34), *respectively.*

Proof. Let $\lambda\in\mathbb{C}^+$ be given. Note that in view of (32) we have that

$$\int_0^t v(s)\,d[\vec{\eta}](s)=\int_0^t\bar{v}(s)\,d[\vec{\eta}](s)=\sum_{k=1}^n\frac{(\eta_k-\eta_{k-1})}{t_k-t_{k-1}}\int_{t_{k-1}}^{t_k}v(s)\,ds.$$

Thus using (33), the Fubini theorem, and Theorem 8, we see that the left-hand side of (36) equals the expression

$$\int_{L_2[0,t]} \exp\left\{-\frac{1}{2\lambda}\int_0^t (v(s)-\bar{v}(s))^2\,ds\right\} \prod_{k=1}^{n}\left(\frac{\lambda}{2\pi(t_k-t_{k-1})}\right)^{1/2}$$

$$\cdot \int_{\mathbb{R}^n} \exp\left\{-\frac{\lambda}{2}\sum_{k=1}^{n}\frac{(\eta_k-\eta_{k-1})^2}{(t_k-t_{k-1})}+i\sum_{k=1}^{n}\frac{(\eta_k-\eta_{k-1})}{(t_k-t_{k-1})}\int_{t_{k-1}}^{t_k} v(s)\,ds\right\} d\vec{\eta}\,d\sigma(v)$$

$$= \int_{L_2[0,t]} \exp\left\{-\frac{1}{2\lambda}\int_0^t (v(s)-\bar{v}(s))^2\,ds\right\}\left(\frac{\lambda}{2\pi}\right)^{n/2}$$

$$\cdot \int_{\mathbb{R}^n} \exp\left\{-\frac{\lambda}{2}\sum_{k=1}^{n}\xi_k+i\sum_{k=1}^{n}\xi_k(t_k-t_{k-1})^{-1/2}\int_{t_{k-1}}^{t_k} v(s)\,ds\right\} d\xi_1\cdots d\xi_n\,d\sigma(v)$$

$$= \int_{L_2[0,t]} \exp\left\{-\frac{1}{2\lambda}\int_0^t (v(s)-\bar{v}(s))^2\,ds\right.$$

$$\left.-\frac{1}{2\lambda}\sum_{k=1}^{n}\frac{1}{t_k-t_{k-1}}\left(\int_{t_{k-1}}^{t_k} v(s)\,ds\right)^2\right\} d\sigma(v)$$

$$= \int_{L_2[0,t]} \exp\left\{-\frac{1}{2}\|v\|_2^2+\frac{1}{2\lambda}\|\bar{v}\|_2^2-\frac{1}{2\lambda}\|\bar{v}\|_2^2\right\} d\sigma(v)$$

$$= \int_{L_2[0,t]} \exp\left\{-\frac{1}{2\lambda}\|v\|_2^2\right\} d\sigma(v),$$

which establishes (36). To establish (37), use the summation procedure (10) and proceed as above; carrying out the integration with respect to $\vec{\eta}=(\eta_1,\cdots,\eta_n)$ is rather long and tedious.

Remark 7. Theorems 9 and 10 have ν-dimensional counterparts. For example, if $F\in S(\nu)$ and if $X(\vec{x})=(\vec{x}(t_1),\cdots,\vec{x}(t_n))$ for $\vec{x}$ in $C_0^{\nu}[0,t]$, then the equation corresponding to (33) is

$$E(F(\vec{x})|X(\vec{x}))(\vec{\eta}_1,\cdots,\vec{\eta}_\nu)$$

$$= \int_{L_2^{\nu}[0,t]} \exp\left\{i\sum_{j=1}^{\nu}\int_0^t v_j(s)\,d[\vec{\eta}_j](s)-\frac{i}{2q}\sum_{j=1}^{\nu}\int_0^t (v_j(s)-\bar{v}_j(s))^2\,ds\right\} d\sigma(\vec{V})$$

where $\vec{V}=(v_1,\cdots,v_\nu)$ and $\vec{\eta}_j=(\eta_{j,1},\cdots,\eta_{j,n})$ for $j=1,\cdots,\nu$.

Acknowledgment. The first author wishes to express his gratitude to Professor G. W. Johnson for his encouragement and valuable advice as well as the hospitality of the University of Nebraska.

THE RIEMANN–HILBERT PROBLEM AND INVERSE SCATTERING

XIN ZHOU†

Abstract. The connection between the Riemann–Hilbert factorization on self-intersecting contours and a class of singular integral equations is studied with a pair of decomposing algebras. This provides an effective way of treating the inverse scattering problem for first-order systems. We also show that the matrix functions with positive definite real parts on the real axis and Schwarz reflection invariant elsewhere only have zero partial indices. In particular, this implies the solvability for the inverse scattering problem with skew Schwarz reflection invariant system coefficients $J(z)$ and $q(\cdot, z)$. This includes, for instance, the system associated with the generalized sine-Gordon equation.

Key words. factorization, inverse scattering, partial indices

1. Introduction.

Recent progress in the theory of the inverse scattering method motivates the study of the Riemann–Hilbert problem with self-intersecting contours. This paper shows that although it is inadequate to study the Riemann–Hilbert problem with this type of contours for a single decomposing algebra, we may still acquire, by working on a pair of decomposing algebras (see §9), the classical results which have been obtained in the case of nonself-intersecting contours [7]. This provides a new approach for the study of the inversion of the Beals–Coifman scattering data.

It is by now well understood [3], [6], [12], that the inverse scattering problem for the first order $n \times n$ system

$$\frac{d}{dx}\mathbf{m} - \operatorname{ad} J(z)\mathbf{m} = q(x, z)\mathbf{m} \tag{1.1}$$

for certain rational $J(z)$ and $q(\cdot, z)$ can be formulated as a Riemann–Hilbert problem with zero partial indices and a parameter x. The inverse scattering of AKNS system (2×2 and $J(z) = zJ$, $q(x, z) = q(x)$ [2]) has been formulated as a Gelfand–Levitan–Marchenko integral equation with its integral operator being compact and vanishing in norm as $x \to -\infty$ (or $+\infty$). These nice properties give the existence and the desired decay for the solution of the Gelfand–Levitan–Marchenko equation near $x = -\infty$ (or$+\infty$). They also aid in showing the solvability of the inverse scattering problem for skew Hermitian J and $q(x)$ [2], and the generic solvability for general J and $q(x)$. The solution of a Riemann–Hilbert problem with zero partial indices may also be obtained by solving a singular integral equation. However, the singular integral operator thereof need not have the nice properties stated above for the Gelfand–Levitan–Marchenko equation. Yet the complexity of the contours involved in the inverse scattering problem forbids the direct application of the existing general theory of the Riemann–Hilbert problem. With all of these difficulties, the inverse scattering problem for the $n \times n$ AKNS system was rigorously treated in [3] by splitting the problem, via a careful rational approximation, into a small norm problem of a singular integral equation and

*Received by the editors January 19, 1988; accepted for publication (in revised form) July 27, 1988.

†Department of Mathematics, University of Wisconsin–Madision, Madison, Wisconsin 53706. This work was done when the author was at the University of Rochester.

a linear algebraic problem. Thereafter the same method was applied to the inverse scattering for two other systems [1], [9].

In this paper we study the inverse scattering problem of system (1.1) for a class of $J(z)$ and $q(\cdot, z)$ (see §8) with a more direct method based on the Fredholm theory of singular integral operators. Our extended theory of the Riemann–Hilbert problem for decomposing algebras makes it possible to establish a singular integral equation which may be viewed as a natural extension of the Gelfand–Levitan–Marchenko equation. More precisely, we obtain a singular integral equation

$$m = I + C_x m \tag{1.2}$$

for all x real (also for all t real in the time evolution problem) with the following properties:

(1) The operator $Id - C_x$ admits an explicit regularization in the form

$$(Id - \tilde{C}_x)(Id - C_x) = Id + T_x \tag{1.3}$$

where $\tilde{C}_x$ is the operator for an associated Riemann–Hilbert problem and T_x is a compact operator.

(2) (The Fredholm alternative.) The Fredholm index of $Id - C_x$ is zero.

(3) $T_x \to 0$ in norm as $x \to -\infty$.

(4) When the scattering data (less I) is supported away from an open set containing the poles of $J(z)$, C_x is entire in x (also in t in the time evolution problem). We remark that for the 2×2 AKNS system the regularization is not necessary. In this case, on a Hardy space C_x in (1.2) is compact and vanishes in norm as $x \to -\infty$. In fact, the Fourier transform of (1.2) on the Hardy space is the Gelfand–Levitan–Marchenko equation.

Many useful results for the inverse scattering problem may be deduced directly from (1.2) with the above properties. For instance, properties 2 and 3 provide the invertibility of $Id - C_x$ near $x = -\infty$. The decay of $m - I$ near $x = -\infty$ depends on the oscillatory integral $C_x I$ by

$$m - I = (Id - C_x)^{-1} C_x I = O(C_x I).$$

Moreover, in case the scattering data is supported away from an open set containing the poles of $J(z)$, the analytic Fredholm theorem helps to invert $Id - C_x$. This enables us to give a proof of the generic solvability (Theorem 6.3) with an explicit perturbation. We point out here that the x-dependent data is not bounded as $x \to \infty$ in the Sobolev spaces. In [3] the x-dependent norms on Sobolev spaces were introduced to obtain the small norm problem on these spaces. By our method, this can be avoided by using the Fredholm alternative, which shows that if $Id - C_x$ is invertible on $\mathbf{L}^2$, then it is invertible on every space set theoretically contained in the span of the constant functions and $\mathbf{L}^2$ as long as the regularization is valid for such a space.

In addition, our method exhibits the following advantages in comparison with that introduced in [3]:

(1) The rational approximation used in [3] is local to the parameter t although for x it can be done once for $x \leq 0$ and once for $x \geq 0$. The produced algebraic systems for $x \leq 0$ and for $x \geq 0$ are not well connected. In case of Schwartz class scattering data (the scattering data and their arbitrary order derivatives having arbitrary orders of polynomial decay at all the poles of $J(z)$), to derive the arbitrary polynomial decay for corresponding potentials, infinitely many different algebraic systems are required. While (1.2) stands for x and t globally. This, for instance, enables us to obtain the

density part of the generic solvability independent of the winding number constraint (see [3, p. 79]). Although for the asymptotic behavior as $x \to +\infty$ we still need a different operator $Id - C_x^{\#}$, this operator is connected with $Id - C_x$ simply by a right invertible multiplier (see (7.5)). Also, for Schwartz class scattering data, the single equation (1.2) is adequate for deriving the arbitrary polynomial decay for the corresponding potentials at $x = -\infty$.

(2) The underlying spaces are less restrictive. In general the condition for the regularization (1.2) is weaker than requiring the density of the rational functions. For instance, the Hölder spaces are not separable (see [5], [7, p. 60]), but the regularization is still valid (see [10]). We remark that, for unbounded contours, the Hölder continuity of f at ∞ is required in the sense that $z^{-1}f(z^{-1})$ is Hölder continuous at 0. Note that the transform $f \mapsto z^{-1}f(z^{-1})$ commutes with the Cauchy integral operators.

(3) The operator of the algebraic system used in [3] does not have property 4 above.

It is a classical result [8] that the matrix functions with positive definite real part on a line have only zero partial indices. This result implies that the inverse scattering problem for the $n \times n$ AKNS system with $\operatorname{Re} J = \operatorname{Re} q = 0$ is always solvable [4]. We show in this paper (Theorem 9.2) that the matrix functions with positive definite real parts on the real axis and the Schwarz reflection invariant elsewhere only have zero partial indices. This applies to the systems with $J(\bar{z})^* + J(z) = 0$ and $q(x, \bar{z})^* + q(x, z) = 0$. The contours involved could be very complicated. For example, when $J(z) = z^n J$, $J + J^* = 0$ [9], the contours consist of finitely many straight lines intersecting at the origin; for the generalized sine-Gordon equation (we replace the spectral parameter z by iz in [1]), the contour consists of the real axis and the unit circle.

In §2, the required decomposing algebras $\mathbf{H}^k(\Sigma^{\pm})$ are constructed based on Sobolev spaces. We point out here that the Cauchy integral operators are under no circumstances defined componentwise. In §3, the Riemann–Hilbert problem is introduced in a narrow sense merely to meet the requirements for the study of the inverse scattering problem. However, the related singular integral operators constructed there play central roles in the study of the Riemann–Hilbert problem in the general sense as well. Section 4 gives the regularization. Several immediate results are given with short proofs. Some of these results can be generalized by means of the techniques introduced in §9.

In §5, the generalized triangular factorization is introduced in order to accommodate the systems in which $J(z)$ may have some equal diagonal entries. In §6, the inverse scattering problem is studied. We introduce the factorized scattering data which differ from the transformed scattering data in [3]. Also the augmented contours are introduced to convert the discrete scattering data into the "continuous." The resulting Riemann–Hilbert problem is completely equivalent to the original one. In §7, by means of the generalized triangular factorization, we study the Riemann–Hilbert problem for the systems in which $J(z)$ may have some equal diagonal entries. This may also help to obtain the conditions for the decay of the potentials at the nonoblique directions for the generalized wave equation and the generalized sine-Gordon equation [1]. In §8, we construct $q(x, z)$ from the fundamental solutions of the Riemann–Hilbert problem of $e^{x \operatorname{ad} J(z)}v$ for arbitrary rational diagonal matrix functions $J(z)$ when $e^{x \operatorname{ad} J(z)}v$ is in the Sobolev spaces. We see that the z dependence of q is far from arbitrary. For the class of q obtained this way, the direct problem can be worked out by virtue of the method introduced in [3].

In §9, the general theory of the Riemann–Hilbert problem is studied. Certain classical results are extended to the case of self-intersecting contours with a pair of decomposing algebras. A partial index argument is used in the proof of Theorem 9.2 to attain generality. This is useful for the problem in which we only wish to construct solutions for certain nonlinear PDEs for which the "scattering data" and the contours need not be characterized as in this paper. Certainly, the partial index argument may be avoided if we only consider the Riemann–Hilbert factorization for scattering data, since then we have the Fredholm alternative.

2. H spaces and the Cauchy operators. To avoid a flood of parentheses we follow the rule that when operator actions and matrix multiplications are mixed in a row, we do them in order from right to left. For example,

$$AbcBd \stackrel{\text{def}}{=} A(b(c(Bd))). \tag{2.1}$$

We denote by $\mathbf{M}_n$ the complex $n \times n$ matrix algebra with the inner product

$$(a, b) \stackrel{\text{def}}{=} \operatorname{tr} b^* a. \tag{2.2}$$

The corresponding norm is denoted by $|\cdot|$. An element $h \in \mathbf{M}_n$ may also denote the functions constantly equal to h on the spaces understood from the context. In the sequel, we will simply call an $\mathbf{M}_n$-valued function a matrix function.

Let $\Sigma \subset \mathbb{C}$ be a finite union of simple smooth curves that can be either closed on the $\mathbb{C}$ plane or extended to be closed on the Riemann sphere. The set of the intersections of these contours is denoted by S and assumed to be finite. Clearly Σ is smooth except at the points of S. It is readily verified that Σ admits an orientation in the sense that Σ is the positively oriented boundary for an open set Ω^+ and the negatively oriented boundary for $\Omega^- \stackrel{\text{def}}{=} \mathbb{C} \setminus (\Sigma \cup \Omega^+)$.

Clearly Ω^+ and Ω^- can only have finitely many components and Σ has two possible orientations. Any other "orientations" fail to make the Cauchy operators defined below complementary projections. The oriented Σ is still denoted by Σ while $-\Sigma$ is used to denote Σ with the opposite orientation. The symbol Σ^+ (Σ^-) is also used to denote Σ when it is viewed as the boundary of Ω^+ (Ω^-). The $\mathbf{L}^p$ norm of a function $f : \Sigma \to \mathbf{M}_n$ is defined as

$$\|f\|_p = \left(\int_\Sigma |f|^p \right)^{1/p} |dz|. \tag{2.3}$$

We will simply write $\mathbf{L}^p(\Sigma)$ for $\mathbf{L}^p(\Sigma, \mathbf{M}_n)$.

The Cauchy integral operators C_+ and C_- on $\mathbf{L}_2(\Sigma)$ are defined as

$$C_\pm f(z'') = \lim_{z' \to z''} \frac{1}{2\pi i} \int_\Sigma \frac{f(z)dz}{z - z'} \tag{2.4}$$

where the nontangential limit $z' \to z''$ is taken from Ω^+, Ω^-, respectively. We make the assumption on Σ that $C_\pm$ are bounded from $\mathbf{L}^2$ to $\mathbf{L}^2$. The recent development in the $\mathbf{L}^p$ theory of singular integral operators on curves typically allows the curves to have corners with positive angles. Since Σ is a positively oriented contour for Ω^+ and a negatively oriented contour for Ω^-, $\pm C_\pm$ can be shown to be complementary projections. A function in $\ker C_+$ has an analytic extension to Ω^- while a function in $\ker C_-$ has an analytic extension to Ω^+.

Let Γ be a piecewise smooth simple curve. We denote by $\mathbf{H}^k(\Gamma)$ all the matrix functions f such that $f^{(j)} \in \mathbf{L}^2(\Gamma)$ for all $j = 0, \cdots, k$ in the distribution sense. For the details of constructing such functions, see [3, pp. 70–71].

We make a further assumption that $\partial\Omega_\nu$ for each component Ω_ν of $\mathbb{C}\setminus\Sigma$ does not have self-intersections. $\mathbf{H}^k(\Sigma\setminus S)$ for $k>0$ is the Hilbert space of all the matrix functions f on Σ such that $f\restriction\Sigma_\nu\in\mathbf{H}^k(\Sigma_\nu)$ for every component Σ_ν of $\Sigma\setminus S$. The norm of this Hilbert space $\|f\|_{2,k}\stackrel{\text{def}}{=}(\sum_{j=0}^k\|f^{(j)}\|_2^2)^{1/2}$ will be called the $\mathbf{H}^k$ norm. We point out that for $f\in\mathbf{H}^k(\Sigma\setminus S)$, $f^{(j)}$ for $j=0,\cdots,k-1$ are continuous on Σ_ν with limits on $\partial\Sigma_\nu$ after a correction of the function on a set of measure zero. Since the Cauchy integral operators are not bounded on $\mathbf{H}^k(\Sigma\setminus S)$, we need the subspaces $\mathbf{H}^k(\Sigma^+)$ and $\mathbf{H}^k(\Sigma^-)$ for $k>0$ of $\mathbf{H}^k(\Sigma\setminus S)$. $\mathbf{H}^k(\Sigma^+)$ contains all f on Σ such that $f\restriction\partial\Omega_\nu\in\mathbf{H}^k(\partial\Omega_\nu)$ for every component Ω_ν of Ω^+ and $\mathbf{H}^k(\Sigma^-)$ such that $f\restriction\partial\Omega_\nu\in\mathbf{H}^k(\partial\Omega_\nu)$ for every component Ω_ν of Ω^-. $\mathbf{H}^k(\Sigma)\stackrel{\text{def}}{=}\mathbf{H}^k(\Sigma^+)\cap\mathbf{H}^k(\Sigma^-)$.

The $\mathbf{H}$ spaces defined above are Hilbert spaces with continuous pointwise multiplication. This follows from the fact that the norm $\|f\|_{2,k}$ dominates the norm $\sum_{j=0}^{k-1}\|f^{(j)}\|_\infty$. These spaces are Banach algebras if their norms are replaced by certain equivalent ones. For convenience, sometimes we denote $\Sigma\setminus S$, Σ, Σ^+, or Σ^- by Σ^*. For consistency, sometimes we also denote $\mathbf{L}^2(\Sigma)$ by $\mathbf{H}^0(\Sigma^*)$, but it is not an algebra under pointwise multiplication.

The rational functions are dense in $\mathbf{H}^k(\partial\Omega_\nu)$ for every component Ω_ν of $\mathbb{C}\setminus\Sigma$. In [3] this is proven for sectors. The proof can easily be generalized. We denote by R^+ (R^-) the set of all the matrix functions with their restrictions on $\partial\Omega_\nu$ rational (after a possible modification at the self-intersections) for every component Ω_ν of Ω^+ (Ω^-). Then $R=R^+\cap R^-$ is the set of all the rational matrix functions. We also denote by R_+^+ (R_-^-) the set of all the functions in R^+ (R^-) extended to be componentwise holomorphic on Ω^+ (Ω^-). $R_\pm=R\cap R_\pm^\pm$. Clearly, under this assumption, $R^+\cap\mathbf{L}^2$ ($R^-\cap\mathbf{L}^2$) is dense in $\mathbf{H}^k(\Sigma^+)$ ($\mathbf{H}^k(\Sigma^-)$). If u is a function on $\mathbb{C}\setminus\Sigma$, by u_+ and u_- we denote the limits, if they exist, of $u(z)$ as z approaches $\Sigma\setminus S$ from Ω^+ and Ω^- respectively.

PROPOSITION 2.1. *C_+, C_- are bounded from $\mathbf{H}^k(\Sigma^-)$, $\mathbf{H}^k(\Sigma^+)$ to $\mathbf{H}^k(\Sigma)$, respectively. And C_+, C_- are bounded from $\mathbf{H}^k(\Sigma^+)$, $\mathbf{H}^k(\Sigma^-)$ to $\mathbf{H}^k(\Sigma^+)$, $\mathbf{H}^k(\Sigma^-)$, respectively.*

Proof. For instance, for C_+, if $r\in R^-\cap\mathbf{L}^2$, it is easily checked that C_+r is rational and therefore belongs to $\mathbf{H}^k(\Sigma)$. The boundedness of C_+ is deduced from the integration by parts on Σ^-. Since $R^-\cap\mathbf{L}^2$ is dense in $\mathbf{H}^k(\Sigma^-)$, we conclude that C_+ is bounded from $\mathbf{H}^k(\Sigma^-)$ to $\mathbf{H}^k(\Sigma)$. We have a parallel argument for C_-. The remaining part of the proposition follows from that $C_+-C_-=Id$. The proof can also be made independent of the rational approximation to meet the need of the decomposing algebras in which the rational functions are not necessarily dense. □

A function $f\in\mathbf{H}^k(\Sigma)$ can be approximated in $\mathbf{H}^k$ norm by either functions $r^+\in R^+\cap\mathbf{L}^2$ or functions $r^-\in R^-\cap\mathbf{L}^2$. Since

$$f-(C_+r^- - C_-r^+)=C_+(f-r^-)-C_-(f-r^+), \tag{2.5}$$

f can be in fact simply approximated by the rational functions $C_+r^- - C_-r^+$. Therefore $R\cap\mathbf{L}^2$ is dense in $\mathbf{H}^k(\Sigma)$. Furthermore $R_+^+\cap\mathbf{L}^2$ is dense in $\ker C_-$ and $R_-^-\cap\mathbf{L}^2$ dense in $\ker C_+$.

PROPOSITION 2.2. *In the $\mathbf{L}^2$ space, if $f\in\ker C_+$ and g is componentwise holomorphic on Ω^- and extends continuously to the boundary of each component of Ω^-, then $fg\in\ker C_+$.*

We have a parallel result regarding $\ker C_-$.

Proof. Since g is bounded, C_+fg can be approximated in $\mathbf{L}^2$ norm by C_+r_fg where r_f is an $\mathbf{L}^2$ rational approximation of f with no poles in Ω^-. We may conclude that $C_+fg = 0$ from $C_+r_fg = 0$. □

For the uniformity of the demonstration, we assume that Σ is unbounded. We embed $\mathbf{H}^k(\Sigma^*)$ for $k \geq 0$ into a larger Hilbert space $\mathbf{H}_I^k(\Sigma^*)$ consisting of matrix functions f on Σ with the limit $f(\infty)$ at ∞ such that

$$f - f(\infty) \in \mathbf{H}^k(\Sigma^*).$$

The norm for $\mathbf{H}_I^k(\Sigma^*)$ is defined as the square root of

$$|f(\infty)|^2 + \|f - f(\infty)\|_k^2.$$

This norm is again denoted by $\|\cdot\|_k$. The norm of a bounded operator $A : \mathbf{H}_I^k(\Sigma^*) \to \mathbf{H}_I^k(\Sigma^*)$ is denoted by $\|A\|_k$.

Clearly $\mathbf{H}_I^k(\Sigma^*)$ is isomorphic to the Hilbert space direct sum of $\mathbf{H}^k(\Sigma^*)$ and $\mathbf{M}_n$. For $k > 0$, $\mathbf{H}_I^k(\Sigma^*)$ is an inverse closed Banach algebra with identity element I (see §9).

3. Riemann–Hilbert problem and the related integral operators.

DEFINITION 3.1. A matrix function v on Σ is said to be some data on Σ of smoothness degree $k \geq 1$ if v admits a factorization $v = b^{--1}b^+$ for nonsingular $b^\pm$ such that $b^\pm - I \in \mathbf{H}^k(\Sigma^\pm)$.

Let $w^+ = b^+ - I$, $w^- = I - b^-$. We call $w = (w^+, w^-)$ a factorized data of v. The set of all the data defined above is denoted by D_k and all the corresponding factorized data by FD_k.

Clearly a data v may correspond to more than one factorized data. In the following the Riemann–Hilbert problem is described in a narrow sense in terms of the factorized data. For the Riemann–Hilbert problem in a more general sense see §9.

DEFINITION 3.2. Let $w \in FD_k$, a vector $m \in \mathbf{H}_I^j(\Sigma)$ for some $j = 0, \cdots, k$ is said to be a solution of the Riemann–Hilbert problem of data w if

$$mb^\pm - m(\infty) \in \operatorname{ran} C_\pm \tag{3.1}$$

Clearly $m_\pm \overset{\text{def}}{=} mb^\pm \in \mathbf{H}_I^j(\Sigma^\pm)$. We denote by $\mathbf{m}$ the componentwise holomorphic extension of $m_\pm$. The function m is called a vanishing solution if $m(\infty) = 0$, and a fundamental solution if $m(\infty) = I$ and if $\det \mathbf{m}$ vanishes nowhere. We also call $m_\pm$ or $\mathbf{m}$ the solution of the Riemann–Hilbert problem of v or of w.

PROPOSITION 3.1. *The Riemann–Hilbert problem of v has a fundamental solution only if*

$$\frac{1}{2\pi}\int_\Sigma d \arg \det v = 0, \tag{3.2}$$

and conversely, if $m \in \mathbf{H}_I^k(\Sigma)$ with $k > 0, m(\infty) = I$ is a solution of the Riemann–Hilbert problem of v and (3.2) is fulfilled, then m is a fundamental solution. Furthermore, if $\det v = 1$, then $\det \mathbf{m} = 1$.

Proof. Suppose that v admits a fundamental solution $m_\pm$, then $\det m_\pm$ is a fundamental solution of the scalar Riemann–Hilbert problem of $\det v$. Therefore (3.2) is fulfilled.

For the converse part, let $\mathbf{m}$ be a solution that meets the hypotheses and (3.2) holds. It follows that $\det \mathbf{m}$ is a solution for the scalar Riemann–Hilbert problem of $\det v$ with $\det \mathbf{m}(\infty) = 1$. Condition (3.2) implies that the scalar Riemann–Hilbert

problem of $\det v$ admits a fundamental solution $\mathbf{m}_1$; then clearly $(\det \mathbf{m})\mathbf{m}_1^{-1}$ is an entire function with limit 1 at ∞ and therefore equals 1. The last part of the proposition also easily follows from the fact that $\mathbf{m}_1 = 1$ in this special case. □

PROPOSITION 3.2. *If the Riemann–Hilbert problem of $w \in FD_k$ admits a fundamental solution $m \in \mathbf{H}_I^j(\Sigma)$ for some $j > 0$, then it is unique in $\mathbf{L}_I^2(\Sigma)$.*

Proof. Let $n \in \mathbf{L}_I^2(\Sigma)$ also be a fundamental solution. Applying Proposition 2.2 we have

$$nm^{-1} - I = nb^{\pm}(mb^{\pm})^{-1} - I \in \ker C_+ \cap \ker C_- = 0. \qquad \square$$

The Riemann–Hilbert problem of $w \in FD_k$ is related to an operator C_w bounded from $\mathbf{H}_I^j(\Sigma)$ to $\mathbf{H}_I^j(\Sigma)$ for every $j = 0, \cdots, k$ defined as

$$(C_w\phi) = C_+\phi w^- + C_-\phi w^+.$$

PROPOSITION 3.3. *The vector $m \in \mathbf{L}_I^2(\Sigma)$ is a solution of the Riemann–Hilbert problem of w with $m(\infty) = h$ if and only if m is a solution of the system*

$$m = h + C_w m^{\times}. \tag{3.4}$$

Proof. The above system can be written as

$$m = h + C_+ m w^- + C_- m w^+. \tag{3.5}$$

Suppose that m is a solution of this system. From 3.5 clearly $m(\infty) = h$. Thus we have

$$\begin{aligned} C_+ m(w^+ + w^-) &= C_+ m w^- + C_- m w^+ - C_- m w^+ + C_+ m w^+ \\ &= m - h + m w^+ = m b^+ - m(\infty), \end{aligned} \tag{3.6}$$

and similarly

$$C_- m(w^+ + w^-) = m b^- - m(\infty). \tag{3.7}$$

Therefore 3.1 is satisfied. Conversely, suppose that m is a solution of the Riemann–Hilbert problem of w with $m(\infty) = h$, then

$$\begin{aligned} C_+ m w^- + C_- m w^+ &= C_+(m - m(\infty)) \\ &\quad - C_+(m b^- - m(\infty)) - C_-(m - m(\infty)) \\ &\quad + C_-(m b^+ - m(\infty)) = m - h. \end{aligned}$$

Therefore (3.5) is satisfied. □

The following proposition gives the equivalence relation between $Id - C_w$ and $Id - C_{w'}$ when w and w' belong to the same v.

PROPOSITION 3.4. *Suppose that w and w' are the factorized data of the same data v. Let $u = b'^+ b^{+-1} (= b'^- b^{--1} \in \mathbf{H}_I^k(\Sigma))$ and define an invertible operator U on $\mathbf{H}_I^k(\Sigma)$ as*

$$U\phi = \phi u.$$

Then we have the relation $(Id - C_w)U = Id - C_{w'}$.

Proof.

$$\begin{aligned} (Id - C_w)U\phi &= \phi u - C_+\phi u(I - b^-) + C_-\phi u(I - b^+) \\ &= \phi u - C_+\phi(u - b'^-) - C_-\phi(b'^+ - u) \\ &= \phi - C_+\phi w'^- - C_-\phi w'^+ = (Id - C_{w'})\phi. \end{aligned} \qquad \square$$

4. Regularization. For $w \in FD_k$, we define the associated factorized data $\tilde{w}$ of w as $\tilde{w}^{\pm} = \pm b^{\pm -1} \mp I$ where $b^{\pm}$ are determined by w as in Definition 3.1. Clearly $\tilde{w}$ also belongs to FD_k. Since $\tilde{w}$ is determined by w, we define operator T_w as

$$T_w\phi = C_+(C_-\phi(w^+ + w^-))\tilde{w}^- + C_-(C_+\phi(w^+ + w^-))\tilde{w}^+. \tag{4.1}$$

Clearly T_w is bounded from $\mathbf{H}_I^i(\Sigma)$ to $\mathbf{H}_I^i(\Sigma)$ for any $i = 0, \cdots, k$. It can be shown by the rational approximations of $\tilde{w}^+$ and $\tilde{w}^-$ that T_w is compact.

Remark. In general, the density of rational functions ensure the compactness of T_w. Nonetheless, as mentioned in the introduction, T_w can be compact on certain spaces without the density of the rational functions.

PROPOSITION 4.1. *$Id - C_w$ is Fredholm and*

$$Id + T_w = (Id - C_{\tilde{w}})(Id - C_w). \tag{4.2}$$

Proof. Using the fact that $\pm C_{\pm}$ are complementary projections gives

$$\begin{aligned} C_{\tilde{w}}C_w\phi &= C_+(C_w\phi)\tilde{w}^- + C_-(C_w\phi)\tilde{w}^+ \\ &= C_+(C_+\phi w^- + C_-\phi w^+)\tilde{w}^- + C_-(C_+\phi w^- + C_-\phi w^+)\tilde{w}^+ \\ &= C_+(C_-\phi(w^+ + w^-))\tilde{w}^- + C_-(C_+\phi(w^+ + w^-))\tilde{w}^+ \\ &\quad + C_+(\phi w^-)\tilde{w}^- - C_-(\phi w^+)\tilde{w}^+ \\ &= T_w\phi + C_+\phi(w^- + \tilde{w}^-) + C_-\phi(w^+ + \tilde{w}^+) \\ &= (T_w + C_{\tilde{w}} + C_w)\phi. \end{aligned}$$

Since C_w and $C_{\tilde{w}}$ are in the symmetric positions, $Id - C_{\tilde{w}}$ is also a right regulator for $Id - C_w$. Therefore the operator $Id - C_w$ is Fredholm (see [10, p. 33]). □

In the rest of this section, we assume that $w^{\pm}$ are nilpotent merely to meet the requirements for the study of the inverse scattering problem. In §9, we will see that this assumption can be replaced by (3.2).

PROPOSITION 4.2 (Fredholm alternative). *The operator $Id - C_w$ has zero Fredholm index and is invertible whenever $Id + T_w$ is.*

Proof. Since $w^{\pm}$ are nilpotent, it follows from the fact that $\det(I \pm \varsigma w^{\pm}) = 1$ that ςw is in FD_k for any complex number ς. This continuously (analytically) deforms C_w to zero. Therefore the Fredholm index of $Id - C_w$ is zero. Now if $Id + T_w$ is invertible, then $Id - C_w$ is injective and therefore invertible. □

PROPOSITION 4.3 (Analytic Fredholm alternative). *If $w = w_\varsigma$ depends on a parameter ς analytically, then either $(Id - C_{w_\varsigma})^{-1}$ is meromorphic in ς or $Id - C_{w_\varsigma}$ is invertible for no ς.*

Proof. The corresponding $\tilde{w}_\varsigma$ is clearly also analytic in ς. Now suppose that $Id - C_{w_\varsigma}$ is invertible for $\varsigma = \varsigma_0$. Then there is a compact operator B such that $Id - C_{\tilde{w}_\varsigma} + B$ is injective for $\varsigma = \varsigma_0$ (see [10, pp. 34–38]). Therefore

$$(Id - C_{\tilde{w}_\varsigma} + B)(Id - C_{w_\varsigma}) = Id + T_{w_\varsigma} + B(Id - C_{w_\varsigma})$$

is injective for $\varsigma = \varsigma_0$ and so its inverse is meromorphic in ς. It follows from Proposition 4.2 that

$$(Id - C_{w_\varsigma})^{-1} = (Id + T_{w_\varsigma} + B(Id - C_{w_\varsigma}))^{-1}(Id - C_{\tilde{w}_\varsigma} + B)$$

whenever the right-hand side exists. Therefore $(Id - C_{w_\varsigma})^{-1}$ is meromorphic in ς.

Combining Proposition 4.2 with Proposition 3.2 gives Proposition 4.4. □

PROPOSITION 4.4. *If the Riemann–Hilbert problem of $w \in FD_k$ admits a fundamental solution $m \in \mathbf{H}_I^j(\Sigma)$ for some $j > 0$, then $Id - C_w$ is invertible on $\mathbf{H}_I^j(\Sigma)$ for all $j = 0, \cdots, k$.*

PROPOSITION 4.5. *Suppose that $w \in FD_k$. If $Id - C_w$ on space $\mathbf{H}_I^j(\Sigma)$ is invertible for any $j \leq k$, then it is invertible for all $j \leq k$.*

Proof. Suppose that $Id - C_w$ is invertible on $\mathbf{L}_I^2(\Sigma)$, then $\ker(Id - C_w) = 0$ in $\mathbf{L}_I^2(\Sigma)$ and so in $\mathbf{H}_I^j(\Sigma)$ for any $j = 0, \cdots, k$. Therefore by the Fredholm alternative, $Id - C_w$ is invertible on all these spaces.

Now suppose that $Id - C_w$ is invertible on $\mathbf{H}_I^j(\Sigma)$ for some j with $1 \leq j \leq k$; then $m = (Id - C_w)^{-1} I$ is a fundamental solution for the Riemann–Hilbert problem in $\mathbf{H}_I^j(\Sigma)$. Therefore $Id - C_w$ is invertible on $\mathbf{L}_I^2(\Sigma)$. □

5. Generalized triangular factorization. The study of the inverse scattering problem for system (1.1) (in which J may have some equal diagonal entries) requires the following notation.

For $A \in \mathbf{M}_n$, the operator $\operatorname{ad} A$ on $\mathbf{M}_n$ is defined as $\operatorname{ad} A(B) = [A, B] \stackrel{\text{def}}{=} AB - BA$. Let $A \in \mathbf{M}_n$ be real and diagonal, then $\operatorname{ad} A$ is a self-adjoint operator on $\mathbf{M}_n$. For $B \in \mathbf{M}_n$, we call $\chi_{(-\infty,0)}(\operatorname{ad} A)(B)$, $\chi_{(0,+\infty)}(\operatorname{ad} A)(B)$, and $\chi_{\{0\}}(\operatorname{ad} A)(B)$ the A lower triangular, A upper triangular, and A diagonal part of B, respectively. The phrases such as "A (off) diagonal," "A (strictly) upper triangular," and "A (strictly) lower triangular" are understood.

To visualize the above terminologies, we permute the basis of $\mathbf{M}_n$, such that the diagonal entries of A are reordered nonincreasingly. Then A has the form

$$A = \begin{pmatrix} a_1 I_1 & 0 & \dots & 0 \\ 0 & a_2 I_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & a_k I_k \end{pmatrix}, \tag{5.1}$$

where $a_1, \cdots, a_k$ are distinct and $I_1, \cdots, I_k$ are some identity blocks. Accordingly, any matrix $B \in \mathbf{M}_n$ can be written as

$$B = \begin{pmatrix} B_{11} & B_{12} & \dots & B_{1n} \\ B_{21} & B_{22} & \dots & B_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ B_{n1} & B_{n2} & \dots & B_{nn} \end{pmatrix}, \tag{5.2}$$

where B_{ij}, $1 \leq i, j \leq n$, are blocks such that the orders of $B_{11}, B_{22}, \cdots, B_{nn}$ are equal to those of $I_1, I_2, \cdots, I_n$, respectively. Under this expression,

$$\chi_{(-\infty,0)}(\operatorname{ad} A)(B) = \begin{pmatrix} 0 & 0 & \dots & 0 \\ B_{21} & 0 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ B_{n1} & B_{n2} & \dots & 0 \end{pmatrix}, \tag{5.3}$$

$$\chi_{(0,+\infty)}(\operatorname{ad} A)(B) = \begin{pmatrix} 0 & B_{12} & \dots & B_{1n} \\ 0 & 0 & \dots & B_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 0 \end{pmatrix}, \tag{5.4}$$

and

$$\chi_{\{0\}}(\operatorname{ad} A)(B) = \begin{pmatrix} B_{11} & 0 & \dots & 0 \\ 0 & B_{22} & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & B_{nn} \end{pmatrix}. \tag{5.5}$$

We also call

$$d^k(B) \stackrel{\text{def}}{=} \det \begin{pmatrix} B_{11} & B_{12} & \dots & B_{1k} \\ B_{21} & B_{22} & \dots & B_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ B_{k1} & B_{k2} & \dots & B_{kk} \end{pmatrix}, \qquad 1 \le k \le n \tag{5.6}$$

the A upper principal minors of B, and respectively

$$d_k(B) \stackrel{\text{def}}{=} \det \begin{pmatrix} B_{kk} & B_{k,k+1} & \dots & B_{kn} \\ B_{k+1,k} & B_{k+1,k+1} & \dots & B_{k+1,n} \\ \vdots & \vdots & \ddots & \vdots \\ B_{nk} & B_{n,k+1} & \dots & B_{nn} \end{pmatrix}, \qquad 1 \le k \le n \tag{5.7}$$

the A lower principal minors of B. Note that these A principal minors are just a part of the lower and upper principal minors of B in the usual sense. It is easy to check that we have the following proposition for the generalized triangular factorization.

PROPOSITION 5.1. *If no A upper principal minors of $v \in \mathbf{M}_n$ vanish, then v admits a unique triangular factorization*

$$v = b^{-1}\Delta a \tag{5.8}$$

such that $b - I$ is strictly A lower triangular, $a - I$ strictly A upper triangular, and Δ A diagonal.

6. The inverse scattering problem. Let $J = \operatorname{diag}(\lambda_1(z), \cdots, \lambda_n(z))$ be a rational matrix function with its constant term being zero. We assume that $J(z)$ and $\operatorname{ad} J(z)$ have exactly the same poles on the Riemann sphere and denote the set of these poles by P_J.

We define $\Sigma_0 \subset \mathbb{C}$ as the closure of

$$\{z \in \mathbb{C} | \operatorname{Re}(\lambda_j(z) - \lambda_k(z)) = 0, \quad \text{some } \lambda_j \neq \lambda_k\}. \tag{6.1}$$

and denote by S the set of all the self-intersections of Σ_0. Let $\Omega_0^{\pm}$ be the regions corresponding to Σ_0. Clearly, all the poles of $J(z)$ lie on $\Sigma \cup \{\infty\}$. Since $J(z)$ is fixed, the phrases such as "$\operatorname{ad}(\operatorname{Re} J(z))$ diagonal," and so forth, will be simply replaced by "z diagonal," etc. The spectrum projection operators $\chi_{(-\infty,0)}(\operatorname{ad}(\operatorname{Re} J(z)))$, $\chi_{(0,+\infty)}(\operatorname{ad}(\operatorname{Re} J(z)))$, and $\chi_{\{0\}}(\operatorname{ad}(\operatorname{Re} J(z)))$ are constant in each component of $\mathbb{C} \setminus \Sigma_0$. For $z \in \Sigma_0 \setminus S$ by z^+, we mean a point in Ω_0^+ near z and by z^- a point in Ω_0^- near z. Thus we can use phrases such as "z^+ upper triangular" and "z^- upper triangular," etc. A simple fact we will use is that, if for $z \in \Sigma_0 \setminus S$, a is z^- lower (upper) triangular and z diagonal, then it is z^+ upper (lower) triangular. This follows simply from the fact that $\operatorname{Re}(\lambda_i(z) - \lambda_j(z))$ is harmonic in $(\operatorname{Re} z, \operatorname{Im} z)$, and so it changes sign across the curve $\{\operatorname{Re}(\lambda_i(z) - \lambda_j(z)) = 0\}$.

At this stage, we make the assumption that all the diagonal entries of $J(z)$ are distinct. In the next section, we will consider the possibility of removing this restriction. The data for the Riemann–Hilbert problem for inverse scattering depend on a parameter x as $v_x \stackrel{\text{def}}{=} e^{x \operatorname{ad} J(z)} v$.

Let D be a finite subset of $\mathbb{C}$ disjoint from Σ_0 (see the remarks following Definition 6.3). The continuous parts of the scattering data, denoted by v_c, are supported on Σ_0 and the discrete parts of the scattering data, denoted by v_d, are supported on D. In the following the scattering data are characterized by five conditions. The first four are essentially based on the characterizations for the scattering data given in [3]. The last one is designed to ensure that $e^{x \operatorname{ad} J(z)} v$ is in the right Sobolev spaces.

DEFINITION 6.1. The discrete part and the continuous part of the scattering data of smoothness degree $k \geq 1$ are defined as follows:

(1) $v_c - I \in \mathbf{H}^k(\Sigma \setminus S)$, and $v_d(z_i)$ is strictly z_i upper triangular with a single nonzero entry for each $z_i \in D$;

(2) For each $z' \in S \setminus P_J$, there is a componentwise polynomial matrix function $a_{k,z'}(z - z')$ on $\mathbb{C} \setminus \Sigma$ such that $a_{k,z'}(z - z') - I$ is z strictly upper triangular and such that near $z = z'$

$$v_c(z) = (a^-_{k,z'}(z - z'))^{-1} a^+_{k,z'}(z - z') + o(|z - z'|^{k-1}) \tag{6.2}$$

(3) $v_c(z)$ is z diagonal and all the z^- lower principal minors are 1;

(4) A winding number constraint about the z^- upper principal minors of $v_c(z)$ and v_d. Since the winding number constraint will not be explicitly used in this paper we do not describe it here. For details see [3].

(5) If $z = \infty$ is a pole of $J(z)$ with multiplicity n, then

$$z^{j(n-1)}(v_c - I)^{(k-j)} \in \mathbf{L}^2 \quad \text{for } j = 1, \cdots, k; \tag{6.3}$$

if $z = z_0$ is a finite pole of $J(z)$ with multiplicity n, then

$$(z - z_0)^{-j(n+1)}(v_c - I)^{(k-j)} \in \mathbf{L}^2 \quad \text{for } j = 1, \cdots, k. \tag{6.4}$$

DEFINITION 6.2. Let D be covered by $|\Lambda|$ disjoint closed disks that do not intersect with Σ_0 such that each $z_i \in D$ is the center of exactly one of these disks. We add the boundary circles of these disks to form an augmented contour Σ. Since these added circles do not intersect with Σ_0, we may keep the original orientation on the Σ_0 part of Σ and clearly this determines the orientation uniquely for Σ.

DEFINITION 6.3. Now we define the scattering data v supported on Σ as follows:

(1) $v = v_c$ on Σ_0;

(2) On the added circle surrounding $z_i \in D \cap \Omega_0^{\pm}$, $v = I \pm v_d(z_i)/(z - z_i)$.

We denote by SD_k the set of all scattering data on Σ defined above.

Condition (6.2) guarantees that $v \in D_k$ (see Proposition 6.1 below). Conditions (6.3) and (6.4) guarantee $v_x \overset{\text{def}}{=} e^{x \operatorname{ad} J(z)} v \in D_k$ for every $x \in \mathbb{R}$.

Let $\mathbf{m}(x, z)$ be the fundamental solution of the Riemann–Hilbert problem of v_x. Using the fact $v_d(z_i)^2 = 0$, we see that $\mathbf{m}(x, z)$, from outside the added circle surrounding $z_i \in D$, extends meromorphically to inside the circle as

$$\mathbf{m}_i \overset{\text{def}}{=} \mathbf{m}\left(I + \frac{e^{x \operatorname{ad} J(z)} v_d(z_i)}{z - z_i}\right).$$

Using $v_d(z_i)^2 = 0$ and $(\operatorname{ad} J'(z_i) v_d(z_i)) v_d(z_i) = 0$ we obtain

$$\mathbf{m}_{i,-1} = \mathbf{m}_{i,0} e^{x \operatorname{ad} J(z_i)} v_d(z_i)$$

where $\mathbf{m}_{i,-1}$ ($\mathbf{m}_{i,0}$) is the -1st (0th) Laurent coefficient of $\mathbf{m}_i$ at z_i. This relation is used in [3] to describe the Riemann–Hilbert problem with discrete spectrum.

For the inverse scattering problem, it often happens that, on a portion of Σ_0, only certain columns of $\mathbf{m}$ commit the jump. Therefore the remaining columns may be permitted to have poles. This gives rise to the discrete scattering data on the contour Σ_0. In this case, the added circles may intersect with Σ_0. But if $v_d(z_i)(v(z) - I) = (v(z) - I) v_d(z_i) = 0$ for z in a neighborhood of z_i, we may still define the scattering data on the augmented contour in a similar fashion as in Definition 6.3.

DEFINITION 6.4. A factorized data $w \in FD_k$ of $v \in SD_k$ is said to be a factorized scattering data if

(1) $w^-(z)$ is z^- strictly upper triangular and $w^+(z)$ z^+ strictly upper triangular;

(2) $w^\pm(z)$ are z diagonal in an open set containing P_J.

The set of all the factorized scattering data obtained above is denoted by FSD_k.

PROPOSITION 6.1. *Every scattering data $v \in FD_k$ admits a factorized scattering data w.*

Proof. We cover $S \setminus P_J$ by disjoint small disks in the way that each disk contains exactly one $z' \in S \setminus P_J$. Since all the z^- lower principal minors of v_c are equal to 1, v_c admits a triangular factorization $v_c = b_1^{--1} b_1^+$ such that $b_1^+(z) - I$, $(b_1^-(z) - I)$ is z^- strictly lower (upper) triangular. Since $v_c(z)$ is z diagonal, $b_1^\pm(z)$ are also z diagonal and therefore $b_1^+(z)$ is z^+ upper triangular. Clearly $b_1^\pm - I \in \mathbf{H}^k(\Sigma_0 \setminus S)$. Define $f_{z'}(z)$ on Σ_0 near each $z' \in S \setminus P_J$ such that on each curve of Σ_0 ending at z', $f_{z'}(z)$ equals the Taylor polynomial of degree $k-1$ for $a_{k,z'}^- b_1^{--1}$ at z' which also equals, by condition 2 in Definition 6.1, the Taylor polynomial of degree $k-1$ for $a_{k,z'}^+ b_1^{+-1}$ at z' from the very curve. It follows that $f_{z'}(z) - I$ is z^+ and z^- strictly upper triangular and therefore z strictly upper triangular. Clearly there exists $f \in \mathbf{H}_I^k(\Sigma_0 \setminus S)$ satisfying:

(1) $f = I$ outside these disks;

(2) $f(z) - I$ is z strictly upper triangular;

(3) For each $z' \in S \setminus P_J$, f agrees with $f_{z'}$ in a neighborhood of z'.

It is easily checked that $f b_1^\pm \in \mathbf{H}_I(\Sigma_0^\pm)$ from conditions (2) and (5) in Definition 6.1. Now we define $b^\pm = f b_1^\pm$ on Σ_0 and $b^+ = v$, $b^- = I$ on the added circles, then clearly $b^\pm$ give rise to the desired factorized scattering data. □

We write $w_x = (e^{x \operatorname{ad} J(z)} w^+, e^{x \operatorname{ad} J(z)} w^-)$.

We remark that the factorized scattering data agrees with the transformed scattering data defined in [3] in an open set containing P_J. Therefore it is z diagonal in an open set containing P_J. This is very important because then the operator C_{w_x} is well defined for all $x \in \mathbb{R}$. Also when $v - I$ has a support away from an open set containing P_J, w has such a support as well. This preserves the analyticity in x.

THEOREM 6.1. *If w is a factorized scattering data, $\|T_{w_x}\|_0 \to 0$ as $x \to -\infty$.*

Proof. First we approximate $\tilde{w}^-$ in $\mathbf{L}^\infty$ norm by a function $u \in R^- \cap \mathbf{L}^2$, where $u(z)$ is chosen to be z strictly upper triangular with only simple poles $\{\zeta_i\}$. We denote the residue of u at ζ_i by u_{ζ_i}. Then $C_+(C_-\phi e^{x \operatorname{ad} J(z)}(w^+ + w^-))e^{x \operatorname{ad} J(z)}\tilde{w}^-$ is approximated in $\mathbf{L}^2$ norm by $C_+(C_-\phi e^{x \operatorname{ad} J(z)}(w^+ + w^-))e^{x \operatorname{ad} J(z)} u$ uniformly for $\|\phi\|_0 \le 1$. The latter equals

$$\sum_{\zeta_i \in \Omega^-} (C_{\zeta_i} \phi e^{x \operatorname{ad} J(z)}(w^+ + w^-)) \frac{e^{x \operatorname{ad} J(\zeta_i)} u_{\zeta_i}}{z - \zeta_i}.$$

Since u_{ζ_i} is strictly ζ_i upper triangular, (6.5) approaches zero in $\mathbf{L}^2$ as $x \to -\infty$ uniformly for $\|\phi\|_0 \le 1$.

For $C_-(C_+\phi e^{x \operatorname{ad} J(z)}(w^+ + w^-))e^{x \operatorname{ad} J(z)}\tilde{w}^+$, a similar argument works. □

Near $x = -\infty$, $(Id - C_{w_x})^{-1}$ can be calculated through the expansion

$$(Id - C_{w_x})^{-1} = \sum_{k=0}^{\infty} (-1)^k T_{\tilde{w}_x}^k (Id - C_{\tilde{w}_x}) \tag{6.5}$$

with the estimate $\|T_{\tilde{w}_x}^k (Id - C_{\tilde{w}_x})\|_0 = O(\|T_{w_x}\|_0^k)$.

THEOREM 6.2. *If $v \in FD_k$ and $v - I$ is supported away from a neighborhood of P_J, then for some transformed scattering data w of v, $(Id - C_{w_x})^{-1}$ is meromorphic*

in $x \in \mathbb{C}$, viewed as a function from $\mathbb{C}$ to the space of all the bounded operators on $\mathbf{H}_I^j(\Sigma)$ for $j = 0, \cdots, k$.

Proof. Clearly w can be made supported away from an open set containing P_J. Therefore w_x is entire in x. It follows from Theorem 6.1 and Proposition 4.5 that $(Id - C_{w_x})^{-1}$ is meromorphic in x. □

THEOREM 6.3. (Generic solvability). *SD_k^o is an open and dense subset of SD_k, where SD_k^o is the set of all the scattering data $v \in SD_k$ such that the corresponding Riemann–Hilbert problem admits a fundamental solution for every $x \in \mathbb{R}$.*

Proof. If $v \in SD_k^o$, and w is some factorized scattering data of v, then $Id - C_{w_x}$ is invertible for all $x \in \mathbb{R}$. By Proposition 4.5, to study the invertibility of $Id - C_{w_x}$, we only need to work on $\mathbf{L}_I^2(\Sigma)$. Note that w can be chosen in a way that it varies continuously with respect to v. If K is a compact subset of $\mathbb{R}$, by the continuity of C_{w_x} in x it must be still invertible for all $x \in K$ when w varies slightly. For x near $-\infty$, $\|T_{w_x}\|_0 < 1$. This inequality holds when w varies slightly. This says that $Id - C_{w_x}$ is invertible in a neighborhood of $x = -\infty$ and an open set containing w. Condition (4) in Definition 6.1 implies that the Riemann–Hilbert problem admits a solution in $\mathbf{L}_I^2(\Sigma)$ in an open set containing $x = +\infty$ and an open set containing w, and so implies the invertibility of $Id - C_{w_x}$ in an open set containing $x = +\infty$ and an open set containing w. Therefore we may conclude that SD_k^o is open in SD_k.

For the density part of the theorem, we assume that $w \in FSD_k$ is supported away from an open set containing P_J. By Theorem 6.2 on almost all the lines parallel to real axis $Id - C_{w_x}$ is invertible. This is tantamount to saying that for almost all the purely imaginary α, $Id - C_{(w_\alpha)_x}$ is invertible for all $x \in \mathbb{R}$. Where $w_\alpha \stackrel{\text{def}}{=} (e^{\alpha \operatorname{ad} J(z)} w^+, e^{\alpha \operatorname{ad} J(z)} w^-)$ is again a factorized scattering data. This proves the density part of the theorem because α can be chosen to be arbitrarily small. □

7. $J(z)$ with some equal diagonal entries. Now we consider the inverse problem with J which may have some equal diagonal entries. Basically everything still works with the generalized triangular factorization. In this case condition (3) in Definition 6.1 is replaced by:

$v_c(z)$ is z diagonal and admits a factorization $v_c = b^{--1} b^+$ such that $b^-(z) - I$ is z^- strictly lower triangular and $b^+(z) - I$ z^- strictly upper triangular (and therefore z^+ strictly upper triangular).

Note that this change is consistent with the direct problem. Set $z_0 \notin \Sigma$. It is easily seen that all the results obtained in §6 are still valid, except condition (4) in Definition 6.1 cannot be simply described in terms of the winding numbers of certain principal minors. This is because in condition (4) a Riemann–Hilbert problem of a z_0 diagonal matrix function (it is not necessarily diagonal) is involved. Since this problem and, more generally, the problem of discrete scattering data describing all possible multiple poles, has a great deal to do with the direct problem as well, we will study it in a different paper. In the following, we only consider a special case which assumes that $\Sigma = \Sigma_0$ and that the z^- upper principal minors of $v_c(z)$ do not vanish. By Proposition 5.1, v admits a factorization $v = b^{--1} \Delta b^+$ such that $b^+(z) - I$ is z^+ strictly lower triangular and $b^-(z) - I$ strictly z^- lower triangular, and $\Delta(z)$ is z_0 diagonal for a $z_0 \notin \Sigma$. Since $v(z)$ is z diagonal, $b^\pm(z)$ must also be z diagonal by the uniqueness of the triangular factorization. It is consistent with the direct problem to assume a statement similar to condition (2) in Definition 6.1 with the modification that $a_{k,z'}(z - z')$ is z lower triangular and nonsingular at $z = z'$. We write (6.2) down

again

$$v(z) = (a^-_{k,z'}(z - z'))^{-1} a^+_{k,z'}(z - z') + o(|z - z'|^{k-1}). \tag{7.1}$$

Let $b^{\pm}_{k,z'}(z - z')$ be the z_0 diagonal part of $a^{\pm}_{k,z'}(z - z')$. Then by the uniqueness of the triangular factorization,

$$\Delta(z) = (b^-_{k,z'}(z - z'))^{-1} b^+_{k,z'}(z - z') + o(|z - z'|^{k-1}). \tag{7.2}$$

It can be shown by virtue of the proof for Proposition 6.1, $\Delta(z) \in D_k$. It is consistent with the direct problem to assume that the Riemann–Hilbert problem of Δ admits the fundamental solution $\delta_\pm$ (see the "winding number constraint" in [3]), we have

$$\Delta = \delta_-^{-1} \delta_+. \tag{7.3}$$

$\delta_\pm$ are z_0 diagonal because Δ is. Define $v^\# = \delta_- v \delta_+^{-1}$ and $b^{\#\pm} = \delta_\pm b^\pm \delta_\pm^{-1}$. Then $v^\# = b^{\#--1} b^{\#+}$. It is easily checked that $v^\#$ also satisfies condition (2) in Definition 6.1 with the modification that $a_{k,z'}(z - z') - I$ is z strictly lower triangular. $v^\#$ satisfies all the conditions in Definition 6.1 with the upper and the lower triangularities switched. Therefore near $x = +\infty$, $e^{x \operatorname{ad} J(z)} v^\#$ admits a Riemann–Hilbert factorization

$$e^{x \operatorname{ad} J(z)} v^\# = m_-^{\#-1} m_+^\#. \tag{7.4}$$

Since $\delta_\pm$ is z_0 diagonal, $m_\pm \overset{\text{def}}{=} m^\#_\pm \delta_\pm$ is the solution for $e^{x \operatorname{ad} J(z)} v$. It is easily seen from system (1.1) that the potential constructed from $v^\#$ equals that from v.

Remark. Now let w, $w^\#$, and w_0 be certain factorized data of v, $v^\#$, and Δ, respectively, then (see (9.9))

$$Id - C_w = (Id - C_{w^\#}) U^\# (Id - C_{w_0}) U^{-1}, \tag{7.5}$$

where U and $U^\#$ are the invertible multipliers for corrections of the factorizations of v and $v^\#$ respectively as in Proposition 3.4. By virtue of the proof of Proposition 4.1, $Id - C_{w_0}$ is invertible because the Riemann–Hilbert problem of Δ admits the fundamental solution $\delta_\pm$. Therefore $Id - C_w$ and $Id - C_{w^\#}$ are connected by a right invertible multiplier.

Note in the above that Δ in general is not diagonal; therefore the Riemann–Hilbert problem is not a scalar problem. In §9, we will see that for the inverse problem for certain systems the Riemann–Hilbert problem of Δ always admits a fundamental solution.

The above generalization certainly has some effects on the direct problem as well. For example, the potentials of the $n \times n$ AKNS system need to be J off diagonal and clearly this is more restrictive than being off diagonal.

8. Reconstruction of the potentials. Let $m(x, \cdot)$ be a fundamental solution of w_x. We ask what kind of potentials $q(x, z)$ can be constructed such that

$$\mathbf{m}'(x, z) - \operatorname{ad} J(z) \mathbf{m}(x, z) = q(x, z) \mathbf{m}(x, z). \tag{8.1}$$

Clearly if such a $q(x, z)$ exists, it is uniquely determined by $\mathbf{m}$ because $\mathbf{m}$ is nonsingular. Let $q(x, z)$ be an undetermined rational function in z with the same poles as $J(z)$ in the way that if $z = \infty$ is a pole of $J(z)$ of the multiplicity n, then it is a pole of $q(x, z)$ of multiplicity $n - 1$; and if $z = z_0$ is a finite pole of $J(z)$ of multiplicity n, then it is also a pole of $q(x, z)$ of multiplicity n. Now we formally define an operator L on functions of variable $(x, z) \in \mathbb{R} \times \Sigma$ as

$$L\phi(x, z) = \left(\frac{d}{dx} - \operatorname{ad} J(z) - q(x, z) \right) \phi(x, z). \tag{8.2}$$

Let m be a fundamental solution of the Riemann–Hilbert problem of w; a formal calculation gives

$$(Id - C_{w_x})Lm = (Id - C_{w_x})Lm - L(Id - C_{w_x})m - q = [L, C_{w_x}]m - q. \tag{8.3}$$

To make the above calculation rigorous, let $w \in FSD_1$, and if ∞ is a pole of $J(z)$ with multiplicity n, assume $z^{2n-1}w^{\pm} \in \mathbf{L}^2(\Sigma)$, and if z_0 is a finite pole of $J(z)$ with multiplicity n, assume $(z - z_0)^{-(2n+1)}v \in \mathbf{L}^2(\Sigma)$. Under these assumptions, $\operatorname{ad} Jw \in FSD_1$, then since $(d/dx)C_{w_x} = C_{\operatorname{ad} Jw_x}$, $(d/dx)m(x, \cdot) \in \mathbf{L}^2(\Sigma)$. Also $C_{w_x}Lm \in \mathbf{L}^2$. Therefore the above calculation can be carried out rigorously. If

$$[L, C_{w_x}]m - q = 0, \tag{8.4}$$

then $Lm = C_{w_x}Lm \in \mathbf{L}^2$. Since the Riemann–Hilbert problem admits a fundamental solution, $Id - C_{w_x}$ is injective (invertible). It follows that $Lm = 0$. It is easily checked that this extends to (8.1). Therefore (8.4) is the formula for the reconstruction of q. Expression (8.4) may be written explicitly as

$$\int_\Sigma \left(\frac{\operatorname{ad} J(\zeta) - \operatorname{ad} J(z)}{\zeta - z} m(x, \zeta) + \frac{q(x, \zeta) - q(x, z)}{\zeta - z} m(x, \zeta) \right) d\mu_x(\zeta) = q(x, z), \tag{8.5}$$

with $d\mu_x(z) = (2\pi i)^{-1} e^{x \operatorname{ad} J(z)} w(z) dz$.

Example 8.1. ($n \times n$ AKNS) $J(z) = zJ$, $q(x, z) = q(x)$.

$$q(x) = \operatorname{ad} J \int_\Sigma m(x, \zeta) d\mu_x(\zeta). \tag{8.6}$$

Therefore in the direct problem we must assume that q is J off diagonal.

Example 8.2. (For Landau–Lifshitz equation [11]). Let $J(z) = z^{-1}J$, $q(x, z) = z^{-1}q(x)$.

$$-q = \operatorname{ad} J \int_\Sigma \zeta^{-1} m(x, \zeta) d\mu_x(\zeta) + q \int_\Sigma \zeta^{-1} m(x, \zeta) d\mu_x(\zeta). \tag{8.7}$$

This can be written as

$$q(x, z) + J(z) = \left(\int_\Sigma \zeta^{-1} m(x, \zeta) d\mu_x(\zeta) + I \right) J \left(\int_\Sigma \zeta^{-1} m(x, \zeta) d\mu_x(\zeta) + I \right)^{-1} \tag{8.8}$$

Therefore in this case in the direct problem we must assume that $q + J$ is similar to J.

In (8.8), $\int_\Sigma \zeta^{-1} m(x, \zeta) d\mu_x(\zeta) + I$ is nonsingular because it is $m(x, 0)$. In general, q is always solvable from (8.4), which determines the basic algebraic structures of the potentials. We point out that this is consistent with the gauge transform in the direct problem in order to acquire the desired decay at the poles of $J(z)$ for the scattering data.

PROPOSITION 8.1. *For the $n \times n$* AKNS *system, it is given in* [3] *that near $x = -\infty$,*

$$\|C_{w_x} I\| = O(x^{-k-1}). \tag{8.9}$$

Let m be a fundamental solution of w, then

$$\|m(x, \cdot) - I\|_0 = O(x^{-k-1}) \quad \text{as } x \to -\infty. \tag{8.10}$$

Proof. Since

$$(Id - C_{w_x})^{-1} = (Id - T_{w_x})^{-1}(Id - C_{\tilde{w}_x}) \quad \text{for } x \text{ near } -\infty\,, \tag{8.11}$$

$$\|(Id - C_{w_x})^{-1}\|_0 \leq c \quad \text{for } x \text{ near } -\infty , \tag{8.12}$$

for some constant c independent of x. It follows

$$\|m(x,\cdot) - I\|_0 = \|(Id - C_{w_x})^{-1} C_{w_x} I\|_0 \leq c\|C_{w_x} I\|_0 = O(x^{-k-1}). \tag{8.13}$$

The desired decay of the potential q at $x = -\infty$ can be derived by using

$$q = \frac{\operatorname{ad} J}{2\pi i}\left(\int_{\Sigma^+} m e^{x \operatorname{ad} J(z)} w^+ + \int_{\Sigma^-} m e^{x \operatorname{ad} J(z)} w^-\right). \tag{8.14}$$

At $x = +\infty$, we consider the problem normalized at $x = +\infty$ (see [3, p. 79]). For general $J(z)$, to obtain the desired decay for q, we need to study the asymptotic behaviors of the oscillatory integral $C_{w_x} I$ and its Laurent expansion at the poles of $J(z)$. We remark here that if $v_c = 0$, then by contour integration, C_{w_x} reduces to an algebraic operator and the integrals in (8.6), (8.8), and (8.14) to summations.

We conclude this section by a proposition often seen in the inverse scattering problem.

PROPOSITION 8.2. $\operatorname{tr} q = 0$.

Proof. $Lm = 0$ gives

$$q = m' m^{-1} + (J - mJm^{-1}). \tag{8.15}$$

Therefore

$$\operatorname{tr} q = \operatorname{tr} m' m^{-1}. \tag{8.16}$$

The estimate near P_J yields $\operatorname{tr} q = 0$. □

9. Further results in the Riemann–Hilbert problem and their applications to the inverse scattering problem. In this section, we work on a pair of decomposing algebras (defined below) in place of $\mathbf{H}_J^k(\Sigma^\pm)$.

Let Σ be a contour in the Riemann sphere passing ∞ and $C(\Sigma^\pm)$ be the algebra of all scalar functions on Σ with their restrictions on the boundary of each component of $\Omega^\pm$ being continuous (after a modification at the self-intersections). Letting $B \subset C(\Sigma^\pm)$ be a Banach algebra, we denote by B^0 the maximal ideal of B consisting of all functions in B vanishing at ∞. The Banach algebra $B \subset C(\Sigma^\pm)$ is said to be

(1) Inverse closed if the fact that $\phi \in B$ is invertible in $C(\Sigma^\pm)$ implies that ϕ is invertible in B;

(2) Componentwise independent if for every vector $\phi \in B$ and every component Ω_ν of $\Omega^\pm$, the function ϕ_ν equal to ϕ on $\partial\Omega_\nu$ and zero elsewhere is in B;

(3) Decomposing if $C_\pm$ are bounded on B_0.

We write $B_n = \mathbf{M}_n \otimes B$ and denote by GB_n the general linear group of B_n and by SB_n the special linear group of B_n.

If B is a decomposing algebra, we denote by $\mathcal{B}_n$ the space of componentwise holomorphic matrix functions $\mathbf{m}$ on Ω with their boundary values $m_\pm \in m_\pm(\infty) + C_\pm B_n^0$ by $G\mathcal{B}_n$, the general linear group of $\mathcal{B}_n$. The following theorem for a pair of decomposing algebras on a self-intersecting contour Σ is a generalization of the classical Riemann–Hilbert factorization theorem in a single decomposing algebra.

THEOREM 9.1. *Let $E(\Sigma^\pm) \subset C(\Sigma^\pm)$ be a pair of inverse closed componentwise independent decomposing algebras satisfying*

(1) $R^\pm \subset E(\Sigma^\pm) \subset \mathbf{L}_J^2(\Sigma)$,

(2) $C_+E^0(\Sigma^-), C_-E^0(\Sigma^+) \subset E(\Sigma) \overset{\text{def}}{=} E(\Sigma^+) \cap E(\Sigma^-)$,

(3) *For every $a_\pm \in E(\Sigma^\pm)$, the operator $\phi \mapsto C_\pm a_\pm C_\mp \phi$ on $E^0(\Sigma^+)$ and $E^0(\Sigma^-)$ is compact,*

then every $v \in GE_n(\Sigma^-) \cdot GE_n(\Sigma^+)$ *admits a Riemann–Hilbert factorization*

$$v = m_- \theta m_+ \tag{9.1}$$

where $\mathbf{m} \in G\mathcal{E}_n(\Sigma)$ *and* θ *is as in* (9.2) *below with the integers* k_i *uniquely determined by* v *up to a permutation. These integers are called the partial indices of* v.

Furthermore, if in addition, $\det v = 1$, *then* $\mathbf{m}$ *can be chosen such that* $\det \mathbf{m} = 1$ *and therefore* $v \in SE_n(\Sigma^-) \cdot SE_n(\Sigma^+)$.

Proof. Our proof is based on a standard induction over the number of components of $\mathbb{C} \setminus \Sigma$.

We first assume that $v \in GE_n(\Sigma^-)$. Let Ω' be a component of Ω^-. By the assumption that $\partial\Omega'$ does not have self-intersections, if $\Sigma = \partial\Omega'$, then we are done according to the results in [7]. Otherwise we write $\Sigma_2 = \partial\Omega'$, $\Sigma_1 = \overline{\Sigma \setminus \Sigma_2}$ and $\Omega_i = \bar{\mathbb{C}} \setminus \Sigma_i$ for $i = 1, 2$. We have the disjoint unions

$$\Omega^- = \Omega_1^- \cup \Omega_2^-, \qquad \Omega_1^+ = \Omega_2^- \cup \Omega^+,$$

where none of Ω_1^-, Ω_2^-, or Ω^+ is empty. Fix $z_+ \in \Omega^+$, $z_- \in \Omega_1^-$ and $z'_- \in \Omega_2^-$.

We write $v_i = v \restriction \Sigma_i$ for $1 = 1, 2$. Then $v_1 \in GE_n(\Sigma_1^-)$ where $E_n(\Sigma_1^-)$ is the restriction of $E_n(\Sigma^-)$ on Σ^-. Clearly $E_n(\Sigma_1^-)$ is also an inverse closed componentwise independent decomposing algebra.

Inductively we assume that v_1 admits a Riemann–Hilbert factorization relative to Σ_1,

$$v_1 = m_{1-} \theta_1 m_{1+}$$

where

$$\theta_1 = \operatorname{diag}\left[\left(\frac{z - z_+}{z - z_-}\right)^{j_1}, \cdots, \left(\frac{z - z_+}{z - z_-}\right)^{j_n}\right]$$

and $\mathbf{m}_1 \in G\mathcal{E}_n(\Sigma_1) \subset G\mathcal{E}_n(\Sigma)$.

Define on Σ_2, $v_3 = \mathbf{m}_1 v_2 \mathbf{m}_1^{-1} \hat{\theta}_1 \in GE_n(\Sigma_2^-)$ where

$$\hat{\theta}_1 = \operatorname{diag}\left[\left(\frac{z - z_-}{z - z'_-}\right)^{j_1}, \cdots, \left(\frac{z - z_-}{z - z'_-}\right)^{j_n}\right].$$

Inductively we assume that v_3 admits a Riemann–Hilbert factorization relative to Σ_2,

$$v_3 = m_{2-} \theta_2 m_{2+}$$

where

$$\theta_2 = \operatorname{diag}\left[\left(\frac{z - z_+}{z - z'_-}\right)^{k_1}, \cdots, \left(\frac{z - z_+}{z - z'_-}\right)^{k_n}\right]$$

and $\mathbf{m}_2 \in G\mathcal{E}_n(\Sigma_2) \subset G\mathcal{E}_n(\Sigma)$. Set

$$\theta = \operatorname{diag}\left[\left(\frac{z - z_+}{z - z_-}\right)^{k_1}, \cdots, \left(\frac{z - z_+}{z - z_-}\right)^{k_n}\right] \tag{9.2}$$

and $\hat{\theta}_2 = \theta_2 \theta^{-1}$.

Define the componentwise holomorphic function $\mathbf{m}$ on $\mathbb{C} \setminus \Sigma$,

$$\mathbf{m} = \begin{cases} \hat{\theta}_2 \mathbf{m}_2 \hat{\theta}_1^{-1} \mathbf{m}_1 & \text{on } \Omega^+ \\ \mathbf{m}_1 \theta_1 \hat{\theta}_1 \mathbf{m}_2^{-1} \theta_2^{-1} & \text{on } \Omega_1^- \\ \mathbf{m}_1^{-1} \mathbf{m}_2 & \text{on } \Omega_2^- \end{cases} \in G\mathcal{E}_n(\Sigma).$$

Then on Σ_1,

$$\begin{aligned} m_-\theta m_+ &= m_{1-}^{-1}\theta_1\hat{\theta}_1\mathbf{m}_2^{-1}\theta_2^{-1}\theta\hat{\theta}_2\hat{\theta}_1^{-1}m_{1+} \\ &= m_{1-}^{-1}\theta_1 m_{1+} = v_1, \end{aligned}$$

and on Σ_2,

$$\begin{aligned} m_-\theta m_+ &= \mathbf{m}_1^{-1}m_{2-}\theta\hat{\theta}_2 m_{2+}\hat{\theta}_1^{-1}\mathbf{m}_1 \\ &= \mathbf{m}_1^{-1}v_3\hat{\theta}_1^{-1}\mathbf{m}_1 = v_2. \end{aligned}$$

We have the parallel result for $v \in GE_n(\Sigma^+)$.

For general v we write $v = b^-b^+$ such that $b^\pm \in GE_n(\Sigma^-)$. We have already obtained that b^- admits a Riemann–Hilbert factorization

$$b^- = m_-\theta m_+.$$

Since $m_+ - m_+(\infty) \in \operatorname{ran} C_+$, $m_+ \in GE_n(\Sigma^+)$. Therefore $\theta m_+ b^+ \in GE_n(\Sigma^+)$. Thus we have the Riemann–Hilbert factorization

$$\theta m_+ b^+ = m'_-\theta' m'_+.$$

Finally we obtain the Riemann–Hilbert factorization for v,

$$v = (m_- m'_-)\theta' m'_+.$$

The proof for the uniqueness of the partial indices is the same as that in [7].

For the remaining part of the theorem, assume $\det v = 1$. Clearly we may choose m_+ such that $\det m_+(\infty) = 1$. Then the fact that

$$1 = \det v = \det m_- \det\theta \det m_+$$

is a scalar Riemann–Hilbert factorization of 1 forces $\det m_- = \det\theta \det m_+ = 1$. □

In the sequal we replace m_- in Theorem 9.1 by m_-^{-1}. We define the factorized data with respect to a pair of decomposing algebras featured in Theorem 9.1 in the same manner as those previously defined with respect to $\mathbf{H}_I^k(\Sigma^\pm)$.

For a Fredholm operator A we write

$$\alpha(A) = \dim\ker(A); \tag{9.3}$$

$$\beta(A) = \dim\operatorname{coker}(A). \tag{9.4}$$

and the Fredholm index of A as

$$i(A) \overset{\text{def}}{=} \alpha(A) - \beta(A). \tag{9.5}$$

Since $v(\infty) = I$, $m_-(\infty) = m_+(\infty)$. Without loss, we assume $m_\pm(\infty) = I$ (otherwise we may change the basis of $\mathbf{M}_n$). In the following, we show that the classical results regarding the relation between the partial indices and the Fredholm index of the corresponding operators are still valid for the Riemann–Hilbert factorization in a pair of decomposing algebras.

THEOREM 9.2. *Let $k_1, \cdots, k_n$ be the partial indices of v. For any factorized data w of v, we have*

$$\alpha(Id - C_w) = n\sum_{k_j>0} k_j, \tag{9.6}$$

$$\beta(Id - C_w) = -n\sum_{k_j<0} k_j, \tag{9.7}$$

$$i(Id - C_w) = n\sum k_j = \frac{n}{2\pi}\int_\Sigma d\arg\det v. \tag{9.8}$$

Proof. It follows from Proposition 3.4 that we only need to work for a particular factorized data. Here we choose w with $b^+ \stackrel{\text{def}}{=} \theta m_+$ and $b^- \stackrel{\text{def}}{=} m_-$. Then w is a factorized data of v in (9.1). We also define w_1 from $b^\pm \stackrel{\text{def}}{=} m_\pm$, and w_2 from $b^+ = \theta$, $b^- = I$. Then $Id - C_{w_1}$ is invertible because w_1 admits a fundamental solution $m_\pm$. For w_2, (9.6), (9.7), and (9.8) hold by the same proof used in [7]. Now the theorem follows from the relation

$$Id - C_w = (Id - C_{w_1})(Id - C_{w_2}). \tag{9.9}$$ □

We denote by $\dagger$ the Schwarz reflection for the matrix functions, $f^\dagger(z) = f(\bar{z})^*$, and the reflection of a subset of $\mathbb{C}$ about the real axis $\mathbb{R}$. Now we consider the Riemann–Hilbert problem with the contours invariant under the reflection about the real axis. We assume that Σ contains the real axis $\mathbb{R}$; if it does not, then $\Sigma \cap \mathbb{R}$ must be a finite set we may add $\mathbb{R}$ to the contour.

THEOREM 9.3. *Let v be a data supported on a Schwarz reflection invariant contour. Then v has only zero partial indices if* $\operatorname{Re} v \restriction \mathbb{R} \geq 0$, *and* $v = v^\dagger \restriction \Sigma \setminus \mathbb{R}$.

Proof. Clearly we only need to prove the $\mathbf{L}^2$ invertibility of $Id - C_w$ for an arbitrary factorized data w of v. Applying the Schwarz reflection on the Riemann–Hilbert factorization in 9.1 gives

$$v^\dagger = m_+^\dagger \theta^\dagger m_-^{-1\dagger}.$$

It follows from the facts that $\overline{z^\mp} \in \Omega^\mp$ and that

$$(m_\pm^\dagger)^{-1} \in \ker C_\pm$$

that $-k_1, \cdots, -k_n$ are the partial indices of $v^\dagger$. Therefore

$$\beta(Id - C_w) = \alpha(Id - C_{w'}),$$

where w' is a factorized data for $v^\dagger$. Since $v^\dagger$ also satisfies the conditions for v in this theorem, it suffices to show that $\alpha(Id - C_w) = 0$.

Let Ω_ν be a component of $\mathbb{C} \setminus \Sigma$ on the upper half-plane. Then clearly $\Omega_\nu^\dagger$ is a component of $\mathbb{C} \setminus \Sigma$ on the lower half-plane and $\partial\Omega_\nu = (\partial\Omega_\nu)^\dagger$ with the orientation preserved. Let $m \in \ker(Id - C_w)$, then $m_\pm \stackrel{\text{def}}{=} m b^\pm$ give rise to a vanishing solution of the Riemann–Hilbert problem of v. Let $m_{\nu 1}, m_{\nu 2}$ be the boundary values of $\mathbf{m} \restriction \Omega_\nu$, $\mathbf{m} \restriction \Omega_\nu^\dagger$, respectively. Then by the rational approximation (we are working in $\mathbf{L}^2$ space) and a contour integral argument we have

$$\int_{\partial\Omega_\nu} m_{\nu 1} m_{\nu 2}^\dagger = 0.$$

We add them up for all Ω_ν on the upper half-plane to have

$$\sum \int_{\pm\partial\Omega_\nu} m_{\nu 1} m_{\nu 2}^\dagger = 0$$

where $\pm$ is chosen to make $\pm\partial\Omega_\nu$ a positively oriented contour for Ω_ν. Now we assert that

$$\sum \int_{\pm\partial\Omega_\nu} m_{\nu 1} m_{\nu 2}^\dagger = \int_{-\infty}^{\infty} m_- V m_-^\dagger \tag{9.10}$$

where $V = v$ or $v^\dagger$ on different locations. To prove the assertion let Σ_ν be a component of $\Sigma \setminus S$ on the open upper half-plane. Then Σ_ν is part of the common boundary of

a component Ω_ν^+ and a component Ω_ν^- on the upper half-plane. Clearly $\Omega_\nu^{+\dagger}, \Omega_\nu^{-\dagger}$ are components of Ω^-, Ω^+ respectively on the lower half-plane. Now set m_1^+, m_1^- to be the boundary values of $\mathbf{m}$ on Σ_ν from $\Omega_\nu^+, \Omega_\nu^-$, respectively and m_2^+, m_2^- the boundry values of $\mathbf{m}$ on $\Sigma_\nu^\dagger$ from $\Omega_\nu^{-\dagger}, \Omega_\nu^{+\dagger}$, respectively. Clearly the integrals on Σ_ν appear twice in the sum once as

$$\int_{\Sigma_\nu} m_{1+} m_{2-}^\dagger = \int_{\Sigma_\nu} m_{1-} v m_{2-}^\dagger \tag{9.11}$$

and once as

$$\int_{-\Sigma_\nu} m_{1-} m_{2+}^\dagger = \int_{-\Sigma_\nu} m_{1-} v^\dagger m_{2-}^\dagger. \tag{9.12}$$

Since they are off the real axis $v = v^\dagger$, the two integrals cancel. Therefore only the integrals on the real axis survive in the sum. It is easily seen that these integrals are all oriented from left to right and the sum of them gives the right-hand side of (9.10). The assertion is proven. We have

$$\int_{-\infty}^{\infty} m_- V m_-^\dagger = 0. \tag{9.13}$$

Adding this equation to its Schwarz reflection (or Hermitian conjugation) gives

$$\int_{-\infty}^{\infty} m_- (v + v^\dagger) m_-^\dagger = 0. \tag{9.14}$$

Since on $\mathbb{R}$, $\operatorname{Re} v \geq 0$, and $v(\infty) = I$, we have $m_-(z) = 0$ almost everywhere near $z = \infty$ on $\mathbb{R}$. It can be shown by a Cauchy integral argument that the meromorphic extension of m_- near $z = \infty$ equals zero. Since v is nonsingular $m_\pm = 0$ on whole contour Σ. We conclude $\ker(Id - C_w) = 0$. □

For the inverse scattering problem, if v is Hermitian, then $v(z) > 0$ because v is nonsingular and continuous with $v(\infty) = I$. It is shown in [4] that the Riemann–Hilbert problem for the inverse scattering of the $n \times n$ AKNS system with $J + J^* = 0$, and $q + q^* = 0$ is always solvable. Theorem 9.2 implies the following generalization.

If $J + J^* = q + q^* = 0$ for all real z, by the Schwarz reflection principle, $J + J^\dagger = q + q^\dagger = 0$. In this case Σ obviously contains $\mathbb{R}$. Also since the solution $\mathbf{m}$ of the system satisfies $\mathbf{m}^{-1} = \mathbf{m}^\dagger$, it is deduced from this that $v = v^\dagger$ and $\operatorname{Re} v > 0$ on $\mathbb{R}$. Therefore for this kind of system the inverse problem is always solvable.

Finally, for the problem without poles, it follows from the uniqueness of the generalized triangular factorization that $v = v^\dagger$ implies $\Delta = \Delta^\dagger$ in §7. Therefore the conditions for the decay of the potentials at $x = +\infty$ can be explicitly obtained. This also applies to the systems for the generalized wave equation and the generalized sine-Gordon equation for the decay in the nonoblique directions.

Acknowledgment. Professor Adrian Nachman has given many useful suggestions for this work.

ASYMPTOTIC EXPANSION OF THE PEARCEY INTEGRAL NEAR THE CAUSTIC*

DAVID KAMINSKI†

Abstract. An asymptotic expansion of the function

$$P(x,y)=\int_{\mathbf{R}}\exp\{i(t^4/4+xt^2/2+yt)\}dt$$

is constructed which remains uniformly valid as $x\to-\infty$ for (x,y) near the caustic $4x^3+27y^2=0$ in the real xy-plane. The result remains valid for a range of complex x and y when P is extended to $\mathbf{C}\times\mathbf{C}$ by analytic continuation.

Key words. uniform asymptotic expansions, Pearcey integral, diffraction integrals, caustics

AMS(MOS) subject classifications. 41A60, 30E15, 33A70

1. Introduction.

The Pearcey function of two real variables x and y is defined by

$$P(x,y)=\int_{-\infty}^{+\infty}\exp\left\{i\left(\frac{t^4}{4}+x\frac{t^2}{2}+yt\right)\right\}dt. \tag{1.1}$$

It is one of a class of "generalized Airy functions"

$$Y_0(x_1,\cdots,x_{m-2})=\int_{-\infty}^{+\infty}\exp\left\{i\left(x_1\theta+\cdots+x_{m-2}\theta^{m-2}+\frac{\theta^m}{m}\right)\right\}d\theta \tag{1.2}$$

(see [7, p. 456]), the usual Airy integral being a constant multiple of $Y_0(x_1)$, and the Pearcey function being $Y_0(y,x/2)$. The role of the oscillatory integrals (1.2) in geometrical optics is well known, $|Y_0|^2$ being related to the intensity of light at caustics characterized by catastrophes which the phase functions represent (see [6, p. 337]).

The function in (1.1) arose in Pearcey's investigation of electromagnetic fields near a "cusp" [11], and so bears his name. More recent work involving (1.1) includes optics [13], scattering theory [5], quantum mechanics [9, p. 172], and the theory of nonlinear waves [8].

Also, just as the Airy function plays an important role in the theory of uniform asymptotic expansions of integrals with two coalescing saddle points [3], the functions Y_0 in (1.2) play a corresponding role in the uniform asymptotic theory of integrals with $m-1$ coalescing saddle points [14]. Consequently, the functions Y_0, for physical as well as mathematical reasons, represent an important class of special functions paralleling the role played by the classical Airy function. We shall restrict our attention to $P(x,y)$ (or, $Y_0(y,x/2)$) in the remainder of this paper.

If we apply the method of stationary phase to (1.1), we find that the asymptotic behaviour of P depends on one or three stationary points, provided one of the variables stays fixed. If we denote the phase function in (1.1) by $\phi(t;x,y)$ and let $\delta=4x^3+27y^2$, then $\phi_t=0$ gives three stationary points if $\delta<0$, and only one if $\delta>0$. However,

as $\delta \to 0$, we have some (or all) stationary points coalescing, and in the transition from negative to positive δ, it is not clear how P behaves. Therefore, it is the large negative x-behaviour of (1.1) for (x, y) near the "caustic" $\delta = 0$ that concerns us (if x is positive, then δ is always positive).

If $x \to -\infty$, then for δ to remain small, we must have $|y| \to \infty$. Since $P(x, y)$ is clearly an even function of y, we may restrict ourselves to the case $y > 0$; furthermore, we shall find it to be notationally convenient to replace x by $-x$ in (1.1) and examine $x \to +\infty$. With these conventions, $\delta = 0$ implies $y = 2x^{3/2}/\sqrt{27}$. This suggests that we examine $P(-x, y)$ with $y = \mu x^{3/2}$; when $\mu = 2/\sqrt{27}$, we are right at the caustic. With this relation between x and y, we find that as x and y tend to infinity along $y = \mu x^{3/2}$, μ fixed,

$$P(-x, \mu x^{3/2}) \sim \sum_{j=1}^{3} e^{ix^2 f(t_j;\mu) + \frac{\pi}{4} i \cdot \operatorname{sign}(3t_j^2 - 1)} \sqrt{\frac{2\pi}{x|3t_j^2 - 1|}}. \tag{1.3}$$

Here, $0 \le \mu < 2/\sqrt{27}$, $f(t; \mu) = t^4/4 - t^2/2 + \mu t$, and the t_j are the real roots of $f_t = 0$ (cf. §2 for a description of the t_j). At the caustic $\mu = 2/\sqrt{27}$, we find that

$$P\left(-x, \frac{2x^{3/2}}{\sqrt{27}}\right) \sim \sqrt{\frac{2\pi}{3x}} e^{i(\pi/4 - 2x^2/3)} + \frac{\Gamma(1/3)}{3^{1/3} x^{1/6}} e^{ix^2/12} + \frac{\Gamma(2/3)}{i \cdot 2 \cdot 3^{2/3} \cdot x^{5/6}} e^{ix^2/12} \tag{1.4}$$

and for $\mu > 2/\sqrt{27}$,

$$P(-x, \mu x^{3/2}) \sim \sqrt{\frac{2\pi}{x(3t_0^2 - 1)}} e^{\pi i/4 + ix^2 f(t_0;\mu)} \tag{1.5}$$

where t_0 denotes the only real zero of f_t.

Note that the approximations in (1.3)–(1.5) are of radically differing characters. As $\mu \to (2/\sqrt{27})^-$, t_2 and $t_3 \to 1/\sqrt{3}$ and hence the approximation (1.3) becomes singular; see §2. The important observation to make, at this point, is that as $\delta \to 0$ (i.e., $\mu \to 2/\sqrt{27}$) only two stationary points are coalescing. To exploit this phenomenon, we retain μ as a uniformity parameter and rewrite (1.1) as a sum of two contour integrals, one of which has exactly two relevant, coalescing, saddle points. This allows us to apply a cubic transformation introduced by Chester, Friedman, and Ursell [3], and to construct a uniform asymptotic expansion of (1.1) as $x \to -\infty$ with δ varying in an interval containing 0 (i.e., μ in an interval containing $2/\sqrt{27}$). The expansion we present is in fact valid for certain complex values of the arguments when $P(x, y)$ is extended to $\mathbf{C} \times \mathbf{C}$ by analytic continuation.

At the time of writing, we became aware of a recent publication by Stamnes and Spjelkavik [12] who also noted that only two stationary points coalesce, but their subsequent derivations of asymptotic expansions of the Pearcey function are purely formal. For a brief discussion of their arguments, see §6.

2. Alternate representation. An application of Jordan's inequality shows that, for real x and y, the path of integration in (1.1) may be rotated onto the contour Γ in the complex t-plane, where Γ is the straight line through the origin making an angle of $\pi/8$ with the positive real axis. With this integral representation we can analytically continue $P(x, y)$ to an entire function in $\mathbf{C} \times \mathbf{C}$.

Let

$$\mu = \frac{2}{\sqrt{27}} - \alpha \tag{2.1}$$

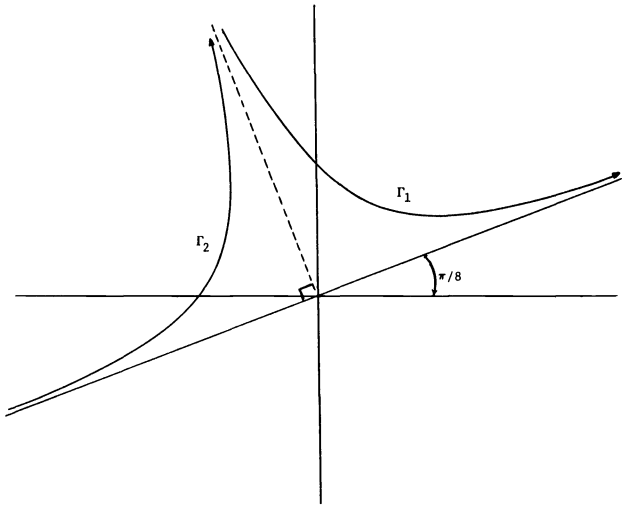

FIG. 1. *The contours* Γ, Γ_1, *and* Γ_2.

and set $y = \mu x^{3/2}$. With x real and positive, the change of variable $t \to x^{1/2}t$ gives

$$P(-x, \mu x^{3/2}) = x^{1/2} \int_{\Gamma} e^{ix^2(t^4/4 - t^2/2 + \mu t)} dt. \tag{2.2}$$

Since this integral converges for all complex μ and for x with $|\arg x| < \pi/4$, subsequent work is valid for these values of x and μ.

By Cauchy's theorem, we may write

$$P(-x, \mu x^{3/2}) = x^{1/2} \int_{\Gamma_1} e^{ix^2(t^4/4 - t^2/2 + \mu t)} dt + x^{1/2} \int_{\Gamma_2} e^{ix^2(t^4/4 - t^2/2 + \mu t)} dt \tag{2.3}$$

where Γ_1 is the contour beginning at $\infty e^{5\pi i/8}$ and ending at $\infty e^{\pi i/8}$, and Γ_2 is the contour beginning at $\infty e^{9\pi i/8}$ and ending at $\infty e^{5\pi i/8}$ (see Fig. 1).

For $i = 1, 2$, set

$$P_i(\lambda; \mu) = \int_{\Gamma_i} e^{i\lambda f(t;\mu)} dt \tag{2.4}$$

where, as in §1, we have put

$$f(t; \mu) = \frac{t^4}{4} - \frac{t^2}{2} + \mu t. \tag{2.5}$$

P_i is analytic for all μ and all λ with $\operatorname{Re} \lambda > 0$.

Since $f_t(t; \mu) = 0$ has the solutions

$$\begin{aligned} t_1(\mu) &= -\frac{2}{\sqrt{3}} \sin\left(\frac{\pi}{3} + \phi\right) \\ t_2(\mu) &= \frac{2}{\sqrt{3}} \sin \phi \\ t_3(\mu) &= \frac{2}{\sqrt{3}} \sin\left(\frac{\pi}{3} - \phi\right) \end{aligned}$$

for $\Delta = -4 + 27\mu^2 < 0$, with ϕ given by

$$3\phi = \arcsin\left(\mu\frac{\sqrt{27}}{2}\right), \ |\phi| \leq \pi/6$$

(see [10]), we see that as $\Delta \to 0^-$ (i.e., $\mu \to (2/\sqrt{27})^-$), $t_1 \to -2/\sqrt{3}$, $t_2 \to 1/\sqrt{3}$, $t_3 \to 1/\sqrt{3}$. Thus the two positive roots of $f_t = 0$ coalesce as $\mu \to 2/\sqrt{27}$, but remain well separated from the negative root.

If $\Delta > 0$, we can invoke Cardan's formulae (or use the trigonometric solution above with ϕ complex) to observe the same phenomenon, only this time, as $\Delta \to 0^+$, the complex conjugate pair of roots of $f_t = 0$ coalesce to $1/\sqrt{3}$ with the real root remaining isolated.

Also, by examining $\sin\phi$ and $\sin(\pi/3 - \phi)$ for $\phi \in]0, \pi/6[$, we find that $t_3(\mu) > 1/\sqrt{3} > t_2(\mu)$ for $\mu < 2/\sqrt{27}$.

With this background, we shall obtain the large λ behaviour of the $P_i(\lambda;\mu)$ as $\lambda \to \infty$. This in turn will yield the desired expansion of (2.3) as $x \to \infty$ uniformly for $\mu \in [\mu_0, \mu_1]$ where $0 < \mu_0 < 2/\sqrt{27} < \mu_1$.

3. Uniform expansion of P_1. Since P_1 has two relevant coalescing saddle points, this suggests invoking a cubic transformation as is done in [3] or [2, §9.2]. For convenience, we shall choose α, given in (2.1), as our uniformity parameter since the saddles coincide when α vanishes.

As the saddles coalesce at $t = 1/\sqrt{3}$, we develop f as follows:

$$\begin{aligned} f(t;\mu) &= -\frac{\alpha}{\sqrt{3}} + \frac{1}{12} - \alpha z + \frac{z^3}{\sqrt{3}} + \frac{z^4}{4} \\ &\equiv g(z;\alpha) - \frac{\alpha}{\sqrt{3}} + \frac{1}{12} \end{aligned}$$

where we have set $z = t - 1/\sqrt{3}$. Thus

$$P_1(\lambda;\mu) = e^{-i\lambda(\alpha/\sqrt{3} - 1/12)} \int_{\Gamma_1'} e^{i\lambda g(z;\alpha)} dz$$

where Γ_1' is the translate of Γ_1 by $1/\sqrt{3}$. Note that the zeroes of $g_z(z;\alpha)$ are given by

$$\begin{aligned} z_1(\alpha) &= -\frac{2}{\sqrt{3}}\sin\left(\phi + \frac{\pi}{3}\right) - \frac{1}{\sqrt{3}} \\ z_2(\alpha) &= \frac{2}{\sqrt{3}}\sin\phi - \frac{1}{\sqrt{3}} \\ z_3(\alpha) &= \frac{2}{\sqrt{3}}\sin\left(\frac{\pi}{3} - \phi\right) - \frac{1}{\sqrt{3}} \end{aligned}$$

where

$$3\phi = \arcsin\left(1 - \frac{\alpha\sqrt{27}}{2}\right), \ |\phi| \leq \frac{\pi}{6}.$$

As in §2, by examining $\sin\phi$ and $\sin(\pi/3 - \phi)$, we have $z_1(\alpha) < -1 < z_2(\alpha) < 0 < z_3(\alpha)$ for $\alpha > 0$ sufficiently small. When $\alpha < 0$, z_2 and z_3 are complex conjugates. In either case, $\alpha \to 0$ implies $z_2(\alpha), z_3(\alpha) \to 0$.

Now we introduce the change of variables

$$g(z;\alpha) = \frac{u^3}{3} - \zeta u + \eta \tag{3.1}$$

where $\zeta = \zeta(\alpha)$ and $\eta = \eta(\alpha)$ are to be determined. In order that (3.1) defines an analytic function $u(z)$ near z_2 and z_3, we require that z_2 and z_3 correspond to $-\zeta^{1/2}$ and $\zeta^{1/2}$ respectively. Accordingly, we find that

$$\zeta^{3/2} = \frac{3}{4}[g(z_2;\alpha) - g(z_3;\alpha)] \tag{3.2}$$

and

$$\eta = \frac{1}{2}[g(z_2;\alpha) + g(z_3;\alpha)]. \tag{3.3}$$

Equation (3.1) may be solved explicitly to give three possible candidates for our change of variables: for $\zeta \neq 0$,

$$\begin{aligned} u_1(z;\alpha) &= -2\zeta^{1/2}\sin(\pi/3 + \psi) \\ u_2(z;\alpha) &= 2\zeta^{1/2}\sin\psi \\ u_3(z;\alpha) &= 2\zeta^{1/2}\sin(\pi/3 - \psi) \end{aligned}$$

with

$$\sin 3\psi = \frac{3(\eta - g(z;\alpha))}{2\zeta^{3/2}};$$

for $\zeta = 0$, we have $u = (3[g(z) - \eta])^{1/3}$ and, again, there are three branches. Please note that we frequently omit mentioning the explicit dependence of g on α.

From (3.2) and (3.3), we have

$$\sin 3\psi = \frac{\frac{3}{2}[g(z_3) - g(z_2)]}{2\zeta^{3/2}} = -1$$

when $z = z_2$, and when $z = z_3$ we get

$$\sin 3\psi = \frac{\frac{3}{2}[g(z_2) - g(z_3)]}{2\zeta^{3/2}} = +1.$$

Thus, we have

$$\begin{aligned} u_1(z_2;\alpha) &= -\zeta^{1/2} & u_1(z_3;\alpha) &= -2\zeta^{1/2} \\ u_2(z_2;\alpha) &= -\zeta^{1/2} & u_2(z_3;\alpha) &= \zeta^{1/2} \\ u_3(z_2;\alpha) &= 2\zeta^{1/2} & u_3(z_3;\alpha) &= \zeta^{1/2}. \end{aligned}$$

Therefore, $u_2(z;\alpha)$ is the desired uniformly analytic solution to (3.1). We now set $u(z;\alpha) \equiv u_2(z;\alpha)$.

Before continuing further, let us briefly examine the nature of the mapping (3.1). From Chester, et al. [3], we know that $u(z;\alpha)$ is uniformly analytic and one-to-one near $z = 0$. Much more, however, can be said. In the following we will show that the mapping (3.1) in the present case is in fact one-to-one and analytic along the contour Γ_1'.

In the subsequent analysis, assume $\alpha > 0$. The mapping from the z- to u-planes can be most easily studied by introducing intermediate variables Z, ψ given by

$$\begin{aligned} Z &= g(z;\alpha) - \eta \\ \sin 3\psi &= -3Z/2\zeta^{3/2} \\ u &= 2\zeta^{1/2}\sin\psi; \end{aligned}$$

see, for example, Copson [4]. We begin by decomposing the z-plane into four regions, each of which maps onto the Z-plane. A useful device in this process is the determination of all curves that g sends to the real Z-axis. We adopt the notational convention of denoting that part of a region Ω that has positive imaginary part by Ω^+.

The mapping $Z = g(z;\alpha) - \eta$ clearly takes the real line in the z-plane to the real line in the Z-plane in the following manner:

$$\begin{aligned} &Z([z_3, +\infty[) = [-\tfrac{2}{3}\zeta^{3/2}, +\infty[\\ &Z([z_2, z_3]) = [-\tfrac{2}{3}\zeta^{3/2}, \tfrac{2}{3}\zeta^{3/2}] \\ &Z([z_1, z_2]) = [g(z_1) - \eta, \tfrac{2}{3}\zeta^{3/2}] \\ &Z(]-\infty, z_1]) = [g(z_1) - \eta, +\infty[, \end{aligned} \tag{3.4}$$

the mapping Z being one-to-one on each interval. The remaining curves are the nontrivial solutions of

$$\begin{aligned} \operatorname{Im}(g(z;\alpha) - \eta) = 0 \quad &= \quad \operatorname{Im} g(z;\alpha) \\ &= \quad \operatorname{Im}(g(z;\alpha) - g(z_k;\alpha)), \ k = 1,2,3 \end{aligned} \tag{3.5}$$

since each critical point z_k being real implies that $g(z_k;\alpha)$ is real. Note that since the left half of (3.5) is independent of k, the solution curves arising from the right half of (3.5) are the same for each k.

Develop g about the critical point $z = z_k$. Then (3.5) becomes

$$\operatorname{Im}\left(\frac{g''(z_k;\alpha)}{2}t^2 + \frac{g'''(z_k;\alpha)}{6}t^3 + \frac{1}{4}t^4\right) = 0$$

where we have set $t = z - z_k = \sigma + i\tau$, and suppressed dependence on k. Thus

$$0 = \frac{2\sqrt{3}z_k + z_k^2}{2}\cdot 2\sigma\tau + \frac{2\sqrt{3} + 6z_k}{6}(3\sigma^2\tau - \tau^3) + (\sigma^3\tau - \sigma\tau^3)$$

or, since we have accounted for $\tau \equiv 0$ in (3.4),

$$0 = (2\sqrt{3}z_k + 3z_k^2)\sigma + \frac{2\sqrt{3} + 6z_k}{2}\sigma^2 + \sigma^3 - \left(\frac{2\sqrt{3} + 6z_k}{6} + \sigma\right)\tau^2$$

yielding

$$\tau = \pm\sqrt{\frac{(2\sqrt{3}z_k + 3z_k^2)\sigma + \frac{2\sqrt{3}+6z_k}{2}\sigma^2 + \sigma^3}{\frac{2\sqrt{3}+6z_k}{6} + \sigma}} \tag{3.6}$$

wherever the quantity inside the outer surd is nonnegative.

Since $\sigma = \tau = 0$ satisfies (3.6) and $\sigma + i\tau = z - z_k$, each z_k lies on at least one of the curves determined by (3.6). Equation (3.6) gives rise to three curves; two of

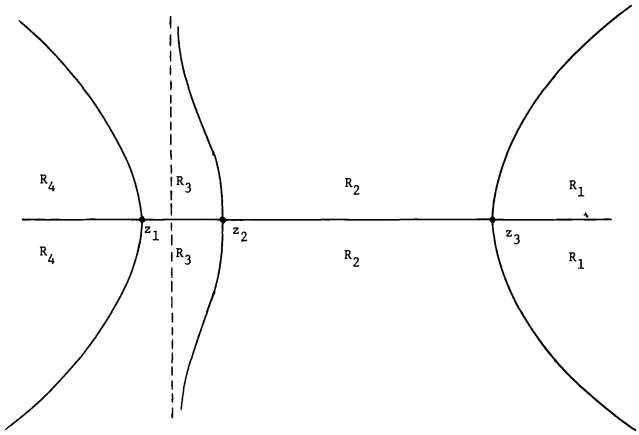

FIG. 2. *Curves that map to the real Z-axis (solid curves) and the regions R_j, $j = 1, 2, 3, 4$.*

these curves have the 45^0 lines through the origin as asymptotes, and the other (the one containing z_2) has the vertical line $\sigma = -(2\sqrt{3} + 6z_k)/6$ as its asymptote. These curves are displayed in Fig. 2.

The curves that do not lie along the real z-axis partition the z-plane into four regions, R_1, R_2, R_3, and R_4, each of which maps in a one-to-one fashion onto the Z-plane (on the boundaries, the map g may be two-to-one) (see Fig. 2).

Consider R_1^+ and the map $z \to g(z;\alpha) - \eta$. From (3.4) we know that $[z_3, +\infty[$ maps onto $[-\frac{2}{3}\zeta^{3/2}, +\infty[$, and the curve bounding the upper extent of R_1^+ is mapped to $]-\infty, -\frac{2}{3}\zeta^{3/2}]$. Thus we see that R_1^+ maps to the upper half of the Z-plane. As well, the steepest descent curve of $ig(z;\alpha)$ from $z = z_3$ to $\infty e^{\pi i/8}$ lies within R_1^+ and maps to a vertical line in the Z-plane running through $Z = -\frac{2}{3}\zeta^{3/2}$. In Figs. 3-5, shaded regions map to shaded regions, dotted lines represent steepest descent curves, and in each figure, letters that correspond represent points that correspond under each indicated map (see Fig. 3).

Under the map $\sin 3\psi = -3Z/2\zeta^{3/2}$, we note the following: $Z = -\frac{2}{3}\zeta^{3/2}$ is mapped to $\psi = \pi/6$; with $\psi \in [\pi/6, \pi/2]$, Z is real and in $[-\frac{2}{3}\zeta^{3/2}, \frac{2}{3}\zeta^{3/2}]$, and the rays $\pi/6 + i\tau$, $\pi/2 + i\tau$, $\tau \geq 0$ map to the segments $]-\infty, -\frac{2}{3}\zeta^{3/2}]$ and $[\frac{2}{3}\zeta^{3/2}, +\infty[$ in the Z-plane, respectively. Moreover, a straightforward calculation reveals that the steepest descent curve lying in the Z-plane maps to the curve $\gamma = \frac{1}{3} \cdot \log[(1 - \cos 3\beta)/(\sin 3\beta)]$, $\psi = \beta + i\gamma$, $\gamma \geq 0$, $\beta \leq \pi/3$, in the ψ-plane (see Fig. 3).

The map $u = 2\zeta^{1/2} \sin\psi$ takes the interval $[\frac{\pi}{6}, \frac{\pi}{2}]$ in the ψ-plane to $[\zeta^{1/2}, 2\zeta^{1/2}]$ in the u-plane, and maps $\frac{\pi}{2} + i\tau$, $\tau \geq 0$ onto $[2\zeta^{1/2}, +\infty[$. The image of the ψ-plane ray $\frac{\pi}{6} + i\tau$, $\tau \geq 0$, is the curve

$$u = \zeta^{1/2}[\cosh\tau + i\sqrt{3}\sinh\tau],$$

which we see as being the first quadrant branch of the hyperbola $(\operatorname{Re} u)^2 - \frac{1}{3}(\operatorname{Im} u)^2 = \zeta$ (to see this, put $\operatorname{Re} u = \zeta^{1/2}\cosh\tau$, $\operatorname{Im} u = \sqrt{3}\zeta^{1/2}\sinh\tau$ and employ the identity $\cosh^2\tau - \sinh^2\tau = 1$). The steepest descent curve in the ψ-plane maps to the steepest descent curve of $i(u^3/3 - \zeta u + \eta)$ beginning at $u = \zeta^{1/2}$ and ending at $\infty e^{\pi i/6}$. This is most easily seen by examining $Z = u^3/3 - \zeta u + \eta$ directly; see Fig. 3.

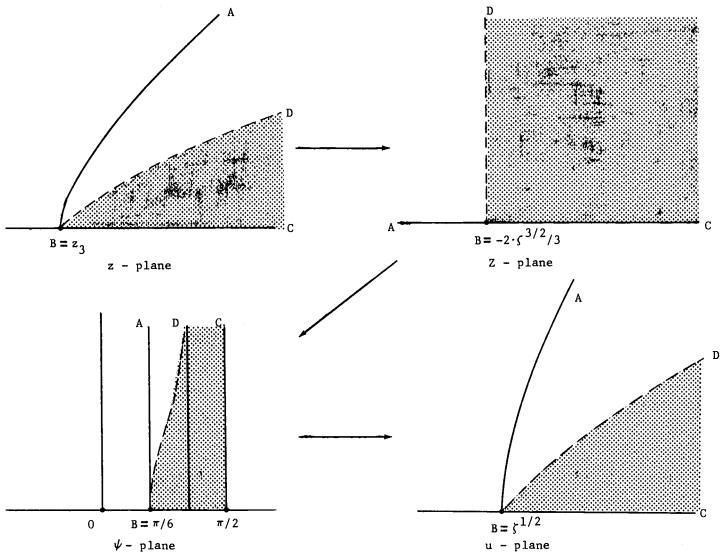

FIG. 3. *Effect of the mappings* $Z = g(z;\alpha) - \eta$, $Z = -\frac{2}{3}\zeta^{3/2} \cdot \sin 3\psi$, $u = 2\zeta^{1/2} \sin\psi$ *on* R_1^+.

In a completely similar fashion, we find the images of R_2^+ and R_3^+ under the sequence of transformations $z \to Z \to \psi \to u$. The effect of these maps are presented in Figs. 4-5.

Collecting these maps together gives a conformal map from $R_1^+ \cup R_2^+ \cup R_3^+$ to the upper half of the u-plane which is one-to-one, although the intermediate transformations fail to be one-to-one when applied to all of $R_1^+ \cup R_2^+ \cup R_3^+$.

In the event that $\alpha < 0$, we would proceed as before, this time using (3.5) with $k = 1$ since (3.6) holds only for the real saddle z_1. Note that Im $\eta = 0$ for $\alpha < 0$.

If we take Γ_1' to be the steepest descent curve beginning at $\infty e^{5\pi i/8}$ and ending at $z = z_2$, followed by the straight line segment $[z_2, z_3]$, and thereafter the steepest descent curve from $z = z_3$ to $\infty e^{\pi i/8}$, then $u(z;\alpha)$ maps Γ_1' onto the curve formed by steepest descent curves from $-\zeta^{1/2}$ to $\infty e^{5\pi i/6}$, and $+\zeta^{1/2}$ to $\infty e^{\pi i/6}$, along with the line segment $[-\zeta^{1/2}, \zeta^{1/2}]$, suitably oriented. Call the image of Γ_1' in the u-plane C. We may now write

$$e^{i\lambda(\alpha/\sqrt{3}-1/12)} P_1(\lambda;\mu) = \int_C e^{i\lambda(u^3/3-\zeta u+\eta)} g_0(u;\alpha)\,du$$

where we have put $g_0(u;\alpha) = dz/du$. Define, as in [2], the function sequences $\{g_n\}$, $\{h_n\}$, $\{p_n\}$, and $\{q_n\}$ by

$$\begin{aligned} p_n(\alpha) &= \tfrac{1}{2}[g_n(\zeta^{1/2};\alpha) + g_n(-\zeta^{1/2};\alpha)] \\ q_n(\alpha) &= \tfrac{1}{2\zeta^{1/2}}[g_n(\zeta^{1/2};\alpha) - g_n(-\zeta^{1/2};\alpha)] \\ g_n(u;\alpha) &= p_n(\alpha) + q_n(\alpha)u + (u^2 - \zeta)h_n(u;\alpha) \\ g_{n+1}(u;\alpha) &= \tfrac{d}{du}h_n(u;\alpha), \quad n = 0, 1, 2, \cdots. \end{aligned} \tag{3.7}$$

Then, by successive substitution and partial integration, we obtain

$$e^{i\lambda(\alpha/\sqrt{3}-1/12)} P_1(\lambda;\mu) \sim e^{i\lambda\eta} \sum_{n=0}^{\infty} \left(\frac{i}{\lambda}\right)^n [p_n(\alpha)F(\lambda;\zeta) + q_n(\alpha)G(\lambda;\zeta)]$$

as $\lambda \to \infty$, uniformly in ζ. Here,

$$F(\lambda;\zeta) = \int_C e^{i\lambda(u^3/3-\zeta u)}\,du$$

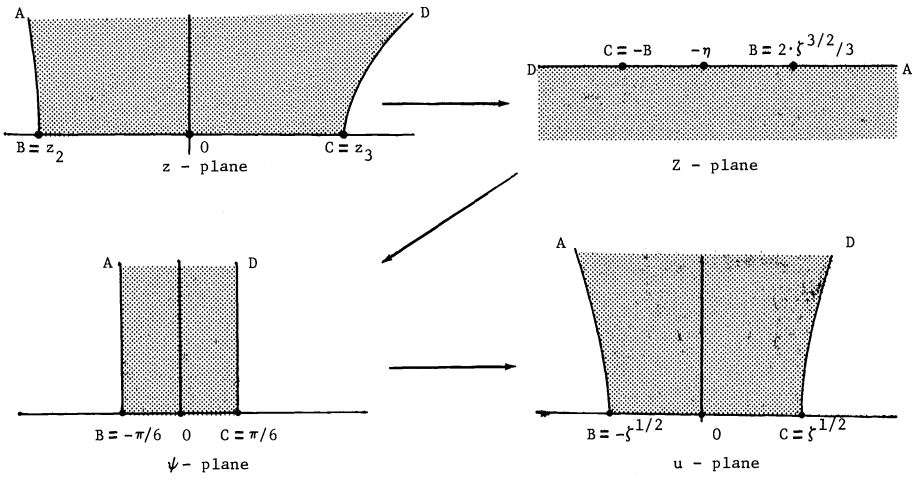

FIG. 4. *Effect of the sequence of maps* $z \to Z \to \psi \to u$ *applied to* R_2^+.

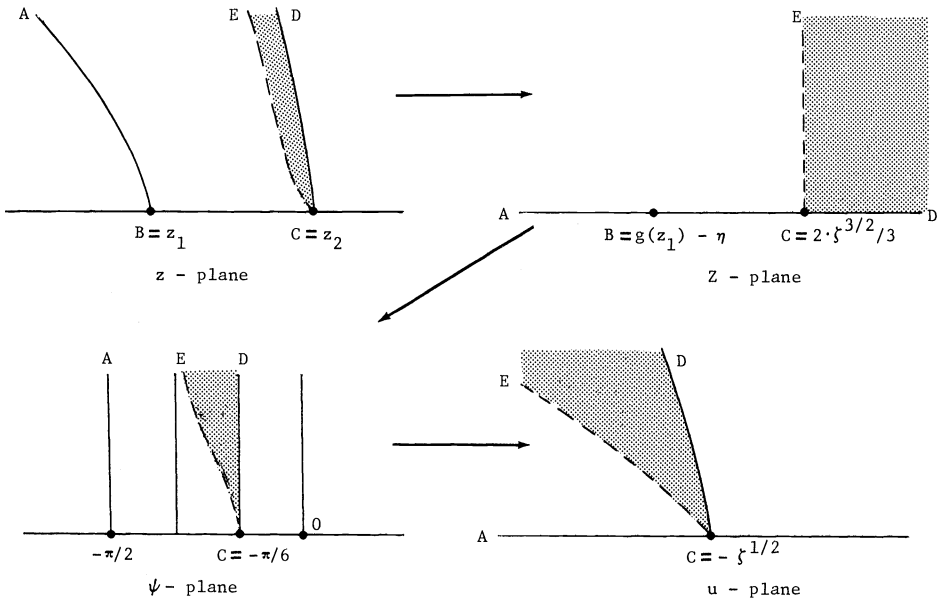

FIG. 5. *Effect of the sequence of maps* $z \to Z \to \psi \to u$ *applied to* R_3^+.

$$G(\lambda;\zeta) = \int_C ue^{i\lambda(u^3/3-\zeta u)}du,$$

both integrals converging absolutely and uniformly for $\operatorname{Re}\lambda > 0$, $\zeta \in \mathbf{C}$. By a simple change of variables, we see that in $\operatorname{Re}\lambda > 0$,

$$F(\lambda;\zeta) = \frac{2\pi}{\lambda^{1/3}} \cdot Ai(-\lambda^{2/3}\zeta)$$
$$G(\lambda;\zeta) = \frac{2\pi}{i\lambda^{2/3}} \cdot Ai'(-\lambda^{2/3}\zeta).$$

Hence,

$$e^{i\lambda(\alpha/\sqrt{3}-1/12)}P_1\left(\lambda;\frac{2}{\sqrt{27}}-\alpha\right) \sim e^{i\lambda\eta}\cdot\frac{2\pi}{\lambda^{1/3}} \cdot\sum_{n=0}^{\infty}\left[p_n(\alpha)Ai(-\lambda^{2/3}\zeta)+\frac{1}{i\lambda^{1/3}}q_n(\alpha)Ai'(-\lambda^{2/3}\zeta)\right]\left(\frac{i}{\lambda}\right)^n$$

as $\lambda \to \infty$, uniformly in α near zero. In §6, we shall have occasion to use the approximation

$$P_1\left(\lambda;\frac{2}{\sqrt{27}}-\alpha\right) = e^{i\lambda(1/12-\alpha/\sqrt{3}+\eta)} \cdot\left\{p_0(\alpha)\frac{2\pi}{\lambda^{1/3}}\cdot Ai(-\lambda^{2/3}\zeta)\cdot\left[1+O\left(\frac{1}{\lambda}\right)\right] + q_0(\alpha)\frac{2\pi}{i\lambda^{2/3}}\cdot Ai'(-\lambda^{2/3}\zeta)\left[1+O\left(\frac{1}{\lambda}\right)\right]\right\} \tag{3.8}$$

for $\lambda \to \infty$ as above.

4. The coefficients $p_0(\alpha)$ and $q_0(\alpha)$. Although expressions for $p_0(\alpha)$ and $q_0(\alpha)$ can be calculated routinely, because of the labour involved in obtaining limiting forms as $\alpha \to 0$, we reproduce some of the requisite analysis. The reader will appreciate the difficulty in calculating higher coefficients from these two examples.

We begin by remarking that the following analysis remains valid for all (small) complex α, provided we choose the principal branch for $\alpha^{1/2}$. For the purpose of exposition, we shall take $\alpha > 0$.

Differentiate (3.1) twice with respect to u; this gives

$$g_{zz}\left(\frac{dz}{du}\right)^2 + g_z\left(\frac{d^2z}{du^2}\right) = 2u.$$

Evaluation at $z = z_3$, and the use of the fact that z_3 corresponds with $\zeta^{1/2}$, gives

$$(2\sqrt{3}z_3 + 3z_3^2)\left(\frac{dz}{du}\right)^2\Big|_{u=\zeta^{1/2}} = 2\zeta^{1/2}$$

whence

$$\frac{dz}{du}\Big|_{u=\zeta^{1/2}} = \pm\sqrt{\frac{2\zeta^{1/2}}{2\sqrt{3}z_3+3z_3^2}}.$$

Since z_3, for $\alpha > 0$, is a local minimum of $g(z;\alpha)$, $g_{zz}(z_3;\alpha)$ is positive, and so the expression under the square root is positive. Also, as z increases with u,

$$\frac{dz}{du}\Big|_{u=\zeta^{1/2}} = \sqrt{\frac{2\zeta^{1/2}}{2\sqrt{3}z_3 + 3z_3^2}}.$$

Similarly,

$$\frac{dz}{du}\Big|_{u=-\zeta^{1/2}} = \sqrt{\frac{-2\zeta^{1/2}}{2\sqrt{3}z_2 + 3z_2^2}}.$$

Since $g_0(u;\alpha) = dz/du$, we have, from the first two equations of (3.7) with $n = 0$,

$$p_0(\alpha) = \frac{1}{2}\left\{\sqrt{\frac{2\zeta^{1/2}}{2\sqrt{3}z_3 + 3z_3^2}} + \sqrt{\frac{-2\zeta^{1/2}}{2\sqrt{3}z_2 + 3z_2^2}}\right\} \tag{4.1}$$

$$q_0(\alpha) = \frac{1}{2\zeta^{1/2}}\left\{\sqrt{\frac{2\zeta^{1/2}}{2\sqrt{3}z_3 + 3z_3^2}} - \sqrt{\frac{-2\zeta^{1/2}}{2\sqrt{3}z_2 + 3z_2^2}}\right\}. \tag{4.2}$$

Use of equation (3.2) allows us to express (4.1) and (4.2) completely in terms of the function g.

$p_0(\alpha)$ and $q_0(\alpha)$ can also be obtained from relations involving only z_1, the zero of g' that remains isolated from z_2 and z_3. To see this, we observe

$$\begin{aligned} g'(z) &= z^3 + \sqrt{3}z^2 - \alpha \\ &= z^3 - (z_1 + z_2 + z_3)z^2 + (z_1z_2 + z_1z_3 + z_2z_3)z - z_1z_2z_3, \end{aligned}$$

and hence

$$\begin{aligned} z_1 + z_2 + z_3 &= -\sqrt{3}, \\ z_1z_2 + z_1z_3 + z_2z_3 &= 0, \\ z_1z_2z_3 &= \alpha. \end{aligned}$$

Use of the latter three equations permits the expression of ζ^3, p_0q_0, and p_0/q_0, in terms of α and z_1. For example, we find

$$p_0q_0 = \frac{z_1^2}{2\alpha}\left[\frac{3z_1^2 + 2\sqrt{3}z_1 - 3}{6\sqrt{3}z_1^2 + 6z_1 - 9\alpha}\right].$$

However, these expressions are not appreciably simpler than (4.1) and (4.2), in view of the symmetry we exploit below.

In the limit $\alpha \to 0^+$, we find that $\phi \to \frac{\pi}{6}^-$. Write

$$\phi = \frac{\pi}{6} - \theta.$$

Then

$$z_2 = \frac{1}{\sqrt{3}}[\cos(-\theta) + \sqrt{3}\sin(-\theta) - 1]$$

and

$$z_3 = \frac{1}{\sqrt{3}}[\cos(\theta) + \sqrt{3}\sin(\theta) - 1].$$

If we let

$$\chi(\theta) = \frac{1}{\sqrt{3}}[\cos(\theta) + \sqrt{3}\sin(\theta) - 1], \tag{4.3}$$

we have $z_2 = \chi(-\theta), z_3 = \chi(\theta)$. Furthermore, from $\sin 3\phi = \arcsin(1 - \sqrt{27}\alpha/2)$, we have

$$\phi = \frac{\pi}{6} - \frac{1}{3} \cdot 3^{3/4}\alpha^{1/2}\left(1 + \frac{\sqrt{3}}{8}\alpha + \frac{81\alpha^2}{32 \cdot 20} + O(\alpha^3)\right)$$

so that

$$\theta = \frac{\alpha^{1/2}}{3^{1/4}}\left[1 + \frac{\sqrt{3}}{8}\alpha + \frac{81\alpha^2}{32 \cdot 20} + O(\alpha^3)\right]. \tag{4.4}$$

The Maclaurin series for sine involves only odd powers, and that for cosine only even powers. Hence, the approximation for $z_3(\alpha)$ gives

$$z_3(\alpha) = \frac{\alpha^{1/2}}{3^{1/4}} - \frac{\alpha}{6} + \frac{5 \cdot 3^{1/4}}{72}\alpha^{3/2} - \frac{3^{1/2}}{27}\alpha^2 + O(\alpha^{5/2}).$$

The corresponding approximation for $z_2(\alpha)$ follows by replacing $\alpha^{1/2}$ by $-\alpha^{1/2}$ in that for $z_3(\alpha)$.

Indeed, any function of z_3 gives rise to a function of z_2 by the process of replacing $\alpha^{1/2}$ by $-\alpha^{1/2}$. Using this, we have

$$g(z_3) = -2 \cdot 3^{-5/4}\alpha^{3/2}\left[1 - \frac{3^{1/4}}{8}\alpha^{1/2} + \frac{3^{1/2}}{24}\alpha + O(\alpha^{3/2})\right]$$

and

$$g(z_2) = 2 \cdot 3^{-5/4}\alpha^{3/2}\left[1 + \frac{3^{1/4}}{8}\alpha^{1/2} + \frac{3^{1/4}}{24}\alpha + O(\alpha^{3/2})\right].$$

These two equations and (3.2) imply

$$\zeta^{1/2}(\alpha) = 3^{-1/12}\alpha^{1/2}\left[1 + \frac{\alpha}{24\sqrt{3}} + O(\alpha^2)\right],$$

where we have made use of the binomial formula.

Continuing, we get

$$g_{zz}(z_3) = 2 \cdot 3^{1/4}\alpha^{1/2}\left[1 + 3^{-3/4}\alpha^{1/2} - \frac{7 \cdot 3^{-1/2}}{24}\alpha + O(\alpha^{3/2})\right]$$

and

$$g_{zz}(z_2) = -2 \cdot 3^{1/4}\alpha^{1/2}\left[1 - 3^{-3/4}\alpha^{1/2} - \frac{7 \cdot 3^{-1/2}}{24}\alpha + O(\alpha^{3/2})\right]$$

whence

$$\sqrt{\frac{-2\zeta^{1/2}}{2\sqrt{3}z_2+3z_2^2}} = 3^{-1/6}\left[1+\frac{3^{-3/4}}{2}\alpha^{1/2}+O(\alpha)\right]$$

and

$$\sqrt{\frac{2\zeta^{1/2}}{2\sqrt{3}z_3+3z_3^2}} = 3^{-1/6}\left[1-\frac{3^{-3/4}}{2}\alpha^{1/2}+O(\alpha)\right].$$

These two approximations (together with that obtained for $\zeta^{1/2}$) in formulae (4.1) and (4.2) yield

$$p_0(\alpha) = 3^{-1/6}[1+O(\alpha)], \tag{4.5}$$

and

$$q_0(\alpha) = -\frac{3^{-5/6}}{2}[1+O(\alpha)], \tag{4.6}$$

as $\alpha \to 0$.

5. Expansion of P_2. Because Γ_2 begins and ends in valleys at ∞, we see that the contour can be deformed into the steepest descent path leading away from the saddle point t_1. The determination of the steepest descent path follows.

We begin by expanding f about the point $t = t_1$:

$$if(t;\mu) = if(t_1;\mu) + i\left(\frac{3t_1^2-1}{2}\right)(t-t_1)^2 + it_1(t-t_1)^3 + \frac{i}{4}(t-t_1)^4.$$

Let $z = t - t_1 = x + iy$. Steepest descent paths are among the level curves $0 = \mathrm{Im}[if(t;\mu) - if(t_1;\mu)]$. Consequently,

$$\frac{1}{2}(3t_1^2-1)(x^2-y^2) + t_1(x^3-3xy^2) + \frac{1}{4}(x^4-6x^2y^2+y^4) = 0$$

gives steepest paths. Solving for y as a function of x gives

$$y = \pm\frac{1}{\sqrt{2}}\left\{6x^2+12t_1x+2(3t_1^2-1) \pm \sqrt{(6x^2+12t_1x+2(3t_1^2-1))^2 - 4(x^4+4t_1x^3+2(3t_1^2-1)x^2)}\right\}^{1/2}$$

wherever the real square roots are defined. We see that the steepest descent curve through t_1 begins at $\infty e^{-7\pi i/8}$ and ends at $\infty e^{5\pi i/8}$. Fig. 6 displays hills and valleys in the case $\delta = 0$ (or $\mu = 2/\sqrt{27}$). Shaded regions represent valleys, the unshaded regions being hills. Solid curves (excluding the real axis) represent steepest descent or ascent paths according as they lie in shaded or unshaded regions respectively.

Let Γ_{2+} be the steepest descent curve running from t_1 to $\infty e^{5\pi i/8}$, and let Γ_{2-} be the steepest descent contour running from t_1 to $\infty e^{-7\pi i/8}$. Then we have

$$P_2(\lambda;\mu) = \int_{\Gamma_{2+}} e^{i\lambda f}dt - \int_{\Gamma_{2-}} e^{i\lambda f}dt.$$

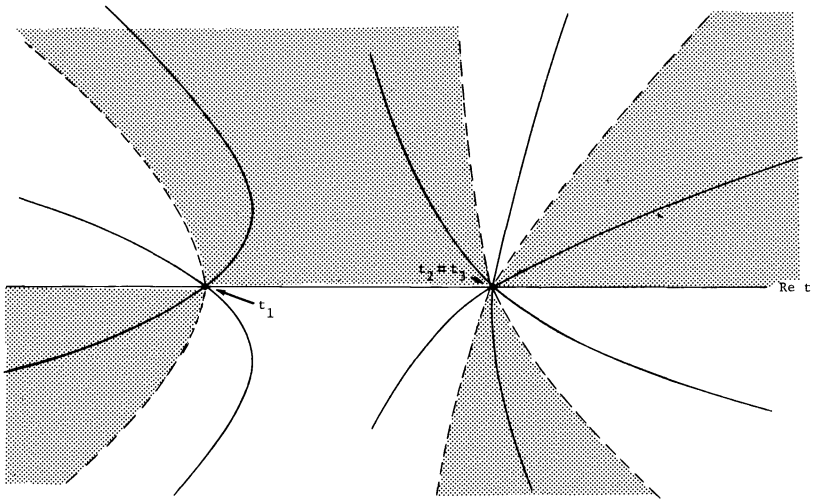

FIG. 6. *Hills and valleys defined by steepest curves through* t_1.

Let $w = if(t_1;\mu) - if(t;\mu)$ so that on $\Gamma_{2\pm}$, w is positive and increasing as we move away from t_1.

Let t_+ be the solution of $w = if(t_1;\mu) - if(t;\mu)$ on Γ_{2+}, t_- being the corresponding solution on Γ_{2-}. By the Lagrange inversion theorem, since

$$w = -\frac{i}{2}(3t_1^2 - 1)(t_\pm - t_1)^2 - it_1(t_\pm - t_1)^3 - \frac{i}{4}(t_\pm - t_1)^4$$

on $\Gamma_{2\pm}$ respectively, there are numbers $a_n^\pm$ for which

$$t_\pm = t_1 + \sum_{n=1}^{\infty} \frac{a_n^\pm}{n!} w^{n/2}$$

whence

$$\frac{dt_+}{dw} - \frac{dt_-}{dw} = \sum_{n=1}^{\infty} \frac{a_n^+ - a_n^-}{2(n-1)!} w^{\frac{n}{2}-1}.$$

Thus

$$P_2(\lambda;\mu) \sim e^{i\lambda f(t_1;\mu)} \sum_{n=1}^{\infty} \frac{a_n^+ - a_n^-}{2(n-1)!} \frac{\Gamma(n/2)}{\lambda^{n/2}}$$

as $\lambda \to \infty$; see arguments in [4, §§30 and 33].

The first few terms are easily found to be

$$a_1^+ = e^{\pi i/4} \left(\frac{2}{3t_1^2 - 1}\right)^{1/2}$$

$$a_2^+ = -i \left(\frac{2}{3t_1^2 - 1}\right) \cdot \left(\frac{2t_1}{3t_1^2 - 1}\right)$$

$$
\begin{aligned}
a_3^+ &= e^{3\pi i/4}\left(\frac{2}{3t_1^2-1}\right)^{3/2}\cdot\left[\frac{-3}{2(3t_1^2-1)}+\frac{15t_1^2}{2(3t_1^2-1)^2}\right]\\
a_1^- &= e^{5\pi i/4}\left(\frac{2}{3t_1^2-1}\right)^{1/2}\\
a_2^- &= a_2^+\\
a_3^- &= e^{-\pi i/4}\left(\frac{2}{3t_1^2-1}\right)^{3/2}\cdot\left[\frac{-3}{2(3t_1^2-1)}+\frac{15t_1^2}{2(3t_1^2-1)^2}\right]
\end{aligned}
$$

whence

$$
P_2(\lambda;\mu)=e^{i\lambda f(t_1;\mu)}\cdot\left\{\sqrt{\frac{\pi}{3t_1^2-1}}\frac{1+i}{\lambda^{1/2}}+\frac{(-3-6t_1^2)\pi^{1/2}}{4\cdot(3t_1^2-1)^{7/2}}\frac{1-i}{\lambda^{3/2}}+O\left(\frac{1}{\lambda^{5/2}}\right)\right\} \tag{5.1}
$$

where the O-symbol is uniform in μ for μ in a compact interval in $\mathbf{R}_+$ containing $2/\sqrt{27}$. A general expression for the $a_n^\pm$ is available to us via the binomial theorem, but it is too unwieldy to be of intrinsic value. We note that $a_n^+ = a_n^-$ for even n.

6. Uniform expansion of P at the caustic. We have obtained expansions of P_1 and P_2. Using (2.3), (3.8), and (5.1), and restoring the large parameter x and the function f, we get the uniform approximation as $x\to\infty$:

$$
\begin{aligned}
P\left(-x,\left(\frac{2}{\sqrt{27}}-\alpha\right)x^{3/2}\right) &= e^{ix^2[f(t_2;\mu)+f(t_3;\mu)]/2}\\
&\quad\cdot\left\{p_0(\alpha)\frac{2\pi}{x^{1/6}}\cdot Ai(-x^{4/3}\zeta)\left[1+O\left(\frac{1}{x^2}\right)\right]\right.\\
&\quad\left.+\,q_0(\alpha)\frac{2\pi}{ix^{5/6}}\cdot Ai'(-x^{4/3}\zeta)\left[1+O\left(\frac{1}{x^2}\right)\right]\right\}\\
&\quad+e^{ix^2 f\left(t_1;\frac{2}{\sqrt{27}}-\alpha\right)}\sqrt{\frac{\pi}{3t_1^2-1}}\frac{1+i}{x^{1/2}}\cdot\left[1+O\left(\frac{1}{x^2}\right)\right].
\end{aligned} \tag{6.1}
$$

Here, $t_1(\mu)=t_1((2/\sqrt{27})-\alpha)=-(2/\sqrt{3})\sin(\frac{\pi}{3}+\phi)$ where $3\phi=\arcsin(1-(\sqrt{27}/2)\alpha)$. The nature of the approximation when ζ is bounded away from 0 is readily available when the asymptotic forms of the Airy function and its derivative are used [1]; recall that

$$
Ai(z)=\frac{e^{-2z^{3/2}/3}}{2\sqrt{\pi}z^{1/4}}\left(1+O\left(\frac{1}{z^{3/2}}\right)\right),\quad|\arg z|<\pi, \tag{6.2}
$$

$$
\begin{aligned}
Ai(-z) &= \frac{1}{\sqrt{\pi}z^{1/4}}\left[\sin\left(\frac{\pi}{4}+\frac{2}{3}z^{3/2}\right)\left(1+O\left(\frac{1}{z^3}\right)\right)\right.\\
&\quad\left.-\cos\left(\frac{\pi}{4}+\frac{2}{3}z^{3/2}\right)\left(\frac{5}{48z^{3/2}}+O\left(\frac{1}{z^{9/2}}\right)\right)\right],\\
&\quad|\arg z|<\frac{2\pi}{3}
\end{aligned} \tag{6.3}
$$

$$
Ai'(z)=\frac{-z^{1/4}e^{-2z^{3/2}/3}}{2\sqrt{\pi}}\left(1+O\left(\frac{1}{z^{3/2}}\right)\right),\quad|\arg z|<\pi, \tag{6.4}
$$

$$
Ai'(-z)=-\frac{z^{1/4}}{\sqrt{\pi}}\left[\cos\left(\frac{\pi}{4}+\frac{2}{3}z^{3/2}\right)\left(1+O\left(\frac{1}{z^3}\right)\right)\right.
$$

$$+ \sin\left(\frac{\pi}{4}+\frac{2}{3}z^{3/2}\right)\left(\frac{-7}{48z^{3/2}}+O\left(\frac{1}{z^{9/2}}\right)\right)\Bigg], \tag{6.5}$$

$$|\arg z| < \frac{2\pi}{3},$$

as $z \to \infty$ in the indicated sectors.

If α is positive and bounded away from 0, then so is ζ. Hence

$$\begin{aligned} x^{-1/6}Ai(-x^{4/3}\zeta) &= \frac{1}{\sqrt{\pi}\zeta^{1/4}x^{1/2}}\left\{\sin\left(\frac{\pi}{4}+\frac{2}{3}x^2\zeta^{3/2}\right)\left(1+O\left(\frac{1}{x^4}\right)\right)\right. \\ &\quad \left. - \cos\left(\frac{\pi}{4}+\frac{2}{3}x^2\zeta^{3/2}\right)\left(\frac{5}{48x^2\zeta^{3/2}}+O\left(\frac{1}{x^6}\right)\right)\right\} \end{aligned}$$

and

$$\begin{aligned} x^{-5/6}Ai'(-x^{4/3}\zeta) &= \frac{-\zeta^{1/4}}{\sqrt{\pi}x^{1/2}}\left\{\cos\left(\frac{\pi}{4}+\frac{2}{3}x^2\zeta^{3/2}\right)\left(1+O\left(\frac{1}{x^4}\right)\right)\right. \\ &\quad \left. + \sin\left(\frac{\pi}{4}+\frac{2}{3}x^2\zeta^{3/2}\right)\left(\frac{-7}{48x^2\zeta^{3/2}}+O\left(\frac{1}{x^6}\right)\right)\right\} \end{aligned}$$

by (6.3) and (6.5). Thus, (6.1) reduces to a sum of three oscillatory terms, each of order $x^{-1/2}$ as $x \to \infty$. This is what we would expect from stationary phase inside the caustic (compare (1.3)).

On the other hand, if α is negative and bounded away from 0, then $\zeta^{3/2}$ lies in a segment of the imaginary axis bounded away from the origin. Accordingly, $\arg \zeta^{3/2} = \pm\pi/2$ so that the asymptotic forms (6.2) and (6.4) show that (6.1) reduces to an oscillatory term of order $x^{-1/2}$, plus two exponentially decaying terms. This is consistent with stationary phase outside the caustic (compare (1.5)).

Finally, we examine (6.1) when $\alpha = 0$. Again from [1], we see that $Ai(0) = \Gamma(1/3)/(2\cdot 3^{1/6}\pi)$ and $Ai'(0) = -3^{1/6}\Gamma(2/3)/(2\pi)$. Since $1+i = \sqrt{2}e^{\pi i/4}$, $t_1(2/\sqrt{27}) = -2/\sqrt{3}$, and $\eta = 0$, (6.1) reduces to

$$\begin{aligned} P\left(-x, \frac{2}{\sqrt{27}}x^{3/2}\right) &= e^{-2ix^2/3+\pi i/4}\sqrt{\frac{2\pi}{3x}} + e^{ix^2/12}\frac{\Gamma(1/3)}{3^{1/3}x^{1/6}} \\ &\quad - e^{ix^2/12}\frac{i\Gamma(2/3)}{2\cdot 3^{2/3}x^{5/6}} + O\left(\frac{1}{x^{2+(1/6)}}\right) \end{aligned}$$

as $x \to +\infty$. Thus we recover (1.4). Here, use has been made of (4.5) and (4.6).

A full expansion of $P(-x, \mu x^{3/2})$ follows from the expansions of P_1 and P_2, although the coefficients become more complicated as more terms are included. The extension to complex values of x and μ (for the analytic continuation of P) can be accomplished through the expansions for P_1 and P_2 for λ, μ complex, although as applications center on real values, we have not been overly concerned with developing the full range of complex values for which our expansion is valid.

We now turn to the work in [12]. Here, the authors examine the asymptotic behaviour of the function

$$\tilde{P}(X,Y) = \int_{-\infty}^{+\infty} \exp(i(t^4 + Xt^2 + Yt))dt \tag{6.6}$$

for large values of the parameters X, Y. P and $\tilde{P}$ are related by

$$\tilde{P}(X,Y) = \frac{1}{\sqrt{2}}P\left(X, \frac{Y}{\sqrt{2}}\right).$$

In developing the expansions of $\tilde{P}(X,Y)$ away from the caustic $27Y^2+8X^3=0$, Stamnes and Spjelkavik first apply the method of stationary phase to integrals of the form

$$\int_{-\infty}^{+\infty} g(t)e^{ikh(t)}dt, \quad k\to\infty, \tag{6.7}$$

with $g(t)=1$, and $h(t)=t^4+Xt^2+Yt$. They then set $k=1$ to yield the desired large X or large Y behaviour of $\tilde{P}$; see [12, p. 1338, §3.1].

For X and Y near the caustic, the authors formally invoke the method of Chester et al. [3], and indeed, include a brief outline of the uniform asymptotic theory for integrals of the form (6.7) in an appendix. Let J_U denote the contribution to the integral (6.7) due to the coalescing stationary points (thus, J_U plays the same role as our P_1 (cf. (2.4))). The authors claim that

$$J_U \sim 2\pi e^{ik[h(t_2)+h(t_3)]}\sum_{m=0}^{2}(p_mF_m+q_mG_m) \tag{6.8}$$

as $|X|,Y\to\infty$, uniformly valid near the caustic; see [12, eq. (3.31)]. Here, $h(t)$ is the phase function of (6.7) with Y replaced by $-Y$, and t_2 and t_3 are the critical points of $h(t)$ that coalesce as (X,Y) approaches the caustic, (X,Y) remaining bounded away from the origin in the XY-plane. The functions F_m and G_m are given by

$$\begin{aligned} F_0&=k^{-1/3}Ai(-\zeta k^{2/3}) & G_0&=-ik^{-2/3}Ai'(-\zeta k^{2/3})\\ F_1&=0 & G_1&=ik^{-4/3}Ai(-\zeta k^{2/3})\\ F_2&=2k^{-5/3}Ai'(-\zeta k^{2/3}) & G_2&=2ik^{-4/3}\zeta Ai(-\zeta k^{2/3}) \end{aligned}$$

where

$$\frac{4}{3}\zeta^{3/2}=h(t_3)-h(t_2).$$

The p_m and q_m are determined similarly as in (3.7) of this paper, and are presented in the appendix of [12, eqs. (A18)–(A23)].

However, care must be taken in using expansion (6.8) to obtain the large negative-X behaviour of $\tilde{P}$ near the caustic. (There is a typographical error in the phase function $h(t_2)+h(t_3)$, which should likely be half the stated value.) Throughout the appendix and §2 of [12], k appears as a large positive parameter. Yet, in several places, k is set equal to one prior to examining the large X behaviour of (6.7); see, for instance, equations (3.5), (5.3) and the discussion in §3.2 and note the absence of k in expansion (3.30). This naturally leads one to suspect that the same is being done in (6.8), although no explicit mention of this is made in [12]. It should be pointed out that (6.8) is that part of the expansion of

$$P^*(X,Y;k)=\int_{-\infty}^{+\infty}\exp(ik(t^4+Xt^2+Yt))dt$$

due to the coalescing saddles of the phase function t^4+Xt^2+Yt, and not part of an expansion of $\tilde{P}$. However, expansion (6.8) can be used to deduce the large negative-X behaviour of $\tilde{P}$ near the caustic via the relation

$$\tilde{P}(X,Y)=k^{1/4}P^*(\bar{X},\bar{Y};k),$$

where k is a large parameter, $X = k^{1/2}\bar{X}$ and $Y = k^{3/4}\bar{Y}$. Note that $27Y^2 + 8X^3 = k^{3/2}(27\bar{Y}^2 + 8\bar{X}^3)$; thus, if (X, Y) is near the caustic, so is $(\bar{X}, \bar{Y})$.

The integral P^* is also related to the Pearcey function $P(x, y)$ given in (1.1) by

$$P^*(X, Y; k) = 2^{-1/2}k^{-1/4}P(k^{1/2}X, 2^{-1/2}k^{3/4}Y).$$

By setting $x = -k^{1/2}X$ and $\mu = 2^{-1/2}(-X)^{-3/2}Y$ in our expansion for $P_1(x^2; \mu)$ (cf. (3.8)), we obtain the first three terms in (6.8). Thus, modulo misprints, (6.8) appears correct.

Finally, we turn to the "transitional approximation" developed in [12]. This was used in the numerical evaluation of $\tilde{P}(X, Y)$ for (X, Y) in a band covering the caustic extending 0.05 units in the X-direction on either side of the caustic, with $Y > 0$ (see [12, p. 1349, second paragraph]). In this calculation, it was assumed that $X^2 + Y^2 > 16$ and $|X|, Y \leq 8$. The "transitional approximation" developed is an asymptotic approximation of J_T in the immediate vicinity of the caustic [*sic*], where J_T represents the contribution to (6.6) due to coalescing stationary points of $h(t)$. The authors assert that

$$(6.9)\quad J_T \sim 2\pi d \cdot \exp(ih_0)\left[Ai(z) + icAi^{(4)}(z) - \frac{c^2}{2}Ai^{(8)}(z) - \frac{ic^3}{6}Ai^{(12)}(z) + \cdots\right]$$

where

$$\begin{aligned} h_0 &= -\tfrac{5}{36}X^2 + Y(\tfrac{-X}{6})^{1/2} & h_1 &= -8[\tfrac{Y}{8} - (\tfrac{-X}{6})^{3/2}] \\ h_3 &= -4(\tfrac{-X}{6})^{1/2} & h_4 &= 1 \\ d &= (3|h_3|)^{-1/3} & \epsilon &= \operatorname{sgn}(h_3) \\ z &= \epsilon h_1 d & c &= h_4 d^4 \end{aligned}$$

see [12, p. 1343, eq. (3.30)].

There are two points which we wish to make regarding the preceding approximation. First, the derivation is purely formal with no mention being made of the region of validity. Second, the authors did not actually use the expansion in the form given in (6.9), but instead used one in which each of the Airy functions $Ai^{(4j)}$, $j = 0, 1, 2, 3$, is replaced by the first term in its Maclaurin expansion; cf. the first three lines on p. 1344 of [12]. That is, the authors replace (6.9) by

$$(6.10)\qquad J_T = 2\pi d \cdot e^{ih_0}\left\{\sum_{j=0}^{3} c^j Q_j(z) + O(c^4)\right\},$$

where each Q_j is an expression of the form α or βz, α and β being constants.

In order for this to be valid, the implied O-terms in (6.10) involving z, resulting from approximating the $Ai^{(4j)}$ by the first terms of their Maclaurin series, must be $O(c^4)$ for large $|X|$. In particular, we must have $z = O(c^4)$. Since $z = -h_1 c^{1/4}$, this is equivalent to

$$h_1 = O(c^{15/4})$$

or, upon restoring X and Y,

$$Y - 8(-X/6)^{3/2} = O((-X)^{-5/2})$$

whence

$$27Y^2 + 8X^3 = O((-X)^{-1}).$$

This displays a condition on how quickly the point (X, Y) must approach the caustic.

In closing, we note that our work in developing a uniform expansion of $P(x, y)$ near the caustic is easily extended to that of deriving uniform expansions of $\partial P/\partial x$ and $\partial P/\partial y$ near the caustic for a range of complex x and y.

Acknowledgments. The author is indebted to Professor R. Wong for his guidance throughout the development of this work, and to Professor F. Ursell for detecting an error in an earlier version of this paper and for providing comments that greatly improved the discussion in §6.

INFINITE INTEGRALS INVOLVING THREE SPHERICAL BESSEL FUNCTIONS*

A. GERVOIS†‡ AND H. NAVELET†

Abstract. The integrals $\int_0^\infty t^n j_{l_1}(at) j_{l_2}(bt) j_{l_3}(ct)\, dt$ are calculated, where j_l is the spherical Bessel function for any integer indices n, l_1, l_2, l_3 and real positive parameters a, b, c using two different methods. In the first, $n+l_1+l_2+l_3$ must be an even integer but the techniques may be generalized to ordinary Bessel functions with *noninteger* indices. The second method does not depend on the parity of $n+l_1+l_2+l_3$ but remains valid only for integer indices.

Key words. spherical Bessel functions, infinite integrals, Appell functions

AMS(MOS) subject classifications. 33A40, 44A15, 33A35

1. Introduction.

Nuclear physicists [1] are often faced with integrals of the form

$$\int_0^\infty t^n j_{l_1}(at) j_{l_2}(bt) j_{l_3}(ct)\, dt \tag{1.1}$$

where l_1, l_2, l_3 are positive (or zero) integers and the integer n satisfies convergence conditions

$$-(l_1+l_2+l_3) \leqq n \leqq 2.$$

Parameters a, b, c are real positive and the $j_l(x)$ are the spherical Bessel functions

$$j_l(x) = \sqrt{\pi/2x} J_{l+1/2}(x). \tag{1.2}$$

A calculation of (1.1) has already been performed, in the frame of coupled channel theory [2], but with the following restrictions:

(1.3)
- (a) $n = 2 - M$, M is an even integer such that $0 \leqq M \leqq l_1+l_2+l_3-2l_M$, $l_M = m_{ax}(l_1, l_2, l_3)$.
- (b) $l_1+l_2+l_3$ is even.
- (c) $|l_1-l_2| < l_3 < l_1+l_2$.
- (d) The parameters a, b, c obey the triangular inequality, namely

$$|a-b| < c < a+b.$$

Restrictions (b) and (c) correspond to conservation of parity and angular momentum, respectively. They allow the use of spherical harmonics and Clebsch-Gordon coefficients. As to $n=2$, this condition simply says that $t^2\, dt$ is the volume element in the three-dimensional space. The result is written as a sum of expressions

$$\begin{pmatrix} l_1 & l_2 & l_3 \\ m & -m & 0 \end{pmatrix} P_{l_1}^m(\cos\theta_{13}) P_{l_2}^{-m}(\cos\theta_{23})$$

where the first factor is a Clebsch-Gordon and the $P_l^{\pm m}$ are Legendre polynomials. Angles θ_{13}, θ_{23} may be defined only because of the peculiar geometry of the system (condition (d)). In spite of its elegance, the proof of [2] remains specific to half-integer Bessel functions and needs crucially all conditions listed above.

Actually, there exists a formal expression [3] for the integral

$$I(\lambda, \mu, \nu, \rho) \equiv \int_0^\infty t^{\lambda-1} J_\mu(at) J_\nu(bt) H_\rho^{(1)}(ct)\, dt \tag{1.4}$$

provided the convergence conditions

$$\mathrm{Re}\,(\lambda) < \tfrac{5}{2}, \quad \mathrm{Re}\,(\lambda+\mu+\nu-|\rho|) > 0 \quad (\mathrm{Re}\,(\lambda+\mu+\nu+\rho) > 0 \text{ for the integral where } H_\rho^{(1)}(ct) \text{ is replaced by } J_\rho(ct)), \tag{1.5}$$

hold for the indices λ, μ, ν, ρ.

We have

$$I(\lambda, \mu, \nu, \rho) = \frac{1}{2\pi} e^{i\pi\beta} \left(\frac{2}{c}\right)^\lambda \left(\frac{a}{c}\right)^\mu \left(\frac{b}{c}\right)^\nu \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\gamma)\Gamma(\gamma')} \times F_4\left(\alpha, \beta, \gamma, \gamma'; \frac{a^2}{c^2}, \frac{b^2}{c^2}\right) \tag{1.6a}$$

with

$$\alpha = \frac{\lambda+\mu+\nu+\rho}{2}, \quad \beta = \frac{\lambda+\mu+\nu-\rho}{2}, \quad \gamma = \mu+1, \quad \gamma' = \nu+1 \tag{1.6b}$$

and F_4 is the Appell [4] function, defined as a double series in the convergence domain $|c| > |a| + |b|$.

However, this result is not useful because the function F_4 cannot be calculated easily and the analytic continuation is not possible when a, b, c may be considered as the sides of a triangle.

Simplifications occur when F_4 factorizes into functions of one variable that allows an analytic continuation in a, b, c. These cases have been listed long ago [5a], [5b], and in previous works [6a], [6b], [7a], [7b], we have used this factorization to calculate numerous integrals of type (1.4) when λ, μ, ν, ρ are related by one or two linear relations. By using recurrence relations between Bessel functions it is possible to enlarge the number of integrals of type (1.4) that can be computed analytically. These new integrals correspond to λ, μ, ν, ρ values differing from the previous ones by an integer. This integer is always positive for the parameter λ. As we will see in § 2, this general method is a powerful tool to get as a byproduct integrals of type (1.1) but with the restriction $l_1+l_2+l_3+n$ even. In § 3, we use a direct method, specific of the spherical Bessel functions [1], but which removes the restriction $l_1+l_2+l_3+n$ even.

2. First method. We consider here integrals $I(\lambda, \mu, \nu, \rho)$, (1.4) and in a first step do not impose any restriction on the indices except the convergence conditions (1.5). In § 2.1, we show how recurrence relations between Bessel functions lead to recurrence relations between contiguous integrals $I(\lambda, \mu, \nu, \rho)$. We then derive a whole class of integrals that can be calculated from already known integrals in an explicit form (§ 2.2). In the last section, § 2.3, we apply these results to integrals (1.1).

2.1. Recurrence relations. The well-known recurrence relation between three contiguous (nonmodified) Bessel functions

$$t[Z_{\sigma+1}(t) + Z_{\sigma-1}(t)] = 2\sigma Z_\sigma(t) \tag{2.1}$$

where $Z_\sigma = J_\sigma$, Y_σ or $H_\sigma^{(1)}$ leads to a straightforward relation between contiguous integrals. Setting $t = cx$, $\sigma = \rho - 1$, we have for any λ, μ, ν, ρ,

$$I(\lambda+2, \mu, \nu, \rho) + I(\lambda+2, \mu, \nu, \rho-2) = \frac{2}{c}(\rho-1) I(\lambda+1, \mu, \nu, \rho-1). \tag{2.2}$$

Similarly, the differential relations

$$\left(\frac{\sigma}{z} \pm \frac{\partial}{\partial z}\right) Z_\sigma(tz) = t Z_{\sigma\mp1}(tz) \tag{2.3}$$

together with integration by parts yield other (less obvious) relations. For example, we will need

$$I(\lambda+1,\mu,\nu+1,\rho)=\frac{b}{c}I(\lambda+1,\mu,\nu,\rho-1)-\frac{a}{c}I(\lambda+1,\mu+1,\nu+1,\rho-1)$$
$$-\frac{2+\nu-\mu-\lambda-\rho}{c}I(\lambda,\mu,\nu+1,\rho-1). \tag{2.4}$$

We now consider the case

$$\nu-\mu=q,\qquad \lambda+\mu+\rho-\nu=2(k+1),$$
$$\mathcal{J}_{\mu\ \rho}^{q\ k}\equiv\int_0^\infty dt\,t^{1-\rho+q+2k}J_\mu(at)J_{\mu+q}(bt)H_\rho^{(1)}(ct) \tag{2.5}$$

where q, k are positive or zero integers. The justification of this restriction will appear clearly later. For these integrals, (2.2) reads

$$\mathcal{J}_{\mu\ \rho}^{q\ k+1}=-\mathcal{J}_{\mu\ \rho-2}^{q\ k}+\frac{2}{c}(\rho-1)\mathcal{J}_{\mu\ \rho-1}^{q\ k}$$

whence, by recursion

$$\mathcal{J}_{\mu\ \rho}^{q\ k}=\sum_{p=0}^{k}C_k^p\left(\frac{2}{c}\right)^{k-p}(-)^p\frac{\Gamma(\rho-p)}{\Gamma(\rho-k)}\mathcal{J}_{\mu\ \rho-k-p}^{q\ 0}$$

and (2.4) becomes

$$\mathcal{J}_{\mu\ \rho}^{q+1\ 0}=\frac{b}{c}\mathcal{J}_{\mu\ \rho-1}^{q\ 0}-\frac{a}{c}\mathcal{J}_{\mu+1\ \rho-1}^{q\ 0}$$

because the last term in the right-hand side cancels out. By recursion again, we get

$$\mathcal{J}_{\mu\ \rho}^{q\ 0}=\sum_{m=0}^{q}C_q^m(-)^m\left(\frac{b}{c}\right)^{q-m}\left(\frac{a}{c}\right)^m\mathcal{J}_{\mu+m\quad\rho-q}^{0\ 0}.$$

This allows us to write $\mathcal{J}_{\mu\ \rho}^{q\ k}$ as a finite linear combination of known integrals $\mathcal{J}_{\mu'\ \rho'}^{0\ 0}$ [5]

$$\mathcal{J}_{\mu\ \rho}^{q\ k}=\sum_{p=0}^{k}C_k^p\left(\frac{2}{c}\right)^{k-p}(-)^p\frac{\Gamma(\rho-p)}{\Gamma(\rho-k)}\sum_{m=0}^{q}C_q^m(-)^m\left(\frac{b}{c}\right)^{q-m}\left(\frac{a}{c}\right)^m\mathcal{J}_{\mu'\ \rho'}^{0\ 0} \tag{2.6a}$$

with

$$\mu'=\mu+m\quad(m=0,1,\cdots,q),\qquad \rho'=\rho-k-p-q\quad(p=0,1,\cdots,k) \tag{2.6b}$$

and

$$\mathcal{J}_{\mu'\ \rho'}^{0\ 0}\equiv\int_0^\infty t^{1-\rho'}J_{\mu'}(at)J_{\mu'}(bt)H_{\rho'}^{(1)}(ct)\,dt. \tag{2.7}$$

Note that $\rho'=(k-p)+(\rho-2k-q)$ is positive for $k>p$. Indeed, the convergence condition at $t=\infty$ implies $\rho-q-2k>-\frac{1}{2}$.

2.2. New integrals. The general expression (1.6) for $I(\lambda,\mu,\nu,\rho)$ is of particular interest when F_4 factorizes into functions of one variable (in general, ${}_2F_1$ functions). These factorizations [5a], [5b] roughly fall into three cases:

(i) $\lambda=1$, any μ, ν, ρ.

(ii) $\lambda=\nu+2$, $\mu=\pm\rho$ (and $\lambda=\mu+2$, $\nu=\pm\rho$).

(iii) $\lambda=2\pm\rho$, $\mu=\nu$.

Some of the corresponding integrals may be found in the usual table handbooks [8], [9]. We calculate others in recent papers [6a], [6b], [7a], [7b]. In case (i) F_4 is the product of two ${}_2F_1$ functions in intermediate variables and recurrence relations (2.4)-(2.6) then simply say that when λ is a (strictly) positive integer the integral $I(\lambda, \mu, \nu, \rho)$—or the corresponding F_4 function—is now a finite sum of such products of ${}_2F_1$ functions in the same variable. However, up to now, there is no simple close formula for such integrals in the more general case; we have seen some peculiar cases in previous publications [10].

Cases (ii) and (iii) are partially the same. In the following, we will drop the configuration of indices $\lambda = 2+\nu$, $\mu = -\rho$ although the same technique probably works in that case too. For the remaining possibilities, without any restriction, we may assume $\lambda = 2-\rho$, $\mu = \nu$ and we get then precisely the integral $\mathcal{J}^{0\ 0}_{\mu\ \rho}$ of definition (2.7). Here we recall the corresponding factorization for F_4:

$$F_4\left(\mu+1, \mu+1-\rho, \mu+1, \mu+1; -\frac{X}{(1-X)(1-Y)}, -\frac{Y}{(1-X)(1-Y)}\right)$$
$$= [(1-X)(1-Y)]^{\mu+1-\rho}\, {}_2F_1(\mu+1-\rho, 1-\rho, \mu+1; XY),$$

which yields for $\mathcal{J}^{0\ 0}_{\mu\ \rho}$ the final expression [6a]:

$$\text{(2.8a)} \qquad \mathcal{J}^{0\ 0}_{\mu'\ \rho'} = \frac{i}{\pi}\sqrt{\frac{2}{\pi}}\frac{(ab)^{\rho'-1}}{c^{\rho'}}(sh\tilde{U}_c)^{\rho'-1/2}\, e^{i\pi(\rho'-1/2)}\mathcal{Q}^{-\rho'+1/2}_{\mu'-1/2}(ch\tilde{U}_c),$$

$$c < |a-b|,$$

$$\text{(2.8b)} \qquad = \frac{i}{\pi}\sqrt{\frac{2}{\pi}}\frac{(ab)^{\rho'-1}}{c^{\rho'}}(shU_c)^{\rho'-1/2}\, e^{i\pi(\mu'-1/2)}\mathcal{Q}^{-\rho'+1/2}_{\mu'-1/2}(chU_c),$$

$$c > a+b,$$

$$\text{(2.8c)} \qquad = \frac{1}{\pi}\sqrt{\frac{2}{\pi}}\frac{(ab)^{\rho'-1}}{c^{\rho'}}(\sin\varphi_c)^{\rho'-1/2}\left\{\frac{\pi}{2}P^{-\rho'+1/2}_{\mu'-1/2}(\cos\varphi_c) - iQ^{-\rho'+1/2}_{\mu'-1/2}(\cos\varphi_c)\right\},$$

$$|a-b| < c < a+b.$$

The hyperbolic angles $\tilde{U}_c$, U_c relative to c when a, b, c do not form a triangle are defined by

$$\text{(2.9a)} \qquad c^2 = a^2+b^2-2ab\, ch\tilde{U}_c \quad \text{if } c < |a-b|,$$

$$\text{(2.9b)} \qquad c^2 = a^2+b^2+2ab\, chU_c \quad \text{if } c > a+b.$$

In the triangle configuration, φ_c is the true angle:

$$\text{(2.9c)} \qquad c^2 = a^2+b^2-2ab\cos\varphi_c, \qquad |a-b| < c < a+b$$

and similar relations hold for the angles or hyperbolic angles relative to a and b. The $\mathcal{P}^\tau_\sigma$, $\mathcal{Q}^\tau_\sigma$ (respectively, P^τ_σ, Q^τ_σ) are the Legendre functions outside the cut ((2.8a) and (2.8b)) (respectively, on the cut ((2.8c)) (see, for example, [11]). We must point out that $\mathcal{Q}^\tau_\sigma$ is not defined when $\sigma+\tau$ is a negative integer; however, a definition by continuation is possible when $\tau = -r$ is an integer too, using relation $\mathcal{Q}^{-r}_\sigma = (-)^r(\Gamma(\sigma-r+1)/\Gamma(\sigma+r+1))\mathcal{Q}^r_\sigma$. This will be useful later. Note that $e^{i\pi\tau}\mathcal{Q}^{-\tau}_\sigma$ is real when z is real and greater than one, so that (2.8a) is pure imaginary and $\int t^{1-\rho'}J_{\mu'}J_{\mu'}J_{\rho'}$ is zero when $c < |a-b|$ and this holds by analytic continuation when $\mu'-\rho'$ is a negative integer. If $c > a+b$ and $\mu'-\rho'$ is a nonnegative integer, $\int t^{1-\rho'}J_{\mu'}J_{\mu'}J_{\rho'}$ is also zero because of the $\sin(\mu'-\rho')\pi$ factor. When $\mu'-\rho'$ is a negative integer, the limit exists but is not zero. This will be seen in more detail in the next section.

Now, any integral $\mathcal{J}_{\mu\ \rho}^{q\ k}$ where the indices differ by integer number is rewritten as a finite sum of such Legendre functions using summation (2.6). We give here some examples (Re is the real part).

(i) Sine transforms (or cosine transforms)

$$\int_0^\infty t^{q+2k} J_\mu(at) J_{\mu+q}(b) \operatorname{sinct} dt = \sqrt{\pi c/2}\ \mathrm{Re}\,(\mathcal{J}_{\mu\ 1/2}^{q\ k}).$$

(ii) For $\rho = \nu - \mu$ and $k = 0$, we recover results calculated by another method in [10] for $\lambda = 2$ and any real μ, ν.

(iii) Bessel J_0 (or $J_1 \cdots$) transforms

$$\int_0^\infty t^{1+q+2n} J_\nu(at) J_{\nu+q}(bt) J_0(ct)\, dt = \mathrm{Re}\,(\mathcal{J}_{\nu\ 0}^{q\ n}).$$

(iv) Integrals with fractional indices such as that involving the Airy function $J_{1/3}$, for instance,

$$\int_0^\infty t^{2n+1} J_{1/3}(at) J_{1/3}(bt) J_0(ct)\, dt = \mathrm{Re}\,(\mathcal{J}_{1/3\ 0}^{0\ n})$$

or

$$\int_0^\infty t^{2/3+q} J_{1/3}(ct) J_\mu(at) J_{\mu+q}(bt)\, dt = \mathrm{Re}\,(\mathcal{J}_{\mu\ 1/3}^{q\ 0}).$$

2.3. Application to spherical Bessel functions. Let us come back to integrals (1.1). We assume without any loss of generality that $l_3 \geqq l_2 \geqq l_1$ and we set $l_2 = l_1 + q$. The correspondence with integrals $I(\lambda, \mu, \nu, \rho)$ or $\mathcal{J}_{\mu\ \rho}^{q\ k}$ obviously gives $\mu = l_1 + \frac{1}{2}$, $\nu = l_2 + \frac{1}{2}$, $\rho = l_3 + \frac{1}{2}$, $\lambda = 2 - \rho + q + 2k = n - \frac{1}{2}$, and

$$\begin{aligned} &\int_0^\infty t^n j_{l_1}(at) j_{l_2}(bt) j_{l_3}(ct)\, dt \\ &= \left(\frac{\pi}{2}\right)^{3/2} \frac{1}{\sqrt{abc}} \int_0^\infty t^{n-3/2} J_{l_1+1/2}(at) J_{l_2+1/2}(bt) J_{l_3+1/2}(ct)\, dt \\ &= \left(\frac{\pi}{2}\right)^{3/2} \frac{1}{\sqrt{abc}}\, \mathrm{Re}\left\{ \mathcal{J}_{l_1+1/2, l_3+1/2}^{l_2-l_1, (n-2+l_3-l_2+l_1)/2} \right\} \end{aligned} \tag{2.10}$$

where Re denotes the real part, provided

$$n + l_1 + l_2 + l_3 \quad \text{is even}, \tag{2.11a}$$

$$n - 2 + l_3 - l_2 + l_1 \geqq 0. \tag{2.11b}$$

The first condition is actually fulfilled in nuclear physics problems and is related to the conservation of parity. Condition (2.11b) is automatically satisfied for $n = 2$ or $n = 1$ as $l_3 \geqq l_2 \geqq l_1$ and $l_1 + l_2 + l_3$ has a given parity. For $n = 0$, cases $l_1 = 0$, $l_2 = l_3 = l$ cannot be treated directly by this method. A derivation in the spirit of this paper is given in Appendix A. Note then, that the integral is a pure Fourier transform, and the result when a, b, c do not form a triangle may be found in handbooks of tables (see, for instance, [8]).

Now, when conditions (2.11) are fulfilled, using (2.6)-(2.8) with $2k = n - 2 + l_3 - l_2 + l_1$, $q = l_2 - l_1$, we get the result as a sum of integrals (2.8) with μ', ρ' half integers ($\mu' = l_1 + m + \frac{1}{2} = l_1' + \frac{1}{2}$, $\rho' = l_3 + \frac{1}{2} - k - p - q = l_3' + \frac{1}{2}$). Note that $l_3' \geqq 0$,

although it is not clear in this form. For the sake of completeness, we rewrite (2.10) when using (2.6):

$$\int_0^\infty t^n j_{l_1}(at) j_{l_2}(bt) j_{l_3}(bt)\, dt$$

$$= \left(\frac{\pi}{2}\right)^{3/2} \frac{1}{\sqrt{abc}} \sum_{p=0}^{k} C_k^p \left(\frac{2}{c}\right)^{k-p} (-)^p \frac{\Gamma(l_3+\frac{1}{2}-p)}{\Gamma(l_3+\frac{1}{2}-k)} \tag{2.12a}$$

$$\cdot \sum_{m=0}^{q} C_q^m (-)^m \left(\frac{b}{c}\right)^{q-m} \left(\frac{a}{c}\right)^m \operatorname{Re} \mathcal{J}^0_{l_1'+1/2,\, l_3'+1/2},$$

$$l_3 \geqq l_2 \geqq l_1, \quad q = l_2 - l_1, \quad 2k = n - 2 + l_3 - l_2 + l_1, \tag{2.12b}$$

$$l_1' = l_1 + m, \qquad l_3' = l_3 - k - p - q, \tag{2.12c}$$

and

$$\operatorname{Re} \mathcal{J}^0_{l_1'+1/2,\, l_3'+1/2} \equiv \int_0^\infty t^{1/2-l_3'} J_{l_1'+1/2}(at) J_{l_1'+1/2}(bt) J_{l_3'+1/2}(ct)\, dt$$

$$= 0 \quad \text{if } c < |a-b|$$

$$= \frac{1}{\sqrt{2\pi}} \frac{1}{ab} \left(\frac{ab}{c}\right)^{l_3'+1/2} (\sin\varphi_c)^{l_3'} P_{l_1'}^{-l_3'}(\cos\varphi_c)$$

$$|a-b| < c < a+b \tag{2.13}$$

$$= 0 \quad \text{for } c > a+b \text{ and } l_1' \geqq l_3'$$

$$= (-)^{l_3'} \sqrt{\frac{2}{\pi}} \frac{1}{ab} \left(\frac{ab}{c}\right)^{l_3'+1/2} \frac{(shU_c)^{l_3'}}{\Gamma(l_1'+l_3'+1)\Gamma(l_3'-l_1')} \mathcal{Q}_{l_1'}^{l_3'}(chU_c)$$

$$\text{for } c > a+b \text{ and } l_1' < l_3'.$$

As l_1', l_3' are positive integers, $(\sin\varphi_c)^{l_3'} P_{l_1'}^{-l_3'}(\cos\varphi_c)$ is a polynomial in $\cos\varphi_c$ of degree $l_1'+l_3'$ whereas $(shU_c)^{l_3'} \mathcal{Q}_{l_1'}^{l_3'}(chU_c)$ is a polynomial in chU_c of degree $l_1'+l_3'-1$ when $l_3' > l_1'$ (see Appendix B).

At this stage, some comments are in order.

(i) It is worth noting that there is a shorter way to get the integrals of type (2.10) when a, b, and c do not obey the triangular inequalities.

Indeed if $c > a+b$

$$\operatorname{Re} I\left(n-\frac{1}{2}; l_1+\frac{1}{2}, l_2+\frac{1}{2}, l_3+\frac{1}{2}\right)$$

$$= \frac{\frac{1}{2}\left(\frac{2}{c}\right)^{n-1/2} \left(\frac{a}{c}\right)^{l_1+1/2} \left(\frac{b}{c}\right)^{l_2+1/(2\times\Gamma)} \left(\frac{l_1+l_2+l_3+n+1}{2}\right)}{\Gamma\left(l_1+\frac{3}{2}\right)\Gamma\left(l_2+\frac{3}{2}\right)\Gamma\left(1-\left(\frac{l_1+l_2+n-l_3}{2}\right)\right)}$$

$$\times F_4\left(\frac{l_1+l_2+l_3+n+1}{2}, \frac{l_1+l_2+n-l_3}{2}, l_1+\frac{3}{2}, l_2+\frac{3}{2}; \frac{a^2}{c^2}, \frac{b^2}{c^2}\right)$$

and similar formulae for $a > c+b$ ($c \leftrightarrow a$ and $l_3 \leftrightarrow l_1$) or $b > a+c$ ($c \leftrightarrow b$ and $l_3 \leftrightarrow l_2$). Then for $n+l_1+l_2+l_3$ even, $(l_1+l_2+n-l_3)/2$ is an integer and the integral vanishes

if $l_1+l_2+n-l_3 \geqq 2$. In the other configuration ($l_1+l_2+n-l_3 \leqq 0$) the F_4 function is a polynomial of degree $(l_3-(l_1+l_2+n))/2=p$ in the variable a^2/c^2 and b^2/c^2 of the form

$$F_4\left(\alpha, -p, \gamma, \gamma', \frac{a^2}{c^2}, \frac{b^2}{c^2}\right) = \sum_{k=0}^{p} (\alpha)_k (-p)_k \sum_{m=0}^{k} \frac{\left(\frac{a^2}{c^2}\right)^m \left(\frac{b^2}{c^2}\right)^{k-m}}{(\gamma)_m (\gamma')_{k-m} m!(k-m)!}$$

where $(\beta)_q = \Gamma(\beta+q)/\Gamma(\beta)$ is the Pochammer symbol.

For instance, the case $l_1+l_2+n=l_3$ leads to a very simple formula since the F_4 function reduces to one (for reasons of convergence $l_3 \leqq l_1+l_2+2$):

$$\int_0^\infty t^{l_3-(l_1+l_2)} j_{l_1}(at) j_{l_2}(bt) j_{l_3}(ct)\, dt$$

$$= \frac{\pi^{3/2}}{2^{3+l_1+l_2-l_3}} \frac{a^{l_1} b^{l_2}}{c^{l_3+1}} \times \frac{\Gamma(l_3+\frac{1}{2})}{\Gamma(l_1+\frac{3}{2})\Gamma(l_2+\frac{3}{2})}, \qquad c > a+b.$$

Note that this result is valid in the general case when $(\lambda+\mu+\nu-\rho)/2$ is an integer. Thus we have the well-known formula:

$$\int_0^\infty t^{\rho-\nu-\mu-1} J_\mu(at) J_\nu(bt) J_\rho(ct)\, dt = \frac{1}{2} \frac{\left(\frac{a}{2}\right)^\mu \left(\frac{b}{2}\right)^\nu \Gamma(\rho)}{\left(\frac{c}{2}\right)^\rho \Gamma(\nu+1)\Gamma(\mu+1)}, \qquad c > a+b.$$

Unfortunately, this method does not apply when a, b, c obey the triangular inequalities because, as emphasized before, the analytic continuation of the F_4 function is unknown in the general case.

(ii) The proof above holds when $n \geqq 0$ and is still valid when $n<0$, provided $n-2+l_3-l_2+l_1 \geqq 0$.

It is easy to show now that it also holds when $n-2+l_3-l_2+l_1<0$, i.e., for any negative integer n provided the convergence condition at $t=0$ $(n+l_1+l_2+l_3) \geqq 0$ holds.

Let us show it briefly. We set $m=|n|=-n$. As $m \leqq l_1+l_2+l_3$, we may split m into three terms $m=m_1+m_2+m_3$ such that m_i is an integer and $0 \leqq m_i \leqq l_i$. Now, using m_i times the recurrence relation (2.1), we replace j_{l_i}/t^{m_i} by a linear combination of m_i+1 spherical Bessel functions $j_{l_i'}$ ($l_i'=l_i+m_i,\ l_i+m_i-2, \cdots, l_i-m_i+2,\ l_i-m_i$) and the whole integrand is now a sum of products of spherical Bessel functions with no power term. For example, when we use

$$\frac{j_1(at)}{t} = \frac{a}{3}[j_2(at)+j_0(at)], \qquad \frac{j_1(bt)}{t} = \frac{b}{3}[j_2(bt)+j_0(bt)],$$

$$\frac{j_2(ct)}{t^2} = c^2\left[\frac{j_4(ct)}{35} + \frac{2j_2(ct)}{21} + \frac{j_0(ct)}{15}\right]$$

the integral

$$\int_0^\infty \frac{j_1(at) j_1(bt) j_2(ct)}{t^4}\, dt$$

is a sum of known integrals $\int_0^\infty j_{l_1'}(at) j_{l_2'}(bt) j_{l_3'}(ct)\, dt$ with l_1', $l_2'=0, 2$; $l_3'=0, 2, 4$.

To summarize, we have enlarged the conditions (1.3) that were necessary in the proof of [2] to the case where a, b, and c, respectively (l_1, l_2, and l_3) do not obey the triangular inequalities and where n is no longer restricted to be equal to two. The result is given in terms of a linear combination of Legendre functions of one angle or

pseudo-angle φ_c, U_c, or $\hat{U}_c$ instead of products of Legendre polynomials in φ_a and φ_b in the triangular case (see Table 1). The method is general and applies also when the index of the Bessel functions is noninteger.

TABLE 1

Expression of the integral with three spherical Bessel functions in terms of the Legendre functions when $n+l_1+l_2+l_3$ *is even.*

$$I=\int_0^\infty dt\, t^n j_{l_1}(at)j_{l_2}(bt)j_{l_3}(ct), \qquad n\geqq 2, \quad n+l_1+l_2+l_3\geqq 0.$$

For $n<0$, we come back to integrals with $n=0$ using recurrence (2.1). For $n=l_1=0$ and $l_2=l_3=l$ see Appendix equations (A1)-(A2). In all other cases, if $l_3\geqq l_2\geqq l_1$

$$I=\left(\frac{\pi}{2}\right)^{3/2}\frac{1}{\sqrt{abc}}\,\mathrm{Re}\,\mathcal{J}^{q\ k}_{l_1+1/2\ l_3+1/2}$$

where $q=l_2-l_1$, $k=(n-2+l_3-l_2+l_1)/2$ are positive or zero integers,

$$\mathcal{J}^{q\ k}_{l_1+1/2\ l_3+1/2}=\sum_{p=0}^{k}C_k^p\left(\frac{2}{c}\right)^{k-p}(-)^p\frac{\Gamma(l_3+\tfrac{1}{2}-p)}{\Gamma(l_3+\tfrac{1}{2}-k)}\sum_{m=0}^{q}C_q^m(-)^m\left(\frac{b}{c}\right)^{q-m}\left(\frac{a}{c}\right)^m\mathcal{J}^{0}_{l_1'+1/2\ l_3'+1/2}$$

$$l_1'=l_1+m, \quad l_3'=l_3-k-p-q, \quad (l_3'\geqq 0)$$

and

$$\mathcal{J}^{0}_{l_1'+1/2\ l_3'+1/2}=0 \quad \text{if } c<|a-b|$$

$$=0 \quad \text{if } c>a+b \text{ and } l_1'\geqq l_3'$$

$$=(-)^{l_3'}\sqrt{\frac{2}{\pi}}\frac{1}{ab}\left(\frac{ab}{c}\right)^{l_3'+1/2}\frac{(shU_c)^{l_3'}}{\Gamma(l_1'+l_3'+1)\Gamma(l_3'-l_1')}\mathcal{Q}_{l_1'}^{l_3'}(chU_c) \quad \text{if } c>a+b \text{ and } l_1'<l_3'$$

$$=\frac{1}{\sqrt{2\pi}}\frac{1}{ab}\left(\frac{ab}{c}\right)^{l_3'+1/2}(\sin\varphi_c)^{l_3'}P_{l_1'}^{-l_3'}(\cos\varphi_c) \quad \text{if } |a-b|<c<a+b.$$

N.B. If $|a-b|<c<a+b$, $c^2=a^2+b^2-2ab\cos\varphi_c$; if $c>a+b$, $c^2=a^2+b^2+2ab\,chU_c$.

However, the method fails to work when $n+l_1+l_2+l_3$ is odd. This case corresponds to a case of factorization $\lambda=\nu+2$, $\mu=-\rho$ and the F_4 function reduces to an F_1 function [4] with a positive integer index that yields a logarithmic singularity while for even parity this index is a negative integer and the corresponding F_1 is thus a polynomial. For these reasons, we give another method that is specific to the spherical Bessel functions.

3. Second method (spherical Bessel functions only). The method holds for any positive (or zero) integers l_1, l_2, l_3 $(-(l_1+l_2+l_3)\leqq n\leqq 2)$ and any real positive parameters a, b, c and it is specific to half-integer Bessel functions. Contrary to the preceding section, the final expression is not written as a sum of Legendre functions changing when going from a triangle to a nontriangle configuration: it appears as a finite sum of simple rational functions of a, b, c directly with a singularity that depends on the parity of the quantity $n+l_1+l_2+l_3$.

Integrals

$$A_{l_1,l_2,l_3,n}=\int_0^\infty t^n j_{l_1}(at)j_{l_2}(bt)j_{l_3}(ct)\,dt \tag{3.1}$$

may be calculated directly, using the expansion of the spherical Bessel functions. Following [1] we write

$$j_l(\rho)=\frac{e^{i\rho}}{2\rho}\sum_{m=0}^{l}\frac{\exp\left(i\pi/2(l-m+1)\right)}{m!}\frac{(l+m)!}{(l-m)!}\left(\frac{1}{2\rho}\right)^m+\text{c.c.} \tag{3.2}$$

where c.c. denotes the complex conjugate. The integrand is rewritten as follows:

$$\sum_{\{m_i\}} \sum_{\pm} \sum_{i} \prod \frac{(l_i+m_i)!}{m_i!(l_i-m_i)!} \exp\left(\mp \frac{i\pi}{2}(l_i-m_i+1)\right)$$

$$\cdot \frac{e^{it(\pm a\pm b\pm c)}}{(2a)^{m_1+1}(2b)^{m_2+1}(2c)^{m_3+1}} t^{n-3-m_1-m_2-m_3} \tag{3.3}$$

$$0 \leqq m_i \leqq l_i, \qquad i=1,2,3.$$

The integral

$$\int_0^\infty e^{it(\pm a\pm b\pm c)} t^{n-3-m_1-m_2-m_3}\, dt = \lim_{\varepsilon\to 0^+} \int_0^\infty e^{it(\pm a\pm b\pm c)}(t+\varepsilon)^{n-3-m_1-m_2-m_3}\, dt \tag{3.4}$$

is divergent, but the whole sum (3.3) is convergent. Then, we first calculate $\int_0^\infty e^{it(\pm a\pm b\pm c)}(t+\varepsilon)^{n-3-m_1-m_2-m_3}$, which exists for $\varepsilon>0$ and retain only its finite part when $\varepsilon\to 0^+$, *as it gives the only contribution to the final result.* The basic integral

$$I_p = \int_0^\infty \frac{e^{i\lambda t}}{(t+\varepsilon)^p}\, dt \tag{3.5}$$

$\lambda = \pm a \pm b \pm c$, real, is a polynomial in $1/\varepsilon$ plus a singular part I_1:

$$I_p = \frac{(i\lambda)^{p-1}}{(p-1)!} I_1 + \frac{1}{(p-1)!} \sum_{l=0}^{p-2} \frac{(p-2-l)!(i\lambda)^p}{\varepsilon^{p-1-l}}$$

and when $\varepsilon\to 0^+$, I_1 has a logarithmic behavior

$$I_1 = \int_0^\infty \frac{e^{i\lambda t}}{t+\varepsilon}\, dt = -\ln|\lambda| - \ln(e^\gamma\cdot\varepsilon) + \frac{i\pi}{2}\operatorname{sgn}(\lambda) + O(\varepsilon) \tag{3.6}$$

where γ is the Euler constant and $\operatorname{sgn}(x) = x/|x|$ is the sign function.

From (3.5)-(3.6), we get

$$\text{finite part } I_p = -\frac{(i\lambda)^{p-1}}{(p-1)!}\left[\ln|\lambda| + \ln e^\gamma - \frac{i\pi}{2}\operatorname{sgn}(\lambda)\right] \tag{3.7}$$

but $\ln(e^\gamma)$ will not appear in the final result as it cancels together with the $\ln\varepsilon$ terms. Using (3.7) and (3.3)-(3.4), we get all the integrals (3.1).

For example, we calculate integrals that escape the method of § 2.3:

$$\int_0^\infty j_0(at)j_0(bt)j_0(ct)\, dt = \frac{\pi}{2\sup(a,b,c)} \text{ outside the triangle}$$

$$= \frac{\pi}{8abc}\Lambda(\sqrt{a},\sqrt{b},\sqrt{c}), \qquad |a-b|<c<a+b$$

where $\Lambda(\sqrt{x},\sqrt{y},\sqrt{z}) = x^2+y^2+z^2-2xy-2yz-2zx$.

$$\int_0^\infty j_1(at)j_1(bt)j_0(ct)\, dt = 0 \quad \text{if } c>a+b$$

$$= \frac{\pi}{96a^2b^2c}[c-(a+b)]^2\{c^2+2c(a+b)-3(a-b)^2\},$$

$$|a-b|<c<a+b$$

$$= \frac{\pi}{3!}\frac{\inf(a,b)}{[\sup(a,b)]^2}, \qquad c<|a-b|$$

to be checked with the result in [1].

Both integrals are for $n+l_1+l_2+l_3$ even but $l_3+l_1-l_2+n-2$ negative. Note that a nonzero contribution appears outside the triangle. For odd $n+l_1+l_2+l_3$ we calculate

$$4abc\int_0^\infty tj_0(at)j_0(bt)j_0(ct)\,dt$$
$$= c\ln\left|\frac{c^2-(a-b)^2}{c^2-(a+b)^2}\right| + a\ln\left|\frac{a^2-(b-c)^2}{a^2-(b+c)^2}\right| + b\ln\left|\frac{b^2-(c-a)^2}{b^2-(c+a)^2}\right|,$$

which is symmetrical in a, b, c.

More generally, using expansion (3.3), we get for integrals (3.1) the final result:

$$\begin{aligned} A_{l_1l_2l_3n} = (-)^q\pi[&F_{l_1l_2l_3n}(a,b,c)\ \mathrm{sgn}\,(c+a+b)\\ &+(-)^{l_2}F_{l_1l_2l_3n}(a,-b,c)\ \mathrm{sgn}\,(c+a-b)\\ &+(-)^{l_1}F_{l_1l_2l_3n}(-a,b,c)\ \mathrm{sgn}\,(c-a+b)\\ &+(-)^{l_1+l_2}F_{l_1l_2l_3n}(-a,-b,c)\ \mathrm{sgn}\,(c-a-b)] \end{aligned} \tag{3.8}$$

when $l_1+l_2+l_3+n=2q$ is even ($\mathrm{sgn}\,(x)$ is again the sign function), and

$$\begin{aligned} A_{l_1l_2l_3n} = (-)^{q'+1}2[&F_{l_1l_2l_3n}(a,b,c)\ln|c+a+b|\\ &+(-)^{l_2}F_{l_1l_2l_3n}(a,-b,c)\ln|c+a-b|\\ &+(-)^{l_1}F_{l_1l_2l_3n}(-a,b,c)\ln|c-a+b|\\ &+(-)^{l_1+l_2}F_{l_1l_2l_3n}(-a,-b,+c)\ln|c-(a+b)|] \end{aligned} \tag{3.9}$$

when $l_1+l_2+l_3+n=2q'-1$ is odd. The function F includes all the combinatory coefficients of expansion (3.3):

$$\begin{aligned} F_{l_1l_2l_3n}(a,b,c) = \sum_{\{m_i\}} &\frac{(-)^{m_1+m_2+m_3}}{(2a)^{m_1+1}(2b)^{m_2+1}(2c)^{m_3+1}}\prod_{i=1}^{3}\frac{(l_i+m_i)!}{(l_i-m_i)!\,m_i!}\\ &\times\frac{(c+a+b)^{m_1+m_2+m_3+2-n}}{(m_1+m_2+m_3+2-n)!} \end{aligned} \tag{3.10}$$

TABLE 2

Expression of the integrals with three spherical Bessel functions in terms of rational functions of a, b, c and of the singularity.

$$\int_0^\infty t^n j_{l_1}(at)j_{l_2}(bt)j_{l_3}(ct)\,dt$$

$$= (-)^q\pi[F_{l_1l_2l_3n}(a,b,c)\ \mathrm{sgn}\,(c+a+b)+(-)^{l_2}F_{l_1l_2l_3n}(a,-b,c)\ \mathrm{sgn}\,(c+a-b)$$
$$+(-)^{l_1}F_{l_1l_2l_3n}(-a,b,c)\ \mathrm{sgn}\,(c-a+b)+(-)^{l_1+l_2}F_{l_1l_2l_3n}(-a,-b,c)\ \mathrm{sgn}\,(c-a-b)]$$
$$\text{if } n+l_1+l_2+l_3=2q$$

$$= (-)^{q'+1}2[F_{l_1l_2l_3n}(a,b,c)\ln|c+a+b|$$
$$+(-)^{l_2}F_{l_1l_2l_3n}(a,-b,c)\ln|c+a-b|+(-)^{l_1}F_{l_1l_2l_3}(a,b,c)\ln|c-a+b|$$
$$+(-)^{l_1+l_2}F_{l_1l_2l_3n}(-a,-b,c)\ln|c-a-b|]$$
$$\text{if } n+l_1+l_2+l_3=2q'-1$$

with

$$\mathrm{sgn}\,(x)=\frac{x}{|x|},$$

$$F_{l_1l_2l_3n}(a,b,c)=\sum_{\{m_i\}}\frac{(-)^{m_1+m_2+m_3}}{(2a)^{m_1+1}(2b)^{m_2+1}(2c)^{m_3+1}}\prod_{i=1}^{3}\frac{(l_i+m_i)!}{(l_i-m_i)!\,m_i!}\,\frac{(c+a+b)^{m_1+m_2+m_3+2-n}}{(m_1+m_2+m_3+2-n)!}.$$

Results (3.8), (3.9) are not expressed in terms of special functions as in the previous section. Nevertheless, they are not too difficult to handle for practical purposes, both because functions $F_{l_1 l_2 l_3 n}$ are simple rational functions and because the different behavior when a, b, c form or do not form a triangle appears through a unique singular multiplicative factor, i.e., the logarithmic term when $n+l_1+l_2+l_3$ is odd, the sign function when it is even.

Note once again that it is by no means necessary to assume that $n+l_1+l_2+l_3$ is even, nor that $n \geqq 0$ as the proof holds for any integer n such that $2-n \geqq 0$ and $n+l_1+l_2+l_3 \geqq 0$. The results of this section are summarized in Table 2.

Appendix A. Solution when $n=0$, $l_1=0$, $l_2=l_3=l$. We rewrite, using integration by parts,

$$I=\int_0^\infty t^{-3/2} J_{1/2}(at) J_\nu(bt) J_\nu(ct)\, dt \qquad (\nu = l+\tfrac{1}{2})$$

as

$$\begin{aligned} 2\nu I &= a\int_0^\infty t^{-1/2} J_{3/2}(at) J_\nu(bt) J_\nu(ct)\, dt \\ &\quad + \int_0^\infty t^{-1/2} J_{1/2}(at)[bJ_{\nu-1}(bt)J_\nu(ct) + cJ_\nu(bt)J_{\nu-1}(ct)]\, dt \\ &= -a \operatorname{Re} \mathcal{J}^{0\ 0}_{\nu\ 3/2}(b,c,a) + b \operatorname{Re} \mathcal{J}^{\nu-1-1/2\ 0}_{1/2\ \nu}(a,b,c) \\ &\quad + c \operatorname{Re} \mathcal{J}^{\nu-1-1/2\ 0}_{1/2\ \nu}(a,c,b). \end{aligned}$$

Thus

$$(2l+1)I = -a \operatorname{Re} \mathcal{J}^{0\ 0}_{l+1/2\ 3/2}(b,c,a) + b \operatorname{Re} \mathcal{J}^{l-1\ 0}_{1/2\ l+1/2}(a,b,c) + \operatorname{Re} c\mathcal{J}^{l-1\ 0}_{1/2\ l+1/2}(a,c,b)$$

where the dependence on parameters a, b, c is made explicit. Now, from (2.6) and (2.13), we get easily the (known) result when a, b, c do not form a triangle [8]. We have

$$\int_0^\infty j_0(at) j_l(bt) j_l(ct)\, dt = \left(\frac{\pi}{2}\right)^{3/2} \frac{1}{\sqrt{abc}} I$$

(A1)

$$\begin{aligned} &= 0 && \text{if } a > (b+c) \\ &= (2l+1)^{-1} \frac{\pi}{2} \left(\frac{b}{c}\right)^l \frac{1}{c} && \text{if } c > a+b \\ &= (2l+1)^{-1} \frac{\pi}{2} \left(\frac{c}{b}\right)^l \frac{1}{b} && \text{if } b > a+c. \end{aligned}$$

In the triangle case $|a-b| < c < a+b$, the result is a more complicated sum, namely

$$\begin{aligned} (2l+1)I = \Bigg\{ & -a \operatorname{Re} \mathcal{J}^{0\ 0}_{l+1/2\ 3/2}(b,c,a) \\ & + \sum_{m=0}^{l-1} (-)^m C^m_{l-1} \left[\left(\frac{b}{c}\right)^{l-1-m} \left(\frac{a}{c}\right)^m b \operatorname{Re} \mathcal{J}^{0\ 0}_{m+1/2\ 3/2}(a,b,c) + b \leftrightarrow c \right] \Bigg\}. \end{aligned}$$

Now, from (2.6)

$$\operatorname{Re} \mathcal{J}^0_{m+1/2\ 3/2}{}^0(a, b, c) = \frac{1}{\sqrt{2\pi}} \sqrt{\frac{ab}{c}} \cdot \frac{1}{c} P_m^{-1}(\cos \varphi_c) \sin \varphi_c,$$

$$\operatorname{Re} \mathcal{J}^0_{l+1/2\ 3/2}{}^0(b, c, a) = \frac{1}{\sqrt{2\pi}} \sqrt{\frac{cb}{a}} \cdot \frac{1}{a} P_l^{-1}(\cos \varphi_a) \sin \varphi_a,$$

(A2)
$$\int_0^\infty j_0(at) j_l(bt) j_l(ct)\, dt = (2l+1)^{-1} \frac{\pi}{4} \left\{ -\frac{\sin \varphi_a}{a} P_l^{-1}(\cos \varphi_a) + \sum_{m=0}^{l-1} (-)^m C_{l-1}^m \times \left[\left(\frac{b}{c}\right)^{l-m} \left(\frac{a}{c}\right)^m \frac{\sin \varphi_c}{c} P_m^{-1}(\cos \varphi_c) + b \leftrightarrow c \right] \right\}.$$

Note the functional relation

$$\mathcal{J}^{l-1\ 0}_{3/2\ l+1/2}(a, b, c) \equiv \mathcal{J}^0_{l+1/2\ 3/2}{}^0(b, c, a)$$

where the sum of $l-1$ Legendre polynomials in variable $\cos \varphi_c$ is expressed as a unique Legendre polynomial in $\cos \varphi_a$.

Appendix B. The proof goes as follows:

$$\mathcal{Q}_l^m(Z) = (Z^2-1)^{m/2} \frac{d^m}{dZ^m} \mathcal{Q}_l(Z)$$

with

$$\mathcal{Q}_l(Z) = \left\{ \frac{1}{2} \mathcal{P}_l(Z) \ln \frac{Z+1}{Z-1} + W_{l-1}(Z) \right\}$$

where $\mathcal{P}_l(Z)$ is the usual Legendre polynomial and $W_{l-1}(Z)$ is a polynomial of degree $l-1$ in Z. Thus

$$\text{for } m > l \quad \frac{d^m}{dZ^m} W_{l-1}(Z) = \frac{d^m}{dZ^m} \mathcal{P}_l(Z) = 0,$$

which implies that there is no logarithmic term in $\mathcal{Q}_l^m(Z)$. Furthermore,

$$\frac{d^p}{dZ^p} \ln \left\{ \frac{(Z+1)}{(Z-1)} \right\} = \frac{V_{p-1}(Z)}{(Z^2-1)^p}$$

where $V_{p-1}(Z)$ is a polynomial of degree $p-1$. The Leibniz formula yields

$$(Z^2-1)^{m/2} \mathcal{Q}_l^m(Z) = \frac{1}{2} (Z^2-1)^m \sum_{p=0}^{l} \frac{d^p \mathcal{P}_l(Z)}{dZ^p} \times \frac{V_{m-p-1}(Z)}{(Z^2-1)^{m-p}} C_m^p$$

$$= \frac{1}{2} \sum_{p=0}^{l} \frac{d^p \mathcal{P}_l(Z)}{dZ^p} \times V_{m-p-1}(Z) C_m^p (Z^2-1)^p$$

$$= \frac{1}{2} \sum_{p=0}^{l} (Z^2-1)^{p/2} \mathcal{P}_l^p(Z) \times V_{m-p-1}(Z) C_m^p.$$

Since $(Z^2-1)^{p/2} \mathcal{P}_l^p(Z)$ is a polynomial of degree $l+p$, $(Z^2-1)^{m/2} \mathcal{Q}_l^m(Z)$ is a polynomial of degree $l+m-1$.

q-EXTENSIONS OF CLAUSEN'S FORMULA AND OF THE INEQUALITIES USED BY DE BRANGES IN HIS PROOF OF THE BIEBERBACH, ROBERTSON, AND MILIN CONJECTURES*

GEORGE GASPER†

Abstract. A q-extension of the terminating form of Clausen's ${}_3F_2$ series representation for the square of a ${}_2F_1(a,b;a+b+1/2;z)$ series is derived. It is used to prove the nonnegativity of certain basic hypergeometric series and to derive q-extensions of the inequalities and differential equations de Branges used in his proof of the Bieberbach, Robertson, and Milin conjectures.

Key words. Clausen's formula, basic hypergeometric series, nonnegative polynomials, inequalities, q-difference equations, Bieberbach, Robertson, and Milin conjectures

AMS(MOS) subject classifications. primary 33A99; secondary 30C50

1. Introduction.

In 1828 Clausen [15] used second- and third-order differential equations to prove the formula

$$\left\{{}_2F_1\left[\begin{matrix}a,b\\a+b+1/2\end{matrix};z\right]\right\}^2={}_3F_2\left[\begin{matrix}2a,2b,a+b\\2a+2b,a+b+1/2\end{matrix};z\right],\qquad |z|<1. \tag{1.1}$$

The above ${}_2F_1$ and ${}_3F_2$ are special cases of ${}_rF_s$ hypergeometric series defined by

$${}_rF_s\left[\begin{matrix}a_1,\cdots,a_r\\b_1,\cdots,b_s\end{matrix};z\right]=\sum_{n=0}^{\infty}\frac{(a_1)_n\cdots(a_r)_n}{n!(b_1)_n\cdots(b_s)_n}z^n,$$

where $(a)_n$ is the shifted factorial defined by

$$(a)_n=\prod_{k=0}^{n-1}(a+k).$$

Almost 150 years later, Clausen's formula was used in Askey and Gasper [4] to prove that

$${}_3F_2\left[\begin{matrix}-n,n+\alpha+2,(\alpha+1)/2\\\alpha+1,(\alpha+3)/2\end{matrix};\frac{1-x}{2}\right]\geq 0,\qquad -1\leq x\leq 1, \tag{1.2}$$

when $\alpha>-2$ and $n=0,1,2,\cdots$, and then this inequality was used to prove the positivity of certain important kernels involving sums of Jacobi polynomials (also see Askey [3, Lecture 8] and the extensions in Gasper [18], [19]). In 1984 the special cases $\alpha=2,4,6,\cdots$ of (1.2) were used by de Branges [11], [12] to complete the last part of his proof of the Milin [30, p. 55] conjecture that if f is in the class S of functions

$$f(z)=z+c_2z^2+c_3z^3+\cdots$$

that are analytic and univalent in the unit disk $|z|<1$ and if

$$\log\frac{f(z)}{z}=2\sum_{k=1}^{\infty}\gamma_kz^k,$$

then

$$\sum_{k=1}^{n} k(n+1-k)|\gamma_k|^2 \leq \sum_{k=1}^{n} \frac{n+1-k}{k}, \qquad n = 1, 2, \cdots. \tag{1.3}$$

It was already known that Milin's conjecture implied Robertson's [33] conjecture that if f is an odd function in S, then

$$\sum_{k=1}^{n} |c_{2k-1}|^2 \leq n, \qquad n = 2, 3, \cdots, \tag{1.4}$$

and that Robertson's conjecture implied Bieberbach's [9] conjecture that if f is in S, then

$$|c_n| \leq n, \qquad n = 2, 3, \cdots. \tag{1.5}$$

Since ${}_rF_s$ series are limit cases of ${}_r\phi_s$ basic hypergeometric series [25], [38]

$${}_r\phi_s\left[\begin{matrix} a_1, \cdots, a_r \\ b_1, \cdots, b_s \end{matrix}; q, z\right] = \sum_{n=0}^{\infty} \frac{(a_1, \cdots, a_r; q)_n}{(q, b_1, \cdots, b_s; q)_n} [(-1)^n q^{\binom{n}{2}}]^{1+s-r} z^n, \tag{1.6}$$

where $\binom{n}{2} = n(n-1)/2$,

$$(a_1, a_2, \cdots, a_r; q)_n = (a_1; q)_n (a_2; q)_n \cdots (a_r; q)_n$$

and $(a; q)_n$ is the q-shifted factorial defined by

$$(a; q)_n = \prod_{k=0}^{n-1} (1 - aq^k),$$

it is natural to search for q-extensions (also called q-analogues and, in the terminology of [10], quantum generalizations) of Clausen's formula (1.1), the inequalities (1.2), and of the other parts of de Branges' proof of the Milin conjecture.

In this paper we will derive a q-extension of Clausen's formula (1.1) for terminating series and various q-extensions of the inequalities (1.2)and of some other inequalities. In addition, since the existence of decreasing solutions of de Branges' differential equations

$$\sigma_n(t) + \frac{t}{n}\sigma_n'(t) = \sigma_{n+1}(t) - \frac{t}{n+1}\sigma_{n+1}'(t), \qquad 1 \leq t < \infty, \tag{1.7}$$

played a crucial role in his proof of the Milin conjecture, we derive q-extensions of (1.7) and show that they have solutions which have negative first q-derivatives. Some prospects for further research are pointed out.

2. q-Extensions of Clausen's formula (1.1). In 1940 Jackson [27] derived a general theorem about solutions of q^θ equations, where q^θ is the operator $\exp((\log q) \cdot x\frac{d}{dx})$, which gives [28, p. 171] the product formula

$$\begin{aligned} &{}_2\phi_1\left[\begin{matrix} q^{2a}, q^{2b} \\ q^{2a+2b+1} \end{matrix}; q^2, z\right] {}_2\phi_1\left[\begin{matrix} q^{2a}, q^{2b} \\ q^{2a+2b+1} \end{matrix}; q^2, qz\right] \\ &\quad = {}_4\phi_3\left[\begin{matrix} q^{2a}, q^{2b}, q^{a+b}, -q^{a+b} \\ q^{2a+2b}, q^{a+b+1/2}, -q^{a+b+1/2} \end{matrix}; q, z\right], \qquad |z| < 1, |q| < 1. \end{aligned} \tag{2.1}$$

Since

$$\lim_{q\uparrow 1}\frac{(q^a;q)_n}{(1-q)^n}=(a)_n,\qquad \lim_{q\uparrow 1}(-q^a;q)_n=2^n, \tag{2.2}$$

Clausen's formula (1.1) is a limit case of Jackson's product formula (2.1). However, unlike in (1.1), the left side of (2.1) is not a square and so (2.1) cannot be used to write sums of basic hypergeometric series as sums of squares of basic hypergeometric series as was done in [4], [18] for hypergeometric series to prove the nonnegativity of certain sums of hypergeometric series. Also, by considering negative integer values of a, we find that the series on the right side of (2.1) can assume negative values. It is natural to consider replacing the left side of (1.1) by

$$\left\{{}_2\phi_1\left[\begin{matrix}q^a,q^b\\q^{a+b+1/2}\end{matrix};q,z\right]\right\}^2 \tag{2.3}$$

but, unfortunately, this square of a ${}_2\phi_1$ series does not equal a basic hypergeometric series of the type in (1.6) as can be easily seen by computing the coefficient of z^2 in its power series expansion. Thus, in order to find a basic hypergeometric series which is the square of a basic hypergeometric series we are forced to look for another q-extension of (1.1).

One way to proceed is to recall that in [4] Clausen's formula was used to write (1.2) as a sum of squares of ultraspherical polynomials

$$\begin{aligned}C_n^\lambda(x)&=\frac{(2\lambda)_n}{n!}{}_2F_1\left[\begin{matrix}-n,n+2\lambda\\\lambda+1/2\end{matrix};\frac{1-x}{2}\right]\\&=\frac{(\lambda)_n}{n!}e^{in\theta}{}_2F_1\left[\begin{matrix}-n,\lambda\\1-n-\lambda\end{matrix};e^{-2i\theta}\right],\qquad x=\cos\theta,\end{aligned} \tag{2.4}$$

and to recall that in his work [34]–[36] during the 1890's on the now famous Rogers–Ramanujan identities, Rogers [36] considered the q-extension

$$C_n(x;\beta\mid q)=\frac{(\beta;q)_n}{(q;q)_n}e^{in\theta}{}_2\phi_1\left[\begin{matrix}q^{-n},\beta\\q^{1-n}\beta^{-1}\end{matrix};q,q\beta^{-1}e^{-2i\theta}\right],\quad x=\cos\theta, \tag{2.5}$$

of (2.4). Askey and Ismail [6] showed that these polynomials were orthogonal on $(-1,1)$ with respect to an absolutely continuous weight function and called them the continuous q-ultraspherical polynomials to distinguish them from the (discrete) q-ultraspherical polynomials

$$C_n^\lambda(x;q)=\frac{(q^{2\lambda};q)_n}{(q;q)_n}{}_2\phi_1\left[\begin{matrix}q^{-n},q^{n+2\lambda}\\q^{\lambda+1/2}\end{matrix};q,qx\right] \tag{2.6}$$

which are orthogonal [2, (3.8)] with respect to a discrete measure with point masses at $x=q^k$, $k=0,1,2,\cdots$. They also showed that

$$C_n^\lambda(x)=\lim_{q\uparrow 1}C_n(x;q^\lambda\mid q) \tag{2.7}$$

and

$$C_n(\cos\theta;\beta\mid q)=\frac{(\beta^2;q)_n}{\beta^{n/2}(q;q)_n}{}_4\phi_3\left[\begin{matrix}q^{-n},\beta^2q^n,\beta^{1/2}e^{i\theta},\beta^{1/2}e^{-i\theta}\\\beta q^{1/2},-\beta q^{1/2},-\beta\end{matrix};q,q\right]. \tag{2.8}$$

In 1895 Rogers [36, p. 29] employed an induction argument to prove the linearization formula

$$C_m(x;\beta \mid q)C_n(x;\beta \mid q) = \sum_{k=0}^{\min(m,n)} \frac{(q;q)_{m+n-2k}(\beta;q)_{m-k}(\beta;q)_{n-k}}{(q;q)_k(q;q)_{m-k}(q;q)_{n-k}} \cdot \frac{(\beta;q)_k(\beta^2;q)_{m+n-k}(1-\beta q^{m+n-2k})}{(\beta q;q)_{m+n-k}(\beta^2;q)_{m+n-2k}(1-\beta)} C_{m+n-2k}(x;\beta \mid q). \tag{2.9}$$

A simple computational proof of (2.9) was given by the author in [20]. For additional proofs, see Bressoud [14] and Rahman [31]. Note that if we use (2.5) or (2.8) on the right side of (2.9), we get a double sum that does not reduce to a single sum when $n = m$, even after changing the order of summation and trying to apply known summation formulas. This is also true when (2.8) is replaced by the formulas obtained by applying Sears' transformation formula [37, (8.3)]

$${}_4\phi_3\left[\begin{matrix} a, b, c, q^{-n} \\ d, e, f \end{matrix}; q, q\right] = \frac{(de/ab, df/ab; q)_n}{(e, f; q)_n} \left(\frac{ab}{d}\right)^n {}_4\phi_3\left[\begin{matrix} d/a, d/b, c, q^{-n} \\ d, de/ab, df/ab \end{matrix}; q, q\right] \tag{2.10}$$

where $\text{def} = abcq^{1-n}$ and $n = 0, 1, 2, \cdots$, to the ${}_4\phi_3$ series in (2.8).

The right side of (2.8) suggests that we should still look at expansions involving $e^{i\theta}$ and $e^{-i\theta}$ among the parameters. Since the polynomials on the right side of (2.9) are of even degree in x when $n = m$, we could try to use the expansion [7, p. 41]

$$C_{2n}(\cos\theta;\beta \mid q) = \frac{(\beta^2;q)_{2n}(-q, -q^{1/2};q)_n}{(q;q)_{2n}(-\beta, -\beta q^{1/2};q)_n} q^{-n/2} \cdot {}_4\phi_3\left[\begin{matrix} q^{-n}, \beta q^n, q^{1/2}e^{2i\theta}, q^{1/2}e^{-2i\theta} \\ \beta q^{1/2}, -q^{1/2}, -q \end{matrix}; q, q\right], \tag{2.11}$$

in which the ${}_4\phi_3$ series terminates after $n+1$ terms, even though $C_{2n}(x;\beta|q)$ is a polynomial of degree $2n$ in x. But, by using (2.11) in the right side of (2.9) and changing the order of summation we get a sum of terminating very well poised ${}_8\phi_7$ series that are not balanced and hence not summable by Jackson's formula [38, (3.3.1.1)].

However, if we apply (2.10) to (2.11) to get

$$C_{2n}(\cos\theta;\beta \mid q) = \frac{(\beta^2;q)_{2n}}{\beta^n(q;q)_{2n}} {}_4\phi_3\left[\begin{matrix} q^{-n}, \beta q^n, \beta e^{2i\theta}, \beta e^{-2i\theta} \\ \beta q^{1/2}, -\beta q^{1/2}, -\beta \end{matrix}; q, q\right] \tag{2.12}$$

and use (2.12) in the right side of (2.9) we obtain

$$\begin{aligned} &\{C_n(\cos\theta;\beta \mid q)\}^2 \\ &\quad = \sum_{k=0}^{n} \frac{(\beta, \beta; q)_{n-k}(\beta;q)_k(\beta^2;q)_{2n-k}(1-\beta q^{2n-2k})}{(q, q; q)_{n-k}(q;q)_k(\beta q;q)_{2n-k}(1-\beta)} \\ &\quad\quad \cdot \beta^{k-n} \sum_{j=0}^{n-k} \frac{(q^{k-n}, \beta q^{n-k}, \beta e^{2i\theta}, \beta e^{-2i\theta}; q)_j}{(q, \beta q^{1/2}, -\beta q^{1/2}, -\beta; q)_j} q^j \\ &\quad = \frac{(\beta^2;q)_{2n}(\beta, \beta; q)_n}{\beta^n(\beta;q)_{2n}(q, q; q)_n} \sum_{j=0}^{n} \frac{(q^{-n}, \beta q^n, \beta e^{2i\theta}, \beta e^{-2i\theta}; q)_j}{(q, \beta q^{1/2}, -\beta q^{1/2}, -\beta; q)_j} q^j \\ &\quad\quad \cdot {}_6\phi_5\left[\begin{matrix} \beta^{-1}q^{-2n}, \beta^{-1/2}q^{1-n}, -\beta^{-1/2}q^{1-n}, \beta, q^{j-n}, q^{-n} \\ \beta^{-1/2}q^{-n}, -\beta^{-1/2}q^{-n}, \beta^{-2}q^{1-2n}, \beta^{-1}q^{1-n-j}, \beta^{-1}q^{1-n} \end{matrix}; q, \beta^{-2}q^{1-j}\right] \end{aligned} \tag{2.13}$$

in which, fortunately, the ${}_6\phi_5$ series is summable by the summation formula [38, (3.3.1.4)]

$$(2.14)\qquad {}_6\phi_5\left[\begin{matrix}a, qa^{1/2}, -qa^{1/2}, b, c, q^{-n}\\ a^{1/2}, -a^{1/2}, aq/b, aq/c, aq^{n+1}\end{matrix}; q, \frac{aq^{n+1}}{bc}\right] = \frac{(aq, aq/bc; q)_n}{(aq/b, aq/c; q)_n}, \qquad n = 0, 1, 2, \cdots,$$

where four misprints have been corrected. Using (2.14) to sum the ${}_6\phi_5$ series in (2.13) gives

$$(2.15)\qquad \{C_n(\cos\theta; \beta \mid q)\}^2 = \frac{(\beta^2, \beta^2; q)_n}{(q, q; q)_n}\beta^{-n}{}_5\phi_4\left[\begin{matrix}q^{-n}, \beta^2 q^n, \beta, \beta e^{2i\theta}, \beta e^{-2i\theta}\\ \beta^2, \beta q^{1/2}, -\beta q^{1/2}, -\beta\end{matrix}; q, q\right]$$

and hence, by (2.8), we have the following q-extension of the terminating case of Clausen's formula (1.1)

(2.16)

$$\left\{{}_4\phi_3\left[\begin{matrix}q^{-n}, \beta^2 q^n, \beta^{1/2}e^{i\theta}, \beta^{1/2}e^{-i\theta}\\ \beta q^{1/2}, -\beta q^{1/2}, -\beta\end{matrix}; q, q\right]\right\}^2 = {}_5\phi_4\left[\begin{matrix}q^{-n}, \beta^2 q^n, \beta, \beta e^{2i\theta}, \beta e^{-2i\theta}\\ \beta^2, \beta q^{1/2}, -\beta q^{1/2}, -\beta\end{matrix}; q, q\right],$$

where $n = 0, 1, 2, \cdots$. This formula was derived independently by Mizan Rahman. He and the author independently observed that it can be derived by using (2.8) inside the Rahman and Verma [32, (1.20)] integral representation for the product of two continuous q-ultraspherical polynomials and then integrating termwise to get (2.15) and hence (2.16).

By setting $a = \beta^{1/2}e^{i\theta}$, $b = \beta^{1/2}e^{-i\theta}$ and $z = \beta q^n$, formula (2.16) can be written in the form

(2.17)

$$\left\{{}_4\phi_3\left[\begin{matrix}a, b, abz, ab/z\\ abq^{1/2}, -abq^{1/2}, -ab\end{matrix}; q, q\right]\right\}^2 = {}_5\phi_4\left[\begin{matrix}a^2, b^2, ab, abz, ab/z\\ a^2b^2, abq^{1/2}, -abq^{1/2}, -ab\end{matrix}; q, q\right],$$

which holds when the series on both sides terminate. For, by (2.16), (2.17) holds when abz or ab/z is a negative integer power of q and, if a or b is a negative integer power of q, then both sides of (2.17) are rational functions of z which are equal for $z = abq^n$, $n = 0, 1, 2, \cdots$, and hence must be equal for all (complex) values of z. Notice that by replacing a, b, z in (2.17) by q^a, q^b, $e^{i\theta}$ with $x = \cos\theta$ and letting $q \uparrow 1$, we get Clausen's formula (1.1) with $z = (1 - x)/2$ for the terminating case when a or b is a negative integer.

To see that (2.17) does not hold in the nonterminating case, it suffices to observe that if, e.g., (2.17) held for $b = 0$, then it would follow fromthe q-binomial theorem [38, (3.2.2.11)] that $((aq; q)_\infty)^2 = (a^2q; q)_\infty(q; q)_\infty$, which is clearly false for, e.g., $a = q^{-1/2}$. A nonterminating q-extension of (1.1) containing the square of an ${}_8\phi_7$ series and the sum of two ${}_5\phi_4$ series will be given in [26].

Note that, in addition to the formulas that follow when (2.10) is applied to the ${}_4\phi_3$ in (2.17), we can apply the quadratic transformation formula [7, (3.2)]

$$(2.18)\qquad {}_4\phi_3\left[\begin{matrix}a^2, b^2q, c, d\\ abq, -abq, -cd\end{matrix}; q, q\right] = {}_4\phi_3\left[\begin{matrix}a^2, b^2q, c^2, d^2\\ a^2b^2q^2, -cd, -cdq\end{matrix}; q^2, q^2\right],$$

which holds when both series terminate, to obtain that (2.17) is equivalent to the formula

$$(2.19)\qquad \left\{{}_4\phi_3\left[\begin{matrix}a^2, b^2, abz, ab/z\\ a^2b^2q, -ab, -abq\end{matrix}; q^2, q^2\right]\right\}^2 = {}_5\phi_4\left[\begin{matrix}a^2, b^2, ab, abz, ab/z\\ a^2b^2, abq^{1/2}, -abq^{1/2}, -ab\end{matrix}; q, q\right]$$

when both series terminate. Also, if we replace a, b, z, q in (2.17) by their squares and apply (2.18), we obtain that

(2.20)
$$\left\{{}_4\phi_3\left[\begin{matrix}a^2, b^2, abz, ab/z\\ abq^{1/2}, -abq^{1/2}, -a^2b^2\end{matrix}; q, q\right]\right\}^2 = {}_5\phi_4\left[\begin{matrix}a^4, b^4, a^2b^2, a^2b^2z^2, a^2b^2/z^2\\ a^4b^4, a^2b^2q, -a^2b^2q, -a^2b^2\end{matrix}; q^2, q^2\right]$$

when both series terminate.

Another proof of (2.17) can be given by observing that from the product formulas (2.8) or (2.10) in Gasper and Rahman [24] it follows that if a, b, abz, or ab/z is a negative integer power of q, then

(2.21)
$$\begin{aligned}
&\left\{{}_4\phi_3\left[\begin{matrix}abz, ab/z, a, b\\ -ab, abq^{1/2}, -abq^{1/2}\end{matrix}; q, q\right]\right\}^2\\
&= \sum_{r\geq 0}\sum_{s\geq 0}\frac{(abz, ab/z; q)_{r+s}(a, b, -a, -b; q)_r}{(-ab, -ab; q)_{r+s}(q, -q, abq^{1/2}, -abq^{1/2}; q)_r}\\
&\quad\cdot\frac{(a, b, -a, -b; q)_s}{(q, -1, abq^{1/2}, -abq^{1/2}; q)_s}\,\frac{1+q^{r-s}}{1+q^s}\,q^{r+s}\\
&= \sum_{k\geq 0}\frac{(abz, ab/z, a, -a, b, -b; q)_k}{(q, -1, abq^{1/2}, -abq^{1/2}, -ab, -ab; q)_k}\,q^k\\
&\quad\cdot\sum_{s=0}^{k}\frac{(q^{-k}, -q^{-k}, a, -a, b, -b, a^{-1}b^{-1}q^{1/2-k}, -a^{-1}b^{-1}q^{1/2-k}; q)_s}{(q, -q, a^{-1}q^{1-k}, -a^{-1}q^{1-k}, b^{-1}q^{1-k}, -b^{-1}q^{1-k}, abq^{1/2}, -abq^{1/2}; q)_s}\,\frac{1+q^{2s-k}}{1+q^{-k}}\,q^{2s}\\
&= \sum_{k\geq 0}\frac{(abz, ab/z, a, b, -a, -b; q)_k}{(q, -1, abq^{1/2}, -abq^{1/2}, -ab, -ab; q)_k}\,q^k\\
&\quad\cdot{}_5\phi_4\left[\begin{matrix}q^{-2k}, -q^{2-k}, a^2, b^2, a^{-2}b^{-2}q^{1-2k}\\ -q^{-k}, a^{-2}q^{2-2k}, b^{-2}q^{2-2k}, a^2b^2q\end{matrix}; q^2, q^2\right]\\
&= {}_5\phi_4\left[\begin{matrix}a^2, b^2, ab, abz, ab/z\\ a^2b^2, abq^{1/2}, abq^{1/2}, -ab\end{matrix}; q, q\right],
\end{aligned}$$

since it can be shown that

(2.22)
$$\begin{aligned}
&{}_5\phi_4\left[q^{-2k}, -q^{2-k}, a^2, b^2, a^{-2}b^{-2}q^{1-2k} - q^{-k}, a^{-2}q^{2-2k}, b^{-2}q^{2-2k}, a^2b^2q; q^2, q^2\right]\\
&\qquad = \frac{(-1, a^2, b^2, ab, -ab; q)_k}{(a^2b^2, a, -a, b, -b; q)_k}, \qquad k = 0, 1, 2, \cdots,
\end{aligned}$$

by using the case $d = eq^{1/2} = (aq)^{1/2}$ of Jackson's summation formula [38, (3.3.1.1)]. A slightly more direct proof of (2.17) can be given by starting with the expansion [24, (2.2)] used to derive [24, (2.8)].

3. q-Extensions of (1.2). At the last step in his proof of the Milin conjecture, de Branges [12] used the fact that for any positive integer r the functions

(3.1)
$$\sigma_n(t) = \frac{n\Gamma(n+r+2)}{\Gamma(2n+2)\Gamma(r+1-n)}\int_t^\infty {}_3F_2\left[\begin{matrix}n-r, n+r+2, n+1/2\\ 2n+1, n+3/2\end{matrix}; s^{-1}\right]s^{-n-1}ds$$

when $n = 1, \cdots, r$ and $\sigma_n(t) = 0$ when $n > r$, satisfy the differential equations (1.7) and

$$(3.2)\quad \sigma_n'(t)) = -\frac{n\Gamma(n+r+2)t^{-n-1}}{\Gamma(2n+2)\Gamma(r+1-n))}{}_3F_2\left[\begin{matrix} n-r, n+r+2, n+1/2 \\ 2n+1, n+3/2 \end{matrix}; t^{-1}\right] \le 0$$

for $t \ge 1$ when $n = 1, \cdots, r$. In [13], to estimate the coefficients of powers of unbounded Riemann mapping functions, he used the fact that the more general functions

(3.3)

$$\sigma_n(t) = \frac{\Gamma(n+1)\Gamma(n+r+2\nu+2\lambda+1)4^{-n}t^{2\nu}}{\Gamma(n+\nu+1)\Gamma(n+2\nu)\Gamma(n+\nu+\lambda+1)\Gamma(r+1-n)} \cdot \int_t^\infty {}_3F_2\left[\begin{matrix} n-r, n+r+2\nu+2\lambda+1, n+\nu+1/2 \\ 2n+2\nu+1, n+\nu+\lambda+1 \end{matrix}; s^{-1}\right] s^{-n-2\nu-1}ds$$

when $n = 1, \cdots, r$ and $\sigma_n(t) = 0$ when $n > r$, satisfy the differential equations

$$(3.4)\quad \frac{n}{n+2\nu}\sigma_n(t) + \frac{t\sigma_n'(t)}{n+2\nu} = \frac{n+2\nu+1}{n+1}\sigma_{n+1}(t) - \frac{t\sigma_{n+1}'(t)}{n+1}$$

and

(3.5)

$$\frac{d}{dt}[t^{-2\nu}\sigma_n(t)] = -\frac{\Gamma(n+1)\Gamma(n+r+2\nu+2\lambda+1)4^{-n}}{\Gamma(n+\nu+1)\Gamma(n+2\nu)\Gamma(n+\nu+\lambda+1)\Gamma(r+1-n)} \cdot {}_3F_2\left[\begin{matrix} n-r, n+r+2\nu+2\lambda+1, n+\nu+1/2 \\ 2n+2\nu+1, n+\nu+\lambda+1 \end{matrix}; t^{-1}\right] \le 0$$

for $t \ge 1$ when $\nu > -1/2$, $\lambda \ge 0$, and $n = 1, \cdots, r$.

Since (3.5) reduces to (3.2) when $\nu = \lambda + 1/2 = 0$, in addition to deriving q-extensions of (1.2) we will derive q-extensions of the inequalities

$$(3.6)\quad {}_3F_2\left[\begin{matrix} -n, n+a, b \\ 2b, (a+1)/2 \end{matrix}; \frac{1-x}{2}\right] \ge 0, \qquad -1 \le x \le 1,$$

where $a \ge 2b > -1$ and $n = 0, 1, \cdots$, which imply the inequalities in (3.5) and reduce to (1.2) when $a = \alpha + 2$ and $b = (\alpha+1)/2$.

Let $0 < q < 1$, $n = 0, 1, 2, \cdots$, and let a, b, α, β, γ, δ, θ be real parameters. Then

$$(3.7)\quad \lim_{q\to 1} {}_5\phi_4\left[\begin{matrix} q^{-n}, q^{n+a}, q^b, q^\alpha e^{i\theta}, q^\beta e^{-i\theta} \\ q^{2b}, q^{(a+1)/2}, -q^\gamma, -q^\delta \end{matrix}; q, q\right] = {}_3F_2\left[\begin{matrix} -n, n+a, b \\ 2b, (a+1)/2 \end{matrix}; \frac{1-x}{2}\right], \quad x = \cos\theta,$$

and so, in order to derive a q-extension of (3.6), it suffices to find values of α, β, γ, δ for which the ${}_6\phi_5$ series in (3.7) are nonnegative when $a \ge 2b > -1$.

Observe that from (2.16)

$$(3.8)\quad {}_5\phi_4\left[\begin{matrix} q^{-n}, q^{n+2b}, q^b, q^b e^{i\theta}, q^b e^{-i\theta} \\ q^{2b}, q^{b+1/2}, -q^{b+1/2}, -q^b \end{matrix}; q, q\right] = \left\{{}_4\phi_3\left[\begin{matrix} q^{-n}, q^{n+2b}, q^{b/2}e^{i\theta/2}, q^{b/2}e^{-i\theta/2} \\ q^{b+1/2}, -q^{b+1/2}, -q^b \end{matrix}; q, q\right]\right\}^2 \ge 0,$$

which shows that the ${}_5\phi_4$ series in (3.7) are nonnegative when $a = 2b$, $\alpha = \beta = \delta = b$, and $\gamma = b + 1/2$. In view of the "sums of squares" method [18, §8], we will consider sums of the nonnegative ${}_5\phi_4$ series in (3.8).

The author showed in [18, §8] that besides the sum of squares of ultraspherical polynomials used in [4, (1.16)] to prove (1.2) we could also use the sum of squares in [18, (8.17)] and observed that these two expansions are special cases of the expansion [18, (8.18)]

$$
\begin{aligned}
&{}_3F_2\left[\begin{matrix}-n, n+\alpha+2, (\alpha+1)/2 \\ \alpha+1, (\alpha+3)/3\end{matrix}; (1-x^2)(1-y^2)\right] \\
&\quad = \sum_{j=0}^{n} \frac{n!(n+\alpha+2)_j \left(\frac{\alpha+2}{2}\right)_j}{j!(n-j)! \left(\frac{\alpha+3}{2}\right)_j (j+\alpha+1)_j} (1-y^2)^j \\
&\qquad \cdot \left\{ \frac{j!(n-j)!}{(\alpha+1)_j (2j+\alpha+2)_{n-j}} C_j^{(\alpha+1)/2}(x) C_{n-j}^{j+(\alpha+2)/2}(y) \right\}^2,
\end{aligned} \tag{3.9}
$$

which can be derived from the Fields and Wimp [17] expansion formula

$$
\begin{aligned}
{}_{r+t}F_{s+u}\left[\begin{matrix}a_R, c_T \\ b_S, d_U\end{matrix}; xw\right] &= \sum_{j=0}^{\infty} \frac{(a_R)_j (\alpha)_j (\beta)_j}{(b_S)_j (\gamma+j)_j} \frac{(-x)^j}{j!} \\
&\quad \cdot {}_{r+2}F_{s+1}\left[\begin{matrix}j+\alpha, j+\beta, j+a_R \\ 1+2j+\gamma, j+b_S\end{matrix}; x\right] {}_{t+2}F_{u+2}\left[\begin{matrix}-j, j+\gamma, c_T \\ \alpha, \beta, d_U\end{matrix}; w\right],
\end{aligned} \tag{3.10}
$$

where we used the contracted notation of representing $a_1, a_2, \cdots, a_r$ by a_R, $(a_1)_j (a_2)_j \cdots (a_r)_j$ by $(a_R)_j$, and $j+a_1, j+a_2, \cdots, j+a_r$ by $j+a_R$. Recently the author derived a bibasic extension [22, (4.5)] of (3.10) which contained Verma's [40] q-analogues and gave the general expansion [22, (4.7)]

(3.11)

$$
\begin{aligned}
&{}_{r+t}\phi_{s+u}\left[\begin{matrix}a_R, c_T \\ b_S, d_U\end{matrix}; q, xw\right] \\
&\quad = \sum_{j=0}^{\infty} \frac{(c_T, e_K, \sigma, \gamma q^{j+1}/\sigma; q)_j}{(q, d_U, f_M, \gamma q^j; q)_j} \left(\frac{x}{\sigma}\right)^j [(-1)^j q^{\binom{j}{2}}]^{u+m-t-k} \\
&\qquad \cdot {}_{t+k+4}\phi_{u+m+3}\left[\begin{matrix}\gamma q^{2j}/\sigma, q^{j+1}\sqrt{\gamma/\sigma}, -q^{j+1}\sqrt{\gamma/\sigma}, \sigma^{-1}, c_T q^j, e_K q^j \\ q^j\sqrt{\gamma/\sigma}, -q^j\sqrt{\gamma/\sigma}, \gamma q^{2j+1}, d_U q^j, f_M q^j\end{matrix}; q, xq^{j(u+m-t-k)}\right] \\
&\qquad \cdot {}_{r+m+2}\phi_{s+k+2}\left[\begin{matrix}q^{-j}, \gamma q^j, a_R, f_M \\ \gamma q^{j+1}/\sigma, q^{1-j}/\sigma, b_S, e_K\end{matrix}; q, wq\right],
\end{aligned} \tag{3.11}
$$

where we used a contracted notation analogous to that used in (3.10). Formulas (3.10) and (3.11) hold when the series terminate and when the parameters and variables are such that the series converge absolutely.

In this section we will use the following $\sigma \to \infty$ limit case of the $m = 2$, $f_1 = f_2 = 0$ case of (3.11)

$$
\begin{aligned}
&{}_{r+t}\phi_{s+u}\left[\begin{matrix} a_R, c_T \\ b_S, d_U \end{matrix}; q, xw\right] \\
&\quad = \sum_{j=0}^{\infty} \frac{(c_T, e_K; q)_j}{(q, d_U, \gamma q^j; q)_j} x^j [(-1)^j q^{\binom{j}{2}}]^{u+3-t-k} \\
&\quad \cdot {}_{t+k}\phi_{u+1}\left[\begin{matrix} c_T q^j, e_K q^j \\ \gamma q^{2j+1}, d_U q^j \end{matrix}; q, x q^{j(u+3-t-k)}\right] \\
&\quad \cdot {}_{r+2}\phi_{s+k}\left[\begin{matrix} q^{-j}, \gamma q^j, a_R \\ b_S, e_K \end{matrix}; q, wq\right],
\end{aligned} \tag{3.12}
$$

which is equivalent to [39, (3.1)]. Set

$$\gamma = q^{2b}, a_1 = q^b, a_2 = q^b e^{i\theta}, a_3 = q^b e^{-i\theta}, b_1 = q^{2b}, b_2 = -q^b,$$

$$c_1 = q^{-n}, c_2 = q^{n+a}, d_1 = q^{(a+1)/2} = -d_2, e_1 = q^{b+1/2} = -e_2, x = q, w = 1,$$

in the $r = 3$, $s = t = u = k = 2$ case of (3.12) to obtain

$$
\begin{aligned}
&{}_5\phi_4\left[\begin{matrix} q^{-n}, q^{n+a}, q^b, q^b e^{i\theta}, q^b e^{-i\theta} \\ q^{2b}, q^{(a+1)/2}, -q^{(a+1)/2}, -q^b \end{matrix}; q, q\right] \\
&\quad = \sum_{j=0}^{n} \frac{(q^{-n}, q^{n+a}, q^{b+1/2}, -q^{b+1/2}; q)_j}{(q, q^{(a+1)/2}, -q^{(a+1)/2}, q^{j+2b}; q)_j} (-1)^j q^{j+\binom{j}{2}} \\
&\quad \cdot {}_4\phi_3\left[\begin{matrix} q^{j-n}, q^{j+n+a}, q^{j+b+1/2}, -q^{j+b+1/2} \\ q^{2j+2b+1}, q^{j+(a+1)/2}, -q^{j+(a+1)/2} \end{matrix}; q, q\right] \\
&\quad \cdot {}_5\phi_4\left[\begin{matrix} q^{-j}, q^{j+2b}, q^b, q^b e^{i\theta}, q^b e^{-i\theta} \\ q^{2b}, q^{b+1/2}, -q^{b+1/2}, -q^b \end{matrix}; q, q\right].
\end{aligned} \tag{3.13}
$$

By Andrews' [1, Thm. 1] q-analogue of Watson's ${}_3F_2$ summation formula

$$
{}_4\phi_3\left[\begin{matrix} a, b, c^{1/2}, -c^{1/2} \\ c, (abq)^{1/2}, -(abq)^{1/2} \end{matrix}; q, q\right] = \frac{a^{n/2}(aq, bq, cq/a, cq/b; q^2)_\infty}{(q, abq, cq, cq/ab; q^2)_\infty}, \tag{3.14}
$$

where $b = q^{-n}$ and n is a nonnegative integer, the ${}_4\phi_3$ series in (3.13) equals zero when $n - j$ is odd and equals

$$\frac{(q, q^{a-2b}; q^2)_k}{(q^{2n-4k+a+1}, q^{2n-4k+2b+2}; q^2)_k} q^{2k(n-2k+b+1/2)}$$

when $n - j = 2k$ and $k = 0, 1, \cdots$. Hence, from (3.13) and (3.8),

$$
\begin{aligned}
&{}_5\phi_4\left[\begin{matrix} q^{-n}, q^{n+a}, q^b, q^b e^{i\theta}, q^b e^{-i\theta} \\ q^{2b}, q^{(a+1)/2}, -q^{(a+1)/2}, -q^b \end{matrix}; q, q\right] \\
&\quad = \sum_{k=0}^{[n/2]} \frac{(-1)^n (q^{-n}, q^{n+a}, q^{b+1/2}, -q^{b+1/2}; q)_{n-2k}}{(q, q^{(a+1)/2}, -q^{(a+1)/2}, q^{n-2k+2b}; q)_{n-2k}} \\
&\quad \cdot \frac{(q, q^{a-2b}; q^2)_k}{(q^{2n-4k+a+1}, q^{2n-4k+2b+2}; q^2)_k} q^{2k(n-2k+b+1/2)+(n-2k)(n-2k+1)/2} \\
&\quad \cdot \left\{ {}_4\phi_3\left[\begin{matrix} q^{2k-n}, q^{n-2k+2b}, q^{b/2} e^{i\theta/2}, q^{b/2} e^{-i\theta/2} \\ q^{b+1/2}, -q^{b+1/2}, -q^b \end{matrix}; q, q\right] \right\}^2.
\end{aligned} \tag{3.15}
$$

Since $(-1)^n(q^{-n};q)_{n-2k} \geq 0$, it is clear from (3.15) that

$$(3.16)\qquad {}_5\phi_4\left[\begin{matrix} q^{-n}, q^{n+a}, q^b, q^b e^{i\theta}, q^b e^{-i\theta} \\ q^{2b}, q^{(a+1)/2}, -q^{(a+1)/2}, -q^b \end{matrix}; q, q\right] \geq 0$$

when $a \geq 2b > -1$ and $0 < q < 1$, which gives a q-extension of (3.6) and hence of the inequalities (1.2) used by de Branges in his proof of the Bieberbach, Robertson, and Milin conjectures.

Another q-extension of (3.6) can be derived by observing that from (3.12) we have

$$(3.17)\quad {}_6\phi_5\left[\begin{matrix} q^{-n}, q^{n+a}, q^b, -q^b, q^{a/2}e^{i\theta}, q^{1/2\,a}e^{-i\theta} \\ q^{2b}, q^{(a+1)/2}, -q^{(a+1)/2}, -q^{a/2}, -q^{a/2} \end{matrix}; q, q\right]$$

$$= \sum_{j=0}^{n} \frac{(q^{-n}, q^{n+a}, q^{a/2}, q^{a/2}e^{i\theta}, q^{a/2}e^{-i\theta}; q)_j}{(q, q^{(a+1)/2}, -q^{(a+1)/2}, -q^{a/2}, q^{j+a-1}; q)_j}(-1)^j q^{j+\binom{j}{2}}$$

$$\cdot {}_5\phi_4\left[\begin{matrix} q^{j-n}, q^{n+j+a}, q^{j+a/2}, q^{j+a/2}e^{i\theta}, q^{j+a/2}e^{-i\theta} \\ q^{2j+a}, q^{j+(a+1)/2}, -q^{j+(a+1)/2}, -q^{j+a/2} \end{matrix}; q, q\right]$$

$$\cdot {}_4\phi_3\left[\begin{matrix} q^{-j}, q^{j+a-1}, q^b, -q^b \\ q^{2b}, q^{a/2}, -q^{a/2} \end{matrix}; q, q\right]$$

$$= \sum_{k=0}^{[n/2]} \frac{(q^{-n}, q^{n+a}, q^{a/2}, q^{a/2}e^{i\theta}, q^{a/2}e^{-i\theta}; q)_{2k}}{(q, q^{(a+1)/2}, -q^{(a+1)/2}, -q^{\frac{1}{2}a}, q^{2k+a-1}; q)_{2k}}$$

$$\cdot \frac{(q, q^{a-2b}; q^2)_k}{(q^a, q^{2b+1}; q^2)_k} q^{2k^2+k+2kb}$$

$$\cdot \left\{ {}_4\phi_3\left[\begin{matrix} q^{2k-n}, q^{n+2k+a}, q^{k+a/4}e^{i\theta/2}, q^{k+a/4}e^{-i\theta/2} \\ q^{2k+(a+1)/2}, -q^{2k+(a+1)/2}, -q^{2k+a/2} \end{matrix}; q, q\right] \right\}^2$$

by (3.14) and (3.8). Hence,

$$(3.18)\qquad {}_6\phi_5\left[\begin{matrix} q^{-n}, q^{n+a}, q^b, -q^b, q^{a/2}e^{i\theta}, q^{a/2}e^{-i\theta} \\ q^{2b}, q^{(a+1)/2}, -q^{(a+1)/2}, -q^{a/2}, -q^{a/2} \end{matrix}; q, q\right] \geq 0$$

when $a \geq 2b > -1$ and $0 < q < 1$, which is a q-extension of (3.6) that is different from (3.16). The expansions (8.12) and (8.17) in [18] are special cases of the $q \uparrow 1$ limit cases of (3.15) and (3.17), respectively, when (2.15) and [18, (8.10)] are used.

A q-extension of (3.9) can be derived by using (3.12) and (2.15) to obtain the expansion

(3.19)

$${}_7\phi_6\left[\begin{matrix} q^{-n}, q^{n+\alpha+2}, q^{(\alpha+1)/2}, q^{(\alpha+1)/2}e^{2i\theta}, q^{(\alpha+1)/2}e^{-2i\theta}, q^{(\alpha+2)/2}e^{2i\tau}, q^{(\alpha+2)/2}e^{-2i\tau} \\ q^{\alpha+1}, q^{(\alpha+3)/2}, -q^{(\alpha+3)/2}, -q^{(\alpha+2)/2}, -q^{(\alpha+2)/2}, -q^{(\alpha+1)/2} \end{matrix}; q, q\right]$$

$$= \sum_{j=0}^{n} \frac{(q^{-n}, q^{n+\alpha+2}, q^{(\alpha+2)/2}, q^{(\alpha+2)/2}e^{2i\tau}, q^{(\alpha+2)/2}e^{-2i\tau}; q)_j}{(q, q^{(\alpha+3)/2}, -q^{(\alpha+3)/2}, -q^{(\alpha+2)/2}, q^{j+\alpha+1}; q)_j}(-1)^j q^{j+\binom{j}{2}}$$

$$\cdot \left\{ \frac{(q;q)_j (q;q)_{n-j}}{(q^{\alpha+1};q)_j (q^{2j+\alpha+2};q)_{n-j}} q^{1/2\,(j+\alpha+3/2)} \right.$$

$$\left. \cdot C_j(\cos\theta; q^{(\alpha+1)/2} \mid q) C_{n-j}(\cos\tau; q^{j+(\alpha+2)/2} \mid q) \right\}^2,$$

which is clearly nonnegative for real θ and τ when $\alpha > -2$. The case $\alpha = -2$ can be handled as a limit case of $(q^{\alpha+2};q)_n$ times the ${}_7\phi_6$ series in (3.19); see [4, p. 720] for the hypergeometric case.

Additional nonnegative sums and, in particular, the nonnegativity of q-extensions of the sums of Jacobi polynomials in [18, (8.19), (8.20), (8.22)] will be considered in [23].

4. q-Extensions of de Branges' differential equations. From (3.3) and the identity $(a)_n = \Gamma(n+a)/\Gamma(a)$ it follows that

(4.1)
$$\sigma_n(t) = c\frac{n!(2\nu+2\lambda+1)_{n+r}4^{-n}t^{-n}}{(r-n)!(\nu+1)_n(2\nu+1)_n(\nu+\lambda+1)_n} \cdot {}_4F_3\left[\begin{matrix} n-r, n+r+2\nu+2\lambda+1, n+\nu+1/2, n+2\nu \\ 2n+2\nu+1, n+\nu+\lambda+1, n+2\nu+1 \end{matrix}; t^{-1}\right]$$

for $n = 1, \cdots, r$ with $c = \Gamma(2\nu+2\lambda+1)/[\Gamma(\nu+1)\Gamma(2\nu+1)\Gamma(\nu+\lambda+1)]$. In view of the limit (3.7), we set $t = 2/(1-x)$ and consider the functions

$$\tau_n(x) = c^{-1}\sigma_n\left(\frac{2}{1-x}\right). \tag{4.2}$$

Then de Branges' differential equation (3.4) is equivalent to

$$\frac{n}{n+2\nu}\tau_n(x) + \frac{1-x}{n+2\nu}\tau_n'(x) = \frac{n+2\nu+1}{n+1}\tau_{n+1}(x) - \frac{1-x}{n+1}\tau_{n+1}'(x) \tag{4.3}$$

which can be rewritten in the form

$$\frac{d}{dx}[(1-x)^{-n}\tau_n(x)] = -\frac{n+2\nu}{n+1}(1-x)^{-2n-2\nu-1}\frac{d}{dx}[(1-x)^{n+2\nu+1}\tau_{n+1}(x)]. \tag{4.4}$$

Let $0 < q < 1$, $x = \cos\theta$ and let a, α, λ, ν, θ be real numbers. A q-extension of $(1-x)^\alpha$ can be obtained by extending the definition of the q-shifted factorial to

$$(a;q)_\alpha = \frac{(a;q)_\infty}{(aq^\alpha;q)_\infty} \tag{4.5}$$

and observing that, by the q-binomial theorem [38, (3.2.2.11)],

$$\lim_{q\to 1} 2^{-\alpha}(q^a e^{i\theta}, q^a e^{-i\theta};q)_\alpha = (1-x)^\alpha. \tag{4.6}$$

Hence, if we define

$$u_n(x) = A_{n,r}(q^{\nu+1}e^{i\theta}, q^{\nu+1}e^{-i\theta};q)_n \cdot {}_6\phi_5\left[\begin{matrix} q^{n-r}, q^{n+r+2\nu+2\lambda+1}, q^{n+\nu+1/2}, q^{n+2\nu}, q^{n+\nu+1}e^{i\theta}, q^{n+\nu+1}e^{-i\theta} \\ q^{2n+2\nu+1}, q^{n+\nu+\lambda+1}, q^{n+2\nu+1}, -q^{n+\nu+\lambda+1}, -q^{n+\nu+1/2} \end{matrix}; q, q\right] \tag{4.7}$$

with

$$A_{n,r} = \frac{(q;q)_n(q^{2\nu+2\lambda+1};q)_{n+r}4^{-2n}}{(q;q)_{r-n}(q^{\nu+1}, q^{2\nu+1}, q^{\nu+\lambda+1};q)_n}, \qquad n = 1, \cdots, r, \tag{4.8}$$

and $A_{n,r} = 0$ when $n > r$, then

$$\lim_{q\to 1} u_n(x) = \tau_n(x). \tag{4.9}$$

To obtain a q-extension of differentiation that plays the same role for $(ae^{i\theta}, ae^{-i\theta};q)_n$ as d/dx does for x^n, Askey and Wilson [7, p. 33] defined the operators δ_q and D_q by

$$\delta_q f(e^{i\theta}) = f(q^{1/2}e^{i\theta}) - f(q^{-1/2}e^{i\theta}), \tag{4.10}$$

$$D_q h(x) = \frac{\delta_q h(x)}{\delta_q x}, \tag{4.11}$$

where $x = (e^{i\theta} + e^{-i\theta})/2 = \cos\theta$, and observed that

$$\delta_q(ae^{i\theta}, ae^{-i\theta};q)_n = aq^{-1/2}(1-q^n)(e^{i\theta} - e^{-i\theta})(aq^{1/2}e^{i\theta}, aq^{1/2}e^{-i\theta};q)_{n-1} \tag{4.12}$$

and

$$\frac{\delta_q \prod_{k=0}^{n-1}(1 - 2axq^k + a^2q^{2k})}{\delta_q x} = \frac{-2a(1-q^n)}{1-q}\prod_{k=0}^{n-2}(1 - 2axq^{k+1/2} + a^2q^{2k+1}). \tag{4.13}$$

They noted that when $q \to 1$ formula (4.13) becomes

$$\frac{d}{dx}(1 - 2ax + a^2)^n = -2an(1 - 2ax + a^2)^{n-1} \tag{4.14}$$

and more generally,

$$\lim_{q\to 1} D_q h(x) = \lim_{q\to 1}\frac{\delta_q h(x)}{\delta_q x} = \frac{df(x)}{dx}. \tag{4.15}$$

To derive a q-extension of (4.4) and the inequalities (3.5), first observe that (4.12) extends to

$$\delta_q(ae^{i\theta}, ae^{-i\theta};q)_\alpha = aq^{-1/2}(1-q^\alpha)(e^{i\theta} - e^{-i\theta})(aq^{1/2}e^{i\theta}, aq^{1/2}e^{-i\theta};q)_{\alpha-1}, \tag{4.16}$$

which gives

$$D_q(ae^{i\theta}, ae^{-i\theta};q)_\alpha = \frac{-2a(1-q^\alpha)}{1-q}(aq^{1/2}e^{i\theta}, aq^{1/2}e^{-i\theta};q)_{\alpha-1}. \tag{4.17}$$

Hence, corresponding to the inequality (3.5), we have that

$$\begin{aligned} &D_q[(q^{1-\nu}e^{i\theta}, q^{1-\nu}e^{-i\theta};q)_{2\nu}u_n(x)] \\ &= A_{n,r}\sum_{k=0}^{r-n}\frac{(q^{n-r}, q^{n+r+2\nu+2\lambda+1}, q^{n+\nu+1/2}, q^{n+2\nu};q)_k q^k}{(q, q^{2n+2\nu+1}, q^{n+\nu+\lambda+1}, q^{n+2\nu+1}, -q^{n+\nu+\lambda+1}, -q^{n+\nu+1/2};q)_k} \\ &\quad \cdot D_q[(q^{1-\nu}e^{i\theta}, q^{1-\nu}e^{-i\theta};q)_{n+k+2\nu}] \\ &= -\frac{2(1-q^{n+2\nu})}{1-q}q^{1-\nu}A_{n,r}(q^{3/2-\nu}e^{i\theta}, q^{3/2-\nu}e^{-i\theta};q)_{n+2\nu-1} \\ &\quad \cdot {}_5\phi_4\left[\begin{matrix} q^{n-r}, q^{n+r+2\nu+2\lambda+1}, q^{n+\nu+1/2}, q^{n+\nu+1/2}e^{i\theta}, q^{n+\nu+1/2}e^{-i\theta} \\ q^{2n+2\nu+1}, q^{n+\nu+\lambda+1}, -q^{n+\nu+\lambda+1}, -q^{n+\nu+1/2}\end{matrix};q,q\right] \le 0 \end{aligned} \tag{4.18}$$

by (3.16), when $\nu > -\frac{1}{2}$, $\lambda \ge 0$ and $n = 1, \cdots, r$. This explains why we chose the ${}_6\phi_5$ in (4.7).

To derive a q-extension of (4.4) notice that, corresponding to the left side of (4.4), we have

(4.19)

$$D_q[(q^{n+\nu+1}e^{i\theta}, q^{n+\nu+1}e^{-i\theta}; q)_{-n}u_n(x)] = A_{n,r}$$
$$\cdot D_q\left({}_6\phi_5\left[\begin{matrix} q^{n-r}, q^{n+r+2\nu+2\lambda+1}, q^{n+\nu+1/2}, q^{n+2\nu}, q^{n+\nu+1}e^{i\theta}, q^{n+\nu+1}e^{-i\theta} \\ q^{2n+2\nu+1}, q^{n+\nu+\lambda+1}, q^{n+2\nu+1}, -q^{n+\nu+\lambda+1}, -q^{n+\nu+1/2} \end{matrix}; q, q\right]\right)$$
$$= \frac{(1-q^{n-r})(1-q^{n+r+2\nu+2\lambda+1})(1-q^{n+\nu+1/2})(1-q^{n+2\nu})(-2)q^{n+\nu+2}}{(1-q)(1-q^{2n+2\nu+1})(1-q^{n+\nu+\lambda+1})(1-q^{n+2\nu+1})(1+q^{n+\nu+\lambda+1})(1+q^{n+\nu+1/2})} A_{n,r}$$
$$\cdot {}_6\phi_5\left[\begin{matrix} q^{n+1-r}, q^{n+r+2\nu+2\lambda+2}, q^{n+\nu+3/2}, q^{n+2\nu+1}, q^{n+\nu+3/2}e^{i\theta}, q^{n+\nu+3/2}e^{-i\theta} \\ q^{2n+2\nu+2}, q^{n+\nu+\lambda+2}, q^{n+2\nu+2}, -q^{n+\nu+\lambda+2}, -q^{n+\nu+3/2} \end{matrix}; q, q\right].$$

Similarly,

(4.20)

$$(q^{n+\nu+3/2}e^{i\theta}, q^{n+\nu+3/2}e^{-i\theta}; q)_{-2n-2\nu-1} D_q[(q^{-n-\nu}e^{i\theta}, q^{-n-\nu}e^{-i\theta}; q)_{n+2\nu+1}u_{n+1}(x)]$$
$$= -\frac{2(1-q^{2n+2\nu+2})}{1-q} q^{-n-\nu} A_{n+1,r}$$
$$\cdot {}_6\phi_5\left[\begin{matrix} q^{n+1-r}, q^{n+r+2\nu+2\lambda+2}, q^{n+\nu+3/2}, q^{n+2\nu+1}, q^{n+\nu+3/2}e^{i\theta}, q^{n+\nu+3/2}e^{-i\theta} \\ q^{2n+2\nu+2}, q^{n+\nu+\lambda+2}, q^{n+2\nu+2}, -q^{n+\nu+\lambda+2}, -q^{n+\nu+3/2} \end{matrix}; q, q\right],$$

which, combined with (4.19), gives the following q-extension of (4.4)

(4.21) $$D_q[(q^{n+\nu+1}e^{i\theta}, q^{n+\nu+1}e^{-i\theta}; q)_{-n}u_n(x)]$$
$$= -\frac{1-q^{n+2\nu}}{1-q^{n+1}} B_{n,r}(q^{n+\nu+3/2}e^{i\theta}, q^{n+\nu+3/2}e^{-i\theta}; q)_{-2n-2\nu-1}$$
$$\cdot D_q[(q^{-n-\nu}e^{i\theta}, q^{-n-\nu}e^{-i\theta}; q)_{n+2\nu+1}u_{n+1}(x)]$$

with

(4.22) $$B_{n,r} = \frac{16q^{3n-r+2\nu+2}}{(1+q^{n+\nu+\lambda+1})(1+q^{n+\nu+1})(1+q^{n+\nu+1/2})^2}.$$

Clearly, $B_{n,r} \to 1$ and (4.21) tends to (4.4) as $q \to 1$; but, unlike (4.4), the difference equation (4.21) depends on r. However, if we consider following positive multiple of u_n

(4.23) $$U_n(x) = \frac{4^{2n}q^{3n^2/2+n(2\nu+1/2-r)}}{(-q^{\nu+\lambda+1}, -q^{\nu+1}, -q^{\nu+1/2}, -q^{\nu+1/2}; q)_n} u_n(x),$$

we find that it satisfies the difference equation

(4.24) $$D_q[(q^{n+\nu+1}e^{i\theta}, q^{n+\nu+1}e^{-i\theta}; q)_{-n}U_n(x)]$$
$$= -\frac{1-q^{n+2\nu}}{1-q^{n+1}} (q^{n+\nu+3/2}e^{i\theta}, q^{n+\nu+3/2}e^{-i\theta}; q)_{-2n-2\nu-1}$$
$$\cdot D_q[(q^{-n-\nu}e^{i\theta}, q^{-n-\nu}e^{-i\theta}; q)_{n+2\nu+1}U_{n+1}(x)],$$

which is independent of r.

Similarly, setting

(4.25)

$$V_n(x) = C_{n,r}(q^{\nu+\lambda+1}e^{i\theta}, q^{\nu+\lambda+1}e^{-i\theta}; q)_n$$
$$\cdot {}_7\phi_6\left[\begin{matrix} q^{n-r}, q^{n+r+2\nu+2\lambda+1}, q^{n+\nu+1/2}, -q^{n+\nu+1/2}, q^{n+2\nu}, q^{n+\nu+\lambda+1}e^{i\theta}, q^{n+\nu+\lambda+1}e^{-i\theta} \\ q^{2n+2\nu+1}, q^{n+\nu+\lambda+1}, -q^{n+\nu+\lambda+1}, q^{n+2\nu+1}, -q^{n+\nu+\lambda+1/2}, -q^{n+\nu+\lambda+1/2} \end{matrix}; q, q\right]$$

with

(4.26)

$$C_{n,r} = \frac{(q;q)_n(q^{2\nu+2\lambda+1};q)_{n+r}q^{3n^2/2+n(2\nu+1/2-r)}}{(q;q)_{r-n}(q^{\nu+1}, q^{2\nu+1}, q^{\nu+\lambda+1}, -q^{\nu+1}, -q^{\nu+\lambda+1}, -q^{\nu+\lambda+1/2}, -q^{\nu+\lambda+1/2};q)_n}$$

when $n = 1, \cdots, r$ and $C_{n,r} = 0$ when $n > r$, we obtain that $V_n(x) \to \tau_n(x)$ as $q \to 1$, $V_n(x)$ satisfies the following q-extension of (4.4)

(4.27)
$$D_q[(q^{n+\nu+\lambda+1}e^{i\theta}, q^{n+\nu+\lambda+1}e^{-i\theta}; q)_{-n}V_n(x)]$$
$$= -\frac{1-q^{n+2\nu}}{1-q^{n+1}}(q^{n+\nu+\lambda+3/2}e^{i\theta}, q^{n+\nu+\lambda+3/2}e^{-i\theta}; q)_{-2n-2\nu-1}$$
$$\cdot D_q[(q^{-n-\nu+\lambda}e^{i\theta}, q^{-n-\nu+\lambda}e^{-i\theta}; q)_{n+2\nu+1}V_{n+1}(x)]$$

and, by (3.18),

(4.28)

$$D_q[(q^{1+\lambda-\nu}e^{i\theta}, q^{1+\lambda-\nu}e^{-i\theta}; q)_{2\nu}V_n(x)] = -\frac{2(1-q^{n+2\nu})}{1-q}q^{1+\lambda-\nu}C_{n,r}$$
$$\cdot (q^{\lambda+3/2-\nu}e^{i\theta}, q^{\lambda+3/2-\nu}e^{-i\theta}; q)_{n+2\nu-1}$$
$$\cdot {}_6\phi_5\left[\begin{matrix} q^{n-r}, q^{n+r+2\nu+2\lambda+1}, q^{n+\nu+1/2}, -q^{n+\nu+1/2}, q^{n+\nu+\lambda+1/2}e^{i\theta}, q^{n+\nu+\lambda+1/2}e^{-i\theta} \\ q^{2n+2\nu+1}, q^{n+\nu+\lambda+1}, -q^{n+\nu+\lambda+1}, -q^{n+\nu+\lambda+1/2}, -q^{n+\nu+\lambda+1/2} \end{matrix}; q, q\right] \le 0$$

when $\nu > -1/2$, $\lambda \ge 0$ and $n = 1, \cdots, r$.

The q-extensions of de Branges' inequalities and differential equations contained in this paper suggest that it might be possible to extend some of the other parts of his proof of the Bieberbach, Robertson, and Milin conjectures. Besides (1.2) and (1.7), de Branges also used the fact that if $F(t,z)$ is a Löwner family of Riemann mapping functions, then

$$t\frac{\partial}{\partial t}F(t,z) = \varphi(t,z)z\frac{\partial}{\partial z}F(t,z), \tag{4.29}$$

where $\varphi(t,z)$ is a power series with constant coefficient equal to 1,which represents a function with positive real part in the unit disk for every index t, and the coefficients of $\varphi(t,z)$ are measurable functions of t. q-Extensions of the Löwner [29] theory and of the coefficient estimates for Riemann mapping functions in [12] and [13, Thms. 1–4] are still open. In view of the definition of D_q in (4.11), a prospect for a q-extension of (4.29) is the equation

$$(1-x)D_qG(x,z) = \Phi(x,z)z\frac{\partial}{\partial z}G(x,z) \tag{4.30}$$

or this equation with the partial derivative replaced by a difference operator. For an extremal function that is a q-extension of the Koebe function, the ${}_1F_0$ series representation for the Koebe function

$$k(z) = \frac{z}{(1-z)^2} = z\,{}_1F_0\left[\begin{matrix} 2 \\ - \end{matrix}; z\right] \tag{4.31}$$

suggests that a natural choice is the "q-Koebe" function

$$k_q(z) = z\ {}_1\phi_0\left[\begin{matrix} q^2 \\ - \end{matrix}; q, z\right] = \frac{z}{(1-z)(1-qz)}. \tag{4.32}$$

Note that, just as the Koebe function is starlike, $k_q(z)$ is a starlike function when $-1 < q < 1$, which can be shown by using [16, Thm. 2.10] and the positivity of the Poisson kernel for Fourier series.

THE EXISTENCE AND BEHAVIOR OF VISCOUS STRUCTURE FOR PLANE DETONATION WAVES*

DAVID H. WAGNER†

Abstract. A necessary condition and a sufficient condition are proved for the existence of steady plane wave solutions to the Navier–Stokes equations for a reacting gas. These solutions represent plane detonation waves, and converge to ZND detonation waves as the viscosity, heat conductivity, and species diffusion rates tend to zero. It is assumed that the Prandtl number is $\frac{3}{4}$, but arbitrary Lewis numbers are permitted. No assumption is made concerning the activation energy.

It is shown that the stagnation enthalpy and the entropy flux are always monotone for such solutions, and that the mass density and pressure are nearly always not monotone, as predicted by the ZND theory.

In certain parameter ranges, typically that of large diffusion, many of these waves have the appearance of a weak detonation followed by an inert shock wave. This confirms a phenomenon observed in numerical calculations and in a model system by Colella, Majda, and Roytburd.

Key words. shock waves, detonation waves, combustion

AMS(MOS) subject classifications. 76L05, 80A32, 80A25, 35L65

1. Introduction.

Detonation waves are compressive, exothermically reacting shock waves. One of the curiosities of combustion theory is that there also exist expansive "shock waves" known as *deflagration waves*, which will not be discussed in this paper. We will give a mathematically rigorous, but simple, discussion of the *viscous structure* of plane detonation waves.

We begin with a brief discussion of the inviscid theory, known as the Chapman–Jouguet (CJ) theory. By means of a Galilean transformation we may reduce the problem to one of studying steady plane waves. If we assume that the thickness of the reaction zone is zero, if we neglect all diffusion effects such as viscosity, heat conduction, and diffusion of species, and any external forces such as gravity, and if we look for steady plane waves, then we obtain the following system of differential equations:

$$
\begin{aligned}
&\text{(a)} \quad (\rho u)_x = 0,\\
&\text{(b)} \quad \left[\rho u^2 + p(\rho, T)\right]_x = 0,\\
&\text{(c)} \quad \left((\rho(u^2/2 + e(\rho, T, Y)) + p(\rho, T))u\right)_x = 0,\\
&\text{(d)} \quad (\rho u Y)_x = -\rho u(Y_-)\delta(x - x_0).
\end{aligned}
\tag{1.1}
$$

Here x is a space coordinate in the direction normal to the wave, x_0 is the location of the wave, and ρ, T, u, p, e, and Y are the mass density, temperature, x component of velocity, pressure, specific internal energy, and mass fraction of the reactant, respectively. Y_- is the unburned value of Y. As is standard practice, we have represented the extremely complicated chemical reaction by a simplified, one-step chemistry: reactant $\rightarrow$ product. From (1.1a) we see that the mass flux, ρu, has a constant value; we denote this value by m. The fluxes of momentum (1.1b) and energy (1.1c) are also constant; from this fact we obtain the *Rankine–Hugoniot conditions* for a shock wave, which

*Received by the editors January 29, 1988; accepted for publication January 17, 1989.

†Department of Mathematics, University of Houston, Houston, Texas 77204-3476. This research was supported by National Science Foundation grant DMS-8601917 and Air Force Office of Scientific Research grant AFOSR 86-0218.

in the inviscid theory is represented by a jump discontinuity in the unknowns. The difference between inert gas dynamics, and the exothermic reactive theory discussed here, lies in the fact that Y varies from a positive value on the unburned side of the wave, which we take to lie on the left side, to a zero value on the burned, or right side. Because the internal energy e depends on Y, the change in Y causes the classical Hugoniot curve (the solution locus of (1.1c)) of gas dynamics to move. As a consequence, we find that, for a given value of m, a given shock state on the left may now be connected by a shock wave to two possible states on the right, except for certain critical values of m for which there is a unique burned state — the *Chapman–Jouguet point* — see Fig. 1. In addition, the curve of possible burned states, parameterized by m, has two components. One component, corresponding to compressive waves, is called the detonation branch, and the other component, corresponding to expansive waves, is called the deflagration branch. By way of contrast, in an inert gas, for a given value of m, a state is usually connected to only one state on the right, and the curve of possible terminal shock states is usually connected.

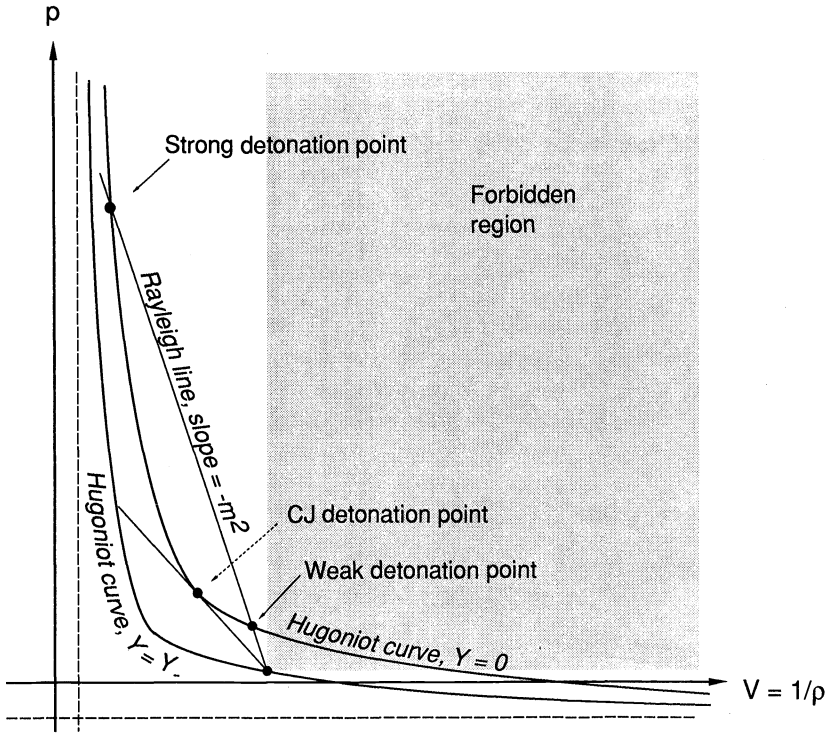

FIG. 1. *The Chapman–Jouguet diagram.*

The combustive shock waves of the CJ theory are classified as follows. A wave connecting the unburned state to the closer detonation point is called a *weak* detonation wave, and a connection to the farther detonation point is called a *strong* detonation. A detonation wave terminating at the Chapman–Jouguet point is called a *Chapman–Jouguet* detonation. Deflagration waves are similarly classified. For the exothermic, irreversible reactions considered here, strong deflagrations violate the second law of thermodynamics and are unphysical, and weak detonations are rare. If we permit an endothermic region then strong deflagrations and weak detonations are possible and

perhaps even probable [FD].

The CJ theory for detonation waves is useful for deriving the Rankine–Hugoniot conditions, and for classifying the types of wave. However, this theory is physically flawed, because in reality the reaction zone is much thicker than the shock layer. This is due to the fact that the chemical reaction depends on molecular collisions and requires a distance much longer than the mean free path to achieve significant completion. The shock layer, however, has been experimentally observed to be several mean free paths thick. Consequently the appropriate inviscid model is the one developed independently by Zel'dovich, von Neumann, and Döring [Z], [ZK], [N1], [N2], [D], and which is known as the ZND model. In this model equation (1.1d) is replaced by a similar equation, but with a finite reaction rate:

$$(\rho u Y)_x = -r(\rho, Y, T) \tag{1.1d'}$$

For our purposes it is reasonable to assume that the reaction rate function r is continuous, nonnegative, and monotone in each variable. Our mathematical treatment will require that we assume that r vanishes whenever the temperature T is less than a given *ignition temperature* T_i. For a known reaction rate r (1.1a–c, d′) can be solved explicitly; the only detonation wave solutions are strong or CJ detonations. These waves, which are known as ZND waves, begin with a jump discontinuity which is an inert shock wave. This shock wave heats the gas above the ignition temperature; the reaction proceeds, with the velocity and temperature following a curve of equilibrium states for (1.1b, c), parameterized by Y. One of the interesting features of these waves is the peak in the pressure and density which is known as the *von Neumann spike*. By way of contrast, in inert shock waves the pressure and density are usually monotone [Gi].

The equations of inert, inviscid, non-heat-conducting gas dynamics are an example of a nonlinear hyperbolic system of conservation laws. In the theory for such systems it is standard practice to set admissibility criteria to distinguish physical from unphysical shock waves. One of the criteria in which much faith is put is to accept a shock wave as physical if it is *structurally stable*. A shock wave is structurally stable if it is the limit of solutions to models which include more physical effects, such as viscosity and heat conduction, as these models tend to the original inviscid model in which these effects are neglected. For steady plane detonation waves the effects of viscosity, heat conduction, and species diffusion may be considered to obtain the (steady) *reacting compressible Navier–Stokes equations*:

$$\begin{aligned}
&\text{(a)} \quad (\rho u)_x = 0, \\
&\text{(b)} \quad \left(\rho u^2 + p(\rho, T)\right)_x = (\mu u_x)_x, \\
&\text{(c)} \quad \left[\left(\rho\left(u^2/2 + e(\rho, T, Y)\right) + p(\rho, T)\right) u\right]_x = (\lambda T_x)_x + (\mu u u_x)_x + (q\rho D Y_x)_x, \\
&\text{(d)} \quad (\rho u Y)_x = (\rho D Y_x)_x - r(\rho, T, Y).
\end{aligned} \tag{1.2}$$

Here μ is the coefficient of viscosity, λ is the heat conductivity, D is the diffusion rate for the reactant, and q is the difference in the heats of formation of the reactant and the product [Wi].

In this paper we prove a necessary condition and a sufficient condition for the existence of heteroclinic solutions of (1.2) which extend from an unburned state at $x = -\infty$ to the strong detonation point at $x = \infty$. These conditions also apply to the Chapman–Jouguet detonation. See (4.8) and (5.3). For simplicity we restrict our

attention to the case where the *Prandtl number* is $\frac{3}{4}$ ($\mu = \lambda/c_p$). In the limit as λ, μ, and D tend to zero (with other parameters fixed) these solutions tend to the ZND wave. Thus the ZND wave is structurally stable to this particular perturbation of the model.

For all of these solutions the *stagnation enthalpy* $H = c_pT + u^2/2$ is monotone, as is the *entropy flux*: $mS - \lambda T_x/T$. For most of the strong detonation waves the density and the pressure attain their maxima in the interior of the wave; this corresponds to the von Neumann spike which occurs in the ZND wave. However, for a certain parameter range, namely whenever

$$\frac{L}{2}\left(1 - \sqrt{\frac{1 + 4Dk\phi(T^*)}{u^{*2}}}\right) > \frac{1}{\gamma}\left(1 - M^{*-2}\right),$$

where $L = \lambda/\rho Dc_p$ is the *Lewis number*, M^* and T^* are the Mach number and temperature at the strong detonation point, and $k\phi(T^*)$ is the reaction rate as defined in (2.9), there exists a continuum of solutions which look like a weak detonation followed by a gas dynamic shock wave. For these waves the pressure and temperature are monotone. This pathological behavior has been noted before in [Wo2], [FD], [LL], [HoSt], and in numerical computations of solutions of the time-dependent Navier–Stokes equations for a reacting gas [CMR]. In these numerical computations it was observed that the weak detonation-shock wave solutions are dynamically stable as solutions of the time-dependent equations in one space dimension.

Since Zel'dovich, von Neumann, and Döring [Z], [N1], [N2], [D] described the typical plane detonation heuristically as an inert shock wave followed by a deflagration, there have been a number of papers on the structure problem for plane detonations. A common assumption has been that the Prandtl number is $\frac{3}{4}$ and that the Lewis number is 1. Under these assumptions Hirschfelder and Curtiss gave a good analysis of the behavior of structure profiles [HC], and Wood proved the existence of structure for "small" reaction rates [Wo1]. The approach taken here has much in common with Wood's, except that we have been more precise in our analysis, our results are stronger and more general, and we give explicit and fairly sharp statements of just how small the rate parameter must be.

A typical expression for the reaction rate is given by the Arrhenius law:

$$r(\rho, T, Y) = k\rho \cdot Ye^{-\theta/T}, \tag{1.3}$$

where θ is the activation energy E/R. In mathematical combustion theory it is standard practice to simplify models such as (1.2) by taking an appropriate distinguished limit as k and θ tend to infinity. This has the effect of reducing the thickness of the reaction zone to zero. Bush and Fendell [BF] gave a description of CJ detonations using asymptotic expansions in the limit of infinite activation energy. Stewart and Holmes proved the existence of viscous structure for (1.2), assuming a large, finite activation energy [HoSt]. Lu and Ludford gave a simplified analysis of weak, strong, and CJ detonations in the infinite activation energy limit [LL].

It is desirable to understand the existence of structure for plane detonation waves with no assumptions concerning activation energy, independent of any desire for mathematical generality. Because (under the ZND hypothesis) the reaction zone is much thicker than the shock layer, this problem should be studied for activation energies that are small compared to the reciprocals of the heat conductivity, viscosity, and species diffusion rate.

Gardner proved the existence of travelling plane detonation wave solutions to the Lagrangian reacting compressible Navier–Stokes equations [Ga]. He made no assumption on the Lewis and Prandtl numbers. However, he omitted the species diffusion term from the energy balance equation, and this term is not usually neglected. It may be that the effect of this term on the solution is very small. However, we will demonstrate in this paper that inclusion of this term permits a much more natural treatment of the problem and better bounds on the solution.

The remainder of the paper is organized as follows. In §2 we explain our assumptions in more detail, and we show that under these assumptions, and the assumption that the Lewis number is 1, that (1.2) is reduced to a system of three differential equations. This material has been extracted and specialized from [Wi]. It is included for clarity and completeness of exposition. In §3 we present the simple topological argument that proves the existence of viscous structure for steady plane detonation waves. In §4 we prove the estimate that makes the topological argument work, and we conclude this section with a sufficient condition for the existence of structure. In §5 we prove, using simple energy estimates on the stagnation enthalpy, a necessary condition for the existence of structure; if this condition is not satisfied then viscous structure does not exist. In §6 we give the generalization to arbitrary Lewis numbers. In §7 we discuss the behavior of the solutions for various parameter values. In §8 we present a rigorous discussion of the ZND limit. We conclude, in §9, with a proof that the entropy flux is monotone.

2. Reduction to three equations. We make the basic thermodynamic assumption that both the reactant and product satisfy the same ideal gas law, and differ only in their heats of formation. Thus the pressure is independent of Y:

$$p = R\rho T. \tag{2.1}$$

We further assume that the internal energy depends linearly on Y, so that we have:

$$e = c_v T + qY, \tag{2.2}$$

where c_v is the specific heat at constant volume. These assumptions are probably not essential to the results that follow, and they could probably be replaced with more qualitative conditions similar to Weyl's conditions for the equation of state for an inert gas. However, these assumptions are essential to the simplifications that follow.

Observe that (1.2) can be integrated once to yield $\rho u = m = constant$. If for any unknown U we let $U_\pm$ be the limit of U as x tends to $\pm\infty$, we have:

$$\begin{aligned}
&\text{(a)} \quad \mu u_x = m(u - u_\pm) + p - p_\pm \\
&\text{(b)} \quad \lambda T_x + \mu u u_x + q\rho D Y_x \\
&\qquad\qquad = m\left[c_v\,(T - T_\pm) + q\,(Y - Y_\pm) + \frac{1}{2}\left(u^2 - u_\pm^2\right) + R\,(T - T_\pm)\right] \\
&\text{(c)} \quad (\rho D Y_x)_x = mY_x + r(\rho, Y, T)
\end{aligned} \tag{2.3}$$

Let $H = c_p T + u^2/2$ be the stagnation enthalpy. Here $c_p = c_v + R$ and is the specific heat at constant pressure. Then (2.3b) may be rewritten as:

$$(\lambda/c_p)H_x + (\mu - \lambda/c_p)\left(\frac{u^2}{2}\right)_x = m\,(H - H_\pm + q(\epsilon - \epsilon_\pm))\,, \tag{2.4}$$

where $\epsilon = Y - \rho D Y_x/m$ is a *reaction progress variable.* When the Prandtl number is $\frac{3}{4}$, then $\mu = \lambda/c_p$ and we have:

$$\left(\frac{\lambda}{mc_p}\right) H_x = H - H_\pm + q(\epsilon - \epsilon_\pm). \tag{2.5}$$

It is convenient to let y satisfy

$$\frac{dy}{dx} = \frac{mc_p}{\lambda}, \tag{2.6}$$

so that the left-hand side of (2.5) becomes H_y. The system (2.3) reduces to a system of four first-order equations:

$$\begin{aligned}
&\text{(a)} \quad mu_y = m(u - u_\pm) + mR\left(\frac{T}{u} - \frac{T_\pm}{u_\pm}\right)\\
&\text{(b)} \quad H_y = H - H_\pm + q(\epsilon - \epsilon_\pm)\\
&\text{(c)} \quad \epsilon_y = -\frac{\lambda}{m^2 c_p} r(\rho, Y, T)\\
&\text{(d)} \quad Y_y = \frac{\lambda}{\rho D c_p}(Y - \epsilon).
\end{aligned} \tag{2.7}$$

Note that

$$(H - H_+)_y + \frac{\rho D c_p}{\lambda} q Y_y = H - H_+ + qY. \tag{2.8}$$

Thus if the *Lewis number*, $L = \lambda/\rho D c_p$, is 1, we see that the quantity $H - H_+ + q(Y - Y_+)$ satisfies the differential equation $f' = f$ and can be bounded only if it is identically zero. As we are interested only in bounded solutions, we may, in this case, restrict our attention to the plane $H - H_+ + q(Y - Y_+) = 0$, and (2.7) reduces to a system of three equations: (2.7a–c) with Y replaced by $(H_+ - H)/q$. We will not actually need to assume that the Lewis number is 1, however, this case is easier to understand.

Some of the results concerning this system are easier to interpret if we replace u by the *specific volume* $V = 1/\rho = u/m$. In this case (2.7a) becomes:

$$V_y = V - V_\pm + \frac{R}{m^2}\left(\frac{T}{V} - \frac{T_\pm}{V_\pm}\right). \tag{2.7a′}$$

With the exception of our discussion of entropy, we will restrict our attention to the system (2.7a′, b–d) = (2.7) for the remainder of this paper.

Following standard practice, we will resolve the *cold boundary difficulty* by means of an *ignition temperature* assumption. The cold boundary difficulty consists of the fact that the Arrhenius reaction rate (1.3) does not vanish, but is merely very small, at the unburned state. Thus no solution of (2.7) can tend to the unburned state as $x \to \infty$. Clearly this problem stems more from our unphysical, infinite domain than from any flaw in the reaction rate. However, as is customary, we will resolve this problem by modifying r so that it is zero for $T < T_i$, where T_i is the *ignition temperature*, and is chosen to be greater than the unburned temperature T_-.

Accordingly we will consider reaction rates of the form:

$$r(\rho, Y, T) = k\rho Y \phi(T), \tag{2.9}$$

where ϕ is a nonnegative Lipschitz monotone function of T, which vanishes for $T < T_i$.

In the next three sections we will usually assume that the Lewis number is 1, for ease of understanding. In §6 we will explain how to generalize to arbitrary Lewis numbers.

3. A picture is worth .... We now describe a region in (V, H, ϵ) space. The topological properties of the flow for (2.7) in this region will imply the existence of the desired structure profiles and will yield other properties as well.

For any bounded solution of (2.7) on which some quantity is strictly monotone, (V, H, ϵ) must tend to a rest state of (2.7) as y tends to $\pm\infty$. From (2.7c) we see that $r(\rho, Y, T)$ must vanish at any rest state. For our modified kinetics this can only happen if $Y = 0$ or $T < T_i$. Rest states satisfying $Y = 0$ are possible *burned states*; those satisfying $T < T_i$ are possible *unburned*, or *fresh gas* states. By (2.7d), ϵ is decreasing, so that the unburned state is at $y = -\infty$ and the burned state is at $y = +\infty$. Thus $Y_+ = 0$ and $\epsilon_+ = (Y - \rho D Y_x/m)_+ = 0$. Note that our choice of the coordinate y, and of V, makes the system (2.7) independent of the sign of $m = \rho u$.

At the unburned state, Y has a given value, Y_-, which, since Y is a mass fraction, is naturally bounded by 1. Since $\epsilon_- = Y_-$, we have, by (2.7b), $H_+ - H_- = qY_-$, which is the total heat per unit mass released by the reaction. Then (2.7a′) yields

$$\begin{aligned} &V_+ - V_- + \frac{R}{m^2}\left(\frac{T_+}{V_+} - \frac{T_-}{V_-}\right) \\ &\quad = (V_+ - V_-)\left(1 - \frac{R}{2c_p}\right) + \frac{R}{m^2 c_p}\left(\frac{H_- + qY_-}{V_+} - \frac{H_-}{V_-}\right) = 0. \end{aligned} \tag{3.1}$$

Let γ be the ratio of specific heats, $c_p/c_v = c_p/(c_p - R)$. Then (3.1) becomes:

$$V_+^2 - \left(V_- + \frac{2(\gamma-1)H_-}{m^2(\gamma+1)V_-}\right)V_+ + \frac{2(\gamma-1)}{m^2(\gamma+1)}(H_- + qY_-) = 0. \tag{3.2}$$

If we solve this for V_+ we obtain

$$V_+ = \frac{V_-}{\gamma+1}\left(\left(\gamma + \frac{1}{M_-^2}\right) \pm \sqrt{\left(1 - \frac{1}{M_-^2}\right)^2 - \frac{2(\gamma^2-1)qY_-}{u_-^2}}\right), \tag{3.3}$$

where

$$M^2 = \frac{u^2}{c^2} = \frac{u^2}{(\gamma p/\rho)}$$

is the square of the Mach number, and c is the sound speed. Note that if

$$\left(1 - \frac{1}{M_-^2}\right)^2 < \frac{2(\gamma^2-1)qY_-}{u_-^2} \tag{3.4}$$

then (3.1) has no solution. The two values of M^2 where equality holds in (3.4) correspond to exactly one burned state each. These burned states are the Chapman–Jouguet points; see Fig. 1.

For values of M^2 greater than the Chapman–Jouguet detonation value, there are two possible burned states. The flow at the unburned state is supersonic, as is the case for the upstream side of a nonreacting shock wave. At the strong detonation state the flow is subsonic, which corresponds to the downstream side of a nonreacting shock wave. However, at the weak detonation state the flow is supersonic, and this violates the nonreacting shock wave entropy condition.

The effect of the Mach number on the flow pattern for (2.7) at a burned state is as follows. The linearization of (2.7) at a burned state has the following eigenvalues:

$$\begin{aligned}
&\text{(a)} \quad \sigma_1 = 1 - \frac{R}{2c_p} - \frac{RH_+}{m^2V_+^2c_p} = \frac{2(u_+^2 - \gamma p_+/\rho_+)}{2\gamma u_+^2} = \frac{1}{\gamma M_+^2}(M_+^2 - 1) \\
&\text{(b)} \quad \sigma_2 = 1 \\
&\text{(c)} \quad \sigma_{3,4} = \frac{L}{2}\left[1 \pm \sqrt{1 + 4Dk\phi(T_+)u_+^2}\right].
\end{aligned} \tag{3.5}$$

Thus, the strong detonation state has a two-dimensional stable manifold, and the weak detonation state has a one-dimensional stable manifold. From this simple fact it is already clear that although a weak detonation may be possible, a strong detonation is much more likely. The eigenvectors corresponding to $\sigma_1, \sigma_2, \sigma_3, \sigma_4$ are as follows.

$$\begin{aligned}
\sigma_1 &: \quad X_1 = (1,\ 0,\ 0,\ 0), \\
\sigma_2 &: \quad X_2 = ((\gamma - 1),\ m^2\gamma V_+(1 - \sigma_1),\ 0,\ 0), \\
\sigma_3 &: \quad X_3 = \left(\frac{q(\gamma - 1)}{\gamma m^2 V_+(\sigma_3 - \sigma_1)},\ q,\ \sigma_3 - 1,\ \frac{L(\sigma_3 - 1)}{L - \sigma_3}\right), \\
\sigma_4 &: \quad X_4 = \left(\frac{q(\gamma - 1)}{\gamma m^2 V_+(\sigma_4 - \sigma_1)},\ q,\ \sigma_4 - 1,\ \frac{L(\sigma_4 - 1)}{L - \sigma_4}\right).
\end{aligned}$$

From (2.7b) we note that $H_y > 0$ if $H - H_+ + q\epsilon > 0$. On the surface $H - H_+ + q\epsilon = 0$ we have that

$$(H - H_+ + q\epsilon)_y = -\frac{q\lambda}{m^2c_p}r \leq 0. \tag{3.6}$$

Therefore the region where $H_y \geq 0$ is *negatively invariant*, that is, the flow for (2.7) can only exit this region; it cannot enter. On the surface $V_y = 0$ (or $u_y = 0$) we have

$$V_{yy} = \frac{\gamma - 1}{m^2\gamma V_+}H_y. \tag{3.7}$$

Thus, inside the region $H_y \geq 0$, the region $V_y \leq 0$ is negatively invariant. Also the region $H \leq H_+$ is negatively invariant within $H_y \geq 0$.

All of the solutions that we find will lie in the region $H_y \geq 0$, $H \leq H_+$. However, detonation waves that are close to ZND waves will exit the region $V_y \leq 0$, attain a minimum value of V (or u) and maximum values of p and ρ, and then tend to the strong detonation state. To prove the existence of these waves, we need another boundary of the form $V = \textit{constant}$. A natural choice is

$$V = V_0 = \frac{(\gamma - 1)H_-}{(\gamma + 1)m^2V_-}. \tag{3.8}$$

V_0 is the value of V at the end state of a nonreacting shock wave with initial state (V_-, H_-); this is the minimum value of V for a ZND detonation. The part of this

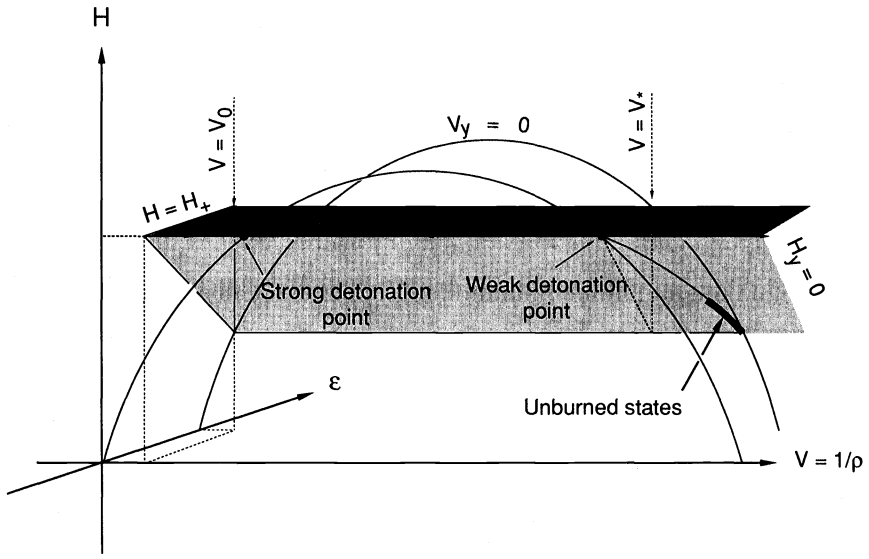

FIG. 2

surface lying within $H_y \geq 0$, $\epsilon < \epsilon_-$, also lies within $V_y \geq 0$. Therefore the region $V \geq V_0$ is positively invariant within the region $H_y \geq 0$, $\epsilon < \epsilon_-$.

Let (V_*, T_*) be the value of (V, T) at the weak detonation state, and let (V^*, T^*) be the value at the strong detonation state. Consider the region W defined by $H_y \geq 0$, $\epsilon \leq \epsilon_-$, $H \leq H_+$, $V_0 \leq V \leq V_*$ (see Fig. 2). The flow for (2.7) enters W through a connected part of the boundary, namely, the union of the surfaces $V = V_*$, $\epsilon = \epsilon_-$, $V = V_0$. The flow leaves W through two components, $H_y = 0$, and $H = H_+$, which are separated by the positively invariant set P defined by $H_y = 0 = H - H_+$, $V_0 \leq V \leq V_*$. The following theorem of Wazewski [Wz1], [Wz2], which we quote from [C], implies that the set of all points in W which eventually flow out of W must also have two components.

DEFINITION 1. Let Γ be a topological space and let $\mathbb{R}$ denote the real numbers. Let a continuous function from $\Gamma \times R \to \Gamma$ be denoted by $(\gamma, t) \to \gamma \cdot t$. This function is called a *flow on* Γ if the following conditions are satisfied for all $\gamma \in \Gamma$ and $s, t \in \mathbb{R}$:

$$\text{(a)} \quad \gamma \cdot 0 = \gamma$$
$$\text{(b)} \quad \gamma \cdot (s + t) = (\gamma \cdot s) \cdot t.$$

If $\Gamma' \subset \Gamma$ and $U \subset \mathbb{R}$, let $\Gamma' \cdot U$ be the set of points $\gamma \cdot t$ such that $\gamma \in \Gamma'$ and $t \in U$.

DEFINITION 2. If $W \subset \Gamma$, let W° be the set of points $\gamma \in W$ such that, for some positive t, $\gamma \cdot t \notin W$. Let W^- be the set of points $\gamma \in W$ such that for any positive t, $(\gamma \cdot (0, t)) \not\subset W$. The set W^- is contained in W and is called the exit set of W. The set W is called a *Wazewski set* if the following conditions are satisfied:

(a) If $\gamma \in W$ and $(\gamma \cdot [0, t]) \subset cl(W)$ then $(\gamma \cdot [0, t]) \subset W$,

(b) W^- is closed relative to W°.

THEOREM. (*Wazewski*). *If W is a Wazewski set then W^- is a strong deformation retract of W° and W° is open relative to W^-.*

The set W that we have described above is a Wazewski set, as is the union of W with the set Q described in the next section. Since W° is homotopic to W, which has two components, W° must also have two components.

What separates these two components is S, the stable manifold for the strong detonation state, because any point which is not in one of these components must stay in W as y tends to infinity. Because H is always increasing within W, this solution must tend to a rest state, namely the strong detonation state. One boundary of this stable manifold is P; another is F, the stable manifold for the weak detonation state.

If there is a connected set in W consisting of points that tend to an unburned state U, as y tends to $-\infty$, and this set intersects both components of the exit set of W, then at least one of these points must be in S. The orbit of such a point is a viscous structure profile for a strong detonation wave.

In the next section we give sufficient conditions for the existence of such a set of points.

4. Some simple estimates. Orbits leaving an unburned state U which lies in $T < T_i$ will stay in the plane $\epsilon = \epsilon_-$ until the surface $T = T_i$ is reached. Consider the curve G given by $H_y \geq 0$, $T = T_i$, $\epsilon = \epsilon_-$, and $V_y \leq 0$. All of the points of G flow towards U as y tends to $-\infty$. The endpoints of G flow out of $H_y \geq 0$, $V_y \leq 0$, immediately. Our strategy is to add a tunnel from W to G so that the exit set of the extended set is still disconnected. The existence of such a tunnel will imply the existence of a viscous structure profile from U to the strong detonation state. The tunnel is:

$$Q = \{(V, H, \epsilon) : V \geq V_*,\ H_y \geq 0,\ V_y \leq 0,\ \epsilon_- \geq \epsilon \geq g(T),\ \text{and } T \geq T_i\}$$

The function g will be chosen so that the flow enters Q through the boundary $\epsilon = g(T)$, and so that $g(T) \geq \epsilon_i$ for $T_i \leq T \leq T_*$, where

$$\epsilon_i = \min\left\{\epsilon \;\middle|\; \begin{array}{l}\text{There exist } H \text{ and } V \text{ such that} \\ H_y(H,V,\epsilon) = V_y(H,V,\epsilon) = \phi(T) = \phi\left(\dfrac{(H - m^2V^2/2)}{c_p}\right) = 0\end{array}\right\}.$$

so that

$$\begin{aligned} q(\epsilon_- - \epsilon_i) &= \left(c_p - \frac{R}{2}\right)(T_i - T_-) \\ &\quad + \frac{u_-^2}{4\gamma^2 M_-^4}\left(1 - \gamma^2 M_-^4 + (\gamma M_-^2 + 1)\sqrt{(\gamma M_-^2 + 1)^2 - 4\gamma M_-^2 \frac{T_i}{T_-}}\right) \end{aligned} \tag{4.1}$$

See Fig. 3. Note that $\epsilon_- - \epsilon_i > 0$ whenever $T_i > T_-$. Also note that the flow enters Q through $\epsilon = \epsilon_-$ and $T = T_i$, while it exits through $H_y = 0$ and $V_y = 0$. The two components of the exit set are separated by the point $H_y = V_y = 0$, $T = T_i$. In order to choose the function g, we note that within Q, we have that

$$\frac{d\epsilon}{dT} = \frac{\epsilon_y}{T_y} = \frac{-\lambda\rho K\left(c_p(T_* - T) + m^2\dfrac{(V_*^2 - V^2)}{2}\right)\phi(T)}{qm^2\left(c_p(T - T_*) - m^2\dfrac{(V - V_*^2)}{2} + q\epsilon - R\left(T - T_*\dfrac{V}{V_*}\right)\right)}. \tag{4.2}$$

The right-hand side of (4.2) is monotone in V within Q. To see that the denominator is monotone in V for $V_* \le V \le V_-$, replace (V_*, T_*) by (V_-, T_-) and differentiate with respect to V, holding T constant. This denominator is also monotone in H as a function of (H, V). In the numerator, we decrease V to V_*. In the denominator, we decrease V, holding T constant, until we reach a value V_1 which satisfies either $H = H_+ - q\epsilon$ or $V_1 = V_*$. In the first case we obtain:

$$\left|\frac{d\epsilon}{dT}\right| \le \frac{\lambda K c_p (T_* - T)\phi(T)}{-m^2 q V_* \left(m^2(V_1^2 - V_1 V_*) - R(T - T_* V_1/V_*)\right)}. \tag{4.3}$$

Then $T = (H_+ - q\epsilon - m^2 V_1^2/2)/c_p$, and we have that:

$$\left|\frac{d\epsilon}{dT}\right| \le \frac{\lambda k c_p^2 (T_* - T)\phi(T)}{R m^2 q^2 V_* (\epsilon - f(V_1))}. \tag{4.4}$$

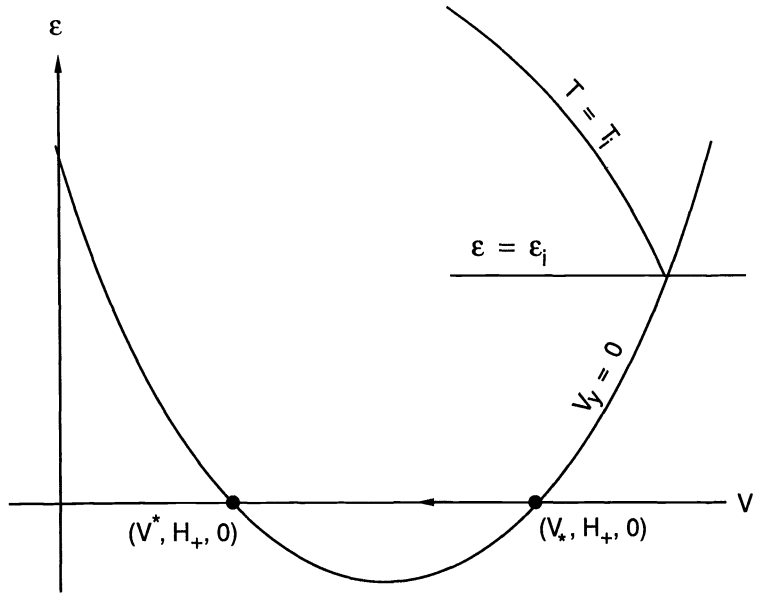

FIG. 3. *The plane* $H_y = H - H_+ + q\epsilon = 0$.

In the second case, we decrease the denominator further by decreasing H while holding $V = V_*$, until we reach $H = H_+ - q\epsilon$. This again yields (4.3), with $V_1 = V_*$ and a smaller value of T in the denominator; however, this value of T equals $(H_+ - q\epsilon - m^2 V_*^2/2)/c_p$. We still obtain (4.4), with $V_1 = V_*$.

Suppose $g(T) \ge \epsilon_i$ for $T_i \le T \le T_*$. Then $\epsilon \ge \epsilon_i$ within Q. Furthermore, $f(V_1) \le \epsilon_i$ within Q (see Fig. 3). Let

$$g'(T) = \frac{\lambda k c_p^2}{R m^2 q^2 V_*} \frac{(T_* - T)\phi(T)}{g(T) - \epsilon_i}, \quad g(T_i) = \epsilon_-. \tag{4.5}$$

Then the flow enters Q through $\epsilon = g(T)$ as long as $g(T) \ge \epsilon_i$. If we solve (4.4), we find that along $\epsilon = g(T)$ we have:

$$(\epsilon - \epsilon_i)^2 = (\epsilon_- - \epsilon_i)^2 - \frac{2\gamma c_p}{(\gamma - 1) m^2 q^2 V_*} \int_{T_i}^{T} \lambda k (T_* - T)\phi(T) dT. \tag{4.6}$$

Since we need to have $\epsilon > \epsilon_i$ for $T_i \le T \le T_*$, we require

$$\epsilon_- > \epsilon_i + \left(\frac{2\gamma c_p}{(\gamma-1)m^2 q^2 V_*} \int_{T_i}^{T_*} \lambda k (T_* - T)\phi(T)\, dT \right)^{1/2}. \tag{4.7}$$

Thus, (4.7) is a sufficient condition for the existence of a strong detonation structure profile. Since both λ and k can depend on T [Wi], it is important to keep them inside the integral.

For a CJ detonation wave, $(V_*, T_*) = (V^*, T^*)$. Condition (4.7) still implies the existence of a structure profile.

As λ tends to zero, with the other parameters held constant, condition (4.7) must be satisfied. In particular, since $\epsilon_- > \epsilon_i$ whenever $T_- < T_i$, we see that the strong and CJ detonations always have viscous structure when λ is sufficiently small. This is the limit of the "small rate parameter" considered by Wood [Wo1].

The region $(V_y < 0) \cap (H_y > 0) \cap (V > V_*) \cap (\epsilon < g(T))$ is negatively invariant, and contains the weak detonation point, and an interval of unburned states, including one corresponding to $\epsilon = \epsilon_i$, $T = T_i$, in its boundary. Since the exit set of this region is homotopic to a circle, and the region itself is contractible, another application of Wazewski's theorem shows that the one-dimensional stable manifold for the weak detonation point must be trapped in this region. Consequently one unburned state with $\epsilon = \epsilon_w$, $T = T_w$, $V = V_w$, which does not satisfy (4.7) must be connected to the weak detonation. Since this weak detonation is a boundary for the stable manifold of the strong detonation point, all unburned states with $\epsilon_- > \epsilon_w$ must be connected to the strong detonation point. As λ tends to zero, (ϵ_w, T_w, V_w) must tend to (ϵ_i, T_i, V_i).

5. A necessary condition. We obtain a necessary condition for the existence of viscous structure using energy estimates similar to those used in work on premixed laminar flames [BNS], [Ma], [Wg]. Observe that

$$H_{yy} = H_y - \frac{\lambda \rho k}{m^2 c_p}(H_+ - H)\phi(T). \tag{5.1}$$

If we multiply (5.1) by 1, H, and then H_y, and integrate each equation from $-\infty$ to $+\infty$, we obtain, using the fact that all derivatives tend to zero as y tends to $\pm\infty$:

$$\begin{aligned}
&\text{(a)} \quad H_+ - H_- = q\epsilon_- = \int_{-\infty}^{\infty} \frac{\lambda\rho k}{m^2 c_p}(H_+ - H)\phi(T)\, dy, \\
&\text{(b)} \quad \int_{-\infty}^{\infty} (H_y)^2\, dy = \int_{-\infty}^{\infty} \frac{\lambda\rho k}{m^2 c_p}(H_+ - H)H\phi(T)\, dy - \frac{H_+^2 - H_-^2}{2}. \\
&\text{(c)} \quad \int_{-\infty}^{\infty} (H_y)^2\, dy = \int_{-\infty}^{\infty} \frac{\lambda\rho k}{m^2 c_p}(H_+ - H)\phi(T)H_y\, dy \\
&\text{(d)} \quad \ge \int_{H_-}^{H_+} \frac{\lambda k}{m^2 c_p V_-}(H_+ - H)\phi\left((H - m^2 V_-^2/2)/c_p\right) dH.
\end{aligned} \tag{5.2}$$

Here we have used the fact that V_- is the maximum value of V on any detonation structure profile. Combining (5.2)(a–c) we find that:

$$\begin{aligned}
(H_+ - H_-)^2 m^2 c_p V_- &= (qY_- m)^2 c_p V_- \\
&\ge \int_{H_-}^{H_+} 2\lambda k (H_+ - H)\phi\left((H - m^2 V_-^2/2)/c_p\right) dH, \\
&= \int_{T_-}^{T_- + qY_-/c_p} 2\lambda k c_p \left(qY_- - c_p(T - T_-)\right)\phi(T)\, dT.
\end{aligned} \tag{5.3}$$

We may obtain a clearer interpretation of (5.3) with a little rearrangement and change of variables:

$$m^2 V_- \geq \int_0^1 2\lambda k c_p (1-\tau)\phi\left(T_- + \frac{qY_-\tau}{c_p}\right) d\tau. \tag{5.3'}$$

Thus, (5.3') constitutes a necessary condition for the existence of a detonation structure profile. Note that if we replace V_- by V_+, then we also obtain a necessary condition for the existence of a deflagration structure profile. Also, (5.3') is satisfied whenever $m^2 V_- \geq \lambda k \phi(T_- + qY_-/c_p)/c_p$.

6. Arbitrary Lewis numbers. When the Lewis number, $L = \lambda/\rho D c_p$, is not identically 1, then we must work with all four equations of (2.7). Consequently the region R must be extended to a region in $\mathbb{R}^4$. We require, therefore, additional boundaries for R, that is, upper and lower bounds for Y. It is interesting that we can obtain natural bounds for Y in terms of H, similar to the bounds that have been obtained for premixed laminar flames.

LEMMA. *Let*

$$\Lambda_* = \inf(L, 1) \tag{6.1}$$

$$\Lambda^* = \sup(L, 1)$$

Then

$$\Lambda_*(H_+ - H) \leq qY \leq \inf(q\epsilon, \Lambda^*(H_+ - H)) \tag{6.2}$$

defines a negatively invariant region for (2.7).

Proof. We proceed exactly as in [Wg], using (2.8):

$$\begin{aligned}\frac{d}{dy}\left(H - H_+ + \frac{qY}{\Lambda_*}\right) &= (H - H_+)_y + \frac{q}{\Lambda_*} Y_y \\ &\leq (H - H_+)_y + \frac{q\rho D c_p}{\lambda} Y_y \\ &= H - H_+ + qY \\ &\leq H - H_+ + \frac{q}{\Lambda_*} Y.\end{aligned}$$

This last quantity is zero on the boundary of the region defined by

$$H - H_+ + \frac{q}{\Lambda_*} Y \geq 0.$$

Consequently this region is negatively invariant for (2.7). Similarly, the region defined by

$$H - H_+ + \frac{q}{\Lambda^*} Y \leq 0$$

is negatively invariant, within the region $Y \leq \epsilon$. This last condition is required to ensure that $Y_y \leq 0$. The region $Y \leq \epsilon$ is negatively invariant because on $Y = \epsilon$,

$$\begin{aligned}\frac{d}{dy}(\epsilon - Y) &= \epsilon_y - Y_y \\ &= \epsilon_y \leq 0.\end{aligned}$$

□

The topological argument is a little more sophisticated than the one given in §3. The region W is defined as before, with the additional inequality (6.2). The exit set for W is now connected; using the lemma we see that it is a union of four parts: $\Sigma_{out} = \Sigma_1 \cup \Sigma_2 \cup \Sigma_3 \cup \Sigma_4$, where

$$\Sigma_1 = \{(V,\ H,\ \epsilon,\ Y) \mid H = H_+,\ Y = 0,\ 0 < \epsilon \le \epsilon_-,\ V_0 < V < V_*\}$$

$$\Sigma_2 = \left\{(V,\ H,\ \epsilon,\ Y) \,\middle|\, \begin{array}{l} qY = \min(q\epsilon,\ \Lambda^*(H_+ - H)),\ 0 < \epsilon \le \epsilon_-, \\ V_0 < V < V_*,\ 0 \le H_+ - H \le q\epsilon \end{array}\right\}$$

$$\Sigma_3 = \{(V,\ H,\ \epsilon,\ Y) \mid H_+ - H = q\epsilon,\ \Lambda_*\epsilon \le Y \le \epsilon,\ 0 < \epsilon \le \epsilon_-,\ V_0 < V < V_*\}$$

$$\Sigma_4 = \left\{(V,\ H,\ \epsilon,\ Y) \,\middle|\, \begin{array}{l} qY = \Lambda_*(H_+ - H),\ 0 < \epsilon \le \epsilon_-, \\ V_0 < V < V_*,\ 0 \le H_+ - H \le q\epsilon \end{array}\right\}.$$

Note, however, that Σ_{out} is homotopic to a circle. The circle may be visualized as a path from Σ_1 to Σ_2 to Σ_3 to Σ_4 and back to Σ_1. This path cannot be contracted to a point within Σ_{out} because Σ_{out} does not contain the positively invariant line segment

$$P = \{(V,\ H,\ \epsilon,\ Y) : qY = H_+ - H = q\epsilon = 0, V_0 \le V \le V_*\}.$$

Again, Wazewski's principle implies that the set W_{out} of all points in W which eventually flow out of W must also be homotopic to a circle. The curve G of §4, given by $H_y \ge 0$, $T = T_i$, $\epsilon = \epsilon_-$, $V_y \le 0$, is now extended, via (6.2), to a set G^* which is homeomorphic to a disk. The tunnel Q is also extended via (6.2). The estimates of §4 now show that the exit set of $W \cup Q$ is also homotopic to a circle. The boundary of G^* is homeomorphic to a circle and intersects the exit set of $W \cup Q$ with nonzero degree. Since a disk is not homotopic to a circle, at least one of the points of G^* must not exit W. This point must in fact tend to the strong detonation burned state. The sufficient condition (4.7) is now

$$\epsilon_- > \epsilon_i + \left(\frac{2\gamma c_p}{(\gamma-1)m^2q^2V_*}\int_{T_i}^{T_*} \lambda k\Lambda^*(T_* - T)\phi(T)dT\right)^{1/2}. \tag{6.3}$$

7. Behavior. We have shown that strong or CJ detonation structure profiles exist if (4.7) is satisfied. From this we can see that the existence of these profiles depends on the values of λ, ϕ, and k, relative to m, q, and γ, between the unburned state and the weak detonation point. We will now show that the behavior of the solution depends strongly on the values of these parameters near the strong detonation point.

At the strong detonation point the linearization of (2.7) has two negative eigenvalues:

$$\text{(a)}\quad \sigma_1 = \frac{1}{\gamma}\left(1 - M^{*-2}\right)$$

$$\text{(b)}\quad \sigma_3 = \frac{L}{2}\left(1 - \sqrt{1 + \frac{4Dk\phi(T^*)}{u^{*2}}}\right). \tag{7.1}$$

The relative sizes of σ_1 and σ_3 determine the node structure of the flow for (2.7) at the strong detonation point. If $Dk\phi(T^*)/u^{*2}$ is very small, or if L is very small (which

would be physically unusual), so that $0 > \sigma_3 > \sigma_1$, then the flow has a node tangent to the eigenvector

$$X_3 = \left[\frac{q(\gamma-1)}{\gamma m^2 V^*(\sigma_3-\sigma_1)},\ q,\ \sigma_3-1,\ \frac{L(\sigma_3-1)}{L-\sigma_3}\right].$$

Thus, all but one of the structure profiles approaches the strong detonation state tangent to X_3. The one orbit that approaches tangent to X_1 is the purely nonreacting shock profile which connects the weak detonation state to the strong detonation state. The $(V,\ H,\ \epsilon)$ components of X_3 have the signs $(+,\ +,\ -)$. Thus, at the end of the wave, V and H are increasing and ϵ, which must be monotone, is decreasing. Since $V^* < V_-$, V cannot be monotone throughout the entire solution. Once the solution leaves the region $V_y < 0$, it cannot reenter, because H is monotone increasing. Hence V attains its minimum value at a single point of the solution. This minimum value must be greater than V_0, the minimum value for a ZND detonation.

The pressure must also attain an extremum in this case:

$$\begin{aligned}\frac{dp}{dy} &= \frac{R}{V}\frac{dT}{dy} - \frac{RT}{V^2}\frac{dV}{dy}\\ &= \frac{R}{c_p}\left(\frac{H_y}{V} - m^2\left(1+\frac{c_pT}{u^2}V_y\right)\right).\end{aligned}$$

Since the flow is tangent to X_3 at the strong detonation state, we have, as the solution approaches that point,

$$\begin{aligned}\frac{dp}{dy} &= \frac{RH_y}{c_pV^*}\left(1-\frac{\gamma-1+M^{*-2}}{\gamma(\sigma_3-\sigma_1)}\right)\\ &= \frac{RH_y}{c_pV^*(\sigma_3-\sigma_1)}\left(\frac{L}{2}\left(1-\sqrt{1+\frac{4Dk\phi(T^*)}{u^{*2}}}\right)-1\right)\\ &< 0.\end{aligned}$$

Since p is increasing when $V_y < 0$, p must attain a maximum in the interior of the wave.

The temperature behaves differently. Near the strong detonation state, we have

$$\begin{aligned}\frac{dT}{dy} &= \frac{1}{c_p}\left(H_y - m^2VV_y\right)\\ &= \frac{1}{c_p}\left(\frac{\gamma m^2V^*(\sigma_3-\sigma_1)}{\gamma-1} - m^2V^*\right)V_y\\ &= \frac{m^2V^*}{c_p(\gamma-1)}\left(\frac{\gamma L}{2}\left(1-\sqrt{1+\frac{4Dk\phi(T^*)}{u^{*2}}}\right)+M^{*-2}-\gamma\right)V_y.\end{aligned}$$

Thus, if M^{*-2} is less than γ, we see that T decreases near the burned state. Consequently T must attain a maximum value in the interior of the wave. This is consistent with the behavior of the ZND wave corresponding to this case; see [Wi, pp. 194–197].

If M^{*-2} is greater than γ , then T decreases near the burned state if $\sigma_3 - \sigma_1$ is sufficiently small, but positive. In the inviscid limit for this case, as D, λ, and μ tend to zero, σ_3 tends to zero and T must increase near the burned state. It is a natural

conjecture that T is monotone throughout the wave in this case. We say, therefore, that the flow is *strongly subsonic* near the burned state if $\gamma M^{*2} < 1$. If this condition is satisfied, then the maximum value of the temperature on the surface $V_y = 0$ (the Rayleigh line) occurs at a value of H higher than H_+, for on the surface $V_y = 0$,

$$\frac{dT}{dV} = \frac{T}{V}\left(1 - \gamma M^2\right).$$

and

$$\frac{dH}{dV} = \frac{Vm^2}{\gamma - 1}\left(1 - M^2\right),$$

whereas

$$\frac{d\left(M^2\right)}{dV} = \frac{M^2}{V}\left(1 + \gamma M^2\right) > 0.$$

(See [Wi]). As a consequence, the corresponding ZND wave, which follows the intersection of the surface $V_y = 0$ and the plane $H_y = 0$, must have a monotone temperature whenever the burned state is strongly subsonic.

This phenomenon may be explained by noting that M_* depends on the total heat released per unit mass, qY_-, and increases as qY_- increases with other parameters, particularly m, held constant. Thus the strong detonation burned state is strongly subsonic if the heat release is too weak, relative to the strength of the wave, to create a temperature spike. In experiments (see [Wi, §6.2.1] and references cited therein), strong detonation waves are observed principally when a piston, or other external force, is used to overdrive the wave; in this respect strong detonation waves resemble inert shock waves. Detonation waves that are not overdriven will decay to a Chapman–Jouguet detonation. Chapman–Jouguet detonations may be thought of as reacting shock waves that are driven by the reaction with no external force. Thus these waves are "pure" reacting shock waves, and qY_- is a parameter between inert shock waves with monotone temperature profiles and Chapman–Jouguet waves with temperature spikes.

As M^* tends to 1, σ_1 tends to zero, which leads us to the next case. If $Dk\phi(T^*)/u^{*2}$ is very large, or if L is very large, or if M_* is very close to 1, so that $0 > \sigma_1 > \sigma_3$, then the flow forms a node tangent to the eigenvector

$$X_1 = (1,\ 0,\ 0,\ 0).$$

In this case the solution may behave in an unusual manner. Detonations with Y_- close to ϵ_i, (T_- close to T_i) will follow the trajectory of the weak detonation, and then turn near the weak detonation burned state, and approach the strong detonation point along the trajectory of the inert shock profile. Thus these structure profiles look like a weak detonation followed by an inert shock wave. See Fig. 4, where a heuristic picture of the flow in the stable manifold is presented.[1] Similar observations have been made in [Wo2], [FD], [LL], and most recently for numerical calculations and for a simpler model in [CMR], where it was noted that these pathological waves are actually numerically stable as solutions of the time-dependent reacting compressible

[1]Note that we have not proved that the stable manifold has no folds, so that V and e are global coordinates for the stable manifold, or that there is a monotone relationship between Y_- and the solution curves, such as depicted in Fig. 4. For a proof of such monotonicity for premixed laminar flames with $L > 1$, see [Ma].

Navier–Stokes equations. These authors also observed (numerically) an interesting phenomenon, namely that if the turning point of these solutions is sufficiently close to the weak detonation state, that is, if the spatial separation between the weak detonation and the inert shock wave is sufficiently large, then a bifurcation occurs wherein these two waves decouple and the inert shock moves slower than the weak detonation as predicted in [Wo2]. In this sense, a weak detonation can be observed. Weak detonations are also observed experimentally [FD], as a consequence of very complicated chemistry, change in equation of state, and endothermic or reversible reactions. A more significant point, made in [CMR], is that since $k\phi(T^*)/u^{*2}$ can be significantly large, it is important, in making machine calculations, to use an approximation scheme which does not add too much artificial diffusion, because this can radically change the character of the solution.

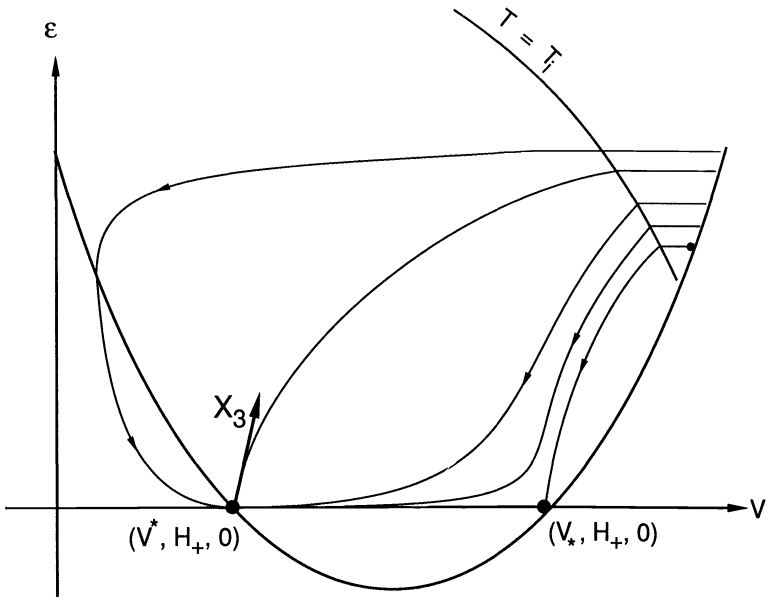

FIG. 4. *The flow in the stable manifold when* $0 > \sigma_1 > \sigma_3$.

For larger values of Y_-, there will be one wave which approaches the strong detonation state tangent to X_3, and others which approach tangent to X_1 but with V increasing. For the singular wave tangent to X_3 all quantities will be monotone, but for the others the pressure and density will attain maximum values. Since $H = c_pT + (m/\rho)^2/2$ is constant along X_1, the existence of a density peak in these waves implies the existence of a temperature peak.

For the CJ detonation, the burned state Mach number is 1, so that the above remarks apply to the behavior of this wave. All but one of the CJ detonation structure profiles must approach tangent to the eigenvector $\pm(1,0,0,0)$. However, solutions cannot approach along $+(1,0,0,0)$ (the right side) because $V_y > 0$ there. Consequently there is one monotone CJ structure profile (presumably the one with minimum heat release) and the rest have peaks in pressure, density, and temperature.

8. The ZND limit. We have noted that as λ tends to zero (or λ and D, with L constant), then the sufficient condition (4.7), or (6.3), must be satisfied. The structure

profiles satisfy natural a priori bounds, namely

$$V_0 \le V \le V_-,$$
$$H_- \le H \le H_+,$$
$$0 \le \Lambda_* \epsilon \le Y \le \epsilon \le Y - .$$

Thus, for any sequence $\lambda_n \to 0$, there is a corresponding sequence $(V_n,\ H_n,\ \epsilon_n,\ Y_n)$ of structure profiles with fixed end states, and which are uniformly bounded. Since H, ϵ, and Y are monotone, and V has at most one minimum, these profiles are also uniformly bounded in total variation. By Helly's theorem, some subsequence of this sequence must converge to a limit in L^1_{loc}. Taking a further subsequence we obtain convergence almost everywhere. The limit function is therefore a weak solution to (1.1a–c, d′). If $T_- < T_i$ then the limit is a ZND strong or CJ detonation. If $T_- = T_i$ then the limit is a continuous weak detonation which follows the curve $(H_y = 0) \cap (V_y = 0) \cap (\epsilon = Y)$ from $(V_i,\ H_i,\ \epsilon_i,\ Y_i)$ to $(V_*,\ H_*,\ 0,\ 0)$.

9. The second law of thermodynamics. In several shock structure problems, and particularly in MHD [CS1], [CS2], [Ge], the entropy flux has played an important role. In MHD the structure equations take the form

$$\frac{du}{dx} = B \nabla P(u)$$

where B is a positive diagonal matrix and P is the entropy flux. The gradient-like structure that this gives to the problem is essential to our understanding of the solution to this very complicated system. In other areas it is useful to postulate that the entropy flux must be monotone [HaSe1],[HaSe2]; the inequality expressing this monotonicity is called the *Clausius–Duhem inequality.* We show here, assuming only that the reaction is exothermic and irreversible ($r(\rho, Y, T) \ge 0$), that the entropy flux is monotone along a viscous structure profile for a plane steady detonation or deflagration wave. We have not used this fact in the above discussion, although it would have proved useful if we had not already known that H must be monotone.

The entropy flux is

$$P = mS - \lambda T_x / T.$$

Using Gibb's law: $TdS = de + pdV - qdY$ [Wi], we find that

$$\frac{dP}{dx} = \frac{m}{T}\left(\frac{de}{dx} + p\frac{dV}{dx} - q\frac{dY}{dx}\right) + \frac{\lambda T_x^2}{T^2} - \frac{(\lambda T_x)_x}{T}.$$

Using (1.2), we have

$$\begin{aligned}\frac{dP}{dx} &= \frac{\lambda T_x^2}{T^2} - \frac{1}{T}\left(\left[\left[\rho\left(u^2/2 + e(\rho,T,Y)\right) + p(\rho,T)\right]u\right]_x - (\mu u u_x)_x - (q\rho D Y_x)_x\right) \\ &\quad + \frac{m}{T}\left(\frac{de}{dx} + p\frac{dV}{dx} - q\frac{dY}{dx}\right) \\ &= \frac{\lambda T_x^2}{T^2} + \frac{\mu u_x^2}{T} + \frac{qr}{T} \ge 0.\end{aligned}$$

Note that dP/dx only vanishes at rest points of (1.2). However, (1.2) is not gradient-like with respect to P, because

$$dP = -\frac{\lambda T_x}{T} dT + \frac{q d\epsilon}{T} - \frac{\mu u_x}{T} du;$$

since q/T does not vanish, neither does the gradient of P. This may be an anomaly which is due to the simple representations of the chemistry and the reaction rate which are used here.

Acknowledgments. The author would like to thank Professor Andrew Majda for his encouragement and support, the National Science Foundation and the Air Force Office of Scientific Research for their financial support, and Steffen Heinze for pointing out several typographical mistakes.

BERNSTEIN FUNCTIONS AND THE DIRICHLET PROBLEM*

ALAN R. ELCRAT† AND KIRK E. LANCASTER†

Abstract. For a nonconvex, symmetric quadrilateral, the nonparametric minimal surface arising from an associated Dirichlet problem can be described in terms of the Weierstrass representation and the stereographic projection of its Gauss map. The Bernstein function—which arises by truncation of the re-entrant corner by a concave arc and by requiring the normal vector to be horizontal there—has the same Gauss map image. This leads to a Riemann-Hilbert problem that can be solved and leads to the existence of this surface.

Key words. nonparametric minimal surface, Riemann-Hilbert problem, Bernstein function

AMS(MOS) subject classifications. 35J65, 53A10

Introduction. If Ω is a nonconvex, planar domain and ϕ is a continuous function, defined on $\partial\Omega$, for which the Dirichlet problem for the minimal surface equation does not have a continuous solution, it is natural to ask about the behavior of generalized, "variational" solutions near boundary points where the solution is discontinuous and to determine the geometric nature of the graph. In the particular case of a symmetric, nonconvex quadrilateral with boundary values that are zero on the outer edges and which increase linearly to a positive value on the edges adjacent to the re-entrant corner, these questions have been asked by Finn [F1] and Nitsche [N] and have been studied recently by Elcrat and Lancaster [EL]. If the latter results are combined with the subsequent work of Lancaster [L1], we can assert that this problem is well understood. In fact, an experimental soap film realization of the solution is shown in [EL]. The domain in this case is regular for the minimal surface equation at all but one of its boundary points, and the next step in complexity is a domain whose boundary consists of two arcs, one convex and one concave. In particular we can consider a truncation of the re-entrant quadrilateral by a concave arc. The critical first step in understanding this new problem is the construction of a Bernstein function, a solution of the minimal surface equation whose normal derivative is infinite there. This surface serves as an upper bound for the trace of generalized solutions on the concave arc and can be used as a comparison function for other domains.

In this work we reconsider the solution of the re-entrant quadrilateral problem and, in the process, obtain an existence theorem for a Bernstein function in the truncated quadrilateral. The approach that we use is based on the intuitive observation that for these two surfaces the Gauss maps have the same image. By a stereographic projection we can consider this image as a domain in the complex plane and if we introduce the Weierstrass representation of minimal surfaces in terms of analytic functions f and g, using *this* domain for the complex parameter, the second function g reduces to the identity. Furthermore, f satisfies explicit linear boundary conditions given by properties of the normal vector of the surface sought. This means that our problem reduces to a Riemann-Hilbert problem for the analytic function f. The remarkable fact is that the solution of the re-entrant quadrilateral problem and the Bernstein function satisfy conditions that differ only by an inhomogeneous term in one of the boundary conditions. It turns out that, using results for Riemann-Hilbert problems with discontinuous coefficients [M], we can deduce the existence of a solution of the inhomogeneous

Riemann-Hilbert problem from existence for the homogeneous problem. We must prove, in order to complete the chain of deductions, that the solution of the re-entrant quadrilateral problem is a surface whose Gauss map has the required properties and that the analytic function f solving the inhomogeneous problem leads to a surface of the required type. These tasks demand some effort, which accounts for most of the text of the paper.

The significance of this work derives not only from proving the existence of a useful comparison function, but from its construction using a geometric transformation that changes a nonlinear problem into a linear one, which can be solved by giving the solution of a boundary value problem for an analytic function. This idea currently relates to a variety of problems in applied mathematics—for example, numerical conformal mapping [H], [T] and free boundary problems in fluid mechanics [M], [ET]. Although the idea of reconstructing a surface from its Gauss map has been known for a long time, we are not aware of many examples in which an explicit construction can be given of a surface whose boundary geometry is prescribed. Furthermore, the construction of a new minimal surface from a known one using our procedure is new.

1. The re-entrant quadrilateral problem. In this section, we will specify the geometry, set the notation, and state some required theorems from previous work. Let $\alpha, \beta, \gamma \in (0, \pi/2)$ with $\alpha+\gamma<\pi/2$. Set $A_0=(0, -\sin(\gamma)/\sin(\alpha))$, $A_1=(-\sin(\alpha+\gamma), \cos(\alpha+\gamma))$, $A_2=A_3=(0,0)$, and $A_4=(\sin(\alpha+\gamma), \cos(\alpha+\gamma))$ (see Fig. 1). Let Ω be the region bounded by the nonconvex symmetric quadrilateral $A_3A_4A_0A_1A_2$. Let $\phi \in C^0(\partial\Omega)$ equal zero on $A_1A_0A_4$, increase linearly from 0 at A_1 to $\tan(\beta)$ at A_2, and increase linearly from 0 at A_4 to $\tan(\beta)$ at A_3.

Set

$$\Gamma_1=\{(x, y, 0)\,|\,(x, y)\in A_0A_1\},$$
$$\Gamma_2=\{(x, y, \phi(x, y))\,|\,(x, y)\in A_1A_2\},$$
$$\Gamma_4=\{(x, y, \phi(x, y))\,|\,(x, y)\in A_3A_4\},$$
$$\Gamma_5=\{(x, y, 0)\,|\,(x, y)\in A_4A_0\},$$

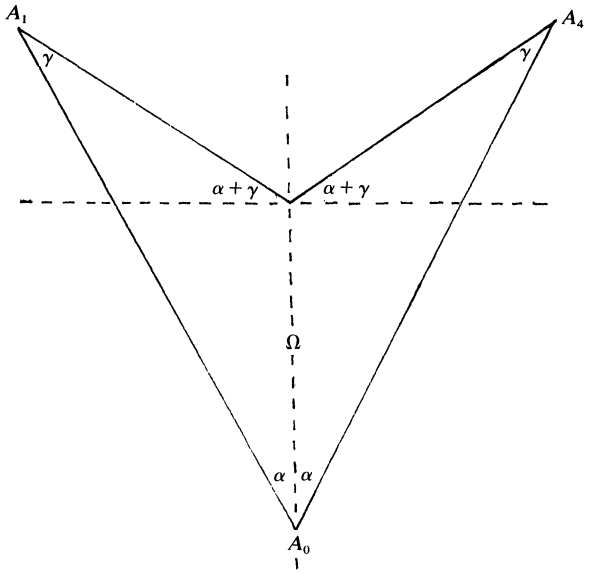

FIG. 1

where, for example, A_0A_1 is the closed line segment between A_0 and A_1. Define Γ to be $\Gamma_1 \cup \Gamma_2 \cup \Gamma_4 \cup \Gamma_5$.

Set

$$T_1 = \{(u, v) \mid v = \tan(\alpha)u\},$$
$$T_2 = \{(u, v) \mid (u+u_0)^2 + (v-v_0)^2 = r^2\},$$
$$T_3 = \{(u, v) \mid u^2 + v^2 = 1\},$$
$$T_4 = \{(u, v) \mid (u-u_0)^2 + (v-v_0)^2 = r^2\},$$
$$T_5 = \{(u, v) \mid v = -\tan(\alpha)u\},$$

where $(u_0, v_0) = \cot(\beta)(\sin(\alpha+\gamma), \cos(\alpha+\gamma))$, and $r = \csc(\beta)$.

Let

$$H_1 = \{(x, y, z) \mid y = \tan(\alpha)x\},$$
$$H_2 = \{(x, y, z) \mid -\cos(\beta)\sin(\alpha+\gamma)x + \cos(\beta)\cos(\alpha+\gamma)y + \sin(\beta)z = 0\},$$
$$H_3 = \{(x, y, z) \mid z = 0\},$$

and

$$H_4 = \{(x, y, z) \mid \cos(\beta)\sin(\alpha+\gamma)x + \cos(\beta)\cos(\alpha+\gamma)y + \sin(\beta)z = 0\},$$
$$H_5 = \{(x, y, z) \mid y = -\tan(\alpha)x\}.$$

Note that T_k is the stereographic projection of the great circle $H_k \cap S^2$, for $k = 1, \cdots, 5$, and that H_k is orthogonal to Γ_k, for $k = 1, 2, 4, 5$. The stereographic projection of any unit vector orthogonal to Γ_k or to the z-axis will be in T_k or T_3 ($k = 1, 2, 4, 5$).

Let w_0 be the origin and let w_k be the point of intersection of $T_k \cap T_{k+1}$ that lies in the upper half-plane for $k = 1, \cdots, 4$. Let σ_k be the shorter (closed) arc of T_k between w_{k-1} and w_k, $k = 1, \cdots, 5$, where $w_5 = w_0$. Set $\sigma = \sigma_1 \cup \cdots \cup \sigma_5$ and define D ($= D(\alpha, \beta, \gamma)$) to be the open region in the plane bounded by σ. Note that D is contained in the open unit disc B and $\sigma_3 = \partial D \cap \partial B$ (see Fig. 2).

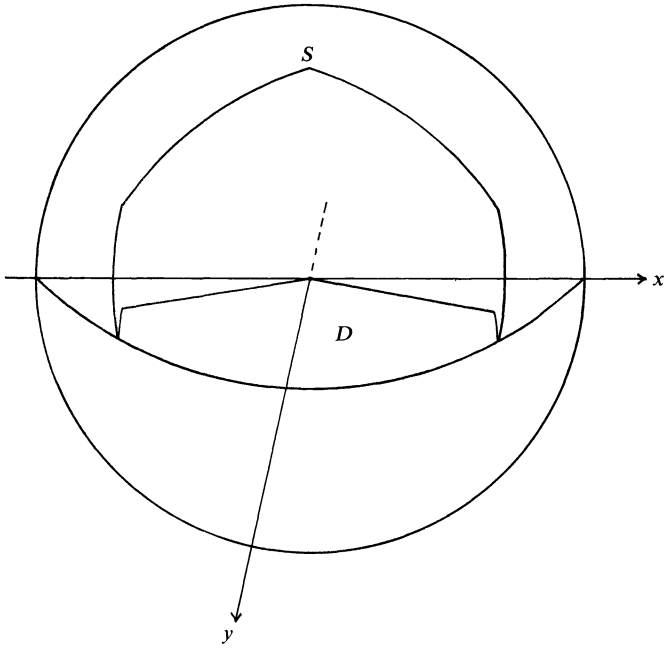

FIG. 2

Set $B^+ = \{(u, v) \in B \mid v > 0\}$. We will consider D, B^+, and B as subsets of $\mathbb{C}$ when this is convenient. When doing so, we will let $w = u + iv$ represent a point of D and $\omega = u + iv$ represent a point of B^+ or B. D will be shown to be the image of the Gauss maps for the surfaces discussed in this paper.

Let $F \in BV(\Omega)$ minimize

$$J(v) = \int\int_{\Omega} \sqrt{1 + |Dv|^2} + \int_{\partial\Omega} |v - \phi|$$

over $v \in BV(\Omega)$. Then $F \in C^2(\Omega) \cap C^0(\bar{\Omega} \backslash \{A_2\})$ and $F = \phi$ on $\partial\Omega \backslash \{A_2\}$. Define S_0 to be the graph of F over Ω and S to be the closure of S_0. The graph of F is the re-entrant quadrilateral surface discussed in [EL] (see the Introduction). From [L1] and [L2] we obtain Proposition 1.

PROPOSITION 1. *There exists* $Y \in C^2(B^+: \mathfrak{R}^3) \cap C^0(\overline{B^+}: \mathfrak{R}^3)$ *such that* Y *is conformal and has harmonic components, and* Y *maps* B^+ *homeomorphically onto* S_0, $\partial' B^+$ $(= \partial B^+ \cap \partial B)$ *strictly monotonically onto* Γ, *and* $\partial'' B^+$ $(= \partial B^+ \cap B)$ *into the z-axis. Furthermore,* $Y(-1, 0) = Y(1, 0) = (A_2, \phi(A_2))$, $Y(-u, v) = \operatorname{diag}(-1, 1, 1) Y(u, v)$ *for* $(u, v) \in B^+$, Y *has a branchpoint at* $(0, 0)$, Y *maps* $\{(u, v) \in \partial B^+ \mid u \geqq 0, v \geqq 0\}$ *onto* $\Gamma_4 \cup \Gamma_5$, *and* Y *extends by reflection across* $\partial'' B^+$ *as a parametric minimal surface.*

It will be useful for us to transplant this parametrization of S to another domain. Let us define

$$\frac{d}{dw} = \frac{1}{2}\left(\frac{\partial}{\partial u} - i\frac{\partial}{\partial v}\right), \qquad \frac{d}{d\omega} = \frac{1}{2}\left(\frac{\partial}{\partial u} - i\frac{\partial}{\partial v}\right).$$

Then $Y_\omega(0) = 0$. Let h_1 be the conformal map from D onto B^+ sending w_0 to i, w_2 to -1, and w_3 to 1 and let h_2 be the conformal map of B onto B^+ sending i to i, -1 to -1, and 1 to 1. Define $h: D \to B$ by $h = h_2^{-1} \circ h_1$. Note that h_1 extends analytically across $\partial D \backslash \{w_0, \cdots, w_4\}$ and has nonvanishing derivative on $\bar{B} \backslash \{w_0, \cdots, w_4\}$ (e.g., [GL]). Similarly, h_2 extends analytically across $B \backslash \{-1, 1\}$ and has nonvanishing derivative on $\bar{B} \backslash \{-1, 1\}$. The asymptotic behavior of h_1 and h_2 at corners is known (i.e., [H, p. 359]). Set

$$X(w) = Y(h_1(w)) \quad \text{for } w \in \bar{D},$$

$$\tilde{X}(\omega) = Y(h_2(\omega)) \quad \text{for } \omega \in \bar{B}.$$

Let $X(w) = (x(w), y(w), z(w))$. The symbols X, $x(w)$, $y(w)$, and $z(w)$ will represent the parametric minimal surface defined above and its components throughout this article.

For $k = 0, 1, 4$, define $\omega_k \in \partial B$ so that $\tilde{X}(\omega_k) = (A_k, \phi(A_k))$ and define $\omega_2 = -1$ and $\omega_3 = 1$. Note $\omega_0 = i$ by symmetry. Let s_k be the (closed) arc on ∂B between ω_{k-1} and ω_k that does not contain any of the other ω's, for $k = 1, \cdots, 5$, where $\omega_5 = \omega_0$. As a consequence of Lemma 1, we note that $h(w_k) = \omega_k$, $k = 0, \cdots, 4$.

Let $g: D \to \mathbb{C}$ and $\tilde{g}: B \to \mathbb{C}$ be the stereographic projections (from the north pole) of the Gauss map of S_0 when S_0 is parametrized by X and $\tilde{X}$, respectively (see Fig. 3). If we write the components of $\tilde{X}$ as $\tilde{x}$, $\tilde{y}$, $\tilde{z}$, then

$$g(w) = z_w(w)/(x_w(w) - iy_w(w)) \quad \text{for } w \in D,$$

$$\tilde{g}(\omega) = \tilde{z}_\omega(\omega)/(\tilde{x}_\omega(\omega) - i\tilde{y}_\omega(\omega)) \quad \text{for } \omega \in B.$$

Further, g and $\tilde{g}$ are meromorphic in D and B, respectively. For the parametrizations

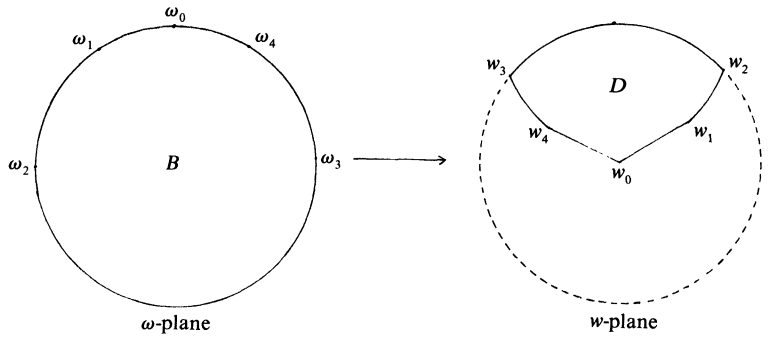

FIG. 3

we have chosen, the Gauss map of each point of S_0 lies in the lower hemisphere, and so g and $\tilde{g}$ are analytic maps from D and B, respectively, into B. Using continuation by reflection and [B], we see that g and $\tilde{g}$ may be extended to be the stereographic projections of the Gauss map of S and that $g \in C^0(\bar{D})$, $\tilde{g} \in C^0(\bar{B})$, and $g(w) = \tilde{g}(h(w))$ for $w \in D$.

LEMMA 1. *$\tilde{g}(\omega) = h^{-1}(\omega)$ for $\omega \in \bar{B}$ and $g(w) = w$ for $w \in \bar{D}$.*

Proof. As noted earlier, the unit normals to Γ_k lie in the plane H_k, $k = 1, 2, 4, 5$, and so $\tilde{g}$ maps s_k into T_k, $k = 1, \cdots, 5$. Using [B], we see that $\tilde{g}$ maps ω_k into ω_k, $k = 0, \cdots, 4$. If we consider various planes and apply the maximum principle (cf. [EL]), we see that $\tilde{g}$ maps s_k onto σ_k, $k = 1, 2, 4, 5$. (These planes are the xy-plane, the plane through Γ_1 and Γ_2, and the plane through Γ_3 and Γ_4.) From [L1], we see that $\tilde{g}(s_3) = \sigma_3$ and $\tilde{g}$ is injective on s_3. Thus $\tilde{g}$ maps ∂B onto ∂D.

Note that the winding number of $\tilde{g}(\partial B)$ about each point of D is 1. By the argument principle, $\tilde{g}$ takes on each value in D exactly once and does not take any values outside D; thus $\tilde{g}$ is a conformal map of B onto D. By the Osgood-Carathéodory Theorem [H, p. 346], $\tilde{g}$ is a homeomorphism of $\bar{B}$ onto $\bar{D}$. Now $\tilde{g}(\omega_k) = w_k$, $k = 0, \cdots, 4$, and $h(w_k) = \omega_k$ for $k = 0, 2, 3$, so $\tilde{g} = h^{-1}$. Furthermore, $g(w) = \tilde{g}(h(w)) = w$ for $w \in \bar{D}$. □

We are interested in the Weierstrass f and g representations of S. Define

$$f(w) = x_w(w) - iy_w(w) \quad \text{for } w \in D,$$

$$\tilde{f}(\omega) = \tilde{x}_\omega(\omega) - i\tilde{y}_\omega(\omega) \quad \text{for } \omega \in B.$$

Then f and $\tilde{f}$ are analytic on D and B, respectively, and the Weierstrass f and g representations of X and of $\tilde{X}$, respectively, are (f, g) and $(\tilde{f}, \tilde{g})$. Note $f(w) = \tilde{f}(h(w))h'(w)$ for $w \in D$. Since X and $\tilde{X}$ can be extended by harmonic continuation, we see that $f \in A(\bar{D}\backslash\{w_0, \cdots, w_4\})$.

In the next two lemmas, we obtain information about f, $\tilde{f}$ that is required for a precise formulation of a Riemann-Hilbert problem for f in the next section.

LEMMA 2. *$\tilde{f}$ has a simple zero at $-i$ and f has a simple zero at i.*

Proof. We may extend Y (from Proposition 1) by reflection across $\partial'' B^+$. Since $Y_\omega(0) = 0$, $h_1(i) = 0 = h_2(-i)$, $X_w(w) = Y_\omega(h_1(w))h_1'(w)$ for $w \in \bar{D}\backslash\{w_0, \ldots, w_4\}$, and $\tilde{X}_\omega(\omega) = Y_\omega(h_2(\omega))h_2'(\omega)$ for $\omega \in \bar{B}\backslash\{\omega_0, \cdots, \omega_4\}$, we see that $X_w(i) = 0$ and $\tilde{X}_\omega(-i) = 0$ and so $f(i) = 0$ and $f(-i) = 0$.

Let us write $Y(\omega) = (x^*(\omega), y^*(\omega), z^*(\omega))$. From [L2], we know that

$$(z^* + ix^*)(\omega) = (H(\omega))^2,$$

where $H(0)=0$ and

$$DH(0)=\operatorname{diag}(e,e), \qquad e\in\Re\backslash\{0\}.$$

If we write $H(\omega)=H_1(u,v)+iH_2(u,v)$, then $z^*(\omega)=(H_1(u,v))^2-(H_2(u,v))^2$ and

$$\begin{aligned}\operatorname{Re}(z^*_{\omega\omega}(\omega))&=\tfrac{1}{4}(z^*_{uu}-z^*_{vv})(\omega)\\&=\tfrac{1}{2}\{H_1H_{1uu}+(H_{1u})^2-H_2H_{2uu}-(H_{2u})^2\\&\qquad -H_1H_{1vv}-(H_{1v})^2+H_2H_{2vv}+(H_{2v})^2\}(\omega).\end{aligned}$$

As $\omega\in B^+$ approaches 0, $\operatorname{Re}(z^*_{\omega\omega}(\omega))$ approaches $\frac{1}{2}\{(H_{1u}(0))^2-(H_{2u}(0))^2-(H_{1v}(0))^2+(H_{2v}(0))^2\}=e^2$ (since in [G, p. 279], it is shown that the second partials of H_1, H_2 are $o(|\omega|^{-1})$) and so $z^*_{\omega\omega}(0)\neq 0$.

Now $z(w)=z^*(h_1(w))$ and so $z_{ww}(w)=z^*_{ww}(h_1(w))(h_1'(w))^2+z^*_w(h_1(w))h_1''(w)$. Then $z_{ww}(i)\neq 0$, and similarly $\tilde{z}_{ww}(-i)\neq 0$. Since $f(w)g(w)=z_w(w)$, $f_w(w)g(w)+f(w)g_w(w)=z_{ww}(w)$ and so $f_w(i)=z_{ww}(i)\neq 0$. Similarly, $\tilde{f}_{\omega}(-i)\neq 0$. □

Let $\lambda_k\pi$ be the angle formed by the intersection of Γ_k and Γ_{k+1}, $k=0,\cdots,4$, where $\Gamma_0=\Gamma_5$ and $\Gamma_3=\{(0,0,z)|z\leqq\phi(A_2)\}$. Let $\delta_k\pi$ be the angle at w_k formed by the tangent lines to σ_k and σ_{k+1} that D "fills."

LEMMA 3. *$\tilde{f}$ has an integrable singularity at ω_k for each $k\in\{0,\cdots,4\}$. In fact, $\tilde{f}(\omega)=O(|\omega-\omega_k|^{\lambda_k-1})$ and $(\omega-\omega_k)^{1-\lambda_k}\tilde{f}(\omega)\to l_k\in\mathbb{C}\backslash\{0\}$ as $\omega\in\bar{B}\backslash\{\omega_k\}$ approaches ω_k, for each $k=0,\cdots,4$.*

Proof. Let $T:\Re^3\to\Re^3$ be the rigid motion sending $\tilde{X}(\omega_k)$ to the origin that maps the line segments forming the angle $\lambda_k\pi$ of Γ_k and Γ_{k+1} at $\tilde{X}(\omega_k)$ into the upper half of the plane $z=0$ as follows: (a) the images of the line segments form equal angles with the y-axis and (b) $T\circ\tilde{X}$ maps s_{k+1} into the first quadrant of the xy-plane. Let us write $T(\xi)=L_k(\xi+r_k)$ for $\xi\in\Re^3$, where $r_k\in\Re^3$ is fixed and L_k is a rotation of $\Re^3$. For $k=0$, $r_0=(-A_0,0)$, and, in matrix form, $L_0=\operatorname{diag}(-1,1,-1)$.

Let h_k be the conformal map of B^+ onto $B(0,1)$ with $h_k(0)=\omega_k$ and $h_k'(0)>0$. Let us now fix $k\in\{0,\cdots,4\}$ and set $Z=T\circ\tilde{X}\circ h_k$. Then $Z(\omega)=(\hat{x}(\omega),\hat{y}(\omega),\hat{z}(\omega))$ maps B^+ onto $T(S)$ and sends $0+0i$ to $(0,0,0)$. Set $\lambda=\lambda_k$. By Theorem 3 of [D],

$$\begin{aligned}\hat{x}_{\omega}(\omega)&=\omega^{\lambda-1}H_2(\omega)+\omega^{-\lambda}H_3(\omega),\\\hat{y}_{\omega}(\omega)&=-i\omega^{\lambda-1}H_2(\omega)+i\omega^{-\lambda}H_3(\omega),\\\hat{z}_{\omega}(\omega)&=H_1(\omega)\end{aligned}$$

for $\omega\in\bar{B}^+\backslash\{0\}$ in the neighborhood of zero,

$$\omega(H_1(\omega))^2+4H_2(\omega)H_3(\omega)\equiv 0,$$

$H_2(0)\neq 0$, and $H_3(0)=0$. If we define $F(\omega)=(\tilde{x}\circ h_k)_{\omega}(\omega)-i(\tilde{y}\circ h_k)_{\omega}(\omega)$, then $F(\omega)=c\omega^{\lambda-1}+o(1)$ for some constant $c\neq 0$. When $k=0$, we remark that $F(\omega)=\omega^{\lambda-1}H_2(\omega)$. Since h_k maps an analytic portion of B^+ into an analytic portion of B, we see that $\tilde{f}(\omega)=0(|\omega-\omega_k|^{\lambda_k-1})$ and $\tilde{f}(\omega)=l_k(\omega-\omega_k)^{\lambda_k-1}+O(|\omega-\omega_k|^{\lambda_k})$ for a constant $l_k\neq 0$. □

Now h is the conformal map of D onto B that maps w_k to ω_k, $k=0,\cdots,4$. We see that for $w\in\bar{D}\backslash\{w_k\}$ near w_k, $\delta=\delta_k$, $\varepsilon=1/\delta_k$,

$$\begin{aligned}h(w)-\omega_k&=c_k(w-w_k)^{\varepsilon}+o(|w-w_k|^{\varepsilon}),\\h'(w)&=\frac{c_k}{\delta}(w-w_k)^{\varepsilon-1}+o(|w-w_k|^{\varepsilon-1})\end{aligned}$$

for some $c_k \in \mathbb{C}\backslash\{0\}$ (e.g., [H, p. 359]). Furthermore,

$$(h^{-1})(\omega) - w_k = e_k(\omega - \omega_k)^{\sigma} + O(|\omega - \omega_k|^{\sigma}),$$

$$(h^{-1})'(\omega) = e_k\delta(\omega - \omega_k)^{\delta-1} + o(|\omega - \omega_k|^{\delta-1})$$

for $\omega \in \bar{B}\backslash\{\omega_k\}$ near ω_k, where $e_k \in \mathbb{C}\backslash\{0\}$. Since $f(w) = \tilde{f}(h(w))h'(w)$, Lemma 3 gives, for $v = -1 + \lambda_k/\delta$,

$$f(w) = c_k(w - w_k)^{v} + o(|w - w_k|^{v})$$

as $w \in \bar{D}\backslash\{w_k\}$ approaches w_k and $f(h^{-1}(\omega)) = c_k(\omega - \omega_k)^{v\delta} + o(|\omega - \omega_k|^{v\delta})$ as $\omega \in \bar{B}\backslash\{\omega_k\}$ approaches ω_k for some $c_k \in \mathbb{C}\backslash\{0\}$.

Note that $\lambda_0\pi = 2\alpha$ and $\delta_0\pi = \pi - 2\alpha$; $\lambda_1\pi = \cos^{-1}(\cos(\gamma)\cos(\beta))$ and $\delta_1\pi > \pi/2$; $\lambda_2\pi = \pi/2 - \beta$ and $\delta_2\pi > \pi/2$; $\lambda_3\pi = \pi/2 - \beta$ and $\delta_3 > \pi/2$; and $\lambda_4\pi = \cos^{-1}(\cos(\gamma)\cos(\beta))$ and $\delta_4\pi > \pi/2$. Thus $f(h^{-1}(\omega))$ has an integrable singularity at ω_1, ω_2, ω_3, and ω_4. Also, at ω_0, $f(h^{-1}(\omega)$ has an integrable singularity if $\alpha < \pi/4$ and has a "fractional zero" if $\alpha > \pi/4$.

2. The Hilbert problem. We wish to derive a homogeneous boundary value problem for which $f(w)$ is a solution. Let $f(u+iv) = f_1(u, v) + if_2(u, v)$, where f_1 and f_2 are real-valued. Since $g(w) = w$,

$$x_w(w) = f(w)(1 - w^2)/2,$$

$$y_w(w) = if(w)(1 + w^2)/2,$$

$$z_w(w) = wf(w)$$

for $w \in D$. Since $d/dw = \frac{1}{2}((\partial/\partial u) - i(\partial/\partial v))$, taking real and imaginary parts gives us

$$x_u(u, v) = (1 - u^2 + v^2)f_1 + 2uvf_2,$$

$$x_v(u, v) = 2uvf_1 - (1 - u^2 + v^2)f_2,$$

$$y_u(u, v) = -2uvf_1 + (1 + u^2 - v^2)f_2,$$

$$y_v(u, v) = -(1 + u^2 - v^2)f_1 + 2uvf_2,$$

$$z_u(u, v) = 2(uf_1 - vf_2),$$

$$z_v(u, v) = 2(-vf_1 - uf_2).$$

Let us set $m_1 = \cot(\alpha)$, $m_2 = \cot(\alpha + \gamma)$, $m_4 = -\cot(\alpha + \gamma)$, $m_5 = -\cot(\alpha)$, $n_1 = 0$, $n_2 = -\tan(\beta)\csc(\alpha + \gamma)$, $n_4 = \tan(\beta)\csc(\alpha + \gamma)$, and $n_5 = 0$. The condition $(x, y, z) \in \Gamma_k$ is equivalent to $y = m_k x + b_k$, $z = n_k x + c_k$, $k = 1, 2, 4, 5$, where (b_k, c_k) are constants depending on α, β, γ, k. We know that X maps σ_k into Γ_k, $k = 1, 2, 4, 5$, and maps σ_3 into the z-axis. If we parametrize σ_k by $w_k(t) = (u_k(t), v_k(t))$, then $X(w_k(t)) \in \Gamma_k$ and so $y(w_k(t)) = m_k x(w_k(t)) + b_k$, $z(w_k(t)) = n_k x(w_k(t)) + c_k$ for $k = 1, 2, 4, 5$ and $x(w_3(t)) = y(w_3(t)) = 0$. Differentiating with respect to t yields the two equivalent equations $y_u u_k' + y_v v_k' = m_k(x_u u_k' + x_v v_k')$, $z_u u_k' + z_v v_k' = n_k(x_u u_k' + x_v v_k')$ when $k = 1, 2, 4, 5$ and $x_u u_3' + x_v v_3' + y_v v_3' = 0$ when $k = 3$. If we now write $x_u, \cdots, z_v$ in terms of f_1, f_2, u, v and rearrange each equation slightly, we obtain

$$a_k(u, v)f_1(u, v) + b_k(u, v)f_2(u, v) = 0$$

when $(u, v) \in \sigma_k$, for $k = 1, \cdots, 5$, where

$$a_1(u, v) = -\cos(2\alpha),$$

$$a_2(u, v) = 2uv(v - v_0) - (1 + u^2 - v^2)(u - u_0) - \cot(\alpha + \gamma)(1 - u^2 + v^2)(v - v_0) + 2\cot(\alpha + \gamma)uv(u - u_0),$$

$$a_3(u, v) = 2v(u^2 - v^2),$$

$$a_4(u, v) = 2uv(v - v_0) - (1 + u^2 - v^2)(u - u_0) + \cot(\alpha + \gamma)(1 - u^2 + v^2)(v - v_0) - 2\cot(\alpha + \gamma)uv(u - u_0),$$

$$a_5(u, v) = \cos(2\alpha),$$

$$b_1(u, v) = \sin(2\alpha),$$

$$b_2(u, v) = (1 + u^2 - v^2)(v - v_0) + 2uv(u - u_0) - 2\cot(\alpha + \gamma)uv(v - v_0) - \cot(\alpha + \gamma)(1 - u^2 + v^2)(u - u_0),$$

$$b_3(u, v) = -4uv^2,$$

$$b_4(u, v) = (1 + u^2 - v^2)(v - v_0) + 2uv(u - u_0) + 2\cot(\alpha + \gamma)uv(v - v_0) + \cot(\alpha + \gamma)(1 - u^2 + v^2)(u - u_0),$$

$$b_5(u, v) = \sin(2\alpha).$$

We point out that if $Z : \bar{D} \to R^3$ is C^1 on $\bar{D}$ except at a finite number of points of D, $Z \in C^0(\bar{D})$, and $Z(w) = (p(w)(1 - w^2)/2,\ ip(w)(1 + w^2)/2,\ wp(w))$, where $p(w) = p_1(u, v) + ip_2(u, v)$, then the condition $a_k p_1 + b_k p_2 = 0$ on σ_k is equivalent to $Z(\sigma_k)$ being a line segment parallel to Γ_k if $k \neq 3$ and parallel to the z-axis if $k = 3$. The forthcoming modification of a_2, a_4, b_2, b_4 will not change this observation.

In the theory of Hilbert problems with discontinuous coefficients, the coefficient $G = a - ib$ must be bounded away from 0 [M, pp. 42–53]. In our case $a_2(w_2) = b_2(w_2) = 0$ and $a_4(w_3) = b_4(w_3) = 0$ and so some modification is required. If $(u, v) \in \sigma_2$, then $u = -u_0 + r\cos(\theta)$ and $v = v_0 + r\sin(\theta)$ for some $\theta \in (-\pi/2, \pi/2)$. Set $t = \tan(\theta/2)$ and note that $\cos(\theta) = (1 - t^2)/(1 + t^2)$, $\sin(\theta) = 2t/(1 + t^2)$, $t \in [t_0, t_1]$, where $t_0 = \tan(\theta_0/2)$, $t_1 = \tan(\theta_1/2)$, and θ_0, θ_1 are in $(-\pi/2, \pi/2)$. Let $c(t) = a_2(w_2(t))$, $d(t) = b_2(w_2(t))$, and $e(t)$ be the greatest common divisor of $c(t)$ and $d(t)$. Let us define new functions $a_2(u, v)$ and $b_2(u, v)$ for $(u, v) \in \sigma_2$ by setting $a_2(w_2(t)) = c(t)/e(t)$ and $b_2(w_2(t)) = d(t)/e(t)$. We may repeat this process and replace a_4 and b_4.

Define $a(u, v)$ and $b(u, v)$ on $\partial D \backslash \{w_0, \cdots, w_4\}$ by setting $a = a_k$ and $b = b_k$ on $\sigma_k \backslash \{w_{k-1}\}$. Note that each a_k and b_k is continuous on σ_k and so a and b have one-sided limits at $w_0, \cdots, w_4$. Also a and b are certainly piecewise Lipschitz continuous on ∂D. Now a and b are discontinuous at $w_1, \cdots, w_4$ and at w_0 unless $\alpha \geqq \pi/4$. Set $G(w) = a(w) - ib(w)$.

Let R be defined on ∂D (or almost everywhere on ∂D). Consider the Hilbert problem $H(\cdot, R)$ of finding a function analytic in D that satisfies $\operatorname{Re}(G\psi) = R$ on $\partial D \backslash \{w_0, \cdots, w_4\}$ and that has the "singularity pattern of f" at $w_0, \cdots, w_4$. The "index" of this problem (with indicated behavior at w_k, $k = 0, \cdots, 4$) is 1 and the general solution can be found using [M, pp. 42–53]. If ψ_0 denotes a solution of $H(\cdot, 0)$, then $\psi(w) = \psi_0(w)(c + H(w))$, where H is the analytic function in D whose imaginary part on ∂D is $R/(iG\psi_0)$. This is true since $\operatorname{Re}(G\psi) = c\operatorname{Re}(G\psi_0) + \operatorname{Re}(G\psi_0 H) = 0 + \operatorname{Im}(H) = R$ on ∂D (recall that $\operatorname{Re}(G\psi_0) = 0$ on ∂D). The analytic function H can be found by using the Schwarz formula; formally,

$$H^*(\omega) = \frac{1}{2\pi i}\int_{|t|=1} \frac{R^*(t)(t + \omega)\, dt}{G^*(t)\psi_0^*(t)t(t - \omega)}$$

for $\omega \in \partial B$, where $H^*(\omega) = H(h^{-1}(\omega))$ and similarly for R^*, G^*, ψ^*. For later use, set $\alpha_k = \lambda_k - \delta_k$ for $k = 0, \cdots, 4$ and note $\alpha_k < 0$ if $k = 1, \cdots, 4$.

3. Bernstein functions. We will now formulate a boundary value problem that will lead to the surfaces to be constructed. Let $A_3^* = (x_3^*, y_3^*)$ be a point on $\partial\Omega$ strictly between A_3 and A_4. Set $A_2^* = (x_2^*, y_2^*) = (-x_3^*, y_3^*) \in \partial\Omega$. Let K be a C^2 curve in $\mathfrak{R}^2$ between A_2^* and A_3^* such that K is symmetric with respect to the y-axis, K and $\partial\Omega$ are tangent at A_2^* and A_3^*, and K is strictly concave with respect to $\{(x, y+t) \mid (x, y) \in K, t \leqq 0\}$. Let us parametrize K by $(x, k(x))$, $x_2^* \leqq x \leqq x_3^*$. We know that $k''(x) > 0$ unless $x \in E = \{x \in (x_2^*, x_3^*) \mid k''(x) = 0\}$, which we assume is finite, and possibly at x_2^* and x_3^*. We require $0 \notin E$. We will impose additional restrictions on k near $E \cup \{x_2^*, x_3^*\}$.

We wish to parametrize K in a special way. Since K is strictly concave and is tangent to $\partial\Omega$ at A_2^* and A_3^*, we see that for each $e^{i\theta} \in \sigma_3$ there is a unique point $(A(\theta), B(\theta))$ on K such that the tangent line to K at $(A(\theta), B(\theta))$ is orthogonal to $(\cos(\theta), \sin(\theta))$, and conversely. The parametrization $(A(\theta), B(\theta))$, $\alpha + \gamma \leqq \theta \leqq \pi - (\alpha + \gamma)$, is continuous, is C^1 on $N = \{\theta \in (\alpha + \gamma, \pi - (\alpha + \gamma)) \mid A(\theta) \notin E\}$, and satisfies

$$(A'(\theta), B'(\theta)) \cdot (\cos(\theta), \sin(\theta)) = 0$$

and so $B'(\theta) = -\cot(\theta) A'(\theta)$, for $\theta \in N$. The symmetry of K implies $A'(\pi - \theta) = A'(\theta)$ and $B'(\pi - \theta) = -B'(\theta)$. We can easily check that $k'(A(\theta)) = -\cot(\theta)$, which could be taken as a definition of $A(\theta)$, and $A'(\theta) = \csc^2(\theta)/k''(A(\theta))$.

Let us assume that there exists $\beta \in (0, 1)$ and $C_1 > 0$ such that $k''(x) \geqq C_1 |x - \bar{x}|^\beta$, whenever x is sufficiently close to $\bar{x}$, for each $\bar{x} \in E$. If $k''(x_2^*) = k''(x_3^*) = 0$, let us assume that there exist $\gamma \in (0, -\alpha_3/\delta_3)$ and $C_2 > 0$ such that $k''(x) \geqq C_2 |x - x_3^*|^\gamma$ whenever $x \leqq x_3^*$ is sufficiently near x_3. Let us examine $A(\theta)$ and $A'(\theta)$. If $k''(A(\theta^*)) = 0$, then $A'(\theta) \to \infty$ as $\theta \to \theta^*$ and so $|A(\theta) - A(\theta^*)| \geqq 2|\theta - \theta^*|$ for $\theta \in (\theta_2^*, \theta_3^*)$ near θ^*. Now if $w = e^{i\theta}$ and $w^* = e^{i\theta^*}$ then

$$|A(\theta) - A(\theta^*)| \geqq 2|\arg(w) - \arg(w^*)| = 2|\mathrm{Ln}(w) - \mathrm{Ln}(w^*)| \geqq |w - w^*|$$

and $A'(\theta) = \csc^2(\theta)/k''(A(\theta)) \leqq 2\csc^2(\theta^*) C_1 |A(\theta) - A(\theta^*)|^{-\beta} \leqq C' |w - w^*|^{-\beta}$ if w is near w^*, and similarly for w_2 and w_3.

Finally let us assume that $k \in C^{2,\delta}((x_2, x_3))$ for some $0 < \delta \leqq \min\{\beta, \gamma\}$. Then $|A'(\lambda_2) - A'(\lambda_1)| \leqq C(\lambda_1, \lambda_2) |\lambda_2 - \lambda_1|^\delta$ for all $\lambda_1, \lambda_2 \in (\theta_2^*, \theta_3^*)$ with $\lambda_1, \lambda_2 \notin N$, and for λ_1, λ_2 in a compact subset of N, $C(\lambda_1, \lambda_2)$ is uniformly bounded.

Define $R(w) = 0$ if $w \notin \sigma_3$ and $R(w) = A'(\theta)$ if $e^{i\theta} = w \in \sigma_3$ and $k''(A(\theta)) \neq 0$. Let $R^*(\omega) = R(h^{-1}(\omega))$, $G^*(\omega) = G(h^{-1}(\omega))$, $\psi_0 = f$, and $\psi_0^* = \tilde{f}$. Recall that $\tilde{f}(\omega) = (\omega + i) e(\omega)$ with $e(-i) \neq 0$ and, for $k = 2, 3$,

$$\tilde{f}(\omega) = c_k (\omega - \omega_k)^{\alpha_k} + O(|\omega - \omega_k|^{\alpha_k}).$$

Note that $R^*(\omega)$ is Hölder continuous at ω_2 and ω_3 with exponent $-\alpha_3 - (\gamma/\delta_3) > 0$ (use [H, p. 359] and $R^*(\omega) = O(|\omega - \omega^*|^{-\beta})$ if $\omega^* \in E^* = \{\omega \in s_3 \mid \arg(h^{-1}(\omega)) \notin N\}$). Finally R^* is Hölder continuous on $\partial B \backslash E \cup \{-i\}$ and uniformly Hölder continuous on each compact subset of $\partial B \backslash E \cup \{-i\}$.

Define

$$H^*(\omega) = \frac{1}{2\pi i(\omega + i)} \left[\text{P.V.} \int_{\partial B} \frac{R^*(t)(t+\omega)\, dt}{G^*(t) e(t) t(t-\omega)} - \text{P.V.} \int_{\partial B} \frac{R^*(t)(t+\omega)\, dt}{G^*(t) e(t) t(t+i)} \right]$$

for all $\omega \in \bar{B} \backslash E^*$. Since

$$\frac{\omega + i}{(t+i)(t-\omega)} = \frac{1}{t-\omega} - \frac{1}{t+i},$$

we see that

$$H^*(\omega)=\frac{1}{2\pi i}\,\text{P.V.}\int_{\partial B}\frac{R^*(t)(t+\omega)\,dt}{G^*(t)f(t)t(t-\omega)(t+i)}$$

for $\omega\in\bar{B}\backslash E^*\cup\{-i\}$, where we take principal values at $-i$ and at ω if $\omega\in\partial B$. Using Theorem 14.1c of [H], we see that H^* is analytic in B and continuous on $\bar{B}\backslash E^*\cup\{-i\}$. Furthermore,

$$\text{Im}\,(H^*(\omega))=R^*(\omega)/(iG^*(\omega)\tilde{f}(\omega))$$

for each $\omega\in\partial B\backslash E^*\cup\{-i\}$ [H, pp. 100-103] and $H(\omega)=O(|\omega-\omega^*|^{-\beta})$ for $\omega\in\bar{B}$ near $\omega^*\in E^*$, as a simple argument shows.

Since $H(w)=H^*(h(w))$ is continuous on $\bar{D}\backslash\{e^{i\theta}\in\sigma_3\,|\,A(\theta)\in E\}\cup\{i\}$, we can define

$$c_0=c_0(K,D)=-\inf\{\text{Re}\,(H(w))\,|\,w\in\sigma\backslash\sigma_3\}.$$

Since $R=0$ on $\sigma\backslash\sigma_3$, $\text{Im}\,(H(w))=0$ if $w\in\sigma\backslash\sigma_3$ and so

$$c_0=-\inf_{\sigma\backslash\sigma_3}H=\sup_{\sigma\backslash\sigma_3}(-H).$$

Note that if $c\geqq c_0$, $c+H(w)>0$ for w at all but a finite number of points of $\sigma\backslash\sigma_3$.

DEFINITION. For a curve K as above and any $\ell>\sqrt{(x_2^*)^2+(y_2^*)^2}$, define $\Omega(K,\ell)$ as the domain bounded by K and the line segments between A_2^* and ℓA_1, ℓA_1 and ℓA_0, ℓA_0 and ℓA_4, and ℓA_4 and A_3^* (see Fig. 4).

Set $\phi_\ell(x,y)=\ell\phi(x/\ell,y/\ell)$ for $(x,y)\in\partial\Omega(k,\ell)$.

PROBLEM $B(K,\ell)$. For a curve K as above and $\ell>\sqrt{(x_2^*)^2+(y_2^*)^2}$, find $F^+\in C^2(\Omega(K,\ell))\cap C^0(\overline{\Omega(K,\ell)})$ that satisfies the minimal surface equation in $\Omega(K,\ell)$ with $F^+=\phi_\ell$ on $\partial\Omega(K,\ell)\backslash K$ such that as $(x,y)\in\Omega(K,\ell)$ approaches $(x_0,y_0)\in\{(x,y)\in K\,|\,x\notin E\}$, the exterior normal derivative of F^+ at (x,y) approaches ∞.

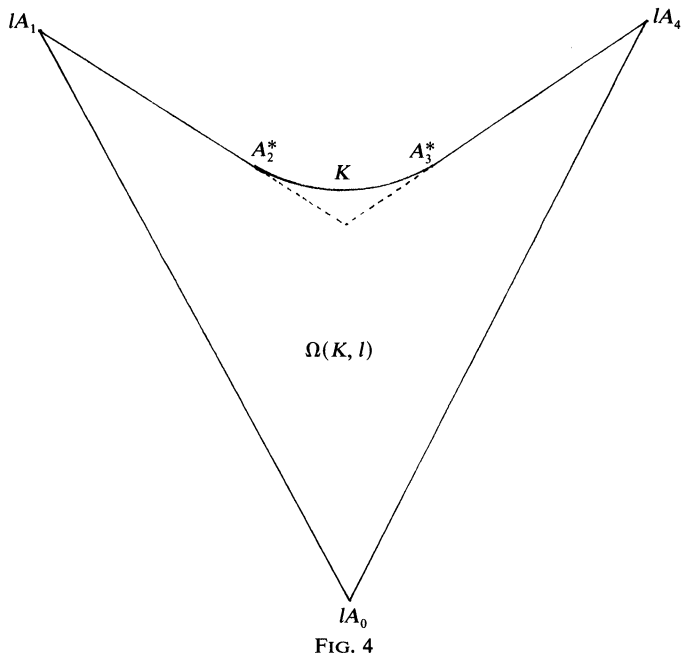

FIG. 4

We will find a number $\ell_0 = \ell_0(K)$ such that $B(K, \ell)$ has a (necessarily unique) solution if $\ell \geqq \ell_0$. If $\ell < \ell_0$, we obtain a candidate that does not solve $B(K, \ell)$.

For c real, define $\psi(w, c) = f(w)(c + H(w))$ and note that $\psi(\cdot, c)$ solves $H(\cdot, R)$ (on $h^{-1}(E^*)$, R is not defined). Clearly, f is continuous at i. Define

$$x(w, c) = \operatorname{Re}\left(\int_0^w \frac{1}{2}\psi(t, c)(1 - t^2)\, dt\right)$$

for $w \in \bar{D}$. Set $\ell_0 = \ell_0(K) = \frac{1}{2}\csc(\alpha + \gamma)(x(w_4, c_0) - x(w_1, c_0))$ and define $c(\ell) = c(K, \ell) = \ell - \ell_0(K) + C_0(K)$. Define

$$y(w, c) = \operatorname{Re}\left(\int_0^w \frac{i}{2}\psi(t, c)(1 + t^2)\, dt\right) - (c - c_0(K) + \ell_0(K)) \sin(\alpha)/\sin(\gamma),$$

$$z(w, c) = \operatorname{Re}\left(\int_0^w t\psi(t, c)\, dt\right),$$

$$X(w, c) = (x(w, c), y(x, c), z(w, c))$$

for $w \in \bar{D}$. Note that $X(\cdot, c) \in C^0(\bar{D})$ and $X(w, c) = X(w, c_0) + (c - c_0)X(w)$. In particular, $x(w_4, c(\ell)) - x(w_1, c(\ell)) = x(w_4, c_0) - x(w_1, c_0) + (c(\ell) - c_0)(x(w_4) - x(w_1)) = 2\ell_0 \sin(\alpha + \gamma) + 2(c(\ell) - c_0)\sin(\alpha + \gamma) = 2\ell \sin(\alpha + \gamma)$.

Note that

$$X_w(w, c) = (c + H(w))X_w(w)$$

for $w \in \bar{D} \backslash h^{-1}(E^*)$ and $c + H(w)$ is real and positive if $w \in \sigma \backslash \sigma_3$ and $c > c_0$ ($c = c_0$ implies $c + H(w) > 0$ on $\sigma \backslash \sigma_3$ except at a finite number of points). Thus the sign pattern of $x_u(\cdot, c), \cdots, z_v(\cdot, c)$ is the same as that of $x_u, \cdots, z_v$ on $\sigma \backslash \sigma_3$ if $c \geqq c_0$.

Suppose $w = e^{i\theta} \in \sigma_3 \backslash (h^{-1}(E^*) \cup \{w_2, w_3\})$. Since

$$a(w)f_1(w, c) + b(w)f_2(w, c) = A'(\theta),$$

$$a(w)f_1(w, c) + b(w)f_2(w, c) = \frac{d}{d\theta}(x(\cos(\theta), \sin(\theta), c)),$$

where $f = f_1 + if_2$ and $c \in R$, we see that $d/d\theta\,(x(\cos(\theta), \sin(\theta), c)) = A'(\theta)$.

Since $x(\cdot, \cdot, c)$ is continuous, we obtain $x(\cos(\theta), \sin(\theta), c) = A(\theta) + A_0$, for $\alpha + \gamma \leqq \theta \leqq \pi - (\alpha + \gamma)$. One unit normal to $X(\bar{D}, c)$ at $w = e^{i\theta}$ with $\theta \in N$ is $(\cos(\theta), \sin(\theta), 0)$. Since $d/d\theta\,(X(\cos(\theta), \sin(\theta), c))$ lies in the tangent plane of $X(\bar{D}, c)$ at w, we see that $d/d\theta\,(y(\cos(\theta), \sin(\theta), c)) = -\cot(\theta)A'(\theta) = B'(\theta)$. Thus $y(\cos(\theta), \sin(\theta), c) = B(\theta) + B_0$ and the projection onto the xy-plane of $X(\sigma_3, c)$ is the translation of K by (A_0, B_0).

Suppose $w \in \sigma \backslash \sigma_3$. Then $R(w) = 0$ and $a(w)f_1(w, c) + b(w)f_2(w, c) = 0$. As we indicated in § 2, $X(\sigma_k, c)$ lies on a line parallel to Γ_k, $k = 1, 2, 4, 5$. If $\ell \geqq \ell_0(K)$, then $c(\ell) \geqq c_0$ and so $X(\cdot, c(\ell))$ maps ∂D strictly monotonically onto the Jordan curve $X(\partial D, c(\ell))$. Now $H_2(u, v) = \operatorname{Im}(H^*(h(u + iv)))$ is odd on ∂D so $f_1(u, v, c(\ell))$ is an even function of u and $f_2(u, v, c(\ell))$ is an odd function of u for $(u, v) \in \bar{D}$. Thus $x(u, v, c(\ell))$ is odd in u, $y(u, v, c(\ell))$ and $z(u, v, c(\ell))$ are even in u (and $X(\partial D, c(\ell)$ is a simple Jordan curve that is symmetric with respect to the yz-plane and has a simple projection on the xy-plane). Also $X(0, c(\ell)) = \ell(A_0, 0)$ and $x(w_4, c(\ell)) - x(w_1, c(\ell)) = 2\ell \sin(\alpha + \gamma)$ implies $X(\sigma_1, c(\ell)) = \ell\Gamma_1$, $X(\sigma_5, c(\ell)) = \ell\Gamma_5$, and the projection of $X(\partial D, c(\ell))$ on the xy-plane is $\partial\Omega(K, \ell)$. Using [R, p. 36], we see that $X(D, c(\ell))$ has no interior branchpoints and, since $g(w) = w$, $X(D, c(\ell))$ must be the graph of a function F^+. From our discussion, we see that F^+ is a solution of $B(K, \ell)$.

We give the following example to illustrate the applicability range of these theorems. We compare the results obtained using our methods with those obtained using catenoids, which are standard comparison surfaces.

Example. Suppose $\alpha = \pi/8$, $\gamma = \pi/8$, and $\beta = \pi/4$. Note that $A_0 = (0, -1)$, $A_1 = (-1/\sqrt{2}, 1/\sqrt{2})$, and $A_4 = (-1/\sqrt{2}, 1/\sqrt{2})$. Let $\varepsilon \in (0, \beta/2\pi]$; say, $\varepsilon = 0.1$. Define $k \in C^{2,0.1}([-\frac{1}{2}, \frac{1}{2}])$ by $k''(x) = c(1-4x^2)^{\varepsilon}$, $k'(0) = 0$, and $k(-\frac{1}{2}) = k(\frac{1}{2}) = \frac{1}{2}$, where $1/c = \int_0^{0.5} (1-4t^2)^{\varepsilon}\, dt$. Note that $k'(-\frac{1}{2}) = -1$ and $k'(\frac{1}{2}) = 1$; also, $k(x)$ satisfies the conditions mentioned at the beginning of § 3. Let $K = \{(x, k(x)): -\frac{1}{2} \leqq x \leqq \frac{1}{2}\}$ and set $\ell_0 = \ell_0(K)$. Let $U = \Omega(K, \ell_0)$.

We are interested in two questions. First, what information can we obtain about the existence of a solution of problem $B(K, \ell_0)$ using our construction and catenoids? Second, if $\xi \in C^2(U) \cap C^0(\bar{U} \backslash K)$ is a solution of the minimal surface equation in U and $\xi \leqq \phi_{\ell_0}$ on $\partial U \backslash K$, what information can we obtain concerning the behavior of ξ near $(\pm\frac{1}{2}, \frac{1}{2})$, in particular, concerning the lim sup of $\xi(x, y)$ as $(x, y) \in \bar{U}$ approaches $(\pm\frac{1}{2}, \frac{1}{2})$, using our construction and using catenoids? With respect to our construction, we saw that a solution $F \in C^0(\bar{U})$ of $B(K, \ell_0)$ exists. Also, from § 4 we see that $\xi(x, y) \leqq F(x, y)$ for $(x, y) \in \bar{U} \backslash K$ and so $\limsup_{(x,y)\to(\pm 1/2, 1/2)} \xi(x, y) \leqq F(\pm\frac{1}{2}, \frac{1}{2}) = \ell_0 - 1/\sqrt{2}$. With respect to using catenoids, as the following paragraph indicates, the existence of a bounded solution $\psi \in C^2(U) \cap C^0(\bar{U} \backslash K)$ of the minimal surface equation in U with $\psi = \phi_{\ell_0}$ on $\partial U \backslash K$ and $\partial\psi/\partial\eta = +\infty$ almost everywhere on K cannot be obtained using catenoids; at best, perhaps the existence of $\psi \in BV(\Omega)$ with $\operatorname{tr}(\psi) \in L^1(\partial U)$ might be possible. Furthermore, no information concerning lim sup $\xi(x, y)$ as $(x, y) \in U$ approaches $(\pm\frac{1}{2}, \frac{1}{2})$ can be obtained using this method.

Suppose $x_0 \in (-\frac{1}{2}, \frac{1}{2})$. Let $A(a, b)$ be the annulus with center $(x_0 - ak'(x_0)w(x_0), k(x_0) + aw(x_0))$, inner radius a and outer radius b, where $w(x) = (1 + (k'(x))^2)^{-1/2}$; note that the inner boundary $\partial_a A$ of $A(a, b)$ is tangent to K at $(x_0, k(x_0))$ and the center of $A(a, b)$ lies "above" K. Suppose the outer boundary $\partial_b A$ of $A(a, b)$ does not interest U and $\partial_a A$ lies below K (see Fig. 5). Note then that $a > R(x_0)$ and $b - a > 1/\sqrt{2}$, where $R(x)$ is the radius of curvature of K at $(x, k(x))$ (i.e., $1/R(x) = k''(x)w^3(x)$). Let the graph of $u \in C^2(A(a, b)) \cap C^0(\overline{(A(a, b))})$ be a piece of a catenoid such that $u = 0$ on $\partial_b A$ and $\partial u/\partial n = -\infty$ on $\partial_a A$. Then $\xi(x, y) \leqq u(x, y)$

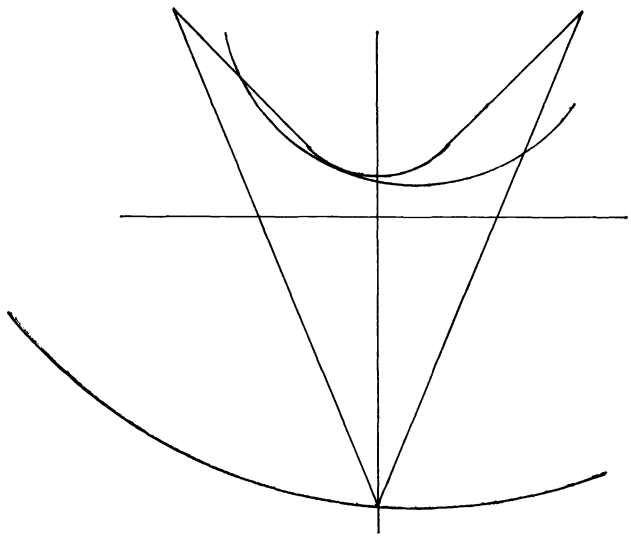

FIG. 5

for $(x, y) \in U \cap A(a, b)$ (e.g., [F1]), provided that $u \geqq \phi_{\ell_0}$ on $\partial U \cap A(a, b)$. Define $\lambda(r; a, b) = a \cosh^{-1}(b/a) - a \cosh^{-1}(r/a)$ for $r \geqq a$ and let $r(x, y)$ be the distance between (x, y) and the center of $A(a, b)$. Then $u(x, y) = \lambda(r(x, y); a, b)$ and $u(x, y) > \lambda(r(x, y); R(x_0), R(x_0) + 1/\sqrt{2})$. Now $u(x, y)$ is (possibly) an upper bound for $\xi(x, y)$ at $(x_0, K(x_0))$ and the least $u(x_0, k(x_0))$ could be is (greater than) $L(x_0)$, where $L(x) = R(x) \cosh^{-1}(1 + 1/\sqrt{2}R(x))$. Thus, the smallest upper bound catenoids could provide for ξ on K is $L(x)$. Since $R(x) \to \infty$ as $x \to \pm\frac{1}{2}$, $L(x) \to \infty$ as $x \to \pm\frac{1}{2}$. In particular, if we take $\xi = F$, we see that the use of catenoids does not imply that F is bounded (much less continuous).

4. Applications. Using the comparison lemma due to Finn [F1] (see also [F2]), we see that the results of the previous section imply the following theorem.

THEOREM. *Let K and $\Omega(K, \ell)$ be as in § 3 with $\ell \geqq \ell_0(K)$. Then there exists $F^+ \in C^0(\overline{\Omega(K, \ell)}) \cap C^2(\Omega(K, \ell))$, a solution of the minimal surface equation in $\Omega(K, \ell)$ with $F^+ = \phi_\ell$ on $\partial\Omega(K, \ell) \setminus K$, such that*

$$f \leqq F^+ \quad \text{on } \Omega(L, \ell)$$

for every solution f of the minimal surface equation in $\Omega(K, \ell)$ with $f \leqq \phi_\ell$ on $\partial\Omega(K, \ell) \setminus K$.

One of the distinctive features of this result is that the curvature of K need not be bounded away from zero; the curvature of K can vanish on E and at the endpoints of K. As we saw in the example in § 3, standard comparison surfaces such as the catenoid are not useful in this case. In fact, the existence theorem we have proven does not follow from known results obtained by the variational theory such as those of [G]. It would be interesting to see if we could apply that theory, using refinements such as those recently reported in [F2], to obtain these results.

Suppose U is a domain in the plane whose boundary consists of a concave, symmetric arc K and a locally convex arc L such that the tangent lines to the endpoints of K make an angle larger than $\pi/2$ and K satisfies the conditions of § 3. Here we may assume that U has been rotated and translated into a suitable position. Then for $\ell \geqq \ell_0(K)$ sufficiently large, $U \subseteq \Omega(K, \ell)$ and $\partial U \cap \partial\Omega(K, \ell) = K$ (see Fig. 6).

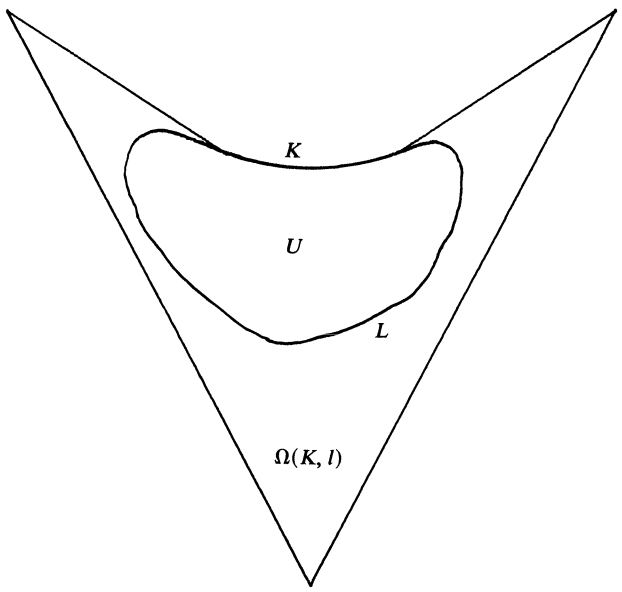

FIG. 6

COROLLARY. *Let U and $\Omega(K, \ell)$ be as above. Let $\psi \in L^\infty(L)$ and let $f \in C^2(U)$ be a solution of the minimal surface equation in U such that $f = \psi$ almost everywhere on L. Then*

$$f \leqq F^+ + \sup_L \psi \quad \text{on } U,$$

where $F^+ = F^+(K, \ell) \in C^0(\overline{\Omega(K, \ell)})$.

The proof of this corollary follows from the general maximum principle and the previous theorem.

Acknowledgment. The authors acknowledge numerous helpful conversations with Bob Gulliver concerning this work and thank him for his criticism and encouragement.

APPLICATIONS OF SHILNIKOV'S THEORY TO SEMILINEAR ELLIPTIC EQUATIONS*

C. J. BUDD†

Abstract. This paper shows how techniques from the theory of dynamical systems may be employed to study semilinear elliptic equations having nonlinearities that grow faster than the critical Sobolev exponent. In particular, techniques from Shilnikov's theory are used to study the symmetric solutions of the equation

$$\Delta u + \lambda(u^p + u^q) = 0, \qquad u|_{\partial B} = 0,$$

where B is the unit ball in $\mathbb{R}^3$ and $q < 3 < 5 < p$. In particular, there is shown to be a critical value of λ at which the above equation has an infinite number of positive solutions.

Key words. semilinear elliptic equations, dynamical systems, Shilnikov's theory, bifurcation, critical Sobolev exponents

AMS(MOS) subject classifications. 34B15, 35J25, 35J65

1. Introduction. In this paper we will use methods from the theory of dynamical systems to study the positive solutions of the following differential equation:

$$u_{rr} + \frac{2}{r} u_r + u^p + u^q = 0, \qquad u(0) = N, \quad u_r(0) = 0, \tag{1.1}$$

where $p > 5$ and $q < 3$.

An application of standard theory given, for example, in Smoller and Wasserman [21] or Ni and Serrin [16] shows that $u(r)$ is an analytic function of N and has a first positive zero, defined by $\mu(N) < \infty$, that is also an analytic function of N. We may thus deduce that a solution of problem (1.1) is also a radially symmetric solution of the following partial differential equation problem:

$$\Delta u + u^p + u^q = 0, \qquad u > 0 \quad \text{in } B, \qquad u|\partial B = 0, \tag{1.2}$$

where

$$B = \{\mathbf{x} \in \mathbb{R}^3 : |\mathbf{x}| \leqq \mu(N)\}$$

and Δ is the usual Laplacian operator in $\mathbb{R}^3$. (Although for clarity we restrict our discussion to $\mathbb{R}^3$, the techniques described in this paper apply equally to $\mathbb{R}^n$ with $n > 2$.)

When p is less than the critical Sobolev exponent for $\mathbb{R}^3$, namely, $p_c \equiv 5$, the solutions of problem (1.2) may be studied by employing methods from the calculus of variations. Details of this study are given by Brezis and Nirenberg in [2]. When $p > 5$, however, much less is known about the solutions of problems (1.1), (1.2). The object of this paper is to show how ideas from the theory of dynamical systems may be used to obtain information about the structure of solutions of problem (1.1) for this range of p. We will establish the following theorem.

THEOREM 1.1. *Let $u(r)$ be a solution of problem* (1.1); *then there exists a value $\mu_\infty < \infty$ and a sequence N_n with $n \in \mathbb{N}$ such that $u(0) \equiv N_n \to \infty$ as $n \to \infty$ and $\mu(N_n) = \mu_\infty$.*

This theorem implies, in particular, that problem (1.2) has an infinite number of positive solutions when $B \equiv B_\infty$ has radius μ_∞.

A proof of Theorem 1.1 was given originally by Budd and Norbury [3], but it is technical and requires careful use of methods from functional analysis. In this paper we use methods from the theory of dynamical systems to give an alternative proof of this result and to provide a deeper insight into the structure of the solution set. In particular, we use methods from Shilnikov's theory, the theory of normal forms, and a theorem due to Belitskii to obtain our result. Similar ideas have been used to study problems related to (1.1) with $p < p_c$ and some examples are given by Jones and Küpper [11] and by Jones, Küpper, and Plakties [12].

The function u^q in problem (1.1) may be replaced by a more general function $g(u)$ satisfying the three conditions (E1)-(E3) described in § 3. We may further extend the techniques described in this paper to study other "supercritical" systems also having nonlinearities that grow too rapidly for the usual techniques from the calculus of variations to be applicable. An example of such a system is the degenerate Laplacian equation

$$\nabla \cdot [|\nabla u|^{m-2}\nabla u] + u^p + u^q = 0, \tag{1.3}$$

with

$$p > [(m-1)n + m]/(n-m), \tag{1.4}$$

described in Ni and Serrin [16]. (Here n is the dimension of the space, and we note that problem (1.3) reduces to (1.1) if $m = 2$ and $n = 3$.)

2. Dynamical systems related to elliptic equations. The idea of using dynamical system methods to study problems similar to (1.1) was introduced by Fowler [7] with further examples given by Joseph and Lundgren in [13]. Recently, Jones and Küpper [11] have used such methods extensively to study the case $p < 5$; in [4] we examine the case $p \approx 5$. In the latter two cases, particular attention is given to special topological features of the phase plane associated with (1.1) that alter as p passes through the critical value $p_c = 5$.

We introduce the following variables (described originally by Fowler [7]).

Let $t = \operatorname{Ln} r$ and let

$$s(t) = r^\gamma, \quad a(t) = r^\alpha u(r), \quad b(t) = r^{1+\alpha} u_r(r), \tag{2.1}$$

where $\alpha = 2/(p-1)$ so that $\alpha < \frac{1}{2}$ when $p > 5$ and

$$\gamma = \frac{p-q}{p-1}. \tag{2.2}$$

(The introduction of the third variable $s(t)$ is crucial to the theory developed in this paper, as it allows us to transform the second-order ordinary differential equation (1.1) into a three-dimensional autonomous dynamical system. The original idea of using this extra variable is due to Jones and Küpper [11].)

Under this change of variables, problem (1.1) transforms into the following dynamical system:

$$\begin{aligned} \frac{da}{dt} &= \dot{a} = \alpha a + b, \\ \frac{db}{dt} &= \dot{b} = (\alpha - 1)b - a^p - s^2 h(a, s), \\ \frac{ds}{dt} &= \dot{s} = \gamma s, \end{aligned} \tag{2.3}$$

where $h(a, s) \equiv a^q$. Our choice of γ here ensures that all coefficients in (2.3) are C^∞ functions of a, b, and s if $a \neq 0$. We may, in fact, consider problems with a slightly more general nonlinearity than u^q, namely, $g(u)$. To retain the regularity of the coefficients of problem (2.3) we will insist that $g(u)$ satisfies the following condition:

$$s^{2p/(p-q)} g(as^{-2/(p-q)}) = s^2 h(a, s),$$

where the function $s^2 h(a, s)$ is $C^{1,1}$ in a and s if $a \neq 0$. It is this more general problem that we consider for the remainder of this paper. An example of such a function is $g(u) = ju^q + ku^{q'}$ with $q' < q$. The existence of a regular solution to problem (1.1) is guaranteed by the usual existence theory described, for example, by Smoller and Wasserman in [21]. Such a solution satisfies the conditions $u(r) \to N$, $u_r(r) \to 0$ as $r \to 0$ and $u(\mu) = 0$. From the form of the transformation (2.1) it is evident that the corresponding solution of problem (2.3) is a one-dimensional trajectory that leaves the origin $(a, b, s) = (0, 0, 0)$ when $t = -\infty$ and intersects the plane $a = 0$ when $t = \log \mu(N)$. Because the differential equation (1.1) is derived from an elliptic partial differential equation we may immediately deduce some properties of the corresponding solutions of problem (2.3).

LEMMA 2.1. (i) *If $N > 0$, then the solution trajectory of problem* (2.1) *corresponding to the solution of* (1.1) *initially lies in the quadrant $a > 0 > b$.*

(ii) *If $b = 0$, then $a\dot{b} < 0$.*

(iii) *If $ab > 0$, then $a\dot{a} \geqq 0$.*

(iv) *If $a = 0$, then $\dot{a}b > 0$.*

Proof. Observations (i) and (ii) are immediate deductions from the maximum principle (see Protter and Weinberger [19]), while (iii) and (iv) follow from the definitions of a and b. □

We now make a more detailed study of the system described by (2.3). If $p > 3$ the origin is an unstable saddle point with eigenvalues $\gamma, \alpha > 0$ and $(\alpha - 1) < 0$ with corresponding eigenvectors $(a, b, s) = (0, 0, 1)$; $(1, 0, 0)$ and $(1, -1, 0)$. A trajectory corresponding to a solution of (1.1) leaves the origin tangent to the eigenvector $(1, 0, 0)$. (It is especially interesting that the nature of the singularity at the origin changes precisely at the point $p = 3$, where the uniqueness proofs of Coffman [6] and McLeod and Serrin [15] do not apply to problems similar to (1.1). However, a recent result due to Kaper and Kwong [23] has extended the techniques above to the complete range $1 < p < (n+2)/(n-2)$ in $\mathbb{R}^n$.)

The remaining singular points of the system (2.3) are located at the two points

$$\mathbf{P}_\pm \equiv (a, b, s) = \pm(k, -\alpha k, 0), \qquad k^{p-1} = \alpha(1 - \alpha). \tag{2.4}$$

A local analysis of (2.1) at the points $\mathbf{P}_\pm$ shows that its linearisation about this point has eigenvalues

$$(\alpha - \tfrac{1}{2} \pm i\omega, \gamma) \quad \text{where } \omega^2 = 2p(p-3)(p-1)^{-2} - \tfrac{1}{4}. \tag{2.5}$$

When $3 < p < 5$ then $\alpha > \frac{1}{2}$ and the singular points are unstable spirals. However, they become stable spirals if we reverse the sign of t. This transformation in t allows us to use the methods described in this paper to study the solutions of problem (1.1) for $p < 5$ and $r \gg 1$. When $p = 5$ then $\alpha = \frac{1}{2}$, and the restriction of system (2.3) to the plane $s = 0$ leads to a Hamiltonian dynamical system. This structure is exploited by Budd in [4], where system (2.3) for the particular exponent range $(p - 5) \ll 1$ is studied as an example of a perturbed Hamiltonian system.

When $p>5$, α satisfies the inequality $0<\alpha<\frac{1}{2}$ and the singular point has two complex conjugate eigenvalues with real part $\alpha-\frac{1}{2}<0$ and an eigenvalue $\gamma>0$. This point is therefore of the saddle focus type. (For the more general degenerate Laplacian equation (1.3), if we take $m=2$ then the points $\mathbf{P}_{\pm}$ are spiral attractors if $2<n<10$, with a similar restriction on the value of n for other values of m.) We may now deduce the following results from the Stable Manifold Theorem (Guckenheimer and Holmes [9]).

LEMMA 2.2. *The point $\mathbf{P}_+$ has a two-dimensional stable manifold W_s and a one-dimensional unstable manifold $M(t)$. The function $M(t)$ is a C^∞ function of t and is tangent to the line $(k, -\alpha k, e^{\gamma t})$ as $t\to-\infty$. The set W_s is a subset of the plane $s=0$.*

Proof. This result follows immediately from the regularity of the coefficients in (2.3) and their behaviour as the term $(a-k, b+\alpha k, s)\to 0$. □

This special structure of the points $\mathbf{P}_{\pm}$ allows us to consider the use of solution methods similar to those developed by Shilnikov [20] when studying the solution structure of problem (1.1). We observe, however, that as $\dot{s}\geqq 0$ for all $t>0$, the trajectory $M(t)$ does not return to the point $\mathbf{P}_{\pm}$ as $t\to\infty$, and therefore we may not apply Shilnikov methods directly to problem (2.3). We will show later, however, that the topology of $M(t)$ plays an important role in the structure of the solutions of problem (2.3).

To proceed further, we now study the attracting set at the point $\mathbf{P}_+$, which lies in the plane $s=0$. A straightforward calculation shows that this plane in an invariant of the system (2.3) and that the restriction of this system to the plane gives the following autonomous dynamical system:

$$\dot{a}=\alpha a+b, \qquad \dot{b}=(\alpha-1)b-a^p. \tag{2.6}$$

To study this system we make the following calculation, described, for example, by Joseph and Lundgren [13]. Let the function $W(N, r)$ be the solution of the following ordinary differential equation problem:

$$\begin{aligned} &W_{rr}+\frac{2}{r}W_r+W^P=0,\\ &W(N,0)=N, \qquad W_r(0)=0. \end{aligned} \tag{2.7}$$

An application of the transformation (2.1) to the function $W(N, r)$ transforms (2.7) into the system (2.6). Let $(A_N(t), B_N(t))$ be the solution trajectory of problem (2.6) that corresponds to $W(N, r)$. It is significant that the effect of N in the transformation above does not alter the locus described by $(A_N(t), B_N(t))$ but merely alters its parameterisation with t. We show this by establishing the following lemma.

LEMMA 2.3. *Let $(A_N(t), B_N(t))$ be defined as above; then*

$$(A_N(t), B_N(t))=(A_1(t+\log N/\alpha), B_1(t+\log N/\alpha)).$$

Proof. It is well known that if $W(N, r)$ is the solution of problem (2.7), then

$$W(N, r)=NW(1, rN^{1/\alpha}). \tag{2.8}$$

Hence,

$$\begin{aligned} A_N(t)&=Ne^{\alpha t}W(1, e^{t+\log N/\alpha})\\ &=e^{\alpha(t+\log N/\alpha)}W(1, e^{t+\log N/\alpha})=A_1(t+\log N/\alpha). \end{aligned}$$

A similar calculation follows for $B_N(t)$. □

It is further shown by Chandrasekhar [5] that a solution trajectory of the system (2.6) corresponding to $W(N, r)$ leaves the origin when $t=-\infty$ and tends toward $\mathbf{P}_+$ as $t\to\infty$. Thus, if we define a curve $\mathbf{O}_+$ to be the locus described by $(A_N(t), B_N(t), 0)$,

then $\mathbf{O}_+$ lies in the stable manifold for the point $\mathbf{P}_+$ defined by system (2.3) while also being an unstable manifold for the origin.

Figure 1 shows the point $\mathbf{P}_+$ and gives a picture of the locus of $M(t)$ and of $\mathbf{O}_+$.

3. Applications of Shilnikov's theory. The original applications of the ideas of Shilnikov [20] lie in the examination of periodic orbits associated with a homoclinic orbit that leaves a stationary point $\mathbf{P}$ along its unstable manifold and that returns along a spiral trajectory in the attracting set of $\mathbf{P}$. Examples of these applications are given by Glendinning and Sparrow [8] and by Tresser [22]. Although this structure does not occur for the system (2.3) we may exploit specific features of the original elliptic system (1.1) to allow us to employ similar techniques to study problem (2.3). We now state the main result of this section.

THEOREM 3.1. *Let $u(r)$ be the solution of the ordinary differential equation problem*

$$u_{rr}+\frac{2}{r}u_r+u^p+g(u)=0, \tag{3.1}$$
$$u(0)=N, \qquad u_r(0)=0.$$

Furthermore, we suppose that the following conditions hold.

(E1) *The function $g(u)$ satisfies the following regularity condition: There is a positive value $q<p$ such that*

$$s^{2p/(p-q)}g(as^{-2/(p-q)})=s^2h(a,s),$$

where the function $s^2h(a,s)$ is $C^{1,1}$ as $s\to 0$ $(a\neq 0)$ and is C^2 if $s\neq 0$.

(E2) *Let $V(N,r)$ be a solution of the scaled equation*

$$V_{rr}+\frac{2}{r}V_r+V^p+N^{-p}g(NV)=0, \tag{3.2}$$
$$V(0)=1, \qquad V_r(0)=0$$

and let $W(1,r)$ be a solution of problem (2.6). Then for each fixed $r>0$

$$|(V(N,r),V_r(N,r))-(W(1,r),W_r(1,r))|<C(r)N^{q-p}$$

as $N\to\infty$, where $C(r)$ does not depend on N.

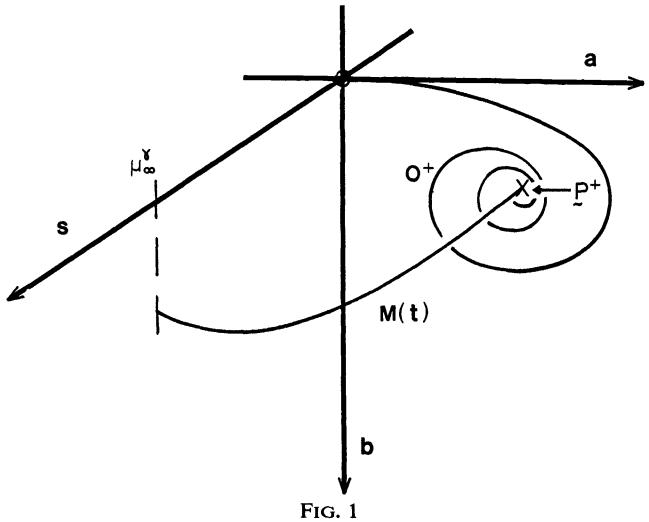

FIG. 1

(E3) *Let $M(t)$ be the unstable manifold of $\mathbf{P}_+$ constructed in § 2; then $M(t)$ intersects the plane $a=0$ when $s=(\mu_\infty)^\gamma<\infty$.*

Then, if $\mu(N)$ is defined to be the first positive zero of $u(r)$, as $N\to\infty$,

$$\mu(N)=\mu_\infty+EK(N)\cos(\omega \operatorname{Ln} N/\alpha+F)(1+o(1))+O(K(N)^2), \tag{3.3}$$

where $K(N)=N^{-(p-5)/4}$ and E, F are constants.

In § 4 we show that each of (E1)-(E3) is satisfied if $g(u)=u^q$ and $q<3$.

Proof. To prove this result we will define a map from N to a set Σ_0 in the phase space (a, b, s) defined by the transformation (2.1) and we will then employ Shilnikov's theory to map Σ_0 to a neighbourhood of the intersection of $M(t)$ with the plane $a=0$. We define Σ_0 as follows.

Let $\mathbf{O}_+$ be the curve constructed in § 2 and let (e,f) be a point lying on $\mathbf{O}_+$ in a neighbourhood of the point $\mathbf{P}_+$. We suppose that $(e,f)=(A_1(t_1), B_1(t_1))$ and we set $t_N=t_1-\log N/\alpha$. Let the curve $(a_N(t), b_N(t), s_N(t))$ be the solution trajectory of system (2.2) corresponding to the solution of problem (3.1). We define the set Σ_0 by

$$\Sigma_0=\{(a_N(t_N)b_N(t_N), s_N(t_N)): N>0\}.$$

LEMMA 3.2. *The set Σ_0 is a one-dimensional submanifold of $\mathbb{R}^3$. As $N\to\infty$, then*

$$\begin{aligned}&|(a_N(t_N)-e, b_N(t_N)-f)|<2C(\exp(t_1))N^{q-p},\\ &s_N(t_N)=\exp(\gamma t_1)N^{(q-p)/2}.\end{aligned} \tag{3.4}$$

Thus Σ_0 approaches the point $(e, f, 0)$ and is ultimately tangent to the line $(a, b)=(e, f)$.

Proof. The topological structure of Σ_0 as a subset of $\mathbb{R}^3$ follows from the analytic dependence of $u(r)$ on N. To establish (3.4) we make use of the condition (E2). A simple calculation shows that $V(N, r)=N^{-1}u(rN^{-1/\alpha})$, and hence we may deduce from (E2) that if r is fixed, then

$$r^\alpha|N^{-1}u(rN^{-1/\alpha})-W(1, r)|<r^\alpha C(r)N^{q-p} \quad \text{as } N\to\infty.$$

We now put $r=\exp(t_1)$, which implies that $r^\alpha N^{-1}=\exp(t_N)$. Thus $r^\alpha N^{-1}u(rN^{-1/\alpha})=e^{\alpha t_N}u(e^{t_N})=a_N(t_N)$ and $r^\alpha w(1, r)=e$. This gives the bound for $a_N(t_N)$ and a similar calculation describes the behaviour of $b_N(t_N)$.

Finally, $s_N(t_N)=\exp(\gamma t_N)=\exp(\gamma t_1)N^{-\gamma/\alpha}$. □

We will now construct a map Φ from the set Σ_0 to a set Σ_1 lying in the plane $a=0$ and including a neighbourhood of the point Q, where

$$Q=M(t)\cap\{a=0\},$$

and where the existence of the point Q is guaranteed by our assumption (E3).

Let $\mathbf{Z}$ be a point lying in Σ_0 and suppose that $\mathbf{T}(t)$ is the solution trajectory of problem (2.3) that intersects $\mathbf{Z}$. We define $\Phi(\mathbf{Z})$ such that $\Phi\colon \Sigma_0\to\Sigma_1$ by

$$\Phi(\mathbf{Z})=\mathbf{T}(t)\cap\Sigma_1.$$

Our main geometrical result describing the map Φ is given as follows.

LEMMA 3.3. *The image of Σ_0 under the map Σ_1 is a logarithmic spiral lying in Σ_1 centered on Q.*

Proof. To prove this result we proceed as in the proof of Shilnikov's theorem [20] using a presentation based on that given by Guckenheimer and Holmes [9]. We decompose Φ into two operators Φ_I and Φ_0 such that Φ_I maps Σ_0 to a set Σ_ε lying in a neighbourhood of $\mathbf{P}_+$ and Φ_0 maps Σ_ε to Σ_1.

If we set $c(t) = a(t) - k$ and $d(t) = b(t) + \alpha k$ then close to $\mathbf{P}_+$, system (2.3) has the following form:

$$\begin{aligned} \dot{c} &= \alpha c + d, \\ \dot{d} &= \alpha(1-\alpha)c + (\alpha - 1)d + R(s, c, d), \\ \dot{s} &= \gamma s. \end{aligned} \tag{3.5}$$

A simple calculation using the smoothness of the function $h(a, s)$ defined by the assumption (E1) shows that the function $R(s, c, d)$ is $C^{1,1}$ in a neighbourhood of the point $(c, d, s) = (0, 0, 0)$. Furthermore $R(\mathbf{0}) = DR(\mathbf{0}) = 0$ (although R has nonvanishing terms of second order in c, d, and s).

To simplify our calculations on system (3.5) we introduce a local change of coordinates to eliminate the nonlinear term $R(s, c, d)$. The existence of a homeomorphism with this property is guaranteed by the Hartman-Grobman theorem [9]. However, to obtain the results needed in this paper, we require our map to be a C^1 diffeomorphism whose existence is guaranteed by the following result due to Belitskii [1].

THEOREM 3.4 (Belitskii). *Let* $\mathbf{x}$ *satisfy the differential equation*

$$\dot{\mathbf{x}} = L\mathbf{x} + R(\mathbf{x}),$$

where L *is a linear operator,* $R(\mathbf{x}) \in C^{1,1}$, *and* $R(0) = DR(0) = 0$. *Furthermore, suppose that the eigenvalues* λ_i *of* L *satisfy the nonresonance condition*

$$\lambda_i \neq \lambda_j + \lambda_k \tag{3.6}$$

if $\operatorname{Re}(\lambda_j) < 0 < \operatorname{Re}(\lambda_k)$. *Then there exists a* C^1 *diffeomorphism* $T: x \to y$ *such that*

$$T(0) = 0, \quad DT(0) = I, \quad \dot{y} = L\mathbf{y}.$$

Proof. See [1] and the discussion of normal forms in Chapter 3 of [9]. □

LEMMA 3.5. *Let* L *be the linear operator in system* (3.5); *then condition* (3.6) *is satisfied.*

Proof. The eigenvalues of L are given by (2.5) and have the values $(5-p)/2(p-1) \pm i\omega$ and $(p-q)/(p-1)$. Condition (3.6) follows from the observation that $\omega \neq 0$. The regularity of the coefficients required for an application of the theorem is immediate from condition (E1). □

LEMMA 3.6. *Let* T *be the map constructed in Theorem* 3.4 *such that* $T: (c, d, s) \to (C, D, S)$. *In a neighbourhood* $\mathfrak{M}$ *of* $\mathbf{P}_+$ *the system* (3.5) *takes the following form*:

$$\begin{aligned} \dot{C} &= \alpha C + D, \\ \dot{D} &= \alpha(1-\alpha)C + (\alpha - 1)D, \\ \dot{S} &= \gamma S. \end{aligned} \tag{3.7}$$

Furthermore, T *maps the plane* $\mathfrak{M} \cap \{s = 0\}$ *into the plane* $\{S = 0\}$.

Proof. Result (3.7) follows immediately from the definition of T. Now if $\mathfrak{M}$ is sufficiently small, any point in $\mathfrak{M} \cap \{s = 0\}$ lies on a stable manifold of the origin. Consequently its image under T must also lie on a stable manifold of the origin in the transformed coordinates and hence lies in $\{S = 0\}$. □

It is evident from inspection of system (3.7) that the image $\hat{M}(t)$ of the unstable manifold $M(t)$ of the point $\mathbf{P}_+$ is locally the curve $(C, D, S) = (0, 0, e^{\gamma t})$. Now let $\hat{\Sigma}_\varepsilon$ be a set lying in the image of $\mathfrak{M}$, centred on the point $(0, 0, \varepsilon)$ and lying in the plane $S = \varepsilon$. Furthermore, let us take the point $(e, f, 0)$ sufficiently close to $\mathbf{P}_+$ so that if N_0 is sufficiently large, a subset of Σ_0 defined by taking $N > N_0$ lies in $\mathfrak{M}$. We define $\hat{\Sigma}_0$

to be the image of Σ_0 under T and construct a map Φ_I from $\hat{\Sigma}_0$ to $\hat{\Sigma}_\varepsilon$ as follows. Let $\hat{\mathbf{Z}} \in \hat{\Sigma}_0$ and let $\hat{u}$ be the solution trajectory of (3.7) that contains $\hat{\mathbf{Z}}$. We define Φ_I by

$$\Phi_I(Z) \equiv (C_\varepsilon, D_\varepsilon) = \hat{u} \cap \hat{\Sigma}_\varepsilon.$$

LEMMA 3.7. *Let $\hat{Z} = (x, y, S)$ with $S < \varepsilon$; then*

$$\Phi_I(\hat{Z}) = e^{(\alpha - 1/2)\delta}(x \cos \omega\delta - y \sin \omega\delta, x \sin \omega\delta + y \cos \omega\delta), \tag{3.8}$$

where $\delta = \log((\varepsilon s)^{-1/\gamma})$ and ω is defined by (2.5).

Proof. This result follows immediately on explicit solution of the linear system (3.7). □

We now examine the nature of the set $\hat{\Sigma}_0$.

LEMMA 3.8. *Let the point $(E, F, 0)$ be the image of the point $(e - k, f + \alpha k, 0)$ under the map T. Furthermore, let $u_N \equiv (a_N(t), b_N(t), s_N(t))$ be the solution trajectory of* (2.3) *corresponding to the solution of problem* (3.1). *Then the point $\hat{\mathbf{Z}}_N$ where the image of this trajectory under T intersects $\hat{\Sigma}_0$ is given by*

$$\hat{\mathbf{Z}} = (E, F, \exp(\gamma t_1) N^{(q-p)/2}) + O(mN^{(q-p)/2}) + O(N^{q-p}), \tag{3.9}$$

where $\|m\|$ may be taken arbitrarily small by taking (E, F) sufficiently close to $(0, 0)$.

Proof. To prove this result we use the fact that the map T is C^1 near the origin and $DT(0) = I$. Then

$$u_N \cap \Sigma_0 \equiv \mathbf{Z}_N = (e - k, f + \alpha k, 0) + \ell_N,$$

where

$$\ell_N = (O(N^{q-p}), O(N^{q-p}), \exp(\gamma t_1) N^{(q-p)/2}).$$

(Here the estimate for ℓ_N follows from (3.4).)

From the continuity of DT we may deduce that $DT(e - k, f + \alpha k, 0) = I + m$, where $\|m\|$ may be taken arbitrarily small by taking $(e - k, f + \alpha k)$ sufficiently close to $(0, 0)$. It thus follows from the mean value theorem that $\hat{\mathbf{Z}}_N = TZ_N$ has the form (3.9). □

We may now explicitly calculate the image of $\hat{Z}_N$ under the action of Φ_I in terms of the parameter N.

LEMMA 3.9. *Let u_N be constructed as in Lemma* 3.8; *then the point $\hat{\mathbf{y}}_N$, where the image of u_N under T intersects $\hat{\Sigma}_\varepsilon$, is given by*

$$\begin{aligned} &\hat{\mathbf{y}}_N \equiv \hat{\mathbf{x}}_N + (0, 0, \varepsilon), \text{ where } \hat{\mathbf{x}}_N = (A_1 K(N)[\cos(A_2 + \omega \log(DN^{1/\alpha})), \\ &\sin(A_2 + \omega \log(DN^{1/\alpha})] * ((1 + O(m)), 0) \text{ as } N \to \infty, \end{aligned} \tag{3.10}$$

where $K(N) = N^{-(p-5)/4}$ with A_1, A_2, and D constant.

Proof. We combine the results (3.8) and (3.9). From (3.9) we see that the value of δ in (3.8) is given by

$$\delta = \log(DN^{1/\alpha}(1 + O(m)), \qquad N \to \infty,$$

where D is a suitable constant. Thus

$$e^{(\alpha - 1/2)\delta} = A_1 N^{-(p-5)/4}(1 + O(m)). \tag{3.11}$$

Similarly, $x \cos \omega\delta = [E + O(N^{(q-p)/2})] \cos \omega\delta$, with a similar result for y. Putting these values together and collecting the error terms of order m, we deduce (3.10). □

Thus as N increases, the point $\hat{\mathbf{y}}_N$ traces out a logarithmic spiral ζ_ε lying in $\hat{\Sigma}_\varepsilon$ and centred on $(0, 0, \varepsilon)$.

LEMMA 3.10. *Let $\mathbf{y}_N$ be the pre-image of the point $\hat{\mathbf{y}}_N$ under the map T so that $T(\mathbf{y}_N) = \hat{\mathbf{y}}_N$. Then*

$$\mathbf{y}_N = T^{-1}(0, 0, \varepsilon) + \mathbf{x}_N, \qquad \text{where } \mathbf{x}_N = \hat{\mathbf{x}}_N(1 + O(m)). \tag{3.12}$$

Proof. We may deduce from Theorem 3.4 that the map T is a diffeomorphism. The result (3.12) then follows by linearising the inverse of T about the point $(0, 0, \varepsilon)$. We note that if ε is small the linearisation of T^{-1} is close to the identity so that we may take $\|T^{-1} - I\| = O(m)$. □

We will now construct a map Φ_0 from the pre-image Σ_ε of the set $\hat{\Sigma}_\varepsilon$ to the set Σ_1 by computing the flow of solutions of problem (2.3) that have initial data lying in Σ_ε. Let $\mathbf{Q}$ be the intersection of $M(t)$ with the plane $a = 0$ (the existence of which is guaranteed by assumption (E3)) and let $\mathbf{Q}_\varepsilon$ be the intersection of $M(t)$ with Σ_ε. Thus $\mathbf{Q}_\varepsilon = T^{-1}(0, 0, \varepsilon)$. The flow from $\mathbf{Q}_\varepsilon$ along $M(t)$ to $\mathbf{Q}$ is nonsingular and thus from the regularity condition (E1) the flow map Φ_0 is a diffeomorphism from the neighbourhood of $\mathbf{Q}_\varepsilon$ in $\hat{\Sigma}_\varepsilon$ to a neighbourhood of $\mathbf{Q}$ in the plane $a = 0$. Hence the image of the logarithmic spiral ζ_ε under the action of Φ_0 is a spiral lying in the plane $a = 0$. This proves Lemma 3.3. □

To complete the proof of Theorem 3.1 we consider the form of the spiral ζ. As the map Φ_0 is a C^2 diffeomorphism we may locally linearise it about the point $\mathbf{Q}_\varepsilon$. Thus the image of the point $\mathbf{Q}_\varepsilon + \mathbf{x}_N$, when $\|x_N\|$ is sufficiently small, is given by

$$\Phi_0(\mathbf{Q}_\varepsilon + \mathbf{x}_N) = \mathbf{Q} + D\Phi_0 \mathbf{x}_N + O(\|x_N\|^2) \tag{3.13}$$

$$= \mathbf{Q} + D\Phi_0 \hat{\mathbf{x}}_N (1 + O(m) + O(K(N))), \tag{3.14}$$

where the point $\mathbf{Q} + D\Phi_0 \mathbf{x}_N + O(\|x_N\|^2)$ lies in the plane $a = 0$. The s coordinate of this point thus gives us the value of $\mu(N)$ defined in Theorem 3.1. Furthermore, the coordinates of the point $\mathbf{Q}$ are given by

$$\mathbf{Q} = (0, \mu_\infty^{\alpha+1} M'(\mu_\infty), \mu_\infty^{\gamma}).$$

To obtain (3.3) we combine the two expressions (3.10) and (3.14). The values of the constants E and F in (3.3) follow from the coefficients of the linear operator $D\Phi_0$ described by (3.14).

This concludes the proof of Theorem 3.1. □

We indicate in Fig. 2 the main steps in the proof of this theorem, and in Fig. 3 we further show a graph of $\mu(N)$ obtained from the expression (3.3). Figure 3 shows a very strong similarity to Fig. 3.4 in [9]. This observation reinforces the link indicated

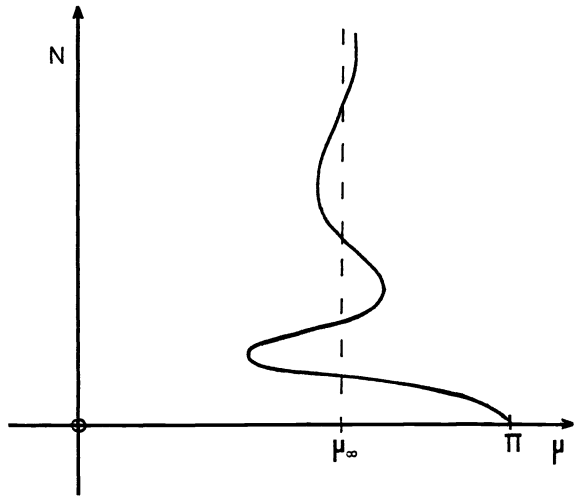

FIG. 3

in this paper between the structure of the homoclinic orbits studied by Shilnikov and the elliptic equations considered here.

4. Applications to elliptic equations. To apply Theorem 3.1 to elliptic equations of the form (1.1) we must establish that conditions (E1)-(E3) hold for system (3.1) if $g(u) \equiv u^q$. Initially we will establish condition (E2), as (E1) is automatically satisfied for the nonlinearity u^q.

LEMMA 4.1. *Let $V(N, r)$ be a solution of problem* (3.2) *and let $g(u)$ satisfy the condition that $g(u)/u^q$ is bounded above as $u \to \infty$. Then there is a function $K(r)$ bounded independently of N such that*

$$|(V(N, r) - W(1, r), V_r(N, r) - W_r(N, r))| < N^{q-p}K(r).$$

Proof. We may observe from the maximum principle that the function $V(N, r)$ is bounded above by 1 on the interval on which it is positive. We may thus deduce from our assumption on the growth of the function $g(u)$ that the function $N^{-p}g(NV)$ is bounded by $N^{q-p}k(V)$, where $k(V)$ is bounded independently of N as $N \to \infty$.

We define L to be the following Volterra integral operator:

$$Lf(s) = \int_0^s t(1-(t/s))f(t)\,dt \equiv \int_0^s m(t, s)f(t)\,dt.$$

Problem (3.1) may then be put into the following form:

$$V(s) = 1 + L[V^p + N^{q-p}k(V)].$$

Now let $W(r)$ be the solution of problem (2.7) with $N = 1$. It follows that

$$W(r) = 1 + L[W^p].$$

If we now set $x(r) = W(r) - V(r)$, then $x(r)$ satisfies the following equation:

$$x(r) = L[(V+x)^p - V^p - N^{q-p}k(V)]. \tag{4.1}$$

By the Mean Value Theorem we may deduce that

$$(V+x)^p - V^p = p[V + \theta x]^{p-1}x,$$

where $0<\theta<1$. Thus from the maximum principle we can see that $|(V+\theta x)|<1$ and hence

$$|x(s)| \leqq L[p|x|+N^{5-p}|k(V)|]. \tag{4.2}$$

As the kernel $m(r, s)$ is bounded we may deduce from Gronwall's Lemma [10] that there is a function $K(r)$ bounded independently of N such that

$$|x(r)| \leqq N^{(5-p)}K(r). \tag{4.3}$$

A similar bound for $|x_r(r)|$ then follows on differentiating the identity (4.2) and substituting the bound given in (4.3). This establishes condition (E2). (A very similar calculation can also be made to study the degenerate Laplacian problem (1.3).) □

To complete the proof of Theorem 1.1 we must establish condition (E3), which entails a global characterisation of the manifold $\mathbf{M}(t)$. A simple calculation shows that such a solution of the problem (2.3) corresponds to a singular solution $M(r)$ of the differential equation problem (1.1). This solution satisfies the conditions

(4.4) $r^{\alpha}M(r)\to k$ and $r^{\alpha+1}M_r(r)\to -\alpha k$ as $r\to 0$, where k is defined by the identity (2.4).

We may now appeal to the following theorem, established by Ni and Serrin [17].

THEOREM 4.2. *Let $M(r)$ be the solution of problem* (1.1) *that satisfies the singular initial conditions described in* (4.4). *Furthermore, suppose that for some $q<3$ the function $g(u)$ has the form*

$$u^p+g(u)=\lambda u^q+h(u) \quad \lambda>0,$$

where

$$h(u)>0 \quad \text{if } u>0.$$

If these conditions hold, then there is a value $\mu_\infty<\infty$ such that $M(\mu_\infty)=0$ and thus (E3) is satisfied. □

The condition $q<3$ stated above is important to the proof of Theorem 4.2 as it rules out the possibility of a "ground-state" solution of problem (1.1), namely, a solution that tends to zero as $r\to\infty$ but is everywhere positive. It is not clear, however, what happens in the case $3\leqq q<5$. A recent result due to Lin and Ni [14] shows that there does exist a ground-state solution of problem (1.1) if $p>5$ and $q=(p+1)/2$, although this does not necessarily imply that condition (E3) is not true in this case. Numerical calculations seem to imply that (E3) remains true for all q such that $3<q<5$. For $q\geqq 5$ an application of Pohozaev's identity [18] implies that condition (E3) cannot be satisfied.

Again a similar calculation can be made for the singular solutions of the degenerate Laplacian equation.

Having established identity (3.3) for the solutions of problem (1.1), we may now establish Theorem 1.1 by choosing values of N such that the function $G(N)$ vanishes where

$$G(N)\equiv \cos(\omega \operatorname{Ln} N/\alpha+F)(1+o(1))+O(K(N)).$$

Because $K(N)$ tends to zero as N tends to infinity, the existence of such a sequence is guaranteed. This proves Theorem 1.1. □

ON A HYPERBOLIC QUENCHING PROBLEM IN SEVERAL DIMENSIONS*

RICHARD A. SMITH†

Abstract. Let $\phi \in C^1(-\infty, M)$ be nonnegative and increasing and satisfy $\lim_{u \to M^-} \phi(u) = \infty$. The problem $u_{tt} = \Delta_n u + \varepsilon\phi(u)$ in $D \times (0, T)$, $u = 0$ on $\partial D \times (0, T)$, $u(x, 0) = u_0(x)$, and $u_t(x, 0) = v_0(x)$ in D, is shown to have a unique local continuous solution for $\varepsilon > 0$ sufficiently small in dimensions $n = 1, 2, 3$ under appropriate assumptions on ϕ, u_0, v_0, and ∂D. The solution u can be continued as long as $u < M$. A potential well theory is shown to be unobtainable for this problem in the Sobolev space $H_0^1(D)$ for $n \geqq 2$; however, an a priori inequality for solutions guarantees global existence via energy considerations. Numerical evidence is given indicating that such an a priori inequality is sometimes satisfied by solutions when $n \geqq 2$.

AMS(MOS) subject classification. 35

1. Introduction.

Let D be an open, bounded subset of $\mathbb{R}^n$ with boundary ∂D. Let ϕ: $(-\infty, M) \to (0, \infty)$, $M > 0$, be continuously differentiable, monotone increasing, convex, and satisfy $\lim_{u \to M^-} \phi(u) = \infty$; and let $\varepsilon > 0$. In this paper the following initial-boundary value problem is considered:

$$\begin{aligned} &u_{tt} = \Delta_n u + \varepsilon\phi(u) \quad \text{in } D \times (0, T), \\ &u = 0 \quad \text{on } \partial D \times (0, T), \\ &u(x, 0) = u_0(x), \qquad u_t(x, 0) = v_0(x) \quad \text{in } D, \end{aligned} \tag{An}$$

where Δ_n denotes the n-dimensional Laplacian.

Let (A1) denote problem (An) with $D = (0, 1)$. When $\phi(u) = 1/(M - u)$, a solution of (A1) has a physical interpretation as describing the motion of a wire composed of a magnetic material and carrying an electric current in the presence of another current-carrying wire [8]. Chang and Levine [2] have shown that for suitably regular initial data, problem (A1) has a unique local piecewise C^2 solution u that can be continued as long as $u < M$. They have also established the existence of numbers $\varepsilon_1 > \varepsilon_0 > 0$ such that

(a) If $\varepsilon \geqq \varepsilon_1$, then for some finite $T > 0$,

$$\lim_{t \to T^-} \left(\sup_{0 < x < 1} u(x, t) \right) = M;$$

hence one of u_{tt}, u_{xx} becomes infinite on $[0, 1] \times [0, T)$.

(b) If $0 < \varepsilon \leqq \varepsilon_0$, and the initial data u_0, v_0 are appropriately restricted, there is a $\delta = \delta(\varepsilon) > 0$ such that

$$|u(x, t)| \leqq M - \delta \quad \text{on } [0, 1] \times [0, \infty).$$

Note that by applying to (A1) the change of scale $x' = Lx$, $t' = Lt$, $\varepsilon = L^2$, we obtain (A1) with ε replaced by 1 and x' varying between 0 and L. Results (a) and (b) assert, therefore, that global solutions do not exist for long wires, but do exist for short wires.

If u behaves as in (a), it is said to *quench* in finite time. Speaking loosely, we say that a solution of some evolutionary problem quenches in finite (or infinite) time T if some norm of the solution remains bounded, while some norm of one of its derivatives becomes unbounded, on the interval $[0, T)$ [7].

For space dimensions $n \geqq 2$ and ε sufficiently large, solutions of problem (An) also quench in finite time [2]. However, the proof of (b) in [2] relies strongly on the inequality

$$4u^2(x, t) \leqq \int_0^1 |u_x(x, t)|^2 \, dx, \tag{1.1}$$

which guarantees the imbedding of $H_0^1(0, 1)$ into $C([0, 1])$. In general, no such imbedding $H_0^1(D) \to C(\bar{D})$, or even $H_0^1(D) \to L_\infty(D)$, is possible in higher dimensions, and the question of existence of global solutions of (An) for $n \geqq 2$ remains open.

If instead of (An) we consider the abstract problem

$$\text{(B)} \qquad \begin{aligned} &\frac{d^2u}{dt^2} + Au = \varepsilon\phi(u), \qquad 0 < t < \infty, \\ &u(0) = u_0 \in V, \qquad u'(0) = v_0 \in L_2(D), \end{aligned}$$

where $V \subseteq L_2(D)$ imbeds in $L_\infty(D)$ and A is an operator of elliptic type mapping V into its dual, then a global existence theorem for ε sufficiently small may be proved (see Levine and Smiley [9]). Their results apply, for example, to solutions of (B) when D is the interior of a rectangle in $\mathbb{R}^2$, $u(x, t) = \Delta_2 u(x, t) = 0$ on $\partial D \times [0, \infty)$, A is the biharmonic operator Δ_2^2, and $V = H^2(D) \cap H_0^1(D)$.

Acker and Walter [1] have proved a higher-dimensional global existence theorem for small ε for solutions of

$$\text{(C)} \qquad \begin{aligned} &u_t = \Delta_n u + \varepsilon\phi(u) && \text{in } D \times (0, T), \\ &u = 0 && \text{on } \partial D \times (0, T), \\ &u(x, 0) = u_0(x) && \text{in } D. \end{aligned}$$

Their proof relies on consequences of the maximum principle for parabolic problems, which are available only in much weaker forms for hyperbolic problems. Hyperbolic problems in which the driving term $\varepsilon\phi(u)$ appears in a boundary condition instead of in the differential equation have also been studied [8], but the question of global existence of solutions in space dimensions higher than 1 also remains unanswered. For a comprehensive survey of the literature on quenching, see Levine [7].

In this paper, problem (An) is shown to have a unique local continuous solution u in low dimensions for small ε under appropriate assumptions on ϕ, u_0, v_0, and ∂D that can be continued as long as $u < M$. It is also shown that for any $\varepsilon > 0$, there exists no potential well about any equilibrium solution of (An), so that a proof of global existence along the lines of Sattinger [11] is not possible. Nevertheless, an a priori inequality for solutions of (An) similar to (1.1) is shown, via energy considerations, to guarantee global existence. Numerical evidence is given suggesting that such an a priori inequality is sometimes satisfied by solutions of (An).

2. Theoretical considerations. Local continuous solutions of (An) for $n = 2, 3$ are obtained by applying the abstract theory of Reed [10] to an appropriately modified problem.

In this section ϕ' will be assumed to be bounded and uniformly Lipschitz continuous on intervals of the form $(-\infty, M-\delta]$, $\delta>0$. For $0<\delta<M$ define

$$\phi_\delta(u)=\begin{cases}\phi(u), & u\leqq M-\delta,\\ \phi(M-\delta/2), & u\geqq M-\delta/2.\end{cases}$$

Then by suitably defining ϕ_δ on the interval $(M-\delta, M-\delta/2)$, we may arrange that $\phi_\delta\in C^1(\mathbb{R})$ and ϕ' is bounded and uniformly Lipschitz continuous on $\mathbb{R}$. Let (An, δ) represent problem (An) with ϕ replaced by ϕ_δ.

It is assumed that problem (An) has a stationary solution $f\in C^2(\bar{D})$, which is analytic in D and satisfies

$$\Delta_n f+\varepsilon\phi(f)=0 \quad \text{in } D,$$
$$f=0 \quad \text{on } \partial D.$$

Such is indeed the case when, e.g., D is a ball in $\mathbb{R}^n$ and $\phi(u)=(M-\alpha u)^\beta$, α, $\beta<0$ (see Joseph and Lundgren [5]).

Applying the transformation $\bar{u}=u-f$ to problem (An, δ), we obtain the problem

$$\begin{aligned}&\bar{u}_{tt}=\Delta_n\bar{u}+\varepsilon\psi_\delta(x,\bar{u}) \quad \text{in } D\times(0,T),\\ &\bar{u}=0 \quad \text{on } \partial D\times(0,T),\\ &\bar{u}(x,0)=u_0(x)-f(x), \quad \bar{u}_t(x,0)=v_0(x) \quad \text{in } D,\end{aligned}\tag{2.1}$$

where $\psi_\delta(x,u)\equiv\phi_\delta(u+f(x))-\phi_\delta(f(x))$. By setting

$$\bar{v}=\bar{u}_t, \quad \eta=\begin{pmatrix}\bar{u}\\ \bar{v}\end{pmatrix}, \quad \eta_0=\begin{pmatrix}u_0-f\\ v_0\end{pmatrix},$$

$$F(\eta)=\begin{pmatrix}0\\ \varepsilon\psi_\delta(x,\bar{u})\end{pmatrix}, \qquad A=-\begin{pmatrix}0 & I\\ \Delta_n & 0\end{pmatrix},$$

we may write (2.1) as the equivalent system

$$\begin{aligned}&\eta'(t)=-A\eta(t)+F(\eta(t)), \qquad 0<t<T,\\ &\eta(0)=\eta_0.\end{aligned}\tag{2.2}$$

Let H denote the Hilbert space of real-valued functions $H_0^1(D)\oplus L_2(D)$, with inner product

$$\left\langle\begin{pmatrix}u\\ v\end{pmatrix},\begin{pmatrix}w\\ z\end{pmatrix}\right\rangle=\int_D\nabla u\cdot\nabla w\,dx+\int_D vz\,dx.\tag{2.3}$$

Provided ∂D is of class C^2, A is a closed skew-adjoint operator on H with domain $\operatorname{dom}(A)\equiv[H^2(D)\cap H_0^1(D)]\oplus H^1(D)$, and generates on H the continuous one-parameter group $W(t)=e^{-tA}$. Therefore (2.2) can be reformulated as the integral equation problem

$$\eta(t)=e^{-tA}\eta_0+\int_0^t e^{-(t-s)A}F(\eta(s))\,ds,\tag{2.4}$$

which may then be solved by the contraction mapping principle.

The following theorem summarizes results proved in [10].

THEOREM 2.5. *Let ∂D be of class C^2, and for a fixed $m\geqq 1$ let η_0 be in* $\operatorname{dom}(A^m)$. *Let $\|\cdot\|$ denote the norm on H induced by* (2.3). *Suppose that for all $1\leqq j\leqq m$,*

$$\|A^jF(\eta)\|\leqq C(\|\eta\|,\cdots,\|A^{j-1}\eta\|)\|A^j\eta\|,\tag{2.6}$$

$$\|A^j(F(\eta)-F(\nu))\| \leqq C(\|\eta\|, \|\nu\|, \cdots, \|A^j\eta\|, \|A^j\nu\|)\|A^j(\eta-\nu)\| \tag{2.7}$$

for all η, ν *in* $\operatorname{dom}(A^j)$, *where the constants* C *are nondecreasing, everywhere finite functions of all their variables. Then there is a* $T>0$ *such that* (2.2) *has a unique continuously differentiable solution* $\eta(t)$ *for* $0 \leqq t < T$, *with* $\phi(t)$ *in* $\operatorname{dom}(A^m)$ *for all* $0 \leqq t < T$.

If in addition $\|\eta(t)\|$ *is bounded on any finite interval of existence of* $\eta(t)$, *then* $\eta(t)$ *exists globally in time.*

Let $\|\cdot\|_p$ denote the norm in $L_p(D)$, and let $K_1, K_2, \cdots$ denote positive constants. If $\eta \in \operatorname{dom}(A)$ has first component u, then

$$\begin{aligned}\|AF(\eta)\|^2 &= \varepsilon^2 \int_D |\nabla \psi_\delta(x, u)|^2\, dx \\ &\leqq K_1[\|\phi_\delta'(u+f)|\nabla u|\|_2^2 + \||\phi_\delta'(u+f)-\phi_\delta'(f)||\nabla f|\|_2^2] \\ &\leqq K_2[\|\nabla u\|_2^2 + \|u\|_2^2] \leqq K_3\|\nabla u\|_2^2 \leqq K_4\|A\eta\|^2,\end{aligned}$$

where use was made of the boundedness and uniform Lipschitz continuity of ϕ_δ' on $\mathbb{R}$, the boundedness of $|\nabla f|$ on $\bar{D}$, and the Poincaré inequalities

$$\|u\|_2 \leqq K\|\nabla u\|_2 \leqq K^2\|\Delta_n u\|_2 \tag{2.8}$$

valid for $u \in H^2(D) \cap H_0^1(D)$. This establishes (2.6) with $j=1$.

If η, $\nu \in \operatorname{dom}(A)$ have respective first components u, w, then by applying Hölder's inequality, the Sobolev inequality

$$\|u\|_p \leqq C_p\|\nabla u\|_2, \qquad 1 \leqq p \leqq \frac{2n}{n-2} \tag{2.9}$$

valid for $u \in H^1(D)$, and (2.8), we obtain

$$\begin{aligned}\|A(F(\eta)-F(\nu))\| &\leqq K_1[\|u-w\|_2^2 + \|\nabla(u-w)\|_2^2 + \|\nabla u\|_4^2\|u-w\|_4^2] \\ &\leqq K_2\|\Delta_n(u-w)\|_2^2 + K_3\|\Delta_n u\|_2^2\|\nabla(u-w)\|_2^2 \\ &\leqq K_4(1+\|A\eta\|^2)\|A(\eta-\nu)\|^2.\end{aligned}$$

This establishes (2.7) with $j=1$ for $1 \leqq n \leqq 4$.

From the integral equation (2.4), from the fact that $|\psi_\delta(x, u)| \leqq C|u|$ for some constant $C>0$ for all $x \in \bar{D}$ and $u \in \mathbb{R}$, and from (2.8), we obtain

$$\begin{aligned}\|\eta(t)\| &\leqq \|e^{-tA}\eta_0\| + \left\| \int_0^t e^{-(t-s)A}F(\eta(s))\, ds \right\| \\ &\leqq \|\eta_0\| + \int_0^t \|F(\eta(s))\|\, ds \\ &\leqq K_1\left[\|\eta_0\| + \int_0^t \|\eta(s)\|\, ds\right];\end{aligned}$$

hence, by Gronwall's inequality,

$$\|\eta(t)\| \leqq K_1\|\eta_0\| e^{K_1 t}$$

for all t in the existence interval for $\eta(t)$.

The above arguments and Theorem 2.5 together yield the following corollary.

COROLLARY 2.10. *Let* $D \subseteq \mathbb{R}^n$ *with* $1 \leqq n \leqq 4$ *have a* C^2 *boundary, and suppose that* $\eta_0 \in \operatorname{dom}(A) = [H^2(D) \cap H_0^1(D)] \oplus H^1(D)$. *Then for all* $0 < \delta < M$ *and for all sufficiently small* $\varepsilon > 0$, *problem* (2.2) *has a unique continuously differentiable solution* $\eta(t)$ *that is global in time and remains in* $\operatorname{dom}(A)$ *for all* $t \geqq 0$.

Four remarks are in order. Note that the proof of Corollary 2.10 does not require ϕ to be convex. Theorem 2.5 cannot be used to obtain greater regularity of solutions of (2.2) due to the lack of a Poincaré inequality of the form

$$\|\nabla^j u\|_2 \leqq C\|\nabla^{j+1} u\|_2, \qquad u \in H^{j+1}(D) \cap H_0^1(D)$$

for $j \geqq 2$. The first component $\bar{u}$ of the solution $\eta = \binom{\bar{u}}{\bar{u}_t}$ in Corollary 2.10 with $n = 2$ or 3 is continuous on $\bar{D} \times [0, \infty)$ in view of the imbedding inequality

$$\max_{x \in \bar{D}} |\bar{u}(x, t)| \leqq C\|\Delta_n \bar{u}(\cdot, t)\|_2^2$$

valid for $\bar{u}(\cdot, t) \in H^2(D) \cap H_0^1(D)$, $1 \leqq n \leqq 3$, and the continuity in time of $\bar{u}$ in the norm on $H^2(D) \cap H_0^1(D)$. Since $H^2(D)$ imbeds in $C(\bar{D})$ only for $n = 1, 2, 3$ [3, p. 30], any extension of Corollary 2.10 to cases $n \geqq 5$ would not be useful for the purposes of this paper.

Now suppose that the solution η in Corollary 2.10 with $n = 2$ or 3 begins with $\max_{x \in \bar{D}} [u_0(x)] < M - \delta$. If $\max_{x \in \bar{D}} [\bar{u}(x, t) + f(x)] < M - \delta$ for all $t \geqq 0$, then $u = \bar{u} + f$ is a global solution of problem (An). Otherwise there is a first time $T_0 > 0$ at which $\max_{x \in \bar{D}} [\bar{u}(x, T_0) + f(x)] = M - \delta$; by choosing $0 < \delta_1 < \delta$ and applying Corollary 2.10 to problem (2.2) with δ replaced by δ_1, we may extend $\bar{u} + f$ uniquely to an interval $[0, T_1)$ with $T_1 > T_0$ such that $\max_{x \in \bar{D}} [\bar{u}(x, t) + f(x)] < M - \delta_1$ for $0 \leqq t < T_1$, and $u = \bar{u} + f$ solves (An) on $\bar{D} \times [0, T_1)$. This argument establishes the following corollary.

COROLLARY 2.11. *Let $D \subseteq \mathbb{R}^n$ with $n = 2$ or 3 have a C^2 boundary, and suppose that $\binom{u_0}{v_0} \in \operatorname{dom}(A)$ with $\max_{x \in \bar{D}} u_0(x) < M$. Then for all sufficiently small $\varepsilon > 0$, the system form of problem* (An)

$$\begin{pmatrix} u \\ u_t \end{pmatrix}' = -A \begin{pmatrix} u \\ u_t \end{pmatrix} + \begin{pmatrix} 0 \\ \varepsilon\phi(u) \end{pmatrix}, \qquad 0 < t < T,$$

$$\begin{pmatrix} u \\ u_t \end{pmatrix}\Bigg|_{t=0} = \begin{pmatrix} u_0 \\ v_0 \end{pmatrix}$$

has a unique solution $\binom{u}{u_t} \in \operatorname{dom}(A)$ on some time interval $[0, T)$ that is continuously differentiable in time in the norm on H. The solution can be continued as long as $\max_{x \in \bar{D}} u(x, t) < M$.

Define $\Phi(u) = \int_0^u \phi(s)\, ds$. A solution u of (An) with the regularity properties given in Corollary 2.11 satisfies the energy equality

$$E(t) \equiv \frac{1}{2} \int_D |u_t|^2\, dx + J(u) = E(0), \tag{2.12}$$

where

$$J(u) = \frac{1}{2} \int_D |\nabla u|^2\, dx - \varepsilon \int_D \Phi(u)\, dx$$

represents the potential energy of u at time t.

By defining $j(\lambda) = J(f + \lambda u)$ for $\lambda \geqq 0$, we may examine the behavior of J along rays emanating from the stationary solution f of problem (An) in the function space $H_0^1(D)$. Note that

$$\begin{aligned} j'(0) &= \int_D \nabla f \cdot \nabla u\, dx - \varepsilon \int_D \phi(f) u\, dx \\ &= \int_D \nabla f \cdot \nabla u\, dx + \int_D (\Delta f) u\, dx = 0. \end{aligned}$$

Let $f_{\max} = \max_{x \in \bar{D}} f(x)$; then by (2.8),

$$j''(0) = \int_D |\nabla u|^2 \, dx - \varepsilon \int_D \phi'(f) u^2 \, dx$$

$$\geqq \int_D |\nabla u|^2 \, dx - \varepsilon \phi'(f_{\max}) \int_D u^2 \, dx$$

$$\geqq (1 - \varepsilon K^2 \phi'(f_{\max})) \int_D |\nabla u|^2 \, dx.$$

Suppose f satisfies $f_{\max} \to 0$ as $\varepsilon \to 0^+$. (Equilibrium solutions with this property do exist; see [5].) Then for all sufficiently small ε we have $1 - \varepsilon K^2 \phi'(f_{\max}) > 0$, and hence $j''(0) > 0$; i.e., J is convex along rays emanating from f. This is a necessary condition for f being a local minimum of J in $H_0^1(D)$.

Nevertheless, as the following results show, there exists no potential well about any stationary solution of (An) for any $\varepsilon > 0$ and any $n \geqq 2$.

LEMMA 2.13. *Let $\varepsilon > 0$ be fixed, and let f be an equilibrium solution of* (An), *$n \geqq 2$. Choose $x_0 \in D$ such that $f(x_0) = f_{\max}$. Then for any $\delta > 0$ we may find a ball $B_M \subseteq D$ with center x_0, and functions $\{w_\lambda : f_{\max} < \lambda \leqq M\} \subseteq C_0^\infty(D)$, such that $w_\lambda = \lambda - f$ on B_M and $\int_D |\nabla w_\lambda|^2 \, dx < \delta$ for all $f_{\max} < \lambda \leqq M$.*

Proof. Let $B(x_0, a)$, $B(x_0, b)$ denote concentric open balls in $\mathbb{R}^n$ with center x_0 and respective radii $0 < a < b$. By Friedman [3, p. 9] there exists a $\zeta \in C^\infty(\mathbb{R}^n)$ such that $\zeta = 1$ in $B(x_0, a)$, $0 \leqq \zeta \leqq 1$ in $B(x_0, b) - B(x_0, a)$, and $\zeta = 0$ outside $B(x_0, b)$. The function ζ will be called a C^∞ cutoff from $B(x_0, a)$ to $B(x_0, b)$. Note that for $0 < \rho < 1$, $\zeta_\rho(x) \equiv \zeta(x/\rho)$ is a C^∞ cutoff from $B(x_0, a\rho)$ to $B(x_0, b\rho)$ satisfying $|\nabla \zeta_\rho(x)| \leqq K_0/\rho$ for all $x \in \mathbb{R}^n$, where $K_0 > 0$ depends on a, b, but is independent of ρ. □

The proof for $n \geqq 3$ proceeds as follows. Choose $0 < a < b$, and for each $f_{\max} \leqq \lambda \leqq M$ and each $\rho > 0$ define

$$w_{\lambda,\rho} = \zeta_\rho(\lambda - f).$$

Then for all ρ sufficiently small $w_{\lambda,\rho} \in C_0^\infty(D)$, and $w_{\lambda,\rho} = \lambda - f$ on $B(x_0, a\rho)$. Now f is nonnegative on $\bar{D}$ by the maximum principle, so for $f_{\max} \leqq \lambda \leqq M$

$$\int_D |\nabla w_{\lambda,\rho}|^2 \, dx = 2 \int_{B(x_0, b\rho)} [|\nabla \zeta_\rho|^2 |\lambda - f|^2 + |\zeta_\rho|^2 |\nabla f|^2] \, dx$$

$$\leqq 2 V_n (K_0^2 M^2 + \rho^2 \max_{\bar{D}} |\nabla f|^2) \rho^{n-2},$$

where V_n denotes the volume of the unit ball in $\mathbb{R}^n$. By taking $\rho = \rho_0 > 0$ sufficiently small, we may arrange that

$$\int_D |\nabla w_{\lambda,\rho_0}|^2 \, dx < \delta \quad \text{for all } f_{\max} \leqq \lambda \leqq M.$$

We may then take B_M to be $B(x_0, a\rho_0)$, and w_λ to be w_{λ,ρ_0} for $f_{\max} \leqq \lambda \leqq M$.

When $n = 2$, choose fixed $b > a > 0$ so small that $B(x_0, b) \subseteq D$. Let $r = |x - x_0|$ denote the distance from x_0 to x in $\mathbb{R}^2$. For $f_{\max} < \lambda \leqq M$, choose $B \equiv \lambda - f_{\max} > A > 0$, and choose $0 < 2\rho < a$. For $\alpha < 0$ let

$$C = \frac{B - A}{\rho^\alpha - b^\alpha}, \qquad D = \frac{A\rho^\alpha - Bb^\alpha}{\rho^\alpha - b^\alpha},$$

so that $C\rho^\alpha + D = B$ and $Cb^\alpha + D = A$. Let ζ denote a C^∞ cutoff from $B(x_0, 1)$ to $B(x_0, 2)$, and define $\zeta_\rho(r) = \zeta(r/\rho)$. Let $\zeta_{a,b}$ be a C^∞ cutoff from $B(x_0, a)$ to $B(x_0, b)$. For $f_{\max} < \lambda \leqq M$ define

$$w_{\lambda,\rho}(x) = \zeta_{a,b}(r)[\zeta_\rho(r)(\lambda - f(x) - Cr^\alpha - D) + Cr^\alpha + D].$$

Thus setting

$$I_1 = \int_{B(x_0,2\rho)} |\nabla f|^2 \, dx,$$

$$I_2 = \int_{B(x_0,2\rho)-B(x_0,\rho)} |\nabla \zeta_\rho|^2 |\lambda - f - Cr^\alpha - D|^2 \, dx,$$

$$I_3 = \int_\rho^b |\nabla(Cr^\alpha)|^2 r \, dr,$$

$$I_4 = \int_a^b |\nabla \zeta_{a,b}|^2 |Cr^\alpha + D|^2 r \, dr,$$

we may obtain that

$$\int_D |\nabla w_{\lambda,\rho}|^2 \, dx \leqq K_1 \sum_{j=1}^4 I_j$$

for an absolute constant $K_1 > 0$.

Since $|\nabla f|$ is bounded on $B(x_0, b)$, we may choose a $\rho_0 > 0$ independent of A, α, and λ such that $I_4 < \delta/(4K_1)$ for all $0 < \rho \leqq \rho_0$.

Using the facts that $Cr^\alpha + D$ is positive and decreasing for $0 < r \leqq b$, and that $|\nabla \zeta_\rho| \leqq K_0/\rho$ for some absolute constant $K_0 > 0$, we may show that

$$I_2 \leqq 6\pi K_0^2 [C^2(1-2^\alpha)^2 \rho^{2\alpha} + \max_{x \in \overline{B(x_0,2\rho)}} |f(x) - f_{\max}|^2],$$

$$I_3 = \frac{\alpha C^2}{2}(b^{2\alpha} - \rho^{2\alpha}), \qquad I_4 \leqq K_2[A^2 + C^2(a^\alpha - b^\alpha)^2],$$

for some positive absolute constant K_2. It is a simple matter to show that the expressions $C^2(1-2^\alpha)^2\rho^{2\alpha}$, $(\alpha C^2/2)(b^{2\alpha} - \rho^{2\alpha})$, $C^2(a^\alpha - b^\alpha)^2$ can be made arbitrarily small independent of λ, $f_{\max} < \lambda \leqq M$, by taking $|\alpha| > 0$, $\rho > 0$ sufficiently small. Hence by choosing $A = A_0$, $\rho = \rho_1 < \rho_0$, $\alpha = \alpha_0$ all sufficiently close to zero, we may arrange that $I_j < \delta/4K_1$ for $1 \leqq j \leqq 4$ for all $f_{\max} < \lambda \leqq M$. Set $B_M = B(x_0, \rho_1)$, and $w_\lambda = w_{\lambda,\rho_1}$ with $A = A_0$, $\alpha = \alpha_0$. Then $\int_D |\nabla w_\lambda|^2 \, dx < \delta$ for all $f_{\max} < \lambda \leqq M$. □

In particular, for any $\varepsilon > 0$, $n \geqq 2$, there are functions $v_M = w_M + f$ with essential supremum equal to M in any neighborhood of f in $H_0^1(D)$.

LEMMA 2.14. *Let $y(t)$ denote the solution of the ordinary initial boundary value problem*

$$\begin{aligned} &\ddot{y} = \varepsilon \phi(y) \qquad t > 0, \\ &y(0) = y_0, \qquad \dot{y}(0) = 0, \end{aligned} \tag{2.15}$$

where $y_0 < M$. Then there is a finite $T_q > 0$ such that $\lim_{t \to T_q^-} y(t) = M$, i.e., y quenches in finite time. As $y_0 \to M^-$, $T_q \to 0^+$.

Proof. The uniform Lipschitz continuity of ϕ on intervals of the form $(-\infty, M - \delta]$, $\delta > 0$, guarantees that (2.15) has a unique local C^2 solution $y(t)$ that can be continued as long as $y(t) < M$. On the existence interval $[0, T_q)$ for y, $\ddot{y} > 0$ and hence $\dot{y}(t)$ is

strictly increasing in t. Since $\dot{y}(0)=0$, $\dot{y}(t)>0$ and hence $y(t)>y_0$ for $0<t<T_q$. Since ϕ is strictly increasing,

$$\ddot{y}(t)>\varepsilon\phi(y_0),$$

so that

$$y(t)-y_0>\varepsilon\phi(y_0)t^2,$$

for $0\leqq t<T_q$. Hence

$$\sqrt{(M-y_0)/\varepsilon\phi(y_0)}>T_q.$$

Clearly, $T_q\to 0^+$ as $y_0\to M^-$. □

THEOREM 2.16. *Let ε, δ, T_0 be any fixed positive numbers, and let k be any nonnegative integer. Let $f\in C^k(\bar{D})$ be an equilibrium solution of* (An) *with $n\geqq 2$. Then there exists $u_0\in C^k(\bar{D})$ with $u_0=0$ on ∂D, $\max_{\bar{D}} u_0<M$, and $\int_D|\nabla(u_0-f)|^2\,dx<\delta$, such that the solution u of problem* (An) *with $v_0=0$ quenches in finite time $T\leqq T_0$.*

Proof. Let $w_\lambda\in C_0^\infty(\bar{D})$ be the functions satisfying $w_\lambda=\lambda-f$ on B_M, $\int_D|\nabla w_\lambda|^2\,dx<\delta$ for all $f_{\max}<\lambda\leqq M$, whose existence is guaranteed by Lemma 2.13. Let $\rho>0$ denote the radius of B_M. By Lemma 2.14, we may choose $y_0<M$ so close to M that the solution $y=y(t,y_0)$ of (2.15) quenches in time $T_q\leqq\min\{T_0,\rho\}$.

Define $u_0=w_{y_0}+f$; then $u_0\in C^k(\bar{D})$, $u_0=0$ on ∂D, $u_0=y_0$ on B_M, and $\int_D|\nabla(u_0-f)|^2\,dx<\delta$. If u denotes the solution of problem (An) with this u_0 and with $v_0=0$, we have

$$u(x,t)=y(t,y_0)$$

for all (x,t) in the retrograde characteristic cone with vertex (x_0,ρ) and base $B_M\times\{0\}$. Hence u must quench in time $T\leqq T_q$. □

The idea of comparing solutions inside retrograde characteristic cones in the half-space $t\geqq 0$ was used by Keller [6] to show pointwise blowup in finite time of solutions of $u_{tt}=c^2\Delta_n u+f(u)$ for certain $f\in C^2(\mathbb{R})$.

Suppose u is a continuous solution of (An) with sufficient regularity to satisfy energy equality (2.12) (or the inequality $E(t)\leqq E(0)$) for all t in its existence interval. Define

$$u^+_{\max}=u^+_{\max}(t)\equiv\max_{x\in\bar{D}}(u(x,t),0),\qquad \gamma=\gamma(t)\equiv(u^+_{\max})^{-2}\int_D|\nabla u|^2\,dx.$$

Then

$$\gamma\leqq 2(u^+_{\max})^{-2}[E(0)+\varepsilon\mu(D)\Phi(u^+_{\max})]\equiv g(u^+_{\max}), \tag{2.17}$$

where $\mu(D)$ denotes the n-dimensional Lebesgue measure of D.

When $E(0)\geqq 0$, $g(s)$ achieves a positive absolute minimum $g_m=g(s_0)$ on the interval $(0,M]$. Note that $g(M/2)$, and hence g_m itself, can be made arbitrarily small by taking both $\varepsilon>0$ and $E(0)\geqq 0$ sufficiently small.

If u satisfies an a priori inequality of the form

$$\gamma(t)\geqq g_m,\qquad t\geqq 0 \tag{2.18}$$

and begins in the region R depicted in Fig. 1 (i.e., with $u^+_{0,\max}<s_0$), then $u^+_{\max}$ remains bounded away from M for all time, and u will be a global solution of (An).

When $n=1$ we have $\gamma(t)\geqq 4$ for all $t\geqq 0$ by (1.1), and these observations underlie the proof of the result (b) of [2, §1].

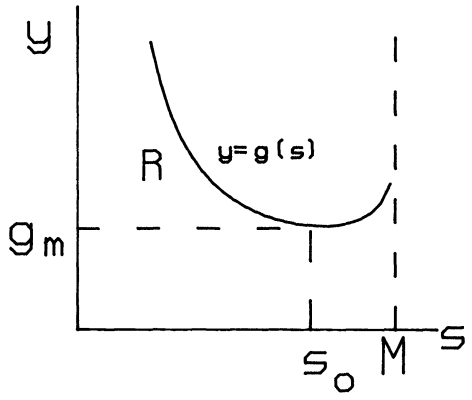

FIG. 1. *An invariant region for solutions of* (An) *satisfying* (2.18).

3. Numerical results. A simple explicit finite-difference scheme was used to approximate solutions $u = u(r, t)$ of

(Rn)

$$u_{tt} = u_{rr} + \frac{n-1}{r} u_r + \varepsilon\phi(u), \quad 0 < r < 1, \quad 0 < t < T, \tag{3.1}$$

$$u_r(0, t) = u(1, t) = 0, \qquad 0 < t < T, \tag{3.2}$$

$$u(r, 0) = u_0(r), \quad u_t(r, 0) = v_0(r), \quad 0 < r < 1, \tag{3.3}$$

which are radial solutions of (An) when $r = |x|$ and D is the unit ball centered at the origin in $\mathbb{R}^n$.

The difference scheme used is adapted from John [4, pp. 172–174]. Divide the interval $[0, 1]$ into N subintervals of equal length $h = 1/N$, and let k denote the stepsize in time, with

$$\lambda \equiv \frac{k}{h} \leqq 1. \tag{3.4}$$

For $1 \leqq i \leqq N+1$, $j \geqq 0$, $w = w(r, t)$ define

$$w_{ij} = w((i-1)h, jk).$$

Let δ_t denote the divided difference operator

$$\delta_t w_{ij} = \frac{1}{k}\left[w_{i,j+1} - \frac{1}{2}(w_{i+1,j} + w_{i-1,j}) \right],$$

with space averaging in the lower step; and let δ_r denote the central divided difference operator

$$\delta_r w_{ij} = \frac{1}{2h}[w_{i+1,j} - w_{i-1,j}].$$

For $2 \leqq i \leqq N-1$ and $j \geqq 0$, (3.1) was replaced by the difference equation

$$\delta_t^2 w_{ij} = \delta_r^2 w_{ij} + \frac{n-1}{(i-1)h} \delta_r w_{ij} + \varepsilon\phi(w_{ij}). \tag{3.5}$$

Values $w_{0,j}, w_{-1,j}, \cdots$ were interpreted by extending w as an even function of r through $r = 0$. For $i = 1$, (3.1) was replaced by

$$\delta_t^2 w_{1j} = n\delta_r^2 w_{1j} + \varepsilon\phi(w_{1j}). \tag{3.6}$$

For $i = N$, backward differences in r were used, and space averaging was abandoned wherever necessary to avoid going past $r = 1$. A Taylor series approximation was used to obtain the values w_{i1}.

The difference scheme is stable, consistent, and convergent when applied to the pure initial boundary value problem obtained by linearizing (3.1) about a stationary solution f. Grave difficulties are encountered, however, in attempts to prove consistency and convergence for (3.4)-(3.6), due to the boundary conditions and the presence of the nonlinearity ϕ. In particular, we are unable to derive useful upper bounds for higher difference quotients of w. This is analogous to the difficulties encountered with the abstract approach to the differential problem in § 2. Therefore for the numerical tests the following checks and safeguards were implemented.

(a) The Courant-Friedrichs-Lewy condition (3.4), a necessary condition for stability, was ensured to be satisfied by taking $\lambda = \frac{1}{4}$ in all tests;

(b) Stationary solutions f of (Rn) were approximated by the shooting method using the classical fourth-order Runge-Kutta method. The difference scheme (3.4)-(3.6) was then applied with $u_0 = f$, $v_0 = 0$ as a check of the computer code. Since the

7	2.563	6.000

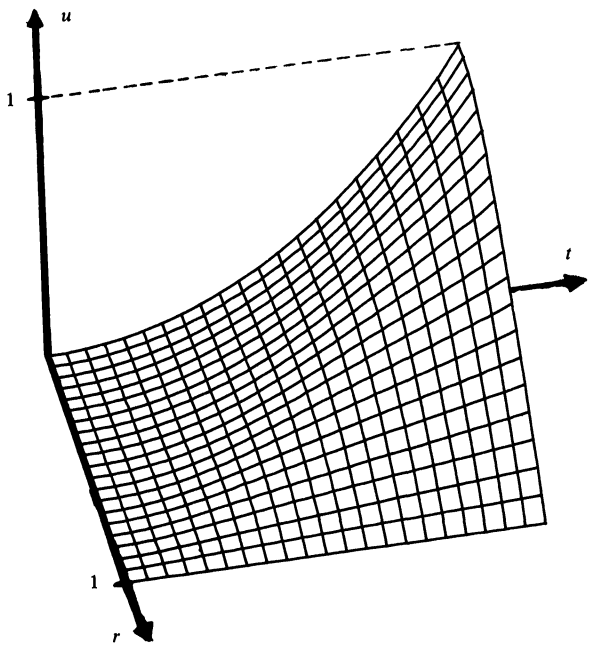

FIG. 2. *A solution of* (3.5), (3.6) *with* $\varepsilon > \varepsilon_n$.

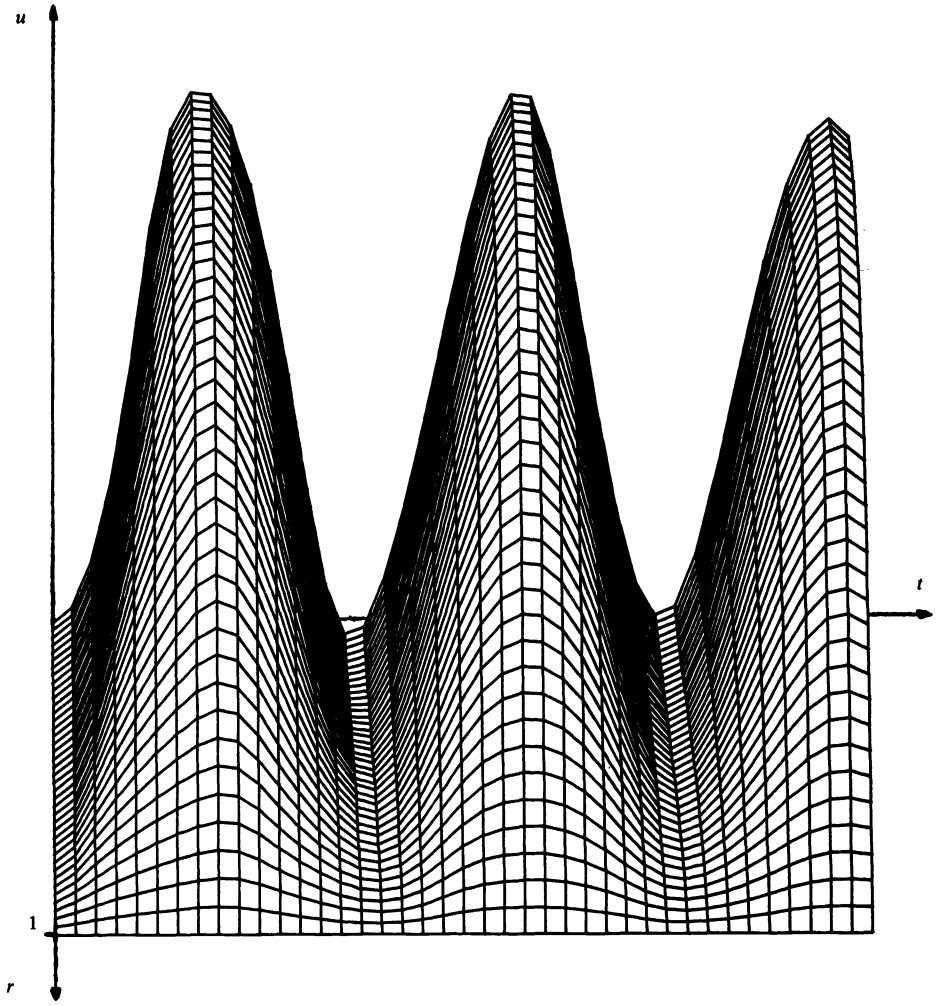

FIG. 3. *A solution of* (3.5), (3.6) *with* $\varepsilon < \varepsilon_n$.

approximate stationary solutions are not exact, these checks (as well as checks with $v_0 = 0$, $u_0 =$ small perturbation of f) served as empirical evidence of the scheme's stability;

(c) The convergence of the scheme (3.5), (3.6) was checked empirically for several examples by letting h, $k \to 0$ while keeping $\lambda = \frac{1}{4}$; and

(d) The difference scheme satisfies an energy inequality related to (2.12). Care was taken so that the total energy of the difference approximation remained nearly constant.

Double-precision arithmetic was used for all computations. The experiments were performed on a National Advanced Systems AS/9160 computer with MVS/SP operating system.

To isolate the effects of the term $\varepsilon\phi(u)$, solutions of (3.5), (3.6) with $u_0 = v_0 = 0$ were computed in dimensions $n = 2$, 3, and 7. The behavior of such solutions agrees qualitatively with behavior reported in [2] for solutions in the case $n = 1$. In particular, in each dimension n considered there appears to be an $\varepsilon_n > 0$ such that solutions

quench in finite time when $\varepsilon > \varepsilon_n$ and do not quench (even in infinite time) when $\varepsilon < \varepsilon_n$. For $\varepsilon < \varepsilon_n$ the solution displays a sequence of relative maxima that occur along the line $r = 0$, $t > 0$; the first such relative maximum appears to be an absolute maximum which approaches 1 from below as ε approaches ε_n from below.

Table 1 lists values of ε_n obtained when $\phi(u) = (1-u)^{-1}$; the value of ε_1 is taken from [2].

Figures 2 and 3 contrast the behavior of a solution w of (3.5), (3.6) for values of ε, respectively, greater than and less than ε_n. Figures 2 and 3 were generated using $\phi(u) = (1-u)^{-1}$, $n = 2$, and $h = 1/200$. In Fig. 2, $\varepsilon = 1.5 > \varepsilon_2$, and the solution quenches in time $T = 1.01$, while in Fig. 3, $\varepsilon = 0.9 < \varepsilon_2$, and the solution is displayed for $0 \leqq t \leqq 8$.

The stability of the solution f of the stationary problem

$$f(r) + \frac{n-1}{r} f'(r) + \varepsilon\phi(f(r)) = 0, \qquad 0 < r < 1, \tag{3.7}$$

$$f'(0) = f(1) = 0, \tag{3.8}$$

satisfying $f_{\max} \to 0^+$ as $\varepsilon \to 0^+$, was also investigated. Care must be taken in computing f, since solutions of (3.7), (3.8), are not always unique. Indeed, in [5], Joseph and Lundgren show that for $\phi(u) = (1+\alpha u)^{\beta}$ with α, $\beta < 0$, $\tau = 1/(\beta - 1)$, $\bar{\varepsilon} = (\tau/\alpha)(n-2-\tau)$, and $f(\beta) = 2\beta\tau + 2(2\beta\tau)^{1/2}$:

(a) There is an $\varepsilon_* > 0$ such that positive solutions of (3.7), (3.8) do not exist when $\varepsilon > \varepsilon_*$;

(b) For $3 \leqq n < 2 + f(\beta)$ and $\varepsilon_* > \bar{\varepsilon}$, there is a large but finite number of positive solutions when $\varepsilon < \bar{\varepsilon}$ is close to $\bar{\varepsilon}$, and a countably infinite number of solutions when $\varepsilon = \bar{\varepsilon}$; and

(c) For $n \geqq 2 + f(\beta)$ and $\bar{\varepsilon} = \varepsilon_*$, there is exactly one positive solution when $\varepsilon < \varepsilon_*$. See Table 1 for values of ε_* when $\phi(u) = (1-u)^{-1}$ and $n = 1, 2, 3, 7$.

Bifurcation diagrams plotting ε as a function of $f_{\max}$ were generated using the procedure described in [5]. We then checked that the shooting method converged to the stationary solution with smallest $f_{\max}$. Figure 4 contains bifurcation diagrams for $n = 2, 3, 9$ when $\alpha = -1$, $\beta = -3$.

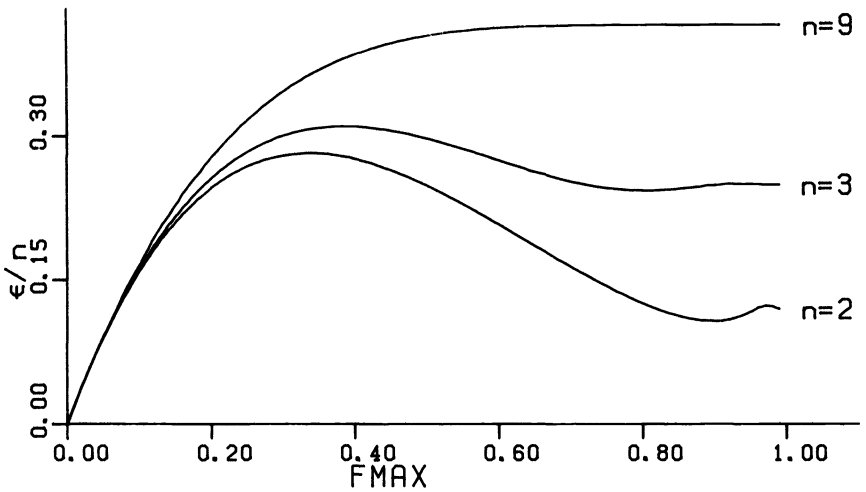

FIG. 4. *Bifurcation diagram for positive solutions of* (3.7), (3.8) *when* $\phi(u) = (1-u)^{-3}$.

Perturbations p of f used as initial data u_0 were of the form $p = vf$ for $1 < v < 1/f_{\max}$ or of the form

$$p(r) = \begin{cases} v, & 0 \leqq r \leqq r_0, \\ f(r), & r_1 \leqq r \leqq 1, \end{cases}$$

where $0 < r_0 < r_1 < 1$, $f_{\max} < v < 1$, and p is defined on $r_0 \leqq r \leqq r_1$ to be strictly decreasing and C^2 on $[0, 1]$. Numerical experiments with initial data $u_0 = p$, $v_0 = 0$ indicate that whenever p is sufficiently close to f in sup-norm, the a priori inequality (2.18) is

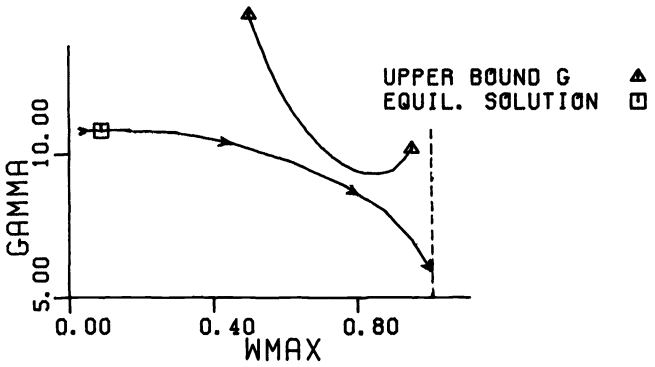

FIG. 5. *Quenching trajectory for γ when $\lambda = 0.5$, $E(0) = 2.0$.*

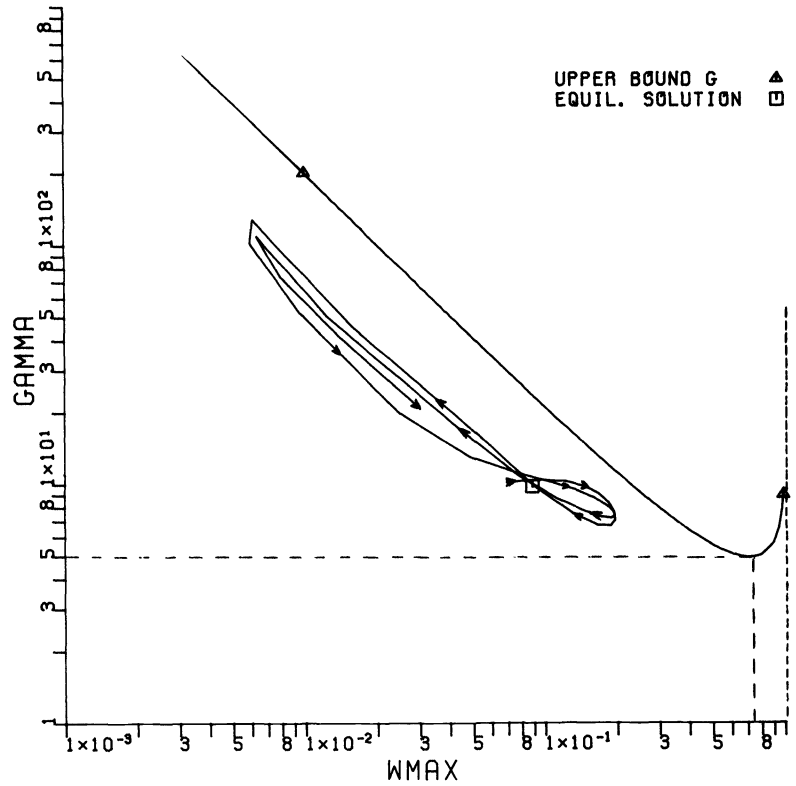

FIG. 6. *Nonquenching trajectory for γ when $\nu = 0.5$, $E(0) = 0$.*

satisfied for all time by solutions of (3.5)-(3.8). Figures 5 and 6 contrast the trajectories of $\gamma(t)$ in quenching and nonquenching cases. Figures 5 and 6 were generated with $n=3$, $\phi(u)=(1-u)^{-1}$, $u_0=vf$, $v_0(r)=\mu(1-r^2)$, where μ was chosen so that $E(0)\geqq 0$, $\varepsilon=0.5$, $h=1/100$.

Acknowledgment. The author thanks Howard A. Levine for many helpful discussions.

ISOPERIMETRIC INEQUALITIES FOR THE STEFAN PROBLEM*

B. GUSTAFSSON† AND J. MOSSINO‡

Abstract. The weak solution (θ, h) of the Stefan problem in some annular domain $\omega \times (0, T)$ is compared with the weak solution (Θ, H) of the "symmetrized" problem, in $\Omega \times (0, T)$, where Ω is a symmetrical annulus having the same measure as ω. For the one-phase Stefan problem—$\theta \geqq 0$, $h \in (-\alpha, 0)$ when $\theta = 0$—it is shown in particular that the "volume of ice" (meas $\{h(t) = -\alpha\}$) remains greatest in spherical symmetry (with initial data decreasing along the radii).

Résumé. Cet article compare la solution faible (θ, h) du problème de Stefan dans un domaine $\omega \times (0, T)$ (où ω est une couronne) avec celle du problème "symétrisé" (Θ, H) dans $\Omega \times (0, T)$, où Ω est une couronne symétrique de même mesure que ω. Pour le problème de Stefan à une phase—$\theta \geqq 0$, $h \in (-\alpha, 0)$ là où $\theta = 0$—on voit en particulier que le "volume de glace" (mes $\{h(t) = -\alpha\}$) est maximum en symétrie de révolution (avec donnée initiale décroissante le long du rayon).

Key words. one-phase Stefan problem, two-phase Stefan problem, solid phase-liquid phase, regularized problem, symmetrized problem, decreasing rearrangement, equimeasurable functions, isoperimetric inequalities

AMS(MOS) subject classifications. 35K55, 35B05

1. Introduction.

We consider the Stefan problem in its simplest form and in an annular space geometry: find a pair (θ, h) of functions defined in $q = \omega \times (0, T)$ such that, in some weak sense,

$$\begin{aligned} &\frac{\partial h}{\partial t} - \Delta\theta = 0 \quad \text{in } q, \\ &\theta = g \quad \text{on } \sigma = \partial\omega \times (0, T), \\ &h|_{t=0} = h_0, \\ &h \in a(\theta) \quad \text{a.e. in } q. \end{aligned} \tag{1.1}$$

Here we have the following:

- $\omega = \omega_0 \backslash \bar{\omega}_1$, where ω_0, ω_1 are bounded domains in $\mathbb{R}^N$ $(N \geqq 2)$ with smooth boundaries $\gamma_0 = \partial\omega_0$ and $\gamma_1 = \partial\omega_1$, and satisfying $\bar{\omega}_1 \subset \omega_0$.
- g is constant on each of $\sigma_0 = \gamma_0 \times (0, T)$ and $\sigma_1 = \gamma_1 \times (0, T)$, let us say

$$g = \begin{cases} 0 & \text{on } \sigma_0, \\ 1 & \text{on } \sigma_1. \end{cases}$$

- a is a strictly monotone graph in $\mathbb{R}^2$ (regarded as a map from $\mathbb{R}$ into subsets of $\mathbb{R}$). The typical form of a for the Stefan problem is

$$a(\theta) = \begin{cases} \alpha_0(\theta - \lambda) - \alpha & \text{for } \theta < \lambda, \\ [-\alpha, 0] & \text{for } \theta = \lambda, \\ \alpha_1(\theta - \lambda) & \text{for } \theta > \lambda, \end{cases} \tag{1.2}$$

where α, α_0, α_1 are positive constants, $\lambda \in [0, 1]$. However, our main results are valid for an arbitrary maximal monotone graph a such that $a([0, 1])$ is bounded, and such that the inverse graph $b = a^{-1}$ is a Lipschitz continuous function on $a([0, 1])$.

• $h_0 \in L^\infty(\omega)$ and satisfies an extra condition (see (1.6), (1.7) below), which essentially means that $\theta_0 = b(h_0)$ belongs to $H^1(\omega)$ and satisfies $0 \leqq \theta_0 \leqq 1$.

The physical interpretation of (1.1) when a is of the form (1.2) is that θ is the temperature and h the enthalpy of some matter that undergoes a phase change (solid-liquid) at temperature λ. The number α is proportional to the latent heat for the phase change, and α_0 and α_1 are proportional to the heat capacities of the solid and liquid states, respectively (α, α_0, α_1 are also inversely proportional to the thermal conductivity coefficients). With more general a (often single-valued), there are many other interpretations of (1.1) (e.g., porous medium equation).

Our boundary and initial data, g and h_0 above, are such that the solution (θ, h) of (1.1), by the maximum principle, will satisfy $0 \leqq \theta \leqq 1$ in all q. In the case of (1.2) with $\lambda = 0$, the temperature in the solid phase (the latter generally defined as the region where $h \leqq -\alpha$ ($h = -\alpha$ in this case)) therefore must be constantly equal to zero. Similarly, in the case $\lambda = 1$, the temperature in the liquid phase $\{h \geqq 0\}$ ($h = 0$ in this case) is constantly equal to 1. Thus, for these extreme cases, in practice we have a one-phase Stefan problem, while for $0 < \lambda < 1$, the problem really is a two-phase problem.

One standard way of making (1.1) precise is to say that (θ, h) is a weak solution of (1.1) if

$$\theta \in L^\infty(q), \quad h \in L^\infty(q), \quad h \in a(\theta) \quad \text{a.e. in } q,$$

$$\int\int_q \left(h \frac{\partial \varphi}{\partial t} + \theta \Delta \varphi \right) dx\, dt = \int_0^T \int_\gamma g \frac{\partial \varphi}{\partial \nu}\, d\gamma\, dt - \int_\omega h_0(x) \varphi(x, 0)\, dx \tag{1.3}$$

for every "test function" $\varphi \in \mathscr{C}^1(\bar{q})$ satisfying $(\partial^2 \varphi / \partial x_i\, \partial x_j) \in \mathscr{C}(\bar{q})$ and $\varphi = 0$ on $\sigma \cup (\omega \times \{T\})$ (see, e.g., [3] or [4]).

Existence and uniqueness of weak solutions can be proved in several different ways. One method, developed by Oleinik [9] (in one space dimension) and Friedman [3] (see also [4]) is to obtain the weak solution as a limit as $\varepsilon \to 0$ ($\varepsilon > 0$) of the classical solutions $(\theta_\varepsilon, h_\varepsilon)$ of some regularized problems

$$\begin{aligned} &\frac{\partial h_\varepsilon}{\partial t} - \Delta \theta_\varepsilon = 0 \quad \text{in } q, \\ &\theta_\varepsilon = g \quad \text{on } \sigma, \\ &h_{\varepsilon|_{t=0}} = h_{\varepsilon_0}, \\ &h_\varepsilon = a_\varepsilon(\theta_\varepsilon) \quad \text{in } q. \end{aligned} \tag{$1.1)_\varepsilon$}$$

Here a_ε (from $[0, 1]$ to $a([0, 1])$) are single-valued smooth functions with

$$a_\varepsilon' \geqq \delta > 0 \qquad (\delta \text{ independent of } \varepsilon) \tag{1.4}$$

such that $a_\varepsilon \to a$ as $\varepsilon \to 0$, in the sense that

$$b_\varepsilon = a_\varepsilon^{-1} \text{ (from } a([0, 1]) \text{ to } [0, 1]) \text{ converges uniformly to } b = a^{-1}. \tag{1.5}$$

Moreover, h_{ε_0} are smooth functions such that

$$h_{\varepsilon_0} \to h_0 \quad \text{in } L^1(\omega), \tag{1.6}$$

and that, in terms of $\theta_{\varepsilon_0} = b_\varepsilon(h_{\varepsilon_0})$,

$$0 \leqq \theta_{\varepsilon_0} \leqq 1 \quad \text{in } \omega, \qquad \theta_{\varepsilon_0}|_{\partial\omega} = g,$$

$$\int_\omega |\nabla \theta_{\varepsilon_0}|^2\, dx \text{ is bounded independently of } \varepsilon \quad \text{as } \varepsilon \to 0. \tag{1.7}$$

In this paper, our aim is to give isoperimetric inequalities for the Stefan problem (1.1). They are not standard, since the problem is multivalued, and the domain is doubly connected. The principal one of them, (2.1) below (from which some other inequalities follow as corollaries), is obtained by passing to the limit in the corresponding inequality $(2.1)_\varepsilon$ for $(1.1)_\varepsilon$. The proof of $(2.1)_\varepsilon$ is a direct parabolic one that relies on the techniques developed in [8] for linear parabolic problems. Some of our corollaries confirm the intuitive idea that, among all domains $\omega = \omega_0 \backslash \bar{\omega}_1$, with ω_0, ω_1, of given measures (volumes), and all equimeasurable initial data h_0, the solid "melts slowest" in the symmetrized domain, with symmetrized h_0 ($H_0 = \mathbf{H}_0 = \mathbf{h}_0$). These results were announced in a previous note [5].

One drawback of our method is that it seems to require constant boundary values for θ (on each component of the boundary), and initial data guaranteeing that $0 \leqq \theta \leqq 1$ holds throughout q (where 0 and 1 are the constant boundary values for θ).

Isoperimetric inequalities for a problem similar to $(1.1)_\varepsilon$ have been obtained earlier by Vazquez [10], in the case $\omega = \mathbb{R}^N$, by an elliptic approach (and using semigroup theory). This approach does not seem to work in our geometry.

2. Statements of results. Our isoperimetric inequalities are inequalities between certain quantities for the problems (1.1) and $(1.1)_\varepsilon$, and the corresponding quantities for certain "symmetrized problems" ($\widetilde{(1.1)}$ and $\widetilde{(1.1)}_\varepsilon$ below). Before describing these symmetrized problems, we must introduce some general notation:

- σ_N denotes the volume of the unit ball in $\mathbb{R}^N$.
- $|E|$ denotes the volume (N-dimensional Lebesgue measure) of a measurable set E in $\mathbb{R}^N$ (also: $|x| = (x_1^2 + \cdots + x_N^2)^{1/2}$ if $x \in \mathbb{R}^N$).
- $f_+ = \max\{f, 0\}$, $f_- = \max\{-f, 0\}$.
- With $\omega = \omega_0 \backslash \bar{\omega}_1$ as in § 1, Ω_j ($j = 0, 1$) denotes the open balls in $\mathbb{R}^N$ centered at the origin and having the same volumes as ω_j. Thus $\bar{\Omega}_1 \subset \Omega_0$. We also set $\Omega = \Omega_0 \backslash \bar{\Omega}_1$, $Q = \Omega \times (0, T)$, $\Gamma_j = \partial\Omega_j$. In general, when a lowercase letter is used for a certain quantity in the original problem, the corresponding capital letter will be used for the same quantity in the symmetrized problem.
- If f is a measurable function defined in ω, f_* denotes the decreasing rearrangement of f:

$$f_*(s) = \operatorname{Inf}\{\xi \in \mathbb{R}: |x: f(x) > \xi| \leqq s\},$$

defined for $s \in \bar{\omega}_* = [0, |\omega|]$ ($\omega_* = (0, |\omega|)$), while $\mathbf{f}$ denotes the rearrangement of f, defined in Ω, that decreases along radii:

$$\mathbf{f}(x) = f_*(\sigma_N |x|^N - m_1),$$

where $m_1 = |\omega_1|$, $x \in \Omega$. If f is defined in q, we consider its rearrangements with respect to the space variable: $f_*(s, t) = (f(\cdot, t))_*(s)$, $\mathbf{f}(x, t) = f_*(\sigma_N |x|^N - m_1, t)$.

Now, the symmetrized problem corresponding to (1.1) is

$$\widetilde{(1.1)} \qquad \begin{aligned} &\frac{\partial H}{\partial t} - \Delta\Theta = 0 \quad \text{in } Q, \\ &\Theta = G \quad \text{on } \Sigma = \partial\Omega \times (0, T), \\ &H|_{t=0} = \mathbf{h}_0, \\ &H \in a(\Theta) \quad \text{a.e. in } Q, \end{aligned}$$

where

$$G = \begin{cases} 0 & \text{on } \Sigma_0 = \Gamma_0 \times (0, T) = \partial\Omega_0 \times (0, T), \\ 1 & \text{on } \Sigma_1 = \Gamma_1 \times (0, T) = \partial\Omega_1 \times (0, T). \end{cases}$$

The problem corresponding to $(1.1)_\varepsilon$ is

$$(\widetilde{1.1})_\varepsilon \qquad \begin{aligned} &\frac{\partial H_\varepsilon}{\partial t} - \Delta \Theta_\varepsilon = 0 \quad \text{in } Q, \\ &\Theta_\varepsilon = G \quad \text{on } \Sigma, \\ &H_\varepsilon|_{t=0} = \mathbf{h}_{\varepsilon_0}, \\ &H_\varepsilon = a_\varepsilon(\Theta_\varepsilon) \quad \text{in } Q. \end{aligned}$$

Our main technical tool is the following result.

THEOREM 1. *For classical solutions of* $(1.1)_\varepsilon$ *and* $(\widetilde{1.1})_\varepsilon$, *we have the comparison*

$$(2.1)_\varepsilon \qquad \int_0^s h_{\varepsilon *}(\sigma, t)\, d\sigma - \int_0^t \int_{\gamma_1} \frac{\partial \theta_\varepsilon}{\partial \nu}\, d\gamma\, d\tau \leqq \int_0^s H_{\varepsilon *}(\sigma, t)\, d\sigma - \int_0^t \int_{\Gamma_1} \frac{\partial \Theta_\varepsilon}{\partial \nu}\, d\gamma\, d\tau$$

for every (s, t) *in* $\bar{q}_* = \bar{\omega}_* \times [0, T] = [0, |\omega|] \times [0, T]$ $(= \bar{Q}_*)$. *Here* $\partial/\partial \nu$ *denotes the outward normal derivative, and* $d\gamma$ *the* $(N-1)$*-dimensional Lebesgue measure of* $\partial\omega$ *and* $\partial\Omega$.

Similarly, for weak solutions of (1.1) *and* $(\widetilde{1.1})$ (*see* (1.3)),

$$(2.1) \qquad \int_0^s h_*(\sigma, t)\, d\sigma - \int_0^t \int_{\gamma_1} \frac{\partial \theta}{\partial \nu}\, d\gamma\, d\tau \leqq \int_0^s H_*(\sigma, t)\, d\sigma - \int_0^t \int_{\Gamma_1} \frac{\partial \Theta}{\partial \nu}\, d\gamma\, d\tau$$

for almost every $t \in (0, T)$ *and every* $s \in \bar{\omega}_*$.

Remarks. (1) In (2.1), the terms involving $\partial\theta/\partial\nu$ and $\partial\Theta/\partial\nu$ must be interpreted in a weak sense (see (4.10) below) because we are not guaranteed enough regularity for $\partial\theta/\partial\nu$ and $\partial\Theta/\partial\nu$ to make classical sense.

(2) Some isoperimetric inequalities involving a rearrangement and a "capacity term" (such as $\int_{\gamma_1} (\partial\theta/\partial\nu)\, d\gamma$ in (2.1)) have been previously obtained for elliptic problems in doubly connected domains, with boundary conditions 0 and 1 (respectively) on the two components of the boundary (see [7, p. 62] and [2, p. 168]).

The proof of Theorem 1 appears in §§ 3 and 4. We now give some other isoperimetric inequalities that have more physical significance and therefore can be viewed as the main results of the paper. They are all simple consequences of Theorem 1, and are proved in § 5.

If the solutions (θ, h) and (Θ, H) are "good enough," this meaning in particular that the sets $\{x \in \omega\colon h(x, \tau) > h_*(s, \tau)\}$ and $\{x \in \Omega\colon H(x, \tau) > H_*(s, \tau)\}$ have regular boundaries (in ω and Ω): $\gamma(s, \tau) = \{x \in \omega\colon h(x, \tau) = h_*(s, \tau)\}$ and $\Gamma(s, t) = \{x \in \Omega\colon H(x, \tau) = H_*(s, \tau)\}$ for almost every $\tau \in (0, t)$, then (2.1) can also be written:

$$(2.2) \qquad -\int_0^t \int_{\gamma(s,\tau)} \frac{\partial \theta}{\partial \nu}\, d\gamma\, d\tau \geqq -\int_0^t \int_{\Gamma(s,\tau)} \frac{\partial \theta}{\partial \nu}\, d\gamma\, d\tau$$

(the normal derivatives being directed outward from the sets mentioned above). The members of (2.2) are nonnegative and have the physical interpretation of being the total heat flows during the time interval $(0, t)$ from the warmest parts of volume s of ω and Ω, respectively, into the complementary colder parts. Note that these parts of ω and Ω change continuously with time.

In the particular cases $s = 0$ and $s = |\omega|$, (2.1) reduces to

$$(2.3) \qquad \int_0^t \int_{\gamma_1} \frac{\partial \theta}{\partial \nu}\, d\gamma\, d\tau \geqq \int_0^t \int_{\Gamma_1} \frac{\partial \Theta}{\partial \nu}\, d\gamma\, d\tau \qquad (\geqq 0),$$

$$(2.4) \qquad -\int_0^t \int_{\gamma_0} \frac{\partial \theta}{\partial \nu}\, d\gamma\, d\tau \geqq -\int_0^t \int_{\Gamma_0} \frac{\partial \Theta}{\partial \nu}\, d\gamma\, d\tau \qquad (\geqq 0)$$

for almost every $t \in (0, T)$. (Equation $(2.1)_\varepsilon$ reduces similarly.)

Another consequence of (2.1) is that, for any measurable set $E(t) \subset \omega$, with $|E(t)| = s$,

$$\int_0^t \int_{\gamma_1} \frac{\partial \theta}{\partial \nu} d\gamma\, d\tau - \int_{E(t)} h(x,t)\, dx \geqq \int_0^t \int_{\Gamma_1} \frac{\partial \Theta}{\partial \nu} d\gamma\, d\tau - \int_{m_1 < \sigma_N |x|^N < m_1 + s} H(x,t)\, dx. \tag{2.5}$$

In the case of a one-phase problem, let us say with $\lambda = 0$, the quantity

$$t' = \sup \left\{ t \in [0, T]: \int_0^\tau \int_{\gamma_0} \frac{\partial \theta}{\partial \nu} d\gamma\, d\tau' = 0, \text{ a.e. } \tau \in (0, t) \right\} \tag{2.6}$$

can be interpreted as the first instant at which the liquid phase reaches γ_0 (when $\lambda > 0$, $t' = 0$). With the similar definition for the symmetrized problem, T' also appears to be the time at which all the solid has melted.

We then obtain, for weak solutions of (1.1) and ($\widetilde{1.1}$), some noteworthy comparisons.

THEOREM 2. *With the above definitions*

$$t' \leqq T', \tag{2.7}$$

$$\int_s^{|\omega|} h_*(\sigma, t)\, d\sigma \geqq \int_s^{|\omega|} H_*(\sigma, t)\, d\sigma \tag{2.8}$$

for almost every $t \in (0, t')$, *and all* $s \in \bar{\omega}_*$. *More generally,*

$$\int_s^{|\omega|} \Phi(h_*(\sigma, t))\, d\sigma \geqq \int_s^{|\omega|} \Phi(H_*(\sigma, t))\, d\sigma \tag{2.9}$$

for almost every $t \in (0, t')$, *and all* $s \in \bar{\omega}_*$, *where* Φ *is any concave nondecreasing function. This implies*

$$\operatorname*{ess\,inf}_{\omega} h(t) \geqq \operatorname*{ess\,inf}_{\Omega} H(t) \quad \text{a.e. } t \in (0, t'), \tag{2.10}$$

$$\|(h(t) - \beta)_-\|_{L^p(\omega)} \leqq \|(H(t) - \beta)_-\|_{L^p(\Omega)} \quad \text{a.e. } t \in (0, t') \tag{2.11}$$

for every $\beta \in \mathbb{R}$ *and every* $p \in [1, \infty]$, *and*

$$|\{x \in \omega: h(x,t) = -\alpha\}| \leqq |\{x \in \Omega: H(x,t) = -\alpha\}| \quad \text{a.e. } t \in (0, t'). \tag{2.12}$$

The latter inequality expresses that the volume of the solid remains greater in spherical geometry (up to time t'*).*

3. Proof of (2.1)$_\varepsilon$. Let $(\theta_\varepsilon, h_\varepsilon)$ be the (unique) classical solution of $(1.1)_\varepsilon$ (cf. [6]). By the maximum principle, $0 \leqq \theta_\varepsilon \leqq 1$ in all q. Let $t \in (0, T)$ be fixed. Then, for any $\eta \in (0, 1)$, we have, by $(1.1)_\varepsilon$,

$$0 = \int_\omega \left(\frac{\partial h_\varepsilon}{\partial t} - \Delta \theta_\varepsilon \right) (\theta_\varepsilon - \eta)_+\, dx$$

$$= \int_{\theta_\varepsilon > \eta} \frac{\partial h_\varepsilon}{\partial t} (\theta_\varepsilon - \eta)\, dx + \int_{\theta_\varepsilon > \eta} |\nabla \theta_\varepsilon|^2\, dx - \int_{\gamma_1} \frac{\partial \theta_\varepsilon}{\partial \nu} (\theta_\varepsilon - \eta)\, d\gamma.$$

As (see, e.g., [7, p. 9])

$$\frac{d}{d\eta}\int_{\theta_\varepsilon>\eta}\frac{\partial h_\varepsilon}{\partial t}(\theta_\varepsilon-\eta)\,dx=-\int_{\theta_\varepsilon>\eta}\frac{\partial h_\varepsilon}{\partial t}\,dx,$$

we obtain

$$0=-\int_{\theta_\varepsilon>\eta}\frac{\partial h_\varepsilon}{\partial t}\,dx+\frac{d}{d\eta}\int_{\theta_\varepsilon>\eta}|\nabla\theta_\varepsilon|^2\,dx+\int_{\gamma_1}\frac{\partial\theta_\varepsilon}{\partial\nu}\,d\gamma. \tag{3.1}$$

Let $\mu(\eta)=|\{x\in\omega\colon \theta_\varepsilon(x,t)>\eta\}|$. Using standard rearrangement techniques (see [7]), we get, for almost every $\eta\in(0,1)$,

$$N^2\sigma_N^{2/N}(m_1+\mu(\eta))^{2-(2/N)}\leqq\left[\frac{d}{d\eta}\int_{\theta_\varepsilon>\eta}|\nabla\theta_\varepsilon|\,dx\right]^2\leqq\mu'(\eta)\frac{d}{d\eta}\int_{\theta_\varepsilon>\eta}|\nabla\theta_\varepsilon|^2\,dx. \tag{3.2}$$

Here the first inequality is the isoperimetric inequality relating the volume of the set $\omega_1\cup\{\theta_\varepsilon>\eta\}$ to its perimeter, the latter taken in the sense of De Giorgi (see, e.g., [7] for details). The second inequality is obtained from the Cauchy-Schwarz inequality applied to the difference quotients corresponding to the derivatives after passing to the limit. Combining (3.1) with (3.2) gives

$$N^2\sigma_N^{2/N}(m_1+\mu(\eta))^{2-(2/N)}\leqq-\mu'(\eta)\left[\int_{\gamma_1}\frac{\partial\theta_\varepsilon}{\partial\nu}\,d\gamma-\int_{\theta_\varepsilon>\eta}\frac{\partial h_\varepsilon}{\partial t}\,dx\right] \tag{3.3}$$

for almost every $\eta\in(0,1)$.

Next define

$$k(s,t)=\int_0^s h_{\varepsilon *}(\sigma,t)\,d\sigma. \tag{3.4}$$

Using results from the theory of relative rearrangement (see [8, Thm. 1.2, p. 60; proof of (2.12), p. 67]), we obtain for almost every η (namely, those for which $|\theta_\varepsilon=\eta|=0$),

$$\begin{aligned}\int_{\theta_\varepsilon>\eta}\frac{\partial h_\varepsilon}{\partial t}\,dx&=\int_{h_\varepsilon>a_\varepsilon(\eta)}\frac{\partial h_\varepsilon}{\partial t}\,dx\\&=\int_0^{\mu(\eta)}\left(\frac{\partial h_\varepsilon}{\partial t}\right)_{*h_\varepsilon}(\sigma,t)\,d\sigma\\&=\int_0^{\mu(\eta)}\frac{\partial h_{\varepsilon *}}{\partial t}(\sigma,t)\,d\sigma\\&=\frac{\partial k}{\partial t}(\mu(\eta),t).\end{aligned} \tag{3.5}$$

(It should be noted that the rigorous proof of (3.5) is one of the most difficult results in [8]. As it is quite long, we do not repeat it here. We just recall that $(\partial h_\varepsilon/\partial t)_{*h_\varepsilon}$ is called the relative rearrangement of $\partial h_\varepsilon/\partial t$ with respect to h_ε, and may be conceived of as the directional derivative of the map $f\to f_*$, taken at the point h_ε, in the direction $\partial h_\varepsilon/\partial t$.)

Thus (3.3) becomes

$$N^2\sigma_N^{2/N}(m_1+\mu(\eta))^{2-(2/N)}\leqq-\mu'(\eta)\left[\int_{\gamma_1}\frac{\partial\theta_\varepsilon}{\partial\nu}\,d\gamma-\frac{\partial k}{\partial t}(\mu(\eta),t)\right] \tag{3.6}$$

(for almost every $\eta \in (0, 1)$). Set (for $t \in (0, T)$ still fixed)

$$F(s) = \int_{\gamma_1} \frac{\partial \theta_\varepsilon}{\partial \nu}\, d\gamma - \frac{\partial k}{\partial t}(s, t). \tag{3.7}$$

Then F is a continuous function on $\bar{\omega}_*$ because $\partial k/\partial t(s, t) = \int_0^s (\partial h_{\varepsilon *}/\partial t)(\sigma, t)\, d\sigma = \int_0^s (\partial h_\varepsilon/\partial t)_{*h_\varepsilon}(\sigma, t)\, d\sigma$ and $(\partial h_\varepsilon/\partial t)_{*h_\varepsilon}(\sigma, t)$ is integrable as a function of σ (see [8]). We will now prove that F is also nonnegative on $\bar{\omega}_*$.

By (3.6), $(F \circ \mu)(\eta) \geqq 0$ for almost every $\eta \in (0, 1)$. Since μ is continuous from the right, so is $F \circ \mu$. It follows that $F \circ \mu \geqq 0$ on $[0, 1)$, and then on $[0, 1]$, since $(F \circ \mu)(1) = F(0) = \int_{\gamma_1} (\partial \theta_\varepsilon/\partial \nu)\, d\gamma \geqq 0$. It follows next that $F \circ \bar{\mu} \geqq 0$ on $(0, 1]$, where $\bar{\mu}(\eta) = |\theta_\varepsilon \geqq \eta|$, for $\mu(\eta - \delta) \to \bar{\mu}(\eta)$ as $\delta \downarrow 0$. Furthermore,

$$(F \circ \bar{\mu})(0) = F(|\omega|) = \int_{\gamma_1} \frac{\partial \theta_\varepsilon}{\partial \nu}\, d\gamma - \int_0^{|\omega|} \frac{\partial h_{\varepsilon *}}{\partial t}(\sigma, t)\, d\sigma.$$

This last integral also equals $\int_\omega (\partial h_\varepsilon/\partial t)\, dx = \int_\omega \Delta \theta_\varepsilon\, dx = \int_{\partial \omega} (\partial \theta_\varepsilon/\partial \nu)\, d\gamma$ (see [8]; also compare (3.5)), so

$$(F \circ \bar{\mu})(0) = -\int_{\gamma_0} \frac{\partial \theta_\varepsilon}{\partial \nu}\, d\gamma \geqq 0.$$

Thus $F \circ \bar{\mu} \geqq 0$ on all $[0, 1]$. Now let $s \in \bar{\omega}_*$, and set $\eta = \theta_{\varepsilon *}(s)$, $s' = \mu(\eta)$, $s'' = \bar{\mu}(\eta)$. Then $s' \leqq s \leqq s''$, and we will prove that $F \geqq 0$ on $[s', s'']$. We have $\partial F/\partial s = -(\partial h_{\varepsilon *}/\partial t)$. Since $\theta_\varepsilon \in H^1(0, T; L^2(\omega))$ (see [4] or § 4 below), $\theta_{\varepsilon *} \in H^1(0, T; L^2(\omega_*))$ and $\partial h_{\varepsilon *}/\partial t = a_\varepsilon'(\theta_{\varepsilon *})\, \partial \theta_{\varepsilon *}/\partial t$ is almost everywhere constant on (s', s'') (see [8, pp. 60, 63]). Therefore F is affine on $[s', s'']$, and since $F(s')$ and $F(s'')$ were shown to be nonnegative, we conclude that $F \geqq 0$ on $[s', s'']$. In particular $F(s) \geqq 0$ and since $s \in \bar{\omega}_*$ was arbitrary this proves that $F \geqq 0$ on $\bar{\omega}_*$.

Now (3.3) can be written

$$1 \leqq -N^{-2} \sigma_N^{-(2/N)} (m_1 + \mu(\eta))^{(2/N)-2} F(\mu(\eta)) \mu'(\eta) \quad \text{a.e. } \eta \in (0, 1).$$

Using that $\mu(\eta)$ is a nonincreasing function, integration from η to η', where $0 \leqq \eta < \eta' \leqq 1$, gives

$$\eta' - \eta \leqq N^{-2} \sigma_N^{-(2/N)} \int_{\mu(\eta')}^{\mu(\eta)} (m_1 + s)^{(2/N)-2} F(s)\, ds.$$

As in [7, pp. 24, 31] and [8], this shows that

$$N^{-2} \sigma_N^{-(2/N)} (m_1 + s)^{(2/N)-2} F(s) + \frac{\partial \theta_{\varepsilon *}}{\partial s} \geqq 0 \quad \text{a.e. } s \in \omega_*. \tag{3.8}$$

Now we take the time-dependence into account. Set

$$y(s, t) = \int_0^s h_{\varepsilon *}(\sigma, t)\, d\sigma - \int_0^t \int_{\gamma_1} \frac{\partial \theta_\varepsilon}{\partial \nu}(x, \tau)\, d\gamma\, d\tau \tag{3.9}$$

for $(s, t) \in \bar{\omega}_* \times [0, T]$. Then

$$\frac{\partial y}{\partial t}(s, t) = -F(s), \qquad \frac{\partial y}{\partial s}(s, t) = h_{\varepsilon *}(s, t).$$

Since $\theta_\varepsilon = b_\varepsilon(h_\varepsilon)$, where $b_\varepsilon = a_\varepsilon^{-1}$ is strictly increasing, we also have

$$\theta_{\varepsilon *} = b_\varepsilon(h_{\varepsilon *}) = b_\varepsilon\left(\frac{\partial y}{\partial s}\right).$$

Therefore (3.8) shows that y satisfies

$$N^{-2} \sigma_N^{-(2/N)} (m_1 + s)^{(2/N)-2} \frac{\partial y}{\partial t} - \frac{\partial}{\partial s}\left(b_\varepsilon\left(\frac{\partial y}{\partial s}\right)\right) \leqq 0 \quad \text{a.e. in } q_* = \omega_* \times (0, T), \tag{3.10}$$

i.e., y is a subsolution of a parabolic equation. Moreover, we get the following boundary and initial conditions for y:

$$\frac{\partial y}{\partial s}(0,t)=a_\varepsilon(1), \qquad \frac{\partial y}{\partial s}(|\omega|,t)=a_\varepsilon(0), \tag{3.11}$$
$$y(s,0)=y_{\varepsilon_0}(s),$$

where $y_{\varepsilon_0}(s)=\int_0^s h_{\varepsilon_0 *}(\sigma)\,d\sigma$.

For the symmetrized problem $(\widetilde{1.1})_\varepsilon$ we obtain as in [8], for

$$Y(s,t)=\int_0^s H_{\varepsilon *}(\sigma,t)\,d\sigma-\int_0^t\int_{\Gamma_1}\frac{\partial\Theta_\varepsilon}{\partial\nu}(x,\tau)\,d\gamma\,d\tau, \tag{$\widetilde{3.9}$}$$

$$N^{-2}\sigma_N^{-(2/N)}(m_1+s)^{(2/N)-2}\frac{\partial Y}{\partial t}-\frac{\partial}{\partial s}\left(b_\varepsilon\left(\frac{\partial Y}{\partial s}\right)\right)=0 \quad \text{in } q_*(=Q_*), \tag{$\widetilde{3.10}$}$$

$$\frac{\partial Y}{\partial s}(0,t)=a_\varepsilon(1), \qquad \frac{\partial Y}{\partial s}(|\omega|,t)=a_\varepsilon(0), \tag{$\widetilde{3.11}$}$$
$$Y(s,0)=y_{\varepsilon_0}(s)$$

(observe that $(\mathbf{h}_{\varepsilon_0})_*=h_{\varepsilon_0 *}$). In fact, since Θ_ε, H_ε, are radially symmetric and decreasing, the first line in $(\widetilde{1.1})_\varepsilon$ can be written:

$$\frac{\partial H_{\varepsilon *}}{\partial t}-\frac{\partial}{\partial s}\left(N^2\sigma_N^{(2/N)}(m_1+s)^{2-(2/N)}\frac{\partial\Theta_{\varepsilon *}}{\partial s}\right)=0 \quad \text{in } q_*.$$

Now, we get $(\widetilde{3.10})$ by integrating between 0 and s, noting that

$$\frac{\partial H_{\varepsilon *}}{\partial t}=\frac{\partial^2 Y}{\partial s\,\partial t} \quad \text{and} \quad \int_{\Gamma_1}\frac{\partial\Theta_\varepsilon}{\partial\nu}\,d\gamma=-N^2\sigma_N^{(2/N)}m_1^{2-(2/N)}\frac{\partial\Theta_{\varepsilon *}}{\partial s}(0).$$

Now $(2.1)_\varepsilon$ of Theorem 1 simply states that $y\leqq Y$ in $\bar{q}_*$. To prove this inequality, we multiply the difference between (3.10) and $(\widetilde{3.10})$ by $(y-Y)_+$ and integrate with respect to s for fixed t. Taking the boundary conditions for y and Y into account and using that b_ε is monotone increasing, we get

$$\begin{aligned}
0&\geqq\int_0^{|\omega|}(m_1+s)^{(2/N)-2}\frac{\partial(y-Y)}{\partial t}(y-Y)_+\,ds\\
&\quad-N^2\sigma_N^{2/N}\int_0^{|\omega|}\frac{\partial}{\partial s}\left[b_\varepsilon\left(\frac{\partial y}{\partial s}\right)-b_\varepsilon\left(\frac{\partial Y}{\partial s}\right)\right](y-Y)_+\,ds\\
&=\frac{1}{2}\int_0^{|\omega|}(m_1+s)^{(2/N)-2}\frac{\partial}{\partial t}(y-Y)_+^2\,ds\\
&\quad+N^2\sigma_N^{2/N}\int_0^{|\omega|}\left[b_\varepsilon\left(\frac{\partial y}{\partial s}\right)-b_\varepsilon\left(\frac{\partial Y}{\partial s}\right)\right]\frac{\partial}{\partial s}(y-Y)_+\,ds\\
&=\frac{1}{2}\frac{d}{dt}\int_0^{|\omega|}(m_1+s)^{(2/N)-2}(y-Y)_+^2\,ds\\
&\quad+N^2\sigma_N^{2/N}\int_{y>Y}\left[b_\varepsilon\left(\frac{\partial y}{\partial s}\right)-b_\varepsilon\left(\frac{\partial Y}{\partial s}\right)\right]\left[\frac{\partial y}{\partial s}-\frac{\partial Y}{\partial s}\right]ds\\
&\geqq\frac{1}{2}\frac{d}{dt}\int_0^{|\omega|}(m_1+s)^{(2/N)-2}(y-Y)_+^2\,ds.
\end{aligned}$$

Since $y = Y$ for $t = 0$, it follows that

$$\int_0^{|\omega|} (m_1 + s)^{(2/N)-2} (y - Y)_+^2 \, ds \leqq 0 \quad \text{for } t \geqq 0,$$

and hence that $y \leqq Y$ in $\bar{q}_*$ as desired.

4. Proof of (2.1). The weak solution (θ, h) of (1.1) is obtained as the limit of the solution $(\theta_\varepsilon, h_\varepsilon)$ of $(1.1)_\varepsilon$ as $\varepsilon \to 0$, and we will accordingly obtain (2.1) by letting $\varepsilon \to 0$ in $(2.1)_\varepsilon$. For convenience we review part of the construction of (θ, h).

Let $(\theta_\varepsilon, h_\varepsilon)$ be the solution of $(1.1)_\varepsilon$, and let $q_t = \omega \times (0, t)$ for $t \in (0, T)$. Then we have

$$\begin{aligned} 0 &= \int\int_{q_t} \frac{\partial \theta_\varepsilon}{\partial \tau} \left(\frac{\partial h_\varepsilon}{\partial \tau} - \Delta \theta_\varepsilon \right) dx \, d\tau \\ &= \int\int_{q_t} \frac{\partial \theta_\varepsilon}{\partial \tau} \frac{\partial h_\varepsilon}{\partial \tau} \, dx \, dt + \int_0^t \left[\int_\omega \nabla \frac{\partial \theta_\varepsilon}{\partial \tau} \nabla \theta_\varepsilon \, dx - \int_{\partial \omega} \frac{\partial \theta_\varepsilon}{\partial \tau} \frac{\partial \theta_\varepsilon}{\partial \nu} \, d\gamma \right] d\tau \end{aligned}$$

or

$$\int\int_{q_t} a_\varepsilon'(\theta_\varepsilon) \left| \frac{\partial \theta_\varepsilon}{\partial \tau} \right|^2 dx \, d\tau + \frac{1}{2} \int_\omega |\nabla \theta_\varepsilon|^2 \, dx = \frac{1}{2} \int_\omega |\nabla \theta_{\varepsilon_0}|^2 \, dx.$$

By assumptions (1.4) and (1.7), when $\varepsilon \to 0$, $\int_\omega |\nabla \theta_{\varepsilon_0}|^2 \, dx$ is bounded, and a_ε' is bounded from below. Hence

$$\int\int_{q_t} \left| \frac{\partial \theta_\varepsilon}{\partial \tau} \right|^2 dx \, d\tau \leqq C, \tag{4.1}$$

$$\int_\omega |\nabla \theta_\varepsilon(x, t)|^2 \, dx \leqq C, \tag{4.2}$$

for some constant C independent of ε and t. By the maximum principle, the families $\{\theta_\varepsilon\}_{\varepsilon > 0}$ and $\{h_\varepsilon\}_{\varepsilon > 0}$ are bounded in $L^\infty(q)$, and, by the above estimates, it then follows that $\{\theta_\varepsilon\}_{\varepsilon > 0}$ is bounded in $L^\infty(0, T; H^1(\omega))$ and in $H^1(q)$. By repeated extraction of subsequences from $\{\varepsilon\}$ we thus can find a sequence ε_n such that

$$\begin{aligned} &\theta_{\varepsilon_n} \to \theta \text{ weakly* in } L^\infty(q) \text{ and } L^\infty(0, T; H^1(\omega)), \\ &\qquad \text{weakly in } H^1(q), \\ &\qquad \text{strongly in } L^2(q) \text{ (by compactness)}, \\ &h_{\varepsilon_n} \to h \text{ weakly* in } L^\infty(q) \end{aligned} \tag{4.3}$$

for some pair (θ, h) satisfying

$$\theta \in L^\infty(q) \cap H^1(q) \cap L^\infty(0, T; H^1(\omega)), \qquad h \in L^\infty(q). \tag{4.4}$$

In the following, we shall replace ε_n by ε for simplicity.

Now (θ, h) is the required weak solution. In fact, it follows immediately that (1.3) holds, since $(\theta_\varepsilon, h_\varepsilon)$ satisfies the same equation with h_0 replaced by h_{ε_0}. To check that $h \in a(\theta)$ almost everywhere, it is enough (since a is maximally monotone) to check that

$$\langle h' - h, \theta' - \theta \rangle \geqq 0 \tag{4.5}$$

(where $\langle f, g\rangle = \iint_q fg\,dx\,dt$) for all θ', $h' \in L^\infty(q)$ satisfying $h' \in a(\theta')$ almost everywhere. Writing

$$\langle h'-h, \theta'-\theta\rangle = \langle h_\varepsilon - h, \theta'-\theta\rangle + \langle h'-h_\varepsilon, \theta_\varepsilon-\theta\rangle + \langle h'-h_\varepsilon, \theta'-\theta_\varepsilon\rangle, \tag{4.6}$$

we have (as $\varepsilon \to 0$)

$$\langle h_\varepsilon - h, \theta'-\theta\rangle \to 0 \tag{4.7}$$

since $h_\varepsilon \to h$ weakly* in $L^\infty(q)$ (by (4.3)), and

$$|\langle h'-h_\varepsilon, \theta_\varepsilon-\theta\rangle| \leqq \|h'-h_\varepsilon\|_{L^2(q)} \|\theta_\varepsilon-\theta\|_{L^2(q)} \to 0, \tag{4.8}$$

since $\theta_\varepsilon \to \theta$ in $L^2(q)$, and $\|h'-h_\varepsilon\|_{L^2(q)}$ is bounded (by (4.3)).

Remark. This is the only place where we use the fact that $b = a^{-1}$ is Lipschitz continuous. This property of a makes it possible to choose a_ε satisfying (1.4), from which we get the estimate (4.1) for $\partial\theta_\varepsilon/\partial t$; then weak convergence in $H^1(q)$ and strong convergence in $L^2(q)$ of θ_ε to θ follows. Observe that (4.2) holds independently of (1.4).

For the last term in (4.6), we have

$$\begin{aligned}\langle h'-h_\varepsilon, \theta'-\theta_\varepsilon\rangle &= \langle h'-h_\varepsilon, b(h')-b_\varepsilon(h_\varepsilon)\rangle \\ &= \langle h'-h_\varepsilon, b_\varepsilon(h')-b_\varepsilon(h_\varepsilon)\rangle + \langle h'-h_\varepsilon, b(h')-b_\varepsilon(h')\rangle.\end{aligned}$$

The first bracket in the last member is nonnegative as b_ε is nondecreasing, and the second one tends to zero with ε, as b_ε converges uniformly to b:

$$|\langle h'-h_\varepsilon, b(h')-b_\varepsilon(h')\rangle| \leqq \|h'-h_\varepsilon\|_{L^\infty(q)} \int_q |b(h')-b_\varepsilon(h')|\,dx\,dt.$$

Then

$$\varliminf_{\varepsilon\to 0} \langle h'-h_\varepsilon, \theta'-\theta_\varepsilon\rangle \geqq 0. \tag{4.9}$$

Now (4.5) follows by combining (4.7)-(4.9). Thus (θ, h) is a weak solution.

We now pass to the limit in $(2.1)_\varepsilon$. First, we have to give a weak interpretation of the two members of (2.1), since the regularity of θ that we have is not enough for $\partial\theta/\partial\nu$ and $\partial\Theta/\partial\nu$ to make classical sense.

Let φ be an arbitrary smooth function in ω (say, $\varphi \in \mathscr{C}^2(\bar\omega)$) with boundary values $\varphi = 0$ on γ_0, $\varphi = 1$ on γ_1. Then for (θ, h), a "good enough" solution of $(\partial h/\partial t) - \Delta\theta = 0$,

$$\begin{aligned}\int_0^t \int_{\gamma_1} \frac{\partial\theta}{\partial\nu}\,d\gamma\,d\tau &= \int_0^t \int_{\partial\omega} \varphi \frac{\partial\theta}{\partial\nu}\,d\gamma\,d\tau \\ &= \int_0^t \int_\omega \nabla\varphi\,\nabla\theta\,dx\,d\tau + \int_0^t \int_\omega \varphi\,\Delta\theta\,dx\,d\tau \\ &= \int_0^t \int_\omega \nabla\varphi\,\nabla\theta\,dx\,d\tau + \int_\omega (h(x,t)-h_0(x))\varphi(x)\,dx.\end{aligned} \tag{4.10}$$

Here the last member makes sense for almost every t for any $\theta \in L^\infty(0, T; H^1(\omega))$, $h \in L^\infty(q)$, and defines an (almost everywhere) bounded measurable function of t. Therefore, when (θ, h) is the weak solution of (1.1) satisfying (4.4), we choose the last member of (4.10) to be our definition of $\int_0^t \int_{\gamma_1} (\partial\theta/\partial\nu)\,d\gamma\,d\tau$ for almost every $t \in (0, T)$; we choose similarly for $\int_0^t \int_{\Gamma_1} \partial\Theta/\partial\nu\,d\gamma\,d\tau$. We still have to check that this definition is independent of the choice of φ. This amounts to showing that if $\varphi \in \mathscr{C}^2(\bar\omega)$ has boundary values zero on $\partial\omega$, then

$$\int_0^t \int_\omega \nabla\varphi\,\nabla\theta\,dx\,d\tau + \int_\omega (h(x,t)-h_0(x))\varphi(x)\,dx = 0 \quad \text{a.e. } t \in (0, T). \tag{4.11}$$

Now, (4.11) is an equation of the form $\int_0^t f(\tau)\,d\tau + F(t) = 0$ for almost every $t \in (0, T)$, for two functions f and F in $L^1(0, T)$. The latter equation is equivalent to $\int_0^T f(t)\psi(t)\,dt = \int_0^T F(t)\psi'(t)\,dt$ for every $\psi \in \mathscr{C}^1[0, T]$ with $\psi(T) = 0$. Thus (4.11) is equivalent to

$$\int_0^T \int_\omega \nabla\theta(x, t)\nabla\varphi(x)\psi(t)\,dx\,dt = \int_0^T \int_\omega (h(x, t) - h_0(x))\varphi(x)\psi'(t)\,dx\,dt \tag{4.12}$$

for ψ as above. Now, the truth of (4.12) follows by integration in the definition (1.3) for a weak solution, taking $\varphi(x)\psi(t)$ as a test function (this integration by parts is justified by $\theta \in L^\infty(0, T; H^1(\omega))$ for (θ, h) a weak solution of (1.1)).

For later use we remark that $\int_0^t \int_{\gamma_0} (\partial\theta/\partial\nu)\,d\gamma\,d\tau$ may be defined by the same formula (4.10), taking a test function with the exchanged boundary values, e.g., $1 - \varphi$, with φ as in (4.10). Then, for such φ's,

$$\int_0^t \int_{\gamma_0} \frac{\partial\theta}{\partial\nu}\,d\gamma\,d\tau = -\int_0^t \int_\omega \nabla\varphi\,\nabla\theta\,dx\,d\tau + \int_\omega (h(x, t) - h_0(x))(1 - \varphi(x))\,dx, \tag{4.10}'$$

and from (4.10), (4.10)',

$$\begin{aligned} \int_0^t \int_{\gamma_0} \frac{\partial\theta}{\partial\nu}\,d\gamma\,d\tau + \int_0^t \int_{\gamma_1} \frac{\partial\theta}{\partial\nu}\,d\gamma\,d\tau &= \int_\omega (h(x, t) - h_0(x))\,dx \\ &= \int_0^{|\omega|} (h_*(\sigma, t) - h_{0*}(\sigma))\,d\sigma. \end{aligned} \tag{4.13}$$

Now, with $\varphi \in \mathscr{C}^2(\bar{\omega})$ (respectively, $\Phi \in \mathscr{C}^2(\bar{\Omega})$) in (4.10), (2.1) (to be proven) becomes

$$\begin{aligned} &\int_0^t \int_\omega \nabla\theta\,\nabla\varphi\,dx\,d\tau + \int_\omega (h(x, t) - h_0(x))\varphi(x)\,dx - \int_0^s h_*(\sigma, t)\,d\sigma \\ &\qquad \geqq \int_0^t \int_\Omega \nabla\Theta\,\nabla\Phi\,dx\,d\tau + \int_\Omega (H(x, t) - \mathbf{h}_0(x))\Phi(x)\,dx - \int_0^s H_*(\sigma, t)\,d\sigma \end{aligned} \tag{4.14}$$

for $s \in \bar{\omega}_*$ and almost every $t \in (0, T)$. For fixed $s \in \bar{\omega}_*$, both members above are integrable functions of t. Therefore (4.14) is equivalent to a statement that, for every $s \in \bar{\omega}_*$, and every nonnegative function $\psi \in \mathscr{C}[0, T]$,

$$\begin{aligned} &\int_0^T \int_0^t \int_\omega \nabla\theta(x, \tau)\nabla\varphi(x)\psi(t)\,dx\,d\tau\,dt + \iint_q (h(x, t) - h_0(x))\varphi(x)\psi(t)\,dx\,dt \\ &\qquad - \int_0^T \int_0^s h_*(\sigma, t)\psi(t)\,d\sigma\,dt \\ &\qquad \geqq \int_0^T \int_0^t \int_\Omega \nabla\Theta(x, \tau)\nabla\Phi(x)\psi(t)\,dx\,d\tau\,dt \\ &\qquad\qquad + \iint_Q (H(x, t) - \mathbf{h}_0(x))\Phi(x)\psi(t)\,dx\,dt \\ &\qquad\qquad - \int_0^T \int_0^s H_*(\sigma, t)\psi(t)\,d\sigma\,dt \end{aligned} \tag{4.15}$$

(we have to make this extra integration because the convergence h_ε to h is not established for fixed t (see (4.3)), as we would need to get (4.14) from the corresponding $(4.14)_\varepsilon$).

By $(2.1)_\varepsilon$, we have $(4.15)_\varepsilon$, that is, (4.15) holds with θ, Θ, h, H, h_0, $\mathbf{h}_0$ replaced by θ_ε, Θ_ε, h_ε, H_ε, h_{ε_0}, $\mathbf{h}_{\varepsilon_0}$, respectively. For the first terms on the left-hand sides of

(4.15) and $(4.15)_\varepsilon$, we have

$$\int_0^T \int_0^t \int_\omega \nabla\theta_\varepsilon(x,\tau)\nabla\varphi(x)\psi(t)\,dx\,d\tau\,dt \to \int_0^T \int_0^t \int_\omega \nabla\theta(x,\tau)\nabla\varphi(x)\psi(t)\,dx\,d\tau\,dt$$

as $\varepsilon \to 0$, because $\theta_\varepsilon \to \theta$ weakly* in $L^\infty(0, T; H^1(\omega))$ (see (4.3)). We have similar results for the first terms on the right-hand sides of (4.15) and $(4.15)_\varepsilon$. As for the second terms on the left-hand sides,

$$\iint_q (h_\varepsilon(x,t) - h_{\varepsilon_0}(x))\varphi(x)\psi(t)\,dx\,dt \to \iint_q (h(x,t) - h_0(x))\varphi(x)\psi(t)\,dx\,dt$$

because $h_\varepsilon \to h$ weakly* in $L^\infty(q)$ (see (4.3)), and $h_{\varepsilon_0} \to h_0$ in $L^1(q)$ (see (1.6)). Similarly, for the right-hand sides, ($\mathbf{h}_{\varepsilon_0} \to \mathbf{h}_0$ in $L^1(Q)$ follows from $h_{\varepsilon_0} \to h_0$ because the rearrangement operator is a contraction in L^p-spaces (see [7, pp. 7, 8])). For the last terms on the left-hand sides we have

$$\underline{\lim}_{\varepsilon\to 0} \int_0^T \int_0^s h_{\varepsilon_*}(\sigma,t)\psi(t)\,d\sigma\,dt \geqq \int_0^T \int_0^s h_*(\sigma,t)\psi(t)\,d\sigma\,dt \tag{4.16}$$

(the map $h \to \int_0^T \int_0^s h_*(\sigma,t)\psi(t)\,d\sigma\,dt$ is weakly lower semicontinuous $L^1(q) \to \mathbb{R}$). In fact, for every measurable subset $E(t) \subset \omega$, with $|E(t)| = s$, by the Hardy-Littlewood inequality

$$\int_0^s h_{\varepsilon_*}(\sigma,t)\,d\sigma \geqq \int_{E(t)} h_\varepsilon(x,t)\,dx;$$

hence

$$\int_0^T \int_0^s h_{\varepsilon_*}(\sigma,t)\psi(t)\,d\sigma\,dt \geqq \int_0^T \int_{E(t)} h_\varepsilon(x,t)\psi(t)\,dx\,dt,$$

and, if we let $\varepsilon \to 0$,

$$\underline{\lim}_{\varepsilon\to 0} \int_0^T \int_0^s h_{\varepsilon_*}(\sigma,t)\psi(t)\,d\sigma\,dt \geqq \int_0^T \int_{E(t)} h(x,t)\psi(t)\,dx\,dt$$

(since $h_\varepsilon \to h$ weakly in $L^1(q)$ by (4.3)). Now, $E(t)$ can be chosen such that $|E(t) = s|$ and

$$\int_{E(t)} h(x,t)\,dx = \int_0^s h_*(\sigma,t)\,d\sigma,$$

which proves (4.16). Finally we consider the last terms in the right-hand sides of (4.15) and $(4.15)_\varepsilon$. It is clear (by uniqueness of solutions) that Θ_ε, Θ, H_ε, and H are radially symmetric, i.e., are functions of $r = |x|$ and t only. Moreover, Θ_ε and H_ε are nonincreasing as functions of $|x|$ for fixed t (i.e., $\Theta_\varepsilon(x,t) \geqq \Theta_\varepsilon(y,t)$ whenever $|x| \leqq |y|$), as can be seen by applying the parabolic maximum principle to $\partial\Theta_\varepsilon/\partial r$ and $\partial H_\varepsilon/\partial r$ (this pair of functions satisfies a parabolic equation). It also follows that Θ and H are nonincreasing as functions of $|x|$ because the set of such functions (nonincreasing in $|x|$) is closed and convex in, e.g., $L^2(Q)$ and therefore weakly closed in $L^2(Q)$ (use (4.3)). From the above, we get

$$\int_0^s H_{\varepsilon_*}(\sigma,t)\,d\sigma = \int_{m_1 < \sigma_N |x|^N < m_1+s} H_\varepsilon(x,t)\,dx, \tag{4.17}$$

$$\int_0^s H_*(\sigma,t)\,d\sigma = \int_{m_1 < \sigma_N |x|^N < m_1+s} H(x,t)\,dx, \tag{4.18}$$

and since $H_\varepsilon \to H$ weakly* in $L^\infty(Q)$ (see (4.3)) we finally obtain, as $\varepsilon \to 0$,

$$\int_0^T \int_0^s H_{\varepsilon_*}(\sigma, t)\psi(t)\, d\sigma\, dt \to \int_0^T \int_0^s H_*(\sigma, t)\psi(t)\, d\sigma\, dt.$$

Now, all the above shows that (4.15) results from letting $\varepsilon \to 0$ in $(4.15)_\varepsilon$. This completes the proof of Theorem 1.

5. Proofs of (2.2)–(2.5) and (2.7)–(2.12). We first observe that, in view of (4.13), (2.1) also can be written:

$$(5.1)\quad -\int_0^t \int_{\gamma_0} \frac{\partial \theta}{\partial \nu}\, d\gamma\, d\tau + \int_s^{|\omega|} h_*(\sigma, t)\, d\sigma \geqq -\int_0^t \int_{\Gamma_0} \frac{\partial \Theta}{\partial \nu}\, d\gamma\, d\tau + \int_s^{|\omega|} H_*(\sigma, t)\, d\sigma.$$

By taking $s = 0$ in (2.1), and $s = |\omega|$ in (5.1), we obtain (2.3) and (2.4).

More generally, for "classical" solutions (θ, h) and (Θ, H), if $s > 0$ is such that $\gamma(s, \tau) = \{x \in \omega\colon h(x, \tau) = h_*(s, \tau)\}$ and $\Gamma(s, \tau) = \{x \in \Omega\colon H(x, \tau) = H_*(s, \tau)\}$ are regular curves (in particular, if they have measure zero) for almost every $\tau \in (0, t)$, using the technique of relative rearrangement [8] gives us

$$\begin{aligned}
\int_0^s (h_*(\sigma, t) - h_{0*}(\sigma))\, d\sigma &= \int_0^s \int_0^t \frac{\partial h_*}{\partial \tau}(\sigma, \tau)\, d\tau\, d\sigma \\
&= \int_0^t \int_0^s \frac{\partial h_*}{\partial \tau}(\sigma, \tau)\, d\sigma\, d\tau \\
&= \int_0^t \int_{h(x,\tau) > h_*(s,\tau)} \frac{\partial h}{\partial \tau}\, dx\, d\tau \\
&= \int_0^t \int_{h(x,\tau) > h_*(s,\tau)} \Delta\theta\, dx\, d\tau \\
&= \int_0^t \int_{\gamma_1} \frac{\partial \theta}{\partial \nu}\, d\gamma\, d\tau + \int_0^t \int_{\gamma(s,\tau)} \frac{\partial \theta}{\partial \nu}\, d\gamma\, d\tau
\end{aligned}$$

($\partial/\partial\nu$ the outward normal of $\{h(x, \tau) > h_*(s, \tau)\}$); we proceed similarly for (Θ, H). Thus in (2.1),

$$\int_0^t \int_{\gamma_1} \frac{\partial \theta}{\partial \nu}\, d\gamma\, d\tau - \int_0^s h_*(\sigma, t)\, d\tau = -\int_0^t \int_{\gamma(s,\tau)} \frac{\partial \theta}{\partial \nu}\, d\gamma\, d\tau - \int_0^s h_{0*}(\sigma)\, d\sigma,$$

and similarly for (Θ, H), which explains (2.2). (Note also that $(\mathbf{h}_0)_* = h_{0*}$.)

Now, (2.5) holds because, by the Hardy-Littlewood inequality, $\int_{E(t)} h\, dx \leqq \int_0^s h_*\, d\sigma$, when $|E(t)| = s$, and $\int_{m_1 < \sigma_N |x|^N < m_1 + s} H\, dx = \int_0^s H_*\, d\sigma$ (see (4.18)).

Next, suppose that $\int_0^t \int_{\gamma_0} \partial\theta/\partial\nu\, d\gamma\, d\tau = 0$ (the integral being at least defined by (4.10)′), for almost every $t \in (0, t')$ for some $t' > 0$. This occurs in the one-phase problem (with $\lambda = 0$) if the liquid phase does not reach γ_0 initially (because θ is identically zero in the solid phase when $\lambda = 0$). By (2.4), then also

$$\int_0^t \int_{\Gamma_0} \frac{\partial \Theta}{\partial \nu}\, d\gamma\, d\tau = 0 \quad \text{a.e. } t \in (0, t'),$$

that is, we get (2.7), and (5.1) simply reduces to (2.8) for $t \in (0, t')$.

Now (2.9) follows easily as in the convexity result [1, p. 174], and (2.10) follows from (2.8) by dividing by $|\omega| - s$ and letting s tend to $|\omega|$. Choosing $\Phi(h) = -[(h - \beta)_-]^p$ ($p \geqq 1$) in (2.9) with $s = 0$, we obtain (2.11) for $p < \infty$; letting p tend to ∞ then gives

(2.11) for $p=\infty$. Choosing $\Phi(h)=-(h-\beta)_-/(\alpha+\beta)$, $\beta>-\alpha$, in (2.9) with $s=0$, we finally obtain (2.12) by letting $\beta\to-\alpha$ (observe that $h, H\geqq-\alpha$ almost everywhere when $\lambda=0$).

Acknowledgment. The authors are grateful to J. I. Diaz for several valuable discussions on the subject of the paper.

SHORT-TIME ASYMPTOTICS OF THE HEAT KERNEL ON A CONCAVE BOUNDARY*

PEI HSU†

Abstract. A probabilistic method is used to study short-time asymptotic behavior of heat kernel in the exterior of an insulated smooth convex body. The expansion of the heat kernel $p(t, a, b)$ when both a and b are on the boundary is obtained by reducing the problem to the computation of a Wiener functional on a Brownian bridge. The leading terms of $\log p(t, a, b)$ are proved to be

$$-\frac{\rho^2}{2t} - \frac{\mu_1 \rho^{1/3}}{t^{1/3}} \int_0^\rho N(s)^{2/3} ds - \left(\frac{d}{2} + \frac{1}{6}\right) \log t + C_0 + o(1)$$

where ρ is the distance between a and b, $N(s)$ is the normal curvature of the geodesic joining a and b, and C_0 is an explicitly identified constant.

Key words. heat kernel, Laplace–Beltrami operator, normal curvature, diffusion process on manifold, Brownian bridge, Feynman–Kac formula, Girsanov formula

1. Introduction.

Let M be the exterior of a smooth, strictly convex body in Euclidean space. Let a, b be two points on the boundary such that there is a unique distance-minimizing curve γ joining them which lies completely in M. Since ∂M is concave viewed from M, it is clear then γ must be the unique geodesic joining a and b in ∂M when ∂M is viewed as a Riemannian manifold with induced metric. Let us denote the length of γ by $\rho = d(a, b)$.

Let $p(t, x, y)$ be the heat kernel of the Laplace operator $\Delta/2$ on the domain M with the Neumann boundary condition on ∂M. In this paper we are interested in the asymptotic behavior of $p(t, a, b)$ as $t \to 0$. Recall the basic result of Varadhan [10]:

$$\lim_{t \to 0} t \log p(t, a, b) = -\frac{1}{2} \rho^2. \tag{1.1}$$

Our problem is to seek an improvement of (1.1) which reflects the geometry of the boundary near the geodesic γ. It has long been recognized in the diffraction theory that the correction to (1.1) takes the following form

$$\log p(t, a, b) = -\frac{\rho^2}{2t} - \frac{C}{t^{1/3}} + o\left(\frac{1}{t^{1/3}}\right) \tag{1.2}$$

where C is a positive constant. In fact, using the idea of path integration, Buslaev [2] was able to give a heuristic argument of (1.2) and identified constant C explicitly. However, to make his argument into a mathematically acceptable proof seems not to be a simple matter. Equation (1.2) has long been known in physics literature as Busleav's conjecture.

We will study the expansion (1.2) by a probabilistic method initiated by Molchanov [9]. Our result can be briefly described as follows. We parametrize the geodesic γ by arclength. Let $N(s)$ be the normal curvature of γ (as a curve in $\partial M \hookrightarrow M$) at point $\gamma(s)$. $N(s)$ is simply the curvature of γ when viewed as a curve in the Euclidean space. Since ∂M is the exterior of a strictly convex body, $N(s)$ is strictly positive along γ. The asymptotic behavior of $p(t,a,b)$ is described by

$$\log p(t,a,b) = -\frac{\rho^2}{2t} - \frac{\mu_1 \rho^{1/3}}{t^{1/3}} \int_0^\rho N(s)^{2/3} ds - \left(\frac{d}{2} + \frac{1}{6}\right) \log t + C_0 + o(1).$$

Here μ_1 is the first eigenvalue of $\phi''(x)/2 - |x|\phi(x) + \mu\phi(x) = 0$ on R^1 and C_0 is nonzero constant.

Probabilistically, the heat kernel $p(t,x,y)$ is the transition density function of reflecting Brownian motion on M. By a series of asymptotic analyses, we reduce the computation of $p(t,a,b)$ to that of the following Wiener functional on the standard Brownian bridge $\hat{W}$:

$$E\left[\exp\left\{-\lambda \int_0^1 l(s)|\hat{W}_s| ds\right\}\right], \tag{1.3}$$

where l is a smooth, strictly positive function.

Our research is inspired by the work of Ikeda [5], where a special case of the present problem is discussed. In [5], manifold M is assumed to have the form of a warped product (thus the normal curvature $N(s)$ is a constant). This assumption allows us to construct Brownian motion on M by skew product and to simplify the analysis involved. In our present work, we have further explored some ideas from [5]. For a related problem under a different context, see Melrose and Taylor [8].

The plan of this work is as follows. In §2, we make precise our geometric assumptions and state our main theorem. The proof of the main theorem is outlined in §3. In order not to interrupt the main line of argument, verifications of some intermediate results used in §3 are relegated to §§4 and 5. The asymptotic analysis of the Wiener functional (1.3) is carried out in §6.

Note. The author was informed that Professor N. Ikeda has also obtained results related to the present work.

2. Assumptions and the main theorem. Unfortunately the Euclidean coordinate system is not suitable for our work. We therefore need a little elementary differential geometry. Although we may sometimes discuss the problem under general differentio-geometrical setting, the case where M is the exterior of a smooth, strictly convex body is our primary concern. We will see that various geometrical assumptions we make along the way are satisfied in this important case.

So let us assume that (M,g) is a Riemannian manifold with smooth boundary ∂M. We assume that ∂M is strictly concave when viewed from M. Mathematically this means that the second fundamental form (defined below) of ∂M is strictly positive definite. Now let a and b be two points on ∂M such that there is a unique geodesic in ∂M joining them on which they are not conjugate. For example, a and b can be any two nonantipodal points on a sphere. The geodesic is the arc of the great circle passing through a and b of lesser length. We can set up a semigeodesic coordinate system $\tilde{x} = (x^2, \cdots, x^d)$ on ∂M in a neighborhood of γ with a as the origin and x^2 in the direction of the geodesic γ (cf. Molchanov [9, p. 10]). We let $x = (x^1, \tilde{x})$ be the

point in M which lies on the geodesic passing through $\tilde{x}$ and perpendicular to ∂M with $x^1 = d(x, \partial M)$.

Instead of M, which has a boundary, we can consider $(M^- \cup M, g)$ the double of M. Here M^- is just a copy of M, and M and M^- are identified along the boundary. The heat kernel on $M^- \cup M$ and the Neumann heat kernel on M are related in a very simple way (see §3 below).

The second fundamental form H of the boundary ∂M can be identified with the matrix

$$H_{ij} = H\left(\frac{\partial}{\partial x^i}, \frac{\partial}{\partial x^j}\right) = \left\langle \nabla_i \frac{\partial}{\partial x^j}, \frac{\partial}{\partial x^1} \right\rangle$$

($\nabla_i = \nabla_{\partial/\partial x^i}$ is the covariant derivative). The normal curvature of γ at $\gamma(s)$ is by definition

$$N(s) = H_{\gamma(s)}(\dot{\gamma}(s), \dot{\gamma}(s))$$

(see [7, p. 44]). For brevity, we sometimes write $H_{ij}(s)$ for $H_{ij}(\gamma(s))$ and $g(s)$ for $g(\gamma(s))$. The following lemma clarifies the geometric meaning of the second fundamental form.

LEMMA 2.1. *Let $g = (g_{ij})$ be the metric matrix in the semigeodesic coordinates.* (a) *We have*

$$g_{1i}(x) = \delta_{1i}, \qquad g_{2i}(0, \tilde{x}) = \delta_{2i}, \quad i = 1, \cdots, d.$$

(b) *Near the boundary ∂M, the metric matrix has the expansion*

$$g_{ij}(x) = g_{ij}(0, \tilde{x}) + 2H_{ij}(\tilde{x})|x^1| + O(|x^1|^2), \qquad 2 \le i, j \le d.$$

Proof. Since the coordinate line $\tilde{x} = \text{const.}$ is a geodesic perpendicular to N, we have $g_{1i}(0, \tilde{x}) = \delta_{1i}$ for $x \in \partial M$ and $\nabla_1(\partial/\partial x^1) = 0$. This implies

$$\nabla_1 g_{1i} = \left\langle \frac{\partial}{\partial x^1}, \nabla_1 \frac{\partial}{\partial x^i} \right\rangle = \frac{1}{2}\nabla_i \left\langle \frac{\partial}{\partial x^1}, \frac{\partial}{\partial x^1} \right\rangle = 0.$$

It follows that $g_{1i}(x) = \delta_{1i}$. The same proof applies to $g_{2i}(0, \tilde{x})$. Part (a) is proved.

By the definition of the second fundamental form and part (a), we have on ∂M

$$H_{ij}(\tilde{x}) = \left\langle \frac{\partial}{\partial x^j}, \nabla_i \frac{\partial}{\partial x^1} \right\rangle = \left\langle \frac{\partial}{\partial x^i}, \nabla_1 \frac{\partial}{\partial x^j} \right\rangle = \frac{1}{2}\nabla_1 g_{ij}.$$

Part (b) follows immediately.

We will prove our asymptotic formula for the heat kernel under the following two geometrical assumptions.

Assumption (A). The normal curvature $N(s) = H_{22}(s), 0 \le s \le \rho$, is *strictly* positive along the geodesic γ.

Assumption (B). For any neighborhood G of γ in M, there exists $\epsilon > 0$ such that any piecewise smooth curve in M joining a and b with length $\le d(a, b) + \epsilon$ lies completely inside G. Equivalently, $d(a, b) < d(a, \partial G) + d(b, \partial G)$ for any neighborhood G of γ.

It is easy to verify that in the case where M is the exterior of a strictly convex body in the Euclidean space, the above assumptions (A) and (B) are satisfied.

Let (μ_1, ϕ_1) be the first normalized eigenpairs of the eigenvalue problem

$$\frac{1}{2}\phi''(x) - |x|\phi(x) + \mu\phi(x) = 0, \qquad x \in R^1.$$

We are in a position to state our main result.

THEOREM. *Let M be a Riemannian manifold with boundary and $p(t,x,y)$ the heat kernel of the Laplace–Beltrami operator $\Delta/2$ on M under the Neumann boundary condition (insulated boundary). Suppose that a and b are two points on the boundary such that there is a unique geodesic in the boundary ∂M joining them along which they are not conjugate. Then under further assumptions* (A) *and* (B), *we have as $t \to 0$,*

$$p(t,a,b) \approx \gamma H(a,b)\rho^{2/3}[N(a)N(b)]^{1/6}t^{-(d/2+1/6)} \exp\left\{-\frac{\rho^2}{2t} - \frac{\mu_1\rho^{1/3}}{t^{1/3}}\int_0^\rho N(s)^{2/3}ds\right\},$$

where

$$\gamma = 2(2\pi)^{-(d-1)/2}|\phi_1(0)|^2$$

and

$$H(a,b) = \frac{[g(a)g(b)]^{-1/4}}{\left[\det\int_0^\rho g(s)^{-1}ds\right]^{1/2}}\rho^{2/3}.$$

Remark. $H(a,b)$ has an intrinsic geometric meaning, cf. Molchanov [9, p. 14–15].

Before proving this theorem, we need to transform Assumption (B) into a form more suitable for computation. Let G be any neighborhood of γ; by Assumption (B) we have $d(a,b) < d(a,\partial G) + d(b,\partial G)$. One important consequence of this assumption is that the computation of the asymptotic behavior of $p(t,a,b)$ can be localized inside G. This means that the metric outside G has no effect on the asymptotics of $p(t,a,b)$. In fact if p_{g_1} and p_{g_2} are two heat kernels for the metrics g_1 and g_2 which coincide on G, then we have

$$\lim_{t\to 0}\frac{p_{g_1}(t,a,b)}{p_{g_2}(t,a,b)} = 1$$

(See Azencott [1, p. 157]). Note that in [1], the above relation is proved under the assumption $d(a,b) < \max\{d(a,\partial G), d(b,\partial G)\}$. The result holds, however, under the more relaxed condition $d(a,b) < d(a,\partial G)+d(b,\partial G)$. See Hsu [4] for details. Therefore, for the purpose of computing the asymptotics of $p(t,a,b)$, we may arbitrarily alter the metric outside G to facilitate the computation. Thus we can assume that $M = R^n_+ = \{x = (x^1, x^2, \cdots, x^n) : x^1 \geq 0\}$, $M^- \cup M = R^n$, and that the metric is Euclidean outside a small neighborhood G of γ. Let $g^{-1} = (g^{ij})$ be the inverse of the metric matrix. From Lemma 2.1 a simple calculation shows

$$g^{22}(x) = 1 - 2H_{22}(\tilde{x})|x^1| + O(|x^1|^2).$$

We can then impose the following global assumptions on g^{22}:

Assumption (B1). For all $x \in R^n$, we have $g^{22}(x) \leq 1$.

Assumption (B2). There exists a constant $\gamma > 0$ such that for all $x \in R^n$,

$$1 - 2H_{22}(\tilde{x})|x^1| - \gamma|x^1|^2 \leq g^{22}(x) \leq 1 - 2H_{22}(\tilde{x})|x^1| + \gamma|x^1|^2.$$

The reason that we can make Assumptions (B1) and (B2) is simple: These two assumptions hold on a small neighborhood G of the geodesic γ. We can then choose the metric so that they also hold outside G. Let us emphasize once more that (B1) and (B2) are derived from (A) and (B) and the above mentioned localization principle. We may prove our main theorem under these assumptions without losing the generality of our result.

Remark. A casual reader might think Assumption (B) is redundant because it should always hold. (B) may fail if M is not complete in its Riemannian metric. Since the Euclidean space is complete, (B) indeed holds in this case. On the other hand, Assumption (A) is essential.

Finally let us look at a simple example where (B1) and (B2) are satisfied by the obvious choice of coordinates.

Example. Let $M \subset R^2$ be the exterior component of the ellipse: $x = a\cos\theta, y = \sin\theta$. Introduce coordinates (θ, t) on M:

$$x = \left(a + \frac{bt}{\lambda(\theta)}\right)\cos\theta, \qquad y = \left(b + \frac{at}{\lambda(\theta)}\right)\sin\theta$$

where $\lambda(\theta)^2 = a^2\sin^2\theta + b^2\cos^2\theta$. A simple calculation shows

$$dx^2 + dy^2 = dt^2 + \lambda(\theta)^2\left(1 + \frac{ab}{\lambda(\theta)^3}t\right)^2 d\theta^2.$$

Let

$$x^1 = t, \qquad x^2 = \int_0^\theta \lambda(u)du.$$

We have

$$g^{22}(x) = \left(1 + \frac{ab}{\lambda(\theta)^3}x^1\right)^{-2}$$

and

$$H_{22}(x^2) = \frac{ab}{\lambda(\theta)}.$$

Clearly, Assumptions (A), (B), (B1), and (B2) are satisfied.

3. Proof of the theorem. Let $g^{-1} = (g^{ij})$ be the inverse of the metric matrix g. The Laplace–Beltrami operator on $(M^- \cup M = R^d, g)$ is given by

$$\Delta = \frac{1}{\sqrt{\det g}}\frac{\partial}{\partial x^i}\left(\sqrt{\det g}\, g^{ij}\frac{\partial}{\partial x^j}\right) = g^{ij}\frac{\partial^2}{\partial x^i \partial x^j} + 2b^i\frac{\partial}{\partial x^i}$$

where

$$b^i = \frac{1}{2}\frac{1}{\sqrt{\det g}}\frac{\partial}{\partial x^j}(\sqrt{\det g}\, g^{ij}).$$

Let $X = \{X_t = (X_t^1, \cdots, X_t^d) : t \geq 0\}$ be the Riemannian Brownian motion on $(M^- \cup M, g)$, i.e., the diffusion process generated by $\Delta/2$ (cf. Ikeda–Watanabe [6, Chaps. IV, V]). Denote by $\tau : M^- \cup M \to M$ the natural projection. Then the process $\tau(X)$ is the reflecting Brownian motion on (M, g). Let p^X and $p^{\tau(X)} = p$ be the respective transition density. Then obviously

$$p(t, x, y) = p^X(t, x, y) + p^X(t, x, y^*)$$

where $\{y, y^*\} = \tau^{-1}(y)$. In particular, since $b^* = b$

$$p(t,a,b) = 2p^X(t,a,b). \tag{3.1}$$

Diffusion process X can be obtained as the solution of the stochastic differential equation on R^d:

$$dX_s = \sigma(X_s)\,dB_s + b(X_s)\,ds.$$

Here σ is a smooth square root of g and B is a standard Brownian motion in R^d.

The behavior of the heat kernel $p(t,a,b)$ depends on the law of the Brownian bridge from a and conditioned to reach b at time t. As $t \to 0$, the Brownian bridge tends to travel along the geodesic γ with uniform speed ρ/t. Let

$$Y_s = X_s - \frac{s\rho}{t}e_2.$$

(e_2 is the unit vector $(0,1,0,\cdots,0)$ in x^2-direction.) We therefore expect Y to be a process with small magnitude. The equation for Y is

$$dY_s = \sigma\left(Y_s + \frac{s\rho}{t}e_2\right)dB_s + \left[b\left(Y_s + \frac{s\rho}{t}e_2\right) - \frac{\rho}{t}e_2\right]ds.$$

We now alter the drift of this equation by the Girsanov transform. Consider a new equation

$$dZ_s = \sigma\left(Z_s + \frac{s\rho}{t}e_2\right)dB_s + c\left(Z_s + \frac{s\rho}{t}e_2; t\right)ds. \tag{3.2}$$

Let P^Y and P^Z denote the laws of the processes Y and Z on the sample path space $C([0,t] \to R^n)$. By the Girsanov formula (Ikeda–Watanabe [6, p. 180]), we have

$$\frac{dP^Y}{dP^Z} = \exp\left[\int_0^t \left\langle h\left(Z_s + \frac{s\rho}{t}e_2; t\right), dB_s\right\rangle - \frac{1}{2}\int_0^t \left\|h\left(Z_s + \frac{s\rho}{t}e_2; t\right)\right\|^2 ds\right] \stackrel{\text{def}}{=} N_t.$$

where

$$h(x;t) = \sigma(x)^{-1}\left[b(x) - c(x;t) - \frac{\rho}{t}e_2\right]. \tag{3.3}$$

Let D be a neighborhood of a (the origin of the coordinates). We have

$$\begin{aligned} P[X_t \in D + \rho e_2] &= P[Y_t \in D] = E[N_t; Z_t \in D] \\ &= \int_D E\left[N_t \middle| Z_t = y\right] P\left[Z_t \in dy\right]. \end{aligned}$$

It follows from this and (3.2) that

$$p(t,a,b) = \frac{2}{\sqrt{\det g(\rho)}} E[N_t \big| Z_t = 0]\, p^Z(0,0;t,0). \tag{3.4}$$

where $p^Z(s,z;v,x)$ is the transition density of the process Z (with respect to the Lebesgue measure) defined by (3.2). Formula (3.4) is the key to the subsequent discussion.

We now choose the drift c in (3.2):

$$c(x;t) = b(x) - b^1(x)\, e_1 - \frac{\rho}{t}\,[I - g(x)^{-1}]\, e_2. \tag{3.5}$$

Or, what is the same thing (see (3.3))

$$h(x;t) = \sigma(x)\left[b^1(x)\, e_1 - \frac{\rho}{t} e_2\right]. \tag{3.6}$$

The advantage of this choice will be clear later. Note that

$$c^1\left(z + \frac{s\rho}{t} e_2\right) \equiv 0.$$

This means that the first component Z^1 of (3.2) is simply a one-dimensional Brownian motion.

The last two factors on the right-hand side of (3.4) will now be analyzed separately. First of all, we have the following lemma.

LEMMA 3.1. *As $t \to 0$, we have*

$$p^Z(0,0;t,0) = \left(\frac{1}{2\pi t}\right)^{d/2} H_1\left[1 + O(\sqrt{t})\right]$$

where

$$H_1 = \rho^{d/2}\left[\det \int_0^\rho g(s)^{-1} ds\right]^{-1/2}.$$

To study $E[N_t \big| Z_t = 0]$, set

$$Z_s^* = Z_s + \frac{s\rho}{t} e_2$$

for brevity. Using (3.6), we verify easily

$$\begin{aligned}
&\int_0^t \langle h(Z_s^*;t), dB_s\rangle \\
&\qquad = \int_0^t \langle \sigma(Z_s^*)^{-1} h(Z_s^*;t),\, dZ_s - c(Z_s^*;t)\, ds\rangle \\
&\qquad = -\frac{\rho^2}{t^2}\int_0^t [1 - g^{22}(Z_s^*)]\, ds - \frac{\rho}{t} Z_t^2 + \int_0^t b^1(Z_s^*)\, dZ_s^1 + \frac{\rho}{t}\int_0^t b^2(Z_s^*)\, ds.
\end{aligned}$$

We also have

$$\|h(Z_s^*;t)\|^2 = \frac{\rho^2}{t^2} - \frac{\rho^2}{t^2}[1 - g^{22}(Z_s^*)] + |b^1(Z_s^*)|^2.$$

It follows that

$$\log N_t = -\frac{\rho^2}{2t} - \Theta_t + \log H_2 + F_t \tag{3.7}$$

with

$$\Theta_t = \frac{\rho^2}{2\, t^2}\int_0^t [1 - g^{22}(Z_s^*)]\, ds \tag{3.8}$$

$$H_2 = \exp\left\{\int_0^\rho b^2(se_2)\,ds\right\} = \left[\frac{\det g(\rho)}{\det g(0)}\right]^{1/4}$$

and

(3.9)

$$F_t = -\frac{\rho}{t}Z_t^2 + \int_0^t b^1(Z_s^*)\,dZ_s^1 + \frac{\rho}{t}\int_0^t \left[b^2(Z_s^*) - b^2\left(\frac{s\rho}{t}e_2\right)\right] ds - \frac{1}{2}\int_0^t |b^1(Z_s^*)|^2 ds.$$

It is clear now that the proof of the main theorem in §2 will be completed if we show the following three lemmas.

LEMMA 3.2. *Let $\hat{W}$ be the standard Brownian bridge. We have*

$$\lim_{t\to 0} \frac{E\left[\exp\{-\Theta_t\}\middle| Z_t = 0\right]}{E\left[\exp\left\{-\frac{\rho^2}{\sqrt{t}}\int_0^1 N(s\rho)|\hat{W}_s|ds\right\}\right]} = 1.$$

LEMMA 3.3. *We have*

$$\lim_{t\to 0} \frac{E\left[\exp\{-\Theta_t + F_t\}\middle| Z_t = 0\right]}{E\left[\exp\{-\Theta_t\}\middle| Z_t = 0\right]} = 1.$$

Let

$$S(\lambda; l) \overset{\text{def}}{=} E\left[\exp\left\{-\lambda\int_0^1 l(s)|\hat{W}_s|ds\right\}\right].$$

LEMMA 3.4. *Let $l : [0,1] \to R_+$ be twice continuously differentiable and strictly positive on the closed interval $[0,1]$, then for any $k \geq 0$*

$$S(\lambda; l) = \sqrt{2\pi}|\phi_1(0)|^2[l(0)\,l(1)]^{1/6}\lambda^{1/3}\exp\left\{-\mu_1\lambda^{2/3}\int_0^1 l(s)^{2/3}ds\right\}[1 + O(\lambda^{-k})].$$

The next three sections are devoted to the proof of Lemmas 3.1 to 3.4.

4. Proof of Lemma 3.1. Throughout the rest of this paper, letters $c_1, c_2, \cdots$, whose values may change from one appearance to another, represent constants depending only on the geometry of the manifold.

By (3.2), the function $p^Z(s,z;v,y)$ is the fundamental solution of the parabolic operator

$$L = \frac{\partial}{\partial s} + \frac{1}{2}g^{ij}\left(z + \frac{s\rho}{t}e_2\right)\frac{\partial^2}{\partial z^i \partial z^j} + c^i\left(z + \frac{s\rho}{t}e_2; t\right)\frac{\partial}{\partial z^i}. \tag{4.1}$$

Let us investigate the coefficients c more carefully. First of all, as we have pointed out before, $c^1 \equiv 0$. By Lemma 2.1

$$g(x)^{-1} = \begin{pmatrix} 1 & 0 \\ 0 & \tilde{g}(\tilde{x})^{-1} - 2\tilde{g}(\tilde{x})^{-1}H(\tilde{x})\tilde{g}(\tilde{x})^{-1}|x^1| + O(|x^1|^2) \end{pmatrix}.$$

($\tilde{g}$ is the last $(n-1)\times(n-1)$ principal minor of g). Hence near the geodesic γ

$$\tilde{c}(z + se_2) = \tilde{b}(z + se_2) - \frac{2\rho}{t}D(s)\,e_2|z^1| + \frac{1}{t}O(|z^1|\|z\|) \tag{4.2}$$

where

$$D(s) = \tilde{g}(se_2)^{-1} H(se_2)\, \tilde{g}(se_2)^{-1}.$$

We prove Lemma 3.1 by the method of parametrix (cf. Friedman [3]). We need to pay special attention to the dependence of the coefficients on t.

Let L^x be the operator obtained from L by freezing the coefficients of L at $z = x$. Set for a positive definite matrix A

$$\Gamma(A, y) = \frac{1}{(2\pi)^{d/2}\sqrt{\det A}} \exp\left\{-\frac{1}{2}\langle y, A^{-1}y\rangle\right\}.$$

Let

$$u_0(s, z; v, x) = \Gamma(\lambda_x(s, v), x - z)$$

with

$$\lambda_x(s, v) = \int_s^v g\left(x + \frac{l\rho}{t}e_2\right)^{-1} dl.$$

We have

$$u_0(0, 0; t, 0) = \left(\frac{1}{2\pi t}\right)^{d/2} H_1 \tag{4.3}$$

with the same H_1 as in the statement of Lemma 3.1.

Now $p^Z = u$ can be obtained by iteration from the equation

$$u(s, z; v, x) = u_0(s, z; v, x) + \int_s^v dl \int_{R^d} u(s, z; l, y)(L - L^x)\, u_0(l, y; v, x) dy.$$

We thus obtain an absolutely convergent series $p^Z = \sum_{m=0}^{\infty} u_m$. Using the easy estimate

$$\|g(z) - g(x)\| + t\|c(z; t) - c(x; t)\| \le c_3\|z - x\| \tag{4.4}$$

which follows from (3.5), we verify by induction the following estimate:

$$|u_m(s, z; v, x)| \le \frac{c_1 c_2^m}{\Gamma(m/2 + 1)} \left[1 + \frac{\sqrt{v - s}}{t}\right] (v - s)^{(m-d)/2} \exp\left\{-\frac{\|z - x\|^2}{c_1(v - s)}\right\}.$$

It follows immediately that

$$p^Z(s, z; x, v) \le \frac{c_4}{(v - s)^{d/2}} \left[1 + \frac{v - s}{t}\right] \exp\left\{-\frac{\|z - x\|^2}{c_4(v - s)}\right\}. \tag{4.5}$$

Now that we have

$$\sum_{m=2}^{\infty} |u_m(0, 0; t, 0)| \le c_5 t^{-(d-1)/2},$$

it is easy to see from (4.3) that the assertion of Lemma 3.1 is implied by the inequality

$$|u_1(0, 0; t, 0)| \le c_6 t^{-(d-1)/2}, \tag{4.6}$$

which we are about to show. By the iteration formula

$$u_1(0,0;t,0) = \int_0^t dl \int_{R^d} \Gamma(\lambda_y(0,l),y)[L - L^0]\Gamma(\lambda_0(l,t),y)\,dy. \tag{4.7}$$

From (4.2), we have

$$L - L^0 = \alpha^{ij}\frac{\partial^2}{\partial y^i \partial y^j} + \beta^i \frac{\partial}{\partial y^i} + \frac{\rho}{t}\gamma^i \frac{\partial}{\partial y^i} - \frac{2\rho}{t}\sum_{i=2}^{n} D_{2i}\left(\frac{s\rho}{t}\right)|y^1|\frac{\partial}{\partial y^i}$$

with $\alpha = \alpha(y,l,t)$, etc., satisfying

$$\|\alpha\| + \|\beta\| + \|\gamma\|^{1/2} \le c_7\|y\|. \tag{4.8}$$

This fact together with (4.7) gives

$$\begin{aligned} u_1(0,0;t,0) = &-\frac{2\rho}{t}\int_0^t D_{2i}\left(\frac{l\rho}{t}\right) dl \int_{R^n} [\Gamma(\lambda_y(0,l),y) - \Gamma(\lambda_0(0,l),y)]|y^1| \\ &\times \frac{\partial}{\partial y_i}\Gamma(\lambda_0(l,t),y)dy + O(t^{-(d-1)/2}). \end{aligned} \tag{4.9}$$

(Inserting $\Gamma(\lambda_0(0,l),y)$ creates a term equal to zero after integration.) Finally using the inequality

$$|\Gamma(\lambda_y(0,l),y) - \Gamma(\lambda_0(0,l),y)| \le c_8 l^{-d/2}\|y\|e^{-\|y\|/c_8 l}$$

we obtain (4.6) from (4.9) by simple estimation. The proof of Lemma 3.1 is therefore complete.

5. Proof of Lemma 3.2 and Lemma 3.3. We adopt the following notational convention. If $G(Z)$ is a functional of the process Z, the same functional of Z conditioned by $Z_t = 0$ is denoted by $\hat{G}$, i.e., $\hat{G} = G(\hat{Z})$. Also if $x \in R^n$, then $\tilde{x} = (x^2, \cdots, x^d)$.

Set

$$Z_s^t = \frac{Z_{st}}{\sqrt{t}}, \qquad M^t = \max_{0\le s\le 1}\|Z_s^t\|, \qquad \tilde{M}^t = \max_{0\le s\le 1}\|\tilde{Z}_s^t\|.$$

As mentioned immediately before Lemma 3.1, the process

$$\{W_s \overset{\text{def}}{=} Z_s^{t,1}; 0 \le s \le 1\}$$

is a one-dimensional Brownian motion.

Let P_W be the law of $\tilde{Z}^t$ conditioned by the process W. This means that under the probability P_W, the process $\tilde{Z}^t$ is the solution of the stochastic differential equation

$$d\tilde{Z}_s^t = \tilde{\sigma}(\sqrt{t}W_s e_1 + \sqrt{t}\tilde{Z}_s^t + s\rho e_2)\,d\tilde{B}_s + \sqrt{t}\tilde{c}(\sqrt{t}W_s e_1 + \sqrt{t}\tilde{Z}_s^t + s\rho e_2)\,ds.$$

In this equation $W = \{W_s; 0 \le s \le 1\}$ is assumed to be deterministic. Let p^{Z^t} be the transition density of Z^t and let $p_W^{\tilde{Z}^t}$ be that of the process $\tilde{Z}^t$ under the probability P_W.

Inequality (4.6) and Lemma 3.1 can be paraphrased as follows:

$$p^{Z^t}(s,z;v,x) \le \frac{c_2}{(v-s)^{d/2}} e^{-\|z-x\|^2/c_2(v-s)} \le \frac{c_3}{\|z-x\|^d}$$

$$p^{Z^t}(0,0;1,0) = \left(\frac{1}{2\pi}\right)^{d/2} [1+O(\sqrt{t})] \ge c_4.$$

The proof of Lemma 3.1 can be applied to obtain the following estimates for function $p^{\tilde{Z}^t}_W$:

$$p^{\tilde{Z}^t}_W(s,\tilde{z};v,\tilde{x}) \le \frac{c_2}{(v-s)^{(d-1)/2}} e^{-\|\tilde{z}-\tilde{x}\|^2/c_2(v-s)} \le \frac{c_3}{\|\tilde{z}-\tilde{x}\|^{(d-1)}} \tag{5.1a}$$

and

$$p^{\tilde{Z}^t}_W(0,0;t,0) \ge c_4 \left[1 - c_5 \int_0^1 |W_s| ds\right]. \tag{5.1b}$$

To see this, we only need to observe that (4.2) and estimates (4.4) and (4.8), which are crucial to the proof there, should be replaced by

$$\tilde{c}(\sqrt{t}W_{s/t}e_1 + \tilde{z} + se_2) = \tilde{b}(\sqrt{t}W_{s/t}e_1 + \tilde{z} + se_2) - \frac{2\rho}{t}\left[\tilde{I} - \tilde{g}(\sqrt{t}W_{s/t}e_1 + \tilde{z} + se_2)^{-1}\right] e_2 + \frac{1}{\sqrt{t}} O(|W_{s/t}|\,\|\tilde{z}\|)$$

$$\left\|\tilde{g}(\sqrt{t}W_{s/t}e_1 + \tilde{z}) - \tilde{g}(\sqrt{t}W_{s/t}e_1 + \tilde{x})\right\| \le c_6\|\tilde{z}-\tilde{x}\|$$

$$\left\|\tilde{c}(\sqrt{t}W_{s/t}e_1 + \tilde{z};t) - \tilde{c}(\sqrt{t}W_{s/t}e_1 + \tilde{x};t)\right\| \le \frac{c_6}{t}\|\tilde{z}-\tilde{x}\|$$

and

$$\|\alpha\| + \|\beta\| \le c_7\|\tilde{y}\|, \qquad \|\gamma\| \le c_7\sqrt{t}|W_{s/t}|\,\|\tilde{y}\|.$$

with constants c_6, c_7 independent of W and t.

LEMMA 5.1. *There exist constants c_0, c_1 independent of t such that for sufficiently large $a \gg 1$,*

$$P_W\left[\hat{\tilde{M}}^t > a\right] \le e^{-c_1 a^2} \qquad \text{if } \int_0^1 |W_s| ds \le c_0. \tag{a}$$

and

$$P\left[\hat{M}^t > a\right] \le e^{-c_1 a^2}. \tag{b}$$

Proof. Let

$$\tau_a = \inf\left\{s : \|\tilde{Z}^t_s\| \ge a\right\}.$$

By the Markov property, we have, for any neighborhood D of the origin in $R^{(d-1)}$,

$$P_W\left[\tilde{M}^t > a, \tilde{Z}^t_1 \in D\right] = E_W\left[\int_D p^{\tilde{Z}^t}_W(a,\tau_a;1,y)\,dy; \tau_a < 1\right]. \tag{5.2}$$

Divide (5.2) by $P\left[\tilde{Z}_1^t \in D\right]$ and use (5.1). Letting $|D| \to 0$, we see that for $a \gg 1$,

$$P_W\left[\hat{\tilde{M}}^t > a\right] \leq \frac{1}{2}\left[1 - c_5\int_0^1 |W_s|ds\right]^{-1} P_W\left[\tilde{M}^t > a\right]. \tag{5.3}$$

To estimate the last probability, we note that the equation of $\tilde{Z}^t$ is

$$d\tilde{Z}_s^t = dQ_s + \sqrt{t}\tilde{c}(\sqrt{t}W_s e_1 + \sqrt{t}\tilde{Z}_s^t + s\rho e_2)\,ds \tag{5.4}$$

where

$$dQ_s = \tilde{\sigma}(\sqrt{t}W_s e_1 + \sqrt{t}\tilde{Z}_s^t + s\rho e_2)\,d\tilde{B}_s.$$

By Lemma 2.1 and (3.5) the drift in (5.4) is bounded by

$$\sqrt{t}\left\|c(\sqrt{t}W_s e_1 + \sqrt{t}\tilde{Z}_s^t + s\rho e_2; t)\right\| \leq c_8\sqrt{t} + c_8|W_s|.$$

Also note that $Q_s^i, i = 2, \cdots$ are martingale with bounded characteristic: $[Q^i]_1 \leq d\|\sigma\|_\infty^2$. It follows that for some $a \geq 2c_8$ and all $t \leq 1$

$$\begin{aligned} P_W\left[\tilde{M}^t > a\right] \leq & P_W\left[\max_{0\leq s\leq 1}\|Q_s\| > \frac{a}{2}\left(1 - \int_0^1 |W_s|ds\right)\right] \\ \leq & dP_W\left[\max_{0\leq s\leq d\|\sigma\|_\infty^2}\|\beta_s\| > \frac{a}{2}\left(1 - \int_0^1 |W_s|ds\right)\right] \\ \leq & d\exp\left\{-c_9 a^2\left(1 - \int_0^1 |W_s|ds\right)^2\right\} \end{aligned}$$

(β is an independent one-dimensional Brownian motion). Part (a) follows immediately from (5.3) by choosing, for example, $c_0 < \min(c_5^{-1}, 1)$ and $c_1 > c_9(1 - c_0)^2$. The proof of part (b) is similar and easier.

LEMMA 5.2. *For any positive ϵ, K and $0 < \delta < 1/6$, there exists a positive constant $t_0 = t_0(\epsilon, K, \delta)$ such that for all $t \leq t_0$,*

$$P\left[\int_0^1 |\hat{W}_s|ds \leq Kt^{1/6}, \quad \max_{0\leq s\leq 1}|\hat{W}_s| \geq \epsilon t^{-1/6}\right] \leq \exp\left\{-t^{-(1/3+\delta)}\right\}.$$

Proof. This lemma is proved in Lemma 5.4 of Ikeda [5, p. 188–189].

We now turn to the following proof.

Proof of Lemma 3.2. Set

$$A_{t,K} = \left\{\omega : \int_0^1 |\hat{W}_s|ds \leq Kt^{1/6}\right\}$$

$$B_{t,\epsilon} = \left\{\omega : \max_{0\leq s\leq 1}|\hat{W}_s| \geq \epsilon t^{-1/6}\right\}.$$

Also set

$$G_t = \hat{\tilde{M}}^t \int_0^1 |\hat{W}_s|ds.$$

We have from (3.8)

$$\hat{\Theta}_t = \frac{\rho^2}{2t}\int_0^1 [1 - g^{22}(\sqrt{t}\hat{Z}_s^t + s\rho e_2)]\,ds.$$

Assumption (B2) implies

$$2H_{22}(\tilde{z}+se_2)|z^1| - \gamma|z^1|^2 \le 1 - g^{22}(z+se_2) \le 2H_{22}(\tilde{z}+se_2)|z^1| + \gamma|z^1|^2.$$

Since

$$|H_{22}(\tilde{z}+se_2) - N(s)| \le c_1\|\tilde{z}\|$$

and $N(s)$ is strictly positive by Assumption (A), we have

$$\hat{\Theta}_t \le \frac{\rho^2}{\sqrt{t}}\left[1 + c_4\epsilon\gamma t^{1/3}\right]\int_0^1 N(s\rho)|\hat{W}_s|ds + c_3G_t \text{ on } B_{t,\epsilon}^c. \tag{5.5}$$

Symmetrically, we have

$$\hat{\Theta}_t \ge \frac{\rho^2}{\sqrt{t}}\left[1 - c_4\epsilon\gamma\|_\infty t^{1/3}\right]\int_0^1 N(s\rho)|\hat{W}_s|ds - c_3G_t \quad \text{on } B_{t,\epsilon}^c. \tag{5.6}$$

Now Lemma 5.1(a) implies that if $t \le (c_0/K)^{1/6}$

$$E_{\hat{W}}\left[\exp\{c_3G_t\}\right] \le \exp\left\{c_5\int_0^1 |\hat{W}_s|ds + c_5\left(\int_0^1 |\hat{W}_s|ds\right)^2\right\} \quad \text{on } A_{t,K}. \tag{5.7}$$

(Integration by parts!) By the Schwartz inequality, (5.7) gives

$$E_{\hat{W}}\left[\exp\{-c_3G_t\}\right] \ge \exp\left\{-c_5\int_0^1 |\hat{W}_s|ds - c_5\left(\int_0^1 |\hat{W}_s|ds\right)^2\right\} \quad \text{on } A_{t,K}. \tag{5.8}$$

We also have

$$\hat{\Theta}_t \ge 2c_6Kt^{-1/3} - \frac{\rho^2\gamma}{2}\int_0^1 |\hat{W}_s|^2ds \quad \text{on } A_{t,K}^c.$$

Hence for $\eta = [2c_6/\rho^2\|f\|_\infty]^{1/2}$, we have

$$\hat{\Theta}_t \ge c_6Kt^{-1/3} \quad \text{on } A_{t,K}^c \cap B_{t,\eta\sqrt{K}}^c. \tag{5.9}$$

Observe that

$$E\left[G(\hat{Z})\right] = E\left[E_{\hat{W}}\left[G(\hat{W}e_1 + \hat{\tilde{Z}})\right]\right].$$

Thus, on the one hand, using (5.5), (5.8), and Lemma 5.2, we have

$$\begin{aligned}
&E\left[\exp\left\{-\hat{\Theta}_t\right\}\right] \\
&\quad \ge E\left[\exp\left\{-\hat{\Theta}_t\right\}; A_{t,K}\cap B_{t,\epsilon}^c\right] \\
&\quad \ge E\left[\exp\left\{-\frac{\rho^2}{\sqrt{t}}[1 + c_4\epsilon\gamma t^{1/3} + c_7t^{1/2} + c_7Kt^{2/3}]\int_0^1 N(s\rho)|\hat{W}_s|ds\right\}; A_{t,K}\cap B_{t,\epsilon}^c\right] \\
&\quad \ge E\left[\exp\{\cdots\}\right] - E\left[\exp\{\cdots\}; A_{t,K}^c\right] - P\left[A_{t,K}\cap B_{t,\epsilon}\right] \\
&\quad \ge \left[\exp\left\{-\frac{\rho^2}{\sqrt{t}}[1 + c_4\epsilon\gamma t^{1/3} + c_7t^{1/2} + c_7Kt^{2/3}]\int_0^1 N(s\rho)|\hat{W}_s|ds\right\}\right] \\
&\quad - \exp\left\{-c_8Kt^{-1/3}\right\} - \exp\left\{-c_8t^{-(1/3+\delta)}\right\}.
\end{aligned}$$

On the other hand, by Assumption (B1), we have $\hat{\Theta}_t \geq 0$; hence using (5.6), (5.7), (5.9), and Lemma 5.2, we have

$$\begin{aligned} E\left[\exp\left\{-\hat{\Theta}_t\right\}\right] \leq & E\left[\exp\left\{-\hat{\Theta}_t\right\}; A_{t,K} \cap B_{t,\epsilon}^c\right] + E\left[\exp\left\{-\hat{\Theta}_t\right\}; A_{t,K}^c \cap B_{t,\eta\sqrt{K}}^c\right] \\ & + P\left[B_{t,\eta\sqrt{K}}\right] + P[A_{t,K} \cap B_{t,\epsilon}] \\ \leq & E\left[\exp\left\{-\frac{\rho^2}{\sqrt{t}}[1 - c_4\epsilon\gamma t^{1/3} - c_7 t^{1/2} - c_7 K t^{2/3}] \int_0^1 N(s\rho)|W_s| ds\right\}\right] \\ & + \exp\left\{c_6 K t^{-1/3}\right\} + \exp\left\{-c_8 K t^{-1/3}\right\} + \exp\left\{-t^{-(1/3+\delta)}\right\}. \end{aligned}$$

By Lemma 3.4, which we will prove independently in §6, there exist constants c_9 and c_{10} such that as $t \to 0$, for any $k \geq 0$,

$$E\left[\exp\left\{-\frac{\rho^2}{\sqrt{t}} \int_0^1 N(s\rho)|\hat{W}_s| ds\right\}\right] \sim c_9\, t^{-1/6} \exp\left\{-c_{10} t^{-1/3}\right\}. \tag{5.10}$$

Choose $K > c_{10}/\min(c_6, c_8)$. Using (5.10) and the above bounds for $E\left[\exp\{-\hat{\Theta}_t\}\right]$, we obtain

$$\exp\{-c_{11}\epsilon\gamma\} \leq \lim_{t\to 0}\left\{\begin{matrix}\sup \\ \inf\end{matrix}\right\} \frac{E\left[\exp\{-\hat{\Theta}_t\}\right]}{E\left[\exp\left\{-\frac{\rho^2}{\sqrt{t}} \int_0^1 N(s\rho)|\hat{W}_s| ds\right\}\right]} \leq \exp\{c_{11}\epsilon\gamma\}.$$

($c_{11} = 2\, c_4 c_{10}/3$.) Letting $\epsilon \to 0$, we obtain Lemma 3.2.

Proof of Lemma 3.3. Let us first prove: There exist constants c_1 and c_2 such that for any $|q| \geq 1$

$$E\left[\exp\{q\hat{F}_t\}\right] \leq c_1 e^{c_2 q^2 t}. \tag{5.11}$$

Set

$$\begin{aligned} C_u = & \sqrt{t} \int_0^u b^1(\sqrt{t}\hat{Z}_s^t + s\rho e_2)\, d\hat{W}_s + \int_0^u \left[b^2(\sqrt{t}\hat{Z}_s^t + s\rho e_2) - b^2(s\rho e_2)\right] ds \\ & + \int_0^u \left|b^1(\sqrt{t}\hat{Z}_s^t + s\rho e_2)\right|^2 ds. \end{aligned}$$

Then we have $\hat{F}_t = C_1$. Obviously

$$\left\{E\left[\exp\{q\hat{F}_t\}\right]\right\}^2 \leq E\left[\exp\{2qC_{1/2}\}\right] E\left[\exp\{2q(C_1 - C_{1/2})\}\right].$$

Thus it is enough to prove the estimate for each of the factors on the right-hand side of the above inequality. The proofs for the two factors are the same. Take, for example, the first factor. Since $\hat{W}$ is a standard Brownian bridge, we can write

$$d\hat{W}_s = dW_s - \frac{\hat{W}_s}{1-s} ds$$

for a Brownian motion W. Set

$$A_u = 2q\sqrt{t}\int_0^u b^1(\sqrt{t}\hat{Z}_s^t + s\rho e_2)\,dW_s - 2q^2t\int_0^u \left|b^1(\sqrt{t}\hat{Z}_s^t + s\rho e_2)\right|^2 ds$$

and

$$D_u = 2qC_u - A_u.$$

We have

$$\{E\left[\exp\{2qC_{1/2}\}\right]\}^2 \le E\left[\exp\{2A_{1/2}\}\right] E\left[\exp\{2D_{1/2}\}\right]. \tag{5.12}$$

The first factor on the right-hand side is equal to 1 by the choice of A_u. As for the second factor, we have the bound

$$2|D_{1/2}| \le c_3q^2t + c_3q\sqrt{t}M^t.$$

It follows immediately from Lemma 5.1(b) that the second factor in (5.12) is bounded by $c_4e^{2c_2q^2t}$. This implies

$$E\left[\exp\{qC_{1/2}\}\right] \le c_1e^{c_2q^2t}.$$

Inequality (5.11) is proved.

We now complete the proof of Lemma 3.3. By Lemma 3.2, we have

$$E\left[\exp\left\{-c\hat{\Theta}_t\right\}\right] \ge \exp\left\{-c_5^{-1}t^{-1/3}\right\} \tag{5.13}$$

for fixed c. We use the cases $c = 1, 2$. Let $p > 1$ and $1/p + 1/q = 1$. By (5.11), (5.13) and the Schwartz inequality we obtain

$$\begin{aligned}
&E\left[\exp\left\{-\hat{\Theta}_t + \hat{F}_t\right\}\right] \\
&\quad\le \left\{E\left[\exp\left\{-\hat{\Theta}_t\right\}\right]\right\}^{1/p}\left\{E\left[\exp\left\{-2\hat{\Theta}_t\right\}\right]\right\}^{1/2q}\left\{E\left[\exp\left\{2q\hat{F}_t\right\}\right]\right\}^{1/2q} \\
&\quad\le E\left[\exp\left\{-\hat{\Theta}_t\right\}\right] c_1^{1/2q}\exp\left\{\frac{c_5}{2}(q^3t)^{-1/3} + 2c_2qt\right\}
\end{aligned}$$

and

$$\begin{aligned}
&E\left[\exp\left\{-\hat{\Theta}_t + \hat{F}_t\right\}\right] \\
&\quad\ge \left\{E\left[\exp\left\{-\hat{\Theta}_t\right\}\right]\right\}^{p}\left\{E\left[\exp\left\{-2\hat{\Theta}_t\right\}\right]\right\}^{-p/2q}\left\{E\left[\exp\left\{-\frac{2q}{p}\hat{F}_t\right\}\right]\right\}^{-p/2q} \\
&\quad\ge E\left[\exp\left\{-\hat{\Theta}_t\right\}\right] c_1^{-p/2q}\exp\left\{-\frac{c_5}{2}p(q^3t)^{-1/3} - 2c_2p^{-1}qt\right\}.
\end{aligned}$$

Taking $q = t^{-1/2}$ and letting $t \to 0$, we obtain immediately Lemma 3.3.

6. Proof of Lemma 3.4. Assume first that l is a constant. Using the scaling property of Brownian motion, we have

$$S(\lambda; t) = E\left[\exp\left\{-\int_0^{(\lambda l)^{2/3}} |W_s|ds\right\}\middle| W_{(\lambda l)^{2/3}} = 0\right]$$

(W is one-dimensional Brownian motion). By the Feynmann–Kac formula,

$$S(\lambda; l) = \sqrt{2\pi}(\lambda l)^{1/3} q((\lambda l)^{2/3}, 0, 0)$$

where $q(s, x, y)$ is the fundamental solution of

$$L = \frac{\partial}{\partial t} - \frac{1}{2}\frac{\partial^2}{\partial x^2} + |x|.$$

We have the eigenexpansion

$$q(s, x, y) = \sum_{m=0}^{\infty} \exp\{-\mu_m s\}\phi_m(x)\phi_m(y).$$

It follows easily that for any $k \geq 0$,

$$S(\lambda; l) = \sqrt{2\pi}|\phi_1(0)|^2(\lambda l)^{1/3} \exp\left\{-\mu_1(\lambda l)^{2/3}\right\}\left[1 + O(\lambda^{-k})\right]. \tag{6.1}$$

Thus Lemma 3.4 holds in this special case. For the general case, let

$$\begin{aligned}
L(s) &= \int_0^s l(u)^{2/3} du \\
\mu(s) &= \frac{1}{3}\frac{d}{ds}\left[\log l(L^{-1}(s))\right] \\
\psi(s) &= L(1)\,\mu(L(1)\,s) \\
T_\lambda &= \lambda^{2/3} L(1) \\
J_\psi &= \frac{1}{2}\int_0^1 [\psi'(s) + \psi(s)^2]|\hat{W}_s|^2 ds \\
\Omega(\lambda, \psi) &= J_\psi + \lambda \int_0^1 |\hat{W}_s| ds
\end{aligned}$$

(L^{-1} is the inverse function of L). It is not difficult to see that Lemma 3.4 is implied by the following two relations:

$$S(\lambda; l) = \left[\frac{l(0)\,l(1)}{L(1)^3}\right]^{1/6} E\left[\exp\left\{-\Omega(T_\lambda^{3/2}, \psi)\right\}\right] \tag{6.2}$$

$$\lim_{\lambda \to \infty} \frac{E\left[\exp\{-\Omega(\lambda, \psi)\}\right]}{E\left[\exp\{-\Omega(\lambda, 0)\}\right]} = 1. \tag{6.3}$$

To show (6.2), let δ be the δ-function at $x = 0$, and set

$$u_\lambda(s, x) = E_x\left[\exp\left\{-\lambda \int_s^1 l(s)|W_s| ds\right\} \delta(W_1)\right].$$

We have $S(\lambda; l) = \sqrt{2\pi} u_\lambda(0, 0)$. Function $u_\lambda(s, x)$ satisfies

$$\frac{\partial u}{\partial s} + \frac{1}{2}\frac{\partial^2 u}{\partial x^2} - \lambda l(s)|x|u = 0, \qquad u(1, \cdot) = \delta.$$

Introduce a new function $w_\lambda(s,x)$ by

$$u_\lambda(s,x) = [\lambda l(1)]^{1/3} w_\lambda\left(\lambda^{2/3}L(s), [\lambda l(s)]^{1/3}x\right).$$

Then

$$S(\lambda;l) = \sqrt{2\pi}[\lambda l(1)]^{1/3} w_\lambda(0,0). \tag{6.4}$$

We verify directly that $w_\lambda(s,x)$ satisfies the equation

$$\frac{\partial w}{\partial s} + \frac{1}{2}\frac{\partial^2 w}{\partial x^2} + \lambda^{-2/3}\mu(\lambda^{-2/3}s)\,x\,\frac{\partial w}{\partial x} - |x|w = 0, \qquad w(T_\lambda,\cdot) = \delta$$

By the Girsanov formula and the Feynman–Kac formula, we can write

$$w_\lambda(0,0) = E\left[\exp\{A(\lambda)\}\delta(W_{T_\lambda})\right]$$

where

$$A(\lambda) = \lambda^{-2/3}\int_0^{T_\lambda} \mu\left(\frac{s}{\lambda^{2/3}}\right) W_s dW s - \frac{1}{2}\lambda^{-4/3}\int_0^{T_\lambda} \mu\left(\frac{s}{\lambda^{2/3}}\right)^2 |W_s|^2 ds - \int_0^{T_\lambda} |W_s| ds.$$

Using the scaling property of Brownian motion, we can write

$$w_\lambda(0,0) = \frac{1}{\sqrt{2\pi T_\lambda}} E\left[\exp\{B(\lambda)\}\right] \tag{6.5}$$

with

$$B(\lambda) = \int_0^1 \psi(s)\hat{W}_s d\hat{W}_s - \frac{1}{2}\int_0^1 \psi(s)^2|\hat{W}_s|^2 ds - T_\lambda^{3/2}\int_0^1 |\hat{W}_s| ds.$$

By Itô's formula,

$$\begin{aligned} B(\lambda) &= -\frac{1}{2}\int_0^1 [\psi'(s) + \psi(s)^2]|\hat{W}_s|^2 ds - T_\lambda^{3/2}\int_0^1 |\hat{W}_s| ds - \frac{1}{2}\int_0^1 \psi(s)\,ds \\ &= -\Omega(T_\lambda,\psi) - \frac{1}{6}\log\frac{l(1)}{l(0)}. \end{aligned}$$

The desired formula (6.2) follows from (6.4) and (6.5).

It remains to prove (6.3). We claim

$$\exists p > 1: \qquad C(p) \stackrel{\text{def}}{=} E\left[\exp\{-pJ_\psi\}\right] < \infty. \tag{6.6}$$

Let $\{X_1, X_2, \cdots\}$ be a sequence of independently and identically distributed random variables with standard normal distribution $N(0,1)$. Then the Brownian bridge $\hat{W}_s$ can be expanded as

$$\hat{W}_s = \frac{\sqrt{2}}{\pi}\sum_{k=1}^{\infty} X_k \frac{\sin k\pi s}{k}.$$

We have

$$J_\psi = \frac{1}{2}\sum_{k,l=1}^{\infty} a_{kl} X_k X_l$$

with

$$a_{kl} = \frac{2}{\pi^2}\int_0^1 [\psi'(s) + \psi(s)^2]\frac{\sin k\pi s}{k}\frac{\sin l\pi s}{l}ds.$$

Let H be the Hilbert space

$$H = \left\{f \in AC[0,1]: \quad f(0) = f(1) = 0, \quad \|f\|_H^2 \stackrel{\text{def}}{=} \int_0^1 |f'(s)|^2 ds < \infty\right\}.$$

Let $\{e_1, e_2, \cdots\}$ be an orthonormal basis for H. Define $A : H \to H$ by $Ae_k = \sum_{l=1}^{\infty} a_{kl}e_l$. Let $\alpha_1, \alpha_2, \cdots$ ($\alpha_i \to 0$) be the eigenvalues of A with normalized eigenvectors $f_1, f_2, \cdots$. Define (c_{kl}) by $e_k = \sum_{l=1}^{\infty} c_{kl}f_l$. The random variables $Y_i = \sum_{l=1}^{\infty} c_{li}X_l, i = 1, 2, \cdots$ are again i.i.d. with standard normal $N(0,1)$. Furthermore $J_\psi = \frac{1}{2}\sum_{i=1}^{\infty} \alpha_i |Y_i|^2$. It follows that as long as $1 + p\alpha_i \geq 0$ for all i, we have

$$C(p) = E\left[\exp\left\{-\frac{p}{2}\sum_{i=1}^{\infty}\alpha_i|Y_i|^2\right\}\right] = \prod_{i=1}^{\infty}(1 + p\alpha_i)^{-1/2}. \tag{6.7}$$

The infinite product (6.7) converges to a finite value if and only if the series $\sum_{i=1}^{\infty}\alpha_i$ converges and $1 + p\alpha_i > 0$ for all i. On the other hand, from the definition of $C(p)$, we know $C(p)$ is finite for small p. Thus the the series $\sum_{i=1}^{\infty}\alpha_i$ indeed converges. It is now clear that $C(p)$ is finite for those p such that $1 + p\alpha_i > 0$ for all i. Thus $C(p) < \infty$ for some $p > 1$ if and only if all eigenvalues $\alpha_i > -1$ (note that $\alpha_i \to 0$), or what is the same thing,

$$\forall f \in H: \qquad \langle Af, f\rangle_H > -\|f\|_H^2. \tag{6.8}$$

A direct computation shows that

$$\langle Af, f\rangle = \int_0^1 [\psi'(s) + \psi(s)^2]\,|f(s)|^2 ds.$$

Relation (6.8) follows then from the elementary fact: for all $f \in H$

$$\int_0^1 [\psi'(s) + \psi(s)^2]|f(s)|^2 ds + \int_0^1 |f'(s)|^2 ds = \int_0^1 [\psi(s)f(s) - f'(s)]^2 ds > 0.$$

Equation (6.6) is proved.

We can now finish the proof of (6.3). Let

$$C_{\lambda,\epsilon} = \left\{\omega : |J_\psi| \leq \epsilon\lambda^{1/3}\int_0^1 |\hat{W}_s|ds\right\}$$

and

$$D_{\lambda,K} = \left\{\omega : \int_0^1 |\hat{W}_s|ds > K\lambda^{-1/3}\right\}.$$

Then on $C_{\lambda,\epsilon}$

$$\lambda[1 - \epsilon\lambda^{-2/3}]\int_0^1 |\hat{W}_s|ds \leq \Omega(\lambda, \psi) \geq \lambda[1 + \epsilon\lambda^{-2/3}]\int_0^1 |\hat{W}_s|ds.$$

On the set $D_{\lambda,K}$

$$\Omega(\lambda,\psi) \geq J_\psi + K\lambda^{2/3}.$$

It follows that on the one hand

$$\begin{aligned} E\left[\exp\{-\Omega(\lambda,\psi)\}\right] \leq & E\left[\exp\left\{-\lambda[1-\epsilon\lambda^{-2/3}]\int_0^1 |\hat{W}_s|ds\right\}\right] \\ & + C(1)\exp\{-K\lambda^{2/3}\} + C(p)^{1/p}P\left[C^c_{\lambda,\epsilon}\cap D^c_{\lambda,K}\right]^{1/q}. \end{aligned} \tag{6.9}$$

Note that we have proved $C(1)$ and $C(p)$ are finite. On the other hand, we have

$$\begin{aligned} E\left[\exp\{-\Omega(\lambda,\psi)\}\right] \geq & E\left[\exp\left\{-\lambda[1+\epsilon\lambda^{-2/3}]\int_0^1 |\hat{W}_s|ds\right\}\right] \\ & - \exp\{-K\lambda^{2/3}\} - P\left[C^c_{\lambda,\epsilon}\cap D^c_{\lambda,K}\right]. \end{aligned} \tag{6.10}$$

Note that

$$C^c_{\lambda,\epsilon}\cap D^c_{\lambda,K} \subset \left\{\omega : \int_0^1 |\hat{W}_s|ds \leq K\lambda^{-1/3}, \max_{0\leq s\leq 1}|\hat{W}_s| \geq \epsilon c(\psi)\,\lambda^{1/3}\right\}.$$

with $c(\psi) = \|\psi' + \psi^2\|_\infty^{-1}$. Take $K > \mu_1 L(1)$. By Lemma 5.2 and (6.1), (6.9), and (6.10),

$$e^{-2\mu_1\epsilon/3} \leq \lim_{\lambda\to\infty}\left\{\begin{matrix}\sup\\ \inf\end{matrix}\right\}\frac{E\left[\exp\{-\Omega(\lambda,\psi)\}\right]}{E\left[\exp\{-\Omega(\lambda,0)\}\right]} \leq e^{2\mu_1\epsilon/3}.$$

Letting $\epsilon \to 0$ we obtain (6.3). The proof is complete.

Acknowledgment. The author is grateful to Professor S.R.S. Varadhan for helpful discussions, especially on the material in §6.

GLOBAL EXISTENCE FOR SEMILINEAR PARABOLIC SYSTEMS*

JEFF MORGAN†

Abstract. Global existence results are obtained for semilinear parabolic systems of partial differential equations of the form

$$u_t = D\Delta u + f(u) \quad \text{on } \Omega \times (0, T),$$

with bounded initial data and various boundary conditions, where D is an $m \times m$ diagonal matrix with positive entries on the diagonal, Ω is a smooth bounded domain in R^n, and $f: R^m \to R^m$ is locally Lipschitz. These results are based on f satisfying a Lyapunov-type condition, and generalize a previous result of Hollis, Martin, and Pierre [*SIAM J. Math. Anal.*, 18 (1987), pp. 744-761]. This theory is applied to some specific reaction-diffusion and nerve conduction problems.

Key words. reaction-diffusion systems, global existence, Lyapunov function

AMS(MOS) subject classifications. 35K45, 35B35

1. Introduction and motivation. In recent years, there has been a great deal of research concerning global existence for solutions of semilinear parabolic systems of partial differential equations. The problem has been approached via invariant sets, differential inequalities, semigroup theory, and many other methods (see [1], [3], [16], [19]). More recently, Hollis, Martin, and Pierre [10] studied this problem by examining systems of two unknowns, where one of the unknowns is bounded and the nonlinearity obeys a simple Lyapunov-type condition. The results obtained in this work are a generalization of this idea.

Much of the motivation for this work comes from studying systems of ordinary differential equations. Suppose that m is a positive integer, $f: \mathbf{R}^m \to \mathbf{R}^m$ is continuously differentiable, and $y_0 \in \mathbf{R}^m$. Consider the following system:

$$\begin{aligned} y' &= f(y), \qquad t > 0, \\ y &= y_0, \qquad t = 0. \end{aligned} \tag{1.1}$$

Local existence is well known for such systems. That is, there exists a real number $T_{\max} > 0$ such that (1.1) has a unique noncontinuable solution $y(t)$ on $[0, T_{\max})$. Furthermore, if $T_{\max} < \infty$, then $|y(t)| \to \infty$ as $t \to T_{\max}^-$. Hence, (1.1) has a solution for all $t > 0$ (a global solution) if y does not blow up in finite time. One method for determining whether (1.1) has a solution for all $t > 0$ is the following Lyapunov-type criterion.

PROPOSITION 1.1. *Suppose that $H: \mathbf{R}^m \to [0, \infty)$ is a smooth function satisfying*

(i) $|H(z)| \to \infty$ *as* $|z| \to \infty$;

(ii) *There exists a real number M such that*

$$\nabla H(z) \cdot f(z) \leqq MH(z) \quad \textit{for all } z \in \mathbf{R}^m.$$

Then $T_{\max} = \infty$.

It is interesting to note that if $M \leqq 0$ then the level sets of H determine invariant regions for solutions of (1.1).

Actually, systems of the form (1.1) are a special case of the following. Suppose Ω is a bounded domain in $\mathbf{R}^n$ with a smooth boundary $\partial\Omega$ (say, $\partial\Omega$ is an $(n-1)$-

* Received by the editors September 28, 1987; accepted for publication (in revised form) October 25, 1988.
† Department of Mathematics, Texas A&M University, College Station, Texas 77843.

dimensional $C^{2+\mu}$ manifold, such that Ω lies locally on one side of $\partial\Omega$), D is an $m \times m$ diagonal matrix with positive entries d_i on the diagonal, Δ is the Laplacian operator, ∇ is the gradient operator, ∂ is the derivative operator, $\partial/\partial\eta$ is the derivative with respect to the outward unit normal on $\partial\Omega$, and $v_0 \in L^\infty(\Omega, \mathbf{R}^m)$. Consider the system

$$
\begin{aligned}
&v_t(x,t) = D\Delta v(x,t) + f(v(x,t)), && x \in \Omega, \quad t > 0,\\
&\partial v(x,t)/\partial\eta = 0, && x \in \partial\Omega, \quad t > 0,\\
&v(x,0) = v_0(x), && x \in \Omega.
\end{aligned} \tag{1.2}
$$

Note that if $v_0 \equiv y_0$, then $v(x,t) \equiv y(t)$, where y solves (1.1).

Local existence for (1.2) is similar to that for (1.1) (complete statements are given in § 2). That is, there exists a real number $T_{\max} > 0$ such that (1.2) has a unique, classical, noncontinuable solution $v(x,t) = (v_i(x,t))$ on $\Omega \times [0, T_{\max})$. Furthermore, if $T_{\max} < \infty$, then $|v_i(\cdot,t)|_{\infty,\Omega} \to \infty$ as $t \to T_{\max}^-$, for some $1 \leqq i \leqq m$.

Note that the criterion for determining global existence for (1.2) is essentially the same as that for (1.1). That is, (1.2) has global existence if v does not blow up in finite time in the sup-norm. However, determining global existence for (1.2), even when f is quite simple, can be a difficult task. In general it is not known whether global existence for (1.1) guarantees global existence for (1.2). We might hope that the invariant regions for (1.1) (obtained, for example, when $M = 0$ in Proposition 1.1) would also be invariant regions for (1.2). Unfortunately, if the d_i are distinct, the only invariant regions for (1.2) are products of intervals (see Smoller [20]). Consequently, the spread of solutions of (1.2) outside more general invariant regions for (1.1) leads us to believe that global existence for (1.1) does not imply global existence for (1.2). Although this work does not resolve this problem, conditions similar to those given in Proposition 1.1, and guaranteeing global existence for (1.2), are stated in § 2. The principal portion of these conditions can be stated as follows.

Suppose that $\mathbf{I}$ is an invariant region (possibly unbounded) for (1.2), $v(x,t) = (v_i(x,t))$ solves (1.2) on cl $(\Omega) \times [0, T_{\max})$, and there exists a function $H \in C^2(\mathbf{I}, [0,\infty))$ such that:

(1.3) $\partial^2 H(z)$ is nonnegative definite for all $z \in \mathbf{I}$;

(1.4) $H(z) \to \infty$ as $|z| \to \infty$;

(1.5) There exists $M \in \mathbf{R}$ such that $\nabla H(z) \cdot f(z) \leqq MH(z)$ for all $z \in \mathbf{I}$.

Note that (1.3) and (1.4) assert that H is a convex, coercive function from $\mathbf{I}$ to $[0,\infty)$, and that (1.5) imposes a growth restriction on the vector field f across level sets of H. The additional conditions given in § 2 place a polynomial growth restriction on f, along with an "intermediate sum" restriction that allows us to handle distinct diffusion coefficients d_i. When the diffusion coefficients are not distinct, we have the following simple result.

PROPOSITION 1.2. *If $d_i = d_j$ for all $1 \leqq i, j \leqq m$ and there exists a function $H \in C^2(\mathbf{I}, [0,\infty))$ satisfying (1.3)-(1.5), then $T_{\max} = \infty$. Furthermore, if $M \leqq 0$ then there exists $N > 0$ such that $|v(\cdot,t)|_{\infty,\Omega} \leqq N$ for all $t \geqq 0$.*

Proof. Set $u(x,t) = H(v(x,t))$ on $\Omega \times [0, T_{\max})$. Then from (1.3)-(1.5), $u \geqq 0$ and

$$
\begin{aligned}
&u_t(x,t) \leqq d_1 \Delta u(x,t) + Mu(x,t), && (x,t) \in \Omega \times (0, T_{\max}),\\
&\partial u(x,t)/\partial\eta = 0, && (x,t) \in \partial\Omega \times (0, T_{\max}),\\
&u(x,0) = H(v(x,0)), && x \in \Omega.
\end{aligned} \tag{1.6}
$$

Thus, if $K = |H(v(x, 0))|_{\infty,\Omega}$, then application of the strong maximum principle (see Sperb [21, § 2.3]) implies that $0 \leqq u(x, t) \leqq Ke^{Mt}$ on $\Omega \times [0, T_{\max})$. Hence, from the basic existence theorem given above and (1.4), we have $T_{\max} = \infty$. Furthermore, if $M \leqq 0$, then there exists $N > 0$ such that $|v(\cdot, t)|_{\infty,\Omega} \leqq N$ for all $t \geqq 0$.

We remark that if, in addition to (1.3)-(1.5), H also satisfies $H(z) = 0$ if and only if $z = 0$, then $M < 0$ implies $|v(\cdot, t)|_{\infty,\Omega} \to 0$ as $t \to \infty$.

Conditions (1.3)-(1.5) are actually a generalization (see § 5) of a "dissipativity condition" considered by Groger [8] requiring a function related to the dissipation rate of the chemical reactions to be nonnegative. From the work of Horn, Feinberg, and Jackson [5], [11], [12] on mass-action kinetics in reaction networks, it follows that this condition is satisfied for many systems of practical interest. Also, many standard "energy inequalities" arising in mechanical problems correspond to the choices $H(v) = c_1 v_1^2 + \cdots + c_m v_m^2$ for some positive constants $c_1, \cdots, c_m$. For chemical systems we usually choose quite different H's, as illustrated in § 5.

The material in this paper is organized as follows. The notation and main results are given in § 2. In § 3 we develop some useful a priori bounds, and in § 4 we prove the results stated in § 2. Section 5 contains applications of this theory to some reaction-diffusion and nerve conduction problems.

2. Notation and statements of main results. We assume that the reader is familiar with the standard L^p and Sobolev spaces. If $0 \leqq \tau < T$ and $1 \leqq p < \infty$, then $W^{2,1,p}(\Omega \times (\tau, T))$ will denote the Banach space consisting of the elements u of $L^p(\Omega \times (\tau, T))$, having the distributional derivatives $D_t^r D_x^s u$, where $2r + s \leqq 2$ and each of the derivatives lies in $L^p(\Omega \times (\tau, T))$. The norm is defined by

$$|u|^{(2)}_{p,\Omega\times(\tau,T)} = \sum_{2r+s\leqq 2} |\partial_t^r \partial_x^s u|_{p,\Omega\times(\tau,T)}.$$

If $\alpha, \beta \in \mathbf{R}^m$, then $\alpha \leqq \beta$ if and only if $\alpha_i \leqq \beta_i$ for all $1 \leqq i \leqq m$. Also, the positive orthant of $\mathbf{R}^m$ is defined by $\mathbf{P}^m = \{x \in \mathbf{R}^m : x_i > 0 \text{ for all } 1 \leqq i \leqq m\}$, and the nonnegative orthant of $\mathbf{R}^m$ is defined by $\mathrm{cl}(\mathbf{P}^m)$.

Throughout, Ω will be given as in § 1. Furthermore, if s and t are real numbers satisfying $0 \leqq s < t$, then $\Omega \times [s, t]$ will be denoted by $Q[s, t]$. Similarly, $\Omega \times [s, t)$, $\Omega \times (s, t)$, and $\Omega \times (s, t]$ will be denoted by $Q[s, t)$, $Q(s, t)$, and $Q(s, t]$, respectively.

The primary concern of this work is the system

$$\begin{aligned} &v_t(x, t) = D\Delta v(x, t) + f(v(x, t)), && x \in \Omega, \quad t > 0, \\ &Bv(x, t) = \gamma, && x \in \partial\Omega, \quad t > 0, \\ &v(x, 0) = v_0(x), && x \in \Omega, \end{aligned} \tag{2.1}$$

where D and f are given as in § 1, and B and γ satisfy the following assumptions:

(A1) $\alpha = (\alpha_i)$, $\gamma = (\gamma_i) \in \mathbf{R}^m$ and $B = (B_i)$ is a diagonal operator given by $Bv = (B_i v_i)$, where $B_i v_i = \alpha_i v_i + \beta(\partial v_i / \partial \eta)$ for all $1 \leqq i \leqq m$. Furthermore, α, β, and γ satisfy: (i) $\alpha_k \geqq 0$ and $\beta \in \{0, 1\}$ for all $1 \leqq k \leqq m$; (ii) if $\beta = 0$ then $\alpha_k = 1$ for all $1 \leqq k \leqq m$; and (iii) if $\alpha_i = 0$ for some $1 \leqq i \leqq m$, then $\alpha \equiv 0$, $\beta = 1$, and $\gamma \equiv 0$.

(A2) $v_0 = (v_{i0}) \in L^\infty(\Omega, \mathbf{R}^m)$.

Conditions (A1), (A2) guarantee local existence and uniqueness for (2.1). A proof of the following theorem can be found in Hollis, Martin, and Pierre [10, Prop. 1, p. 745].

THEOREM 2.1. *Suppose that* (A1), (A2) *hold. Then there exists* $T_{\max} > 0$ *and* $N = (N_i) \in C([0, T_{\max}), \mathbf{R}^m)$ *such that*

(i) (2.1) *has a unique, classical, noncontinuable solution* $v(x, t)$ *on* $\mathrm{cl}(\Omega)\times[0, T_{\max})$; *and*

(ii) $|v_i(\cdot, t)|_{\infty,\Omega} \leqq N_i(t)$ *for all* $1 \leqq i \leqq m$, $0 \leqq t < T_{\max}$.

Moreover, if $T_{\max} < \infty$, *then* $|v_i(\cdot, t)|_{\infty,\Omega} \to \infty$ *for some* $1 \leqq i \leqq m$.

For the remainder of this paper $\mathbf{I}$ will be a (possibly unbounded) subset of $\mathbf{R}^m$ for which (2.1) is invariant. Since our primary interest lies in the case when the "diffusion coefficients" d_i are distinct, it follows from our comment in § 1 that there exist (possibly unbounded) intervals $\mathbf{I}_i$ of $\mathbf{R}$ such that $\mathbf{I} = \mathbf{I}_1 \times \cdots \times \mathbf{I}_m$. In addition, this invariance assumption seems to warrant the following.

(A3) If $1 \leqq i \leqq m$ and $\alpha_i \neq 0$, then $\gamma_i/\alpha_i \in \mathbf{I}_i$. Furthermore, $v_0(x) \in \mathbf{I}$ for all x.

In order to state a version of Proposition 1.1 for (2.1), we give a restricted version of (1.3)-(1.5). Suppose $v = (v_i)$ solves (2.1) and there exist functions $H \in C^2(\mathbf{I}, \mathbf{R})$ and $h_i \in C^2(\mathbf{I}_i, \mathbf{R})$ for each $1 \leqq i \leqq m$ such that:

(H1) $H(z) = \sum_{i=1}^m h_i(z_i)$ for all $z \in \mathbf{I}$.

(H2) $h_i(z_i)$, $h_i''(z_i) \geqq 0$ for all $z_i \in \mathbf{I}_i$, $1 \leqq i \leqq m$.

(H3) $H(z) \to \infty$ if and only if $|z| \to \infty$ in $\mathbf{I}$.

(H4) There exists $A = (a_{ij}) \in \mathbf{R}^{m\times m}$ satisfying $a_{ij} \geqq 0$, $a_{ii} > 0$ for all $1 \leqq i, j \leqq m$, such that for each $1 \leqq j \leqq m$, either (i) there exist r, K_1, $K_2 \geqq 0$, independent of j, such that $\sum_{i=1}^j a_{ji} h_i'(z_i) f_i(z) \leqq K_1(H(z))^r + K_2$ for all $z \in \mathbf{I}$; or (ii) there exists $\zeta \geqq 1$ such that for all $\zeta \leqq p < \infty$ there exist $0 < \delta_p < 1$ and K_{3p}, $K_{4p} \in C([0, \infty))$ such that for all $0 \leqq \tau < T < T_{\max}$ we have $|h_j(v_j)|_{p,Q[\tau,T]} \leqq K_{3p}(T-\tau) + K_{4p}(T-\tau)|H(v)|^{\delta_p}_{p,Q[\tau,T]}$.

(H5) There exist q_1, K_5, $K_6 \geqq 0$ such that for all $1 \leqq i \leqq m$ we have $h_i'(z_i) f_i(z) \leqq K_5(H(z))^{q_1} + K_6$ for all $z \in \mathbf{I}$.

(H6) There exist K_7, $K_8 \geqq 0$ such that $\nabla H(z) \cdot f(z) \leqq K_7 H(z) + K_8$ for all $z \in \mathbf{I}$.

Remarks. (i) Conditions (H1)-(H3) and (H6) are a restatement of (1.3)-(1.5) with a "splitting condition" imposed on H. We show in § 3 that these conditions are sufficient to obtain certain a priori bounds on $H(v)$.

(ii) Hypothesis (H4) requires that either there exists a polynomial upper bound for the jth "intermediate sum," or $h_j(v_j)$ satisfies an L^p growth restriction. Note that (H4)(ii) is satisfied if v_j can be bounded a priori on $Q(0, T_{\max})$. The results we obtain are dependent on r if (H4)(ii) does not always hold, but the restrictions on r allow nontrivial nonlinearities in f. We show in § 4 that if (H4)(ii) holds for all $1 \leqq j \leqq m$, then $T_{\max} = \infty$.

(iii) Hypothesis (H5) is essentially a polynomial growth restriction on f. The results we obtain are independent of the size of q_1.

In § 5, we will see that several model systems satisfy (H1)-(H6). Our first result is stated as Theorem 2.2.

THEOREM 2.2. *Suppose* (A1)-(A3) *and* (H1)-(H5) *hold. If there exist* $a > 0$ *and* $g \in C([0, \infty))$ *such that*

$$\left| \int_0^t (H(v(\cdot, s)))^a \, ds \right|_{\infty,\Omega} \leqq g(t) \quad \text{for all } 0 < t < T_{\max}, \tag{2.2}$$

and $r < 1 + a$, *then* $T_{\max} = \infty$.

Although it is not obvious, Theorem 2.2 gives us a generalization of Proposition 1.2 to cases of general diffusion coefficients and more general boundary conditions. Suppose that (A1)-(A3), (H1), (H2), and (H6) are satisfied. Then it will be shown in § 3 that (2.2) holds with $a = 1$, independent of m and n! Hence, if $r < 2$ in (H4)(i), then this theorem provides a global existence result independent of space dimension and size of diffusion coefficients. Thus, returning to consider systems (1.1) and (1.2),

we see that global existence for (1.1), with an appropriate H, implies global existence for (1.2) for a large class of nontrivial systems.

Theorem 2.2 also generalizes the global existence result of Hollis, Martin, and Pierre, who considered systems of the form (2.1) with $m=2$ and the following assumptions:

(a) $f_1(0, z_2), f_2(z_1, 0) \geqq 0$ for all $z_1, z_2 \geqq 0$.

(b) $v_{i0}(x) \geqq 0$, for all $x \in \Omega$, $i=1,2$.

(c) $f_1(v(x,t))+f_2(v(x,t)) \leqq M(v_1(x,t))$, for some $M \in C([0,\infty))$ on $Q(0, T_{\max})$.

(d) There exists $g \in C([0,\infty))$ such that $|v_1(\cdot, t)|_{\infty,\Omega} \leqq g(t)$ for all $0<t<T_{\max}$.

Assumptions (a) and (b) above imply that cl $(\mathbf{P}^2)$ is invariant for (2.1) (see Lightbourne and Martin [15]), whereas (c) and (d) are simple cases of (H6) and (H4)(ii), respectively, with $H(v)=v_1+v_2+$constant. Hence, these assumptions imply that the hypotheses of Theorem 2.2 hold.

We can also extend a version of a very general result of Amann's [2] (which was given for nonlinear parabolic systems) as it applies to systems of the form (2.1). Amann's result (as it applies to (2.1)) can be stated as follows. Suppose that:

(i) There exist K, $r>0$ such that for all $1 \leqq j \leqq m$

$$|f_j(v(x,t))| \leqq K\left(\sum_{i=1}^{m} v_i(x,t)+1\right)^r \quad \text{on } Q(0, T_{\max});$$

(ii) There exist $g \in C([0,\infty))$ and $a>0$ *such that for all* $1 \leqq i \leqq m$

$$\left|\int_\Omega |v_i(x,\cdot)|^a \, dx\right|_{\infty,(0,t)} \leqq g(t) \quad \text{for all } 0<t<T_{\max};$$

(iii) $r<1+2a/n$;

then $T_{\max}=\infty$. We state our extension as Theorem 2.3.

THEOREM 2.3. *Suppose* (A1)-(A3) *and* (H1)-(H5) *hold. If there exist* $a>0$ *and* $g \in C([0,\infty))$ *such that*

$$\left|\int_\Omega (H(v(x,\cdot)))^a \, dx\right|_{\infty,(0,t)} \leqq g(t) \quad \textit{for all } 0<t<T_{\max},$$

$$r<\begin{cases} 1+2a/n, & n \geqq 2, \\ 1+a/n, & n=1, \end{cases} \tag{2.3}$$

then $T_{\max}=\infty$.

Note that assumption (H4)(i) allows the possibility of higher-order terms cancelling in "intermediate-sums." Hence, an $L^a(\Omega)$ a priori bound for the solution of (2.1) might be used more effectively in Theorem 2.3 than in Amann's result. Also, if (A1)-(A3), (H1), (H2), and (H6) hold, then (as shown in § 3) (2.3) holds with $a=1$. Consequently, Theorem 2.3 can be applied to many nontrivial systems.

Global existence results for (2.1) can also be given in terms of $L^a(Q(0,T))$ a priori bounds.

THEOREM 2.4. *Suppose* (A1)-(A3) *and* (H1)-(H5) *are satisfied. If there exist* $a>0$ *and* $g \in C([0,\infty))$ *such that*

$$\int_0^t \int_\Omega (H(v(x,s)))^a \, dx \, ds \leqq g(t) \quad \textit{for all } 0<t<T_{\max} \tag{2.4}$$

and $r<1+2a/(n+2)$, *then* $T_{\max}=\infty$.

As above, we show in § 3 that if (A1)-(A3), (H1), (H2), and (H6) hold, then (2.4) is satisfied with $a=2$. Thus, when $n=1$, quadratic upper bounds on "intermediate sums" are permitted.

3. A priori estimates. In this section, we show that solutions of (2.1) satisfy certain norm bounds if conditions (A1)-(A3), (H1)-(H3), and (H6) are satisfied. It should be noted that for a particular system, better a priori bounds might be obtainable than the ones given here, but these will at least indicate the merit of Theorems 2.2-2.4.

The following technical lemma will be useful in this section and § 5. We omit the straightforward proof.

LEMMA 3.1. *Suppose that* (A1), (A3), *and* (H1)-(H3) *are satisfied. Then there exist* $\delta=(\delta_i)$, $\sigma=(\sigma_i)\in R^m$, *and* $\xi\in\{0,1\}$ *such that* $\delta_i h_i(v_i(x,t))+\xi\,\partial(h_i(v_i(x,t)))/\partial\eta\leqq\sigma_i$ *on* $\partial\Omega\times(0,T_{\max})$ *for all* $1\leqq i\leqq m$. *Furthermore, parts* (i)-(iii) *of* (A1) *are satisfied with* δ, σ, *and* ξ *in place of* α, β, *and* γ, *respectively.*

Throughout the remainder of this section, $h_i(v_i(x,t))$, $h_i'(v_i(x,t))f_i(v(x,t))$, and $h_i(v_{i0}(x))$ will be denoted by $u_i(x,t)$, $F_i(x,t)$, and $u_{i0}(x)$, respectively.

The first result in this section yields bounds for $H(v)$ in $L^1(0,T)$.

THEOREM 3.2. *Suppose that* (A1)-(A3), (H1), (H2), *and* (H6) *are satisfied. Then there exists* $g\in C([0,\infty))$ *such that*

$$\|H(v(\cdot,\cdot))|_{1,(0,t)}|_{\infty,\Omega}\leqq g(t)\quad \textit{for all } 0<t<T_{\max}.$$

Proof. From (2.1), (H1), (H2), and (H6), we have

$$\nabla H(v(x,t))\cdot v_t(x,t)\leqq\nabla H(v(x,t))\cdot D\Delta v(x,t)+K_7H(v(x,t))+K_8$$

$$\leqq\sum_{i=1}^{m}d_i\Delta u_i(x,t)+K_7H(v(x,t))+K_8\quad\text{on } Q(0,T_{\max}).$$

Thus, if $0<\tau<T_{\max}$, then integration with respect to time yields

$$H(v(x,t))\leqq\Delta\int_\tau^t\sum_{i=1}^{m}d_iu_i(x,s)\,ds+H(v(x,\tau))+K_7\int_\tau^t H(v(x,s))\,ds \tag{3.1}$$

$$+K_8(t-\tau)\qquad\text{on } Q(\tau,T_{\max}).$$

Set $d=\max\{d_1,\cdots,d_m\}$, $M=K_7d/\min\{d_1,\cdots,d_m\}$, $L=|H(v(\cdot,\tau))|_{\infty,\Omega}$, and $w(x,t)=\int_\tau^t\sum_{i=1}^m(d_i/d)u_i(x,s)\,ds$ on $Q(\tau,T_{\max})$. Then

$$w_t(x,t)\leqq d\Delta w(x,t)+L+Mw(x,t)+K_8(t-\tau)\quad\text{on } Q(\tau,T_{\max}). \tag{3.2}$$

Referring to Lemma 3.1, set $b=\min\{\delta_1,\cdots,\delta_m\}$, $c=\xi$, and $e=\max\cdot\{\sigma_1,\cdots,\sigma_m\}$. Then

$$bw(x,t)+c\frac{\partial w(x,t)}{\partial\eta}\leqq e(t-\tau)\quad\text{on } \partial\Omega\times(\tau,T_{\max}). \tag{3.3}$$

Furthermore,

$$w(x,\tau)\equiv 0\quad\text{on } \Omega. \tag{3.4}$$

Consequently, application of the strong maximum principle for parabolic equations (see Sperb [21, § 2.3]) to (3.2)-(3.4), along with part (ii) of Theorem 2.1, implies that there exists $g\in C([0,\infty))$ such that $|w(\cdot,t)|_{\infty,\Omega}\leqq g(t)$ for all $0<t<T_{\max}$.

The next result yields $L^1(\Omega)$ a priori bounds for the solution of (2.1).

THEOREM 3.3. *Suppose that* (A1)-(A3), (H1)-(H3), *and* (H6) *are satisfied. If* $\sigma\equiv 0$ *or* $\xi\neq 0$ *in Lemma* 3.1, *then there exists* $g\in C([0,\infty))$ *such that* $|H(v(\cdot,t))|_{1,\Omega}\leqq g(t)$ *for all* $0<t<T_{\max}$.

Proof. Integrating (4.1) over Ω with $\tau = 0$, applying integration by parts, and setting $L_1 = |\Omega||H(v_0)|_{\infty,\Omega}$, we obtain

$$|H(v(\cdot, t))|_{1,\Omega} \leqq \int_0^t \int_{\partial\Omega} \sum_{i=1}^{m} d_i \frac{\partial u_i(x, s)}{\partial \eta}\, d\Sigma\, ds + L_1 + K_7 \int_0^t |H(v(\cdot, s))|_{1,\Omega}\, ds + K_8|\Omega| t \tag{3.5}$$

for all $0 < t < T_{\max}$, with $d\Sigma$ denoting the usual surface measure on $\partial\Omega$. Thus, if $\sigma \equiv 0$ or $\xi \neq 0$, then $\partial u_i(x, s)/\partial \eta \leqq \sigma_i$ for all $1 \leqq i \leqq m$ on $\partial\Omega \times (0, T_{\max})$. Hence, if we set $L_2 = \sum_{i=1}^{m} (d_i \sigma_i |\partial\Omega| + K_8|\Omega|)$, we obtain

$$|H(v(\cdot, t))|_{1,\Omega} \leqq L_2 t + L_1 + K_7 \int_0^t |H(v(\cdot, s))|_{1,\Omega}\, ds \quad \text{for all } 0 < t < T_{\max}. \tag{3.6}$$

Application of Gronwall's inequality to (3.6) proves the result.

As is mentioned in § 2, $L^2(Q(0, T))$ norm bounds are also obtainable for solutions of (2.1). We state this result as Theorem 3.4.

THEOREM 3.4. *Suppose that* (A1)-(A3), (H1)-(H3), *and* (H6) *are satisfied. If* $\sigma \equiv 0$ *or* $\xi \neq 0$ *in Lemma* 3.1, *then there exists* $g \in C([0, \infty))$ *such that* $|H(v)|_{2,Q(0,t)} \leqq g(t)$ *for all* $0 < t < T_{\max}$.

Proof. Choose $d > \max\{d_1, \cdots, d_m\}$ and $0 < \tau < T_{\max}$. For $1 \leqq i \leqq m+1$, let z_i be the solution of

$$\begin{aligned} &z_{it}(x, t) = d_i \Delta z_i(x, t) + F_i(x, t) \quad \text{on } Q(\tau, T_{\max}), \\ &\delta_i z_i(x, t) + \xi \frac{\partial z_i(x, t)}{\partial \eta} = \sigma_i \quad \text{on } \partial\Omega \times (\tau, T_{\max}), \\ &z_i(x, \tau) = L_i \quad \text{on } \Omega \end{aligned} \tag{3.7}$$

with $F_{m+1}(x, t) = K_7 H(v(x, t)) + K_8 - \nabla H(v(x, t)) \cdot f(v(x, t))$, $d_{m+1} = d_m$, $\delta_{m+1} = \delta_m$, $\sigma_{m+1} = \sigma_m$, and $L_{m+1} = L_m$, where $L_i = |u_i(\cdot, \tau)|_{\infty,\Omega}$ for all $1 \leqq i \leqq m$. Then, from the strong maximum principle for parabolic equations, we have $z_i(x, t) \geqq u_i(x, t)$ for all $1 \leqq i \leqq m$, and there exists $g_1 \in C([0, T_{\max}))$ such that $0 \leqq |z_i(\cdot, t)|_{\infty,\Omega} \leqq g_1(t)$ for all $\tau \leqq t < T_{\max}$.

Proceeding as in the proof of Theorem 3.2, set

$$w(x, t) = \int_\tau^t \sum_{i=1}^{m} \frac{d_i}{d} z_i(x, s)\, ds \quad \text{on } Q[\tau, T_{\max}),$$

$$b = \min\{\delta_1, \cdots, \delta_m\}, \quad c = \xi, \quad e = \max\{\sigma_1, \cdots, \sigma_m\}.$$

Then

$$\begin{aligned} w_t(x, t) &= d\Delta w(x, t) + \sum_{i=1}^{m+1} z_i(x, \tau) + \sum_{i=1}^{m+1} \left(\frac{d_i}{d} - 1\right) z_i(x, t) + K_7 \int_\tau^t H(v(x, s))\, ds \\ &\quad + K_8(t - \tau) \qquad \text{on } Q(\tau, T_{\max}), \\ bw(x, t) + c\frac{\partial w(x, t)}{\partial \eta} &\leqq e(t - \tau) \quad \text{on } \partial\Omega \times (\tau, T_{\max}), \\ w(x, \tau) &= 0 \quad \text{on } \Omega. \end{aligned}$$

Note that there exists $g_2 \in C([0, \infty))$ such that $|w(\cdot, t)|_{\infty,\Omega} \leqq g_2(t)$ for all $\tau < t < T_{\max}$, where g_2 satisfies the same properties as the function g given in Theorem 3.2. Similarly,

for each $1 \leqq i \leqq m$, z_i satisfies the same $L^1(\Omega)$ norm bounds as $H(v)$ in Theorem 3.3. Also, from above, for $\tau < t < T_{\max}$ and $1 \leqq i \leqq m+1$, we have

$$
\begin{aligned}
&\int_\tau^t \int_\Omega z_i \sum_{j=1}^{m+1} \left(\frac{d_j}{d} - 1\right) z_j \, dx \, ds \\
&\quad = \int_\tau^t \int_\Omega z_i \left[w_t - d\Delta w - G - K_7 \int_\tau^s H(v(x,r))\, dr \right] dx \, ds \\
&\quad = \int_\tau^t \int_\Omega \left\{ z_i \left[w_t - G - K_7 \int_\tau^s H(v(x,r))\, dr \right] - dw\, \Delta z_i \right\} dx \, ds \\
&\qquad - d \int_\tau^t \int_{\partial\Omega} \left(z_i \frac{\partial w}{\partial \eta} - w \frac{\partial z_i}{\partial \eta} \right) d\Sigma \, ds,
\end{aligned} \tag{3.8}
$$

where $G(x,t) = \sum_{i=1}^{m+1} z_i(x,\tau) + K_8(t-\tau)$ on $Q(\tau, T_{\max})$.

Now,

$$
\begin{aligned}
\int_\tau^t \int_\Omega dw\, \Delta z_i \, dx \, ds &= \int_\tau^t \int_\Omega \frac{d}{d_i} w(z_{it} - F_i)\, dx \, ds \\
&= \int_\Omega \frac{d}{d_i} w(x,t) z_i(x,t)\, dx - \int_\tau^t \int_\Omega \frac{d}{d_i} (z_i w_t + w F_i)\, dx \, ds.
\end{aligned}
$$

Making this substitution in (3.8), noting that $w_t(x,t) = \sum_{j=1}^{m+1} (d_j/d) z_j(x,t)$, and combining terms, we obtain

$$
\begin{aligned}
&\int_\tau^t \int_\Omega \left(\sum_{i=1}^{m+1} \frac{d_i}{d} z_i \right) \left(\sum_{j=1}^{m+1} \left(\frac{d_j}{d} - 1 \right) z_j \right) dx \, ds \\
&\quad = \int_\tau^t \int_\Omega \left(\sum_{i=1}^{m+1} \left(\frac{d_i}{d} + 1 \right) z_i \right) \left(\sum_{j=1}^{m+1} \frac{d_j}{d} z_j \right) dx \, ds \\
&\qquad - \int_\Omega w(x,t) \sum_{i=1}^{m+1} z_i(x,t)\, dx \\
&\qquad - \int_\tau^t \int_\Omega \sum_{i=1}^{m+1} \frac{d_i}{d} z_i \left[G + K_7 \int_\tau^t H(v(x,r))\, dr \right] dx \, ds \\
&\qquad + \int_\tau^t \int_\Omega w(K_7 H(v) + K_8)\, dx \, ds \\
&\qquad - \int_\tau^t \int_{\partial\Omega} \sum_{i=1}^{m+1} d_i \left[z_i \frac{\partial w}{\partial \eta} - w \frac{\partial z_i}{\partial \eta} \right] d\Sigma \, ds.
\end{aligned}
$$

Thus,

$$
\begin{aligned}
2 \int_\tau^t \int_\Omega \sum_{i=1}^{m+1} \frac{d_i}{d} (z_i)^2 \, dx \, ds &= \int_\Omega w(x,t) \sum_{i=1}^{m+1} z_i(x,t)\, dx - \int_\tau^t \int_\Omega w(K_7 H(v) + K_8)\, dx \, ds \\
&\quad + \int_\tau^t \int_\Omega \sum_{i=1}^{m+1} \frac{d_i}{d} z_i \left[G + K_7 \int_\tau^t H(v(x,r))\, dr \right] dx \, ds \\
&\quad + \int_\tau^t \int_{\partial\Omega} \sum_{i=1}^{m+1} d_i \left[z_i \frac{\partial w}{\partial \eta} - w \frac{\partial z_i}{\partial \eta} \right] d\Sigma \, ds.
\end{aligned} \tag{3.9}
$$

If $\delta \equiv \xi = 0$, then the fourth term on the right-hand side of (3.9) is identically zero. If $\xi \neq 0$, then the fourth term on the right-hand side of (3.9) can be bounded above by $\int_\tau^t \int_{\partial\Omega} d_i z_i(e+\delta_i w)\, d\Sigma\, ds$. Thus, if we apply Hölder's inequality and Theorems 3.2 and 3.3 to the right-hand side of (3.9), then the result follows.

4. Proofs of global existence results. Throughout this section, we assume that (A1)-(A3) and (H1)-(H5) hold. Suppose $v(x, t)$ solves (2.1) on $\mathrm{cl}(\Omega)\times[0, T_{\max})$, $0 \leqq \tau < T < T_{\max}$, and δ, σ, and ξ are given by Lemma 3.1. Furthermore, suppose $1 < p < \infty$, $\theta \in L^p(Q(\tau, T))$ satisfies $|\theta|_{p,Q(\tau,T)} = 1$ and $\theta \geqq 0$, and for $1 \leqq i \leqq m$, Ψ_i is the solution of

$$
\begin{aligned}
&\Psi_{it}(x, t) = -d_i \Delta \Psi_i(x, t) - \theta(x, t) && \text{on } Q[\tau, T),\\
&b_1 \Psi_i(x, t) + \xi \partial \Psi_i(x, t)/\partial\eta = 0 && \text{on } \partial\Omega \times [\tau, T),\\
&\Psi_i(x, T) = 0 && \text{on } \Omega,
\end{aligned} \tag{4.1}
$$

where $b_1 = \min\{\delta_1, \cdots, \delta_m\}$.

Note that if $w_i(x, t) = \Psi_i(x, T-t)$ on $\mathrm{cl}(\Omega)\times[0, T-\tau]$, then

$$
\begin{aligned}
&w_{it}(x, t) = d_i \Delta w_i(x, t) + \theta(x, T-t) && \text{on } Q(0, T-\tau],\\
&b_1 w_i(x, t) + \xi \partial w_i(x, t)/\partial\eta = 0 && \text{on } \partial\Omega \times (0, T-\tau],\\
&w_i(x, 0) = 0 && \text{on } \Omega.
\end{aligned} \tag{4.2}
$$

Thus, the well-known results (cf. Ladyzenskaja, Solonnikov, and Uralceva [13, Thm. 9.1, p. 341]) and basic maximum principles imply that $\Psi_i \in W^{2,1,p}(Q(\tau, T))$ and $\Psi_i \geqq 0$. Furthermore, we have the following important lemma.

LEMMA 4.1. *For all $1 < p < \infty$ and $1 \leqq i, j \leqq m$, there exists $C_{p(T-\tau)} > 0$ (independent of θ) such that*

(i) $|\Psi_i(\tau)|_{p,\Omega}, |\Psi_i|^{(2)}_{p,Q(\tau,T)} \leqq C_{p(T-\tau)}$,

(ii) $$\int_\tau^T \int_{\partial\Omega} \left[\Psi_j(x, t) \frac{\partial(h_i(v_i(x, t)))}{\partial\eta} - h_i(v_i(x, t)) \frac{\partial \Psi_j(x, t)}{\partial\eta} \right] d\Sigma\, ds \leqq C_{p(T-\tau)}.$$

Furthermore, if $1 < p < (n+2)/2$ and $q = p(n+2)/(n+2-2p)$ then there exists $K_{q(T-\tau)}$ such that

(iii) $|\Psi_i|_{q,Q(\tau,T)} \leqq K_{q(T-\tau)}$.

Proof. Parts (i) and (iii) follow immediately from (4.1), (4.2), [13, Thm. 9.1, p. 341], and [10, Lemma 2, p. 750]. For part (ii), note that we have $\xi \in \{0, 1\}$. Let $C_{p(T-\tau)}$ be given to satisfy part (i). If $\xi = 1$, then

$$
\begin{aligned}
\int_\tau^T \int_{\partial\Omega} \left[\Psi_i \frac{\partial(h_i(v_i))}{\partial\eta} - h_i(v_i) \frac{\partial \Psi_j}{\partial\eta} \right] d\Sigma\, ds &\leqq \int_\tau^T \int_{\partial\Omega} (\Psi_j(\sigma_i - \delta_i h_i(v_i)) + b_1 h_i(v_i))\, d\Sigma\, ds\\
&\leqq \int_\tau^T \int_{\partial\Omega} \sigma_i \Psi_j\, d\Sigma\, ds\\
&\leqq \sigma_i |\partial\Omega|^{(p-1)/p} \int_\tau^T |\Psi(\cdot, s)|_{p,\partial\Omega}\, ds\\
&\leqq \sigma_i |\partial\Omega|^{(p-1)/p} \int_\tau^T L_p |\Psi_j(\cdot, s)|_{2,p,\Omega}\, ds\\
&\leqq \sigma_i |\partial\Omega|^{(p-1)/p} L_p C_{p(T-\tau)} (T-\tau)^{(p-1)/p},
\end{aligned}
$$

from the definition of b_1, part (i), Hölder's inequality, and the Trace Class Imbedding Theorem (cf. Grisvard [7, Chap. 1, Thm. 1.5.1.2]).

Similarly, if $\xi = 0$, then $\delta_i = 1$ for all $1 \leqq i \leqq m$. Thus, $\Psi_j \equiv 0$ and $\partial \Psi_j / \partial \eta \leqq 0$ on $\partial\Omega \times (\tau, T)$, for all $1 \leqq j \leqq m$. Therefore,

$$\int_\tau^T \int_{\partial\Omega} \left[\Psi_j \frac{\partial (h_i(v_i))}{\partial \eta} - h_i(v_i) \frac{\partial \Psi_j}{\partial \eta} \right] d\Sigma \, ds \leqq \int_\tau^T \int_{\partial\Omega} \sigma_i \left| \frac{\partial \Psi_j}{\partial \eta} \right| d\Sigma \, ds \leqq M_{p(T-\tau)}$$

as above. The result follows.

The following lemma is fundamental to all of the results in this section.

LEMMA 4.2. *Suppose that for all* $1 \leqq j \leqq m$, (H4)(ii) *holds. Then* $T_{\max} = \infty$.

Proof. Suppose (by way of contradiction) that $T_{\max} < \infty$. Consequently, by hypothesis, for all $1 \leqq p < \infty$ there exist M_p, $N_p > 0$, and $0 < \delta_p < 1$ such that

$$|H(v)|_{p,Q(\tau,T)} \leqq M_p + N_p |H(v)|^{\delta_p}_{p,Q(\tau,T)}. \tag{4.3}$$

Thus, $|H(v)|_{p,Q(\tau,T)} < \infty$ for all $1 \leqq p < \infty$. It then follows that

$$|K_5(H(v))^{q_1} + K_6|_{p,Q(\tau,T)} < \infty \quad \text{for all } 1 \leqq p < \infty, \tag{4.4}$$

where K_5, K_6, and q_1 are given in (H5). Now, let $1 \leqq j \leqq m$, set $w = h_j(v_j)$, and suppose $M = |H(v_0)|_{\infty,\Omega}$. Then from the convexity of h_j, Lemma 3.1, and standard maximum principles we have $w \leqq z$, where z solves

$$\begin{aligned} &z_t = d_j \Delta z + K_5 (H(v))^{q_1} + K_6 \quad \text{on } \Omega \times (0, T_{\max}), \\ &\delta_j z + \xi \frac{\partial z}{\partial \eta} = \sigma_j \quad \text{on } \partial\Omega \times (0, T_{\max}), \\ &z = M \quad \text{on } \Omega \times \{0\}. \end{aligned} \tag{4.5}$$

Furthermore, from [13, Thm. 9.1, p. 341] and the Sobolev Imbedding Theorem we have the existence of $\bar{M} > 0$ such that $|z(\cdot, t)|_{\infty,\Omega} < \bar{M}$ for all $0 \leqq t < T_{\max}$. That is, $|h_i(v_i(\cdot, t))|_{\infty,\Omega} < \bar{M}$ for all $0 \leqq t < T_{\max}$. Hence, from (H3), there exists $N > 0$ such that $|v_j(\cdot, t)|_{\infty,\Omega} < N$ for all $0 \leqq t < T_{\max}$ and $1 \leqq j \leqq m$. This contradicts (via Theorem 2.1) our assumption that $T_{\max} < \infty$, and therefore $T_{\max} = \infty$.

Throughout the remainder of this section, we will denote $h_i(v_i(x, t))$, $h_i'(v_i(x, t)) f_i(v(x, t))$, and $h_i(v_{i0}(x))$ by $u_i(x, t)$, $F_i(x, t)$, and $u_{i0}(x)$, respectively.

Proof of Theorem 2.2. Suppose there exists $1 \leqq j \leqq m$ such that u_j does not satisfy (H4)(ii), and if $1 \leqq i \leqq m$ such that $i < j$, then u_i satisfies (H4)(ii). Then (H4)(i) is satisfied for j.

Let $\tau = 0$ in (4.1). Then for $i \leqq j$,

$$\begin{aligned} \int_0^T \int_\Omega u_i \theta \, dx \, ds &= \int_0^T \int_\Omega u_i (-\Psi_{jt} - d_j \Delta \Psi_j) \, dx \, ds \\ &\leqq -\int_0^T \int_\Omega u_i \Psi_{jt} \, dx \, ds - \frac{d_j}{d_i} \int_0^T \int_\Omega \Psi_j d_i \Delta u_i \, dx \, ds \\ &\quad + C_{pT} \quad \text{from Lemma 4.1.} \end{aligned} \tag{4.6}$$

Now, from (H2) and (2.1),

$$\begin{aligned} -\int_0^T \int_\Omega \Psi_j \, d_i \Delta u_i \, dx \, ds &\leqq \int_0^T \int_\Omega \Psi_j (F_i - u_{it}) \, dx \, ds \\ &= \int_0^T \int_\Omega (\Psi_j F_i + u_i \Psi_{jt}) \, dx \, ds + \int_\Omega \Psi_j(x, 0) u_{i0}(x) \, dx. \end{aligned} \tag{4.7}$$

Making this substitution in (4.6) yields

$$\int_0^T \int_\Omega u_i\theta \, dx \, ds \leqq \left(\frac{d_j}{d_i}-1\right) \int_0^T \int_\Omega u_i \Psi_{jt} \, dx \, ds + \frac{d_j}{d_i}\left(\int_0^T \int_\Omega \Psi_j F_i \, dx \, ds + \int_\Omega \Psi(x,0) u_{i0}(x) \, dx\right) + C_{pT}. \tag{4.8}$$

Consequently, if we apply (H4)(i), then

$$\int_0^T \int_\Omega \sum_{i=1}^{j} \frac{d_i}{d_j} a_{ji} u_i \theta \, dx \, ds \leqq \sum_{i=1}^{j-1} a_{ji}\left(1-\frac{d_i}{d_j}\right) \int_0^T \int_\Omega u_i \Psi_{jt} \, dx \, ds + \int_0^T \int_\Omega \Psi_j [K_1 (H(v))^r + K_2] \, dx \, ds + \sum_{i=1}^{j} a_{ji}\left[\int_\Omega \Psi_j(x,0) u_{i0}(x) \, dx + \frac{d_i}{d_j} C_{pT}\right]. \tag{4.9}$$

Now, if we apply Hölder's inequality, Lemma 4.1, and (H4)(ii) for $i<j$ to the first term on the right-hand side of (4.9), then

$$\sum_{i=1}^{j-1} a_{ji}\left(1-\frac{d_i}{d_j}\right) \int_0^T \int_\Omega u_i \Psi_{jt} \, dx \, ds \leqq \sum_{i=1}^{j-1} a_{ji} \left|1-\frac{d_i}{d_j}\right| C_{pT}(K_{3q}(T) + K_{4q}(T)|H(v)|^{\delta q}_{q,Q(0,T)}), \tag{4.10}$$

where $1/p+1/q=1$.

Note that from Lemma 4.1, $|\Psi_{jt}(x,\cdot)|_{p,(0,T)}$ exists for almost all $x \in \Omega$. Thus, if we apply the Sobolev Imbedding Theorem, then there exists $L_{pT}>0$ such that

$$|\Psi_j(x,\cdot)|_{\infty,(0,T)} < L_{pT} |\Psi_j(x,\cdot)|_{1,p,(0,T)} \quad \text{for almost all } x \in \Omega. \tag{4.11}$$

Hence,

$$||\Psi_j(x,\cdot)|_{\infty,(0,T)}|_{p,\Omega} \leqq L_{pT} |\Psi_j|^{(2)}_{p,Q(0,T)} \leqq L_{pT} C_{pT} \quad \text{from Lemma 4.1.} \tag{4.12}$$

So, applying Hölder's inequality and (4.12), we have

$$\begin{aligned} \int_0^T \int_\Omega \Psi_j (H(v))^r \, dx \, ds &= \int_\Omega \int_0^T \Psi_j (H(v))^r \, ds \, dx \\ &\leqq \int_\Omega |\Psi_j(x,\cdot)|_{\infty,(0,T)} \int_0^T (H(v))^r \, ds \, dx \\ &\leqq ||\Psi_j(\cdot,\cdot)|_{\infty,(0,T)}|_{p,\Omega} \left| \int_0^T (H(v(\cdot,s)))^r \, ds \right|_{q,\Omega} \\ &\leqq L_{pT} C_{pT} \left| \int_0^T (H(v(\cdot,s)))^r \, ds \right|_{q,\Omega}. \end{aligned} \tag{4.13}$$

Without loss of generality, assume $r>0$. If $r \leqq a$, then

$$\left| \int_0^T (H(v(\cdot,s)))^r \, ds \right|_{q,\Omega} \leqq |\Omega|^{1/q} T^{(a-r)/a} (g(T))^{r/a}. \tag{4.14}$$

Now suppose $a<r<1+a$. If p is sufficiently close to 1 and $k=a[p-r(p-1)]/[p-a(p-1)]$, then $a/k>1$, $a(r-k)/(a-k)=p/(p-1)$, and $p(a-k)/[a(p-1)]<1$. Thus,

$$\left|\int_0^T (H(v(\cdot,s)))^r\,ds\right|_{q,\Omega} = \left|\int_0^T (H(v(\cdot,s)))^{r-k}(H(v(\cdot,s)))^k\,ds\right|_{q,\Omega} \leqq (g(T))^{k/a}|H(v)|^{p(a-k)/a(p-1)}_{q,Q(0,T)}|\Omega|^{(pk-a)/ap}. \tag{4.15}$$

If we now apply (4.10)-(4.15) and Lemma 4.1 to the right-hand side of (4.9), then

$$\begin{aligned}\int_0^T\int_\Omega \sum_{i=1}^{j} a_{ji}\frac{d_i}{d_j}u_i\theta\,dx\,ds &\leqq \sum_{i=1}^{j-1} a_{ji}\left|1-\frac{d_i}{d_j}\right| C_{pT}(K_{3q}(T)+K_{4q}(T)|H(v)|^{\delta q}_{q,Q(0,T)}) \\ &\quad + K_1L_{pT}C_{pT}[|\Omega|^{1/q}T^{(a-r)/a}g(T) \\ &\qquad + |\Omega|^{(pk-a)/ap}(g(T))^{k/a}|H(v)|^{p(a-k)/a(p-1)}_{q,Q(0,T)}] \\ &\quad + \sum_{i=1}^{j} a_{ji}C_{pT}\left[|u_{i0}|_{q,Q(0,T)}+\frac{d_i}{d_j}\right].\end{aligned} \tag{4.16}$$

Then, since $0<\delta_q$, $p(a-k)/a(p-1)<1$, we see that there exist K_{7q}, $K_{8q}\in C([0,\infty))$ and $0<\varepsilon_q<1$ for all q sufficiently large such that

$$|u_i|_{q,Q(0,T)} \leqq K_{7q}(T)+K_{8q}(T)|H(v)|^{\varepsilon_q}_{q,Q(0,T)} \quad \text{for all } 0<T<T_{\max}. \tag{4.17}$$

It follows that (H4)(ii) holds for j. Therefore we have a contradiction, and hence (H4)(ii) is satisfied for all $1\leqq i\leqq m$. Consequently, the result follows from Lemma 4.2.

Proof of Theorem 2.3. As in the proof of Theorem 2.2, suppose there exists $1\leqq j\leqq m$ such that (H4)(ii) is not satisfied for j, and if $1\leqq i\leqq m$ such that $i<j$, then (H4)(ii) is satisfied for i. Then (H4)(i) is satisfied for j. Setting $\tau=0$ in (4.1), we see that (4.6)-(4.10) are satisfied.

Case 1. Suppose $n\geqq 3$. Note that if $p>1$, then $|\Psi_j(\cdot,s)|_{2,p,\Omega}$ exists for almost all $0<s<T$. Also, if $1<p<n/2$, then the Sobolev Imbedding Theorem implies that there exists $M_p>0$ such that if $q=pn/(n-2p)$, then $|\Psi_j(\cdot,s)|_{q,\Omega}\leqq M_p|\Psi_j(\cdot,s)|_{2,p,\Omega}$ for almost all $0<s<T$. Thus,

$$\left(\int_0^T |\Psi_j(\cdot,s)|^p_{q,\Omega}\,ds\right)^{1/p} \leqq M_p\left(\int_0^T |\Psi_j(\cdot,s)|^p_{2,p,\Omega}\,ds\right)^{1/p} \leqq M_pC_{pT}. \tag{4.18}$$

Consequently,

$$\begin{aligned}&\int_0^T\int_\Omega \Psi_j(H(v))^r\,dx\,ds \\ &\quad \leqq \int_0^T\left(\int_\Omega (\Psi_j)^q\,dx\right)^{1/q}\left(\int_\Omega (H(v))^{rpn/((p-1)n+2p)}\,dx\right)^{(p-1)/p+2/n} ds \\ &\quad \leqq \left(\int_0^T |\Psi_j(\cdot,s)|^p_{p,\Omega}\,ds\right)^{1/p} \\ &\qquad \times\left(\int_0^T\left(\int_\Omega (H(v))^{rpn/((p-1)n+2p)}\,dx\right)^{1+(2p/n(p-1))} ds\right)^{(p-1/p)} \\ &\quad \leqq M_pC_{pT}\left(\int_0^T\left(\int_\Omega (H(v))^{rpn/((p-1)n+2p)}\,dx\right)^{1+(2p/n(p-1))} ds\right)^{(p-1/p)}.\end{aligned} \tag{4.19}$$

Note that for $p>1$, $rpn/((p-1)n+2p)<rn/2$. Hence, if $0<r\leqq 2a/n$, then $rn/2\leqq a$, and there exists $\varepsilon_{pn}>0$ such that

$$\int_0^T\int_\Omega \Psi_j(H(v))^r\,dx\,ds \leqq M_pC_{pT}|\Omega|^{\varepsilon_p}\left(\int_0^T (g(s))^{1+2p/n(p-1)}\,ds\right)^{(p-1)/p}. \tag{4.20}$$

So, suppose $2a/n<r<1+2a/n$. Then for $p>1$ and sufficiently close to 1, if $k=ap[n(p-1)(1-r)+2p]/[p(1-a)+a][(p-1)n+2p]$, then $0<k<a$, $(rpn/((p-1)n+2p)-k)(a/(a-k))=(p/p-1)$, and $(1+2p/(n(p-1)))(a-k)/a<1$. Hence,

$$\begin{aligned}
&\left(\int_0^T\left(\int_\Omega (H(v))^{rpn/((p-1)n+2p)}\,dx\right)^{1+2p/(n(p-1))}ds\right)^{(p-1)/p}\\
&\quad=\left(\int_0^T\left(\int_\Omega (H(v))^{rpn/((p-1)n+2p)-k}(H(v))^k\,dx\right)^{1+2p/(n(p-1))}ds\right)^{(p-1)/p}.\\
&\quad\leqq\left(\int_0^T\left(\int_\Omega (H(v))^{p/(p-1)}\,dx\right)^{(1+2p/(n(p-1)))(a-k)/a}\right.\\
&\qquad\left.\times\left(\int_\Omega (H(v))^a\,dx\right)^{(1+2p/(n(p-1)))k/a}ds\right)^{(p-1)/p}\\
&\quad\leqq |g|_{\infty,(0,T)}^{(1+2p/(n(p-1)))(k(p-1)/(ap))}T^{(kn(p-1)+2p(k-a))/(anp)}|H(v)|_{p/(p-1),Q(0,T)}^{(1+2p/(n(p-1)))(a-k)/a}.
\end{aligned}\tag{4.21}$$

Then, as in the proof of Theorem 2.2, (4.10), (4.19), (4.20), and (4.21) combined with (4.9) imply that (H4)(ii) holds for j. Thus, we have a contradiction, and (H4)(ii) holds for all $1\leqq i\leqq m$. Consequently, the result follows from Lemma 4.2.

Case 2. Suppose $n\leqq 2$. As in Case 1, if $p>1$, then $|\Psi_j(\cdot,s)|_{2,p,\Omega}$ exists for almost all $0<s<T$. Then (from the Sobolev Imbedding Theorem) there exists $M_p>0$ such that $|\Psi_j(\cdot,s)|_{\infty,\Omega}\leqq M_p|\Psi_j(\cdot,s)|_{2,p,\Omega}$ for almost all $0<s<T$. Consequently,

$$\left(\int_0^T |\Psi_j(\cdot,s)|_{\infty,\Omega}^p\,ds\right)^{1/p}\leqq M_p\left(\int_0^T |\Psi_j(\cdot,s)|_{2,p,\Omega}^p\,ds\right)^{1/p}\leqq M_pC_{pT}. \tag{4.22}$$

Then, as in Case 1, we have

$$\begin{aligned}
&\int_0^T\int_\Omega \Psi_j(H(v))^r\,dx\,ds\\
&\quad\leqq\int_0^T |\Psi_j(\cdot,s)|_{\infty,\Omega}\int_\Omega (H(v))^r\,dx\,ds\\
&\quad\leqq\left(\int_0^T |\Psi_j(\cdot,s)|_{\infty,\Omega}^p\,ds\right)^{1/p}\left(\int_0^T\left(\int_\Omega (H(v))^r\,dx\right)^{p/(p-1)}ds\right)^{(p-1)/p}\\
&\quad\leqq M_pC_{pT}\left(\int_0^T\left(\int_\Omega (H(v))^r\,dx\right)^{p/(p-1)}ds\right)^{(p-1)/p}.
\end{aligned}\tag{4.23}$$

Now, if $r\leqq a$, then there exists $\delta_r\geqq 0$ such that

$$\left(\int_0^T\left(\int_\Omega (H(v))^r\,dx\right)^{p/(p-1)}ds\right)^{(p-1)/p}\leqq|\Omega|^{\delta_r}\left(\int_0^T (g(s))^{(p-1)r/pa}\,ds\right)^{(p-1)/p}. \tag{4.24}$$

If $a<r<1+a$ and $p>1$ is sufficiently close to 1, then setting $k=a[r(p-1)-p]/(a(p-1)-p)$ implies $a/k>1$, $(a-k)p/(a(p-1))<1$, and $a(r-k)/$

$(a-k)=p/(p-1)$. Hence,

$$\begin{aligned}
&\left(\int_0^T\left(\int_\Omega (H(v))^r\,dx\right)^{p/(p-1)}ds\right)^{(p-1)/p}\\
&\quad=\left(\int_0^T\left(\int_\Omega (H(v))^{r-k}(H(v))^k\,dx\right)^{p/(p-1)}ds\right)^{(p-1)/p}\\
&\quad\leqq\left(\int_0^T\left(\int_\Omega (H(v))^{p/(p-1)}\,dx\right)^{(a-k)p/(a(p-1))}\left(\int_\Omega (H(v))^a\,dx\right)^{kp/(a(p-1))}ds\right)^{(p-1)/p}\\
&\quad\leqq |g|_{\infty,(0,T)}^{k/a}T^{(kp-a)/ap}|H(v)|_{p/(p-1),Q(0,T)}^{(a-k)p/(a(p-1))}.
\end{aligned}\tag{4.25}$$

We can now combine (4.9), (4.10), and (4.23)-(4.25) to show that (H4)(ii) holds for j. Thus, we have a contradiction, and therefore (H4)(ii) holds for all $1\leqq i\leqq m$. Thus, from Lemma 4.2, the result follows.

Proof of Theorem 2.4. As in the proof of Theorem 2.2, suppose there exists $1\leqq j\leqq m$ such that u_j does not satisfy (H4)(ii), and if $1\leqq i\leqq m$ such that $i<j$, then u_i satisfies (H4)(ii). Then (H4)(i) is satisfied for j. Setting $\tau=0$ in (4.1), we see that (4.5)-(4.10) are satisfied. Also, note that from Lemma 4.1, if

$$1<p<\frac{n+2}{2},\qquad q=\frac{p(n+2)}{n+2-2p},$$

then

$$|\Psi_j|_{q,Q(0,T)}\leqq K_{qT}.\tag{4.26}$$

Thus,

$$\begin{aligned}
&\int_0^T\int_\Omega \Psi_j(H(v))^r\,dx\,ds\\
&\quad\leqq |\Psi_j|_{q,Q(0,T)}\left(\int_0^T\int_\Omega (H(v))^{rp(n+2)/((p-1)(n+2)+2p)}\,dx\,ds\right)^{(p-1)/p+2/(n+2)}\\
&\quad\leqq K_{qT}\left(\int_0^T\int_\Omega (H(v))^{rp(n+2)/((p-1)(n+2)+2p)}\,dx\,ds\right)^{(p-1)/p+2/(n+2)}.
\end{aligned}\tag{4.27}$$

Clearly, $p(n+2)/((p-1)(n+2)+2p)<(n+2)/2$. So, if $r\leqq 2a/(n+2)$, then $rp(n+2)/((p-1)(n+2)+2p)<a$. Consequently,

$$\begin{aligned}
&\left(\int_0^T\int_\Omega (H(v))^{rp(n+2)/((p-1)(n+2)+2p)}\,dx\,ds\right)^{(p-1)/p+2/(n+2)}\\
&\qquad\leqq T^{1-rp(n+2)/(a[(p-1)(n+2)+2p])}|H(v)|_{a,Q(0,T)}^{r/a}.
\end{aligned}\tag{4.28}$$

Now, suppose $2a/(n+2)<r<1+2a/(n+2)$. If p is sufficiently close to 1 and we set

$$k=\frac{ap[(p-1)(n+2)+2p]-arp(p-1)(n+2)}{[p-a(p-1)][(p-1)(n+2)+2p]},$$

then $a/k>1$, $(rp(n+2)/((p-1)(n+2)+2p)-k)a/(a-k)=p/(p-1)$, and $((p-1)/p$

$+2/(n+2))(a-k)/a<(p-1)/p$. Hence, there exists $0<\delta_q<1$ such that

$$\left(\int_0^T\int_\Omega (H(v))^{rp(n+2)/((p-1)(n+2)+2p)}\,dx\,ds\right)^{(p-1)/p+2/(n+2)}$$

$$=\left(\int_0^T\int_\Omega (H(v))^{rp(n+2)/((p-1)(n+2)+2p)-k}(H(v))^k\,dx\,ds\right)^{(p-1)/p+2/(n+2)} \tag{4.29}$$

$$\leqq (g(T))^{(k/a)((p-1)/p+2/(n+2))}|H(v)|^{\delta_q}_{q,Q(0,T)}.$$

Then, as in the proof of Theorem 2.2, combining (4.9), (4.10), and (4.27)-(4.29), we see that (H4)(ii) holds for j. This is a contradiction, and therefore (H4)(ii) holds for all $1\leqq i\leqq m$. Therefore, from Lemma 4.2, the result follows.

5. Applications. In this section we show that if (2.1) is a system modeling reaction-diffusion, then conditions (H1)-(H3) and (H6) generalize a "dissipativity condition" used by Groger [8] that requires a function closely related to the dissipation rate of the chemical reactions to be nonnegative. We also use Theorem 2.2 to analyze specific systems modeling certain reaction-diffusion and nerve conduction problems.

Assume that (2.1) is a system modeling reaction-diffusion and $v(x,t)$ solves (2.1). The dissipativity condition considered by Groger can be stated as follows.

There exist $a\in P^m$ and $g\in C(P^m,R)$ such that

$$\lim_{|z|\to\infty} g(z)/|z|=0, \text{ and for all } z\in P^m,\ -\sum_{i=1}^m f_i(z)\ln(z_i/a_i)+g(z)\geqq 0, \tag{5.1}$$

where, as noted by Groger, $-\sum_{i=1}^m f_i(v(x,t))\ln(v_i(x,t)/a_i)$ can be interpreted as a suitably scaled dissipation rate of the chemical reactions.

Now, suppose that P^m is invariant for (2.1), $a\in P^m$, and $H:P^m\to R$ is defined by $H(z)=\sum_{i=1}^m h_i(z_i)$, where $h_i(z_i)=z_i\ln(z_i/a_i)-z_i+a_i$. Then simple calculation shows that h_i, $h_i''\geqq 0$ on P^m, and $H(z)\to\infty$ if and only if $|z|\to\infty$ in P^m. Furthermore, from (5.1) and the definition of H, there exist M, $N>0$ such that $g(z)\leqq M\sum_{i=1}^m z_i+N$ and $H(z)+(\exp(1)-1)\sum_{i=1}^m a_i\geqq\sum_{i=1}^m z_i$ for all $z\in P^m$. Thus, $-\sum_{i=1}^m f_i(z)\ln(z_i/a_i)+g(z)\geqq 0\Leftrightarrow\sum_{i=1}^m h_i'(z_i)f_i(z)\leqq g(z)\Rightarrow\sum_{i=1}^m h_i'(z_i)f_i(z)\leqq MH(z)+M(\exp(1)-1)\sum_{i=1}^m a_i+N$ for all $z\in P^m$. That is, H satisfies (H1)-(H3) and (H6). Consequently, (H1)-(H3) and (H6) are a generalization of Groger's dissipativity condition. Hence, from the theory of Horn, Feinberg, and Jackson [5], [11], [12], on mass-action kinetics, it follows that many systems of practical interest satisfy these assumptions. Also, the a priori bounds obtained in § 3 apply to these systems.

There are also several model systems that satisfy (H1)-(H6). Before giving a few of these, we state the following theorem, whose proof can be found in [15].

THEOREM 5.1. *If for all* $1\leqq i\leqq m$, f_i *satisfies* $f_i(z)\geqq 0$ *whenever* $z\in\mathrm{cl}(\mathbf{P}^m)$ *and* $z_i=0$ *and* (A3) *holds with* $\mathbf{I}=\mathrm{cl}(P^m)$, *then* (2.1) *is invariant on* $\mathrm{cl}(\mathbf{P}^m)$.

5.1. Model systems. (I) The Brusselator is described in Prigogine and Nicolis [18] and models a simple reaction-diffusion system. The equations are given by

$$\begin{aligned}
&u_t(x,t)=d_1\Delta u(x,t)+Fv-v^2(x,t)u(x,t), \quad x\in\Omega, \quad t>0,\\
&v_t(x,t)=d_2\Delta v(x,t)+E-(F+1)v(x,t)+v^2(x,t)u(x,t), \quad x\in\Omega, \quad t>0,\\
&B(u(x,t),v(x,t))=\gamma, \quad x\in\partial\Omega, \quad t>0,\\
&(u(x,0),v(x,0))=(u_0(x),v_0(x)), \qquad x\in\Omega,
\end{aligned} \tag{5.2}$$

where d_1, d_2, E, $F>0$, and u_0, $v_0 \in L^\infty(\Omega, [0,\infty))$. If we denote $f_1(u,v) = Kv - v^2u$ and $f_2(u,v) = L-(K+1)v+v^2u$, then clearly Theorems 2.1 and 5.1 are satisfied. Hence, (5.2) is invariant on cl $(\mathbf{P}^2)$, and if $H(u,v) = u+v$, then (H1)-(H6) hold with $A = \left(\begin{smallmatrix}1 & 0\\ 1 & 1\end{smallmatrix}\right)$, $r=1$, $K_1 = F$, $K_2 = 0$, $K_5 = F+1$, $K_6 = E$, $q_1 = 3$, $K_7 = 0$, and $K_8 = E$. Thus, from Theorems 3.2 and 2.2, $T_{\max} = \infty$.

We note that Hollis, Martin, and Pierre [10] show u and v to be uniformly bounded independently of α, β, and γ, as long as (A1) and (A3) are satisfied. Still, this example illustrates the ease with which our main results can be applied.

(II) Rothe [19, p. 157] considers the system

$$\begin{cases} u_t(x,t) = d_1\Delta u(x,t) + w(x,t) - u(x,t)v(x,t), \\ v_t(x,t) = d_2\Delta v(x,t) + w(x,t) - u(x,t)v(x,t), & x\in\Omega, \quad t>0, \\ w_t(x,t) = d_3\Delta w(x,t) + u(x,t)v(x,t) - w(x,t), \\ \begin{cases} B(u(x,t), v(x,t)) = \gamma, & x\in\partial\Omega, \quad t>0, \\ (u(x,0), v(x,0), w(x,0)) = (u_0(x), v_0(x), w_0(x)), & x\in\Omega \end{cases} \end{cases} \tag{5.3}$$

as a model for the reaction

$$U + V \rightleftarrows W, \tag{5.4}$$

where u, v, and w are the concentrations of U, V, and W, respectively, reacting according to (5.4) with diffusion rates d_1, d_2, $d_3>0$, and initial concentrations u_0, v_0, $w_0 \in L^\infty(\Omega, [0,\infty))$. For the case of Neumann boundary conditions, Rothe [19] shows that $T_{\max} = \infty$ if $n \leqq 5$.

Suppose n is arbitrary, $f_1(u,v,w) = f_2(u,v,w) = w - uv$, and $f_3(u,v,w) = uv - w$. Then Theorems 2.1 and 5.1 are satisfied, and (5.3) is invariant on cl $(\mathbf{P}^3)$. Also, if $H(u,v,w) = u+v+2w$, then (H1)-(H6) hold with

$$A = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ 1 & 1 & 2 \end{pmatrix},$$

$r=1$, $K_1=1$, $K_2=0$, $K_5=1$, $K_6=0$, $q_1=2$, and $K_7 = K_8 = 0$. Thus, from Theorems 3.2 and 2.2 we have $T_{\max} = \infty$.

(III) Lasry [14] considers the following system as a model to study the properties of nerve conduction:

$$\begin{aligned} &u_t(x,t) = d_1\Delta u(x,t) + K(1-\rho(x,t))u(x,t) - g(\beta(x,t))v(x,t), && x\in\Omega, \quad t>0, \\ &v_t(x,t) = d_2\Delta v(x,t) + g(\beta(x,t))u(x,t) + K(1-\rho(x,t))v(x,t), && x\in\Omega, \quad t>0, \\ &B(u(x,t), v(x,t)) = \gamma, && x\in\partial\Omega, \quad t>0, \\ &(u(x,0), v(x,0)) = (u_0(x), v_0(x)), && x\in\Omega. \end{aligned} \tag{5.5}$$

Here, d_1, $d_2>0$, u_0, $v_0 \in L^\infty(\Omega, R)$, (ρ, β) are polar coordinates for (u,v), $K>0$, and g is a smooth 2π periodic function. Note that although β and hence g are undefined when $\rho = 0$, ug and vg can be defined to be zero when $u = v = 0$. Hence, if $f_1(u,v) = K(1-\rho)u - g(\beta)v$ and $f_2(u,v) = g(\beta)u + K(1-\rho)v$, then f_1 and f_2 are locally Lipschitz. Consequently, Theorem 2.1 holds, and if $H(u,v) = u^2+v^2$ for all $(u,v)\in P^2$, then (H1)-(H6) are satisfied with $A = \left(\begin{smallmatrix}1 & 0\\ 1 & 1\end{smallmatrix}\right)$, $r=1$, $K_1 = 4(K + |g|_{\infty,[0,2\pi]})$, $K_2 = 0$, $K_5 = 8(K+|g|_{\infty,[0,2\pi]})$, $q_1 = 3$, $K_6 = 0$, $K_7 = K$, and $K_8 = 0$. Hence, from Theorems 3.2 and 2.2, we have $T_{\max} = \infty$.

BIFURCATION OF HOMOCLINIC ORBITS AND BIFURCATION FROM THE ESSENTIAL SPECTRUM*

C. A. STUART†

Abstract. Bifurcation for nonlinear eigenvalue problems involving a second-order ordinary differential equation on the line is considered. Solutions are required to vanish at infinity in both directions and so correspond to homoclinic orbits. When posed in function spaces, the problem concerns bifurcation from the continuous spectrum. The present approach is based on a rescaling that reduces the problem to that of continuing a nontrivial homoclinic orbit in a context where the perturbations are not periodic and are not smooth with respect to uniform convergence. Nonetheless, the nondegeneracy required for continuation amounts to finding simple zeros of a function analogous to Melnikov's function.

Key words. bifurcation, essential spectrum, Melnikov function, homoclinic orbit

AMS(MOS) subject classification. 34B15

1. Introduction.

We consider the following eigenvalue problem:

$$u''(x)+\lambda u(x)+f(\lambda, x, u(x), u'(x))=0 \quad \text{for } x\in\mathbb{R}, \tag{1.1}$$

$$\lim_{x\to-\infty} u(x)=\lim_{x\to+\infty} u(x)=0 \tag{1.2}$$

where the function f satisfies the following conditions:

(A1) $f\in C^1(\mathbb{R}^4)$ and for all $(\lambda, x)\in\mathbb{R}^2$, $f(\lambda, x, ., .)\in C^2(\mathbb{R}^2)$. Furthermore, there exists $B\in C(\mathbb{R}^2)$ such that for all $(\lambda, x, p, q)\in\mathbb{R}^4$,

$$|f(\lambda, x, p, q)|\leqq B(\lambda, p)(p^2+q^2)^{1/2},$$

$$|\partial_i f(\lambda, x, p, q)|\leqq B(\lambda, p)(p^2+q^2)^{1/2} \quad \text{for } i=2, 3, 4.$$

This means that $u\equiv 0$ is a solution of (1.1), (1.2) for every $\lambda\in\mathbb{R}$ and we are interested in pairs (λ, u) satisfying (1.1), (1.2) with $u\not\equiv 0$. This kind of problem has often been used as an example in the study of bifurcation from the essential spectrum [7]-[11], [13]-[15], [17] since in appropriate function spaces the linearisation of (1.1), (1.2) about $u\equiv 0$ has the interval $[0, \infty)$ as spectrum. In this setting, conditions are given determining whether or not there is bifurcation in $L^p(\mathbb{R})$ from $\lambda=0$ in the following sense:

(1.3) There exists a sequence $\{(\lambda_n, u_n)\}$ of solutions of (1.1), (1.2) such that $u_n\not\equiv 0$, $\lambda_n\to 0$, and $|u_n|_p\to 0$ where $|\cdot|_p$ denotes the usual norm on $L^p(\mathbb{R})$.

Although (1.3) constitutes the basic definition of bifurcation at $\lambda=0$, it is possible and even desirable to envisage bifurcation in stronger senses such as follows:

(1.4) There exists a connected set $\mathscr{C}$ in $\mathbb{R}\times[L^p(\mathbb{R})\backslash\{0\}]$ such that (λ, u) is a solution of (1.1), (1.2) for all $(\lambda, u)\in\mathscr{C}$ and the solution $(0, 0)$ belongs to the closure of $\mathscr{C}$ in $\mathbb{R}\times L^p(\mathbb{R})$.

or even:

(1.5) There exist $\delta>0$ and $\phi\in C((-\delta, 0), L^p(\mathbb{R}))$ such that, for $-\delta<\lambda<0$, $(\lambda, \phi(\lambda))$ is a solution of (1.1), (1.2) with $\phi(\lambda)\not\equiv 0$ and $\lim_{\lambda\to 0-}|\phi(\lambda)|_p=0$.

Clearly, (1.5) implies (1.4), which in turn implies (1.3); but in general these notions of bifurcation are distinct.

Bifurcation in the sense of (1.3) can be established by variational methods [10]–[13], [16]. Very roughly, if f has the special form

$$f(\lambda, x, p, q) = r(x)|p|^{\sigma}p \tag{1.6}$$

where $r \in C(\mathbb{R})$ and $\sigma > 0$, the variational approach has been applied to cases where either $Q = \lim_{|x|\to\infty} r(x) = 0$ or

$$Q = \lim_{|x|\to\infty} r(x) > 0 \quad \text{and} \quad \tfrac{1}{2}\{r(x)+r(-x)\} \gneqq Q \quad \forall x \in \mathbb{R}$$

(see [12], [13], [15], [16] for other conditions and generalisations), and the solutions (λ_n, u_n) obtained in this way have a simple variational characterisation as follows. u_n minimizes an appropriate potential function over a manifold of codimension 1. However, the variational approach does not yield information about bifurcation in the sense of (1.4) or (1.5) and, of course, not all equations have a variational structure.

Bifurcation in the sense of (1.4) has been discussed by Toland [17] for the special case (1.6). His method replaces (1.1), (1.2) by the same equation on the interval $(-L, L)$ with boundary conditions $u(-L) = u(L) = 0$. To extract useful information about the limit $L \to \infty$, Toland's method must require that $r(x) = r(-x)$ for all $x \in \mathbb{R}$ and r nonincreasing on $[0, \infty)$. Other results on this kind of bifurcation are contained in [1] and [18].

Bifurcation in the sense of (1.5) was first discussed by Küpper and Reimer [7] in the case (1.6) where r is constant on $\mathbb{R}$. In this case (1.1) is autonomous and can be analysed by quadrature. For nonconstant r, the problem is treated in [14], where in the context of (1.6) it is required that

$$r(x) = r(-x) \quad \forall x \in \mathbb{R} \text{ and } Q \equiv \lim_{|x|\to\infty} r(x) > 0.$$

More recently, Magnus [8], [9] has developed a powerful apparatus for establishing bifurcation in the sense of (1.5) and has applied it to some specific examples of the type (1.6).

In this note, we continue the study of bifurcation in the sense of (1.5) for the problem (1.1), (1.2). The present approach is a little different from that used by Magnus [9], but the two methods have much in common. It may be said that Magnus [9] reduces (1.1), (1.2) to the problem of perturbing a nondegenerate critical point of an appropriate potential function, whereas here we reduce (1.1), (1.2) to a situation in which bifurcation can be established by an application of the Crandall–Rabinowitz theorem [5] on bifurcation from a simple eigenvalue. Both treatments require several changes of variable, but in the present approach they seem more intuitive and consequently are easier to find in some systematic way. Furthermore, our discussion brings out the relationship between our conditions and work on bifurcations of homoclinic orbits using Melnikov's method [2], [3], [6]. Note that (1.1), (1.2) corresponds to seeking homoclinic orbits of (1.1). Finally we note that our approach does not require any variational structure and the behaviour of $|\cdot|_p$ as $\lambda \to 0$ is determined.

After some preliminary work in § 2, the main result is Theorem 3.2 of § 3. However, the hypotheses of that theorem are not formulated directly in terms of the function f in (1.1). Checking these hypotheses involves choosing new variables in ways that depend on the behaviour of f. The remainder of the paper is devoted to showing how this can be done in various circumstances. First, the special form (1.6) is dealt with in § 4, then various more complicated cases are treated in § 5 as higher-order perturbations of (1.6).

2. Rescaling. As in [14], the first step is to introduce the new variables

$$k = |\lambda|^{1/2} \quad \text{and} \quad v(x) = k^{-\alpha} u\left(\frac{x}{k}\right) \tag{2.1}$$

where $\alpha > 0$ is a constant to be chosen later. Then, if (k, v) satisfies

$$v''(x) - v(x) + k^{-(2+\alpha)} f\left(-k^2, \frac{x}{k}, k^{\alpha} v(x), k^{\alpha+1} v'(x)\right) = 0 \quad \forall x \in \mathbb{R}, \tag{2.2}$$

$$\lim_{x \to -\infty} v(x) = \lim_{x \to +\infty} v(x) = 0, \tag{2.3}$$

$$k > 0, \tag{2.4}$$

it is easily verified that (λ, u) satisfies (1.1), (1.2), where

$$\lambda = -k^2 \quad \text{and} \quad u(x) = k^{\alpha} v(kx). \tag{2.5}$$

Furthermore,

$$|u|_p = |\lambda|^{(\alpha - 1/p)/2} |v|_p. \tag{2.6}$$

Since we are trying to solve (1.1), (1.2) near $\lambda = 0$, we suppose that $\alpha > 0$ can be chosen in such a way that (2.2) has a well-defined but nontrivial limit as $k \to 0+$.

(A2) There exists $\alpha > 0$ and $g \in C^2(\mathbb{R}^2)$ such that

$$\lim_{k \to 0+} k^{-(2+\alpha)} f\left(-k^2, \frac{x}{k}, k^{\alpha} p, k^{\alpha+1} q\right) = g(p, q)$$

for all $x \neq 0$ and all $p, q \in \mathbb{R}$. Furthermore, there exists $B \in C(\mathbb{R})$ such that for all $(p, q) \in \mathbb{R}^2$,

$$|g(p, q)| \leqq B(p)(p^2 + q^2)^{1/2},$$

$$|\partial_i g(p, q)| \leqq B(p)(p^2 + q^2)^{1/2} \quad \text{for } i = 1, 2.$$

When (A2) is satisfied, we set

$$h(k, x, p, q) = k^{-(2+\alpha)} f\left(-k^2, \frac{x}{k}, k^{\alpha} p, k^{\alpha+1} q\right) - g(p, q) \tag{2.7}$$

and note that in general $h(k, o, p, q)$ does not tend to zero as $k \to 0+$. Due to this nonuniformity of the limit in (A2), the standard results and methods concerning the bifurcation of homoclinic orbits cannot be applied to (2.2), (2.3) as $k \to 0$. The limit must be taken in some space such as $L^p(\mathbb{R})$ or $H^{-1}(\mathbb{R})$ that allows for nonuniform convergence. Once this space has been chosen, the domain of the operators concerned is fixed by the requirement that $u'' - u$ should define an isomorphism between the spaces concerned. For simplicity, in what follows we only discuss the case

$$X = H^1(\mathbb{R}) \quad \text{and} \quad Y = H^{-1}(\mathbb{R}), \tag{2.8}$$

but other frameworks such as

$$X = W^{2,1}(\mathbb{R}) \quad \text{and} \quad Y = L^1(\mathbb{R}) \tag{2.9}$$

are possible and would yield results under different conditions on the nonlinear term f. Also, a dynamical-systems approach does not control $|\cdot|_p$.

From now on we fix the setting as (2.8) and we must ensure a certain minimal regularity of the operator induced by f between these spaces. To obtain this regularity

it is usually necessary to rescale the parameter k. For this, we denote by Γ a function having the following properties:

$$\Gamma \in C^1((0, \varepsilon), (0, \infty)) \quad \text{with } \lim_{k \to 0+} \Gamma(k) = 0 \text{ and } \Gamma'(k) > 0 \quad \text{for } 0 < k < \varepsilon. \tag{2.10}$$

In this case the inverse function Γ^{-1} will be denoted by γ, and we introduce a new variable s related to k by

$$s = \Gamma(k), \qquad k = \gamma(s). \tag{2.11}$$

Recalling that $X = H^1(\mathbb{R})$ and $Y = H^{-1}(\mathbb{R}) = X^*$, we note that an isomorphism $L: X \to Y$ is defined by

$$\langle Lv, \phi \rangle = -\int_{-\infty}^{\infty} v'\phi' + v\phi \, dx \tag{2.12}$$

where $\langle ., . \rangle$ denotes the duality between X and X^*.

Furthermore, by the growth conditions in (A1) and (A2), operators $G: X \to Y$ and $H: (0, \Gamma(\varepsilon)) \times X \to Y$ can be defined by

$$\langle G(v), \phi \rangle = \int_{-\infty}^{\infty} g(v(x), v'(x))\phi(x) \, dx, \tag{2.13}$$

$$\langle H(s, v), \phi \rangle = \int_{-\infty}^{\infty} h(\gamma(s), x, v(x), v'(x))\phi(x) \, dx \tag{2.14}$$

for $v, \phi \in X$, since $g(v(\ ), v'(\cdot))$ and $h(\gamma(s), \cdot, v(\ ), v'(\ )) \in L^2(\mathbb{R})$ for all $v \in X$.

Setting $J = (-\Gamma(\varepsilon), \Gamma(\varepsilon))$ we extend H to $J \times X$ by setting $H(0, v) = 0$ for all $v \in X$ and $H(s, v) = H(-s, v)$ for $-\Gamma(\varepsilon) < s < 0$ and $v \in X$.

Finally, we define $F: J \times X \to Y$ by

$$F(s, v) = Lv + G(v) + H(s, v). \tag{2.15}$$

Clearly, if $F(s, v) = 0$ then $(\gamma(s), v)$ satisfies (2.2), (2.3) in the weak sense provided that $s \neq 0$. However, the conditions (A1) and (A2) ensure that v is actually a classical solution decaying exponentially to zero as $|x| \to \infty$.

LEMMA 2.1. *Let the conditions* (A1) *and* (A2) *be satisfied and let*

$$F(s, v) = 0 \quad \textit{for } (s, v) \in J \times X \quad \text{with } v \neq 0. \tag{2.16}$$

Then

$$v \in C^3(\mathbb{R}) \cap H^3(\mathbb{R}), \tag{2.17}$$

$$\lim_{|x| \to \infty} |x|^{-1} \log \{v(x)^2 + v'(x)^2\}^{1/2} = -1. \tag{2.18}$$

If $s > 0$, *then* $(\gamma(s), v)$ *satisfies* (2.2), (2.3), (2.4) *classically, whereas if* $s = 0$, *then* v *satisfies*

$$v''(x) - v(x) + g(v(x), v'(x)) = 0 \quad \forall x \in \mathbb{R}. \tag{2.19}$$

Remarks. By (2.17), v' and $v'' \in X$ when (1.16) is satisfied. The result (2.18) implies that for all $\varepsilon \in (0, 1)$

$$\lim_{|x| \to \infty} e^{(1-\varepsilon)|x|} v(x) = \lim_{|x| \to \infty} e^{(1-\varepsilon)|x|} v'(x) = 0. \tag{2.20}$$

From (2.20) and results on asymptotic equivalence we can deduce that (2.20) holds even for $\varepsilon = 0$, but since we do not need this result we omit it.

Proof. From (2.16) it follows that

$$\int_{-\infty}^{\infty} v'\phi'\,dx = \int_{-\infty}^{\infty} \{-v+G(v)+H(s,v)\}\phi\,dx \quad \forall \phi \in X$$

and by (A1) and (A2), $-v+G(v)+H(s,v)\in L^2(\mathbb{R})$ for all $(s,v)\in J\times X$. Hence $v\in H^2(\mathbb{R})$ and $v''-v+G(v)+H(s,v)=0$ almost everywhere on $\mathbb{R}$. But $v\in H^2(\mathbb{R})$ implies that $v\in C^1(\mathbb{R})$ with

$$\lim_{|x|\to\infty} v(x) = \lim_{|x|\to\infty} v'(x) = 0. \tag{2.21}$$

Thus by (A1) and (A2), $-v+G(v)+H(s,v)\in C(\mathbb{R})$ and so $v\in C^2(\mathbb{R})$. This proves that v satisfies either (2.2) when $s\neq 0$ or (2.19) when $s=0$ in the classical sense. From the smoothness of f and g given by (A1) and (A2) it then follows that $v\in C^3(\mathbb{R})$. By differentiating (2.2) (respectively, (2.19)) with respect to x and using (2.21) we can conclude that $v\in H^3(\mathbb{R})$. Finally, (2.21) and the estimates for f and g given by (A1) and (A2) mean that (2.18) can be deduced from Theorem 5 of [4, Chap. IV] applied to (2.2) (respectively, (2.19)).

In view of this result, bifurcation in the sense of (1.5) can be established for (1.1), (1.2) by showing the following:

(2.22) There exist $\delta>0$ and $\psi\in C((0,\delta), X\setminus\{0\})$ such that $F(s,\psi(s))=0$ for $0<s<\delta$.

In fact the pair $(\lambda,\phi(\lambda))$ defined by

$$\lambda = -\gamma(s)^2, \qquad \phi(\lambda)(x) = |\lambda|^{\alpha/2}\psi(\Gamma(|\lambda|^{1/2}))(|\lambda|^{1/2}x) \tag{2.23}$$

satisfies (1.1), (1.2) for $0<s<\delta$, $s=\Gamma(\sqrt{-\lambda})$ and $\phi\in C((-\delta_1,0), X\setminus\{0\})$. Hence there is bifurcation for (1.1), (1.2) in the sense of (1.5) provided that

$$\lim_{\lambda\to 0-} |\phi(\lambda)|_p = \lim_{\lambda\to 0-} |\lambda|^{(\alpha-1/p)/2}|\psi(\Gamma(|\lambda|^{1/2}))|_p = 0. \tag{2.24}$$

One way of resolving (2.22) and (2.24) simultaneously is to show that

(2.25) There exist $\delta>0$ and $\psi\in C([0,\delta), X\setminus\{0\})$ such that $F(s,\psi(s))=0$ for $0\leqq s<\delta$.

If (2.25) is satisfied it follows that there is bifurcation in the sense of (1.5) whenever $p\geqq \max\{2, 1/\alpha\}$ because

$$\lim_{\lambda\to 0-} |\psi(\Gamma(|\lambda|^{1/2}))|_p = |\psi(0)|_p > 0 \quad \text{since } X = H^1(\mathbb{R})$$

is continuously embedded in $L^p(\mathbb{R})$ for $2\leqq p\leqq\infty$.

In the next section we give conditions implying that (2.25) is satisfied. The method used requires a certain degree of smoothness of the function $F: J\times X\to Y$ that is ensured by the following assumption:

(A3) $F\in C^1(J\times X, Y)$ and the second-order derivatives D_v^2F, D_sD_vF, and D_vD_sF exist and are continuous on $J\times X$.

By strengthening (A1) and (A2), we can ensure (as in §§ 4 and 5) that $F(s,\cdot)\in C^2(X,Y)$ for each $s\in J$. Thus the content of (A3) really concerns the smoothness of F with respect to s, and the point is to be able to choose Γ and γ given by (2.10), (2.11) so that (A3) is valid.

3. Continuation of a homoclinic orbit. In the previous section the problem of bifurcation in the sense of (1.5) for (1.1), (1.2) has been reduced to (2.25). One way of establishing (2.25) is to suppose that the limit equation $F(0, v) = 0$ has a nontrivial solution v_0 in X and then to ensure that v_0 can be continued to yield a branch of solutions of $F(s, v) = 0$ for s near 0. Thus we begin with the following assumption:

(A4) There exists $v_0 \in X \setminus \{0\}$ such that $F(0, v_0) = 0$.

Next we must establish properties of v_0 and F that will allow us to continue v_0. First we note that the equation $F(0, v_0) = 0$ is equivalent to the autonomous equation (2.19) with v_0 satisfying (2.17) and (2.18). Setting $z = v_0'$, we have that $z \in X$ and satisfies

$$z''(x) - z(x) + a(x)z(x) + b(x)z'(x) = 0 \quad \forall x \in \mathbb{R} \tag{3.1}$$

where

$$a(x) = \partial_1 g(v_0(x), v_0'(x)) \quad \text{and} \quad b(x) = \partial_2 g(v_0(x), v_0'(x)). \tag{3.2}$$

From (2.20) and (A2) it follows that a and b decay exponentially to zero as $|x| \to \infty$. Hence the integrating factor for (3.1) defined by

$$i(x) = \exp \int_0^x b(y)\, dy \tag{3.3}$$

has the following properties:

$$i \in C^2(\mathbb{R}), \quad i' = bi \quad \text{and} \quad 0 < L_1 \leqq i(x) \leqq L_2 < \infty \quad \forall x \in \mathbb{R}. \tag{3.4}$$

From this it follows easily that

$$v \in X \Leftrightarrow iv \in X \tag{3.5}$$

and (3.1) is equivalent to its symmetric form

$$(iz')' - i[1 - a]z = 0 \quad \text{on } \mathbb{R}. \tag{3.6}$$

To discuss the properties of the linearisation of F at v_0, it is convenient to define a linear operator $C(v_0)\colon X \to Y$ by

$$C(v_0)u = au + bu' \tag{3.7}$$

where a and b are given by (3.2). Then by (A1)-(A3),

$$D_v F(0, v_0)u = Lu + C(v_0)u \quad \forall u \in X. \tag{3.8}$$

When no confusion is likely to arise we write C for $C(v_0)$.

Recalling (2.8), we have the following version of the Fredholm alternative.

LEMMA 3.1. *Let the conditions* (A1)-(A4) *be satisfied. Then*

(i) $C\colon X \to Y$ *is compact*;

(ii) $\ker(L + C) = \operatorname{span}\{v_0'\}$;

(iii) $\langle (L + C)w, iu \rangle = \langle (L + C)u, iw \rangle$, for all $u, w \in X$;

(iv) *For* $\xi \in Y$, *the equation* $(L + C)u = \xi$ *has a solution in* X *if and only if* $\langle \xi, iv_0' \rangle = 0$.

Proof. (i) This is an easy consequence of the fact that $\lim_{|x| \to \infty} a(x) = \lim_{|x| \to \infty} b(x) = 0$ together with the compactness of the Sobolev embeddings on compact intervals.

(ii) If $u \in \ker(L + C)$, we have that $u \in X$ and $\langle (L + C)u, \phi \rangle = 0$, for all $\phi \in X$. In particular, u is a weak solution of the linear equation (3.1) having coefficients a and b in $C^1(\mathbb{R})$. Thus, $u \in C^3(\mathbb{R})$ and satisfies (3.1) classically. From (3.1) we can now conclude that $u \in H^2(\mathbb{R})$ and so, in particular,

$$\lim_{|x| \to \infty} u(x) = \lim_{|x| \to \infty} u'(x) = 0. \tag{3.9}$$

But v_0' also satisfies (3.1) and the conditions (3.9). Hence, if $u \notin \operatorname{span}\{v_0'\}$ it would follow that all solutions of (3.1) satisfy (3.9). Since a and b decay exponentially to zero as $|x| \to \infty$, this would contradict Theorem 2 of [4, Chap. IV]. Hence we may conclude that $u \in \operatorname{span}\{v_0'\}$.

(iii) For $u, w \in X$,

$$\begin{aligned}\langle (L+C)w, iu\rangle &= -\langle w', (iu)'\rangle + \langle -w + aw + bw', iu\rangle \\ &= -\langle w', biu + iu'\rangle + \langle -w + aw + bw', iu\rangle \\ &= -\langle w', iu'\rangle + \langle -w + aw, iu\rangle \\ &= \langle (L+C)u, iw\rangle.\end{aligned}$$

(iv) Since $L: X \to Y$ is an isomorphism and $C: X \to Y$ is compact, the Fredholm alternative implies that $(L+C)u = \xi$ has a solution if and only if $\langle \xi, v\rangle = 0$ for all $v \in \ker (L+C)^*$. But $v \in \ker(L+C)^*$ means that $v \in Y^*$ and $\langle (L+C)^* v, w\rangle = 0$, for all $w \in X$. Since $Y^* = X$, this is equivalent to the conditions

$$v \in X \quad \text{and} \quad \langle (L+C)w, v\rangle = 0 \quad \forall w \in X.$$

By (3.5), this can be expressed equivalently as

$$v = iz \quad \text{where } z \in X \quad \text{and} \quad \langle (L+C)w, iz\rangle = 0 \quad \forall w \in X,$$

and using part (iii) this becomes

$$v = iz \quad \text{where } z \in X \quad \text{and} \quad \langle (L+C)z, iw\rangle = 0 \quad \forall w \in X.$$

When we appeal once again to (3.5) this is equivalent to

$$v = iz \quad \text{and} \quad z \in \ker (L+C)$$

and so by part (ii), it follows that

$$\ker (L+C)^* = i \ker (L+C) = i \operatorname{span}\{v_0'\}.$$

This proves (iv).

We now turn to the problem of continuing the solution v_0 given by (A4). The simplest approach would be to show that $D_v F(0, v_0): X \to Y$ is an isomorphism and hence to apply the Implicit Function Theorem. However, this cannot be done since $D_v F(0, v_0)$ is not invertible on X and v_0 is not an isolated zero of $F(0, \cdot)$ in X. In fact, defining a translation operator T_τ by

$$T_\tau v(x) = v(x+\tau) \quad \text{for } x, \tau \in \mathbb{R} \tag{3.10}$$

we see that

$$F(0, T_\tau v_0) = 0 \quad \forall \tau \in \mathbb{R}. \tag{3.11}$$

Furthermore, $\tau \to T_\tau v_0$ is continuously differentiable since

$$v_0' \in X \quad \text{and} \quad \frac{d}{dt}(T_\tau v_0) = T_\tau v_0'.$$

Hence, $0 = (d/dt)F(0, T_\tau v_0) = D_v F(0, T_\tau v_0) T_\tau v_0'$ for all $\tau \in \mathbb{R}$ and in particular, as we already know,

$$v_0' \in \ker D_v F(0, v_0) = \ker (L+C).$$

One way of resolving this difficulty is to suppose that f has symmetries (even with respect to x and $u'(x)$) allowing us to remove the above degeneracy by restricting the discussion to the subspaces of X and Y consisting of even elements. This is what is done in [14] but in the present discussion we are trying to obtain results for cases where f does not have these symmetries. The idea now is to consider the curve

$$\mathscr{C} = \{(0, T_\tau v_0) : \tau \in \mathbb{R}\} \subset \mathbb{R} \times X \tag{3.12}$$

as a curve of trivial solutions for the equation $F(s, v) = 0$ and to seek values of the phase parameter τ at which a branch of solutions bifurcates from $\mathscr{C}$ into the region $(0, \infty) \times X$.

We shall show that the appropriate values of τ are characterised as the simple zeros of the function $M: \mathbb{R} \to \mathbb{R}$ defined by

$$M(\tau) = \langle D_s H(0, T_\tau v_0), T_\tau(iv_0') \rangle. \tag{3.13}$$

We note that since $v_0'' \in X$, it follows from (A3) that $M \in C^1(\mathbb{R})$ with

$$M'(\tau) = \langle D_u D_s H(0, T_\tau v_0) T_\tau v_0', T_\tau(iv_0') \rangle + \langle D_s H(0, T_\tau v_0), T_\tau(iv_0')' \rangle. \tag{3.14}$$

The function M defined by (3.13) depends on the choice of the solution v_0 of $F(0, v) = 0$, so we denote it temporarily by $M_{v_0}(\tau)$. For $t \in \mathbb{R}$, $T_t v_0$ is also a solution of $F(0, v) = 0$, so we could use it to define another function $M_{T_t v_0}(\tau)$. However, these two functions are related by

$$M_{v_0}(\tau) = C(t) M_{T_t v_0}(\tau - t) \tag{3.15}$$

where $C(t) = \exp\{\int_0^t \partial_2 g(v_0(y), v_0'(y))\, dy\}$.

When the conditions (A1)-(A4) are satisfied, the function M defined by (3.13) will be referred to as a Melnikov function for (1.1), (1.2). This is reasonable terminology because if our procedure is applied to a situation covered by Melnikov theory [2], [3], [6], then the function M generated by our method coincides with the standard Melnikov function. However, because of the nonuniformity of the limit in (A2), Melnikov theory in its usual form [2], [3], [6], cannot be applied to (2.2), (2.3), (2.4). We prove our result by an application of the classical theorem on bifurcation from a simple eigenvalue in the form due to Crandall and Rabinowitz. Many situations covered by standard Melnikov theory could also be treated in this way.

THEOREM 3.2. *Let the conditions* (A1)-(A4) *be satisfied and suppose that there exists* $\tau_0 \in \mathbb{R}$ *such that*

$$M(\tau_0) = 0 \quad \text{and} \quad M'(\tau_0) \neq 0$$

where $M: \mathbb{R} \to \mathbb{R}$ *is the Melnikov function defined by* (3.13) *using a solution* $v_0 \in X$ *of* $F(0, v) = 0$ *given by* (A4). *Let* $W = \{v \in X : \langle v, T_{\tau_0} v_0' \rangle = 0\}$. *Then*:

(a) *The equation*

$$[L + C(T_{\tau_0} v_0)] z = -D_s H(0, T_{\tau_0} v_0)$$

has a unique solution $z_0 \in W$ *where* C *is defined by* (3.7) *with* v_0 *replaced by* $T_{\tau_0} v_0$. *Let* $Z = \{v \in W : \langle v, z_0 \rangle = 0\}$. *Then*:

(b) *There exist* $\delta > 0$ *and functions*

$$\eta \in C((-\delta, \delta), \mathbb{R}) \quad \text{and} \quad \mu \in C((-\delta, \delta), Z)$$

such that $\eta(0) = \tau_0$, $\mu(0) = 0$, *and* $F(s, \psi(s)) = 0$ *for all* $s \in (-\delta, \delta)$, *where* $\psi(s) = T_{\eta(s)} v_0 + s z_0 + s\mu(s)$.

(c) *Setting* $\delta_1 = \gamma(\delta)^2$ *and*

$$\phi(\lambda)(x) = |\lambda|^{\alpha/2} \psi(\Gamma(|\lambda|^{1/2}))(|\lambda|^{1/2} x) \quad \text{for } -\delta_1 < \lambda < 0,$$

we have that $\phi \in C((-\delta_1, 0), X\backslash\{0\})$ *and* $|\phi(\lambda)|_p = |\lambda|^{(\alpha-1/p)/2}|\psi(\Gamma(|\lambda|^{1/2}))|_p$ *for* $1 \leqq p \leqq \infty$, *where* $\alpha > 0$ *is the constant in* (A2), *where* Γ *and* γ *are the functions given by* (2.10) *and* (2.11) *used to define* H *in* (2.14). *There is bifurcation in* $L^p(\mathbb{R})$ *for* (1.1), (1.2) *in the sense of* (1.5) *provided that* $p \geqq \min\{2, 1/\alpha\}$.

Proof. Replacing v_0 by $T_{\tau_0}v_0$ and recalling (3.15), we suppose henceforth that $\tau_0 = 0$ and so $W = \{w \in X: \langle v_0', w\rangle = 0\}$. Define an operator $N: \mathbb{R}\times J \times W \to Y$ by

$$N(\tau, s, w) = F(s, w + T_\tau v_0)$$

where F is given by (2.15). Thus $\mathscr{C}$ becomes the line $\mathbb{R}\times\{0\}\times\{0\}$ of trivial solutions for N since by (3.11), $N(\tau, 0, 0) = 0$ for all $\tau \in \mathbb{R}$.

By (A3), $N \in C^1(\mathbb{R}\times J \times W, Y)$ and furthermore,

$$D_\tau N(\tau, s, w) = D_u F(s, w + T_\tau v_0) T_\tau v_0',$$

and for $(\mu, z) \in \mathbb{R}\times W$,

$$\begin{aligned} D_{(s,w)}N(\tau, s, w)(\mu, z) &= \mu D_s F(s, w + T_\tau v_0) + D_u F(s, w + T_\tau v_0) z \\ &= \mu D_s H(s, w + T_\tau v_0) + D_u F(s, w + T_\tau v_0) z, \end{aligned}$$

$$D_\tau\{D_{(s,w)}N(\tau, s, w)(\mu, z)\} = \mu D_u D_s H(s, w + T_\tau v_0) T_\tau v_0' + D_u^2 F(s, w + T_\tau v_0)[T_\tau v_0', z].$$

Thus by (A3), N has the regularity required by the Crandall-Rabinowitz theorem [5] and so to establish bifurcation at $\tau_0 = 0$ we must check the following:

(i) $\ker D_{(s,w)}N(0, 0, 0) = \operatorname{span}\{(1, z_0)\}$ where $z_0 \in W$;

(ii) $\operatorname{codim} D_{(s,w)}N(0, 0, 0) = 1$;

(iii) $D_\tau\{D_{(s,w)}N(0, 0, 0)(1, z_0)\} \notin \operatorname{Im} D_{(s,w)}N(0, 0, 0)$.

By insisting that the eigenvector has the form $(1, z_0)$ we ensure that the branch of solutions of $N(\tau, s, w) = 0$ bifurcating at $(0, 0, 0)$ can be parameterized by s.

For (i) we note that $(\mu, z) \in \ker D_{(s,w)}N(0, 0, 0) \Leftrightarrow (\mu, z) \in \mathbb{R}\times W$ and

$$\mu D_s H(0, v_0) + (L + C)z = 0 \tag{3.16}$$

where $C: X \to Y$ is defined by (3.7) with $C = C(v_0)$. Thus, by Lemma 3.1, there is an eigenvector of the form $(1, z_0) \in \mathbb{R}\times X$ if and only if

$$\langle D_s H(0, v_0), iv_0'\rangle = 0, \tag{3.17}$$

and in this case the requirement $z_0 \in W$ determines z_0 uniquely by

$$(L + C)z_0 = -D_s H(0, v_0) \tag{3.18}$$

since $\ker(L + C) = \operatorname{span}\{v_0'\}$. The condition (3.17) is satisfied since $M(0) = 0$. Thus (i) is verified and so is part (a) of the theorem.

For (ii), we note that $\xi \in \operatorname{Im} D_{(s,w)}N(0, 0, 0) \Leftrightarrow \xi \in Y$ and there exists $(\mu, z) \in \mathbb{R}\times W$ such that

$$\xi = \mu D_s H(0, v_0) + (L + C)z.$$

By Lemma 3.1 and (3.17) this is equivalent to $\langle \xi, iv_0'\rangle = 0$, and so

$$\operatorname{Im} D_{(s,w)}N(0, 0, 0) = \{\xi \in Y: \langle \xi, iv_0'\rangle = 0\}.$$

This establishes (ii).

For (iii) we note that it is now enough to show that

$$\langle D_\tau\{D_{(s,w)}N(0, 0, 0)(1, z_0)\}, iv_0'\rangle \neq 0$$

where $z_0 \in W$ is determined by (3.18). Since

$$\begin{aligned} D_{(s,w)}N(\tau, 0, 0)(1, z_0) &= D_sH(0, T_\tau v_0) + D_uF(0, T_\tau v_0)z_0 \\ &= D_sH(0, T_\tau v_0) + Lz_0 + D_uG(T_\tau v_0)z_0 \\ &= D_sH(0, T_\tau v_0) + Lz_0 + (T_\tau a)z_0 + (T_\tau b)z_0' \end{aligned}$$

we find that

$$D_\tau\{D_{(s,w)}N(\tau, 0, 0)(1, z_0)\} = D_uD_sH(0, T_\tau v_0)T_\tau v_0' + (T_\tau a)'z_0 + (T_\tau b)'z_0'$$

where the prime stands for differentiation with respect to x. Thus condition (iii) amounts to showing that

$$\langle D_uD_sH(0, v_0)v_0' + a'z_0 + b'z_0', iv_0' \rangle \neq 0.$$

But

$$\begin{aligned} \langle a'z_0 + b'z_0', iv_0' \rangle &= -\langle Cz_0, (iv_0')' \rangle - \langle az_0' + bz_0'', iv_0' \rangle \\ &= -\langle (L+C)z_0, (iv_0')' \rangle + \langle Lz_0, (iv_0')' \rangle - \langle az_0' + bz_0'', iv_0' \rangle \end{aligned}$$

and

$$\begin{aligned} \langle Lz_0, (iv_0')' \rangle &= -\langle z_0', (iv_0')'' \rangle - \langle z_0, (iv_0')' \rangle \\ &= -\langle z_0', (biv_0')' + (iv_0'')' \rangle - \langle z_0, (iv_0')' \rangle \\ &= -\langle z_0', (biv_0')' + i[1-a]v_0' \rangle - \langle z_0, (iv_0')' \rangle \quad \text{by (3.6)} \\ &= -\langle z_0', (biv_0')' - iav_0' \rangle \\ &= \langle z_0'', biv_0' \rangle + \langle z_0', iav_0' \rangle. \end{aligned}$$

Hence

$$\langle a'z_0 + b'z_0', iv_0' \rangle = -\langle (L+C)z_0, (iv_0')' \rangle = \langle D_sH(0, v_0), (iv_0')' \rangle \quad \text{by (3.18).}$$

Thus condition (iii) is reduced to

$$\langle D_uD_sH(0, v_0)v_0', iv_0' \rangle + \langle D_sH(0, v_0), (iv_0')' \rangle \neq 0$$

and by (3.14) this is just the condition $M'(0) \neq 0$. This proves that condition (iii) is satisfied.

When we note that

$$\mathbb{R} \times W = \text{span}\{(1, z_0)\} \oplus [\{0\} \times Z]$$

it follows by Theorem 1.7 of [5] that there exist $\delta > 0$ and functions

$$\eta \in C((-\delta, \delta), \mathbb{R}), \qquad \theta \in C((-\delta, \delta), \{0\} \times Z)$$

such that

$$\eta(0) = 0, \qquad \theta(0) = (0, 0)$$

and

$$N(\eta(s), s(1, z_0) + s\theta(s)) = 0 \quad \text{for } s \in (-\delta, \delta).$$

Setting $\theta(s) = (0, \mu(s))$, we have that $\mu \in C((-\delta, \delta), Z)$, $\mu(0) = 0$, and

$$\begin{aligned} 0 &= N(\eta(s), s, sz_0 + s\mu(s)) \\ &= F(s, T_{\eta(s)}v_0 + sz_0 + s\mu(s)) \quad \text{for } s \in (-\delta, \delta). \end{aligned}$$

This proves (b) in the case $\tau_0 = 0$.

Finally (c) follows directly from (b) as noted in (2.23), (2.24) of § 2.

Remarks. (1) While this paper was being refereed, a revised version of [9] appeared in *Proc. Roy. Soc. Edinburgh Sect.* A, 110 (1988), pp. 1-25. In an addendum, Magnus derived a result (Theorem 6.4) showing how an equation such as that in part (a) above arises in his context.

(2) An essential step in the above proof involves seeking a solution v near $T_{\tau_0}v_0$ in the form

$$v = w + T_\tau v_0 \quad \text{where } w \in W \text{ and } \tau \text{ is near } \tau_0.$$

In fact all v near $T_{\tau_0}v_0$ in X admit such a representation and it is unique. To see this set $f(\tau, r) = \langle T_\tau v_0, T_{\tau_0} v_0' \rangle - r$, and use the Implicit Function Theorem.

4. The main example. In this section we apply the general method to the case where f has the following special form:

$$f(\lambda, x, p, q) = r(x)|p|^\sigma p \quad \text{for } (\lambda, x, p, q) \in \mathbb{R}^4, \quad \text{or} \tag{4.1}$$

$$= r(x)|p|^{\sigma+1} \quad \text{for } (\lambda, x, p, q) \in \mathbb{R}^4 \tag{4.1'}$$

where

(H1) $r \in C^1(\mathbb{R})$ with $\lim_{|x|\to\infty} r(x) = Q > 0$ and $r' \in L^\infty(\mathbb{R})$, where $\sigma > 1$ in case (4.1) and $\sigma \geqq 1$ in case (4.1').

From (H1) it follows that f satisfies the conditions (A1) and (A2) provided that in (A2) we set

$$\alpha = \frac{2}{\sigma},\ g(p, q) = Q|p|^\sigma p, \text{ or } = Q|p|^{\sigma+1} \text{ and } h(k, x, p, q) = R(x/k)|p|^\sigma p \tag{4.2}$$
$$\text{or } = R(x/k)|p|^{\sigma+1}, \text{ where } R(x) = r(x) - Q.$$

In what follows we will usually write out the formulae that are valid for the case (4.1). The corresponding results for the case (4.1') are obtained by a trivial modification. In particular, the essential formulae for the Melnikov function discussed in Theorem 4.3 are identical for (4.1) and (4.1') since the solution v_0 given by (4.26) is positive.

To obtain the regularity of the Nemytskii operators defined by (2.13)-(2.15) required in (A3), we must make an appropriate choice of the function Γ (and hence γ). This depends on the rate at which r converges to Q and the next hypothesis distinguishes a number of situations in which a successful choice of Γ is known.

(H2) With $R(x) = r(x) - Q$ we suppose that one of the following conditions is satisfied:

(i) There exist $\beta \in (0, 1)$, $\nu \geqq 0$, and $L(\pm\infty) \in \mathbb{R}$ such that

$$\lim_{x\to\pm\infty} R'(x)|x|^{\beta+1}[\ln|x|]^{-\nu} = L(\pm\infty); \tag{4.3}$$

(ii) There exist $L(+\infty) \in \mathbb{R}$ and $\psi \in L^1(\mathbb{R})$ such that

$$\lim_{|x|\to\infty} x\psi(x) = 0, \tag{4.4}$$

$$R(x) = -\frac{xL(+\infty)}{1+x^2} + \psi(x) \quad \forall x \in \mathbb{R}; \tag{4.5}$$

(iii) There exist $\beta \in (1, 3/2)$, $\nu \geqq 0$, and $L(\pm\infty) \in \mathbb{R}$ such that (4.3) holds and $\int_{-\infty}^{\infty} R(x)\,dx = 0$.

Remarks. (1) Since both $(L\pm\infty)$ can be zero, the exponents β and ν are not uniquely determined by (4.3). In fact, if the condition is satisfied for exponents β and ν it is also satisfied for β_1 and ν_1 provided that

$$\beta_1 < \beta \quad \text{and} \quad \nu_1 \geqq 0$$

or

$$\beta_1 = \beta \quad \text{and} \quad \nu_1 \geqq \nu.$$

We shall show that the function $\Gamma\colon (0,1)\to\mathbb{R}$ defined by

$$\Gamma(k) = \int_0^k t^{\beta-1}[-\ln t]^{\nu}\, dt \tag{4.6}$$

when r satisfies (H2)(i) or (H2)(iii) with exponents β and ν, or by

$$\Gamma(k) = k \tag{4.7}$$

when r satisfies (H2)(ii), establishes a change of variables for which (A3) is satisfied. Consequently, a Melnikov function M can be defined for any such pair of exponents β and ν. However, there is at most one pair (β, ν) for which the corresponding M is not identically zero.

(2) When (H2)(i) or (H2)(iii) holds, it follows from l'Hôpital's rule that

$$\lim_{x\to\pm\infty} R(x)|x|^{\beta}[\ln|x|]^{-\nu} = \mp\frac{L(\pm\infty)}{\beta} \tag{4.8}$$

whereas (H2)(ii) implies that

$$\lim_{x\to\pm\infty} R(x)|x| = \mp L(+\infty). \tag{4.9}$$

Consequently, if (H2)(i) or (H2)(ii) holds with $L(\pm\infty)\neq 0$, it follows that $R\notin L^1(\mathbb{R})$. On the other hand, if $R\in L^1(\mathbb{R})$ and $\lim_{|x|\to\infty} xR(x)=0$ then (H2)(ii) holds with $L(+\infty)=0$. The case (H2)(iii) enables us to deal with situations where $R\in L^1(\mathbb{R})$ and $\int_{-\infty}^{\infty} R(x)\, dx = 0$. In this case it is useful to set

$$P(x) = \int_{-\infty}^{x} R(t)\, dt \tag{4.10}$$

and to note that by l'Hôpital's rule

$$\lim_{x\to\pm\infty} P(x)|x|^{\beta-1}[\ln|x|]^{-\nu} = \lim_{x\to\pm\infty} \frac{R(x)|x|^{\beta}}{(1-\beta)}[\ln|x|]^{-\nu} = \pm\frac{L(\pm\infty)}{\beta(\beta-1)}. \tag{4.11}$$

From this it follows that

$$\lim_{x\to\pm\infty} \{xR(x)-P(x)\}|x|^{\beta-1}[\ln|x|]^{-\nu} = \frac{L(\pm\infty)}{1-\beta}. \tag{4.12}$$

When r satisfies (H1) and (H2), the function Γ defined by (4.6) or (4.7) satisfies (2.10) and its inverse γ is defined on $(0,\Gamma(1))$. Furthermore, for $0<s<\Gamma(1)$,

$$\gamma'(s)\gamma(s)^{\beta-1}[-\ln\gamma(s)]^{\nu} = 1. \tag{4.13}$$

In particular, when $\nu=0$ we have that

$$\gamma(s) = (\beta s)^{1/\beta}. \tag{4.14}$$

In the present context, the operators G and H defined by (2.13)-(2.15) are given by

$$G(v)(x) = Q|v(x)|^{\sigma}v(x), \tag{4.15}$$

$$H(s, v)(x) = \begin{cases} R\left(\dfrac{x}{\gamma(s)}\right)|v(x)|^{\sigma}v(x) & \text{for } 0 < s < \Gamma(1), \\ 0 & \text{for } s = 0, \\ -H(-s, v)(x) & \text{for } -\Gamma(1) < s < 0, \end{cases} \tag{4.16}$$

$$F(s, v) = Lv + G(v) + H(s, v). \tag{4.17}$$

In (4.15), (4.16) we have supposed that f has the form (4.1). When (4.1′) holds we replace $|v|^{\sigma}v$ by $|v|^{\sigma+1}$ in these definitions.

LEMMA 4.1. *Let f satisfy the conditions* (H1) *and* (H2) *and let Γ be defined according to* (4.6), (4.7). *The operator F defined by* (4.17) *satisfies the condition* (A3) *with $X = H^1(\mathbb{R})$ and $Y = H^{-1}(\mathbb{R})$. Furthermore, for $v \in X$, $D_sF(0, v) = D_sH(0, v) \in Y$ is the distribution defined by the following formulae for $w \in X$:*

$$\langle D_sF(0, v), w\rangle = \langle D_sH(0, v), w\rangle$$

$$= L(-\infty)\int_{-\infty}^{0} |x|^{-\beta}[|v|^{\sigma}vw](x)\,dx - L(+\infty)\int_{0}^{\infty} |x|^{-\beta}[|v|^{\sigma}vw](x)\,dx$$

in case (H2)(i),

$$= L(+\infty)\left[\int_{-1}^{1} \ln|x|\{|v|^{\sigma}vw\}'(x)\,dx - \int_{|x|\geq 1} x^{-1}[|v|^{\sigma}vw](x)\,dx\right]$$

$$+ \int_{-\infty}^{\infty} \psi(x)\,dx\,|v(0)|^{\sigma}v(0)w(0) \quad \textit{in case } (\text{H2})(\text{ii}),$$

$$= \frac{L(-\infty)}{(1-\beta)}\int_{-\infty}^{0} |x|^{1-\beta}[|v|^{\sigma}vw]'(x)\,dx + \frac{L(+\infty)}{(1-\beta)}\int_{0}^{\infty} |x|^{1-\beta}[|v|^{\sigma}vw]'(x)\,dx$$

in case (H3)(iii).

These formulae hold in the case where f has the form (4.1). *The corresponding results for the case* (4.1′) *are obtained by replacing $|v|^{\sigma}v$ by $|v|^{\sigma+1}$.*

Proof. We treat the case where f has the form (4.1). Since $\sigma > 1$, it follows by standard arguments that

$$G \text{ and } H(s, \cdot) \in C^1(X, Y) \quad \text{for all } s \in J = (-\Gamma(1), \Gamma(1)).$$

For the regularity of H with respect to s we deal in some detail with the case (H2)(i). For the other cases we simply mention the essential modifications that are necessary. To simplify the integral expressions it is convenient to set

$$L(x) = \mp L(\pm\infty) \quad \text{for } x \gtrless 0. \tag{4.18}$$

Suppose that R satisfies (H2)(i) and set

$$A = \max\{|L(\pm\infty)|\}, \qquad B = 2A/(1-\beta).$$

Then for $v, w \in X$,

$$\begin{aligned}\left|\int_{-\infty}^{\infty} L(x)|x|^{-\beta}[|v|^{\sigma}vw](x)\,dx\right| &\\ \leqq \| |v|^{\sigma}vw|_{\infty}\int_{-1}^{1}|L(x)|\,|x|^{-\beta}\,dx + A|v^{\sigma}|_{\infty}\int_{|x|\geqq 1}|v|\,|w|\,dx &\\ \leqq B|v|_{\infty}^{\sigma+1}|w|_{\infty} + A|v|_{\infty}^{\sigma}|v|_2|w|_2 &\\ \leqq (A+B)\|v\|_X^{\sigma+1}\|w\|_X. &\end{aligned} \tag{4.19}$$

Hence the form $\langle E_1(v), w\rangle = \int_{-\infty}^{\infty} L(x)|x|^{-\beta}[|v|^{\sigma}vw](x)\,dx$ defines an element $E_1(v) \in X^* = Y$ and $\|E_1(v)\|_Y \leqq (A+B)\|v\|_X^{\sigma+1}$. Similar estimates show that $E_1 \in C^1(X, Y)$ and

$$\langle DE_1(v)z, w\rangle = \int_{-\infty}^{\infty} L(x)|x|^{-\beta}(\sigma+1)|v|^{\sigma}zw\,dx \quad \text{for } v, z, w \in X.$$

Furthermore, for $s > 0$ and $v, w \in X$,

$$\begin{aligned}\left|\left\langle \frac{H(s,v)}{s} - E_1(v), w\right\rangle\right| &\leqq \|w\|_{\infty}\{A_1(s,v) + A_2(s,v)\} \\ &\leqq \|w\|_X\{A_1(s,v) + A_2(s,v)\}\end{aligned} \tag{4.20}$$

where

$$A_1(s,v) = \int_{|x|\leqq 2\gamma(s)} \left|R\left(\frac{x}{\gamma(s)}\right)\frac{|x|^{\beta}}{s} - L(x)\right| |x|^{-\beta}|v|^{\sigma+1}\,dx,$$

$$A_2(s,v) = \int_{|x|\geqq 2\gamma(s)} \left|R\left(\frac{x}{\gamma(s)}\right)\frac{|x|^{\beta}}{s} - L(x)\right| |x|^{-\beta}|v|^{\sigma+1}\,dx.$$

Clearly,

$$A_1(s,v) \leqq |v|_{\infty}^{\sigma+1}\left\{|R|_{\infty}\frac{2\gamma(s)}{s} + A\int_{|x|\leqq 2\gamma(s)}|x|^{-\beta}\,dx\right\}$$

and so $\lim_{s\to 0+} A_1(s,v) = 0$, since $\beta \in (0,1)$ and

$$\lim_{s\to 0+}\frac{\gamma(s)}{s} = \lim_{s\to 0+}\gamma'(s) = \lim_{s\to 0+}\gamma(s)^{1-\beta}[-\ln\gamma(s)]^{-\nu} = 0 \quad \text{by (4.13).}$$

For $|x| \geqq 2\gamma(s)$,

$$\begin{aligned}\left|R\left(\frac{x}{\gamma(s)}\right)\right|\frac{|x|^{\beta}}{s} = \frac{\gamma(s)^{\beta}}{s}\left|R\left(\frac{x}{\gamma(s)}\right)\right|\left|\frac{x}{\gamma(s)}\right|^{\beta}\left[\ln\left|\frac{x}{\gamma(s)}\right|\right]^{-\nu}\left[\ln\left|\frac{x}{\gamma(s)}\right|\right]^{\nu} &\\ \leqq \frac{\gamma(s)^{\beta}}{s}C\left[\ln\left|\frac{x}{\gamma(s)}\right|\right]^{\nu} \quad \text{by (4.8)} &\end{aligned}$$

where

$$\begin{aligned}C = \sup_{|z|\geqq 2} R(z)|z|^{\beta}[\ln|z|]^{-\nu} < \infty &\\ \leqq \frac{\gamma(s)^{\beta}}{s}C[-\ln\gamma(s)]^{\nu}[1+\ln|x|]^{\nu} &\end{aligned}$$

provided that $-\ln \gamma(s) \geqq 1$ since $\nu \geqq 0$. But by (4.13), $\lim_{s\to 0+} (\gamma(s)^\beta/s)[-\ln \gamma(s)]^\nu = \beta$ and $\lim_{s\to 0+} -\ln \gamma(s) = \infty$. Hence there exists $s_0 > 0$ such that

$$\left| R\left(\frac{x}{\gamma(s)}\right)\right| \frac{|x|^\beta}{s} \leqq C(\beta+1)[1+\ln|x|]^\nu \tag{4.21}$$

for $|x| \geqq 2\gamma(s)$ and $0 < s < s_0$.

Furthermore, for $x \neq 0$, by l'Hôpital's rule,

$$\begin{aligned}
&\lim_{s\to 0+} R\left(\frac{x}{\gamma(s)}\right)\frac{|x|^\beta}{s} \\
&= -\lim_{s\to 0+} R'\left(\frac{x}{\gamma(s)}\right)\frac{x|x|^\beta\gamma'(s)}{\gamma(s)^2} \\
&= -\frac{x}{|x|}\lim_{s\to 0+} R'\left(\frac{x}{\gamma(s)}\right)\left|\frac{x}{\gamma(s)}\right|^{\beta+1}\left[\ln\left|\frac{x}{\gamma(s)}\right|\right]^{-\nu}\left[\ln\left|\frac{x}{\gamma(s)}\right|\right]^{\nu}\gamma'(s)\gamma(s)^{\beta-1} \\
&= \mp L(\pm\infty) \quad \text{for } x \gtrless 0 \quad \text{by (4.3)}
\end{aligned} \tag{4.22}$$

since by (4.13)

$$\lim_{s\to 0+}\left[\ln\left|\frac{x}{\gamma(s)}\right|\right]^\nu \gamma'(s)\gamma(s)^{\beta-1} = \lim_{s\to 0+}\left[\frac{\ln|x| - \ln\gamma(s)}{-\ln\gamma(s)}\right]^\nu = 1.$$

Now, denoting the characteristic function of $\{x: |x| \geqq 2\gamma(s)\}$ by χ_s, we have that

$$A_2(s, v) = \int_{-\infty}^{\infty} \chi_s(x)\left| R\left(\frac{x}{\gamma(s)}\right)\frac{|x|^\beta}{2} - L(x)\right| |x|^{-\beta}|v(x)|^{\sigma+1}\, dx$$

where the integrand is bounded by

$$\{C(\beta+1)[1+\ln|x|]^\nu + A\}|x|^{-\beta}|v(x)|^{\sigma+1}$$

provided that $0 < s < s_0$. Hence the Dominated Convergence Theorem applies and we conclude from (4.22) that $\lim_{s\to 0+} A_2(s, v) = 0$. Returning to (4.20), we have that

$$\lim_{s\to 0}\left\| \frac{H(s, v)}{s} - E_1(v)\right\|_Y = 0,$$

proving that H is differentiable with respect to s at $s = 0$ and that $D_sH(0, v) = E_1(v)$. For $s > 0$,

$$\langle D_sH(s, v), w\rangle = -\int_{-\infty}^{\infty} R'\left(\frac{x}{\gamma(s)}\right)\frac{x\gamma'(s)}{\gamma(s)^2}[|v|^\sigma vw](x)\, dx$$

and by arguments similar to those above we find that

$$\lim_{s\to 0+} \|D_sH(s, v) - E_1(v)\|_Y = 0.$$

From this and the continuity of $E_1: X \to Y$, it follows that $H \in C^1(J \times X, Y)$.

The discussion of the derivatives D_sD_vH and D_vD_sH is similar to that for D_sH, and we find that

$$D_sD_vH(0, v) = D_vD_sH(0, v) = DE_1(v) \quad \forall v \in X.$$

In this way we see that F satisfies (A1) when (H2)(i) holds.

Turning to the case where r satisfies (H2)(ii), we note that it is enough to establish the result for the following special cases:

$$R(x) = x/(1+x^2), \tag{4.23}$$

$$R(x) = \psi(x). \tag{4.24}$$

We discuss (4.23) first. Defining a bilinear form by

$$\langle E_2(v), w\rangle = -\int_{-1}^{1} \ln|x|\{|v|^\sigma vw\}'(x)\,dx + \int_{|x|\geqq 1} x^{-1}\{|v|^\sigma vw\}(x)\,dx \tag{4.25}$$

we show that for each $v \in X$, it defines a bounded linear functional on X. In fact,

$$\begin{aligned}\left|\int_{-1}^{1} \ln|x|\{|v|^\sigma vw\}'(x)\,dx\right| &\leqq \int_{-1}^{1} |\ln|x||\{(\sigma+1)|v|^\sigma|v'||w| + |v|^{\sigma+1}|w'|\}\,dx \\ &\leqq (\sigma+1)|v|_\infty^\sigma |w|_\infty D|v'|_2 + |v|_\infty^{\sigma+1} D|w'|_2 \\ &\leqq D(\sigma+2)\|v\|_X^{\sigma+1}\|w\|_X\end{aligned}$$

where

$$D = \left\{\int_{-1}^{1} (\ln|x|)^2\,dx\right\}^{1/2}$$

and

$$\left|\int_{|x|\geqq 1} x^{-1}\{|v|^\sigma vw\}(x)\,dx\right| \leqq |v|_\infty^\sigma |v|_2 |w|_2 \leqq \|v\|_X^{\sigma+1}\|w\|_X.$$

Thus $E_2(v) \in X^* = Y$ for all $v \in X$ and by similar arguments $E_2 \in C^1(X, Y)$. For $s > 0$ and $v, w \in X$,

$$\begin{aligned}\left\langle \frac{H(s,v)}{s}, w\right\rangle &= \int_{-\infty}^{\infty} \frac{1}{s} R\left(\frac{x}{s}\right)[|v|^\sigma vw](x)\,dx \\ &= \int_{-1}^{1} \frac{x}{s^2+x^2}\{|v|^\sigma vw(x) - |v|^\sigma vw(0)\}\,dx \\ &\quad + \int_{|x|\geqq 1} \frac{x^2}{s^2+x^2} x^{-1}\{|v|^\sigma vw\}(x)\,dx \\ &= -\int_{-1}^{1} \frac{1}{2}\ln(s^2+x^2)\{|v|^\sigma vw\}'(x)\,dx \\ &\quad + \frac{1}{2}\ln(s^2+1)\{|v|^\sigma vw(1) - |v|^\sigma vw(-1)\} \\ &\quad + \int_{|x|\geqq 1} \frac{x^2}{s^2+x^2} x^{-1}\{|v|^\sigma vw\}(x)\,dx.\end{aligned}$$

Using this expression, it is now easy to show that

$$\lim_{s\to 0+} \left\| \frac{H(s,v)}{s} - E_2(v)\right\|_Y = 0$$

and so $D_s H(0, v) = E_2(v)$ for all $v \in X$.

The other properties are established in a similar fashion for (4.23) and so we now pass to the discussion of (4.24).

In this case we set

$$\langle E_3(v), w\rangle = \int_{-\infty}^{\infty} \psi(x)\,dx|v(0)|^\sigma v(0)w(0).$$

Since

$$|\langle E_3(v), w\rangle| \leqq \left| \int_{-\infty}^{\infty} \psi(x)\, dx \right| |v|_\infty^{\sigma+1} |w|_\infty$$
$$\leqq \left| \int_{-\infty}^{\infty} \psi(x)\, dx \right| \|v\|_X^{\sigma+1} \|w\|_X$$

we see that $E_3(v) \in Y$ for all $v \in X$ and by standard arguments $E_3 \in C^1(X, Y)$.

Now for $s > 0$ and $v, w \in X$,

$$\left\langle \frac{H(s, v)}{s}, w \right\rangle = \int_{-\infty}^{\infty} \psi\left(\frac{x}{s}\right) \frac{1}{s} [|v|^\sigma vw](x)\, dx$$
$$= -\int_{-\infty}^{\infty} P\left(\frac{x}{s}\right) [|v|^\sigma vw]'(x)\, dx \quad \text{where } P(x) = \int_{-\infty}^{x} R(t)\, dt$$

and so

$$\left\langle \frac{H(s, v)}{s} - E_3(v), w \right\rangle = -\int_{-\infty}^{\infty} \left[P\left(\frac{x}{s}\right) - N(x) \right] [|v|^\sigma vw]'(x)\, dx$$

where

$$N(x) = \begin{cases} 0 & \text{if } x < 0, \\ \displaystyle\int_{-\infty}^{\infty} \psi(t)\, dt & \text{if } x > 0. \end{cases}$$

Since $\lim_{s \to 0+} P(x/s) - N(x) = 0$ for all $x \neq 0$ it is now easy to show, using dominated convergence, that

$$\lim_{s \to 0+} \left\| \frac{H(s, v)}{s} - E_3(v) \right\|_Y = 0.$$

This proves that $D_s H(0, v) = E_3(v)$ when (4.24) holds and the remaining properties of H are established in a similar fashion.

Finally, we consider the case where r satisfies (H2)(iii). As usual we begin by studying the bilinear form defined by

$$\langle E_4(v), w\rangle = \frac{L(-\infty)}{(1-\beta)} \int_{-\infty}^{0} |x|^{1-\beta} [|v|^\sigma vw]'(x)\, dx$$
$$+ \frac{L(+\infty)}{(1-\beta)} \int_{0}^{\infty} |x|^{1-\beta} [|v|^\sigma vw]'(x)\, dx. \tag{4.25}$$

Now setting $\left| \int_{-\infty}^{0} |x|^{1-\beta} [|v|^\sigma vw]'(x)\, dx \right| = I_1$, we have that

$$I_1 \leqq \int_{-\infty}^{0} |x|^{1-\beta} \{(\sigma+1)|v|^\sigma |v'||w| + |v|^{\sigma+1}|w'|\}(x)\, dx$$
$$\leqq \int_{-\infty}^{-1} \{(\sigma+1)|v|^\sigma |v'||w| + |v|^{\sigma+1}|w'|\}(x)\, dx$$
$$+ \int_{-1}^{0} |x|^{1-\beta} \{(\sigma+1)|v|^\sigma |v'||w| + |v|^{\sigma+1}|w'|\}(x)\, dx$$
$$\leqq (\sigma+1)|v|_\infty^\sigma |v'|_2 |w|_2 + |v|_\infty^\sigma |v|_2 |w'|_2$$
$$+ (\sigma+1)|v|_\infty^\sigma |w|_\infty F |v'|_2 + |v|_\infty^{\sigma+1} F |w'|_2$$

where

$$F=\left\{\int_{-1}^{0}|x|^{2(1-\beta)}\,dx\right\}^{1/2},$$

$$I_1\leqq(\sigma+2)(F+1)\|v\|_X^{\sigma+1}\|w\|_X.$$

The second integral in (4.25) is estimated in the same way, so we can conclude that $E_4\in C^1(X, Y)$. For $s>0$ and $v, w\in X$, we have that

$$\left\langle\frac{H(s,v)}{s}, w\right\rangle=\int_{-\infty}^{\infty}R\left(\frac{x}{\gamma(s)}\right)\frac{1}{s}[|v|^{\sigma}vw](x)\,dx$$

$$=-\int_{-\infty}^{\infty}P\left(\frac{x}{\gamma(s)}\right)\frac{\gamma(s)}{s}[|v|^{\sigma}vw]'(x)\,dx$$

where $P(x)=\int_{-\infty}^{x}R(t)\,dt$. Since $\int_{-\infty}^{\infty}R(t)\,dt=0$ we can use l'Hôpital's rule and obtain

$$\lim_{s\to0+}P\left(\frac{x}{\gamma(s)}\right)\frac{\gamma(s)}{s}=\lim_{s\to0+}\left\{-R\left(\frac{x}{\gamma(s)}\right)\frac{x\gamma'(s)}{\gamma(s)}+P\left(\frac{x}{\gamma(s)}\right)\gamma'(s)\right\}$$

$$=-\lim_{s\to0+}\left\{\frac{x}{\gamma(s)}R\left(\frac{x}{\gamma(s)}\right)-P\left(\frac{x}{\gamma(s)}\right)\right\}\gamma'(s)=-\frac{L(\pm\infty)}{1-\beta}|x|^{\beta-1}$$

by (4.12) and (4.13).

Arguing much as in (H2)(i), the Dominated Convergence Theorem can now be used to show that

$$\lim_{s\to0+}\left\|\frac{H(s,v)}{s}-E_4(v)\right\|_Y=0\quad\forall v\in X,$$

and the proof is completed in the usual way.

LEMMA 4.2. *Let f satisfy conditions* (H1) *and* (H2) *and consider the function $F\colon J\times X\to Y$ defined by* (4.17) *via the transformation* (4.6), (4.7). *Then*

$$\{v\in X\backslash\{0\}\colon F(0,v)=0\}=\{\pm T_\tau v_0\colon\tau\in\mathbb{R}\}\quad\textit{in case (4.1)}$$

$$=\{T_\tau v_0\colon\tau\in\mathbb{R}\}\quad\textit{in case (4.1')}$$

where

$$v_0(x)=\left\{\frac{\sigma+2}{2Q}\right\}^{1/\sigma}ch^{-2/\sigma}\left(\frac{\sigma x}{2}\right)\quad\textit{for } x\in\mathbb{R}. \tag{4.26}$$

In particular, (A4) *is satisfied by v_0, which is even and positive.*

Proof. If $v\in X$ and $F(0, v)=0$, it follows from Lemma 2.1 that $v\in H^3(\mathbb{R})\cap C^3(\mathbb{R})$ and v satisfies (2.19). By (4.2), in the case (4.1), (2.19) is

$$v''(x)-v(x)+Q|v(x)|^{\sigma}v(x)=0\quad\forall x\in\mathbb{R}. \tag{4.27}$$

By direct calculation we show that

$$\left\{v\in C^2(\mathbb{R})\backslash\{0\}\colon\text{(4.27) is satisfied and }\lim_{|x|\to\infty}v(x)=0\right\}=\{\pm T_\tau v_0\colon\tau\in\mathbb{R}\}.$$

Since $v_0, v_0'\in X$ this completes the proof in case (4.1). The case (4.1') is similar.

By Lemmas 4.1 and 4.2, we know that when r satisfies (H1) and (H2) and Γ is defined by (4.6), (4.7), the conditions (A1)-(A4) of § 3 are all fulfilled, and it is sufficient

to consider the Melnikov function generated by the function v_0 given in (4.26). From Lemma 4.1 and definition (3.13), the Melnikov function M is given by

$$M(\tau) = \langle D_s H(0, T_\tau v_0), T_\tau v_0' \rangle$$

since $i(x) \equiv 1$ by (4.2).

When we set

$$m_\beta(\tau) = \begin{cases} \displaystyle\int_0^\infty \frac{x^{1-\beta}}{(1-\beta)} [v_0^{\sigma+1} v_0']'(x+\tau)\, dx & \text{for } \beta \neq 1, \\ \displaystyle\int_0^\infty \ln x [v_0^{\sigma+1} v_0']'(x+\tau)\, dx & \text{for } \beta = 1, \end{cases} \tag{4.28}$$

where v_0 is given by (4.26), it follows from Lemma 4.1 that the Melnikov function for (4.1) or (4.1′) is given by

$$M(\tau) = L(-\infty) m_\beta(-\tau) + L(+\infty) m_\beta(\tau) \quad \text{in cases (H1)(i) and (H1)(iii),} \tag{4.29}$$

$$= L(+\infty)[m_1(-\tau) + m_1(\tau)] + \int_{-\infty}^{\infty} \psi(x)\, dx\, v_0(\tau)^{\sigma+1} v_0'(\tau) \tag{4.30}$$

in case (H2)(ii).

In connection with (4.28), it is worth noting that

$$[v_0^{\sigma+1} v_0']' = \frac{(v_0^{\sigma+2})''}{\sigma+2} \tag{4.31}$$

$$= (\sigma+2) v_0^{\sigma+2} \left\{ 1 - \frac{(3\sigma+4)}{(\sigma+2)^2} Q v_0^\sigma \right\}, \tag{4.32}$$

and furthermore $m_\beta(\tau) = dn_\beta(\tau)/d\tau$, where

$$n_\beta(\tau) = \begin{cases} \displaystyle\int_0^\infty \frac{x^{1-\beta}}{(1-\beta)} [v_0^{\sigma+1} v_0'](x+\tau)\, dx & \text{for } \beta \neq 0, \\ \displaystyle\int_0^\infty \ln x [v_0^{\sigma+1} v_0'](x+\tau)\, dx & \text{for } \beta = 1. \end{cases}$$

It is easy to prove that $\lim_{|\tau| \to \infty} n_\beta(\tau) = 0$ for $0 < \beta < 3/2$ and

$$M(\tau) = \frac{d}{d\tau} \{ -L(-\infty) n_\beta(-\tau) + L(+\infty) n_\beta(\tau) \} \quad \text{in cases (H2)(i) and (H2)(iii)}$$

$$= \frac{d}{d\tau} \left\{ -L(+\infty) n_1(-\tau) + L(+\infty) n_1(\tau) + \int_{-\infty}^{\infty} \psi(x)\, dx \frac{v_0(\tau)^{\sigma+2}}{(\sigma+2)} \right\}$$

in case (H2)(ii).

Thus in all cases M is the derivative of a function converging to zero as $\tau \to \pm\infty$.

This ensures that in all cases there exists at least one $\tau_0 \in \mathbb{R}$ such that $M(\tau_0) = 0$. By Theorem 3.2 we must seek the simple zeros of M.

In terms of bifurcation in the sense of (1.5) for the problem (1.1), (1.2) we obtain the following result.

THEOREM 4.3. *Let f be of the form* (4.1) *where* (H1) *and* (H2) *are satisfied. Suppose that*

$$M(\tau_0) = 0 \quad \textit{and} \quad M'(\tau_0) \neq 0 \tag{4.33}$$

where M is the Melnikov function defined by (4.29), (4.30). *Then there is bifurcation in $L^p(\mathbb{R})$ for* (1.1), (1.2) *in the sense of* (1.5) *provided that $p \geqq \min\{2, \sigma/2\}$. Furthermore the branch of solutions has the form given by Theorem* 3.2 *with $\alpha = 2/\sigma$, where v_0 is defined by* (4.26) *and Γ by* (4.6), (4.7).

This result is an immediate consequence of Theorem 3.2 and Lemmas 4.1 and 4.2. In general it seems that the location of simple zeros of M must be treated by numerical integration. See the Appendix. However, there are some cases in which the solution is easy. For example, if

$$R \in L^1(\mathbb{R}) \quad \text{with} \lim_{|x|\to\infty} xR(x) = 0 \quad \text{and} \quad \int_{-\infty}^{\infty} R(x)\,dx \neq 0, \tag{4.34}$$

then we are in case (H2)(ii) with $L(+\infty) = 0$ and

$$M(\tau) = \int_{-\infty}^{\infty} R(x)\,dx\, v_0(\tau)^{\sigma+1} v_0'(\tau).$$

Hence,

$$M(0) = 0 \quad \text{and} \quad M'(0) = -\int_{-\infty}^{\infty} R(x)\,dx \frac{\sigma}{2}\left[\frac{\sigma+2}{Q}\right]^{(\sigma+2)/\sigma} \neq 0 \quad \text{by (4.32).} \tag{4.35}$$

Another easy case is that in which R satisfies (H2)(i) with

$$L(+\infty) = -L(-\infty) \neq 0. \tag{4.36}$$

In this case,

$$M(0) = L(+\infty)[-m_\beta(0) + m_\beta(0)] = 0,$$

and

$$\begin{aligned} M'(0) = 2L(+\infty)m_\beta'(0) &= L(+\infty)\int_0^\infty \frac{x^{1-\beta}}{(1-\beta)}\left\{\frac{v_0^{\sigma+2}}{\sigma+2}\right\}'''(x)\,dx \\ &= -L(+\infty)\int_0^\infty x^{-\beta}\left\{\frac{v_0^{\sigma+1}}{\sigma+2}\right\}''\,dx \\ &= -\frac{L(+\infty)}{(\sigma+2)}\lim_{\varepsilon\to 0+}\int_\varepsilon^\infty x^{-\beta}\{v_0^{\sigma+2}\}''\,dx \\ &= -\frac{L(+\infty)}{(\sigma+2)}\lim_{\varepsilon\to 0+}\left\{x^{-\beta}(v_0^{\sigma+2}(x))'\Big|_\varepsilon^\infty + \beta\int_\varepsilon^\infty x^{-\beta-1}\{v_0^{\sigma+2}\}'\,dx\right\} \\ &= -\frac{\beta L(+\infty)}{(\sigma+2)}\int_0^\infty x^{-\beta-1}\{v_0(x)^{\sigma+1}\}'\,dx \quad \text{since } v_0'(0) = 0 \\ &\neq 0 \quad \text{since } (v_0(x)^{\sigma+1})' < 0 \quad \text{for } x > 0. \end{aligned} \tag{4.37}$$

We end this section with two typical examples showing how the various cases in (H2) arise.

Example 4.4. Let f be of the form (4.1) with

$$r(x) = Q + C(1+x^2)^{-\gamma} \quad \text{for } x \in \mathbb{R}$$

where $C \in \mathbb{R}\backslash\{0\}$, $Q > 0$, and $\gamma > 0$.

First we note that since r is even, this case is covered by the result in [14]. In terms of the present discussion we note that (H1) is satisfied provided that $\sigma > 1$. Then

(H2)(i) holds for $\beta \leqq \min\{2\gamma, 1\}$, where $L(\pm\infty) = 0$ unless $\beta = 2\gamma < 1$ and $\nu = 0$, in which case $L(\pm\infty) = \pm 2\gamma C$. Hence for $0 < \gamma < \frac{1}{2}$, we use $\beta = 2\gamma$ and $\nu = 0$ in (H2)(i) to obtain the Melnikov function

$$M(\tau) = -4\gamma C \int_0^\infty x^{-\beta}[v_0^{\sigma+1} v_0'](x+\tau)\, dx$$

and by (4.36), $M(0) = 0$ and $M'(0) \neq 0$. If $\gamma > \frac{1}{2}$, then (H2)(ii) is satisfied with $L(+\infty) = 0$ and we obtain the Melnikov function

$$M(\tau) = C \int_{-\infty}^\infty (1+x^2)^{-\gamma}\, dx\, v_0(\tau)^{\sigma+1} v_0'(\tau).$$

By (4.34), $M(0) = 0$ and $M'(0) \neq 0$. None of the results in this paper covers the case $\gamma = \frac{1}{2}$, but due to the evenness of R the result in [14] applies.

Example 4.5. Let f be of the form (4.1) with

$$r(x) = Q + Cx(1+x^2)^{-\gamma} \quad \text{for } x \in \mathbb{R}$$

where $C \in \mathbb{R}\backslash\{0\}$, $Q > 0$, and $\gamma > \frac{1}{2}$.

In this case the results in [14] do not apply since r is not even. In terms of the present discussion (H1) holds provided that $\sigma > 1$, and (H2)(i) is satisfied provided that $\beta \leqq \min\{2\gamma - 1, 1\}$, where $L(\pm\infty) = 0$ unless $\beta = 2\gamma - 1 < 1$ and $\nu = 0$ in which case $L(\pm\infty) = (1-2\gamma)C$. Thus we get a nontrivial Melnikov function by using $\beta = 2\gamma - 1$ and $\nu = 0$ in (H2)(i) provided that $\frac{1}{2} < \gamma < 1$. For $\gamma = 1$ we apply the case (H2)(ii) with

$$L(+\infty) = -1 \quad \text{and} \quad \psi \equiv 0.$$

For $\gamma > 1$ the case (H2)(ii) again applies with $L(+\infty) = 0$, but we obtain a trivial Melnikov function since $\int_{-\infty}^\infty R(x)\, dx = 0$. However, for $\gamma > 1$ we see that r satisfies (H2)(iii) provided that

$$\beta \leqq \min\{2\gamma - 1, \tfrac{3}{2}\}$$

where $L(\pm\infty) = 0$ unless $\beta = 2\gamma - 1 < 3/2$ and $\nu = 0$, in which case $L(\pm\infty) = (1-2\gamma)C$. Thus for $1 < \gamma < 5/4$ we obtain a nontrivial Melnikov function by using (H2)(iii) with $\beta = 2\gamma - 1$ and $\nu = 0$.

5. More general nonlinearities. In this section we discuss nonlinearities f in (1.1) that are sums of terms of the form (4.1), and we also allow perturbations containing a factor u'. The basic idea is to select the dominant contribution, together with the appropriate change of variables, ensuring that it leads to a nontrivial Melnikov function as in § 4. Then we show that the remaining terms are regular (in the sense of (A3)) and lead to Melnikov functions that are identically zero for this same change of variables. In the simplest cases the dominant term is the one with the smallest value of the exponent σ, so we discuss this kind of situation first. However, there are problems where the dominant term is not given by the smallest power of u, and we conclude with some examples of this kind.

We suppose that the nonlinearity f in (1.1) can be written as

$$f(\lambda, x, p, q) = f_0(x, p) + \sum_{i=1}^N \lambda^{n_i} f_i(x, p) q^{\delta_i} \tag{5.1}$$

where f_i is of the form (4.1) or (4.1′) for $0 \leqq i \leqq N$ with coefficient r_i and exponent σ_i. Setting $r_0 = r$ and $\sigma_0 = \sigma$, we suppose that f_0 satisfies (H1) and (H2) with exponent β in (H2) ($\beta = 1$ for the case (H2)(ii)) and $R(x) = Q - r(x)$.

For $1 \leqq i \leqq N$ we suppose that

$$n_i \in \{0, 1, 2, \cdots\} = \mathbb{N}, \qquad \delta_i \in \{0, 1\}$$

and we set

$$\mu_i = 2n_i - 2 + \frac{2\sigma_i}{\sigma} + \delta_i\left(1 + \frac{2}{\sigma}\right).$$

For $\alpha = 2/\sigma$ we find that

$$k^{-(2+\alpha)} f\left(-k^2, \frac{x}{k}, k^{\alpha} p, k^{\alpha+1} q\right) = Q|p|^{\sigma} p + R\left(\frac{x}{k}\right)|p|^{\sigma} p + \sum_{i=1}^{N} (-1)^{n_i} k^{\mu_i} f_i\left(\frac{x}{k}, p\right) q^{\delta_i}$$

when f_0 satisfies (4.1), whereas if f_0 satisfies (4.1′) we simply replace $|p|^{\sigma} p$ by $|p|^{\sigma+1}$.

Let $\gamma = \Gamma^{-1}$ be the change of variables associated with r via (H2) and (4.6), (4.7). Let F_0: $J \times X \to Y$ be the operator associated with f_0 as in (4.17). Thus if f_0 satisfies (4.1)

$$F_0(s, v)(x) = v''(x) - v(x) + Q|v(x)|^{\sigma} v(x) + R\left(\frac{x}{\gamma(s)}\right)|v(x)|^{\sigma} v(x)$$

and if f_0 satisfies (4.1′) we simply replace $|v|^{\sigma} v$ by $|v|^{\sigma+1}$. As usual $X = H^1(\mathbb{R})$ and $Y = H^{-1}(\mathbb{R})$. By Lemmas 4.1 and 4.2, F satisfies (A3).

For $1 \leqq i \leqq N$, we set

$$K_i(k, v)(x) = (-1)^{n_i} f_i\left(\frac{x}{k}, v(x)\right) v'(x)^{\delta_i}$$

and

$$H_i(s, v) = \begin{cases} \gamma(s)^{\mu_i} K_i(\gamma(s), v) & \text{for } 0 < s < \Gamma(1), \\ 0 & \text{for } s = 0, \\ -H_i(-s, v) & \text{for } -\Gamma(1) < s < 0. \end{cases}$$

The object now is to give conditions implying that H_i satisfies (A3) and $D_s H_i(0, v) \equiv 0$ for $1 \leqq i \leqq N$. From this it will follow that f satisfies the conditions (A1)–(A4) with v_0 given by (4.26) and Melnikov function given by (4.29), (4.30). This objective is attained by imposing the following conditions.

(H3) For $1 \leqq i \leqq N$, $r_i \in C^1(\mathbb{R}) \cap L^{\infty}(\mathbb{R})$ with $|x r_i'(x)| \leqq C$ for all $x \in \mathbb{R}$ with $\mu_i > \beta$ unless $r_i \equiv 0$. Furthermore, $f_1(x, p) = r_1(x) p$ and $\delta_1 = 1$, whereas for $2 \leqq i \leqq N$, f_i has the form (4.1) or (4.1′) with $\sigma_i > 1$ or $\sigma_i \geqq 1$ and $\delta_i \in \{0, 1\}$.

Under the above hypotheses it is easy to see that f, given by (5.1), satisfies (A1) and (A2). Also for $s > 0$,

$$D_s H_i(s, v)(x) = (-1)^{n_i} \gamma(s)^{\mu_i - 1} \gamma'(s) \cdot \left\{\mu_i r_i\left(\frac{x}{\gamma(s)}\right) - \frac{x}{\gamma(s)} r_i'\left(\frac{x}{\gamma(s)}\right)\right\} |v(x)|^{\sigma_i} v(x) v'(x)^{\delta_i}$$

if f_i has the form (4.1), and in the case (4.1′) we simply replace $|v|^{\sigma_i} v$ by $|v|^{\sigma_i + 1}$. However, $\mu_i > \beta > 0$, and by (4.13)

$$\lim_{s \to 0+} \gamma(s)^{\mu_i - 1} \gamma'(s) = \lim_{s \to 0+} \gamma(s)^{\mu_i - \beta} [-\ln \gamma(s)]^{-\nu} = 0.$$

Since r_i and $x r_i'(x) \in L^{\infty}(\mathbb{R})$ it follows easily that $\|D_s H(s, v)\|_Y \to 0$ as $s \to 0$ and by a similar argument that

$$\left\| \frac{H(s, v)}{s} \right\|_Y \to 0 \quad \text{as } s \to 0.$$

Thus we see that (H3) implies that $H_i \in C^1(J \times X, Y)$ with $D_s H_i(0, v) \equiv 0$ for $1 \leqq i \leqq N$. The information concerning second partial derivatives for H_i required by (A3) is checked by the same argument. Hence we have established the following result.

THEOREM 5.1. *Let f be of the form* (5.1) *and suppose that* (H1), (H2) *are satisfied by r and σ and that* (H3) *holds. Let $\gamma = \Gamma^{-1}$ be the change of variables defined by* (4.6), (4.7) *via* (H2) *using r and σ. Then conditions* (A1)-(A4) *are fulfilled by f, and the Melnikov function M for f is determined by r and σ through* (4.26) *and* (4.29), (4.30). *In particular, there is bifurcation in $L^p(\mathbb{R})$ for* (1.1), (1.2) *in the sense of* (1.5) *provided that* (4.33) *holds and $p \geqq \min\{2, \sigma/2\}$.*

When $n_i = 0$ for $1 \leqq i \leqq N$, $\delta_i = 0$ for $2 \leqq i \leqq N$, and $r_1 \equiv 0$, it follows from (H3) that $\sigma_i > \sigma$ for all $i \geqq 2$ and hence the dominant contribution to f comes from the smallest power σ. We end with some examples of situations where the dominant contribution comes from a higher power of u.

Example 5.2.

$$f(\lambda, x, p, q) = \frac{x^2}{1+x^2} p^3 + \frac{x}{(1+x^2)^2} p^2.$$

Setting

$$Q = 1, \quad R(x) = -\frac{1}{1+x^2}, \quad r_1(x) = \frac{x}{(1+x^2)^2},$$

we have $f(\lambda, x, p, q) = p^3 + R(x)p^3 + r_1(x)p^2$, where $\lim_{|x|\to\infty} R(x) = \lim_{|x|\to\infty} r_1(x) = 0$. Clearly, (A1) is satisfied and setting $\alpha = 1$ and $g(p, q) = p^2$, we find that (A2) is also satisfied. Furthermore, R and $r_1 \in L^1(\mathbb{R})$ with

$$\lim_{|x|\to\infty} xR(x) = \lim_{|x|\to\infty} xr_1(x) = 0.$$

Hence both R and r_1 satisfy (H2)(ii) with $L(\pm\infty) = 0$. Thus by Lemmas 4.1 and 4.2, (A3) is satisfied (with change of variable $\gamma(s) = s$) and

$$\langle D_s H(0, v), w\rangle = \int_{-\infty}^{\infty} R(x)\, dx\, v(0)^3 w(0) + \int_{-\infty}^{\infty} r_1(x)\, dx\, v(0)^2 w(0)$$
$$= -\pi v(0)^3 w(0) \quad \text{for all } w \in X.$$

Since $g(p, q) = p^3$ we see that (A4) holds with $v_0(x) = \sqrt{2}\, ch^{-1}x$ and the Melnikov function in this case is $M(\tau) = 4\pi sh\pi ch^{-5}\tau$. By (4.35), $M(0) = 0$ and $M'(0) \neq 0$.

Example 5.3.

$$f(\lambda, x, p, q) = \{1 + (1+x^2)^{-1/4}\}p^3 + (1+x^2)^{-1/2}p^2.$$

Clearly (A1) holds. Setting $\alpha = 1$ and $g(p, q) = p^3$, we verify easily that (A2) is satisfied. Setting $R(x) = (1+x^2)^{-1/4}$ and $r_1(x) = (1+x^2)^{-1/2}$, we find that

$$\lim_{x\to\pm\infty} R'(x)|x|^{3/2} = \mp\tfrac{1}{2} \quad \text{and} \quad \lim_{x\to\pm\infty} r_1'(x)|x|^{3/2} = 0.$$

Hence both R and r_1 satisfy (H2)(i) with $\beta = \frac{1}{2}$, $\nu = 0$, and

$$L(\pm\infty) = \mp\tfrac{1}{2} \quad \text{for } R,$$
$$L(\pm\infty) = 0 \quad \text{for } r_1.$$

It follows that (A3) is satisfied (with $\gamma(s) = s^2/4$) and that

$$\langle D_s H(0, v), w\rangle = \frac{1}{2}\int_{-\infty}^{\infty} |x|^{-1/2} v(x)^3 w(x)\, dx.$$

Again we are in a situation where (A4) holds with

$$v_0(x) = \sqrt{2}\, ch^{-1} x$$

and in this case the Melnikov function is

$$M(\tau) = -2 \int_{-\infty}^{\infty} |x|^{-1/2} \frac{sh(x+\tau)}{[ch(x+\tau)]^5}\, dx.$$

By (4.37), $M(0) = 0$ and $M'(0) < 0$.

Appendix. We present the graphs of some of the Melnikov functions encountered in § 4 (Figs. 1-6). They were obtained through numerical integration by François Meynard.

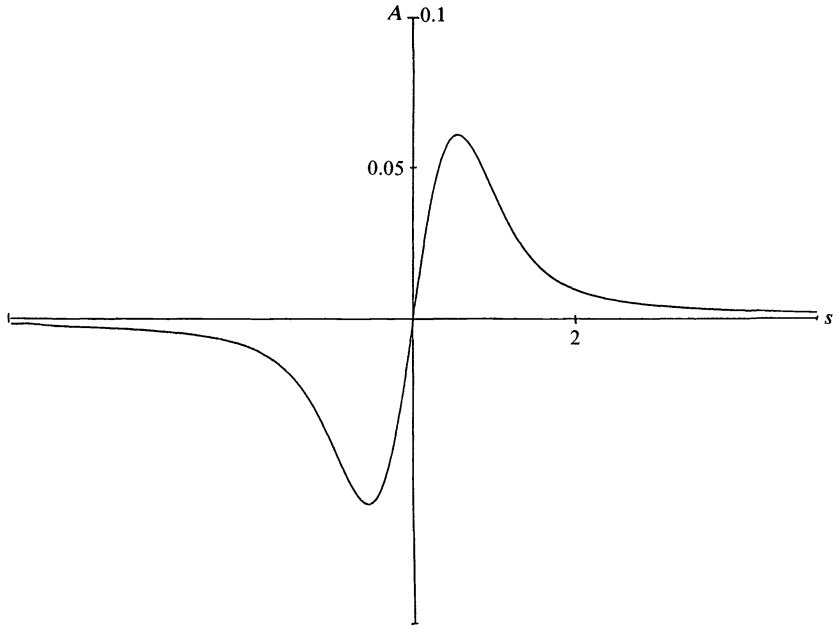

FIG. 1. $\sigma = 2$; $\beta = 0.5$; $L(-\infty) = -1$; $L(+\infty) = 1$. *One value for* s_0: $s_0 = 0$. *This agrees with* (4.36).

It is convenient to begin with some simplifications of the original formula. From (4.26), (4.28), and (4.32), we find that for $\beta \neq 1$,

$$m_\beta(\tau) = \int_0^{\infty} \frac{x^{1-\beta}}{(1-\beta)}\, w(x+\tau)\, dx$$

where

$$w(x) = \frac{(\sigma+2)^{2+2/\sigma}}{(2Q)^{1+2/\sigma}} \frac{1}{ch^{\alpha}(\sigma x/2)} \left\{ 1 - \frac{(1+1/\alpha)}{ch^2(\sigma x/2)} \right\}$$

and

$$\alpha = 2 + \frac{4}{\sigma}.$$

Hence there exists $C(Q, \sigma) > 0$ such that for $\beta \neq 1$,

$$M(\tau) = \frac{C(Q,\sigma)}{(1-\beta)} A\left(\frac{\sigma\tau}{2}\right)$$

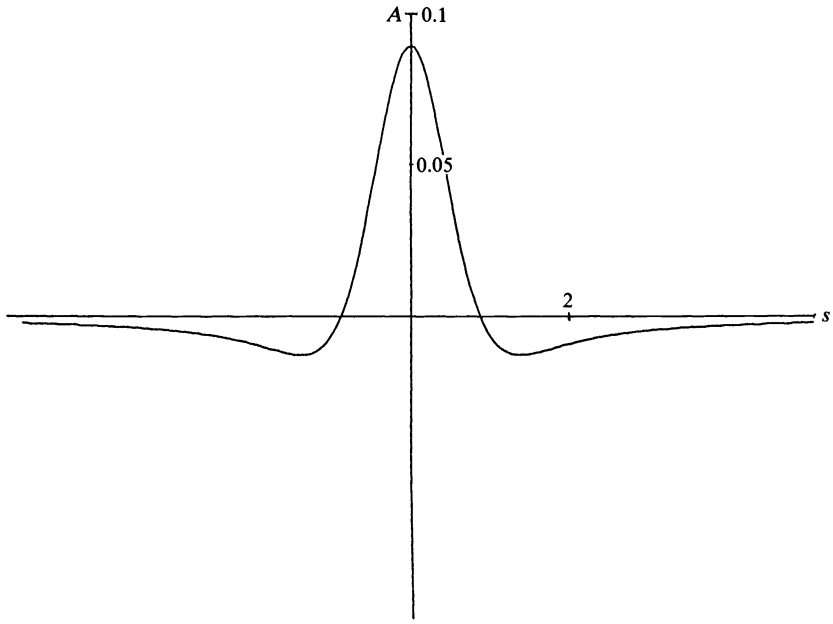

FIG. 2. $\sigma = 2$; $\beta = 0.5$; $L(-\infty) = 1$; $L(+\infty) = 1$. *Two values for* s_0: $s_0 \simeq +0.87$; $s_0 \simeq -0.87$.

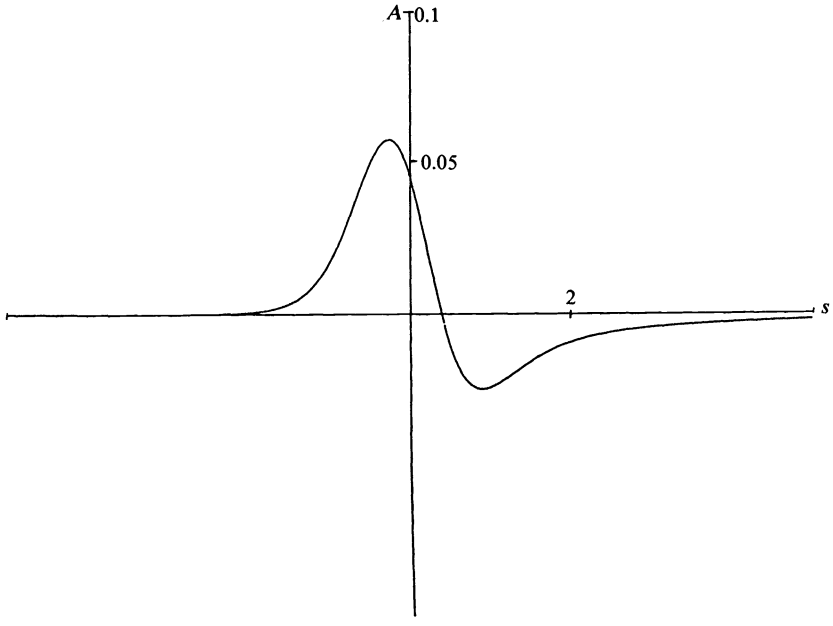

FIG. 3. $\sigma = 2$; $\beta = 0.5$; $L(-\infty) = 1$; $L(+\infty) = 0$. *One value for* s_0: $s_0 \simeq +0.37$.

where $A(s) = L(-\infty)B(-s) + L(+\infty)B(s)$ with

$$B(s) = \int_0^\infty x^{1-\beta} \frac{1}{ch^\alpha(x+s)} \left\{ 1 - \frac{(1+1/\alpha)}{ch^2(x+s)} \right\} dx.$$

Then (4.33) is equivalent to $\tau_0 = 2s_0/\sigma$, where $A(s_0) = 0$ and $A'(s_0) \neq 0$.

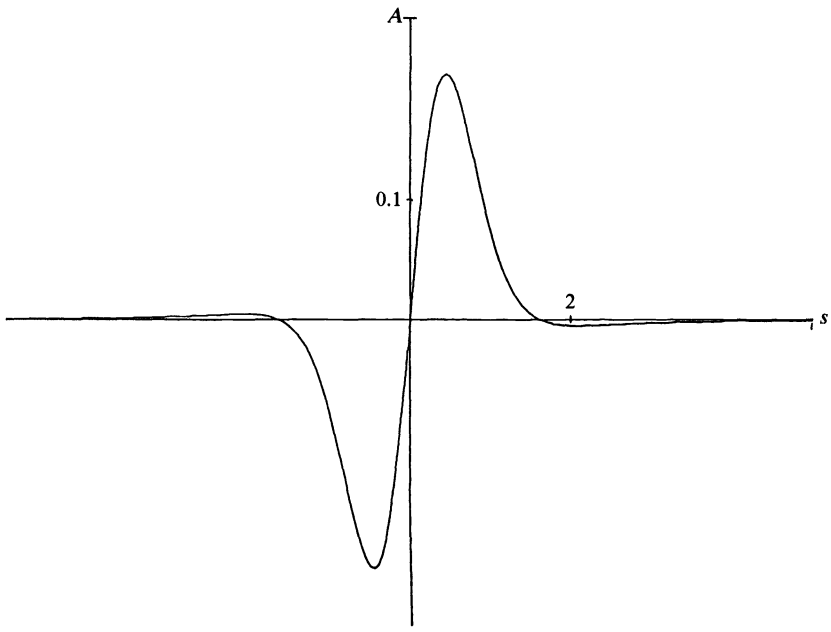

FIG. 4. $\sigma = 2$; $\beta = 1.25$; $L(-\infty) = -1$; $L(+\infty) = 1$. *Three values for* s_0: $s_0 = 0$; $s_0 \simeq +1.63$; $s_0 \simeq -1.63$.

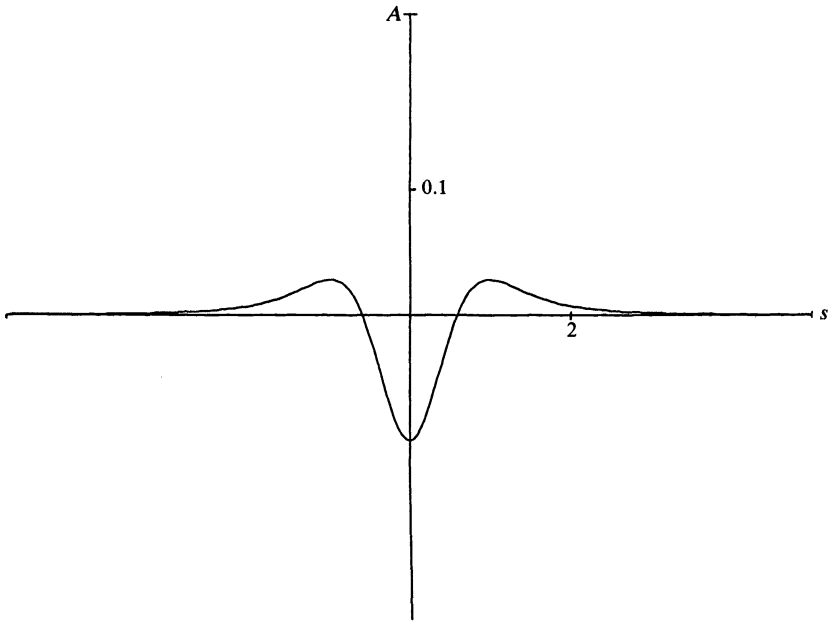

FIG. 5. $\sigma = 2$; $\beta = 1.25$; $L(-\infty) = 1$; $L(+\infty) = 1$. *Two values for* s_0: $s_0 \simeq +0.63$; $s_0 \simeq -0.63$.

For $\sigma = 2$ ($\alpha = 4$), Figs. 1-6 represent the function A for various values of β and $L(\pm\infty)$.

Acknowledgments. I am very grateful to Robert Magnus for showing me his work [9] prior to publication. From it I learned a great deal about the problem. I also thank David Chillingworth for his helpful remarks.

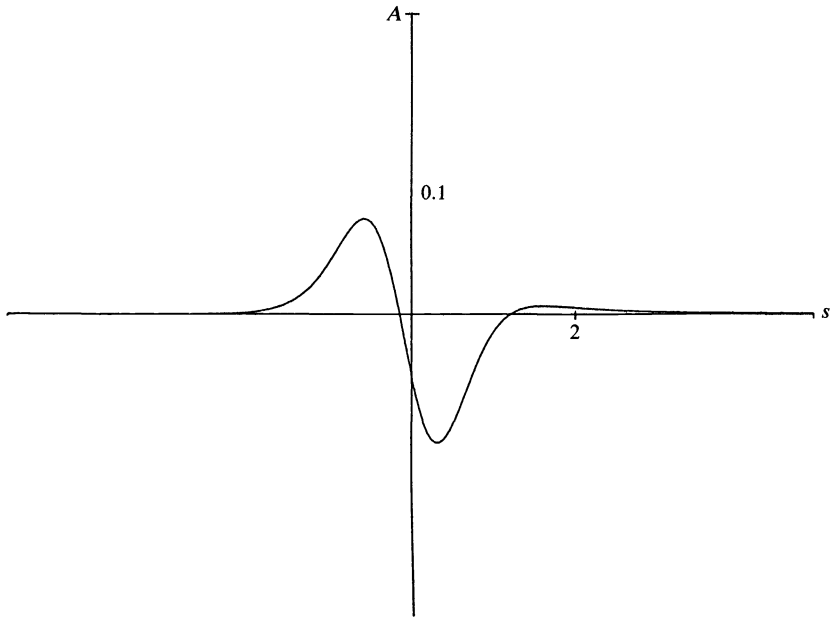

FIG. 6. $\sigma = 2$; $\beta = 1.25$; $L(-\infty) = 1$; $L(+\infty) = 0$. *Two values for* s_0: $s_0 \simeq +1.27$; $s_0 \simeq -0.13$.

EQUIVALENCE OF DIFFERENTIAL OPERATORS*

NIKY KAMRAN† AND PETER J. OLVER‡

Abstract. Two versions of the equivalence problem—determining when two second-order differential operators on the line are the same under a change of variables—are solved completely using the Cartan method of equivalence.

Key words. differential operator, Cartan equivalence method, invariant, symmetry, Lie algebra

AMS(MOS) subject classifications. 47E05, 58A15, 34B25

1. Introduction. The basic equivalence problem to be treated here is to determine when two second-order differential operators on the real line can be transformed into each other by an appropriate change of variables. There are two different possible interpretations of the notion of equivalence, depending on whether we wish to preserve the differential expression corresponding to the operator or the Lie bracket between operators. In this paper we treat both versions of the equivalence problem for second-order operators on the line. The problems here are related to the more general equivalence problem for second-order ordinary differential equations [4], [5], [11], but are specialized by linearity. We employ the equivalence method of Cartan, which gives necessary and sufficient conditions for equivalence. Although the simplest of the possible equivalence problems arising in the study of differential operators, these problems provide a good illustration of the power and ease of use of Cartan's equivalence method, which offers a straightforward algorithm for solving these and other equivalence problems important in applications. Extensions to higher-order or higher-dimensional operators can be readily done using the methods of this paper, although the intervening calculations will, as a rule, become much more complicated. In the proof of the theorem, we assume that the reader has a basic familiarity with the Cartan equivalence method as explained, for instance, in [2], [3], [6], and [7], although the reader can certainly understand the final results without all the intervening machinery.

This paper originated in answer to a question raised by Levine [9], who asked when a differential operator can be expressed as a bilinear combination of first-order differential operators that generate a finite-dimensional Lie algebra. This problem has applications to scattering theory in molecular dynamics and quantum chemistry. Indeed, there are now a number of well-established methods for dealing with such operators, where the calculation of eigenvalues, spectra, and dynamics is considerably simplified. The companion paper [8] applies the results of this paper to solving Levine's problem completely.

2. Equivalence problems for differential operators. Consider a second-order differential operator

$$\mathscr{D} = f(x)D^2 + g(x)D + h(x), \tag{2.1}$$

where f, g, h, are analytic functions of the real variable $x \in \mathbb{R}$, and $D = d/dx$. If we apply $\mathscr{D}$ to a scalar-valued function $u(x)$, we obtain the expression

$$\mathscr{D}[u] = fu'' + gu' + hu. \tag{2.2}$$

In particular, we can look at the linear, homogeneous second-order ordinary differential equation $\mathscr{D}[u] = 0$, or the eigenvalue problem $\mathscr{D}[u] = \lambda u$, or the Schrödinger equation $u_t = i\mathscr{D}[u]$, in which $\mathscr{D}$ plays the role of the Hamiltonian.

We will be concerned with the problem of when two such differential operators can be mapped into each other by an appropriate change of coordinates. It turns out that two natural classes of transformations can be employed to change the differential operator. Clearly, as far as the independent and dependent variables are concerned, the appropriate pseudogroup consists of the fiber-preserving transformations that are linear in the fiber variable u:

$$\bar{x} = \varphi(x), \qquad \bar{u} = \psi(x)u. \tag{2.3}$$

The total derivative operators are related by the chain rule formula[1]

$$\bar{D} = \frac{1}{\varphi'(x)} D. \tag{2.4}$$

In the first of our two equivalence problems, we identify the two differential expressions $\bar{\mathscr{D}}[\bar{u}] = \mathscr{D}[u]$ (cf. (2.2)), where

$$\bar{\mathscr{D}} = \bar{f}(\bar{x})\bar{D}^2 + \bar{g}(\bar{x})\bar{D} + \bar{h}(\bar{x})$$

is another second-order differential operator. The explicit formulae for the new coefficient functions $\bar{f}, \bar{g}, \bar{h}$, in terms of the original coefficients f, g, h of $\mathscr{D}$, can be determined using the transformation rule

$$\bar{\mathscr{D}} = \mathscr{D} \cdot \frac{1}{\psi(x)}, \tag{2.5}$$

together with the chain rule (2.4). The first of our equivalence problems for differential operators then amounts to determining conditions on the two differential operators such that there exists a transformation (2.3) that maps one to the other according to (2.5).

The transformation rule (2.5) has the disadvantage of not preserving either the eigenvalue problem or the Schrödinger equation associated with the operator. For instance, $\mathscr{D}[u] = \lambda u$ does not imply $\bar{\mathscr{D}}[\bar{u}] = \lambda \bar{u}$, since we are missing a factor of $\psi(x)$. To rectify this situation, we need to premultiply by $\psi(x)$ and use the alternative transformation rule

$$\bar{\mathscr{D}} = \psi(x) \cdot \mathscr{D} \cdot \frac{1}{\psi(x)}. \tag{2.6}$$

This transformation rule leads to slightly different formulae expressing the new coefficients $\bar{f}, \bar{g}, \bar{h}$, in terms of f, g, h. The transformations (2.6) enjoy the additional property of preserving the standard commutator Lie bracket $[\mathscr{D}, \mathscr{E}] = \mathscr{D} \cdot \mathscr{E} - \mathscr{E} \cdot \mathscr{D}$ between differential operators. The second equivalence problem is to determine conditions on two differential operators such that there exists a transformation (2.3) mapping one to the other according to (2.6).

[1] For simplicity, we will explicitly denote the pull-back maps only in the statements of the theorems.

We will solve both equivalence problems in this paper. Incidentally, if we try to combine all the transformations (2.3), (2.5), (2.6) (for different functions $\psi(x)$), we end up with the trivial result that all second-order differential operators are equivalent under this largest pseudogroup.

To apply Cartan's algorithm to either equivalence problem, we need to recast the transformation rules (2.3), and (2.5) or (2.6), in the language of differential forms. The appropriate space to work in will be the second jet space J^2, which has coordinates x, u, p, q. Here p represents the derivative u', and q the derivative u''. The immediate goal is to construct an appropriate coframe, or pointwise basis for the cotangent space T^*J^2, that will encode the relevant transformation rules for our problem(s). The first remark is that as long as $u \neq 0$, the pseudogroup of transformations (2.3) is uniquely prescribed by imposing the 1-form equations

$$d\bar{x} = \alpha\, dx, \tag{2.7}$$

$$\frac{d\bar{u}}{\bar{u}} = \frac{du}{u} + \beta\, dx. \tag{2.8}$$

Here α and β are functions J^2, whose precise form does not need to be specified in advance. Indeed, the first equation implies that $\bar{x} = \varphi(x)$, with $\alpha = \varphi'$, while the second necessarily requires the linearity of the transformation in u, so that $\bar{u} = \psi(x)u$, with $\beta = \psi'/\psi$. Note that the restriction to $u \neq 0$, which means that we are restricting our attention to either the positive or negative real u-axis, is inessential as far as the differential operator itself is concerned. (Indeed, analytic continuation will extend our results across the apparent singular subspace $u = 0$.)

For the derivative variables p and q to transform correctly, we need to preserve the *contact ideal* on J^2, which is the differential ideal generated by the pair of 1-forms $du - p\, dx$, $dp - q\, dx$. In general, a diffeomorphism $\Phi\colon J^2 \to J^2$ determines a contact transformation if and only if

$$d\bar{u} - \bar{p}\, d\bar{x} = \lambda(du - p\, dx), \tag{2.9}$$

$$d\bar{p} - \bar{q}\, d\bar{x} = \mu(du - p\, dx) + \nu(dp - q\, dx), \tag{2.10}$$

where λ, μ, ν, are functions on J^2. Equations (2.7)–(2.9) by themselves already constitute part of an overdetermined equivalence problem on J^2. There is an algorithm, due to Cartan, to reduce this to an equivalence problem of standard form, but in our case, we can do this by inspection. It is easy to see that the 1-form $(du - p\, dx)/u$ is invariant, so the identification

$$\frac{d\bar{u} - \bar{p}\, d\bar{x}}{\bar{u}} = \frac{du - p\, dx}{u} \tag{2.11}$$

can replace both (2.8) and (2.9). The reader can check that the 1-form identities (2.7), (2.10), (2.11), are equivalent to requiring that the transformation on J^2 be the prolongation of a point transformation of the special form (2.3), with the derivative variables p, q, transforming correctly. Therefore, we take as the first three elements of our eventual coframe the 1-forms

$$\omega_1 = dx, \quad \omega_2 = \frac{du - p\, dx}{u}, \quad \omega_3 = dp - q\, dx, \tag{2.12}$$

with the transformation rules

$$\bar{\omega}_1 = A\omega_1, \quad \bar{\omega}_2 = \omega_2, \quad \bar{\omega}_3 = B\omega_2 + C\omega_3, \quad A, C \neq 0,$$

where A, B, C, are functions on J^2. This much of the coframe is the same for each equivalence problem. To complete the coframe, we need to supplement these 1-forms with an additional 1-form, which will encode the action of the transformation rule (2.5) or (2.6) on the differential operator itself.

In both cases, there is an obvious invariant function for the problem. For the equivalence problem (2.5), the invariant is the differential expression (2.2), i.e.,

$$I(x, u, p, q) = \mathscr{D}[u] = f(x)q + g(x)p + h(x)u. \tag{2.13}$$

For the second problem (2.6), the invariant is slightly more complicated:

$$I(x, u, p, q) = \frac{\mathscr{D}[u]}{u} = \frac{f(x)q + g(x)p}{u} + h(x), \tag{2.14}$$

since we need to take care of the extra factor of ψ. In either case, we have $I(x, u, p, q) = \bar{I}(\bar{x}, \bar{u}, \bar{p}, \bar{q})$ under the identification (2.5) or (2.6). We therefore take our final 1-form to be the differential $\omega_4 = dI$, so that for the equivalence problem (2.5) we have

$$\omega_4 = f\,dq + g\,dp + h\,du + \{f'q + g'p + h'u\}\,dx, \tag{2.15}$$

whereas for the alternative problem (2.6) we take

$$\omega_4 = \frac{f}{u}\,dq + \frac{g}{u}\,dp - \frac{fq + gp}{u^2}\,du + \left\{\frac{f'q + g'p}{u} + h'\right\} dx. \tag{2.16}$$

In both cases, the four 1-forms $\omega_1, \omega_2, \omega_3, \omega_4$, provide a coframe on the subset

$$\Omega^* = \{(x, u, p, q) \in J^2 \,|\, u \neq 0 \text{ and } f(x) \neq 0\}. \tag{2.17}$$

From now on, we restrict our attention to a connected component $\Omega \subset \Omega^*$ of the subset (2.17); note that on such a component, the signs of $f(x)$ and u are fixed. We require only that the last coframe elements agree up to contact, i.e.,

$$\bar{\omega}_4 = D\omega_2 + E\omega_3 + \omega_4.$$

We therefore define the structure group

$$G = \left\{ \begin{pmatrix} A & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & B & C & 0 \\ 0 & D & E & 1 \end{pmatrix} : A, B, C, D, E \in \mathbb{R}, A \cdot C \neq 0 \right\},$$

which happens to be the same for both equivalence problems, even though the two coframes are different.

As a consequence of these preliminary considerations, we have successfully encoded our equivalence problem in terms of a coframe, and have shown the following.

PROPOSITION 2.1. *Let $\mathscr{D}$ and $\bar{\mathscr{D}}$ be second-order differential operators. Let $\{\omega_1, \omega_2, \omega_3, \omega_4\}$ and $\{\bar{\omega}_1, \bar{\omega}_2, \bar{\omega}_3, \bar{\omega}_4\}$ be the corresponding coframes, on open subsets Ω and $\bar{\Omega}$ of the second jet space, given by* (2.12) *and* (2.15) *or* (2.16), *the choice of ω_4 and $\bar{\omega}_4$ depending on the equivalence problem under consideration. The differential operators are equivalent under the pseudogroup* (2.3) *according to the respective transformation rule* (2.5) *or* (2.6) *if and only if there is a diffeomorphism $\Phi: \Omega \to \bar{\Omega}$ that satisfies*

$$\Phi^*(\bar{\omega}_i) = \sum_{j=1}^{4} g_{ij}\omega_j, \qquad i = 1, \cdots, 4,$$

where $g = (g_{ij})$ is a G-valued function on J^2, and Φ^* denotes the pull-back map on differential forms.

To apply Cartan's algorithm for this equivalence problem, we must "lift" the coframes to the space $J^2 \times G$. The *lifted coframe* takes the form

$$\theta_1 = A\omega_1, \quad \theta_2 = \omega_2, \quad \theta_3 = B\omega_2 + C\omega_3, \quad \theta_4 = D\omega_2 + E\omega_3 + \omega_4, \tag{2.18}$$

where the coefficients A, B, C, D, E are now interpreted as coordinates in the structure group G. We then have the standard reformulation of the equivalence condition of Proposition 2.1.

PROPOSITION 2.2. *Under the setup of Proposition* 2.2, *two differential operators* $\mathscr{D}$ *and* $\bar{\mathscr{D}}$ *are equivalent if and only if there is a diffeomorphism* $\Psi: \Omega \times G \to \bar{\Omega} \times G$ *that commutes with the natural left action of* G, *and maps the appropriate lifted coframe elements to each other*:

$$\Psi^*(\bar{\theta}_i) = \theta_i, \qquad i = 1, \cdots, 4. \tag{2.19}$$

3. Solution of the first equivalence problem. To keep our presentation as short as possible, we will assume that the reader has some familiarity with the mechanics of Cartan's equivalence method as discussed, for instance, in [2], [3], and [6]. We will solve both equivalence problems, beginning with the setup (2.5), corresponding to the coframe element (2.15). The solutions are fairly similar intrinsically, although the parametric formulae differ. We present this case in detail, and briefly indicate how the other problem goes in the following section.

We begin with the lifted coframe (2.18), based on the base coframe (2.12), (2.15). The basic tool in Cartan's method is the invariance of the exterior derivative operation under smooth maps, so we begin by computing the differentials $d\theta_i$. They are found to have the form

$$\begin{aligned} d\theta_1 &= \alpha \wedge \theta_1 + \sigma_1, \\ d\theta_2 &= \sigma_2, \\ d\theta_3 &= \beta \wedge \theta_2 + \gamma \wedge \theta_3 + \sigma_3, \\ d\theta_4 &= \delta \wedge \theta_2 + \varepsilon \wedge \theta_3 + \sigma_4. \end{aligned}$$

Here α, β, γ, δ, ε, form a basis for the right-invariant 1-forms on the Lie group G, and the torsion terms take the form

$$\sigma_i = \sum_{j<k} \tau_{ijk} \theta_j \wedge \theta_k, \qquad i = 1, \cdots, 4.$$

In the absorption part of Cartan's process, we are allowed to replace each 1-form α, β, γ, δ, ε by an expression of the form $\alpha + \Sigma z_j \theta_j$, etc., where the functions z_j are chosen so as to make as many of the torsion coefficients τ_{ijk} vanish as possible. In the present setup we can readily "absorb" all the torsion components except

$$\tau_{212} = -\frac{B + Cp}{ACu}, \quad \tau_{213} = \frac{1}{ACu}, \quad \tau_{314} = \frac{C}{Af}, \quad \tau_{414} = \frac{E}{Af}.$$

These components are invariants of the problem. Since they depend on the group parameters, the next step in the process is to normalize them to as simple a form as possible through a suitable choice of the group parameters. There are two possible normalizations for these torsion components, depending on $\kappa_1 = \text{sign}\,(f(x) \cdot u)$, leading to two different branches for the equivalence problem. (However, as we remarked above, as far as the differential operator itself is concerned, the division into two branches is not essential, since we can always change the sign of u by restricting our attention to a different connected component Ω of the domain (2.17). It is nevertheless

convenient to retain the sign through our analysis.) We normalize the torsion components to 0, κ_1, 1, 0, respectively, by setting

$$A=\frac{\sigma_1}{\sqrt{|fu|}},\quad B=-\sigma_2 p\sqrt{\left|\frac{f}{u}\right|},\quad C=\sigma_2\sqrt{\left|\frac{f}{u}\right|},\quad E=0. \tag{3.1}$$

Here $\sigma_1=\pm 1$ is an undetermined sign that must be left ambiguous (even with the specification of κ_1), and $\sigma_2=\sigma_1\cdot(\operatorname{sign} f)$. (See [7] for a detailed discussion of these types of signs.) The normalizations (3.1) have the effect of reducing the original Lie group G to a one-parameter subgroup, with D the only remaining undetermined parameter.

In the second loop through the equivalence procedure, we substitute (3.1) into the formulas for the lifted coframe (2.18) and recompute the differentials. The unabsorbable torsion component $\tau_{413}=D$ can then be normalized to zero by setting $D=0$. Note that we could have avoided adding in contact terms in our definition of θ_4, since ω_4 turns out to already be an invariant form.

By normalizing the torsion components, we have managed to eliminate all of the group parameters. This has had the effect of (a) reducing the structure group to the identity, and (b) reducing the lifted invariant coframe to an invariant coframe on the base space J^2, known as an $\{e\}$-*structure* or local parallelism. The explicit formula for the invariant coframe comes from (2.18), (3.1), and we have

$$\begin{aligned}
\theta_1&=\frac{\sigma_1\,dx}{\sqrt{|fu|}},\\
\theta_2&=\frac{du-p\,dx}{u},\\
\theta_3&=\sigma_2\sqrt{\left|\frac{f}{u}\right|}\left\{-\frac{p}{u}(du-p\,dx)+(dp-q\,dx)\right\},\\
\theta_4&=f\,dq+g\,dp+h\,du+(f'q+g'p+h'u)\,dx.
\end{aligned} \tag{3.2}$$

Indeed, as the reader can check, these 1-forms do satisfy the invariance conditions

$$\bar\theta_i=\theta_i,\qquad i=1,2,3,4,$$

under the pseudogroup of transformations (2.3), (2.5). Applying the exterior derivative to the invariant coframe elements, and re-expressing the resulting 2-forms in terms of the coframe, we find that the structure equations for our problem take the form

$$\begin{aligned}
d\theta_1&=\tfrac12\theta_1\wedge\theta_2,\\
d\theta_2&=\kappa_1\theta_1\wedge\theta_3,\\
d\theta_3&=-I\theta_1\wedge\theta_2+\kappa_1 J\theta_1\wedge\theta_3+\theta_1\wedge\theta_4+\tfrac12\theta_2\wedge\theta_3,\\
d\theta_4&=0,
\end{aligned} \tag{3.3}$$

where

$$I=fq+gp+hu,\qquad J=\sigma_2\sqrt{\left|\frac{u}{f}\right|}\left(\frac12 f'-\frac32 p\frac{f}{u}-g\right). \tag{3.4}$$

Because the coframe is invariant, the functions I and J are the fundamental invariants of the problem. Note that we have recovered our original invariant (2.13) as one of the torsion components in the structure equations (3.3).

The *covariant derivatives* $F_{,\theta_i}$ of a function F with respect to the coframe (3.2) are defined by expressing the differential of F in terms of the invariant coframe:

$$dF = F_{,\theta_1}\theta_1 + F_{,\theta_2}\theta_2 + F_{,\theta_3}\theta_3 + F_{,\theta_4}\theta_4. \tag{3.5}$$

Explicitly,

$$\begin{aligned} F_{,\theta_1} &= \sigma_1\sqrt{|fu|}\,\hat{D}_x F, \\ F_{,\theta_2} &= uF_u + pF_p - \frac{pg+hu}{f}F_q, \\ F_{,\theta_3} &= \sigma_2\sqrt{\left|\frac{u}{f}\right|}\left(F_p - \frac{g}{f}F_q\right), \\ F_{,\theta_4} &= \frac{1}{f}F_q. \end{aligned} \tag{3.6}$$

Here $\hat{D}_x$ denotes the differential operator

$$\hat{D}_x = \frac{\partial}{\partial x} + p\frac{\partial}{\partial u} + q\frac{\partial}{\partial p} + R\frac{\partial}{\partial q}, \tag{3.7}$$

where

$$R = -\frac{gq + hp + f'q + g'p + h'u}{f}. \tag{3.8}$$

Note that if we differentiate the invariant equation $I = \text{constant}$ (which is the same as the ordinary differential equation $\mathscr{D}[u] = \text{constant}$) with respect to x and solve for the third-order derivative $r = u'''$, we recover (3.8). In this sense, $\hat{D}_x$ can be identified with the total derivative operator on J^2.

The covariant derivatives of any of the fundamental invariants (3.4), called the *derived invariants*, are also clearly invariants. Since the differentials of I and J are of the form

$$dI = \theta_4, \qquad dJ = \kappa_1 K\theta_1 + \tfrac{1}{2}J\theta_2 - \tfrac{3}{2}\kappa_1\theta_3,$$

the only independent derived invariant is

$$\begin{aligned} K &= \kappa_1 J_{,\theta_1} = \kappa_1\sigma_1\sqrt{|fu|}\,\hat{D}_x J \\ &= -\frac{3}{2}fq + \frac{3}{4}f\frac{p^2}{u} - \frac{1}{2}p(f'+g) + u\frac{2ff'' - f'^2 + 2f'g - 4fg'}{4f}. \end{aligned} \tag{3.9}$$

(Note that K does not have an ambiguous sign.) We can continue differentiating to deduce higher-order derived invariants; for example,

$$dK = L\theta_1 + (K - \tfrac{3}{2}I)\theta_2 - J\theta_3 - \tfrac{3}{2}\theta_4,$$

so we have one second-order derived invariant

$$L = K_{,\theta_1} = \kappa_1 J_{,\theta_1,\theta_1} = \sigma_1\sqrt{|fu|}\,\hat{D}_x K,$$

which we avoid writing out explicitly.

Given an $\{e\}$-structure as above, we define its *rank* to be the number of functionally independent invariants (including all possible derived invariants). The *order* of the $\{e\}$-structure is the highest-order derived invariant required to complete the independent set of invariants. According to the standard Jacobian criterion for functional

independence, the particular $\{e\}$-structure given by the coframe (3.3) will have rank 4 and order 2, provided $dI \wedge dJ \wedge dK \wedge dL \neq 0$, whereby I, J, K, L are a complete set of functionally independent invariants. Exceptional cases with lower rank (and lower order) can occur if this wedge product vanishes.

To investigate the structure of the invariants in more detail, we proceed as follows. Note first that since $f \cdot u \neq 0$, the invariants I and J are always functionally independent. We can eliminate p and q from the original equations (3.4):

$$p = \frac{f' - 2g}{3f} u - \frac{2}{3} \kappa_1 \sigma_2 J \sqrt{\left| \frac{u}{f} \right|},$$

$$q = -\frac{gp + hu - I}{f} = \frac{2g^2 - f'g - 3fh}{3f^2} u - \frac{2}{3} \kappa_1 \sigma_1 J \frac{g|u|^{1/2}}{|f|^{3/2}} + \frac{I}{f}.$$

Substituting these into (3.9), we find that we can write

$$K = a(x)u + \frac{1}{3} \kappa_1 J^2 - \frac{3}{2} I,$$

where

$$a = \frac{5gf' - 2f'^2 - 2g^2}{6f} + \frac{3}{2} h - g' + \frac{1}{2} f''. \tag{3.10}$$

If the function $a(x) \equiv 0$, then K is a function of I and J. An easy chain rule argument shows that in this case, besides I and J, there are no further independent derived invariants. Therefore, if $a \equiv 0$, the rank of the $\{e\}$-structure is 2, and the order is zero.

Otherwise, if a does not vanish identically, we can take

$$\tilde{K} = a(x)u$$

as a new independent invariant, and compute its derived invariant:

$$\tilde{L} = \tilde{K}_{,\theta_1} = \sigma_1 \sqrt{|fu|}\, \hat{D}_x \tilde{K} = \kappa_1 b(x) |\tilde{K}|^{3/2} - \frac{2}{3} J \tilde{K},$$

where

$$b(x) = \sigma_1 \frac{3a'f + af' - 2ag}{3\sqrt{|fa^3|}}. \tag{3.11}$$

Note that b is an invariant that depends only on x. If b is constant, then $I, J, \tilde{K}$ form a complete set of functionally independent invariants; the rank is 3 and the order 2. Otherwise, for b not constant, we have an $\{e\}$-structure of maximal rank, with $I, J, \tilde{K}, b$ comprising our four fundamental independent invariants. In this case, we complete the solution to the equivalence problem by computing one final derived invariant:

$$b_{,\theta_1} = \sigma_1 \sqrt{|fu|}\, b' = c(x) |\tilde{K}|^{1/2},$$

where

$$c(x) = \sigma_1 \sqrt{|f/a|}\, b'(x) \tag{3.12}$$

is also an invariant. In the case of an $\{e\}$-structure of maximal rank, the *determining function* F for our equivalence problem is prescribed by re-expressing c in terms of b, i.e., we write

$$c(x) = F[b(x)]. \tag{3.13}$$

Note that F may be a multiply-valued function.

Example 3.1. Let us consider the case of a simple operator

$$\mathscr{D} = D^2 + h(x) \tag{3.14}$$

of Sturm–Liouville type, i.e., $f = 1$, $g = 0$. Such operators play a key role in quantum mechanics, scattering theory, and the theory of the Korteweg–de Vries equation. Here

$$a(x) = \tfrac{3}{2}h(x),$$

so we have a structure of rank 2 if and only if $h \equiv 0$ and $\mathscr{D} = D^2$. As a result of our construction, we deduce that a second-order differential operator (2.1) is equivalent to the differential operator D^2 if and only if

$$3ff'' - 2f'^2 + 5f'g - 6fg' - 2g^2 + 9fh = 0. \tag{3.15}$$

Continuing, if $h \neq 0$, then

$$b = \pm\sqrt{\frac{3}{2}}\,\frac{h'}{|h|^{3/2}}.$$

Therefore b is constant if and only if $h(x) = (cx + d)^{-2}$, i.e., we have either a translate of the radial Laplace operator

$$\mathscr{D} = D^2 + \frac{k}{x^2}, \tag{3.16}$$

when $b = -\sqrt{6/k} \neq 0$, or $\mathscr{D} = D^2 + k$, when $b = 0$. Note that $k \neq 0$ can be scaled to 1.

Finally, in the case when b is not constant, then

$$c = \frac{hh'' - \frac{3}{2}h^2}{h^3}.$$

The determining function F will be found by writing

$$\frac{h''}{h^2} = \tilde{F}\left(\frac{h'}{h^{3/2}}\right), \tag{3.17}$$

from which

$$F(t) = \tilde{F}(t) - \tfrac{3}{2}t^2.$$

We note that the ordinary differential equation (3.17) can be solved explicitly by quadratures, owing to the presence of an obvious two-parameter symmetry group of translations in t and scalings; see [10].

In essence, the collection of all the invariants and their derived invariants will completely solve our equivalence problem, providing explicit necessary and sufficient conditions for two differential operators to be equivalent under a transformation (2.5). The following theorem is a consequence of general results on the equivalence of $\{e\}$-structures [6], [7].

THEOREM 3.2. *Let $\mathscr{D}$ and $\bar{\mathscr{D}}$ be real-analytic differential operators. Define the function $a(x)$ by* (3.10). *If $a \not\equiv 0$, then define the functions $b(x)$, $c(x)$ by* (3.11), (3.12). *Then $\mathscr{D}$ and $\bar{\mathscr{D}}$ are equivalent under a change of variables* (2.3), (2.5) *if and only if*:

(i) *$a \equiv \bar{a} \equiv 0$, in which case both $\mathscr{D}$ and $\bar{\mathscr{D}}$ are equivalent to the operator D^2; or*

(ii) *Both a and $\bar{a}$ do not vanish identically and $b = \bar{b}$ are constant, in which case both $\mathscr{D}$ and $\bar{\mathscr{D}}$ are equivalent to either the radial Laplace operator* (3.16) *or the operator $D^2 + 1$; or*

(iii) *Both a and $\bar{a}$ do not vanish identically, both b and $\bar{b}$ are not constant, the determining functions prescribed by* (3.13) *are identical, $F = \bar{F}$, and the equation $b(x) = \bar{b}(\bar{x})$ has a real solution branch.* (*For complex equivalence, the last statement is unnecessary.*)

The change of variables required to map one operator into the other is implicitly given as the solution to the equations

$$b(x)=\bar{b}(\bar{x}), \qquad \bar{a}(\bar{x})\bar{u}=a(x)u, \tag{3.18}$$

restricted so that the signs $\kappa_1=\operatorname{sign}(f\cdot u)$ and $\bar{\kappa}_1=\operatorname{sign}(\bar{f}\cdot\bar{u})$ agree: $\kappa_1=\bar{\kappa}_1$.

In fact, the connection with the operator (3.14) can be used to complete the solution to the equivalence problem.

THEOREM 3.3. *If $\mathscr{D}$ is a second-order differential operator, then there is a transformation* (2.3), (2.5) *taking $\mathscr{D}$ into the operator $\bar{D}^2+\frac{2}{3}a(\bar{x})$, where the potential $a(\bar{x})$ is given by the (relative) invariant* (3.10) *when $\bar{x}=\varphi(x)$. Moreover, two differential operators are equivalent if and only if their corresponding potentials differ by the rescaling and translation group $\bar{a}(\bar{x})=\lambda^2 a(\lambda\bar{x}+\delta)$.*

In other words, the equivalence class of a differential operator under (2.6) is completely determined by its potential; moreover, two potentials are equivalent if and only if they are rescaled translates of each other.

4. Solution of the second equivalence problem. In this case, we begin as before with the lifted coframe (2.18), now based on the base coframe (2.12), (2.16). In the first loop through the equivalence procedure, we are left with the unabsorbable torsion components

$$\tau_{212}=-\frac{B+Cp}{ACu}, \quad \tau_{213}=\frac{1}{ACu}, \quad \tau_{314}=\frac{C}{Afu}, \quad \tau_{414}=\frac{E}{Afu}.$$

Again, there are two branches, depending on $\kappa_1=\operatorname{sign} f$. Here the sign restriction is more essential than in the previous equivalence problem, since we cannot change the sign of f by a transformation of type (2.6). We normalize the torsion components to 0, κ_1, 1, 0, respectively, by setting

$$A=\frac{\sigma_1}{u\sqrt{|f|}}, \quad B=-\sigma_2 p\sqrt{|f|}, \quad C=\sigma_2\sqrt{|f|}, \quad E=0,$$

where σ_1 is an ambiguous sign, and $\sigma_2=\sigma_1\kappa_1$. In the second loop through the equivalence procedure, the unabsorbable torsion components $\tau_{413}=-\tau_{312}=D$ can both be normalized to zero by setting $D=0$. The final invariant coframe is now given by

$$\begin{aligned}
\theta_1&=\frac{\sigma_1\,dx}{u\sqrt{|f|}},\\
\theta_2&=\frac{du-p\,dx}{u},\\
\theta_3&=\sigma_2\sqrt{|f|}\left\{(dp-q\,dx)-\frac{p}{u}(du-p\,dx)\right\},\\
\theta_4&=\frac{f}{u}\,dq+\frac{g}{u}\,dp+\frac{fq+gp}{u^2}\,du+\left\{\frac{f'q+g'p}{u}+h'\right\}dx.
\end{aligned} \tag{4.1}$$

The structure equations take a slightly different form:

$$\begin{aligned}
d\theta_1&=0,\\
d\theta_2&=\kappa_1\theta_1\wedge\theta_3,\\
d\theta_3&=-2J\theta_1\wedge\theta_3+\theta_1\wedge\theta_4,\\
d\theta_4&=0,
\end{aligned} \tag{4.2}$$

where

$$J=\frac{\sigma_1}{4\sqrt{|f|}}\left(2g-f'+\frac{4pf}{u}\right) \tag{4.3}$$

is a fundamental invariant of the problem. Interestingly, the original invariant I given in (2.14) does *not* appear among the structure functions of the adapted coframe. Indeed, it is easy to see that it cannot appear even among the derived invariants of the structure functions, since only the derivative h' appears in the coframe (4.1), so it would be impossible to recover the function h, which appears in the expression for I, by differentiation. Thus, the invariant coframe (4.1) must be supplemented by the additional invariant I to effect the correct solution to the problem. Although we have come up with a nonstandard equivalence problem, Cartan himself was already aware of such possibilities. Indeed, in his original treatment of the equivalence method, he allows for the incorporation of additional function invariants into an equivalence problem, and, as he says, "Rien n'est changé à la solution..." [1, p. 725]. Here, we have one invariant provided by the structure functions, and one additional invariant, both of whose derived invariants must be taken into account when discussing the solution to the problem.

The *covariant derivatives* of a function F with respect to the coframe (4.1) are

$$\begin{aligned}
F_{,\theta_1}&=\sigma_1\sqrt{|f|}\,\hat{D}_x F,\\
F_{,\theta_2}&=uF_u+pF_p-\frac{fq+pg(1-u)}{f}F_q,\\
F_{,\theta_3}&=\frac{\sigma_2 u}{\sqrt{|f|}}\left(F_p-\frac{g}{f}F_q\right),\\
F_{,\theta_4}&=\frac{u}{f}F_q.
\end{aligned} \tag{4.4}$$

Here

$$\hat{D}_x=\frac{\partial}{\partial x}+p\frac{\partial}{\partial u}+q\frac{\partial}{\partial p}+R\frac{\partial}{\partial q}$$

is similar to the total derivative operator (3.7), but

$$R=\frac{fqp+gp^2}{u}-(gq+f'q+g'p+h'u) \tag{4.5}$$

is different. As in § 3, if we differentiate the equation $I=\text{constant}$ with respect to x and solve for the third order derivative $r=u'''$, then we recover the expression (4.5).

Since the differentials of I and J are of the form

$$dI=\theta_4, \qquad dJ=K\theta_1+\theta_3,$$

the only independent derived invariant is

$$\begin{aligned}
K=J_{,\theta_1}&=\sigma_1\sqrt{|f|}\,\hat{D}_x J\\
&=f\frac{qu-p^2}{u^2}+f'\frac{p}{2u}-\frac{2ff''-f'^2+2f'g-4fg'}{8f}.
\end{aligned} \tag{4.6}$$

Furthermore,

$$dK=L\theta_1-2J\theta_3+\theta_4,$$

so we have only one further second-order derived invariant:

$$L = K_{,\theta_1} = J_{,\theta_1,\theta_1} = \sigma_1 \sqrt{|f|}\, \hat{D}_x K.$$

Note that in the case of the transformation rule (2.6), there is always a one-parameter symmetry group of any differential operator, namely, the scaling $u \to \lambda u$. Since the invariants must respect this symmetry, there can be at most three functionally independent invariants. Thus, the rank of this $\{e\}$-structure can be at most 3, and this will happen when $dI \wedge dJ \wedge dK \neq 0$.

To investigate the structure of the invariants in more detail, we proceed as before. We solve (2.14), (4.3), for p and q:

$$p = u\left(\frac{\sigma_2 J}{\sqrt{|f|}} + \frac{f' - 2g}{4f}\right),$$

$$q = \frac{uI - uh - pg}{f} = u\left(\frac{I}{f} - \sigma_1 \frac{gJ}{|f|^{3/2}} + \frac{2g^2 - f'g - 4fh}{4f^2}\right).$$

Thus

$$K = -a(x) + I - \kappa_1 J^2, \tag{4.7}$$

where

$$a = \frac{8gf' - 3f'^2 - 4g^2}{16f} + h - \frac{1}{2}g' + \frac{1}{4}f''. \tag{4.8}$$

The only degenerate case is when a is constant, so the rank is 2 and the order zero. Otherwise the rank is 3, and we can take $a(x)$ as a new invariant. The final derived invariant is

$$b = a_{,\theta_1} = \sigma_1 \sqrt{|f|}\, a'. \tag{4.9}$$

The *determining function* is found by re-expressing b in terms of a:

$$b(x) = F[a(x)]. \tag{4.10}$$

Note that since b has the ambiguous sign σ_1, the determining function F is only prescribed up to an ambiguous $\pm$ sign. (Indeed, the orientation reversing change of variables $x \to -x$, $u \to u$, will change the sign of f.) One solution to this annoying complication is to replace the invariant b by its square $b^2 = \kappa_1 f a'^2$.

THEOREM 4.1. *Let $\mathscr{D}$ and $\bar{\mathscr{D}}$ be real-analytic differential operators. Define the functions $a(x)$, $b(x)$, by* (4.8), (4.9). *Then $\mathscr{D}$ and $\bar{\mathscr{D}}$ are equivalent under a change of variables* (2.3), (2.6) *if and only if the signs $\kappa_1 = \operatorname{sign}(f) = \bar{\kappa}_1 = \operatorname{sign}(\bar{f})$ agree, and either*:

(i) *$a = \bar{a} = k$ are constant, in which case both $\mathscr{D}$ and $\bar{\mathscr{D}}$ are equivalent to the operator $D^2 + k$; or*

(ii) *Both a and $\bar{a}$ are not constant, the determining functions prescribed by* (4.10) *are identical, $F = \bar{F}$, and the equation $a(x) = \bar{a}(\bar{x})$ has a real solution branch.*

Example 4.2. Let us consider the case of the operator $\mathscr{D} = D^2 + h(x)$. In this case, $a(x) = h(x)$; hence we have a structure of rank 2 if and only if h is constant. A differential operator (2.1) is equivalent to the differential operator $D^2 + k$ via (2.6) if and only if $a = k$, i.e.,

$$4ff'' - 3f'^2 + 8f'g - 8fg' - 4g^2 + 16fh = 16kf. \tag{4.11}$$

Otherwise, since $b = h'$, the determining function will be found by writing

$$h' = F(h). \tag{4.12}$$

For a fixed determining function F, the general solution of (4.12) are just the translates of h, i.e., $\tilde{h}(x) = h(x-\delta)$. We conclude that two operators of the form (3.14) are equivalent under the transformation group (2.6) if and only if their potentials are translates of each other.

Conversely, given a determining function F, we can always construct a corresponding potential $h(x)$ by solving the elementary first-order ordinary differential equation (4.12). We thus recover the classical result that a general second-order differential operator can always be transformed into an operator of the form (3.14).

THEOREM 4.3. *If $\mathscr{D}$ is a second-order differential operator, then there is a transformation* (2.6) *taking $\mathscr{D}$ into the operator $\pm\bar{D}^2 + a(\bar{x})$, where the potential $a(\bar{x})$ is given by the invariant* (4.8) *when $\bar{x} = \varphi(x)$, and the sign in front of $\bar{D}^2$ is determined by the sign of f, the coefficient of D^2 in $\mathscr{D}$. Moreover, two differential operators are equivalent if and only if their signs are the same and the corresponding potentials differ by a translation*: $\bar{a}(x) = a(x+\delta)$.

In other words, outside singular points where $f(x) = 0$, the equivalence class of a differential operator under (2.6) is completely determined by its potential and the sign of its leading coefficient; moreover, two potentials are equivalent if and only if they are translates of each other.

5. Symmetries of differential operators. We will call a group of transformations of the form (2.3) a symmetry group of the differential operator $\mathscr{D}$ if the corresponding transformation (2.5) or (2.6) leaves the operator unchanged. (This is more restrictive than the concept of a symmetry group of a differential equation [10].) It is interesting to see what the corresponding infinitesimal symmetry criteria are.

PROPOSITION 5.1. *Given a vector field $\mathbf{v} = \xi(x)(\partial/\partial x) + \eta(x)u(\partial/\partial u)$ that generates a one-parameter group of transformations of the form* (2.3) *on $\mathbb{R}^2$, define a corresponding first-order differential operator $\mathscr{V} = \xi(x)D + \eta(x)$. The group generated by $\mathbf{v}$ is a symmetry group of the differential operator $\mathscr{D}$ of the type* (2.5) *or of the type* (2.6) *if and only if the operator equation*

$$[\mathscr{V}, \mathscr{D}] + \eta \cdot \mathscr{D} = 0 \tag{5.1}$$

or, respectively,

$$[\mathscr{V}, \mathscr{D}] = 0 \tag{5.2}$$

holds.

In either case, the proof is straightforward. In the second case, the scaling vector field with $\eta = 1$ always generates a symmetry group.

Cartan's method gives us a complete handle on the symmetry group of an $\{e\}$-structure. If the structure has rank r and the underlying space has dimension n, then the symmetry group forms a Lie group of dimension $n-r$. For the differential operator equivalence problems, then, $n = 4$, and so the symmetry group will have dimension $4-r$, where r is the number of functionally independent invariants. This leads to the following results.

THEOREM 5.2. *Let $\mathscr{D}$ be a real-analytic differential operator, and consider the symmetries of the type* (2.5). *Define the functions $a(x)$, $b(x)$, $c(x)$ as in* § 3. *Then*:

(i) *$\mathscr{D}$ admits a two-parameter symmetry group if and only if $a \equiv 0$.*

(ii) *$\mathscr{D}$ admits a one-parameter symmetry group if and only if a does not vanish identically, and b is constant.*

(iii) *If b is not constant, then $\mathscr{D}$ can admit only a discrete symmetry group.*

Thus a differential operator (2.1) is equivalent to the differential operator D^2 if and only if it admits a two-parameter group of symmetries which is also equivalent to

the condition (3.15). The two-parameter symmetry group for the operator D^2 is, of course, generated by translations $(x, u) \to (x+k, u)$, and the scaling transformations $(x, u) \to (\lambda x, \lambda^2 u)$. Similarly, we have the result that the differential operator is equivalent to the radial Laplace operator (3.16) or the operator D^2+1 if and only if it admits a one-parameter group of symmetries. For the radial Laplace operator (3.16), the symmetry group is the scaling group $(x, u) \to (\lambda x, \lambda^2 u)$; for D^2+1 the translation group remains. Finally, for any other differential operator, the symmetry group is at most a discrete subgroup.

THEOREM 5.3. *Let $\mathcal{D}$ be a real-analytic differential operator, and consider the symmetries of the type* (2.6). *Let $a(x)$ be the corresponding potential* (4.8). *Then $\mathcal{D}$ always admits the one-parameter scaling symmetry group $(x, u) \to (x, \lambda u)$. Moreover, $\mathcal{D}$ admits a two-parameter symmetry group if and only if a is constant; otherwise there is only the possibility of additional discrete symmetries.*

See Hsu and Kamran [4] for more detailed information on the use of Cartan's equivalence method for determining the possible symmetry groups of general second-order ordinary differential equations.

UNCONSTRAINED VARIATIONAL PRINCIPLES FOR EIGENVALUES OF REAL SYMMETRIC MATRICES*

GILES AUCHMUTY†

Abstract. Certain real-valued functions, whose critical points and critical values are related to the eigenvalues and eigenvectors of a real symmetric matrix, are described and analyzed. These functions, in general, are smooth and bounded below. Variational principles for finding various specific eigenvalues and eigenvectors of the matrix A are described. These problems have a Morse theory. They may be written as the difference of two convex functions, so there are also natural dual problems that include the classical constrained variational principles for eigenvalues and eigenvectors.

Key words. eigenvalues, real symmetric matrices, unconstrained optimization, variational principles

AMS(MOS) subject classifications. primary 49G05; secondary 15A18

1. Introduction. This paper describes and analyzes some unconstrained variational principles for the eigenvalues and eigenvectors of a real symmetric matrix. Extensions to weighted eigenproblems and to finding singular values and singular vectors of general real matrices are given.

For almost a century now, variational methods for finding or estimating eigenvalues of symmetric matrices have been synonymous with variants of Rayleigh's principle. They are constrained optimization problems and there is a large literature on such principles and their theory. For recent summaries see Chatelin [4] or Parlett [5].

Here we describe some families of unconstrained variational principles for finding various eigenvalues and eigenvectors of a real symmetric matrix A. As described in § 2, we consider smooth functions E that are the sum of a function of $\|x\|^2$ and a function of $\langle Ax, x\rangle$, with $\|x\|$ being the Euclidean norm. Then the nonzero critical points of E arise at eigenvectors of A of specific norm. The norm of the critical point, and the critical value of E, are functions of the corresponding eigenvalue. The Hessian of E at a critical point has the same eigenvectors as A, so we may compute its (Morse) index and describe the topological type of the critical point.

Much of this paper is devoted to analyzing some specific functions E that are bounded below on $\mathbb{R}^n$ and are minimized, or have critical points, at specific eigenvectors of A. Thus in § 3, a variational principle for the largest eigenvalue of a positive definite symmetric matrix is described and analyzed. It is used to obtain upper and lower bounds on this eigenvalue, and a deflation theory for finding the second, third, and subsequent eigenvalues is developed.

In § 4, we analyze certain families of variational principles including some that are applicable to weighted eigenvalue problems. These results are applied in § 5 to principles for finding the smallest or largest eigenvalues, or the eigenvalues of a symmetric matrix A closest to a preassigned number μ.

Some different classes of functions are described in § 6. They have the property that their only nonzero critical points arise at eigenvectors of A corresponding to positive eigenvalues of A. This property provides some results applicable in stability theory, and also enables us to give variational criteria for determining whether A has any eigenvalues in a given interval and for estimating these eigenvalues.

These principles are extended in § 7 to finding singular values and singular vectors of general real matrices, while § 8 describes some invariance and symmetry properties of these functionals.

All of these functions either have a specific, finite number of critical points, or else the set of critical points is infinite but has a finite number of bounded components. The functions analyzed can all be written as the difference of two convex functions. Hence we can use nonconvex duality theory as in [1] or [7] to describe various dual problems. Some of these are described in § 9; they may be either constrained or unconstrained variational principles.

Some of the analysis described here may be extended to provide variational principles for eigenvalues of compact linear operators on a Hilbert space or for self-adjoint linear elliptic eigenproblems as in [2] and [3]. Much of this analysis, however, is specific to finite-dimensional problems and has been developed with a view towards the numerical computation of eigenvalues.

2. General functionals. Throughout this paper. A will be a real symmetric $n \times n$ matrix with real eigenvalues $\lambda_n \leqq \lambda_{n-1} \leqq \cdots \leqq \lambda_2 \leqq \lambda_1$. We shall use only real arithmetic and the Euclidean norm and inner products

$$\|x\| = \|x\|_2 = \left(\sum_{j=1}^{n} x_j^2 \right)^{1/2}, \qquad \langle x, y \rangle = \sum_{j=1}^{n} x_j y_j$$

for vectors x, y in $\mathbb{R}^n$.

When B is an $m \times n$ real matrix, we shall write B^T for its transpose and $B = (b_{ij})$, with b_{ij} being the i, jth component. $\ker B = \{x \in \mathbb{R}^n : Bx = 0\}$ and I being the $n \times n$ identity matrix. When x, y are in $\mathbb{R}^n$, then $x \otimes y = (x_i y_j)$ is a rank 1, $n \times n$ matrix and the vector x is said to be normalized if $\|x\| = 1$. Any other terms from linear algebra that are not defined here should be taken as in Strang [6].

Our interest is in describing and analyzing certain smooth functions, defined on all of $\mathbb{R}^n$, whose extrema, or critical points, are related to the spectral properties of A. Most of the functions can be written in terms of $\|x\|$, $\|Ax\|$, and $\langle Ax, x \rangle$. In particular, many of the functions will have the form $E : \mathbb{R}^n \to \mathbb{R}$ defined by

$$E(x) = \Phi(\tfrac{1}{2}\|x\|^2) + \Psi(\tfrac{1}{2}\langle Ax, x \rangle) \tag{2.1}$$

where

(A1) $\Phi : [0, \infty) \to \mathbb{R}$ is continuous and twice continuously differentiable on $(0, \infty)$ with $\Phi'(s) \neq 0$ for $s \neq 0$;

(A2) $\Psi : \mathbb{R} \to \mathbb{R}$ is twice continuously differentiable with $\Psi(0) = 0$.

In this section we prove some general results about these functions and their critical points.

We write

$$\nabla E(x) = \left(\frac{\partial E}{\partial x_1}(x), \frac{\partial E}{\partial x_2}(x), \cdots, \frac{\partial E}{\partial x_n}(x) \right)^T,$$

$$D^2 E(x) = \left(\frac{\partial^2 E}{\partial x_i \, \partial x_j}(x) \right)$$

for the gradient and the Hessian, respectively, of E at a point x. For scalar functions, differentiation is denoted by a prime.

A point $\tilde{x}$ in $\mathbb{R}^n$ is said to be a critical point of E if either

(2.2) (i) E is differentiable at $\tilde{x}$ and $\nabla E(\tilde{x}) = 0$, or

(ii) E is not differentiable at $\tilde{x}$.

A critical value of E is the value of $E(\tilde{x})$ when $\tilde{x}$ is a critical point. E is minimized at $\tilde{x}$ provided

$$E(\tilde{x}) = \inf_{x \in \mathbb{R}^n} E(x). \tag{2.3}$$

A critical point $\tilde{x}$ of E is said to be nondegenerate if E is twice continuously differentiable at $\tilde{x}$ and $D^2E(\tilde{x})$ is a nonsingular matrix. When $\tilde{x}$ is a nondegenerate critical point, then its Morse index $i(\tilde{x})$ is the number of negative eigenvalues of $D^2E(\tilde{x})$. The behavior of E near a nondegenerate critical point may be classified by its Morse index. In particular, $\tilde{x}$ is a local minimum (maximum) if its Morse index is zero (or n); it is a saddle point if $1 \leqq i(\tilde{x}) \leqq n-1$.

The significant fact about the function (2.1) is that its nonzero critical points are certain specific eigenvectors of A. Moreover, the eigenvectors of the Hessian of E at critical points are precisely the eigenvectors of A. This may be summarized as follows.

THEOREM 1. *Let A be a real symmetric matrix with E defined by* (2.1). *Assume* (A1) *and* (A2) *hold; then E is twice continuously differentiable on $\mathbb{R}^n - \{0\}$ with*

$$\nabla E(x) = \Phi'(\tfrac{1}{2}\|x\|^2)x + \Psi'(\tfrac{1}{2}\langle Ax, x\rangle)Ax, \tag{2.4}$$

$$\begin{aligned} D^2E(x) = {} & \Phi'(\tfrac{1}{2}\|x\|^2)I + \Phi''(\tfrac{1}{2}\|x\|^2)x \otimes x \\ & + \Psi'(\tfrac{1}{2}\langle Ax, x\rangle)A + \Psi''(\tfrac{1}{2}\langle Ax, x\rangle)Ax \otimes Ax. \end{aligned} \tag{2.5}$$

When $\tilde{x}$ is a nonzero critical point of E, then

(i) *$\tilde{x}$ is an eigenvector of A corresponding to the eigenvalue*

$$\tilde{\lambda} = -\frac{\Phi'(\frac{1}{2}\|\tilde{x}\|^2)}{\Psi'(\frac{1}{2}\langle A\tilde{x}, \tilde{x}\rangle)}; \tag{2.6}$$

(ii) $\|\tilde{x}\| = \mu$, *where μ is a solution of*

$$\Phi'\left(\frac{\mu^2}{2}\right) + \tilde{\lambda}\Psi'\left(\tilde{\lambda}\frac{\mu^2}{2}\right) = 0; \tag{2.7}$$

(iii) *The eigenvectors of $D^2E(\tilde{x})$ are precisely the eigenvectors of A.*

Proof. From (A1)-(A2) we have that E is twice continuously differentiable, except perhaps at $x = 0$. When we use the chain rule, (2.4) and (2.5) follow.

When $\tilde{x}$ is a nonzero critical point of E, then (2.2) and (2.4) imply that

$$\Psi'(\tfrac{1}{2}\langle A\tilde{x}, \tilde{x}\rangle)A\tilde{x} = -\Phi'(\tfrac{1}{2}\|\tilde{x}\|^2)\tilde{x}. \tag{2.8}$$

If $\Psi'(\frac{1}{2}\langle A\tilde{x}, \tilde{x}\rangle) \neq 0$, then (2.6) holds. Suppose this does not hold; then $\Phi'(\frac{1}{2}\|\tilde{x}\|^2)\tilde{x} = 0$. From (A1), $\Phi'(s) \neq 0$ for $s \neq 0$; thus $\tilde{x} = 0$, which contradicts the assumption that $\tilde{x}$ is nonzero. Thus (i) holds.

Take the inner products of (2.8) with $\tilde{x}$. Then,

$$\Psi'\left(\frac{1}{2}\langle A\tilde{x}, \tilde{x}\rangle\right)\langle A\tilde{x}, \tilde{x}\rangle = -\Phi'\left(\frac{\mu^2}{2}\right)\mu^2$$

and we also have $\langle A\tilde{x}, \tilde{x}\rangle = \tilde{\lambda}\mu^2$, with $\tilde{\lambda}$ being the eigenvalue from (i). Hence (2.7) follows, as $\mu \neq 0$.

Let $\{e^{(j)}: 1 \leqq j \leqq n\}$ be an orthonormal set of eigenvectors of A with

$$Ae^{(j)} = \lambda_j e^{(j)}, \qquad 1 \leqq j \leqq n. \tag{2.9}$$

Since (i) and (ii) hold, then $\tilde{x} = \pm\mu e^{(k)}$ for some $\mu > 0$, $1 \leqq k \leqq n$. Then

$$D^2E(\tilde{x})e^{(j)} = [\Phi'(\tfrac{1}{2}\mu^2) + \lambda_j\Psi'(\tfrac{1}{2}\lambda_k\mu^2)]e^{(j)} + [\Phi''(\tfrac{1}{2}\mu^2) + \lambda_k^2\Psi''(\tfrac{1}{2}\lambda_k\mu^2)]\mu^2\delta_{jk}e^{(j)} \tag{2.10}$$

where δ_{jk} is the Kronecker delta.

When $j \neq k$, we have $D^2E(\tilde{x})e^{(j)} = \nu_j e^{(j)}$ with

$$\nu_j = \Phi'(\tfrac{1}{2}\mu^2) + \lambda_j\Psi'(\tfrac{1}{2}\lambda_k\mu^2).$$

When $j = k$, (2.10) implies that $D^2E(\tilde{x})e^{(k)} = \nu_k e^{(k)}$ with

$$\nu_k = \Phi'(\tfrac{1}{2}\mu^2) + \lambda_k\Psi'(\tfrac{1}{2}\lambda_k\mu^2) + [\Phi''(\tfrac{1}{2}\mu^2) + \lambda_k^2\Psi''(\tfrac{1}{2}\lambda_k\mu^2)]\mu^2.$$

Since $\{e^{(j)}: 1 \leqq j \leqq n\}$ is a basis of $\mathbb{R}^n$, we see that this describes all the eigenvectors of $D^2E(\tilde{x})$ and hence (iii) holds.

COROLLARY 1. *Take A, E as in Theorem* 1 *and suppose that $e^{(j)}$ is a normalized eigenvector of A corresponding to an eigenvalue λ_j. Then $\tilde{x} = \pm\mu e^{(j)}$ is a nonzero critical point of E if and only if $\mu \neq 0$ and*

$$\Phi'\left(\frac{1}{2}\mu^2\right) + \lambda_j\Psi'\left(\lambda_j\left(\frac{\mu^2}{2}\right)\right) = 0. \tag{2.11}$$

Proof. If $\tilde{x} = \pm\mu e^{(j)}$ is a nonzero critical point of E, then (2.8) implies (2.11). Conversely, if (2.11) holds for some $\mu \neq 0$ and some $1 \leqq j \leqq n$, then $\pm\mu e^{(j)}$ will be a solution of (2.8) and thus $\tilde{x} = \pm\mu e^{(j)}$ will be a nonzero critical point of E.

Usually the critical values of E depend only on the eigenvalues λ_j of A. We may regard (2.11) as an equation for μ_j^2 in terms of λ_j. Suppose it has only a finite number of solutions $\mu_k^2(\lambda_j)$, $1 \leqq k \leqq K(j)$. Then the corresponding values of $E(\tilde{x})$ are

$$\Phi(\tfrac{1}{2}\mu_k^2(\lambda_j)) + \Psi(\tfrac{1}{2}\lambda_j\mu_k^2(\lambda_j)), \qquad 1 \leqq k \leqq K(j)$$

and this may be regarded as a function of λ_j alone. In all the specific examples analyzed in this paper μ^2 is a single-valued function of λ and the critical values of E are relatively easy to compute.

When B is a general $m \times n$ matrix, consider the function $H: \mathbb{R}^n \to \mathbb{R}$ defined by

$$H(x) = \Phi(\tfrac{1}{2}\|x\|^2) + \theta(\tfrac{1}{2}\|Bx\|^2) \tag{2.12}$$

where both Φ and θ obey (A1). This function can be written in the form (2.1) with $\theta = \Psi$ and $A = B^TB$. The critical points of H are related to the singular vectors of B.

Let $\ker B = \{x \in \mathbb{R}^n: Bx = 0\}$; then the analogue of Theorem 1 is as follows.

THEOREM 2. *Suppose B is a real $m \times n$ matrix and H is defined by* (2.12) *with Φ and θ obeying* (A1). *Then H is twice continuously differentiable on $\mathbb{R}^n - \ker B$ with*

$$\nabla H(x) = \Phi'(\tfrac{1}{2}\|x\|^2)x + \theta'(\tfrac{1}{2}\|Bx\|^2)B^TBx,$$

$$D^2H(x) = \Phi'(\tfrac{1}{2}\|x\|^2)I + \Phi''(\tfrac{1}{2}\|x\|^2)x \otimes x + \theta'(\tfrac{1}{2}\|Bx\|^2)B^TB + \theta''(\tfrac{1}{2}\|Bx\|^2)B^TBx \otimes B^TBx.$$

When $\tilde{x}$ is a critical point of H in $\mathbb{R}^n - \ker B$, then

(i) *$\tilde{x}$ is a singular vector of B corresponding to the singular value*

$$\tilde{\nu} = \left[\frac{\Phi'(\tfrac{1}{2}\|\tilde{x}\|^2)}{\theta'(\tfrac{1}{2}\|B\tilde{x}\|^2)}\right]^{1/2}.$$

(ii) *$\|\tilde{x}\| = \mu$, where μ is a solution of*

$$\Phi'(\tfrac{1}{2}\mu^2) + \tilde{\nu}^2\theta'(\tfrac{1}{2}\tilde{\nu}^2\mu^2) = 0.$$

(iii) *The eigenvectors of $D^2H(\tilde{x})$ are the singular vectors of A.*

Proof. This follows from Theorem 1 as $\|Bx\|^2 = \langle B^TBx, x\rangle$ for all x in $\mathbb{R}^n$, and the (right) singular vectors of B are the eigenvectors of A.

In the following sections, we look at variational principles associated with functions of the form E or H. Essentially we shall be interested in describing functions E or H that have specific minima. Generally the minima of E (or H) arise only at specific eigenvectors (or singular vectors) of A (or B) and we choose the functions so as to find the smallest, the largest, or some other special eigenvalue of A. A function $f:\mathbb{R}^n \to \mathbb{R}$ is said to be coercive on $\mathbb{R}^n$ provided

$$\lim_{\|x\|\to\infty} \frac{f(x)}{\|x\|} = \infty.$$

3. Variational principles for the largest eigenvalues of positive definite matrices. Throughout this section, A will be a positive definite, symmetric $n \times n$ matrix with eigenvalues $0 < \lambda_n \leqq \lambda_{n-1} \leqq \cdots \leqq \lambda_2 \leqq \lambda_1$. Here we shall describe some functions of the form (2.1) whose minima provide information on the largest eigenvalues and eigenvectors of A.

Consider the function $E_q:\mathbb{R}^n \to \mathbb{R}$ defined by

$$E_q(x) = \frac{1}{2}\|x\|^2 - \frac{1}{q}\langle Ax, x\rangle^{q/2} \tag{3.1}$$

where $1 \leqq q < 2$. This function has the form (2.1) with $\Phi(s) = s$, $\Psi(s) = q^{-1}(2s)^{q/2}$. Both Φ and Ψ obey (A1). When $q = 1$, this E_q is proportional to the function g in equation 8.3 of [1], where it was derived as a dual variational problem to Rayleigh's principle. The variational properties of E_q may be summarized as follows.

THEOREM 3. *Let A be a positive definite, symmetric matrix and E_q be defined by* (3.1) *with $1 \leqq q < 2$. Then*

(i) *E_q is coercive on $\mathbb{R}^n$ with*

$$\inf_{x\in\mathbb{R}^n} E_q(x) = \frac{-1}{2\gamma}\lambda_1^{\gamma} \tag{3.2}$$

where

$$\gamma = \frac{q}{(2-q)}. \tag{3.3}$$

This is attained at $\pm\lambda_1^{\gamma/2}e^{(1)}$, where $e^{(1)}$ is a normalized eigenvector corresponding to the eigenvalue λ_1.

(ii) *The nonzero critical points of E_q are at $\pm\lambda_k^{\gamma/2}e^{(k)}$, where $e^{(k)}$ is a normalized eigenvector of A corresponding to the eigenvalue λ_k.*

(iii) *The critical values of E_q are $\{-\lambda_k^{\gamma}/2\gamma;\ 1 \leqq k \leqq n\} \cup \{0\}$.*

(iv) *$\tilde{x} = \pm\lambda_k^{\gamma/2}e^{(k)}$ is a nondegenerate critical point of E_q if and only if λ_k is a simple eigenvalue of A. In this case, the Morse index of $\tilde{x}$ is $k-1$.*

Proof. For any x, we have $\langle Ax, x\rangle \leqq \lambda_1\|x\|^2$, so

$$E_q(x) \geqq \frac{1}{2}\|x\|^2 - \frac{1}{q}\lambda_1^{q/2}\|x\|^q.$$

Thus E_q is coercive when $1 \leqq q < 2$.

Since E_q is continuous and coercive on $\mathbb{R}^n$, it attains a finite infimum. E_q is also continuously differentiable on $\mathbb{R}^n - \{0\}$ with

$$\nabla E_q(x) = x - \langle Ax, x\rangle^{(q-2)/2}Ax. \tag{3.4}$$

Thus the nonzero critical points of E_q obey

$$Ax = \sigma(x)x \tag{3.5}$$

where $\sigma(x) = \langle Ax, x\rangle^{(2-q)/2}$. If $\tilde{x}$ is a nonzero critical point of E_q then it is an eigenvector of A corresponding to the eigenvalue $\tilde{\lambda} = \sigma(\tilde{x})$. Take the inner products of (3.5) with $\tilde{x}$; then

$$\langle A\tilde{x}, \tilde{x}\rangle = \sigma(\tilde{x})\|\tilde{x}\|^2,$$

or

$$\tilde{\lambda}^{\gamma} = \|\tilde{x}\|^2 \quad \text{where } \gamma = \frac{q}{2-q}. \tag{3.6}$$

Thus (ii) follows. Moreover,

$$E_q(\tilde{x}) = \left(\frac{1}{2} - \frac{1}{q}\right)\tilde{\lambda}^{\gamma} = -\frac{1}{2\gamma}\tilde{\lambda}^{\gamma} \tag{3.7}$$

on substituting back into (3.1). Thus (iii) holds and

$$\inf_{x\in\mathbb{R}^n} E_q(x) = \min_{1\leqq j\leqq n} -\frac{1}{2\gamma}\lambda_j^{\gamma} = -\frac{1}{2\gamma}\lambda_1^{\gamma}$$

as claimed in (i).

Differentiating (3.4) we have, when $x \neq 0$,

$$D^2E_q(x) = I - \langle Ax, x\rangle^{(q-2)/2}A + (2-q)\frac{Ax \otimes Ax}{\langle Ax, x\rangle^{2-(q/2)}}. \tag{3.8}$$

Let $\{e^{(1)}, \cdots, e^{(n)}\}$ be an orthonormal set of eigenvectors of A obeying (2.9) and suppose

$$\tilde{x} = \pm\lambda_k^{\gamma/2}e^{(k)}. \tag{3.9}$$

Then $D^2E_q(\tilde{x})e^{(j)} = (1-(\lambda_j/\lambda_k))e^{(j)} + (2-q)\delta_{jk}e^{(j)}$ as $\langle A\tilde{x}, \tilde{x}\rangle = \lambda_k^{2/(2-q)}$. Thus $D^2E_q(\tilde{x})$ is nonsingular if and only if λ_k is a simple eigenvalue of A. When this holds, we see that the number of negative eigenvalues of $D^2E_q(\tilde{x})$ is precisely $k-1$ when (3.9) holds as claimed in (iv).

This result has a number of interesting corollaries. The first is related to the number of critical points of E_q.

COROLLARY 1. *Let A, E_q be as in Theorem 3 and define*

$$C_j = \{x \in \mathbb{R}^n : \|x\|^2 = \lambda_j^{\gamma} \text{ and } Ax = \lambda_j x\} \tag{3.10}$$

for $1 \leqq j \leqq n$. Then the set of nonzero critical points of E_q is $\bigcup_{j=1}^n C_j$.

Moreover,

(a) *If λ_j is a simple eigenvalue of A, then C_j consists of exactly two points;*

(b) *If $\lambda_j = \lambda_{j+1} = \cdots = \lambda_{j+m_j}$ is an eigenvalue of multiplicity $m_j > 1$, then $C_j = C_{j+1} = \cdots = C_{j+m_j}$ is isomorphic to an $(m_j - 1)$-dimensional sphere and each point in this set is a degenerate critical point of E_q.*

Hence the set of all nonzero critical points of E_q has a finite number of bounded, connected components. When A has n distinct eigenvalues, it has exactly $2n$ elements.

Proof. (a) This description of the nonzero critical points of E_q follows from (ii) of Theorem 3. If λ_j is a simple eigenvalue of A, then

$$C_j = \{\pm\lambda_j^{\gamma/2}e^{(j)}\}$$

where $e^{(j)}$ is a normalized eigenvector of A corresponding to the eigenvalue λ_j.

(b) When λ_j is an eigenvalue of A of multiplicity $m_j \geqq 2$, then let $\{e^{(j)}, e^{(j+1)}, \cdots, e^{(j+m_j-1)}\}$ be an orthonormal basis of the eigenspace. Then

$$C_j = \left\{ x \in \mathbb{R}^n : x = \sum_{k=1}^{m_j} c_k e^{(j+k-1)} \text{ and } \sum_{k=1}^{m_j} c_k^2 = \lambda_j^\gamma \right\}.$$

This is diffeomorphic to a sphere of dimension $m_j - 1$, and from (iv) of Theorem 3, each of these critical points is degenerate.

The other claims now follow directly.

This function provides direct, lower bounds on λ_1. For any x, we have

$$\lambda_1^\gamma \geqq -2\gamma E_q(x). \tag{3.11}$$

We often would like to obtain upper bounds on λ_1. This can be done by using property (ii) of Theorem 3 and restricting the domain. Since E_q is coercive, we have that for any $R \geqq 0$

$$\alpha_R = \inf_{\|x\| \geqq R} E_q(x) \tag{3.12}$$

is well defined and finite, and this infimum is attained.

THEOREM 4. *Take A, E_q as in Theorem 3 and suppose that α_R is defined by* (3.12). *If $\alpha_R > -R^2/2\gamma$, then $\lambda_1 < R^{2/\gamma}$.*

Proof. When $R^{2/\gamma} \leqq \lambda_1$, then we have that $x = \pm \lambda_1^{\gamma/2} e^{(1)}$ lies in $A_R = \{x \in \mathbb{R}^n : \|x\| \geqq R\}$. Hence $\alpha_R = \alpha_0 = -\lambda_1^\gamma/2\gamma \leqq -R^2/2\gamma$.

When $\alpha_R > -(R^2/2\gamma)$, then $R > \lambda_1^{\gamma/2}$, as $\hat{x}$ is not in A_R. Thus $\lambda_1 < R^{2/\gamma}$ as required.

When $q = 1$, Theorem 3 reduces, essentially, to Theorem 8.1 of [1]. As q increases from 1 to 2, $\gamma(q) = q/(2-q)$ increases from 1 to infinity and the infimum in (3.2) increases to zero when $\lambda_1 \leqq 1$. For all values of λ_1, the expression $\lambda_1^\gamma/2\gamma$ is convex in γ and when $\lambda_1 > 1$, this goes to infinity as q approaches 2.

Part (iv) of Theorem 3 says that there is a good Morse theory for this function. When $q = 1$, this theory may be regarded as a dual theory to the Courant–Weyl minimax theory for eigenvalues and eigenvectors (see § 5 of [1]). We might ask whether there are modified versions of (3.1) that could provide variational characterizations of the second, third, or other eigenvalues of A.

Let $\{e^{(1)}, e^{(2)}, \cdots, e^{(n)}\}$ be an orthonormal set of eigenvectors of A so that (2.9) holds. Let $1 \leqq k \leqq n-1$ and define

$$V_k = \{x \in \mathbb{R}^n : \langle x, e^{(j)} \rangle = 0 \text{ for } 1 \leqq j \leqq k\}. \tag{3.13}$$

When we restrict E_q to V_k we have the following result.

THEOREM 5. *Let A be a positive definite, symmetric matrix, and let E_q and V_k be defined by* (3.1) *and* (3.13), *respectively. Then*

(i) *E_q is coercive on V_k with*

$$\inf_{x \in V_k} E_q(x) = -\frac{\lambda_{k+1}^\gamma}{2\gamma} \tag{3.14}$$

where γ is given by (3.3). *This is attained on $C_{k+1} \cap V_k$.*

(ii) *The nonzero critical points of E_q on V_k are $\lambda_j^{\gamma/2} \tilde{e}$, where $\tilde{e}$ is a normalized eigenvector of A corresponding to some eigenvalue λ_j of A with $j \geqq k+1$.*

(iii) *The critical values of E_q on V_k are $\{-\lambda_j^\gamma/2\gamma : k+1 \leqq j \leqq n\}$.*

Proof. Since E_q is coercive on $\mathbb{R}^n$, it is coercive on V_k. At a critical point of E_q on V_k, standard Lagrange multiplier theorems imply that

$$\nabla E_q(x) = \sum_{j=1}^{k} \mu_j e^{(j)} \tag{3.15}$$

for some real numbers $\mu_1, \cdots, \mu_k$. That is,

$$\tilde{x} - \langle A\tilde{x}, \tilde{x}\rangle^{(q-2)/2} A\tilde{x} = \sum_{j=1}^{k} \mu_j e^{(j)}.$$

Take inner products with $\tilde{x}$ and $e^{(l)}$ for $1 \leqq l \leqq k$. Since $\tilde{x}$ is in V_k, we find that

$$\|\tilde{x}\|^2 = \langle A\tilde{x}, \tilde{x}\rangle^{q/2},$$

$$\langle \tilde{x}, e^{(l)}\rangle - \lambda_l \langle \tilde{x}, e^{(l)}\rangle \|\tilde{x}\|^{-(2/\gamma)} = \mu_l \quad \text{for } 1 \leqq l \leqq k.$$

Thus $\mu_l = 0$ for $1 \leqq l \leqq k$ as $\langle \tilde{x}, e^{(l)}\rangle = 0$, and so $\tilde{x}$ is an eigenvector of A corresponding to an eigenvalue $\tilde{\lambda} = \langle A\tilde{x}, \tilde{x}\rangle^{(2-q)/2}$. The other results now follow just as in Theorem 3.

This variational principle of minimizing E_q on V_k for the $(k+1)$st eigenvalue λ_{k+1} is a constrained variational principle. It could be rewritten as an unconstrained variational principle by using the canonical projection Q_k of $\mathbb{R}^n$ onto V_k. Let $Q_k : \mathbb{R}^n \to V_k$ and $E_{qk} : \mathbb{R}^n \to \mathbb{R}$ be defined by

$$Q_k x = x - \sum_{j=1}^{k} \langle x e^{(j)}\rangle, \tag{3.16}$$

$$E_{qk}(x) = \frac{1}{2}\|Q_k x\|^2 - \frac{1}{q}\langle AQ_k x, Q_k x\rangle^{q/2} \tag{3.17}$$

We see that

$$E_{qk}(x) = \begin{cases} E_q(x) & \text{for any } x \in V_k, \\ 0 & \text{for any } x \perp V_k, \end{cases}$$

and that

$$\inf_{x \in \mathbb{R}^n} E_{qk}(x) = -\frac{\lambda_{k+1}^{\gamma}}{2\gamma}. \tag{3.18}$$

This value is attained at $\hat{x} = \lambda_{k+1}^{\gamma/2}\tilde{e}$, where $\tilde{e}$ is a normalized eigenvector of A corresponding to the eigenvalue λ_{k+1} of A and lying in V_k. Moreover, if x is any point in $\mathbb{R}^n$ such that $Q_k x = \hat{x}$, we have $E_{qk}(x) = E_{qk}(\hat{x})$. So there is an affine subspace of minimizers of E_{qk} and E_{qk} is not coercive on $\mathbb{R}^n$.

4. Variational principles for other eigenvalues. A number of interesting, unconstrained variational principles for the eigenvalues and eigenvectors of a real symmetric matrix A can be described by the problem of extremizing the function $F_r : \mathbb{R}^n \to \mathbb{R}$ defined by

$$F_r(x) = \tfrac{1}{2}\langle r(A)x, x\rangle - \|x\|. \tag{4.1}$$

Here we require that

(A3) $r(A)$ be a rational function of A and a positive definite matrix.

The simplest examples are when $r(A)$ is linear, quadratic, or a polynomial in A. When $r(A)$ is linear in A, then F_r has the form (2.1). When $r(A) = c_1 A^2 + c_2 I$, then F_r has the form (2.12); both of these cases will be analyzed in § 5. The functional $r(A) = A^{-1}$, with A being positive definite, has been analyzed in § 8 of [1].

Henceforth we shall use the notation

$$E_j = \{x \in \mathbb{R}^n : \|x\| = 1 \text{ and } Ax = \lambda_j x\}, \qquad 1 \leqq j \leqq n.$$

Thus E_j is the set of all normalized eigenvectors of A corresponding to the eigenvalue λ_j. When λ_j is a simple eigenvalue, then $E_j = \{\pm e^{(j)}\}$ consists of exactly two points. Otherwise two or more of the sets E_j will be the same and each will be a bounded, closed, connected set. We shall also write

$$E_j^r = \{x \in \mathbb{R}^n : \|x\| = 1 \text{ and } r(A)x = r(\lambda_j)x\} \quad \text{for } 1 \leqq j \leqq n.$$

THEOREM 6. *Let A be a real symmetric matrix, and let F_r be defined by* (4.1) *with* (A3) *holding. Then*

(4.2) (i) *F_r is coercive on $\mathbb{R}^n$ and* $\inf_{x \in \mathbb{R}^n} F_r(x) = \min_{1 \leqq j \leqq n} -\dfrac{1}{2r(\lambda_j)}$.

(ii) *The nonzero critical points of F_r are $\tilde{x} = r(\lambda_k)^{-1} e^{(k)}$, where $e^{(k)}$ is in E_k^r and $1 \leqq k \leqq n$. F_r is minimized at the points $\hat{x} = r(\lambda_J)^{-1} e^{(J)}$, with $e^{(J)}$ in E_J^r and J being an integer that minimizes $r(\lambda_j)$, for $1 \leqq j \leqq n$.*

(iii) *The critical values of F_r are 0 and $-(2r(\lambda_k))^{-1}$ for $1 \leqq k \leqq n$.*

(iv) *$\tilde{x} = r(\lambda_k)^{-1} e^{(k)}$ is a nondegenerate critical point of F_r if and only if $r(\lambda_j) \neq r(\lambda_k)$ for all $j \neq k$, $1 \leqq j \leqq n$. The eigenvalues of $D^2 F_r(\tilde{x})$ are $\{r(\lambda_j) - r(\lambda_k) : 1 \leqq j \leqq n, j \neq k\} \cup \{r(\lambda_k)\}$.*

Proof. Since $r(A)$ is positive definite, there exists $c > 0$ such that

$$\langle r(A)x, x \rangle \geqq c\|x\|^2.$$

Hence $F_r(x) \geqq c(\|x\|^2 - \|x\|)/2$ for all x in $\mathbb{R}^n$.

Thus F_r is coercive on $\mathbb{R}^n$ and attains a finite infimum. F_r is continuously differentiable on $\mathbb{R}^n - \{0\}$ with

$$\nabla F_r(x) = r(A)x - \frac{x}{\|x\|}. \tag{4.3}$$

Thus the nonzero critical points $\tilde{x}$ of F_r are eigenvectors of $r(A)$ with $\|\tilde{x}\|$ being the inverse of the eigenvalues of $r(A)$. From the spectral mapping theorem we know that the eigenvalues of $r(A)$ are $\{r(\lambda_j) : 1 \leqq j \leqq n\}$. Thus the first part of (ii) holds.

Moreover, $\langle r(A)\tilde{x}, \tilde{x} \rangle = \|\tilde{x}\| = r(\lambda_j)^{-1}$, so $F_r(\tilde{x}) = -(1/2r(\lambda_j))$ for some j. Hence the rest of (ii), (iii), and (4.2) hold.

Differentiating (4.3) we find that, when $x \neq 0$,

$$\begin{aligned} D^2 F_r(x) &= r(A) - \frac{I}{\|x\|} + \frac{x \otimes x}{\|x\|^3} \\ &= r(A) - \|x\|^{-1} Q \end{aligned} \tag{4.4}$$

where $Q = I - P$ and P is the projection in the direction x;

$$Py = \frac{\langle x, y \rangle x}{\|x\|^2} \quad \text{for } y \text{ in } \mathbb{R}^n. \tag{4.5}$$

Thus when $\tilde{x} = r(\lambda_k)^{-1} e^{(k)}$ we have

$$D^2 F_r(\tilde{x}) = r(A) - r(\lambda_k)(I - P_k)$$

where $P_k y = \langle y, e^{(k)} \rangle e^{(k)}$ is the projection in the direction of this eigenvector. Thus

$$D^2 F_r(\tilde{x})\, e^{(j)} = \begin{cases} (r(\lambda_j) - r(\lambda_k)) e^{(j)} & \text{if } j \neq k, \\ r(\lambda_k) e^{(k)} & \text{if } j = k. \end{cases}$$

Hence (iv) of Theorem 6 holds, and for any particular $r(A)$ we can compute the Morse index of a nondegenerate critical point.

COROLLARY. *Suppose that A and F_r are as in Theorem 6. Then the set of all critical points of F_r has a finite number of bounded, closed components. It is finite if and only if $r(A)$ has n simple eigenvalues.*

Proof. This follows from (ii) of Theorem 6. We have that each E_j^r consists of exactly two points whenever $r(\lambda_j)$ is a simple eigenvalue of $r(A)$; otherwise it is an infinite set.

The results in this theorem could be generalized to the function where $\|x\|$ in (4.1) is replaced by $\|x\|^q/q$ with $1<q<2$, but this does not seem to provide any different information.

Sometimes we are interested in finding weighted, or generalized, eigenvalues and eigenvectors of A with respect to another positive definite symmetric matrix C. In this case we replace (4.1) with the function $J:\mathbb{R}^n\to\mathbb{R}$ defined by

$$J(x)=\tfrac{1}{2}\langle r(A)x, x\rangle-\langle Cx, x\rangle^{1/2}. \tag{4.6}$$

Now we assume that the weighted eigenproblem

$$Ax=\nu Cx \tag{4.7}$$

has real eigenvalues $\nu_n\leqq\nu_{n-1}\leqq\cdots\leqq\nu_1$, and we define the corresponding sets of normalized eigenvectors by

$$J_k=\{x\in\mathbb{R}^n\colon Ax=\nu_k Cx, \langle Cx, x\rangle=1\},$$

$$J_k^r=\{x\in\mathbb{R}^n\colon r(A)x=r(\nu_k)Cx, \langle Cx, x\rangle=1\}$$

where $1\leqq k\leqq n$.

The analogue of Theorem 6 is as follows.

THEOREM 7. *Let A, C be real symmetric matrices with C being positive definite and define J by* (4.6) *with* (A3) *holding. Then*

(4.8) (i) *J is coercive on $\mathbb{R}^n$ and* $\inf_{x\in\mathbb{R}^n} J(x)=\min_{1\leqq k\leqq n}-\dfrac{1}{2r(\nu_k)}$.

(ii) *The nonzero critical points of J are $\tilde{x}=r(\nu_k)^{-1}e^{(k)}$, where $e^{(k)}$ is in J_k^r and $1\leqq k\leqq n$. J is minimized at $\hat{x}=r(\nu_K)^{-1}e^{(K)}$, where K is the integer where $r(\nu_k)$ is minimized.*

(iii) *The critical values of J are 0 and $(-2r(\nu_k))^{-1}$ for $1\leqq k\leqq n$.*

(iv) *$\tilde{x}=r(\nu_k)^{-1}e^{(k)}$ is a nondegenerate critical point of J if and only if $r(\nu_j)\neq r(\nu_k)$ for all $j\neq k$, $1\leqq j\leqq n$. The eigenvalues of $D^2J(\tilde{x})$ with respect to C are $\{r(\nu_j)-r(\nu_k)\colon 1\leqq j\leqq n, j\neq k\}\cup\{r(\nu_k)\}$.*

Proof. This proof is similar to that of Theorem 6. Since C is bounded, we have $\langle Cx, x\rangle^{1/2}\leqq\|C\|^{1/2}\|x\|$, so

$$J(x)\geqq\frac{c}{2}\|x\|^2-\|C\|^{1/2}\|x\|$$

where c is as in Theorem 6. Hence J is coercive. Also, if $x\neq 0$,

$$\nabla J(x)=r(A)x-Cx/\sqrt{\langle Cx, x\rangle},$$

and now (i)-(iii) follow just as in Theorem 6. The Hessian at x is

$$D^2J(x)=r(A)-(C/\sqrt{\langle Cx, x\rangle})+\frac{Cx\otimes Cx}{\langle Cx, x\rangle^{3/2}}.$$

When $\tilde{x} = r(\nu_k)^{-1} e^{(k)}$ we have $\langle C\tilde{x}, \tilde{x}\rangle = \langle Ce^{(k)}, e^{(k)}\rangle / r(\nu_k)^2 = 1/r(\nu_k)^2$ so

$$D^2 J(\tilde{x}) e^{(j)} = r(A)e^{(j)} - r(\nu_k) Ce^{(j)} + r(\nu_k)^3 \langle C\tilde{x}, e^{(j)}\rangle C\tilde{x},$$

$$= \begin{cases} (r(\nu_j) - r(\nu_k))\, Ce^{(j)} & \text{if } j \neq k, \\ r(\nu_k) Ce^{(k)} & \text{if } j = k, \end{cases}$$

and thus (iv) holds.

In the remainder of this paper, we shall not pursue these generalized eigenvalue problems, but most of the results still hold mutatis mutandis. Essentially we replace $\|x\|$ by $\langle Cx, x\rangle^{1/2}$ and we obtain slightly more complicated expressions for derivatives and Hessians.

5. Examples of variational principles. By choosing $r(A)$ appropriately we can describe variational principles for certain different eigenvalues and eigenvectors of A. The first two examples have $r(A)$ linear or quadratic in A.

Example 1(a). Let $r(A) = A - \mu I$, where μ is chosen so that $\mu < \lambda_n$, with λ_n being the least eigenvalue of A. When A is positive definite we may take $\mu = 0$.

Define $F_1 : \mathbb{R}^n \to \mathbb{R}$ by

$$F_1(x) = \frac{1}{2}\langle Ax, x\rangle - \frac{\mu}{2}\|x\|^2 - \|x\|. \tag{5.1}$$

The following theorem shows that minimizing F_1 on $\mathbb{R}^n$ provides upper bounds on λ_n.

THEOREM 8. *Let A, μ, F_1 be as above. Then*

(i) $\inf_{x\in\mathbb{R}^n} F_1(x) = -1/2(\lambda_n - \mu)$ *and this is attained at* $(\lambda_n - \mu)^{-1} e^{(n)}$, *where* $e^{(n)}$ *is in* E_n.

(ii) *The nonzero critical points of* F_1 *are* $\{(\lambda_k - \mu)^{-1} e^{(k)} : e^{(k)} \in E_k\}$.

(iii) *The critical values of* F_1 *are* $\{-\frac{1}{2}(\lambda_k - \mu)^{-1} : 1 \leqq k \leqq n\} \cup \{0\}$.

(iv) $\tilde{x} = (\lambda_k - \mu)^{-1} e^{(k)}$ *is a nondegenerate critical point of* F_1 *if and only if* λ_k *is a simple eigenvalue of* A. *In this case the Morse index of* $\tilde{x}$ *is* $(n-k)$.

Proof. To obtain the proof just substitute $r(A) = A - \mu I$ and $r(\lambda_j) = \lambda_j - \mu$ in Theorem 6.

Example 1(b). We can also take $r(A) = \mu I - A$ if we choose μ so that $\mu > \lambda_1$, with λ_1 being the largest eigenvalue of A. Then define $F_2 : \mathbb{R}^n \to \mathbb{R}$ by

$$F_2(x) = \frac{\mu}{2}\|x\|^2 - \langle Ax, x\rangle - \|x\|. \tag{5.2}$$

In this case $\inf_{x\in\mathbb{R}^n} F_2(x) = -1/2(\mu - \lambda_1)$ and parts (ii)-(iv) of Theorem 8 hold similarly. This time the Morse index of $\tilde{x}$ is k.

Thus minimizing F_2 on $\mathbb{R}^n$ provides lower bounds on λ_1, and the critical points and critical values of F_1, F_2 provide information on all the eigenvalues and eigenvectors of A.

EXAMPLE 2. Let $r(A) = (A - \mu I)^2$, where μ is not an eigenvalue of A. Define $F(\mu, x)$ by

$$F(\mu, x) = \tfrac{1}{2}\|(A - \mu I)x\|^2 - \|x\|. \tag{5.3}$$

The following theorem shows that minimizing $F(\mu, \cdot)$ on $\mathbb{R}^n$ provides information on the eigenvalues of A close to μ.

THEOREM 9. *Let A be a real symmetric matrix with μ not an eigenvalue of A, and let $F(\mu, \cdot)$ be defined by* (5.3). *Then*

$$\text{(i)} \quad \inf_{x\in\mathbb{R}^n} F(\mu, x) = \min_{1\leqq j\leqq n} \frac{-1}{2(\lambda_j - \mu)^2}. \tag{5.4}$$

If J is an integer at which this minimum is attained, then $F(\mu, \cdot)$ is minimized at $(\lambda_J - \mu)^{-2} e^{(J)}$, with $e^{(J)}$ in $E_J^{(2)}$.

(ii) *The nonzero critical points of $F(\mu, \cdot)$ are $(\lambda_k - \mu)^{-2} e^{(k)}$ with $e^{(k)}$ in $E_k^{(2)}$.*

(iii) *The negative critical values of $F(\mu, \cdot)$ are $-\frac{1}{2}(\lambda_k - \mu)^2$ for $1 \leqq k \leqq n$.*

(iv) *$\tilde{x} = (\lambda_k - \mu)^{-2} e^{(k)}$ is a nondegenerate critical point of $F(\mu, \cdot)$ if and only if $(\lambda_k - \mu)^2 \neq (\lambda_j - \mu)^2$ for all $j \neq k$, $1 \leqq j \leqq n$.*

Here $E_k^{(2)} = \{x \in \mathbb{R}^n : \|x\| = 1$ and $(A - \mu I)^2 x = (\lambda_k - \mu)^2 x\}$.

Proof. To obtain the proof just substitute $(\lambda - \mu)^2$ for $r(\lambda)$ in Theorem 6.

We see that as μ varies, the minimum value of $F(\mu, \cdot)$ varies and provides information about all the eigenvalues of A. Let

$$\alpha(\mu) = \min_{1 \leqq j \leqq n} \frac{-1}{2(\lambda_j - \mu)^2} = \inf_{x \in \mathbb{R}^n} F(\mu, x). \tag{5.5}$$

We see that $\alpha(\mu) < 0$ for any real μ and it is singular at the eigenvalues of A. In fact, we have the following results.

LEMMA 5.1. *Let A be a real symmetric matrix with eigenvalues $\lambda_n \leqq \lambda_{n-1} \leqq \cdots \leqq \lambda_2 \leqq \lambda_1$, and let $\alpha(\mu)$ be defined by (5.5). Then*

(i) *α is continuous and monotone decreasing on $(-\infty, \lambda_n)$.*

(ii) *α is continuous and monotone increasing on (λ_1, ∞).*

(5.6) (iii) *If $\alpha(\mu) \leqq -a$ with $a > 0$, then A has an eigenvalue in the interval $[\mu - d, \mu + d]$, where $d = (2a)^{-(1/2)}$.*

(iv) *A is positive definite if and only if $\alpha(0)$ is finite and $\alpha(\mu)$ is monotone decreasing on $(-\infty, 0)$.*

Proof. Parts (i), (ii), and (iv) follow directly from (5.5).

If $\alpha(\mu) \leqq -a$, then from (5.4) there is an integer J such that

$$(\lambda_J - \mu)^2 \leqq \frac{1}{2a}.$$

Thus (iii) follows.

Part (iii) of Lemma 5.1 enables us to find upper and lower bounds on the eigenvalues of A. Suppose we know that there is a unique eigenvalue λ_J of A in an interval (μ_1, μ_2). Then $\alpha(\mu)$ will be monotone decreasing on $[\lambda_J - d_1, \lambda_J)$ and monotone increasing on $(\lambda_J, \lambda_J + d_2]$, where $d_1 = \frac{1}{2}(\lambda_J - \lambda_P)$ and λ_P is the eigenvalue of A closest to λ_J but less than λ_J and $d_2 = \frac{1}{2}(\lambda_N - \lambda_J)$, where λ_N is the eigenvalue of A closest to λ_J but larger than λ_J.

Thus there are a number of simple, effective algorithms to improve these upper and lower bounds on λ_J using information about $\alpha(\mu)$.

Moreover, we can use this to find a maximization principle for λ_n and a minimization principle for λ_1.

Let $C(\mu) = \{x \in \mathbb{R}^n : F(\mu, x) < 0\}$ and let $\tilde{\lambda}_n$ be the second smallest eigenvalue of A, $\tilde{\lambda}_1$ being the second largest eigenvalue of A ($\tilde{\lambda}_n \neq \lambda_n$, $\tilde{\lambda}_1 \neq \lambda_1$). When $\lambda_1 = \lambda_n$ is the only eigenvalue of A we can take $\tilde{\lambda}_n = +\infty$, $\tilde{\lambda}_1 = -\infty$ in the following theorem.

THEOREM 10. *Let A be a real symmetric matrix, and let λ_1, $\tilde{\lambda}_1$, λ_n, $\tilde{\lambda}_n$, $C(\mu)$ be as above. If μ is in $(\lambda_n, \frac{1}{2}(\tilde{\lambda}_n + \lambda_n))$, then*

$$\lambda_n = \max_{x \in C(\mu)} [\mu - 1/\sqrt{2F(\mu, x)}], \tag{5.7}$$

while if μ is in $(\frac{1}{2}(\lambda_1 + \tilde{\lambda}_1, \lambda_1))$, then

$$\lambda_1 = \min_{x \in C(\mu)} [\mu + 1/\sqrt{2F(\mu, x)}]. \tag{5.8}$$

Proof. Suppose μ is in $(\lambda_n, \tilde{\lambda}_n)$; then from Theorem 9 we have

$$\inf_{x\in\mathbb{R}^n} F(\mu, x) = \frac{-1}{2(\lambda_n - \mu)^2} = F(\mu, \hat{x})$$

where $\hat{x} = (\lambda_n - \mu)^{-2} e^{(n)}$ and $e^{(n)}$ is in E_n. Thus for any x in $C(\mu)$ we have

$$\lambda_n \geqq \mu - 1/\sqrt{2F(\mu, x)}$$

and equality holds here when $x = \hat{x}$. Thus (5.7) holds.

The argument for (5.8) is similar.

Example 3. Consider the case where $r(A) = A^{-1}(A^2 + \mu^2 I)$ for some $\mu \geqq 0$. $r(A)$ will be positive definite provided A is. When A is not positive definite, choose $\gamma < \lambda_n$; then similar results will hold if we use $A - \gamma I$ in place of A. Define $F_3 : [0, \infty) \times \mathbb{R}^n \to \mathbb{R}$ by

$$F_3(\mu, x) = \tfrac{1}{2}\langle (A + \mu^2 A^{-1})x, x\rangle - \|x\|. \tag{5.9}$$

Just as in the preceding example, minimizing $F_3(\mu, \cdot)$ on $\mathbb{R}^n$ provides information on the eigenvalues of A close to μ. In this case, however, the problem does not become unbounded below at the eigenvalues of A. The results may be summarized as follows.

THEOREM 11. *Let A be a symmetric positive definite matrix and F_3 be defined by* (5.9). *Then*

$$\text{(5.10)} \quad \text{(i)} \quad \inf_{x\in\mathbb{R}^n} F_3(\mu, x) = \min_{1\leqq j\leqq n} \frac{-\lambda_j}{2(\lambda_j^2 + \mu^2)}.$$

If J is an integer at which this minimum is attained, then $F_3(\mu, x)$ is minimized at $\lambda_J(\lambda_J^2 + \mu^2)^{-1} e^{(J)}$ with $e^{(J)}$ in $E_J^{(3)}$.

(ii) *The nonzero critical points of $f_3(\mu, \cdot)$ are $(\lambda_k/2)(\lambda_k^2 + \mu^2)^{-1} e^{(k)}$ with $e^{(k)}$ in $E_k^{(3)}$.*

(iii) *The critical values of $F_3(\mu, \cdot)$ are 0 and $-\lambda_k(\lambda_k^2 + \mu^2)^{-1}$ for $1 \leqq k \leqq n$.*

(iv) *$\tilde{x} = \lambda_k(\lambda_k^2 + \mu^2)^{-1} e^{(k)}$ is a nondegenerate critical point of $F_3(\mu, \cdot)$ if and only if λ_k is a simple eigenvalue of A and $\lambda_j \lambda_k \neq \mu^2$ for any $j \neq k$, $1 \leqq j \leqq n$.*

Here $E_k^{(3)} = \{x \in \mathbb{R}^n : \|x\| = 1$ and $Ax + \mu^2 A^{-1} x = (\lambda_k + \mu^2/\lambda_k)x\}$.

Proof. Use $r(\lambda) = \lambda/(\lambda^2 + \mu^2)$ in Theorem 6; then the result follows.

The function $r(\lambda) = \lambda/(\lambda^2 + \mu^2)$ is unimodal with $r(0) = r(\infty) = 0$ and is maximized at $\lambda = \mu$. Thus the minimizing J in (5.10) arises at an eigenvalue λ_J of A that is closest to μ in this special sense. By varying μ we can find all the distinct eigenvalues of A from information about the infima of $F_3(\mu, \cdot)$.

6. Variational principles for positive or negative eigenvalues. In the last three sections, the variational principles generally required some assumption involving positive definiteness of a matrix. Now consider the function $\mathcal{G}_p : \mathbb{R}^n \to \mathbb{R}$ defined by

$$\mathcal{G}_p(x) = \frac{1}{p}\|x\|^p - \frac{1}{2}\langle Ax, x\rangle \tag{6.1}$$

with $2 < p < \infty$. This function has the form (2.1), with $\Psi(s) = -s$, $\Phi(s) = Cs^{p/2}$, and C a constant. For calculations we shall often take $p = 3$ or 4. When p increases to $+\infty$, the function $\mathcal{G}_p(x)$ converges pointwise to the function

$$\mathcal{G}_\infty(x) = \chi_1(x) - \tfrac{1}{2}\langle Ax, x\rangle \tag{6.2}$$

where

$$\chi_1(x) = \begin{cases} 0 & \text{if } \|x\| \leqq 1, \\ \infty & \text{otherwise.} \end{cases}$$

$\mathcal{G}_\infty$ arises in the convex analysis formulation of Rayleigh's principle (see § 8 of [1]).

The results on extremizing $\mathcal{G}_p$ may be summarized as follows.

THEOREM 12. *Suppose A is a real symmetric matrix and $\mathcal{G}_p$ is defined by* (6.1) *with $p > 2$. Then*

(6.3) (i) *$\mathcal{G}_p$ is coercive and $\inf_{x \in \mathbb{R}^n} \mathcal{G}_p(x) = (-1/2\nu)[\max(0, \lambda_1)]^\nu$, where $\nu = p/(p-2)$ and λ_1 is the largest eigenvalue of A.*

(ii) *The critical points of $\mathcal{G}_p$ occur at 0 and at $\tilde{x} = \lambda_j^{1/(p-2)} e^{(j)}$, where λ_j is a positive eigenvalue of A and $e^{(j)}$ is in E_j.*

(iii) *When $\lambda_1 > 0$, $\mathcal{G}_p$ is minimized at $\hat{x} = \lambda_1^{1/(p-2)} e^{(1)}$, where $e^{(1)} \in E_1$; if $\lambda_1 \leqq 0$ then $\mathcal{G}_p$ is minimized at $\hat{x} = 0$.*

(iv) *The critical values of $\mathcal{G}_p$ are $\{-\lambda_j^\nu/2\nu : \lambda_j > 0\} \cup \{0\}$.*

(v) *$\tilde{x} = \lambda_k^{1/(p-2)} e^{(k)}$ is a nondegenerate critical point of $\mathcal{G}_p$ if and only if λ_k is a simple eigenvalue of A. In this case the Morse index of $\tilde{x}$ is $(k-1)$. Zero is a nondegenerate critical point of $\mathcal{G}_p$ if and only if A is nonsingular.*

Proof. We have that $\mathcal{G}_p(x) \geqq \|x\|^p/p - \frac{1}{2}\|A\|\,\|x\|^2$ for all x in $\mathbb{R}^n$. Since $p > 2$, $\mathcal{G}_p$ is coercive and it attains its infimum on $\mathbb{R}^n$. Also

$$\nabla \mathcal{G}_p(x) = \|x\|^{p-2} x - Ax. \tag{6.4}$$

Thus if $\tilde{x}$ is a critical point of $\mathcal{G}_p$ then $\tilde{x} = 0$, or else $\tilde{x}$ is an eigenvector of A with eigenvalue $\tilde{\lambda} = \|\tilde{x}\|^{p-2} > 0$. That is, $\tilde{x} = 0$ or $\tilde{x} = \lambda_j^{1/(p-2)} e^{(j)}$ with $\lambda_j > 0$, $e^{(j)} \in E_j$. Thus (ii) holds and $\mathcal{G}_p(\tilde{x}) = 0$ or $-\lambda_j^\nu/2\nu$, where $\nu = p/(p-2)$. Thus (i), (iii), and (iv) follow.

Differentiating (6.4) we find that, when $x \neq 0$,

$$D^2 \mathcal{G}_p(x) = \|x\|^{p-2}[I + (p-2)P_x] - A \tag{6.5}$$

where $P_x y = \langle x, y \rangle x/\|x\|^2$ is the projection in the direction x. When $x = 0$, we have $D^2 \mathcal{G}_p(0) = -A$. When $\tilde{x} = \lambda_k^{1/(p-2)} e^{(k)}$ with $\lambda_k > 0$, we have

$$\begin{aligned} D^2 \mathcal{G}_p(\tilde{x}) e^{(j)} &= \lambda_k (e^{(j)} + (p-2)\delta_{jk} e^{(k)}) - A e^{(j)} \\ &= \begin{cases} (\lambda_k - \lambda_j) e^{(j)} & \text{if } j \neq k, \\ (p-2)\lambda_k e^{(k)} & \text{if } j = k. \end{cases} \end{aligned}$$

Thus (v) holds.

A symmetric matrix is said to be stable, or negative semidefinite, if all its eigenvalues are less than or equal to zero. A simple corollary of this theorem is the following.

COROLLARY 1. *A real symmetric matrix is stable if and only if $\inf_{x \in \mathbb{R}^n} \mathcal{G}_p(x) = 0$.*

Proof. The proof follows from (i) of Theorem 12.

To obtain the negative eigenvalues of A, we substitute $-A$ for A in (6.1). Alternatively, let

$$G_p(x) = \frac{1}{p}\|x\|^p + \frac{1}{2}\langle Ax, x \rangle \tag{6.6}$$

with $2 < p < \infty$, and consider the problem of extremizing G_p. The results may be summarized as follows.

COROLLARY 2. *Let A be a real symmetric matrix and G_p be defined by* (6.6) *with $p>2$. Then*

(i) *G_p is coercive and $\inf_{x\in\mathbb{R}^n} G_p(x)=(-1/2\nu)|\min(0,\lambda_n)|^\nu$ where $\nu=p/(p-2)$ and λ_n is the least eigenvalue of A.*

(ii) *The critical points of G_p occur at 0 and at $x=|\lambda_j|^{1/(p-2)}e^{(j)}$, where λ_j is a negative eigenvalue of A and $e^{(j)}\in E_j$.*

(iii) *The critical values of G_p are 0 and $-|\lambda_j|^\nu/2\nu$, where $\lambda_j<0$.*

(iv) *When $\lambda_n<0$, G_p is minimized at $|\lambda_n|^{1/(p-2)}e^{(n)}$, where $e^{(n)}\in E_n$. If $\lambda_n\geqq 0$, G_p is minimized at zero.*

(v) *Zero is a nondegenerate critical point of G_p if and only if A is nonsingular. When $\tilde{x}=|\lambda_k|^{1/(p-2)}e^{(k)}$ is a critical point of G_p, $\tilde{x}$ is nondegenerate if and only if λ_k is a simple eigenvalue of A. In this case the Morse index of $\tilde{x}$ is $n-k$.*

Proof. The proof is the same as the proof of Theorem 10.

COROLLARY 3. *Let A be a real symmetric matrix. Then A is positive semidefinite if and only if $G_p(x)\geqq 0$ for all x in $\mathbb{R}^n$.*

Proof. From Corollary 1 we see that $\lambda_n\geqq 0$ if and only if $\inf_{x\in\mathbb{R}^n} G_p(x)=0$; hence the result follows.

These variational principles may be modified to find the eigenvalues and eigenvectors of A lying in any preassigned interval. A functional whose critical values identify the eigenvalues of A in the interval (μ,∞) (or $(-\infty,\mu)$) is obtained by replacing A in (6.1) (or (6.6)) by $A-\mu I$.

To see if A has an eigenvalue in the interval (μ_1,μ_2) replace A in (6.1) by $(A-\mu_1 I)(\mu_2 I-A)$ and obtain

$$\mathcal{G}_p(\mu_1,\mu_2,x)=\frac{1}{p}\|x\|^p+\frac{1}{2}[\|Ax\|^2-(\mu_1+\mu_2)\langle Ax,x\rangle+\mu_1\mu_2\|x\|^2]. \tag{6.7}$$

Then we have the following corollary.

COROLLARY 4. *Let A be a real symmetric matrix, and let $\mathcal{G}_p(\mu_1,\mu_2,x)$ be defined by* (6.7). *Then A has an eigenvalue in the interval (μ_1,μ_2) if and only if*

$$\inf_{x\in\mathbb{R}^n}\mathcal{G}_p(\mu_1,\mu_2,x)=-\alpha(\mu_1,\mu_2)<0. \tag{6.8}$$

If $\alpha(\mu_1,\mu_2)>0$ then either λ_+ or λ_- is an eigenvalue of A, where

$$\lambda_\pm=\tfrac{1}{2}[(\mu_1+\mu_2)\pm d], \tag{6.9}$$

$$d^2=(\mu_2-\mu_1)^2-4(2\nu\alpha(\mu_1,\mu_2))^{1/\nu}. \tag{6.10}$$

If there is a $\tilde{c}=\mathcal{G}_p(\mu_1,\mu_2,\tilde{x})<0$ then A has an eigenvalue in the subinterval $[\mu_0-\delta,\mu_0+\delta]$, where $\mu_0=\frac{1}{2}(\mu_1+\mu_2)$ and

$$\delta^2=\tfrac{1}{4}(\mu_1-\mu_2)^2-(2\nu|\tilde{c}|)^{1/\nu}.$$

Proof. Equation (6.7) has the form (6.1) with $(A-\mu_1 I)(\mu_2 I-A)$ replacing A. Thus this infimum is negative if and only if $(A-\mu_1 I)(\mu_2 I-A)$ has a positive eigenvalue from (6.3). The eigenvalues of $(A-\mu_1 I)(\mu_2 I-A)$ are $(\lambda_j-\mu_1)(\mu_2-\lambda_j)$ for $1\leqq j\leqq n$, so (6.8) holds.

Let

$$\nu_1=\max_{1\leqq j\leqq n}(\lambda_j-\mu_1)(\mu_2-\lambda_j)>0$$

$$=(\lambda_J-\mu_1)(\mu_2-\lambda_J)\quad\text{for some } 1\leqq J\leqq n.$$

Then from (6.3), $(2\nu\alpha(\mu_1,\mu_2))^{1/\nu}=(\lambda_J-\mu_1)(\mu_2-\lambda_J)$. This is a quadratic equation for λ_J, whose solution is given by (6.9)-(6.10). More generally, if $\alpha(\mu_1,\mu_2)>|\tilde{c}|$, then we

have

$$(\lambda_J - \mu_1)(\mu_2 - \lambda_J) \geqq (2\nu|\tilde{c}|)^{1/\nu}$$

and thus we have that λ_J lies in $[\mu_0 - d, \mu_0 + d]$ as claimed.

In a similar manner, when μ is not an eigenvalue of A, we can find the eigenvalue closest to μ and greater than μ by substituting $(A-\mu I)^{-1}$ for A in (6.1).

Write

$$J_p(x) = \frac{1}{p}\|x\|^p - \frac{1}{2}\langle (A-\mu I)^{-1}x, x\rangle. \tag{6.11}$$

Then we have the following corollary.

COROLLARY 5. *Suppose A is real symmetric, μ is not an eigenvalue of A, and J_p is defined by* (6.11). *Then*

$$\inf_{x\in\mathbb{R}^n} J_p(x) = \begin{cases} \dfrac{-1}{2\nu}\left[\max\limits_{1\leqq j\leqq n}\left(\dfrac{1}{\lambda_j-\mu}\right)\right]^{\nu} & \text{if } \lambda_1 > \mu, \\ 0 \quad \text{if } \lambda_1 < \mu \end{cases} \tag{6.12}$$

with $\gamma = p/p-2$. When $\lambda_1 > \mu$, then this infimum is attained at $(\lambda_J - \mu)^{-1/(p-2)}e^{(J)}$, where λ_J is the eigenvalue of A closest to μ but larger than μ and $e^{(J)}$ is in E_J.

Proof. The eigenvalues of $(A-\mu I)^{-1}$ are $(\lambda_j - \mu)^{-1}$, and hence (6.12) follows from (6.3) and (6.11).

7. Variational principles for singular values. Suppose B is a general $m \times n$ real matrix. We can modify the preceding variational principles to describe functions whose critical points and critical values identify the singular values and singular vectors of B.

Throughout this section we assume B has singular values

$$\sigma_1 \geqq \sigma_2 \geqq \cdots \geqq \sigma_p \geqq 0 \quad \text{with } p = \min(m, n). \tag{7.1}$$

Let $u^{(j)}$, $v^{(j)}$, respectively, be left and right normalized singular vectors of B corresponding to the singular value σ_j. Thus $\|u^{(j)}\| = \|v^{(j)}\| = 1$ and

$$Bv^{(j)} = \sigma_j u^{(j)}, \qquad B^T u^{(j)} = \sigma_j v^{(j)} \quad \text{for } 1 \leqq j \leqq p. \tag{7.2}$$

The functions to be extremized will all have the form (2.12). We shall look particularly at

$$H_1(x) = \tfrac{1}{2}\|Bx\|^2 - \|x\|, \tag{7.3}$$

$$H_2(x) = \tfrac{1}{2}\|x\|^2 - \|Bx\|, \tag{7.4}$$

$$H_p(x) = \frac{1}{p}\|x\|^p - \frac{1}{2}\|Bx\|^2 \quad \text{for } 2 < p < \infty. \tag{7.5}$$

Here H_1 generalizes $F(0, \cdot)$, where $F(\mu, \cdot)$ is defined by (5.3), H_2 has the form (3.1) with $q = 1$ and $A = B^TB$, and H_p is related to $\mathcal{G}_p$ defined by (6.1) with $A = B^TB$. Each of these functions provides information on the singular values and singular vectors of B.

First consider H_1. Its extremal properties may be summarized as follows.

THEOREM 13. *Let B be a real $m \times n$ matrix and H_1 be defined by* (7.3). *Then*

(i) *H_1 is coercive on $\mathbb{R}^n$ if and only if* rank $B = n$.

(ii) *If* rank $B = n$, *then* $\inf_{x\in\mathbb{R}^n} H_1(x) = -1/2\sigma_n^2$, (7.6)

(7.7) *while if* rank $B \leqq n-1$, *then* $\inf_{x\in\mathbb{R}^n} H_1(x) = -\infty$.

(iii) *H_1 is continuously differentiable on $\mathbb{R}^n - \{0\}$ and the nonzero critical points of H_1 are $\sigma_j^{-2} v^{(j)}$ with $v^{(j)}$ being a normalized right singular vector of B corresponding to σ_j.*

(iv) *The critical values of H_1 are $\{-1/2\sigma_j^2 : 1 \leqq j \leqq p\}$.*

(v) *$\tilde{x} = \sigma_k^{-1} v^{(k)}$ is a nondegenerate critical point of H_1 if and only if σ_k^2 is a simple, nonzero eigenvalue of B^TB. In this case the Morse index of $\tilde{x}$ is $n-k$.*

Proof. If H_1 is coercive on $\mathbb{R}^n$, then there exists $R > 0$ such that

$$\|x\| \geqq R \text{ implies } \|Bx\| \geqq 1.$$

Hence $\|Bx\| \geqq \|x\|/R$ and thus rank $B = n$.

Conversely if rank $B = n$, then there exists $c > 0$ such that

$$\|Bx\| \geqq c\|x\| \quad \text{for all } x \text{ in } \mathbb{R}^n,$$

and hence H_1 is coercive. Thus (i) holds.

Now if rank $B \leqq n-1$, then there is an $\tilde{x} \neq 0$ in $\mathbb{R}^n$ such that $B\tilde{x} = 0$. Then $H(t\tilde{x}) = -t\|\tilde{x}\|$ and, letting $t \to \infty$, we see that (7.7) holds.

Differentiating (7.3), we find that, for $x \neq 0$,

$$\nabla H_1(x) = B^TBx - \frac{x}{\|x\|}. \tag{7.8}$$

Hence if $\tilde{x}$ is a nonzero critical point of H_1 we have that $\tilde{x}$ is a right singular vector of B and $\|\tilde{x}\|^{-1} = \sigma_j^2$ gives the corresponding singular value. Thus (iii) holds and we have

$$\|B\tilde{x}\|^2 = \|\tilde{x}\| = \sigma_j^{-2}$$

on taking inner products with $\tilde{x}$. Hence $H_1(\tilde{x}) = -1/2\sigma_j^2$, so (iv) holds, and when rank $B = n$ then (7.6) holds.

Differentiating (7.8) we obtain

$$D^2H_1(x) = B^TB - \frac{1}{\|x\|}\left(I - \frac{x\otimes x}{\|x\|^2}\right),$$

and thus (v) holds just as in the proof of Theorem 6, with $r(\lambda_j)$ being replaced by the eigenvalues σ_j^2 of B^TB.

Theorem 13 indicates that H_1 will be most informative when rank $B = n$ and thus $m \geqq n$. The functionals for H_2 and H_p, however, are always bounded below. The results may be summarized as follows.

THEOREM 14. *Let B be a real $m \times n$ matrix, and let H_2 be defined by* (7.4). *Then*

(7.9) (i) *H_2 is coercive on $\mathbb{R}^n$ and $\inf_{x\in\mathbb{R}^n} H_2(x) = -\sigma_1^2/2$. This infimum is attained at $\sigma_1 v^{(1)}$, where $v^{(1)}$ is a normalized singular vector corresponding to the singular value σ_1.*

(ii) *H_2 is continuously differentiable on $\mathbb{R}^n - \ker B$ and its critical points are* ker B *together with $\{\sigma_j^2 v^{(j)} : v^{(j)}$ is a normalized right singular vector corresponding to σ_j, $1 \leqq j \leqq p\}$.*

(iii) *The critical values of H_2 are $\{-\sigma_j^2/2 : 1 \leqq j \leqq p\} \cup \{0\}$.*

(iv) *$\tilde{x} = \sigma_k v^{(k)}$, with $\sigma_k \neq 0$, is a nondegenerate critical point of H_2 if and only if σ_k^2 is a simple nonzero eigenvalue of B^TB. In this case its Morse index is $k-1$.*

Proof. We have $H_2(x) = \frac{1}{2}\|x\|^2 - (\langle B^TBx, x\rangle)^{1/2}$. Thus H_2 has the form (3.1) with $q = 1$ and $A = B^TB$. The eigenvalues λ_j of A are related to the singular values σ_j of B by

$$\lambda_j = \begin{cases} \sigma_j^2 & \text{for } 1 \leqq j \leqq p, \\ 0 & \text{if } j > p, \end{cases}$$

and the eigenvectors of A are the right singular vectors of B. The proof of this result now follows the pattern of the proof of Theorem 3 except that now A is only positive semidefinite.

THEOREM 15. *Let B be a real $m \times n$ matrix, and let H_p be defined by* (7.5) *with $p > 2$. Then*

(7.10) (i) *H_p is coercive on $\mathbb{R}^n$ and $\inf_{x \in \mathbb{R}^n} H_p(x) = -\sigma_1^{\eta p}/\eta p$, where $\eta = 2/(p-2)$. This is attained at $\sigma_1^{\eta} v^{(1)}$.*

(ii) *The critical points of H_p occur at 0 and at $\tilde{x} = \sigma_j^{\eta} v^{(j)}$, where σ_j is a positive singular value of B and $v^{(j)}$ is a corresponding normalized singular vector.*

(iii) *The critical values of H_p are $\{-\sigma_j^{p\eta}/p\eta : \sigma_j > 0\} \cup \{0\}$.*

(iv) *$\tilde{x} = \sigma_k^{\eta} v^{(k)}$ is a nondegenerate critical point of H_p if and only if σ_k^2 is a simple eigenvalue of $B^T B$. In this case, the Morse index of $\tilde{x}$ is $(k-1)$.*

Proof. This result is proven in the same manner as Theorem 12 with $B^T B$ in place of A and σ_j^2 in place of λ_j.

It is worth noting that minimizing H_2 or H_p for $p > 2$ provides estimates on σ_1, the largest singular value of B. Minimizing H_1 tells us whether rank B is n and, if that is so, it estimates σ_n. To find other singular values of B we could use functions such as (5.3), (5.9), or (6.7) with A replaced by $B^T B$ or $B^T B + I$, and then use the corresponding theorems to find the singular values closest to μ or in some interval. Similarly, results such as the corollary to Theorem 6 can be proven for each of these functions.

8. Invariance properties. A function $E : \mathbb{R}^n \to \mathbb{R}$ is said to be invariant under a linear transformation $L : \mathbb{R}^n \to \mathbb{R}^n$ provided

$$E(Lx) = E(x) \quad \text{for all } x \text{ in } \mathbb{R}^n. \tag{8.1}$$

If E is invariant under a nonsingular linear transformation L and $\tilde{x}$ is a critical point of E, then $L\tilde{x}$ will also be a critical point of E and it will have the same value as $E(\tilde{x})$ and the same Morse index if it is nondegenerate.

We observe that all the functions introduced so far are invariant under the linear transformation $L = -I$. Particular matrices A often have other symmetries. The following result is often very useful.

THEOREM 16. *Let A be a real symmetric $n \times n$ matrix and let U be a real orthogonal matrix that commutes with A. Then E_q in* § 3, *F_r in* § 4, *F, F_1, F_2, and F_3 in* § 5, *and the functions $\mathcal{G}_p$ and G_p in* § 6 *are invariant under U.*

Proof. All the norms have been 2-norms and U orthogonal implies that $\|Ux\| = \|x\|$. Also $\langle AUx, Ux\rangle = \langle U^{-1}AUx, x\rangle = \langle Ax, x\rangle$ as U commutes with A. Moreover, $\langle r(A)Ux, Ux\rangle = \langle r(A)x, x\rangle$ and $\|(A-\mu I)Ux\| = \|U(A-\mu I)x\| = \|(A-\mu I)x\|$ so all the functions listed above are invariant under U as claimed.

This theorem can be used to analyze symmetries in the sets of critical points of these functions.

9. Dual problems. All of the specific functions introduced in the preceding sections may be written as the difference of two convex functions. Thus we can use nonconvex duality theory, as developed in [1] or [7], to obtain various natural dual problems. As will be seen, many of these are well-known constrained variational problems.

Recall that if $f : \mathbb{R}^n \to \mathbb{R}$ is a function, then its conjugate convex (or polar) function $f^* : \mathbb{R}^n \to (-\infty, \infty]$ is defined by

$$f^*(y) = \sup_{x \in \mathbb{R}^n} [\langle x, y\rangle - f(x)].$$

To describe the dual variational principles we shall need the dual functions of f_1 and f_2, where

$$f_1(x) = \frac{1}{p}\|Ax\|^p, \tag{9.1}$$

$$f_2(x) = \frac{1}{p}\langle Ax, x\rangle^{p/2} \tag{9.2}$$

with $1 \leqq p < \infty$ and A real symmetric. A must be positive semidefinite in (9.2). To describe the polar functions of f_1, f_2 we shall need the indicator functional $\chi_K(x)$ of a closed, convex set K in $\mathbb{R}^n$ defined by

$$\chi_K(x) = \begin{cases} 0 & \text{if } x \in K, \\ \infty & \text{otherwise.} \end{cases} \tag{9.3}$$

LEMMA 9.1. *Suppose A is real symmetric and nonsingular and f_1 is defined by* (9.1). *Then*

(9.4) (i) *When* $1 < p < \infty$ $f_1^*(y) = \|A^{-1}y\|^q/q$ *with* $q = p/(p-1)$;

(9.5) (ii) *When* $p = 1$ $f_1^*(y) = \begin{cases} 0 & \text{if } \|A^{-1}y\| \leqq 1, \\ \infty & \text{otherwise.} \end{cases}$

Proof. (i) When $1 < p < \infty$ we have

$$f_1^*(y) = \sup_{x \in \mathbb{R}^n} \left[\langle x, y\rangle - \frac{1}{p}\|Ax\|^p \right].$$

The expression on the right-hand side is maximized when

$$y = \|Ax\|^{p-2}A^2x \tag{9.6}$$

as A is symmetric. Thus, $A^{-1}y = \|Ax\|^{p-2}Ax$ and $\|A^{-1}y\| = \|Ax\|^{p-1}$. Thus the solution $\hat{x}$ of (9.6) is given by

$$\hat{x} = \frac{A^{-2}y}{\|A^{-1}y\|^r} \quad \text{where } r = \frac{p-2}{p-1}.$$

If we substitute this in the expression for f_1^* we obtain (9.4).

(ii) When $p = 1$, extremality condition (9.6) becomes

$$y = \frac{A^2x}{\|Ax\|}.$$

Thus the maximizing $\hat{x}$ lies in the direction of $A^{-2}y$. Consider

$$\begin{aligned} \Phi(s) &= \langle sA^{-2}y, y\rangle - |s|\,\|A^{-1}y\| \\ &= s\|A^{-1}y\|^2 - |s|\,\|A^{-1}y\|. \end{aligned}$$

We see that $\Phi : \mathbb{R} \to \mathbb{R}$ obeys

$$\max_{-\infty < s < \infty} \Phi(s) = \begin{cases} 0 & \text{if } \|A^{-1}y\| \leqq 1, \\ \infty & \text{otherwise} \end{cases}$$

and thus (9.5) follows. □

It is worth noting that (9.4) implies that for A real symmetric and nonsingular,

$$\frac{1}{p}\|Ax\|^p + \frac{1}{q}\|A^{-1}y\|^q \geqq \langle x, y\rangle \tag{9.7}$$

for all x, y in $\mathbb{R}^n$ and where $1/p+1/q=1$. This is a form of Hölder's (or Young's) inequality. Also, (9.5) says that when $p=1$, $f_1^*(y)=\chi_{K_1}(y)$, where $K_1=\{y\in\mathbb{R}^n: \|A^{-1}y\|\leqq 1\}$.

LEMMA 9.2. *Let A be a positive semidefinite matrix, and let f_2 be defined by* (9.2). *Then*

$$\text{(9.8)}\quad \text{(i)}\quad \textit{When } 1<p<\infty \quad f_2^*(y)=\begin{cases} q^{-1}\langle A^+y, y\rangle^{q/2} & \textit{for } y\in R(A),\\ +\infty & \textit{otherwise};\end{cases}$$

$$\text{(9.9)}\quad \text{(ii)}\quad \textit{When } p=1 \quad f_2^*(y)=\chi_{K_2}(y).$$

Here $q=p/(p-1)$ is the conjugate index to p, A^+ is the Moore-Penrose inverse of A, $R(A)$ is the range of A and $K_2=\{y\in R(A): \langle A^+y, y\rangle\leqq 1\}$.

Proof. We have $f_2^*(y)=\sup_{x\in\mathbb{R}^n}[\langle x, y\rangle-\langle Ax, x\rangle^{p/2}/p]$.

Suppose (i) $1<p<\infty$; then the expression on the right is concave in x and will be maximized if and only if there is a solution $\hat{x}$ of

$$y=\langle Ax, x\rangle^{(p-2)/2}Ax. \tag{9.10}$$

When y is not in the range of A we have $f_2^*(y)=+\infty$. When y is in the range of A, and if $\tilde{x}$ is a solution of (9.10), we have that

$$\langle y, \tilde{x}\rangle=\langle A\tilde{x}, \tilde{x}\rangle^{p/2}$$

on taking inner products with $\tilde{x}$. Substituting, we have

$$f_2^*(y)=\frac{1}{q}\langle A\tilde{x}, \tilde{x}\rangle^{p/2} \quad \text{where}\ \frac{1}{p}+\frac{1}{q}=1. \tag{9.11}$$

Let $\{e^{(1)}, \cdots, e^{(m)}\}$ be an orthonormal set of eigenvectors of A that is a basis of $R(A)$ with $Ae^{(j)}=\lambda_j e^{(j)}$, $1\leqq j\leqq m$, $\lambda_j>0$. Assume $y=\sum_{j=1}^m d_j e^{(j)}$ and $\tilde{x}=\sum_{j=1}^m c_j e^{(j)}$. Then from (9.8), on taking inner products with $e^{(k)}$, we have

$$d_k=\left(\sum_{j=1}^m \lambda_j c_j^2\right)^{(p-2)/2}\lambda_k c_k=\alpha\lambda_k c_k$$

where $\alpha=(\sum_{j=1}^m \lambda_j c_j^2)^{(p-2)/2}>0$. Now from (9.9) we have

$$\sum_{k=1}^m c_k d_k=\frac{1}{\alpha}\sum_{k=1}^m \frac{d_k^2}{\lambda_k}=\alpha^{p/(p-2)} \quad \text{if } p\neq 2.$$

Thus

$$\alpha^{2(p-1)/(p-2)}=\sum_{k=1}^m \frac{d_k^2}{\lambda_k}$$

and so we have a unique positive solution for α if $p\neq 2$. When $p=2$, $\alpha=1$. Thus there is a unique $\tilde{x}$ in $R(A)$ that satisfies (9.10) and this is given by $\tilde{x}=\gamma A^+y$ for some constant γ, with A^+ being the Moore-Penrose inverse.

Now $\langle A^+y, y\rangle=\langle A\tilde{x}, \tilde{x}\rangle^{p-1}$ from (9.10), so (9.11) implies that for y in $R(A)$,

$$f_2^*(y)=\frac{1}{q}\langle A^+y, y\rangle^{p/(2(p-1))}$$

as required.

(ii) When $p=1$, the extremality condition (9.10) becomes

$$y=Ax/\sqrt{\langle Ax, x\rangle}.$$

When y is not in the range of A, $f_2^*(y) = +\infty$. When y is in the range of A, we can do another expansion in positive eigenvectors of A to show that $f_2^*(y) = \chi_{K_2}(y)$.

COROLLARY. *Let A be positive definite and let f_2 be defined by* (9.2). *Then*

(9.12) (i) *When* $p \neq 1$ $f_2^*(y) = \langle A^{-1}y, y\rangle^{q/2}/q$ with $q = p/(p-1)$;

(9.13) (ii) *When* $p = 1$ $f_2^*(y) = \chi_{K_2}(y)$ with $K_2 = \{y \in \mathbb{R}^n : \langle A^{-1}y, y\rangle \leqq 1\}$.

Proof. When A is nonsingular, A^+ becomes A^{-1}.

We are now in a position to describe the dual variational principles to the ones introduced in §§ 3–7. When $E : \mathbb{R}^n \to \mathbb{R}$ is a function of the form

$$E(x) = f_1(Lx) - f_2(x) \tag{9.14}$$

with f_1, f_2 being convex and lower semicontinuous on $\mathbb{R}^n$ and L an $n \times n$ matrix, then the dual problem is to minimize $\mathscr{E} : \mathbb{R}^n \to \bar{\mathbb{R}}$, where

$$\mathscr{E}(y) = f_2^*(L^T y) - f_1^*(y). \tag{9.15}$$

This is described in § 7 of [1] and in Toland [7]. Moreover, Theorem 5.3 of [1] states that, under some regularity conditions, the critical points of E and $\mathscr{E}$ correspond. When the corresponding critical points are nondegenerate they have the same Morse indices. In particular, they are of the same type and have the same critical values.

We shall say that the variational principle of minimizing $\mathscr{E}$ on $\mathbb{R}^n$ is a constrained variational problem if the essential domain of $\mathscr{E} = \{y \in \mathbb{R}^n : |\mathscr{E}(y)| < \infty\}$ is a proper subset of $\mathbb{R}^n$.

When E_q is given by (3.1), then the dual problem is to minimize

$$\mathscr{E}_q(y) = \frac{1}{p}\langle A^{-1}y, y\rangle^{p/2} - \frac{1}{2}\|y\|^2 \tag{9.16}$$

where $p = q' = q/(q-1)$ is the dual index to q and $1 < q < 2$.

When $q = 1$, the dual problem is to minimize

$$\mathscr{E}_1(y) = \chi_{K_2}(y) - \tfrac{1}{2}\|y\|^2 \tag{9.17}$$

where

$$K_2 = \{y \in \mathbb{R}^n : \langle A^{-1}y, y\rangle \leqq 1\}.$$

These results follow from (9.15) and the corollary to Lemma 9.2.

In particular (9.17) is a constrained variational principle but (9.16) is a new class of unconstrained variational problems for the eigenvalues and eigenvectors of A.

When F_r is given by (4.1) then the dual problem is to minimize

$$\mathscr{F}_r(y) = \chi_1(r(A)y) - \tfrac{1}{2}\|y\|^2.$$

Here χ_1 is defined as in (6.2). Equivalently we can look at

$$\tilde{\mathscr{F}}_r(z) = \chi_1(z) - \tfrac{1}{2}\|r(A)^{-1}z\|^2 \tag{9.18}$$

using the fact that $r(A)$ obeys (A3). These are constrained variational problems.

When $r(A) = (A - \mu I)$ or $(A - \mu I)^2$ as in Examples 1 or 2 of § 5, these problems are well-known inverse power methods associated with Rayleigh's principle (see Parlett [5]).

To compute the dual problem to minimizing $\mathscr{G}_p$ given by (6.1) we must first write $A = A_+ - A_-$, where A_+, A_- are defined via the spectral theorem as the parts of A

corresponding to positive and negative eigenvalues of A_-. Then $\langle Ax, x\rangle = \langle A_+x, x\rangle - \langle A_-x, x\rangle$ with both A_+, A_- being positive semidefinite. When A is positive definite, $A_- = 0$. Now

$$\mathcal{G}_p(x) = \frac{1}{p}\|x\|^p + \frac{1}{2}\langle A_-x, x\rangle - \frac{1}{2}\langle A_+x, x\rangle, \tag{9.19}$$

which has the form (9.14) with $L = I$,

$$f_1(x) = \frac{1}{p}\|x\|^p + \frac{1}{2}\langle A_-x, x\rangle,$$

$$f_2(x) = \tfrac{1}{2}\langle A_+x, x\rangle.$$

From Lemma 9.2 and (9.15), we see that the dual problem to minimizing $\mathcal{G}_p$ will be a constrained problem unless A is positive definite. When $A = A_+$ is positive definite, then the dual problem is to minimize

$$\tilde{G}_p(y) = \frac{1}{2}\langle A^{-1}y, y\rangle - \frac{1}{q}\|y\|^q \tag{9.20}$$

with $q = p/(p-1)$ being the dual index to p. This is similar to F_r defined by (4.1) with $r(A) = A^{-1}$ and with $\|x\|$ replaced by $\|y\|^q/q$ with $1 < q < 2$.

Similarly the dual principle, defined by (9.15), to minimizing G_p defined by (6.6) will be a constrained problem unless A is negative definite. When A is negative definite, the dual problem has the form (9.20) with $-A^{-1}$ in place of A^{-1}.

In summary, we have seen that the dual problems to minimizing E_q, with $1 < q < 2$ or $\mathcal{G}_p$ or G_p under definiteness constraints, are new unconstrained problems. The other dual problems are constrained variational problems, some of which are well known. Essentially the dual problem will be unconstrained if and only if both f_1^* and f_2^* in (9.15) are finite everywhere. This occurs provided both f_1 and f_2 are coercive on $\mathbb{R}^n$.

AN EXISTENCE AND UNIQUENESS THEOREM FOR DIFFERENCE EQUATIONS*

DARREL HANKERSON†

Abstract. The nonlinear difference equation $Py(t-k) = f(t, y(t))$ with $(j, n-j)$-conjugate boundary conditions is considered, where $Py(t-k) = 0$ is an nth-order linear difference equation and k is a fixed integer, $0 \le k < n$. Peterson considered this type of problem for the cases $j = n-1$ and $j = 1$. This paper extends his results to the $(j, n-j)$-problem. A comparison theorem for solutions of related linear inequalities is obtained, leading to some disconjugacy results. Then a shooting method type of proof is used to prove existence and uniqueness theorems for certain boundary value problems where f satisfies a two-sided Lipschitz condition.

AMS(MOS) subject classifications. 34C10, 34B10, 39A10

1. Introduction.

In this paper we are interested in proving existence and uniqueness theorems for boundary value problems for the nonlinear difference equation

$$Py(t-k) = f(t, y(t)), \quad t \in [a+k, b+k], \tag{1}$$

where $f(t, y)$ is a continuous function of y for each fixed t in the interval of integers $[a+k, b+k]$. Here, k and n are fixed integers with $0 \le k < n$, and

$$Py(t) \equiv \sum_{i=0}^{n} \alpha_i(t) y(t+i), \quad t \in [a, b],$$

where $\alpha_n(t) \equiv 1$. We will be interested in $(j, n-j)$ boundary conditions of the form

$$\begin{aligned} y(a+i) &= A_i, \quad 0 \le i \le j-1, \\ y(b+n-i) &= B_i, \quad 0 \le i \le n-j-1, \end{aligned}$$

where $1 \le j \le n-1$.

A number of recent papers have considered linear and nonlinear equations of the form (1). The case $n = 2$ and $k = 1$ is discussed in [7], [8], [10], [11], and the case $n = 4$ and $k = 2$ is discussed in [3], [9], [17]. More general n and k are considered in [14]. The main existence-uniqueness theorem presented here will use a shooting method type of proof. Examples of this method applied to difference equations can be found in [1] and [14].

2. Preliminaries.

We are motivated by the results of Peterson in [14] for certain $(n-1, 1)$ and $(1, n-1)$ problems. First, we give some basic definitions. For these definitions, let L be defined by $Ly(t) = \sum_{i=0}^{n} \beta_i(t) y(t+i)$ for $t \in [a, b]$, where $\beta_n(t) \equiv 1$ and $\beta_0(t) \neq 0$ for $t \in [a, b]$.

DEFINITION (HARTMAN [5]). Let $y(t)$ be a solution of $Ly(t) = 0$. We say y has a *generalized zero* at t_0 in case either $y(t_0) = 0$ or there exists an integer j with

† Department of Algebra, Combinatorics, and Analysis, Auburn University, Auburn, Alabama 36849-5307.

$1 \le j \le t_0 - a$ such that

$$(-1)^j y(t_0 - j)y(t_0) > 0,$$
$$y(t) = 0, \quad t_0 - j < t < t_0.$$

We say that $Ly(t) = 0$ is *disconjugate* on $[a, b+n]$ if no solution $y \not\equiv 0$ has n generalized zeros.

The condition $(-1)^n \beta_0(t) > 0$ on $[a, b]$ is necessary for $Ly(t) = 0$ to be disconjugate on $[a, b + n]$. Further discussion concerning this condition can be found in [5] and [13].

DEFINITION (PETERSON [14]). Let J be a subinterval of $[a, b + n]$ with card $J \ge n$, and let $1 \le j \le n - 1$. We say that $Ly(t) = 0$ is *right* $(j, n - j)$*-disconjugate* on J provided there is no nontrivial solution $y(t)$ and integers α, $\beta \in J$ with $\alpha + j \le \beta \le \beta + n - j - 1 \in J$ such that

$$y(\alpha + i) = 0, \quad 0 \le i \le j - 1,$$
$$y(\beta + i) = 0, \quad 0 \le i \le n - j - 2,$$

and y has a generalized zero at $\beta + n - j - 1$. Similarly, we say that $Ly(t) = 0$ is *left* $(j, n - j)$*-disconjugate* on J provided there is no nontrivial solution $y(t)$ and integers α, $\beta \in J$ with $\alpha + j \le \beta \le \beta + n - j - 1 \in J$ such that

$$y(\alpha + i) = 0, \quad 0 \le i \le j - 2,$$
$$y(\beta + i) = 0, \quad 0 \le i \le n - j - 1,$$

and y has a generalized zero at $\alpha + j - 1$.

In this paper, we will say that $Ly(t) = 0$ is $(j, n - j)$*-disconjugate* on an interval J provided it is both right $(j, n - j)$-disconjugate and left $(j, n - j)$-disconjugate on J. Some results on disconjugacy and right and left disconjugacy can be found in [14] and in the references given there.

If $Ly(t) = 0$ is right $(j, n - j)$-disconjugate, then for each fixed $s \in [a, b]$, there is a unique solution $G(t, s)$ of the boundary value problem

$$\begin{aligned} &Lu(t) = \delta_{ts}, \quad t \in [a, b], \\ &u(a + i) = 0, \quad 0 \le i \le j - 1, \\ &u(b + n - i) = 0, \quad 0 \le i \le n - j - 1, \end{aligned} \tag{2}$$

where δ_{ts} is the Kronecker delta. In this case, $G(t, s)$ is called the *Green's function* for (2), and the unique solution of $Ly(t) = h(t)$ with boundary conditions in (2) is given by

$$y(t) = \sum_{s=a}^{b} G(t, s)h(s), \quad t \in [a, b + n].$$

Some of our results use the following theorem concerning the sign of the Green's function (see [15, Thm. 1]). This theorem requires that the equation $Lu(t) = 0$ be defined on a larger interval. As in [15], whenever necessary we extend the coefficients by defining $\beta_i(t) = \beta_i(a)$ for $t < a$, and $\beta_i(t) = \beta_i(b)$ for $t > b$.

THEOREM 2.1. *Assume* $2 \le j \le n - 1$ *and* $Lu(t) = 0$ *is* $(i, n - i)$*-disconjugate on* $[a + j - i, b + n + j - i]$ *for* $i = j - 1, \cdots, n - 1$. *Then the Green's function* $G(t, s)$ *for the* $(j, n - j)$*-boundary value problem*

$$\begin{aligned} &Lu(t) = \delta_{ts}, \\ &u(a + i) = 0, \quad 0 \le i \le j - 1, \\ &u(b + n - i) = 0, \quad 0 \le i \le n - j - 1, \end{aligned}$$

satisfies

$$(-1)^{n-j}G(t,s) > 0, \quad t \in [a+j, b+j],\ s \in [a,b].$$

Remark. In the case that $j = n-1$, Theorem 2.1 requires that $Lu(t) = 0$ be $(n-2,2)$-disconjugate on $[a+1, b+n+1]$. However, Peterson [12, Thm. 8] has shown that in the case of an $(n-1,1)$-problem, we can assume that the equation is $(n-2,2)$-disconjugate on $[a, b+n]$.

We will first prove some comparison theorems for solutions to certain inequalities related to the difference equations

$$Pu(t-k) = q_1(t)u(t) \tag{3}$$

$$Pv(t-k) = q_2(t)v(t) \tag{4}$$

where

$$q_1(t) \geq q_2(t), \quad t \in [a+k, b+k]. \tag{5}$$

In Peterson's paper [14], it was assumed that $1 \leq k < n$. Together with the requirement that $(-1)^n\alpha_0(t) > 0$, this guaranteed that no nontrivial solution of $Py(t-k) = p(t)y(t)$ has $n-1$ zeros at $t, \cdots, t+n-2$ and a generalized zero at $t+n-1$. In the case that $k = 0$, the corresponding condition is that $(-1)^n[\alpha_0(t) - p(t)] > 0$ for $t \in [a,b]$. Note that if $Py(t) = p(t)y(t)$ is right $(j, n-j)$-disconjugate for some j, then this condition necessarily holds.

The following is a modification of the comparison theorem in [14, Thm. 1].

THEOREM 2.2. *Assume $u(t)$ is a solution of*

$$Pu(t-k) \geq q_1(t)u(t)$$

with $u(t) \geq 0$ on $[a+k, b+k]$, and $v(t)$ is a solution of

$$Pv(t-k) \leq q_2(t)v(t)$$

such that $u(a+i) = v(a+i)$, $0 \leq i \leq n-1$. If (5) holds and (4) is right $(n-1,1)$-disconjugate on $[a, b+n]$, then $u(t) \geq v(t)$ for $t \in [a, b+n]$.

Proof. Let $w(t) = u(t) - v(t)$. Then

$$\begin{aligned} Pw(t-k) &= Pu(t-k) - Pv(t-k) \\ &\geq q_1(t)u(t) - q_2(t)v(t). \end{aligned}$$

Hence,

$$Pw(t-k) - q_2(t)w(t) \geq [q_1(t) - q_2(t)]u(t)$$

and so $w(t)$ is a solution of

$$\begin{aligned} &Pw(t-k) - q_2(t)w(t) = \Phi(t) + [q_1(t) - q_2(t)]u(t), \\ &w(a+i) = 0, \quad 0 \leq i \leq n-1, \end{aligned}$$

with $\Phi(t) \geq 0$ on $[a+k, b+k]$. By the variation of constants formula (see Peterson [14]),

$$w(t) = \sum_{s=a+k}^{t+k-1} U(t, s-k+1)[\Phi(s) + (q_1(s) - q_2(s))u(s)],$$

where $U(t,s)$ is the solution of (4) satisfying

$$U(s+i,s)=0, \quad 0\le i\le n-2,$$
$$U(s+n-1,s)=1.$$

Since (4) is right $(n-1,1)$-disconjugate, we have that $U(t,s)>0$ on $[s+n-1,b+n]$. Note that in the variation of constants formula, $t\ge s-k+1$ and all the terms are nonnegative for $s\in[a+k,b+k]$. Since the terms of the sum are understood to be zero for $s>b+k$, we obtain $w(t)\ge 0$. Hence, $u(t)\ge v(t)$ for $t\in[a,b+n]$. □

COROLLARY 2.3. *Assume* (4) *is right* $(n-1,1)$*-disconjugate on* $[a,b+n]$ *and* (5) *holds. If the coefficient* β_0 *of* $u(t-k)$ *in* (3) *satisfies* $(-1)^n\beta_0(t)>0$ *on* $[a,b]$, *then* (3) *is right* $(n-1,1)$*-disconjugate.*

The work in this paper was motivated by the following existence and uniqueness result from Peterson [14, Thm. 3]. Peterson's proof makes use of the comparison result in Theorem 2.2.

THEOREM 2.4. *Assume there is a function* $p(t)$ *defined on* $[a+k,b+k]$ *such that*

$$f(t,u)-f(t,v)\ge p(t)[u-v]$$

when $u\ge v$, $t\in[a+k,b+k]$. *If* $Py(t-k)=p(t)y(t)$ *is right* $(n-1,1)$*-disconjugate on* $[a,b+n]$, *then the boundary value problem* (1),

$$y(a+i)=A_i, \quad 0\le i\le n-2,$$
$$y(b+n)=B,$$

has a unique solution.

3. Existence and uniqueness. We wish to generalize the results of § 2 to the $(j,n-j)$-problem. We begin with the following analogue of the comparison result in Theorem 2.2.

THEOREM 3.1. *Assume* $u(t)$ *is a solution of*

$$Pu(t-k)\ge q_1(t)u(t)$$

and $v(t)$ *is a solution of*

$$Pv(t-k)\le q_2(t)v(t)$$

with $v(t)\ge 0$ *for* $t\in[a+k,b+k]$, *and*

$$u(a+i)=v(a+i), \quad 0\le i\le n-2,$$
$$u(b+n)=v(b+n).$$

If (4) *is right* $(n-1,1)$*-disconjugate on* $[a,b+n]$, (3) *is* $(n-2,2)$*-disconjugate on* $[a,b+n]$, *and* (5) *holds, then* $v(t)\ge u(t)$ *for* $t\in[a,b+n]$.

Proof. By Corollary 2.3, (3) is right $(n-1,1)$-disconjugate on $[a,b+n]$. Set $w(t)=v(t)-u(t)$ for $t\in[a,b+n]$. Then

$$Pw(t-k)=Pv(t-k)-Pu(t-k)\le q_2(t)v(t)-q_1(t)u(t)$$

and so

$$Pw(t-k)-q_1(t)w(t)\le[q_2(t)-q_1(t)]v(t).$$

Hence, $w(t)$ is a solution of

$$\begin{aligned} &Pw(t-k) - q_1(t)w(t) = \Phi(t) + [q_2(t) - q_1(t)]v(t), \\ &w(a+i) = 0, \quad 0 \le i \le n-2, \\ &w(b+n) = 0, \end{aligned} \tag{6}$$

where $\Phi(t) \le 0$ on $[a+k, b+k]$. Then

$$w(t) = \sum_{s=a+k}^{b+k} G(t, s-k)[\Phi(s) + (q_2(s) - q_1(s))v(s)]$$

where $G(t,s)$ is the Green's function for (6). Since (3) is both $(n-1,1)$-disconjugate and $(n-2,2)$-disconjugate, we have by Theorem 2.1 and Remark 2 that $G(t,s) < 0$, $t \in [a+n-1, b+n-1]$. Also, $v(t) \ge 0$ and $q_2(t) - q_1(t) \le 0$, $t \in [a+k, b+k]$, imply that $w(t) \ge 0$ for $t \in [a, b+n]$. Hence $v(t) \ge u(t)$ for $t \in [a, b+n]$. □

COROLLARY 3.2. *If* (4) *is right* $(n-1,1)$*-disconjugate and* (3) *is* $(n-2,2)$*-disconjugate and* (5) *holds, then* (4) *is right* $(n-2,2)$*-disconjugate.*

Proof. By Corollary 2.3, (3) is right $(n-1,1)$-disconjugate. Assume $c, d \in [a, b+n-1]$ with $c+n-2 < d$ and $v(t)$ is a solution of (4) with

$$\begin{aligned} &v(c+i) = 0, \quad 0 \le i \le n-3, \\ &v(c+n-2) = 1, \\ &v(d) = 0. \end{aligned}$$

It suffices to show $v(t)$ does not have a generalized zero at $d+1$. Suppose, on the contrary, that $v(t)$ has a generalized zero at $d+1$. Without loss of generality, assume d is the smallest integer greater than $c+n-2$ such that $v(d) = 0$ and v has a generalized zero at $d+1$.

First consider the case $v(t) \ge 0$ on $[c, d]$. Note that by the choice of d, $v(d-1) > 0$ and hence we must have $v(d+1) \ge 0$. Let $u(t)$ be the solution of (3) with

$$\begin{aligned} &u(c+i) = v(c+i), \quad 0 \le i \le n-2, \\ &u(d+1) = v(d+1). \end{aligned}$$

By Theorem 3.1, $v(t) \ge u(t)$ on $[c, d+1]$, and so $u(d) \le 0$. But then $u(t)$ has $n-2$ consecutive zeros followed by two generalized zeros, contradicting that (3) is both right $(n-1,1)$-disconjugate and right $(n-2,2)$-disconjugate (see [12, Thm. 7]).

Now consider the case $v(t) < 0$ for some $t \in [c+n-1, d-1]$. Let $v_1(t)$ be the solution of (4),

$$\begin{aligned} &v(c+i) = 0, \quad 0 \le i \le n-2, \\ &v(c+n-1) = -1. \end{aligned}$$

Then $v_1(t) < 0$ on $[c+n-1, d]$ and there exists $\alpha > 0$ such that

$$w(t) \equiv v(t) - \alpha v_1(t) \ge 0, \quad t \in [c, d]$$

with equality holding at some $t_0 \in [c+n-1, d-1]$. We can assume $t_0 \ge c+n-1$ is the first point such that $w(t_0) = 0$. Then $w(t) \ge 0$ satisfies

$$\begin{aligned} &Pw(t-k) = q_2(t)w(t), \\ &w(c+i) = 0, \quad 0 \le i \le n-3, \\ &w(c+n-2) = 1, \\ &w(t_0) = 0, \end{aligned}$$

and $w(t)$ has a generalized zero at t_0+1. Applying the first case to $w(t)$ on $[c, t_0+1]$ leads to a contradiction. □

In some of the proofs which follow, uniqueness of solutions to certain boundary value problems for (1) is coupled with the Brouwer Invariance of Domain Theorem [2] to obtain that solutions depend continously on boundary conditions. A typical argument verifying this continuous dependence on boundary conditions can be found in [6].

We are now ready to prove an existence-uniqueness theorem for the $(n-2,2)$-problem. This theorem is an extension of Theorem 2.4.

THEOREM 3.3. *Assume there exist functions $p(t)$ and $r(t)$ defined on $[a+k, b+k]$ such that*

$$p(t)[u-v] \le f(t,u) - f(t,v) \le r(t)[u-v]$$

whenever $u \ge v$, $t \in [a+k, b+k]$. If $Py(t-k) = p(t)y(t)$ is right $(n-1,1)$-disconjugate on $[a, b+n]$ and $Pu(t-k) = r(t)u(t)$ is $(n-2,2)$-disconjugate on $[a, b+n]$, then the boundary value problem (1),

$$\begin{aligned} &y(a+i) = A_i, \quad 0 \le i \le n-3, \\ &y(b+n-i) = B_i, \quad 0 \le i \le 1, \end{aligned} \tag{7}$$

has a unique solution.

Proof. We will use the shooting method in this proof. By Theorem 2.4, there exists a unique solution $y(t,m)$ of the boundary value problem (1),

$$\begin{aligned} &y(a+i) = A_i, \quad 0 \le i \le n-3, \\ &y(a+n-2) = m, \\ &y(b+n) = B_0. \end{aligned}$$

Let $S = \{y(b+n-1, m) \mid m \in \mathbf{R}\}$. A standard argument using the Brouwer Invariance of Domain Theorem shows that $y(b+n-1, m)$ is a continuous function of m. Hence, S is a nonempty connected set. Thus to prove existence, it suffices to show that S is neither bounded below nor above.

Fix $m_1 > m_2$ and set

$$z(t) = \frac{y(t,m_1) - y(t,m_2)}{m_1 - m_2}.$$

Note that

$$\begin{aligned} Pz(t-k) &= \frac{Py(t-k,m_1) - Py(t-k,m_2)}{m_1 - m_2} \\ &= \frac{f(t, y(t,m_1)) - f(t, y(t,m_2))}{m_1 - m_2}. \end{aligned}$$

Now define

$$q(t) = \begin{cases} \dfrac{f(t, y(t,m_1)) - f(t, y(t,m_2))}{y(t,m_1) - y(t,m_2)}, & y(t,m_1) \ne y(t,m_2), \\ p(t), & y(t,m_1) = y(t,m_2). \end{cases}$$

Then $z(t)$ is the solution of the boundary value problem

$$\begin{aligned} &Pz(t-k) = q(t)z(t), \\ &z(a+i) = 0, \quad 0 \le i \le n-3, \\ &z(a+n-2) = 1, \\ &z(b+n) = 0. \end{aligned}$$

Note also that $p(t) \leq q(t) \leq r(t)$ for $t \in [a+k, b+k]$. Since $Py(t-k) = p(t)y(t)$ is right $(n-1,1)$-disconjugate, we have that both

$$Pz(t-k) = q(t)z(t) \tag{8}$$

and

$$Pu(t-k) = r(t)u(t) \tag{9}$$

are right $(n-1,1)$-disconjugate by Corollary 2.3. Now use the fact that (9) is also $(n-2,2)$-disconjugate and apply Corollary 3.2 to obtain that (8) is right $(n-2,2)$-disconjugate. It follows that $z(t) \geq 0$ on $[a, b+n]$. Next, apply Theorem 3.1 to obtain that $z(t) \geq u(t)$, where $u(t)$ is the solution of (9),

$$\begin{aligned} &u(a+i) = z(a+i), \quad 0 \leq i \leq n-2, \\ &u(b+n) = z(b+n). \end{aligned}$$

Hence,

$$y(t, m_1) - y(t, m_2) \geq u(t)(m_1 - m_2)$$

for $t \in [a, b+n]$. Letting $t = b+n-1$ we obtain

$$y(b+n-1, m_1) - y(b+n-1, m_2) \geq u(b+n-1)(m_1 - m_2). \tag{10}$$

Since (9) is both $(n-1,1)$ and $(n-2,2)$-disconjugate on $[a, b+n]$, it follows from [12, Thm. 7] that $u(t) > 0$ on $[a+n-2, b+n-1]$. Letting $m_1 \to \infty$ we see that

$$\lim_{m \to \infty} y(b+n-1, m) = \infty,$$

and similarly, letting $m_2 \to -\infty$ we see that

$$\lim_{m \to -\infty} y(b+n-1, m) = -\infty.$$

It follows that $S = \mathbf{R}$ and the existence part of the proof is complete.

For the uniqueness of solutions, suppose on the contrary that $y_1(t)$ and $y_2(t)$ are distinct solutions of the boundary value problem (1), (7). Since solutions to the $(n-1,1)$-problem are unique, we can write $y_1(t) = y(t, m_1)$, $y_2(t) = y(t, m_2)$, for some $m_1 \neq m_2 \in \mathbf{R}$. Without loss of generality, we can assume that $m_1 > m_2$. But then (10) shows that $y(b+n-1, m_1) \neq y(b+n-1, m_2)$, contradicting the assumption that both $y_1(t)$ and $y_2(t)$ were solutions to the same $(n-2,2)$-problem. Hence the uniqueness condition is satisfied and the proof is complete. □

Example. Let Δ be defined by $\Delta y(t) = y(t+1) - y(t)$ and consider the difference equation $\Delta^5 y(t-1) = e^{1-t} \sin y(t)$ for $t \in [1,4]$. Note that for $u \geq v$, $-[u-v] \leq e^{1-t}(\sin u - \sin v) \leq [u-v]$ for $t \in [1,4]$. Using [16, Thm. 2], we can show that the equation $\Delta^5 y(t-1) = -y(t)$ is right $(4,1)$-disconjugate on $[0,8]$, and $\Delta^5 y(t-1) = y(t)$ is $(3,2)$-disconjugate on $[0,8]$. By Theorem 3.3, there is a unique solution of the boundary value problem

$$\begin{aligned} &\Delta^5 y(t-1) = e^{1-t} \sin y(t), \quad t \in [1,4], \\ &y(i) = A_i, \quad 0 \leq i \leq 2, \\ &y(8-i) = B_i, \quad 0 \leq i \leq 1. \end{aligned}$$

We conclude with a comparison theorem and an existence-uniqueness theorem for the general case.

THEOREM 3.4. *Let* $1 \le j \le n-1$. *Assume* $u(t)$ *is a solution of*

$$Pu(t-k) \ge q_1(t)u(t)$$

and $v(t)$ *is a solution of*

$$Pv(t-k) \le q_2(t)v(t)$$

with

$$\begin{aligned} &u(a+i) = v(a+i), \quad 0 \le i \le j-1, \\ &u(b+n-i) = v(b+n-i), \quad 0 \le i \le n-j-1. \end{aligned}$$

If one of the following holds:

1. $u(t) \ge 0$ *on* $[a+k, b+k]$ *and* (4) *is either disconjugate on* $[a, b+n]$ *or* $(i, n-i)$*-disconjugate on* $[a+j-i, b+n+j-i]$ *for* $j-1 \le i < n$, *or*
2. $v(t) \ge 0$ *on* $[a+k, b+k]$ *and* (3) *is either disconjugate on* $[a, b+n]$ *or* $(i, n-i)$*-disconjugate on* $[a+j-i, b+n+j-i]$ *for* $j-1 \le i < n$,

then $(-1)^{n-j}u(t) \ge (-1)^{n-j}v(t)$ *for* $t \in [a, b+n]$.

Proof. First assume that condition 1 holds. Set $w(t) = u(t) - v(t)$. Then

$$Pw(t-k) = Pu(t-k) - Pv(t-k) \ge q_1(t)u(t) - q_2(t)v(t)$$

and so

$$Pw(t-k) - q_2(t)w(t) \ge (q_1(t) - q_2(t))u(t).$$

Hence, $w(t)$ is a solution of

$$\begin{aligned} &Pw(t-k) - q_2(t)w(t) = \Phi(t) + [q_1(t) - q_2(t)]u(t), \\ &w(a+i) = 0, \quad 0 \le i \le j-1, \\ &w(b+n-i) = 0, \quad 0 \le i \le n-j-1, \end{aligned} \tag{11}$$

where $\Phi(t) \ge 0$ on $[a+k, b+k]$. Then

$$w(t) = \sum_{s=a+k}^{b+k} G(t, s-k)[\Phi(s) + (q_1(s) - q_2(s))u(s)]$$

where $G(t,s)$ is the Green's function for (11). By the disconjugacy assumptions on (4), we have that $(-1)^{n-j}G(t,s) > 0$, $t \in [a+j, b+j]$. Since $u(t) \ge 0$ and $q_1(t) - q_2(t) \ge 0$ for $t \in [a+k, b+k]$, it follows that $(-1)^{n-j}w(t) \ge 0$ for $t \in [a, b+n]$. Hence, in this case, $(-1)^{n-j}u(t) \ge (-1)^{n-j}v(t)$ for $t \in [a, b+n]$.

The proof in the case where condition 2 holds is similar and will be omitted. □

THEOREM 3.5. *Let* $1 \le j \le n-1$. *Assume there exist functions* $p(t)$, $r(t)$, *defined on* $[a,b]$ *such that*

$$p(t)[u-v] \le f(t,u) - f(t,v) \le r(t)[u-v]$$

whenever $u \ge v$, $t \in [a,b]$. *If* $Py(t) = p(t)y(t)$ *and* $Py(t) = r(t)y(t)$ *are disconjugate on* $[a, b+n]$, *then the boundary value problem*

$$\begin{aligned} &Py(t) = f(t, y(t)), \quad t \in [a,b], \\ &y(a+i) = A_i, \quad 0 \le i \le j-1, \\ &y(b+n-i) = B_i, \quad 0 \le i \le n-j-1, \end{aligned}$$

has a unique solution.

Proof. The proof is by induction on decreasing values of j. The cases $j = n-1$ and $j = n-2$ are contained in Theorems 2.4 and 3.3. Assume $j \leq n-3$ and that the theorem holds if j is replaced by $j+1$. Then there exists a unique solution $y(t,m)$ to the $(j+1, n-j-1)$-problem

$$\begin{aligned} &Py(t) = f(t, y(t)), \quad t \in [a,b], \\ &y(a+i) = A_i, \quad 0 \leq i \leq j-1, \\ &y(a+j) = m, \\ &y(b+n-i) = B_i, \quad 0 \leq i \leq n-j-2. \end{aligned}$$

Fix $m_1 > m_2$ and define $z(t)$ and $q(t)$ as in the proof of Theorem 3.3. Then $z(t)$ is the solution of the boundary value problem

$$\begin{aligned} &Pz(t) = q(t)z(t), \\ &z(a+i) = 0, \quad 0 \leq i \leq j-1, \\ &z(a+j) = 1, \\ &z(b+n-i) = 0, \quad 0 \leq i \leq n-j-2. \end{aligned}$$

Note that $p(t) \leq q(t) \leq r(t)$ for $t \in [a,b]$. By results of Eloe [4] and Peterson [13], the equation $Pz(t) = q(t)z(t)$ is disconjugate on $[a, b+n]$.

To simplify the notation, we consider the case that $n-j$ is odd; the case for $n-j$ even is similar. Let $v(t)$ be the solution of

$$\begin{aligned} &Pv(t) = p(t)v(t), \\ &v(a+i) = z(a+i), \quad 0 \leq i \leq j, \\ &v(b+n-i) = z(b+n-i), \quad 0 \leq i \leq n-j-2. \end{aligned}$$

By the disconjugacy assumptions, we have $v(t) \geq 0$ for $t \in [a, b+n]$. By Theorem 3.4, it follows that $z(t) \geq v(t)$ for $t \in [a, b+n]$.

The remainder of the proof can be modeled after the proof of Theorem 3.3. □

HIDDEN VARIABLE FRACTAL INTERPOLATION FUNCTIONS*

M. F. BARNSLEY†, J. ELTON†, D. HARDIN‡, AND P. MASSOPUST§

Abstract. Interpolation functions $f: [0, 1] \to \mathbb{R}$ of the following nature are constructed. Given data

$$\{(t_n, x_n) \in [0, 1] \times \mathbb{R}: n = 0, 1, 2, \cdots, N\}$$

with $0 = t_0 < t_1 < \cdots < t_N = 1$, f obeys

$$f(t_n) = x_n, \qquad n = 0, 1, 2, \cdots, N.$$

Furthermore, the graph of f is the projection of a set G in $\mathbb{R}^M$ (M an integer greater than or equal to 2) that is homeomorphic to [0, 1] and is the attractor for an iterated function system consisting of affine maps in $\mathbb{R}^M$. The latter characterization ensures that f can be computed rapidly while possessing many "hidden" variables, on which its values continuously depend, which allow great flexibility and diversity in the interpolant, making it potentially useful in approximation theory. Estimates and exact values for the fractal dimensions of G and the graph of f are obtained.

Key words. fractal, self-affine, iterated function systems, fractal dimension, fractal interpolation

1. Introduction.

A function $F: [0, 1] \to \mathbb{R}^n$ is self-affine if its graph G obeys

$$G = \cup\, w_i(G)$$

where the union is over a finite set of affine maps $w_i: \mathbb{R}^{n+1} \to \mathbb{R}^{n+1}$. There has been recent interest in such functions with $n = 1$ because of their potential utility in approximation theory [B], [BH] and in computer graphics [DHN]. Specific properties when $n = 1$ include the availability of fast algorithms for computing the values of such functions; the possibility of choosing the w_i so that F interpolates given values; and the computability of their moments $\int_0^1 x^n F(x)\, dx$, their indefinite integrals

$$\int_0^x \int_0^{x_1} \cdots \int_0^{x_p} F(x_{p+1})\, dx_{p+1}\, dx_p \cdots dx_1,$$

and their Fourier transforms, $\hat{F}(k) = \int_0^1 e^{ikx} F(x)\, dx$. Moreover, in the case of equally spaced interpolation points, the fractal dimension of these functions can be expressed in terms of the coefficients in the affine transformations. Such functions yield solutions to special types of functional equations [H], and have been related to special types of dynamical systems [HM] for which Lyapunov exponent calculations can be made.

Here our main aim is to show how the class of one-dimensional interpolation functions can be usefully widened by considering the projections of the graphs of higher-dimensional self-affine functions. We show that we still have the advantages of rapid computability, the feasibility of interpolation, and the ability to express the fractal dimension in terms of underlying parameters. The class of functions obtained is much more diverse because their values depend continuously on all of the "hidden" variables, namely, the coefficients of the possibly high-dimensional affine maps that determine the function. In pursuing our main aim we will reveal a number of facts about multidimensional curves, including space-filling and fractal-filling curves, that are surprising and suggest new lines of investigation and applications.

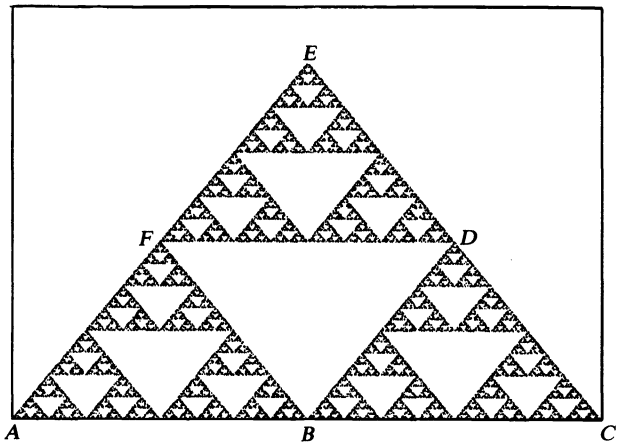

FIG. 1. *The Sierpinski triangle. A, B, C, D, E, F label vertices of three subtriangles.*

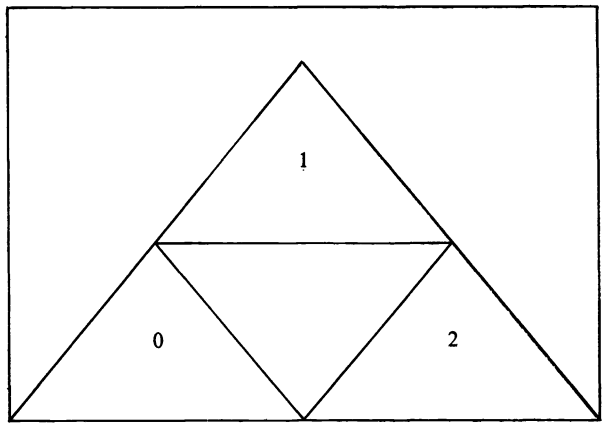

FIG. 2. 0, 1, *and* 2 *label the images of the large triangle under maps* w_0, w_1, *and* w_2, *respectively.*

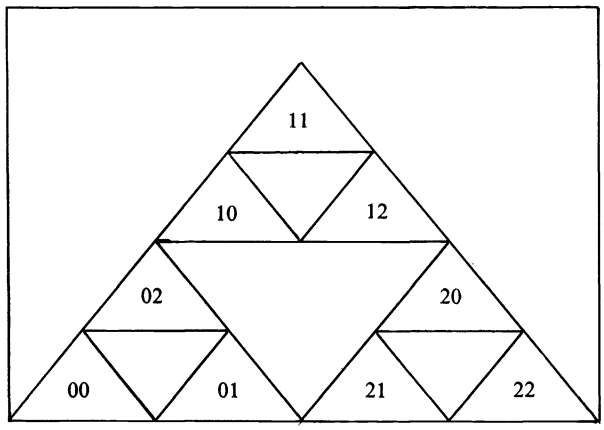

FIG. 3. 00, 01, $\cdots$, 22 *label the images of the triangles in Fig.* 2 *under the maps* w_0, w_1, *and* w_2.

We show how the class of functions introduced here was conceived. Let $S \subset \mathbb{R}^2$ denote the Sierpinski triangle, illustrated in Fig. 1 and specified more precisely below. Label points A, B, C, D, E, and F on S as in Fig. 1. Let w_0, w_1, w_2 be three affine transformations $w_i: \mathbb{R}^2 \to \mathbb{R}^2$, of the form

$$w\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix}\begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} e \\ f \end{pmatrix}$$

where a, b, c, d, e, and f are real constants. The maps are uniquely specified by the requirements $w_0(A) = A$, $w_0(E) = B$, $w_0(C) = F$, $w_1(A) = F$, $w_1(E) = E$, $w_1(C) = D$, $w_2(A) = D$, $w_2(E) = B$, $w_2(C) = C$. Thus w_0 takes the triangle ACE onto the subtriangle AFB, w_1 takes ACE onto FDE, and w_2 takes ACE onto BDC. The orientations are important as we will see. Each map is a strict contraction, and S is the unique compact subset of $\mathbb{R}^2$ so that [BD], [H]

$$S = \bigcup_{i=0}^{2} w_i(S).$$

We now construct a continuous map ϕ of $[0, 1]$ onto S. Each point of S possesses at least one address, which consists of a triadic decimal $\sigma = .\sigma_1\sigma_2\sigma_3 \cdots \sigma_n \cdots$, where $\sigma_i \in \{0, 1, 2\}$, and each $\sigma \in [0, 1]$ corresponds to a unique point on S (see [BD], [H]). The point $\phi(\sigma) \in S$ corresponding to $\sigma \in [0, 1]$ may be computed by

$$\phi(\sigma) = \lim_{n \to \infty} w_{\sigma_1} \circ w_{\sigma_2} \circ \cdots \circ w_{\sigma_n}(A).$$

This addressing system is readily understood: the original large triangle is mapped onto three smaller triangles labeled 0, 1, and 2 under maps w_0, w_1, and w_2, respectively; see Fig. 2. All addresses that begin with .0 correspond to points in region 0. Now apply all three maps to the latter subtriangles to obtain nine smaller triangles labeled 00, 01, $\cdots$, 22 as illustrated in Fig. 3. All addresses that begin with .12 correspond to points that lie in the region labeled 12.

We can show [H], [B] that the map $\phi: [0, 1] \to S$ is continuous; see also § 2.2. The curve obtained can be thought of as a "space"-filling curve where the space is S with fractal dimension $\log 3/\log 2$. This curve can also be obtained as the limit of the recursive refinement procedure suggested in Fig. 4; we find a sequence of piecewise linear functions $\phi_n: [0, 1] \to S$ that converges uniformly to ϕ.

Now let us write $\phi(t) = (f(t), h(t))$. Then $f: [0, 1] \to \mathbb{R}$ is an example of the type of function discussed in this paper, which we call a hidden variable fractal interpolation function. A plot of $f(t)$ corresponding to $A = (0, 0)$, $C = (1, 0)$, and $E = (\frac{1}{2}, \sqrt{3}/2)$ is shown in Fig. 5. First, we note that $f(t)$ is not self-affine: its graph does not consist of the union of affine images of itself. Second, $f(t)$ can be computed using standard iterated function system (IFS) algorithms, which are rapid because the graph of f is the projection of the attractor for a set of three-dimensional affine maps. Third, the fractal dimension of f can be computed exactly (it is $2 - \log_3 2$). Fourth, given any set of data (t_i, x_i) for $i = 0, 1, 2, \cdots, N$, a generalization of the above procedure yields a function f that interpolates the data while retaining many degrees of freedom.

The structure of this paper is as follows. In § 2 we review iterated function system (IFS) theory, including the basic characterization and computation of attractors of IFS; then we give the basic theorem on the existence of attractors of IFS that are graphs of certain functions with domains and ranges in compact metric spaces. These domains and ranges may themselves be fractal objects, characterized as attractors of IFS. We show, in particular, the construction by which these graphs can be made to

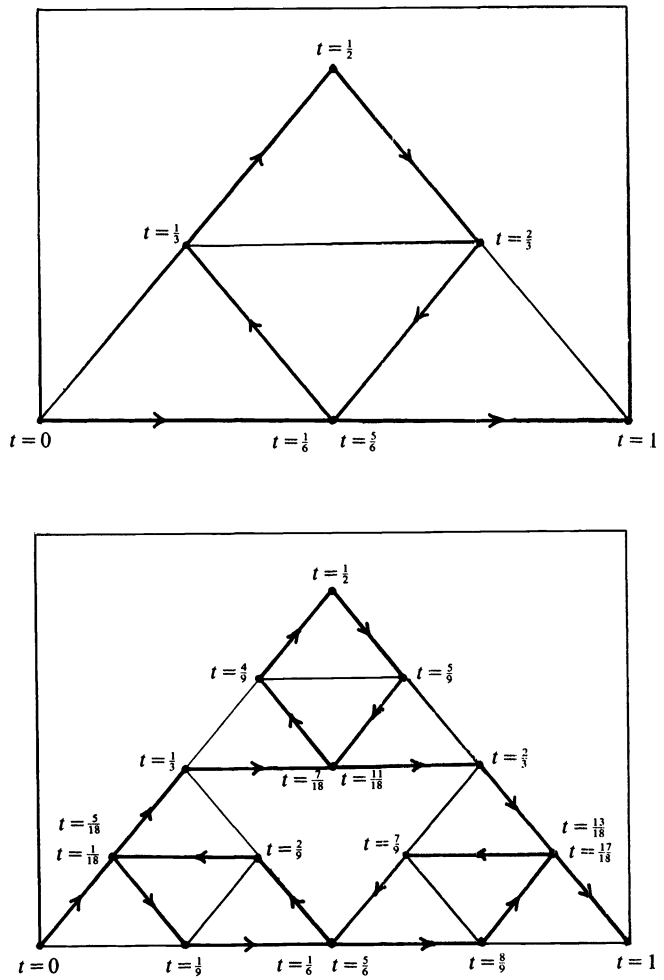

FIG. 4. *Illustration of the generation of the "space-filling" curve* $\phi: [0, 1] \to S$ *by recursive refinement.*

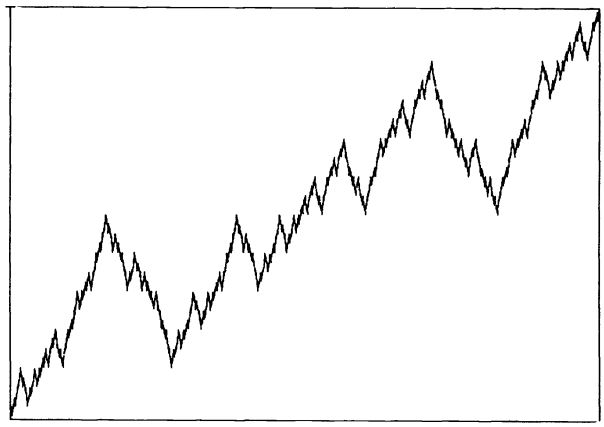

FIG. 5. *Plot of a hidden variable fractal function corresponding to a Sierpinski triangle, as described in the text.*

interpolate data. Examples are given to illustrate the appearance and diversity of these functions.

In § 3 we estimate the fractal dimension of the graphs of certain functions that map attractors of IFS onto attractors of IFS, in the case where the IFSs are formed of similitudes that contract more on one attractor than on the other. When a certain open set condition prevails the estimate is the actual value.

Section 4 is devoted to the main hard theorem: (a) we prove the conjecture of Hardin and Massopust [HM] on the fractal dimension of self-affine functions in one dimension; (b) we compute the fractal dimension of certain hidden variable interpolation functions.

2. Construction of fractal interpolation functions.

2.1. Attractors of IFS and the deterministic algorithm for their evaluation. Let K be a compact metric space with metric $d(\cdot, \cdot)$. Let $w_i: K \to K$ for $i = 1, 2, \cdots, N$, where N is a finite positive integer, be strict contractions; that is, there exists a constant $0 \leqq s < 1$ such that

$$d(w_i(x), w_i(y)) \leqq s \cdot d(x, y) \quad \forall x, y \in K, \quad \forall i.$$

We call $(K, w_i: i = 1, 2, \cdots, N)$ an IFS. (This definition of an iterated function system is more restrictive than elsewhere (see [BD], for example) but serves well for this paper.) There exists a unique compact set $A \subset K$ such that

$$A = \cup\, w_i(A).$$

A is called the attractor of the IFS.

Let H denote the set of nonempty compact subsets of K, and endow it with the Hausdorff metric

$$h(B, C) = \max\left\{\max_{x \in B} \min_{y \in C} d(x, y), \max_{y \in C} \min_{x \in B} d(x, y)\right\}$$

for all $B, C \in H$. Then H is a complete metric space. Define $W: H \to H$ by

$$W(B) = \cup\, w_i(B).$$

Then W is a strict contraction with

$$h(W(B), W(C)) \leqq s \cdot h(B, C) \quad \forall B, C \in H;$$

and A is the unique fixed point of W.

The deterministic algorithm for the computation of A is to choose any $A_0 \in H$ and define

$$A_{n+1} = W(A_n).$$

Then

$$A = \lim_{n \to \infty} A_n.$$

Suppose, for example, that $K = [0, 1] \times [0, 1] \subset \mathbb{R}^2$. Then $h(A_n, A) \leqq s^n(1 - s)$, whence the number of iterations needed to evaluate A to a desired precision is readily calculated.

The deterministic algorithm is well suited to the evaluation of A when it is the graph of a function in $\mathbb{R}^n$. An illustration is given in Fig. 6, where we show the computation of an attractor for two affine maps in $\mathbb{R}^2$. In other situations, for example, when A represents a digitized image, or not all the maps are contractions, or we are concerned with measures supported on A, the random iteration algorithm (described, for example, in [BD]) is more appropriate.

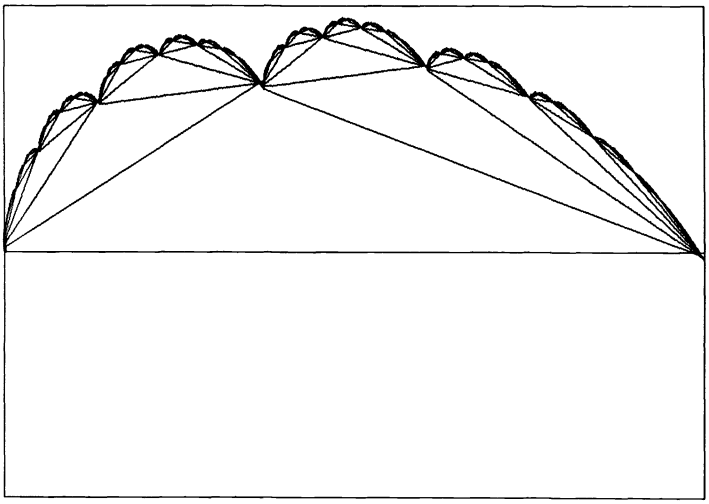

FIG. 6. *A sequence of graphs of functions* $A_0, A_1, A_2, \cdots$, *computed using the deterministic algorithm, that converge to the attractor* A *of an* IFS *in* $\mathbb{R}^2$ *consisting of a pair of affine maps.*

2.2. Construction of functions using IFS. In this section we present a general construction for an IFS whose attractor is the graph of a function $F: I \to K$ where J $(\supset I)$ and K are compact metric spaces.

We use $d(\cdot, \cdot)$ for the distance function in both J and K; the argument will specify which function is applied. We define a distance

$$d((t_1, X_1), (t_2, X_2)) = d(t_1, t_2) + \theta d(X_1, X_2) \tag{2.1}$$

between points (t_1, X_1) and (t_2, X_2) in $J \times K$, where $\theta > 0$ is to be specified. Then $J \times K$ is a compact metric space.

Let $l: J \to J$ be a strict contraction: there is a constant $0 \leqq s_1 < 1$ so that

$$d(l(t_1), l(t_2)) \leqq s_1 \cdot d(t_1, t_2) \quad \forall t_1, t_2 \in J. \tag{2.2}$$

Let $k: J \times K \to K$ and let there be constants c and s_2, with $0 \leqq s_2 < 1$, so that

$$d(k(t_1, X), k(t_2, X)) \leqq c \cdot d(t_1, t_2) \quad \forall t_1, t_2 \in J, \quad X \in K, \tag{2.3}$$

$$d(k(t, X_1), k(t, X_2)) \leqq s_2 \cdot d(X_1, X_2) \quad \forall t \in J, \quad X_1, X_2 \in K. \tag{2.4}$$

LEMMA 2.1. *If* θ *in* (2.1) *is equal to* $(1 - s_1)/2c$, *then* $W: J \times K \to J \times K$ *defined by* $W(t, X) = (l(t), k(t, X))$, *with* l *and* k *as above, is a strict contraction.*

Proof.

$$\begin{aligned} d(W(t_1, X_1), W(t_2, X_2)) &= d(l(t_1), l(t_2)) + \theta d(k(t_1, X_1), k(t_2, X_2)) \\ &\leqq s_1 d(t_1, t_2) + \theta d(k(t_1, X_1), k(t_2, X_1)) \\ &\qquad + \theta d(k(t_2, X_1), k(t_2, X_2)) \\ &\leqq (s_1 + \theta c) d(t_1, t_2) + \theta s_2 d(X_1, X_2) \\ &\leqq q(d(t_1, t_2) + \theta d(X_1, X_2)) \\ &= q d((t_1, X_1), (t_2, X_2)) \end{aligned}$$

where $q = \max\{(s_1 + \theta c), s_2\} < 1$. □

Now we consider the following construction. Let $W_i: J \times K \to J \times K$ for $i = 1, 2, \cdots, N$ be a finite set of maps of the structure

$$W_i(t, X) = (l_i(t), k_i(t, X)) \tag{2.5}$$

where l_i, k_i obey (2.2)-(2.4), and let θ in (2.1) be chosen according to Lemma 2.1. Then $(J \times K, W_i: i = 1, 2, \cdots, N)$ is an IFS and possesses a unique attractor G. Also $(J, l_i: i = 1, 2, \cdots, N)$ is an IFS; we denote its attractor by I. Let $P_t: J \times K \to J$ be the projection operator defined by $P_t(t, X) = t$ for all $(t, X) \in J \times K$. Then clearly $P_t G = I$. We will give conditions so that G is the graph of a function $F: I \to K$.

Let

$$(t_j, X_j) \in J \times K \quad \text{for } j = 0, 1, 2, \cdots, N \tag{2.6}$$

and suppose

$$W_i(t_0, X_0) = (t_{i-1}, X_{i-1}) \quad \text{and} \quad W_i(t_N, X_N) = (t_i, X_i) \quad \text{for } i = 1, 2, \cdots, N. \tag{2.7}$$

Then $\{(t_j, X_j): i = 0, 1, \cdots, N\} \subset G$ because $(t_0, X_0) \in G$ as it is the fixed point of W_1, $(t_N, X_N) \in G$ as it is the fixed point of W_N, and $(t_i, X_i) \in G$ for $i = 1, 2, \cdots, N-1$ as $W_i(t_N, X_N) = (t_i, X_i)$.

Now assume that the maps $l_i: I \to I$ are invertible over their ranges $l_i(I)$, that

$$l_i(I) \cap l_j(I) = \phi \quad \text{when } |i - j| \notin \{0, 1\}, \tag{2.8}$$

$$l_i(I) \cap l_{i+1}(I) = t_i \quad \text{for } i = 1, 2, \cdots, N-1. \tag{2.9}$$

THEOREM 1. *Let $\{J \times K, W_i: i = 1, 2, \cdots, N\}$ be an* IFS *of the special structure described above, so that it obeys* (2.5)-(2.9). *Then its attractor G is the graph of a continuous function $F: I \to K$ such that*

$$F(t_j) = X_j \quad \textit{for } j = 0, 1, 2, \cdots, N.$$

Proof. I is a compact metric space with the distance function d inherited from J. Let $\mathcal{F} = \{f: I \to K: f \text{ is continuous on } I, f(t_0) = X_0, f(t_N) = X_N\}$. Define a metric d on $\mathcal{F}$ by

$$d(f_1, f_2) = \max\{d(f_1(t), f_2(t)): t \in I\}.$$

Then $\mathcal{F}$ is a complete metric space because the uniform limit of continuous functions is continuous. Define $T: \mathcal{F} \to \mathcal{F}$ by

$$(Tf)(t) = k_i(l_i^{-1}(t), f(l_i^{-1}(t))) \quad \text{for } t \in l_i(I), f \in \mathcal{F}.$$

(Recall that $I = \cup\, l_i(I)$.) We show that T is well defined and that it takes $\mathcal{F} \to \mathcal{F}$. In view of (2.8) and (2.9), $(Tf)(t)$ is well defined at points $t \in I \backslash \{t_0, t_1, \cdots, t_N\}$. Also, it is continuous on each of the compact sets $l_i(t)$. Now observe that

$$\begin{aligned}
\lim_{\substack{t \to t_i \\ t \in l_i(I)}} (Tf)(t) &= k_i(l_i^{-1}(t_i), f(l_i^{-1}(t_i))) \\
&= k_i(t_N, f(t_N)) = k_i(t_N, X_N) \\
&= k_{i+1}(t_0, x_0) = k_{i+1}(t_0, f(t_0)) \\
&= k_{i+1}(l_{i+1}^{-1}(t_i), f(l_{i+1}^{-1}(t_i))) = \lim_{\substack{t \to t_i \\ t \in l_{i+1}(I)}} (Tf)(t),
\end{aligned}$$

which shows $(Tf)(t)$ is both well defined and continuous at each of the points $\{t_0, t_1, \cdots, t_N\}$. Moreover,

$$\begin{aligned}(Tf)(t_0) &= k_1(l_1^{-1}(t_0), f(l_1^{-1}(t_0))) \\ &= k_1(t_0, f(t_0)) = k_1(t_0, X_0) = X_0, \\ (Tf)(t_N) &= k_N(l_N^{-1}(t_N), f(l_N^{-1}(t_N))) \\ &= k_N(t_N, f(t_N)) \\ &= k_N(t_N, X_N) = X_N,\end{aligned}$$

so indeed $Tf \in \mathcal{F}$ when $f \in \mathcal{F}$.

We now show that T is a strict contraction in $\mathcal{F}$. For $t \in l_i(I)$ and $f_1, f_2 \in \mathcal{F}$, we have

$$\begin{aligned}d((Tf_1)(t), (Tf_2)(t)) &= d(k_i(l_i^{-1}(t), f_1(l_i^{-1}(t))), k_i(l_i^{-1}(t), f_2(l_i^{-1}(t)))) \\ &\leqq s_2 \cdot d(f_1(l_i^{-1}(t)), f_2(l_i^{-1}(t))) \\ &\leqq s_2 \cdot d(f_1, f_2)\end{aligned}$$

whence $d(Tf_1, Tf_2) \leqq s_2 d(f_1, f_2)$. Hence T possesses a unique fixed point, namely a function $F \in \mathcal{F}$ such that $TF = F$. We readily verify that the graph of F is an attractor for the IFS $(J \times K, W_i: i = 1, 2, \cdots, N)$ and so it must equal G. □

Example 1. Let $J = [0, 1]$ and let $0 = t_0 < t_1 < \cdots < t_N = 1$. Then choose $l_i(t) = t_{i-1} + (t_i - t_{i-1})t$, so that the attractor of the IFS $\{J, l_i: i = 1, 2, \cdots, N\}$ is $I = [0, 1]$. Let K be a sufficiently large bounded subset of $\mathbb{R}$ and

$$\begin{aligned}&k_i(t, X) = b_i t + a_i X + e_i, \\ &b_i = c_i(x_N - x_0) - (x_i - x_{i-1}), \\ &e_i = x_{i-1} - c_i x_0, \qquad |c_i| < 1 \quad \text{for } i = 1, 2, \cdots, N.\end{aligned}$$

Here the a_i's are the only adjustable parameters, once the interpolation points $\{(t_j, x_j): j = 0, 1, \cdots, N\}$ have been specified. The attractor of the corresponding IFS $(J \times K, W_i: i = 1, 2, \cdots, N)$, where

$$W_i\begin{pmatrix} t \\ x \end{pmatrix} = \begin{pmatrix} (t_i - t_{i-1}) & 0 \\ b_i & a_i \end{pmatrix}\begin{pmatrix} t \\ x \end{pmatrix} + \begin{pmatrix} t_{i-1} \\ e_i \end{pmatrix}$$

is the graph of a self-affine function $F: [0, 1] \to \mathbb{R}$ such that

$$F(t_j) = x_j, \qquad j = 0, 1, 2, \cdots, N.$$

An illustration is provided in Fig. 7. Such functions are considered in [B] and [BH].

Example 2. Let $J = [0, 1]$ and let $0 = t_0 < t_1 < t_2 < t_3 = 1$. Then choose $l_i(t) = t_{i-1} + (t_i - t_{i-1})t$, so that the attractor of the IFS $(J, l_i: i = 1, 2, 3)$ is $I = [0, 1]$. Let $K = [0, 1] \times [0, 1] \subset \mathbb{R}^2$ and let the maps $k_i(t, X)$ depend only on $X = (x, y)$, and each be of the form

$$k\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} a & c \\ b & d \end{pmatrix}\begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} e \\ f \end{pmatrix}$$

where the constants a, b, c, d, e, f are fixed by requiring that

$$\begin{aligned}&k_1(0, 0) = (0, 0), \quad k_1(1, 0) = (.25, .5), \quad k_1(.5, 1) = (.5, 0), \\ &k_2(0, 0) = (.25, .5), \quad k_2(.5, 1) = (.5, 1), \quad k_2(1, 0) = (.75, .5), \\ &k_3(0, 0) = (.75, .5), \quad k_3(.5, 1) = (.5, 0), \quad k_3(1, 0) = (1, 0).\end{aligned}$$

The attractor G for the resulting IFS will be the graph of a function $F: [0, 1] \to [0, 1] \times [0, 1]$ such that $F(t_0) = (0, 0)$, $F(t_1) = (.25, .5)$, $F(t_2) = (.75, .5)$, $F(t_3) = (1, 0)$.

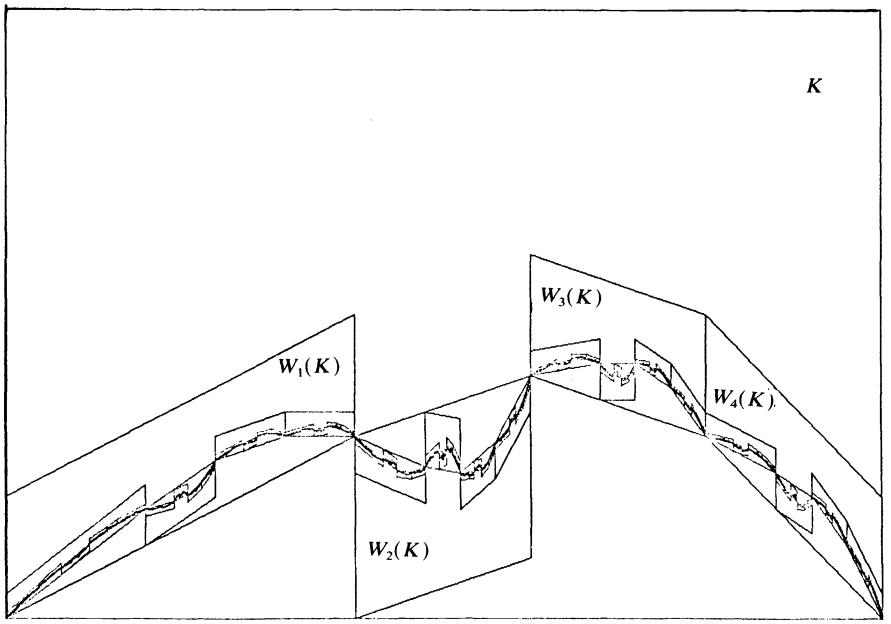

FIG. 7. *Example of a self-affine function in one dimension. The interpolation points are marked* ●, *and the vertical scaling parameters are* $a_1 = 0.2$, $a_2 = -0.3$, $a_3 = 0.2$, *and* $a_4 = 0.2$. *See Example* 1.

In particular, if we write $F(t) = (f(t), h(t))$, then $f(t)$ interpolates according to $f(t_0) = 0$, $f(t_1) = .25, f(t_2) = .75, f(t_3) = 1$. Various views of G, including the graph of f, are shown in Fig. 8. We see that G is a Sierpinski triangle when viewed from "above" the xy-plane, while it provides an intricate one-dimensional function $h(t)$ when projected onto the yt-plane. Note that this example is "diagonal" in that there is no coupling between the t and X variables. F is a map, from the elementary attractor I onto the attractor S, of a two-dimensional IFS, and is the same as the map ϕ constructed in the introduction using the code space.

Example 3. Let J here be $J \times K$ in Example 2, so that t here corresponds to (t, X) in Example 2. Let $l_i(t)$ here be $(l_i(t), k_i(t, X))$ in Example 2. Then I here is the graph $G \subset \mathbb{R}^3$ in Example 2. Let K here be $J \times K$ in Example 1, and the maps k_i here be the maps W_i in Example 1, with $N = 3$. Then the attractor for the IFS $(J \times K, W_i, i \in \{1, 2, 3\})$ obtained here will be the graph of a function that maps the entity represented in Fig. 8 onto the function shown in Fig. 7. Again, we are here dealing with a diagonal construction where the maps k_i depend only on X.

Example 4. Let $J = [0, 1]$ and let $t_0 = 0$, $t_1 = \frac{1}{2}$, and $t_2 = 1$. Choose $l_i(t) = (t_i - t_{i-1})t + t_{i-1}$. Let $K = [0, 1] \times [0, 1]$ and define maps $k_i(t, X)$: $K \to K$ by

$$k_i(t, X) = \begin{pmatrix} \frac{1}{2} & \frac{1}{2}(-1)^{i-1} \\ \frac{1}{2}(-1)^{i-1} & -\frac{1}{2} \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} (i-1) & \frac{1}{2} \\ (i-1) & \frac{1}{2} \end{pmatrix}$$

where $X = (x, y)$ and $i \in \{1, 2\}$. Then the attractor A for the IFS $(K, k_i, i \in \{1, 2\})$ is a Peano Curve. Figure 9 shows A and also different views of G, the attractor of the IFS $(J \times K, W_i, i \in \{1, 2, 3\})$ with $W_i(t, X) = (l_i(t), k_i(t, X))$. Note that k_i is again diagonal in that it is not coupled to t.

Example 5. Let $J = [0, 1]$ and $K = [0, 1] \times [0, 1]$. Let $\{X_j : j \in \{0, \cdots, N\}\}$ and $\{(t_j, \Theta_j) : j \in \{0, \cdots, N\}\}$ be given sets of distinct data points in K and $J \times K$, respectively, with $0 = t_0 < \cdots < t_N = 1$.

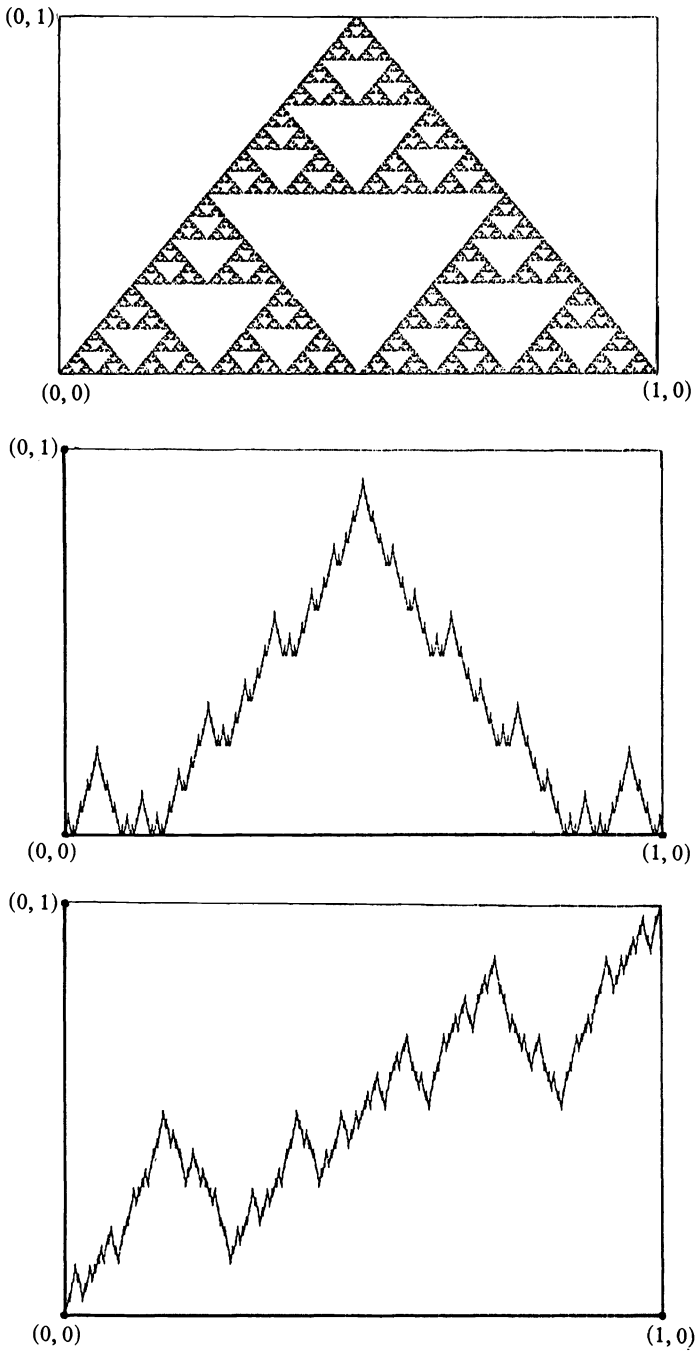

FIG. 8. *Several views of the attractor G for the* IFS *in Example* 2.

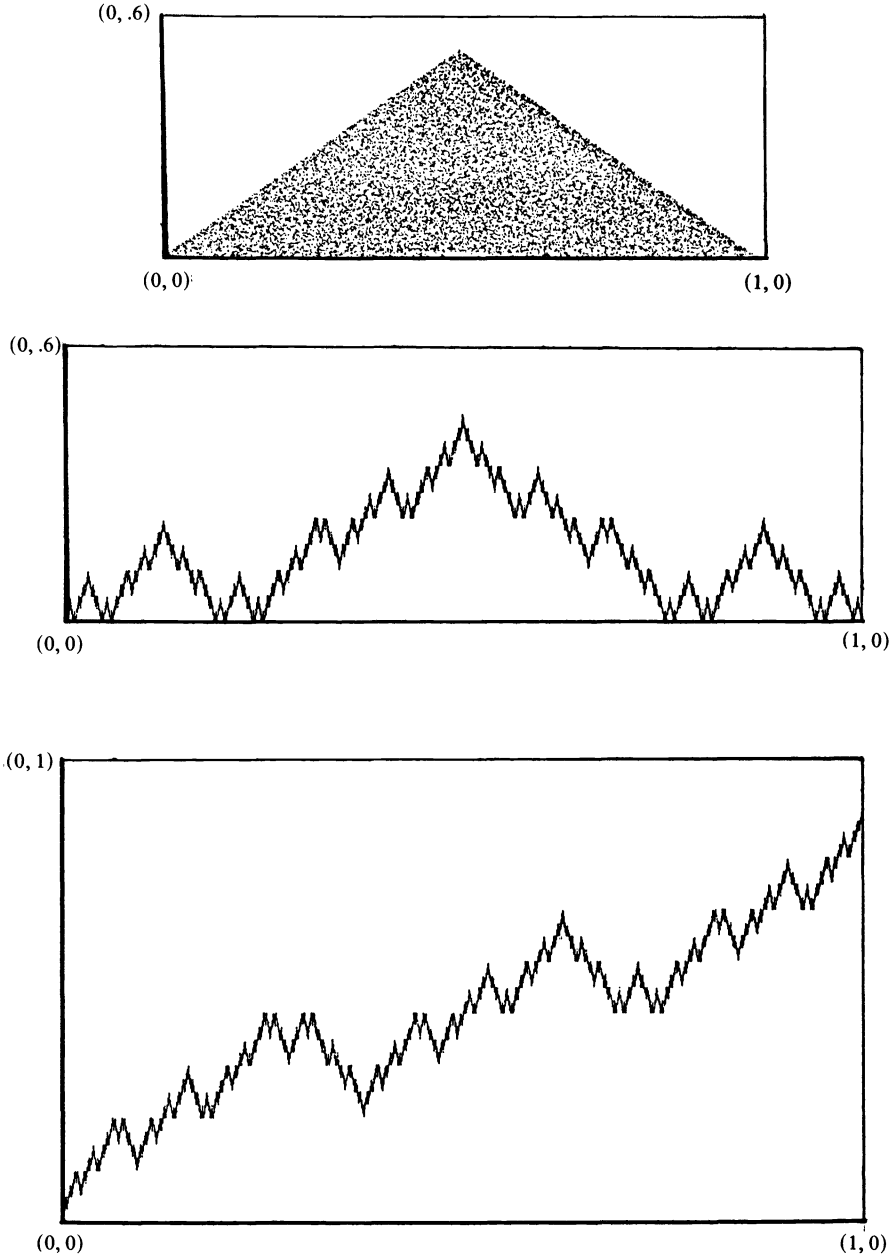

FIG. 9. *Several views of the attractor G for the* IFS *in Example* 4.

Define maps $l_i : J$ by

$$l_i(t) = (t_i - t_{i-1})t + t_{i-1}$$

and k_i: $J \times K \to K$ by

$$k_i(t, X) = \begin{pmatrix} \Delta\xi_i - \Delta x_i & \Delta x_i & -\Delta y_i \\ \Delta\eta_i - \Delta y_i & \Delta y_i & \Delta x_i \end{pmatrix} \begin{pmatrix} t \\ x \\ y \end{pmatrix} + \begin{pmatrix} \xi_{i-1} \\ \eta_{i-1} \end{pmatrix}$$

with $X_j = (x_j, y_j)$ and $\Theta_j = (\xi_j, \eta_j)$, for all $j \in \{0, \cdots, N\}$.

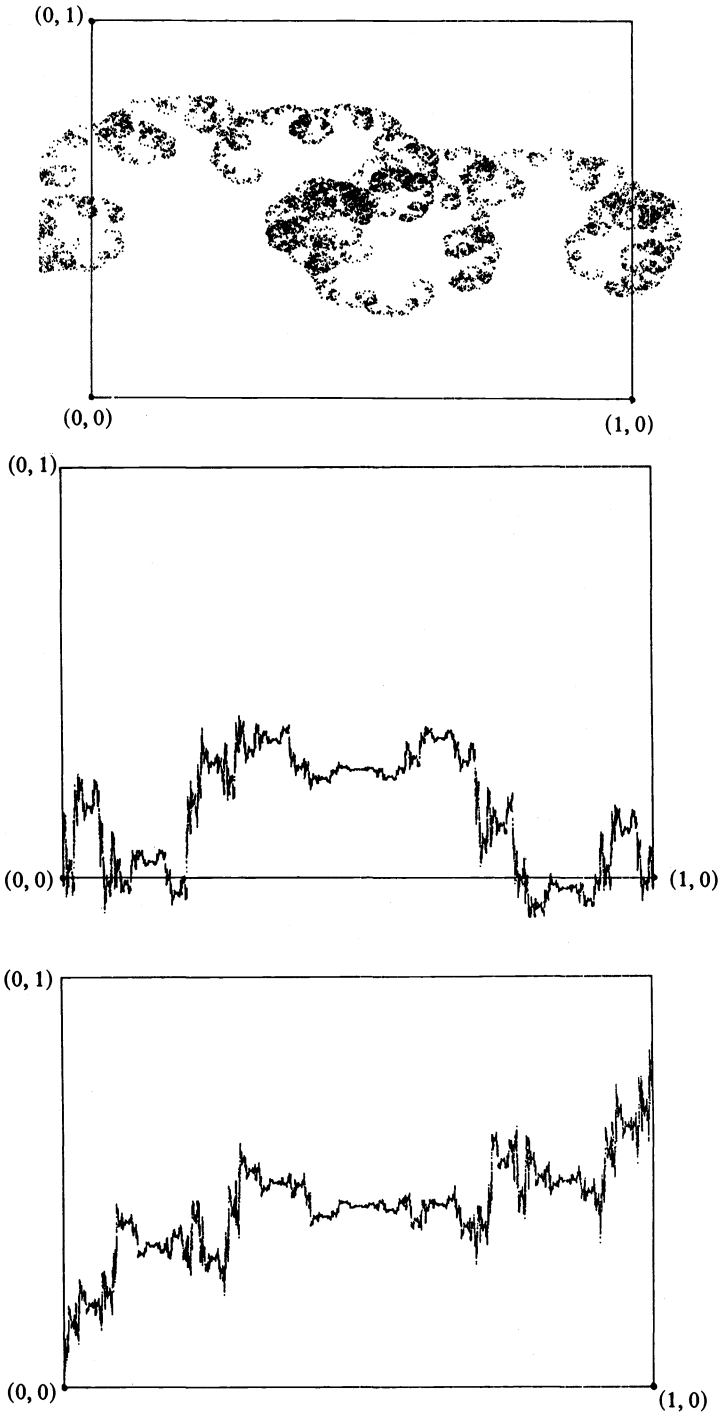

FIG. 10. *Views of the projections of the attractor for the* IFS *in Example* 5.

Then the attractor G of the IFS $(J \times K, W_i, i \in \{1, \cdots, N\})$, where $W_i(t, X) = (l_i(t), k_i(t, X))$, is the graph of a continuous function containing $\{(t_j, \Theta_j): j \in \{0, \cdots, N\}\}$.

Note that if $\Theta_j = X_j$, for all $j \in \{0, \cdots, N\}$, then the k_i are maps as considered in Example 2 and the projection of G onto K is the attractor A for the IFS

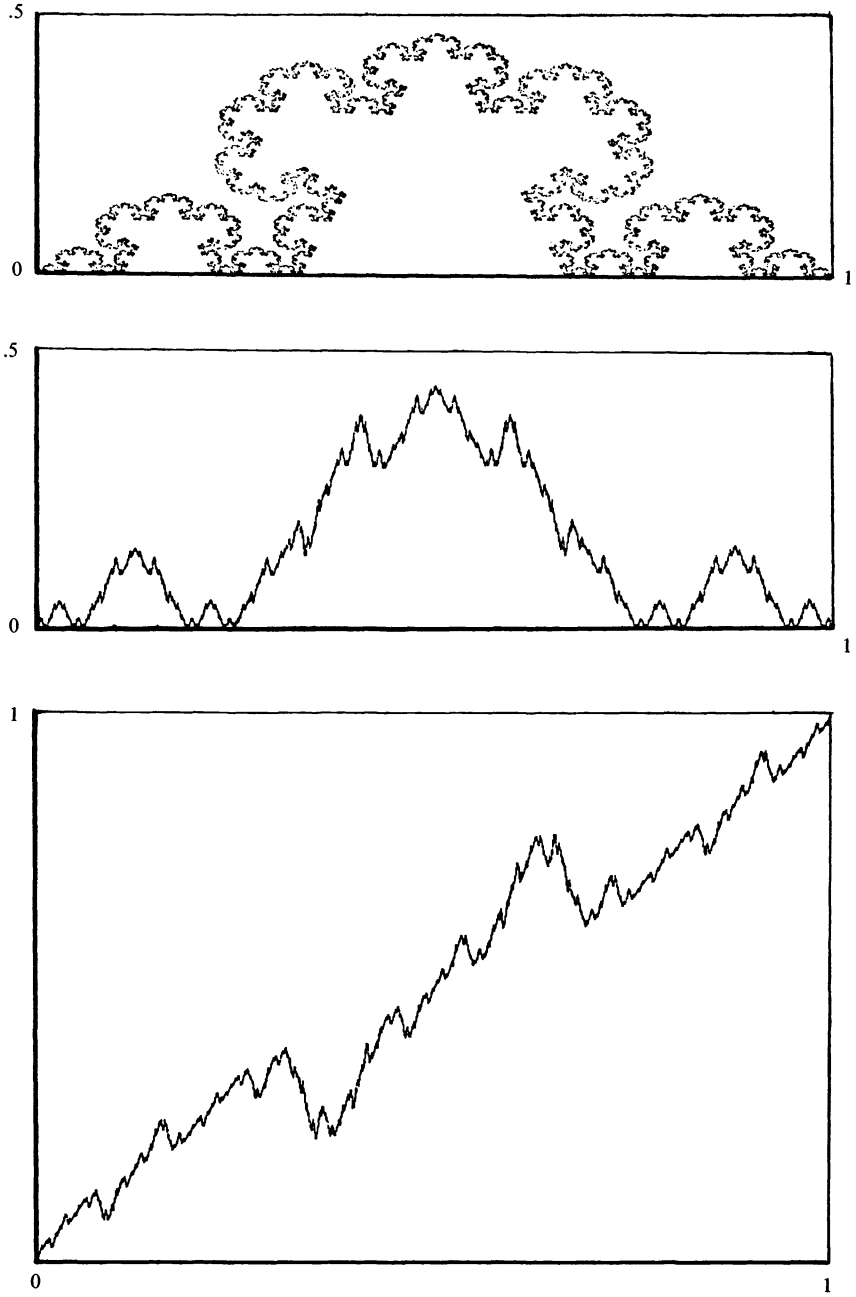

FIG. 11. *Several views of the attractor for the* IFS *in Example* 6.

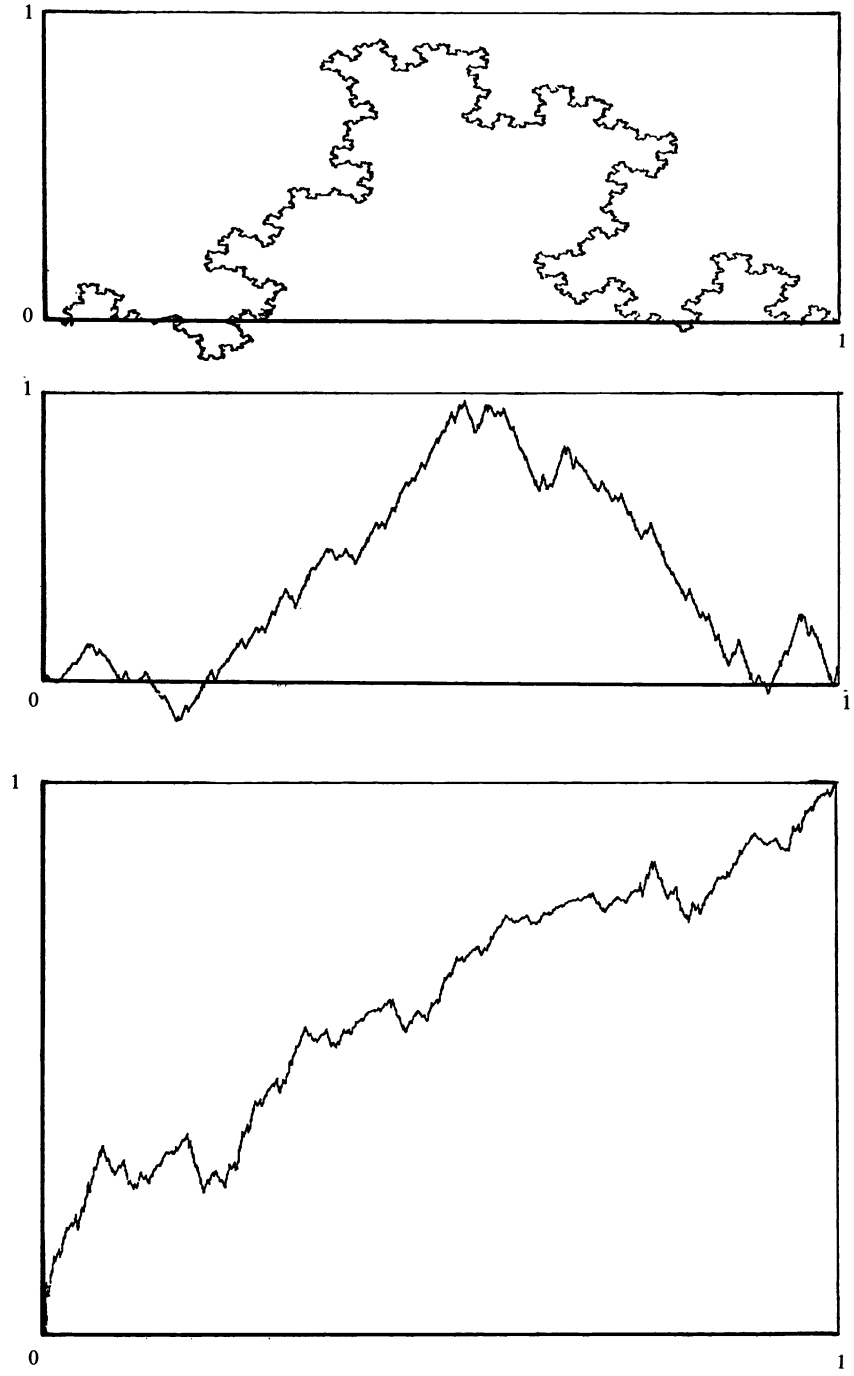

FIG. 12. *Views of the attractor G for an* IFS *of the form as in Example* 7.

$(K, k_i, i \in \{1, \cdots, N\})$, where $k_i : K \to K$:

$$k_i \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} \Delta x_i & -\Delta y_i \\ \Delta y_i & \Delta x_i \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} x_{i-1} \\ y_{i-1} \end{pmatrix}.$$

Figure 10 shows different views of G for $N = 4$, $\{X_j : j \in \{0, \cdots, 4\}\} = \{(0, 0), (\frac{1}{4}, \frac{1}{2}), (\frac{1}{2}, \frac{1}{4}), (\frac{3}{4}, \frac{1}{2}), (1.0)\}$ and $\{(t_j, \Theta_j) : j \in \{0, \cdots, 4\}\} = \{(0, 0, 0), (\frac{1}{4}, \frac{3}{10}, \frac{3}{5}), (\frac{55}{100}, \frac{3}{5}, \frac{3}{10}), (\frac{7}{10}, \frac{1}{2}, \frac{2}{5}), (1, 1, \frac{1}{5})\}$.

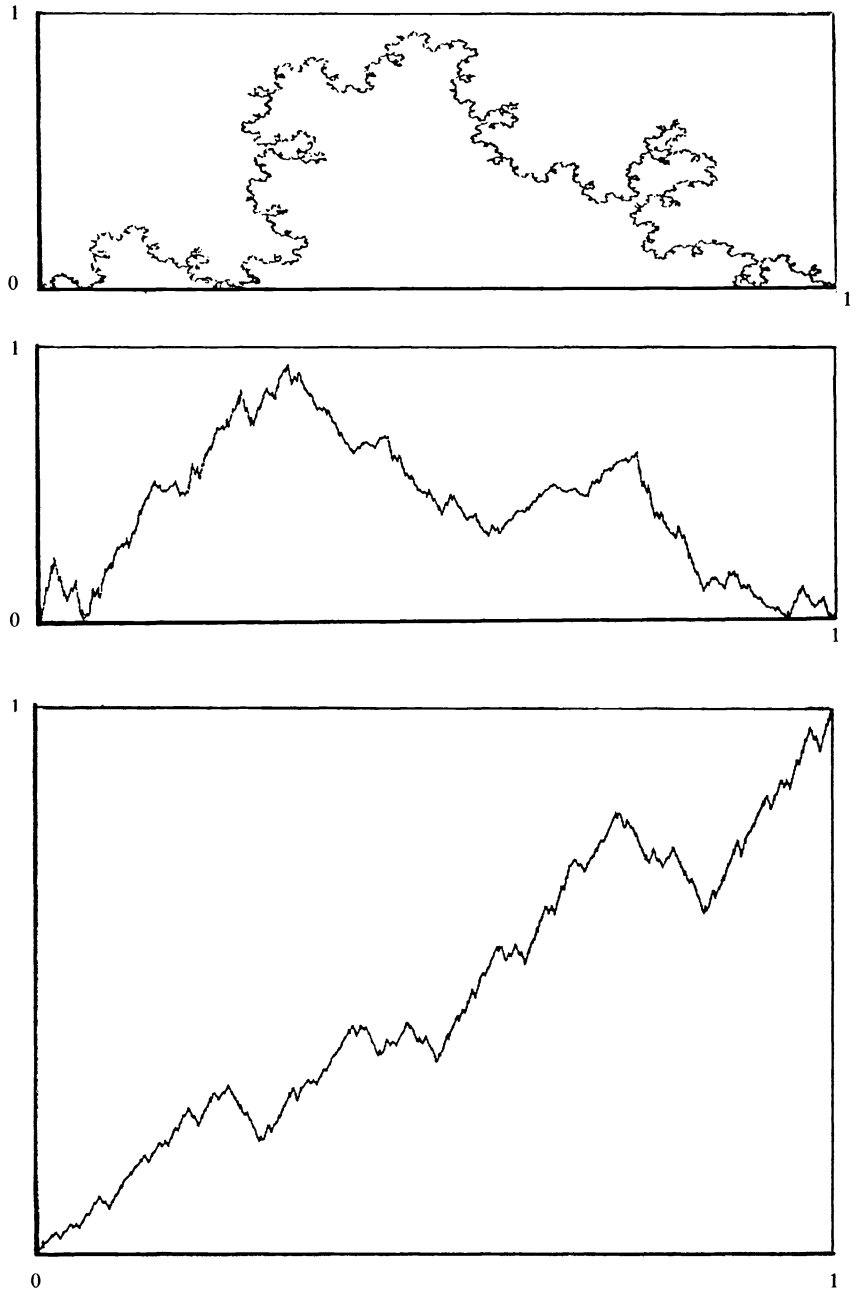

FIG. 13. *Views of the attractor for an* IFS *of the form as in Example* 7.

Example 6. Let $J=[0,1]$ and $K=[0,1]\times[0,1]$. Choose maps $W_i(t,X): J\times K$ with

$$W_i(t,X)=\begin{pmatrix}1/N & 0 & 0\\ 0 & s_i\cos\theta_i & -s_i\sin\theta_i\\ 0 & s_i\sin\theta_i & s_i\cos\theta_i\end{pmatrix}(t,X)+\begin{pmatrix}(i-1)/N\\ \alpha_i\\ \beta_i\end{pmatrix},$$

$i\in\{1,\cdots,N\}$. Let $N=4$. Determine s_i, θ_i, α_i, and β_i such that $W_1(0,0,0)=(0,0,0)$, $W_4=(1,1,0)=(1,1,0)$, $W_2(0,0,0)=W_1(1,1,0)=(\frac{1}{4},\frac{1}{3},0)$, $W_3(0,0,0)=W_2(1,1,0)=(\frac{1}{2},\frac{1}{2},\sqrt{3}/4)$, $W_4(0,0,0)=W_3(1,1,0)=(\frac{3}{4},\frac{2}{3},0)$. Figure 11 shows views of the attractor G of the IFS $(J\times K, W_i, i\in\{1,\cdots,4\})$.

Example 7. Let J, K be as in Example 6. Let maps $W_i: J\times K$ be defined as in Example 6 above. Determine the parameters s_i, θ_i, α_i, and β_i according to (2.7) for some set of interpolation points $\{(t_j,X_j): j\in\{1,\cdots,4\}\}$. Figure 12 shows three views of the corresponding attractor, for an arbitrarily chosen set of parameter values. Figure 13 corresponds to a different set of parameter values.

3. Fractal dimension of graphs of self-affine functions.

3.1. Definition of fractal dimension and related topics. Let E be a bounded set in $\mathbb{R}^n$ and for $\varepsilon>0$ let $\mathcal{N}(\varepsilon)$ be the minimum number of balls of diameter ε necessary to cover E. If

$$\lim_{\varepsilon\to 0}\frac{\log\mathcal{N}(\varepsilon)}{\log 1/\varepsilon}\equiv\dim(E) \tag{3.1}$$

exists, then it is called the (fractal) dimension (also known as the capacity or box-counting dimension) of E. Note that if E is a surface of finite area A then $\mathcal{N}(\varepsilon)\propto A\varepsilon^{-2}$ and thus $\dim(E)=2$ or if E is a curve of finite length L then $\mathcal{N}(\varepsilon)\propto L\varepsilon^{-1}$ and hence $\dim(E)=1$.

Sometimes it is useful to consider covers by sets other than ε-balls. Let $\{\mathcal{C}_\varepsilon: \varepsilon>0\}$ be a family of covers of E and let $\mathcal{N}^*(\varepsilon)$ be the minimum number of sets $C\in\mathcal{C}_\varepsilon$ needed to cover E. Suppose that there exist positive constants c_1 and c_2 so that

$$c_1\mathcal{N}(\varepsilon)\leqq\mathcal{N}^*(\varepsilon)\leqq c_2\mathcal{N}(\varepsilon)$$

then it is clear that $\mathcal{N}(\varepsilon)$ in (3.1) can be replaced by $\mathcal{N}^*(\varepsilon)$. Another notion of dimension is Hausdorff dimension $\mathrm{HD}(E)$:

$$\mathrm{HD}(E)=\sup\{0\leqq d<\infty: H_d(E)>0\}$$

with

$$H_d(E)=\lim_{\varepsilon\to 0}\left(\inf_{\mathcal{U}}\sum_i|U_i|^d\right)$$

where the inf is taken over all countable covers $\mathcal{U}$ of E such that $|U_i|\leqq\varepsilon$ and $|U_i|=\sup\{|x-y|: x,y\in U_i\}$.

Note that

$$\mathrm{HD}(E)\leqq\liminf_{\varepsilon\to 0}\frac{\log\mathcal{N}(\varepsilon)}{\log 1/\varepsilon}.$$

Let $(K, w_i, i=1,\cdots,N)$ be an IFS with attractor A and suppose that:

(3.2) (a) $w_i: K\to K$ is a similitude, i.e., $d(w_i(x),w_i(y))=s_id(x,y)$, for some $0\leqq s_i<1$ for all i;

(b) There exists a nonempty open set O such that $\cup w_i(O) \subseteq O$ and $w_i(O) \cap w_j(O) = \phi$ for $i \neq j$.

Then a result of [Mo] (similar results are found in [H] and [BD]) shows that HD (A) is the unique positive solution of $\sum_{i=1}^{N} s_i^d = 1$. We now show that under conditions (3.2), dim (A) = HD (A).

PROPOSITION 1. *Let* $\{K, w_i, i = 1, \cdots, N\}$ *be an* IFS *satisfying* (3.2). *If* A *is the attractor of this* IFS, *then* HD (A) = dim (A).

Proof. For $\varepsilon > 0$ let $\mathcal{N}(\varepsilon)$ ($\mathcal{N}_i(\varepsilon)$, $i = 1, \cdots, N$) be the minimum number of ε-balls required to cover A ($w_i(A)$, $i = 1, \cdots, N$), respectively. Since w_i is a similitude we have $\mathcal{N}_i(\varepsilon) = \mathcal{N}(\varepsilon / s_i)$ and thus

$$\mathcal{N}(\varepsilon) \leqq \sum_{i=1}^{N} \mathcal{N}_i(\varepsilon) = \sum_{i=1}^{N} \mathcal{N}\left(\frac{\varepsilon}{s_i}\right).$$

Let $\underline{s} = \min\{s_i: i = 1, \cdots, N\}$ and $\bar{s} = \max\{s_i: i = 1, \cdots, N\}$. Let D be the unique positive solution of $\sum_{i=1}^{N} s_i^D = 1$ and choose $c > 0$ such that

$$\mathcal{N}(\varepsilon) \leqq c\varepsilon^{-D} \quad \text{for } \underline{s} \leqq \varepsilon \leqq 1. \tag{3.3}$$

Suppose $\mathcal{N}(\varepsilon) \leqq c\varepsilon^{-D}$ for $(\bar{s})^n \underline{s} \leqq \varepsilon \leqq 1$. Then if $(\bar{s})^{n+1} \underline{s} \leqq \varepsilon \leqq \underline{s}$ we have $(\bar{s})^n \underline{s} \leqq \varepsilon / s_i \leqq 1$ and so $\mathcal{N}(\varepsilon) \leqq \sum_{i=1}^{N} \mathcal{N}(\varepsilon / s_i) \leqq \sum_{i=1}^{N} c s_i^D \varepsilon^{-D} = c\varepsilon^{-D}$. By induction

$$\mathcal{N}(\varepsilon) \leqq c\varepsilon^{-D} \quad \text{for } 0 < \varepsilon \leqq 1$$

and so

$$\limsup_{\varepsilon \to 0} \frac{\log \mathcal{N}(\varepsilon)}{\log 1/\varepsilon} \leqq D.$$

But also, as previously noted,

$$\liminf_{\varepsilon \to 0} \frac{\log \mathcal{N}(\varepsilon)}{\log 1/\varepsilon} \geqq D$$

and so dim $(A) = D$. □

3.2. Dimension of self-affine functions. We now consider dim (G) (recall the notation of § 2). We restrict our attention to the following situation:

(a) $k_i: K \to K$, i.e., no coupling between J and K;

(b) $d(l_i(\tau_1), l_i(\tau_2)) \leqq s_i d(\tau_1, \tau_2) \quad \forall \tau_1, \tau_2 \in J,$

$d(k_i(\xi_i), k_i(\xi_2)) \leqq s_i d(\xi_1, \xi_2) \quad \forall \xi_1, \xi_2 \in K \quad$ where $0 < s_i < 1 \quad \forall i = 1, \cdots, N.$

THEOREM 2. *Let* $F: I \to K$ *be as in* § 2, *and let* D *be the unique positive solution of* $\sum_{i=1}^{N} s_i^D = 1$. *Then* dim $(G) \leqq D$.

Proof. Let $\mathcal{N}(\varepsilon)$ ($\mathcal{N}_i(\varepsilon)$) be the minimum number of ε-balls needed to cover G ($W_i(G)$). Since W_i maps any (ε / s_i)-ball into an ε-ball we have $\mathcal{N}_i(\varepsilon) \leqq \mathcal{N}(\varepsilon / s_i)$ and thus

$$\mathcal{N}(\varepsilon) \leqq \sum_{i=1}^{N} \mathcal{N}_i(\varepsilon) \leqq \sum_{i=1}^{N} \mathcal{N}\left(\frac{\varepsilon}{s_i}\right).$$

As in Proposition 1 this implies dim $(G) \leqq D$. □

We now consider the special case where the IFS $\{K, k_i, i = 1, \cdots, N\}$ satisfies the conditions of (3.2). In particular, we have Example 6 in mind; however, we will remain slightly more general here. Let D be the unique positive solution of $\sum_{i=1}^{N} s_i^D = 1$. By

Theorem 2, $\dim(G) \leqq D$. However, as $A = \operatorname{proj}_K G$ we have $\dim(G) \geqq \dim(A) = D$ and thus we have Corollary 1.

COROLLARY 1. $\dim(G) = D$.

Next consider the "equal scaling" case of Example 2.6: $l_i(t) = t/N + (i-1)/N$, for all $i = 1, \cdots, N$. We can relax the conditions $s_i \geqq 1/N$ in Corollary 1.

THEOREM 3. $\dim(G) = D$, *where* D *is the unique positive solution of* $\sum_{i=1}^{N} s_i^D = 1$.

Proof. For simplicity we assume all s_i's are nonzero. Let $\mathscr{C}(n) = \{[(i-1)/N^n, i/N^n] \times B: i = 1, \cdots, N^n$, with B a $1/n$-ball in $K\}$. Let $\mathscr{N}^*(n)$ be the minimum number of sets from $\mathscr{C}(n)$ and let $\mathscr{N}(\varepsilon)$ and $\mathscr{N}_p(\varepsilon)$ be the minimum number of ε-balls necessary to cover G and $A = \operatorname{proj}_K G$, respectively. Note that $\mathscr{N}^*(n) \geqq \mathscr{N}(2/N^n)$. Let

$$G_i = G|_{[(i-1)/N^n, i/N^n] \times K}$$

and let $\omega_1 \omega_2 \cdots \omega_n$, where $\omega_i \in \{1, \cdots, N\}$, be the code corresponding to $[(i-1)/N^n, i/N^n]$. Let $\mathscr{B}$ be a minimal $(1/N^n \prod_{i=1}^{n} s_{\omega_i})$-cover of A. By applying $W_{\omega_1} \cdots W_{\omega_n}$ to $\{[0,1] \times B \mid B \in \mathscr{B}\}$ we can cover G_i with

$$\mathscr{N}_p\left(\frac{1}{N^n \prod_{i=1}^{n} s_{\omega_i}}\right)$$

sets from $\mathscr{C}(n)$. Thus

$$\begin{aligned}
\mathscr{N}^*(n) &\leqq \sum_{\omega_1=1}^{N} \cdots \sum_{\omega_n=1}^{N} \mathscr{N}_p\left(\frac{1}{N^n \prod_{i=1}^{N} s_{\omega_i}}\right) \\
&\leqq N^{nD} c \sum_{\omega_1=1}^{N} \cdots \sum_{\omega_n=1}^{N} \prod_{i=1}^{N} s_{\omega_i}^D \\
&= N^{nD} c \left(\sum_{i=1}^{N} s_i^D\right) = c N^{nD}
\end{aligned}$$

by (3.3). Thus for $2/N^n \leqq \varepsilon \leqq 2/N^{n-1}$ we have

$$\frac{\log \mathscr{N}(\varepsilon)}{\log 1/\varepsilon} \leqq \frac{\log(cN^{nD})}{\log(N^{n-1}/2)}$$

and so

$$\limsup_{\varepsilon \to 0} \frac{\log \mathscr{N}(\varepsilon)}{\log 1/\varepsilon} \leqq D.$$

As $\dim(A) = D$ we have the desired result. □

4. Fractal dimension of projections of self-affine functions.

4.1. The dimension of one-dimensional self-affine functions. In this section we consider the dimension of the graphs of the functions constructed in Example 1. (We use the notation of Example 1 here.) We show that if

$$\sum_{i=1}^{N} |a_i| > 1 \quad \text{and} \quad \{(t_j, x_j): j = 0, \cdots, N\} \text{ is not collinear,} \tag{4.1}$$

then $\dim(G)$ is given by

$$\sum_{i=1}^{N} |a_i| b_i^{\dim(G)-1} = 1. \tag{4.2}$$

Let $h(d)=\sum_{i=1}^{N}|a_i|b_i^{d-1}$. Since $h(d)$ is strictly decreasing, $\lim_{d\to-\infty}h(d)=\infty$, and $h(2)\leqq\max_{i=1,\cdots,N}|a_i|<1$, there is a unique $D\in(-\infty,2)$ such that $h(D)=1$. Also $D>1$ if and only if $\sum_{i=1}^{N}|a_i|>1$; thus (4.2) uniquely determines $\dim(G)\in(1,2)$.

Let us now define a class of covers that allows us to relate covers of different sizes.

DEFINITION. For $0<\varepsilon<1$, $\{\tau_l\}_{l=0}^{m}$ is called an *ε-partition* if

(a) $\tau_l\in(-\varepsilon/2,1)$,

(b) $\varepsilon/2<\tau_{l+1}-\tau_l\leqq\varepsilon$,

for $l=1,2,\cdots,n-1$. A cover $\mathscr{C}$ of G will be called an *ε-column cover of G* with associated ε-partition $\{\tau_l\}_{l=0}^{m}$ if there are positive integers $n_0,\cdots,n_m$ and real numbers $\xi_0,\cdots,\xi_m$ such that

$$\mathscr{C}=\{[\tau_k,\tau_k+\varepsilon]\times[\xi_k+(j_k-1)\varepsilon,\xi_k+j_k\varepsilon]:j_k=1,\cdots,n_k;\ k=0,1,\cdots,m\}.$$

Note that $\mathscr{C}$ consists of $\sum_{k=0}^{m}n_k$ closed $\varepsilon\times\varepsilon$ squares arranged in $m+1$ columns. Let $|\mathscr{C}|$ denote the cardinality of $\mathscr{C}$ and define $\mathscr{N}^*(\varepsilon)=\min\{|\mathscr{C}|:\mathscr{C}$ is an ε-column cover of $G\}$ and let $\mathscr{N}(\varepsilon)$ be the minimum number of $\varepsilon\times\varepsilon$ squares $[a,a+\varepsilon]\times[b,b+\varepsilon]$, $a,b\in\mathbb{R}$, required to cover G. Lemma 4.1 below shows that $\mathscr{N}^*(\varepsilon)$ can be used in the calculation of $\dim(G)$.

LEMMA 4.1. *$\mathscr{N}(\varepsilon)\leqq\mathscr{N}^*(\varepsilon)\leqq2\mathscr{N}(\varepsilon)$, for all $0<\varepsilon<1$.*

Proof. Clearly, $\mathscr{N}(\varepsilon)\leqq\mathscr{N}^*(\varepsilon)$.

We introduce a third class of covers: a cover $\mathscr{C}$ of G will be called an *ε-nonoverlapping cover of G* if it consists of $\varepsilon\times\varepsilon$ squares with nonintersecting interiors of the form $[k\varepsilon,(k+1)\varepsilon]\times[y,y+\varepsilon]$, where $k\in\{0,1,\cdots,[\![1/\varepsilon]\!]\}$ and $y\in\mathbb{R}$. Define $\mathscr{N}^{**}(\varepsilon)=\min\{|\mathscr{C}|:\mathscr{C}$ is an ε-nonoverlapping cover of $G\}$.

Clearly, $\mathscr{N}^{**}(\varepsilon)\leqq2\mathscr{N}(\varepsilon)$. If $\mathscr{C}$ is a minimal ε-nonoverlapping cover of G then, since G is the graph of a continuous function, $\mathscr{C}$ is also an ε-column cover of G. Thus $\mathscr{N}^*(\varepsilon)\leqq\mathscr{N}^{**}(\varepsilon)\leqq2\mathscr{N}(\varepsilon)$. □

In the proof of Theorem 4 we show that $\mathscr{N}(\varepsilon)$ satisfies the functional inequality

$$(*)\qquad \sum_{i=1}^{N}\frac{|a_i|}{b_i}\mathscr{N}^*\left(\frac{\varepsilon}{b_i}\right)-\frac{\beta_1}{\varepsilon}\leqq\mathscr{N}^*(\varepsilon)\leqq\sum_{i=1}^{N}\frac{|a_i|}{b_i}\mathscr{N}^*\left(\frac{\varepsilon}{b_i}\right)+\frac{\beta_2}{\varepsilon}$$

for some $\beta_1,\beta_2>0$ and all $0<\varepsilon<1$.

To show that the $1/\varepsilon$ term becomes negligible we need the following lemma.

LEMMA 4.2. *If (4.1) is satisfied, then*

$$\lim_{\varepsilon\to0}\varepsilon\mathscr{N}^*(\varepsilon)=\infty.$$

Proof. As $\{(t_j,x_j):j=0,\cdots,N\}$ is not collinear there is some $l\in[1,\cdots,N-1]$ such that $V\equiv|t_l-(t_N-t_0)x_l-t_0|>0$. Let $\underline{b}=\min\{b_i:i=1,\cdots,N\}$. Since F is continuous we obtain

$$\begin{aligned}N(\varepsilon)&\geqq\sum_{i_1=1}^{N}\cdots\sum_{i_k=1}^{N}\left(|a_{i_1}\cdots a_{i_k}|\frac{V}{\varepsilon}\right)\\&\geqq\left(\sum_{i=1}^{N}|a_i|\right)^k\frac{V}{\varepsilon}\quad\text{for }0<\varepsilon<\underline{b}^k\text{ and }k\in\mathbb{N}.\end{aligned}$$

Since $(\sum_{i=1}^{N}|a_i|)>1$ the lemma is proved. (See [HM] for more detail.) □

The investigation of the following theorem commenced in [BH] and [HM].

THEOREM 4. *Let F be the function with graph G generated by the* IFS *$(K,W_i,i=1,\cdots,N)$, where*

$$W_i\begin{pmatrix}t\\x\end{pmatrix}=\begin{pmatrix}b_i&0\\c_i&a_i\end{pmatrix}\begin{pmatrix}t\\x\end{pmatrix}+\begin{pmatrix}t_{i-1}\\x_{i-1}\end{pmatrix}\quad\forall i=1,\cdots,N$$

with a_i, b_i, c_i, t_i, x_i *as in Example* 1. *If* $\sum_{i=1}^{N}|a_i|>1$ *and* $\{(t_j, x_j): j=0, 1, \cdots, N\}$ *is not collinear, then* $\dim(G)$ *is the unique real solution* D *of* $\sum_{i=1}^{N}|a_i|b_i^{D-1}=1$; *otherwise* $\dim(G)=1$.

Proof. We first obtain functional inequalities for $\mathcal{N}^*(\varepsilon)$. Let $0<\varepsilon<1$ and let $\mathscr{C}$ be a minimal ε-column cover of G with associated ε-partition $\{\tau_j\}_{j=0}^{m}$. For $i\in\{1, \cdots, N\}$ let $[a, b+\varepsilon]$, $a, b\in\mathbb{R}$, be the smallest interval of the form $[\tau_k, \tau_l+\varepsilon]$ that covers $[t_{i-1}, t_i]$. Let

$$\mathscr{C}_i=\{C\in\mathscr{C}: C\subset[\tau_k, \tau_l+\varepsilon]\times\mathbb{R}\}$$

and $\mathcal{N}_i=|\mathscr{C}_i|$. Since F is continuous, $\max_{t\in[0,1]}|F(t)|=M<\infty$. Since there are at most two columns in $\mathscr{C}_i\cap\mathscr{C}_{i+1}$ there is some $\alpha_1>0$ such that $\sum_{i=1}^{N}\mathcal{N}_i\leqq\mathcal{N}^*(\varepsilon)+\alpha_1/\varepsilon$ for $0<\varepsilon<1$.

Suppose $a_i\neq 0$. Then W_i is invertible. Consider a typical column R in $\mathscr{C}_i$ that consists of n $\varepsilon\times\varepsilon$ squares; then $W_i^{-1}(R)$ is a parallelogram that can be covered by

$$\left[\!\left[\frac{nb_i}{|a_i|}+\left|\frac{c_i}{b_i}\right|+1\right]\!\right]$$

squares of side ε/b_i as in Fig. 14. Applying W_i^{-1} generates an (ε/b_i)-column cover $\mathscr{D}_i$ of G. Since there are at most $2b_i/\varepsilon+2$ columns in $\mathscr{C}_i$ there is some $\beta_1>0$ so that

$$\mathcal{N}^*(\varepsilon)\geqq\sum_{i=1}^{N}\mathcal{N}_i-\frac{b_1}{\varepsilon}\geqq\sum_{i=1}^{N}\frac{|a_i|}{b_i}\mathcal{N}^*\left(\frac{\varepsilon}{b_i}\right)-\frac{c_1}{\varepsilon}.$$

Next we obtain a lower bound for $\mathcal{N}^*(\varepsilon)$. Let $\mathscr{D}_i$ be a best ε/b_i-column cover of G and R a typical column of $\mathscr{D}_i$. Note that $W_i(R)$ is a parallelogram that can be covered by

$$\left[\!\left[n\frac{|a_i|}{b_i}+\frac{|c_i|}{b_i}+1\right]\!\right]$$

$\varepsilon\times\varepsilon$ squares. In this way we generate a cover $\mathscr{C}_i$ of $W_i(G)$ consisting of $\varepsilon\times\varepsilon$ squares. As there are at most $[(2b_i/\varepsilon)+2]$ columns of $\mathscr{D}_i$ there is some $\alpha_2>0$ such that

$$|\mathscr{C}_i|\leqq\frac{|a_i|}{b_i}\mathcal{N}^*\left(\frac{\varepsilon}{b_i}\right)+\frac{\alpha_2}{\varepsilon}\quad\text{for } 0<\varepsilon<1.$$

Note that $\cup\,\mathscr{C}_i$ may not be an ε-column cover of G because the columns of $\mathscr{C}_i$ may not join up properly with those of $\mathscr{C}_{i+1}$; however, an ε-column cover $\mathscr{C}$ can be constructed from $\cup\,\mathscr{C}_i$ by replacing at most two columns from $\mathscr{C}_i\cup\mathscr{C}_{i+1}$ with at most two properly spaced columns, and so

$$\mathcal{N}^*(\varepsilon)\leqq|\mathscr{C}|\leqq\sum_{i=1}^{N}|\mathscr{C}_i|+(N)\left(\frac{4n}{\varepsilon}+1\right).$$

Thus there is $\beta_2>0$ such that

$$\mathcal{N}^*(\varepsilon)\leqq\sum_{i=1}^{N}\frac{|a_i|}{b_i}\mathcal{N}^*\left(\frac{\varepsilon}{b_i}\right)+\frac{\beta_2}{\varepsilon}$$

and so we have established (*).

Case 1. Condition (4.1) is satisfied.

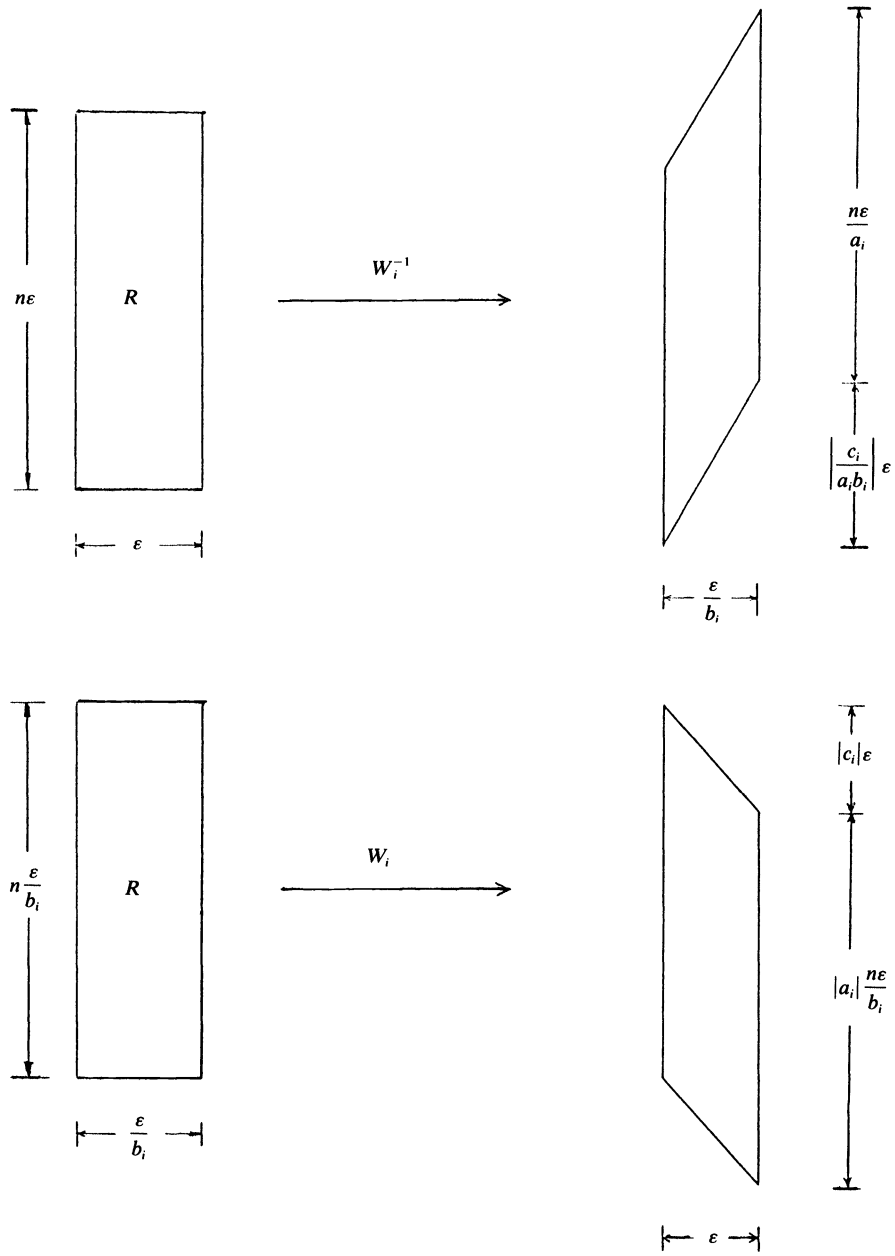

FIG. 14. *The rectangle $\mathcal{R}$ and its images under the maps W_i and W_i^{-1}. See the proof of Theorem* 4.

Here we will show that there exist positive constants B_1, B_2, and ε_0 so that $B_1\varepsilon^{-D} < \mathcal{N}^*(\varepsilon) < B_2\varepsilon^{-D}$ for $0 < \varepsilon < \varepsilon_0$. (Recall that D is the unique solution of $h(D) = 1$ and that $D \in (1, 2)$.)

Let $\underline{b} = \min\{b_i: i = 1, \cdots, N\}$, $\bar{b} = \max\{b_i: i = 1, \cdots, N\}$, and $\gamma = \sum_{i=1}^{N} |a_i| > 1$. By Lemma 2.1 we can select $\varepsilon_0 > 0$ small enough so that

$$\mathcal{N}^*(\varepsilon) \geqq 2\left(\frac{\beta_1}{\gamma - 1}\right)\varepsilon^{-1} \quad \text{for } 0 < \varepsilon \leqq \frac{\varepsilon_0}{\underline{b}}.$$

Pick $k_1 > 0$ small enough so that $k_1 \varepsilon_0^{-D} \leqq (\beta_1/(\gamma-1))\varepsilon_0^{-1}$ and select k_2 large enough so that

$$\mathcal{N}^*(\varepsilon) \leqq \frac{\beta_2}{1-\gamma}\varepsilon^{-1} + k_2\varepsilon^{-D} \quad \text{for } \varepsilon_0 \leqq \varepsilon \leqq \frac{\varepsilon_0}{\underline{b}}.$$

Define

$$\underline{\phi}(\varepsilon) = \left(\frac{\beta_1}{\gamma-1}\right)\varepsilon^{-1} + k_1\varepsilon^{-D},$$

$$\bar{\phi}(\varepsilon) = \left(\frac{\beta_2}{1-\gamma}\right)\varepsilon^{-1} + k_2\varepsilon^{-D}.$$

Then we have

$$\underline{\phi}(\varepsilon) \leqq \mathcal{N}^*(\varepsilon) \leqq \bar{\phi}(\varepsilon) \tag{4.3}$$

for $\varepsilon_0 \leqq \varepsilon \leqq \varepsilon_0/\underline{b}$. Note that

$$\underline{\phi}(\varepsilon) = \sum_{i=1}^{N} \frac{|a_i|}{b_i}\phi\left(\frac{\varepsilon}{b_i}\right) - \frac{\beta_1}{\varepsilon},$$

$$\bar{\phi}(\varepsilon) = \sum_{i=1}^{N} \frac{|a_i|}{b_i}\bar{\phi}\left(\frac{\varepsilon}{b_i}\right) + \frac{\beta_2}{\varepsilon}.$$

If $\bar{b}\varepsilon_0 \leqq \varepsilon \leqq \varepsilon_0$ then $\varepsilon_0 \leqq \varepsilon/b_i \leqq \varepsilon_0/\underline{b}$ so that

$$\begin{aligned}\mathcal{N}^*(\varepsilon) &\leqq \sum_{i=1}^{N} \frac{|a_i|}{b_i}\mathcal{N}^*\left(\frac{\varepsilon}{b_i}\right) + \frac{\beta_2}{\varepsilon} \\ &\leqq \sum_{i=1}^{N} \frac{|a_i|}{b_i}\bar{\phi}\left(\frac{\varepsilon}{b_i}\right) + \frac{\beta_2}{\varepsilon} = \bar{\phi}(\varepsilon)\end{aligned}$$

and in the same way $\mathcal{N}^*(\varepsilon) \geqq \underline{\phi}(\varepsilon)$ for $\bar{b}\varepsilon_0 \leqq \varepsilon \leqq \varepsilon_0$.

Suppose (4.3) holds for $\bar{b}^n\varepsilon_0 \leqq \varepsilon \leqq \varepsilon_0$; then, as in the preceding argument, (4.3) must hold for $\bar{b}^{n+1}\varepsilon_0 \leqq \varepsilon \leqq \varepsilon_0$. By induction (4.3) holds for $0 < \varepsilon \leqq \varepsilon_0$. Since $D > 1$ there exist positive constants B_1 and B_2 such that $B_2\varepsilon^{-D} \leqq \underline{\phi}(\varepsilon) \leqq \mathcal{N}(\varepsilon) \leqq \bar{\phi}(\varepsilon) \leqq B_2\varepsilon^{-D}$ for $0 < \varepsilon \leqq \varepsilon_0$.

Case 2. $\gamma = \sum_{i=1}^{N} |a_i| < 1$.

As in Case 1, select $k_2 > 0$ so that $\mathcal{N}^*(\varepsilon) \leqq \bar{\phi}(\varepsilon) = (\beta_2/(1-\gamma))\varepsilon^{-1} + k_2\varepsilon^{-D}$ for $0 < \varepsilon \leqq 1$. Since $D < 1$ and $\beta_2/(1-\gamma) > 0$ we obtain $\mathcal{N}(\varepsilon) \leqq B_2\varepsilon^{-1}$ for some $B_2 > 0$.

As G is the graph of a continuous function on $[0, 1]$ we have $\mathcal{N}(\varepsilon) \geqq 1/\varepsilon$ and thus $\dim(G) = 1$.

Case 3. $\gamma = \sum |a_i| = 1$.

Let $\bar{\phi}(\varepsilon) = (\beta_2/\sum_{i=1}^{N} |a_i| \ln(b_i))(\ln(\varepsilon)/\varepsilon) + k_2/\varepsilon$ and note that

$$\bar{\phi}(\varepsilon) = \sum_{i=1}^{N} \frac{|a_i|}{b_i}\bar{\phi}\left(\frac{\varepsilon}{b_i}\right) + \frac{\beta_2}{\varepsilon}$$

for $\varepsilon > 0$ and any $k_2 \in \mathbb{R}$. As in Cases 1 and 2, select $k_2 > 0$ so that $\mathcal{N}(\varepsilon) \leqq \bar{\phi}(\varepsilon)$ for $0 < \varepsilon \leqq 1$, which shows that $\dim(G) = 1$.

Case 4. $\{(t_j, x_j): j = 0, \cdots, N\}$ is collinear.

G is a line segment and thus $\dim(G) = 1$. □

4.2. Dimension of projections. Let us now calculate the dimension of $g = \text{graph}(f)$ under the assumption that (3.2)(a) is satisfied and that $J = [0, 1]$.

THEOREM 5. *Let $f: I \to \mathbb{R}$ be defined as in § 1 above and let g be its graph. Suppose that A satisfies* (3.2). *Then* $\dim(g)$ *is the unique positive solution d of*

$$\sum_{i=1}^{N} s_i b_i^{d-1} = 1 \tag{4.4}$$

where $b_i = t_i - t_{i-1}$, for all i.

Proof. We will use the notation introduced in the proof of Theorem 4. Let $\{\tau_l\}_{l=0}^{m}$ be an ε-partition with associated ε-column cover $\mathscr{C}$. Assume that $\mathscr{C}$ is also a minimal cover of g. Choose $k \in \{1, \cdots, m\}$ and consider the collection C_k of all $\varepsilon \times \varepsilon$ squares from $\mathscr{C}$ that lie above $[\tau_{k-1}, \tau_k]$. The continuity of f implies that C_k is a rectangle of width ε and height h_k. Let $\Pi = \{\Pi_\theta: \theta \in [0, 2\pi)\}$ be a plane bundle whose axis is the t-axis. Let $\Pi_\theta \in \Pi$ and let $h_k(\theta)$ be the height of the projection of $g|_{[\tau_{k-1}, \tau_k]}$ onto Π_θ. Denote by $\bar{\delta}_k(\underline{\delta}_k)$ the maximum (minimum) of $h_k(\theta)$ over $\theta \in [0, 2\pi)$.

Define $\bar{\mathcal{N}} = \sum_k \bar{\delta}_k/\varepsilon$ and $\underline{\mathcal{N}} = \sum_k \underline{\delta}_k/\varepsilon$. Then

$$\underline{\mathcal{N}}(\varepsilon) \leqq \mathcal{N}^*(\varepsilon) \leqq \bar{\mathcal{N}}(\varepsilon).$$

Following the argument given in the proof of Theorem 4 we obtain functional inequalities for $\underline{\mathcal{N}}(\varepsilon)$ and $\bar{\mathcal{N}}(\varepsilon)$. (Note that $\{(\tau_j, x_j): j \in \{0, \cdots, N\}\}$ is collinear $\Leftrightarrow$ $\sum_{i=1}^{N} s_i = 1$.) These functional inequalities then imply that

$$\underline{\mathcal{N}}(\varepsilon) \geqq A\varepsilon^{-d} \quad \text{and} \quad \bar{\mathcal{N}}(\varepsilon) \leqq B\varepsilon^{-d}$$

for positive constants A and B and where d is the unique real solution of $\sum_{i=1}^{N} s_i b_i^{d-1} = 1$. □

Example 8. Let $K = [0, 1] \times [0, 1]$ and let g be the graph of f, which is the projection of the attractor G of the IFS $(J \times K, W_i, i \in \{1, \cdots, 3\})$, where the maps $W_i: J \times K$ are defined by

$$W_i(t, X) = \begin{pmatrix} b_i & 0 & 0 \\ 0 & a_i & -c_i \\ 0 & c_i & a_i \end{pmatrix} (t, X) + \begin{pmatrix} \alpha_i \\ \beta_i \\ \gamma_i \end{pmatrix}$$

and the constants a_i, b_i, c_i, α_i, β_i, and γ_i are determined by (2.7) with $\{(0, 0, 0), (\frac{3}{10}, \frac{7}{10}, \frac{2}{5}), (\frac{7}{10}, \frac{2}{5}, \frac{3}{10}), (1, 1, 0)\}$ as the set of interpolation points. Then $b_1 = \frac{3}{10}$, $b_2 = \frac{2}{5}$, $b_3 = \frac{3}{10}$, and the scaling factors are $s_i = \sqrt{65}/10$, $s_2 = \sqrt{10}/10$, and $s_3 = \sqrt{45}/10$. The dimension d of g is then approximately $d \approx 1.5075$. Figure 15 shows the projections of G.

If in addition we now assume that the attractor A of the IFS $(K, k_i, i = 1, \cdots, N)$ also satisfies (3.2b), then we can derive the following relation between $\dim(g)$ and $\dim(K) = n$.

COROLLARY 2. Under the hypotheses of Theorem 5 and the assumption that (3.2b) holds, we have that

$$1 \leqq \dim(g) \leqq 2 - \frac{1}{n}. \tag{4.5}$$

Proof. The statement follows readily from the Cauchy-Schwartz inequality applied to (4.4) and the fact that $\Sigma\, s_i \geqq 1$ and $\Sigma\, s_i^n \leqq 1$ (the first inequality reflects the connectedness of A, and the second, the fact that $\dim(A) \leqq n$). □

Example 9. For the attractor G in Example 2 we have $s_1 = s_2 = s_3 = \frac{1}{2}$ and $b_1 = b_2 = b_3 = \frac{1}{3}$. Hence $d = 2 - \log 2/\log 3 \approx 1.3691 < 1.5$.

Example 10. For the attractor of Example 4 we have $s_1 = s_2 = 1/\sqrt{2}$ and $b_1 = b_2 = \frac{1}{2}$. Thus $d = 1 + \log_2 \sqrt{2} = 1.5$.

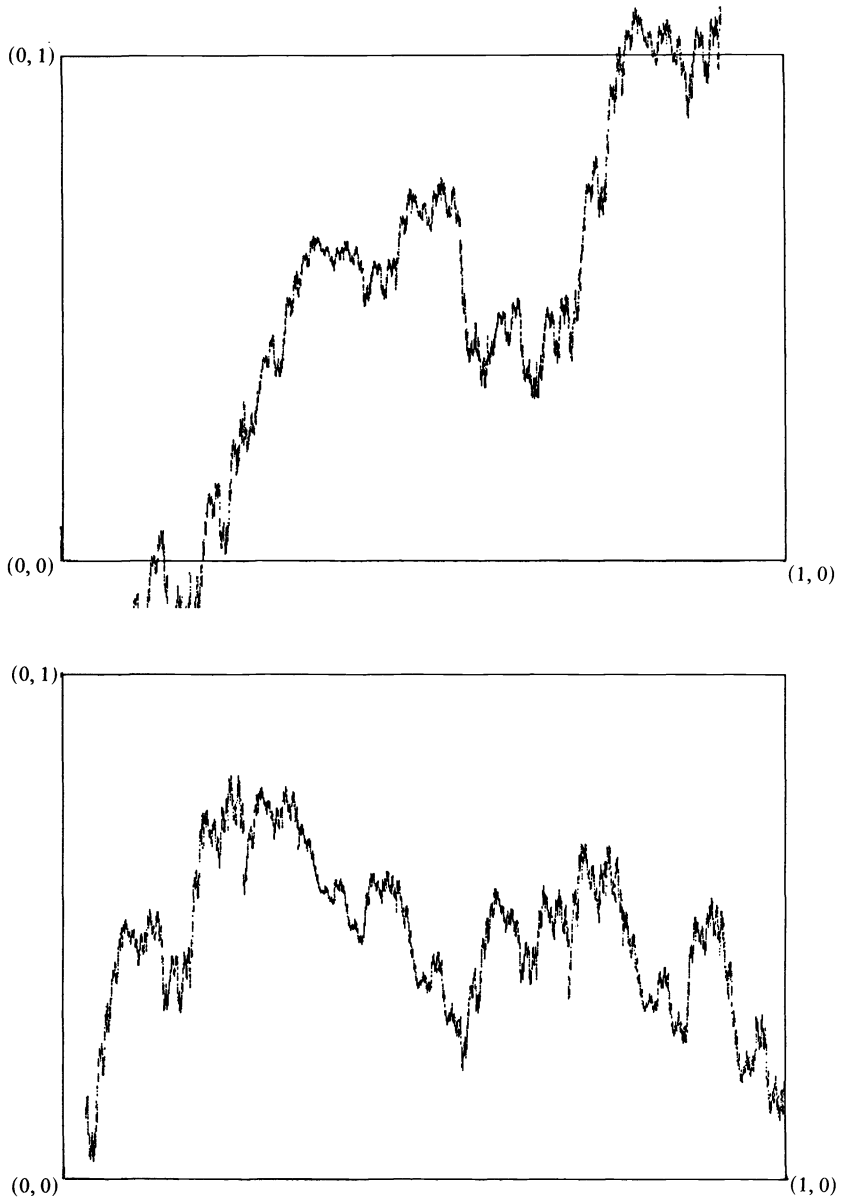

FIG. 15. *The projections of the attractor G for the* IFS *in Example* 8.

Example 11. Let $J=[0,1]$ and $K=[0,1]\times[0,1]\times[0,1]$. Define maps $W_i: J\times K$ by

$$W_i(t,X)=\begin{pmatrix} \frac{1}{4} & 0 & 0 & 0 \\ 0 & a_i & c_i & d_i \\ 0 & e_i & f_i & g_i \\ 0 & h_i & k_i & l_i \end{pmatrix}(t,X)+\begin{pmatrix} (i-1)/4 \\ \alpha_i \\ \beta_i \\ \gamma_i \end{pmatrix}$$

for all $i\in\{1,\cdots,4\}$, where the constants a_i, c_i, d_i, e_i, f_i, g_i, h_i, k_i, l_i, α_i, β_i, and γ_i are determined by (2.7) with $\{(t_j,X_j): j\in\{0,\cdots,4\}\}=\{(0,0,0,0),\ (\frac{1}{4},\frac{1}{4},\sqrt{3}/8,\sqrt{6}/6),$

$(\frac{1}{2}, \frac{1}{2}, \sqrt{3}/4, \sqrt{6}/6), (\frac{3}{4}, \frac{3}{4}, \sqrt{3}/4, 0), (1, 1, 0, 0)\}$. Then $s_1 = s_2 = s_3 = s_4 = \frac{1}{2}$ and $b_1 = b_2 = b_3 = b_4 = \frac{1}{4}$. Hence $d = 1.5 < 2 - \frac{1}{3} = \frac{8}{3}$.

The following example due to M. Berger shows that if (3.2a) does not hold, then (4.5) need not be true.

Example 12. Let $J = [0, 1]$ and $K = [0, 1] \times [0, 1]$ and define maps $W_i: J \times K$ by

$$W_i(t, X) = \begin{pmatrix} b_i & 0 & 0 \\ 0 & b_i & 0 \\ 0 & \Delta y_i & a_i \end{pmatrix} (t, X) + \begin{pmatrix} x_{i-1} \\ X_{i-1} \end{pmatrix}$$

where $X_i = \binom{x_i}{y_i}$, $b_i = x_i - x_{i-1}$, $\Delta y_i = y_i - y_{i-1}$, and $|a_i| < 1$, for all $i \in \{1, \cdots, N\}$, for some positive integer $N > 1$. Suppose further that (4.1) holds.

From Theorem 4 we know then that the attractor A of the IFS $(J \times K, W_i, i \in \{1, \cdots, N\})$ is the graph G of a continuous function (see also Example 1) and that $d = \dim(G)$ satisfies $\sum_{i=1}^{N} |a_i| b_i^{d-1} = 1$. For all $\varepsilon > 0$ we can choose a_i and b_i such that $2 - d < \varepsilon$. Let g be the projection of G onto the ty-plane. Then g is identical to G since the scalings along the t-axis are the same as along the x-axis. Hence $\dim(g) = \dim(G) = d$, and we see that (4.5) need not hold.

Acknowledgments. We thank Dr. Marc Berger for providing Example 12 and Norman Fickel for correcting an error in the proof of Theorem 4.

THE DIMENSION SPECTRUM OF THE MAXIMAL MEASURE*

ARTUR O. LOPES†

Abstract. A variety of complicated fractal objects and strange sets appears in nonlinear physics. In diffusion-limited aggregation, the probability of a random walker landing next to a given site of the aggregate is of interest. In percolation, the distribution of voltages across different elements in a random-resistor network (see [T. Halsey et al., *Phys. Rev. A* (3), 33 (1986), pp. 1141-1151]) may be of interest. These examples can be better analyzed by dividing certain objects in pieces labeled by indexes, but that leads to working with fractal sets and the notion of dimension [Halsey et al. (1986)].

The dimension spectrum of a system has been introduced and measured experimentally, and a substantial literature in physics addresses this topic. In several important cases, rigorous proofs of the results presented in [Halsey et al. (1986)] have been established.

Here, rigorous mathematical proofs of some results in this theory are given, specifically for the maximal entropy measure of a hyperbolic rational map in the complex plane. In this case the fractal object is the Julia set (see [H. Brolin, *Ark. Mat.*, 6 (1966), pp. 103-114], [A. Freire, A. Lopes, and R. Mañé, *Bol. Soc. Brasil Mat.*, 14 (1983), pp. 45-62]), which has been extensively studied in the physics literature.

Key words. Hausdorff dimension, entropy, maximal measure, rational maps, pressure, spectrum of dimension, large deviation

AMS(MOS) subject classification. 58F11

0. Introduction. In recent years the role of the concept of dimension has been investigated by several authors in trying to understand nonconservative dynamical systems.

The possibility of an infinite number of generalized dimensions of fractals appears in a natural way in the context of relevent physical problems of critical phenomena. This topic is particularly active in the physics literature. Such problems appear in the configuration of Ising models, percolation clusters, and fully developed turbulence. In general, we can describe such models by dividing the object into pieces and rescaling. In this situation we very often obtain several different values of dimension.

We are interested in developing the thermodynamic formalism for chaotic repellers obtained from hyperbolic rational maps in the complex plane and its relation to the spectrum of dimensions.

The same problem for attractors has been investigated in [9]. In general, an attractor can have an arbitrarily fine-scaled interwoven structure of hot and cold spots (high and low probability densities). By hot and cold spots we mean points on the attractor for which the frequency of visitation to the region for typical orbits is either much greater than average (a hot spot) or much less than average (a cold spot). In these several different points we can have different local values of dimension, and the aim of this theory is to understand the situation globally.

Now we will explain more carefully the situation we are going to consider. We will analyze the dimension spectrum of the maximal measure (sometimes called the balanced measure) [1], [8], [17] of a hyperbolic rational map f on the complex plane

$$f(z)=\frac{P(z)}{Q(z)}$$

where P and Q are complex polynomials.

The dimension spectrum of a system was introduced and measured experimentally by Halsey et al. [10], Hentschel and Procaccia [11], and Jensen et al. [12]. See also [2], [5], [9], [26], and [27] for analyses of important cases.

In [2] and [27] the theory is applied to several different systems, among them cookie-cutter maps, and it is related to the measure of maximal entropy. In [5] critical mappings of the circle with golden rotation number are considered.

We will use thermodynamic formalism as in [27] and also classical large deviation theory as in [5] to obtain our result for the maximal measure of a hyperbolic rational map.

For each complex number z and positive real number ξ, denote by $B(z, \xi)$ the ball of center z and radius ξ in the usual norm of $\mathbf{R}^2$.

We will say that a certain measure v has exponent α on z if

$$v(B(z, \xi)) \approx \xi^{\alpha}$$

for ξ small enough. (Here $\approx$ means $\lim_{\xi \to 0} (\log v(B(z, \xi))/\log \xi) = \alpha$.)

We will also say that z scales with exponent α.

Given a measure v, one of the main goals of the Dimension Spectrum Theory is to understand the set of points that scales with exponent α.

For α fixed, the structure of such a set of points can be very complicated, and this set can also have v-measure zero and two-dimensional Lebesgue measure zero. The Hausdorff dimension gives more detailed information on how small the sets of the plane with two-dimensional Lebesgue measure zero are. When the Hausdorff dimension of a set is a noninteger number, we say that this set is a fractal. It is natural to ask, in terms of Hausdorff dimension, how small these sets are with respect to the variable α.

Experimental results in [10] and [12] have suggested that the Hausdorff dimension of such sets is a differentiable function of α, in the case of a certain measure of critical mappings of the circle with rotation number equal to the golden-mean.

We point out, as has been done in [5], that without some restrictions on the measure v, nothing interesting can be said about the problem.

A given probability v is called invariant for a map f if

$$v(f^{-1}(E)) = v(E)$$

for any set E, where the probability is defined.

If we are working in the context of statistical physics with problems in the one-dimensional $\mathbf{Z}$ lattice, and in each position we have two possibilities of spin, let us say $+$ and $-$, then the natural space to consider is the Bernoulli model $\{+, -\}^{\mathbf{Z}}$. As we do not have any reason to consider a distinguished position for the value zero in our lattice, then in our problem we will consider only probabilities that are invariant by the shift map (see [3] and [29] for more references). This is a simple motivation for considering invariant probabilities in general problems.

In cases where f is a rational map, the support of any invariant probability is the Julia set (see [4], [6], [8], [21] for definitions). In almost all the cases this set is of fractal dimension [6], [14]. There are no smooth invariant measures to consider in this situation.

Consider, for example, the map $f_{\xi} = z^2 + \xi$ when ξ is small. In this case the Julia set is a nowhere-differentiable Jordan curve for $\xi \neq 0$. In fact, the Julia set is a fractal Jordan curve for ξ inside the main cardioid of the Mandelbrot set (and $\xi \neq 0$) [6].

The Julia set can also be a Cantor set or even a combination of parts that are locally disconnected and locally connected. The Julia set can even be the all complex plane for some nonhyperbolic rational maps. In the case of hyperbolic rational maps anyway, the Julia set always has two-dimensional Lebesgue measure zero.

There is an important conjecture that claims that the hyperbolic rational maps are dense in the set of rational maps (see [21]).

In [8] and [17] it has been shown that among all invariant probabilities, there exists a special one that obtains the maximal value of the entropy (see [19], [33] for exact definitions). We will call this probability the maximal measure.

The entropy of an invariant probability is a measure of the degree of randomness of the system given by the action of the map f and the invariant probability we are considering. In this case the maximal measure is the more chaotic one.

Following the principle that in the absence of external thermal sources nature tends to maximize entropy, we can see the maximal measure as some kind of Gibbs state. If we must take into account external sources, we are then led to consider maximal pressure probabilities (see [3], [29] for interesting considerations about this). In § 1, for some other reasons, we will have to consider maximal pressure probabilities.

We will denote by u the maximal measure for a hyperbolic rational map. We point out that, in [8] and [17], the results are for general rational maps, and hyperbolicity is not assumed.

Here we will develop all the theory to show the following theorem.

THEOREM. *Consider u the maximal measure of a hyperbolic rational map; then the Hausdorff dimension of the set of points that scale with exponent α is a real analytic function of the variable α.*

We will relate these concepts of scaling exponents with the pressure, the Legendre transform of the pressure, entropy, and large deviation. In fact, one of the main ingredients of the proof is the close relation of pressure and free-energy (see § 1 for definitions). This relationship is explored in a more general context in [16].

The analogous claim for nonhyperbolic rational maps is not always true. In [26] an example of a quadratic polynomial is shown such that there exists a point α where there is no differentiability. In this situation we can say, using an analogy with statistical physics, that phase transition exists.

The theorem stated here can also be seen as a statement concerning the nonexistence of phase transitions for the maximal entropy measure of a hyperbolic rational map.

A natural question to ask is, why do large deviation techniques appear in the understanding of the problem? The reason is that there exists a certain δ such that for a u-almost-everywhere point z in the Julia set, the point z scales with exponent δ (see [22], [20]). This follows basically from properties related to the Birkhoff Ergodic Theorem [19]. If we want to consider a certain fixed α different from the above-mentioned δ and look for the set of points z that scales with exponent α, then we are in part not covered by the Birkhoff Ergodic Theorem. The above-mentioned theorem is a result on mean values and, therefore, in considering deviations of the mean, we must use large deviation techniques. We refer the reader to Ellis [7] for references concerning large deviation. We can find the general theory of ergodic theory and thermodynamic formalism in Walters [33], Mañé [19], and Ruelle [29], [30].

Several results are known for the maximal measure [1], [8], [13]–[15], [17], [18], [20], [22]. In particular, the moments of this measure can be obtained by a three-term relation from the coefficients of the rational map (see [1], [13]). The three-term relation is a consequence of the functional equation that the complex potential generated by

the maximal measure satisfies around infinity [13]. This functional equation is known as the Bochner equation in the case of polynomial maps [1]. In the case where the rational map is not a polynomial, the functional equation has another form (see [13], [14]). There are several connections of such results with Classical Potential Theory [31], [4], [13]. In particular, [4] and [13] show that this maximal measure is the charge distribution in the Julia set if and only if f is a polynomial.

The degree of the rational map f will be denoted by d. We will also denote by J the Julia set. The entropy of the maximal measure is $\log d$ [8], [17].

We will show here that, in fact, the set of points that scale with exponent α can be considered as the support of another measure (different from u, and we will not lose dimensionality with this procedure (see the proof of Theorem 4)). We refer the reader to [9]–[12] and [26] for some applications of the spectrum of dimension theory to statistical mechanics.

It is worthwhile mentioning the following heuristic analogy. In problems of physics, when we can apply renormalization techniques, in general, it is because we have some good self-similar properties. We can take a partition of the object we want to consider, and from this partition, by some well-defined procedure, we can obtain another with some additional coarse information. Now, the procedure is repeated with the new partition. If we have some good self-similar properties, we can expect to have with this procedure microscopic information from the macroscopic information. In this case, scaling properties appear in a natural way. The spectrum of dimension techniques are suitable for application in this situation. Perhaps one reason this theory works well for a rational map f is because we can think of the inverse branches of f as a natural way to obtain new partitions. Because these inverse branches are holomorphic, we have good self-similarity properties that come from the conformality and from the Koebe Distortion Theorem (see [8]).

Here is the structure of this paper. In § 1 we will introduce the main properties of ergodic theory and large deviations that we will use. In § 2 we will present the main theorem and give an outline of the proof. In § 3 we will give the formal proof of the main theorem.

1. Ergodic theory and large deviation. Let $M(f)$ be the set of invariant probabilities for f, that is, the set of measures v such that $v(f^{-1}(A)) = v(A)$ for any set A in the Borel sigma-field of $\mathbf{R}^2$. The support of all these measures is J.

DEFINITION 1. For a Hölder continuous $g: J \to \mathbf{R}$ and $v \in M(f)$, we will define the pressure of v with respect to g by

$$h(v) + \int g(z)\, dv(z)$$

where $h(v)$ denotes the entropy of v. We will denote such an expression by $P(v, g)$.

DEFINITION 2. We will call $P(g) = \sup \{P(v, g) | v \in M(f)\}$ the topological pressure of the function g.

In the case where f is hyperbolic, there exists a unique measure that attains such supremum. This measure is ergodic. These measures are sometimes called Gibbs measures [3], [29], [30]. There exist examples of C^k maps such that this supremum is not attained (see references in [19], [33]).

DEFINITION 3. In the case where there exists a unique probability in $M(f)$, denoted by $v(g)$, such that $P(g) = h(v(g)) + \int g(z) d(v(g))(z)$ we will call this measure the maximal pressure measure for $g: J \to \mathbf{R}$. When f is hyperbolic, this is always the case [3], [28].

DEFINITION 4. For g constant and equal to zero, the maximal pressure measure is called the maximal measure.

Let z_0 be a point in the Riemann sphere, and for each $n \in \mathbf{N}$, let us denote by $z(n, i, z_0)$, $i \in \{1, 2, \cdots, d^n\}$ the d^n-solutions (with multiplicity) of the equation

$$f^n(z) = z_0.$$

We denote the delta Dirac measure on z by $\delta(z)$.

Let $u(n, z_0)$ be the probability

$$d^{-n} \sum_{i=1}^{d^n} \delta(z(n, i, z_0)).$$

In [8] and [17], it has been shown that for any z_0 (but at most two exceptional points), and independent of z_0, there exists the weak limit

$$\lim_{n\to\infty} u(n, z_0) = u,$$

and the measure u is the maximal measure of the rational map f. Hyperbolicity is not assumed to obtain this result. Also, u is ergodic and has entropy $\log d$. We will denote z_i^n the $z(n, i, z_0)$ for a certain fixed z_0.

DEFINITION 5. For any real $t \in \mathbf{R}$ we will denote $P(t) = P(g)$, when $g(z) = -t \log |f'(z)|$.

From [23] and [24] it is known that $P(t)$ is convex and real analytic in the variable t when f is hyperbolic.

DEFINITION 6. For a given probability v we will call the Hausdorff dimension of the measure v, denoted by $\mathrm{HD}(v)$, the value $\inf\{\mathrm{HD}(A) | v(A) = 1, A \text{ a Borel set in } J\}$. Here $\mathrm{HD}(A)$ is the Hausdorff dimension of the set A.

DEFINITION 7. For any real $t \in \mathbf{R}$ we will denote $u(t)$ as the maximal pressure measure for $g(z) = -t \log |f'(z)|$.

It also follows from [20], [22], and [24] that if f is hyperbolic, then

$$P'(t) = -\int \log |f'(z)| d(u(t))(z) = -h(u(t)) \cdot (\mathrm{HD}(u(t)))^{-1}.$$

THEOREM 1 [20]. *Let f be a rational map and let $v \in M(f)$ be an ergodic probability; then there exists a Borel set A such that $v(A) = 1$, and for all $z \in A$,*

$$\lim_{r\to 0} \frac{\log v(B(z, r))}{\log r} = h(v)\left(\int \log |f'(z)| \, dv(z)\right)^{-1} = \mathrm{HD}(v)$$

where $B(z, r)$ denotes the disk of radius r and center at z.

THEOREM 2 [28]. *If f is a hyperbolic rational map, then*

$$P(t) = \lim_{n\to\infty} \frac{1}{n} \log \sum_{i=1}^{d^n} |(f^n)'(z_i^n)|^{-t}.$$

In § 2 we will explain why we need the pressure in this formulation.

Let $W = \{W_n : n = 1, 2, 3, \cdots\}$ be a sequence of random variables that are defined on probability spaces $\{(\tau_n, \mathcal{F}_n, P_n), n = 1, 2, \cdots\}$ and that take values in $\mathbf{R}$, where τ_n is a set, $\mathcal{F}_n$ a σ-field, and P_n a probability.

Here we will consider $\tau_n = J$, and $\mathcal{F}_n$ the Borel σ-field on J, $n \in \mathbf{N}$.

DEFINITION 8. For each $n \in \mathbf{N}$ define

$$c_n(t) = n^{-1} \log E_n\{\exp tW_n\}$$

where E_n is the expected value with respect to P_n.

We will consider in this case the weak topology in the space of signed-measures in J.

The following hypotheses are assumed to hold:

(a) Each function $c_n(t)$ is finite for all $t \in \mathbf{R}$.

(b) $c(t) = \lim_{n\to\infty} c_n(t)$ exists and is finite for all $t \in \mathbf{R}$.

(c) $c(t)$ is differentiable as a function of $t \in \mathbf{R}$.

THEOREM 3 [7]. *Assume hypotheses* (a), (b), *and* (c) *hold, and denote for each compact Borel set K in E*

$$Q_n(K) = P_n\{z \in J | n^{-1} W_n \in K\} \quad \text{and} \quad I(z) = \sup_{t\in\mathbf{R}} \{zt - c(t)\}, \quad z \in \mathbf{R}.$$

Then the following conclusion holds:

$$\lim_{n\to\infty} n^{-1} \log Q_n(K) = -\inf_{z\in K} \{I(z)\}.$$

DEFINITION 9. The function $c(t)$ is called the free energy of W_n.

DEFINITION 10. The function $I(z)$ is called the deviation function of the process [7]. In fact it is the Legendre transform of $c(t)$. The function $I(z)$ contains information about the deviations of the mean of the process.

2. An outline of the proof of the main theorem. Some ideas presented here were adapted from ideas in [5] and [27].

It follows from [8] that in the hyperbolic case, for any $z \in J$ (this is not a u-almost-everywhere statement), there exists

$$\lim_{\varepsilon\to 0} \lim_{n\to\infty} n^{-1} \log u(B(z, n, \varepsilon)) = -\log d$$

where $B(z, n, \varepsilon) = \{y \in J | j \in \{0, 1, \cdots, n-1\}, |f^j(y) - f^j(z)| < \varepsilon\}$.

It is also true in the hyperbolic case that the diameter $d(z, \nu, \varepsilon)$ of $B(z, n, \varepsilon)$ is of the order $|(f^n)'(z)|^{-1}$, for any $z \in J$, for n large and ε small [8], [22].

Therefore, if we ask whether z is such that $u(B(z, \xi)) \approx \xi^\alpha$, it is natural to consider the above definition.

DEFINITION 11. Let $J(\alpha)$ be the set of points $z \in J(f)$ such that there exists the limit

$$\lim_{n\to\infty} n^{-1} \log |(f^n)'(z)|^{-\alpha} = -\log d.$$

In this case, $u(B(z, n, \varepsilon))$ is of order $d(z, n, \varepsilon)^\alpha$. When we use arguments of [20] it follows that this is equivalent to requiring that z satisfies

$$\lim_{\xi\to 0} \frac{\log u(B(z, \xi))}{\log \xi} = \alpha.$$

DEFINITION 12. Let $\mathfrak{f}(\alpha)$ be the Hausdorff dimension of the set $J(\alpha)$.

THEOREM 4. *Suppose f is a hyperbolic rational map and u the maximal measure. Then for a given α, there exists a unique $t \in \mathbf{R}$ such that $P'(t) = -\log d/\alpha$, and $\mathfrak{f}(\alpha) = \mathrm{HD}(u(t))$, where $u(t)$ is the maximal pressure measure for $-t \log |f'(z)|$. The function $\mathfrak{f}$ is real analytic on α.*

We will now give an outline of the proof of Theorem 4 as we mentioned in the Introduction.

The proof is divided in two parts; this is very characteristic of large deviation results [7]. We must deal with the lower bound and the upper bound in separate cases.

In the first part, we show $f(\alpha) \geqq \mathrm{HD}(u(t))$, where t satisfies a Legendre condition of the form $P'(t) = -\log d/\alpha$. This part can be seen as an application of the formula

$\mathrm{HD}(v) = h(v)/\int \log |f'(z)| dv(z)$ (that is true for any invariant measure v [20], [22]) and the Manning-McCluskey picture, which means in our case that $\mathfrak{f}(\alpha)$ is the Legendre transform of the pressure [24].

The pressure contains information about $u(t)$ in the form

$$P'(t) = -\int \log |f'(z)| d(u(t))(z).$$

This information is about the Lyapunov number of $u(t)$. Using this information we obtain a set with dimension $\mathrm{HD}(u(t))$ such that for any point z on it, the measure u scales with exponent α in z. This set is the support of the measure $u(t)$. In this way we show $\mathfrak{f}(\alpha) \geqq \mathrm{HD}(u(t))$.

Now, in the second part, it is more difficult to show that $\mathfrak{f}(\alpha) \leqq \mathrm{HD}(u(t))$.

We will try to give a heuristic idea of the proof, even under the risk of oversimplifying some more difficult and subtle parts of the demonstration. First, to have a geometrical picture of the problem, consider for simplification $f(z) = z^2 + \xi z$, when ξ is small. In this case $d = 2$. Note that zero is a fixed point of f. The main ideas of the proof are presented in this simplified case. The Julia set in this situation is a nowhere-differentiable Jordan curve. This curve is very close to the unitary circle and the dynamics of f is very similar to that of z^2 on the unitary circle (they are in fact topologically conjugated). Now consider a nonself-intersecting curve γ_1^0, from zero to ∞, cutting the Julia set in the unique fixed point in this set. Taking pre-images of this curve, we obtain the new curves γ_1^1 and γ_2^1. The Julia set without these two curves has two connected components denoted by A_1^1 and A_2^1, each one with u-measure $d^{-1} = \frac{1}{2}$.

Now consider γ_1^2, γ_2^2, γ_3^2, and γ_4^2, the pre-images of the curves γ_1^1 and γ_2^1. Now the Julia set without these four curves has four connected components denoted by A_1^2, A_2^2, A_3^2, and A_4^2. Each of these components has measure $d^{-2} = 2^{-2}$. Repeating the procedure inductively, we obtain at level n, a total of $d^n = 2^n$ curves $\gamma_1^n, \gamma_2^n, \cdots, \gamma_{2^n}^n$. The Julia set without these 2^n curves has 2^n connected components denoted by $A_1^n, A_2^n, \cdots, A_{2^n}^n$, each one with u-measure $2^{-n} = d^{-n}$. If we select an initial point z_0 not in γ_1^0, then we can suppose that in each A_i^n, $i \in \{1, 2, \cdots, 2^n\}$ there exists one and only one $z(n, i, z_0)$ (see the notation in § 1).

Now we look at level n, which has the elements of the partition $A_1^n, A_2^n, \cdots, A_{2^n}^n$ that contains elements z such that $|f^{n'}(z)|^{-\alpha}$ is of order d^{-n}. By the Koebe Distortion Theorem (see [8]) we conclude (in fact, we have to consider subsets of the A_i^n, $i \in \{1, \cdots, 2^n\}$, but we do not want to be too technical here in § 2) that if A_i^n contains a z such as the one above, then the $z(n, i, z_0)$ contained in A_i^n also has this property.

Note that from the Birkhoff Ergodic Theorem (concerning mean values) and the Shannon-McMillan-Breiman Theorem (about entropy of partitions), almost all the $z(n, i, z_0)$ should satisfy

$$|f^{n'}(z(n, i, z_0))|^{-\mathrm{HD}(u)}$$

and be of order d^{-n}. This is a simplified way to look at the formula

$$\mathrm{HD}(u) = \frac{h(u)}{\int \log |f'(z)| \, du(z)}.$$

Therefore, the large deviation here appears to give information on how many elements $z(n, i, z_0)$, $i \in \{1, 2, \cdots, 2^n\}$ deviate from the mean and satisfy that $|(f^n)'(z(n, i, z_0))|^{-\alpha}$ is of order d^{-n}.

Here it becomes clear why we must consider the pressure $P(t)$ in the formulation given by Theorem 2. We must consider the random variable given by $-\log|f^{n'}(z)|$ in the pre-orbits of z_0 at level n. At this moment the close relation of $c(t)$ and $P(t)$, which we will explain in § 3, is essential.

The diameter of each element A_i^n of the partition is of order $|f^{n'}(z(n, i, z_0))|^{-1}$, where $z(n, i, z_0)$ is the only pre-image of z_0 at level n in A_i^n.

From the considerations above, we can cover the set of points that scale with exponent α with a controlled number of elements of the partition, and we also have control of the diameter of the elements of the partition that we are using to cover the set $J(\alpha)$. This partition can be obtained with a diameter as small as we want. The value $\mathrm{HD}(u(t))$ (it appears here as information that comes from a Legendre transform) is exactly the value that we must consider for the Hausdorff measure to be finite. In this way we prove finally that $\mathcal{f}(\alpha) \leqq \mathrm{HD}(u(t))$.

The above explanation is not exactly as the proof will be done, but it gives a good idea of the main ingredients of the demonstration.

3. Proof of the main theorem. Here we will show the proof of the following theorem.

THEOREM. *Suppose f is a hyperbolic rational map and u is the measure of maximal entropy. Then for a given α, there exists a unique $t \in \mathbf{R}$ such that $P'(t) = -\log d/\alpha$ and $\mathcal{f}(\alpha) = \mathrm{HD}(u(t))$, where $u(t)$ is the maximal pressure measure for $-t\log|f'(z)|$. The function $\mathcal{f}$ is real analytic in the variable α.*

Proof. (a) $\mathcal{f}(\alpha) \geqq HD(u(t))$.

For a given α, from the convexity and analyticity of $P(t)$ (see [28]), we have that there exists a unique t such that $P'(t) = -\log d/\alpha$. For this value of t, consider $u(t)$ the maximal pressure measure for the function $g = -t\log|f'|$. From the ergodic theorem we have that for a set A such that $u(t)(A) = 1$, for all $z \in A$,

$$\lim_{n\to\infty} \frac{1}{n} \log|(f^n)'(z)|^{-1} = -\int \log|f'(z)| d(u(t))(z) = P'(t) = -\frac{\log d}{\alpha}.$$

Therefore

$$\lim_{n\to\infty} n^{-1} \log|f^{n'}(z)|^{-\alpha} = -\log d$$

and $A \subset J(\alpha)$.

As the Hausdorff dimension of $u(t)$ is infimum of the Hausdorff dimension of all sets of measure zero, we have $\mathcal{f}(\alpha) \geqq \mathrm{HD}(u(t))$.

(b) $\mathcal{f}(\alpha) \leqq \mathrm{HD}(u(t))$.

Now we will use a large deviation property as introduced in § 1.

Consider for each $n \in \mathbf{N}$ the measure $u(n, z_0)$ as defined in § 1.

We will denote z_i^n the $z(n, i, z_0)$ to make the notation simpler. To apply Theorem 3, consider $\tau_n = J$, $\mathcal{F}_n =$ Borel σ-field on J, and $P_n = u(n, z_0)$. Consider also the random variable $W_n = -\log|f^{n'}(z)|$.

From Theorem 3 we have that

$$\lim_{n\to\infty} n^{-1} \log \sum_{i=1}^{d^n} |f^{n'}(z_i^n)|^{-t} = P(t)$$

$$= \sup_{v \in M(f)} \left\{ h(v) - t \int \log|f'(z)|\, dv(z) \right\}.$$

Therefore

$$c(t) = \lim_{n\to\infty} n^{-1} \log E_n\{\exp t\, W_n\}$$

$$= \lim_{n\to\infty} n^{-1} \log d^{-n}\left(\sum_{i=1}^{d^n} |f^{n'}(z_i^n)|^{-t}\right) = P(t) - \log d.$$

This relation of pressure and free energy is essential for the rest of the proof.

From the differentiability with respect to t of $P(t)$ [16], [19], we have that for any $\beta \in \mathbf{R}$ and $\xi > 0$

$$\lim_{n\to\infty} n^{-1} \log P_n\{n^{-1} W_n \in (\beta - \xi, \beta + \xi)\}$$

is almost equal to $-I(\beta)$, where $I(\beta) = \sup_{s\in R}\{s\beta - c(s)\}$.

Therefore for $\beta = -\log d/\alpha$, we have $I(\beta) = t\beta - c(t)$, where $c'(t) = -\log d/\alpha$.

As $P'(s) = c'(s)$ for any $s \in \mathbf{R}$, we remark that t is the same one obtained in part (a) of this proof.

Therefore, $I(\beta) = -t\int \log|f'(z)| d(u(t))(z) - h(u(t)) + t\int \log|f'(z)| d(u(t))(z) + \log d = \log d - h(u(t))$.

Therefore

$$\lim_{n\to\infty} \log P_n\{n^{-1} W_n \in (-\log d\alpha^{-1} - \xi, -\log d\alpha^{-1} + \xi)\}$$

is approximately equal to $h(u(t)) - \log d$. In this case

$$d^{-n} \# \{z_i^n | i \in \{1, \cdots, d^n\}, n^{-1} \log |f^{n'}(z_i^n)|^{-1} \in (-\log d\alpha^{-1} - \xi, -\log d\alpha^{-1} + \xi)\}$$

is of order $\exp((h(u(t)) - \log d)n)$, and finally

$$\# \left\{ z_i^n | i \in (1, \cdots, d^n\} \text{ and } |f_i^{n'}(z_i^n)|^{-1} \in \left(\exp\left(\left(-\frac{\log d}{\alpha} - \xi\right)n\right), \exp\left(\left(-\frac{\log d}{\alpha} + \xi\right)n\right)\right)\right\}$$

is of order

$$(*) \qquad \exp(h(u(t)) - (\log d)n) \exp(\log d^n) = \exp(h(u(t))n).$$

As mentioned in § 2, this information allows us to control the number of points with a certain deviation of the mean.

Now we will state some properties of hyperbolic rational maps that are proved in [8] and [18].

Considering perhaps a finite iterate of f, we know from [18] that there exists a curve δ containing all the critical values of f such that:

(a) $u(\delta) = 0$.

(b) $\hat{X} = \mathbf{C} - \delta$ is a topological disk.

(c) There exist branches $\phi_i : \hat{X} \to \bar{\mathbf{C}}$, $i = 1, \cdots, d$, of $f^{-1}|\hat{X}$ that are injective and $f(\hat{X}_i) = \hat{X}$ where $\hat{X}_i = \phi_i(\hat{X})$.

(d) The set $X = (\cap_{n\geqq 0} f^{-n}(\cap_{m\geqq 0} f^m(\hat{X}^c)))^c$ has u-measure zero, and satisfies

$$f^{-1}(X) = X.$$

(e) Set $X_i = \hat{X}_i \cap X$; then the disjoint union $X = \cup_{i=1}^d X_i$ is such that if $n \leqq 1$, $1 \leqq i_j \leqq d$, $j = 1, \cdots, n$, we have d^n sets of the form $(\cap_{j=1}^n f^{-j}(X_{i_j}))$. Let us denote each such set by A_i^n, $i \in \{1, \cdots, d^n\}$.

From [18] we have $u(A_i^n) = d^n$.

(f) We can suppose there exists just one z_i^n in each A_i^n because we can obtain u as $\lim_{n\to\infty} u(n, z_0)$ and this limit does not depend on z_0.

Now let us return to the proof of the theorem. First we will show that $J(\alpha) \cap X$ has dimension smaller than $\mathrm{HD}(u(t))$, where X depends on the curve δ. Then we move the curve δ a little and we obtain the same result. By the injectivity (c) we have that these $J(\alpha) \cap X$ cover $J(\alpha)$ when we consider several different disjoint curves δ, and from this it follows that $f(\alpha) \leqq \mathrm{HD}(u(t))$.

Now we will show that $J(\alpha) \cap X$ has dimension smaller than $\mathrm{HD}(u(t))$ for any curve δ. This will be obtained in the following way. Consider a conformal representation $\phi : X \to D_1$ and $X(r) = \phi^{-1}(D_r)$ (where $D_r = \{z \in \mathbf{C} \mid |z| < r\}$, $0 \leqq r \leqq 1$). Consider also for each A_i^n, $i \in \{1, 2, \cdots, d^n\}$, the corresponding $A_i^n(r)$ such that $A_i^n(r) = f^{-n}(X_r)$ for some branch f^{-n} and $A_i^n(r) \subset A_i^n$, and assume $\phi(z_i^n) = 0$.

We will first show $J(\alpha) \cap \{\cap_{n\geqq 0} f^{-n}(\hat{X}(r))\}$ has dimension smaller than $HD(u(t))$. Note that $J(\alpha)$ is invariant by f. In this case, using the same proof presented in [32] for Theorem 4 and in [25] for Theorem 1.1, we conclude that $\lim_{r\to 1} \mathrm{HD}(J(\alpha) \cap (\cap_{n\geqq 0} f^{-n}(\hat{X}(r)))) = \mathrm{HD}(J(\alpha) \cap X) \leqq \mathrm{HD}(u(t))$. Therefore, it is enough to show that $\mathrm{HD}(J(\alpha) \cap (\cap_{n\geqq 0} f^{-n}(\hat{X}(r))) \leqq \mathrm{HD}(u(t))$, and we will show this now.

From the distortion theorem for univalent functions [8], there exist $c_r, C_r > 0$ such that for n large enough

$$(**) \qquad c_r < |(f^n)'(t)|\,|(f^n)'(z)|^{-1} < C_r$$

for any t, z in $A_i^n(r)$. It also follows from [8] that for any $\xi > 0$, there exists $K > 0$ such that for n large enough, if $D(n, i, \xi)$ is the ball of center z_i^n and radius $K|(f^n)'(z_i^n)|^{-(1-\xi)}$, then

$$(***) \qquad D(n, i, \xi) \supset A_i^n.$$

Consider $Y = J(\alpha) \cap X$. Then for each $z \in Y \cap f^{-n}(\hat{x}(r))$ such that $|(f^n)'(z)|^{-\alpha}$ is of order d^{-n} we have that z is in a certain $A_{i_j}^n(r)$ and therefore from (**)

$$|(f^n)'(z_i^n)|^{-\alpha} \text{ and } |(f^n)'(z)|^{-\alpha} \text{ are of order } d^{-n}.$$

The cardinal of such possible z_i^n is of the order $\exp(h(u(t))n)$ from (*). It is also true that such z is in $D(n, i, \xi)$ from (***).

Now let us remember some properties of $\mathrm{HD}(Y)$. From each $\mathbf{T} > 0$ consider

$$\mathrm{HD}_{\mathbf{T}}(Y) = \lim_{\delta\to 0} \mathrm{HD}_{\mathbf{T},\delta}(Y) = \inf_{\substack{Y \subset \cup B_i \\ \operatorname{diam} B_i \leqq \delta}} \sum (\operatorname{diam} B_i)^T$$

where B_i are balls in $\mathbf{C}$.

We also know that if for all $\mathbf{T} > \mathrm{HD}(u(t))$ we have $H_{\mathbf{T}}(Y)$ finite, then $\mathrm{HD}(Y) \leqq \mathrm{HD}(u(t))$.

Now observe that for each $n \in \mathbf{N}$, Y is contained in $\exp(h(u(t)n))$ balls of radius $K|(f^n)'(z_i^n)|^{-(1-\xi)}$, and $|(f^n)'(z_i^n)|^{-1}$ is of order $\exp(-\log d \cdot n \cdot \alpha^{-1})$. For each n the sum

$$\sum (\operatorname{diam} D(n, i, \varepsilon))^T \leqq K \exp(h(u(t))n) \exp(-T \log d \cdot n \cdot \alpha^{-1}(1-\varepsilon))$$
$$= K \exp(h(u(t)) - \mathbf{T} \log d\alpha^{-1}(1-\varepsilon)n).$$

For

$$\mathbf{T} > \mathrm{HD}(u(t)) = h(u(t)) \left(\int \log |f'(t)| du(t) \right)^{-1} = -h(u(t)) P'(t)^{-1}$$

$$= h(u(t)) \cdot \alpha (\log d)^{-1}$$

we have that the above sum is uniformly bounded. As the diameter $D(n, i, \varepsilon)$ goes to zero [8] because f is hyperbolic, we have

$$\mathrm{HD}\left(J(\alpha) \cap \left(\bigcap_{n \geqq 0} f^{-n}(\hat{X}(r)) \right) \right) \leqq \mathrm{HD}(u(t))$$

and finally the theorem is proved.

The analyticity of $f(\alpha)$ follows from the analyticity of $P(t)$ [23], [28].

As we have mentioned in the Introduction, no dimensionality is lost by considering the support of $u(t)$ instead of $J(\alpha)$ because, as we have just shown, the two sets have the same Hausdorff dimension.

Acknowledgments. We thank P. Collet for supplying us with references on the subject and J. Yorke for some helpful conversations on the topic.

SUPERADDITIVE FUNCTIONS AND A STATISTICAL APPLICATION*

S. Y. TRIMBLE†, JIM WELLS‡, AND F. T. WRIGHT§

Abstract. It is shown that the reciprocals of a class of Laplace transforms are superadditive. This is used to establish the uniqueness of maximum likelihood estimates for a statistical inference problem.

Key words. superadditive, Laplace transform, gamma function, maximum likelihood estimates

AMS(MOS) subject classifications. 26D15, 33A15, 62H12

1. Introduction. In this paper we show that, for $p \geqq 2$ and for x and y in $(0, \infty)$,

$$\frac{1}{\sum_{k=0}^{\infty}(1/(x+k)^p)} + \frac{1}{\sum_{k=0}^{\infty}(1/(y+k)^p)} < \frac{1}{\sum_{k=0}^{\infty}(1/(x+y+k)^p)}. \tag{1}$$

This will follow as a special case of the superadditivity of a class of reciprocals of Laplace transforms, as established in Theorem 2. The special case of (1) when $p=2$ is used to establish the strict concavity of $\log[L(r, s)]$, where

$$L(r, s) := \left[\frac{\Gamma(r+s)}{\Gamma(r)\Gamma(s)} G_1^{r-1} G_2^{s-1}\right]^n.$$

(Here, Γ denotes the gamma function, G_1 and G_2 are both positive, $G_1+G_2<1$, and n is an integer.) This, in turn, will establish the uniqueness of the maximum likelihood estimates of the parameters in the beta distribution.

First, we present a new and simple characterization of a subclass of the completely monotonic functions.

2. Strongly completely monotonic functions. Recall that a real-valued function g is *completely monotonic on* $(0, \infty)$ if and only if $(-1)^n g^{(n)}(x) \geqq 0$, where $0<x<\infty$ and $n=0, 1, 2, \cdots$. We are interested in the more restrictive condition:

$$\begin{aligned}&(-1)^n x^{n+1} g^{(n)}(x) \text{ is nonnegative and nonincreasing for } 0<x<\infty\\ &\text{and } n=0, 1, \cdots.\end{aligned} \tag{2}$$

Such functions will be called *strongly completely monotonic on* $(0, \infty)$. As an example, the function $g(x)=1/x^2$ is strongly completely monotonic in $(0, \infty)$; however, the function $g(x)=e^{-x}$ is completely monotonic, but not strongly completely monotonic.

THEOREM 1. *The function g is strongly completely monotonic on* $(0, \infty)$ *if and only if*

$$g(x) = \int_0^{\infty} e^{-xt}\phi(t)\, dt, \tag{3}$$

where ϕ *is nonnegative and nondecreasing, and where the integral converges for all x in* $(0, \infty)$.

Proof. If g is given by (3), then

$$(4)\qquad \begin{aligned}(-1)^n x^{n+1} g^{(n)}(x) &= x^{n+1}\int_0^\infty t^n e^{-xt}\phi(t)\,dt \\ &= \int_0^\infty \tau^n e^{-\tau}\phi\left(\frac{\tau}{x}\right)d\tau \geqq 0,\end{aligned}$$

because $\phi(x)\geqq 0$. Furthermore, the left side is a nonincreasing function of x because $\phi(x)$ is nondecreasing.

Conversely, suppose g is strongly completely monotonic on $(0,\infty)$. Then g is completely monotonic and, according to a representation theorem of Bernstein [5, p. 161], there is a nondecreasing (not necessarily bounded) α such that

$$g(x)=\int_0^\infty e^{-xt}\,d\alpha(t) \qquad (0<x<\infty).$$

Furthermore, we may assume that α is normalized, that is, $\alpha(0)=0$ and $\alpha(x)=(\alpha(x-)+\alpha(x+))/2$ for $0<x<\infty$ [5, pp. 13-14]. Using the Post-Widder inversion formula [5, p. 290], it follows that

$$\alpha(t)-\alpha(0+)=\lim_{n\to\infty}\int_0^t (-1)^n\left(\frac{n}{u}\right)^{n+1} g^{(n)}\left(\frac{n}{u}\right)du$$

for all t in $(0,\infty)$. From (2), it follows that the integrands are nondecreasing functions of u. Hence the integrals, and consequently α itself, are convex functions of t. The properties of convex functions imply that there is a nonnegative and nondecreasing function ϕ such that $\alpha'(t)=\phi(t)$ except, possibly, for a countable set on $(0,\infty)$. Representation (3) follows. □

3. A class of superadditive functions. Let

$$\mathcal{F}=\{f: f \text{ is a continuous, real-valued, nonnegative function defined on } [0,\infty) \text{ satisfying } f(0)=0\}.$$

If $f\in\mathcal{F}$, then f is said to be *superadditive* provided that, for x and y in $(0,\infty)$,

$$(5)\qquad f(x+y)\geqq f(x)+f(y).$$

Beckenback [1, p. 424] remarked that "tests for superadditivity appear to be difficult to establish, and more difficult to apply." In this section and the next, we establish a test for superadditivity and apply it to a problem in statistical inference.

If $f\in\mathcal{F}$, then f is said to be *star-shaped* provided that, for α in $(0,1)$ and x in $(0,\infty)$,

$$f(\alpha x)\leqq \alpha f(x).$$

This is equivalent to saying that

$$(6)\qquad f(x)/x \text{ is nondecreasing on } (0,\infty).$$

It follows from (6) that

$$f(x+y)=x\frac{f(x+y)}{x+y}+y\frac{f(x+y)}{x+y}\geqq x\frac{f(x)}{x}+y\frac{f(y)}{y}=f(x)+f(y).$$

Hence, if f is star-shaped, it is also superadditive. (See Hardy, Littlewood, and Polya [4, p. 83] and Bruckner and Ostrow [2, pp. 1207-1209].) We remark that, if $f(x)/x$ is strictly increasing on $(0,\infty)$, then strict inequality always holds in (5).

THEOREM 2. *Suppose g is strongly completely monotonic and $xg(x)$ does not reduce to a constant, i.e., ϕ is not constant in* (3). *Define f by $f(0)=0$ and $f(x)=1/g(x)$ if $0<x<\infty$. Then f is star-shaped and therefore superadditive. Furthermore, strict inequality always holds in* (5).

Proof. Let $n=0$ in (2). Then $xg(x)$ is nonnegative and nonincreasing, and (6) holds for f. An analysis of (4) shows that $xg(x)$ is strictly decreasing if and only if ϕ is not a constant function. The remarks after (6) complete the proof of this theorem. □

To illustrate, suppose $p \geqq 2$. For $t>0$, we define

$$\phi_p(t) = t^{p-1}/(1-e^{-t}).$$

If we set $\phi_p(0)=0$ for $p>2$ and $\phi_2(0)=1$, it follows that ϕ_p is a continuous, increasing function on $[0,\infty)$. Furthermore, if $x>0$, the Lebesgue monotone convergence theorem implies that

$$\begin{aligned}\int_0^\infty e^{-xt}\phi_p(t)\,dt &= \int_0^\infty \sum_{k=0}^{\infty} t^{p-1}\,e^{-(x+k)t}\,dt \\ &= \sum_{k=0}^{\infty}\int_0^\infty t^{p-1}\,e^{-(x+k)t}\,dt \\ &= \Gamma(p)\sum_{k=0}^{\infty}\frac{1}{(x+k)^p}.\end{aligned}$$

An application of Theorem 2 yields (1) in the Introduction.

It is worth observing that (1) fails for p in the interval $(1,2)$. Indeed, if $1<p<2$, it can be shown that there is a positive number $n(p)$ such that (1) is reversed if x and y are in the interval $(n(p),\infty)$.

In the next section, we shall need the special case of (1) when $p=2$. We then have an inequality concerning the psi (digamma) function, $\psi(x)=\Gamma'(x)/\Gamma(x)$, since $\psi'(x)=\sum_{k=0}^{\infty}1/(x+k)^2$. Actually, $1/\psi'(x)$ is more than superadditive: it is convex on $(0,\infty)$. This fact, which we shall not need in the sequel, follows from a rather tedious argument that establishes the inequality $(\psi'')^2 \geqq \frac{1}{2}\psi'\psi'''$. This derivative inequality is equivalent to

$$\sum_{k=0}^{\infty}\frac{1}{(x+k)^3} \geqq \frac{\sqrt{3}}{2}\left(\sum_{k=0}^{\infty}\frac{1}{(x+k)^2}\right)^{1/2}\left(\sum_{k=0}^{\infty}\frac{1}{(x+k)^4}\right)^{1/2},$$

an inequality of the form

$$\sum a_k b_k \geqq C\sqrt{\sum a_k^2}\,\sqrt{\sum b_k^2}$$

with $a_k=1/(x+k)$, $b_k=1/(x+k)^2$, and $C=\sqrt{3}/2$. Thus the convexity of $1/\psi'(x)$ may be formulated as an inverse Cauchy-Schwartz inequality.

4. A statistical inference problem. Suppose we model a random phenomenon using a beta distribution that has probability density function given by

$$f(x;r,s)=\frac{\Gamma(r+s)}{\Gamma(r)\Gamma(s)}x^{r-1}(1-x)^{s-1}, \qquad 0 \leqq x \leqq 1.$$

Here, r and s are positive numbers to be chosen later. Suppose that $X_1, X_2, \cdots, X_n$ is a random sample. The likelihood for this sample is

$$L(r,s;x_1,x_2,\cdots,x_n)=\prod_{i=1}^{n} f(x_i;r,s)=\left[\frac{\Gamma(r+s)}{\Gamma(r)\Gamma(s)}G_1^{r-1}G_2^{s-1}\right]^n, \tag{7}$$

where $G_1=[\prod_{i=1}^n x_i]^{1/n}$ and $G_2=[\prod_{i=1}^n (1-x_i)]^{1/n}$.

One way of choosing r and s is to find their values that maximize the right side of (7), these being the maximum likelihood estimates. If $G_1 = 0$ or $G_2 = 0$, the right side of (7) can be made infinite by choosing r or s less than 1. So it is natural to assume that $G_1 > 0$ and $G_2 > 0$, which is not a severe restriction because the probability of this happening is 1.

Gnanadesikan, Pinkham, and Hughes [3] have studied the maximum likelihood estimates for (7) but have not addressed the question of the existence and uniqueness of such a solution. This question is important because, in practice, the maximum likelihood estimates are often found by using iterative techniques. Gnanadesikan, Pinkham, and Hughes do observe that $G_1 + G_2 \leqq 1$ with equality if and only if $x_1 = x_2 = \cdots = x_n$, which occurs with probability 0. So, we could assume

$$G_1 + G_2 < 1, \tag{8}$$

which, like our earlier restrictions on G_1 and G_2, would not be severe. In fact, the next result shows that there is also a mathematical reason for assuming (8).

THEOREM 3. *The logarithm of the likelihood function* (7) *is strictly concave on* $(0, \infty) \times (0, \infty)$. *Hence, it has at most one local extremum, which must, if it exists, be an absolute maximum. In fact, the likelihood function has an absolute maximum if and only if* (8) *holds.*

Proof. We write the left side of (7) simply as $L(r, s)$, and view it as defined on $(0, \infty) \times (0, \infty)$. The Hessian matrix of $-\log L(r, s)^{1/n}$ is

$$\begin{bmatrix} \psi'(r) - \psi'(r+s) & -\psi'(r+s) \\ -\psi'(r+s) & \psi'(s) - \psi'(r+s) \end{bmatrix}.$$

The diagonal elements of this matrix are positive on $(0, \infty) \times (0, \infty)$ because ψ' is strictly decreasing, and the determinant is positive on $(0, \infty) \times (0, \infty)$ because of (1). Hence, the matrix is positive definite. Consequently, $\log L(r, s)$ is strictly concave on $(0, \infty) \times (0, \infty)$ and has a local extremum at no more than one point. If this extremum exists, it is necessarily an absolute maximum.

A point will produce a local extremum of $L(r, s)$ if and only if the partial derivatives of $\log L(r, s)$ are both zero there. This requirement yields the following system:

$$\begin{aligned} \psi(r) - \psi(r+s) &= \log G_1, \\ \psi(s) - \psi(r+s) &= \log G_2. \end{aligned} \tag{9}$$

To investigate (9), we establish (10) and (11) below.

Suppose that g is a function defined on $(0, \infty)$ such that $r \leqq g(r)$ for all r. Then $g(r) = r + n(r) + \theta(r)$, where $n(r)$ is a nonnegative integer and $0 \leqq \theta(r) < 1$. Now $\psi(x+1) = \psi(x) + (1/x)$ for $x > 0$. So, for q a nonnegative integer, $\psi(x+q) = \psi(x) + \sum_{k=0}^{q-1} 1/(x+k)$. (If $q = 0$, define $\sum_{k=0}^{q-1} 1/(x+k) = 0$.) If $r \geqq 1$, it follows that

$$\begin{aligned} \log \frac{g(r)-1}{r} &< \log \frac{g(r)-\theta(r)}{r} = \log \frac{r+n(r)}{r} \\ &= \int_0^{n(r)} \frac{dx}{r+x} \leqq \sum_{k=0}^{n(r)-1} \frac{1}{r+k} = \psi(r+n(r)) - \psi(r) \\ &\leqq \psi(g(r)) - \psi(r). \end{aligned} \tag{10}$$

In a similar manner, if $r > 1$,

$$\psi(g(r)) - \psi(r) < \log \frac{g(r)}{r-1}. \tag{11}$$

Without loss of generality, suppose $\log G_2 \geqq \log G_1$. Subtracting the equations in (9) we conclude that, if r and s satisfy (9), we must have

$$\psi(s) - \psi(r) = \log G_2/G_1 \geqq 0. \tag{12}$$

Since ψ is strictly increasing, (12) can be regarded as defining a function $s(r)$ that satisfies $s(r) \geqq r$ for r in $(0, \infty)$. Then (10)-(12) imply that

$$\lim_{r\to\infty} \frac{s(r)}{r} = \frac{G_2}{G_1}. \tag{13}$$

Further, (10), (11), and (13) imply that

$$\lim_{r\to\infty} [\psi(r+s(r)) - \psi(r)] = \log(1 + G_2/G_1). \tag{14}$$

Now $\psi'(x+1) = \psi'(x) - 1/x^2$. Since $\psi'(x+1) > 0$, it follows that $\psi'(x) > 1/x^2$. So $\psi(r+s(r)) - \psi(r) \geqq \psi(2r) - \psi(r) = \int_r^{2r} \psi'(x)\,dx > 1/(2r)$. Hence,

$$\lim_{r\to 0+} [\psi(r+s(r)) - \psi(r)] = +\infty. \tag{15}$$

From (14) and (15), we conclude that the equation

$$\psi(r+s(r)) - \psi(r) = -\log G_1 \tag{16}$$

is satisfied for some r if $-\log G_1 > \log(1 + G_2/G_1)$, i.e., $1 > G_1 + G_2$. Furthermore, if $\psi(r+s(r)) - \psi(r)$ is a strictly decreasing function of r on $(0, \infty)$, then (16) is satisfied for some r if and only if $1 > G_1 + G_2$, i.e., if and only if (8) holds. Since (12) and (16) are equivalent to (9), it only remains to show that $\psi(r+s(r)) - \psi(r)$ is strictly decreasing. But using (1), (12), and the implicit function theorem, we see that

$$\frac{d}{dr}[\psi(r+s(r)) - \psi(r)] = \psi'(r)\psi'(r+s(r))\left[\frac{1}{\psi'(r)} + \frac{1}{\psi'(s(r))} - \frac{1}{\psi'(r+s(r))}\right] < 0. \qquad \square$$

APPLICATIONS OF A TECHNIQUE FOR EVALUATING INDEFINITE INTEGRALS CONTAINING PRODUCTS OF THE SPECIAL FUNCTIONS OF PHYSICS*

JEAN C. PIQUETTE†

Abstract. An earlier article [J. C. Piquette and A. L. Van Buren, *SIAM J. Math. Anal.*, 15 (1984), pp. 845-855] described an analytical technique for evaluating indefinite integrals involving special functions. The technique replaces the integral by an inhomogeneous set of coupled first-order differential equations. This coupled set does not explicitly contain the special functions of the integrand, and any particular solution of the set is sufficient to obtain an analytical result for the indefinite integral. One difficulty with the technique is that the process of uncoupling one of the functions of the set from the remainder is not straightforward and, in some instances, may be intractable. In the present article, the relevant set is uncoupled for a number of special cases in which the integrand contains one or more Bessel functions, Legendre functions, Hermite functions, or Laguerre functions. The utility of the given analytical expressions is demonstrated by presenting several examples. Several of the indefinite integrals evaluated have not been previously tabulated.

1. Introduction. A previous article [1] presented an analytical technique for evaluating indefinite integrals of the form

$$I = \int dx f(x) \prod_{i=1}^{m} R_{\mu_i}^{(i)}(x) \tag{1}$$

where $R_{\mu_i}^{(i)}(x)$ is of the ith type of special functions of order μ_i obeying the set of recurrence relations

$$R_{\mu+1}^{(i)}(x) = a_\mu(x) R_\mu^{(i)}(x) + b_\mu(x) R_{\mu-1}^{(i)}(x), \tag{2a}$$

$$DR_\mu^{(i)}(x) = c_\mu(x) R_\mu^{(i)}(x) + d_\mu(x) R_{\mu-1}^{(i)}(x). \tag{2b}$$

Here a_μ, b_μ, c_μ, and d_μ are known functions corresponding to $R_\mu^{(i)}$. The symbol D represents d/dx. The function $f(x)$ and the product $\prod R_\mu^{(i)}$ both are assumed continuous (or with at most a finite number of discontinuities) over an interval $[x_1, x_2]$, ensuring that the integral I exists in the same interval. The technique is a generalization of one used by Sonine [2] (described by Watson [3]) to evaluate indefinite integrals involving products of Bessel functions. Piquette and Van Buren [1] extended the technique to include most of the special functions of physics, including Legendre functions, Hermite functions, and Laguerre functions. The technique replaces the integral that is to be evaluated by an inhomogeneous set of coupled first-order differential equations. The coupled set does not explicitly contain any of the special functions $R_\mu^{(i)}$, and *any particular solution* of the set is sufficient to yield an analytical expression for the integral I. Here we use the term "birecurrent functions" that was introduced in [1] for the functions $R_\mu^{(i)}$.

The method of [1] assumes that the integral I of (1) may be represented by

$$I = \sum_{p_1=0}^{1} \sum_{p_2=0}^{1} \cdots \sum_{p_m=0}^{1} A_{p_1 p_2 \cdots p_m}(x) \prod_{i=1}^{m} R_{(\mu_i+p_i)}^{(i)}(x), \tag{3}$$

* Received by the editors March 9, 1987; accepted for publication (in revised form) November 18, 1988.

† Naval Research Laboratory, Underwater Sound Reference Detachment, P.O. Box 568337, Orlando, Florida 32856-8337.

where the 2^m coefficients $A_{p_1 p_2 \cdots p_m}(x)$ are functions to be determined. The technique replaces the integral I with the coupled set of differential equations

$$f(x)\delta_{0,p} = DA_p + \sum_{\{q\}} B_{pq} A_q, \tag{4}$$

where δ is a Kronecker delta defined to be zero unless $p_1 = p_2 = \cdots = p_m = 0$. In (4), the shorthand notation $A_p = A_{p_1 p_2 \cdots p_m}(x)$ and $B_{pq} = B_{p_1, p_2, \cdots, p_m, q_1, q_2, \cdots, q_m}(x)$ has been used. Also, the notation $\sum_{\{q\}}$ represents the multiple summations $\sum_{q_1=0}^{1} \sum_{q_2=0}^{1} \cdots \sum_{q_m=0}^{1}$. The functions B_{pq} are known functions resulting from repeated applications of the relations of (2) and the regrouping of terms in the form $\prod_{i=1}^{m} R_{\mu_i + p_i}^{(i)}$. An analytical expression for the functions B_{pq} appears in a subsequent publication [4].

One difficulty with the technique is that the process of uncoupling one function A_p from the remainder of the set is not straightforward, and may be intractable in certain cases. To increase the general utility of the method, the present article provides uncoupled equations for several special cases in which the integrand involves one or more Bessel functions, Legendre functions, Hermite functions, or Laguerre functions. The usefulness of the expressions is demonstrated by obtaining solutions to the uncoupled equations in several particular cases, thereby obtaining the associated indefinite integrals. Several of these have not been previously tabulated.

2. Integrands containing one birecurrent function. First we will consider integrals of the general form

$$I = \int dx f(x) R_\mu(x). \tag{5}$$

In this case, the assumed form generated by (3) reduces to

$$I = A_0(x) R_\mu(x) + A_1(x) R_{\mu+1}(x). \tag{6}$$

The resulting coupled set obtained from (4) is

$$\begin{aligned} &-A_0(x)[a_\mu(x)d_\mu(x) - b_\mu(x)c_\mu(x)] \\ &\quad + b_\mu(x)DA_0(x) + b_\mu(x)d_{\mu+1}(x)A_1(x) = b_\mu(x)f(x), \end{aligned} \tag{7a}$$

$$d_\mu(x)A_0(x) + b_\mu(x)DA_1(x) + b_\mu(x)c_{\mu+1}(x)A_1(x) = 0. \tag{7b}$$

Note in this case that, since (7b) does not contain DA_0, this equation can be solved algebraically for A_0 in terms of A_1 and DA_1. This expression may be substituted into (7a) to yield an uncoupled equation for A_1. Since we have used generic expressions for the functions a, b, c, and d, it is clear that the coupled set (7a, b) can always be uncoupled regardless of which particular function R_μ is contained in (5). Therefore, the method always results in a set that can be uncoupled when it is applied to integrals containing a single birecurrent function. Of course, obtaining a particular solution to the resulting uncoupled inhomogeneous differential equation is not straightforward. However, a number of special cases have been considered successfully in [1]. Also, the uncoupled equations for the special cases where R_μ represents either a Bessel, a Legendre, a Hermite, or a Laguerre function are also given in [1]. Therefore, we will not consider this case further in the present article.

3. Integrands containing two Legendre functions. Unlike the case considered in § 2, the coupled set for the case in which the integrand contains two arbitrary birecurrent

functions cannot be uncoupled for the general case in a straightforward way. In this section, we consider the particular case in which the integral of interest is of the form

$$I = \int dx f(x) P_\mu(x) P_\nu(x), \tag{8}$$

where P can be either the first or the second solution to the Legendre differential equation. For the moment, we restrict our attention to cases in which $\mu \neq \nu$. In this case, the general assumed form generated by (3) yields the expression

$$\begin{aligned} I = {} & A_{00}(x) P_\mu(x) P_\nu(x) + A_{01}(x) P_\mu(x) P_{\nu+1}(x) \\ & + A_{10}(x) P_{\mu+1}(x) P_\nu(x) + A_{11}(x) P_{\mu+1}(x) P_{\nu+1}(x). \end{aligned} \tag{9}$$

The function A_{11} can be uncoupled from the coupled set obtained from (4) to give

$$\begin{aligned} & (x^2-1)^2 D^4 A_{11}(x) + 10x(x^2-1) D^3 A_{11}(x) \\ & \quad -2(4-\mu-\nu+\mu x^2+\nu x^2+\mu^2 x^2+\nu^2 x^2-\mu^2-\nu^2-12x^2) D^2 A_{11}(x) \\ & \quad -6x(-2+\mu+\nu+\mu^2+\nu^2) D A_{11}(x) \\ & \quad +(\mu+\nu)(-1+\mu-\nu)(1+\mu-\nu)(2+\mu+\nu) A_{11}(x) \\ & = 2(1+\mu)(1+\nu) D f(x). \end{aligned} \tag{10}$$

The remaining functions A can be expressed in terms of $A_{11}(x)$ and its derivatives. The expressions are

$$\begin{aligned} A_{00}(x) = {} & \frac{-x}{1+\mu+\nu} f(x) - \frac{(x^2-1)}{(\mu-\nu)(1+\mu+\nu)} D f(x) \\ & + g_{000}(x) A_{11}(x) + g_{001}(x) D A_{11}(x) + g_{002}(x) D^2 A_{11}(x) \\ & + g_{003}(x) D^3 A_{11}(x) + g_{004}(x) D^4 A_{11}(x), \end{aligned} \tag{11}$$

$$\begin{aligned} A_{01}(x) = {} & \frac{-(1+\nu)}{(\mu-\nu)(1+\mu+\nu)} f(x) + g_{010}(x) A_{11}(x) + g_{011}(x) D A_{11}(x) \\ & + g_{012}(x) D^2 A_{11}(x) + g_{013}(x) D^3 A_{11}(x), \end{aligned} \tag{12}$$

$$\begin{aligned} A_{10}(x) = {} & \frac{(1+\mu)}{(\mu-\nu)(1+\mu+\nu)} f(x) + g_{100}(x) A_{11}(x) + g_{101}(x) D A_{11}(x) \\ & + g_{102}(x) D^2 A_{11}(x) + g_{103}(x) D^3 A_{11}(x). \end{aligned} \tag{13}$$

The parametric functions g in (11)-(13) are given by

$$\begin{aligned} g_{000}(x) = {} & [\mu+\nu+\mu\nu+\mu\nu^2-2\nu x^2+\mu^2\nu \\ & +\mu^2\nu^2-\nu^2x^2+2\nu^3x^2+\nu^4x^2-\mu\nu x^2-4\mu\nu^2x^2 \\ & -\mu\nu^3x^2+2\mu^2\nu x^2-\mu^2\nu^2x^2+\mu^3\nu x^2+\mu^2-2\nu^3-\nu^4] \\ & \div[(1+\mu)(1+\nu)(\mu-\nu)(1+\mu+\nu)], \end{aligned} \tag{14}$$

$$\begin{aligned} g_{001}(x) = {} & -x[12-12\nu-3\mu\nu^2-4\mu x^2+16\nu x^2 \\ & +3\mu^2\nu+3\mu^2x^2+\mu^3x^2+9\nu^2x^2-\nu^3x^2 \\ & +3\mu\nu^2x^2-3\mu^2\nu x^2-3\mu^2-\mu^3-9\nu^2+\nu^3-12x^2] \\ & \div[2(1+\mu)(1+\nu)(\mu-\nu)(1+\mu+\nu)], \end{aligned} \tag{15}$$

$$(16)\quad g_{002}(x)=-\frac{[(x^2-1)(8-\mu-3\nu-5\mu x^2+9\nu x^2+\mu^2x^2+3\nu^2x^2-\mu^2-3\nu^2-24x^2)]}{2(1+\mu)(1+\nu)(\mu-\nu)(1+\mu+\nu)},$$

$$(17)\quad g_{003}(x)=\frac{x(-1+x^2)^2(10+\mu-\nu)}{2(1+\mu)(1+\nu)(\mu-\nu)(1+\mu+\nu)},$$

$$(18)\quad g_{004}(x)=\frac{(-1+x^2)^3}{2(1+\mu)(1+\nu)(\mu-\nu)(1+\mu+\nu)},$$

$$(19)\quad g_{010}(x)=\frac{-\mu x(1+\mu-\nu)(2+\mu+\nu)}{(1+\mu)(\mu-\nu)(1+\mu+\nu)},$$

$$(20)\quad g_{011}(x)=-\frac{[2-3\mu-\nu+3\mu x^2+\nu x^2+3\mu^2x^2+\nu^2x^2-3\mu^2-\nu^2-6x^2]}{2(1+\mu)(\mu-\nu)(1+\mu+\nu)},$$

$$(21)\quad g_{012}(x)=\frac{3x(-1+x^2)}{(1+\mu)(\mu-\nu)(1+\mu+\nu)},$$

$$(22)\quad g_{013}(x)=\frac{(-1+x^2)^2}{2(1+\mu)(\mu-\nu)(1+\mu+\nu)},$$

$$(23)\quad g_{100}(x)=\frac{\nu x(1-\mu+\nu)(2+\mu+\nu)}{(1+\nu)(\mu-\nu)(1+\mu+\nu)},$$

$$(24)\quad g_{101}(x)=\frac{[2-\mu-3\nu+\mu x^2+3\nu x^2+\mu^2x^2+3\nu^2x^2-\mu^2-3\nu^2-6x^2]}{2(1+\nu)(\mu-\nu)(1+\mu+\nu)},$$

$$(25)\quad g_{102}(x)=\frac{-3x(-1+x^2)}{(1+\nu)(\mu-\nu)(1+\mu+\nu)},$$

$$(26)\quad g_{103}(x)=\frac{-(-1+x^2)^2}{2(1+\nu)(\mu-\nu)(1+\mu+\nu)}.$$

Although the expressions above are complicated, they are straightforward to evaluate, with the exception of (10), the differential equation for A_{11}. However, recall that *any particular solution* of (10) is adequate for obtaining the integral of (8). There are several cases in which this is not difficult to do.

For example, if $f(x)=1$ in (8), the inhomogeneous term in (10) vanishes. Therefore, a particular solution to (10) is simply $A_{11}(x)=0$. Substituting this into (11)-(26) immediately yields the indefinite integral

$$(27)\quad \int dx\, P_\mu(x)P_\nu(x)=\frac{-xP_\mu(x)P_\nu(x)}{1+\mu+\nu}-\frac{(1+\nu)}{(\mu-\nu)(1+\mu+\nu)}P_\mu(x)P_{\nu+1}(x)+\frac{(1+\mu)}{(\mu-\nu)(1+\mu+\nu)}P_{\mu+1}(x)P_\nu(x)$$

when the resulting expressions for A_{00}, A_{01}, and A_{10} are substituted into (9). An integral equivalent to (27) can be found, for example, in [5].

The differential equation (10) can also be solved for most functions $f(x)$ of the form x^l, where l is a natural number, thus yielding the antiderivative

$$(28)\quad I=\int dx\, x^lP_\mu(x)P_\nu(x).$$

A particular solution to (10) for $f(x)=x^l$ can be represented by the truncated series

$$A_{11}(x)=\sum_{p}^{l-1}{}' b_p x^p. \tag{29}$$

In (29), the quantities b_p are constants given by

$$b_{l-1}=\frac{(2l)(1+\mu)(1+\nu)}{(\mu+\nu+l+1)(\mu+\nu-l+1)[(\mu-\nu)^2-l^2]}, \tag{30a}$$

$$b_p=-\frac{(p+1)(p+2)\{(p+3)(p+4)b_{p+4}(1-\delta_{p,l-3})+2b_{p+2}[\mu+\nu+\mu^2+\nu^2-(p+2)^2]\}}{(\mu+\nu+p+2)(\mu+\nu-p)[(\mu-\nu)^2-(p+1)^2]} \tag{30b}$$

$$(0\leqq p<l-1).$$

The prime on the summation in (29) signifies that $p=0, 2, \cdots, l-1$ when l is odd, and $p=1, 3, \cdots, l-1$ when l is even. The particular case $l=0$ is excluded, but note that this case is covered by (27). The orders μ and ν are arbitrary (and may even be complex), except for the particular cases in which the denominators in (30) vanish. The desired antiderivative corresponding to any particular value of l is obtained by substituting the resulting expression for A_{11} into (11)-(26). The results of these calculations are then substituted into (9). This process is difficult to perform for the general case. However, one particular case is

$$\begin{aligned}\int dx\, x^5 P_{1/3}(x)P_{2/3}(x)=&\left(-\frac{335}{2352}-\frac{515x^2}{392}+\frac{235x^4}{336}+\frac{x^6}{3}\right)P_{1/3}(x)P_{2/3}(x)\\&+\left(\frac{685x}{784}-\frac{575x^3}{1176}-\frac{5x^5}{48}\right)P_{1/3}(x)P_{5/3}(x)\\&+\left(\frac{235x}{196}-\frac{295x^3}{588}-\frac{2x^5}{21}\right)P_{2/3}(x)P_{4/3}(x)\\&+\left(-\frac{5}{6}+\frac{65x^2}{196}+\frac{25x^4}{588}\right)P_{4/3}(x)P_{5/3}(x).\end{aligned} \tag{31}$$

The uncoupled equations given by (10)-(26) are not valid if $\mu=\nu$. In this special case a different uncoupling scheme is required. The uncoupled set for this case is given by

$$\begin{aligned}&(-1+x^2)^2D^3A_{11}(x)+6x(-1+x^2)D^2A_{11}(x)\\&\quad-2(1-2\nu+2\nu x^2+2\nu^2x^2-2\nu^2-3x^2)DA_{11}(x)\\&\quad-4\nu(\nu+1)xA_{11}(x)=2(\nu+1)^2f(x),\end{aligned} \tag{32}$$

$$A_{00}(x)=\frac{(-1+x^2)^2}{2(1+\nu)^2}D^2A_{11}(x)+\frac{(-1+x^2)(2+\nu)}{(1+\nu)^2}xDA_{11}(x)+\frac{(\nu+x^2)}{(1+\nu)}A_{11}(x), \tag{33}$$

$$A_{01}(x)=-\frac{(-1+x^2)}{2(1+\nu)}DA_{11}(x)-xA_{11}(x), \tag{34}$$

and $A_{10}(x)=A_{01}(x)$. As one particular example of this case, we let $f(x)=x$; a particular solution of (32) is then $A_{11}=-(1+\nu)/2\nu$. When the resulting solutions obtained from (33) and (34) are substituted into (9), this yields the integral

$$\int dx\, x[P_\nu(x)]^2=\frac{-(1+\nu)}{2\nu}\left[\left(\frac{x^2+\nu}{1+\nu}\right)[P_\nu(x)]^2-2xP_\nu(x)P_{\nu+1}(x)+[P_{\nu+1}(x)]^2\right]. \tag{35}$$

The expressions given in (32)-(34) also apply if the integral of interest is

$$I = \int dx f(x) P_\nu(x) Q_\nu(x), \tag{36}$$

where $Q_\nu(x)$ is the second solution to Legendre's differential equation. This follows from the fact that the functions P and Q each obey the same recurrence relations. As a particular example of this, let $f(x) = x^3$ in (32). A particular solution of this differential equation is then

$$A_{11}(x) = \frac{(1+\nu)(-4+2\nu+\nu x^2+\nu^2x^2+2\nu^2)}{6\nu(1-\nu)(2+\nu)}. \tag{37}$$

Substituting this into (33) and (34), we obtain the integral

$$\begin{aligned}\int dx\, x^3 P_\nu(x) Q_\nu(x) &= -\frac{(-3\nu-4\nu x^2+6\nu x^4+\nu^2x^2+3\nu^2x^4+\nu^3x^2+2\nu^2+2\nu^3-4\nu^2)P_\nu(x)Q_\nu(x)}{6\nu(-1+\nu)(2+\nu)} \\ &\quad + \frac{x(1+\nu)(-4+\nu+2\nu x^2+\nu^2x^2+2\nu^2)}{6\nu(-1+\nu)(2+\nu)}[P_\nu(x)Q_{\nu+1}(x)+P_{\nu+1}(x)Q_\nu(x)] \\ &\quad + \frac{(1+\nu)(-4+2\nu+\nu x^2+\nu^2x^2+2\nu^2)}{6\nu(1-\nu)(2+\nu)} P_{\nu+1}(x)Q_{\nu+1}(x)\end{aligned} \tag{38}$$

when the resulting solutions for the functions A are substituted into the representation of (9).

4. Integrands containing the square of a Bessel function. We now turn our attention to integrals of the form

$$I = \int dx f(x) Z_\nu^2(x), \tag{39}$$

where Z_ν is an arbitrary cylinder function, i.e., any solution of Bessel's differential equation. In this case, (3) provides the representation

$$I = A_{00}(x)Z_\nu^2(x) + 2A_{01}(x)Z_\nu(x)Z_{\nu+1}(x) + A_{11}(x)Z_{\nu+1}^2(x). \tag{40}$$

Once again, we can uncouple A_{11} from the set generated by (4), giving

$$\begin{aligned}&x^3D^3A_{11}(x) - 3x^2D^2A_{11}(x) + x(7-4\nu^2+4x^2)DA_{11}(x) \\ &\quad + 4(-2+2\nu^2-x^2)A_{11}(x) = 2x^3f(x),\end{aligned} \tag{41}$$

$$A_{00}(x) = \frac{1}{2}D^2A_{11}(x) - \frac{(3+2\nu)}{2x}DA_{11}(x) + \frac{(2+2\nu+x^2)}{x^2}A_{11}(x), \tag{42}$$

$$A_{01}(x) = \frac{1}{2}DA_{11}(x) - \frac{(1+\nu)}{x}A_{11}(x). \tag{43}$$

As an example of this class of integrals, we first let $f(x) = 1/x^2$ in (39). Next, we consider the case in which $f(x) = 1/x^4$. The first of these examples results in the integral

$$\int \frac{Z_\nu^2(x)}{x^2}dx = \frac{1+2\nu+2x^2}{(4\nu^2-1)x}Z_\nu^2(x) - \frac{2}{-1+2\nu}Z_\nu(x)Z_{\nu+1}(x) - \frac{2x}{1-4\nu^2}Z_{\nu+1}^2(x), \tag{44}$$

and the second example yields

$$\int \frac{Z_\nu^2(x)}{x^4}\,dx = \frac{[-9-6\nu+x^2(6+16\nu+8\nu^2)+36\nu^2+24\nu^3+16x^4]}{3x^3(1-4\nu^2)(9-4\nu^2)} Z_\nu^2(x)$$

$$-\left[\frac{2(-3+4\nu+4\nu^2+8x^2)}{3x^2(1-2\nu)(9-4\nu^2)}\right] Z_\nu(x)Z_{\nu+1}(x) \tag{45}$$

$$-\frac{2(1-4\nu^2-8x^2)}{3x(1-4\nu^2)(9-4\nu^2)} Z_{\nu+1}^2(x)$$

when the particular solutions to (41) for A_{11}, given by the coefficients of the $Z_{\nu+1}^2(x)$ terms in (44) and (45), are substituted into (42) and (43), and the resulting expressions are used in (40). A result equivalent to (44) can be deduced using [6, p. 257, eq. 21], although that formula is restricted to Bessel functions of the first kind. This integral can also be found in formula (4) of [7, § 1.13.3, p. 50]. To obtain a result equivalent to (45) combine formulas (1) and (4) of [7, § 1.13.3, p. 50].

5. Integrands containing the square of a Hermite function or the square of a Laguerre function. We next consider integrals of the form

$$I = \int dx f(x) H_\nu^2(x), \tag{46}$$

where H_ν is any solution of the Hermite differential equation. In this case, (3) gives the assumed form

$$I = A_{00}(x)H_\nu^2(x) + 2A_{01}(x)H_\nu(x)H_{\nu+1}(x) + A_{11}(x)H_{\nu+1}^2(x). \tag{47}$$

The coupled set resulting from (4) may be uncoupled to yield

$$D^3A_{11}(x) + 6xD^2A_{11}(x) + 2(5+4\nu+4x^2)DA_{11}(x) + 16x(1+\nu)A_{11}(x) = 2f(x), \tag{48}$$

$$A_{00}(x) = \tfrac{1}{2}D^2A_{11}(x) + xDA_{11}(x) + 2(1+\nu)A_{11}(x), \tag{49}$$

$$A_{01}(x) = \tfrac{1}{2}DA_{11}(x). \tag{50}$$

Next consider the integral

$$I = \int dx f(x) L_\nu^2(x), \tag{51}$$

where L_ν is any solution of the Laguerre differential equation. The assumed form of the solution provided by (3) for this case is

$$I = A_{00}(x)L_\nu^2(x) + 2A_{01}(x)L_\nu(x)L_{\nu+1}(x) + A_{11}(x)L_{\nu+1}^2(x). \tag{52}$$

The coupled set generated by (4) may be uncoupled to obtain the equations

$$x^2D^3A_{11}(x) + 3x(1+x)D^2A_{11}(x)$$

$$+(1+8x+4\nu x+2x^2)DA_{11}(x) + 2(1+2x)(1+\nu)A_{11}(x) \tag{53}$$

$$= 2(1+\nu)^2 f(x),$$

$$A_{00}(x) = \frac{x^2}{2(1+\nu)^2} D^2A_{11}(x) + \frac{x(3+2\nu+x)}{2(1+\nu)^2} DA_{11}(x) + \frac{(1+\nu+x)}{1+\nu} A_{11}(x), \tag{54}$$

$$A_{01}(x) = -\frac{x}{2(1+\nu)} DA_{11}(x) - A_{11}(x). \tag{55}$$

6. Integrands containing higher powers of birecurrent functions. In addition to the special cases presented above, the general cases of integrands containing a single *arbitrary* birecurrent function raised to either the second, third, or fourth power have each been uncoupled analytically. It is reasonable to conjecture that integrands of the form

$$I = \int dx f(x)[R_\mu(x)]^n, \tag{56}$$

where n is a natural number, can always be uncoupled. However, an analytical demonstration of this has proved elusive so far.

As one example in this category, we consider the integral

$$I = \int dx f(x) Z_\nu^4(x), \tag{57}$$

where Z_ν is again any solution of Bessel's differential equation. The assumed form generated by (3) in this case yields

$$\begin{aligned} I = {} & A_{0000}(x)Z_\nu^4(x) + A_{1111}(x)Z_{\nu+1}^4(x) + 4A_{0001}(x)Z_\nu^3(x)Z_{\nu+1}(x) \\ & + 6A_{0011}(x)Z_\nu^2(x)Z_{\nu+1}^2(x) + 4A_{0111}(x)Z_\nu(x)Z_{\nu+1}^3(x). \end{aligned} \tag{58}$$

The function $A_{1111}(x)$ can be uncoupled from the set produced by (4) to give

$$\begin{aligned} & x^5 D^5 A_{1111}(x) - 10x^4 D^4 A_{1111}(x) - 5x^3(-13+4\nu^2-4x^2) D^3 A_{1111}(x) \\ & \quad + 15x^2(-19+12\nu^2-8x^2) D^2 A_{1111}(x) \\ & \quad + x(781-128\nu^2x^2-740\nu^2+64\nu^4+392x^2+64x^4) D A_{1111}(x) \\ & \quad - 64(16-6\nu^2x^2-20\nu^2+4\nu^4+9x^2+2x^4) A_{1111}(x) = 24x^5 f(x). \end{aligned} \tag{59}$$

The remaining functions A are expressed in terms of $A_{1111}(x)$ by the equations

$$\begin{aligned} A_{0000}(x) = {} & \frac{1}{24} D^4 A_{1111}(x) - \frac{(5+2\nu)}{12x} D^3 A_{1111}(x) \\ & - \frac{(-55-36\nu+4\nu^2-16x^2)}{24x^2} D^2 A_{1111}(x) \\ & + \frac{(-175-148\nu-40\nu x^2+28\nu^2+16\nu^3-84x^2)}{24x^3} D A_{1111}(x) \\ & + \frac{(32+32\nu+16\nu x^2-8\nu^2-8\nu^3+20x^2+3x^4)}{3x^4} A_{1111}(x), \end{aligned} \tag{60}$$

$$\begin{aligned} A_{0001}(x) = {} & \frac{1}{24} D^3 A_{1111}(x) - \frac{(3+2\nu)}{8x} D^2 A_{1111}(x) \\ & + \frac{(37+42\nu+8\nu^2+10x^2)}{24x^2} D A_{1111}(x) \\ & - \frac{(8+12\nu+3\nu x^2+4\nu^2+4x^2)}{3x^3} A_{1111}(x), \end{aligned} \tag{61}$$

$$A_{0011}(x) = \frac{1}{12} D^2 A_{1111}(x) - \frac{(7+6\nu)}{12x} D A_{1111}(x) + \frac{(4+6\nu+2\nu^2+x^2)}{3x^2} A_{1111}(x), \tag{62}$$

$$A_{0111}(x) = \frac{1}{4} D A_{1111}(x) - \frac{(1+\nu)}{x} A_{1111}(x). \tag{63}$$

In view of the complexity of the differential equation (59), it is difficult to obtain solutions for arbitrary orders ν. Therefore, in this case, we restrict our attention to examples of particular orders.

As one example in this category, we consider $f(x)=1/x$, $\nu=1$. A particular solution to (59) for this case is $A_{1111}(x)=x^2/4$. This produces the integral

$$\begin{aligned}\int dx\frac{Z_1^4(x)}{x}&=\frac{x^2}{4}Z_2^4(x)+\left(\frac{3}{4}+\frac{x^2}{4}\right)Z_1^4(x)-\frac{3x}{2}Z_1(x)Z_2^3(x)\\&\quad+6\left(\frac{1}{2}+\frac{x^2}{12}\right)Z_1^2(x)Z_2^2(x)+4\left(-\frac{3x}{8}-\frac{1}{2x}\right)Z_1^3(x)Z_2(x).\end{aligned}\tag{64}$$

As a second example, we let $f(x)=1/x^3$ and $\nu=3$. A particular solution to (59) can also be obtained for this case, thus yielding the integral

$$\begin{aligned}\int dx\frac{Z_3^4(x)}{x^3}&=\left(\frac{1}{24}+\frac{1}{2x^2}+\frac{2}{x^4}+\frac{x^2}{378}\right)Z_3^4(x)+\left(\frac{5}{216}+\frac{2}{27x^2}+\frac{x^2}{378}\right)Z_4^4(x)\\&\quad+4\left(-\frac{x}{108}-\frac{5}{54x}-\frac{1}{3x^3}\right)Z_3(x)Z_4^3(x)\\&\quad+6\left(\frac{7}{216}+\frac{1}{3x^2}+\frac{4}{3x^4}+\frac{x^2}{1134}\right)Z_3^2(x)Z_4^2(x)\\&\quad+4\left(-\frac{x}{108}-\frac{1}{8x}-\frac{1}{x^3}-\frac{4}{x^5}\right)Z_3^3(x)Z_4(x).\end{aligned}\tag{65}$$

Since the analytical expressions for the uncoupled equations resulting from the special cases when $n=2$, 3, 4 are extremely complicated, they will not be displayed. We will instead provide a tabulation of indefinite integrals obtained by computing particular solutions to these uncoupled equations for certain special cases. In view of the very little previous work that has been done concerning integrals containing more than two special functions, (64), (65), and the following integrals appear to be original tabulations:

$$\begin{aligned}\int dx\,x^2Z_{1/3}^3(x)&=\left(-\frac{4}{9}x-\frac{16}{81x}\right)Z_{1/3}^3(x)-(4x/3)Z_{1/3}(x)Z_{4/3}^2(x)\\&\quad+\left(\frac{8}{9}+x^2\right)Z_{1/3}^2(x)Z_{4/3}(x)+\frac{2}{3}x^2Z_{4/3}^3(x),\end{aligned}\tag{66}$$

$$\begin{aligned}\int dx\,x[P_{1/3}(x)]^3&=\left(\frac{125x^4}{12}-\frac{14}{3}x^2-\frac{5}{12}\right)[P_{1/3}(x)]^3+(-4+20x^2)P_{1/3}(x)[P_{4/3}(x)]^2\\&\quad+(9x-25x^3)[P_{1/3}(x)]^2P_{4/3}(x)-\frac{16}{3}x[P_{4/3}(x)]^3,\end{aligned}\tag{67}$$

$$\begin{aligned}\int dx\,e^{-3x^2}x^2H_{2/3}^3(x)&=e^{-3x^2}\{-\tfrac{1}{12}x(5+6x^2)H_{2/3}^3(x)+\tfrac{1}{8}(1+6x^2)H_{2/3}^2(x)H_{5/3}(x)\\&\quad-\tfrac{3}{8}xH_{2/3}(x)H_{5/3}^2(x)+\tfrac{1}{16}H_{5/3}^3(x)\},\end{aligned}\tag{68}$$

$$\begin{aligned}&\int dx\,e^{-2x^2}x^3H_{-2/3}^3(x)\\&=\frac{e^{-2x^2}}{16}\left\{\frac{9x}{4}H_{1/3}^3(x)+\frac{9}{4}(1-4x^2)H_{1/3}^2(x)H_{-2/3}(x)\right.\\&\quad\left.-9x(1-x^2)H_{1/3}(x)H_{-2/3}^2(x)+\frac{1}{4}(-8+20x^2)H_{-2/3}^3(x)\right\},\end{aligned}\tag{69}$$

$$\int dx\, e^{-3x} x L_{2/3}^3(x)$$

$$= e^{-3x}\left\{ L_{2/3}^3(x)\left[\frac{125}{24}-\frac{625x}{24}+\frac{853x^2}{16}-\frac{675x^3}{16}+\frac{225x^4}{16}-\frac{27x^5}{16}\right]\right.$$

$$+ L_{5/3}^3(x)\left[-\frac{125}{24}+\frac{125x}{12}-\frac{125x^2}{16}\right] \tag{70}$$

$$+3\left[\frac{125}{24}-\frac{125x}{8}+\frac{275x^2}{16}-\frac{75x^3}{16}\right] L_{2/3}(x) L_{5/3}^2(x)$$

$$\left.+3\left[-\frac{125}{24}+\frac{125x}{6}-\frac{515x^2}{16}+\frac{135x^3}{8}-\frac{45x^4}{16}\right] L_{2/3}^2(x) L_{5/3}(x)\right\},$$

$$\int dx\, x[P_{1/2}(x)]^4 = \left(-\frac{5}{16}-\frac{19}{4}x^2\right)[P_{1/2}(x)]^4+\frac{81}{4}xP_{1/2}(x)[P_{3/2}(x)]^3$$

$$+6\left(-\frac{9}{16}-\frac{9}{2}x^2\right)[P_{1/2}(x)]^2[P_{3/2}(x)]^2 \tag{71}$$

$$+4\left(\frac{33x}{16}+3x^3\right)[P_{1/2}(x)]^3 P_{3/2}(x)-\frac{81}{16}[P_{3/2}(x)]^4.$$

In (66)-(71), Z denotes the Bessel function, P the Legendre function, H the Hermite function, and L the Laguerre function.

Note added in proof. Since the time of writing, additional progress has been made on the uncoupling problem. A manuscript [8] describing this work has been submitted for publication.

A NONTERMINATING q-CLAUSEN FORMULA AND SOME RELATED PRODUCT FORMULAS*

GEORGE GASPER† AND MIZAN RAHMAN‡

Abstract. This paper uses Gasper's proof of Rogers' linearization formula for the continuous q-ultraspherical polynomials and a quadratic transformation formula for well-poised basic hypergeometric ${}_2\phi_1$ series to derive a nonterminating q-analogue of Clausen's formula for the square of a certain hypergeometric series. This formula is extended to a q-analogue of the Ramanujan and Bailey extension of Clausen's formula by employing the Gasper and Rahman nonterminating q-extension of the Sears–Carlitz quadratic transformation formula. Additional product formulas are derived.

Key words. basic hypergeometric series, Clausen's formula, q-analogues, Ramanujan and Bailey product formula, nonnegative functions

AMS(MOS) subject classifications. primary 33A99; secondary 26D15

1. Introduction.

Clausen's [13] formula

$$\left\{{}_2F_1\left(a,b;a+b+\frac{1}{2}x\right)\right\}^2 = {}_3F_2\left(2a,2b,a+b;2a+2b,a+b+\frac{1}{2};x\right), \tag{1.1}$$

$|x|<1$, provides a rare example of a hypergeometric series that is expressible as the square of another hypergeometric series. Ramanujan's [25] rapidly convergent series representations for $1/\pi$, one of which was employed by Gosper in 1985 to compute π to more than 17,000,000 decimal digits, are based on special cases of (1.1); see the Chudnovskys' survey paper [12]. Clausen's formula was used in Askey and Gasper [4] to prove the nonnegativity of a certain sum of Jacobi polynomials which, in turn, played an important role in de Branges' [10] celebrated proof of the Bieberbach conjecture. One might say that it was de Branges' work that revived an interest in the methods that Askey and Gasper used in their proofs of the nonnegativity of certain sums and integrals of orthogonal polynomials; see, for example, Askey [1], [2] and Gasper [14].

Current literature in special functions also reveals a vigorous interest in generalizing almost every result in ordinary hypergeometric series to basic hypergeometric series. An ${}_r\phi_s$ basic hypergeometric series in base q is defined by

$${}_r\phi_s\left[\begin{matrix}a_1,\cdots,a_r\\ b_1,\cdots,b_s\end{matrix};q,z\right] = \sum_{n=0}^{\infty}\frac{(a_1,\cdots,a_r;q)_n}{(q,b_1,\cdots,b_s;q)_n}[(-1)^n q^{\binom{n}{2}}]^{1+s-r}z^n, \tag{1.2}$$

where $\binom{n}{2} = n(n-1)/2$,

$$(a_1,a_2,\cdots,a_r;q)_n = \prod_{j=1}^{r}(a_j;q)_n \tag{1.3}$$

and $(a;q)_n$ is the q-shifted factorial defined by

$$(1.4)\qquad (a;q)_n = \begin{cases} 1, & n=0 \\ (1-a)(1-aq)\cdots(1-aq^{n-1}), & n=1,2,\cdots \end{cases}.$$

The base q is usually a complex number with absolute value less than 1. The series (1.2) terminates if one of the numerator parameters is of the form $q^{-m}, m=0,1,2,\cdots$. It is assumed there are no zero factors in the denominators of the terms of the series. If $r=s+1$ and the series does not terminate then we assume that $|z|<1$ and $|q|<1$ to ensure convergence.

Jackson [21], who spent almost all of his mathematical career in studying basic hypergeometric series, derived the following product formula

$$(1.5)\qquad {}_2\phi_1\left[\begin{matrix} q^a, & q^b \\ & q^{a+b+1/2} \end{matrix}; q, x\right] {}_2\phi_1\left[\begin{matrix} q^a, & q^b \\ q^{(a+b)/2} & \end{matrix}; q, xq^{1/2}\right]$$
$$= {}_4\phi_3\left[\begin{matrix} q^a, q^b, & q^{(a+b)/2}, & -q^{(a+b)/2} & \\ & q^{a+b}, & q^{(a+b)/2+1/4}, & -q^{(a+b)/2+1/4} \end{matrix}; q, xq^{1/2}\right],$$

where $|x|<1$ and $|q|<1$, as a q-analogue of (1.1) in the sense that it tends to Clausen's formula as $q \to 1^-$. Additional proofs of (1.5) have been given by Singh [28], Nassrallah [23], and Jain and Srivastava [22].

Unfortunately, the left side of (1.5) is not a square and so (1.5) does not have this most important property of (1.1); in particular, (1.5) cannot be used to write certain sums of basic hypergeometric series as sums of squares of basic hypergeometric series as was done in [4], [14] for hypergeometric series. Recently, the authors independently derived (see [16]) such a formula by showing that

$$(1.6)\qquad \left\{{}_4\phi_3\left[\begin{matrix} a, & b, & abz, & ab/z \\ & abq^{1/2}, & -abq^{1/2}, & -ab \end{matrix}; q, q\right]\right\}^2$$
$$= {}_5\phi_4\left[\begin{matrix} a^2, & b^2, & ab, & abz, & ab/z \\ & a^2b^2, & abq^{1/2}, & -abq^{1/2}, & -ab \end{matrix}; q, q\right]$$

provided the series terminate. The terminating case of Clausen's formula follows from (1.6) by replacing a, b, z by $q^a, q^b, e^{i\theta}$, respectively, setting $x=(1-\cos\theta)/2$, and then letting $q \to 1$. Formula (1.6) was employed in [16] to prove the nonnegativity of certain basic hypergeometric series and to derive q-analogues of the Askey–Gasper [4] inequality

$$(1.7)\qquad \frac{(\alpha+2)_n}{n!}\,{}_3F_2\left[\begin{matrix} -n, & n+\alpha+2, & \frac{\alpha+1}{2} \\ & \frac{\alpha+3}{2}, & \alpha+1 \end{matrix}; x\right] \geq 0,$$

where $0 \leq x \leq 1, \alpha \geq -2$, and $n=0,1,2,\cdots$, and of the differential equations de Branges [10], [11] used in his proof of the Bieberbach conjecture.

Since (1.6) holds only when the series terminate (see [16]), while (1.1) holds for $|x|<1$ irrespective of whether the series terminate, it is irresistible to inquire whether there is a nonterminating q-Clausen formula that gives (1.6) in the terminating case, possibly after application of a transformation formula. As was pointed out in [16], there are several ways of deriving (1.6), such as using the Rogers' [27] linearization formula for the continuous q-ultraspherical polynomials $C_n(x;\beta|q)$, the Gasper and Rahman [17] formula for the product of terminating ${}_4\phi_3$ series, or the Rahman and

Verma [24] integral representation for the product $C_n(x;\beta|q)C_n(y;\beta|q)$. Even though each of these formulas involves only terminating series, we will show that a slight modification of Gasper's proof in [15] of Rogers' linearization formula leads to the following nonterminating q-analogue of Clausen's formula (1.1):

(1.8)

$$g^2(x) = \frac{\left(axq^{1/2}/b, bxq^{1/2}/a; q\right)_\infty}{\left(xq^{1/2}/ab, abxq^{1/2}; q\right)_\infty} {}_5\phi_4\left[\begin{matrix} a^2, b^2, ab, -ab, -abq^{1/2} \\ abq^{1/2}, a^2b^2, abxq^{1/2}, abq^{1/2}/x \end{matrix}; q, q\right]$$
$$+ \frac{(qx, qx, a^2, b^2; q)_\infty}{\left(abq^{1/2}, abq^{1/2}, ab/xq^{1/2}, abxq^{1/2}; q\right)_\infty}$$
$$\cdot {}_5\phi_4\left[\begin{matrix} axq^{1/2}/b, bxq^{1/2}/a, xq^{1/2}, -xq^{1/2}, -xq \\ xq, qx^2, abxq^{1/2}, xq^{3/2}/ab \end{matrix}; q, q\right],$$

where $(a;q)_\infty = \prod_{k=0}^{\infty}(1-aq^k)$, $\quad |q|<1$, $|qx|<1$,

$$g(x) = \frac{(qa^2x^2, qb^2x^2; q^2)_\infty}{(qx^2, qa^2b^2x^2; q^2)_\infty} {}_8W_7\left(-abxq^{-1/2}; a, b, -a, -b, -x; q, -qx\right), \tag{1.9}$$

and

(1.10)

$$ {}_{r+1}W_r(a; b_1, b_2, \cdots, b_{r-2}; q, z)$$
$$= {}_{r+1}\phi_r\left[\begin{matrix} a, qa^{1/2}, -qa^{1/2}, b_1, b_2, \cdots, b_{r-2} \\ a^{1/2}, -a^{1/2}, aq/b_1, aq/b_2, \cdots, aq/b_{r-2} \end{matrix}; q, z\right].$$

When $r = s+1$ the basic hypergeometric series (1.2) is said to be balanced if $z = q$ and $b_1b_2\cdots b_s = qa_1a_2\cdots a_{s+1}$; it is called well-poised if $b_1 = qa_1/a_2$, $b_2 = qa_1/a_3, \cdots, b_s = qa_1/a_{s+1}$, and it is called very well-poised if, in addition, $a_2 = qa_1^{1/2}, a_3 = -qa_1^{1/2}$. The ${}_4\phi_3$ series in (1.6) and the ${}_5\phi_4$ series in (1.6) and (1.8) are all balanced while the series in (1.9) and (1.10) are very well-poised.

We will derive (1.8) and some equivalent forms of it in §2 and show in §3 that the Clausen's formula (1.1) is a limit case of (1.8). Also, in §4 we shall derive a q-analogue of the Ramanujan [26] and Bailey [6], [7] extension of Clausen's formula

(1.11)

$$ {}_2F_1\left[\begin{matrix} a, b \\ c \end{matrix}; \frac{1-\sqrt{1-x}}{2}\right] {}_2F_1\left[\begin{matrix} a, b \\ a+b+1-c \end{matrix}; \frac{1-\sqrt{1-x}}{2}\right]$$
$$= {}_4F_3\left[\begin{matrix} a, & b, & (a+b)/2, & (a+b+1)/2 \\ & c, & a+b, & a+b+1-c \end{matrix}; x\right]$$

which gives (1.1) when $c = a+b+\frac{1}{2}$ and the quadratic transformation

$$ {}_2F_1\left[\begin{matrix} a, b \\ (a+b+1)/2 \end{matrix}; \frac{1-\sqrt{1-x}}{2}\right] {}_2F_1\left[\begin{matrix} a/2, b/2 \\ (a+b+1)/2 \end{matrix}; x\right] \tag{1.12}$$

is used. See Askey [3].

2. Proof of (1.8). Rogers' continuous q-ultraspherical polynomials, $C_n(x;\beta|q)$, are defined by

$$C_n(x;\beta|q) = \sum_{k=0}^{n} \frac{(\beta;q)_k(\beta;q)_{n-k}}{(q;q)_k(q;q)_{n-k}} \cos(n-2k)\theta$$

$$= \frac{(\beta;q)_n}{(q;q)_n} e^{in\theta}\, {}_2\phi_1\left[\begin{matrix} q^{-n}, & \beta \\ & \beta^{-1}q^{1-n} \end{matrix}; q, q\beta^{-1}e^{-2i\theta}\right] \tag{2.1}$$

where $x = \cos\theta$ and $n = 0, 1, \cdots$. Using an induction argument, Rogers [27, p. 29] proved that

$$C_m(x;\beta|q)C_n(x;\beta|q) = \sum_{k=0}^{\min(m,n)} a_k(m,n)C_{m+n-2k}(x;\beta|q), \tag{2.2}$$

where

$$a_k(m,n) = \frac{(\beta;q)_k(\beta;q)_{m-k}(\beta;q)_{n-k}(q;q)_{m+n-2k}}{(q;q)_k(q;q)_{m-k}(q;q)_{n-k}(\beta^2;q)_{m+n-2k}}$$

$$\cdot \frac{(\beta^2;q)_{m+n-k}(1-\beta q^{m+n-2k})}{(\beta q;q)_{m+n-k}(1-\beta)}. \tag{2.3}$$

Gasper [16] deduced (1.6) from (2.2) by setting $m = n$, using Askey and Ismail's [5] ${}_4\phi_3$ series representation for $C_n(x;\beta|q)$ and the ${}_6\phi_5$ summation formula [29, IV. 9].

The key to the discovery of a nonterminating q-Clausen formula is the observation that Gasper's [15] proof of (2.2) is independent of the fact that the parameter n in the ${}_2\phi_1$ series in (2.1) is a nonnegative integer.

In view of (2.1) let

$$f(x) = {}_2\phi_1\left[\begin{matrix} \alpha, & \beta \\ & \alpha q/\beta \end{matrix}; q, qx/\beta\right] \tag{2.4}$$

which reduces to the ${}_2\phi_1$ series in (2.1) when $\alpha = q^{-n}$ and $x = e^{-2i\theta}$. Temporarily assume that $|x| \le 1$, and $|q| < |\beta| < 1$. From Heine's transformation formula [8, §8.4, Eq. (2)] it follows that

$$f(x) = \frac{(\beta x;q)_\infty}{(qx/\beta;q)_\infty}\, {}_2\phi_1\left[\begin{matrix} \alpha q/\beta^2, & q/\beta \\ & \alpha q/\beta \end{matrix}; q, \beta x\right]. \tag{2.5}$$

Multiplying the two ${}_2\phi_1$ series in (2.4) and (2.5) and collecting the coefficients of x^j we find that

$$f^2(x) = \frac{(\beta x;q)_\infty}{(qx/\beta;q)_\infty} \sum_{j=0}^{\infty} A_j \frac{(\alpha q/\beta^2, q/\beta;q)_j}{(q, \alpha q/\beta;q)_j}(\beta x)^j, \tag{2.6}$$

where

$$A_j = {}_4\phi_3\left[\begin{matrix} q^{-j}, & \beta, & \beta q^{-j}/\alpha, & \alpha \\ & \beta q^{-j}, & \beta^2 q^{-j}/\alpha, & \alpha q/\beta \end{matrix}; q, q\right] \tag{2.7}$$

is a terminating balanced series. Following [15] we now use Watson's transformation formula [8, §8.5, Eq. (2)] to express the ${}_4\phi_3$ series in (2.7) as a very well-poised ${}_8\phi_7$ series:

$$A_j = \frac{(\alpha q/\beta, \alpha^2 q/\beta^2; q)_j}{(\alpha^2 q/\beta, \alpha q/\beta^2; q)_j}\, {}_8W_7\left(\alpha^2/\beta; \alpha, \alpha, \beta, \alpha^2 q^{j+1}/\beta^2, q^{-j}; q, q/\beta\right). \tag{2.8}$$

Using (2.8) in (2.6) immediately leads to the formula

$$\begin{aligned} f^2(x) = {} & \frac{(\beta x; q)_\infty}{(qx/\beta; q)_\infty} \sum_{k=0}^{\infty} \frac{(\alpha^2/\beta; q)_k (1 - \alpha^2 q^{2k}/\beta)(\alpha, \alpha, \beta; q)_k}{(q; q)_k (1 - \alpha^2/\beta)(\alpha q/\beta, \alpha q/\beta, \alpha^2 q/\beta^2; q)_k} \\ & \cdot \frac{(\alpha^2 q/\beta^2; q)_{2k}}{(\alpha^2 q/\beta; q)_{2k}} \left(\frac{qx}{\beta}\right)^k {}_2\phi_1\left[\begin{matrix} \alpha^2 q^{2k+1}/\beta^2, & q/\beta \\ & \alpha^2 q^{2k+1}/\beta \end{matrix}; q, \beta x\right]. \end{aligned} \tag{2.9}$$

The interesting property of the ${}_2\phi_1$ series in (2.4), (2.5), and (2.9) is that they are well poised and so we may apply the quadratic transformation formula [18, Eq. (3.8)]

$$\begin{aligned} & {}_2\phi_1\left[\begin{matrix} a, & b \\ & aq/b \end{matrix}; q, qx/b^2\right] \\ & = \frac{(qx/b, aqx^2/b^2; q)_\infty}{(aqx/b, qx^2/b^2; q)_\infty}\, {}_8W_7\left(ax/b; x, a^{1/2}, -a^{1/2}, (aq)^{1/2}, -(aq)^{1/2}; q, qx/b^2\right). \end{aligned} \tag{2.10}$$

We then use Bailey's transformation formula [8, §8.5, Eq. (3)] to express the resulting ${}_8W_7$ as a sum of two nonterminating balanced ${}_4\phi_3$ series. After some simplifications this gives

$$\begin{aligned} & {}_2\phi_1\left[\begin{matrix} \alpha^2 q^{2k+1}/\beta^2, & q/\beta \\ & \alpha^2 q^{2k+1}/\beta \end{matrix}; q, \beta x\right] \\ & = \frac{(\alpha x q/\beta; q)_\infty}{(\beta x/\alpha; q)_\infty} \frac{(-\alpha/\beta x)^k q^{\binom{k+1}{2}}}{(\alpha q/\beta x, \alpha x q/\beta; q)_k} \\ & \quad \cdot {}_4\phi_3\left[\begin{matrix} \alpha q^k, \alpha q^{k+1/2}/\beta, -\alpha q^{k+1/2}/\beta, -\alpha q^{k+1}/\beta \\ \alpha^2 q^{2k+1}/\beta, \alpha x q^{k+1}/\beta, \alpha q^{k+1}/\beta x \end{matrix}; q, q\right] \\ & \quad + \frac{(qx, \alpha, \alpha x q, \alpha^2 q/\beta^2; q)_\infty}{(\beta x, \alpha q/\beta, \alpha/\beta x, \alpha^2 q/\beta; q)_\infty} \cdot \frac{(\alpha q/\beta, \alpha/\beta x; q)_k}{(\alpha, \alpha x q; q)_k} \frac{(\alpha^2 q/\beta; q)_{2k}}{(\alpha^2 q/\beta^2; q)_{2k}} \\ & \quad \cdot {}_4\phi_3\left[\begin{matrix} \beta x, x q^{1/2}, -x q^{1/2}, -xq \\ qx^2, \alpha x q^{k+1}, \beta x q^{1-k}/\alpha \end{matrix}; q, q\right]. \end{aligned} \tag{2.11}$$

Since we have assumed that $|x| \le 1$ and $|q| < |\beta| < 1$, we can now substitute (2.11) into (2.9) and change the order of summation to obtain the formula

$$\begin{aligned} f^2(x) = {} & \frac{(\beta x, \alpha x q/\beta; q)_\infty}{(qx/\beta, \beta x/\alpha; q)_\infty} \sum_{m=0}^{\infty} \frac{(\alpha; q)_m (\alpha^2 q/\beta^2; q)_{2m} q^m}{(q, \alpha x q/\beta, \alpha q/\beta x, \alpha^2 q/\beta, \alpha q/\beta; q)_m} \\ & \cdot {}_6W_5\left(a^2/\beta; a, \beta, q^{-m}; q, \alpha q^{m+1}/\beta^2\right) \\ & + \frac{(\alpha, \alpha^2 q/\beta^2, qx, \alpha q x; q)_\infty}{(\alpha q/\beta, \alpha^2 q/\beta, qx/\beta, \alpha/\beta x; q)_\infty} \sum_{m=0}^{\infty} \frac{(\beta x, x q^{1/2}, -x q^{1/2}, -xq; q)_m}{(q, qx^2, \alpha x q, \beta x q/\alpha; q)_m} q^m \\ & \cdot {}_6W_5\left(\alpha^2/\beta; \alpha, \beta, \alpha q^{-m}/\beta x; q, x q^{m+1}/\beta\right). \end{aligned} \tag{2.12}$$

By [29, IV. 9]

$$(2.13)\qquad {}_6W_5\left(\alpha^2/\beta;\alpha,\beta,q^{-m};q,\alpha q^{m+1}/\beta^2\right)=\frac{(\alpha^2q/\beta,\alpha q/\beta^2;q)_m}{(\alpha q/\beta,\alpha^2q/\beta^2;q)_m},$$

and by [29, IV. 7]

$$(2.14)\qquad \begin{aligned}&{}_6W_5\left(a^2/\beta;\alpha,\beta,\alpha q^{-m}/\beta x;q,xq^{m+1}/\beta\right)\\&=\frac{(\alpha^2q/\beta,\alpha q/\beta^2,xq,\alpha xq/\beta;q)_\infty}{(\alpha q/\beta,\alpha^2q/\beta^2,\alpha xq,xq/\beta;q)_\infty}\frac{(\alpha xq,xq/\beta;q)_m}{(xq,\alpha xq/\beta;q)_m}.\end{aligned}$$

Using (2.13) and (2.14) we then obtain the formula

$$(2.15)\qquad \begin{aligned}&\left\{{}_2\phi_1\left[\begin{matrix}\alpha,\beta\\ q/\beta\end{matrix};q,qx/\beta\right]\right\}^2\\&=\frac{(\beta x,\alpha xq/\beta;q)_\infty}{(xq/\beta,\beta x/\alpha;q)_\infty}\,{}_5\phi_4\left[\begin{matrix}\alpha,\alpha q^{1/2}/\beta,\alpha q/\beta^2,-\alpha q^{1/2}/\beta,-\alpha q/\beta\\ \alpha q/\beta,\alpha^2q/\beta^2,\alpha q/\beta x,\alpha xq/\beta\end{matrix};q,q\right]\\&\quad+\frac{(\alpha,\alpha q/\beta^2,xq,xq,\alpha xq/\beta;q)_\infty}{(\alpha q/\beta,\alpha q/\beta,xq/\beta,xq/\beta,\alpha/\beta x;q)_\infty}\\&\quad\cdot{}_5\phi_4\left[\begin{matrix}\beta x,&xq/\beta,&xq^{1/2},&-xq^{1/2},&-xq\\ &qx,&qx^2,&\beta xq/\alpha,&\alpha xq/\beta\end{matrix};q,q\right],\end{aligned}$$

which gives the square of a well-poised ${}_2\phi_1$ series as the sum of two balanced ${}_5\phi_4$ series. By analytic continuation, (2.15) holds when $|q|<1$ and $|qx/\beta|<1$.

If $\alpha=q^{-n},n=0,1,\cdots$, then $(\alpha;q)_\infty=0$ and so

$$(2.16)\qquad \begin{aligned}f^2(x)&=\frac{(\beta x,xq^{1-n}/\beta;q)_\infty}{(\beta xq^n,qx/\beta;q)_\infty}\\&\quad\cdot{}_5\phi_4\left[\begin{matrix}q^{-n},&q^{1/2-n}/\beta,&q^{1-n}/\beta^2,&-q^{1/2-n}/\beta,&-q^{1-n}/\beta\\ &q^{1-n}/\beta,&q^{1-2n}/\beta^2,&xq^{1-n}/\beta,&q^{1-n}/\beta x\end{matrix};q,q\right]\\&=b_n\,{}_5\phi_4\left[\begin{matrix}q^{-n},&\beta^2q^n,&\beta,&\beta x,&\beta/x\\ &\beta^2,&\beta q^{1/2},&-\beta q^{1/2},&-\beta\end{matrix};q,q\right],\end{aligned}$$

where

$$(2.17)\qquad \begin{aligned}b_n&=\frac{(\beta x,q^{-n},q^{1-n}/\beta^2,q^{1/2-n}/\beta,-q^{1/2-n}/\beta,-q^{1-n}/\beta;q)_n}{(q,q^{1-n}/\beta,q^{1-2n}/\beta^2,q^{1-n}/\beta x;q)_n}q^n\\&=\frac{(\beta^2,\beta q^{1/2},-\beta q^{1/2},-\beta;q)_n}{(\beta,\beta^2q^n;q)_n}\left(\frac{x}{\beta}\right)^n=\frac{(\beta^2,\beta^2;q)_n}{(\beta,\beta;q)_n}\left(\frac{x}{\beta}\right)^n.\end{aligned}$$

However, by [5, Eq. (3.10)],

$$(2.18)\qquad f(x)=\frac{(\beta^2;q)_n}{(\beta;q)_n}\left(\frac{x}{\beta}\right)^{n/2}{}_4\phi_3\left[\begin{matrix}q^{-n},&\beta^2q^n,&(\beta x)^{1/2},&(\beta/x)^{1/2}\\ &\beta q^{1/2},&-\beta q^{1/2},&-\beta\end{matrix};q,q\right].$$

It follows from (2.16)–(2.18) that

$$(2.19)\qquad \begin{aligned}&\left\{{}_4\phi_3\left[\begin{matrix}q^{-n},&\beta^2q^n,&(\beta x)^{1/2},&(\beta/x)^{1/2}\\ &\beta q^{1/2},&-\beta q^{1/2},&-\beta\end{matrix};q,q\right]\right\}^2\\&={}_5\phi_4\left[\begin{matrix}q^{-n},&\beta^2q^n,&\beta,&\beta x,&\beta/x\\ &\beta^2,&\beta q^{1/2},&-\beta q^{1/2},&-\beta\end{matrix};q,q\right],\end{aligned}$$

which is formula (1.6) written in a special form.

Before closing this section we need to show that (2.15) is equivalent to (1.8). By (2.10) and Bailey's ${}_8\phi_7$ transformation formula [9, Eq. (4.3)], we have

$$
\begin{aligned}
&{}_2\phi_1\left[\begin{matrix}\alpha, & \beta\\ & \alpha q/\beta\end{matrix}; q, qx/\beta\right]\\
&\quad = \frac{(x(\alpha q)^{1/2}, -x(\alpha q)^{1/2}, qx\alpha^{1/2}/\beta, -qx\alpha^{1/2}/\beta; q)_\infty}{(xq^{1/2}, -xq^{1/2}, qx/\beta, -\alpha xq/\beta; q)_\infty}\\
&\quad\cdot {}_8W_7\left(-\alpha x/\beta; \alpha^{1/2}, (\alpha q)^{1/2}/\beta, -\alpha^{1/2}, -(\alpha q)^{1/2}/\beta, -x; q, -qx\right).
\end{aligned}
\tag{2.20}
$$

Now set $a = \alpha^{1/2}$ and $b = (\alpha q)^{1/2}/\beta$ to obtain from (2.15) that

$$
\begin{aligned}
&\left\{\frac{(qa^2x^2, qb^2x^2; q^2)_\infty}{(qx^2, qa^2b^2x^2; q^2)_\infty}\, {}_8W_7\left(-qbxq^{-1/2}; a, b, -a, -b, -x; q, -qx\right)\right\}^2\\
&\quad = \frac{(axq^{1/2}/b, bxq^{1/2}/a; q)_\infty}{(xq^{1/2}/ab, abxq^{1/2}; q)_\infty}\, {}_5\phi_4\left[\begin{matrix}a^2, b^2, ab, -ab, -abq^{1/2}\\ abq^{1/2}, a^2b^2, abxq^{1/2}, abq^{1/2}/x\end{matrix}; q, q\right]\\
&\qquad + \frac{(qx, qx, a^2, b^2; q)_\infty}{(abq^{1/2}, abq^{1/2}, ab/xq^{1/2}, abxq^{1/2}; q)_\infty}\\
&\qquad\cdot {}_5\phi_4\left[\begin{matrix}axq^{1/2}/b, bxq^{1/2}/a, xq^{1/2}, -xq^{1/2}, -xq\\ qx, qx^2, abxq^{1/2}, xq^{3/2}/ab\end{matrix}; q, q\right], \quad |qx|<1, \quad |q|<1,
\end{aligned}
\tag{2.21}
$$

which is formula (1.8).

3. Some variations of (2.9). If we replace a and b by q^a and q^b, respectively, in (2.21) and take the limit $q \to 1^-$, then the left side can be seen to approach the left side of (1.1) with x replaced by $-4x(1-x)^{-2}$ while the first term on the right of (2.21) approaches the right side of (1.1) with x replaced by $-4x(1-x)^{-2}$. So (2.21) can justifiably be called a q-Clausen formula provided we can show that the limit of the second term on the right side as $q \to 1^-$ is zero. This can be done by using the asymptotics of the theta functions somewhat along the lines followed in [24], but an easier approach is to use (2.20) for the ${}_2\phi_1$ function in (2.9) and then take the term-by-term limit from a uniformly convergent double series. First, by an obvious transformation of summation indices we obtain from (2.9), (2.20), and (1.9) that

$$
\begin{aligned}
g^2(x) &= \frac{(a^2xq^{1/2}, -a^2xq^{1/2}, -abxq^{1/2}, bxq^{1/2}/a; q)_\infty}{(xq^{1/2}, -xq^{1/2}, abxq^{1/2}, -a^3bxq^{1/2}; q)_\infty}\\
&\cdot \sum_{m=0}^{\infty} \frac{(-a^3bxq^{-1/2}; q)_m(1+a^3bxq^{2m-1/2})(a^2, ab, -a^2, -ab, -x; q)_m}{(q; q)_m(1+a^3bxq^{-1/2})(-abxq^{1/2}, -a^2xq^{1/2}, abxq^{1/2}, a^2xq^{1/2}, a^3bq^{1/2}; q)_m}\\
&\cdot (-xq)^m\, {}_8W_7\left(a^3bq^{-1/2}; a^2, aq^{1/2}/b, -abq^{1/2}, -a^3bxq^{m-1/2}, q^{-m}; q, bq^{1/2}/ax\right).
\end{aligned}
\tag{3.1}
$$

Then, replacing a, b by q^a, q^b and letting $q \to 1^-$, we obtain

$$
\left\{{}_2F_1(a, b; a+b+\tfrac{1}{2}; z)\right\}^2 = \sum_{m=0}^{\infty} \frac{(2a)_m(a+b)_m}{m!(3a+b+\frac{1}{2})_m} z^m
\tag{3.2}
$$

$$\cdot {}_5F_4\left[\begin{matrix} 3a+b-\frac{1}{2}, (3a+b)/2+\frac{3}{4}, 2a, a-b+\frac{1}{2}, -m \\ (3a+b/2)-\frac{1}{4}, a+b+\frac{1}{2}, 2a+2b, 3a+b+\frac{1}{2}+m \end{matrix}; 1\right]$$

$$= \sum_{m=0}^{\infty} \frac{(2a)_m (a+b)_m}{m!(3a+b+\frac{1}{2})_m} z^m \frac{(3a+b+\frac{1}{2})_m (2b)_m}{(a+b+\frac{1}{2})_m (2a+2b)_m} \qquad \text{(by [29, III.13])}$$

$$= {}_3F_2\left[\begin{matrix} 2a, & 2b, & a+b \\ & a+b+\frac{1}{2}, & 2a+2b \end{matrix}; z\right]$$

where $z = -4x(1-x)^{-2}$. This completes the proof that (2.21) is a q-analogue of Clausen's formula (1.1). Clausen's formula can be used to show that if a and b are replaced by q^a and q^b in (2.21), then the second term on the right side tends to zero as $q \to 1^-$.

Similarly, it can be shown that formula (2.15) is a q-analogue of the formula

$$\left\{ {}_2F_1\left[\begin{matrix} a, & b \\ a+1-b \end{matrix}; x\right]\right\}^2$$

(3.3)

$$= (1-x)^{-2a} \, {}_3F_2\left[\begin{matrix} a, a+\frac{1}{2}-b, a+1-2b \\ a+1-b, 2a+1-2b \end{matrix}; -\frac{4x}{(1-x)^2}\right],$$

where $|x| < 1$ and $|4x(1-x)^{-2}| < 1$.

It may be of interest to point out some other aspects of (3.1). The very well-poised ${}_8W_7$ series on the right side of (3.1) is terminating and so can be transformed to a terminating balanced ${}_4\phi_3$ series by Watson's formula [8, §8.5, Eq. (2)]. Thus we find that

$$g^2(x) = \frac{(a^2xq^{1/2}, -a^2xq^{1/2}, -abxq^{1/2}, bxq^{1/2}/a; q)_\infty}{(xq^{1/2}, -xq^{1/2}, abxq^{1/2}, -a^3bxq^{1/2}; q)_\infty}$$

$$\cdot \sum_{m=0}^{\infty} \frac{(-a^3bxq^{-1/2}; q)_m (1+a^3bxq^{2m-1/2})(a^2, ab, -ab; q)_m}{(q; q)_m (1+a^3bxq^{-1/2})(-abxq^{1/2}, -a^2xq^{1/2}, a^2xq^{1/2}; q)_m} \tag{3.4}$$

$$\cdot \left(\frac{xq^{1/2}}{ab}\right)^m {}_4\phi_3\left[\begin{matrix} q^{-m}, & -a^3bxq^{m-1/2}, & b^2, & -abq^{1/2} \\ & a^2b^2, & abq^{1/2}, & abxq^{1/2} \end{matrix}; q, q\right].$$

If a^2 or ab or $-ab$ is of the form q^{-n}, $n = 0, 1, 2, \cdots$, then by changing the order of summation the double sum on the right side becomes a sum of very well-poised ${}_6\phi_5$ series which can be summed by [29, IV. 9], reducing the right side of (3.4) to a multiple of a ${}_5\phi_4$ series. This is essentially the route taken in [16] to derive (1.6). In general, this change in order of summation is not valid since the double series does not converge absolutely, as can be seen by observing that if it were absolutely convergent then we would have

$$g^2(x) = \frac{(a^2xq^{1/2}, -a^2xq^{1/2}, -abxq^{1/2}, bxq^{1/2}/a; q)_\infty}{(xq^{1/2}, -xq^{1/2}, abxq^{1/2}, -a^3bxq^{1/2}; q)_\infty}$$

$$\cdot \sum_{k=0}^{\infty} \frac{(a^2, b^2, ab, -ab, -abq^{1/2}; q)_k (-a^3bxq^{1/2}; q)_{2k}}{(q, a^2b^2, abq^{1/2}, abxq^{1/2}, -abxq^{1/2}, a^2xq^{1/2}, -a^2xq^{1/2}; q)_k} \tag{3.5}$$

$$\cdot q^{-k^2/2} \left(-\frac{xq}{ab}\right)^k {}_6W_5\left(-a^3bxq^{2k-1/2}; a^2q^k, abq^k, -abq^k; q, xq^{1/2-k}/ab\right),$$

but the ${}_6W_5$ series clearly diverges for sufficiently large values of k when $x \neq 0$.

By applying Bailey's [9, Eqs. (4.3)–(4.6)] transformation formulas to the ${}_8W_7$ series in (2.21) and transformation formulas for well-poised series to the ${}_2\phi_1$ series in (2.15), these formulas can be written in many equivalent forms. In particular, since it follows from (3.8) and (3.9) in [18] that

$$(3.6)\qquad {}_4\phi_3\left[\begin{matrix} a, & qa^{1/2}, & -qa^{1/2}, & b \\ & a^{1/2}, & -a^{1/2}, & aq/b \end{matrix}; q, x\right] = (1-bx)\,{}_2\phi_1\left[\begin{matrix} aq, bq \\ aq/b \end{matrix}; q, x\right],$$

which can also be verified directly, (2.15) can be used to write the square of a very well-poised ${}_4\phi_3$ series as a sum of two balanced ${}_5\phi_4$ series. In addition, Jackson's [20] transformation formula

$$(3.7)\qquad {}_2\phi_1\left[\begin{matrix} a, & b \\ & c \end{matrix}; q, x\right] = \frac{(ax;q)_\infty}{(x;q)_\infty}\,{}_2\phi_2\left[\begin{matrix} a, & c/b \\ c, & ax \end{matrix}; q, bx\right]$$

can be applied to the ${}_2\phi_1$ series in (2.15) to derive formulas which after changes in variables are q-analogues of the formulas

$$(3.8)\qquad \left\{{}_2F_2\left[\begin{matrix} a, & b \\ (a+b+1)/2 \end{matrix}; x\right]\right\}^2 = {}_3F_2\left[\begin{matrix} a, b, (a+b)/2 \\ a+b, & (a+b+1)/2 \end{matrix}; 4x(1-x)\right]$$

and

$$(3.9)\qquad \left\{{}_2F_1\left[\begin{matrix} a, & 1-a \\ & c \end{matrix}; x\right]\right\}^2 = (1-x)^{2c-2}\,{}_3F_2\left[\begin{matrix} a+c-1, c-a, c-\frac{1}{2} \\ c, 2c-1 \end{matrix}; 4x(1-x)\right],$$

where $|x|<1$ and $|4x(1-x)|<1$.

4. Additional product formulas. Let us start by proceeding as in the derivation of (2.6) to derive the more general formula

$$\begin{aligned} &{}_2\phi_1\left[\begin{matrix} a, & b \\ & c \end{matrix}; q, x\right]\,{}_2\phi_1\left[\begin{matrix} \alpha, & \beta \\ & \gamma \end{matrix}; q, y\right] \\ &\quad = \frac{(\alpha\beta y/\gamma;q)_\infty}{(y;q)_\infty}\,{}_2\phi_1\left[\begin{matrix} a, & b \\ & c \end{matrix}; q, x\right]\,{}_2\phi_1\left[\begin{matrix} \gamma/\alpha, & \gamma/\beta \\ & \gamma \end{matrix}; q, \frac{\alpha\beta y}{\gamma}\right] \\ &\quad = \frac{(\alpha\beta y/\gamma;q)_\infty}{(y;q)_\infty}\sum_{j=0}^{\infty} B_j \frac{(\gamma/\alpha, \gamma/\beta; q)_j}{(q, \gamma; q)_j}\left(\frac{\alpha\beta y}{\gamma}\right)^j \end{aligned} \qquad (4.1)$$

with

$$(4.2)\qquad B_j = {}_4\phi_3\left[\begin{matrix} q^{-j}, & q^{1-j}/\gamma, & a, & b \\ & \alpha q^{1-j}/\gamma, & \beta q^{1-j}/\gamma, & c \end{matrix}; q, \frac{xq}{y}\right]$$

provided $\max(|x|, |y|, |\alpha\beta y/\gamma|) < 1$. In order to apply Watson's transformation formula [8, §8.5, Eq. (2)] to the ${}_4\phi_3$ series in (4.2), it is necessary that the series be balanced, that is

$$(4.3)\qquad \gamma = \alpha\beta c/ab \qquad \text{and} \qquad y = x.$$

Then, assuming that (4.3) holds,

$$B_j = \frac{(\alpha c/a, \alpha c/b; q)_j}{(\alpha c, \alpha c/ab; q)_j}\, {}_8W_7\left(\alpha c/q; a, b, \alpha, \alpha\beta c^2 q^{j-1}/ab, q^{-j}; q, q/\beta\right) \tag{4.4}$$

and hence

$$\begin{aligned}
&{}_2\phi_1\left[\begin{matrix} a, & b \\ & c \end{matrix}; q, x\right]\ {}_2\phi_1\left[\begin{matrix} \alpha, & \beta \\ & \alpha\beta c/ab \end{matrix}; q, x\right] \\
&= \frac{(abx/c; q)_\infty}{(x; q)_\infty} \sum_{j=0}^{\infty} \frac{(\beta c/ab, \alpha c/a, \alpha c/b; q)_j}{(q, \alpha\beta c/ab, \alpha c; q)_j} \left(\frac{abx}{c}\right)^j \\
&\quad \cdot \sum_{k=0}^{j} \frac{(1-\alpha c q^{2k-1})(\alpha c/q, a, b, \alpha, \alpha\beta c^2 q^{j-1}/ab, q^{-j}; q)_k}{(1-\alpha c/q)(q, \alpha c/a, \alpha c/b, c, abq^{1-j}/\beta c, \alpha c q^j; q)_k} \left(\frac{q}{\beta}\right)^k \\
&= \frac{(abx/c; q)_\infty}{(x; q)_\infty} \sum_{k=0}^{\infty} C_k \frac{(1-\alpha c q^{2k-1})\,(\alpha c/q, a, b, \alpha; q)_k (\alpha\beta c^2/abq; q)_{2k}}{(1-\alpha c/q)(q, c, \alpha\beta c/ab, \alpha\beta c^2/abq; q)_k (\alpha c; q)_{2k}} x^k
\end{aligned} \tag{4.5}$$

with

$$C_k = {}_4\phi_3\left[\begin{matrix} \alpha\beta c^2 q^{2k-1}/ab, & \beta c/ab, & \alpha c q^k/a, & \alpha c q^k/b \\ & \alpha c q^{2k}, & \alpha\beta c q^k/ab, & \alpha\beta c^2 q^{k-1}/ab \end{matrix}; q, \frac{abx}{c}\right]. \tag{4.6}$$

To proceed further we now observe that the quadratic transformation formula (2.11) is a special case of the authors' nonterminating extension [18, Eq. (1.2)]

$$\begin{aligned}
&{}_3\phi_2\left[\begin{matrix} a, & b, & c \\ & aq/b, & aq/c \end{matrix}; q, \frac{aqx}{bc}\right] \\
&= \frac{(ax; q)_\infty}{(x; q)_\infty}\, {}_5\phi_4\left[\begin{matrix} a^{1/2}, & -a^{1/2}, & (aq)^{1/2}, & -(aq)^{1/2}, & aq/bc \\ & aq/b, & aq/c, & ax, & q/x \end{matrix}; q, q\right] \\
&\quad + \frac{(a, aq/bc, aqx/b, aqx/c; q)_\infty}{(aq/b, aq/c, aqx/bc, x^{-1}; q)_\infty} \\
&\quad \cdot {}_5\phi_4\left[\begin{matrix} xa^{1/2}, & -xa^{1/2}, & x(aq)^{1/2}, & -x(aq)^{1/2}, & aqx/bc \\ & aqx/b, & aqx/c, & xq, & ax^2 \end{matrix}; q, q\right]
\end{aligned} \tag{4.7}$$

of the Sears–Carlitz transformation formula for a terminating well-poised ${}_3\phi_2$ series. Thus, if we set $\alpha = a$ and $\beta = aq/c$ then the ${}_4\phi_3$ series in (4.6) reduces to a well-poised ${}_3\phi_2$ series to which we can apply (4.7) to extend (2.11) to

$$\begin{aligned}
&{}_3\phi_2\left[\begin{matrix} acq^{2k}/b, q/b, cq^k \\ acq^{2k}, aq^{k+1}/b \end{matrix}; q, \frac{abx}{c}\right] \\
&= \frac{(ax; q)_\infty (-cq/bx)^k q^{\binom{k}{2}}}{(bx/c; q)_\infty (ax, cq/bx; q)_k} \\
&\quad \cdot {}_5\phi_4\left[\begin{matrix} aq^k, (ac/b)^{1/2}q^k, -(ac/b)^{1/2}q^k, (ac/b)^{1/2}q^{k+1/2}, -(ac/b)^{1/2}q^{k+1/2} \\ & acq^{2k}, aq^{k+1}/b, axq^k, cq^{k+1}/bx \end{matrix}; q, q\right] \\
&\quad + \frac{(ac/b, a, abx, aqx/c; q)_\infty (aq/b, c/bx; q)_k (ac; q)_{2k}}{(ac, aq/b, abx/c, c/bx; q)_\infty (a, abx; q)_k (ac/b; q)_{2k}} \\
&\quad \cdot {}_5\phi_4\left[\begin{matrix} x(ab/c)^{1/2}, -x(ab/c)^{1/2}, x(abq/c)^{1/2}, -x(abq/c)^{1/2}, abx/c \\ & abxq^k, aqx/c, bxq^{1-k}/c, abx^2/c \end{matrix}; q, q\right].
\end{aligned} \tag{4.8}$$

Substituting (4.8) into (4.5) and changing the order of summation, we find that

$$
\begin{aligned}
&{}_2\phi_1\left[\begin{matrix}a, & b\\ & c\end{matrix};q,x\right]\ {}_2\phi_1\left[\begin{matrix}a, & aq/c\\ & aq/b\end{matrix};q,x;q,x\right]\\
&\quad=\frac{(ax,abx/c;q)_\infty}{(x,bx/c;q)_\infty}\sum_{m=0}^{\infty}\frac{(a;q)_m(ac/b;q)_{2m}q^m}{(q,aq/b,ax,cq/bx,ac;q)_m}\\
&\quad\quad\cdot\ {}_6W_5\left(ac/q;a,b,q^{-m};q,cq^m/b\right)\\
&\quad\quad+\frac{(ac/b,a,abx,aqx/c;q)_\infty}{(ac,aq/b,x,c/bx;q)_\infty}\sum_{m=0}^{\infty}\frac{(abx/c;q)_m(abx^2/c;q)_{2m}q^m}{(q,abx^2/c,aqx/c,abx,bxq/c;q)_m}\\
&\quad\quad\cdot\ {}_6W_5\left(ac/q;a,b,cq^{-m}/bx;q,xq^m\right).
\end{aligned}
\tag{4.9}
$$

Since each of the above ${}_6W_5$ series is summable by [29, IV. 7], it follows from (4.9) that we have the product formula

$$
\begin{aligned}
&{}_2\phi_1\left[\begin{matrix}a, & b\\ & c\end{matrix};q,x\right]\ {}_2\phi_1\left[\begin{matrix}a, & aq/c\\ & aq/b\end{matrix};q,x\right]\\
&\quad=\frac{(ax,abx/c;q)_\infty}{(x,bx/c;q)_\infty}\ {}_6\phi_5\left[\begin{matrix}a,c/b,(ac/b)^{1/2},-(ac/b)^{1/2},(acq/b)^{1/2},-(acq/b)^{1/2}\\ aq/b,c,ac/b,ax,cq/bx\end{matrix};q,q\right]\\
&\quad\quad+\frac{(a,c/b,ax,bx,axq/c;q)_\infty}{(c,aq/b,x,x,c/bx;q)_\infty}\\
&\quad\quad\cdot\ {}_6\phi_5\left[\begin{matrix}x,abx/c,x(ab/c)^{1/2},-x(ab/c)^{1/2},x(abq/c)^{1/2},-x(abq/c)^{1/2}\\ ax,bx,axq/c,bxq/c,abx^2/c\end{matrix};q,q\right],
\end{aligned}
\tag{4.10}
$$

where $|x|<1$ and $|q|<1$. This formula reduces to (2.15) when $a=\alpha, b=\beta, c=\alpha q/\beta$ and x is replaced by qx/β.

By applying transformation formulas to the ${}_2\phi_1$ series in (4.10), this formula can be written in many equivalent forms. In particular, to derive a q-analogue of the Ramanujan and Bailey product formula (1.11), replace b in (4.10) by c/b and apply Jackson's transformation formula (3.7) to obtain

$$
\begin{aligned}
&{}_2\phi_2\left[\begin{matrix}a, & b\\ c, & ax\end{matrix};q,\frac{cx}{b}\right]\ {}_2\phi_2\left[\begin{matrix}a, & b\\ abq/c, & ax\end{matrix};q,\frac{axq}{c}\right]\\
&\quad=\frac{(x,ax/b;q)_\infty}{(ax,x/b;q)_\infty}\ {}_6\phi_5\left[\begin{matrix}a,b,(ab)^{1/2},-(ab)^{1/2},(abq)^{1/2},-(abq)^{1/2}\\ abq/c,c,ab,ax,bq/x\end{matrix};q,q\right]\\
&\quad\quad+\frac{(a,b,cx/b,axq/c;q)_\infty}{(c,abq/c,ax,b/x;q)_\infty}\\
&\quad\quad\cdot\ {}_6\phi_5\left[\begin{matrix}x,abx,x(a/b)^{1/2},-x(a/b)^{1/2},x(aq/b)^{1/2},-x(aq/b)^{1/2}\\ ax,cx/b,axq/c,xq/b,ax^2/b\end{matrix};q,q\right]
\end{aligned}
\tag{4.11}
$$

when $\max(|q|,|axq/c|,|cx/b|)<1$. If we replace a,b,x in (4.11) by $q^a,q^b,z/(z-1)$, respectively, and let $q\to 1^-$, we get

$$
\begin{aligned}
&{}_2F_1\left[\begin{matrix}a, & b\\ & c\end{matrix};z\right]\ {}_2F_1\left[\begin{matrix}a, & b\\ & a+b-c+1\end{matrix};z\right]\\
&\quad={}_4F_3\left[\begin{matrix}a, & b, & (a+b)/2, & (a+b+1)/2\\ & c, & a+b, & a+b+1-c\end{matrix};4z(1-z)\right],
\end{aligned}
\tag{4.12}
$$

which on setting $z = (1 - \sqrt{1-x})/2$ gives (1.11). Note that when $c = (abq)^{1/2}$, formula (4.11) gives the square of the series

$$ {}_2\phi_2\left[\begin{matrix} a, & b \\ (abq)^{1/2}, & ax \end{matrix}; q, x(aq/b)^{1/2}\right] $$

as a sum of two balanced ${}_5\phi_4$ series.

DUALITY FOR FAMILIES OF NATURAL VARIATIONAL PRINCIPLES IN NONLINEAR ELECTROSTATICS*

J. F. TOLAND† AND J. R. WILLIS†

Abstract. Standard duality theory embeds a given minimisation problem into a family of such problems and relates the solution of the original problem to a particular member of the dual family of problems. This theory is extended, in the specific context of the nonlinear electrostatic theory of a composite dielectric material, by considering a family of minimisation problems, parametrised by the imposed data, whose solutions define a convex function of this data. Here, the primary variable is the electric field. A corresponding family of dual problems is constructed, in which the primary variable is the electric displacement. The novelty of the formulation is that the duality is interpreted in terms of the space of the parameters that define the original family, so that the dual family generates a convex function of a dual set of parameters. It is demonstrated, under mild hypotheses on the electric properties of the nonlinear dielectric material, that these two convex functions are Legendre transforms of each other. As a by-product, the precise complementary duality principle between individual pairs of variational problems (as opposed to families of variational problems) is elucidated.

Key words. duality, Legendre transforms, electrostatics

AMS(MOS) subject classifications. 49A55, 49A52, 49A27, 78A30

1. Introduction. This paper is concerned with two families of variational problems in the nonlinear electrostatic theory of a composite dielectric material. In one the dependent variable is the electric potential, and in the other family it is the electric displacement field. Each family is parametrised by the imposed data, and as such each minimisation problem defines a convex function of the space of imposed data. Our main goal is to show that, under very generous hypotheses on the electric properties of the nonlinear dielectric material, these two convex functions are Legendre transforms of one another. As a by-product, the precise complementary duality principle between individual pairs of variational problems (as opposed to the families of variational problems) is elucidated. The main result is explained in detail in § 3.4, but it is appropriate to give a sketch of it here.

Let Ω denote a connected open bounded set containing a composite material with variable dielectric constant. The material may contain regions of conductor where the dielectric constant is infinite, and regions of insulator where the dielectric constant is zero. Let Γ_φ denote a prescribed nonplanar portion of the boundary Γ of Ω, and let H_p denote a space of functions on Ω vanishing in a weak sense on Γ_φ. Then the primary family of boundary value problems may be written loosely as

$$\min_{\varphi \in H_p} \frac{1}{|\Omega|} \int_\Omega \mathbf{E}(x, \nabla\varphi(x) + \Lambda)\, dx = F(\Lambda). \tag{1.1}$$

Here $\mathbf{E}: \Omega \times \mathbf{R}^3 \to \bar{\mathbf{R}} = \mathbf{R} \cup \{+\infty\}$ denotes the electric energy density function (whose properties are described in detail in § 3.2), $\Lambda \in \mathbf{R}^3$, and the equilibrium potential $\Phi = \varphi + \Lambda.x$ is $\Lambda.x$ in a weak sense on Γ_φ. The significance of this formulation is as follows. First, in the particular case that $\Gamma_\varphi = \Gamma$, Λ is the mean value over Ω of the equilibrium electric field; this case has direct relevance to composite media and is highlighted in [6] and [7], for example. Other cases may also have physical significance. For instance, if Γ_φ consists of portions of two distinct parallel planes and Φ is prescribed

* Received by the editors June 15, 1988; accepted for publication November 30, 1988.
† School of Mathematical Sciences, University of Bath, Bath BA2 7AY, United Kingdom.

to be constant on each, then Λ provides a measure of the potential difference between the planes, although it is not, in general, the mean value over Ω of the electric field. In every case, $F(\Lambda)$ is the mean energy function associated with Λ. An alternative formulation is to let $\mathbf{E}^*(x, \cdot)$ be the Legendre transform of $\mathbf{E}(x, \cdot)$ and to pose a variational problem for the electric displacement which can be written loosely as

$$\min_{\substack{\operatorname{Div} w^*=0,\\ (1/|\Omega|)\int_\Omega w^*(x)\,dx=\lambda^*,\\ w^*.n=0 \quad \text{on } \Gamma\setminus\Gamma_\varphi}} \frac{1}{|\Omega|}\int_\Omega \mathbf{E}^*(x, w^*(x))\,dx = f_*(\lambda^*). \tag{1.2}$$

A noteworthy feature of problem (1.2) is that no boundary data are imposed in the case $\Gamma = \Gamma_\varphi$; λ^* prescribes only the mean of w^* over Ω.

Our purpose is to say precisely that f_* and F are Legendre duals of one another and to establish (3.12) and (3.13) when the variational principles are correctly formulated in Sobolev spaces over a domain Ω with sufficient regularity on the boundary. It is important to recognise that this result is different from one that says that two variational problems (as opposed to two families of variational problems) are related by duality. As a consequence of the present considerations we find an answer to the following question. If, for given $\Lambda \in \mathbf{R}^3$, φ is a solution of (1.1), what is the mean electric displacement that must be imposed in problem (1.2) to obtain the same equilibrium? The solution is given in § 3.4.

This paper puts the work of Talbot and Willis [6] and Willis [7] in its application to electrostatics in a precise functional analytic context. These authors seem to have been the first to address the question of duality for families of variational problems parametrised by spaces of prescribed data. In fact, the duality theory is implicit in the work of Ekeland and Temam [2], although § 2 of this article seems to be the first place where the present implications of classical Fenchel duality theory have been explicitly recognised for a generally parametrised family of variational problems. Clearly, the work of § 3 is only one special case where this viewpoint is valuable. Extensions to certain others, as addressed, for example, by Talbot and Willis [6], Willis [7], and Ponte-Castañeda and Willis [4] would be straightforward. On the other hand, an extension to finite deformation nonlinear elasticity would be less so, in view of the need to relax convexity assumptions (see, e.g., Ball [1]). This latter problem is a subject of ongoing research.

2. The duality theory. Let V, V^*; W, W^*; and X, X^* be three pairs of topological vector spaces in separating duality, the duality pairing being denoted by $\langle , \rangle$, and let

$$\mathscr{F}\colon V \times W \times X \to \bar{\mathbf{R}} \quad \text{(the extended reals)}$$

be a proper, convex, lower semicontinuous function (proper means $\mathscr{F} \not\equiv -\infty$ anywhere, and $\mathscr{F} \not\equiv +\infty$). For fixed $\Lambda \in X$, let

$$F(\Lambda) = \inf_{v \in V} \mathscr{F}(v, 0, \Lambda). \tag{2.1}$$

Now define $\Phi_\Lambda\colon V \times W \times X \to \bar{\mathbf{R}}$ by

$$\Phi_\Lambda(v, w, \lambda) = \mathscr{F}(v, w, \Lambda + \lambda).$$

Then

$$F(\Lambda) = \inf_{u \in V} \Phi_\Lambda(u, 0, 0). \tag{2.2}$$

By standard Fenchel duality (see Ekeland and Temam [2])

$$F(\Lambda) \geqq \sup_{(w^*,\lambda^*)\in W^*\times X^*} -\Phi_\Lambda^*(0, w^*, \lambda^*), \tag{2.3}$$

whence

$$\begin{aligned} F(\Lambda) &\geqq \sup_{(w^*,\lambda^*)\in W^*\times X^*} \{\langle \lambda^*, \Lambda\rangle - \mathscr{F}^*(0, w^*, \lambda^*)\} \\ &= \sup_{\lambda^*\in X^*} \{\langle \lambda^*, \Lambda\rangle - \inf_{w^*\in W^*} \mathscr{F}^*(0, w^*, \lambda^*)\}. \end{aligned} \tag{2.4}$$

Here $\mathscr{F}^*$ denotes the Legendre transform of $\mathscr{F}$ (which is called the polar function of $\mathscr{F}$ by Ekeland and Temam [2]).

Now let

$$F_*(\lambda^*) = \inf_{w^*\in W^*} \mathscr{F}^*(0, w^*, \lambda^*).$$

Then (2.4) says that

$$F(\Lambda) \geqq \sup_{\lambda^*\in X^*} \{\langle \lambda^*, \Lambda\rangle - F_*(\lambda^*)\}.$$

In other words,

$$F(\Lambda) \geqq (F_*)^*(\Lambda), \qquad \Lambda \in X. \tag{2.5}$$

Taking the Legendre transform of both sides of (2.5) gives

$$F^*(\Lambda^*) \leqq (F_*)^{**}(\Lambda^*) \leqq F_*(\Lambda^*), \qquad \Lambda^* \in X^*. \tag{2.6}$$

We now apply standard theory to the question of equality in (2.5). We adopt the convention that equality in (2.5) means that both quantities are finite and equal for all $\Lambda \in X$. There follows the well-known criterion for equality (Ekeland and Temam [2, Chap. III, Prop. 2.1]).

PROPOSITION 2.1. *Equality in* (2.5) *holds if and only if* $h_\Lambda(0, 0)$ *is finite and* h_Λ *is lower semicontinuous at* $(0, 0)$, *where*

$$h_\Lambda(w, \lambda) = \inf_{v\in V} \mathscr{F}(v, w, \Lambda + \lambda). \tag{2.7}$$

It is interesting to ask whether equality in (2.6) follows from equality in (2.5). This will be so if and only if F_* is a proper convex lower semicontinuous function of Λ^*. The next proposition gives hypotheses when it is.

Let $\Lambda^* \in X^*$, $w \in W$, and

$$H_{\Lambda^*}(w) = \inf_{(v,\Lambda)\in V\times X} \{\mathscr{F}(v, w, \Lambda) - \langle \Lambda^*, \Lambda\rangle\}.$$

PROPOSITION 2.2. *The function* $F_*: X^* \to \bar{\mathbf{R}}$ *is a proper convex lower semicontinuous function if* $H_{\Lambda^*}(0)$ *is finite and* H_{Λ^*} *is lower semicontinuous at* $0 \in W$ *for each* $\Lambda^* \in X^*$.

Proof. Let Λ^* be fixed,

$$\Psi(v^*, w^*, \lambda^*) = \mathscr{F}^*(v^*, w^*, \Lambda^* + \lambda^*)$$

and note that (since $\mathscr{F}^{**} = \mathscr{F}$)

$$\Psi^*(v, w, \Lambda) = \mathscr{F}(v, w, \Lambda) - \langle \Lambda^*, \Lambda\rangle.$$

By hypothesis,

$$H_{\Lambda^*}(w) = \inf_{(v,\Lambda)\in V\times X} \Psi^*(v, w, \Lambda)$$

is finite and lower semicontinuous at $0 \in W$. Hence by [2, Chap. III, Prop. 2.1],

$$\hat{H}(v^*, \lambda^*) = \inf_{w^* \in W^*} \mathscr{F}^*(v^*, w^*, \Lambda^* + \lambda^*)$$

defines a function which is finite and lower semicontinuous at $(0,0) \in V^* \times X^*$. A fortiori, $\hat{H}(0, \cdot): X^* \to \bar{\mathbf{R}}$ is finite and lower semicontinuous at $0 \in X^*$. But $\hat{H}(0, \lambda^*) = F_*(\Lambda^* + \lambda^*)$. Hence F_* is finite and lower semicontinuous on X^*. □

Let us suppose that the hypotheses of both propositions hold. We then conclude that

$$F(\Lambda) = (F_*)^*(\Lambda), \qquad \Lambda \in X \tag{2.8}$$

and

$$F^*(\Lambda^*) = F_*(\Lambda^*), \qquad \Lambda^* \in X^*. \tag{2.9}$$

Moreover,

$$F(\Lambda) + F_*(\Lambda^*) \geqq \langle \Lambda, \Lambda^* \rangle, \tag{2.10}$$

and

$$F(\Lambda) + F_*(\Lambda^*) = \langle \Lambda, \Lambda^* \rangle \tag{2.11}$$

if and only if either one of the following two extremality conditions hold:

$$\Lambda^* \in \partial F(\Lambda) \quad \text{or} \quad \Lambda \in \partial F_*(\Lambda^*). \tag{2.12}$$

Remark. If F and F_* are defined and finite on a finite-dimensional space, then the subdifferentials are everywhere nonempty. In § 3.4 the significance of these observations is made clear in a particular example.

Now we are in a position to formulate the electrostatic boundary value problems sufficiently precisely so that the results indicated in § 1 can be inferred from the above interpretation of duality theory.

3. Mathematical formulation.

3.1. The composite. In this section we specify the domain occupied by the composite and its dielectric properties in a sufficiently precise way so that the duality theory of the preceding section can be invoked in appropriate spaces of admissible functions. What we have in mind is a body of composite material possibly containing interior regions of conducting material where the dielectric constant is infinite and regions of insulating material where the dielectric constant is zero.

Let $\Omega \subset \mathbf{R}^3$ be a bounded, open connected set which represents the region occupied by the composite, including insulating and conducting regions. Let Γ denote the Lipschitz boundary of Ω. Suppose that the closed subset F of Ω occupied by insulator is the union of a set of zero measure and the closure of an open set with Lipschitz continuous boundary. (It is possible to weaken this assumption on boundary regularity by supposing only minimal smoothness in the sense of Stein [5, Chap. VI, § 3].) The conducting region in Ω will be denoted by G, and it is a closed set which does not intersect F. Let $\Gamma_\varphi \subset \Gamma$ denote a subset of Γ of positive two-dimensional measure, which is not a subset of a plane. (Γ_φ may contain flat portions of the boundary Γ, provided it is not entirely coplanar.)

3.2. The electric energy density function. The electric displacement D may be written formally in terms of the electric field E as $D = \mathbf{E}'(x, E)$, where $'$ denotes differentiation with respect to E, and $x \in \Omega$. To pose the electrostatic boundary value

problem variationally there is no need for $\mathbf{E}$ to be differentiable, but the regularity of solutions of the variational problem is determined by the differentiability of $\mathbf{E}$. We assume, first of all, that $\mathbf{E}$, which is possibly infinite at points $x \in G$, is a Carathéodory function:

(i) For all $E \in \mathbf{R}^3$, $x \to \mathbf{E}(x, E)$ is measurable on Ω;

(ii) For almost all $x \in \Omega$, $E \to \mathbf{E}(x, E)$ is continuous on $\mathbf{R}^3$.

In addition we suppose

(iii) $E \to \mathbf{E}(x, E)$ is a proper, convex, extended real-valued function for almost all $x \in \Omega$;

(iv)

$$\left| \int_\Omega \mathbf{E}(x, u(x))\, dx \right| < \infty$$

for all smooth functions u such that $u(x) = 0, x \in G$;

(v)

$$\mathbf{E}(x, E) = 0, \quad x \in F, \quad E \in \mathbf{R}^3;$$

(vi) There exist $q > 1$, $b : \Omega \to (0, \infty)$, and $c \in L_1(\Omega)$ such that

$$\mathbf{E}(x, E) \geqq b(x)|E|^q - c(x), \qquad x \in \Omega \backslash F,$$

where $1/b \in L_\alpha(\Omega)$, for some $\alpha > 1/(q-1)$.

Conditions (i) and (ii) are more or less unavoidable in a modern treatment of the calculus of variations; (iii)-(vi) ensure that the variational problem is bounded below and is convex, and guarantees the lower semicontinuity needed to invoke the theory of § 2 in certain Sobolev spaces of pth power integrable functions where

$$p = \frac{\alpha q}{1+\alpha} > 1. \tag{3.1}$$

Condition (iv) allows Ω to contain a region G of conducting material. We simply put

$$\mathbf{E}(x, 0) = 0, \qquad x \in G,$$

$$\mathbf{E}(x, E) = +\infty, \quad x \in G, \quad E \neq 0.$$

The integrand in the variational problem then penalises the conducting region naturally and forces $E = 0$ in G. Condition (v) allows Ω to contain regions of insulator.

3.3. Function spaces. Let $\hat{C}_\infty$ denote the space of all smooth functions on Ω that are zero in a neighbourhood of Γ_φ, and let $\hat{H}_p$ denote the completion of $\hat{C}_\infty$ with respect to the norm

$$\|u\|_p^p = \int_\Omega \{|u(x)|^p + |\nabla u(x)|^p\}\, dx.$$

Throughout this section p is given by the formula (3.1). We note, immediately, that if $u \in \hat{C}_\infty$, then Poincaré's inequality [3, Thm. 3.6.4] yields

$$\int_\Omega |u(x)|^p\, dx \leqq (\text{const}) \int_\Omega |\nabla u(x)|^p\, dx.$$

Hence the norm $\|\cdot\|_p$ is equivalent to $|\cdot|_p$ where

$$|u|_p^p = \int_\Omega |\nabla u(x)|^p\, dx, \qquad u \in \hat{H}_p.$$

Moreover, it follows that the space

$$V_p = \{E = \nabla\varphi : \varphi \in \hat{H}_p\}$$

is a closed subspace of $(L_p(\Omega))^3$. Since Γ_φ is not a subset of a plane, we know that the only constant function in V_p is zero.

Now we are in a position to formulate the electrostatic boundary value problem in a precise way.

3.4. Boundary value problems. The family of primal problems parametrised by $\Lambda \in \mathbf{R}^3$ is

$$\mathscr{P}_\Lambda: \inf_{E \in V_p} \frac{1}{|\Omega|} \int_\Omega \mathbf{E}(x, \Lambda + E(x))\, dx. \tag{3.2}$$

To put this in the context of § 2, we define our spaces of functions as follows:

$X = \{\Lambda : \Lambda \in \mathbf{R}^3\}$, the constant functions in $(L_p(\Omega))^3$;
$V = V_p$, a closed subspace of $(L_p(\Omega))^3$ with $V \cap X = \{0\}$;
$W =$ any topological complement of $X \oplus V$ in $(L_p(\Omega))^3$;
$X^* = (V \oplus W)^\perp \subset (L_{p'}(\Omega))^3$;
$V^* = (X \oplus W)^\perp \subset (L_{p'}(\Omega))^3$;
$W^* = (X \oplus V)^\perp \subset (L_{p'}(\Omega))^3$;

where $p^{-1} + p'^{-1} = 1$ and $\perp$, as usual, means the annihilator. Each is a normed linear space with respect to the norm inherited from $(L_p(\Omega))^3$ or $(L_{p'}(\Omega))^3$. Let $\langle u, v\rangle = (1/|\Omega|) \int_\Omega u(x) \cdot v(x)\, dx$, $(u, v) \in (L_p(\Omega))^3 \times (L_{p'}(\Omega))^3$.

LEMMA 3.1. *Each of* (X, X^*), (V, V^*), *and* (W, W^*) *is a pair of Banach spaces in separating duality (using the dual pairing of* $(L_p(\Omega))^3$ *and* $(L_{p'}(\Omega))^3$ *given above), and* X^* *has dimension three.*

Proof. Because of the symmetry in the definitions, it will suffice to show that the result holds for (W, W^*). If $w \in W$, then by the Hahn-Banach theorem there exists a bounded linear functional f on $(L_p(\Omega))^3$ such that $f(w) \neq 0$ and $f(X \oplus V) = 0$, since $X \oplus V$ is a closed subspace. Hence $f \in W^*$ and $f(w) \neq 0$. Now suppose $w^* \in W^*$. If $w^* \neq 0$, then there exists $u \in (L_p(\Omega))^3$ such that $w^*(u) \neq 0$. But $u = v + w + x \in V \oplus W \oplus X$, and so $w^*(w) \neq 0$ since $w^*(v + x) = 0$. Hence (W, W^*) are in separating duality.

Since X has dimension three, let $X = \operatorname{span}\{e_1, e_2, e_3\}$. By the Hahn-Banach theorem there exist three bounded linear functionals f_1, f_2, and f_3 on $(L_p(\Omega))^3$ such that $f_i(e_j) = \delta_{ij}$ and $f_i(V \oplus W) = 0$, $i = 1, 2, 3$. Hence these are three linearly independent elements of X^*. Now suppose that $f \in X^*$ and $x = \alpha e_1 + \beta e_2 + \gamma e_3 \in X$. Then $f(V \oplus W) = 0$, and $f(x) = f(\alpha e_1 + \beta e_2 + \gamma e_3) = f(e_1) f_1(x) + f(e_2) f_2(x) + f(e_3) f_3(x)$ and so $f \in \operatorname{span}\{f_1, f_2, f_3\}$. □

Let us suppose now that, with respect to the function spaces just specified, the functional

$$\mathscr{F}(v, w, \Lambda) = \frac{1}{|\Omega|} \int_\Omega \mathbf{E}(x, v(x) + w(x) + \Lambda)\, dx$$

satisfies the hypotheses of the propositions of § 2. (The proof that this is so under the assumptions of §§ 3.1 and 3.2 is the substance of § 4.) To calculate the dual family of problems parametrised by $\Lambda^* \in X^*$, we need to calculate the Legendre transform of $\mathscr{F}$. Now $|\mathscr{F}(0, 0, 0)| < \infty$ by condition (iv), and so, by [2, Chap. IX, Prop. 2.1], we find

that

$$\begin{aligned}
&\mathscr{F}^*(0, w^*, \Lambda^*) \\
&\quad = \sup_{(v,w,\Lambda)\in V\times W\times X} \left\{ \langle \Lambda, \Lambda^* \rangle + \frac{1}{|\Omega|} \int_\Omega \{ w(x)\cdot w^*(x) - \mathbf{E}(x, v(x)+w(x)+\Lambda)\}\, dx \right\} \\
&\quad = \sup_{(v,w,\Lambda)\in V\times W\times X} \frac{1}{|\Omega|} \int_\Omega \{ (v+w+\Lambda)\cdot(\Lambda^*+w^*) - \mathbf{E}(x, v+w+\Lambda\}\, dx \\
&\quad = \sup_{u\in (L_p(\Omega))^3} \frac{1}{|\Omega|} \int_\Omega \{ u\cdot(\Lambda^*+w^*) - \mathbf{E}(x, u)\}\, dx \\
&\quad = \frac{1}{|\Omega|} \int \mathbf{E}^*(x, \Lambda^*(x)+w^*(x))\, dx,
\end{aligned}$$

where $\mathbf{E}^*(x, u^*) = \sup_{u\in\mathbf{R}^3} \{u\cdot u^* - \mathbf{E}(x, u)\}$ for all $u^*\in\mathbf{R}^3$. (Here $\cdot$ denotes the usual inner product in $\mathbf{R}^3$.)

Hence, in the light of § 3.3, the dual family is parametrised by the three-dimensional linear space X^* as follows:

$$\mathscr{P}^*_{\Lambda^*}\colon \inf_{w^*\in W^*} \frac{1}{|\Omega|} \int_\Omega \mathbf{E}^*(x, \Lambda^*(x)+w^*(x))\, dx, \tag{3.3}$$

and for each $\Lambda^*\in X^*$ we let $F_*(\Lambda^*)$ denote the right-hand side of (3.3). The physical significance of $P^*_{\Lambda^*}$ may be elucidated by the following observations.

If $x\in F$, then $\mathbf{E}(x, E) = 0$ for all E, and so

$$\mathbf{E}^*(x, 0) = 0, \quad \mathbf{E}^*(x, u^*) = +\infty, \quad u^*\neq 0.$$

As a consequence, any $w^*\in W^*$ where the integral in (3.3) is finite has the property that $\Lambda^*(x)+w^*(x) = 0$ almost everywhere on F, the region containing the insulator. If $\Lambda^*\in X^*$ is fixed, then (3.3) is finite only if, in a weak sense,

$$\operatorname{Div}(\Lambda^*+w^*) = 0 \quad \text{on } \Omega, \tag{3.4}$$

$$(\Lambda^*+w^*) = 0 \quad \text{on } F, \tag{3.5}$$

$$(\Lambda^*+w^*).n = 0 \quad \text{on } \Gamma\backslash\Gamma_\varphi, \tag{3.6}$$

and

$$\frac{1}{|\Omega|} \int_\Omega (\Lambda^*(x)+w^*(x))\, dx = \frac{1}{|\Omega|} \int_\Omega \Lambda^*(x)\, dx, \tag{3.7}$$

since, by definition of the spaces,

$$\int_\Omega (\Lambda^*(x)+w^*(x))\cdot\nabla\varphi(x)\, dx = 0, \quad \varphi\in\hat{H}_p \quad \text{and} \quad \int_\Omega w^*(x)\, dx = 0. \tag{3.8}$$

Because of Lemma 3.1, we know that the mapping

$$\Lambda^* \to \frac{1}{|\Omega|} \int_\Omega \Lambda^*(x)\, dx \tag{3.9}$$

is a linear bijection from X^* onto $\mathbf{R}^3$. Therefore, the family of dual principles can

be rewritten in terms of variational problems for electric displacements with mean $\lambda^* = 1/|\Omega| \int_\Omega \Lambda^*(x)\,dx$ as follows (see (1.2)):

$$\mathscr{P}_{\lambda^*}: \inf_{\substack{u^* \in (L_{p'}(\Omega))^3, \\ \operatorname{Div} u^* = 0, \\ (1/|\Omega|)\int u^*(x)\,dx = \lambda^*, \\ u^* \cdot n = 0 \quad \text{on } \Gamma \setminus \Gamma_\varphi}} \frac{1}{|\Omega|} \int_\Omega \mathbf{E}^*(x, u^*(x))\,dx. \tag{3.10}$$

Note that for $(\Lambda, \Lambda^*) \in X \times X^*$,

$$\langle \Lambda, \Lambda^* \rangle = \frac{1}{|\Omega|} \int_\Omega \Lambda \cdot \Lambda^*(x)\,dx = \Lambda \cdot \lambda^*, \tag{3.11}$$

and note that the primary family of problems can be written in a weak sense as

$$\mathscr{P}_\Lambda: \inf_{\substack{\varphi \in W^{1,p}(\Omega), \\ \varphi = \Lambda \cdot x \quad \text{on } \Gamma_\varphi}} \frac{1}{|\Omega|} \int_\Omega \mathbf{E}(x, \nabla\varphi(x))\,dx.$$

(This means that φ is admissible if $(\varphi - \Lambda \cdot x) \in \hat{H}_p$.) The duality theory of § 2 can now be written out in the following weak sense:

$$F^*(\lambda^*) = f_*(\lambda^*) \quad \text{and} \quad (f_*)^*(\Lambda) = F(\Lambda), \tag{3.12}$$

i.e.,

$$\inf_{\substack{\varphi \in W^{1,p}(\Omega), \\ \varphi = \Lambda \cdot x \quad \text{on } \Gamma}} \frac{1}{|\Omega|} \int_\Omega \mathbf{E}(x, \nabla\varphi(x))\,dx + \inf_{\substack{u^* \in (L_{p'}(\Omega))^3, \\ \operatorname{Div} u^* = 0, \\ (1/|\Omega|)\int u^*(x)\,dx = \lambda^*, \\ u^* \cdot n = 0 \quad \text{on } \Gamma \setminus \Gamma_\varphi}} \frac{1}{|\Omega|} \int_\Omega \mathbf{E}^*(x, u^*(x))\,dx \geqq \Lambda \cdot \lambda^*$$

and equality holds if and only if

$$\lambda^* \in \partial F(\Lambda) \quad \text{and} \quad \Lambda \in \partial f_*(\lambda^*), \tag{3.13}$$

where $f_*(\lambda^*)$ denotes the right-hand side of (3.9) and ∂F denotes the subdifferential of F.

To complete the discussion, we note that both F and f_* are defined on $\mathbf{R}^3$ and are convex. Hence at every point Λ, $\partial F(\Lambda) \neq \varnothing$, and at every point λ^*, $\partial f_*(\lambda^*) \neq \varnothing$. Moreover, under the hypotheses on $\mathbf{E}$, $F(\Lambda)$ and $f_*(\lambda^*)$ are both attained at points of $\hat{H}_p$ and W^*.

The physical significance of these observations is an answer to the following question. If $\Lambda \in \mathbf{R}^3$ and $\mathscr{P}_\Lambda$ has equilibrium potential given by $\Lambda \cdot x + \varphi$, $\varphi \in \hat{H}_p$, what mean electric displacement must be prescribed to obtain *the same equilibrium* in this nonlinear problem? The answer is obtained by solving the first equation in (3.13).

Note that, because of the growth condition (vi) on the electric energy density function, there always exists $\varphi \in H_p$ such that $F(\Lambda) = \mathscr{F}(\Lambda + \nabla\varphi)$.

4. Lower semicontinuity. This section contains proofs of the technical results needed to invoke the theory of § 2 for the nonlinear dielectric functions. Throughout we will suppose that Ω and $\mathbf{E}$ are as specified in §§ 3.1 and 3.2, and that $p = \alpha q/(1+\alpha) > 1$. Let $\mathscr{F}: (L_p(\Omega))^3 \to \bar{\mathbf{R}}$ be defined by

$$\mathscr{F}(u) = \frac{1}{|\Omega|} \int_\Omega \mathbf{E}(x, u(x))\,dx, \qquad u \in (L_p(\Omega))^3. \tag{4.1}$$

Because of conditions (i)-(vi) in § 3, $\mathscr{F}$ is a proper convex function, and our first task is to show that it is lower semicontinuous with respect to the norm topology on $(L_p(\Omega))^3$. Suppose $u_n \to u$ in $(L_p(\Omega))^3$. Then, extracting a subsequence if necessary, we may suppose that $u_n \to u$ pointwise almost everywhere. Since $\mathbf{E}$ is bounded below on $\Omega\backslash F$ by the integrable function $-c$ and condition (v) holds, it is immediate from Fatou's lemma that

$$\mathscr{F}(u) \leqq \liminf \frac{1}{|\Omega|} \int_\Omega \mathbf{E}(x, u_n(x))\, dx.$$

In other words, $\mathscr{F}$ is lower semicontinuous on $(L_p(\Omega))^3$. Because $\mathscr{F}$ is convex it is lower semicontinuous with respect to weak convergence as well. Hence we can infer (2.5) and (2.6) without making any growth assumptions (such as condition (vi)) on $\mathbf{E}$. But we need to verify the hypotheses of Propositions 2.1 and 2.2 to get equality in these inequalities.

Let $\Lambda \in X$ and let h_Λ be defined by (2.7). Then $h_\Lambda(0, 0) < \infty$ by condition (iv). Let Λ be fixed, and let $(w_n, \lambda_n) \in W \times X$ be such that $(w_n, \lambda_n) \to (0, 0)$, and let $v_n \in V$ be such that

$$(4.2) \quad \mathscr{F}(v_n + w_n + \lambda_n + \Lambda) = \frac{1}{|\Omega|} \int_\Omega \mathbf{E}(x, v_n + w_n + \lambda_n + \Lambda)\, dx \leqq h_\Lambda(w_n, \lambda_n) + 1/n.$$

Now the boundary of $(\Omega\backslash F)$ is Lipschitz, and so by Stein's extension theory [5, Chap. VI, § 3], there is no loss of generality in supposing that

$$\|v_n\|_{(L_p(\Omega))^3} \leqq (\text{const}) \|v_n\|_{(L_p(\Omega\backslash F))^3} \quad \text{since } \mathbf{E}(x, E) = 0, \quad x \in F.$$

If $h_\Lambda(w_n, \lambda_n) \to \infty$ as $n \to \infty$, then it is trivial that $h_\Lambda(0, 0) \leqq \liminf h_\Lambda(w_n, \lambda_n)$. So suppose $h_\Lambda(w_n, \lambda_n)$ is bounded, by M, say. Then by (4.2) and condition (vi), putting $v_n + w_n + \lambda_n + \Lambda = u_n$, we get

$$\int_{\Omega\backslash F} |u_n(x)|^p\, dx = \int_{\Omega\backslash F} |[b(x)^{p/q} |u_n(x)|^p](b(x))^{-p/q}|\, dx$$

(by Hölder's inequality)

$$\leqq \left\{ \int_{\Omega\backslash F} b(x) |u_n(x)|^q\, dx \right\}^{p/q} \left\{ \int_{\Omega\backslash F} b(x)^{-p/(q-p)}\, dx \right\}^{(q-p)/q}$$

$$\leqq \left\{ \int_\Omega \mathbf{E}(x, u_n(x))\, dx + \|c\|_{L_1(\Omega)} \right\}^{p/q} \left\{ \int_\Omega \left| \frac{1}{b(x)} \right|^\alpha \right\}^{(q-p)/q},$$

since $\mathbf{E}(x, E) = 0$, $x \in F$. Hence $\|u_n\|_{(L_p(\Omega\backslash F))^3}$ is bounded. Since $w_n + \lambda_n \to 0$ in $(L_p(\Omega))^3$, we conclude that (v_n) is bounded in $(L_p(\Omega\backslash F))^3$ and hence in $(L_p(\Omega))^3$. Since $p > 1$, (v_n) has a weakly convergent subsequence, $v_n \overset{w}{\to} v$, say, and $v \in V$ because V is weakly closed. Since $\mathscr{F}$ is weakly lower semicontinuous in $(L_p(\Omega))^3$ we find that

$$h_\Lambda(0, 0) \leqq \mathscr{F}(v + \Lambda) \leqq \liminf \mathscr{F}(v_n + w_n + \lambda_n + \Lambda)$$

$$\leqq \liminf h_\Lambda(w_n, \lambda_n),$$

which proves that the hypotheses of Proposition 2.1 hold.

Finally, to verify the hypotheses of Proposition 2.2, we note that the argument for H_{Λ^*} being finite and for H_{Λ^*} being lower semicontinuous is identical to the one that we have just given. □

ELECTROSTATIC PROBLEMS FOR TWO CONDUCTING SPHERES*

ANDREW H. VAN TUYL†

Abstract. Investigations are carried out for two spheres at given potentials V_1 and V_2, and for two spheres at potential zero in the presence of an outside unit point charge. Integral representations involving elliptic functions are obtained for the solutions of these problems, starting from series solutions in dipolar coordinates. These integral representations are used to obtain the asymptotic behavior of the charge density as the distance ε between the spheres tends to zero. Integral representations are found for the limiting charge density as $\varepsilon \to 0$, and convergent and asymptotic expansions for the limiting charge density are obtained. These results are used to investigate circles of zero charge density in the limit $\varepsilon \to 0$.

Key words. electrostatic problems, two spheres, potential, charge density

AMS(MOS) subject classification. 31B20

1. Introduction. The potential outside two charged conducting spheres was first given by Poisson [17] in 1811. Further investigations were carried out by Plana [16] in 1845, Kirchhoff [10] in 1861, and Carl Neumann [13] in 1863. Dipolar coordinates were used in [13], and the Green function for the exterior of two spheres was given for the first time. Later work concerning two charged spheres includes investigations by Jeffery [5], who developed the use of dipolar coordinates further, and Russell [18]–[21]. A detailed treatment of electrostatic problems for two spheres has been given by Kottler in [11]. More recently, electrostatic problems for two spheres have been of interest in connection with the conductivity of granular materials (Keller [9], Batchelor and O'Brien [2], and Jeffrey [6], for example). In [7], Jeffrey has used an approach for nearly touching spheres based on the method of matched asymptotic expansions.

The present paper is concerned with investigations of the solutions of the electrostatic problems for two spheres defined by the following conditions: (1) The spheres are at given potentials V_1 and V_2; (2) The spheres are at potential zero in the presence of an outside point charge. These will be referred to as the first and second problems, respectively. The present investigation starts from the solutions of the first and second problems in dipolar coordinates in the form given by Ernst Neumann [14]. The solutions of these problems, including the potentials, charge densities, and total charges, are first expressed in terms of definite integrals that involve elliptic functions. From these integrals, definite integral representations are found for the limits of the charge densities in the first and second problems as the distance ε between the spheres goes to zero. Convergent and asymptotic expansions are obtained for the charge density at the inner axial points of the spheres as ε goes to zero, and for the limiting charge density.

Kirchhoff [10] found that the charge density at the inner axial points of two spheres with potentials and radii equal to unity is asymptotically proportional to $\varepsilon^{-3/2} \exp(-2^{-1}\pi^2\varepsilon^{-1/2})$ as ε tends to zero, correcting the orders of magnitude ε^2 and ε^3 given by Poisson [17] and Plana [16], respectively. In § 7 of the present paper, Kirchhoff's result is obtained from the integral representation for the charge density

* Received by the editors September 29, 1987; accepted for publication (in revised form) November 18, 1988. These results have been obtained at various times during the past 40 years, starting from portions of the author's unpublished Ph.D. thesis. Most of the results of §§ 4–6 were obtained at Indiana University in 1953 under Army Ordnance Contract DA-33-008 ord-454.

† Applied Mathematics Branch, Code R44, Naval Surface Warfare Center, Silver Spring, Maryland 20903-5000.

in § 6. In § 8, the corresponding result is found for the charge density in the second problem. It is found that the behavior with respect to ε remains the same as in the first problem, but with a coefficient which depends on the position of the point charge.

In § 10, the limiting charge densities in the first and second problems as $\varepsilon \to 0$ are expressed in terms of definite integrals. In §§ 11–14, these integrals are used to obtain various expansions, both convergent and asymptotic, for the limiting charge density. One of these expansions is a power series expansion in the neighborhood of the outer axial point. In § 15, this expansion is used to find the ratio $V_2/V_1 > 1$ such that, in the limit $\varepsilon \to 0$, all the charge on sphere 1 is negative while V_1 is positive.

2. Dipolar coordinates. Dipolar coordinates η, θ, and ϕ are defined by the equations

$$x + i\rho = ia \cot \tfrac{1}{2}(\theta + i\eta), \tag{2.1}$$

$$y = \rho \cos \phi, \qquad z = \rho \sin \phi, \tag{2.2}$$

with $a > 0$, $\rho > 0$. Let the points $(a, 0, 0)$ and $(-a, 0, 0)$ in Cartesian coordinates be denoted by A_1 and A_2, respectively. The coordinate surface $\eta =$ constant is a sphere with A_1 and A_2 as inverse points, and $\theta =$ constant is a spindle with A_1 and A_2 as vertices.

When $\eta_1 > 0$, the sphere $\eta = \eta_1$ has radius a csch η_1 and center at $x = a \coth \eta_1$, $y = z = 0$. Let P_1 be an arbitrary point on the sphere $\eta = \eta_1 > 0$, let its center be denoted by O_1, and let the angle between O_1P_1 and the negative x-axis be denoted by ω_1. Denoting the coordinates of P_1 by the subscript 1, we have

$$x_1 = a(\coth \eta_1 - \operatorname{csch} \eta_1 \cos \omega_1), \qquad \rho_1 = a \operatorname{csch} \eta_1 \sin \omega_1. \tag{2.3}$$

From (2.1) and (2.2), it follows that

$$\sin \theta_1 = \frac{\sinh \eta_1 \sin \omega_1}{\cosh \eta_1 - \cos \omega_1}, \tag{2.4}$$

with $\theta_1 = \pi$ when $\omega_1 = 0$ and $\theta_1 = 0$ when $\omega_1 = \pi$.

Given the two spheres $\eta = \eta_1$ and $\eta = \eta_2$, $\eta_1 > 0 > \eta_2$, the former contains A_1 in its interior and the latter contains A_2. Let their radii be r_1 and r_2, respectively, and let the distance between their centers be c. Since A_1 and A_2 are inverse with respect to both spheres, we have

$$\sqrt{r_1^2 + a^2} + \sqrt{r_2^2 + a^2} = c, \tag{2.5}$$

which yields

$$a = \sqrt{\left(\frac{c^2 - r_2^2 + r_1^2}{2c}\right)^2 - r_1^2} = \sqrt{\left(\frac{c^2 - r_1^2 + r_2^2}{2c}\right)^2 - r_2^2}. \tag{2.6}$$

Substituting $c = r_1 + r_2 + \varepsilon$, $\varepsilon > 0$, we find from either expression for a in (2.6) that

$$a = \frac{\sqrt{\varepsilon(\varepsilon + 2r_1)(\varepsilon + 2r_2)(\varepsilon + 2r_1 + 2r_2)}}{2(\varepsilon + r_1 + r_2)}. \tag{2.7}$$

In the special case $r_1 = r_2 = r$, (2.7) simplifies to

$$a = \tfrac{1}{2}\sqrt{\varepsilon(\varepsilon + 4r)}. \tag{2.8}$$

We also have

$$\eta_1 = \sinh^{-1} \frac{a}{r_1}, \qquad \eta_2 = -\sinh^{-1} \frac{a}{r_2}. \tag{2.9}$$

We can calculate a, η_1, and η_2 by use of (2.7)-(2.9) when r_1, r_2, and ε are known. When $\varepsilon \to 0$, we see that

$$a = \sqrt{\frac{2r_1r_2\varepsilon}{r_1+r_2}}[1+O(\varepsilon)], \tag{2.10}$$

$$\eta_1 = \sqrt{\frac{2r_2\varepsilon}{r_1(r_1+r_2)}}[1+O(\varepsilon)], \tag{2.11}$$

and

$$\eta_1 - \eta_2 = \sqrt{\frac{2(r_1+r_2)\varepsilon}{r_1r_2}}[1+O(\varepsilon)]. \tag{2.12}$$

From (2.4), (2.10), and (2.11), we find that

$$\theta_1 = \left(\frac{a}{r_1}\cot\frac{\omega_1}{2}\right)[1+O(\varepsilon)] \tag{2.13}$$

as $\varepsilon \to 0$. Finally, at a given point in space, we find from (2.1) that

$$\eta = \frac{2ax}{x^2+\rho^2}[1+O(\varepsilon)] \tag{2.14}$$

and

$$\theta = \frac{2a\rho}{x^2+\rho^2}[1+O(\varepsilon)] \tag{2.15}$$

as $\varepsilon \to 0$. Equation (2.7) does not appear to be in the literature.

3. Solutions of the electrostatic problems. In the coordinate system of § 2, let the given spheres be the coordinate surfaces $\eta = \eta_1$ and $\eta = \eta_2$, respectively, $\eta_1 > 0 > \eta_2$. In the first problem, we assume that the spheres are charged to constant potentials V_1 and V_2, respectively. In the second problem, the spheres are at zero potential in the presence of a unit point charge at the point $(\eta_0, \theta_0, \phi_0)$, where $\eta_1 > \eta_0 > \eta_2$. We will start with the solutions of these problems as given by Ernst Neumann in [14].

It is convenient to express the solutions of the first and second problems in terms of the function

$$I(\zeta, \theta) = \frac{1}{2}\sum_{n=0}^{\infty}\frac{\exp(N\zeta)}{\sinh N\delta}P_n(\cos\theta), \tag{3.1}$$

where $N = n+\frac{1}{2}$, $0 \leqq \theta \leqq \pi$, $P_n(\cos\theta)$ is the Legendre polynomial of degree n, $\delta > 0$, and $\operatorname{Re}\zeta < \delta$. We see that $I(\zeta, \theta)$ is an analytic function of ζ for $\operatorname{Re}\zeta < \delta$, and that (3.1) and

$$\frac{\partial I(\zeta, \theta)}{\partial\zeta} = \frac{1}{2}\sum_{n=0}^{\infty}\frac{N\exp(N\zeta)}{\sinh N\delta}P_n(\cos\theta) \tag{3.2}$$

are continuous with respect to θ at $\theta = 0$ and π when $\operatorname{Re}\zeta < \delta$. The latter follows immediately from uniform convergence with respect to θ in the interval $0 \leqq \theta \leqq \pi$, since we then have $|P_n(\cos\theta)| \leqq 1$.

Let the potential outside the spheres in the first problem be written in the form

$$V = \left(\frac{V_1+V_2}{2}\right)V^{(1)} + \left(\frac{V_1-V_2}{2}\right)V^{(2)}. \tag{3.3}$$

Then from [14] and (3.1), we have

$$V^{(1)} = \psi^{1/2}[I(\zeta_1, \theta) + I(-\zeta_1, \theta) - I(\zeta_2, \theta) - I(-\zeta_2-2\delta, \theta)], \tag{3.4}$$

and

$$V^{(2)} = \psi^{1/2}[I(\zeta_1, \theta) - I(-\zeta_1, \theta) + I(\zeta_2, \theta) - I(-\zeta_2 - 2\delta, \theta)], \tag{3.5}$$

where $\psi = 2(\cosh \eta - \cos \theta)$, $\delta = \eta_1 - \eta_2$, $\zeta_1 = \eta - \eta_1 - \eta_2$, and $\zeta_2 = \eta - \delta$. For the charge density on sphere 1, we have

$$D_1 = \left(\frac{V_1 + V_2}{2}\right) D_{11} + \left(\frac{V_1 - V_2}{2}\right) D_{12}, \tag{3.6}$$

where

$$D_{11} = \frac{\psi_1^{3/2}}{4\pi a} \frac{\partial}{\partial \zeta} [I(\zeta, \theta_1) + I(-\zeta, \theta_1)]|_{\zeta = -\eta_2} \tag{3.7}$$

and

$$D_{12} = \frac{\psi_1^{3/2}}{4\pi a} \frac{\partial}{\partial \zeta} [I(\zeta, \theta_1) - I(-\zeta, \theta_1)]|_{\zeta = -\eta_2}, \tag{3.8}$$

with $\psi_1 = 2(\cosh \eta_1 - \cos \theta_1)$. Finally, the coefficients of capacity and induction are given by

$$C_{11} = 2a \lim_{\theta \to 0} I(-\eta_1 - \eta_2, \theta), \tag{3.9}$$

$$C_{12} = -2a \lim_{\theta \to 0} I(-\delta, \theta), \tag{3.10}$$

and

$$C_{22} = 2a \lim_{\theta \to 0} I(\eta_1 + \eta_2, \theta). \tag{3.11}$$

The charge density on sphere 2 is obtained from (3.6)-(3.8) by interchanging subscripts 1 and 2 and reversing the signs of η_1 and η_2.

The potential satisfying the second problem is the Green function for the exterior of the spheres with respect to the point $(\eta_0, \theta_0, \phi_0)$. Denoting this potential by $G = 1/r + H$, we have

$$\begin{aligned} H = -\frac{\psi_0^{1/2}\psi^{1/2}}{2a} &[I(\zeta_1 + \eta_0, \gamma) + I(-\zeta_1 - \eta_0, \gamma) \\ &- I(\zeta_2 - \eta_0, \gamma) - I(-\zeta_2 + \eta_0 - 2\delta, \gamma)], \end{aligned} \tag{3.12}$$

where $\psi_0 = 2(\cosh \eta_0 - \cos \theta_0)$ and $\cos \gamma = \cos \theta \cos \theta_0 + \sin \theta \sin \theta_0 \cos (\phi - \phi_0)$. Finally, the charge density and total charge on sphere 1 are given by

$$D_1^* = -\frac{\psi_0^{1/2}\psi_1^{3/2}}{8\pi a^2} \frac{\partial}{\partial \zeta} [I(\zeta, \gamma_1) + I(-\zeta, \gamma_1)]|_{\zeta = \eta_0 - \eta_2} \tag{3.13}$$

and

$$Q_1^* = -\psi_0^{1/2}[I(\eta_0 - \eta_1 - \eta_2, \theta_0) - I(-\eta_0 - \delta, \theta_0)], \tag{3.14}$$

respectively. As before, we obtain D_2^* and Q_2^* by interchanging the subscripts 1 and 2 and reversing the signs of η_0, η_1, and η_2. We note that $-D_1^*$ and $-D_2^*$ form the kernel for the solution of the Dirichlet problem for the exterior of the two spheres.

4. Analytic continuation of $I(\zeta, \theta)$. When $0 < \theta < \pi$ and $\operatorname{Re} \zeta < \delta$, $\delta > 0$, we find that

$$\begin{aligned} I(\zeta, \theta) - I(\zeta - 2\delta, \theta) &= \sum_{n=0}^{\infty} \exp N(\zeta - \delta) P_n(\cos \theta) \\ &= [2 \cosh (\zeta - \delta) - 2 \cos \theta]^{-1/2}. \end{aligned} \tag{4.1}$$

We see that the right side of (4.1) is positive when ζ is real, and that it is single valued when the ζ-plane is cut along the line $\operatorname{Re}\zeta=\delta$ from $\delta+(2\pi n+\theta)i$ to $\delta+[(2n+2)\pi-\theta]i$ and from $\delta-(2\pi n+\theta)i$ to $\delta-[(2n+2)\pi-\theta]i$, $n\geqq 0$. Since $I(\zeta-2\delta,\theta)$ is analytic for $\operatorname{Re}\zeta<3\delta$, it follows that it is the analytic continuation of $I(\zeta,\theta)-[2\cosh(\zeta-\delta)-2\cos\theta]^{-1/2}$ in the region $\delta<\operatorname{Re}\zeta<3\delta$. Repeated application of (4.1) leads to the result

$$I(\zeta,\theta)=\sum_{r=1}^{m}\{2\cosh[\zeta-(2r-1)\delta]-2\cos\theta\}^{-1/2}+I(\zeta-2m\delta,\theta) \tag{4.2}$$

with $m\geqq 1$, valid for $\operatorname{Re}\zeta<(2m+1)\delta$ when the ζ-plane is cut from $(2r-1)\delta+(2n\pi+\theta)i$ to $(2r-1)\delta+[(2n+2)\pi-\theta)]i$ and from $(2r-1)\delta-(2n\pi+\theta)i$ to $(2r-1)\delta-[(2n+2)\pi-\theta]i$, $n\geqq 0$, $1\leqq r\leqq m$.

We have

$$|I(\zeta-2m\delta,\theta)|<\frac{|\exp(\zeta/2)|\exp(-m\delta)}{\sinh(\delta/2)} \tag{4.3}$$

for sufficiently large m. Hence, the expansion

$$I(\zeta,\theta)=\sum_{r=1}^{\infty}\{2\cosh[\zeta-(2r-1)\delta]-2\cos\theta\}^{-1/2} \tag{4.4}$$

holds for all ζ in the cut plane. Substitution of (4.4) in (3.3)-(3.5) gives the solution of the first problem as obtained by the method of images.

5. Integral representations for $I(\zeta,\theta)$. As before, let $\delta>0$ and $0<\theta<\pi$. When $-\delta<\operatorname{Re}\zeta<\delta$, we have

$$I(\zeta,\theta)+I(-\zeta,\theta)=\sum_{n=0}^{\infty}\frac{\cosh N\zeta}{\sinh N\delta}P_n(\cos\theta) \tag{5.1}$$

and

$$I(\zeta,\theta)-I(-\zeta,\theta)=\sum_{n=0}^{\infty}\frac{\sinh N\zeta}{\sinh N\delta}P_n(\cos\theta). \tag{5.2}$$

Substituting

$$P_n(\cos\theta)=\frac{2}{\pi}\int_{\theta}^{\pi}\frac{\sin Nt\,dt}{(2\cos\theta-2\cos t)^{1/2}} \tag{5.3}$$

[23, p. 315], in (5.1) and interchanging summation and integration, we obtain

$$I(\zeta,\theta)+I(-\zeta,\theta)=\frac{2}{\pi}\int_{\theta}^{\pi}(2\cos\theta-2\cos t)^{-1/2}\sum_{n=0}^{\infty}\frac{\cosh N\zeta\sin Nt}{\sinh N\delta}dt \tag{5.4}$$

when $-\delta<\operatorname{Re}\zeta<\delta$. The interchange of summation and integration is valid by [3, p. 495], since the series in (5.4) is uniformly convergent with respect to t for $\theta\leqq t\leqq\pi$, while the integral of $(2\cos\theta-2\cos t)^{-1/2}$ between θ and π is convergent. Similarly, from

$$P_n(\cos\theta)=\frac{2}{\pi}\int_{0}^{\theta}\frac{\cos Nt\,dt}{(2\cos t-2\cos\theta)^{1/2}} \tag{5.5}$$

[23, p. 315], and (5.2), we have

$$I(\zeta,\theta)-I(-\zeta,\theta)=\frac{2}{\pi}\int_{0}^{\theta}(2\cos t-2\cos\theta)^{-1/2}\sum_{n=0}^{\infty}\frac{\sinh N\zeta\cos Nt}{\sinh N\delta}dt \tag{5.6}$$

when $-\delta < \operatorname{Re}\zeta < \delta$. Finally, let k be defined by the equation

$$\delta = \pi K'/K, \tag{5.7}$$

where K is the complete elliptic integral of the first kind with modulus k and $K' = K(k')$, $k'^2 = 1 - k^2$. Then from (5.4), (5.6), and [23, p. 511], we obtain the integral representations

$$I(\zeta, \theta) + I(-\zeta, \theta) = \frac{Kk}{\pi^2}\int_\theta^\pi (2\cos\theta - 2\cos t)^{-1/2} \times \left[\operatorname{sn}\frac{K}{\pi}(t+i\zeta) + \operatorname{sn}\frac{K}{\pi}(t-i\zeta)\right] dt \tag{5.8}$$

and

$$I(\zeta, \theta) - I(-\zeta, \theta) = -i\frac{Kk}{\pi^2}\int_0^\theta (2\cos t - 2\cos\theta)^{-1/2} \times \left[\operatorname{sn}\frac{K}{\pi}(t+i\zeta) - \operatorname{sn}\frac{K}{\pi}(t-i\zeta)\right] dt \tag{5.9}$$

for $-\delta < \operatorname{Re}\zeta < \delta$, $0 < \theta < \pi$.

From (4.4), it follows that

$$I(\zeta - \delta, \theta) \pm I(-\zeta - \delta, \theta) = I(\zeta - \delta, \theta) \pm I(-\zeta + \delta, \theta) \mp (2\cosh\zeta - 2\cos\theta)^{-1/2} \tag{5.10}$$

for all ζ in the cut ζ-plane. When $\operatorname{Re}\zeta > 0$, we can verify that

$$\int_\theta^\pi (2\cos\theta - 2\cos t)^{-1/2}\left[\csc\frac{1}{2}(t+i\zeta) + \csc\frac{1}{2}(t-i\zeta)\right] dt = 2\pi(2\cosh\zeta - 2\cos\theta)^{-1/2} \tag{5.11}$$

and

$$\int_0^\theta (2\cos t - 2\cos\theta)^{-1/2}\left[\csc\frac{1}{2}(t+i\zeta) - \csc\frac{1}{2}(t-i\zeta)\right] dt = -2\pi i(2\cosh\zeta - 2\cos\theta)^{-1/2}. \tag{5.12}$$

The former can be shown by substituting $\cos(t/2) = \cos(\theta/2)\sin\phi$, and the latter, by substituting $\sin(t/2) = \sin(\theta/2)\sin\phi$. From (5.8)-(5.12), and using the addition theorem for sn u, we obtain

$$I(\zeta - \delta, \theta) + I(-\zeta - \delta, \theta) = \frac{K}{\pi^2}\int_\theta^\pi (2\cos\theta - 2\cos t)^{-1/2} \cdot \left\{\operatorname{ns}\frac{K}{\pi}(t+i\zeta) + \operatorname{ns}\frac{K}{\pi}(t-i\zeta) - \frac{\pi}{2K}\left[\csc\frac{1}{2}(t+i\zeta) + \csc\frac{1}{2}(t-i\zeta)\right]\right\} dt \tag{5.13}$$

and

$$I(\zeta - \delta, \theta) - I(-\zeta - \delta, \theta) = -\frac{iK}{\pi^2}\int_0^\theta (2\cos t - 2\cos\theta)^{-1/2} \cdot \left\{\operatorname{ns}\frac{K}{\pi}(t+i\zeta) - \operatorname{ns}\frac{K}{\pi}(t-i\zeta) - \frac{\pi}{2K}\left[\csc\frac{1}{2}(t+i\zeta) - \csc\frac{1}{2}(t-i\zeta)\right]\right\} dt \tag{5.14}$$

when $0 < \operatorname{Re}\zeta < 2\delta$. However, both sides of (5.13) and (5.14) are seen to be analytic for $-2\delta < \operatorname{Re}\zeta < 2\delta$, and hence, it follows by analytic continuation that they are valid

in the larger region. The preceding treatment can be extended to give integral representations which are valid in still wider strips of the ζ-plane.

Substituting $\cos(t/2)=\cos(\theta/2)\sin\phi$ in (5.8) and (5.13), and $\sin(t/2)=\sin(\theta/2)\sin\phi$ in (5.9) and (5.14), we find that

$$\lim_{\theta\to\pi}[I(\zeta,\theta)+I(-\zeta,\theta)]=\frac{Kk}{\pi}\operatorname{cd}\frac{iK\zeta}{\pi}, \tag{5.15}$$

$$\lim_{\theta\to 0}[I(\zeta,\theta)-I(-\zeta,\theta)]=-\frac{iKk}{\pi}\operatorname{sn}\frac{iK\zeta}{\pi}, \tag{5.16}$$

and

$$\lim_{\theta\to\pi}[I(\zeta-\delta,\theta)+I(-\zeta-\delta,\theta)]=\frac{K}{\pi}\left(\operatorname{dc}\frac{iK\zeta}{\pi}-\frac{\pi}{2K}\sec\frac{i\zeta}{2}\right), \tag{5.17}$$

$$\lim_{\theta\to 0}[I(\zeta-\delta,\theta)-I(-\zeta-\delta,\theta)]=-\frac{iK}{\pi}\left(\operatorname{ns}\frac{iK\zeta}{\pi}-\frac{\pi}{2K}\csc\frac{i\zeta}{2}\right). \tag{5.18}$$

We see that (5.8) and (5.13) remain valid for $\theta=0$, and that (5.9) and (5.14) remain valid for $\theta=\pi$. In particular, from (5.13), we have

$$\lim_{\theta\to 0}I(-\delta)=\frac{K}{2\pi^2}\int_0^{\pi}\left(\operatorname{ns}\frac{Kt}{\pi}-\frac{\pi}{2K}\csc\frac{t}{2}\right)\csc\frac{t}{2}\,dt. \tag{5.19}$$

6. Integral representations for the solutions of the electrostatic problems. We have $-\delta<\eta-\eta_1-\eta_2<\delta$ and $-2\delta<\eta<2\delta$ when $2\eta_2<\eta<2\eta_1$, where $\delta=\eta_1-\eta_2$. Then from (3.4), (3.5), and the preceding section, and using the addition theorem for sn u, we obtain

$$V^{(1)}=\frac{2K}{\pi^2}\psi^{1/2}\int_{\theta}^{\pi}(2\cos\theta-2\cos t)^{-1/2}\operatorname{Re}\left\{\operatorname{ns}\frac{K}{\pi}[(t+i(\eta-2\eta_1)]\right.$$
$$\left.-\operatorname{ns}\frac{K}{\pi}(t+i\eta)+\frac{\pi}{2K}\csc\frac{1}{2}(t+i\eta)\right\}dt \tag{6.1}$$

and

$$V^{(2)}=\frac{2K}{\pi^2}\psi^{1/2}\int_{0}^{\theta}(2\cos t-2\cos\theta)^{-1/2}\operatorname{Im}\left\{\operatorname{ns}\frac{K}{\pi}[t+i(\eta-2\eta_1)]\right.$$
$$\left.+\operatorname{ns}\frac{K}{\pi}(t+i\eta)-\frac{\pi}{2K}\csc\frac{1}{2}(t+i\eta)\right\}dt \tag{6.2}$$

when $2\eta_2<\eta<2\eta_1$. We see that the region exterior to the spheres, defined by $\eta_2<\eta<\eta_1$, is included in this inequality. It is easily verified that differentiation of the integrals in the preceding section with respect to ζ can be carried out under the integral sign. From (3.7), (3.8), (5.7), and (5.8), we therefore have

$$D_{11}=\frac{K^2k}{2\pi^4a}\psi_1^{3/2}\int_{\theta_1}^{\pi}(2\cos\theta_1-2\cos t)^{-1/2}\operatorname{Im}\operatorname{cn}\frac{K}{\pi}(t+i\eta_2)\operatorname{dn}\frac{K}{\pi}(t+i\eta_2)\,dt \tag{6.3}$$

and

$$D_{12}=\frac{K^2k}{2\pi^4a}\psi_1^{3/2}\int_{0}^{\theta_1}(2\cos t-2\cos\theta_1)^{-1/2}\operatorname{Re}\operatorname{cn}\frac{K}{\pi}(t+i\eta_2)\operatorname{dn}\frac{K}{\pi}(t+i\eta_2)\,dt. \tag{6.4}$$

From (3.9)-(3.11), and the results of the preceding section, noting that $-\delta < \eta_1 + \eta_2 < \delta$, we find that

$$C_{11} = \frac{aKk}{\pi^2}\int_0^{\pi} \operatorname{Re}\operatorname{sn}\frac{K}{\pi}[t + i(\eta_1+\eta_2)]\csc\frac{t}{2}\,dt + \frac{iaKk}{\pi}\operatorname{sn}\frac{iK}{\pi}(\eta_1+\eta_2), \tag{6.5}$$

$$C_{12} = -\frac{aK}{\pi^2}\int_0^{\pi}\left(\operatorname{ns}\frac{Kt}{\pi} - \frac{\pi}{2K}\csc\frac{t}{2}\right)\csc\frac{t}{2}\,dt, \tag{6.6}$$

and

$$C_{22} = C_{11} - \frac{2iaKk}{\pi}\operatorname{sn}\frac{iK}{\pi}(\eta_1+\eta_2). \tag{6.7}$$

Similarly, in the second problem, we have $-\delta < \eta - \eta_1 - \eta_2 + \eta_0 < \delta$ and $-2\delta < \eta - \eta_0 < 2\delta$ when $\eta_2 < \eta < \eta_1$ and $\eta_2 < \eta_0 < \eta_1$. Then as before, we have

$$\begin{aligned} H = -\frac{K}{\pi^2}\psi_0^{1/2}\int_{\gamma}^{\pi}(2\cos\gamma - 2\cos t)^{-1/2}\operatorname{Re}\Big\{&\operatorname{ns}\frac{K}{\pi}[t + i(\eta-\eta_1-\eta_2+\eta_0)] \\ &- \operatorname{ns}\frac{K}{\pi}[t+i(\eta-\eta_0)] + \frac{\pi}{2K}\csc\frac{1}{2}[t+i(\eta-\eta_0)]\Big\}\,dt, \end{aligned} \tag{6.8}$$

$$\begin{aligned} D_1^* = -\frac{K^2k}{4\pi^4a^2}\psi_0^{1/2}\psi_1^{3/2} &\cdot \int_{\gamma_1}^{\pi}(2\cos\gamma_1 - 2\cos t)^{-1/2}\operatorname{Im}\operatorname{cn}\frac{K}{\pi}[t+i(\eta_2-\eta_0)]\operatorname{dn}\frac{K}{\pi}[t+i(\eta_2-\eta_0)]\,dt, \end{aligned} \tag{6.9}$$

and

$$\begin{aligned} Q_i^* = -\frac{K}{\pi^2}\psi_0^{1/2}\Bigg\{&\int_{\theta_0}^{\pi}(2\cos\theta_0 - 2\cos t)^{-1/2} \\ &\cdot \operatorname{Re}\left\{\operatorname{ns}\frac{K}{\pi}[t+i(\eta_0-2\eta_1)] - \operatorname{ns}\frac{K}{\pi}(t+i\eta_0) + \frac{\pi}{2K}\csc\frac{1}{2}(t+i\eta_0)\right\}dt \\ &+ \int_0^{\theta_0}(2\cos t - 2\cos\theta_0)^{-1/2} \\ &\cdot \operatorname{Im}\left\{\operatorname{ns}\frac{K}{\pi}[t+i(\eta_0-2\eta_1)] + \operatorname{ns}\frac{K}{\pi}(t+i\eta_0) - \frac{\pi}{2K}\csc\frac{1}{2}(t+i\eta_0)\right\}dt\Bigg\} \end{aligned} \tag{6.10}$$

when $\eta_2 < \eta < \eta_1$ and $\eta_2 < \eta_0 < \eta_1$.

7. Behavior of D_{11} at the inner axial point as $\varepsilon \to 0$. Passing to the limit $\theta_1 = \pi$ in (6.3) by use of the substitution $\cos(t/2) = \cos(\theta_1/2)\sin\phi$, substituting $\eta_2 = \eta_1 - \pi K'/K$, and using the addition theorems for cn u and dn u, we obtain

$$D_{11}|_{\theta_1=\pi} = -i\frac{K^2kk'^2}{4\pi^3a}\psi_1^{3/2}\frac{\operatorname{sn}\dfrac{iK\eta_1}{\pi}}{\operatorname{cn}^2\dfrac{iK\eta_1}{\pi}}. \tag{7.1}$$

This expression was given in an equivalent form by Kirchhoff [10, p. 99], in terms of a modulus related to the present one by Landen's transformation. To obtain a series

for $D_{11}|_{\theta_1=\pi}$ which converges rapidly for small ε, we first find by use of Jacobi's imaginary transformation [23, p. 506] that

$$D_{11}|_{\theta_1=\pi}=\frac{K^2k'^2}{4\pi^3a}\psi_1^{3/2}\operatorname{sn}\left(\frac{K\eta_1}{\pi},k'\right)\operatorname{cn}\left(\frac{K\eta_1}{\pi},k'\right). \tag{7.2}$$

Noting that $k'^2\operatorname{sn}(u,k')\operatorname{cn}(u,k')=-(d/du)\operatorname{dn}(u,k')$ and referring to [23, p. 511], we obtain the expansion

$$D_{11}|_{\theta_1=\pi}=\frac{\psi_1^{3/2}}{2\pi a}\left(\frac{K}{K'}\right)^2\sum_{n=1}^{\infty}\frac{nq'^n}{1+q'^{2n}}\sin\frac{nK\eta_1}{K'}, \tag{7.3}$$

where $q'=\exp(-\pi K/K')$. Denoting the remainder after the first term of the series in (7.3) by R, we have

$$|R|<\sum_{n=2}^{\infty}nq'^n<\frac{2q'^2}{(1-q')^2} \tag{7.4}$$

and hence,

$$D_{11}|_{\theta_1=\pi}=\frac{\psi_1^{3/2}}{2\pi a}\left(\frac{K}{K'}\right)^2q'\sin\frac{K\eta_1}{K'}[1+O(q')] \tag{7.5}$$

as $\varepsilon\to 0$. Finally, expressing (7.5) in terms of geometric quantities by use of (5.7) and the asymptotic results of § 2, we obtain

$$D_{11}|_{\theta_1=\pi}=(\pi/\sigma)\sin\beta\,(\sigma/\varepsilon)^{3/2}\exp[-2^{-1}\pi^2(\sigma/\varepsilon)^{1/2}][1+O(\varepsilon)] \tag{7.6}$$

where

$$\beta=\frac{\pi r_2}{r_1+r_2},\qquad \sigma=\frac{2r_1r_2}{r_1+r_2}. \tag{7.7}$$

When the radii of the spheres are equal, we have $\eta_1=-\frac{1}{2}\log q=\pi K'/2K$, and we find

$$D_{11}|_{\theta_1=\pi}=\frac{(1+q^{1/2})^2}{2\pi^3(1-q^{1/2})q^{1/4}}\cdot\frac{K^2k'^2k^{1/2}}{1+k}. \tag{7.8}$$

Transforming (7.8) to the modulus k_1 by Landen's transformation [23, p. 507], where $k_1=(1-k')/(1+k')$, and denoting the corresponding values of q and K by q_1 and K_1, respectively, we obtain

$$D_{11}|_{\theta_1=\pi}=\frac{(1+q_1)^2}{4\pi^3(1-q_1)q_1^{1/2}}\cdot k_1k_1'K_1^2. \tag{7.9}$$

Equation (7.9) agrees with [10, p. 100] when the subscripts are omitted, after correcting 2π to 4π on pp. 89 and 97 of [10].

8. Behavior of D_1^* at the inner axial point. When $\theta_1=\pi$, we have $\gamma_1=\pi-\theta_0$. Substituting $\theta_1=\pi$ and $\eta_2=\eta_1-\pi K'/K$ in (6.9), replacing t by $\pi-t$, and using Jacobi's imaginary transformation, we obtain

$$\begin{aligned}D_1^*|_{\theta_1=\pi}=&-\frac{K^2k'^2}{4\pi^4a^2}\psi_0^{1/2}\psi_1^{3/2}\int_0^{\theta_0}(2\cos t-2\cos\theta_0)^{-1/2}\\&\cdot\operatorname{Re}\operatorname{sn}\left[\frac{K}{\pi}(\eta_1-\eta_0+it),k'\right]\operatorname{cn}\left[\frac{K}{\pi}(\eta_1-\eta_0+it),k'\right]dt.\end{aligned} \tag{8.1}$$

Expanding the integrand as in (7.3) and interchanging summation and integration, we find

(8.2)

$$D_1^*|_{\theta_1=\pi} = -\frac{\psi_0^{1/2}\psi_1^{3/2}}{2\pi^2 a^2}\left(\frac{K}{K'}\right)^2 \sum_{n=1}^{\infty} \frac{nq'^n}{1+q'^{2n}} \sin\frac{nK}{K'}(\eta_1-\eta_0)\int_0^{\theta_0} \frac{\cosh\dfrac{nK}{K'}\,t\,dt}{(2\cos t - 2\cos\theta_0)^{1/2}}.$$

When $0 \leqq \theta_0 < \pi$, the interchange of summation and integration is justified by [3, p. 495]. Referring to [23, p. 315], we can write (8.2) as a series of Legendre functions of the form

$$D_1^*|_{\theta_1=\pi} = -\frac{\psi_0^{1/2}\psi_1^{3/2}}{4\pi a^2}\left(\frac{K}{K'}\right)^2 \sum_{n=1}^{\infty} \frac{nq'^n}{1+q'^{2n}} \sin\frac{nK}{K'}(\eta_1-\eta_0) P_{-1/2+i(nK/K')}(\cos\theta_0). \tag{8.3}$$

As $\varepsilon \to 0$, we will assume that the point (x_0, ρ_0, ϕ_0) is fixed and that it remains outside both spheres. Defining

$$g = \lim_{\varepsilon\to 0} \frac{\eta_0}{\eta_1} = \frac{2x_0 r_1}{x_0^2+\rho_0^2} \tag{8.4}$$

we see that the condition

$$-\frac{r_2}{r_1} < g < 1 \tag{8.5}$$

insures that the point charge lies outside both spheres when they are tangent to each other.

We have

$$\left| \int_0^{\theta_0} \frac{\cosh\dfrac{nKt}{K'}\,dt}{(2\cos t - 2\cos\theta_0)^{1/2}} \right| < \pi \cosh\frac{nK\theta_0}{K'} < \pi q'^{-n\theta_0/\pi} \tag{8.6}$$

for θ_0 sufficiently near 0. Hence, writing

$$D_1^*|_{\theta_1=\pi} = -\frac{\psi_0^{1/2}\psi_1^{3/2}}{4\pi a^2}\left(\frac{K}{K'}\right)^2 \left\{ \frac{q' \sin\dfrac{K}{K'}(\eta_1-\eta_0)}{1+q'^2} P_{-1/2+i(K/K')}(\cos\theta_0) + R \right\}, \tag{8.7}$$

we obtain

$$|R| < \pi \sum_{n=2}^{\infty} nq'^{n(1-\theta_0/\pi)} < \frac{2\pi q'^{2(1-\theta_0/\pi)}}{(1-q'^{1-\theta_0/\pi})^2}. \tag{8.8}$$

Since $\theta_0 \to 0$ as $\varepsilon \to 0$, we have $|R| = O(q'^{1-\xi})$ for any fixed number ξ in the interval $0 < \xi < 1$.

When $0 \leqq \theta_0 < \sqrt{6}$, we have

$$\theta_0^2 - t^2 > 2\cos t - 2\cos\theta_0 > \left(1-\frac{\theta_0^2}{6}\right)(\theta_0^2-t^2) > 0, \tag{8.9}$$

and hence,

$$(8.10)\quad \int_0^1 \frac{\cosh\frac{K\theta_0 t}{K'}\,t}{\sqrt{1-t^2}}\,dt < \int_0^{\theta_0} \frac{\cosh\frac{K}{K'}\,t\,dt}{(2\cos t - 2\cos\theta_0)^{1/2}} < \frac{1}{\sqrt{1-\frac{\theta_0^2}{6}}}\int_0^1 \frac{\cosh\frac{K\theta_0}{K'}\,t}{\sqrt{1-t^2}}\,dt.$$

Referring to [23, p. 366], we find that (8.10) is equivalent to

$$(8.11)\quad I_0\left(\frac{K\theta_0}{K'}\right) < P_{-1/2+i(K/K')}(\cos\theta_0) < \frac{1}{\sqrt{1-\frac{\theta_0^2}{6}}}\,I_0\left(\frac{K\theta_0}{K'}\right),$$

where $I_0(z)$ is the modified Bessel function of the first kind of order zero. It follows that

$$(8.12)\quad P_{-1/2+i(K/K')}(\cos\theta_0) = I_0\left(\frac{K\theta_0}{K'}\right)[1+O(\varepsilon)],$$

as $\varepsilon \to 0$. Finally, from (8.7), (8.12), and the asymptotic results of § 2, we have[1]

$$(8.13)\quad D_1^*|_{\theta_1=\pi} = -\frac{(\pi/\sigma)}{\sqrt{x_0^2+\rho_0^2}}\sin\lambda\, I_0(\beta h)(\sigma/\varepsilon)^{3/2}\exp\left[-2^{-1}\pi^2(\sigma/\varepsilon)^{1/2}\right][1+O(\varepsilon)]$$

where β and σ are given by (7.8), g is defined by (8.4), and

$$(8.14)\quad h = \lim_{\varepsilon\to 0}\frac{\theta_0}{\eta_1} = \frac{2\rho_0 r_1}{x_0^2+\rho_0^2}, \qquad \lambda = \beta(1-g).$$

The preceding results do not hold uniformly with respect to the location of the point charge when $0 \leqq \theta_0 \leqq \pi$. When $x_0 = 0$, we see that the value of ε required for a given relative error tends to zero as ρ_0 tends to zero.

9. An asymptotic expansion for D_{12} at the inner axial point. Substituting $\eta_2 = \eta_1 - \pi K'/K$ in (6.4) and using the addition theorems for sn u and cn u, we find that

$$(9.1)\quad D_{12} = \frac{K^2}{2\pi^4 a}\psi_1^{3/2}\int_0^{\theta_1}(2\cos t - 2\cos\theta_1)^{-1/2}\,\mathrm{Re}\,\frac{\mathrm{dn}\left[\frac{K}{\pi}(\eta_1 - it), k'\right]}{\mathrm{sn}^2\left[\frac{K}{\pi}(\eta_1 - it), k'\right]}\,dt.$$

Hence,

$$(9.2)\quad D_{12}|_{\theta_1=\pi} = \frac{K^2}{4\pi^4 a}\psi_1^{3/2}\int_0^{\pi}\mathrm{Re}\,\frac{\mathrm{dn}\left[\frac{K}{\pi}(\eta_1 - it), k'\right]}{\mathrm{sn}^2\left[\frac{K}{\pi}(\eta_1 - it), k'\right]}\sec\frac{t}{2}\,dt.$$

Noting that dn $u/\mathrm{sn}^2 u = -(d/du)$ cs u, and referring to [23, p. 512], we obtain

$$(9.3)\quad \frac{\mathrm{dn}\left(\frac{Kz}{\pi}, k'\right)}{\mathrm{sn}^2\left(\frac{Kz}{\pi}, k'\right)} = \left(\frac{\pi}{2K'}\right)^2\csc^2\frac{Kz}{2K'} + \frac{2\pi^2}{K'^2}\sum_{n=1}^{\infty}\frac{nq'^{2n}}{1+q'^{2n}}\cos\frac{nKz}{K'}$$

[1] This corrects the corresponding result in the author's PhD. thesis.

for $|\operatorname{Im} z|<2\pi$. In particular, (9.3) holds for $\operatorname{Im} z=-\pi$. Hence, the left-hand side of (9.3) is purely imaginary for $z=\eta_1-i\pi$, and we have

$$\operatorname{Re}\frac{\operatorname{dn}\left[\frac{K}{\pi}(\eta_1-it),k'\right]}{\operatorname{sn}^2\left[\frac{K}{\pi}(\eta_1-it),k'\right]}=\frac{1}{2}\left(\frac{\pi}{K'}\right)^2\left\{\frac{1-\cos\frac{K\eta_1}{K'}\cosh\frac{Kt}{K'}}{\left(\cosh\frac{Kt}{K'}-\cos\frac{K\eta_1}{K'}\right)^2}-\frac{1-\cos\frac{K\eta_1}{K'}\cosh\frac{K\pi}{K'}}{\left(\cosh\frac{K\pi}{K'}-\cos\frac{K\eta_1}{K'}\right)^2}\right\}$$

$$+2\left(\frac{\pi}{K'}\right)^2\sum_{n=1}^{\infty}\frac{nq'^{2n}\cos\frac{nK\eta_1}{K'}}{1+q'^{2n}}\left(\cosh\frac{nKt}{K'}-\cosh\frac{nK\pi}{K'}\right). \tag{9.4}$$

From (9.2) and (9.4), justifying interchange of summation and integration by the Weierstrass test, we obtain

$$D_{12}|_{\theta_1=\pi}=\frac{\psi_1^{3/2}}{8\pi^2 a}\left(\frac{K}{K'}\right)^2\left\{\int_0^{\pi}\left[\frac{1-\cos\frac{K\eta_1}{K'}\cosh\frac{Kt}{K'}}{\left(\cosh\frac{Kt}{K'}-\cos\frac{K\eta_1}{K'}\right)^2}-\frac{1-\cos\frac{K\eta_1}{K'}\cosh\frac{K\pi}{K'}}{\left(\cosh\frac{K\pi}{K'}-\cos\frac{K\eta_1}{K'}\right)^2}\right]\sec\frac{t}{2}\,dt\right.$$

$$\left.+4\sum_{n=1}^{\infty}\frac{nq'^{2n}}{1+q'^{n}}\cos\frac{nK\eta_1}{K'}\int_0^{\pi}\left(\cosh\frac{nKt}{K'}-\cosh\frac{nK\pi}{K'}\right)\sec\frac{t}{2}\,dt\right\}. \tag{9.5}$$

Denoting the sum in (9.5) by S and the integral in the summation by I, we have

$$\begin{aligned}|I|&=2\int_0^{\pi}\frac{\sinh\frac{nK(\pi+t)}{2K'}\sinh\frac{nK(\pi-t)}{2K'}}{\cos(t/2)}\,dt\\&<2\pi\sinh\frac{nK\pi}{K'}\int_0^{nK\pi/2K'}\frac{\sinh t}{t}\,dt\\&<2\pi\sinh\frac{nK\pi}{K'}\cosh\frac{nK\pi}{2K'}\\&<\pi q'^{-3n/2}\end{aligned} \tag{9.6}$$

and

$$|S|<\pi\sum_{n=1}^{\infty}nq'^{n/2}=\pi\frac{q'^{1/2}}{(1-q'^{1/2})^2}. \tag{9.7}$$

Hence, with $\delta=\eta_1-\eta_2=\pi K'/K$ as before and $\mu=K\eta_1/K'$, we have

$$D_{12}|_{\theta_1=\pi}=\frac{\psi_1^{3/2}}{8\pi a\delta}\left\{\int_0^{\pi^2/\delta}[g(u)-g(\pi^2/\delta)]\sec\frac{\delta u}{2\pi}\,du+R^{(1)}\right\}, \tag{9.8}$$

where

$$g(u)=\frac{1-\cos\mu\cosh u}{(\cosh u-\cos\mu)^2}, \tag{9.9}$$

and

$$|R^{(1)}|<\frac{4\pi q'^{1/2}}{(1-q'^{1/2})^2}. \tag{9.10}$$

We have the identity

$$\sec x = \sum_{m=0}^{n} \frac{(-1)^m E_{2m}}{(2m)!} x^{2m} + \frac{(-4)^{n+1} x^{2n+2}}{(2n+1)! \cos x} \int_0^{1/2} E_{2n+1}(t) \cos 2xt \, dt \tag{9.11}$$

[15, p. 35], where the E_m and $E_m(t)$ are the Euler numbers and Euler polynomials, respectively. Noting that $(-1)^{n+1} E_{2n+1}(t) \geqq 0$ for $0 \leqq t \leqq \frac{1}{2}$, and referring to [15, pp. 24–25], we obtain

$$(-1)^{n+1} \int_0^{1/2} E_{2n+1}(t) \cos 2xt \, dt < (-1)^{n+1} \int_0^{1/2} E_{2n+1}(t) \, dt = \frac{(-1)^{n+1} E_{2n+2}}{(2n+2) 2^{2n+2}} \tag{9.12}$$

when $0 < x < \pi/2$. We therefore have

$$\begin{aligned} &\int_0^{\pi^2/\delta} [g(u) - g(\pi^2/\delta)] \sec \frac{\delta u}{2\pi} \, du \\ &\quad = \sum_{m=0}^{n} \frac{(-1)^m E_{2m}}{(2m)!} \left(\frac{\delta}{2\pi}\right)^{2m} \int_0^{\pi^2/\delta} u^{2m} [g(u) - g(\pi^2/\delta)] \, du + R_n^{(2)}, \end{aligned} \tag{9.13}$$

where

$$|R_n^{(2)}| < \frac{(-1)^{n+1} E_{2n+2}}{(2n+2)!} \left(\frac{\delta}{2\pi}\right)^{2n+2} \int_0^{\pi^2/\delta} u^{2n+2} |g(u) - g(\pi^2/\delta)| \sec \frac{\delta u}{2\pi} \, du. \tag{9.14}$$

We have $\mu = \pi\eta_1/(\eta_1 - \eta_2)$, and hence, μ takes the values $0 \leqq \mu < \pi$ when $0 \leqq \eta_1 < \infty$. When $0 \leqq \mu \leqq \pi$, we find that

$$\begin{aligned} |g(u)| &< \frac{1 + \cosh u}{(\cosh u - 1)^2} = \frac{2(1 + e^{-u})^2}{(1 - e^{-u})^4} e^{-u} \\ &< 7.04 e^{-u} \end{aligned} \tag{9.15}$$

when $u > \log 5$, and

$$|g(u)| < 2.0001 e^{-u} \tag{9.16}$$

when $u > 12$. Similarly, from

$$g'(u) = -\frac{2 \sin^2 \mu \sinh u}{(\cosh u - \cos \mu)^3} + \frac{\cos \mu \sinh u}{(\cosh u - \cos \mu)^2}, \tag{9.17}$$

we obtain

$$\begin{aligned} |g'(u)| &< \frac{2 \sinh u}{(\cosh u - 1)^3} + \frac{\sinh u}{(\cosh u - 1)^2} \\ &= \left[\frac{8(1 + e^{-u}) e^{-u}}{(1 - e^{-u})^5} + \frac{2(1 + e^{-u})}{(1 - e^{-u})^3}\right] e^{-u} \\ &< 2.0001 e^{-u} \end{aligned} \tag{9.18}$$

when $0 \leqq \mu \leqq \pi$ and $u > 12$. We also have

$$u^2 |g(u)| < \frac{u^2 (1 - \cos \mu)}{(1 - \cos \mu + u^2/2)^2} < 1 \tag{9.19}$$

for all $u > 0$ and for $0 \leqq \mu \leqq \pi$, and

$$x_n e^{-x} \leqq \int_x^{\infty} u^n e^{-u} \, du < 2x^n e^{-x} \tag{9.20}$$

for $x>2n$, $n\geqq 0$. The second inequality follows from the asymptotic expansion for the incomplete gamma function [1, p. 263], and can also be obtained by use of integration by parts and induction. From the preceding, we find that

$$\begin{aligned}
&\int_0^{\pi^2/2\delta} u^{2n+2}|g(u)-g(\pi^2/\delta)|\sec\frac{\delta u}{2\pi}\,du \\
&\quad<\sqrt{2}\int_0^{\log 5} u^{2n}\,du+7.04\sqrt{2}\int_{\log 5}^{\pi^2/2\delta} u^{2n+2}\,e^{-u}\,du+\frac{7.04\sqrt{2}}{2n+3}\left(\frac{\pi^2}{2\delta}\right)^{2n+3} e^{-\pi^2/\delta} \\
&\quad=\sqrt{2}\int_0^{\log 5}[u^{2n}-7.04u^{2n+2}\,e^{-u}]\,du \qquad (9.21)\\
&\qquad+7.04\sqrt{2}\int_0^{\pi^2/2\delta} u^{2n+2}\,e^{-u}\,du+\frac{7.04\sqrt{2}}{2n+3}\left(\frac{\pi^2}{2\delta}\right)^{2n+3} e^{-\pi^2/\delta} \\
&\quad<7.04\sqrt{2}\left\{(2n+2)!-(\pi^2/2\delta)^{2n+2}\,e^{-\pi^2/2\delta}\left[1-\frac{e^{-1}}{2n+3}\right]\right\} \\
&\quad<7.04\sqrt{2}(2n+2)!
\end{aligned}$$

for $0\leqq\mu\leqq\pi$ and $\pi^2/\delta>4n+4$, $n\geqq 0$, since $\log 5<2$, $(\pi^2/2\delta)^{2n+2}\,e^{-\pi^2/2\delta}<(2n+2)!/2\sqrt{\pi}$, and $\int_0^{\log 5}(u^{2n}-7.04u^{2n+2}\,e^{-u})\,du<\int_0^{\log 5}(u^{2n}-7.04u^{2n+2}/5)\,du<0$. Noting that $|g(u)-g(\pi^2/\delta)|'\leqq|g'(u)|$, we find from (9.18) that

$$\begin{aligned}
\left|g(u)-g\left(\frac{\pi^2}{\delta}\right)\right|\sec\frac{\delta u}{2\pi}&<2.0001(e^{-u}-e^{-\pi^2/\delta})\sec\frac{\delta u}{2\pi} \\
&<\frac{4.0002\pi}{\delta}\left(\frac{e^{-u}-e^{-\pi^2/\delta}}{\pi^2/\delta-u}\right) \qquad (9.22)\\
&<\frac{4.0002\pi}{\delta}\,e^{-u}
\end{aligned}$$

for $u>12$. Hence,

$$\begin{aligned}
\int_{\pi^2/2\delta}^{\pi^2/\delta} u^{2n+2}|g(u)-g(\pi^2/\delta)|\sec\frac{\delta u}{2\pi}\,du&<\frac{8.0004}{\pi}\left(\frac{\pi^2}{2\delta}\right)\int_{\pi^2/2\delta}^{\pi^2/\delta} u^{2n+2}\,e^{-u}\,du \qquad (9.23)\\
&<\frac{16.0008}{\pi}\left(\frac{\pi^2}{2\delta}\right)^{2n+3} e^{-\pi^2/2\delta}
\end{aligned}$$

when $\pi^2/\delta>24$. It follows from (9.21) and (9.23) that $R_n^{(2)}=O(\delta^{2n+2})$ as $\delta\to 0$, and hence, that the right-hand side of (9.13) is an asymptotic expansion. We see that (9.13) is also convergent, since it can be shown that integration and summation can be interchanged when the Maclaurin series for $\sec(\delta u/2\pi)$ is substituted in the left side of (9.13). Alternatively, it can be shown directly that $R_n^{(2)}$ is $O(n^{-1})$ as $n\to\infty$ and that the nth term of the series in (9.13) is $O(n^{-2})$.

To obtain a simpler, but divergent, asymptotic expansion, we write

$$\begin{aligned}
&\sum_{m=0}^{n}\frac{(-1)^m E_{2m}}{(2m)!}\left(\frac{\delta}{2\pi}\right)^{2m}\int_0^{\pi^2/\delta} u^{2m}[g(u)-g(\pi^2/\delta)]\,du \qquad (9.24)\\
&\quad=\sum_{m=0}^{n}\frac{(-1)^m E_{2m}}{(2m)!}\left(\frac{\delta}{2\pi}\right)^{2m}\int_0^{\infty} u^{2m}g(u)\,du+R_n^{(3)},
\end{aligned}$$

where

$$R_n^{(3)} = -\sum_{m=0}^{n} \frac{(-1)^m E_{2m}}{(2m)!}\left(\frac{\delta}{2\pi}\right)^{2m}\left\{\int_{\pi^2/\delta}^{\infty} u^{2m} g(u)\, du + \frac{g(\pi^2/\delta)}{2m+1}\left(\frac{\pi^2}{\delta}\right)^{2m+1}\right\}. \tag{9.25}$$

It follows from (9.16) and (9.20) that

$$|R_n^{(3)}| < \sum_{m=0}^{n} \frac{(-1)^m E_{2m}}{(2m)!}\left(\frac{\pi}{2}\right)^{2m}\left\{2\, e^{-\pi^2/\delta} + \frac{2.0001}{2m+1}\left(\frac{\pi^2}{\delta}\right) e^{-\pi^2/\delta}\right\} \tag{9.26}$$

for $\pi^2/\delta > 12$.

Referring to [4, p. 38], we have

$$\begin{aligned}\int_0^{\infty} u^{2m} g(u)\, du &= -\frac{d}{d\mu}\sin\mu \int_0^{\infty} \frac{u^{2m}\, du}{\cosh u - \cos\mu} \\ &= (-1)^m (2\pi)^{2m} B_{2m}\left(\frac{\mu}{2\pi}\right),\end{aligned} \tag{9.27}$$

where $B_n(x)$ is the nth Bernoulli polynomial. Finally, noting that $\delta = -\log q$, we obtain the asymptotic expansion

$$D_{12}|_{\theta_1=\pi} = -\frac{\psi_1^{3/2}}{8\pi a \log q}\left\{\sum_{m=0}^{n} \frac{E_{2m} B_{2m}(\mu/2\pi)}{(2m)!}(\log q)^{2m} + R_n\right\} \tag{9.28}$$

for $|\log q| < \pi^2/(4n+12)$, $n \geqq 0$, where

$$R_n = R^{(1)} + R_n^{(2)} + R_n^{(3)}. \tag{9.29}$$

When δ is sufficiently small, we can obtain more convenient bounds for the exponentially small terms in the remainder. By use of the inequality

$$(2n+2)! > (2n+2)^{2n+2}\, e^{-(2n+2)}\sqrt{2\pi(2n+2)}, \tag{9.30}$$

$n \geqq 0$, we obtain

$$\frac{x^{2n+3}\, e^{-x}}{(2n+2)!} < \left(\frac{x}{2n+2}\right)^{2n+3} e^{-x+2n+2}\sqrt{\frac{n+1}{\pi}} \tag{9.31}$$

for $x > 0$. We see that $x^{2n+3}\, e^{-x}$ is decreasing for $x > 2n+3$. Hence, when $x > 2c(n+1)$, $c > 1$, we have

$$\begin{aligned}\frac{x^{2n+3}\, e^{-x}}{(2n+2)!} &< c^{2n+3}\, e^{-(c-1)(2n+2)}\sqrt{\frac{n+1}{\pi}} \\ &< \frac{c^3\, e^{-2(c-1)}}{\sqrt{\pi}},\end{aligned} \tag{9.32}$$

since the right side of the first line of (9.32) is decreasing with respect to n for $n \geqq 0$. In particular, we find

$$\frac{x^{2n+3}\, e^{-x}}{(2n+2)!} < \frac{3^3\, e^{-4}}{\sqrt{\pi}} < 0.28, \qquad x > 6n+6 \tag{9.33}$$

$$< \frac{6^3\, e^{-10}}{\sqrt{\pi}} < 0.0056, \qquad x > 12n+12. \tag{9.34}$$

Similarly, we have

$$\frac{x^{2n+2}\, e^{-x}}{(2n+2)!} < \frac{6^2\, e^{-10}}{2\sqrt{\pi}} < 0.0005 \tag{9.35}$$

and

$$\frac{x^{2n+2}\,e^{-x/2}}{(2n+2)!}<\frac{6^2\,e^{-4}}{2\sqrt{\pi}}<0.1861 \tag{9.36}$$

when $x>12n+12$.

From (9.10) and (9.36), we obtain

$$|R^{(1)}|<2.36(2n+2)!\left(\frac{\delta}{\pi^2}\right)^{2n+2} \tag{9.37}$$

when $\pi^2/\delta>12n+12$. Similarly, from (9.14), (9.21), (9.23), and (9.33), it follows that

$$|R_n^{(2)}|<11.4(-1)^{n+1}E_{2n+2}\left(\frac{\pi}{2}\right)^{2n+2}\left(\frac{\delta}{\pi^2}\right)^{2n+2}. \tag{9.38}$$

Using the inequality

$$\frac{(-1)^nE_{2n}}{(2n)!}\left(\frac{\pi}{2}\right)^{2n}<\frac{4}{\pi} \tag{9.39}$$

[1, p. 805], we obtain the simpler bounds

$$|R_n^{(2)}|<14.6(2n+2)!\left(\frac{\delta}{\pi^2}\right)^{2n+2}, \tag{9.40}$$

$\pi^2/\delta>12n+12$, and

$$|R_n^{(3)}|<\frac{8}{\pi}(n+1)\,e^{-\pi^2/\delta}+\frac{8.0004}{\pi}\left(\frac{\pi^2}{\delta}\right)e^{-\pi^2/\delta}\sum_{m=0}^{n}1/(2m+1), \tag{9.41}$$

$\pi^2/\delta>12$. As in (9.31)-(9.36), we find that $(n+1)x^{2n+2}\,e^{-x}$ and $x^{2n+3}\,e^{-x}\sum_{m=0}^{n}1/(2m+1)$ have the same upper bounds as (9.35) and (9.34), respectively, when $x>12n+12$. We therefore obtain

$$|R_n^{(3)}|<0.016(2n+2)!\left(\frac{\delta}{\pi^2}\right)^{2n+2} \tag{9.42}$$

when $\pi^2/\delta>12n+12$, which is almost negligible compared with $R^{(1)}$ and $R_n^{(2)}$. Finally, we have

$$|R_n|<17.0(2n+2)!\left(\frac{\delta}{\pi^2}\right)^{2n+2} \tag{9.43}$$

for $\pi^2/\delta>12n+12$ and $0\leqq\mu\leqq\pi$.

We see that μ is a function of ε for given values of r_1 and r_2 except in the cases $r_1\to\infty$ with r_2 constant, $r_1=r_2$, and $r_2\to\infty$ with r_1 constant. We then have $\mu=0$, $\pi/2$, and π, respectively. In the case $\mu=0$, sphere 1 is an infinite plane when r_2 is finite. Similarly, when $\mu=\pi$, sphere 2 is an infinite plane when r_1 is finite. We have

$$\begin{aligned} B_{2n}(\mu/2\pi)&=B_{2n}, && \mu=0\\ &=-2^{-2n}(1-2^{1-2n})B_{2n}, && \mu=\pi/2\\ &=-(1-2^{1-2n})B_{2n}, && \mu=\pi \end{aligned} \tag{9.44}$$

[1, pp. 805-806], and from (2.9)-(2.12),

$$
\begin{aligned}
-\log q &= \sinh^{-1}\frac{a}{r_2} \sim \sqrt{\frac{2\varepsilon}{r_2}}, && \mu = 0 \\
&= 2\sinh^{-1}\frac{a}{r} \sim 2\sqrt{\frac{\varepsilon}{r}}, && r_1 = r_2 = r \\
&= \sinh^{-1}\frac{a}{r_1} \sim \sqrt{\frac{2\varepsilon}{r_1}}, && \mu = \pi.
\end{aligned} \tag{9.45}
$$

We can express (9.28) as an asymptotic expansion in powers of ε by use of (2.7)-(2.9). The approximation of lowest order is given by

$$D_{12}|_{\theta_1=\pi} = (2\pi\varepsilon)^{-1}[1+O(\varepsilon)], \tag{9.46}$$

and is independent of the radii. The leading term of (9.46) is also given by an approximate analysis of Maxwell [12, p. 154] for the case of two nearly parallel charged surfaces.

10. Integral representations for the limiting charge density as $\varepsilon \to 0$. It follows from (7.1), (9.1), and (9.3) that

$$
\begin{aligned}
D_{11} = \frac{\psi_1^{3/2}}{4\pi^2 a}\left(\frac{K}{K'}\right)^2 \Bigg\{ & \sin\frac{K\eta_1}{K'} \int_{\theta_1}^{\pi} \frac{\sinh\frac{Kt}{K'}\,dt}{\left(\cosh\frac{Kt}{K'} - \cos\frac{K\eta_1}{K'}\right)^2 (2\cos\theta_1 - 2\cos t)^{1/2}} \\
& + 4\sum_{n=1}^{\infty} \frac{nq'^{2n}\sin\frac{nK\eta_1}{K'}}{1+q'^{2n}} \int_{\theta_1}^{\pi} \frac{\sinh\frac{nKt}{K'}\,dt}{(2\cos\theta_1 - 2\cos t)^{1/2}} \Bigg\}
\end{aligned} \tag{10.1}
$$

and

$$
\begin{aligned}
D_{12} = \frac{\psi_1^{3/2}}{4\pi^2 a}\left(\frac{K}{K'}\right)^2 \Bigg\{ & \int_0^{\theta_1} \frac{\left(1 - \cos\frac{K\eta_1}{K'}\cosh\frac{Kt}{K'}\right) dt}{\left(\cosh\frac{Kt}{K'} - \cos\frac{K\eta_1}{K'}\right)^2 (2\cos t - 2\cos\theta_1)^{1/2}} \\
& + 4\sum_{n=1}^{\infty} \frac{nq'^{2n}\cos\frac{nK\eta_1}{K'}}{1+q'^{2n}} \int_0^{\theta_1} \frac{\cosh\frac{nKt}{K'}\,dt}{(2\cos t - 2\cos\theta_1)^{1/2}} \Bigg\}
\end{aligned} \tag{10.2}
$$

when $0 < \theta_1 < \pi$. Let the sums in (10.1) and (10.2) be denoted by S_1 and S_2, respectively. We have

$$
\begin{aligned}
\left| \int_{\theta_1}^{\pi} \frac{\sinh\frac{nKt}{K'}\,dt}{(2\cos\theta_1 - 2\cos t)^{1/2}} \right| &< \sinh\frac{nK\pi}{K'} \int_{\theta_1}^{\pi} \frac{dt}{(2\cos\theta_1 - 2\cos t)^{1/2}} \\
&< \frac{1}{2} q'^{-n} K(\cos\theta_1)
\end{aligned} \tag{10.3}
$$

where $K(k)$ is the complete elliptic integral of the first kind with modulus k. Hence,

$$
\begin{aligned}
|S_1| &< \frac{1}{2} K(\cos\theta_1) \sum_{n=1}^{\infty} nq'^n = \frac{q'K(\cos\theta_1)}{2(1-q')^2} \\
&= O[q'\log(1-q)]
\end{aligned} \tag{10.4}
$$

as $\varepsilon \to 0$. Similarly,

$$\left| \int_0^{\theta_1} \frac{\cosh \frac{nKt}{K'}\, dt}{(2\cos t - 2\cos\theta_1)^{1/2}} \right| < q'^{-n} K(\sin\theta_1), \tag{10.5}$$

and

$$\begin{aligned} |S_2| &< \frac{q'K(\sin\theta_1)}{(1-q')^2} \\ &= O(q'). \end{aligned} \tag{10.6}$$

It follows that

$$\lim_{\varepsilon\to 0} D_{11} = \lim_{\varepsilon\to 0} \frac{\psi_1^{3/2}}{4\pi^2 a} \left(\frac{K}{K'}\right)^2 \sin\frac{K\eta_1}{K'}\, I_1 \tag{10.7}$$

and

$$\lim_{\varepsilon\to 0} D_{12} = \lim_{\varepsilon\to 0} \frac{\psi_1^{3/2}}{4\pi^2 a} \left(\frac{K}{K'}\right)^2 I_2, \tag{10.8}$$

where

$$I_1 = \int_{\theta_1}^{\pi} \frac{\sinh \frac{Kt}{K'}\, dt}{\left(\cosh\frac{Kt}{K'} - \cos\frac{K\eta_1}{K'}\right)^2 (2\cos\theta_1 - 2\cos t)^{1/2}}, \tag{10.9}$$

$$I_2 = \int_0^{\theta_1} \frac{\left(1 - \cos\frac{K\eta_1}{K'}\cosh\frac{Kt}{K'}\right) dt}{\left(\cosh\frac{Kt}{K'} - \cos\frac{K\eta_1}{K'}\right)^2 (2\cos t - 2\cos\theta_1)^{1/2}}. \tag{10.10}$$

Substituting $\sin(t/2) = u\sin(\theta_1/2)$ in (10.9) and (10.10), we obtain

$$I_1 = \int_1^{\csc(\theta_1/2)} \frac{\sinh \frac{Kt(u)}{K'}\, du}{\left[\cosh\frac{Kt(u)}{K'} - \cos\frac{K\eta_1}{K'}\right]^2 \sqrt{u^2-1}} \tag{10.11}$$

and

$$I_2 = \int_0^1 \frac{\left(1 - \cos\frac{K\eta_1}{K'}\cosh\frac{Kt(u)}{K'}\right) du}{\left[\cosh\frac{Kt(u)}{K'} - \cos\frac{K\eta_1}{K'}\right]^2 \sqrt{1-u^2}}, \tag{10.12}$$

where $t(u) = 2\sin^{-1}(u\sin(\theta_1/2))$. We have

$$\lim_{\varepsilon\to 0} \frac{K\eta_1}{K'} = \beta, \tag{10.13}$$

where β is given by (7.7), and

$$\lim_{\varepsilon\to 0} \frac{Kt(u)}{K'} = \lim_{\varepsilon\to 0} \frac{K\theta_1 u}{K'} = \alpha u, \tag{10.14}$$

where

$$\alpha = \beta \cot(\omega_1/2). \tag{10.15}$$

We also have

$$\lim_{\varepsilon\to 0} \frac{\psi_1^{3/2}}{4\pi^2 a}\left(\frac{K}{K'}\right)^2 = \frac{r_2^2 \csc^3(\omega_1/2)}{4r_1(r_1+r_2)^2}. \tag{10.16}$$

It can be shown by the Weierstrass test that I_1 and I_2 are uniformly convergent with respect to ε in an interval $0 \leqq \varepsilon \leqq \varepsilon_1$ for $0 < \omega_1 \leqq \pi$. Hence, they are continuous at $\varepsilon = 0$. Finally, when $\omega_1 \neq 0$, we obtain

$$\lim_{\varepsilon\to 0} D_{11} = \frac{r_2^2 \csc^3(\omega_1/2)}{4r_1(r_1+r_2)^2} \sin\beta \int_1^\infty \frac{\sinh \alpha u\, du}{(\cosh \alpha u - \cos\beta)^2\sqrt{u^2-1}} \tag{10.17}$$

and

$$\lim_{\varepsilon\to 0} D_{12} = \frac{r_2^2 \csc^3(\omega_1/2)}{4r_1(r_1+r_2)^2} \int_0^1 \frac{(1-\cos\beta\cosh\alpha u)\, du}{(\cosh\alpha u - \cos\beta)^2\sqrt{1-u^2}}. \tag{10.18}$$

The discussion for D_{11} holds also for D_1^* when we assume that (8.5) is satisfied, giving

$$\lim_{\varepsilon\to 0} D_1^* = -\lim_{\varepsilon\to 0} \frac{\psi_0^{1/2}\psi_1^{3/2}}{8\pi^2 a^2}\left(\frac{K}{K'}\right)^2 \sin\frac{K(\eta_1-\eta_0)}{K'} I_3, \tag{10.19}$$

where

$$I_3 = \int_{\gamma_1}^{\pi} \frac{\sinh\dfrac{Kt}{K'}\, dt}{\left(\cosh\dfrac{Kt}{K'} - \cos\dfrac{K(\eta_1-\eta_0)}{K'}\right)^2 (2\cos\gamma_1 - 2\cos t)^{1/2}}. \tag{10.20}$$

Proceeding as before, we find

$$\lim_{\varepsilon\to 0} D_1^* = -\frac{r_2^2 \csc^3(\omega_1/2)}{4r_1(r_1+r_2)^2(x_0^2+\rho_0^2)^{1/2}} \sin\lambda \int_1^\infty \frac{\sinh\kappa u\, du}{(\cosh\kappa u - \cos\lambda)^2\sqrt{u^2-1}}, \tag{10.21}$$

where

$$\begin{aligned} \kappa &= \lim_{\varepsilon\to 0} K\gamma_1/K' \\ &= \beta\sqrt{\cot^2(\omega_1/2) - 2h\cot(\omega_1/2)\cos(\phi-\phi_0)+h^2}, \end{aligned} \tag{10.22}$$

and where h and λ are given by (8.14).

We see that (10.17) gives the charge density in the first problem when the spheres are tangent and at unit potential, and that (10.21) gives the charge density in the second problem when the spheres are tangent. Carl Neumann [13, p. 46] has expressed the latter in terms of a definite integral involving the Bessel function $J_0(z)$.

11. Expansions near $\omega_1 = 0$ for the limits of D_{11} and D_1^*. We have

$$\begin{aligned} \frac{\sinh\alpha u}{(\cosh\alpha u - \cos\beta)^2} &= -\frac{1}{u\sin\beta}\frac{\partial^2}{\partial\alpha\,\partial\beta}\log(1-e^{-\alpha u+i\beta})(1-e^{-\alpha u-i\beta}) \\ &= \frac{2}{\sin\beta}\sum_{n=1}^{\infty} n\sin n\beta\, e^{-n\alpha u} \end{aligned} \tag{11.1}$$

for $\alpha u > 0$ when β is real. Substituting (11.1) in (10.17) and referring to [22, p. 172], we find

$$\lim_{\varepsilon\to 0} D_{11} = \frac{r_2^2 \csc^3(\omega_1/2)}{2r_1(r_1+r_2)^2} \sum_{n=1}^{\infty} n \sin n\beta\, K_0(n\alpha), \tag{11.2}$$

where $K_0(z)$ is the modified Bessel function of the second kind of order zero. The interchange of summation and integration is valid by [3, p. 495] as before. From the asymptotic expansion of $K_0(z)$ [23, p. 374], it follows that (11.2) is convergent for $0 < \omega_1 < \pi$. For sufficiently large α, we have

$$\frac{K_0(n\alpha)}{K_0(\alpha)} = \frac{e^{-(n-1)\alpha}}{\sqrt{n}}[1+O(\alpha^{-1})] < e^{-(n-1)\alpha}, \qquad n \geqq 2. \tag{11.3}$$

Hence,

$$\left| \sum_{n=2}^{\infty} n \sin n\beta \frac{K_0(n\alpha)}{K_0(\alpha)} \right| < \sum_{n=1}^{\infty} (n+1)\, e^{-n\alpha} < \frac{2\, e^{-\alpha}}{(1-e^{-\alpha})^2} = O(e^{-\alpha}), \tag{11.4}$$

and

$$\frac{1}{\sin\beta} \sum_{n=1}^{\infty} n \sin n\beta\, K_0(n\alpha) = K_0(\alpha)[1+O(e^{-\alpha})]. \tag{11.5}$$

It follows that as $\omega_1 \to 0$,

$$\begin{aligned} \lim_{\varepsilon\to 0} D_{11} &= \frac{r_2^2 \csc^3(\omega_1/2)}{2r_1(r_1+r_2)^2} \sin\beta\, K_0(\alpha)[1+O(e^{-\alpha})] \\ &= \frac{r_2^2 \csc^3(\omega_1/2) \sin\beta}{2r_1(r_1+r_2)^2} \sqrt{\frac{\pi}{2\alpha}}\, e^{-\alpha} \\ &\quad \cdot \left[1 + \sum_{m=1}^{n} (-1)^m \frac{1^2 \cdot 3^2 \cdots (2m-1)^2}{2^{3m} m!\, \alpha^m} + O(\alpha^{-n-1}) \right]. \end{aligned} \tag{11.6}$$

Expressed in terms of ω_1, we have

$$\lim_{\varepsilon\to 0} D_{11} = \frac{2r_2^2 \sin\beta}{r_1(r_1+r_2)^2} \sqrt{\frac{\pi}{\beta}}\, \omega_1^{-5/2}\, e^{-2\beta/\omega_1}[1+O(\omega_1)]. \tag{11.7}$$

Starting from (10.21), in the same way we find that

$$\lim_{\varepsilon\to 0} D_1^* = -\frac{r_2^2 \csc^3(\omega_1/2)}{2r_1(r_1+r_2)^2(x_0^2+\rho_0^2)^{1/2}} \sum_{n=1}^{\infty} n \sin n\lambda\, K_0(n\kappa) \tag{11.8}$$

for $0 < \lambda < \pi$ and $\kappa > 0$ when (8.5) is satisfied, and that

$$\lim_{\varepsilon\to 0} D_1^* = -\frac{2r_2^2 \sin\lambda}{r_1(r_1+r_2)^2(x_0^2+\rho_0^2)^{1/2}} \sqrt{\frac{\pi}{\beta}}\, \omega_1^{-5/2}\, e^{-2\beta/\omega_1}[1+O(\omega_1)] \tag{11.9}$$

as $\omega_1 \to 0$ with $\omega_1 < 2\cot^{-1} h$. When $\omega_1 = 2\cot^{-1} h$ while $\phi = \phi_0$, we have $\kappa = 0$. We see that the latter occurs arbitrarily close to $\omega_1 = 0$ when $x_0 = 0$ and $\rho_0 > 0$ is sufficiently small.

12. An asymptotic expansion for the limit of D_{12}. When the integrand of

$$I = \int_0^1 \frac{(1-\cos\beta\cosh\alpha u)\, du}{(\cosh\alpha u - \cos\beta)^2 \sqrt{1-u^2}} \tag{12.1}$$

is expanded in powers of $e^{-\alpha u}$ as in § 11 and integration and summation are interchanged, the resulting series does not converge. However, we can obtain an asymptotic

expansion for large α by use of the identity

$$(1-z^2)^{-1/2}=\sum_{m=0}^{n}\frac{(2m)!}{2^{2m}(m!)^2}z^{2m}+f_n(z), \tag{12.2}$$

where

$$f_n(z)=\frac{(2n+1)!}{2^{2n}(n!)^2}(1-z^2)^{-1/2}\int_0^z t^{2n+1}(1-t^2)^{-1/2}\,dt \tag{12.3}$$

[26, p. 108], $n\geqq 0$, which is valid when z^2-1 is not a positive real number. When $0<x<1$, we can verify that

$$\int_0^x t^{2n+1}(1-t^2)^{-1/2}\,dt<\frac{x^{2n+2}}{1+(1-x^2)^{1/2}}<x^{2n+2}, \tag{12.4}$$

and hence, that

$$0<f_n(x)<\frac{(2n+1)!}{2^{2n}(n!)^2}x^{2n+2}(1-x^2)^{-1/2}. \tag{12.5}$$

From the preceding, we obtain

$$I=\sum_{m=0}^{n}\frac{(2m)!}{2^{2m}(m!)^2}\alpha^{-2m-1}\int_0^\alpha\frac{(1-\cos\beta\cosh v)v^{2m}\,dv}{(\cosh v-\cos\beta)^2}+R_n^{(1)}, \tag{12.6}$$

where

$$|R_n^{(1)}|<\frac{(2n+1)!}{2^{2n}(n!)^2}\alpha^{-2n-3}\int_0^\alpha\frac{|1-\cos\beta\cosh v|v^{2n+2}\,dv}{(\cosh v-\cos\beta)^2\sqrt{1-\left(\frac{v}{\alpha}\right)^2}} \tag{12.7}$$

for $n\geqq 0$. Referring to (9.15), (9.19), and (9.21), we find

$$\begin{aligned}\int_0^{\alpha/2}\frac{|1-\cos\beta\cosh v|v^{2n+2}dv}{(\cosh v-\cos\beta)^2\sqrt{1-\left(\frac{v}{\alpha}\right)^2}}&<\frac{2}{\sqrt{3}}\int_0^{\alpha/2}\frac{|1-\cos\beta\cosh v|}{(\cosh v-\cos\beta)^2}v^{2n+2}\,dv\\ &<\frac{2}{\sqrt{3}}\int_0^{\log 5}(u^{2n}-7.04u^{2n+2}e^{-u})\,du\\ &\quad+\frac{14.08}{\sqrt{3}}\int_0^{\alpha/2}u^{2n+2}e^{-u}\,du\\ &<\frac{14.08}{\sqrt{3}}(2n+2)!\end{aligned} \tag{12.8}$$

for $0\leqq\beta\leqq\pi$ and $\alpha>4n+4$, $n\geqq 0$. We have

$$\int_0^1\frac{u^{2n+2}\,du}{\sqrt{1-u^2}}=\frac{(2n+2)!}{2^{2n+2}[(n+1)!]^2}\left(\frac{\pi}{2}\right)<\frac{1}{2}\sqrt{\frac{\pi}{n+1}}, \tag{12.9}$$

$n\geqq 0$. The inequality follows by use of the asymptotic expansion for the gamma function. As in (9.15), it follows that

$$\frac{|1-\cos\beta\cosh v|}{(\cosh v-\cos\beta)^2}<2.005e^{-v} \tag{12.10}$$

when $v>8$. Using (12.10) and (9.30), and noting that $\alpha^{2n+3}e^{-\alpha/2}$ is a decreasing

function for $\alpha > 4n+6$, we obtain

$$\int_{\alpha/2}^{\alpha} \frac{|1-\cos\beta\cosh v|v^{2n+2}\,dv}{(\cosh v-\cos\beta)^2\sqrt{1-\left(\frac{v}{\alpha}\right)^2}} < 2.005\alpha^{2n+3}\,e^{-\alpha/2}\int_0^1 \frac{u^{2n+2}\,du}{\sqrt{1-u^2}}$$

$$\begin{aligned} &< \frac{2.005(2n+2)!\,\alpha^{2n+3}\,e^{-\alpha/2}}{(2n+2)^{2n+2}\,e^{-2n-2}\sqrt{2\pi(2n+2)}}\sqrt{\frac{\pi}{4n+4}} \\ &= \frac{2.005}{2}(2n+2)!\left(\frac{\alpha}{2n+2}\right)^{2n+3} e^{-\alpha/2+2n+2} \\ &< \frac{2.005}{2}8^3\,e^{-6}(2n+2)! \\ &< 1.273(2n+2)! \end{aligned} \tag{12.11}$$

when $\alpha > 16n+16$, $n \geqq 0$. Hence, it follows that (12.6) is an asymptotic expansion for I, where

$$|R_n^{(1)}| < 9.403\frac{(2n+1)!}{2^{2n}(n!)^2}(2n+2)!\,\alpha^{-2n-3}. \tag{12.12}$$

As in the case of the asymptotic expansion of § 9, (12.6) is also a convergent expansion. In order to obtain a simpler asymptotic expansion, for which the coefficients can be expressed in terms of known functions, we write

$$\begin{aligned} &\sum_{m=0}^{n}\frac{(2m)!}{2^{2m}(m!)^2}\alpha^{-2m-1}\int_0^{\alpha}\frac{(1-\cos\beta\cosh v)v^{2m}\,dv}{(\cosh v-\cos\beta)^2} \\ &\quad = \sum_{m=0}^{n}\frac{(2m)!}{2^{2m}(m!)^2}\alpha^{-2m-1}\int_0^{\infty}\frac{(1-\cos\beta\cosh v)v^{2m}\,dv}{(\cosh v-\cos\beta)^2} + R_n^{(2)}, \end{aligned} \tag{12.13}$$

where

$$R_n^{(2)} = -\sum_{m=0}^{n}\frac{(2m)!}{2^{2m}(m!)^2}\alpha^{-2m-1}\int_{\alpha}^{\infty}\frac{(1-\cos\beta\cosh v)v^{2m}\,dv}{(\cosh v-\cos\beta)^2}. \tag{12.14}$$

It follows from (9.16) and (9.20) that

$$|R_n^{(2)}| < 4.0002\alpha^{-1}\,e^{-\alpha}\sum_{m=0}^{n}\frac{(2m)!}{2^{2m}(m!)^2} \tag{12.15}$$

for $\alpha > 4n+12$. Finally, referring to (9.27), we obtain the asymptotic expansion

$$\lim_{\varepsilon\to 0} D_{12} = \frac{r_2^2\csc^3(\omega_1/2)}{4\pi r_1(r_1+r_2)^2}\left\{\sum_{m=0}^{n}\frac{(-1)^m(2m)!}{(m!)^2}B_{2m}\left(\frac{\beta}{2\pi}\right)\left(\frac{\pi}{\alpha}\right)^{2m+1} + R_n\right\}, \tag{12.16}$$

where

$$R_n = R_n^{(1)} + R_n^{(2)}. \tag{12.17}$$

The preceding estimates for $R_n^{(1)}$ and $R_n^{(2)}$ hold for $\alpha > 16n+16$ and for $0 \leqq \beta \leqq \pi$, $n \geqq 0$.

From (12.12) and (12.9), we obtain

$$\begin{aligned} |R_n^{(1)}| &< 18.806\alpha^{-3}, \quad n=0 \\ &< \frac{9.403(2n+1)}{\sqrt{\pi n}}(2n+2)!\,\alpha^{-2n-3}, \qquad n \geqq 1 \end{aligned} \tag{12.18}$$

when $\alpha > 16n+16$. Proceeding as in (9.30)-(9.36), we find that

$$\alpha^{2n+2} e^{-\alpha} \sum_{m=0}^{n} \frac{(2m)!}{2^{2m}(m!)^2} < \frac{8^2 e^{-14}}{2\sqrt{\pi}} < 0.000016 \tag{12.19}$$

when $\alpha > 16n+16$. From (12.15) and (12.19), it follows that

$$\begin{aligned} |R_n^{(2)}| &< 4.0002\alpha^{-2n-3}\left\{\alpha^{2n+2} e^{-\alpha} \sum_{m=0}^{n} \frac{(2m)!}{2^{2m}(m!)^2}\right\} \\ &< 0.00007(2n+2)!\,\alpha^{-2n-3}. \end{aligned} \tag{12.20}$$

Finally, we obtain

$$\begin{aligned} |R_n| &< 18.9\alpha^{-3}, \quad n=0 \\ &< \frac{9.45(2n+1)}{\sqrt{\pi n}}(2n+2)!\,\alpha^{-2n-3}, \quad n \geqq 1 \end{aligned} \tag{12.21}$$

when $\alpha > 16n+16$ and $0 \leqq \beta \leqq \pi$.

The case $\beta = \pi$ corresponds to the limit $r_2 \to \infty$ with r_1 held constant. Hence, sphere 2 becomes the plane $x=0$ in this limit, and from (10.15), we find

$$\alpha = \pi \cot(\omega_1/2). \tag{12.22}$$

As $\omega_1 \to 0$, we have

$$\begin{aligned} \lim_{\varepsilon \to 0} D_{12} &= \frac{r_2}{r_1(r_1+r_2)} \cdot \frac{1}{\pi\omega_1^2} \cdot [1+O(\omega_1^2)], \qquad 0 < \beta < \pi \\ &= \frac{1}{\pi r_1 \omega_1^2}[1+O(\omega_1^2)], \qquad \beta = \pi. \end{aligned} \tag{12.23}$$

Similarly, the case $\beta = 0$ is obtained by passing to the limit $r_1 \to \infty$ with r_2 held constant. In this limit, sphere 1 becomes the plane $x=0$. Let $(0, y_1, z_1)$ be a given point on the plane $x=0$, with $\rho_1 = \sqrt{y_1^2+z_1^2}$. Then taking the limits $r_1 \to \infty$ and $\omega_1 \to 0$ such that $r_1\omega_1 = \rho_1$, we obtain

$$\begin{aligned} \alpha &= \lim_{r_1 \to \infty} \frac{\pi r_2}{r_1+r_2} \cot\frac{\rho_1}{2r_1} \\ &= \frac{2\pi r_2}{\rho_1}, \end{aligned} \tag{12.24}$$

and

$$\lim_{\varepsilon \to 0} D_{12} = \frac{2r_2^2}{\pi\rho_1^3}\left\{\sum_{m=0}^{n} \frac{(-1)^m(2m)!\,B_{2m}}{(m!)^2}\left(\frac{\pi}{\alpha}\right)^{2m+1} + R_n\right\}, \tag{12.25}$$

where R_n is bounded by (12.21).

13. Expansions for the limiting charge density in terms of inverse radicals. By the procedure of [23, p. 134], we obtain

$$\frac{1}{\cosh z-\cos\beta}=\frac{1}{1-\cos\beta}+\frac{2}{\sin\beta}\left\{\sum_{n=0}^{\infty}\left[\frac{2\pi n+\beta}{z^2+(2\pi n+\beta)^2}-\frac{1}{2\pi n+\beta}\right]\right.$$
$$\left.-\sum_{n=1}^{\infty}\left[\frac{2\pi n-\beta}{z^2+(2\pi n-\beta)^2}-\frac{1}{2\pi n-\beta}\right]\right\} \tag{13.1}$$

for $0<\beta<\pi$ and for all values of z not equal to $\pm i(2\pi n+\beta)$ or $\pm i(2\pi n-\beta)$. We then have

$$\frac{\sinh z}{(\cosh z-\cos\beta)^2}=-\frac{\partial}{\partial z}\frac{1}{\cosh z-\cos\beta}$$
$$=\frac{4z}{\sin\beta}\left\{\sum_{n=0}^{\infty}\frac{2\pi n+\beta}{[z^2+(2\pi n+\beta)^2]^2}-\sum_{n=1}^{\infty}\frac{2\pi n-\beta}{[z^2+(2\pi n-\beta)^2]^2}\right\} \tag{13.2}$$

and

$$\frac{1-\cos\beta\cosh z}{(\cosh z-\cos\beta)^2}=-\frac{\partial}{\partial\beta}\cdot\frac{\sin\beta}{\cosh z-\cos\beta}$$
$$=-2\left\{\sum_{n=0}^{\infty}\frac{z^2-(2\pi n+\beta)^2}{[z^2+(2\pi n+\beta)^2]^2}-\sum_{n=1}^{\infty}\frac{z^2-(2\pi n-\beta)^2}{[z^2+(2\pi n-\beta)^2]^2}\right\} \tag{13.3}$$

when we use the expansion

$$\csc^2\frac{\beta}{2}=4\sum_{n=-\infty}^{\infty}\frac{1}{(2\pi n+\beta)^2}. \tag{13.4}$$

The latter follows, for example, by differentiating an expansion for $\cot(\beta/2)$ in [3, p. 296]. From (13.2) and (10.17), we find

$$\lim_{\varepsilon\to 0}D_{11}=\frac{\pi r_2^2\csc^3(\omega_1/2)}{4r_1(r_1+r_2)^2}\sum_{n=-\infty}^{\infty}\frac{2\pi n+\beta}{[\alpha^2+(2\pi n+\beta)^2]^{3/2}} \tag{13.5}$$

for $0<\beta<\pi$ and $\alpha\geqq 0$, and from (13.3) and (10.18), we have

$$\lim_{\varepsilon\to 0}D_{12}=\frac{\pi r_2^2\csc^3(\omega_1/2)}{4r_1(r_1+r_2)^2}\left\{\sum_{n=0}^{\infty}\frac{2\pi n+\beta}{[\alpha^2+(2\pi n+\beta)^2]^{3/2}}+\sum_{n=1}^{\infty}\frac{2\pi n-\beta}{[\alpha^2+(2\pi n-\beta)^2]^{3/2}}\right\}. \tag{13.6}$$

The interchanges of integration and summation are justified by [3, pp. 499 and 495], respectively. Similarly, from (13.2) and (10.21), we obtain

$$\lim_{\varepsilon\to 0}D_1^*=-\frac{\pi r_2^2\csc^3(\omega_1/2)}{4r_1(r_1+r_2)^2(x_0^2+\rho_0^2)^{1/2}}\sum_{n=-\infty}^{\infty}\frac{2\pi n+\lambda}{[\kappa^2+(2\pi n+\lambda)^2]^{3/2}} \tag{13.7}$$

when $0<\lambda<\pi$, $\kappa\geqq 0$, and (8.5) is satisfied.

We can express (13.5) and (13.6) in terms of ω_1 by substituting (7.7) and (10.15). Denoting r_2/r_1 by b, we obtain

$$\lim_{\varepsilon\to 0}D_{11}=\frac{b^2}{4\pi r_1}\sum_{n=-\infty}^{\infty}\frac{2n(b+1)+b}{\{n^2(b+1)^2-2n(b+1)[n(b+1)+b]\cos\omega_1+[n(b+1)+b]^2\}^{3/2}} \tag{13.8}$$

and

(13.9)
$$\lim_{\varepsilon\to 0} D_{12}=\frac{b^2}{\pi r_1}\left\{\sum_{n=0}^{\infty}\frac{2n(b+1)+b}{\{n^2(b+1)^2-2n(b+1)[n(b+1)+b]\cos\omega_1+[n(b+1)+b]^2\}^{3/2}}\right.$$
$$\left.+\sum_{n=1}^{\infty}\frac{2n(b+1)-b}{\{n^2(b+1)^2-2n(b+1)[n(b+1)-b]\cos\omega_1+[n(b+1)-b]^2\}^{3/2}}\right\}.$$

When $b=1$, these expansions become

(13.10)
$$\lim_{\varepsilon\to 0} D_{11}=\frac{1}{4\pi r_1}\sum_{n=0}^{\infty}\frac{(-1)^n(2n+1)}{[(n+1)^2-2n(n+1)\cos\omega_1+n^2]^{3/2}},$$

(13.11)
$$\lim_{\varepsilon\to 0} D_{12}=\frac{1}{4\pi r_1}\sum_{n=0}^{\infty}\frac{2n+1}{[(n+1)^2-2n(n+1)\cos\omega_1+n^2]^{3/2}}.$$

The expansion (13.8) was given by Poisson [17, pp. 74–79] for $b=1, 2$, and 4 and for $r_1=1$, with the case $b=1$ expressed in the form (13.10).

14. Power series expansions for the limiting charge density. We can express (13.5) and (13.6) as power series in α by expanding each term in powers of α and interchanging the order of summation. The interchange is valid because of the absolute convergence of the double series obtained. We find

(14.1)
$$\lim_{\varepsilon\to 0} D_{11}=\frac{r_2^2\csc^3(\omega_1/2)}{16\pi r_1(r_1+r_2)^2}\cdot\sum_{n=0}^{\infty}(-1)^n\frac{(2n+1)!}{2^{2n}(n!)^2}\left[\zeta\left(2n+2,\frac{\beta}{2\pi}\right)-\zeta\left(2n+2,1-\frac{\beta}{2\pi}\right)\right]\left(\frac{\alpha}{2\pi}\right)^{2n}$$

and

(14.2)
$$\lim_{\varepsilon\to 0} D_{12}=\frac{r_2^2\csc^3(\omega_1/2)}{16\pi r_1(r_1+r_2)^2}\cdot\sum_{n=0}^{\infty}(-1)^n\frac{(2n+1)!}{2^{2n}(n!)^2}\left[\zeta\left(2n+2,\frac{\beta}{2\pi}\right)+\zeta\left(2n+2,1-\frac{\beta}{2\pi}\right)\right]\left(\frac{\alpha}{2\pi}\right)^{2n},$$

where $\zeta(s, a)$ is the generalized zeta function. It follows by the ratio test that (14.1) and (14.2) converge for $|\alpha|<\beta$ when $0<\beta\leqq\pi$. Similarly, from (13.7), we have

(14.3)
$$\lim_{\varepsilon\to 0} D_1^*=-\frac{r_2^2\csc^3(\omega_1/2)}{16\pi r_1(r_1+r_2)^2(x_0^2+\rho_0^2)^{1/2}}\cdot\sum_{n=0}^{\infty}(-1)^n\frac{(2n+1)!}{2^{2n}(n!)^2}\left[\zeta\left(2n+2,\frac{\lambda}{2\pi}\right)-\zeta\left(2n+2,1-\frac{\lambda}{2\pi}\right)\right]\left(\frac{\kappa}{2\pi}\right)^{2n}$$

for $|\kappa|<\lambda$, with $0<\lambda<\pi$.

We see that (14.1) and (14.2) converge for $\pi/2<\omega_1\leqq\pi$, and that α vanishes when $\omega_1=\pi$. It follows from (10.22) that $\kappa=0$ when $\omega_1=2\cot^{-1}h$ and $\phi=\phi_0$, where h is given by (8.14). Hence, (14.3) converges in a region of sphere 1 containing this point in its interior. When $\phi=\phi_0$ and $h\geqq 1$, (14.3) converges for $2\cot^{-1}(h+1)\leqq\omega_1\leqq 2\cot^{-1}(h-1)$. When $h<1$, we find that (14.3) converges for $2\cot^{-1}(h+1)\leqq\omega_1\leqq\pi$ when $\phi=\phi_0$, and for $2\cot^{-1}(1-h)\leqq\omega_1\leqq\pi$ when $\phi=\phi_0+\pi$.

Starting from the expansion (13.4), we can express the coefficients of (14.2) in an alternate form. We have

$$\zeta\left(2n+2,\frac{\beta}{2\pi}\right)+\zeta\left(2n+2,1-\frac{\beta}{2\pi}\right)=(2\pi)^{2n+2}\sum_{n=-\infty}^{\infty}(2\pi n+\beta)^{-2n-2}$$

$$=\frac{(2\pi)^{2n+2}}{4(2n+1)!}\frac{d^{2n}}{d\beta^{2n}}\csc^2\frac{\beta}{2}, \tag{14.4}$$

and hence,

$$\lim_{\varepsilon\to 0} D_{12}=\frac{\pi r_2^2\csc^3(\omega_1/2)}{16r_1(r_1+r_2)^2}\sum_{0}^{\infty}\frac{(-1)^n\alpha^{2n}}{2^{2n}(n!)^2}\left(\frac{d}{d\beta}\right)^{2n}\csc^2\frac{\beta}{2}. \tag{14.5}$$

When $r_1=r_2$, and hence, $\beta=\pi/2$, we have

$$\lim_{\varepsilon\to 0} D_{12}=\frac{\csc^3(\omega_1/2)}{4\pi r_1}\sum_{n=0}^{\infty}(-1)^n\frac{(2n+1)!}{2^{2n}(n!)^2}\left\{\sum_{k=0}^{\infty}(2k+1)^{-2n-2}\right\}\left(\frac{2\alpha}{\pi}\right)^{2n}$$

$$=\frac{\pi\csc^3(\omega_1/2)}{16r_1}\sum_{n=0}^{\infty}\frac{(2^{2n+2}-1)B_{2n+2}}{n!(n+1)!}\alpha^{2n}, \tag{14.6}$$

where B_n is the nth Bernoulli number. We note that we can also obtain (14.2), (14.5), and (14.6) directly by substituting the Maclaurin expansion of $(1-\cos\beta\cosh\alpha u)/(\cosh\alpha u-\cos\beta)^2$ in (10.18) and interchanging integration and summation.

15. Circles of zero charge density. We see that $\lim_{\varepsilon\to 0} D_{11}$ and $\lim_{\varepsilon\to 0} D_{12}$ are finite and positive for $\omega_1=\pi$, and that $\lim_{\varepsilon\to 0} D_{12}$ becomes infinite as $\omega_1\to 0$. When $V_2>V_1>0$, it follows from (3.6) that $\lim_{\varepsilon\to 0} D_1$ is always negative in the neighborhood of $\omega_1=0$, and that it vanishes for some value of ω_1 between zero and π when V_2/V_1 is sufficiently near 1. As V_2/V_1 increases, a value is reached above which the charge on sphere 1 is completely negative.

The power series expansion for the limiting charge density in the neighborhood of $\omega_1=\pi$ is given by

$$\lim_{\varepsilon\to 0} D_{11}=\sum_{n=0}^{\infty}a_n\alpha^{2n},\qquad \lim_{\varepsilon\to 0} D_{12}=\sum_{n=0}^{\infty}b_n\alpha^{2n} \tag{15.1}$$

together with (3.6), where a_n and b_n are defined by (14.1) and (14.2), respectively. When a circle of zero charge density lies sufficiently near the point $\omega_1=\pi$, it satisfies the equation

$$\sum_{n=0}^{\infty}(a_n-\rho b_n)\alpha^{2n}=0, \tag{15.2}$$

where

$$\rho=\frac{V_2-V_1}{V_2+V_1}. \tag{15.3}$$

If $a_1-\rho b_1$ does not vanish when $a_0-\rho b_0=0$, we can invert this series and obtain α^2 as a series in powers of $(a_0-\rho b_0)/(a_1-\rho b_1)$. We see that this condition is satisfied when

$$\frac{b_1}{a_1}<\frac{b_0}{a_0} \tag{15.4}$$

for $0<\beta<\pi$, and we can then verify that $-(a_0-\rho b_0)/(a_1-\rho b_1)>0$ when $a_0-\rho b_0>0$. We see that (15.4) follows from the inequalities

$$1<\frac{\zeta(2,\beta/2\pi)}{\zeta(2,1-\beta/2\pi)}<\frac{\zeta(4,\beta/2\pi)}{\zeta(4,1-\beta/2\pi)} \tag{15.5}$$

for $0<\beta<\pi$. The first inequality is obviously satisfied, since $\beta/2\pi<\frac{1}{2}$, and the second follows from the result that $\zeta(s,a_1)/\zeta(s,a_2)$ is an increasing function of s when $a_2>a_1>0$. To prove the latter result, we use the relation

$$\frac{\zeta(s,a_1)}{\zeta(s,a_2)}=\int_0^\infty \frac{x^{s-1}\,e^{-a_1x}}{1-e^{-x}}\,dx \Big/ \int_0^\infty \frac{x^{s-1}\,e^{-a_2x}}{1-e^{-x}}\,dx \tag{15.6}$$

[23, p. 266], and refer to a theorem by Karlin [8, Thm. 3.4, p. 285]. It follows that (15.4) holds, and hence, that $\alpha^2\sim-(a_0-\rho b_0)/(a_1-\rho b_1)$ as $a_0-\rho b_0\to 0$. Hence, the charge on sphere 1 is completely negative when

$$\frac{V_2}{V_1}>\frac{1+a_0/b_0}{1-a_0/b_0}. \tag{15.7}$$

We find that the right-hand side of (15.7) becomes infinite as $r_1/r_2\to\infty$, and that it tends to 1 as $r_1/r_2\to 0$. Thus, when sphere 2 is a plane, the charge on sphere 1 is completely negative in the limit $\varepsilon\to 0$. When $r_1=r_2$, we have

$$\frac{1+a_0/b_0}{1-a_0/b_0}=\frac{\pi^2+8G}{\pi^2-8G}=6.765\cdots, \tag{15.8}$$

where $G=\sum_{n=0}^{\infty}(-1)^n(2n+1)^2$ is Catalan's constant.

VARIATIONAL PRINCIPLES FOR EIGENVALUES OF COMPACT OPERATORS*

GILES AUCHMUTY†

Abstract. Variational principles for finding real and complex nonzero eigenvalues, and associated eigenvectors, of a linear compact operator K on a Hilbert space are developed and analyzed. When K is self-adjoint, certain unconstrained variational problems are described for finding the positive, respectively, negative, eigenvalues of K and the corresponding eigenvectors. These principles are extended to generalized eigenproblems and to nonlinear compact operators. For nonself-adjoint linear operators, a minimization problem for certain positive real eigenvalues is described. All the positive real eigenvalues may be described as critical points of a Lagrangian functional. These characterizations are then extended to describe complex eigenvalues and eigenvectors of nonself-adjoint, compact linear operators.

Key words. variational principles, eigenvalue problems, nonself-adjoint compact operators

AMS(MOS) subject classifications. primary 49G05; secondary 47B05

1. Introduction and notation. This paper describes and analyzes some variational principles for the eigenvalues and eigenvectors of a compact operator on a Hilbert space. When the operator is linear, these variational principles are related to those described in [2]–[4] and arise by systematic use of some simple concepts from convex analysis.

Let H be a real, separable Hilbert space with an inner product $\langle\ ,\ \rangle$ and let $K: H \to H$ be a compact linear operator. When K is self-adjoint there is an extensive theory, based on Rayleigh's principle, characterizing the eigenvalues and eigenvectors of K as solutions of various constrained variational problems (see [6] or [10]). In § 2 we describe certain functionals, defined and finite on all of H, whose critical points are eigenvectors of K corresponding to either positive or negative eigenvalues. These functionals have well-defined second derivatives and we can characterize the Morse indices of the critical points. The theory extends related results for self-adjoint matrix eigenproblems as described in § 6 of [3]. Variational principles for generalized eigenproblems are also developed, as are principles for certain eigenvalues and eigenvectors of nonlinear compact operators.

In § 3 these results are extended to obtain a variational principle for some positive eigenvalues, and corresponding eigenvectors, of a nonself-adjoint, compact, linear operator K. The basic constructions here are based on some methods from convex analysis; in particular, the use of conjugate convex functions. The solutions of this variational principle are saddle points of a Lagrangian. We then show, in Theorem 7, that each eigenvector of K, corresponding to a real positive eigenvalue, may be characterized as a critical point of this Lagrangian.

The next section, § 4, generalizes this work and describes how to characterize the complex eigenvalues and eigenvectors of a compact operator as the critical points of a Lagrangian depending on an angular variable θ.

The work described in this paper originated as part of a project to develop variational principles for various nonself-adjoint eigenproblems such as those described in Chandrasekhar's [5] book on hydrodynamic stability. Both theoretically and numerically, there often are advantages to formulating problems as critical point problems.

Moreover, variational characterizations often lead to good constructive methods for finding solutions. The principles described here appear to be quite different from those obtained for the largest eigenvalues of stochastic matrices as described, for example, in Horn and Johnson [9].

Whenever a term is not defined in this paper, it should be taken in the sense of Zeidler's text [11]. Given a functional $f: H \to \mathbb{R}$, its Gateaux derivative, or gradient, will be denoted by $\nabla f(x)$ and a point $\hat{x}$ in H is a critical point of f whenever $\nabla f(\hat{x}) = 0$. A critical value of f is the value of f at a critical point and the Gateaux second derivative of f will be denoted $D^2 f(x)$.

The functional f is said to be coercive on H provided

$$\liminf_{\|u\| \to \infty} \frac{f(u)}{\|u\|} = \infty.$$

2. Self-adjoint compact operator eigenproblems. Let H be a real Hilbert space and $K: H \to H$ be a compact, linear self-adjoint operator.

Let the positive eigenvalues of K be $\{\lambda_j: j \in J_+\}$. Here J_+ is a subset of the positive integers and we shall assume that

$$\lambda_1 > \lambda_2 > \cdots > \lambda_n > 0 \quad \text{whenever } n \in J_+.$$

Similarly, the negative eigenvalues of K are $\{\lambda_j: j \in J_-\}$ with J_- being a subset of the negative integers and

$$\lambda_{-1} < \lambda_{-2} < \cdots < \lambda_{-n} < 0 \quad \text{whenever } n \in J_-.$$

Either J_+ or J_- may be empty. For each $j \in J_- \cup J_+$, we shall let

$$E_j = \{e \in H: Ke = \lambda_j e \text{ and } \|e\| = 1\} \tag{2.1}$$

be the corresponding set of normalized eigenvectors. When λ_j is a simple eigenvalue of K, then E_j consists of two points. If λ_j is an eigenvalue of multiplicity $m > 1$, then E_j is diffeomorphic to an $(m-1)$-dimensional sphere.

Consider the functional $F_p: H \to \mathbb{R}$ defined by

$$F_p(u) = \frac{1}{p}\|u\|^p - \frac{1}{2}\langle Ku, u\rangle \tag{2.2}$$

with $2 < p < \infty$. The first variational principle we shall analyze is that of minimizing F_p on H. Define

$$\alpha_p = \inf_{u \in H} F_p(u).$$

THEOREM 1. *Suppose H, K, F_p, α_p as above, with $p > 2$; then*

(i) *F_p is weakly lower semicontinuous (w.l.s.c.) and coercive on H and*

$$\alpha_p = \frac{-1}{2r}[\max(0, \lambda_1)]^r \tag{2.3}$$

where $\gamma = (p-2)^{-1}$ and

$$r = p\gamma. \tag{2.4}$$

(ii) *When J_+ is empty, then F_p is minimized at 0; otherwise it is minimized at $\tilde{u} = \lambda_1^{\gamma} e$, where e is in E_1.*

(iii) *The critical points of* F_p *are* 0 *and* $\tilde{u} = \lambda_j^{\gamma} e_j$, *where* j *is in* J_+, *and* e_j *is in* E_j.

(iv) *The critical values of* F_p *are* 0 *and* $(-1/2r)\lambda_j^r$ *for* j *in* J_+.

Proof. Let $f_p(u) = (1/p)\|u\|^p$. Then f_p is continuous and convex; hence it is w.l.s.c. The quadratic form $\langle Ku, u\rangle$ is weakly continuous since K is compact; hence F_p is w.l.s.c. Moreover,

$$F_p(u) \geqq \frac{1}{p}\|u\|^p - \|K\|\,\|u\|^2.$$

Since $p > 2$, this is coercive. Hence F_p is bounded below on H and attains its infimum α_p.

F_p is Gateaux differentiable on H with

$$\nabla F_p(u) = \|u\|^{p-2}u - Ku \tag{2.5}$$

so $\tilde{u}$ is a critical point of F_p if and only if it solves

$$Ku = \|u\|^{p-2}u. \tag{2.6}$$

Hence $\tilde{u} = 0$ or $\tilde{u}$ is an eigenvector of K corresponding to the (positive) eigenvalue $\tilde{\lambda}$ with $\tilde{\lambda} = \|\tilde{u}\|^{p-2}$.

When $\tilde{\lambda} = \lambda_j$, we see that $\tilde{u} = \lambda_j^{\gamma} e_j$ with e_j in E_j.

Take inner products of (2.6) with $\tilde{u}$; then

$$\langle K\tilde{u}, \tilde{u}\rangle = \|\tilde{u}\|^p$$

so

$$F_p(\tilde{u}) = \left(\frac{1}{p} - \frac{1}{2}\right)\|\tilde{u}\|^p = \frac{2-p}{2p}\|\tilde{u}\|^p = \left(\frac{2-p}{2p}\right)\tilde{\lambda}^r. \tag{2.7}$$

Hence (iii) and (iv) follow.

Since $p > 2$, F_p is minimized when $\tilde{\lambda}$ is largest. This occurs at λ_1 when J_+ is nonempty, or at $\tilde{u} = 0$ if J_+ is empty. Thus (2.3), (2.4), and (ii) follow. □

This theorem shows that the unconstrained variational problem of minimizing F_p on H provides a variational principle for finding λ_1 and eigenvectors lying in E_1.

If we can find a $\tilde{u} \in H$ such that $F_p(\tilde{u}) < 0$, it then follows that K has at least one positive eigenvalue λ_1. This can be used to obtain a lower bound on λ_1 as stated in the following result.

COROLLARY 1. *Suppose* $K : H \to H$ *is a compact, linear self-adjoint operator and* F_p *is defined by* (2.2) *with* $p > 2$. *Suppose* $F_p(\tilde{u}) < 0$; *then the largest positive eigenvalue* λ_1 *of* K *obeys*

$$\lambda_1^r = \sup_{u \in C_0} -2rF_p(u) \geqq -2rF_p(\tilde{u}) \tag{2.8}$$

where r *is given by* (2.4) *and* C_0 *is the set of* u *in* H *such that* $F_p(u) < 0$.

Proof. The proof follows from (2.7) and part (ii) of the theorem. □

To find upper bounds on λ_1, one can consider the functional $F_p : H \times [0, \infty) \to \mathbb{R}$ defined by

$$F_p(u, \mu) = \frac{1}{p}\|u\|^p + \frac{\mu}{2}\|u\|^2 - \frac{1}{2}\langle Ku, u\rangle. \tag{2.9}$$

We see that $F_p(u, 0) = F_p(u)$ for all u in H, and for any $\mu_1 > \mu_2 \geqq 0$, we have

$$F_p(u, \mu_1) \geqq F_p(u, \mu_2) \quad \text{for all } u \text{ in } H.$$

Consider the problem of minimizing $F_p(u, \mu)$ on H and let

$$\alpha_p(\mu) = \inf_{u \in H} F_p(u, \mu) \quad \text{with } \mu > 0. \qquad \square$$

COROLLARY 2. *Suppose K, H as above and $F_p(\cdot, \mu)$ is defined by* (2.9) *with $\mu > 0$. Then*

(i) *F_p is w.l.s.c. and coercive on H;*

(ii) (2.10) $$\alpha_p(\mu) = \frac{-1}{2r}[\max(0, \lambda_1 - \mu)]^r$$

is a strictly increasing function of μ on $[0, \lambda_1)$.

Moreover, $\alpha_p(\mu) = 0$ if and only if $\mu \geqq \lambda_1$.

Proof. We have $F_p(u, \mu) = F_p(u) + \mu/2\|u\|^2$.

The extra term here is w.l.s.c. since $\mu > 0$ and helps the coercivity. Thus (i) holds, and

$$\nabla F_p(u, \mu) = \|u\|^{p-2}u + \mu u - Ku.$$

Hence the argument in Theorem 1 provides (2.10). The other results follow from inspection of (2.10).

This provides upper bounds on λ_1, for if we can show that $\inf_{u \in H} F_p(u, \tilde{\mu}) = 0$, then $\lambda_1 \leqq \tilde{\mu}$. $\square$

It is worth noting that we may find the negative eigenvalues of K by replacing K with $-K$ in (2.2). The results may be stated in terms of minimizing

(2.11) $$\tilde{F}_p(u) = \frac{1}{p}\|u\|^p + \frac{1}{2}\langle Ku, u\rangle$$

on H with $p > 2$. Let $\tilde{\alpha}_p = \inf_{u \in H} \tilde{F}_p(u)$.

COROLLARY 3. *Suppose $K : H \to H$ is a self-adjoint, compact linear operator and $\tilde{F}_p$ is defined by* (2.11) *with $p > 2$. Then*

(i) *$\tilde{F}_p$ is w.l.s.c. and coercive on H.*

(ii) *$\tilde{\alpha}_p = -(1/2r)[\max(0, -\lambda_{-1})]^r$ and this is attained at $\tilde{x} = |\lambda_{-1}|^\gamma e$ with e in E_{-1}.*

(iii) *The critical points of $\tilde{F}_p$ are 0 and $|\lambda_j|^\gamma e$ with j in J_- and e in E_j.*

(iv) *The critical values of $\tilde{F}_p$ are 0 and $(-1/2r)|\lambda_j|^r$ for j in J_-.*

Proof. The proof is just like that of Theorem 1, except now

$$\nabla \tilde{F}_p(u) = \|u\|^{p-2}u + Ku$$

and hence the critical points of $\tilde{F}_p$ arise at eigenvectors of K corresponding to negative eigenvalues. $\square$

LEMMA 2.1. *$\nabla F_p : H \to H$ defined by* (2.5) *is Gateaux differentiable with $D^2F_p(0) = -K$ and*

(2.12) $$D^2F_p(u) = \|u\|^{p-2}I - K + (p-2)\|u\|^{p-2}P_u$$

for $u \neq 0$. Here $P_u x = \langle x, u\rangle u/\|u\|^2$ is the projection in the direction u. F_p is convex on H if and only if K is negative semidefinite.

Proof. Consider $\phi(t) = \|u + th\|^{p-2}(u + th)$ for $t \geqq 0$, h in H. We see that

$$t^{-1}(\phi(t) - \phi(0)) = h\|u + th\|^{p-2} + \frac{1}{t}[\|u + th\|^{p-2} - \|u\|^{p-2}]u.$$

Taking limits as t decreases to 0, with $u \neq 0$ we see that

$$\lim_{t \to 0^+} t^{-1}(\phi(t) - \phi(0)) = \|u\|^{p-2}h + (p-2)\|u\|^{p-4}\langle u, h\rangle u.$$

Hence (2.12) follows. When $u = 0$, this limit is zero. F_p will be convex on H if and only if $\langle D^2F_p(u)h, h\rangle \geqq 0$ for all u in H. This implies that $-K$ is positive semidefinite. □

When $\tilde{u}$ is a nonzero critical point of F_p, one may define $\tilde{u}$ to be nondegenerate if zero is not in the spectrum of $D^2F_p(\tilde{u})$. When $\tilde{u}$ is a nonzero, nondegenerate, critical point of F_p, the Morse index of $\tilde{u}$ is defined as the number of negative eigenvalues of $D^2F_p(\tilde{u})$ counting multiplicity. For each j, let d_j be the multiplicity of λ_j as an eigenvalue of K. The following theorem shows that the unconstrained variational problem of extremizing F_p on H has a nice Morse theory. It is a counterpart to the Courant-Fischer-Weyl minimax theory associated with Rayleigh's principle.

THEOREM 2. *Suppose $\tilde{u} = \lambda_j^{\gamma} e$ with e in E_j, j in J_+ being a nonzero critical point of F_p. Then $\tilde{u}$ is a nondegenerate critical point of F_p if and only if λ_j is a simple eigenvalue of K. In this case, the Morse index of $\tilde{u}$ is $\sum_{k=1}^{j-1} d_k$.*

Proof. Let $e^{(k)}$ be a normalized eigenvalue of K that is orthogonal to e. Using the facts that $\|\tilde{u}\|^{p-2} = \lambda_j$, $P_{\tilde{u}} = P_e$, we have

$$D^2F_p(\tilde{u})e^{(k)} = (\lambda_j - \lambda_k)e^{(k)}$$

as $\langle e^{(k)}, e\rangle = 0$. Moreover, $D^2F_p(\tilde{u})e = (p-2)\lambda_j e$.

Since K has a complete orthonormal set of eigenfunctions, so does $D^2F_p(\tilde{u})$. Its eigenvalues are $\lambda_j - \lambda_k$ for $k \neq j$ and $(p-2)\lambda_j$ if λ_j is a simple eigenvalue of K. When λ_j is an eigenvalue of K of multiplicity $d_j > 1$, then we can choose a normalized eigenvector $\tilde{e}$ of K orthogonal to e and such that $D^2F_p(\tilde{u})\tilde{e} = 0$. Hence $\tilde{u}$ will be a degenerate critical point of F_p if and only if λ_j is a simple eigenvalue of K.

When $\tilde{u}$ is nondegenerate, we see from the expressions for $D^2F_p(\tilde{u})e^{(k)}$ that the number of negative eigenvalues of $D^2F_p(\tilde{u})$, counting multiplicity, will be $\sum_{k=1}^{j-1} d_j$. □

It is worth noting that

$$\lim_{p \to \infty} F_p(u) = \chi_1(u) = \begin{cases} 0 & \text{if } \|u\| \leqq 1, \\ \infty & \text{otherwise} \end{cases}$$

where χ_1 is the indicator functional of the unit ball in H.

Rayleigh's principle for finding the largest positive eigenvalue of K is equivalent to minimizing

$$F_\infty(u) = \chi_1(u) - \tfrac{1}{2}\langle Ku, u\rangle.$$

This may be regarded as the convex analysis version of Rayleigh's principle (see [1, § 8]).

The functionals F_p defined by (2.2) define a one-parameter family of variational problems that are smooth, unconstrained and converge, in a certain sense, to Rayleigh's principle as p increases to infinity.

There are a number of interesting and useful extensions of these principles. One may obtain variational principles for other eigenvalues by imposing orthogonality conditions. Suppose one knows the m largest eigenvalues $\lambda_1, \lambda_2, \cdots, \lambda_m$ of K and the corresponding eigenspaces. Let $\{e_1, \cdots, e_M\}$ be a corresponding set of orthonormal eigenfunctions of K which is a basis for the direct sum of these eigenspaces. Define

$$H_m = \{u \in H : \langle u, e_j\rangle = 0, 1 \leqq j \leqq M\} \tag{2.13}$$

and consider the problem of minimizing F_p on H_m.

THEOREM 3. *Let $K: H \to H$ be a compact, self-adjoint linear operator and F_p, H_m be defined by* (2.2), (2.13), *respectively, and with $p > 2$. Then*:

(i) *F_p is w.l.s.c. and coercive on H_m.*

(ii) $\alpha_{pm} = \inf_{u \in H_m} F_p(u) = (-1/2r)[\max(0, \lambda_{m+1})]^r$.

(iii) *When $\alpha_{pm} < 0$, this infimum is attained at $\hat{x} = \lambda_{m+1}^{\gamma} e$, where e lies in E_{m+1}.*

Proof. H_m is a closed subspace of H. Since (i) holds on H, it holds on H_m; then α_{pm} is finite and it is attained.

A critical point $\tilde{u}$ of F_p on H_m obeys

$$\nabla F_p(u) = \sum_{j=1}^{M} \mu_j e_j = \|u\|^{p-2} u - Ku \tag{2.14}$$

from the Lagrange multiplier rule. Take inner products of (2.14) with e_k for $1 \leqq k \leqq M$; then, using the self-adjointness of K,

$$\langle K\tilde{u}, e_k \rangle = \lambda_k \langle \tilde{u}, e_k \rangle = \|\tilde{u}\|^{p-2} \langle \tilde{u}, e_k \rangle - \mu_j \delta_{jk}$$

where δ_{jk} is the Kronecker delta.

Since $\tilde{u}$ is in H_m, this implies $\mu_k = 0$ for each $1 \leqq k \leqq M$ and thus $\tilde{u}$ is either zero or an eigenvector of K corresponding to the eigenvalue $\tilde{\lambda} = \|\tilde{u}\|^{p-2}$.

The rest of this proof now parallels that of Theorem 1. □

There are also similar results for finding $\lambda_{-(m+1)}$ by minimizing $\tilde{F}_p$ on the subspace orthogonal to the eigenspaces corresponding to $\lambda_{-1}, \lambda_{-2}, \cdots, \lambda_{-m}$.

Another generalization of these principles is to the generalized eigenproblem of finding nontrivial solutions u of

$$Ku = \lambda Au \tag{2.15}$$

where $A: H \to H$ is a continuous, self-adjoint, linear operator which is also positive definite. That is, there is an $a_0 > 0$ such that

$$\langle Au, u \rangle \geqq a_0 \|u\|^2 \quad \text{for all } u \text{ in } H. \tag{2.16}$$

In this case, define $J_p: H \to \mathbb{R}$ by

$$J_p(u) = \frac{1}{p} \langle Au, u \rangle^{p/2} - \frac{1}{2} \langle Ku, u \rangle \tag{2.17}$$

with $2 < p < \infty$ and consider the problem of minimizing J_p on H.

Let

$$\nu_p = \inf_{u \in H} J_p(u)$$

and $E_{jA} = \{u \in H: Ku = \lambda_j Au \text{ and } \langle Au, u \rangle = 1\}$.

THEOREM 4. *Let $K: H \to H$ be a compact, self-adjoint, linear operator and $A: H \to H$ be continuous, linear, self-adjoint and positive definite. Suppose J_p is defined by* (2.17) *with $p > 2$, then*

(i) *J_p is w.l.s.c. and coercive on H with*

$$\nu_p = \frac{-1}{2r} [\max(0, \lambda_1)]^r$$

and λ_1 is the largest positive eigenvalue of (2.15).

(ii) *When $\nu_p < 0$, then J_p is minimized at $\hat{x} = \lambda_1^{\gamma} e$, where e is in E_{1A}. If $\nu_p = 0$, J_p is minimized at zero.*

(iii) *The critical points of J_p are zero and $\lambda_j^{\gamma} e_j$, where λ_j is a positive eigenvalue of* (2.15) *and e_j is in E_{jA}.*

(iv) *The critical values of J_p are zero and $(-1/2r)\lambda_j^r$, where λ_j is a positive eigenvalue of* (2.15).

Proof. We have that J_p is w.l.s.c. and coercive as before, since A is positive definite. Now

$$\nabla J_p(u) = \langle Au, u\rangle^{(p-2)/2} Au - Ku. \tag{2.18}$$

Hence $\tilde{u}$ is zero or an eigenvector of (2.15) corresponding to the positive eigenvalue

$$\tilde{\lambda} = \langle A\tilde{u}, \tilde{u}\rangle^{(p-2)/2}.$$

Take inner products of (2.18) with $\tilde{u}$; then

$$\langle K\tilde{u}, \tilde{u}\rangle = \langle A\tilde{u}, \tilde{u}\rangle^{(p/2)} = \tilde{\lambda}^r,$$

so

$$J_p(\tilde{u}) = \left(\frac{1}{p} - \frac{1}{2}\right)\tilde{\lambda}^r.$$

Thus $\tilde{u} = \lambda_j^{\gamma} e$, where e is in E_{jA} and λ_j is a positive eigenvalue of (2.15). The proof now parallels that of Theorem 1. □

Finally, it is worth noting that similar variational principles may be studied for nonlinear, compact, potential operators. Let $K: H \to H$ be a nonlinear operator which is the derivative of a functional $\mathcal{K}: H \to \mathbb{R}$ which is weakly continuous and obeys

$$\limsup_{\|u\|\to\infty} \frac{\mathcal{K}(u)}{\|u\|^q} = M \tag{2.19}$$

with M finite and for some $0 \leqq q \leqq \infty$. Then consider $\mathcal{F}: H \to \mathbb{R}$ defined by

$$\mathcal{F}(u) = \frac{1}{p}\|u\|^p - \mathcal{K}(u) \tag{2.20}$$

with $p > \min(1, q)$. We have the following result.

THEOREM 5. *Suppose $\mathcal{K}: H \to \mathbb{R}$ is a weakly continuous, Gateaux-differentiable functional that obeys* (2.19) *and let $\mathcal{F}$ be defined by* (2.20) *with $p > \min(1, q)$. Then*

(i) *F is w.l.s.c. and coercive on H and*

$$\alpha = \inf_{u\in H} \mathcal{F}(u) \text{ is finite.} \tag{2.21}$$

(ii) *The infimum in* (2.21) *is attained at a point $\hat{u}$ in H obeying*

$$\nabla\mathcal{K}(u) = \lambda u \tag{2.22}$$

with

$$\lambda = \|\hat{u}\|^{p-2} \geqq 0. \tag{2.23}$$

Proof. Since $\mathcal{K}$ is weakly continuous, $\mathcal{F}$ is w.l.s.c. Also

$$\frac{\mathcal{F}(u)}{\|u\|^q} = \frac{1}{p}\|u\|^{p-q} - \frac{\mathcal{K}(u)}{\|u\|^q}.$$

Thus

$$\liminf_{\|u\|\to\infty} \frac{\mathcal{F}(u)}{\|u\|^q} \geqq \liminf_{\|u\|\to\infty} \left(\frac{1}{p}\|u\|^{p-q} - M\right) = +\infty$$

as $p > q$, so $\mathcal{F}$ is coercive. Thus α is finite and this infimum is attained. $\mathcal{F}$ is Gateaux differentiable with

$$\nabla\mathcal{F}(u) = \|u\|^{p-2}u - \nabla\mathcal{K}(u)$$

so any minimizer must obey (2.22), (2.23). □

Now consider $\mathcal{F}: H \to \mathbb{R}$ defined by

$$\tilde{\mathcal{F}}(u) = \frac{1}{p}\|u\|^p + \mathcal{K}(u) \tag{2.24}$$

and assume

$$\liminf_{\|u\|\to\infty} \frac{\mathcal{K}(u)}{\|u\|^q} = M > -\infty \tag{2.25}$$

for some $0 \leqq q < \infty$.

COROLLARY 4. *Suppose $\mathcal{K}: H \to \mathbb{R}$ is a weakly continuous, Gateaux-differentiable functional obeying* (2.25) *and that $\tilde{\mathcal{F}}$ is defined by* (2.24) *with $p > \min(1, q)$. Then*

(i) *$\mathcal{F}$ is w.l.s.c. and coercive on H and*

$$\tilde{\alpha} = \inf_{u\in H} \tilde{\mathcal{F}}(u) \text{ is finite.}$$

(ii) *This infimum is attained at a point $\tilde{u}$ in H obeying* (2.22) *with $\tilde{\lambda} = -\|\tilde{u}\|^{p-2} \leqq 0$.*

Proof. The proof is just as before. □

Note that in these results, we have not required any symmetries for $\mathcal{K}$, so there is no reason to believe that $\tilde{u} = 0$ is a critical point of $\mathcal{K}$ or that zero is an eigenvalue of $\nabla\mathcal{K}$ in Theorem 5.

3. Eigenproblems for nonself-adjoint compact operators. Henceforth $K: H \to H$ will be a linear compact operator which is not necessarily self-adjoint. Let $K_s = \frac{1}{2}(K + K^*)$ and $K_a = \frac{1}{2}(K - K^*)$ be the symmetric and antisymmetric parts of K.

Define $F: H \to \mathbb{R}$ by

$$F(u) = \frac{1}{p}\|u\|^p - \frac{1}{2}\langle K_s u, u\rangle \tag{3.1}$$

where $2 < p < \infty$. The conjugate convex function $F^*: H \to \mathbb{R}$ is defined by

$$F^*(v) = \sup_{u\in H} [\langle u, v\rangle - F(u)]. \tag{3.2}$$

We will need the following results about F^*.

LEMMA 3.1. *Suppose F is defined by* (3.1) *with $p > 2$, K_s is a linear, self-adjoint, compact operator and F^* is defined by* (3.2). *Then*

(i) *F^* is w.l.s.c. and convex on H.*

(ii) *$F^*(0) = -\inf_{u\in H} F(u) = (1/2r)[\max(0, \lambda_1)]^r$ where λ_1 is the largest eigenvalue of K_s and r is defined by* (2.4).

(iii) *$F^*(v) \geqq 0$ for all v in H.*

Proof. Since $Q(u, v) = \langle u, v\rangle - F(u)$ is convex and weakly continuous in v for each u in H, this supremum is w.l.s.c. and convex so (i) holds. We have (ii) from Theorem 1, and (iii) holds upon putting $u = 0$ into the right-hand side of (3.2). □

From definition (3.2) of F^* we see that

$$F(u) + F^*(v) \geqq \langle u, v\rangle \tag{3.3}$$

for all (u, v) in $H \times H$. This is sometimes called a generalized Young's inequality. In this problem F need not, in general, be convex, so the strong results of convex analysis do not hold. However, we have the following.

LEMMA 3.2. *Suppose F and F^* are defined by* (3.1) *and* (3.2), *then* (3.3) *holds for all (u, v) in $H \times H$. If equality holds in* (3.3) *at $(\hat{u}, \hat{v})$, then*

$$\nabla F(\hat{u}) = \hat{v}. \tag{3.4}$$

Proof. From (3.2), for each v in H, $F^*(v) \geqq \langle u, v\rangle - F(u)$ for all u in H. Thus (3.3) holds. Moreover, if $F^*(\hat{v}) = \langle \hat{u}, \hat{v}\rangle - F(\hat{u})$, then $\hat{u}$ maximizes $\langle u, v\rangle - F(u)$ on H. Hence it obeys (3.4). □

Define the functional $E : H \to \mathbb{R}$ by

$$E(u) = F(u) + F^*(K_a u) \tag{3.5}$$

and consider the problem of minimizing E on H.

THEOREM 6. *Suppose $K : H \to H$ is a linear compact operator and E, F are as above. Then*

(i) *E is w.l.s.c. and coercive on H, so E attains its infimum on H.*

(ii) *$E(u) \geqq 0$ for all u in H, and if $E(\hat{u}) = 0$ then $\hat{u}$ is a solution of*

$$Ku = \|u\|^{p-2}u. \tag{3.6}$$

Proof. F and F^* are w.l.s.c. from Theorem 1 and Lemma 3.1, respectively. F is coercive from Theorem 1, while F^* is nonnegative. Hence E is coercive and (i) holds.

From (3.3) we have $E(u) = F(u) + F^*(K_a u) \geqq \langle K_a u, u\rangle = 0$ for all u in H and using the antisymmetry of K_a.

From Lemma 3.2, equality holds here provided

$$K_a u = \nabla F(u) = \|u\|^{p-2}u - K_s u,$$

which is (3.6). □

We see that when K is a self-adjoint operator, $K_a = 0$ and then $E(u) = F(u) + F^*(0) = F(u) - \alpha_p$, with α_p being the infimum of F on H.

Note that not every solution of (3.6) obeys $E(\hat{u}) = 0$. In particular we have $E(0) = F^*(0)$ is given by (ii) of Lemma 3.1, and thus when $\lambda_1 > 0$, $E(0)$ will be nonzero.

To illustrate this result, consider the following example.

Let $K : H \to H$ be a compact, linear operator and let $\{e_j : j \in J_1\}$ be an orthonormal set of eigenfunctions of K_s corresponding to nonzero eigenvalues of K_s. Let H_1 be the closed subspace spanned by this set.

Extend this to an orthonormal basis $\{e_j : j \in J\}$ of H and assume $J_2 = J - J_1$ is nonempty. We have

$$\langle K_s u, u\rangle = \sum_{j \in J_1} \lambda_j \langle u, e_j\rangle^2 \tag{3.7}$$

for all u in H, where $\{\lambda_j : j \in J_1\}$ is the set of nonzero eigenvalues of K_s. In this case we can prove the following.

LEMMA 3.3. *Assume K, H as above with F defined by* (3.1) *and* (3.7). *Let λ_1 be the largest positive eigenvalue of K_s and v be orthogonal to H_1. Then*

$$F^*(v) = \begin{cases} \dfrac{1}{q}\|v\|^q & \text{when } \|v\| \geqq \lambda_1^{\nu}, \\ \dfrac{1}{2r}\lambda_1^r + \dfrac{1}{2\lambda_1}\|v\|^2 & \text{when } \|v\| \leqq \lambda_1^{\nu}. \end{cases} \tag{3.8}$$

Here $q = p/p-1$ is the conjugate index to p, $r = p/p-2$ is as in (2.4) *and $\nu = r/q$. When K_s has no positive eigenvalues, then*

$$F^*(v) = \frac{1}{q}\|v\|^q$$

for all v in $H_2 = H \ominus H_1$.

Proof. From (3.2), we see that we have to maximize

$$\langle u, v\rangle - \frac{1}{p}\|u\|^p + \frac{1}{2}\sum_{j\in J_1}\lambda_j\langle u, e_j\rangle^2$$

on H. This functional is weakly upper semicontinuous (w.u.s.c.) and its negative is coercive on H, so it attains its supremum.

The functional is Gateaux differentiable on H, so its supremum must occur at a critical point. Write $u_j = \langle u, e_j\rangle$ for all j in J. The critical points arise at $\hat{u}$, where

$$v_j - \|\hat{u}\|^{p-2}\hat{u}_j + \lambda_j\hat{u}_j = 0 \quad \text{for } j \text{ in } J_1, \tag{3.9}$$

$$v_j - \|\hat{u}\|^{p-2}\hat{u}_j = 0 \quad \text{for } j \text{ in } J_2. \tag{3.10}$$

When v is in H_2, we have $v_j = 0$ for j in J_1 and from (3.10),

$$\|\hat{u}\|^{2(p-2)}\sum_{j\in J_2}\hat{u}_j^2 = \|v\|^2.$$

Let $\hat{u} = \hat{u}^{(1)} + \hat{u}^{(2)}$ be the orthogonal decomposition of $\hat{u}$ defined by the projections onto H_1, H_2. This last equation implies $\|\hat{u}^{(1)}\|^2 = \|\hat{u}\|^2 - (\|v\|/\|\hat{u}\|^{p-2})^2$ upon rearrangement.

If $\hat{u}^{(1)} = 0$ then $\|v\| = \|\hat{u}\|^{p-1}$ and $\langle K_s\hat{u}, \hat{u}\rangle = 0$. Then $F^*(v) = \langle\hat{u}, v\rangle - (1/p)\|\hat{u}\|^p = (1/q)\|v\|^q$.

When $\hat{u}^{(1)} \neq 0$, we must have $\|\hat{u}\|^{p-2} = \lambda_k$ for some k in J_1. In this case

$$\|\hat{u}^{(1)}\|^2 = \lambda_k^{2/p-2} - \frac{\|v\|^2}{\lambda_k^2} = \frac{1}{\lambda_k^2}(\lambda_k^{2\nu} - \|v\|^2)$$

where $\nu = (p-1)/(p-2) = r/q$.

If $\|v\| \geqq \lambda_1^{\nu}$ then this is impossible, so $\hat{u}^{(1)} = 0$. When $\|v\| < \lambda_1^{\nu}$, let $K_1(v) = \{k \in J_1 : \|v\| \leqq \lambda_k^{\nu}\}$. $K_1(v)$ is a finite set when $v \neq 0$, and $\|u^{(1)}\| = \rho_k$, where ρ_k is any of the values $\rho_k^2 = (\lambda_k^{2\nu} - \|v\|^2)/\lambda_k^2$, $k \in K_1(v)$.

Suppose $\|u^{(1)}\| = \rho_k$; then $\|\hat{u}\|^{p-2} = \lambda_k$ and we have

$$\langle\hat{u}, v\rangle - \|\hat{u}\|^p + \langle K_s\hat{u}, \hat{u}\rangle = 0$$

upon taking inner products of (3.9) and (3.10) with $\hat{u}$. Thus the value of (3.9) at $\hat{u}$ is

$$\frac{1}{q}\|\hat{u}\|^p - \frac{1}{2}\langle K_s\hat{u}, \hat{u}\rangle = \frac{1}{q}\lambda_k^r - \frac{1}{2\lambda_k}(\lambda_k^{2\nu} - \|v\|^2).$$

Considered as a function of λ_k, this is maximized when λ_k is largest, that is, at λ_1, and then

$$F^*(v) = \left(\frac{1}{q} - \frac{1}{2}\right)\lambda_1^r + \frac{1}{2\lambda_1}\|v\|^2$$

which yields (3.8) as claimed. □

Suppose now that $K : H \to H$ is a compact linear operator obeying $(K1)$: $H_1 =$ range K_s is a proper closed subspace of H spanned by an orthonormal set $\{e_j : j \in J_1\}$, with $K_s e_j = \lambda_j e_j$ for all j in J_1 and $(K2)$: range $K_a \subseteq H_2 = H_1^{\perp}$.

Then the functional E for this problem is defined by

$$E_p(u) = \frac{1}{p}\|u\|^p - \frac{1}{2}\langle K_s u, u\rangle + F_p^*(K_a u) \tag{3.11}$$

where $F_p^*(v)$ is given by (3.8) and involves only constants r, q depending on p, λ_1 depending on K_s and $\|K_a u\|$.

In particular, we see that $F_p^*(v)$ is an increasing function of $\|v\|$. Thus if K is a compact linear operator obeying $(K1)$ and $(K2)$ then E_p is minimized at $\hat{u}$ in H, where

$\|K_a\hat{u}\| = 0$ and $\hat{u}$ minimizes $F(u) = \frac{1}{2}\|u\|^p - \frac{1}{2}\langle K_s u, u\rangle$. From Theorem 1, this implies $\hat{u} = \lambda_1^\gamma e_1$, where λ_1 is the largest eigenvalue of K_s, e_1 is a corresponding normalized eigenfunction and $\gamma = (p-2)^{-1}$.

If $\tilde{u}$ is a critical point of F corresponding to an eigenvalue λ_j of K_s with $0 < \lambda_j < \lambda_1$, then

$$E_p(\tilde{u}) = \frac{1}{2r}(\lambda_1^r - \lambda_j^r) > 0$$

so $\tilde{u}$ does not minimize E_p on H.

Nevertheless, we have $K_a\tilde{u} = 0$ from assumption $(K2)$ and $K_s\tilde{u} = \lambda_j\tilde{u} = \|\tilde{u}\|^{p-2}\tilde{u}$.

Thus $K\tilde{u} = \|\tilde{u}\|^{p-2}\tilde{u}$, but $E_p(\tilde{u}) > 0$. This shows, again, that the converse of (ii) in Theorem 6 does not hold.

Example. Let Ω be a Lebesgue measurable set in $\mathbb{R}^n$ and $L^2(\Omega)$ be the space of all L^2- integrable, measurable, real-valued functions defined on Ω. This is a Hilbert space with respect to the inner product

$$\langle u, v\rangle = \int_\Omega u(x)v(x)\,dx.$$

Define a linear operator $K: L^2(\Omega) \to L^2(\Omega)$ by

$$Ku(x) = \int_\Omega G(x, y)u(y)\,dy$$

where $G: \Omega \times \Omega \to \mathbb{R}$ is a measurable function obeying $\int_\Omega \int_\Omega |G(x, y)|^2\,dx\,dy < \infty$. Then, from standard results, K is a compact linear operator.

Assume that $G(x, y) = G_1(x, y) + G_2(x, y)$, where

(i) $G_1(x, y) = G_1(y, x)$ a.e. on $\Omega \times \Omega$,

$$G_1(x, y) = \sum_{j=1}^{J} \lambda_j e_j(x)e_j(y)$$

with $\{e_j : 1 \leqq j \leqq J\}$ an orthonormal set in $L^2(\Omega)$, and

(ii) $G_2(x, y) = -G_2(y, x)$ a.e. on $\Omega \times \Omega$ and

$$\int_\Omega G_2(x, y)e_j(y)\,dy = 0 \quad \text{a.e. on } \Omega \text{ for } 1 \leqq j \leqq J.$$

When G obeys (i), (ii), then K obeys conditions $(K1)$, $(K2)$, and we have that K_s is the compact operator defined by the finite-rank kernel G_1 and K_a is the compact operator defined by the kernel G_2.

The functional $E: L^2(\Omega) \to \mathbb{R}$ for this problem is

$$E(u) = \frac{1}{p}\left(\int_\Omega u^2(x)\,dx\right)^{p/2} - \frac{1}{2}\int_\Omega \int_\Omega G_1(x, y)u(x)u(y)\,dx\,dy + F_p^*(K_2u)$$

where $K_2u(x) = \int_\Omega G_2(x, y)u(y)\,dy$ and

$$F_p^*(K_2u) = \begin{cases} \dfrac{1}{q}\left(\displaystyle\int_\Omega |K_2u(x)|^2\,dx\right)^{q/2} & \text{if } \|K_2u\| \geqq \lambda_1^\nu, \\ \dfrac{1}{2r}\lambda_1^r + \dfrac{1}{2\lambda_1}\displaystyle\int_\Omega |K_2u(x)|^2\,dx & \text{if } \|K_2u\| < \lambda_1^\nu. \end{cases}$$

Here $q = p/p-1$, $r = p/p-2$, and we assume $\lambda_1 \geqq \lambda_j$ for all $1 \leqq j \leqq J$, and $\lambda_1 > 0$.

The first two terms in the expression for $E(u)$ constitute the explicit expression for the functional F_p, defined in § 2, when K corresponds to the integral kernel G_1 on $L^2(\Omega)$.

The analysis here depends on the computation of F^* in Lemma 3.3. Other formulae for computing F^* may be based on the results in [7] and [8].

4. Lagrangian formulation. We may find further information about this variational principle for the eigenvalues of nonself-adjoint operators by considering a saddle-point formulation of the problem.

Define $L: H \times H \to \mathbb{R}$ by

$$L(u, v) = \langle K_a u, v\rangle + \frac{1}{p}(\|u\|^p - \|v\|^p) - \frac{1}{2}[\langle K_s u, u\rangle - \langle K_s v, v\rangle] \tag{4.1}$$

$$= \langle K_a u, v\rangle + F_p(u) - F_p(v)$$

where $2 < p < \infty$, and F_p, K_a, K_s are as in § 3.

When L is defined by (4.1), we see that

$$E(u) = \sup_{v \in H} L(u, v) \tag{4.2}$$

upon using (3.2) and (3.5). Thus the primal problem $(\mathcal{P})$ of minimizing E on H is equivalent to finding $\alpha = \inf_{u \in H} \sup_{v \in H} L(u, v)$.

The dual problem is obtained by defining

$$G(v) = \inf_{u \in H} L(u, v). \tag{4.3}$$

It is $(\mathcal{P}^*)$ to maximize G on H and to find

$$\alpha^* = \sup_{v \in H} \inf_{u \in H} L(u, v).$$

The functional L is said to have a saddle point if there is a $(\hat{u}, \hat{v})$ in $H \times H$ such that

$$L(\hat{u}, v) \leqq L(\hat{u}, \hat{v}) \leqq L(u, \hat{v}) \tag{4.4}$$

for all u, v in H. L has a saddle point $(\hat{u}, \hat{v})$ if and only if $\hat{u}$ is a solution of the primal problem $(\mathcal{P})$, $\hat{v}$ is a solution of the dual problem and $\alpha = \alpha^*$. See Theorem 3.1 in [1] for this and related results.

We always have $\alpha^* \leqq \alpha$ and when $\alpha^* < \alpha$ we call $\delta = \alpha - \alpha^*$ the duality gap. The basic properties of the Lagrangian (4.1) may be summarized as follows.

THEOREM 7. *Let $K: H \to H$ be a compact, linear operator and define L by* (4.1) *with $2 < p < \infty$. Then*

(i) *$L(u, v) = -L(v, u)$ for all u, v in H.*

(ii) *$L(., v)$ and $-L(u, .)$ are w.l.s.c. and coercive on H.*

(iii) *Equation* (4.2) *holds, and if G is defined by* (4.3), *then $G(v) = -E(v)$.*

(iv) *L has a saddle point if and only if $\alpha = 0$.*

(v) *L is Gâteaux differentiable on $H \times H$ and $(\hat{u}, \hat{u})$ is a critical point of L if and only if $\hat{u}$ is a solution of* (3.6).

Proof. Part (i) holds by inspection and (ii) holds as in the proof of Theorem 1. Equation (4.2) follows from (3.2)-(3.5) and the last part of (iii) holds from the skew-symmetry of L.

From Theorem 6, we have that α, α^* are finite and are attained, so there exists $\hat{u}$ in H such that $\alpha = E(\hat{u}) = -\alpha^*$.

Thus the duality gap is $\delta = \alpha - \alpha^* = 2\alpha$. Hence when $\alpha \neq 0$, there cannot be a saddle. When $\alpha = 0$, we have from (ii) that there is a $\hat{v}$ in H such that

$$E(\hat{u}) = \sup_{v \in H} L(\hat{u}, v) = L(\hat{u}, \hat{v}). \tag{4.5}$$

But $E(\hat{u}) = 0$ and $L(\hat{u}, \hat{u}) = 0$ so we can take $\hat{v} = \hat{u}$ in (4.5). Then $(\hat{u}, \hat{u})$ will be a saddle point of L when $\alpha = 0$.

L is Gateaux differentiable with respect to both u and v and we have

$$D_u L(u, v) = -K_a v + \|u\|^{p-2} u - K_s u,$$
$$D_v L(u, v) = K_a u - \|v\|^{p-2} v + K_s v.$$

Thus $(\hat{u}, \hat{u})$ will be a critical point of L if and only if $\hat{u}$ obeys (3.6). □

From this theorem, we see that the problem of finding a $\hat{u}$ in H such that $E(\hat{u}) = 0$ is equivalent to finding a saddle point of this Lagrangian. Moreover, the nonzero critical points of this Lagrangian of the form $(\hat{u}, \hat{u})$ are eigenvectors of K corresponding to positive eigenvalues. Thus this Lagrangian provides a critical-point formulation for finding the positive eigenvalues of a general linear compact operator.

We can be more specific about the saddle points of L.

COROLLARY 5. *Under the conditions of Theorem* 7, $(0, 0)$ *is a saddle point of* L *if and only if* $\langle K_s u, u\rangle \leqq 0$ *for all* u *in* H. *Moreover,* $(\hat{u}, \hat{u})$ *is a saddle point of* L *if and only if* $E(\hat{u}) = 0$.

Proof. From (ii) of Lemma 3.1, we have $F^*(0) = 0$ if and only if

$$\langle K_s u, u\rangle \leqq 0 \quad \text{for all } u \in H. \tag{4.6}$$

Thus $E(0) = F^*(0) = 0$ if and only if (4.6) holds. □

From Theorem 7, we see that L has a saddle point if and only if $\alpha = 0$ and in the proof we showed that when $\alpha = 0$ the saddle points have the form $(\hat{u}, \hat{u})$, where $\hat{u}$ is a solution of $E(\hat{u}) = 0$.

The Lagrangian (4.1) is not convex-concave unless (4.6) holds; hence the set of saddle points of L, in general, is not a convex set even when it is nonempty.

This Lagrangian has a well-defined second derivative given by

$$D^2 L(u, v) = \begin{pmatrix} D^2 F(u) & -K_a \\ K_a & -D^2 F(v) \end{pmatrix}$$

with $D^2 F(u)$, $D^2 F(v)$ being defined by the expressions in Lemma 2.1. Just as in Theorem 2, we can use this to define nondegeneracy and type of a critical point of L.

The variational and critical point principles described here appear to be new, even in the finite-dimensional (i.e., matrix) case. In particular, they are different from those described in [4].

5. Complex eigenvalues and eigenvectors. In this section we characterize the complex eigenvalues and eigenvectors of a linear compact operator $K : H \to H$ as the critical points of a real-valued Lagrangian $\mathscr{L}$ depending on an angular variable θ.

Since we want to work only in real arithmetic, we need to rewrite some of the standard definitions. A complex number $\lambda = \lambda_1 + i\lambda_2$ is said to be an eigenvalue of K if there is a nonzero vector (v_1, v_2) in $H \times H$ such that

$$\begin{aligned} Kv_1 &= \lambda_1 v_1 - \lambda_2 v_2, \\ Kv_2 &= \lambda_2 v_1 + \lambda_1 v_2. \end{aligned} \tag{5.1}$$

These are the real and imaginary parts of the usual characterization with $v = v_1 + iv_2$ and $v_1, v_2 \in H$.

If $\lambda = |\lambda| e^{i\theta}$, then this may be rewritten as

$$\mathscr{K}(\theta)\begin{pmatrix} v_1 \\ v_2 \end{pmatrix} = \begin{pmatrix} \cos\theta K & \sin\theta K \\ -\sin\theta K & \cos\theta K \end{pmatrix}\begin{pmatrix} v_1 \\ v_2 \end{pmatrix} = |\lambda|\begin{pmatrix} v_1 \\ v_2 \end{pmatrix}. \tag{5.2}$$

Define $H_2 = H \times H$; then H_2 is a Hilbert space under the inner product $[v, w] = \langle v_1, w_1\rangle + \langle v_2, w_2\rangle$, where $v = \binom{v_1}{v_2}$, $w = \binom{w_1}{w_2}$ are in H_2. Henceforth H_2 will have this inner product, the corresponding norm, and the induced topology. Let $S^1 = [0, 2\pi]$ with the endpoints identified; then for each θ in S^1 we have $\mathcal{K}(\theta): H_2 \to H_2$ is a compact linear operator. From the equivalence of (5.1) and (5.2) we see that K has a nonzero complex eigenvalue $|\lambda|e^{i\theta}$ if and only if $\mathcal{K}(\theta)$ has a positive real eigenvalue $|\lambda|$.

This problem, of characterizing positive real eigenvalues of compact operators, was treated in § 3, so we will extend these results to this case.

Let

$$\mathcal{K}_s(\theta) = \tfrac{1}{2}(\mathcal{K}(\theta) + \mathcal{K}^*(\theta)) = \begin{pmatrix} \cos\theta K_s & \sin\theta K_a \\ -\sin\theta K_a & \cos\theta K_s \end{pmatrix}$$

where K_s, K_a are the symmetric and antisymmetric parts of K. Similarly

$$\mathcal{K}_a(\theta) = \tfrac{1}{2}(\mathcal{K}(\theta) - \mathcal{K}^*(\theta)) = \begin{pmatrix} \cos\theta K_a & \sin\theta K_s \\ -\sin\theta K_s & \cos\theta K_a \end{pmatrix}.$$

Define $G: H_2 \times S^1 \to \mathbb{R}$ by

$$G(v, \theta) = \frac{1}{p}[\|v_1\|^2 + \|v_2\|^2]^{p/2} - \frac{1}{2}[\mathcal{K}_s(\theta)v, v] \tag{5.3}$$

where $v = (v_1, v_2)$ is in H_2 and $2 < p < \infty$.

Then

$$G(v, \theta) = \frac{1}{p}[\|v_1\|^2 + \|v_2\|^2]^{p/2} - \frac{\cos\theta}{2}[\langle K_s v_1, v_1\rangle + \langle K_s v_2, v_2\rangle] + \sin\theta\langle K_a v_1, v_2\rangle$$

in terms of the components v_1, v_2.

Define the conjugate convex function $G^*: H_2 \times S^1 \to \mathbb{R}$ by

$$G^*(w, \theta) = \sup_{v \in H_2} ([v, w] - G(v, \theta))$$

and the functional $\mathcal{G}: H_2 \times S^1 \to \mathbb{R}$ by

$$\mathcal{G}(v, \theta) = G(v, \theta) + G^*(\mathcal{K}_a(\theta)v, \theta). \tag{5.4}$$

Consider the variational principle of minimizing $\mathcal{G}(v, \theta)$ on $H_2 \times S^1$.

THEOREM 8. *Suppose $K: H \to H$ is a compact linear operator and $\mathcal{K}(\theta)$, G, $\mathcal{G}$ are defined as above. Then*

(i) *$\mathcal{G}(., \theta)$ is w.l.s.c. and coercive on H_2 for each θ in S^1;*

(ii) *$\mathcal{G}(v, \theta) \geqq 0$ for all v in H_2;*

(iii) *If $\mathcal{G}(\hat{v}, \hat{\theta}) = 0$ then $\hat{v}$ is a solution of*

$$\mathcal{K}(\hat{\theta})\hat{v} = |\lambda|\hat{v} \tag{5.5}$$

with

$$|\lambda| = \|\hat{v}\|^{p-2}. \tag{5.6}$$

Proof. This follows just as in the proof of Theorem 6. Here we are working with $\mathcal{K}(\theta)$ and H_2 in place of K and H.

The Lagrangian corresponding to this function $\mathcal{G}$ is $\mathcal{L}$: $H_2 \times H_2 \times S^1 \to \mathbb{R}$ defined by

$$\mathcal{L}(v, w, \theta) = \langle \mathcal{K}_a(\theta)v, w\rangle + \mathcal{G}(v, \theta) - \mathcal{G}(w, \theta) \tag{5.7}$$

Again this is skew-symmetric in v and w with

$$\mathscr{L}(w, v, \theta) = -\mathscr{L}(v, w, \theta)$$

and our interest is in finding the critical points of $\mathscr{L}(.,., \theta)$.

THEOREM 9. *Suppose $K: H \to H$ is a compact linear operator and $\mathscr{K}(\theta)$, $\mathscr{L}$ are defined as above. Then $\mathscr{L}(.,., \theta)$ is Gateaux differentiable on H_2 and a nonzero point $(\hat{w}, \hat{w}, \hat{\theta})$ is a critical point of $\mathscr{L}(.,., \hat{\theta})$ if and only if $\hat{w}_1 + i\hat{w}_2$ is an eigenvector of K corresponding to the complex eigenvalue $\hat{\lambda} = \|\hat{w}\|^{p-2} e^{i\hat{\theta}}$.*

Proof. Just as in Theorem 7, we have

$$D_v \mathscr{L}(v, w, \theta) = -\mathscr{K}_a(\theta) w + \|v\|^{p-2} v - \mathscr{K}_s(\theta) v,$$

$$D_w \mathscr{L}(v, w, \theta) = \mathscr{K}_a(\theta) v = \|w\|^{p-2} w + \mathscr{K}_s(\theta) w.$$

Thus $(\hat{w}, \hat{w}, \hat{\theta})$ is a critical point of $\mathscr{L}(.,., \hat{\theta})$ if and only if $\hat{w}$ obeys

$$\mathscr{K}(\hat{\theta}) w = \|w\|^{p-2} w$$

and this is equivalent to having $w_1 + iw_2$ a complex eigenvector of K corresponding to the eigenvalue $\lambda = |\hat{\lambda}| e^{i\hat{\theta}}$ with $|\hat{\lambda}| = \|\hat{w}\|^{p-2}$ as required. □

These last two theorems show that all nonzero eigenvalues and eigenvectors of a compact, linear operator K defined on a real Hilbert space may be found from the critical points of this real-valued functional $\mathscr{L}$. The functional $\mathscr{L}$ is twice continuously Gateaux differentiable and defines an unconstrained problem. Throughout this paper, p can be taken as any number in $(2, \infty)$. The choices $p = 3$ or 4 lead to particularly simple formulae for these linear eigenvalue problems. For nonlinear problems, as described in Theorem 5 and its corollary, the choice of p depends on the properties of K.

DECAYING SOLUTIONS OF SEMILINEAR ELLIPTIC EQUATIONS IN $\mathbf{R}^N$*

EZZAT S. NOUSSAIR† AND CHARLES A. SWANSON‡

Abstract. This paper is concerned with the existence and asymptotic behavior of positive solutions of semilinear elliptic problems of second order in $\mathbf{R}^N$, $N \geqq 2$. Positive solutions in $\mathbf{R}^N$ that decay uniformly to zero at ∞ are obtained under various structure conditions by either a direct variational approach or a new approximation procedure. Sharp decay estimates are proved for two general classes of problems.

Key words. elliptic, semilinear, positive solution, asymptotic estimate

AMS(MOS) subject classifications. 35J65, 35P30

1. Introduction. Existence theorems and sharp asymptotic estimates are obtained for positive solutions $u(x)$ in $\mathbf{R}^N$, $N \geqq 2$, of semilinear elliptic eigenvalue problems of the form

$$\begin{aligned} &-\Delta u + b(|x|)u = \lambda p(|x|)f(u), \qquad x \in \mathbf{R}^N, \\ &u \in C^2_{\text{loc}}(\mathbf{R}^N), \qquad \lim_{|x|\to\infty} u(x) = 0 \end{aligned} \tag{1}$$

for some $\lambda > 0$, where b, p are bounded, locally Hölder continuous functions in $\mathbf{R}_+ = [0, \infty)$, $b(r) \geqq 0$, $p(r) > 0$, f is locally Lipschitz continuous in $\mathbf{R}_+$, $f(t) \leqq 0$ for all $t \geqq T$ and some constant T, $f(t) > 0$ for $0 < t < T$, and $f(t) = 0(t^\gamma)$ as $t \to 0+$, $\gamma > 1$. In general, $p(r)$ is not restricted by any monotony or decay conditions at ∞. The conditions on $f(t)$ imply that (1) has a *bounded nonlinearity*, i.e., $f(t)$ is bounded above in $\mathbf{R}_+$.

The extensive literature on the theory and applications of (1), usually dealing with the case of constants b, p or special structure, is indicated in [1], [2], [4]-[9], [11]-[15], and references cited in these sources. Differential equations of this type arise in many scientific areas including quantum field theory, fluid mechanics, astrophysics, gas dynamics, chemistry, and Riemannian geometry.

Our results are separated into two basically distinct cases:

(i) $b(r) \geqq b_0 > 0$; and (ii) $b(r) \geqq 0$. A primary goal is to deal with case (ii) when $p(r)$ does not satisfy a strong decay condition, such as $p(r) = O(r^{-a})$ as $r \to \infty$, $a > 2$. The usual variational approaches in the Sobolev space $W^{1,2}_0(\mathbf{R}^N)$ are not possible in case (ii) since (1) generally has no positive solutions $u \in L^2(\mathbf{R}^N)$, as is well known in the "zero mass" case $b(r) \equiv 0$. Also the method of subsolutions and supersolutions has not been successful in case (ii). The fascination of such problems is in part due to the sensitive dependence of the conclusions on the asymptotic behaviour of $f(u)$ as $u \to 0+$ and $p(r)$ as $r \to \infty$, measured by the constants γ and a in (4) below. To date there is no indication that the difficulties inherent in case (ii) can be handled by the methods of ordinary differential equations, e.g., the shooting method, trajectory analysis, fixed-point theorems, or Lyapunov techniques. Instead, our method employs a sequence of differential equations

$$-\Delta u_k + \left[b(|x|) + \frac{1}{k} \right] u_k = \lambda_k p(|x|) f(u_k), \qquad x \in \mathbf{R}^N, \tag{2}$$

of type (i), with positive radial solutions $u_k \in W_0^{1,2}(\mathbf{R}^N)$ and corresponding $\lambda_k > 0$, $k = 1, 2, \cdots$. The idea is to prove that $\{u_k\}$ has a subsequence that converges locally uniformly in $C^2(\mathbf{R}^N)$ to a positive solution u of (1) as $k \to \infty$. For the full γ range described by (4), this is the first procedure devised to date that can treat the zero mass case (and generalizations) regardless of the nonlinear structure of $f(u)$.

A necessary prerequisite for this program is the construction of such positive pairs (λ_k, u_k) of (2) without the assumption of any monotony or decay conditions on $p(r)$ as $r \to \infty$. As far as we are aware, such a theorem is not contained among similar results of Berestycki and Lions [1], [2], Gidas, Ni, and Nirenberg [5], Strauss [13], Stuart [14], and others. Accordingly, we have sketched a proof of Theorem 1 below that we believe is of independent interest in view of its relevance to nonlinear field theory [2], [13].

THEOREM 1. *In case* (i), *problem* (1) *has a positive solution pair* (λ, u_λ), *with* $u_\lambda \in W_0^{1,2}(\mathbf{R}^N)$, *such that* $u_\lambda(x)$ *and* $|\nabla u_\lambda(x)|$ *are asymptotically bounded by constant multiples of* $|x|^{(1-N)/2} \exp(-\sqrt{b_0}\,|x|)$ *as* $|x| \to \infty$.

In case (ii) a positive solution pair (λ, u_λ) of (1) does not exist in general without restrictions on p or γ. An example showing this is

$$\begin{aligned} &-\Delta u = \lambda(1+|x|^a)^{-1}(u^\gamma - u^\beta), \qquad x \in \mathbf{R}^N, \quad N \geqq 3, \\ &u \in C^2_{\mathrm{loc}}(\mathbf{R}^N), \qquad \lim_{|x|\to\infty} u(x) = 0 \end{aligned} \tag{3}$$

for $a \geqq 0$, $1 < \gamma < \beta$. In fact, if such a solution pair exists, then u_λ satisfies

$$-\Delta u_\lambda \geqq (\lambda/2)(1+|x|^a)^{-1} u_\lambda^\gamma$$

for all sufficiently large $|x|$, implying $\gamma > (N-a)/(N-2)$ by a well-known oscillation criterion [10, p. 76]. In the case where $a = 2$, it therefore follows from Theorem 2 below that the condition $\gamma > 1$ is necessary and sufficient for the existence of a positive solution pair (λ, u_λ).

For Theorem 2 we impose the additional hypothesis

$$\begin{aligned} &p(r) = O(r^{-a}) \quad \text{as } r = |x| \to \infty, \quad N \geqq 3, \\ &\gamma > 1 \quad \text{if } a \geqq 2, \qquad \gamma > \frac{N-2a+2}{N-2} \quad \text{if } 0 \leqq a < 2. \end{aligned} \tag{4}$$

THEOREM 2. *In case* (ii), *if* (4) *holds, problem* (1) *has a positive solution pair* (λ, u_λ) *with* $u_\lambda \in L^{2N/(N-2)}(\mathbf{R}^N)$ *and* $u_\lambda(r) = O(r^{(2-N)/2})$ *uniformly as* $r \to \infty$.

For a domain $G \subset \mathbf{R}^N$, the norms in $L^q(G)$, $L^q(\mathbf{R}^N)$, and $E = W_0^{1,2}(\mathbf{R}^N)$ will be denoted by $\|\cdot\|_{q,G}$, $\|\cdot\|_q$, and $\|\cdot\|_{1,2}$, respectively. We will use the notation

$$f_T(t) = \begin{cases} f(t) & \text{if } 0 \leqq t \leqq T, \\ 0 & \text{otherwise,} \end{cases}$$

$$F(t) = \int_0^t f(s)\,ds, \qquad F_T(t) = \int_0^t f_T(s)\,ds,$$

$$I(\phi) = \frac{1}{2}\int_{\mathbf{R}^N} [|\nabla\phi|^2 + b\phi^2]\,dx, \qquad \phi \in E,$$

$$J(\phi) = \int_{\mathbf{R}^N} pF_T(\phi)\,dx, \qquad \phi \in E,$$

$$(Pv)(x) = \frac{1}{\mu(S_1)}\int_{S_1} v(|x|\omega)\,d\mu(\omega),$$

where μ denotes the usual surface measure on the unit sphere S_1 in $\mathbf{R}^N$. The operator P is an orthogonal projection from $L^2(\mathbf{R}^N)$ into radial L^2 functions. It is known [14, Lemma 6.1] that P extends to a bounded linear mapping from E into E such that

$$\|\nabla Pv\|_2 \leqq \|P|\nabla v|\,\|_2 \leqq \|\nabla v\|_2, \qquad v \in E. \tag{5}$$

Geometrically $(Pv)(x) = V(r)$ represents the spherical mean of $v(x)$ over the sphere S_r of radius r in $\mathbf{R}^N$.

Proof of Theorem 1. Let $\{v_n\}$ be a weakly convergent sequence in E, with weak limit v, and define $u = Pv$, $u_n = Pv_n$. Then [14, Lemma 6.1] $\{u_n\}$ is uniformly bounded in the norm $\|\cdot\|_{1,2}$ in E, and so also in the norm $\|\cdot\|_2$. By the hypothesis that $p(x)$ is bounded and $f(t) = O(t^\gamma)$ as $t \to 0$, there exists a constant $C > 0$ such that

$$\begin{aligned} |J(u_n) - J(u)| &\leqq \int_{\mathbf{R}^N} \int_{u(x)}^{u_n(x)} C|t|^\gamma \, d|t| \, dx \\ &\leqq 2^{\gamma-1} C \int_0^1 [G(u_n, u, \theta) + H(u_n, u, \theta)] \, d\theta \end{aligned} \tag{6}$$

by Fubini's Theorem in $L^1(\mathbf{R}^N \times [0,1])$ and a slight computation, where

$$G(u_n, u, \theta) = \int_B |u_n(x) - u(x)|[|u(x)|^\gamma + \theta^\gamma |u_n(x) - u(x)|^\gamma] \, dx, \tag{7}$$

$$H(u_n, u, \theta) = \int_{B'} |u_n(x) - u(x)|[|u(x)|^\gamma + \theta^\gamma |u_n(x) - u(x)|^\gamma] \, dx, \tag{8}$$

and B' denotes the complement of the unit ball B in $\mathbf{R}^N$. The Cauchy-Schwarz inequality yields

$$G(u_n, u, \theta) \leqq \|u_n - u\|_{2,B}[\|u\|_{2\gamma,B}^\gamma + \theta^\gamma \|u_n - u\|_{2\gamma,B}^\gamma],$$

and hence the compactness of the Sobolev embedding $W_0^{1,2}(B) \subset L^q(B)$ for $2 \leqq q \leqq 2N/(N-2)$, $N \geqq 3$ (or $q \geqq 1$, $N = 2$) guarantees the existence of a subsequence of $\{u_n\}$, again denoted by $\{u_n\}$, such that $\lim_{n\to\infty} G(u_n, u, \theta) = 0$.

To obtain an analogue of this for (8), we use an a priori estimate of Strauss [13, Lemma 1] for radial functions $z \in E$:

$$|z(r)| \leqq C_0 \zeta(r) \|z\|_{1,2}, \qquad |x| = r \geqq 1 \tag{9}$$

where $\zeta(r) = r^{(1-N)/2}$, $N \geqq 2$, and C_0 is a positive constant independent of z. Application of (9) to (8) shows that there exists a constant K, independent of n, such that

$$H(u_n, u, \theta) \leqq K \|\zeta^{\gamma-1}(u_n - u)\|_{2,B'}[\|u\|_{2,B'} + \theta^\gamma \|u_n - u\|_{2,B'}].$$

From the decay of $\zeta(r)$ as $r \to \infty$, multiplication by $\zeta^{\gamma-1}$ is a compact operator from $W_0^{1,2}(B')$ into $L^2(B')$ by a theorem of Berger and Schechter [3, Thm. 2.7], i.e., $\lim_{n\to\infty} \|\zeta^{\gamma-1}(u_n^* - u)\|_{2,B'} = 0$ for a subsequence $\{u_n^*\}$ of $\{u_n\}$, implying that $\lim_{n\to\infty} H(u_n^*, u, \theta) = 0$. It then follows from (6)-(8), if $v_n \to v$ weakly in E, that

$$\lim_{n\to\infty} J(Pv_n^*) = J(Pv) \tag{10}$$

for a subsequence $\{v_n^*\}$ of $\{v_n\}$, i.e., the functional J_p: $v \to J(Pv)$ is weakly sequentially compact.

By the continuity of p and F_T, there exists a nontrivial radial function $\phi \in E$ such that $d = J(\phi) > 0$. Consider the constrained minimization problem

$$M = \inf\{I(v): v \in E, J(Pv) = d\},$$

and let $\{v_n\}$ be a minimizing sequence in E with $\lim_{n\to\infty} I(v_n) = M$. Since I is an equivalent norm on E, $\{v_n\}$ is bounded in E and therefore has a weakly convergent subsequence, also denoted by $\{v_n\}$, to a function $v \in E$. Since (10) holds for a subsequence $\{v_n^*\}$, it follows that $Pv \not\equiv 0$ since $d = J(Pv)$ and $J(0) = 0$. The Euler-Lagrange principle shows that $I'(v) = \lambda J'(Pv)$ for some real λ, where I' and J' denote Fréchet derivatives. By the assumption $f(t) = o(t)$ as $t \to 0$, standard procedure enables us to write the last functional equation as

$$\int_{\mathbf{R}^N} [\nabla v \cdot \nabla w + bvw]\, dx = \lambda \int_{\mathbf{R}^N} pf_T(Pv) Pw\, dx \tag{11}$$

for all $w \in E$. Since $Pw \in E$ for all $w \in E$, this can be rewritten as [14, Lemma 6.1]

$$\int_{\mathbf{R}^N} [\nabla(Pv) \cdot \nabla w + b(Pv)w]\, dx = \lambda \int_{\mathbf{R}^N} pf_T(Pv) w\, dx \tag{12}$$

for all $w \in E$, from which $u = Pv$ is a nontrivial weak solution of the problem

$$-\Delta u + bu = \lambda p f_T(u), \qquad u \in E. \tag{13}$$

Since (12) holds in particular for $w = Pv$, it follows that $\lambda \neq 0$. In view of the regularity hypotheses on b, p, f, standard elliptic regularity theory shows that $u \in C^{2+\alpha}_{\text{loc}}(\mathbf{R}^N)$ for some $\alpha \in (0, 1)$, i.e., u is a classical solution of (13).

To verify that $u \geqq 0$ throughout $\mathbf{R}^N$, suppose to the contrary that $u < 0$ in a nonempty set Ω. The definition of f_T shows that $-\Delta u + bu = 0$ in Ω and $u|_{\partial\Omega} = 0$, implying the contradiction $u(x) \equiv 0$ in Ω by the maximum principle.

Since $u(x)$ is nontrivial and nonnegative in $\mathbf{R}^N$, (12) with $w = Pv = u$ shows that $\lambda > 0$. Also $0 \leqq u(x) \leqq T$ in $\mathbf{R}^N$, for if $u(x_0) > T$ is a positive maximum of a solution of (13), then in appropriate coordinates

$$\lambda p(|x|) f_T(u(x_0)) = -(\Delta u)(x_0) + b(|x_0|)u(x_0) \geqq b_0 u(x_0) > 0,$$

contrary to the definition of $f_T(t)$. Therefore $f_T(u) = f(u)$ in (13), and hence u is a solution of (1). Since $f(t) \geqq 0$ for $0 \leqq t \leqq T$, $-\Delta u + bu \geqq 0$ in $\mathbf{R}^N$, implying that $u(x) > 0$ throughout $\mathbf{R}^N$ by the strong maximum principle. The decay estimates in Theorem 1 can be deduced from the property $\lim_{|x|\to\infty} u(x) = 0$ uniformly in $\mathbf{R}^N$ (since $u \in E$) by a slight modification of the argument of Gidas, Ni, and Nirenberg [5, Prop. 4.1].

3. Proof of Theorem 2. The idea of the proof is to apply Theorem 1 to the sequence of equations (2) and appeal to the three lemmas below. We will use the following additional notation:

$$I_k(\phi) = \frac{1}{2} \int_{\mathbf{R}^N} \left[|\nabla \phi|^2 + \left(b + \frac{1}{k} \right) \phi^2 \right] dx, \quad \phi \in E, \quad k = 1, 2, \cdots. \tag{14}$$

LEMMA 1. *Under the assumptions of Theorem* 2, *for every* $k = 1, 2, \cdots$ *there exists a positive solution pair* (λ_k, u_k) *of* (2) *such that* $u_k \in E$, *the sequence* $\{\|\nabla u_k\|_2\}$ *is bounded, and*

$$0 < u_k(r) \leqq M r^{(2-N)/2}, \qquad r \geqq 1 \tag{15}$$

for a positive constant M *independent of* k.

Proof. Such a sequence (λ_k, u_k) is guaranteed by Theorem 1, where $u_k = Pv_k$ and v_k is a solution of the constrained minimization problem

$$I_k(v_k) = \inf\{I_k(v): v \in E, J(Pv) = d\}. \tag{16}$$

It follows from (5), (14), and (16) that

$$\|\nabla u_k\|_2^2 = \|\nabla Pv_k\|_2^2 \leqq \|\nabla v_k\|_2^2 \leqq 2I_k(v_k) \leqq 2I_1(v_1).$$

Hence $\|\nabla u_k\|_2$ is bounded, implying (15) by the estimate of Berestycki and Lions for radial functions in E [2, Lemma AIII].

LEMMA 2. *The sequence $\{u_k\}$ in Lemma 1 has a subsequence that converges locally uniformly in $C^2(\mathbf{R}^N)$ to a nontrivial function $u \in C^2_{\text{loc}}(\mathbf{R}^N)$ satisfying*

$$0 \leqq u(r) \leqq Mr^{(2-N)/2}, \qquad r \geqq 1. \tag{17}$$

Proof. The existence of such a convergent subsequence is a consequence of the uniform estimate (15) by a standard argument based on Schauder and L^q-estimates in bounded domains of $\mathbf{R}^N$ (see, e.g., [11, Thm. 4.3]). To prove that the limit $u(r)$ is not identically zero, we use (15), the uniform bound $0 < u_k(r) \leqq T$ in $\mathbf{R}^N$, and the assumption $F(t) = O(t^{\gamma+1})$ as $t \to 0+$ to conclude that there exists a positive constant C, independent of k, such that

$$\begin{aligned} 0 < d = J(u_k) &= \int_{\mathbf{R}^N} p(|x|)F(u_k(|x|))\,dx \\ &\leqq C \int_{\mathbf{R}^N} p(|x|)[u_k(|x|)]^{\gamma+1}\,dx. \end{aligned} \tag{18}$$

By (4) and (15), $p(r)[u_k(r)]^{\gamma+1} \leqq C_1 r^{-b}$ for $r \geqq 1$, where $C_1 > 0$ is another constant independent of k and

$$b = a + \frac{(N-2)(\gamma+1)}{2} > N$$

since $(N-2)(\gamma+1) > 2N-2a$ by (4). Therefore $pu_k^{\gamma+1} \in L^1(\mathbf{R}^N)$, and since $\{pu_k^{\gamma+1}\}$ converges pointwise to $pu^{\gamma+1} \in L^1(\mathbf{R}^N)$, the Dominated Convergence Theorem applied to (18) shows that

$$0 < d \leqq C \int_{\mathbf{R}^N} p(|x|)[u(|x|)]^{\gamma+1}\,dx,$$

proving that u is nontrivial.

LEMMA 3. *The sequence $\{\lambda_k\}$ in Lemma 1 is bounded.*

Proof. The analogue of (11) for (λ_k, u_k) is (taking $w = v = v_k$, $u_k = Pv_k$ in (11))

$$\int_{\mathbf{R}^N} \left[|\nabla v_k|^2 + \left(b + \frac{1}{k}\right) v_k^2\right] dx = \lambda_k \int_{\mathbf{R}^N} pu_k f(u_k)\,dx,$$

implying by (14) and (16) that

$$2I_1(v_1) \geqq 2I_k(v_k) = \lambda_k \int_{\mathbf{R}^N} pu_k f(u_k)\,dx, \tag{19}$$

$k = 1, 2, \cdots$. It follows as in Lemma 2 that $pu_k f(u_k) \in L^1(\mathbf{R}^N)$ and $\{pu_k f(u_k)\}$ converge pointwise to $puf(u) \in L^1(\mathbf{R}^N)$. By Fatou's Lemma,

$$\liminf_{k\to\infty} \int_{\mathbf{R}^N} pu_k f(u_k)\,dx \geqq \int_{\mathbf{R}^N} puf(u)\,dx = \delta > 0$$

since u is not identically zero by Lemma 2 and $f(u)>0$ in $0<u<T$. It is then a consequence of (19) that $2I_1(v_1)\geqq\delta\lambda_k$, and hence $\{\lambda_k\}$ is bounded.

To complete the proof of Theorem 2, let λ be the limit of a convergent subsequence of $\{\lambda_k\}$. Since a subsequence of $\{u_k\}$ converges to u in $C^2_{\text{loc}}(\mathbf{R}^N)$ we can let $k\to\infty$ in (2) to conclude that $u=u_\lambda$ is a solution of the differential equation in (1). Since $\|\nabla u_k\|_2$ is bounded by Lemma 1, $\{\|u_k\|_{2N/(N-2)}\}$ also is bounded by a standard Sobolev Embedding Theorem. In view of the convergence of $\{u_k\}$ to u_λ, Fatou's Lemma shows that $u_\lambda\in L^{2N/(N-2)}(\mathbf{R}^N)$. We can prove that $|(\nabla u)(|x|)|$, as well as $u(|x|)$, has uniform limit zero as $|x|\to\infty$ by use of interior Hölder estimates for (1).

Since $\lambda\geqq 0$, it must be that $\lambda>0$, for otherwise u_λ would be a nontrivial, nonnegative solution of $\Delta u_\lambda=0$ in $\mathbf{R}^N$ with uniform limit zero at ∞, contradicting the maximum principle. The strict positivity of u_λ throughout $\mathbf{R}^N$ then follows from the strong maximum principle.

4. Asymptotic estimates. The asymptotic estimate (17) for the solution $u(r)$ of (1) in Theorem 2 can be sharpened to

$$u(r)=O(r^{2-N+\varepsilon})\quad\text{as } r=|x|\to\infty \tag{20}$$

for arbitrary $\varepsilon>0$. To prove (20), first note from (4) that

$$\gamma-1=2(2-a+2\delta)/(N-2) \tag{21}$$

for some $\delta>0$. Consider the recursive sequence defined by

$$\sigma_0=\frac{N-2}{2},\quad \sigma_{k+1}=\frac{1}{2}[(a-2)+\sigma_k(\gamma+1)],\quad k=0,1,2,\cdots. \tag{22}$$

Then $\sigma_k\geqq\sigma_0$ by induction and hence

$$\sigma_{k+1}-\sigma_k=\tfrac{1}{2}[a-2+\sigma_k(\gamma-1)]\geqq\delta,\qquad k=0,1,2,\cdots,$$

implying that $\{\sigma_k\}$ is increasing and $\sigma_k\to\infty$ as $k\to\infty$. Let m be the smallest integer for which $\sigma_{m+1}\geqq N-2-\varepsilon$. We know from (17) that $u(r)=O(r^{-\sigma_0})$ as $r\to\infty$. If $u(r)=O(r^{-\sigma_{k-1}})$ for an integer k, $1\leqq k\leqq m$, consider the function $v_A(r)=A(1+r^2)^{-\sigma_k/2}$, $r\geqq 0$, for a constant $A>0$. A calculation gives

$$-(\Delta v_A)(r)=\frac{A\sigma_k[(N-2-\sigma_k)r^2+N]}{(1+r^2)^{(\sigma_k+4)/2}},$$

whereas the assumptions on p and f imply that $u(r)$ satisfies

$$-(\Delta u)(r)\leqq\lambda p(r)f(u(r))\leqq Cr^{-a-\gamma\sigma_{k-1}},\qquad r\geqq 1$$

for some positive constant C. Since $\sigma_k<N-2-\varepsilon$ for $k\leqq m$, and $\sigma_k+2<a+\gamma\sigma_{k-1}$ by (21) and (22), positive constants A and R can be selected such that

$$-(\Delta v_A)(r)\geqq-(\Delta u)(r)\quad\text{for } r\geqq R,$$
$$v_A(R)\geqq u(R).$$

Since $v_A(r)\to 0$ and $u(r)\to 0$ as $r\to\infty$, the maximum principle implies that $v_A(r)\geqq u(r)$ for all $r\geqq R$, and hence $u(r)=O(r^{-\sigma_k})$ as $r\to\infty$. In particular, $u(r)=O(r^{-\sigma_m})$ as $r\to\infty$.

To complete the proof of (20) we redefine $\sigma'_{m+1}=N-2-\varepsilon$, so $\sigma'_{m+1}\leqq\sigma_{m+1}$ by our choice of m. The argument above can then be repeated with σ_{k-1}, σ_k replaced by σ_m, σ'_{m+1}, respectively, in view of the inequalities

$$\sigma'_{m+1}+2\leqq\sigma_{m+1}+2<a+\gamma\sigma_m,$$

resulting in $u(r)=O(r^{-\sigma'_{m+1}})$ as $r\to\infty$.

Under any one of the three additional hypotheses I, II, or III below, ε can be replaced by zero in the asymptotic estimate (20), i.e., the solution $u(r)$ of (1) in Theorem 2 has a "removable singularity" at ∞:

(I) $\liminf_{r\to\infty} r^{\nu}b(r) = +\infty$ for some $\nu < a+(N-2)(\gamma-1)$.

(II) $\gamma > (N-a+2)/(N-2)$.

(III) $b(r) \equiv 0$, f, $p \in C^1(0,\infty)$, and there exist positive constants C_1, C_2, C_3, C_4, t_0, and r_0 such that

(A) $C_1 t^{\gamma} \leqq f(t) \leqq C_2 t^{\gamma}$ for $0 < t \leqq t_0$, where γ satisfies (4) for $0 \leqq a < 2$;

(B) $C_3 r^{-a} \leqq p(r) \leqq C_4 r^{-a}$ for $r \geqq r_0$;

(C) $(\log p)'(r) = O(r^{-1})$ as $r \to \infty$, $(\log g)'(t) = O(1)$ as $t \to 0+$, where $g(t) = t^{-\gamma} f(t)$, $t > 0$.

The *upper* estimates for $f(t)$ and $p(r)$ in (A) and (B) have already been imposed, of course, as hypotheses for Theorem 2. The proof below in case (III) is based on an a priori estimate of Gidas and Spruck [6, Thm. 3.6(iii)] for equations of type $-\Delta u = h(r)u^{\gamma}$, requiring extra conditions similar to (B) and (C) above.

COROLLARY. *If any one of the conditions* (I)-(III) *holds, the solution* $u(r)$ *of* (1) *in Theorem* 2 *satisfies* $u(r) = O(r^{2-N})$ *and* $u'(r) = O(r^{1-N})$ *as* $r \to \infty$.

Proof. (I) Since $f(t) = O(t^{\gamma})$ as $t \to 0+$, it follows from (1), (20), for a sufficiently large constant $R_0 > 0$, that

$$\begin{aligned} -\Delta u &\leqq [Cr^{-a}u^{\gamma-1} - b(r)]u \\ &\leqq [\tilde{C}r^{-\nu} - b(r)]u \leqq 0 \end{aligned} \tag{23}$$

for all $r \geqq R_0$, where C, $\tilde{C}$ are positive constants and

$$\nu = a+(N-2-\varepsilon)(\gamma-1) < a+(N-2)(\gamma-1).$$

The comparison function $v(r) = Ar^{2-N}$ satisfies $\Delta v = 0$ and $v(R_0) \geqq u(R_0)$ for a sufficiently large constant $A > 0$. Let $w = v - u$. Then

$$-\Delta w \geqq 0 \quad \text{for } r = |x| \geqq R_0, \ w(R_0) \geqq 0, \quad \text{and} \quad w(r) \to 0 \quad \text{as } r \to \infty,$$

implying that $u(r) \leqq v(r)$ for all $r \geqq R_0$ by the maximum principle.

(II) As in (23), u satisfies

$$-\Delta u \leqq Cr^{-a-\gamma(N-2-\varepsilon)} \quad \text{for } r \geqq R_0.$$

A calculation shows that $v(r) = A(1+r^2)^{(2-N)/2}$ is a solution of

$$-\Delta v = AN(N-2)(1+r^2)^{-(N+2)/2}, \qquad r \geqq 0.$$

Since $a+\gamma(N-2) > N+2$ by assumption (II), ε can be selected small enough and $R \geqq R_0$ large enough that $-\Delta(v-u) \geqq 0$ for all $r \geqq R$. The conclusion then follows as in case (I) by a sufficiently large choice of $A > 0$.

(III) For $b(r) \equiv 0$, the solution $u(r)$ in Theorem 2 satisfies $-\Delta u = \lambda h(r)u^{\gamma}$, where $h(r) = p(r)g(u(r))$. Since $u(r) \to 0$ as $r \to \infty$, conditions (A) and (B) imply that there is a constant $r_1 \geqq r_0$ such that

$$C_1 C_3 r^{-a} \leqq h(r) \leqq C_2 C_4 r^{-a} \quad \text{for all } r \geqq r_1. \tag{24}$$

In view of (1) and the decay estimate in Theorem 2, there exists a constant $C > 0$ such that

$$0 < -[r^{N-1}u'(r)]' = \lambda r^{N-1}p(r)f(u(r)) \leqq Cr^{\alpha}, \qquad r \geqq r_1, \tag{25}$$

where $\alpha = -a-\gamma(N-2)/2+N-1$. Integration over (r_1, r) implies that

$$0 < -u'(r) \leqq K_1 r^{1-N} + K_2 r^{\beta}, \qquad r > r_1 \tag{26}$$

for some constants $K_1>0$, $K_2>0$, $\beta=\alpha-N+2$. Since $\gamma(N-2)>N-2a+2$ for $0\leqq a<2$ by (4), it follows that $\beta<-N/2$, from which $u'(r)=O(r^{-N/2})$ as $r\to\infty$ by (26). Then assumption (C) yields the asymptotic estimate

$$(\log h)'(r)=(\log p)'(r)+(\log g)'(u(r))u'(r)=O(r^{-1}) \tag{27}$$

as $r\to\infty$. In view of (24) and (27), Theorem 3.6(iii) of [6] is applicable for γ in our range (4), $0\leqq a<2$, implying that either $u(r)=O(r^{2-N})$ as $r\to\infty$ or $u(r)\geqq Cr^{(a-2)/(\gamma-1)}$ for large r. However, the second alternative is impossible since $u\in L^{2N/(N-2)}(\mathbf{R}^N)$ by Theorem 2 and

$$\left(\frac{a-2}{\gamma-1}\right)\left(\frac{2N}{N-2}\right)>-N \quad \text{by (4).}$$

If we use the estimate $u(r)=O(r^{2-N})$ instead of the estimate stated in Theorem 2, then α in (25) is replaced by

$$\alpha=-a-\gamma(N-2)+N-1<a-3<-1,$$

implying the boundedness of $r^{N-1}u'(r)$ for $r\geqq r_1$.

HYPERBOLIC-PARABOLIC SINGULAR PERTURBATIONS FOR QUASILINEAR EQUATIONS*

BENJAMIN F. ESHAM, JR.† AND RICHARD J. WEINACHT‡

Abstract. A hyperbolic-parabolic singular perturbation problem is considered for a quasilinear wave equation that arises in one-dimensional nonlinear elasticity. An initial boundary value problem is treated, in which there is an initial layer at $t=0$. It is proved that the solution of the reduced problem approximates the solution of the full problem uniformly on sets bounded in the time direction. An initial-layer corrector and an additional outer expansion term are provided, which yield a uniform $\mathcal{O}(\varepsilon^2)$ approximation.

Key words. singular perturbations, hyperbolic, parabolic, quasilinear, nonlinear wave equations, nonlinear elasticity, nonlinear heat equations

AMS(MOS) subject classifications. 35B25, 35B45, 35B65, 35C20, 35K20, 35L05, 35L20, 73C50, 73D35, 73K03

1. Introduction.

In this paper we consider the singular perturbation problem

$$\varepsilon^2 u_{tt} + u_t - [\sigma(u_x)]_x = f(x,t), \qquad x\in(0,1), \quad t>0, \tag{1.1}$$

$$u(x,0;\varepsilon)=\phi(x),\ \varepsilon u_t(x,0;\varepsilon)=\psi(x), \qquad x\in[0,1], \tag{1.2}$$

$$u(0,t;\varepsilon)=u(1,t;\varepsilon)=0, \qquad t\geqq 0, \tag{1.3}$$

that arises in one-dimensional nonlinear elasticity. For small positive ε, the function u can be interpreted as the nondimensional displacement of the planar oscillations of a (nonlinear) hyperelastic string that is oscillating in a highly viscous medium. The scaling leading to (1.1)-(1.3) in the linear case ($\sigma(z)=z$) is given in [8].

For nonzero ε, (1.1) was considered in an often-referenced but unpublished 1975 work of Nishida (see Nishida [11] where the Cauchy problem is treated). Equation (1.1), as well as corresponding linear and semilinear versions [5], [9], has also been considered as a model for heat conduction to avoid the paradox of infinite speeds of propagation for the parabolic problem (see the bibliographies of [11] and [12]).

For $\varepsilon=0$ we have, in place of (1.1)-(1.3), the well-posed parabolic initial boundary value problem

$$U_t - [\sigma(U_x)]_x = f(x,t), \qquad x\in(0,1), \quad t>0, \tag{1.4}$$

$$U(x,0)=\phi(x), \qquad x\in[0,1], \tag{1.5}$$

$$U(0,t)=U(1,t)=0, \qquad t\geqq 0, \tag{1.6}$$

where the initial condition on u_t in (1.2) has been omitted. Thus there is a nonuniformity near $t=0$, where an initial layer is present.

Our main result (Theorem 5) is the following: on the closure of any rectangular region $Q\doteq(0,1)\times(0,t_0)$ in xt-space on which (1.1)-(1.3) has the solution u, with properties given by Theorem 2, and on which (1.4)-(1.6) has solution U, with properties given by Theorem 3, we have

$$u(x,t;\varepsilon)=U(x,t)+\varepsilon U_1(x,t)+\varepsilon V(x,t/\varepsilon^2)+\mathcal{O}(\varepsilon^2) \quad \text{as } \varepsilon\to 0^+ \tag{1.7}$$

uniformly on $\bar{Q}$. In (1.7) the function U_1 is a first-order corrector to the outer solution U and the function V is an initial-layer corrector, which we describe in greater detail later in this introduction.

In a previous paper [6], we considered, in place of (1.1), the nonlinear wave equation

$$\varepsilon^2 u_{tt} + u_t - g\left\{\int_0^1 u_x^2(x,t)\,dx\right\} u_{xx} = f(x,t) \tag{1.8}$$

with a nonlocal *scalar nonlinearity*. We refer to [6] for further information about singular perturbations for hyperbolic equations and related works, mentioning here only the recent work of Benaouda and Madaune-Tort [1] on semilinear hyperbolic-parabolic singular perturbations. The required estimates for (1.8) are somewhat less complicated than the present case, and it was the insight gained there that enabled us to handle (1.1).

A key point in our analysis here and in [6] consists of higher-order ε-weighted energy estimates. Energy estimates for hyperbolic singular perturbation problems seem to have been introduced by deJager [3] (see also deJager and Geel [4] and Geel [7]). Higher-order energy estimates were also used by Nishida [11] and have been used effectively in recent years for problems in continuum mechanics (see, for example, Dafermos and Nohel [2] and Slemrod [13]) in more complicated situations than that considered here, but not concerning singular perturbations.

Several points should be emphasized. Quite a bit of smoothness is required for our result. This is due in part to our method, but it should also be observed that the uniform nature of the result (1.7), with correctors present, requires smoothness beyond that needed for the existence of weak solutions of (1.1)-(1.3).

With the extra smoothness, we prove the local existence-uniqueness of $u = u_\varepsilon$ in (1.1)-(1.3) for any ε in some interval $(0, \varepsilon_0]$ and U in (1.4)-(1.6). Nishida [11] obtains global smooth solutions for the Cauchy problem for (1.1), provided a small data assumption is satisfied. Our asymptotic result is of an ideal type in that it is valid uniformly on any rectangular domain for which the above-mentioned u and U are valid.

Our methods do not use any tools that are specifically tied to one space dimension. It is therefore expected that our results can be carried over to more space variables, but with an attendant increase in regularity assumptions.

Both $u = u_\varepsilon$ and U are treated by the Schauder technique. A related linear problem for u is considered in § 2 and the nonlinear hyperbolic problem in § 3. Section 4 contains the corresponding result for U as well as the (linear) problem for the corrector U_1. There also the elementary problems for the initial-layer correctors are solved explicitly. The main result appears in § 5.

Let us now close this introduction by describing the problems that characterize the higher-order correction terms. The natural Ansatz [8], [9]

$$u(x,t;\varepsilon) = U(x,t) + \sum_{n=1}^{N} [U_n(x,t) + V_{n-1}(x, t/\varepsilon^2)]\varepsilon^n, \tag{1.9}$$

where $\tau \doteq t/\varepsilon^2$ is the stretched time variable, leads in the usual way to the following problems. For the outer solution U_1 we have the linear parabolic problem (P_1):

$$U_{1_t} - [\sigma'(U_x) U_{1_x}]_x = 0, \qquad (x,t) \in Q, \tag{1.10}$$

$$U_1(x,0) = \psi(x), \qquad x \in [0,1], \tag{1.11}$$

$$U_1(0,t) = U_1(1,t) = 0, \qquad t \in [0, t_0]. \tag{1.12}$$

For the initial-layer correctors V_n, we have simple linear ODE problems. For the initial-layer corrector $V \equiv V_0$ of lowest order, we have the problem $(\tilde{P}_0)$:

$$\ddot{V} + \dot{V} = 0, \qquad \tau > 0, \quad x \in (0, 1), \tag{1.13}$$

$$\dot{V}(x, 0) = \psi(x), \qquad x \in [0, 1], \tag{1.14}$$

$$V(0, \tau) = V(1, \tau) = 0, \qquad \tau > 0, \tag{1.15}$$

together with the matching condition

$$\lim_{\tau \to \infty} V(x, \tau) = 0, \qquad x \in [0, 1]. \tag{1.16}$$

Here and below, $\partial/\partial\tau$ is denoted by "$\cdot$".

The higher-order initial-layer correctors are determined by very similar problems. In particular, for V_1 we have the problem $(\tilde{P}_1)$:

$$\ddot{V}_1 + \dot{V}_1 = 0, \qquad \tau > 0, \quad x \in (0, 1), \tag{1.17}$$

$$\dot{V}_1(x, 0) = -U_t(x, 0), \qquad x \in [0, 1], \tag{1.18}$$

$$V_1(0, \tau) = V_1(1, \tau) = 0, \qquad \tau > 0, \tag{1.19}$$

with the same matching condition as for V,

$$\lim_{\tau \to \infty} V_1(x, \tau) = 0, \qquad x \in [0, 1]. \tag{1.20}$$

The problems for the outer solutions U_n, $n \geqq 2$, are found to be *nonhomogeneous* linear parabolic problems, but are similar to that for U_1. The same is true for the ODEs for the initial-layer correctors V_n, $n \geqq 2$. The proof of uniform asymptotic validity for the Nth order expansion (1.9) follows from a priori estimates like (5.1). The method should be clear from our treatment here of the case $N = 1$.

2. A related linear problem. As a tool in treating (1.1)-(1.3), we consider the related linear hyperbolic problem $(\mathscr{P}_\varepsilon)$:

$$L_\varepsilon[u] \doteq \varepsilon^2 u_{tt} + u_t - a(x, t; \varepsilon) u_{xx} = f(x, t), \qquad x \in (0, 1), \quad 0 < t < t_0, \tag{2.1}$$

$$u(x, 0; \varepsilon) = \phi(x), \quad \varepsilon u_t(x, 0; \varepsilon) = \psi(x), \qquad x \in [0, 1], \tag{2.2}$$

$$u(0, t; \varepsilon) = u(1, t; \varepsilon) = 0, \qquad t \in [0, t_0], \tag{2.3}$$

under hypotheses on the data $\{\phi, \psi, f\}$ and $a(x, t; \varepsilon)$ appropriate for the subsequent use of the Schauder technique in dealing with the nonlinear problem (1.1)-(1.3) on $Q \doteq (0, 1) \times (0, t_0)$, which we refer to as (P_ε).

Specifically, we make the following hypotheses for arbitrary ε_0 in $(0, 1]$ and $t_0 > 0$. Assume

$$a \in H^3(Q), \tag{a.1}$$

and, for positive constants a_0 and a_1, independent of $(x, t; \varepsilon) \in \bar{Q} \times (0, \varepsilon_0]$

$$0 < a_0 \leqq a(x, t; \varepsilon), \tag{a.2}$$

$$\int_0^{t_0} \|a_t(\cdot, t; \varepsilon)\|_{L^\infty(0,1)}\, dt \leqq a_1, \tag{a.3}$$

$$L^\infty(0, 1) \text{ norms of } \{a(\cdot, 0; \varepsilon), a_x(\cdot, 0; \varepsilon), \varepsilon a_t(\cdot, 0; \varepsilon)\} \leqq a_1, \tag{a.4}$$

$$L^2(0, 1) \text{ norms of } \{a_{xx}(\cdot, 0; \varepsilon), \varepsilon a_{tx}(\cdot, 0; \varepsilon), \varepsilon^3 a_{tt}(\cdot, 0; \varepsilon)\} \leqq a_1, \tag{a.5}$$

$$L^2(Q) \text{ norms of } \{a_x, a_{xx}, a_{xxx}, \varepsilon a_{tx}, \varepsilon a_{txx}, \varepsilon^3 a_{tt}, \varepsilon^3 a_{ttx}, \varepsilon^5 a_{ttt}\} \leqq a_1. \tag{a.6}$$

Moreover, we impose the compatibility condition

$$a_x(0, t; \varepsilon) = a_x(1, t; \varepsilon) = 0, \qquad t \in [0, t_0], \quad \varepsilon \in (0, \varepsilon_0]. \tag{a.7}$$

For the data, we require that

$$\phi \in H^4(0, 1), \qquad \phi = \phi'' = 0 \quad \text{at } x = 0, 1, \tag{ϕ.1}$$

$$\psi \in H^3(0, 1), \qquad \psi = \psi'' = 0 \quad \text{at } x = 0, 1, \tag{ψ.1}$$

$$f \in H^3(Q), \qquad f = f_{xx} = 0 \quad \text{at } x = 0, 1. \tag{f.1}$$

In what follows, we will often abbreviate $L^\infty(0, t_0; L^2(0, 1))$ as $L^\infty(L^2)$.

THEOREM 1. *If a, ϕ, ψ, and f satisfy the above hypotheses, the problem $(\mathcal{P}_\varepsilon)$ has a unique classical solution $u \in C^2(\bar{Q})$ with $D^\alpha u \in L^\infty(L^2)$, $|\alpha| \leqq 4$, such that each of the following norms is bounded by a constant independent of ε in $(0, \varepsilon_0]$:*

(r.1) *$L^\infty(Q)$ norms of* $\{u, u_x, u_{xx}, u_{xxx}, \varepsilon u_t, \varepsilon u_{tx}, \varepsilon u_{txx}, \varepsilon^3 u_{tt}, \varepsilon^3 u_{ttx}, \varepsilon^5 u_{ttt}\}$,

(r.2) *$L^\infty(L^2)$ norms of* $\{u_{xxxx}, \varepsilon u_{txxx}, \varepsilon^3 u_{ttxx}, \varepsilon^5 u_{tttx}, \varepsilon^7 u_{tttt}\}$,

(r.3) *$L^2(Q)$ norms of* $\{u_t, u_{tx}, u_{txx}, u_{txxx}, \varepsilon^2 u_{tt}, \varepsilon^2 u_{ttx}, \varepsilon^2 u_{ttxx}, \varepsilon^4 u_{ttt}, \varepsilon^4 u_{tttx}, \varepsilon^6 u_{tttt}\}$.

Proof. Imposing on the m-term Faedo-Galerkin approximation

$$u_m \equiv u_m(x, t; \varepsilon) \doteq \sum_{k=1}^{m} A_{km}(t; \varepsilon) \sin k\pi x, \tag{2.4}$$

the orthogonality conditions with $L^2(0, 1)$ inner product $\langle \cdot, \cdot \rangle$

$$\langle L_\varepsilon u_m - f_m, \sin l\pi x \rangle = 0, \qquad l = 1, 2, \cdots, m, \tag{2.5}$$

as well as projected initial conditions, we are led to the following initial-value problem for the coefficients $\{A_{lm}\}_{l=1}^m$

$$\varepsilon^2 A_{lm}'' + A_{lm}' + 2 \sum_{k=1}^{m} k^2 \pi^2 a_{lk}(t; \varepsilon) A_{km} = f_l(t), \tag{2.6}$$

$$A_{lm}(0; \varepsilon) = 2\langle \phi, \sin l\pi x \rangle, \qquad \varepsilon A_{lm}'(0; \varepsilon) = 2\langle \psi, \sin l\pi x \rangle, \tag{2.7}$$

for $l = 1, 2, \cdots, m$. The functions $a_{lk}(t; \varepsilon)$, $f_m(x, t)$ and $f_l(t)$ are defined by

$$a_{lk}(t; \varepsilon) = \langle a(x, t; \varepsilon) \sin k\pi x, \sin l\pi x \rangle$$

and

$$f_m(x, t) = \sum_{l=1}^{m} f_l(t) \sin l\pi x = 2 \sum_{l=1}^{m} \langle f(x, t), \sin l\pi x \rangle \sin l\pi x. \tag{2.8}$$

From elementary regularity results for systems of linear ODEs, it follows that the unique solution $\{A_{lm}\}_{l=1}^m$ of (2.6)-(2.7) belongs to $H^5(0, t_0)$, so that u_m, $m = 1, 2, \cdots$, belongs to $C^4(\bar{Q}) \cap H^5(Q)$ and, in fact, is analytic as a function of x for fixed t.

To show the convergence of the u_m to the solution u of $(\mathcal{P}_\varepsilon)$, we use energy estimates of higher order with appropriate ε-weights. Let

$$E(t) \doteq \frac{1}{2} \int_0^1 \left\{ \sum_{0 \leqq |\alpha| \leqq 3} \varepsilon^{4\alpha_2 + 2} |D^\alpha u_{m_t}|^2 + a(x, t; \varepsilon) \sum_{\alpha_1 = 0}^{3} |D_x^{\alpha_1} u_{m_x}|^2 \right\} dx \tag{2.9}$$

where the usual multi-index $\alpha=(\alpha_1,\alpha_2)$ is used: $D^\alpha=D_x^{\alpha_1}D_t^{\alpha_2}$. The term in $E(t)$ corresponding to $\alpha=(0,0)$ is the usual energy at time t of the vibrating string governed by (2.1).

Our basic energy estimate is

$$\begin{aligned}E(t)+\frac{1}{4}\int_0^t\int_0^1\sum_{0\leqq|\alpha|\leqq3}\varepsilon^{4\alpha_2}|D^\alpha u_{m_t}|^2\,dx\,ds\\ \leqq\left(F(0)+\frac{1}{2}\|f_m\|^2_{H^3(Q)}\right)\exp\left\{\int_0^t K(s)\,ds\right\}\end{aligned}\tag{2.10}$$

where

$$F(t)=\frac{1}{2}\sum_{0\leqq|\alpha|\leqq3}\varepsilon^{4\alpha_2}\int_0^1\{\varepsilon^2|D^\alpha u_{m_t}|^2+a(x,t;\varepsilon)|D^\alpha u_{m_x}|^2\}\,dx,\tag{2.11}$$

$$K(s)=K_0\left(1+\sup_{0\leqq x\leqq1}|a_t(x,s)|+\int_0^1\left\{\sum_{1\leqq|\alpha|\leqq2}\varepsilon^{4\alpha_2+2}|D^\alpha a_t|^2+\sum_{\alpha_1=0}^{2}|D_x^{\alpha_1}a_x|^2\right\}dx\right).\tag{2.12}$$

The constant K_0 is independent of m and ε.

The estimate (2.10) is established in the appendix, where it is also shown how appropriate estimates of f_m in the $H^3(Q)$ norm and of $F(0;\varepsilon)$ lead to the inequality

$$\begin{aligned}\sup_{0\leqq t\leqq t_0}\int_0^1\left(\sum_{0\leqq|\alpha|\leqq3}\varepsilon^{4\alpha_2+2}|D^\alpha u_{m_t}|^2+\sum_{\alpha_1=0}^{3}|D^\alpha u_{m_x}|^2\right)dx\\ +\sum_{0\leqq|\alpha|\leqq3}\varepsilon^{4\alpha_2}\int_0^{t_0}\int_0^1|D^\alpha u_{m_t}|^2\,dx\,ds\leqq C\end{aligned}\tag{2.13}$$

with constant C independent of m and ε.

From this energy inequality, we see that each of the sequences $\{D^\alpha u_m\}_{m=1}^\infty$, for $0\leqq|\alpha|\leqq4$, is bounded in $L^\infty(L^2)$ and so contains a weak* convergent subsequence. If u denotes the weak* limit of the subsequence for $\alpha=(0,0)$, then for $0<|\alpha|\leqq4$, there is a subsequence $\{D^\alpha u_{m_j}\}_{j=1}^\infty$ that has limit $D^\alpha u$, the αth weak $L^2(Q)$ derivative of u. Hence $D^\alpha u\in L^\infty(L^2)$, $0\leqq|\alpha|\leqq4$, and $u\in H^4(Q)$, so that $u\in C^2(\bar{Q})$ by the Sobolev embedding theorem.

To see that the limit u satisfies (2.1), we merely let m_j tend to infinity in

$$\int_0^{t_0}\int_0^1(Lu_{m_j}-f_{m_j})\mu(t)\sin l\pi x\,dx\,dt=0$$

for arbitrary $\mu\in L^2(0,t_0)$. It follows by a standard density argument that (2.1) is satisfied almost everywhere in Q and hence everywhere in $\bar{Q}$, since all the functions involved are continuous in $\bar{Q}$.

To see that the weak* limit u satisfies the initial condition $u(x,0)=\phi(x)$, we proceed in a similar and familiar way. We note that for $\alpha\in L^2(0,1)$ and $\beta\in C^1[0,t_0]$, such that $\beta(0)=1$ and $\beta(t_0)=0$,

$$\int_0^{t_0}\int_0^1 u_{m_j}(x,t)\alpha(x)\beta'(t)\,dx\,dt\to\int_0^{t_0}\int_0^1 u(x,t)\alpha(x)\beta'(t)\,dx\,dt,$$

and

$$\int_0^{t_0}\int_0^1 u_{m_j,t}(x,t)\alpha(x)\beta(t)\,dx\,dt\to\int_0^{t_0}\int_0^1 u_t(x,t)\alpha(x)\beta(t)\,dx\,dt,$$

from which

$$\int_0^1 u_{m_j}(x,0)\alpha(x)\,dx \to \int_0^1 u(x,0)\alpha(x)\,dx,$$

and the condition follows since $u_m(x,0)=\phi_m(x)\to\phi(x)$ in $L^2(0,1)$. A similar argument shows that $\varepsilon u_t(x,0)=\psi(x)$ and that $u=u_{xx}=0$ when $x=0,1$.

It is conceivable that there are distinct subsequences of $\{u_m\}$ that converge to different limits, and thus generate different solutions of $(\mathscr{P}_\varepsilon)$. However, global uniqueness for solutions of $(\mathscr{P}_\varepsilon)$ follows from an easy energy integral argument. In particular, if u and $\bar{u}$ are classical solutions of $(\mathscr{P}_\varepsilon)$, the function $z \doteq u-\bar{u}$ satisfies the corresponding completely homogeneous IBVP. With

$$\mathbb{E}(t)\doteq\frac{1}{2}\int_0^1 [\varepsilon^2 z_t^2 + a(x,t;\varepsilon)z_x^2]\,dx,$$

we quickly derive the identity and bound

$$\begin{aligned}\mathbb{E}(t)+\int_0^t\int_0^1 z_t^2\,dx\,ds &= \int_0^t\int_0^1\left[\frac{1}{2}a_t z_x^2 - a_x z_x z_t\right]dx\,ds\\ &\leqq \frac{1}{2}\int_0^t\int_0^1 z_t^2\,dx\,ds + K_1\int_0^1 \mathbb{E}(s)\,ds,\end{aligned}$$

where

$$K_1 \doteq a_0^{-1}\left\{\sup_{\bar{Q}}|a_t| + \sup_{\bar{Q}}|a_x|^2\right\}.$$

Gronwall's lemma immediately implies

$$\mathbb{E}(t)\equiv 0 \Rightarrow z\equiv 0 \Rightarrow u\equiv\bar{u}.$$

It follows that each subsequence of $\{u_m\}$ must converge to the unique solution u of $(\mathscr{P}_\varepsilon)$.

The assertions (r.2) and (r.3) of Theorem 1 on the order ε behavior of the various derivatives of u follow directly from the inequality (2.13) when we use the lower semicontinuity property of weak* limits. With these established, (r.1) follows by means of the Sobolev embedding theorem. This completes the proof of Theorem 1. □

3. The quasilinear hyperbolic equation. With Theorem 1 of § 2 established, the way has been prepared to approach the questions of existence and uniqueness for the quasilinear problem (P_ε) by means of the Schauder technique and the Banach contraction mapping theorem. Indeed, the fixed point will also be seen to inherit the regularity and order ε behavior built into the linear problem $(\mathscr{P}_\varepsilon)$. We proceed then with the following theorem.

THEOREM 2. *Let f, ϕ and ψ satisfy hypotheses* (f.1), (ϕ.1), *and* (ψ.1), *respectively. Let $\sigma\in C^4(\mathbb{R})$ with $0<\sigma_0\leqq\sigma'(z)$ for all $z\in\mathbb{R}$. Then the quasilinear hyperbolic problem (P_ε) consisting of* (1.1)-(1.3) *on Q has a unique classical solution $u\in C^2(\bar{Q})$ with $D^\alpha u\in L^\infty(L^2)$, $|\alpha|\leqq 4$, such that conclusions* (r.1), (r.2), *and* (r.3) *of Theorem* 1 *hold. The interval $[0,t_0]$ may be small, but it is independent of ε in $(0,\varepsilon_0]$.*

Proof. Let $\mathscr{Y}=\mathscr{Y}(\varepsilon,t_0)$ be the complete metric space

$$\mathscr{Y}=\{v\in L^\infty(0,t_0;H_0^1(0,1))\,|\,v_t\in L^\infty(0,t_0;L^2(0,1))\}$$

with ε-dependent metric $d=d_\varepsilon$ defined by

$$d^2(v,\bar{v})\doteq\sup_{0\leqq t\leqq t_0}\int_0^1[(v_x-\bar{v}_x)^2+\varepsilon^2(v_t-\bar{v}_t)^2]\,dx.$$

For suitable functions $v = v(x, t; \varepsilon)$, with $\varepsilon \in (0, \varepsilon_0]$, let

$$\delta(v) \doteq \max_{0 \leqq |\alpha| \leqq 3} \left\{ \sup_{0 \leqq t \leqq t_0} \int_0^1 \varepsilon^{4\alpha_2+2} |D^\alpha v_t|^2 \, dx, \right.$$

$$\left. \sup_{0 \leqq t \leqq t_0} \int_0^1 |D_x^{\alpha_1} v_x|^2 \, dx, \varepsilon^{4\alpha_2} \int_0^{t_0} \int_0^1 |D^\alpha v_t|^2 \, dx \, ds \right\}.$$

Let $\mathscr{X} \equiv \mathscr{X}(M, t_0, \varepsilon)$ be the subset of $\mathscr{Y}$ consisting of functions $v = v(x, t; \varepsilon)$ such that for given positive M

$$\{v \in H^4(Q): D^\alpha v \in L^\infty(0, t_0; L^2(0, 1)), |\alpha| < 4, \text{ and } \delta(v) \leqq M^2\}$$

and

$$v(0, t; \varepsilon) = v(1, t; \varepsilon) = v_{xx}(0, t; \varepsilon) = v_{xx}(1, t; \varepsilon) = 0,$$

$$v(x, 0; \varepsilon) = \phi(x), \qquad \varepsilon v_t(x, 0; \varepsilon) = \psi(x),$$

$$\varepsilon^2 v_{tt}(x, 0; \varepsilon) = f(x, 0) + \sigma'(\phi'(x))\phi''(x) - \psi(x)/\varepsilon.$$

The set $\mathscr{X}$ is a closed subset of $\mathscr{Y}$. Indeed, let $\{v_n\}$ be a sequence in $\mathscr{X}$ that converges to $\tilde{v} \in \mathscr{Y}$ in the metric on $\mathscr{Y}$. Since $L^\infty(L^2)$ is the dual space of $L^1(L^2)$, any bounded set in $L^\infty(L^2)$ is sequentially compact in the weak* topology of $L^\infty(L^2)$. Since $\delta(v_n) \leqq M^2$, $n = 1, 2, \cdots$, each of the sequences $\{D^\alpha v_n\}$, $|\alpha| \leqq 4$ is bounded in $L^\infty(L^2)$ and so has a subsequence that converges to an element of $L^\infty(L^2)$, $D^\alpha v_{n_j} \to w^\alpha$, weak*. If v is the limit function corresponding to $\alpha = (0, 0)$, it follows easily from definitions that $w^\alpha = D^\alpha v$, the αth weak L^2 derivative of v. Also, by the lower semicontinuity property of weak* sequential convergence,

$$\|\varepsilon^{2\alpha_2+1} D^\alpha v_t\|_{L^\infty(L^2)} \leqq \varliminf_{n \to \infty} \|\varepsilon^{2\alpha_2+1} D^\alpha v_{n_t}\|_{L^\infty(L^2)} \leqq M,$$

$$\|D_x^{\alpha_1} v_x\|_{L^\infty(L^2)} \leqq \varliminf_{n \to \infty} \|D_x^{\alpha_1} v_{n_x}\|_{L^\infty(L^2)} \leqq M,$$

for $|\alpha| \leqq 3$, and by a similar argument involving weak convergence in $L^2(Q)$,

$$\|\varepsilon^{2\alpha_2} D^\alpha v_t\|_{L^2(Q)} \leqq M, \qquad |\alpha| \leqq 3.$$

Hence we conclude that $\delta(v) \leqq M^2$. The conditions on ∂Q are seen to hold for v by arguments similar to those in Theorem 1. Since $v_n \to \tilde{v}$ with respect to the metric d, we clearly have $v_n \to \tilde{v} \in \mathscr{Y}$ weakly in $L^2(Q)$. On the other hand, a subsequence (v_{n_j}) has been shown to converge to $v \in \mathscr{X}$ weakly in $L^2(Q)$. By uniqueness of weak limits, each subsequence must converge to $v = \tilde{v}$. Hence $\tilde{v} \in \mathscr{X}$ and $\mathscr{X}$ is closed.

For a given v in $\mathscr{X}$, consider the linear IBVP (2.1)–(2.3), with

$$a(x, t; \varepsilon) \doteq \sigma'(v_x(x, t; \varepsilon)).$$

It is a straightforward matter to verify that this function satisfies hypotheses (a.1)–(a.7) of Theorem 1. Hence, for each v in $\mathscr{X}$, we obtain a unique solution u of $(\mathscr{P}_\varepsilon)$ that enjoys all the properties guaranteed by Theorem 1. Denote this solution map by $\mathbb{S}$: $u = \mathbb{S}v$.

Seeking fixed points of $\mathbb{S}$, we first show that $\mathbb{S}$ maps $\mathscr{X}$ into itself for appropriately chosen M and t_0. For v in $\mathscr{X}$ the energy inequality (2.10) implies, by the lower semicontinuity property of weak* limits,

$$\delta(u) \leqq \left(k_0[\|\phi\|_{H^4(0,1)}^2 + \|\psi\|_{H^3(0,1)}^2 + \|f(x, 0)\|_*^2] + \frac{1}{2}\|f\|_{H^3(Q)}^2 \right) \exp\left\{ \int_0^{t_0} K(s) \, ds \right\},$$

where $K(s)$ is given by (2.12) and

$$\|f(x,0)\|_*^2 \doteq \sum_{|\alpha|\leqq 2} \int_0^1 |D^\alpha f(x,0)|^2\,dx.$$

We now choose $M>1$ so large that the data at $t=0$ is bounded above as

$$k_0[\|\phi\|^2_{H^4(0,1)}+\|\psi\|^2_{H^3(0,1)}+\|f(x,0)\|_*^2]\leqq \tfrac{1}{2}M,$$

and then choose t_0 sufficiently small so that $\|f\|^2_{H^3(Q)}<\frac{1}{2}M$. In considering the exponential factor, it is important to note that

$$\begin{aligned}\int_0^{t_0} \sup_{0\leqq x\leqq 1} |a_t|\,dt &= \int_0^{t_0} \sup_{0\leqq x\leqq 1} |(t_0^{-1/4}\sigma''(v_x))(t_0^{1/4}v_{tx})|\,dt\\ &\leqq \frac{1}{2}\sup_{\bar Q}|\sigma''(v_x)|^2\sqrt{t_0}+\frac{1}{2}\sqrt{t_0}\int_0^{t_0}\int_0^1 (v_{tx}^2+v_{txx}^2)\,dx\,dt\\ &\leqq k(M)\sqrt{t_0},\end{aligned}$$

where k depends on M, but not on ε. It follows from the assumed order ε behavior of the derivatives of v in $\mathscr{X}$ that

$$\int_0^1 \left\{\sum_{1\leqq|\alpha|\leqq 2}\varepsilon^{4\alpha_2+2}|D^\alpha a_t|^2+\sum_{\alpha_1=0}^{2}|D_x^{\alpha_1}a_x|^2\right\}dx\leqq k(M)$$

holds for a constant depending on M but independent of ε. Hence

$$\exp\left\{\int_0^{t_0}K(s)\,ds\right\}\leqq \exp\{k(M)\sqrt{t_0}\}\leqq M,$$

provided t_0 is chosen sufficiently small. This implies that $\delta(u)\leqq M^2$. The remaining subsidiary conditions in $\mathscr{X}$ follow from the fact that u is a classical solution of $(\mathscr{P}_\varepsilon)$ on $\bar Q$. Hence $u\in\mathscr{X}$ and $\mathbb{S}:\mathscr{X}\to\mathscr{X}$.

To show that $\mathbb{S}$ is a contraction on $\mathscr{X}$ with respect to the metric d, let $v,\bar v\in\mathscr{X}$ and $u\doteq\mathbb{S}v$, $\bar u\doteq\mathbb{S}\bar v$. Then $w\doteq u-\bar u$ is a classical solution of the linear initial boundary value problem consisting of the PDE

$$\varepsilon^2 w_{tt}+w_t-\sigma'(v_x)w_{xx}=[\sigma'(v_x)-\sigma'(\bar v_x)]\bar u_{xx}, \tag{3.1}$$

and the conditions (2.2)-(2.3) with $\phi(x)\equiv\psi(x)\equiv 0$. The energy of w defined by

$$\tilde E(t)\doteq\frac{1}{2}\int_0^1[\varepsilon^2 w_t^2+\sigma'(v_x)w_x^2]\,dx \tag{3.2}$$

satisfies

$$\begin{aligned}&\tilde E(t)+\int_0^t\int_0^1 w_t^2\,dx\,ds\\ &\leqq\int_0^t\int_0^1\left\{w_t[(\sigma'(v_x)-\sigma'(\bar v_x))\bar u_{xx}-\sigma''(v_x)v_{xx}w_x]+\frac{1}{2}\sigma''(v_x)v_{tx}w_x^2\right\}dx\,ds,\end{aligned} \tag{3.3}$$

and so by estimates of the right-hand side similar to those in the Appendix, we obtain via Gronwall's lemma

$$\tilde E(t)\leqq C_1 t_0 d^2(v,\bar v)\exp\left\{\int_0^{t_0}\tilde K(s)\,ds\right\},$$

with

$$C_1 \doteq \sup_{\substack{\bar{Q} \\ 0<\theta<1}} |\sigma''(\theta v_x + (1-\theta)\bar{v}_x)\tilde{u}_{xx}|^2,$$

independent of ε, and kernel given by

$$\tilde{K}(s) \doteq \max\{1, \sigma_0^{-1}\}\left(\frac{1}{2}\sup_{\bar{Q}} |\sigma''(v_x)v_{xx}| + \sup_{\bar{Q}} |\sigma''(v_x)|\left\{1 + \int_0^1 (v_{tx}^2 + v_{txx}^2)\, dx\right\}\right).$$

The assumptions on v and our results on u guarantee that the $L^1(0, t_0)$ norm of $\tilde{K}(t)$ is bounded independently of ε in $(0, \varepsilon_0]$. Now

$$d^2(u, \bar{u}) \leqq \max\{1, \sigma_0^{-1}\} \sup_{0 \leqq t \leqq t_0} \tilde{E}(t) \leqq Ct_0 d^2(v, \bar{v}),$$

so by choice of t_0 sufficiently small, the map $\mathbb{S}$ is a contraction as asserted. The Banach contraction mapping theorem implies that $\mathbb{S}$ has a unique fixed point in $\mathscr{X}$, which is seen to be a classical solution of (P_ε). Moreover, there is at most one classical solution $u \in C^2(\bar{Q})$ for this t_0 as shown by the following energy integral argument. Let u and $\tilde{u}$ be classical $C^2(\bar{Q})$ solutions of (P_ε); then (3.1)-(3.3) hold with $v = u$ and $\bar{v} = \tilde{u}$. With

$$\sup_{\bar{Q}} \{|\sigma''(u_x)u_{xx}|, |\sigma''(u_x)u_{tx}|, |\sigma''(\theta u_x + (1-\theta)\tilde{u}_x)\tilde{u}_{xx}|\} \leqq k,$$

we quickly obtain the estimate

$$\tilde{E}(t) \leqq \frac{2k^2 + k}{\sigma_0} \int_0^t \tilde{E}(s)\, ds,$$

and, by Gronwall's lemma, $\tilde{E}(t) \leqq 0$, so that $u = \tilde{u}$ follows immediately. □

4. The reduced problem and higher-order correctors. In this section we consider the reduced problem (P_0) and the problems (P_1), $(\tilde{P}_0)$ and $(\tilde{P}_1)$ introduced in § 1. The initial-layer corrector problems $(\tilde{P}_0)$ and $(\tilde{P}_1)$ readily yield explicit solutions given by

$$V(x, \tau) = -\psi(x)\, e^{-\tau}, \tag{4.1}$$

and

$$V_1(x, \tau) = \{\sigma'(\phi'(x))\phi''(x) + f(x, 0)\}\, e^{-\tau}. \tag{4.2}$$

In § 5 our proof of uniform validity for the expansion will require that V_{xx} and $V_{1_{xx}}$ belong to $L^\infty(Q)$. From (4.1) and (4.2) this will certainly be the case if

$$\sigma \in C^3, \quad \phi^{iv} \in L^\infty(0, 1), \quad \psi'' \in L^\infty(0, 1), \quad f_{xx}(x, 0) \in L^\infty(0, 1).$$

As indicated in (1.4)-(1.6), the reduced problem (P_0) corresponding to $\varepsilon = 0$ consists of the quasilinear parabolic PDE

$$U_t - \sigma'(U_x)U_{xx} = f(x, t), \qquad (x, t) \in Q, \tag{4.3}$$

together with the single initial condition

$$U(x, 0) = \phi(x), \qquad x \in [0, 1], \tag{4.4}$$

and the homogeneous boundary conditions

$$U(0, t) = U(1, t) = 0, \qquad t \in [0, t_0]. \tag{4.5}$$

This initial boundary value problem, of course, has been studied in depth both with regard to weak and classical solutions. Nonetheless the kind of results that we seek

for the regularity of the solution do not seem to be explicitly available. Consequently, we are forced to examine this problem with hypotheses compatible with the related hyperbolic problem (P_ε), and, more importantly, sufficient to guarantee existence of a classical solution of (P_1). We state our result concerning the reduced problem as the following theorem.

THEOREM 3. *Let* $\sigma \in C^7(\mathbb{R})$ *satisfy* $0 < \sigma_0 \leqq \sigma'(z)$ *for all* $z \in \mathbb{R}$.

Assume

$$(\phi.2) \qquad \phi \in H^7(0,1), \quad \phi = \phi'' = \phi^{iv} = \phi^{vi} = 0 \quad \text{at } x = 0, 1,$$

$$(f.2) \qquad f \in H^3(Q), \quad D_x^{2\alpha_1 - 1} f \in H^{4-\alpha_1}(Q), \quad \alpha_1 = 1, 2, 3,$$
$$f = f_{xx} = f_{xxxx} = 0 \quad \text{at } x = 0, 1.$$

Then the quasilinear parabolic problem (P_0) has a unique classical solution $U(x, t) \in C^{2,1}(\bar{Q})$ such that $U_{xxxx} = 0$ at $x = 0, 1$ and

$$(r.4) \qquad U_{tx}, U_{xxx}, U_{txx}, U_{xxxx} \in C(\bar{Q}),$$

$$(r.5) \qquad U_{tt}, U_{ttt}, U_{ttx}, U_{txxx}, U_{ttxx}, U_{xxxxx}, U_{txxxx}, U_{tttx}, U_{ttxxx}, U_{txxxxx}, U_{xxxxxx} \in L^\infty(L^2),$$

$$(r.6) \qquad U_{tttxx}, U_{ttxxxx}, U_{txxxxxx}, U_{xxxxxxx} \in L^2(Q).$$

Proof. In spite of the similarity of the pattern of proof here with that of Theorems 1 and 2, we will give the essential details for the convenience of the interested reader.

(i) *A related linear parabolic problem.* First consider a related linear parabolic problem for which the PDE (4.3) is replaced by

$$(4.6) \qquad \tilde{\mathbb{L}} U \doteq U_t - b(x, t) U_{xx} = f(x, t),$$

but the same initial condition (4.4) and boundary conditions (4.5) are retained. We assume for $b(x, t)$ that

$$(b.1) \qquad 0 < b_0 \leqq b(x, t),$$

$$(b.2) \qquad b_x = b_{xxx} = 0, \qquad \text{at } x = 0, 1,$$

$$(b.3) \qquad b \in H^3(Q), \qquad D_x^{2\alpha_1 - 1} b \in H^{4-\alpha_1}(Q), \quad \alpha_1 = 1, 2, 3.$$

The Faedo-Galerkin approximations

$$U_m(x, t) = \sum_{k=1}^{m} B_{km}(t) \sin k\pi x$$

for the linear problem (4.6) satisfy the orthogonality conditions

$$(4.7) \qquad \langle D^\alpha(\tilde{\mathbb{L}} U_m - f_m), D^\alpha U_m \rangle = 0$$

for all 19 multi-indices in

$$\mathbb{I} = \{\alpha = (\alpha_1, \alpha_2) | 0 \leqq \alpha_1 + 2 \max\{\tfrac{1}{2}, \alpha_2\} \leqq 7\}.$$

We note that assumption (b.2) is needed in deriving (4.7) when $\alpha_1 = 3$ and 5. From (4.7) we derive an integral relation for each $\alpha \in \mathbb{I}$:

$$\frac{1}{2}\int_0^1 |D^\alpha U_m|^2 \, dx + \int_0^t \int_0^1 b(x, s) |D^\alpha U_{m_x}|^2 \, dx \, ds$$
$$= \frac{1}{2}\int_0^1 |D^\alpha U_m(x, 0)|^2 \, dx + \int_0^t \int_0^1 D^\alpha f_m D^\alpha U_m \, dx \, ds$$
$$+ \int_0^t \int_0^1 D^\alpha U_m \left\{ \sum_{\substack{0 \leqq \beta \leqq \alpha \\ 0 < |\beta|}} \binom{\alpha}{\beta} D^\beta b D^{\alpha - \beta} U_{m_{xx}} - b_x D^\alpha U_{m_x} \right\} dx \, ds.$$

To put these results together, we define

$$\mathscr{E}(t) \doteq \frac{1}{2} \sum_{\alpha \in \mathbb{I}} \int_0^1 |D^\alpha U_m|^2 \, dx.$$

Estimates similar to the hyperbolic case appearing in the Appendix result in the inequality

$$\mathscr{E}(t) + \frac{1}{2} b_0 \sum_{\alpha \in \mathbb{I}} \int_0^t \int_0^1 |D^\alpha U_m|^2 \, dx \, ds \leqq \mathscr{E}(0) + \frac{1}{2} \|f_m\|_\star^2 + \int_0^t K_0(s) \mathscr{E}(s) \, ds,$$

where

$$\|f_m\|_\star^2 \doteq \sum_{\alpha \in \mathbb{I}} \int_0^{t_0} \int_0^1 |D^\alpha f_m|^2 \, dx \, ds$$

and

$$K_0(s) = C \left\{ 1 + t_0^{-1/2} + \sum_{\alpha \in \mathbb{I}_0} \|D^\alpha b\|_{L^\infty(Q)} + \int_0^1 \left(\sum_{\alpha \in \mathbb{I}_1} |D^\alpha b|^2 + t_0^{1/2} \sum_{\alpha \in \mathbb{I}_2} |D^\alpha b|^2 \right) dx \right\},$$

with

$$\mathbb{I}_0 = \{\alpha = (\alpha_1, \alpha_2) | 1 \leqq \alpha_1 + 2\alpha_2 \leqq 3\},$$

$$\mathbb{I}_1 = \{\alpha = (\alpha_1, \alpha_2) | 4 \leqq \alpha_1 + 2\alpha_2 \leqq 6, \alpha \neq (6, 0)\},$$

$$\mathbb{I}_2 = [\alpha = (\alpha_1, \alpha_2) | \alpha_1 + 2 \max \{\tfrac{1}{2}, \alpha_2\} = 7];$$

note that $|\mathbb{I}_0| = 5$, $|\mathbb{I}_1| = 9$, and $|\mathbb{I}_2| = 4$. By Gronwall's lemma,

$$(4.8) \quad \mathscr{E}(t) + \frac{1}{2} b_0 \int_0^t \int_0^1 \sum_{\alpha \in \mathbb{I}} |D^\alpha U_{m_x}|^2 \, dx \, ds \leqq \left\{ \mathscr{E}(0) + \frac{1}{2} \|f_m\|_\star^2 \right\} \exp \int_0^{t_0} K_0(s) \, ds.$$

Hypotheses (ϕ.2) and (f.2) are sufficient to guarantee that the right-hand side is bounded by a constant independent of m. To see this, write

$$\mathscr{E}(0) = \frac{1}{2} \sum_{\alpha_1 = 0}^{6} \int_0^1 |D_x^{\alpha_1} U_m(x, 0)|^2 \, dx + \frac{1}{2} \sum_{\substack{\alpha \in \mathbb{I} \\ \alpha_2 > 0}} \int_0^1 |D^\alpha U_m(x, 0)|^2 \, dx.$$

In the first sum, the terms satisfy

$$\int_0^1 |D_x^{\alpha_1} U_m(x, 0)|^2 \, dx = \int_0^1 |\phi_m^{(\alpha_1)}|^2 \, dx \leqq \int_0^1 |\phi^{(\alpha_1)}|^2 \, dx.$$

For the second sum, we note that

$$\langle D^\alpha (\tilde{\mathbb{L}} U_m - f_m), D^\alpha U_{m_t} \rangle = 0, \qquad \alpha \in \mathbb{I}_3,$$

where $\mathbb{I}_3 = \{\alpha = (\alpha_1, \alpha_2) | 0 \leqq \alpha_1 + 2\alpha_2 \leqq 5\}$. Then

$$\int_0^1 |D^\alpha U_m(x, 0)|^2 \, dx \leqq C \int_0^1 \left\{ |D^\alpha f_m(x, 0)|^2 + \sum_{0 \leqq \beta \leqq \gamma} |D^\beta b(x, 0) D^{\gamma - \beta} U_{m_{xx}}(x, 0)|^2 \right\} dx,$$

where $\gamma = (\alpha_1, \alpha_2 - 1)$ for $\alpha \in \mathbb{I}$, $\alpha_2 > 0$. The norm $\|f_m\|_\star$ and $\int_0^1 |D^\alpha f_m(x, 0)|^2 \, dx$, for $\alpha \in \mathbb{I}$, $\alpha_2 > 0$, are bounded independently of m as is done in (A.11) of the Appendix. Hence each of the sequences

$$\{D^\alpha U_m\}_{\alpha \in \mathbb{I}} \text{ is bounded in } L^\infty(L^2),$$

$$\{D^\alpha U_m\}_{\alpha \in \mathbb{I}_4} \text{ is bounded in } L^2(Q).$$

Here $\mathbb{I}_4 = \{\alpha = (\alpha_1, \alpha_2) | \alpha_1 + 2 \max\{\frac{1}{2}, \alpha_2\} = 8\}$. Uniqueness follows from the identity and bound for the difference, $Z \doteq U - \tilde{U}$, of two classical $C^{2,1}(\bar{Q})$ solutions

$$\frac{1}{2}\int_0^1 Z^2\,dx + \int_0^t \int_0^1 bZ_x^2\,dx\,ds = -\int_0^t \int_0^1 b_x Z_x Z\,dx\,ds$$

$$\leqq \frac{b_0}{2}\int_0^t \int_0^1 Z_x^2\,dx\,ds + b_0^{-1} \sup_{\bar{Q}} |b_x|^2 \int_0^t \left\{\frac{1}{2}\int_0^1 Z_x^2\,dx\,ds\right\}$$

by Gronwall's lemma. The remaining portion of the proof for the linear problem is entirely analogous to the final part of the proof of Theorem 1.

(ii) *Contraction mapping and Schauder technique.* A proper setting for Banach's contraction mapping theorem is obtained by defining a complete metric space

$$\mathbb{Z} \doteq L^\infty(0, t_0; H^1(0, 1)),$$

with

$$\|V\|_z^2 \equiv \|V\|_{L^\infty(H^1)}^2 \doteq \sup_{0 \leqq t \leqq t_0} \int_0^1 [V^2 + V_x^2]\,dx,$$

and a closed subset $\mathbb{X}(M, t_0)$ of $\mathbb{Z}$, consisting of functions V on Q with generalized derivatives

$$D^\alpha V \in L^\infty(0, t_0; L^2(0, 1)), \qquad D^\alpha V \in L^2(Q), \quad \alpha \in \mathbb{I},$$

satisfying

$$V(x, 0) = \phi(x), \qquad V = V_{xx} = V_{xxxx} = 0 \quad \text{at } x = 0, 1,$$

and

$$\rho(V) \doteq \max_{\alpha \in \mathbb{I}} \{\|D^\alpha V\|_{L^\infty(L^2)}, \|D^\alpha V_x\|_{L^2(Q)}\} \leqq M.$$

For $V \in \mathbb{X}$, let $\mathbb{T}$ be the solution operator associated with the linear initial boundary value problem

$$U_t - \sigma'(V_x) U_{xx} = f(x, t),$$
$$U(0, t) = U(1, t) = 0,$$
$$U(x, 0) = \phi(x),$$

so that $U = \mathbb{T} V$. The proof is complete if $\mathbb{T}$ is a contraction map on $\mathbb{X}$. With $b(x, t) \doteq \sigma'(V_x(x, t))$, it can easily be checked that conditions (b.1), (b.2), and (b.3) are satisfied, so $\mathbb{T}$ is well defined. That $\mathbb{T}$ maps $\mathbb{X}$ into $\mathbb{X}$ for M sufficiently large and t_0 sufficiently small follows from (4.8).

Let $V, \bar{V} \in \mathbb{X}(M, t_0)$ and $U = \mathbb{T} V$, $\bar{U} = \mathbb{T} \bar{V}$; then $W \doteq U - \bar{U}$ satisfies

$$\mathcal{L} W \doteq W_t - \sigma'(V_x) W_{xx} - (\sigma'(V_x) - \sigma'(\bar{V}_x)) \bar{U}_{xx} = 0$$

and completely homogeneous initial-boundary conditions. From

$$\int_0^t \int_0^1 D_x^{\alpha_1} \mathcal{L} W \cdot D_x^{\alpha_1} W\,dx\,ds = 0, \qquad \alpha_1 = 0, 1,$$

we can show that

$$\int_0^1 W^2(x, t)\,dx \leqq k_1 t_0\, e^{k_2 t_0} \|V - \bar{V}\|_z^2,$$

and

$$\int_0^1 W_x^2(x, t)\, dx \leqq k_3 t_0 \| V - \bar{V} \|_z^2,$$

where

$$k_1 \doteq \sup_{\substack{\bar{Q} \\ 0 \leqq \theta \leqq 1}} |\sigma''(\theta V_x + (1-\theta)\bar{V}_x)\bar{U}_{xx}|^2,$$

$$k_2 \doteq 1 + \sigma_0^{-1} \sup_{\bar{Q}} |\sigma''(V_x) V_{xx}|^2,$$

$$k_3 \doteq \sigma_0^{-1} \sup_{\substack{\bar{Q} \\ 0 \leqq \theta \leqq 1}} |\sigma''(\theta V_x + (1-\theta)\bar{V}_x)\bar{U}_{xx}|.$$

Putting these together, we have

$$\| U - \bar{U} \|_z \leqq \kappa \| V - \bar{V} \|_z,$$

for $\kappa < 1$, provided t_0 is sufficiently small. □

We also include a sketch of the proof of existence and uniqueness for problem (P_1) in order to indicate precisely how the smoothness of $U(x, t)$ is intimately involved in obtaining a classical solution $U_1(x, t)$. This is recorded in the following theorem.

THEOREM 4. *Let σ, ϕ, and f satisfy the hypotheses of Theorem* 3 *and suppose*

$$(\psi.2) \qquad \psi \in H^6(0, 1), \qquad \psi = \psi'' = \psi^{iv} = 0 \quad \text{at } x = 0, 1.$$

Then the linear parabolic problem (P_1) has a unique classical solution $U_1(x, t) \in C^{2,1}(\bar{Q})$ such that

$$(r.7) \qquad U_{1_{tx}}, U_{1_{xxx}} \in C(\bar{Q}),$$

$$(r.8) \qquad U_{1_{tt}}, U_{1_{txx}}, U_{1_{ttx}}, U_{1_{ttt}}, U_{1_{xxxx}}, U_{1_{txxx}}, U_{1_{ttxx}}, U_{1_{xxxxx}}, U_{1_{txxxx}} \in L^\infty(L^2),$$

$$(r.9) \qquad U_{1_{tttx}}, U_{1_{ttxxx}}, U_{1_{xxxxxx}}, U_{1_{txxxxx}} \in L^2(Q).$$

Proof. It is convenient to consider the equation

$$\mathbb{L} U \doteq U_{1_t} - (c(x, t) U_{1_x})_x = 0,$$

where we assume that

$$(c.1) \qquad 0 < c_0 \leqq c(x, t),$$

$$(c.2) \qquad c_x = c_{xxx} = 0 \quad \text{at } x = 0, 1,$$

$$(c.3) \qquad c \in H^3(Q), \qquad D_x^{2\alpha_1 - 1} c \in H^{4-\alpha_1}(Q), \qquad \alpha_1 = 1, 2, 3.$$

We find that the Faedo-Galerkin approximations

$$W_m(x, t) = \sum_{k=1}^{m} C_{km}(t) \sin k\pi x$$

satisfy

$$(4.9) \qquad \langle D^\alpha \mathbb{L} W_m, D^\alpha W_m \rangle = 0$$

for $\alpha \in \mathbb{J} = \{\alpha = (\alpha_1, \alpha_2) | 0 \leqq \alpha_1 + 2 \max\{\frac{1}{2}, \alpha_2\} \leqq 6\}$, where $|\mathbb{J}| = 15$. We note that (c.2) is needed when $\alpha_1 = 3$ and 5. From (4.9) it follows that

$$\frac{1}{2}\int_0^1 |D^\alpha W_m|^2\,dx + \int_0^t \int_0^1 c(x,s)|D^\alpha W_{m_x}|^2\,dx\,ds$$
$$= \frac{1}{2}\int_0^1 |D^\alpha W_m(x,0)|^2\,dx - \int_0^t \int_0^1 D^\alpha W_{m_x} \sum_{\substack{0 \leqq \beta \leqq \alpha \\ 0 < |\beta|}} \binom{\alpha}{\beta} D^\beta c D^{\alpha-\beta} W_{m_x}\,dx\,ds$$

holds for each $\alpha \in \mathbb{J}$. Define

$$E^*(t) \doteq \frac{1}{2}\sum_{\alpha \in \mathbb{J}} \int_0^1 |D^\alpha W_m|^2\,dx;$$

then, with estimates similar to those in the Appendix, we arrive at the inequality

$$E^*(t) + \frac{1}{2}c_0 \int_0^t \int_0^1 \sum_{\alpha \in \mathbb{J}} |D^\alpha W_{m_x}|^2\,dx\,ds \leqq E^*(0) + \int_0^t \mathbb{K}(s)E^*(s)\,ds, \tag{4.10}$$

in which

$$\mathbb{K}(s) \doteq C\left\{\sum_{\alpha \in \mathbb{J}_1} \|D^\alpha c\|^2_{L^\infty(Q)} + \int_0^1 \sum_{\alpha \in \mathbb{J}_2} |D^\alpha c(x,s)|^2\,dx\right\}$$

where

$$\mathbb{J}_1 = \{\alpha = (\alpha_1, \alpha_2) | 1 \leqq \alpha_1 + 2\alpha_2 \leqq 3\}$$

and

$$\mathbb{J}_2 = \{\alpha = (\alpha_1, \alpha_2) | 4 \leqq \alpha_1 + 2\alpha_2 \leqq 6,\ \alpha \neq (6,0)\}.$$

It is important that the conditions imposed on the data of the problem enable us to bound $E^*(0)$ independently of m. Note that we may write

$$E^*(0) = \frac{1}{2}\sum_{\alpha_1=0}^{5} \int_0^1 |D_x^{\alpha_1} W_m(x,0)|^2\,dx + \frac{1}{2}\sum_{\substack{\alpha \in \mathbb{J} \\ \alpha_2 > 0}} \int_0^1 |D^\alpha W_m(x,0)|^2\,dx.$$

For the first sum, we obtain directly from the initial condition, by means of Bessel's inequality, the bound

$$\int_0^1 |D_x^{\alpha_1} W_m(x,0)|^2\,dx = \int_0^1 |\psi_m^{(\alpha_1)}(x)|^2\,dx \leqq \int_0^1 |\psi^{(\alpha_1)}(x)|^2\,dx$$

for $\alpha_1 = 0, 1, \cdots, 5$. For the second sum, we note that the orthogonality relations

$$\langle D^\alpha \mathbb{L} W_m, D^\alpha W_{m_t}\rangle = 0, \qquad \alpha \in \mathbb{J}_3,$$

where $\mathbb{J}_3 = \{\alpha = (\alpha_1, \alpha_2) | 0 \leqq \alpha_1 + 2\alpha_2 \leqq 4\}$, $|\mathbb{J}_3| = 9$, can be used to get

$$\int_0^1 |D^\alpha W_m(x,0)|^2\,dx \leqq C \int_0^1 \sum_{0 \leqq \beta \leqq \gamma} |D^\beta c(x,0) D^{\gamma-\beta} W_{m_x}(x,0)|^2\,dx,$$

where $\gamma = (\alpha_1 + 1, \alpha_2 - 1)$ for $\alpha \in \mathbb{J}$, $\alpha_2 > 0$, and C is a positive integer. This serves to bound each term of the second sum by initial data. It is clear that we need the traces

$$D^\alpha c(x,0) \in L^2(0,1), \qquad \alpha \in \{\alpha = (\alpha_1, \alpha_2) | 0 \leqq \alpha_1 + 2\alpha_2 \leqq 5\}.$$

Our assumption (c.3) is sufficient to guarantee that these traces exist. It is also at this point that we require $\psi \in H^6(0,1)$.

The proof now proceeds in a familiar way by applying Gronwall's lemma to (4.10). Uniqueness follows since the difference of two $C^{2,1}(\bar{Q})$ solutions, $Z \doteq U_1 - \hat{U}_1$, satisfies the identity

$$\frac{1}{2}\int_0^1 Z^2(x, t)\,dx + \int_0^t \int_0^1 c(x, s) Z_x^2(x, s)\,dx\,ds = 0.$$

The regularity of $U(x, t)$, the classical solution of (P_0), provided by Theorem 3, has been designed precisely so that $c(x, t) \doteq \sigma'(U_x(x, t))$ satisfies (c.1), (c.2), and (c.3). □

5. The main result. The analysis of the previous three sections permits some brevity here. In particular, when we form the problem for the remainder, analysis of existence and uniqueness is not needed since the remainder is a sum of functions whose regularity properties have been established. We have also investigated the order ε behavior of the derivatives of u so that here we can proceed with certain knowledge. All that is required at this point is the establishment of an a priori estimate for the remainder, allowing determination of its order ε behavior. Our main result then is contained in the following theorem.

THEOREM 5. *Let f, ϕ, ψ, and σ satisfy the same hypotheses as in Theorem* 4. *Denoting, as above, by Q the rectangular region $(0, 1)\times(0, t_0)$, let u be the solution of problem* (P_ε):

$$\begin{aligned} &\varepsilon^2 u_{tt} + u_t - \sigma'(u_x)u_{xx} = f(x, t), && (x, t) \in Q,\\ &u(x, 0; \varepsilon) = \phi(x), \qquad \varepsilon u_t(x, 0) = \psi(x), && x \in [0, 1],\\ &u(0, t; \varepsilon) = u(1, t; \varepsilon) = 0, && t \in [0, t_0], \end{aligned}$$

with the properties established in Theorem 2. *For the same t_0, let U and U_1, respectively, be the zeroth-order and first-order outer solutions given by Theorems* 3 *and* 4. *Let εV be the lowest-order initial-layer corrector given by* (4.1). *Then*

$$u(x, t; \varepsilon) = U(x, t) + \varepsilon U_1(x, t) + \varepsilon V(x, t/\varepsilon^2) + \mathcal{O}(\varepsilon^2) \quad \text{as } \varepsilon \to 0^+$$

uniformly on $\bar{Q}$. The interval $[0, t_0]$ may be small, but it is independent of ε in $(0, \varepsilon_0]$.

Proof. Let r denote the remainder term defined by

$$r \doteq u - [U + \varepsilon U_1 + \varepsilon V + \varepsilon^2 V_1],$$

where $\varepsilon^2 V_1$ is the corrector given by (4.2). For ease of notation, let

$$e \doteq U + \varepsilon U_1 + \varepsilon V + \varepsilon^2 V_1.$$

An easy computation shows that r satisfies the nonlinear hyperbolic equation

$$\varepsilon^2 r_{tt} + r_t - \sigma'(u_x)r_{xx} - b(r_x) = h(x, t; \varepsilon)$$

in the classical sense in $\bar{Q}$, where

$$b(r_x) \doteq [\sigma'(e_x + r_x) - \sigma'(e_x)]\, e_{xx},$$

and

$$\begin{aligned} h(x, t; \varepsilon) \doteq &-\varepsilon^2 U_{tt} - \varepsilon^3 U_{1_{tt}} + [\sigma'(e_x) - \sigma'(U_x)]U_{xx}\\ &-\varepsilon \frac{\partial}{\partial x}[\sigma'(U_x)U_{1_x}] + \sigma'(e_x)[\varepsilon U_{1_{xx}} + \varepsilon V_{xx} + \varepsilon^2 V_{1_{xx}}]. \end{aligned}$$

The remainder r also assumes the initial conditions

$$r(x, 0; \varepsilon) = -\varepsilon^2[\sigma'(\phi'(x))\phi''(x) + f(x, 0)]$$

and

$$\varepsilon r_t(x, 0; \varepsilon) = -\varepsilon^2[\sigma''(\phi'(x))\phi''(x)\psi'(x) + \sigma'(\phi'(x))\psi''(x)]$$

for $x \in [0, 1]$, as well as the homogeneous boundary conditions

$$r(0, t; \varepsilon) = r(1, t; \varepsilon) = 0, \qquad t \in [0, t_0].$$

By means of energy integrals, the following pointwise estimate can be established for such a function r

$$|r(x, t; \varepsilon)|^2 \leqq C\left\{\hat{E}(0) + \frac{1}{2}\int_0^{t_0}\int_0^1 h^2\, dx\, ds\right\}, \tag{5.1}$$

where the constant C is independent of ε in $(0, \varepsilon_0]$ and $\hat{E}$ is the energy

$$\hat{E}(t) \doteq \frac{1}{2}\int_0^1 [\varepsilon^2 r_t^2 + \sigma'(u_x) r_x^2]\, dx.$$

Assuming for the moment the validity of the bound (5.1), the theorem is completed by showing that the right-hand side is $\mathcal{O}(\varepsilon^4)$. With the initial conditions satisfied by r, this is obvious for $\hat{E}(0)$. The integral of the square of h over Q will also be $\mathcal{O}(\varepsilon^4)$ provided this holds for each of the terms whose sum comprises h. Thanks to the regularity of U and U_1 obtained in Theorems 3 and 4, this assertion clearly holds for the first two terms in h. A little more care is required for the remaining terms, which, by use of Taylor's theorem, may be written as the sum

$$\begin{aligned}
&[\varepsilon\sigma''(U_x)U_{xx}]V_x + [\varepsilon\sigma'(U_x)]V_{xx} + [\varepsilon^2\sigma''(U_x)U_{xx}]V_{1_x} + [\varepsilon^2\sigma'(e_x)]V_{1_{xx}} \\
&\qquad + \varepsilon^2[(U_{1_{xx}} + V_{xx})\sigma''(\theta e_x + (1-\theta)U_x)(U_{1_x} + V_x + \varepsilon V_{1_x})] \\
&\qquad + \varepsilon^2[\tfrac{1}{2}\sigma''(\theta e_x + (1-\theta)U_x)U_{xx}(U_{1_x} + V_x + \varepsilon V_{1_x})^2].
\end{aligned}$$

The last two terms here contribute $\mathcal{O}(\varepsilon^4)$ to the estimate, due to the regularity established in § 4 for U, U_1, V, and V_1. The remaining terms are each in the form of a product of an $\mathcal{O}(\varepsilon)$ factor and a corrector. When integration with respect to t is carried out in the integral over Q of the square of these terms, the factor $\exp\{-t/\varepsilon^2\}$ in the corrector gives rise to an additional ε^2, and thus, the result here is also seen to be $\mathcal{O}(\varepsilon^4)$.

It thus remains only to establish the uniform bound (5.1), which is done by estimating the right-hand side of the energy identity

$$\begin{aligned}
\hat{E}(t) + \int_0^t\int_0^1 r_t^2\, dx\, ds &= \hat{E}(0) + \int_0^t\int_0^1 r_t[b(r_x) + h]\, dx\, ds \\
&\quad + \int_0^t\int_0^1 \left\{\frac{1}{2} r_x^2 \frac{\partial}{\partial t}\sigma'(u_x) - r_x r_t \frac{\partial}{\partial x}\sigma'(u_x)\right\} dx\, ds.
\end{aligned} \tag{5.2}$$

We have by the arithmetic-geometric mean (A-G) inequality

$$\begin{aligned}
\int_0^t\int_0^1 |r_t b(r_x)|\, dx\, ds &\leqq \frac{1}{2\eta}\int_0^t\int_0^1 r_t^2\, dx\, ds \\
&\quad + \eta \sup_{\substack{\bar{Q} \\ 0<\theta<1}} \{|e_{xx}||\sigma''(\theta u_x + (1-\theta)e_x)|\}^2 \int_0^t\int_0^1 \frac{1}{2} r_x^2\, dx\, ds,
\end{aligned}$$

and then note that the last integral is bounded by

$$\sigma_0^{-1}\int_0^t \hat{E}(s)\,ds.$$

The integral of $r_t h$ is bounded by (A-G) with $\eta = 1$. Letting $a(x, t; \varepsilon) = \sigma'(u_x(x, t; \varepsilon))$, we have further that

$$\int_0^t\int_0^1 \left|\frac{1}{2}a_t r_x^2\right| dx\,ds \leqq \int_0^t \left(\sup_{0\leqq x\leqq 1}|a_t|\int_0^1 \frac{1}{2}r_x^2\,dx\right) ds$$

$$\leqq \sigma_0^{-1}\int_0^t \left\{1+\int_0^1 [a_t^2+a_{tx}^2]\,dx\right\} E(s)\,ds,$$

where Sobolev's inequality is used. The last term in (5.2) is treated similarly,

$$\int_0^t\int_0^1 |a_x r_x r_t|\,dx\,ds \leqq \frac{1}{2\eta}\int_0^t\int_0^1 r_t^2\,dx\,ds + \eta\int_0^t \left\{\left(\sup_{0\leqq x\leqq 1}|a_x|^2\right)\int_0^1 \frac{1}{2}r_x^2\,dx\right\} ds,$$

with the last term here bounded above by

$$\sigma_0^{-1}\eta\int_0^t \left\{\int_0^1 (a_x^2+a_{xx}^2)\,dx\right\}\hat{E}(s)\,ds.$$

Hence choosing $\eta = 2$ to cancel the second term on the left-hand side of (5.2) and letting

$$\mathcal{K}(s) = \frac{2}{\sigma_0}\left[\sup_{\substack{\bar{Q}\\ 0<\theta<1}} (|e_{xx}||\sigma''(\theta u_x + (1-\theta)\,e_x)|)^2\right.$$

$$\left. + \int_0^1 (a_x^2+a_{xx}^2)\,dx + \frac{1}{2}\left(1+\int_0^1 (a_t^2+a_{tx}^2)\,dx\right)\right],$$

we see that

$$\hat{E}(t) \leqq \hat{E}(0) + \frac{1}{2}\int_0^{t_0}\int_0^1 h^2\,dx\,ds + \int_0^t \mathcal{K}(s)\hat{E}(s)\,ds,$$

from which we obtain (5.1) by means of Gronwall's lemma and the Sobolev inequality. It is important to be aware that an ε-independent bound of the $L^1(0, t_0)$ norm of $\mathcal{K}(t)$ follows from the conclusions in Theorem 2 on the order ε behavior of the derivatives of the solution of the quasilinear hyperbolic equation. This completes the proof of the theorem. □

Appendix: Energy inequality. We wish first to establish (2.9):

$$\text{(A.1)}\quad E(t) + \frac{1}{4}\sum_{0\leqq|\alpha|\leqq 3}\varepsilon^{4\alpha_2}\int_0^t\int_0^1 |D^\alpha v_t|^2\,dx\,ds \leqq \left\{F(0) + \frac{1}{2}\|f_m\|^2_{H^3(Q)}\right\}\exp\int_0^t K(s)\,ds$$

for $v \equiv u_m$ given by (2.4). It will be clear that analogues of (A.1) are valid for higher-order α under appropriate conditions, but we operate under the hypotheses of Theorem 1, in which $|\alpha| \leqq 3$.

To prove (A.1) we start by considering, for any multi-index α, $0 \leqq |\alpha| \leqq 3$, the "energy" E_α defined by

$$E_\alpha(t) \equiv E_\alpha(t, \varepsilon; v) \doteq \frac{1}{2}\int_0^1 (\varepsilon^2|D^\alpha v_t|^2 + a(x, t; \varepsilon)|D^\alpha v_x|^2)\,dx,$$

where $D^\alpha \equiv D_x^{\alpha_1} D_t^{\alpha_2}$. Then our basic energy identity is

$$
\begin{aligned}
E_\alpha(t) + \int_0^t \int_0^1 |D^\alpha v_t|^2 \, dx \, ds &= E_\alpha(0) + \frac{1}{2} \int_0^t \int_0^1 a_t |D^\alpha v_x|^2 \, dx \, ds \\
&+ \int_0^t \int_0^1 D^\alpha v_t \left\{ \sum_{\substack{0 \leqq \beta \leqq \alpha \\ 0 < |\beta|}} \binom{\alpha}{\beta} D^\beta a D^{\alpha-\beta} v_{xx} - a_x D^\alpha v_x + D^\alpha f_m \right\} dx \, ds
\end{aligned} \tag{A.2}
$$

where f_m is the $L^2(0, 1)$ projection of f as defined in (2.8). The identity (A.2) is obtained from the $L^2(0, 1)$ orthogonality relation

$$\langle D^\alpha (L_\varepsilon v - f_m), D^\alpha v_t \rangle = 0, \qquad |\alpha| \leqq 3,$$

which follows directly from (2.5) by integration by parts. The vanishing of $a_x(x, t)$ at $x = 0$ and $x = 1$ is required in our hypotheses specifically so that this holds for $\alpha = (3, 0)$.

Multiplying (A.2) by $\varepsilon^{4\alpha_2}$ and summing over α, $0 \leqq |\alpha| \leqq 3$, yields

$$
\begin{aligned}
&F(t) + \sum_{0 \leqq |\alpha| \leqq 3} \varepsilon^{4\alpha_2} \int_0^t \int_0^1 |D^\alpha v_t|^2 \, dx \, ds \\
&\quad = F(0) + \sum_{0 \leqq |\alpha| \leqq 3} \varepsilon^{4\alpha_2} \int_0^t \int_0^1 D^\alpha v_t \\
&\qquad \times \left\{ \sum_{\substack{0 \leqq \beta \leqq \alpha \\ 0 < |\beta|}} \binom{\alpha}{\beta} D^\beta a D^{\alpha-\beta} v_{xx} - a_x D^\alpha v_x + D^\alpha f_m \right\} dx \, ds \\
&\qquad + \frac{1}{2} \sum_{0 \leqq |\alpha| \leqq 3} \varepsilon^{4\alpha_2} \int_0^t \int_0^1 a_t |D^\alpha v_x|^2 \, dx \, ds
\end{aligned} \tag{A.3}
$$

where, as in (2.10),

$$F(t) \doteq \sum_{0 \leqq |\alpha| \leqq 3} \varepsilon^{4\alpha_2} E_\alpha(t).$$

Defining, as in (2.9),

$$E(t) \doteq \frac{1}{2} \int_0^1 \left\{ \sum_{0 \leqq |\alpha| \leqq 3} \varepsilon^{4\alpha_2 + 2} |D^\alpha v_t|^2 + a(x, t; \varepsilon) \sum_{\alpha_1 = 0}^{3} |D_x^{\alpha_1} v_x|^2 \right\} dx,$$

we now derive the energy estimate

$$E(t) + \frac{1}{4} \sum_{0 \leqq |\alpha| \leqq 3} \varepsilon^{4\alpha_2} \int_0^t \int_0^1 |D^\alpha v_t|^2 \, dx \, ds \leqq F(0) + \frac{1}{2} \|f_m\|_{H^3(Q)}^2 + \int_0^t K(s) E(s) \, ds \tag{A.4}$$

from which (A.1) follows by using Gronwall's lemma.

There are several different estimates needed in order to bound the various terms in (A.3) to establish (A.4). Proper care must be exercised in associating powers of ε with derivatives of a and v so that only $\mathcal{O}(1)$ quantities appear. The term involving $D^\alpha f_m$ is bounded easily via the arithmetic-geometric mean inequality

$$\varepsilon^{4\alpha_2} \int_0^t \int_0^1 |D^\alpha v_t D^\alpha f_m| \, dx \, ds \leqq \frac{1}{2} \int_0^t \int_0^1 \{ \varepsilon^{4\alpha_2} |D^\alpha v_t|^2 + |D^\alpha f_m|^2 \} \, dx \, ds,$$

and hence the sum over α of such terms is bounded by

$$\frac{1}{2} \left\{ \|f_m\|_{H^3(Q)}^2 + \sum_{0 \leqq |\alpha| \leqq 3} \varepsilon^{4\alpha_2} \int_0^t \int_0^1 |D^\alpha v_t|^2 \, dx \, ds \right\} \tag{A.5}$$

where we have used, and will repeatedly use, the fact that $0<\varepsilon\leqq\varepsilon_0\leqq 1$. Similarly, by means of

$$\frac{1}{2}\varepsilon^{4\alpha_2}\int_0^t\int_0^1 |a_t||D^\alpha v_x|^2\,dx\,ds\leqq\frac{1}{2}\varepsilon^{4\alpha_2}\int_0^t \sup_{0\leqq x\leqq 1}|a_t|\left\{\int_0^1 |D^\alpha v_x|^2\,dx\right\}ds,$$

the sum involving the last term in (A.3) is bounded by

$$\mu\int_0^t \sup_{0\leqq x\leqq 1}|a_t(x,s)|E(s)\,ds, \tag{A.6}$$

where $\mu\doteq\max\{1, a_0^{-1}\}$. For the term involving $a_xD^\alpha v_x$, we use

$$\begin{aligned}&\varepsilon^{4\alpha_2}\int_0^t\int_0^1 |a_xD^\alpha v_tD^\alpha v_x|\,dx\,ds\\ &\leqq\frac{1}{2}\int_0^t \sup_{0\leqq x\leqq 1}|a_x(x,s)|\int_0^1\{\varepsilon^{4\alpha_2+2}|D^\alpha v_t|^2+\varepsilon^{4\alpha_2-2}|D^\alpha v_x|^2\}\,dx\,ds,\end{aligned} \tag{A.7}$$

when $\alpha_2>0$, while for $\alpha_2=0$, we have, for any $\eta>0$,

$$\int_0^t\int_0^1 |a_xD^\alpha v_tD^\alpha v_x|\,dx\,ds\leqq\frac{1}{2}\int_0^t\int_0^1\{\eta a_x^2|D^\alpha v_x|^2+\eta^{-1}|D^\alpha v_t|^2\}\,dx\,ds. \tag{A.8}$$

Thus the sum over α of such terms is bounded above by

$$\int_0^t\left\{\sup_{0\leqq x\leqq 1}|a_x(x,s)|+\eta\mu\sup_{0\leqq x\leqq 1}|a_x(x,s)|^2\right\}E(s)\,ds+\frac{1}{2\eta}\sum_{\alpha_1=0}^{3}\int_0^t\int_0^1|D_x^{\alpha_1}v_t|^2\,dx\,ds. \tag{A.9}$$

The remaining terms involve $D^\beta a$ and are a bit more sensitive. When $\beta=(1,0)$ the estimates (A.7) and (A.8) apply with $D^\alpha v_x$ replaced by $D^{\alpha-\beta}v_{xx}$. For $\beta=(0,1)$ we may use (A.7) if we replace a_x by a_t and $D^\alpha v_x$ by $D^{\alpha-\beta}v_{xx}$. For $|\beta|>1$, $\beta_2\neq 0$, we have

$$\begin{aligned}&\varepsilon^{4\alpha_2}\int_0^t\int_0^1 D^\alpha v_tD^\beta aD^{\alpha-\beta}v_{xx}|\,dx\,ds\\ &\leqq\int_0^t\left[\int_0^1\varepsilon^{4\beta_2-2}|D^\beta a|^2\,dx\right]^{1/2}\\ &\quad\times\left[\int_0^1\varepsilon^{4\alpha_2+2}|D^\alpha v_t|^2\varepsilon^{4(\alpha_2-\beta_2)}|D^{\alpha-\beta}v_{xx}|^2\,dx\right]^{1/2}ds\\ &\leqq\int_0^t\left[\int_0^1\varepsilon^{4\beta_2-2}|D^\beta a|^2\,dx\right]^{1/2}\\ &\quad\times\sup_{0\leqq x\leqq 1}|\varepsilon^{2(\alpha_2-\beta_2)}D^{\alpha-\beta}v_{xx}|\left[\int_0^1\varepsilon^{4\alpha_2+2}|D^\alpha v_t|^2\,dx\right]^{1/2}ds\\ &\leqq\frac{1}{2}\int_0^t\left[\int_0^1\varepsilon^{4\beta_2-2}|D^\beta a|^2\,dx\right]\left[\int_0^1\varepsilon^{4(\alpha_2-\beta_2)}|D^{\alpha-\beta}v_{xxx}|^2\,dx\right]ds\\ &\quad+\frac{1}{2}\int_0^t\int_0^1\varepsilon^{4\alpha_2+2}|D^\alpha v_t|^2\,dx\,ds.\end{aligned} \tag{A.10}$$

It should be mentioned that in (A.10) we have used the elementary Sobolev inequality

$$|D^\alpha v(x,t)|^2\leqq\int_0^1|D^\alpha v_x(\xi,t)|^2\,d\xi,$$

which is valid for the $C^4(\bar{Q})$ function $v = u_m$, in view of the fact that $D^\alpha v$ has a zero in $[0, 1]$ for each t.

For $|\beta| > 1$, $\alpha_2 = 0$, the same sort of estimation as in (A.10) yields

$$\int_0^t \int_0^1 |D^\alpha v_t D^\beta a D^{\alpha-\beta} v_{xx}|^2 \, dx \, ds$$

$$\leqq \frac{\eta}{2} \int_0^t \left[\int_0^1 |D_x^{\beta_1} a|^2 \, dx \right] \int_0^1 |D_x^{\alpha_1-\beta_1} v_{xxx}|^2 \, dx \, ds + \frac{1}{2\eta} \int_0^t \int_0^1 |D_x^{\alpha_1} v_t|^2 \, dx \, ds.$$

There is one additional case, when $\beta = (2, 0)$, $\alpha = (2, 1)$, for which, proceeding as in (A.10),

$$\varepsilon^4 \int_0^t \int_0^1 |D^\alpha v_t D^\beta a D^{\alpha-\beta} v_{xx}|^2 \, dx \, ds$$

$$\leqq \frac{1}{2} \int_0^t \left[\int_0^1 |D^\beta a|^2 \, dx \right] \int_0^1 \varepsilon^2 |D^{\alpha-\beta} v_{xxx}|^2 \, dx \, ds + \frac{1}{2} \int_0^t \int_0^1 \varepsilon^6 |D^\alpha v|^2 \, dx \, ds.$$

Merely collecting these estimates for the right-hand side and choosing η appropriately to obtain the coefficient $\frac{1}{4}$ for the double integral on the left-hand side, we see that there is a constant K_0, independent of ε, x, and t such that (A.1) holds with $K(s)$ given by (2.12). In simplifying the expression for K, we have used the elementary inequality

$$|a_x| \leqq \tfrac{1}{2}(1 + |a_x|^2)$$

as well as the Sobolev inequality

$$|\omega(x, t)|^2 \leqq C_0 \int_0^1 (|\omega(\xi, t)|^2 + |\omega_x(\xi, t)|^2) \, d\xi,$$

where C_0 is an absolute constant. With this, the proof of (A.1) is complete.

We now show that the right-hand side of (A.1) is bounded independently of m and ε. Consider first obtaining a uniform bound for the norms $\{\|f_m\|_{H^3(Q)}\}_{m=1}^\infty$. Note that $f \in H^3(Q)$ implies $D_t^{\alpha_2} f(\cdot, t) \in H^{3-\alpha_2}(0, 1)$, $\alpha_2 = 0, 1, 2, 3$, for almost all t in $(0, t_0)$ by Fubini's theorem. We have assumed that $f = f_{xx} = 0$ when $x = 0, 1$, and it follows that $f_t = f_{tt} = 0$ at $x = 0, 1$ as well. Since the family $\{\sin k\pi x\}_{k=1}^\infty$ is dense in $L^2(0, 1)$ and each of the spaces

$$S_k = \{v \in H^k(0, 1) | v = D_x^{2[k/3]} v = 0 \text{ at } x = 0, 1\},$$

$k = 1, 2, 3$, we find by means of Bessel's inequality that, for almost all t in $(0, t_0)$,

$$\int_0^1 |D^\alpha f_m|^2 \, dx \leqq \int_0^1 |D^\alpha f|^2 \, dx, \qquad |\alpha| \leqq 3. \tag{A.11}$$

Integrating over $(0, t_0)$ and adding, we find that $\|f_m\|_{H^3(Q)} \leqq \|f\|_{H^3(Q)}$. Next consider that

$$F(0) = \frac{1}{2} \sum_{|\alpha| \leqq 3} \varepsilon^{4\alpha_2} \int_0^1 \{\varepsilon^2 |D^\alpha u_{m_t}(x, 0)|^2 + a(x, 0; \varepsilon) |D^\alpha u_{m_x}(x, 0)^2\} \, dx$$

$$= \frac{1}{2} \sum_{\alpha_1=0}^{3} \int_0^1 \{\varepsilon^2 |D^\alpha u_{m_t}(x, 0)|^2 + a(x, 0; \varepsilon) |D^\alpha u_{m_x}(x, 0)|^2\} \, dx$$

$$+ \frac{1}{2} \sum_{\substack{|\alpha| \leqq 3 \\ \alpha_2 > 0}} \varepsilon^{4\alpha_2} \int_0^1 \{\varepsilon^2 |D^\alpha u_{m_t}(x, 0)|^2 + a(x, 0; \varepsilon) |D^\alpha u_{m_x}(x, 0)|^2\} \, dx.$$

From the initial conditions, for the first sum, we have

$$\frac{1}{2}\sum_{\alpha_1=0}^{3}\int_0^1 \{\varepsilon^2|D^\alpha u_{m_t}(x,0)|^2+a(x,0;\varepsilon)|D^\alpha u_{m_x}(x,0)|^2\}\,dx$$

$$\leqq\frac{1}{2}\sum_{\alpha_1=0}^{3}\int_0^1 \{|\psi^{(\alpha_1)}(x)|^2+a(x,0;\varepsilon)|\phi^{(\alpha_1+1)}(x)|^2\}\,dx$$

$$\leqq\frac{1}{2}\{\|\psi\|^2_{H^3(0,1)}+\|a(x,0;\varepsilon)\|_{L^\infty(0,1)}\|\phi\|^2_{H^4(0,1)}\}.$$

Also, the orthogonal relations

$$\langle D^\alpha(Lu_m-f_m),\, D^\alpha u_{m_{tt}}\rangle=0, \qquad |\alpha|\leqq 2,$$

can be used to get the bounds

$$\int_0^1 \varepsilon^{4\alpha_2+6}|D^\alpha u_{m_{tt}}(x,0)|^2\,dx$$

$$\leqq C\int_0^1\Bigg\{\sum_{0\leqq\beta\leqq\alpha}|(\varepsilon^{2\beta_2}D^\beta a(x,0))(\varepsilon^{2(\alpha_2-\beta_2)+1}D^{\alpha-\beta}u_{m_{xx}}(x,0))|^2$$

$$+\varepsilon^{4\alpha_2+2}|D^\alpha u_{m_t}(x,0)|^2+|D^\alpha f_m(x,0)|^2\Bigg\}\,dx,$$

for $|\alpha|\leqq 2$, in which we have been careful to place the available powers of ε so that only $\mathcal{O}(1)$ quantities appear on the right, in accordance with hypotheses (a.4) and (a.5), the initial conditions, and the results obtained for the α_2+1 case from the previous cases. Projections of the initial data (2.2) are easily bounded independently of m using Bessel's inequality, and an argument similar to that leading to (A.11) shows that

$$\int_0^1 |D^\alpha f_m(x,0)|^2\,dx\leqq\int_0^1 |D^\alpha f(x,0)|^2\,dx$$

holds for $|\alpha|\leqq 2$, with the traces existing at $t=0$ since $f\in H^3(Q)$. Note finally that the exponential factor in (A.1) is $\mathcal{O}(1)$ from the order ε behavior of the derivatives of $a(x,t;\varepsilon)$ assumed in (a.3) and (a.6).

SEMIDISCRETE APPROXIMATIONS OF HYPERBOLIC BOUNDARY VALUE PROBLEMS WITH NONHOMOGENOUS DIRICHLET BOUNDARY CONDITIONS*

I. LASIECKA† AND J. SOKOLOWSKI‡

Abstract. Finite-element approximations of the wave equation with nonhomogenous and "nonsmooth" Dirichlet boundary data are considered. These approximations are based on a special variational regularization of the problem introduced by J. L. Lions. The convergence rates of the approximations with nonsmooth boundary data are derived.

Key words. semidiscrete approximations, hyperbolic boundary value problems, nonhomogenous and nonsmooth Dirichlet data

AMS(MOS) subject classification. 35L

1. Introduction. Let Ω be an open bounded domain in R^n with smooth boundary Γ. Let $A(x, \partial)$ be a second-order strongly elliptic operator of the form

$$A(x, \partial)u = \sum_{i,j=1}^{n} \frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial}{\partial x_j}u\right)$$

where $a_{ij} = a_{ji} \in C^{\infty}(\bar{\Omega})$ and

$$\sum_{i,j=1}^{n} a_{ij}(x)\xi_i\xi_j \geqq \alpha \sum_{i=1}^{n} \xi_i^2, \quad \alpha > 0 \quad \forall \xi_i \in R, \quad \forall x \in \Omega.$$

Consider the following second-order scalar hyperbolic equation:

$$\begin{aligned} &\ddot{u}(x, t) = A(x, \partial)u(x, t) && \text{in } \Omega \times (0, T) \equiv Q, \\ &u(x, 0) = \dot{u}(x, 0) = 0 && \text{in } \Omega, \\ &u(\sigma, t) = g(\sigma, t) && \text{in } \Gamma \times (0, T) \equiv \Sigma. \end{aligned} \tag{1.1}$$

The main goal of this paper is as follows. Under minimal regularity assumptions imposed on the boundary term g, we introduce finite-element approximation of (1.1) and establish convergence and the rates of convergence of the algorithm in $L_2(\Omega)$ norms. Our motivation for studying approximations of second-order hyperbolic equations with nonsmooth boundary data comes from problems arising in numerical considerations related to a variety of boundary control problems where the solutions are definitely nonsmooth, for example, optimization problems with boundary controls, the time-optimal boundary control problem, and Riccati equations arising from boundary control problems. To construct and prove related convergence of numerical algorithms for these problems, a preliminary step is to establish appropriate approximation of problem (1.1) with nonsmooth boundary data g—say, $g \in L_2(\Sigma)$ or $g \in H^1[0, T; H^{-1/2}(\Gamma)]$. To the authors' knowledge, the literature on finite-element methods for the second-order hyperbolic equation with Dirichlet boundary conditions deals only with nonhomogenous boundary data, which are smooth. This is not surprising, also in view of the fact that the maximal regularity of problem (1.1) with nonhomogenous boundary data $mL_2(\Sigma)$ has been established only recently (see [LT1],

[L2], [LLT]). The presence of the nonhomogenous and nonsmooth Dirichlet boundary data is responsible for two immediate difficulties: (i) Dirichlet problem (1.1) does not admit a natural variational formulation that could then be taken as a basis for a numerical approximation. (ii) Low regularity of the boundary data g (hence of the solution) rules out the usual technique for proving stability and convergence of the numerical scheme based on $H^1(\Omega)\times L_2(\Omega)$ energy estimates. While the first difficulty can be handled by selecting an appropriate approximation of the elliptic operator that would take into account the nonhomogenous terms on the boundary (see, for example, [B2], [B7], [N1], [S1]), the second difficulty becomes crucial in relation to the derivation of stability estimates for the sought-after numerical algorithm. Let us elaborate more on this point. A standard finite-element approximation approach in the hyperbolic (as well as the parabolic) case is to define a semidiscrete algorithm by taking an appropriate space-approximation of the underlined elliptic operator. The estimates on the rate of convergence—which, of course, depend on the smoothness of the solutions—can be obtained by taking the difference of the two solutions and by using results on elliptic approximations. It is known, however [R1], that even if the elliptic approximations yield the optimal rates of convergence, nevertheless, the rates for hyperbolic problems are nonoptimal because they require one extra time-derivative of the solution. Since we cannot obtain optimal *convergence rates*, we would at least like to obtain *convergence* of the numerical algorithm in the "right topologies," i.e., where the maximal regularity of the map $g\to u$ takes place. To accomplish this we need to establish stability estimates for numerical schemes in precisely the same topologies (in fact, for the homogenous boundary data, this can be done by using the $H^1(\Omega)\times L_2(\Omega)$ energy methods mentioned earlier). This issue, however, raises another question: What is the maximal regularity of the map $g\to u$. As we have noted, this seemingly innocent question has only recently been answered in an optimal way (see [LT1], [L2], [LLT]). In the references above it is shown, in particular, that the map $g\to u$ is bounded from

$$L_2(\Sigma)\to C[0, T; L_2(\Omega)], \tag{1.2}$$

or more generally,

$$H^{s,s}(\Sigma)\to H^{s,s}(Q)\cap C[0, T; H^s(\Omega)], \qquad s\geqq 0 \tag{1.3}$$

where in (1.3) we must assume that for $s>\frac{1}{2}$, g satisfies some appropriate compatibility conditions at the origin. Results (1.2) and (1.3) improve by one-half derivative the previous results on regularity of solutions to (1.1) given in [LM]. Equipped with maximal regularity results for the original problem, we now wish to devise a numerical algorithm that can provide (i) the best possible rates of convergence (here we are resigned to "loosening" one derivative), and (ii) stability estimates reconstructing as much as possible the regularity properties of the original solution. Since our prime interest is to consider nonsmooth boundary data, it is precisely the second point mentioned above that limits our choices of elliptic approximations. The reason for this is twofold. First, the available elliptic estimates deal with more regular (in-space) boundary data—typically $g\in H^p(\Gamma)$; $p\geqq\frac{3}{2}$ (see [B2], [B7], [N1], [S1]). Second, standard techniques of proofs based on H^1-coercivity of elliptic problems are not applicable because we consider boundary data that do not yield $H^1(\Omega)$ solutions. Thus the sought-after elliptic approximation should allow for the treatment of nonsmooth boundary data g and, moreover, should be suitable for yielding hyperbolic estimates in lower norms. What we propose here is based on the idea originally introduced by Lions in [L1], where the original Dirichlet problem is "approximated" by the following sequence of problems with natural variational boundary conditions. For every $\varepsilon>0$,

parameter tending to zero, let u_ε be the solution of

$$\begin{aligned} &\ddot{u}_\varepsilon(x,t) = A(x,\partial)u_\varepsilon(x,t) && \text{in } Q,\\ &u_\varepsilon(x,0) = \dot{u}_\varepsilon(x,0) = 0 && \text{in } \Omega,\\ &\varepsilon\frac{\partial u_\varepsilon(\sigma,t)}{\partial\eta} + \beta u_\varepsilon(\sigma,t) = \beta g(\sigma,t) && \text{in } \Sigma \end{aligned} \tag{1.4}$$

where $\partial/\partial\eta$ stands for the co-normal derivative with respect to the operator A and where β is a second-order strongly elliptic self-adjoint operator defined on Γ (we can take $\beta = -\Delta_\Gamma + I$, where Δ_Γ is Laplace's Beltrami operator). This implies, in particular,

$$\langle \beta u, v\rangle \leqq C|u|_{H^1(\Gamma)}|v|_{H^1(\Gamma)}, \tag{1.4a}$$

$$\langle \beta u, u\rangle \geqq C_0|u|^2_{H^1(\Gamma)} \tag{1.4b}$$

where $c_1 c_0 > 0$ and $\beta^{-1}: H^s(\Gamma) \to H^{s+2}(\Gamma)$ exists and it is bounded.

Note that if we take $\beta \equiv I$ in (1.4), then the projection of (1.4) onto finite-dimensional subspaces of $H^1(\Omega)$ is a hyperbolic counterpart to the Penalty Method introduced by Babuška [B2] for elliptic problems. However, with $\beta = I$ in (1.4), the solution $u_\varepsilon(t)$ is *not bounded* in $L_2(\Omega)$ (uniformly with respect to the parameter $\varepsilon > 0$) by $|g|_{L_2(\Sigma)}$. We recall that the same bound holds true for the original solution (1.1) (see (1.21)). This shows that (1.4) with $\beta = I$ is *not a good* "approximation" of the original hyperbolic problem because it does not reconstruct the regularity properties of the original solutions. The presence of the Laplace Beltrami operator on the boundary forces stronger convergence of the traces of u_ε which, in turn, is necessary to obtain the appropriate stability of the solution (see [LS1], [L1]). In fact, it is shown in [LS1] (see also [L1]) that the following convergence result takes place.

THEOREM 1.1 [LS1].

(i) *For any* $g \in L_2(\Sigma)$

$$\|u_\varepsilon - u\|_{C[0,T;L_2(\Omega)]} \to 0,$$

$$\|u_\varepsilon\|_{C[0,T;L_2(\Omega)]} \leqq C|g|_{L_2(\Sigma)};$$

(ii) $$\|u_\varepsilon - u\|_{C[0,T;L_2(\Omega)]} \leqq C\varepsilon\|g\|_{H^{1,1}(\Sigma)};$$

(iii) $$\|u_\varepsilon - u\|_{C[0,T;H^1(\Omega)]} \leqq C\varepsilon\|g\|_{H^{2,2}(\Sigma)};$$

(iv) $$|u_\varepsilon|_\Gamma - g|_{L_2[0,T;H^2(\Gamma)]} \leqq C\varepsilon|g|_{H^{1,1}(\Sigma)}.$$

In defining a semidiscrete approximation of the original problem (1.1), a natural idea is to "project" the variational form of (1.4) onto the finite-dimensional subspaces. To this end, let h be the parameter of discretization tending to zero and let V_h stand for the approximating space of $H^1(\Omega)$ with the usual approximation properties (to be specified later) and such that $\tilde{V}_h \equiv V_{h|\Gamma} \subset H^1(\Gamma)$. As an approximation of $u_\varepsilon(t)$ (solution to (1.4)) we take $u_{h,\varepsilon}(t) \in V_h$ such that

$$\begin{aligned} &(\ddot{u}_{h,\varepsilon}(t), \phi_h)_\Omega + a(u_{h,\varepsilon}(t), \phi_h) + \frac{1}{\varepsilon}\langle \beta u_{h,\varepsilon}(t), \phi_h\rangle_\Gamma = \frac{1}{\varepsilon}\langle \tilde{P}_h g, \beta\phi_h\rangle_\Gamma,\\ &\phi_h \in V_h,\\ &u_{h,\varepsilon}(0) = \dot{u}_{h,\varepsilon}(0) = 0 \end{aligned} \tag{1.5}$$

where $a(u, v)$ is the bilinear form associated with $A(x, \partial)$, i.e.,

$$\begin{aligned} a(u,v) &= \sum_{i_j=1}^{n}\left(a_{ij}(x)\frac{\partial u}{\partial x_j}, \frac{\partial v}{\partial x_i}\right)_\Omega\\ &= \sum_{i,j=1}^{n}\int_\Omega a_{ij}(x)\frac{\partial u}{\partial x_j}\frac{\partial v}{\partial x_j}\,dx \end{aligned}$$

and $\tilde{P}_h$ is the orthogonal projection form $L_2(\Gamma)$ onto $\tilde{V}_h$. Later we will use (1.5) with $\varepsilon = \varepsilon(h) = h^\gamma$ for some $\gamma > 0$. The corresponding solution will be denoted by u_h.

Remark 1.1. Note that the procedure described above (i) is well defined directly on $g \in L_2(\Sigma)$, and (ii) gives V_h as subspaces of $H^1(\Omega)$ that are not required to satisfy boundary conditions.

The main goal of this paper is to establish stability and the rates of convergence of the approximation $u_h(t)$ to the original solution $u(t)$. In fact, our main results in the case when V_h consists of piecewise linear functions (see Corollaries 3.1 and 3.2) establish, in particular, that with $\varepsilon = \varepsilon(h) = h$ in (1.5) we have

(1.6) (convergence)

(i) $\|u - u_h\|_{C[0,T;L_2(\Omega)]} \leqq Ch[|\dot{g}|_{H^1(\Sigma)} + |g|_{L_2[0,T;H^1(\Gamma)]}]$,

(ii) $\|u - u_h\|_{C[0,T;H^{1/2-\rho}(\Omega)]} \leqq Ch[|\dot{g}|_{H^{3/2}(\Sigma)} + |g|_{L_2[0,T;H^{3/2}(\Gamma)]}]$

where $\rho > 0$ is arbitrarily small;

(1.7) (stability)

(i) $\|u - u_h\|_{C[0,T;L_2(\Omega)]} \leqq C[|g|_{H^1[0,T;H^{-1/2+\rho}(\Gamma)]} + |g|_{L^2(\Sigma)}]$,

(ii) $\|u - u_h\|_{C[0,T;H^{1/2-\rho}(\Omega)]} \leqq C[|g|_{H^1[0,T;H^\rho(\Gamma)]} + |g|_{H^{1/2-\rho}(\Sigma)}]$

where C stands for a generic constant independent on $h > 0$ and g. For boundary data that display more regularity properties and satisfy the appropriate compatibility conditions, higher-order rates of convergence are given in Corollary 3.2.

Remark 1.2. Note that—in view of the optimal convergence results for the wave equation with homogenous boundary conditions, where an extra derivative in the solution is necessary (see [R1] and also [B1], [D1], [B3]) and optimal regularity of the solutions to Dirichlet problems (see 1.2)—estimates (1.6) are optimal. Although the stability results in (1.7) improve "almost" by one-half derivative the stability estimates implied by the convergence result in (1.6), they are still nonoptimal with respect to the sharp regularity of the solution u. In fact, $g \in L_2(\Sigma)$ will produce the solution $u \in C[0T; L_2(\Omega)]$ (see [L1], [LT2], [LLT]); thus we would expect the stability estimate (1.7)(i) to hold for any $g \in L_2(\Sigma)$ (instead of $\dot{g} \in L_2[0, T; H^{-1/2+\rho}(\Gamma)]$).

Remark 1.3. In the analysis of the approximation error, a crucial role is played by the very special behavior of the traces of hyperbolic solutions (see § 2). In fact, the solutions to wave equations are shown [LLT] to have better regularity on the boundary than interior regularity and the trace theorem would imply. This fact will be used in an essential way in the process of proving (1.6) and (1.7).

Remark 1.4. The results of numerical computations performed with linear splines on two-dimensional domain are given in [LS2]. In fact, the results of [LS2] confirm our theoretical findings presented in this paper.

The outline of the paper is as follows. In § 2 we discuss the properties and regularity of the continuous solution $u(t)$ as well as those of the regularized solution $u_\varepsilon(t)$. In § 3, we define semidiscrete approximating subspaces and approximations of (1.1). The main results of the paper, Theorems 3.1 and 3.2 and Corollaries 3.1 and 3.2, are stated at the end of § 3. The proofs of these results are relegated to § 5, while § 4 is devoted to a number of technical lemmas needed for those proofs.

The following notation will be used in the paper. $(\cdot,)$, (respectively, $\|\cdot\|$) denotes the usual $L_2(\Omega)$ inner product (respectively, the norm in $L_2(\Omega)$). $\langle \cdot, \cdot \rangle$ (respectively, $|\cdot|$) denotes the $L_2(\Gamma)$ inner product (respectively, the norm in $L_2(\Gamma)$). $H^s(\Omega)$, $H^{r,s}(Q)$, for $r, s > 0$, are the usual Sobolev spaces defined as in [LM]; if $r = s$ we use $H^r(Q) \equiv H^{r,r}(Q)$, $H^{-s} = (H^s)'$, $s \geqq 0$, where X' stands for the dual (pivotal) space to X. $\mathscr{L}(X \to Y)$ denotes the space of linear transformations from X to Y. $L_p[0, T; X]$, $1 \leqq p \leqq \infty$, denotes the space of $u(t) \in X$ such that $L_p[0, T]$ norm of $\|u(t)\|_x$ is well

defined. A^α, $0 \leqq \alpha \leqq 1$, stands for fractional powers of operator A (A^α are well defined for positive and self-adjoint operators; see, e.g., [P1]).

2. Regularity properties of the continuous solutions and some background material. To give a proper foundation to our approximation results, we should first ask what is the optimal regularity of the solution u for a given boundary data g. Until recently, the available regularity results (given in [LM]) were far from optimal. Only a few years ago, the issue of optimal regularity was settled. Below we collect some of these results.

THEOREM 2.1 [L2], [LLT], [LT1], [LT2]. *With $g \in L_2(\Sigma)$, let u be the solution to* (1.1). *Then*

(a) $u \in C[0, T; L_2(\Omega)]$,

(b) $\dot{u} \in C[0, T; (H_0^1(\Omega))']$,

(c) $\partial u/\partial \eta \in H^{-1,-1}(\Sigma)$.

If $g \in H^{r,r}(\Sigma)$, $r > 0$ and g satisfies the appropriate compatibility conditions, then

(a') $u \in C[0, T; H^r(\Omega)]$,

(b') $\dot{u} \in C[0, T; H^{r-1}(\Omega)]$,

(c') $\partial u/\partial \eta \in H^{r-1,r-1}(\Sigma)$.

Remark 2.1. Note that the boundary regularity results given in Theorem 2.1(c) and (c') do not follow from the interior regularity of u. Solutions behave "better" on the boundary than should follow from the interior regularity (a), (a') and the trace theory.

Regularity properties of the solutions $u_\varepsilon(t)$ to problem (1.4) will play a crucial role in establishing the error estimates for $u_{h,\varepsilon} - u_\varepsilon$. These properties have been studied recently in [L1] and [LS]. Below we collect some of these results.

THEOREM 2.2 [L1], [LS]. *Let u_ε be the solution to* (1.4). *Then*

(a) $\|u_\varepsilon\|_{C[0,T;L_2(\Omega)]} \leqq^1 C|g|_{L_2(\Sigma)}$.

Assuming additionally that $g(0) = 0$, we have

(b) $\|u_\varepsilon\|_{H^{1,1}(Q)} + \|u_\varepsilon\|_{C[0,T;H^1(\Omega)]} \leqq C|g|_{H^{1,1}(\Sigma)}$,

(c) $|u_\varepsilon|_\Gamma|_{L_2[0,T;H^1(\Gamma)]} \leqq C|g|_{H^{1,1}(\Sigma)}$,

(d) $|\dot{u}_\varepsilon|_\Gamma|_{L_2(\Sigma)} + \left|\frac{\partial u_\varepsilon}{\partial \eta_A}\right|_{L_2(\Sigma)} \leqq C|g|_{H^{1,1}(\Sigma)}$.

More generally, if g satisfies the appropriate compatibility conditions guaranteeing that $u_\varepsilon \in C[0, T; H^s(\Omega)]$ for $s > 1$, then

(e) $\|u_\varepsilon\|_{H^{s,s}(Q)} + \|u_\varepsilon\|_{C[0,T;H^s(\Omega)]} \leqq C|g|_{H^{s,s}(\Sigma)}$,

(f) $|u_\varepsilon|_\Gamma|_{L_2[0,T;H^s(\Gamma)]} \leqq C|g|_{H^{s,s}(\Sigma)}$,

(g) $|\dot{u}_\varepsilon|_\Gamma|_{H^{s-1,s-1}(\Sigma)} + \left|\frac{\partial u_\varepsilon}{\partial \eta}\right|_{H^{s-1,s-1}(\Sigma)} \leqq C|g|_{H^{s,s}(\Sigma)}$

where the constant C is uniform with respect to $\varepsilon > 0$.

[1] From now on we assume that a generic constant C depends on neither $\varepsilon > 0$ nor $h > 0$.

Remark 2.2. Note that the regularity properties of $u_\varepsilon(t)$ recover, uniformly in the parameter $\varepsilon > 0$, the regularity properties of the solution $u(t)$ to (1.1). This fact, together with convergence results given by Theorem 2.1, shows that (1.4) is a "good" approximation of (1.1). As already mentioned, the "more natural" approach—scheme (1.4) with $\beta = I$—does not have the same properties.

Later we will also use the regularity properties at the solutions to the following "elliptic problem":

$$\begin{aligned} &A(x,\partial)v_\varepsilon = f \quad \text{in } \Omega, \\ &\varepsilon\frac{\partial v_\varepsilon}{\partial \eta} + \beta v_\varepsilon = 0 \quad \text{on } \Gamma. \end{aligned} \tag{2.1}$$

Define the operator $A_\varepsilon : L_2(\Omega) \to L_2(\Omega)$ by $A_\varepsilon u \equiv A(x,\partial)u$ on $\mathscr{D}(A_\varepsilon) = \{u \in L_2(\Omega)\colon A(x,\partial)u \in L_2(\Omega);\ \varepsilon(\partial u/\partial \nu) + \beta u = 0 \text{ on } \Gamma\}$.

With the definition above, (2.1) is equivalent to

$$A_\varepsilon v_\varepsilon = f. \tag{2.1'}$$

It can be easily shown that A_ε is self-adjoint on $L_2(\Omega)$. The bilinear form $a_\varepsilon(u, v)$ associated with A_ε is given by

$$a_\varepsilon(u, v) \equiv -(A_\varepsilon u, v) = a(u, v) + 1/\varepsilon\langle \beta u, v\rangle \quad \text{for all } u, v \in H^1(\Omega);\ u|_\Gamma, v|_\Gamma \in H^1(\Gamma). \tag{2.2}$$

The following regularity results for (2.1) have been established in [LS].

LEMMA 2.3 [LS]. *Let $v_\varepsilon = A_\varepsilon^{-1} f$, the solution of* (2.1). *Then*

$$\|v_\varepsilon\|_{H^1(\Omega)} + \frac{1}{\sqrt{\varepsilon}}|v_\varepsilon|_{H^1(\Gamma)} + \left|\frac{\partial v_\varepsilon}{\partial \eta}\right|_{H^{-1/2}(\Gamma)} + \frac{1}{\varepsilon}|\beta v_\varepsilon|_{H^{-1/2}(\Gamma)} \leqq C\|f\|_{H^{-1}(\Omega)}, \tag{2.3}$$

$$\|v_\varepsilon\|_{H^2(\Omega)} + \frac{1}{\sqrt{\varepsilon}}|v_\varepsilon|_{H^2(\Gamma)} \leqq C\|f\|_{L_2(\Omega)}, \tag{2.4}$$

$$\|v_\varepsilon\|_{H^s(\Omega)} + \frac{1}{\sqrt{\varepsilon}}|v_\varepsilon|_{H^s(\Gamma)} \leqq C\|f\|_{H^{s-2}(\Omega)}, \qquad 1 \leqq s \leqq 2. \tag{2.5}$$

Later, we will find it convenient to represent the solution $u(t)$ of (1.1) as well as the solution $u_\varepsilon(t)$ of (1.4) in semigroup form. To accomplish this, let us define the operator $A: L_2(\Omega) \to L_2(\Omega)$ given by

$$Au = A(x,\partial)u, \qquad u \in \mathscr{D}(A) \equiv H_0^1(\Omega) \cap H^2(\Omega).$$

It is well known that A is the generator of an analytic semigroup on $L_2(\Omega)$ and it generates cosine $C(t)$ and sine $S(t)$ operators in $L_2(\Omega)$ (see [F1]). Next we define the so-called "Dirichlet map":

$D: L_2(\Gamma) \to L_2(\Omega)$ by

$$\begin{cases} A(x,\partial)Dg = 0 & \text{in } \Omega, \\ Dg|_\Gamma = g & \text{in } \Gamma. \end{cases} \tag{2.6}$$

From elliptic theory [LM] we know that

$$D \in \mathscr{L}(H^s(\Gamma) \to H^{s+1/2}(\Omega)) \quad \text{for all real } s. \tag{2.7}$$

Using the definitions above, we are in a position to represent the solution $u(t)$ in the semigroup form as in [LT1]:

$$u(t) = A\int_0^t S(t-z)Dg(z)\,dz \equiv (Lg)(t). \tag{2.8}$$

Theorem 2.1 gives

$$L \in \mathscr{L}(L_2(\Sigma) \to C[0, T; L_2(\Omega)]). \tag{2.9}$$

Similarly, we will represent the solution $u_\varepsilon(t)$ of (1.4) via the semigroup formula. To accomplish this we introduce the map $N_\varepsilon : L_2(\Gamma) \to L_2(\Omega)$ defined by

$$\begin{aligned} &A(x, \partial)N_\varepsilon g = 0 && \text{in } \Omega, \\ &\varepsilon\frac{\partial}{\partial\eta}(N_\varepsilon g) + \beta(N_\varepsilon g) = \beta g && \text{on } \Gamma. \end{aligned} \tag{2.10}$$

It can be shown [LS] that

$$N_\varepsilon \in \mathscr{L}(L_2(\Gamma) \to H^{1/2}(\Omega)) \text{ with the norm independent on } \varepsilon > 0. \tag{2.11}$$

The following identities are simple consequences of the Green formula (see [LS]):

$$\begin{aligned} &N_\varepsilon^* A_\varepsilon u = \frac{\partial}{\partial\eta} u \quad \forall u \in \mathscr{D}(A_\varepsilon), \\ &N_\varepsilon^* A_\varepsilon u = \frac{1}{\varepsilon}\beta u \quad \forall u \in C^\infty(\Omega). \end{aligned} \tag{2.12}$$

Since A_ε is self-adjoint and the spectrum of A_ε is on the real negative axis, A_ε generates cosine $C_\varepsilon(t)$ and sine $S_\varepsilon(t)$ operators on $L_2(\Omega)$. Therefore, following the same arguments as in [LT1], we show that the solution $u_\varepsilon(t)$ of (1.4) can be written as

$$u_\varepsilon(t) = A_\varepsilon\int_0^t S_\varepsilon(t-z)N_\varepsilon g(z)\,dz \equiv (L_\varepsilon g)(t). \tag{2.13}$$

From Theorem 2.2(a) it follows that

$$L_\varepsilon \in \mathscr{L}(L_2(\Sigma) \to C[0, T; L_2(\Omega)]) \text{ with the norm } \textit{independent} \text{ of } \varepsilon > 0. \tag{2.14}$$

Considering L_ε as acting from $L_2(\Sigma)$ into $L_2(Q)$, we compute its adjoint $L_\varepsilon^* : L_2(Q) \to L_2(\Sigma)$:

$$\begin{aligned} (L_\varepsilon^* f)(t) &= N_\varepsilon^* A_\varepsilon \int_t^T S_\varepsilon(z-t)f(z)\,dz \quad \text{by (2.8)} \\ &= \frac{\partial}{\partial\eta}\int_t^T S_\varepsilon(z-t)f(z)\,dz. \end{aligned} \tag{2.15}$$

As a consequence of (2.14), we have

$$L_\varepsilon^* \in \mathscr{L}(L_1[0, T; L_2(\Omega)] \to L_2(\Sigma)) \text{ with the norm independent of } \varepsilon > 0. \tag{2.16}$$

The solution $u_\varepsilon(t)$ given by (2.13) (or equivalently by (1.4)) can also be represented as the solution of the following abstract ordinary differential equation problem:

$$\begin{aligned} &\ddot{u}_\varepsilon(t) = A_\varepsilon u_\varepsilon(t) - A_\varepsilon N_\varepsilon g(t) \quad \text{on } \mathscr{D}(A_\varepsilon)', \\ &u_\varepsilon(0) = \dot{u}_\varepsilon(0) = 0. \end{aligned} \tag{2.17}$$

Equations (2.17) together with (2.8) and (2.14) lead to the following variational formulation of problem (1.4) (see also [L1]):

(2.18) $(\ddot{u}_\varepsilon(t), \phi)+a(u_\varepsilon(t), \phi)+1/\varepsilon\langle\beta u_\varepsilon(t), \phi\rangle=1/\varepsilon\langle\beta g, \phi\rangle$ for all $\phi\in\mathcal{D}(A_\varepsilon^{1/2})\equiv\{\phi\in H^1(\Omega), \phi_\Gamma\in H^1(\Gamma)\}$.

Note that the semidiscrete scheme (1.5) can be obtained from (2.18) by restricting the test functions ϕ to lie in the finite-dimensional subspace V_h.

3. Approximating subspaces and semidiscrete approximations of (1.4) and (1.1), and statement of main results. Let $h>0$ be the parameter of discretization tending to zero. Let V_h be a family of the finite-dimensional subspaces of $H^1(\Omega)$, of order $r\geqq 2$ satisfying local and inverse assumptions (see [B1, p. 98]) in addition to the following properties:

(3.1) (a) $V_h|_\Gamma\subset H^1(\Gamma)$;

(b) $\forall u\in H^s(\Omega)$

$$\inf_{\phi_h\in V_h}[\|u-\phi_h\|+h\|u-\phi_h\|_{H^1(\Omega)}+h^{1/2}|u-\phi_h|+h^{3/2}|u-\phi_h|_{H^1(\Gamma)}]$$

$$\leqq Ch^s\|u\|_{H^s(\Omega)}, \qquad \tfrac{3}{2}\leqq s\leqq r;$$

(c) $\|u-P_hu\|_{H^l(\Omega)}\leqq Ch^{s-l}\|u\|_{H^s(\Omega)}$, $0\leqq s\leqq r$, $0\leqq l<\frac{3}{2}$, $s-l\geqq 0$

where P_h is the orthogonal projection in $L_2(\Omega)$ (with respect to $L_2(\Omega)$ as inner product) onto V_h.

(d) For any $\phi_h\in\tilde{V}_h\equiv V_h|_\Gamma$,[2] there exists $\phi_h\in V_h$ such that $\phi_h|_\Gamma=\tilde{\phi}_h$ and $\|\phi_h\|_{H^s(\Omega)}\leqq C|\tilde{\phi}_h|_{H^{s-1/2}(\Gamma)}$, $0<s\leqq 1$.

It is well known that properties are standard and are satisfied by piecewise polynomials defined on the uniform mesh. Property (3.1)(d) with $s=1$ has been shown to be true in [B4] for polynomials defined on triangles. Arguments similar to those in [B4] have been used in [LS2] to prove that the inequality in (3.1)(d) can be extended to negative norms (i.e., $0<s<1$).

Below we state our main results on stability and the rate of convergence of the solution $u_{h,\varepsilon}(t)$ to $u_\varepsilon(t)$ in $H^s(\Omega)$ topology $0\leqq s<\frac{1}{2}$.

THEOREM 3.1 (stability). *Let u_ε be the weak solution of problem* (1.4) *and let $u_{h,\varepsilon}$ be the approximate solution of problem* (1.5). *Then with $\rho>0$ arbitrarily small, we have*:

(i) $\|u_{h,\varepsilon}\|_{C[0,T;H^{(1/2)-\rho}(\Omega)]}\leqq C|g|_{H^1[0,T;H^\rho(\Gamma)]}$.

(ii) $$\|u_{h,\varepsilon}\|_{C[0,T;L_2(\Omega)]}\leqq C\left[1+\frac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right]|g|_{H^1[0,T;H^{-(1/2)+\rho}(\Gamma)]}$$

where $\sigma\geqq 1$ and $r\geqq 1+(\sigma-1)/2\rho$.

(iii) *If in addition we assume that $V_h^0\subset V_h$,[3] then*

$$\|u_{h,\varepsilon}\|_{C[0,T;L_2(\Omega)]}\leqq C|g|_{H^1[0,T;H^{-1/2+\rho}(\Gamma)]}.$$

Here C is independent on h, ε, and g.

THEOREM 3.2 (convergence). *Let u_ε (respectively, $u_{h,\varepsilon}$) be the solution of* (1.4) (*respectively*, (1.5)). *Assume that g satisfies the appropriate compatibility conditions at*

[2] It is well known that $\tilde{V}_h\subset H^1(\Gamma)$ is an approximating subspace of $L_2(\Gamma)$ of the same order r as V_h (see [B2, Thm. 4.22]).

[3] V_h^0 stands for the subspace of $H_0^1(\Omega)\cap V_h$ with approximating properties (3.1).

the origin to guarantee that $\dot{u} \in C[0T; H^s(\Omega)]$. *Then for any* $\rho > 0$ *arbitrarily small,* $\delta \geqq 1$, $s \geqq 1$ *there exists a constant* C *independent of* h, ε, *and* g *such that*:

(i) $$\|u_\varepsilon - u_{h,\varepsilon}\|_{C[0,T;L_2(\Omega)]} \leqq Ch^{s-\rho}\left[1+\frac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right]^2 [|\dot{g}|_{H^s(\Sigma)}+|g|_{L_2[0,T;H^s(\Gamma)]}]$$

where $r \geqq 1+(s-1)(\sigma-1)/\rho$.[4]

(ii) $$\|u_\varepsilon - u_{h,\varepsilon}\|_{C[0,T;H^{(1/2)-\rho}(\Omega)]} \leqq Ch^{s-(1/2)-2\rho} f(h)[|\dot{g}|_{H^s(\Sigma)}+|g|_{L_2[0,T;H^s(\Gamma)]}]$$

where

$$f(h) \equiv \left\{ \begin{array}{ll} h^\rho & \text{if } s < \frac{3}{2} \\ \left(1+\dfrac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right) & \text{if } r \geqq 1+\dfrac{(s-1)(\sigma-1)}{2\rho} \end{array} \right\}.$$

If in addition we assume that $V_h^0 \subset V_h$, *then for* $1 \leqq s \leqq r-\frac{1}{2}$ *we have*:

(iii) $$\|u_\varepsilon - u_{h,\varepsilon}\|_{C[0,T;L_2(\Omega)]} \leqq Ch^s[|\dot{g}|_{H^s(\Sigma)}+|g|_{L_2[0,T;H^s(\Gamma)]}].$$

(iv) $$\|u_\varepsilon - u_{h,\varepsilon}\|_{C[0,T;H^{(1/2)-\rho}(\Omega)]} \leqq Ch^{s-1/2}[|\dot{g}|_{H^s(\Sigma)}+|g|_{L_2[0,T;H^s(\Gamma)]}].$$

Let us set in (1.5) $\varepsilon = \varepsilon(h) = h^\gamma$ for some $\gamma > 1$, and let us denote the corresponding solution $u_{h,\varepsilon(h)}$ by u_h. After combining the results of Theorems 1.1, 3.1, and 3.2 we obtain the following corollary.

COROLLARY 3.1 (stability).

(i) $$\|u_h - u\|_{C[0,T;H^{(1/2)-\rho}(\Omega)]} \leqq C[|g|_{H^1[0,T;H^\rho(\Gamma)]}+|g|_{H^{(1/2)-\rho}(\Sigma)}].$$

(ii) $$\|u_h - u\|_{C[0,T;L_2(\Omega)]} \leqq C[|g|_{H^1[0,T;H^{-1/2+\rho}(\Gamma)]}+|g|_{L_2(\Sigma)}]$$

where $r \geqq 1+(1+\gamma)/2\rho$.

(iii) *If* $V_h^0 \subset V_h$ *then*

$$\|u_h - u\|_{C[0,T;L_2(\Omega)]} \leqq C[|g|_{H^1[0,T;H^{-(1/2)+\rho}(\Gamma)]}+|g|_{L_2(\Sigma)}].$$

COROLLARY 3.2 (convergence). *Let* u (*respectively,* u_h) *be the solution of problem* (1.1) (*respectively,* (1.5) *with* $\varepsilon(h) = h^\gamma$ *for some* $\gamma > 0$). *Then for any* $\rho > 0$ *arbitrarily small,* $s \geqq 1$ *we have the following*:

(i) $$\|u - u_h\|_{C[0,T;L_2(\Omega)]} \leqq C[h^{s-\rho}+h^\gamma][|\dot{g}|_{H^s(\Sigma)}+|g|_{L_2[0,T;H^s(\Gamma)]}]$$

where $r \geqq 1+(s-1)(1+\gamma)/\rho$.

(ii) $$\|u - u_h\|_{C[0,T;H^{(1/2)-\rho}(\Omega)]} \leqq C[h^{s-(1/2)-\rho}+h^\gamma][|\dot{g}|_{H^s(\Sigma)}+|g|_{L_2[0,T;H^s(\Gamma)]}]$$

where $r \geqq 1+(s-1)(1+\gamma)/\rho$ *if* $s \geqq \frac{3}{2}$.

(iii) *If in addition we assume that* $V_h^0 \subset V_h$, *then* (i) *and* (ii) *hold for any* $1 \leqq s \leqq r-\frac{1}{2}$ *and* $\rho = 0$.

Remark 3.1. Note that the rates of convergence established in part (iii) (respectively, (i), (ii)) are optimal (respectively, quasi-optimal) in the following sense: they reconstruct the optimal regularity of the solution (compare Theorem 2.1) (modulo the usual loss of one derivative). The estimates of the error given in part (iii) under the additional assumption that $V_h^0 \subset V_h$ reconstruct also the best approximation properties of the underlined approximating subspaces. If condition $V_h^0 \subset V_h$ fails, then for $s > 1$ we need to use higher-order polynomials to obtain the quasi-optimal error reflecting the optimal regularity of the solutions.

[4] If $s = 1$, then we can take $\rho = 0$, $\delta > 1$ arbitrary, and $r \geqq 1$.

Remark 3.2. Stability estimates provided by Corollary 3.1 improve by one-half derivative the stability results "implied" by the convergence results. Nevertheless, the stability estimates are still nonoptimal, since we are loosening one-half derivative with respect to the optimal regularity of the solutions (see Theorem 2.1).

Remark 3.3. We can, of course, interpolate between the results of Corollaries 3.1 and 3.2. For example, interpolation between the $L_2(\Omega)$-estimates of Corollaries 3.1 and 3.2 applied with $s=\gamma=1$ yields

$$\|u-u_h\|_{C[0,T;L_2(\Omega)]} \leqq Ch^{(1-Q)}[|\dot{g}|_{H^{1-3/2Q+Q\rho,1-Q}(\Sigma)}+|g|_{L_2[0,T;H^{1-3/2Q+Q\rho}(\Gamma)]}]$$

where $\rho>0$ is arbitrarily small and $0\leqq Q\leqq 1$.

The rest of the paper is devoted to the proofs of the main results.

4. Lemmas needed for the proofs of Theorems 3.1 and 3.2. The proofs of Theorems 3.1 and 3.2 will follow through the sequence of lemmas.

LEMMA 4.1. *Let $y\in H^{1+s}(\Omega)$ and $y|_\Gamma\in H^{1+s}(\Gamma)$. Then there exists $\hat{y}_h\in V_h$ such that*

$$\|y-\hat{y}_h\|_{H^1(\Omega)}+\frac{1}{\sqrt{\varepsilon}}|y-\hat{y}_h|_{H^1(\Gamma)} \leqq Ch^s\left[\|y\|_{H^{1+s}(\Omega)}+\frac{1}{\sqrt{\varepsilon}}|y|_{H^{1+s}(\Gamma)}\right], \qquad 0\leqq s<\frac{1}{2}. \tag{4.1}$$

If in addition we assume that $V_h^0\subset V_h$, then (4.1) *holds for $0\leqq s\leqq r-\frac{3}{2}$.* (4.2)

Otherwise (4.3)

$$\|y-\hat{y}_h\|_{H^1(\Omega)}+\frac{1}{\sqrt{\varepsilon}}|y-\hat{y}_h|_{H^1(\Gamma)} \leqq C(\rho)h^{s-\rho}\left[\frac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}+1\right]\|y\|_{H^{s+1}(\Omega)}+\frac{C}{\sqrt{\varepsilon}}h^s|y|_{H^{1+s}(\Gamma)}$$

where $\rho\geqq 0$, $0\leqq s\leqq r-\frac{3}{2}$, $\sigma\geqq 1$; $r\geqq 1+s(\sigma-1)/2\rho$, and C does not depend on h, ε, y.

Proof. Define $y^*=Dy|_\Gamma$, where $D: L_2(\Gamma)\to L_2(\Omega)$ is given by (2.6). From (2.7) it follows that

$$\|y^*\|_{H^{1+\alpha+1/2}(\Omega)} \leqq C|y|_\Gamma|_{H^{1+\alpha}(\Gamma)} \quad \text{for all } \alpha\in R. \tag{4.4}$$

Let $z\equiv y-y^*$. Then $z|_\Gamma=0$ and from (4.4) (applied with $\alpha=s-\frac{1}{2}$) it follows

$$\|z\|_{H^{1+s}(\Omega)} \leqq C[\|y\|_{H^{1+s}(\Omega)}+|y_{|\Gamma}|_{H^{1/2+s}(\Gamma)}] \quad \text{for all real } s. \tag{4.5}$$

If $s<\frac{1}{2}$, by Theorem 4.2.2 of [B1], we can select $z_h\in V_h$ such that

$$\|z-z_h\|_{H^1(\Omega)} \leqq Ch^s\|z\|_{H^{1+s}(\Omega)} \quad \text{and} \quad z_h|_\Gamma=0. \tag{4.6a}$$

If $V_h^0\subset V_h$, by the approximation properties of V_h^0 we can take $z_h\in V_h^0$ such that (4.6a) holds for all $0\leqq s\leqq r-1$. Otherwise, by applying Theorem 4.4 of [B3], we can select $z_h\in V_h$ such that

$$\begin{aligned}&\|z-z_h\|_{H^1(\Omega)} \leqq C(\rho)h^{s-\rho}\|z\|_{H^{s+1}(\Omega)},\\ &|z_h|_{H^1(\Gamma)} \leqq C(\rho)h^{s-\rho+\sigma/2-1}\|z\|_{H^{s+1}(\Omega)}\end{aligned} \tag{4.6b}$$

where $\rho>0$ is arbitrary, $\sigma\geqq 1$, and $r\geqq 1+s(\sigma-1)/2\rho$.

Next define $\hat{y}_h\equiv z_h+y_h^*\in V_h$, where $y_h^*\equiv P_hy^*$. From (3.1c) applied with $l=1$ and for $0\leqq s\leqq r-1$ it follows that

$$\begin{aligned}\|\hat{y}_h-y\|_{H^1(\Omega)} &\leqq \|z-z_h\|_{H^1(\Omega)}+\|y^*-y_h^*\|_{H^1(\Omega)} \leqq \|z-z_h\|_{H^1(\Omega)}+Ch^s\|y^*\|_{H^{1+s}(\Omega)}\\ &\leqq \|z-z_h\|_{H^1(\Omega)}+Ch^s|y_{|\Gamma}|_{H^{s+(1/2)}(\Gamma)},\end{aligned} \tag{4.7}$$

$$\frac{1}{\sqrt{\varepsilon}}|\hat{y}_h-y|_{H^1(\Gamma)} \leqq \frac{1}{\sqrt{\varepsilon}}|y^*-y_h^*|_{H^1(\Gamma)}+\frac{1}{\sqrt{\varepsilon}}|z_h|_{H^1(\Gamma)}. \tag{4.8}$$

On the other hand, by (3.1c), inverse approximation properties, and the approximating properties of $\tilde{V}_h$ it follows that

$$|y^* - P_h y^*|_{H^1(\Gamma)} \leqq Ch^s \|y^*\|_{H^{s+3/2}(\Omega)}, \qquad 0 \leqq s \leqq r - \tfrac{3}{2}.$$

Thus, for $0 \leqq s \leqq r - \frac{3}{2}$

$$|y^* - y_h^*|_{H^1(\Gamma)} \leqq Ch^s \|y^*\|_{H^{s+3/2}(\Omega)} \leqq Ch^s [y_{|\Gamma}|_{H^{s+1}(\Gamma)}] \tag{4.9}$$

where in the last inequality we have used again (2.7).

After collecting the results given in (4.5), (4.6a), and (4.7)-(4.9) we arrive at the desired conclusion stated in (4.1) and (4.2). As for (4.3), this follows from (4.5), (4.6b), and (4.7)-(4.9). □

LEMMA 4.1′. *Let* $y \in H^{1+s}(\Omega)$, $\partial y/\partial \eta|_\Gamma \in H^{s-1}(\Gamma)$, *and*

$$\varepsilon \frac{\partial y}{\partial \eta} + \beta y = \beta g_h \quad \text{on } \Gamma \quad \text{where } g_h \in \tilde{V}_h.$$

Then there exists $\hat{y}_h \in V_h$ *such that*

$$\|y - \hat{y}_h\|_{H^1(\Omega)} + \frac{1}{\sqrt{\varepsilon}} |y - \hat{y}_h|_{H^1(\Gamma)} \leqq Ch^s \left[\|y\|_{H^{1+s}(\Omega)} + |g_h|_{H^{s+1}(\Gamma)} + \sqrt{\varepsilon} \left| \frac{\partial y}{\partial \eta} \right|_{H^{s-1}(\Gamma)} \right], \qquad 0 \leqq s < \frac{1}{2}. \tag{4.10}$$

If in addition $V_h^0 \subset V_h$, *then* (4.10) *holds for* $0 \leqq s \leqq r - \frac{3}{2}$. (4.11)

Otherwise, (4.12)

$$\|y - \hat{y}_h\|_{H^1(\Omega)} + \frac{1}{\sqrt{\varepsilon}} |y - \hat{y}_h|_{H^1(\Gamma)} \leqq C(\rho) h^{s-\rho} \left(1 + \frac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right) \cdot \left[\|y\|_{H^{1+s}(\Omega)} + |g_h|_{H^{s+1}(\Gamma)} + \sqrt{\varepsilon} \left| \frac{\partial y}{\partial \nu} \right|_{H^{s-1}(\Gamma)} \right]$$

where $\rho > 0$, $0 \leqq s \leqq r - \frac{3}{2}$, $\delta \geqq 1$, *and* $r \geqq 1 + s(\sigma - 1)/2\rho$.

Proof. Since $g_h \in \tilde{V}_h$, there exists $\phi_h \in V_h$ such that $\phi_h|_\Gamma = g_h$ and

$$\|\phi_h\|_{H^{s+1}(\Omega)} \leqq C|g_h|_{H^{s+1}(\Gamma)}, \qquad 0 \leqq s \leqq r - 1. \tag{4.13}$$

Let $\hat{y}_h^1$ be an approximation of $y - \phi_h$ selected according to Lemma 4.1.

Define $\hat{y}_h \equiv \hat{y}_h^1 - \phi_h$. Then

$$\|y - \hat{y}_h\|_{H^1(\Omega)} + \frac{1}{\sqrt{\varepsilon}} |y - \hat{y}_h|_{H^1(\Gamma)} = \|y - \phi_h - \hat{y}_h^1\|_{H^1(\Omega)} + \frac{1}{\sqrt{\varepsilon}} |y - \phi_h - \hat{y}_h^1|_{H^1(\Gamma)}. \tag{4.14}$$

Since $(y - \phi_h)|_\Gamma = -\varepsilon \beta^{-1} (\partial y/\partial \eta)$, we obtain

$$\frac{1}{\sqrt{\varepsilon}} |y - \phi_h|_{H^{1+s}(\Gamma)} \leqq \sqrt{\varepsilon} \left| \beta^{-1} \frac{\partial y}{\partial \eta} \right|_{H^{1+s}(\Gamma)} \leqq C\sqrt{\varepsilon} \left| \frac{\partial y}{\partial \eta} \right|_{H^{s-1}(\Gamma)} \tag{4.15}$$

where in the last inequality we have used the regularity of β as stated in (1.4′). Now, the assessments (4.10)-(4.12) of Lemma (4.1′) follow directly from Lemma 4.1 applied to $y - \phi_h$ and from the regularity properties (4.13) and (4.15). □

Next let us introduce the operator $P_{h,\varepsilon}: \mathcal{D}(A_\varepsilon^{1/2}) \to V_h$ defined as the projection onto V_h with respect to the norm generated by the bilinear form $a_\varepsilon(u, v)$. More precisely, $y_h \equiv P_{h,\varepsilon} y$ if and only if

$$a_\varepsilon(y_h - y, \phi_h) = 0 \quad \text{for all } \phi_h \in V_h. \tag{4.16}$$

The following lemma gives the estimates for the rate of convergence of $P_{h,\varepsilon} y$ to y.

LEMMA 4.2. *Let $y \in H^{1+s}(\Omega)$. Then*

$$\|P_{h,\varepsilon} y - y\|_{H^1(\Omega)} + \frac{1}{\sqrt{\varepsilon}} |P_{h,\varepsilon} y - y|_{H^1(\Gamma)} \leqq Ch^s \left[\|y\|_{H^{s+1}(\Omega)} + \frac{1}{\sqrt{\varepsilon}} |y|_\Gamma|_{H^{1+s}(\Gamma)} \right], \tag{4.17a}$$

$$\|P_{h,\varepsilon} y - y\|_{H^{1-s}(\Omega)} \leqq Ch^{2s} \left[\|y\|_{H^{1+s}(\Omega)} + \frac{1}{\sqrt{\varepsilon}} |y|_\Gamma|_{H^{1+s}(\Gamma)} \right], \qquad 0 \leqq s < \frac{1}{2}, \tag{4.17b}$$

If $V_h^0 \subset V_h$ then (4.17a) *remains valid for all $0 \leqq s \leqq r - \frac{3}{2}$,* (4.18a)

$$\|P_{h,\varepsilon} y - y\| \leqq Ch^{s+1} \left[\|y\|_{H^{1+s}(\Omega)} + \frac{1}{\sqrt{\varepsilon}} |y|_\Gamma|_{H^{1+s}(\Gamma)} \right], \qquad 0 \leqq s \leqq r - \frac{3}{2}, \tag{4.18b}$$

in the general case where $r \geqq 1 + s(\sigma - 1)/2\rho$, $0 \leqq s \leqq r - \frac{3}{2}$, $\sigma > 1$, $\rho \geqq 0$ arbitrary, we have

$$\begin{aligned} &\|P_{h,\varepsilon} y - y\|_{H^1(\Omega)} + \frac{1}{\sqrt{\varepsilon}} |P_{h,\varepsilon} y - y|_{H^1(\Gamma)} \\ &\quad \leqq C(\rho) h^{s-\rho} \left[1 + \frac{h^{\sigma/2-1}}{\sqrt{\varepsilon}} \right] \left[\|y\|_{H^{1+s}(\Omega)} + \frac{1}{\sqrt{\varepsilon}} |y|_{H^{s+1}(\Gamma)} \right], \end{aligned} \tag{4.19a}$$

$$\|P_{h,\varepsilon} y - y\| \leqq C(\rho) h^{s+1-2\rho} \left(1 + \frac{h^{\sigma/2-1}}{\sqrt{\varepsilon}} \right)^2 \left[\|y\|_{H^{1+s}(\Omega)} + \frac{1}{\sqrt{\varepsilon}} |y|_{H^{s+1}(\Gamma)} \right]. \tag{4.19b}$$

Proof. For a given $y \in H^{1+s}(\Omega)$ let $\hat{y}_h$ be the element in V_h chosen according to Lemma 4.1. Then with $y_h \equiv P_{h,\varepsilon} y$ we have

$$a_\varepsilon(y_h - \hat{y}_h, v_h) = a_\varepsilon(y - \hat{y}_h, v_h), \qquad v_h \in V_h.$$

Setting $v_h = y_h - \hat{y}_h$ yields

$$\|y_h - \hat{y}_h\|_{H^1(\Omega)}^2 + \frac{1}{\varepsilon} |\beta^{1/2}(y_h - \hat{y}_h)|^2 \leqq C \left[\|\hat{y}_h - y\|_{H^1(\Omega)}^2 + \frac{1}{\varepsilon} |\hat{y}_h - y|_{H^1(\Gamma)}^2 \right].$$

Statements (4.17a), (4.18a), and (4.19a) are now direct consequences of Lemma 4.1 and triangle inequality.

As for (4.17b), (4.18b), and (4.19b) we use the "duality argument." Indeed, let $p \in L_2(\Omega)$. Define v_ε as the solution of

$$A_\varepsilon v_\varepsilon = p. \tag{4.20}$$

With the notation above we have

$$(y - P_{h,\varepsilon} y, P) = (y - P_{h,\varepsilon} y, A_\varepsilon v_\varepsilon) = a_\varepsilon(y - P_{h,\varepsilon} y, v_\varepsilon) = a_\varepsilon(y - P_{h,\varepsilon} y, v_\varepsilon - \hat{v}_{h\varepsilon})$$

where in the last step we have used (4.16) with $\hat{v}_{h\varepsilon}$—an approximation of v_ε chosen

according to Lemma 4.1. Hence

$$|(y-P_{h,\varepsilon}y,\,p)| \leqq C\|y-P_{h,\varepsilon}y\|_{H^1(\Omega)}\|v_\varepsilon-\hat{v}_{h,\varepsilon}\|_{H^1(\Omega)}+\frac{1}{\varepsilon}|y-P_{h,\varepsilon}y|_{H^1(\Gamma)}|v_\varepsilon-\hat{v}_{h,\varepsilon}|_{H^1(\Gamma)}$$

$$\leqq Ch^s\left[\|y\|_{H^{1+s}(\Omega)}+\frac{1}{\sqrt{\varepsilon}}|y|_\Gamma|_{H^{1+s}(\Gamma)}\right] \tag{4.21}$$

$$\cdot\begin{cases} h^s\left[\|v_\varepsilon\|_{H^{1+s}(\Omega)}+\dfrac{1}{\sqrt{\varepsilon}}|v_\varepsilon|_{H^{1+s}(\Gamma)}\right], & 0\leqq s<\dfrac{1}{2} \\ h\left[\|v_\varepsilon\|_{H^2(\Omega)}+\dfrac{1}{\sqrt{\varepsilon}}|v_\varepsilon|_{H^2(\Gamma)}\right], & 0\leqq s\leqq r-1 \quad \text{if } V_h^0\subset V_h \end{cases}$$

(by Lemma 2.3, (2.4), and (2.5))

$$\leqq Ch^s\left[\|y\|_{H^{1+s}(\Omega)}+\frac{1}{\sqrt{\varepsilon}}|y|_\Gamma|\right]_{H^{1+s}(\Omega)}\cdot\begin{cases} h^s\|p\|_{H^{s-1}(\Omega)}, & 0\leqq s<\frac{1}{2} \\ h\|p\|0\leqq s\leqq r-\frac{3}{2} & \text{if } V_h^0\subset V_h \end{cases}$$

which completes the proof of (4.17b) and (4.18b).

As for (4.19b), we use (4.3) in Lemma 4.1 to obtain

$$|(y-P_{h,\varepsilon}y,\,p)| \leqq C(\rho)h^{(s-\rho)}\left(1+\frac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right)\left[\|y\|_{H^{s+1}(\Omega)}+\frac{1}{\sqrt{\varepsilon}}|y|_{H^{s+1}(\Gamma)}\right]$$

$$\cdot\, h^{1-\rho}\left(1+\frac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right)\left[\|v_\varepsilon\|_{H^2(\Omega)}+\frac{1}{\sqrt{\varepsilon}}|v_\varepsilon|_{H^2(\Gamma)}\right]$$

$$\leqq C(\rho)h^{s+1-2\rho}\left(1+\frac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right)^2\|p\|\left[\|y\|_{H^{s+1}(\Omega)}+\frac{1}{\sqrt{\varepsilon}}|y|_{H^{s+1}(\Gamma)}\right],$$

which completes the proof of Lemma 4.2.

LEMMA 4.2′. *Let $y\in H^{1+s}(\Omega)$ and $\varepsilon(\partial y/\partial\eta)+\beta y=\beta g_h$ on Γ with $g_h\in\tilde{V}_h$. Denote*

$$|||y|||_{s,\varepsilon}\equiv\|y\|_{H^{1+s}(\Omega)}+|g_h|_{H^{1+s}(\Gamma)}+\sqrt{\varepsilon}\left|\frac{\partial y}{\partial\eta}\right|_{H^{s-1}(\Gamma)}.$$

With the notation above we have

$$\|P_{h,\varepsilon}y-y\|_{H^1(\Omega)}+\frac{1}{\sqrt{\varepsilon}}|P_{h,\varepsilon}y-y|_{H^1(\Gamma)}\leqq Ch^s|||y|||_{s,\varepsilon}, \tag{4.22a}$$

$$\|P_{h,\varepsilon}y-y\|_{H^{1-s}(\Omega)}\leqq Ch^{2s}|||y|||_{s,\varepsilon} \quad \textit{if } 0\leqq s<\tfrac{1}{2}. \tag{4.22b}$$

If $V_h^0\subset V_h$ and $0\leqq s\leqq r-\frac{3}{2}$, then

(4.23a) (4.22a) *holds for all $0\leqq s\leqq r-\frac{3}{2}$,*

$$\|P_{h,\varepsilon}y-y\|\leqq Ch^{s+1}|||y|||_{s,\varepsilon}, \tag{4.23b}$$

$$\|P_{h,\varepsilon}y-y\|_{H^{1-s_1}(\Omega)}\leqq Ch^{s_1+s}|||y|||_{s,\varepsilon} \quad \textit{where } 0\leqq s_1\leqq\tfrac{1}{2}. \tag{4.23c}$$

If $\rho > 0$, $0 \leqq s \leqq r - \frac{3}{2}$, $\delta \geqq 1$, *and* $r \geqq 1 + s(\sigma - 1)/2\rho$, *then*

$$\|P_{h,\varepsilon} y - y\|_{H^1(\Omega)} + \frac{1}{\sqrt{\varepsilon}} |P_{h,\varepsilon} y - y|_{H^1(\Gamma)} \leqq C(\rho) h^{s-\rho} \left(1 + \frac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right) |||y|||_{s,\varepsilon}, \tag{4.24a}$$

$$\|P_{h,\varepsilon} y - y\| \leqq C(\rho) h^{s+1-2\rho} \left(1 + \frac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right)^2 |||y|||_{s,\varepsilon}, \tag{4.24b}$$

$$\|P_{h,\varepsilon} y - y\|_{H^{1-s_1}(\Omega)} \leqq C(\rho) h^{s_1+s-\rho} \left(1 + \frac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right) |||y|||_{s,\varepsilon} \tag{4.24c}$$

where $0 \leqq s_1 < \frac{1}{2}$.

The proof of Lemma 4.2′ follows the same conceptual arguments as those used for the proof of Lemma 4.2. The only difference is that to estimate the terms in (4.21) we use Lemma 4.1′ instead of Lemma 4.1.

The following statements are the corollaries of Lemma 4.2.

COROLLARY 4.3. *Let* $A_{h,\varepsilon} : V_h \to V_h$ *be defined as the Galerkin approximation of* A_ε, *i.e.*,

$$(A_{h,\varepsilon} u_h, v_h) = (A_\varepsilon u_h, V_h) = a_\varepsilon(u_h, v_h), \qquad u_h, v_h \in V_h.$$

For any $f_h \in V_h$ *we have*

$$\begin{aligned} &\|(A_\varepsilon^{-1} - A_{h,\varepsilon}^{-1}) f_h\|_{H^{1-s}(\Omega)} \leqq C h^{2s} \|f_h\|_{H^{s-1}(\Omega)}, \qquad 0 \leqq s < \tfrac{1}{2}, \\ &\|(A_\varepsilon^{-1} - A_{h,\varepsilon}^{-1}) f_h\|_{H^1(\Omega)} + \frac{1}{\sqrt{\varepsilon}} |(A_\varepsilon^{-1} - A_{h,\varepsilon}^{-1}) f_h|_{H^1(\Gamma)} \\ &\leqq \begin{cases} C h \|f_h\| & \text{if } V_h^0 \subset V_h, \\ C(\rho) h^{1-\rho} \left[1 + \dfrac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right] \|f_h\| & \text{where } r \geqq 1 + \dfrac{\sigma - 1}{2\rho}, \quad \sigma > 1, \quad \rho > 0. \end{cases} \end{aligned} \tag{4.25}$$

Indeed, Corollary 4.3 follows directly from Lemma 4.2 after we set

$$v_\varepsilon \equiv A_\varepsilon^{-1} f_h, \qquad v_{h,\varepsilon} \equiv A_{h,\varepsilon}^{-1} f_h,$$

noting that

$$a_\varepsilon(v_\varepsilon - v_{h,\varepsilon}, \phi_h) = 0 \quad \text{for all } \phi_h \in V_h,$$

and using the regularity of v_ε as stated in Lemma 2.3. □

From Corollary 4.3 we also obtain Lemma 4.4.

LEMMA 4.4.

$$\|A_{h,\varepsilon}^{-1} f_h\|_{H^{s+1}(\Omega)} \leqq C \|f_h\|_{H^{s-1}(\Omega)}, \qquad 0 \leqq s < \tfrac{1}{2}.$$

Proof. By using the inverse approximation property, (2.5), and (4.25), we obtain

$$\begin{aligned} \|A_{h,\varepsilon}^{-1} f_h\|_{h^{s+1}(\Omega)} &\leqq \|(A_{h,\varepsilon}^{-1} - P_h A_\varepsilon^{-1}) f_h\|_{H^{s+1}(\Omega)} + \|P_h A_\varepsilon^{-1} f_h\|_{H^{s+1}(\Omega)} \\ &\leqq C h^{-2s} \|(A_{h,\varepsilon}^{-1} - P_h A_\varepsilon^{-1}) f_h\|_{H^{1-s}(\Omega)} + \|A_\varepsilon^{-1} f_h\|_{H^{s+1}(\Omega)} \\ &\leqq C \|f_h\|_{H^{s-1}(\Omega)}. \end{aligned}$$

□

Remark. Note that the estimate of Lemma 4.4 is a discrete counterpart of the regularity result stated in (2.5).

Next we prove Lemma 4.5.

LEMMA 4.5.

$$|\tilde{P}_h\beta A_{h,\varepsilon}^{-1}f_h|_{H^{s-1/2}(\Gamma)} \leqq C\varepsilon \|f_h\|_{H^{s-1}(\Omega)}, \qquad 0 \leqq s < \tfrac{1}{2}, \tag{4.26}$$

$$|\tilde{P}_h\beta A_{h,\varepsilon}^{-1}f_h|_{H^{(1/2)-\rho}(\Gamma)} \leqq C\varepsilon \begin{cases} \|f_h\| & \text{if } V_h^0 \subset V_h, \\ \left(1+\dfrac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right)\|f_h\| & \text{where } \rho>0 \text{ arbitrarily small,} \\ \delta \geqq 1 \quad \text{and} \quad r \geqq 1+\dfrac{\sigma-1}{2\rho}. \end{cases} \tag{4.27}$$

Proof of Lemma 4.5. Let $v_h \equiv A_{h,\varepsilon}^{-1}f_h$ or, equivalently, $A_{h,\varepsilon}v_h = f_h$. Then

$$\frac{1}{\varepsilon}\langle \beta v_h, \phi_h\rangle = -(f_h, \phi_h) - a(v_h, \phi_h) \quad \text{for all } \phi_h \in V_h, \tag{4.28}$$

or after using the Green formula

$$\frac{1}{\varepsilon}(\beta v_h, \phi_h) = -(f_h, \phi_h) + (A(x,\partial)v_h, \phi_h) - \left\langle \frac{\partial}{\partial \eta} v_h, \phi_h \right\rangle, \qquad \phi_h \in V_h. \tag{4.29}$$

Now we will use the property (3.1d). For any $\tilde{\phi}_h \in \tilde{V}_h$ we take $\phi_h \in V_h$ such that $\phi_h|_\Gamma = \tilde{\phi}_h$ and for $0 < \alpha \leqq 1$, $\|\phi_h\|_{H^\alpha(\Omega)} \leqq C|\tilde{\phi}_h|_{H^{\alpha-(1/2)}(\Gamma)}$. Thus we can write

$$\frac{1}{\varepsilon}\langle \tilde{P}_h\beta v_h, \tilde{\phi}_h\rangle = \frac{1}{\varepsilon}\langle \beta v_h, \tilde{\phi}_h\rangle = -(f_h, \phi_h) - a(v_h, \phi_h). \tag{4.30}$$

Hence for $0 \leqq s < \frac{1}{2}$

$$\frac{1}{\varepsilon}\langle \tilde{P}_h\beta v_h, \tilde{\phi}_h\rangle \leqq C[\|f_h\|_{H^{s-1}(\Omega)}\|\phi_h\|_{H^{1-s}(\Omega)} + \|v_h\|_{H^{1+s}(\Omega)}\|\phi_h\|_{H^{1-s}(\Omega)}]$$

(by Lemma 4.4 applied to the second term above)

$$\begin{aligned} &\leqq C[\|f_h\|_{H^{s-1}(\Omega)}\|\phi_h\|_{H^{1-s}(\Omega)}] \\ &\leqq C\|f_h\|_{H^{s-1}(\Omega)}|\tilde{\phi}_h|_{H^{(1/2)-s}(\Gamma)} \end{aligned} \tag{4.31}$$

where in the last step we used (3.1d). Since (4.31) holds for all $\tilde{\phi}_h \in H^{(1/2)-s}(\Gamma)$, (4.26) follows via duality.

As for (4.27) we write

$$\begin{aligned} \frac{1}{\varepsilon}|\tilde{P}_h\beta A_{h,\varepsilon}^{-1}f_h|_{H^{(1/2)-\rho}(\Gamma)} &\leqq \frac{1}{\varepsilon}|\tilde{P}_h\beta(A_{h,\varepsilon}^{-1} - A_\varepsilon^{-1})f_h|_{H^{(1/2)-\rho}(\Gamma)} \\ &\quad + \frac{1}{\varepsilon}|\beta A_\varepsilon^{-1}f_h|_{H^{(1/2)-\rho}(\Gamma)}. \end{aligned} \tag{4.32}$$

We will prove that

$$\frac{1}{\varepsilon}|\beta A_\varepsilon^{-1}f|_{H^{1/2}(\Gamma)} \leqq C\|f\|. \tag{4.33}$$

Indeed, let $v_\varepsilon \equiv A_\varepsilon^{-1} f$. Then

$$\frac{1}{\varepsilon}\langle \beta v_\varepsilon, \phi\rangle = -a(v_\varepsilon, \phi) + (f, \phi) = (A(x,\partial)v_\varepsilon, \phi) - \left\langle \frac{\partial v_\varepsilon}{\partial \eta}, \phi \right\rangle + (f, \phi), \quad \phi \in D(A_\varepsilon^{1/2}). \tag{4.34}$$

Let $\tilde{\phi} \in H^{-1/2}(\Gamma)$. By (2.7), $\phi \equiv D\tilde{\phi} \in L_2(\Omega)$ and from (4.34) we obtain

$$\frac{1}{\varepsilon}\langle \beta v_\varepsilon, \tilde{\phi}\rangle \leqq C\left[\|v_\varepsilon\|_{H^2(\Omega)} \|D\tilde{\phi}\| + \left|\frac{\partial v_\varepsilon}{\partial \eta}\right|_{H^{1/2}(\Gamma)} |\tilde{\phi}|_{H^{-1/2}(\Gamma)} + \|f\|\,\|\phi\| \right] \quad \text{for all } \tilde{\phi} \in H^{-1/2}(\Gamma). \tag{4.35}$$

Hence by virtue of (2.7) and (2.4) in Lemma 2.3,

$$\frac{1}{\varepsilon}\langle \beta v_\varepsilon, \tilde{\phi}\rangle \leqq C\|f\|\,|\tilde{\phi}|_{H^{-1/2}(\Gamma)}$$

which via duality proves (4.33).

To complete the proof of (4.27), in view of (4.33), it is enough to estimate $1/\varepsilon |\tilde{P}_h \beta (A_{h,\varepsilon}^{-1} - A_\varepsilon^{-1}) f_h|_{H^{1/2-\rho}(\Gamma)}$.

With $v_{h,\varepsilon} \equiv A_{h,\varepsilon}^{-1} f_h$ and $v_\varepsilon \equiv A_\varepsilon^{-1} f_h$ it is straightforward to show that

$$a(v_{h,\varepsilon} - v, \phi_h) + \frac{1}{\varepsilon}\langle \beta(v_{h,\varepsilon} - v), \phi_h\rangle = 0 \quad \text{for } \phi_h \in V_h.$$

Thus for any $\tilde{\phi}_h \in \tilde{V}_h$ we have

$$\frac{1}{\varepsilon}\langle \tilde{P}_h \beta(v_{h,\varepsilon} - v), \tilde{\phi}_h\rangle = -a(v_h - v, \phi_h) \tag{4.36}$$

where ϕ_h is selected according to (3.1d), i.e., $\phi_h|_\Gamma = \tilde{\phi}_h$ and

$$\|\phi_h\|_{H^\rho(\Omega)} \leqq C|\tilde{\phi}_h|_{H^{-1/2+\rho}(\Gamma)} \tag{4.37}$$

where $\rho > 0$ arbitrarily small.

From (4.36) and Corollary 4.3 we obtain

$$\frac{1}{\varepsilon}\langle \tilde{P}_h \beta(v_{h,\varepsilon} - v), \tilde{\phi}_h\rangle \leqq C\|v_{h,\varepsilon} - v\|_{H^1(\Omega)} \|\phi_h\|_{H^1(\Omega)} \leqq \begin{cases} C\|f_h\|\,\|\phi_h\| & \text{if } V_h^0 \subset V_h, \\ C\left(1 + \dfrac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right)\|f_h\|\,\|\phi_h\|_{H^\rho(\Omega)} \end{cases} \tag{4.38}$$

where in the last inequality we have used the inverse approximation property. Combining (4.37) with (4.38) and using duality yields

$$\frac{1}{\varepsilon}|\tilde{P}_h \beta(v_{h,\varepsilon} - v)|_{H^{(1/2)-\rho}(\Gamma)} \leqq C \begin{cases} \|f_h\| & \text{if } V_h^0 \subset V_h, \\ \left(1 + \dfrac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right)\|f_h\| & \text{otherwise.} \end{cases} \tag{4.39}$$

Formulas (4.39) and (4.33) inserted into (4.32) complete the proof of (4.27), and, hence, of the lemma. □

In the sequel, we will find it convenient to use semigroup representations of the solution to (1.5), $u_{h,\varepsilon}(t)$. To this end let $S_{h,\varepsilon}(t)$ (respectively, $C_{h,\varepsilon}(t)$): $V_h \to V_h$ be the sine (respectively, cosine) operators associated with $A_{h,\varepsilon}$, where $A_{h,\varepsilon}$ is defined in Corollary 4.3. This means

$$\begin{aligned} &\ddot{C}_{h,\varepsilon}(t)x_h = A_{h,\varepsilon}x_h, \qquad C_{h,\varepsilon}(0)x_h = x_h, \\ &\dot{C}_{h,\varepsilon}(0)x_h = 0, \qquad\quad \dot{C}_{h,\varepsilon}(t) = A_{h,\varepsilon}S_{h,\varepsilon}(t). \end{aligned} \tag{4.40}$$

Using the notation above it can be easily verified that with $g_h \equiv \tilde{P}_h g$, $u_{h,\varepsilon}(t)$, the solution to (1.5) can be represented as

$$u_{h,\varepsilon}(t) = \int_0^t S_{h,\varepsilon}(t-z)P_hA_\varepsilon N_\varepsilon g_h(z)\,dz \equiv (L_{h,\varepsilon}g)(t) \tag{4.41}$$

or in the differential form as

$$\begin{aligned} &\ddot{u}_{h,\varepsilon}(t) = A_h u_{h,\varepsilon}(t) - P_hA_\varepsilon N_\varepsilon g_h(t), \\ &u_{h,\varepsilon}(0) = \dot{u}_{h,\varepsilon}(0) = 0. \end{aligned} \tag{4.42}$$

Remark. Note that although $A_\varepsilon N_\varepsilon$ is unbounded (even more so $\mathcal{D}(A_\varepsilon N_\varepsilon) \equiv 0$), $P_hA_\varepsilon N_\varepsilon g_h$ is well defined for any $g \in L_2(\Sigma)$. Indeed, by (2.17), $(P_hA_\varepsilon N_\varepsilon g_h, \phi_h) = \langle g_h, N_\varepsilon^* A_\varepsilon \phi_h\rangle = 1/\varepsilon\langle g_h, \beta\phi_h\rangle$ for all $\phi_h \in V_h$.

The next lemma deals with the approximation properties of sine $S_{h,\varepsilon}(t)$ and cosine $C_{h,\varepsilon}(t)$ operators.

LEMMA 4.6.

$$\|C_{h,\varepsilon}v_h\|_{L^\infty[0,T;L_2(\Omega)]} + \|S_{h,\varepsilon}v_h\|_{L^\infty[0,T;H^1(\Omega)]} \leqq C\|v_h\|, \tag{4.43}$$

$$\|C_{h,\varepsilon}v_h\|_{L^\infty[0,T;\mathcal{D}(A_\varepsilon^{1/2})]} \leqq C\|v_h\|_{\mathcal{D}(A_\varepsilon^{1/2})}, \tag{4.44}$$

$$\|C_{h,\varepsilon}v_h\|_{L^\infty[0,T;\mathcal{D}(A_\varepsilon^{\alpha})]} \leqq C\|v_h\|_{\mathcal{D}(A_\varepsilon^{\alpha})}, \qquad 0 \leqq \alpha \leqq \tfrac{1}{2}. \tag{4.45}$$

Proof. Define $y_h(t) \equiv S_{h,\varepsilon}(t)v_h$ with $v_h \in V_h$. Then

$$\ddot{y}_h(t) = A_{h,\varepsilon}y_h(t), \quad y_h(0) = 0, \quad \dot{y}_h(0) = v_h,$$

or equivalently,

$$(\ddot{y}_h(t), \phi_h) + a(y_h(t), \phi_h) + \frac{1}{\varepsilon}\langle \beta y_h(t), \phi_h\rangle = 0, \qquad \phi_h \in V_h. \tag{4.46}$$

Setting $\phi_h = \dot{y}_h(t)$ yields

$$\frac{d}{dt}\left[\|\dot{y}_h(t)\|^2 + \|y_h(t)\|^2_{H^1(\Omega)} + \frac{1}{\varepsilon}|\beta^{1/2}y_h(t)|^2\right] = 0.$$

Hence

$$\|C_{h,\varepsilon}(t)v_h\|^2 + \|S_{h,\varepsilon}(t)v_h\|^2_{H^1(\Omega)} + \frac{1}{\varepsilon}|\beta^{1/2}S_{h,\varepsilon}(t)v_h|^2 \leqq C\|v_h\|,$$

which gives (4.43).

To prove (4.44) we take $y_h(t) \equiv C_{h,\varepsilon}(t)v_h$. The same argument as above yields

$$\left[\|A_h S_{h,\varepsilon}(t)v_h\|^2 + \|C_{h,\varepsilon}(t)v_h\|^2_{H^1(\Omega)} + \frac{1}{\varepsilon}|\beta^{1/2}C_{h,\varepsilon}(t)v_h|^2\right] \leqq C\left[\|v_h\|^2_{H^1(\Omega)} + \frac{1}{\varepsilon}|\beta^{1/2}v_h|^2\right]. \tag{4.47}$$

Formula (4.44) follows from (4.47) after we note that

$$\|x\|^2_{D(A_\varepsilon^{1/2})} \sim \|x\|^2_{H^1(\Omega)} + \frac{1}{\varepsilon}|\beta^{1/2}x|^2.$$

Formula (4.45) is the result of interpolation between (4.43) and (4.45). □

5. Proofs of Theorems 3.1 and 3.2.

Proof of Theorem 3.1. Using the semigroup representation of $u_{h,\varepsilon}(t)$ given by (4.41) and integrating (4.41) by parts, we obtain

$$\begin{aligned} u_{h,\varepsilon}(t) = (L_{h,\varepsilon}g)(t) &= \int_0^t \frac{d}{dz} C_{h,\varepsilon}(t-z)A_{h,\varepsilon}^{-1}P_hA_\varepsilon N_\varepsilon g_h(z)\,dz \\ &= A_{h,\varepsilon}^{-1}P_hA_\varepsilon N_\varepsilon g_h(t) - C_{h,\varepsilon}(t)A_{h,\varepsilon}^{-1}P_hA_\varepsilon N_\varepsilon g_h(0) \\ &\quad - \int_0^t C_{h,\varepsilon}(t-z)A_{h,\varepsilon}^{-1}P_hA_\varepsilon N_\varepsilon \dot{g}_h(z)\,dr \end{aligned} \tag{5.1}$$

where we have used the properties of $S_{h,\varepsilon}(t)$ and $C_{h,\varepsilon}(t)$, the operators given in (4.40).

From $g_h = \tilde{P}_h g \in H^1[0, T; H^{-1/2}(\Gamma)]$ it follows, in particular, that

$$|g_h|_{C[0,T;H^{-1/2+\rho}(\Gamma)]} \leqq C|g_h|_{H^1[0,T;H^{-1/2+\rho}(\Gamma)]} \leqq C|g|_{H^1[0,T;H^{-1/2+\rho}(\Gamma)]}. \tag{5.2}$$

Thus, in view of (5.2) and (4.43) in Lemma 4.6, parts (ii) and (iii) of Theorem 3.1 will be proved as soon as we establish the following inequality:

$$\|A_{h,\varepsilon}^{-1}P_hA_\varepsilon N_\varepsilon \tilde{P}_h g\| \leqq C|g|_{\bar{H}^{1/2+\rho}(\Gamma)} \cdot \begin{cases} 1 & \text{if } V_h^0 \subset V_h, \\ \left(1 + \dfrac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right), & r \geqq 1 + \dfrac{\sigma-1}{2\rho}. \end{cases} \tag{5.3}$$

To verify (5.3) we define

$$T_{h,\varepsilon}g \equiv A_{h,\varepsilon}^{-1}P_hA_\varepsilon N_\varepsilon \tilde{P}_h g \tag{5.4}$$

where $T_{h,\varepsilon}: L_2(\Gamma) \to V_h \subset L_2(\Omega)$. Then it is easy to verify that

$$(T_{h,\varepsilon}^* f_h, g) = (f_h, T_{h,\varepsilon}g), f_h \in V_h, g \in L_2(\Gamma)$$

is given by

$$T_{h,\varepsilon}^* f_h = \tilde{P}_h N_\varepsilon^* A_\varepsilon A_{h,\varepsilon}^{-1} f_h = \frac{1}{\varepsilon}\tilde{P}_h \beta A_{h,\varepsilon}^{-1} f_h$$

where in the last equality we used (2.8).

Now we recall (4.27) in Lemma 4.5 to claim that

$$\|T^*_{h,\varepsilon} f_h\|_{H^{1/2-\rho}(\Gamma)} \leqq C\|f_h\| \begin{cases} 1 & \text{if } V_h^0 \subset V_h, \\ \left(1+\dfrac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right), & r \geqq 1+\dfrac{\sigma-1}{2\rho}, \end{cases}$$

and hence by the duality

$$\|T_{h,\varepsilon} g\| \leqq C|g|_{H^{-1/2+\rho}(\Gamma)} \begin{cases} 1 & \text{if } V_h^0 \subset V_h, \\ \left(1+\dfrac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right), & r \geqq 1+\dfrac{\sigma-1}{2\rho} \end{cases}$$

which in view of (5.4) is exactly (5.3).

The proof of parts (ii) and (iii) of Theorem 3.1 is thus completed. For the proof of part (i) we use similar arguments. Indeed, first note that

$$D(A_\varepsilon^\alpha) = H^{2\alpha}(\Omega) \alpha < \tfrac{1}{4}. \tag{5.5}$$

In fact,

$$D(A^{1/2}) \subset D(A_\varepsilon^{1/2}).$$

Hence

$$H^{2\alpha}(\Omega) = D(A^\alpha) \subset D(A_\varepsilon^\alpha), \qquad \alpha < \tfrac{1}{4}. \tag{5.6}$$

On the other hand,

$$D(A_\varepsilon^{1/2}) \subset H^1(\Omega);$$

consequently,

$$D(A_\varepsilon^\alpha) \subset H^{2\alpha}(\Omega), \qquad \alpha < \tfrac{1}{2}. \tag{5.7}$$

Formula (5.7) combined with (5.6) yields (5.5).

By (5.5) and (4.45) in Lemma 4.6 applied with $\alpha < \frac{1}{4}$, we obtain

$$\|C_{h,\varepsilon}(t) v_h\|_{H^{2\alpha}(\Omega)} \leqq C\|v_h\|_{H^{2\alpha}(\Omega)}, \qquad \alpha < \tfrac{1}{4}.$$

Thus, to prove part (i) of Theorem 3.1 (recall (5.1)), it is enough to show that

$$\|A_{h,\varepsilon}^{-1} P_h A_\varepsilon N_\varepsilon \tilde{P}_h g\|_{H^{1/2}(\Omega)} \leqq C|g|_{H^\rho(\Gamma)}. \tag{5.8}$$

On the other hand, (5.8) follows easily from a dual version of (4.26) in Lemma 4.5 applied with $s = \frac{1}{2} - \rho$. The proof of Theorem 3.1 is thus completed. □

Next we prove Theorem 3.2.

Proof of Theorem 3.2. Let $\bar{u}_\varepsilon$ (respectively, $u_{h,\varepsilon}$) be the solution to (1.4) with $g \equiv \tilde{P}_h g$ (respectively, (1.5)). Then

$$((\ddot{\bar{u}}_\varepsilon - \ddot{u}_{h,\varepsilon})(t), \phi_h) + a_\varepsilon(\bar{u}_\varepsilon(t) - u_{h,\varepsilon}(t), \phi_h) = 0, \qquad \phi_h \in V_h.$$

Let $e_{h,\varepsilon}(t) \equiv P_{h,\varepsilon}\bar{u}_\varepsilon(t) - u_{h,\varepsilon}(t) \in V_h$. Then

$$\begin{aligned} &(\ddot{e}_{h,\varepsilon}(t), \phi_h) + a_\varepsilon(e_{h,\varepsilon}(t), \phi_h) = (P_{h,\varepsilon}\ddot{\bar{u}}_\varepsilon(t) - \ddot{\bar{u}}_\varepsilon(t), \phi_h), \\ &e_{h,\varepsilon}(0) = \dot{e}_{h,\varepsilon}(0) = 0. \end{aligned} \tag{5.9}$$

Equations (5.9) can be equivalently rewritten as

$$\ddot{e}_{h,\varepsilon}(t)+A_{h,\varepsilon}e_{h,\varepsilon}(t)=P_h(P_{h,\varepsilon}-I)\ddot{u}_\varepsilon(t),$$

$$e_{h,\varepsilon}(0)=\dot{e}_{h,\varepsilon}(0)=0,$$

or in the semigroup form as

$$e_{h,\varepsilon}(t)=\int_0^t S_{h,\varepsilon}(t-z)P_h(P_{h,\varepsilon}-I)\ddot{u}_\varepsilon(z)\,dz.$$

After integrating the above expression by parts and using $S_{h,\varepsilon}(0)=0$, we obtain

$$e_{h,\varepsilon}(t)=-S_{h,\varepsilon}(t)P_h(P_{h,\varepsilon}-I)\dot{u}_\varepsilon(0)-\int_0^t C_{h,\varepsilon}(t-z)P_h(P_{h,\varepsilon}-I)\dot{u}_\varepsilon(z)\,dz. \tag{5.10}$$

Since $\dot{u}_\varepsilon(0)=0$, (4.43) in Lemma 4.6 implies

$$\|e_{h,\varepsilon}(t)\|\leqq C\|P_h(P_{h,\varepsilon}-I)\dot{u}_\varepsilon\|_{L_1[0,T;L_2(\Omega)]}$$

(by the stability of orthogonal projection P_h)

$$\leqq C\|(P_{h,\varepsilon}-I)\dot{u}_\varepsilon\|_{L_1[0,T;L_2(\Omega)]}.$$

Now we will apply Lemma 4.2′. In fact, (4.23b) and (4.24b) in Lemma 4.2′ give

$$\|e_{h,\varepsilon}(t)\|\leqq Ch^{s+1}\left\{\begin{array}{l}1 \quad \text{if } V_h^0\subset V_h, \quad s+1\leqq r\\ h^{-2\rho}\left(1+\dfrac{h^{\sigma/2-1}}{2\rho}\right)^2, \quad r\geqq 1+\dfrac{s(\sigma-1)}{2\rho}, \quad 0\leqq s\leqq r-1\end{array}\right\} \tag{5.11}$$

$$\cdot\left[\|\dot{u}_\varepsilon\|_{L_1[0,T;H^{s+1}(\Omega)]}+|\dot{g}_h|_{L_1[0,T;H^{s+1}(\Gamma)]}+\sqrt{\varepsilon}\left|\frac{\partial}{\partial\eta}\dot{u}_\varepsilon\right|_{L_1[0,T;H^s(\Gamma)]}\right].$$

On the other hand, if we set

$$z_\varepsilon\equiv\dot{u}_\varepsilon(t),$$

then

$$\ddot{z}_\varepsilon(t)=A(x,\partial)z \quad \text{in } Q,$$

$$\left\{\begin{array}{l}z_\varepsilon(0)=\dot{u}_\varepsilon(0)=0\\ \dot{z}_\varepsilon(0)=A(x,\partial)\ddot{u}_\varepsilon(0)=0\end{array}\right. \quad \text{in } Q, \tag{5.12}$$

$$\frac{\varepsilon\partial z_\varepsilon}{\partial\eta}+\beta z_\varepsilon=\beta\dot{g} \quad \text{in } \Sigma.$$

Theorem 2.2(e) and (g) applied to (5.12) yield, in particular (provided $\dot{g}$ satisfies the appropriate compatibility conditions), that

$$\|z_\varepsilon\|_{L^\infty[0,T;H^{s+1}(\Omega)]}+\left|\frac{\partial z_\varepsilon}{\partial\eta}\right|_{L_2[0,T;H^s(\Gamma)]}\leqq C|\dot{g}_h|_{H^{s+1,s+1}(\Sigma)}\leqq C|\dot{g}|_{H^{s+1,s+1}(\Sigma)}. \tag{5.13}$$

Formula (5.13) together with (5.11), applied with $s\equiv s-1$, gives

$$\|e_{h,\varepsilon}(t)\|_{L_2(\Omega)}\leqq Ch^s|\dot{g}|_{H^{s,s}(\Sigma)}f(h,\rho,\sigma,\varepsilon) \tag{5.14}$$

where

$$f(h,\rho,\sigma,\varepsilon)\equiv\begin{cases}1 & \text{if } V_h^0\subset V_h,\quad 1\leqq s\leqq r\\ h^{-2\rho}\left[1+\dfrac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right]^2, & r\geqq 1+\dfrac{(s-1)(\sigma-1)}{2\rho},\quad 1\leqq s.\end{cases}$$

Writing

$$u_\varepsilon-u_{h,\varepsilon}=u_\varepsilon-\bar{u}_\varepsilon+(I-P_{h,\varepsilon})\bar{u}_\varepsilon+e_{h,\varepsilon} \tag{5.15}$$

and applying part (a) of Theorem 2.2 together with the approximation properties for $\tilde{P}_h$ to the first term in (5.15), (4.23b) and (4.24b) to the second term, and (5.14) to the third term gives parts (i) and (iii) of Theorem 3.2. Finally, we will prove parts (ii) and (iv) of Theorem 3.2.

Recalling (5.10) and (4.45), and applying (5.5) with $\alpha=\frac{1}{2}-\rho$ yields

$$\|e_{h,\varepsilon}(t)\|_{H^{1/2-\rho}(\Omega)}\leqq C\|(P_{h,\varepsilon}-I)\dot{u}_\varepsilon\|_{L_1[0,T;H^{1/2-\rho}(\Omega)]}. \tag{5.16}$$

From (4.22b), (4.23c), and (4.24c) applied to the right-hand side of (5.16), we obtain

$$\begin{aligned}\|e_{h,\varepsilon}(t)\|_{H^{1/2-\rho}(\Omega)}&\leqq Ch^{1/2+s}\cdot k(h,\rho,\sigma,\varepsilon)\\ &\cdot\left[\|\dot{u}_\varepsilon\|_{L_1[0,T;H^{s+1}(\Omega)]}+|\dot{g}_h|_{L_1[0,T;H^{s+1}(\Gamma)]}+\sqrt{\varepsilon}\left|\frac{\partial\dot{u}_\varepsilon}{\partial\eta}\right|_{L_1[0,T;H^{s-1}(\Gamma)]}\right]\end{aligned} \tag{5.17a}$$

where

$$k(h,\rho,\sigma,\varepsilon)\equiv\begin{cases}h^{-\rho} & \text{if } s<\frac{1}{2}\\ 1 & \text{if } V_h^0\subset V_h,\quad s\leqq r-\frac{3}{2}\\ h^{-2\rho}\left(1+\dfrac{h^{\sigma/2-1}}{\sqrt{\varepsilon}}\right), & r\geqq 1+\dfrac{s(\sigma-1)}{2\rho}.\end{cases} \tag{5.17b}$$

Theorem 2.2(e)-(g) applied to (5.12) (recall $z_\varepsilon\equiv\dot{u}_\varepsilon$) gives

$$\|\dot{u}_\varepsilon\|_{L_1[0,T;H^{s+1}(\Omega)]}+\sqrt{\varepsilon}\left|\frac{\partial\dot{u}_\varepsilon}{\partial\eta}\right|_{L_1[0,T;H^{s-1}(\Gamma)]}\leqq C|\dot{g}_h|_{H^{s+1}(\Sigma)}\leqq C|\dot{g}|_{H^{s+1}(\Sigma)}. \tag{5.18}$$

Combining (5.17) and (5.18) yields

$$\|e_{h,\varepsilon}(t)\|_{H^{1/2-\rho}(\Omega)}\leqq Ch^{1/2+s}|\dot{g}|_{H^{s+1}(\Sigma)}\cdot k(h,\rho,\sigma,\varepsilon) \tag{5.19}$$

where $k(h,\rho,\sigma,\varepsilon)$ is given by (5.17b).

To complete the proof of parts (ii) and (iv) of Theorem 3.2, we apply the triangle inequality to (5.15). To estimate the first term on the right-hand side of (5.15) we interpolate between parts (a) and (b) of Theorem 2.2. This gives

$$\begin{aligned}\|u_\varepsilon-\bar{u}_\varepsilon\|_{C[0,T;H^{1/2-\rho}(\Omega)]}&\leqq\|L_\varepsilon(g-\tilde{P}_hg)\|_{C[0,T;H^{1/2-\rho}(\Omega)]}\\ &\leqq C|g-\tilde{P}_hg|_{H^{1/2-\rho}(\Sigma)}\\ &\leqq Ch^{1/2+s-\rho}|g|_{H^{s+1-2\rho}(\Sigma)}.\end{aligned} \tag{5.20}$$

To estimate the second term on the right-hand side of (5.15) we again use (4.22b), (4.23c), (4.24c) together with the regularity properties of $\bar{u}_\varepsilon$ as stated in Theorem 2.2. This gives

$$\|(I-P_{h,\varepsilon})\bar{u}_\varepsilon(t)\|_{H^{1/2-\rho}(\Omega)}\leqq Ch^{1/2+s}\cdot k(h,\rho,\sigma,\varepsilon)\cdot[|g|_{H^{s+1}(\Sigma)}+|\dot{g}|_{H^{s+1}(\Sigma)}]. \tag{5.21}$$

Collecting the results of (5.19), (5.20), (5.21) and (5.15) completes the proof of parts (ii) and (iv) of Theorem 3.2. □

UNIQUENESS OF SOLUTIONS FOR THE GENERALIZED KORTEWEG-DE VRIES EQUATION*

J. GINIBRE† AND Y. TSUTSUMI‡

Abstract. The uniqueness of L^2 and H^1 solutions of the Cauchy problem for the generalized Korteweg-de Vries (KdV) equation

$$\partial_t u + D^3 u + a(u)Du = 0$$

with $a \in \mathscr{C}(\mathbb{R}, \mathbb{R})$ and with initial data u_0 in weighted L^2 or H^1 spaces according to

$$(1+x_+)^{\beta/2} u_0 \in L^2, \qquad (1+x_+)^{\gamma/2} Du_0 \in L^2$$

is studied for some $\beta, \gamma \geqq 0$. Several uniqueness classes are exhibited, and the a priori estimates are derived for the corresponding norms of smooth solutions in terms of the initial data required to implement compactness existence proofs of solutions in those classes. For (weighted) L^2 solutions, the results given here cover the case where $|a(\rho)| \leqq C|\rho|^p$ with $0 < p < \frac{7}{2}$, $\beta = 1/p - \frac{1}{4}$ if $p \leqq 2$ and $\beta = \frac{1}{4}$ if $p \geqq 2$. For the ordinary KdV equation with $p = 1$, the result $\beta = \frac{3}{4}$ improves over previously known results by a factor of 2. For H^1 solutions, uniqueness and a priori estimates with initial data $u_0 \in H^1$ (namely, $\beta = \gamma = 0$) are proved provided $p > \frac{3}{2}$. For the ordinary KdV equation with $p = 1$, the results given here yield uniqueness and a priori estimates for $\beta + \gamma \geqq \frac{1}{2}$, $\beta \geqq 3\gamma/5$ (for instance, $\beta = \frac{1}{2}$, $\gamma = 0$, or $\beta = (3/16)$, $\gamma = (5/16)$).

Key words. Korteweg-de Vries (KdV) equation, Cauchy problem, uniqueness of solutions

AMS(MOS) subject classifications. primary 35Q20; secondary 35G25, 35D99

1. Introduction.

In this paper we study the uniqueness of solutions of the Cauchy problem for the generalized Korteweg-de Vries (GKdV) equation

$$\partial_t u + D^3 u = DV'(u) \tag{1.1}$$

for $t \geqq 0$, $x \in \mathbb{R}$, with initial data

$$u(0, x) = u_0(x) \qquad (x \in \mathbb{R}). \tag{1.2}$$

Here $D = d/dx$, the prime denotes the derivative, and $V \in \mathscr{C}^2(\mathbb{R}, \mathbb{R})$ with $V(0) = V'(0) = 0$. The function V is the potential that appears in the (formally conserved) energy for (1.1) (see (4.1) below). In the notation of [10], (1.1) is written equivalently as

$$\partial_t u + D^3 u + a(u)Du = 0 \tag{1.1'}$$

with $a = -V''$. For $a(\rho) = \rho$, (1.1') is the (ordinary) Korteweg-de Vries equation, and for $a(\rho) = \rho^2$, (1.1') is the modified Korteweg-de Vries equation.

A large amount of work has been devoted to the existence problem for solutions of (1.1), (1.2). It concerns either the ordinary KdV equation with $a(\rho) = \rho$ [2]-[5], [12], [16]-[18] or the generalized equation (1.1') with a monomial or a smooth function [1], [9], [10], [15], [19]-[21]. The available results include, in particular, the existence of global weak solutions in $L^\infty(\mathbb{R}, L^2)$ for initial data $u_0 \in L^2$ and in $L^\infty(\mathbb{R}, H^1)$ for initial data $u_0 \in H^1$. They require suitable growth restrictions on the function a at

infinity. There also exists a wealth of results concerning more regular solutions, for instance, solutions that are continuous functions of time with values in Sobolev spaces H^s for $s>\frac{3}{2}$ corresponding to initial data in H^s. We refer to [10] and [14] for a general survey.

The problem of the uniqueness of the solutions of (1.1), (1.2), on the other hand, is still largely open. There exists a well-known result according to which the solution is unique if $u_0\in H^s$ with $s>\frac{3}{2}$ (see [2], [9], [16]), but that result does not cover the case of H^1 solutions. More recently, new uniqueness results were proved in the special case $a(\rho)=\rho$ of the ordinary KdV equation for initial data u_0 in weighted L^2 spaces with either exponential [10] or polynomial [12] weight. The method of proof uses the smoothing properties of the KdV equation, and propagation in time of space decay. It is not, however, directly applicable to cases other than $a(\rho)=\rho$.

In the present paper, we study the uniqueness problem for L^2 or H^1 solutions of (1.1), (1.2)—more precisely, solutions in $L^\infty_{\text{loc}}([0, T), L^2)$ or in $L^\infty_{\text{loc}}([0, T), H^1)$ for some $T>0$ (possibly $T=\infty$), for initial data u_0 in (possibly weighted) L^2 or H^1 spaces, more precisely, for u_0 satisfying

$$(1+x_+)^{\beta/2}u_0\in L^2, \tag{1.3}$$

$$(1+x_+)^{\gamma/2}Du_0\in L^2, \tag{1.4}$$

for some $\beta, \gamma\geqq 0$, where $x_+=\max(x, 0)$. In particular, we obtain several uniqueness classes for solutions of (1.1), (1.2) under suitable assumptions of β, γ, and V (or a). Of course, uniqueness results of this kind are of interest only insofar as the uniqueness classes thereby obtained are suitable for proving the existence of solutions. One possible method for proving existence consists of first constructing smooth solutions of a regularized version of problem (1.1), (1.2), then deriving a priori estimates of the solutions in terms of the initial data, and finally exploiting those estimates to remove the regularization by a limiting procedure based on compactness arguments. The limiting procedure, in general, takes a weak-star limit in a space X^* that is the dual of some Banach space X; the a priori estimates, which hold for the X^* norm of the regularized solutions, carry over to the limit, so that X^* turns out to be an adequate space for the existence of solutions.

In the present paper we do not consider the problem of existence. However, we provide the technical material required to implement the previous type of existence proof, by deriving a priori estimates of sufficiently smooth solutions of (1.1), (1.2), in the norms that define the previous uniqueness classes, in terms of the available norms of the initial data. Those estimates strongly indicate that the previous uniqueness classes are in fact suitable for existence and uniqueness insofar as they are duals of Banach spaces. That indication can be made into a proof with little additional work by combining our results with many of the available existence results. However, we refrain from making any formal statement to that effect in this paper, because the smoothness assumptions that we make on V (or a) are weaker than the assumptions made in the existence proofs available in the literature. In a subsequent paper, we will prove the existence of solutions of (1.1) under weaker assumptions on V than those of the present paper, and extend the uniqueness proofs of this paper into existence and uniqueness proofs in the uniqueness classes obtained here.

We now give a rough outline of our results, namely, uniqueness and a priori estimates, as just explained, concentrating on the assumptions on V (or a) and on u_0. More precise statements, in particular, the description of the uniqueness classes, will be found in the main body of the paper, whose contents are described below.

In the case of L^2 solutions, the assumption on V (or a) reduces to

$$|a(\rho)| \leqq C|\rho|^p \tag{1.5}$$

for all $\rho \in \mathbb{R}$ and some $p > 0$, and the assumption on u_0 reduces to (1.3). Our results cover the case $0 < p \leqq 2$ with $\beta = 1/p - \frac{1}{4}$, and, by the use of two different methods, either $2 \leqq p < 3$ with $\beta = \frac{1}{2} - 1/(2p)$ with the simpler one, or $2 \leqq p < \frac{7}{2}$ with $\beta = \frac{1}{4}$ with the more elaborate one. In particular, for the ordinary KdV equation with $p = 1$, we obtain $\beta = \frac{3}{4}$, thereby improving the corresponding result of [12] by a factor of 2. For the modified KdV equation, we obtain the lower value $\beta = \frac{1}{4}$.

In the case of H^1 solutions, the assumptions on V (or a) reduce to condition (1.5), but now only for small ρ (say for $|\rho| \leqq 1$), to the condition that a be absolutely continuous with locally bounded derivative, and to a lower semiboundedness condition on V (see (4.22) below). The assumptions on u_0 include (1.3) and (1.4). Our results cover the cases where $p \geqq 1$, $\beta \geqq \gamma(4-p)_+/(4+p)$ with either of the two conditions

$$(p+1)(\beta+\gamma) \geqq 1, \tag{1.6}$$

$$(3-p)_+\beta + (\rho-1)(2+3\min(\beta, \gamma)) > 1. \tag{1.7}$$

In particular by (1.7) we prove uniqueness for $u_0 \in H^1$ provided $p > \frac{3}{2}$, thereby recovering a result previously obtained by Tsutsumi [22]. That result covers, in particular, the case of the modified KdV equation corresponding to $p = 2$. For the ordinary KdV equation with $p = 1$, we cannot prove uniqueness for $u_0 \in H^1$ only, but we obtain uniqueness (for instance) for $\beta = \frac{1}{2}$, $\gamma = 0$ or for $\beta = 3/(16)$, $\gamma = 5/(16)$, by using (1.6).

The proofs of our results rely on two sets of estimates. The first set consists of the well-known weighted L^2, H^1, and H^2 estimates that have been widely used by many previous authors. Those estimates can in part be viewed as weighted space time integrability properties associated with the free evolution group $U(t) = \exp(-tD^3)$ that solves the linear equation obtained from (1.1) when $V = 0$. By interpolation, they can be combined with similar weighted L^∞ estimates coming from known estimates of the propagator of $U(t)$, which is the classical Airy function. The second set of estimates consists of space time integrability properties that stand in close analogy with similar properties of other equations, and in particular of the Schrödinger equation [7], [11], [23].

This paper is organized as follows. In § 2, we derive the linear estimates of $U(t)$ just described. The Schrödinger-like estimates are contained in Lemmas 2.1 and 2.2, the weighted L^∞ estimates in Lemmas 2.3 and 2.4, the weighted L^2 and H^1 estimates in Lemma 2.5, and the interpolation between the last two estimates in Lemma 2.6.

In § 3 we derive our results on L^2 solutions. We first obtain the basic uniqueness classes that are suitable for $p \leqq 2$ and $p \geqq 2$ in Propositions 3.1 and 3.2, respectively. We then set out to derive a priori estimates for the norms that appear in their definition. In both cases, one of those norms plays only an auxiliary role and can be estimated in terms of the others (Propositions 3.3 and 3.4, respectively). To proceed further, we use a well-known weighted L^2 identity (I.1) to derive weighted L^2 and other estimates (Proposition 3.5), following previous authors (see especially [10] and [12]). That step completes the proof of a priori estimates for $p \leqq 2$. For $p \geqq 2$, more work is needed and we offer two methods. One of them is based on Sobolev inequalities and covers the case $2 \leqq p < 3$ with $\beta = \frac{1}{2} - 1/(2p)$, yielding as a byproduct a new uniqueness class (Proposition 3.6). The second (more elaborate) method covers the case $2 \leqq p < \frac{7}{2}$ with $\beta = \frac{1}{4}$, and also yields a new uniqueness class (Proposition 3.7). We then address the problem of deriving the basic identity (I.1) under minimal smoothness assumptions and analyze that condition in some detail (Proposition 3.8). When combined with

Proposition 3.5, that study makes it possible to exhibit new uniqueness classes both for $p \leqq 2$ (Proposition 3.9) and for $p \geqq 2$ (Proposition 3.10), but those classes are probably not suitable for a treatment of the existence problem (see Remark 3.8).

In § 4, we derive our results on H^1 solutions. We first remark that weighted L^2 estimates can be obtained from (I.1) more simply and in stronger form than for L^2 solutions (Proposition 4.1). We then obtain the basic uniqueness class in Proposition 4.2, which is a mild generalization of a known result. To proceed further, we need a second, well-known, weighted H^1 identity (I.2). As it turns out, it is easier to derive that identity under natural smoothness assumptions than to derive (I.1) for L^2 solutions, and we analyze it in some detail (Proposition 4.3). Following previous authors, we derive therefrom weighted H^1 and other estimates (Proposition 4.4). Using those preliminaries, we turn to the derivation of a priori estimates of the norms that define the uniqueness class of Proposition 4.2. That can be done again by two methods. The first method leads to condition (1.6) (under assumptions (1.3), (1.4)) and yields as a byproduct a new uniqueness class (Proposition 4.5). The second (more elaborate) method leads to condition (1.7) and also yields a new uniqueness class (Proposition 4.6), slightly smaller than the previous one. Combining those results with Propositions 4.3 and 4.4 makes it possible to exhibit still another uniqueness class (Proposition 4.7), which, in contrast with the previous ones, is probably not suitable for a treatment of the existence problem if $p < 2$. We conclude that section with some comments on the assumptions of Propositions 4.5 and 4.6.

We conclude this Introduction by giving some notation that will be used without further explanation throughout this paper. We denote by $\|\cdot\|_r$ the norm in $L^r \equiv L^r(\mathbb{R})$, and by $\langle .,. \rangle$ the scalar product in L^2. Pairs of conjugate indices are written as r, $\bar{r}$, with $1/r + 1/\bar{r} = 1$. For any interval $I \subset \mathbb{R}$, for any Banach space X, we denote by $\mathscr{C}_w(I, X)$ the space of weakly continuous functions from I to X, and by $L^q(I, X)$ (respectively, $L^q_{\mathrm{loc}}(I, X)$) the space of measurable functions v from I to X such that $\|v(\cdot); X\| \in L^q(I)$ (respectively, $L^q_{\mathrm{loc}}(I)$). We will make extensive use of the following spaces. Let $1 \leqq q, r, s \leqq \infty$. For any $j \in \mathbb{Z}$, let χ_j be the characteristic function of the interval $[j - \frac{1}{2}, j + \frac{1}{2}]$. We define $l^s(L^q(I, L^r))$ as the space of functions v of space time defined for $(x, t) \in \mathbb{R} \times I$ for which the following quantity (taken as the norm) is finite:

$$\|v; l^s(L^q(I, L^r))\| = \left\{ \sum_{j \in \mathbb{Z}} \left[\int_I dt \left(\int dx \, |\chi_j v|^r \right)^{q/r} \right]^{s/q} \right\}^{1/s} < \infty.$$

We also define the local spaces $l^s(L^q_{\mathrm{loc}}(I, L^r))$ as the spaces of functions v defined in $\mathbb{R} \times I$ and such that for any compact interval $J \Subset I$, the restriction $v|_J$ belongs to $l^s(L^q(J, L^r))$. Similarly, we define the spaces $L^q(I, l^s(L^r))$ with norm

$$\|v; L^q(I, l^s(L^r))\| = \left\{ \int_I dt \left[\left(\sum_{j \in \mathbb{Z}} \int dx \, |\chi_j v|^r \right)^{s/r} \right]^{q/s} \right\}^{1/q} < \infty$$

and the corresponding local spaces $L^q_{\mathrm{loc}}(I, l^s(L^r))$. Clearly $L^q(I, l^s(L^r)) \equiv L^q(I, L^r)$ if $s = r$. By the Minkowski inequality the continuous embedding $l^s(L^q(I, L^r)) \subset L^q(I, l^s(L^r))$ holds if $s \leqq q$ and the converse embedding holds if $s \geqq q$. The Hölder and Young inequalities hold in all those spaces, as a consequence of the corresponding inequalities applied independently in each of the three component spaces.

In all the estimates performed in this paper, we use C to denote various constants, possibly depending on various indices $(\alpha, \beta, \gamma, p, q, r, s)$, but not on the functions to be estimated, and possibly different from one line to the next. In the entire paper, we assume without further repetition that the function V in (1.1) satisfies $V \in \mathscr{C}^2(\mathbb{R}, \mathbb{R})$, $V(0) = V'(0) = 0$. Additional assumptions, if any, will be stated where needed. Finally,

we denote by χ_+ and χ_- the characteristic functions of $\mathbb{R}^+$ and $\mathbb{R}^-$, respectively, and for any $\lambda \in \mathbb{R}$, we define $\lambda_\pm = \max(\pm\lambda, 0)$.

2. Linear estimates. In this section, we derive a number of preliminary estimates on the free evolution group

$$U(t) = \exp(-tD^3) \tag{2.1}$$

that will be essential in the rest of this paper. The group $U(\cdot)$ solves the Cauchy problem for the linear equation

$$\partial_t u + D^3 u = f, \tag{2.2}$$

with initial condition $u(0) = u_0$ through the formula

$$u(t) = U(t)u_0 + \int_0^t d\tau U(t-\tau) f(\tau). \tag{2.3}$$

Since all the estimates considered here are linear, it suffices to derive them for smooth functions. They can then be extended by continuity to all functions for which they make sense.

The group $U(\cdot)$ is unitary in L^2. For each t, $U(t)$ can be represented as the convolution with the function

$$S_t(x) = (3t)^{-1/3} \operatorname{Ai}(x(3t)^{-1/3}) \tag{2.4}$$

where Ai is the classical Airy function

$$\operatorname{Ai}(x) = (2\pi)^{-1} \int d\xi \exp(i\xi^3/3 + ix\xi). \tag{2.5}$$

It satisfies the estimates [8, p. 213]

$$|\operatorname{Ai}(x)| \leqq C(1+x_-)^{-1/4} \exp(-cx_+^{3/2}), \tag{2.6}$$

$$|\operatorname{Ai}'(x)| \leqq C(1+x_-)^{1/4} \exp(-cx_+^{3/2}). \tag{2.7}$$

From (2.4) and (2.6) we obtain an estimate

$$|S_t(x)| \leqq t^{-1/3} A(x) + Ct^{-1/4} \chi_-(1+|x|)^{-1/4} \tag{2.8}$$

for some smooth bounded function A with support in $[-1, \infty)$ and (faster than) exponential decrease at $+\infty$, uniformly for t in bounded intervals. Furthermore,

$$\|S_t\|_\infty = Ct^{-1/3}. \tag{2.9}$$

Similarly,

$$|DS_t(x)| \leqq t^{-2/3} A(x) + Ct^{-3/4} \chi_-(1+|x|)^{1/4}. \tag{2.10}$$

From the unitarity of U and from (2.9), we can derive the following properties.

LEMMA 2.1. *The following estimates hold*:

$$\|U(t)f\|_r \leqq Ct^{-(1/3-2/(3r))} \|f\|_{\bar{r}} \tag{2.11}$$

for all $t \neq 0$ *and all* r, $2 \leqq r \leqq \infty$,

$$\|U(\cdot)f\colon L^q(\mathbb{R}, L^r)\| \leqq C\|f\|_2 \tag{2.12}$$

for all r, $2 \leqq r \leqq \infty$, *with* $2/q = \frac{1}{3} - 2/(3r)$,

$$\left\| \int_I d\tau\, U(\cdot - \tau) f(\tau);\ L^{q_1}(\mathbb{R}, L^{r_1}) \right\| \leqq C\|f;\ L^{\tilde{q}_2}(I, L^{\tilde{r}_2})\| \tag{2.13}$$

for all r_i, $2 \leqq r_i \leqq \infty$, $i = 1, 2$, *with* $2/q_i = \frac{1}{3} - 2/(3r_i)$ *and for any interval* I.

Summary proof. Estimates (2.11)-(2.13) are the analogues of well-known estimates for the Schrödinger equation, and are proved in exactly the same manner. The estimate (2.11) follows by interpolation from the cases $r=2$ (unitarity of U) and $r=\infty$, where it follows from (2.9) through the Young inequality. We refer to [7, Prop. 4.4] for (2.12) and to [11] and [23] for (2.13). □

For later reference, we state explicitly the special cases $r=\infty$, $q=6$ of (2.12) and $r_1=\infty$, $q_1=6$, $r_2=2$, $q_2=\infty$ of (2.13):

$$\|U(\cdot)f;\, L^6(\mathbb{R}, L^\infty)\| \leqq C\|f\|_2, \tag{2.14}$$

$$\left\| \int_I d\tau\, U(\cdot-\tau)f(\tau);\, L^6(\mathbb{R}, L^\infty) \right\| \leqq C\|f;\, L^1(I, L^2)\|. \tag{2.15}$$

We also remark that the integration interval on the left-hand side of (2.13), (2.15) may also depend on the time variable. In that case, the interval on the right-hand side must be replaced by the union of the intervals that occur in the left-hand side.

We now turn to a similar set of estimates satisfied by the operator

$$e^x U(t) e^{-x} = \exp[-t(D-1)^3]. \tag{2.16}$$

LEMMA 2.2. *Let $T>0$. Then the following estimates hold:*

$$\|\exp[-t(D-1)^3]f\|_r \leqq C\, e^t t^{-((1/3)-(2/(3r)))}\|f\|_{\bar r} \tag{2.17}$$

for all $t>0$ and all r, $2\leqq r\leqq\infty$ (with the same C as in (2.11)),

$$\|\exp[-\cdot(D-1)^3]f;\, L^q([0, T], L^r]\| \leqq C\, e^T\|f\|_2 \tag{2.18}$$

for all r, $2\leqq r\leqq\infty$, with $2/q=\frac{1}{3}-2/(3r)$ (with the same C as in (2.12)),

$$\left\| \int_0^\cdot d\tau \exp[-(\cdot-\tau)(D-1)^3]f;\, L^{q_1}([0, T], L^{r_1}) \right\| \leqq C\, e^T\|f;\, L^{\bar q_2}([0, T], L^{\bar r_2})\| \tag{2.19}$$

for all r_i, $2\leqq r_i\leqq\infty$, $i=1, 2$, with $2/q_i=\frac{1}{3}-2/(3r_i)$ (with the same C as in (2.13)),

$$\left\| \int_0^\cdot d\tau \exp[-(\cdot-\tau)(D-1)^3]Df;\, L^q([0, T], L^\infty) \right\| \leqq C_q\, e^T T^{1/q-1/6}\|f;\, L^2([0, T], L^2)\| \tag{2.20}$$

for all q, $2\leqq q<6$ (C_q blows up as q increases to 6).

Proof. Estimates (2.17)-(2.19) follow immediately from estimates (2.11)-(2.13) if we expand $(D-1)^3$ in the exponential and note that the operator $\exp(-3tD)$ is the operator of translation by $3t$ and is therefore isometric in L^r for all r, while the diffusion operator $\exp(3tD^2)$ is a contraction in L^r for all r, $1\leqq r\leqq\infty$, and all $t\geqq 0$.

We now turn to the proof of (2.20). To prove that the operator K defined by

$$Kf(t) = \int_0^t d\tau \exp[-(t-\tau)(D-1)^3]Df(\tau) \tag{2.21}$$

is bounded from $L^2([0, T], L^2)$ to $L^q([0, T], L^\infty)$, it suffices to prove that the adjoint operator in $L^2([0, T], L^2)$, namely, the operator K^* defined by

$$K^*f(t) = -\int_t^T d\tau \exp[(\tau-t)(D+1)^3]Df(\tau) \tag{2.22}$$

is bounded from $L^{\bar{q}}([0, T], L^1)$ to $L^2([0, T], L^2)$. For that purpose we compute

$$\begin{aligned}&\|K*f; L^2([0, T], L^2)\|^2\\ &= \int_0^T dt \int_t^T d\tau\, d\tau' \langle Df(\tau), \exp[(\tau'-\tau)(D^3+3D)\\ &\qquad +(\tau+\tau'-2t)(3D^2+1)]Df(\tau')\rangle.\end{aligned} \tag{2.23}$$

Now the operator $D\exp(3tD^2)$ is represented by the convolution with the function

$$(-x/6t)(12\pi t)^{-1/2}\exp(-x^2/(12t))$$

and is therefore bounded in L^r for all r, $1\leqq r\leqq\infty$, by the Young inequality, with

$$\|\exp(3tD^2)Df\|_r \leqq (3\pi t)^{-1/2}\|f\|_r. \tag{2.24}$$

Using (2.11) with $r=\infty$ and (2.24), we estimate

$$\begin{aligned}&\|K*f; L^2([0, T], L^2)\|^2\\ &\leqq C\int_0^T dt \int_t^T d\tau\, d\tau' |\tau-\tau'|^{-1/3}\left(\frac{\tau+\tau'}{2-t}\right)^{-1}\exp(\tau+\tau'-2t)\|f(\tau)\|_1\|f(\tau')\|_1\\ &\leqq Ce^{2T}\int_0^T d\tau\, d\tau' |\tau-\tau'|^{-1/3}\|f(\tau)\|_1\|f(\tau')\|_1\int_0^{\min(\tau,\tau')} dt\left(\frac{\tau+\tau'}{2-t}\right)^{-1}.\end{aligned} \tag{2.25}$$

We perform the last integral and continue (2.25) as

$$\begin{aligned}&\cdots\leqq Ce^{2T}\int_0^T d\tau\, d\tau' |\tau-\tau'|^{-1/3}\log(2T|\tau-\tau'|^{-1})\|f(\tau)\|_1\|f(\tau')\|_1\\ &\leqq Ce^{2T}T^{2/q-1/3}\||\cdot|^{-1/3}\log(2|\cdot|^{-1}); L^{q/2}([-1, 1])\|f; L^{\bar{q}}([0, T], L^1)\|^2\end{aligned} \tag{2.26}$$

for all q, $2\leqq q<6$, by the Young inequality and an elementary homogeneity argument. The estimate (2.20) follows from (2.26) by duality, as explained above, and the constant C_q can be read off from (2.26). □

We now turn to the derivation of a set of weighted estimates for the operator $U(\cdot)$. The first estimates of this type are in L^∞ and rely on a direct use of (2.7).

LEMMA 2.3. *Let h be a continuous nonnegative function satisfying*

$$\begin{aligned}&h(x)=\exp(\alpha x) \quad \textit{for some } \alpha>0 \textit{ and all } x\leqq 0,\\ &0\leqq h(y)\leqq h(x)\leqq\exp[\alpha(x-y)]h(y) \quad \textit{for all } x\geqq y.\end{aligned} \tag{2.27}$$

Then the following estimate holds:

$$h^{1/2}(x)|DS_t(x-y)|h^{-1/2}(y)\leqq\begin{cases} C(t)t^{-3/4}(1+y)^{1/4} & \textit{for } y\geqq x_+,\\ C(t)t^{-3/4}\exp(-\gamma|x-y|/2) & \textit{for } y\leqq x_+\end{cases} \tag{2.28}$$

for $0\leqq\gamma<\alpha$, where $C(t)$ is uniformly bounded in t on bounded intervals and in γ for $0\leqq\gamma\leqq\gamma_0<\alpha$.

Proof. (C and c in this proof denote absolute constants, possibly different from one line to the next.) From (2.4), (2.7) we obtain

$$|DS_t(x-y)|\leqq Ct^{-3/4}(t^{1/12}+(y-x)_+^{1/4})\exp[-ct^{-1/2}(x-y)_+^{3/2}]. \tag{2.29}$$

We consider different cases. For $y\geqq x\geqq 0$, we use the fact that $h(x)\leqq h(y)$ to obtain

$$h^{1/2}(x)|DS_t(x-y)|h^{-1/2}(y)\leqq Ct^{-3/4}(t^{1/2}+y^{1/4}). \tag{2.30}$$

For $y \geqq 0 \geqq x$, we use the fact that $h(y) \geqq 1$, $h(x) = \exp(\alpha x)$ to obtain

$$h^{1/2}(x)|DS_t(x-y)|h^{-1/2}(y) \leqq Ct^{-3/4}(t^{1/12} + y^{1/4} + \sup_{x \leqq 0} |x|^{1/4} e^{\alpha x/2}) \tag{2.31}$$
$$= Ct^{-3/4}(t^{1/12} + y^{1/4} + (2\alpha e)^{-1/4})$$

by an elementary computation. For $y \leqq x$ or $x \leqq y \leqq 0$, we use the fact that $h(x)h^{-1}(y) \leqq \exp[\alpha(x-y)]$. Combining that estimate with (2.29), we obtain for $y \leqq x$

$$h^{1/2}(x)|DS_t(x-y)|h^{-1/2}(y) \leqq Ct^{-2/3} \exp(-\gamma|x-y|/2)$$
$$\cdot \sup_{x \geqq y} \exp[(\alpha+\gamma)(x-y)/2 - ct^{-1/2}(x-y)^{3/2}] \tag{2.32}$$
$$= Ct^{-2/3} \exp[-\gamma|x-y|/2 + ct(\alpha+\gamma)^3].$$

Finally, for $x \leqq y \leqq 0$ and $\gamma < \alpha$,

$$h^{1/2}(x)|DS_t(x-y)|h^{-1/2}(y) \leqq Ct^{-3/4} \exp(\gamma(x-y)/2)$$
$$\cdot \left\{ t^{1/12} + \sup_{x \leqq y} (y-x)^{1/4} \exp[(\alpha-\gamma)(x-y)/2] \right\} \tag{2.33}$$
$$= Ct^{-3/4} \exp(\gamma(x-y)/2)[t^{1/12} + (2(\alpha-\gamma)e)^{-1/4}].$$

Collecting (2.30)-(2.33) yields (2.28) with

$$C(t) = C\{1 + t^{1/12} \exp[ct(\alpha+\gamma)^3] + (\alpha-\gamma)^{-1/4}\}. \tag{2.34}$$

This proves the lemma. □

As an immediate consequence of Lemma 2.3, we obtain the following weighted $L^1 - L^\infty$ estimates for the operator U.

LEMMA 2.4. *Let h be a continuous function satisfying* (2.27). *Then the following estimates hold*:

$$\|h^{1/2}U(t)Dv\|_\infty \leqq C(t)t^{-3/4}\|h^{1/2}(1+x_+)^{1/4}v\|_1, \tag{2.35}$$

$$\left\| h^{1/2} \int_0^\cdot d\tau\, U(\cdot - \tau)Df(\tau);\ L^q([0,T], L^\infty) \right\| \tag{2.36}$$
$$\leqq C(T)\|h^{1/2}(1+x_+)^{1/4}f;\ L^l([0,T], L^1)\|,$$

for all q, l with $0 < 1/q = 1/l - \frac{1}{4} < \frac{3}{4}$ or for $q = \infty$, $l > 4$, and with $C(\cdot)$ uniformly bounded on the compact subsets of $\mathbb{R}^+$.

Proof. Inequalities (2.35) and (2.36) follow from (2.28) with $\gamma = 0$. Inequality (2.36) requires in addition the use of the Hardy-Littlewood-Sobolev inequality [8, p. 117] or of the Hölder inequality in time, depending on whether $q < \infty$ or $q = \infty$. □

We now turn to the derivation of weighted L^2-estimates. The basic result is the following.

LEMMA 2.5. *Let either $h \in \mathscr{C}^3(\mathbb{R}, \mathbb{R}^+)$ satisfy $h' \geqq 0$ and $h''' \leqq ch$ or $h \in \mathscr{C}(\mathbb{R}, \mathbb{R}^+)$ satisfy $h' \geqq 0$ and $h''^2 \leqq c^2 hh'$. For all f such that $h^{1/2}f \in L^1_{\mathrm{loc}}([0,T), L^2)$ and all t, $0 \leqq t < T$, define*

$$g(t) = \int_0^t d\tau \exp[c(t-\tau)/2]\|h^{1/2}f(\tau)\|_2. \tag{2.37}$$

Then the following estimates hold for all $t \geqq 0$, $t > 0$:

$$\|h^{1/2}U(t)u_0\|_2 \leqq e^{ct/2}\|h^{1/2}u_0\|_2, \tag{2.38}$$

$$\left\| h^{1/2} \int_0^t d\tau\, U(t-\tau)f(\tau) \right\|_2 \leqq g(t), \tag{2.39}$$

$$\left\| h^{1/2} \int_0^{\cdot} d\tau\, U(\cdot - \tau) f(\tau);\, L^\infty([0, T], L^2) \right\| \leqq e^{cT/2} \| h^{1/2} f;\, L^1([0, T], L^2) \|, \tag{2.40}$$

$$\| h'^{1/2} U(\cdot) D u_0;\, L^2([0, T], L^2) \| \leqq 2^{-1/2}\, e^{cT/2} \| h^{1/2} u_0 \|_2, \tag{2.41}$$

$$\left\| h'^{1/2} \int_0^{\cdot} d\tau\, U(\cdot - \tau) D f(\tau);\, L^2([0, T], L^2) \right\| \leqq 2^{-1/2} g(T) \leqq 2^{-1/2}\, e^{cT/2} \| h^{1/2} f;\, L^1([0, T], L^2) \|. \tag{2.42}$$

Proof. Let u be defined by (2.3) for smooth u_0 and f. From the differential equation (2.2) and the commutation relation

$$[D^3, h] = 3Dh'D + [D, h''] = 3Dh'D + h''', \tag{2.43}$$

possibly followed by the Schwarz inequality in the form

$$\begin{aligned} \langle u, [D, h'']u \rangle &\leqq 2c^{1/2} \| h^{1/2} u \| \, \| h'^{1/2} Du \| \\ &\leqq \langle Du, h'Du \rangle + c \langle u, hu \rangle, \end{aligned}$$

we obtain the identity

$$\partial_t \langle u, hu \rangle + 3 \langle Du, h'Du \rangle = \langle u, h'''u \rangle + 2 \langle u, hf \rangle \tag{2.44}$$

and from that estimate

$$\partial_t \langle u, hu \rangle + 2 \langle Du, h'Du \rangle \leqq c \langle u, hu \rangle + 2 |\langle u, hf \rangle|. \tag{2.45}$$

Omitting the term with Du, we obtain

$$\partial_t \| h^{1/2} u \|_2 \leqq (c/2) \| h^{1/2} u \|_2 + \| h^{1/2} f \|_2 \tag{2.46}$$

and by integration

$$\| h^{1/2} u(t) \|_2 \leqq e^{ct/2} \| h^{1/2} u_0 \|_2 + g(t), \tag{2.47}$$

from which we get (2.38) and (2.39) by taking successively $f = 0$ and $u_0 = 0$. Inequality (2.40) follows immediately from (2.39) and the definition of g. Next we integrate (2.45) in the interval $[0, T]$ to obtain

$$\begin{aligned} &\| h^{1/2} u(T) \|_2^2 + 2 \| h'^{1/2} Du;\, L^2([0, T], L^2) \|^2 \\ &\quad \leqq \| h^{1/2} u_0 \|_2^2 + \int_0^T dt\, \{ c \| h^{1/2} u(t) \|_2^2 + 2 \| h^{1/2} u(t) \|_2 \| h^{1/2} f(t) \|_2 \}. \end{aligned} \tag{2.48}$$

We omit the first term in the left-hand side of (2.48) and apply the resulting inequality successively with $f = 0$ and with $u_0 = 0$. For $f = 0$, we estimate the right-hand side by substituting (2.47) with $g = 0$ and obtain

$$\cdots \leqq \| h^{1/2} u_0 \|_2^2 \left[1 + c \int_0^T dt\, e^{ct} \right] = e^{cT} \| h^{1/2} u_0 \|_2^2. \tag{2.49}$$

This proves (2.41). For $u_0 = 0$, we estimate the right-hand side of (2.48) by substituting (2.47) with $u_0 = 0$ and obtain

$$\cdots \leqq \int_0^T dt\, \{ c g(t)^2 + 2 g(t) \| h^{1/2} f(t) \|_2 \} = \int_0^T dt\, 2 g(t) g'(t) = g(T)^2 \tag{2.50}$$

after noting that

$$g'(t) = \| h^{1/2} f(t) \|_2 + (c/2) g(t).$$

Formula (2.42) then follows from (2.48) continued by (2.50). □

We finally obtain a set of useful estimates by interpolation between those of Lemma 2.4 and those of Lemma 2.5.

LEMMA 2.6. *Let h_0 be a continuous function satisfying* (2.27) *and let h_1 satisfy the assumptions made on h in Lemma* 2.5. *Then the following estimate holds*:

$$\left\| h_0^{1/2-1/r} h_1^{1/r} \int_0^{\cdot} d\tau\, U(\cdot-\tau) Df(\tau);\, L^q([0,T],L^r) \right\| \leqq C(T) \| h_0^{1/2-1/r} h_1^{1/r} (1+x_+)^{1/4-(1/2r)} f;\, L^l([0,T],L^r) \| \tag{2.51}$$

for all $T>0$ and all r, $2 \leqq r \leqq \infty$, with

$$\frac{1}{r} < \frac{1}{q} = \frac{1}{l} - \frac{1}{4} - \frac{1}{2r} < \frac{3}{4} - \frac{1}{2r} \tag{2.52}$$

for $r>2$, and equality everywhere for $r=2$.

Proof. The result follows by interpolation between (2.36) written with h, q, r replaced by h_0, q_0, r_0, and (2.42) with h replaced by h_1. In particular q, l, and r are related to q_0, l_0, and r_0 by the convexity relations

$$\frac{1}{l} = \frac{1-2/r}{l_0} + \frac{2}{r}, \qquad \frac{1}{q} = \frac{1-2/r}{q_0} + \frac{1}{r}$$

and condition (2.52) simply expresses the condition $0 < 1/q_0 = 1/l_0 - \frac{1}{4} < \frac{3}{4}$ from Lemma 2.4. □

In the applications, we will often use smooth weighting factors that satisfy in particular the assumptions of Lemmas 2.4 and 2.5, decreasing exponentially when x tends to $-\infty$ and increasing as a power when x tends to $+\infty$. We will use a two-parameter family $\{h_{\alpha\beta}\}$, $\alpha>0$, $\beta \geqq 0$, satisfying the following properties: $h_{\alpha\beta} \in \mathscr{C}^\infty$, $h_{\alpha\beta}(x) = \exp(\alpha x)$ for $x \leqq 0$, $h_{\alpha\beta}(x) \sim Cx^\beta$ when $x \to +\infty$, $0 \leqq h'_{\alpha\beta} \leqq \alpha h_{\alpha\beta}$, and additional estimates for higher derivatives. For definiteness, we choose a nonnegative $\mathscr{C}^\infty$ function φ with compact support contained in $[-1,1]$ and with $\|\varphi\|_1 = 1$, and we define for $\alpha>0$, $\beta \geqq 0$

$$\omega_{\alpha\beta}(x) = \alpha \quad \text{for } x \leqq 1,$$
$$\omega_{\alpha\beta}(x) = \beta(x-1+\beta/\alpha)^{-1} \quad \text{for } x \geqq 1,$$
$$\tilde{\omega}_{\alpha\beta} = \omega_{\alpha\beta} * \varphi, \qquad h_{\alpha\beta}(x) = \exp\left\{ \int dy\, \tilde{\omega}_{\alpha\beta}(y) \right\}.$$

This family of functions meets all our requirements and will be used without further comments.

3. Uniqueness of L^2 solutions. In this section we derive our results on the uniqueness of L^2 solutions of the GKdV equation (1.1), more precisely of solutions in $(L^\infty_{\mathrm{loc}} \cap \mathscr{C}_W)([0,T],L^2)$ for some $T>0$, and we discuss the uniqueness classes that emerge naturally from them. The method is standard and consists of showing that a suitable norm of the difference of two solutions with the same initial data satisfies a linear inequality that compels it to be zero. Since the problem is local, it is sufficient to consider small time intervals, and since the equation is time-translation invariant, we can take the initial time to be zero. We first proceed formally and consider two solutions u_1, u_2 of (1.1) with common initial data $u_1(0) = u_2(0) = u_0$, defined in a time interval $[0,T)$. The difference $w = u_1 - u_2$ satisfies the equation

$$\partial_t w + D^3 w = DV'(u_1) - DV'(u_2) = D(\tilde{V}'' w) \tag{3.1}$$

where

$$\tilde{V}'' = \int_0^1 d\lambda\, V''(\lambda u_1 + (1-\lambda)u_2). \tag{3.2}$$

Since $w(0)=0$, w satisfies the integral equation

$$w(t)=\int_0^t d\tau\, U(t-\tau)D(\tilde{V}''w(\tau)). \tag{3.3}$$

Under suitable mild assumptions on V, u_1, and u_2, (3.1) and (3.3) make sense and are equivalent (under the initial condition $w(0)=0$) in a weak (distributional) sense. We will often assume that V satisfies the condition (1.5) or equivalently

$$|V''(\rho)|\leqq C|\rho|^p \tag{3.4}$$

for some $p>0$ and all $\rho\in\mathbb{R}$. We consider successively the cases $p\leqq 2$ and $p\geqq 2$. Our basic uniqueness result in the case $p\leqq 2$ is the following proposition.

PROPOSITION 3.1. *Let V satisfy* (3.4) *with $0<p\leqq 2$, let $u_0\in L^2$, and let $T>0$ (possibly $T=\infty$). Then* (1.1) *with initial data $u(0)=u_0$ has at most one solution satisfying*

$$u\in(L^\infty_{\mathrm{loc}}\cap\mathscr{C}_w)([0,T),L^2), \tag{3.5}$$

$$(1+x_+)^{\beta/2}u\in L^{q_1}_{\mathrm{loc}}([0,T),L^2), \tag{3.6}$$

$$h_{\alpha 0}^{1/2}u\in L^{q_1}_{\mathrm{loc}}([0,T),L^r)\quad \textit{for some } \alpha>0 \tag{3.7}$$

where

$$\frac{2}{q_1}=\beta=\frac{1}{p}-\frac{1}{4}, \tag{3.8}$$

$$\frac{1}{r}=\frac{1}{2}-\frac{p}{4}, \tag{3.9}$$

$$\frac{1}{q}<\frac{3}{4}-\frac{1}{2r}\equiv\frac{1}{2}+\frac{p}{8}. \tag{3.10}$$

Proof. Let u_1 and u_2 be two solutions satisfying (3.5)–(3.7) with common initial data $u_1(0)=u_2(0)=u_0$ and let $h=h_{\alpha 0}$. By (3.7), $h^{1/2}w\in L^q_{\mathrm{loc}}([0,T),L^r)$. Without loss of generality, we can assume that $q<r$. We estimate $h^{1/2}w$ by Lemma 2.6 with $h_1=h_{\alpha 1}$ and $h_0=h=h_{\alpha 0}$ and obtain for any $t\in[0,T)$

$$\|h^{1/2}w;\, L^q([0,T],L^r)\|\leqq C\|h^{1/2}(1+x_+)^{1/4+1/(2r)}\tilde{V}''w;\, L^l([0,t],L^{\bar{r}})\| \tag{3.11}$$

with q, r, and l satisfying (2.52). We next estimate the right-hand side by the Hölder inequality as

$$\cdots\leqq C\|h^{1/2}w;\, L^q([0,t],L^r)\|\,\|(1+x_+)^{1/4+1/(2r)}\tilde{V}'';\, L^m([0,t],L^s)\| \tag{3.12}$$

with $1/s=1-2/r$ and $1/m=1/l-1/q=\frac{1}{4}+1/(2r)$. The last norm is then estimated by using (3.6) as

$$\cdots\leqq C\sum_{i=1,2}\|(1+x_+)^{\beta/2}u_i;\, L^{q_1}([0,t],L^{r_1})\|^p \tag{3.13}$$

with

$$\beta=\frac{2}{q_1}=\frac{1}{2p}+\frac{1}{rp},\qquad \frac{1}{r_1}=\frac{1}{ps}=\frac{1}{p}-\frac{2}{rp}, \tag{3.14}$$

or equivalently

$$\beta=\frac{2}{q_1}=\frac{1}{p}-\frac{1}{2r_1},\qquad \frac{1}{r}=\frac{1}{2}-\frac{p}{2r_1}. \tag{3.15}$$

For $0<p\leqq 2$, we can choose $r_1=2$, so that (3.15) reduces to (3.8), (3.9), while the second inequality in (2.52) reduces to (3.10). Recalling (3.11)–(3.13), using the assumption (3.6), and taking t sufficiently small, we obtain $h^{1/2}w=0$ and therefore $w=0$ in $[0, t]$. □

Remark 3.1. For low values of p, (3.8) yields unpleasant values $q_1<1$. This is seen to arise from a natural assumption on $|u|^p$ and to create no trouble.

Remark 3.2. The values of q, r, and q_1 ensure in particular that $|u|^{p+1}\in L^l(L^{\bar r})$ with $l>1$, $\bar r\geqq 1$, so that the equation (1.1) makes sense in $\mathcal{D}'$.

Next we turn to the case $p\geqq 2$. The basic uniqueness result follows.

PROPOSITION 3.2. *Let V satisfy* (3.4) *with $p\geqq 2$, let $u_0\in L^2$, and let $T>0$ (possibly $T=\infty$). Then* (1.1) *with initial data $u(0)=u_0$ has at most one solution satisfying* (3.5) *and*

$$(3.16)_+ \qquad \chi_+(1+x)^{1/4}|u|^p\in L^{q_1}_{\mathrm{loc}}([0, T), L^1) \quad \textit{for some } q_1>4,$$

$$(3.16)_- \qquad \chi_-|u|^p\in l^\infty(L^{q_1}_{\mathrm{loc}}([0, T), L^1)) \quad \textit{for some } q_1>4,$$

$$(3.17)_+ \qquad \chi_+u\in L^q_{\mathrm{loc}}([0, T), L^\infty) \quad \textit{for some } q>\tfrac{4}{3},$$

$$(3.17)_- \qquad \chi_-\, e^{\alpha x/2}u\in l^\infty(L^q_{\mathrm{loc}}([0, T), L^\infty)) \quad \textit{for some } q>\tfrac{4}{3} \textit{ and some } \alpha>0.$$

Proof. Let u_1 and u_2 be two solutions satisfying (3.5), $(3.16)_\pm$, and $(3.17)_\pm$ with initial data $u_1(0)=u_2(0)=u_0$. Let $h=h_{\alpha 0}$. By $(3.17)_\pm$, $\chi_+h^{1/2}w\in L^q_{\mathrm{loc}}([0, T), L^\infty)$ and $\chi_+h^{1/2}w\in l^\infty(L^q_{\mathrm{loc}}([0, T), L^\infty))$. We estimate $h^{1/2}w$ by inserting the estimate (2.28) of Lemma 2.3 into the integral equation (3.3) and obtain

$$\begin{aligned}|h^{1/2}w(t, x)|\leqq C(t)\int_0^t d\tau\,|t-\tau|^{-3/4}\\ \cdot\Big\{\int_{y\geqq 0} dy\,(1+y)^{1/4}|\tilde V''(\tau, y)||h^{1/2}w(\tau, y)|\\ +\int_{y\leqq 0} dy\,\exp(-\gamma|x-y|/2)|\tilde V''(\tau, y)||h^{1/2}w(\tau, y)|\Big\}\\ \equiv J_+(x)+J_-(x).\end{aligned} \tag{3.18}$$

The contribution $J_+(x)$ of the region $y\geqq 0$ is estimated in $L^q([0, t])$ by the Hardy–Littlewood–Sobolev inequality [8, p. 117] as

$$\begin{aligned}\|J_+;\, L^q([0, t], L^\infty)\|\leqq C(t)\|\chi_+h^{1/2}w;\, L^q([0, t], L^\infty)\|\\ \cdot\|\chi_+(1+\cdot)^{1/4}\tilde V'';\, L^4([0, t], L^1)\|\end{aligned} \tag{3.19}$$

and the last norm is estimated by the use of (3.4) and $(3.16)_+$ as

$$C\sum_{i=1,2} t^{1/4-1/q_1}\|\chi_+(1+\cdot)^{1/4}|u_i|^p;\, L^{q_1}([0, t], L^1)\|. \tag{3.20}$$

The contribution $J_-(x)$ of the region $y\leqq 0$ is decomposed into the sum of the contributions of unit intervals:

$$J_-(x)\leqq C(t)\sum_{j\in\mathbf{Z}^-}\exp(-\gamma|x-j|/2)\int_0^t d\tau\,|t-\tau|^{-3/4}\|\chi_j\chi_-h^{1/2}w(\tau)\|_\infty\|\chi_j\chi_-\tilde V''(\tau)\|_1.$$

For $x \geqq 0$ we omit x in the exponential and estimate the time integral as before to obtain

$$\begin{aligned} \|\chi_+ J_-; L^q([0,t], L^\infty)\| &\leqq C(t) \sum_{j \leqq 0} e^{\gamma j/2} \|\chi_j \chi_- h^{1/2} w; L^q([0,t], L^\infty)\| \\ &\quad \cdot \|\chi_j \chi_- \tilde{V}''; L^4([0,t], L^1)\| \\ &\leqq C(t) t^{1/4-1/q_1} \|\chi_- h^{1/2} w; l^\infty(L^q([0,t], L^\infty))\| \\ &\quad \cdot \sum_{i=1,2} \|\chi_- |u_i|^p; l^\infty(L^{q_1}([0,t], L^1))\| \end{aligned} \tag{3.21}$$

by taking the sup over j of the last two norms in the middle member and using $(3.16)_-$. For $x \leqq 0$, we estimate similarly (with $k \leqq 0$)

$$\begin{aligned} \|\chi_k J_-; L^q([0,t], L^\infty)\| &\leqq C(t) \sum_{j \leqq 0} \exp(-\gamma|j-k|/2) \\ &\quad \cdot \|\chi_j \chi_- h^{1/2} w; L^q([0,t], L^\infty)\| \, \|\chi_j \chi_- \tilde{V}''; L^4([0,t], L^1)\| \end{aligned}$$

so that by the Young inequality in l' spaces and $(3.16)_-$ again

$$\begin{aligned} \|\chi_- J_-; l^\infty(L^q([0,t], L^\infty))\| &\leqq C(t) t^{1/4-1/q_1} \|\chi_- h^{1/2} w; l^\infty(L^q([0,t], L^\infty))\| \\ &\quad \times \sum_{i=1,2} \|\chi_- |u_i|^p; l^\infty(L^{q_1}([0,t], L^1))\|. \end{aligned} \tag{3.22}$$

Collecting the estimates (3.19)-(3.22) and defining

$$|||w||| = \|\chi_+ h^{1/2} w; L^q([0,t], L^\infty)\| + \|\chi_- h^{1/2} w; l^\infty(L^q([0,t], L^\infty))\|, \tag{3.23}$$

we obtain a linear inequality

$$|||w||| \leqq C(t) t^{1/4-1/q_1} M |||w||| \tag{3.24}$$

with

$$M = \sum_{i=1,2} \{\|\chi_+ (1+\cdot)^{1/4} |u_i|^p; L^{q_1}([0,t], L^1)\| + \|\chi_- \gamma u_i|^p; l^\infty(L^{q_1}([0,t], L^1))\|\}. \tag{3.25}$$

It follows from (3.24) by taking t sufficiently small that $|||w||| = 0$ and therefore that $w = 0$ in $[0, t]$. □

Remark 3.3. We could have stated $(3.16)_\pm$ in a slightly weaker form by taking $q_1 = 4$ and assuming in addition that for any fixed $s \in [0, T)$

$$\lim_{t > s, t \downarrow s} \|\chi_- |u|^p; l^\infty(L^4([s,t], L^1))\| = 0.$$

However, the only practical way to enforce that condition is through $(3.16)_-$ as stated with $q_1 > 4$. The condition $q_1 > 4$ is not really needed in $(3.16)_+$, where $q_1 = 4$ would be sufficient, and has been imposed for consistency.

We now turn to analyzing (3.5)-(3.7) and (3.5), $(3.16)_\pm$, $(3.17)_\pm$ that appear in Propositions 3.1 and 3.2, respectively, and in particular to deriving a priori estimates of the corresponding norms in terms of the initial data for smooth solutions of the equation (1.1). The degree of smoothness required in the following arguments is actually rather low. Aside from the decay at $+\infty$ in space that occurs, for instance, in (3.6) and $(3.16)_+$ and will have to be assumed explicitly in some form, it will be sufficient that the solutions satisfy $u \in (L^\infty_{\mathrm{loc}} \cap \mathscr{C}_w)([0, T), H^1)$ for all the other conditions to be satisfied and all subsequent calculations to make sense (see in particular Remark 3.7 below).

The first task is to dispose of the harmless assumptions (3.7) in Proposition 3.1 and $(3.17)_\pm$ in Proposition 3.2. This is done in Propositions 3.3 and 3.4 below.

PROPOSITION 3.3. *Let V satisfy*

$$|V'(\rho)| \leqq C|\rho|^{p+1} \tag{3.26}$$

with $0<p\leqq 2$, *let* $u_0\in L^2$, *let* $T>0$ (*possibly* $T=\infty$), *and let* u *be a solution of* (1.1) *with initial data* $u(0)=u_0$ *satisfying* (3.5)–(3.7) *with* (3.9), (3.10), *and*

$$\frac{2}{q_1}<\beta=\frac{1}{p}-\frac{1}{4}, \tag{3.27}$$

$$\max\left(\frac{1}{2}-\frac{p}{4},\frac{p}{12}\right)\equiv\max\left(\frac{1}{r},\frac{1}{6}-\frac{1}{3r}\right)<\frac{1}{q}. \tag{3.28}$$

Then, for any $t\in[0,T)$ *the norm of* $h_{\alpha 0}^{1/2}u$ *in* $L^q([0,t],L^r)$ *is estimated a priori in terms of* t, *of the norm of* u *in* $L^\infty([0,t],L^2)$ *and of the norm of* $(1+x_+)^{\beta/2}u$ *in* $L^{q_1}([0,t],L^2)$.

Proof. The proof is a slight variant of that of Proposition 3.1. We prove the result in successive intervals $[s_j,s_{j+1}]$ covering the interval $[0,t]$, with $s_0=0$. In each such interval, u satisfies the integral equation

$$u(t)=U(t-s)u(s)+\int_s^t d\tau\, U(t-\tau)DV'(u(\tau)) \tag{3.29}$$

with $s=s_j$. The free term in (3.29) is estimated by the use of (2.12) and the Hölder inequality as

$$\|h_{\alpha 0}^{1/2}U(\cdot-s)u(s);L^q(I,L^r)\|\leqq C|I|^{1/q-1/6+(1/3r)}\|u(s)\|_2 \tag{3.30}$$

with $I=[s_j,s_{j+1}]$. The integral in (3.29) is estimated in $L^q(I,L^r)$ by the same method as in the proof of Proposition 3.1 as

$$C\|h_{\alpha 0}^{1/2}u;L^q(I,L^r)\|\,\|(1+x_+)^{\beta/2}u;L^{q_1}(I,L^{r_1})\|^p|I|^\varepsilon \tag{3.31}$$

with $\varepsilon=\frac{1}{2}-p/8-p/q_1>0$. Now the right-hand side of (3.30) is obviously estimated in terms of the norm of u in $L^\infty(\cdot,L^2)$, while the coefficient of the first norm in (3.31) can be made less than or equal to $\frac{1}{2}$ (for instance) by taking I sufficiently small, depending only on the norm of $(1+x_+)^{\beta/2}u$ in $L^{q_1}(\cdot,L^{r_1})$, thereby providing an a priori estimate of the norm of $h_{\alpha 0}^{1/2}u$ in $L^q(I,L^r)$ in terms of the relevant quantities. □

PROPOSITION 3.4. *Let* V *satisfy* (3.26) *with* $p\geqq 2$, *let* $u_0\in L^2$, *let* $T>0$ (*possibly* $T=\infty$), *and let* u *be a solution of* (1.1) *with initial data* $u(0)=u_0$ *satisfying* (3.5), $(3.16)_\pm$, *and* $(3.17)_\pm$ *with* $\frac{4}{3}<q<6$.

Then, for any $t\in[0,T)$, *the norms of* χ_+u *in* $L^q([0,t],L^\infty)$ *and of* $\chi_-h_{\alpha 0}^{1/2}u$ *in* $l^\infty(L^q([0,t],L^\infty))$ *are estimated a priori in terms of* t *and of the norms of* u *in* $L^\infty([0,t],L^2)$, *of* $\chi_+(1+x)^{1/4}|u|^p$ *in* $L^{q_1}([0,t],L^1)$, *and of* $\chi_-|u|^p$ *in* $l^\infty(L^{q_1}([0,t],L^1))$.

Proof. The proof proceeds along the same lines as that of Proposition 3.3 by using the estimates of the proof of Proposition 3.2 instead of those of the proof of Proposition 3.1. We again prove the result in successive intervals $[s_j,s_{j+1}]$ covering $[0,t]$, with $s_0=0$. In each such interval I, u satisfies the integral equation (3.29) with $s=s_j$. The free term is now estimated by the use of (2.14) and with $h=h_{\alpha 0}$ as

$$\|h^{1/2}U(\cdot-s)u(s);L^q(I,L^\infty)\|\leqq C|I|^{1/q-1/6}\|u(s)\|_2. \tag{3.32}$$

The integral in (3.29) is estimated by the use of (2.28) and (3.26) as

$$\begin{aligned} h^{1/2}\int_s^t d\tau\, U(t-\tau)DV'(u(\tau))&\leqq C(|I|)\int_s^t d\tau\,|t-\tau|^{-3/4}\\ &\cdot\left\{\int_{y\geqq 0}dy\,(1+y)^{1/4}h^{1/2}|u(\tau,y)|^{p+1}\right.\\ &\left.+\int_{y\leqq 0}dy\exp(-\gamma|x-y|/2)h^{1/2}|u(\tau,y)|^{p+1}\right\}\\ &\equiv J_+(x)+J_-(x). \end{aligned} \tag{3.33}$$

We estimate J_+ and J_- as in the proof of Proposition 3.2 and obtain

$$\begin{aligned}(3.34)\qquad &\|J_+;\, L^q(I, L^\infty)\| \\ &\leqq C(|I|)|I|^{1/4-1/q_1}\|\chi_+ h^{1/2}u;\, L^q(I, L^\infty)\|\, \|\chi_+(1+\cdot)^{1/4}|u|^p;\, L^{q_1}(I, L^1)\|,\end{aligned}$$

$$\begin{aligned}(3.35)\qquad &\|\chi_+ J_-;L^q(I, L^\infty)\| + \|\chi_- J_-;\, l^\infty(L^q(I, L^\infty))\| \\ &\leqq C(|I|)|I|^{1/4-1/q_1}\|\chi_- h^{1/2}u;\, l^\infty(L^q(I, L^\infty))\|\, \|\chi_-|u|^p;\, l^\infty(L^{q_1}(I, L^1))\|.\end{aligned}$$

From (3.32), (3.33), and (3.35), we obtain an inequality of the form

$$(3.36)\qquad |||u||| \leqq C|I|^{1/q-1/6}\|u:\, L^\infty(I, L^2)\| + C(|I|)|I|^{1/4-1/q_1}M|||u|||$$

where $|||u|||$ is defined as in (3.23) and M as in (3.25), but with one single function u. The coefficient of $|||u|||$ in the right-hand side of (3.36) can be made less than or equal to $\frac{1}{2}$ (for instance) by taking I sufficiently small, depending only on the norms of u contained in M that correspond to $(3.16)_\pm$, thereby providing an a priori estimate of $|||u|||$ in terms of the latter norms. □

We now turn to the analysis of the main conditions (3.5), (3.6) of Proposition 3.1 and (3.5), $(3.16)_\pm$ of Proposition 3.2. An essential tool will be the following identity [10], [12] satisfied by the solutions of (1.1), a preliminary version of which has already been used in § 2:

$$(3.37)\qquad \partial_t\langle u, hu\rangle + 3\langle Du, h'Du\rangle = \langle u, h'''u\rangle - 2\int h'(uV'(u) - V(u))$$

or in integral form

$$\begin{aligned}(I.1)\qquad &\langle u, hu\rangle(t) + 3\int_0^t d\tau\, \langle Du, h'Du\rangle(\tau) \\ &= \langle u_0, hu_0\rangle + \int_0^t d\tau \left\{\langle u, h'''u\rangle(\tau) - 2\int h'(uV'(u) - V(u))(\tau)\right\}.\end{aligned}$$

We will henceforth refer to this identity as (I.1). Clearly it makes sense, for all $t \in [0, T)$, for $h \in \mathscr{C}^3(\mathbb{R}, \mathbb{R})$ with compactly supported h', provided

$$(3.38)\qquad u \in (L^\infty_{\mathrm{loc}} \cap \mathscr{C}_w)([0, T), L^2) \cap L^2_{\mathrm{loc}}([0, T), H^1_{\mathrm{loc}}),$$

$$(3.39)\qquad uV'(u) - V(u) \in L^1_{\mathrm{loc}}([0, T), L^1_{\mathrm{loc}}).$$

It is known that under suitable assumptions, (I.1) for positive increasing h implies that $h^{1/2}u \in L^\infty_{\mathrm{loc}}(L^2)$ as soon as $h^{1/2}u_0 \in L^2$ [10], [12]. Since we will make repeated use of that fact in various contexts, we prove it under assumptions that seem reasonably optimal. For that purpose we need some auxiliary estimates, which will arise as part of Lemma 3.2 below. We state that lemma here for convenience, although we will not need it in its full generality until the proof of Proposition 4.4 below. We begin with an elementary inequality that we give without proof.

LEMMA 3.1. *Let $0 \leqq \delta < 1$. Then for any $\varepsilon > 0$ and any $x, y \in \mathbb{R}^+$, the following estimate holds:*

$$(3.40)\qquad x^\delta y^{1-\delta} \leqq \varepsilon x + b_\varepsilon y$$

where

$$b_\varepsilon = (1-\delta)(\delta/\varepsilon)^{\delta/(1-\delta)}.$$

LEMMA 3.2. *Let $W \in \mathscr{C}(\mathbb{R}, \mathbb{R}^+)$ satisfy*

$$0 \leqq W(\rho) \leqq \varepsilon\rho^6 + a_\varepsilon|\rho|^{p+2}$$

for some p, $0 \leqq p < 4$ and all $\rho \in \mathbb{R}$. Let $h \in \mathscr{C}^1(\mathbb{R}, \mathbb{R}^+)$, $h > 0$. Then for any $\varepsilon' > 0$, the following estimate holds:

$$\begin{aligned}\|hW(u)\|_1 \leqq 5\{&(\varepsilon\|u\|_2^4 + \varepsilon' a_\varepsilon \|u\|_2^p)\langle Du, hDu\rangle + \varepsilon\|u\|_2^4\langle u, h^{-1}h'^2u\rangle \\ &+ a_\varepsilon\langle u, h^\nu u\rangle^{1+p/4}\langle u, h^{-1}h'^2u\rangle^{p/4} + a_\varepsilon b_{\varepsilon'}\langle u, h^\nu u\rangle^{1/\nu}\|u\|_2^{p+2-2/\nu}\}\end{aligned} \tag{3.41}$$

with $\nu = (4-p)/(4+p)$, for all $u \in L^2 \cap H^1_{\mathrm{loc}}$ for which all norms in the right-hand side are finite.

Proof. Clearly

$$\|hW(u)\|_1 \leqq \varepsilon I_4 + a_\varepsilon I_p \tag{3.42}$$

where

$$\begin{aligned}I_p = \||h|u|^{p+2}\|_1 &\leqq \langle u, h^\nu u\rangle \|h^{1-\nu}|u|^p\|_\infty \\ &= \langle u, h^\nu u\rangle \|h^{(1+\nu)/2}u^2\|_\infty^{p/2}.\end{aligned}$$

Now by an elementary computation

$$\begin{aligned}|h^{(1+\nu)/2}u^2| &\leqq [(1+\nu)/2]\langle u, h^{(\nu-1)/2}|h'|u\rangle + 2\|h^{\nu/2}u\|_2\|h^{1/2}Du\|_2 \\ &\leqq 5^{1/2}\langle u, h^\nu u\rangle^{1/2}\{\langle u, h^{-1}h'^2u\rangle + \langle Du, hDu\rangle\}^{1/2}\end{aligned} \tag{3.43}$$

by the Schwarz inequality, so that

$$I_p \leqq 5\langle u, h^\nu u\rangle^{1+p/4}\{\langle u, h^{-1}h'^2u\rangle^{p/4} + \langle Du, hDu\rangle^{p/4}\}. \tag{3.44}$$

We use (3.44) directly with p replaced by 4 to estimate I_4. On the other hand, we estimate the term containing Du in I_p by applying Lemma 3.1 with $\delta = p/4$ and $x = \langle Du, hDu\rangle\|u\|_2^p$, and obtain

$$\langle u, h^\nu u\rangle^{1+p/4}\langle Du, hDu\rangle^{p/4} \leqq \varepsilon'\|u\|_2^p\langle Du, hDu\rangle + b_{\varepsilon'}\langle u, h^\nu u\rangle^{1/\nu}\|u\|_2^{p+2-2/\nu}. \tag{3.45}$$

Substituting (3.45) into (3.44) and then into (3.42) yields (3.41). □

We now prove the basic set of estimates that can be derived from the identity (I.1).

PROPOSITION 3.5. *Let V satisfy the condition*

$$\lim_{|\rho|\to\infty} |\rho|^{-6}(\rho V'(\rho) - V(\rho))_- = 0. \tag{3.46}$$

Let $T > 0$, let $u_0 \in L^2$, and let u be a solution of the equation (1.1) *with initial data $u(0) = u_0$, satisfying* (3.38) *and* (3.39), *and such that* (I.1) *holds for all $h \in \mathscr{C}^3$ with compactly supported h'. Then*:

(1) *$Du \in l^\infty(L^2_{\mathrm{loc}}([0, T), L^2))$ and for all $t \in [0, T)$, Du is estimated in $l^\infty(L^2([0, t], L^2))$ in terms of t and of $\|u_0\|_2$.*

(2) *Let $h \in \mathscr{C}^3(\mathbb{R}, \mathbb{R}^+)$ satisfy $0 \leqq h' \leqq c_1(1+h)$, $h''^2 \leqq c_2 h'(1+h)$, $h''' \leqq c_3(1+h)$, and let $h^{1/2}u_0 \in L^2$. Then $h^{1/2}u \in L^\infty_{\mathrm{loc}}([0, T), L^2)$, $h'^{1/2}Du \in L^2_{\mathrm{loc}}([0, T), L^2)$ and for all $t \in [0, T)$, $h^{1/2}u$ is estimated in $L^\infty([0, t], L^2)$ and $h'^{1/2}Du$ is estimated in $L^2([0, t], L^2)$ in terms of t and of $\|(1+h)^{1/2}u_0\|_2$. In addition,* (I.1) *holds for that specific h.*

Remark 3.4. Condition (3.46) is satisfied, in particular, if V satisfies either (3.4) or (3.26) for some p, $0 \leqq p < 4$. Furthermore, in that case the integrability condition (3.39) follows from (3.38).

Proof of Proposition 3.5. We first note that (I.1) with $h \equiv 1$ implies the conservation of the L^2 norm, namely, $\|u(t)\|_2 = \|u_0\|_2$ for all $t \in [0, T)$. Condition (3.46) is not needed for that remark.

Next we consider $h \in \mathscr{C}^3(\mathbb{R}, \mathbb{R}^+)$ with compactly supported h'. From (3.46) and the conditions $V \in \mathscr{C}^2$, $V(0) = V'(0) = 0$, it follows that for any $\varepsilon > 0$, there exists $a_\varepsilon \geqq 0$ such that

$$(\rho V'(\rho) - V(\rho))_- \leqq \varepsilon \rho^6 + a_\varepsilon \rho^2 \tag{3.47}$$

for all $\rho \in \mathbb{R}$. We now estimate the last integral in the right-hand side of (I.1) by using (3.47), estimating the contribution of the term $\varepsilon\rho^6$ in the same way as in the proof of Lemma 3.2, with h replaced by h' (see especially (3.44) with $p = 4$, $\nu = 0$). We obtain

$$-\int h'(uV'(u) - V(u)) \leqq 5\varepsilon \|u\|_2^4 \langle Du, h'Du\rangle + (5\varepsilon c_2 \|u\|_2^4 + a_\varepsilon c_1)\langle u, (1+h)u\rangle. \tag{3.48}$$

Taking ε sufficiently small, depending only on $\|u_0\|_2$, for instance,

$$\varepsilon \|u\|_2^4 = \tfrac{1}{10},$$

we obtain from (I.1)

$$\langle u, hu\rangle(t) + 2\int_0^t d\tau \langle Du, h'Du\rangle(\tau) \leqq \langle u_0, hu_0\rangle + C\int_0^t d\tau \langle u, (1+h)u\rangle(\tau) \tag{3.49}$$

where C depends on $\|u_0\|_2$ and on h through c_1, c_2, and c_3 only.

We now prove part 1. For that purpose, we choose a function $\psi_0 \in \mathscr{C}^3$ with $0 \leqq \psi_0 \leqq 1$, $\psi_0(x) = 1$ (respectively, 0) for $|x| \leqq \frac{1}{2}$ (respectively, $|x| \geqq 1$), we define ψ_j by $\psi_j(x) = \psi_0(x - j)$ for all $j \in \mathbb{Z}$, and we apply (3.49) with $h = h_j$ defined by

$$h_j(x) = \int_{-\infty}^x \psi_j(y)\, dy,$$

thereby obtaining

$$2\|\chi_j Du;\, L^2([0, t], L^2)\|^2 \leqq (1 + Ct)(1 + \|\psi_0\|_1)\|u_0\|_2^2.$$

This proves part 1.

To prove part 2 under the relevant assumptions on h, we approximate h by a sequence h_N with compactly supported h'_N such that $h_N(x) = h(x)$ for $|x| \leqq N$, $h_N(x) =$ const. for $x \geqq N+1$ and for $x \leqq -(N+1)$, and such that h_N satisfies the same assumptions as h with constants c_1, c_2, c_3 uniform in N. We then apply (3.49) with h replaced by h_N and obtain from it estimates for $\langle u, h_N u\rangle$ and for $\langle Du, h'_N Du\rangle$ in terms of $\langle u_0, (1+h)u_0\rangle$, uniformly in N, by the Gronwall inequality. Taking the limit $N \to \infty$ yields the required estimates with the given h. Finally, (I.1) for that h follows from the estimates and from the Dominated Convergence Theorem. □

We now return to the analysis of conditions (3.5), (3.6) of Proposition 3.1 and $(3.16)_\pm$, $(3.17)_\pm$ of Proposition 3.2. In both cases, the conservation of the L^2-norm for (smooth) solutions satisfying (I.1) yields an a priori estimate in $L^\infty([0, T), L^2)$, thereby disposing of (3.5).

Next we consider condition (3.6) of Proposition 3.1 corresponding to $p \leqq 2$ in (3.4). In that case, it follows from Proposition 3.5 applied with $h = h_{0\beta}$ that smooth solutions of the equation (1.1) satisfy an a priori estimate in the space defined by (3.6), actually with $q_1 = \infty$, in terms of $\|(1 + x_+)^{\beta/2} u_0\|_2$. That result, together with Proposition 3.3 and L^2-norm conservation indicates that for $p \leqq 2$, (3.5)–(3.7) with (3.9), (3.10), (3.27), (3.28) define a suitable class for existence and uniqueness, with u_0 satisfying only the assumption $(1 + x_+)^{\beta/2} u_0 \in L^2$ with $\beta = 1/p - \frac{1}{4}$.

We now turn to the analysis of the main condition $(3.16)_{\pm}$ that occurs in Proposition 3.2 corresponding to the more difficult case $p \geqq 2$. We first give sufficient conditions for the corresponding norms of smooth solutions to satisfy a priori estimates. That can be done in either of two ways, the first of which is based on Proposition 3.5. We will need two auxiliary results. The first is the following elementary Sobolev estimate, which we give without proof.

LEMMA 3.3. *Let I be a bounded interval, let χ be its characteristic function, and let $u \in H^1(I)$. Then the following estimate holds*:

$$\|\chi u\|_\infty^2 \leqq |I|^{-1}\|u\|_2^2 + 2\|\chi u\|_2\|\chi Du\|_2. \tag{3.50}$$

The second auxiliary result that we need is the following lemma.

LEMMA 3.4. *Let $h \in \mathscr{C}(\mathbb{R}, \mathbb{R}^+)$ satisfy $0 \leqq h' \leqq c_1 h$ and $|h''| \leqq c_2 (hh')^{1/2}$. Let $t > 0$, and let u be such that $h^{1/2}u \in L^\infty([0, t], L^2)$ and $h'^{1/2}Du \in L^2([0, t], L^2)$. Let $2 \leqq r < \infty$, and let $h_1 \in \mathscr{C}(\mathbb{R}, \mathbb{R}^+)$ satisfy $h_1^2 \leqq h^{r/2+1}h'^{r/2-1}$. Then $h_1|u|^2 \in L^{q_1}([0, t], L^1)$ and the following estimate holds*:

$$\begin{aligned} &\|h_1|u|^r; L^{q_1}([0, t], L^1)\| \\ &\quad \leqq C\{t^{1/q_1}\|h^{1/2}u; L^\infty([0, t], L^2)\|^r + \|h^{1/2}u; L^\infty([0, t], L^2)\|^{r/2+1} \\ &\qquad \cdot \|h'^{1/2}Du; L^2([0, t], L^2)\|^{r/2-1}\} \end{aligned} \tag{3.51}$$

with $1/q_1 = r/4 - \frac{1}{2}$.

Proof. We estimate pointwise for $\tau \in [0, t]$

$$\|h_1|u|^r\|_1 \leqq \|h^{1/2}u\|_2^2 \|h_2 u^2\|_\infty^{r/2-1} \tag{3.52}$$

with $h_2 = (hh')^{1/2}$. Then by derivation and integration

$$\|h_2 u^2\|_\infty \leqq \tfrac{1}{2}\langle u, |h_2'|u\rangle + \|h^{1/2}u\|_2 \|h'^{1/2}Du\|_2. \tag{3.53}$$

Now

$$|h_2'| = \tfrac{1}{2}(hh')^{-1/2}|h'^2 + hh''| \leqq \tfrac{1}{2}(c_1^{3/2} + c_2)h$$

so that

$$\|h_1|u|^r\|_1 \leqq C\{\|h^{1/2}u\|_2^r + \|h^{1/2}u\|_2^{r/2+1}\|h'^{1/2}Du\|_2^{r/2-1}\} \tag{3.54}$$

from which the result follows by taking the L^{q_1} norm and applying the Hölder inequality in time. □

We can now derive a first set of a priori estimates of the norms that correspond to $(3.16)_{\pm}$ for sufficiently smooth solutions of (1.1) with V satisfying (3.4), $2 \leqq p < 3$, and exhibit a new uniqueness class in that case.

PROPOSITION 3.6. (1) *Let $2 \leqq p < 3$ and $\beta = \frac{1}{2} - 1/(2p)$. Let $T > 0$, and let us satisfy*

$$(1 + x_+)^{\beta/2}u \in L^\infty_{\mathrm{loc}}([0, T), L^2), \tag{3.55}$$

$$\chi_+(1 + x)^{(\beta-1)/2}Du \in L^2_{\mathrm{loc}}([0, T), L^2), \tag{3.56}_+$$

$$\chi_- Du \in l^\infty(L^2_{\mathrm{loc}}([0, T), L^2)). \tag{3.56}_-$$

Then $(3.16)_{\pm}$ is satisfied and the following estimates hold:

$$\begin{aligned} &\|\chi_+(1 + x)^{1/4}|u|^p; L^{q_1}([0, t], L^1)\| \\ &\quad \leqq C\{t^{1/q_1}\|h_{\alpha\beta}^{1/2}u; L^\infty([0, t], L^2)\|^p + \|h_{\alpha\beta}^{1/2}u; L^\infty([0, t], L^2)\|^{p/2+1} \\ &\qquad \cdot \|h'^{1/2}_{\alpha\beta}Du; L^2([0, t], L^2)\|^{p/2-1}\}, \end{aligned} \tag{3.57}_+$$

$$\begin{aligned} &\|\chi_-|u|^p; l^\infty(L^{q_1}([0, t], L^1))\| \\ &\quad \leqq C\{t^{1/q_1}\|\chi_- u; L^\infty([0, t], L^2)\|^p + \|\chi_- u; L^\infty([0, t], L^2)\|^{p/2+1} \\ &\qquad \cdot \|\chi_- Du; l^\infty(L^2([0, t], L^2))\|^{p/2-1}\}, \end{aligned} \tag{3.57}_-$$

for all $t \in [0, T)$, with $\alpha > 0$ and $1/q_1 = p/4 - \frac{1}{2}$ ($< \frac{1}{4}$).

(2) *Let V satisfy* (3.4) *with* $2 \leqq p < 3$. *Let* $T > 0$, *and let* $u_0 \in L^2$ *be such that* $(1+x_+)^{\beta/2} u_0 \in L^2$, *with* $\beta = \frac{1}{2} - 1/(2p)$. *Then* (1.1) *with initial data* $u(0) = u_0$ *has at most one solution satisfying* (3.5), (3.55), $(3.56)_\pm$, *and* $(3.17)_\pm$. *Any such solution satisfies* $(3.16)_\pm$ *with* $1/q_1 = p/4 - \frac{1}{2}$.

Proof. Part 1. It follows from $(3.56)_\pm$ that the last norm in $(3.57)_+$ is finite. The "+" part of the statement and $(3.57)_+$ follow immediately from Lemma 3.4 with $r = p$, $h = h_{\alpha\beta}$ and with $h_1 = c\chi_+(1+x)^{1/4}$ for $x \geqq 0$, the value of β being adjusted for that purpose. The "−" part and $(3.57)_-$ follow similarly from Lemma 3.3 and the Hölder inequality in time.

Part 2. Part 2 follows immediately from part 1 and Proposition 3.2. □

It follows from Proposition 3.4, from Proposition 3.6, part 1, and from Proposition 3.5, parts 1 and 2, the latter applied with $h = h_{\alpha\beta}$, that for V satisfying (3.4) with $2 \leqq p < 3$, the norms of smooth solutions of (1.1) corresponding to (3.55), $(3.56)_\pm$, $(3.17)_\pm$ and therefore also the norms corresponding to $(3.16)_\pm$ satisfy a priori estimates in terms of the initial data, and more precisely of $\|(1+x_+)^{\beta/2} u_0\|_2$ with $\beta = \frac{1}{2} - 1/(2p)$. That result indicates that for $2 \leqq p < 3$, (3.5), $(3.16)_\pm$, $(3.17)_\pm$ with $1/q_1 = p/4 - \frac{1}{2}$ and $\frac{4}{3} < q < 6$ define a suitable class for existence and uniqueness provided only $(1+x_+)^{\beta/2} u_0 \in L^2$. Similarly, (3.5), (3.55), $(3.56)_\pm$, $(3.17)_\pm$ with $1/q_1 = p/4 - \frac{1}{2}$ and $\frac{4}{3} < q < 6$ define another (smaller) suitable class.

The value of p in Proposition 3.6 is restricted to $p < 3$. This limitation comes from (actually expresses) the condition $q_1 > 4$ in $(3.16)_\pm$. Furthermore, the value of β that appears in the condition on u_0 increases with p. We will obtain better results in both respects by the second method, described below, of ensuring condition $(3.16)_\pm$.

PROPOSITION 3.7. *Let* $T > 0$ (*possibly* $T = \infty$). *Let* $p \geqq 2$.

(1) *Let u satisfy* (3.5) *and the conditions*

$$(1+x_+)^{1/8} u \in L^\infty_{\mathrm{loc}}([0, T), L^2), \tag{3.58}$$

$$\chi_+ u \in L^q_{\mathrm{loc}}([0, T), L^\infty), \tag{3.59}_+$$

$$\chi_- u \in l^\infty(L^q_{\mathrm{loc}}([0, T), L^\infty)), \tag{3.59}_-$$

with $q > \max(\frac{4}{3}, 4(p-2))$. *Then* $(3.16)_\pm$ *is satisfied with* $q_1 = q/(p-2) > 4$, *and for all* $t \in [0, T)$, *the following estimates hold*:

$$\begin{aligned} &\|\chi_+(1+x)^{1/4}|u|^p;\ L^{q_1}([0, T], L^1)\| \\ &\quad \leqq \|\chi_+(1+x)^{1/8} u;\ L^\infty([0, t], L^2)\|^2 \|\chi_+ u;\ L^q([0, t], L^\infty)\|^{p-2}, \end{aligned} \tag{3.60}_+$$

$$\begin{aligned} &\|\chi_-|u|^p;\ l^\infty(L^{q_1}([0, t], L^1))\| \\ &\quad \leqq \|\chi_- u;\ L^\infty([0, t], L^2)\|^2 \|\chi_- u;\ l^\infty(L^q([0, t], L^\infty))\|^{p-2}. \end{aligned} \tag{3.60}_-$$

Furthermore $(3.17)_\pm$ *hold with the same q and obvious estimates.*

(2) *Let V satisfy* (3.26) *with* $2 \leqq p < \frac{7}{2}$. *Let* $T > 0$, *let* $u_0 \in L^2$, *and let u be a solution of* (1.1) *with initial data* $u(0) = u_0$ *satisfying* (3.58), $(3.59)_\pm$ *with*

$$\max(\tfrac{4}{3}, 4(p-2)) < q < 6, \tag{3.61}$$

and in addition $Du \in l^\infty(L^2_{\mathrm{loc}}([0, T), L^2))$. *Then, for all* $t \in [0, T)$, *the norms of* $\chi_+ u$ *in* $L^q([0, t], L^\infty)$ *and of* $\chi_- u$ *in* $l^\infty(L^q([0, t], L^\infty))$ *are estimated in terms of t and of the norms of* $(1+x_+)^{1/8} u$ *in* $L^\infty([0, t], L^2)$, *and of* Du *in* $l^\infty(L^2, ([0, t], L^2))$.

(3) *Let V satisfy* (3.4) *with* $2 \leqq p < \frac{7}{2}$, *let* $T > 0$, *and let* $u_0 \in L^2$ *satisfy* $(1+x_+)^{1/8} u_0 \in L^2$. *Then* (1.1) *with initial data* $u(0) = u_0$ *has at most one solution satisfying* (3.5), (3.58),

and $(3.59)_{\pm}$ *with* q *satisfying* (3.61). *Any such solution satisfies* $(3.16)_{\pm}$ *with* $q_1 = q/(p-2)$ *and* $(3.17)_{\pm}$.

Proof. Part 1. Part 1 and $(3.60)_{\pm}$ follow immediately from the Hölder inequality.

Part 2. We prove the result in successive intervals $[s_j, s_{j+1}]$ covering the interval $[0, t]$, with $s_0 = 0$. In each such interval I, u satisfies the integral equation (3.29) with $s = s_j$. We proceed in two steps. The first step consists of estimating u in $l^\infty(L^q(I, L^\infty))$. For that purpose, we take a $\mathscr{C}^3$ function ψ with compact support, to be chosen more precisely later. Let χ be the characteristic function of the support of ψ. If u is a solution of (1.1), then ψu satisfies

$$\partial_t(\psi u) + D^3(\psi u) = 3D(\psi' Du) + \psi''' u + D(\psi V'(u)) - \psi' V'(u) \tag{3.62}$$

and therefore also the integral equation

$$\begin{aligned} \psi u(t) &= \chi U(t-s)\psi u(s) + \chi \int_s^t d\tau\, U(t-\tau) \\ &\quad \cdot \{3D(\psi' Du(\tau)) + \psi''' u(\tau) + D(\psi V'(u(\tau))) - \chi' V'(u(\tau))\} \\ &= \chi U(t-s)\psi u(s) + \sum_{1 \leqq i \leqq 4} J_i(t) \end{aligned} \tag{3.63}$$

where we have used the support properties of ψ and where the quantities $J_i(t)$, $i = 1, \cdots, 4$ are the contributions of the four terms in the last bracket.

We now estimate all terms in $L^q(I, L^\infty)$. The free term is estimated as before by (2.14) and the Hölder inequality as

$$\| U(\cdot - s)\psi u(s); L^q(I, L^\infty)\| \leqq C|I|^{1/q-1/6} \|u(s)\|_2. \tag{3.64}$$

To estimate J_1, we rewrite it as

$$J_1(t) = 3\chi e^{-x} \int_s^t d\tau \exp[-(t-\tau)(D-1)^3](D-1)e^x \psi' Du(\tau). \tag{3.65}$$

Furthermore,

$$(D-1)e^x \psi' Du = D(e^x \psi' Du - e^x \psi' u) + e^x(\psi' + \psi'')u. \tag{3.66}$$

The contributions to $J_1(t)$ of the first and second terms in the right-hand side of (3.66) are estimated by Lemma 2.2 (see especially (2.20) and (2.19), respectively) and the Hölder inequality as

$$\begin{aligned} \|J_1; L^q(I, L^\infty)\| &\leqq Ce^{|I|} \|\chi e^{-x}\|_\infty \{\|\psi'\, e^x\|_\infty (|I|^{1/q-1/6} \|\chi Du; L^2(I, L^2)\| \\ &\qquad + |I|^{1/q+1/3} \|\chi u; L^\infty(I, L^2)\|) \\ &\qquad + \|(\psi' + \psi'')\, e^x\|_\infty |I|^{1/q+5/6} \|\chi u; L^\infty(I, L^2)\|\} \\ &\leqq C(|I|)|I|^{1/q-1/6} (\|\chi Du; L^2(I, L^2)\| + \|\chi u; L^\infty(I, L^2)\|) \end{aligned} \tag{3.67}$$

where $C(|I|)$ depends on ψ in a translation-invariant manner. In particular, the exponentials in the various norms cancel up to a constant factor because of the support properties of ψ.

We estimate J_2 by (2.15) and the Hölder inequality as

$$\|J_2; L^q(I, L^\infty)\| \leqq C|I|^{1/q+5/6} \|\psi'''\|_\infty \|\chi u; L^\infty(I, L^2)\|. \tag{3.68}$$

We estimate J_3 and J_4 simply by using (2.10) and (2.9) so that

$$\|J_3(t) + J_4(t)\|_\infty \leqq C(|I|) \int_0^t d\tau\, |t-\tau|^{-3/4} \|\chi V'(u(\tau))\|_1 \tag{3.69}$$

where we have taken advantage of the support properties of χ and ψ', and $C(|I|)$ depends on ψ in a translation invariant manner. Taking the norm in $L^q(I)$ and using the Young and Hölder inequalities, we obtain

$$\|J_3+J_4;\ L^q(I,L^\infty)\| \leqq C(|I|)|I|^{1/4-(p-2)}\|\chi u;\ L^\infty(I,L^2)\|^2\|\chi u;\ L^q(I,L^\infty)\|^{p-1}. \tag{3.70}$$

Recalling the estimates (3.64), (3.67), (3.68), and (3.70), we obtain

$$\begin{aligned}\|\psi u;\ L^q(I,L^\infty)\| \leqq C(|I|)\{&|I|^{1/q-1/6}(\|\chi Du;\ L^2(I,L^2)\|+\|u;\ L^\infty(I,L^2)\|)\\ &+|I|^{1/4-(p-2)/q}\|u;\ L^\infty(I,L^2)\|^2\|\chi u;\ L^q(I,L^\infty)\|^{p-1}\}.\end{aligned} \tag{3.71}$$

We now choose a function $\psi_0\in\mathscr{C}^3$ with $0\leqq\psi_0\leqq 1$, $\psi_0(x)=1$ for $|x|\leqq\frac{1}{2}$ and $\psi_0(x)=0$ for $|x|\geqq 1$, and for all $j\in\mathbb{Z}$, we define ψ_j by $\psi_j(x)=\psi_0(x-j)$ so that for all $j\in\mathbb{Z}$,

$$\chi_j\leqq\psi_j\leqq\bar{\chi}_j\leqq\chi_{j-1}+\chi_j+\chi_{j+1}$$

where $\bar{\chi}_j$ is the characteristic function of the support $[j-1, j+1]$ of ψ_j. We now apply (3.71) with $\psi=\psi_j$ and take the supremum over j to obtain

$$\begin{aligned}\|u;\ l^\infty(L^q(I,L^\infty))\| \leqq C(|I|)\{&|I|^{1/q-1/6}(\|Du;\ l^\infty(L^2(I,L^2))\|+\|u;\ L^\infty(I,L^2)\|)\\ &+|I|^{1/4-(p-2)/q}\|u;\ L^\infty(I,L^2)\|^2\|u;\ l^\infty(L^q(I,L^\infty))\|^{p-1}\}.\end{aligned} \tag{3.72}$$

Now let

$$y(t)=\|u;\ l^\infty(L^q([s,t],L^\infty))\|. \tag{3.73}$$

It follows from (3.72) that $y(\cdot)$ is a continuous (actually Hölder continuous with exponent $\varepsilon=\min(1/q-\frac{1}{6},\frac{1}{4}-(p-2)/q)$) function of t and tends to zero when t decreases to s. Furthermore, (3.72) with $I=[s,t]$ yields an inequality of the form

$$y(t)\leqq a(t)+b(t)y(t)^{p-1} \tag{3.74}$$

where $a(t)$ and $b(t)$ tend to zero as $|t-s|^\varepsilon$ when t decreases to s. By an elementary and standard argument, this inequality implies that $y(t)$ is estimated a priori for $|t-s|$ sufficiently small, depending only on the norms of u in $L^\infty(\cdot,L^2)$ and of Du in $l^\infty(L^2(\cdot,L^2))$. Applying that argument in successive intervals $[s_j,s_{j+1}]$ yields the required a priori estimate of u in $l^\infty(L^q(\cdot,L^\infty))$.

The second step of the proof consists of estimating χ_+u in $L^q(\cdot,L^\infty)$, taking advantage of the estimate already obtained in the first step. For that purpose, we take $h=h_{\alpha 0}$ for some $\alpha>0$ and estimate $h^{1/2}u$ by inserting (2.28) of Lemma 2.3 into the integral equation (3.29) to obtain for $t\in I$

$$\begin{aligned}|h^{1/2}u(t,x)| \leqq{}& |h^{1/2}U(t-s)u(s)|+C(|I|)\int_s^t d\tau\,|t-\tau|^{-3/4}\\ &\cdot\Big\{\int_{y\geqq 0}dy\,(1+y)^{1/4}h^{1/2}|u(\tau,y)|^{p+1}\\ &\quad+\int_{y\leqq 0}dy\,\exp(-\gamma|x-y|/2)h^{1/2}|u(\tau,y)|^{p+1}\Big\}\\ \equiv{}& |h^{1/2}U(t-s)u(s)|+J_+(x)+J_-(x)\end{aligned} \tag{3.75}$$

(cf. (3.33)). By the same method as in the proof of Proposition 3.4, we estimate

$$\begin{aligned}&\|J_+;\ L^q(I,L^\infty)\|\\ &\quad\leqq C(|I|)|I|^{1/4-(p-2)/q}\|\chi_+(1+\cdot)^{1/8}u;\ L^\infty(I,L^2)\|^2\|\chi_+u;\ L^q(I,L^\infty)\|^{p-1},\end{aligned} \tag{3.76}$$

$$\|\chi_+ J_-;\, L^q(I, L^\infty)\| \leqq C(|I|)|I|^{1/4-(p-2)/q}\|\chi_- u;\, L^\infty(I, L^2)\|^2 \cdot \sum_{j\leqq 0} \exp\left(\frac{\gamma j}{2}\right)\|\chi_j\chi_- u;\, L^q(I, L^\infty)\|^{p-1}, \tag{3.77}$$

so that by collecting (3.64), (3.76), and (3.77)

$$\begin{aligned}\|\chi_+ u;\, L^q(I, L^\infty)\| &\leqq C|I|^{1/q-1/6}\|u;\, L^\infty(I, L^2)\| \\ &\quad + C(|I|)|I|^{1/4-(p-2)/q}\|(1+x_+)^{1/8}u;\, L^\infty(I, L^2)\| \\ &\quad \times\{\|\chi_+ u;\, L^q(I, L^\infty)\|^{p-1} + \|\chi_- u;\, l^\infty(L^q(I, L^\infty))\|^{p-1}\}.\end{aligned} \tag{3.78}$$

Therefore we again obtain an inequality of the type (3.74), for the quantity

$$y_+(t) = \|\chi_+ u;\, L^q([s, t], L^\infty)\|.$$

The end of the proof is then identical with that in the first step.

Part 3. This part follows immediately from part 1 and Proposition 3.2. □

It follows from Proposition 3.7, part 2 and from Proposition 3.5, part 1, and part 2 applied with $h = h_{\alpha 1/4}$, that for smooth solutions of (1.1) with V satisfying (3.4) and $2 \leqq p < \frac{7}{2}$, the norms corresponding to (3.58), $(3.59)_\pm$, and therefore, by Proposition 3.7, part 1, the norms corresponding to $(3.16)_\pm$ and $(3.17)_\pm$ with (3.61) and $q_1 = q/(p-2)$, satisfy a priori estimates in terms of the initial data, and more precisely in terms of $\|(1+x_+)^{1/8}u_0\|_2$. That result indicates that for $2 \leqq p < \frac{7}{2}$, (3.5), $(3.16)_\pm$, and $(3.17)_\pm$ with (3.61) and $q_1 = q/(p-2)$ define a suitable class for existence and uniqueness, provided only $(1+x_+)^{1/8}u_0 \in L^2$. Similarly (3.5), (3.58), $(3.59)_\pm$, (3.61) define another (smaller) suitable class. Note also that Proposition 3.7 improves over Proposition 3.6 as regards both the range of p and the value of β.

An interesting question left open at this stage is to determine sufficient smoothness conditions under which (I.1) and the a priori estimates of Proposition 3.5 hold true. Such conditions could be used, in particular, to exhibit uniqueness classes other than those defined in Propositions 3.1, 3.2, 3.6, and 3.7. Now the use of (I.1) requires that u satisfy (3.38). Although we are not able to derive (I.1) under that smoothness condition alone, we can go some way in that direction. For that purpose, we need a family of mollifiers $\varphi \in \mathscr{C}_0^\infty(\mathbb{R}, \mathbb{R}^+)$ with φ even and $\|\varphi\|_1 = 1$. We will eventually let φ tend to $\mathbb{1}$ in the sense that we will let μ tend to infinity in the one-parameter family $\{\varphi_\mu\}$ defined by $\varphi_\mu(x) = \mu\varphi_1(\mu x)$ for some fixed φ_1.

We can then prove the following result.

PROPOSITION 3.8. *Let V satisfy* (3.4) *with* $0 \leqq p \leqq 4$. *Let* $T > 0$, *let* $u_0 \in L^2$, *and let u be a solution of* (1.1) *with initial data* $u(0) = u_0$ *satisfying* (3.38). *Then*:

(1) *For any* $h \in \mathscr{C}^3$ *with compact support, for all* $t \in [0, T)$, *the following limit exists*:

$$\begin{aligned}&\exists \lim_{\varphi\to\mathbb{1}} 2\int_0^t d\tau\, \langle hDu_\varphi,\, V'(u_\varphi) - \varphi * V'(u)\rangle(\tau) \\ &= \langle u, hu\rangle(t) - \langle u_0, hu_0\rangle + 3\int_0^t d\tau\, \langle Du, h'Du\rangle(\tau) \\ &\quad - \int_0^t d\tau\, \langle u, h'''u\rangle(\tau) + 2\int_0^t d\tau \int h'(uV'(u) - V(u))(\tau)\end{aligned} \tag{3.79}$$

where φ is a mollifier, $u_\varphi = \varphi * u$, and all terms in the right-hand side are defined by absolutely convergent integrals.

(2) *If* $p \leqq 2$, *the identity* (I.1) *holds for all* $h \in \mathscr{C}^3$ *with compact support.*

(3) *Assume that* $p<4$ *and that the identity* (I.1) *holds for all* $h \in \mathscr{C}^3$ *with compact support. Then* $Du \in l^\infty(L^2_{\mathrm{loc}}([0, T), L^2))$. *Furthermore, for all* $\psi \in \mathscr{C}^2$ *with compact support, for all* $t \in [0, T)$, *the following limit exists*:

$$\exists \lim_{a \to \pm\infty} 3 \int_0^t d\tau \, \langle Du, \psi_a Du \rangle(\tau) = \|\psi\|_1 l_1^{\pm}(t) \tag{3.80}$$

where ψ_a *is defined by* $\psi_a(x) = \psi(x-a)$. *The functions* $l_1^{\pm}(t)$ *are nondecreasing in* t *and satisfy*

$$l_1^+(t) - l_1^-(t) = \|u(t)\|_2^2 - \|u_0\|_2^2 \tag{3.81}$$

for all $t \in [0, T)$. *The identity* (I.1) *holds for all* $h \in \mathscr{C}^3$ *with compactly supported* h' *if and only if* $l_1^{\pm}(t) = 0$ *for all* $t \in [0, T)$.

Proof. Part 1. We first remark that under the assumptions made here, $V'(u) \in L^1_{\mathrm{loc}}([0, T); L^2_{\mathrm{loc}})$. In fact, let χ be the characteristic function of a bounded interval. Then by Lemma 3.3,

$$\|\chi V'(u)\|_2 \leqq \|\chi |u|^{p+1}\|_2 \leqq C\{\|\chi u\|_2^{p+1} + \|\chi u\|_2^{1+p/2} \|\chi Du\|_2^{p/2}\}, \tag{3.82}$$

which belongs to $L^1_{\mathrm{loc}}([0, T))$ for $p \leqq 4$.

We now turn to the proof of (3.79). The function u_φ satisfies the equation

$$\partial_t u_\varphi + D^3 u_\varphi = D(\varphi * V'(u)). \tag{3.83}$$

Furthermore, $u_\varphi \in L^\infty_{\mathrm{loc}}([0, T), H^k)$ and $D(\varphi * V'(u)) \in L^1_{\mathrm{loc}}([0, T), H^k_{\mathrm{loc}})$ for any nonnegative integer k. By the same computation as in the proof of Lemma 2.5 (see (2.44)), we obtain for any $t \in [0, T)$

$$\begin{aligned}
&\langle u_\varphi, h u_\varphi \rangle(t) - \langle \varphi * u_0, h(\varphi * u_0) \rangle + 3 \int_0^t d\tau \, \langle Du_\varphi, h' Du_\varphi \rangle(\tau) - \int_0^t d\tau \, \langle u_\varphi, h''' u_\varphi \rangle(\tau) \\
&\quad = 2 \int_0^t d\tau \, \langle u_\varphi, hD(\varphi * V'(u)) \rangle \\
&\quad = 2 \int_0^t d\tau \, \langle u_\varphi, hDV'(u_\varphi) \rangle + 2 \int_0^t d\tau \, \langle u_\varphi, hD(\varphi * V'(u) - V'(u_\varphi)) \rangle \\
&\quad = -2 \int_0^t d\tau \int h'(u_\varphi V'(u_\varphi) - V(u_\varphi)) + 2 \int_0^t d\tau \, \langle h' u_\varphi + hDu_\varphi, (V'(u_\varphi) - \varphi * V'(u)) \rangle.
\end{aligned} \tag{3.84}$$

We then let φ tend to $\mathbb{1}$ wherever possible in (3.84), using the fact that the convolution with φ tends to $\mathbb{1}$ strongly in H^k for any $k \geqq 0$ and in L^r for any r, $1 \leqq r < \infty$. Under the assumptions made, all terms in the first member of (3.84) converge to the obvious limits. Next we consider the first term in the last member. From the identity

$$u_\varphi V'(u_\varphi) - V(u_\varphi) - (uV'(u) - V(u)) = (u_\varphi - u) \int_0^1 d\lambda \, \tilde{u} V''(\tilde{u}) \tag{3.85}$$

with $\tilde{u} = \lambda u_\varphi + (1-\lambda)u$, we obtain, with χ being the characteristic function of Support h' and $\bar{\chi}$ that of Support h' + Support φ,

$$\|\chi(\cdot)\|_1 \leqq C \|\chi(u_\varphi - u)\|_2 \|\bar{\chi} |u|^{p+1}\|_2, \tag{3.86}$$

which converges to zero in $L^1_{\mathrm{loc}}([0, T))$ by (3.82) and the Dominated Convergence Theorem.

The same argument shows that the contribution of $h'u_\varphi$ in the last integral in (3.84) tends to zero as φ tends to $\mathbb{1}$, so that the only term left uncontrolled at this stage in (3.84) is the contribution of hDu_φ to that same integral. This proves (3.79).

Part 2. In the same way as in part 1, we prove that $V'(u_\varphi)-\varphi * V'(u)$ now converges to zero in $L^2_{\text{loc}}([0, T), L^2_{\text{loc}})$. In fact,

$$V'(u_\varphi)-V'(u)=(u_\varphi-u)\int_0^1 d\lambda\ V''(\tilde{u})$$

so that by Lemma 3.3 (see (3.82)), with χ the characteristic function of a bounded interval I, and $\bar{\chi}$ that of $I+\text{Support }\varphi$,

$$\|\chi(V'(u_\varphi)-V'(u))\|_2 \leqq C\|u_\varphi-u\|_2\{\|\bar{\chi}u\|_2^p+\|\bar{\chi}u\|_2^{p/2}\|\bar{\chi}Du\|_2^{p/2}\},$$

which tends to zero in $L^2_{\text{loc}}([0, T))$ for $p\leqq 2$. Consequently, the integral in the left-hand side of (3.79) tends to zero for compactly supported h. This completes the proof of part 2.

Part 3. Let $\psi\in\mathscr{C}^2$ have compact support $[-R, R]$. Without loss of generality we can assume that $(0\leqq)\psi'^2\leqq C\psi$ and that $\|\psi\|_1=1$. We define $h_a^{\pm}$ by

$$h_a^{\pm}(x)=\pm\int_{\mp\infty}^{x} dy\,\psi_a(y)$$

so that $h_a^{\pm}(x)=1$ for $x\gtrless a\pm R$ and $h_a^{\pm}(x)=0$ for $x\lesseqgtr a\mp R$. We apply the identity (I.1) with $h=h_a^+h_b^-$ and $b-a\geqq 2R$ to obtain

$$\begin{aligned}&\langle u(t), hu(t)\rangle-\langle u_0, hu_0\rangle+3\int_0^t d\tau\,\langle Du, (\psi_a-\psi_b)Du\rangle(\tau)\\ &-\int_0^t d\tau\,\langle u, (\psi_a''-\psi_b'')u\rangle(\tau)\\ &=-2\int_0^t d\tau\int(\psi_a-\psi_b)(uV'(u)-V(u))(\tau).\end{aligned}\tag{3.87}$$

By the same computation as in the proof of Lemma 3.2, applied with h replaced by ψ and $W(u)=uV'(u)-V(u)$ (see especially (3.43)) and by using the support properties of ψ, we can estimate the contribution of ψ_b to the right-hand side of (3.87) as

$$\begin{aligned}&\left|2\int_0^t d\tau\int\psi_b(uV'(u)-V(u))(\tau)\right|\\ &\quad\leqq C\int_0^t d\tau\,\{\|\chi_b u\|_2^{p+2}+\|\chi_b u\|_2^{2+p/2}\langle Du, \psi_b Du\rangle^{p/4}\}(\tau)\\ &\quad\leqq C\int_0^t d\tau\,\|\chi_b u\|_2^{p+2}+Ct^{1-p/4}\left\{\int_0^t d\tau\,\langle Du, \psi_b Du\rangle(\tau)\right\}^{p/4}\\ &\qquad\times\|\chi_b u; L^\infty([0, t], L^2)\|^{2+p/2}\end{aligned}\tag{3.88}$$

where χ_b is the characteristic function of $[b-R, b+R]$. From (3.87), (3.88), it follows that for fixed a, the integral

$$y(t)=\int_0^t d\tau\,\langle Du, \psi_b Du\rangle(\tau)$$

satisfies an inequality of the type

$$y(t) \leqq A(t) + B(t) y(t)^{p/4}$$

with $A(t)$ and $B(t)$ uniformly bounded with respect to b and therefore, for $p < 4$, $y(t)$ is uniformly bounded with respect to b. By the same argument with a and b interchanged, this proves that $Du \in l^\infty(L^2_{\mathrm{loc}}([0, T), L^2))$. We next let b tend to infinity for fixed a in (3.87). From the previous fact, from (3.88), from the fact that $\|\chi_b u\|_2$ tends to zero pointwise in t as $b \to \infty$, and from the Dominated Convergence Theorem, it follows that the contribution of ψ_b'' to the left-hand side of (3.87) and that of ψ_b to the right-hand side tend to zero as $b \to \infty$. We then obtain the existence of the limit:

$$\begin{aligned} \exists \lim_{b\to\infty} 3 \int_0^t d\tau \, \langle Du, \psi_b Du\rangle(\tau) &= \langle u, h_a^+ u\rangle(t) - \langle u_0, h_a^+ u_0\rangle \\ &\quad + 3 \int_0^t d\tau \, \langle Du, \psi_a Du\rangle(\tau) - \int_0^t d\tau \, \langle u, \psi_a'' u\rangle(\tau) \\ &\quad + 2 \int_0^t d\tau \int \psi_a (uV'(u) - V(u))(\tau). \end{aligned} \tag{3.89}$$

The same argument applies to the limit $a \to -\infty$ for fixed b. The fact that the limit in (3.80) depends on ψ only through $\|\psi\|_1$ is easily seen by defining $h_a^\pm$ with two different functions ψ_a^+, ψ_b^- at a and b, the only constraint being that $\|\psi^+\|_1 = \|\psi^-\|_1$ in order that h have compact support. The right-hand side of (3.89) then depends only on ψ_a^+ and is therefore independent of the specific choice of ψ^- satisfying that constraint.

Relation (3.81) follows by taking successively the limits $b \to +\infty$ and $a \to -\infty$ in (3.87), or $a \to -\infty$ in (3.89).

The last statement follows in one direction by applying the identity (I.1) for the (compactly supported) function $h_a^+ h_b^-$ with h_a^+, h_b^- defined as before, and letting $b \to \infty$ and $a \to -\infty$, and in the opposite direction by applying (I.1) with $h = h_a^\pm$ and letting a tend to $\pm\infty$. □

Remark 3.5. In the proof of part 3, we could have replaced the assumption that V satisfies (3.4) with $p < 4$ by the weaker semiboundedness condition (3.46) of Proposition 3.5, at the expense of using again the estimates of Lemma 3.2. We have refrained from doing so because we are interested in part 3 of Proposition 3.8 only in the more restricted context considered here.

Remark 3.6. Relation (3.81) suggests that under the weak assumptions made on the smoothness of solutions, the local H^1 norm may act as a source at $+\infty$ and/or a sink at $-\infty$ for the L^2 norm of the solutions, and some kind of boundary condition at $\pm\infty$ must be imposed to exclude that effect. Note also that if we are interested only in the estimates of the kind provided by Proposition 3.5, only the condition on $l_1^+(t)$ is important, since then for the relevant h, (I.1) is replaced by an inequality in the right direction.

Remark 3.7. If $u \in (L^\infty_{\mathrm{loc}} \cap \mathscr{C}_W)([0, T), H^1)$, then (I.1) holds for any $h \in \mathscr{C}^3$ with compactly supported h' and condition (3.4) with $p \leqq 4$ is not needed for that purpose. (See Proposition 4.1 below.)

Using Propositions 3.5 and possibly 3.8, we finally exhibit different uniqueness classes for (1.1) than those described in Proposition 3.1 for $p \leqq 2$ and in Propositions 3.2, 3.6, and 3.7 for $p \geqq 2$. We consider first the case $p \leqq 2$.

PROPOSITION 3.9. *Let V satisfy* (3.4) *with* $0<p\leqq 2$, *let* $(1+x_+)^{\beta/2}u_0\in L^2$ *with* $\beta=1/p-\frac{1}{4}$, *and let* $T>0$ (*possibly* $T=\infty$). *Then* (1.1) *with initial data* $u(0)=u_0$ *has at most one solution satisfying* (3.38), *that is, condition*

$$\liminf_{j\to+\infty}\|\chi_j Du;\ L^2([0,t],L^2)\|=0 \tag{3.90}$$

for all $t\in T$, *and condition* (3.7) *with* (3.9), (3.10). *Any such solution satisfies*

$$(1+x_+)^{\beta/2}u\in L^\infty_{\mathrm{loc}}([0,T),L^2).$$

Proof. The result follows immediately from Propositions 3.1, 3.5, and 3.8 and from Remark 3.6. □

We next turn to the case $p\geqq 2$.

PROPOSITION 3.10. *Let V satisfy* (3.4) *with* $p\geqq 2$, *let* $u_0\in L^2$, *and let* $T>0$. *Then* (1.1) *with initial data* $u(0)=u_0$ *has at most one solution u satisfying* (3.38), (I.1) *for all* $h\in\mathscr{C}^3$ *with compactly supported* h', *and either of the two sets of conditions*:

(1) $2\leqq p<3$, $(1+x_+)^{\beta/2}u_0\in L^2$ *for* $\beta=\frac{1}{2}-1/(2p)$, *and u satisfies* $(3.17)_\pm$.

(2) $2\leqq p<\frac{7}{2}$, $(1+x_+)^{1/8}u_0\in L^2$, *and u satisfies* $(3.59)_\pm$ *with q satisfying* (3.61).

Proof. The result follows immediately from Propositions 3.2, 3.5, and 3.6 under conditions 1, and from Propositions 3.2, 3.5, and 3.7 under conditions 2. □

Remark 3.8. We had to keep (3.90) in Proposition 3.9 and (I.1) in Proposition 3.10 as independent assumptions, since we are unable to derive (I.1) for solutions of (1.1) satisfying only (3.38). An unpleasant consequence is that it is unclear whether the uniqueness classes defined in Propositions 3.9 and 3.10 are suitable for existence proofs. In fact, all the relevant norms (including that of Du in $l^\infty(L^2(\cdot,L^2))$) are estimated a priori in terms of the initial data for smooth solutions, but conditions such as (3.90) are not preserved when taking weak-star limits.

4. Uniqueness of H^1 solutions. In this section, we derive our results on the uniqueness of H^1 solutions of the GKdV equation (1.1), more precisely of solutions in $(L^\infty_{\mathrm{loc}}\cap C_W)([0,T),H^1)$ for some $T>0$. Such solutions can also be called finite energy solutions: for such a solution, the energy

$$E(u)=\tfrac{1}{2}\|Du\|_2^2+\int dx\ V(u) \tag{4.1}$$

is well defined for each $t\in[0,T)$ and formally conserved, i.e., $E(u(t))=\text{const}$. Conversely, energy conservation and a semiboundedness property of V imply an a priori estimate of the solution in $L^\infty([0,T),H^1)$ (see Proposition 4.4 below for more precise statements). H^1 solutions satisfy Propositions 3.5 and 3.8 with stronger conclusions and weaker assumptions on V. We state that and a related result immediately for later reference.

PROPOSITION 4.1. *Let* $u_0\in H^1$, *let* $T>0$, *and let* $u\in(L^\infty_{\mathrm{loc}}\cap C_W)([0,T),H^1)$ *be a solution of* (1.1) *with initial data* $u(0)=u_0$. *Then*:

(1) *The identity* (I.1) *holds for all* $h\in\mathscr{C}^3$ *with compactly supported* h'. *The L^2-norm of u is conserved, namely,* $\|u(t)\|_2=\|u_0\|_2$ *for all* $t\in[0,T)$.

(2) *Let* $h\in\mathscr{C}^3(\mathbb{R},\mathbb{R}^+)$ *satisfy* $0\leqq h'\leqq c_1(1+h)$, $h'''\leqq c_3(1+h)$ *and let* $h^{1/2}u_0\in L^2$. *Then* $h^{1/2}u\in L^\infty_{\mathrm{loc}}([0,T),L^2)$, $h'^{1/2}Du\in L^2_{\mathrm{loc}}([0,T),L^2)$ *and for all* $t\in[0,T)$, $h^{1/2}u$ *is estimated in* $L^\infty([0,t],L^2)$ *and* $h'^{1/2}Du$ *is estimated in* $L^2([0,t],L^2)$ *in terms of t, of* $\|(1+h)^{1/2}u_0\|_2$ *and of* $\|Du;\ L^\infty([0,t),L^2)\|$. *In addition* (I.1) *holds for that specific h.*

(3) $u\in l^2(L^\infty_{\mathrm{loc}}([0,T),L^2))$ *and for all* $t\in[0,T)$, u *is estimated in* $l^2(L^\infty([0,t],L^2))$ *in terms of t and of* $\|u;\ L^\infty([0,t],H^1)\|$.

Proof. Part 1. By a Sobolev inequality and elementary arguments, $u \in L^\infty_{\mathrm{loc}}([0, T), L^\infty)$ and the map $u \to V'(u)$ is continuous from H^1 to L^2. Part 1 is then proved in the same way as Proposition 3.8. In particular, the left-hand side of (3.79) tends to zero when φ tends to $\mathbb{1}$.

Part 2. Part 2 is proved in the same way as Proposition 3.5, with the last term in (I.1) now simply estimated as

$$\left|2\int h'(uV'(u)-V(u))\right| \leqq M(\|u\|_\infty)\langle u, h'u\rangle \tag{4.2}$$

for some locally bounded function M. Note also that the statement on $h'^{1/2}Du$ adds new information only if h' is unbounded.

Part 3. Let $\psi \in \mathscr{C}^3$ have compact support, and let χ be the characteristic function of the support of ψ. From (I.1) with $h = \psi$ we obtain by direct estimation

$$\begin{aligned}\langle u, \psi u\rangle(t) \leqq \langle u_0, \psi u_0\rangle + 3c_1 \int_0^t d\tau\, \langle Du, \chi Du\rangle(\tau) \\ + \int_0^t d\tau\, \|\chi u(\tau)\|_2^2 (c_3 + 2c_1 M(\|u(\tau)\|_\infty))\end{aligned} \tag{4.3}$$

where $c_1 = \|\psi'\|_\infty$, $c_3 = \|\psi'''\|_\infty$, and $M(\rho) = \sup_{|\rho'| \leqq \rho} |V''(\rho')|$. We now choose a function $\psi_0 \in \mathscr{C}^3$ with $0 \leqq \psi_0 \leqq 1$, $\psi_0(x) = 1$ for $|x| \leqq \frac{1}{2}$ and $\psi_0(x) = 0$ for $|x| \geqq 1$, and for all $j \in \mathbb{Z}$, we define ψ_j by $\psi_j(x) = \psi_0(x - j)$. We apply (4.3) with $\psi = \psi_j$, take the norms in $L^\infty([0, t])$, and take the sum over j to obtain

$$\begin{aligned}\|u; l^2(L^\infty([0, t], L^2))\|^2 &\leqq 2\|u_0\|_2^2 + 6c_1 \int_0^t d\tau\, \|Du(\tau)\|_2^2 \\ &\quad + 2(c_3 + 2c_1 M(\|u; L^\infty([0, t], L^\infty)\|)) \int_0^t d\tau\, \|u(\tau)\|_2^2 \\ &= 2\|u\|_2^2\{1 + t(c_3 + 2c_1 M(\|u; L^\infty([0, t], L^\infty)\|))\} \\ &\quad + 6c_1 \|Du; L^2([0, t], L^2)\|_2^2\end{aligned} \tag{4.4}$$

where the last equality follows from the conservation of the L^2-norm. Part 3 then follows from (4.4). □

We now turn to our basic uniqueness result. As in § 3, it is based on a linear inequality for a suitable norm of the difference of two solutions. That inequality now arises from a variant of (I.1). In this section we will often assume (in addition to the general assumptions $V \in \mathscr{C}^2$, $V(0) = V'(0) = 0$) that V'' is absolutely continuous ($\equiv AC$) with $V''(0) = 0$ and with locally bounded (Radon-Nikodym or distributional) derivative V'''. We will, however, refrain from assuming $V \in \mathscr{C}^3$, since we do not want to exclude such cases as $V''(u) = |u|$.

PROPOSITION 4.2. *Let V'' be AC with $V''(0) = 0$, and let V''' be locally bounded. Let $u_0 \in H^1$, and let $T > 0$ (possibly $T = \infty$). Then* (1.1) *with initial data $u(0) = u_0$ has at most one solution such that*

$$u \in (L^\infty_{\mathrm{loc}} \cap C_w)([0, T), H^1), \tag{4.5}$$

$$\chi_+ Du \in L^1_{\mathrm{loc}}([0, T), L^\infty). \tag{4.6}$$

Proof. Let u_1 and u_2 be two solutions satisfying (4.5), (4.6) with common initial data $u_1(0) = u_2(0) = u_0$, let $w = u_1 - u_2$, and let $h = h_{\alpha 0}$ for some $\alpha > 0$. The proof is based on a variant of (I.1) satisfied by w. For clarity, we give only the algebraic part

of the proof of that identity in differential form. Under the smoothness assumption (4.5), the functional analytic details can be easily filled in by the mollifier method of Propositions 3.8 and 4.1. From (3.1) and the same computation as in the proof of Lemma 2.5 (see (2.44)), we obtain

$$\partial_t\langle w, hw\rangle + 3\langle Dw, h'Dw\rangle - \langle w, h'''w\rangle = 2\langle w, hD(\tilde{V}''w)\rangle. \tag{4.7}$$

For $x \geqq 0$, we use the identity

$$2wD(\tilde{V}''w) = D(w^2\tilde{V}'') + w^2(D\tilde{V}'')$$

to obtain

$$2\int_0^\infty dx\, hwD(\tilde{V}''w) = \langle w, h\chi_+(D\tilde{V}'')w\rangle - \langle w, h'\chi_+\tilde{V}''w\rangle - (hw^2\tilde{V}'')(0). \tag{4.8}$$

For $x \leqq 0$, we use the identity

$$2wD(\tilde{V}''w) = 2D(w^2\tilde{V}'') - 2w(Dw)\tilde{V}''$$

to obtain

$$2\int_{-\infty}^0 dx\, hwD(\tilde{V}''w) = -2\langle Dw, h\chi_-\tilde{V}''w\rangle - 2\langle w, h'\chi_-\tilde{V}''w\rangle + 2(hw^2\tilde{V}'')(0). \tag{4.9}$$

Adding (4.8) and (4.9), we obtain

$$\begin{aligned} 2\langle w, hD(\tilde{V}''w)\rangle = {} & \langle w, h\chi_+(D\tilde{V})w\rangle - \langle w, h'\chi_+\tilde{V}''w\rangle - 2\langle w, h'\chi_-\tilde{V}''w\rangle \\ & - 2\langle Dw, h\chi_-\tilde{V}''w\rangle + \tilde{V}''(0)(\langle w, h'\chi_-w\rangle + 2\langle Dw, h\chi_-w\rangle) \end{aligned} \tag{4.10}$$

(the argument denoted as zero in (4.8)-(4.10) is the space variable x). Using the properties of h, namely, $\chi_-h' = \alpha\chi_-h$ and $0 \leqq \chi_+h' \leqq \alpha\chi_+h$, and an elementary quadratic inequality, from (4.10) we obtain

$$\begin{aligned} 2\langle w, hD(\tilde{V}''w)\rangle \leqq {} & (\|\chi_+D\tilde{V}''\|_\infty + 3\alpha\|\tilde{V}''\|_\infty + 2\alpha^{-1}\|\chi_-\tilde{V}''\|_\infty^2) \\ & \times\langle w, hw\rangle + 2\langle Dw, h'\chi_-Dw\rangle. \end{aligned} \tag{4.11}$$

The result now follows from (4.7) and (4.11) by Gronwall's inequality, insofar as $\tilde{V}'' \in L^2_{\mathrm{loc}}([0, T), L^\infty)$ and $\chi_+D\tilde{V}'' \in L^1_{\mathrm{loc}}([0, T), L^\infty)$. The former property follows from (4.5), actually with L^∞ instead of L^2 in time, while the latter follows from (4.6) and the additional assumption on V''. □

Remark 4.1. Condition (4.6) of Proposition 4.2 may seem inadequate for a later treatment of the existence problem along the lines sketched in the Introduction, since L^1 is not the dual of a Banach space. However, we can replace L^1 by L^q with any $q \geqq 1$ in (4.6) and the subsequent a priori estimates will actually hold with $q = 6$.

The remaining part of this section is devoted to the analysis of conditions (4.6) for H^1 solutions. As will become clear in the subsequent discussion, the fact that no difficulty arises from the lack of local regularity, namely, for high values of p in (3.4), is in contrast to the case of L^2 solutions considered in the previous section. On the other hand, there remains a difficulty, caused by the lack of decrease at infinity in space, giving rise in particular to the lower bound $p > \frac{3}{2}$ if no further assumption is made on u_0 than $u_0 \in H^1$. An important tool in overcoming that difficulty is a second

well-known identity [10], satisfied by the solutions of (1.1), which we will henceforth refer to as (I.2) and which we formulate in the following integral form:

$$\langle Du, hDu\rangle(t)+2\int hV(u(t))+3\int_0^t d\tau\,\langle D^2u, h'D^2u\rangle(\tau)+\int_0^t d\tau\int h'V'(u(\tau))^2$$

$$=\langle Du_0, hDu_0\rangle+2\int hV(u_0) \tag{I.2}$$

$$+\int_0^t d\tau\left\{\langle Du, h'''Du\rangle(\tau)+2\int h'''V(u(\tau))-4\langle Du, h'DV'(u)\rangle(\tau)\right\}.$$

Clearly (I.2) makes sense for $h\in\mathscr{C}^3$ with compactly supported h' provided

$$u\in(L^\infty_{\mathrm{loc}}\cap C_w)([0,T), H^1)\cap L^2_{\mathrm{loc}}([0,T), H^2_{\mathrm{loc}}). \tag{4.12}$$

Identity (I.2) can be used to derive weighted H^1 estimates for solutions of (1.1) in the same way as (I.1) was used to derive weighted L^2 estimates for those solutions. We could therefore proceed immediately to the derivation of those estimates, in close analogy with Proposition 3.5, by assuming (I.2), and leave its derivation for a later stage, in analogy with our treatment of (I.1) in § 3. However, the situation for (I.2) is better than that for (I.1), and we are almost able to derive (I.2) for solutions of (1.1) satisfying (4.12). We will therefore reverse the order and begin with the derivation of (I.2).

PROPOSITION 4.3. *Let $T>0$, let $u_0\in H^1$, and let u be a solution of* (1.1) *with initial data $u(0)=u_0$ satisfying* (4.12). *Then*:

(1) *For any $h\in\mathscr{C}^3$ with compact support, for any $t\in[0,T)$, u satisfies* (I.2). *Furthermore, $u\in l^\infty(L^2_{\mathrm{loc}}([0,T), H^2))$ and for all $\psi\in\mathscr{C}^2$ with compact support, for all $t\in[0,T)$, the following limits exist*:

$$\exists\lim_{a\to\pm\infty} 3\int_0^t d\tau\,\langle D^2u, \psi_aD^2u\rangle(\tau)=2\|\psi\|_1 l_2^{\pm}(t) \tag{4.13}$$

where ψ_a is defined by $\psi_a(x)=\psi(x-a)$. The functions $l_2^{\pm}(t)$ are nondecreasing in t and satisfy

$$l_2^+(t)-l_2^-(t)=E(u(t))-E(u_0) \tag{4.14}$$

for all $t\in[0,T)$. Identity (I.2) *holds for all $h\in\mathscr{C}^3$ with compactly supported h' if and only if $l_2^{\pm}(t)=0$ for all $t\in[0,T)$.*

(2) *Assume in addition either that*

$$\liminf_{j\to\pm\infty}\|\chi_jD^2u;\, L^2([0,t], L^2)\|=0 \tag{4.15}$$

for all $t\in[0,T)$, or that V satisfies (3.4) *for some $p\geqq 2$ and for all $\rho\in[-1,1]$. Then* (I.2) *holds for all $h\in\mathscr{C}^3$ with compactly supported h'.*

Proof. Part 1. We first remark that the map $u\to V'(u)$ is continuous from H^1 to H^1. In fact, since $DV'(u)=V''(u)Du$, it suffices to prove that the map $u\to V''(u)$ is continuous from H^1 to L^∞. This follows from the continuous embedding $H^1\subset L^\infty$ and from the fact that V'' is uniformly continuous on bounded intervals.

We now turn to the proof of (I.2). We use the same mollifier method as in the proof of Proposition 3.6. From (3.83), we obtain by the same computation as in the

proof of Lemma 2.5 (see (2.44))

$$\begin{aligned}&\langle Du_\varphi, hDu_\varphi\rangle(t)-\langle \varphi * Du_0, h(\varphi * Du_0)\rangle+3\int_0^t d\tau\,\langle D^2u_\varphi, h'D^2u_\varphi\rangle(\tau)\\&\quad-\int_0^t d\tau\,\langle Du_\varphi, h'''Du_\varphi\rangle(\tau)=2\int_0^t d\tau\,\langle Du_\varphi, hD^2(\varphi * V'(u))\rangle(\tau).\end{aligned}\tag{4.16}$$

The integrand on the right-hand side of (4.16) can be rewritten as

$$\begin{aligned}\langle Du_\varphi, hD^2(\varphi * V'(u))\rangle&=\langle D^2u_\varphi, hD(V'(u_\varphi)-\varphi * V'(u))\rangle\\&\quad-\langle Du_\varphi, h'D(\varphi * V'(u))\rangle\\&\quad+\langle D^2u_\varphi, h'V'(u_\varphi)\rangle+D^3u_\varphi, hV'(u_\varphi)\rangle.\end{aligned}\tag{4.17}$$

Again using (3.83) to re-express the last term, we obtain by an elementary computation

$$\begin{aligned}\cdots&=-\partial_t\int hV(u_\varphi)-\tfrac{1}{2}\langle\varphi * V'(u), h'(\varphi * V'(u))\rangle+\int h'''V(u_\varphi)\\&\quad-\langle Du_\varphi, h'D(\varphi * V'(u)+V'(u_\varphi))\rangle\\&\quad+\langle D(\varphi * V'(u)), h(V'(u_\varphi)-\varphi * V'(u))\rangle\\&\quad+\langle D^2u_\varphi, hD(V'(u_\varphi)-\varphi * V'(u))\rangle.\end{aligned}\tag{4.18}$$

We substitute (4.18) into the right-hand side of (4.16) and take the limit $\varphi\to\mathbb{1}$ wherever possible. By using only the assumptions that $u\in L^\infty_{\mathrm{loc}}([0,T), H^1)$ and $h\in\mathscr{C}^3$ with compactly supported h', we obtain from the fact that u_φ tends to u, and that $\varphi * V'(u)$ and $V'(u_\varphi)$ tend to $V'(u)$ in H^1, that all terms tend to the obvious limits. Possible exceptions are the first integral on the left-hand side of (4.16) and the contribution of the last term in (4.18). If in addition $u\in L^2_{\mathrm{loc}}([0,T), H^2_{\mathrm{loc}})$, the former integral also tends to the obvious limit, so that

$$\begin{aligned}&\exists\lim_{\varphi\to\mathbb{1}} 2\int_0^t d\tau\,\langle D^2u_\varphi, hD(V'(u_\varphi)-\varphi * V'(u))\rangle(\tau)\\&\quad=\langle Du, hDu\rangle(t)+2\int hV(u(t))+3\int_0^t d\tau\,\langle D^2u, h'D^2u\rangle(\tau)\\&\qquad+\int_0^t d\tau\int h'V'(u(\tau))^2-\langle Du_0, hDu_0\rangle-2\int hV(u_0)\\&\qquad-\int_0^t d\tau\left\{\langle Du, h'''Du\rangle(\tau)+2\int h'''V(u(\tau))-4\langle Du, h'DV'(u)\rangle(\tau)\right\}.\end{aligned}\tag{4.19}$$

Furthermore, the integral on the left-hand side of (4.19) tends to zero when $\varphi\to\mathbb{1}$ if in addition h has compact support, thereby proving (I.2) in that special case. The remaining statements in part 1 of the proposition are proved by the same method as part 3 of Proposition 3.8, using, in particular, (I.2) with $h=h_a^+h_b^-$ and letting a (respectively, b) vary and/or tend to $-\infty$ (respectively, $+\infty$) for fixed b (respectively, a). We omit the details.

Part 2. Under assumption (4.15), we obtain from (4.13) that $l_2^\pm(t)=0$ and (I.2) for $h\in\mathscr{C}^3$ with compactly supported h' follow from the last statement of part 1. To prove (I.2) under the additional assumption on V we start from (4.19) and prove directly that the left-hand side is zero. Since $D^2u\in l^\infty(L^2([0,t], L^2))$ by part 1, it suffices

to prove that $D(V'(u_\varphi)-\varphi * V'(u))$ tends to zero in $l^1(L^2([0,t],L^2))$. Since $V'(u_\varphi)$ and $\varphi * V'(u)$ tend to $V'(u)$ in H^1 for each t, that fact will follow from the Dominated Convergence Theorem and from an estimate of $DV'(u)$ and $DV'(u_\varphi)$ uniformly in φ. We concentrate on $DV'(u)$. The same estimate will hold for $DV'(u_\varphi)$. By the additional assumption on V, it is sufficient to estimate $|u|^p Du$. Now from Lemma 3.3, we obtain

$$\|\chi_j|u|^p Du\|_2 \leqq C(\|\chi_j Du\|_2\|\chi_j u\|_2^p + \|\chi_j Du\|_2^{1+p/2}\|\chi_j u\|_2^{p/2}) \tag{4.20}$$

so that by the Hölder inequality

$$\begin{aligned}&\||u|^p Du;\, l^1(L^2([0,t],L^2))\| \\ &\leqq C\{\|Du;\, L^2([0,t],L^2)\|\,\|u;\, l^{2p}(L^\infty([0,t],L^2))\| \\ &\quad + \|Du;\, l^{p+2}(L^{p+2}([0,t],L^2))\|^{1+p/2}\|u;\, l^p(L^\infty([0,t],L^2))\|^{p/2}\}.\end{aligned} \tag{4.21}$$

The result now follows from the fact that $Du \in L^\infty([0,t],L^2) \subset l^q(L^q([0,t],L^2))$ for all q, $2 \leqq q \leqq \infty$, and that $u \in l^2(L^\infty([0,t],L^2)) \subset l^q(L^\infty([0,t],L^2))$ for all $q \geqq 2$ by Proposition 4.1, part 3. □

We now turn to the derivation of weighted $L^\infty(H^1)$ estimates for solutions of (1.1), in close analogy with Proposition 3.5.

PROPOSITION 4.4. *Let V satisfy the conditions*

$$\lim_{|\rho|\to\infty} |\rho|^{-6} V_-(\rho) = 0, \tag{4.22}$$

$$V_-(\rho) \leqq C|\rho|^{p+2} \quad \text{for all } \rho \in [-1,1], \tag{4.23}$$

for some p, $0 \leqq p < 4$, and some $C \geqq 0$. Let $T > 0$, let $u_0 \in H^1$, and let u be a solution of (1.1) *with initial data $u(0) = u_0$, satisfying* (4.12), *and such that* (I.2) *holds for all $h \in \mathscr{C}^3$ with compactly supported h'. Then*:

(1) *The energy is conserved, namely, $E(u(t)) = E(u_0)$ for all $t \in T$, and u is estimated in $L^\infty([0,T),H^1)$ in terms of $\|u_0;\, H^1\|$.*

(2) *$D^2u \in l^\infty(L^2_{\mathrm{loc}}([0,T),L^2))$, and for all $t \in [0,T)$, D^2u is estimated in $l^\infty(L^2([0,t],L^2))$ in terms of t and $\|u_0;\, H^1\|$.*

(3) *Let $h \in \mathscr{C}^3(\mathbb{R},\mathbb{R}^+)$ satisfy $0 \leqq h' \leqq c_1(1+h)$ and $|h'''| \leqq c_3(1+h)$. Let $h^{1/2}Du_0 \in L^2$, $hV_+(u_0) \in L^1$, and let $h^{\nu/2}u$, $(1+h)^{-1/2}h'u \in L^\infty_{\mathrm{loc}}([0,T),L^2)$, where $\nu = (4-p)/(4+p)$. Then $h^{1/2}Du \in L^\infty_{\mathrm{loc}}([0,T),L^2)$, $hV_+(u) \in L^\infty_{\mathrm{loc}}([0,T),L^1)$, $h'^{1/2}D^2u \in L^2_{\mathrm{loc}}([0,T);L^2)$, $h'^{1/2}V'(u) \in L^2_{\mathrm{loc}}([0,T);L^2)$, and for all $t \in [0,T)$, the corresponding norms in the interval $[0,t]$ are estimated in terms of t, of $\|(1+h)^{1/2}Du_0\|_2$, of $\|hV_+(u_0)\|_1$, and of the norms of $(1+h)^{\nu/2}u$ and $(1+h)^{-1/2}h'u$ in $L^\infty([0,t],L^2)$. In addition,* (I.2) *holds for that specific choice of h.*

Proof. Part 1. Part 1 follows from (I.2) with $h \equiv 1$ and from Lemma 3.2 applied with $h \equiv 1$ and $W = V_-$.

Next we consider an h with compactly supported h'. From (I.2) with h replaced by $(1+h)$ we obtain

$$\begin{aligned}&\langle Du, (1+h)Du\rangle(t) + 2\int (1+h)V(u(t)) + 3\int_0^t d\tau\,\langle D^2u, h'D^2u\rangle(\tau) \\ &\quad + \int_0^t d\tau \int h'V'(u(\tau))^2 \leqq \langle Du_0, (1+h)Du_0\rangle + 2\int (1+h)V(u_0) \\ &\quad + \int_0^t d\tau \Big\{(c_3 + 4c_1\|V''(u);\, L^\infty([0,t],L^\infty)\|)\langle Du, (1+h)Du\rangle(\tau) \\ &\qquad + 2c_3\int (1+h)|V(u(\tau))|\Big\}.\end{aligned} \tag{4.24}$$

From Lemma 3.2 (see especially (3.41)) applied with $W = V_-$ and h replaced by $(1+h)$, it follows that the quantity

$$F(u) = \langle Du, (1+h)Du\rangle + \int (1+h)V(u) + C \tag{4.25}$$

is positive in the interval $[0, t]$ for some constant $C \geqq 0$ depending only on the norms of $(1+h)^{\nu/2}u$ and $(1+h)^{-1/2}h'u$ in $L^\infty([0, t], L^2)$. Furthermore, F satisfies an inequality of the type

$$\begin{aligned} &F(u(t)) + 3\int_0^t d\tau\, \langle D^2u, h'D^2u\rangle(\tau) + \int_0^t d\tau \int h'V'(u(\tau))^2 \\ &\leqq F(u_0) + A + B\int_0^t d\tau\, F(u(\tau)) \end{aligned} \tag{4.26}$$

by Lemma 3.2 again and by part 1, with A and B depending only on $\|u_0; H^1\|$ and on the norms of $(1+h)^{\nu/2}u$ and $(1+h)^{-1/2}h'$ in $L^\infty([0, t], L^2)$.

Part 2. Part 2 now follows from (4.26) applied with the same h as in the proof of Proposition 3.5, part 1. (Note, in particular, that for that choice, A and B in (4.26) and C in (4.25) are estimated in terms of $\|u_0; H^1\|$ and that $F(u(t))$ is estimated in terms of $\|u_0; H^1\|$ uniformly in t.)

Part 3. Part 3 follows from (4.25) and (4.26) by approximating h by a sequence of functions h_N with compactly supported h'_N as in the proof of Proposition 3.5, part 2, estimating the corresponding F_N uniformly in N by (4.26) and the Gronwall inequality, taking the limit $N \to \infty$, and again applying Lemma 3.2. We omit the details. □

Remark 4.2. In the applications, the fact that $h^{\nu/2}u$ and $(1+h)^{-1/2}h'u$ belong to $L^\infty_{\text{loc}}([0, T), L^2)$ will follow from the obvious assumptions on u_0 through Proposition 4.1. We have kept these properties as assumptions in Proposition 4.4 to avoid additional assumptions on h that would be irrelevant for the main estimate (4.24).

We now come back to the analysis of condition (4.6). We first give an elementary treatment thereof that is inspired by the estimates of § 3 and makes it possible to exhibit a different uniqueness class.

PROPOSITION 4.5. *Let V satisfy* (3.4) *for some $p \geqq 1$ and all $\rho \in [-1, 1]$. Let $T > 0$, and let $u_0 \in H^1$ be such that $(1+x_+)^{\beta/2}u_0 \in L^2$ and $(1+x_+)^{\gamma/2}Du_0 \in L^2$ for some $\beta, \gamma \geqq 0$ satisfying*

$$(p+1)(\beta+\gamma) \geqq 1. \tag{4.27}$$

(1) *Let u be a solution of* (1.1) *with initial data $u(0) = u_0$, satisfying* (4.5) *and in addition*

$$(1+x_+)^{\gamma/2}Du \in L^\infty_{\text{loc}}([0, T), L^2). \tag{4.28}$$

Then u also satisfies

$$\chi_+ Du \in L^6_{\text{loc}}([0, T), L^\infty) \tag{4.29}$$

and for all $t \in [0, T)$, χ_+Du is estimated in $L^6([0, t], L^\infty)$ in terms of t, of $\|(1+x_+)^{\beta/2}u_0\|_2$, and of the norm of $(1+x_+)^{\gamma/2}Du$ in $L^\infty([0, t], L^2)$.

(2) *In addition let V'' be AC with $V''(0)=0$ and V''' locally bounded. Then* (1.1) *with initial data $u(0)=u_0$ has at most one solution satisfying* (4.5) *and* (4.28). *Any such solution satisfies* (4.29).

Proof. Part 1. Let u be a solution of (1.1) with $u(0)=u_0$, satisfying (4.5) and (4.28). Du satisfies

$$\begin{aligned} Du(t) &= U(t)Du_0+\int_0^t d\tau\, U(t-\tau)D(V''(u)Du)(\tau) \\ &\equiv U(t)Du_0+J(t). \end{aligned} \tag{4.30}$$

We estimate the free term by (2.14) as

$$\|U(\cdot)Du_0;\, L^6(\mathbb{R}^+,\, L^\infty)\| \leqq C\|Du_0\|_2. \tag{4.31}$$

Using the fact that $\chi_+ \leqq h_{\alpha 0} \leqq C$ and the estimate (2.35) we obtain for $\chi_+ J$

$$\|\chi_+ J;\, L^\infty([0,\, t],\, L^\infty)\| \leqq C(t)t^{1/4}\|(1+x_+)^{1/4}V''(u)Du;\, L^\infty([0,\, t],\, L^1)\|.$$

By (3.4) for $|\rho| \leqq 1$, the last norm is estimated as

$$M(\|u;\, L^\infty([0,\, t],\, L^\infty)\|)\|(1+x_+)^{1/4}|u|^p Du;\, L^\infty([0,\, t],\, L^1)\|.$$

Next we estimate for each t

$$\|(1+x_+)^{1/4}|u|^p Du\|_1 \leqq \|(1+x_+)^{\beta/2}u\|_2\|(1+x_+)^{\gamma/2}Du\|_2\|(1+x_+)^{\varepsilon}u^2\|_\infty^{(p-1)/2}$$

with $(p-1)\varepsilon = \frac{1}{2}-\beta-\gamma$. For $\varepsilon \leqq 0$, the last norm is estimated by $(2\|u\|_2\|Du\|_2)^{1/2}$. For $\varepsilon > 0$, we obtain by derivation and integration

$$\|(1+x_+)^{\varepsilon}u^2\|_\infty \leqq C(\|(1+x_+)^{\beta/2}u\|_2^2+\|(1+x_+)^{\beta/2}u\|_2\|(1+x_+)^{\gamma/2}Du\|_2)$$

provided $\varepsilon - 1 \leqq \beta$ and $\varepsilon \leqq (\beta+\gamma)/2$. The latter condition is identical to (4.27) while the former reduces to

$$(p+1)(\beta+\gamma)+(p-1)(\beta-\gamma+2) \geqq 1$$

and follows from (4.27) provided $\gamma \leqq 2$, a condition that we can impose without loss of generality. Collecting the previous estimates, we obtain

$$\begin{aligned} &\|\chi_+ J;\, L^\infty([0,\, t],\, L^\infty)\| \\ &\quad \leqq C(t)t^{1/4}M(\|u;\, L^\infty([0,\, t],\, L^\infty)\|) \\ &\qquad \times\{\|(1+x_+)^{\beta/2}u;\, L^\infty([0,\, t],\, L^2)\|^p\|(1+x_+)^{\gamma/2}Du;\, L^\infty([0,\, t],\, L^2)\| \\ &\qquad\quad +\|(1+x_+)^{\beta/2}u;\, L^\infty([0,\, t],\, L^2)\|^{(p+1)/2} \\ &\qquad\qquad \times\|(1+x_+)^{\gamma/2}Du;\, L^\infty([0,\, t],\, L^2)\|^{(p+1)/2}\}. \end{aligned} \tag{4.32}$$

The last two norms in (4.32) are controlled, respectively, by Proposition 4.1, part 2 applied with $h=h_{0\beta}$, and by (4.28).

Part 1 then follows from (4.31) and (4.32).

Part 2. Part 2 follows immediately from part 1 and Proposition 4.2. □

Proposition 4.5 enables us to cover the case of the ordinary KdV equation corresponding to $p=1$. In that case, (4.27) reduces to $\beta+\gamma \geqq \frac{1}{2}$. On the other hand, it does not yield uniqueness under the assumption that $u_0 \in H^1$ only, even for higher values of p. We now turn to a more elaborate method for ensuring (4.6), which will remedy that defect. The general result stated in Proposition 4.6 below contains as a special case a result obtained previously by Tsutsumi [22], according to which uniqueness holds for H^1 data provided $p > \frac{3}{2}$ in (3.4). Since that result has special interest and since its proof is simpler than that of the more general one, we state it separately.

PROPOSITION 4.6. *Let V'' be AC with $V''(0)=0$ and V''' locally bounded, and let V satisfy* (3.4) *for some $p\geqq 1$ and all $\rho\in[-1,1]$. Let $T>0$ and let $u_0\in H^1$. Then*:

(1) *Let $p>\frac{3}{2}$. Let u be a solution of* (1.1) *with initial data $u(0)=u_0$, satisfying* (4.12). *Then u also satisfies*

$$Du\in L^6_{\mathrm{loc}}([0,T),L^\infty) \tag{4.33}$$

and for all $t\in[0,T)$, Du is estimated in $L^6([0,t],L^\infty)$ in terms of t, of the norms of u in $L^\infty([0,t],H^1)$ and of D^2u in $l^\infty(L^2([0,t],L^2))$.

(2) *Let $p>\frac{3}{2}$. Then* (1.1) *with initial data $u(0)=u_0$ has at most one solution satisfying* (4.12). *Any such solution satisfies* (4.33).

In addition let u_0 satisfy $(1+x_+)^{\beta/2}u_0\in L^2$ and $(1+x_+)^{\gamma/2}Du_0\in L^2$ for some β, $\gamma\geqq 0$ satisfying

$$(3-p)_+\beta+(p-1)(2+3\min(\beta,\gamma))>1. \tag{4.34}$$

Then:

(3) *Let u be a solution of* (1.1) *with initial data $u(0)=u_0$, satisfying* (4.12) *and* (4.28). *Then u also satisfies* (4.29), *and for all $t\in[0,T)$, χ_+Du is estimated in $L^6([0,t],L^\infty)$ in terms of t, of $\|(1+x_+)^{\beta/2}u_0\|_2$ and of the norms of $(1+x_+)^{\gamma/2}Du$ in $L^\infty([0,t],L^2)$ and of D^2u in $l^\infty(L^2([0,t],L^2))$.*

(4) *Equation* (1.1) *with initial data $u(0)=u_0$ has at most one solution satisfying* (4.12) *and* (4.28). *Any such solution satisfies* (4.29).

Proof. Part 1. Let u be a solution of (1.1) with $u(0)=u_0$ satisfying (4.12). By Proposition 4.1, part 3, $u\in l^2(L^\infty_{\mathrm{loc}}([0,T),L^2))$. We estimate Du by using (4.30) and estimating the free term by (4.31). We then split J as follows:

$$J(t)=J_1(t)+J_2(t)=\int_0^t d\tau\, U(t-\tau)\{V'''(u)(Du)^2+V''(u)D^2u\}(\tau) \tag{4.35}$$

where J_1 and J_2 are the contributions of the terms in the last bracket. We estimate J_1 by the use of (2.9) as

$$\begin{aligned}\|J_1;L^\infty([0,t],L^\infty)\|&\leqq Ct^{2/3}\|V'''(u)(Du)^2;L^\infty([0,t],L^1)\|\\&\leqq Ct^{2/3}M_1(\|u;L^\infty([0,t],L^\infty)\|)\|Du;L^\infty([0,t],L^2)\|^2\end{aligned} \tag{4.36}$$

where $M_1(\rho)=\sup_{|\rho'|\leqq\rho}|V'''(\rho')|$. The last member of (4.36) is estimated in terms of the norm of u in $L^\infty([0,t],H^1)$. We now turn to J_2. Using the estimate (2.8), we can estimate J_2 as follows:

$$\begin{aligned}|J_2(t,x)|&\leqq\int_0^t d\tau\,|t-\tau|^{-1/3}\int dy\,A(x-y)(V''(u)D^2u)(\tau,y)\\&\quad+C\int_0^t d\tau\,|t-\tau|^{-1/4}\int_{y\geqq x}dy(1+y-x)^{-1/4}(V''(u)D^2u)(\tau,y)\\&=J_2^-(t,x)+J_2^+(t,x)\end{aligned} \tag{4.37}$$

where A is a bounded function with exponential decrease. Using the Hölder inequality in spaces $l^r(L^r(\cdot,L^r))$, we estimate J_2^- as

$$\begin{aligned}\|J_2^-;L^\infty([0,t],L^\infty)\|&\leqq Ct^{1/6}\|A;l^1(L^2)\|\,\|V''(u);L^\infty([0,t],L^\infty)\|\\&\quad\times\|D^2u;l^\infty(L^2([0,t],L^2))\|.\end{aligned} \tag{4.38}$$

The norm of $V''(u)$ is estimated in terms of that of u in the same space, and therefore of the norm of u in $L^\infty([0,t],H^1)$. The last norm in (4.38) is finite by Proposition 4.3,

part 1. This takes care of J_2^-. We now turn to the (more delicate) estimate of J_2^+. The function $|t|^{-1/4}(1+|x|)^{-1/4}$ belongs to $l^r(L^q(I, L^\infty))$ for any bounded interval I and $q<4<r$. Using that fact together with $1/q+1/r=\frac{1}{2}$, $r>4$, by the Hölder inequality we obtain

$$\begin{aligned}&\|J_2^+; L^\infty([0,t], L^\infty)\| \\ &\leqq Ct^{1/4-1/r}\|V''(u)D^2u; l^{\bar r}(L^{\bar q}([0,t], L^1))\| \\ &\leqq Ct^{1/4-1/r}\|V''(u); l^{\bar r}(L^r([0,t], L^2))\|\,\|D^2u; l^\infty(L^2([0,t], L^2))\|.\end{aligned} \tag{4.39}$$

The last norm is finite by Proposition 4.3, part 1, while the norm of V'' is estimated by

$$\|\cdot\| \leqq M(\|u; L^\infty([0,t], L^\infty)\|)\,\||u|^p; l^{\bar r}(L^r([0,t], L^2))\| \tag{4.40}$$

by the use of (3.4) for $|\rho|\leqq 1$. Now by Proposition 4.1, part 3, $u\in l^m(L^\infty(\cdot, L^2))$ for all m, $2\leqq m\leqq\infty$. Furthermore, it follows from the fact that $u\in L^\infty(\cdot, H^1)$ that $u\in l^s(L^s(\cdot, H^1))$ for all s, $2\leqq s\leqq\infty$, with

$$\|u; l^s(L^s([0,t], H^1))\| \leqq t^{1/s}\|u; L^\infty([0,t], H^1)\|. \tag{4.41}$$

We use Lemma 3.3, the Hölder inequality in time and in the discrete l^r variable and the previous remarks to estimate the last norm in (4.40) as

$$\begin{aligned}&\||u|^p; l^{\bar r}(L^r([0,t], L^2))\| \\ &\leqq C\|u; l^m(L^\infty([0,t], L^2))\|^{(p+1)/2}\|u; l^s(L^s([0,t], H^1))\|^{(p-1)/2}t^{1/r-(p-1)/(2s)} \\ &\leqq C\|u; l^2(L^\infty([0,t], L^2))\|^{(p+1)/2}\|u; L^\infty([0,t], H^1)\|^{(p-1)/2}t^{1/r}\end{aligned} \tag{4.42}$$

provided we can choose $m\geqq 2$, $s\geqq 2$ such that

$$\frac{p-1}{s}\leqq\frac{2}{r}, \tag{4.43}$$

$$\frac{p-1}{s}+\frac{p+1}{m}=\frac{2}{\bar r}. \tag{4.44}$$

It is convenient to choose m and s by imposing the additional condition

$$\frac{p+1}{m}-\frac{p-1}{s}=1$$

so that $(p+1)/m=\frac{3}{2}-1/r$, $(p-1)/s=\frac{1}{2}-1/r$. In that case, conditions $m\geqq 2$, $s\geqq 2$ both become equivalent to $p\geqq 2/\bar r$, which can be ensured with $r>4$ provided $p>\frac{3}{2}$ while condition (4.43) reduces to $r\leqq 6$ that can be imposed separately. The required estimate of J_2^+ now follows from (4.39), (4.40), and (4.42), from Proposition 4.1, part 3 and Proposition 4.3, part 1. Part 1 of this proposition follows from that estimate and from (4.31), (4.36), and (4.38).

Part 2. Part 2 follows immediately from part 1 and from Proposition 4.2.

Part 3. Because of part 1, we can assume that $p\leqq 3$ without loss of generality. We again estimate χ_+Du by using (4.30), and estimate the free term J_1 and J_2^- as in the proof of part 1. To estimate $\chi_+J_2^+$, we start from (4.37), decompose the contribution of the y integral as the sum of the contributions of unit intervals, and apply Lemma 3.3 in each interval, thereby obtaining for each $k\geqq 0$

$$\begin{aligned}\|\chi_kJ_2^+(t)\|_\infty \leqq M\int_0^t d\tau\,|t-\tau|^{-1/4}\sum_{j\geqq k}(1+j-k)^{-1/4}\|\chi_jD^2u(\tau)\|_2 \\ \times(\|\chi_ju(\tau)\|_2^p+\|\chi_ju(\tau)\|_2^{(p+1)/2}\|\chi_jDu(\tau)\|_2^{(p-1)/2})\end{aligned} \tag{4.45}$$

where M depends on $\|u; L^\infty([0,t], L^\infty)\|$ according to (4.40). We now factorize and estimate the integrand in (4.45) by using the fact that $(1+j-k)\leqq 1+j$ since $0\leqq k\leqq j$,

and we continue (4.45):

$$
\begin{aligned}
\cdots \leqq M \int_0^t d\tau \sum_{j \geqq k} & \{\|\chi_j D^2 u(\tau)\|_2\}\{|t-\tau|^{-1/4}\|\chi_j(1+x)^{\beta/2}u\|\}^{(3-p)/2} \\
& \times\{|t-\tau|^{-1/4}(\|\chi_j(1+x)^{\beta/2}u\|_2+\|\chi_j(1+x)^{\gamma/2}Du\|_2)\}^{(p-1)/2} \\
& \times\{(1+j-k)^{-\mu/2}\|\chi_j(1+x)^{\delta/2}u\|_2^{p-1}\}
\end{aligned} \tag{4.46}
$$

with $\delta = \min(\beta, \gamma)$ and

$$
2\mu = (3-p)\beta + 3(p-1)\delta + 1. \tag{4.47}
$$

We estimate the last member of (4.46) by using the Hölder inequality in time and in the discrete variable j, with the four successive brackets taken in $l^\infty(L^2)$, $l^2(L^2)$ $(\equiv L^2(l^2))$, $l^2(L^2)$, and $l^2(L^\infty)$, respectively, thereby continuing (4.46):

$$
\begin{aligned}
\cdots \leqq M & \|\chi_+ D^2 u;\, l^\infty(L^2([0,t],L^2))\|\, t^{1/4}\|\chi_+(1+x)^{\beta/2}u;\, L^\infty([0,t],L^2)\|^{(3-p)/2} \\
& \times(\|\chi_+(1+x)^{\beta/2}u;\, L^\infty([0,t],L^2)\| \\
& \quad +\|\chi_+(1+x)^{\gamma/2}Du;\, L^\infty([0,t],L^2)\|)^{(p-1)/2} \\
& \times\left\{\sum_{j\geqq k}(1+j-k)^{-\mu}\|\chi_j(1+x)^{\delta/2}u;\, L^\infty([0,t],L^2)\|^{2(p-1)}\right\}^{1/2}.
\end{aligned} \tag{4.48}
$$

The last factor in (4.48) is then estimated by

$$
\|\chi_+(1+x)^{\delta/2}u;\, l^2(L^\infty([0,t],L^2))\|^{p-1} \tag{4.49}
$$

either in an obvious way if $p \geqq 2$ since μ is positive, or by the Hölder inequality in the discrete variable provided

$$
\mu + p - 1 > 1,
$$

which coincides with (4.34). Now the norms appearing in (4.48), except for the last one, are controlled by Proposition 4.3, part 1, by Proposition 4.1, part 2 applied with $h = h_{0\beta}$ and by (4.28), while the norm in (4.49) is controlled in terms of the previous one by a straightforward extension of Proposition 4.1, part 3. The required estimate of $\chi_+ J_2^+$ now follows from (4.45), (4.46), (4.48), and (4.49). Part (3) of this proposition follows from that estimate and from (4.31), (4.36), and (4.38).

Part 4. Part 4 follows immediately from part 3 and Proposition 4.2. □

Remark 4.3. All the solutions of (1.1) considered in Proposition 4.5 and in parts (3) and (4) of Proposition 4.6 satisfy automatically the condition $(1+x_+)^{\beta/2}u \in L^\infty_{\mathrm{loc}}([0,T),L^2)$ by Proposition 4.1, part 2. Furthermore, it follows from the proofs of Propositions 4.5 and 4.6 that (4.29) and (4.33) can be supplemented with the statements that

$$
\chi_+ Du - \chi_+ U(\cdot)Du_0 \in L^\infty_{\mathrm{loc}}([0,T),L^\infty), \tag{4.50}
$$

$$
Du - U(\cdot)Du_0 \in L^\infty_{\mathrm{loc}}([0,T),L^\infty) \tag{4.51}
$$

with the same estimates as those given in connection with (4.29), (4.33).

Using Proposition 4.4, we can obtain sufficient conditions for the various norms appearing in the uniqueness classes, namely, the norms associated with (4.6), (4.12), and (4.28) to be a priori estimated in terms of the initial data, and we can exhibit a new uniqueness class.

PROPOSITION 4.7. *Let V satisfy the condition* (4.22) *and the condition* (3.4) *for some* p, $1 \leqq p < 4$, *and for all* $\rho \in [-1,1]$. *Let* $T > 0$, *and let* $u_0 \in H^1$ *satisfy* $(1+x_+)^{\beta/2}u_0 \in L^2$ *and* $(1+x_+)^{\gamma/2}Du_0 \in L^2$ *for some* $\beta, \gamma \geqq 0$ *satisfying* $\beta \geqq \nu\gamma$, *where* $\nu = (4-p)/(4+p)$, *and* $\gamma \leqq \beta + 2$.

(1) *Let u be a solution of* (1.1) *with initial data $u(0)=u_0$, satisfying* (4.12) *and in addition* (4.15) *if $p<2$. Then u satisfies $D^2u\in l^\infty(L^2_{\mathrm{loc}}([0,T),L^2))$ and* (4.28), *and for all $t\in[0,T)$, u is estimated in $L^\infty([0,t],H^1)$, D^2u is estimated in $l^\infty(L^2([0,t],L^2))$ and $(1+x_+)^{\gamma/2}Du$ is estimated in $L^\infty([0,t],L^2)$ in terms of t of $\|(1+x_+)^{\beta/2}u_0\|_2$ and of $\|(1+x_+)^{\gamma/2}Du_0\|_2$.*

(2) *In addition let V'' be AC with $V''(0)=0$ and V''' locally bounded, and let p, β, γ satisfy either* (4.27) *or* (4.34). *Then the equation* (1.1) *with initial data $u(0)=u_0$ has at most one solution satisfying* (4.12) *and in addition* (4.15) *if $p<2$. Any such solution satisfies* (4.28) *and* (4.29).

Proof. Part 1. Part 1 follows from Proposition 4.4. Assumption (3.4) implies (4.23) with the same p by integration. The statements and estimates on u in $L^\infty(\cdot,H^1)$ and D^2u in $l^\infty(L^2(\cdot,L^2))$ are a repetition of parts 1 and 2 of Proposition 4.4. The statements and estimates on $(1+x_+)^{\gamma/2}Du$ in $L^\infty(\cdot,L^2)$ follow from part 3 of Proposition 4.4 applied with $h=h_{\alpha\gamma}$ for some $\alpha>0$. The additional assumptions required on $h^{\nu/2}u$ and $(1+h)^{1/2}h'u$ follow from Proposition 4.1, part 2, applied with $h_{\alpha\beta}$ for some $\alpha>0$, under the conditions $\beta\geqq\nu\gamma$ and $\gamma\leqq\beta+2$. Finally, the assumption $hV_+(u_0)\in L^1$ follows from Lemma 3.2 applied with $W=V$.

Part 2. Part 2 follows from part 1 and from Proposition 4.5, part 2 and Proposition 4.6, parts 2 and 4. □

Proposition 4.7 indicates that under the additional assumptions (4.23), $\beta\geqq\nu\gamma$ and $\gamma\geqq\beta+2$, the uniqueness classes defined in Proposition 4.5, part 2 and Proposition 4.6, parts 2 and 4 are actually suitable for existence and uniqueness provided only $(1+x_+)^{\beta/2}u_0\in L^2$ and $(1+x_+)^{\gamma/2}Du_0\in L^2$, with the appropriate assumptions on V, β, and γ made in those propositions. That need not be the case, however, for the uniqueness class defined in Proposition 4.7 for $p<2$, since the condition (4.15) is not preserved when taking weak-star limits (cf. Remark 3.8).

We conclude this section with some comments on the assumptions of Propositions 4.5–4.7. In view of parts 1 and 2 of Proposition 4.6, parts (3) and (4) of that proposition and to a large extent Proposition 4.5 are interesting only for $1\leqq p\leqq\frac{3}{2}$, and, in particular, for the ordinary KdV equation corresponding to $p=1$. In that case, the interaction $V''(u)$ does not decrease sufficiently fast as x tends to $+\infty$ for H^1 data, and an additional decrease must be assumed on the data, either on u or on Du. Which of Propositions 4.5 and 4.6 is better depends on the values of β and γ. For $\gamma=0$, condition (4.34) is always weaker than (4.27), except in the limiting case $p=1$, $\beta=\frac{1}{2}$, which is allowed by (4.27) but not by (4.34). On the other hand, for low values of p and β, (4.27) yields better results through a better use of γ. For instance, for $p=1$, (4.27) together with $\beta\geqq\nu\gamma$ allows for $\beta=\frac{3}{16}$, $\gamma=\frac{5}{16}$, which is not covered by (4.34). This may be due in part to the fact that in Proposition 4.6, parts 3 and 4, we have not used the property $\chi_+(1+x_+)^{(\gamma-1)/2}D^2u\in L^2_{\mathrm{loc}}([0,T),L^2)$, which follows from Proposition 4.4, part 3, but we will not elaborate on that point.

ON A KIND OF PREDATOR-PREY SYSTEM*

DING SUNHONG†

Abstract. In this paper a kind of predator-prey system given in [*SIAM J. Appl. Math.*, 35 (1978), pp. 617-625] is considered. Utilizing the theory of ordinary differential equations, two theorems for a general predator-prey system are proved, completing the investigation of the predator-prey system.

Key words. predator-prey system, limit cycle, Poincaré-Bendixon theorem

AMS(MOS) subject classification. 34C

A predator-prey system is a simple and typical mathematical model of the ecological system. Recently, many ecologists and mathematicians have been paying attention to establishing many mathematical models for the predator-prey system, have been investigating these mathematical models, and have been interpreting these ecological systems from a scientific viewpoint [2], [5], [7], [8]. Unfortunately, it is not easy to investigate the predator-prey system completely. In this paper we give two theorems on the existence of unique periodic solutions and the nonexistence of periodic solutions for a kind of predator-prey system. Applying these two theorems, we complete the investigation of the predator-prey system, that has been done in [3], in the global parameter space.

The mathematical model of the predator-prey system given in [3] is

$$\begin{aligned} \dot{X} &= \gamma X(1-X/K) - YX^n/(a+X^n), \\ \dot{Y} &= Y(\mu X^n/(a+X^n) - D), \qquad n=1,2 \end{aligned} \tag{1}$$

where X and Y are functions of t, $\dot{X}=dX/dt$, $\dot{Y}=dY/dt$, and γ, a, μ, K, and D are positive parameters.

We consider a general form of (1):

$$\dot{X}=\varphi(X)-g(Y)\psi(X), \qquad \dot{Y}=h(Y)(\mu\psi(X)-D) \tag{2}$$

where

(H1) $\varphi(X)\in C^1(0,+\infty)$, $\varphi(0)=0$,
$\psi(X)\in C^1(0,+\infty)$, $\psi(0)=0$ and $\psi'(X)>0$;

(H2) $h(Y)\in C(0,+\infty)$, $h(0)=0$ and $h'(Y)>0$,
$g(Y)\in C(0,+\infty)$, $g(0)=0$ and $g'(Y)>0$;

(H3) μ and D are positive parameters.

Let $F(X)=\varphi(X)/\psi(X)$. In the domain

$$\Omega=\{(X,Y)\,|\,X>0,\ Y>0\},$$

(2) is equivalent to

$$\begin{aligned} \dot{X} &= \varphi(X)(F(X)-g(Y)) = G(X,Y), \\ \dot{Y} &= h(Y)(\mu\psi(X)-D) = H(X,Y). \end{aligned} \tag{3}$$

According to the ecological meaning, we investigate (1)-(3) in the domain Ω only. Since $\psi'(X)>0$ as $X>0$, the equation $\mu\psi(X)-D=0$ has at most one positive solution λ; hence (2) or (3) has at most one singular point $P(\lambda, g^{-1}(F(\lambda)))$ in the domain Ω. Theorem 1 is on the existence of a unique periodic solution for (2) or (3).

THEOREM 1. *Let $P(\lambda, g^{-1}(F(\lambda)))$ be a unique singular point of* (3) *in the domain Ω, let conditions* (H1)-(H3) *be satisfied, let $F'(\lambda)\neq 0$, and let $F'(X)\psi(X)/(\mu\psi(X)-D)$ be nonincreasing in the intervals $(0,\lambda)$ and $(\lambda,+\infty)$. Then* (3) *has at most one stable limit cycle in the domain Ω.*

Proof. Define a function

$$V(X, Y)=\int_{\lambda}^{X}\frac{\mu\psi(\xi)-D}{\psi(\xi)}\,d\xi+\int_{g^{-1}(F(\lambda))}^{Y}\frac{g(\eta)-F(\lambda)}{h(\eta)}\,d\eta.$$

Then

$$\left(\frac{dV}{dt}\right)_{(3)}=(F(X)-F(\lambda))(\mu\psi(X)-D) \tag{4}$$

where $(dV/dt)_{(3)}$ denotes the total derivative of the function $V(X, Y)$ along a path of (3) corresponding to a solution $(X(t), Y(t))$. Since $F'(X)\psi(X)/(\mu\psi(X)-D)$ is nonincreasing in the intervals $(0,\lambda)$ and $(\lambda,+\infty)$ and $F'(\lambda)\neq 0$, then $F'(\lambda)>0$. On the contrary, assume $F'(\lambda)<0$; then $\lim_{X\to\lambda_{+0}}F'(X)\psi(X)/(\mu\psi(X)-D)=-\infty$. Because $F'(X)\psi(X)/(\mu\psi(X)-D)$ is nonincreasing in the interval $(\lambda,+\infty)$, $F'(X)\psi(X)/(\mu\psi(X)-D)<-\infty$ as $X>\lambda$, a contradiction. Then there exists a neighborhood of λ, denoted by U, such that

$$\left(\frac{dV}{dt}\right)_{(3)}=(F(X)-F(\lambda))(\mu\psi(X)-D)>0, \tag{5}$$

as $X\in U\backslash\{\lambda\}$. $P(\lambda, g^{-1}(F(\lambda)))$ is an unstable singular point of (3). If (3) has limit cycles in the domain Ω, one of them is closest to the singular point P, which is inside stable and is denoted by Γ_1.

Let Γ be any closed orbit of (3); then

$$\oint_{\Gamma}\operatorname{div}(G, H)\,dt=\oint_{\Gamma}\psi'(X)(F(X)-g(Y))\,dt$$
$$+\oint_{\Gamma}\psi(X)F'(X)\,dt+\oint_{\Gamma}g'(Y)(\mu\psi(X)-D))\,dt.$$

Since

$$\oint_{\Gamma}\psi'(X)(F(X)-g(Y))\,dt=\oint_{\Gamma}(\psi'(X)/\psi(X))\,dX=0,$$
$$\oint_{\Gamma}g'(Y)(\mu\psi(X)-D)\,dt=\oint_{\Gamma}(g'(Y)/g(Y))\,dY=0,$$

then

$$\oint_{\Gamma}\operatorname{div}(G, H)\,dt=\oint_{\Gamma}\psi(X)F'(X)\,dt. \tag{6}$$

The X-coordinates of leftmost point M and rightmost point N at the orbit Γ_1 are denoted by $X_M=\min_{(X,Y)\in\Gamma_1}X$, $X_N=\max_{(X,Y)\in\Gamma_1}X$, respectively (see Fig. 1). Define

$$f_1(X)=F'(X)-\frac{F'(X_M)\psi(X_M)(\mu\psi(X)-D)}{(\mu\psi(X_M)-D)\psi(X)}.$$

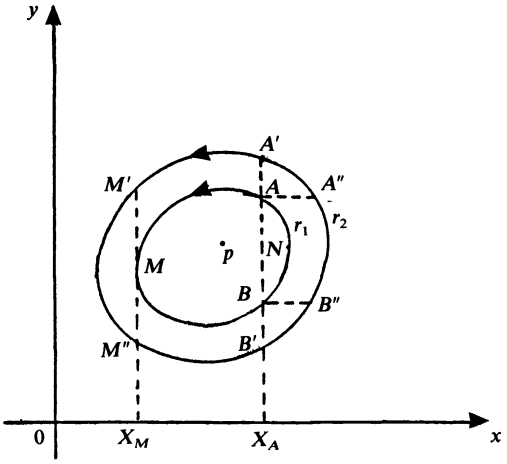

FIG. 1

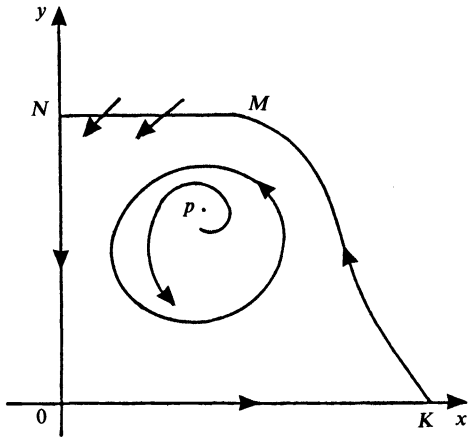

FIG. 2

$f_1(X_M)=0$, $f_1(X)\psi(X)/(\mu\psi(X)-D)$ is nonincreasing in the intervals $(0,\lambda)$ and $(\lambda,+\infty)$, the same as for $F'(X)\psi(X)/(\mu\psi(X)-D)$, therefore $f_1(X)<0$ as $X\in(0,X_M)$ and $f_1(X)>0$ as $X\in(X_M,\lambda)$. For any closed orbit Γ of (3) we have

$$\oint_\Gamma \operatorname{div}(G,H)\,dt=\oint_\Gamma \psi(X)f_1(X)\,dt \tag{7}$$

where $f_1(\lambda)=F'(\lambda)>0$. If $f_1(X)$ is not less than zero in the interval (λ,X_N) also, then

$$\oint_{\Gamma_1} \operatorname{div}(G,H)\,dt>0.$$

On the contrary, the closed orbit Γ_1 is inside stable. Hence there must exist an X_A, $\lambda<X_A<X_N$, such that $f_1(X)>0$ as $X\in(X_M,X_A)$, $f_1(X)<0$ as $X\in(0,X_M)\cup(X_A,+\infty)$.

There exists another limit cycle that is outside and closest to the limit cycle Γ_1, denoted by Γ_2. The vertical line through the point M intersects the orbit Γ_2 at the point M' and M'' (see Fig. 1). The horizontal line $X=X_A$ intersects the orbit Γ_2 at the point A' and B'. The horizontal line through the point A intersects the orbit Γ_2 at the point A''; the horizontal line through the point B intersects the orbit Γ_2 at the point B'' (see Fig. 1). We have

$$\oint_{\Gamma_1}\psi(X)f_1(X)\,dt=\left(\int_{\widehat{AM}}+\int_{\widehat{MB}}+\int_{\widehat{BNA}}\right)\psi(X)f_1(X)\,dt, \tag{8}$$

$$\oint_{\Gamma_2}\psi(X)f_1(X)\,dt=\left(\int_{\widehat{A'M'}}+\int_{\widehat{M'M''}}+\int_{\widehat{M''B'}}+\int_{\widehat{B'B''}}+\int_{\widehat{B''A''}}+\int_{\widehat{A''A'}}\right)\psi(X)f_1(X)\,dt. \tag{9}$$

Let $Y=Y_1(X)$ and $Y=Y_2(X)$ denote the functions of curves $\widehat{AM}$ and $\widehat{A'M'}$, respectively; then

$$\begin{aligned}&\int_{\widehat{A'M'}}\psi(X)f_1(X)\,dt-\int_{\widehat{AM}}\psi(X)f_1(X)\,dt\\ &\quad=-\left(\int_{X_M}^{X_A}\frac{f_1(X)\,dx}{F(X)-g(Y_1(X))}-\int_{X_M}^{X_A}\frac{f_1(X)\,dX}{F(X)-g(Y_2(X))}\right)\end{aligned} \tag{10}$$

$$= -\int_{X_M}^{X_A} \frac{f_1(X)(g(Y_2(X)) - g(Y_1(X)))}{(F(X) - g(Y_1(X)))(F(X) - g(Y_2(X)))} < 0.$$

Similarly, we can prove

$$\int_{\widehat{M''B'}} \psi(X) f_1(X)\, dt - \int_{\widehat{MB}} \psi(X) f_1(X)\, dt < 0. \tag{10'}$$

Since $f_1(X) > 0$ as $X \in (X_M, X_A)$, $f_1(X) < 0$ as $X \in (0, X_M) \cup (X_A, +\infty)$, we have

$$\int_{\widehat{M'M''}} \psi(X) f_1(X)\, dt = -\int_{Y_{M'}}^{Y_{M''}} \frac{\psi(X) f_1(X)\, dy}{h(Y)(\mu\psi(X) - D)} < 0, \tag{11}$$

$$\int_{\widehat{B'M''}} \psi(X) f_1(X)\, dt = \int_{X_{B'}}^{X_{B''}} \frac{f_1(X)\, dx}{F(X) - g(Y)} < 0, \tag{11'}$$

$$\int_{\widehat{A''A'}} \psi(X) f_1(X)\, dt < 0 \tag{11''}$$

where (X, Y) in every integral are the coordinates of the points at corresponding curves; $Y_{M'}$ and $Y_{M''}$ are Y-coordinates of the points M' and M'', respectively; and $X_{B'}$ and $X_{B''}$ are X-coordinates of the points B' and B''. Let $X = X_1(Y)$ and $X = X_2(Y)$ denote the functions of the curves $\widehat{BA}$ and $\widehat{B''A''}$, respectively; then

$$\begin{aligned} &\int_{\widehat{B''A''}} \psi(X) f_1(X)\, dt - \int_{\widehat{BA}} \psi(X) f_1(X)\, dt \\ &= \int_{Y_B}^{Y_A} \frac{\psi(X_2(Y)) f_1(X_2(Y))\, dY}{h(Y)(\mu\psi(X_2(Y)) - D)} - \int_{Y_B}^{Y_A} \frac{\psi(X_1(Y)) f_1(X_1(Y))\, dY}{h(Y)(\mu\psi(X_1(Y)) - D)} < 0. \end{aligned} \tag{12}$$

Combining (8)-(12), we have

$$\oint_{\Gamma_2} \operatorname{div}(G, H)\, dt - \oint_{\Gamma_1} \operatorname{div}(G, H)\, dt < 0. \tag{13}$$

Since

$$\oint_{\Gamma_1} \operatorname{div}(G, H)\, dt \leqq 0, \tag{14}$$

then

$$\oint_{\Gamma_2} \operatorname{div}(G, H)\, dt < 0. \tag{15}$$

If Γ_1 is a stable limit cycle, then Γ_1 and Γ_2 are both stable limit cycles, a contradiction. Now assume Γ_1 is a semistable limit cycle. Define

$$H(X) = \int_{\lambda}^{X} \frac{(\mu\psi(\xi) - D)\, d\xi}{\psi(\xi)} \quad \text{as } X > 0$$

and consider a new equation:

$$\dot{X} = \psi(X)(\bar{F}(X) - g(Y)), \qquad \dot{Y} = h(Y)(\mu\psi(X) - D) \tag{16}$$

where

$$\bar{F}(X) = \begin{cases} F(X) & \text{as } 0 < X < \lambda, \\ F(X) - \alpha H(X) & \text{as } \lambda < X, \quad 0 \leqq \alpha \ll 1. \end{cases}$$

As α varies, (16) is a rotated vector field and it is the equation (3) when $\alpha = 0$. According to the theory of the rotated vector field [1], as $0 < \alpha \ll 1$ the semistable limit cycle Γ_1

is broken down to two limit cycles Γ_1' and Γ_1'', Γ_1' is on the inside of Γ_1'', Γ_1' is a stable limit cycle, and Γ_1'' is an unstable limit cycle. From (13) we have

$$\oint_{\Gamma_1''} \operatorname{div}(G, H)\, dt - \oint_{\Gamma_1'} \operatorname{div}(G, H)\, dt < 0,$$

a contradiction. After the discussion above we conclude that (3) has at most one stable limit cycle in the domain Ω. The proof is complete.

Remark 1. If $(\lambda, g^{-1}(F(\lambda)))$ is an unstable singular point in the domain Ω, i.e., equation $\mu\psi(X) - D = 0$ has a positive solution λ, K is the smallest positive solution of the equation $\varphi(X) = 0$, $K > \lambda$ and $\varphi(X) > 0$ as $X \in (0, K)$, then (3) has at least one limit cycle in the domain Ω. The point $K(K, 0)$ is a saddle-type singular point in the domain $\bar{\Omega} = \{(X, Y) \mid X \geqq 0, Y \geqq 0\}$. If the orbit of (3) from the saddle point in the domain $\bar{\Omega}$ does not approach infinity, there exists the highest point M at this orbit (see Fig. 2). The horizontal line from the point M intersects the X-axis at the point N. Then if the closed curve $\widehat{KMNOK}$ surrounds a Poincaré-Bendixon region, by the Poincaré-Bendixon theorem, equation (3) has at least one stable limit cycle in the domain Ω. Adding the conditions $K > \lambda$ and $\varphi(X) > 0$ as $X \in (0, K)$ in Theorem 1, we have that (3) has exactly one stable limit cycle in the domain Ω.

Remark 2. If $F'(X)\psi(X)/(\mu\psi(X) - D)$ is nonincreasing in the intervals $(0, \lambda)$ and (λ, K), K is mentioned in Remark 1, and $K > \lambda$, the conclusion of Theorem 1 also holds.

THEOREM 2. *If all the positive solutions X, Y of the system of equations*

$$H(X) = H(Y), \qquad F(X) = F(Y) \tag{17}$$

satisfy $X = Y$, then equation (3) *does not have a periodic solution in the domain Ω.*

Proof. Since $\psi(0) = 0$ and $\psi'(X) > 0$, then $\psi(X) > 0$ as $X > 0$. Assume λ is the unique positive solution of the equation $\mu\psi(X) - D = 0$ in the interval $(0, +\infty)$. $H(X)$ is monotone decreasing in the interval $(0, \lambda)$ and monotone increasing in the interval $(\lambda, +\infty)$. $H(X)$ has inverse functions in the intervals $(0, \lambda)$ and $(\lambda, +\infty)$, denoted by $X_2(H)$ and $X_1(H)$, respectively. Suppose (3) has a periodic solution, i.e., (3) has a closed orbit surrounding the singular point P, denoted by Γ. Let the equations of the curve Γ be

$$X = \Gamma_1(Y) \quad \text{as } \lambda \leqq X,$$

$$Y = \Gamma_2(Y) \quad \text{as } 0 < X \leqq \lambda.$$

There exist $Y_{\min}$ and $Y_{\max}$, a Y-coordinate of the lowest point and a Y-coordinate of the highest point at the orbit Γ, respectively, and from (3) there hold

$$\frac{dH(\Gamma_1(Y))}{dY} = \frac{F(X_1(H(\Gamma_1(Y)))) - g(Y)}{h(Y)}, \tag{18}$$

$$\frac{dH(\Gamma_2(Y))}{dY} = \frac{F(X_2(H(\Gamma_2(Y)))) - g(Y)}{h(Y)} \tag{18'}$$

where $Y_{\min} \leqq Y \leqq Y_{\max}$. From (18) and (18'), the curves $\Gamma_1(Y)$ and $\Gamma_2(Y)$ are the solutions of the boundary value problems

$$\frac{d\bar{H}}{dY} = \frac{F(X_1(\bar{H})) - g(Y)}{h(Y)}, \qquad \bar{H}(Y_{\min}) = \bar{H}(Y_{\max}) = 0 \tag{19}$$

and

$$\frac{d\bar{H}}{dY}=\frac{F(X_2(\bar{H}))-g(Y)}{h(Y)}, \qquad \bar{H}(Y_{\min})=\bar{H}(Y_{\max})=0, \tag{19'}$$

respectively. We will prove that $F(X_1(\bar{H}))\not\equiv F(X_2(\bar{H}))$ as $\bar{H}>0$. Without loss of generality, assume $F(X_1(\bar{H}))<F(X_2(\bar{H}))$ as $\bar{H}>0$; then

$$\frac{F(X_1(\bar{H}))-g(Y)}{h(Y)}<\frac{F(X_2(\bar{H}))-g(Y)}{h(Y)} \quad \text{as } \bar{H}>0. \tag{20}$$

If (19) and (19') both have solutions denoted by $\bar{H}_1(Y)$ and $\bar{H}_2(Y)$, respectively, then there exists $0<\varepsilon\ll 1$, such that $\bar{H}_1(Y)<\bar{H}_2(Y)$ when $Y_{\min}<Y<Y_{\min}+\varepsilon$ and $\bar{H}_1(Y)>\bar{H}_2(Y)$ when $Y_{\max}-\varepsilon<Y<Y_{\max}$. Then there exists Y_0, $Y_{\min}+\varepsilon<Y_0<Y_{\max}-\varepsilon$, such that $\bar{H}_1(Y_0)=\bar{H}_2(Y_0)$ and $d\bar{H}_1(Y_0)/dY\geqq d\bar{H}_2(Y_0)/dY$, a contradiction. Now we prove $F(X_1(\bar{H}))\not\equiv F(X_2(\bar{H}))$ as $\bar{H}>0$. If there is an $\bar{H}_0>0$ such that $F(X_1(\bar{H}_0))=F(X_2(\bar{H}_0))$, and if we let $X_0=H_1(\bar{H}_0)$ and $Y_0=X_2(\bar{H}_0)$, then $F(X_0)=F(Y_0)$, $H(X_0)=H(Y_0)$ and $X_0>Y_0>0$, which contradicts the condition of the theorem. So $F(X_1(\bar{H}))\not\equiv F(X_2(\bar{H}))$ as $\bar{H}>0$. The theorem is proved.

Now we use Theorems 1 and 2 to investigate the predator-prey system (1).

THEOREM 3. *There are three types of global structure of the predator-prey system* (1), *in which* (1)

(a) *Has an unique stable limit cycle in the domain* Ω, *and all the trajectories of* (1) *in the domain* Ω *approach this limit cycle*;

(b) *Has a stable singular point* $P(\lambda, g^{-1}(F(\lambda)))$ *in the domain* Ω, *and all the trajectories of* (1) *in the domain* Ω *terminate at the singular point*;

(c) *Does not have any singular point in the domain* Ω, *and all trajectories of* (1) *in the domain* Ω *terminate at the point* $K(K,0)$.

The types of global structure of (1) *under the various conditions of the parameters* γ, a, μ, K, *and* D *are*:

when $n=1$

Distribution of parameters	$\mu>D>0$		$D\geqq\mu>0$
	$K>(\mu+D)a/(\mu-D)$	$K\leqq(\mu+D)a/(\mu-D)$	
Types of structure	type (a)	type (b)	type (c)

when $n=2$

Distribution of parameters		$2D>\mu>D>0$		
	$\mu\geqq 2D>0$	$K>K^*$	$K\leqq K^*$	$D\geqq\mu>0$
Types of structure	type (b)	type (a)	type (b)	type (c)

where $K^*=2D\sqrt{aD/(\mu-D)}/(2D-\mu)$.

Before we prove Theorem 3 we give the following lemma.

LEMMA 4. *If* $0<Y\leqq X$, *then*

$$\frac{X-Y}{X+Y}\leqq\frac{1}{2}(\ln X-\ln Y). \tag{21}$$

The equality holds if and only if $X=Y$.

Proof. Assume $S \geqq 1$; then $(S-1)^2 \geqq 0$, and moreover $(S+1)^2 \geqq 4S$. Therefore $2/(S+1)^2 \leqq 1/2S$, and integrating, we have

$$\int_1^r \frac{2dS}{(S+1)^2} \leqq \int_1^r \frac{1}{2}\frac{dS}{S}, \qquad 1-\frac{2}{r+1} \leqq \frac{1}{2}\ln r. \tag{22}$$

Let $r = X/Y$; from (22) we obtain (21). If $X = Y$, then the equality in (21) holds. Inversely, if the equality in (22) holds, then $r = 1$, i.e., $X = Y$. The lemma is proved.

Proof of Theorem 3.

(i) When $n = 1$, $F(X) = \gamma(1 - X/K)(a + X)$. As $K > a + 2\lambda = a(\mu + D)/(\mu - D)$, $0 < D < \mu$, then

$$KF'(\lambda) = \gamma(-2\lambda + K - a) > 0.$$

Let

$$\begin{aligned}\Delta(X) &= F'(X)\psi(X)/(\mu\psi(X) - D) \\ &= \gamma(-2X^2 + (K-a)X)/K((\mu - D)X - Da);\end{aligned}$$

then

$$\Delta'(X) = \frac{-2(\mu - D)X^2 + 4DaX - (K-a)Da}{K((\mu - D) - Da)^2}.$$

The determinant of $-2(\mu - D)X^2 + 4DaX - (K-a)Da$ is $8Da(\mu - d) \times (2\lambda + a - K) < 0$. Hence $\Delta'(X) < 0$ as $X \in (0, +\infty)\backslash\{\lambda\}$, i.e., $\Delta(X)$ is nonincreasing in the intervals $(0, \lambda)$ and $(\lambda, +\infty)$. Using Theorem 1 and Remark 1, when $n = 1$ and $K > a + 2\lambda$, we have that (1) has exactly one stable limit cycle in the domain Ω. The global structure in this case is of type (a).

(ii) When $n = 1$, $\mu > D > 0$, $K \leqq a + 2\lambda = a(\mu + D)/(\mu - D)$, then

$$H(X) = (\mu - D)(X - \lambda) - Da(\ln X - \ln \lambda).$$

Now (17) is

$$\begin{aligned}&(\mu - D)(X - Y) - Da(\ln X - \ln Y) = 0, \\ &(K - a)(X - Y) - (X^2 - Y^2) = 0.\end{aligned} \tag{23}$$

If the system of equations has positive solutions X^*, Y^*, satisfying $X^* \neq Y^*$, without loss of generality, assume $0 < X^* < Y^*$, then we have

$$\begin{aligned}&(\mu - D)(X^* - Y^*) - Da(\ln X^* - \ln Y^*) = 0, \\ &(K - a)(X^* - Y^*) - (X^* + Y^*)(X^* - Y^*) = 0.\end{aligned} \tag{24}$$

Since $K \leqq (\mu + D)a/(\mu - D)$, from (23) there is

$$\begin{aligned}\frac{Y^* - X^*}{Y^* + X^*} &= \frac{Da}{(\mu - D)(K - a)}(\ln Y^* - \ln X^*) \\ &\geqq \frac{1}{2}(\ln Y^* - \ln X^*),\end{aligned}$$

a contradiction. Hence the system of equations (23) has no such positive solutions X^*, Y^*, satisfying $X^* \neq Y^*$. Therefore by Theorem 2, (1) has no closed trajectory in the domain Ω. The singular point $P(\lambda, g^{-1}(F(\lambda)))$ in this case is stable, and all the trajectories of (1) terminate at this singular point. The global structure of (1) in this case is of type (b).

(iii) When $n=1$, $\mu \leqq D$, there is no singular point in the domain Ω for (1). In the domain Ω, $K(K,0)$ is a stable node-type singular point and $O(0,0)$ is a saddle-type singular point, and all the trajectories of (1) in the domain Ω terminate at the point $K(K,0)$. The global structure in this case is of type (c).

(iv) When $n=2$, $0<D<\mu<2D$, $K>K^*=2D\lambda/(2D-\mu)$,

$$F(X)=\gamma(1-X/K)(a+X^2)/X,$$

$$\lambda^2F'(\lambda)=\gamma(-a+\lambda^2-3\lambda^3/K)$$

$$=\gamma a(\mu-D)(2D-\mu-2D\lambda/K)>0,$$

$$\Delta(X)=F'(X)\psi(X)/(\mu\psi(X)-D)$$

$$=\gamma(-a+X^2-3X^3/K)/((\mu-D)X^2-Da),$$

$$\Delta'(X)=\frac{2\gamma(((\mu-D)a-Da)+3DaX/K-(\mu-D)X^3/K)X}{((\mu-D)X^2-Da)^2}.$$

Since

$$\lambda^2K(((\mu-D)a-Da)+3DaX/K-(\mu-D)X^3/K)<-Da(X-\lambda)^2(X+2\lambda)<0,$$

as $X\in(0,\lambda)\cup(\lambda,+\infty)$, then $\Delta'(X)<0$, as $X\in(0,+\infty)\backslash\{\lambda\}$, i.e., $\Delta(X)$ is nonincreasing in the intervals $(0,\lambda)$ and $(\lambda,+\infty)$. According to Theorem 1 and Remark 1, (1) has exactly one stable limit cycle in the domain Ω as $n=2$ and $K>K^*$. The global structure of (1) in this case is of type (a).

(v) When $n=2$, $0<D<\mu<2D$, $K\leqq K^*$, the system (17) is

$$(1-X/K)(a+X^2)/X=(1-Y/K)(a+Y^2)/Y,$$

$$(\mu-D)(X-\lambda)+Da\left(\frac{1}{X}-\frac{1}{\lambda}\right)=(\mu-D)(Y-\lambda)+Da\left(\frac{1}{Y}-\frac{1}{\lambda}\right). \tag{25}$$

The system of equations has no such positive solutions X^*, Y^*, $X^*\neq Y^*$. On the contrary, if (25) has such solutions, we have

$$-a+X^*Y^*-(X^*+Y^*)X^*Y^*/K=0,$$

$$X^*Y^*=\lambda^2, \tag{26}$$

$$X^*+Y^*=(\lambda^2-a)K/\lambda^2=(2D-\mu)K/D$$

$$\leqq 2\sqrt{\frac{2D}{\mu-D}}=2\lambda, \tag{27}$$

$$2\lambda=2\sqrt{X^*Y^*}<(X^*+Y^*)\leqq 2\lambda,$$

a contradiction. By Theorem 2, (1) has no closed trajectory in the domain Ω, and all the trajectories of (1) in the domain Ω terminate at the stable singular point $P(\lambda, g^{-1}(F(\lambda)))$. The global structure of (1) in this case is of type (b).

(vi) When $n=2$, $\mu \geqq 2D>0$, similar to case (v), we have systems of equations (25) and (26). From (26), we have

$$0<X^*+Y^*=(2D-\mu)K/D \leqq 0,$$

a contradiction, and the same result as in case (v) holds.

(vii) When $n=2$, $0 \geqq \mu > D$, similar to case (iii), the same result holds.

Combining (i)-(vii) completes the proof.

We give Figs. 3-5 to illustrate the types of the structure (a), (b), and (c), respectively.

In Fig. 3, type (a), the system (1) finally approaches a closed orbit. The numbers of predator and prey both vary periodically.

In Fig. 4, type (b), the system (1) finally terminates at a unique stable equilibrium, i.e., terminates at the stable singular point $P(\lambda, g^{-1}(F(\lambda)))$. The numbers of predator and prey limit to nonzero constants.

In Fig. 5, type (c), the birth rate of the predator is less than its death rate, i.e.,

$$\dot{Y}=Y(\mu X^n/(a+X^n)-D)<0.$$

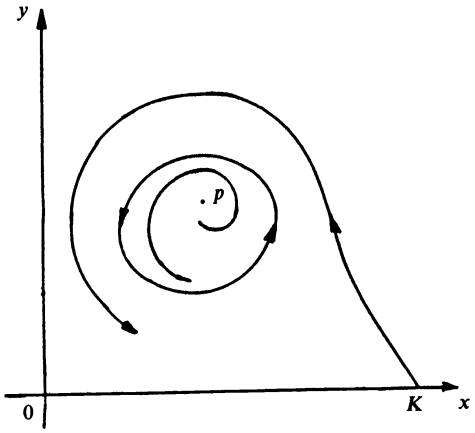

FIG. 3

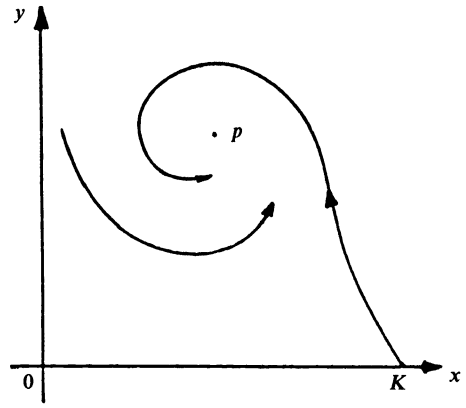

FIG. 4

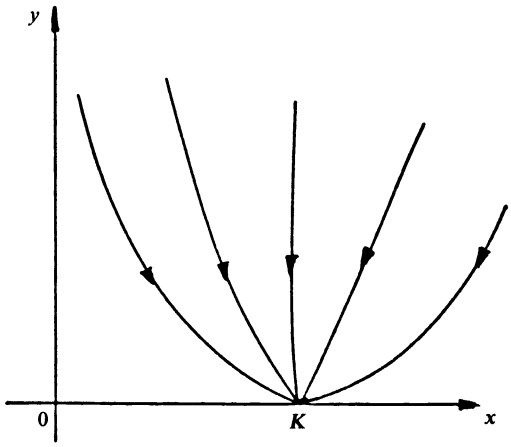

FIG. 5

The number of predators is monotonic decreasing, and finally terminates at zero. The number of prey will be constant, $\dot{X} = X(1 - X/K) = 0$ as $X = K$. The predator-prey system (1) will be exterminated.

Acknowledgment. We thank a referee who pointed out a recent paper of Kuang and Kreedman who obtained similar results using a different method.

THE UNIQUENESS AND STABILITY OF THE REST STATE FOR STRONGLY COUPLED OSCILLATORS*

G. BARD ERMENTROUT† AND WILLIAM C. TROY†

Abstract. In this paper it is shown that an unstable steady state can be stabilized in the presence of sufficient inhomogeneity and strong diffusion for a continuum and discrete model. These results are applied to a pair of coupled oscillators and to an oscillatory reaction-diffusion system. It is also shown that for the reaction-diffusion system, the trivial rest state is the unique phase-locked solution. Some additional numerical results are presented that illustrate the nature of this bifurcation for a realistic model oscillator.

Key words. oscillation, stability, reaction-diffusion equations

AMS(MOS) subject classifications. 35B35, 58F10

1. Introduction. This paper is a continuation of an analysis of an oscillatory reaction-diffusion system in the presence of a gradient in natural frequencies. In our previous article [1], we have shown the existence of a periodic (phase-locked) solution and shown some of its behavior via numerical methods. In this paper, we are interested in the stabilization and uniqueness of the rest state (which is unstable in the absence of the diffusion). This phenomenon of restabilization has been explored numerically for the Brusselator by Bar-Eli [2] and has been shown for a simple λ-ω model in [3]. In both of the latter cases, two discrete oscillators are coupled diffusively and it is shown that if the two uncoupled frequencies are different enough, then there is a stable equilibrium for coupling strengths in some intermediate range. More recently, a different mechanism for the stabilization of a rest state (and thus, the death of the oscillation) was discussed in [4] for *identical* oscillators coupled *directly* rather than diffusively. In a sense, this is the inverse of Smale's mechanism by which two coupled "dead" cells could spontaneously begin to oscillate if allowed to interact through diffusion. In the Smale article [5], though, the two cells are identical and the mechanism is more akin to a Turing instability of the Hopf type (see, e.g., [6]).

In this paper, we are mainly interested in a continuum of cells with a linear gradient of frequencies that are coupled by ordinary diffusion. We prove the stability and uniqueness of the stationary trivial solution for sufficiently strong diffusion and a large enough gradient in frequencies. We will also consider a general pair of coupled oscillators in $\mathbb{R}^n$ and show how the trivial state can be restabilized if the two are different enough and the coupling is sufficiently strong. In § 2, we describe the discrete model and prove the stability result. Section 3 introduces the continuum model and the stability theorem is stated and proved. Section 4 is devoted to a proof of the uniqueness of the trivial solution as a phase-locked state.

2. Two coupled oscillators. Consider the following pair of coupled nonlinear differential equations:

$$\frac{du}{dt} = F(u) + \beta(v-u), \tag{2.1}$$

$$\frac{dv}{dt} = \sigma F(v) + \beta(u-v) \tag{2.2}$$

where β is a scalar representing the strength of coupling and σ is a parameter that distinguishes the rates of the two systems. In particular, when $\beta = 0$ we may suppose that each system oscillates about some rest point which we may assume to be zero with no loss in generality. Then the ratio of the frequencies of the two oscillators is σ. We assume that in the absence of coupling, the equilibrium point $u = v = 0$ is unstable. It will remain so for sufficiently small strengths of coupling. We now show how the nature of this instability determines whether it is always unstable for all choices of (β, σ). In fact, we will show that if the eigenvalues of the linearized uncoupled system are complex and the imaginary part is large enough, there are ranges of parameters β and σ such that the coupled system is linearly stable.

Let A be the Jacobian of F evaluated at $u = 0$. Consider the following linear system:

$$\frac{du}{dt} = Au + \beta(v - u), \tag{2.3}$$

$$\frac{dv}{dt} = \sigma Av + \beta(u - v). \tag{2.4}$$

LEMMA 2.1. *If (ν, ϕ) is an eigenvalue-eigenvector pair for the matrix A, then (γ, ξ) is an eigenvalue-eigenvector pair for the matrix*

$$M = \begin{bmatrix} A - \beta I & \beta I \\ \beta I & \sigma A - \beta I \end{bmatrix}$$

where $\xi = (\phi, s\phi)^T$, γ satisfies

$$\gamma^2 + (2\beta - \nu(\sigma + 1))\gamma + \nu(\sigma\nu - \beta(\sigma + 1)) = 0 \tag{2.5}$$

and $(1, s)^T$ is the eigenvector corresponding to γ for the 2×2 matrix

$$\begin{bmatrix} \nu - \beta & \beta \\ \beta & \sigma\nu - \beta \end{bmatrix}.$$

Proof. Substitute the vector ξ into the eigenvalue equation for M and use the fact that $A\phi = \nu\phi$. □

LEMMA 2.2. *Let $\nu = \lambda + i\omega$ denote an eigenvalue of A.*

(i) *If $\omega = 0$ and $\lambda > 0$, then $(0, 0)$ is unstable as a solution to* (2.3).

(ii) *If $\lambda < 0$, then the corresponding pair of eigenvalues for the linear system* (2.3)-(2.4) *have negative real parts.*

Proof. We need only analyze the roots of (2.5).

(i) If ν is real and positive, then for stability, we must have the coefficients of (2.5) both positive, i.e.,

$$\frac{\sigma}{\sigma + 1} > \frac{\beta}{\nu} > \sigma + 1.$$

Since the first expression is less than 1 and the last is greater, this is an obvious impossibility.

(ii) If ν is real and negative, then the coefficients of (2.5) are both positive so that all the roots have negative real parts. Suppose that ν is complex with a negative real part. We will prove that it is impossible for eigenvalues of (2.5) to cross the imaginary axis. When $\beta = 0$, the eigenvalues are ν and $\sigma\nu$, both having negative real parts. We follow these eigenvalues as β increases. There are two ways in which instability could occur; one of the two eigenvalues of (2.5) could become real and cross through zero, or it could cross into the right halfplane through the imaginary

axis. Since ν is complex, the former is impossible; there will be a zero eigenvalue if and only if $\beta = \sigma\nu/(\sigma+1)$, which is complex. Thus, if instabilities are to occur, they must be through the imaginary axis. We differentiate (2.5) with respect to β and find that

$$\frac{d\gamma}{d\beta} = \frac{-|\nu(\sigma-1)-2\gamma|^2+2\beta[\nu(\sigma+1)-2\gamma]}{|-\nu(\sigma+1)+2\gamma+2\beta|^2}. \tag{2.6}$$

Suppose that for some β, $\gamma = i\kappa$ (i.e., $\mathrm{Re}\,(\gamma)=0$). Then, the real part of $d\gamma/d\beta$ is strictly negative since $\mathrm{Re}\,(\nu)=\lambda<0$. Thus, it is impossible to cross the imaginary axis, and the roots to (2.5) lie in the left-half complex plane. □

Lemma 2.2 takes care of the case of real eigenvalues and complex eigenvalues with negative real parts. The only remaining case is the most interesting from our point of view: the case of complex eigenvalues with positive real parts. The proof of (ii) depended crucially on the fact that $\mathrm{Re}\,(\nu)<0$; the proof cannot be pushed through to show that eigenvalues remain on the right halfplane for all β. In fact, it is clear from (2.6) that for small β, $d\gamma/d\beta<0$ so that the eigenvalues move toward the left. But, as β gets larger, (2.6) may become positive again. As $\beta\to\infty$, one of the roots to (2.5) tends to $\frac{1}{2}\nu(\sigma+1)$, which has a positive real part. Thus, it is not obvious that eigenvalues can be pushed to the left halfplane.

LEMMA 2.3. *Let $q=\lambda/\omega$, where $\nu=\lambda+i\omega$. If q is sufficiently small, then there are regimes of β and σ such that the roots of* (2.5) *have negative real parts.*

Proof. The solutions to (2.5) are

$$\gamma = -\beta+\nu(\varepsilon+1)\pm\sqrt{\beta^2+\varepsilon^2\nu^2} \tag{2.7}$$

where $\varepsilon=(\sigma-1)/2$. Choose $\beta\approx\beta^*=|\varepsilon\omega|\sqrt{1-q^2}$ and substitute into (2.7). Using the fact that $\nu^2=\omega^2(q^2+2iq-1)$, we see that the maximal real part (corresponding to the +) is approximately

$$\mathrm{Re}\,\gamma \approx \omega[-\varepsilon\sqrt{1-q^2}+q(\varepsilon+1)+\varepsilon\sqrt{q}]. \tag{2.8}$$

For q sufficiently small and $\varepsilon>0$ (corresponding to $\sigma>1$, which may be assumed with no loss of generality), it is clear that $\mathrm{Re}\,\gamma<0$ as required. For β near β^*, the real part of the eigenvalue stays negative. □

Remark. It is clearly necessary that $\sigma\neq 1$ to obtain restabilization for any value of β. Indeed, setting $\varepsilon=0$ ($\sigma=1$) in (2.8) yields an eigenvalue ν that has a positive real part. The asymmetry in the problem is absolutely necessary for the coupling to change the signature of the eigenvalues. Furthermore, the greater the asymmetry, the larger q may be. The largest allowable q is roughly 0.35; for q greater than this, (2.8) is always positive for all $\varepsilon\geqq 0$. We also note that this is an intermediate value of coupling strength, β, neither very large, nor very small.

The following proposition follows from the previous lemmas.

PROPOSITION 2.1. *Suppose that zero is an unstable equilibrium point for* (2.3) *or* (2.4) *when $\beta=0$. Assume the instability is due to a single pair of complex conjugate eigenvalues $\lambda\pm i\omega$. Then, if λ/ω is small enough, these are values of σ and β for which the origin is an asymptotically stable equilibrium point.*

Remarks. The hypothesis on the signs and relative sizes of the eigenvalues is satisfied, for example, after a Hopf bifurcation.

In [3], we study a pair of symmetrically coupled oscillators and show that if the frequency difference between them is sufficiently large, then as the coupling increases, the amplitude of the phase-locked solution decreases and eventually goes to zero in a manner analogous to the continuum model considered in [1].

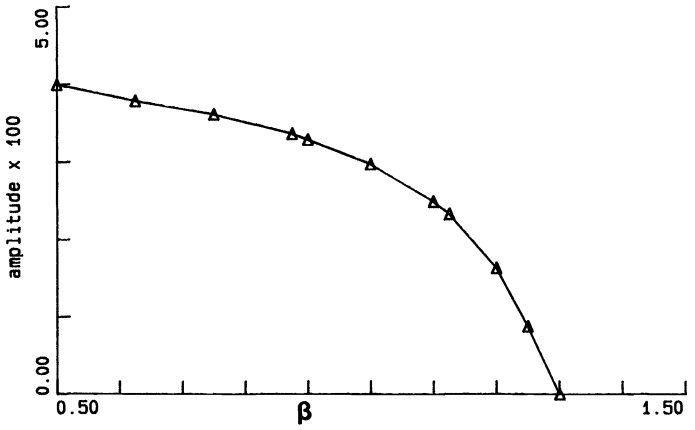

FIG. 1. *The difference between the maximum and minimum value of $u(t)$ as a function of the strength of diffusion for the Wilson-Cowan equations with $\sigma = 2$.*

Before continuing with the stability of the equilibrium for a continuous model, we describe some numerical results for a coupled oscillator model of the form (2.1)-(2.2). We consider a two-dimensional system, specifically the Wilson-Cowan equations [7]:

$$\frac{du}{dt} = -u + f(16.0u - 20.0v - 0.5), \tag{2.9}$$

$$\frac{dv}{dt} = -v + f(18.0u - 3.0) \tag{2.10}$$

where $f(u) = .5(1+\tanh(u))$. With these parameter values, the Wilson-Cowan equations oscillate about an unstable equilibrium point, $(u, v) = (0.110065, 0.115304)$. The eigenvalues of the Jacobian are $0.58045 \pm i\ 3.77018$, so that $q = 0.15396$. We have chosen $\sigma = 2$, so that the value $\beta^* = 1.862$. In Fig. 1, we have sketched the amplitude of $u(t)$ (i.e., the difference between the maximum and minimum values of $u(t)$) as a function of the parameter β for $\beta \in [0.5, 1.5]$. In this regime, the two oscillators are phase-locked in a 1:1 ratio. The amplitude gradually decreases until at a critical value of $\beta \approx 1.3$, the steady state is restabilized. This phenomenon is identical to that proved in [3] for a special solvable oscillator model. We have applied these results to a variety of other oscillator models and find similar behavior; if the difference in natural frequencies is too great, then for certain strengths of coupling, the rest state is restabilized as the amplitude of coupling decreases.

3. The continuum model. In [1], we have analyzed the phase-locked behavior of a simple reaction-diffusion equation with a linear frequency gradient:

$$\frac{\partial u}{\partial t} = \lambda(R)u - \omega(R, x)v + d\frac{\partial^2 u}{\partial x^2}, \tag{3.1}$$

$$\frac{\partial v}{\partial t} = \lambda(R)v + \omega(R, x)u + d\frac{\partial^2 v}{\partial x^2}, \tag{3.2}$$

$$\frac{\partial u}{\partial x}(0, t) = \frac{\partial u}{\partial x}(1, t) = \frac{\partial v}{\partial x}(0, t) = \frac{\partial v}{\partial x}(1, t) = 0 \tag{3.3}$$

where $R=u^2+v^2$, $\omega(R,x)=\omega_0-\hat{\sigma}x+q(1-R)$, and $\lambda(R)=\Lambda(1-R)$. In absence of diffusion, (3.1)-(3.2) admit stable periodic solutions with frequency $\omega_0+\hat{\sigma}x$. In [1], we have shown that for d large enough and $q=0$, there are periodic (phase-locked) solutions to (3.1)-(3.3). We have also shown numerically that for fixed $d\geqq 1$, as $\hat{\sigma}$ increases, the maximum amplitude $\sqrt{R}$ decreases to zero. We also conjectured that for $\hat{\sigma}$ large enough, the rest state stabilized. In the next section, we prove that for sufficiently large $\hat{\sigma}$ the solution $u=v=0$ is the unique periodic solution to (3.1)-(3.3). In this section, we prove that $u(x,t)=v(x,t)=0$ is a linearly stable solution to (3.1)-(3.3).

It is convenient to introduce the complex variable $w(x,t)=u(x,t)+iv(x,t)$. The linear stability problem is then

$$\frac{\partial w}{\partial t}=[\Lambda+i(\omega_0-\hat{\sigma}x)]w+d\frac{\partial^2 w}{\partial x^2}, \tag{3.4}$$

$$\frac{\partial w}{\partial x}(0,t)=\frac{\partial w}{\partial x}(1,t)=0. \tag{3.5}$$

We seek solutions to (3.4)-(3.5) of the form $w(x,t)=\exp(-[\hat{\lambda}+i\omega_0]t)z(x)$. $z(x)$ satisfies the ordinary differential equation

$$dz''+(\Lambda-i\hat{\sigma}x)z=-\hat{\lambda}z, \tag{3.6}$$

$$z'(0)=z'(1)=0. \tag{3.7}$$

Divide through by d and let $c=\Lambda/d$, $\sigma=\hat{\sigma}/d$, $\lambda=\hat{\lambda}/d$. Equation (3.6) becomes

$$z''+(c-i\sigma x)z=-\lambda z. \tag{3.8}$$

Finally, we let $\lambda=\alpha+i\delta$, $z=re^{i\theta}$, $\psi=\theta'$, $s=r'/r$, so that (3.7), (3.8) become

$$s'=\psi^2-s^2-(\alpha+c), \tag{3.9}$$

$$\psi'=\sigma x-\delta-2s\psi, \tag{3.10}$$

$$s(0)=\psi(0)=0, \tag{3.11}$$

$$s(1)=\psi(1)=0. \tag{3.12}$$

The origin is stable if and only if solutions to (3.6)-(3.7) have solutions with $\mathrm{Re}\,(\hat{\lambda})>0$, for then $w(x,t)$ decays exponentially in time. Since $\alpha=\mathrm{Re}\,(\hat{\lambda})/d$, to prove the equilibrium is stable we must show that (3.9)-(3.12) has a solution if and only if $\alpha>0$. It is clear from (3.8) that when $\sigma=0$, (3.7)-(3.8) has a solution, $z\equiv C$, a constant, and $\lambda=-c<0$, so that the origin is unstable. Thus, it is crucial that $\sigma\neq 0$. We can assume with no loss of generality that $\sigma>0$; if $\sigma<0$, then let $x\to 1-x$ in (3.4)-(3.5) and let $\omega_0\to\omega_0+\sigma$. We will prove the following theorem.

THEOREM 3.1. *Let $0\leqq c\leqq 1$. There is a $\sigma^*>0$ such that if* (3.9)-(3.12) *has a solution for some $\sigma>\sigma^*$ then $\alpha>0$.*

Since the proof is somewhat technical in nature, we give a short outline of the proof. Our goal is to show that if σ is large and (3.9)-(3.12) has a solution, then α must be positive. Thus, for the sake of contradiction, we assume that for every large σ there is an $\alpha\equiv\alpha(\sigma)\leqq 0$ for which (3.9)-(3.12) does indeed have a solution. The first step in our analysis is to prove that any solution to (3.9)-(3.12) must satisfy $|s(x)|\leqq\tan(1)$ for all $x\in(0,1)$. Next, we determine that if (3.9)-(3.12) holds then δ, α, and σ must lie in the parameter range $\alpha\geqq -c$ and $\sigma\geqq\delta>0$. We then define a σ^* independent of α, c, and δ, and assume that a solution exists for some $\sigma>\sigma^*$, $\alpha\in[-c,0]$ and $\delta\in[0,\sigma]$. We break the remaining analysis into two subcases, $0\leqq\delta\leqq\sigma/2$ and

$\sigma/2 \leqq \delta \leqq \sigma$. For the first case, we consider the x-intervals $I_1 = [\frac{5}{8}, \frac{3}{4}]$ and $I_2 = [\frac{3}{4}, \frac{7}{8}]$. We need to show that $|s(x_0)| = \tan(1)$ at some $x_0 \in I_1 \cup I_2$ to arrive at a contradiction. The key to this is to analyze (3.10) and obtain a lower bound estimate on the function $|\psi|$. We first show that there is an $M > 0$ (independent of σ) such that if $|\psi| \geqq M$ at some point in I_1, then $|\psi| \geqq M$ for all $x \in I_2$. This lower bound on $|\psi|$ is then used in (3.9) to show that $|s|$ must exceed $\tan(1)$. The remainder of this subcase is therefore devoted to proving that for all large values of σ, $|\psi| \geqq M$ at some value in I_1. The second case, $\sigma/2 \leqq \delta \leqq \sigma$ is handled in the same fashion. Here, we analyze the behavior of ψ on $J_1 = [\frac{1}{8}, \frac{1}{4}]$ and $J_2 = [\frac{1}{4}, \frac{3}{8}]$.

LEMMA 3.1. *If* (1)-(4) *has a solution then* $|s| \leqq \tan(1)$ *for all* $x \in [0, 1]$.

Proof. From (3.9) we have $s' \geqq -(s^2+1)$ on $[0, 1]$. Thus, $ds/(s^2+1) \geqq -dx$ and so $\tan^{-1}(s(x)) \geqq \tan^{-1}(s(x_0)) - (x - x_0)$ for $x_0 \in [0, 1)$ and $x_0 \leqq x \leqq 1$. From this, we conclude that $\tan^{-1}(s(1)) \geqq \tan^{-1}(s(x_0)) - 1$. If $s(x_0) > \tan(1)$ for some $x_0 \in [0, 1)$, then $s(1) > 0$. This contradicts (3.12). □

Proof of Theorem 3.1. Suppose that a solution of (3.9)-(3.12) exists for some $\sigma > 0$, $\delta \in \mathbb{R}$, and $\alpha \leqq 0$. If $0 < \sigma < \delta$, then $\psi'(0) < 0$ and $\psi'(1) < 0$. There must be a first $\hat{x} \in (0, 1)$ such that $\psi(\hat{x}) = 0$ and $\psi'(\hat{x}) \geqq 0$. However, from (3.10), $\psi'(\hat{x}) = \sigma\hat{x} - \delta \leqq \sigma - \delta$, a contradiction. Therefore, $\delta \leqq \sigma$. If $\delta < 0$, then $\psi'(0) > 0$ and $\psi'(1) > 0$. At the first positive zero $\hat{x}$ of ψ we would have $\psi'(\hat{x}) \leqq 0$. However, $\psi'(\hat{x}) = \sigma\hat{x} - \delta > 0$, a contradiction. Therefore, it must be the case that $0 \leqq \delta \leqq \sigma$.

Next, suppose that $\alpha < -c$. Then, $s'(0) > 0$ and $s'(1) > 0$. At the next zero $\hat{x}$ of s we would have $s(\hat{x}) \geqq 0$ and $s'(\hat{x}) \leqq 0$. However, from (3.9) $s'(\hat{x}) = \psi^2(\hat{x}) - (\alpha + c) > 0$, a contradiction. Therefore, $\alpha \geqq -c$. We assume for the sake of contradiction that there is an unbounded, increasing sequence $\{\sigma_i\}_{i \geqq 0}$ such that for each i there is an $\alpha_i \in [-c, 0]$ and $\delta_i \in [0, \sigma_i]$ for which (3.9)-(3.12) has a solution. For notational simplicity, we omit the subscripts.

Let $L \equiv \tan(1)$ and define $M = 2(L^2 + 32L + 1)^{1/2}$ and

$$\sigma^* = \max\left\{256 \cdot M + 16 \cdot M \cdot L, \frac{112}{7} M + 14 \cdot M \cdot L\right\}.$$

We assume that $\sigma > \sigma^*$ and that there is an $\alpha \in [-c, 0]$, $\delta \in [0, \sigma]$ such that (3.9)-(3.12) has a solution. There are two subcases to consider.

Case (i). $0 \leqq \delta \leqq \sigma/2$. Consider the intervals $I_1 = [\frac{5}{8}, \frac{3}{4}]$ and $I_2 = [\frac{3}{4}, \frac{7}{8}]$. Suppose that $\psi(\frac{7}{8}) < -M$. If $\psi \leqq -M$ on all of I_1 then $\psi^2 \geqq M^2$, and hence $s' \geqq M^2 - L^2 - 1$ on I_1. Thus, $s(x) \geqq (M^2 - L^2 - 1)(x - \frac{5}{8}) - L$ and it follows that $s(\frac{3}{4}) \geqq (M^2 - L^2 - 1)/8 - L > L$, a contradiction. Therefore, $\psi(\hat{x}) > -M$ at some $\hat{x} \in [\frac{5}{8}, \frac{3}{4}]$. If $\psi(\tilde{x}) = -M$ at some first $\tilde{x} \in (\hat{x}, \frac{7}{8}]$ then $\psi'(\tilde{x}) \leqq 0$. However, $\psi'(\tilde{x}) \geqq \sigma(\tilde{x} - \frac{1}{2}) + 2sM > -2LM + \sigma/8 > 0$, a contradiction. Therefore, $\psi \geqq -M$ on all of I_2. Next, suppose that $\psi(\frac{3}{4}) > M$. Then it follows as above that $\psi > M$ on all of I_2. But then $s' \geqq M^2 - L^2 - 1$ on I_2 and an integration of this inequality leads to $s(x) \geqq (M^2 - L^2 - 1)(x - \frac{3}{4}) - L$. Hence, $s(\frac{7}{8}) > L$, a contradiction. Therefore, $\psi(\frac{3}{4}) < M$. Suppose that $\psi(\hat{x}) = M$ at some first $\hat{x} \in (\frac{3}{4}, \frac{13}{16})$. Then $\psi'(\hat{x}) > 0$. It then follows as above that $\psi > M$ for all $x \in (\frac{13}{16}, \frac{7}{8})$. Again, from (3.9) it follows that $s' \geqq M^2 - L^2 - 1$ on $(\frac{13}{16}, \frac{7}{8})$. Integrating, we obtain $s(x) \geqq (M^2 - L^2 - 1)(x - \frac{13}{16}) - L$. Therefore, $s(\frac{7}{8}) \geqq (M^2 - L^2 - 1)/16 - L > L$, a contradiction. We conclude that $\psi \leqq M$ for all $x \in (\frac{3}{4}, \frac{13}{16}) \equiv I_3$. On I_3, $\psi' \geqq \sigma/4 - 2LM$, so that $\psi(x) \geqq (\sigma/4 - 2LM)(x - \frac{3}{4}) - M$. Thus, $\psi(\frac{13}{16}) \geqq (\sigma/4 - 2LM)/16 - M > M$, a contradiction. We have shown that if $0 \leqq \delta \leqq \sigma/2$, there can be no solution to (3.9)-(3.12).

Case (ii). $\sigma/2 \leqq \delta \leqq \sigma$. Consider the intervals, $J_1 = [\frac{1}{8}, \frac{1}{4}]$ and $J_2 = [\frac{1}{4}, \frac{3}{8}]$. Suppose that $\psi(\hat{x}) < -M$ at some $\hat{x} \in [\frac{1}{8}, \frac{1}{4}]$. If $\psi(\tilde{x}) = M$ at some first $\tilde{x} \in (\hat{x}, \frac{3}{8}]$, then $\psi'(\tilde{x}) \geqq 0$. However, $\psi'(\tilde{x}) = \sigma(\tilde{x} - \frac{1}{2}) + 2sM$, so that $\psi'(\tilde{x}) < -\sigma/8 + 2LM < 0$, a contradiction.

Therefore, $\psi < -M$ on J_2. Thus, $s' \geqq M^2 - L^2 - 1$ on J_2 and it follows that $s(x) \geqq -L + (M^2 - L^2 - 1)(x - \frac{1}{4})$ on J_2 with $s(\frac{3}{8}) > L$, a contradiction. Thus, it must be the case that $\psi > -M$ on all of $J_1 = [\frac{1}{8}, \frac{1}{4}]$. If $\psi(\hat{x}) < M$ at some $\hat{x} \in [\frac{1}{4}, \frac{3}{8}]$, then it follows as above that $\psi < M$ on all of $J_1 \subseteq [\frac{1}{8}, \hat{x}]$. That is, $|\psi| < M$ for $\frac{1}{8} \leqq x \leqq \frac{3}{8}$. However, it follows from (3.10) that $\psi' \leqq -\sigma/4 + 2LM$ for all $x \in J_1$, hence $\psi(x) \leqq (2LM - \sigma/4)/8 + M < -M$, a contradiction. Therefore, it must be the case that $\psi > M$ for all $x \in J_2$. Thus, $s' \geqq M^2 - L^2 - 1$ and $s \geqq -L + (M^2 - L^2 - 1)(x - \frac{1}{4})$ on J_2. But, then, $u(\frac{3}{8}) \geqq (M^2 - L^2 - 1)/8 - L > L$, a contradiction. This eliminates the possibility of solutions to (3.9)-(3.12) for $\sigma/2 \leqq \delta \leqq \sigma$.

These two cases show that if σ is sufficiently large, there can be no solutions to (3.9)-(3.12) with $c \leqq 1$. □

Remark. The theorem requires that $c \leqq 1$. The reason for this is that we must bound $u(x)$ and this bound depends on $\tan(c)$. Thus, we could improve this bound slightly, by requiring that $c < \pi/2$. As we noted in our previous paper [1], if the size of the attraction to the limit cycle Λ is large compared to the diffusion d (i.e., c is large), then this phenomenon will not occur. Instead, as the gradient in frequency σ increases, the phase-locked periodic solutions to (3.1)-(3.3) will break up into complex high-dimensional tori. In fact, we can obtain bounds on the largest allowable frequency gradient σ as a function of the ratio d/Λ, before phase-locking is lost (in preparation). Our results here and in the previous paper show that if the diffusivity is large, phase-locking persists as σ increases until the amplitude of the solution goes to zero. The rest state remains stable for all higher values of σ.

The results of this theorem are essentially the continuum analogue of the results in [4] for a pair of coupled λ-ω oscillators. This may lead us to generalize the stability results of § 2 to an analogous continuum model

$$\frac{\partial u}{\partial t} = (1 + \sigma x) F(u) + d \frac{\partial^2 u}{\partial x^2} \tag{3.13}$$

subject to the boundary conditions

$$\frac{\partial u}{\partial x}(1, t) = \frac{\partial u}{\partial x}(0, t) = 0 \tag{3.14}$$

where d and σ are scalars. We have numerically solved (3.13)-(3.14) using the Wilson-Cowan equations as described in § 2. We find that as σ increases the amplitude of the oscillation tends to zero and for a large enough value of σ, the rest state appears to become stable. If we linearize (3.13) about the equilibrium state and let A denote the Jacobian of F at this equilibrium, we obtain

$$\frac{\partial u}{\partial t} = (1 + \sigma x) A u + d \frac{\partial^2 u}{\partial x^2} \tag{3.15}$$

along with the boundary conditions (3.14). As in § 2, we let ν and ϕ be an eigenvalue-eigenvector pair for the matrix A, i.e., $A\phi = \nu\phi$. We suppose that $u(x, t) = \phi z(x)\, e^{\lambda t}$, where $z(x)$ is a complex scalar function of x, and λ is a complex parameter. It is seen that z satisfies

$$\lambda z = (1 + \sigma x)\nu z + d z'', \tag{3.16}$$

$$z'(0) = z'(1) = 0. \tag{3.17}$$

This is similar to the problem solved by Theorem 3.1. Based on this, we conjecture that if $\mathrm{Re}(\nu)/\mathrm{Im}(\nu)$ is sufficiently small (as was required in § 2), then for d and σ

large enough, the eigenvalues λ of (3.16)-(3.17) have negative real parts. The proof of this is not as simple as that of Theorem 3.1, and it is hoped that we can eventually sharpen the statement and prove it.

For two-dimensional problems, we can intuitively understand what is going on from a geometric point of view as follows. Think of the equal strength diffusion as trying to pull points on each of the spatially distributed limit cycles together. For strong frequency gradients, the points (if uncoupled) would not be close to each other as time increases. Thus, nearby spatial points that are far away in phase will be pulled toward each other by the strong diffusion. Since they are at distant phases, the "easiest" way to pull them closer in state is through the equilibrium point about which they oscillate. Thus, the limit cycles will be shrunken to a single point by the strong diffusive forces (see Fig. 2).

4. Uniqueness of the trivial solution. We turn now to the question of uniqueness of the zero rest state $(u, v) = (0, 0)$ as a solution to (3.1)-(3.3). We consider the case $q = 0$, the "no twist" situation for which the uncoupled limit cycle of (3.1)-(3.3) has "radial isochrons" (see [3] for a discussion of this assumption and its consequences for two coupled oscillators). We look for periodic solutions of (3.1)-(3.3) that are of the form:

$$(u(x, t), v(x, t)) = (r(x) \cos(\theta(x, t)), r(x) \sin(\theta(x, t))), \tag{4.1}$$

$$\theta(x, t) = \int^x \phi(s)\, ds + \left(\Omega + \frac{\sigma}{2}\right) t. \tag{4.2}$$

We see that if a solution of this form exists, then it is t-periodic with period $2\pi/(\Omega + \sigma/2)$. As in § 3, we introduce the new variable $s(x) = r'(x)/r(x)$, so that in these variables, (3.1)-(3.3) become:

$$\begin{aligned}
&\text{(a)} \quad r' = rs, \\
&\text{(b)} \quad s' = \alpha^2(r^2 - 1) + \phi^2 - s^2, \\
&\text{(c)} \quad \phi' = \alpha^2\sigma(x - \tfrac{1}{2}) - 2s\phi, \\
&\text{(d)} \quad s(0) = \phi(0) = 0, \qquad 0 \leqq r(0) \leqq 1, \\
&\text{(e)} \quad s(1) = 0
\end{aligned} \tag{4.3}$$

where $\alpha^2 = 1/d$. In [1], we have shown that for each $r(0) \in [0, 1]$ and $\alpha^2 < 1$, there was a σ such that (4.3) has a solution. We will now show that for σ sufficiently large, the only solution to (4.3) is $r \equiv 0$, corresponding to $(u, v) = (0, 0)$.

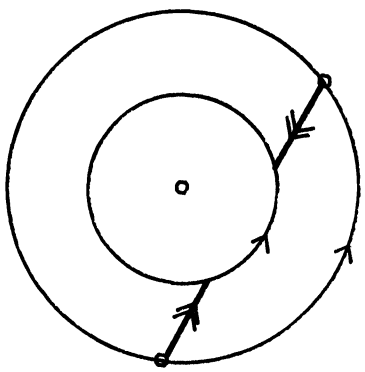

FIG. 2. *Two points that initially are close in phase are pulled apart by differences in frequency and the resultant limit cycle is "pinched" together by strong diffusive forces.*

THEOREM 4.1. *Let* $0<\alpha\leqq 1$ *and* $q=0$. *Then there is a* $\sigma^*=\sigma^*(\alpha)>0$ *such that if* $\sigma>\sigma^*$ *then there is no value of* $r(0)\geqq 0$ *for which* (4.3) *has a solution.*

As the proof is again rather technical, we will sketch an outline. The first step is to set $L=\alpha\tan(\alpha)$, $0<\alpha<1$ and prove that if $s(x_0)=L$ for some $x_0\in(0,1)$, then $s(1)\neq 0$. Thus, a solution to (4.3) must satisfy $s(x)<L$ for all $x\in(0,1)$. We assume, for the sake of contradiction, that a solution of the boundary value problem does indeed exist, for some $\alpha\in(0,1)$ and some $r(0)\in[0,1)$. To obtain a contradiction, we need to analyze the equation for u. Since ψ appears in the equation, we must first obtain lower bound estimates on ψ^2 by analyzing (4.3)(c). Thus, the next step of the proof is to prove that there are values $\delta\in(0,\frac{1}{4})$ and $C>0$ independent of σ such that $\psi^2\geqq C\sigma^2$ for all $x\in[\delta/2,\delta]$. With this estimate in hand we then turn to the s equation. First we obtain a lower bound on s, namely, $-\tan(\sigma)<s<L$ for $x\in[\delta/2,\delta]$. It then follows that $s^2\leqq Q^2$ on $[\delta/2,\delta]$, where $Q=\max\{L,\tan(\delta)\}$. These estimates on s^2 and ψ^2 are then substituted into (4.3)(b), and we obtain $s'\geqq-(\alpha^2+Q^2)+C\sigma^2$ for $x\in[\delta/2,\delta]$. This last inequality is used to show that for large σ, s must reach L at some $x_0\in[\delta/2,\delta]$. As shown earlier, this implies that $s(1)\neq 0$, and we have the needed contradiction.

Proof of Theorem 4.1. We first derive a criterion which guarantees that (4.3)(e) cannot hold. From (4.3)(b) it is seen that

$$s'\geqq-(\alpha^2+s^2).$$

Integrating this inequality leads to

$$\frac{1}{\alpha}\tan^{-1}(s(x)/\alpha)\geqq\frac{1}{\alpha}\tan^{-1}(s(x_0)/\alpha)-(x-x_0)\quad\text{for all } x_0.$$

Letting $x_0\in(0,1)$ and $x=1$, we find

$$\frac{1}{\alpha}\tan^{-1}(s(1)/\alpha)\geqq\frac{1}{\alpha}\tan^{-1}(s(x_0)/\alpha)-1+x_0.$$

Thus, if the right-hand side is positive, i.e.,

$$\frac{1}{\alpha}\tan^{-1}(s(x_0)/\alpha)>1-x_0,$$

then the left-hand side is also positive and $s(1)\neq 0$. It suffices to prove that there is a $\sigma^*>0$ such that if $\sigma>\sigma^*$, there is an $x_0(\sigma)\in(0,1)$ and a $s(x_0)>0$ with $\tan^{-1}(s(x_0)/\alpha)=\alpha$, i.e.,

$$s(x_0)=\alpha\tan(\alpha)\equiv L.$$

If $0<\alpha<\pi/2$, L is finite and positive; furthermore, L is independent of σ. We will show that as σ increases, s rises to L at some $x_0\in(0,1)$. For technical reasons, we require that x_0 lies in $(0,\frac{1}{2})$.

Suppose that for some $r(0)\in[0,1)$ and all large σ that $s(x)<L$ for all $x\in(0,\frac{1}{4})$. We note that $\phi(x)<0$ for all $x\in(0,\frac{1}{4}]$. For otherwise, since $\phi(0)=0$ and $\phi'(0)=-\alpha^2\sigma/2<0$, there must be some first $\hat{x}\in(0,\frac{1}{4}]$ for which $\phi(\hat{x})=0$ and $\phi'(\hat{x})\geqq 0$. But, from (4.3)(c) $\phi'(\hat{x})=\alpha^2\sigma(\hat{x}-\frac{1}{2})<0$, a contradiction. Thus if $s(x)<L$ for all $x\in(0,\frac{1}{4})$, then from (4.3)(c),

$$\phi'<\alpha^2\sigma(x-\tfrac{1}{2})-2L\phi.$$

Integrating this inequality leads to

$$\phi(x)<\frac{\alpha^2\sigma}{2L}\left[x-\frac{1}{2L}-\frac{1}{2}+\left(\frac{1}{2}+\frac{1}{2L}\right)e^{-2Lx}\right]\equiv\frac{\alpha^2\sigma}{2Lg(x)}.$$

The function $g(x)$ satisfies the following:

$$g(0)=0, \quad g'(0)<0, \quad g''(0)>0 \quad \text{for all } x>0.$$

Thus, $g(x)<0$ for x small and positive, but for x sufficiently large, $g(x)>0$, since $g''>0$. Let $\tilde{x}=\ln(1+L)/2L$ denote the value of x at which g' vanishes and let $\delta=\min\{\frac{1}{4}, \tilde{x}/2\}$. Note that δ is independent of σ. Now consider the interval $[0, \delta]$. $g'(x)<g'(\delta)<0$ for all $x\in[0,\delta]$. Let $-M=g'(\delta)$, so that $g'(x)<-M$ for $x\in[0,\delta]$. Thus, $g(x)<-Mx$ and $\phi(x)<-\alpha^2\sigma Mx/2L$ for $x\in[0,\delta]$. In particular, over the interval $I\equiv[\delta/2, \delta]$, we have $\phi(x)<-\alpha^2\sigma M\delta/4L$. So,

$$\phi^2(x)\geqq\sigma^2 C, \qquad x\in I \tag{4.4}$$

where $C=\alpha^4M^2\delta^2/16L^2$ is independent of σ.

We turn to the s equation. We have assumed that $s\leqq L$ in I. We compute a lower bound on s. Since $\alpha\leqq 1$, $s'\geqq-(1+s^2)$ from (4.3)(b) for all $x\geqq 0$ as long as a solution exists. Integrating this over $[0, x)$, we find that $s(x)\geqq-\tan(x)$ for all $x\in[0,\frac{1}{2}]$. This implies that $s(x)\geqq-\tan(\delta)$ for $x\in I$ and therefore

$$-\tan(\delta)\leqq s(x)\leqq L \quad \text{for } x\in I. \tag{4.5}$$

Let $Q=\max\{L, \tan(\delta)\}$. Then $s^2\leqq Q^2$ in I and Q depends only on α. Equations (4.3)(b), (4.4), and (4.5) imply that

$$s'\geqq-(\alpha^2+Q^2)+C\sigma^2 \quad \text{for } x\in I.$$

We integrate this from $\delta/2$ to δ and obtain

$$s(x)\geqq s(\delta/2)+[C\sigma^2-(\alpha^2+Q^2)](x-\delta/2).$$

Since $s(\delta/2)\geqq-\tan(\delta)$, we find

$$s(\delta)\geqq-\tan(\delta)+[C\sigma^2-(\alpha^2+Q^2)]\delta/2.$$

C and Q are independent of σ, so there is a $\sigma^*=\sigma^*(\alpha)$, independent of $r(0)$ such that for $\sigma>\sigma^*$, $s(\delta)>L$. This implies that $s(x_0)=L$ for some $x_0\in(0,\delta)$, contradicting our assumption that $s(x)<L$ for all $x\in(0,1)$. Thus, $s(1)\neq 0$. □

Remarks. (1) We emphasize that this theorem and the previous theorem depend on the fact that the diffusion d was sufficiently large. In fact, if d is too small, this phenomenon does not happen; rather, desynchronized solutions appear. Thus, the loss of the periodic solution to a stable equilibrium depends on several criteria: the frequency gradient must be large, the diffusion must be sufficiently strong, and finally, the diffusion must be close to scalar. The last condition seems to be needed through the heuristic argument given at the end of § 3 and Fig. 2. In another paper (in preparation) the case of very weak diffusion along with $O(1)$ frequency gradients is explored for the special system (3.1)-(3.3) as well as for general reaction-diffusion equations.

(2) Numerical integration of (3.1)-(3.3) indicates that with strong diffusion, the periodic solution shrinks to zero even in the presence of the twist term q. This term, of course, has no effect on the stability of the rest state, so we believe the uniqueness also holds for $q\neq 0$.

THE UTILITY OF AN INVARIANT MANIFOLD DESCRIPTION OF THE EVOLUTION OF A DYNAMICAL SYSTEM*

A. J. ROBERTS†

Abstract. The long-time evolution of a physical system may be dominated by a small number of modes. An invariant manifold description of the asymptotic evolution, briefly discussed here in two simple examples, can give a powerful and useful view of the physical system. The relationship between invariant manifolds and centre manifolds is also discussed, as is the relationship between invariant manifolds and modal numerical approximations. Many classical approximations in fluid mechanics can be viewed as approximating the evolution on an approximate invariant manifold.

Key words. asymptotic expansions, evolution equations, invariant manifolds, centre manifold theory, numerical approximation

AMS(MOS) subject classifications. 34E05, 35K22, 58F40, 76A99

1. Introduction. Centre manifold theory can provide a powerful asymptotic description of the long-time evolution of a physical system. For some simple examples see Carr [5] or Guckenheimer and Holmes [8]; for more sophisticated applications see Roberts [15]-[18], Bernhoff [3], Arneodo, Coullet, and Spiegel [1], Arneodo and Thoul [2], Coullet and Spiegel [7], and Mercer and Roberts [9]. In essence, centre manifold theory describes the evolution of a system in terms of the evolution of a relatively small number of dominant modes. These modes are those that have marginal stability (the linear growth rates are essentially zero) and are therefore long-lived. However, in some practical applications the requirement that the retained modes are marginal is unduly restrictive. Here we investigate two simple dynamical systems and derive a method to describe their long-time asymptotic behavior when the decay rates of their dominant modes are not "essentially zero."

That this sort of analysis will be of relevance can be seen by considering some examples; the theory of quasistationary probability distributions (see Parson and Pollett [12] or Pollett and Roberts [13]) furnishes one. A system with a given number of states and given probabilistic transition rates typically has an absorbing state, corresponding to a zero eigenvalue, to which the system eventually evolves. However, it is sometimes the case that a long-lived transient state (i.e., quasistationary), corresponding to a small negative eigenvalue, is of vital importance. To be effective, the asymptotic description of the system's evolution must include both the absorbing state and the nonmarginal quasistationary state. As another example, consider any infinite-dimensional system with a continuous spectrum (see Bernhoff [3] for an example in convection, or Roberts [16] for a model system). Somewhere in such a continuous spectrum, centre manifold theory requires a dividing line to be drawn between those modes whose linear growth and decay rates are essentially zero and those modes whose decay rates are definitely nonzero. Such a dividing line in a continuum is clearly more or less arbitrary and is an uncomfortable thing to draw. Some rationale for including or excluding modes corresponding to a continuous spectrum is needed. As a last example, Taylor [25] showed that longitudinal dispersion in channels and rivers may be greatly enhanced by the effects of shear in the current. However, the asymptotic equation he derived

appears to be of limited practical value, as it takes too long for the system to evolve onto the centre manifold implicit in his asymptotic equations. If, instead of just one dominant marginal mode, one or two additional nonmarginal modes are retained (see Chikwendu and Ojiakor [6], Smith [24], or Roberts [21]), then the resultant asymptotic description promises to be much more useful in its application.

The task of this paper is to describe the modifications, and their implications, of the formal centre manifold procedure described by Coullet and Spiegel [7] and Roberts [15]-[18], when the dominant modes do not necessarily have an essentially zero growth rate. The result is the description of an invariant manifold of the system (rather than a centre manifold characterised by eigenvalues having precisely zero growth rate). This is introduced in § 2, where a simple dynamical system and its evolution are discussed. The occurence of zero divisors in the resultant asymptotic formula has implications for both the range of validity of this invariant manifold description, discussed in § 3, and for the typically divergent character of the centre manifold description of a bifurcation problem, discussed in § 4.

A general, formal procedure for deriving such descriptions is then introduced in the context of a particular problem, that of finding a quasistationary probability distribution. The central approximation, which involves only elementary algebraic concepts, is discussed in § 5. Then in § 6 the method of Coullet and Spiegel [7], appropriate when the system is subject to small nonlinearities or other perturbations, is modified to give a description of an invariant manifold (rather than a centre manifold). It is this formal procedure that is expected to be of immense practical utility.

Furthermore, this invariant manifold viewpoint provides a rational basis for the derivation of appropriate initial conditions for such low-dimensional descriptions of the evolution of the dynamical system. This is developed in a subsequent paper (Roberts [20]).

In § 7, it is argued that truncated-modal numerical solutions of a set of equations can be viewed as a particularly simple approximation of an invariant manifold. This view then indicates how such numerical models may be improved without increasing the number of retained modes. It also suggests how to economically solve stiff sets of ordinary differential equations (see Roberts [19]).

Last, § 8 discusses how the concept of an invariant manifold, as a state which the system will ultimately approach, may be generalised. The concept is useful in physical situations where the invariant manifold is not necessarily approached at large times, but is in some sense central to the behaviour of the physical system. Some applications of this are to the irrotational approximation and vortex dynamics, pole solutions of solitons, quasigeostrophy, incompressibility, and the continuum theory of monatomic gases.

2. A formal invariant manifold description. Here a formal procedure to calculate an invariant manifold of a simple example system is given. The results are then used to illustrate what appear to be general features of such an invariant manifold description. Consider the nonlinear autonomous pair of different equations:

$$\dot{x} = \lambda x - xy, \tag{2.1a}$$

$$\dot{y} = -y + x^2, \tag{2.1b}$$

where $(\dot{})$ denotes d/dt and λ is some parameter. This is a system that is often used to illustrate the pitchfork bifurcation as it has fixed points at $(0, 0)$ and $(\pm\sqrt{\lambda}, \lambda)$. The trajectories are illustrated in Fig. 1 of Roberts [14], and a centre manifold analysis, based on λ being small (i.e., essentially zero) is given in § 3 of Roberts [15]. The

problem we now address is: what is the long-time behaviour of (2.1) if we consider λ to be small but not necessarily near zero?

Suppose $|\lambda|$ is significantly smaller than 1 but is not so small that λx can be considered a "nonlinear" term (see Carr [5]). Linearly, (2.1) has trajectories

$$y \sim A|x|^{-1/\lambda} \quad \text{as } |x| \to 0, \tag{2.2}$$

which, for small λ, are quite "flat." Hence, to an error that decreases exponentially with time (as e^{-t} since the other eigenvalue of the linearised system is -1) and to an error of order $|x|^{-1/\lambda}$, we could describe the long-time evolution of the linearised version of (2.1) as

$$\dot{x} \approx \lambda x \quad \text{on } y \approx 0. \tag{2.3}$$

This is just an elementary description of the stability of the fixed point at the origin. To produce an improved asymptotic description of (2.1) we need to include the effects of the nonlinearity. Suppose that $y = h(x; \lambda)$ is an invariant manifold of (2.1) on which the system evolves, according to $\dot{x} = \lambda x - xh(x; \lambda)$ by (2.1a). Then

$$\dot{y} = h'\dot{x} = h'(\lambda x - xh) \quad \text{and} \quad \dot{y} = -h + x^2,$$

where a prime sign denotes $\partial/\partial x$ keeping λ constant, and so the manifold $y = h(x; \lambda)$ must satisfy the differential equation

$$h + \lambda x h' = x^2 + xhh'. \tag{2.4}$$

By virtue of the linear result (2.3) we recognise that we should find a manifold $y = h(x; \lambda)$ that is "flat" near the origin; that is, (2.4) should be solved such that

$$h = O(x^2) \quad \text{as } |x| \to 0. \tag{2.5}$$

Typically, equations such as (2.4) are solved via an asymptotic expansion (for an exception see § 2 in Roberts [15]), which is what we now do. Suppose h may be expanded in the formal power series

$$h \sim \sum_{n=2}^{\infty} h_n x^n \quad \text{as } x \to 0 \tag{2.6}$$

(actually a finite truncation of this sum may be all that is valid; see the discussion in the next section). Upon substituting this into (2.4) and grouping all terms of the same power of x, we find

$$(1 + n\lambda)h_n = \begin{cases} 1, & n = 2, \\ \sum_{m=2}^{n-2} m h_m h_{n-m}, & n = 3, 4, \cdots. \end{cases} \tag{2.7}$$

Solving these equations in succession, we easily deduce

$$h_2 = \frac{1}{(1+2\lambda)}, \quad h_4 = \frac{2}{(1+2\lambda)^2(1+4\lambda)}, \quad h_6 = \frac{12}{(1+2\lambda)^3(1+4\lambda)(1+6\lambda)}, \tag{2.8}$$

and so on ($h_n = 0$ for odd n by the symmetry of (2.1)). Thus the invariant manifold description we obtain is that system (2.1) settles exponentially quickly onto a manifold given by

$$y \approx \frac{x^2}{(1+2\lambda)} + \frac{2x^4}{(1+2\lambda)^2(1+4\lambda)} + \frac{12x^6}{(1+2\lambda)^3(1+4\lambda)(1+6\lambda)}, \tag{2.9}$$

on which its evolution is governed by

$$\dot{x} \approx \lambda x - \frac{x^3}{(1+2\lambda)} - \frac{2x^5}{(1+2\lambda)^2(1+4\lambda)} - \frac{12x^7}{(1+2\lambda)^3(1+4\lambda)(1+6\lambda)}. \tag{2.10}$$

3. Range of validity. The new features in the asymptotic description above arise from the form of the left-hand side of (2.4). In a centre manifold analysis λ is assumed to be asymptotically zero and the term $\lambda x h'$ would appear on the right-hand side as a perturbation term. However, here this term is of the same order as h itself and must appear on the left. Its effect is to cause divisors of the form $(1+n\lambda)$, and higher powers, to appear in the asymptotic description (see (2.8)-(2.10)). For negative λ, in particular for $-1 \leqq \lambda < 0$, this gives rise to the embarrassing possibility of dividing by zero. Furthermore, even if a division by precisely zero is avoided, a division by nearly zero, especially when compounded at higher order, is nearly as bad. Fortunately, this problem of zero divisors serves as a useful and informative warning.

Suppose that we have described an invariant manifold by a particular solution of (2.4), $y = h_p(x;\lambda)$. Other invariant manifolds are given by neighbouring solutions of (2.4), namely, $y = h_p + \hat{h}(x;\lambda)$, where $\hat{h}$ is small and satisfies the linearised equation

$$\hat{h} + \lambda x \hat{h} = x h_p' \hat{h} + x h_p \hat{h}'. \tag{3.1}$$

For small x the right-hand side of (3.1) is negligible, and so (as in (2.2)), $\hat{h} \sim A|x|^{-1/\lambda}$ as $x \to 0$ for arbitrary A. Hence, the invariant manifold described is unique only up to order $|x|^{-1/\lambda}$, but this is precisely the order at which a zero divisor occurs. Thus the zero divisor is indicative of the nonuniqueness of the invariant manifold. Consequently the invariant manifold is blurred by an amount $O(|x|^{-1/\lambda})$, and we conclude that there is little point in calculating terms of higher order than $|x|^{-1/\lambda}$ (it is at this order that the initial conditions determine which particular manifold to choose).

Indeed, the conclusion above is related to the property (Shub [22, p. 61]) that for $-1 \leqq \lambda < 0$ the invariant manifold is only guaranteed to be C^r where $r > -1/\lambda$. That is, the invariant manifold is typically not analytic, but it is differentiable to a finite order; thus the assumed asymptotic series (2.6) must be truncated before this order. (For $\lambda < -1$ no zero divisors appear, and this particular invariant manifold is C^∞. However, it is then of little interest to the long-term evolution of the dynamical system, as the decay on this invariant manifold is much quicker than the decay elsewhere.)

The above argument only applies for negative λ. For positive λ the invariant manifold is C^∞ and no small divisors appear. However, it is only C^∞ sufficiently close to the origin. At the finite amplitude fixed point $(\pm\sqrt{\lambda}, \lambda)$ the decay rates of the linearised equations are the slow $-\sqrt{\lambda}$ and the rapid -1; consequently we expect the invariant manifold that passes through the origin to be C^r at the finite-amplitude fixed point where $r < 1/\sqrt{\lambda}$. As discussed above, the invariant manifold relevant to the long-term evolution is thus "blurred" by an amount $O(A(x \pm \sqrt{\lambda})^{1/\sqrt{\lambda}})$, but such blurring of the invariant manifold is not readily apparent in the asymptotic description (2.8)-(2.10). Nonetheless, for such positive λ it may be appropriate to calculate terms of higher order than $|x|^{1/\sqrt{\lambda}}$. This is not so much to fix the whole of the invariant manifold, as to refine predictions about the location and nature of the finite-amplitude fixed points (or attractors).

4. Relation to the centre manifold analysis. A centre manifold analysis of system (2.1) has been described in § 3 of Roberts [15], and is based on the assumption that λ, x, and y are all asymptotically small. The results obtained in equation (3.49) of [15] are precisely the same as the small λ asymptotic expansion of the invariant manifold result obtained here in (2.9) and (2.10). For example, if the manifold $h(x;\lambda)$ is expanded in powers of λ, we find

$$y = h(x;\lambda) \sim (1 - 2\lambda + 4\lambda^2)x^2 + 2(1 - 8\lambda + 44\lambda^2)x^4 \quad \text{as } x, \lambda \to 0,$$

which is precisely equation (3.49c) of Roberts [15]. The first consequence of this observation is that this invariant manifold approach gives equivalent results, to any power in λ, as the centre manifold approach to this same problem.

The second consequence is that the comments on the range of validity of the invariant manifold results given in the previous section also apply to the centre manifold analysis. Thus, for λ too far from its critical value of zero, there is little use in endeavouring to be too precise about the centre manifold and the evolution on it.

Last, as noted by Sijbrand [23], we can observe that a centre manifold description of bifurcation will typically be asymptotic; only rarely will the resulting series converge. Expressions (2.8) for the coefficients h_n of the invariant manifold contain the divisors $(1+m\lambda)$. In fact, the coefficient h_{2n} will typically be of the form

$$h_{2n} = H_n \prod_m (1+2m\lambda)^{-[n/m]},$$

where H_n is some number independent of λ, and where [ ] denotes the integer part function. Thus the centre manifold results, which are equivalent to expanding h_n in powers of λ, will involve the expansions in λ of $(1+m\lambda)^{-p}$ for arbitrarily large m and will therefore have a zero radius of convergence. That is, a centre manifold expansion of bifurcation problems is typically divergent (asymptotic descriptions of invariant manifolds in bifurcation problems may often converge to some extent; see Roberts [19]). However, for problems that do not involve a bifurcation, a centre manifold description can converge. Three examples of this are described by Mercer and Roberts [9] for shear dispersion in a channel, Roberts [17] for slowly varying waves, and Pollett and Roberts [13] for quasistationary probability distributions.

5. A quasistationary probability distribution. Given that the concept of an invariant manifold is useful in the description of the long-time evolution of a system, we need to find a general method for deriving such an asymptotic description. The method will be a modification of that given by Coullet and Spiegel [7] (also explained and extended in Roberts [15]-[19]) to systems where the retained modes do not necessarily have an essentially zero growth rate. This section introduces the example problem of finding a quasistationary probability distribution, modified in the next section, where the general method of finding an invariant manifold and the evolution on it is discussed.

Consider a Markov process consisting of three states, labelled 1, 2, 3, where the probability vector $\mathbf{p}$ of the system evolves according to[1]

$$\frac{d\mathbf{p}}{dt} = Q\mathbf{p}, \tag{5.1}$$

in which the rate matrix Q is

$$Q = \begin{bmatrix} 0 & \lambda & \lambda \\ 0 & -\lambda-\frac{1}{2} & \frac{1}{2} \\ 0 & \frac{1}{2} & -\lambda-\frac{1}{2} \end{bmatrix}, \tag{5.2}$$

where λ is a positive parameter. Observe that since total probability must be conserved, the column sums of Q are all zero. The problem is then to determine an appropriate description of the long-time behaviour of (5.1).

[1] Probabilists, please note that Q and $\mathbf{p}$ are the transpose of what you are used to. This is because the example is meant to be illustrative and almost everyone else is accustomed to this form for ordinary differential equations.

Since (5.1) is a linear system, its analysis is particularly simple and is essentially just an elementary change of basis problem. However, it is the viewpoint developed here (rather than the analytical details) that is very valuable and that provides the basis for the powerful formal procedure discussed in the next section.

We start by finding that the eigenvalues and eigenvectors of the matrix Q are

Eigenvalue	Eigenvector	Left eigenvector
0	$\mathbf{e}_1=\begin{bmatrix}1\\0\\0\end{bmatrix}$	$\hat{\mathbf{z}}_1=[1 \quad 1 \quad 1]$
$-\lambda$	$\mathbf{e}_2=\begin{bmatrix}-2\\1\\1\end{bmatrix}$	$\hat{\mathbf{z}}_2=[0 \quad 1 \quad 1]$
$-(1+\lambda)$	$\mathbf{e}_3=\begin{bmatrix}0\\1\\-1\end{bmatrix}$	$\hat{\mathbf{z}}_3=[0 \quad 1 \quad -1]$

Clearly, state 1 is an absorbing state and so the probability vector $\mathbf{p}$ ultimately evolves to be $\mathbf{e}_1$. However, if λ is a number significantly smaller than $(1+\lambda)$, then the time until absorption is relatively long and the system has time to evolve into a quasi-stationary state (involving the eigenvector corresponding to λ, namely, $\mathbf{e}_2$) and only then does it slowly evolve into the absorbing state. Thus a significant asymptotic description of (5.1) involves not only the absorbing state corresponding to the eigenvalue zero, but also involves the quasistationary state corresponding to the small (but nonzero) eigenvalue. Thus we need an invariant manifold analysis rather than a centre manifold analysis.

The analysis proceeds by posing the ansatz

$$\mathbf{p}(t)=\mathbf{v}(\mathbf{x}) \quad \text{such that} \quad \frac{d\mathbf{x}}{dt}=\mathbf{g}(\mathbf{x}), \tag{5.3}$$

where $\mathbf{x}=[x_1, x_2]^T$ are the probabilities x_1 of being in the absorbing state, and x_2 the quasistationary state, thus $\mathbf{x}$ evolves slowly. Substituting this into the governing equation (5.1), using the chain rule, and letting $\mathbf{v}_\mathbf{x}$ denote the 3×2 matrix $[\partial v_i/\partial x_j]$ we find that $\mathbf{v}$ and $\mathbf{g}$ must satisfy

$$Q\mathbf{v}=\mathbf{v}_\mathbf{x}\mathbf{g}. \tag{5.4}$$

As this is linear we can solve it exactly by supposing

$$\mathbf{v}=V\mathbf{x} \quad \text{and} \quad \mathbf{g}=G\mathbf{x}, \tag{5.5}$$

where V is a 3×2 matrix and G is a 2×2 matrix. Thus, since (5.4) must be true for all x, we deduce that V and G must satisfy

$$QV=VG. \tag{5.6}$$

This is a type of eigenproblem. Normally we would choose V to diagonalise Q (remember that we are interested only in the small eigenvalues of Q); that is, the columns of V are eigenvectors of Q, and G is the diagonal matrix of the corresponding

eigenvalues (the small ones only). In a centre manifold analysis these significant eigenvalues would be all zero; here they are 0 and $-\lambda$. This fails if Q is nondiagonalisable, in which case G may be chosen in Jordan form and (5.6) is then solved. However, the conventional practice of choosing G to be either diagonal or in Jordan form need not be followed. The choice of how to solve (5.6) is arbitrary (as long as the eigenvalues of G are the significant small ones); it all depends upon what the "amplitudes" $\mathbf{x}$ will represent in the asymptotic description. Here it is desirable (but not essential) for the evolution equation $d\mathbf{x}/dt = G\mathbf{x}$ itself to represent a Markov process, thus describing the evolution between two distinct states. Hence each row of V is chosen to have at most one nonzero element and the column sums of V are all 1 (that the column sums of G are zero then follows immediately).

Next, the invariant manifold of interest is the one spanned by the eigenvectors $\mathbf{e}_1$ and $\mathbf{e}_2$, these being the long-lived modes as they correspond to the small eigenvalues zero and $-\lambda$. Imposing the above discussed constraints, we change the basis of this subspace to

$$\mathbf{q}_1 = \mathbf{e}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} \quad \text{and} \quad \mathbf{q}_2 = \mathbf{e}_1 + \tfrac{1}{2}\mathbf{e}_2 = \begin{bmatrix} 0 \\ \frac{1}{2} \\ \frac{1}{2} \end{bmatrix}, \tag{5.7}$$

and deduce the solution

$$V = [\mathbf{q}_1 | \mathbf{q}_2] = \begin{bmatrix} 1 & 0 \\ 0 & \frac{1}{2} \\ 0 & \frac{1}{2} \end{bmatrix} \quad \text{and correspondingly} \quad G = \begin{bmatrix} 0 & \lambda \\ 0 & -\lambda \end{bmatrix}. \tag{5.8}$$

That is, the invariant manifold description of the evolution of (5.1) is that

$$\mathbf{p} = \mathbf{q}_1 x_1 + \mathbf{q}_2 x_2 \quad \text{such that} \quad \frac{d\mathbf{x}}{dt} = \begin{bmatrix} 0 & \lambda \\ 0 & -\lambda \end{bmatrix} \mathbf{x}. \tag{5.9}$$

Thus, to an error that decreases as does $\exp[-(1+\lambda)t]$, we conclude that the long-time evolution of (5.1) is from the quasistationary state $\mathbf{q}_2$ to the absorbing state $\mathbf{q}_1$ at the rate λ.

6. The formal invariant manifold procedure. Problems of the type discussed in the previous section are elementary, but, being linear, they are fundamental to a perturbative analysis of nonlinear systems or of a family of similar systems. In this section a formal method is outlined for deriving the invariant manifold description of a system when the description is in the typically necessary form of an asymptotic series (as in § 2). This method is a modification of that given by Coullet and Spiegel [7], and to be more or less definite, the method is described in the context of a particular problem.

Suppose that (5.1) is modified in some manner by the inclusion of some asymptotically small linear or nonlinear terms $\mathbf{r}(\mathbf{p})$ to

$$\frac{d\mathbf{p}}{dt} = Q\mathbf{p} + \mathbf{r}(\mathbf{p}). \tag{6.1}$$

The procedure to find an asymptotic description of the corresponding invariant manifold (possibly curved) and the evolution on it is to assume that the unknowns $\mathbf{v}$ and $\mathbf{g}$ may be expanded in an asymptotic series. That is, we pose

$$\mathbf{p}(t) = \mathbf{v}(\mathbf{x}) \sim \sum_{k=0}^{\infty} \mathbf{v}^k(\mathbf{x}) \quad \text{such that} \quad \frac{d\mathbf{x}}{dt} = \mathbf{g}(\mathbf{x}) \sim \sum_{k=0}^{\infty} \mathbf{g}^k(\mathbf{x}), \tag{6.2}$$

where all terms of "order" k are grouped into $\mathbf{v}^k$ and $\mathbf{g}^k$ (the precise definition of order depends upon the form of the perturbing terms $\mathbf{r}(\mathbf{p})$ and need not concern us here). Upon substituting the ansatz (6.2) into (6.1), using the chain rule, and grouping all terms of the same order together (see Roberts [15], [16] for similar details), we find the sequence of equations

$$Q\mathbf{v}^k = \sum_{l=0}^{k} \mathbf{v}_{\mathbf{x}}^l \mathbf{g}^{k-l} - \mathbf{r}^k \tag{6.3}$$

to be solved, where $\mathbf{r}^k$ is a function of $\mathbf{v}^0, \cdots, \mathbf{v}^{k-1}$ that depends upon the form of the perturbation $\mathbf{r}(\mathbf{p})$, and where $\mathbf{r}^0 = 0$.

The $k=0$ equation is just the linear pseudo-eigenproblem (5.4) solved in the previous section. The relevant solution is $\mathbf{v}^0 = V\mathbf{x}$ and $\mathbf{g}^0 = G\mathbf{x}$, where V and G are given by (5.8).

The real interest of this section is in calculating the higher-order correction terms $\mathbf{v}^k$ and $\mathbf{g}^k$. At order k, (6.3) has the form

$$Q\mathbf{v}^k - \mathbf{v}_{\mathbf{x}}^k G\mathbf{x} = V\mathbf{g}^k + \mathbf{s}^k, \tag{6.4}$$

where $\mathbf{s}^k$ is known, as it depends only upon lower-order quantities that have already been calculated. This equation is to be solved for $\mathbf{v}^k$ and $\mathbf{g}^k$ (for clarity the superscript k will be omitted henceforth). It has to be solved independently of whatever values $\mathbf{x} = [x_1, x_2]^T$ may take, and so we consider x_1 and x_2 to be independent indeterminants (see Coullet and Spiegel [7]); that is, we consider (6.4) to be an equation that is a multinomial in x_1 and x_2. Thus we try for a solution in the form

$$\mathbf{v} = \sum_{m,n} \mathbf{v}_{mn} x_1^m x_2^n, \qquad \mathbf{g} = \sum_{m,n} \mathbf{g}_{mn} x_1^m x_2^n \quad \text{supposing } \mathbf{s} = \sum_{m,n} \mathbf{s}_{mn} x_1^m x_2^n, \tag{6.5}$$

where the sums may go from zero to some limit.

Upon substituting (6.5) into (6.4), equating like powers of $x_1^m x_2^n$, and using the particular form of G given in (5.8) we obtain

$$(Q + n\lambda I)\mathbf{v}_{mn} = \begin{cases} V\mathbf{g}_{mn} + \mathbf{s}_{mn}, & n = 0, \\ V\mathbf{g}_{mn} + \mathbf{s}_{mn} + (m+1)\lambda \mathbf{v}_{m+1,n-1}, & n \geqq 1. \end{cases} \tag{6.6}$$

Note that for a different form of G the coupling terms in (6.6), here $\mathbf{v}_{m+1,n-1}$, between distinct equations would be different. In particular, if G is diagonal then there are no coupling terms (and the solution is easier).

For whatever range of m and n is appropriate, (6.6) is solved such that the equations $m+n =$ constant are solved in the sequence $n = 0, 1, 2, \cdots$ (because of the particular nature of the coupling term). The $n=0$ equation is

$$Q\mathbf{v}_{m0} = V\mathbf{g}_{m0} + \mathbf{s}_{m0}. \tag{6.7}$$

Now Q has a zero eigenvalue and is therefore singular. To solve this equation the right-hand side has to be in the range of Q, that is, orthogonal to the left eigenvector $\hat{\mathbf{z}}_1$. This gives one linear equation to determine the two unknowns of $\mathbf{g}_{m0}$; the other necessary equations come from the precise definition of what the "amplitudes" x_1 and x_2 represent. Typically we want $\mathbf{v}_{mn}$ to have no component of the tangent space to the invariant manifold (that space spanned by $\mathbf{e}_1$ and $\mathbf{e}_2$); that is, we want $\mathbf{v}_{mn}$ to be orthogonal to $\hat{\mathbf{z}}_1$ and $\hat{\mathbf{z}}_2$. (More generally, we would want $\mathbf{v}_{mn}$ to have definite components of $\mathbf{e}_1$ and $\mathbf{e}_2$, depending upon what x_1 and x_2 are defined to be.) Premultiplying (6.7) by $\hat{\mathbf{z}}_2$ we then find

$$-\lambda(\hat{\mathbf{z}}_2 \mathbf{v}_{m0}) = \hat{\mathbf{z}}_2 V\mathbf{g}_{m0} + \hat{\mathbf{z}}_2 \mathbf{s}_{m0},$$

which, since the left-hand side is known (and is typically zero), forms the other linear equation to determine $\mathbf{g}_{m0}$. Once $\mathbf{g}_{m0}$ is found, (6.7) may be solved to determine $\mathbf{v}_{m0}$ up to an arbitrary multiple of the homogeneous solution $\mathbf{e}_1$. The precise multiple is determined by requiring that $\hat{\mathbf{z}}_1\mathbf{v}_{m0}$ be in accord with the definitions of x_1 and x_2 (usually requiring it to be zero).

Equation (6.6) with $n=1$, and its solution, are the same as those discussed above except that $\mathbf{v}_{m+1,0}$ appears as an additional known term of the right-hand side, and except that the roles of $\hat{\mathbf{z}}_1$ and $\hat{\mathbf{z}}_2$ are interchanged.

Equation (6.6) with $n \geqq 2$ is of the form

$$(Q+n\lambda I)\mathbf{v}_{mn} = V\mathbf{g}_{mn} + \mathbf{s}_{mn} + (m+1)\lambda\mathbf{v}_{m+1,n-1}, \tag{6.8}$$

where $\mathbf{s}_{mn}$ and $\mathbf{v}_{m+1,n-1}$ are known forcing terms. The difference here is that $Q+n\lambda I$ is, in general, not singular. In this case the two linear equations to determine $\mathbf{g}_{mn}$ come from requiring that $\mathbf{v}_{mn}$ have specific components (typically zero) of $\mathbf{e}_1$ and $\mathbf{e}_2$. Multiplying on the left by the two corresponding eigenvectors, we obtain

$$n\lambda(\hat{\mathbf{z}}_1\mathbf{v}_{mn}) = \hat{\mathbf{z}}_1 V\mathbf{g}_{mn} + \hat{\mathbf{z}}_1(\mathbf{s}_{mn} + (m+1)\lambda\mathbf{v}_{m+1,n-1}),$$

$$(n-1)\lambda(\hat{\mathbf{z}}_2\mathbf{v}_{mn}) = \hat{\mathbf{z}}_2 V\mathbf{g}_{mn} + \hat{\mathbf{z}}_2(\mathbf{s}_{mn} + (m+1)\lambda\mathbf{v}_{m+1,n-1}).$$

Upon determining $\mathbf{g}_{mn}$ we can then (almost always) solve (6.8) for $\mathbf{v}_{mn}$. This whole formal procedure for calculating the invariant manifold, given by $\mathbf{v}$, and the evolution on it, governed by $\mathbf{g}$, can be carried out to as high an order as is desired or practical.

However, if by some mischance the matrix $Q+n\lambda I$ appearing in (6.8) is singular (for $n \geqq 2$), then the asymptotic calculation can proceed no further. This is no cause for alarm, as it is equivalent to the divisions by $(1+n\lambda)$ seen and discussed in §§ 2–4. Indeed, such an occurrence (or near occurrence) warns us not to proceed, as the details at this and higher orders are then irrelevant to the invariant manifold analysis.

In summary, the procedure calculates terms in the low-dimensional asymptotic description (6.2) of the dynamical system (6.1). Typical limitations of such a description are illustrated in the discussions of the simple problem (2.1) in §§ 2–4. A remaining problem is to find the initial condition $\mathbf{x}(0)$ for the low-dimensional asymptotic description (6.2) that best matches an initial condition $\mathbf{p}(0)$ of the full system (6.1); this is discussed in Roberts [20].

7. Relation to numerical models. Many numerical solutions of a set of differential equations involve finding the behaviour of some limited number of an infinite number of complete modes. A well-known example is the set of Lorenz equations (see § 2.3 of Guckenheimer and Holmes [8]) that form an elementary numerical model of convection. The usual procedure is to decide upon a complete set of modes (typically Fourier modes), select a finite number of these with which the solution is expressed, and then substitute this into the governing equations. Identities (typically trigonometric) are used to simplify products of modes (the generation of unrepresented harmonics being ignored), and the coefficients of each mode then give equations governing the amplitude of that particular mode in the solution.

This whole conventional process can now be viewed as approximating an invariant manifold and the evolution on it. First, the subspace spanned by the retained modes (say there are N modes) is a tangent space to a corresponding N-dimensional invariant manifold, and is thus an approximation of it. Second, the evolution on this "flat" approximation to the invariant manifold is given by the equations obtained in the numerical approximation. All this leads to the possibility that such modal numerical models may be improved through this viewpoint. Instead of looking for a solution in

some "flat" N-dimensional vector space, the procedure introduced in earlier sections may be used to calculate the curving nature of the corresponding N-dimensional invariant manifold. Then the equations describing the evolution on this invariant manifold would form an improved numerical model.

Such modal numerical models obtained via this formal invariant manifold procedure would be improved in the sense that they take into account some of the dynamics of the otherwise ignored modes without explicitly including these modes in the final equations. As an example, the Lorenz equations could be modified through this approach to provide a more accurate model of convection, not by increasing the number of retained modes, but by making the three ordinary differential equations more appropriate at larger amplitudes. Thus this invariant manifold procedure is likely to be a very powerful and useful hybrid between numerical models and asymptotic expansions. How well it performs in application to the Kuramoto-Sivashinsky equations is discussed in Roberts [19].

8. Generalised applications of invariant manifolds. In almost all of the literature, the concept of an invariant manifold is applied only to dynamical systems that are dissipative, and consequently the manifold is typically stable and typically contains the large-time behaviour of the system under consideration. However, many invariant manifolds are not strictly stable but are nevertheless of immense practical importance. In this section we point out some examples that we have come across.

The simplest example of an invariant manifold that is not strictly stable occurs in any system with an (integral) invariant. Often it will be a result of conservation of mass, energy, or momentum. Such an invariant of the flow of the system restricts it to some manifold embedded in the solution space. Typically such invariants do not reduce the dimensionality of the problem significantly, but by only a few degrees of freedom. Thus there is little to be achieved by explicitly restricting the system to the corresponding invariant manifold.

An important invariant manifold in fluid mechanics is invoked by the irrotational assumption. One of the basic theorems relevant to Newtonian fluids is that if the vorticity of the fluid flow $\omega = \nabla \times \mathbf{u}$ is initially zero, then it is zero for all time. This justifies restricting attention to that class of flows that lie on the "flat" invariant manifold $\omega = 0$, that is, irrotational flow. One interesting aspect is that this approximation is usually invoked only for inviscid fluids where there is no dissipative mechanism. Thus the irrotational invariant manifold is usually not strictly stable.

An interesting class of invariant manifolds are associated with solitons. We give two examples. Burgers' equation

$$\frac{\partial u}{\partial t} + u\frac{\partial u}{\partial x} = \nu \frac{\partial^2 u}{\partial x^2} \tag{8.1}$$

has the $2N$-dimensional invariant manifold

$$u = -2\nu \sum_{n=1}^{N} [x - z_n(t)]^{-1}, \tag{8.2}$$

which is written in terms of N complex parameters z_n that evolve in time according to

$$\dot{z}_n = -2\nu \sum_{m \neq n} (z_n - z_m)^{-1} \tag{8.3}$$

(see Bullough and Caudrey [4]). The interesting point here is that the expressions for the invariant manifold of (8.1) and the evolution on it are exact. Furthermore, Burgers' equation is dissipative and so an invariant manifold of the above form is likely to be

stable. An invariant manifold with a similar form can be found for the Korteweg-de Vries equation that models the behaviour of long waves in many physical systems. The governing differential equation is

$$\frac{\partial u}{\partial t}+3u\frac{\partial u}{\partial x}+\frac{1}{2}\frac{\partial^3 u}{\partial x^3}=0. \tag{8.4}$$

This has the invariant manifold

$$u=2\sum_{n=1}^{N}[x-z_n(t)]^{-2} \tag{8.5}$$

(see Bullough and Caudrey [4]), on which the complex parameters evolve according to

$$\dot{z}_n=6\sum_{m\neq n}(z_n-z_m)^{-2}, \tag{8.6}$$

provided that the initial conditions for the complex parameters satisfy

$$\sum_{m\neq n}(z_m-z_n)^{-3}=0 \quad \forall n. \tag{8.7}$$

(The dimensionality of the invariant manifold is a little obscure because of the constraint that (8.7) imposes on the complex parameters z_n.) Interestingly, this invariant manifold can be used to describe the interaction of solitary waves; the conservation of the individuality of solitary waves is thus seen as a consequence of the conservation of the double poles in (8.5) as they evolve in the complex plane according to (8.6).

A similar sort of invariant manifold occurs in the two-dimensional flow of an inviscid, irrotational, and incompressible fluid. There a very important class of flows can be built up with point vortices. A $2N$-dimensional invariant manifold is described by the (scalar) vorticity field

$$\omega=\sum_{n=1}^{N}\kappa_n\delta(x-x_n)\delta(y-y_n), \tag{8.8}$$

where the locations of the vortices evolve according to

$$\dot{z}_n^*=\frac{1}{2\pi i}\sum_{\substack{m=1\\ m\neq n}}^{N}\frac{\kappa_m}{z_n-z_m}, \tag{8.9}$$

in which $z_n=x_n+iy_n$. One aspect of this invariant manifold is that it has real physical singularities. Despite this and the fact that there is no dissipation to make this an attracting manifold, it is of immense practical utility.

Other useful invariant manifolds involve neglecting oscillatory components in the full dynamical system. Thus the invariant manifold only acts as some sort of centre for the flow of the system and may best be viewed as a subcentre manifold (see Sijbrand [23, § 7] for definition and properties). Some examples are the incompressible approximation in fluid mechanics, which neglects sound waves; the quasigeostrophic approximation in atmospheric dynamics, which neglects the relatively fast gravity waves in the atmosphere (see Lorenz [10], Vautard and Legras [26], Roberts [20, § 4]); the derivation of continuum mechanics from the kinetic theory of gases, which neglects the oscillatory components in the solutions of Liouville's equations (see Muncaster [11]); and the derivation of shallow water wave equations, which neglects the oscillation of short water waves.

I imagine that all of these last four examples could be rederived and extended using the formal procedure outlined in this paper. Such derivations would provide valuable new insight into the physical nature of the approximations.

STABILITY OF PERIODIC SOLUTIONS IN THERMOSTAT CONTROL*

GUSTAF GRIPENBERG†

Abstract. A stability criterion is given for periodic solutions of an equation describing thermostat control. The proof is based on a perturbation result for discrete functional equations.

Key words. thermostat, periodic solutions, local stability

AMS(MOS) subject classifications. 34K35, 45D05, 45M05

1. Introduction and statement of results. The purpose of this paper is to establish a criterion for the local stability of periodic solutions of the equation

$$y(t)=\int_{-\infty}^{t} a(t-s)u(s)\,ds, \qquad t\in\mathbf{R}, \tag{1}$$

where $u:\mathbf{R}\to\{0,1\}$ is determined by the requirement that if $u(t)=1$ and y reaches an upper level θ_{high} at time t, then $u(t+)=0$, and conversely, if $u(t)=0$ and y reaches a lower level θ_{low} at time t, then $u(t+)=1$.

This equation can be used to describe systems controlled by a thermostat. For example, consider a situation where a heater is turned ON if the temperature at some fixed point drops to a level θ_{low} and is turned OFF if the temperature rises to a level θ_{high}, where $\theta_{\text{low}}<\theta_{\text{high}}$. It is convenient to normalize the equation in such a way that without heating the temperature is zero and with continuous heating it is 1. The function a is determined by the requirement that if the heating is turned on at time zero for the first time, then the temperature should be $\int_0^t a(s)\,ds$ at time $t>0$. Without going into further details about how the heating process affects the temperature (e.g., through diffusion), we see that (1) can be used as a reasonable model if no external influences are involved.

In [2] and [3], where temperature regulation by thermostats is also considered, the main emphasis is on questions regarding existence of solutions and on a precise description of the heating process involving diffusion. In [5] this work is continued and some sufficient conditions for the existence of periodic solutions are given. In [1] thermostat control in a diffusion model is considered as well, and the existence, and in some cases, uniqueness, of periodic solutions is established.

In [6]–[8] a class of switching systems is considered where the state equation is of the form $y'(t)=f_j(y(t))$ and where the index j, and hence the state equation, is changed when the solution reaches a "switching surface." In [8] sufficient conditions for periodic solutions are given for this kind of system. Note that a linear system $x'(t)=Ax(t)+u(t)z$, $y(t)=Cx(t)$, can be written in the form of (1), but the analysis of (1) is not dependent on any underlying structure of this form.

In [4] the existence of periodic solutions of (1) is established, but there the dependence of u on y is in general a slightly weaker form of thermostat control (although the difference appears only in the case where y has a local maximum equal to θ_{high} or a local minimum equal to θ_{low}). Here we will use the following notion of thermostat control.

* Received by the editors January 25, 1988; accepted for publication (in revised form) November 22, 1988.

DEFINITION. If $I \subset \mathbf{R}$ is an interval and $y: I \to \mathbf{R}$ is a continuous function, then a function $u: I \to \{0, 1\}$ is (strictly) *thermostat controlled* by y with respect to the higher limit θ_{high} and the lower limit θ_{low} on the interval I provided that u is left-continuous with right-hand limits on I, and the following conditions hold for all $t \in I$:

(i) $u(t) = 1$ if $y(t) < \theta_{\text{low}}$;

(ii) $u(t) = 0$ if $y(t) > \theta_{\text{high}}$;

(iii) If $y(t) = \theta_{\text{high}}$ and $u(t) = 1$, then $u(t+) = 0$, and if $u(t) - u(t+) = 1$, then $y(t) = \theta_{\text{high}}$;

(iv) If $y(t) = \theta_{\text{low}}$ and $u(t) = 0$, then $u(t+) = 1$, and if $u(t) - u(t+) = -1$, then $y(t) = \theta_{\text{low}}$.

Note that by this definition, the function u is constant on those intervals where $y(t) \in (\theta_{\text{low}}, \theta_{\text{high}})$.

In order to study the stability of periodic solutions we allow small perturbations and therefore we consider the equation

$$y(t) = \int_{-\infty}^{t} a(t-s)u(s)\,ds + e(t), \qquad t \geqq 0, \tag{2}$$

where u is given on $(-\infty, 0]$ and u is strictly thermostat controlled by y on $(0, \infty)$.

Since the function u can take only two values, it is completely determined by the switching times at which it jumps from zero to 1 or from 1 to zero. We will use the notation that u is 1 on the intervals $(v_n(u), w_n(u)]$ and zero on the intervals $(w_n(u), v_{n+1}(u)]$. No generality is lost if we assume that $v_0(u) = 0$. It turns out, however, that it is advantageous to use the interswitching intervals $T_n(u) = w_n(u) - v_n(u)$ and $S_n(u) = v_{n+1}(u) - w_n(u)$ instead of the switching times. Then local stability means that if e is small, $T_n(u)$ is close to some T and $S_n(u)$ is close to some S for all negative indices n; then $T_n(u)$ and $S_n(u)$ will remain close to T and S for all future (provided the system is thermostat controlled). A precise statement of what is meant by local stability is given in (• •) below. Next, we give a formal definition of $T_n(u)$ and $S_n(u)$.

DEFINITION. If $u: \mathbf{R} \to \{0, 1\}$ is left-continuous with right-hand limits, $u(0) = 0$ and $u(0+) = 1$, then the numbers $\{T_n(u)\}$ and $\{S_n(u)\}$ are defined by

$$u(t) = \begin{cases} 1, & t \in \left(-\sum_{j=n}^{-1} (T_j(u) + S_j(u)), -\sum_{j=n}^{-1} (T_j(u) + S_j(u)) + T_n \right], & n < 0, \\ 1, & t \in \left(\sum_{j=0}^{n-1} (T_j(u) + S_j(u)), \sum_{j=0}^{n-1} (T_j(u) + S_j(u)) + T_n \right], & n \geqq 0, \\ 0, & t \in \left(-\sum_{j=n}^{-1} (T_j(u) + S_j(u)) + T_{n+1}, -\sum_{j=n+1}^{-1} (T_j(u) + S_j(u)) \right], & n < 0, \\ 0, & t \in \left(\sum_{j=0}^{n-1} (T_j(u) + S_j(u)) + T_n, \sum_{j=0}^{n} (T_j(u) + S_j(u)) \right], & n \geqq 0. \end{cases}$$

It is easy to see that if u is strictly thermostat controlled by y on $(0, \infty)$, (2) holds, $\sup_{t \geqq 0} |e(t)| < \min\{\theta_{\text{low}}, 1 - \theta_{\text{high}}\}$, and if $\int_0^\infty a(t)\,dt = 1$, then $T_n(u)$ and $S_n(u)$ are defined for all $n \geqq 0$.

Since the history of the function u is determined by the values of $T_n(u)$ and $S_n(u)$ for $n < 0$, it turns out that it is possible to show that the problem of stability is reduced to a study of the stability of a discrete functional equation of the form

$$\sum_{j=-\infty}^{n} \alpha_{n-j}\xi_j = \Phi_n(\{\xi_{n-j}\}_{j=0}^{\infty}) + \varphi_n, \qquad n \geqq 0, \tag{3}$$

$$\xi_i = \psi_i, \qquad i < 0.$$

It is well known that the z-transform is useful when we study linear difference equations. The criterion for stability of the linear part of (3) is $\det[\sum_{n=0}^{\infty} z^n \alpha_n] \neq 0$ when $|z| \leqq 1$. We will see that $f(z)/(1-z)$, where f is the function appearing in (•), is exactly of this form, and that we get local stability for the nonlinear equation. (The factor $1-z$ is due to the translation invariance of the problem.)

Next we give a precise formulation of our result on the stability of periodic solutions.

THEOREM. *Assume that*

(i) $0 < \theta_{\text{low}} < \theta_{\text{high}} < 1$;

(ii) $a \in L^1(\mathbf{R}^+; \mathbf{R}) \cap AC_{\text{loc}}((0, \infty); \mathbf{R})$, $\int_0^\infty a(t)\,dt = 1$, *and* $\int_0^\infty t^2 |a'(t)|\,dt < \infty$;

(iii) $e \in C(\mathbf{R}^+; \mathbf{R})$;

(iv) $u : \mathbf{R} \to \{0, 1\}$ *is left-continuous with right-hand limits,* $u(0) = 0$, $u(0+) = 1$, *and* u *is strictly thermostat controlled by the solution* y *of* (2) *on* $(0, \infty)$;

(v) *There are positive numbers* T *and* S *such that there exists a periodic solution* (y_*, u_*) *of* (1) *with* $u_* = 1$ *on intervals of length* T, $u_* = 0$ *on intervals of length* S, $u_*(0) = 0$, $u_*(0+) = 1$, *and* u_* *is strictly thermostat controlled by* y_* *on* $\mathbf{R}$;

(vi) $y_*'(0-) < 0$ *and* $y_*(T-) > 0$.

Then the following two conditions (•) *and* (••) *are equivalent:*

(•) *The function*

$$f(z) \overset{\text{def}}{=} \sum_{j=1}^{\infty} (a(j(T+S)) - a(j(T+S)-T)) \sum_{j=1}^{\infty} (a(j(T+S)-S) - a(j(T+S)))$$

$$+ \sum_{j=1}^{\infty} (2a(j(T+S)) - a(j(T+S)-T)$$

$$- a(j(T+S)-S)) \sum_{j=1}^{\infty} a(j(T+S))z^j - \left(\sum_{j=1}^{\infty} a(j(T+S))z^j\right)^2$$

$$+ \frac{1}{z} \sum_{j=1}^{\infty} a(j(T+S)-S)z^j \sum_{j=1}^{\infty} a(j(T+S)-T)z^j$$

has a simple zero at $z = 1$ *and no other zeros in* $\{z \in \mathbf{C} \mid |z| \leqq 1\}$;

(••) *There exist numbers* $\delta > 0$ *and* $C < \infty$ *such that the inequalities*

$$|T_i(u) - T| \leqq \delta, \quad |S_i(u) - S| \leqq \delta, \quad i < 0,$$

$$|e(t)| \leqq \delta, \qquad t \geqq 0$$

imply that for every $n \geqq 0$

$$|T_n(u) - T| + |S_n(u) - S| \leqq C\left(\sup_{i<0} \{|T_i(u) - T|, |S_i(u) - S|\} + \sup_{t \geqq 0} |e(t)|\right), \tag{4}$$

and in the case where $\lim_{t\to\infty} e(t) = 0$ *it follows that*

$$T_n(u) \to T \quad \text{and} \quad S_n(u) \to S \quad \text{as } n \to \infty.$$

It is easy to see that $y_*'(0-) = \sum_{j=1}^{\infty} (a(j(T+S)) - a(j(T+S)-T))$ and $y_*'(T-) = \sum_{j=1}^{\infty} (a(j(T+S)-S) - a(j(T+S)))$. The assumption that u_* is strictly thermostat controlled by y_* implies that $y_*'(0-) \leqq 0$ and $y_*'(T-) \geqq 0$. It is not really necessary to assume that a is locally absolutely continuous, but this assumption makes the formulation of the appropriate hypotheses on the kernel a much simpler. Note also that the condition (ii) is satisfied for the kernels given in the examples in [3] and [5].

In [4, Thm. 5], it is shown that if $m \geqq 1$ is an integer and $a(t) = (1/m!)t^m e^{-t}$, then there exist positive numbers α so that there are $\lfloor (m-1)/4 \rfloor + 1$ different periodic solutions (y_*, u_*) of (1) and u_* is strictly thermostat controlled by y_* on $\mathbf{R}$ with respect to $\frac{1}{2}+\alpha$ and $\frac{1}{2}-\alpha$. (Note that there is an error in [4, Thm. 5] at this point since $\lfloor (m-1)/4 \rfloor + 1$ has been replaced there by $\lfloor m/4 \rfloor + 1$.) If the theorem above is applied in the case where $m = 5$, so that there are two periodic solutions, then numerical calculations indicate that the stability condition (•), and hence also (• •), is satisfied for the solution with the longer period only.

For completeness we state and prove the result concerning (3) that we need. Let us denote the set of integers by $\mathbf{Z}$, the set of positive integers by $\mathbf{Z}_+$, the set of negative integers by $\mathbf{Z}_-$, and the set of natural numbers, i.e., the nonnegative integers, by $\mathbf{N}$. By $|\cdot|$ we denote some norm in $\mathbf{R}^m$, and also the corresponding matrix norm.

If $\zeta : \mathbf{Z}_+ \to \mathbf{R}^m$ and $x \in \mathbf{R}^m$ then we let $[x, \zeta]$ denote the sequence given by $[x, \zeta]_j = \zeta_j$ if $j > 0$ and $[x, \zeta]_0 = x$.

PROPOSITION. *Assume that*:

(a) $\alpha \in l^1(\mathbf{N}; \mathbf{R}^{m\times m})$ *and* $\det[\alpha_0] \neq 0$;

(b) $\varphi \in l^\infty(\mathbf{N}; \mathbf{R}^m)$;

(c) *For each* $j \geqq 0$ *the mapping* $\zeta \in l^\infty(\mathbf{N}; \mathbf{R}^m) \mapsto \Phi_j(\zeta) \in \mathbf{R}^m$ *is continuous and* $\|\Phi(\zeta)\|_{l^\infty(\mathbf{N})} = o(\sup_{j\geqq 0} |\eta_j \zeta_j|)$ *as* $\|\zeta\|_{l^\infty(\mathbf{N})} \to 0$, *where* η *is some element in* $l_0^\infty(\mathbf{N}; \mathbf{R})$;

(d) $\psi \in l^\infty(\mathbf{Z}_-; \mathbf{R}^m)$;

(e) *There exist a constant* $\gamma > 0$ *and a continuous function* $\Gamma : \mathbf{R}^+ \to \mathbf{R}^+$ *with* $\Gamma(0) = 0$ *such that if* $\phi \in l^\infty(\mathbf{Z}_+; \mathbf{R}^m)$ *and* $f \in \mathbf{R}^m$ *with* $\|\phi\|_{l^\infty(\mathbf{Z}_+)} \leqq \gamma$ *and* $|f| \leqq \gamma$, *then there exists for each* $n \in \mathbf{N}$ *a unique solution of* x *of*

$$\alpha_0 x = \Phi_n([x, \phi]) + f, \tag{5}$$

and $|x| \leqq \Gamma(|f| + \|\phi\|_{l^\infty(\mathbf{Z}_+)})$.

Then the following two conditions (*) *and* (**) *are equivalent*:

(*) $\det[\sum_{n=0}^\infty z^n \alpha_n] \neq 0$ *for* $|z| \leqq 1$;

(**) *There exist numbers* $\delta > 0$ *and* $C < \infty$ *such that*

$$|\psi_i| \leqq \delta, \qquad i < 0,$$

$$|\varphi_j| \leqq \delta, \qquad j \geqq 0$$

imply that there is a unique solution ξ *of* (3), *for every* $n \geqq 0$,

$$|\xi_n| \leqq C\left(\sup_{i<0} |\psi_i| + \sup_{0\leqq k\leqq n} |\varphi_k|\right), \tag{6}$$

and, in the case where $\lim_{n\to\infty} \varphi_n = 0$, *it follows that*

$$\xi_n \to 0 \quad \text{as } n \to \infty.$$

We see from the proof of this proposition that the continuity assumption in (c) is needed only when we establish the necessity of (*). Observe that no assumptions about Lipschitz continuity are made and note also that the assumption $\det[\alpha_0] \neq 0$ in (a) actually follows from (e) (without this assumption there is clearly no hope of finding a unique solution).

If we are interested only in the stability of the solutions and do not care about the asymptotic stability, then we can take $\eta \equiv 1$ in (c).

2. Proof of the theorem. First we introduce some notation. We write $T_n = T_n(u)$, $S_n = S_n(u)$, and

$$\Delta S_n = S_n - S,$$

$$\Delta T_n = T_n - T,$$

$$v_n = \begin{cases} \sum_{j=0}^{n-1} (T_j + S_j), & n > 0, \\ -\sum_{j=n}^{-1} (T_j + S_j), & n \leqq 0, \end{cases}$$

$$w_n = v_n + T_n,$$

$$V_n = n(T+S),$$

$$W_n = V_n + T.$$

This definition says that u takes the value 1 on the intervals $(v_n, w_n]$ and zero on the intervals $(w_n, v_{n+1}]$. Similarly, $u_* = 1$ on $(V_n, W_n]$ and $u_* = 0$ on the intervals $(W_n, V_{n+1}]$. Below we will need the following relations for $n > j$:

$$\begin{aligned} &v_n + T - v_j - (V_n + T - V_j) = \sum_{i=j}^{n-1} (\Delta T_i + \Delta S_i), \\ &v_n + T - w_j - (V_n + T - W_j) = \sum_{i=j+1}^{n-1} (\Delta T_i + \Delta S_i) + \Delta S_j, \\ &w_n + S - v_j - (W_n + S - V_j) = \Delta T_n + \sum_{i=j}^{n-1} (\Delta T_i + \Delta S_i), \\ &w_n + S - w_j - (W_n + S - W_j) = \Delta T_n + \sum_{i=j+1}^{n-1} (\Delta T_i + \Delta S_i) + \Delta S_j. \end{aligned} \tag{7}$$

Since we want to obtain an equation that gives T_n as a function of T_j and $S_j, j < n$, it is advantageous to have a function that is otherwise equal to u but does not jump from 1 to zero at $v_n + T_n$. Therefore we define

$$u_\tau(t) = \begin{cases} u(t), & t \leqq \tau, \\ u(\tau+), & t > \tau. \end{cases}$$

As the number τ we will use both v_n and w_n. When we replace u by u_τ we must replace y by the function

$$y_\tau(t) = \int_{-\infty}^{t} a(t-s) u_\tau(s)\, ds. \tag{8}$$

Note that the reason for introducing these new functions is purely technical.

It is clear that T_n is determined as the smallest positive number for which $y_{v_n}(v_n + T_n) + e(v_n + T_n) = \theta_{\text{high}}$ and S_n as the smallest positive number for which $y_{w_n}(w_n + S_n) + e(w_n + S_n) = \theta_{\text{low}}$.

Now a straightforward calculation, where we use (7) and the facts that $V_n - V_j = (n-j)(T+S)$ and $V_n - W_j = (n-j)(T+S) - T$, shows that for all $n \geqq 0$ we have

$$\begin{aligned} &y_{v_n}(v_n + T) - y_*(V_n + T) \\ &\quad = \int_{-\infty}^{v_n + T} a(v_n + T - s) u_{v_n}(s)\, ds - \int_{-\infty}^{V_n + T} a(V_n + T - s) u_*(s)\, ds \end{aligned}$$

$$
\begin{aligned}
&= \sum_{j=-\infty}^{n-1} \left(\int_{v_n+T-v_j}^{v_n+T-v_j} a(s)\,ds - \int_{V_n+T-W_j}^{V_n+T-V_j} a(s)\,ds \right) \\
&= \sum_{j=-\infty}^{n-1} \left(\int_{V_n+T-V_j}^{v_n+T-v_j} a(s)\,ds - \int_{V_n+T-W_j}^{v_n+T-w_j} a(s)\,ds \right) \\
&= \sum_{j=-\infty}^{n-1} a((n-j)(T+S)+T) \sum_{i=j}^{n-1} (\Delta T_i + \Delta S_i) \qquad (9) \\
&\qquad - \sum_{j=-\infty}^{n-1} a((n-j)(T+S)) \left(\sum_{i=j+1}^{n-1} (\Delta T_i + \Delta S_i) + \Delta S_j \right) \\
&\qquad + \sum_{j=-\infty}^{n-1} \int_{V_n+T-V_j}^{v_n+T-v_j} (a(s) - a(V_n+T-V_j))\,ds \\
&\qquad - \sum_{j=-\infty}^{n-1} \int_{V_n+T-W_j}^{v_n+T-w_j} (a(s) - a(V_n+T-W_j))\,ds.
\end{aligned}
$$

We rewrite the terms on the right-hand side in (9) that are linear in ΔT_i and ΔS_i:

$$
\begin{aligned}
&\sum_{j=-\infty}^{n-1} a((n-j)(T+S)+T) \sum_{i=j}^{n-1} (\Delta T_i + \Delta S_i) \\
&\qquad - \sum_{j=-\infty}^{n-1} a((n-j)(T+S)) \left(\sum_{i=j+1}^{n-1} (\Delta T_i + \Delta S_i) + \Delta S_j \right) \\
&= \sum_{i=-\infty}^{n-1} \left(\sum_{j=n-i}^{\infty} a(j(T+S)+T) \right) (\Delta T_i + \Delta S_i) \qquad (10) \\
&\qquad - \sum_{i=-\infty}^{n-1} \left(\sum_{j=n-i+1}^{\infty} a(j(T+S)) \right) (\Delta T_i + \Delta S_i) \\
&\qquad - \sum_{i=-\infty}^{n-1} a((n-i)(T+S))\,\Delta S_i.
\end{aligned}
$$

A similar calculation shows that

$$
\begin{aligned}
&y_{w_n}(w_n+S) - y_*(W_n+S) \\
&= \int_{-\infty}^{w_n+S} a(w_n+S-s) u_{w_n}(s)\,ds - \int_{-\infty}^{W_n+S} a(W_n+S-s) u_*(s)\,ds \\
&= \sum_{j=-\infty}^{n} \left(\int_{w_n+S-w_j}^{w_n+S-v_j} a(s)\,ds - \int_{W_n+S-W_j}^{W_n+S-V_j} a(s)\,ds \right) \\
&= \sum_{j=-\infty}^{n} \left(\int_{W_n+S-V_j}^{w_n+S-v_j} a(s)\,ds - \int_{W_n+S-W_j}^{w_n+S-w_j} a(s)\,ds \right) \qquad (11) \\
&= \sum_{j=-\infty}^{n} a((n-j+1)(T+S)) \left(\sum_{i=j}^{n-1} (\Delta T_i + \Delta S_i) + \Delta T_n \right) \\
&\qquad - \sum_{j=-\infty}^{n-1} a((n-j)(T+S)+S) \left(\sum_{i=j+1}^{n-1} (\Delta T_i + \Delta S_i) + \Delta T_n + \Delta S_j \right) \\
&\qquad + \sum_{j=-\infty}^{n} \int_{W_n+S-V_j}^{w_n+S-v_j} (a(s) - a(W_n+S-V_j))\,ds \\
&\qquad - \sum_{j=-\infty}^{n} \int_{W_n+S-W_j}^{w_n+S-w_j} (a(s) - a(W_n+S-W_j))\,ds.
\end{aligned}
$$

Here the linear terms are

$$\begin{aligned}
&\sum_{j=-\infty}^{n} a((n-j+1)(T+S))\left(\sum_{i=j}^{n-1}(\Delta T_i+\Delta S_i)+\Delta T_n\right)\\
&\qquad-\sum_{j=-\infty}^{n-1} a((n-j)(T+S)+S)\left(\sum_{i=j+1}^{n-1}(\Delta T_i+\Delta S_i)+\Delta T_n+\Delta S_j\right)\\
&\quad=\sum_{i=-\infty}^{n-1}\left(\sum_{j=n-i+1}^{\infty} a(j(T+S))\right)(\Delta T_i+\Delta S_i)+\sum_{j=1}^{\infty} a(j(T+S))\,\Delta T_n \qquad (12)\\
&\qquad-\sum_{i=-\infty}^{n-1}\left(\sum_{j=n-i+1}^{\infty} a(j(T+S)+S)\right)(\Delta T_i+\Delta S_i)\\
&\qquad-\sum_{j=1}^{\infty} a(j(T+S)+S)\Delta T_n-\sum_{i=-\infty}^{n-1} a((n-i)(T+S)+S)\,\Delta S_i.
\end{aligned}$$

Since $y_*(V_n+T)=\theta_{\text{high}}=y_{v_n}(v_n+T_n)+e(v_n+T_n)=y_{v_n}(w_n)+e(w_n)$ we see that

$$\begin{aligned}
&y_{v_n}(v_n+T)-y_*(V_n+T)+y'_*(W_n-)\,\Delta T_n\\
&\quad=-\int_0^{\Delta T_n}(y'_{v_n}(w_n-s)-y'_*(W_n-))\,ds-e(w_n). \qquad (13)
\end{aligned}$$

A similar argument gives

$$\begin{aligned}
&y_{w_n}(w_n+S)-y_*(W_n+S)+y'_*(V_{n+1}-)\Delta S_n\\
&\quad=-\int_0^{\Delta S_n}(y'_{w_n}(v_{n+1}-s)-y'_*(V_{n+1}-))\,ds-e(v_{n+1}). \qquad (14)
\end{aligned}$$

From now on we assume that $e(w_n)$ and $e(v_n)$ are some given numbers, although we otherwise treat ΔT_n and ΔS_n as unknown in the equations we study.

If we combine (9) and (11) with (10) and (12), and finally also with (13) and (14), then we can rewrite the resulting two equations in vector form as

$$\sum_{j=-\infty}^{n}\alpha_{n-j}\begin{pmatrix}\Delta T_j\\ \Delta S_j\end{pmatrix}=\Phi_n\left(\left\{\begin{pmatrix}\Delta T_{n-j}\\ \Delta S_{n-j}\end{pmatrix}\right\}_{j=0}^{\infty}\right)-\begin{pmatrix}e(w_n)\\ e(v_{n+1})\end{pmatrix},\qquad n\geqq 0, \qquad (15)$$

where for each $n\geqq 0$, α_n is a 2×2 real-valued matrix, and Φ_n is a nonlinear function defined on sequences.

Now we want to apply our proposition and must verify all the assumptions.

A rather lengthy but quite straightforward calculation shows that we have

$$\det\left[\sum_{n=0}^{\infty} z^n\alpha_n\right]=\frac{f(z)}{1-z},$$

where f is the function defined in (•).

Next we consider assumption (c). Let b be a continuous nondecreasing function on $\mathbf{R}^+$ such that $b(0)=1$, $\lim_{t\to\infty} b(t)=\infty$, and $\int_0^\infty t^2 b(t)|a'(t)|\,dt<\infty$. Define the sequence $\{\eta_j\}_{j=0}^{\infty}$ by $\eta_j=1/b(j\min\{S,T\})$.

From (7) we conclude that

$$|v_n+T-v_j-(V_n+T-V_j)| \leqq \sum_{i=j}^{n-1} |\Delta T_i+\Delta S_i|$$

$$\leqq (n-j)\frac{1}{\eta_{n-j}} \sup_{i\leqq n}\{\eta_{n-i}(|\Delta T_i|+|\Delta S_i|)\}, \tag{16}$$

since the sequence η is nondecreasing and therefore $\sum_{i=j}^{n-1} 1/\eta_{n-i} \leqq (n-j)/\eta_{n-j}$.

Assume that $\sup_{i\leqq n}(|\Delta T_i|+|\Delta S_i|) \leqq \min\{S, T\}/2$. By (16) we have the following estimate:

$$\left|\sum_{j=-\infty}^{n-1}\int_{V_n+T-V_j}^{v_n+T-v_j}(a(s)-a(V_n+T-V_j))\,ds\right|$$

$$\leqq \left|\sum_{j=-\infty}^{n-1}\int_{V_n+T-V_j}^{v_n+T-v_j} a'(s)(v_n+T-v_j-s)\,ds\right|$$

$$\leqq \sup_{i\leqq n}\{\eta_{n-i}(|\Delta T_i|+|\Delta S_i|)\}$$

$$\times \sum_{j=-\infty}^{n-1}\int_{|s-(V_n+T-V_j)|\leqq\sum_{i=j}^{n-1}(|\Delta T_i|+|\Delta S_i|)} (n-j)\frac{1}{\eta_{n-j}}|a'(s)|\,ds.$$

It is clear that every term in the sum on the right-hand side in the inequality above converges to zero as $\sup_{i\leqq n}(|\Delta T_i|+|\Delta S_i|)\to 0$. To show that the sum itself goes to zero we use the dominated convergence theorem. This can be done, as we have the dominating sum

$$\sum_{j=-\infty}^{n-1}\int_{|s-(V_n+T-V_j)|\leqq(n-j)\min\{T,S\}/2}(n-j)\frac{1}{\eta_{n-j}}|a'(s)|\,ds$$

$$\leqq \frac{1}{\min\{S, T\}^2}\int_0^\infty\int_t^\infty sb(s)|a'(s)|\,ds\,dt<\infty.$$

We conclude that

$$\sum_{j=-\infty}^{n-1}\int_{V_n+T-V_j}^{v_n+T-v_j}(a(s)-a(V_n+T-V_j))\,ds$$

$$= o\left(\sup_{i\leqq n}\{\eta_{n-i}(|\Delta T_i|+|\Delta S_i|)\}\right) \quad \text{as } \sup_{i\leqq n}(|\Delta T_i|+|\Delta S_i|)\to 0.$$

In the same way we show that this conclusion holds for all the other nonlinear terms in (9) and (11) as well.

From (8) we get the following expressions for derivatives:

$$y'_{v_n}(w_n+t)=\sum_{j=-\infty}^{n-1}(a(w_n+t-v_j)-a(w_n+t-w_j))+a(w_n+t-v_n),$$

$$y'_{w_n}(v_{n+1}+t)=\sum_{j=-\infty}^{n}(a(v_{n+1}+t-v_j)-a(v_{n+1}+t-w_j)).$$

Thus we have

$$|y'_{v_n}(w_n+t)-y'_*(W_n-)|$$

$$\leqq \sum_{j=-\infty}^{n-1}|a(w_n+t-v_j)-a(W_n-V_j)|$$

$$+\sum_{j=-\infty}^{n-1}|a(w_n+t-w_j)-a(W_n-W_j)|+|a(w_n+t-v_n)-a(W_n-V_n)|.$$

Let us consider, for example, the first of these sums:

$$\sup_{|t|\leqq|\Delta T_n|}\sum_{j=-\infty}^{n-1}|a(w_n+t-v_j)-a(W_n-V_j)|$$

$$\leqq\sum_{j=-\infty}^{n-1}\int_{|s-(W_n-V_j)|\leqq 2|\Delta T_n|+\sum_{i=j}^{n-1}(|\Delta T_i|+|\Delta S_i|)}|a'(s)|\,ds.$$

It is clear that every term in this sum converges to zero as $\sup_{i\leqq n}(|\Delta T_i|+|\Delta S_i|)\to 0$, and we can again use the dominated convergence theorem and the fact that $\int_0^\infty t|a'(t)|\,dt<\infty$ to prove that the whole sum converges toward zero. All other terms can be treated in a similar manner; this gives the desired result that

$$\int_0^{\Delta T_n}(y'_{v_n}(w_n-s)-y'_*(W_n-))\,ds=o\left(\sup_{i\leqq n}\{\eta_{n-i}(|\Delta T_i|+|\Delta S_i|)\}\right),$$

$$\int_0^{\Delta S_n}(y'_{w_n}(v_{n+1}-s)-y'_*(V_{n+1}-))\,ds=o\left(\sup_{i\leqq n}\{\eta_{n-i}(|\Delta T_i|+|\Delta S_i|)\}\right)$$

as $\sup_{i\leqq n}(|\Delta T_i|+|\Delta S_i|)\to 0$.

We conclude that assumption (c) is satisfied.

Assumption (vi) implies that $\det[\alpha_0]\neq 0$ and from (13), (14), and the argument given above we can see that the existence assumption (e) is satisfied as well. (Here we use the fact that $u_*(t)<\theta_{\text{high}}$ on (V_n, W_n), and $u_*(t)>\theta_{\text{low}}$ on (W_n, V_{n+1}).)

Now an application of the proposition completes the proof. □

3. Proof of the proposition. We use the following notation: If $n\in\mathbf{Z}$ and if $\{\zeta_j\}$ is a sequence of elements in $\mathbf{R}^m$ defined at least for all indices $j\leqq n$, then the sequence $H_n\zeta:\mathbf{N}\to\mathbf{R}^m$ is defined by $(H_n\zeta)_j=\zeta_{n-j}$, i.e., $H_n\zeta$ consists of the part of ζ "before" n.

It is well known that condition (*) implies that there exists a resolvent kernel $\rho\in l^1(\mathbf{N};\mathbf{R}^m)$ such that

$$\sum_{j=0}^{n}\alpha_{n-j}\rho_j=\sum_{j=0}^{n}\rho_{n-j}\alpha_j=\delta_{0n},\qquad n\geqq 0.$$

(Here $\delta_{ij}=I$ if $i=j$ and zero otherwise.)

Choose

$$\varepsilon\in\left(0,\frac{\gamma}{1+\|\alpha\|_{l^1(\mathbf{Z}_+)}}\right]$$

to be so small that

(17) If $\|\zeta\|_{l^\infty(\mathbf{N})}\leqq\max\{\Gamma(2\varepsilon+\varepsilon\|\alpha\|_{l^1(\mathbf{Z}_+)}),\varepsilon\}$ then $\|\Phi(\zeta)\|_{l^\infty(\mathbf{N})}\leqq\dfrac{\|\zeta\|_{l^\infty(\mathbf{N})}}{2\|\rho\|_{l^1(\mathbf{N})}}$.

Take

(18) $$C=2(1+\|\alpha\|_{l^1(\mathbf{Z}_+)})\|\rho\|_{l^1(\mathbf{N})},$$

(19) $$\delta=\frac{\varepsilon}{2C}.$$

Let ψ and φ satisfy

$$|\psi_i|\leqq\delta,\qquad i<0,$$

$$|\varphi_j|\leqq\delta,\qquad j\geqq 0.$$

Assume that $n \geqq 0$ is such that (3) has a unique solution ξ_j for all $j < n$ and (6) holds with n replaced by $j < n$.

Since $C \geqq 1$, this assumption holds when $n = 0$.

Note that $|\xi_j| \leqq \varepsilon$ for all $j < n$. It follows that

$$\left| \varphi_n - \sum_{j=-\infty}^{n-1} \alpha_{n-j} \xi_j \right| < \varepsilon(1 + \|\alpha\|_{l^1(\mathbf{Z}_+)}),$$

and since (3) can be rewritten as

$$\alpha_0 \xi_n = \Phi([\xi_n, \{\xi_{n-j}\}_{j=1}^{\infty}]) + \varphi_n - \sum_{j=-\infty}^{n-1} \alpha_{n-j} \xi_j,$$

we conclude from assumption (e) that there exists a unique solution ξ_n such that $|\xi_n| \leqq \Gamma(\varepsilon(2 + \|\alpha\|_{l^1(\mathbf{Z}_+)}))$. If $|\xi_n| \leqq C(\sup_{i<0} |\psi_i| + \sup_{0 \leqq k \leqq n} |\varphi_k|)$, then the induction step is completed. Otherwise $\|H_j \xi\|_{l^\infty(\mathbf{N})} \leqq |\xi_n|$ when $j \leqq n$, so we get from (17) that

$$|\Phi_j(H_j \xi)| \leqq \frac{|\xi_n|}{2\|\rho\|_{l^1(\mathbf{N})}}, \qquad 0 \leqq j \leqq n. \tag{20}$$

With the aid of the resolvent kernel ρ we can write ξ_n as

$$\xi_n = \sum_{j=0}^{n} \rho_{n-j} \left(\Phi_j(H_j \xi) + \varphi_j - \sum_{i=-\infty}^{-1} \alpha_{j-i} \psi_i \right). \tag{21}$$

It follows from (20) and (21) that

$$|\xi_n| \leqq \tfrac{1}{2} |\xi_n| + \|\rho\|_{l^1(\mathbf{N})} \left(\sup_{0 \leqq k \leqq n} |\varphi_k| + \|\alpha\|_{l^1(\mathbf{N})} \sup_{i<0} |\psi_i| \right),$$

and we conclude that (6) holds. This completes the induction argument.

Assume next that $\lim_{n \to \infty} \varphi_n = 0$ but that $\limsup_{n \to \infty} |\xi_n| > 0$. It is clear from (6) and from our choice of δ that $|\xi_n| \leqq \varepsilon$ for all n. Hence we get from (17) that

$$\limsup_{n \to \infty} |\Phi_n(H_n \xi)| \leqq \frac{\limsup_{n \to \infty} |\xi_n|}{2\|\rho\|_{l^1(\mathbf{N})}}.$$

(Only at this point do we need the assumption that $\eta_j \to 0$; otherwise we could take $\eta_j \equiv 1$.)

On the other hand, it follows from (21) that

$$\limsup_{n \to \infty} |\xi_n| \leqq \|\rho\|_{l^1(\mathbf{N})} \limsup_{n \to \infty} |\Phi_n(H_n \xi)|$$

and combining these two inequalities we get the desired contradiction.

Next, let us show that if (*) does not hold, then (**) fails too. First we consider the case where there exists a point z_0 such that $|z_0| < 1$ and z_0 is a simple zero of the function $\det[\sum_{n=0}^{\infty} z^n \alpha_n]$ and there are no other zeros of this function in the set $\{z \mid |z| \leqq |z_0|\}$ except $\overline{z_0}$. Clearly, we may assume that $z_0 \neq 0$ and from now on we also assume that z_0 is not real. Otherwise, some small changes in the proof would be necessary.

Since z_0 is a simple zero, it follows that in a neighborhood of this point we have

$$\left[\sum_{n=0}^{\infty} z^n \alpha_n \right]^{-1} = \frac{1}{2} \frac{z_0}{z_0 - z} A + B(z), \tag{22}$$

where $A \in \mathbf{C}^{m \times m} \backslash 0$ and B is a matrix-valued function that is analytic at z_0. From (22) we immediately see that $\sum_{n=0}^{\infty} z_0^n \alpha_n A = 0$. Since all the other zeros (except $\overline{z_0}$) of

$\det[\sum_{n=0}^{\infty} z^n\alpha_n]$ have absolute value larger than $|z_0|$, there exist a number $r\in(|z_0|,1]$ and a sequence ϱ such that

$$\sum_{j=0}^{\infty} r^j|\varrho_j|<\infty, \tag{23}$$

$$\rho_j=\Re[z_0^{-j}A]+\varrho_j, \qquad j\geqq 0. \tag{24}$$

(Observe that here $\Re M$ is the matrix with each element equal to the real part of the corresponding element in M.)

Let ε be a positive number such that if $\|\zeta\|_{l^\infty(\mathbf{N})}\leqq 4\varepsilon$, then

$$\|\Phi(\zeta)\|_{l^\infty(\mathbf{N})}\leqq\|\zeta\|_{l^\infty(\mathbf{N})}\frac{1}{8}\min\left\{\frac{1}{\sum_{j=0}^{\infty}r^j|\varrho|},\frac{r-|z_0|}{|A|}\right\}. \tag{25}$$

Assume that (**) holds and let δ and C be the numbers given there. Pick a positive number q such that $4\varepsilon r^{q+1}<\min\{\delta,\varepsilon/C\}$. Let $v\in\mathbf{C}^m$ be such that $|v|=1$ and $|\Re[Av]|\geqq\frac{1}{2}|A|$.

Define the set Ω by

$$\Omega=\{\{\vartheta_j\}_{j=0}^{q}|\,\vartheta_j\in\mathbf{R}^m,|\vartheta_j|\leqq 4\varepsilon r^{q-j},j=0,1,2,\cdots,q\}$$
$$\times\left\{w\in\mathbf{C}^m\middle||w|\leqq\frac{\varepsilon}{|A|}r^q\right\}.$$

Next we consider a mapping $(\vartheta,w)\in\Omega\mapsto(G(\vartheta,w),g(\vartheta,w))$ defined as follows:

$$\begin{aligned}G_n(\vartheta,w)=&\frac{3\varepsilon}{|A|}\Re[z_0^{q-n}Av]-\sum_{j=n+1}^{q}\Re[z_0^{-n+j}A]\Phi_j(H_j\xi)\\&+\sum_{j=0}^{n}\varrho_{n-j}\Phi_j(H_j\xi),\qquad n=0,1,2,\cdots,q,\quad g(\vartheta,w)=\sum_{j=0}^{q}z_0^j\Phi_j(H_j\xi),\end{aligned} \tag{26}$$

where

$$\xi_n=\begin{cases}\Re\left[z_0^{-n}A\left(\dfrac{3\varepsilon}{|A|}z_0^q v-w\right)\right], & n<0,\\ \vartheta_n, & n=0,1,2,\cdots,q.\end{cases}$$

It is clear that the mapping $(\vartheta,w)\mapsto(G(\vartheta,w),g(\vartheta,w))$ is continuous (in the topology of $\mathbf{R}^{m\times(q+1)}\times\mathbf{C}^m$), and we must show that it maps Ω into itself. First we observe that if $(\vartheta,w)\in\Omega$, then $\sup_{j\leqq q}|\xi_j|\leqq 4\varepsilon$ and $\|H_j\xi\|_{l^\infty(\mathbf{N})}\leqq 4\varepsilon r^{q-j}$, when $0\leqq j\leqq q$. Therefore it follows from our choice of ε and the fact that $|z_0|<r\leqq 1$ that

$$\left|\sum_{j=n+1}^{q}\Re[z_0^{-n+j}A]\Phi_j(H_j\xi)\right|\leqq 4\varepsilon\frac{r-|z_0|}{8|A|}|A|\sum_{j=n+1}^{q}|z_0|^{-n+j}r^{q-j}\leqq\frac{\varepsilon}{2}r^{q-n},$$

$$\left|\sum_{j=0}^{n}\varrho_{n-j}\Phi_j(H_j\xi)\right|\leqq\frac{1}{8\sum_{j=0}^{\infty}r^j|\varrho_j|}\sum_{j=0}^{n}|\varrho_{n-j}|4\varepsilon r^{q-j}\leqq\frac{\varepsilon}{2}r^{q-n},$$

$$\left|\sum_{j=0}^{q}z_0^j\Phi_j(H_j\xi)\right|\leqq\frac{4\varepsilon(r-|z_0|)}{8|A|}\sum_{j=0}^{q}|z_0|^j r^{q-j}\leqq\frac{r^q\varepsilon}{|A|}.$$

Furthermore,

$$\left|\frac{3\varepsilon}{|A|}\Re[z_0^{q-n}Av]\right|\leqq 3\varepsilon r^{q-n},$$

and so we see that the range of the mapping in question is contained in Ω.

Since Ω is convex, we can apply Schauder's fixed-point theorem and find $(\vartheta^*, w^*) \in \Omega$ such that $G(\vartheta^*, w^*) = \vartheta^*$ and $g(\vartheta^*, w^*) = w^*$. Define ξ^* by

$$\xi_n^* = \begin{cases} \Re\left[z_0^{-n} A\left(\frac{3\varepsilon}{|A|} z_0^q v - w^*\right)\right], & n < 0, \\ \vartheta_n^*, & n = 0, 1, 2, \cdots, q. \end{cases}$$

We can now rewrite the definition of G to get

$$\xi_n^* = \Re\left[z_0^{-n} A\left(\frac{3\varepsilon}{|A|} z_0^q v - w^*\right)\right] + \sum_{j=0}^{n} (\Re[z_0^{n-j} A] + \varrho_{n-j})\Phi_j(H_j \xi^*).$$

But in view of (24) this implies that ξ^* satisfies the equation

$$\sum_{j=0}^{n} \alpha_{n-j}\xi_j = \Phi_n(H_n\xi), \qquad 0 \leqq n \leqq q,$$

$$\xi_i = \Re\left[z_0^{-i} A\left(\frac{3\varepsilon}{|A|} z_0^q v - w\right)\right], \qquad i < 0.$$

Finally, note that

$$|\xi_q^*| = |G_q(\vartheta^*, w^*)| \geqq \frac{3\varepsilon}{2} - \frac{\varepsilon}{2} = \varepsilon,$$

and we get the desired contradiction since (**) implies that $|\xi_q^*| \leqq C 4\varepsilon r^{q+1} < \varepsilon$.

If our assumption on the zero z_0 is not satisfied, but $\det[\sum_{n=0}^{\infty} z^n \alpha_n]$ has some zero with absolute value less than or equal to 1, then we proceed as follows: Assume that (**) holds and let δ and C be the positive numbers given there. Next choose a sequence $\beta \in l^1(\mathbf{N}; \mathbf{R}^m)$ such that

$$\|\alpha - \beta\|_{l^1(\mathbf{N})} < \frac{1}{16C}$$

and such that $\det[\sum_{n=0}^{\infty} z^n \beta_n]$ has a simple zero in some point z_0 with $|z_0| < 1$ and no other zeros except $\overline{z_0}$, with absolute value less than or equal to $|z_0|$. It is not too difficult to see that this can always be done.

As we have seen in the above, we can find a sequence $\psi \in l^\infty(\mathbf{Z}_-; \mathbf{R}^m)$ and an integer $q > 0$ such that $\sup_{i<0} |\psi_i|$ is arbitrarily small and the solution ξ^* of the equation

$$\sum_{j=0}^{n} \beta_{n-j}\xi_j = \Phi_n(H_n\xi), \qquad 0 \leqq n \leqq q,$$

$$\xi_i = \psi_i, \qquad i < 0$$

satisfies $|\xi_j^*| \leqq 16C \sup_{i<0} |\psi_i|$, $0 \leqq j \leqq q$, and $|\xi_q^*| \geqq 4C \sup_{i<0} |\psi_i|$. But then ξ^* is also a solution of the equation

$$\sum_{j=0}^{n} \alpha_{n-j}\xi_j = \Phi_n(H_n\xi) + \varphi_n, \qquad 0 \leqq n \leqq q,$$

$$\xi_i = \psi_i, \qquad i < 0,$$

where $\varphi_n = \sum_{j=0}^{n} (\alpha_{n-j} - \beta_{n-j})\xi_j^*$. But now $|\varphi_j| \leqq 16C \sup_{i<0} |\psi_i|/(16C)$, $0 \leqq j \leqq q$, and since $|\xi_q| \geqq 4C \sup_{i<0} |\psi_i^*|$ we get a contradiction. □

FAR-FIELD PATTERNS FOR ACOUSTIC WAVES IN AN INHOMOGENEOUS MEDIUM*

DAVID COLTON†, ANDREAS KIRSCH‡, AND LASSI PÄIVÄRINTA§

Abstract. This paper is concerned with the class of far-field patterns corresponding to the scattering of time-harmonic acoustic plane waves by an inhomogeneous medium of compact support. This class is shown to be complete in $L^2(\partial\Omega)$ (where $\partial\Omega$ is the unit sphere) for any positive value of the wave number, with the possible exception of a discrete set of wave numbers called transmission eigenvalues. The existence of a unique weak solution to the interior transmission problem (which plays a basic role in a new method for solving the inverse scattering problem) is also established for any positive value of the wave number provided the wave number is not a transmission eigenvalue.

Key words. far-field patterns, acoustic waves, inverse scattering

AMS(MOS) subject classifications. 35P25, 76Q05

1. Introduction. In this paper, as in a previous paper by Colton [1], we are concerned with the class of far-field patterns corresponding to the scattering of time-harmonic acoustic plane waves by an inhomogeneous medium of compact support. In [1] it is shown that this class of far-field patterns is complete in $L^2(\partial\Omega)$, where $\partial\Omega$ is the unit sphere provided that the wave number is sufficiently small. The purpose of this paper is to remove this restriction on the wave number and show that the class of far-field patterns is complete in $L^2(\partial\Omega)$ for any positive value of the wave number with the possible exception of a discrete set of wave numbers called *transmission eigenvalues.* (In the case of a spherically symmetric medium it is shown in [3] that these transmission eigenvalues actually exist and can be numerically determined from the far-field data.) We will also consider a recently introduced boundary value problem for the reduced wave equation called the *interior transmission problem,* which plays a basic role in a new method for solving the inverse scattering problem introduced by Colton and Monk in [3]. In [3] it is shown that there exists a unique weak solution to the interior transmission problem provided the wave number is sufficiently small. Here we will establish the existence of a unique weak solution to the interior transmission problem for any positive value of the wave number provided the wave number is not a transmission eigenvalue.

In passing, we would like to note the recent paper of Kirsch [6], which also studies the relationship between far-field patterns and the interior transmission problem for acoustic waves, as well as the work of Colton and Päivärinta [4], which considers the case of electromagnetic wave propagation in an inhomogeneous medium.

2. Wave propagation in an inhomogeneous medium and far-field patterns. Consider the scattering due to a nonabsorbing inhomogeneous medium of compact support of

the incident plane wave

$$u^i(\mathbf{x}, t) \equiv \exp[ik\mathbf{x}\cdot\hat{\alpha} - i\omega t] \tag{2.1}$$

where $k>0$ is the wave number, ω is the frequency, and $\hat{\alpha}$, $|\hat{\alpha}|=1$, is the direction of propagation. Let $c(\mathbf{x})$, $\mathbf{x}\in R^3$, denote the local speed of sound and assume that $c(\mathbf{x})=c_0>0$ for $r=|\mathbf{x}|>a$ where c_0 is a constant. Then, if $k=\omega/c_0>0$, $n(\mathbf{x})=(c_0/c(\mathbf{x}))^2$, and we factor out the term $e^{-i\omega t}$, under appropriate assumptions (cf. [8]) the mathematical problem we are faced with is to determine the velocity potential $u(\mathbf{x})$ of the total field such that

$$\Delta_3 u + k^2 n(\mathbf{x}) u = 0 \quad \text{in } R^3, \tag{2.2}$$

$$u(\mathbf{x}) \equiv \exp[ik\mathbf{x}\cdot\hat{\alpha}] + u^s(\mathbf{x}), \tag{2.3}$$

$$\lim_{r\to\infty} r\left(\frac{\partial u^s}{\partial r} - iku^s\right) = 0 \tag{2.4}$$

where $u^s(\mathbf{x})$ denotes the scattered field, and the Sommerfeld radiation condition (2.4) is assumed to hold uniformly for $\hat{\mathbf{x}}=\mathbf{x}/|\mathbf{x}|$ on the unit sphere $\partial\Omega$. As in [1] and [3], we will make the assumption that $n(\mathbf{x})$ is positive and continuously differentiable and that

$$B=\{\mathbf{x}\in R^3: n(\mathbf{x})\neq 1\} \tag{2.5}$$

is simply connected (with C^2 boundary ∂B) and contains the origin. In particular, this implies that for $\mathbf{x}\in B$, either $c(\mathbf{x})>c_0$ or $0<c(\mathbf{x})<c_0$.

The scattering problem (2.2)-(2.4) is easily seen to be equivalent to the integral equation

$$u(\mathbf{x}) = \exp[ik\mathbf{x}\cdot\hat{\alpha}] - k^2\int_B\int \Phi(\mathbf{x},\mathbf{y})m(\mathbf{y})u(\mathbf{y})\,d\mathbf{y} \tag{2.6}$$

where $u(\mathbf{x})=u(\mathbf{x}; k, \hat{\alpha})$,

$$m(\mathbf{x}) = 1 - n(\mathbf{x}) \tag{2.7}$$

and

$$\Phi(\mathbf{x},\mathbf{y}) = \frac{\exp[ik|\mathbf{x}-\mathbf{y}|]}{4\pi|\mathbf{x}-\mathbf{y}|}. \tag{2.8}$$

From (2.3) and (2.6) it is seen that $u^s(\mathbf{x})$ has the asymptotic behavior

$$u^s(\mathbf{x}) = \frac{e^{ikr}}{r}F(\hat{\mathbf{x}}; k, \hat{\alpha}) + O\left(\frac{1}{r^2}\right) \tag{2.9}$$

where

$$F(\hat{\mathbf{x}}; k, \hat{\alpha}) = -\frac{k^2}{4\pi}\int_B\int \exp[-ik\hat{\mathbf{x}}\cdot\mathbf{y}]m(\mathbf{y})u(\mathbf{y})\,d\mathbf{y}. \tag{2.10}$$

The function $F(\hat{\mathbf{x}}; k, \hat{\alpha})$ is known as the *far-field pattern* corresponding to the incident plane wave (2.1). Noting that for $\mathbf{x}\in B$, $m(\mathbf{x})$ is either always positive or always negative, we assume without loss of generality that $m(\mathbf{x})$ is positive for $\mathbf{x}\in B$ and define the Hilbert space $L^2_m(B)$ by

$$L^2_m(B) = \left\{u: u \text{ measurable}, \int_B\int m|u|^2\,d\mathbf{x} < \infty\right\} \tag{2.11}$$

with the inner product given by

$$(f, g) = \int_B \int mf\bar{g}\, d\mathbf{x}. \tag{2.12}$$

(If $m(\mathbf{x})$ is negative for $\mathbf{x} \in B$, then $m(\mathbf{x})$ must be replaced by $-m(\mathbf{x})$ in the definition above.) We now define the compact operator $\mathbf{T}_k : L^2_m(B) \to L^2_m(B)$ by

$$\mathbf{T}_k u = \int_B \int \Phi(\mathbf{x}, \mathbf{y}) m(\mathbf{y}) u(\mathbf{y})\, d\mathbf{y} \tag{2.13}$$

and write (2.6) in the short form

$$u = \exp[ik\mathbf{x} \cdot \hat{\alpha}] - k^2 \mathbf{T}_k u. \tag{2.14}$$

The existence of a unique solution to (2.6) (or 12.14) is established in [8] and [3].

Let $\{\hat{\alpha}_n\}_1^\infty$ be a countable dense set of vectors on the unit sphere $\partial\Omega$ and for each fixed $k > 0$ define the class $\mathbf{F}$ of far-field patterns by

$$\mathbf{F} = \{F(\hat{\mathbf{x}}; k, \hat{\alpha}_n) : n = 1, 2, 3, \cdots\}. \tag{2.15}$$

Our aim is to show that, except possibly for a discrete set of values of $k > 0$, the set $\mathbf{F}$ is complete in $L^2(\partial\Omega)$. To do this we will need four lemmas. The first of these is the following *reciprocity principle.*

LEMMA 1. *Let $F(\hat{\mathbf{x}}; k, \hat{\alpha})$ be the far-field pattern corresponding to the incident plane wave* (2.1). *Then*

$$F(\hat{\mathbf{x}}; k, \hat{\alpha}) = F(-\hat{\alpha}; k, -\hat{\mathbf{x}}).$$

Proof. Using the representation theorem for the scattered field u^s [2] and the asymptotic behavior of the fundamental solution $\Phi(\mathbf{x}, \mathbf{y})$, we have

$$\begin{aligned}
F(\hat{\mathbf{x}}; k, \hat{\alpha}) &= \frac{1}{4\pi} \int_{\partial B} \left\{ u^s(\mathbf{y}, k, \hat{\alpha}) \frac{\partial}{\partial \nu_y} \exp[-ik\hat{\mathbf{x}} \cdot \mathbf{y}] \right. \\
&\qquad \left. - \exp[-ik\hat{\mathbf{x}} \cdot \mathbf{y}] \frac{\partial}{\partial \nu} u^s(\mathbf{y}; k, \hat{\alpha}) \right\} ds(\mathbf{y}) \\
&= \frac{1}{4\pi} \int_{\partial B} \left\{ u^s(\mathbf{y}; k, \hat{\alpha}) \frac{\partial}{\partial \nu} (u(\mathbf{y}; k, -\hat{\mathbf{x}}) - u^s(\mathbf{y}; k, -\hat{\mathbf{x}})) \right. \\
&\qquad \left. - (u(\mathbf{y}; k, -\hat{\mathbf{x}}) - u^s(\mathbf{y}; k, -\hat{\mathbf{x}})) \frac{\partial}{\partial \nu} u^s(\mathbf{y}; k, \hat{\alpha}) \right\} ds(\mathbf{y}) \\
&= \frac{1}{4\pi} \int_{\partial B} \left\{ (u(\mathbf{y}; k, \hat{\alpha}) - \exp[ik\mathbf{y} \cdot \hat{\alpha}]) \frac{\partial}{\partial \nu} u(\mathbf{y}; k, -\hat{\mathbf{x}}) \right. \\
&\qquad \left. - u(\mathbf{y}; k, -\hat{\mathbf{x}}) \frac{\partial}{\partial \nu} (u(\mathbf{y}; k, \hat{\alpha}) - \exp[ik\mathbf{y} \cdot \hat{\alpha}]) \right\} ds(\mathbf{y}) \\
&= \frac{-1}{4\pi} \int_{\partial B} \left\{ \exp[ik\mathbf{y} \cdot \hat{\alpha}] \frac{\partial}{\partial \nu} u(\mathbf{y}; k, -\hat{\mathbf{x}}) \right. \\
&\qquad \left. - u(\mathbf{y}; k, -\hat{\mathbf{x}}) \frac{\partial}{\partial \nu} \exp[ik\mathbf{y} \cdot \hat{\alpha}] \right\} ds(\mathbf{y}) \\
&= F(-\hat{\alpha}; k, -\hat{\mathbf{x}})
\end{aligned} \tag{2.16}$$

where ν is the unit outward normal to ∂B and we use the identities

$$\begin{aligned}&\int_{\partial B}\left\{u^s(\mathbf{y};k,\hat{\alpha})\frac{\partial}{\partial\nu}u^s(\mathbf{y};k,-\hat{\mathbf{x}})-u^s(\mathbf{y};k,-\hat{\mathbf{x}})\frac{\partial}{\partial\nu}u^s(\mathbf{y};k,\hat{\alpha})\right\}ds(\mathbf{y})=0,\\&\int_{\partial B}\left\{u(\mathbf{y};k,\hat{\alpha})\frac{\partial}{\partial\nu}u(\mathbf{y};k,-\hat{\mathbf{x}})-u(\mathbf{y};k,-\hat{\mathbf{x}})\frac{\partial}{\partial\nu}u(\mathbf{y};k,\hat{\alpha})\right\}ds(\mathbf{y})=0,\end{aligned}\tag{2.17}$$

which follow from Green's theorem.

LEMMA 2. *The orthogonal complement of* $\mathbf{F}$ *in* $L^2(\partial\Omega)$ *consists of those functions* $g\in L^2(\partial\Omega)$ *for which there exists* $w\in C^2(B)\cap C^1(\bar{B})$ *and* v *defined by*

$$v(\mathbf{x})=\int_{\partial\Omega}g(\hat{\mathbf{y}})\exp[ik\mathbf{x}\cdot\hat{\mathbf{y}}]\,ds(\hat{\mathbf{y}})\tag{2.18}$$

such that $\{v, w\}$ *is a solution to*

$$\begin{aligned}&\Delta_3 w+k^2n(\mathbf{x})w=0 && \text{in } B,\\&\Delta_3 v+k^2v=0 && \text{in } B,\\&w=v && \text{on } \partial B,\\&\frac{\partial w}{\partial\nu}=\frac{\partial v}{\partial\nu} && \text{on } \partial B.\end{aligned}\tag{2.19}$$

Remark. Functions v of the form (2.18) are called *Herglotz wave functions* with *Herglotz kernel* g (cf. [5]). The boundary value problem (2.19) is the (homogeneous) *interior transmission problem* first studied in [3].

Proof. Let $\mathbf{F}^\perp$ denote the orthogonal complement to $\mathbf{F}$. We will show that if $g\in\mathbf{F}^\perp$ then g satisfies the assumptions stated in the lemma. The fact that, if g satisfies the assumptions of the lemma, then $g\in\mathbf{F}^\perp$, follows from a simple application of Green's formula.

Suppose $g\in\mathbf{F}^\perp$, i.e.,

$$\int_{\partial\Omega}F(\hat{\mathbf{x}};k,\hat{\alpha}_n)\overline{g(\hat{\mathbf{x}})}\,ds(\hat{\mathbf{x}})=0\tag{2.20}$$

for $n=1,2,\cdots$. From Lemma 1 and the continuity of F as a function of $\hat{\alpha}$ we have that

$$\int_{\partial\Omega}F(-\hat{\alpha};k,-\hat{\mathbf{x}})\overline{g(\hat{\mathbf{x}})}\,ds(\hat{\mathbf{x}})=0\tag{2.21}$$

for all $\hat{\alpha}\in\partial\Omega$, i.e.,

$$\int_{\partial\Omega}F(\hat{\mathbf{x}};k,\hat{\alpha})\overline{g(-\hat{\alpha})}\,ds(\hat{\alpha})=0\tag{2.22}$$

for all $\hat{\mathbf{x}}\in\partial\Omega$. By superposition we note that the left-hand side of (2.22) is the far-field pattern of the scattered field w^s corresponding to the incident field

$$\begin{aligned}w^i(\mathbf{x})&=\int_{\partial\Omega}\overline{g(-\hat{\alpha})}\exp[ik\mathbf{x}\cdot\hat{\alpha}]\,ds(\hat{\alpha})\\&=\int_{\partial\Omega}g(\hat{\alpha})\exp[ik\mathbf{x}\cdot\hat{\alpha}]\,ds(\hat{\alpha}).\end{aligned}\tag{2.23}$$

But from (2.22) we have that the far-field pattern of w^s vanishes and hence w^s vanishes in $R^3\backslash B$, i.e., if $w = w^s + w^i$, then $w = w^i$ on ∂B and $\partial w/\partial \nu = \partial w^i/\partial \nu$ on ∂B. Taking the conjugate of w now implies the lemma.

To show that $\mathbf{F}$ is complete in $L^2(\partial\Omega)$ except for possibly a discrete set of k values, it now suffices by Lemma 2 and the theory of Herglotz wave functions [5] to show that the eigenvalues of (2.19) form a discrete set, i.e., except for possibly a discrete set of k values the only solution of (2.19) is $\{v, w\}$ identically zero. To this end we define the discrete set I by

$$I = \{k: k^2 \text{ is a Dirichlet eigenvalue of } -\Delta_3 \text{ in } B\}$$

and define the vector space W by

$$W = \left\{ u \in C^2(B) \cap C^1(\bar{B}): u = \frac{\partial u}{\partial \nu} = 0 \text{ on } \partial B, \int_B \int \frac{1}{m} (|u|^2 + |\Delta_3 u|^2)\, d\mathbf{x} < \infty \right\}.$$

We make W a Hilbert space $\bar{W}$ by defining on W the inner product

$$\langle u, v\rangle = \int_B \int \frac{1}{m} (u\bar{v} + \Delta_3 u \Delta_3 \bar{v})\, d\mathbf{x}, \qquad u, v \in W \tag{2.24}$$

and completing W with respect to the norm $|u| = \sqrt{\langle u, u\rangle}$.

We first want to define an isomorphism $\mathbf{S}(k)$ on $\bar{W}$ that depends analytically on k for k in a complex neighborhood of $k_0 \in R^+$. To do this, we let $G(\mathbf{x}, \mathbf{y})$ be the Dirichlet Green's function for $\Delta_3 + k^2$ in B, $k \in R^+\backslash I$, and make the assumption that there exists a positive constant $\gamma = \gamma(k)$ such that for all $\mathbf{y}, \mathbf{z} \in \bar{B}$ we have

$$\left| \int_B \int \frac{\sqrt{m(\mathbf{y})m(\mathbf{z})}}{m(\mathbf{x})} G(\mathbf{x}, \mathbf{y}) G(\mathbf{x}, \mathbf{z})\, d\mathbf{x} \right| \leqq \gamma(\mathrm{k}) \tag{2.25}$$

where the integral in (2.25) is uniformly convergent. Roughly speaking, condition (2.25) says that, if $m(\mathbf{x})$ is continuously differentiable, then for $\mathbf{y} \in \partial B$, $m(\mathbf{x}) = O(|\mathbf{x} - \mathbf{y}|^\alpha)$, $1 \leqq \alpha < 3$, as $\mathbf{x} \to \mathbf{y}$. We can now prove the following two lemmas.

LEMMA 3. *Assume that* (2.25) *is valid. Then for all* $k_0 \in R^+$ *there exists a positive constant* $c = c(k_0)$ *such that*

$$|u|^2 \leqq c(k_0) \int_B \int \frac{1}{m} |\Delta_3 u + k_0^2 u|^2\, d\mathbf{x}$$

for $u \in \bar{W}$.

Proof. We first choose $k_0 \in R^+\backslash I$. Then for $u \in \bar{W}$ we have the representation

$$u(\mathbf{x}) = -\int_B \int (\Delta_3 + k_0^2) u(\mathbf{y}) G(\mathbf{x}, \mathbf{y})\, d\mathbf{y}, \qquad \mathbf{x} \in B \tag{2.26}$$

and hence we have

$$\begin{aligned} \int_B \int \frac{1}{m} |u|^2\, d\mathbf{x} = \int_B \int \int_B \int (\Delta_3 + k_0^3) u(\mathbf{y}) (\Delta_3 + k_0^2) \overline{u(\mathbf{z})} \\ \cdot \int_B \int \frac{1}{m(\mathbf{x})} G(\mathbf{x}, \mathbf{y}) G(\mathbf{x}, \mathbf{y}) G(\mathbf{x}, \mathbf{z})\, d\mathbf{x}\, d\mathbf{y}\, d\mathbf{z}. \end{aligned} \tag{2.27}$$

We now see that

$$\begin{aligned} \int_B \int \frac{1}{m} |u|^2\, d\mathbf{x} &\leqq \gamma(k_0) \left| \int_B \int \frac{1}{\sqrt{m}} (\Delta_3 + k_0^2) u\, d\mathbf{x} \right|^2 \\ &\leqq \gamma(k_0)\, \mathrm{vol}\, B \int_B \int \frac{1}{m} |(\Delta_3 + k_0^2) u|^2\, d\mathbf{x}. \end{aligned} \tag{2.28}$$

In addition,

$$\int_B \int \frac{1}{m} |\Delta_3 u|^2 \, d\mathbf{x} \leqq 2 \int_B \int \frac{1}{m} |\Delta_3 u + k_0^2 u|^2 \, d\mathbf{x} + 2k_0^2 \int_B \int \frac{1}{m} |u|^2 \, d\mathbf{x} \tag{2.29}$$

and (2.28), (2.29) imply the lemma is true for $k_0 \in R^+ \backslash I$.

Now assume $k_0 \in I$ and let $k_1 \in R^+ \backslash I$. From the analysis above, we see that $\Delta_3 + k_1^2 \colon \bar{W} \to L^2_{1/m}(B)$ is injective and has closed range, i.e., $\Delta_3 + k_1^2$ is a semi-Fredholm operator. But $\Delta_3 + k_0^2 = \Delta_3 + k_1^2 + (k_0^2 - k_1^2)$ is also semi-Fredholm since from (2.25) and Rellich's lemma I: $\bar{W} \hookrightarrow L^2_{1/m}(B)$ is easily seen to be compact (a bit more effort shows that this can also be established without assuming that (2.25) is uniformly convergent). Since $\Delta_3 + k_0^2$ is injective (represent u as in (2.26) with $G(\mathbf{x}, \mathbf{y})$ replaced by $\Phi(\mathbf{x}, \mathbf{y})$ and note that the norm in $L^2_{1/m}(B)$ dominates the norm in $L^2(B)$) we can now conclude that the lemma is true for $k = k_0$ since the range of a semi-Fredholm operator is closed.

The lemma is now proved.

Now fix $k_0 \in R^+$ and define for $u, v \in \bar{W}$ the inner product

$$\langle u, v \rangle_{k_0} = \int_B \int \frac{1}{m} (\Delta_3 u + k_0^2 u)(\Delta_3 \bar{v} + k_0^2 \bar{v}) \, d\mathbf{x} \tag{2.30}$$

with norm $|u|_{k_0} = \sqrt{\langle u, v \rangle_{k_0}}$. By Lemma 3 the norm $|\cdot|_{k_0}$ is equivalent to $|\cdot|$ for any $k_0 \in R^+$.

LEMMA 4. *For arbitrary complex k define the sesquilinear form* $\mathbf{B}$ *on* $\bar{W}$ *by*

$$\mathbf{B}(u, v; k) = \int_B \int \frac{1}{m} (\Delta_3 + k^2) u (\Delta_3 + k^2) \bar{v} \, d\mathbf{x}$$

where it is assumed that (2.25) *is valid. Then for every $k_0 \in R^+$ there exists $\varepsilon > 0$ such that if $|k - k_0| < \varepsilon$ then*

$$|\mathbf{B}(u, v; k) - \mathbf{B}(u, v; k_0)| \leqq C |u|_{k_0} |v|_{k_0}$$

where C is a constant satisfying $0 < C < 1$.

Proof. $\mathbf{B}$ is well defined by Lemma 3. We have

$$\begin{aligned} \mathbf{B}(u, v; k) - \mathbf{B}(u, v; k_0) &= (k^2 - k_0^2) \int_B \int \frac{1}{m} (u \Delta_3 \bar{v} + \bar{v} \Delta_3 u) \, d\mathbf{x} \\ &\quad + (k^4 - k_0^4) \int_B \int \frac{1}{m} u \bar{v} \, d\mathbf{x} \end{aligned} \tag{2.31}$$

and hence by Schwarz's inequality

$$\begin{aligned} |\mathbf{B}(u, v; k) - \mathbf{B}(u, v; k_0)| &\leqq |k^2 - k_0^2| \left(\int_B \int \frac{1}{m} |u|^2 \, d\mathbf{x} \right)^{1/2} \left(\int_B \int \frac{1}{m} |\Delta_3 v|^2 \, d\mathbf{x} \right)^{1/2} \\ &\quad + |k^2 - k_0^2| \left(\int_B \int \frac{1}{m} |v|^2 \, d\mathbf{x} \right)^{1/2} \left(\int_B \int \frac{1}{m} |\Delta_3 u|^2 \, d\mathbf{x} \right)^{1/2} \\ &\quad + |k^4 - k_0^4| \left(\int_B \int \frac{1}{m} |u|^2 \, d\mathbf{x} \right)^{1/2} \left(\int_B \int \frac{1}{m} |v|^2 \, d\mathbf{x} \right)^{1/2}. \end{aligned} \tag{2.32}$$

From Lemma 3 we now have that

$$|\mathbf{B}(u, v; k) - \mathbf{B}(u, v; k_0)| \leqq (2|k^2 - k_0^2| + |k^4 - k_0^4|) c(k_0) |u|_{k_0} |v|_{k_0}. \tag{2.33}$$

Hence if $|k - k_0|$ is sufficiently small, then $(2|k^2 - k_0^2| + |k^4 - k_0^4|) c(k_0)$ is less than 1 and the lemma follows.

Since $\mathbf{B}(u, v; k_0) = \langle u, v\rangle_{k_0}$, we see from Lemma 4 that for each $v \in \bar{W}$, $\mathbf{B}(u, v; k)$ is a bounded linear functional on $\bar{W}$. Hence, by the Riez representation theorem, there exists $v_k \in \bar{W}$ such that

$$\mathbf{B}(u, v; k) = \langle u, v_k\rangle_{k_0}. \tag{2.34}$$

Since $v \mapsto v_k$ is linear, there exists a linear operator $\mathbf{T} = \mathbf{T}(k)$ such that

$$\mathbf{B}(u, v; k) = \langle u, \mathbf{T}(k)v\rangle_{k_0} \tag{2.35}$$

for all $u, v \in \bar{W}$. Since from Lemma 4 we have that

$$|\mathbf{B}(u, v; k)| \leqq (1 + C)|u|_{k_0}, \tag{2.36}$$

we see that $\mathbf{T}(k)$ is a bounded operator. Now let $\mathbf{S}(k)$ be the adjoint of $\mathbf{T}(k)$ in W, i.e.,

$$B(u, v; k) = \langle \mathbf{S}(k)u, v\rangle_{k_0}. \tag{2.37}$$

We claim that $\mathbf{S}(k)$ is an isomorphism on $\bar{W}$ that depends analytically on k. The analyticity follows from the theory of operator-valued analytic functions [7] since from (2.37), $\mathbf{S}(k)$ is weakly analytic and hence strongly analytic. $\mathbf{S}(k)$ is injective, since if $\mathbf{S}(k)u = 0$, then $\mathbf{B}(u, v; k) = 0$ for every $v \in \bar{W}$, and hence from Lemma 4 we have $\mathbf{B}(u, u; k_0) = 0$, which implies that $u = 0$. The range of $\mathbf{S}(k)$ is dense in W, since if $\langle \mathbf{S}(k)u, v\rangle_{k_0} = 0$ for every $u \in \bar{W}$, then by (2.37), $\mathbf{B}(u, v; k) = 0$ for every $u \in \bar{W}$ and from Lemma 4 we can conclude that $v = 0$. Hence, to show that $\mathbf{S}(k)$ is an isomorphism, we now only need to show that the range of $\mathbf{S}(k)$ is closed. It suffices to show that there exists $\delta > 0$ such that for every $u \in \bar{W}$,

$$|\mathbf{S}(k)u|_{k_0} \geqq \delta |u|_{k_0} \tag{2.38}$$

and we need only consider u such that $|u|_{k_0} = 1$. For such a u we have

$$\begin{aligned} |\mathbf{S}(k)u|_{k_0} &= \sup_{|v|_{k_0} \leqq 1} |\langle v, \mathbf{S}(k)u\rangle_{k_0}| \\ &= \sup_{|v|_{k_0} \leqq 1} |\mathbf{B}(u, v; k)| \\ &\geqq |\mathbf{B}(u, u; k)|, \end{aligned} \tag{2.39}$$

$$\begin{aligned} |\mathbf{B}(u, u; k)| &\geqq \mathbf{B}(u, u; k_0) - |\mathbf{B}(u, u; k) - \mathbf{B}(u, u; k_0)| \\ &\geqq |u|_{k_0}^2 - C|u|_{k_0}^2 \\ &= 1 - C. \end{aligned} \tag{2.40}$$

Inequality (2.38) now follows from (2.39) and (2.40), recalling that $|u|_{k_0} = 1$.

We are now in a position to prove the main result of this section.

THEOREM 1. *Assume that* (2.25) *is valid. Then, except possibly for a discrete set of values of* $k > 0$, *the set* $\mathbf{F}$ *is complete in* $L^2(\partial\Omega)$.

Proof. We began by defining a projection operator $\mathbf{P}_k$ in $L_m^2(B)$ depending on $k \in R^+$. Let $f \in L_m^2(B)$ and for fixed $k_0 \in R^+$ define the linear functional l_f by

$$l_f(\phi) = \int_B \int \bar{f}(\Delta_3 + k^2)\mathbf{S}^{-1}(k)\phi \, d\mathbf{x} \tag{2.41}$$

where $\phi \in \bar{W}$ and k is such that $|k - k_0| < \varepsilon$, where ε is defined as in Lemma 4. Then l_f is bounded on $\bar{W}$ by Lemma 3 and the fact that $\mathbf{S}^{-1}(k)$ is bounded. By the Riesz representation theorem, there exists $p_f \in \bar{W}$ such that for all $\phi \in \bar{W}$

$$l_f(\phi) = \langle \phi, p_f\rangle_{k_0} \tag{2.42}$$

where p_f depends on k and the mapping $f \mapsto p_f$ is bounded from $L_m^2(B)$ into $\bar{W}$. Then

$$\langle p_f, \phi \rangle_{k_0} = \int_B \int f(\Delta_3 + k^2)\overline{\mathbf{S}^{-1}(k)\phi}\, d\mathbf{x} \tag{2.43}$$

and $\mathbf{S}^{-1}(k)$ is analytic since the isomorphism $\mathbf{S}(k)$ is also. Hence we have that $\overline{\mathbf{S}^{-1}(k)\phi}$ can be analytically continued off the real axis and from (2.43) the mapping $f \mapsto p_f$ is weakly analytic. Hence, the mapping is strongly analytic, i.e., $p_f = p_f(k)$ is an analytic function of k in a neighborhood of every point in R^+. We now define the analytic operator $\mathbf{P}_k : L_m^2(B) \to L_m^2(B)$ by

$$\mathbf{P}_k f = \frac{1}{m}(\Delta_3 + k^2)p_f. \tag{2.44}$$

Note that $\mathbf{P}_k f \in L_m^2(B)$ since

$$\begin{aligned} \int_B \int m|\mathbf{P}_k f|^2\, d\mathbf{x} &= \int_B \int \frac{1}{m}|\Delta_3 p_f + k^2 p_f|^2\, d\mathbf{x} \\ &= |p_f|_k^2 \\ &\leqq c\|f\|_{L_m^2(B)} \end{aligned} \tag{2.45}$$

for some constant c.

We now want to show that $\mathbf{P}_k$ is a projection operator for $k \in R^+$. To this end, let H be the vector space

$$H = \text{span}\,\{j_l(k|\mathbf{x}|)\, Y_l^m(\hat{\mathbf{x}}) : l = 0, 1, 2, \cdots, -l \leqq m \leqq l\}$$

where $j_l(k|\mathbf{x}|)$ is a spherical Bessel function and $Y_l^m(\hat{\mathbf{x}})$ is a spherical harmonic, and let $\bar{H}$ denote the closure of H in $L_m^2(B)$ and $H^\perp$ the orthogonal complement of H in $L_m^2(B)$. Then for $f \in H$ we have

$$\int_B \int \bar{f}(\Delta_3\phi + k^2\phi)\, d\mathbf{x} = \int_B \int \phi(\Delta_3\bar{f} + k^2\bar{f})\, d\mathbf{x} = 0 \tag{2.46}$$

for all $\phi \in \bar{W}$, and by a limiting process, (2.46) is also valid for $f \in \bar{H}$. Hence, since $\mathbf{S}$ is an isomorphism, $p_f = 0$ for $f \in \bar{H}$. For $f \in H^\perp$ we have

$$\begin{aligned} m(x)f(x) &= -(\Delta_3 + k^2)\int_B \int m(\mathbf{y})f(\mathbf{y})\Phi(\mathbf{x}, \mathbf{y})\, d\mathbf{y} \\ &= -(\Delta_3 + k^2)\mathbf{T}_k f \end{aligned} \tag{2.47}$$

and, by the addition formula for Bessel functions and the unique continuation property of solutions to the Helmholtz equation, $\mathbf{T}_k f$ is in $\bar{W}$. Hence from the definition of p_f we have

$$\begin{aligned} l_f(\mathbf{S}(k)\phi) &= \langle \mathbf{S}(k)\phi, p_f \rangle_{k_0} \\ &= \mathbf{B}(\phi, p_f; k), \end{aligned} \tag{2.48}$$

i.e., from (2.41) and (2.47),

$$\begin{aligned} &\int_B \int \frac{1}{m}(\Delta_3\overline{p_f} + k^2\overline{p_f})(\Delta_3\phi + k^2\phi)\, d\mathbf{x} \\ &\quad = -\int_B \int \frac{1}{m}(\Delta_3\overline{\mathbf{T}_k f} + k^2\overline{\mathbf{T}_k f})(\Delta_3\phi + k^2\phi)\, d\mathbf{x} \end{aligned} \tag{2.49}$$

for all $\phi \in \bar{W}$ and $k \in R^+$. Hence

$$p_f + \mathbf{T}_k f = 0 \tag{2.50}$$

for $f \in H^\perp$. Hence $\mathbf{P}_k f = f$ for $f \in H^\perp$, i.e., for $k \in R^+$, $\mathbf{P}_k$ is a projection operator (depending analytically on the parameter k).

We have shown above that $\mathbf{P}_k h = 0$ for $h \in \bar{H}$. In particular, if $\{v, w\}$ is a solution of (2.19) then $\mathbf{P}_k v = 0$. Furthermore, we see that $(1/k^2)(w - v) \in \bar{W}$ and for $k \in R^+$

$$\begin{aligned} l_w(\mathbf{S}(k)\phi) &= \int_B \int \bar{w}(\Delta_3 \phi + k^2 \phi)\, d\mathbf{x} \\ &= \int_B \int \frac{1}{m}(\Delta_3 + k^2)\left(\frac{\bar{w} - \bar{v}}{k^2}\right)(\Delta_3 + k^2)\phi\, d\mathbf{x} \\ &= \frac{1}{k^2}\langle \mathbf{S}(k)\phi, w - v\rangle_{k_0}, \end{aligned} \tag{2.51}$$

i.e., $p_w = (1/k^2)(w - v)$ and $\mathbf{P}_k w = (1/m)(\Delta_3 + k^2)((w - v)/k^2) = w$. If we now use Green's formula to rewrite (2.19) in the form

$$\begin{aligned} w(\mathbf{x}) - v(\mathbf{x}) &= -\int_B \int \Phi(\mathbf{x}, \mathbf{y})(\Delta_3 + k^2)(w(\mathbf{y}) - v(\mathbf{y}))\, d\mathbf{y} \\ &= -k^2(\mathbf{T}_k w)(\mathbf{x}) \end{aligned} \tag{2.52}$$

and apply the operator $\mathbf{P}_k$ to both sides of (2.52), we arrive at the operator equation

$$w + k^2 \mathbf{P}_k \mathbf{T}_k w = 0. \tag{2.53}$$

Since $\mathbf{P}_k$ is bounded, $\mathbf{P}_k \mathbf{T}_k$ is compact, and since $\mathbf{P}_k \mathbf{T}_k$ is an analytic function of k, we can conclude from the theory of analytic Fredholm operators that $(\mathbf{I} + k^2 \mathbf{P}_k \mathbf{T}_k)^{-1}$ is a meromorphic function of k (cf. [7]). Hence, from (2.53) $w = 0$, except possibly for a discrete set of values of k. From (2.19) this implies $v = 0$ and the theorem follows. □

The discrete set of values of $k > 0$ such that the set $\mathbf{F}$ is possibly not complete consists of those numbers $k > 0$ such that $\mathbf{I} + k^2 \mathbf{P}_k \mathbf{T}_k$ is not invertible. But $\mathbf{I} + k^2 \mathbf{P}_k \mathbf{T}_k$ not being invertible is equivalent to $\mathbf{I} + k^2 \mathbf{P}_k \mathbf{T}_k \mathbf{P}_k$ not being invertible, i.e., by the Fredholm alternative and the self-adjointness of $\mathbf{P}_k$, $\mathbf{I} + k^2 \mathbf{P}_k \mathbf{T}_k^* \mathbf{P}_k$ is not invertible. This is equivalent to saying that $\mathbf{I} + k^2 \mathbf{P}_k \mathbf{T}_k^*$ is not invertible. Note that in $L_m^2(B)$ we have that

$$\mathbf{T}_k^* v = \int_B \int \bar{\Phi}(\mathbf{x}, \mathbf{y}) m(\mathbf{y}) v(\mathbf{y})\, d\mathbf{y} \tag{2.54}$$

where $\bar{\Phi}(\mathbf{x}, \mathbf{y})$ denotes the compex conjugate of $\Phi(\mathbf{x}, y)$.

DEFINITION 1. Values of $k > 0$ such that $\mathbf{I} + k^2 \mathbf{P}_k \mathbf{T}_k^*$ is not invertible are called *transmission eigenvalues.*

As noted in the Introduction, transmission eigenvalues in general exist (cf. [3] for the special case of a spherically stratified medium). The above discussion shows that the transmission eigenvalues form a discrete set if (2.25) is valid.

3. Transmission eigenvalues and the interior transmission problem. In this section of our paper we will show how the transmission eigenvalues are related to the existence of nontrivial solutions to what we will call the homogeneous interior transmission problem. If k is not a transmission eigenvalue we will show that there exists a unique

solution to the interior transmission problem first discussed in [3]. The interior transmission problem we are about to consider arises in a natural way in connection with the inverse scattering problem of determining the index of refraction $n(\mathbf{x})$ from the far-field pattern $F(\hat{\mathbf{x}}; k, \hat{\alpha})$ for fixed k, $\hat{\alpha} \in \partial\Omega$, $\hat{\mathbf{x}} \in \partial\Omega$. This was first discussed in [3] and here we will merely outline the basic ideas. The "direct approach" for solving the inverse scattering problem is to determine $n(\mathbf{x})$ from (2.10) (recalling that $m(\mathbf{x}) = 1 - n(\mathbf{x})$) and the scattering problem (2.2)-(2.4). The "dual approach" introduced by Colton and Monk in [3] is to first determine $g \in L^2(\partial\Omega)$ such that

$$\int_{\partial\Omega} F(\hat{\mathbf{x}}; k, \hat{\alpha}) g(\hat{\mathbf{x}})\, ds(\hat{\mathbf{x}}) = 1 \tag{3.1}$$

for fixed k and $\hat{\alpha} \in \partial\Omega$. Then, if we define the Herglotz wave function v by (2.18) it can be shown as in Lemma 2 (see also [6]) that (3.1) is satisfied if and only if $\{v, w\}$ satisfies the *interior transmission problem*

$$\Delta_3 w + k^2 n(\mathbf{x}) w = 0 \qquad \text{in } \Omega_b, \tag{3.2}$$

$$\Delta_3 v + k^2 v = 0 \qquad \text{in } \Omega_b, \tag{3.3}$$

$$w(\mathbf{x}) - v(\mathbf{x}) = \frac{e^{-ikr}}{r} \qquad \text{on } \partial\Omega_b, \tag{3.4}$$

$$\frac{\partial w}{\partial r}(\mathbf{x}) - \frac{\partial v}{\partial r}(\mathbf{x}) = \frac{\partial}{\partial r}\frac{e^{-ikr}}{r} \qquad \text{on } \partial\Omega_b \tag{3.5}$$

where $\Omega_b = \{\mathbf{x}: |\mathbf{x}| < b\}$, $b > a$ (note that by unique continuation $v(\mathbf{x}) = w(\mathbf{x})$ for $\mathbf{x} \in \Omega_b \backslash B$). The "dual approach" for solving the inverse scattering problem is to now determine $n(\mathbf{x})$ from (3.1) and the interior transmission problem (3.2)-(3.5) [3]. From the point of view of applications, it suffices to consider only weak solutions of the interior transmission problem, since Theorem 3.3 of [3] shows that every weak solution, if it exists, can be approximated by a classical solution $\{v_0, w_0\}$ such that v_0 is a Herglotz wave function.

DEFINITION 2. The pair $\{v, w\}$ is said to be a *weak solution* of the interior transmission problem if

(a) $v \in \bar{H}$ (where H is defined in Theorem 1),

(b) $w \in L^2_m(B)$ satisfies $v = w + k^2 \mathbf{T}_k^* w$,

(c) For $\mathbf{x} \in \partial\Omega_b$, $k^2 \mathbf{T}_k^* w = -e^{-ikr}/r$.

As remarked after Lemma 2, the *homogeneous interior transmission problem* is to find a solution $\{v, w\}$ of (3.2), (3.3) such that

$$w(\mathbf{x}) - v(\mathbf{x}) = 0 \qquad \text{on } \partial\Omega_b, \tag{3.4'}$$

$$\frac{\partial w}{\partial r}(\mathbf{x}) - \frac{\partial v}{\partial r}(\mathbf{x}) = 0 \quad \text{on } \partial\Omega_b. \tag{3.5'}$$

The corresponding weak formulation is to find a pair $\{v, w\}$ such that (a) and (b) of Definition 2 are satisfied and for $x \in \partial\Omega_b$,

$$k^2 \mathbf{T}_k^* w = 0. \tag{3.6}$$

From (3.6) and the addition formula for Bessel functions we see that since $k > 0$, $w \in H^{\perp}$, and hence if $\{v, w\}$ is a weak solution of the homogeneous interior transmission problem then

$$0 = w + k^2 \mathbf{P}_k \mathbf{T}_k^* w, \tag{3.7}$$

i.e., for a nontrivial weak solution of the homogeneous interior transmission problem to exist for $k>0$, k must be a transmission eigenvalue. Conversely, if k is a transmission eigenvalue then there exists $w\in L^2_m(B)$, $w\neq 0$, such that (3.7) is valid. Then $w\in H^{\perp}$ and hence (3.6) is true by the addition formula for Bessel functions. Furthermore, setting $\mathbf{T}_k^* w = h+\mathbf{P}_k\mathbf{T}_k^* w$, $h\in\bar{H}$, we see that $v=w+k^2\mathbf{T}_k^* w$, where $v=k^2 h\in\bar{H}$, i.e., $\{v, w\}$ is a weak nontrivial solution of the homogeneous interior transmission problem.

In [3], the existence of a unique weak solution to the interior transmission problem is proved only for values of k sufficiently small. We can now do much better.

THEOREM 2. *Suppose $k>0$. Then if k is not a transmission eigenvalue there exists a unique weak solution to the interior transmission problem.*

Proof. If two weak solutions of the interior transmission problem exist then their difference satisfies the homogeneous interior transmission problem, and, since $k>0$ is not a transmission eigenvalue, from the discussion preceding this theorem the difference must be identically zero. Hence we have established uniqueness.

To prove existence, we introduce the vector space H_0 defined by

$$H_0=\text{span}\,\{j_l(k|\mathbf{x}|)\,Y_l^m(\hat{\mathbf{x}}):\ l=1,2,\cdots,\ -l\leqq m\leqq l\} \tag{3.8}$$

and let $\mathbf{P}_k^0: L^2_m(B)\to H_0^{\perp}$ be the projection operator from $L^2_m(B)$ onto the orthogonal complement $H_0^{\perp}$ of H_0. Suppose for $k>0$ we can find a constant c and function $w\in L^2_m(B)$ such that

$$c\mathbf{P}_k^0 j_0 = w+k^2\mathbf{P}_k\mathbf{T}_k^* w, \tag{3.9}$$

$$-k^2(j_0, w)=1 \tag{3.10}$$

where $j_0(k|\mathbf{x}|)$ is the spherical Bessel function of order zero. (We note that $\mathbf{P}_k^0 j_0\neq 0$.) Then $w\in H_0^{\perp}$ and setting $j_0=h_0+\mathbf{P}_k^0 j_0$, $h_0\in\bar{H}_0$, $\mathbf{T}_k^* w=h_1+\mathbf{P}_k\mathbf{T}_k^* w$, $h_1\in\bar{H}$, we see that

$$v=w+k^2\mathbf{T}_k^* w \tag{3.11}$$

where $v=c(j_0-h_0)+k^2 h_1\in\bar{H}$. From (3.10) and the fact that $w\in H_0^{\perp}$ we see from the addition formula for Bessel functions that part (c) of Definition 2 is satisfied, i.e., $\{v, w\}$ is a weak solution of the interior transmission problem. Hence to show existence it suffices to show the existence of a solution to (3.9), (3.10).

To solve (3.9), (3.10), it suffices to find a solution w_0 of

$$\mathbf{P}_k^0 j_0 = w_0+k^2\mathbf{P}_k\mathbf{T}_k^* w_0 \tag{3.12}$$

such that $(j_0, w_0)\neq 0$, since setting $\gamma=(j_0, w_0)$, $c=-1/k^2\gamma$, $w=-w_0/k^2\gamma$ gives a solution of (3.9), (3.10). But since k is not a transmission eigenvalue we know that there exists a unique solution of (3.12). Hence to complete the proof of the theorem it suffices to show that $(j_0, w_0)\neq 0$, where w_0 is the solution of (3.12). Suppose, on the contrary, that $(j_0, w_0)=0$. Then, since from (3.12) we have that $w_0\in H_0^{\perp}$, we can conclude that in fact $w_0\in H^{\perp}$. Then, since $\mathbf{P}_k\mathbf{P}_0^0 j_0=\mathbf{P}_k j_0=0$, we have from (3.12) that $w_0+k^2\mathbf{P}_k\mathbf{T}_k^* w_0=0$, which implies that $w_0=0$ since k is not a transmission eigenvalue. But from (3.12) this is a contradiction since $\mathbf{P}_k j_0\neq 0$. Hence $(j_0, w_0)\neq 0$ and the theorem is proved. □

In conclusion, we mention two possible topics for future research that we feel are particularly interesting. The first is to see if Theorems 1 and 2 are true when $n(\mathbf{x})$ can assume the value 1, i.e., the sound speed in the inhomogeneous medium can be both greater than and less than the sound speed of the host medium. (Note that if $n(\mathbf{x})$ is identically equal to 1 then, by the unique continuation principle for the Helmholtz equation, no solution exists to the interior transmission problem for any value of k.)

The second problem of interest to consider is the inverse spectral problem of determining the index of refraction $n(\mathbf{x})$ from the transmission eigenvalues. This is of particular interest for the inverse scattering problem since, as mentioned in the Introduction, the transmission eigenvalues can be numerically determined from the far-field data.

HÖLDER'S INEQUALITY FOR FUNCTIONS OF LINEARLY DEPENDENT ARGUMENTS*

FLORIN AVRAM† AND MURAD S. TAQQU‡

Abstract. Functions with values in L^p on a torus, in $L_p(-\infty,+\infty)$, or in l_p, $1 \leqq p \leqq \infty$ are considered. These functions are allowed to have linearly dependent arguments. A generalized Hölder inequality for products of such functions is established. The proofs involve the use of convex polytypes associated with polymatroids and the Riesz–Thorin interpolation theorem.

Key words. polymatroid, convexity, L_p spaces, power counting, Riesz–Thorin

AMS(MOS) subject classifications. primary 26A16; secondary 52A25

1. The generalized Hölder inequality.

A. Here we present the generalized Hölder inequality for products of functions of linearly dependent arguments obtained in [AB] for L_p functions, $1 \leqq p \leqq \infty$, on the torus. Corresponding results for other spaces such as $L_p(-\infty,+\infty)$ and l_p are also presented. These generalized Hölder inequalities can be used to obtain central and noncentral limit theorems for dependent random variables, e.g., time series with long-range dependence (see [T] and [A]). Long-range dependence is often encountered in nature, for example, in geophysical time series and in the context of critical phenomena in physics.

B. Let M be an $m \times n$ matrix, $\mathbf{x} = (x_1, \cdots, x_m)$, and let $l_1(\mathbf{x}), \cdots, l_n(\mathbf{x})$ be n linear transformations such that

$$(l_1(\mathbf{x}), \cdots, l_n(\mathbf{x})) = (x_1, \cdots, x_m)M.$$

Let $f_j, j = 1, \cdots, n$ be functions on $L_{p_j}(d\mu)$, $1 \leqq p_j \leqq \infty$.

We want to find conditions on $z_j = 1/p_j$, $j = 1, \cdots, n$, so that the generalized Hölder inequality

$$\text{(GH)} \qquad \left| \int \prod_{j=1}^{n} f_j(l_j(\mathbf{x})) \prod_{i=1}^{m} d\mu(x_i) \right| \leqq K \prod_{j=1}^{n} \|f_j\|_{p_j}$$

holds.

The key observation is that it is enough to find those points $\mathbf{z} = (z_1, \cdots, z_n)$ with coordinates z_i equal to zero or one, for which (GH) holds; then by the Riesz–Thorin interpolation theorem, (GH) will hold for the smallest convex set generated by these points.

C. We consider the following three cases:

(Ca) μ is Lebesgue measure, normalized to unity, on the torus and the matrix M has only integer elements.

(Cb) μ is a counting measure (i.e., $\int f(x)\, d\mu(x)$ means $\sum_{x=-\infty}^{+\infty} f(x)$). Moreover,

the matrix M has only integer elements and all its nonsingular $m \times m$ minors have determinant ± 1.

(Cc) μ is Lebesgue measure and all the nonsingular $m \times m$ minors of M have determinants bounded below in absolute value by $1/K$.

D. Let A denote both a subset of columns of M and also the set of indices labeling the columns. Let $r(A)$ be the rank of the matrix with columns A. The subsets of M include $A = \varnothing$ whose rank is zero.

THEOREM. *Suppose, respectively, that conditions* (Ca), (Cb), *or* (Cc) *hold. Then the generalized Hölder inequality* (GH) *holds for any* $\mathbf{z} = (z_1, \cdots, z_n) \in [0, 1]^n$ *satisfying, respectively,*

(a1) $\sum_{j \in A} z_j \leqq r(A)$, *for all* A;

(b1) $\sum_{j \in A} z_j + r(A^c) \geqq r(M)$, *for all* A *and* $r(M) = m$;

(c1) $\sum_{j=1}^n z_j = r(M) = m$, *and either condition* (a1) *or* (b1).

The constant K *in* (GH) *equals* 1 *in cases* (Ca) *and* (Cb).

Remarks. (1) We can have $n < m$ in case (Ca) but not in cases (Cb) and (Cc). In fact, neither conditions (b1) or (c1) nor the generalized Hölder inequality (GH) are satisfied when $n < m$. (To verify that condition (b1) fails when $n < m$, take A to be all the columns of M. Then (b1) becomes $\sum_{j=1}^n z_j \geqq m$, having no solution $\mathbf{z} = (z_1, \cdots, z_n) \in [0, 1]^n$ when $n < m$.)

(2) The additional condition $\sum_{j=1}^n z_j = r(M)$ in (c1) says that (a1) (and (b1)) must be equalities when $A = M$.

In practice, it is not necessary to check that (a1) or (b1) hold for all A. It is enough to focus on flat and padded sets, which we now define.

Let $s(A)$ denote the *span* of A, i.e., the set of all linear combinations of columns in A that are contained in M. *Flats* are maximal dependent subsets, i.e., subsets of M that coincide with their span ($A = s(A)$). The set A is *padded* if any column $\mathbf{a}$ in A is also in $s(A \backslash \{\mathbf{a}\})$, i.e., if it is a linear combination of other columns of A. Note that a flat set is not necessarily a padded set (singletons are flats but not padded), nor is a padded set necessarily a flat set. For example, if M corresponds to the complete graph with 4 vertices, i.e.,

$$M = \begin{pmatrix} 1 & 0 & 0 & 1 & 1 & 0 \\ 1 & 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 1 & 0 & 1 \end{pmatrix}$$

and if A is the subset consisting of the first four columns, then A is padded but not flat.

Because $z_i \geqq 0$, condition (a1) holds if it holds for all sets A that are flats. Condition (b1) holds if it holds for all sets A^c that are flats. In fact, because $0 \leqq z_i \leqq 1$, we have the following proposition.

PROPOSITION. *Conditions* (a1) *and* (b1) *in the theorem are, respectively, equivalent to*

(a1′) $r(A) - \sum_{j \in A} z_j \geqq 0$, *for all* A *flat and padded.*

(b1′) $r(M) - r(A) - \sum_{j \in A^c} z_j \leqq 0$, *for all* A *flat and padded and* $r(M) = m$.

Remarks. (1) The sets $\varnothing$ and M are flat and $\varnothing$ is padded. The set $A = \varnothing$ always satisfies (a1′) and the set $A = M$ always satisfies the inequality in (b1′).

(2) A is independent if $r(A) = |A|$. Any flat can be expressed as $s(A)$ where A is independent and, for such A, $r(s(A)) = r(A) = |A|$. Condition (a1′) is then equivalent to

$$|A| - \sum_{j \in s(A)} z_j \geqq 0 \quad \forall A \text{ independent.}$$

Such relations, known as power counting conditions in mathematical physics, ensure the convergence of the left-hand side of (GH) when the integrands are regularly varying functions (see, for example, [FT] and [TT]).

2. Examples.

(1) As an example of (a1'), consider the integral

$$J = \int_T \int_T f_1(x_1) f_2(x_2) f_3(x_1 + x_2) f_4(x_1 - x_2)\, dx_1\, dx_2$$

where T denotes the torus $[0, 1]$, so $f_j(x \pm 1) = f_j(x)$, $j = 1, \cdots, 4$. Here $m = 2$, $n = 4$, and

$$M = \begin{pmatrix} 1 & 0 & 1 & 1 \\ 0 & 1 & 1 & -1 \end{pmatrix}$$

has rank $r(M) = 2$. The flats consist of $\varnothing$, the single columns, and M. Only $\varnothing$ and M are flat and padded. Since (a1') always holds for $\varnothing$, it is sufficient to apply it to M. The theorem yields

$$|J| \leqq \|f_1\|_{1/z_1} \|f_2\|_{1/z_2} \|f_3\|_{1/z_3} \|f_4\|_{1/z_4}$$

for any $\mathbf{z} = (z_1, z_2, z_3, z_4) \in [0, 1]^4$ satisfying $z_1 + z_2 + z_3 + z_4 \leqq 2$, e.g., if $\mathbf{z} = (0, 1, \frac{1}{4}, \frac{1}{2})$, then

$$|J| \leqq \left(\sup_{0 \leqq x \leqq 1} |f_1(x)| \right) \left(\int_0^1 |f_2(x)|\, dx \right) \left(\int_0^1 f_3^4(x)\, dx \right)^{1/4} \left(\int_0^1 f_4^2(x)\, dx \right)^{1/2}.$$

(2) To illustrate (b1'), consider

$$S = \sum_{x_1 = -\infty}^{\infty} \sum_{x_2 = -\infty}^{\infty} f_1(x_1) f_2(x_2) f_3(x_1 + x_2) f_4(x_1 - x_2).$$

Since m, n, and M are as in Example (1), we have $r(M) = m$ and the only flat and padded sets are $\varnothing$ and M. Since it is sufficient to apply (b1') to $\varnothing$, the theorem yields $|S| \leqq \|f_1\|_{1/z_1} \|f_2\|_{1/z_2} \|f_3\|_{1/z_3} \|f_4\|_{1/z_4}$ for any $\mathbf{z} = (z_1, z_2, z_3, z_4) \in [0, 1]^4$ satisfying $z_1 + z_2 + z_3 + z_4 \geqq 2$, e.g., $|S| \leqq \prod_{j=1}^4 (\sum_{x=-\infty}^{+\infty} f_j^2(x))^{1/2}$.

(3) An application of (c1) yields

$$\left| \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f_1(x_1) f_2(x_2) f_3(x_1 + x_2) f_4(x_1 - x_4)\, dx_1\, dx_2 \right| \leqq \prod_{j=1}^{4} \left(\int_{-\infty}^{+\infty} |f_j(x)|^{1/z_j}\, dx \right)^{z_j}$$

for any $\mathbf{z} = (z_1, z_2, z_3, z_4) \in [0, 1]^4$ satisfying $z_1 + z_2 + z_3 + z_4 = 2$.

(4) The usual Hölder inequality provides an extreme example of (c1), where $M = (1, \cdots, 1)$, $r(M) = m = 1$, and $r(A) = 1$, for all A. Then condition (c1) becomes $\sum_{j=1}^n z_j = 1$.

(5) The other extreme occurs when there are $n = m$ functions. If the linear transformations are of full rank ($r(M) = m$), then (c1) or a direct change of variable yields the trivial condition $z_j = 1$, $j = 1, \cdots, m$.

3. Proofs. Throughout, we consider the cases (a), (b), (c), characterized by the conditions (Ca), (Cb), (Cc), respectively.

LEMMA 1. *Let $\mathbf{z} = (z_1, \ldots, z_n)$ have all coordinates equal to zero or one, and let $A_{\mathbf{z}}$ denote the set of columns of the matrix M corresponding to those j's for which $z_j = 1$. Then* (GH) *holds if, respectively,*

(a2) $r(A_{\mathbf{z}}) = |A_{\mathbf{z}}|$ (*i.e., $A_{\mathbf{z}}$ is an "independent" set*);

(b2) $r(A_{\mathbf{z}}) = r(M) = m$ (*i.e., $A_{\mathbf{z}}$ is a "generating" set*);

(c2) $r(A_{\mathbf{z}}) = |A_{\mathbf{z}}| = r(M) = m$ (*i.e., $A_{\mathbf{z}}$ is a "basis"*).

The constant K in (GH) *equals* 1 *in cases* (a) *and* (b).

Proof. We replace $x_1, \cdots, x_m$ by a linear combination of new variables $u_1, \cdots, u_m$, as follows. In case (a), we have $r(A_{\mathbf{z}}) = |A_{\mathbf{z}}| \leqq m$. We let the $u_i = x_i$, $i = 1, \cdots, m - |A_{\mathbf{z}}|$ and set the remaining u_i's equal to the $l_j(\mathbf{x}), j \in A_{\mathbf{z}}$. In case (b) we let the u_i's be any independent subset of the $l_j(\mathbf{x}), j \in A_{\mathbf{z}}$. In case (c), we set $u_i = l_i(\mathbf{x})$, $i \in A_{\mathbf{z}}$.

In each of the cases, after switching to the new variables and bounding f_j by $|f_j|$, we can move the sup norms $\|f_j\|_{1/0}, j \notin A_{\mathbf{z}}$ outside the integrals. The conditions of the lemma ensure that what remains, namely $\prod_{j \in A_{\mathbf{z}}} |f_j|$, is integrable.

Note that in case (a), no constant K appears because the multiplicity of the linear map over the torus exactly cancels the Jacobian of the transformation. Note also that in the case (b), there may be more functions $|f_j|$ with $z_j = 1$ than variables u_j. But the multiple sum only increases if the arguments of these $|f_j|$ are changed to new arguments independent of u_i, $i = 1, \cdots, m$, and if these new arguments are summed. □

LEMMA 2. *The conditions* (a2), (b2), (c2) *and* (a1), (b1), (c1) *are, respectively, equivalent for points $\mathbf{z} = (z_1, \cdots, z_n)$ whose coordinates are all equal to zero or one.*

Proof. (a) $r(A_{\mathbf{z}}) = |A_{\mathbf{z}}|$ is equivalent to: for all $A \subset A_{\mathbf{z}}$, $r(A) = |A| = \sum_{j \in A} z_j$. For general A, write $A = A' \cup A''$, where $A' \subset A_{\mathbf{z}}$, $A'' \subset A_{\mathbf{z}}^c$. Then $\sum_{j \in A} z_j = \sum_{j \in A'} z_j = r(A') \leqq r(A' \cup A'') = r(A)$.

(b) One direction follows from

$$\begin{aligned} \sum_{j \in A} z_j + r(A^c) &= |A \cap A_{\mathbf{z}}| + r(A^c) \\ &\geqq r(A \cap A_{\mathbf{z}}) + r(A^c) \\ &\geqq r(A \cap A_{\mathbf{z}}) + r(A^c \cap A_{\mathbf{z}}) \\ &\geqq r(A_{\mathbf{z}}) \\ &= r(M) = m. \end{aligned}$$

To get the other direction, set $A^c = A_{\mathbf{z}}$.

(c) Suppose $\sum_{i=1}^n z_i = r(M) = m$. Then (a1) and (b1) are equivalent because when either one holds,

$$\sum_{j=1}^n z_j = \sum_{j \in A} z_j + \sum_{j \in A^c} z_j \leqq \sum_{j \in A} z_j + r(A^c).$$

So (c1)⇒(c2) by parts (a) and (b). To get (c2)⇒(c1) note that $|A_{\mathbf{z}}| = m \Leftrightarrow \sum_{j=1}^n z_j = m$, and use parts (a) and (b). □

Proof of the theorem. Consider the convex domain in $[0, 1]^n$ generated by $\mathbf{z} = (z_1, \cdots, z_n)$ satisfying condition (a1), (b1), (c1), respectively. The extreme points of the domain have coordinates all equal to zero or one.

Indeed, in case (a), condition (a1) characterizes the independent polytope of a polymatroid with the rank $r(\cdot)$ as submodular function [W, Thm. 18.3.1]. Edmonds' formula [W, Thm. 18.4.1] applies. The formula relates coordinates of the extreme points of the independence polytope to rank differences. Since all coordinates lie in [0, 1] and since the rank function is integer-valued, the coordinates of the extreme points can only be zero or one.

In case (b), let r^* be the rank function of the dual matroid [W, Thm. 2.1.2], i.e., $r^*(A)=|A|-r(M)+r(A^c)$. Condition (b1) can be rewritten $\sum_{j\in A}(1-z_j)\leqq |A|-r(M)+r(A^c)$, i.e.,

$$\sum_{j\in A}(1-z_j)\leqq r^*(A).$$

Edmonds' formula then applies to $1-z_j$.

Finally, in case (c), the extreme points for (c1) are a subset of the extreme points for (a1) and (b1).

Thus, by Lemmas 2 and 1, the generalized Hölder inequality (GH) holds for all $\mathbf{z}=(z_1,\ldots,z_n)$ that are extreme points of the convex domain characterized by (a1), (b1), (c1), respectively. To show that it holds for all $\mathbf{z}$ belonging to the convex domain use the Riesz-Thorin interpolation theorem [BL, Exercise 1.6.13, p. 18] with $z_j=1/p_j$ and $T=L_{p_1}\times\cdots\times L_{p_n}\to L_1$. □

Proof of the proposition. To prove (a1′)⇒(a1), we must show that $d(A)\equiv r(A)-\sum_{j\in A}z_j\geqq 0$ for all A. If A is padded and flat, then $d(A)\geqq 0$ by (a1′). If A is padded and not flat, then

$$d(A)\geqq r(A)-\sum_{j\in s(A)}z_j=r(s(A))-\sum_{j\in s(A)}z_j=d(s(A))\geqq 0 \tag{1}$$

by (a1′) since $s(A)$ is padded and flat. If A is not padded, there exists a column $\mathbf{a}_i\in A$ such that $\mathbf{a}_i\notin s(A\backslash\{\mathbf{a}_i\})$ are hence

$$d(A)=d(A\backslash\{\mathbf{a}_i\})+1-z_i\geqq d(A\backslash\{\mathbf{a}_i\}). \tag{2}$$

If $d(A\backslash\{\mathbf{a}_i\})\geqq 0$, we are done. If it is not, keep repeating the argument and use the fact that $d(\varnothing)\geqq 0$.

To prove (b1′)⇒(b1), we must show that $d'(A)\equiv r(M)-r(A)-\sum_{j\in A^c}z_j\geqq 0$ for all A. An argument similar to the preceding one applies. Merely replace (1) by

$$d'(A)\leqq r(M)-r(A)-\sum_{j\in(s(A))^c}z_j=r(M)-r(s(A))-\sum_{j\in(s(A))^c}z_j=d'(s(A))\leqq 0$$

and (2) by

$$d'(A)=d(A\backslash\{\mathbf{a}_i\})-1+z_i\leqq d(A\backslash\{\mathbf{a}_i\}).$$

We have $d(\varnothing)\leqq 0$ since $\varnothing$ is padded and flat. □

4. Extension. It is natural to expect that a generalized Hölder inequality holds for functions of several variables $f_j(x_1,\cdots,x_k)$ belonging to a tensor product space $L_{p_1}\otimes\cdots\otimes L_{p_k}$. There are many such tensor product spaces [LC]. The smallest one (corresponding to the greatest cross norm) is defined as follows: if f is a finite sum of products, then

$$\|f\|_{p_1,\cdots,p_k}=\inf\sum_{u=1}^{s}\prod_{v=1}^{k}\|f^{(u,v)}(x_v)\|_{p_v},$$

where the infimum is taken over all decompositions of $f(x_1,\cdots,x_k)$ in the form $\sum_{u=1}^{s}\prod_{v=1}^{k}f^{(u,v)}(x_v)$. The corresponding tensor space is obtained by completing the set of finite sums of products under this norm. A natural analogue of the theorem holds for such a space (e.g., see [AB, Thm. 1′]). It would be interesting to find out whether (GH) holds over larger L_p tensor product spaces (corresponding to smaller cross norms).

Acknowledgment. We thank Norma Terrin for useful discussions.

FUCHSIAN SYSTEMS ASSOCIATED WITH THE $P^2(\mathbb{F}_2)$-ARRANGEMENT*

KOUICHI SAKURAI† AND MASAAKI YOSHIDA‡

Abstract. A family of Fuchsian systems of differential equations in two variables that interpolate Appell's F_1 and F_4 are constructed. Their geometric properties are also studied.

Key words. Fuchsian system, Appell's hypergeometric equations, orbifold, uniformization, Weyl group

AMS(MOS) subject classification. 33A35

0. Introduction. In this paper, we construct a family $E(s)$ of Fuchsian differential equations, depending on the two-dimensional parameter s, defined on the complex projective plane $M=\mathbb{C}P^2$ with regular singularities along

$$H: xyz(x-y)(y-z)(z-x)\{(x+y-z)^2-4xy\}=0$$

where $[x, y, z]$ is a system of homogeneous coordinates on M.

We call this arrangement H, of six lines and one conic, the $P^2(\mathbb{F}_2)$-arrangement, because the set of lines in the projective plane $P^2(\mathbb{F}_2)$ over the finite field $\mathbb{F}_2=\{0, 1\}$ consists of seven lines corresponding to the seven components of H. The arrangement H relates the Weyl group $W(F_4)$ of type F_4 as follows. The 24 mirrors of the reflections in the Coxeter group F_4 defines a hyperplane arrangement in $\mathbb{C}^4$. Passing to $\mathbb{C}P^3$, this arrangement defines a plane arrangement in $\mathbb{C}P^3$ called the $W(F_4)$-arrangement. The restriction $\tilde{H}$ of the $W(F_4)$-arrangement to any projective plane N in the arrangement consists of 13 lines in $\mathbb{C}P^2$ that can be given by the equation

$$\tilde{H}: XYZ(X^2-Y^2)(Y^2-Z^2)(Z^2-X^2)(X+Y+Z)(-X+Y+Z)(X-Y+Z)\cdot(X+Y-Z)=0$$

where $[X, Y, Z]$ is a system of homogeneous coordinates on N. The arrangement H is the image of $\tilde{H}$ under the map $\pi: N\to M$ given by

$$\pi: [X, Y, Z]\to[x, y, z]=[X^2, Y^2, Z^2].$$

The map π is the quotient map by the group $K(\simeq\mathbb{Z}_2+\mathbb{Z}_2)$ generated by $[X, Y, Z]\to[-X, Y, Z]$ and $[X, Y, Z]\to[X, -Y, Z]$ (see Fig. 1).

The two subarrangements

$$H': xyz(x-y)(y-z)(z-x)=0, \qquad H'': xyz\{(x+y-z)^2-4xy\}=0$$

of the arrangement H are well known as the singular loci of Appell's hypergeometric differential equations F_1 and F_4, respectively (see Fig. 2). Our equation interpolates the equation F_1 and the modified equation F_4' (see § 2) of F_4. More precisely, for some special values of the parameter s, our equation $E(s)$ turns out to be the equation F_1 and for some other special values of s, it turns out to be the equation F_4'. Moreover, the principal parts of the equations $E(s)$, after some normalization, are *linear* combinations of those of the equations F_1 and F_4'. We must say that it is a surprising result if we recall the nonlinearity of the integrability condition (see § 1). This mysterious phenomenon is also reported in [Yos2].

For some special values of the parameter s, the equation $E(s)$ happens to give the uniformizing equations (see § 3) of the hyperbolic orbifolds found by Hunt and

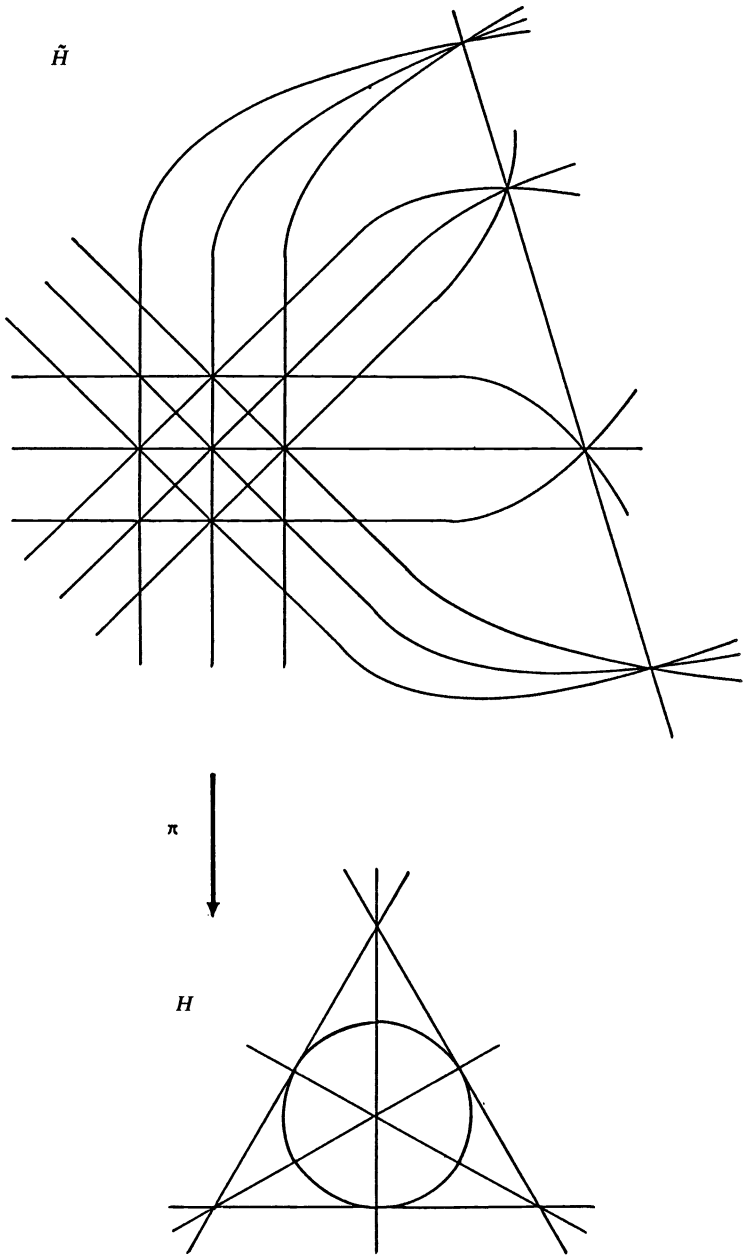

FIG. 1

Höfer [Hun], [Höf], where a hyperbolic orbifold is an orbifold whose universal uniformization is the complex unit ball $\mathbb{B}^2 = \{(z_1, z_2) \in \mathbb{C}^2 \mid |z_1|^2 + |z_2|^2 < 1\}$.

1. The main theorem. We consider a system in the form

$$\text{(E)} \qquad \frac{\partial^2 w}{\partial x_i \partial x_j} = \sum_{k=1}^{2} P_{ij}^k(x) \frac{\partial w}{\partial x_k} + P_{ij}^0(x) w, \qquad i, j = 1, 2$$

defined on $M = \mathbb{C}P^2$, where w is the unknown and $x = (x_1, x_2)$ is a system of inhomogeneous coordinates on M.

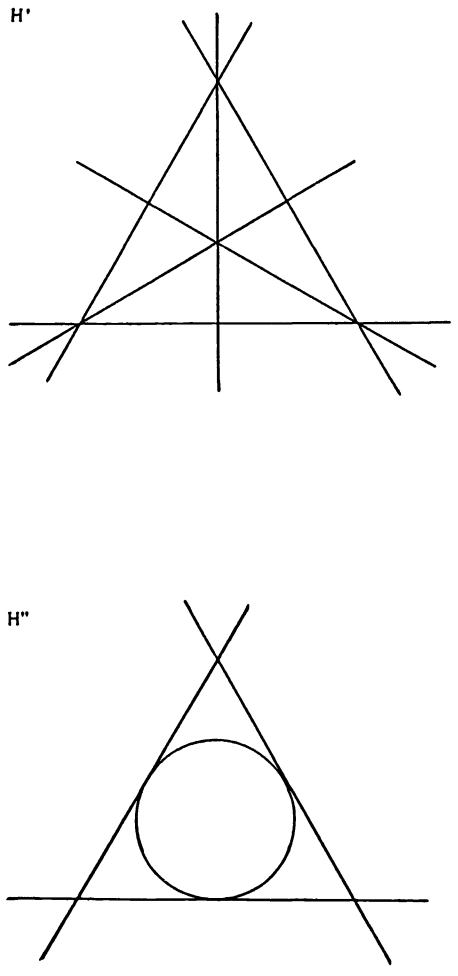

FIG. 2

DEFINITION. System (E) is said to be *in normal form* if

$$\text{(N)} \qquad \sum_{j=1}^{2} P_{ij}^{j}(x) = 0 \quad \text{for } i = 1, 2.$$

DEFINITION. System (E) is said to be *completely integrable* if (E) has three linearly independent solutions.

Any completely integrable system in the form (E) can be transformed into the uniquely determined system in normal form by replacing the unknown w by its product with a nonzero function of x. The consequent system is called the *normal form* of (E) [Yos1].

It is known [Yos3] that (E) in normal form is completely integrable if and only if the coefficients $\{P_{ij}^{k}\}$ satisfy the following equations:

$$P_{ij}^{k}(x) = P_{ji}^{k}(x), \qquad i, j = 1, 2, \quad k = 0, 1, 2,$$

$$P_{11}^{0}(x) = -\frac{\partial P_{11}^{1}(x)}{\partial x_1} - \frac{\partial P_{11}^{2}(x)}{\partial x_2} + 2\{P_{11}^{1}(x)\}^2 - 2P_{22}^{2}(x)P_{11}^{2}(x),$$

$$P^0_{12}(x)=\frac{\partial P^2_{22}(x)}{\partial x_1}+\frac{\partial P^1_{11}(x)}{\partial x_2}+P^1_{22}(x)P^2_{11}(x)-P^1_{11}(x)P^2_{22}(x),$$

$$P^0_{22}(x)=-\frac{\partial P^2_{22}(x)}{\partial x_2}-\frac{\partial P^1_{22}(x)}{\partial x_1}+2\{P^2_{22}(x)\}^2-2P^1_{11}(x)P^1_{22}(x),$$

$$(IC)_1 := -2\frac{\partial^2 P^1_{11}(x)}{\partial x_1\partial x_2}-\frac{\partial^2 P^2_{11}(x)}{\partial x_2^2}+6P^1_{11}(x)\frac{\partial P^1_{11}(x)}{\partial x_2}-3P^2_{11}(x)\frac{\partial P^2_{22}(x)}{\partial x_2}$$
$$-3P^2_{22}(x)\frac{\partial P^2_{11}(x)}{\partial x_2}+3P^1_{11}(x)\frac{\partial P^2_{22}(x)}{\partial x_1}-\frac{\partial^2 P^2_{22}(x)}{\partial x_1^2}$$
$$-2P^2_{11}(x)\frac{\partial P^2_{11}(x)}{\partial x_1}-P^1_{22}(x)\frac{\partial P^2_{11}(x)}{\partial x_1}=0,$$

$$(IC)_2 := -2\frac{\partial^2 P^2_{22}(x)}{\partial x_2\partial x_1}-\frac{\partial^2 P^1_{22}(x)}{\partial x_1^2}+6P^2_{22}(x)\frac{\partial P^2_{22}(x)}{\partial x_1}-3P^1_{22}(x)\frac{\partial P^1_{11}(x)}{\partial x_1}$$
$$-3P^1_{11}(x)\frac{\partial P^1_{22}(x)}{\partial x_1}+3P^2_{22}(x)\frac{\partial P^1_{11}(x)}{\partial x_2}-\frac{\partial^2 P^1_{11}(x)}{\partial x_2^2}$$
$$-2P^1_{22}(x)\frac{\partial P^2_{11}(x)}{\partial x_2}-P^2_{11}(x)\frac{\partial P^1_{22}(x)}{\partial x_2}=0.$$

LEMMA 1 [Yos3]. *Let $Q^k_{ij}(\xi)$ $(i,j,k=1,2)$ be the coefficients of the normal form of the transformed system of* (E) *by the coordinate change $\xi=\xi(x)$. Then we have*

$$Q^k_{ij}(\xi)=\sum_{l=1}^{2}\frac{\partial^2\xi_l}{\partial x_i\partial x_j}\frac{\partial x_k}{\partial \xi_l}-\frac{1}{3}\left(\delta^k_i\frac{\partial}{\partial x_j}+\delta^k_j\frac{\partial}{\partial x_i}\right)\log\left(\det\left(\frac{\partial\xi}{\partial x}\right)\right)$$
$$+\sum_{p,q,r=1}^{2}P^r_{pq}(x)\frac{\partial\xi_p}{\partial x_i}\frac{\partial\xi_q}{\partial x_j}\frac{\partial x_k}{\partial\xi_r}$$

where δ^k_j is the Kronecker symbol.

If $Q^k_{ij}(x)=P^k_{ij}(x)$ $(i,j,k=1,2)$, then the system (E) is said to be *invariant* under the transform $x\to\xi$.

DEFINITION. *A projective solution* of a completely integrable system (E) is the pair $z=(z_1,z_2)$ of ratios $z_i=w_i/w_0$ $(i=1,2)$ of three linearly independent solutions w_0, w_1, and w_2 of (E).

DEFINITION. A projective solution of (E) is said to be *ramifying at $O=(0,0)$ along $x_1=0$ with exponent α* if there exists a projective solution $z=(z_1,z_2)$, which is expressed as follows:

$$z_1(x)=x_1^\alpha v_1,\quad z_2(x)=v_2,\quad \det\left(\frac{\partial z}{\partial x}\right)=x_1^{\alpha-1}u$$

for some $\alpha\in\mathbb{C}$, where v_1, v_2, and u are holomorphic at O, not divisible by x_1.

LEMMA 2 [Yos2]. *If a projective solution of* (E) *in normal form is ramifying along $x_1=0$ with exponent α, then the coefficients P^k_{ij} of* (E) *have the following properties*:

(R) $P^2_{22}(x)$, $x_1P^2_{11}(x)$, $(1/x_1)\,P^1_{22}(x)$, *and* $P^1_{11}(x)-(\alpha-1/3x_1)$ *are holomorphic.*

DEFINITION. System (E) in the normal form is said to have *ramifying singularities* along $x_1=0$ with exponent α if the condition (R) holds.

To state the theorem we prepare some notation. Let $[x, y, z]$ be a system of homogeneous coordinates on M related to (x_1, x_2) by $x_1 = x/z$ and $x_2 = y/z$. Let $H_i (i = 1, \cdots, 7)$ denote the following curves:

$$H_1: \{x = 0\}, \quad H_2: \{y = 0\}, \quad H_3: \{z = 0\}, \quad H_4: \{x = y\},$$
$$H_5: \{y = z\}, \quad H_6: \{z = x\}, \quad H_7: \{(x+y-z)^2 - 4xy = 0\},$$

so we have $H = \bigcup_{i=1}^{7} H_i$. Let G be the transformation group on M generated by $[x, y, z] \to [z, x, y]$ and $[x, y, z] \to [y, x, z]$. Note that G is isomorphic to the symmetric group in three letters.

THEOREM. *For given complex numbers $s_i \neq 1$ $(i = 1, \cdots, 7)$, there is a completely integrable differential equation $E(s)$, in normal form, with ramifying singularities along H_i with exponent s_i if and only if*

$$s_1 = s_2 = s_3, \quad s_4 = s_5 = s_6, \quad 6s_1 - 3s_4 - 2s_7 + 2 = 0.$$

(In particular, $E(s)$ is G-invariant.) The four coefficients of $(E(s))$ are explicitly given as follows:

$$P^1_{11}(x_1, x_2) = \frac{S^1}{x_1} + \frac{S^4(x_1 - 2x_2 + 1)}{2(x_1 - 1)(x_1 - x_2)} + \frac{4S^7 x_2}{(x_1 + x_2 - 1)^2 - 4x_1 x_2},$$

$$P^2_{11}(x_1, x_2) = \frac{-3S^4 x_2(x_2 - 1)}{2x_1(x_1 - 1)(x_1 - x_2)} + \frac{4S^7 x_2(x_2 - 1)}{x_1\{(x_1 + x_2 - 1)^2 - 4x_1 x_2\}},$$

$$P^1_{22}(x_1, x_2) = P^2_{11}(x_2, x_1), \qquad P^2_{22}(x_1, x_2) = P^1_{11}(x_2, x_1),$$

where $S^i = \frac{1}{3}(s_i - 1)$.

Remark. Other coefficients P^k_{ij} of (E) are uniquely determined by the equalities (N) and by the assumption that (E) is completely integrable. Therefore, in the sequel, to describe the system (E) in normal form we give only the four coefficients P^1_{11}, P^2_{11}, P^2_{22}, and P^1_{22} of (E).

2. Relation between $E(s)$ and Appell's hypergeometric differential equations. Appell's hypergeometric equation $F_1(a, b, b', c)$ is a differential equation with regular singularities on $\bigcup_{i=1}^{6} H_i$, while it is nonsingular along H_7. The normal form of $F_1(a, b, b', c)$ is given by

$$P^1_{11}(a, b, b', c; x_1, x_2)$$
$$= \frac{1}{3} \frac{x_2(x_2 - 1)}{f_1} \{(c - b')x_2 + (2b - c)x_1 + (b' - (a + b + 1))x_1 x_2 + (a - b + 1)x_1^2\},$$

$$P^2_{11}(a, b, b', c; x_1, x_2) = \frac{(x_2(x_2 - 1))^2}{f_1} b,$$

$$P^2_{22}(a, b, b', c; x_1, x_2) = P^1_{11}(a, b', b, c; x_2, x_1),$$

$$P^1_{22}(a, b, b', c; x_1, x_2) = P^2_{11}(a, b', b, c; x_2, x_1),$$

where $f_1 = x_1 x_2 (x_1 - 1)(x_2 - 1)(x_1 - x_2)$.

PROPOSITION 1. *Equation $E(s)$ with $s_7 = 1$ coincides with the normal form of Appell's F_1 which is G-invariant. Precise correspondence between $E(s) = E(s_1, s_2, s_3)$ and $F_1(a, b, b', c)$ is given by*

$$E(s_1, s_4, 1) = F_1(-s_1 - s_4 + 1, -\tfrac{1}{2}(s_4 - 1), -\tfrac{1}{2}(s_4 - 1), -\tfrac{1}{2}(2s_1 + s_4 - 3)).$$

This identity is valid for all $s_1, s_4 \in \mathbb{C}$.

Appell's hypergeometric equation $F_4(a, b, c, c')$ is a differential equation with four linearly independent solutions and has regular singularities on $\bigcup_{i=1}^{3} H_i \cup H_7$, while it is nonsingular along $\bigcup_{i=4}^{6} H_i$. The solution space of $F_4(a, b, c, c')$ has three-dimensional invariant subspace if $b = c + c' + 1$ [Kat]. The corresponding equation is called the modified F_4 and denoted by $F_4'(a, b, c, c')$. The four coefficients of the normal form of $F_4'(a, b, c, c')$ are given by

$$P_{11}^1(a, b, c, c'; x_1, x_2) = -\frac{1}{3}\frac{1}{f_4}\{c(x_2-1)^2 + (a-(b+c+2c'-1))x_1 + (a+5b-c-2c'+1)x_1x_2 + (a-(b+2c'-1))x_1^2\},$$

$$P_{11}^2(a, b, c, c'; x_1, x_2) = \frac{x_2^2}{f_4}\{(a-b-c'+1)x_1 + (a+b-c'+1)(1-x_2)\},$$

$$P_{22}^2(a, b, c, c'; x_1, x_2) = P_{11}^1(a, b, c', c; x_2, x_1),$$

$$P_{22}^1(a, b, c, c'; x_1, x_2) = P_{11}^2(a, b, c', c; x_2, x_1),$$

where $f_4 = x_1x_2\{(x_1+x_2-1)^2 - 4x_1x_2\}$.

PROPOSITION 2. *Equation $E(s)$ with $s_4 = 1$ coincides with the normal form of Appell's modified F_4, which is G-invariant. Precise correspondence between $E(s)$ and $F_4'(a, b, c, c')$ is given by*

$$E(s_1, 1, 3s_1 - \tfrac{1}{2}) = F_4'(-3s_1+1, 2s_1+1, -s_1+1, -s_1+1).$$

3. Uniformizing equations of some hyperbolic orbifolds. We briefly recall the definitions of orbifolds and their uniformizations. Let X be a complex manifold, let S be a hypersurface of X, let $S = \bigcup_j S_j$ be its decomposition into irreducible components, and let b_j be either infinity or an integer called the weight attached to the corresponding S_j. The triple (X, S, b) is called an *orbifold* if for every point in $X - \bigcup \{S_j \mid b_j = \infty\}$ there is an open neighborhood U and a covering manifold that ramifies along $U \cap S$ with the given indices b. It is called *uniformizable* if there is a global covering manifold (called a *uniformization*) of X with the given ramification datum (S, b). If X is uniformizable, there exists a uniformization $\tilde{X}$ that is simply connected, called the *universal uniformization*. Let X be an orbifold and $\tilde{X}$ be its universal uniformization. The multivalued inverse map $X \to \tilde{X}$ of the projection $\tilde{X} \to X$ is called the *developing map*.

If the universal uniformization of an orbifold (X, S, b) is isomorphic to the complex ball (we call such an orbifold hyperbolic), there exists a unique Fuchsian differential equation in normal form such that its projective solution gives the developing map. The equation is called the *uniformizing equation* of the orbifold (X, S, b). For more details see [Yos2].

In his thesis, Hunt [Hun] has studied N-dimensional hyperbolic orbifolds. He has discovered a three-dimensional hyperbolic orbifold attached to the $W(\mathbb{F}_4)$-arrangement. Restricting to a plane in the $W(\mathbb{F}_4)$-arrangement, we have a two-dimensional hyperbolic orbifold attached to a line arrangement in $\mathbb{C}P^2$—the $P^2(\mathbb{F}_2)$-arrangement. Furthermore, Höfer [Höf] has shown that there are only four hyperbolic orbifolds over this arrangement. These orbifolds are given as follows. Consider the arrangement $\tilde{H}$ in N. Define the weight function b on N as in Table 1 (see Fig. 3).

COROLLARY. *Uniformizing differential equations of the above orbifolds are obtained by pulling back $E(s)$ under the map π, where the values of the parameter s are given as in Table 2.*

Remark. In the case where $s_7=1$, $E(s)$ reduces to Appell's F_1, which has been studied by Terada [Ter] and Deligne and Mostow [DM].

4. Proof of the results. Let the projective planes M, N, arrangements $\tilde{H}$, H, the group K, and the projection $\pi: N \to M$ be as above. The arrangement $\tilde{H}$ in N consists of 13 lines:

$$\tilde{H}_1=\{X=0\}, \quad \tilde{H}_2=\{Y=0\}, \quad \tilde{H}_3=\{Z=0\},$$
$$\tilde{H}_4=\{X^2-Y^2=0\}, \quad \tilde{H}_5=\{Y^2-Z^2=0\}, \quad \tilde{H}_6=\{Z^2-X^2=0\},$$
$$\tilde{H}_7=\{(X+Y+Z)(-X+Y+Z)(X-Y+Z)(X+Y-Z)=0\}.$$

Note that $\pi(\tilde{H}_i)=H_i$ $(i=1,\cdots,7)$ and $\pi(\tilde{H})=H$.

We construct a K-invariant differential equation $(\tilde{E})$ defined on N with ramifying singularities along $\tilde{H}_i$ with exponent t_i $(i=1,\cdots,7)$. We follow the method established in [Yos3].

LEMMA 3 [Yos3]. *If* (E) *has ramifying singularities along the line at infinity, then the total degree of the rational function* $P^k_{ij}(x)$ *is negative for* $i, j, k=1, 2$.

By Lemma 3, we can put

$$\tilde{P}^1_{11}=X_2(X_2^2-1)A/F, \quad \tilde{P}^2_{11}=X_2^2(X_2^2-1)^2B/F,$$
$$\tilde{P}^2_{22}=X_1(X_1^2-1)C/F, \quad \tilde{P}^1_{22}=X_1^2(X_1^2-1)^2D/F,$$

where

$$A=\sum_{i+j\leqq 8} a(i,j)X_1^iX_2^j, \quad B=\sum_{i+j\leqq 5} b(i,j)X_1^iX_2^j,$$
$$C=\sum_{i+j\leqq 8} c(i,j)X_1^iX_2^j, \quad D=\sum_{i+j\leqq 5} d(i,j)X_1^iX_2^j,$$
$$F=X_1X_2(X_1^2-1)(X_2^2-1)(X_1^2-X_2^2)(X_1+X_2+1)(-X_1+X_2+1)(X_1-X_2+1)\cdot(X_1+X_2-1).$$

The assumption that the system (E) is K-invariant says that

$$a(i,j)=c(i,j)=0 \quad \text{unless } i\equiv j\equiv 0 \bmod 2,$$
$$b(i,j)=0 \quad \text{unless } i+1\equiv j\equiv 0 \bmod 2,$$
$$d(i,j)=0 \quad \text{unless } i\equiv j+1\equiv 0 \bmod 2.$$

Applying Lemma 2, along every component of $\tilde{H}$, we obtain finitely many linear equations with unknowns $a(i,j),\cdots,d(i,j)$. By solving these, all the coefficients $a(i,j),\cdots,d(i,j)$ are expressed in terms of t_i $(i=1,\cdots,7)$:

$$\begin{aligned}A(X_1,X_2)=&-T^1(X_1^2-1)(X_1^2-X_2^2)\{(X_1^2+X_2^2-1)^2-4X_1^2X_2^2\}\\&-T^4X_1^2(X_1^2-2X_2^2+1)\{(X_1^2+X_2^2-1)^2-4X_1^2X_2^2\}\\&-8T^7X_1^2X_2^2(X_1^2-1)(X_1^2-X_2^2),\end{aligned}$$
$$B(X_1,X_2)=3T^4X_1\{(X_1^2+X_2^2-1)^2-4X_1^2X_2^2\}-8T^7X_1(X_1^2-1)(X_1^2-X_2^2),$$
$$C(X_1,X_2)=-A(X_2,X_1), \quad D(X_1,X_2)=-B(X_2,X_1),$$

where $T^i=\frac{1}{3}(t_i-1)$; moreover, these linear equations require that t_i's satisfy $T^1=T^2=T^3$, $T^4=T^5=T^6$, $3T^1-3T^4-2T^7=0$.

Now we study the integrability condition. The integrability condition of $\tilde{E}(t)$ is given by

$$(IC)_1=-64T^7(3T^1-3T^4-2T^7)X_1^2X_2^3(X_1^2-1)^2(X_2^2-1)^3(X_1^2-X_2^2)^2/F^2,$$
$$(IC)_2=-64T^7(3T^1-3T^4-2T^7)X_1^3X_2^2(X_1^2-1)^3(X_2^2-1)^2(X_1^2-X_2^2)^2/F^2.$$

Since the parameter has the relation such that $3T^1-3T^4-2T^7=0$, we have $(IC)_1=(IC)_2=0$.

Finally, we project $\tilde{E}(t)$ by the quotient map $\pi: M \to M/K \cong N$, where π is given by $(X_1, X_2) \to (x_1, x_2)=(X_1^2, X_2^2)$. By Lemma 1, coefficients P_{ij}^k of the normal form of $\pi(\tilde{E}(t))$ are given as follows:

$$P_{11}^1(x)=-\frac{1}{6x_1^2}+\frac{1}{2x_1}\tilde{P}_{11}^1(X), \qquad P_{22}^2(x)=-\frac{1}{6x_2^2}+\frac{1}{2x_2}\tilde{P}_{22}^2(X),$$

$$P_{11}^2(x)=\frac{x_2}{2x_1^2}\tilde{P}_{11}^2(X), \qquad P_{22}^1(x)=\frac{x_1}{2x_2^2}\tilde{P}_{22}^1(X).$$

Since π is branching along only the three lines $\bigcup_{i=1}^3 H_i$ with indices 2, there are the relations among the exponents such that $t_1=2s_1$, $t_4=s_4$, and $t_7=s_7$. Thus we obtain the differential equations we want. Easy calculations show the remaining claims of the theorem.

Propositions 1 and 2 are proved by straightforward computation, so we omit the detail. If $s_7=1$, the equations $(IC)_1=(IC)_2=0$ are satisfied. This proves the last statement of Proposition 1.

5. Linear structure of the set of solutions of the nonlinear differential equation (IC). The integrability condition

IC $$(IC)_1=(IC)_2=0$$

of (E) with (N) is a system of nonlinear differential equations with unknowns $\{P_{ij}^k\}=\{P_{11}^1=-P_{12}^2, P_{11}^2, P_{22}^1, P_{22}^2=-P_{12}^1\}$. There is a one-to-one correspondence between the set of solutions of **IC** and the set of completely integrable systems (E) in normal form. We have a great interest in rational solutions of **IC** of which corresponding systems (E) have transcendental solutions. The method used in § 4 is a practical one for finding such solutions.

Since the system **IC** is by no means linear, we cannot expect that linear combinations $\{t_1R_{ij}^k+t_2Q_{ij}^k\}(t_1, t_2 \in \mathbb{C})$ of two solutions $\{R_{ij}^k\}$ and $\{Q_{ij}^k\}$ of **IC** are also solutions of **IC**; indeed, it is not true in general. But sometimes miracles occur. Propositions 1 and 2 say that the coefficients $\{P_{ij}^k\}$ of the principal parts of $E(s)$ are linear combinations of the coefficients of the principal parts of the normal form of Appell's F_1 (with a special parameter) and those of the system F_4' (with a special parameter). In [Yos2], it is shown that linear combinations $\{t_1R_{ij}^k+t_2Q_{ij}^k\}$ of two solutions $\{R_{ij}^k\}$ and $\{Q_{ij}^k\}$ of **IC** are solutions of **IC**:

$\{R\}$
$$R_{11}^1(x, y)=3/x+81x^2y^3(2-x^3-y^3)/w,$$
$$R_{11}^2(x, y)=81xy(1+x^3-y^6-x^3y^3)/w,$$
$$R_{22}^2(x, y)=R_{11}^1(y, x), \qquad R_{22}^1(x, y)=R_{11}^2(y, x),$$

$\{Q\}$
$$Q_{11}^1(x, y)=3x^2(y^3-1)(1+x^3-2y^3)/2h,$$
$$Q_{11}^2(x, y)=-9xy(y^3-1)^2/2h,$$
$$Q_{22}^2(x, y)=Q_{11}^1(y, x), \qquad Q_{22}^1(x, y)=Q_{11}^2(y, x),$$

where

$$w=\prod_{a,b=0}^{2}(\omega^a x+\omega^b y+1)=(x^3+y^3+1)^3-27x^3y^3,$$
$$h=(x^3-1)(y^3-1)(x^3-y^3).$$

These two examples suggest the existence of some linear structure of the set of solutions of **IC** that is as yet veiled in mystery.

We conclude this paper by giving a useful system to test whether $t_1R_{ij}^k+t_2Q_{ij}^k$ $(t_1, t_2\in\mathbb{C})$ are solutions of **IC**.

PROPOSITION 3. *Let* $\{R_{ij}^k\}$ *and* $\{Q_{ij}^k\}$ *be solutions of* **IC**. *Then*:

(1) *For all* $t\in\mathbb{C}$, $\{tR_{ij}^k\}$ *are solutions of* **IC** *if and only if* $\{R_{ij}^k\}$ *satisfy the following conditions*:

$$2\frac{\partial^2 R_{11}^1}{\partial x_1\partial x_2}+\frac{\partial^2 R_{11}^2}{\partial x_2^2}+\frac{\partial^2 R_{22}^2}{\partial x_1^2}=0,$$

$$2\frac{\partial^2 R_{22}^2}{\partial x_2\partial x_1}+\frac{\partial^2 R_{22}^1}{\partial x_1^2}+\frac{\partial^2 R_{11}^1}{\partial x_2^2}=0.$$

(2) $\{R_{ij}^k+Q_{ij}^k\}$ *is a solution of* **IC** *if and only if* $(\{R_{ij}^k\},\{Q_{ij}^k\})$ *satisfy the following equations*:

$$\begin{aligned}
&6\left\{R_{11}^1\frac{\partial Q_{11}^1}{\partial x_2}+Q_{11}^1\frac{\partial R_{11}^1}{\partial x_2}\right\}\\
&\quad-3\left\{R_{11}^2\frac{\partial Q_{22}^2}{\partial x_2}+Q_{11}^2\frac{\partial R_{22}^2}{\partial x_2}-R_{22}^2\frac{\partial R_{11}^2}{\partial x_2}-Q_{22}^2\frac{\partial R_{11}^2}{\partial x_2}+R_{11}^1\frac{\partial Q_{22}^2}{\partial x_1}+Q_{11}^1\frac{\partial R_{22}^2}{\partial x_1}\right\}\\
&\quad-2\left\{R_{11}^2\frac{\partial Q_{22}^1}{\partial x_1}+Q_{11}^2\frac{\partial R_{22}^1}{\partial x_1}\right\}-\left\{R_{22}^1\frac{\partial Q_{11}^2}{\partial x_1}+Q_{22}^1\frac{\partial R_{11}^2}{\partial x_1}\right\}=0,\\
&6\left\{R_{22}^2\frac{\partial Q_{22}^2}{\partial x_1}+Q_{22}^2\frac{\partial R_{22}^2}{\partial x_1}\right\}\\
&\quad-3\left\{R_{22}^1\frac{\partial Q_{11}^1}{\partial x_1}+Q_{22}^1\frac{\partial R_{11}^1}{\partial x_1}-R_{11}^1\frac{\partial Q_{22}^1}{\partial x_1}-Q_{11}^1\frac{\partial R_{22}^1}{\partial x_1}+R_{22}^2\frac{\partial Q_{11}^1}{\partial x_2}+Q_{22}^2\frac{\partial R_{11}^1}{\partial x_2}\right\}\\
&\quad-2\left\{R_{22}^1\frac{\partial Q_{11}^2}{\partial x_2}+Q_{22}^1\frac{\partial R_{11}^2}{\partial x_2}\right\}-\left\{R_{11}^2\frac{\partial Q_{22}^1}{\partial x_2}+Q_{11}^2\frac{\partial R_{22}^1}{\partial x_2}\right\}=0.
\end{aligned}$$

Acknowledgment. The authors are grateful to Professor Mitsuo Kato who kindly informed us of the system F_4' and the usefulness of the system Reduce 3.2, which we used to carry out our complicated computation.

ON AN INTEGRAL TRANSFORM INVOLVING A CLASS OF MATHIEU FUNCTIONS*

D. NAYLOR†

Abstract. This paper constructs a formula of inversion for an integral transform whose kernel involves a type of Mathieu function of the third kind. The particular Mathieu function involved, $\psi = M_\nu^{(3)}(x+\frac{1}{2}i\pi)$, satisfies the equation $\psi_{xx} = (u^2+2h^2\cosh 2x)\psi$ together with the condition that $\psi(x,u)\to 0$ as $x\to\infty$. The transform in question can be used to generate solutions of the damped wave equation in infinite regions bounded by elliptic cylinders when a complex boundary condition is applied on the internal boundary.

Key words. integral transforms, Mathieu functions

AMS(MOS) subject classifications. 44A15, 33A55

1. Introduction. In a previous paper [2] the author considered the problem of determining the behavior for large values of u of a certain basic solution of the differential equation

$$y_{xx} = (u^2+2h^2\cosh 2x)y. \tag{1.1}$$

The solutions of this equation are related to the modified Mathieu functions $M_\nu^{(j)}(z)$, $j=1,2,3,4$, that satisfy

$$y_{zz} = (u^2-2h^2\cosh 2z)y. \tag{1.2}$$

Equation (1.1) transforms into (1.2) by means of the change of variable $z = x+\frac{1}{2}i\pi$ so that the functions $M_\nu^{(j)}(x+\frac{1}{2}i\pi)$ satisfy (1.1). The quantity ν, the characteristic exponent, used in the standard notation of the Mathieu functions is connected with the parameter u^2 by a complicated equation that [1] for large values of u assumes the form

$$u^2 = \nu^2 + O(h^4\nu^{-2}). \tag{1.3}$$

It is known [1] that

$$\begin{aligned} M_\nu^{(3)}(z) &= H_\nu^{(1)}(2h\cosh z)[1+O(\operatorname{sech} z)], \\ M_\nu^{(4)}(z) &= H_\nu^{(2)}(2h\cosh z)[1+O(\operatorname{sech} z)], \end{aligned} \tag{1.4}$$

as $\operatorname{Re}(z)\to\infty$ in any strip $|\operatorname{Im}(z)|\leqq$ constant, the parameter ν being held fixed. The functions $H_\nu^{(1)}$, $H_\nu^{(2)}$ denote the Hankel functions, the notation being that of Watson [8]. Since $\cosh(x+\frac{1}{2}i\pi) = i\sinh x$ and

$$\begin{aligned} H_\nu^{(1)}(ix) &= -\frac{2i}{\pi}\exp\left(-\frac{1}{2}i\nu\pi\right)K_\nu(x), \\ H_\nu^{(2)}(ix) &= \frac{2i}{\pi}\exp\left(-\frac{1}{2}i\nu\pi\right)K_\nu(x)+2\exp\left(\frac{1}{2}i\nu\pi\right)I_\nu(x), \end{aligned}$$

it follows that

$$\begin{aligned} M_\nu^{(3)}\left(x+\frac{1}{2}i\pi\right) &= -\frac{2i}{\pi}\exp\left(-\frac{1}{2}i\nu\pi\right)K_\nu(2h\sinh x)[1+O(\operatorname{cosech} x)], \\ M_\nu^{(4)}\left(x+\frac{1}{2}i\pi\right) &= \left[\frac{2i}{\pi}\exp\left(-\frac{1}{2}i\nu\pi\right)K_\nu(2h\sinh x)+2\exp\left(\frac{1}{2}i\nu\pi\right)I_\nu(2h\sinh x)\right] \\ &\quad\cdot[1+O(\operatorname{cosech} x)], \end{aligned}$$

* Received by the editors July 6, 1987; accepted for publication (in revised form) January 20, 1989.
† Department of Applied Mathematics, University of Western Ontario, London, Ontario, Canada N6A 5B9.

as $x \to \infty$. Finally, since [8, p. 202]

$$K_\nu(x) \sim (\pi/2x)^{1/2} e^{-x}, \qquad I_\nu(x) \sim (2\pi x)^{-1/2} e^{x},$$

as $x \to \infty$, we find that

$$\begin{aligned} M_\nu^{(3)}(x+\tfrac{1}{2}i\pi) &\sim -i(\pi h \sinh x)^{-1/2} \exp(-2h \sinh x - \tfrac{1}{2}i\nu\pi), \\ M_\nu^{(4)}(x+\tfrac{1}{2}i\pi) &\sim (\pi h \sinh x)^{-1/2} \exp(2h \sinh x + \tfrac{1}{2}i\nu\pi) \end{aligned} \tag{1.5}$$

as $x \to \infty$, for fixed ν. It follows from these formulas that there is essentially only one solution of (1.1) that remains bounded as $x \to +\infty$. This solution is the function $M_\nu^{(3)}(x+\frac{1}{2}i\pi)$, which for brevity we denote as $\psi(x, u)$. In [2] attention was concentrated on this solution, the object being to obtain sufficient information to investigate an integral transform having this function as kernel. Let $e^{-\lambda x} f(x) \in L^2(a, \infty)$; then the integral transform in question is defined by means of

$$F(u) = \int_a^\infty f(x)\psi(x, u)\, dx. \tag{1.6}$$

This transform is of use when it is required to construct solutions of the damped wave equation in regions exterior to cylinders of an elliptic cross section, in which case the radial eigenfunctions satisfy an equation such as (1.1), the quantity u^2 being an eigenvalue parameter, and it is the aim of the present paper to construct a formula of inversion for (1.6). The underlying expansion problem is that posed by the differential equation (1.1) on the interval $a \leqq x < \infty$ together with the condition that

$$ky(a) + y'(a) = 0 \tag{1.7}$$

where $k = k_1 + ik_2$ denotes a complex constant.

In the remainder of this section the asymptotic formulas derived in [2], giving the behavior of $\psi(x, u)$ as $u \to \infty$, are stated. In all of these formulas, x is supposed to be positive and fixed.

$$\begin{aligned} \psi(x, u) = 2\left(\frac{2}{\pi u}\right)^{1/2} &\exp\left(-\frac{1}{2}i\nu\pi + \frac{1}{2}iu\pi - \frac{1}{4}i\pi\right) \\ &\cdot \left\{\cosh\left[u \log\left(\frac{2u}{he}\right) - ux - \frac{1}{2}iu\pi - \frac{1}{4}i\pi\right] + O(u^{-1})\right\} \end{aligned} \tag{1.8}$$

as $u \to \infty$ in the sector $\frac{1}{2}\pi - \varepsilon \leqq \arg u \leqq \frac{1}{2}\pi$, and

$$\begin{aligned} \psi(x, u) = -2\left(\frac{2}{\pi u}\right)^{1/2} &\exp\left(-\frac{1}{2}i\nu\pi - \frac{1}{2}iu\pi + \frac{1}{4}i\pi\right) \\ &\cdot \left\{\cosh\left[u \log\left(\frac{2u}{he}\right) - ux + \frac{1}{2}iu\pi + \frac{1}{4}i\pi\right] + O(u^{-1})\right\} \end{aligned} \tag{1.9}$$

as $u \to \infty$ in the sector $-\frac{1}{2}\pi \leqq \arg u \leqq -\frac{1}{2}\pi + \varepsilon$. A simpler formula is valid as $u \to \infty$ in the sector $|\arg u| \leqq \frac{1}{2}\pi - \varepsilon$ where it can be shown that

$$\psi(x, u) = -i\left(\frac{2}{\pi u}\right)^{1/2} \exp\left[u \log\left(\frac{2u}{he}\right) - ux - \frac{1}{2}i\nu\pi\right][1 + O(u^{-1})]. \tag{1.10}$$

In fact, it will be shown in the next section of the paper that (1.10) also holds as $u \to \infty$ in the domain $\operatorname{Re}(u) \geqq c$ where c denotes a positive constant.

Formulas (1.8)-(1.10) were developed in [2] by applying formulas obtained by Pitts [4], who has also shown [5] that asymptotic formulas for the derivative $\psi_x(x, u)$ can be obtained from the corresponding formulas (1.8)-(1.10) by formal differentiation with respect to x so that, for example,

$$\psi_x(x, u) = -2\left(\frac{2u}{\pi}\right)^{1/2} \exp\left(-\frac{1}{2} i\nu\pi + \frac{1}{2} iu\pi - \frac{1}{4} i\pi\right) \cdot \left\{\sinh\left[u \log\left(\frac{2u}{he}\right) - ux - \frac{1}{2} iu\pi - \frac{1}{4} i\pi\right] + O(u^{-1})\right\} \tag{1.11}$$

as $u \to \infty$ in $\frac{1}{2}\pi - \varepsilon \leqq \arg u \leqq \frac{1}{2}\pi$.

2. The integral theorem. To construct a formula of inversion to be associated with the integral transform defined by (1.6), it is necessary to introduce a second basic solution $\phi(x, u)$ of (1.1). This solution will be defined as that generated by the initial values $\phi(a, u) = 1$, $\phi_x(a, u) = -k$ and so satisfies a condition like (1.7). The function $\phi(x, u)$ is necessarily a linear combination of $M_\nu^{(3)}$ and $M_\nu^{(4)}$, and it is easily verified that

$$\phi(x, u) = -\tfrac{1}{4} i\pi[g(u) M_\nu^{(4)}(x + \tfrac{1}{2} i\pi) - g_1(u) M_\nu^{(3)}(x + \tfrac{1}{2} i\pi)] \tag{2.1}$$

where

$$g(u) = kM_\nu^{(3)}(a + \tfrac{1}{2} i\pi) + M_\nu^{(3)'}(a + \tfrac{1}{2} i\pi), \tag{2.2}$$

$$g_1(u) = kM_\nu^{(4)}(a + \tfrac{1}{2} i\pi) + M_\nu^{(4)'}(a + \tfrac{1}{2} i\pi). \tag{2.3}$$

In this paper it is assumed that the constant k appearing in the boundary condition (1.7) is independent of u and in this case it can be shown [7], by writing the appropriate integral equation satisfied by $\phi(x, u)$, that this function is an entire function of the complex variable u and that for fixed values of x and large values of u in the halfplane $\operatorname{Re}(u) \geqq 0$,

$$\phi(x, u) = \cosh u(x - a) - ku^{-1} \sinh u(x - a) + O[u^{-2} e^{u(x-a)}]. \tag{2.4}$$

Before formulating the integral theorem, it is necessary to state certain results concerning the eigenvalues of the problem being investigated. These eigenvalues are the zeros p_n of the function $g(u)$ and it is assumed that they are arranged in ascending order of magnitude so that $|p_1| \leqq |p_2| \leqq |p_3| \cdots$. It is shown in the Appendix that if k is complex there are no real zeros and no purely imaginary zeros. If $\operatorname{Im}(k) > 0$ the zeros are located in the first and third quadrants of the complex u-plane, while if $\operatorname{Im}(k) < 0$ they are located in the second and fourth quadrants. Henceforth we will assume for definiteness that $\operatorname{Im}(k) > 0$. In this case, although no zero p_n can actually lie on the imaginary axis, it can be shown that those zeros of sufficiently large magnitude lie close to, and approach, that axis as their magnitudes tend to infinity, in the sense that $\operatorname{Re}(p_n) \to 0$ and $|\operatorname{Im}(p_n)| \to \infty$ as $n \to \infty$. It follows that all of the zeros can be positioned in a strip of finite width parallel to the imaginary axis of the complex u-plane.

THEOREM. *Let $f(x)$ be continuous for $x \geqq a > 0$ and suppose that $f(x)$ is of bounded variation in the neighborhood of x and that $e^{-\lambda x} f(x) \in L^2(a, \infty)$ where $\lambda \geqq 0$; then* (1.6) *implies*

$$f(x) = -\frac{1}{i\pi} \int_L \frac{u\phi(x, u) F(u)\, du}{g(u)} \tag{2.5}$$

where L denotes a line $\operatorname{Re}(u) = c$ parallel to the imaginary axis of the complex u-plane, $c > \max(\lambda, \frac{1}{2})$, and L is positioned so that all of the zeros of the function $g(u)$ lie to the left of it.

The method adopted to establish the above theorem will follow that used in [3], where an integral transform involving Bessel functions is discussed. This method stems from an inspection of equations (1.8)-(1.10) and (2.4), which show that when u is large the functions $\psi(x, u)$ and $\phi(x, u)$ behave for varying x like suitable combinations of the exponentials e^{ux} and e^{-ux}. By relating the Mathieu functions to the corresponding exponential or hyperbolic functions, the proof of the inversion formula (2.5) can be reduced to that of the Mellin inversion formula.

To verify (2.5), we let $L(R)$ denote the straight line in the complex u-plane drawn from $c-iR$ to $c+iR$, where c is the constant introduced in the theorem, and then form the equation

$$\int_{L(R)} \frac{u\phi(x, u)F(u)\,du}{g(u)} = \int_{L(R)} \frac{u\phi(x, u)\,du}{g(u)} \int_a^\infty f(t)\psi(t, u)\,dt. \tag{2.6}$$

This equation follows after inserting the expression (1.6) for $F(u)$. The order of integration of the repeated integral present on the right-hand side of (2.6) is now reversed. To justify this step it will be proved that, for finite values of R, the repeated integral in question exists when the integrand appearing therein is replaced by its modulus. With this purpose in mind we first apply the Schwarz inequality, revealing that

$$\left| \int_a^\infty f(t)\psi(t, u)\,dt \right| \leqq \|e^{-\lambda t}f(t)\| \cdot \|e^{\lambda t}\psi(t, u)\| \tag{2.7}$$

where $\|\cdot\|$ denotes the $L^2(a, \infty)$ norm so that

$$\|e^{\lambda t}\psi\| = \left(\int_a^\infty e^{2\lambda t}|\psi(t, u)|^2\,dt \right)^{1/2}. \tag{2.8}$$

A suitable bound on the value of this integral is obtained in the Appendix, where it is shown that

$$(u_1^2-\lambda^2)(u_2^2+\lambda^2) \int_a^\infty e^{2\lambda t}|\psi(t, u)|^2\,dt \leqq \frac{1}{4} u_1\, e^{2\lambda a}(|u\psi(a)|+|\psi'(a)|)^2 \tag{2.9}$$

where $u = u_1 + iu_2$ and $u_1 > \lambda$. It follows from (2.7) and (2.9) that the integral obtained from that on the right-hand side of (2.6), after taking the absolute values of all the terms in the integrand, does not exceed the quantity

$$\frac{\sqrt{c}\, e^{\lambda a}\|e^{-\lambda t}f\|}{2(c^2-\lambda^2)^{1/2}} \int_{-R}^{R} \left| \frac{u\phi(x, u)}{g(u)} \right| \frac{(|u\psi(a, u)|+|\psi_x(a, u)|)\,du_2}{(u_2^2+\lambda^2)^{1/2}}$$

since $u_1 = c$ on the path $L(R)$. This quantity is finite since the integrand is continuous on the path of integration and the latter is of finite extent. This permits the interchange of the order of integration in the integral on the right-hand side of (2.6) and leads to

$$\int_{L(R)} \frac{u\phi(x, u)F(u)\,du}{g(u)} = \int_a^\infty f(t)\,dt \int_{L(R)} \frac{u\phi(x, u)\psi(t, u)\,du}{g(u)}. \tag{2.10}$$

The next step is to determine the behavior of the integrand appearing on the right-hand side of (2.10) when the variable u is large and located in the halfplane $\mathrm{Re}\,(u) \geqq c$. First we note that, for large values of u in the stated halfplane, (1.8) and (1.9) both reduce to the simpler formula (1.10). That is to say, (1.10) holds as $u \to \infty$ in the halfplane $\mathrm{Re}\,(u) \geqq c$. To see this we write $u = re^{i\theta}$ and note that

$$u \log\left(\frac{2u}{he}\right) - ux - \frac{1}{2} iu\pi - \frac{1}{4} i\pi = A + iB \tag{2.11}$$

where

$$A = r\cos\theta\left[\log\left(\frac{2r}{he}\right) - x\right] + \left(\frac{1}{2}\pi - \theta\right) r\sin\theta,$$
$$B = r\sin\theta\left[\log\left(\frac{2r}{he}\right) - x\right] - \left(\frac{1}{2}\pi - \theta\right) r\cos\theta - \frac{1}{4}\pi. \tag{2.12}$$

Both terms on the right-hand side of (2.12) are nonnegative for r large and $0 \leqq \theta \leqq \frac{1}{2}\pi$. If u lies in the stated halfplane then $r\cos\theta \geqq c$, which is positive, and therefore A is not less than $c[\log(2r/he) - x]$, which is large and positive for sufficiently large r. Therefore $\cosh(A+iB) = \frac{1}{2}e^{A+iB} + O(u^{-c})$ where $c \geqq \frac{1}{2}$, and on making this change in (1.8) we find that the latter formula reduces to

$$\psi = -i\left(\frac{2}{\pi u}\right)^{1/2} \exp\left[u\log\left(\frac{2u}{he}\right) - ux - \frac{1}{2}i\nu\pi\right][1 + O(u^{-1})]. \tag{2.13}$$

Similarly, it can be shown that the real part of the argument appearing inside the hyperbolic function in (1.9) is also large and positive in the relevant part of the complex u-plane so that this function can be replaced by an exponential function. When this change is carried out we again obtain (2.13), which therefore holds as $u \to \infty$ throughout the region $\mathrm{Re}\,(u) \geqq c$. The asymptotic form of the function $g(u) = k\psi(a, u) + \psi_x(a, u)$ that also occurs in (2.10) can be deduced at once from the above formulas for ψ, from which it follows that

$$g(u) = i\left(\frac{2u}{\pi}\right)^{1/2} \exp\left[u\log\left(\frac{2u}{he}\right) - ua - \frac{1}{2}i\nu\pi\right][1 + O(u^{-1})] \tag{2.14}$$

as $u \to \infty$ in $\mathrm{Re}\,(u) \geqq c$. The asymptotic behavior of the function $\phi(x, u)$ also present in (2.10) is given by (2.4), and on combining this formula with (2.13) and (2.14) we find that

$$\frac{u\phi(x, u)\psi(t, u)}{g(u)} = -\frac{1}{2}e^{u(x-t)} - \frac{1}{2}e^{u(2a-x-t)} + h(u, x, t) \tag{2.15}$$

where $h(u, x, t) = O[u^{-1}e^{u(x-t)}]$ as $u \to \infty$ in $\mathrm{Re}\,(u) \geqq c$, uniformly on finite x and t intervals. Since $\phi(x, u)$, $\psi(t, u)$, $g(u)$ are analytic functions of u, the function $h(u, x, t)$ is also analytic except for simple poles at the zeros p_n of $g(u)$.

On inserting (2.15) into the integral on the right-hand side of (2.10) we obtain

$$\begin{aligned}\int_{L(R)} \frac{u\phi(x, u)F(u)\,du}{g(u)} = &-\frac{1}{2}\int_{L(R)} e^{ux}\,du \int_a^\infty e^{-ut}f(t)\,dt \\ &-\frac{1}{2}\int_{L(R)} e^{u(2a-x)}\,du \int_a^\infty e^{-ut}f(t)\,dt \\ &+\int_a^\infty f(t)\,dt \int_{L(R)} h(u, x, t)\,du\end{aligned} \tag{2.16}$$

after inverting the order of integration in the first and second repeated integrals on the right-hand side of (2.16). This process is again justified for finite values of R by absolute convergence since on writing $e^{-ct}f = e^{-(c-\lambda)t}\cdot e^{-\lambda t}f$, it is found after using the Schwarz inequality that $e^{-\lambda t}f \in L^2(a, \infty)$ implies $e^{-ct}f \in L(a, \infty)$.

Now by the Mellin inversion theorem [6], since $x > a$ we find that

$$\lim_{R\to\infty} \int_{c-iR}^{c+iR} e^{ux}\,du \int_a^\infty e^{-ut}f(t)\,dt = 2i\pi f(x) \tag{2.17}$$

while by the same theorem, the second term on the right-hand side of (2.16) tends to zero as $R \to \infty$ since $2a - x < a$ therein. Hence, on proceeding to the limit as $R \to \infty$ in (2.16), we obtain

$$\lim_{R\to\infty} \int_{L(R)} \frac{u\phi(x,u)F(u)\,du}{g(u)} = -i\pi f(x) + \lim_{R\to\infty} \int_a^\infty f(t)\,dt \int_{L(R)} h(u,x,t)\,du. \tag{2.18}$$

To complete the proof of (2.5) of the theorem it is necessary to verify that

$$\lim_{R\to\infty} \int_a^\infty f(t)\,dt \int_{L(R)} h(u,x,t)\,du = 0. \tag{2.19}$$

To obtain this result it will first be shown that

$$\int_{L(R)} [h(u,x,t) - h(u,t,x)]\,du = O(R^{-1}) \tag{2.20}$$

as $R \to \infty$, uniformly for any bounded interval of values of t. This result will be established with the aid of Cauchy's theorem and for this purpose we need some properties of the function $h(u,x,t) - h(u,t,x)$, which by (2.15) is given by

$$h(u,x,t) - h(u,t,x) = \sinh u(x-t) + uj(u,x,t) \tag{2.21}$$

where

$$j(u,x,t) = [\phi(x,u)\psi(t,u) - \phi(t,u)\psi(x,u)]/g(u).$$

It is shown in the argument that follows that the function on the left-hand side of (2.21) is an odd function of u that is $O(u^{-1}\, e^{u|x-t|})$ as $u \to \infty$ throughout the complex u-plane. The function $j(u,x,t)$, regarded as a function of x, satisfies the basic equation (1.1) and automatically vanishes at the value $x = t$. Furthermore, the derivative of this function with respect to x, also evaluated at $x = t$, equals $-W(\phi,\psi)/g(u)$, where $W(\phi,\psi)$ denotes the Wronskian. Since this Wronskian equals $k\psi(a,u) + \psi_x(a,u)$, its value at $x = a$, and this by (2.2) equals $g(u)$, it follows that $j(u,x,t)$ is the solution of (1.1) defined by the initial values $j(u,t,t) = 0$, $j_x(u,t,t) = -1$. Therefore $j(u,x,t)$ is an entire function of u^2, that is, an even entire function of u and, in addition [7, p. 10],

$$j(u,x,t) = -u^{-1} \sinh u(x-t) + O(u^{-2}\, e^{u|x-t|})$$

as $u \to \infty$ throughout the u-plane, uniformly for any bounded intervals of values of x and t. It follows from (2.21) that the function $h(u,x,t) - h(u,t,x)$ is, as stated, an odd function of u that is entire and that is $O(u^{-1}\, e^{u|x-t|})$ as $u \to \infty$ uniformly on any bounded interval of values of t.

Equation (2.20) may now be obtained by integrating the function $h(u,x,t) - h(u,t,x)$ around the boundary of the rectangle $0 \leqq \mathrm{Re}\,(u) \leqq c$, $-R \leqq \mathrm{Im}\,(u) \leqq R$. Since this function is odd in u the contribution from the line joining the points $\pm iR$ vanishes while the stated asymptotic bound on this function shows that the contributions from the top and bottom sides of the rectangle are each $O(R^{-1})$. This leaves the contribution from the remaining side $L(R)$ as $O(R^{-1})$, as stated in (2.20), since by Cauchy's theorem the sum of the integrals around all four sides is zero.

We may now return to the proof of (2.19). The integral present in the latter equation will be expressed as the sum of two integrals, obtained by dividing the t-interval into the parts (a,x) and (x,∞), and it will be shown that both of these integrals tend to zero as $R \to \infty$.

We consider first the integral

$$\int_a^x f(t)\,dt \int_{L(R)} h(u, x, t)\,du. \tag{2.22}$$

According to the relation (2.20) the expression (2.22) may be rewritten as the integral

$$\int_a^x f(t)\,dt \int_{L(R)} h(u, t, x)\,du + O(R^{-1}). \tag{2.23}$$

An estimate of the inner integral, the one along the path $L(R)$, occurring in this expression can be obtained by deforming the path onto the semicircle drawn to the right of $L(R)$ and having this line as diameter. On this semicircle

$$h(u, t, x) = O[R^{-1}\, e^{-(x-t)R\cos\theta}]$$

so that

$$\left|\int_{L(R)} h(u, t, x)\,du\right| \leqq \int_{-\pi/2}^{\pi/2} e^{-(x-t)R\cos\theta}\,d\theta$$

$$\leqq \begin{cases} \pi R^{-1}(x-t)^{-1}, & a \leqq t < x, \\ \pi, & a \leqq t \leqq x. \end{cases} \tag{2.24}$$

In view of the fact that the first of the two bounds on the right-hand side of (2.24) is not suitable in the vicinity of the value $t = x$, we subdivide the t-integration in (2.23) into the parts $(a, x - R^{-1/2})$ and $(x - R^{-1/2}, x)$, applying the first bound to the first subinterval and the second bound to the second subinterval. It is then found that the modulus of (2.23) is not greater than the quantity

$$\pi R^{-1} \int_a^{x-R^{-1/2}} |f(t)|(x-t)^{-1}\,dt + \pi \int_{x-R^{-1/2}}^{x} |f(t)|\,dt + O(R^{-1}). \tag{2.25}$$

Both integrals here are $O(R^{-1/2})$ since $(x-t)^{-1} \leqq R^{1/2}$ in the first integral and the domain of integration in the second integral is of length $R^{-1/2}$. Therefore all three terms appearing in (2.25) tend to zero as $R \to \infty$.

We consider next the integral

$$\int_x^\infty f(t)\,dt \int_{L(R)} h(u, x, t)\,du. \tag{2.26}$$

To treat this integral, the interval (x, ∞) is decomposed into the parts (x, x_0) and (x_0, ∞), where x_0 is chosen greater than x and large enough to ensure that

$$\left(\int_{x_0}^\infty e^{-2\lambda t}|f(t)|^2\,dt\right) < \varepsilon \tag{2.27}$$

where ε is arbitrarily small and positive.

The contribution of the interval (x, x_0) to the value of the integral (2.26) is the integral

$$\int_x^{x_0} f(t)\,dt \int_{L(R)} h(u, x, t)\,du. \tag{2.28}$$

Since $h(u, x, t) = O[u^{-1}\, e^{u(x-t)}]$, where now $t \geqq x$, and this tends to zero as $u \to \infty$ in the region on the right-hand side of $\mathrm{Re}\,(u) = c$, it can be seen on following an argument similar to that used to discuss the integral (2.22) that the integral (2.28) also tends to zero as $R \to \infty$.

To complete the analysis of (2.26) it will now be proved that

$$\left|\int_{x_0}^{\infty} f(t)\,dt \int_{L(R)} h(u, x, t)\,du\right| \leqq M\varepsilon \tag{2.29}$$

where M is a constant, and R large enough. In view of the definition (2.15) of the function $h(u, x, t)$, the integral present in (2.29) is equal to the sum

$$\begin{aligned}&\frac{1}{2}\int_{x_0}^{\infty} f(t)\,dt \int_{L(R)} e^{u(x-t)}\,du+\frac{1}{2}\int_{x_0}^{\infty} f(t)\,dt \int_{L(R)} e^{u(2a-x-t)}\,du\\ &\quad+\int_{x_0}^{\infty} f(t)\,dt \int_{L(R)} \frac{u\phi(x, u)\psi(t, u)\,du}{g(u)}.\end{aligned} \tag{2.30}$$

The first two repeated integrals appearing in (2.30) are similar to those on the right-hand side of (2.16) and vanish as $R\to\infty$, as is seen on reversing the order of integration and applying the Mellin inversion theorem, since x and $2a-x$ both lie outside the interval of integration (x_0, ∞) in (2.30).

The third double integral present in (2.30) may be shown to be $O(\varepsilon)$ by deforming the path $L(R)$ onto the rays $W(R)$ and the circular arcs $C(R)$ depicted in Fig. 1. The rays are defined by $u = c + s\,e^{\pm i\theta_0}$ where s varies from zero to R and θ_0 is an acute angle, and the arcs connecting the extremities of $L(R)$ and $W(R)$ are of radius R. On replacing $L(R)$ by $W(R)$ and $C(R)$, the double integral in question is replaced by

$$\int_{W(R)} \frac{u\phi(x, u)\,du}{g(u)} \int_{x_0}^{\infty} f(t)\psi(t, u)\,dt+\int_{C(R)} \frac{u\phi(x, u)\,du}{g(u)} \int_{x_0}^{\infty} f(t)\psi(t, u)\,dt \tag{2.31}$$

after reversing the orders of integration in both repeated integrals, a process that is permissible since it will be apparent in the course of the argument that follows that both integrals are absolutely convergent. The inner integrals present in (2.31) are estimated by means of the Schwarz inequality, which, by analogy with (2.7), shows in view of (A9) with λ replaced by 2λ therein that

$$\int_{x_0}^{\infty} |f(t)\psi(t, u)|\,dt \leqq \frac{\varepsilon(u_1)^{1/2}\,e^{\lambda a}|u\psi(x_0, u)-\psi_x(x_0, u)|}{4(u_1^2-\lambda^2)^{1/2}(u_2^2+\lambda^2)^{1/2}}.$$

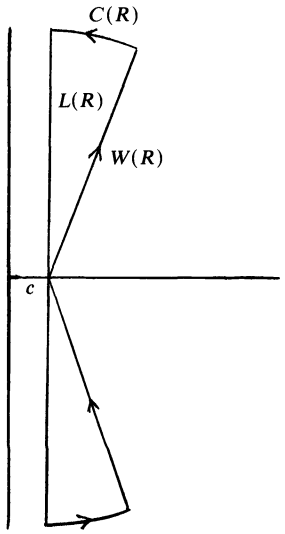

FIG. 1. *Complex u-plane.*

On using this result together with (2.4), (2.13), and (2.14) to estimate the values of ϕ, ψ, $g(u)$ for large values of u, it is found that

$$\left|\frac{u\phi(x,u)}{g(u)}\int_{x_0}^{\infty}|f(t)\psi(t,u)|\,dt\right| \leqq \frac{\varepsilon u_1^{1/2}\,e^{\lambda a}|u\,e^{-u(x_0-x)}|}{2(u_1^2-\lambda^2)^{1/2}(u_2^2+\lambda^2)^{1/2}}$$

$$\leqq \frac{\varepsilon\exp(\lambda a-(x_0-x)R\cos\theta)}{2(c-\lambda)^{1/2}\sin\theta} \tag{2.32}$$

since $u_1^2-\lambda^2=(u_1-\lambda)(u_1+\lambda)\geqq(c-\lambda)u_1$.

The expression (2.32) is integrable along the path $W(R)$ so that the first repeated integral in (2.31) exists as $R\to\infty$ and is clearly $O(\varepsilon)$. The use of the bound (2.32) on the arcs $C(R)$ shows that the second repeated integral in (2.31) does not exceed the quantity

$$\frac{\varepsilon R\,e^{\lambda a}}{2(c-\lambda)^{1/2}\sin\theta_0}\int_{\theta_0}^{\pi/2}e^{-(x_0-x)R\cos\theta}\,d\theta.$$

It is readily shown that the integral appearing in this expression is $O(R^{-1})$ so that the whole expression is $O(\varepsilon)$ for arbitrarily large values of R. It follows that both of the repeated integrals in (2.31) are $O(\varepsilon)$ and so the same is true of the third such integral in (2.30). Since the other two integrals in (2.30) tend to zero as $R\to\infty$, the result (2.29) follows for large enough values of R. Since (2.22) and (2.28) tend to zero as $R\to\infty$, the result (2.19) follows on adding all three integrals (2.22), (2.28), and (2.29). Finally, as a consequence of (2.19), (2.18) reduces to the inversion formula stated in the theorem.

3. The eigenfunction expansion. An explicit expansion in eigenfunctions can be deduced from (2.5) by deforming the path of integration onto the imaginary axis and taking the residues at the poles traversed. Since the functions $\phi(x,u)$, $\psi(x,u)$, and therefore $F(u)$, $g(u)$, are even functions of u, the integral taken along the entire imaginary axis vanishes, leaving the contributions from the residues at the zeros of $g(u)$. Since at such a zero the function $\phi(x,u)$ defined by (2.1) reduces to $\frac{1}{4}i\pi g_1(u)\psi(x,u)$, we find on calculating the residues the expansion

$$f(x)=-\frac{1}{2}i\pi\sum_{n=1}^{\infty}\frac{p_n g_1(p_n)\psi(x,p_n)F(p_n)}{g'(p_n)} \tag{3.1}$$

where the summation extends over all of the zeros p_n of $g(u)$ that lie in the first quadrant of the complex u-plane.

To justify the procedure it will be assumed that $f\in L^2(a,\infty)$ and we revert to (2.5) rewritten in the form

$$f(x)=-\frac{1}{i\pi}\lim_{R\to\infty}\int_{c-iR}^{c+iR}\frac{u\phi(x,u)F(u)\,du}{g(u)}. \tag{3.2}$$

We now apply Cauchy's theorem to the rectangle $0\leqq\operatorname{Re}(u)\leqq c$, $-R\leqq\operatorname{Im}(u)\leqq R$, where R is chosen so that the top side of the rectangle passes between consecutive poles of the integrand. To achieve this the quantity R will be allowed to tend to infinity through the sequence of values R_n defined by $R_n\log(2R_n/he)-aR_n=n$, where n is an integer that tends to infinity. With this choice the sides of the rectangle will, by (A15), avoid the poles. In addition, we note that the quantity B, introduced in (2.11) with x set equal to a therein, will be such that $B\sim(n+\frac{1}{4})\pi$ as $n\to\infty$. We now verify

that the integrals along the top and bottom sides vanish in the limit as $R \to \infty$. The integral along the top side is equal to

$$J = \int_0^c \frac{u\phi(x, u)\, du_1}{g(u)} \int_a^\infty f(t)\psi(t, u)\, dt. \tag{3.3}$$

We again divide the integration with respect to t into the parts (a, x_0), (x_0, ∞) where x_0 is chosen to satisfy (2.27) with λ set equal to zero therein, and write $J = J_1 + J_2$ where

$$J_1 = \int_0^c \frac{u\phi(x, u)\, du_1}{g(u)} \int_a^{x_0} f(t)\psi(t, u)\, dt, \tag{3.4}$$

$$J_2 = \int_0^c \frac{u\phi(x, u)\, du_1}{g(u)} \int_{x_0}^\infty f(t)\psi(t, u)\, dt. \tag{3.5}$$

First we consider J_2. On applying the Schwarz inequality to the t-integral in J_2, we find that

$$\int_{x_0}^\infty |f(t)\psi(t, u)|\, dt \leqq \varepsilon \left(\int_{x_0}^\infty |\psi|^2\, dx \right)^{1/2} \leqq \varepsilon \|\psi\|$$

where $\|\psi\|$ denotes the norm based on the interval (a, ∞) and is obtainable from (A12). On estimating the values of $\psi(a, u)$, $\psi_x(a, u)$ appearing in (A12) with the aid of (1.8) and (1.11) we find since $B \sim (n + \frac{1}{4})\pi$ that

$$\int_{x_0}^\infty |f(t)\psi(t, u)|\, dt \leqq \varepsilon \left(\frac{2}{\pi R u_1} \right)^{1/2} \left| \exp\left(\frac{1}{2} i(u - \nu)\pi \right) \right| \cdot [1 + \sinh 2A + O(u^{-1} e^A)]^{1/2}. \tag{3.6}$$

Similarly, we find that

$$|g(u)| \sim 2 \left| \frac{u}{\pi} \right|^{1/2} \left| \exp\left(\frac{1}{2} i(u - \nu)\pi \right) \right| \cdot [\cosh 2A + O(u^{-1} e^A)]^{1/2}. \tag{3.7}$$

It follows from (3.6) and (3.7) that

$$\left| \frac{1}{g(u)} \int_{x_0}^\infty f(t)\psi(t, u)\, dt \right| \leqq \varepsilon \left| \frac{1}{2} R u u_1 \right|^{-1/2} = \varepsilon \left(\frac{1}{2} R u_1 \right)^{-1/2} (R^2 + u_1^2)^{-1/4}.$$

On taking the modulus of (3.5) and using the above result and the fact that $\phi(x, u)$ is, by (2.4), bounded in the strip $0 \leqq \mathrm{Re}\,(u) \leqq c$, it follows that

$$|J_2| \leqq M\varepsilon \left(\frac{2}{R} \right)^{1/2} \int_0^c u_1^{-1/2} (R^2 + u_1^2)^{1/4}\, du_1 \tag{3.8}$$

where M is a constant. On taking u_1/R as new variable of integration in (3.8), it is seen that the integral appearing in the latter equation is $O(R^{1/2})$ as $R \to \infty$ so that $|J_2| \leqq M'\varepsilon$, where M' is a further constant, independent of R.

We now turn our attention to the quantity J_1 defined by (3.4) and which, by (2.15), may be written as

$$J_1 = \int_a^{x_0} f(t)\, dt \int_0^c \left[h(u, x, t) - \frac{1}{2} e^{u(x-t)} - \frac{1}{2} e^{u(2a-x-t)} \right] du_1. \tag{3.9}$$

Since $h = O(u^{-1} e^{u(x-t)})$ and this is simply $O(R^{-1})$ uniformly in t, since $u = u_1 + iR$ on the path of integration, the contribution of the function $h(u, x, t)$ to the value of the repeated integral on the right-hand side of (3.9) is $O(R^{-1})$. In regard to the first

exponential term on the right-hand side of (3.9), we find on carrying out the integration with respect to u_1, that the contribution of this term equals the integral

$$\int_a^{x_0} [e^{c(x-t)}-1](x-t)^{-1}\, e^{iR(x-t)} f(t)\, dt.$$

This integral tends to zero as $R\to\infty$ by the Riemann-Lebesgue lemma. A similar argument reveals that the contribution of the second exponential term present on the right-hand side of (3.9) vanishes in the limit as $R\to\infty$. Thus as $R\to\infty$, $J_1\to 0$ and $J\to J_2$, which is arbitrarily small so that $J\to 0$ as $R\to\infty$. Therefore the integral along the top side vanishes in the limit as this side recedes to infinity. A similar result holds for the integral along the bottom side of the rectangle, and this justifies the derivation of the expansion (3.1).

Appendix. In this Appendix the bounds on $\|e^{\lambda t}\psi(t,u)\|$ utilized in § 2 are derived. In addition some properties of the zeros of the function $g(u)$ are established. The required bounds may be obtained from the differential equation (1.1) by multiplying the latter by $e^{\lambda x}\bar{y}$, where $\bar{y}$ denotes the complex conjugate of y and $\lambda \geqq 0$, and integrating by parts, this leads to

$$\begin{aligned}&\int_a^\infty e^{\lambda x}(u^2+2h^2\cosh 2x)|y|^2\,dx\\ &\quad=-e^{\lambda a}\bar{y}(a)y_x(a)-\lambda\int_a^\infty e^{\lambda x}\bar{y}y_x\,dx-\int_a^\infty e^{\lambda x}|y_x|^2\,dx.\end{aligned}\tag{A1}$$

Further relations may be obtained by noting that $2\,\mathrm{Re}\,(y_x\bar{y}_{xx})=y_x\bar{y}_{xx}+\bar{y}_x y_{xx}$ so that

$$2\,\mathrm{Re}\int_a^\infty e^{\lambda x}y_x\bar{y}_{xx}\,dx=-e^{\lambda a}|y_x(a)|^2-\lambda\int_a^\infty e^{\lambda x}|y_x|^2\,dx.\tag{A2}$$

Similarly, we find that

$$2\,\mathrm{Re}\int_a^\infty e^{\lambda x}\bar{y}y_x\,dx=-e^{\lambda a}|y(a)|^2-\lambda\int_a^\infty e^{\lambda x}|y|^2\,dx,\tag{A3}$$

$$\begin{aligned}&2\,\mathrm{Re}\int_a^\infty e^{\lambda x}\cosh 2x\bar{y}y_x\,dx\\ &\quad=-e^{\lambda a}\cosh 2a|y(a)|^2-\int_a^\infty e^{\lambda x}(\lambda\cosh 2x+2\sinh 2x)|y|^2\,dx.\end{aligned}\tag{A4}$$

Setting $\bar{y}_{xx}=(u^2+2h^2\cosh 2x)\bar{y}$ in (A2), we obtain

$$2\,\mathrm{Re}\int_a^\infty e^{\lambda x}(u^2+2h^2\cosh 2x)\bar{y}y_x\,dx=-e^{\lambda a}|y_x(a)|^2-\lambda\int_a^\infty e^{\lambda x}|y_x|^2\,dx.\tag{A5}$$

Eliminating the integral involving the term $e^{\lambda x}\cosh 2x\bar{y}y_x$ between (A4) and (A5) yields

$$\begin{aligned}&2(u_1^2-u_2^2)\,\mathrm{Re}\int_a^\infty e^{\lambda x}\bar{y}y_x\,dx+4u_1u_2\,\mathrm{Im}\int_a^\infty e^{\lambda x}\bar{y}y_x\,dx\\ &\quad=-e^{\lambda a}|y_x(a)|^2+2h^2e^{\lambda a}\cosh 2a|y(a)|^2-\lambda\int_a^\infty e^{\lambda x}|y_x|^2\,dx\\ &\qquad+2h^2\int_a^\infty e^{\lambda x}(\lambda\cosh 2x+2\sinh 2x)|y|^2\,dx.\end{aligned}\tag{A6}$$

On extracting the imaginary parts, it follows from (A1) that

$$\lambda \operatorname{Im} \int_a^\infty e^{\lambda x} \bar{y} y_x \, dx = -e^{\lambda a} \operatorname{Im} \bar{y}(a) y_x(a) - 2u_1 u_2 \int_a^\infty e^{\lambda x} |y|^2 \, dx. \tag{A7}$$

On taking the real part of equation (A1) and then eliminating the integrals involving the terms $\operatorname{Re} \bar{y} y_x$, $\operatorname{Im} \bar{y} y_x$, and $|y_x|^2$ that occur in (A1), (A3), (A6), and (A7), after some reduction we find

$$\begin{aligned} &\left(u_1^2 - \frac{1}{4}\lambda^2\right)\left(u_2^2 + \frac{1}{4}\lambda^2\right) \int_a^\infty e^{\lambda x} |y|^2 \, dx + \lambda h^2 \int^\infty e^{\lambda x} (\lambda \cosh 2x + \sinh 2x) |y|^2 \, dx \\ &= \frac{1}{8} \lambda \, e^{\lambda a} \left[\left(u_2^2 - u_1^2 + \frac{1}{2}\lambda^2 - 2h^2 \cosh 2a \right) |y(a)|^2 + |y_x(a)|^2 - \lambda \operatorname{Re} y(a) \bar{y}_x(a) \right] \\ &\qquad + \frac{1}{2} u_1 u_2 \, e^{\lambda a} \operatorname{Im} y(a) \bar{y}_x(a). \end{aligned} \tag{A8}$$

The function y present in this equation is now taken to be the basic solution $\psi(x, u)$ introduced in § 1. To obtain a simple expression for the desired bound on the quantity $\|e^{\lambda x} \psi(x, u)\|$, first we consider large values of u. For such values we may employ (1.8) to show that

$$\operatorname{Re} \psi(x, u) \bar{\psi}_x(x, u) = -\frac{4}{\pi} |e^{i(u-v)\pi}| [\cos \theta \sinh 2A - \sin \theta \sin 2B + O(u^{-1} e^A)].$$

The expression on the right-hand side of this equation is negative for (large) values of u in the domain $\operatorname{Re}(u) \geqq c > 0$ since, by (2.12), A is large and positive there. Suppose now that we confine attention to the halfplane $u_1 \geqq \frac{1}{2}\lambda$; then, replacing λ by $2u_1$ in all of the terms appearing in the expression on the right-hand side of (A8) except the exponential ones, we show that the magnitude of this expression does not exceed that of the quantity

$$\begin{aligned} &\tfrac{1}{4} u_1 \, e^{\lambda a} [(u_2^2 + u_1^2) |\psi(a)|^2 + |\psi_x(a)|^2 - 2u_1 \operatorname{Re} \psi(a) \bar{\psi}_x(a) + 2u_2 \operatorname{Im} \psi(a) \bar{\psi}_x(a)] \\ &\quad = \tfrac{1}{4} u_1 \, e^{\lambda a} |u\psi(a) - \psi_x(a)|^2 \end{aligned}$$

where $\psi(a)$, $\psi_x(a)$ denote $\psi(a, u)$, $\psi_x(a, u)$, respectively. Equation (A8) now gives the inequality

$$\left(u_1^2 - \frac{1}{4}\lambda^2\right)\left(u_2^2 + \frac{1}{4}\lambda^2\right) \int_a^\infty e^{\lambda x} |\psi|^2 \, dx \leqq \frac{1}{4} u_1 \, e^{\lambda a} |u\psi(a) - \psi_x(a)|^2. \tag{A9}$$

This bound holds whenever u is large and $\operatorname{Re}(u) > \frac{1}{2}\lambda$. If u is not large, the bound (A9) still holds, by the method of derivation, at those parts of the halfplane $\operatorname{Re}(u) > \frac{1}{2}\lambda$ where the quantity $\operatorname{Re} \psi(a, u) \bar{\psi}_x(a, u)$ is negative. If this quantity is positive a slightly different bound applies, for then it is clear that the expression on the right-hand side of (A8) does not exceed the quantity

$$\begin{aligned} &\tfrac{1}{4} u_1 \, e^{\lambda a} [(u_2^2 + u_1^2) |\psi(a)|^2 + |\psi_x(a)|^2 + 2u_1 \operatorname{Re} \psi(a) \bar{\psi}_x(a) + 2u_2 \operatorname{Im} \psi(a) \bar{\psi}_x(a)] \\ &\quad = \tfrac{1}{4} u_1 \, e^{\lambda a} |\bar{u}\psi(a) + \psi_x(a)|^2 \end{aligned}$$

so that, in this case,

$$\left(u_1^2 - \frac{1}{4}\lambda^2\right)\left(u_2^2 + \frac{1}{4}\lambda^2\right) \int_a^\infty e^{\lambda x} |\psi|^2 \, dx \leqq \frac{1}{4} u_1 \, e^{\lambda a} |\bar{u}\psi(a) + \psi_x(a)|^2. \tag{A10}$$

It follows from (A9) and (A10) that

$$\text{(A11)} \qquad \left(u_1^2-\frac{1}{4}\lambda^2\right)\left(u_2^2+\frac{1}{4}\lambda^2\right)\int_a^\infty e^{\lambda x}|\psi|^2\,dx \leqq \frac{1}{4}u_1\,e^{\lambda a}(|u\psi(a)|+|\psi_x(a)|)^2.$$

This inequality holds throughout the halfplane $\operatorname{Re}(u)>\frac{1}{2}\lambda$, and on replacing λ by 2λ we obtain the result (2.9) used earlier.

The properties of the zeros of the function $g(u)$ may be deduced in the following manner, starting with (A7). This equation holds for all real values of λ, and on setting $\lambda=0$ it reduces, when y is replaced by ψ, to

$$\text{(A12)} \qquad 2u_1u_2\int_a^\infty |\psi|^2\,dx = -\operatorname{Im}\bar{\psi}(a,u)\psi_x(a,u).$$

If u is a zero of the function $g(u)=k\psi(a,u)+\psi_x(a,u)$, (A12) takes the form

$$2u_1u_2\int_a^\infty |\psi|^2\,dx = \operatorname{Im} k|\psi(a,u)|^2.$$

It follows at once from this equation that the product u_1u_2 has the same sign as $\operatorname{Im}(k)$ and cannot vanish unless k is real. Thus if $\operatorname{Im}(k)\neq 0$ there can be no real and no purely imaginary zeros. If $\operatorname{Im}(k)$ is positive, so is u_1u_2, and the zeros are confined to the first and third quadrants of the u-plane. However, if $\operatorname{Im}(k)$ is negative, the zeros must be positioned in the second and fourth quadrants.

We now consider the location of the large zeros and for this purpose suppose, as in the paper, that $\operatorname{Im}(k)>0$ in which case the zeros lie in the first and third quadrants of the complex u-plane. Those zeros of large magnitude that are located in the first quadrant may be obtained by substituting the asymptotic formulas (1.8) and (1.10) into $g(u)=k\psi(a,u)+\psi_x(a,u)$ and equating the result to zero. This leads to the equation

$$u\log\left(\frac{2u}{he}\right)-ua-\frac{1}{2}iu\pi-\frac{1}{4}i\pi = in\pi+O(u^{-1})$$

where n is a large enough positive integer. On setting $u=r_n e^{i\theta_n}$ and separating real and imaginary parts, we find

$$\text{(A13)} \qquad r_n\cos\theta_n\left[\log\left(\frac{2r_n}{he}\right)-a\right]+\left(\frac{\pi}{2}-\theta_n\right)r_n\sin\theta_n = O(r_n^{-1}),$$

$$\text{(A14)} \qquad r_n\sin\theta_n\left[\log\left(\frac{2r_n}{he}\right)-a\right]-\left(\frac{\pi}{2}-\theta_n\right)r_n\cos\theta_n = \left(n+\frac{1}{4}\right)\pi+O(r_n^{-1}).$$

Since there are no real and no purely imaginary zeros, the values $\theta_n=0,\ \pi/2$ are ruled out. Therefore both terms on the left-hand side of (A13) are positive and each must tend to zero as $r_n\to\infty$. Thus $r_n\cos\theta_n[\log(2r_n/he)-a]\to 0$ as $r_n\to\infty$, implying that $r_n\cos\theta_n\to 0$, that is, the zeros of successively larger and larger magnitudes approach the imaginary axis. It also follows that $\theta_n\to\pi/2$ as $n\to\infty$, and on using these results in (A13) and (A14) we obtain the approximate equations

$$\text{(A15)} \qquad \begin{aligned} r_n\left[\log\left(\frac{2r_n}{he}\right)-a\right] &\sim \left(n+\frac{1}{4}\right)\pi+O(r_n^{-1}),\\ \theta_n &\sim \frac{1}{2}\pi+O\left(\frac{r_n^{-2}}{\log r_n}\right).\end{aligned}$$

Acknowledgment. The author thanks the referee for corrections and comments that led to the extension of the validity of (2.5) to functions of exponential growth.

TRANSFORMATIONS OF THE JACOBIAN AMPLITUDE FUNCTION AND ITS CALCULATION VIA THE ARITHMETIC-GEOMETRIC MEAN*

KENNETH L. SALA†

Abstract. With the aid of the Poisson summation formula, expressions for the Jacobian amplitude function, am $(z; m)$, along with the complete set of Jacobian elliptic functions are given that, aside from their branchpoints and poles, respectively, are convergent throughout the complex plane for arbitrary parameter m. By utilizing the expression for am $(z; m)$, its periodicity properties are determined in each of the regions $m<0$, $0<m<1$, and $m>1$. Novel yet fundamental identities are presented describing various linear and quadratic transformations of the Jacobian amplitude function. Finally, that method based on the arithmetic-geometric mean and most widely employed for calculating the Jacobian elliptic functions is shown to be, when interpreted explicitly in terms of am $(z; m)$ and its transformation properties, a method first and foremost for the calculation of the Jacobian amplitude and co-amplitude functions from which the elliptic functions themselves are subsequently evaluated by means of simple, trigonometric identities.

Key words. Jacobian amplitude function transformations, Jacobian elliptic functions, arithmetic-geometric mean

1. Introduction.

The most familiar of the twelve-member family of Jacobian elliptic functions (JEF) is the copolar trio

$$sn(z; m) = \sin[\text{am}(z; m)] = \frac{\Theta_3}{\Theta_2}\frac{\Theta_1(z/\Theta_3^2; q)}{\Theta_4(z/\Theta_3^2; q)},$$

$$cn(z; m) = \cos[\text{am}(z; m)] = \frac{\Theta_4}{\Theta_2}\frac{\Theta_2(z/\Theta_3^2; q)}{\Theta_4(z/\Theta_3^2; q)}, \tag{1.1}$$

$$dn(z; m) = \frac{d}{dz}\text{am}(z; m) = \frac{\Theta_4}{\Theta_3}\frac{\Theta_3(z/\Theta_3^2; q)}{\Theta_4(z/\Theta_3^2; q)},$$

where am $(z; m)$ is the Jacobian amplitude function, m is the Jacobian parameter ($k=+m^{1/2}$ is the modulus), $q=\exp[-\pi K'(m)/K(m)]$ is the nome with $K(m)$ and $K'(m)=K(1-m)$ the Jacobian quarter periods, and $\Theta_i(z; q)$, $i=1, \cdots, 4$, are the theta functions with Θ_i denoting $\Theta_i(z=0; q)$. The remaining members of the JEF family can be defined directly either as reciprocals or ratios of these three functions or by adding to the argument z one or both of the quarter periods, e.g., $cd(z; m) = cn(z; m)/dn(z; m) = sn(z+K; m)$. In what follows we will assume that the parameter m is real but otherwise arbitrary while the variable $z=x+iy$ is, in general, arbitrary and complex. Comprehensive descriptions of elliptic functions and JEF in particular may be found in [8], [10], [20], and [23], while extensive compendia of the properties of JEF are given in [5], [13], [15], and [17]. In general, well-known identities involving JEF will be cited without specific reference since they may be found in any of the aforementioned works.

The canonical definitions of the JEF given by (1.1) represent two characteristically distinct approaches to the description of these functions. Historically, the JEF were first defined as inverses of elliptic integrals with the basis of this approach summarized

by the fundamental identity $\text{am}(z; m) = F^{-1}(z; m)$ where $F(z; m)$ is the elliptic integral of the first kind (a historical account of the development of elliptic function theory is given by Alling [1]). However, the study of the JEF via the amplitude function is not and has never been the favored approach principally for the reason that, since $\text{am}(z; m)$ is not itself an elliptic function, this approach could not effectively exploit the many general and powerful theorems for elliptic functions but would instead be forced to rely almost exclusively on "brute force" algebraic methods. With origins traceable to Jacobi's seminal work *Fundamenta Nova* [12], the preferred approach to the study of the JEF has been through the theta functions, which, of course, are entire functions with simple zeros. In modern texts on elliptic function theory (e.g., Chandrasekharan [8]), the function $\text{am}(z; m)$ is ignored altogether.

To describe the amplitude function thus as one of the more obscure higher transcendental functions would be an understatement. The extent of its inconspicuousness is best illustrated with the example of the classical problem of the simple pendulum. The angular displacement Θ of a point mass μ constrained to swing in a vertical plane by a massless, rigid rod of length R is described by the nonlinear equation (Whittaker [22])

$$\frac{d^2\Theta}{dt^2} + \frac{g}{R}\sin\Theta = 0, \tag{1.2}$$

or, equivalently,

$$\frac{1}{2}\mu R^2\left[\frac{d\Theta}{dt}\right]^2 + \mu g R(1-\cos\Theta) = E_0 \tag{1.3}$$

where the total energy E_0 is a constant. Note that (1.2) is also identical in form to the traveling wave, sine-Gordon equation. With the most general possible initial conditions of $\Theta = 0$ and $d\Theta/dt = [2E_0/\mu R^2]^{1/2}$ for $t = 0$ (this choice places no restrictions on the value of E_0), the exact general solution to (1.2) and (1.3) is simply

$$\Theta(t) = 2 \cdot \text{am}\left[\left(\frac{g}{mR}\right)^{1/2} t; m\right], \qquad m = \frac{2\mu g R}{E_0} \tag{1.4}$$

a result that follows immediately from the identities $(d/dx)\text{am}(x; m) = dn(x; m)$ and $(d/dx)\, dn(x; m) = -(m/2)\sin[2\text{am}(x; m)]$. Despite the simplicity of this result, the explicit solution (1.4) has heretofore never been published even though dozens of texts and papers have treated the simple pendulum problem "exactly." Invariably, these "exact" treatments solve not explicitly for $\Theta(t)$ but rather for the variable $\sin(\Theta/2)$ (see, e.g., Whittaker [22] and Alling [1]) and, furthermore, choose to either ignore entirely the rotating ($m < 1$) pendulum by adopting initial conditions that restrict the value of m to $m > 1$, or to treat the cases of $m < 1$ and $m > 1$ as distinct problems (the special case of $m = 1$ is also often treated separately). The distinction, however, between $\Theta(t)$ and $\sin(\Theta/2)$ is not a trivial one; the latter is a true doubly periodic function for all values of the parameter $m \neq 1$ whereas the amplitude function possesses a real period if and only if $m > 1$, i.e., only the $\text{am}(z; m)$ solution as given in (1.4) explicitly and unequivocally distinguishes between the oscillating ($m > 1$) and rotating ($m < 1$) pendulum solutions. In addition, it is important to note that (1.4) is a solution to the pendulum equation (1.2) for arbitrary values of m, i.e., it is solely the initial conditions that determine the specific value of the parameter m. Thus we have, from (1.4), that $\sin(\Theta/2) = sn[(g/mR)^{1/2}t; m] = k^{-1}sn[(g/R)^{1/2}t; 1/m]$, revealing that both cases of a parameter greater than 1 and less than 1 (as well as $m = 1$) are succinctly and

completely delineated by the result in (1.4) and that, in contrast, the "traditional" division of this problem into two (or three) distinct cases is unnecessarily redundant.

In the following, utilizing a completely novel representation for am $(z; m)$ that is convergent throughout the complex plane excepting only the logarithmic branchpoints of the function (hereafter the term "unrestricted representation" will be used to denote any representation of a function that is valid throughout the complex plane except at any isolated, singular points and/or branchpoints of the function), we examine its periodicity for all real values of m. We also present various linear and quadratic transformations of the amplitude function corresponding to, e.g., the complementary parameter transformation, the Landen and Gauss transformations, etc. Although the expression of these transformations in terms of the JEF are well known, the results presented here for am $(z; m)$ are, with one exception, new results. As will be evident, the transformations for am $(z; m)$ offer concise, straightforward representations for these transformations and, in certain cases, offer a simple representation for which the corresponding JEF transformation is considerably more complicated. An example of the latter is the ascending Landen transformation that takes a simple form for am $(z; m)$ whereas the identities involving the JEF are algebraic. In addition, the formulae presented here offer further insight into the nature of these basic transformations beyond that associated strictly with the JEF formulae.

Principally for reasons of computational efficiency, the most widely used method for calculating the JEF (and elliptic integrals) is that based on the arithmetic-geometric mean along with various supplemental relations normally involving specific transformations directly related to the function to be evaluated (see the general articles by King [14], Carlson [6], and Milne-Thomson [17]). The term "arithmetic-geometric mean" will henceforth be understood to include whatever supplemental relations are used in conjunction with the arithmetic-geometric mean itself in the overall calculation of the specific function in question. The final section of this paper describes the method of the arithmetic-geometric mean explicitly in terms of the amplitude function and its transformation properties and will demonstrate that the method of the arithmetic-geometric mean is first and foremost a technique for the calculation **NOT** of the JEF but rather of am $(z; m)$ directly (along with the "coam" function am $(K-z; m)$). It is emphasized that the intent of this section is not to define or present algorithms for the arithmetic-geometric mean as applied to the calculation of the JEF; there exist several excellent, comprehensive descriptions of this technique [1], [6], [7], [9], [14], [16], including strictly algebraic versions [6], [21], computer algorithms [4], [11], as well as versions permitting complex parameters [9]. Rather, we wish to show that the actual basis for this technique is best and most clearly described in terms of the transformation formulae for am $(z; m)$ presented in the first parts of this paper.

2. Unrestricted representations for the Jacobian functions. The Fourier series for the functions $dn(z; m)$ and am $(z; m)$ may be written in the following form:

$$\begin{aligned} dn(z; m) &= \frac{\pi}{2K} + \frac{2\pi}{K} \sum_{n=1}^{\infty} \frac{q^n}{1+q^{2n}} \cos\left(\frac{n\pi z}{K}\right) \\ &= \frac{\pi}{2K} \sum_{n=-\infty}^{\infty} \operatorname{sech}\left[n\pi \frac{K'}{K}\right] e^{in\pi z/K} \end{aligned} \tag{2.1}$$

and

$$\operatorname{am}(z; m) = \int_0^z dn(z; m)\, dz = \frac{\pi z}{2K} + 2 \sum_{n=1}^{\infty} \frac{1}{n} \frac{q^n}{1+q^{2n}} \sin\left(\frac{n\pi z}{K}\right). \tag{2.2}$$

However, as a consequence of the fact that the variable z and the summation index n are cofactors in the Fourier series representations, these expressions are only valid throughout the restricted domain $|\mathrm{Im}\,(z/K)| < \mathrm{Im}\,(iK'/K)$. For example, for $0 < m < 1$ where both K and K' are real, these expressions are valid only in the infinite strip $|\mathrm{Im}\,(z)| < K'(m)$. In addition, or rather as a result of this limitation, the Fourier series such as that given by (2.1) for $dn(z; m)$ account explicitly only for the periodicity properties with respect to the quarter-period $K(m)$ and completely fail to describe the behavior with respect to the quarter-period $iK'(m)$. To arrive at an unrestricted representation for $dn(z; m)$, we apply the Poisson summation formula (see Bellman [2] for a discussion and examples of the applicability of this formula)

$$\sum_{n=-\infty}^{\infty} f(n) = \sum_{n=-\infty}^{\infty} \left[\int_{-\infty}^{\infty} f(u)\, e^{2\pi i n u}\, du \right] \tag{2.3}$$

to the second of (2.1) with $f(n) = \mathrm{sech}\,[n\pi K'/K] \exp\{in\pi z/K\}$. Replacing the variable "n" with "u" and evaluating the integral given in (2.3) leads directly to the result

$$dn(z; m) = \frac{\pi}{2K'} \sum_{n=-\infty}^{\infty} \mathrm{sech}\left[\frac{\pi K}{K'} \left(n + \frac{z}{2K} \right) \right]. \tag{2.4}$$

This expression for the function $dn(z; m)$ is superior to the Fourier series representation (2.1) in that, (a) equation (2.4) is convergent throughout the entire complex plane, poles excepted, and, (b) partly as a consequence of this, it describes equally explicitly the periodicity of $dn(z; m)$ with respect to *both* $K(m)$ and $K'(m)$ (the actual periods are $2K(m)$ and $4iK'(m)$). Indeed, since the variable z and the summation index n appear as additive terms in (2.4) in contrast to the Fourier series, (2.1), where they are multiplicative factors, the *only* condition required to ensure convergence of the expression (2.4) is $\mathrm{Re}\,(K/K') \neq 0$ which, for real m, is equivalent to $m \neq 0$.

The analogous Poisson-sum-transformed expressions for $sn(z; m)$ and $cn(z; m)$, from which the remaining members of the JEF family are derived as noted previously, are found by following exactly similar procedures as for the case of $dn(z; m)$ above, i.e., the Fourier series for these functions are first converted to a summation over an index "n" running from $-\infty$ to $+\infty$, the summation term is substituted into (2.3), and, following a substitution of the variable "n," the integration is performed. The final results may be compactly expressed in the following form, with $A = \pi/2K'$:

$$dn(z; m) = A \sum_{n=-\infty}^{\infty} \mathrm{sech}\left[\frac{\pi K}{K'} \left(n + \frac{z}{2K} \right) \right],$$

$$k \cdot cn(z; m) = A \sum_{n=-\infty}^{\infty} (-1)^n \mathrm{sech}\left[\frac{\pi K}{K'} \left(n + \frac{z}{2K} \right) \right], \tag{2.5}$$

$$k \cdot sn(z; m) = A \sum_{n=-\infty}^{\infty} (-1)^n \tanh\left[\frac{\pi K}{K'} \left(n + \frac{z}{2K} \right) \right],$$

$$k' \cdot nd(z; m) = A \sum_{n=-\infty}^{\infty} \mathrm{sech}\left[\frac{\pi K}{K'} \left(n + \frac{1}{2} + \frac{z}{2K} \right) \right],$$

$$-kk' \cdot sd(z; m) = A \sum_{n=-\infty}^{\infty} (-1)^n \mathrm{sech}\left[\frac{\pi K}{K'} \left(n + \frac{1}{2} + \frac{z}{2K} \right) \right], \tag{2.6}$$

$$k \cdot cd(z; m) = A \sum_{n=-\infty}^{\infty} (-1)^n \tanh\left[\frac{\pi K}{K'} \left(n + \frac{1}{2} + \frac{z}{2K} \right) \right],$$

$$cs(z;\, m) = A \sum_{n=-\infty}^{\infty} \operatorname{csch}\left[\frac{\pi K}{K'}\left(n+\frac{z}{2K}\right)\right],$$

(2.7)
$$ds(z;\, m) = A \sum_{n=-\infty}^{\infty} (-1)^n \operatorname{csch}\left[\frac{\pi K}{K'}\left(n+\frac{z}{2K}\right)\right],$$

$$ns(z;\, m) = A \sum_{n=-\infty}^{\infty} (-1)^n \coth\left[\frac{\pi K}{K'}\left(n+\frac{z}{2K}\right)\right],$$

$$-k' \cdot sc(z;\, m) = A \sum_{n=-\infty}^{\infty} \operatorname{csch}\left[\frac{\pi K}{K'}\left(n+\frac{1}{2}+\frac{z}{2K}\right)\right],$$

(2.8)
$$k' \cdot nc(z;\, m) = A \sum_{n=-\infty}^{\infty} (-1)^n \operatorname{csch}\left[\frac{\pi K}{K'}\left(n+\frac{1}{2}+\frac{z}{2K}\right)\right],$$

$$dc(z;\, m) = A \sum_{n=-\infty}^{\infty} (-1)^n \coth\left[\frac{\pi K}{K'}\left(n+\frac{1}{2}+\frac{z}{2K}\right)\right].$$

The symmetry of these expressions is striking; with the exception of certain factors of $\pm i$, the right-hand sides of (2.5)-(2.8) are, interestingly, exactly the set of (symmetrical) primitive elliptic functions originally defined by Neville [18], [19]. All twelve of these expressions are valid throughout the complex plane for arbitrary $m \neq 0$, their respective poles excepted. Each of the numbered equations represents a copolar trio of the JEF while the three quartets formed from the respective members of each of these trios are coperiodic. The expressions for *sn*, *cn*, and *dn* recently have been presented and discussed by Boyd [3]. However, to the best of the author's knowledge, (2.5)-(2.8) for the complete JEF family have not been published previously.

Integration of (2.4) results in an expression for the amplitude function in the form

(2.9)
$$\operatorname{am}(z;\, m) = \sum_{n=-\infty}^{\infty} \operatorname{gd}\left[\frac{\pi K}{K'}\left(n+\frac{z}{2K}\right)\right]$$

(2.10)
$$= \operatorname{gd}\left[\frac{\pi z}{2K'}\right] + \sum_{n=1}^{\infty}\left[\operatorname{gd}\left[\frac{\pi K}{K'}\left(n+\frac{z}{2K}\right)\right] - \operatorname{gd}\left[\frac{\pi K}{K'}\left(n-\frac{z}{2K}\right)\right]\right]$$

where $\operatorname{gd}(z)$ is the Gudermannian function. Equations (2.9) and (2.10) converge throughout the complex plane except at the logarithmic branchpoints $z = 2sK + (2t+1)iK'$ where s and t are arbitrary integers. Equation (2.9) will serve as the basis for the derivation of the various identities in the following work so that the results obtained will be valid without restrictions on the range of z; those results obtained by direct reference to the analogous JEF relations, i.e., by "inversion," are generally accompanied by restrictions on the range of the real and/or imaginary parts of the variable z.

It is worthwhile noting that although the unrestricted representations given above for the JEF and for $\operatorname{am}(z;\, m)$ are much more attractive for analytical purposes than their limited Fourier series counterparts, neither set of expressions, for purposes of numerical calculation, is as computationally efficient as those methods based either on the arithmetic-geometric mean or on the use of the theta functions (cf. [4], [6], [11], [14]). High precision, numerical evaluation of the JEF or $\operatorname{am}(z;\, m)$ using the Fourier series is truly practical only when $m \approx 0$ or, using the expressions above, when $m \approx 1$.

Since the characteristics of the function $\operatorname{am}(z;\, m)$ in the complex plane are so intimately connected with the nature of the Gudermannian function, a brief accounting

of gd (z) is in order at this point. Because the function sech (z) is a singly periodic, meromorphic function with simple poles at the points $(2t+1)i\pi/2$ with residues of $(-1)^{t+1}i$ where $t=0, \pm1, \pm2, \cdots$, the Gudermannian function defined as the definite integral (Jahnke and Emde [13])

$$\text{gd}\,(z)=\alpha+i\beta=\int_0^z \text{sech}\,(z)\,dz, \qquad z\neq(2n+1)\frac{i\pi}{2},$$

where α and β are strictly real, is a single-valued, analytic function provided that the complex plane is cut along the branchlines lying on the imaginary axis from $(4t+1)i\pi/2$ to $(4t+3)i\pi/2$ (logarithmic branchpoints for gd (z)) where t is an arbitrary integer. Relations such as $\sinh(z)=\tan[\text{gd}\,(z)]$ and $\cosh(z)=\sec[\text{gd}\,(z)]$ follow directly from the definition above. The real and imaginary parts of gd (z) for $x\neq0$ are given explicitly and uniquely by the relations

$$\begin{aligned}\alpha&=\text{gd}\,(x)+\tan^{-1}[\text{csch}\,(x)]-\tan^{-1}[\cos(y)\,\text{csch}\,(x)],\\ \beta&=\tanh^{-1}[\sin(y)\,\text{sech}\,(x)]\end{aligned} \tag{2.11}$$

with $\text{gd}\,(x)=2\tan^{-1}[\tanh(x/2)]$ and where $|\alpha|<\pi$ and $|\alpha|\to\pi/2$, $|\beta|\to0$ as $|x|\to\infty$ for all y. For $x=0$ and $y\neq(2t+1)i\pi/2$, we have $\alpha=0$ and $\beta=\tanh^{-1}[\sin(y)]$. Note that gd (z) is singly periodic with period $2\pi i$ and that $\text{gd}\,(-z)=-\text{gd}\,(z)$ and $\text{gd}\,(z^*)=\text{gd}^*\,(z)$. Expanding sech (z) in terms of exp $(\pm z)$ and integrating leads to an unrestricted representation for the Gudermannian function in the form

$$\text{gd}\,(z)=\text{sgn}\,(x)\frac{\pi}{2}-2\sum_{n=0}^{\infty}\frac{(-1)^n}{2n+1}[\text{sgn}\,(x)\cosh[(2n+1)z]-\sinh[(2n+1)z]], \tag{2.12}$$

which is convergent throughout the complex plane, the logarithmic branchpoints $z=(2t+1)i\pi/2$ excepted, and where sgn $(x)=+1, 0$, or -1 according to $x>0$, $x=0$, or $x<0$, respectively (the real part of gd (z) vanishes along the imaginary axis). It follows directly from (2.12) that

$$\text{gd}\,(x+iy\pm in\pi)=\text{sgn}\,(x)\frac{1-(-1)^n}{2}\pi+(-1)^n\,\text{gd}\,(x+iy) \tag{2.13}$$

revealing a finite discontinuity (of 2π) in the real part of gd (z) across each of the branchcuts $(x=0, \cos(y)<0)$.

Before proceeding to examine the specific properties of the Jacobian amplitude function, it is appropriate at this point to discuss briefly its general characteristics in the complex plane given the basic results immediately above. Neville [18, pp. 18–20] has shown that the integral of an elliptic function having zero residues defines a doubly (additive) pseudoperiodic, meromorphic function. The function am $(z; m)$, in contrast, as the integral of the elliptic function $dn(z; m)$ having nonzero residues (specifically, $dn(z; m)$ has simple poles with residues of $-i$ at the points $2sK+(4t+1)iK'$ and $+i$ at the poles $2sK+(4t-1)iK'$, where s, t are arbitrary integers), is, in general, a doubly pseudoperiodic function with logarithmic branchpoints. Thus am $(z; m)$, were it defined solely by (1.1) and (2.2), would be an infinitely multiple-valued function of z with branches differing by integral multiples of 2π corresponding to the infinite number of possible paths of integration from zero to z encircling the poles of $dn(z; m)$ in different ways. However, by cutting the complex plane along the line segments joining these logarithmic branchpoints, specifically from $2sK+(4t+1)iK'$ to $2sK+(4t+3)iK'$, where s, t are integers, the function am $(z; m)$ is made single-valued and analytic throughout the cut, complex plane. Finally, a principal branch is selected from among

these single-valued branches by the requirement $\operatorname{am}(z=0; m)=0$. The real part of $\operatorname{am}(z; m)$ will be discontinuous (by 2π) across each of the branchlines. In nearly all respects, as the form of (2.9) intimates, the Jacobian amplitude function $\operatorname{am}(z; m)$ may be effectively considered as a doubly pseudoperiodic generalization of the singly periodic Gudermannian function $\operatorname{gd}(z)$, noting in particular the degeneracy $\operatorname{am}(z; m=1)=\operatorname{gd}(z)$.

3. The periodicity properties of am $(z; m)$ for real m. Exactly as with the JEF, the behavior of the function $\operatorname{am}(z; m)$ is characteristically different in the three distinct regions: $-\infty<m<0$, $0<m<1$, and $1<m<\infty$. From (2.9), which is valid for all parameter values, it follows that the amplitude function is always at least singly periodic when $m\neq 0$, with a period of $4iK'(m)$. Exploiting the fact that the amplitude function for real m, like the JEF, is strictly real whenever z is real, expressions for am are given in the regions $m<0$ and $m>1$ that reflect this characteristic. Unless specifically noted, the degenerate cases of $\operatorname{am}(z; m=0)=z$ and $\operatorname{am}(z; m=1)=\operatorname{gd}(z)$ are generally excluded from the relations below. Finally, it should be noted that, in all of the work to follow, the numerical value of the parameter m will generally be restricted to $0<m<1$ and parameters that are less than zero or greater than 1 will then be expressed explicitly in terms of m, e.g., a parameter greater than 1 will be represented by $1/m$ where $0<m<1$.

3.1. am $(z; m)$ for $0<m<1$. An arbitrary point in the complex plane may be represented as

$$z+2sK+2itK'=x+iy+2sK+2itK', \qquad |x/2K|<1 \quad \text{and} \quad |y/K'|<1 \tag{3.1}$$

where s and t are integers and where, for $0<m<1$, both K and K' are real. Only the lines $y=(2t+1)K'$, which include the logarithmic branchpoints of $\operatorname{am}(z; m)$, are excluded from the representation (3.1). When we use (2.12) and the expression for $\operatorname{am}(z; m)$ given by (2.10), it is a straightforward task to derive the result:

$$\operatorname{am}(z+2sK+2itK'; m)=s\pi+\operatorname{sgn}(x)\frac{1-(-1)^t}{2}\pi+(-1)^t\operatorname{am}(z; m). \tag{3.2}$$

Thus we have $\operatorname{am}(z+2sK+2itK'; m)=\operatorname{am}(z; m)$ if and only if $s=0$ and t is even and so, for $0<m\leqq 1$, the function $\operatorname{am}(z; m)$ is a singly periodic function with the strictly imaginary period $4iK'$. Equation (3.2) corresponds exactly with the relief figures for $\operatorname{am}(z; m)$ given by Jahnke and Emde [13]. Note that the branchlines so clearly illustrated in those figures are also explicitly accounted for by (3.2). For example, taking $s=2$, $t=1$, and $z=x>0$, we have $\operatorname{am}(4K+2iK'+x; m)=3\pi-\operatorname{am}(x; m)$, whereas $\operatorname{am}(4K+2iK'-x; m)=\pi+\operatorname{am}(x; m)$.

3.2. am $(z; m)$ for $m<0$. Denoting a negative parameter (imaginary modulus) by the expression $-m/m'$ where $m'=1-m$ and $0<m<1$, we have the identities [5], [10], [15], [23]

$$K(-m/m')=k'K(m), \qquad K'(-m/m')=k'K'(m)+ik'K(m). \tag{3.3}$$

Note that the sign used in this identity for $K'(-m/m')$ is ambiguous for real m; either a + or − may be used (consistently) without affecting the validity of the final results [19, pp. 103–107]. The expression (2.9) for the amplitude function with negative parameter then takes the following form:

$$\operatorname{am}\left(z; -\frac{m}{m'}\right)=\sum_{n=-\infty}^{\infty}\operatorname{gd}\left[\frac{\pi K}{K'+iK}\left(n+\frac{z}{2k'K}\right)\right]. \tag{3.4}$$

This expression is cumbersome in that the individual terms in the summation are complex when z is strictly real even though the function $\operatorname{am}(z; -m/m')$ itself is real in such a case. To overcome this shortcoming, consider the expression

$$G(z) = \sum_{n=-\infty}^{\infty} \left[(1+ia) \operatorname{sech}\left[a\pi\left(z+n+\frac{1}{2}\right)\right] - \operatorname{sech}\left[\frac{a\pi}{1+ia}(z+n)\right]\right]$$

where $a = K/K'$. This function $G(z)$ is a doubly periodic function since $G(z+1) = G(z+2i/a) = G(z)$ with possible poles at the isolated points $z_{st} = (s+\frac{1}{2}) + (2t+1)i/2a$, i.e., $G(z)$ is an elliptic function. It is, however, straightforward to prove that the limit $(z - z_{st}) \cdot G(z) = 0$ as $z \to z_{st}$ so that the function $G(z)$ is indeed without poles. As a consequence of Liouville's theorem, an elliptic function without poles must be a constant and, in fact, we have that $G(z) \equiv 0$. By integration we arrive at the desired result

$$\operatorname{am}\left(z; -\frac{m}{m'}\right) = \sum_{n=-\infty}^{\infty} \operatorname{gd}\left[\frac{\pi K}{K'}\left(n+\frac{1}{2}+\frac{z}{2k'K}\right)\right] - \frac{\pi}{2} \tag{3.5}$$

for which the only complex dependence is implicitly through z. Representing an arbitrary point in the complex plane as above with $|x/2k'K|$ and $|y/k'K'| < 1$ and using the representation (2.12) in (3.5) leads to the result

$$\begin{aligned} &\operatorname{am}\left[z \pm k'K + 2sK\left(-\frac{m}{m'}\right) + 2itK'\left(-\frac{m}{m'}\right); -\frac{m}{m'}\right] \\ &\quad = (s-t)\pi + (1 \pm \operatorname{sgn}(x))\frac{1-(-1)^t}{2}\pi \\ &\qquad + (-1)^t \operatorname{am}\left(z \pm k'K; -\frac{m}{m'}\right). \end{aligned} \tag{3.6}$$

The left-hand side of (3.6) will equal $\operatorname{am}(z \pm k'K; -m/m')$ if and only if $s = t = 2L$ so that $\operatorname{am}(z; -m/m')$ is singly periodic with the strictly imaginary period $4K(-m/m') + 4iK'(-m/m') = 4ik'K'$.

3.3. am $(z; m)$ for $m > 1$. Denoting a parameter greater than 1 by $1/m$ where $0 < m < 1$, we have [5], [10], [15], [23]

$$K(1/m) = kK(m) + ikK'(m), \qquad K'(1/m) = kK'(m) \tag{3.7}$$

noting that, exactly as for (3.3), the sign on the right-hand side of this equation is arbitrary (Neville [19, pp. 103–107]). The expression for $\operatorname{am}(z; 1/m)$ from (2.9) becomes

$$\begin{aligned} \operatorname{am}\left(z; \frac{1}{m}\right) &= \sum_{n=-\infty}^{\infty} \operatorname{gd}\left[\frac{\pi K}{K'}\left(n+\frac{z}{2kK}\right) + in\pi\right] \\ &= \sum_{n=-\infty}^{\infty} (-1)^n \operatorname{gd}\left[\frac{\pi K}{K'}\left(n+\frac{z}{2kK}\right)\right]. \end{aligned} \tag{3.8}$$

Then, with $|x/2kK|$ and $|y/kK'| < 1$, we find, using (2.13),

$$\begin{aligned} &\operatorname{am}\left(z + 2sK\left(\frac{1}{m}\right) + 2itK'\left(\frac{1}{m}\right); \frac{1}{m}\right) \\ &\quad = (-1)^s \operatorname{sgn}(x)\frac{1-(-1)^{s+t}}{2}\pi + (-1)^t \operatorname{am}\left(z; \frac{1}{m}\right). \end{aligned} \tag{3.9}$$

Thus we find that am $(z; 1/m)$ is a *doubly* periodic function, i.e., am $(z+2sK(1/m)+2itK'(1/m); 1/m) = \text{am}\,(z; 1/m)$ if *both* s and t are, independently, even integers. One of the periods, $4ikK'$, is strictly imaginary, while the other, $4kK$, is strictly real.

4. Linear and quadratic transformations of the amplitude function. This section will present the (linear) negative parameter, reciprocal parameter, and complementary parameter transformations as well as the (quadratic) Landen and Gauss transformations of the Jacobian amplitude function. Although only two linear transformations plus the Landen transformation are strictly necessary since the remaining linear and quadratic transformations can then be derived from these [8], [10], [20], all of the above-mentioned transformations are included here since they are the most familiar and widely used of the JEF transformations. The convention followed here for the nomenclature of the quadratic transformations is that defined by Carlson [6] for which the variable changes in the same/opposite manner as the parameter for the Gauss/Landen transformations. Concise yet general discussions of the transformation theory of elliptic functions may be found in the texts by Erdélyi et al. [10], Chandrasekharan [8], and Rauch and Lebowitz [20].

4.1. The negative parameter (imaginary modulus) transformation. The relationship between am $(z; m)$ and am $(z; -m/m')$ follows immediately from the identity given in (3.5), i.e.,

$$\text{am}\left(k'z; -\frac{m}{m'}\right) = \frac{\pi}{2} - \text{am}\,(K-z; m), \qquad -\infty < m < 1 \tag{4.1}$$

from which follow directly the JEF transformations $dn(k'z; -m/m') = nd(z; m)$, and so on. This transformation was first given by Jacobi in *Fundamenta Nova* [12, p. 90] and, apparently, subsequently forgotten. The amplitude function in the region $m<0$ is characteristically very similar to am $(z; m)$ with $0<m<1$. In each case, the function is singly periodic with an imaginary period $= 4i \cdot \text{Re}\,[K'(m)]$ while, for z strictly real, both am $(x; m)$ and am $(x; -m/m')$ are unbounded, monotonically increasing functions and so are invertible over the entire real axis. Finally, we note that limit am $(z; m) \equiv 0$ as $m \to -\infty$.

4.2. The complementary parameter (imaginary argument) transformation. Replacing m with m' in (2.9) gives immediately

$$\text{am}\,(z; m') = \sum_{n=-\infty}^{\infty} \text{gd}\left[\frac{\pi K'}{K}\left(n+\frac{z}{2K'}\right)\right]. \tag{4.2}$$

However, to relate am $(z; m)$ directly to am $(z; m')$, the familiar transformation for $dn(z; m')$ is rewritten as [5], [10], [23]

$$dn(z; m') = \frac{d}{dz}\,\text{am}\,(z; m') = \frac{dn(iz; m)}{cn(iz; m)} = \frac{-i}{\cosh\,(i\Phi)}\,\frac{d\Phi}{dz} = \frac{d}{dz}\,\text{gd}\,(-i\Phi) \tag{4.3}$$

where $\phi = \text{am}\,(iz; m)$. Integrating from zero to z yields the result

$$\text{am}\,(z; m') = \text{gd}\,[-i \cdot \text{am}\,(iz; m)], \qquad 0 \leqq m \leqq 1 \tag{4.4}$$

where $|\text{Re}\,(z)| < K'(m)$ and $|\text{Im}\,(z)| < K(m)$. Equations (3.1) and (3.2) may be used to extend the applicability of this result for arbitrary values of z. In certain respects, this transformation could be aptly subtitled the "circular-hyperbolic transformation" since it relates the "nearly circular" JEF to their "nearly hyperbolic" counterparts, i.e., the amplitude and elliptic functions with $m \approx 0$ to those with $m \approx 1$. In the extreme

limit of $m=0$, (4.4) gives $\operatorname{am}(z;1)=\operatorname{gd}(z)$. Finally, note that the parameters m and m' are interchangeable in (4.4) so that $\operatorname{am}(z;m)=\operatorname{gd}[-i\cdot\operatorname{am}(iz;m')]$.

4.3. The descending Landen transformation. Dealing for the moment with general, iterative subscripts, we define, for $0\leqq m_i\leqq 1$, the transformations $m_{i+1}\leftrightarrow m_i$ as

$$m_{i+1}=f_-(m_i)=\left[\frac{1-k_i'}{1+k_i'}\right]^2,\qquad m_i=f_+(m_{i+1})=\frac{4k_{i+1}}{(1+k_{i+1})^2} \tag{4.5}$$

such that $0\leqq m_{i+1}\leqq m_i\leqq 1$ and $f_-[f_+(m)]=f_+[f_-(m)]=m$. The quarter periods for the two parameters connected by f_- and f_+ are related as

$$K_{i+1}=\frac{1+k_i'}{2}K_i \quad\text{and}\quad K_{i+1}'=(1+k_i')K_i' \tag{4.6}$$

so that

$$\frac{K_{i+1}'}{K_{i+1}}=2\frac{K_i'}{K_i} \quad\text{and}\quad q_{i+1}=q_i^2. \tag{4.7}$$

Setting $i=0$ and using the notation $m_0=m$, we can write the identities

$$\operatorname{am}(z;m)=\sum_{n=-\infty}^{\infty}\operatorname{gd}\left[\frac{\pi K_1}{K_1'}\left(2n+(1+k')\frac{z}{2K_1}\right)\right] \tag{4.8}$$

and

$$\operatorname{am}(K-z;m)=\sum_{n=-\infty}^{\infty}\operatorname{gd}\left[\frac{\pi K_1}{K_1'}\left(2n+1-(1+k')\frac{z}{2K_1}\right)\right]. \tag{4.9}$$

Combining these equations gives the descending Landen transformation for the amplitude function

$$\operatorname{am}[(1+k')z;m_1]=\operatorname{am}(z;m)-\operatorname{am}(K-z;m)+\frac{\pi}{2},\qquad 0\leqq m<1. \tag{4.10}$$

4.4. The reciprocal parameter transformation. Using the relations for the quarter periods, (3.7), along with (4.8) and (4.9) above, we have directly

$$\operatorname{am}\left[(1-k')z;\frac{1}{m_1}\right]=\operatorname{am}(z;m)+\operatorname{am}(K-z;m)-\frac{\pi}{2},\qquad 0<m<1. \tag{4.11}$$

Up to this point, all of the transformations given for $\operatorname{am}(z;m)$ involve precisely those parameters that characterize the analogous JEF transformations. Although (4.11) is the correct, general form of the transformation relating the amplitude functions in the regions $0<m<1$ and $m>1$, it does not directly relate m to $1/m$ as its name suggests. To resolve this point, reference is made to (3.9) and the fact that, when and only when $m>1$, is $\operatorname{am}(z;m)$ a strictly oscillatory function with respect to *both* K and K'. Hence, except at its branchpoints, the function $\operatorname{am}(z;m>1)$ is bounded throughout the entire complex plane, and we may properly represent it as an inverse of some combination of JEF. From the familiar identity for $dn(u+v;m)$ it follows that, for $|\operatorname{Re}(u)/K|$, $|\operatorname{Re}(v)/K|<1$ and $|\operatorname{Im}(u)/K'|$, $|\operatorname{Im}(v)/K'|<1$,

$$\operatorname{am}(u+v;m)=\tan^{-1}[sc(u;m)\,dn(v;m)]+\tan^{-1}[dn(u;m)sc(v;m)]. \tag{4.12}$$

In particular, setting $u=kx$ and $v=iky$ leads to

$$\begin{aligned}\operatorname{am}(kx+iky;m)=&\tan^{-1}[sc(kx;m)dc(ky;m')]\\&+i\cdot\tanh^{-1}[dn(kx;m)sn(ky;m')].\end{aligned} \tag{4.13}$$

Transforming $m \to 1/m$ and rearranging terms within the brackets results in

$$\text{am}\left(kx+iky;\frac{1}{m}\right)=\sin^{-1}\left[\frac{k\cdot sn(x;\,m)}{[1-dn^2(x;\,m)sn^2(y;\,m')]^{1/2}}\right] + i\cdot\tanh^{-1}[k\cdot cn(x;\,m)sd(y;\,m')]. \tag{4.14}$$

In the strictest sense, relations such as these are incorrect whenever $1/m<1$ unless the values of the real and imaginary parts of the variable z are specifically restricted as stated above or as in (3.1) and (3.2). In contrast, however, the identity of (4.14) is valid *as written* when $1/m>1$ for arbitrary z, the branchpoints excepted. Thus, the reciprocal parameter transformation for the amplitude function, (4.14), can be rewritten succinctly (although essentially symbolically when z is complex) in the form

$$\text{am}\,(kz;\,1/m)=\sin^{-1}[k\cdot sn(z;\,m)],\qquad 0<m\leqq 1 \tag{4.15}$$

noting that limit am $(z;\,m)\equiv 0$ as $m\to\infty$. In particular, note that, for z real (or $y=4tK'$), the pragmatic identity am $(kx;\,1/m)=\sin^{-1}[k\cdot sn(x;\,m)]$ gives the correct value of the amplitude function for all values of x.

The similarity between the reciprocal parameter transformation in the form of (4.11) and the descending Landen transformation, (4.10), is remarkable and is, in part, related to the fact that $f_+(m_1)=f_+(1/m_1)$. By combining these two equations and invoking the result in (4.1), it is possible to write a completely general identity that relates the amplitude functions in the three regions of real m as follows:

$$\text{am}\,(z;\,m)=\text{am}\,(k'z;\,-m/m')+\text{am}\,((1-k')z;\,1/m_1) \tag{4.16}$$

with $(-m/m')\leqq 0\leqq m\leqq 1\leqq(1/m_1)$.

4.5. The ascending Landen transformation. Adding (4.10) and (4.11) leads immediately to the ascending Landen transformation for the amplitude function as follows:

$$\begin{aligned}\text{am}\,(z;\,m)&=\tfrac{1}{2}\,\text{am}\,[(1+k')z;\,m_1]+\tfrac{1}{2}\,\text{am}\,[(1-k')z;\,1/m_1]\\&=\tfrac{1}{2}\,\text{am}\,[(1+k')z;\,m_1]+\tfrac{1}{2}\sin^{-1}[k_1 sn[(1+k')z;\,m_1]].\end{aligned} \tag{4.17}$$

Note that many texts refer simply to "the Landen transformation," invariably meaning the descending Landen transformation corresponding to (4.10) above. The relationships for the JEF corresponding to (4.10) are rational ones [5], [23], whereas those corresponding to the ascending Landen transformation, (4.17), are algebraic relations. This is one instance in which, apart from its conciseness, the form of the amplitude function transformation is simple and straightforward in comparison to its JEF counterpart.

4.6. The ascending/descending Gauss transformations. The ascending/descending Gauss transformations are derived by combining the complementary parameter transformation with the descending/ascending Landen transformations [8], [10], [20]. From (4.4) and (4.10), for $0<m<1$, follows the ascending Gauss transformation in the form

$$\text{gd}\,[i\cdot\text{am}\,[(1+k_1)z;\,m]]=\text{gd}\,[i\cdot\text{am}\,(z;\,m_1)]+\text{gd}\,[i\cdot\text{am}\,(z+iK_1';\,m_1)]+\frac{\pi}{2} \tag{4.18}$$

while, from (4.4) and (4.17), the descending Gauss transformation is found to be

$$\begin{aligned}\text{gd}\,[i\cdot\text{am}\,(z;\,m_1)]&=\frac{1}{2}\,\text{gd}\,[i\cdot\text{am}\,(1+k_1)z;\,m]\\&\quad+\frac{1}{2}\,\text{gd}\left[i\frac{\pi}{2}-i\cdot\text{am}\,[K-(1+k_1)z;\,m]\right].\end{aligned} \tag{4.19}$$

As with the Landen transformations, many texts that refer simply to "the Gauss transformation" invariably mean the ascending Gauss transformation for which the transformation formulae for the JEF are rational expressions [5], [23], unlike those corresponding to the descending Gauss transformation for which the JEF identities are algebraic.

5. The method of the arithmetic-geometric mean and am $(x; m)$. Although, in principle, the method of the arithmetic-geometric mean (AGM) (or the theta functions) could be employed for a complex variable (and, conceivably, for complex m [9]), it is considerably more practical to calculate the real and imaginary parts of am $(z; m)$ and the JEF separately using identities such as (4.13). Thus, only strictly real variables x will hereinafter be considered. In addition, this section will deal with the "classical" method of the AGM (e.g., King [14]) utilizing various trigonometric or hyperbolic recursion identities as opposed to purely algebraic versions [6], [21]. The former, while nominally less efficient computationally, offer the advantage of calculating the true value of am $(x; m)$ for arbitrarily large $|x|$, i.e., including the contribution $s\pi$ given in (3.2). Moreover, while the relations between the method of the AGM and the transformations presented here hold true whichever version is adopted, these relations are more explicit and thus more readily recognized in the "classical" case.

The method of the AGM begins by iteratively calculating, with $0 < m < 1$, the trio of numbers

$$a_{n+1} = \tfrac{1}{2}(a_n + b_n), \quad b_{n+1} = (a_n b_n)^{1/2}, \quad c_{n+1} = \tfrac{1}{2}(a_n - b_n) \tag{5.1}$$

with starting values of $a_0 = 1$, $b_0 = k'$, and $c_0 = k$. The numbers a_n and b_n converge rapidly to a common limit $(= \pi/2K)$ while c_n, as a measure of the "error" with $c_n^2 = a_n^2 - b_n^2$, vanishes quadratically, i.e., $c_{n+1} = c_n^2/4a_{n+1}$. The calculation is stopped at the Nth step where, to some prescribed degree of accuracy, c_N is negligible. For the descending Landen version of the AGM, a sequence of angles $\phi_{N-1}, \phi_{N-2}, \cdots, \phi_0$ is then calculated sequentially using the recurrence relation

$$\sin(2\Phi_{n-1} - \Phi_n) = \frac{c_n}{a_n} \sin(\Phi_n) \quad \text{with } \Phi_N = 2^N a_N x \tag{5.2}$$

to which the amplitude function and the JEF are related as

$$\begin{aligned} &\text{am}(x; m) = \Phi_0, \qquad \text{am}(K - x; m) = \Phi_0 - \Phi_1 + \frac{\pi}{2}, \\ &sn(x; m) = \sin(\Phi_0), \qquad cn(x; m) = \cos(\Phi_0), \\ &dn(x; m) = \frac{cn(x; m)}{sn(K - x; m)} = \frac{\cos(\Phi_0)}{\cos(\Phi_0 - \Phi_1)}. \end{aligned} \tag{5.3}$$

Attention is drawn to the first two identities of (5.3) that, to the best of the author's knowledge, have not heretofore been given in any of the papers dealing with the AGM as a method of evaluating the JEF. Yet, given these two results, it follows that the evaluation of the JEF is, in fact, entirely incidental to this method, i.e., it is am $(x; m)$ and am $(K - x; m)$, which are the primary quantities found via the AGM from which the JEF are then calculated from simple trigonometric expressions.

To indeed establish the validity of the identities listed in (5.3), it is first noted that the (a_n, b_n, c_n) scale described by (5.1) is exactly equivalent to sequential applications

of the descending operator $f_-(m_i)$ of (4.5), i.e.,

$$
\begin{aligned}
&k_0 = k \\
&k_1 = (1-k_0')/(1+k_0') = f_-(m) = c_1/a_1 \\
&k_2 = (1-k_1')/(1+k_1') = f_-^2(m) = c_2/a_2 \\
&\quad\vdots \qquad\qquad \vdots \qquad\qquad \vdots \\
&k_{n+1} = (1-k_n')/(1+k_n') = f_-^{n+1}(m) = c_{n+1}/a_{n+1}
\end{aligned} \tag{5.4}
$$

and where $K(m) = (\pi/2)(1+k_1)(1+k_2)\cdots = (\pi/2a_N)$. With the identification of $k_n = c_n/a_n$, the recurrence relation (5.2) is immediately recognized as the ascending Landen transformation for the amplitude function, (4.17), so that the ϕ_n sequence is equivalent to

$$
\begin{aligned}
&\Phi_0 = \operatorname{am}(x; m) \\
&\Phi_1 = \operatorname{am}\left(\frac{2x}{(1+k_1)}; m_1\right) \\
&\Phi_2 = \operatorname{am}\left(\frac{4x}{(1+k_1)(1+k_2)}; m_2\right) \\
&\quad\vdots \qquad\qquad \vdots \\
&\Phi_n = \operatorname{am}\left(\frac{2^n x}{(1+k_1)(1+k_2)\cdots(1+k_n)}; m_n\right).
\end{aligned} \tag{5.5}
$$

Note that, even though it is the *descending* Landen transformation that is the basis of this particular version of the AGM and transforms the variable $\phi_0 \to \phi_N$ as immediately above, it is the *ascending* Landen transformation for $\operatorname{am}(x; m)$ that is used in the actual calculations to transform $\phi_N \to \phi_0$. With the aid of (4.10), the sequence of amplitude functions, (5.5), may be re-expressed as

$$
\begin{aligned}
\Phi_n = {} & \operatorname{am}(x; m) + (1-\delta_{n0})\left[\frac{\pi}{2} - \operatorname{am}(K-x; m)\right] \\
& + (1-\delta_{n0})(1-\delta_{n1}) \sum_{i=1}^{n-1} \sum_{j=1}^{2^{i-1}} \\
& \cdot \left[\operatorname{am}\left[\frac{2j-1}{2^i} K + x; m\right] - \operatorname{am}\left[\frac{2j-1}{2^i} K - x; m\right]\right]
\end{aligned} \tag{5.6}
$$

and

$$
\begin{aligned}
\Phi_n &= \frac{\pi}{2K} 2^n x + \sum_{j=1}^{\infty} \frac{2q^{2^n j}}{j(1+q^{2^{n+1}j})} \sin\left(\frac{2^n j\pi x}{K}\right) \\
&= \frac{\pi}{2K} 2^n x + \sum_{j=1}^{\infty} \frac{1}{j} \operatorname{sech}\left[\frac{2^n j\pi K'}{K}\right] \sin\left(\frac{2^n j\pi x}{K}\right).
\end{aligned} \tag{5.7}
$$

Equation (5.6), in particular, establishes the identities given in (5.3), while (5.7) offers explicit testimony to the extraordinarily rapid convergence inherent to the AGM. This latter equation states that, for the nth step, the first-order deviation of the variable ϕ_n from linearity will go as q raised to the 2^n power, i.e., given the relation of (4.7) for the nome, the "error" is reduced quadratically on each iteration.

The particular version of the AGM as just described with $b_0 = k'$ and the use of the recurrence relation (5.2) is referred to as the descending Landen version of the AGM. When we use $b_0 = k$ and (4.10) as the recurrence relation, the ascending Landen version of the AGM sequentially raises the parameter to unity where $\phi_N \approx \mathrm{gd}$. Ascending and descending versions of the AGM based on Gauss transformations are also possible (Carlson [6]). The use of an ascending and a descending transformation, in particular, allows the numerical range of m to be restricted to $0 < m \leqq \frac{1}{2}$. Whatever the particular version adopted, however, the calculation of the JEF from the final results, as for (5.3), proves to be incidental to the method in that the primary quantities that are calculated via the ϕ_n are the amplitude function $\mathrm{am}\,(x; m)$ along with the "coam" function $\mathrm{am}\,(K - x; m)$.

Calculation of $\mathrm{am}\,(x; m)$ along with the JEF for parameter values outside the range of $0 < m < 1$ may be done as directly and efficiently as for the case of $0 < m < 1$ through the use of the transformation formulae (4.1) and (4.11). To calculate the amplitude function and the JEF for the case of a negative parameter $-M$ where $0 < M < \infty$, the AGM is calculated as above with a parameter $m = M/(1+M)$ and a variable x/k' to give the results

$$\begin{gathered} \mathrm{am}\,(x; -M) = \Phi_1 - \Phi_0, \qquad \mathrm{am}\,(K(-M) - x; -M) = (\pi/2) - \Phi_0, \\ sn(x; -M) = \sin(\Phi_1 - \Phi_0), \qquad cn(x; -M) = \cos(\Phi_1 - \Phi_0), \\ dn(x; -M) = \cos(\Phi_1 - \Phi_0)/\cos(\Phi_0). \end{gathered} \tag{5.8}$$

To calculate the elliptic functions for the case of a parameter $M > 1$, the AGM as described above is calculated using a parameter $m = f_+(m_1)$, where $m_1 = 1/M$, and a variable $x/(1-k')$ to give the results

$$\begin{gathered} \mathrm{am}\,(x; M) = 2\Phi_0 - \Phi_1, \qquad \mathrm{am}\,(x/k_1; 1/M) = \Phi_1, \\ sn(x; M) = \sin(2\Phi_0 - \Phi_1), \qquad cn(x; M) = \cos(2\Phi_0 - \Phi_1), \\ dn(x; M) = \cos(\Phi_1). \end{gathered} \tag{5.9}$$

Note that, in the case of $M > 1$, it is not the coam function that is calculated along with $\mathrm{am}\,(x; M)$ but rather $\mathrm{am}\,(x/k_1; 1/M)$, which yields the value of $dn(x; M)$ directly. The directness of these algorithms, i.e., the calculation of the actual values of the amplitude function(s), may be contrasted with algorithms that calculate the JEF for parameters less than zero or greater than 1 as either rational or algebraic expressions involving values of JEF having $0 < m < 1$ (e.g., [4]).

6. Concluding remarks. The results presented in this paper have shown that the various linear and quadratic transformations of the JEF can be represented concisely by the corresponding transformation of the Jacobian amplitude function $\mathrm{am}\,(z; m)$. The nature of the amplitude function for arbitrary, real m has been shown to be markedly different according to whether $m < 1$ or $m > 1$, being a singly periodic function with a strictly imaginary period when $m < 1$ and $m \neq 0$ while, for $m > 1$, $\mathrm{am}\,(z; m)$ is a doubly periodic function with both a real and an imaginary period. Finally, the method of the arithmetic-geometric mean has been shown to be principally a method for the calculation of the functions $\mathrm{am}\,(x; m)$ and $\mathrm{am}\,(K - x; m)$ directly from which then follow the values of the various JEF.

Acknowledgments. The author thanks Dr. R. Somorjai of the National Research Council of Canada and Dr. M. Sablatash of the Communications Research Center, for many helpful discussions during the course of this work. I also extend my appreciation to the various individuals who refereed this paper, in particular the first referee, for their constructive criticisms and suggestions.
